absorption band centered at 555 nm in the region of 420–900 nm, such a weak absorbance can be assigned to the IPCT transition from I^- to m-NO_2Bz-1-Apy$^+$ ions [12a–d]. Therefore, the two bands centered at 473 nm and ~862 nm in Fig. 7b might originate from the transition in $[Ni(mnt)_2]^{2-}$ or IPCT transition between the cation and the anion. Thus, we further investigated the influence of the concentration of the [*p*-NO_2Bz-1-Apy]$^+$ cation on the spectroscopic feature of the $[Ni(mnt)_2]^{2-}$ anion in acetonitrile (where the concentration of $(Bu_4N)_2[Ni(mnt)_2]$ is 5.0×10^{-5} mol L^{-1}), and the results are shown in Fig. 8b. As the concentration of [*p*-NO_2Bz-1-Apy]$^+$ cation increases, the intensity of the band at 473 nm does not change while the band at 862 nm obviously increases and the band becomes broadened. Accordingly, the band with maximum at 473 nm can be attributed to the intramolecular electronic transition in the $[Ni(mnt)_2]^{2-}$ anion, which is in agreement with the analysis in the literature [38]. In the UV–Vis–NIR spectrum of $(Bu_4N)_2[Ni(mnt)_2]$ in acetonitrile, the band at 862 nm was also observed with $\varepsilon = 289$, which was interpreted as a parity forbidden d–d type transition [38]. In our case, the observation that absorption intensity increases with higher concentration of cation demonstrates that the IPCT transition should also contribute to the broad and moderate band at 862 nm.

3.3. DFT and TDDFT analyses

The IPCT band position depends on the energy gap between the donor HOMO and the acceptor LUMO, as for complexes **1**–**5**, the donor ($[Ni(mnt)_2]^{2-}$ anion) are the same for each complex, therefore, only the energy level of the cationic LUMO affects the relative position of the IPCT band. Fig. 9 shows the Kohn-Sham frontier orbitals and their levels for each cation in complexes **1**–**5**. From this two conclusions can be drawn: (1) the cationic HOMO contributes mainly from the orbitals of the benzene molecule as well as the substituent group; (2) the cationic LUMO is essentially composed of the orbitals of the pyridine molecule, and the substituent group has a negligible contribution to the cationic LUMO. This finding implies the cationic features (electronic property, steric hindrance and so on) have minor influence on the LUMO orbitals of the investigated cations (the maximum energy difference is 0.5442 eV between *p*-NO_2Bz-1-Apy$^+$ and *p*-CH_3Bz-1-Apy$^+$ species). As a result, it can be understandable that IPCT band position (the broad near IR absorbance band) is almost independent of the substituent group feature in the benzene ring of cation in acetonitrile solution. TDDFT calculations were further performed for the five cations together with the $[Ni(mnt)_2]^{2-}$ anion, and the transition states, excitation energies, CI coefficients, and oscillator strengths are given in Table 5. For five cations, except for *p*-BrBz-1-Apy$^+$, the calculations disclosed that no absorption exists over 400 nm region, and these results are in agreement with the experimental spectra. The discrepancy between calculation and experiment spectra for *p*-BrBz-1-Apy$^+$ could be attributed to the poor asymptotic behavior of the exchange-correlation potential of the TD-DFT method [39]. And for the $[Ni(mnt)_2]^{2-}$ anion, the transitions HOMO → LUMO + 2 and HOMO − 3 → LUMO + 1 give rise to a modest absorption band at 827 nm. As illustrated in Fig. 10, the HOMO − 3 is mainly contributed from the d_{z^2} orbital of Ni^{2+} ion, and the HOMO and LUMO + 1 have largely the character of the π orbitals of mnt^{2-} ligands with small contributions from the $d_{x^2-y^2}$ orbital of Ni^{2+} ion. Contrastively, the LUMO + 2 is virtually a pure ligand orbital, so the lower frequency absorbance band (~862 nm in experimental absorbance spectra) can be assigned to combined transitions of partial forbidden d–d, allowed d–π* (MLCT in the

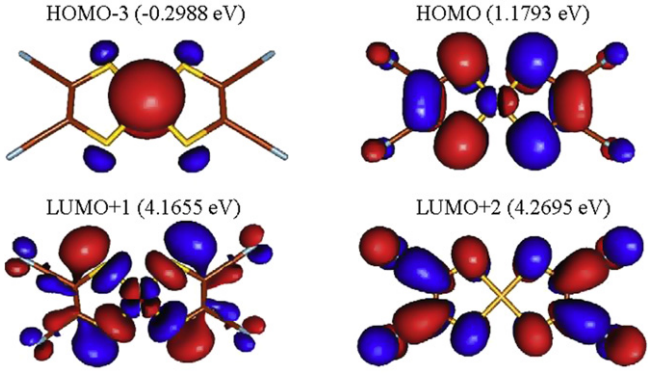

Fig. 10. The orbitals of the $[Ni(mnt)_2]^{2-}$ anion which are involved in the near-IR absorbance bands.

$[Ni(mnt)_2]^{2-}$ anion) and π–π^* (in the mnt^{2-} ligand) as well as the IPCT transition. And now, the observation could be well understood that the solid UV–Vis–NIR spectroscopic feature of **1** is different from those of the other four complexes in the low energy region, on the one hand, the very close packing interactions between the anions and the cations in **1** could broaden the low energy absorption band [40]; on the other hand, the geometric optimization indicates that the perfect planar molecular geometry is the most stable configuration for the $[Ni(mnt)_2]^{2-}$ anion. Thus, the heavy distortion of the anionic molecular geometry in **1** could raise the energy level of its HOMO, which gives rise to the IPCT band red-shift [11], and two factors mentioned above probably cause **1** having a more broaden band in the low energy region than those of other four complexes in the solid state.

4. Conclusions

We presented the UV–Vis–NIR spectra in both solid state and acetonitrile solution for five ion-pair complexes based on $[Ni(mnt)_2]^{2-}$ and the benzylidene-1-aminopyridinium derivatives. In the solid state, complexes **2**–**5** show similar spectral features, namely, the intense absorption in the UV/visible region with the moderate absorbance in the near IR region of 750–1000 nm, while complex **1** exhibits the intense absorbance from UV/visible to near IR region (200–1100 nm). Such a spectral feature makes this compound an excellent candidate as a near-IR dye for DSSC and Q-switching laser. The unique spectral property of **1** can be attributed to its distinctive crystal structure features, the strong intermolecular $\pi\cdots\pi$ stacking interactions between the anions and the cations as well as the heavy deviation from the planarity of the anionic geometry. DFT and TDDFT calculations disclosed that the near-IR absorbance bands in **1**–**5** are assigned to the combined transitions of d–d, MLCT and π–π^* in the $[Ni(mnt)_2]^{2-}$ anion as well as the IPCT transition from the HOMO of the $[Ni(mnt)_2]^{2-}$ anion to the LUMO of the RBz-1-Apy$^+$ cation. For **1**–**5**, the IPCT band position is almost independent of the substituent group features in the benzene ring of the cation due to the substituent group in the benzene ring has only a very minor contribution to the cationic LUMO, and that modifying the molecular structure of the pyridine moiety could adjust the IPCT band property for the ion-pair complexes of pyridinium derivatives with $[Ni(mnt)_2]^{2-}$.

Carbide Co. and treated by means of general procedure before use [25]. Other reagents and solvents were purchased commercially and used without further purification unless specially noted. Doubly distilled water was used to prepare buffer solutions.

2.2. Preparation of ligands and complexes

5,5′-Dimethyl-2,2′-dipyridyl was purchased from Aldrich Chemical Co. 5,5′-Dibromomethyl-2,2′-dipyridyl, $L^1Br_2 \cdot 4H_2O$ and L^2Br_2 were synthesized and characterized according to our previous method [23]. *cis*-$[Ru(phen)_2Cl_2] \cdot 2H_2O$ was prepared and characterized according to the literature procedures [26].

2.2.1. $[Ru(phen)_2(L^1)](PF_6)_4 \cdot 3CH_3CN$ (**1**)

A mixture of *cis*-$[Ru(phen)_2Cl_2] \cdot 2H_2O$ (0.28 g, 0.5 mmol), $L^1Br_2 \cdot 4H_2O$ (0.31 g, 0.5 mmol) and ethylene glycol (30.0 cm^3) was heated at 130 °C under the protection of argon for 6 h, during which the solution turned red. The solution was cooled to room temperature. After filtration dropwise addition of saturated NH_4PF_6 resulted in a red-orange precipitate which was filtered and recrystallized with CH_3CN/CH_3OH (1:1, v/v), and red single crystals were obtained. Yield: 0.60 g (70.6%). *Anal. Calc. for $C_{54}H_{65}F_{24}N_{11}P_4Ru$ (1549.09): C, 41.87; H, 4.23; N, 9.95. Found: C, 41.58; H, 4.20; N, 9.88%.*

2.2.2. $[Ru(phen)_2(L^2)](PF_6)_4 \cdot 1.5CH_3OH \cdot 0.5H_2O$ (2)

This complex was obtained by a similar procedure described for complex **1**. L^2Br_2 (0.36 g, 0.5 mmol) was used instead of $L^1Br_2 \cdot 4H_2O$. The crude product was recrystallized with CH_3CN/CH_3OH (1:1, v/v), red single crystals were obtained. Yield: 0.53 g (64.7%). *Anal. Calc. for $C_{61.5}H_{80}F_{24}N_8O_2P_4Ru$ (1644.24): C, 44.92; H, 4.90; N, 6.81. Found: C, 44.95; H, 4.92; N, 6.84%.*

2.3. General methods

Elemental analyses (C, H and N) were carried out with a Perkin–Elmer 240 C elemental analyzer. UV–Vis and emission spectra were measured on Perkin–Elmer Lambda-850 spectrophotometer and Ls55 spectrofluorophotometer, and circular dichroism (CD) spectra were measured on a Jasco J-810 spectropolarimeter.

Buffer (5 mM tris(hydroxymethyl)aminomethane (Tris) hydrochloride, 50 mM NaCl, pH 7.2) was used for absorption titration, emission titration, equilibrium dialysis, and viscosity experiments. Solutions of CT-DNA in buffer gave a ratio of UV absorbance at 260 and 280 nm of 1.8–1.9:1, indicating that the DNA was sufficiently free of protein [27]. The concentration of CT-DNA was determined spectrophotometrically assuming a molar absorption is 6600 M^{-1} cm^{-1} (260 nm) [28].

The absorption and emission titration of the Ru(II) complexes were performed by using a fixed complex concentration to which increments of the DNA stock solution were added. The concentration of the $[Ru(phen)_2(L)]^{4+}$ solution was 10 μM. Complex-DNA solutions were allowed to incubate for 5 min before the absorption spectra were recorded. Titrations for each sample were repeated at least three times. The intrinsic binding constant K_b of a complex to CT-DNA was determined from Eq. (1) [29–32], where [DNA] is the concentration of DNA in base pair, ε_a is the extinction coefficient (A_{abs}/[M]) observed for the absorption band at a given DNA concentration, ε_f and ε_b are the extinction coefficient for the free Ru(II) complex and the extinction coefficient for the Ru(II) complex in the fully bound form, respectively; K_b is the equilibrium binding constant in M^{-1}, C_t is the total Ru(II) complex concentration, and s is the binding site size. Eq. (1) has been applied to absorption titration data for noncooperative metallointercalator binding to CT-DNA.

$$(\varepsilon_a - \varepsilon_f)/(\varepsilon_b - \varepsilon_f) = (b - (b^2 - 2K_b^2 C_t[DNA]/s)^{1/2}/2K_b C_t \quad (1a)$$

$$b = 1 + K_b C_t + K_b[DNA]/2s \quad (1b)$$

Equilibrium dialysis was carried out in the dark and held at room temperature for 12 h with 5 mL of CT-DNA (1.0 mM) sealed in a dialysis bag and 10 mL of the Ru(II)-polypyridyl complex (50 μM) outside the bag. The bandwidth was 1 nm and the response time was 1 s. For each CD spectrum, repeated at least three times, spectral data were collected at 0.1 nm intervals with a scan speed of 300 nm min^{-1}. DNA was dialyzed thoroughly prior to the experiments. For the equilibrium dialysis and CD studies, blank experiment of the complex was also been carried out, and did not show obvious CD signal.

Viscosity measurements were carried out using an Ubbelohde viscometer maintained at a constant temperature of 30.0 ± 0.1 °C in a thermostatic bath. DNA samples with an approximate average length of 200 base pairs were prepared by sonication in order to minimize complexities arising from DNA flexibility [33]. Flow time was measured with a digital stopwatch. Each sample was measured three times and an average flow time was calculated. Data are presented as $(\eta/\eta^0)^{1/3}$ versus binding ratio ([Ru]/[DNA]) [34], where η is the viscosity of DNA in the presence of complex and η^0 is the viscosity of DNA alone.

2.4. X-ray crystallography

Single crystal X-ray diffraction experiments were carried out with a Bruker Smart Apex CCD area detector at 173(2) and 293(2) K for complexes **1** and **2**, respectively. The dimensions of crystals of complexes **1** and **2** used for X-ray diffraction analysis were 0.48 × 0.40 × 0.38 mm (**1**) and 0.52 × 0.41 × 0.20 mm (**2**), respectively. Data collection was performed with Mo Kα radiation (k = 0.71073 Å) for **1** and Cu Kα radiation (k = 1.54178 Å) for **2**. Absorption corrections were applied by using the SADABS program [35]. The structures were solved by direct methods, and all non-hydrogen atoms were refined anisotropically by least-squares on F^2 using the SHELXTL program [36]. These were first refined isotropically and then anisotropically. The hydrogen atoms of the ligands were placed in calculated positions with fixed isotropic thermal parameters and the structures factor calculations were included in the final stage of full-matrix least-squares refinement. A summary of the crystal data was given in Table 1.

3. Results and discussion

3.1. Description of the molecular structures

Figs. 1 and 2 depict the structures of complexes **1** and **2**, respectively. Selected bond distances and bond angles of complexes **1** and **2** are given in Table 2. Both complexes contain a six-coordinated ruthenium atom chelated by two phen ligands and one dicationic L ligand. The coordination geometry about the ruthenium atom is a distorted octahedron, with a bite angle of 79.5° in **1** and 79.2° in **2** averaged over three bidentate ligands. This distortion from an ideal octahedral geometry is due to the customary narrow bite angles of the bipyridine moieties, as observed in some other ruthenium complexes [37]. The mean Ru–N bond length for **1** (2.065 Å) and **2** (2.068 Å) are typical value for this type of Ru(II) complex (2.059–2.069 Å) [38,39]. The torsion angles between pyridine pairs of two bpy ligands of the complexes are nonequivalent, **1** being 15.6° and **2** being 2.8°.

3.2. Absorption spectra

The absorption spectra of both Ru(II) complexes are characterized by two intense ligand-centered transitions (LC) in the UV re-

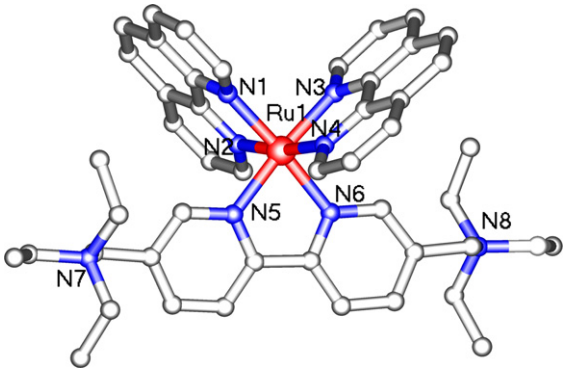

Fig. 1. X-ray crystal structure of **1**. All the hydrogen atoms are omitted for clarity.

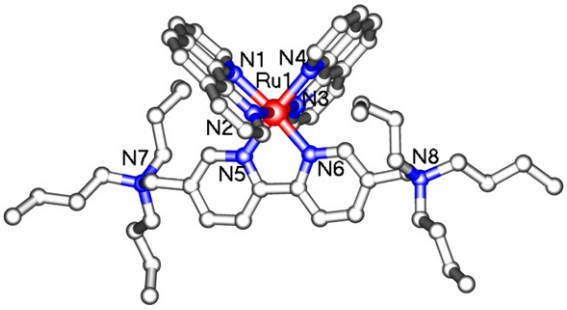

Fig. 2. X-ray crystal structure of **2**. All the hydrogen atoms are omitted for clarity.

gion, at 263, 293 nm for **1** and 262, 294 nm for **2**, and a metal-to-ligand charge transfer (MLCT) in the visible region, at 430 and 437 nm for **1** and **2**, respectively. The visible bands around 430 nm arise from the metal ($d\pi$) to the ligand (π^*) charge transfer (MLCT) transitions, and the ultraviolet bands around 260 nm and 295 nm belong to $\pi \rightarrow \pi^*$ transitions of the ligands. When DNA is added into the solution, different hypochromism (H%), as defined by $H\% = 100\%\ (A_{free} - A_{bound})/A_{free}$, is observed for both LC and MLCT transition absorptions. Hypochromism and red shifting changes indicate weak interactions between the DNA bases and the complexes and such results are consistent with the geometry of the main ligands. Although the two complexes have only subtle differences, the difference in behavior of the complexes with different main ligands in terms of spectral properties is distinct. The electronic spectral traces of the complexes titrated with DNA are shown in Fig. 3. The other related data were shown in Table 3.

To compare quantitatively the affinity of these complexes towards DNA, the intrinsic binding constants K_b of these complexes to DNA are determined by monitoring the changes of absorbance in the MLCT band with increasing concentration of DNA. The intrinsic binding constants K_b of complexes **1** and **2** obtained were 7.73×10^4 M^{-1} and 2.50×10^4 M^{-1}, respectively, from the decay of

	262	263	1	10.37		

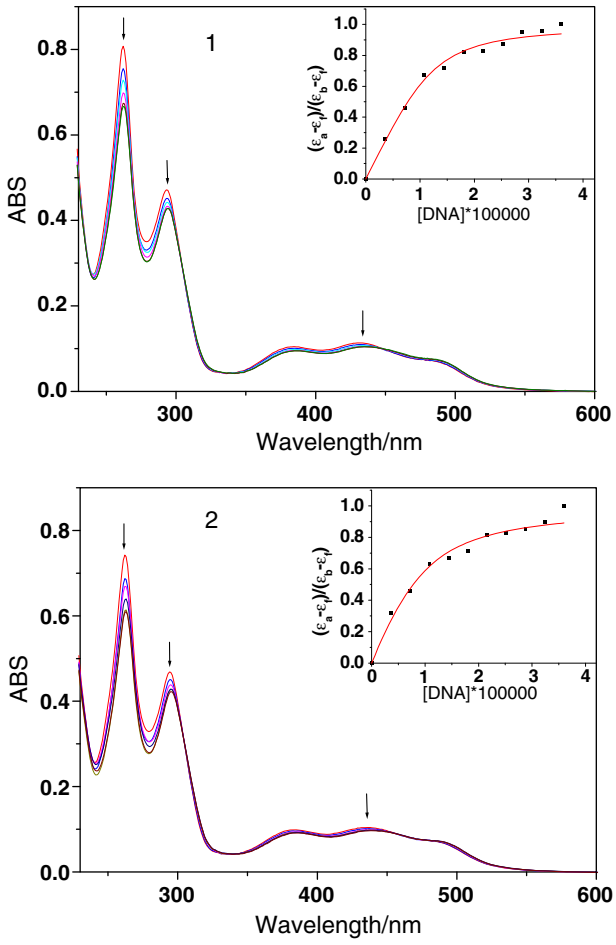

Fig. 3. Absorption spectra of **1** and **2** in Tris buffer (pH 7.2) in the presence of increasing amounts of CT-DNA. [Ru] = 10 μM, [DNA] = 0–120 μM from top to bottom. Arrows indicate the change in absorbance upon increasing the DNA concentration. Inset: plot of $(\varepsilon_a - \varepsilon_f)/(\varepsilon_b - \varepsilon_f)$ vs. [DNA] and the nonlinear fit for the titration of DNA to Ru(II) complexes.

the absorbance. The binding constant K_b of 1 is greater than that of **2**, showing the DNA-binding affinity of **1** stronger than that of **2**. The K_b values of the two complexes we studied in this paper are much smaller than those observed for many DNA intercalative complexes of type $[Ru(phen)_2L]^{2+}$: $K_b = 5.1 \times 10^6\ M^{-1}$ for $[Ru(phen)_2dppz]^{2+}$ (dppz = dipyrido[3,2-*a*:2′,3′-*c*]phenazine]) [31], $1.2 \times 10^5\ M^{-1}$ for $[Ru(phen)_2(actatp)]^{2+}$ (actatp = acenaphthereno[1,2-*b*]-1,4,8,9-tetraazariphenylence) [32] and $1.1 \times 10^5\ M^{-1}$ for $[Ru(phen)_2(PPIP)]^{2+}$ (2-(4′-phenoxy-phenyl)imidazo[4,5-*f*][1,10]-phenanthroline) [40]. It is interesting to find the intrinsic binding activity of complexes **1** and **2** are much higher than $[Ru(phen)_3]^{2+}$ ($0.55 \times 10^4\ M^{-1}$) and their analogue $[Ru(phen)_2(bpy)](PF_6)_2$ ($0.36 \times 10^4\ M^{-1}$) [41]. Although the mechanism is not clear, it is also important since the increasing of the charge of the ligands can enhance the affinity of complexes and DNA.

3.3. Emission spectra

Upon excitation using a wavelength of 430 and 436 nm for complexes **1** and **2** respectively, both of the complexes can emit fluorescence with a maximum wavelength of about 630 nm. The results of the emission titration for these complexes with DNA are shown in Fig. 4. The fluorescence intensity of these complexes increased with the increase of DNA concentration, reaching a maximum at the ratio of [DNA]/[Ru] ≈ 20:1, at which there is a 3.71- and 2.96-fold increase in the fluorescence intensity of the complexes compared with that in the absence of DNA for **1** and **2,** respectively. The results suggest that both of the complexes can be protected from solvent water molecules by the hydrophobic environment inside the DNA helix, since that the butyl has a bigger sterical hindrance than ethyl, complex **1** can be protected more efficiently than complex **2**.

3.4. Enantioselective binding studies

Circular dichroic spectra can provide information about the chirality of spectroscopically active species in solution. The *rac*-metal complexes give a zero CD but show induced circular dichroic (ICD)

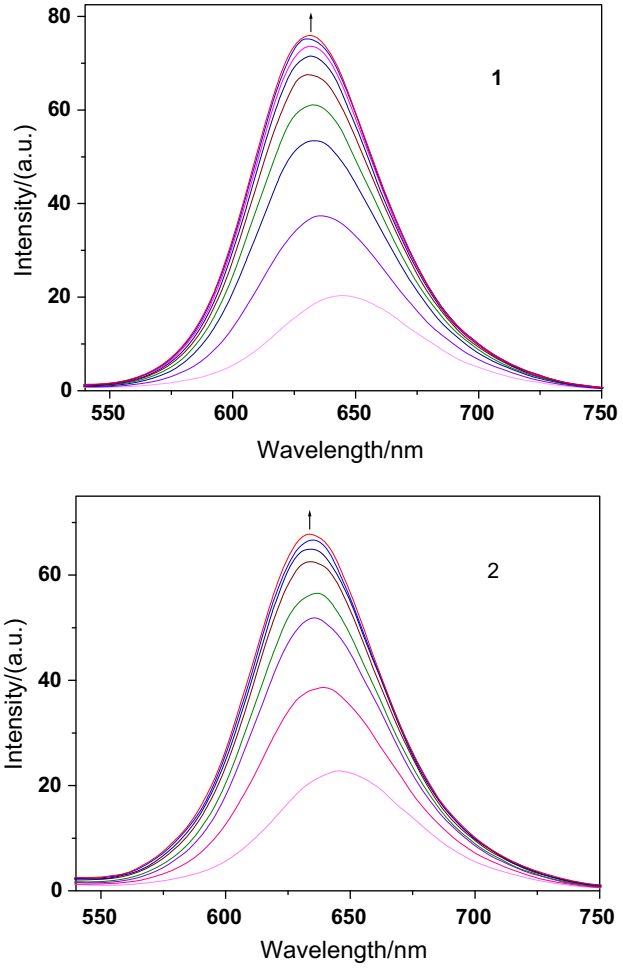

Fig. 4. Emission spectra of **1** and **2** in Tris buffer (pH 7.2) in the presence of increasing amounts of CT-DNA, [Ru] = 10 μM, [DNA] = 0–200 μM. Arrow shows the emission intensity changes upon increasing DNA concentrations.

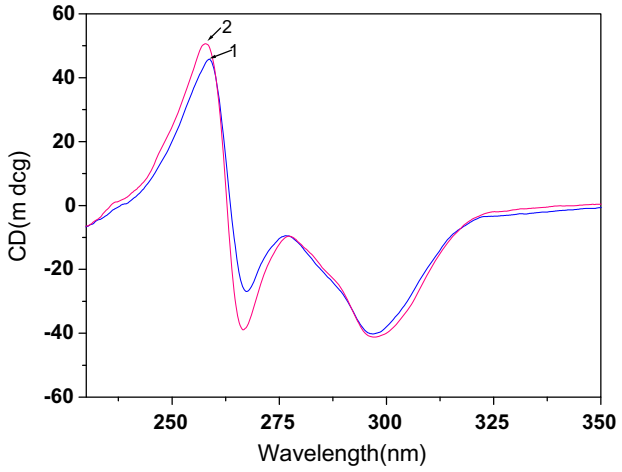

Fig. 5. CD spectra of **1** and **2** in 5 mM Tris–HCl and 50 mM NaCl (pH 7.2) in the presence of CT-DNA, [Ru] = 50 μM, [DNA] = 1.0 mM.

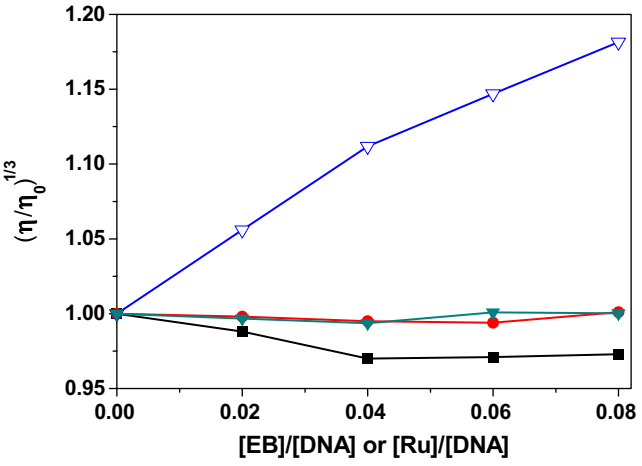

Fig. 6. Effects of increasing amounts of **1** (■), **2** (●), EB(▽) and $Ru(bpy)_3^{2+}$ (▼) on the relative viscosities of CT-DNA at 30 ± 0.1 °C, [DNA] = 0.5 mM, r = [Ru]/[DNA] ($\times 10^{-2}$).

signals on enantiopreferential binding to DNA providing further and definitive confirmation for their DNA binding [42,13]. Thus, the CD spectral technique has been used to study the enantiopreferential DNA binding of *rac*-metal complexes. According to the proposed binding model [43,44], the Δ-enantiomer of the complex, a right-handed propeller-like structure, will display a greater affinity than the Λ-enantiomer with the right-handed calf-thymus DNA helix, due to the appropriate steric matching. Therefore, the enantiospecific binding of complex to DNA can be observed clearly from circular dichroism spectra.

The CD spectra in the UV region of 230–350 nm for complexes **1** and **2** after their racemic solution has been dialyzed against DNA are shown in Fig. 5. Both of the dialysates of the Ru(II) complexes show strong CD signals consist of a positive (258 nm) and two negative bands (267 and 297 nm). This is typical of exciton coupled ICD arising due to enantiopreferential binding of the Δ-enantiomer of the *rac*-complex and/or ligand–ligand interactions among DNA bound/unbound complexes [45]. The CD spectra results indicate that both complexes show good enantioselectivity when binding with DNA, and the Δ-enantiomers reveal the potential to bind preferentially to right-handed CT-DNA.

3.5. Viscosity studies

Optical photophysical probes provide necessary, but not sufficient clues to support a binding model. Hydrodynamic measurements (i.e., viscosity and sedimentation) that are sensitive to length change are regarded as the least ambiguous and the most critical tests of a binding model in solution in the absence of crystallographic structural data [12,46,47]. A classical intercalation model results in lengthening the DNA helix as base pairs are separated to accommodate the bound ligand, leading to the increase of DNA viscosity. In contrast, a semi-intercalation of ligand could bend (or kink) the DNA helix, reduce its effective length, and concomitantly, its viscosity. In addition, some complexes such as $[Ru(bpy)_3]^{2+}$, which interacts with DNA by an electrostatic binding mode, have no influence on DNA viscosity [48].

The changes in relative viscosity of rod-like CT-DNA in the presence of $[Ru(phen)_2(L)]^{4+}$ (L^1 or L^2), EB (ethidium bromide = 3,8-diamino-5-ethyl-6-phenylphenanthridinium bromide) and $[Ru(bpy)_3]^{2+}$ are shown in Fig. 6. EB, a well-known DNA intercalator, increases the relative viscosity strongly by lengthening the DNA double helix through intercalation. On the contrary, $[Ru(bpy)_3]^{2+}$, which binds to DNA in the electrostatic mode, exerts essentially no effect on DNA viscosity. As can be seen from Fig. 6, the viscosity of DNA decreases with increasing concentration of **1**, which is consistent with bending or kinking of the helix upon binding *rac*-Ru(II) complex to DNA [45]. In contrast, the viscosity of DNA remains almost unchanged upon addition of **2**. The results suggest that the binding modes of complexes **1** and **2** are different and **1** may partially intercalate between DNA base-pairs while **2** most likely interact with DNA in an electrostatic binding mode.

4. Conclusion

Two new Ru(II) complexes $[Ru(phen)_2(L)]^{4+}$ where the ligand L contains dicationic pendants have been synthesized. The experimental and theoretical studies show that the main ligand with dicationic pendants can cause some interesting differences in the properties of the resulting complexes. The results indicate that **1** has a greater DNA affinity than **2**. It is a very interesting finding that the two complexes reveal good enantioselectivity when binding with DNA. In addition, the experimental results suggest that complexes **1** and **2** bind to DNA in different modes, i.e., **1** by semi-intercalation and **2** by electrostatic binding mode.

N^6-R-adenine **N^6,N^6-diR-adenine**

R = propyl, pentyl, hexyl, benzyl R = butyl

Scheme 1.

$[Ru^{III}Cl_4(DMSO)[H\text{-}(BAP)]] \cdot 0.5H_2O$ (**5**) have been spectroscopically characterized (BAP = N^6-benzylaminopurine). Moreover, in an attempt to obtain similar complexes from $RuCl_3 \cdot 3H_2O$ in DMSO/HCl [16] or from *cis*-$[RuCl_2(DMSO)_4]$ in EtOH/HCl we have obtained a microcrystalline solid of an outer-sphere complex of Ru(II), $[H\text{-}(BAP)][Ru^{II}Cl_3(DMSO)_3]$ (**6**). A similar crystalline Ru(II) complex has been isolated with the creatinine bioligand, $[H\text{-}(creat)][Ru^{II}Cl_3(DMSO)_3]$ (**7**) which has been structurally solved by X-ray diffraction for comparison purposes.

2. Experimental

2.1. Materials, analysis and physical measurements

All organic, including 6-benzylaminopurine (BAP) and creatinine, and inorganic ($RuCl_3 \cdot xH_2O$) reagents were used without further purification (Sigma and Aldrich). The starting complexes $[(DMSO)_2H][trans\text{-}Ru^{III}Cl_4(DMSO)_2]$ and $(NH_4)[trans\text{-}Ru^{III}Cl_4(DMSO)_2]$ were synthesized according to the procedure of Alessio et al. [16] and *cis*-$[RuCl_2(DMSO)_4]$ to the method reported by Evans et al. [17].

Tris–HCl, [tris(hydroxymethyl)aminomethane] hydrochloride, and HEPES, [4-(hydroxyethyl)-1-piperazineethanesulfonic acid] were obtained from ICN (Spain). pBR322 plasmid DNA and DTT (1,4-dithio-DL-threitol) were from Boehringer Mannheim (Germany). EDTA and ethydium bromide were from Sigma and ultrapure agarose was obtained from Pronadisa (Spain).

Elemental analyses were carried out using Carlo-Erba models 1106 and 1108 and Thermo Finningan Flash 1112 microanalysers. Infrared spectra (KBr pellets) were recorded on a Bruker IFS 66 and on a Nicole Impact 400. UV–Vis spectra were recorded on a Varian Cary 300 Bio UV–Vis spectrophotometer. ^1H and ^{13}C NMR spectra were obtained with a Bruker AMX 300 spectrometer. Proton and carbon chemical shifts in dimethylsulfoxide (DMSO-d_6), chloroform ($CDCl_3$) and deuterated water (D_2O) solutions were referenced itself to DMSO-d_6 [^1H NMR δ(DMSO) = 2.47 ppm ^{13}C NMR δ(DMSO) = 40.0 ppm], to $CDCl_3$ [^1H NMR $\delta(CDCl_3)$ = 7.26 ppm ^{13}C NMR $\delta(CDCl_3)$ = 77.0 ppm] and to D_2O [^1H NMR δ(D_2O) = 4.79 ppm], respectively. Conductivity measurements were carried out on a Crison 525 conductimeter at 25 °C.

2.2. Syntheses

2.2.1. Synthesis of N^6-substituted adenines

These ligands were obtained according to previously described methods [18,19]: a suspension of 0.5 g (3.2 mmol) of 6-chloropurine in 10 ml of *n*-butanol and 1.5 ml of triethylamine was refluxed with the required amount (3.2 mmol) of the corresponding amine during several hours. The resulting solution was evaporated in vacuum, yielding a syrup which was treated with concentrated ammonium hydroxide and evaporated again. The resulting solids were filtered off and washed with cold water and cold acetone to remove the triethylammonium hydrochloride impurities. Dissolution of these compounds in HCl 2 M or in EtOH/HCl yields the corresponding salt. Yields, elemental analyses, and ^1H NMR data are included in Table 1, and IR data of protonated ligands is discussed in Table 4. A more complete spectroscopic characterization of these ligands synthesized and their respective hydrochloride salts is included as Supplementary data.

2.2.2. Synthesis of $[Ru^{III}Cl_4(DMSO)[H\text{-}(N^6\text{-pentyladenine})]]$ (**1**), $[Ru^{III}Cl_4(DMSO)[H\text{-}(N^6\text{-hexyladenine})]]$ (**2**), $[Ru^{III}Cl_4(DMSO)\text{-}[H\text{-}(N^6\text{-dibutyladenine})]]$ (**3**), $[Ru^{III}Cl_4(DMSO)[H\text{-}(N^6\text{-propyladenine})]] \cdot 0.5EtOH$ (**4**) and $[Ru^{III}Cl_4(DMSO)[H\text{-}(BAP)]] \cdot 0.5H_2O$ (**5**)

A 0.05 mmol sample of $[NH_4][trans\text{-}RuCl_4(DMSO)_2]$ was dissolved in 5 ml of EtOH/HCl (0.1 M). The resulting solution was stirred for 5 min at room temperature and 0.1 mmol of the ligand dissolved in 2 ml of EtOH/HCl (0.1 M) were added. The orange solution was stirred for 15 min until a deep orange solution was obtained. Orange crystals appeared in the solution after 24 h. The crystals were filtered off and dried in vacuum. Yield 40%.

s = singlet; d = doblet; t = triplet; quint = quintuplet; hex = hexaplet; br = broad; J_{est} = estimated coupling constant.

(methanol): λ 358 (ε 319 × M^{-1} cm^{-1}). Λ_M/Ω^{-1} cm^2 mol^{-1} (10^{-3} mol dm^{-3} in DMSO, 25°C) = 50.

Although complex (**6**) and the structurally solved [H-(creat)][$Ru^{II}Cl_3(DMSO)_3$] (**7**) present the same anion complex unit (see Section 3), comparison of their powder X-ray diffraction patterns revealed that both compounds do not have the same packing. Details of the synthesis and description of the structure of the creatinine complex (**7**) are included in the Supplementary data (Appendix B).

2.3. X-ray crystallography

Suitable crystals of (**1**), (**2**), (**3**) and (**7**) were selected for X-ray single crystal diffraction experiments and mounted at the tip of glass fibres on an Enraf-Nonius CAD4 diffractometer producing graphite monochromated Mo Kα radiation (λ = 0.71073 Å). In each case, after the random search of 25 reflections, the indexation procedure gave rise to the cell parameters (see Table 2 for a summary of the crystal data). Intensity data were collected in the ω–2θ scan mode and corrected for Lorenz and polarization effects. The absorption correction was performed following the empirical Ψ-scan [20] (**7**) and DIFABS [21] (**1**, **2** and **3**) methods. The structural resolution procedure was made using the WInGX package [22]. Solving for structure factor phases was performed by SIR2002 [23] (**7**) and SIR2004 [24] (**1**, **2** and **3**), and the full matrix refinement by SHELXL97 [25] for all of them. Non-H atoms were refined anisotropically and H-atoms were introduced in calculated positions and refined riding on their parents atoms except for protonation sites (**1**, **2** and **3**). H-atoms of protonation [H(3)] were located in Fourier maps and refined isotropically. A summary of refinement parameters can also be seen in Table 2. In **1**, **2** and **3**, the coordinated DMSO present rotational disorder which has been modelled assuming two fragments with complementary occupancies. Also, the aliphatic chain of the adenines has been split in two (**1**) or four (**2**) different positions to account for the observed disorder.

2.4. Preparation of adducts DNA–metal complexes

Fifteen nanograms of pBR322 DNA were incubated in an appropriate volume with the required complex concentration corresponding to the molar ratio ri = 0.5. Ruthenium complexes were dissolved in HEPES buffer (4 mM HEPES, 10 mM KCl and 2 mM $MgCl_2$, pH 7.4). The different solutions were passed through 0.2 nm FPO30/3 filters (Scheicher & Schuell, Germany). The incubation was run at 37 °C for 4 h.

2.5. Atomic force microscopy (sample preparation and imaging)

Samples were prepared by placing a drop (3 μl) of DNA solution or DNA–metal solution onto freshly cleaved green mica (Ted Pella, Inc., CA, US). After adsorption for 5 min at room temperature, the sample was gently rinsed with MilliQ water and dried under a stream of compressed argon gas. Imaging was performed using a multimode atomic force microscope with a Nanoscope IIIa controller (Veeco/Digital Instruments, Santa Barbara, CA, USA) operating in air and at room temperature (t = 23 ± 2 °C) and a relative humidity (RH) always lower than 45%. Commercially available cantilevers (NCH Pointprobe, Nanosensors, Norderfriedrichskoog, Germany) were used for tapping mode scanning with a root mean square amplitude of 0.7 V (~9 nm) and a drive frequency of ~300 kHz. Images were captured in height mode at a scan rate of ~1 Hz in a 512 × 512 pixel format.

2.6. Gel electrophoresis of drug-pBR322 complexes

pBR322 DNA aliquots (0.25 μg/mL) were incubated in TE buffer (10 mM Tris–HCl, 1 mM EDTA, pH 7.5) at molar ratio ri = 0.50 for electrophoresis study. Incubation was carried out in the dark at 37 °C for 24 h. 4 μL of charge marker were added to aliquots parts of 20 μL of the compound–DNA complex. The mixture was electrophoresed in agarose gel (1% in TBE buffer, Tris–Borate–EDTA) for 5 h at 1.5 V/cm. Afterwards, the DNA was dyed with ethydium bromide solution (0.75 μg/mL in TBE) for 6 h. A sample of free DNA was used as control. The experiment was carried out in an ECOGEN horizontal tank connected to a PHARMACIA GPS 200/400 variable potential power supply and the gel was photographed with an image Master VDS, Pharmacia Biotech.

3. Results and discussion

3.1. Description of X-ray structures [$Ru^{III}Cl_4$(DMSO)[H-(N^6-pentyladenine)]] (**1**), [$Ru^{III}Cl_4$(DMSO)[H-(N^6-hexyladenine)]] (**2**) and [$Ru^{III}Cl_4$(DMSO)[H-(N^6,N^6-dibutyladenine)]] (**3**)

The zwitterionic inner-sphere complexes (**1**), (**2**) and (**3**) (Figs. 1–3) present slightly distorted octahedral coordination around Ru(III) ion with four chlorido ligands in the basal plane and the two axial positions occupied by a S atom of a DMSO molecule and the N(9) atom present in the corresponding purine ring. These complexes show a similar disposition to that found in NAMI-A [4].

Previous crystallographic studies have demonstrated that the most probable site of coordination on unsubstituted purines is the imidazole N(9) nitrogen atom. When N(9) is blocked, N(7) is the site of coordination and there are only few exceptions that violate these general guidelines [26].

All Ru(III) complexes show metal–nitrogen [2.139(12) for (**1**), 2.113(12) for (**2**) and 2.141(4) Å for (**3**)] and metal–sulfur bond lengths [2.272(5) for (**1**), 2.264(5) for (**2**) and 2.2629(16) for (**3**)], comparable to those of related complexes [13,15,27]. The Ru–Cl bond distances [ranging from 2.325(4) to 2.359(4) Å for (**1**), 2.329(4) to 2.350(4) Å for (**2**) and 2.3439(18) to 2.3607(17) Å for (**3**)] are in agreement with published values found in the related structures above mentioned. The same can be mentioned with the *cis* angles around the metal which vary between 86.7(3)° and 94.14(17)° for (**1**), 87.6(3)° and 94.49(18)° for (**2**) and 87.73(14)° and 93.39(7)° for (**3**), while the *trans* angles are between 176.44(19)° and 178.5(4)° for (**1**), 177.80(18)° and 177.25(17)° for (**2**) and 176.34 (15)° and 177.56(6)° for (**3**). On the other hand, a comparison between the protonated adenines [(**1**), (**2**) and (**3**)] and neutral adenine shows a more significant increment of the C(2)–N(3)–C(4) angle which is in agreement with N(3) protonation [26]. Selected bond distances and angles are shown in Table 3.

As observed previously [15], in the three complexes the protonated adenine ligand is involved in an intramolecular hydrogen bond with *cis* chlorido ligand: N(3)–H···Cl = 2.68 for (**1**), 2.60 for (**2**) and 2.54 for (**3**).

By comparison of powder X-ray diffraction patterns of complex (**6**) and the structurally solved [H-(creat)][$Ru^{II}Cl_3$(DMSO)$_3$] (**7**) it is possible to deduce that both compounds do not have the same packing. Detailed description of the structure of the outer-sphere creatinine complex [H-(creat)][$Ru^{II}Cl_3$(DMSO)$_3$] (**7**) is included in the Supplementary data. The anion has a facial octahedral structure with three chlorido ligands and three DMSO (coordinated

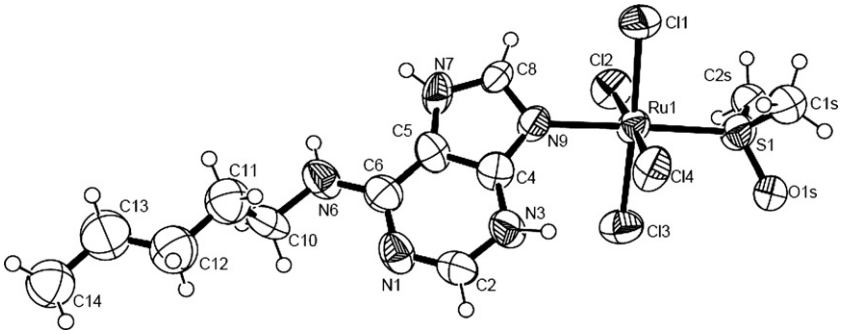

Fig. 1. ORTEP of [$Ru^{III}Cl_4$(DMSO)[H-(N^6-pentyladenine)]] (**1**). Displacement ellipsoids are drawn at 50% probability level and H atoms are drawn as circles of arbitrary radii.

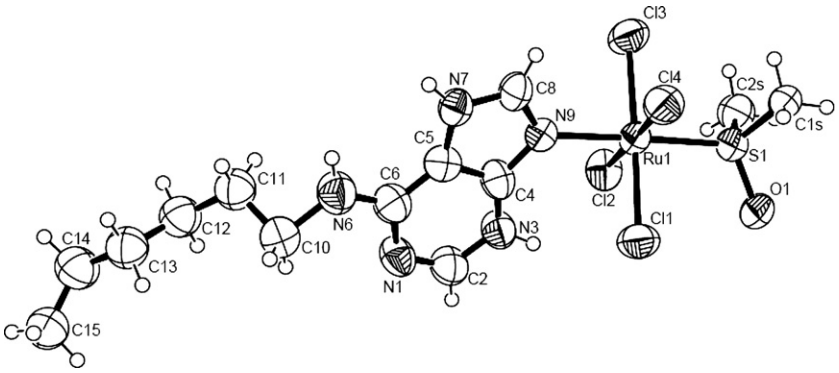

Fig. 2. ORTEP of [$Ru^{III}Cl_4$(DMSO)[H-(N^6-hexyladenine)]] (**2**). Displacement ellipsoids are drawn at 50% probability level and H atoms are drawn as circles of arbitrary radii.

via *S*) molecules (Fig. 4). Selected bond distances and angles are shown in Table 2 of Supplementary data.

3.2. Infrared spectra

The IR spectra of inner-sphere complexes, [$Ru^{III}Cl_4$(DMSO)[H-(N^6-pentyladenine)]] (**1**), [$Ru^{III}Cl_4$(DMSO)[H-(N^6-hexyladenine)]] (**2**), [$Ru^{III}Cl_4$(DMSO)[H-(N^6,N^6-dibutyladenine)]] (**3**), [$Ru^{III}Cl_4$(DMSO)[H-(N^6-propyladenine)]] · 0.5EtOH (**4**) and [$Ru^{III}Cl_4$(DMSO)[H-(BAP)]] · 0.5H_2O (**5**) were compared with those of protonated ligands. Tentative band assignments (cm^{-1}) for N^6-substituted adenines according to literature [28–30] and some characteristic changes in the complex bands are shown in Table 4. The most relevant features are related to the binding between the Ru(III) and a nitrogen atom of the purine ring [bond through the N(9) atom of adenine and protonation of the N(3) atom]. These changes are: (i) very small shifts on the bands related to [δ(NHR)] and [δ(C=N–H)] of protonated N^6-substituted adenine which indicate the zwitterionic form of the complexes. The bands appearing at 1662–1668 cm^{-1} and 1611–1615 cm^{-1} show small shifts probably as a consequence of a change in H-bonding (in complex **3**, only one band is observed at 1637 cm^{-1}); (ii) The 1513–1520 cm^{-1} band assignable to ν[C(4)–N(9)] + δ[C(8)–H] + δ[CH_2] disappears in all spectra of the complexes; iii) The band at *ca.* 1460 cm^{-1} related

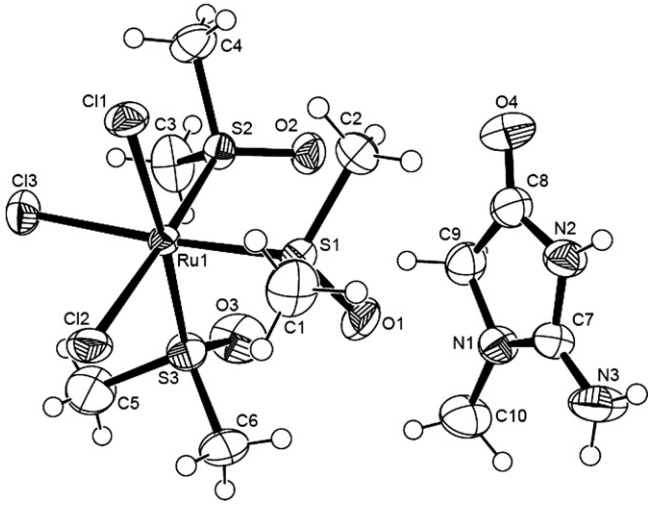

Fig. 4. ORTEP of [H-creat][Ru^{II}Cl$_3$(DMSO)$_3$] (**7**). Displacement ellipsoids are drawn at 50% probability level and H atoms are drawn as circles of arbitrary radii.

to ν[C(8)–N(9)] splits into a shoulder at *ca.* 1480 cm^{-1} and a medium intensity band between 1440 and 1460 cm^{-1}. These features agree with the coordination of Ru to the N(9) atom of the adenine ligand. Finally, strong bands at *ca.* 1070 cm^{-1} assignable to ν(S=O) of the S-bonded DMSO molecules and *ca.* 1020 cm^{-1} [ρ_r(CH$_3$)] as well as a weak intensity peak at *ca.* 430 cm^{-1} related to ν(Ru–S) modes, are observed in all the complexes.

The IR spectrum of the outer-sphere complex [H-(BAP)][Ru^{II}Cl$_3$(DMSO)$_3$] (**6**) was compared with that of [H-(creat)][Ru^{II}Cl$_3$(DMSO)$_3$] (**7**) (See Supplementary data). Both spectra are typical of *fac*-[Ru^{II}Cl$_3$(DMSO)$_3$]$^-$ units in which two strong bands are observed. The first one at 1095 cm^{-1} with small shoulder at *ca.* 1080 cm^{-1} due to ν(S=O) of the S-bonded DMSO molecules and the second at 1019 cm^{-1} corresponding to ρ_r(CH$_3$). The bands due to ν(ring) exhibit essentially the same pattern of that observed for the protonated ligand with important differences with respect to the spectra of the inner-sphere complexes. The medium intensity peak at 428 cm^{-1} is related to ν(Ru–S).

3.3. ^{1}H NMR spectra of Ru(II) compounds

The ^{1}H NMR spectrum of [H-(BAP)][Ru^{II}Cl$_3$(DMSO)$_3$] (**6**) in D$_2$O shows three singlets between 3.37 and 3.27 ppm attributed to the methyl protons of dimethylsulphoxide [31]. The presence of more than one signal in D$_2$O results from the formation of different aquospecies as has been previously reported in the literature [16]. In a few days, the solution turns to greenish gray and the signals of the spectrum show a progressive broadening and shifting which are indicative of decomposition of the complex and presence of paramagnetic Ru(III) species. On the other hand, the corresponding spectrum in DMSO-d_6 shows only one signal for the six equivalent methyl groups of dimethylsulphoxide at 3.29 ppm, as it was expected. Similar results are obtained in the corresponding creatinine complex [H-(creat)][Ru^{II}Cl$_3$(DMSO)$_3$] (**7**).

3.4. Electronic spectra

The electronic spectra of the **1–4** complexes were obtained in methanol solution and are suggestive of octahedral geometry around Ru(III). As observed in similar Ru(III) compounds a band centred at 400 nm with charge-transfer character is observed [($\varepsilon = 1.94 \times 10^3$) for **1**; ($1.58 \times 10^3$) for **2**; ($3.39 \times 10^3$) for **3** and ($1.82 \times 10^3$) for **4**]. The electronic spectrum of complex **5** was performed in DMSO solution due to its low solubility in MeOH, [405 nm ($\varepsilon = 1.35 \times 10^3$)]. Moreover, an important band corresponding to the $\pi \rightarrow \pi^*$ transition of the protonated adenine ring, is present [280 (1.1×10^4) for **1**; 277 (1.57×10^4) for **2**; 288 (2.08×10^4) for **3**, 275 (1.08×10^4) for **4** and 282 (6.3×10^3) for **5**]. A freshly solution was used in all our measurements in order to avoid the known hydrolysis processes of these Ru(III) complexes in methanol [16].

The electronic spectrum of the complex [H-(BAP)][Ru^{II}Cl$_3$(DMSO)$_3$] (**6**) was obtained in a freshly prepared methanol solution and is suggestive of octahedral geometry around Ru(II). The observed band at 358 ($\varepsilon = 319$) nm is assigned to the transition $^1A_{1g} \rightarrow {}^1T_{1g}$.

3.5. Ruthenium complexes–plasmidic DNA interactions

Atomic force microscopy and electrophoretic mobility (Figs. 5 and 6, respectively) were used to verify the interactions of isolated ruthenium complexes and DNA pBR322. Plasmidic DNA was incubated for 4 h at 37 °C with the series of complexes **1–5** at identical concentrations.

In Fig. 5a plasmid pBR322 DNA without previous treatment, in mixed covalently closed circular (ccc) and open (oc) forms, was AFM imaged. AFM images of the same DNA treated with the complexes **1–5** are presented in Fig. 5b–f. There are not noticeable differences in the images corresponding to the different complexes.

[$Ru^{III}Cl_4$(DMSO)[H-(BAP)]] · 0.5H_2O (**5**) (f). In all cases, Ru:DNA base pairs relationship is 1:20 (each circular plasmid has 4361 base pairs).

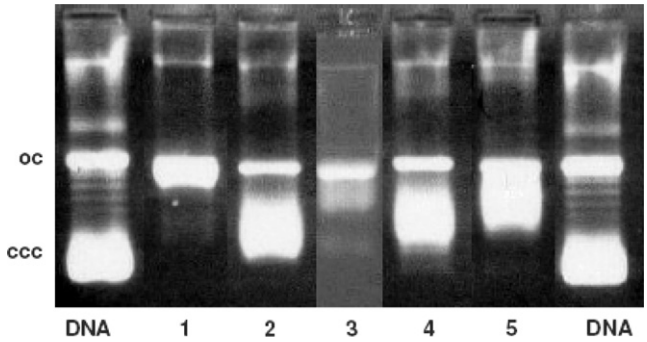

Fig. 6. Electrophoresis experiments: Plasmidic DNA pBR322 (DNA control), incubated in presence of: [$Ru^{III}Cl_4$(DMSO)[H-(N^6-pentyladenine)]] (**1**), [$Ru^{III}Cl_4$-(DMSO)[H-(N^6-hexyladenine)]] (**2**), [$Ru^{III}Cl_4$(DMSO)[H-(N^6-dibutyladenine)]] (**3**), [Ru^{III}-Cl_4(DMSO)[H-(N^6-propyladenine)]] · 0.5EtOH (**4**), [$Ru^{III}Cl_4$(DMSO)[H-(BAP)]] · 0.5H_2O (**5**).

Probably the type of interaction is identical for all the series and the variation of the nature and length of the chain do not affect it. However, in all of them, kinks can be observed confirming interaction with DNA in agreement with electrophoretic mobility results. Nuclease activity is not observed in the different complexes and the modifications indicated confirm that these complexes do not cleave the pBR322 plasmid DNA. They yield more coiled and/or more associated plasmids which are in agreement with different types of interactions between these ruthenium complexes and the corresponding DNA: ruthenium covalent binding to the heterocyclic nitrogens, intercalation of the adenine ring and electrostatic interaction of the protonated nitrogens and the phosphate groups of other plasmidic units.

The influence of the compounds on the tertiary structure of DNA was determined by its ability to modify the electrophoretic mobility of the covalently closed circular (ccc) and open (oc) forms of pBR322 plasmid DNA. Fig. 6 shows, from left to right,

the mobility of the native pBR322 plasmid DNA and the plasmid DNA incubated with the compounds **1–5**. The behavior of the gel electrophoretic mobility of these two forms, ccc and oc, of pBR322 plasmid and DNA ruthenium compounds adducts (Fig. 6) presents differences in comparison to the DNA pattern. Incubation with complexes (**1**) and (**3**) show that only the form oc of DNA is present, while in case of the other compounds (**2**), (**4**) and (**5**) the DNA pattern is modified showing a wide band with lower mobility than ccc form of free plasmid control as it was observed previously [15]. Probably, the insertion of the purine ligand in the double helix origins opening of the DNA forms. We are aware that under physiological conditions ruthenium compounds are prone to various hydrolytic processes [2,17,22,57] but the exact study of such reactions was out of the scope of this work.

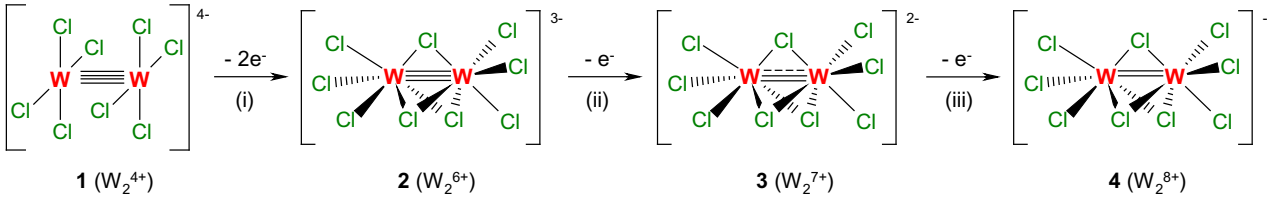


Scheme 1.

However, despite the rich and facile redox chemistry of the ditungsten center W_2^{n+} ($n = 4, 6, 7$) the application of these complexes in catalysis has been largely unexploited. This can be attributed to several reasons. In aqueous or aqueous acidic media (HCl 3–12 M) the chemistry of the alkali salts of these compounds is in general complex in nature and only **2** is stable [15–17]. In organic media **1**$Na_4(THF)_x$ is stable in THF up to 0 °C and the salts of **2**–**4** with organic cations are soluble and stable in inert organic solvents (CH_2Cl_2, THF), but the synthetic utility of the W_2^{n+} redox couples is impeded by: (a) the great ease of oxidation of **1** to **2** and the difficulty of reducing **2** to **1**; (b) the failure to perform the **2** → **3** oxidation in a convenient and controlled manner; and (c) the inability to obtain **4** directly from the oxidation of **1**–**3**. Additional complications arise from disproportionation and/or comproportionation reactions between **2**, **3** and **4** influenced by the solvent(s), the nature of the counter organic ion(s) and the presence of the halide ligand [10]. Finally, a major obstacle is the complexities entailed by the different synthetic methods for their preparation, especially of the salts with organic cations, which are elaborate or serendipitous.

Attempts to prepare salts of **1** with organic cations from the WCl_4 reduction with Na/Hg amalgam in toluene or THF produced respectively the two- or three-electron oxidized complexes **2**$(HTMPP)_3$ and **3**$(PPN)_2$ (yield 50%), despite the neutral or even reducing conditions. Efforts to obtain **2a** or **2**$(Et_4N)_3$ by mimicking the synthesis of the $[Mo_2(\mu\text{-}Cl)_3Cl_6]^{3-}$ analog [18] e.g. the comproportionation reaction of the halocarbonylmolybdates $[Mo(CO)_5Cl]^-$ with anhydrous molybdenum halides is not applicable with tungsten. Indeed, reaction of $[W(CO)_5Cl]^-$ with WCl_6 in CH_2Cl_2 in the presence of TBACl gives a mixture of $[WCl_6]^-$, $[WCl_6]^{2-}$ and **3a** in low yield (~20%) [19].

The cation exchange pathway from the alkaline salts of **2** [20–24] (addition of TBACl into solutions of **2**K_3 in concentrated hydrochloric acid) has been previously reported [25–29], but the yield is notoriously low, variable, and no experimental details are given. In addition, this methodology requires the demanding synthesis of the alkaline salts obtained from the reduction of the WO_4^{2-} ion in aqueous HCl solutions chemically, electrochemically (**2**K_3) [30,31] or from the oxidation of **1**$Na_4(THF)_x$ (**2**Na_3) [32], and $[W_2(mhp)_4]$ (**2**Cs_3) [33] by $HCl_{(g)}$ in THF or CH_3OH, respectively. Oxidation of **2a** obtained from the latter route with molecular chlorine in CH_2Cl_2 provides **3a** along with decomposition products [13]. Another example of formation of a relevant W_2^{7+} derivative has been the isolation of $TPP[W_2(\mu\text{-}Cl)_3Cl_5(THF)]$ (**5**) formed from the one-electron photochemical oxidation (induced by visible light) of $TPP[W_2(\mu\text{-}Cl)_3Cl_4(THF)_2]$ (**6**) by CCl_4 [34].

Herein, as a part of our studies in exploiting the reactivity of multiply bonded clusters [35] we report novel insights in the redox chemistry of the aforementioned complexes in organic media, by chemical and electrochemical means. This resulted not only in developing new effective preparative methods for the synthesis of **2a**,**b** and **3a**,**b**, but also in conditions where the bimetallic W_2^{n+} ($n = 6, 7$) redox couple becomes functional and a potential candidate for mediating stoichiometric or catalytic oxidations of organic compounds [36].

2. Experimental

2.1. Starting materials

Starting materials and solvents were purchased from Sigma–Aldrich and are of the highest available purities. Chlorobenzene was purchased from Fluka. **1**$Na_4(THF)_x$ [6], **2**K_3 [30], **4**(TEBA) [10], $PhICl_2$ [37], and PhIO [38] were prepared according to literature procedures. TBACl was purified by recrystallization from acetone. Toluene was distilled over Na, THF and diethyl ether over Na/Ph_2CO, MeCN, CH_2Cl_2, and chlorobenzene over P_2O_5 in an inert atmosphere. Acetone was distilled over Drierite. Carbon tetrachloride was fractionally distilled. $HCl_{(g)}$ was passed through a trap containing concentrated H_2SO_4 and subsequently through a tube containing silicon oxide and activated charcoal. DMSO was used without further purification. All solvents were degassed by three freeze-pump-thaw cycles, with the exception of water and methanol, which were degassed by bubbling nitrogen or argon for 0.5 h. All operations were performed under a dinitrogen (99.999%) or argon (99.999%) atmosphere, using Schlenk techniques on an inert gas/vacuum manifold or in a drybox (O_2, H_2O < 1 ppm).

2.2. Physical techniques

UV–Vis spectra were measured on a Hitachi U-2000 or a Varian Cary 50 Bio spectrophotometer. GC–MS experiments were performed on a Varian 3400 CX GC coupled to a Varian Saturn 2000 MS (Column 30 m × 0.25 mm ID, 0.25 μm, DB5-MS; injection 1 μL, 50:1 split; flow 1 mL/min-He, constant flow; oven 50 °C/hold 3.00 min, 7 °C/min to 150 °C, 50 °C/min to 280 °C, 280 °C/hold 2.12 min, 5 °C/min to 300 °C, 300 °C/hold 4.00 min; injector 280 °C; transfer line 280 °C; MSD scan range 10–600 amu). Dihydrogen was detected by gas chromatography (GC; Varian 90-P). Mass spectrometric analyses were done using electrospray ionization on a Thermo-Finnigan TSQ7000 triple-quadrupole. The heated inlet capillary was kept at 250 °C and the electrospray needle voltage was 4.5 kV. All other voltages were optimized to maximize ion transmission and minimize unwanted fragmentation and were determined during the regular tuning and calibration of the instrument. Nitrogen sheath gas was supplied to the electrospray source at 80 psi. Samples were infused into the source at a rate of 10 μL/min using a 500 μL Gastight syringe (Hamilton, Reno, NV) in a Pump 11 syringe pump (Harvard Apparatus, Holliston, MA). The same analyses were also done using a Fisons VG Quattro with a VG Biotech ionization source and CH_2Cl_2 or acetonitrile solutions were infused directly. The capillary voltage was 3.0 or 3.5 V, and the orifice to skimmer potential (cone voltage) was varied between 15 and 45 V depending on sensitivity. The source temperature was 353 K. Mass spectra were recorded with a scan range of m/z 200–2000 for positive and negative ions. EPR measurements were obtained with an upgraded Bruker ER-200D spectrometer interfaced with a personal computer and equipped with an Oxford ESR 900 cryostat, an Anritsu MF76A frequency counter, and a Bruker 035 M NMR gaussmeter. The Signal-Channel unit was replaced with an SR830 digital lock-in amplifier from Stanford Research. The perpendicular

4I02ST cavity was used, and the microwave frequency was 9.41 GHz. Atomic Absorption analyses were done with a GF AAS (Varian SpectrAA-640Z) instrument with Zeeman background correction. Electrochemical measurements were performed with an AUTOLAB PGSTAT100 electrochemical work station (EcoChemie B.V.) in the dry box. Cyclic voltammetry was performed using a Au disk electrode (1.6 mm in diameter) as the working electrode, a thin Pt foil as the counter electrode (8 cm^2) and a Ag/Ag^+ (0.01 M $AgNO_3$ and 0.1 M $TBAPF_6$ in MeCN) non-aqueous reference electrode with a prolonged bridge (0.1 M $TBAPF_6$ in MeCN). The working electrode was polished using successively 6, 3, 1 μm diamond paste on a DP-Nap polishing cloth, all obtained from Struers (Westlake, OH), washed with water, acetone and air-dried. The Pt foil and Pt gauge electrodes were cleaned in a $1 \div 4$ (v/v) $H_2O_2 \div$ concentrated H_2SO_4 solution and oven-dried. The concentration of the samples was 3 mM and the concentration of $TBAPF_6$ (supporting electrolyte) was 0.1 M. The potential sweep rate varied in the limits of 10–1000 mV/s. All of the voltammograms were compensated for the solution resistance. Bulk electrolysis was conducted in the dry-box with a three-compartment H-cell with compartments separated by 1 cm diameter fritted glass discs (Ace Glass 10–20 μm pore diameter). The working electrode and the counter electrode compartments were made of 25 mL screw-cap vials. Holes were drilled through the cup of the working electrode compartment allowing placement of a BAS Au-disk working electrode for monitoring, if necessary, the progress of the electrolysis, a thin Pt foil to be used as the working electrode during electrolysis, and a bridge to the reference electrode. A Pt-gauge electrode was placed in the counter electrode compartment. Electrolysis was carried out until the faradaic current decayed below 2% of its initial value.

2.3. Preparation of **2a** and **2b** by cation exchange

To a degassed mixture of **2**K_3 (0.804 g, 1.0 mmol) and TBACl (0.834 g, 3.0 mmol) was added methylene chloride (30 mL) and the mixture was stirred for 24 h. After filtration, the solution was concentrated (~10 mL). The addition of excess diethyl ether (20 mL) under stirring for 30 min yielded a green precipitate, which was separated by filtration and dried. The solid was recrystallized from methylene chloride/diethyl ether. Yield: 1.16 g (82%) of **2a**. UV–Vis (CH_2Cl_2): λ_{max} (ε_M) 462 (3600), 602 (33), 760 (23) nm ($M^{-1}\,cm^{-1}$). ESI-MS, *m*/*z*: 1413.86 ([**2a**+H]$^+$), 343.28 ($[W_2Cl_9]^{2-}$), 360.72 ($[WCl_5]^-$), 616.73 ($[W_2Cl_7]^-$), 651.69 ($[W_2Cl_8]^-$), 929.07 ($[TBAW_2Cl_9]^-$).

The same procedure was followed with TPPCl (1.124 g, 3.0 mmol) instead of TBACl yielding 1.26 g (74%) of **2b**. UV–Vis (CH_2Cl_2): λ_{max} (ε_M) 462 (4300), 608 (38), 760 (26) nm ($M^{-1}\,cm^{-1}$).

2.4. Preparation of **2a** and **2b** by cation exchange from the biphasic system H_2O/CH_2Cl_2

To a degassed mixture of **2**K_3 (0.804 g, 1.0 mmol) and TBACl (0.834 g, 3.0 mmol) or TPPCl (1.124 g, 3.0 mmol) was added methylene chloride (20 mL) and the mixture was stirred for 4 h. Then water (10 mL) was added and stirring continued for another 20 min. The aqueous layer was separated, water (10 mL) was added again and the mixture was kept under stirring for 1 h. This procedure was repeated once more and, after removing the water, the solution was concentrated under vacuum and diethyl ether (20 mL) was added. The precipitate formed was recrystallized from acetone/diethyl ether and was dried under vacuum. Yield: 1.26 g (86%) of **2a**, 1.33 g (78%) of **2b**.

2.5. Preparation of **2a** and **2b** from WCl_4

To a degassed mixture of WCl_4 (3.26 g, 10.0 mmol) and TBACl (4.17 g, 15.0 mmol) or TPPCl (5.63 g, 15.0 mmol) was added toluene (20 mL). The mixture was transferred to another flask, which contained Na/Hg 0.44% w/w (104.5 g, 20.0 mmol Na) and was stirred for 24 h, filtered through Celite, and stripped under vacuum. The residue was dissolved in acetonitrile (10 mL), filtered, concentrated, and cooled at −20 °C to yield a green precipitate. This was filtered, recrystallized from acetonitrile and dried under vacuum. Yield: 6.36 g (90%) of **2a**, 7.34 g (86%) of **2b**. *Anal.* Calc. for $C_{48}H_{108}N_3W_2Cl_9$ **2a**: C, 40.77; H, 7.70; N, 2.97. Found: C, 40.69; H, 7.64; N, 2.87%. *Anal.* Calc. for $C_{72}H_{60}P_3W_2Cl_9$ **2b**: C, 50.72; H, 3.55. Found: C, 50.55; H, 3.49%.

2.6. Preparation of **2a** from $W(CO)_6$ and Me_3SiCl

To a degassed mixture of $W(CO)_6$ (1.05 g, 3.0 mmol) and TBACl (0.840 g, 3.0 mmol) was added chlorobenzene (20 mL) and the mixture was heated to reflux with constant stirring for 15 min. Then, Me_3SiCl (15 mL) was added and the reaction mixture was refluxed for another 7 h. The solution was then cooled down to room temperature and the solvent was removed under vacuum. The gelatinous residue was dissolved in methylene chloride (10 mL). The addition of excess diethyl ether (20 mL) yielded a green precipitate, which was separated by filtration. This procedure was repeated 4 times and the product was finally dried under vacuum. Yield: 1.58 g (74%).

2.7. Preparation of **3a** and **3b** from the biphasic system HCl (6 M)/CH_2Cl_2

To a degassed mixture of **2**K_3 (0.804 g, 1.0 mmol),) and TBACl (0.834 g, 3.0 mmol) was added methylene chloride (10 mL) and aqueous HCl 6 M (10 mL) and the mixture was stirred for 20 min. The aqueous layer was removed, aqueous HCl 6 M (10 mL) was added again and the mixture was kept under stirring for 30 min. The organic phase was collected and the solution was concentrated (~5 mL). Addition of excess diethyl ether (20 mL) under stirring for 30 min yielded a blue-violet precipitate, which was separated by filtration and dried. The solid was recrystallized by dissolving in acetone/diethyl ether and was dried under vacuum. Yield: 1.02 g (87%) of **3a**. UV–Vis (CH_2Cl_2): λ_{max} (ε_M) 576 (2400), 734 (1500) nm ($M^{-1}\,cm^{-1}$). ESI-MS, *m*/*z*: 326 ($[WCl_4]^-$), 360.5 ($[WCl_5]^-$), 651.5 ($[W_2Cl_8]^-$), 929 ($[TBAW_2Cl_9]^-$).

The same procedure was followed with TPPCl (1.124 g, 3.0 mmol) instead of TBACl yielding 1.36 g (>99%) of **3b**. UV–Vis (CH_2Cl_2): λ_{max} (ε_M) 582 (2500), 732 (1550) nm ($M^{-1}\,cm^{-1}$). ESI–MS, *m*/*z*: 1704.07 ([**3b** + TPP]$^+$), 341.78 ($[W_2Cl_9]^{2-}$), 360.72 ($[WCl_5]^-$).

2.8. Preparation of **3a** by oxidation of **2a**

2.8.1. Oxidation by $HCl_{(g)}$

Compound **2a** (0.141 g, 0.15 mmol) was dissolved in methylene chloride (5 mL) and $HCl_{(g)}$ was bubbled through the solution until the color changed from green to blue-violet. The solution was concentrated to half volume and upon addition of diethyl ether (5 mL) under stirring, a blue-violet precipitate was yielded, which was separated by filtration and dried under vacuum. Yield: 0.109 g (93%) of **3a**.

The same reaction in acetonitrile or THF afforded similar yields.

2.8.2. Oxidation by metal halides

To a degassed mixture of **2a** (0.141 g, 0.1 mmol) and anhydrous $CuCl_2$ (0.013 g, 0.1 mmol) was added methylene chloride (5 mL) and the mixture was stirred for 20 min, followed by filtration. The addition of excess diethyl ether (20 mL) under stirring for 30 min yielded a blue-violet precipitate, which was separated by filtration and dried under vacuum. Yield: 0.107 g (91%) of **3a**.

The same procedure was followed with the other metal chlorides employed in this study: $FeCl_3$ (0.016 g, 0.1 mmol), $HgCl_2$ (0.027 g, 0.1 mmol), $SnCl_2$ (0.019 g, 0.1 mmol), $AlCl_3$ (0.013 g, 0.1 mmol) all of which afforded similar yields (90–92%).

Examination of the products by Atomic Absorption shows negligible amounts of Cu, Fe, Hg, Sn, Al.

2.8.3. Oxidation by CCl_4

Compound **2a** (0.070 g, 0.050 mmol) was dissolved in methylene chloride (20 mL) and excess of carbon tetrachloride (2 mL) was added. The solution was stirred for 3 h in the dark or in the presence of visible light. The addition of excess diethyl ether (40 mL) under stirring yielded a blue-violet precipitate, which was separated by filtration and dried under vacuum. Yield: 0.035 g (60%) of **3a**.

Similarly, the reaction of **2a** in CCl_4, where it is insoluble, and stirring overnight produced **3a** in nearly quantitative yield.

2.8.4. Oxidation by $PhICl_2$

Compound **2a** (0.021 g, 0.15 mmol) and $PhICl_2$ (0.021 g, 0.075 mmol) were dissolved in methylene chloride (7.5 mL) and the solution was stirred for 10 min followed by filtration. The addition of excess diethyl ether (20 mL) under stirring yielded a blue-violet precipitate, which was separated by filtration and dried. Yield: 0.153 g (87%) of **3a**.

2.9. Preparation of *3a* and *3b* from $W(CO)_6$ (with Cl-donors)

2.9.1. 1,2-$C_2H_4Cl_2$

To a degassed mixture of $W(CO)_6$ (2.46 g, 7.0 mmol) and TBACl (1.95 g, 7.0 mmol) or TPPCl (2.63 g, 7.0 mmol) was added chlorobenzene (30 mL) and the mixture was heated to reflux with constant stirring for 15 min. 1,2-Dichloroethane (15 mL) was added and the mixture was refluxed further for 7 h. The solution was cooled at room temperature. Addition of diethyl ether (20 mL) yielded a blue-violet precipitate, which was separated by filtration and dried. The solid was recrystallized from acetonitrile. Yield: 5.25 g (85%) of **3a**, 4.89 g (89%) of **3b**. *Anal.* Calc. for $C_{32}H_{72}N_2W_2Cl_9$ **3a**: C, 32.80; H, 6.19; N, 2.39. Found: C, 32.66; H, 6.02; N, 2.29%. *Anal.* Calc. for $C_{48}H_{40}P_2W_2Cl_9$ **3b**: C, 42.22; H, 2.95. Found: C, 41.5; H, 2.79%.

2.9.2. $PhICl_2$

To a degassed mixture of $W(CO)_6$ (1.05 g, 3.0 mmol) and TBACl (0.840 g, 3.0 mmol) or TPPCl (1.12 g, 3.0 mmol) was added chlorobenzene (20 mL) and the mixture was heated to reflux with constant stirring for 15 min. Then, $PhICl_2$ (1.44 g, 5.25 mmol) was added in portions under continuous stirring. After the addition was complete, the reaction mixture was refluxed for another 5 h. The solution was then cooled at room temperature. The addition of excess diethyl ether (20 mL) yielded a blue-violet precipitate, which was separated by filtration and dried under vacuum. Yield: 1.39 g (79%) of **3a**, 1.49 g (73%) of **3b**.

2.10. Formation of *3b* by bulk electrolysis

A 3.0 mM solution of **2b** in CH_2Cl_2, containing also 0.1 M of supporting electrolytic salt ($TBAPF_6$) was placed in the working electrode compartment of the electrolytic cell. The middle compartment and the counter electrode compartments were filled with a supporting electrolyte solution in CH_2Cl_2 of the same concentration. Electrodes were placed in the working and the counter electrode compartments as described above. Based on the cyclic voltammogram of **2**, a potential in the mass transfer-controlled region for the oxidation of **2b** to **3b** 0.750 V was applied on the Pt foil working electrode and current was allowed to pass under constant stirring until its value fell below 2% of its original one. During the course of the electrolysis the color of the solution changed quickly from green to violet. The quantitative conversion of **2b** into **3b** was monitored spectrophotometrically by taking aliquots. Although **3b** was not isolated, based on the extinction coefficient of **3**, the oxidation of **2b** to **3b** was quantitative (>99%).

2.11. Reaction of *3a* with $PhCH_2OH$

Compound **3a** (19.5 mg, 25.0 μmol) was dissolved under anaerobic conditions in methylene chloride (5 mL) followed by addition of $PhCH_2OH$ (2.6 μl, 2.7 mg, 25.0 μmol) and TBACl (7.0 mg, 25.0 μmol). The mixture was stirred for 24 h under Ar at $T = 298$ K. At the end of the reaction the solvent was removed under vacuum and the products (PhCHO: 18%, $PhCH_2Cl$: 27%) were characterized by GC–MS, ^1H and ^{13}C NMR.

3. Results and discussion

3.1. Synthetic aspects

Scheme 2 summarizes the major synthetic routes explored in this work.

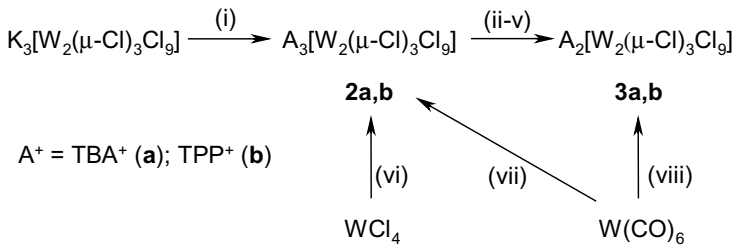
We have encountered difficulties while preparing **2a** via the cation exchange route. The yield was low, variable and occasionally gray residues insoluble to common organic solvents were formed. In the case of **2b** only the latter were obtained. These are, most likely, mixed salts of the type $\mathbf{2}(TPP)_{3-x}K_x$, ($x = 1, 2$) deriving from incomplete cation exchange and are insoluble in aqueous media and sparingly soluble in organic solvents [39,40].

This method can be improved by adding $\mathbf{2}K_3$ into solutions of CH_2Cl_2 containing the organic cation and provides after 24 h of stirring **2a**,**b** in ~80% yield. Since $\mathbf{2}K_3$ is stable both in H_2O and in aqueous HCl 6–12 M, the procedure can be further improved in terms of purification, by carrying the exchange in biphasic media ($\mathbf{2}K_3/H_2O/CH_2Cl_2$/organic salt, yield 78%). Interestingly, when aqueous HCl 6–12 M was used ($\mathbf{2}K_3$/HCl 6–12 M/CH_2Cl_2/organic salts), the green color of the organic layer containing **2a**,**b** changes to blue-violet, due to the formation of **3a**,**b**, as evidenced by UV–Vis, indicating a facile one-electron oxidation of **2a**,**b** by HCl. This was independently verified from the reaction of **2a**,**b** in CH_2Cl_2 with carefully purified $HCl_{(g)}$. Fast conversion to **3a**,**b** occurs at room temperature in a nearly quantitative manner, with the products being stable in excess of $HCl_{(g)}$. The reaction is slower in polar solvents (THF, MeCN), and does not proceed in protic ones (MeOH, H_2O, aqueous HCl 6–12 M) or in equimolar mixtures of CH_2Cl_2/MeOH. The oxidation can be also carried out heterogeneously, simply by addition of acidic silica to solutions of **2a**,**b** in CH_2Cl_2 under vigorous stirring.

Similarly, under the same conditions and with comparable efficiency, Lewis acids ($AlCl_3$, $SnCl_2$ in CH_2Cl_2) or metal halide oxidants, such as $FeCl_3$, $CuCl_2$, and $HgCl_2$ (in CH_2Cl_2, THF, MeCN) induce the same oxidation.

Also, addition of CCl_4 to a green solution of **2a**,**b** in CH_2Cl_2 results in formation of **3a**,**b** within 3 h. The reaction proceeds also in the dark in contrast to the conversion of **5** to **6**, where visible light is required [34]. The solid state interaction of green **2a**,**b** with CCl_4 yields blue-violet crystals of **3a**,**b** after stirring overnight. Detection in the reaction products of C_2Cl_6 (by GC–MS) indicates that the reaction proceeds through Cl-atom abstraction via homolytic cleavage of a C–Cl bond in CCl_4.

The high tendency of the W^{4}–W bonds to be oxidized by hydrohalic acids is a recurrent and general property which has been responsible for the slow development of the chemistry of W_2^{4+}



Scheme 2. Synthetic pathways for the preparation of the **2a**,**b** and **3a**,**b** complexes: (i) CH_2Cl_2, TBACl or TPPCl, r.t., t = 24 h, or CH_2Cl_2/H_2O, TBACl or TPPCl, r.t., t = 4 h. (ii) CH_2Cl_2, $HCl_{(g)}$, r.t., t = 20 min, or CH_2Cl_2/aqueous HCl 6 M, TBACl or TPPCl, r.t., t = 20 min. (iii) CH_2Cl_2, $FeCl_3$ or $CuCl_2$ or $HgCl_2$ or $SnCl_2$ or $AlCl_3$, r.t., t = 20 min. (iv) Bulk electrolysis in CH_2Cl_2, E = 0.750 V. (v) CH_2Cl_2, CCl_4, r.t., t = 3 h. (vi) Toluene, Na/Hg, TBACl or TPPCl, r.t., t = 24 h. (vii) $W(CO)_6$, Me_3SiCl, TBACl, chlorobenzene, reflux, t = 7 h. (viii) Chlorobenzene, 1,2-dichloroethane, TBACl or TPPCl, reflux, t = 7 h.

complexes [1]. Mechanistically, the first step of the overall two-electron oxidation process (Eq. (1)) proceeds presumably via the formation of the $[W_2(\mu\text{-}H)(\mu\text{-}Cl)_2Cl_6]^{3-}$ hydride.

$$Na_4[W_2Cl_8](THF)_x \overset{THF,HCl_{(g)}}{\underset{-78\,^\circ C}{\rightarrow}} [HW_2Cl_9]^{4-} \text{ or } [HW_2Cl_8]^{3-} \overset{HCl_{(g)}}{\rightarrow} Na_3[W_2Cl_9] + H_2 + Cl^- \quad (1)$$

IR evidence obtained from the low temperature (−10 °C) reaction of $[W_2(TFA)_4]$ (TFA = trifluoroacetate anion) with concentrated hydrochloric acid supports this reaction sequence [41]. Further support is provided by the isolation and structural characterization of $[W_2(\mu\text{-}H)(\mu\text{-}Cl)Cl_2(O_2CPh)_2(^nBu_3P)_2]$ [42], $[W_2(\mu\text{-}H)(\mu\text{-}Cl)Cl_4(dppm)_2]$ [43], $[W_2(\mu\text{-}H)(\mu\text{-}Cl)Cl_5(Etpy)_4]$ [44], $[Mo_2(\mu\text{-}H)(\mu\text{-}Cl)_2Cl_6]^{3-}$ [45], $[MoW(\mu\text{-}H)(\mu\text{-}Cl)_2Cl_6]^{3-}$ [46] deriving from analogous genuine HCl additions to the $W\equiv W$, $Mo\equiv W$, and $Mo\equiv Mo$ bonds contained in the $[W_2Cl_4(^nBu_3P)_4]$, $[W_2Cl_4(dppm)_2]$ (dppm = $Ph_2CH_2CH_2Ph_2$), $[W_2(mph)_4]$, $[Mo_2(\mu\text{-}CH_3COO)_4]$, $K_4[Mo_2Cl_8]$ and $[MoW(\mu\text{-}^tBuCOO)_4]$ precursors. There is no evidence in the literature concerning the intimate details of the subsequent steps leading to the formation of **2**.

The ability of $W\equiv W$ bonds to undergo further an overall one-electron oxidation by protic acids in aprotic media (**2a**,**b**, CH_2Cl_2, $HCl_{(g)}$), in contrast to their stability in protic solvents (**2**K_3, aqueous HCl 6–12 M) can be attributed, at least in part, to solvation effects of the proton [47], and also to the exact nature of **2a**,**b** due to solvent dependent ligand mobility and/or *fsbo-esbo* equilibria [1,48]. Although we have detected formation of H_2 (by GC) we have not managed yet to isolate any intermediate or obtain spectroscopic evidence (UV–Vis) from the reaction of **2a** with $HCl_{(g)}$ or with stoichiometric amounts of non-complexing protonic acids (HBF_4, CF_3SO_3H) in CH_2Cl_2 or MeCN.

These findings constitute simple and facile routes for the preparation of **3a**,**b**, and also, they point out that the PPN^+ may be responsible for the three-electron oxidation of **1**$Na_4(THF)_x$ [9]. However, when we repeated the reaction replacing PPNCl with TBACl or TPPCl, instead of **3a**,**b**, pale green-gray insoluble residues were obtained. In contrast, the same reaction in toluene instead of THF provides **2a**,**b** in high yield (∼90%). Attempts to reduce **2a**,**b** to **1a**,**b** with amalgams of Na, Zn, Al in THF at low temperature (−10 to 0 °C) were not successful.

Furthermore, the direct high yield preparation of **3a**,**b** has been possible by paralleling McCarley's method for the synthesis of the $(^nPr_4N)_2[W_2(\mu\text{-}Br)_3Br_6]$ analog [12]. Thus, reaction of $W(CO)_6$ in boiling PhCl in the presence of the organic salts employing $PhICl_2$ or 1,2-$C_2H_4Cl_2$ as oxidants and halide sources, instead of WCl_6 or WCl_4, gives the desired products. In the first case, slow stepwise addition of the $PhICl_2$ to the reaction mixture is required in order to minimize overoxidation, whereas in the second case the reaction proceeds cleanly in a nearly quantitative manner (yield ∼95%). In contrast, when Me_3SiCl was used under the same conditions **2a** is isolated in 74% yield, but formation of a gelatinous residue makes the purification difficult.

Oxidation of **2a**,**b** with $PhICl_2$ or PhIO in CH_2Cl_2 is more convenient than with Cl_2 and gives **3a**,**b** in ∼80% yield. Attempts to obtain **4a**,**b** from the stoichiometric oxidation of **3a**,**b** as above were not successful, producing colorless solutions.

3.2. Electrochemical studies

The oxidation of **2b** was investigated by cyclic voltammetry in CH_2Cl_2, CH_3CN and DMSO. Pertinent data are summarized in Table 1. As shown spectroelectrochemically (*vide infra*), **2b** undergoes two well-separated oxidations to **3b** and **4b**:

$$\mathbf{2b}(W_2^{6+}) \underset{+e^-}{\overset{-e^-}{\rightleftharpoons}} \mathbf{3b}(W_2^{7+}) \underset{+e^-}{\overset{-e^-}{\rightleftharpoons}} \mathbf{4b}(W_2^{8+})$$

From the $i_{p,a}/i_{p,c}$ and the voltammetric peak-to-peak separation ($\Delta E_{p\text{-}p}$) values it is concluded that within the time scale of cyclic voltammetry at 0.02–1.0 V s^{-1} the first oxidation wave is both chemically and kinetically reversible in all three solvents. The second oxidation is chemically irreversible in DMSO and CH_3CN, in accord with the observed instability of **4** upon dissolution in these solvents. The case of CH_2Cl_2, however, is worth commenting on (see Fig. 1). Although at first glance the second oxidation wave may seem to lack chemical reversibility ($i_{p,a}/i_{p,c}$ = 1.39), voltammograms normalized by dividing the faradaic current by the square root of the potential sweep rate are fully superimposable over a wide range of sweep rates, indicating that both waves are fully chemically *as well as* kinetically reversible. That is, if in analogy to what is observed in DMSO and CH_3CN, the second wave in CH_2Cl_2 was chemically irreversible, then the return part of the first wave would be also compromised, because after a potential excursion through **4b** there would be less **3b** available to be re-reduced to **2b** in the reverse sweep. Therefore, we are forced to attribute the high $i_{p,a}/i_{p,c}$ value (=1.39) for the second wave in CH_2Cl_2 to large differences in the diffusion coefficients of **2b**/**3b** on one hand and of **4b** on the other. Indeed, considering the homogeneous comproportionation reaction of **4b** with **2b** [49,50], and based on the fact that the $i_{p,a}$ values for both waves are about equal ($i_{p,a}(1)/i_{p,a}(2) \sim 0.92$), we conclude that the diffusion coefficients of **2b** and **3b** are about equal as well. Thus we can attribute the high $i_{p,a}/i_{p,c}$ value for the second wave entirely to differences in diffusion coefficients, D_i, and we can set $i_{p,a}/i_{p,c} = (D_{\mathbf{3b}}/D_{\mathbf{4b}})^{1/2}$, meaning that $D_{\mathbf{3b}}/D_{\mathbf{4b}}$ = 1.9. The lower diffusion coefficient of **4b** implies extensive ion pairing, namely that in CH_2Cl_2 the $\{W_2^{8+}\}$ species exists in close association with its counter ions.

Bulk electrolysis of **2b** in CH_2Cl_2 at 0.750 V for 14 min using an H-cell afforded **3b** quantitatively. The reaction was monitored by UV–Vis (Fig. 2). The two isosbestic points (402 and 508 nm; Fig. 2, right) indicate clean conversion of **2b** to **3b**. Fig. 2, left shows absorption spectra of **3b** and **4b** for comparison. The absorption

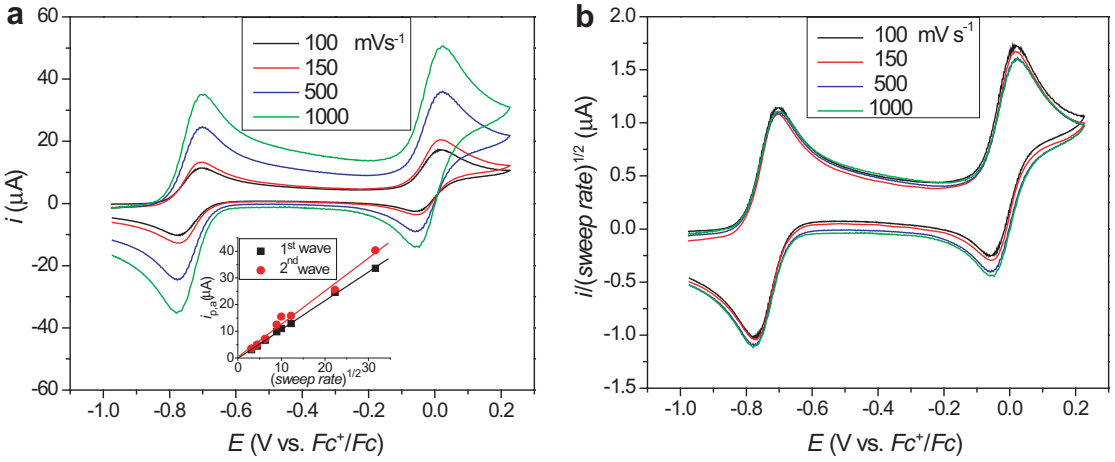

Fig. 1. (a) Cyclic voltammetry of **2b** (3.0 mM) in CH_2Cl_2/0.1 M $TBAPF_6$ with a Au-disk electrode (1.6 mm in diameter) at various sweep rates, as indicated. Inset: Randles–Sevcic plots for the anodic parts of both waves. (b) Same curves as in part (a), divided by the square root of the sweep rate. Experiments were carried out in a dry-box.

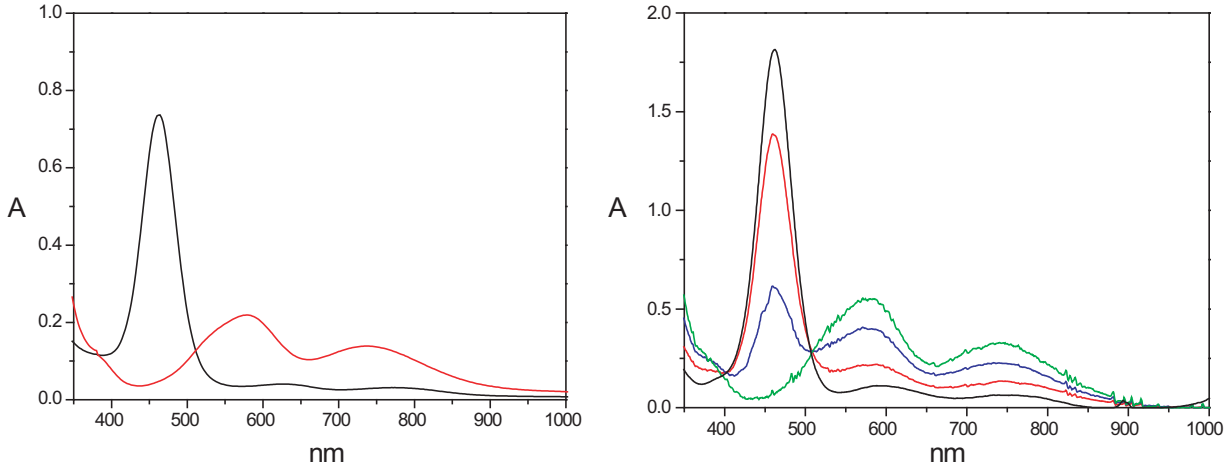

Fig. 2. Left: electronic absorption spectra of **2b** (2×10^{-4} M, black) and **3b** (9×10^{-5} M, red) in CH_2Cl_2. The two spectra were taken independently, in different solutions. Right: successive spectra during the bulk electrolysis of **2b** in CH_2Cl_2 (5×10^{-4} M) at 0.750 V; $t = 0$ s (black), $t = 30$ s (red), $t = 7$ min (blue), $t = 14$ min (green). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

maxima are similar to those reported in the literature [9,25,51] Electrolysis at 1.100 V for another 1 min gave a mixture of **3b** and **4b**, as shown by the UV–Vis spectrum of the reaction mixture (for **4b** λ_{max} (ε_M) 650 (825), 530 (370), 360 (sh), and 305 (22 600) nm (M^{-1} cm^{-1}) [10]). The degree of conversion of **3b** to **4b** could not be calculated accurately, because the bands of the two species are overlapping. The formation of **4b** was confirmed from the second derivative spectra ($d^2A/d\lambda^2$). Electrolysis at higher potentials and/or for longer time periods resulted in decomposition products, which were not pursued further. These results are consistent with previous reports on electrolysis of $\mathbf{2}K_3$ in a basic aluminum chloride/methyl-3-ethyl-imidazolium chloride molten salt [52].

3.3. ESI-MS spectra

Electrospray ionization mass spectrometry was additionally used for the characterization of **2a**,**b** and **3a**,**b**. The experimental isotope clusters obtained are in agreement with the theoretical masses and isotope patterns. The ESI(+) spectra showed signals centered at $m/z = 1415.86$ and 1704.70, which are attributed to

Table 2
Peaks observed in the ESI-MS spectra of **2a**, **3a**,**b**

Compound	*m/z* experimental	*m/z* calculated	Fragment

3b	1704.07	1704	$[\mathbf{3b}+TPP]^+$
	341.78	343.5	$[W_2Cl_9]^{2-}$
	360.72	361	$[WCl_5]^-$

($[\mathbf{2a}+H]^+$) and ($[\mathbf{3b}+TPP]^+$) respectively. In the ESI(−) spectra the most characteristic peaks were at *m/z* = 929.07 ($[TBAW_2Cl_9]^-$), and 341.78 ($[W_2Cl_9]^{2-}$). Other signals were also present, attributable to di- or mononuclear fragments, as shown in Table 2. **4**(TEBA) was too sensitive to obtain reliable spectra.

3.4. Electron paramagnetic resonance

The EPR spectra of **2a**, **3a** and **4**(TEBA) in CH_2Cl_2 solutions were taken at room and at 25 K temperatures and are shown in Fig. 3. All spectra exhibit a simple derivative shape signal at $g = 1.75$, except for **3a**, which shows an additional weak peak at $g = 2.8$ at 25 K. The **2a** signal is weak and the *g* value is compatible with previously reported powder spectra of $\mathbf{2}K_3$ and $\mathbf{2}Cs_3$ at 77 K [53]. The **4**(TEBA) signal is asymmetric.

3.5. Reactions of *3a,b* with $PhCH_2OH$

Compounds **2a**,**b** are inactive towards $PhCH_2OH$ at ambient temperature. In contrast, **3a**,**b** are anaerobically reduced to **2a**,**b** (**3a**,**b**/$PhCH_2OH$/TBACl or TPPCl = 1/1/1, $t = 24$ h), as was confirmed by the electronic absorption spectrum (CH_2Cl_2, $T = 298$ K) of the reaction solution, producing PhCHO (18%) and $PhCH_2Cl$ (27%). No PhCOOH was detected. The ability of **3** to oxidize $PhCH_2OH$ resembles partly to that of the hexanuclear clusters $[M_6X_{14}]^-$ (M = Mo, X = Cl; M = W, X = Br) reported previously [36]. The system is under investigation, and details of the mechanism of this reaction, as well as chemical and electrochemical catalytic studies with $PhCH_2OH$ and other organic substrates will be reported in due course.

4. Conclusions

The principal results of this work can be summarized as following:

(i) New simple and facile high-yield chemical and electrochemical synthetic routes for **2a**,**b** and especially for **3a**,**b**, have been developed, which are expected to facilitate studies of their functionality in organic media;

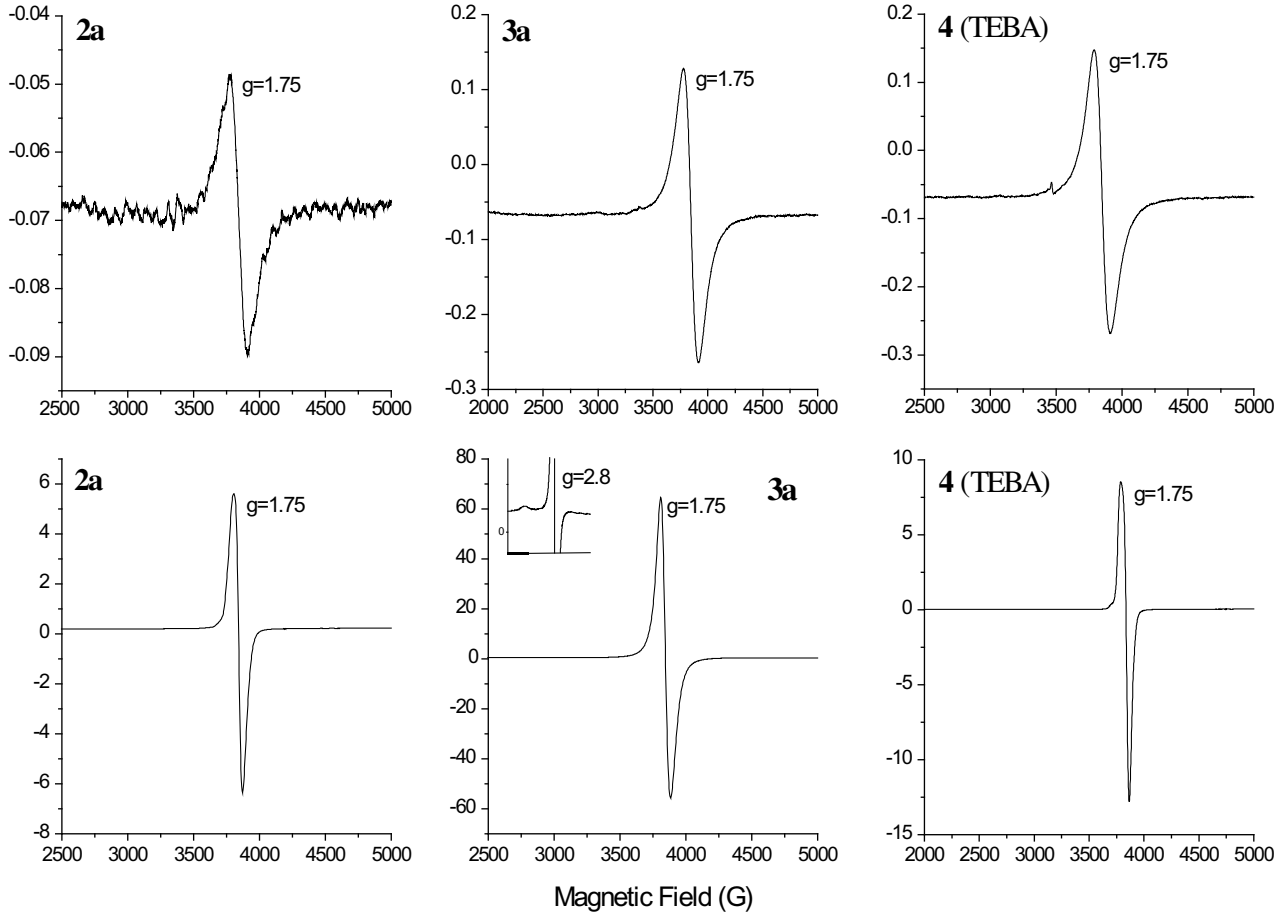

Fig. 3. X-band EPR spectra of **2a**, **3a**, and **4**(TEBA) in CH_2Cl_2 solution at room (top) and at 25 K (bottom) temperatures. Conditions: 9.4 GHz, modulation 10 Gpp, mW power of 50 mW. The EPR of **4**(TEBA) at 25 K was recorded with a modulation of 1Gpp, which translates in a multiplication factor of 10 if it is to be compared with the others.

(ii) The $W^{\equiv}W$ bonds contained in **2a**,**b** are capable of undergoing facile one-electron oxidation in aprotic organic solvents by protons or Lewis acids, in sharp contrast to their stability in acidic protic media (CH_3OH, $HCl_{(aq)}$ 6–12 M);

(iii) Complex **3** acts as a convenient anaerobic one-electron oxidant of $PhCH_2OH$ to PhCHO. Future studies are directed towards elucidating the mechanism of this reaction, tuning the reactivity of **3a**,**b**, and making the **2**/**3** redox-couple of potential utility in catalytic oxidations of alcohols and other organic substrates.

Acknowledgements

We thank the Special Account for Research Grants of the University of Athens (70/4/3342), and the EPEAEK II "PYTHAGORAS" (70/3/7327) (co-funded by the European Social Fund and National Resources) for financial assistance. We also thank Mr. George Karapanagos at the Institute of Materials Science, NCSR "Demokritos", Greece, for obtaining the EPR spectra and Dr. Nathan Leigh at the University of Missouri-Columbia for obtaining the ESI-MS spectra.

semicarbazone complexes, Quiroga and Navarro have observed the sensible increase in the number of studies of their antibacterial, antiviral, antifungal and antitumour activity [12]. For instance, a report of Cu^{II}, Zn^{II}, Cd^{II} or Hg^{II} complexes with thiosemicarbazone derived from vanillin shows their activity against pathogen fungus belonging to the groups *Alternaria* (sp.), *Paecilomyces* (sp.) and *Pestalotia* (sp.) [13].

In the present work we have chosen thiosemicarbazones with the group 2-ethoxy-3-methoxy-benzaldehyde, which can be considered a ester derivative similar of vanillin, and the fragment *fac*-$[Re(CO)_3]^+$. Besides the interesting bioinorganic properties mentioned above, the exploration of the coordinative behaviour of these ligands against tricarbonylrhenium(I) and the structures resulting of their molecular association and their spectroscopic behaviour, is also worth to be studied.

2. Results and discussion

2.1. Synthesis and spectroscopic characterization

The ligands derived from 2-ethoxy-3-methoxy-benzaldehyde thiosemicarbazone were obtained by refluxing a mixture methanol/water solution for 2 h (Scheme 1).

Reaction of the three ligands with *fac*-$[ReX(CO)_3(CH_3CN)_2]$ afforded six adducts (Scheme 2) with general formula *fac*-$[ReX(CO)_3(HL)]$ (**1**).

Elemental analysis and mass spectrometry confirmed the stoichiometry $[ReX(CO)_3(HL)]$. The mass spectra of the metallic species contains a signal corresponding to the molecular ion, although the peak due to the species $[M-X]^+$ is more intense.

Furthermore, facial geometry around the rhenium atom is suggested by the three strong bands $\nu(C{\equiv}O)$ in IR (sometimes collapsed) in the range 1889–2027 cm^{-1}. The ligand bands corresponding to the N–H groups appear between 3181 and 3508 cm^{-1} and are hardly modified by coordination. Regarding the typical bands from the thiosemicarbazide fragment, the frequencies of the band C=N, in the free ligands in the range 1543–1556 cm^{-1}, shift to the region 1555–1630 cm^{-1} in the spectra of all the complexes. Nevertheless, the band corresponding to the C=S mode shifts from 783 to 788 cm^{-1} in free ligands to 740–771 cm^{-1} in the rhenium complexes, in agreement with the coordination of the ligand by the sulfur atom. This behaviour has been observed in other TSC complexes and it is consistent with the S,N coordination of the ligand [8,11,14,15].

In general, all proton signals in the ^1H NRM spectra in acetone-d_6 of the complexes are shifted at low field (around 0.5 ppm) respect the free ligands. Differently, the signal of the N(2)–H proton moves around 2 ppm. Similar behaviour has been observed in rhenium(I) complexes of hydrazones [16] and thiosemicarbazones [11,14], where the N(2)–H group is a member of the chelate ring resulting after the S,N-coordination. However, when the thiosemicarbazone is coordinated as a S-monodentate ligand, the N(2)–H proton signal behaves as the rest of the ligand signals [10].

To explore the influence of temperature and nature of the rhenium precursor in the reaction product, the reaction of HL^1 with $[ReX(CO)_5]$ were tested in toluene. In the bromine derivative, the

characterization of the product showed the formation of the same adduct, $[ReBr(CO)_3(HL^1)]$ (**1a′**), exclusively. However when the chloride derivative was used, the spectroscopic data suggested the coexistence of the compound **1a** and also some product derivate of the deprotonation.

On the other hand, the X-ray study of the crystals obtained from methanol solutions **1b** and **1c** showed the formation of binuclear thiosemicarbazonate complexes (Scheme 2). In a process similar to observed in the rhenium(I) complex of ferrocenylaldehyde thiosemicarbazone [11], the deprotonation of the TSC ligand induces the labilization of the halogen in a position occupied by sulfur atom from other TSC coordinated.

These complexes **2a**, **2b** and **2c** were obtained by reaction of bromine derivatives, **1a′**, **1b′** and **1c′**, with NaOH in methanol. In all of them, the three carbonyl IR bands are consistent with the facial geometry around rhenium atom, and the ν(C=S) bands at 714–740 cm^{-1}, suggest some weakening of the bond. The vibration frequencies of C=N bonds shift to a larger wavenumbers than in free ligands (1610–1710 cm^{-1}).

The ^1H NMR spectra of these compounds in acetone-d_6 show all the proton signals shifted at low field respect to the free ligands and as expected the signals for N(2)–H are absent.

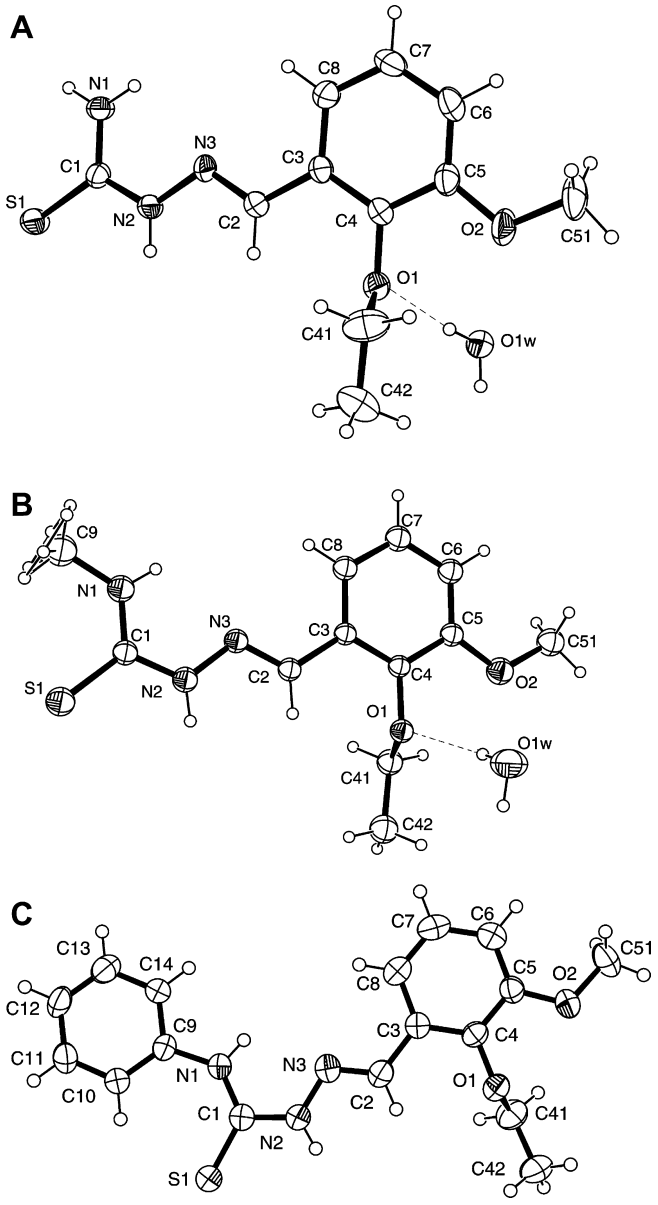

Fig. 1. Molecular structures of $HL^1 \cdot H_2O$ (A), $HL^2 \cdot 1/2H_2O$ (B) and HL^3 (C).

2.2. Crystal and molecular structure of the ligands

The molecular structures of the free ligands are shown in Fig. 1 along with the atomic numbering scheme used. Crystal data and selected bond lengths and angles are listed in Tables 1 and 2, respectively.

Ligands HL^1 and HL^2 crystallized as mono- and hemi-hydrates, respectively, and the water molecule is linked by hydrogen bond to the oxygen atom of the ethoxy group (O(1)W). The role of this molecule in both structures is discussed in detail below. In HL^2, two TCS ligand molecules per asymmetric unit were identified showing differences between distances and angles statistically insignificant and, consequently, the average values are including in Table 2.

In all the cases, the distances C(1)–S(1), C(2)–N(3), N(2)–N(3) and N(2)–C(1) suggest that, in spite of the usual delocalization of π electrons along the thiosemicarbazide chain [17], the canonical form of the free ligand depicted in Scheme 1 is likely the main form in solid state.

The molecular structure of these ligands shows *E* configuration around C(1)–N(2), N(2)–N(3), N(3)–C(2) and C(2)–C(3) bonds. However, *Z* configuration in the C(1)–N(1) bond has been linked with the existence of intramolecular hydrogen-bonding interactions N(1)–H···N(3). The distance N(1)–N(2) decrease from $HL^1 \approx HL^2 > HL^3$ (Table 3). Before conclude that the shortening is due to the increasing of the interaction strength, note that the angle N(1)–C(1)–S(1) widen following the same path. Thus, these findings are also compatible with the increase of steric hindrance of the R group linked to N(1) and the sulfur atom.

In the three cases, the molecule of the ligand can be considered planar: the angles between the ideal plane of the thiosemicarbazide chain N(1)/S(1)/C(1)/N(2)/N(3)/C(2) and the carbon atoms that define the phenyl ring are 7.34(3)°, 6.67(8)° and 2.4(2)° for HL^1, HL^2 and HL^3, respectively.

[a] Symmetry transformations used to generate equivalent atoms: #1 = $-x$, y, $-z+½$; #2 = $-x$, $-y+2$, $-z+1$; #3 = $-x-½$, $y+½$, $-z+½$; #4 = $-x$, $-y$, $-z$; #5 = $-x$, $-y-1$, $-z+1$.

The molecular association in $HL^1 \cdot H_2O$ is strongly dominated by the presence of the water molecule. Two HL^1 molecules are associated with two water molecules by N(1)–H···O(1W) interactions (Table 3) showing in both cases the water molecule an acceptor hydrogen behaviour (Fig. 2A). The interaction between a sulfur atom from TSC and the water, which is now a H-bond donor, probably assists to the formation of these "virtual molecular-tetramer". These units are associated by N(2)–H···S(1) interactions along the *c* axis. In turn, these chains are associated by hydrogen bonds between water and the oxygen atoms, O(1), from a neighbouring ethoxy group in the brick-wall-like arrangement showed in Fig. 2B.

As mentioned before, two molecules of HL^2 can be observed per asymmetric unit. Though important differences are not observed in molecular distances and angles, the differences become more marked when the crystal packing is considered. One of the HL^2 molecules is associated with other, crystallographically equivalent (labelled A in Fig. 2C) by two water molecules as in HL^1, involving two hydrogen bonds pairs N(1A)–H···O(1W) and O(1W)–H···O(1A) (Table 3). These molecules are also associated with molecules non-crystallographically equivalent (labelled B) by N(2A)–H···S(1B) and N(2B)–H···S(1A) interactions (Fig. 2C). These units formed by four ligand molecules and two water molecules are packed by weak contacts O(1W)–H···π, in a herringbone pattern as usually observed in aromatic derivatives.

The HL^3 molecules are also coupled N(2)–H···S(1)#5 by hydrogen bond (Fig. 2E) and the dimers are associated in a herringbone pattern by weak interactions involving methoxy and aromatic C–H groups as H-donors and oxygen atom (ethoxy) or π-clouds as acceptors, respectively (Fig. 2F).

2.3. Crystal and molecular structure of $[ReBr(HL^1)(CO)_3] \cdot ½C_7H_8$ (**1a′** · **½C₇H₈**)

Single crystals of the complex **1a′**, obtained from the mother liquor (toluene) contains one solvent molecule per each two molecules of the complex. The toluene molecule is in the cell origin and, consequently, disordered. In the final model we have considered the methyl group on two alternate positions with occupation factors 50% and the aromatic ring centre at the origin. Moreover, two independent molecules that correspond to the two enantiomer of the *fac* configuration (OC-6-33) appear in the asymmetric, although there are also differences concerning the relative orientation of the aromatic ring and the bromo ligand.

The molecular structure of (**1a′** · **½C₇H₈**) together the numbering scheme used is depicted in Fig. 3A. Crystal data and relevant interatomic distances and angles relative to the coordination sphere are included in Tables 4 and 5, respectively.

The ligand HL^1 is coordinated to Re(I) through the sulfur and azomethine nitrogen N(3) atoms. This coordination mode changes the configuration of the bond C(1)–N(2) from *E*, observed in the structure of free ligand HL^1 (*vide supra*), to *Z* to forms a five-membered chelate ring. This ring is approximately planar and the angles respect to the aromatic ring are 39.4(3)° (Re(1) molecule) and 50.3(4)° (Re(2) molecule). The rhenium atom is octahedrally coordinated to three carbonyl carbon atoms in *fac* arrangement, a bromine atom, the azomethine nitrogen and the sulfur atom of the thiosemicarbazone, main distortion being in the angle S–Re–N (<80°) due to the formation of the chelate ring. The bond distances in Re–N(3), Re–S and Re–Br are statistically equivalent in both molecules and they are very similar to observed previously in others *fac*-$Re(CO)_3$ adducts with TSC chelate ligands [8,9,11,14].

Aside the change of the configuration in the bond C(1)–N(2), the coordination of HL^1 to rhenium modifies also the configuration about the C(2)–N(3) bond to *Z*. Both changes and the non-planar structure of the ligand are likely due to steric hindrances between the aromatic ring, and its ether group, with the fragment $\{Re(CO)_3\}$.

Finally, respect to the molecular structure, the non-planar structure of TSC and the metallic fragment asymmetry, allows the coexistence of two possible distributions of 2-ethoxy-3-methoxy-benzaldehyde fragment: one with the group positioned to the direction occupied by the bromine atom and the other in the opposite direction. Both are in the crystal and probably coexist also in solution but, in contrast to ferrocenyl derivatives, they no produce different signals in the ^1H NMR spectrum [11].

The description of the molecular packing in the crystal is complex since the two enantiomers are associated in different fashion. Beside the weak C–H···acceptor interactions, the Re(1) molecule is associated with other symmetrically equivalent molecules (Fig. 3B) by hydrogen bonds between N–H azomethine and thioamide groups and the bromine atom (N(1A)–H(1A1)···Br(1)#1 = 0.86, 2.557, 3.372(8) Å, 158.54; N(2A)–H(2A2)···Br(1) = 0.86, 2.939, 3.465(8) Å, 147.78°; #1 = $-x+2$, $-y+2$, $-z+1$). These associations, and the metric values from these interactions, have been observed in other rhenium(I) thiosemicarbazones derived from ferrocenylcarbaldehyde [11] and β-keto esters [14]. In the present case, the two interactions are reinforced by an additional interaction which involve the thioamide nitrogen and the ethoxy group from the partner molecule.

In addition, the interactions between molecules containing Re(2) atom, involve the bromine atom in a very similar way to

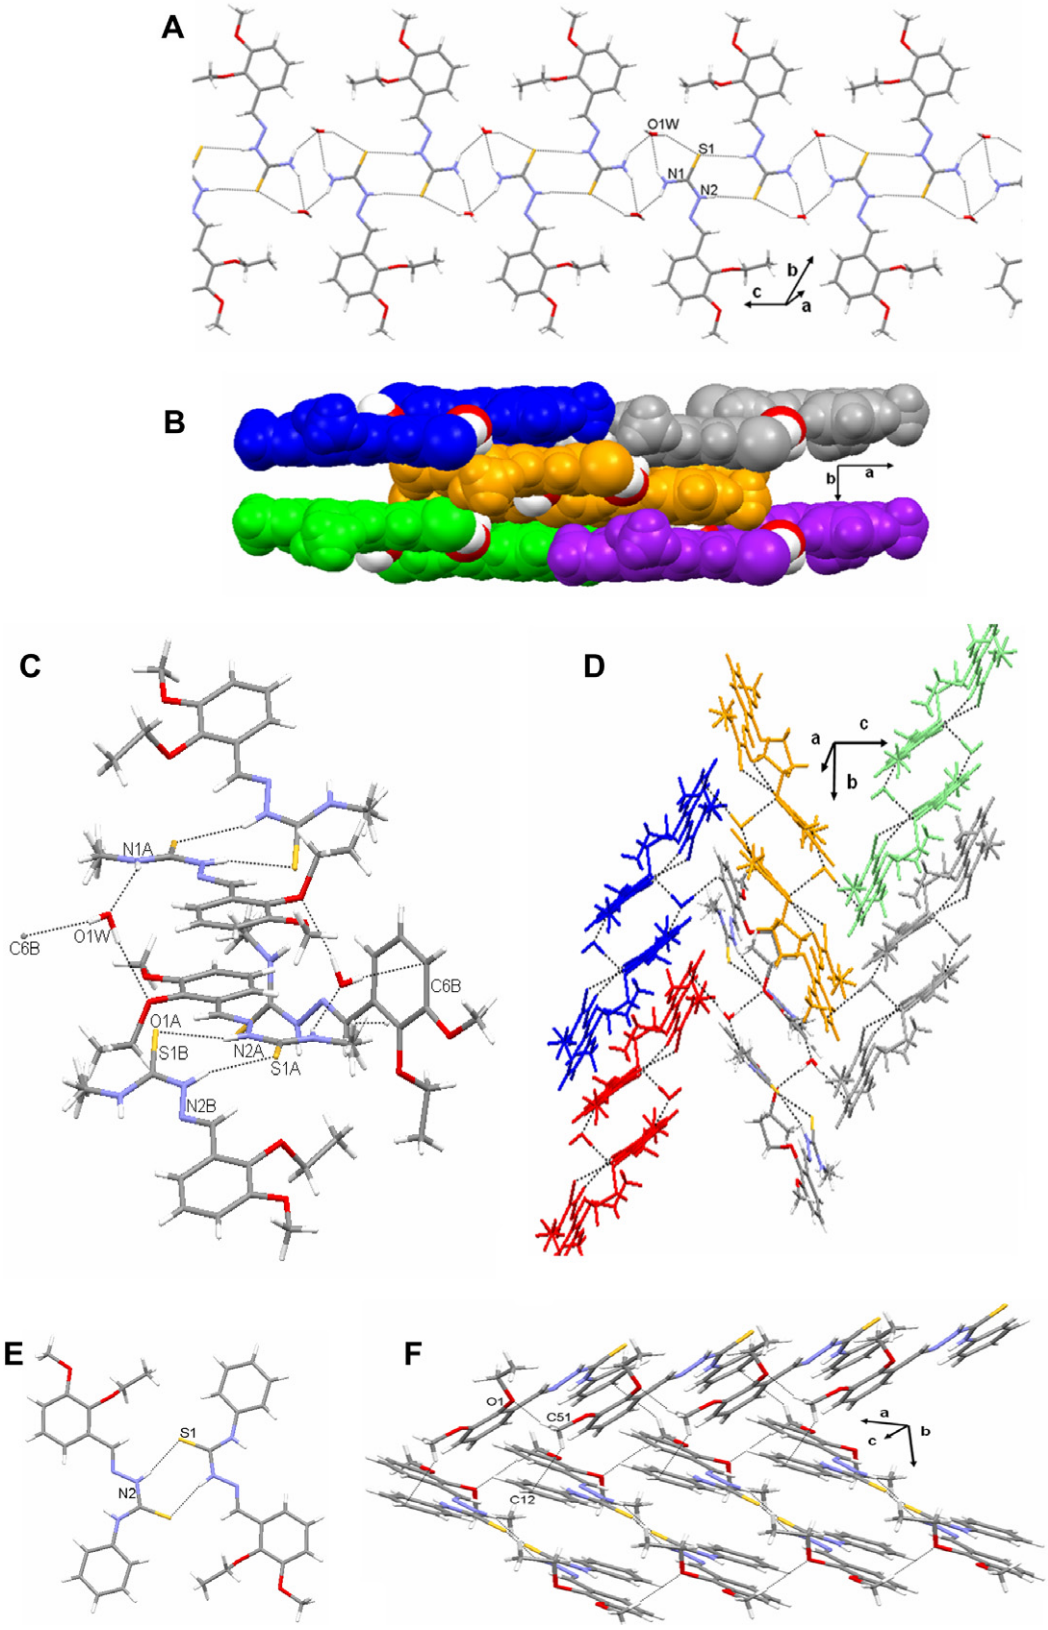

Fig. 2. Supramolecular association in $HL^1 \cdot H_2O$ (A and B), $HL^2 \cdot \frac{1}{2}H_2O$ (C and D) and HL^3 (E and F).

Re(1) molecules, but now, the N(1B)–H group establishes H-bonds (N(1B)–H(1B2)···O(1B)$^{\#2}$ = 0.86, 2.50, 2.934(11) Å, 111.9°; N(1B)–H(1B2)···O(2B)$^{\#2}$ = 0.86, 2.19, 3.042(10) Å, 171.5°; #2 = $-x$, $1-y$, $-z$) with the ether groups of a neighbouring molecule. Consequently, dimers are associated in chains running parallel to *a* axis (Fig. 3C).

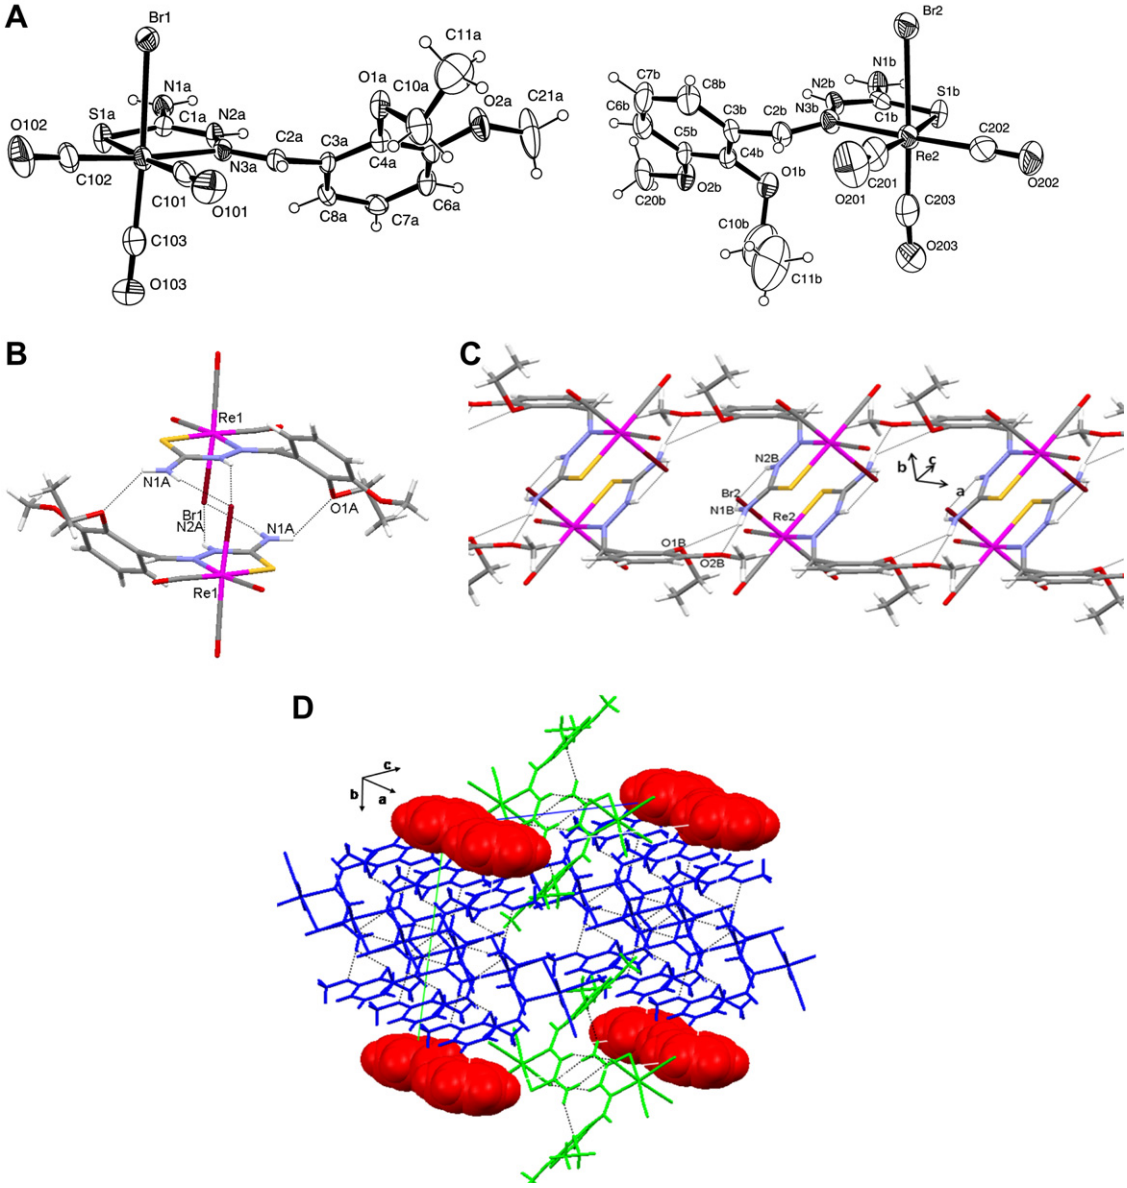

Fig. 3. The molecular structure (A) and crystal packing (B–D) in **1a**′ · **½C$_7$H$_8$**.

Finally, the molecular packing is completed with weak interactions between donor C–H groups and carbonyl as acceptors and can be described considering the packing of the chains of Re(2) molecules, in *b* direction, hosts the Re(1) dimers and toluene molecules (Fig. 3D).

*2.4. Crystal and molecular structure of [Re$_2$(L^2)$_2$(CO)$_6$] (**2b**) and [Re$_2$(L^3)$_2$(CO)$_6$] · 2CH$_3$OH (**2c** · 2CH$_3$OH)*

Single crystals of **2b** and **2c** were obtained by slow concentration from methanol solutions of the previously isolated adducts. The observed disorder of the methyl or the ethoxy group was modulated by refinement of two alternate positions for these groups with occupancies of 80% and 25%. Crystal and structure refinement data for both compounds are showed in Table 4. Relevant length bonds and angles are included in Table 5 meanwhile the molecular structures, showing the numbering scheme used are depicted in Fig. 4.

The ligand deprotonation and the interaction of the rhenium with the sulfur atom of a neighbouring molecule at the position occupied by the halogen atom creates dimers. A difference between both, is that in **2c** this interaction produces centrosymmetric dimers, similar to observed in the ferrocenylcarbaldehyde thiosemicarbazonates [11] but in **2b** both thiosemicarbazonate groups are in the same side of the Re$_2$S$_2$ fragment. This different group orientation and the formation of the Re$_2$S$_2$ diamond, does not impose important differences in bond lengths and angles (Table 6).

The rhenium atoms retains its octahedral coordination, but now interacts with two sulfur atoms, and the sulfur belonging to the partner in the dimer, is farther away than its own sulfur. In fact, the Re–S–Re bridge is relatively asymmetric, as in others dimer structures based on this type of interaction [18,19]. In the diamond Re$_2$S$_2$, the bond angles close to 90° and the distance Re–Re is too long (>3.75 Å) for means any significant bonding interaction.

As observed in ferrocenyl derivatives [11], the Re–N(3) and Re–S(1A) distances are statistically equivalents to the observed in **1a**′. However, the C(1)–S(1) distance is longer than in the free ligands or the adduct **1b**, in agree with a higher thiol character. In addition, the angle between the plane of benzaldehyde ring and the TSC

plane (12° and 15° in **2b** and 9.5° in **2c**) shows a more planar ligand in complexes **2b** and **2c** than in **1a′**.

In the supramolecular structure of **2b**, dimers are associated by hydrogen bonds between the N–H thioamide nitrogen group and the oxygen atom of the ethoxy group of a neighbour dimer (N(1A)–H(1A2)···O(1A)$^{\#1}$ = 0.86, 2.268, 2.934(7) Å, 134.32°; #1 = 1 − x, ½ + y, ½ − z). This interaction links the units [Re$_2$(L^2)$_2$(CO)$_6$] in chains running parallel along b axis (Fig. 4C).

In **2c**, the presence of methanol affects the association of the centrosymmetric dimers. The two molecules of methanol are symmetrically independents and they are associated by O(2M)–H···O(1M) bonds and at the same time, one of them establishes a hydrogen chelate bond with two oxygen atoms of the methoxy and ethoxy group (O(1M)–H(1M)···O(2) = 0.82, 2.083, 2.844(8) Å, 154.08°; O(1M)–H(1M)···O(1) = 0.82, 2.592, 3.221(7) Å, 134.56°). The other methanol molecule behaves as hydrogen bond acceptor with the N–H group of a neighbour dimer (N(1)–H(1)···O(2M)$^{\#1}$ = 0.86, 1.976, 2.830(8) Å, 171.65°; #1 = −x, −y, 2 − z). These interactions make ribbons running transverse to the crystallographic directions a and b.

3. Experimental

3.1. Materials and methods

All solvents used for synthesis were dried over appropriate drying agents, degassed using a vacuum line and distilled under an Ar atmosphere [20]. Adducts [ReX(CO)$_3$(CH$_3$CN)$_2$] were synthesized by Farona and Kraus' published methods [21] from the corresponding [ReX(CO)$_5$] [22].

Elemental analyses were carried out on a Fisons EA-1108. Melting points (mp) were determined on a Gallenkamp MFB-595 and are uncorrected. Mass spectra were recorded on a VG Autospec Micromass spectrometer operating under FAB conditions (nitrobenzyl alcohol matrix). Infrared spectra were recorded from KBr pellets on a Bruker Vector 22FT. The ^{1}H NMR spectra were obtained on a Bruker ARX-400 spectrometer from acetone-d_6 solutions.

3.2. General synthesis of the ligands HL^1, HL^2 and HL^3

To a mixture of a water solution (15 mL) of thiosemicarbazide and a methanol solution (15 mL) of 2-ethoxy-3-methoxy-benzaldehyde was added one $H_2SO_{4(c)}$ drop. To avoid the precipitation of 2-ethoxy-3-methoxy-benzaldehyde some methanol (about 15 mL) was added. The reaction mixture was heated under reflux for 2 h. The resulting solid was filtered off and vacuum dried over KOH/CaCl$_2$. Single crystals were obtained after slow evaporation of the mother liquor.

3.2.1. Data for HL^1

Thiosemicarbazide (500 mg, 5.49 mmol)/2-ethoxy-3-methoxybenzaldehyde (0.5 mL, 3.08 mmol). White crystalline solid. Yield: 1783 mg (89.2%). 4-Phenyl-3-thiosemicarbazide (500 mg, 2.99 mmol)/2-ethoxy-3-methoxybenzaldehyde (0.5 mL, 3.08 mmol). White crystalline solid. Yield: 771 mg (77.1%). M.p.: 204 °C. *Anal.* Calc. for $C_{17}H_{19}N_3O_2S$: C, 61.9; H, 5.9; N, 12.7; S, 9.7. Found: C, 61.7; H, 6.0; N, 12.7; S, 9.6%. Mass spectrum [*m*/*z* (%)]: 330.09(100) $[M]^+$. IR data (KBr, cm^{-1}): 3508m, 3333m, 3298m ν(NH); 1556s ν(C=N); 788w ν(C=S). ^1H NMR data (ppm): 10.77s (1) δ(N(2)–H); 9.88s (1) δ(N(1)–H); 8.64s (1) δ(C(2)–H); 7.75d (1) δ(C(7)–H); 7.73d (2) δ(N(1)–R^1); 7.36t (2) δ(N(1)–R^1); 7.19t (1) δ(N(1)–R^1); 7.06s (1) δ(C(6,8)–H); 7.05s (1) δ(C(6,8)–H); 4.10m (2) δ(O(4)–R^2); 3.88s (3) δ(O(5)–R^3); 1.36m (3) δ(O(4)–R^2).

*3.3. General synthesis of the complexes [ReX(CO)$_3$(HL)] (**1**)*

To a solution of the corresponding HL ligand in freshly distilled chloroform (15 mL) was added the corresponding equimolecular quantity of *fac*-[ReX(CO)$_3$(CH_3CN)$_2$] (X = Cl, Br). The yellow mixture was stirred at room temperature for 1 h. The resulting yellow solution was concentrated *in vacuo* to *ca.* 3 mL and stored at room temperature after dropwise addition of diethyl ether until saturation. Yellow solid formed was filtered off and vacuum dried.

*3.3.1. Data for **1a** (HL^1, X = Cl)*

Yield: 227 mg (89.7%). M.p.: 177 °C. *Anal.* Calc. for $C_{14}H_{15}ClN_3O_5SRe$: C, 30.1; H, 2.7; N, 7.5; S, 5.7. Found: C, 29.9; H, 2.6; N, 7.3; S, 5.4%. Mass spectrum [*m*/*z* (%)]: 559 (16.3) $[M]^+$, 524 (100) $[M-Br]^+$, 467 (26.3) $[M-2CO]^+$, 438 (9.7) $[M-3CO]^+$. IR data (KBr, cm^{-1}): 3442m ν(NH); 2027vs, 1922vs, 1903vs $\nu(CO_{fac})$; 1630vs ν(C=N); 757w ν (C=S). ^1H NMR data (ppm): 12.49s (1) δ(N(2)–H); 8.78s (1) δ(C(2)–H); 8.20s (2) δ(N(1)–H); 7.47d (1) δ(C(6)–H); 7.23m (2) δ(C(7,8)–H); 4.18m (2) δ(O(4)–R^2); 3.89s (3) δ(O(5)–R^3); 1.27t (3) δ(O(4)–R^2).

*3.3.2. Data for **1a′** (HL^1, X = Br)*

Yield: 240 mg (88.6%). M.p.: 195–202 °C. *Anal.* Calc. for $C_{14}H_{15}BrN_3O_5SRe$: C, 27.8; H, 2.5; N, 6.7; S, 5.3. Found: C, 27.5; H, 2.3; N, 6.1; S, 5.1%. Mass spectrum [*m*/*z* (%)]: 603 (19.7) $[M]^+$, 524 (100) $[M-Br]^+$, 467 (24.3) $[M-2CO]^+$, 438 (10.3) $[M-3CO]^+$. IR data (KBr, cm^{-1}): 3441m, 3420m ν(NH); 2027vs, 1923vs,

Yellow single crystals of **2c** $\cdot$ 2(CH_3OH) suitable for X-ray diffraction were obtained by slow evaporation of a methanol solution of **1c**.

3.5. X-ray data collection, structure determination and refinement

Crystallographic data were collected on a Bruker SMART CCD-1000 diffractometer at 293 K using graphite monochromated Mo Kα radiation (λ = 0.71073 Å), and were corrected for Lorentz, polarization and absorption effects [23]. The structures were solved by direct methods using the program SHELX 97 [24]. All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were inserted at calculated positions and refined as riders [24]. Graphics were produced with PLATON [25] and MERCURY [26].

Aldrich Chemical Company, Inc. USA and were used as received. The precursor complexes $[\{(\eta^6\text{-arene})RuCl(\mu\text{-}Cl)\}_2]$, $[(\eta^6\text{-arene})RuCl_2(PyCN)]$ (arene = benzene and *p*-cymene), $[(\eta^5\text{-}C_5H_5)RuCl(PPh_3)_2]$ and $[(\eta^5\text{-}C_5Me_5)MCl(\mu\text{-}Cl)\}_2]$ (M = Rh and Ir) and the ligand (1,2-diphenylimino)acenaphthene (Ph-BIAN) were prepared and purified according to the published procedures [11,5f]. Microanalysis and FAB mass spectra were acquired from the Sophisticated Analytical Instrument Facility, Central Drug Research Institute, Lucknow. Electronic and luminescence spectra were recorded on a Shimadzu UV-1601 and Perkin–Elmer LS-45 spectrofluorophotometers, respectively. NMR spectra were acquired on a JEOL AL 300 MHz spectrometer, where chemical shifts were referenced to internal tetramethylsilane for ^{1}H NMR and phosphorous trichloride for ^{31}P NMR at room temperature.

2.2. Synthesis and characterization of $[(\eta^6\text{-}C_6H_6)RuCl(Ph\text{-}BIAN)]BF_4$ (**1**)

(a) To a suspension of the chloro-bridged dimeric ruthenium complex $[\{(\eta^6\text{-}C_6H_6)RuCl(\mu\text{-}Cl)\}_2]$ (0.502 g, 1.0 mmol) in methanol (25 mL), Ph-BIAN (0.664 g, 2.0 mmol) was added and the suspension was stirred at room temperature for ~10.0 h. Slowly it dissolved and gave a clear brown-black solution. It was filtered through Celite to remove any solid impurities. The filtrate was treated with NH_4BF_4 dissolved in methanol and left for slow crystallization. The dark brown product thus obtained was separated by filtration, washed with diethyl ether and dried under *vacuum*. It was further recrystallized from dichloromethane/diethyl ether. Yield: 0.471 g (68 %). *Anal.* Calc. (%) for $C_{30}ClF_4H_{22}N_2BRu$: C, 52.02; H, 3.18; N, 4.05. Found: C, 51.94; H, 2.83; N, 4.24%. FAB-MS: m/z = 547 (547) [M^+]; 512 (512) [$M-Cl^+$]. ^{1}H NMR (δ ppm, 300 MHz, $CDCl_3$, 298 K): 8.05 (d, 2H, J = 7.5 Hz), 7.99 (d, 2H, J = 7.2 Hz), 7.85 (d, 2H, J = 6.9 Hz), 7.73 (t, 2H, J = 6.6 Hz), 7.61 (m, 4H, J = 8.1 Hz), 7.44 (t, 2H, J = 7.5 Hz), 6.92 (d, 2H, J = 7.2 Hz), 5.58 (s, 6H). (b) Alternately, complex **1** can be synthesized by the reaction of $[(\eta^6\text{-}C_6H_6)RuCl_2(PyCN)]$ with Ph-BIAN in methanol under stirring conditions at room temperature.

2.3. Synthesis and characterization of $[(\eta^6\text{-}C_{10}H_{14})RuCl(Ph\text{-}BIAN)]BF_4$ (**2**)

This was prepared following the above synthetic procedure for **1** using $[\{(\eta^6\text{-}C_{10}H_{14})RuCl(\mu\text{-}Cl)\}_2]$ (0.612 g, 1.0 mmol) in place of $[\{(\eta^6\text{-}C_6H_6)RuCl(\mu\text{-}Cl)\}_2]$. Red brown, Yield: 0.531 g (71 %). *Anal.* Calc. (%) for $BC_{34}ClF_4H_{30}N_2Ru$: C, 54.55; H, 4.01; N, 3.74. Found: C, 53.88; H, 3.82; N, 3.57%. FAB-MS: m/z = 603 (603) [M^+]; 568 (568) [$M-Cl^+$]. ^{1}H NMR (δ ppm, 300 MHz, $CDCl_3$, 298 K): 7.99 (d, 2H, J = 8.1 Hz), 7.93 (d, 2H, J = 6.6 Hz), 7.82 (d, 2H, J = 6.3 Hz), 7.74 (t, 2H, J = 6.9 Hz), 7.62 (m, 4H), 7.43 (t, 2H, J = 8.1 Hz), 6.89 (d, 2H, J = 6.9 Hz), 5.33 (s, 4H), 2.51 (sep., 1H, J = 6.9 Hz), 1.99 (s, 3H), 1.09 (d, 6H, J = 6.9Hz). UV–Vis: λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 462 (2.3×10^4), 310 (3.9×10^4), 255 (4.1×10^4) nm. Emission: λ_{em} (λ_{ex}, $\Phi/10^{-6}$) = 547 (462, 1.8) nm.

2.4. Synthesis and characterization of $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)(Ph\text{-}BIAN)]BF_4$ (**3**)

A suspension of the ruthenium complex $[(\eta^5\text{-}C_5H_5)RuCl(PPh_3)_2]$ (0.728 g, 1.0 mmol) in methanol (25 mL) was treated with Ph-BIAN (0.332 g, 1.0 mmol) and the solution was refluxed for ~10.0 h. The resulting dark purple-black solution was filtered through Celite, and a saturated methanolic solution of NH_4BF_4 was added to the filtrate and left for slow crystallization. The dark purple-black product thus obtained was filtered and washed with diethyl ether and dried under vacuum. The product was further recrystallized from dichloromethane/diethyl ether. Yield: 0.584 g (69 %). *Anal.* Calc. (%) for $BC_{47}F_4H_{36}N_2PRu$: C, 66.58; H, 4.25; N, 3.30. Found: C, 65.98; H, 4.11; N, 3.87%. FAB-MS: m/z = 763 (760) [M^+]; 500 (498) [$M-PPh_3^+$]. ^{1}H NMR (δ ppm, 300 MHz, $CDCl_3$, 298 K): 8.13 (d, J = 8.1 Hz), 8.01 (d, J = 7.0 Hz), 7.91 (t, J = 7.1 Hz), 7.71 (t, J = 6.9 Hz), 7.60 (m), 4.65 (s). ^{31}P NMR (δ ppm, 120 MHz, $CDCl_3$): 43.29 (s). UV–Vis: λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 561 (1.9×10^4), 323 (2.6×10^4), 244 (4.1×10^4) nm. Emission: λ_{em} (λ_{ex}, $\Phi/10^{-6}$) = 617 (561, 0.9) nm.

2.5. Synthesis and characterization of $[(\eta^5\text{-}C_5(CH_3)_5)RhCl(Ph\text{-}BIAN)]BF_4$ (**4**)

This was prepared following the above synthetic procedure for **1** using $[\{(\eta^5\text{-}C_5(CH_3)_5)RhCl(\mu\text{-}Cl)\}_2]$ (0.618 g, 1.0 mmol) in place of $[\{(\eta^6\text{-}C_6H_6)RuCl(\mu\text{-}Cl)\}_2]$. Red brown, Yield: 0.499 g (72 %). *Anal.* Calc. (%) for $BC_{34}ClF_4H_{31}N_2Rh$: C, 58.87; H, 4.47; N, 4.04. Found: C, 58.68; H, 4.82; N, 4.37%. ^{1}H NMR (δ ppm, 300 MHz, $CDCl_3$, 298 K): 7.98 (d, 2H, J = 8.1 Hz), 7.95 (d, 2H, J = 7.8 Hz), 7.83 (d, 2H, J = 7.5 Hz), 7.71–7.52 (m, 6H), 7.41 (t, 1H, J = 8.1Hz), 6.91 (d, 2H, J = 6.9 Hz), 1.33 (s, 15H). UV–Vis: λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 375 (3.5×10^4), 314 (3.9×10^3), 257 (4.1×10^4) nm.

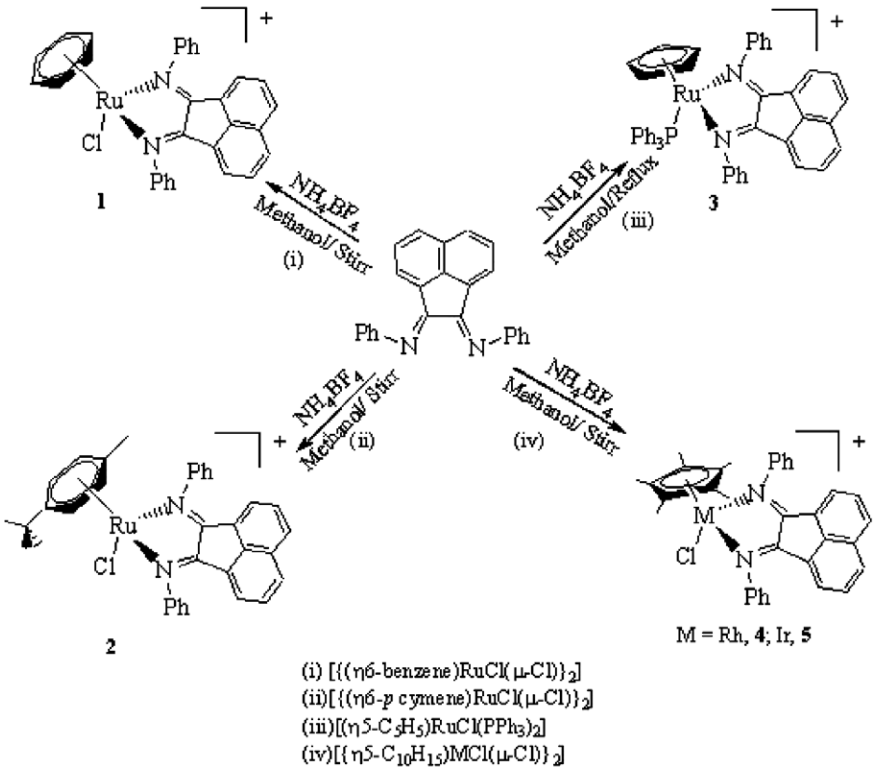
2.6. Synthesis and characterization of $[(\eta^5\text{-}C_5(CH_3)_5)IrCl(Ph\text{-}BIAN)]BF_4$ (**5**)

This was prepared following the above synthetic procedure for **1** using $[\{(\eta^5\text{-}C_5(CH_3)_5)IrCl(\mu\text{-}Cl)\}_2]$ (0.796 g, 1.0 mmol) in place of $[\{(\eta^6\text{-}C_6H_6)RuCl(\mu\text{-}Cl)\}_2]$. Red brown, Yield: 0.547 g (70 %). *Anal.* Calc. (%) for $BC_{34}ClF_4H_{31}N_2Ir$: C, 52.17; H, 3.96; N, 3.58. Found: C, 52.31; H, 3.82; N, 3.77%. ^{1}H NMR (δ ppm, 300 MHz, $CDCl_3$, 298K): 8.02 (d, 2H, J = 8.1 Hz), 7.99 (d, 2H, J = 6.9 Hz), 7.78 (d, 2H, J = 7.8 Hz), 7.71–7.52 (m, 6H), 7.43 (t, 2H, J = 7.8 Hz), 6.99 (d, 2H, J = 7.5 Hz), 1.31 (s, 15H). UV–Vis: λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 435 (2.2×10^4), 319 (3.9×10^4), 244 (4.0×10^4) nm.

3. Results and discussion

3.1. Synthesis and characterization of the complexes **1**–**5**

The cationic mononuclear complexes $[(\eta^6\text{-arene})Ru(Ph\text{-}BIAN)Cl]^+$ (η^6-arene = benzene, **1** and *p*-cymene, **2**) (Scheme 1) have been synthesized by the reactions of the arene ruthenium precursor complexes $[\{(\eta^6\text{-arene})RuCl(\mu\text{-}Cl)\}_2]$ with Ph-BIAN in methanol at room temperature. Complexes **1** and **2** were also prepared by the reaction of the complexes $[(\eta^6\text{-arene})RuCl_2(PyCN)]$ (η^6-arene = benzene **1,** *p*-cymene, **2**; PyCN = 4-cyanopyridine) with Ph-BIAN in methanol. It was observed that in the reactions of the arene ruthenium complexes containing 4-cyanopyridine $[(\eta^6\text{-arene})RuCl_2(PyCN)]$ with Ph-BIAN, the coordinated 4-cyanopyridine gets substituted by Ph-BIAN to afford the complexes **1** and **2**. This observation is consistent with our earlier findings on the analogous arene ruthenium $[(\eta^6\text{-arene})RuCl_2(PyCN)]$ and 3:3-bis allyl ruthenium complexes $[(\eta^3\text{:}\eta^3\text{-}C_{10}H_{16})RuCl_2(PyCN)]$ incorporating 4-cyanopyridine, where the respective bases (EPh_3, E = P, As, Sb; bipy, phen) displaced the metal bound 4-cyanopyridine [12]. Treatment of $[(\eta^5\text{-}C_5H_5)RuCl(PPh_3)_2]$ with Ph-BIAN in refluxing methanol led to the formation of the cationic ruthenium complex $[(\eta^5\text{-}C_5H_5)Ru(Ph\text{-}BIAN)(PPh_3)]^+$ (Scheme 1), which was isolated as the BF_4^- salt.



Scheme 1.

The pentamethylcyclopentadienyl complexes $[(\eta^5\text{-}C_5Me_5)M(Ph\text{-}BIAN)Cl]^+$ [M = Rh (**4**), Ir (**5**)] were obtained by the reactions of the chloro-bridged dimeric complexes $[\{(\eta^5\text{-}C_5Me_5)MCl(\mu\text{-}Cl)\}_2]$ [M = Rh and Ir] with two equivalents of Ph-BIAN in methanol and these were isolated as BF_4^- salts.

Spectral and analytical data of complexes **1**–**5** corroborate well to the proposed formulations. FAB-MS spectra of the complexes displayed prominent peaks corresponding to the molecular ion fragment. Representative spectra of **1**–**3** are shown in Fig. 1. Complexes **1** and **2** displayed the loss of chloride in the first step, whereas **3** displayed the loss of the coordinated triphenylphosphine. In these complexes the metal to Ph-BIAN bond is stronger and remains intact. The FAB-MS spectral results corroborate well to the proposed formulation of the complexes.

^{1}H NMR spectral data of the complexes, along with their assignments, are recorded in the experimental section. In the ^{1}H NMR spectra of complexes **1** and **2**, the protons associated with the arene moiety and Ph-BIAN displayed downfield shifts as compared to that in the precursor complexes and uncoordinated ligand, respectively. The ^{1}H NMR spectrum of complex **1** exhibited resonances at δ 8.05 (d, 2H), 7.99 (d, 2H), 7.85 (d, 2H), 7.73 (t, 2H), 7.62 (t, 4H), 7.44 (t, 2H) and 6.92 (d, 2H) ppm corresponding to Ph-BIAN protons and at δ 5.58 (s) ppm corresponding to the coordinated η^6-C_6H_6 ring protons. Similarly, in the ^{1}H NMR spectrum of complex **2** Ph-BIAN protons resonated at δ 7.99 (d, 2H, 8.1 Hz), 7.93 (d, 2H, 6.6 Hz), 7.82 (d, 2H, 6.3 Hz), 7.74 (t, 2H, 6.9 Hz), 7.62 (m, 4H), 7.43 (t, 2H, 8.1 Hz) and 6.89 (d, 2H, 6.9 Hz) ppm, while the protons associated with the *p*-cymene ring resonated at δ 5.33 (s, 4H), 2.51 (sep, 1H, 6.9 Hz), 1.99 (s, 3H) and 1.09 (d, 6H, 6.9 Hz) ppm. It was observed that the protons corresponding to Ph-BIAN resonated at almost same position in all the complexes. Further, the protons associated with the η^5-C_5H_5 ring in complex **3** resonated at 4.65 ppm and the methyl protons corresponding to the pentamethylcyclopentadienyl rings in complexes **4** and **5** appeared as a singlet at ~1.30 ppm. The position and integrated intensity of the various signals corresponded well to the formulation of respective complexes. In the ^{31}P NMR spectrum of complex **3**, the ^{31}P nuclei of the coordinated triphenylphosphine resonated as a singlet in the normal range at 43.29 ppm.

Electronic and emission spectral data for all the complexes are recorded in the experimental section. Comparative electronic spectra for the mononuclear complexes **1**–**5** are shown in Fig. 2. The electronic spectra of the ruthenium complexes **1** and **2** displayed bands at ~446, 310 and 255 nm. On the basis of its intensity and position, the lower energy absorption band at 446 nm has been assigned to a [Ru(II) → π^* Ph-BIAN] metal-to-ligand charge transfer (MLCT), where the high-lying filled orbital is localized on the metal centre and the low-lying empty orbital is localized on Ph-BIAN. Bands at around 300 nm could be attributed to intra-ligand π–π^* transitions. Similar trends of absorptions have been observed in the electronic spectra of complexes **3**–**5**.

The luminescence properties of complexes **1**–**3** were examined at room temperature in dichloromethane, Fig. 3. Upon excitation at their respective excitation bands (in parentheses), the complexes exhibited moderate emissions [577 nm (446 nm) for **1**, 547 nm (462 nm) for **2** and 617 nm (561 nm) for **3**]. The emission spectra were found to be parallel to their respective absorption bands, therefore these bands may be assigned to the ^{3}MLCT energy state of $Ru_{d\pi}$-$BIAN_{\pi^*}$. The observed results could be attributed to the fact that the excited state energy can be fine tuned with different substituents on the ligands that can be either electron donating or electron withdrawing [1c,1d,1e,13]. Emission from arene ruthenium complexes is often quenched following a non-radiative deactivation pathway [14]. Further, the non-radiative decay could be hindered by a judicious choice of ligands that controls the energy gap between the lowest excited energy state and the ground state (Table 1).

3.2. Solid-state characterization of complex *5*

Suitable crystals with distinct morphology were grown from a dichloromethane solution and diethylether by slow diffusion. The

coordination geometry about the metal centre is a typical *piano-stool* geometry. The average Ir—C_{cp^*} distance is 2.151 Å (range 2.133–2.166 Å; Ir–C_{ct} 1.810 Å) [16,17a]. The Ir–Cl and Ir–N distances are normal and have values of 2.4047 and 2.101 Å, respectively [16a–18]. The chelating N–Ir–N bite for the coordination of the imino nitrogen of Ph-BIAN is 76.9°. The arrangement of phenyl rings with respect to the acenaphthene ring is almost orthogonal, with a dihedral angle of 71.97°. The acenaphthene ring is planar with a deviation of 0.76°. The C–C(C_5Me_5) bond lengths in C_5Me_5 are in the range 1.25–1.472 Å, with an average value of 1.368 Å, and the exterior C(C_5Me_5)–C(C_5Me_5) average bond length is 1.473 Å. The C–C bond lengths within the Cp^* ring and the C–CH_3 bond lengths are normal [19].

3.3. Catalytic application of complexes *1*–*5*

To evaluate the selectivity and efficiency of complexes **1**–**5** as catalysts towards the reduction of the mono/di-formyl group, terephthalaldehyde was used as a model substrate. Hydrogenation was initiated by introducing formic acid–sodium acetate and terephthalaldehyde (1.0 mmol) in water (a few drops of freshly distilled THF was used to dissolve the catalyst) and air at 40 °C with 1% catalyst. All the complexes were found to catalyze the hydrogenation of terephthalaldehyde to produce 4-hydroxymethybenzaldehyde in aqueous solution (Table 3). It was observed that in all cases only one formyl group of terephthalaldehyde was selectively reduced. Further, we found that the rhodium complex Rh-BIAN (**4**) led to almost complete conversion of terephthalaldehyde into 4-hydroxymethybenzaldehyde in 45 min. The analogous iridium complex Ir-BIAN (**5**) was less active as compared to the rhodium complex Rh-BIAN (**4**) and complete conversion of the substrate took place in 2 h. RuPC-BIAN (**2**) required 3 h for the same reduction and RuCP-BIAN (**3**) is least effective in this regard. Among the ruthenium *p*-cymeme and benzene complexes, the ruthenium *p*-cymene complex (**2**) is more effective than its benzene (**1**) analogue. This may be due to the inductive effect of the isopropyl and methyl substituents on the capped arene ligand. Further, Rh-BIAN was also found to catalyze the hydrogenation of 2-acetyl-naphthalene, however only 20% conversion was achieved even after 10 h.

4. Conclusion

In conclusion, in this work a new series of mononuclear *piano-stool* complexes [(η^6-arene)Ru(Ph-BIAN)Cl]BF_4 [η^6-arene = C_6H_6 (**1**), $C_{10}H_{14}$ (**2**)], [(η^5-C_5H_5)Ru(Ph-BIAN)PPh_3]BF_4 (**3**) and [(η^5-C_5Me_5)M(Ph-BIAN)Cl]BF_4 [M = Rh (**4**), Ir (**5**)] have been synthesized using a highly conjugated diimine ligand with a rigid acenaphthene skeleton. Apart from the non-radiative nature of arene ruthenium complexes, the reported complexes were found to be luminescent at room temperature in dichloromethane. Furthermore, it has been shown that complexes **1**–**5** effectively catalyze the reduction of terephthalaldehyde, and among these the rhodium complex [(η^5-C_5Me_5)Rh(Ph-BIAN)Cl]BF_4 (**4**) is an effective hydrogenating catalyst for use in water and air, and delivers faster rates without requiring inert gas protection or substrate solubility in water.

Crystallographic data: Crystals suitable for single crystal X-ray diffraction analyses for **5** were grown from dichloromethane and diethyl ether at room temperature using the diffusion technique. Preliminary data on the space group and unit cell dimensions as well as intensity data were collected on a R-AXIS RAPID II diffractometer using graphite monochromatized Mo Kα radiation. The structure was solved by direct methods and refined using SHELX 97 [20]. The non-hydrogen atoms were refined with anisotropic thermal parameters. The H-atoms attached to carbon atoms were included as a fixed contribution and were geometrically calculated and refined using the SHELX riding model.

5. Supplementary data

CCDC 670670 contains the supplementary crystallographic data for complex **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. General and physical measurements

Solvents were purchased from Aldrich and dried by usual procedures. *Trans*-[Pt(N_4CR)$_2$(PPh_3)$_2$] **1** [R = Me **1a**, Et **1b**, Ph **1c**], *trans*-[Pt(CN)(N_4CEt)(PPh_3)$_2$] **4** and *cis*-[Pt(N_3)$_2$(PPh_3)$_2$] **5** were prepared according to published procedures [12,20]. C, H and N elemental analyses were carried out by the Microanalytical Service of the Instituto Superior Técnico. ^{1}H, ^{13}C and ^{31}P{^{1}H} NMR spectra (in $CDCl_3$) were measured on a Varian Unity 300 spectrometer at ambient temperature. The chemical shifts (δ) are expressed in ppm relative to Si(Me)$_4$ (^{1}H and ^{13}C) or 85% H_3PO_4 (^{31}P). *J* values are in Hertz. Infrared spectra (4000–400 cm^{-1}) were recorded on a Bio-Rad FTS 3000MX and a Jasco FT/IR-430 instruments in KBr pellets and the wavenumbers are in cm^{-1}.

Electrospray mass spectra of 5-substituted-1*H*-tetrazoles were carried out with an ion-trap instrument (Varian 500-MS LC Ion Trap Mass Spectrometer) equipped with an electrospray (ESI) ion source. The solutions (in CH_2Cl_2) were continuously introduced into the mass spectrometer source with a syringe pump at a flow rate of 10 μL/min. The drying gas temperature was maintained at 350 °C and dinitrogen was used as nebulizer gas at a pressure of 35 psi. Scanning was performed from *m/z* = 50–1500. The compounds were observed in the negative mode (capillary voltage = −4000 V). The microwave irradiation experiments were undertaken in a focused microwave CEM Discover reactor (10 mL, 13 mm diameter, 300 W) which is fitted with a rotational system and an IR detector of temperature.

2.2. Compounds preparation

2.2.1. *trans*-[Pt(5-phenethyltetrazolato)$_2$(PPh_3)$_2$] (**1d**)

(i) By refluxing: A solution of *cis*-[Pt(N_3)$_2$(PPh_3)$_2$] **5** (0.080 g, 0.10 mmol) in $NCCH_2CH_2Ph$ (8 mL) was refluxed for 12 h whereupon the solvent was removed *in vacuo*. The oily residue was treated with diethyl ether to obtain, upon stirring, a white semicrystalline solid. This was washed repeatedly with 5 mL portions of water, and then with ethanol and lastly with diethyl ether. Recrystallization from a chloroform/diethyl ether mixture gave off-white crystals of *trans*-[Pt(5-phenethyltetrazolato)$_2$(PPh_3)$_2$] **1d**.

(ii) By focused microwave irradiation: In this method, identical amounts of the reagents described above were added to a cylindrical Pyrex tube which was then placed in the focused microwave reactor. The system was left under irradiation for 1 h at 100 °C. The solvent was then removed *in vacuo* and the resulting oily residue was treated in a manner similar to that described above to obtain a white crystalline solid of **1d**. Yield: 52% (method i) and 50% (method ii). IR (cm^{-1}): 1629 (C=N). ^{1}H NMR ($CDCl_3$), δ 2.51 (m, 8H, CH_2), 7.11–7.51 (m, 40H, aromatic). ^{13}C{^{1}H} NMR ($CDCl_3$), δ 27.19 (CH_2), 34.47 (CH_2), 125.84–141.79 ($C_{aromatic}$), 164.46 (C=N). ^{31}P{^{1}H} NMR ($CDCl_3$), δ 16.51 (J_{Pt-P} = 2726 Hz). *Anal.* Calc. for $PtC_{54}H_{48}N_8P_2$: C, 60.79; H, 4.50; N, 10.50. Found: C, 60.49; H, 4.30; N, 10.39%.

2.2.2. *trans*-[Pt(C≡CPh)$_2$(PPh_3)$_2$] (**7a**)

A solution of *cis*-[Pt(N_3)$_2$(PPh_3)$_2$] **5** (0.080 g, 0.10 mmol) in ethynylbenzene (3 mL) was taken in a cylindrical Pyrex tube which was then placed in the focused microwave reactor. The system was irradiated for 1 h at 100 °C. Then the mixture was cooled and excess of diethyl ether was added to precipitate a yellow compound which was isolated by filtration and washed with diethyl ether and dried at room temperature. The resultant compound **7a** was recrystallized from a dichloromethane and diethyl ether solvent mixture. Yield: 65%. IR (cm^{-1}): 2109 (C≡C). ^{1}H NMR ($CDCl_3$), δ 6.27–6.92 (m, 10H, C_6H_5), 7.33–7.86 (m, 30H, P(C_6H_5)). ^{31}P{^{1}H} NMR ($CDCl_3$), δ 18.60 (J_{Pt-P} = 2650 Hz). *Anal.* Calc. for $PtC_{52}H_{40}P_2$: C, 67.75; H, 4.37. Found: C, 67.32; H, 4.46%. Due to poor solubility no reliable results were obtained for ^{13}C NMR spectroscopy.

2.2.3. *trans*-[Pt(*p*-MeC_6H_4C≡C)$_2$(PPh_3)$_2$] (**7b**)

This compound was prepared by a similar method to that used for **7a**, but by using 1-ethynyl-4-methylbenzene as the solvent. Yield: 62%. IR (cm^{-1}): 2105 (C≡C). ^{1}H NMR ($CDCl_3$), δ 2.16 (s, 6H, CH_3), 6.16–6.73 (m, 8H, C_6H_4), 7.34–7.82 (m, 30H, P(C_6H_5)). ^{31}P{^{1}H} NMR ($CDCl_3$), δ 18.55 (J_{Pt-P} = 2655 Hz). *Anal.* Calc. for $PtC_{54}H_{44}P_2$: C, 68.27; H, 4.67. Found: C, 67.98; H, 4.82%. Due to poor solubility no reliable results were obtained for ^{13}C NMR spectroscopy.

2.2.4. *trans*-dicyano bis(triphenylphosphine)platinum(II) complex 2 and 5-substituted-1H-tetrazoles

This compound was prepared in identical ways starting from **1a**, **1c**, **1d**, **7a** or **7b** by refluxing any of these complexes in propionitrile for 24 h. The following synthesis is described as a representative case.

A solution of *trans*-[Pt(N_4CCH_3)$_2$ (PPh_3)$_2$] **1a** (0.088 g, 0.10 mmol) in NCEt (8 mL) was refluxed for 24 h whereupon the solvent was removed to half of its volume *in vacuo*. The reaction mixture was left to cool to room temperature and was treated with diethyl ether (5 mL). The white solid **2** was isolated by filtration and washed with diethyl ether for several times and chromatographic purification of the complex on SiO_2 was carried out using dichloromethane/diethyl ether (10:1). The mother liquor was evaporated to dryness and the resulting compound was identified as 5-methyl-1*H*-tetrazole.

A slight modification was followed when starting from *trans*-[Pt(5-ethyltetrazolato)$_2$(PPh_3)$_2$] **1b**. When refluxing its solution in propionitrile, the intermediate complex *trans*-[Pt(CN)(5-ethyltetrazolato)(PPh_3)$_2$] **4** started to precipitate after 6 h, whereupon 5 mL of DMF (dimethylformamide) was added to solubilize the complex, thus allowing the reaction to proceed further.

2.2.5. *trans*-[Pt(CN)$_2$(PPh_3)$_2$] (**2**)

Yield: 60%. IR (cm^{-1}): 2129 (C≡N). ^{1}H NMR ($CDCl_3$), δ 7.43–7.72 (m, 30H, aromatic). ^{13}C{^{1}H} NMR ($CDCl_3$), δ 125.70 (C≡N), 128.49–141.08 ($C_{aromatic}$). ^{31}P{^{1}H} NMR ($CDCl_3$), δ 14.42 (J_{Pt-P} = 2377 Hz). *Anal.* Calc. for $PtC_{38}H_{30}N_2P_2$: C, 59.14; H, 3.92; N, 3.63. Found: C, 59.13; H, 3.90; N, 3.25%.

2.2.6. 5-Methyl-1H-tetrazole (**3a**)

Yield: 70%. IR (cm^{-1}): 1629 (C=N). ^{1}H NMR ($CDCl_3$), δ 2.60 (s, 3H, CH_3). ^{13}C{^{1}H} NMR ($CDCl_3$), δ 9.18 (CH_3), 153.21 (C=N). ESI-MS, *m/z* 83 [M−H]$^-$.

2.2.7. 5-Ethyl-1H-tetrazole (**3b**)

Yield: 75%. All the spectroscopic and ESI-MS data are in agreement with those reported earlier [18].

2.2.8. 5-Phenyl-1H-tetrazole (**3c**)

Yield: 80%. IR (cm^{-1}): 1636 (C=N). ^{1}H NMR ($CDCl_3$), δ 7.43–8.16 (m, 5H, aromatic). ^{13}C{^{1}H} NMR ($CDCl_3$), δ 126.34–133.93 ($C_{aromatic}$), 158.49 (C=N). ESI-MS, *m/z* 145 [M−H]$^-$.

2.2.9. 5-Phenethyl-1H-tetrazole (**3d**)

Yield: 77%. IR (cm^{-1}): 1634 (C=N). ^{1}H NMR ($CDCl_3$), δ 3.09 (t, J_{HH} = 9 Hz, 2H, CH_2), 3.24 (t, J_{HH} = 9 Hz, 2H, CH_2), 7.12–7.54 (m, 5H, aromatic). ^{13}C{^{1}H} NMR ($CDCl_3$), δ 25.40 (CH_2), 33.64 (CH_2), 126.58–139.61 ($C_{aromatic}$), 155.94 (C=N). ESI-MS, *m/z* 173 [M−H]$^-$.

2.3. Single-crystal X-ray crystallography

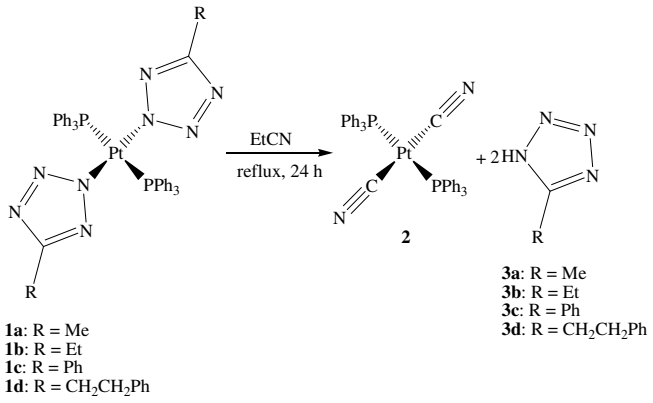
Single crystals of **2** were obtained by diffusing diethyl ether in dichloromethane solutions of the complex. X-ray diffraction suitable crystals of **7a** were obtained by slow evaporation of the reaction mixture.

X-ray intensity data were measured at 150 K on a Bruker AXS-KAPPA APEX II CCD-based diffractometer (Mo Kα radiation, λ = 0.71073 Å) using omega scans of 0.5° per frame, and a full sphere of data was obtained. Raw data frame integration and corrections were performed with Bruker SAINT. An empirical absorption correction was applied with SADABS. Direct methods structure solution were performed with SHELXS-97 package [21] and refined with SHELXL-97 [22] with the WinGX graphical user interface [23]. All hydrogens were inserted in calculated positions. Least square refinement with anisotropic thermal motion parameters for all the non–hydrogen atoms and isotropic for the remaining atoms were employed. Crystallographic parameters and residuals are given in Table 1.

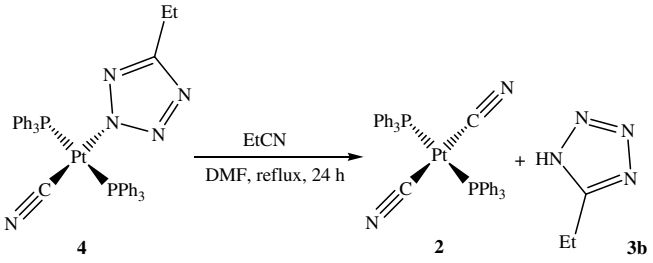
3. Results and discussion

The phenethyltetrazolato complex *trans*-[Pt(N$_4$CR)$_2$(PPh$_3$)$_2$] **1d** (R = CH$_2$CH$_2$Ph) was prepared by using either the traditional refluxing method or by microwave irradiation (M.W.) as reported in a previous paper for the synthesis of the analogous complexes **1a** (R = Me), **1b** (R = Et) and **1c** (R = Ph) [12]. Treatment of any of these complexes with an excess of propionitrile in refluxing conditions leads ultimately to the dicyano-Pt^{II} compound *trans*-[Pt(CN)$_2$(PPh$_3$)$_2$] **2**, isolated as a white crystalline solid in moderate yield (*ca.* 60%), with concomitant formation of the corresponding 5-substituted-1*H*-tetrazoles **3** in good yields (*ca.* 80%) (Scheme 1).

The dicyano-complex **2** was synthesized and reported for the first time by Bailar et al. [24], using [PtCl$_2$(PPh$_3$)$_2$] and KCN as the source of the cyano-ligand. When starting from *trans*-[Pt(N$_4$CEt)$_2$(PPh$_3$)$_2$] **1b**, the addition of a small amount of DMF is required to prevent the precipitation of the intermediate mono-cyano complex *trans*-[Pt(CN)(N$_4$CEt)(PPh$_3$)$_2$] **4**. This intermediate has been isolated by a method described elsewhere [12] and converts to *trans*-[Pt(CN)$_2$(PPh$_3$)$_2$] **2** by dissolving in DMF and then refluxing a propionitrile solution for 24 h (Scheme 2).



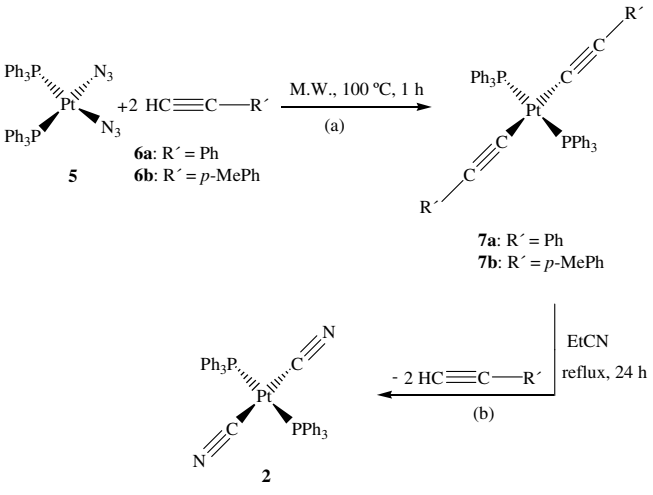
Scheme 1.



Scheme 2.

In all the above cases the dicyano-complex **2** precipitates on addition of diethyl ether and is further purified chromatographically using dichloromethane/diethyl ether as eluent. Evaporation of the mother liquor provides the respective 5-substitued-1*H*-tetrazole **3** (Scheme 1) as an off-white solid.

The dialkynyl complexes *trans*-[Pt(C≡CR′)$_2$(PPh$_3$)$_2$] **7** (R′ = Ph **7a**, *p*-MeC$_6$H$_4$ **7b**), analogous to the dicyano compound **2**, were obtained by reaction of *cis*-[Pt(N$_3$)$_2$(PPh$_3$)$_2$] **5** with ethynylbenzene **6a** or 1-ethynyl-4-methylbenzene **6b**, respectively (reaction a, Scheme 3), under focused microwave irradiation (1 h, 100 °C, 300 W). This unexpected overall replacement of the azide ligands by alkynyl groups occurs instead of the anticipated formation of triazolato complexes upon metal-promoted [2+3] cycloaddition

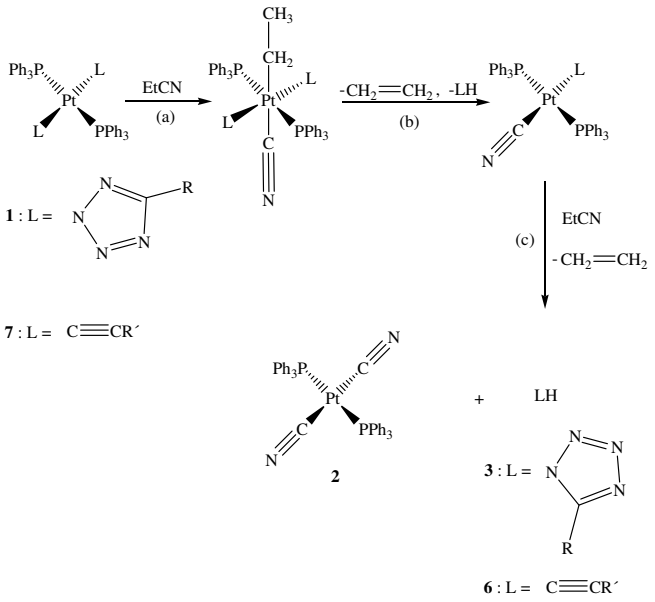


Scheme 3.

between the ligated azides and the alkynes. Complex **7a** was previously synthesized [25] starting from *cis*-$[PtCl_2(PPh_3)_2]$. Both **7a** and **7b** have been characterized by means of IR, ^1H, and $^{31}P\{^1H\}$ NMR spectroscopies, elemental analyses and X-ray crystallographically (for complex **7a**). The observed spectroscopic data are in accordance with those of related alkynyl complexes reported elsewhere [26]. The dialkynyl complexes **7a** and **7b** also furnish the dicyano-platinum complex **2** upon refluxing in propionitrile for 24 h (reaction b, Scheme 3).

The formation of the dicyano-platinum(II) complex **2** is believed to proceed, in all the cases, *via* activation of the C–CN bond in propionitrile. In fact, all the attempts to transform the bis(tetrazolato) complexes **1** or the dialkynyl complexes **7** into **2** in the absence of propionitrile have failed (the starting materials were then recovered quantitatively), namely when a CH_2Cl_2 solution of **1** or **7** was refluxed for 36 h or heated under focused M.W. irradiation (2 h, 100 °C), also in solid phase (SiO_2) without solvent. These results indicate that propionitrile is the precursor of the cyanide ligand in complex **2**.

A possible pathway for the conversion of the bis(tetrazolato) complexes **1** or the dialkynyl compounds **7** into **2** is proposed in Scheme 4. It involves an oxidative addition of propionitrile (which thus undergoes NC–C bond cleavage) to Pt^{II} to give a cyano-ethyl-Pt^{IV} intermediate (reaction a, Scheme 4), followed by β-elimination from the ethyl ligand to form ethylene, and reductive elimination of the corresponding 5-substituted-1*H*-tetrazole **3** or alkyne **6** to yield the mixed cyano-tetrazolato or cyano-alkynyl platinum(II) complex, respectively (reaction b, Scheme 4). In most of the cases the high solubility of these mono-cyano complexes in propionitrile allows the reaction to proceed further towards a second oxidative addition of EtCN and reductive elimination step (reaction c, Scheme 4), ultimately giving the dicyano-complex **2**. The evolution of ethylene gas assists in driving these reactions. Efforts to isolate the intermediate mixed cyano-tetrazolato or cyano-alkynyl complexes failed except in the case of *trans*-$[Pt(N_4CEt)_2(PPh_3)_2]$ **1b** where *trans*-$[Pt(CN)(N_4CEt)(PPh_3)_2]$ **4** precipitates from the reaction mixture due to its poor solubility in propionitrile. Quantitative recovery of complex **1a** or **1c** upon prolonged refluxing in benzonitrile or in acetonitrile, respectively, *i.e.* N≡CR solvents with R groups which can not undergo β-elimination, reinforces the proposed mechanistic pathway.



Scheme 4.

Table 2
Selected bond distances (Å) and angles (°) for complexes **2** and **7a**

	2	7a
Bond lengths		
Pt1–P1	2.3210(12)	2.3118(7)
Pt1–C1	1.987(5)	2.004(3)
N1–C1	1.154(7)	
C1–C2		1.204(4)
Bond angles		
P1–Pt1–C1	88.25(13)	86.68(8)
P1–Pt1–C1[a]	91.75(13)	93.34(8)
Pt1–C1–C2		173.0(2)
Pt1–C1–N1	176.8(4)	

[a] Symmetry operation to generate equivalent atom: $-x, -y, -z$.

The 5-substituted-1*H*-tetrazoles **3** were isolated in good yields (*ca.* 80%) and characterized by IR, ^1H and ^{13}C NMR spectral data and electrospray mass spectrometry (ESI-MS). The ^{13}C NMR resonances of the tetrazole ring carbon atoms *C*=N (153.2–159.9 ppm) are observed at a higher field than those of the corresponding complex precursors **1** (*ca.* 164 ppm).

The obtained complex **2** was characterized by elemental analysis, IR and ^1H, $^{13}C\{^1H\}$ and $^{31}P\{^1H\}$ spectroscopies. The IR band at 2129 cm^{-1} and the ^{13}C resonance at 125.7 ppm confirm the presence of the cyano ligand in the complex [27]. In the $^{31}P\{^1H\}$ NMR spectrum, the $J(^{31}P\text{-}^{195}Pt)$ value of 2726 Hz is typical for the *trans* configuration in solution [28].

The single-crystal X-ray diffraction structural analyses of **2** and **7a** confirm the formulations of the respective complexes. Selected bond lengths and angles and crystallographic data are given in Tables 1 and 2. The crystal structure of *trans*-$[Pt(CN)_2(PPh_3)_2]$ with one methanol molecule as solvent of crystallization was reported previously [29].

In both compounds **2** and **7a**, the metal center is essentially square-planar, the Pt atoms lie on inversion centers and the bulky PPh_3 ligands are mutually *trans* (Figs. 1 and 2). The bond lengths

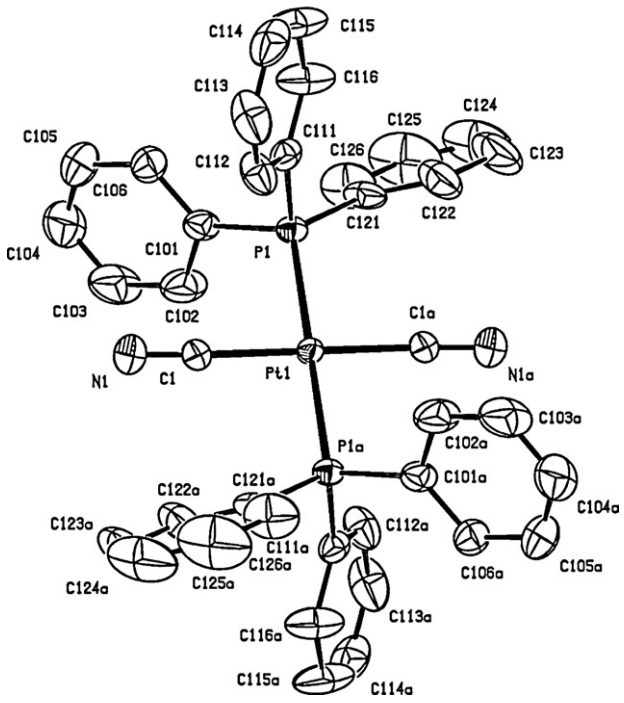


Fig. 1. Molecular structure of *trans*-$[Pt(CN)_2(PPh_3)_2]$ **2** with atomic numbering scheme (ellipsoids are drawn at 50% probability).

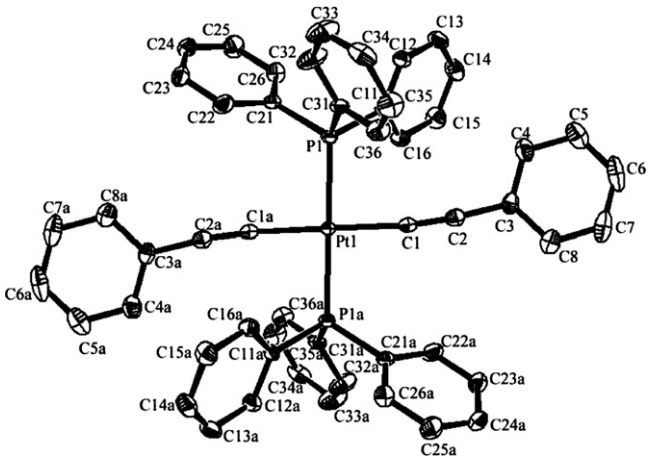

Fig. 2. Molecular structure of *trans*-[Pt(C≡CPh)$_2$(PPh$_3$)$_2$] **7a** with atomic numbering scheme (ellipsoids are drawn at 50% probability).

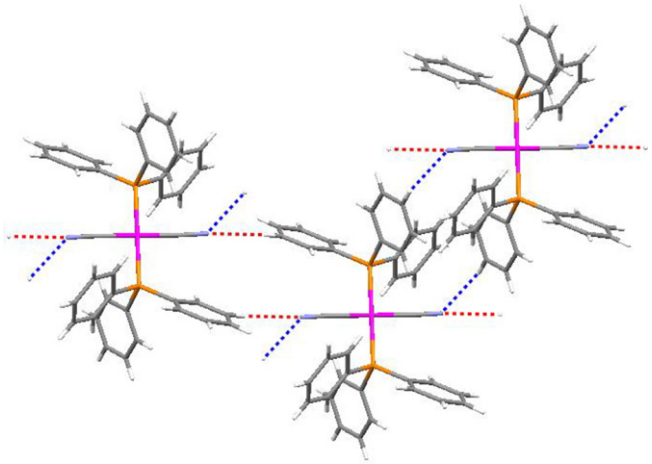

Fig. 3. A three-dimensional sheet of **2**. The C–H···N weak hydrogen bonding interactions that sustain the sheets are shown as dots (blue dots refer to the H114···N1 interaction and the red dots to the H123···N1 interaction). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

between the platinum ion and the donating atoms are within the ranges reported for related Pt(II) complexes [30].

The centrosymmetric molecules of **2** are connected by a set of C–H···N weak hydrogen bonding interactions, which arrange the molecules into three-dimensional sheets (Fig. 3) since the nitrogen N1 lone pair of one molecule is oriented towards the phenyl hydrogen atoms H114 and H123, of two other molecules. The H114···N1 and H123···N1 distances for these interactions are 2.55 Å and 2.74 Å, respectively.

4. Conclusion

In this work, we have shown that both the bis(tetrazolato) and the dialkynyl complexes *trans*-[Pt(N$_4$CR)$_2$(PPh$_3$)$_2$] and *trans*-[Pt(C≡CR′)$_2$(PPh$_3$)$_2$], respectively, react with propionitrile to furnish dicyano-complex *trans*-[Pt(CN)$_2$(PPh$_3$)$_2$] *via* an unusual oxidative addition (involving NC–C bond cleavage of two propionitrile molecules) followed by a reductive elimination process. It also provides an alternative metal-assisted route to prepare 5-substituted-1*H*-tetrazole compounds in an easy and convenient way. The extension of these methods to the preparation of (i) other cyano-complexes, namely of the types [Pt(CN)$_2$L$_2$] and [Pt(CN)$_2$X$_2$L$_2$] (X = single-electron donating ligand, L = two-electron donor ligand), without the need to use toxic chemicals (such as an alkali metal cyanide) and (ii) other 5-substituted tetrazoles (simply by changing the R group of the organonitrile NCR precursors), are worth to be pursued.

Acknowledgements

This work has been partially supported by the Fundação para a Ciência e a Tecnologia (FCT) and its POCI 2010 program (FEDER funded) (Portugal). S.M. and J.L. express gratitude to the FCT for their post-doc. fellowships (grants SFRH/BPD/14690/2003 and SFRH/BPD/20927/2004).

Appendix A. Supplementary data

CCDC 680289 and 680290 contain the supplementary crystallographic data for **7a** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.06.031.

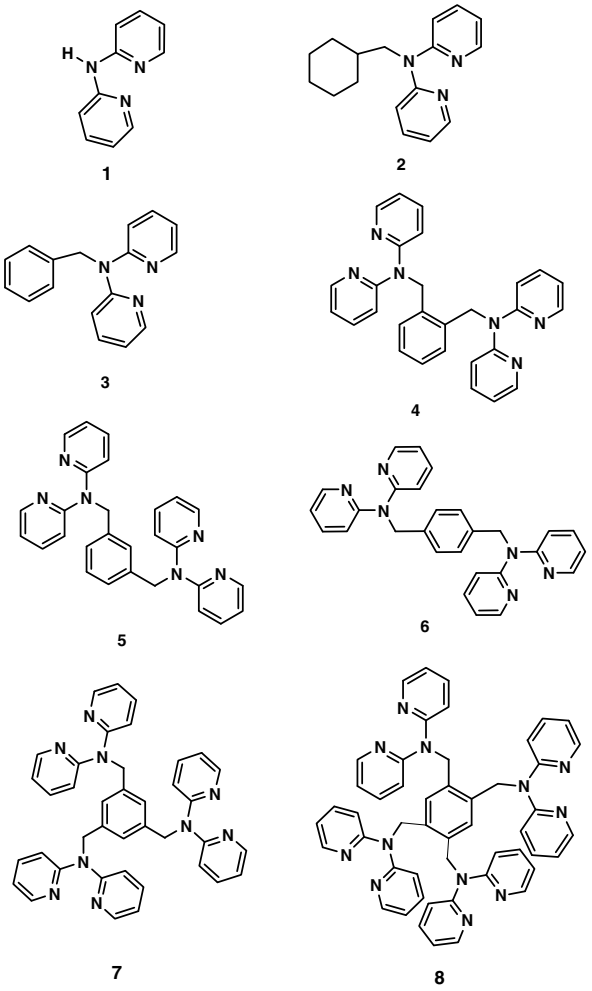
complexes [4,13,16] of two related *N*-substituted mono-dpa derivatives have been investigated as part of biologically orientated studies.

As an extension of the above we now report the results of an investigation of the interaction of the '*N*-methylene substituted' dpa derivatives **2**–**8** with copper(II) and **1**, **4**–**6** with palladium(II).



2. Experimental

2.1. Physical methods

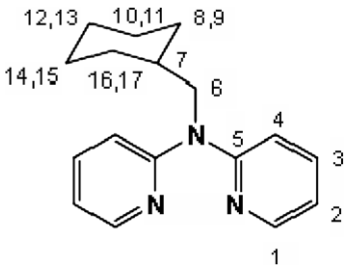
Electrospray (ES) mass spectra were recorded using a Micromass LCT-TOF mass spectrometer; EI and FAB spectra were recorded using a Kratos MS80RFA mass spectrometer. HRMS were determined on samples loaded in dichloromethane and run in an acetonitrile matrix. Melting points are uncorrected. NMR spectra were determined on a DRX-500 Bruker spectrometer or on Varian 300 and 500 MHz spectrometers.

2.2. Ligand synthesis

The syntheses of the di-2-pyridylamine derivatives di-2-pyridylaminomethylbenzene (**3**) [14,17,18], 1,2-bis(di-2-pyridylaminomethyl)benzene (**4**) [14], 1,3-bis(di-2-pyridylaminomethyl)benzene (**5**) [14], and 1,4-bis(di-2-pyridylaminomethyl)benzene (**6**) [14] and 1,3,5-tris(di-2-pyridylaminomethyl)benzene (**7**) [14] have been reported previously. Di-2-pyridylamine was obtained commercially.

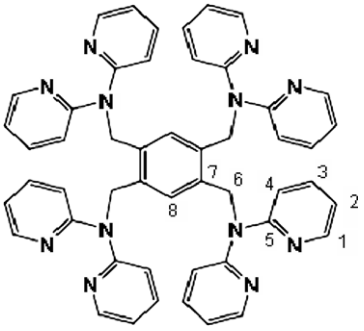
2.2.1. *N*-Cyclohexylmethyl-2,2′-dipyridylamine (**2**)

To 2,2′-dipyridylamine (0.952 g, 5.56 mmol) in DMF (5 mL) was added finely ground KOH (0.81 g; 14.4 mmol). Bromomethylcyclohexane (0.984 g, 5.56 mmol) in DMF (3 mL) was added dropwise and the reaction mixture was stirred for 24 h at room temperature; a colour change to bright yellow occurred. The solvent was removed under reduced pressure and the pale yellow solid that remained was dissolved in water and extracted with chloroform (4×100 mL). The combined chloroform extracts were dried over $MgSO_4$. The solution was filtered and the solvent was removed from the filtrate under reduced pressure to yield the crude product which was purified on a chromatographic column (Silica Gel KG 60) employing CH_2Cl_2–MeOH (95:5) as eluent; 0.8 g of the crude product yielded 0.08 g of pure product as a yellow oil (the first fraction eluted from the column). ESI-MS $m/z = 268$ $[M+H]^+$; ^1H NMR ($CDCl_3$) δ 8.30 (dd, 2H, H1), 7.47 (t, 2H, H3), 7.05 (d, 2H, $3J = 8.4$ Hz, H4), 6.80 (t, 2H, H2), 4.04 (s, 2H, H6), 1.81 (m, 1H, H7), 1.58–1.71 (m, 5H, H8, H9, H11, H12), 1.12 (m, 3H, H10, H11, H14, H15), 0.96 (m, 2H, H16, H17). ^{13}C NMR ($CDCl_3$): δ 157.0 (C5), 148.0 (C1), 137.1 (C3), 116.8 (C2), 114.9 (C4), 54.0 (C6), 37.2 (C7), 30.9 (C8, C9, C14, C15), 26.5 (C12, C13), 25.9 (C10, C11, C16, C17).



2.2.2. 1,2,4,5-Tetrakis(di-2-pyridylaminomethyl)benzene (**8**)

Di-2-pyridylamine (1.00 g, 5.84 mmol) and potassium hydroxide (1.31 g, 23.4 mmol) were stirred in DMSO for 1 h, 1,2,4,5-tetrakis(bromomethyl)benzene (0.642 g, 1.89 mmol) was added and the solution stirred for a further 48 h. Addition of water gave a yellow precipitate which was washed with water and then recrystallised from a chloroform–petroleum ether mixture. Yield: 0.396 g (34%); m.p. 238–241 °C. Calc. for $C_{50}H_{42}N_{12} \cdot 2H_2O$: C, 70.90; H, 5.47; N, 19.84. Found: C, 71.03; H, 5.36; N, 20.01%. ES-MS $m/z = 811$ $[M+H]^+$. HRMS: calc. for $[C_{50}H_{43}N_{12}]^+$ 811.3729; found 811.3734. ^1H NMR ($CDCl_3$): δ 8.16 (d, 8H, H1), 7.33 (br, 8H, H3), 7.14 (s, 2H, H8), 6.84 (d, 8H, H4), 6.78 (dd, 8H, H2), 5.42 (s, 8H, H6). ^{13}C NMR ($CDCl_3$): δ 156.8 (C5), 148.0 (C1), 137.0 (C3), 133.6 (C7), 123.6 (C8), 116.9 (C2), 114.5 (C4), 52.1(C6).



2.3. Complex synthesis

2.3.1. [Cu(2)(μ-Cl)Cl]$_2$

$CuCl_2 \cdot 2H_2O$ (34 mg, 0.20 mmol) in warm ethanol (5 mL) was added with stirring to **2** (54 mg, 0.20 mmol) in warm ethanol (5 mL). Diffusion of diethylether vapour overnight into this solution yielded green crystals. These were separated, washed with ether, and dried in air. Yield: 58 mg (72%); m.p. >218 °C (decomp.). Calc. for $C_{34}H_{42}Cl_4Cu_2N_6$: C, 50.81; H, 5.27; N, 10.46. Found: C, 50.43; H, 5.10; N, 10.31%. ESI-MS m/z = 635 $[2L+Cu+Cl]^+$, 268 $[L+H]^+$.

2.3.2. [Cu(3)(μ-Cl)Cl]$_2 \cdot H_2O$

$CuCl_2 \cdot 2H_2O$ (20 mg; 0.12 mmol) in warm ethanol (5 mL) was added with stirring to a warm solution of **3** (30 mg, 0.12 mmol) in ethanol (5 mL). Diffusion of diethylether vapour over several days into this solution yielded green crystals. These were separated, washed with ether, and dried in air. Yield: 39 mg (82%); m.p. > 202 °C (decomp.). Calc. for $C_{34}H_{30}Cl_4Cu_2N_6{\cdot}H_2O$: C, 50.44; H, 3.98; N, 10.38. Found: C, 50.83; H, 3.61; N, 10.44%. A crystal was subsequently removed from the ethanol reaction solution and used directly (without air drying) for the X-ray structure determination; the structure analysis showed it to be the di-ethanol solvate, $[Cu(3)(\mu\text{-}Cl)(Cl)]_2 \cdot 2C_2H_5OH$.

2.3.3. [Cu$_2$(4)(NO$_3$)$_4$]

$Cu(NO_3)_2 \cdot 2.5H_2O$ (23.0 mg, 0.095 mmol) in methanol (5 mL) was added to a dichloromethane solution (5 mL) of **4** (20.0 mg, 0.045 mmol). On standing a blue solid precipitated that was collected and dried under vacuum. Yield: 25 mg (67%); m.p. 261–263 °C (decomp.). Calc. for $C_{28}H_{24}N_{10}O_{12}Cu_2$: C, 41.03; H, 2.95; N, 17.09. Found: C, 40.99; H, 3.08; N, 17.06%.

2.3.4. [Cu$_2$(5)(NO$_3$)$_4$] · 2CH$_3$OH

$Cu(NO_3)_2 \cdot 2.5H_2O$ (22.8 mg, 0.094 mmol) in methanol (5 mL) was added to **5** (20.0 mg, 0.045 mmol) in dichloromethane (5 mL). On standing a blue crystalline product precipitated. This was collected, dissolved in methanol, and recrystallised via vapour diffusion of ether into the methanol solution. The product was collected by filtration and dried under vacuum. Yield: 22 mg (54%); m.p. > 175 °C (decomp.). Calc. for $C_{28}H_{24}N_{10}O_{12}Cu_2 \cdot 2CH_3OH$: C, 40.77; H, 3.65; N, 15.85. Found: C, 40.57; H, 3.26; N, 15.96%.

2.3.5. [Cu$_2$(6)(CH$_3$OH)$_2$(NO$_3$)$_4$]

$Cu(NO_3)_2 \cdot 2.5H_2O$ (23.6 mg, 0.098 mmol) in methanol (5 mL) was added to a dichloromethane solution (5 mL) of **6** (19.9 mg, 0.045 mmol). On standing blue crystals formed which were found suitable for X-ray crystallography. They were collected by filtration and dried under vacuum. Yield: 23 mg (59%); m.p. 275–277 °C (decomp.). Calc. for $C_{30}H_{32}N_{10}O_{14}Cu_2$: C, 40.77; H, 3.65; N, 15.85. Found: C, 40.81; H, 3.46; N, 16.03%.

2.3.6. [Cu$_4$(8)](NO$_3$)$_4$] · 4H$_2$O

$Cu(NO_3)_2 \cdot 2.5H_2O$ (26.3 mg, 0.109 mmol) in methanol (5 mL) was added to **8** (20.5 mg, 0.025 mmol) in dichloromethane (5 mL). The solution was concentrated by slow evaporation to give a blue crystalline solid that was collected by filtration and dried under vacuum. Yield: 23.5 mg (58%); m.p. 224–227 °C (dec.). Calc. for $C_{50}H_{42}N_{20}O_{24}Cu_4.4H_2O$: C, 36.77, H, 3.09, N, 17.15. Found: C, 37.20; H, 2.78; N, 16.75%.

2.3.7. [Pd(1)$_2$](PF$_6$)$_2$ · 2CH$_3$OH

$Pd(OAc)_2$ (2.2 mg, 0.01 mmol) in methanol (10 mL) was added to a stirred solution of **1** (1.8 mg, 0.01 mmol) in methanol (5 mL) followed by NH_4PF_6 (5 mg, 0.03 mmol) in methanol (3 mL) and the solution was stirred for 3 h at room temperature. It was then filtered and the filtrate allowed to stand at 4 °C over several weeks to yield a small number of orange-yellow crystals, one of which was used directly for the X-ray structure determination. ^{1}H NMR (DMSO-d_6): δ 11.6 (s, 1H), 8.10 (t, 2H), 7.60 (t, 6H), 7.26 (t, 6H), 7.10 (d, 6H), 4.05 (br, 1H, HO–CH$_3$), 3.08 (s, 3H, H3C–OH).

2.3.8. [Pd$_2$(4)Cl$_4$]

$PdCl_2$ (16.6 mg, 0.094 mmol) in 2 M hydrochloric acid (2 mL) was added to a dichloromethane–methanol solution (1:1; 8 mL) of **4** (20.2 mg, 0.045 mmol). A pale yellow solid precipitated. This was collected, washed with methanol, and dried under vacuum. Yield: 29 mg (81%); m.p. > 330 °C. Calc. for $C_{28}H_{24}N_6Cl_4Pd_2$: C, 42.08; H, 3.03; N, 10.52. Found: C, 41.85; H, 2.81; N, 10.24%.

2.3.9. [Pd$_2$(4)(OAc)$_4$]

$Pd(OAc)_2$ (29 mg, 0.13 mmol) in a 1:1-mixture of THF/toluene (8 mL) was added dropwise to **4** (29 mg, 0.060 mmol) in dichloromethane (3 mL). Yellow-orange crystals formed over several days. These were isolated, washed with ether, and dried under vacuum. Yield 42 mg (79%); m.p. > 240 °C (decomp.) Calc. for $C_{34}H_{36}N_6O_8Pd_2$: C, 48.43; H, 4.07; N, 9.41. Found: C, 48.15; H, 4.13; N, 9.12%. ^{1}H NMR (DMSO-d_6): δ 8.10 (d, 4H), 7.91 (d, 4H), 7.79 (t, 4H), 7.10–7.22 (m, 8H), 6.24 (br, s, 4H).

2.3.10. [Pd$_2$(5)Cl$_4$]

$PdCl_2$ (17.5 mg, 0.099 mmol) in 2 M hydrochloric acid (2 mL) was added to a dichloromethane–methanol solution (1:1; 8 mL) of **5** (20.9 mg, 0.047 mmol). Immediately a pale yellow precipitate formed that was collected, washed with methanol, and dried under vacuum. Yield: 27 mg (81%); m.p. 300–301 °C (decomp.). Calc. for $C_{28}H_{24}N_6Cl_4Pd_2$: C, 42.08; H, 3.03; N, 10.52. Found: C, 42.03; H, 2.93; N, 10.32%.

2.3.11. [Pd$_2$(6)Cl$_4$]

$PdCl_2$ (16.6 mg, 0.094 mmol) in 2 M hydrochloric acid (2 mL) was added to a dichloromethane–methanol solution (1:1; 8 mL) of **6** (19.9 mg, 0.045 mmol). A pale yellow precipitate formed that was collected, washed with methanol and dried under vacuum. Yield: 29 mg (80%); m.p. > 330 °C. Calc. for $C_{28}H_{24}N_6Cl_4Pd_2$: C, 42.08; H, 3.03; N, 10.52. Found: C, 41.97; H, 3.01; N, 10.24%.

2.3.12. [Pd$_2$(6)(OAc)$_4$] · CH$_2$Cl$_2$

$Pd(OAc)_2$ (23 mg, 0.103 mmol) in a 1:1-mixture of THF/toluene (8 mL) was added dropwise to **6** (23 mg, 0.051 mmol) in dichloromethane (3 mL). The solution was let stand and after two days bright yellow crystals had formed. These were isolated, washed with ether, and dried under vacuum. Yield: 32 mg (65%); m.p. > 240 °C (decomp.). Calc. for $C_{34}H_{36}N_6O_8Pd_2 \cdot CH_2Cl_2$: C, 45.49; H, 3.92; N, 8.60. Found: C, 45.92; H, 3.87; N, 8.97%. ^{1}H–NMR (DMSO-d_6): δ 8.24 (d, 4H), 7.95 (t, 4H), 7.86 (s, 4H), 7.45 (d, 4H), 7.23 (t, 4H), 5.41 (s, 4H).

2.4. Solvent extraction experiments

Liquid–liquid extraction experiments were performed at 23 ± 1 °C in microcentrifuge tubes (2 cm^3) with a phase ratio $V_{(org)}$:$V_{(aq)}$ of 1:1 (500 μL each). The aqueous phase contained $[Cu(ClO_4)_2]$ (1×10^{-4} M), sodium perchlorate (5×10^{-3} M) as supporting anion and the zwitterionic buffer system, HEPES/NaOH, at pH 7.2; as a precaution, the pH of the aqueous phase was monitored before and after each experiment with the aid of a InLab423 pH electrode. The organic phase contained a known concentration of ligand in chloroform (1×10^{-3} M). All experiments involved the mechanical shaking of the two-phase system for 30 min by which time equilibrium was reached (as established by preliminary

experiments). At the end of this time, the phases were separated, centrifuged and the depletion of the metal ion concentrations in the aqueous phase was measured using an ICP-MS (ELAN 9000/ Perkin Elmer) spectrometer.

2.5. Crystallography

Structures $[Cu(\mathbf{2})(\mu\text{-}Cl)Cl]_2$, $[Cu(\mathbf{3})(\mu\text{-}Cl)Cl]_2 \cdot 2C_2H_5OH$, $[Pd(\mathbf{1})_2](PF_6)_2 \cdot 2CH_3OH$, $[Pd_2(\mathbf{4})(OAc)_4] \cdot 4H_2O$ and $[Pd_2(\mathbf{6})(OAc)_4] \cdot 2CH_2Cl_2$ were collected on a Nonius Kappa CCD with ω and φ scans to approximately 53° 2θ at either 293(2) or 198(2) K. Data collections were undertaken with COLLECT [19], cell refinement with Dirax/lsq [20], and data reduction with EvalCCD [21]. Structure $[Cu_2(\mathbf{6})(CH_3OH)_2(NO_3)_4]$ was collected at 168(2) K with a Siemens CCD area detector with ω and φ scans to approximately 52° 2θ. Data integration and reduction were undertaken with SAINT and XPREP [22]. Each structure was solved by direct methods using SHELXS-97 [23]. Both diffractometers employed graphite-monochromated Mo Kα radiation generated from a sealed tube (0.71073 Å). Multi-scan empirical absorption corrections were applied to all data sets using the program SADABS [24]. All structures were refined and extended with SHELXL-97 [25]. In general, ordered non-hydrogen atoms with occupancies greater than 0.5 were refined anisotropically. Partial occupancy carbon, nitrogen and oxygen atoms were refined isotropically. Carbon-bound hydrogen atoms were included in idealised positions and refined using a riding model. Oxygen and nitrogen-bound hydrogen atoms that were structurally evident in the difference Fourier map were included and refined with bond length and angle constraints. Specific refinement details follow below. Tables of bonds, angles and H-bond geometries are presented in the ESI.

2.5.1. $[Cu(2)(\mu\text{-}Cl)Cl]_2$

Formula $C_{34}H_{42}Cl_4Cu_2N_6$, *M* 803.62, monoclinic, space group $P2_1/n$(#14), *a* 10.614(1), *b* 12.951(1), *c* 13.312(1) Å, *β* *99.74(1)*°, *V* 1803.5(3) Å^3, D_{calc} 1.480 g cm^{-3}, *Z* 2, crystal size 0.40 by 0.30 by 0.05 mm, colour green, habit plate, temperature 293(2) Kelvin, λ(Mo Kα) 0.71073 Å, μ(Mo Kα) 1.509 mm^{-1}, $T(\text{SADABS})_{min,max}$ 0.5836, 0.9284, $2\theta_{max}$ 52.00, *hkl* range −13 12, −15 15, −16 16, *N* 23057, N_{ind} 3531(R_{merge} 0.0585), *N*obs 2513 ($I > 2\sigma(I)$), *N*var 188, residuals* $R_1(F)$ 0.0538, $wR_2(F^2)$ 0.1419, GoF(all) 1.144, $\Delta\rho_{min,max}$ −0.688, 1.127 e Å^{-3}, *A* 0.0580, *B* 2.2400.

2.5.1.1. Specific details. The cyclohexyl rings are disordered and were modelled over two positions with equal occupancies. A number of restraints and constraints were necessary to facilitate realistic modelling in this region. Each of the carbon atoms in the rings were refined with identical thermal parameters.

2.5.2. $[Cu(3)(\mu\text{-}Cl)Cl]_2 \cdot 2C_2H_5OH$

Formula $C_{38}H_{42}Cl_4Cu_2N_6O_2$, *M* 883.66, triclinic, space group $P\bar{1}$(#2), *a* 7.467(1), *b* 8.460(1), *c* 16.422(1) Å, *α* *96.43(1)*°, *β* *97.23(1)*°, *γ* 104.80(1)°, *V* 983.70(19) Å^3, *D*calc 1.492 g cm^{-3}, *Z* 1, crystal size 0.98 by 0.21 by 0.07 mm, colour blue, habit plate, temperature 293(2) K, λ(Mo Kα) 0.71073 Å, μ(Mo Kα) 1.394 mm^{-1}, $T(\text{SADABS})_{min,max}$ 0.3143, 0.9087, $2\theta_{max}$ 54.00, *hkl* range −9 9, −9 9, −20 20, *N* 16407, *N*ind 3888(R_{merge} 0.0244), N_{obs} 3268 ($I > 2\sigma(I)$), N_{var} 236, residuals* $R_1(F)$ 0.0318, $wR_2(F^2)$ 0.0846, GoF(all) 1.079, $\Delta\rho_{min,max}$ −0.468, 0.662 e Å^{-3}, *A* 0.0401, *B* 0.6659.

2.5.3. $[Pd(\mathbf{1})_2](PF_6)_2 \cdot 2CH_3OH$

Formula $C_{22}H_{26}F_{12}N_6O_2P_2Pd$, *M* 802.83, triclinic, space group $P\bar{1}$(#2), *a* 8.170(1), *b* 8.560(1), *c* 10.968(1) Å, *α* *84.42(1)*°, *β* *81.61(1)*°, *γ* *74.76(1)*°, *V* 730.76(14) Å^3, D_{calc} 1.824 g cm^{-3}, *Z* 1, crystal size 0.31 by 0.16 by 0.09 mm, colour colourless, habit block, temperature 198(2) K, λ(Mo Kα) 0.71073 Å, μ(Mo Kα) 0.855 mm^{-1}, $T(\text{SADABS})_{min,max}$ 0.7774, 0.9270, $2\theta_{max}$ 52.00, *hkl* range −10 10, −10 10, −13 13, *N* 15943, N_{ind} 2866 (R_{merge} 0.0454), N_{obs} 2674 ($I > 2\sigma(I)$), N_{var} 212, residuals* $R_1(F)$ 0.0279, $wR_2(F^2)$ 0.0687, GoF(all) 1.101, $\Delta\rho_{min,max}$ −0.714, 0.607 e Å^{-3}, *A* 0.0358, *B* 0.3469.

2.5.4. $[Pd_2(\mathbf{6})(OAc)_4] \cdot 2CH_2Cl_2$

Formula $C_{38}H_{40}Cl_4N_6O_8Pd_2$, *M* 1063.36, monoclinic, space group $P2_1/c$(#14), *a* 9.073(1), *b* 13.903(1), *c* 17.021(1) Å, *β* *99.46(1)*°, *V* 2117.9(3) Å^3, D_{calc} 1.667 g cm^{-3}, *Z* 2, crystal size 0.33 by 0.27 by 0.18 mm, colour yellow, habit block, temperature 293(2) K, λ(Mo Kα) 0.71073 Å, μ(Mo Kα) 1.159 mm^{-1}, $T(\text{SADABS})_{min,max}$ 0.7010, 0.8185, $2\theta_{max}$ 56.00, *hkl* range −11 11, −18 18, −22 22, *N* 44135, N_{ind} 5079(R_{merge} 0.0326), N_{obs} 4107 ($I > 2\sigma(I)$), N_{var} 264, residuals* $R_1(F)$ 0.0380, $wR_2(F^2)$ 0.1120, GoF(all) 1.069, $\Delta\rho_{min,max}$ −0.793, 1.268 e Å^{-3}, *A* 0.0571, *B* 2.5642.

2.5.5. $[Pd_2(\mathbf{4})(OAc)_4] \cdot 4H_2O$

Formula $C_{36}H_{44}N_6O_{12}Pd_2$, *M* 965.57, orthorhombic, space group *Pccn*(#56), *a* 13.263(1), *b* 14.559(1), *c* 23.120(1) Å, *V* 4464.4(5) Å^3, D_{calc} 1.437 g cm^{-3}, *Z* 4, crystal size 0.40 by 0.21 by 0.21 mm, colour yellow, habit block, temperature 293(2) K, λ(Mo Kα) 0.71073 Å, μ(Mo Kα) 0.866 mm^{-1}, $T(\text{SADABS})_{min,max}$ 0.7232, 0.8390, $2\theta_{max}$ 50.80, *hkl* range −10 15, −17 16, −27 26, *N* 20125, N_{ind} 4047 (R_{merge} 0.0567), N_{obs} 3148 ($I > 2\sigma(I)$), N_{var} 273, residuals* $R_1(F)$ 0.0734, $wR_2(F^2)$ 0.2027, GoF(all) 1.219, $\Delta\rho_{min,max}$ −0.623, 1.067 e Å^{-3}, *A* 0.0788, *B* 17.6798.

2.5.5.1. Specific details. There is a region of disordered solvent present within the lattice. Attempts were made to refine this as a variety of different solvents including toluene, thf and dichloromethane. The results, however, were not satisfactory. As such, the electron density associated with this region was modelled as isotropic water molecules. The hydrogen atoms of these water molecules could not be located in the Fourier difference map and so were not modelled. In total there are six positions modelled with a total occupancy of 3.1 per complex molecule. In addition there is one ordered anisotropic water molecule (occupancy 0.45) modelled.

2.5.6. $[Cu_2(\mathbf{6})(CH_3OH)_2(NO_3)_4]$

Formula $C_{30}H_{32}Cu_2N_{10}O_{14}$, *M* 883.74, monoclinic, space group $P2_1/n$(#14), *a* 8.336(3), *b* 13.148(5), *c* 16.660(6) Å, *β* *91.955(5)*°, *V* 1824.9(11) Å^3, D_{calc} 1.608 g cm^{-3}, *Z* 2, crystal size 0.37 by 0.20 by 0.12 mm, colour blue, habit block, temperature 168(2) K, λ(Mo Kα) 0.71073 Å, μ(Mo Kα) 1.247 mm^{-1}, $T(\text{SADABS})_{min,max}$ 0.778, 0.861, $2\theta_{max}$ 52.88, *hkl* range −4 10, −16 16, −20 20, *N* 14750, N_{ind} 3651(R_{merge} 0.0394), N_{obs} 2538 ($I > 2\sigma(I)$), N_{var} 257, residuals* $R_1(F)$ 0.0355, $wR_2(F^2)$ 0.0827, GoF(all) 0.985, $\Delta\rho_{min,max}$ −0.350, 0.296 e Å^{-3}, *A* 0.0454, *B* 0.0000.

* $R_1 = \sum||F_o| - |F_c||/\sum|F_o|$ for $F_o > 2\sigma(F_o)$; $wR_2 = (\sum w(F^2_o - F^2_c)^2/\sum(wF^2_c)^2)^{1/2}$ all reflections $w = 1/[\sigma^2(F^2_o) + (AP)^2 + BP]$ where $P = (F^2_o + 2F^2_c)/3$.

3. Results and discussion

3.1. Copper(II) complexes

New copper(II) complexes incorporating the dpa derivatives **2**–**8** were synthesised during the present study. Reaction of the cyclohexylmethylene substituted 2,2′-dipyridylamine derivative **2** with copper(II) chloride in ethanol followed by ether vapour diffusion into the reaction solution yielded a green crystalline species of type $[Cu(\mathbf{2})(\mu\text{-}Cl)Cl]_2$. The X-ray structure (Fig. 1) of this product revealed a μ-dichloro bridged dimer, disposed around an inversion centre, containing five-coordinate copper(II) ions, with the latter separated by 3.73 Å. The N_2Cl_3 coordination sphere is best

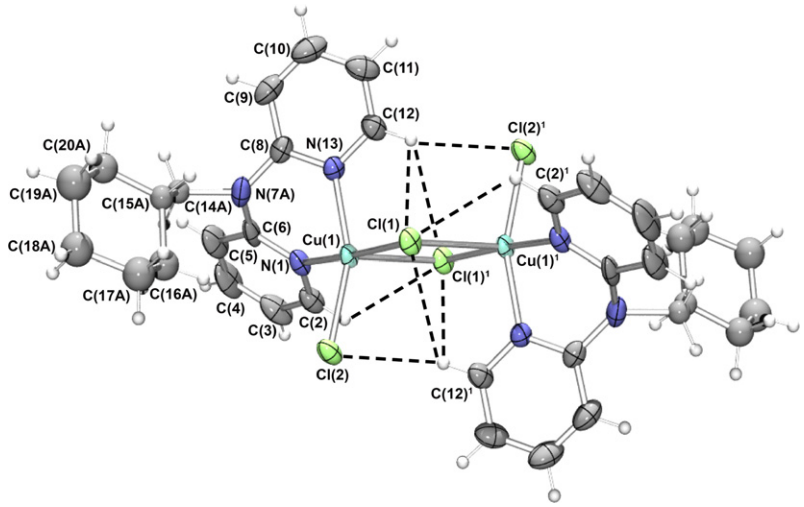


Fig. 1. ORTEP [27] representation of $[Cu(\mathbf{2})(\mu\text{-}Cl)Cl]_2$ shown with 30% probability ellipsoids. The second disordered position of the cyclohexane rings is omitted for clarity. Symmetry code used for generating equivalent atoms: $-x$, $1-y$, $1-z$. Dashed lines indicate H···Cl interactions.

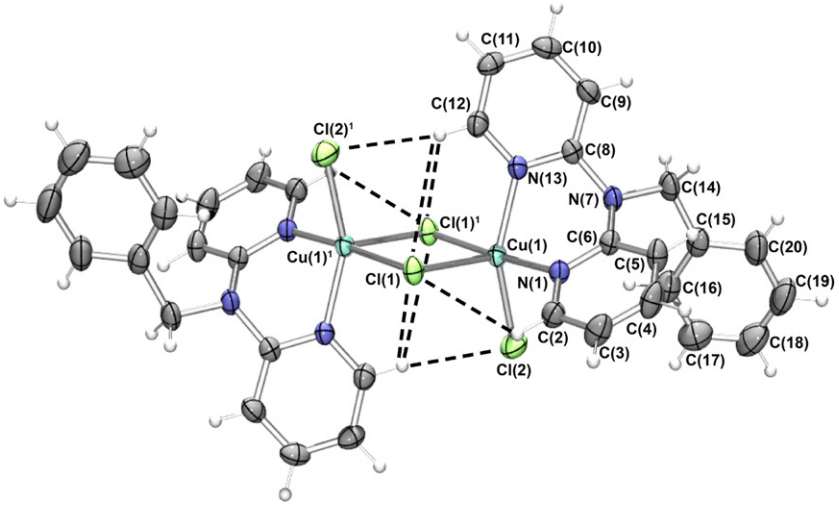

Fig. 2. ORTEP [27] representation of the dimer complex unit $[Cu(\mathbf{3})(\mu\text{-}Cl)Cl]_2 \cdot 2C_2H_5OH$ (thermal ellipsoids at 50% level) with solvent molecules omitted for clarity. Symmetry code used for generating equivalent atoms: $2-x$, $1-y$, $1-z$. Dashed lines indicate H···Cl interactions.

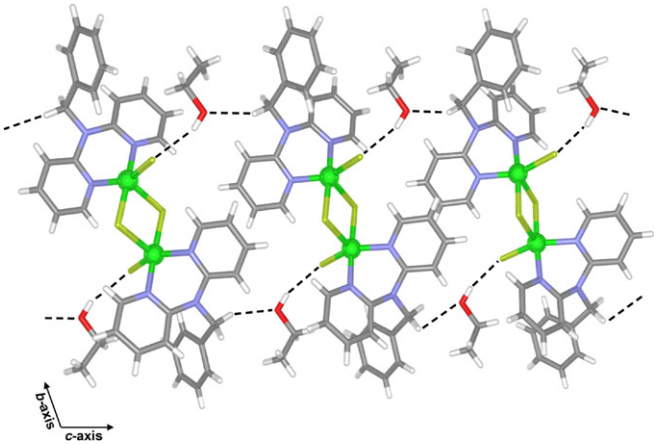

Fig. 3. A schematic representation of part of the $[Cu(\mathbf{3})(\mu\text{-}Cl)Cl]_2 \cdot 2C_2H_5OH$ crystal lattice viewed down the *a*-axis.

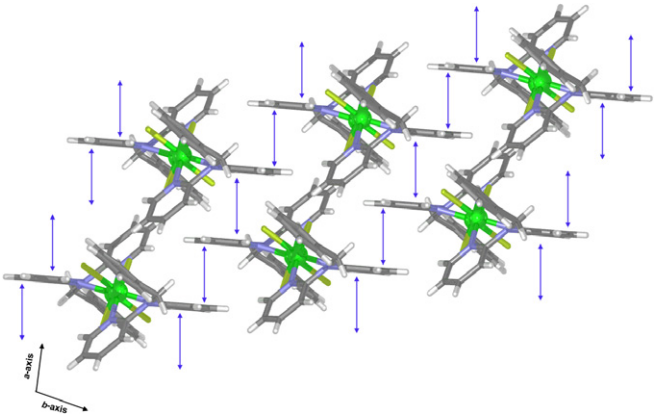

Fig. 4. A schematic representation of the 2-D sheet-like motif formed through offset face-to-face π–π interactions in $[Cu(\mathbf{3})(\mu\text{-}Cl)Cl]_2 \cdot 2C_2H_5OH$; π–π interactions indicated by arrows.

described as a distorted square pyramid ($\tau = 0.33$) [26]. The dimeric arrangement is stabilised by a number of intramolecular C–H···Cl-interactions between the metal-bound Cl^- ligand and pyridyl hydrogen atoms. (C(12)–H(12)···Cl(2)^1 = 2.75 Å; C(2)–H(2)···Cl(1)^1 = 2.96 Å; C(12)–H(12)···Cl(1) = 2.85 Å, C(12)–H(12)···Cl(1)^1 = 3.27 Å). These interactions are shown as dashed lines in Fig. 1.

[Cu(**3**)(μ-Cl)Cl]$_2 \cdot 2C_2H_5OH$ was synthesised in an analogous fashion to the above dinuclear complex, [Cu(**2**)(μ-Cl)Cl]$_2$, and both X-ray structures (Fig. 2) are very similar (the former is again disposed around an inversion centre), with the coordination sphere of each copper centre being slightly closer to a trigonal bipyramidal in the structure incorporating **3** (τ, Cu(1) = 0.46) [26]. Again, the overall arrangement is stabilised by a number of weak pyridine H-chloride interactions, the strongest of which occurs between H(12) and Cl(2)^1 (=2.45 Å); these interactions are indicated by dashed lines in Fig. 2.

In contrast to the cyclohexylmethylene-containing structure just discussed, ethanol solvent molecules are present in the lattice of the corresponding benzyl-containing derivative, [Cu(**3**)(μ-Cl)Cl]$_2 \cdot 2C_2H_5OH$. Each ethanol oxygen atom is hydrogen bonded to one of the coordinated chloride ions: (O(21)–H(21)···Cl(2), 2.45 Å); in addition, each ethanol oxygen acts as an acceptor for a weak contact from one of the methylene hydrogen atoms (C(14)–H(14A)···O(21) 2.60 Å). The latter results in the formation of a one-dimensional ribbon-like arrangement which propagates

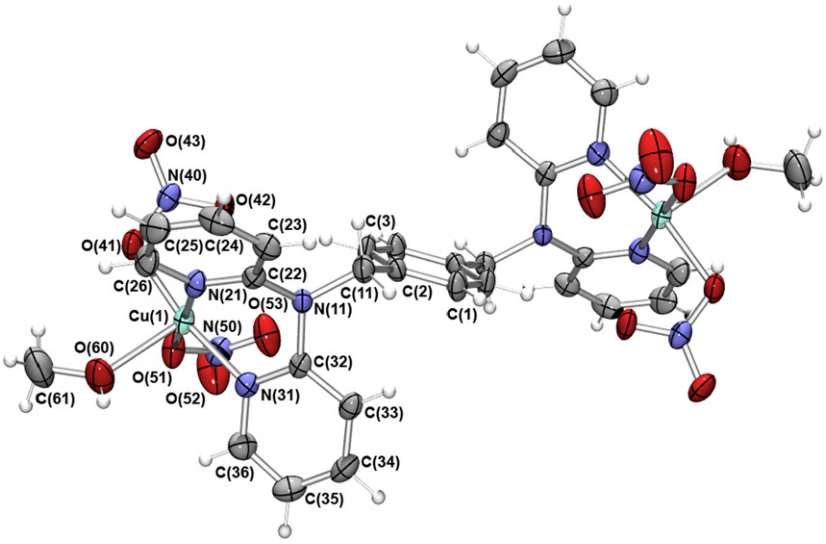

Fig. 5. ORTEP [27] depiction of the X-ray structure of [Cu_2(**6**)$(CH_3OH)_2(NO_3)_4$] shown with 50% probability ellipsoids. Symmetry code for generating equivalent atoms: $-x$, $-y$, $2 - z$.

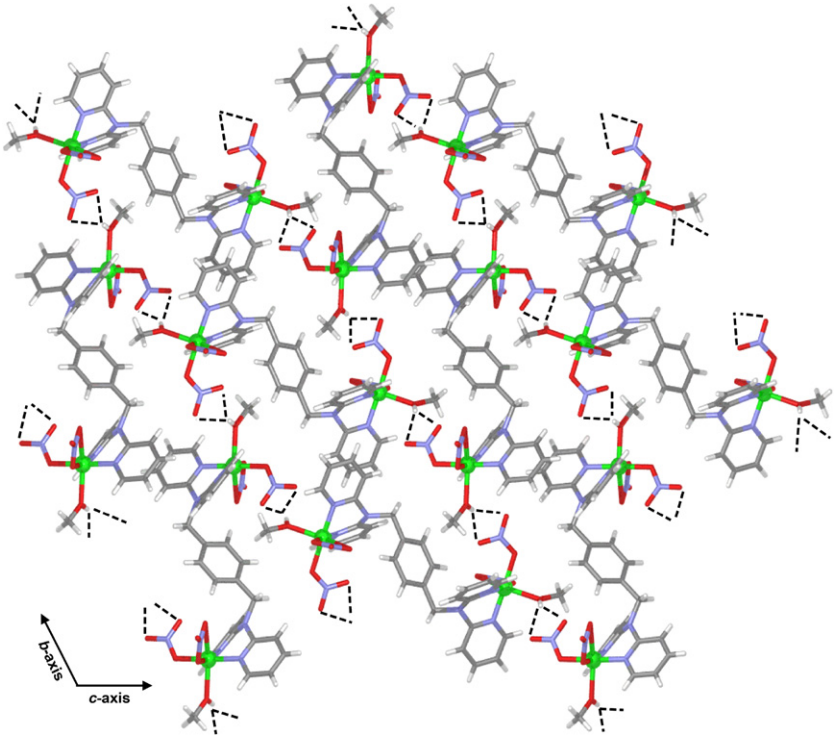

Fig. 6. The two-dimensional sheet-like arrangement formed via H-bonding interactions between [Cu_2(**6**)$(CH_3OH)_2(NO_3)_4$] units.

down the crystallographic *c*-axis. A schematic representation of a section of this packing is presented in Fig. 3.

The substitution of a phenyl ring for the cyclohexane ring clearly increases the possibility of π–π interactions occurring within the lattice of $[Cu(\mathbf{3})(\mu\text{-}Cl)Cl]_2 \cdot 2C_2H_5OH$ when compared to $[Cu(\mathbf{2})(\mu\text{-}Cl)Cl]_2$. Indeed, no significant π–π interactions were observed in the crystal packing of the latter, while there are two distinct offset face-to-face π–π interactions present in the lattice of $[Cu(\mathbf{3})(\mu\text{-}Cl)Cl]_2 \cdot 2C_2H_5OH$. The stacking occurs exclusively between alternate N(13)-containing rings throughout the lattice (centroid–centroid 3.73 Å, $\beta = 17.5°$ [28]; there is a second weak interaction, centroid–centroid 4.44 Å, β 40.5°, with the closest C–C distance C(10)–C(11) being 3.44 Å). These interactions result in the formation of a two-dimensional sheet-like motif extending in the *ab*-plane (Fig. 4). Each of these sheets is linked by the hydrogen bonds described above to form an overall three-dimensional polymeric arrangement.

As observed previously for the silver complexes of **4**–**6** [14], complexes of **4** could be expected to bind in a bis-bidentate fashion towards a single metal ion, while **5** and **6** might complex with two metal ions, one to each of the dpa sites. The latter arrangement is confirmed by the X-ray structure of $[Cu_2(\mathbf{6})(CH_3OH)_2(NO_3)_4]$ (Fig. 5); this product crystallised in the monoclinic space group $P2_1/n$, with the complex disposed around an inversion centre. In contrast to the two structures discussed above, each copper ion in this complex has a square-pyramidal geometry ($\tau = 0.02$) [26], with two pyridyl nitrogen donors and two monodentate nitrate anions occupying the basal plane and a coordinated methanol molecule bound in the apical position. The copper–copper separation is 11.206(1) Å.

The packing for the $[Cu_2(\mathbf{6})(CH_3OH)_2(NO_3)_4]$ complex shows that each dinuclear complex unit is linked through O–H···O hydrogen bonds involving coordinated methanol on one complex and the oxygen atom of a nitrate anion on an adjacent complex. The presence of these interactions results in the two-dimensional pattern illustrated in Fig. 6; a number of weak pyridyl hydrogen–oxygen interactions interconnect these layers.

3.1.1. Liquid–liquid extraction studies

Comparative two-phase solvent extraction experiments (water/chloroform) were carried out for copper(II) perchlorate in the aqueous phase at pH 7.2 (HEPES/NaOH buffer) and ligands **1**–**3**, **5**, **7** or **8** in the chloroform phase. Under the conditions employed, the extraction of copper into the chloroform phase was negligible for the single dpa derivatives (<4% which is within experimental error of zero) whereas the bis-dpa derivative, **6**, and the tri-dpa derivative, **7**, showed marginal extraction at 6% and 7%, respectively. In contrast, the tetrakis-derivative, **8**, gave 36% extraction of the copper(II) perchlorate under identical conditions. As expected, increasing the number of DPA subunits (with presumably a corresponding increase in the lipophilicity) thus results in increased extraction efficiency for the above ligand series.

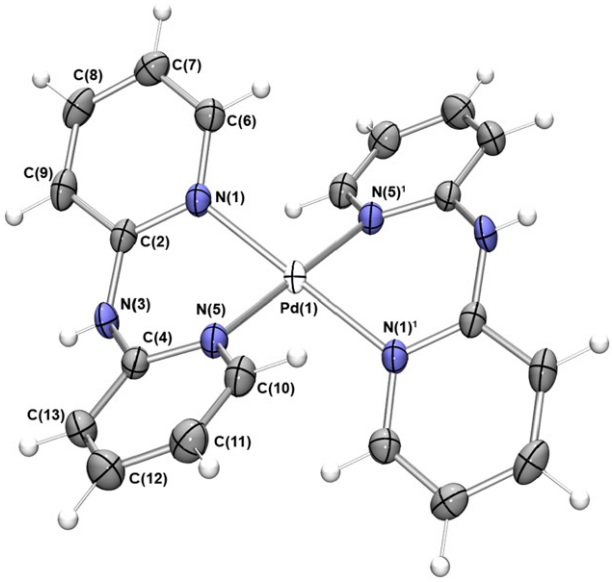

Fig. 7. ORTEP [27] plot of $[Pd(\mathbf{1})_2]^{2+}$ showing atom labels (thermal ellipsoids at the 50% probability level). Counter ion and solvent molecules are omitted for clarity. Symmetry code used for generating equivalent atoms: $1-x, -y, -z$.

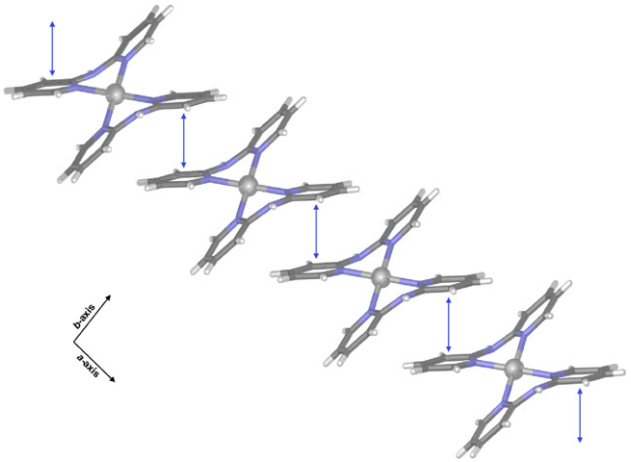

Fig. 9. A schematic representation of the chain formed by π–π interactions present in $[Pd(\mathbf{1})_2](PF_6)_2 \cdot 2CH_3OH$.

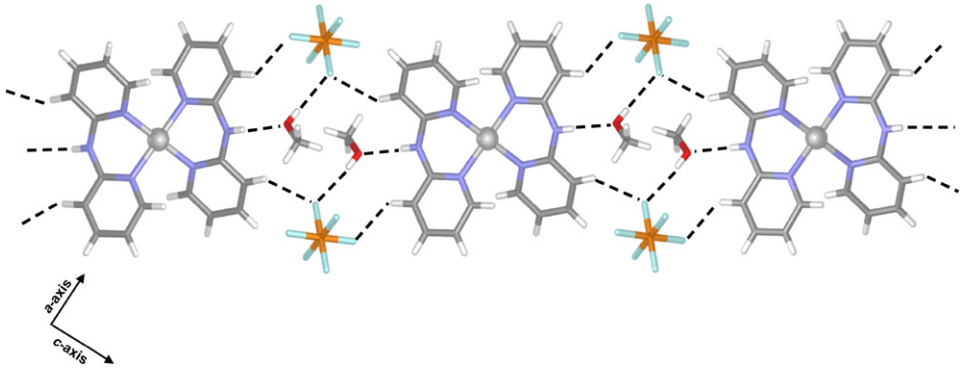

Fig. 8. Schematic representation of the one-dimensional polymeric chain formed through hydrogen bonding interactions between $[Pd(\mathbf{1})_2](PF_6)_2 \cdot 2CH_3OH$ units.

3.2. Palladium(II) complexes

As expected, the X-ray structure of $[Pd(\mathbf{1})_2](PF_6)_2 \cdot 2CH_3OH$ confirms that two 2,2′-dipyridylamine ligands bind in a bidentate fashion via their pyridyl nitrogen atoms to the palladium(II) centre in a square planar manner. An ORTEP [27] plot of the $[Pd(\mathbf{1})_2]^{2+}$ cation is shown in Fig. 7. The palladium to nitrogen bond lengths of 2.02 Å and N–Pd–N bond angles (for example, N(1)–Pd(1)–N(5) = 86°) are both within the expected range for square planar palladium(II) complexes of this type. The palladium(II) ion is located on an inversion centre. The combination of the flexible central nitrogen atom, N(3), which displays some sp^2 character (C(2)–N(3)–C(4) = 127°) and steric effects between the pyridyl rings, results in each of the dpa moieties bowing somewhat from the plane formed by the metal ion and donor atoms. This is reflected in the C(6)–N(1)–N(5)^1–C(10)^1 torsion angle of 60°.

The crystal packing for $[Pd(\mathbf{1})_2](PF_6)_2 \cdot 2CH_3OH$ (Fig. 8) is characterised by significant hydrogen bond interactions between the complex cation, the PF_6 counter ion and the methanol solvate molecules. The N–H···O interactions between the secondary amine nitrogens and methanol oxygens show a nearly ideal geometry (N–H···O, 2.11 Å; 176°). As well as the hydrogen bonding interactions, there are a number of pyridine hydrogen–fluorine interactions. These latter interactions result in the formation of a one-dimensional chain arrangement (Fig. 8). A number of other weaker phenylene hydrogen–fluorine interactions are also present in the lattice with H–F distances between 2.44 and 2.53 Å.

In addition to the above, offset face-to-face π–π-stacking occurs between pyridine rings to link the adjacent hydrogen bonded chains of the type described above, (centroid–centroid 3.65 Å, β = 12.3° [28]), resulting in a two-dimensional motif. The π–π-stacking and 'bowing' present in the cations is illustrated in Fig. 9.

The structures of the $[Pd_2(\mathbf{4})(OAc)_4] \cdot 4H_2O$ and $[Pd_2(\mathbf{6})(OAc)_4] \cdot 2CH_2Cl_2$ incorporating the isomeric ligands **4** and **6** exhibit some similar features. Both complexes are dinuclear, with each palladium centre showing square planar coordination in which two cis pyridyl nitrogen and two cis acetate oxygen atoms surround each metal centre (see Figs. 10 and 11). Each palladium ion lies only 0.01 Å and 0.03 Å out of the N_2O_2-donor planes for the complexes incorporating **4** and **6**, respectively. Selected bond lengths and angles for both complexes are given in the ESI.

An intramolecular, face-to-face, π–π interaction is present in the structure of $[Pd_2(\mathbf{4})(OAc)_4] \cdot 4H_2O$ (Fig. 10). In addition, the non-coordinated oxygen atom of each acetate ligand acts as an acceptor for hydrogen bonding from the hydrogen of a solvate water molecule. Individual complex units are connected by intermolecular O–H···O hydrogen bonds (O(1w)–H(2w)···O(2), 2.3 Å, 127°; O(1w)–H(1w)···O(4), 2.69 Å, 91°), resulting in a two-dimensional motif which propagates in the *ab*-plane as shown schematically in Fig. 12. There are also a number of weak pyridyl hydrogen–oxygen interactions present within the lattice.

In a similar manner to that occurring in the structure of $[Cu_2(\mathbf{6})(NO_3)_4] \cdot 2MeOH$ discussed previously, $[Pd_2(\mathbf{6})(OAc)_4] \cdot 2CH_2Cl_2$ (Fig. 11) is disposed around an inversion centre such that half the complex is present in the asymmetric unit. However, in contrast to the copper(II)-containing structure there are few significant formal interactions present within the lattice. Analysis of the crystal packing of this complex reveals a number of weak intermolecular C–H···O interactions involving methylene (H11) and aryl (H14B) hydrogen atoms. The geometries of these C–H···O (acetate) interactions are similar to those reported previously for a related palladium acetate complex (C···O = 3.47–3.65 Å) [29]. Other weak intramolecular C–H···N interactions are also present (see ESI).

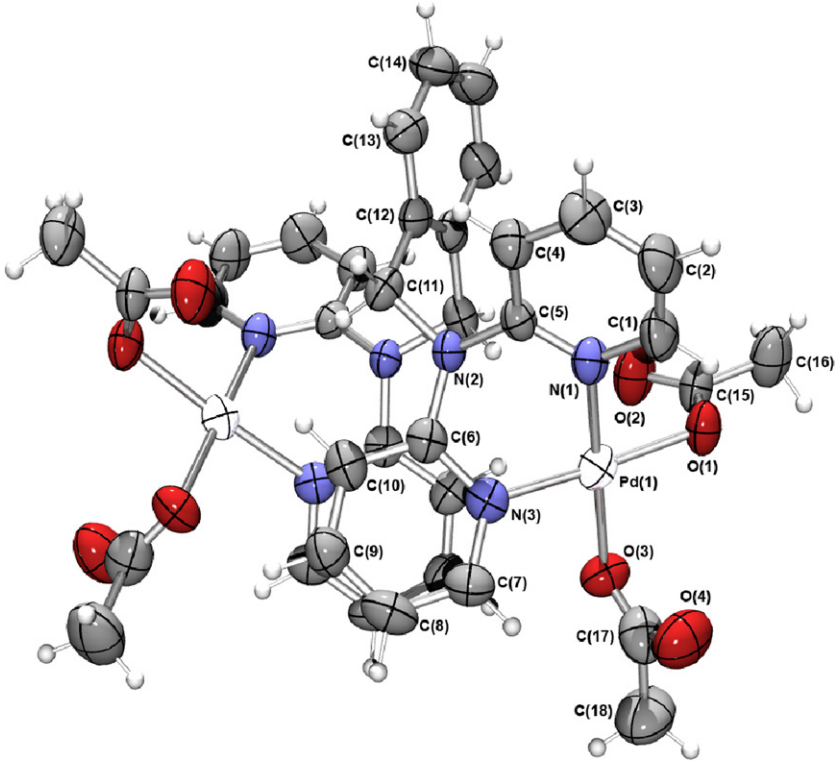

Fig. 10. ORTEP [27] representation of $[Pd_2(\mathbf{4})(OAc)_4] \cdot 4H_2O$ shown with 50% probability ellipsoids. Solvent molecules removed for clarity. Symmetry code used for generating equivalent atoms: ½ − *x*, ½ − *y*, *z*.

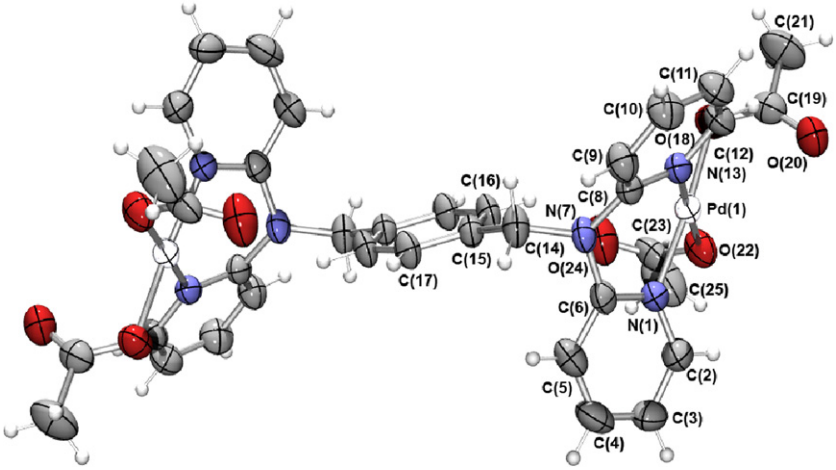

Fig. 11. ORTEP [27] representation of $[Pd_2(\mathbf{6})(OAc)_4] \cdot 2CH_2Cl_2$ shown with 50% probability ellipsoids. Solvent molecules omitted for clarity. Symmetry code used for generating equivalent atoms: $-x, 1-y, 1-z$.

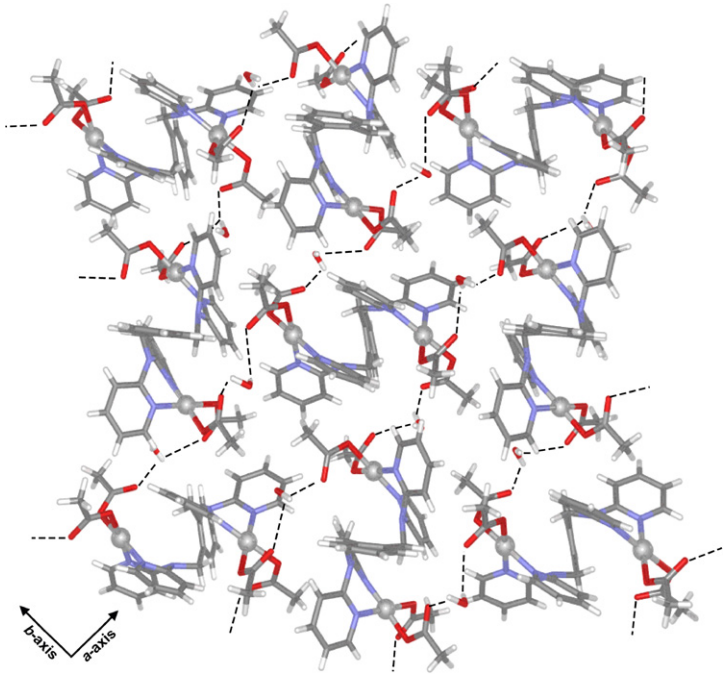

Fig. 12. Schematic representation of the two-dimensional hydrogen bonded network in $[Pd_2(\mathbf{4})(OAc)_4] \cdot 4H_2O$. Dashed lines represent hydrogen bonding interactions.

4. Concluding remarks

The interaction of copper(II) and palladium(II) with an extended series of linked dipyridylamine derivatives has been explored and shown to result in a diverse range of interesting coordination geometries and lattice architectures, with the latter ranging from essentially discrete to three-dimensional polymeric. Liquid–liquid ($H_2O/CHCl_3$) extraction experiments involving copper(II) in the aqueous phase and **1–3, 5,7** and **8** in the organic phase show that the efficiency of extraction depends markedly on the number of dpa-subunits in the ligand employed, with the tetrakis-dpa derivative **8** acting as the most efficient extractant for copper of the six ligands investigated.

a tridentate ligand L generated *in situ*, and two chlorides directly bonded to Cu(II). The formation of the tridentate ligand is unexpected as the starting materials in the stated molar proportions are used as a synthetic protocols for the preparation of biguanides [7]. Here we report role of the *in situ* generated tridentate ligand on the self-assembly of the superstructure of the molecular complex **1**.

2. Experimental

2.1. Materials and measurements

All reactions were carried out in aerobic condition and in water solvent. Cyanamide (Lancaster), dicyandiamide (Aldrich) and ethylenediamine dihydrochloride (Fluka) were used as received. All other chemicals were of reagent grade and used without further purification. The elemental analyses were done using a Perkin–Elmer 2400 Series-II elemental analyzer. The IR spectra were recorded from KBr pellets at a range of 500–4000 cm^{-1} on a Perkin–Elmer RXI FT-IR spectrophotometer with a spectral resolution of 4 cm^{-1}. UV–Vis spectral data were obtained from Shimadzu UVPC 1601 spectrophotometer. EPR spectral data were recorded using Varian E-109C spectrometer fitted with a liquid nitrogen quartz dewar, 9.1 GHz microwave frequency, 100 kHz modulation, 30 dB power, 3200 G sweep center, 4000 G sweep width, 240 s sweep time. Diphenylpicrylhydrazyl (dpph, $g = 2.0037$) was used to calibrate the spectra. Electrochemical measurements were done in nitrogen atmosphere with a three-electrode setup, consisting of a glassy carbon working, a saturated calomel reference and a Pt wire auxiliary electrodes using a EG&G PARC electrochemical analysis system, model 250/5/0. An ECDA-Pt02 platinum disk electrode obtained from Con-Serv Enterprises, India, and a planar EG&G PARC G0229 glassy carbon milli electrode were used as the working electrodes in cyclic voltammetry. The measurements (1.0 mM Cu(II) complex) were done in aqueous solution in presence of 0.1 M KCl as supporting electrolyte at 25 °C and the data are uncorrected for junction potentials. Room temperature Magnetic moment was measured by using a PAR-155 vibrating sample magnetometer. Solution conductivity was measured by a Systronics (India) direct reading conductivity meter (model 304).

2.2. Synthesis of the complex $[CuLCl_2] \cdot H_2O$ (**1**) [L = 1-(2-aminoethyl)biguanide] (**1**)

To an aqueous solution of 0.10 mol cyanamide (NH_2CN) added 0.05 mol ethylenediamine dihydrochloride (in 25 mL water). 0.025 mol $CuCl_2 \cdot 2H_2O$ (in 25 mL water) was added into this solution. The solution mixture was then either kept for ~2 months at room temperature (25–30 °C) when deep blue crystals suitable for X-ray analysis were separated or refluxed at ~80 °C for 10 h when the same blue crystals were formed on cooling to room temperature. The crystals were separated by filtration, washed with ethanol and dried in air. Alternatively, using dicyandiamide (0.05 mol, half of the cyanamide) instead of cyanamide and following the same procedures as described above resulted in the formation of **1** as confirmed by X-ray crystallography. The compound **1** can be prepared in high yield (80%, based on Cu) in either way. *Anal.* Calc. for $C_4H_{12}Cl_2N_6Cu \cdot H_2O$: C, 16.18; H, 4.72; N, 28.32. Found: C, 16.24; H, 4.79; N, 28.18%. Selected IR peaks (KBr/cm^{-1}): ν(C–N) 1308 (w) and 1267 (m), ν(N–H) 3300 (s) and 3231 (s), ν(C–H) 2940 (m) and ν(O–H) 3435 (sh).

2.3. X-ray crystallographic study

Suitable single crystals of complex **1** were mounted on a Siemens Smart CCD diffractometer equipped with a graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 298(2) K. Absorption corrections were performed using the SADABS program after the diffracting frames were reduced [8]. The structure was solved by the direct methods and refined by full-matrix least-squares fitting on F^2 by SHELXTL-97 [9]. All non-hydrogen atoms were refined with anisotropic thermal parameters. H atoms of C and N atoms were located at geometrically calculated positions and treated by a mixture of independent and constrained refinement. H atoms of the water molecule were located from difference Fourier maps.

3. Results and discussion

3.1. Synthetic observations

The tridentate ligand, L, $H_2N–(CH_2)_2–N{=}C(NH_2)–NH–C(NH_2){=}NH$, is formed *in situ* in the reaction media in presence of Cu^{2+} resulting in complex **1**. In an attempt to remove Cu^{2+} from **1** to isolate the ligand by passing H_2S gas through the aqueous solution of **1** resulted in decomposition of the ligand though Cu(II) can be quantitatively removed as CuS. We have also verified that the tridentate ligand L cannot be synthesized separately in absence of Cu^{2+}. We thus conclude that the Cu^{2+} acts as a template in the synthesis of **1**. Though we are unable to uncover the exact role of Cu^{2+} for the formation of this tridentate ligand but we have verified that similar synthetic procedure failed when Ni^{2+}, Co^{2+}, Zn^{2+}, Fe^{2+} or Fe^{3+} salts were used instead of Cu^{2+}. A possible route for the formation of the ligand L might be proposed as the one-ended attack of one amine group of ethylenediamine to the cyanamide and in turn another cyanamide, Scheme 1 (or one dicyandiamide instead of two molecules of cyanamide, Scheme 2) and simultaneous rearrangements of protons is presented in Schemes 1 and 2. It might also be possible (but could not be resolved at present) that two cyanamide molecules at first dimerises to form dicyandiamide which then reacts with ethylenediamine (Scheme 2).

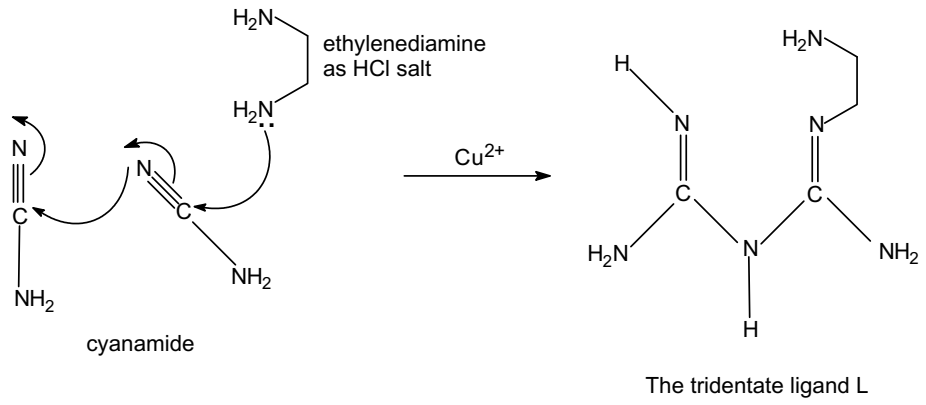
3.2. Physico-chemical observations

The complex **1** shows magnetic moment ($\mu_{eff} = 1.65$ BM at 25.0 °C) corresponding to a single unpaired electron. Complex **1** is highly soluble in water and conductivity measurements (438 Ω^{-1} cm^2 M^{-1}) established its 1:2 electrolytic nature in aqueous media [10] indicating that the two chlorides become free from Cu(II) in aqueous media. An aqueous solution of **1** shows spectral peaks at 650 nm ($\varepsilon = 48$ M^{-1} cm^{-1}) and a shoulder at 960 nm ($\varepsilon = 11$ M^{-1} cm^{-1}).

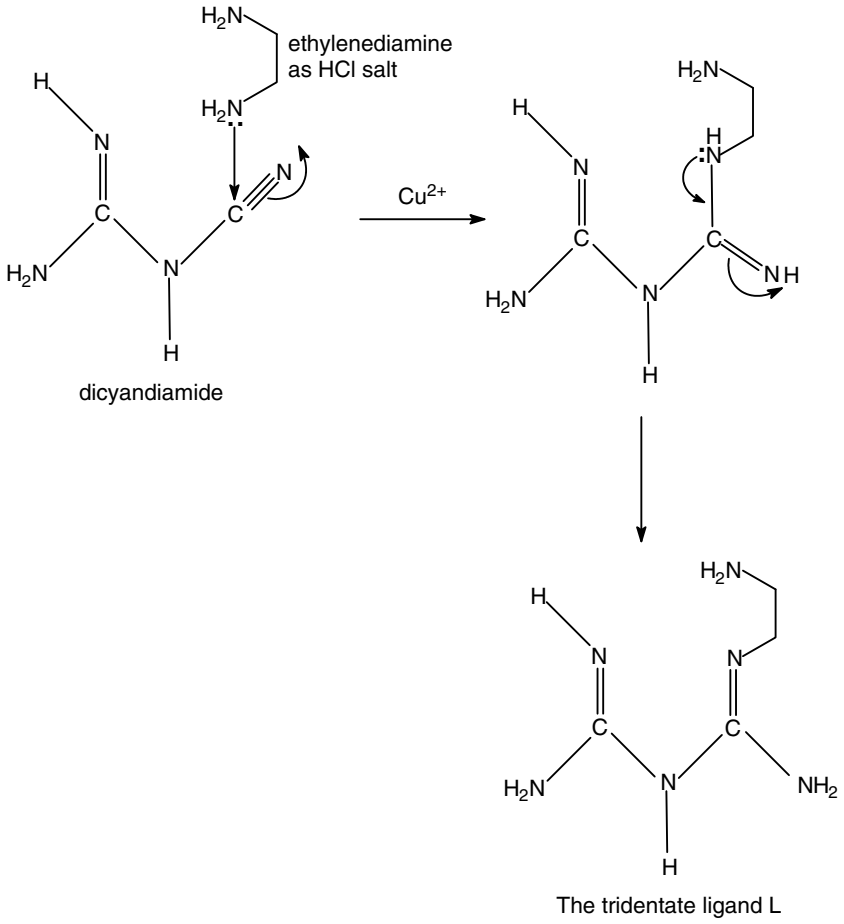
3.3. X-ray crystallographic study

3.3.1. Description of the crystal structure of $[CuLCl_2] \cdot H_2O$ ($L = H_2N–(CH_2)_2–N{=}C(NH_2)–NH–C(NH_2){=}NH$, a tridentate ligand formed in situ in the reaction media)

Fig. 1 presents the structure of **1**, $[CuLCl_2] \cdot H_2O$ [L = 1-(2-aminoethyl) biguanide], showing N_3Cl_2 coordination that results in square pyramid geometry where three N and Cl1 occupy the base of the square pyramidal coordination environment while Cl2 occupies the apical position. The Cu–N bonds in **1** range from 1.917(4) to 1.975(4) Å, similar to those in complexes of $[CuL(NCS)] \cdot SCN$ and $[CuL(cyanoguanidine)] \cdot SO_4 \cdot H_2O$ [11,12], in which four N atoms coordinated to Cu(II) cation in a square plane. The Cu–Cl bonds have two models, their bond distances being 2.327(2) and 2.906(2) Å, respectively. Compared to other coordinated forms of CuN2Cl2 and CuN3Cl [13,14], the Cu–Cl bond lengths are much longer in **1**. The Cu–Cl2 long bond is expected for a d^9 system due to Jahn–Teller effect. The Cu1–Cl2 apical bond (2.906(2) Å)



Scheme 1.



Scheme 2.

length is quiet high indicating predominantly ionic nature of this bond compared to Cu1–Cl1 equatorial bond. The tridentate ligand, L, formed *in situ*, binds to the Cu(II) in a meridional fashion with the Cu–N bond distances ranging from 1.918(4)–1.978(4) Å. The five-membered chelate ring is puckered while the adjacent six-membered ring is planar, the planarity being attributed to the π-cloud delocalisation. This is evident from the N–C bond lengths, which are considerably shorter in the six-membered ring. Even in the six-membered ring, N(1)–C(4) [1.296(6) Å] and N(2)–C(3) [1.299(6) Å] are shorter than the other N–C bonds [1.350(6)–1.389(6) Å] that suggests the π-electron density is somewhat more localized over the two terminal N–C bonds in the six-membered ring.

The overall 3D supramolecular built-up of the complex is the result of the self-assembly of a primary supramolecular dimeric unit (Fig. 2) through multi directional self-recognition. This multiway self-recognition has been facilitated by the active participation of a solvent water molecule. Monomeric units give rise to centrosymmetric supramolecular dimers through strong hydrogen bonds N4–H4···Cl2^{iv} and N5–H5B···Cl2^{iv} (iv = $1-x,-y,2-z$). These dimeric units self-recognize each other through N6–H6A···Cl1^{v} (v = $x,-1+y,z$) hydrogen bond and assemble along the *b* axis. This self-assem-

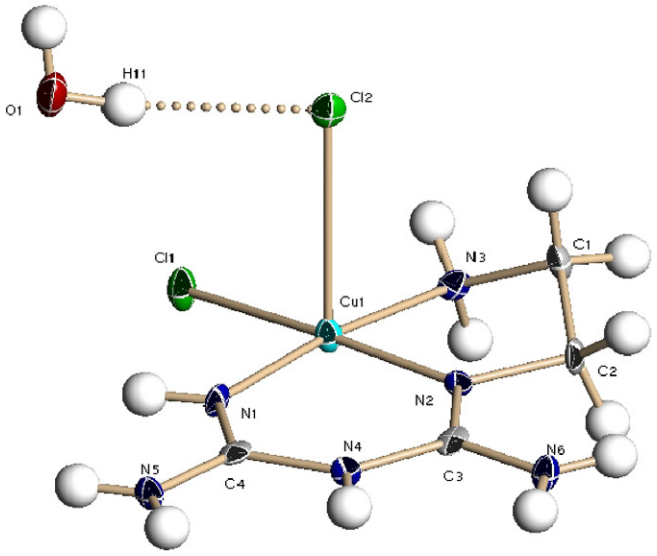


Fig. 1. ORTEP and atom-numbering scheme for $[CuLCl_2] \cdot H_2O$ (**1**), dotted line is for hydrogen bond.

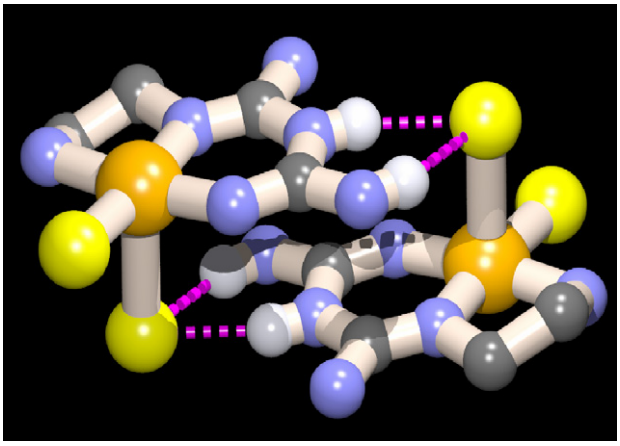

Fig. 2. N–H···Cl hydrogen bond assisted supramolecular dimer. Color code: N, dark turquoise; Cl, bright gold; C, gray; H, silver; Cu, bronze. (For interpretation of the references to colour in figure legends, the reader is referred to the web version of this article.)

bly is reinforced with the participation of a water molecule (O1) that act as acceptor for N6–H6B···O1^{iv}, N1–H1···O1^{i}, N5–H5A···O1^{i} (i = 1 − *x*,1 − *y*,2 − *z*; iv = 1 − *x*,−*y*,2 − *z*) hydrogen bonds and donor for O1–H11···Cl2 hydrogen bonds (Fig. 3). The water molecules also cross-link adjacent dimeric units along *a* axis through O1–H12···Cl1^{vi} (vi = 1 + *x*,*y*,*z*) hydrogen bond and lead the 2D-layered assembly of the dimeric units (Fig. 4). Water in this supramolecular assembly has acted as a T type connector establishing contact among three adjacent dimeric units. It is to be noted that a single water molecule in this 2D assembly has taken part in five hydrogen bonding contacts and thus stabilized the supramolecular assembly in a crucial way.

Self-recognition of dimeric units along the crystallographic *c* axis through complementary N3–H3A···Cl2^{iii} and N3–H3A···Cl1^{ii} (ii = −*x*,1 − *y*,1 − *z*; iii = −1 + *x*,*y*,*z*) hydrogen bonds help the 3D supramolecular assembly of the 2D layers (Fig. 5). Crystallographic data and structural refinements are summarized in Table 1 while the selected bond parameters are shown in Table 2. Hydrogen bond distances and angles are presented in Table 3.

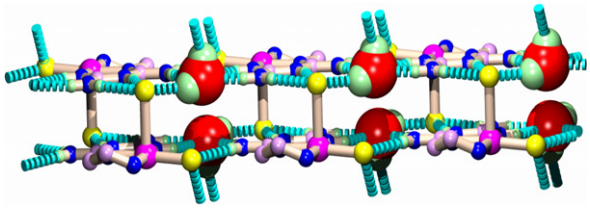

Fig. 3. Assembly of dimers along *b*-axis through self-recognition via N6–H6A···Cl1^{v} (v = *x*,−1 + *y*,*z*) hydrogen bond that is reinforced by water molecules. Color code: O, red; Cu, pink; N, blue; H, aquamarine; Cl, bright gold.

3.4. Electrochemical studies

Cyclic voltammetric study of **1** in aqueous medium displayed an irreversible reductive response at −0.65 V versus SCE (Fig. 6) which is assignable to Cu^{II}/Cu^{I} redox couple. The anodic counterparts are at −0.13 V and 0.05 V. The peak at −0.13 V in the reverse scan is associated with a narrow width of anodic response with a large peak current and is possibly due to surface adsorbed Cu metal [15]. However, the peak at 0.05 V is not observable on scanning between 700 and −500 mV that possibly indicates the peak at 0.05 V

is not associated with any oxidation of Cu(II) leading to Cu(III), rather may be assigned to reoxidation of deposited Cu on electrode.

3.5. EPR studies

The EPR spectroscopy is particularly informative for understanding the electronic structure of Cu(II) complexes [16,17]. The nearly axial features of the well-resolved X-band spectrum (Fig. 7) of the mononuclear **1** in the frozen state (water:ethylene glycol = 1:1 v/v, 77 K) with $g_{||}$ (2.276) > $g_{\perp}$ (2.035) > 2.00 and $A_{||}$ (170×10^{-4} cm^{-1}) > $A_{\perp}$ (60×10^{-4} cm^{-1}), are consistent with a typical monomeric tetragonal Cu(II) environment and a $^1B_1$ $d_{x^2-y^2}$ ground state [18]. The g tensor and A tensor values are quite similar for Cu(II) in an analogous pseudoplanar N_2O_2 equatorial environment [19]. Conductivity measurements of **1** in solution indicated loss of two chloride ions and thus in mixed water–ethylene glycol solvent an overall N_2O_2 coordination seems feasible. The apparent similarity in the hyperfine coupling and g-values is clearly indicative of the orbital containing unpaired electron (SOMO) involves a predominant metal contribution. Consequently, an alternative hypothetical ground electronic state with an unpaired electron localized mainly on the ligand ($Cu^{III}L^{2-}$) is clearly ruled out. This fact, that is the localization of larger spin density on the Cu nucleus as is expected for lower electronegativity of the ligand (lower pi-acidity) is further supported by the considerably high $A_{||}$ value [20].

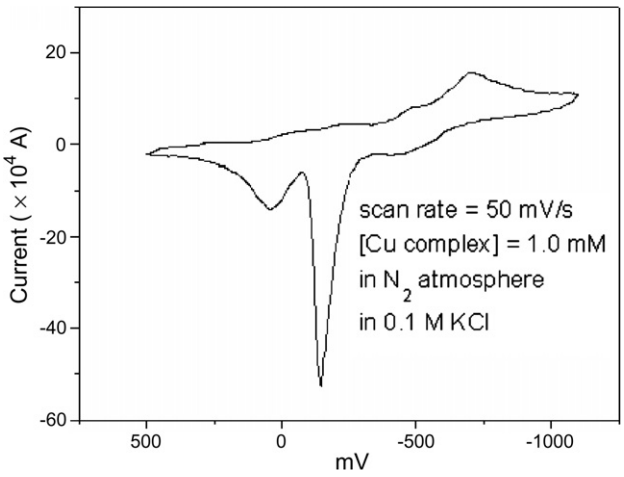

Fig. 6. Cyclic volammogram of **1**. Experimental conditions are shown within the figure.

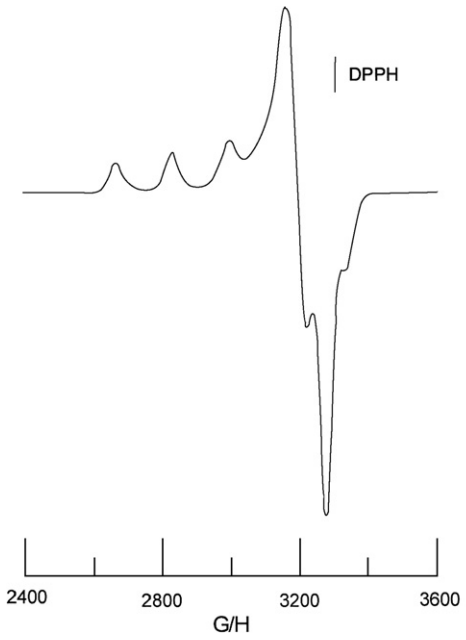

Fig. 7. EPR spectrum of **1** at 77 K.

2. Experimental

Potassium tetraorganodichalcogenoimidodiphosphinates were prepared according to literature methods: K[(SPMe$_2$)(SPPh$_2$)N] [14], K[(SPPh$_2$){OP(OEt)$_2$}N], K[(OPPh$_2$){OP(OEt)$_2$}N] [15]. Solvents were purified by standard procedures and were freshly distilled prior to use. IR spectra were recorded in the range 4000–400 cm^{-1} in KBr pellets on a Jasco FTIR-615 machine. Mass spectra were recorded on a FINNIGAN MAT 8200 instrument (CI). EPR spectra were recorded at 77 K and at room temperature on a Bruker ESP 300 spectrometer operating in X-band, equipped with an ER 035 M Bruker NMR gaussmeter and a HP 3530B Hewlett–Packard microwave frequency counter, and only at room temperature on a X-band Radiopan SE/X 2543 Spectrometer, respectively. All g factors were determined with ±0.05 accuracy. Magnetic measurements in the temperature range of 1.8–300 K were carried out on powdered samples of complex **3**, at a magnetic field of 0.5 T and at 2 K in the range of 0–5 T, using a Quantum Design SQUID based MPMSXL-5 type magnetometer. Corrections are based on subtracting the sample-holder signal and the contribution $\chi_D = 1181 \times 10^{-6}$ cm^3 mol^{-1} was estimated from the Pascal constants [16]. Elemental analyses were performed on a VarioEL analyzer.

2.1. Preparation of bis[P,P-dimethyl-P′,P′-diphenyl-dithioimidodiphosphinato]manganese(II), Mn[(SPMe$_2$)(SPPh$_2$)N]$_2$ (**1**)

A reaction mixture of K[(SPMe$_2$)(SPPh$_2$)N] (0.515 g, 1.420 mmol) and MnCl$_2 \cdot$ 4H$_2$O (0.140 g, 0.707 mmol) in methanol (50 ml) was stirred at room temperature for 24 h. The solvent was completely removed in vacuum and the remaining solid was extracted with toluene. The clear solution was concentrated in vacuum, yielding the title compound as a colourless crystalline product. Yield: 0.261 g (52%), m.p. 119–120 °C. *Anal.* Calc. for C$_{28}$H$_{32}$MnN$_2$P$_4$S$_4$: C, 47.79; H, 4.58; N, 3.98. Found: C, 47.68; H, 4.52; N, 3.97%. IR (cm^{-1}): 1197s, br [ν_{as}(P$_2$N)], 589s [ν(*Ph*PS)], 571s [ν(*Me*PS)]. CI$_{pos}$ MS (*m*/*z*, %): 703 (42) [M$^+$], 324 (100) [{(SPMe$_2$)(SPPh$_2$)N}$^+$]. CI$_{neg}$ MS (*m*/*z*, %): 703 (18) [M$^-$], 324 (57) [{(SPMe$_2$)(SPPh$_2$)N}$^-$], 110 (100) [(SPMe$_2$ + NH$_3$)$^-$].

Compounds **2** and **3** were similarly prepared:

*Bis[P,P-diethoxy-P′,P′-diphenyl-P′-thioimidodiphosphinato] manganese(II)], Mn[(SPPh$_2$){OP(OEt)$_2$}N]$_2$ (**2**)* from K[(SPPh$_2$){OP(OEt)$_2$}N] (0.720 g, 1.769 mmol) and MnCl$_2 \cdot$ 4H$_2$O (0.175 g, 0.883 mmol). Yield: 0.315 g (45%), m.p. 95 °C. *Anal.* Calc. for C$_{32}$H$_{40}$MnN$_2$O$_6$S$_2$P$_4$: C, 48.55; H, 5.09; N, 3.54. Found: C, 48.61; H, 5.05; N, 3.55%. IR (cm^{-1}): 1265vs [ν_{as}(P$_2$N)], 1104s [ν(PO)], 1033vs, br [ν(POC)], 599s [ν(PS)]. CI$_{pos}$ MS (*m*/*z*, %): 792 (100) [(M+H)$^+$], 370 (92) [{(SPPh$_2$){OP(OEt)$_2$}NH}$^+$]. CI$_{neg}$ MS (*m*/*z*, %): 792 (12) [(M+H)$^-$], 368 (100) [{(SPPh$_2$){OP(OEt)$_2$}N}$^-$], 336 (26) [{(PPh$_2$){OP(OEt)$_2$}N}$^-$].

*Bis[P,P-diethoxy-P′,P′-diphenyl-imidodiphosphinato]manganese(II) water solvate, Mn[(OPPh$_2$){OP(OEt)$_2$}N]$_2$(H$_2$O) (**3**)* from K[(OPPh$_2$){OP(OEt)$_2$}N] (0.151 g, 1.317 mmol) and MnCl$_2 \cdot$ 4H$_2$O (0.130 g, 0.658 mmol). Yield: 0.36 g (70%), m.p. 100–102 °C. *Anal.* Calc. for C$_{32}$H$_{42}$MnN$_2$O$_9$P$_4$: C, 49.43; H, 5.44; N, 3.60. Found: C, 49.75; H, 5.18; N, 3.65%. IR (cm^{-1}): 1244vs [ν_{as}(P$_2$N)], 1157vs, 1143vs [ν(PO)], 1067vs, 1041vs [ν(POC)]. CI$_{pos}$ MS (*m*/*z*, %): 759 (52) [{Mn{(OPPh$_2$){OP(OEt)$_2$}N}$_2$}$^+$], 353 (100) [{(OPPh$_2$){OP(OEt)$_2$}NH}$^+$]. CI$_{neg}$ MS (*m*/*z*, %): 760 (12) [{Mn{(OPPh$_2$){OP(OEt)$_2$}N}$_2$+H}$^-$], 352 (100) [{(OPPh$_2$){OP(OEt)$_2$}N}$^-$], 336 (26) [{(PPh$_2$){OP(OEt)$_2$}N}$^-$].

3. Crystal structure determination

Colourless block crystals of Mn[(SPMe$_2$)(SPPh$_2$)N]$_2$ (**1**) and Mn[(OPPh$_2$){OP(OEt)$_2$}N]$_2$(H$_2$O) (**3**) were attached with epoxy glue on cryoloops. The data were collected on a Bruker SMART APEX CCD diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). Data reduction was performed using the SAINT-PLUS software and the data were corrected for absorption effects using the SADABS program [17]. The details of the crystal structure determination and refinement are given in Table 1.

Table 1
Crystal data and structure refinement for Mn[(SPMe$_2$)(SPPh$_2$)N]$_2$ (**1**) and Mn[(OPPh$_2$){OP(OEt)$_2$}N]$_2$(H$_2$O) (**3**)

Cell refinement gave cell constants corresponding to monoclinic (**1**) and triclinic (**3**) cells. The structures were solved by direct methods [18] and refined using the SHELXTL [19] version of SHELX-97 [20]. Compound **3** is centrosymmetric with an inversion centre in the middle of the Mn$_2$O$_2$ ring and thus half of the molecule is generated by symmetry. The hydrogen atoms were refined with a riding model and a mutual isotropic thermal parameter, excepting the hydrogen atoms from the water molecule in **3**, which were located on the difference map and refined at a O–H distance of 0.82(5) and 0.80(5) Å, respectively. C16 in **3** is disordered and was refined over two positions with 49% and 51% occupancy. The drawings were created with the DIAMOND program [21].

4. Results and discussion

Manganese(II) complexes were obtained in moderate yields by salt metathesis reactions between MnCl$_2 \cdot$ 4H$_2$O and the potassium salt of the appropriate tetraorganodichalcogenoimidodiphosphinic acid, in a 1:2 molar ratio.

$$MnCl_2 \cdot 4H_2O + 2K[(XPR_2)(YPR'_2)N] \rightarrow Mn[(XPR_2)(YPR'_2)N]_2(nH_2O) + 2KCl + (4-n)H_2O$$

X = Y = S; R = Ph, R′ = Me; $n = 0$ (**1**)

X = S, Y = O; R = Ph, R′ = OEt; $n = 0$ (**2**)

X = Y = O; R = Ph, R′ = OEt; $n = 1$ (**3**)

The complexes were isolated as colourless (**1** and **3**) or slight pink (**2**) solids and were characterized by mass spectrometry, IR and EPR spectroscopy. For compounds **1** and **3** the crystal and molecular structure was determined by single-crystal X-ray diffraction.

In the CI mass spectra of the title compounds either the molecular or the pseudo-molecular ions appear with high or medium intensity, *i.e.* $[Mn\{(SPPh_2)(SPMe_2)N\}_2]^+$ (*m/z* 703, 42%), $[Mn\{(SPPh_2)\{OP(OEt)_2\}N\}_2 + H]^+$ (*m/z* 792, 100%) and $[Mn\{(OPPh_2)\{OP(OEt)_2\}N\}_2]^+$ (*m/z* 759, 52%) for **1**, **2** and **3**, respectively. For derivative **3** the dimeric species or fragments with a higher mass than that corresponding to the monomeric species were not observed by chemical ionization.

The IR spectra are consistent with the coordination of the ligand units in the deprotonated form, through both chalcogen atoms. The strong absorption bands observed for the Mn(II) complexes in the ranges 1250–1200, 1150–1110 and 600–550 cm^{-1} were assigned to $\nu_{as}(P_2N)$, ν(PO) and ν(PS) stretching vibrations, respectively, in comparison with the potassium salts used as starting materials [14,15].

The EPR spectra of the manganese(II) complexes are expected to display a fine structure of five lines. However, only for compounds **2** and **3** the fine structure was observed, while for the derivative **1** only a broad band was found at room temperature ($g = 1.94$), due probably to the paramagnetic ion clusters present in this sample. The line width (390 Gs for **1**, 502 Gs and 400 Gs for the central line of **2** and **3**, respectively) is consistent with a strong crystal field around the paramagnetic ions. This behaviour might be explained by the strong interaction with the crystal field created by the ligands and the covalent interactions between the Mn(II) ion and the ligands. The *g* values determined at room temperature for the compounds **2** and **3** (2.01 and 2.03, respectively) are also consistent with strong covalent interactions. Theoretical calculations allowed us to determine the crystal field constant D (431 Gs) for the species **3**, which exhibits a fine structure. In the case of this polycrystalline material we average the θ angle between the direction of the magnetic induction and the symmetry axes of the magnetic centre from 0 to $\pi/2$ in the Spin Hamiltonian [22].

The EPR spectrum of the complex **3** at 4.2 K exhibits a single broad line with $g = 1.98$, $\Delta H_{pp} = 565$ Gs (ΔH_{pp} = peak to peak linewidth) and shows a partial resolved hyperfine structure due to the interaction between the transition inside Krammer's doublet (±1/2) and the ^{55}Mn(II) nuclear spin $I = 5/2$, of a value about 95 Gs (Fig. 1).

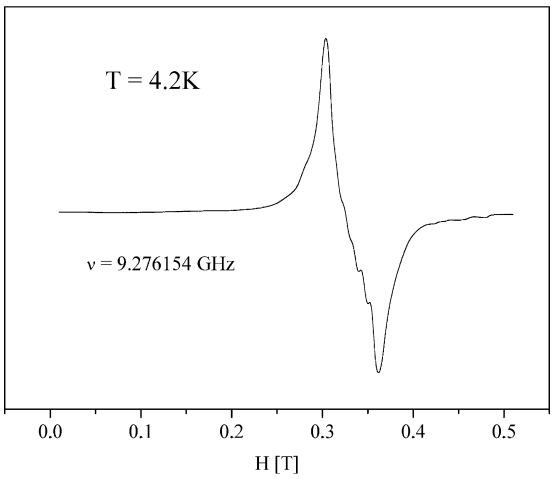

Fig. 1. EPR spectrum of **3** at 4.2 K.

4.1. Crystal and molecular structure of $Mn[(SPMe_2)(SPPh_2)N]_2$ (**1**)

The molecular structure of **1** was determined by single-crystal X-ray diffraction. Important bond distances and angles are listed in Table 2.

The crystal of **1** consists of distinct monomeric units separated by normal van der Waals distances. An ORTEP-like diagram with the atom numbering scheme is given in Fig. 2.

The dithioato ligand units behave monometallic biconnective, resulting in a *spiro*-bicyclic system with a slightly distorted tetrahedral MnS_4 core (S–Mn–S bond angles in the range 106.3–113.9°). One of the endocyclic angles is larger [S(3)–Mn(1)–S(4) 111.02(4)°], while the other one [S(1)–Mn(1)–S(2) 109.32(4)°] is close to the tetrahedral value of 109.5°. The dihedral angle between the S(1)/Mn(1)/S(2) and S(3)/Mn(1)/S(4) planes is 87.46(4)°, larger than those observed for $Mn[(SPPh_2)_2N]_2$ (86.8°) [7] and $Mn[(SPPr^i_2)(SPPh_2)N]_2$ [78.99(3)°] [8], and slightly smaller than that one found for $Mn[(SPPr^i_2)_2N]_2$ [88.12(1)°] [8]. The Mn–S bond distances [av. 2.423(1) Å] are similar to those found in $Mn[(SPPh_2)_2N]_2$ [av. 2.443(12) Å] [7].

Table 2

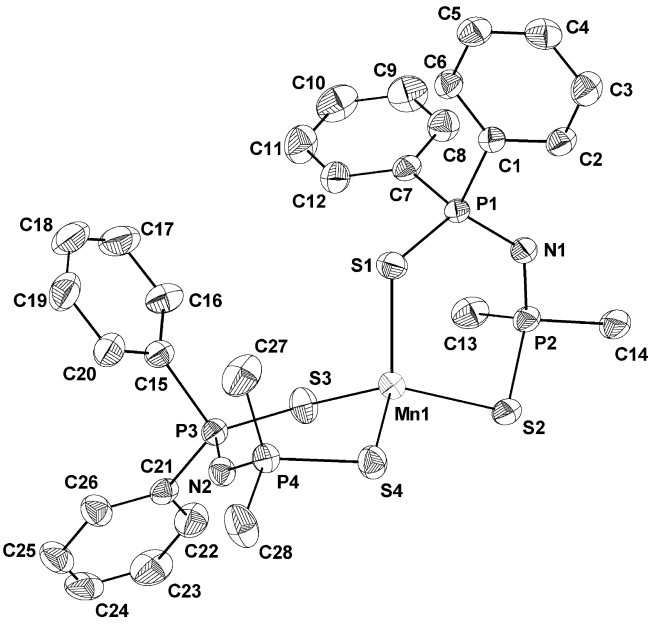

Fig. 2. ORTEP plot at 40% probability and atom numbering scheme for **1**. For clarity, the hydrogen atoms are omitted.

The two six-membered MnS_2P_2N chelate rings are not planar and display twisted chair conformations with the Mn(1)/N(1) and Mn(1)/N(2) atoms, respectively, in apices. In contrast, twisted boat conformations were observed for other reported dithioato derivatives, *i.e.* $Mn[(SPPh_2)_2N]_2$ [7] and $Mn[(SPPr^i_2)_2N]_2$ [8] (with phosphorus and sulfur atoms in the apices) or $Mn[(SPPr^i_2)(SPPh_2)N]_2$ [8] (with manganese and nitrogen atoms in apices), respectively.

The phosphorus–sulfur [range of 2.0155(15)–2.0213(14) Å] and phosphorus–nitrogen [range of 1.582(3)–1.595(3) Å] distances, respectively, are intermediate between the single and the double bonds [cf. $Ph_2P(=S)–N=P(–SMe)Ph_2$ [23]: P=S 1.954(1) Å, P–S 2.071(1) Å, P=N 1.562(2) Å, P—N 1.610(2) Å. The P–N–P angles are different in the two ligand moieties [P(1)–N(1)–P(2) 129.5(2) and P(3)–N(2)–P(4) 134.7(2)°], both being considerably larger in comparison with the free acid [P–N–P 126.1(4)°] [24], and thus suitable to accommodate around the metal centre.

[a] Symmetry equivalent positions (−*x*, −*y*, −*z*) are given by "a".

4.2. Crystal and molecular structure of $Mn[(OPPh_2)\{OP(OEt)_2\}N]_2(H_2O)$ (**3**)

Selected bond distances and angles for **3** are listed in Table 3 and the ORTEP-like diagram with the atom numbering scheme is given in Fig. 3.

The crystal contains discrete dimer associations in which the metal centres are bridged by the oxygen atoms of the $OP(OEt)_2$ groups from two ligand units acting as bimetallic triconnective moieties, thus resulting in a fused tricyclic $Mn_2O_4P_4N_2$ system. The other two ligands chelate each a metal atom, resulting in an overall structure which resembles that found in the dimeric $[Mn\{(OPPh_2)_2N\}_2]_2$ [9]. However some significant differences have to be noted. The central four-membered Mn_2O_2 ring in the dimer of the title compound **3** is planar, while it is slightly folded in the related $[Mn\{(OPPh_2)_2N\}_2]_2$. This behaviour is consistent with a larger nonbonding Mn···Mn distance in **3** than in $[Mn\{(OPPh_2)_2N\}_2]_2$ [3.4073(6) Å versus 3.378(3) Å].

The overall conformation of the $[Mn\{(OPPh_2)_2N\}_2]_2$ dimer might be described as *cis*, *i.e.* with the six-membered MnO_2P_2N rings formed by ligands of the same type placed on the same side of the four-membered Mn_2O_2 ring (Fig. 4 a) [9]. By contrast, the fused tricyclic $Mn_2O_4P_4N_2$ system in the dimer of **3** is considerably flattened, with equivalent atoms of the six-membered MnO_2P_2N rings deviated on opposite sides of the central planar Mn_2O_2 core [deviations from Mn_2O_2 plane: O(3) 0.042, P(3) 0.226, N(2) −0.160 Å, and P(4) 0.419 Å, respectively]. The chelate MnO_2P_2N rings are placed on opposite sides of this flattened tricyclic system and the overall conformation in the dimer of **3** might be described as *trans* (Fig. 4 b).

The oxygen atom from a water molecule completes a distorted octahedral coordination geometry around the manganese atoms in the dimer of **3**, in contrast with the trigonal bipyramidal geometry observed for the related $[Mn\{(OPPh_2)_2N\}_2]_2$ analogue [9]. Moreover, the water molecules are involved in hydrogen bonding with

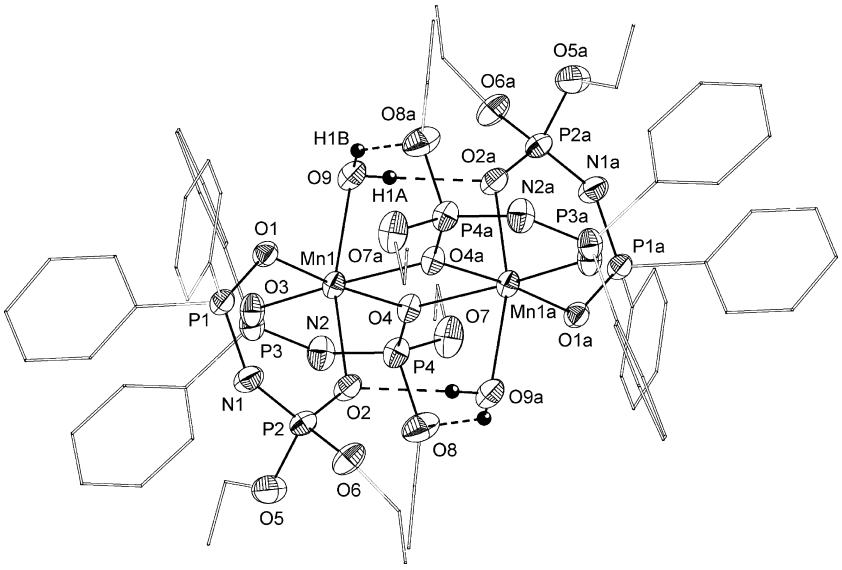

Fig. 3. ORTEP plot of the dimer unit in the crystal of **3**. The atoms are drawn with 30% probability ellipsoids [symmetry equivalent atoms (−*x*, −*y*, −*z*) are given by "a"]. For clarity, the hydrogen atoms, other than water hydrogens, are omitted.

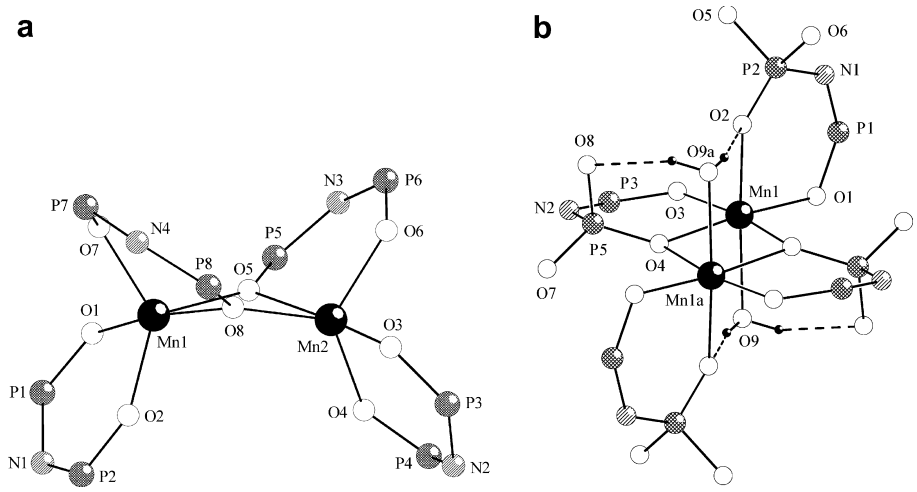

Fig. 4. Dimer cores in (a) $[Mn\{(OPPh_2)_2N\}_2]_2$ [9], and (b) title compound **3**. For clarity, the hydrogen atoms, other than water hydrogens, and the carbon atoms are omitted.

the oxygen atom connected to the metal centre from the chelating ligand [H(1A)···O(2a) 2.05 Å] and one oxygen atom of an ethoxy group from the bridging ligand [H(1B)···O(8a) 2.30 Å], respectively (Fig. 3).

The monometallic biconnective MnO_2P_2N rings show distorted chair conformations with nitrogen and manganese atoms in apices, while for the bridging ligands the corresponding MnO_2P_2N rings exhibit distorted boat conformations, with bridging O(4) and P(3) atoms in apices.

The Mn–O distances in the Mn–O–Mn bridge are equivalent [Mn(1)–O(4) 2.237(2), Mn(1)–O(4a) 2.247(2) Å] and considerably longer than the Mn(1)–O(3) bond distance [2.102(2) Å] in the same ligand unit. Even longer is the Mn–O_{water} bond distance [Mn(1)–O(9) 2.271(3) Å]. For the monometallic biconnective ligand moiety the Mn–O bonds are also not equivalent [Mn(1)–O(1) 2.088(2), Mn(1)–O(2) 2.168(2) Å], a behaviour which contrasts with that observed for the ligand moieties exhibiting a similar, but symmetric, coordination pattern in the related $[Mn\{(OPPh_2)_2N\}_2]_2$ dimer [9].

The phosphorus–nitrogen [range 1.553(3)–1.595(3) Å] and phosphorus–oxygen distances [range 1.496(2)–1.508(2) Å], respectively, are of a magnitude intermediate between a single and a double bond, thus suggesting some delocalization of the π electrons on the OPNPO system in all four ligand units (cf. $[(Me_3Si)_2N–P(=N^tBu)S]_2$ [25]: P=N 1.529(2) Å, P–N 1.662(2) Å; $Ph_2P(O)OH$ [26]: P=O 1.486(6) Å, P–O 1.526(6) Å).

4.3. Magnetic properties

The magnetic behaviour of complex **3** in the form of $\chi_{Mn}T$ versus T curve is shown in Fig. 5 (χ_{Mn} is the molar magnetic susceptibility per Mn(II) ion). The value of $\chi_{Mn}T$ product at room temperature is 4.87 $cm^3\ mol^{-1}\ K$ ($\mu_{eff.}$ = 6.24 B.M.), which is slightly larger than that calculated for $S = 5/2$ with $g = 2$ (4.375 $cm^3\ mol^{-1}\ K$, $\mu_{eff.}$ = 5.92 B.M.). Upon lowering the temperature, $\chi_{Mn}T$ decreases gradually and reaches a value of 0.61 $cm^3\ mol^{-1}\ K$ at 1.8 K.

The temperature variation of χ_{Mn}^{-1}, from room temperature down to 10 K, follows a Curie–Weiss law ($\chi_M = C/(T - \Theta)$), with C = 5.36 $cm^3\ mol^{-1}\ K$ and $\Theta = -28.9$ K. Below 10 K, the slope of χ_{Mn}^{-1} changes (inset to Fig. 5). The magnetic susceptibility can be analyzed using the isotropic spin Hamiltonian: $H = -2JS_1S_2$. The temperature dependence of the magnetic susceptibility is given by the equation [27]:

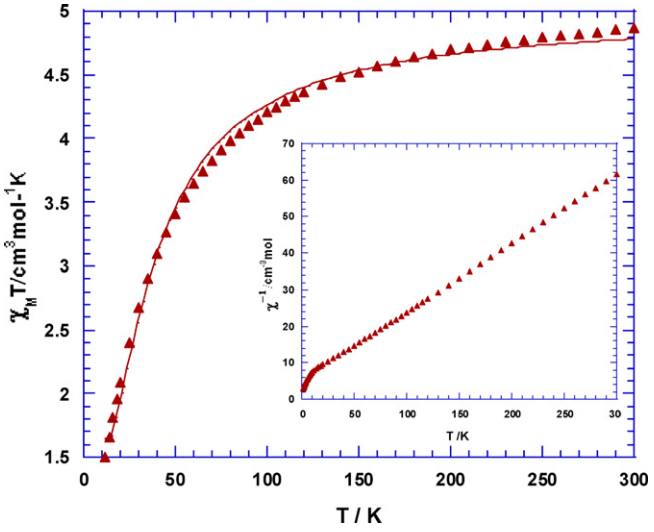

Fig. 5. Plot of $\chi_{Mn}T$ vs. T in the temperature range 10–300 K for **3**. The solid line represents the best fit to the experimental data with the parameters reported in the text (inset: temperature dependence of χ_{Mn}^{-1}).

$$\chi_{Mn} = \frac{Ng^2\beta^2}{kT}\frac{55 + 30e^{5x} + 14e^{9x} + 5e^{12x} + e^{14x}}{11 + 9e^{5x} + 7e^{9x} + 5e^{12x} + 3e^{14x} + e^{15x}}, \qquad x = \frac{-2J}{kT}$$

Additional interdimer interactions have been introduced in the frame of the mean-field approximation [28]:

$$\chi_{Mn}^{corr} = \frac{\chi_{Mn}}{1 - \frac{2J'}{N\beta^2g^2}\chi_{Mn}}$$

zJ' is the intermolecular exchange parameter and z is the number of the nearest neighbours. Least-square fit to the experimental data gives $J = -3.5\ cm^{-1}$, $zJ' = -1.0\ cm^{-1}$, g = 1.99.

5. Supplementary data

CCDC 656244 and 656245 contain the supplementary crystallographic data for **1** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

the form of coordination compounds, modulates the effect of the ligand itself [21]. The structure of quinic acid is that of a polyfunctional natural ligand containing an α-hydroxycarboxylic acid moiety on one side of the molecule and three alcoholic moieties on the other side. Hence, its chemical structure provides efficient anchors to metal ionic targets, exemplified through variable binding modes in a diverse spectrum of metal ionic geometries.

In view of the known accumulation [22–24] and toxicity of Al(III) in plants, animals and humans, its toxic manifestations entail a deep knowledge of its chemistry at the molecular level. Therefore, the aqueous speciation of this metallotoxin in binary and ternary systems, containing readily available cellular targets, is a valuable source of information. Through the aqueous speciation of such Al(III) binary and ternary systems, soluble and potentially bioavailable forms of the metal ion arise with suitable substrate ligands. It is likely that such Al(III) forms participate in molecular processes linked to that metal ion's toxicity. Poised to delineate the molecular chemistry involved in the establishment of Al(III) toxicity in cellular fluids, we launched efforts targeting the interactions of Al(III) with the natural binder D-(−)-quinic acid. To this end, we herein report on (a) the aqueous speciation of the binary Al(III)–quinic acid system, (b) pH-specific synthetic efforts to characterize species projected through the aqueous speciation of the binary Al(III)–quinic acid system, and (c) the association of the physicochemical profile of specific soluble and potentially bioavailable forms of Al(III)–quinate species, with the biological activity of that metal ion.

2. Experimental

2.1. Materials and methods

All experiments were carried out under aerobic conditions. Nanopure quality water was used for all the reactions. $Al(NO_3)_3 \cdot 9H_2O$, $AlCl_3 \cdot 6H_2O$ and quinic acid were purchased from Aldrich. Potassium hydroxide was supplied by Fluka. The Al(III) stock solution used for potentiometric measurements was prepared from recrystallized $AlCl_3 \cdot 6H_2O$ and its metal ion concentration was determined gravimetrically through its oxinate. The stock solution contained 0.1 M HCl to prevent hydrolysis of the metal ion. The exact concentrations of the ligand solution were determined by potentiometric titration, using the Gran method [25].

2.2. Physical measurements

FT-Infrared spectra were recorded on a Perkin Elmer 1760X FT-infrared spectrometer. A ThermoFinnigan Flash EA 1112 CHNS elemental analyser was used for the simultaneous determination of carbon, and hydrogen (%). The analyser is based on the dynamic flash combustion of the sample (at 1800 °C) followed by reduction, trapping, complete GC separation and detection of the products. The instrument is (a) fully automated and controlled by a PC via the Eager 300 dedicated software, and (b) capable of handling solid, liquid or gaseous substances.

A TA Instruments, model Q 600, system was used to run the simultaneous TGA–DSC experiments. The instrument mass precision is 0.1 μg. About 20 mg of sample was placed in an open alumina sample pan for each experiment. High purity helium and air (80/20 in N_2/O_2) were used at a constant flow rate of 100 mL/min, depending on the conditions required for running the experiment(s). During the experiments, the sample weight loss and rate of weight loss were recorded continuously under dynamic conditions, as a function of time or temperature, in the range 30–1000 °C. Prior to activating the heating routine program, the entire system was purged with the appropriate gas for 10 min, at a rate of 400 mL/min, to ensure that the desired environment was established.

2.3. Solid-state NMR

High resolution solid-state ^{13}C magic angle spinning (MAS) NMR spectra were measured at 100.63 MHz on a Bruker MSL400 NMR spectrometer, capable of high power ^1H-decoupling. The spinning rate used for the ^1H–^{13}C cross polarization and magic angle spinning experiments was 5 kHz at ambient temperature (25 °C). Each solid-state spectrum was the result of the accumulation of 200 scans. The recycle delay used was 4 s, the 90° pulse was 5 μs and the contact time was 1 ms. All the solid-state spectra were referenced to adamantane, which showed two peaks at 26.5 and 37.6 ppm, respectively, and to the external reference of TMS.

2.4. Solution NMR

The samples for solution NMR studies were prepared by dissolving the crystalline complex in D_2O, at concentrations in the range 0.02–0.10 M. The NMR spectra were recorded on a Bruker AM360 (^{13}C) spectrometer. Chemical shifts (δ) are reported in ppm relative to the internal reference, TMS.

2.5. pH-potentiometric measurements

The stability constants of the proton and Al(III) complexes of the title ligand were determined by pH-potentiometric titrations of 25 mL samples in the pH range 2–9 or until precipitation occurred, under a purified argon atmosphere. Care was taken to ensure that titrimetric data were recorded and collected under conditions taking into consideration the kinetically sluggish Al(III). Duplicate titrations were performed. The reproducibility of the titrations was within 0.005 pH units. Titration points obtained when 5 min was not enough to attain pH equilibrium were omitted from the evaluation. The ionic strength was adjusted to 0.2 M with KCl. The temperature was maintained during the measurements at 25 ± 0.1 °C. The titrations were performed with a carbonate-free KOH solution of known concentration (ca. 0.2 M). The ligand concentration was 0.002, 0.004 or 0.008 M and the metal:ligand ratios were 0:1, 1:1, 1:2 or 1:4. All other experimental conditions were the same as in earlier studies [26,27].

The pH was measured with a computer-controlled Molspin titration system elaborated for titrations at low concentrations and a Metrohm 6.0234.100 combined glass electrode, calibrated for hydrogen ion concentration according to Irving et al. [28]. The concentration stability constants $\beta_{pqr} = [M_pA_qH_r]/[M]^p[A]^q[H]^r$ were calculated with the PSEQUAD computer program [29,30]. The uncertainties (3SD values) of the stability constants are given in the parentheses in Table 3. The stability constants used for the hydroxo species of Al(III) were taken from Ref. 30 and are corrected to $I = 0.2$ M using the Davies equation: −5.49 for $[AlH_{-1}]^{2+}$, −13.54 for $[Al_3H_{-4}]^{5+}$, −108.62 for $[Al_{13}H_{-32}]^{7+}$ and −23.40 for $[AlH_{-4}]^{-}$.

2.6. Preparation of the complex $K[Al(C_7H_{11}O_6)_3] \cdot (OH) \cdot 4H_2O$

A quantity of $Al(NO_3)_3 \cdot 9H_2O$ (0.25 g, 0.68 mmol) was placed in a flask and dissolved in 5.5 mL of H_2O. Subsequently, quinic acid (0.39 g, 2.0 mmol) was added slowly with continuous stirring. The solution was heated to 50 °C for 1 h until all of the reagents dissolved, and then it was cooled. Aqueous KOH was then added slowly to adjust the pH to a final value of 4.0. The resulting solution was stirred overnight. The following morning, addition of cold ethanol at 4 °C resulted, after a couple of weeks, in the deposition of a colorless crystalline material. The crystals were isolated by filtration and dried in vacuo. The yield was 0.34 g (~70%). *Anal.* Calc. for **1**, $K[Al(C_7H_{11}O_6)_3] \cdot (OH) \cdot 4H_2O$, $AlC_{21}H_{42}KO_{23}$, M.W. 728.63: C, 34.58; H, 5.76. Found: C, 34.41; H, 5.87%.

3. X-ray crystallography

3.1. Crystal structure determination

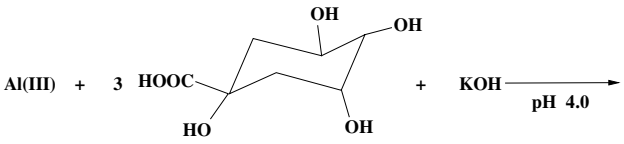
X-ray quality crystals of compound **1** were grown from mixtures of water–ethanol solutions. A single crystal, with dimensions 0.26 × 0.22 × 0.20 mm, was mounted on the tip of a glass fiber with epoxy glue. Single crystal analysis was carried out on a Bruker SMART 1K CCD diffractometer. The frame data were acquired with the SMART software [31] using Mo Kα radiation (λ = 0.71073 Å). Final values of the cell parameters were obtained from the least-squares refinement of the positions of 807 reflections. A total of 1271 thirty-second frames were collected in three sets with 0.3° ω-scans. The frames were then processed using the SAINT software [32] to provide the *hkl* file corrected for Lorentz and polarization effects. No absorption correction was applied. Further experimental crystallographic details: for **1**, θ range for data collection = 1.92–23.2°; number of reflections collected/unique/used, 14960/1641[$R_{(int)}$ = 0.0245]/1580; 154 parameters refined; $F(000)$ = 1536; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.842/−0.285 e/Å^3; goodness-of-fit = 1.111; R/R_w (for all data), 0.0481/0.1427. Table 1 summarizes the crystallographic structural and refinement parameters.

The structure was solved by direct methods using the SHELX-90 program [33] and refined by least-squares methods on F^2, SHELXL-97 [34], incorporated in SHELXTL, Version 5.1 [35]. The initial E-maps yielded all non-hydrogen atom positions. Hydrogen atoms on carbon atoms were geometrically positioned and left riding on their parent atoms during the structure refinement. Hydrogen atom positions, which belong to water or hydroxyl groups, were first determined from E-maps, brought to reasonable distances from their parent oxygen atoms, and then fixed. The final assignment satisfies electroneutrality for the entire compound, on the premise that the aluminum ions are formally in the oxidation state +3. All non-hydrogen atoms were refined anisotropically.

4. Results and discussion

4.1. Synthesis

The synthesis of compound **1** was pursued through the facile reaction of Al(III) with quinic acid in aqueous media. The pH, at which the reaction was run, was 4.0. The adjustment of the pH was achieved with aqueous KOH. The stoichiometric reaction leading to the isolation of **1** is shown below (Reaction (1)):



$K[Al(C_7H_{11}O_6)_3]\cdot(OH)$ + 3 H$^+$ Reaction 1

The compound was isolated in the pure crystalline form upon addition of ethanol to the reaction mixture at 4 °C. Elemental analysis of the isolated colorless crystalline material suggested the molecular formulation $K[Al(C_7H_{11}O_6)_3]\cdot(OH)\cdot 4H_2O$. Further spectroscopic inspection by FT-IR revealed the presence of quinates bound to Al(III), thus confirming the aforementioned formulation (**1**).

Compound **1** is soluble in water, but insoluble in organic solvents, like methanol, acetonitrile, chlorinated solvents ($CHCl_3$, CH_2Cl_2), toluene and DMF. The material is stable in air at room temperature for extended periods of time.

4.2. X-ray crystallographic structure of $K[Al(C_7H_{11}O_6)_3]\cdot(OH)\cdot 4H_2O$ (**1**)

The X-ray crystal structure of **1** reveals the presence of a lattice comprised of $[Al(C_7H_{11}O_6)_3]$ units and K^+ ions counteracted by discrete OH^- ions. The compound crystallizes in the cubic space group $P2_13$. The ORTEP diagram along with a perspective view of **1** is shown in Figs. 1 and 2. Selected interatomic distances and bond angles for **1** are listed in Table 2. The structure consists of a mononuclear core unit assembled by a central Al(III) ion surrounded by three quinate ligands. The latter moieties bind to the metal ion through the carboxylate and protonated alcoholic oxygens O(1′) and O(3), respectively. Formation of the Al(III) assembly proceeds through the formation of a five-membered ring, rendering the

Angles (°)	
O(1)–Al(1)–O(1)′	90.57(11)
O(1)–Al(1)–O(3)	166.03(9)
O(1)–Al(1)–O(3)′	101.03(10)
O(1)–Al(1)–O(3)″	81.65(9)
O(3)′–Al(1)–O(3)	88.45(11)

Symmetry operation (′): $-y + 3/2, -z + 1, x - 1/2$; (″) $z + 1/2, -x + 3/2, -y + 1$.

arising species quite stable. Therefore, the six coordination sites around Al(III) are taken up by the three quinate ligands bound in the same bidentate fashion. The rest of the alcoholic groups of the quinate ligands do not bind Al(III), dangling away from its coordination sphere. The overall coordination geometry in **1** is distorted octahedral. Charge balance consideration and inspection of the bond lengths of the alcoholic and carboxylate groups indicate that the ligand is singly deprotonated, with the site of deprotonation being the terminal carboxylate group, while the α-alcoholic moiety remains protonated.

The Al–O bond distances in **1** are in line with those in other Al(III) oxygen-containing complexes, like $(NH_4)_5[Al(C_6H_4O_7)_2] \cdot 2H_2O$ (**2**) (1.844(3)–1.961(3) Å) [36], $(NH_4)_4[Al(C_6H_4O_7)(C_6H_5O_7)] \cdot 3H_2O$ (**3**) (1.836(1)–1.959(1) Å) [37], the dinuclear $(NH_4)_4[Al_2(C_6H_4O_7)(C_6H_5O_7)_2] \cdot 4H_2O$ (**4**) (1.835(3)–1.932(3) Å) [38], the trinuclear $(NH_4)_5[Al_3(C_6H_4O_7)_3(OH)(H_2O)] \cdot (NO_3) \cdot 6H_2O$ (**5**) [39] (1.832(5)–1.935(5) Å), and the M(III)–O distances in the congener complexes $(NH_4)_3[Ga(C_2O_4)_3] \cdot 3H_2O$ (1.961–1.976 Å) [40], $(NH_4)_4[Ga(C_6H_4O_7)(C_6H_5O_7)] \cdot 3H_2O$ (1.893(1)–2.058(1) · Å) and $(NH_4)_5[Ga(C_6H_4O_7)_2] \cdot 2H_2O$ (1.902(2)–2.056(2) Å). The Al–O distances are also similar to M(III)–O distances observed in other mononuclear M(III)–hydroxycarboxylate complexes such as $(NH_4)_5[Fe(C_6H_4O_7)_2] \cdot 2H_2O$ (1.953(2)–2.068(2) · Å) [41,42], $(NH_4)_3[Ga(C_6H_5O_7)_2] \cdot 4H_2O$ (1.890(2)–2.054(2) · Å) [43], and $(NH_4)_4[Cr(C_6H_4O_7)(C_6H_5O_7)] \cdot 3H_2O$ (1.933(2)–1.993(2) · Å) [44].

The protonated alcoholic moiety participates in hydrogen bonding interactions. Therefore, the presence of potassium ions along with the discrete OH^- groups in the lattice and the solvent water molecules further stabilizes the above-mentioned network, contributing to the stability of the crystal lattice in **1**.

4.3. FT-IR spectroscopy

The FT-infrared spectrum of **1** in KBr revealed the presence of vibrationally active carboxylate groups. Thus, antisymmetric as well as symmetric vibrations for the carboxylate groups in the coordinated quinate ligand were present in the spectrum. Specifically, antisymmetric stretching vibrations $\nu_{as}(COO^-)$ for the carboxylate carbonyls appeared between 1676 cm^{-1} and 1653 cm^{-1} for **1**. Symmetric vibrations $\nu_s(COO^-)$ for the same groups emerged in the range between 1384 cm^{-1} and 1365 cm^{-1} for **1**. The frequencies of the observed carbonyl vibrations were shifted to lower values in comparison to the corresponding vibrations in free quinic acid, thereby indicating changes in the vibrational status of the quinate ligand upon binding to the Al(III) ion [45]. The difference between the symmetric and antisymmetric stretches, $\Delta(\nu_{as}(COO^-) - \nu_s(COO^-))$, was greater than 200 cm^{-1}, indicating that the carboxylate groups of the quinate ligand were either free or coordinated to Al(III) in a monodentate fashion [46]. The latter contention was subsequently confirmed by the X-ray crystallography. All of the above assignments were in agreement with past observations in mononuclear $Al(III)O_6$ complexes [47], and in line with previous reports on carboxylate-containing ligands bound to metal ions [36,48–55].

4.4. Solid-state NMR spectroscopy

The MAS ^{13}C-NMR spectrum of **1** is consistent with the coordination mode of quinate around the Al(III) ion. The spectrum showed several discrete peak features. Two of those lie in the high field region, whereas the rest lie at lower fields. The two peaks in the high field region (34.4 and 40.7 ppm), were attributed to the C(6) and C(2) carbons, respectively, of the CH_2 groups in the quinate ligands bound to the central Al(III) ion. The resonances at 67.0, 71.3, 74.5 and 79.0 ppm were assigned to the C(5), C(3), C(4) and C(1) carbons, respectively, of the bound quinate. The signal at 180.0 ppm in the lower field region was assigned to the carboxylate carbon C(7) coordinated to the Al(III) central ion. This signal was shifted to lower fields in comparison to the corresponding signal in the free quinic acid. A similar pattern of ^{13}C resonances was observed in the case of mononuclear complexes containing other α-hydroxycarboxylate ligands (i.e. citrate), such as $(NH_4)_5[Al(C_6H_4O_7)_2] \cdot 2H_2O$ [36].

4.5. Solution NMR spectroscopy

The solution ^{13}C NMR spectrum of complex **1** was measured in D_2O (Fig. 3). The spectrum revealed the presence of several resonances. The two resonances in the high field region (38.9 and 43.2 ppm), were attributed to the C(6) and C(2) carbons, respectively, of the CH_2 groups in the quinate ligands bound to the central Al(III) ion. The resonances at 69.7, 74.0, 77.8 and 81.7 ppm were assigned to the C(5), C(3), C(4) and C(1) carbons, respectively, of the bound quinate. The signal at 183.6 ppm in the lower field region was assigned to the carboxylate carbon C(7) coordinated to the Al(III) central ion. This signal was shifted to lower fields in comparison to the corresponding signal in the free quinic acid. The shift was ~1.2 ppm downfield and was comparable to that observed in the MAS ^{13}C solid-state spectrum of **1**. It is worth noting that the pattern of resonances observed was similar to that observed in the solid state ^{13}C-MAS NMR spectrum of **1**. Further inquiry, however, into the solution ^1H NMR spectroscopy of compound **1** in D_2O revealed the presence of free quinate in equilibrium with

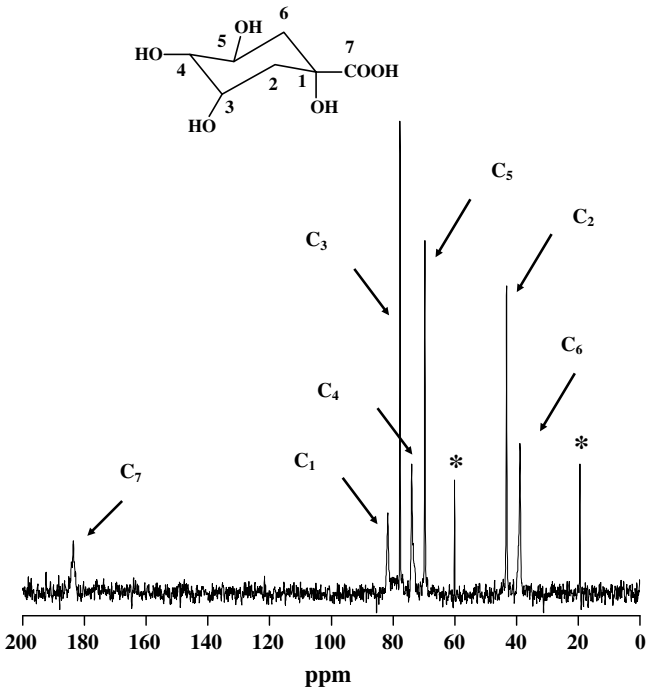

Fig. 3. ^{13}C NMR of **1** in solution (D_2O), at the autogenous pH. The signals marked with a star (*) belong to ethanol from the reaction mixture.

the species under investigation (See Supplementary data). Collectively, the data in solution support the presence of a mononuclear complex like **1,** but not identical in composition with that in the solid state.

4.6. Speciation studies

Potentiometric titrations were carried out on the ligand quinic acid alone and the binary system Al(III)–quinic acid in various metal ion to ligand molar ratios. Quinic acid contains only one dissociable proton in the measurable pH range (pK(HA) = 3.34(2)). The alcoholic hydroxyl groups are very weakly acidic dissociating up to pH ~ 13. For the titratable quinate carboxylate group, the pK_a value of 3.34 was obtained and was found to be very close to the values reported by Clifford (3.40) [56] and Luethy-Krause et al. (3.36) [57]. The obtained metal ion-ligand titration curves were evaluated with different potential speciation models. As quinic acid contains an α-hydroxycarboxylate moiety, the speciation model found for lactic acid [58,59] was tested first. An acceptable fit between the experimental and calculated titration curves for the binary Al(III)–quinic acid system was achieved by considering the species $[Al(H_2O)_6]^{3+}$ (Al), $[AlL]^{2+}$ (LH = $C_7H_{12}O_6$, L = $C_7H_{11}O_6^-$), $[AlLH_{-1}]^+$, $[AlLH_{-3}]^-$, $[AlL_2H_{-1}]^0$, the dinuclear form $[Al_2L_2H_{-4}]^0$, the polynuclear form $[Al_{13}L_4H_{-32}]^{3+}$, and the mononuclear $[AlH_{-4}]^-$ species toward the end of the investigated pH range. The fit was reasonably good in the overall employed pH and concentration range, indicating that the adopted speciation model was satisfactorily defined. Other binary Al(III):quinate complexes, including variably protonated and deprotonated species, were rejected by the computer program (PSEQUAD) during the computational process. The omission of any of the metal–ligand species decreased the fit by at least 30%. Accordingly, it can be stated that the suggested speciation model, with stability constants listed in Table 3, is the best model describing the solution state of the Al(III)–quinate system in the pH and concentration range studied. The uncertainties (3SD values) of the stability constants are given in parentheses. The pH range of their optimal formation is also reported. The species emerging from the speciation distribution of the binary system are basically in line with the overall structural characteristics encountered in species **1**, which was synthesized and isolated in the solid state. The collective data, however, indicate that the 3 × (COO^-, OH) type six-coordinate octahedral geometry, observed in the solid state species **1**, does not persist in solution in the whole pH range up to neutral pH.

Table 3
Proton (log$K$) and Al(III)–quinate complex formation constants (logβ) at I = 0.15 M (NaCl) and 25 °C[a]

Species	Quinic acid	logβ	pH range of participating species
	HL ($C_7H_{12}O_6$)	3.34(2)

[b] Goodness of fit between the experimental and the calculated titration curves, expressed in mL of titrant.

On the basis of the analytical and crystallographic data, the alcoholic group of the quinate retains its proton upon binding to Al(III). Thus, there is no expected pH-dependence of the deprotonation of that group and the specific mode of binding to Al(III) over the investigated pH range. However, it has been proven by pH-potentiometric, NMR and CD spectroscopic methods that Al(III) may induce deprotonation of the weakly acidic alcoholic-OH group in various α-hydroxycarboxylic acids (such as lactic acid, malic acid, citric acid) [60,61]. The titration curves in the absence and presence of Al(III) suggest clearly formation of the mononuclear 1:1 complexes $[Al(H_2O)_6]^{3+}$, $[AlL]^{2+}$ and $[AlLH_{-1}]^+$, and the 1:2 complex $[AlL_2H_{-1}]^0$ in the acidic region up to pH 5. In the early part of that range, the predominant species is $[Al(H_2O)_6]^{3+}$. The latter three species $[AlL]^{2+}$, $[AlLH_{-1}]^+$ and $[AlL_2H_{-1}]^0$ contain a singly deprotonated quinate ligand bound to Al(III). As the pH of the aqueous solution increases from 2 to 5, the fraction of the mononuclear species such as $[AlL]^{2+}$, $[AlLH_{-1}]^+$ and $[AlL_2H_{-1}]^0$ increases progressively. Around pH 4.5, the predominant species is $[AlLH_{-1}]^+$. Towards the end of the specific pH range, new species such as the mononuclear $[AlLH_{-3}]^-$, and the dinuclear form $[Al_2L_2H_{-4}]^0$ arise.

In the pH range 5–7, three species emerge, namely $[AlLH_{-3}]^-$, $[Al_2L_2H_{-4}]^0$ and the polynuclear cluster form $[Al_{13}L_4H_{-32}]^{3+}$. In the pH range 5–5.5, the predominant species is the dinuclear species $[Al_2L_2H_{-4}]^0$, gradually growing in from the latter part of the previously described pH range and reaching a maximum around 5.2. Slowly emerging in the same pH range is the mononuclear $[AlLH_{-3}]^-$ species, which eventually predominates over the entire range of values beyond 5.5. Slightly above that pH value, a polynuclear assembly of Al(III) ions bound to quinates, namely $[Al_{13}L_4H_{-32}]^{3+}$, emerges as a participant, albeit at a minor fraction compared to the other two species. In a fashion similar to the Al(III)–lactic acid system, what was suggested as $[Al_2L_2H_{-4}]^0$ and $[Al_{13}L_4H_{-32}]^{3+}$ are oligo(poly)nuclear hydroxo species [58,59].

Albeit not definitively proven, it is worth noting that the dinuclear species $[Al_2L_2H_{-4}]^0$ may originate from the previously emerging $[AlLH_{-1}]^0$ species, for which a clear picture of the coordination mode of quinate was proposed. On these grounds, dinuclear com-

plex formation through the mononuclear species as a synthon could be perceived to proceed through (a) employment of the coordinated quinate carboxylate group binding to an adjacent $[AlLH_{-1}]^+$ species unit (and vice versa) through the second oxygen anchor, (b) utilization of the alcoholic moiety as a bridge between abutting $[AlLH_{-1}]^+$ units, and (c) deprotonation of coordinated water molecule(s) leading to OH^- moieties potentially acting as template bridges to the adjacently located $[AlLH_{-1}]^+$ units. Thus, hydroxo bridged dinuclear assembly formation could be promoted. This thesis is consistent with the fact that hydroxo and dihydroxo bridges are a characteristic feature in Al(III) complexation chemistry, leading to dinuclear species in the solid state. Representative examples of such species are complexes of trivalent metal ions such as $[(Al_3(C_6H_4O_7)_2(OH)_2(H_2O)_4]_2 \cdot (NO_3) \cdot 6H_2O$ [62], $Na_6[Al_6(C_6H_6O_8)_4(OH)_8] \cdot 21H_2O$ [63], $[Al_{13}(\mu_3\text{-}OH)_6(\mu_2\text{-}OH)(C_6H_8NO_5)_6(H_2O)_6] \cdot (NO_3)_3$ [64], and $[Al_2(OH)_2(C_4H_5NO_4)_2(H_2O)_2]$ [65], and Cr(III) i.e. $([(H_2O)_4Cr(OH)_2Cr(H_2O)_4]^{4+}$ [66,67], $[Cr(tpa)(OH)]_2(ClO_4)_4\ 4H_2O$ [68], $[Cr(gly)_2(OH)]_2$ [69,70] and $[Cr(pic)_2(OH)]_2^{4+}$ [71]), already reported in the literature. Analogous chemistry has been observed in the case of Cu(II) and VO(II). On similar grounds, all of these metal ions were shown to be able to induce deprotonation of the weakly acidic alcoholic-OH function in various hydroxyl group derivatives when the OH group lies adjacent to another strongly coordinating donor group [58,59,72–74].

What emerges as a noteworthy observation from the aqueous speciation scheme is the 1:1 and 1:2 Al(III):quinate stoichiometry for the majority of the species present in it. In both cases of Al(III):quinate ratios, the binding mode of the quinate ligand(s) could be either through the carboxylate group or through the carboxylate and α-alcoholate groups, while the remaining polyol functionalities do not enter the coordination sphere of Al(III). It appears that the bidentate coordination of α-hydroxycarboxylate containing ligands through carboxylate groups may also be preferred in other divalent or trivalent metal ions, such as Cu(II) [72], Co(II) [75], Al(III)[73] and VO(II) [74]. Accordingly, it is very probable that the deprotonated species between Al(III) and quinic acid form isomeric structures and the coordination sphere of the metal ion is filled by monodentate or bidentate bound quinate, hydroxo and water ligands. The additional H_{-1} in species, such as $[AlLH_{-1}]^+$, $[AlL_2H_{-1}]^0$, could emerge upon dissociation of the α-OH group and coordination of the incipient α-O^- group or dissociation of a coordinated water molecule from $[AlL]^{2+}$ and $[AlL_2]^+$. Considering the data in this pH range, it appears that $\log K(AlL_2H_{-1})$ (characteristic for the equilibrium $AlLH_{-1} + L \rightleftarrows AiL_2H_{-1}$) is 2.55 and is similar to the $\log K(AlL)$ value of 1.84, indicating that only one ligand molecule is coordinated via a deprotonated alcoholate. The second ligand is bound to Al(III) in a (COO^-, OH) fashion. This value also indicates favorable formation for $[AlL_2H_{-1}]^0$ over that of $[AlLH_{-1}]^+$, due to charge neutralization. As a matter of fact, the two species coexist in the same pH range, with the former species comprising 30% of the total Al(III) fraction compared to ~50% for the latter species at pH ~ 4.5 (Fig. 4).

In the high pH zone, from 7 to 9, the two species present are $[AlLH_{-3}]^-$ and $[AlH_{-4}]^-$, both mononuclear in nature. In the first case, the mixed hydroxo $[AlLH_{-3}]^-$ species might exhibit isomeric binding modes. To this end, one formulation could include a singly deprotonated quinate, three hydroxides originating from the deprotonation of an equivalent number of bound water molecules, with the coordinated quinate preventing precipitation of $Al(OH)_3$ [76]. In the other binding mode, quinate coordinates in a bidentate (COO^-, O^-) fashion and only two OH^- ions are ionized in the coordination sphere of the metal ion. The $[AlLH_{-3}]^-$ species is the only species present around pH 7 and is the predominant species of the physiological pH range and even beyond that. The second species, $[AlH_{-4}]^- = [Al(OH)_4]^-$ ($\log \beta_{1-4} = -23.4$), emerges as a minor tetrahedral Al(III) species after pH 7 and reaches a maximum of 35% of the total fraction of Al(III) toward the high end of the investigated pH range. In a fashion similar to the Al(III)–lactate system, polynuclear species such as $Al_2L_2H_{-4}$ and $Al_{13}L_4H_{-32}$ also form in the pH range 4–7, in a significant but lower concentration than in the former system, probably due to the larger spatial requirement of the quinate ligand.

4.7. Thermal studies

The thermal decomposition of the title complex was studied by TGA–DSC under an atmosphere of oxygen (Fig. 5). The complex $K[Al(Quinic)_3] \cdot (OH) \cdot 4H_2O$ (**1**) is thermally stable up to 30 °C. From that point on, a fairly broad heat process points to the dehydration of **1**, with the release of lattice water molecules between 30 and 180 °C, signifying an endothermic process. The observed weight loss amounts to 9.63%, a value close to the calculated value of 9.88% based on the molecular formula of the title complex. Beyond the specific temperature, it appears that the quinate ligand loses its integrity. In a second step, the release of carbon dioxide is observed from the compound between 180 °C and 225 °C. The observed weight loss amounts to 6.13%, a value very close to the calculated value of 6.04% based on the molecular formula of the title complex. Subsequently, consecutive steps ensue between 225 and 500 °C that are associated with further decomposition of the organic part of the molecule. No clear plateaus are reached in these stages, suggesting that the derived products are unstable and

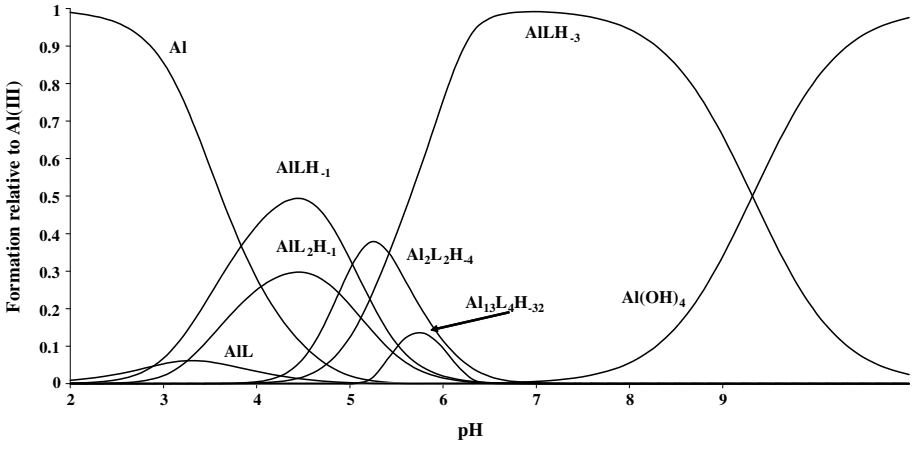

Fig. 4. Speciation curves for complexes forming in the Al(III)–quinic acid system; c_{Al} = 0.001 mol dm^{-3}, c_{ligand} = 0.003 mol dm^{-3}. Charges are omitted for clarity.

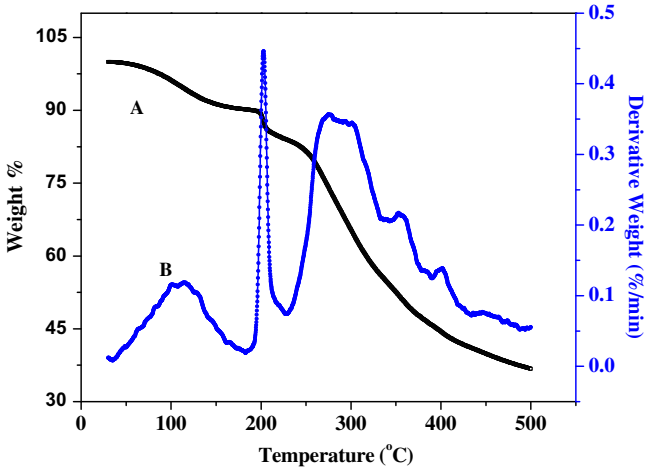

Fig. 5. TGA (A) and DSC (B) analysis of **1**.

decompose further. The total weight loss of 86.8% due to the decomposition of the title complex is reached at 518 °C, with no further loss up to 800 °C. This value is in good agreement with the calculated weight loss derived upon the thesis that the product at that temperature (500 °C) is Al_2O_3. The DSC profile of the complex exhibits clear features that correspond to the aforementioned TGA processes. Collectively, the specified number of observed processes very likely reflects discrete mechanistic steps for the decomposition pathways of **1**.

5. Discussion

5.1. A closer look at the aqueous Al(III)–quinic acid chemistry

As a metallotoxin, Al(III) has been linked to a number of pathological conditions in plants (soil acidity complex) [77] and humans (Alzheimer's disease) [11,12,16]. In both cases, its cellular toxicity entails a diverse aqueous chemistry at the molecular level, that, in turn, is linked to the existence of soluble and bioavailable forms of that metal ion influencing its chemical reactivity. To this end, understanding Al(III) toxicity is closely tied to well-characterized soluble forms of Al(III) that can promote its reactivity with physiological targets through ensuing ternary interactions. Drawn by the paucity of such well-defined forms of Al(III) in aqueous media that promote interactions leading to aberrant cellular (neuro)physiologies, a structural speciation approach was adopted encompassing pH-dependent synthetic reactions between Al(III) and the physiological substrate D-(−)-quinic acid. At the optimally established pH 4, the new binary species $K[Al(C_7H_{11}O_6)_3]\cdot(OH)\cdot 4H_2O$ (**1**) arose and was isolated in a pure crystalline form. The physicochemical characterization of **1** projected structural and chemical properties relating to the following:

(a) The arisen aqueous chemistry in this binary system under the employed conditions is linked to the formation of discrete complexes of Al(III) bearing quinate ligands. The specificity of the reaction pH was crucial in deriving the new material in a pure and crystalline form. pH-specific synthesis had previously been successfully applied in the case of soluble metal-hydroxycarboxylate species involving trivalent (Al(III), Ga(III), Fe(III)) [36,37,41] and divalent metal ions (Co(II), Mn(II)) [49,50].

The physicochemical properties of **1** contribute significantly to understanding its nature both in the solid state and in solution (*vide infra*). In this regard, delineation of the composition of the coordination sphere of Al(III) in solution reflects distinct structural features on species arising from the interaction of the metal ion with natural O-containing low molecular mass substrates in biologically relevant media. The fact that in solution species such as $[AlL_2]^+$ or $[AlL_2H_{-1}]^0$ may arise consolidates further the emergence of Al(III)–O_6 moieties (very likely octahedral, albeit not unequivocally delineated as such by NMR beyond pH 4–5 due to parallel formation of $Al(OH)_3$) in aqueous media through binary and ternary interactions of Al(III) with O-containing targets. The so arisen interactions could reflect a general multifactorial contribution to $[AlL_2]^+$ or $[AlL_2H_{-1}]^0$ emergence as a speciation participant, primarily influenced by factors such as pH, ligand deprotonation state, H-bond formation and others. Along with the thermal behavior, the overall data formulate a well-defined physicochemical profile for **1**, supporting its solid-state nature and its solution signature.

(b) The structural characterization of **1** reveals distinct traits of the interaction between Al(III) and quinic acid. Firstly, the mode of coordination of the ligand with the metal ion is specific and derives from the propensity of the α-hydroxycarboxylate moiety to promote metal ion binding. A key factor driving this particular reactivity of Al(III) is the formation of stable five-membered rings for the quinate ligands bound to Al(III). Secondly, the employment of the alcoholic moiety of the α-hydroxycarboxylate group to bind Al(III) is marked by a retention of the proton on the specific oxygen (as evidenced by the solid-state structure of the isolated species **1**). The aqueous speciation work, however, provides further insight into the chemical behavior of the quinate ligand anchored to Al(III). Specifically, both singly ionized quinate as well as doubly ionized quinate moieties appear to anchor to Al(III), giving rise to binding isomers for specific species such as $[AlLH_{-1}]^+$ and $[AlL_2H_{-1}]^0$. This behavior may imply similarities to the aqueous Al(III) chemistry at pH values lower or higher than the one employed here, or to the chemistry of other divalent/trivalent metal ions with the same ligand. In no cases so far, however, have doubly deprotonated quinate-containing mononuclear octahedral metal complexes been synthesized and isolated, thus projecting the interconnection of the inherent chemical properties of the various metal ions with the complexity and diversity of species present in aqueous media. To this end, the possibility that the Al(III)–quinate binary system would give rise to new, thus far elusive, species in a pH-dependent fashion cannot be discounted.

(c) The three alcoholic groups almost diametrically located with respect to the α-hydroxycarboxylate moiety play totally different roles. They do not participate in the formation of five-member metallacyclic rings, like the α-hydroxycarboxylate moiety does, which further stabilizes the entire mononuclear complex. In the case of divalent metal ions, such as Mn(II) [78], participating in binary systems with quinic acid, the terminal alcoholic moieties were variably involved in the formulation of the coordination sphere of the metal ion, differentiating the structural environment of abutting Mn(II) ions in the arising solid-state lattice, without losing their protons. Specifically, one of the polyolic group members acts as a bridge between adjacently located metal ion centers, leading to the formation of dinuclear species $[Mn_2(C_7H_{11}O_6)_4]_n\cdot nH_2O$ infinitely extended in a polymeric and molecular lattice. Even though that behavior was observed in the crystalline state only, it projects the potential affinity of polyol functionalities for metal ion coordination, such as Al(III), as ligand terminals on diverse physiological substrates interacting with it in biologically relevant fluids.

5.2. Correlation of structural diversity in the aqueous binary Al(III)–quinate speciation with the synthetic chemistry

The aqueous speciation in the binary Al(III)–quinic acid system (Fig. 4) can be described satisfactorily by considering the presence of (a) 1:1 Al(III)–quinate complexes in the form $[AlL_n(H_{-1})_p]^{q+}$ ($n = 0$, $p = 0$, q = 3; $n = 1$, $p = 1$, q = 1; $n = 1$, $p = 0$, $q = 2$), the neutral $[AlL_2H_{-1}]^0$ and dinuclear $[Al_2L_2H_{-4}]^0$ forms, the anionic

$[AlL_n(H_{-1})_p]^{q-}$ ($n = 0$, $p = 4$, $q = 1$; $n = 1$, $p = 3$, $q = 1$) and polynuclear $[Al_{13}L_4H_{-32}]^{3+}$ forms, and (b) 1:2 mononuclear Al(III)–quinate species $[AlL_2H_{-1}]^0$.

On the basis of the aforementioned observations, it is logical to juxtapose the results of the aqueous speciation with the solid-state structure of compound **1** and its physicochemical properties in the solid state and in solution. To that end, the solid-state structure of **1** suggests the existence of an octahedral Al(III) central metal ion surrounded by three singly deprotonated quinate ligands, thus filling all of the six available coordination sites. In solution, the NMR data obtained for **1** upon dissolution and at the equilibrium state suggest that (a) the species does not retain its solid-state structure in solution, thereby releasing quinate away from the coordination sphere of Al(III), and (b) even the binding mode of the quinate may change from (COO^-, OH) to (COO^-, O^-) coordination. Consistent with this general behavior is the suggestion offered by the aqueous speciation that, in the pH range investigated synthetically, there are two species prevailing. These are $[AlLH_{-1}]^+$ and $[AlL_2H_{-1}]^0$. Consequently: (a) the fact that **1** has been isolated in the solid state with the specific molecular lattice composition and physicochemical properties reflects the lattice dynamics of Al(III)–quinate complexation in the solid state, and (b) $[AlL_2H_{-1}]^0$ might be the species that **1** dissociates to upon dissolution in water at the autogenous pH (consistent with the pH range at which the synthesis of **1** was pursued).

The aforementioned remarks lend further credence to the notion that $[AlL_2H_{-1}]^0$, a zero-valent complex (like **1**), is likely the arising species in solution consistent with the potential reactions shown below:

$$[AlL_3]^0 \rightleftarrows [AlL_2]^+ + L^-$$

$$[AlL_2]^+ \rightleftarrows [AlL_2H_{-1}]^0 + H^+$$

To a first approximation, dissociation of $[AlL_3]^0$ to $[AlL_2]^+$ is followed by further deprotonation of one of the Al(III)–bound water molecules, or one of the α-OH groups of the quinate molecules, leading to the formation of $[AlL_2H_{-1}]^0$. Thus, (a) the mononuclear octahedral complex, isolated in the solid state, affords upon dissolution another mononuclear, presumably octahedral complex, containing fewer quinates (two), (b) the charge of $[AlL_3]^0$ (**1**) in the solid state (zero) is maintained upon dissolution of the complex and the formation of the emerging complex $[AlL_2H_{-1}]^0$. The chemical and potential biological repercussions of that property could be relevant to molecular mechanisms of Al(III) toxicity.

From a structural point of view, the quinate ligand is configured so as to promote formation of variable size species extending from low molecular mass complexes to high molecular mass aqueous assemblies. In analogy to other α-hydroxycarboxylate metal ion binders, such as lactic acid, citric acid, malic acid, etc., a chemistry of such breadth would be expected to afford dinuclear and potentially multinuclear Al(III)–quinate clusters. Consistent with this notion is the suggestion offered by the aqueous speciation distribution of this binary system that the dinuclear complex $[Al_2L_2H_{-4}]^0$ exists in the pH range 4–7 and a higher nuclearity cluster $[Al_{13}L_4H_{-32}]^{3+}$ is present in the pH range 5–6.5. With regard to the binding mode of the di- and polynuclear species, the most likely assumption concerning the $Al_2L_2H_{-4}$ complex would be the tentative formula $[Al_2(OH)_2(H_{-1}L)_2]^0$, i.e. a dihydroxo-bridged species in which both quinate ions are doubly deprotonated and bound in a bidentate fashion around the $Al_2(OH)_2$ core. A similar core structure has been reported in $[Al_2(\mu\text{-}OH)_2(\text{nitrilotriacetate})_2]^-$ [79]. Concerning the high-nuclearity species $Al_{13}L_4H_{-32}$, we have no clear suggestion as to the binding mode of quinate in this species. It should be mentioned, however, that for a similar polynuclear species bearing the hydrolytic $[Al_{13}O_4(OH)_{24}]^{7+}$ core and thought to arise upon interaction of Al(III) with lactate, ^{27}Al NMR studies by Marklund and Öhman [58] concluded that in fact the species was not a complex to which lactate ions were coordinated. These assumptions are consistent with the existence of structural features not unlike those encountered in (1) dinuclear oxo- or hydroxo-bridges seen in species such as $K_2[Cr_2(C_6H_6NO_6)_2(OH)_2]\cdot 6H_2O$ [80], $Ba[\{Fe(nta)(H_2O)\}_2O]\cdot 4H_2O$ [81], $[Ga(heidi)(H_2O)]_2$ [82], $[Al(heidi)(H_2O)]_2$ [64] and $[Fe(heidi)(H_2O)]_2$ [83,84], which have been synthesized and isolated, and (2) polynuclear species that could emerge from the herein investigated binary system. As to the latter category of species, the importance of the M:ligand ratio in achieving high nuclearity species has been noted as a key factor in the chemistry of a number of trivalent metal ions like Fe(III), Al(III), Ga(III) and others. Thus, species such as $[Fe_{19}(\mu_3\text{-}O)_6(\mu_3\text{-}OH)_6(\mu_2\text{-}OH)_8(heidi)_{10}(H_2O)_{12}]^+$, $[Fe_{17}(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_6(\mu_2\text{-}OH)_{10}(heidi)_8(H_2O)_{12}]^{3+}$ [83], $[Al_{13}(\mu_3\text{-}OH)(\mu_2\text{-}OH)_{12}(heidi)_6(H_2O)_6]^{3+}$ [64], $[Ga_8(\mu_3\text{-}OH)(\mu_2\text{-}OH)_8(heidi)_4(H_2O)_4(py)_2]^{2+}$ [82] and $[Ga_{13}(\mu_3\text{-}OH)(\mu_2\text{-}OH)_{12}(heidi)_6(H_2O)_6]^{3+}$ [82] have been synthesized. On the basis of the above remarks, pertinent synthetic and physicochemical studies are currently in progress in our lab to complement the already conducted aqueous speciation studies.

5.3. From the aqueous chemistry of the binary Al(III)–quinate system to toxicity

Aside from humans, most plants are fairly sensitive to Al(III) toxicity, a major factor affecting significantly crop productivity in agriculture [77,85] around the world. Therefore, essential in understanding the toxicity of Al(III) at the cellular level, is an in-depth knowledge of the (bio)chemistry of that metal ion with intracellular and/or extracellular targets of variable mass and distinct biological activity. A key contributor to that knowledge is (a) the aqueous speciation of binary/ternary systems of a kinetically sluggish Al(III) with its elicited targets as a function of pH and molecular stoichiometry, and (b) the structure and properties of soluble and bioavailable species of Al(III)–L (substrate) species partaking of the requisite speciation [86]. To this end, the herein described complex **1** is a good example of a species, which (a) in the solid state contains the key physicochemical characteristics of an efficient metal ion binder (ligand to metal ratio, structural features, etc.) anchored onto Al(III), as previously proposed for plant tea organic acids interacting with that metal ion [87,88], (b) in solution, turns into mononuclear Al(III) species bearing a variable metal:ligand ratio while concurrently retaining the overall solid-state characteristics of the binary species, and (c) gives rise to $[AlL_2H_{-1}]^0$, bearing a net neutral charge, presenting a soluble Al(III) entity poised to traverse cellular structures (e.g. membranes) and participate in further chemical reactivity by eliciting interactions from variable mass and structure cellular targets involved in cytosolic and nuclear processes (i.e. cellular-neuronal integrity, degeneration, etc.). Further synthetic chemistry targeting such well-defined yet elusive aqueous Al(III)–quinate pH-structural variants, components of the speciation of that binary system, are under way.

6. Conclusions

The work presented here, projects the nature of the aqueous interactions between Al(III) and a natural O-containing substrate, ultimately leading to well-defined complexes in the solid state and in solution. Both the aqueous speciation study and the invoked synthetic approaches offer invaluable data adumbrating the profile of soluble species in the binary Al(III)–quinate system through the correlation of their structural properties in those two phases. Given the importance of binary and ternary interactions of Al(III) with variable mass cellular targets, understanding the nature and physicochemical properties of **1** in the solid state and in solution is the first step in the delineation of the complex distribution of Al(III)–

quinate species and any related Al(III)–(O-substrate) interactions under conditions dictated by cellular environmental factors and biological settings [89]. Undoubtedly, the contribution of the pH-dependent synthetic chemistry to the investigation of (a) the molecular processes involving this otherwise kinetically sluggish Al(III), and (b) the relationships to molecular neuro(toxic) effects in higher organisms and humans, is significant. To the degree that soluble and bioavailable Al(III)-bound (α-hydroxy)carboxylate-containing biological targets, such as $[AlL_2H_{-1}]^0$, are likely involved in chemical processes underlying (neuro)toxic effects in biological media, further synthetic and solution studies on this specific, as well as other hydroxycarboxylate-bearing binary systems, are expected to shed light on their nature. Work along these lines is currently in progress in our labs.

Acknowledgments

This work was supported by a "Pythagoras" grant from the National Ministry of Education and Religious Affairs, and by a "PENED" grant co-financed by the E.U. European Social Fund (75%) and the Greek Ministry of Development-GSRT (25%), and by the Hungarian Research Fund (OTKA No. NI61786).

Appendix A. Supplementary data

CCDC 678110 contains the supplementary crystallographic data for $K[Al(C_7H_{11}O_6)_3] \cdot (OH) \cdot 4H_2O$ (**1**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.06.029.

2.2. Physical measurements

Elemental analyses were carried out on a Carlo Erba Model 1108 and Perkin–Elmer 240B microanalyser. IR spectra were recorded on a Bruker IFS-66V spectrophotometer as KBr disks (4000–400 cm^{-1}) or polyethylene-sandwiched Nujol mulls (500–100 cm^{-1}). Electronic spectra were obtained on a Shimadzu UV-3101PC spectrophotometer equipped with a reflectance accessory. X-band EPR spectra of the complexes were obtained in 3 mm pyrex tubes with a Bruker EMX spectrometer using a conventional Dewar insert at liquid nitrogen temperature and Cr^{II} as the reference. Room temperature magnetic moments were determined on a DSM-8 magnetic susceptibility balance, and the instrument was calibrated using nickel metal.

2.3. X-ray crystallography

Suitable single crystals were mounted on a glass fiber and these samples were used for data collection. Data were collected at room temperature and with Mo Kα radiation ($\lambda = 0.71073$ Å) on a Bruker SMART CCD 1000 diffractometer. The data were processed with SAINT [14] and corrected for absorption using SADABS [15]. The structures were solved by direct methods [16], which revealed the position of all non-hydrogen atoms. These atoms were refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [17]. Hydrogen atoms were located in difference maps (**1** and **3**) or placed geometrically, but the OH^- and H_2O hydrogen atoms were located unambiguously from difference Fourier maps (**2** and partly in **4**). All hydrogen atoms were included as fixed contributions riding on attached atoms with isotropic atomic displacement parameters constrained to be 1.2 times those of their carrier atoms. Criteria for a satisfactory complete analysis were the ratios of *rms* shift to standard deviation less than 0.001 and no significant features in final difference maps. Atom scattering factors were taken from the International Tables for Crystallography [18]. Crystal and refinement data are listed in Table 1.

2.4. Preparation of the complexes

2.4.1. Synthesis of $[Cu(bpy)(\mu_2\text{-MANO})]_2 \cdot 8H_2O$ (**1**), $[Cu(bpy)(MANO)] \cdot 4H_2O$ (**2**), and $[Cu_4(_3\text{-}OH)_2(_2\text{-}MANO)_2(bpy)_4](phglyo)_2 \cdot 8H_2O$ (**3**)

To a stirred suspension of $Cu_2CO_3(OH)_2$ (0.100 g, 0.452 mmol) in distilled water (15 mL) were added a solution of mandelic acid (0.138 g, 0.907 mmol) in water (10 mL) and then *bpy* (0.142 g, 0.909 mmol). The mixture was heated under reflux for 3 h and was then stirred at room temperature for a further 7 d. The resulting blue solution was filtered and slow evaporation of the solvent in air at room temperature afforded micro-crystals of **1**, which were separated by filtration. The resulting solution was left in open air, and slow evaporation of the solvent at room temperature gave a few blue crystals of **2** suitable for a single-crystal X-ray analysis. Finally, after about ten weeks, an unidentified brown solid and crystals of **3** were obtained from the final solution and these were easily separated. A similar result for **3** has been obtained by passing a strong flow of air through the dissolution for 12 days.

*2.4.1.1. $[Cu(bpy)(\mu_2\text{-MANO})]_2 \cdot 8H_2O$ (**1**).* Yield: 61% (122 mg), based on $C_{36}H_{44}Cu_2N_4O_{14}$ ($M_r = 883.83$). *Anal.* calc. C, 48.9; H, 5.0; N, 6.3. Found: C, 49.4; H, 5.1; N, 6.2%. IR (KBr pellets, cm^{-1}): 3388 m,br ν(OH), 1654 m,br δ(OH), 1600 $\nu_{as}(CO_2)$, 1499 m, 1446 m ν(bpy, C=N + C=C), 1391 m $\nu_s(CO_2)$, 640 w, 422 w (bpy, ring), 338 w ν(CuO), 264 w ν(CuN). UV–Vis (λ_{max}, cm^{-1}) in solid state: 23690, 16110, 15600, 14347. EPR (room temperature): $g_{||} = 2.26$, $g_{\perp} = 2.10$.

*2.4.1.2. $[Cu(bpy)(MANO)] \cdot 4H_2O$ (**2**).* Yield: 28% (90 mg), based on $C_{18}H_{22}CuN_2O_7$ ($M_r = 441.92$). *Anal.* calc. C, 48.9; H, 5.0; N, 6.3. Found: C, 49.2; H, 4.8; N, 6.3%. IR (KBr pellets, cm^{-1}): 3422 m,br ν(OH), 1622 s, br δ(OH), 1592 s $\nu_{as}(CO_2)$, 1492 m, 1446 m ν(bpy, C=N + C=C), 1358 m,br $\nu_s(CO_2)$, 636 w, 426 w (bpy, ring), 394 w ν(CuO), 280 w ν(CuN). UV–Vis (λ_{max}, cm^{-1}) in solid state: 23697, 17270, 15925. μ_{eff} (BM): 1.82. EPR (room temperature): $g_{||} = 2.24$, $g_{\perp} = 2.06$.

Table 1
Crystal data and structure refinement for $[Cu(bpy)(\mu_2\text{-MANO})]_2 \cdot 8H_2O$ (**1**), $[Cu(bpy)(MANO)] \cdot 4H_2O$ (**2**), $[Cu_4(\mu_3\text{-}OH)_2(\mu_2\text{-}MANO)_2(bpy)_4](phglyo)_2 \cdot 8H_2O$ (**3**) and $[Cu_4(\mu_3\text{-}OH)_2(\mu_2\text{-}OH)_2(OH_2)_2(phen)_4](Bza)_2(OH)_2 \cdot 5H_2O$ (**4**)

2.4.1.3. [$Cu_4(\mu_3\text{-}OH)_2(\mu_2\text{-}MANO)_2(bpy)_4](phglyo)_2 \cdot 8H_2O$ (3). Yield: <5% (10 mg), based on $C_{72}H_{72}Cu_4N_8O_{22}$ (M_r = 1653.54). *Anal.* calc. C, 52.2; H, 4.4; N, 6.8. Found: C, 50.6; H, 4.7; N, 6.7%. IR (KBr pellets, cm^{-1}): 3430 m,br ν(OH), 1610sh δ(OH), 1605 s $\nu_{as}(CO_2)$, 1518 m, 1429sh *ν*(bpy, C═N + C═C), 1384 m,br $\nu_s(CO_2)$, 642 w, 431 w (bpy, ring), 398 w *ν*(CuO), 293 w *ν*(CuN). Owing to the extremely low yield, magnetic characterization was not carried out.

*2.4.2. Synthesis of [$Cu_4(_3\text{-}OH)_2(_2\text{-}OH)_2(OH_2)_2(phen)_4](Bza)_2(OH)_2 \cdot 5H_2O$ (**4**)*

To a stirred suspension of $Cu_2CO_3(OH)_2$ (0.100 g, 0.452 mmol) in distilled water (15 mL) were added a solution of mandelic acid (0.138 g, 0.907 mmol) in water (10 mL) and then phen (0.180 g, 0.908 mmol). The mixture was heated under reflux for 3 h and then magnetic stirring was maintained at room temperature for a week. The resulting greenish-blue solid was filtered off, washed with water and dried over calcium chloride. This solid was not identified. After about six weeks, the resulting solution was left in open air, and slow evaporation of the solvent at room temperature gave a few greenish single crystals of **4** suitable for X-ray diffraction studies and these were separated by hand. Yield: <10% (13 mg), based on $C_{62}H_{62}Cu_4N_8O_{17}$ (M_r = 1445.36). *Anal.* calc.: C, 51.5; H, 4.3; N, 7.8. Found: C, 51.7; H, 4.8; N, 7.4%. IR (KBr pellets, cm^{-1}): 3363 s,br *ν*(OH), 1612 s,br *δ*(OH), 1586 s $\nu_{as}(CO_2)$, 1519 w, 1427 m *ν*(phen, C═N + C═C), 1387 m,br $\nu_s(CO_2)$, 628 w, 430 w (bpy, ring), 384 w *ν*(CuO), 255 w *ν*(CuN). Owing to the extremely low yield, magnetic characterization was not carried out. A similar result has been obtained by passing a strong flow of air through the dissolution for eight days.

3. Results and discussion

Aqueous solutions resulting from reactions between $Cu_2(OH)_2CO_3$, mandelic acid (H_2MANO) and 2,2′-bipyridine (bpy) or 1,10-phenanthroline (phen), after prolonged exposure to air, yield crystals of $[Cu(bpy)(\mu_2\text{-}MANO)]_2 \cdot 8H_2O$ (**1**), $[Cu(bpy)(MANO)] \cdot 4H_2O$ (**2**), $[Cu_4(\mu_3\text{-}OH)_2(\mu_2\text{-}MANO)_2(bpy)_4](phglyo)_2 \cdot 8H_2O$ (**3**) or $[Cu_4(\mu_3\text{-}OH)_2(\mu_2\text{-}OH)_2(OH_2)_2(phen)_4](Bza)_2(OH)_2 \cdot 5H_2O$ (**4**), where phglyo is the phenylglyoxylate anion and Bza is the benzoate anion, respectively. These reactions do not occur under anaerobic conditions.

In the 3000–3500 cm^{-1} region, the IR spectra of complexes show two bands, generally of medium intensity, corresponding to OH stretching vibrations. The strong band around 1605–1585 cm^{-1} is attributable to ν_{asym}(OCO), and the band between 1355 and 1390 cm^{-1} to ν_{sym}(OCO). The values of $\Delta\nu = \nu_{asym}(O\text{-}CO) - \nu_{sym}(OCO)$, 199–234 cm^{-1}, are typical of monodentate carboxylato groups [19] and very similar to those found in copper(II)/α-hydroxycarboxylato/1,10-phen or bpy systems [20]. The bands around 1490 and 1450 cm^{-1} are due to the C═C and C═N stretching modes of the coordinated diimine molecules. On the other hand weak bands at 640 and 420 cm^{-1} correspond to the pyridine ring deformations. A weak band around 400 cm^{-1} is assignable to *ν*(CuO), and the band between 250 and 300 cm^{-1} is tentatively identified as due to *ν*(CuN) [21].

The electronic (diffuse reflectance) spectra of complexes **1** and **2** show three broad bands in the visible region. A band is observed at 23700 cm^{-1} and must be due to metal-ligand charge-transfer processes (MLCT) probably $\pi \rightarrow d_{x^2-y^2}$ and d_{z^2} (Cu^{II}). In contrast to other copper(II) complexes, in this case there does not seems to be a clear correlation between the position of the maximum of this band and the coordination geometry or the nature of the ligand coordinated to the metal. The band that is observed in the lower energy region of the spectrum, between 17270 and 15600 cm^{-1}, correspond to a d–d transition [22].

3.1. Description of crystal structures

*3.1.1. Structure of $[Cu(bpy)(_2\text{-}MANO)]_2 \cdot 8H_2O$ (**1**)*

The asymmetric unit is formed by two half molecules (**I** and **II**). The structure of the molecule **I** of $[Cu(bpy)(\mu_2\text{-}MANO)]_2$, is shown in Fig. 1. These compounds consist of a centrosymmetric dimer in which the non-carboxy mandelato oxygens bridge between copper atoms that are each chelated by a *bpy* molecule and are also coordinated by a carboxy mandelato oxygen. The resulting coordination polyhedra are square pyramids (Addison's τ = 0.14 in **I** and 0.11 in **II** [23]) with the copper atom at the center of a base plane defined by the *bpy* nitrogen atoms, the carboxy oxygen and one of the bridging alkoxide oxygen atoms. As one would expect in square pyramidal copper complexes, the Cu-apex distance Cu1–O13[a], 2.269(4)/2.292(4) Å, is longer than the bond lengths in the base [Cu1–O13 = 1.938(4)/1.935(4) Å] due to the $\sigma^*(d_{z^2})^2\sigma^*(d_{x^2-y^2})^1$ configuration of the copper(II) ion (Table 2). The oxygen bridge is thus very asymmetric, in spite of the overall symmetry of the dimer. The basal Cu–O distance and the Cu–N distances [1.987(1)–2.017(1) Å] are within the usual range for complexes of copper(II) with chelating *bpy*, bridging alkoxido and non-bridging carboxylato ligands [24]. The axial Cu–O distance is similar to those found in other dimers with asymmetric alkoxido bridges [25]. However, the narrow Cu–O–Cu bridging angles [92.54(17)/87.71(15)° in **I** and 90.28(6)° in **II**] mean that the Cu···Cu distance in the dimer is only 3.0491(15)/3.0582(14) Å, and according to magneto-structural correlations for bis-alkoxide bridged cooper dimers [26–28] the acute Cu–O–Cu. angle would lead to a ferromagnetic coupling in compound **1**.

The half-dimer that forms the asymmetric unit is not completely flat. In **I** the deviations from the least-squares planes of the 2,2′-bipyridine and mandelato ligands are 0.043(6) and 0.108(4) Å, respectively, for C22 and C11. These two least-squares planes (represented by N11—N12 and O11—O13) make a dihedral angle of 38.1(2)° and the copper atom lies 0.231(2) Å nearer to O13[a] than the base plane of the coordination polyhedron. The corresponding distances and angles in **II** are 0.021(6) Å (C49), 0.080(3) Å (C31), 38.9(2)° (N31—N32 and O21—O23) and 0.240(2) Å (O23[a]), respectively.

The packing in the lattice is dominated by different hydrogen bonding networks (Table 3). There are hydrogen bonds between

the water molecules and between one of these and the uncoordinated mandelato oxygen (O12, O22). In the crystals, however, these sets of hydrogen bonds result in the water molecules binding together the stepped chains of dimers that are created in the [1 0 0] and [0 1 0] directions for molecules **I** and **II**, respectively, through π–π interactions between the pyridine rings of one half-dimer and those of the opposite half-dimer of a neighboring molecule [centroid–centroid distances 3.754(4)/3.934(4) Å]. The interconnections of dimers and water molecules result in 1D chains with base vectors [1 1 0] (Fig. 2).

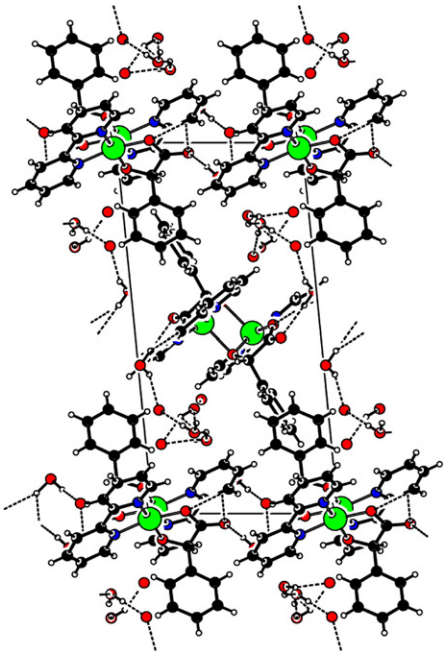

Fig. 2. View of the crystal cell and hydrogen bonds of **1** in the plane *bc*.

3.1.2. Structure of [Cu(bpy)(MANO)] · 4H2O (*2*)

Relevant bond distances and angles are given in Table 2. A molecular representation of the neutral complex is shown in Fig. 3. The copper atom is coordinated to the nitrogen atoms of the single *bpy* ligand and two oxygen atoms belonging to a dideprotonated bidentate mandelato ligand (which like *bpy* forms a five-membered chelate ring), giving rise to a square-planar environment (mean deviation = 0.0682 Å) in which the copper atom lies in the least-squares plane defined by the four nitrogen and oxygen atoms [0.0235(9) Å]. The Cu–N distances are longer than the Cu–O distances and similar to the Cu–N distances in **1**. However, the square-planar coordination geometry leads to the Cu–O distance being shorter than the Cu–O distance in **1** (Table 2). In the complex there are stacking interactions between the *bpy* rings of neighboring molecules, with an inter-ring distance of 3.824(2) Å and these are chelate-ring type [centroid–centroid distance 3.523(1) Å]. Finally, the presence of water of crystallization gives rise to an infinite 3D framework of hydrogen bonds (Table 3).

*3.1.3. Structures of $[Cu_4(_3\text{-}OH)_2(_2\text{-}MANO)_2(bpy)_4](phglyo)_2 \cdot 8H_2O$ (**3**) and $[Cu_4(_3\text{-}OH)_2(_2\text{-}OH)_2(OH_2)_2(phen)_4](Bza)_2(OH)_2 \cdot 5H_2O$ (**4**)*

Compounds **3** and **4** are tetranuclear copper(II) complexes with chair-like stepped cubane structures. The molecular structures and atom-labelling schemes are shown for **3** and **4** in Figs. 4 and 5, respectively. Selected bond distances and angles are presented in Table 4.

The structure of **3** consists of divalent $[Cu_4(\mu_3\text{-}OH)_2(\mu_2\text{-}MANO)_2(bpy)_4]^{2+}$ cations (MANO = dianionic mandelato), phenylglyoxylate anions and water molecules. The crystal structure of **4** consists of tetravalent $[Cu_4(OH)_4(phen)_4(H_2O)_2]^{4+}$ complex cations, benzoate and hydroxide anions and H_2O molecules. In this compound the colour of the crystals and the coordination geometry suggest an oxidation state +2 for the copper ions, consequently in order to preserve charge neutrality 6 OH^- groups are required. As we describe later the oxygen atoms labelled as O3 and O6 are involved in a typical hydrogen pattern with two benzoate anions, but the hydrogen atoms of these oxygen atoms could not be successful located in the structure calculation, therefore there is uncertainty about the correspondence of O3 or O6 with a OH^- group.

The two compounds have different Cu_4O_4 cores. In **3** the core is $Cu_4(OH)_2O_2$ (Fig. 6), with a triple-bridging OH and the alkoxide oxygen of the mandelato ligand acting as a bridge between two copper atoms. However, in **4** the $Cu_4(OH)_4$ core (Fig. 7) is formed by triple-bridging and double-bridging OH ligands.

In both compounds the two crystallographically independent copper atoms are pentacoordinated with similar coordination arrangements but different environments. In both cases the coordination polyhedra are essentially square pyramids (geometry 4 + 1), but with a different degree of distortion towards trigonal bipyramid for each compound. The trigonality index τ [23] for the metal centers in **3** the values are 0.34 (Cu1) and 0.36 (Cu2) and in **4** is 0.16 for the two copper atoms, showing the greater distortion of the polyhedra in the first compound.

In **4** the material coordination environment for each Cu is distinct: two nitrogen atoms provided by a phen ligand and two OH bridging ligands ($O1_{\mu_2}$ and $O1_{\mu_3}$) form the equatorial planes around Cu1 and Cu2, but the axial sites are occupied by a ligand (O3) for Cu1 and by an OH μ_3-bridging ligand ($O2^i$) for Cu2. The basal distances are in the range 1.917–2.022 Å and the longer Cu1–O3 (2.240 Å) and Cu2–$O2^i$ (2.342 Å) distances result from the Jahn–Teller distortion around the metal atoms. This axial-equatorial bridge formed by the hydroxide ion at Cu2 is unusual even for hy-

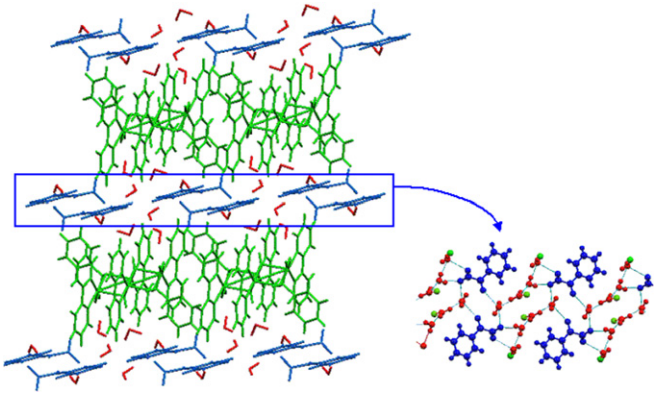

Fig. 9. 3D network in **3** (view down *b*-axis).

droxo-bridged copper(II) dimers [29] but has also been found in some tetranuclear copper hydroxo-complexes [30]. The Cu—OH_{μ_2} distances [1.928(6) and 1.917(5) Å], as expected, are shorter than the Cu—OH_{μ_3} distances [1.942(5) and 1.953(5) Å].

In **3**, the coordination environments around the Cu atoms are also different. The basal plane around Cu1, with bond distances in the range 1.909–1.992 Å, is formed by two nitrogen atoms of one bpy molecule and by the two oxygen atoms of one dianionic bidentate chelating mandelato molecule. The apical position is occupied by the triple-bridging OH ligand at 2.385(3) Å. The equatorial plane of Cu2, with bond distances in the range 1.959–2.026 Å, consists of two nitrogen atoms (bpy) as well as two oxygen atoms from two OH ligands. The axial site is occupied by the bridging alkoxide oxygen of the mandelato ligand at a distance of 2.208(3) Å. The shortest Cu–Cu distances are 3.0015(12) Å in **3** and 2.9011(13) Å in **4**, which rules out the existence of direct Cu to Cu interactions such as those observed, e.g. in copper acetate (2.64 Å) [31].

In both compounds the four Cu atoms form flat rhomboids with sides of length 2.9011(13) Å (Cu1–Cu2) and 3.5225(15) Å (Cu1–Cu2^a, a = 1 − *x*, 1 − *y*, −*z*) in **4** and 3.4964(9) Å (Cu1–Cu2) and 3.1023(9) Å (Cu–Cu2^a, a = −*x*, −*y*, −*z*) in **3**. The short diagonals of the rhomboids (Cu2–Cu2^a) are 3.177(7) Å in **4** and 3.0015(12) Å in **3** and the long diagonals (Cu1–Cu1^a) are 5.617(2) Å in **4** and 5.890 Å in **3**.

The "step structures" are defined by three four-membered rings. These rings in **4** are the strictly planar Cu2–O2–Cu2^a–O2^a ring, because there is an inversion center in the middle of this core, and the other two four member ring, Cu2–O1–Cu1–O2 and Cu^a–O1^a–Cu2^a–O2^a, also related by symmetry, which have a dihedral angle between them of 75.0°. In **3** the planar ring is Cu2–O1–Cu2^a–O1^a and the non-planar ring is Cu1–O13–Cu2–O1, with a dihedral angle of 85.8°.

In both tetranuclear compounds the supramolecular organization results from the combination of several weak intermolecular interactions and these are briefly described below.

In **3** the cationic species are assembled through CH···O-type hydrogen bonding to give 2D layers parallel to (001) (Fig. 8). The C···O distances are in the range 3.199–3.443 Å (Table 5). In all of these interactions the acceptor is the uncoordinated oxygen atom (O12) of the MANO ligand and the donors are CH-bpy and CH-MANO groups, as represented in Fig. 8. In this way each cation interacts with four neighboring ones. The 2D layer is also stabilized by π–π stacking interactions between the bpy rings, where the shortest distance between the center of the rings is 3.719 Å and these have a dihedral angle of 3.15°.

These sheets are linked by strong hydrogen bonding between the lattice water, the phglyo anions and the hydroxo and mandelato ligands of cations [Ow···Ophglyo; Ow···Ow; Ow···OMANO and OH(cation)···Ow]. As a result, a chain of hydrogen-bonded phglyo

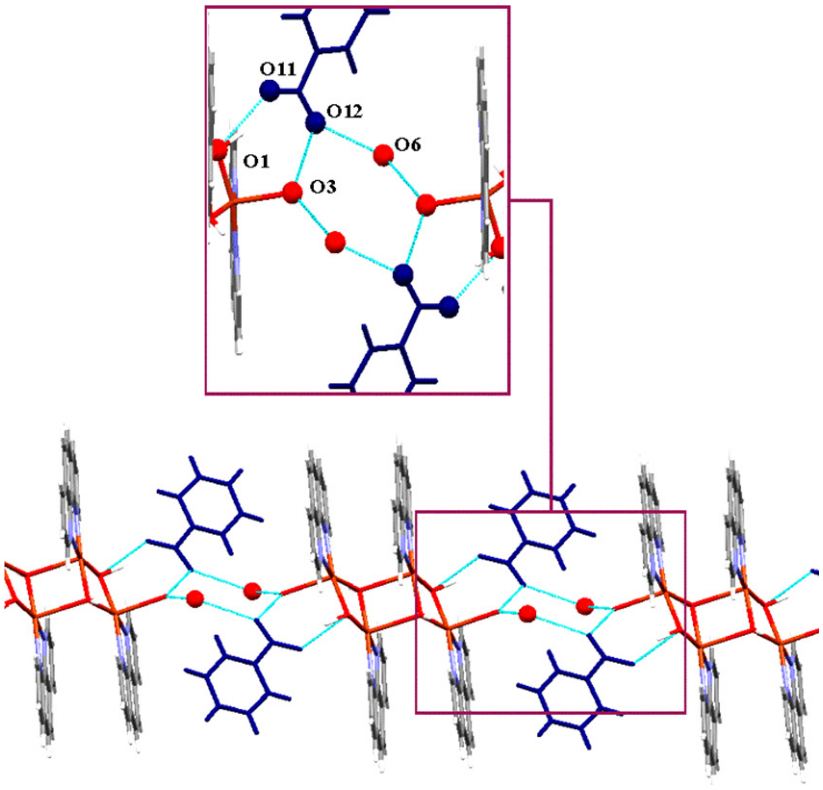

Fig. 10. 1D linkage by hydrogen bonds in **4** (view down the *b*-axis).

anions and water lattice molecules join the sheets of cations, as represented in Fig. 9. The O···O distances (Table 5) range between 2.745 and 2.925 Å.

In **4** a 1D chain, which is represented in Fig. 10, is formed by strong hydrogen bonding, with O···O distances in the range 2.723–2.786 Å (Table 5), showing a characteristic hexagonal pattern involving two benzoate anions, two O6 atoms and the coordinated O3 and the μ_2-OH (O1) of two tetranuclear cationic species.

On the other hand, owing to the interdigitation of phen rings, the neighboring 1D chains are self-assembled into 2D sheets through π–π interactions that are characterized by distances of 3.632(5) and 3.736(5) Å and interplanar dihedral angles α of 2.97° and 1.43°, indicating the parallelism of the phen rings (Fig. 11). The interactions C(15)H(phen)···O3 between chains, with a C···O distance of 3.48(1) Å, also contributes to the formation of this 2D sheet.

The intercalation of benzoate anions on both sides of the sheets expands the structure into a 3D network (Fig. 12). As a result of this intercalation, the aromatic ring planes of benzoate anions overlap in an offset or displaced geometry with significant ring slippage [32], to the extent that there are only limited atom-atom interactions, with the shortest distance being 3.47(3) Å for C4···C5 (1 − *x*, −*y*, 1 − z). In the resulting 3D structure the water molecules of crystallization other than O6 (labelled as O5, O7 and O8) are weakly linked by hydrogen bonding with D···A distances greater than 3.2 Å (Table 5), as shown in Fig. 13.

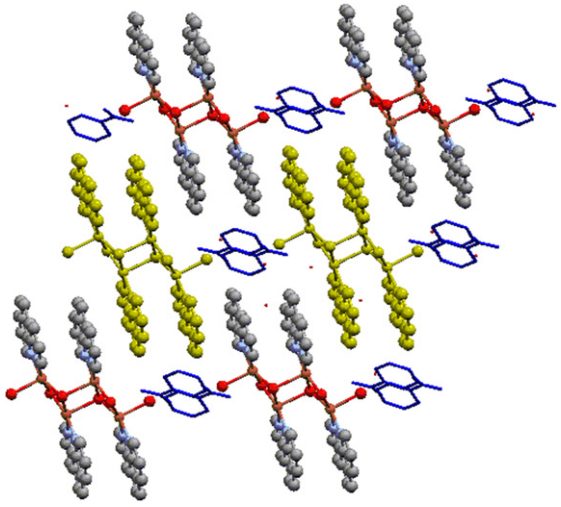

Fig. 11. π–π Stacking interactions between the chains of **4** (view down the *b*-axis).

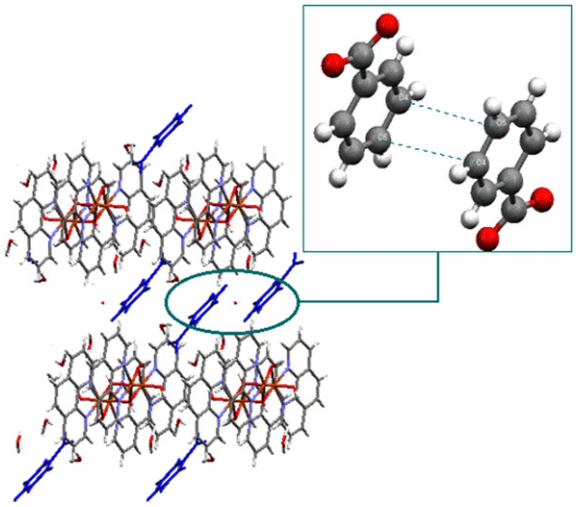

Fig. 12. Interaction between the 2D sheets through the benzoate anions in **4** (down the *c*-axis).

3.2. Oxidative cleavage mechanism

Numerous kinetic studies have been carried out on hydroxy-acid oxidation reactions, particularly using H_2MANO and different oxidizing agents such as (2,2′-bipyridine)copper(II) permanganate [33], potassium permanganate in acid solution [34], lead tetraacetate [35], benzo-dipteridine with Zn^{2+}, Co^{2+} or Ni^{2+} ions and the presence of a basic amine (such as Et_3N) in MeCN or *t*-BuOH [13,36], polyanilines and salts of transition metals such as copper(II) or iron(III) chlorides [37], O_2 and copper(II) [38] or cobalt(II) chlorides [39]. In all cases, it was concluded that the possible pathway for oxidative H_2MANO cleavage follows two different routes depending on the catalytic pathway, giving rise to the formation of benzoic acid (HBza) and/or benzaldehyde (Bz). According to these findings, as well as the results of our own studies, we propose the two routes summarized in Scheme 1.

Route 'a' involves an initial step for the dehydrogenation of H_2MANO and formation of phenylglyoxylic acid (Hphglyo) (1) and a second step for its oxidative decarboxylation to HBza (2) or its decarboxylation to Bz (3). Alternatively, route 'b', which also consists of two steps, begins with oxidative decarboxylation to give Bz (3) followed by the easy and expected oxidation of this aldehyde to HBz.

This dual mechanism has been confirmed by studies in which $CoCl_2$ was used as a catalyst. The results showed that route 'a' for the oxidation of phglyo to Bza is a very slow process, whereas route 'b' for the oxidation of Bz to Bza is a very fast reaction [39].

Our experimental results proved that the phenylglyoxylate anion is included in the formula of compound **3** as a result of the reaction between H_2MANO and Cu^{II} in the presence of bpy. On the other hand, the benzoate anion is also present in compound **4** as a result of a similar reaction, but with phen instead of bpy.

On the basis of the similarities between our studies and those carried out with $CoCl_2$ as a catalyst [39], it seems clear that the specific structure of the aromatic diimine used plays a very important role in determining the route that is followed in the catalytic reaction. Thus, when the reaction in question occurs in the presence of bpy, H_2MANO will be converted in Hphglyo by route 'a' and, be-

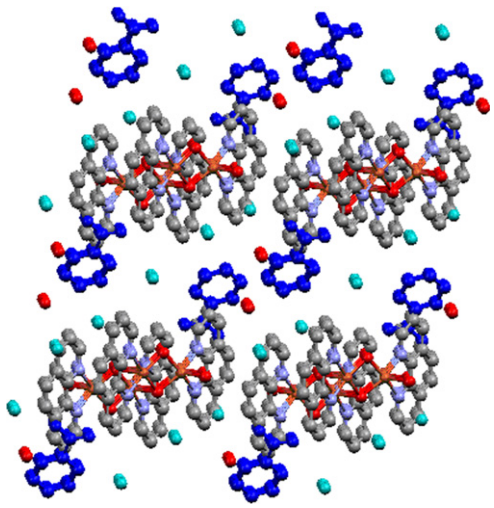

Fig. 13. 3D network in **4**, showing the water molecules of crystallization.

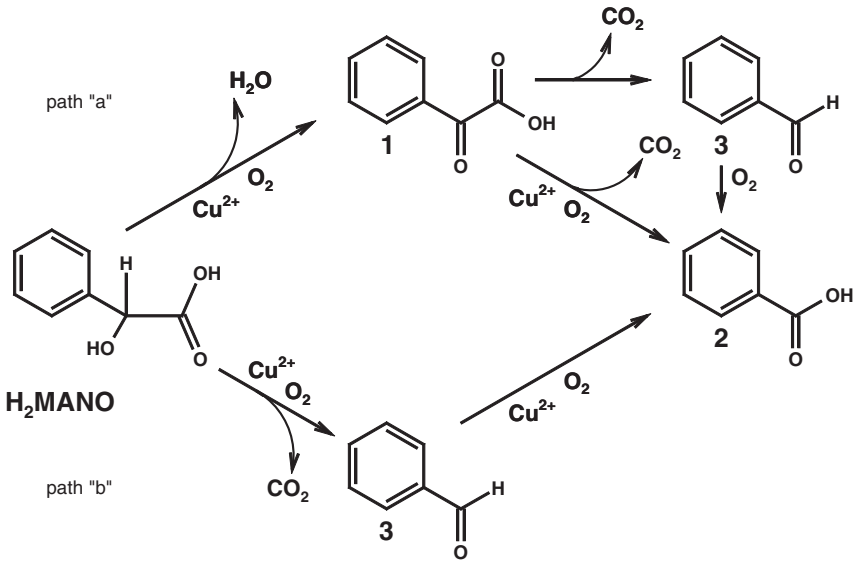

Scheme 1.

cause oxidative decarboxylation of phglyo to Bza is very slow, compound **3** crystallizes with phglyo as a counter-anion. In contrast, when the reaction occurs in the presence of phen, H_2MANO will be converted to Bz by route 'b'. In this case, the rapid oxidation of Bz to Hbza means that compound **4** crystallizes with Bza as a counter-anion.

4. Conclusions

The Cu^{II}/O_2 system in aqueous basic media constitutes a path for the oxidative decarboxylation of mandelic acid. Phenylglyoxylic acid or benzoic acid are obtained, depending on nature of the diimine ancillary ligands. The reaction exhibits an autocatalytic nature and follows two stages, as one of the products [a ternary copper(II) complex] enhances the rate of the reaction. The reaction also represents a confirmation of oxidative decarboxylation of mandelic acid proposed by other authors [39] and, more importantly, the results provide crystallographic evidence to support the oxidation of mandelic acid in the presence of a transition metal ion.

5. Supplementary data

CCDC 665140, 665139, 638839 and 638840 contain the supplementary crystallographic data for **1**, **2**, 3 and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

binuclear copper(II) complexes containing hexa (amine compartment) and tetra (imine compartment) coordination sites. The amine compartment consists of two secondary nitrogens, two tertiary nitrogens and two phenolic oxygens (N4O2), whilst the imine compartment comprises of two imine nitrogens and two phenolic oxygens (N2O2). In these systems, one metal is in a 6-coordinate site and the other is in a 4-coordinate site, if a ligand like ClO_4^- is coordinated, this site can be made into a 5-coordinate site [14,15]. The antimicrobial studies of the complexes are also discussed.

2. Experimental

2.1. Analytical and physical measurements

Elemental analysis of the complexes were obtained using a Haereus CHN rapid analyzer. ^{1}H NMR spectra were recorded using a JEOL GSX 400 MHZ NMR spectrometer. Electronic spectral studies were carried out on a Hitachi 320 spectrophotometer in the range 200–1100 nm. IR spectra were recorded on a Shimadzu FTIR 8300 series spectrophotometer on KBr disks in the range 4000–400 cm^{-1}. Molar conductivity was measured using an Elico digital conductivity bridge model CM-88 using a freshly prepared solution of the complex in dimethylformamide. The atomic absorption spectral data were recorded using a Varian spectra AA-200 model atomic absorption spectrophotometer. Mass spectra were obtained on a JEOL SX-102 (FAB) mass spectrometer. Cyclic voltammograms were obtained on a CHI-600A electrochemical analyzer. The measurements were carried out under oxygen free conditions using a three-electrode cell in which a glassy carbon electrode was the working electrode, a saturated Ag/AgCl electrode was the reference electrode and a platinum wire was used as the auxiliary electrode. A ferrocene/ferrocenium (1+) couple was used as an internal standard and $E_{1/2}$ of the ferrocene/ferrocenium (Fc/Fc^+) couple under the experimental conditions was 470 mV. Tetra(*n*-butyl)ammonium perchlorate (TBAP) was used as the supporting electrolyte. The room temperature magnetic moment was measured on a PAR vibrating sample magnetometer Model-155. Variable-temperature magnetic studies were performed on a PAR model 155 vibrating sample magnetometer in the temperature range 77–300 K, and the instrument was calibrated using metallic nickel as supplied with the instrument. The X-band ESR spectra of the Cu(II) complexes were recorded using DMF as a solvent at liquid nitrogen temperature on a Varian EPR-E 112 spectrometer with diphenylpicrylhydrazine (DPPH) as the reference. The catalytic oxidation of catechol to *o*-quinone and the hydrolysis of 4-nitrophenylphosphate by the copper(II) complexes were studied in a 10^{-3} M dimethylformamide solution. The reaction was followed spectrophotometrically by choosing the strongest absorption band of *o*-quinone at 390 nm and monitoring the increase in the absorbance, and the hydrolysis of 4-nitrophenylphosphate was monitored by following the UV absorbance change at 420 nm (assigned to the 4-nitrophenolate anion) as a function of time. A plot of $\log(A_\infty/A_\alpha - A_t)$ versus time was made for each complex and the rate constant for the catalytic oxidation and the hydrolysis of 4-nitrophenylphosphate was calculated.

2.1.1. Chemicals and reagents

5-Methyl salicylaldehyde [21], 3-chloromethyl-5-methyl salicylaldehyde [22], 1,4,8,11-tetraazatricyclo [9.3.1.1^{4,8}] hexadecane [23] and 1,8-[bis(3-formyl-2-hydroxy-5-methyl)benzyl]-4,11-diazaniatricyclo[9.3.1.1^{4,8}]hexadecane dichloride [quaternary ammonium salt] [24] were prepared by following the literature methods. Analytical grade methanol, acetonitrile and dimethylformamide were purchased from Qualigens and were used as such. TBAP, used as a supporting electrolyte in the electrochemical measurements, was purchased from Fluka and recrystallised from hot methanol. **Caution!** TBAP is potentially explosive; hence care should be taken in handling the compound. All other chemicals and solvents were of analytical grade and were used as received without any further purification.

2.2. Synthesis of the ligand (L)

2.2.1. Synthesis of 1,8-[bis(3-formyl-2-hydroxy-5-methyl)benzyl]-l,4,8,11-tetraazacyclotetradecane (L)

The compound 1,8-[bis(3-formyl-2-hydroxy-5-methyl)benzyl]-4,11-diazaniatricyclo[9.3.1.1^{4,8}]hexadecane dichloride (1 g, 0.0017 mol) was dissolved in 200 ml of an aqueous NaOH solution (0.3 M) with stirring. Excess NaOH is used to hydrolyze the methylene bridge inside the cyclam unit. After stirring for 4 h, the solution was extracted with $CHCl_3$ (5 × 30 mL). The combined $CHCl_3$ extracts were dried with anhydrous $MgSO_4$, and then concentrated under vacuum to give the expected compound 1,8-[bis(3-formyl-2-hydroxy-5-methyl)benzyl]-l,4,8,11-tetraazacyclotetradecane. Yield: 72%. M.p.: 282 °C (dec). *Anal.* Calc. for $C_{28}H_{40}N_4O_4$: C, 67.72; H, 8.12; N, 11.28. Found: C, 67.64; H, 8.02; N, 11.17%; IR data (KBr disc, cm^{-1}): 3389, 3285, 1680; ^{1}H NMR, δ (ppm in $CDCl_3$): 1.5 (m, 4H, β-CH_2), 2.32 (m, 18H, α-CH_2), 2.51 (s, 6H Ar-CH_3) 4.1 (s, 4H, N–CH_2-Ar), 7.26 (d, 4H, Ar-H), 9.92 (s, 2H, Ar-CHO), 12.54 (2H, br s, Ar-OH). ^{13}C NMR, δ (ppm in $CDCl_3$): 28.3, 49.4, 51.6, 54.8., 55.2, 55.7, 60.5, 122.4, 126.2, 126.8, 131.0, 136.8, 157.6, 196.0.

2.3. Synthesis of the macrobicyclic binuclear copper(II) complexes

2.3.1. $[Cu_2L^{1a}(ClO_4)](ClO_4)$

A methanolic solution of copper(II) perchlorate hexahydrate (0.74 g, 0.002 mol) was added to a hot solution of ligand L (1.00 g, 0.002 mol) in methanol, followed by the addition of 1,2-diaminoethane (0.12 g, 0.002 mol) and triethylamine (0.41 g, 0.004 mol) in methanol. After an hour, another 1 equiv. of copper(II) perchlorate (0.74 g, 0.002 mol) was added and the solution was refluxed in a water bath for 24 h. A minute quantity of insoluble polymer complexes was formed in the reaction. The resulting solution was filtered whilst hot to remove these insoluble polynuclear complexes, then all the solvents were removed under reduced pressure. After evaporation of the solvent, a dark green compound was collected by filtration, which was recrystallised in acetonitrile, and dried in vacuum.

Yield: 0.92 g (55%). *Anal.* Calc. for $C_{30}H_{42}N_6O_{10}Cl_2Cu_2$: C, 42.66; H, 5.01; N, 9.95; Cu, 15.06. Found: C, 42.62; H, 4.98; N, 9.98; Cu, 15.01%. FAB mass (*m*/*z* (%)): $[Cu_2L^{1a}(ClO_4)–ClO_4]^+$ 745. Conductance (Λ_m, S cm^2 mol^{-1}) in DMF: 77. Selected IR data (KBr, cm^{-1}): 3327, 1618, 1103, 1197, 1088, 626. λ_{max}, nm (ε, M^{-1} cm^{-1}) in DMF: 749 (sh), 555 (184), 357 (10800), 269 (14400). g = 2.10, μ_{eff}: 1.44 B.M.

The complexes $[Cu_2L^{1b}(ClO_4)](ClO_4)$, $[Cu_2L^{1c}(ClO_4)](ClO_4)$, $[Cu_2L^{1d}(ClO_4)](ClO_4)$ and $[Cu_2L^{1e}(ClO_4)](ClO_4)$ were synthesized by following the above procedure using 1,3-diaminopropane (0.15 g, 0.002 mol), 1,4-diaminobutane (0.18 g, 0.002 mol), 1,2-diaminobenzene (0.22 g, 0.002 mol) and 1,8-diaminonaphthalene (0.32 g, 0.002 mol) respectively, instead of using 1,2-diaminoethane.

2.3.2. $[Cu_2L^{1b}(ClO_4)](ClO_4)$

Dark green compound. Yield: 0.94 g (55%). *Anal.* Calc. for $C_{31}H_{44}N_6O_{10}Cl_2Cu_2$: C, 43.36; H, 5.16; N, 9.79; Cu, 14.80. Found: C, 43.32; H, 5.13; N, 9.75; Cu, 14.78%. 3. Results and discussion

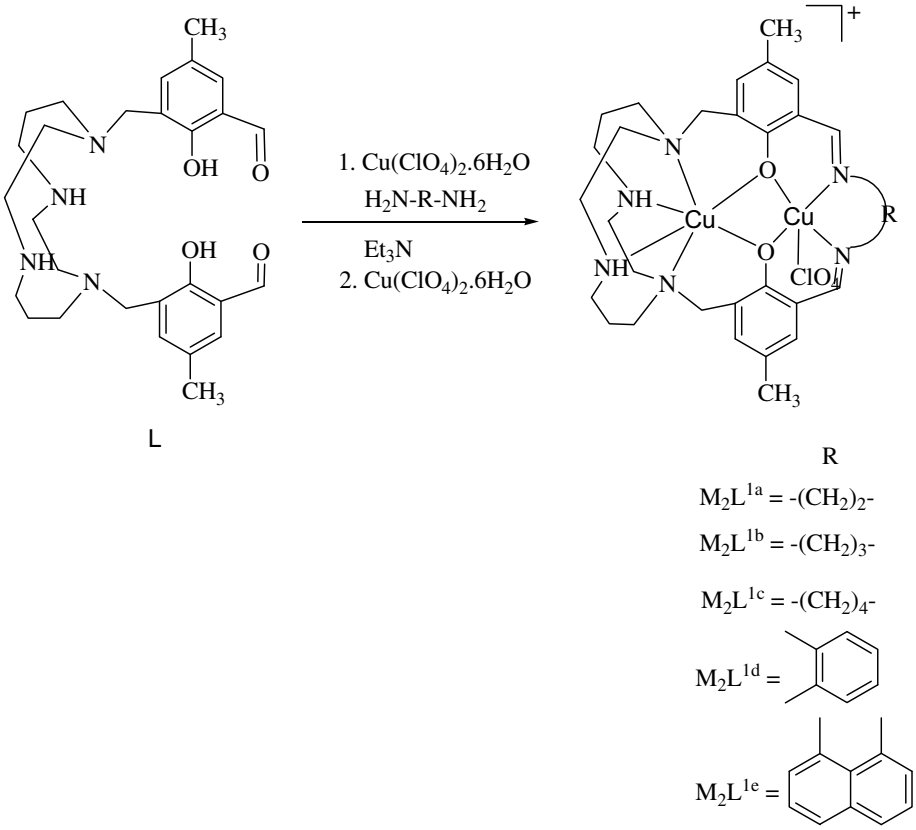
A series of macrobicyclic binuclear copper(II) complexes were synthesized by the Schiff's base condensation of the ligand (L) with diamines in the presence of the metal ion. The synthetic pathway for the binuclear complexes is shown in Scheme 1. In all the binuclear copper(II) complexes, one of the copper(II) ions is in the amine compartment and is six coordinated, whilst the other is in the imine compartment and is five coordinated. All attempts to grow single crystals of the complexes (e.g. by the diffusion of diethyl ether vapor into DMF solutions or recrystallisation of the complexes from acetonitrile) failed and only dark green powders or micro crystals were obtained. Spectral, electrochemical, catalytic data and antimicrobial activities of the complexes were recorded.

3.1. Spectral studies

The IR spectra of all the binuclear copper(II) complexes show bands in the region 3327–3353 cm^{-1}, indicating the presence of NH groups in the complexes. The IR spectra of ligand L shows a band at 1680 cm^{-1} due to the presence of a C=O (–CHO) group. All the complexes show a sharp band in the region 1618–1629 cm^{-1} due to the presence of C=N in the complexes. This shows that the aldehyde groups have been completely converted into imine groups, by the disappearance of the aldehydic C=O stretching band at around 1680 cm^{-1} and the appearance of a strong band at around 1618–1629 cm^{-1} assigned to the C=N stretching vibration mode (Schiff-base condensation) [25–27]. All the binuclear copper(II) complexes showed two sharp peaks at near 1100 cm^{-1} and a peak at around 630 cm^{-1}, which are assigned to perchlorate ions [28]. The peak around 1100 cm^{-1} is split, which clearly explains the presence of a coordinated perchlorate ion [29], while the other peak does not show any splitting, indicating the presence of an uncoordinated perchlorate ion. The peak around 630 cm^{-1} belongs to a perchlorate bending vibration and this peak would not show any splitting even if the perchlorate



Scheme 1.

coordinates to a metal. The IR spectral data of the complexes clearly shows the presence of two different types of perchlorate ions. Further, the appearance of new bands in the region 1530–1558 cm^{-1} in all the complexes suggests the presence of phenoxide bridging between the metal ions [30].

The electronic spectra of the copper(II) complexes were obtained in DMF medium. The electronic spectra of all the complexes exhibit three main features. One or two peaks in the range 250–300 nm are assigned to the intra ligand charge transfer transition (π–π^*). An intense peak in the range 380–420 nm is due to a ligand-to-metal charge transfer transition, and the d–d transition for the copper(II) complexes shows one peak in the region 555–672 nm and a shoulder at around 750 nm, which are characteristic of Cu^{2+} in a 5/6 coordination environment [31]. The electronic spectral studies inferred that an increase in λ_{max} (red shift) of the d–d transition of the copper(II) ion in the ligand L^{1a} to L^{1c} and L^{1d} to L^{1e} indicates that the coordination geometry around the copper atom of the complexes is more distorted. This is due to the flexibility of the macrocyclic ring upon increasing the chain length of the imine compartment, which causes more distortion of the geometry [32,33].

3.2. ESR spectral analysis

The room temperature solid state X-band ESR spectra of the binuclear copper(II) complexes were obtained. A broad spectrum with no hyperfine splitting was obtained for the binuclear copper(II) complexes with $g = 2.10$ indicating the presence of an antiferromagnetic interaction [34] between the two copper ions.

3.3. Magnetic studies

The room temperature magnetic moment of the binuclear copper(II) complexes is in the range 1.31–1.55 B.M., which are less than the total spin-only values. The lowering of these magnetic moments is due to antiferromagnetic coupling by superexchange through the phenolic oxygen atoms [35–38]. To evaluate the singlet–triplet energy separation ($-2J$), variable temperature magnetic studies for the binuclear copper(II) complexes $[Cu_2L^{1a}(ClO_4)](ClO_4)$, $[Cu_2L^{1c}(ClO_4)](ClO_4)$ and $[Cu_2L^{1e}(ClO_4)](ClO_4)$ were performed in the temperature range 77–298 K, and the experimental magnetic susceptibility values were fitted to the modified Bleaney–Bowers equation [35b].

$$\chi_m = (N_g^2\beta^2/3kT)[3 + exp(-2J/kT)]^{-1}(1 - P) + (0.45P/T) + N_\alpha,$$

where χ_M is the paramagnetic susceptibility per metal atom after the correction for diamagnetism, P is the fraction of monomeric copper(II) impurities, $-2J$ = singlet–triplet energy separation. $N = 120 \times 10^{-6}$ cm^3 mol^{-1} and $g = 2.20$ for all magnetic simulations. The effective magnetic moment was calculated using the relationship $\mu = 2.828\ (\chi_M \times T)^{1/2}$. Plots of χ_{Cu} versus T and μ_{Cu} versus T for the complexes $[Cu_2L^{1c\ and\ e}(ClO_4)](ClO_4)$ are shown in Figs. 1 and 2. The observed $-2J$ value for the binuclear copper(II) complex $[Cu_2L^{1a}(ClO_4)](ClO_4)$ is 172 cm^{-1}, for $[Cu_2L^{1c}(ClO_4)](ClO_4)$ it is $-2J = 154$ cm^{-1}, and for $[Cu_2L^{1e}(ClO_4)](ClO_4)$ it is 236 cm^{-1}.

Since the nature of the donor atoms and endogenous bridging groups in all the complexes are same, it seems very interesting to compare the magnetic properties of the binuclear copper(II) complexes based on the increasing chain length of the imine compartment to discover the possible effects on the spin exchange interactions in the complexes. As observed in the electrochemical studies, here also a smaller $-2J$ value is observed for the complexes $[CuL^{1a\ and\ c}(ClO_4)]ClO_4$ (-$2J$ = 172 and 154) when compared to the complex $[Cu_2L^{1e}(ClO_4)](ClO_4)$, ($-2J = 236$ cm^{-1}). This may be due to the distorted geometry around the copper atoms as a result of the increasing chain length of the imine compartment, which causes more distortion of the geometry [38]. Reports suggest that both distortion from planar geometry [38] and reduction in electron density on the copper atoms [39] are less favorable for effective spin exchange interactions, and hence smaller exchange integral values were observed for the complexes of the ligands L^{1a} and L^{1c} compared to the complex of the ligand L^{1e}. The most probable reason for the strong antiferromagnetic exchange interaction in the L^{1e} complex may be the greater planarity due to the presence of aromatic diimine ($-2J = 236$ cm^{-1}).

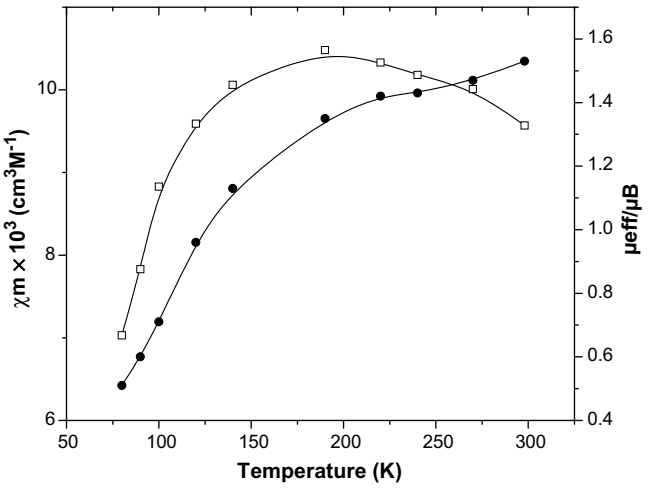

Fig. 2. Temperature-dependence magnetic properties for complex $[Cu_2L^{1e}(ClO_4)](ClO_4)$ where ● is μ_{eff}/μ_B and □ is χ_M.

3.4. Electrochemical properties of the complexes

The electrochemical behavior of the complexes was studied by molar conductance measurements and cyclicvoltammetry in dimethylformamide containing 10^{-1} M tetra(*n*-butyl)ammonium perchlorate. All the complexes show a molar conductance in the range 77–89 Λ_m/S cm^2 mol^{-1} which indicate that the complexes are 1:1 electrolytes [40]. This shows that one of the perchlorates is coordinated to one of the copper atoms. The electrochemical data are summarized in Table 1.

Table 1
Electrochemical[a] (reduction at cathodic potential), hydrolysis of 4-nitrophenylphosphate[b] and catecholase[b] activity data for the complexes

No.	Complexes	E^1_{pc} (V)	E^2_{pc} (V)	Rate constant (k) ($\times 10^{-2}$) min^{-1}	
				NPP	Catecholase

[b] Measured spectrophotometrically in DMF. Concentration of the complexes: 1×10^{-3} M. Concentration of 4-nitrophenylphosphate: 1×10^{-1} M.

3.5. Reduction process at negative potential

The cyclic voltammograms of the copper(II) complexes were recorded in the potential range 0 to −1.4 V in DMF. The cyclic voltammograms for the copper(II) complexes of the ligands L^{1a-1c} are shown in Fig. 3. The macrocyclic doubly phenoxo-bridged dicopper complexes typically undergo two well-separated one electron reductions [41,42]. It is observed that all the binuclear copper(II) complexes show two irreversible reduction waves in the cathodic potential region. The first reduction potential ranges from −0.60 to −1.00 V and the second reduction potential lies in the range −0.94 to −1.26 V. Controlled potential electrolysis was also carried out and the experiment reports that each couple corresponds to a one-electron transfer process. The two reduction processes are assigned as follows:

$$Cu^{II}Cu^{II} \rightarrow Cu^{II}Cu^{I} \rightarrow Cu^{I}Cu^{I}$$

The first reduction potential of the Cu^{2+}/Cu^{+} couple of the $[CuL^{1a-c}(ClO_4)]ClO_4$ complexes in the range −0.60 to −0.78 (Table 1) is similar to that observed for the [Cu(salen)] complexes, and may suggest that the couples observed for these bimetallic complexes refer to reduction of the copper(II) in the 4-coordinate site (imine compartment). Similarly, the second reduction wave is observed for $[CuL^{1a-c}(ClO_4)]ClO_4$ in the range −0.94 to −1.09 V, which is attributed to the reduction of copper(II) in the amine compartment, and may suggest that the couple observed for the bimetallic complexes refers to the reduction of the copper(II) in the 6-coordinate site. Electrochemical studies of similar type complexes with hexa- and tetra coordination sites reported in the literature [42] suggest that the second reduction potential of the binuclear complexes may be assigned to the metal ion in the hexa coordination site.

It is interesting to compare the reduction potential of the copper(II) complexes. It is apparent that the first and second reduction potentials of the binuclear copper(II) complexes of the ligands L^{1a-c} are shifting towards the anodic direction, from −0.78 to −0.60 V and from −1.09 to −0.94 V, respectively, as the number of methylene groups is increased from 2 to 4 in the side chain [43,44]. For example, the first and second reduction potential for the complex $[Cu_2L^{1c}(ClO_4)](ClO_4)$ has E^1_{pc} −0.60 V and E^2_{pc} −0.94 V, which are less negative in comparison to those of the complex $[Cu_2L^{1b}(ClO_4)](ClO_4)$ (E^1_{pc} −0.64 V and E^2_{pc} −1.00 V), which, in turn, are less negative in comparison to those of the complex $[Cu_2L^{1a}(ClO_4)](ClO_4)$ (E^1_{pc} −0.78 V and E^2_{pc} −1.09 V). This shows that as the number of methylene groups between the imine nitrogen (chain length) increases, the entire macrocyclic ring becomes more flexible, which causes easier reduction. This increase in the flexibility increases the cavity size of the macrocyclic ring. Thus, the large size of the cavity can easily hold the reduced cation and stabilizes the formation of Cu(I) in both the compartments. The observed reduction potentials for $[Cu_2L^{1d}(ClO_4)](ClO_4)$ (E^1_{pc} −1.00 V and E^2_{pc} −1.26 V) and $[Cu_2L^{1e}(ClO_4)](ClO_4)$ (E^1_{pc} −0.91 V and E^2_{pc} −1.23 V) show that the reduction of complexes of the ligands L^{1d} and L^{1e} is rather difficult when compared to the reduction of the complexes of the ligands L^{1a-1c} due to the planarity induced by the aromatic ring, which makes the system more rigid. Whatever the precise interpretation of the bimetallic reduction process, it is clear that their magnitude is subject to variation due to changes caused by the nature of the ligand, geometry and by the presence of the other metal [44c].

3.6. Kinetic studies

3.6.1. Hydrolysis of 4-nitrophenylphosphate

The catalytic activity of the copper(II) complexes for the hydrolysis of 4-nitrophenylphosphate was determined spectrophotometrically, following our earlier reports [45a,b]. Plots of $\log(A_\alpha/A_\alpha - A_t)$ versus time for the hydrolysis of 4-nitrophenylphosphate activity of the binuclear copper(II) complexes were obtained and are shown in Fig. 4. The observed initial rate constant values for all the copper(II) complexes are given in Table 1.

The catalytic activities of the binuclear copper(II) complexes are found to increase as the macrocyclic ring size increases, due to the

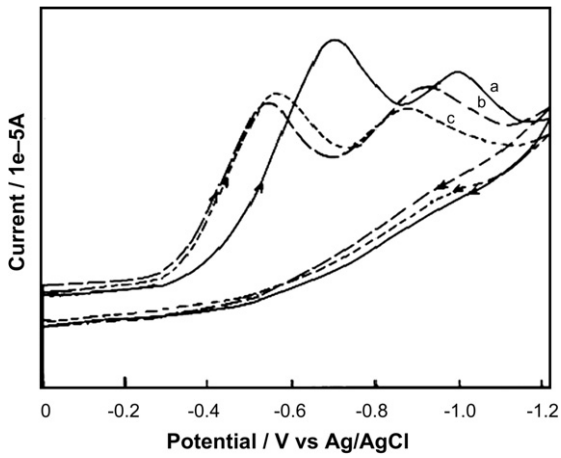

Fig. 3. Cyclic voltammogram of the binuclear copper(II) complexes: (a) $[Cu_2L^{1a}(ClO_4)](ClO_4)$, (b) $[Cu_2L^{1b}(ClO_4)](ClO_4)$, (c) $[Cu_2L^{1c}(ClO_4)](ClO_4)$ (reduction process).

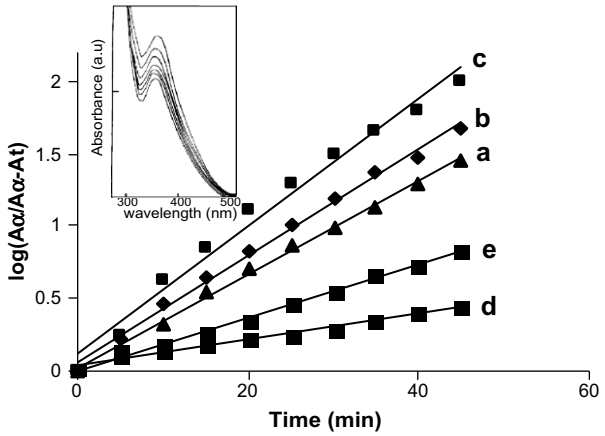

Fig. 4. Hydrolysis of 4-nitrophenylphosphate by binuclear copper(II) complexes: (a) $[Cu_2L^{1a}(ClO_4)](ClO_4)$, (b) $[Cu_2L^{1b}(ClO_4)](ClO_4)$, (c) $[Cu_2L^{1c}(ClO_4)](ClO_4)$, (d) $[Cu_2L^{1d}(ClO_4)](ClO_4)$, (e) $[Cu_2L^{1e}(ClO_4)](ClO_4)$. The inset is the tie dependent growth of the *p*-nitrophenolate chromophore in the presence of $[Cu_2L^{1a}(ClO_4)](ClO_4)$.

intrinsic flexibility, i.e. the increase in the chelate ring size enhances the rate constant of hydrolysis fairly well by producing distortion in the geometry around the metal ion that enhances the accessibility of the metal ion for the bonding of phosphate and OH groups [45c]. The rate constant value for the binuclear copper(II) complex $[Cu_2L^{1c}(ClO_4)](ClO_4)$ is 10.09×10^{-2} min^{-1}, which is higher when compared to complex $[Cu_2L^{1b}(ClO_4)](ClO_4)$ (8.43×10^{-2} min^{-1}), which in turn is more when compared to the complex $[Cu_2L^{1a}(ClO_4)](ClO_4)$ (7.46×10^{-2} min^{-1}). The catalytic activity of the complexes containing aromatic diimines $[Cu_2L^{1d}(ClO_4)](ClO_4)$ and $[Cu_2L^{1e}ClO_4)](ClO_4)$ is found to be less than that of the complexes containing aliphatic diimines. This may be due to the planarity associated with aromatic ring which imparts a lower catalytic efficiency due to the rigidity of the system [46–48].

3.6.2. Oxidation of pyrocatechol (catecholase activity)

The catecholase activity of the copper(II) complexes synthesized in the present work was measured using pyrocatechol as a convenient model substrate for the identification of functional models for the metalloenzymes by following our earlier methods [45a,b].

Plots of $\log(A_\alpha/A_\alpha - A_t)$ versus time for the catecholase activity of the binuclear copper(II) complexes were obtained and are shown in Fig. 5 The observed initial rate constant value for the copper(II) complexes is given in Table 1. The complex $[Cu_2L^{1c}(ClO_4)](ClO_4)$ has higher catalytic activity (7.19×10^{-2} min^{-1}) than the complex $[Cu_2L^{1b}ClO_4)](ClO_4)$ (5.46×10^{-2} min^{-1}), which in turn is more active compared to the $[Cu_2L^{1a}ClO_4)](ClO_4)$ (4.81×10^{-2} min^{-1}) complex. From the results it is observed that the rate

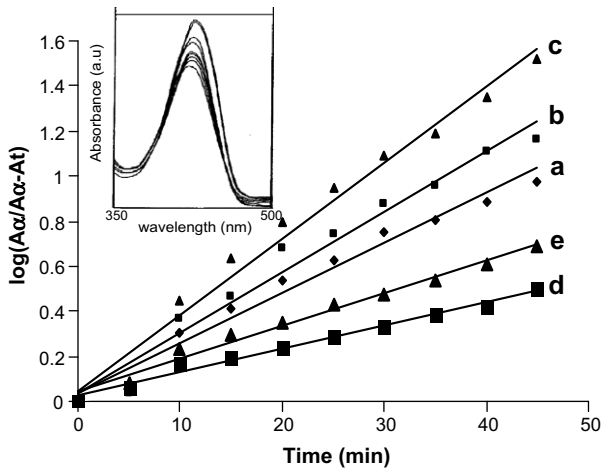

Fig. 5. Catecholase activity of the copper(II) complexes: (a) $[Cu_2L^{1a}(ClO_4)](ClO_4)$, (b) $[Cu_2L^{1b}(ClO_4)](ClO_4)$, (c) $[Cu_2L^{1c}(ClO_4)](ClO_4)$, (d) $[Cu_2L^{1d}(ClO_4)](ClO_4)$, (e) $[Cu_2L^{1e}(ClO_4)](ClO_4)$. The inset is the time dependent growth of the *o*-quinone chromophore in the presence of $[Cu_2L^{1a}(ClO_4)](ClO_4)$.

of oxidation of catechol to *o*-quinone increased as the macrocyclic chain length increased [49a]. The catecholase activity of a highly distorted complex is higher than that of a less distorted complex [49b,c]. It is indeed noteworthy to say that the increase in flexibility due to the increase in the ring size of the macrocycle is a possible reason for the observed higher rate constant value of the complexes.

3.7. Antifungal and antimicrobial activities

Antifungal and antimicrobial activities of the complexes were tested by the cup-plate method using nutrient agar. The radial growth of the colony was recorded on completion of the incubation, and the mean diameter for each complex at a concentration of 100 μg/ml was recorded. The average percentage inhibition of the bactericidal growth medium was compared using the Vincent (Vincent, 1947) equation: $I = 100(C - T)/C$, where I = percentage inhibition, T = average diameter of the bacterial growth on the tested plates and C = average diameter of the growth on the control plates.

3.7.1. Antifungal activity

Studies on the antifungal activity of tetraazamacrocyclic ligands and their complexes are limited in the literature [50–52]. We have evaluated the antifungal activity of all the copper(II) complexes against the phytopathogenic fungus *Candida albicans*. The screening data are reported in Table 2. It is observed from the results that all the tested complexes show some antifungal activity. The activity reported by the present complexes was comparable with the N-substituted tetraazamacrocycles [53,54]. Generally copper(II) and nickel(II) complexes of N-substituted tetraazamacrocycles show higher activity than their corresponding cobalt(III) complexes [55]. Another interesting result observed here is that the complexes of L^{1d} and L^{1e} show higher activity than the complexes of the ligands L^{1a} to L^{1c} which contain aliphatic diimines. It seems from the results that the nature of the ligand and the coordinated metal ion plays a significant role in the inhibition activity. Further the binuclear copper(II) complexes show higher activity than the ligand L.

3.7.2. Antibacterial activity

All the synthesized copper(II) complexes have been screened for their *in vitro* antimicrobial activity against the pathogenic bacteria gram (−) *Escherichia coli* (ATCC 11775), *Pseudomonas aeruginosa* (ATCC 10145), *Bacillus subtilis* (ATCC 6633), *Klebsiella pneumonia* (ATCC 13883) and gram (+) *Staphylococcus aureus* (ATCC 12600) are using the agar dilution method. The screening results are given in Table 2.

All the reported binuclear copper(II) complexes are highly potent against *Pseudomonas aeruginosa*, *Bacillus subtilis*, *Klebsiella pneumonia* and gram (+) *Staphylococcus aureus*. All the tested binuclear copper(II) complexes show moderate activity against gram (−) *Escherichia coli*. All the complexes show superior activity to

Table 2
Antibacterial and antifungal screening data of the complexes

No.	Compound	Representation zone of inhibition					
		Antibacterial (100μg/ml)					Antifungal (100μg/ml)
		Staphylococcus aureus	*Bacillus cearus*	*Klebsiella pneumonia*	*Pseudomonas aureginosa*	*Escherichia coli*	*Candida albicans*
1	$[Cu_2L^{1a}(ClO_4)](ClO_4)$	12	14	14	16	9	12
2	$[Cu_2L^{1b}(ClO_4)](ClO_4)$	12	12	12	14	11	12
3	$[Cu_2L^{1c}(ClO_4)](ClO_4)$	16	18	16	16	11	16
4	$[Cu_2L^{1d}(ClO_4)](ClO_4)$	18	20	22	18	12	22
5	$[Cu_2L^{1e}ClO_4)](ClO_4)$	21	26	24	22	13	21

the ligand L. It is observed from the results that the complexes containing aromatic diimines show higher activity than the complexes containing aliphatic diamines. The observed higher antimicrobial activities of the complexes can be explained on the basis of Tweedy's chelation theory [56]. The lipid membrane that surrounds the cell favors the passage of only lipid soluble materials due to which lipophilicity is an important factor which controls the antimicrobial activity. On chelation, the polarity of the metal ion will be reduced to a greater extent due to the overlap of the ligand orbitals and partial sharing of the positive charge of the metal ion with the donor groups. Further, it increases the delocalization of π-electrons over the whole chelate ring and hence enhances the liposolubility of the complexes. This increased liposolubility enhances the penetration of the complexes into the lipid membrane; the lipophilic group to drive the compound through the semipermeable membrane of the cell; and blocks the metal binding sites in the enzymes of the microorganisms.

The presence of a cyclam unit in the molecule does apparently improve the activity of the complexes. Comparing the activity of the present complexes with the tetraazamacrocyclic copper(II) complexes reported by Roy et al. [57] the present complexes show similar activity. An additional important feature in the biologically active macrocyclic binuclear copper(II) complexes of the present investigation may be imparted by the peculiar nature of the complexes in which the chain length may bring about a change in the coordinating ability. However, further more studies are needed to understand the functions which are responsible for the antifungal and antibacterial activities of the tested complexes.

4. Conclusion

In conclusion, it has been observed that the small variation in the chain length of the imine compartment, (i) causes a red shift in the electronic spectra (ii) shifts the reduction potential anodically on increasing the chain length (iii) shows higher catalytic activity on increasing the chain length. All the complexes show good antimicrobial activity. All these studies of the complexes agree well with the established trends.

2.3. Crystal structure determination

Single crystals of **1** and **2** were mounted on a glass fiber and coated with epoxy resin. X-ray data collection were carried out using a Rigaku Mercury diffractometer (**1**) with a CCD two-dimensional detector and Rigaku R-Axis Rapid II (**2**) with an imaging plate, with graphite monochromated Mo Kα radiation (λ = 0.7107 Å) and at 298(2) K. For **1**, the size of the unit cell was determined from reflections collected on the setting angles of six frames by changing ω by 0.5° for each frame, and intensity data were collected with a ω scan width of 0.5°. For **2**, the size of the unit cell was determined from reflections collected on the setting angles of three frames by changing ω by 3.0° for each frame, and intensity data were collected with a ω scan width of 5.0°. Two different χ settings were used. Empirical absorption correction was performed for all data. The structures were solved by the direct method with subsequent difference Fourier syntheses and the refinement with the SHELXTL (version 5.1) software package [18]. The non-hydrogen atoms were refined anisotropically and hydrogen atoms of pyrazine were placed in calculated positions. The crystal data and structure refinement results are summarized in Table 1. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. Description of the crystal structures

Fig. 1a shows the coordination environment of the copper ion in **1**. In compound **1**, the copper ions adopt a square–pyramidal geometry, defined by trans nitrogen donors from two pyrazine ligands, a sulfate oxygen and an aqua ligand in the equatorial plane and an oxygen atom from the second sulfate group in the axial site, similar to that of $\{[Cu(SO_4)(4,4'\text{-bpy})(H_2O)] \cdot 0.5H_2O\}_n$ [6]. The apical Cu(1)–O(3′) distance of 2.362(5) Å is significantly longer than the equatorial Cu–O distance. In **1**, the Cu(II) ions are linked by pyrazine ligands to form straight one-dimensional chains, and chains in the crystal run parallel along the *a*-axis (Fig. 1b). Each chain is interlinked through sulfate bridges, with axial coordination to Cu(II) ions affording a two-dimensional network (Fig. 1b). The Cu–Cu distance linked by pyz is *ca.* 6.8 Å, and that linked by sulfate ions is *ca.* 4.9 Å. As shown in Fig. 1c, each two-dimensional network is doubly linked by hydrogen bonds of coordinated water molecules with two sulfate oxygen atoms; O(2)···O(4) = 2.67 Å. No solvent molecule other than the coordinated water molecules is contained in the crystal structure of **1**.

Fig. 2a shows the coordination environment of the copper ion in **2**. The copper center is four-coordinated to the two nitrogen atoms of the pyrazine ligands, one water molecule and one oxygen atom of a sulfate ion. The Cu–N bond distances are similar to each other, whereas the Cu–O bond distances are longer, as shown in Table 2. All the bond distances are close to those of typical four-coordinated pyridine complexes [8,19–21], while the geometry around the copper atom is a distorted tetrahedron. Since two protons of coordinated water molecules were determined by X-ray analysis, the oxidation state of copper is +1, considering the stoichiometry in **2**. As shown in Fig. 2b, the pyrazines bridge copper ions to afford zigzag one-dimensional chains. Coordinated water molecules are oriented perpendicular to the chain direction, where each chain is bound by sulfate bridges. The adjacent chains cross at an angle of *ca.* 60°, as shown in Fig. 2c. The Cu–Cu distance of the two copper ions linked by pyz is *ca.* 6.7 Å, and that linked by the sulfate ion is *ca.* 5.8 Å. As in **1**, no solvent molecule other than coordinated water molecules is contained in the crystal structure of **2**.

3.2. Comparison of synthetic conditions for other coordination polymers containing copper and sulfate ions

As mentioned in the experimental section, the significant difference in the synthetic procedure between **1** and **2** is temperature, although the concentrations of the reactant solutions for both compounds are also slightly different. Thus, high temperature (180 °C) probably assists in the reduction of Cu(II) to Cu(I). Table 3 summarizes the synthetic conditions for copper coordination polymers

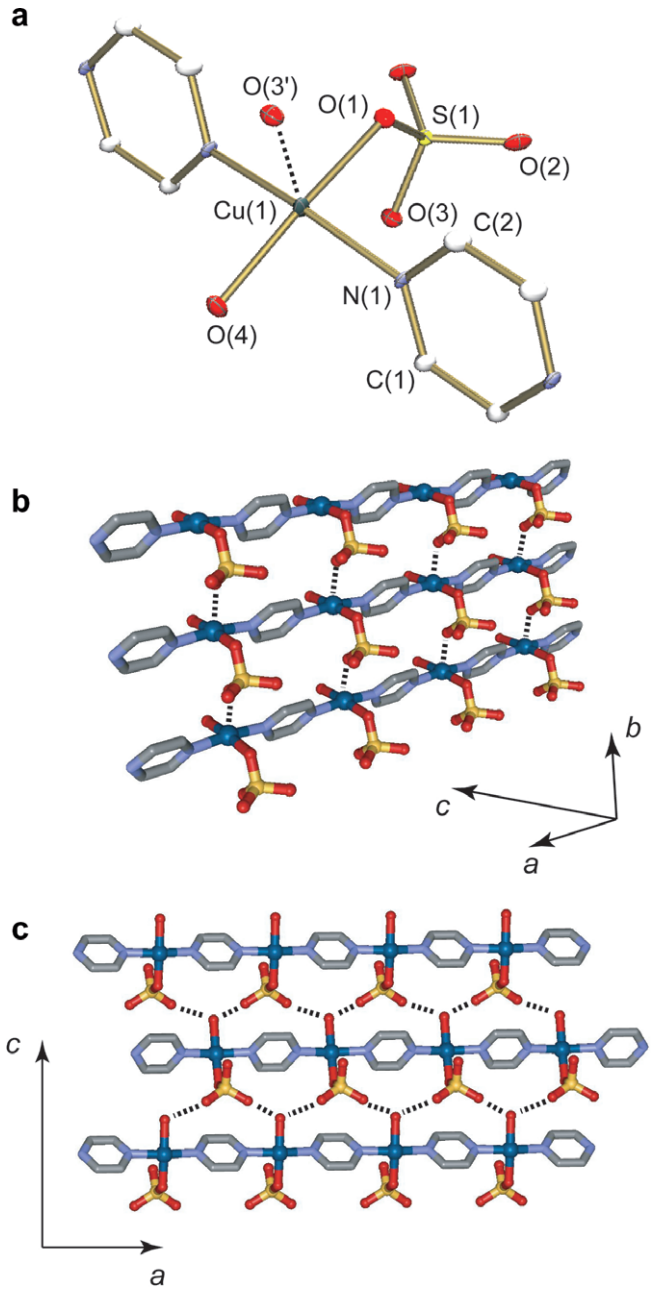

Fig. 1. Crystal structure of $[Cu(SO_4)(pyz)(H_2O)]_n$ (**1**). (a) ORTEP drawing of **1** at the 30% probability level. Hydrogen atoms are omitted for clarity. (b) One-dimensional chains run parallel along the *a*-axis to form a sheet, where SO_4^{2-} anions bridge chains. (c) Overall structure of **1** along the *b*-axis, where each sheet is bound by hydrogen bonds between coordinated water molecules and SO_4^{2-} anions.

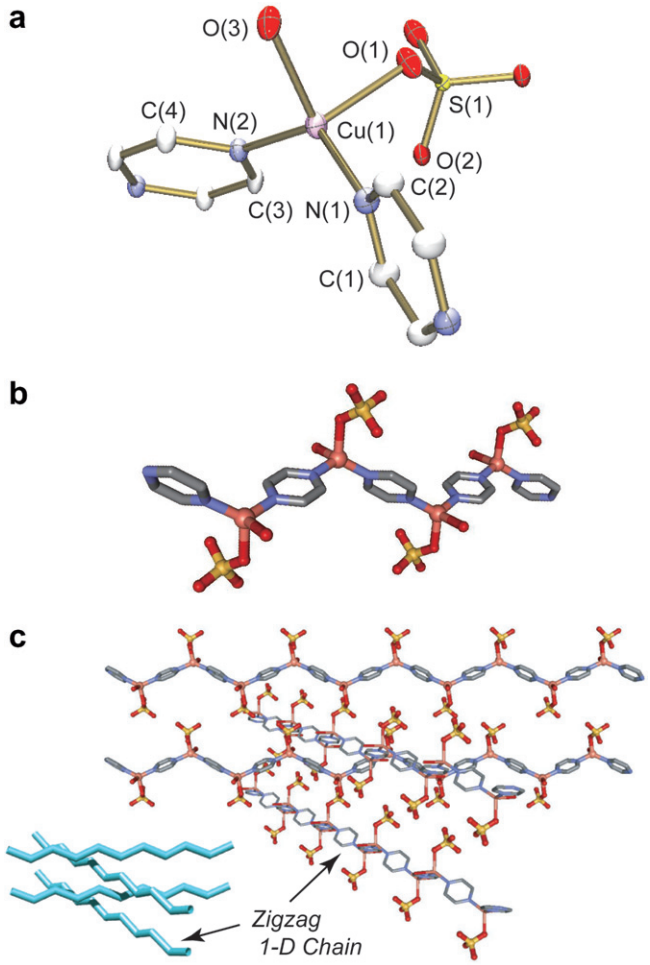

Fig. 2. Crystal structure of $[Cu_2(SO_4)(pyz)_2(H_2O)_2]_n$ (**2**). (a) ORTEP drawing of **2** at the 30% probability level. Hydrogen atoms are omitted for clarity. (b) One-dimensional zigzag chain of $[-Cu-pyz]_n$. (c) Four one-dimensional zigzag chains with the schematic drawing. Each chain is bound with bridging by SO_4^{2-} anions.

comprising sulfate ions and py–X–py type ligands [6,7,22–28], where each compound was synthesized from $Cu(SO_4) \cdot 5H_2O$. The tendency for hot solutions to afford Cu(I) coordination polymers can be seen [6,7]. In addition, room temperature synthesis (namely, self-assembly synthesis) of $Cu(SO_4) \cdot 5H_2O$ and py–X–py-type ligands results in Cu(II) coordination polymers without reduction [22,25–28], although reduction by simple mixing in alcohol at room temperature has been reported several times [19,29].

Taking a previous report into account [4], the reduction of copper ions in **2** would be explained by the Gillard mechanism [30]. This mechanism suggests that attack by nucleophiles occurs at the 2-position of complexed pyridines and induces the reduction of the coordinated metal, releasing H^+ and H_2O_2 species [30]. The

Table 3
Comparison of synthetic conditions (temperature and solvent) for selected coordination polymers comprising copper sulfate and py–X–py type ligands

Compounds	Oxidation state	Synthetic conditions	Ref.
$\{[Cu(SO_4)(4,4'\text{-bpy})(H_2O)] \cdot 0.5H_2O\}_n$	Cu(II)	130 °C (48 h), H_2O	[6]
$\{[Cu_2(SO_4)(4,4'\text{-bpy})_2] \cdot 6H_2O\}_n$	Cu(I)	140 °C (48 h), H_2O/MeOH (v/v = 5:2)	[6]
$\{[Cu_2(SO_4)(4,4'\text{-bpy})_2] \cdot 4H_2O\}_n$	Cu(I)	160 °C (48 h), H_2O	[7]

$\{[Cu(SO_4)(L_2)(H_2O)] \cdot 2H_2O\}_n$	Cu(II)	R.T., H_2O/MeOH (v/v = 2:3)	[27]
$\{[Cu(L_3)_2(H_2O)_2](SO_4)\}_n$	Cu(II)	R.T., H_2O	[28]
$[Cu(SO_4)(pyz)(H_2O)]_n$ (**1**)	Cu(II)	R.T., H_2O	this work
$[Cu_2(SO_4)(pyz)_2(H_2O)_2]_n$ (**2**)	Cu(I)	180 °C (48 h), H_2O	this work

4,4′-bpy = 4,4′-Bipyridine, bpe = 1,2-bis(4-pyridyl)ethane, bpee = *trans*-1,2-bis(4-pyridyl)ethylene, L_1 = 2,5-bis(4-pyridyl)-1,3,4-oxadiazole, L_2 = 2,5-bis(4-pyridyl)-1,3,4-thiadiazole, and L_3 = 1,3-bis(pyridin-4-ylmethyl)urea.

pH of the supernatant solution of **2** is 1.8 in our case, suggesting that high temperature promotes this pathway.

3.3. Infrared spectra of *1* and *2*

The use of vibrational spectroscopy to distinguish between terminal and bridging sulfate ions has been a matter of some interest. The IR bands observed, for the most part, can be separated readily into bands arising either from sulfate anion vibrations or pyrazine vibrations (Fig. S1). In both **1** and **2**, broad bands due to SO_4 stretching vibrations [31] around 1100 cm^{-1} are observed. These can be resolved into three bands each, with one additional medium intensity band, as follows: **1**: 1168, 1115, 1026 and 966 cm^{-1}, **2**: 1154, 1112, 1046 and 974 cm^{-1}. According to previous infrared analyses of sulfate ions [32,33], three infrared lines should be observed in the region from 900 to 1300 cm^{-1} for a unidentate ligand and four for a bidentate ligand, which can be explained by assuming a lowering of symmetry from T_d (free ion) to C_{3v} (unidentate coordination) or C_{2v} (bridged bidentate coordination). Although the crystal structures of **1** and **2** clearly show sulfate bridging between two copper ions, the coordination distance in **1** (2.362(5) Å) is slightly longer (Fig. S2). However, the IR results indicate that sulfate ions act as bidentate ligands in **1**.

4. Conclusion

This work was devoted to the synthesis and analysis of two novel coordination polymers prepared using copper sulfate and pyrazine. Single-crystal X-ray analysis revealed that both **1** and **2** form one-dimensional chains, straight and zigzag respectively, with the configuration determined by the coordination environments. Also, in the system of copper(II) and pyrazine, reduction of Cu(II) assisted by high temperature was observed, and we anticipate such a reduction to be applicable in the construction of Cu(I) coordination polymers using other py–X–py-type ligands.

2. Experimental

2.1. Materials

Commercial ruthenium trichloride, was obtained from Arora Matthey, Kolkata, India, was converted to $RuCl_3 \cdot 3H_2O$ by repeated evaporation with concentrated hydrochloric acid. $AgNO_3$ and dimethylsulfoxide were purchased from Merck, India. Triethylamine, 2,2′-bipyridine, 2,2′,2″-terpyridine, and 1-(2′-pyridylazo)-2-naphthol (Hpan) were purchased from Loba Chemie, Mumbai, India. Pyridine and 4-picoline were purchased from Fluka Chemie. $[Ru(dmso)_4Cl_2]$, $[Ru(trpy)Cl_3]$, $[Ru(bpy)Cl_3]$ and $[Ru(PPh_3)_3Cl_2]$ were synthesized by following reported procedures [7]. Calf thymus (CT) DNA and Tris buffer were procured from Sigma Chemical Company. The dry powder of CT DNA was dissolved in 10 mM Tris buffered saline, pH 7.2 (TBS), and dialyzed overnight against the same buffer so that the A_{260}/A_{280} of the dialyzed solution was greater than 1.90. The DNA concentrations were adjusted according to its absorbance at 260 nm using $\varepsilon_{260} = 6.6\ mM^{-1}\ cm^{-1}$. SC pUC18 DNA and agarose were purchased from Bangalore Genei Pvt. Ltd., Bangalore, India. Purification of dichloromethane, acetonitrile and preparation of tetrabutylammonium perchlorate (TBAP) for electrochemical work were performed as reported in the literature [8]. All other chemicals and solvents were reagent grade commercial materials and were used as received.

2.2. Synthesis

2.2.1. $[Ru(pan)_2]$

Hpan (130 mg, 0.52 mmol) was dissolved in ethanol (50 mL) and triethylamine (55 mg, 0.54 mmol) was added to it. Then $[Ru(dmso)_4Cl_2]$ (100 mg, 0.21 mmol) was added and the mixture was refluxed for 24 h to afford a brownish-violet solution. The solvent was then evaporated and the solid mass obtained was purified by preparative thin layer chromatography on a silica plate using 1:10 acetonitrile–benzene as the eluant. A violet band separated, which was extracted with 1:1 acetonitrile–dichloromethane solution and evaporation of the extract afforded $[Ru(pan)_2]$ as a violet crystalline solid. Yield: 49 mg (40%). *Anal.* Calc. for $C_{30}H_{20}N_6O_2Ru$: C, 60.29; H, 3.35; N, 14.07. Found: C, 60.20; H, 3.39; N, 13.95%. ^1H NMR in $CDCl_3$, δ ppm[1]: 6.61 (t, 2H, $J = 6.2$); 6.85 (d, 2H, $J = 9.2$); 7.32 (d, 2H, $J = 5.3$); 7.39 (t, 4H*); 7.49 (d, 2H, $J = 9.2$); 7.64–7.73 (6H*); 10.07 (d, 2H, $J = 8.5$).

2.2.2. $[Ru(trpy)(pan)]ClO_4$

Hpan (57 mg, 0.23 mmol) was dissolved in ethanol (50 mL) and triethylamine (23 mg, 0.23 mmol) was added to it. Then $[Ru(trpy)Cl_3]$ (100 mg, 0.23 mmol) was added and the mixture was refluxed for 5 h to afford a brownish-red solution. It was then concentrated to about 10 mL, and a saturated aqueous solution of $NaClO_4$ (0.5 mL) was added, whereby a brown precipitate is obtained, which was collected by filtration, washed with cold water, and dried in vacuo over P_4O_{10}. Yield: 100 mg (65%). *Anal.* Calc. for $C_{30}H_{21}N_6O_5ClRu$: C, 52.82; H, 3.08; N, 12.32. Found: C, 52.94; H, 3.14; N, 12.25%. ^1H NMR in $CDCl_3$, δ ppm: 6.50–6.72 (2H*); 6.77 (t, 1H, $J = 6.1$); 7.2–8.0 (10H*); 8.08 (d, 2H, $J = 5.5$); 8.31 (t, 1H, $J = 8.0$); 8.47 (d, 2H, $J = 8.0$); 8.72 (d, 2H, $J = 8.0$); 10.14 (d, 1H, $J = 8.6$).

2.2.3. $[Ru(bpy)(pan)Cl]$

Hpan (70 mg, 0.28 mmol) was dissolved in ethanol (30 mL) and to it was added triethylamine (50 mg, 0.50 mmol). Then $[Ru(bpy)Cl_3]$ (100 mg, 0.28 mmol) was added to the mixture and it was refluxed for 6 h to afford a brown solution. The solvent was then evaporated and the solid mass obtained was purified by preparative thin layer chromatography on a silica plate using 1:5 acetonitrile–benzene as the eluant. A brown band separated, which was extracted with acetonitrile and evaporation of the extract afforded $[Ru(bpy)(pan)Cl]$ as a green crystalline solid. Yield: 104 mg (70%). *Anal.* Calc. for $C_{25}H_{18}N_5OClRu$: C, 55.49; H, 3.33; N, 12.95. Found: C, 55.42; H, 3.39; N, 13.02%. ^1H NMR in $CDCl_3$, δ ppm: 6.65 (t, 1H, $J = 6.4$); 6.78 (d, 1H, $J = 4.8$); 6.85 (d, 1H, $J = 9.2$); 7.00 (t, 1H, $J = 6.5$); 7.26–7.41 (2H*); 7.40 (d, 1H, $J = 9.2$); 7.53 (t, 1H, $J = 7.5$); 7.61–7.65 (2H*); 7.70 (d, 1H, $J = 8.4$); 7.80 (t, 1H, $J = 6.6$); 8.00 (t, 2H, $J = 6.9$); 8.30 (d, 1H, $J = 8.1$); 8.47 (d, 1H, $J = 5.7$); 10.07 (d, 1H, $J = 8.5$); 10.46 (d, 1H, $J = 5.7$).

2.2.4. $[Ru(bpy)(pan)(py)]ClO_4$

To a solution of $[Ru(bpy)(pan)Cl]$ (100 mg, 0.19 mmol) in ethanol (30 mL) was added $AgNO_3$ (31 mg, 0.19 mmol). The mixture was warmed and stirred for 30 min, and the deposited AgCl was separated by filtration. To the filtrate was added pyridine (15 mg, 0.19 mmol). The resulting solution was heated at reflux for 4 h. It was then concentrated to about 10 mL, and a saturated aqueous solution of $NaClO_4$ (0.5 mL) was added, whereby a reddish-brown precipitate is obtained, which was collected by filtration, washed with water, and dried in vacuo over P_4O_{10}. It was further purified by preparative thin layer chromatography on a silica plate. Using 1:5 acetonitrile–benzene as the eluant, a reddish-brown band separated, which was extracted with acetonitrile. Evaporation of this extract gave $[Ru(bpy)(pan)(py)]ClO_4$ as a crystalline solid. Yield: 76 mg (60%). *Anal.* Calc. $C_{30}H_{23}N_6O_5ClRu$: C, 52.66; H, 3.36; N, 12.29. Found: C, 51.97; H, 3.41; N, 12.34. ^1H NMR in $CDCl_3$, δ ppm: 6.81 (d, 2H, $J = 9.2$); 7.09 (t, 1H, $J = 6.3$); 7.19–7.26 (3H*); 7.40 (t, 3H*); 7.51 (d, 1H, $J = 9.3$); 7.60–7.70 (3H*); 7.72–7.81 (4H*); 8.18 (t, 1H, $J = 7.7$); 8.25–8.41 (3H*), 8.57 (d, 1H, $J = 8.0$); 9.82 (d, 1H, $J = 8.4$).

2.2.5. $[Ru(bpy)(pan)(4\text{-}pic)]ClO_4$

This complex was synthesized by following the same above procedure using 4-picoline instead of pyridine. Yield: 77 mg 60%. *Anal.* Calc. for $C_{31}H_{25}N_6O_5ClRu$: C, 53.32; H, 3.58; N, 12.04. Found: C, 53.23; H, 3.49; N, 12.10%. ^1H NMR in $CDCl_3$: δ ppm: 2.38 (s, 3H, CH_3); 6.82 (d, 1H, $J = 9.2$); 7.10 (t, 1H, $J = 6.2$); 7.15–7.20 (4H*); 7.37 (t, 1H, $J = 7.5$); 7.51 (d, 1H, $J = 9.2$); 7.55–7.85 (6H*); 8.00–8.12 (2H*); 8.18 (t, 1H, $J = 7.7$); 8.29–8.24 (3H*), 8.56 (d, 1H, $J = 8.1$); 9.83 (d, 1H, $J = 8.4$).

2.2.6. $[Ru(PPh_3)_2(pan)Cl]$

Hpan (26 mg, 0.10 mmol) was dissolved in ethanol (30 mL) and to it was added triethylamine (10 mg, 0.10 mmol). Then $[Ru(PPh_3)_3Cl_2]$ (100 mg, 0.10 mmol) was added to the solution and it was refluxed for 4 h. The $[Ru(PPh_3)_2(pan)Cl]$ complex separated as a brown precipitate, which was collected by filtration, washed with hexane and dried in air. Yield: 70 mg (74%). *Anal.* Calc. for $C_{51}H_{40}N_3OP_2ClRu$: C, 67.36; H, 4.40; N, 4.62. Found: C, 67.25; H,

[1] Chemical shifts are given in ppm and multiplicity of the signals along with the associated coupling constants (J in Hz) are given in parentheses. Overlapping signals are marked with an asterisk.

4.43; N, 4.66%. ^{1}H NMR in $CDCl_3$, δ ppm: 6.29–6.39 (2H*); 6.7–7.5 (36H*); 7.74 (d, 1H, J = 5.4); 9.20 (d, 1H, J = 8.5). ^{31}P NMR in $CDCl_3$, δ ppm: 24.14.

2.3. Physical measurements

Microanalyses (C, H, N) were performed using a Heraeus Carlo Erba 1108 elemental analyzer. Magnetic susceptibilities were measured using a PAR 155 vibrating sample magnetometer fitted with a Walker Scientific L75FBAL magnet. ^{1}H NMR spectra were recorded in $CDCl_3$ solution on a Bruker Avance DPX 300 NMR spectrometer using TMS as the internal standard. ESR spectra were recorded with a JEOL JES-FA200 X-band spectrometer fitted with a quartz Dewar for measurements at 77 K (liquid dinitrogen). All ESR spectra were calibrated with an aid of DPPH (g = 2.0037). IR spectra were obtained on a Shimadzu FTIR-8300 spectrometer with samples prepared as KBR pellets. Electronic spectra were recorded on JASCO V-570 and Shimadzu 2401 spectrophotometers. Electrochemical measurements were made using a CH Instruments model 600A electrochemical analyzer. A platinum disc working electrode, a platinum wire auxiliary electrode and an aqueous saturated calomel reference electrode (SCE) were used in the cyclic voltammetry experiments. All electrochemical experiments were performed under a dinitrogen atmosphere. All electrochemical data were collected at 298 K and are uncorrected for junction potential. Fluorescence studies were performed with a Hitachi F4500 spectrofluorimeter. Electrophoresis experiments were carried out on a BIORAD electrophoretic system using TBS. The DNA binding studies were carried out as follows: (i) Fluorescence studies were performed with the complex and DNA dissolved separately in TBS, and the samples were excited at 480 nm. (ii) For the DNA–agarose gel studies, SC pUC18 DNA was incubated in the presence of different concentrations of the complexes. These solutions were monitored on agarose gel. The DNA was visualized under UV light.

2.4. X-ray crystallography

Single crystals of $[Ru(pan)_2]$ and $[Ru(PPh_3)_2(pan)Cl]$ were obtained by slow diffusion of acetonitrile into dichloromethane solutions of the complexes, followed by evaporation of the resulting solution. Single crystals of $[Ru(trpy)(pan)]ClO_4$ and [Ru(bpy)-(pan)Cl] were obtained by slow evaporation of a solution of the complex in 1:1 dichloromethane–ethanol and acetonitrile, respectively. Selected crystal data and a summary of the data collection parameters appear below, the full details are provided in Table S1. Data on the [Ru(bpy)(pan)Cl] crystal were collected on a Enraf Nonius CAD-4 diffractometer and those for the other three crystals were collected on an Oxford Diffraction X-Calibur CCD system using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). For these three crystals, X-ray data reduction was carried out using the CRYSALIS program [9c]. The structures were solved by direct methods using the SHELXS-97 program [9a]. In the structure of Ru-$(pan)_2$, the data were very weak and all atoms except for Ru were refined isotropically. In the other structures, all non-hydrogen atoms were refined anisotropically. Empirical absorption corrections were carried out using the ABSPACK program [9b]. The structures were refined on F^2 using the SHELXL-97 program [9a].

Crystal data for $C_{30}H_{20}N_6O_2Ru$, M = 597.59, size 0.05 × 0.05 × 0.30 mm^3, triclinic, space group $P\bar{1}$, a = 8.774(9) Å, b = 12.685(12) Å, c = 12.883(13) Å, α = 62.69(10)°, β = 75.07(9)°, γ = 82.15(8)°, U = 1231(2) Å^3, Z = 2, D_{calc} = 1.612 g cm^{-3}, $F(000)$ = 604, λ = 0.71073 Å, T = 150 K, μ = 0.679 mm^{-1}, 7248 reflections collected, 5936 unique (R_{int} = 0.225). Final goodness-of-fit = 0.414, R_1 = 0.0701, wR_2 = 0.0878, R indices based on 630 reflections with [$I > 2\sigma(I)$].

Crystal data for $C_{30}H_{21}N_6O_5ClRu$, M = 680.03, size 0.05 × 0.10 × 0.20 mm^3, monoclinic, space group $C2/c$, a = 30.611(4) Å, b = 11.6611(14) Å, c = 16.491(2) Å, $\alpha = \gamma$ = 90°, β = 114.595(13)°, U = 5352.5(13) Å^3, Z = 8, D_{calc} = 1.688 g cm^{-3}, $F(000)$ = 2736, λ = 0.71073 Å, T = 150 K, μ = 0.741 mm^{-1}, 18729 reflections collected, 7821 unique (R_{int} = 0.109). Final goodness-of-fit = 0.615, R_1 = 0.0486, wR_2 = 0.0790, R indices based on 2125 reflections with [$I > 2\sigma(I)$].

Crystal data for $C_{25}H_{18}N_5OClRu$, M = 540.96, size 0.10 × 0.10 × 0.40 mm^3, orthorhombic, space group $P2_12_12_1$, a = 10.2654(9) Å, b = 13.2256(12) Å, c = 15.7074(14) Å, $\alpha = \beta = \gamma$ = 90°, U = 2132.5(3) Å^3, Z = 4, D_{calc} = 1.685 g cm^{-3}, $F(000)$ = 1088, λ = 0.71073 Å, T = 100 K, μ = 0.890 mm^{-1}, 14079 reflections collected, 5257 unique (R_{int} = 0.045). Final goodness-of-fit = 1.03, R_1 = 0.039, wR_2 = 0.0967, R indices based on 5257 reflections with [$I > 2\sigma(I)$].

Crystal data for $C_{52}H_{42}N_3OP_2Cl_3Ru$, M = 994.25, size 0.10 × 0.20 × 0.30 mm^3, monoclinic, spacegroup Cm, a = 18.325(3) Å, b = 15.2504(12) Å, c = 9.6397(8) Å, $\alpha = \gamma$ = 90°, β = 122.099(5)°, U = 2282.1(5) Å^3, Z = 4, D_{calc} = 1.447 g cm^{-3}, $F(000)$ = 1016, λ = 0.71073 Å, T = 150 K, μ = 0.632 mm^{-1}, 7207 reflections collected, 4280 unique (R_{int} = 0.040). Final goodness-of-fit = 1.007, R_1 = 0.0384, wR_2 = 0.0845, R indices based on 3596 reflections with [$I > 2\sigma(I)$].

3. Results and discussion

3.1. Syntheses and crystal structures

The primary objective of the present study, as already mentioned above, has been to synthesize a series of ruthenium complexes containing 1-(2′-pyridylazo)-2-naphthol (Hpan, **1**), either as the sole ligand or as one of the ligands. For preparing the homoleptic ruthenium complex of Hpan, $[Ru(dmso)_4Cl_2]$ has been selected as the starting material because of its demonstrated ability to undergo displacement of all the six monodentate ligands by chelating ligands [2j,2n]. Reaction of Hpan with $[Ru(dmso)_4Cl_2]$ in refluxing ethanol in the presence of triethylamine has indeed afforded the expected bis-complex, *viz.* $[Ru(pan)_2]$, in a decent yield (Scheme 1). In order to authenticate coordination mode of ligand (**1**) in this complex, its structure has been determined by X-ray crystallography. The structure is shown in Fig. 1 and selected bond parameters are given in Table 1.

The structure shows that in this complex 1-(2′-pyridylazo)-2-naphthol is coordinated to the metal center, via dissociation of the phenolic proton, as a monoanionic N,N,O-donor (**2**, M = Ru),

with N–Ru–N and N–Ru–O bite angles of ~79°. In this complex ruthenium is thus sitting in a N_4O_2 coordination sphere, which is significantly distorted from ideal octahedral geometry, primarily because of the strain imposed by the two adjacent five-membered chelate rings. The phenolic C–O distance is normal [2n], while the average N–N distance is notably longer than that in uncoordinated azo ligands [10] and the observed elongation is attributable to the metal-to-π^*(azo) back-bonding [11]. The absence of any solvent of crystallization in the crystal lattice of $[Ru(pan)_2]$ indicates the possible existence of non-covalent interactions between the individual complex molecules. To sort this out, packing pattern in the lattice has been examined, which shows that hydrogen-bonding interactions of two types, *viz.* C–H···O and C–H···π interactions, are active in the lattice (Fig. 2). The phenolate-oxygen of each coordinated pan of any complex molecule each coordinated pan of any complex molecule is hydrogen-bonded to two aryl hydrogens of two other pan ligands belonging to two different complex molecules. The δ-hydrogen in the azo-linked phenyl ring of the naphthol fragment of each pan is involved in a C–H···π interaction with the π-cloud over the other ring of the naphthol fragment of another pan of a second neighboring complex molecule. Both of these hydrogen-bonding interactions are extended throughout the entire lattice, and they appear to be responsible for holding the crystal together.

As 1-(2′-pyridylazo)-2-naphthol (**1**) serves as a N,N,O-donor and forms a planar chelate (**2**), in the Ru(pan) fragment only three coordination sites on ruthenium remain accessible. To occupy these three available sites either a planar tridentate ligand, or a combination of a bidentate and a monodentate ligand, or three monodentate ligands can be utilized to obtain the mixed-ligand complexes. Accordingly three different ruthenium starting materials, *viz.* $[Ru(trpy)Cl_3]$ (trpy = 2,2′,2″-terpyridine), $[Ru(bpy)Cl_3]$ (bpy = 2,2′-bipyridine) and $[Ru(PPh_3)_3Cl_2]$, have been chosen. Reactions of ligand (**1**) with these three starting materials in refluxing ethanol in the presence of triethylamine have afforded the targeted mixed-ligand complexes, *viz.* $[Ru(trpy)(pan)]^+$ (isolated as the perchlorate salt), [Ru(bpy)(pan)Cl] and $[Ru(PPh_3)_2(pan)Cl]$, respectively, in good yields (Scheme 1). It is interesting to note here that during synthetic reactions of Hpan with $[Ru(trpy)Cl_3]$ and $[Ru(bpy)Cl_3]$, ruthenium undergoes a one-electron reduction, and either the solvent (ethanol) or the base (NEt_3) might have served as the reducing agent. Structures of these three mixed-ligand complexes have also been determined by X-ray crystallography. Structure of the $[Ru(trpy)(pan)]ClO_4$ complex (Fig. 3) shows that in it the pan ligand is coordinated to ruthenium as before. The remaining three coordination sites on ruthenium are occupied by the three terpyridine-nitrogens in the usual manner. The N_5O coordination sphere around ruthenium is similarly distorted from ideal octahedral geometry as in $[Ru(pan)_2]$, because like the 1-(2′-pyridylazo)-2-naphtholate anion (pan), terpyridine also forms two adjacent five-membered chelate rings. Bond parameters (Table 1) in the Ru(trpy) fragment are found to be normal, as observed in other structurally characterized complexes of ruthenium having this fragment [12]. Bond lengths in the Ru(pan) fragment are comparable to those observed in the $[Ru(pan)_2]$ complex. An examination of the packing pattern in the lattice of the $[Ru(trpy)(pan)]ClO_4$ complex shows the existence of three types of hydrogen-bonding interactions, *viz.* C–H···O, C–H···N and C–H···π interactions (Fig. S1). Two perchlorate-oxygens are hydrogen-bonded to pyridyl-hydrogens of the terpyridine. One pyridyl-hydrogen of the terpyridine is hydrogen-bonded to an azo-nitrogen of the pan ligand of another complex molecule. The γ-hydrogen of the naphthol fragment of pan is involved in a C–H···π interaction with the π-cloud of the pyridine ring of pan of another complex molecule.

Structure of the [Ru(bpy)(pan)Cl] complex (Fig. 4) shows that the pan ligand is coordinated in the expected N,N,O-mode, while the remaining three sites are occupied by a 2,2′-bipyridine, coordinated in the usual N,N-fashion, and a chloride. The observed Ru–Cl length (Table 1) is normal, and so are the bond distances in the Ru(bpy) fragment [13]. The octahedral N_4OCl coordination sphere

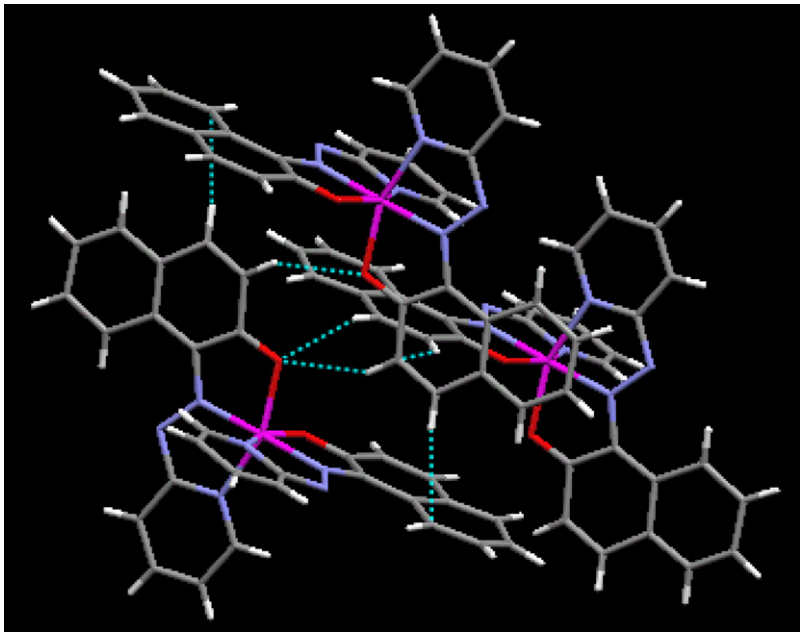

Fig. 2. Packing diagram of $[Ru(pan)_2]$ complex.

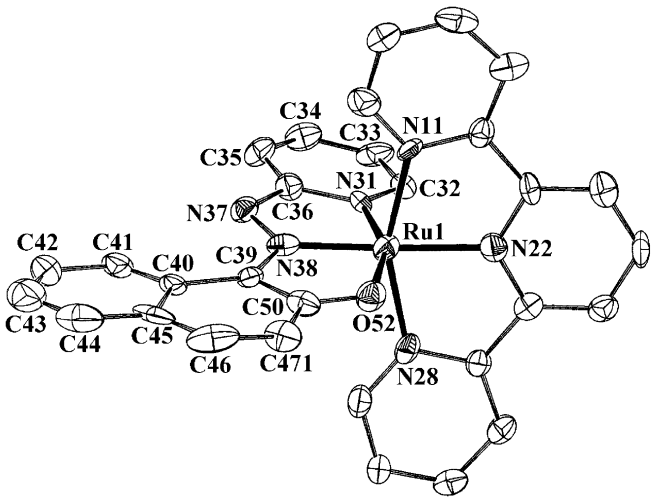

Fig. 3. View of the $[Ru(trpy)(pan)]^+$ complex (ellipsoids at 25% probability, hydrogens not included for clarity).

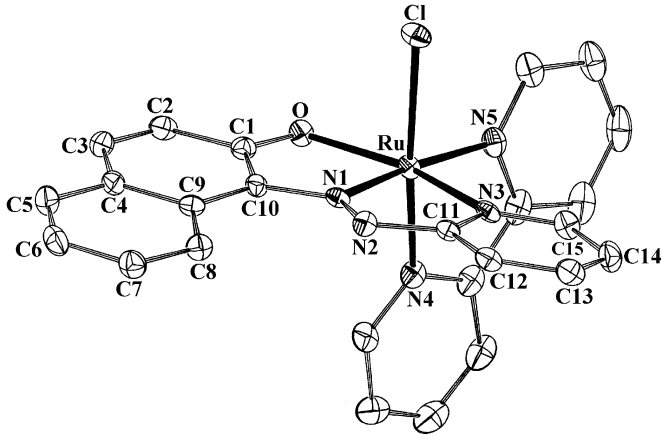

Fig. 4. View of the $[Ru(bpy)(pan)Cl]$ complex (ellipsoids at 25% probability, hydrogens not included for clarity).

in this complex is much less distorted compared to the structures of the $[Ru(pan)_2]$ and $[Ru(trpy)(pan)]^+$ complexes, because of the flexibility associated with a bidentate and a monodentate ligands replacing a tridentate ligand forming two adjacent five-membered chelate rings. An examination of the packing pattern in the lattice of the [Ru(bpy)(pan)Cl] complex shows the existence of three types of non-covalent interactions, *viz.* C–H···O, C–H···Cl and C–H···π interactions (Fig. S2). The phenolate oxygen of pan is hydrogen-bonded to a pyridyl hydrogen of bpy belonging to a neighboring complex molecule. The chloride is hydrogen-bonded to a pyridyl C–H of pan of an adjacent complex molecule. Besides these hydrogen-bonding interactions there are intermolecular C–H···π interactions between two pyridyl C–H's of the bipyridine ligand and naphthyl π-cloud. There is also a C–H···π interaction between a pyridyl C–H of pan ligand of one molecule with a pyridyl π cloud of another.

The structure of the $[Ru(PPh_3)_2(pan)Cl]$ complex (Fig. 5) has mirror symmetry and shows the pan ligand and the chloride sharing an equatorial plane with the metal at the center, where the chloride is obviously trans to the coordinated azo nitrogen, and the two triphenylphosphines occupy the remaining two axial positions and hence they are mutually trans. Compared to the structures of the previous complexes, the N_2OP_2Cl coordination sphere in the present complex is far less distorted, which is attributable to the freedom in disposition of three monodentate ligands. The Ru–P lengths (Table 1) are normal [2i], but the Ru–Cl distance is notably longer than that observed in the [Ru(bpy)(pan)Cl] complex and the observed elongation is attributable to stronger trans effect of the azo-nitrogen than that of the bpy-nitrogen. In the crystal lattice of this complex, there exists one molecule of dichloromethane per molecule of the complex. To find out the non-covalent interaction(s) active in the lattice, particularly between the solvent molecule and the complex molecule, packing pattern in the lattice has been examined (Fig. S3), which reveals that each complex molecule is linked to four surrounding complex molecules through C–H···π interactions. The phenyl C–H of triphenylphosphine is involved in non-covalent interaction with the π cloud on both the pyridyl and naphthyl ring of pan. Each coordinated chloride is engaged in C–H···Cl hydrogen bonding with the hydrogens of the nearest dichloromethane molecule.

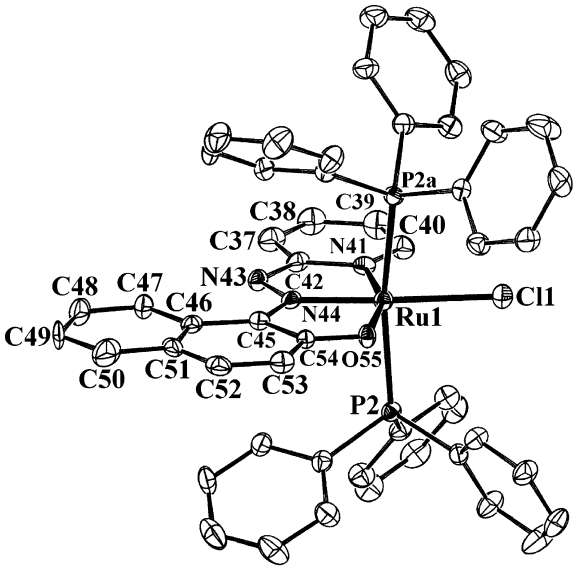

Fig. 5. View of the $[Ru(PPh_3)_2(pan)Cl]$ complex (ellipsoids at 25% probability, hydrogens not included for clarity).

The coordinated chloride in the [Ru(bpy)(pan)Cl] complex has been found to undergo facile displacement by other monodentate ligands under relatively mild condition. This has been manifested in the reactions of [Ru(bpy)(pan)Cl] with pyridine (py) and 4-picoline (pic) carried out in ethanolic medium in the presence of silver ion, for easy removal of the coordinated chloride, which have yielded the desired mixed-ligand complexes, *viz*. $[Ru(bpy)(pan)(py)]^+$ and $[Ru(bpy)(pan)(pic)]^+$, isolated as perchlorate salts in good yields. Composition of these two complexes has been verified by their microanalytical data. Both of these complexes are assumed to have a similar structure as the precursor [Ru(bpy)(pan)Cl] complex, with the chloride replaced by pyridine or 4-picoline.

3.2. Spectral properties

All the six complexes, *viz*. $[Ru(pan)_2]$, $[Ru(trpy)(pan)]ClO_4$, [Ru(bpy)(pan)Cl], $[Ru(PPh_3)_2(pan)Cl]$, $[Ru(bpy)(pan)(py)]ClO_4$ and $[Ru(bpy)(pan)(pic)]ClO_4$, are diamagnetic, which corresponds to the bivalent state of ruthenium (low-spin d^6, $S = 0$) in them. ^1H NMR spectra of these complexes have been recorded in $CDCl_3$ solution and a spectrum has been deposited as supplementary material (Fig. S4). ^1H NMR spectrum of the $[Ru(pan)_2]$ complex shows all the expected signals within 6.5–10.1 ppm, of which the most deshielded doublet at 10.07 ppm is assignable to the proton nearest to the pyridine-nitrogen. Spectra of the other three complexes are complex in nature due to overlap of signals arising from both pan and other organic ligand(s) in the similar region. However, in all these three spectra the isolated doublet near 10.0 ppm, which is diagnostic of coordinated pan, is clearly observed. ^1H NMR spectrum of the $[Ru(bpy)(pan)(py)]ClO_4$ complex shows most of the expected signals clearly, though few signals could not be distinctly identified due to their overlap with other signals. The methyl signal from the 4-picoline fragment of the $[Ru(bpy)(pan)(pic)]ClO_4$ complex is observed at 2.38 ppm, while rest of its ^1H NMR spectrum is very similar to that of the $[Ru(bpy)(pan)(py)]ClO_4$ complex.

Infrared spectra of the complexes show many bands of different intensities within 400–4000 cm^{-1}. Assignment of each individual band to a specific vibration has not been attempted. However, strong bands observed at 1606, 1498, 1199, 1134, 758 cm^{-1} in the spectrum of the $[Ru(pan)_2]$ complex are assignable to the coordinated pan ligand. Such bands are also observed in the other five complexes. In the spectra of the $[Ru(trpy)(pan)]ClO_4$, $[Ru(bpy)(pan)(py)]ClO_4$ and $[Ru(bpy)(pan)(pic)]ClO_4$ complexes two intense bands are observed near 1080 and 620 cm^{-1}, which are attributed to the perchlorate ion. Infrared spectrum of $[Ru(PPh_3)_2(pan)Cl]$ shows sharp bands at 744, 698 and 519 cm^{-1} due to the coordinated PPh_3 ligands.

All the complexes are found to be soluble in ethanol, methanol, acetonitrile, dichloromethane and chloroform, producing reddish-brown solutions. Electronic spectra of the complexes have been recorded in dichloromethane solution. Each complex shows several intense absorptions in the visible and ultraviolet region (Table 2). The absorptions in the ultraviolet region are believed to be due to transitions within the ligand orbitals and those in the visible region are likely to be due to allowed metal-to-ligand charge-transfer transitions. To have a better understanding of the nature of transitions in the visible region, qualitative EHMO calculations have been performed on computer-generated models[2] of all the complexes [14]. Composition of some selected molecular orbitals is given in Table S2 and partial MO diagram of the $[Ru(pan)_2]$ complex is shown in Fig. 6. The top three filled orbitals, *viz*. the highest occupied molecular orbital (HOMO) and the next two filled orbitals (HOMO−1 and HOMO−2), are close in energy and have major contributions from the ruthenium t_2-orbitals and relatively less contributions from the coordinated ligands. The lowest unoccupied molecular orbital (LUMO), though has some contribution from the metal center, is localized mostly on the pan ligand and is concentrated heavily on the azo (-N=N-) fragment. The next couple of vacant orbitals (LUMO + 1, LUMO + 2, etc.) are delocalized over either pan or the co-ligand. The lowest energy absorption in the visible region may therefore be assigned to a transition between the strongly

3.3. Electrochemical properties

Electrochemical properties of all the complexes have been studied by cyclic voltammetry in 1:9 dichloromethane–acetonitrile[3] solution (0.1 M TBAP). The voltammetric data are given in Table 2. All the complexes show two oxidative responses on the positive side of SCE. In view of the composition of the HOMO, the first oxidation is tentatively assigned to the Ru(II)–Ru(III) oxidation. This oxidation is reversible in nature, characterized by a peak-to-peak separation (ΔE_p) of 67–80 mV, which remains unchanged upon changing the scan rate, and the anodic peak-current (i_{pa}) is almost equal to the cathodic peak-current (i_{pc}) as expected for a reversible electron-transfer process. Reversibility of the Ru(II)–Ru(III) oxidation indicates that the one-electron oxidized species might be stable on a time scale much longer than the cyclic voltammetric time scale. To investigate this, as well as to verify assignment of this oxidative response to Ru(II)–Ru(III) oxidation, all the six complexes have been coulometrically oxidized at an appropriate potential[4] in 1:9 dichloromethane–acetonitrile solution (0.1 M TBAP). The oxidations have been smooth and quantitative for each complex. However, the oxidized solutions are found to stable only for the [Ru(bpy)(pan)Cl] and [Ru(PPh$_3$)$_2$(pan)Cl] complexes, which have much less Ru(II)–Ru(III) oxidation potential. For the rest four complexes, color of the solution containing the oxidized species changes rapidly indicating fast decomposition. ESR spectra of solutions containing the [Ru(bpy)(pan)Cl]$^+$ and [Ru(PPh$_3$)$_2$(pan)Cl]$^+$ complexes have been recorded at 77 K. Both the complexes show an axial ESR spectrum with two distinct signals ($g_\perp$ and $g_\parallel$; for the [Ru(bpy)-(pan)Cl]$^+$ complex $g_\perp = 2.28$ and $g_\parallel = 1.90$; for the [Ru(PPh$_3$)$_2$(pan)Cl]$^+$ complex $g_\perp = 2.21$ and $g_\parallel = 1.99$). A selected spectrum is shown in Fig. 7. The observed anisotropic nature of the spectra confirms the +3 oxidation state of ruthenium in the oxidized complexes, which in turn supports assignment of the first oxidative response to Ru(II)–Ru(III) oxidation to be correct. The second oxidative response is irreversible in nature and is tentatively assigned to oxidation of the coordinated pan ligand. A reductive response, quasi-reversible in nature, is displayed by all the complexes near −0.9 V versus SCE, and in view of the composition of the LUMO this reduction is assigned to reduction of the azo (–N=N–) fragment of the coordinated pan ligand. A second irreversible reductive response is observed in the [Ru(trpy)(pan)]ClO$_4$, [Ru(bpy)(pan)Cl],

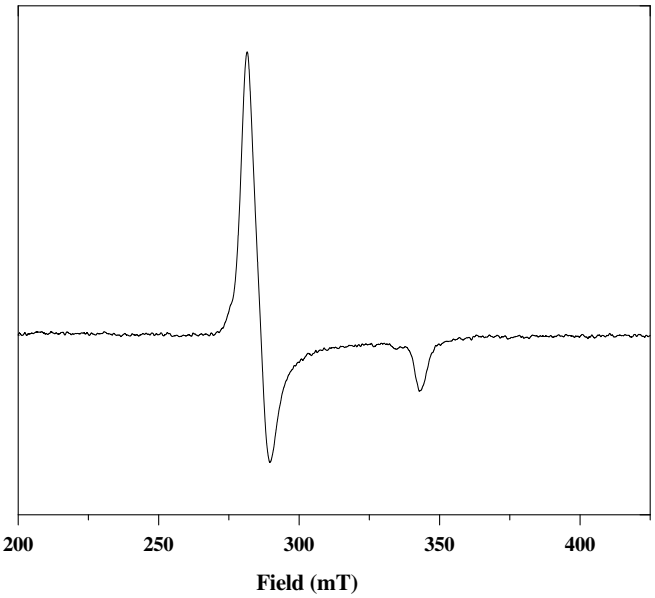

Fig. 7. ESR spectrum of the [Ru^{III}(bpy)(pan)Cl]$^+$ complex in 1:9 dicloromethane–acetonitrile solution at 77 K.

[3] A little dichloromethane was necessary to take the complex into solution. Addition of large excess of acetonitrile was necessary to record the redox responses in proper shape.

[4] Coulometric oxidation has been carried out at a potential 200 mV higher than the anodic peak-potential (E_{pa}).

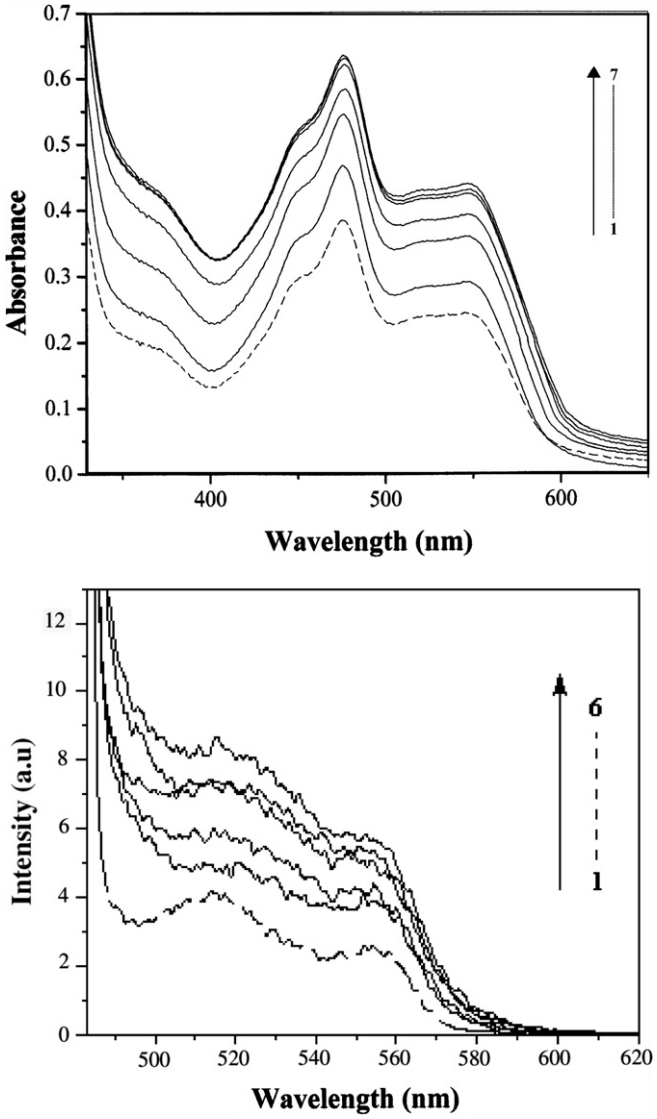

Fig. 8. (a) Absorption spectrum of the [Ru(trpy)(pan)]ClO_4 in Tris–HCl/NaCl buffer (10 mM, pH 7.2) solution in the absence (---) and presence (—) of CT DNA ([DNA]:[complex] = 20:1, 40:1, 50:1, 60:1, 65:1, 70:1; the complex concentration was 30 μM). (b) Fluorescence spectrum of the [Ru(trpy)(pan)]ClO_4 in Tris–HCl/NaCl buffer (10 mM, pH 7.2) solution in the absence (---) and presence (—) of CT DNA ($\lambda_{excitation}$ = 480 nm, [DNA]:[complex] = 40:1, 50:1, 60:1, 65:1, 70:1; the complex concentration was 30 μM).

[Ru(bpy)(pan)(py)]ClO_4 and [Ru(bpy)(pan)(pic)]ClO_4 complexes around −1.6 V versus SCE, which is assigned to reduction of the coordinated polypyridine (trpy or bpy) ligand [13].

3.4. DNA binding properties

As cationic transition metal complexes containing polypyridine ligands are known to display DNA interaction properties [15], we have also explored such possibility in the three such cationic complexes, *viz.* [Ru(trpy)(pan)]ClO_4, [Ru(bpy)(pan)(py)]ClO_4 and [Ru(bpy)(pan)(pic)]ClO_4. These three complexes are fairly soluble in water, another property welcome in DNA binding agents. Interaction of the [Ru(trpy)(pan)]ClO_4 complex with DNA has been monitored initially by absorption and fluorescence spectroscopic studies in Tris–HCl buffer (pH 7.2) solution. In the absorption spectroscopic studies, the maximum at 480 nm, displayed by the complex only, is found to increase in intensity upon addition of DNA. The intensity increases with increasing ratio of [DNA]:[complex] and reaches saturation at [DNA]:[complex] = 70:1 (Fig. 8a). Such increase in intensity of absorption upon interaction with DNA is, though relatively less common, precedent in the literature [16]. In order to explore the interaction one step further, detailed spectrofluorimetric experiments with complex and DNA has also been carried out. The complex shows emission peaks at 515 nm and 554 nm when excited at 480 nm. With the increasing amount of DNA the fluorescence intensity increases for both the peaks (Fig. 8b), and reaches its optimum value in the same ratio (i.e. [DNA]:[complex] = 70:1). Absorption and fluorescence spectroscopic studies in Tris–HCl buffer (pH 7.2) solution in the presence and absence of DNA show that the other two complexes, *viz.* [Ru(bpy)(pan)(py)]ClO_4 and [Ru(bpy)(pan)(pic)]ClO_4, also interact with DNA.

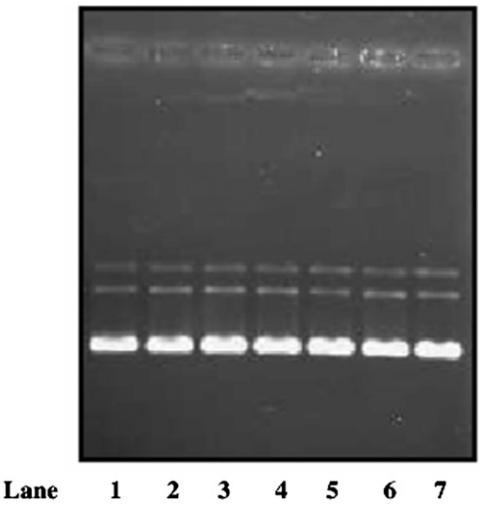

Fig. 9. Results of the gel electrophoresis experiment for [Ru(trpy)(pan)]ClO_4. Lane 1, SC pUC18 DNA control without irradiation. Lane 2, DNA control with irradiation at 254 nm. Lanes 3–7, DNA + complex with [DNA]/[complex] ratio of 1, 20, 40, 60, 70, respectively with irradiation at 254 nm. The complex concentration was 30 μM for Lanes 3–7.

In order to examine whether the above three complexes can also bring about cleavage of DNA upon UV irradiation, a property usually exhibited by such polypyridine complexes [15], interaction of these complexes with a super-coiled DNA, *viz.* SC pUC18 DNA, has been studied by gel electrophoresis. In these experiments SC pUC18 DNA was incubated in the presence of different concentrations of the complexes, followed by irradiation at 254 nm for different time durations. The samples were then analyzed by agarose gel electrophoresis. After the run the DNA was stained with EtBr and visualized by UV transilluminator. A representative picture of EtBr stained DNA is shown in Fig. 9. The extreme left line is for SC pUC18 DNA and in the following five lanes are the bands for increasing DNA complex ratio (i.e. [DNA]/[complex] = 1, 20, 40, 60 and 70. This shows that the complex does not induce any observable conformation changes in SC DNA confirming that they cannot cleave DNA upon UV irradiation. Moreover we could not see any retardation of the SC pUC18 DNA. This is perhaps due to the dissociation of the complex from DNA during the run of gel electrophoresis.

4. Conclusions

The present study shows that 1-(2′-pyridylazo)-2-naphthol (Hpan) can bind strongly to ruthenium as a monoanionic N,N,O-donor affording stable complexes. The mixed-ligand [Ru(bpy)(pan)Cl] complex exhibits interesting reactivity via dissociation of the Ru–Cl bond and such reactions with different bridging and

terminal ligands are currently under exploration. The [Ru(trpy)(pan)]ClO_4, [Ru(bpy)(pan)(py)]ClO_4 and [Ru(bpy)(pan)(pic)]ClO_4 complexes can effectively bind to DNA without causing damage to the DNA double helix.

Acknowledgements

The authors thank the reviewers for their critical comments, which have been useful in revising the manuscript. They also thank Prof. P.K. Bharadwaj, Department of Chemistry, Indian Institute of Technology, Kanpur, for his help with the X-ray diffraction data collection on the crystal of [Ru(bpy)(pan)Cl]. Thanks are also due to Prof. S. Pal of University of Hyderabad (for recording the esr spectra) and, Prof. K.P. Das and Mr. P. Dey of Bose Institute (for their help in recording the fluorescence spectra). Professor Michael G.B. Drew thanks the Engineering and Physical Sciences Research Council, United Kingdom and the University of Reading, for financial help. S. Halder thanks the University Grants Commission, New Delhi [Grant No. 10–2(5)2004(1)-E.U.II] for her fellowship.

Appendix A. Supplementary data

CCDC 644619 and 644622 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Full details of data collection are provided in Table S1and composition of selected molecular orbitals in Table S2. Packing diagrams showing non-covalent interactions in complexes [Ru(trpy)(pan)]ClO_4 (Fig. S1), [Ru(bpy)(pan)Cl] (Fig. S2) and [Ru$(PPh_3)_2$(pan)Cl] (Fig. S3), and ^{1}H NMR spectrum of [Ru$(pan)_2$] (Fig. S4) have been deposited. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.05.023.

N,*N*,*N*′,*N*″,*N*″-pentamethyldiethylenetriamine (Me_5dien) from Fluka and L-histidine was Merck product. All ligands were used without further purification and their purity was greater than 99%. The exact concentrations of the ligand solutions used for potentiometric measurements were determined by the Gran method [10]. Copper(II) chloride solution was purchased from Merck as a Titrisol concentrate for the preparation of standard solutions. The concentration of the metal ion stock solution was standardized by complexometric ethylenediaminetetraacetate (EDTA) titration. Carbonate-free potassium hydroxide solution (the titrant) was prepared and standardized against a standard potassium hydrogen phthalate solution. All solutions were prepared with deionized water. The formulae of the fully protonated form of the ligands used in this study are shown in Scheme 1.

2.2. Potentiometric measurements

The stability constants of the proton and copper(II) complexes were determined by pH-metric titration of 5 cm^3 samples in aqueous solutions. All the measurements were carried out at 0.2 mol dm^{-3} ionic strength (KCl) and 25.0 ± 0.1 °C using a constant-temperature water-bath. The titrations were performed with carbonate-free KOH solution of known concentration (ca. 0.2 mol dm^{-3}) under argon atmosphere over the pH range 2.0 to ≈11.0. For the binary systems the ligand concentration was 4×10^{-3} or 8×10^{-3} mol dm^{-3}. The metal ion to ligand ratios were 1:1, 1:2, 1:4 and 1:8.

For the ternary systems the ratios of copper(II):en/dien/Me_5dien:His were 1:1:1, 1:1:2, 1:2:1 and 1:2:2. Titrations were made on samples containing the copper(II) ion at 4×10^{-3} mol dm^{-3} prepared from $CuCl_2$ salt. The values of stability constants of the complexes formed in the binary systems were kept constant during calculating the potentiometric data of the ternary systems.

The pH-metric titrations were carried out with a Radelkis Op-208/1 instrument equipped with a combination pH electrode (SINGLE PORE, Hamilton) and an ABU-80 autoburette (Radiometer).The electrode system was calibrated by periodic titrations of HCl solution (7.5×10^{-3} mol dm^{-3} in KCl) against standard KOH solution as described earlier [11]. The pH-metric results were used to establish the stoichiometry of the species and to calculate the stability constants of the species formed in the ternary systems. Calculations were performed with the aid of the HYPERQUAD 2006 computer program [12]. The reported standard deviations were calculated by assuming random errors.

The charges of the complexes have been omitted in the text and tables. However, for clarity, it should be mentioned here that the fully deprotonated form of amino acid (His) is L^- while the amines (en), (dien) or (Me_5dien) are neutral.

2.3. UV–Vis spectroscopy

The electronic absorption spectra in the visible range were measured with a BECKMAN DU68 spectrophotometer using 2-cm quartz cells at room temperature. The spectra were recorded digitally (0.5 nm step) over the range 400–900 nm. The metal ion concentration was 4×10^{-3} mol dm^{-3} prepared from $CuCl_2$ salt. For the ternary systems copper(II):en:His, copper(II):dien:His and copper(II):Me_5dien:His the concentration ratios were 1:2:2, 1:1:2 and 1:2:1, respectively. The net ligand-field absorption band of each mixed-ligand species was extracted from the absorption spectra applying the procedure described in Ref. [13].

2.4. EPR spectroscopy

Electron paramagnetic resonance (EPR) spectra were performed on a Bruker 300E X-band spectrophotometer equipped with a Bruker NMR gaussmeter ER 035 M and a Hewlett–Packard frequency counter HP 5350B at 77 K in water/ethyleneglycol (4:1 v/v) solution. The EPR parameters were calculated by computer simulation of the experimental spectra using Bruker's WIN-EPR SimFonia Software Version 1.25. The metal ion concentration and the metal ion

Ligands	Abreviation
 L-histidine	$[H_3L]^{2+}$
 ethylenediamine	$[H_2\text{-en}]^{2+}$
 dietylenotriamina	$[H_3\text{-dien}]^{3+}$
 N,N,N',N'',N''-pentamethyldiethylenetriamine	$[H_3\text{-}Me_5\text{dien}]^{3+}$

Scheme 1.

to ligands molar ratios were the same as those used in the electronic absorption spectra.

3. Results and discussion

The values of the protonation constants of the studied ligands were re-determined under the experimental conditions identical to those applied for the ternary systems. The obtained results are in good agreement with the literature data [14–17].

The fully protonated form of the en contains two dissociable protons (H_2L^{2+}), one at each amino group $-NH_3^+$, while dien and Me_5dien (H_3L^{3+}) are able to release three protons in the whole pH range. His (H_3L^{2+}) contains three protons that dissociate off the ligand in the measurable pH range. The carboxylic function is deprotonated in the acidic pH range. The pK_{COOH} value is 1.73 for this ligand and this corresponds well to the characteristic acidity of the carboxylic groups of the amino acids. The next deprotonation corresponds to the imidazole nitrogen ($pK = 6.07$). The most basic donor for His is the amino group with pK values 9.09. The dissociation of the second proton of the imidazole group ($pK_a \sim 14$) is beyond the pH-metric titration range [2]. Thus, it does not participate in the metal coordination equilibria.

3.1. Cu^{2+}-complexation for binary systems

The binary systems of polyamines Cu^{2+}–en [3,18,19], Cu^{2+}–dien [13,15], Cu^{2+}–Me_5dien [3,16,20] were studied previously, however the stability constants were re-determined in the present work under the condition identical to those applied for the ternary systems.

A major effort was made to study the stability, speciation and structure of copper(II)–histidine complexes [2,3,9,21–24]. The composition of the predominant complexes of copper(II) and L-histidine in aqueous solution depends on the metal ion to ligand ratio, temperature and pH [2]. The major species in the basic solution of this binary system is [Cu(L-His)$_2$] (this complex exists in the equilibria with the mixed-ligand complexes in the studied ternary systems (see below)). Deschamps et al. reported the isolation and X-ray structure determination of this species [25]. Structural studies in solution indicate that this species exists in solution as an equilibrium mixture of isomeric structures having three and four N atoms coordinated to the copper(II) in the equatorial plane [21,22,24]. In the 3N isomer of the [Cu(His)$_2$] species, one histidine is bound glycine-like and the other histamine-like, with possible apical binding of the donor atoms of the side chains. The 4N isomer has all nitrogens in equatorial positions with the cis arrangements of the nitrogens of the same kind [22,24].

3.2. Cu^{2+}-complexation for ternary systems

The equilibrium models for ternary systems and corresponding stability constants giving the best fits of the pH-metric titration curves are presented in Table 1.

The general four-component equilibria can be written as:

$$pM + q(A) + r(His) + sH \leftrightharpoons M_p(A)_q(His)_rH_s$$

where p, q, r and s are the stoichiometric coefficients corresponding to the metal ion, M, A (A = en, dien or Me_5dien), His, and H, respectively; charges are omitted for simplicity.

The overall formation constants are defined as:

$$\beta_{pqrs} = [M_p(A)_q(His)_rH_s]/[M]^p[(A)]^q[(His)]^r[H]^s$$

The β_{1111} and β_{1110} constants express the stability of the [Cu(A)(H–His)]$^{2+}$ and [Cu(A)(His)]$^+$ mixed-ligand species, respectively. According to data in Table 1, the mixed-ligand complexes with [Cu(A)(His)]$^+$ stoichiometry are formed in all systems. In addition, [Cu(A)(H–His)]$^{2+}$ species exists in Cu^{2+}–dien–His and Cu^{2+}–Me_5-dien–His systems.

Despite the fact that the β_{1110} constant expresses the stability of the [Cu(A)(His)]$^+$ mixed-ligand species, it does not represent directly the binding strength between His and copper(II) ions in the presence of polyamine. The equilibrium constant, $K_{Cu(A)(His)}$, derived from the computed values of β_{pqrs}, according to equation: $\log K_{Cu(A)(His)} = \log \beta_{Cu(A)(His)} - \log \beta_{Cu(A)}$ (Table 1, row 4), shows how tightly histidine ligand is bound to the simple [Cu(A)]$^{2+}$ complex. The stepwise stability constants of the mixed-ligand species are much lower for the complexes involving tridentate dien and Me_5-dien than the stability constants of species containing bidentate en. In the case of dien and Me_5dien only one position remains available for the coordination of a second ligand.

The relative stability of the mixed-ligand complexes, as compared with the corresponding simple species formed in the binary systems, could be evaluated in different ways. The relative stability of [M(A)(His)]$^+$ can be expressed in terms of $\Delta \log K$ parameter (the constant due to [M(A)] + [M(His)] $\rightleftharpoons$ [M(A)(His)] + M equilibrium). This constant can be calculated from the experimentally measured stability constants according to the equation: $\Delta \log K = \log \beta_{[M(A)(His)]} - (\log \beta_{[M(A)]} + \log \beta_{[M(His)]})$. The statistical value of $\Delta \log K$ depends on the geometry of the complex and for the distorted octahedral coordination sphere of Cu^{2+} with two different bidentate ligands was deduced as -0.9 [26,27]. The calculated $\Delta \log K$ data are listed in Table 1. It can be seen that, $\Delta \log K$ is equal to -1.22 for [Cu(en)(His)]$^+$ and is very low for [Cu(dien)(His)]$^+$ (-5.35) and for [Cu(Me_5dien)(His)]$^+$ (-5.49). This difference is most likely caused by lower than six-coordination number of

Table 1
Cumulative formation constants ($\log \beta$), derived equilibrium constants ($\log K$) and characteristic parameters for the stability of complexes formed in the ternary systems Cu^{2+}–amine (en, dien or Me_5dien)–L-histidine at 25 °C and $I = 0.2$ mol dm^{-3} (KCl)

No.	Assignments	System Cu^{2+}–A–His; (A = en, dien or Me_5dien)		
		Cu^{2+}–en–His	Cu^{2+}–dien–His	Cu^{2+}–Me_5dien–His
1	$\log \beta_{[Cu(A)(H-His)]}$		27.56 (2)	24.43 (9)
2	$\log \beta_{[Cu(A)(His)]}$	19.47 (1)	20.77 (1)	17.09 (1)
3	$pK_{[Cu(A)(H-His)]}$		6.79	7.34
4	$\log K_{[Cu(A)(His)]}$; [Cu(A)]+His = [Cu(A)(His)][a]	8.89	4.76	4.62
5	$\log K_{[Cu(A)(His)]} - pK_{NH_3^+} - pK_{im}$	−6.27	−10.40

7	σ	10.54	6.58	8.24
8	$\Delta \log K$	−1.22	−5.35	−5.49
9	$\log X$	1.20	2.77	

Charges are omitted for simplicity.

[a] $\log K_{[Cu(A)(His)]} = \log \beta_{[Cu(A)(His)]} - \log \beta_{[Cu(A)]}$; $\log \beta_{[Cu(en)]} = 10.58$, $\log \beta_{[Cu(en)_2]} = 19.73$ [19]; $\log \beta_{[Cu(dien)]} = 16.01$, $\log \beta_{[Cu(dien)_2]} = 20.76$ [15]; $\log \beta_{[Cu(Me_5dien)]} = 12.47$ [20]; $\log \beta_{[Cu(H-His)]} = 14.14$, $\log \beta_{[Cu(His)]} = 10.11$, $\log \beta_{[Cu(H-His)_2]} = 26.97$, $\log \beta_{[Cu(H-His)(His)]} = 23.73$, $\log \beta_{[Cu(His)_2]} = 18.01$, $\log \beta_{[Cu_2(His)_2H_{-2}]} = 8.07$, $\log \beta_{[Cu(His)H_{-1}]} = 1.97$, $\log \beta_{[Cu(His)_2H_{-1}]} = 6.46$ [29].

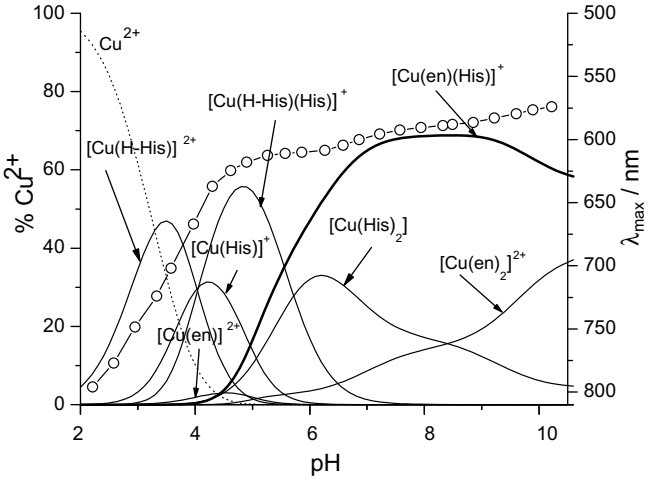

Fig. 1. Species distribution curves as a function of pH and variations of visible absorption maximum wavelength (circle) for the Cu^{2+}–en–His ternary system at 1:2:2 molar ratio; $c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}.

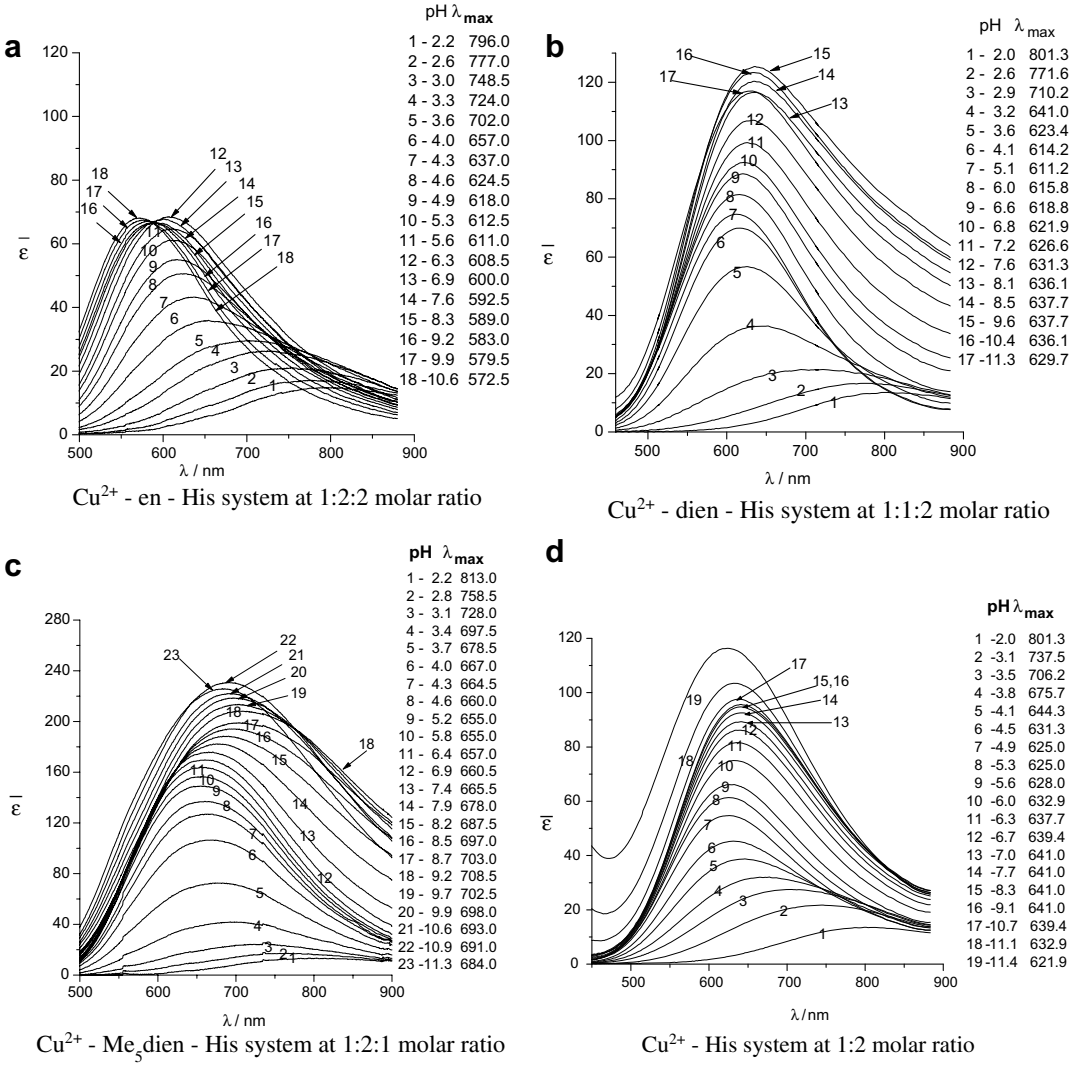
Cu^{2+} in the mixed-ligand complexes formed by dien or Me_5dien [26,27].

It is possible to calculate the $\log X_{M(A)(L)}$ values (the constant due to $[MA_2] + [ML_2] \rightleftharpoons 2[M(A)(L)]$ equilibrium, (Table 1, row 9) which are higher than that expected on a statistical basis (0.6) [28]. This indicates, that the formation of mixed complexes is favoured in the ternary systems of en and dien. For the $[Cu(Me_5\text{-dien})(His)]^+$ mixed-ligand species the $\log X_{M(A)(L)}$ value cannot be calculated, since the complex with 1:2 metal to ligand ratio is not formed in the Cu^{2+}–Me_5dien binary system. It could be noticed that the $\log X_{M(A)(L)}$ value for the system with dien is distinctly higher than that for the system with en. This is a reflection of the ratio of the stepwise formation constants for the binary Cu^{2+}–amine system ($\log(K_{Cu(dien)}/K_{Cu(dien)2}) = 11.26$ is significantly greater than $\log(K_{Cu(en)}/K_{Cu(en)2}) = 1.43$).

Concentration distribution curves for the Cu^{2+}–en–His system at 1:2:2 molar ratio is presented in Fig. 1. It can be seen, that up to pH 4 only a simple species are formed: $[Cu(H–His)]^{2+}$, $[Cu(His)]^+$, $[Cu(H–His)(His)]^+$ and $[Cu(en)]^{2+}$ as a minor one. The EPR parameters of the spectra observed up to pH 4.5 in the liquid solution for the ternary Cu^{2+}–en–His system ($g_{iso} = 2.154$ and $A_{iso} = 59 \times 10^{-4}$ cm^{-1} at pH 3.5 and $g_{iso} = 2.117$ and $A_{iso} = 75 \times 10^{-4}$ cm^{-1} at pH 4.8) are almost identical with those observed for the Cu^{2+}–His



Cu^{2+} - en - His system at 1:2:2 molar ratio

Cu^{2+} - dien - His system at 1:1:2 molar ratio

Cu^{2+} - Me_5dien - His system at 1:2:1 molar ratio

Cu^{2+} - His system at 1:2 molar ratio

Fig. 2. pH-varied absorption spectra of the Cu^{2+}–en–His system at 1:2:2 molar ratio (a), Cu^{2+}–dien–His system at 1:1:2 molar ratio (b), Cu^{2+}–Me_5dien–His system at 1:2:1 molar ratio (c), Cu^{2+}–His system at 1:2 molar ratio (d), ($c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}).

binary system [24], i.e. in this pH range only the simple species of His are formed. Moreover, below pH 4 the absorption spectra exhibit approximately the same changes versus pH for the ternary system with 1:2:2 concentration ratios of Cu^{2+}:en:His as those observed for the binary system with 1:2 concentration ratio of Cu^{2+}:His (Fig. 2a and d). The mixed-ligand species $[Cu(en)(His)]^+$ starts to form at ca. pH 4.5 and dominates in solution above pH 6. In this pH range the absorption spectra for binary and ternary systems are different supporting formation of mixed-ligand complex (Fig. 2). Similarly, the comparison of the EPR spectra for the binary systems with His or en and ternary system allows to detect the formation process of the $[Cu(en)(His)]^+$ mixed-ligand species. The EPR parameters of the liquid and frozen solution observed for Cu–His and Cu–en binary systems (Table 2) are very similar to those reported for $[Cu(His)_2]$ with in-plane coordination mode of the ligands proposed as $\{NH_2, N_{im}, COO^-, NH_2\}$ and $[Cu(en)_2]^{2+}$ with $2\times$ $\{NH_2, NH_2\}$ [17,24,30]. At pH between 8 and 9, when the mixed-ligand species is predicted as predominant in the studied ternary system, the values of the EPR parameters are intermediate between those obtained for the bis(ligand) complexes formed by His or en (Table 2). An apparent decrease of $g_{\|}$ and increase of $A_{\|}$ parameters for $[Cu(en)(His)]^+$ in comparison to the parameters of $[Cu(en)(\alpha\text{-Ala})]^+$ (with $\{NH_2, NH_2, NH_2, COO^-\}$ coordination mode, Table 2) may be unambiguously assigned to 4N donor set and supports the presence of a stronger in-plane ligand field. So, it can be concluded that the coordination in the mixed-ligand species in the studied ternary system is probably realised by amine nitrogens $\{NH_2, NH_2\}$ of en and amine and imidazole nitrogens $\{NH_2, N_{im}\}$ of His in the equatorial plane forming two five-membered chelate rings.

A comparison of relative stability constants for mixed-ligand complexes of His and α-Ala also shows their dissimilarities. The relative stability constants, $\log K_{Cu(en)(\alpha\text{-Ala})} - pK_{NH_3^+} - pK_{COOH}$, which takes into account the difference in the basicity of coordinating amino and carboxylic groups, for the ternary system with α-Ala (−4.96; [29]) is higher than $\log K_{Cu(en)(His)} - pK_{NH_3^+} - pK_{im}$ with His, where coordinating amine and imidazole nitrogens are included (−6.27; Table 1, row 5). This effect may result from the different size of chelate rings formed by amino acids. On the other hand, the comparison of the relative stability constants, $\log K_{Cu(en)(L)} - pK_{NH_3^+} - pK_{NH_{im}^+}$, which takes into account the difference in basicity of the amino group and imidazole nitrogen, for histidine (−6.27; Table 1, row 5) and histamine (−7.97; obtained from data published in [7]) also reveals the stability unlikeness. This fact excludes bidentate, histamine-like $\{N_{am}, N_{im}\}$ coordination mode of His in the mixed-ligand complex strongly suggesting that His coordinates to the metal ion in tridentate manner. Hence, $\{NH_2, NH_2\}$ $\{N_{im}, NH_2, COO^-\}$ groups of the ligands are engaged in copper(II) coordination in the $[Cu(en)(His)]^+$ species, the sixth position is probably occupied by water molecule. The energy of d–d transition for the $[Cu(en)(His)]^+$ species is similar to that stated for $[Cu(en)(\alpha\text{-Ala})]^+$ (Table 2). This is probably the result of the two opposite effects-the involvement of the fourth N-donor into the equatorial position of the metal site and the axial coordination of the carboxylic oxygen.

The calculated concentrations of the copper(II) complex species for the Cu^{2+}–dien–His 1:1:2 molar ratio system as a function of pH presented in Fig. 3a indicate that under these conditions the formation of mixed-ligand species is preceded mainly by the appearance of simple complexes with His and dien. Two patterns of copper hyperfine splitting in EPR spectrum corresponding to equilibrium between $[Cu(dien)]^{2+}$($g_{\|} = 2.234$, $A_{\|} = 194 \times 10^{-4}\ cm^{-1}$) and $[Cu(H\text{–}His)]^{2+}$($g_{\|} = 2.314$, $A_{\|} = 175 \times 10^{-4}\ cm^{-1}$) are observed at pH 3.2 and these EPR parameters are in good agreement with the literature data (Table 2). They are in the equilibrium with Cu_{aqua}^{2+}. The spectrum typical for $[Cu(dien)]^{2+}$ complex is still observed as dominant between pH 4.0 and 5.0 and in a small extent at pH 6.8. At the pH range 6.0–7.0 the spectrum with parameters close to those found for $[Cu(His)_2]$ is also observed in equilibrium with a new spectrum. This new spectrum (obtained by subtraction of the signals due to equilibrial $[Cu(His)_2]$ species from the spectrum observed for the Cu–dien–His system at pH 6.02) should be assigned to the first mixed-ligand species, $[Cu(dien)(H\text{–}His)]^{2+}$, predicted at this pH range (the concentration ca. 18%). Its $A_{\|}$ parameter (Table 2) is greater than for $[Cu(dien)(H\text{-}Asp\text{-}\beta\text{-}ha)]^+$ complex

[a] The Vis absorption bands presented in the table arises from distribution-corrected absorption spectra.

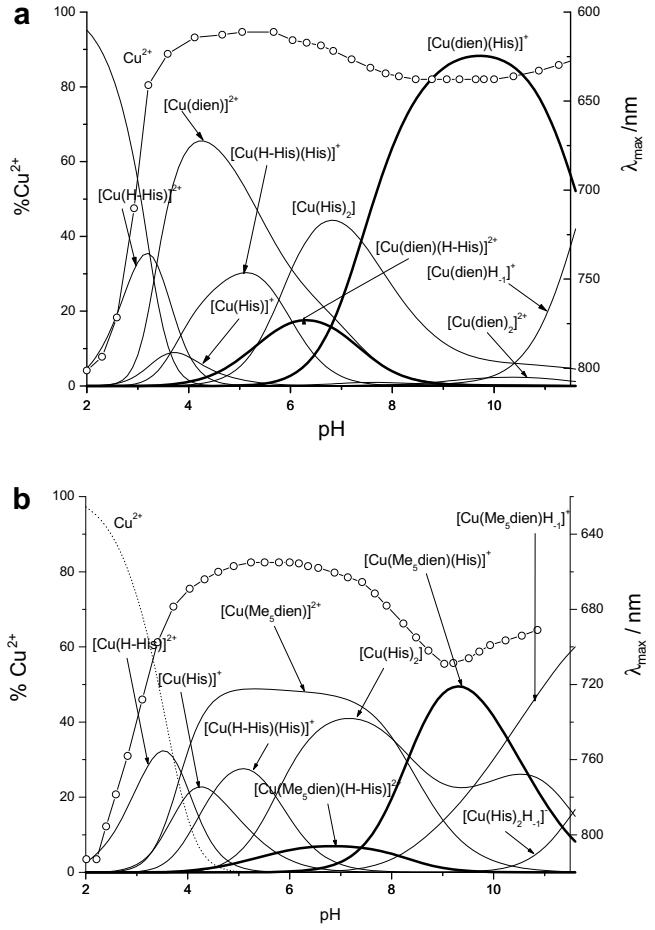

Fig. 3. Species distribution curves as a function of pH and variations of visible absorption maximum wavelength (circle) for the Cu^{2+}–dien–His system at 1:1:2 molar ratio (a) and Cu^{2+}–Me_5dien–His system at 1:2:1 molar ratio (b); $c_{Cu^{2+}} = 4 \times 10^{-3}$ mol dm^{-3}.

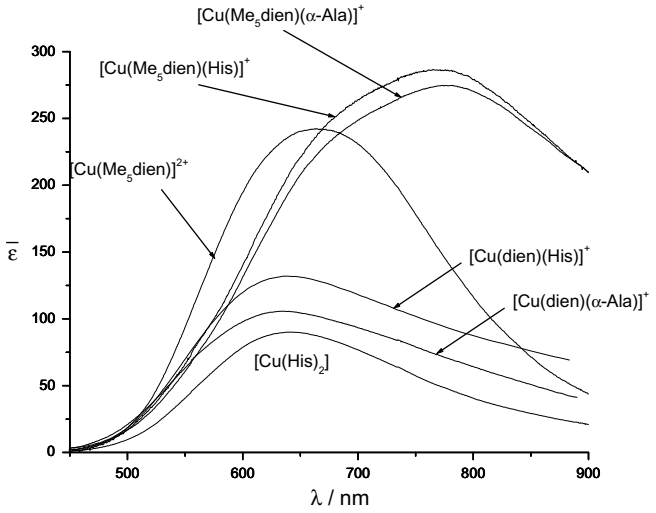

Fig. 4. Distribution-corrected absorption spectra for the $[Cu(dien)(His)]^+$, $[Cu(dien)(\alpha\text{-Ala})]^+$, $[Cu(Me_5dien)(His)]^+$, $[Cu(Me_5dien)(\alpha\text{-Ala})]^+$, $[Cu(Me_5dien)]^{2+}$, $[Cu(His)_2]$ species.

($g_{\|} = 2.218$, $A_{\|} = 190 \times 10^{-4}$ cm^{-1} [16]) with coordination realised by three nitrogens of dien and N_{amino} and $O_{carboxylate}$ of DL-aspartic-β-hydroxamic acid and even greater than for $[Cu(dien)_2]^{2+}$ ($g_{\|} = 2.214$, $A_{\|} = 186 \times 10^{-4}$ cm^{-1} [4]). It strongly suggests that coordination sphere in the Cu^{2+} plane in $[Cu(dien)(H\text{–}His)]^{2+}$ consists of four nitrogen atoms and the carboxylate oxygen of His, which may occupy an axial position, leading to geometry close to square-pyramid. The deprotonation constant, $pK_{[Cu(dien)(H-His)]^{2+}}$, of this mixed-ligand species (Table 1) is higher than that for the imidazole nitrogen atom and lower than that for the amine group in the "free" ligand. This indicates that in $[Cu(dien)(H\text{–}His)]^{2+}$ the amine group of His remains protonated and uncoordinated and deprotonation of this group is promoted by the copper(II) binding in the next mixed-ligand species. In $[Cu(dien)(H\text{–}His)]^{2+}$ the chelate donor system of His consists of $\{N_{im}, COO^-\}$, whereas three nitrogens of dien complete the coordination sphere in the equatorial plane. Above pH 6, due to the loss of one proton, a next $[Cu(dien)(His)]^+$ mixed-ligand species arises and predominates in solution in the pH range 8–11. The effect of this mixed-ligand species formation is observed distinctly in the electronic spectral changes (Figs. 2b and 3a). A comparison between the species distribution curves (Fig. 3a) and pH-varied absorption spectra of the Cu^{2+}–dien–His ternary system (Fig. 2b) clearly indicates that the spectral change, shown as the red shift of visible absorption maximum wavelength (circle in Fig. 3a), is attributable to the formation and decay of the $[Cu(dien)(His)]^+$ mixed-ligand species. From pH 8.5 to 10.5 absorption spectra are very similar ($\lambda_{max} \approx 636$–$637$ nm), what indicates the main contribution of this mixed-ligand complex in this pH range. Additionally, the isolated electronic absorption spectrum for this species at pH 9.6 demonstrates a broad band, asymmetric in the wavelength region 700–900 nm, with poorly noticeable maximum (Fig. 4, Table 2). Such asymmetry is characteristic of the five-coordinate complexes. Moreover, the same spectral behaviour is observed in the Cu^{2+}–dien-α-Ala ternary system what may suggest that the coordination mode in both $[Cu(dien)(His)]^+$ and $[Cu(dien)(\alpha\text{-Ala})]^+$ mixed-ligand species is the same. However, the EPR parameters of the spectra observed within pH range 8–10 for the Cu^{2+}–dien–His ternary system, where $[Cu(dien)(His)]^+$ complex is dominant (Fig. 3a, Table 2), are different to those obtained for $[Cu(dien)(\alpha\text{-Ala})]^+$ (Table 2). The difference between the EPR parameters suggests dissimilar role of the ligands in the complexes; α-Ala completes the coordination number to five by binding Cu^{2+} close to the plane through the amine nitrogen and in an axial position through the carboxylic oxygen. The presence of weak rhombic distortion suggests that the geometry is slightly deviated from square pyramidal towards trigonal bipyramidal [31]. On the other hand smaller $A_{\|}$ and greater $g_{\|}$ for the complex with His as compared to g_z and A_z values for the complex with α-Ala (Table 2) may be treated as indication of weaker in-plane copper–nitrogen bonds (with nitrogen provided by dien and histidine amine) as a result of stronger axial binding through imidazole nitrogen implying displacement Cu^{2+} ion from the plane.

The change of the coordination mode of His in $[Cu(dien)(His)]^+$, $\{NH_2, N_{im}\}$, in the relation to $[Cu(dien)(H\text{–}His)]^{2+}$, $\{N_{im}, COO^-\}$, leads to the formation of a six-membered chelate ring instead of seven-membered in the protonated species. It is interesting to compare the stability of both mixed-ligand species, the deprotonated ($\log K_{[Cu(dien)(His)]} = 4.76$, Table 1) and protonated one ($\log K_{[Cu(dien)(H-His)]} = \log \beta_{[Cu(dien)(H-His)]} - \log \beta_{[Cu(dien)]} - pK_{NH_3^+}) = 2.46$. The higher stability of [Cu(dien)(His)] comparing to [Cu(dien)(H–His)] is probably a result of the formation of a six-membered chelate ring instead of seven-membered.

Concentration distribution curves for the Cu^{2+}–Me_5dien–His system are presented in Fig. 3b. It can be seen, that up to pH 7 simple species with Me_5dien or His, $[Cu(H\text{–}His)]^{2+}$, $[Cu(His)]^+$, $[Cu(Me_5dien)]^{2+}$, $[Cu(H\text{–}His)(His)]^+$, $[Cu(His)_2]$, are mainly formed. The EPR spectrum observed at pH 3.5 in the liquid solution for the ternary Cu^{2+}–Me_5dien–His system ($g_{iso} = 2.155$ and $A_{iso} = 60 \times$

10^{-4} cm^{-1} and g_{iso} = 2.118 and A_{iso} = 73 × 10^{-4} cm^{-1}) is very similar to the spectrum observed for the Cu^{2+}–His binary system [24]. This corresponds to the existence of the equilibrium between the simple species of His in the solution at this pH. The increasing contribution of the $[Cu(Me_5dien)]^{2+}$ complex that is a dominant species between pH 4.0–6.0 is accompanied by a change of EPR spectral feature. The EPR parameters of the spectra observed in the pH range 4.0–5.0 of the liquid and frozen solution are: g_{iso} = 2.120 and A_{iso} = 75 × 10^{-4} cm^{-1} and g_z = 2.238, g_x = 2.060, g_y = 2.050 and A_z = 185, A_x = 24, A_y = 14 × 10^{-4} cm^{-1}, respectively. They are in good agreement with those reported for Cu^{2+} complex with Me_5dien and H_2O molecules [11]. The mixed-ligand species $[Cu(Me_5dien)(H–His)]^{2+}$exists as minor species. The $pK_{[Cu(Me5dien)(H–His)]^{2+}}$ value characteristic of the deprotonation step for the $[Cu(Me_5dien)(H–His)]^{2+}$ complex (Table 1) is higher than the deprotonation constant of the imidazole nitrogen atom and lower than that of the amine group in the "free" ligand. This indicates that in the $[Cu(Me_5dien)(H–His)]^{2+}$ species the amine nitrogen of His is protonated and the imidazole nitrogen and the carboxylic oxygen of His are involved in Cu^{2+} binding, similarly as it is proposed above for $[Cu(dien)(H–His)]^{2+}$. The EPR spectrum of $[Cu(Me_5dien)(H–His)]^{2+}$ species is not identifiable because of its too small contribution in comparison to that for $[Cu(Me_5dien)]^{2+}$ and $[Cu(His)_2]$ in the same pH range.

Above pH 7 the $[Cu(Me_5dien)(His)]^{+}$ species starts to form and reaches a maximum concentration (ca. 50%) at pH ~ 9 (Fig. 3b). The pH varied absorption spectra of Cu^{2+}–Me_5dien–His ternary system are different from those for both Cu^{2+}–Me_5dien [11] and Cu^{2+}–His binary systems (Fig. 2c and d). Furthermore, the pH dependence of λ_{max} in the visible spectra collected on the Cu^{2+}–Me_5dien–His system indicates a significant red shift in the pH region corresponding to the formation of this mixed-ligand species. This is clearly demonstrated in Fig. 3b which shows the λ_{max} versus pH plot together with the species distribution curves. The value of λ_{max} increases from 657 (pH ca. 6.4) to 708 nm (pH ca. 9), but starts to decrease above pH 9.2. Consequently, the red shift which parallels the formation of $[Cu(Me_5dien)(His)]^{+}$ indicates the structural changes around the copper(II) ion and transition from a six to a distorted five-coordination geometry while going from the simple to mixed-ligand species [11,13,15,3,20]. Possible modes of His coordination in the mixed-ligand species are either formation of a $\{NH_2, COO^-\}$ or $\{NH_2, N_{im}\}$ chelate. However, the energy of d–d transition for $[Cu(Me_5dien)(His)]^{+}$ species at around 772 nm (Fig. 4), is similar to those for five-coordinate mixed-ligand species containing Me_5dien and other α-amino acids [3], e.g. $[Cu(Me_5dien)(α\text{-Ala})]^{+}$ (Fig. 4). This fact implies that the coordination modes are similar. On the other hand, the energy of d–d transition for $[Cu(Me_5dien)(His)]^{+}$ species is very close to that for $[Cu(Me_5dien)(α\text{-alaninehydroxamic acid})]$ (790 nm [20]) and $[Cu(Me_5dien)(1,2\text{-diaminopropane})]$ (775 nm [32]) species with 5N coordination. So, the participation of the imidazole nitrogen in coordination in the $[Cu(Me_5dien)(His)]^{+}$ species cannot be excluded. The EPR spectral parameters found for $[Cu(Me_5dien)(His)]^{+}$ species are consistent with those of the five-coordinate mixed-ligand species formed by α-alanine and Me_5dien in copper(II) frozen solution (Table 2) and isolated mixed-ligand complexes $[Cu(Me_5dien)(L\text{-proline})]^{+}$ or $[Cu(Me_5dien)(L\text{-valine})]^{+}$ [3]. Thus, it can be concluded that geometry of the $[Cu(Me_5dien)(His)]^{+}$ species is strongly deviated from square pyramidal towards trigonal bipyramidal, similarly as it was observed for other mixed-ligand species with Me_5dien due to the dominant bulky effect of two methyl substituents at each nitrogen atoms forcing deviation of this *tri*-amine from in-plane coordination.

4. Conclusion

In the studied copper(II)–polyamine–His ternary systems, the potentiometric, VIS and EPR results support the formation of the mixed-ligand complexes with $[Cu(A)(His)]^{+}$ stoichiometry. In the systems with dien and Me_5dien the protonated $[Cu(A)(H–His)]^{2+}$ species also exists in acid solution. The coordination in the $[Cu(en)(His)]^{+}$ species, which dominates in solution above pH 6, is most likely realised by $\{NH_2, NH_2\}$ of en and $\{N_{im}, NH_2, COO^-\}$ of His with sixth coordination position occupied by water molecule. In the protonated $[Cu(dien)(H–His)]^{2+}$ and $[Cu(Me_5dien)(H–His)]^{2+}$ species the Cu^{2+} coordination by three nitrogens of dien or Me_5dien and by $\{N_{im}, COO^-\}$ chelate donor system of His seems to be evident, the amine nitrogen of His is still protonated. For the $[Cu(dien)(His)]^{+}$species, which predominates in basic solution, the geometry slightly deviated from square pyramidal is postulated. In this mixed-ligand species the binding of Cu^{2+} in the equatorial plane is realised by three amine nitrogens of dien and amine nitrogen of His and by imidazole nitrogen at axial position. The change of the coordination mode of His in $[Cu(dien)(His)]^{+}$, $\{NH_2, N_{im}\}$, in the relation to $[Cu(dien)(H–His)]^{2+}$, $\{N_{im}, COO^-\}$, leads to the formation of a six-membered chelate ring instead of seven-membered in the protonated species. However, the geometry of the $[Cu(Me_5dien)(His)]^{+}$ species is strongly deviated from square pyramidal towards trigonal bipyramidal due to the dominant bulky effect of two methyl substituens at each nitrogen atoms.

Acknowledgement

We would like to express our gratitude to Ms. Jadwiga Kędzierska for her technical assistance in the EPR measurements.

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 1100–180 nm in methanol solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer. EPR spectra were recorded at room temperature and 77 K on a Bruker ESP 300 spectrometer operating at X-band equipped with an ER 035M Bruker NMR gaussmeter and HP 5350B Hewlett–Packard microwave frequency counter.

2.2. Preparation of [$CuCl_2$(dppt)] (**1**)

A solution of dppt (0.58 mmol, 0.18 g) in methanol (15 ml) was added to 0.10 g (0.58 mmol) of $CuCl_2 \cdot 2H_2O$ in 10 ml of methanol and stirred for 2 h. The resulting solution was kept for evaporation at room temperature, and after a few days dark red crystals were obtained, filtered off and dried. Yield 75%.

Anal. Calc. for $C_{20}H_{14}N_4Cl_2Cu$: C, 54.01; H, 3.17; N, 12.60. Found: C, 54.70; H, 3.46; N, 12.35%.

IR (KBr; ν/cm^{-1}): 1603(m) and 1515(s), $\nu_{C=N}$ and $\nu_{N=N}$.

UV–Vis (MeOH; λ_{max} [nm] (ε; [$dm^3\ mol^{-1}\ cm^{-1}$])): 775.0 (100), 445.8 (50), 328.4 (36 500), 302.8 (59 750), 242.4 (38 910) and 204.8 (90 870).

2.3. Preparation of [$CuCl_2$(dppt)$_2$] · 2MeOH (**2**)

A procedure similar to that for [$CuCl_2$(dppt)] was used with $CuCl_2 \cdot 2H_2O$ (0.10 g, 0.58 mmol) and dppt (0.36 g, 1.16 mmol). Green crystals of **2** were collected in 80% yield.

Anal. Calc. for $C_{42}H_{36}N_8Cl_2O_2Cu$: C, 61.58; H, 4.43; N, 13.68. Found: C, 60.95; H, 4.68; N, 13.20%.

IR (KBr; ν/cm^{-1}): 3361(br) ν_{O-H}; 1607(m) and 1519(s) ν_{CN} and $\nu_{N=N}$.

UV–Vis (MeOH; λ_{max}[nm] (ε; [$dm^3\ mol^{-1}\ cm^{-1}$])): 769.0 (225), 507.6 (115), 339.4 (22 600), 304.0 (35 770) and 214.0 (68 125).

2.4. Preparation of [Cu(dppt)$_2$(H$_2$O)$_2$](NO$_3$)$_2$ (**3**)

A solution of dppt (0.80 mmol, 0.25 g) in methanol (10 ml) was added to 0.10 g (0.40 mmol) of $Cu(NO_3)_2 \cdot 3H_2O$ in 10 ml of water and stirred for 4 h. The resulting green precipitate was filtered off and recrystallized from methanol. Crystalline precipitate of **3** was collected in 70% yield.

Anal. Calc. for $C_{40}H_{32}N_{10}O_8Cu$: C, 56.90; H, 3.82; N, 16.59. Found: C, 57.35; H, 3.98; N, 16.25%.

IR (KBr; ν/cm^{-1}): 3473(br) ν_{O-H}; 1600 (w), 1530(s) and 1514(m) ν_{CN} and $\nu_{N=N}$; 1384 cm^{-1} (ν_{NO_3}).

UV–Vis (MeOH; λ_{max} [nm] (ε; [$dm^3\ mol^{-1}\ cm^{-1}$])): 676.1 (180), 479.9 (155), 340.1 (26 460), 300.3 (46 590), 240.7 (33 920) and 205.7 (85 180).

2.5. Preparation of [Cu(SO$_4$)(dppt)(H$_2$O)]$_n$ · nH$_2$O (**4**)

A solution of dppt (0.40 mmol, 0.12 g) in methanol (15 ml) was added to 0.10 g (0.40 mmol) of $CuSO_4 \cdot 5H_2O$ in 10 ml of water and stirred for 4 h. The resulting green precipitate was filtered off and recrystallized from methanol. Crystalline precipitate of **4** was collected in 65% yield.

Anal. Calc. for $C_{20}H_{18}N_4O_6SCu$: C, 47.48; H, 3.59; N, 11.07. Found: C, 47.77; H, 3.33; N, 11.85%.

IR (KBr; ν/cm^{-1}): 3650(m) and 3433(br) ν_{O-H}; 1606(br) and 1521(s) $\nu_{C=N}$ and $\nu_{N=N}$; 1196, 1156(sh), 1129, 1021, 934 and 611 cm^{-1} (ν_{SO_4}).

UV–Vis (MeOH; λ_{max} [nm]): 682.3, 464.5, 331.2, 300.9, 240.5 and 202.8.

2.6. Crystal structures determination and refinement

The X-ray intensity data of **1**, **2**, **3** and **4** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption correction [10] were applied. The structures were solved by the partial structure expansion method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were founded from the difference Fourier syntheses and were treated as, "riding" on their adjacent atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the aromatic parent atoms and equal 1.5 times the value of equivalent temperature factor of the methyl parent

carbon atom or oxygen atom. All, except water molecule, hydrogen atoms positions were idealised after each cycle of refinement. The methyl and hydroxyl groups were allowed to rotate about theirs local three-fold axes. SHELXS97 [11], SHELXL97 [12] and SHELXTL [13] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.7. Magnetic measurement

The magnetization of the powdered sample was measured over the temperature range 1.8–300 K at magnetic field 0.5 Tesla, using a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The superconducting magnet was generally operated at a field strength ranging from 0 to 5 Tesla.

The SQUID magnetometer was calibrated with the palladium rod sample. Corrections are based on subtracting the sample-holder signal and contribution χ_D estimated from the Pascal constants [14] and equal $-276 \times 10^{-6}\,cm^3\,mol^{-1}$ for complex. The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2.83(\chi_M T)^{1/2}$ (B.M.).

2.8. Computational details

The geometry of **1** was optimized without any symmetry restrictions in the doublet state using the hybrid B3LYP [15,16] functional of GAUSSIAN-03 [17]. The geometry was fully optimised in methanol utilising IEF-PCM formalism available in GAUSSIAN-03 [18]. The calculations were performed by using the LANL2DZ effective core potential (ECP) set of Hay and Wadt [19] for copper atom and the standard 6-31+G** basis for chloride and nitrogen, 6-31G* for carbon and 6-31G for hydrogen atoms.

Based on the optimized geometry, time-dependent density functional level (TDDFT) calculations were performed at the same B3LYP level and basis sets to calculate the electron transition energies [20].

3. Results and discussion

3.1. Preparation and infrared data

The complexes $[CuCl_2(dppt)]$ (**1**), $[CuCl_2(dppt)_2]\cdot 2MeOH$ (**2**), $[Cu(dppt)_2(H_2O)_2](NO_3)_2$ (**3**) and $[Cu(SO_4)(dppt)(H_2O)]_n\cdot nH_2O$ (**4**) were prepared in good yield by the reaction of 5,6-diphenyl-3-(2-pyridyl)-1,2,4-triazine (dppt) with the appropriate copper salt and molar ratio.

The selected frequencies observed in the IR spectra of $[CuCl_2(dppt)]$ (**1**), $[CuCl_2(dppt)_2]\cdot 2MeOH$ (**2**), $[Cu(dppt)_2(H_2O)_2](NO_3)_2$ (**3**) and $[Cu(SO_4)(dppt)(H_2O)]_n\cdot nH_2O$ (**4**) complexes are given in Section 2. For all the examined complexes the stretching vibrations of the C=N and N=N groups appear at considerable lower values with respect to the ν(C=N) and ν(N=N) of the free 5,6-diphenyl-3-(2-pyridyl)-1,2,4-triazine (dppt) supporting the coordination of the triazine and pyridyl rings to the metal ion [3]. The bands assignable to the bridging sulfate of **4** appear at 934, 1021, 1129, 1156 and 1196 cm^{-1}, whereas the band at 1384 cm^{-1} for **3** suggests the presence of uncoordinated nitrate ion. The broad bands in the range 3650–3100 cm^{-1} in the IR spectra of **2**, **3** and **4** represent the existence of MeOH and H_2O [21].

3.2. Crystal structures

The crystallographic data of **2**, **3** and **4** complexes are summarized in Table 1, The details of hydrogen bonds are given in Table 2, and the molecular structures of **2, 3** and **4** are presented in Figs. 1–3, respectively.

The complex **1** crystallises in the orthorhombic space group *Fdd*2. The coordination geometry about Cu(II) is a *trans* distorted square planar. The Cu ion is coordinated to pyridine and triazine rings of 5,6-diphenyl-3-(2-pyridyl)-1,2,4-triazine ligand and two chloride ions. As the X-ray structure of complex **1** has been recently reported by Eltayeb et al. [22] and quality of our structure is similar, the experimental data for **1** have not been included in the paper.

The copper atom of the compound **2** is located on the inversion centre and occupies special position *a* of the *C*2/*c* space group, thus the asymmetric unit consists of a half of complex molecule and one methanol molecule. By symmetry the environment of copper(II) ion in compound **2** adopts ideal tetragonal bipyramid geometry. The equatorial plane is formed by two pyridine and two triazine nitrogen atoms and the axial sites are occupied by two chloride ions at rather large distances of 2.7062(16), as a consequence of the Jahn–Teller effect. The two dppt ring systems are strictly coplanar and they are bound to central ion in *trans* configuration. Each complex molecule is connected *via* medium strength [23,24] O–H···Cl intermolecular hydrogen bonds with two solvent molecules.

The copper atom of the compound **3** is located on the inversion centre and occupies special position *b* of the $P2_1/n$ space group, thus the asymmetric unit consists of a half of complex cation and one nitrate anion. The overall complex molecule conformation of compound **3** is very similar to these of compound **2**. By symmetry the environment of copper(II) ion adopts ideal tetragonal bipyramid geometry. The equatorial plane is formed by two pyridine and two triazine nitrogen atoms and the axial sites are occupied by two water molecules at rather large distances of 2.3403(19) Å, as a consequence of the Jahn–Teller effect. The two dppt ring systems are strictly coplanar and they are bound to central ion in *trans* configuration. The medium strength O–H···O intermolecular hydrogen bonds of compound **3** joins the molecules to form of hydrogen bonded chain along crystallographic *b*-axis.

All atoms of compound **4** lie in general positions, but the inversion centres located at respectively special positions d and f of the $P\bar{1}$ space group expand the molecule to the one dimensional, ladder type, polymer along crystallographic *a*-axis (the asymmetric unit consists of one Cu^{2+} cation one SO_4^{2-} anion one ligand, one coordinated and one uncoordinated water molecule). Each copper(II) ion is six-coordinate and their coordination geometries are best described as distorted tetragonal bipyramid with the equatorial plane defined by two nitrogen and two oxygen atoms (maximum deviation from the weighted least squares N(2), N(4), O(1), O(2) plane exists for N(4) atom and it is equal to 0.127(2) Å) with copper atom displaced 0.000(2) Å from above mentioned the weighted least squares plane. The Cu(dppt)(H_2O) units are linked by two μ-sulfate-O,O′ bridges forming planar by symmetry Cu_2O_2

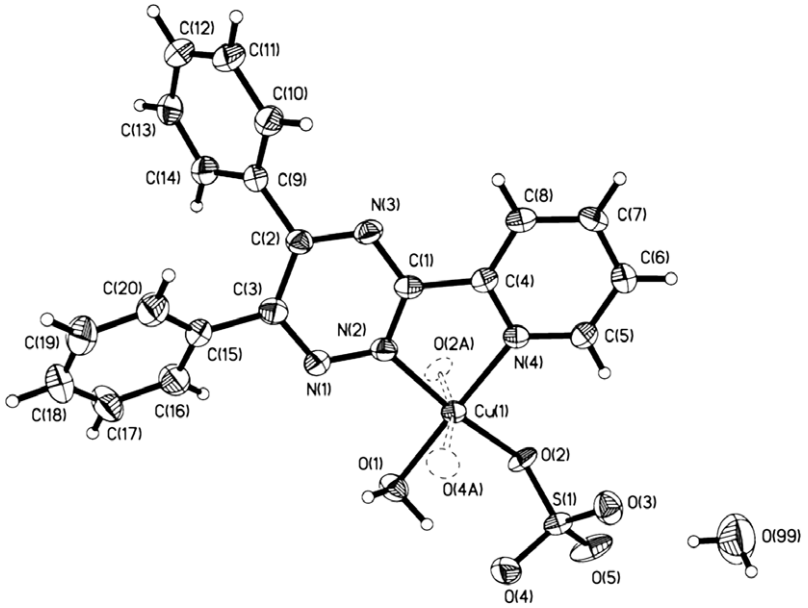

Fig. 3a. Atoms forming asymmetry unit of **4**. Displacement ellipsoids are drawn at 50% probability. The symmetry generated atoms bonded to the asymmetry unit atoms are indicated by dashed lines.

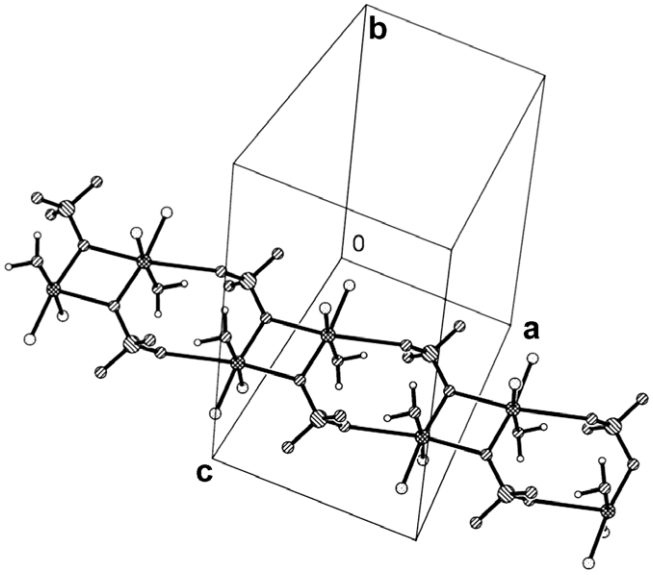

Fig. 3b. The fragment of polymer chain **4**. Atoms not involved in the chain are deleted for clarity. The copper atoms are cross-hatched, the sulphur atoms are backslashed, the oxygen atoms are slashed and nitrogen atoms are dotted.

moiety with two short [1.966(3) Å] and two longer Cu–O distances [2.367(3) Å], two bridging Cu–O–Cu angles of 100.49(12)°, leading to a Cu···Cu separation of 3.3411(11) Å. The sulfate oxygen O(4) is further coordinated to the copper atom of another binuclear unit, resulting in a polymeric structure created by the four-membered Cu_2O_2 and eight-membered $Cu_2O_4S_2$ rings in the spiro arrangement (in the second ring the Cu···Cu distance is 4.8865(11) Å). The structures with two bridging modes for the sulfate groups (μ-O,O′ and μ-O,O), in the same complex are unique. However, a similar arrangement was observed for the $[Cu_4(TPPNOL)_2(\mu\text{-}SO_4)_2](ClO_4)_2$ [HTPPNOL (*N*,*N*,*N*0-tris-(2-pyridylmethyl)-1,3-diaminopropan-2-ol)] complex reported by Fernandes and co-workers [25]. Different bridging modes for the sulfate groups are reflected in the different S–O bond lengths: 1.523(3) Å for S(1)–O(1) and 1.459(4) Å for S(1)–O(4). The solvent water molecule is connected to complex molecule *via* medium strength O–H···O hydrogen bond. The polymer chain is stabilised by medium strength O–H···O intramolecular hydrogen bonds.

The selected bond distances and angles of **2**, **3** and **4** are collected in Tables 3–5. The bite angle of, 6-diphenyl-3-(2-pyridyl)-1,2,4-triazine ranges from 78.99(14)° to 81.19(15)°, and is similar to that reported for the related $[Cu(dppt)_2(H_2O)_2](ClO_4)_2$ complex [79.7(2)°] [6].

For all three complexes, there is no significant difference between Cu–N (pyridine) and Cu–N (triazine) bond lengths, revealing that the two nitrogens are equal in donor strength. The Cu–N bond distances of mononuclear compounds are slightly longer than those in the polymer structure suggesting that the Cu–N bonds in **1**, **2** and **3** complexes are comparatively weaker. However, all the Cu–N bond lengths are consistent with those found in related systems [26].

Table 3

		Cu(1)–O(2)–Cu(1)#1	100.49(12)

#1: $-x+2, -y+2, -z+1$.

3.3. Magnetic properties

The magnetic properties of the complex **4** were determined over the temperature range 1.8–300 K at magnetic field 0.5 Tesla. The experimental data, plotted as temperature variations of the χ_M^{-1} and $\chi_M T$, are shown in Fig. 4.

The value $\chi_M T$ of at 300 K for complex equals 0.415 $cm^3\ mol^{-1}\ K$ (1.82 B.M.). The value of $\chi_M T$ product increases slightly with temperature lowering and reaches 0.425 $cm^3\ mol^{-1}\ K$ (1.85 B.M.) value at 1.8 K.

The values of the Curie and Weiss constants determined from the relation $1/\chi_M = f(T)$ over temperature range 1.8–300 K are equal

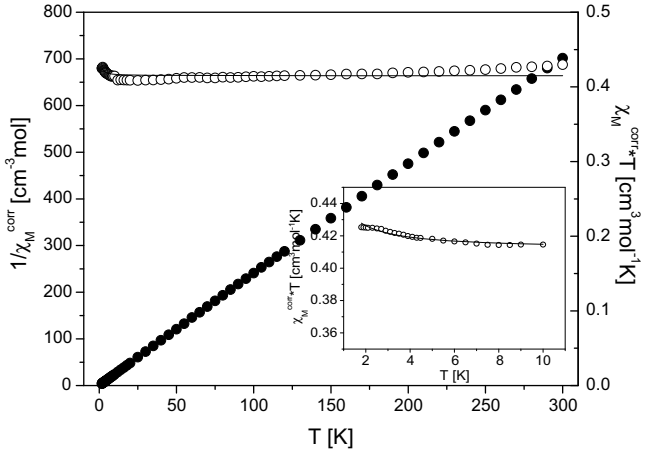

Fig. 4. Temperature dependence of experimental χ_M^{-1} (•) and $\chi_M \cdot T$ (○) for complex **4**. The inset shows dependence $\chi_M T$ vs. T (○) in the lowest temperature range. The solid line is the calculated curve for $\chi_M T$.

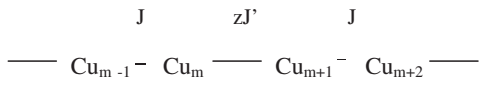
to 0.415 $cm^3\ mol^{-1}$ K and 0.04 K, respectively. A very small, positive value of Weiss constant confirms the occurrence of very weak ferromagnetic interactions between the copper centers in the dimer.

The molecular structure of $[Cu(SO_4)(dppt)(H_2O)]_n \cdot nH_2O$ (**4**) (Fig. 4b) suggests the magnetic exchange interactions in alternating chain:



where J and zJ' are the exchange parameters via (–O–) and (–O–S–O–) bridges, respectively.

The path of the magnetic interaction between Cu^{II} centers inside eight-membered ($Cu_2O_4S_2$) ring is considerably longer than inside four-membered (Cu_2O_2) ring. For that reason the dimer model with pairwise interactions may be used as a good approximation [27]. Hamiltonian $H = -2J\vec{S}_1 \cdot \vec{S}_2$ for $S_1 = S_2 = 1/2$ leads to the Bleaney–Bowers expression (1) [28]. To elucidate the significance of exchange between dimeric subunits in the chain, a molecular field correction term was also included (Eq. (2)) [29]

$$\chi_M = \frac{2N\beta^2 g^2}{3kT}\left[1 + \frac{1}{3}\exp(-2J/kT)\right] \quad (1)$$

$$\chi_M^{corr} = \frac{\chi_M}{1 - \frac{2zJ'}{N\beta^2 g^2}\cdot \chi_M} \quad (2)$$

where N is the Avogadro's number, g – the spectroscopic splitting factor, β – the Bohr magneton, k – the Boltzmann constant, J – exchange parameter and zJ' – molecular field correction (interdimer interaction). The least-squares fit of the experimental data using these equations was limited to the temperature range from 1.8 K up to 300 K and leads to singlet–triplet ($2J$) separation value equals 0.20 cm^{-1}, $g = 2.10$ and $zJ' = 0$, as indicated by the solid curve in Fig. 5. The agreement factor R is equal 4.02×10^{-5}. The criterion used in determination of the best fit was based on minimization of the sum of squares of the deviation: $R = \sqrt{\sum_{i=1}^{n} \frac{1}{(\chi_i^{exp})}\left(\chi_i^{exp} - \chi_i^{calc}\right)^2} \Big/ \sqrt{\sum_{i=1}^{n} \frac{1}{(\chi_i^{exp})^2}}$. Magnetic interaction in the dimeric copper compound strongly depends on Cu–O–Cu angle. For angles close to 97° it is possible to found accidental orthogonality and consequently, J values ~0 or positive [30,31]. The weak ferromagnetic interactions between the copper centers in the dimeric subunits (Cu_2O_2) arise from the value of bridging angle Cu(1)–O(2)–Cu(1)#1 (100.49(12)°) [31].

Results of the calculations on the magnetic data indicated only very weak ferromagnetic interaction between copper centers inside four-membered (Cu_2O_2) rings with value of the singlet–triplet separation $2J = +0.2$ cm^{-1}. The value of molecular field corrections ($zJ' = 0$) indicated total magnetic isolation of the four-membered rings in the crystal lattice.

The variation of the magnetization M versus the magnetic field H for complex **4** at 2 K was shown in Fig. 5. As the magnetic field increases, the M versus H curve indicates linear relation up to ~1 T and then shows a sinusoidal variation up to 5 T near saturation value at $M = 0.97$ B.M.

3.4. EPR spectra

The EPR powder spectra of the complex **4** (Fig. 6) recorded in the X-band at room temperature, 77 K and 4.2 K indicate two poorly resolved lines related to $g_\perp = 2.08$ and $g_\perp = 2.21$ parameters. The observed EPR spectrum is the average spectrum of two copper centers in the ligand field of the distorted tetragonal–bipyramidal symmetry $Cu(1)N_2O_4$ and $Cu(2)N_2O_4$, respectively.

3.5. Geometry optimisation

The geometry of **1** was optimised in a doublet state by the DFT method with the B3LYP functional. The optimized geometric parameters of **1** are gathered in Table 6. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations.

3.6. Electronic spectra

The experimental electronic spectra of **1, 2**, **3** and **4** are presented in Fig. 7. The positions of absorption bands and values of molar absorption coefficients for the complexes are given in the Experimental Part. As can be seen from Fig. 7 the UV/Vis spectra are rather indistinctive for molecular structure determination. For all the complexes the visible region exhibit broad poorly resolved absorption bands with maxima at 775.0 and 445.8 nm for **1**, 769.0 and 507.6 nm for **2**, 676.1 and 479.9 nm for **3** and 682.3 and 464.3 nm for **4**. The UV spectra of the **1, 2, 3** and **4** are also very similar in terms of the position, intensity and shape of the bands.

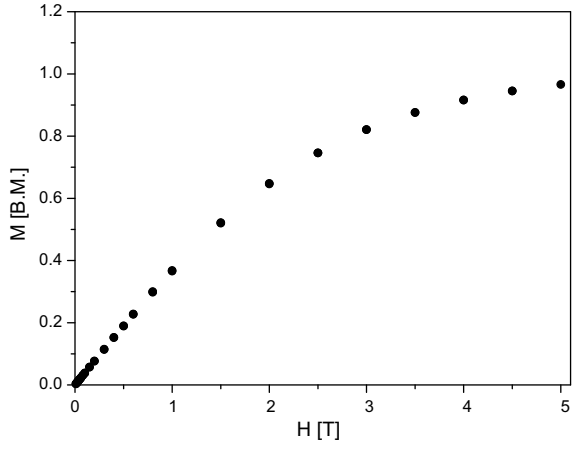


Fig. 5. Field dependence of the magnetization for complex **4**.

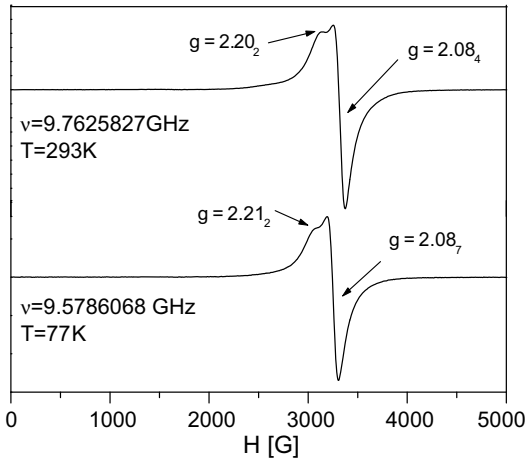

Fig. 6. EPR (X-band) spectrum of powdered **4** at room temperature and 77 K.

Table 6
The optimized bond lengths (Å) and angles (°) for **1**

Bond lengths	Optimized	Bond angles	Optimized
Cu(1)–N(2)	2.067	N(4)–Cu(1)–N(2)	79.47

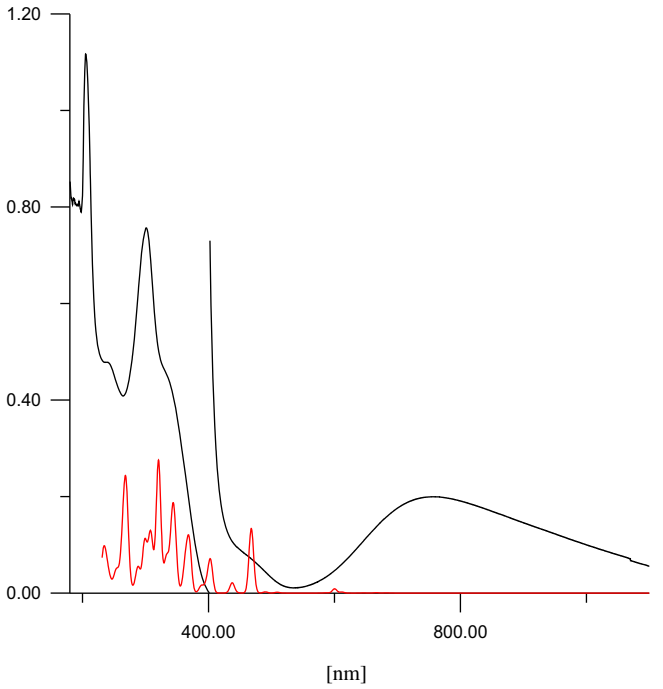

Fig. 8. The experimental (black) and calculated (red) electronic absorption spectra of **1**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

For complex **1** the nature of the transitions observed in the UV–Vis spectra has been studied by the time-dependent density functional (TDDFT) method. The calculated electronic spectrum of **1** in comparison with the experimental one is presented in Fig. 8. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

f – oscillator strength; H – highest occupied molecular orbital; L – lowest unoccupied molecular orbital.

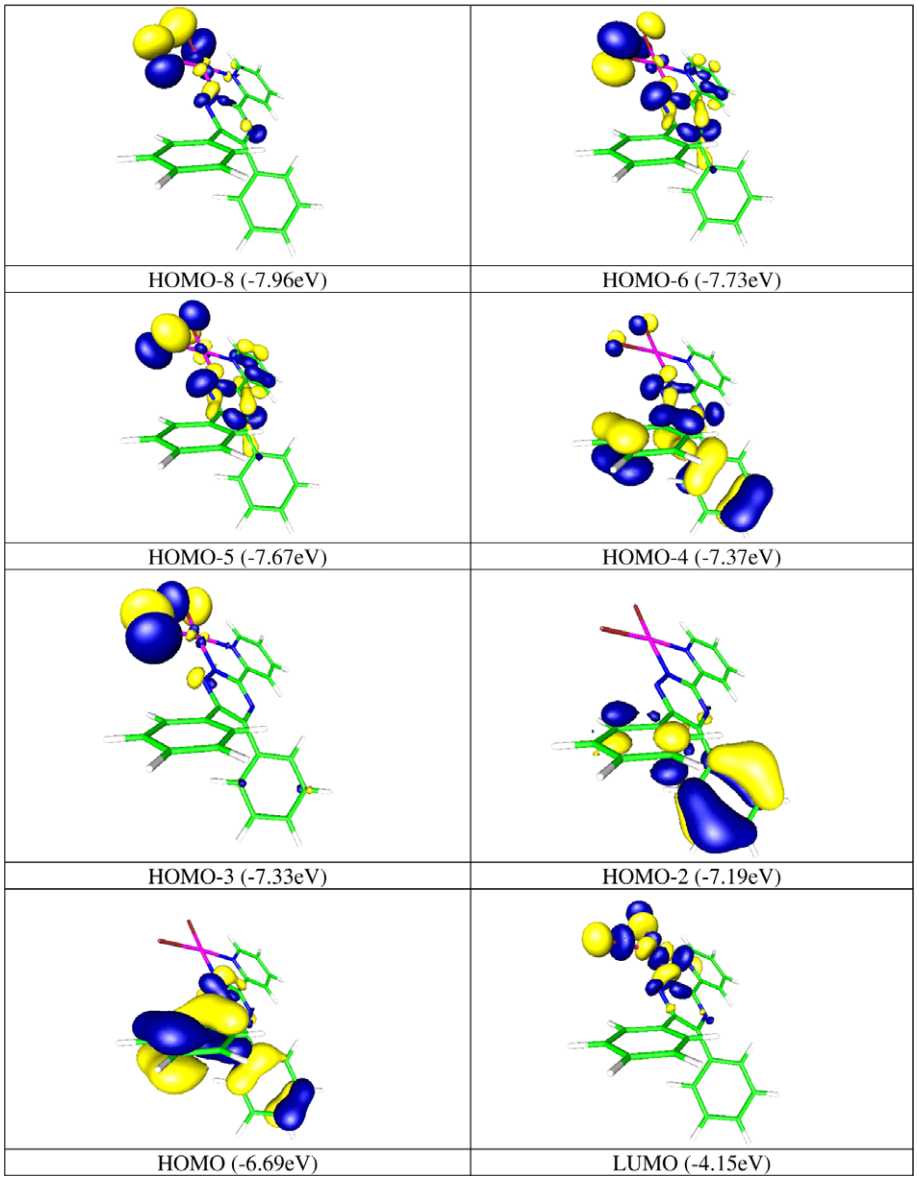

Fig. 9. Contour plots and energy of the selected β-spin HOMO and β-spin LUMO orbitals active in the electronic transitions for complex **1**. The orbitals were plotted with contour values −0.04 (yellow) and 0.04 au (blue). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Table 7 presents the calculated spin allowed electronic transitions of **1** and their assignments to the experimental bands. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.500 are listed in Table 7. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy to the orbitals HOMO and LUMO involved in the electronic transitions. The several contours of occupied and unoccupied MOs (active in the electronic transitions) of **1** are presented in Fig. 9.

The TDDFT/PCM calculations show that the two longest wavelength experimental bands of **1** at 775.0 and 445.8 nm originate in the transitions between some lowest β-spin HOMO orbitals and β-spin LUMO orbital. As can be seen from the Fig. 9, the LUMO orbital with β-spin is mainly Cu $d_{x^2-y^2}$ orbital in character, the β-spin HOMO and HOMO−1 orbitals are composed of the π-bonding orbitals of 5,6-diphenyl-3-(2-pyridyl)-1,2,4-triazine, and the HOMO−14, HOMO−8, HOMO−5 and HOMO−3 are ligand (Cl or dppt) π-bonding orbitals with some contribution of d_{Cu} orbitals. Accordingly, the transitions assigned to the two longest wavelength experimental bands can be seen as mixed Cl/dppt → Cu (LMCT) and d → d (LF). Thus, no 'clear' d–d transition bands occur in the low-lying energy region for **1**. The reason for this is probably due to the fact that the dppt ligand provides high-lying occupied π-bonding orbitals, and as a result the high-lying occupied orbitals are composed of the π-bonding orbitals of 5,6-diphenyl-3-(2-pyridyl)-1,2,4-triazine.

The experimental bands at 328.4, 302.8, 242.4 and 204.8 nm are attributed to the intraligand (IL) (π(dppt) → π*(dppt)) and ligand–ligand charge transfer (π(Cl) → π*(dppt)) transitions.

4 Supplementary data

CCDC 684890, 684891, 684892 and 684893 contain the supplementary crystallographic data for $C_{20}H_{14}N_4Cl_2Cu$, $C_{42}H_{36}Cl_2N_8O_2Cu$, $C_{40}H_{32}N_{10}O_8Cu$ and $C_{20}H_{18}N_4O_6SCu$. milli-Q water-methanol mixture (1:1 ratio). To this solution either nickel(II) chloride hexahydrate, zinc(II) chloride dihydrate or copper(II) chloride tetrahydrate (1 mmol) was added. The solution was stirred for 15 min and kept for crystallization. Upon standing the corresponding complexes $[NiL(H_2O)_3]2H_2O$ (**3**) and $\{[ZnL(H_2O)]4H_2O\}_n$ (**4**), crystallized out as single products in each case after one week. The copper complex $[CuL(py)(H_2O)_2]$ (**5**) was crystallized from pyridine.

The X-ray data were collected at 296 K with Mo Kα radiation ($\lambda = 0.71073$ Å) using a Bruker Nonius SMART CCD diffractometer equipped with a graphite monochromator. The SMART software was used for data collection and also for indexing the reflections and determining the unit cell parameters; the collected data were integrated using SAINT software. The structures were solved by direct methods and refined by full-matrix least-squares calculations using SHELXTL software. All the non-H atoms were refined in the anisotropic approximation against F^2 of all reflections. The H atoms, except those attached to N and O were placed in their calculated positions and refined in the isotropic approximation; those attached to heteroatoms (N, O) were located in the difference Fourier maps, and refined with isotropic displacement coefficients. The crystal data for the complexes are listed in Table 1.

3. Results and discussion

The reaction of 5-methyl-thiazol-2-ylamine with methylbromoacetate gives the di-substituted derivative (2-methoxycarbonylmethylimino-5-methyl-thiazol-3-yl)-acetic acid methyl ester (**1**) (Scheme 1). The important aspect of this reaction is that even when the 5-methyl-thiazol-2-ylamine is reacted with an equimolar amount of methylbromoacetate, the reaction invariably leads to the dialkylated product. Monoalkylated products are not observed in the reaction. This suggests that the second alkylation process on 5-methyl-thiazol-2-ylamine is faster than the first alkylation process (Scheme 1). The dialkylation also takes place with a shift of the endocyclic C=N bond to an exocyclic C=N bond. Compound **1** was characterized by ^1H and ^{13}C NMR spectroscopy, along with other spectroscopic techniques. The formation of the di-substituted product is illustrated in Scheme 2.

The methylester **1** on base hydrolysis (Scheme 1) gives the disodium salt of (2-carboxymethylimino-5-methyl-thiazol-3-yl)acetic acid (Na_2L). The disodium salt (**2**) reacts with nickel(II) chloride, zinc(II) chloride or copper(II) chloride, resulting in mononuclear or polynuclear complexes (Scheme 3). The nickel complex is a mononuclear complex and has the composition $[NiL(H_2O)_3]2H_2O$ (**3**); the zinc complex has the composition $\{[ZnL(H_2O)]4H_2O\}_n$ (**4**), whereas the copper complex crystallized from pyridine (py) and is a mononuclear complex having the composition $[CuL(py)(H_2O)_2]$ (**5**). The crystal structures of all these complexes have been determined.

The nickel complex has a six coordination geometry in which the imine nitrogen and two oxygen atoms of the carboxylate groups coordinate to the nickel, making a five member and seven member cyclic structure (Fig. 1). These three dative bonds along with an aqua ligand occupy the four corners of a plane, and there are two more aqua ligands occupying the axial positions. In

addition to these complex **3** has two molecules of water of crystallization. Some of the important bond distances and angles are listed in Fig. 1. The sulfur atom of the ligand does not participate in coordination. The disodium salt Na_2L has a strong absorption at 1590 cm^{-1} arising from carboxylate stretching, whereas the zinc complex has two sharp signals at 1598 and 1572 cm^{-1}, suggesting the two carboxylates are in two different environments; namely one in a five and the other in a seven member ring structure. The compound has a magnetic moment of 2.62 BM which corresponds to a d^8-electronic configuration. The nickel complex absorbs at 659 nm in DMF due to a d–d transition.

The zinc complex (**4**) has a polymeric structure, having pentacoordinated zinc centres, and each zinc center has a distorted square pyramidal geometry. The basal plane is constructed by the coordination of two oxygen atoms and a nitrogen atom to zinc, along with an aqua ligand. The fifth coordination site is completed by an oxygen atom of a carboxylate from another chelating ligand to a neighboring zinc center. The important bond distances and bond angles are listed in Fig. 2. The repeated part of the complex in the crystal lattice is shown in Fig. 2b.

A careful look at the structure suggests that each building block comprises of four coordinated units built from L and an aqua ligand, these units gets connected to each other through the Zn–O bond from the C=O oxygen of a carboxylate group of a neighboring molecule. Thus, a polymeric chain structure is formed in which all the zinc centers have uniformly five coordination. The coordination polymer has a zig–zag structure extending along the crystallographic *b*-axis. Examples of pentacoordination in zinc are lesser in number, but they are biologically important [5a–l] and they are also formed under specific conditions [5m]. The zinc coordination polymer **4** shows IR absorptions at 1614 and 1564 cm^{-1}; this suggests two different environments for the carboxylate groups. The IR stretching of these groups is different from the nickel complex, this difference is attributed to the fact that the two Zn–O bonds arising from the carboxylate groups in the case of the nickel complexes are equivalent, but in the case of the zinc complex they are different. This is also reflected in the bond lengths, namely Zn1–O1 is 2.048 Å, whereas Zn1–O2 is 2.103 Å. The complex in solution shows desirable proton NMR signals for the ligand.

When the product of the reaction of Na_2L with copper(II) chloride is crystallized from pyridine, a mononuclear complex having the composition $[CuL(py)(H_2O)_2]$ (**5**) is obtained. This complex is similar to the nickel complex (**3**) and can be considered as an analogous copper complex in which one of the three aqua ligands is substituted by a pyridine ligand. The complex has a magnetic moment of 1.95 BM, which is generally observed for a d^9-electronic configuration. Complex **5** has a visible absorption at 840 nm for a d–d transition. Apparently the complex has a distorted octahedral geometry around the copper ion, in which two axial bonds, Cu1–

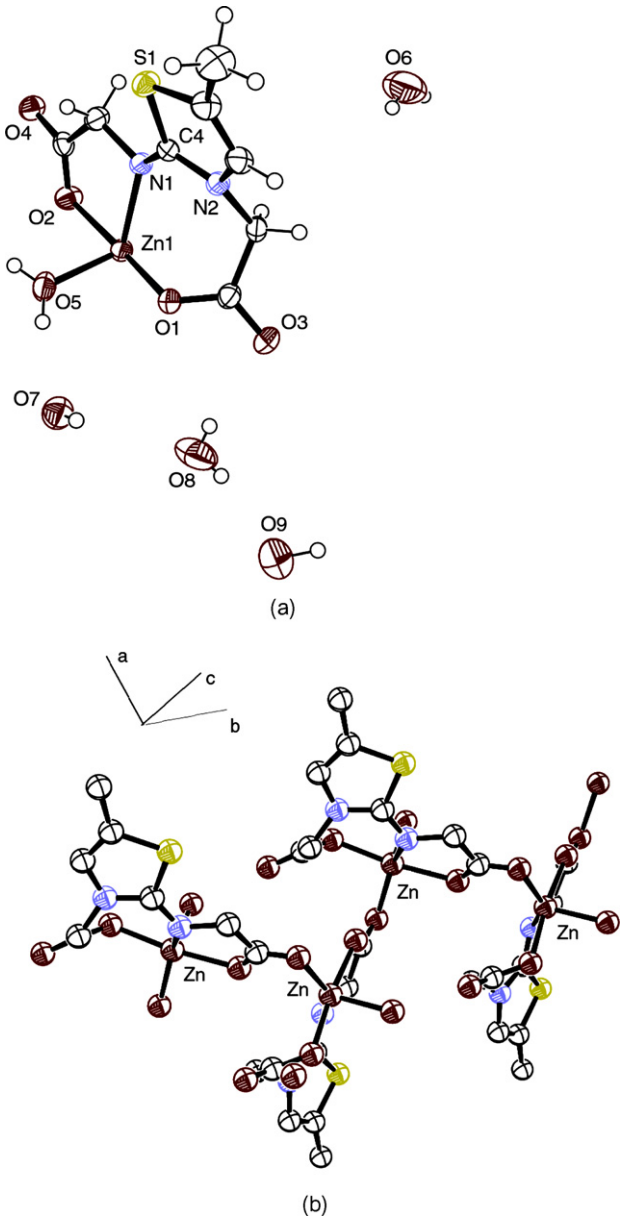

Fig. 2. (a) The repeated units of the coordination polymer **4**. (b) A part of the chain of the coordination polymer **4** (hydrogen atoms are omitted for clarity). Selected bond distances (Å) and bond angles (°): Zn1–O4, 2.0231(12); Zn1–O5, 2.0231(15); Zn1–O1, 2.0479(13); Zn1–N1, 2.0518(14); Zn1–O2, 2.1035(13); ∠O4–Zn1–O5, 110.04(6); ∠O4–Zn1–O1, 93.65(5); ∠O5–Zn1–O1, 84.40(6); ∠O4–Zn1–N1, 138.82(6); ∠O5–Zn1–N1, 110.61(7); ∠O1–Zn1–N1, 96.55(5); ∠O4–Zn1–O2, 92.74(5); ∠O5–Zn1–O2, 90.86(6); ∠O1–Zn1–O2, 173.06(5).

O7, 2.43 Å and Cu1–O8, 2.55 Å, are much longer than the other two Cu–O bonds from the ligand. The Cu1–O8 distance is too long to form a strong Cu–O bond, and thus if this Cu–O interaction is ignored the geometry around copper is distorted square pyramidal (Fig. 3). On the other hand, the pyridine is tightly bound to copper, it has a comparable Cu1–N1 bond distance with the ligand Cu1–N2 distance. Some of the important bond distances and bond angles are listed in Fig. 3. The presence of pyridine as a coordinating ligand in complex **5** suggests that in the case of copper(II) chloride, the reaction with LNa_2 initially forms a tri-aqua complex similar to that of the nickel complex **3**, which then might have undergone a ligand substitution reaction, replacing an aqua ligand by a pyridine, and because of steric congestion in the complex one of the

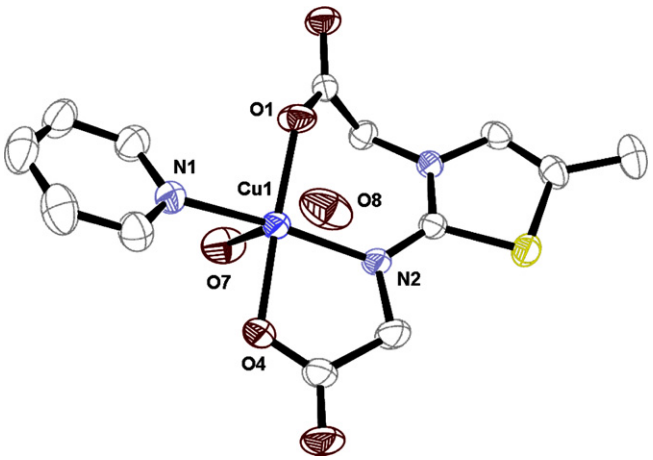

Fig. 3. The structure of complex **5**, the hydrogen atoms are omitted for clarity. Selected bond distances (Å) and bond angles (°): Cu1–O1, 1.967(16); Cu1–O4, 1.960(16); Cu1–N2, 1.981(8); Cu1–N1, 2.015(19); Cu1–O7, 2.430(2); Cu1–O8, 2.555; ∠O4–Cu1–N2, 96.79(7); ∠O4–Cu1–O1, 172.64(8); ∠O1–Cu1–N2, 82.72(7); ∠O4–Cu1–N1, 88.56(8); ∠O1–Cu1–N1, 91.46(8); ∠N2–Cu1–N1, 173.32(8); ∠O4–Cu1–O7, 98.06(8); ∠O1–Cu1–O7, 89.29(8); ∠N2–Cu1–O7, 95.05(8); ∠N1–Cu1–O7, 88.14(8).

aqua ligand remains further away at an axial position of the original six coordinated system.

In conclusion we have synthesized an imine containing flexible dicarboxylic acid through tautomerism in a thiamine derivative and have shown that it can either lead to mononuclear or polynuclear complexes depending on the metals; the hexacoordinated mononuclear nickel complex of L has three aqua ligands on one face leaving scope for further transformations.

4. Supplementary data

CCDC 679648, 679650 and 681972 contain the supplementary crystallographic data for **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

is the sum of the kinetic electron energy density (G_C) and the potential electron energy density (V_C)) derived from the Bader theory also indicate the type of interaction and cooperative effect on the nature of the interactions. The negative value of the Laplacian of the electron density at BCP ($\nabla^2_{\rho BCP} < 0$) designates the concentration of the electron charge in the region between the nuclei of the interacting atoms and is typical of covalent bonds-shared interactions. In the case $\nabla^2_{\rho BCP} > 0$, there is a depletion of the electron charge between atoms, indicating that there is an interaction of closed-shell systems like ions, van der Waals interactions or H-bonds. Hence one can see that the Bader theory arbitrarily provides the characteristics of BCPs based on whether the interaction is covalent in nature. For a negative value of a Laplacian, there is no doubt about its covalency (from the AIM theory point of view). Also, the $-G_C/V_C$ ratio may show the regions belonging to covalent or non-covalent interactions. If such a ratio is greater than 1, then the interaction is non-covalent. In the case of a ratio between 0.5 and 1, the interaction is partly covalent in nature, and where $-G_C/V_C$ is less than 0.5, the interaction is a shared interaction because $\nabla^2_{\rho BCP}$ is smaller than zero [28].

3. Results and discussion

Association of one molecule of cyanic acid with one molecule of water leads to formation of a 1:1 cluster which is denoted as $W1C_H$ (see Table 1, Fig. 1 and S1). C is cyanic acid, W is water and the subscripted letter denotes an atom of HOCN that is incorporated in H-bonding with water, for example $W1C_H$ shows $H_2O\cdots$HOCN. In $W1C_H$, the H of the cyanic acid is connected to the O of water. Our attempts could obtain neither $W1C_O$ nor $W1C_N$ because their starting configurations go to $W1C_H$ upon optimization. In $W1C_O$, the water molecule acts as a hydrogen bond donor (HBD) and the O of the cyanic acid plays the role of a hydrogen bond acceptor (HBA). In the last 1:1 cluster, which was considered to be $W1C_N$, the water molecule acts as the HBD and the N atom of HOCN acts as the HBA.

Since the OCN group is electron deficient, its O and N atoms show a diminished tendency to accept the H atom from a water molecule. In contrast, the electron withdrawing OCN group enhances the positive charge on the H atom of HOCN and improves its HBD capability. In summary, the electron deficiency of OCN enhances the HBD ability of HOCN but is acts against its role as a HBA. Also, the results show that HOCN is a stronger HBD and a weaker HBA than H_2O.

The atoms in the molecules analysis show $\nabla^2_{\rho BCP} > 0$ and $-G_C/V_C < 1$ for $W1C_H$. Thus, it could be mentioned that the HB interactions in $W1C_H$ are partly covalent.

Let us compare the 1:1 cluster studied in the present work at the MP2 level with that which has been reported in our earlier studies for HCNO–H_2O, HNCO–H_2O and HONC–H_2O systems, Table S1 [18–20]. The stabilization energies of $W1C_H$, $W1If_H$ [20], $W1I_H$ [19] and $W1F_H$ [18] are −10.21, −9.99, −5.32 and −4.14 kcal mol^{-1}, respectively. The stabilities of the 1:1 clusters of HOCN and HONC ($W1C_H$ and $W1If_H$) are comparable and are greater than the stabilities of the 1:1 clusters of HNCO and HCNO ($W1I_H$ and $W1F_H$). This is due to the stronger HBD in the former molecules compared to the other two, which arises from greater local charges on the H atoms of the HOCN and HONC molecules.

In addition, the prediction of $W1I_O$, $W1I_N$, $W1If_C$ and $W1F_O$, and failure to predict $W1C_O$ and $W1C_N$ show that HOCN is a poorer HBA than HONC, HNCO and HCNO. Apparently, the group electronegativity depends on the arrangement of the C, N and O atoms in these groups, so that different values of HBA abilities in these isomers lead to the prediction of various stabilities of their 1:1 clusters.

All the starting geometries for the 1:2 clusters of HOCN–HOH–H_2O, H_2O–HOCN–HOH and H_2O–H_2O–HOCN go to a cyclic structure ($W2C_{HN}$) upon optimization. In this structure, the HOCN molecule acts both as a HBD and a HBA. The partly covalent character of the $H_2O\cdots$HOCN bonds and non-covalent character of HOCN$\cdots$HOH could be concluded from the AIM results.

In the 1:2 stoichiometry, upon optimization for HOCN, HONC, HNCO and HCNO, 1, 1, 2 and 4 clusters have been predicted, respectively. The difference in the numbers of 1:2 clusters could be interpreted in term of the HBA ability of these molecules. On the other hand, $W2C_{HN}$ (SE = −21.93 kcal mol^{-1}) has a comparable stability to $W2If_{HC}$ (−20.54), and they are more stable than the 1:2 clusters of the HNCO and HCNO molecules, Table S1.

For 1:3 clusters, the four geometries $W3C_{HO}$, $W3C_{HN(I)}$, $W3C_{HN(II)}$ and $W3C_{HN(III)}$ were obtained. In all of these clusters, the HOCN molecule has both the role of a HBD and a HBA. In the $W3C_{HO}$ cluster, the O atom of HOCN plays the role of a HBA but in $W3C_{HN}$ the N atom of the HOCN molecule has this role. The stabilities of the 1:3 clusters are in the order $W3C_{HO} > W3C_{HN(I)} > W3C_{HN(II)} > W3C_{HN(III)}$. Table 2 shows that the covalent character of the $H_2O\cdots$HOCN bond in the 1:3 clusters has increased with respect to the 1:1 and 1:2 clusters. Like the 1:1 and 1:2 clusters, the stability of the 1:3 cluster of HOCN is slightly greater than the HONC cluster, and in turn they are more stable than the HNCO and HCNO clusters.

In the case of the 1:4 clusters, the starting configurations after optimization go to $W4C_{HO(I)}$, $W4C_{HN(I)}$, $W4C_{HN(II)}$, $W4C_{HNO(I)}$ and $W4C_{HNO(II)}$ as local minima. In all of these structures the HOCN molecule acts both as a HBD and a HBA. The O atom in $W4C_{HO}$, the N atom in $W4C_{HN}$; both N and O atoms in $W4C_{HNO}$ clusters have the role of a HBA in the HOCN molecule. The stabilities of the 1:4 clusters are as follows: $W4C_{HNO(I)} > W4C_{HO(I)} > W4C_{HN(II)} > W4C_{HNO(II)} > W4C_{HN(I)}$.

From a comparison of the AIM results of the 1:4 clusters with the corresponding values for the 1:1, 1:2 and 1:3 clusters in Table 2, it could be concluded that the covalent property of the $H_2O\cdots$HOCN bond is enhanced with the cluster size. It shows that the identity of these interactions depends on the cooperative effect.

Also a comparison of the 1:4 clusters, Table S1, shows that the stabilities of the clusters of HOCN and HONC are close together, and they are more stable than the corresponding 1:4 clusters for HNCO and HCNO. The stabilities of the H_2O–HOCN clusters was predicted as: $W4C_{HN(I)} > W4C_{HNO(II)} > W4C_{HN(II)} > W4C_{HO(I)} > W3C_{HN(III)} > W4C_{HNO(I)} > W3C_{HN(II)} > W3C_{HN(I)} > W3C_{HO} > W2C_{HN} > W1C_H$.

According to the results, clusters with HOCN just as a HBA could not be predicted since they convert to a more stable cluster with HOCN as a HBD during optimization. This is due to the effect of the electron withdrawing character of the OCN groups on the partial charges of the H, N and O atoms. The OCN group, by inducing a greater positive charge on the H of HOCN, enhances its HB interaction with an H_2O molecule. In contrast, the lack of suitable electron

density on the N and O atoms of HOCN diminish their HBA tendency for a HB interaction with H_2O. The stabilization energies become more negative by increasing the cluster size. This indicates that increasing the number of water molecules in the cluster occurs along with enhancement of its stability.

The results of intermolecular bond lengths and bond angles are given in Table 3. The H_2O···HOCN distance decreases from 1.682 Å in W1C$_H$ to 1.584, 1.504 and 1.490 Å in a series of homologue clusters of W2C$_{HN}$, W3C$_{HN(I)}$ and W4C$_{HN(I)}$. This reduction in the H_2O···HOCN bond length is the result of greater stability of the larger clusters. A similar shortening of the HOH···N distances was found so that the HOH···N bond of 2.107 Å in W2C$_{HN}$ reduced to 1.905 and 1.869 Å in W3C$_{HN(I)}$ and W4C$_{HN(I)}$. These values are in line with the increasing calculated cooperative effects (−6.73,

−13.74 and −17.78 kcal mol^{-1}) for the $W2C_{HN}$, $W3C_{HN(I)}$ and $W4C_{HN(I)}$ clusters. Also the homologue clusters $W3C_{HO}$ and $W4C_{HO(I)}$, with 1.993 and 1.917 Å distances for the H···OC bond and CE values of −8.96 and −13.49, represent an increase of stability with cluster size.

As Table 3 shows, elongation of the H–O bond in HOCN with cluster formation was predicted. For instance, the H–O bond length increases from 0.966 Å in free HOCN to 0.987, 1.009, 1.023 and 1.025 Å in $W1C_H$, $W2C_{HN}$, $W3C_{HN(I)}$ and $W4C_{HN(I)}$ respectively. Also the greatest elongation (1.046 Å) was found for $W4C_{HNO(II)}$. Elongation of the H–O bond results from the contribution of its hydrogen as a HBD in hydrogen bond formation. A higher degree of HB interaction causes more lengthening of this bond.

Elongation of the H–X bonds (Δr_{H-X} X = OCN, ONC, NCO, CNO) in similar clusters shows that Δr_{H-X} in HOCN is greater than in HONC, and in turn both these values are greater than in HNCO and HCNO. In contrast, the $H_2O\cdots HX$ distances for X = OCN is slightly shorter than for X = ONC, and both are shorter than X = NCO or CNO, Tables S2–S4 [18–20]. Greater elongations of the H–X bond along with shorter $H_2O\cdots HX$ distances for HOCN clusters results from the stronger contribution as a HBD toward water molecules.

Similar conclusions could be deduced from the red shift of the H–X stretching frequencies, $\Delta\nu_{H-X}$, for clusters with similar structures, Tables S4 and S5. The larger $\Delta\nu_{H-X}$ value of the H–X stretching mode in HOCN clusters is the result of more SE and stronger $H_2O\cdots HX$ bonds. Also the variation of the H–X bond works against the $H_2O\cdots HX$ interaction, so that stronger $H_2O\cdots HOCN$ bonds have weaker H–OCN bonds with bigger values for Δr_{H-X} and $\Delta\nu_{H-X}$. Thus, it might be concluded that greater values of Δr_{H-X} and $\Delta\nu_{H-X}$ in the HOCN cluster indicate that, in comparison with HONC, HNCO and HCNO, the cluster has a better HBD ability to bond to water molecules.

As Table 3 shows, deviations of the HOC and OCN angles in clusters relative to the values predicted for the free HOCN molecule is evident.

From the results of Table 1, the influence of the cooperative effect (CE) on the stability of the studied complexes can be deduced. The cooperative effect is defined [29] as $\Delta E_{CE} = \Delta E_{cluster} - \sum\Delta E_{dimer}$ where the sum is over the 1:1 clusters that make up

the cluster. Thus, for example, $W4C_{HN(I)}$ consists of one 1:1 cluster $W1C_N$, one 1:1 cluster $W1C_H$ and three water dimers with $\Delta E_{CE} = -17.78$ kcal mol^{-1}.

Table 4 gives selected vibrational stretching frequencies (cm^{-1}) with the corresponding intensities (km mol^{-1}) for clusters, along with the H–O frequency shifts in the HOCN subunit.

The greatest change occurs as a large red shift for the H–O stretching frequency (-1450 cm^{-1}) in $W4C_{HNO(II)}$. This red shift gives further evidence about the significant cooperative effect that comes from the greater red shift of H–O with a growing cluster size. For $W1C_H$, $W2C_{HN}$, $W3C_{HN(I)}$ and $W4C_{HN(I)}$, the $H_2O\cdots$HOCN frequencies are 251, 319, 367 and 388 cm^{-1}, and the HOH$\cdots$NCO frequencies are 154, 192 and 222 cm^{-1} for $W2C_{HN}$, $W3C_{HN(I)}$ and $W4C_{HN(I)}$, which confirms an increase in the intermolecular stretching frequencies with an increase in size and consequently stability of the complexes. Also HOH$\cdots$OCN frequencies of 151 and 153 cm^{-1} show a similar trend for the $W3C_{HO}$ and $W4C_{HO(I)}$ clusters.

In general, a comparison of the results in this study with our previous works [18–20] shows that the stability of the clusters is in the order HOCN > HONC > HNCO > HCNO. This arises from the effect of the arrangement of the C, N and O atoms on their group electronegativity towards the H atom. Evidently, a hydrogen attached to a more electronegative O atom has a greater local charge and is better exposed to hydrogen bonding than hydrogens attached to N and C atoms. Therefore, HOCN and HONC are stronger HBDs than HNCO and HCNO. For interpretation of the stronger HBD property of HOCN relative to HONC, it might be mentioned that in OCN the electronegative O and N atoms are on the two sides of the C atom. Thus, the electron releasing vector of the C atom is divided to two smaller vectors between them in opposite directions. Hence, the arrangement of atoms in OCN is such that the N atom cannot compensate for the electron withdrawing effects of the O atom. But in ONC, since the electronegative O and N atoms are on the same side, both the C and N atoms can simultaneously compensate for the electron withdrawing properties of the O atom. Therefore, in HOCN, the H atom has a greater local charge and is a stronger HBD than HONC. Similar discussions and such conclusions could be presented from the B3LYP results, Tables S6–S8.

4. Concluding remarks

The mixed clusters of H_2O and HOCN exhibit clear evidence of cooperative effects of hydrogen bonding in this system. This work discussed hydrogen bonding in terms of the molecular structure for $HX(H_2O)_n$ (X = OCN, ONC, NCO, CNO; n = 1–4) clusters. The results showed that the stability of the hydrogen bonds depends tightly on the arrangement of the C, N and O atoms in the X function. According to our findings for similar structures, the stability of the clusters varies in the order: HOCN > HONC > HNCO > HCNO. This could be interpreted in terms of group electronegativity for the X function in HX, which depends on the order of the C, N and O atoms.

Acknowledgments

We are very grateful to Dr. Mahmood Reza Moradian for reading and corrections of this article.

Appendix A. Supplementary data

Tables of stabilization energies, bond lengths, elongation of H–X, frequency shift of H–X in hydrogen bonded clusters at the MP2/6-311++G(d,p), level of the DFT/B3LYP/6-311++G(d,p) calculations and molecular graphs of the clusters are available. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.05.038.

2. Experimental

2.1. Synthesis of **HL**

A solution of diethyl 4-aminobenzylphosphonate (0.243 g, 1 mmol) in CH_2Cl_2 (15 mL) was added dropwise to a solution of $SCNP(S)(OiPr)_2$ (0.263 g, 1.1 mmol) in the same solvent (15 mL). The mixture was stirred at room temperature for 3 h. The solvent was then removed in vacuum. The residue was recrystallized from a dichloromethane–*n*-hexane mixture 1:5 (v/v). The product was obtained as colorless crystals. Yield: 0.429 g (89%). M.p. 73 °C. ^{1}H NMR ($CDCl_3$): δ = 1.26 (t, $^3J_{H,H}$ = 7.1 Hz, 6H, CH_3, EtO), 1.38 (d, $^3J_{H,H}$ = 6.2 Hz, 12H, CH_3, *i*PrO), 3.14 (d, $^2J_{P,H}$ = 21.5 Hz, 2H, CH_2, $P(O)CH_2$), 4.04 (d. quart, $^3J_{H,H}$ = 7.1 Hz, $^3J_{POCH}$ = 8.8 Hz, 4H, OCH_2, EtO), 4.86 (d. sept, $^3J_{H,H}$ = 6.2 Hz, $^3J_{POCH}$ = 10.5 Hz, 2H, OCH, *i*PrO), 7.19 (d, $^2J_{PNH}$ = 10.4 Hz, 1H, NH, P(S)NH), 7.27–7.53 (m, 4H, C_6H_4), 9.66 (s, 1H, NH). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 26.7 (1P, P=O), 53.4 (1P, P=S). IR: ν = 622 (P=S), 968, 992, 1026 (POC), 1207 (P=O), 1559 (S=C–N), 3126, 3272 (NH) cm^{-1}. *Anal.* Calc. for $C_{18}H_{32}N_2O_5P_2S_2$ (482.53): C, 44.80; H, 6.68; N, 5.81. Found: C, 44.68; H, 6.79; N, 5.74.

2.2. Synthesis of **ML_2**

A suspension of **HL** (0.241 g, 0.5 mmol) in aqueous ethanol (20 mL) was mixed with an ethanol solution of potassium hydroxide (0.031 g 0.55 mmol). An aqueous (20 mL) solution of $ZnCl_2$, $Cd(CH_3COO)_2{\cdot}2H_2O$, $Co(NO_3)_2 \cdot 6H_2O$ (0.041, 0.080 or 0.087 g, respectively; 0.3 mmol) was added dropwise under vigorous stirring to the resulting potassium salt. The mixture was stirred at room temperature for a further 3 h and left overnight. The resulting complex was extracted with dichloromethane, washed with water and dried with anhydrous $MgSO_4$. The solvent was then removed in vacuo. The residue was recrystallized from a dichloromethane/*n*-hexane mixture.

ZnL_2. Complex was obtained as colorless crystals. Yield: 0.157 g (61%). M.p. 163 °C. ^{1}H NMR ($CDCl_3$): δ = 1.08–1.47 (m, 36H, CH_3, EtO + *i*PrO), 3.13 (d, $^2J_{P,H}$ = 21.1 Hz, 4H, CH_2, $P(O)CH_2$), 3.93–4.10 (m, 8H, OCH_2, EtO), 4.79 (d. sept, $^3J_{H,H}$ = 6.2 Hz, $^3J_{POCH}$ = 10.1 Hz, 4H, OCH, *i*PrO), 7.25–7.79 (m, 8H, C_6H_4), 6.53 (s, 2H, NH). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 24.9 (2P, P=O), 56.0 (2P, P=S). IR: ν = 603 (P=S), 1008, 1012 (POC), 1263 (P=O), 1547 (S=C–N), 3305 (NH) cm^{-1}. *Anal.* Calc. for $C_{36}H_{62}N_4O_{10}P_4S_4Zn$ (1028.44): C, 42.04; H, 6.08; N, 5.45. Found: C, 42.13; H, 5.91; N, 5.52.

CdL_2. Complex was obtained as colorless crystals. Yield: 0.231 g (86%). M.p. 109 °C. ^{1}H NMR ($CDCl_3$): δ = 1.17–1.51 (m, 36H, CH_3, EtO + *i*PrO), 3.03 (d, $^2J_{P,H}$ = 21.8 Hz, 4H, CH_2, $P(O)CH_2$), 3.85–4.02 (m, 8H, OCH_2, EtO), 4.82 (d. sept, $^3J_{H,H}$ = 6.2 Hz, $^3J_{POCH}$ = 10.3 Hz, 4H, OCH, *i*PrO), 7.27–7.72 (m, 8H, C_6H_4), 6.71 (s, 2H, NH). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 25.2 (2P, P=O), 56.2 (2P, P=S). IR: ν = 607 (P=S), 1007 (POC), 1259 (P=O), 1539 (S=C–N), 3296 (NH) cm^{-1}. *Anal.* Calc. for $C_{36}H_{62}CdN_4O_{10}P_4S_4$ (1075.46): C, 40.20; H, 5.81; N, 5.21. Found: C, 40.39; H, 5.73; N, 5.30.

CoL_2. Complex was obtained as green crystals. Yield: 0.233 g (91%). M.p. 94 °C. IR: ν = 600 (P=S), 1012 (POC), 1260 (P=O), 1551 (S=C–N), 3311 (NH) cm^{-1}. UV–Vis spectra, [λ_{max}, nm (ε, 1 mol^{-1} dm^3cm^{-1})]: 558 (263), 607 (286), 668 (157). *Anal.* Calc. for $C_{36}H_{62}CoN_4O_{10}P_4S_4$ (1021.99): C, 42.31; H, 6.11; N, 5.48. Found: C, 42.47; H, 6.25; N, 5.41.

2.3. Synthesis of **$Cu(PPh_3)L$**

A suspension of **HL** (0.241 g, 0.5 mmol) in aqueous ethanol (15 mL) was mixed with an ethanol solution of KOH (0.031 g 0.55 mmol). A dichloromethane (15 mL) solution of $Cu(PPh_3)_3I$ (0.489 g, 0.5 mmol) was added dropwise under vigorous stirring to the resulting potassium salt. The mixture was stirred at room temperature for a further hour and a precipitate was filtered off. The filtrate was concentrated until the crystallization began. The residue was recrystallized from a dichloromethane–*n*-hexane mixture 1:5 (v/v). Complex was obtained as colorless crystals. Yield: 0.295 g (73%). M.p. 127 °C. ^{1}H NMR ($CDCl_3$): δ = 1.12–1.44 (m, 18H, CH_3, EtO + *i*PrO), 3.10 (d, $^2J_{P,H}$ = 21.3 Hz, 2H, CH_2, $P(O)CH_2$), 3.89–4.08 (m, 4H, OCH, EtO), 4.73 (d. sept, $^3J_{H,H}$ = 6.1 Hz, $^3J_{POCH}$ = 10.4 Hz, 2H, OCH, *i*PrO), 7.13–7.23, 7.28–7.77 (m, 19H, $C_6H_4 + C_6H_5$), 8.47 (s, 1H, NH). $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = –0.9 (1P, PPh_3), 27.1 (1P, P=O), 55.3 (1P, P=S). IR: ν = 606 (P=S), 962, 974, 998, 1017 (POC), 1252 (P=O), 1530 (S=C–N), 3263 (NH) cm^{-1}. *Anal.* Calc. for $C_{36}H_{46}CuN_2O_5P_3S_2$ (807.36): C, 53.56; H, 5.74; N, 3.47. Found: C, 53.43; H, 5.85; N, 3.34.

2.4. Physical measurements

Infrared spectra (Nujol) were recorded with a Specord M-80 spectrometer in the range 400–3600 cm^{-1}. NMR spectra were obtained on a Varian Unity-300 NMR spectrometer at 25 °C. ^{1}H and $^{31}P\{^1H\}$ spectra were recorded at 299.948 and 75.429 MHz, respectively. Chemical shifts are reported with reference to $SiMe_4$ (^{1}H) and H_3PO_4 ($^{31}P\{^1H\}$). Electronic spectra of absorption in 0.001 M solution of CH_2Cl_2 were measured on a Perkin–Elmer Lambda-35 spectrometer in the range 200–1000 nm. Elemental analyses were performed on a Perkin–Elmer 2400 CHN microanalyser.

2.5. Crystal structure determination and refinement

Crystals of **HL** were obtained by slow evaporation of the solvent from dichloromethane/*n*-hexane solution. $C_{18}H_{32}N_2O_5P_2S_2$, M_r = 482.54 g mol^{-1}, crystal system: monoclinic, space group: $P2_1/c$, a = 7.6294(1), b = 9.3135(2), c = 35.2519(6) Å, β = 94.964 (1)°, V = 2495.48(8) $Å^3$, ρ = 1.284 g cm^{-3}. Cell parameters and intensities of 5931 independent reflections, from which 3689 with $I \geqslant 2\sigma$, were measured (ω-scan, $\theta \leqslant 27.00°$) at 296 K on a Bruker Smart Apex II diffractometer and graphite-monochromatied Mo Kα radiation generated by fine-focus X-ray tube operated at 50 kV and 30 mA. The images were indexed, integrated and scaled using the Apex2 data reduction package [22]. Data were corrected for absorption using SADABS [23] program (μMo 3.71 cm^{-1}). The structure was solved by direct method using SIR-97 [24] program and refined first isotropically and then anisotropically using SHELXL97 [25] and WINGX programs [26]. Hydrogen atoms were revealed from $\Delta\rho$ maps and refined isotropically. The final residuals were R_{ob} = 0.0492, R_{wob} = 0.0903 based on 3689 independent reflections with $F^2 \geqslant 2\sigma$. All figures were made using the program PLATON [27].

Crystals of **$Cu(PPh_3)L$** were obtained by slow evaporation of the solvent from dichloromethane/*n*-hexane solution. $C_{36}H_{46}CuN_2O_5P_3S_2$, M_r = 807.32 g mol^{-1}, crystal system: triclinic, space group: $P\bar{1}$, a = 8.9510(8), b = 11.5966(9), c = 20.0844(16) Å, α = 77.572(6)°, β = 77.538(6)°, γ = 79.331(7)°, V = 1966.8(3) $Å^3$, ρ = 1.363 g cm^{-3}. Cell parameters and intensities of 18274 reflections (7710 unique, R_{int} = 0.0822), from which 4594 had $I \geqslant 2\sigma$, were measured (ω-scan, $\theta \leqslant 25.12°$) at 173 K on a STOE IPDS-II diffractometer and graphite-monochromatied Mo Kα radiation generated by fine-focus X-ray tube operated at 50 kV and 40 mA. The images were indexed, integrated and scaled using the X-Area package [28]. Data were corrected for absorption using PLATON [27] program (μMo 0.826 mm^{-1}). The structure was solved by direct method using SHELXS [29] program and refined first isotropically and then anisotropically using SHELXL97 [25]. Hydrogen atoms were revealed from $\Delta\rho$ maps and refined using a riding model. The final residuals were R_{ob} = 0.0466, R_{wob} = 0.0801 based on

4594 independent reflections with $F^2 \geqslant 2\sigma$. All figures were made using the program PLATON [27].

3. Results and discussion

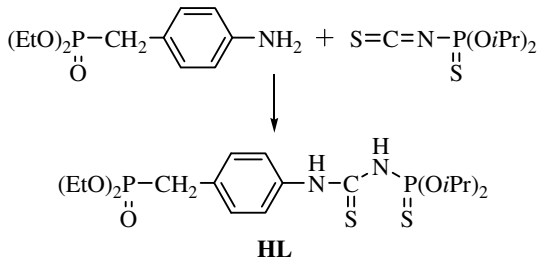
3.1. Synthesis

N-Thiophosphorylated thiourea **HL** was prepared by the addition of diethyl 4-aminobenzylphosphonate $(EtO)_2P(O)CH_2C_6H_4$-4-NH_2 to *O,O'*-diisopropylthiophosphoric acid isothiocyanate $(i\text{PrO})_2P(S)NCS$ (Scheme 1).

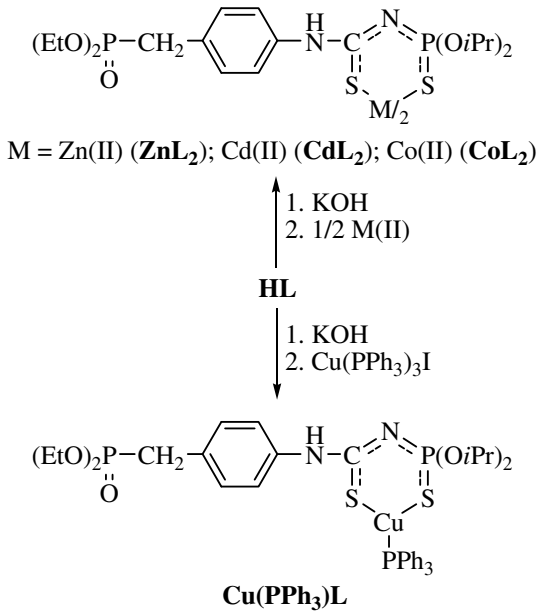
Complexes of **HL** with the Zn(II) (**ZnL_2**), Cd(II) (**CdL_2**) and Co(II) (**CoL_2**) cations were prepared by the following procedure: ligand was converted into potassium salt **KL** and followed by reaction with $ZnCl_2$, $Cd(CH_3COO)_2 \cdot 2H_2O$ or $Co(NO_3)_2 \cdot 6H_2O$ in aqueous EtOH (Scheme 2).

Reaction of the potassium salt of **HL** with $Cu(PPh_3)_3I$ in aqueous $EtOH/CH_2Cl_2$ leads to mononuclear **Cu(PPh$_3$)L** complex (Scheme 2).

The compounds obtained are colorless (**HL**, **ZnL_2** and **CdL_2**) or green (**CoL_2**) crystalline powders, soluble in acetone, benzene, dichloromethane and insoluble in water and *n*-hexane. UV–Vis, ^1H, $^{31}P\{^1H\}$ NMR in solution and IR data indicated that the thiourea **HL** is a 1,5-*S,S'*-ligand.



Scheme 1. Preparation of **HL**.



Scheme 2. Preparation of **ZnL_2**, **CdL_2**, **CoL_2** and **Cu(PPh$_3$)L**.

3.2. IR, UV–Vis and NMR spectroscopic data

The IR spectrum of **HL** contains a weak band at 622 cm^{-1} assigned to the P=S group. It is shifted to low frequencies (600–607 cm^{-1}) in the spectra of complexes **ML_2** and **Cu(PPh$_3$)L** due to the coordination with the cation. Occurrence of the new broad and strong absorption peak at 1530–1551 cm^{-1}, related to the conjugated SCN group [30], also proves the formation of 1,5-*S,S'*-chelate. Presence of the substituted POC groups in **HL** and its complexes are seen in the IR spectra by their absorption bands at 962–1026 cm^{-1}.

There are two bands for the ArNH and P(S)NH groups at 3126 and 3272 cm^{-1} in the IR spectrum of **HL**, whereas a unique band at 3296–3311 and 3263 cm^{-1} related to the ArNH group was observed in the spectra of complexes **ML_2** and **Cu(PPh$_3$)L**, respectively. It should be noted that the band for the ArNH group in the IR spectra of **ML_2** is shifted to high frequencies whereas in **Cu(PPh$_3$)L** this band is practically at the same frequencies relative to the band of the parent ligand **HL**. The similar is observed for the P=O absorption band in the IR spectra. The band at 1259–1263 cm^{-1} in the spectra of **ML_2** corresponds to the P=O group and shifted to high frequencies relative to that in **HL**. The P=O band at 1257 cm^{-1} in the IR spectrum of complex **Cu(PPh$_3$)L** is practically at the same area as it was observed in the parent thiourea (1252 cm^{-1}) due to the intermolecular N–H···O=P hydrogen bonds in a crystal (Figs. 1 and 2). This confirms the preservation of the hydrogen bonding in the structure of **Cu(PPh$_3$)L** and absence of it in complexes **ML_2**.

The $^{31}P\{^1H\}$ NMR spectrum of **HL** in a $CDCl_3$ solution shows two single resonances at 26.7 and 53.4 ppm, corresponding to the phosphorus atoms of the P=O and P=S groups, respectively. In the $^{31}P\{^1H\}$ NMR spectra of complexes **ZnL_2**, **CdL_2** and **Cu(PPh$_3$)L**, the resonance for the phosphoryl and thiophosphoryl groups are shown at 24.9–27.1 and 55.3–56.2 ppm, respectively. The signal corresponding to the P=S group is low-field shifted, whereas the singlet for the P=O group is practically at the same region relative to those in the parent ligand for **Cu(PPh$_3$)L** and low-field shifted in the $^{31}P\{^1H\}$ NMR spectra of complexes **ZnL_2** and **CdL_2**. The signal of the triphenylphosphine group in copper(I) complex is shifted downfield relative to the free PPh_3 and exhibit $^{31}P\{^1H\}$ NMR

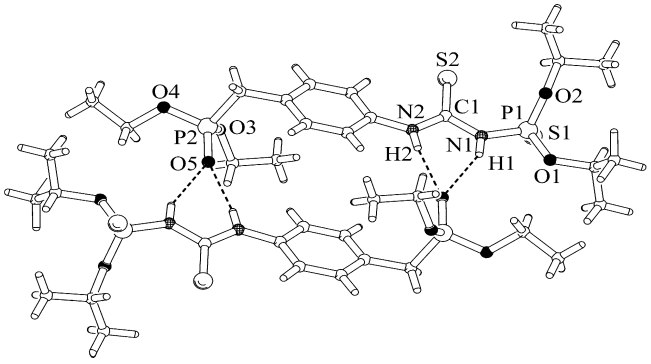


Fig. 1. Molecular structure and hydrogen bonding dimer in crystal of **HL**. Selected bond distances (Å) and angles (°): S(1)–P(1) 1.9166(11), S(2)–C(1) 1.657(3), P(1)–O(1) 1.583(2), P(1)–O(2) 1.561(2), P(1)–N(1) 1.666(2), P(2)–O(3) 1.556(2), P(2)–O(4) 1.570(2), P(2)–O(5) 1.469(2), N(1)–C(1) 1.376(3), N(2)–C(1) 1.346(3); S(1)–P(1)–O(1) 115.73(8), S(1)–P(1)–O(2) 115.57(8), S(1)–P(1)–N(1) 118.90(8), O(1)–P(1)–O(2) 102.92(9), O(1)–P(1)–N(1) 94.11(10), O(2)–P(1)–N(1) 106.58(11), O(3)–P(2)–O(4) 105.24(10), O(3)–P(2)–O(5) 113.44(10), O(4)–P(2)–O(5) 113.67(11), P(1)–N(1)–C(1) 126.8(2), S(2)–C(1)–N(1) 120.3(2), S(2)–C(1)–N(2) 127.1(2), N(1)–C(1)–N(2) 112.6(2). The intermolecular hydrogen bond parameters in the molecule are as follows: N(1)–H(1)···O(5)′(1–x, 1–y, –z): *d*(N–H) 0.81(3), *d*(H···O′) 2.26(3), *d*(N···O′) 2.997(3), ∠(NHO′) 153(3); N(2)–H(2)···O(5)′ (1–x, 1–y, –z): *d*(N–H) 0.79(3), *d*(H···O′) 2.11(3), *d*(N···O′) 2881(3), ∠(NHO′) 167(3).

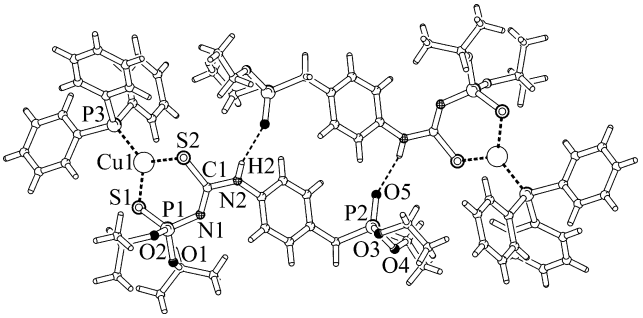

Fig. 2. Molecular structure and hydrogen bonding dimer in crystal of **Cu(PPh$_3$)L**. Selected bond distances (Å) and angles (°): Cu(1)–S(1) 2.2485(11), Cu(1)–S(2) 2.2163(11), Cu(1)–P(3) 2.2142(11), S(1)–P(1) 1.9950(13), S(2)–C(1) 1.754(4), P(1)–O(1) 1.583(3), P(1)–O(2) 1.588(3), P(1)–N(1) 1.600(3), P(2)–O(3) 1.579(4), P(2)–O(4) 1.579(3), P(2)–O(5) 1.474(3), N(1)–C(1) 1.326(5), N(2)–C(1) 1.353(5); S(1)–Cu(1)–S(2) 115.77(4), S(1)–Cu(1)–P(3) 118.63(4), S(2)–Cu(1)–P(3) 124.78(4), Cu(1)–S(1)–P(1) 94.83(5), Cu(1)–S(2)–C(1) 104.63(13), S(1)–P(1)–O(1) 113.38(10), S(1)–P(1)–O(2) 109.24(11), S(1)–P(1)–N(1) 118.28(13), O(1)–P(1)–O(2) 102.08(14), O(1)–P(1)–N(1) 106.69(15), O(2)–P(1)–N(1) 105.71(15), O(3)–P(2)–O(4) 104.27(18), O(3)–P(2)–O(5) 115.38(19), O(4)–P(2)–O(5) 113.47(17), P(1)–N(1)–C(1) 129.1(3), S(2)–C(1)–N(1) 128.4(3), S(2)–C(1)–N(2) 113.9(3), N(1)–C(1)–N(2) 117.6(3). The intermolecular hydrogen bond parameters in the molecule are as follows: N(2)–H(2)···O(5)′ (1–x, 2–y, 1–z): *d*(N–H) 0.84(4), *d*(H···O′) 2.10(4), *d*(N···O′) 2.922(4), ∠(NHO′) 164(4).

chemical shift at −0.9 ppm. In solution, the exchange between free and bound triphenylphosphine group of complex **Cu(PPh$_3$)L** results in a signal broadening of the $^{31}P\{^1H\}$ NMR spectrum, as it was previously observed for the Cu(I) complexes with *N*-thiophosphorylated thioureas and thioamides [31,32].

The ^{1}H NMR spectra of **HL**, **ZnL$_2$**, **CdL$_2$** and **Cu(PPh$_3$)L** contain a set of signals, corresponding to the resulting products. The signals for the CH_3 protons of the $(i\text{PrO})_2\text{P(S)}$ and $(\text{EtO})_2\text{P(O)}$ groups are observed as a doublet, triplet or multiplet at 1.08–1.51 ppm and a doublet of septets, doublet of quartets or multiplet at 3.85–4.86 ppm, corresponding to the OCH and OCH_2 protons. The signals for the C_6H_4 protons in the spectra of **HL**, **ZnL$_2$**, **CdL$_2$** and **Cu(PPh$_3$)L** are shown as a multiplet at 7.25–7.79 ppm. The signals for the C_6H_5 protons in the ^{1}H NMR spectrum of **Cu(PPh$_3$)L** are observed as a multiplet at 7.13–7.23 ppm. The CH_2 protons doublet signals are at 3.03–3.14 ppm. There is a doublet and singlet for the P(S)NH and ArNH protons at 7.19 and 9.66 ppm, respectively, in the spectrum of **HL**, whereas only one singlet signal for the ArNH proton at 6.53–6.71 (**ZnL$_2$** and **CdL$_2$**) and 8.47 [**Cu(PPh$_3$)L**] ppm is observed in the ^{1}H NMR spectra of complexes. This confirms the anionic forms **L** in the structure of complex.

Investigation of complex **CoL$_2$** by NMR spectroscopy was not successful, because of the paramagnetic Co(II) cation presence.

In the UV-spectrum of complex **CoL$_2$** there is an absorption band with peaks at 558 (ε_{max}, 263 mol^{-1} dm^3 cm^{-1}), 607 (ε_{max}, 286 mol^{-1} dm^3 cm^{-1}) and 668 (ε_{max}, 157 mol^{-1} dm^3 cm^{-1}) nm. The specified absorption band corresponds to a transition from the basic state $^4A_2$ to a $^4T_1$(P) state. The thin structure is caused by spin–orbital interaction as a result of which, first, there is a splitting of the state $^4T_1$(P) and, secondly, there are resolved transitions in the next doublet states with the same intensity. Other possible transitions: $^4A_2 \rightarrow {}^4T_2$ and $^4A_2 \rightarrow {}^4T_1$(F) are outside of the visible area. Data of UV-spectroscopy unequivocally confirm the tetrahedral environment of the Co(II) cation in complex **CoL$_2$**.

3.3. Crystal structures

According to the X-ray data, the molecule of **HL** in a crystal is located in a special position at the symmetry centre (Fig. 1).

X-ray analysis of the product **HL** showed that the NC(S)N fragmnet is almost planar, which is evidence of the resonance between the nitrogen lone pair and the double C=S bond. The phosphorus atoms have a distorted tetrahedral configuration typical of phosphates. The conformation of the N–C–N–P fragmnet is almost shielded, torsion angle N(2)–C(1)–N(1)–P(1) is −173.8(2)°. The bonds C(1)–S(2) and P(1)–S(1) are in *anti*-orientation. The molecule of **HL** in the crystal has a *syn*-orientation of the bonds N(1)–H(1) and N(2)–H(2) and an *anti*-orientation of the P(1)–N(1) and N(2)–C(1) bonds. Such arrangement, apparently, is caused by the formation of the intermolecular hydrogen bonds N(1)–H(1)···O(5)′ (1 − *x*, 1 − *y*, −*z*), N(2)–H(2)···O(5)′ (1 − *x*, 1 − *y*, −*z*) and N(1)′–H(1)′···O(5), N(2)′–H′···O(5) (Fig. 1). As a result of the intermolecular interactions, a centosymmetric dimer is formed.

The molecular structure of complex **Cu(PPh$_3$)L** is shown in Fig. 2. The geometry around the Cu atom is trigonal formed by two sulfurs and one PPh_3. S–P and S–C bonds are longer while P–N and N–C are shorter in comparison to those for the free ligand **HL** and have intermediate bond order values between the double and single. The six-membered CuSPNCS metallocyle has the conformation of a distorted boat with the P(1) an S(1) atoms showing the greatest deviation from the least square plane of the CuSPNCS cycle, 0.4260(13) and −0.3256(13) Å, respectively. The fragment NC(S)NP is almost planar, the sulfur of the thiophosphoryl group is significantly deviated from the average plane of this fragment, torsion angle S(1)–P(1)–N(1)–(1) is −57.5(4)°. The phosphorus atoms have a distorted tetrahedral configuration.

In a crystal two molecules of complex **Cu(PPh$_3$)L** also form a centrosymmetric dimer, which is caused by the formation of the intermolecular hydrogen bonds N(2)–H(2)···O(5)′ (1 − *x*, 2 − *y*, 1 − *z*) (Fig. 2). As a result of the intermolecular interactions and steric demanding, only one molecule of PPh_3 is coordinated with the Cu atom. Complex **Cu(PPh$_3$)L** is the first example of copper(I) complexes of *N*-thiophosphorylated thioureas and thioamides of common formula $RC(S)NHP(S)R'_2$ and one molecule of PPh_3.

4. Conclusions

In summary, novel Zn(II), Cd(II), Co(II) and Cu(PPh_3)(I) complexes with *N*-thiophosphorylated thiourea **HL** have been successfully synthesized. Copper(I) complex dissociates in a solution of $CDCl_3$, splitting off a molecule of triphenylphosphine. This process has reversible character.

NMR and UV–Vis experiments in solution and IR have shown that **HL** is a 1,5-*S*,*S*′-ligand in all complexes obtained.

Crystal structures of **HL** and **Cu(PPh$_3$)L** were determined by single crystal X-ray diffraction. According to the X-ray data, both ligand and complex in a crystal form dimer structures by intermolecular hydrogen bonds.

5. Appendix A. Supplementary data

CCDC 680113 and 682359 contain the supplementary crystallographic data for (**HL**) and [**Cu(PPh$_3$)L**]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

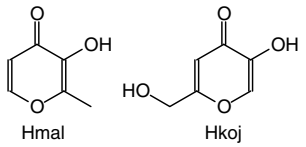

Scheme 1. Structures of the bidentate ligands Hmal and Hkoj.

erenced to TMS and $^{31}P\{^{1}H\}$ spectra were externally referenced to H_3PO_4 (85%, δ 0) with positive chemical shifts downfield the standard. Microanalyses (C, H and N) were obtained on a FISONS EA-1108 elemental analyzer.

2.2. Preparation of complexes

2.2.1. $[ReOCl(mal)_2]$ (**1**)

$(NBu_4)[ReOCl_4]$ (0.117 g, 0.2 mmol) was added to an initially colorless solution of Hmal (0.025 g, 0.2 mmol) in methanol (25 mL). The dark green solution formed was stirred for 1 h at room temperature and then kept at −15 °C for seven days for crystallization. The green crystals obtained were filtered off, washed with a small amount of *n*-hexane and dried under reduced pressure (yield: 0.085 g, 87%). Mp 223–225 °C. *Anal.* Calc. for $C_{12}H_{10}ClO_7Re$: C, 29.54; H, 2.07. Found: C, 29.96; H, 2.44%.

2.2.2. $[ReOCl_2(mal)(PPh_3)]$ (**2**)

A suspension of $[ReOCl_3(PPh_3)_2]$ (0.166 g, 0.2 mmol) and Hmal (0.025 g, 0.2 mmol) in dichloromethane (30 mL) was refluxed for 2 h. After cooling, the homogeneous solution was kept at −15 °C for seven days for crystallization of the product. The green precipitate was filtered off, washed with *n*-hexane and dried under reduced pressure (yield: 0.131 g, 99%). Mp 203–205 °C. *Anal.* Calc. for $C_{24}H_{20}ClO_4PRe$: C, 43.64; H, 3.05. Found: C, 43.67; H, 3.27%.

2.2.3. $[ReOBr_2(mal)(PPh_3)]$ (**3**)

Hmal (0.025 g, 0.2 mmol) was added to a suspension of $[ReOBr_3(PPh_3)_2]$ (0.193 g, 0.2 mmol) in dichloromethane (30 mL). The mixture was refluxed for 4 h. After cooling to room temperature, toluene (10 mL) was added to the solution. Green crystals, obtained by slow evaporation of the resulting solution were filtered off, washed with *n*-hexane and dried under reduced pressure (yield: 0.144 g, 96%). Mp 200–202 °C. *Anal.* Calc. for $C_{24}H_{20}BrO_4PRe$: C, 38.47; H, 2.69. Found: C, 38.76; H, 2.51%.

2.2.4. $[ReOCl_2(koj)(PPh_3)]$ (**4**)

A suspension of $[ReOCl_3(PPh_3)_2]$ (0.167 g, 0.2 mmol) and Hkoj (0.028 g, 0.2 mmol) in methanol (25 mL) was refluxed for 4 h. After cooling to room temperature, *n*-hexane (10 mL) was added to the solution. Green crystals of the complex, formed after 3 days at −15 °C, were filtered off, washed with *n*-hexane and dried under reduced pressure. A second crop of the complex was similarly obtained after four days of a second addition of *n*-hexane (10 mL) (yield: 0.118 g, 87%). Mp 180 °C (dec.). *Anal.* Calc. for $C_{24}H_{20}Cl_2O_5PRe$: C, 42.61; H, 2.98. Found: C, 43.41; H, 3.12%.

2.2.5. $[ReOBr_2(koj)(PPh_3)]$ (**5**)

Hkoj (0.028 g, 0.2 mmol) was added to a suspension of $[ReOBr_3(PPh_3)_2]$ (0.193 g, 0.2 mmol) in methanol (25 mL). The mixture was refluxed for 4 h. After cooling to room temperature, the microcrystalline green solid of the complex, obtained by slow concentration of the resulting solution, was filtered off, washed with *n*-hexane and dried under reduced pressure (yield: 0.142 g, 93%). Mp 210–212 °C. *Anal.* Calc. for $C_{24}H_{20}Br_2O_5PRe$: C, 37.66; H, 2.63. Found: C, 37.55; H, 2.53%.

2.3. Crystallography

The data collection for complex **1** was performed on a Bruker P4 diffractometer. An Enraf-Nonius CAD4 diffractometer was used for the X-ray diffraction measurements on complexes **2**, **3** and **5**. A Nonius KAPPA CCD equipment was used for the data collection for **4**. Standard procedures were applied by the diffractometers, which were equipped with Mo Kα radiation (λ = 0.71073 Å) and graphite monochromators.

Crystals suitable for structure analysis were obtained by crystallization from methanol (**1**), dichloromethane (**2**, **4** and **5**) and 1:1 dichloromethane/*n*-hexane (**3**) solutions of the indicated complexes at −15 °C. The cell constants were calculated from 25 reflections, measured with a wide variation of θ, for complexes **2, 3** and **5**, while 11 909 and 6710 reflections were used by the unit cell calculations for **1** and **4**, respectively. Direct methods [7] were used for the solution of all structures. The hydrogen atoms were found in Fourier-map and refined with isotropic displacement parameter for **1**. They were calculated at idealized positions and refined using the riding model in the structures of **2**, **4** and **5**. For **3**, the free isotropic refinement was combined with the use of the riding model. All non-hydrogen atoms were refined with anisotropic temperature factors, with SHELXL-97 [8]. Additional crystallographic information is given in Table 1.

3. Results and discussion

3.1. Synthesis of the rhenium complexes

The complex **1** was synthesized from $(NBu_4)[ReOCl_4]$ and maltol in methanol, with elimination of 2 equiv. of HCl. Complexes **2–5** were prepared by reacting $[ReOX_3(PPh_3)_2]$ (X = Cl for **2** and **4**; X = Br for **3** and **5**) with Hmal (**2** and **3**) or Hkoj (**4** and **5**) in dichloromethane or methanol, with formation of HX and PPh_3 as by-products. All reactions were carried out in boiling solvents, except the synthesis of **1**, which involved a very reactive starting complex and was performed at room temperature. Pure products were obtained in high yields, as crystalline green solids, directly from the reaction mixtures. Scheme 2 simplifies the synthesis of the complexes presented in the work.

3.2. Crystal structure

3.2.1. Crystal structure of $[ReOCl(mal)_2]$ (**1**)

The structure of the complex **1** is depicted in Fig. 1. The overall geometry around the rhenium atom is best described as highly distorted octahedral, with *cis*-(chloro, oxo) and *cis*-maltolato ligands. One of the monoanionic *O*,*O*-bidentate mal^- ligands occupies two positions in the equatorial plane, while the other bidentate ligand has the keto oxygen positioned equatorially and the alkoxy oxygen situated in axial position, which is *trans* to the oxo ligand. The chlorine atom occupies the remaining equatorial position to form a distorted octahedron. The Re–O(4) distance of 1.678(2) Å is in agreement with its double bond character. The equatorial ClO_3 plane is almost planar with biggest deviation of 0.0554(8) Å observed for O(32). The Re atom is placed 0.2624(7) Å out of this plane toward the oxo ligand. The axial angle O(4)–Re–O(21) = 165.9(7)° also evidences the octahedral distortion. Considering the longer $C(32)–O(22)_{alkoxy}$ and $C(42)–O(32)_{Keto}$ bond lengths as well as the shorter Re–O bond lengths involving the equatorial positioned maltolate versus the axial ligand, it can be stated that the equatorial ligand donates effectively more electron density to the rhenium center than the axial one.

The comparison of the complex **1** with its analog $[ReOBr(mal)_2]$ [4] shows that the Re–X bond distance is elongated by fairly 0.14 Å

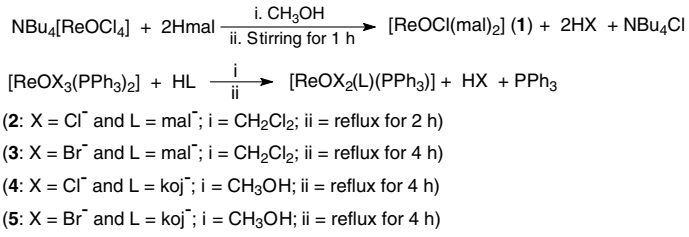

Scheme 2. Synthesis of the complexes **1**–**5**.

by changing the Cl^- ligand to Br^-. This is also observed between the complexes **2–3** and **4–5**. The complex **1**, monoclinic, and [ReOBr(mal)$_2$], triclinic, are not isostructural as are the pairs of compounds **2–3** and **4–5**. The complex [ReOBr(mal)$_2$] shows an elongation for the bonds Re–O(21) and Re–O(22) distances and a shortening for the bonds Re–O(31) and Re–O(32) when compared with the situation in **1**. These are probably results of their different packing modes. The Re–O(4) bond distance and the angles do not suffer considerable variations by changing the chlorine ligand to bromine. Selected bond lengths and angles in complex **1** and in its analogue [ReOBr(mal)$_2$] are given in Table 2.

*3.2.2. Crystal structures of [ReOCl$_2$(mal)(PPh$_3$)] (**2**), [ReOBr$_2$(mal)(PPh$_3$)] (**3**), [ReOCl$_2$(koj)(PPh$_3$)] (**4**) and [ReOBr$_2$(koj)(PPh$_3$)] (**5**)*

The complexes **2** and **3** are isostructural, as are the complexes **4** and **5,** varying only the halogen ligands from chlorine in **2** and **4** to bromine in **3** and **5**. The molecular structures of **2** and **4** are depicted in Figs. 2 and 3, respectively. The molecular structures of **3** and **5** are essentially the same as those of **2** and **4**, respectively, and are therefore not shown here. The molecular labeling schemes of **2** and **4** have also been adopted for the corresponding bromide complexes **3** and **5**. Selected bond lengths and angles for compounds **2–5** are given in Table 3.

The coordination spheres in **2–5** are composed by the oxo ligands, the phosphorus atoms of PPh_3, the halogen ligands, in *cis* arrangement, and the oxygen atoms of the bidentate ligands. It can best be described as a distorted octahedral coordination for the Re(V) central atoms. The alkoxy oxygen atom of the bidentate ligands coordinates in *trans* position to the oxo ligands, while the keto oxygen atoms coordinates *trans* to a halogen ligands. In all complexes, five-membered chelate rings are formed around the Re(V) centers.

The Re–O(4) distances vary between 1.682(4) and 1.661(5) Å in **2–5**, being in the expected range for rhenium(V) monoxo complexes and can be explained by the double bond character of these bonds

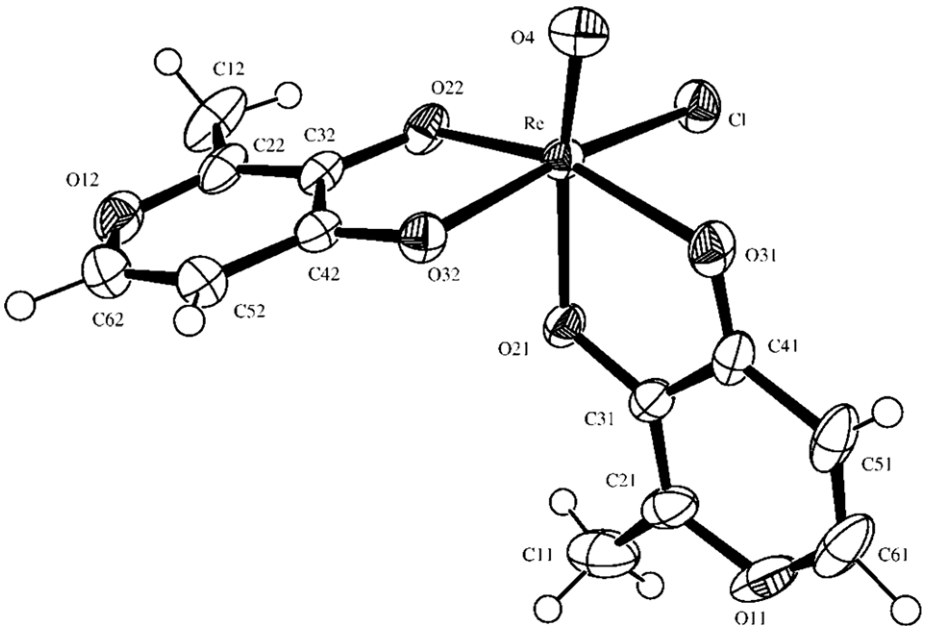

Fig. 1. Molecular structure and labeling scheme of complex [ReOCl(mal)$_2$] (**1**), with thermal ellipsoids drawn at the 50% probability level.

Table 2
Selected bond lengths (Å) and angles (°) for complex **1** and [ReOBr(mal)$_2$] [4]

	1	[ReOBr(mal)$_2$]		**1**	[ReOBr(mal)$_2$]

[a] X = Cl for **1** and Br for [ReOBr(mal)$_2$].

[1,10]. The interatomic Re–O(2) in the range 2.038(4)–2.017(5) Å are considerably longer than the values observed in other complexes, in which alkoxy donors are bonded in *trans* position to the oxo ligands, whose bond lengths are found between 1.928 and 1.888 Å. The comparably short Re–O bond length in the latter compounds is discussed to be a result of delocalization of π-electron density from the oxo bonds to the *trans* situated ones and has also been found for some chelating ligands with phenoxy or alkoxy functionalities, which direct their oxygen donor atoms to the *trans*-positions of the oxo ligands [1,10]. The values of the axial angle O(4)–Re–O(2) angles are found between 165.2(2)° and 163.3(3)° for **2–5** and describe the distortions from an ideal octahedron.

Intermolecular hydrogen bonds of the type OH···X (X = Cl or Br) involving the methylene hydroxyl group from the kojate moiety and the halogen ligand from independent complex molecules, are found in the crystal structures of **4** and **5**, forming a linear chain of complex molecules (Fig. 4).

3.3. Infrared spectroscopy

The deprotonation of maltol and kojic acid is seen by the disappearance of the typical IR absorption bands ν_{as}(OH), which are observed in the range 3270–3178 cm^{-1} in the spectra of the uncoordinated compounds. For complexes **4** and **5**, the ν_{as}(OH) band referring to the methylene hydroxyl group appears at 3443 cm^{-1} and 3445 cm^{-1}, respectively, [11]. The coordination of these ligands as bidentate *O,O′*-donors is evidenced by a bathochromic shift of the ν_{as}(C=O) band at 1655 cm^{-1} in the spectrum of Hmal and at 1660 cm^{-1} in that of Hkoj. They appear in the IR spectra of the complexes **1–5** in the region between 1619 and 1434 cm^{-1}, typically assigned as ν_{as}(C=O + C=C, chelating ligand) and ν_{as}(C=C, PPh_3) [12,13]. The bands attributed to ν_{as}(Re=O) are found in the range 987–953 cm^{-1} in the products, being in all cases shifted in relation to the starting complexes [14,15]. The coordination of the PPh_3 group to the Re(V) center in **2–5** is observed by the presence of strong bands assigned to ν(PPh) at 1098–1096 cm^{-1}, to out of plane deformation of the phenyl ring hydrogen atoms at 753–748 cm^{-1} and to phenyl ring deformation at 696–692 cm^{-1}, without significant changes when compared to the starting complexes [14,15]. The IR datasets of the uncoordinated Hmal and Hkoj and the complexes can be found in Table 4.

3.4. Multinuclear magnetic resonance

Table 5 lists the $^{13}C\{^1H\}$ and ^1H NMR data for **1**, while ^1H and $^{31}P\{^1H\}$ NMR data for **2–5** are given in Table 6. Due to the lack of

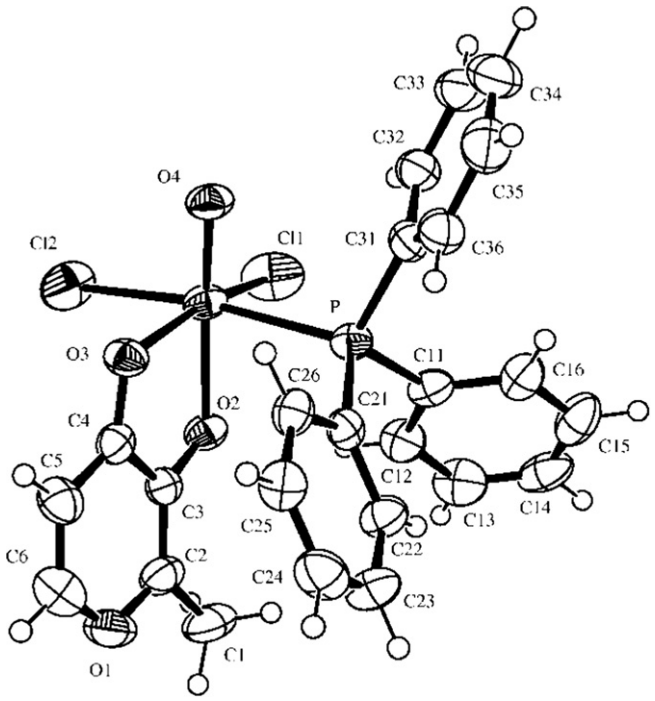

Fig. 2. Molecular structure and labeling scheme of complex $[ReOCl_2(mal)(PPh_3)]$ (**2**), with thermal ellipsoids drawn at the 50% probability level.

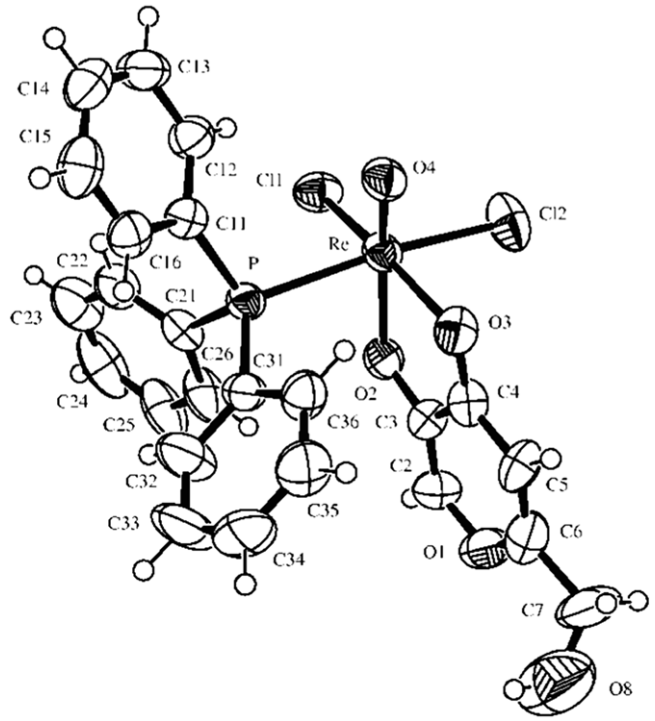

Fig. 3. Molecular structure and labeling scheme of complex $[ReOCl_2(koj)(PPh_3)]$ (**4**), with thermal ellipsoids drawn at the 50% probability level.

solubility, no ^{13}C NMR experiments were carried out for them. Integrations and signal multiplicities are in agreement with all the proposed structures in solution (Scheme 3).

Upon complexation, the resonance of the C7 protons undergo upfield shifts in **1–5**, if compared to the uncoordinated ligands.

[a] X = Cl for **2** and **4** and Br for **3** and **5**.

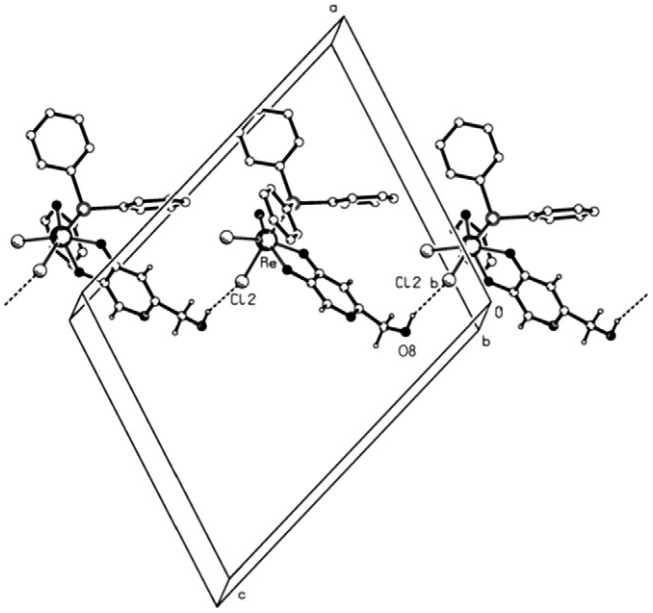

Fig. 4. View of the unit cell of **4** (virtually the same is observed in **5**, in which Cl is changed by Br), showing three complex units interconnected through H-bonds, indicated as dashed lines, forming a linear chain of molecules which is oriented perpendicular to the crystallographic *b*-axis, bisecting the β angle. The H-atoms of the phenyl groups were omitted for clarity. Values found for **4**: O(8)–H(8) = 0.820 Å; H(8)···Cl(2)^b = 2.394 Å, O(8)–H(8)···Cl(2)^b = 159.11°; O(8)···Cl(2)^b = 3.173(1) Å. Values found for **5**: O(8)-H(8) = 0.820 Å; H(8)···Br(2)^b = 2.480 Å, O(8)–H(8)···Br(2)^b = 165.25°; O(8)···Br(2)^b = 3.279 Å. Cl(2)^b and Br(2)^b are generated by using the symmetry operation $-½ + x, ½ - y, -½ + z$.

The protons of hydroxyl groups bounded to C3 in the free ligands are not observed in the spectra of the complexes. This is in agreement with their deprotonation upon the formation of the chelate rings in **1–5**. The resonance of the C(6)–H is overlapped with the PPh_3 protons for most complexes and, therefore, could not be precisely located. The ^1H NMR spectrum of **1** shows two sets of signals in a 1:1 ratio, corresponding to two nonequivalent maltolate units, as has been observed for the analogous complexes $[ReOBr(mal)_2]$ and $[TcOCl(mal)_2]$ [4]. In accord with this study, the ^1H NMR resonances pertaining the maltolate ligand bearing an oxygen atom opposite to the oxo ligand, i.e. axial, are upfield shifted than those

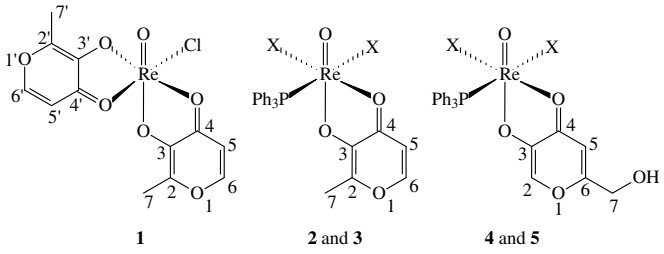

Scheme 3. NMR labeling of the complexes **1–5** (X = Cl for **2** and **4**; X = Br for **3** and **5**).

of the other moiety. Thus, the set of hydrogen signals at 6.99 and 7.52 ppm was assigned to the C5–H and C6–H (axial), respectively, while the set, at 7.12 and 8.03 ppm, was assigned to C5′–H and C6′–H (equatorial), respectively.

The number of observed carbon resonances in complex **1** is in agreement with that expected in the appropriate regions for the proposed structure in solution, which is supposed to be the same as the solid state structure. Like the ^1H NMR spectrum, two sets of signals are observed in the ^{13}C NMR spectrum corresponding to the two nonequivalent mal^- ligands. It is assumed that the ^{13}C NMR signals of the ligand oriented perpendicularly to the octahedral equatorial plane defined in Scheme 3 is upfield shifted with respect to those of the equatorial ligand, which is more strongly bounded to the rhenium center. This assumption is supported by the bond lengths verified in the crystal structure of the complex.

The $^{31}P\{^1H\}$ NMR spectra of **2–5** in CD_2Cl_2 consist of sharp singlets observed in the range between −17.95 and −16.29 ppm, which is consistent with the oxorhenium(V) species given in Scheme 3 [14,15].

4. Conclusions

Five heteroleptic rhenium(V) chelate complexes involving the maltolate or kojate anions acting in the *O,O′*-bidentate mode could be prepared under mild conditions with high yields and were fully characterized both in solution and in the solid state. All complexes are air stable and possess distorted octahedral coordination spheres around the rhenium centers in the solid state, which are retained in the solutions studied.

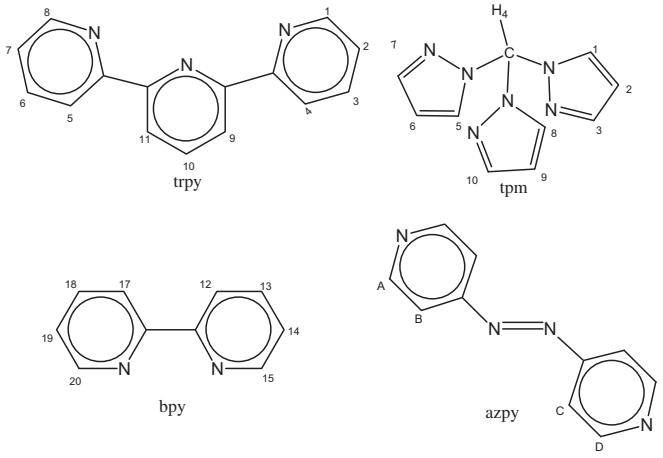

Scheme 1.

electrode, and Ag/AgCl (3 M KCl) as reference electrode. All solutions were prepared in CH_3CN, with 0.1 M TBAH (tetrakis-*n*-butylammonium hexafluorophosphate) as the supporting electrolyte, and thoroughly degassed with argon, prior to each experiment. Cyclic voltammograms were run at a sweep rate of 100 mV s^{-1}. The reported $E_{1/2}$ values were calculated as the average value between the peak values corresponding to the cathodic (E_c) and anodic (E_a) waves: $E_{1/2} = (E_c + E_a)/2$. Controlled potential electrolysis were performed using an OTTLE cell from BAS at a fixed potential of 800 mV, in CH_3CN (0.1 M TBAH), for 10 min. All NMR spectra were obtained in CD_3CN with a Bruker 500 MHz Avance spectrometer. 2D ^1H–^1H COSY and NOESY (mixing time 500 ms) and 2D ^1H–^{13}C HSQC and HMBC experiments were collected in order to unambiguously assign both ^1H and ^{13}C spectra. 2D ^1H–^{15}N HMBC were also recorded to obtain ^{15}N chemical shifts of all ^{15}N non-protonated centers. Chemical analyses were carried out at INQUIMAE, University of Buenos Aires, Buenos Aires, Argentina, with an estimated error of ±0.5%.

2.2. X-ray crystallographic study

Crystal data for $C_{35}H_{27}N_9Ru_1 \cdot 0.85PF_6^- \cdot 0.15CF_3SO_3^- \cdot 0.5CH_3CN$, 987.37 g mol^{-1}, monoclinic, $P2/n$, $a = 14.5890(12)$ Å, $b = 10.7663(9)$ Å, $c = 24.948(2)$ Å, $\beta = 94.491(2)°$, $V = 3906.5(6)$ Å^3, $Z = 2$, $\rho_{calcd} = 1.679$ Mg/m^3, $R_1 = 0.0535$ (0.0794), $wR_2 = 0.1365$ (0.1517), for 14825 reflections with $I > 2\sigma(I)$ (for 19631 reflections [R_{int}: 0.0513] with a total measured of 69467 reflections), goodness-of-fit on $F^2 = 1.081$, largest diff. peak (hole) = 2.277 (−1.790) e Å^{-3}. Measurements were made on a Bruker-Nonius diffractometer equipped with a APPEX 2 4K CCD area detector, a FR591 rotating anode with Mo Kα radiation, Montel mirrors as monochromator and a Kryoflex low temperature device ($T = -173$ °C). Full-sphere data collection was used with ω and φ scans. Programs used: Data collection APEX2 V. 1.0-22 (Bruker-Nonius 2004), data reduction SAINT+ Version 6.22 (Bruker-Nonius 2001), absorption correction SADABS V. 2.10 (2003) and SHELXTL Version 6.10 (Sheldrick, 2000).

2.3. Syntheses

The ligand 4,4′-azo(bis)pyridine was synthesized following a procedure reported in the literature [1]. The precursor [Ru(trpy)(bpy)(H_2O)](PF_6)$_2$ was obtained according to known methods [13].

2.3.1. [Ru(trpy)(bpy)(4,4′-azpy)](PF_6)$_2 \cdot H_2O$, ***1***(PF_6)$_2 \cdot H_2O$

Seventy two milligrams (0.09 mmol) of the known complex [Ru(trpy)(bpy)(H_2O)](PF_6)$_2$ were dissolved in acetone (36 mL), together with 165 mg (0.9 mmol) of 4,4′-azpy. After heating at reflux and stirring for 2 h, the solution was evaporated to *ca.* 10 mL, cooled at room temperature and then diethyl ether (100 mL) was added. The dark red precipitate formed after chilling overnight was removed by filtration, washed with diethyl ether and passed over a Sephadex LH-20 column with a CH_3CN/CH_2Cl_2 (1:1 v/v) mixture. The third eluted red band was rotoevaporated to 5 mL and then precipitated with NH_4PF_6 (2 g/20 mL of H_2O). The obtained red solid was removed by filtration, washed with ether, dried and stored under vacuum over P_4O_{10} for 1 day. Yield: 34 mg (38%). *Anal.* Calc. for $C_{35}H_{29}N_9OP_2F_{12}Ru$ (982.67): C, 42.8; H, 3.0; N, 12.8. Found: C, 42.5; H, 3.0; N, 12.7%. ^1H NMR (CD_3CN, 500.13 MHz): $\delta = 8.86$ (dd, $J = 4.6$ and 1.5 Hz, 2H, H_D), 8.78 (ddd, $J = 5.2$, 1.4 and 0.7 Hz, 1H, H_{15}), 8.71 (ddd, $J = 8.0$, 1.5 and 0.7 Hz, 1H, H_{12}), 8.57 (d, $J = 8.15$ Hz, 2H, H_9 and H_{11}), 8.48 (ddd, $J = 8.1$, 1.3 and 0.7 Hz, 2H, H_4 and H_5), 8.45 (ddd, $J = 8.0$, 1.3 and 0.7 Hz, 1H, H_{17}), 8.36 (dt, $J = 8.0$ and 1.5 Hz, 1H, H_{13}), 8.26 (t, $J = 8.15$, 1H, H_{10}), 8.08 (ddd, $J = 8.1$, 7.5 and 1.4 Hz, 2H, H_3 and H_6), 7.99 (dd, $J = 5.5$ and 1.5 Hz, 2H, H_A), 7.87 (ddd, $J = 8.0$, 5.2 and 1.3 Hz, 1H, H_{14}), 7.86 (ddd, $J = 8.0$, 7.5 and 1.3 Hz, 1H, H_{18}), 7.84 (ddd, $J = 5.5$, 1.4 and 0.7 Hz, 2H, H_1 and H_8), 7.72 (dd, $J = 4.6$ and 1.5 Hz, 2H, H_C), 7.58 (dd, $J = 5.5$ and 1.5 Hz, 2H, H_B), 7.46 (ddd, $J = 7.5$, 5.5 and 1.3 Hz, 2H, H_2 and H_7), 7.31 (ddd, $J = 5.5$, 1.3 and 0.7 Hz, 1H, H_{20}), 7.12 (ddd, $J = 7.3$, 5.5 and 1.3 Hz, 1H, H_{19}) ppm.

^{13}C NMR (CD_3CN, 100.62 MHz) $\delta = 159.1$ (C_{4a} and C_{5a}), 158.5 (C_{9a} and C_{11a}), 158.1 (C_{17a}), 157.8 ($C_{B'}$), 157.4 ($C_{C'}$), 157.2 (C_{12a}), 155.4 (C_A), 154.1 (C_1 and C_8), 152.8 (C_D), 152.7 (C_{15}), 152.2 (C_{20}), 139.7 (C_3 and C_6), 138.8 (C_{13}), 138.5 (C_{18}), 137.3 (C_{10}), 129.6 (C_2 and C_7), 128.6 (C_{14}), 127.7 (C_{19}), 126.0 (C_4 and C_5), 125.5 (C_{12}), 124.9 (C_9 and C_{11}), 124.6 (C_{17}), 119.3 (C_B), 117.0 (C_C) ppm.

2.3.2. [Ru(tpm)(bpy)(4,4′-azpy)](PF_6)$_2 \cdot 3H_2O$, ***2***(PF_6)$_2 \cdot 3H_2O$

Fifty five milligrams (0.07 mmol) of the precursor [Ru(tpm)(bpy)(H_2O)](PF_6)$_2$ were dissolved in acetone (28 mL) together with an excess of 4,4′-azpy (128 mg, 0.7 mmol). After heating under reflux and stirring for 3 h, the solution was evaporated to *ca.* 10 mL, cooled at room temperature and then diethyl ether (100 mL) was added. After keeping in the refrigerator for 24 h, the dark red precipitate was removed by filtration and washed with diethyl ether (2 × 10 mL), dried and stored under vacuum over P_4O_{10} for 1 day. Yield: 62 mg (89%). *Anal.* Calc. for $C_{30}H_{32}N_{12}O_3P_2F_{12}Ru$ (999.66): C, 36.0; H, 3.2; N, 16.8. Found: C, 35.7; H, 2.7; N, 16.6%. ^1H NMR (CD_3CN, 500.13 MHz): $\delta = 9.08$ (s, 1H, H_4), 8.86 (dd, $J = 1.6$ and 4.6 Hz, 2H, H_D), 8.80 (ddd, $J = 8.2$, 1.3, and 0.7 Hz, 2H, H_{12} and H_{17}), 8.65 (ddd, $J = 5.7$, 1.5 and 0.7 Hz, 2H, H_{15} and H_{20}), 8.57 (dd, $J = 2.9$ and 0.5 Hz, 2H, H_1 and H_5), 8.39 (dd, $J = 2.9$ and 0.7 Hz, 1H, H_8), 8.24 (ddd, $J = 8.2$, 7.7, and 1.6 Hz, 2H, H_{13} and H_{18}), 8.00 (dd, $J = 2.3$ and 0.5 Hz, 2H, H_3 and H_7), 7.73 (dd, $J = 4.6$ and 1.6 Hz, 2H, H_C), 7.72 (dd, $J = 5.5$ and 1.6 Hz, 2H, H_A), 7.56 (ddd, $J = 7.7$, 5.6 and 1.3 Hz, 2H, H_{14} and H_{19}), 7.51 (dd, $J = 5.5$ and 1.6 Hz, 2H, H_B), 6.79 (dd, $J = 2.9$ and 2.3 Hz, 2H, H_2 and H_6), 6.61 (dd, $J = 2.3$ and 0.7 Hz, 1H, H_{10}), 6.32 (dd, $J = 2.9$ and 2.3 Hz, 1H, H_9) ppm. ^{13}C NMR (CD_3CN, 100.62 MHz): $\delta = 158.6$ (C_{11} and C_{16}), 157.6 ($C_{C'}$), 157.5 ($C_{B'}$), 156.1 (C_A), 154.0 (C_{15} and C_{20}), 152.7 (C_D), 148.5 (C_3 and C_5), 144.8 (C_{10}), 139.0 (C_{13} and C_{18}), 136.7 (C_1 and C_7), 136.6 (C_8), 127.5 (C_{14} and C_{19}), 126.0 (C_{12} and C_{17}), 118.2 (C_B), 117.0 (C_C), 110.9 (C_2 and C_6), 109.6 (C_9), 77.0 (C_4) ppm.

2.3.3. [(trpy)(bpy)Ru(4,4′-azpy)Ru(NH_3)$_5$](PF_6)$_4 \cdot 10H_2O$, ***3***(PF_6)$_4 \cdot 10H_2O$

A solution of **1** (PF_6)$_2 \cdot H_2O$ (60 mg, 0.062 mmol) in acetone (15 mL) was purged with argon for 30 min. The other precursor [Ru(NH_3)$_5$(H_2O)](PF_6)$_2$ (30 mg, 0.062 mmol), prepared as described before [14], was added to this solution under argon, and the resulting mixture was stirred in darkness, for 2 h, under argon. Deaerated diethyl ether (100 mL) was added and the cloudy solution

was stored in the refrigerator overnight. The red precipitate that formed was removed by filtration, washed with diethyl ether (2×10 mL), sorbed onto a Sephadex LH-20 column and eluted with a CH_3CN/CH_2Cl_2 (1:1 v/v) solution. The second eluted portion (green) was collected, concentrated to *ca.* 5 mL under reduced pressure and precipitated with diethyl ether (50 mL). The dark green solid was removed by filtration, washed with diethyl ether, dried and stored under vacuum over P_4O_{10} for 1 day. Yield: 16 mg (16%). *Anal.* Calc. for $C_{35}H_{62}N_{14}O_{10}P_4F_{24}Ru_2$ (1620.96): C, 25.9; H, 3.9; N, 12.1. Found (mean of several determinations): C, 25.5; H, 3.5; N, 12.8%.

2.3.4. [(trpy)(bpy)Ru(4,4′-azpy)Ru(bpy)(trpy)](PF$_6$)$_4$ · 2H$_2$O, **5**(PF$_6$)$_4$ · 2H$_2$O

211 mg (0.26 mmol) of $[Ru(trpy)(bpy)(H_2O)](PF_6)_2$ were dissolved in acetone (50 mL) together with 4,4′-azpy (24 mg, 0.13 mmol). After heating under reflux and stirring for 15 h, the solution was cooled at room temperature, evaporated to *ca.* 5 mL and precipitated with diethyl ether (50 mL). After keeping in the refrigerator for 24 h, the dark red precipitate was filtered and washed with diethyl ether (2×10 mL). Purification was accomplished by chromatography over Sephadex LH-20, using a CH_3CN/CH_2Cl_2 (1:1 v/v) solution as eluent and collecting only the first of the two obtained fractions. After precipitation with diethyl ether and filtration, the red solid was dried and stored under vacuum over P_4O_{10} for 1 day. Yield: 38 mg (8%). *Anal.* Calc. for $C_{60}H_{50}F_{24}N_{14}O_2P_4Ru_2$ (1781.14): C, 40.5; H, 2.8; N, 11.0. Found: C, 40.7; H, 2.9; N, 10.7%.

3. Results and discussion

3.1. Syntheses and IR spectra

The synthetic procedures used in this work are slight modifications of techniques previously developed in our laboratories [11,12]. The IR spectra of all synthesized complexes display characteristic vibrational modes of the polypyridyl ligands (trpy, tpm, bpy and 4,4′-azpy). Besides, a typical ammonia symmetric deformation mode $\delta_{sym}(NH_3)$ appears in the IR spectrum of the PF_6^- salt of complex **3** at 1270 cm^{-1}, which clearly evidenced a localized oxidation

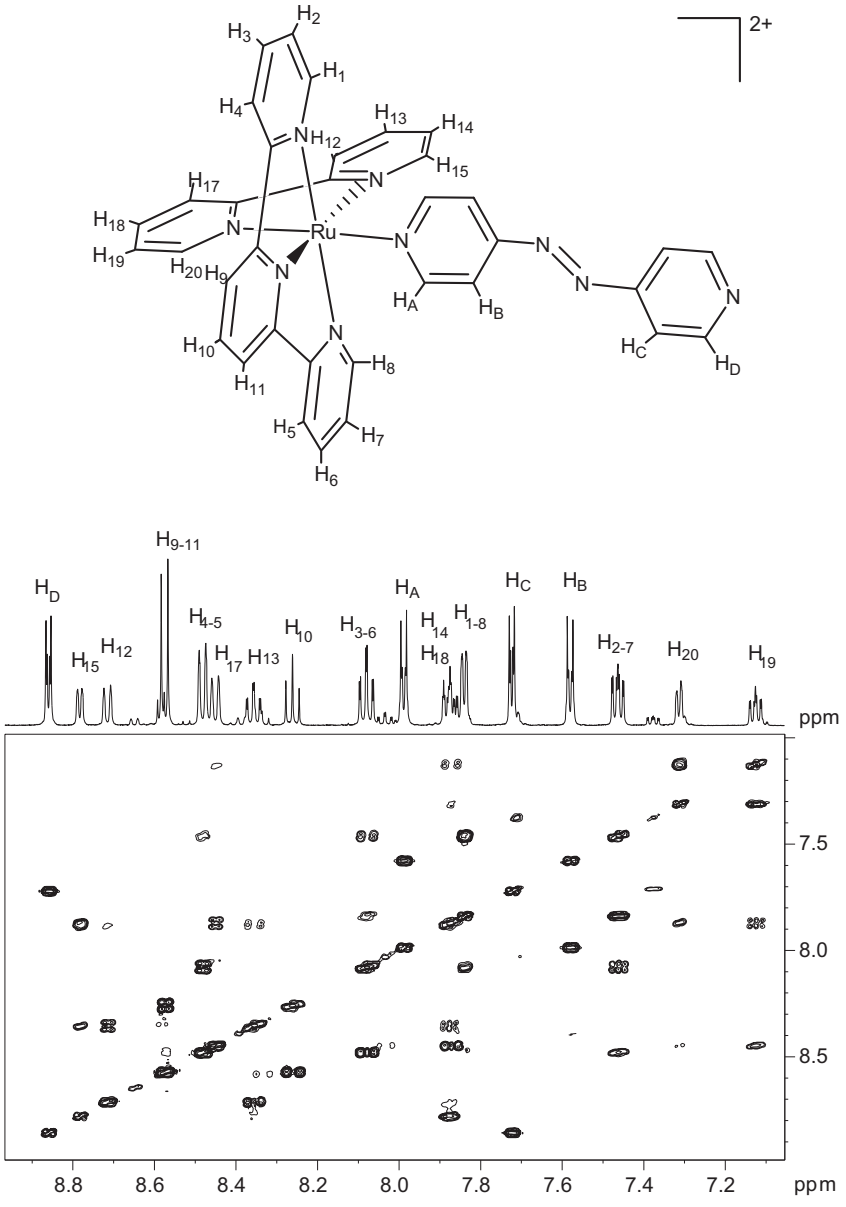

Fig. 1. 2D ^{1}H–^{1}H COSY spectrum of complex **1**.

state (II) for the ammine-bonded Ru atom [10], as shown in Supplementary Fig. 1. The presence of water is also disclosed by the broad band appearing at 1624 cm^{-1} corresponding to H–O–H bending vibrations.

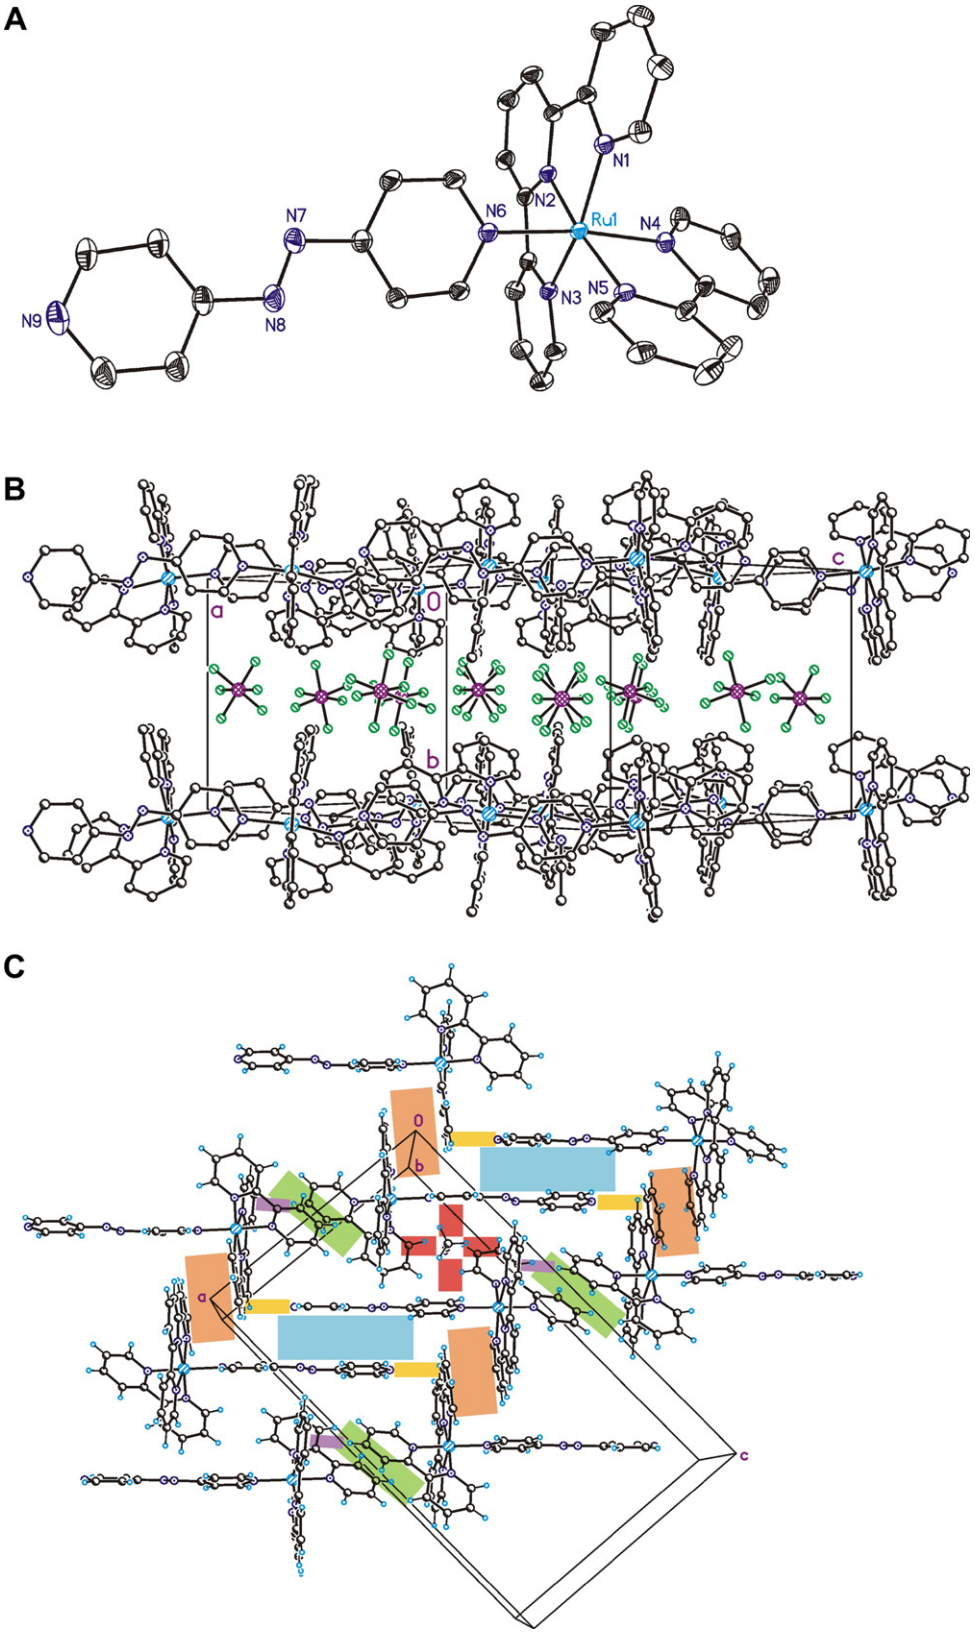

Fig. 2. (A) ORTEP diagram (ellipsoids at 70% probability) for the cationic moiety of **1**, with labelling scheme for N atoms. Hydrogen atoms are omitted in the sake of clarity. (B) View of the crystal packing of **1** showing the cationic and anionic 2D layers. (C) View of the two-dimensional layer formed by the cationic part of the complex showing the intermolecular π interactions marked with colored backgrounds (see text). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

3.2. NMR spectra

Compounds **1** and **2** show well dispersed ^{1}H NMR spectra in the region between 6 and 9 ppm. As an example, Fig. 1 shows the ^{1}H–^{1}H COSY spectra of complex **1** in CD_3CN. Besides, the presence of a symmetry plane simplifies a little bit the NMR spectra: in **1** the plane incorporates the 4,4′-azpy and bpy ligands, whereas in **2** the plane includes the 4,4′-azpy ligand and splits the tmp and bpy ligands in two symmetric moieties. Two-dimensional homonuclear COSY and NOESY spectra, together with ^{13}C and ^{15}N HSQC and HMBC spectra allowed the complete assignment of the signals, as stated in Section 2. The knowledge of the ^{15}N chemical shifts permitted a precise distinction between linked and non-linked connectivities in multicoordinated N-ligands, as discussed before [15].

3.3. Solid state structure

Crystals suitable for X-ray diffraction of $\mathbf{1}(PF_6)_{1.70}(CF_3SO_3)_{0.30}\cdot 0.5CH_3CN$ were obtained by slow diffusion of ether into a concentrated acetone solution of $\mathbf{1}(PF_6)_2$ in the presence of $NaCF_3SO_3$ and a small amount of CH_3CN. An ORTEP diagram of the cation is shown in Fig. 2A. A *trans*-structure of the 4,4′-azpy ligand is disclosed, as already observed in polymeric structures incorporating this ligand [6]. The Ru metal center displays a distorted octahedral coordination with Ru–N bond distances within the range 1.97–2.09 Å (see Table 1), similar to those obtained for related complexes indicating the presence of a strong $d_\pi(Ru) \rightarrow \pi^*(L)$ backbonding [16]. The pyridylic groups of the three ligands are significantly away from planarity with relative rotation angles of 12.6° for bpy, 13.2° for 4,4′-azpy and 15.2° for the peripheral pyridyls of trpy.

In the crystal packing it can be observed that the cationic and anionic parts are forming two-dimensional layers which are contacting through weak interactions (CH-groups with fluorine atoms in the case of PF_6^-, see Fig. 2B). The counter anions are disordered in a proportion 0.85:0.15 (PF_6^- : $CF_3SO_3^-$) occupying exactly the same positions. The cationic part of the crystal has a packing structure that is based on extensive π-interactions within neighboring molecules. In the 3D arrangement represented in Fig. 2C, neighboring azpy ligands are showing a π–π stacking (azo double bond-pyridyl ring with a centroid–centroid distance of 3.5 Å, blue background). Furthermore, this dimer type of arrangement interacts with neighboring dimers via bpy-bpy π–π (shortest distance of 3.6 Å, green background) and bpy-trpy C–H···π ($d_{H\text{-centroid}}$ = 3.3 Å, violet background) contacts. Besides, trpy ligands are having π–π interactions with neighboring trpy ligands (shortest distance 3.6 Å, brown background) and C–H···π interactions with azpy ligands ($d_{H\text{-centroid}}$ = 3.3 Å, yellow background). Finally, the acetonitrile molecules are packing between the metallorganic molecules generating π–π interactions with four pyridyl rings of two trpy and two azpy ligands ($d_{acetonitrile\text{-}trpy}$ = 3.3 Å and $d_{acetonitrile\text{-}azpy}$ = 2.9 Å; red background).

3.4. UV–Vis spectroscopy

The UV–Vis spectra in CH_3CN of all complexes synthesized in this work are shown in Table 2. Fig. 3 shows the UV–Vis spectrum of complex **1** as a representative example. In all cases, the bands between 200 and 300 nm are assigned to intraligand (IL) $\pi \rightarrow \pi^*$ transitions of the polypyridyl ligands (trpy, bpy and 4,4′-azpy). The lowest energy band in complex **1** (λ_{max} = 456 nm) can be assigned to overlapping metal-to-ligand charge transfer (MLCT) transitions $d_\pi(Ru) \rightarrow \pi^*$(trpy), $d_\pi(Ru) \rightarrow \pi^*$(bpy) and $d_\pi(Ru) \rightarrow \pi^*$(4,4′-azpy). In related $[Ru(trpy)(bpy)(L)]^{2+}$ complexes, with L = pz, 4,4′-bpy and BPE (pz = pyrazine; 4,4′-bpy = 4,4′-bipiridine; BPE = *trans*-1,2-bis(4-pyridyl)ethylene), the lowest energy MLCT transitions appear at λ_{max} = 464, 466 and 479 nm, respectively [9,10]. The shift to lower wavelengths detected in **1** points to 4,4′-azpy being the acceptor ligand L with the strongest electron withdrawing effect in the series, similar to that of pz. On the other hand, complex **2** showed two lowest energy bands at λ_{max} = 416 nm and 488 nm, as shown in Table 2, which can be assigned to $d_\pi(Ru) \rightarrow \pi_1^*$(bpy) and overlapping $d_\pi(Ru) \rightarrow \pi_2^*$(bpy) and $d_\pi(Ru) \rightarrow \pi^*$(4,4′-azpy) MLCT transitions, respectively, by comparison to related $[Ru(tpm)(bpy)(L)]^{2+}$ complexes, with L = pz, 4,4′-bpy and BPE [11]. In this case, the strongest electron acceptor character of 4,4′-azpy is evidenced by the highest shift recorded for the lowest energy band.

The dinuclear asymmetric complex **3** revealed two lowest energy bands at λ_{max} = 459 nm and 738 nm, which can be readily assigned to MLCT transitions $d_\pi(Ru_b) \rightarrow \pi^*$(trpy, bpy, 4,4′-azpy) and $d_\pi(Ru_a) \rightarrow \pi^*$(4,4′-azpy), with Ru_b = Ru bonded to bpy and Ru_a = Ru

Table 2
Electronic absorption data of complexes **1**–**5**, in CH_3CN

Complex	λ_{max}, nm (10^{-3} ε_{max}, M^{-1} cm^{-1})
$[Ru(trpy)(bpy)(4,4'\text{-azpy})]^{2+}$	231 (23.8), 242 (23.0), 286 (42.8), 309 (35.7), 456 (12.5)
$[Ru(tpm)(bpy)(4,4'\text{-azpy})]^{2+}$	235 (12.8), 254 (14.4), 286 (31.5), 416 (5.2), 488 (6.8)
$[(trpy)(bpy)Ru(4,4'\text{-azpy})Ru(NH_3)_5]^{4+}$	243 (19.9), 286 (36.4), 309 (30.2), 459 (9.5), 738 (12.6)
$[(trpy)(bpy)Ru(4,4'\text{-azpy})Ru(NH_3)_5]^{5+}$	242 (28.8), 286 (43.8), 309 (37.0), 456 (12.3), 557 (3.1), 670 (1.8)
$[(trpy)(bpy)Ru(4,4'\text{-azpy})Ru(bpy)(trpy)]^{4+}$	242 (27.5), 286 (47.0), 310 (38.6), 458 (13.9), 512 sh

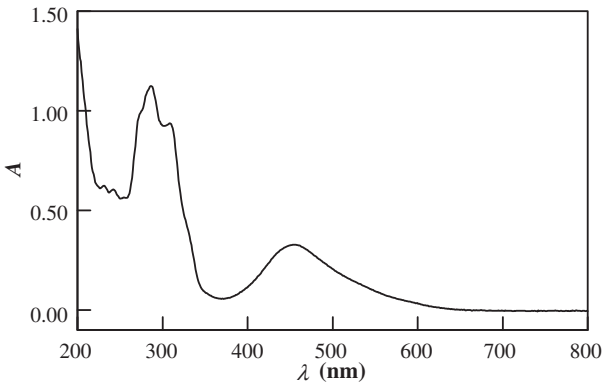

Fig. 3. UV–Vis spectrum of complex **1**, in CH_3CN ($C = 2.6 \times 10^{-5}$ M).

bonded to NH_3, respectively. The previously reported mononuclear species $[Ru(NH_3)_5(4,4'\text{-azpy})]^{+2}$ absorbs at λ_{max} = 645 nm in CH_3CN [1], while the dinuclear species $[(NH_3)_5Ru^{II}(4,4'\text{-azpy})Ru^{II}(NH_3)_5]^{4+}$ has λ_{max} = 710 nm [1], a value similar to that of complex **3**, thus evidencing a comparable electronic distribution. A spectrophotometric titration of **3** was performed by using Br_2 in CH_3CN. After adding a stoichiometric amount of Br_2, the band at λ_{max} = 738 nm disappeared. The same behavior was observed in a controlled potential electrolysis of **3**, as shown in Fig. 4. After applying a potential of 800 mV during 10 min, only the ammine-bonded Ru_a undergoes oxidation to give the mixed-valent species **4**, of formula: $[(trpy)(bpy)Ru^{II}_b(4,4'\text{-azpy})Ru^{III}_a(NH_3)_5]^{5+}$. The reversibility of the process confirms the identity of complex **4**. Gaussian deconvolution of the UV–Vis spectrum of **4** in the region 400–1000 nm, shown as Supplementary Fig. 2, gives λ_{max} = 670 nm for the lowest-energy band, which can be assigned to the intervalence or metal-to-metal charge transfer (MMCT) transition: $[Ru^{II}_b, Ru^{III}_a] \rightarrow [Ru^{III}_b, Ru^{II}_a]$, since the same transition appears at $\lambda_{max} \cong 640$ nm in the corresponding 4,4′-bpy-bridged mixed-valent complex [9].

The dinuclear symmetric complex **5** displays an UV–Vis spectrum very similar to that of the mononuclear species **1**, as shown in Table 2. However, a new shoulder appears at $\lambda_{max} \cong 512$ nm, which can be ascribed to the $d_\pi(Ru) \rightarrow \pi^*(4,4'\text{-azpy})$ MLCT transition, shifted to lower energies as compared to **1**, because of increased electronic delocalization.

3.5. Electrochemistry

The cyclic voltammograms for **1** and **2** display very similar redox potentials associated with the couple Ru^{III}_b/Ru^{II}_b, as displayed in Table 3. Fig. 5 shows the CV of complex **1** as a representative example. In both complexes (**1** and **2**), reversible oxidation wave were observed at $E_{1/2}$ = 1.27 V and $E_{1/2}$ = 1.22 V, respectively (versus SCE). The first one is intermediate between the values obtained for the corresponding Ru couples in the related complexes $[Ru(trpy)(bpy)(pz)]^{2+}$ and $[Ru(trpy)(bpy)(4,4'\text{-bpy})]^{2+}$ ($E_{1/2}$ = 1.34 and 1.23 V, respectively, versus SCE) [9,10], while the second one is intermediate between those of $[Ru(tpm)(bpy)(pz)]^{2+}$ and $[Ru(tpm)(bpy)(4,4'\text{-bpy})]^{2+}$ ($E_{1/2}$ = 1.34 and 1.21 V, respectively, versus SCE) [11].

The dinuclear complex **3** shows two reversible waves in the oxidative range of potentials. The redox potential of the Ru^{III}_b/Ru^{II}_b couple ($E_{1/2}$ = 1.27 V) is the same as that recorded for the mononuclear species **1**, while the redox potential of the Ru^{III}_a/Ru^{II}_a couple ($E_{1/2}$ = 0.45 V), lies again intermediate between the values reported for the related dinuclear complexes $[(trpy)(bpy)Ru^{II}_b(pz)Ru^{II}_a(NH_3)_5]^{4+}$ ($E_{1/2}$ = 0.66 V versus SCE) and $[(trpy)(bpy)Ru^{II}_b(4,4'\text{-bpy})Ru^{II}_a(NH_3)_5]^{4+}$ ($E_{1/2}$ = 0.39 V versus SCE) [9,10]. The difference of redox potential between both Ru couples is therefore: $\Delta E_{1/2} = E_{1/2}(Ru^{III}_b/Ru^{II}_b) - E_{1/2}(Ru^{III}_a/Ru^{II}_a) = 0.82$ V. On the reductive side of the voltammograms, the ligands trpy and bpy display their characteristic reversible waves at $E_{1/2}$ *ca.* −1.3 and −1.6 V, as reported in the literature for similar systems [10]. On the other hand, 4,4′-azpy reductions give rise to one reversible peak at $E_{1/2}$ *ca.* −0.5 V and a quasi-reversible peak at −0.9 V, as expected [1].

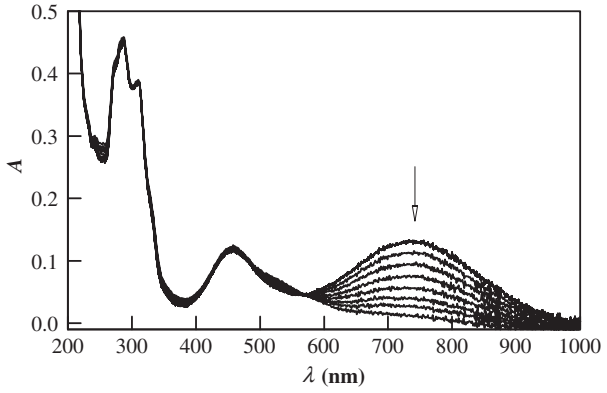

Fig. 4. Controlled potential electrolysis of complex **3**, in CH_3CN ($C = 1.1 \times 10^{-5}$ M), at 800 mV. The arrow indicates increasing times from 0 to 10 min. Each spectrum was taken every minute.

[a] $E_{1/2}$ values are referred to SCE.

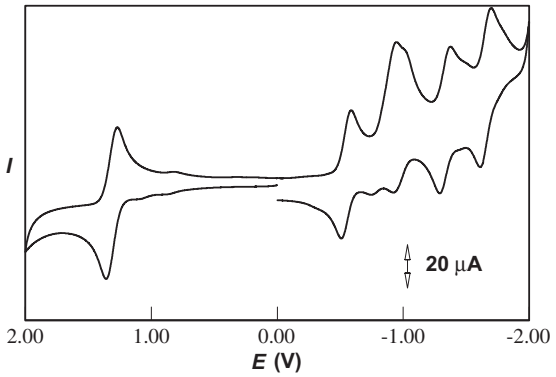

Fig. 5. Cyclic voltammogram of complex **1**, in CH_3CN, 0.1 M TBAH, at v = 100 mV/s. E values are referred to Ag/AgCl.

The cyclic voltammogram of complex **5** is very similar to that of complex **1**, as shown in Table 3. The main distinction is the difference between the cathodic and anodic peaks of the wave corresponding to the redox couple Ru^{III}_b/Ru^{II}_b, which amounts to 127 mV in **5**, pointing to a two-electron process with a comproportionation constant ($K_c \cong 26$) relatively high for weakly coupled mixed-valent complexes [14].

3.6. Intramolecular electron transfer

By using the Marcus–Hush formalism [17], the electronic coupling element can be calculated from the spectral properties of the mixed-valent complex **4**. The parameters $\Delta\tilde{\nu}_{1/2}$ (bandwidth at half-height), ε_{max} (molar absorptivity at the absorption maximum) and $\tilde{\nu}_{max}$ (energy of the intervalence absorption maximum) were obtained after gaussian deconvolution of the visible bands of com-

plex **4** (Supplementary Fig. 2) Using these experimental parameters ($\Delta\tilde{\nu}_{1/2}$ = 4700 cm^{-1}, ε_{max} = 1800 M^{-1} cm^{-1}, $\tilde{\nu}_{max}$=15 000 cm^{-1}) in Eq. (1), where r is the distance (in Å) between both metal centers, estimated as 13.2 Å from the X-ray analysis of complex **1** and the typical Ru_a–N bond length for an aromatic N heterocycle bonded to Ru [16], the electronic coupling was determined to be: H_{AB} = 550 cm^{-1}.

$$H_{AB}\ (cm^{-1}) = 2.06 \times 10^{-2}[(\varepsilon_{max})(\tilde{\nu}_{max})(\Delta\tilde{\nu}_{1/2})]^{1/2}(1/r) \quad (1)$$

H_{AB} is higher by almost a factor of 3 than that determined for the related BPE-bridged mixed-valent species with a similar metal–metal distance (H_{AB} = 189 cm^{-1}), evidencing higher electronic delocalization in the 4,4′-azpy-bridged species. This finding is consistent with previous reports; in effect, Launay et al. have already determined that the comproportionation constant, a measure of the electronic metal–metal interaction, for the mixed-valent species $[(NH_3)_5Ru(4,4'\text{-azpy})Ru(NH_3)_5]^{5+}$ is K_c = 40, a value appreciably higher than that of the isoelectronic BPE complex, for which K_c = 14 [1]. The intermediate value of K_c = 26, determined for the mixed-valent complex [(trpy)(bpy)Ru(4,4′-azpy)Ru(bpy)(trpy)]$^{5+}$, is consistent with the competition between trpy, bpy and 4,4′-azpy for the π-electron density of the metals. Finally, when representing H_{AB} versus r, the slope is increased when including the value for complex **4**, which leads to the conclusion that 4,4′-azpy is a promising ligand for designing "molecular wires", systems in which the electronic transmission is slightly attenuated by the donor–acceptor distance [18].

On the other hand, the reorganization energy λ can be calculated as follows:

$$\lambda = E_{op} - \Delta G^0 - \Delta E_{exc} \quad (2)$$

where ΔG^0 is the free energy difference between both redox centers, assumed as approximately $\Delta E_{1/2}$ = 0.82 V, and ΔE_{exc} is the energy difference between the excited and ground states, estimated as 0.25 eV for several ruthenium complexes in the event that the MMCT transition results in the population of an excited state [19]. Eq. (2) gives a value of λ = 0.79 eV, which is close to the value expected from the slope of the plot of λ versus r calculated for this type of asymmetric mixed-valent complexes [10].

4. Conclusions

New polypyridyl ruthenium mononuclear complexes containing 4,4′-azpy have been prepared and characterized by spectral, diffraction and electrochemical techniques. In complex **1**, extensive π–π interactions within neighboring molecules are disclosed. 4,4′-azpy connects two metal centers in the dinuclear complex **3**, which can be partially oxidized electrochemically to the stable mixed-valent complex **4**. The value of H_{AB} for this latter species is almost 3 times higher than that reported for the related dinuclear complex with BPE, indicating a considerable electronic delocalization in 4,4′-azpy, which confers "molecular wire" properties to complexes with this *N*-heterocycle as a bridging ligand.

Appendix A. Supplementary data

CCDC 669446 contains the supplementary crystallographic data for $[Ru(trpy)(bpy)(4,4'\text{-azpy})](PF_6)_{1.70}(CF_3SO_3)_{0.30} \cdot 0.5CH_3CN$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary Figs. 1 and 2 show the FTIR spectrum of complex **3** and the Gaussian deconvolution of the visible bands of complex **4**, respectively. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.06.014.

depending on electronic configuration. [Mn_2(malonate)$_2$(4,4′-bpy)(H_2O)$_2$] exhibits a square-grid manganese malonate layer motif linked into a 3-D net by 4,4′-bpy tethers, with weak antiferromagnetic superexchange operative between manganese ions within the malonate layer [15]. In contrast, [Cu_2(malonate)$_2$(4,4′-bpy)(H_2O)] manifests coordination polymer layers built from [Cu_4(malonate)$_4$] clusters linked into 2-D through 4,4′-bpy ligands; ferromagnetic coupling within the *anti–syn* malonate-bridged tetranuclear kernels was observed [16].

For some time we have been interested in the synthesis and characterization of coordination polymers containing the organodiimine 4,4′-dipyridylamine (dpa). In contrast to 4,4′-bpy, dpa possesses a kinked disposition of its distal nitrogen donor atoms as well as a potential hydrogen bonding donor point, allowing it to aggregate coordination polymer subunits via supramolecular as well as covalent interactions in oxide or carboxylate systems. In our hands, hydrothermal treatment of transition metal precursors with aliphatic α,ω-dicarboxylates and dpa has resulted in the construction of several coordination polymers, some with unprecedented structural motifs [17–19]. For example, [Ni(adipate)(dpa)(H_2O)]$_n$ exhibited the first-ever example of threefold interpenetration within the PtS structure type [17], and {[Ni(dpa)$_2$(succinate)$_{0.5}$]Cl}$_n$ manifested an unprecedented five-connected self-penetrated network with a "regular" 6^{10} topology [18]. {[Cu_2(malonate)$_2$(dpa)(H_2O)$_2$] · H_2O} displayed both *syn–anti* and *anti–anti* 1-D copper malonate chains linked into 2-D via dpa struts, exhibiting net ferromagnetic interactions between malonate-bridged copper ions [19]. We report herein further investigations in this direction with hydrothermal synthesis and structural characterization of a pair of isostructural acentric divalent metal malonate 3-D network coordination polymers incorporating dpa, {[M_2(malonate)$_2$(dpa)(H_2O)$_2$] · 2H_2O}$_n$ (M = Co, **1**; M = Ni, **2**). Thermal and magnetic properties are also discussed; substantial variances in their magnetic properties are observed.

2. Experimental

2.1. 1 General considerations

$CoCl_2 \cdot 6H_2O$, $NiCl_2 \cdot 6H_2O$ and malonic acid were obtained commercially from Fisher. 4,4′-dipyridylamine (dpa) was prepared via a published procedure [20]. Water was deionized above 3 MΩ in-house. Thermogravimetric analysis was performed on a TA Instruments TGA 2050 Thermogravimetric Analyzer with a heating rate of 5 °C/min up to 900 °C. Elemental analysis was carried out using a Perkin Elmer 2400 Series II CHNS/O Analyzer. IR spectra were recorded on a Mattson Galaxy FTIR Series 3000 using KBr pellets. Variable temperature magnetic susceptibility data (2–300 K) was collected on a Quantum Design MPMS SQUID magnetometer at an applied field of 0.1 T. After each temperature change the sample was kept at the new temperature for 5 min before magnetization measurement to ensure thermal equilibrium. The susceptibility data was corrected for diamagnetism using Pascal's constants [21].

2.2. Preparation of {[Co_2(malonate)$_2$(dpa)(H_2O)$_2$] · 2H_2O}$_n$ (**1**)

$CoCl_2 \cdot 6H_2O$ (88 mg, 0.74 mmol), dpa (127 mg, 0.37 mmol), and malonic acid (47 mg, 0.37 mmol), were placed into 10 mL distilled H_2O in a 23 mL Teflon-lined Parr acid digestion bomb, and then 0.5 mL of a 1.0 M NaOH solution was added was added via pipette. The bomb was sealed and heated at 120 °C for 44 h, whereupon it was cooled slowly to 25 °C. Purple crystals of **1** (52 mg, 50 % yield based on malonic acid) were isolated after washing with distilled water, isopropanol and acetone and drying in air. *Anal.* Calc. for $C_{16}H_{21}Co_2N_3O_{12}$ **1**: C, 34.00; H, 3.74; N, 7.43. Found: C, 34.39; H, 3.57; N, 7.46%. IR (KBr, cm^{-1}): 3853 m, 3749 m, 3670 m, 3648 m, 3472 s, 3281 s, 3193 s, 3097 m, 3013 m, 2928 m, 2366 w, 2343 w, 1952 m, 1634 s, 1607 s, 1557 s, 1519 s, 1443 m, 1351 s, 1220 m, 1151 w, 1060 w, 1021 m, 980 w, 952 w, 911 w, 842 w, 822 m, 704, 661 m, 589 m, 531 m.

2.3. Preparation of {[Ni_2(malonate)$_2$(dpa)(H_2O)$_2$] · 2H_2O}$_n$ (**2**)

The preparation for **1** was followed, with the substitution of $NiCl_2 \cdot 6H_2O$ (88 mg, 0.74 mmol) as the metal source. Green crystals of **2** (76 mg, 72% yield based on malonic acid) were isolated after washing with distilled water, isopropanol and acetone and drying in air. *Anal.* Calc. for $C_{16}H_{21}Ni_2N_3O_{12}$ **2**: C, 34.03; H, 3.75; N, 7.44. Found: C, 34.99; H, 3.68; N, 7.89%. IR (KBr, cm^{-1}): 3652 m, 3472 s, 3181 s, 2925 sm, 1600 s, 1569 s, 1520 s, 1443 m, 1358 s, 1266 w, 1224 m, 1153 w, 1061 w, 1025 m, 1061 w, 1025 m, 983 w, 971 w, 911 w, 843 w, 820 w, 710 m, 661 w, 644 w, 608 w, 529 w.

3. X-ray crystallography

A purple block crystal of **1** with dimensions 0.46 mm × 0.28 mm × 0.10 mm and a green block crystal of **2** with dimensions 0.14 mm × 0.12 mm × 0.06 mm were subjected to single-crystal X-ray diffraction at 173 K using a Bruker-AXS SMART 1k CCD instrument. Reflection data were acquired using graphite–monochromated Mo Kα radiation (λ = 0.71073 Å). The data were integrated via SAINT [22]. Lorentz and polarization effect and empirical absorption corrections were applied with SADABS [23]. The structures were solved using direct methods and refined on F^2 using SHELXTL [24]. All non-hydrogen atoms were refined anisotropically, with the exception of the oxygen atoms belonging to the uncoordinated water molecules. Hydrogen atoms bound to carbon atoms were placed in calculated positions and refined isotropically with a riding model. The hydrogen atoms belonging to the coordinated water molecules in **1** and **2** were found via Fourier difference maps, then restrained at fixed positions and refined isotropically. The hydrogen atoms attached to the uncoordinated water molecules (O6 and O7) could not be located. Relevant crystallographic data for **1** and **2** is listed in Table 1.

4. Results and discussion

4.1. Synthesis and spectral analysis

The coordination polymers **1** and **2** were prepared as single phase crystalline products under hydrothermal conditions via combination of the hydrated metal chloride, malonic acid and 4,4′-dipyridylamine in the presence of additional base. Attempts to prepare dpa-containing malonate coordination polymers using zinc chloride and cadmium nitrate resulted in the formation of the 1-D coordination polymer [$ZnCl_2$(dpa)] [25] and the known 3-D quadruply interpenetrated diamondoid network material {[Cd(dpa)$_2$(NO_3)(H_2O)](NO_3)} [26], respectively. The infrared spectra of **1** and **2** were consistent with their formulations. Sharp, medium intensity bands in the range of ~1570–1200 cm^{-1} were ascribed to stretching modes of the pyridyl rings of the dpa moieties [27]. Features corresponding to pyridyl ring puckering mechanisms were evident in the region between 820 cm^{-1} and 600 cm^{-1}. Asymmetric and symmetric C–O stretching modes of the malonate carboxylate moieties were evidenced by very strong, slightly broadened bands at ~1600 cm^{-1} and ~1350 cm^{-1}. Broad bands in the region of ~3800–3200 cm^{-1} in all cases represent N–H stretching modes within the dpa ligands and O–H stretching modes within water molecules of crystallization. The broadness

of these latter spectral features is attributed to supramolecular hydrogen bonding patterns (*vide infra*).

4.2. Structural description of {[M_2(malonate)$_2$(dpa)(H_2O)$_2$] · 2H_2O} (M = Co, **1**; M = Ni, **2**)

X-ray crystallography revealed that **1** and **2** are isomorphous, crystallizing in the non-centrosymmetric space group *Aba2*. The Flack parameters (0.02(1) for **1**, 0.03(3) for **2**) in both cases indicate a high degree of enantiomeric purity [28]. The formation of chiral coordination polymers due to the "double-bladed" nature of the kinked dpa ligand has been previously observed by Hanton and co-workers [29]. While other single crystals were not examined, it is most likely that a racemic mixture exists in the bulk sample. Spontaneous resolution during self-assembly has been observed in other coordination polymer systems [30].

The asymmetric units of **1** and **2** were virtually identical, possessing one divalent metal atom, one fully deprotonated malonate ligand, one-half of a dpa ligand, one coordinated water molecule, and two crystallographically distinct half-occupied unligated water molecule positions (marked by O6 and O7). The N–H bonds of the dpa ligands lie on crystallographic twofold axes along the *c* crystal direction. As seen in Fig. 1 (shown for **1**), the metal atoms display distorted [MO_5N] octahedral coordination spheres. The equatorial plane of the octahedron is comprised of two mutually *cis* oxygen atoms belonging to a 1,3-chelating malonate ligand, and two other mutually *cis* oxygen atoms, each of which is part of two other malonate ligands. The coordinated water molecule and the nitrogen donor from the dpa ligand occupy the *trans* axial positions. Bond lengths and angles within **1** and **2** (Table 2) are consistent with chelated octahedral coordination complexes of Co and Ni. The bond lengths in **2** are slightly shorter than those in **1**, reflective of well-known ionic radius trends [31].

The 1,3-type chelation of the malonate ligand (at O1 and O2) results in {MOC_3O} "boat"-conformation six-membered rings. Each of the other two malonate oxygen atoms not involved in chelation

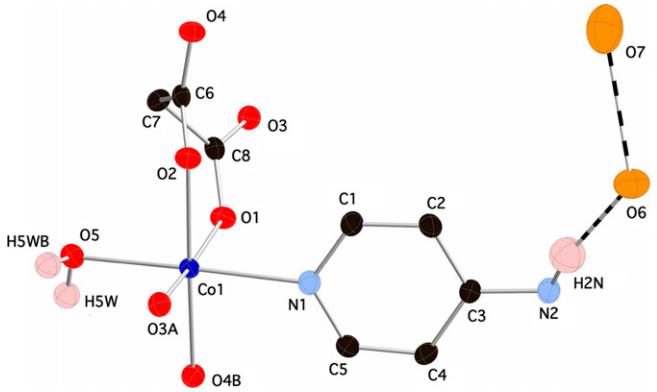

Fig. 1. Coordination environment of **1** with thermal ellipsoids at 50% probability and atom numbering scheme. Most H atoms have been omitted. Hydrogen bonding is indicated as dashed lines. The asymmetric unit of **2** is virtually identical. Symmetry codes A and B are as listed in Table 2.

connects to a different cobalt atom. Therefore each individual malonate ligand is exotridentate, linking three neighboring metal atoms. In turn, each metal atom conjoins to three sets of two others through the carboxylate bridges of the malonate ligands to construct a ruffled two-dimensional (2-D) layer motif coincident with the *bc* crystal plane (Fig. 2). The metal–metal contact distances through the *anti–syn* 1,1-carboxylate linkages in **1** are 5.311(1) Å and 5.445(1) Å; the corresponding distances within **2** are slightly shorter, at 5.247(1) Å and 5.386(1) Å. The metal–metal distances across the bridging 1,3-carboxylate linkages for **1** and **2** are 7.275(1) Å and 7.207(1) Å, respectively. By means of the 1,1-carboxylate and 1,3-carboxylate linkages, each metal atom covalently connects to six others within the 2-D layer motif; thus forming a $3^6.4^6.5^3$ net (**hxl** structure type) as analyzed by TOPOS [32]. However, if only the 1,1-carboxylate linkages are taken into account, a simplified (4,4) rectangular grid network can be invoked for the 2-D [M_2(malonate)$_2$(H_2O)$_2$]$_n$ layers in **1** and **2**; these are similar to those seen in [M_2(malonate)$_2$(4,4′-bpy)(H_2O)$_2$]$_n$ (M = Mn [15], Co [33]; 4,4′-bpy = 4,4′-bipyridine).

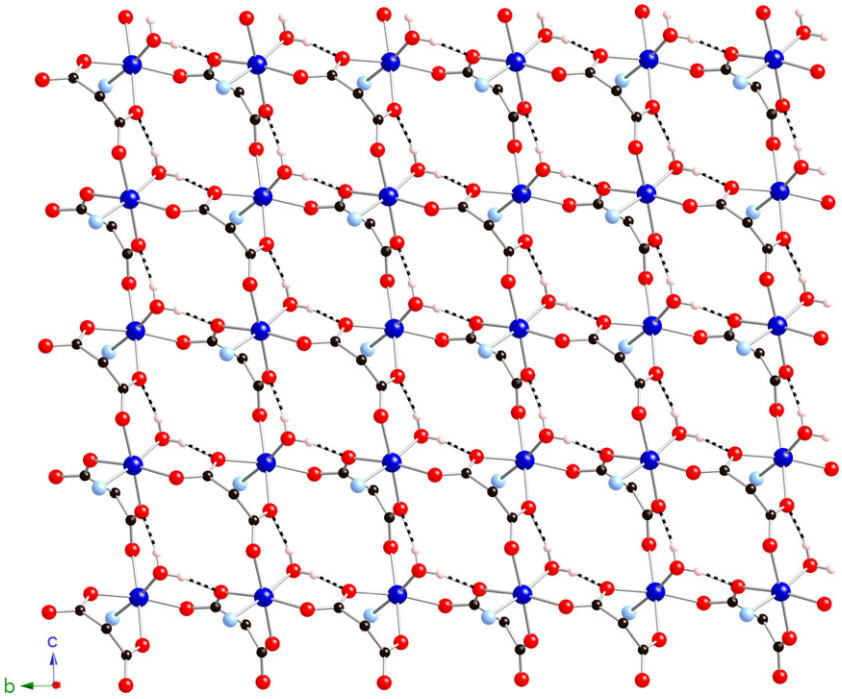

Fig. 2. View down *a* of the six-connected 2-D $[Co_2(malonate)_2(H_2O)]_n$ layer motif in **1**. A similar motif is evident in **2**. Hydrogen bonding is indicated as dashed lines.

Covalent connectivity within the $[M_2(malonate)_2(H_2O)_2]$ layers in **1** and **2** is supplemented by hydrogen bonding pathways between the coordinated water molecules and the malonate oxygen atoms involved in the 1,3-chelating binding pattern. Metrical parameters for these interactions are given in Table 2. In **1**, neighboring coordination octahedra are twisted relative to each other along both the *b* (by ~119.7°) and *c* (by ~102.7°) crystal directions, as measured by O_{aquo}–Co···Co–O_{aquo} torsion angles. The corresponding angles in **2** are extremely similar (~119.8° and ~104.4°). The coordinated water molecules bound to neighboring metal atoms alternate above and below the 2-D layer motifs, as do the nitrogen donor atoms belonging to the dpa ligands.

The 2-D $[M_2(malonate)_2(H_2O)_2]_n$ layers are stacked in an *ABA* pattern along the *a* crystal direction, and covalently linked into 3-D coordination polymer frameworks of formulation $\{[M_2(malonate)_2(dpa)(H_2O)_2]_n$ by means of the dipodal dpa tethering ligands (Fig. 3). The respective through-dpa M–M contact distances for **1** and **2** are 11.674(1) Å and 11.557(1) Å. This Co–Co distance in **1** is ~0.27 Å longer than in its 4,4′-bpy analogue, due to the additional length of the dpa ligand imparted by its central secondary amine subunit. Influenced by the supramolecular environment, the dpa ligands in **1** and **2** adopt somewhat twisted conformations, with inter-ring torsion angles of ~33.2° and ~36.9°, respectively. The linkage of the malonate-based "grid-like" layers through dpa tethers establishes a 3-D coordination polymer framework with $4^4 6^6$ topology (**sqp** lattice) in both **1** and **2** (Fig. 4). In contrast to their previously reported centrosymmetric 4,4′-bpy congeners [15,33], coordination polymers **1** and **2** adopt an acentric space

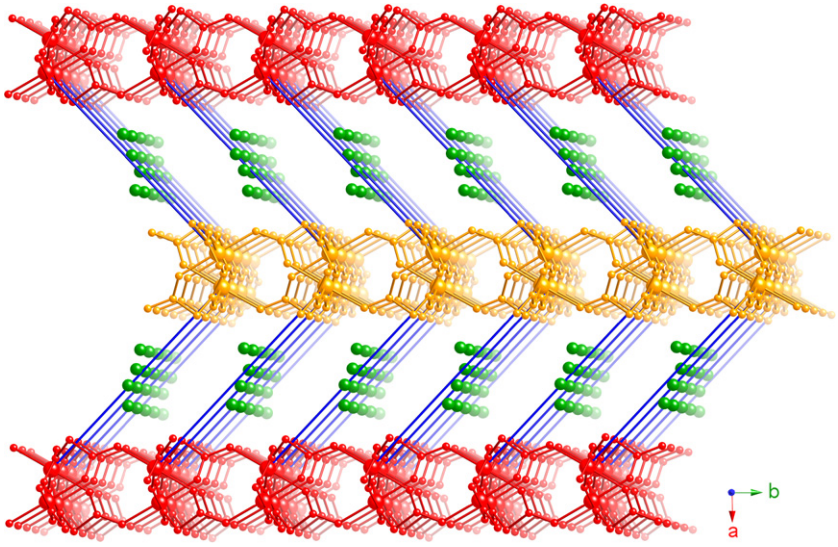

Fig. 3. View down *c* of the 3-D network structure of **1** and **2**. The dpa ligands are shown as rods and the water molecules of crystallization are shown as isolated spheres.

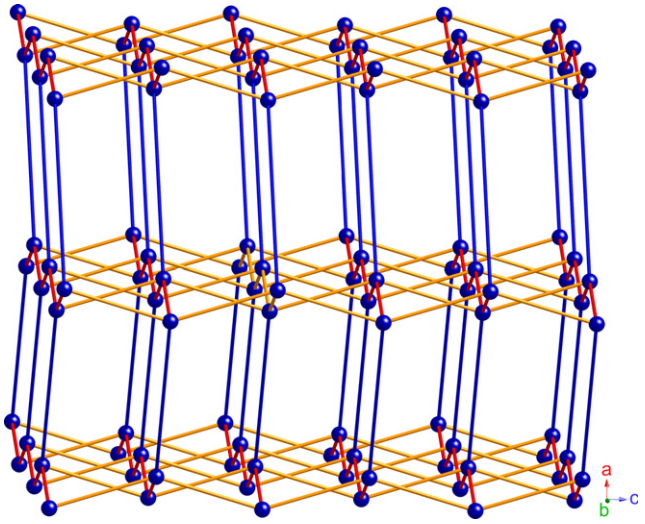

Fig. 4. Simplified network perspective of the 3-D $4^4 6^6$ topology **sqp** coordination polymer connectivity in **1** and **2**.

group due to the central kink and locked inter-ring torsion of their dpa ligands, which possess a local *C*2 point group within their respective crystal structures.

The central N–H subunits of the dpa ligands engage in hydrogen bonding to uncoordinated water molecules (O6) held within interlayer incipient voids. These water molecules in turn hydrogen bond to others (O7), forming discrete water molecule dimers, a commonly observed feature within coordination polymer matrices [34]. Each of the water molecule dimer positions is disordered equally over two symmetry related sets of sites. Distance and angle information for these supramolecular interactions are listed in Table 3. According to calculations performed with PLATON [35], the water molecule-bearing void spaces in **1** and **2** represent 12.9% and 14.0% of their respective unit cell volumes.

4.3. Thermogravimetric analysis

Compounds **1** and **2** were subjected to thermogravimetric analysis to determine the thermal stability of their 3-D coordination polymer frameworks. **1** exhibits dehydration beginning at ~185 °C (13.0% mass loss, 12.7% predicted for four water molecules). It then begins to lose all organic ligands at ~240 °C (56.7% mass loss, 60.2% predicted for one dpa and two malonate ligands), resulting in a CoO remnant (28.1% mass remaining, 26.5% predicted) at ~800 °C. Compound **2** shows a similar pattern of degradation, beginning at ~185 °C with the loss of all coordinated and uncoordinated water molecules (13.2% mass loss, 12.8% predicted). It then loses the rest of its organic ligands beginning at ~270 °C (61.3% mass loss, 66.4% predicted), resulting in the deposition of NiO (25.1% mass remaining, 26.5 % predicted) at ~800 °C. It is possible that the shorter bond lengths in **2** allow its 3-D covalent framework to have a slight enhancement in thermal stability relative to **1**. TGA traces for **1** and **2** are shown in Figs. S1 and S2, respectively.

Table 3
Hydrogen bonding distance (Å) and angle (°) data for **1** and **2**

D–H	d(H···A)	∠DHA	d(D···A)	Symmetry transformation for A
Complex ***1***				
O5–H5WA···O2	1.90(2)	162(2)	2.707(2)	$-x+1/2, y, z+1/2$

4.4. Variable temperature magnetic susceptibility studies

To investigate the spin communication behavior across the 2-D $[M_2(\text{malonate})_2(H_2O)_2]_n$ layer motifs in **1** and **2**, variable temperature magnetic studies were undertaken. The magnetic susceptibility of **1** followed the Curie–Weiss law ($C = \chi_m/T - \Theta$) acceptably above 75 K (Fig. S3), with $C = 3.63$ cm^3 mol Co^{-1} K and $\Theta = -72$ K. The value of C is comparable to that expected (3.37 cm^3 mol Co^{-1} K, with $C = 0.125\ \mu_{LS}^2$, $\mu_{LS} = [L(L+1) + 4S(S+1)]^{1/2}$ and $L = 3$, $S = 3/2$) when taking both spin and unquenched orbital contributions into effect, relevant for Co^{2+} ions. The negative Weiss constant is indicative of antiferromagnetic spin ordering within the $[Co_2(\text{malonate})_2(H_2O)_2]_n$ layers in **1**, although a reduction in magnetic susceptibility due to spin–orbit coupling cannot be ruled out in this system.

A successful attempt was made to model the magnetic susceptibility behavior of **1** using Lines' high-temperature expansion [36] for a quadratic lattice of $S = 3/2$ spins (Eq. (1)), where the magnetochemical variables have their usual meanings. A temperature-independent paramagnetism term (TIP) was included. Non-linear regression of the data above 50 K resulted in a best fit (Fig. 5) with the following parameters: $g = 2.08(2)$, $J = -1.05(8)$ cm^{-3}, and TIP = 0.0037(2) cm^3 mol^{-1} with $R = 1.83 \times 10^{-3} = \{\Sigma[(\chi_m T)_{obs} - (\chi_m T)_{calc}]^2/[(\chi_m T)_{obs}]^2\}^{1/2}$. The negative value of the exchange integral J corroborates the presence of antiferromagnetic interactions between Co^{2+} ions in **1**. However, the relatively mediocre fit at higher temperature, and significant deviations from the fit at $T < 50$ K indicate the possibility of spin–orbit coupling and/or anisotropy. (It should be noted that Lines' equation neglects single-ion effects.) The lack of any maximum in the $\chi_m(T)$ plot for **1** (Fig. S4) marks the likely absence of any long-range low-temperature antiferromagnetic coupling pathways between layer subunits through the organodiimine tethers. Thus the value of J should be considered a rough estimate of the level of modest intralayer antiferromagnetic interactions in **1**.

$$X_m T = \left(\frac{Ng^2\beta^2 T}{2|J|}\right)\left[3\Theta + \sum_{n=1}^{6}\frac{C_n}{\Theta^{n-1}}\right]^{-1} + \text{TIP}(T) \qquad (1)$$

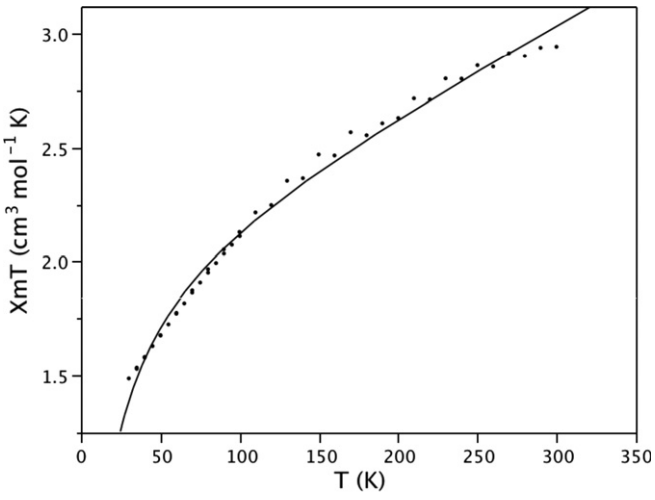

Fig. 5. $\chi_m T$ vs. T plot for **1**. The solid line indicates the best fit to Eq. (1) in the text.

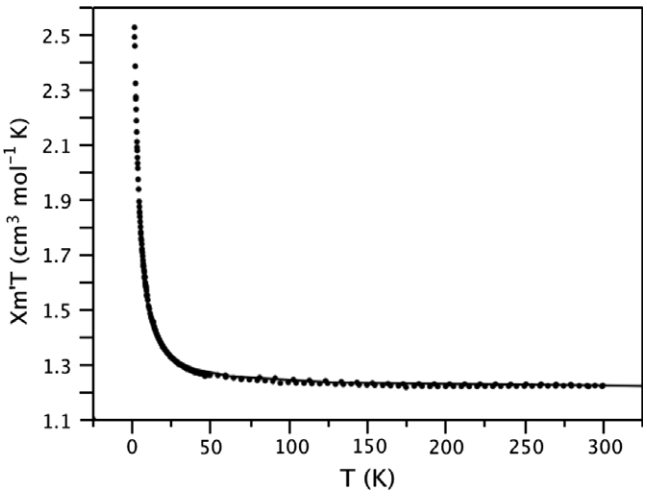

Fig. 6. $\chi_m T$ vs. T plot for **2**. The solid line indicates the best fit to Lines' model for a ferromagnetic square-lattice of $S = 1$ spins.

where $\Theta = kT/(2|J|S(S+1))$ *and* $C_1 = 4$, $C_2 = 1.6$, $C_3 = 0.304$, $C_4 = 0.249$, $C_5 = 0.132$, $C_6 = 0.013$.

The magnetic susceptibility of **2** also follows Curie–Weiss behavior (Fig. S5), but in contrast to **1** does so over the entire temperature range (2–300 K). Parameters C and Θ are 1.21 $cm^3\ mol\ Ni^{-1}\ K$ and 2.0 K, respectively. The value of C is consistent with uncoupled $S = 1$ ions at 300 K (calc. = 1.00 $cm^3\ mol^{-1}\ K$ for $g = 2.0$). In contrast to **1**, ferromagnetic interactions appear to be operative within the 2-D $[M(malonate)_2(H_2O)_2]_n$ subunits in **2** as evidenced by the positive Weiss constant. Weak ferromagnetic interactions in **2** are corroborated by an examination of the $\chi_m T(T)$ plot (Fig. 6). Upon cooling from 300 K and 50 K, a very slow increase in $\chi_m T$ from 1.21 to 1.26 $cm^3\ mol\ Ni^{-1}\ K$, occurs with a more rapid increase at lower temperature. The value of $\chi_m T$ is 2.49 $cm^3\ mol\ Ni^{-1}\ K$ at 2 K, with no sign of a diminution at any point, reflective of a ferromagnetic ground state.

The variable temperature susceptibility of **2** was fit to Lines' square-lattice high-temperature expansion in Eq. (1) (Fig. 6), with different C_n coefficients for $S = 1$ ($C_1 = -4$, $C_2 = 1.834$, $C_3 = -0.445$, $C_4 = 0.224$, $C_5 = -0.132$, $C_6 = 0.019$). No temperature-independent paramagnetism term was necessary for an acceptable fit. The best fit values were $g = 2.201(1)$ and $J = 0.289(1)\ cm^{-3}$ with $R = 1.7 \times 10^{-4}$. The small, yet positive, value of J corroborates the assignment of weak ferromagnetic interactions between the nickel ions in **2**.

Similar divergent magnetic behavior, with carboxylate bridged cobalt 2-D layers exhibiting antiferromagnetism and carboxylate bridged nickel 2-D layers showing ferromagnetism, has been observed in two prior systems, $\{[M(H_2O)_2][M(malonate)_2(H_2O)_2]\}_n$ [14] and $\{M(malate)(4,4'\text{-bpy})_{0.5}] \cdot H_2O\}_n$ (M = Co, Ni) [37]. Differences in the electronic configurations of the *pseudo* octahedrally coordinated high-spin divalent cobalt and nickel ions ($t_{2g}^5 e_g^2$ *versus* $t_{2g}^6 e_g^2$) can give rise to the observed variances in overall magnetic behavior. The greater likelihood of magnetic orbital overlap in **1**, due to the existence of three orbitals with unpaired electrons, can rationalize the greater magnitude of the magnetic interactions in **1**.

5. Conclusions

Hydrothermal synthesis has afforded a pair of isostructural 3-D coordination polymers built from $[M(malonate)_2(H_2O)_2]_n$ layers strutted by the kinked and hydrogen bonding capable tethering organodiimine dpa. While the gross structural features of these compounds resemble those of their previously reported 4,4′-bipyridine congeners, the presence of the dpa ligand enforces acentricity and spontaneous resolution in this coordination polymer system. In addition, the central amine unit of the dpa ligand promotes hydrogen bonding to entrained water molecules of crystallization, resulting in incipient voids of modest volume. The disparate magnetic properties within the square-grid layers of **1** and **2** (moderate antiferromagnetic and weak ferromagnetic, respectively) are reflective of different electronic configurations and magnetic orbital overlap; they reinforce the trends in the magnetic behavior observed in other coordination polymers with divalent cobalt- and nickel-based square-grid layer motifs. The synthetic investigation of other coordination polymer solids based on the underutilized tethering ligand dpa continues in our laboratory.

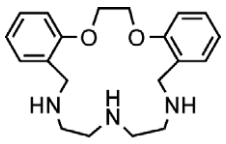
binds to all five ring donors [4], in other cases non-coordination of ether donors was observed [5] with the metal residing either endo or exo with respect to the macrocyclic cavity.

As an extension of the above studies we now report the synthesis and X-ray study of an extended series of new complexes of **L** incorporating the soft metal ions Ag(I), Cd(II), Hg(II) and Pd(II) the results serve to both extend and further exemplify the rich and varied structural chemistry documented so far for complexes of this ligand type.



L

2. Experimental

2.1. General comments

All commercial reagents and solvents were of analytical reagent grade where available. Infrared spectra (KBr pellets) were measured on a Mattson Genesis Series FT-IR spectrophotometer. Microanalyses were performed on a LECO CHNS-932 elemental analyser. The mass spectra were obtained on a JEOL JMS-700 spectrometer (FAB) and Applied Biosystems 4000 Q TRAP (ESI) at the Central Instrument Facility of Gyeongsang National University. Melting points are uncorrected. The preparation of **L** has been reported previously [6]. All metal complexes were dried in a vacuum before microanalysis; the complexes were isolated with typical yields of 20–60%.

2.2. Complex synthesis

Caution: the respective perchlorate-containing complexes are potentially explosive and appropriate precautions should be taken during their preparation, handling and storage.

2.2.1. Preparation of $[Ag_2\mathbf{L}_2(NO_3)_2]$ (**1**)

L (20 mg, 0.059 mmol) in warm methanol (2 mL) was added to one equivalent of $AgNO_3$ in a similar volume of warm acetonitrile. Slow evaporation of this solution yielded **1** as a crystalline product that proved suitable for X-ray analysis. Yield: 30%. [*Anal.* Calc. for $C_{40}H_{54}Ag_2N_8O_{10}$: C, 46.98; H, 5.32; N, 10.96. Found: C, 46.66; H, 4.95; N, 11.14%.] IR (KBr, cm^{-1}): 3276, 2909, 2857, 2349, 1590, 1478, 1422, 1374 (s, NO_3^-), 1303, 1239, 1048, 939, 772. MS (FAB) m/z = 448.1 ($[Ag\mathbf{L}]^+$, $[C_{20}H_{27}AgN_3O_2]^+$). Mp 180–182 °C (decomp.).

2.2.2. Preparation of $[Ag_2\mathbf{L}_2](ClO_4)_2 \cdot 2DMF$ (**2**)

A colorless precipitate of **2** was obtained on mixing equimolar amounts of **L** (20 mg, 0.059 mmol) and $AgClO_4$ in warm methanol (5 mL). Yield: 60%. [*Anal.* Calc. for $C_{40}H_{54}Ag_2Cl_2N_6O_{12}$: C, 48.77; H, 4.96; N, 7.66. Found: C, 48.42; H, 5.41; N, 7.72%.] IR (KBr, cm^{-1}): 3282, 2897, 2349, 1592, 1504, 1433, 1235, 1103 (s, ClO_4^-), 933, 774, 603. MS (FAB) m/z = 448.1 ($[Ag\mathbf{L}]^+$, $[C_{20}H_{27}AgN_3O_2]^+$). Mp 220–225 °C. Vapour diffusion of diethyl ether into a DMF solution of this product yielded crystals of **2** that were suitable for X-ray analysis.

2.2.3. Preparation of $[Ag_2\mathbf{L}_2](PF_6)_2 \cdot 2DMF$ (**3**)

A colourless precipitate of **3** was obtained on mixing equimolar amounts of **L** (20 mg, 0.059 mmol) and $AgPF_6$ in warm methanol (5 mL). Yield: 60%. [*Anal.* Calc. for $C_{40}H_{54}Ag_2F_{12}N_6O_4P_2$: C, 40.42; H, 4.58; N, 7.07. Found: C, 40.21; H, 4.59; N, 7.08%.] IR (KBr, cm^{-1}): 3320, 2904, 2349, 1650, 1478, 1434, 1234, 801 (s, PF_6^-), 785, 522. MS (FAB) m/z = 448.1 ($[Ag\mathbf{L}]^+$, $[C_{20}H_{27}AgN_3O_2]^+$). Mp 248–253 °C (decomp.). Vapour diffusion of diethyl ether into a DMF solution of this product afforded **3** as a crystalline product which was suitable for X-ray analysis.

2.2.4. Preparation of $[Ag_2\mathbf{L}_2](OTf)_2$ (**4**)

Slow evaporation a methanol solution (5 mL) of **L** (20 mg, 0.059 mmol) containing one equivalent of AgOTf afforded **4** as a crystalline product that was suitable for X-ray analysis. Yield: 30%. [*Anal.* Calc. for $C_{42}H_{54}Ag_2F_6N_6O_{10}S_2$: C, 42.15; H, 4.55; N, 7.02; S, 5.36. Found: C, 42.24; H, 4.28; N, 6.93; S, 5.82%.] IR (KBr, cm^{-1}): 3321, 2905, 2349, 1658, 1613, 1479, 1268, 1185, 1064, 932, 737 (s, OTf^-), 614. MS (FAB) m/z = 448.1 ($[Ag\mathbf{L}]^+$, $[C_{20}H_{27}AgN_3O_2]^+$). Mp 210–214 °C (decomp.).

2.2.5. Preparation of $[Ag_2\mathbf{L}_2(\mu\text{-}CN)][Ag(CN)_2] \cdot H_2O$ (**5**)

Addition of **L** (20 mg, 0.059 mmol) in warm methanol (2 mL) to one equivalent of $K[Ag(CN)_2]$ in a similar volume of warm water led, on slow evaporation of the solvent mixture, to **5** as a crystalline product that was suitable for X-ray analysis. Yield: 40%. [*Anal.* Calc. for $C_{43}H_{54}Ag_2N_9O_4$: C, 52.88; H, 5.57; N, 12.91. Found: C, 53.10; H, 5.43; N, 13.01%.] IR (KBr, cm^{-1}): 3230, 2947, 2837, 2125 (s, CN^-), 1602, 1589, 1494, 1448, 1384, 1292, 1244, 1062, 952, 763. MS (ESI) m/z = 922, ($[Ag_2\mathbf{L}_2CN]^+$, $[C_{41}H_{54}Ag_2N_7O_4]^+$). Mp 214–215 °C (decomp.).

2.2.6. Preparation of $[Cd\mathbf{L}_2](ClO_4)_2 \cdot CH_3CN$ (**6**)

L (20 mg, 0.059 mmol) in warm methanol (2 mL) was added to one equivalent of $Cd(ClO_4)_2$ in a similar volume of warm methanol to yield a colorless precipitate of **6**. Yield: 60%. [*Anal.* Calc. for $C_{40}H_{54}CdCl_2N_6O_{12}$: C, 48.32; H, 5.47; N, 8.45. Found: C, 47.90; H, 5.33; N, 7.97%.] IR (KBr, cm^{-1}): 3305, 3258, 2987, 2348, 1480, 1241, 1103 (s, ClO_4^-), 932, 854. MS (ESI) m/z = 895.3 ($[Cd\mathbf{L}_2(ClO_4)]^+$, $[C_{40}H_{54}CdClN_6O_8]^+$). Mp 175–177 °C (decomp.). Single crystals of **6** suitable for X-ray analysis were obtained by vapour diffusion of diethyl ether into an acetonitrile solution of this complex.

2.2.7. Preparation of $[Hg\mathbf{L}(ClO_4)_2]$ (**7**)

L (20 mg, 0.059 mmol) in warm dichloromethane (2 mL) was added to one equivalent of $Hg(ClO_4)_2$ in a similar volume of warm methanol to yield a colorless precipitate of **7**. Yield: 50%. [*Anal.* Calc. for $C_{20}H_{27}Cl_2HgN_3O_{10}$: C, 32.42; H, 3.67; N, 5.67. Found: C, 32.18; H, 3.91; N, 5.62%.] IR (KBr, cm^{-1}): 3375, 3285, 2897, 2348, 1480, 1214, 1102 (s, ClO_4^-), 774, 584. Single crystals of **7** suitable for X-ray analysis were obtained by vapour diffusion of diethyl ether into a DMF solution of this complex.

2.2.8. Preparation of $[Hg\mathbf{L}(SCN)_2] \cdot CH_3CN$ (**8**)

Slow evaporation of a dichloromethane/acetonitrile solution (5 mL) of **L** (20 mg, 0.059 mmol) containing one equivalent of $Hg(SCN)_2$ afforded **8** as a crystalline product that was suitable for X-ray analysis. Yield: 30%. [*Anal.* Calc. for $C_{22}H_{27}HgN_5O_2S_2$: C, 40.15; H, 4.13; N, 10.64; S, 9.74. Found: C, 40.42; H, 4.55; N, 10.25; S, 9.51%.] IR (KBr, cm^{-1}): 3233, 2890, 2100 (s, SCN^-), 1592, 1471, 1269, 934, 734. MS (FAB) m/z = 601.2 ($[Hg\mathbf{L}(SCN)]^+$, $[C_{20}H_{27}HgN_4O_2S]^+$). Mp 170–174 °C (decomp.).

*2.2.9. Preparation of $[Hg_2\mathbf{L}_2](HgI_4)_2 \cdot 2\mathbf{L}$ (**9**)*

Slow evaporation of dichloromethane/acetonitrile solution (5 mL) of **L** (20 mg, 0.059 mmol) containing one equivalent of HgI_2 afforded **9** as a crystalline product that was suitable for X-ray analysis. Yield: 20%. [*Anal.* Calc. for $C_{40}H_{54}Hg_2I_4N_6O_4$: C, 30.18; H, 3.42; N, 5.28. Found: C, 29.87; H, 3.14; N, 5.44%.] IR (KBr, cm^{-1}): 3253, 2930, 2378, 1424, 1204, 943, 752. MS (FAB) m/z = 670.1 ($[Hg\mathbf{L}I]^+$, $[C_{20}H_{27}HgIN_3O_2]^+$). Mp 152–157 °C (decomp.).

*2.2.10. Preparation of $[Hg\mathbf{L}_2](NO_3)_2 \cdot 2CH_3OH$ (**10**)*

Slow evaporation of a dichloromethane/methanol solution (5 mL) containing **L** (20 mg, 0.059 mmol) and one equivalent of $Hg(NO_3)_2$ afforded **10** as a colourless crystalline product that was suitable for X-ray analysis. Yield: 40%. [*Anal.* Calc. for $C_{40}H_{54}HgN_8O_{10}$: C, 47.69; H, 5.40; N, 11.12. Found: C, 47.62; H, 5.34; N, 10.86%.] IR (KBr, cm^{-1}): 3562, 3477, 2839, 2349, 1595, 1479, 1429, 1387 (s, NO_3^-), 1292, 1096, 936, 748. MS (ESI): m/z = 946.8 ($[Hg\mathbf{L}_2(NO_3)]^+$, $[C_{40}H_{54}HgN_7O_7]^+$). Mp 144–145 °C (decomp.).

*2.2.11. Preparation of $[Pd\mathbf{L}Cl]Cl \cdot H_2O$ (**11**)*

A dichloromethane solution (2 mL) of **L** (20 mg, 0.059 mmol) and equal volume of an aqueous solution of K_2PdCl_4 were mixed in a 1:1 molar ratio to yield an orange precipitate of **11**. Yield: 30%. [*Anal.* Calc. for $C_{20}H_{27}Cl_2N_3O_2Pd$: C, 46.30; H, 5.25; N, 8.10. Found: C, 46.21; H, 5.54; N, 7.81%.] IR (KBr, cm^{-1}): 3323, 2842, 2578, 2379, 1568, 1156, 925. MS (FAB) m/z = 484.1 ($[Pd\mathbf{L}Cl]^+$, $[C_{20}H_{27}ClN_3O_2Pd]^+$). Mp 167–168 °C (decomp.). Single crystals of **11** suitable for X-ray analysis were obtained by vapour diffusion of diethyl ether into a methanol solution of this complex.

*2.2.12. Preparation of $[Pd\mathbf{L}(NO_3)]NO_3 \cdot CH_3OH$ (**12**)*

Slow evaporation of a methanol solution (2 mL) of **L** (20 mg, 0.059 mmol) containing one equivalent of $Pd(NO_3)_2$ afforded **12** as orange crystals that was suitable for X-ray analysis. Yield: 30%. [*Anal.* Calc. for $C_{20}H_{27}N_5O_8Pd$: C, 42.00; H, 4.76; N, 12.25. Found: C, 42.31; H, 5.02; N, 12.33%.] IR (KBr, cm^{-1}): 3233, 2956, 2578, 2100, 1424, 1367 (s, NO_3^-), 1156, 925. MS (FAB) m/z = 509.1 ($[Pd\mathbf{L}(NO_3)]^+$, $[C_{20}H_{27}N_4O_5Pd]^+$). Mp 172–173 °C (decomp.).

2.3. X-ray structure determinations

For each determination a suitable crystal was mounted on a Bruker SMART diffractometer equipped with a graphite monochromated Mo Kα (λ = 0.71073 Å) radiation source and a CCD detector and 45 frames of two-dimensional diffraction images were collected and processed to deduce the cell parameters and orientation matrix. A total of 1271 frames of two-dimensional diffraction images were collected. The frame data were processed to give structure factors using the program SAINT [7]. The intensity data were corrected for Lorentz and polarization effects. Empirical absorption corrections were also applied for compounds **2**, **7–8**, **10** and **12** using the program SADABS [8]. The structures were solved by a combination of direct and difference Fourier methods provided by the program package SHELXTL [9], and refined using a full matrix least square against F^2 for all data. All non-H atoms were refined anisotropically. All hydrogen atoms were included in calculated positions with isotropic thermal parameters 1.2 times those of attached atoms. Crystallographic data are summarized in Tables 1–3. Selected geometric parameters for the respective complexes are presented in Tables 4–11.

3. Results and discussion

The following crystalline complexes, $[Ag_2\mathbf{L}_2(NO_3)_2]$ (**1**), $[Ag_2\mathbf{L}_2](ClO_4)_2 \cdot 2DMF$ (**2**), $[Ag_2\mathbf{L}_2](PF_6)_2 \cdot 2DMF$ (**3**), $[Ag_2\mathbf{L}_2](OTf)_2$ (**4**), $[Ag_2\mathbf{L}_2(\mu\text{-}CN)][Ag(CN)_2] \cdot H_2O$ (**5**), $[Cd\mathbf{L}_2](ClO_4)_2 \cdot CH_3CN$ (**6**), $[Hg\mathbf{L}(ClO_4)_2]$ (**7**), $[Hg\mathbf{L}(SCN)_2] \cdot CH_3CN$ (**8**), $[Hg_2\mathbf{L}_2](HgI_4)_2 \cdot 2\mathbf{L}$ (**9**), $[Hg\mathbf{L}_2](NO_3)_2 \cdot 2CH_3OH$ (**10**), $[[Pd\mathbf{L}Cl]Cl \cdot H_2O$ (**11**) and $[Pd\mathbf{L}(NO_3)]NO_3 \cdot CH_3OH$ (**12**) were isolated and characterised using microanalysis, mass spectra, infrared spectroscopy and single-crystal X-ray diffraction. In each case the reaction mixture involved the 1:1 interaction of the corresponding metal salt with **L** in methanol, dichloromethane or acetonitrile (or a mixture of these solvents). Crystals of **1**, **4** and **5**, **8–10** and **12** suitable for X-ray structure determination were obtained on slow evaporation of the corresponding reaction solutions while crystals of the remaining complexes were grown by vapour diffusion of diethyl ether into their DMF (**2**, **3**, **7**), acetonitrile (**6**) or methanol (**11**) solutions.

3.1. Silver(I) complexes

The X-ray structure determinations of **1–5** incorporating different anions (Fig. 1) confirm their 2:2:2 (metal:ligand:anion) stoichiometries. For each of **2–4**, the structure consists of a dimeric arrangement in which two macrocycles in a bent arrangement sandwich two silver(I) ions; in these structures the silver ions are shielded from further interaction with solvent or anions by the folded macrocycles (see Fig. 1). Each silver centre is bonded to two N atoms from one **L** and one N atom from a different **L**, with the ether oxygen donors uncoordinated. A weak Ag···Ag contact (double dashed lines) between adjacent silvers is also present. In **2–4** the individual silver centres may be considered to adopt pseudo-four-coordinate (distorted tetrahedral) geometries. However, in the case of $[Ag_2\mathbf{L}_2(NO_3)_2]$ (**1**), each silver centre has an additional bond to a monodentate nitrato ligand, presumably reflecting the latter's relatively smaller size and comparatively higher affinity for this ion.

A range of di- and polymetallic silver(I) complexes have now been documented to exhibit similar Ag···Ag contacts to those mentioned above for the present complexes (with the literature

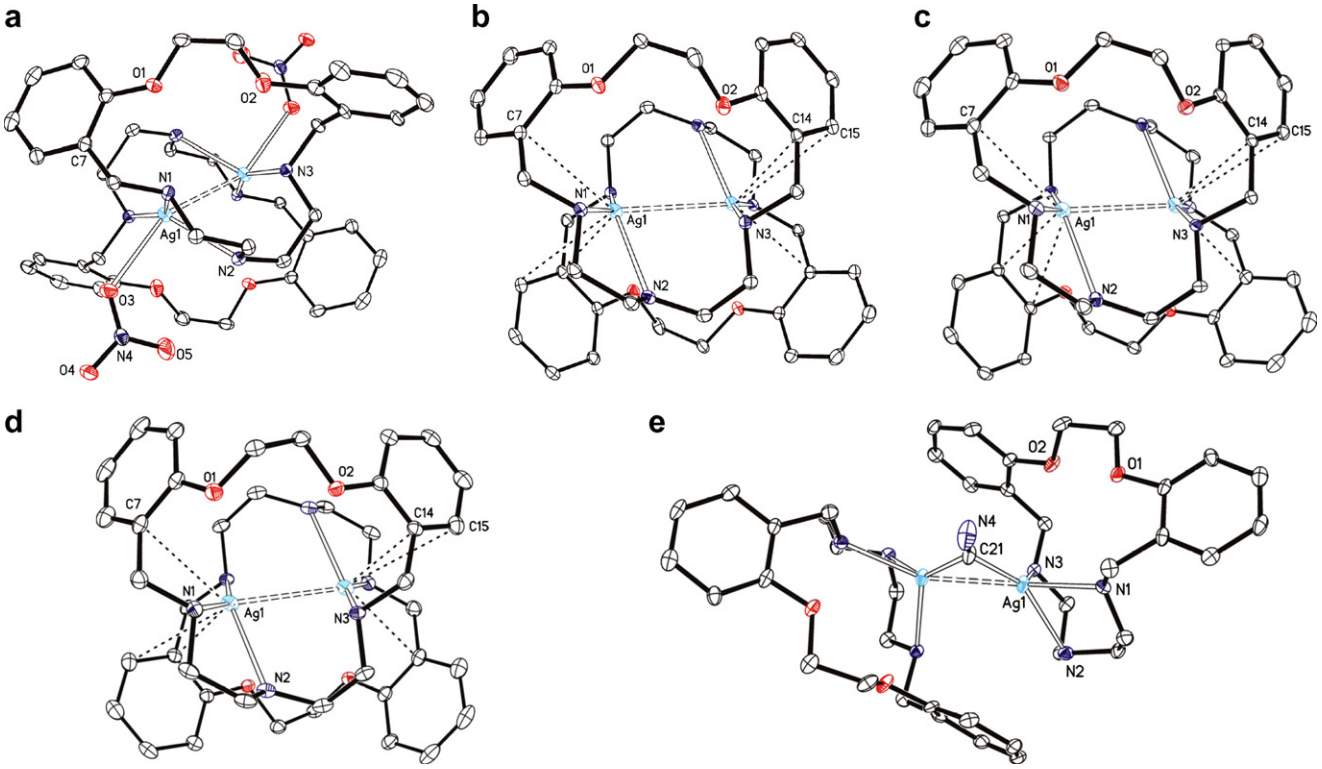

Fig. 1. Dimeric structures of (a) $[Ag_2\mathbf{L}_2(NO_3)_2]$ (**1**), (b) $[Ag_2\mathbf{L}_2](ClO_4)_2 \cdot 2DMF$ (**2**), (c) $[Ag_2\mathbf{L}_2](PF_6)_2 \cdot 2DMF$ (**3**), (d) $[Ag_2\mathbf{L}_2](OTf)_2$ (**4**) and (e) $[Ag_2\mathbf{L}_2(\mu\text{-}CN)][Ag(CN)_2] \cdot H_2O$ (**5**). Hydrogen atoms, non-coordinating anions and non-coordinating solvent molecules are omitted.

internuclear distances falling in the approximate range 2.9–3.3 Å) [10]; the Ag···Ag values are thus significantly shorter than the van der Waals diameter for silver(I) of 3.44 Å [11]. In the present structurally related Ag(I) complexes, **1**–**4**, the internuclear Ag···Ag distances vary with the anion present: [**1** (NO_3^-), 3.3196(7) Å; **2** (ClO_4^-), 3.2413(3) Å; **3** (PF_6^-), 3.1962(6) Å and **4** (OTf^-), 3.1174(6) Å], thus **1** shows the longest contact in keeping with coordination of the nitrate group leading to a weakening of the Ag···Ag interaction through electronic and/or steric effects. In this context it is noted that the closest approach of the remaining anions to a silver centre lies in the range 4.5–5.6 Å.

For the above complexes, the sole coordination of the N_3-donor set of **L** to a single metal centre thus appears to promote both dimerization and formation of a Ag···Ag contact between the respective silver centres in these dinuclear complex species. In addition, some of the relevant silver–aromatic carbon contacts in **2**–**4** are less than the sum of Van der Waals radii (Ag···C 2.9–3.3 Å, dashed lines). Consequently, the preferred anion-free dimerizations of **2**–**4** are due to the weaker affinity of ClO_4^-, PF_6^- and OTf^- than that of NO_3^- (in case of **1**) toward the silver(I) center, allowing the approach of the benzo-group to form such Ag···π interactions.

In the case of $[Ag_2\mathbf{L}_2(\mu\text{-}CN)][Ag(CN)_2]_{\cdot H2}O$ (**5**) a bridging cyano group was observed to link each silver ion in the dinuclear cation [Ag···Ag distance, 2.7437(10) Å; Ag1–C21–Ag1A 78.1(3)°]. The complex adopts a different relative arrangement of the macrocyclic ligands to that present in **1**–**4**, with the macrocyclic ligands orientated away from the dinuclear Ag(I) centres (see Fig. 1e). Once again, the ether oxygens of **L** remaining uncoordinated. The complex is a rare example of a discrete binuclear silver complex incorporating a two-electron μ_2-κC:κC bridging cyanide group, the first compound of this type was reported in 1999 by Schröder et al. [12]. The bridging mode in both these complexes contrasts with the usual linear bridging (μ_2-κC:κN), four-electron-donating CN^- bridges more commonly observed with this anion [13].

3.2. Cadmium complex

The crystal structure of **6** is shown in Fig. 2. The coordination of each **L** to the Cd(II) centre is *via* a facial arrangement of its three nitrogen donors, forming a distorted octahedral array of six N atoms from two **L**, with the ether oxygen donors uncoordinated; the N–Cd–N bite angles vary considerably, ranging from 73° to 155°. Once again, the metal centre is fully shielded by the partially bound macrocycles which surround the cadmium centre in a sandwich-like arrangement. This structure contrasts with that of the related 1:1 complex, $[Cd\mathbf{L}(NO_3)_2]$ reported previously [14] in which all macrocyclic donors coordinate together with two monodentate (O-bound) nitrate ligands such that the Cd(II) centre achieves a seven-coordinate geometry.

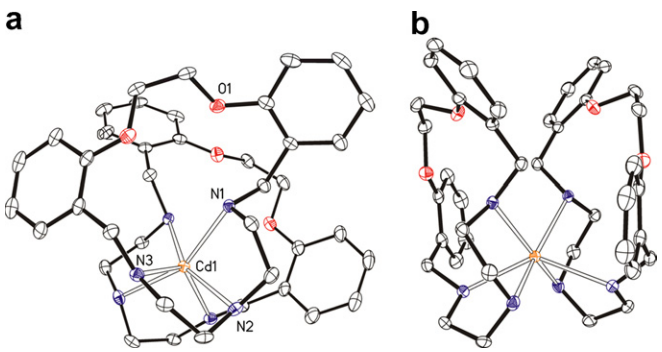

Fig. 2. Molecular structure of $[Cd\mathbf{L}_2](ClO_4)_2 \cdot CH_3CN$ (**6**); (a) top view and (b) side view. Hydrogen atoms and non-coordinating anions are omitted.

3.3. Mercury(II) complexes

The crystal structure of [Hg**L**$(ClO_4)_2$] (**7**) confirms its metal:macrocycle ratio of 1:1. The Hg(II) coordinated to all donors in the macrocyclic N_3O_2-donor set together with two monodentate perchlorato ligands to yield an overall metal coordination geometry of seven (Fig. 3a). The Hg–N bond lengths [Hg–N1 2.275, Hg–N2 2.425 and Hg–N3 2.222 Å] are within the normal literature range for this bond type. Coordination about the Hg(II) centre is not symmetric, with, for example, both ether oxygen atoms being bound asymmetrically; the Hg–O1 bond length is 2.537 Å while that for Hg–O2 is 2.801 Å.

The crystal structure of [Hg**L**$(SCN)_2$] · CH_3CN, **8**, is shown in Fig. 3b. The Hg(II) ion in this complex is five-coordinate, being bound to the three nitrogens of **L** and two sulfur atoms from two thiocyanato ligands; the ether oxygens are not bound. The coordination geometry can best be described as a distorted trigonal bipyramid with two nitrogen donors of **L** and one sulfur atom from a thiocyanato ligand defining the trigonal plane and the axial positions occupied by the remaining ring nitrogen and a sulfur from one of the thiocyanate groups. The S2–Hg1–N2 angle is 168.57°. The latter ions show Hg–S–CN angles of 94.1° and 102.18° in keeping with the usual behaviour of these ions bound to Hg(II) [15].

The structure of **8** contrasts with that of **7**, in that both coordinated anions are located on the same side of the bound macrocycle with the mercury ion positioned ~0.53 Å from the N_3-plane towards the anions, resulting in the metal ion being located well outside the macrocyclic cavity.

The crystal structure of [Hg_2**L**$_2$]$(HgI_4)_2$ · 2**L**, **9**, obtained from the reaction of **L** with one molar equivalent of HgI_2, is shown in Fig. 3c. In this case, the structure consists of a dimeric cation, $[Hg_2\mathbf{L}_2]^{4+}$, and two $(HgI_4)^{2-}$ anions; two non-coordinated macrocycles are also present in the lattice. In the cation, each mercury ion can be described as having a four-coordinate, distorted tetrahedral geometry, being bound to three nitrogens from **L**, with a mercury-mercury bond occupying the fourth position; the bond angles range from 73.1(1)° for N2–Hg1–N3° to 137.3(1)° for N2–Hg1–Hg1A. The Hg–N bond lengths [2.412(4)–2.490(4) Å] are slightly longer than reported previously for such bonds (2.28–2.35 Å) [16]. Both pairs of macrocycle oxygen donors remain uncoordinated (Hg···O distances of 3.59 and 4.06 Å, respectively).

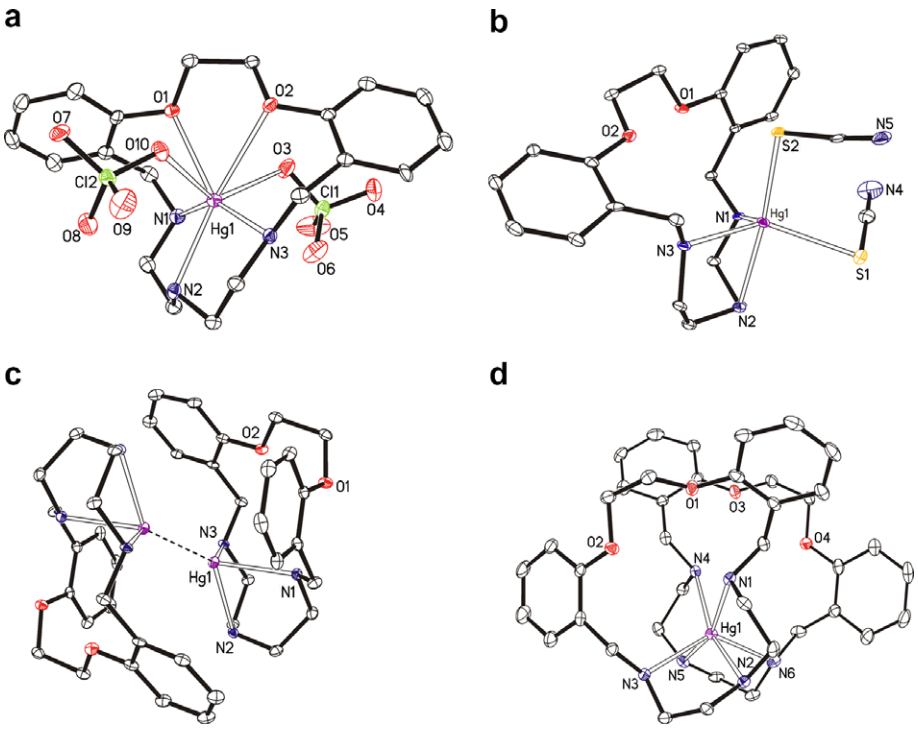

Fig. 3. Molecular structures of (a) [Hg**L**$(ClO_4)_2$] **(7)**, (b) [Hg**L**$(SCN)_2$] · CH_3CN (**8**), (c) [Hg_2**L**$_2$]$(HgI_4)_2$ · 2**L** (**9**) and (d) [Hg**L**$_2$]$(NO_3)_2$ · $2CH_3OH$ (**10**). Hydrogen atoms and non-coordinating solvent and anions are omitted.

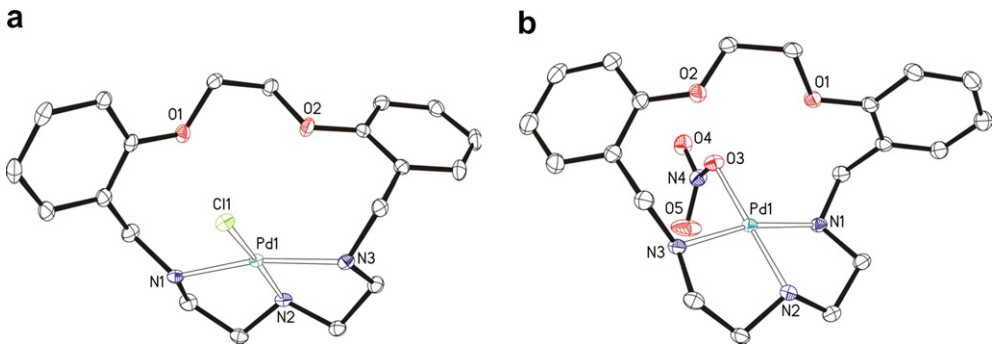

Fig. 4. Molecular structures of (a) [Pd**L**Cl]Cl · H_2O (**11**) and (b) [Pd**L**(NO_3)](NO_3) · CH_3OH (**12**). Hydrogen atoms, non-coordinating anions and solvents are omitted.

Overall, the two macrocycles surround the two mercury centres in a 'twisted' sandwich arrangement. Since there is an imposed inversion at the centre of the Hg(II)–Hg(II) bond, the asymmetric unit contains only half of the structure described above. The mercury atom is located 1.586 Å above the N_3 trigonal plane. The Hg(II)–Hg(II) bond length [2.5459(6) Å] is shorter than reported previously [17]. Only five cases of Hg(II)–Hg(II) bonds (2.7–3.0 Å) [17] were extracted from the CCDC [18] database. We are not aware of any other example of a Hg(II)–Hg(II) bond occurring in a macrocyclic ligand complex that has been characterized by X-ray diffraction. Geometrical parameters for the $[HgI_4]^{2-}$ anion, whose formation apparently aids the stabilization of the $[Hg_2\mathbf{L}_2]^{2+}$ cation in the crystal lattice, are generally similar to those reported previously for this dianion, although some distortion from regular tetrahedral geometry [angles: 102.19(1)–115.43(1)°] is evident in the present case.

When $Hg(NO_3)_2$ was employed in dichloromethane/methanol, $[Hg\mathbf{L}_2](NO_3)_2 \cdot 2CH_3OH$ (**10**), was obtained, which does not contain NO_3^- coordinated to the metal centre. The crystal structure of **10** is shown in Fig. 3d. The coordination of each **L** to the Hg(II) centre is *via* a facial arrangement of its three nitrogen donors, forming a distorted octahedral array of six N atoms from two **L**, with the ether oxygen donors uncoordinated; the N–Hg–N bite angles vary considerably, ranging from 73° to 160°. As occurs for **6**, the metal centre is once again fully shielded by the partially bound macrocycles which surround the mercury centre in a sandwich-like arrangement. Comparing the structures of **7** and **10**, it is noteworthy that two nitrate anions in **10** remain uncoordinated while both perchlorate anions are coordinated to the metal centre in **7** despite the nitrate ion being a stronger ligand than perchlorate ion towards most common metal ions.

3.4. Palladium(II) complexes

Reaction of **L** with K_2PdCl_4 and $Pd(NO_3)_2$ gave the orange complexes $[Pd\mathbf{L}Cl]Cl \cdot H_2O$, **11**, and $[Pd\mathbf{L}(NO_3)](NO_3) \cdot CH_3OH$, **12**. The crystal structures of both products are shown in Fig. 4. As expected for this metal ion, both Pd(II) centres attain a square-planar coordination geometry. Each square plane is somewhat distorted, with the respective coordination sites occupied by three N donors from **L** together with a chloro or nitrato ligand in the remaining site. Once again, the ether oxygens remain uncoordinated in each case. Both structures are analogues of the corresponding acetate-containing complex, $[Pd\mathbf{L}(OAc)]OAc \cdot H_2O$, whose structure was reported in 2004 [5f].

4. Conclusion

From the results presented above, the following observations can be made concerning the influence of the N_3O_2-donor set of **L** (with its three strong binding amine donors and two weaker binding ether oxygen donors) on the nature of its resulting Ag(I), Cd(II), Hg(II) and Pd(II) complexes. Across all four metals, **L** yielded a range of coordination arrangements that included discrete 1:1 (M:**L**) complexation, in which all donor atoms are bound to the central metal (Hg(II)), 1:1 complexation, in which only the N_3-donor set of **L** coordinates to occupy three donor positions of a square-planar (Pd(II)) or trigonal bipyramidal (Hg(II)) arrangement, 1:2 complexation, in which each **L** coordinates only *via* its N_3-donor set to yield a 'sandwich' arrangement with respect to the central metal (Cd(II) and Hg(II)), 2:2 complexation, in which both metal centres are bound to each **L** (Ag(I)) and another 2:2 dinuclear species, in which each **L** binds to a single metal ion, with the respective metal centres linked by a rare [12], two-electron, μ_2-κC:κC cyano bridge (Ag(I)). Finally, Hg(II) also yields a further type of 2:2 dinuclear complex, in which one **L** binds to each Hg(II) metal centre, with these 1:1 subunits then linked by a metal-metal (Hg–Hg) bond.

Based on the present solid state results, the affinity of the ether oxygen donors for Ag(I) and Pd(II) is clearly lower than for Hg(II) across all complexes investigated, with the situation for Cd(II) being unclear since, while non-coordination of ether oxygen occurs in the present 1:2 complex, its coordination is observed in the related 1:1 species, $[Cd\mathbf{L}(NO_3)_2]$, reported previously [14].

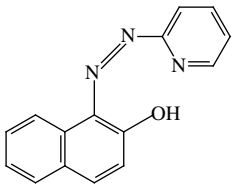

Scheme 1. Structure of HPAN ligand.

basis set, its use with DFT has shown to be sufficient for the geometry optimization and calculation of spectral properties. It gives good agreement with the experimental data and its use is justified in the case of large molecules.

2. Experimental

2.1. General procedure

All the reagents used to the synthesis were commercially available and were used without further purification. The [ReX_3(MeCN)(PPh_3)$_2$] (X = Cl, Br) complexes were prepared according to the literature methods [7].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1000–200 nm in dichloromethane solution. Elemental analyses (C H N) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of [ReBr(PAN)$_2$] · 2$CHCl_3$ (**1**)

[Re(MeCN)Br_3(PPh_3)$_2$] (0.5 g, 0.51 mmol) and HPAN (0.28 g, 1.1 mmol) in chloroform (60 cm^3) were refluxed for 4 h. The starting material gradually dissolved and the color of the reaction solution became dark brown. The volume was condensed to 10 cm^3, diethyl ether (50 cm^3) was added and dark green microcrystalline solid was filtered. The product was washed with EtOH and cold ether, and dried *in vacuo*. (Yield 60%). The crystals suitable for X-ray investigation were obtained by recrystallization from a mixture chloroform/ethanol.

IR (KBr): 1613(s), 1587(m), 1556(w) and 1512(s) ν_{CN} and $\nu_{C=C}$; 1278(s), 1237(vs) and 1208(s) $\nu_{N=N}$. *Anal.* Calc. for $C_{32}H_{22}N_6O_2BrCl_6Re$: 38.38; H, 2.21; N, 8.39. Found: C, 38.96; H, 2.28; N, 8.73%.

2.3. Preparation of [ReCl(PAN)$_2$] (**2**)

A procedure similar to those for **1** was used with [Re(MeCN)Cl_3(PPh_3)$_2$] (0.5 g, 0.58 mmol) and HPAN (0.30 g, 1.2 mmol). A dark green crystalline precipitate of [ReOCl(PAN)$_2$] was collected in 65% yield. The crystals suitable for X-ray structure determination were obtained by slow evaporation from an acetonitrile solution of [ReOCl(PAN)$_2$].

IR (KBr): 1613(s), 1587(m), 1557(w) and 1510(s) ν_{CN} and $\nu_{C=C}$; 1278(s), 1235(vs) and 1206(s) $\nu_{N=N}$. *Anal.* Calc. for $C_{30}H_{20}ClN_6O_2Re$: C, 50.17; H, 2.81; N, 11.70. Found: C, 50.88; H, 2.45; N, 11.20%.

2.4. Crystal structures determination and refinement

The X-ray intensities data of **1** and **2** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption correction using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [24] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 times the value of equivalent temperature factor of the parent atom. The positions of hydrogen atoms were idealised after each cycle of refinement. SHELXS97 [25], SHELXL97 [26] and SHELXTL [27] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

Table 1
Crystal data and structure refinement for **1** and **2** complex

R indices (all data)	R_1 = 0.0443 wR_2 = 0.0767	R_1 = 0.0752 wR_2 = 0.0933
Largest difference in peak and hole (e $Å^{-3}$)	0.848 and −1.029	1.478 and −2.636

2.5. Computational details

The gas phase geometry of [ReOBr(PAN)$_2$] was optimized without any symmetry restrictions in the singlet and triplet states with the DFT method using the hybrid B3LYP functional of GAUSSIAN-03 [28–30]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6-31+G* basis for bromine, oxygen and nitrogen, 6-31G* for carbon and 6-31G for hydrogen atoms [31,32]. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [33] was used for the valence electrons. Additional d function with exponent α = 0.3811 and f function with exponent α = 2.033 on the rhenium atom were added [34]. All vibrations in the calculated vibrational spectrum of [ReOBr(PAN)$_2$] were real thus the calculated geometry corresponds to true energy minimum.

The electronic spectrum of [ReOBr(PAN)$_2$] was calculated with the TDDFT method, and the solvent effect was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM) [35].

2.6. Magnetic measurements

Magnetization measurements of polycrystalline sample of **1** were carried out with a Quantum Design SQUID magnetometer (MPMSXL-5-type) at a magnetic field of 0.5 T over the temperature range 1.8–300 K. Magnetization measurements versus magnetic field (0–5 T) were made at 2 K.

Corrections are based on subtracting the sample – holder signal and contribution χ_D estimated from the Pascal constants [36] and equal – 486×10^{-6} cm^3 mol^{-1} for complex Re(III). The effective magnetic moment was calculated from the equation, $\mu_{eff} = 2{,}83\ (\chi_M^{corr} \times T)^{1/2}$ B.M.

3. Results and discussion

3.1. Preparation and infrared data

The [ReX(PAN)$_2$] (X = Cl, Br) complexes were prepared in good yield by ligand exchange reaction starting from [ReCl$_3$(MeCN)(PPh$_3$)] and 1-(2-pyridylazo)-2-naphthol (HPAN):

$$[ReX_3(MeCN)(PPh_3)_2] + 2HPAN \rightarrow [ReX(PAN)_2] + 2PPh_3 + 2HX$$

They were isolated as dark green microcrystalline solid, soluble in common organic solvents. Attempts to prepare monosubstituted species in the reaction of [ReCl$_3$(MeCN)(PPh$_3$)] with HPAN in 1:1 molar ratio resulted in isolation of [ReX(PAN)$_2$], but with lower yield. The elemental analyses of the [ReX(PAN)$_2$] complexes are in good agreement with their formulation.

Bands due to N=N vibrations of the azo ligand are observed in the range 1280–1200 cm^{-1} in the IR spectra of the [ReX(PAN)$_2$] (X = Cl, Br) complexes. The peaks corresponding to the ν(C=N) and ν(C=C) modes of the PAN ligand appear in the 1625–1500 cm^{-1} range [37].

The calculated (non-scaled) vibrational spectrum of the [ReOBr(PAN)$_2$] is in a reasonable agreement with the experimental one in terms of the band positions and intensities. The most intense band corresponding N=N vibrations of the azo ligand appears at 1237 cm^{-1} in the experimental spectrum, whereas in the calculated spectrum is shifted to higher energy, and exists at 1376 cm^{-1}. It is higher than the experimental one by 11%, what is usual for such approach. The similar shift values are also observed for the other bands.

Table 2
Hydrogen bonds for **1** and **2** complexes

D–H···A	H···A (Å)	D···A (Å)	D–H···A (°)	Symmetry code of A
Complex ***1***				
C(9)–H(9)···N(2)	2.35	2.937(8)	121.1

C(28)–H(28)···O(1)	2.52	3.390(11)	156.9	$-x-0.5, y+0.5, z$

3.2. Crystal structure

The crystallographic data for **1** and **2** complexes are given in Table 1. A summary of bond distances and angles involving hydrogen bonding contacts [38,39] founded in the **1** and **2** structures is given in Table 2. The numbering scheme of [ReOBr(PAN)$_2$] is shown in Fig. 1. The central Re atom of the [ReX(PAN)$_2$] complexes is seven-coordinate, bonding to two nitrogen and one oxygen donors from each of two PAN ligands and having a seventh bond to halide ion. The overall arrangement of the donor atoms around rhenium can be described as slightly distorted capped trigonal prism (Fig. 2), which is one of the three commonly observed geometries for seven-coordinate complexes (capped octahedron, capped trigonal prism and pentagonal bipyramid) [40]. The top and bottom triangle of trigonal prism is constructed of two nitrogen and one oxygen atoms (N4, N6, O1 and N1, N3, O2, respectively) while the halide ion occupies a capping site. The planar in the range of experimental error naphthalene and pyridine rings are inclined at 18.7(2)°, 24.8(2)° (compound **1**) and 20.0(4)°, 22.8(4)° (compound **2**), respectively, for pairs of rings containing C(1)/N(3), C(16)/N(6) atoms.

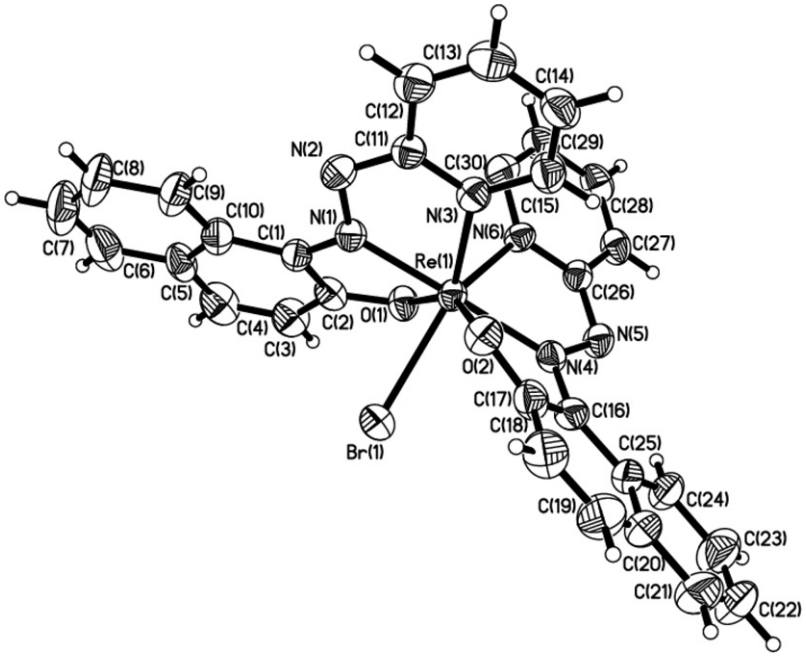

Fig. 1. The molecular structure of [ReBr(PAN)$_2$].

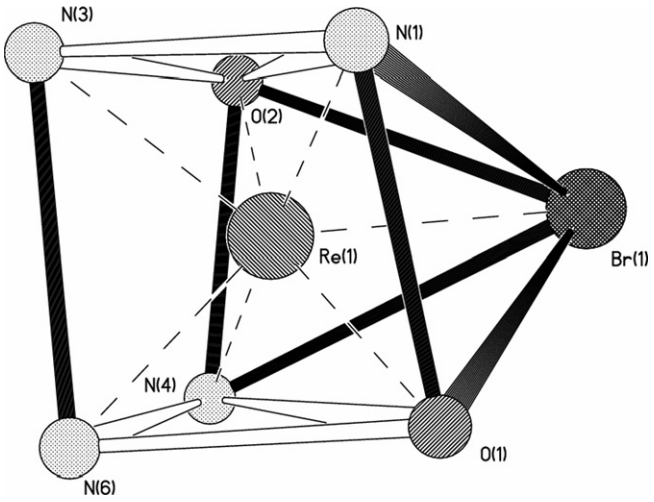

Fig. 2. View of the ReN_4O_2Br coordination polyhedron of $[ReBr(PAN)_2]$.

The selected bond lengths and angles of $[ReX(PAN)_2]$ are given in Tables 3 and 4. For both structures the Re–N_{azo} distances are somewhat shorter than the Re–N_{py} bonds, and the N–N lengths are significantly longer than that (1.25 Å) in uncoordinated azo compounds. The excellent π-acceptor character of azoheterocycles originates from low lying π*(azo) orbitals [41]. The interatomic distances between the rhenium atom and the oxygen atom of PAN ligand are almost equal to an ideal single Re–O bond length. The last one, predicted by the use of Pauling's covalent radius for oxygen and Cotton and Lippard's value for the octahedral covalent radius of rhenium(V), should be *ca.* 2.04 Å [42].

3.3. Magnetic properties

The magnetic properties of complex **1** under the form molar magnetic susceptibility $\chi_M = f(T)$ and $\mu_{eff} = f(T)$ are shown in Fig. 3.

The complex of **1** shows at 0.5 T in the whole temperature range lowering of the magnetic moment is observed, from 2.25 B.M. at 300 K up to 0.18 B.M. at 1.8 K.

This behavior is characteristic of slightly distorted heptanuclear capped trigonal prismatic mononuclear Re(III) complex with d^4 low-spin electron configuration [43,44]. It seems that in the room temperature, in accordance Boltzmann's distribution, are partially populated higher states, which are depopulated with temperature lowering and decreasing of the magnetic moment is observed.

The extended Hückel molecular orbital calculation of Hoffman and al. [45] for capped trigonal prismatic geometry of the coordination sphere of the Re(III) centers results e (xy, $x^2 - y^2$) orbital at low energy and higher energy $a_1(z^2)$ + e (xz,yz) orbitals.

The variation of the magnetization M versus the magnetic field H for complex at 2 K indicates value of the magnetization ~0.0 B.M. for 5 T, confirms totally pairing electrons of the rhenium center and diamagnetic ground state of the complex.

3.4. Geometry optimization and charge distribution

The geometry of $[ReBr(PAN)_2]$ was optimized in triplet and singlet states using the DFT method with the B3LYP functional. The energy of the triplet state is of 20.9 kcal/mol higher. The optimized geometric parameters of the singlet and triplet states are gathered

Table 4
The experimental bond lengths (Å) and angles (°) for **2**

ε – molar absorption coefficient (dm^3 mol^{-1} cm^{-1}).
f – oscillator strength.
H – highest occupied molecular orbital.
L – lowest unoccupied molecular orbital.

Table 5 presents the Mulliken atomic charges for [ReBr(PAN)$_2$]. The calculated charge on the rhenium atom is considerable lower than the formal charge +3, and the charges on the bromide and oxygen atoms are significantly smaller than expected −1, indicating charge donation from the ligands to the central ion.

3.5. Electronic spectra

The nature of the transitions observed in the UV–Vis spectra of the title complexes has been studied by the time-dependent density functional (TDDFT) method. The calculated electronic spectrum of [ReBr(PAN)$_2$] and experimental electronic spectra of **1** and **2** (in acetonitrile) are presented in Fig. 4. Each calculated

transition is represented by a gaussian function $y = ce^{-b(x-x_0)^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. As seen from the Fig. 4, TDDFT/PCM calculations well reproduce the absorption spectrum of [$ReBr(PAN)_2$].

Table 6 presents the most important electronic transitions calculated with the TDDFT method for [$ReBr(PAN)_2$] and their assignments to the observed absorption bands of the complex. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.0300 are listed in Table 6. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy of occupied and unoccupied molecular orbitals involved in the electronic transitions (Fig. 5).

The TDDFT calculations show that the longest wavelength experimental band of **1** at 515.2 nm originates in the transitions between HOMO, HOMO − 1, HOMO − 2, HOMO − 3 and LUMO, LUMO + 1, LUMO + 2. As can be seen from the Fig. 4, the highest occupied molecular orbital is composed of π-bonding orbitals of the PAN and bromide ligands, whereas the HOMO − 1, HOMO − 2 and HOMO − 3 are delocalized on the whole complex. The LUMO, LUMO + 1 and LUMO + 2 are centered on the π-antibonding orbitals of the PAN ligand and the rhenium center. Accordingly, a delocalized *MLLCT* (metal–ligand-to-ligand CT) description seems to be the most suitable (adequate) for character of the band at 515.2 nm. The similar character can be also assigned to the experimental bands at 323.5 and 233.0 nm.

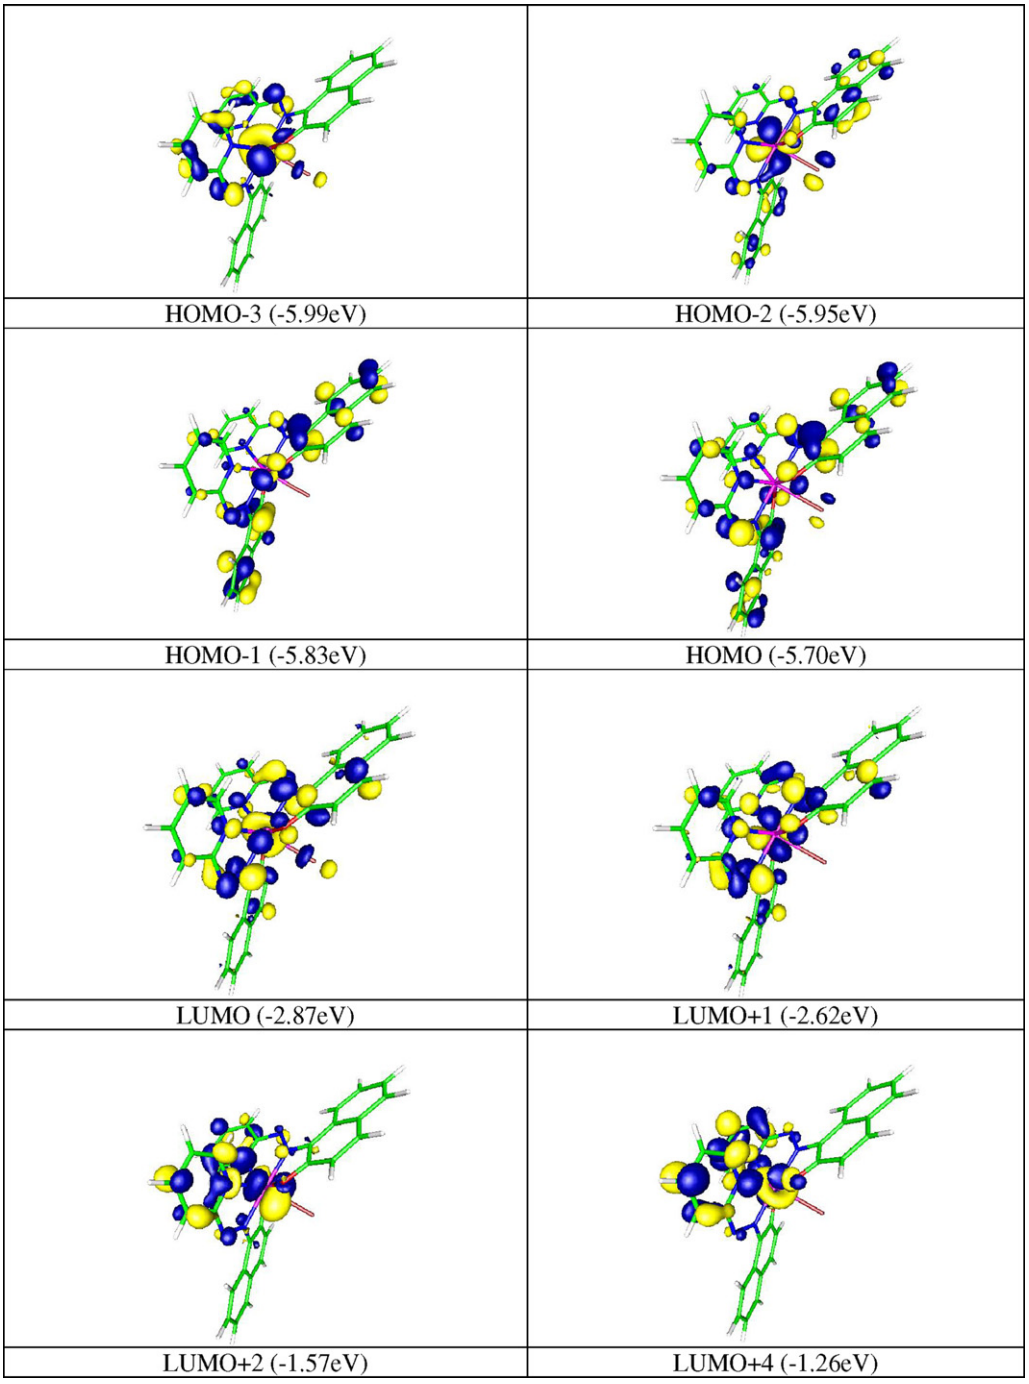

Fig. 5. Contour plots and energy of the selected occupied and unoccupied orbitals active in the electronic transitions. The orbitals were plotted with contour values −0.04 (yellow) and 0.04 au (blue). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

To some extent, the electronic absorption spectra of [Re-X(PAN)$_2$] are similar to those observed for *fac*-[ReCl$_3$(L–L)(PPh$_3$)] with bipy-like ligands. The solution spectra of both [ReBr(PAN)$_2$] and *fac*-[ReCl$_3$(L–L)(PPh$_3$)] [46,47] complexes exhibit intense absorption bands in the visible region, which are not observed for Re(III) complexes with chloride ions in a *meridional* fashion: [ReCl$_3$(bpzm)(PPh$_3$)] [10], [ReCl$_3$(pzH)$_2$(PPh$_3$)] and [ReCl$_3$(3,5-Me$_2$pzH)$_2$(PPh$_3$)] [9]. However, in contrast to the *fac*-[ReCl$_3$(L–L)(PPh$_3$)] displaying multiple transitions in the form of peaks and shoulders in the visible region, the solution spectra of the examined complexes show one broad absorption band. Furthermore, in comparison with *fac*-[ReCl$_3$(bipy)(PPh$_3$)], the longest wavelength experimental bands of the [ReX(PAN)$_2$] complexes are significantly more intense. The DFT calculations confirm larger contribution of π-bonding ligand orbitals in the highest occupied molecular orbitals for [ReBr(PAN)$_2$] than *fac*-[ReCl$_3$(bipy)(PPh$_3$)], whereas the lowest unoccupied molecular orbitals of both [Re-Br(PAN)$_2$] and *fac*-[ReCl$_3$(bipy)(PPh$_3$)] are centered on the π-antibonding ligand orbitals. Accordingly, the longest wavelength experimental bands of [ReCl$_3$(bipy)(PPh$_3$)] are mainly attributed to transitions of $d \rightarrow \pi^*_{bipy}$, whereas the experimental band of [Re-Br(PAN)$_2$] at 515.2 nm can be seen as a mixture of MLCT and LLCT transitions.

Supplementary data

CCDC 687571 and 687572 contain the supplementary crystallographic data for $C_{32}H_{22}N_6O_2BrCl_6Re$ and $C_{30}H_{20}N_6O_2ClRe$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

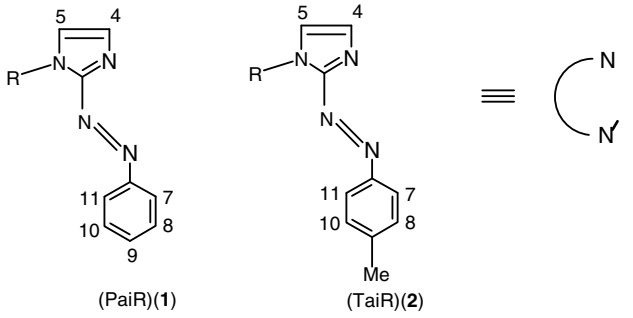
2. Results and discussion

2.1. Synthesis and formulation

Reaction of $[Ru(CO)_2Cl_2]_n$ as a methanol suspension with 1-alkyl-2-(phenylazo)imidazole (PaiR) (**1**) or 1-alkyl-2-(*p*-tolylazo)-imidazole (TaiR) (**2**) (where R = Me (**a**), CH_2CH_3 (**b**), CH_2Ph (**c**)) under refluxing conditions in a dinitrogen atmosphere resulted in a brown solution Eq. (1). Upon slow evaporation of the solvent a brown crystalline product was left. The formulation of the complexes, $[Ru(CO)_2Cl_2(PaiR)]$ (**3**) and $[Ru(CO)_2Cl_2(TaiR)]$ (**4**) have been supported by microanalytical data (Section 4). Although three geometrical isomers (**3** and **4**; **3′** and **4′**; **3″** and **4″**) are possible, we have isolated only one isomer, with the CO groups *cis* to each other (**3** and **4**) and two Cl ligands in a *trans* disposition (Scheme 1). The complexes are diamagnetic, indicating the presence of the metal in the +2 oxidation state (d^6). Three stereo-isomers of **3**/**4**, **3′**/**4′** and **3″**/**4″** are possible. The structure has been established by a single crystal X-ray diffraction study in the case of $[Ru(CO)_2Cl_2(PaiEt)]$ and has a *trans*-(Cl,Cl) geometry, abbreviated as *trans*-(Cl)-$[Ru(CO)_2Cl_2$(PaiR/TaiR)] (**3** or **4**). The higher stability of the *trans*-(Cl)-*cis*-(CO) isomer relative to the *cis*-(Cl)-*trans*-(CO) isomer is not surprising due to the *trans* weakening effect of CO. The selectivity of the *trans*-(Cl) configuration has also been supported by DFT calculations (*vide Section* 2.3). Complexes **3** and **4** undergo a selective mono-decarbonylation reaction upon refluxing with Me_3NO in acetonitrile Eq. (2). In this process one CO is released and MeCN is coordinated, *trans*-(Cl)-$[Ru(CO)Cl_2$(PaiR)(NCMe)] (**5**) and *trans*-(Cl)-$[Ru(CO)Cl_2$(TaiR)(NCMe)] (**6**) are formed. The structure of the mono-carbonylated product (**5**, **6**) is supported by a single stretch ν (CO) in the FT-IR spectra (Fig. 1), elemental analysis and ^{1}H NMR spectroscopic measurements. Although isomerisation to give *cis*-(Cl)-$[Ru(CO)Cl_2$(ligand)(NCMe)] is possible, we cannot establish the presence of this isomer, even in the mixed form. The photochemical treatment of the precursor was also unsuccessful for isomerisation and giving the full decarbonylated complexes. The crystals of these complexes are weakly diffracting for X-ray structure determination. The full removal of CO has not been achieved even under drastic reaction conditions in the presence of a large excess of Me_3NO [69,70]. This reaction yielded an intractable brown solid.



Scheme 1.

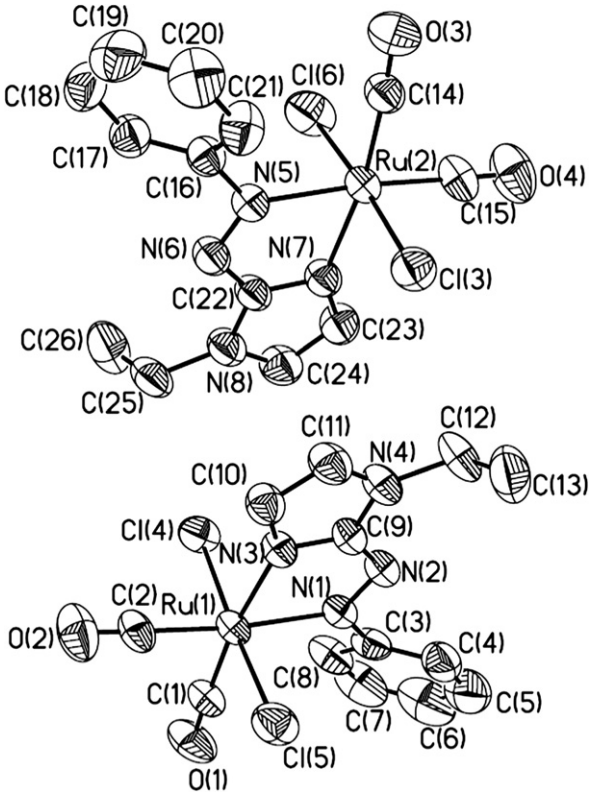


Fig. 1. Molecular structure of two conformers of *trans*-(Cl)-$[Ru(CO)_2Cl_2$(PaiEt)] (**3b**) (30% probability ellipsoids).

2.2. Molecular structure

The X-ray structure of $[Ru(CO)_2Cl_2(PaiEt)]$ (**3b**) is shown in Fig. 1; selected bond parameters are listed in Table 1. The ligands dispositions determine the structure as *trans*-(Cl)-$[Ru(CO)_2Cl_2$(PaiEt)]. The molecule consists of a central Ru surrounded by six donor centers, and the arrangement is distorted octahedral. The atomic arrangement involves two *trans*-chlorine, two *cis*-CO and a chelated 1-ethyl-2-(phenylazo)imidazole (PaiEt) ligand within the $RuCl_2C_2N_2$ coordination sphere. The two CO ligands are *trans* to the azo-N and imidazole-N coordinated centers. The asymmetric unit of the lattice consists of two molecules. A view of the diad, including the atomic numbering scheme, is given in Fig. 1. In terms of bond distances and angles, as well as gross geometry, the two molecules are closely alike to one another. The chelate ring dimensions (∠N(3)–Ru(1)–N(1): 75.13(9) and ∠N(5)–Ru(2)–N(7): 75.28(9)) are comparable with those in other structurally characterized chelates of the azoimine function [26–29,41–44,6,45,7,46–52,12,53–58]. The *trans* chlorine angles, Cl(4)–Ru(1)–Cl(5), 177.14(3) and Cl(3)–Ru(2)–Cl(6), 176.04(3), lie in the range of reported data [51,52,12,53–58]. Other angles about Ru define the distorted octahedral geometry.

The Ru–N(azo) distance (Ru(1)–N(1), 2.132(2); Ru(2)–N(5), 2.123(2) Å) is slightly longer than Ru–N(imidazole) (Ru(1)–N(3), 2.102(2); Ru(2)–N(7), 2.106(2) Å). In general, the Ru–N(azo) bond distance is shorter than the Ru–N(imidazole) bond, which is mainly due to $d\pi(Ru) \rightarrow \pi^*$(azo) back bonding [26–44,6,45,7,46–48]. The –N=N– bond length is 1.275–1.279 Å and is longer than the free ligand azo distance (1.258 Å) [66–68], which supports the $d\pi(Ru)$–π^*(azo) back bonding. Of the Ru–C bond lengths, (Ru(1)–C(1), 1.879(3); Ru(1)–C(2), 1.894(3); Ru(2)–C(14), 1.876(3); Ru(2)–C(15), 1.894(3) Å) the bonds *trans* to Ru–N(imidazole) (Ru(1)–C(1) and Ru(2)–C(14)) are shorter than the bonds

Table 1
Selected bond distances (Å) and bond angles (°) of (**3b**), X-ray and theoretical

Molecule-1		Molecule-2		Calculated structure

that are *trans* to Ru–N(azo) (Ru(1)–C(2) and Ru(2)–C(15)). This is usual due to a better *trans influence* of imidazole-N compared to azo-N donors. The C–O distances (C(1)–O(1), 1.133(4); C(2)–O(2), 1.116(4); C(14)–O(3), 1.130(4); C(15)–O(4), 1.113(4) Å) vary to within 0.01–0.02 Å. The difference between the two molecules in the lattice primarily lies in the detail of the conformation. The pendant phenyl ring is inclined to the mean plane of the chelate ring, and the angles are molecule-1, 36.73(17); molecule-2, 41.99(15). The torsion angles vary in a characteristic manner. Examples from those among the atoms of the chelate ring are: Ru(1)–N(3)–C(9)–N(2): 2.2(4); Ru(2)–N(7)–C(22)–N(6): −3.3(4); C(9)–N(2)–N(1)–Ru(1): −1.3(3); C(22)–N(6)–N(5)–Ru(2): 2.4(3); N(2)–N(1)–Ru(1)–N(3): 1.8(2); N(6)–N(5)–Ru(2)–N(7): −3.2(2). Thus, these two molecules represent a subtle form of conformational isomerism in a metal chelate, sustained by the crystal lattice.

Non-covalent interactions, C–H$\cdots\pi$ and $\pi\cdots\pi$, exist to provide rigidity to the supramolecule. An intermolecular hydrogen bond between one of the coordinated Cl ligands and the H atom of the *ortho* C–H of the pendant azophenyl group of an adjacent molecule constitutes a dimer structure (Fig. 2a). Each dimer interacts with adjacent dimers *via* C–H$\cdots\pi$ and $\pi\cdots\pi$ interactions to generate a supramolecular network (Fig. 2b). The interactions are summarized in Table 2.

2.3. DFT and TD-DFT calculations

DFT and TD-DFT calculations were performed for complexes **3b** and **5b**. All the calculations were performed using the GAUSSIAN03 (G03) [71] software package, running under Windows. The Becke's three-parameter hybrid exchange functional and the Lee–Yang–Parr non-local correlation functional [72] (B3LYP) was used throughout. Elements except ruthenium were assigned a 6-31 G* basis set in our calculations. For ruthenium the Los Alamos effective core potential plus double zeta (LanL2DZ) [73] basis set was employed. Gas and solution-phase geometry optimization was carried out. In all cases, vibrational frequencies were calculated to ensure that the optimized geometries represented local minima. To check the effect of solvation on the calculated optical absorption spectra, we performed TD-DFT calculations of the low lying excitation at the singlet optimized geometry, including the solvation effect by means of the non-equilibrium implementation of the polarizable continuum model [74]; as in the experimental conditions, the chosen solvent was acetonitrile. GaussSum [75] was used to calculate the fractional contributions of various groups to each molecular orbital. This is done using Mulliken population analysis.

The calculated structure of **3b** correlates very well with the results of its X-ray analysis (Fig. 1, Table 1). The theoretical Ru–N bond lengths are about 0.010 Å longer than those observed. Similarly the experimental Ru–Cl distances are shorter by 0.015 Å than the theoretical data. The Ru–C and C–O distances are also reduced by 0.006–0.010 Å in the experimental data compared to the calculated structure. The computation of ν(CO) from the DFT calculation shows a lowering of frequency by 8–10 cm^{-1}.

The DFT calculation shows a lower energy of the HOMO of *trans*-(Cl)-[$Ru(CO)_2Cl_2$(PaiEt)] (**3b**) (E_{HOMO}): −6.17 eV) than that of *cis*-(Cl)-[$Ru(CO)_2Cl_2$(PaiEt)] (**3b′**) (E_{HOMO}): −5.60 eV) and *cis*-(Cl)-*cis*-(CO)-[$Ru(CO)_2Cl_2$(PaiEt)] (**3b″**) (E_{HOMO}): −5.86 eV). This reflects better stability of the *trans*-(Cl,Cl) than *cis*-(Cl,Cl) configuration. An interesting feature of the valence orbitals is that the highest occupied MOs (HOMO, abbreviated as H, H − 1, H − 2, H − 3) contain >65% and >45% of the Cl atomic functions in **3b** and **5b**, respectively. Metal orbitals contribute >20% to H and H − 1. The LUMO (abbreviated L) is mostly characterized by the azoimidazole ligand function (>80%) for both these complexes, while other unoccupied molecular orbitals have CO >20% and Ru contribution varies from 5% to 35%. The results in acetonitrile phase show a significant difference from the gas phase, in particular to the occupied MOs. In the HOMO the contribution of PaiEt (L) is 42% in MeCN and 1% in the gas phase, while the Cl contribution is 28% in MeCN and the gas phase contribution is 67% for **3b**. The situation is different for **5b**: 14% (gas) and 24% (MeCN). H − 1 in the gas and acetonitrile phases remains more or less the same. The HOMO is stabilized by 0.63 eV in **3b** and 0.72 eV in **5b** from the gas to acetonitrile phase. The HOMO is also lowered in energy by 0.54 eV in **3b** compared to **5b** and the HOMO–LUMO energy gaps are 3.04 eV for **3b** and 2.83 eV for **5b** in MeCN (Fig. 3).

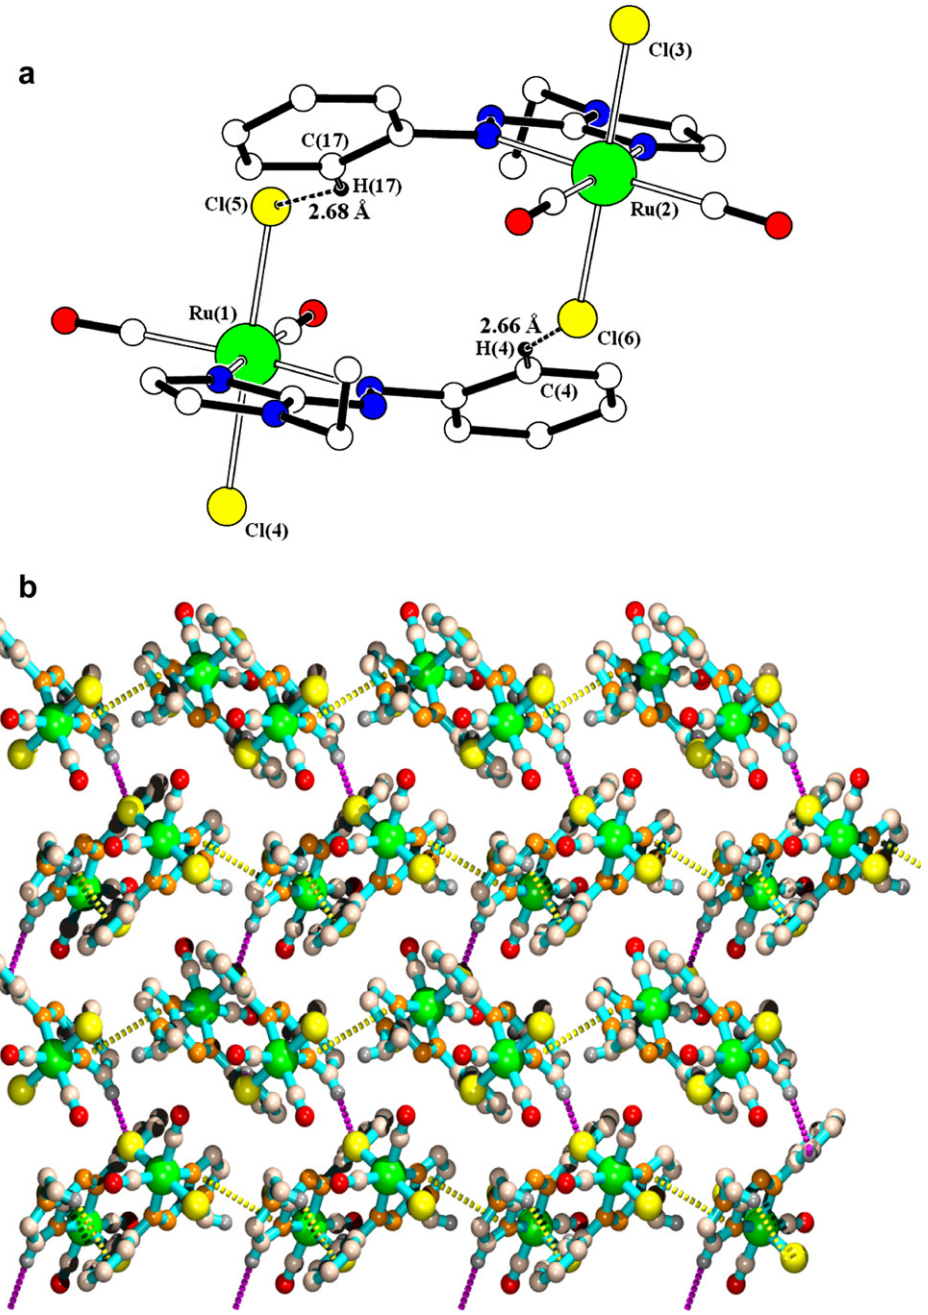

Fig. 2. (a) C–H···Cl hydrogen bonded dimer unit, (b) π···π and CH···π interacted *ab*-plane (π···π; C–H···π in yellow; C–H···Cl in magenta). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

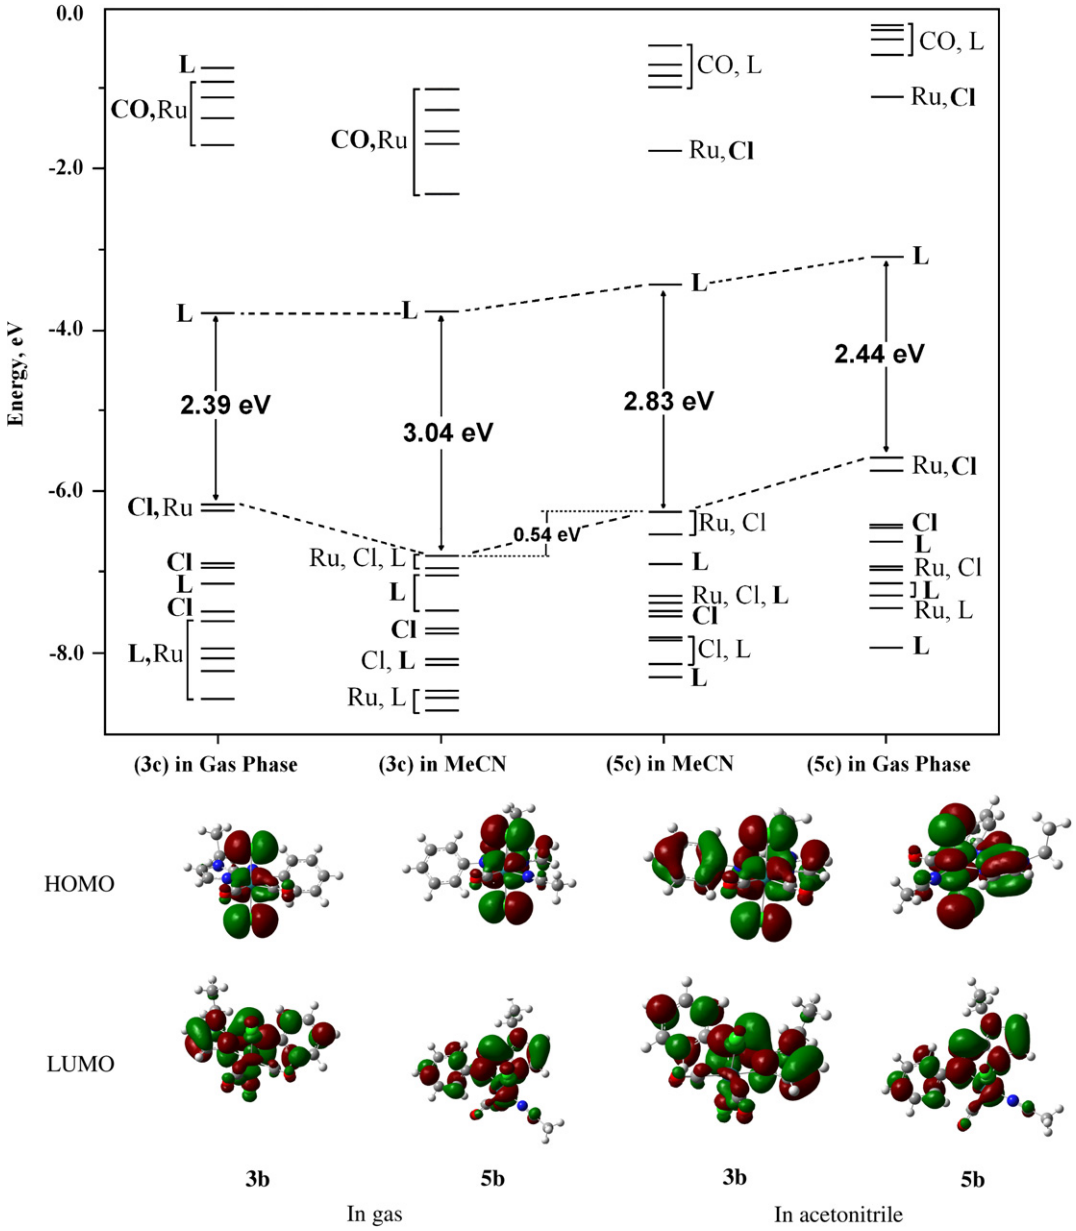

Fig. 3. Energy level correlation diagram of **3b** and **5b** in the gas and acetonitrile phase (top) and HOMO, LUMO picture (bottom).

2.4. Spectra and bonding

The infrared spectra of **3** and **4** show the presence ν (CO) stretching vibrations at 1990–2010 and 2065–2075 cm^{-1} (Table 3) which indicates the *cis* coordination of two CO ligands [67–70,76–78] (Fig. 1.) ν(Ru–Cl) appears at 330–340 cm^{-1}. Other significant peaks appear at 1570–1590 cm^{-1} and 1350–1370 cm^{-1}, corresponding to ν(C=N) and ν(N=N), respectively. The azo stretching is significantly shifted to the lower frequency region compared to the free ligand value (1400–1410 cm^{-1}) [79,80], which supports an efficient back donation, $d\pi(Ru(II)) \rightarrow \pi^*(azo)$. The infrared spectra of **5** and **6** show one ν(CO) at 1980–1985 cm^{-1}, which is in support of mono-carbonyl formulation, and the shifting to the lower frequency region compared to ν(CO) of **3/4** is an indication of better $d\pi(Ru(II)) \rightarrow \pi^*(CO)$ donation in **5/6**. The Mulliken population analysis of **3b** and **5b** show that the positive charge on CO in **5b** (0.18619) is less than that of the CO groups in **3b** (0.21986 and 0.23749). Computation of the major frequencies, ν(C=N), ν(N=N), ν(CO) and ν(Ru–Cl), by the DFT calculation shows a slightly lower frequency (5–10 cm^{-1}) than that of the experimental data, but still being within the reported frequency range.

The electronic spectra of **3** and **4** show an intense broad band at 470–500 nm, and in addition to this the molecules show a more intense and sharp band at 380–400 nm. The lower energy band in the mono-carbonyl complexes (**5** and **6**) has been shifted to a longer wavelength by 15–20 nm compared to the di-carbonyl precursors, **3** and **4** (Fig. 4). Thus, the energy of transition is lowered in **5/6** compared to **3/4**. This is well explained on the basis of the DFT calculation using the optimized geometry of a representative complex. The DFT calculations of **3b** and **5b** show that the HOMO–LUMO energy gap decreased by 0.21 eV in **5b** compared to **3b** in acetonitrile (Fig. 3). The TD-DFT calculations of **3b** and **5b** show that the transition at 470–530 nm (Table 5) could be assigned to $H/H-1 \rightarrow L$. H and H − 1 are localized on parts of the metal and Cl, and L have major ligand character. Thus, the transition is admix-

Table 3

[c] Solvent MeCN, Pt-disk working electrode, Ag/AgCl reference electrode, Pt-wire auxiliary electrode, [nBu$_4$N][ClO$_4$] supporting electrolyte. $E_{Ru(III)/Ru(II)} = 0.5(E_{pa} + E_{pc})$, V for Ru(III)/Ru(II) couple in unit of V, $\Delta E_p = E_{pa} - E_{pc}$, mV where E_{pc} (cathodic-peak-potential), E_{pa} (anodic-peak-potential).

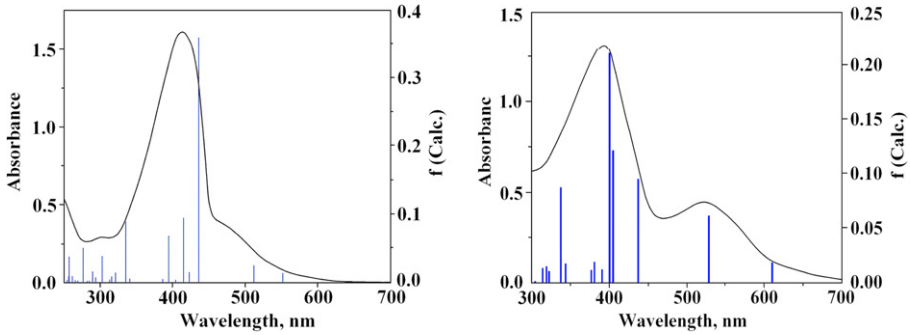

Fig. 4. Experimental UV–Vis spectra and calculated transitions for **3b** (left) and **5b** (right) in acetonitrile.

ture of MLCT and XLCT transitions (X = Cl) [81]. Because of the Cl contribution to H − n (n = 2, 3, 4, 5) (40–80%), the H − n → L transitions may be attributed to XLCT and contribute to the broadening of the band. The transitions H/H − n (n = 1–5) → L + p (p = 1, 2, 3, etc.) may be explained as π(PaiEt) → π^*(CO), an inter-ligand charge transfer transition. This transition is also mixed with π (PaiEt) → π^*(PaiEt) transitions.

The imidazole protons (4- and 5-H) of the coordinated PaiR or TaiR in the complexes *trans*-(Cl)-[Ru(CO)$_2$Cl$_2$(PaiR/TaiR)] (**3**, **4**) show downfield shifting by 0.3–0.4 ppm compared to the free ligand data [75–81] and appear at 7.70–7.85 ppm (4-H) and 7.35–7.50 (5-H) ppm (Table 4). This supports the strong preference of the binding of imidazole-N to Ru(II). 1-Me of the coordinated PaiMe/TaiMe in **3a** or **4a** is singlet at 4.25–4.30 ppm; 1-CH$_2$–CH$_3$ of coordinated PaiEt or TaiEt in **3b** or **4b** appears as a quartet at 4.60–4.65 ppm, (J = 8.0 Hz) and a triplet 1.70–1.72 ppm (J = 7.5 Hz) for –CH$_2$– and –CH$_3$, respectively; 1-CH$_2$–(Ph) in (**3c** and **4c**) is singlet at 5.80–5.90 ppm. The mono-carbonyl complexes, **5** and **6**, in general, show aromatic proton signals at a lower chemical shift position (δ) compare to **3** and **4** (with a difference in chemical shift ($\Delta\delta$) of 0.1–0.3 ppm). This may be due to removal of the strongly π-acidic CO from the Ru(CO)$_2$-motif (**3**, **4**) to prepare the Ru(CO)-motif in **5** and **6**. The coordinated MeCN in **5** and **6** appears as a singlet at 2.07-2.15 ppm for δ (CH$_3$).

2.5. Electrochemistry

The complexes show a Ru(III)/Ru(II) couple (Table 3, Fig. 5) when scanned in the potential range 0.0–2.0 V. The response is quasireversible in nature, as is evident from their peak-to-peak separation (ΔE_p > 100 mV). The nature of the voltammogram does not change with the scan rate (50–250 mV s^{-1}). The Ru(III)/Ru(II) potential, *ca.* 1.35 V, of *trans*-(Cl)-[Ru(CO)$_2$Cl$_2$(PaiR/TaiR)] (**3**, **4**) is significantly shifted to *ca.* 0.85 V for *trans*-(Cl)-[Ru(CO)Cl$_2$(PaiR/TaiR)(NCMe)] (**5**, **6**). This may be due to the better electron withdrawing effect of two CO in **3**, **4** than that of one CO in **5**, **6**. The DFT calculation in acetonitrile also supports the lower energy of the HOMO in **3b** (−6.80 eV) compared to that of **5b** (−6.26 eV). The HOMO is also contributed to by the metal (Ru) orbitals, thus the redox response is assigned to the Ru(III)/Ru(II) couple.

On scanning in the negative direction (0 to −2.0 V), two redox responses are observed. The first response is observed at >−0.70 V, and is quasireversible ($\Delta E_p \geqslant 120$ mV) in nature, while the second one appears at <−1.2 V ($\Delta E_p \geqslant 200$ mV). The chelated ligand belongs to the π-acidic azoimine family and can accommodate two electrons centered at the azo group (–N=N–). The reductive responses are assigned to accommodation of electrons in the azo dominated function [–N=N–]/[–N⋯N–]$^-$ and [–N⋯N]$^-$/[–N–N–]$^{2-}$. Ligand reduction of azoimidazole complexes appear at negative potentials and the present data appear at a less negative value (−0.5 to −0.6 V) than that of *trans*-[Ru(ligand)$_2$Cl$_2$] (−0.7 to −0.8 V). The DFT data have assigned that the LUMO of the complexes are constituted mainly of the azo group of the ligand (>80%) and thus the reduction is considered as electron accommodation at the azo dominated orbitals.

3. Conclusion

A series of di-carbonyl complexes of the formulae *trans*-(Cl)-[Ru(CO)$_2$Cl$_2$(PaiR or TaiR)] (for PaiR: R = Me (**3a**), Et (**3b**), CH$_2$Ph

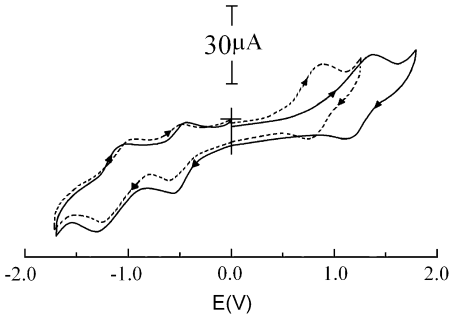

Fig. 5. Cyclic voltammogram of (**3b**) (—) and (**5b**) (– – –) in MeCN using Pt-disk working and Pt-wire auxiliary electrodes and referenced to the Ag/AgCl electrode.

(**3c**); for TaiR: R = Me (**4a**), Et (**4b**), CH_2Ph (**4c**)) has been synthesized by reacting $[Ru(CO)_2Cl_2]_n$ with PaiR or TaiR. The complexes are selectively decarbonylated to isolate *trans*-(Cl)-[$Ru(CO)Cl_2$(PaiR or TaiR)(NCMe)] (**5/6**). However, complete decarbonylation, either by thermal or photochemical methods, has not been possible. The complexes are characterized by spectroscopic data and in one case by an X-ray structure. The computational (DFT) study has discussed the separation of a single isomer on the basis of energy calculation. The electronic structures support metal centered oxidations, and reductions of the chelated ligand.

4. Experimental

4.1. Materials

1-Alkyl-2-(phenylazo)imidazole (**1**) and 1-alkyl-2-(*p*-tolylazo)imidazole (**2**) were synthesized following a previously published procedure [75–81]. $[Ru(CO)_2Cl_2]_n$ was also prepared by the reported method [63,64,76–78]. Imidazole and all other organic chemicals and inorganic salts were available from Sisco Research Lab., Mumbai, India. The purification of acetonitrile and preparation of *n*-tetrabutylammonium perchlorate [nBu$_4$N][ClO_4] for electrochemical work were done as reported before [75–81]. Dinitrogen was purified by bubbling through an alkaline pyrogallol solution. All other chemicals and solvents were of reagent grade and were used without further purification.

4.2. Physical measurements

Microanalytical data (C, H, N) were collected on Perkin–Elmer 2400 CHNS/O elemental analyzer. Spectroscopic data were obtained using the following instruments: UV–Vis spectra, Perkin–Elmer, model Lambda 25; IR spectra (KBr disk, 4000–200 cm^{-1}), Perkin–Elmer, model RX-1; ^{1}H NMR spectra, Bruker (AC) 300 MHz FTNMR spectrometer. Electrochemical measurements were performed using a computer-controlled PAR model 250 VersaStat electrochemical instrument with a Pt-disk electrode. All

Table 6
Summarised crystallographic data for *trans*-(Cl)-[$Ru(CO)_2Cl_2$(PaiEt)](3b)

Empirical formula	$C_{13}H_{12}Cl_2N_4O_2Ru$
Formula weight	428.24
Crystal system	monoclinic
Space group	$P21/c$
a (Å)	10.6772(14)
b (Å)	14.1537(18)
c (Å)	23.074(3)
β (°)	107.173(5)
Size (mm^3)	$0.42 \times 0.19 \times 0.13$
V(Å^3)	3331.5(7)
λ (Å)	0.71073
ρ_{calcd} ($Mg\,m^{-3}$)	1.708
Z	8
T (K)	298(2)
μ(Mo Kα) (mm^{-1})	1.272
Total reflection collected	19700
Unique reflections	6522
Refined parameters	399
Largest difference in peak and hole (e Å^{-3})	0.604 and −0.242
R[a] ($I > 2\sigma(I)$)	0.0330
wR[b]	0.0809
Goodness-of-fit[c]	1.034

[a] $R = \sum||F_o| - |F_c||/\sum|F_o|$.
[b] $wR = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{1/2}$, $w = 1/[s^2(F_o^2) + (0.0417P)^2 + 1.1071P]$, where $P = (F_o^2 + 2F_c^2)/3$.
[c] GOF (Goodness of fit) = $[w(F_o - F_c)/(n_o - n_v)]^{1/2}$, where n_o and n_v denote the number of data and variable.

measurements were carried out under a dinitrogen environment at 298 K with reference to Ag/AgCl in acetonitrile using [nBu_4N][ClO_4] as a supporting electrolyte. The reported potentials are uncorrected for junction potentials.

4.3. Synthesis of trans-(Cl)-[$Ru(CO)_2Cl_2$(PaiEt)] (**3b**)

[$Ru(CO)_2Cl_2$]$_n$ (0.31 g, 1.4 mmol) was dissolved in hot methanol (30 ml). A methanolic solution of PaiEt (0.28 g, 1.4 mmol) was added and the solution was refluxed for 2 h under a dinitrogen atmosphere. The color of the solution changed from orange-red to brown. Under slow evaporation of the solvent, a brown crystalline product was left. The product was further purified from CH2Cl2–MeOH solution. The yield was 0.34 g (58%).

The other complexes were prepared following an identical procedure. The yield varied from 50% to 60%. Microanalytical data: Calc. for $C_{12}H_{10}N_4O_2Cl_2Ru$ (**3a**): C, 34.78; H, 2.41; N, 13.53. Found: C, 34.62; H, 2.38; N, 13.47%. Calc. for $C_{13}H_{12}N_4O_2Cl_2Ru$ (**3b**): C, 36.45; H, 2.80; N, 13.08. Found: C, 36.50; H, 2.81; N, 13.00%. Calc. for $C_{18}H_{14}N_4O_2Cl_2Ru$ (**3c**): C, 44.08; H, 2.86; N, 11.43. Found: C, 43.92; H, 2.81; N, 11.38%. Calc. for $C_{13}H_{12}N_4O_2Cl_2Ru$ (**4a**): C, 36.45; H, 2.80; N, 13.08. Found: C, 36.34; H, 2.78; N, 13.04%. Calc. for $C_{14}H_{14}N_4O_2Cl_2Ru$ (**4b**): C, 38.01; H, 3.17; N, 12.67. Found: C, 37.92; H, 3.23; N, 12.60%. Calc. for $C_{19}H_{16}N_4O_2Cl_2Ru$ (**4c**): C, 45.24; H, 3.17; N, 11.11. Found: C, 45.02; H, 3.21; N, 11.17%.

4.4. Synthesis of trans-(Cl)-[$Ru(CO)Cl_2$(PaiEt)(NCMe)] (5b)

trans-(Cl)-[$Ru(CO)_2Cl_2$(PaiEt)] (**3b**) (0.1 g, 0.24 mmol) was dissolved in dry MeCN and sublimed Me_3NO (0.025 g, 0.33 mmol) was added as a pinch under a dry N_2 environment. The solution was then refluxed for 2 h. The intensity of the bright brown solution was reduced to light brown. The solution was evaporated slowly in air while crystals were deposited on the wall of the beaker. They were collected and dried over a CaCl2 desiccator. These crystals were unstable to X-ray irradiation and we could not perform X-ray diffraction analysis. The yield was 0.087 g (84%).

The other complexes were prepared following an identical procedure. The yield varied from 80% to 90%. Calc. for $C_{13}H_{13}N_5OCl_2Ru$ (**5a**): C, 36.38; H, 2.97; N, 16.30. Found: C, 36.53; H, 3.04; N, 16.39%. Calc. for $C_{14}H_{15}N_5OCl_2Ru$ (**5b**): C, 38.09; H, 3.40; N, 15.87. Found: C, 38.00; H, 3.32; N, 15.83%. Calc. for $C_{19}H_{17}N_5O_2Cl_2$-Ru (**5c**): C, 45.33; H, 3.38; N, 13.92. Found: C, 45.22; H, 3.30; N, 13.98%. Calc. for $C_{14}H_{15}N_5OCl_2Ru$ (**6a**): C, 38.09; H, 3.40; N, 15.87. Found: C, 38.18; H, 3.46; N, 15.82%. Calc. for $C_{15}H_{17}N_5OCl_2Ru$ (**6b**): C, 39.56; H, 3.74; N, 15.38. Found: C, 39.44; H, 3.67; N, 15.30%. Calc. for $C_{20}H_{19}N_5OCl_2Ru$ (**6c**): C, 46.42; H, 3.67; N, 13.54. Found: C, 46.33; H, 3.64; N, 13.48%.

4.5. X-ray crystal structure determination

Crystals of *trans*-(Cl)-[$Ru(CO)_2Cl_2$(PaiEt)] (**3b**) were grown by slow diffusion of a CH_2Cl_2 solution of the complex into hexane. The prismatic red crystal used was of dimensions $0.13 \times 0.19 \times 0.42$ mm. Diffraction data were collected with a Bruker SMART 1 K CCD area-detector diffractometer using fine focused sealed tube graphite-monochromatized Mo Ka radiation (λ = 0.7107 Å). A summary of the crystallographic data and structure refinement parameters are given in Table 6. Data were corrected for Lorentz and polarization effects. Data reduction was carried out using the 'Bruker SAINT' program. The structure was solved by direct methods using SHELXS-97 [82] and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. Full matrix least squares refinements on F_0^2 were carried out using SHELXL-97 [83] with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were constrained to ride on the respective carbon or nitrogen atoms with isotropic displacement parameters equal to 1.2 times the equivalent isotropic displacement of their parent atom in all cases. All calculations were carried out using SHELXS 97 [82] and PLATON 99 [84] programs.

5. Supplementary data

CCDC 645194 contains the supplementary crystallographic data for [$Ru(CO)_2Cl_2$(PaiEt)] (**3b**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

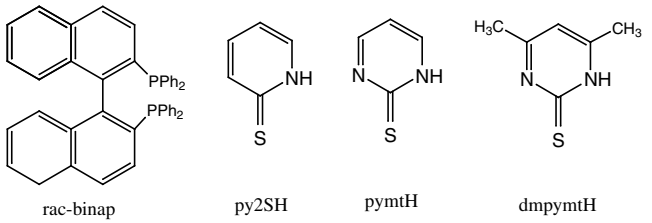
were used as received while pyridine-2-thione, pyrimidine-2-thione and 3,5-dimethyl-pyrimidine-2-thione (Merck or Aldrich) were re-crystallized from hot ethanol prior to their use. All the solvents were purified by respective suitable methods and allowed to stand over molecular sieves. Infra-red spectra in the region of 4000–250 cm^{-1} were obtained in KBr discs with Perkin–Elmer FT-IR Spectrum 1 spectrophotometer. Electronic absorption spectra were measured with a Perkin–Elmer-Hitachi 200 spectrophotometer while a Hitachi F-700 fluorescence spectrophotometer was used to obtain the emission spectra. Melting points were measured in open tubes with a STUART scientific instrument and are uncorrected Scheme 1.



rac-binap py2SH pymtH dmpymtH

Scheme 1. The diphosphane and the heterocyclic thiones used as ligands with their abbreviations.

2.2. Crystal structure determination

Single crystals suitable for crystal structure analysis were obtained by slow evaporation of dichloromethane solutions of the complexes at room temperature. X-ray diffraction data were collected on an Enraf-Nonius Kappa CCD area-detector diffractometer. The programs DENZO [9] and COLLECT [10] were used in data collection and cell refinement. Details of crystal and structure refinement are shown in Table 1. The structures were solved using program SIR97 [11] and refined with program SHELX-97 [12]. Molecular plots were obtained with program ORTEP-3 [13].

2.3. Synthesis of complexes 1–6

Rac-binap (311 mg, 0.5 mmol) was added to a suspension of CuX (0.5 mmol) in 30 cm^3 of dry acetonitrile and the mixture was stirred for 2 h at 50 °C, during which time a white precipitate was formed. A solution of the heterocyclic thione (0.5 mmol) in 20 ml of ethanol was the added slowly, and the reaction mixture was stirred for additional 2 h at 50 °C, whereupon the white precipitate gradually disappeared and the color of the solution turned yellow. The resulting solution was filtered off and left to slowly evaporate at ambient temperature. The microcrystalline solid, which was deposited upon standing for several days, was filtered off and dried *in vacuo*. In some cases major amounts of the product precipitated from the mother-liquid before evaporation. Some of the powder solids were recrystallized from dichloromethane.

UV–Vis (CH_2Cl_2, λ_{max}, $\log\varepsilon$): 230 (5.02), 288 (4.65), 380 (3.86).

3. Results and discussion

3.1. Preparative aspects

Previously when we prepared thione/phosphane mixed-ligand mononuclear copper(I) complexes bearing chelating diphosphanes, we used either flexible oligomethylene backboned symmetric diphosphanes of appropriate chain length, or rigid diphosphanes with bite angles suitable to span tetrahedral positions. In this respect, on the basis of its conformational flexibility, binap was anticipated to adopt the same chelating mode upon coordination to Cu^{I}. Considering the vast majority of the binap complexes used in catalytic processes, the ability of this atropisomeric diphosphane to preferably act as a chelating ligand towards many metals, generating mononuclear complexes is already well established. Thus, in order to obtain tetrahedral mixed-ligand complexes of binap, we used once more our approved straightforward synthetic procedure, involving mixing of copper(I) halides with 1 equivalent of rac-binap at 50 °C, followed by addition of 1 equiv. of the thione ligand, and stirring the resulting mixture for 2 h.

All the compounds prepared by this means were air-stable diamagnetic powdery solids, featuring the stoichiometry employed, and were moderately soluble in chloroform and dichloromethane and only sparingly soluble in acetonitrile, ethanol and acetone. Solutions of the new compounds in common organic solvents were non-conducting, and as expected for compounds derived from a racemic precursor, none of them exhibited any optical activity.

In order to obtain single crystals suitable for X-ray analysis, we engaged intensively with re-crystallisation of the complexes from various solvents, whereby we were at first only moderately successful, being able to crystallise a very small amount of compound **2** from dichloromethane, the molecular structure of which was found to correspond to the racemic compound [CuBr(rac-binap)(py2SH)]. However, during our further attempts, crystals separated from one of the samples of compound **2** were of a clearly different morphology and habit (small yellow blocks) than the well-formed orange prisms of [CuBr(rac-binap)(py2SH)], thus we decided also to perform X-ray crystal structure determination on them. In doing so, we surprisingly noticed that these crystals were composed of a mixture of the two possible enantiomers which, however, were not related to each other by a center of symmetry (compound **2a**).

Generally, for a racemic material in solution, there are two possibilities for crystallization. Both enantiomers may crystallise in a nonchiral space group with, e.g., *S*- and *R*- forms related by a center of symmetry in the single crystal, or, spontaneous resolution may provide equal amounts of *S*- and *R*- enantiopure crystals with identical chiral space groups [14]. Unsurprisingly, molecules of **2** crystallized as a racemic mixture in a nonchiral space group but molecules of **2a** crystallized as a racemic mixture in a chiral space group. The latter was possible because the asymmetric unit of the crystal contained both *S*- and *R*- enantiomers ($Z' = 2$) arranged as independent molecules, i.e., not related by a center of symmetry. Apart from the two different molecular arrangements for racemic mixtures in single crystals of **2** and **2a** other possible arrangements for racemic mixtures in a single crystal include enantiomers that may be related by a non-crystallographic center of symmetry

(Z' = 2) [15] and enantiomers that share identical sites throughout the crystal (solid solution) [16].

Unfortunately thermal analysis of crystals was not informative as the crystals decomposed at temperatures below their melting points.

3.2. Spectroscopy

The infrared spectra of compounds **1**–**9**, recorded in the range 4000–250 cm^{-1} display strong vibrational phosphane bands, which remain practically unshifted upon coordination. In addition, the spectra contain the expected four characteristic "thioamide bands" in the ~1570, ~1360, ~980 and ~740 cm^{-1} regions [17], with shifts due to coordination indicative of an exclusive S-coordination mode.

The electronic absorption spectra of the mixed-ligand complexes recorded in dichloromethane at room temperature are dominated by two intense main bands with maxima in the 230–246 nm and 281–291 nm regions, as well as a third weak broad band in the 379–393 nm region. With reference to the absorption spectrum of the uncoordinated binap, which exhibits three bands at λ_{max} = 216 nm, 244 nm and 290 nm, the first two intense bands are attributable to intraligand $\pi^* \leftarrow \pi$ transitions on the phenyl groups of the phosphane ligand, from which the lower energy second one can be considered as to possess some phosphane-originating MLCT transition character involving π^* orbitals of the phosphane ligand [18–19]. Finally, the weak band in the 379–393 nm region can be ascribed to transitions within the thione orbitals.

As many other copper(I) complexes with certain aryl-phosphanes, compounds **1**–**9** are strongly emissive in the solid state, with λ_{max} values of the broad bands in the 526–555 nm range, when excited at λ = 342–375 nm at room temperature. The excitation and emission data of the complexes under investigation are summarized in Table 2 and a representative excitation and emission spectrum of compound **2** is shown in Fig. 1.

Various copper(I) phosphane complexes are luminescent in the solid state at room temperature, and in many cases the luminescence is found to be a phosphorescence, however the nature of the emissive excited states of these compounds has not been yet definitively clarified [20]. In the complexes presented here, a plausible evidence for the presence of phosphorescence is being provided by the fact that the emission spectra do not overlap with the parent excitation spectra (large Stokes shifts). Moreover, recent TD-DFT calculations [21] showed the luminescence in Cu^I arylphosphane complexes to partially originate from MLCT triplets of type Cu(I) → $\pi^*(PPh_2)$, and this applies apparently also to the compounds under investigation. This assignment is reinforced by the fact that the maxima of the emission bands all undergo significant red shifts relative to the solid state r.t. emission spectrum of the free binap, the phosphorescence band of which appears at 490 nm. A further approach to this controversially discussed complex problem has been made by the group of A. Vogler in a series of systematic investigations on the photophysical properties of Au^+, Ag^+, Re^+ and Cu^+ complexes of binap and related phosphanes [22]. In conclusion, the origin of the luminescence can be tentatively assigned as having mixed character between metal–ligand charge transfer (MLCT) of the type Cu(I) → $\pi^*(PPh_2)$ and ligand–ligand charge transfer (LLCT) of the type thione → $\pi^*(PPh_2)$ or/and halide → $\pi^*(PPh_2)$, with an unambiguous prevalence of the MLCT emission.

3.3. X-ray structural investigations

The X-ray crystal structures of [CuBr(rac-binap)(py2SH)] · $2CH_2Cl_2$ (**2a**), [CuBr(rac-binap)(py2SH)] · CH_2Cl_2 (**2**) and [CuBr(S-binap)(dmpmtH)] · CH_2Cl_2 (**8**) (details of crystal and structure refinement are shown in Table 1) corroborate the spectroscopic results discussed above. Tables 3–5 list selected distances and angles of these complexes.

Yellow single crystals of **2a** were grown from a dichloromethane solution upon slow evaporation during several days. The compound crystallizes in the monoclinic space group $P2_1$ with four discrete formula units in the unit cell. Single-crystal analysis of

compound **2a** indicates the presence of two solvent (dichloromethane) molecules per formula unit, trapped in the crystal lattice; the latter solvate molecules do not interact specifically with the complex molecules and will not be further discussed Fig. 2

As shown in the ORTEP drawing (Fig. 3) there are two individual molecules in the asymmetric unit, molecule A and molecule B, containing S-binap and R-binap, respectively, thus having different absolute configurations. These two molecules are not related to each other by a center of symmetry and this is a rare example of a racemic mixture in a chiral space group. In each molecule, the copper(I) center is surrounded by the P atoms of the chelating binap, the S atom of the thione and the halide atom, in a highly distorted tetrahedral coordination. This distortion is best displayed by the P–Cu–P angles of 98.86° and 99.80° for molecules A and B, respectively, which are markedly deviating from the ideal tetrahedral geometry.

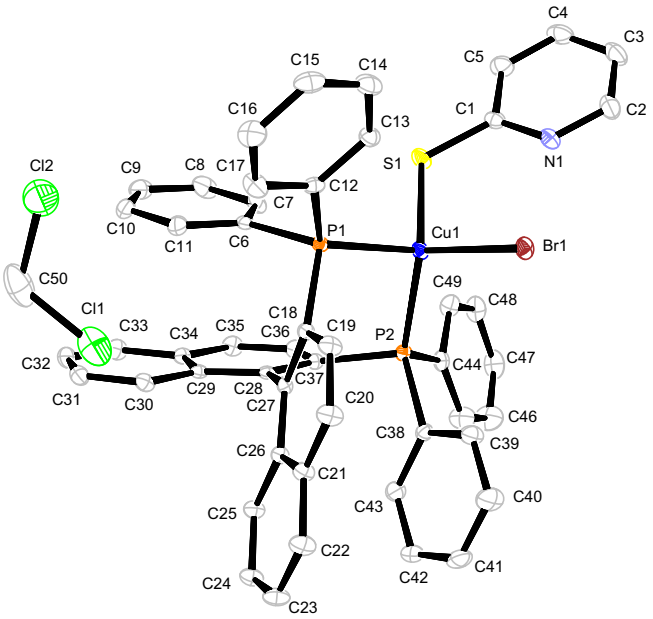

Fig. 3. A view of [CuBr(S-binap)(py2SH)] with displacement ellipsoids shown in the 50% probability level.

With reference to a large number of known tetrahedral mixed-ligand copper(I) complexes with a $CuXSP_2$ core, this P–Cu–P angle, including the two bulkiest ligands, is expected to be the largest one within the tetrahedron, but this is not the case here. However, considering the structural characteristics of the free diphosphane, the steric constrains resulting from this narrow angle seem unavoidable. In fact, the dihedral angle of 88.3° between the two naphthyl groups in free binap, which should provide the ideal situation for the PPh_2 groups to reduce the repulsions between them to a minimum, is narrowed to a value of 73.8(2)° in [CuBr(S-binap)(py2SH)]. On the other hand, the P···P separation of 4.218 Å in

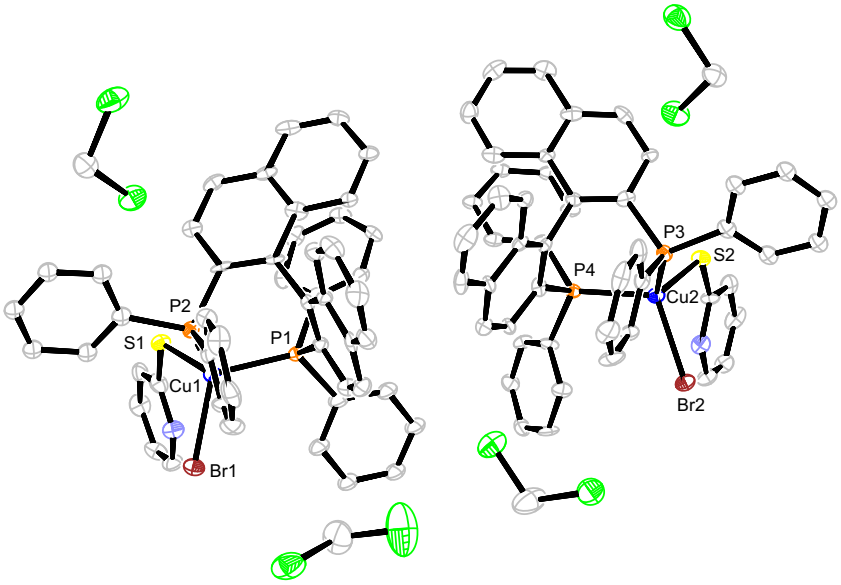

Fig. 2. A view of compound **2a** showing the two enantiomeric molecules with displacement ellipsoids in the 50% probability level.

free binap is shortened to 3.490(3) Å in [CuBr(S-binap)(py2SH)]. This shortening of the P···P distance upon chelation is obviously needed for the formation of Cu–P bonds of appropriate length.

There are only three structurally characterized copper(I) compounds with chelating binap reported so far, namely the cationic complexes [Cu(S-binap)(bpy)]PF_6, and [Cu(S-binap)(dmp)]PF_6 (bpy = 2,2′-bipyridyl and dmp = 2,9-dimethyl-1,10-phenanthroline) [8], as well as [Cu(S-binap)$(CH_3CN)_2$]ClO_4 [7b]. The Cu–P distances in these complexes are clearly shorter than those found in the complexes under investigation. Finally, a comparison of the structural characteristics of [CuBr(rac-binap)(py2SH)] with those of a series of reported monomeric compounds of type [CuX(phosphane)$_2$(S)] or [CuX(diphosphane)(S)], having the same CuP_2SX central core, revealed nearly similar values for the Cu–P, Cu–S and Cu–Br distances [23].

Orange crystals of compounds **2** and **8** were grown upon recrystallization from dichloromethane solutions. Both compounds crystallize in the monoclinic space group $P2_1/n$ with four discrete formula units in the unit cell, as well as one solvent (dichloromethane) molecule per formula unit, trapped in the crystal lattice. Bond lengths and angles around the Cu(I) for **2** and **8** are listed in Tables 3–5, and respective drawings of the molecules with the labeling of the atoms are given in Fig. 3 and 4.

In both cases the content of the asymmetric unit corresponds to a single molecule and the unit cell is comprised of two S- and two R- enantiomers. As it can be seen from the data in Tables 3–5, there are only minor differences in the bond lengths and angles between the three structures under investigation. As in the case of **2**, there is no indication of any specific interaction involving the solvent molecule, but as in many other copper halide complexes containing heterocyclic thione ligands, strong intramolecular hydrogen bridges ([N(1)–H(1) = 0.8800 Å, NH(1)–Br(1) = 2.4000 Å, Br(1)···N(1) = 3.24910(14) Å, Br(1)···H(1)–N(1) = 161.5°] for compound **2** and [N(1)–H(1) = 0.8800 Å, NH(1)–Br(1) = 2.4200 Å, Br(1)···N(1) = 3.28700(2) Å, Br(1)···H(1)–N(1) = 169.0°] for compound **8** contribute to further stabilization of the molecule in the solid state.

Bond lengths and angles involving the metal center are within the range of values found in a large number of complexes with a similar $CuXSP_2$ core. As in the structure of the aforementioned compound **2a**, some conformational adaptation on the part of the diphosphane is required for the benefit of chelation, as it is forced to lose its "relaxed" conformation, suppressing the dihedral angle between the two naphthyl groups by ca. 16 in 2 and ca. 10 in 8, but such a modification of the bite size of the diphosphane may be considered as quite normal. Regarding the geometrical characteristics of the heterocyclic rings in the thione units, coordination to Cu(I) does not causes any significant alterations except for a small lengthening of the C=S bond as a result of charge transfer from the S-atom to the metal.

In summary, we demonstrated the coordination behavior of binap towards copper(I) halides in the presence of heterocyclic thiones. In all the complexes, Cu^I was found to be in a distorted tetrahedral coordination environment with the thione adopting the monodentate-S coordination mode and the diphosphane acting as a chelate. Thus, chelation has been reconfirmed to be the preferred coordination mode for binap, a fact that can be ascribed to its conformational flexibility which allows modifications of the bite angle within a wide range. The new complexes showed interesting luminescent characteristics which will be the object of further prospectively investigations.

obtained from Fluka were used without further purification. The synthesis of the pbpaen ligand was previously reported in the literature [5].

2.2. Syntheses of the complexes

Reported yields for complexes are based upon metal starting materials. CAUTION: Although we have experienced no problems while handling any of the substances described herein, readers are cautioned to handle these compounds as potentially explosive compounds.

2.2.1. [Ni(pbpaen)](ClO4)2 (1) and [Co(pbpaen)](ClO4)3 (2)

A mixture of sodium acetate trihydrate (0.54 g, 4 mmol) and pbpaen pentahydrochloride monohydrate (0.62 g, 1 mmol), in absolute ethanol (30 mL) was stirred whilst boiling (10 min, water bath), then cooled and the sodium chloride which precipitated was filtered off. Nickel(II) or cobalt(II) perchlorate hexahydrate (0.37 g, 1 mmol) in absolute ethanol (20 mL) was added dropwise to the filtrate and the solution was stirred for 2 h at room temperature. Coloured powder formed which was filtered off, recrystallized from water–ethanol (1:1):

[Ni(pbpaen)](ClO4)2 (**1**): Pink crystals suitable for X-ray diffraction were obtained after one month. Yield: 0.47 g (70%, 0.7 mmol), m.p. 225 °C. *Anal.* Calc. for $C_{24}H_{33}N_7NiCl_2O_8$: C, 42.53; H, 4.87; N, 14.47; Ni, 8.7. Found: C, 42.44; H, 4.93; N, 14.29; Ni, 8.3%. $\chi_M = 4310 \times 10^{-6}$ c.g.s. e.m.u, $\mu_{eff} = 3.18\ \mu_B$. IR (KBr) (cm^{-1}): 3322, 3295 (s, ν_{N-H}); 2945–2860 (m, ν_{C-H}); 1603, 1570, 1483, 1442 (s, $\nu_{pyridine\ ring}$) 1090 (vs, $\nu_{ClO_4^-}$). UV/Vis (solid state): $\lambda_{max} = 520$, 810 nm (DMF or H_2O): λ_{max} (ε) = 520 (12), 810 nm (15 $mol^{-1}\ dm^3\ cm^{-1}$).

[Co(pbpaen)](ClO4)3 (**2**): Light brown crystals unsuitable for X-ray were obtained after six weeks. Yield: 0.435 g (70%, 0.7 mmol), m.p. 218 °C. *Anal.* Calc. for $C_{24}H_{33}N_7CoCl_3O_{12}$: C, 37.07; H, 4.25; N, 12.62; Co, 7.6. Found: C, 37.15; H, 4.38; N, 12.50; Co, 7.9%. IR (KBr) (cm^{-1}): 3320, 3285 (s, ν_{N-H}); 2940–2850 (m, ν_{C-H}); 1600, 1565, 1478, 1442 (s, $\nu_{pyridine\ ring}$) 1090 (vs, $\nu_{ClO_4^-}$). UV/Vis (solid state): $\lambda_{max} = 464$ nm; (H_2O or DMF): λ_{max} (ε) = 355 (215), 462 nm (138 $mol^{-1}\ dm^3\ cm^{-1}$).

2.2.2. [Co(bpaen)](ClO4)3 (3)

To the solution of pbpaen pentahydrochloride monohydrate (0.62 g, 1 mmol) dissolved in water (40 mL) was added dropwise with stirring the solution of cobalt(II) perchlorate hexahydrate (0.37 g, 1 mmol) in water (10 mL). Solid sodium carbonate was added in small portions to the mixture with stirring until the pH reached 4. After stirring at room temperature for 1 h, the solvent was removed by rotavapor. Recrystallization of the crude product obtained from water–acetone (1:1) gave after four months yellow brown crystals suitable for X-ray diffraction. Yield: 0.41 g (60%, 0.6 mmol), m.p. 245 °C. *Anal.* Calc. for $C_{18}H_{28}N_6CoCl_{12}O_{12}$: C, 31.50; H, 4.08; N, 12.25; Co, 8.6. Found: C, 31.60; H, 4.21; N, 12.04; Co, 8.9%. IR (KBr) (cm^{-1}): 3325, 3291 (s, ν_{N-H}); 2940–2850 (m, ν_{C-H}); 1600, 1569, 1480, 1445 (s, $\nu_{pyridine\ ring}$) 1095 (vs, $\nu_{ClO_4^-}$). UV/Vis (solid state): $\lambda_{max} = 461$ nm; (DMF or H_2O): λ_{max} (ε) = 354 (218), 460 nm (140 $mol^{-1}\ dm^3\ cm^{-1}$).

2.3. Physical measurements

Elemental analyses (C, H and N) were carried out on a Perkin–Elmer 2400 C, H, N element analyser in our university. The metal analysis was performed on an ICP AES Liberty Series II Varian apparatus. The UV–Visible spectra in solution were recorded on a Perkin–Elmer Lambda 6 spectrophotometer. In the solid state, visible spectra were obtained on a Beckman 5240 spectrophotometer by depositing the compound on Schleicher and Schul filter paper without ashes, and this paper was used as reference. IR spectra were obtained in KBr pellets with a Nicolet Avatar 320. Magnetic susceptibilities were determined at room temperature (20 °C) using $HgCo(SCN)_4$ as a calibrant; diamagnetic susceptibility corrections were calculated from Pascal's constants [8].

2.4. Crystal structure determination

The crystal data were collected on a Siemens SMART three-circle CCD diffractometer using monochromatic Mo Kα radiation ($\lambda = 0.71073$Å). The structure was solved by the direct method and refined by full matrix least squares, based on F^2 using the SHELX-TL software package [9]. An empirical absorption correction based on symmetric equivalent reflections was applied using the SADABS program [10]. All the hydrogen positions were initially located in the difference map and for the final refinement the hydrogen atoms were placed geometrically and held in the riding mode. The last cycles of the refinement included atomic positions for all the atoms, anisotropic thermal parameters for all non-hydrogen atoms and isotropic thermal parameters for all the hydrogen atoms.

Crystal data and refinement details for [Ni(pbpaen)]$(ClO_4)_2$ (**1**) and [Co(bpaen)]$(ClO_4)_3 \cdot$ (**3**) are shown in Table 1. Additional experimental information, including atomic positional parameters, is supplied in CIF format as described in the Supplementary data.

3. Results and discussion

3.1. Synthesis

New complexes [Ni^{II}(pbpaen)]$(ClO_4)_2$ (**1**) and [Co^{III}(pbpaen)]$(ClO_4)_3$ (**2**) were synthesized by treating an ethanolic suspension of the ligand pentahydrochloride salt and 5 equiv of sodium acetate and the appropriate metal(II) perchlorate hexahydrate. These two compounds were isolated as perchlorate salts, confirmed by the presence of a strong band at ca. 1090 cm^{-1} in the IR spectra. In order to synthesize complexes with protonated forms of the ligand, the reactions between the $M(ClO_4)_2 \cdot 6H_2O$ (M = Ni^{2+} or Co^{2+}) and pentahydrochloride pbpaen ligand were realized in an aqueous medium in acidic conditions using Na_2CO_3 as the base.

At pH ≈ 4, the reaction of the Ni^{2+} ion with pbpaen ligand afforded compound **1**, whereas Co^{2+} ion gives $[Co^{III}(bpaen)](ClO_4)_3$ (**3**) compound in which the tripod pbpaen ligand had lost one of the three pyridylmetyl groups procuring then bpaen ligand (bpaen = *N*,*N*-bis{2-[(pyridin-2-ylmethyl)amino]ethyl}ethane-1,2-diamine). At more acidic condition (pH ⩽ 3.5), all our attempts resulted in precipitation of intractable solid. The three complexes were recrystallized from water–ethanol (1:1) (**1** and **2**) or water-acetone (1:1) (**3**) and only compounds **1** and **3** gave suitable crystals for X-ray structure determinations.

3.2. X-ray diffraction studies

3.2.1. $[Ni(pbpaen)](ClO_4)_2$ (**1**)

Complex **1** crystallizes in a monoclinic space group $P2_{1/c}$ with four molecules per unit cell. The molecular structure consists in one $[Ni(pbpaen)]^{2+}$ cation and two ClO_4^- anions. A Platon drawing of the cation $[Ni(pbpaen)]^{2+}$ together with the atoms labelling scheme is shown in Fig. 1, relevant bond lengths and angles in Table 2.

The structure shows the presence of two independent molecules in the crystal lattice. Although pbpaen is a potentially heptadentate ligand, the nickel(II) ion has a coordination number of six in each complex molecule; thus, one of the three pyridyl nitrogen atoms remains uncoordinated. The nickel(II) center is coordinated by the apical nitrogen atom N(3), two aromatic nitrogen atoms [N(1) and N(5)] and three secondary amine nitrogen atoms [N(2), N(4) and N(6)]. The coordination sphere is distorted octahedral with the *trans* angles N(1)–Ni–N(3) = 162.45(9)°, N(2)–Ni–N(5) = 173.72(9)° and N(4)–Ni–N(6) = 160.66(9)°. The bond lengths involving two nitrogen atoms of the same arm (secondary amine and pyridyl) of pbpaen ligand are quite similar [Ni–N(1) = 2.081(2) Å, Ni–N(2) = 2.088(2) Å and Ni–N(4) = 2.171(2) Å, Ni–N(5) = 2.170(2) Å]. The coordination of the apical nitrogen atom induces some strains in the molecule; thus the bond distances of the second coordinated arm of the ligand are increased (≈ +0.086 Å) and the chelate ring formed between pyridyl nitrogen and amine nitrogen is contracted (mean value 78.83°) with respect to an octahedral geometry (90°).

The structure of complex **1** is surprisingly different from hexacoordinated N_6 $[Ni(py)_3tren]^{2+}$ compound [11], with a ligand similar to pbpaen, but containing HC=N bonds instead of H_2C–NH. This latter complex does not exhibit the coordination of the tertiary apical nitrogen atom to the nickel center; Morgenstern and co-workers [12,13] explain this kind of difference by a stronger chelating effect of α-imine linkage present in $(py)_3tren$.

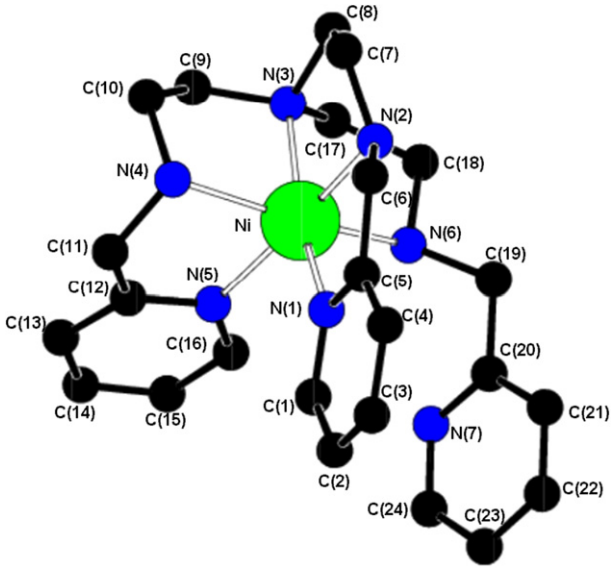

Fig. 1. A Platon drawing of the cation $[Ni(pbpaen)]^{2+}$ and the atoms labelling scheme; hydrogen atoms and perchlorate anions are omitted for clarity.

Table 2
Selected bond lengths (Å) and bond angles (°) for $[Ni(pbpaen)](ClO_4)_2$ (**1**)

Bond lengths			
Ni–N(1)	2.081(2)	Ni–N(4)	2.171(2)

The crystal lattice of complex **1** is stabilized by intra and intermolecular hydrogen bonding systems. One intramolecular H-bond is formed between the hydrogen of the secondary amine nitrogen and the uncoordinated pyridyl nitrogen belonging to the same arm of pbpaen ligand; the distance $NH\cdots N_{pyridyl}$ being 2.761 Å. Two intermolecular H-bonds shows an interesting super-structure based on $O_{ClO_4^-}\cdots HN$ hydrogen interactions between oxygen atoms of one perchlorate anion and the secondary amine groups of the tripod ligand (Fig. 2). The first H-bonds are between two oxygen atoms of ClO_4^- ion and the hydrogen of the secondary amine, forming a two-center chelate H-bonds [14] (average, $O_{ClO_4^-}\cdots HN$ = 3.311 Å). The second hydrogen bond is between the third oxygen atom of the perchlorate anion and the hydrogen of secondary amine of the neighbouring complex; the distance $O_{ClO_4^-}\cdots HN$ being 3.102 Å. The propagation of these hydrogen bonding systems create a polymeric structure giving an interesting one-dimensional sheets like arrays.

3.2.2. $[Co(bpaen)](ClO_4)_3$ (**3**)

Complex **3** crystallizes in an orthorhombic space group *Pna*2 with four molecules per unit cell. The molecular structure consists in one $[Co(bpaen)]^{3+}$ cation (bpaen represents the ligand *N*,*N*-bis{2-[(pyridin-2-ylmethyl)amino]ethyl}ethane-1,2-diamine) and three ClO_4^- anions. Relevant bond lengths and angles are given in Table 3. A Platon drawing of the cation $[Co(bpaen)]^{3+}$ with atoms labelling is illustrated in Fig. 3.

The structure of complex **3** demonstrates that Co^{2+} ion was aerial oxidized to Co(III) in the complex, and one arm of the tripod ligand lost its pyridylmethyl group affording $[Co^{III}(bpaen)](ClO_4)_3$ (**3**) compound. The coordination geometry around the cobalt atom is described as a distorted octahedron with the *cis* bond angles ranging from 82.36(14)° to 86.99(15)° and the *trans* bond angles from 170.67(15)° to 176.84(15)°. As in complex **1**, the strains induced by the coordination of the apical nitrogen atom N(3) of bpaen ligand leads to the difference of the six Co–N bond lengths. The average Co–N distances follow the order $Co{-}N^{amine}_{primary}$ (1.955 Å)≈ $Co{-}N^{amine}_{secondary}$ (1.955 Å) < $Co{-}N^{pyridyl}$ (1.965 Å) expected from the donor capabilities of the lone pairs on the three nitrogen atoms.

The lattice structure of **3** is stabilized by intermolecular hydrogen-bonding network formed by the hydrogen atoms of the primary and secondary amine groups of the bpaen ligand to one oxygen atom of perchlorate anions with the distance of 3.012 Å and 3.045 Å, respectively. Complex cation of **3** is linked into polymers by hydrogen bonds involving the second hydrogen of NH_2 groups and the oxygen atom hydrogen-bonded of the perchlorate

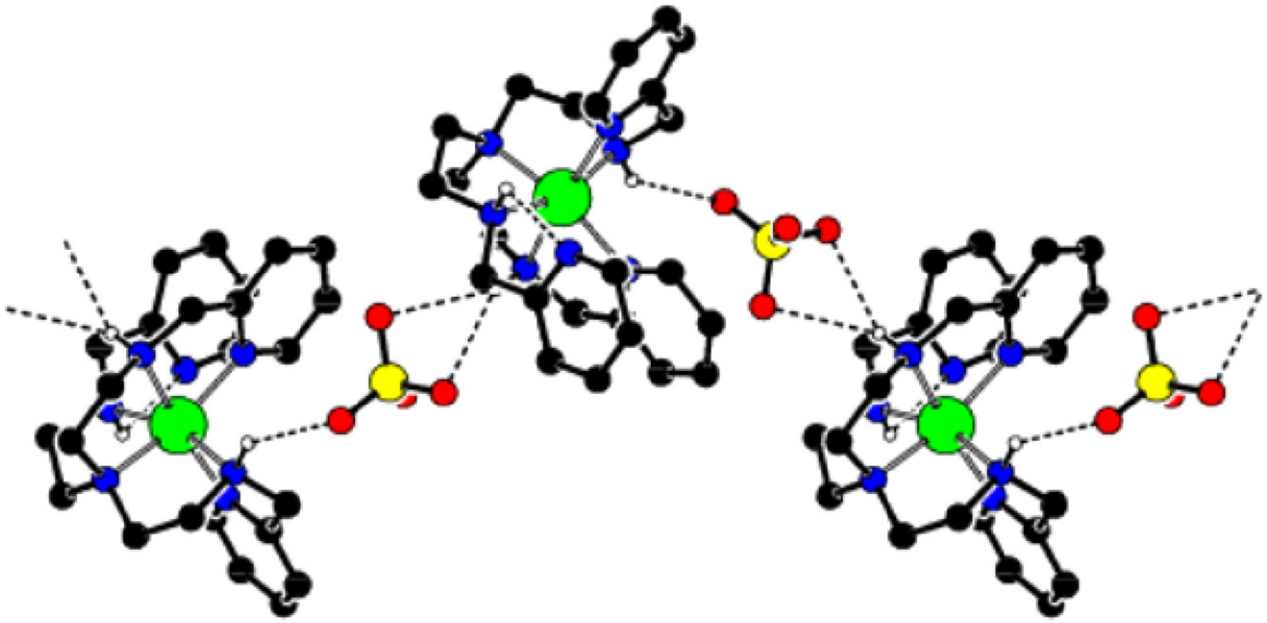

Fig. 2. Extended interactions in **1**, showing the H-bonding contacts.

Table 3
Selected bond lengths (Å) and bond angles (°) for $[Co(bpaen)](ClO_4)_3$ (**3**)

N(2)–Co–N(3)	86.99(15)	N(4)–Co–N(6)	171.65(16)
N(2)–Co–N(4)	94.75(16)	N(5)–Co–N(6)	92.89(15)
N(2)–Co–N(5)	176.84(15)		

anion belonging to the neighbouring complex. Propagation of their interaction leads to the formation of two-dimensional layers (Fig. 4). The closest Co···Co separation within the layers is 10.825 Å.

In both compounds, the bond lengths involving pyridine nitrogen atoms are not significantly different from those involving primary or secondary amine nitrogen atoms. All metal–nitrogen bond lengths in the nickel complex (**1**) are longer than those in the cobalt complex (**3**), what is consistent with the larger radius of Ni(II). In each complex, the M–N bond distances of the two pyridylmethylamine groups belonging to the two bound arms of the tripod ligand are different; this difference is more important in the nickel(II) complex [average, 0.086 Å] than the cobalt(III) compound [average, 0.029 Å]. In addition, the five-chelate bond angles of 78.83–83.46° (average, 81.15°) subtended by the ligand at the nickel atom are smaller than their analogues of 82.36–86.79° (average, 84.58°) in the cobalt complex, in agreement with a larger distortion in the nickel compound.

All attempts to isolate the nickel(II) complex with bpaen ligand in acidic medium (pH ≈ 4), as in the compound **3**, have failed. This seems to demonstrate that the oxidation of the metallic ion is necessary to obtain the substitution of the pbpaen ligand giving bpaen complex.

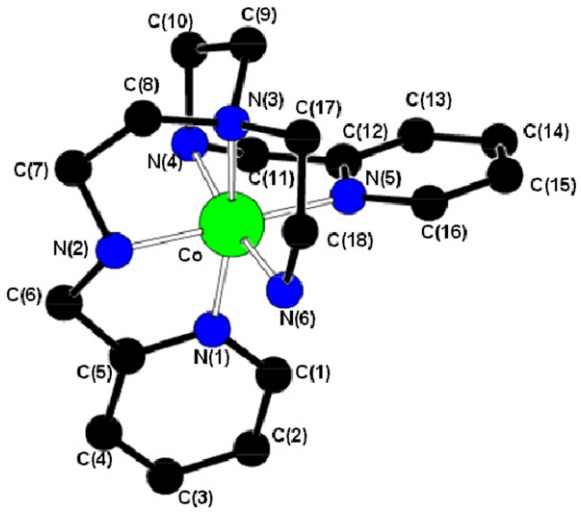

Fig. 3. A Platon drawing of the cation $[Co(bpaen)]^{3+}$ and the atoms labelling scheme; hydrogen atoms and perchlorate anions are omitted for clarity.

3.3. Spectroscopic studies

3.3.1. IR spectra

IR spectra of the nickel(II) and cobalt(III) complexes are similar in pattern to the one of bpbaen. For all the compounds, small shifts are observed for the characteristic secondary amine bands (ca. 3400–3060 cm^{-1}) and those of the pyridyl rings (ca. 1620–1610 cm^{-1}) to lower and higher energies, respectively. These vibrations are similar to those found in the analogous series of complexes with ligands containing pyridyl groups and 5-membered chelate rings [15]. ClO_4^- anions in the three compounds have been characterised by a broad and strong band at 1090–1095 cm^{-1}.

3.3.2. Absorption spectra

The electronic spectra of the three complexes (**1**–**3**) in the solid state are not different from those obtained in H_2O or in DMF solu-

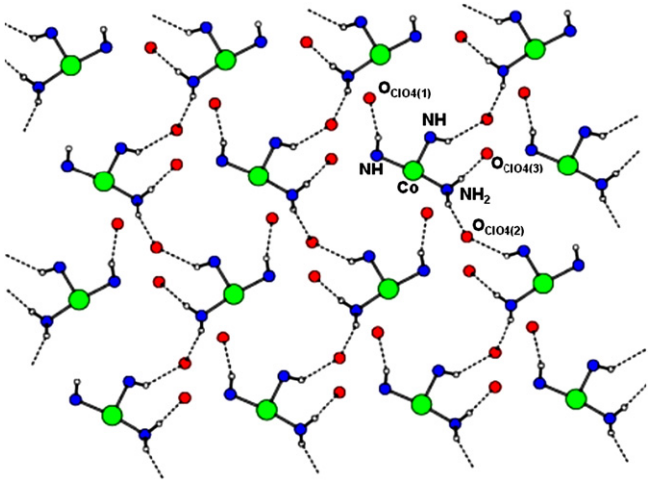

Fig. 4. Part of the lattice structure of $[Co(bpaen)](ClO_4)_3$, showing a two-dimensional layer of cations linked by hydrogen bonding. All atoms not involved in hydrogen-bonding are omitted for clarity.

tion. The absorption spectra of these compounds exhibit essentially similar patterns in the 250–400 nm region, with two strong bands possibly due to intraligand [16,17] and/ or charge transfer transitions.

In the visible region, complex $[Ni(pbpaen)](ClO_4)_2$ (**1**) displays two bands at 890 nm and 560 nm. These two bands arise from $^3A_{2g} \rightarrow {}^3T_{2g}$ and $^3A_{2g} \rightarrow {}^3T_{1g}(^3F)$ transitions. The third band at higher energy is completely obscured by metal–ligand charge-transfer. These observations are consistent with an octahedral geometry around Ni^{2+} ion, and ligand field parameters are calculated using the energy level given by Lever [18]: 10 Dq = 11 270 cm^{-1}, Racah parameter $B = 865\ cm^{-1}$. These parameters, compared to those of octahedral $Ni(pytrien)](ClO_4)_2$ complex (10 Dq = 12 360 cm^{-1}, Racah parameter $B = 826\ cm^{-1}$) [19], are in agreement with NiN_6 chromophores [20,21].

The d–d transitions of complexes **2** and **3** are characteristic of low-spin octahedral cobalt(III) with two spin-allowed absorption bands centred at 462 and 355 nm, and 460 and 354 nm, respectively. The latter bands are almost obscured by the intense low-energy Co–N charge transfer transition. These bands, arising from $^1A_{1g} \rightarrow {}^1T_{1g}$ and $^1A_{1g} \rightarrow {}^1T_{2g}$ d–d transitions, are consistent with those corresponding to $Co^{III}N_6$ chromophore [22–25]. The fact that the two cobalt(III) compounds, **2** and **3**, exhibiting the similar electronic spectra shows that the third uncoordinated pyridyl nitrogen atom of the ligand has no influence on the stereochemistry of these compounds.

Appendix A Supplementary data

CCDC 606972 and 606973 contain the supplementary crystallographic data for $[Ni(pbpaen)](ClO_4)_2$ and $[Co(bpaen)](ClO_4)_3$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.06.016.

[6], *trans*-[Co(diamH$_2$-N$_4$)Cl$_2$][ZnCl$_4$]Cl · 0.5H$_2$O · 0.5(C$_2$H$_5$OH) [6] and several [Co(diam-N$_5$)X]$^{n+}$ compounds [6]. The Co–N and Co–C distances for the azamacrocycle cyano compounds (Table 3) do not differ significantly from those of the non-cyclic bis(ethane-1,2-diamine) compound [7]. The steric factors leading to the unusually short Co–N$_{secondary}$ bonds observed for hexa-coordinate [Co(diam-N$_6$)]Cl$_2$ · ClO$_4$ [5,8] do not affect the distances for the penta- or tetra-coordinated diam and diampro compounds.

The facile acyclation of diam while coordinated to cobalt(III) provides a mechanism for the incorporation of this azamacrocycle moitey into larger structures.

3. Experimental

3.1. Preparation of compounds

3.1.1. *trans*-Di(cyano-κ^1)-(trans-6,13-dimethyl-6,13-bis(propionylamido)-1,4,8,11-tetraazacyclotetradecane-κ^4)cobalt(III) perchlorate dihydrate, *trans*-[Co(diam-N$_4$)(CN)$_2$]ClO$_4$ · 2H$_2$O

This was prepared by heating [Co(diam-N$_6$)]Cl$_2$ · ClO$_4$ · H$_2$O [5,8] or [Co(diam-N$_6$)](ClO$_4$)$_3$ · ½H$_2$O [8] (1 g) in water (10 cm^3) at c. 80 °C with NaCN (0.5 g) and NaOH (0.2 g). The solution rapidly changed from yellow to orange as [Co(diam-N$_5$)(OH)]$^{2+}$ [8] formed and then more slowly to yellow as the product formed. This was filtered from the cold solution and recrystallized from hot water. The compound can by prepared from [Co(diam-N$_5$)(OH)](ClO$_4$)$_2$ · H$_2$O [8] by similarly heating in aqueous solution with NaCN. *Anal.* calc. for C$_{14}$H$_{34}$ClCoN$_8$O$_8$: C, 33.3; H, 6.8; N, 22.2. Found: C, 33.2; H, 6.7; N, 22.3%. IR spectrum: band maxima/cm^{-1}; *ν* (OH): 3580, 3500, 3431, 3366; ν (NH): 3231, 3173; ν (C≡N): 2132sp; *δ* (HNH, HOH): 1624br.

A preparation of the related compound *trans*-[Co(diam-N$_4$)(CN)$_2$] [Co(diamH$_2$-N$_4$)(CN)$_2$](ClO$_4$)$_4$ · 4(H$_2$O) has been reported [3].

3.1.2. *trans*-Di(cyano-κ^1)-(trans-6,13-dimethyl-6,13-bis(propionylamido)-1,4,8,11-tetraazacyclotetradecane-κ^4)cobalt(III) perchlorate dihydrate, *trans*-[Co(diampro-N$_4$)(CN)$_2$]ClO$_4$ · 2H$_2$O

A solution of *trans*-[Co(diam-N$_4$)(CN)$_2$]ClO$_4$ (1 g) and propionic anhydride (1 g) in DMF (5 cm^3) was heated at 80 °C for 1 h. Propan-2-ol (20 cm^3) was then added. The yellow crystalline product was filtered from the cold solution in near quantitative yield and recrystallized from hot water. The crystal for the structural study was grown by evaporation of an aqueous solution. IR spectrum: band maxima/cm^{-1}; *ν* (OH, NH): 3553, 3429, 3300br, 3259, 3139; *ν (C≡N): 2227w,sp, 2137w,sp; amide: 1653s, 1553.*

The acetylamido homologue can be similarly prepared by using acetic anhydride.

Caution: Although no problems were encountered in this work, perchlorate compounds are potentially explosive. They should be prepared in small amounts and handled with care.

3.2. Crystallography

Diffraction data was collected [Bruker SMART] by using a Bruker CCD diffractometer with Mo Kα radiation (fine focus sealed tube with graphite monochromator, $\lambda = 0.71073$ Å), using omega and epsilon scans [10]. Bruker SAINT was used for cell refinement and data reduction [10]. Absorption corrections were by multi-scan, using Bruker SADABS. See Table 4 for details [10].

The structure was solved by direct methods [SHELXS-97] and full-matrix refined [SHELXL-97] [11]. All H-atoms, other than for the water molecule, were positioned geometrically and refined using a riding model with C–H = 0.97 Å, $U_{iso} = 1.2U_{eq}$ (C) for CH$_2$, 0.96 Å, $U_{iso} = 1.5U_{eq}$ (C) for CH$_3$ atoms and 0.90 Å, $U_{iso} = 1.2U_{eq}$ (N) for the NH groups. The H-atoms of the water were located from difference syntheses and their positions refined, with O–H restrained (0.82 Å) and with $U_{iso} = 1.2U_{iso}$ (O) (see Table 4).

Appendix A. Supplementary data

CCDC 683156 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.06.020.

Mg, which yields 4 + 1 coordinated complex, and pyridine molecules are linked via O–H···N hydrogen bonds [15,16].

Most of M(II)Pc complexes in the water-free 4-picoline solution form biaxially ligated M(II)Pc(4-picoline)$_2$ complexes [17,18]. However, in the case of BePc and ZnPc in 4-picoline solution monoaxially ligated complexes are formed [18]. In this work, we investigate the products formed in the effect of hydration of M(II)Pc in the solution of 4-picoline/water. In addition, the novel aqua M(II)-phthalocyaninato complexes (M = Be or Mg) isolated in the crystalline form as 4-picoline solvate have been structurally characterised.

2. Experimental

2.1. Synthesis

The BePc and MgPc compounds were obtained as described elsewhere [12,13]. The ZnPc was obtained from Aldrich (purity 97%). Firstly the BePc, MgPc and ZnPc were transferred by the appropriate transformative recrystallisation procedure in dry 4-picoline (4-Mepy) into [BePc(4-Mepy)](4-Mepy) (**I**), MgPc(4-Mepy)$_2$ (**II**) and ZnPc(4-Mepy) (**III**) complexes as described elsewhere [18]. The (**I**), (**II**) and (**III**) complexes obtained in crystalline form were again recrystallised, however now from not dried (containing water) 4-picoline. The suspension consisting appropriately of the crystallites of **I**, **II** or **III** and wet 4-picoline (assigned now as (a), (b) and (c)) were similar thermally processed as in [18]. Elemental analysis of the products was performed on a dispersive energy spectrometer.

(a) In the case of the sample containing compound **I** in wet 4-picoline, which recrystallisation was performed at 80 °C during several hours, the BePcH$_2$O · (4-Mepy) – **Ia** crystals were formed. *Anal.* Calc. for $C_{38}H_{25}N_9OBe$: C, 72.14; Be, 1.42; N, 19.93; O, 2.53. Found: C, 72.25; Be, 1.44; N, 19.85; O, 2.49%.

(b) In the case of **II** in wet 4-picoline, the prolonged recrystallisation process at 140 °C yield to well-developed crystalline product. The analyses performed for the selected single crystal indicates on the presence of the compound with the composition of [MgPcH$_2$O] · (4-Mepy) – **IIa**. If the hot suspension containing **IIa** crystalline product was slowly cooled to room temperature (in days), the crystals **IIa** transform into another crystals containing more 4-picoline moieties – [MgPcH$_2$O-(4-Mepy)$_2$] · (4- Mepy) (**IIb**). The **IIa** crystals could be only separated from hot suspension of 4-picoline. *Anal.* Calc. for $C_{38}H_{25}N_9OMg$ (**IIa**): C, 70.43; Mg, 3.75; N, 19.46; O, 2.47. Found: C, 70.38; Mg, 3.80; N, 19.51; O, 2.44%. *Anal.* Calc. for $C_{50}H_{39}N_{11}OMg$ (**IIb**): C, 71.99; Mg, 2.91; N, 18.47; O, 1.92. Found: C, 72.05; Mg, 2.94; N, 18.42; O, 1.89%.

(c) Several samples containing ZnPc(4-Mepy) in wet 4-picoline were processed at various thermal conditions, however the recrystallisation effect was invariable and lead, as was identified by X-ray powder diffraction, to the ligand free micro crystalline β-ZnPc [19].

2.2. X-ray powder diffraction measurements

The rest of the samples left after thermogravimetric analyses were measured on a STOE powder diffractometer equipped with a linear position detector (PSD) [20] using Cu Kα_1 radiation (λ = 1.540562 Å) at room temperature.

2.3. X-ray crystallography

Suitable single crystals of **Ia**, IIa and **IIb** were used for data collection on a four-circle KUMA KM4 diffractometer equipped with two-dimensional CCD area detector [21]. The graphite monochromatised Mo Kα radiation (λ = 0.71073 Å) and the ω-scan technique ($\Delta\omega$ = 1°) were used for data collection. Data collection and reduction along with absorption correction were performed using CRYSALIS software package [21].

The structures were solved by direct methods using SHELXS-97 giving positions of almost all non-hydrogen atoms. The remaining atoms were located from subsequent difference Fourier syntheses. The structures were refined using SHELXL-97 [22] with the anisotropic thermal displacement parameters. Hydrogen atoms of the phthalocyanine moieties, water and 4-Mepy molecules were located from the difference Fourier maps, but in the final refinement the positions of all hydrogen atoms were constrained: thermal parameters and distances. Details of the data collection parameters, crystallographic data and final agreement parameters are collected in Table 1. Selected geometrical parameters are listed in Table 2.

2.4. Thermal measurements

Thermal analysis was carried out on a Lines L81 thermobalance apparatus with Pt crucibles. Powdered Al_2O_3 has been used as a reference. The measurements have been performed under static air atmosphere on heating from room temperature to 300 °C at the heating rate of 5 °C min^{-1}.

2.5. UV–Vis measurements

The electronic absorption spectra measurements were carried out at room temperature using a CARRY-VARIAN SE UV–Vis–NIR spectrometer. The solid-state spectra of the samples were recorded for thin film nujol mulls as well as in 4-picoline as N-donor solvent and in 2-ethoxyethanol as O-donor solvent.

3. Results and discussion

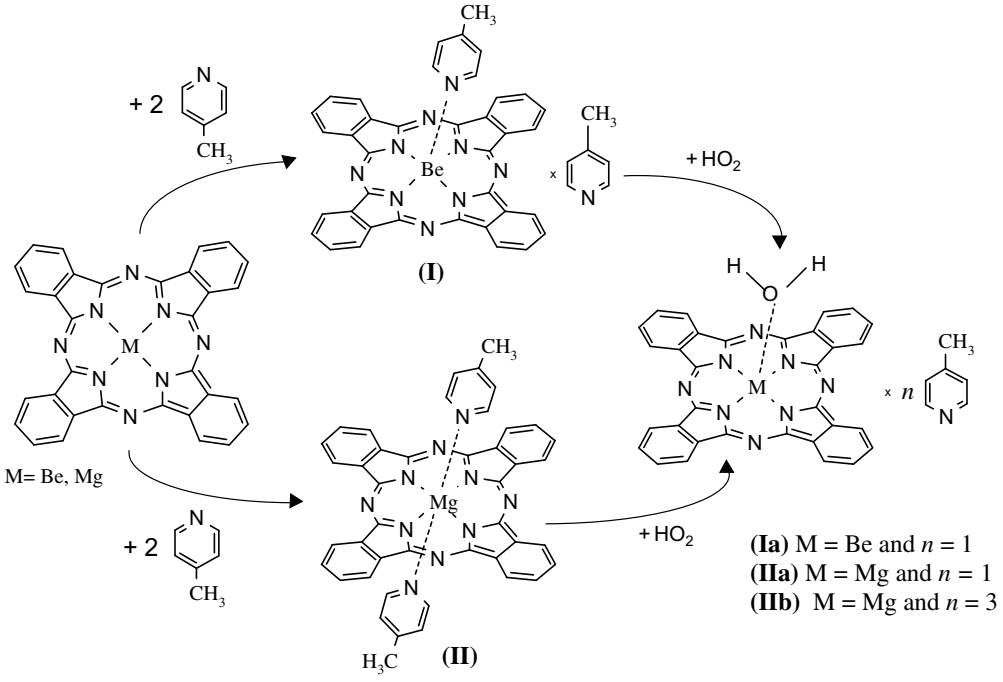
3.1. Synthesis and equilibrium in solution

The BePc(4-Mepy) (**I**), $MgPc(4\text{-Mepy})_2$ (**II**) and ZnPc(4-Mepy) (**III**) complexes were obtained by recrystallisation of MPc's (M = Be, Mg and Zn) in purified water-free 4-picoline and were characterised by us [18]. Now we used these complexes for recrystallisation procedure in not dried (containing water) 4-picoline as described in Section 2. This procedure gave for each complex **Ia**, **IIa** and **IIb** well-developed crystals suitable for X-ray analysis, showing a typical blue–violet colour for phthalocyanine. As was shown previously [18] the recrystallisation of BePc and ZnPc in water-free 4-picoline yield monoaxially coordinated (4 + 1) complexes, while for MgPc yields biaxially ligated (4 + 2) complex. These complexes when recrystallised from moist 4-picoline (containing water) yield aqua M(II) phthalocyaninato complexes. During recrystallisation process the crystals of BePc(4-Mepy) · 4-Mepy (**I**), as well as the crystals of $MgPc(4\text{-Mepy})_2$ (**II**) interact with water molecules and convert depending on the temperature, into aqua(phthalocyaninato(2-)) complexes **Ia**, **IIa** and **IIb** according to the equation illustrated in Scheme 1.

Recrystallisation of ZnPc(4-Mepy) in wet 4-picoline yields, as was identified by the X-ray powder diffraction experiment, ligand-free microcrystalline β-ZnPc [19]. The crystals of **Ia**, **IIa** and **IIb** are well soluble in 4-picoline, pyridine and other N-donor solvents yield a very intensive green–blue colour, depending on the concentration of the complex. These complexes are also soluble in O-donor solvents like 2-methoxyethanol, 2-ethoxyethanol, ethanol, acetone, etc., yielding blue colour of the solution. However, the solubility of the crystals in O-donor solvents is smaller in comparison to the N-donor solvents. These crystals are insoluble in water.

3.2. Thermal stability

In order to determine the thermal stability of the complexes investigated here, the thermal analyses of **Ia**, **IIa** and **IIb** complexes were carried out on the samples of 40 mg and with the same heating rate of 5 °C/min. The thermogravimetric analyses of the solid-state samples are shown in Fig. 1. Compound **Ia** is stable up to about 150 °C, and at higher temperature loses the 4-Mepy and water molecules in one step (Fig. 1a). The observed weight loss of ~18.5% is equal to the calculated sum of the weight loss of 4-picoline (14.7%) and water (3.83%), (Σ = 18.53%). This value indicates



Scheme 1.

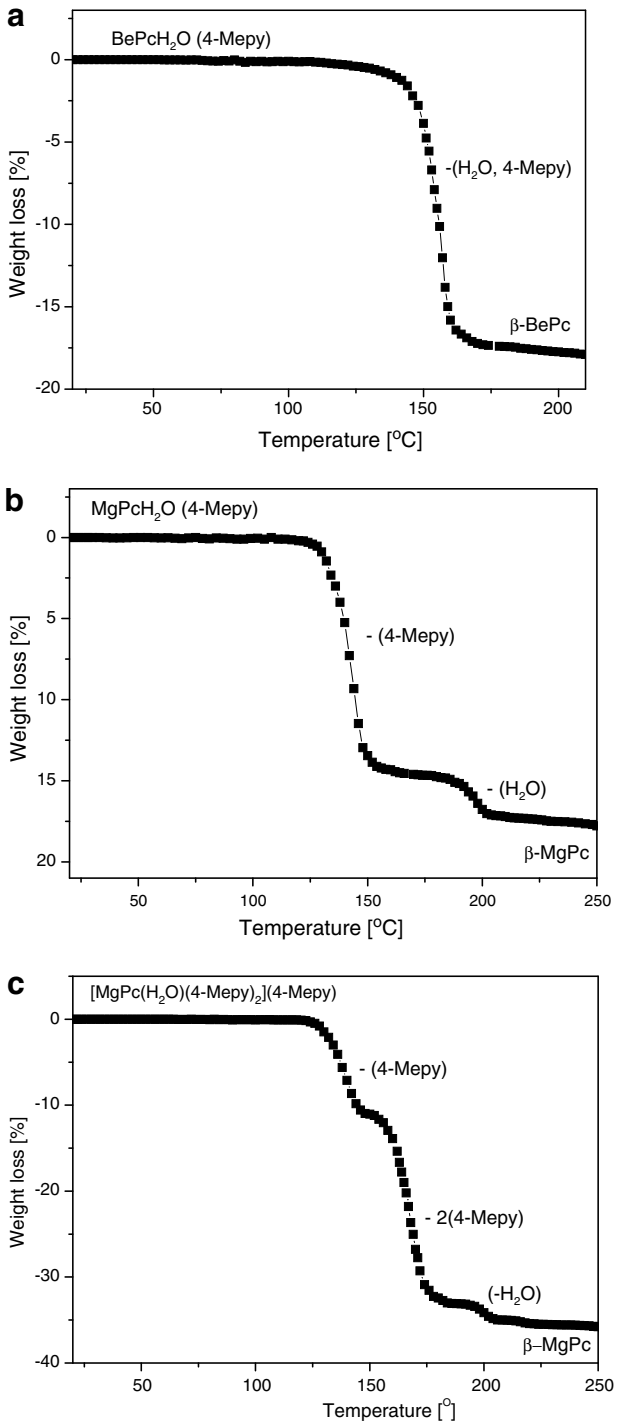


Fig. 1. Thermograms for the solid-state samples of **Ia** (a), **IIa** (b) and **IIb** (c).

that both molecules, 4-Mepy and water, release simultaneously. This result of the thermal analysis is in agreement with the X-ray crystal structure analysis, which shown that 4-picoline and water molecules are joined together by a relatively strong O–H···N hydrogen bond and the Be–O(water) bond of 1.683(5) Å is relatively weak. Quite similar observation was registered in the $(BePcH_2O)\cdot(2\text{-EE})$, where 2-EE = 2-ethoxyethanol, in which the 2-EE and water molecules are released at the same temperature [13].

The complex **IIa** is stable up to ~145 °C (Fig. 1b) at which it loses the 4-picoline molecule and transforms into $MgPcH_2O$ complex. On further heating it loses water molecule (at ~195 °C) and transforms into β-MgPc. This observation is in agreement with the arrangement of molecules in the **IIa** crystal as shown the X-ray structure analysis. In the **IIa** crystal the molecules are arranged in the face-to-face fashion in dimers with the O–H···N interactions between the antiparallel oriented dipole $MgPcH_2O$ molecules with a strong overlap of the π-clouds of the Pc rings. This interactions stabilise the $(MgPcH_2O)_2$ dimeric structure. The 4-picoline molecules are joined to these dimers via O–H···N(4-Mepy) hydrogen bonds, that breaks and the 4-picoline molecules released at ~145 °C (Fig. 1b). The observed weight loss on the heating are ~14.5% (4-Mepy) and 3.2% (water), and are in agreement with the calculated value of 14.35% and 3.24%, respectively.

Compound **IIb** loses it solvent 4-picoline molecules in two steps (Fig. 1c). One of three 4-Mepy molecules is released at ~140 °C, while the other two at ~160 °C. After loss of solvent 4-Mepy molecules the starting compound transforms into $MgPcH_2O$, which during further heating loses water molecule at about 195 °C and finally converts into β-MgPc (which was identified by X-ray powder diffraction technique). The thermogravimetric analysis of the solid-state sample of **IIb** indicates that one 4-Mepy molecule is joined differently than other two 4-Mepy molecules. This observation is in agreement with the X-ray crystal structure analysis, which shown that two 4-Mepy molecules are joined stronger by the O–H···N hydrogen bond than the other one that in the crystal interacts only by van der Waals forces.

Although, in the molecular arrangement in the **Ia** and **IIa** crystals similar $[(M(II)PcH_2O)_2(4\text{-Mepy})_2]$ dimeric aggregates can be found, the thermal stability and decomposition of these solid-state compounds is different. In the Be compound (**Ia**), due to the relatively small radius of Be, the water molecule is weaker joined to the BePc than in Mg complex (**IIa**) and therefore it is released simultaneously together with the 4-Mepy molecule that is joined via O–H···N hydrogen bond with the water. Looking at the molecular arrangement of the Mg complexes (**IIa** and **IIb**), the releasing of 4-Mepy molecules in the two steps in the **IIb** could be understood. The temperature loss of water molecules in both Mg compounds is very similar and comparable with that found in the solid-state sample of aqua magnesium phthalocyanine [23].

All crystals are stable at ambient atmosphere at room temperature. This is in contrast to the pure BePc and MgPc crystals, which especially for MgPc rapidly polycrystallise, because the MgPc molecules interact with the air molecules, O_2 and N_2. The process was confirmed by two separate experiments in pure O_2 and in pure N_2, where MgPc became transformed into complexes with the composition of $(MgPc)_2O_2$ and $(MgPc)_2N_2$, respectively [24]. In the moist atmosphere the MgPc crystals transform rapidly into $MgPc(H_2O)$ complex [25]. This behaviour of MgPc crystals is quite different in relation to the both Mg complexes (**IIa** and **IIb**) investigated here, which are stable under ambient atmosphere and room temperature.

3.3. Stereochemistry and molecular packing

All three crystal structures are built up from $M(II)PcH_2O$ and 4-picoline moieties arranged in different fashions. The independent part of the **Ia** crystal structure consists of $BePcH_2O$ and 4-picoline molecules joined together via almost linear O–H···N hydrogen bond (Fig. 2). The central Be atom of $BePcH_2O$ unit exhibits (4 + 1)-coordination by four equatorial isoindole N atoms of the Pc(2-) macrocyle and by an axial oxygen of water molecule. Owing to the interaction with the axially coordinated oxygen atom, the central Be atom is significantly displaced [0.308(2) Å] from the weighted least-squares plane defined by the four isoindole N atoms. In this complex the shift of Be atom from the N_4-isoindole plane is slightly longer than that found in the crystal of

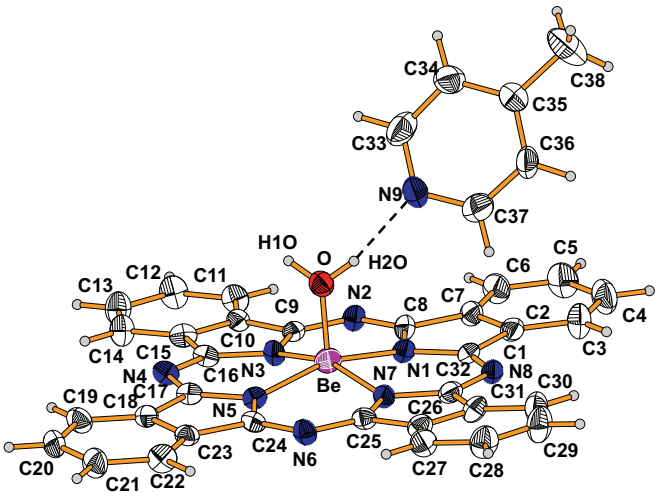

Fig. 2. View of the molecular structure of $BePcH_2O \cdot (4\text{-Mepy})$ with the atom-labelling scheme.

Symmetry code: (i) $-x, -y, -z$.

$BePcH_2O \cdot 2EE$ (2EE = 2-ethoxyethanol), 0.264(4) Å [13]. The four equatorial Be–N bonds with average distance of 1.905 Å are longer than the axial almost perpendicular to the ring plane Be–O bond [1.683(5) Å]. This correlation between the equatorial and axial bonds is quite similar to that observed in the crystal of $BePcH_2O \cdot 2EE$ [13]. However, according to Bock and Glusker [26], the typical Be–O distance in hydrate lies between 1.60–1.63 Å. Thus, it may be concluded that the cavity formed by $(N_{iso})_4$ is too spacious for the Be(II) ion and despite of its shift from the Pc center, it is submersed between the N_4 isoindole atoms as in square well. The phthalocyaninato(2-) macroring due to the interaction with the oxygen atom of water molecule adopts a saucer-shape form. The most deviated atoms from the N_4-plane are C26–C31 [0.102–0.386 Å], since the C atoms the C26–C31 ring interact with the 4-picoline molecule that is hydrogen bonded to water molecule of $BePcH_2O$. Two $BePcH_2O \cdot 4\text{-Mepy}$ units related by the inversion interact via two additional almost linear O–H···N hydrogen bonds (Table 3) forming a dimeric structure (Fig. 3). In the dimer of $(BePcH_2O)_2$ the phthalocyaninato macrocycles are separated by ~3.46 Å (the distance between the N_4–N_4 planes). In the dimer, one H atom of water molecule acts as a bridge with the N-azamethine atom of the other Pc(2-) macroring, and the second H is an acceptor of a lone-electron pair of the ring N atom of 4-picoline molecule (Fig. 3, Table 3). The coordinated water molecule plays essential role in the formation of a dimeric structure, and additionally links the 4-picoline molecule, that is oriented by its H atom in orto position to the N-ring atom in the direction to the N-azamethine atom (N8) of the Pc-ring. This interaction together with the O–H···N hydrogen bonds in the dimer of $(BePcH_2O)_2$ and with the π–π interactions between the back-to-back oriented dimers (~3.38 Å, Fig. 4) are responsible for the stabilisation and the molecular arrangement in the crystal.

The independent part of the **IIa** crystal structure consists of two $MgPcH_2O \cdot 4\text{-Mepy}$ moieties linked together in non-centrosymmetric dimeric unit (Fig. 5). This unit is built up from two aqua magnesium phthalocyanine molecules (marked as A and B) and two 4-picoline molecules. The geometries of both, A and B, $MgPcH_2O$ molecules are similar. The Pc(2-) macrorings are not planar. The central Mg cations have five-fold (4 + 1) coordination, they coordinate equatorial four N-isoindole atoms of Pc(2-) macrocycles and axially the O atoms of water molecules. The axial Mg–O bond lengths of 2.015(2) and 2.009(2) Å in molecule A and B, respectively, are shorter than four equatorial Mg–N_{iso} bonds with the average distance of 2.039 Å. Owing to the interaction with the axially coordinated O atom of water molecules, the central Mg atom in both $MgPcH_2O$ molecules is significantly displaced [0.482(2) Å in molecule A and 0.490(2) Å in molecule B] from the weighted least-squares planes defined by the four isoindole N atoms of Pc. The geometry of the $(MgPcH_2O)_2$ dimer in **IIa** is similar to that found in the triclinic modification of $MgPcH_2O$ [23]. The face-to-face oriented $MgPcH_2O$ molecules are interconnected by two almost linear O–H···N hydrogen bonds (Table 3). The Pc(2-) rings in the dimer are apart by a distance of 3.231(3) Å, indicating π–π clouds interaction, since the distance between the N_4-planes is shorter than 3.4 Å, the sum of the C-atom van der Waals radii of the π-ring system [27]. The 4-picoline molecules that are located away from the dimer interact only via O–H···N hydrogen bonds,

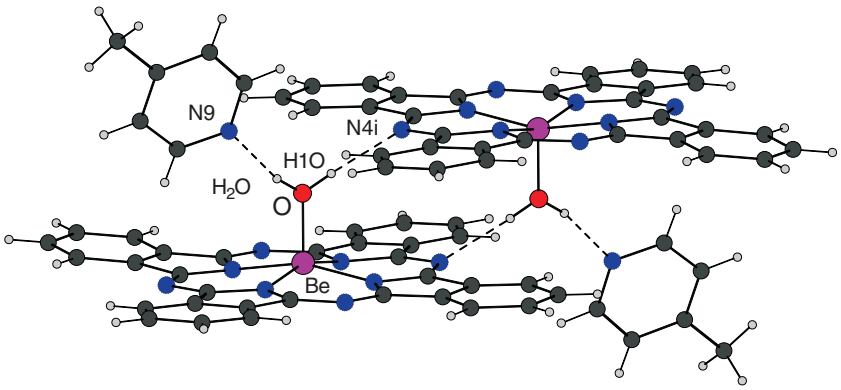

Fig. 3. View of the dimeric structure of **Ia**.

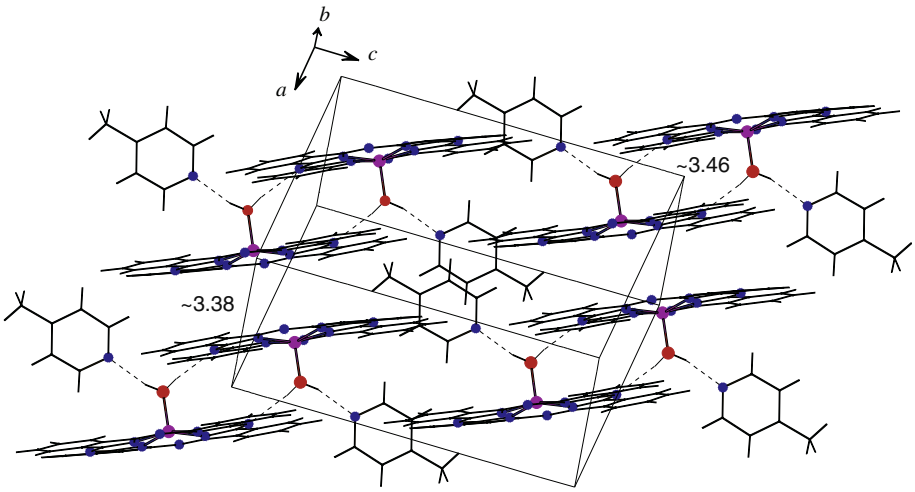

Fig. 4. Arrangement of the $BePcH_2O \cdot (4\text{-Mepy})$ molecules in the unit cell showing π–π interacting back-to-back oriented $(BePcH_2O \cdot (4\text{-Mepy}))_2$ dimeric molecules.

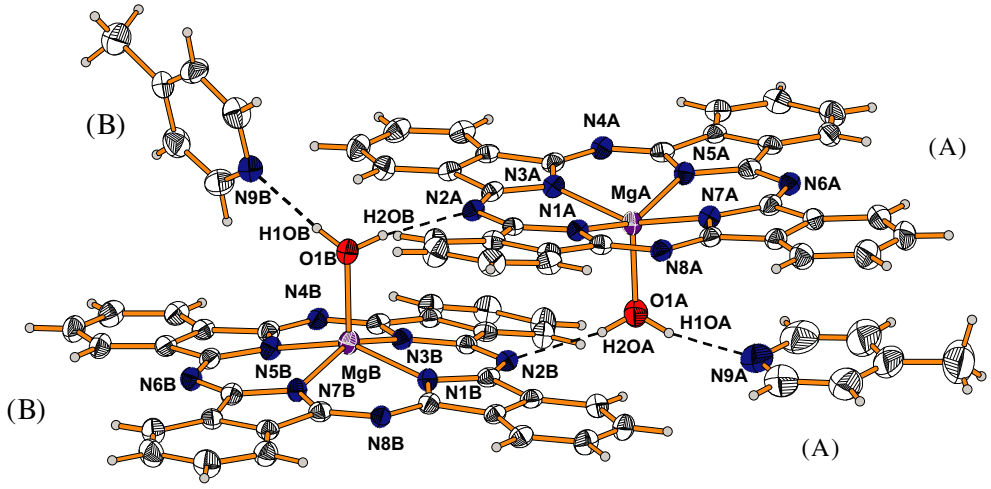

Fig. 5. View of the molecular structure of $(MgPcH_2O \cdot (4\text{-Mepy}))_2$.

in which the 4-picoline molecules act as acceptors by the N-ring atom. This interaction does not disturb the geometry of $(MgPcH_2O)_2$ dimer in relation to the triclinic form of $MgPcH_2O$ that plays an important role in the near-IR spectroscopic properties. The interesting feature of **IIa** crystal structure is the orientation of the 4-picoline molecules in relation to the $(MgPcH_2O)_2$ dimer. The 4-picoline molecule A is almost parallel to the N_4-plane of the $MgPcH_2O$ molecule to which it is linked [4.2(1)°], whereas the molecule B is roughly perpendicular to N_4-plane of $MgPcH_2O$ that join the 4-picoline molecule B [79.2(2)°]. Both O–H···N_{aza} hydrogen bonds linking the $MgPcH_2O$ molecules into a dimer have similar strength and they are weaker than the O–H···N hydrogen bonds joined the 4-picoline molecules into the dimer (Table 3). The difference in the hydrogen bond distances results from the steric interaction between the Pc macrorings in the dimer. The hydrogen bonded $(MgPcH_2O)_2 \cdot 2(4\text{-Mepy})$ aggregates are arranged in a herringbone fashion forming back-to-back stacks along the *c*-axis (Fig. 6). In the stacks the dimers are related by the inversion center. Within the stack the back-to-back distance between the N_4-isoindole planes is equal to ~3.39 Å indicating the π–π interactions between the Pc macrorings.

The asymmetric unit of the **IIb** crystal structure consists of $MgPcH_2O$ unit and three 4-picoline molecules (Fig. 7) The water molecule is directly coordinated to the central Mg cation, which owing to this interaction is shifted out of the N_4-isoindole plane by 0.537(2) Å toward the oxygen atom. Two of three 4-picoline molecules are joined via almost linear O–H···N hydrogen bonds to $MgPcH_2O$ molecule (Table 3), while the third 4-picoline not forms the hydrogen bond. The hydrogen bonded 4-picoline molecules (N9 and N10) to $MgPcH_2O$ are inclined by 63.7(3)° and 61.8(3)° for the 4-picoline molecule containing N9 and N10 atom, respectively. The third 4-picoline molecule is inclined by 73.2(3)° to the N_4-isoindole plane and is roughly parallel to the 4-picoline molecule containing N10 atom, from which it is apart by ~3.51 Å (the dihedral angle between the 4-picoline rings containing N10 and N11 atom is equal to 11.7(3)°). In the crystal the $[MgPcH_2O\text{-}(4\text{-Mepy})_2] \cdot (4\text{-Mepy})$ units related by the inversion center are arranged in the back-to-back fashion with a distance of ~3.613(3) Å between theN_4-isoindole planes of the Pc(2-) ligands. The back-to-back arranged aggregates forming stacks along the *b*-axis (Fig. 8). The face-to-face distance is about twice greater than the back-to-back distance, due to the coordinated water molecules and 4-picoline molecules that are joined via O–H···N hydrogen bonds.

The $MgPcH_2O$ molecule in both crystals (**IIa** and **IIb**) is not planar. The Mg atom is displaced from the N_4-isoindole plane by ~0.5 Å toward the oxygen atom of coordinated water molecule. The displacements observed here are comparable to those

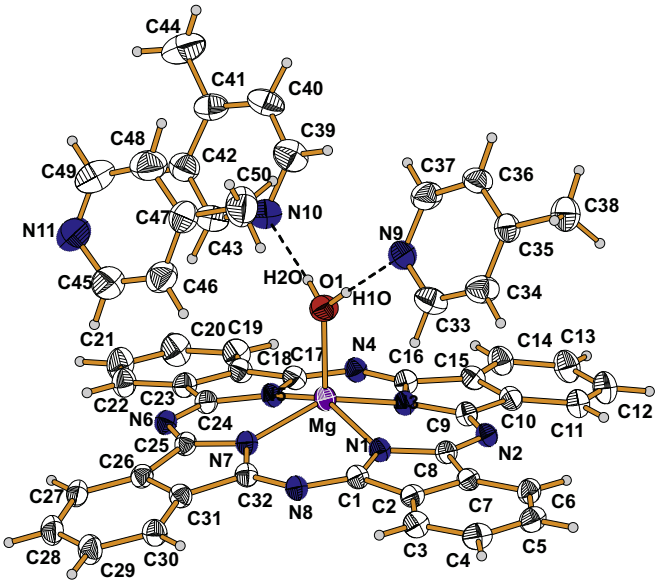

Fig. 7. View of the molecular structure of $(MgPcH_2O \cdot (4\text{-Mepy})_2) \cdot (4\text{-Mepy})$ with the labelling scheme.

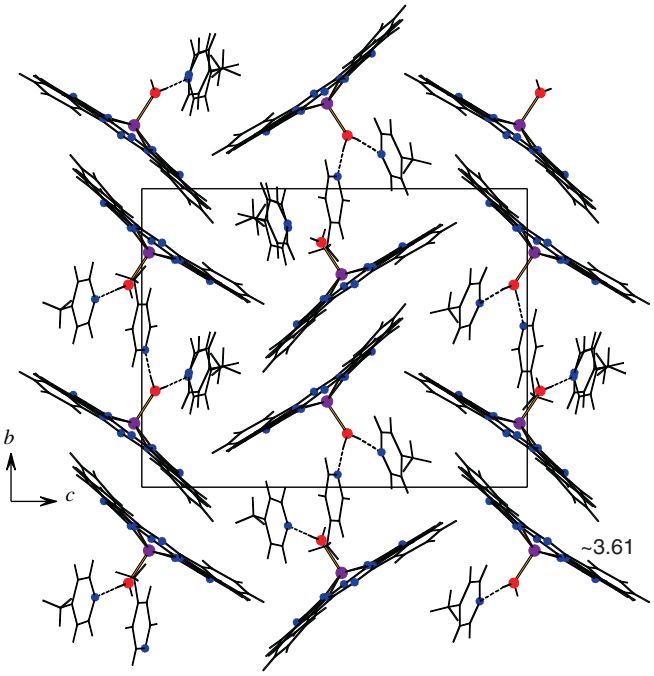

Fig. 8. Arrangement of molecules in the unit cell of **IIb**.

observed in other aqua magnesium phthalocyanine derivatives [28–33]. As can be seen from Table 4 the deviations of the central Mg atom from the N_4-plane in aqua magnesium phthalocyaninato complexes are greater than in aqua magnesium porphyrinato derivatives [34–39] and in chlorophyll derivatives [40–42]. The smaller deviation of Mg from the N_4-plane well correlates with the greater flexibility of the porphyrinato ring and with the larger central hole in relation to the phthalocyaninato macroring. The central Mg atom in both crystals studied here is 4 + 1 coordinated, equatorial by four N-isoindole atoms of Pc(2-) macocycle and axial (almost perpendicular) by oxygen atom of water molecule. The saucer-shape geometry of the Pc(2-) ligand results from the interaction of the positively charged central Mg atom of about +0.5 [43] with the negatively charged oxygen atom of water molecule and is compared to that in the gas-phase structure obtained by molecular orbital calculations [23]. However, the *ab initio* MO calculated axial Mg–O bond [2.142 Å] is significantly longer than that found in both crystals described here (Table 2). Generally the 4 + 1 coordination of Mg is preferred in MgPcL complexes in the case of O-donor ligands (L = O-donor ligands). The axial Mg–O bond length is shorter than the equatorial Mg–N bonds (Table 4). This is quite different in the 4 + 2 coordinated $MgPcL_2$ derivatives in which the axial Mg-N bonds are longer than the equatorial Mg–N bonds [15,18]. Additionally, it can be said, that trans biaxially ligated magnesium phthalocyanine derivatives are known mainly for the N-donor ligands [15,18]. Comparing the molecular arrangement in both Mg complexes studied here can be said, that in **IIa** the molecules are much closely located to each other than in **IIb** (density of the crystals of **IIa** and **IIb** are 1.413 and 1.293 g/cm^3, respectively). The overlap of the Pc ligands and the π–π interactions in **IIa** are greater than in **IIb** (see Figs. 5 and 8). In **IIa** besides the back-to-back interaction the face-to-face overlap in dimer exists. Scheidt and Lee [44] examined the overlap in neutral (structurally characterised) sterically unhindered metal–porphyrinate complexes and discovered trimodal overlapping. According to this rule the π–π interactions in **IIa** are strong, since the interplanar spacing between the Pc-rings is shorter than the sum of the C-atom van der Waals radii of the π-ring system (~3.4 Å) and longer as the distance at which the steric interactions between the π aromatic ring system becomes predominantly repulsive (~3.08 Å). Thus the degree of the π–π stabilisation of the **IIa** structure is greater than in **IIb**.

Table 4
Comparison of the coordination of the central Mg atom in 4 + 1 coordinated magnesium phthalocyaninato and porphyrinato complexes and in chlorophyll derivatives

Complex	Displacement of the Mg atom from the N_4-isoindole plane (Å)	Average Mg–N bond length (Å)	Mg–O bond length (Å)	Ref.

3.4. UV–Vis

Since the studied here complexes are moderately temperature stable as shown by the thermogravimetric analyses, the preparation of the solid-state thin films using a standard technique, i.e. thermal evaporation, were impossible due to the loss of 4-picoline as well as the water molecules. Therefore, the solid-state thin films were prepared from nujol mulls. Only compound **IIa** ($MgPcH_2O \cdot$ 4-Mepy) exhibits a broad-band solid-state near-IR absorption (Fig. 9). The solid-state spectrum of **IIa** is very similar to the solid-state spectrum of triclinic modification of $MgPcH_2O$ [23] and to the UV–Vis spectrum of the literature "X-phase" of magnesium phthalocyanine that has been reported many times (for example see Fig. 1 in Ref. [45]). Thus the intense broad-band near-IR absorption is characteristic only for the solid-state of the **IIa**. The other **IIb** complex is not near-IR active. In 4-picoline solution, the spectra of **IIa** and **IIb** are identical and, as expected, show only in this spectral region the characteristic Q band (Fig. 9). This band arises from the exciton between the HOMO ground state (a_2, π, in C_{4v} symmetry in solution) to the LUMO (e, π^*), the first doubly degenerate excited state. This band is typical and characteristic for the phthalocyaninato(2-) macroring. The Q band exhibits characteristic splitting due to the vibronic coupling in the excited state, which is well known in the literature [46,47]. Comparing the molecular architectures of the Mg-complexes (**IIa** and **IIb**) with the architecture of the active near-IR triclinic modification of $MgPcH_2O$ [23], a similar motif can be found in the crystal structure of **IIa**. This motif adopts the face-to-face oriented $(MgPcH_2O)_2$ dimers that in the crystal structure of **IIa** are running in the direction parallel to [001] (see Fig. 6). The geometry of face-to-face oriented $MgPcH_2O$ molecules in $(MgPcH_2O)_2$ dimer (Table 5) in **IIa** crystal is similar to that found in the active triclinic modification of $MgPcH_2O$ [23]. Thus the approximately C_{4v} symmetry in solution and the double degenerate state yields an expected strong Q band as observed in solution. Upon crystallisation the degeneracy of the excited state is lifted due to the molecular distortion and induces a band splitting. However, theoretical calculations shown that the splitting value arises from the molecular distortion is relatively small in relation to the observed broad-band [45,48]. Thus the molecular distortion (reduces the molecular symmetry from C_{4v} to C_1) that lifts the degeneracy of the excited state is necessary, but not sufficient to explain the observed broad-band. For this reason, as has been suggested in [23] the broadening of the band originates, besides the above-mentioned distortion, also from the molecular arrangement and π–π interactions. The $MgPcH_2O$ molecules in **IIa** form dimers via O–H···N hydrogen bonds between the antiparallel oriented dipole $MgPcH_2O$ molecules with the strong overlap of the π-clouds of the Pc rings, quite similar as found in the active form of $MgPcH_2O$ [23], as well as in the triclinic modification of titanyl and vanadyl phthalocyanines (TiOPc and VOPc), both near-IR active [49–53]. Additionally, it should be added that TiOPc and VOPc similar to the $MgPc(H_2O)$, crystallise in two crystallographic modifications, triclinic and monoclinic forms. Only the face-to-face dimeric structure with the strong and π–π interactions between the π-clouds of Pc rings similar as in crystal **IIa** is found in the triclinic (near-IR active) modification of TiOPc and VOPc. The monoclinic modification of TiOPc and VOPc similar to monoclinic modification of $MgPcH_2O$ [32] is not active in the near-IR.

The spectra of **IIa** and **IIb** in N-donor solvents like 4-picoline or pyridine and in O-donor solvents like 2-ethoxyethanol or 2-methoxyethanol are very similar (Fig. 10), however the Q band is blue shifted in the O-donor solvents. The solutions of the complexes IIa or IIb in pyridine or 4-picoline depend on the concentration of the complex are green–blue, while in the O-donor solvent (like 2-ethoxyetanol, 2-methoxyethanol, etc.) are blue. The **IIa** and **IIb** complexes can be used as dyes for colouring cloths or as a pigments.

4. Conclusions

Recrystallisation of M(II)Pc (M = Be, Mg and Zn) in water-free 4-picoline solution yields to formation of monoaxially coordinated complexes for Be and Zn (BePc(4-Mepy) – I and ZnPc(4-Mepy) – **III**) and biaxially ligated one for Mg ($MgPc(4\text{-}Mepy)_2$ – **II**), while recrystallisation in not dried 4-picoline (containing water) yields to aqua(phthalocyaninato) complexes for Be and Mg ($BePc(H_2O)\cdot(4\text{-}Mepy)$ – **Ia** and $MgPc(H_2O)\cdot(4\text{-}Mepy)$ – **IIa** or $MgPc(H_2O)\cdot 3(4\text{-}Mepy)$ – **IIb**). In the case of ZnPc(4-Mepy), the recrystallisation in wet 4-picoline yields to the β-ZnPc in the microcrystalline form. The ligated by 4-picoline BePc and MgPc complexes (I and **II**) containing relatively hard Be^{2+} and Mg^{2+} cations in water/4-picoline solution prefer O-donor ligands and replace the 4-picoline molecule by water (hard O-ligand) in the coordination sphere of M forming the aqua(phthalocyaninato) complexes. The 4-picoline molecules can interact by lone-pair of electron at the N atom with coordinated water molecules, and could co-crystallise with the aqua(phthalocyaninato) complexes. The quantity of the solvent 4-picoline molecules depends on the crystallisation conditions. The solubility of the aqua(phthalocyaninato) complexes (**Ia**, IIa and **IIb**) is significantly greater than theirs initial M(II)Pc, due to the decreasing of the π–π stabilisation energy in the solid-state.

Appendix A. Supplementary data

CCDC 687352, 5873534 and 687354 contain the supplementary crystallographic data for **Ia**, IIa and **IIb**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.06.024.

	$-PO_3H_2$	–H	Leu-Gly(P)
–H	$-PO_3H_2$		Gly-(Bz)Cys(P), D(−)
			Gly-(Bz)Cys(P), D(+)

solutions. The concentration of nickel(II) chloride stock solution was standardized by complexometric ethylenediaminetetraacetate (EDTA) titration. Carbonate-free potassium hydroxide solution (the titrant) was prepared and standardized against a standard potassium hydrogen phthalate solution.

2.2. Potentiometric measurements

Potentiometric titrations of Leu-Gly, Leu-Gly(P), Gly-(Bz)Cys(P), D(−) and Gly-(Bz)Cys(P), D(+) and complexes with nickel(II) ions in the presence of 0.2 M KCl were performed under purified argon atmosphere at 25 ± 0.5 °C within the pH range of 2.5–10.5 (pH-meter – a Radelkis OP-208/1 instrument and an ABU-80 autoburette (Radiometer)) with CO_2-free ca. 0.13 M KOH as titrant. Changes in pH were monitored with a combined pH electrode SINGLE PORE, Hamilton, calibrated daily in hydrogen-ion concentrations by HCl (7.5×10^{-3} mol dm^{-3} in KCl) against standard KOH solution titrations [8].The resulting titration data were used to calculate the standard electrode potentials, E^0, and the dissociation constant for water ($pK_w = 13.73$). These values were then used to calculate the hydrogen-ion concentration [H^+] from e.m.f. readings. Sample volumes of 5 ml were used. The ligand concentration was 2.5×10^{-3}, 1.9×10^{-3} and 1.8×10^{-3} mol dm^{-3} for Leu-Gly, Leu-Gly(P) and Gly-(Bz)Cys(P), D(−), respectively and the metal ion:ligand ratios were 1:1, 1:2 and 1:6. The data were analyzed using SUPERQUAD program [9]. Standard deviations computed by SUPERQUAD refer to random errors only. The charges of the complexes have been omitted in the figures and tables. For clarity, it should be mentioned that the fully deprotonated forms of the ligands have negative charges L^{2-} and L^- for the monophosphono dipeptides and simple dipeptide, Leu–Gly, respectively.

2.3. NIR–Vis spectroscopy

The absorption spectra were obtained on a Jasco V-570 spectrophotometer using 5 cm and 10 cm quartz cells at room temperature. The spectra were recorded digitally (1.0 nm) over the range 300–1200 nm. The metal ion concentration was 8×10^{-3} mol dm^{-3} for the system with Leu-Gly, 6×10^{-3} mol dm^{-3} for the system with Leu-Gly(P), and concentration ratio of nickel(II):ligand were 1:1 and 1:4. The individual spectra of the nickel(II) complexes were calculated by means of method described in [10]. The absorption bands were fitted to Gaussian components using CFP program [11]. Ligand-field parameters and transition energies were calculated using the LFP program [12]. Both methods were described in detail [11,13,14] (and refs. therein). The assignment of bands is based on fitting the resolved band maxima (deconvolution of spectra) with the calculated transition energies (eigenvectors) using the d^8 quadrate energy levels with full configuration interactions and without spin–orbit coupling.

3. Results and discussion

The fully protonated form (H_3L^+) of Leu-Gly(P), Gly-(Bz)Cys(P), D(−) and Gly-(Bz)Cys(P), D(+) can release three protons. The first proton of the $-PO_3H_2$ group is very acidic (pK ca. 1.0–2.0), and thus this function group is fully deprotonated in the pH range studied in potentiometric titrations (2–10.5) and does not take part in metal coordination equilibria. The second proton comes from the phosphonic function $-PO_3H^-$ and the last one from the amino group $-NH_3^+$. The protonation constants of the studied monophosphono dipeptides together with simple dipeptide, Leu-Gly and the detailed discussion about the acid–base properties of these ligands can be found in our early paper [4].

Nickel(II) complexes of the most common dipeptides have already been studied by several authors and the metal binding modes of the species [NiL]$^+$ and [NiL_2] were described by (NH_2, CO)-coordination of the *N*-terminal [15–18]. Taking into account the octahedral coordination geometry of the metal ion the formation of [NiL_3]$^-$ was also suggested in some cases [17]. The presence of tris(ligand) complexes in well measured concentration requires the application of a high excess of ligand, thus, under our experimental conditions [$Ni(Leu\text{-}Gly)_3$]$^-$ species was not detected. Deprotonation and coordination of the amide functions generally take place at pH ca. 8 and it results in the existence of the species [$NiLH_{-1}$], [NiL_2H_{-1}]$^-$ and [NiL_2H_{-2}]$^{2-}$.

The titrations curves for the systems containing nickel(II) and studied phosphonic ligands were evaluated by assuming the same type of complexes as were determined for the simple aliphatic dipeptides. Due to the higher basicity of $-PO_3^{2-}$, as compared to

Table 2
Logarithmic protonation constants ($\log\beta_n^H$), logarithmic cumulative formation constants ($\log\beta_n$) and derived equilibrium constants ($\log K$) for the complexes formed with Ni^{2+} at 25 °C and I = 0.2 mol dm^{-3} (KCl)

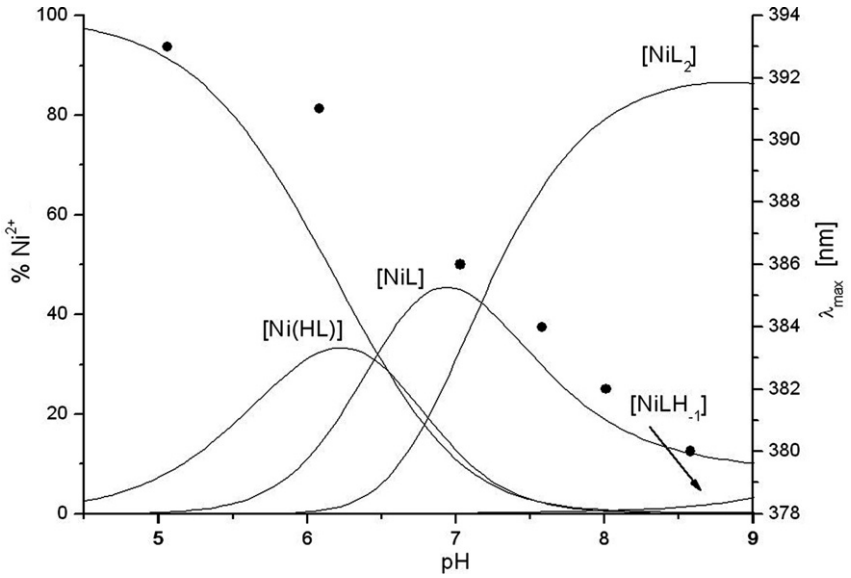

Fig. 1. Distribution diagram of Ni^{2+} complexes with Leu-Gly(P) as a function of pH simulated for conditions used in UV–Vis spectroscopy ($c_{Ni^{2+}}$ = 0.006, c_L = 0.024 mol dm^{-3}). λ_{max} (circle) of UV–Vis spectra recorded in different pH values are overlaid.

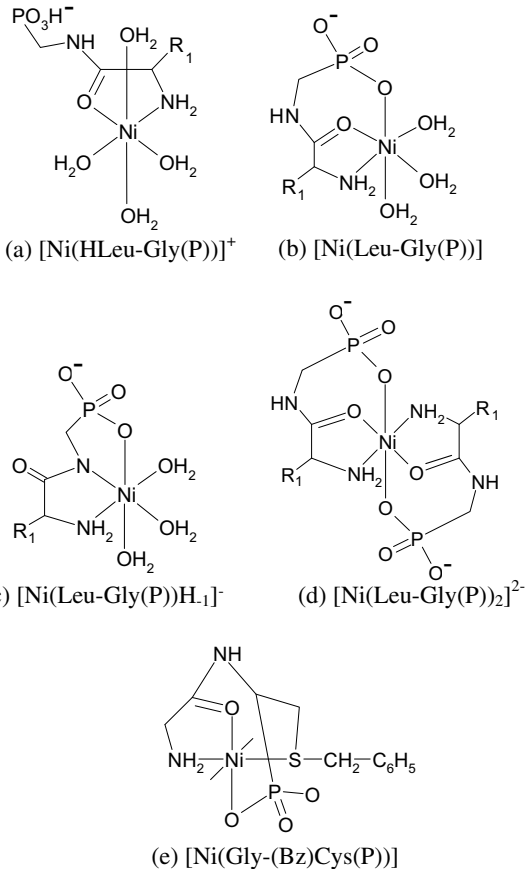
that for COO^-, the formation of protonated complexes was also taken into calculations. The best fits between the measured and calculated titration curves were obtained by assuming the species given in Table 2.

As an illustration, the species distribution diagram of Ni^{2+}–Leu-Gly(P) systems is presented in Fig. 1.

In the Ni^{2+}–Leu-Gly(P) system the formation of complexes starts about pH 5 and the precipitation of nickel hydroxide occurs at 9.0. In the acidic region the first protonated species $[Ni(HL)]^+$ is formed and has the maximum concentration at pH 6–6.5. This species is not formed with Leu-Gly because of the lower basicity of the carboxylate group. Taking into account a fact that the values of $\log K_{[Ni(HL)]} = \log\beta_{[Ni(HL)]} - pK_{PO_3H^-}$ of Leu-Gly(P) and $\log\beta_{[NiL]}$ of Leu-Gly are about of the same order of magnitude (Table 2), we can conclude that Leu-Gly(P) is coordinated to the metal ion in the [Ni(HL)] species in the same way as in the simple dipeptides, i.e., *via* the terminal amine and the peptide carbonyl group. This leads to the formation of the thermodynamically stable five-membered chelate ring. The formation of the major species [NiL] begins above pH 5.5 and reaches maximum concentration of ca. 50% at about pH 7. The $pK_{[Ni(HL)]}$ value (6.45) is identical to the value of the free Leu-Gly(P) (6.45) and corresponds to the dissociation constant of the non-coordinated $-PO_3H^-$ group. Because the basicity of Leu-Gly and Leu-Gly(P) is different, the metal binding abilities of the ligands may be estimated by considering the equilibrium constant of the reaction [21,22]: $M^{2+} + HL = [MLH_{-n}]^{(1-n)+} + (n+1)H^+$. The equilibrium constant of the reaction is K_{-n} (where n = 0, 1, 2) and it can be calculated by the equation: $\log K_{-n} = \log\beta_{11(-n)} - pK(HL)$. The $\log K_0$ and $\log K_{-1}$ values are included in Table 2.

The stability constant of [NiL] (K_0 = −4.60) is somewhat higher than that of the same type of the complex with Leu-Gly (K_0 = −4.71), suggesting the type of coordination shown in Scheme



Scheme 1. Tentative structures of the species formed in the Ni^{2+}–phosphonodipeptides systems.

1. This small stabilizing effect is probably derived from the additional coordination of the deprotonated phosphonic group apart from the amine and carbonyl groups to the nickel(II) ion (see below). The similar situation for other phosphonodipeptides was published in paper [23]. The next step in the ligand dissociation and formation of the $[NiLH_{-1}]^-$ species occurs above pH 8.5. The $pK_{[NiL]}$ value is equal 9.49 and presumably can be ascribed to the peptide amide group. For this species the coordination through amine, peptide amide and phosphonic groups is assumed. Precipitation of hydroxo complex(es) of nickel(II) was observed ca. pH 9. This precipitation suggests that the formation of hydroxo species and amide deprotonation takes place in overlapping processes and the $\log K_{-1}$ value (the $\log K_{-1}$ parameter reflects the relative stability of the $[MLH_{-1}]$ complex) cannot be unambiguously assigned to the overall stabilities of the $[MLH_{-1}]$ with (NH_2, N^-, $-PO_3^{2-}$) coordination modes. Possible structures of the discussed complexes are presented in Scheme 1.

In addition to the 1:1 complexes, the nickel(II) ion forms the $[NiL_2]$ complex. According to Kiss et al. [24] and Hermann et al. [23] we assume for this complex coordination to the metal ion *via* the amine, carbonyl and phosphonate groups. The effect of the $[NiL_2]$ species formation is observed in the electronic spectral changes. Fig. 1 presents variations of visible absorption maximum wavelength of the $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ parent octahedral band together with the species distribution as a function of pH. Its shift to higher energies above pH 6 is due to the involvement of nitrogen donors of ligand molecules in Ni^{2+} coordination. The spectra for the Ni^{2+}–Leu-Gly exhibit, approximately the same changes versus pH. The absorption spectra at the pH value where each species exhibit maximal contribution were resolved into the components corresponding to the individual species existing at that pH (as described in Ref. [10]). In general, the Ni^{2+} complexes with studied ligands (Leu-Gly and Leu-Gly(P)) have a distorted octahedral geometry (Fig. 2).

The molar absorptivity for the individual species was then calculated taking into account their distribution. The distribution-corrected curves for these species are shown in Fig. 3 and their parameters are included in Table 3. However, spectroscopic characterization of $[NiLH_{-1}]^-$ species was impossible because of its very low concentration under the applied experimental conditions and too large overlap with other complexes in the pH range 6–9.

The spectra of studied nickel(II) complexes display three absorption bands at ca. 9400–10020 (1063–998), 15333–16000 (576–625) and 25510–26525 cm^{-1} (392–377 nm), and shoulders

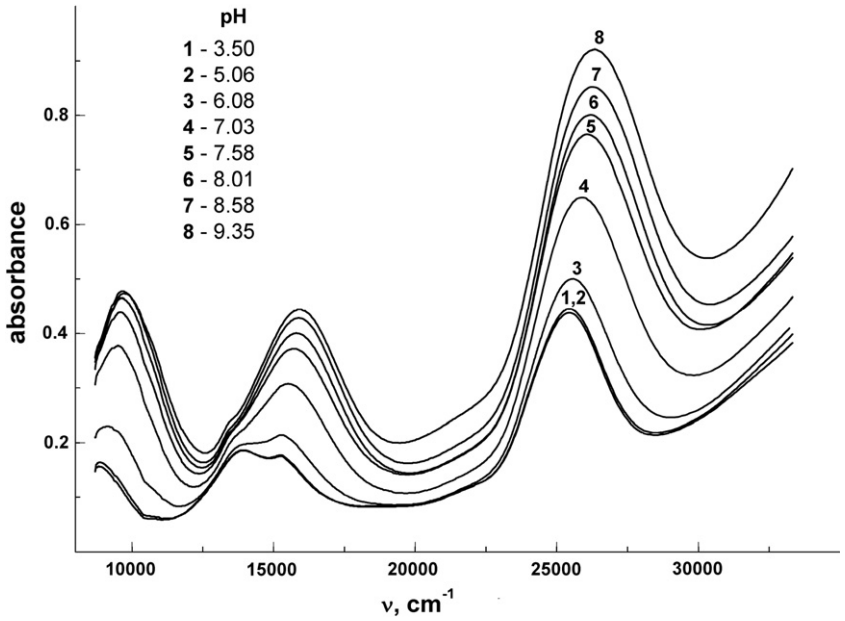


Fig. 2. The pH dependence of the absorption spectra recorded for Ni^{2+}–Leu-Gly(P) system at 1:4 metal:ligand ratio, $c_{Ni^{2+}} = 6.0058 \times 10^{-3}$ mol dm^{-3}.

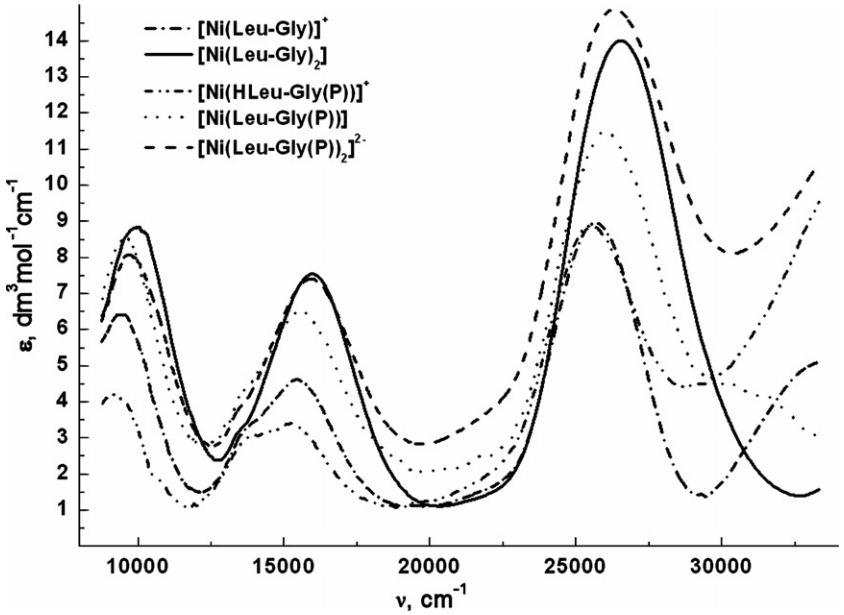

Fig. 3. Comparison of the electronic absorption spectra of nickel(II) complex species studied in aqueous solution at room temperature: $[Ni(Leu\text{-}Gly)]^+$, dash-dot; $[Ni(Leu\text{-}Gly)_2]$, solid; $[Ni(HLeu\text{-}Gly(P))]^+$, dash-dot-dot; $[Ni(Leu\text{-}Gly(P))]$, dot; $[Ni(Leu\text{-}Gly(P))_2]^{2-}$, dash.

at ca. 13 000 cm^{-1} (Fig. 3). The spectra of pseudo-octahedral (e.g., tetragonally distorted) nickel(II) complexes rarely display the lower symmetry components. A few cases are know that the Δ^1_{tetr} tetragonal splitting of $^3T_{2g}[3F]$ parent octahedral state is observed, only. The Δ^2_{tetr} and Δ^3_{tetr} splittings of $^3T_{1g}[^3F]$ and $^3T_{1g}[^3P]$, respectively, are always lower than Δ^1_{tetr}. These resolved tetragonal splittings are considerably lower than 1000 cm^{-1}, from Gaussian analysis of the dihalogenotetrakis(pyridine) nickel(II) complexes [13,25,26]. Whereas, the average band halfwidths of the tetragonal components of all the spectra are not less than 2200 cm^{-1}. This fact explains why the maxima or shoulder are not observed in the experimental solutions spectra, even though the formal symmetry of the complexes is lower. It is immediately evident from Fig. 3 that no tetragonal splitting, even of the first band, is observed. However, the symmetry was assumed to be D_{4h} and the electronic spectra fitted this model.

Fig. 4 shows, as the example, the spectra of the $[Ni(HLeu\text{-}Gly(P)]^+$ and $[Ni(Leu\text{-}Gly(P))_2]^{2-}$ complexes together with Gaussian components. Table 3 presents the ligand-field parameters (crystal field model (CFM) and angular orbital model (AOM)), of some complex species formed with Leu-Gly and Leu-Gly(P) in aqueous solution of nickel(II). Calculated transition energies are compared with those obtained by Gaussian resolution of the experimental spectra. The agreement between experimental and calculated transition energies is satisfactory.

In this and previous papers we used the sign conversion of Perumareddi [27] even though the CFM parameter set was originally introduced by Ballhausen and Moffit [28]. It should be noted that Perumareddi changed the signs of the Ds and Dt parameters. The crystal field parameters (CFM) of the complexes (Table 3) suggest elongation of z axis in pseudo-octahedral complexes, but this affect is lowest for $[Ni(HLeu\text{-}Gly(P))]^+$ species. The symmetry reduction from octahedral to D_{4h}, or C_{4v} (D_{4h} holohedrized symmetry) is due to a weaker donor field along the z axis (i.e., $Dq^{(xy)} > Dq^{(z)}$). The Dq_{xy} values of all the complexes are very close but the lowest for $[Ni(HLeu\text{-}Gly(P))]^+$ complex. Furthermore, the tetragonal Dt parameter values are similar in the errors limit (except $[Ni(HLeu\text{-}Gly(P))]^+$ complex) whilst the $Dq^{(z)}$ parameters are different. This suggests, according to relationship $Dt = (-4/9)(Dq^{(xy)} - Dq^{(z)})$, that influences on the central ion are weaker in the [NiL] species, i.e., both axial and equatorial positions. The greatest differences are observed for the $[Ni(HLeu\text{-}Gly(P))]^+$ species that correspond to the lowest tetragonal distortion, i.e., $Dq^{(xy)} \cong Dq^{(z)}$, and Dt value closes to zero. Thus, in this case axial positions are occupied by water molecules only, whilst equatorial positions are mixed (Scheme 1a). The angular overlap parameters of water molecules are as expected, i.e., $e_\sigma(H_2O) \cong 5000$ and $e_\pi(H_2O) \cong 1500\ cm^{-1}$. In the all other cases AOM parameters are averaged, i.e., for axial and equatorial donors, respectively. Their values confirm also elongation of z axis in pseudo-octahedral complexes. The e_σ and e_π bonding abilities of equatorial donors are stronger then axial.

The stronger effect is observed in the case of the $[NiL_2]$ species. The $Dq^{(xy)}$ is distinctly higher than $Dq^{(z)}$ parameter and Dt parameter is the highest (Table 3). These values clearly indicate that the deprotonated phosphonic groups are involved in the coordination to the metal ions (Scheme 1d). Otherwise, the same tetragonal effects should be observed in the both complex species. A little weaker tetragonal distortion in [NiL] species arises, because of averaged influences of two different groups in an axial positions,

Table 3
Ligand-field parameters, CFM[a] and AOM, of the complex species in aqueous solution, in cm^{-1}

Parameter	$[Ni(Leu\text{-}Gly)]^+$	$[Ni(Leu\text{-}Gly)_2]$	$[Ni(HLeu\text{-}Gly(P))]^+$	$[Ni(Leu\text{-}Gly(P))]$	$[Ni(Leu\text{-}Gly(P))_2]^{2-}$

$e_\pi^{(ax)}$	1841(263)	1723(246)	1427(262)	1915(330)	1756(280)

[a] For Ds and Dt signs formalism of perumareddi was assumed.
[b] B parameter for the ion Ni(II) equals 1084 cm^{-1} (from Ref. [29]).

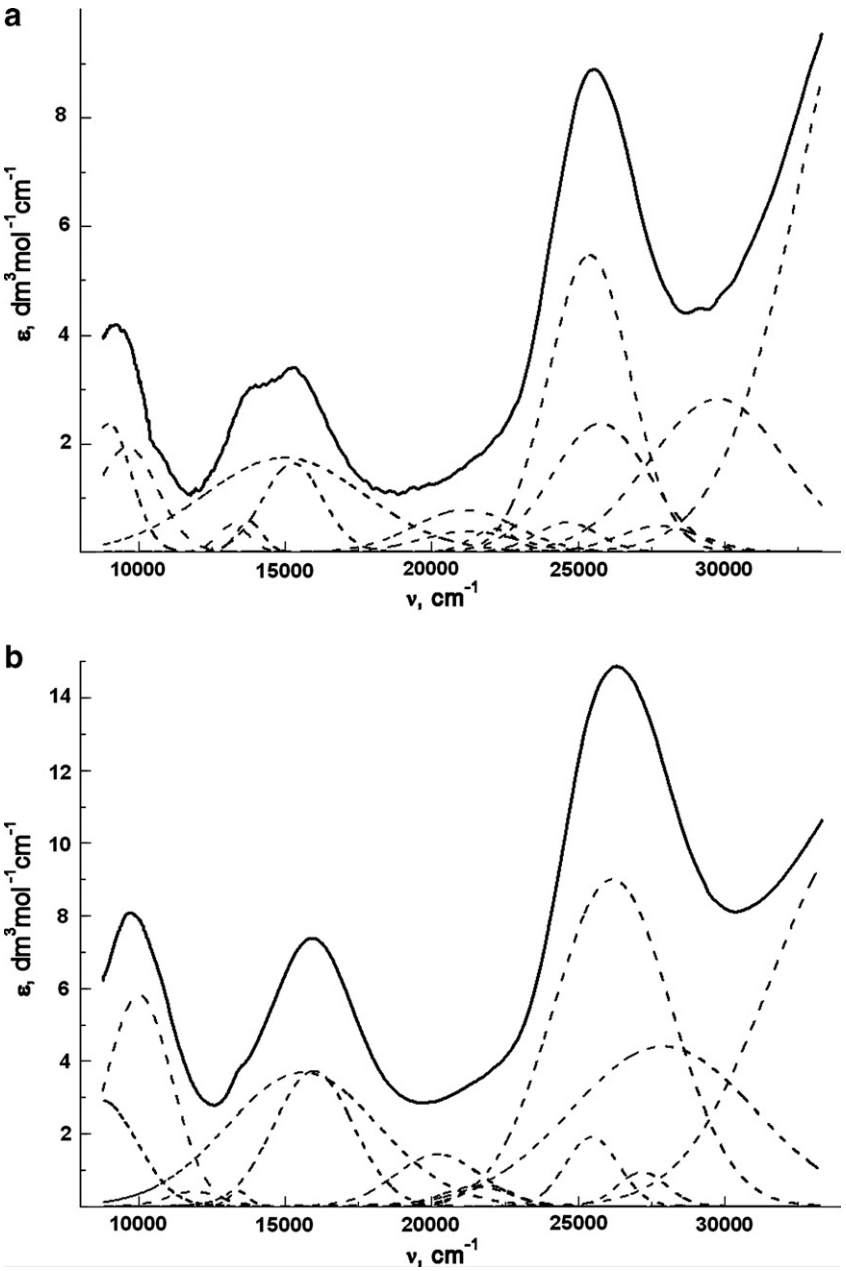

Fig. 4. Electronic absorption spectra in aqueous solution and Gaussian analysis as the example, (a) $[Ni(HLeu\text{-}Gly(P))]^{+}$, (b) $[Ni(Leu\text{-}Gly(P))_2]^{2-}$; experimental spectrum – solid, component bands – dash.

i.e., phosphonic group and water molecule (Scheme 1b). Generally, [NiL] species have somewhat lower Dq values than $[NiL_2]$ species, as well as Racah *B* parameter, for both the ligands analysed. The last shows less covalent character of bonding for $[NiL_2]$ species. The nefeloauxetic β parameters increase in order:

$$[Ni(HLeu\text{-}Gly(P))]^{+} \cong [Ni(Leu\text{-}Gly)]^{+} \cong [Ni(Leu\text{-}Gly(P))] < [Ni(Leu\text{-}Gly)_2] < [Ni(Leu\text{-}Gly(P))_2]^{2-}$$

Due to the fact that in the Ni(II)–Gly-(Bz)Cys(P), D(−) or Ni(II)–Gly-(Bz)Cys(P), D(+) systems the strong tendency to the precipitation was observed, the recording and the detailed analysis of absorption spectra were impossible. Anyway, the equilibrium model for these systems differ if compared with system of Leu-Gly(P) only by the present of an additional $[NiL_2H_{-1}]$ species (Table 2). The overall stability constants can be directly used to compare, because the basicity of these studied phosphonic ligands are almost the same. A comparison of $\log K_n$ of the nickel(II) complexes of Leu-Gly(P) with Gly-(Bz)Cys(P), D(−) or Gly-(Bz)Cys(P), D(+) shows significant differences (Table 2). These values suggest that the thermodynamic stability constants of the species with Gly-(Bz)Cys(P) are higher than with Leu-Gly(P). The differences in $\log K_1$ and $\log K_2$ of ca. 1.0 log units, respectively, suggest additional interaction between sulfur donor atom and nickel(II) in the complex species of Gly-(Bz)Cys(P), D(−) or Gly-(Bz)Cys(P), D(+) (Scheme 1e).

4. Conclusion

Due to the higher basicity of $-PO_3^{2-}$, as compared to that for CO_2^{-}, the formation of 1:1 protonated complexes in nickel(II)-monophosphono dipeptides systems were detected in compared to system with Leu-Gly. From the comparative analysis of the sta-

bility and the NIR–Vis spectroscopy data it has been established that the coordination in [NiHL] species is realised by the terminal amine and the peptide carbonyl group, the axial positions are occupied by water molecules. In this complex species the lowest tetragonal distortion is observed. In the [NiL] species the coordination is through the amine, carbonyl and the deprotonated phosphonic group. The coordination of two different groups in an axial positions (phosphonic group and water molecule) results in a little stronger tetragonal distortion if compare to the protonated species. In the $[NiLH_{-1}]$ species coordination by amine, peptide amide and phosphonic group is assumed. The strongest tetragonal distortion is observed in the case of $[NiL_2]$ species. In this species the deprotonated phosphonic group are involved in the coordination to the metal ions in both axial positions. In the case of nickel(II) complexes with Gly-(Bz)Cys(P), D(−) or Gly-(Bz)Cys(P), D(+) additional interaction between sulfur donor atom and nickel(II) is suggested.

4-nitrobenzophenone thiosemicarbazone ($H4NO_2Bz4M$) (Fig. 1) as well as their ruthenium(II) complexes containing triphenylphosphine or 1,4-bis(diphenylphospine)butane (dppb). A study of the luminescence characteristics of the free thiosemicarbazones and their ruthenium(II) complexes has been performed. X-ray crystal structure of N^4-methyl 4-nitrobenzaldehyde thiosemicarbazone are also reported.

2. Experimental

2.1. Physical measurements

Elemental analyses were performed on a Fison equipment, model EA 1108. A Radiometer Copenhagen Meter Lab., model CDM 230 was employed for molar conductivity measurements. Infrared spectra (KBr pellets) were obtained using a BOMEM MICHELSON instrument, model 102. NMR spectra were obtained at room temperature with a Brucker DRX-400 Avance (400 MHz) spectrometer. For ^1H measurements, $CDCl_3$ was used as solvent and tetramethylsilane (TMS) as internal reference while for $^{31}P\{^1H\}$ (161 MHz), CH_2Cl_2 was used as solvent and H_3PO_4 85% as external reference.

The electrochemical experiments were carried out at room temperature in dichloromethane containing 0.1 mol L^{-1} tetrabutylammonium perchlorate (TBAP) (Fluka Purum) using an electrochemical analyzer from Bioanalytical Systems Inc. (BAS), model 100BW. The working and auxiliary electrodes were stationary Pt foils, and the reference electrode was Ag/AgCl, a medium in which ferrocene is oxidized at 0.48 V (Fc^+/Fc).

Luminescence studies were made on a Perkin–Elmer LS 55 spectrofluorimeter using 10 nm spectral bandpass. Fluorescence measurements were performed in solution using CH_2Cl_2 as solvent conditioned in 1 cm quartz cells. For the phosphorescence measurements, a front solid surface apparatus (Perkin–Elmer) was employed to allow the use of cellulose as the support. The signals were measured directly from the surface dry cellulose substrates (treatment for background reduction [8]) using detector delay and gate times set at 3 ms. Measurements were made in an oxygen free environment established by the use of a purging gas flow (dried nitrogen gas). Solutions (5 μL) of the free thiosemicarbazones and their metal complexes, prepared in CH_2Cl_2, were deposited on the center of the cellulose substrates. These substrates were previously spotted with 5 μL of heavy atom salts solutions which were used as potential heavy atom phosphorescence inducers. Tl(I), Hg(II), Pb(II), Cd(II), Ag(I) and iodine were used as potential heavy atom phosphorescence inducers. Measurements were made after the substrates were dried under vacuum (2 h).

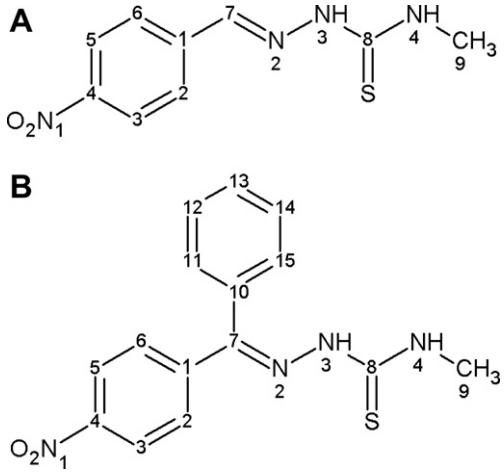

Fig. 1. Structure of (a) N^4-methyl-4-nitrobenzaldehyde thiosemicarbazone ($H4NO_2Fo4M$) and (b) N^4-methyl-4-nitrobenzophenone thiosemicarbazone ($H4NO_2Bz4M$).

2.2. X-ray crystallography

Single crystals of $H4NO_2Fo4M$, adequate for structural X-ray diffraction work, were obtained after slow evaporation of the solvent (ethanol) from the solution. Data were collected with an *Enrof-Nonius Kappa*-CCD [9] diffractometer and graphite-monochromatized Mo Kα radiation. Data were obtained using the PHICHI [10] and EVALCCD [11] software and they were corrected using SADABS [12]. The structure was solved by direct methods and refined on F^2 with anisotropic temperature parameters for all non H atoms [13]. H atoms of the phenyl and methyl groups were positioned geometrically (C–H = 0.93 Å for Csp^2 atoms and C–H = 0.96 Å for Csp^3 atoms) and treated as riding on their respective C atoms, with $U_{iso}(H)$ values set at $1.2U_{eq}Csp^2$ and $1.5U_{eq}Csp^3$.

2.3. Syntheses of $[RuCl_2(PPh_3)_3]$ and $[RuCl_2(dppb)(PPh_3)]$

$[RuCl_2(PPh_3)_3]$ and $[RuCl_2(dppb)(PPh_3)]$ were prepared according to previously described procedures [14,15].

2.4. Synthesis of N^4-methyl 4-nitrobenzaldehyde thiosemicarbazone ($H4NO_2Fo4M$) and N^4-methyl 4-nitrobenzophenone thiosemicarbazone ($H4NO_2Bz4M$)

N^4-Methyl thiosemicarbazide has been purchased from Aldrich and used without further purification. The thiosemicarbazones were obtained by mixing equimolar amounts of 4-nitrobenzaldehyde and 4-nitrobenzophenone (6.6×10^{-3} mol) with N^4-methyl thiosemicarbazide in absolute ethanol (40 mL) with addition of 2–4 drops of concentrated sulfuric acid as catalyst. The reaction mixture was kept under reflux for 6–7 h.

2.5. Syntheses of $[Ru(4NO_2Fo4\,M)_2(PPh_3)_2]$ and $[Ru(4NO_2Bz4M)_2(PPh_3)_2]$

The complexes were obtained by dissolving the desired thiosemicarbazone (0.200 mmol) in CH_2Cl_2 under argon atmosphere followed by addition of solid $[RuCl_2(PPh_3)_3]$ (0.200 mmol). The reaction mixtures were kept under stirring at room temperature for 5 h. The solids precipitated upon addition of anhydrous hexane and were filtered and washed with diethylether.

3. Results and discussion

3.1. Microanalyses and molar conductivity studies of the ruthenium(II) complexes

Microanalyses and molar conductivity data suggest the formation of [Ru(4NO$_2$Fo4M)$_2$(PPh_3)$_2$] (**1**), [Ru(4NO$_2$Bz4M)$_2$(PPh_3)$_2$] (**2**), [Ru(4NO$_2$Fo4M)$_2$(dppb)] (**3**) and [Ru(4NO$_2$Bz4M)$_2$(dppb)] (**4**). In all complexes CH_2Cl_2 crystallization molecules are present, as confirmed by their ^1H NMR spectra.

3.2. Infrared spectral studies

In the infrared spectra, the ν(C=N) stretching vibration of the thiosemicarbazones at 1599 cm^{-1} shifts to 1586–1562 cm^{-1} in the complexes, indicating coordination of the imine nitrogen [6,16,17]. The absorption at 821–830 cm^{-1} in the spectra of the free bases, attributed to the ν(C=S) vibration, shifts to 743–784 cm^{-1} in the spectra of the complexes, indicating coordination through a thiolate sulfur [6,16,17]. Absorptions at 496–486 cm^{-1} and 441–420 cm^{-1} in the spectra of the complexes were tentatively attributed to the ν(Ru–N) and ν(Ru–S) vibrations [18,19]. Hence the infrared spectra indicate coordination through the N–S chelating system.

3.3. NMR spectral studies

The ^1H NMR spectra of the thiosemicarbazones in $CDCl_3$ show a singlet at δ 9.30 which is attributed to N(3)–H. In the spectra of complexes (**1**)–(**4**) ($CDCl_3$) there are no signals attributable to N(3)–H, indicating coordination of the thiosemicarbazones under the anionic form upon deprotonation at N(3). Moreover the singlet at δ 5.27 is compatible with the presence of CH_2Cl_2 solvation molecule in all cases.

In the $^{31}P\{^1H\}$ NMR spectra of the complexes only one singlet was observed in all cases. For complex (**1**) the singlet at δ 38.6 was attributed to *cis*[Ru(4NO$_2$Fo4M)$_2$(PPh_3)$_2$], in which the two PPh_3 molecules are in *cis* position to each other and probably in *trans* position to the imine nitrogens of the thiosemicarbazone chain. In fact, in previous works $^{31}P\{^1H\}$ NMR signals at ca. δ 38 have been assigned by us to phosphines *trans* to the imine nitrogens of the thiosemicarbazone moiety [19,20]. For complex (**2**) the singlet at δ 29.2 was attributed to *trans*[Ru(4-NO_2Bz4M)$_2$(PPh_3)$_2$] in which the two phosphine ligands are *trans* to each other. For complexes (**3**) and (**4**) the singlet occurs at ca. δ 38, suggesting that the phosphorous atoms of the dppb molecule is *trans* to the imine nitrogen of the thiosemicarbazone chain [19–21].

3.4. Electrochemistry

The voltammograms of the thiosemicarbazones show a quasi-reversible process between −0.91 and 0.93 V, which has been attributed to the formation of the Ar-$NO_2^{\cdot-}$ radical. The second process between −1.11 and −1.21 V has been assigned to the formation of the Ar-NHOH species and the irreversible oxidation at 0.20–0.21 V to the formation of Ar-NO (Fig. 2). The observed signals correspond to the well known mechanism for the nitro aromatic reduction, as previously proposed by us [6] and by other authors [22–25]. Eqs. (1)–(3) describe the suggested electrochemical mechanism.

$$\text{Ar-NO}_2 + e^- \leftrightharpoons \text{Ar-NO}_2^{\cdot-} \quad (1)$$

$$\text{Ar-NO}_2^{\cdot-} + 3e^- + 4H^+ \rightarrow \text{Ar-NHOH} + H_2O \quad (2)$$

$$\text{Ar-NHOH} \leftrightharpoons \text{Ar-NO} + 2e^- + 2H^+ \quad (3)$$

The voltammograms of complexes (**1**)–(**4**) show a quasi-reversible process attributed to the Ru^{II}/Ru^{III} oxidation (between 0.68 V and 0.36 V) followed by the Ru^{III}/Ru^{II} reduction (between 0.49 and 0.28 V) (see Table 1). The formation of the Ar-$NO_2^{\cdot-}$ radical has been observed separately in the voltammograms of the complexes (**1**) and (**4**). In the other cases, this radical has not been observed separately, indicating that once formed it reacts immediately. The process occurring in the −1.05 and −1.19 V

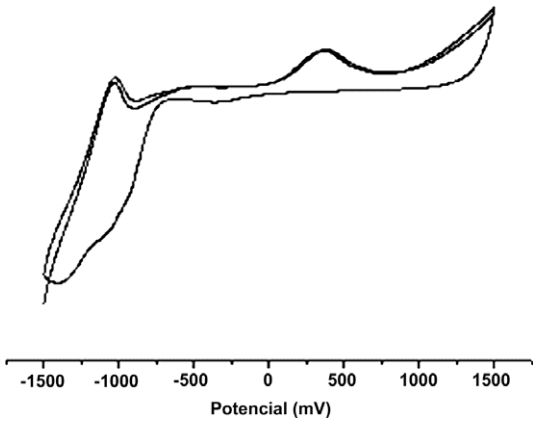

Fig. 2. Cyclic voltammogram of N^4-methyl-4-nitrobenzaldehyde thiosemicarbazone (H4NO$_2$Fo4M) (CH_2Cl_2, 0.1 mol L^{-1} TBAP).

Table 1
Cyclic voltammetry data for the N^4-methyl 4-nitrobenzaldehyde ($H4NO_2Fo4M$) and N^4-methyl 4-nitrobenzophenone thiosemicarbazones ($H4NO_2Bz4M$) (0.100 V s^{-1}, CH_2Cl_2, 0.1 mol L^{-1} TBAP)

Compound	Ar-$NO_2^{\cdot-}$ (V) E_{pc}	Ar-NHOH (V) E_{pc}	Ar-NO (V) E_{pa}
$H4NO_2Fo4M$	−0.93	−1.11	0.21
$H4NO_2Bz4M$	−0.91	−1.21	0.20

range has been attributed to the formation of Ar-NHOH. The remaining processes have been assigned to the thiosemicarbazone moiety, as previously proposed by us [26].

The foregoing results show that the electrochemical behaviors of the two thiosemicarbazones are very similar. Comparison between the values of redox potentials of the two series of complexes (see Table 2) reveal that the complexes with 4-nitrobenzaldehyde thiosemicarbazone undergo oxidation easier than those with 4-nitroacetophenone thiosemicarbazone, probably due to differences in electronic effects of the group attached to C7 (H or C_6H_5). Coordination does not appreciably affect the potential of formation of the Ar-NHOH species, suggesting that its radical precursor must also be formed approximately at the same potential in the free ligands as well as in their corresponding ruthenium(II) complexes.

3.5. Luminescence studies

Similar fluorescence spectra were observed for $H4NO_2Fo4M$, $H4NO_2Bz4M$ and their Ru(II) complexes (Fig. 3). The shapes of the spectral bands of the complexes were characteristic of the thiosemicarbazone ligands with maximum excitation at 214 nm and the respective emission between 293–295 nm. However significantly different fluorescence intensities are observed, which may be explained by the presence of Ru(II) and by the relative rigidity of the molecular structures. When considering $H4NO_2Fo4M$ and its Ru(II) complexes, these effects can be clearly identified. First, the presence of Ru(II) in the molecular structure causes an internal heavy atom effect of transferring electron population from the excited singlet state (S_1) to the excited triplet state (T_1), with a decrease of the population available for the $S_1 \rightarrow S_0$ transition. On the other hand, when the two Ru(II) complexes are compared, the larger fluorescence quantum yield is observed for the more rigid structure, in this case, the $[Ru(4NO_2Fo4M)_2(dppb)]$ (**3**), which is less prone to be affected by radiationless processes caused by the natural vibration of the molecular structure.

For $H4NO_2Bz4M$ and its complexes, the rigidity still explains the higher fluorescence observed for $[Ru(4NO_2Bz4M)_2(dppb)]$ (**4**) comparative to $[Ru(4NO_2Bz4M)_2(PPh_3)_2]$ (**2**). However, fluorescence from (**4**) is also stronger than that characteristic of the $H4NO_2Bz4M$, indicating that the C_6H_5– group of this thiosemicarbazone has a strong contribution to the radiationless loss of energy of the excited state population (through vibrational processes). In this case, the formation of the $[Ru(4NO_2Bz4M)_2(dppb)]$ somehow minimizes vibrational relaxation processes to a point that the fluorescence from $[Ru(4NO_2Bz4M)_2(dppb)]$ is higher than the one from the ligand despite the increase of intercrossing system efficiency caused by Ru(II).

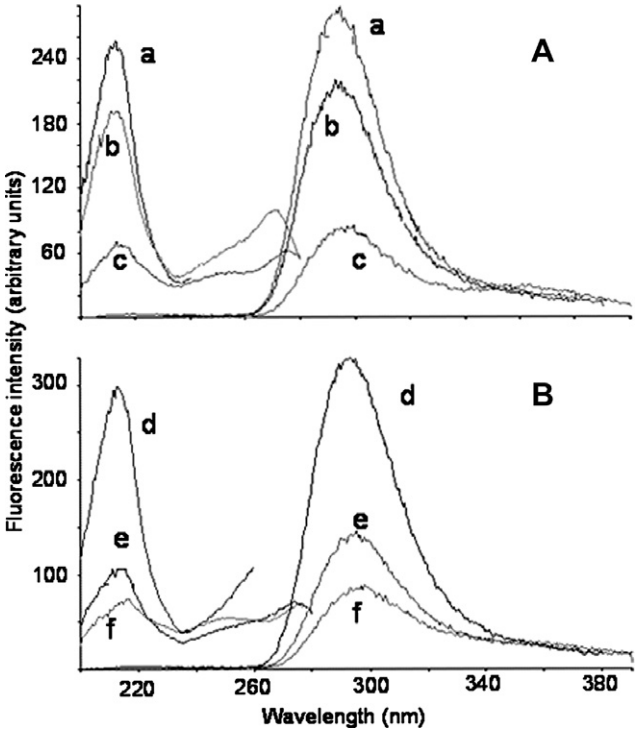

Fig. 3. Emission and excitation fluorescence spectra in CH_2Cl_2 solutions of: A (a) $H4NO_2Fo4M$, (b) $[Ru(4NO_2Fo4M)_2(dppb)]$ (**3**), (c) $[Ru(4NO_2Fo4M)_2(PPh_3)_2]$ (**1**); and B (d) $[Ru(4NO_2Bz4M)_2(dppb)]$ (**4**), (e) $H4NO_2Bz4M$, (f) $[Ru(4NO_2Bz4M)_2(PPh_3)_2]$ (**2**).

No phosphorescence was observed from $H4NO_2Fo4M$, $H4NO_2Bz4M$ and their Ru(II) complexes even if favorable environmental conditions (absence of oxygen, presence of heavy atom enhancers/inducers and in the rigidicity of a dry and solid substrate).

The natural fluorescence from these thiosemicarbazones and their Ru(II) complexes provides a way to identify the presence and to monitor the concentration of these chemical species in biological systems.

3.6. Crystal structure of $H4NO_2Fo4M$

Crystal data and refinement results of $H4NO_2Fo4M$ are shown in Table 3. ORTEP3 view of the structure can be seen in Fig. 4. Table 4 shows selected bond distances [Å] and angles [°]. Hydrogen bonds parameters are shown in Table 5.

$H4NO_2Fo4M$ crystallizes in the triclinic system, P-1 space group with Z = 4 and adopts the *EE* configuration, like N^4-methyl 4-nitroacetophenone thiosemicarbazone ($H4NO_2Ac4M$), the structure of which has been reported previously by us [16].

As expected, the bond distances are very similar in $H4NO_2Fo4M$ and $H4NO_2Ac4M$. However C7–C1 is 1.466(2) in $H4NO_2Fo4M$ and 1.233(4) in $H4NO_2Ac4M$. The C7–N2–N3 and N2–C7–C1 bond angles are 116.70(3)° and 120.77(3)° respectively in $H4NO_2Fo4M$ and 119.6(3)° and 114.6(3)°, respectively, in $H4NO_2Ac4M$, probably due to differences in steric and electronic effects between the group attached to C7 (H or methyl).

The crystal structure of $H4NO_2Fo4M$ is stabilized by N–H···N and C–H···S intra-molecular interactions and by N–H···O, O–H···O, O–H···S and C–H···O intermolecular interactions (Figs. 5a and b). Intra-molecular interactions make both molecules practically planar rigid structures. The angle between the mean plane C1–C2–C3–C4–

C5–C6 and the plane involving N2–N3–C8–N4 is 3.87(1)° and that between the C11–C12–C13–C14–C15–C16 and N12–N13–C18–N14 planes is 6.35(1)°. In $H4NO_2Ac4M$ this angle is 24.7(2)°. Fig. 6 shows the primitive cell in the [0 0 1] direction.

The values of densities and melting points of $H4NO_2Fo4M$ (1.423 Mg/m^3, 225–226 °C) and $H4NO_2Ac4M$ (1.404 Mg/m^3,

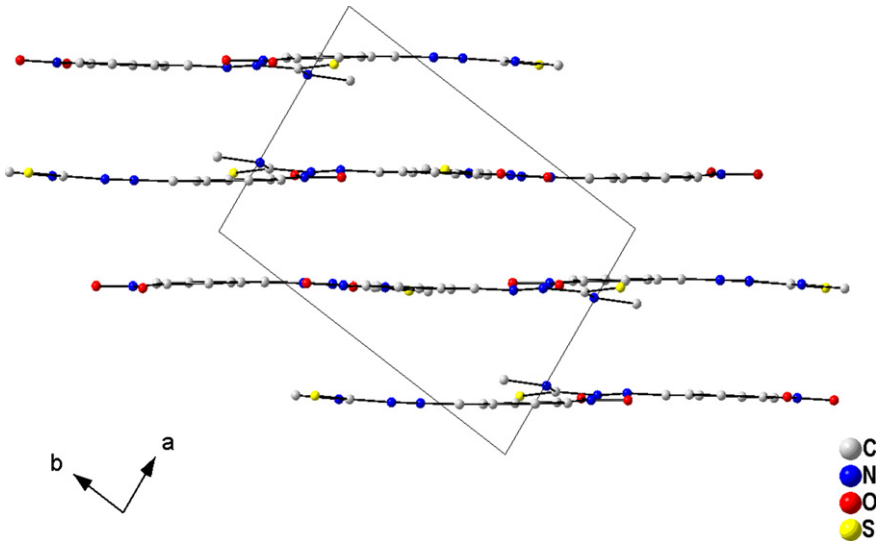

Fig. 6. View of the primitive cell of $H4NO_2Fo4M$ with molecules in a planar arrangement.

216.3–217.6 °C) [16]) are in agreement with a closer packing for the first, as revealed by crystal structure determinations.

4. Conclusions

The above mentioned results suggest that the studied complexes might present anti-trypanosomal activity. Moreover, the intrinsic fluorescence of the thiosemicarbazones and their Ru(II) complexes could be useful for monitoring their uptake into cells and in the investigation of their mechanisms of action.

molecules [26]), and the character of ligands (bpy *versus* phen), in terms of inductive and anisotropic effects, caused by LL and Cl groups within a given coordination sphere/geometry. Finally, we have calculated the respective δ^{1H}_{calc}, δ^{13C}_{calc}, δ^{15N}_{calc} parameters by semi-empirical quantum-chemical methods (B3LYP/LanL2DZ+6-31G**// B3LYP/LanL2DZ+6-31G*).

An additional advantage of these multinuclear magnetic resonance studies is the confirmation of N(1),N(1′) chelation mode of bpy and phen {due to the simplicity and easier comparison of the concerned N-donor ligands, also in case of phen we will use its symmetric numbering C(1a)–N(1)···C(5)–C(5′)···N(1′)–C(1a′), instead of the common one C(1a)–N(1)···C(5)–C(6)···N(10)–C(10a)}. In fact, such bidentate coordination was proved till now only for solid *cis*-[Ir(bpy)$_2$Cl$_2$]Cl · 2H$_2$O and *cis*-[Ir(phen)$_2$Cl$_2$]-NO$_3$ · 3H$_2$O (basing on similarity of their X-ray powder diffraction patterns to the respective Co(III), Rh(III) and Cr(III) analogues [29]), as well as for *cis*-[Ir(phen-κ^{2}N(1),N(1′))$_2$Cl$_2$]PF$_6$ (by single crystal X-ray diffraction (AMIPIV) [30]; all reference codes in this paper derive from the Cambridge Structural Database [31]). Especially in case of bpy this problem is worthy to be discussed as its Ir(III) complexes often exhibit alternative complexation types, either in the solid phase ([Ir(bpy)$_2$(bpy*)]$^{3+}$ in [Ir(bpy-κ^{2}N(1),N(1′))$_2$(bpy*-κ^{2}N(1),C(3′))](ClO$_4$)$_3$ · H$_2$O (BARWIA, BARWIA01) [32,33] and [Ir(bpy)$_2$(bpy**)]$^{2+}$ in [Ir(bpy-κ^{2}N(1),N(1′))$_2$(bpy**-κ^{2}N(1),C(3′))](ClO$_4$)$_2$ · 1/3H$_2$O (CEDYOZ) [16] {bpy*, bpy** = the neutral/negatively (−1) charged N(1),C(3′)-coordinated bpy species, deprotonated at C(3′) and protonated/unprotonated at N(1′)}, together with [Ir(bpy)$_3$]$^{3+}$ in [Ir(bpy-κ^{2}N(1),N(1′))$_3$](ClO$_4$)$_3$ · 7/3H$_2$O (CEZMAV) [32]) or in the solution ([Ir(bpy)(bpy**)Cl]$_2^{2+}$ [34], [Ir(bpy)$_2$(bpy*)]$^{3+}$ [35–37], [Ir(bpy)$_2$(bpy**)]$^{2+}$ [16,37,38], [Ir(bpy)$_2$(bpy***)(H$_2$O)]$^{3+}$ {bpy*** = the neutral, monodentately N(1)-coordinated bpy molecule} [15,39,40], [Ir(bpy)$_2$(bpy · H$_2$O)]$^{3+}$ {bpy · H$_2$O = the covalently hydrated, neutral N(1),N(1′)-chelated bpy molecule} [41], [Ir(bpy)$_2$(bpy***)(OH)]$^{2+}$ [15,42,43], together with [Ir(bpy)$_3$]$^{3+}$ [16,24,44,45]).

2. Experimental

2.1. Materials

K$_3$[IrCl$_6$] was purchased from Aldrich, while bpy and phen · H$_2$O (>99% purity) from POCh Gliwice (Poland).

2.2. Syntheses

K$_2$[Ir(H$_2$O)Cl$_5$] was prepared in a way similar to that described by Delepine [46] and Sinitsyn et al. [8]. Fifty-two milligrams of K$_3$[IrCl$_6$] were dissolved in 50 cm^3 of water and left at the room temperature for 1 week (during which the aquation reaction of [IrCl$_6$]$^{3-}$ + H$_2$O → [Ir(H$_2$O)Cl$_5$]$^{2-}$ + Cl$^-$ spontaneously occurred), with slow evaporation to *ca.* 10 cm^3. The yield of the precipitated K$_2$[Ir(H$_2$O)Cl$_5$] green-brown powder was 37 mg (*ca.* 80%).

Both K[Ir(LL)Cl$_4$] coordination compounds were synthesised by the method of Lee et al. [13], *i.e.* by moderate heating (50 °C, 1 h) of water + ethanol (1:1) solutions containing K$_3$[IrCl$_6$] and bpy or phen (at the 1:1 stoichiometric ratios). *cis*-[Ir(bpy)$_2$Cl$_2$]Cl · 2H$_2$O was obtained according to Watts et al. [15], *i.e.* by intense heating (150 °C, 6 h) of K$_3$[IrCl$_6$] and bpy in glycerol, whereas *cis*-[Ir(phen)$_2$Cl$_2$]Cl · 3H$_2$O was prepared following Gillard et al. [14], *i.e.* by stirring K$_3$[IrCl$_6$] in the melted phen · H$_2$O (110 °C; 6 h); in both cases the fivefold excess of the respective azine ligand (K$_3$IrCl$_6$:LL = 1:10) was used. In all preparations the final reaction mixtures were cooled to the room temperature, and the formed ionic complexes were extracted with water (owing to the insolubility of bpy/phen). They were then separated from the simultaneously formed KCl and/or unreacted K$_3$[IrCl$_6$] by precipitation upon cooling to 5 °C. The yields were *ca.* 30–40%.

2.3. Instrumentation

The far-IR spectra were measured in the 100–400 cm^{-1} range with a Perkin–Elmer Spectrum 2000 FT-IR spectrometer, using polyethylene discs. The ^{1}H–^{13}C and ^{1}H–^{15}N HMBC/HSQC/HMQC spectra (^{1}H, ^{13}C referenced to TMS; ^{15}N to external CH$_3$NO$_2$) were measured in saturated D$_2$O (bpy complexes) or DMSO-d_6 (phen complexes) solutions, at 303 K, using a Varian INOVA 500-MHz NMR spectrometer, equipped with an inverse ^{1}H{^{31}P/^{15}N} 5 mm Z-SPEC Nalorac probe with an actively shielded *z*-gradient coil. The pulse sequencies were principally the same as those used during our earlier studies on the coordination compounds with some other transition metals [26,27]. Some additional ^{1}H NMR measurements for K[Ir(bpy)Cl$_4$] in DMSO-d_6 and K[Ir(phen)Cl$_4$] in D$_2$O were performed by a Bruker Avance 300-MHz NMR spectrometer.

2.4. Crystal structure determination

The green-brown single crystals of K$_2$[Ir(H$_2$O)Cl$_5$] (0.22 × 0.16 × 0.09 mm) were obtained by slow evaporation of the aqueous solution. The X-ray diffraction data were measured with an Oxford Sapphire CCD diffractometer using the Mo Kα radiation (λ = 0.71073 Å), at 293(2) K, by the ω–2θ method. The θ range was 2.99–31.47°. The number of reflections was 7610 ($-19 \leqslant h \leqslant 18$, $-13 \leqslant k \leqslant 11$, $-10 \leqslant l \leqslant 9$) with 1494 independent [R_{int} = 0.0480]. The data were numerically corrected for absorption correction with the OXFORD RED 171 program package [47] with the maximum/minimum transmissions of 0.3290/0.1193. The final *R* indices were as follows: R_1 = 0.0259, wR_2 = 0.0537 (for [$I > 2\sigma(I)$] reflections) and R_1 = 0.0285, wR_2 = 0.0548 (for all data). The structure was solved with the Patterson method, using the SHELX97 program package [48].

2.5. Quantum-chemical calculations

The geometry of free bpy and phen was already determined upon our previous studies on some other transition metal complexes [26,27], whereas that for the Ir(III) complexes was primarily constructed by molecular modelling with Hyperchem 5.1, and then optimised with B3LYP/LanL2DZ+6-31G*. The quantum-chemical calculations of the ^{1}H, ^{13}C and ^{15}N NMR shielding constants, allowing to compute the relevant chemical shifts, were performed using B3LYP/LanL2DZ+6-31G**, in two versions: (a) for isolated molecules; (b) for H$_2$O- or DMSO-solvated species. The methodology was generally the same as described in our previous reports for some Pd(II) and Pt(II) complexes with the derivatives of bpy or phen, as well as with quinolines [49,50]. All calculations were done with the GAUSSIAN03 [51] software installed in the supercomputing centres in Brno and Prague (Czech Republic).

3. Results and discussion

3.1. Crystal and molecular structure of potassium aquapentachloroiridate(III) – K$_2$[Ir(H$_2$O)Cl$_5$]

The perspective view of the K$_2$[Ir(H$_2$O)Cl$_5$] ionic molecule is presented at Fig. 1, while its packing in the crystal lattice – at Fig. 2 (PLATON [52]). The crystal structure data are collected in Table 1, whereas the bond lengths and angles within the [Ir(H$_2$O)Cl$_5$]$^{2-}$ anion – in Table 2.

The crystallographic parameters for K$_2$[Ir(H$_2$O)Cl$_5$] are in agreement with those determined by the X-ray powder diffraction

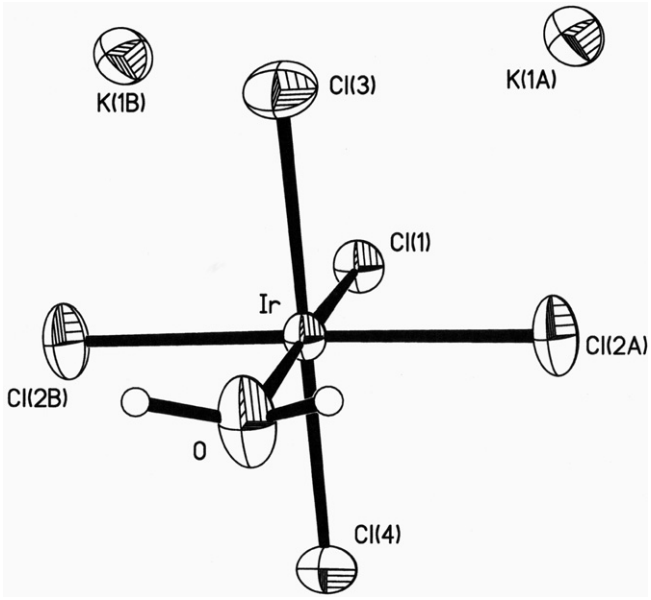

Fig. 1. Molecular structure of $K_2[Ir(H_2O)Cl_5]$.

(orthorhombic; a = 13.58 Å, *b* = 9.26 Å, c = 7.16 Å; *Pnma* space group [8]). They are also very similar to those for $Rb_2[Ir(H_2O)Cl_5]$ (*a* = 13.85(3) Å, *b* = 9.67(2) Å, *c* = 7.23(2) Å, *Pnma* [5]), the respective unit cell dimensions being smaller by only *ca.* 2%. Thus, the increase of the alkali metal ionic radius (from 1.38 Å for K^+ to 1.52 Å for Rb^+ [53]) is insufficient to change the crystal packing of both aquapentachloroiridates(III); however, in case of much larger Cs^+ ions (1.67 Å [53]), *i.e.* for $Cs_2[Ir(H_2O)Cl_5]$, the space group (*Cmcm*) and the unit cell parameters (*a* = 17.283(2) Å, *b* = 8.014(2) Å, *c* = 7.372(1) Å) [5] are different, although the crystal system remains orthorhombic. On the other hand, the replacement of the H_2O ligand by the isoelectronic NH_3 group only slightly affects the crystallization mode, as both potassium and ammonium amminepentachloroiridates(III) are nearly isostructural to $K_2[Ir(H_2O)Cl_5]$ ($K_2[Ir(NH_3)Cl_5]$ – *a* = 13.426(4) Å, *b* = 10.015(2) Å, *c* = 6.8717(7) Å, *Pnma* [7]; $(NH_4)_2[Ir(NH_3)Cl_5]$ – *a* = 13.500(2) Å, *b* = 10.285(3) Å, *c* = 6.896(2) Å, *Pnma* [9]).

The molecular structure of $K_2[Ir(H_2O)Cl_5]$ (Fig. 1) generally resembles that of $K_2[Ir(NH_3)Cl_5]$ [7], and, besides a various crystal packing, $Cs_2[Ir(H_2O)Cl_5]$ [5]. The Ir–O bond length (2.090(4) Å) is comparable to that in $Cs_2[Ir(H_2O)Cl_5]$ (2.091(2) Å [5]) or $[Pt(NH_3)_4][Ir(H_2O)Cl_5] \cdot 2H_2O$ (2.10(1) Å [6]), while the axial Ir–Cl(1) bond (2.322(1) Å) is slightly shorter than the equatorial Ir–Cl(2a,2b,3,4) ones (2.346(2)–2.360(2) Å). An analogous decrease of the interatomic distance between the Ir(III) central atom and

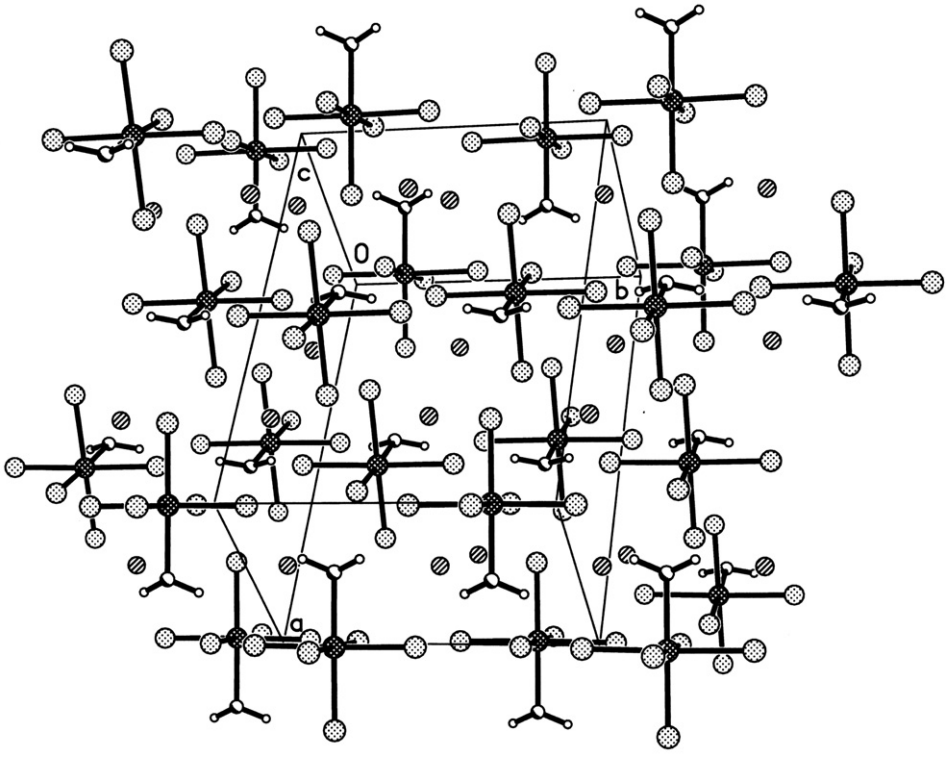

Fig. 2. Crystal packing of $K_2[Ir(H_2O)Cl_5]$.

Table 2
Geometry of $[Ir(H_2O)Cl_5]^{2-}$ in crystalline $K_2[Ir(H_2O)Cl_5]$

Bond length	(Å)	Angle	(°)
Ir–O	2.090(4)	O–Ir–Cl(1)	177.7(2)
Ir–Cl(1)	2.322(1)	Cl(2a)–Ir–Cl(2 b)	178.53(5)
Ir–Cl(2a/2b)	2.347(1)	Cl(3)–Ir–Cl(4)	179.29(6)
Ir–Cl(3)	2.346(2)	O–Ir–Cl(2a/2b)	89.35(3)
Ir–Cl(4)	2.360(2)	O–Ir–Cl(3)	91.4(2)
		O–Ir–Cl(4)	87.9(2)
		Cl(1)–Ir–Cl(2a/2b)	90.64(3)
		Cl(1)–Ir–Cl(3)	90.99(6)
		Cl(1)–Ir–Cl(4)	89.71(5)
		Cl(2a/2b)–Ir–Cl(3)	90.36(3)
		Cl(2a/2b)–Ir–Cl(4)	89.63(3)

Cl(1) is *trans* to O; Cl(2a) is trans to Cl(2b) (both chlorides being related by (x, $-y+3/2$, z) symmetry operation).
Cl(3) is trans to Cl(4) (both chlorides being symmetry-independent).

the chloride anion positioned *trans* to water was noted for $Cs_2[Ir(H_2O)Cl_5]$ ($Ir–Cl_{ax}$ 2.315(1) Å *versus* $Ir–Cl_{eq}$ 2.350(1) Å [5]) and $[Pt(NH_3)_4][Ir(H_2O)Cl_5]\cdot 2H_2O$ ($Ir–Cl_{ax}$ 2.334(4) Å *versus* $Ir–Cl_{eq}$ 2.347(4)–2.373(4) Å [6]), whereas upon the presence of ammonia this effect was opposite (in $K_2[Ir(NH_3)Cl_5]$: $Ir–Cl_{ax}$ 2.365(3) Å *versus* $Ir–Cl_{eq}$ 2.337(3)–2.364(3) Å [7]). An evident elongation of the Ir–Cl(4) bond (2.360(2) Å) comparing to the formally analogous Ir–Cl(2a/2b) and Ir–Cl(3) ones (2.346(2)–2.347(1) Å) reflects a low symmetry of the $[Ir(H_2O)Cl_5]^{2-}$ anion. Nevertheless, the whole range of the Ir–Cl bond lengths in $K_2[Ir(H_2O)Cl_5]$ (2.322(1)–2.360(2) Å) is comparable to that reported for some hexachloroiridate(III) alkali metal salts (2.35(1)–2.37(1) Å for $K_3[IrCl_6]$, $K_3[IrCl_6]\cdot H_2O$ and $(NH_4)_3[IrCl_6]$ [5,54]).

The deviations from an octahedral symmetry concerning the $[Ir(H_2O)Cl_5]^{2-}$ anion can be also characterised by the O–Ir–Cl and Cl–Ir–Cl angles, which are not exactly equal to 180° or 90°, but vary from 177.7(2)° to 179.3(1)°, or from 87.9(2)° to 91.4(2)°. In $Cs_2[Ir(H_2O)Cl_5]$ these parameters were in the 177.3(2)–180.0(0)° or 88.7(1)–91.3(1)° ranges [5], while in $K_2[Ir(NH_3)Cl_5]$ the respective N–Ir–Cl and Cl–Ir–Cl angles ranged from 178.3(1)° to 178.7(1)° or from 88.0(3)° to 90.8(1)° [7]. Generally, such distortions seem to be caused by the replacement of one Cl ligand with a H_2O or NH_3 molecule, as well as by some $K^+\cdots Cl^-$ electrostatic interactions.

In the crystal lattice of $K_2[Ir(H_2O)Cl_5]$, the adjacent $[Ir(H_2O)Cl_5]^-$ anions are positioned in this way that the Cl(1), Cl(3), H_2O, Cl(4) ligands approximately replace each other upon the 90° or 180° rotation around the Cl(2a)–Ir–Cl(2b) axis (Fig. 2). Such a molecular packing is analogous to that described for $K_2[Ir(NH_3)Cl_5]$ [7], what explains the above mentioned crystallographic parameters similarity. All K^+ cations can be generated from one another by several symmetry operations, starting from K(1a) – K(1b) by (x, $-y+3/2$, z); K(1c) by ($-x+1/2$, $y-1/2$, $z-1/2$); K(1d) by ($-x+1/2$, $-y+2$, $z-1/2$); K(1e) by ($x+1/2$, y, $-z+3/2$); K(1f) by ($x+1/2$, $-y+3/2$, $-z+3/2$); K(1g) by ($-x+1/2$, $-y+2$, $z+1/2$); K(1h) by ($-x+1/2$, $y-1/2$, $z+1/2$). Generally, the potassium atoms can be classified into the two categories – distant from Ir(III) by 4.017(2) Å and by 4.067(2) Å. Each of the Cl(1), Cl(3) and Cl(4) chlorides interacts with four K^+ ions (the $Cl\cdots K$ distances varying from 3.241(2) to 3.278(2) Å, from 3.241(2) to 3.412(2) Å, and from 3.229(2) to 3.316(2) Å, respectively), whereas both symmetry-related (x, $-y+3/2$, z) Cl(2a) and Cl(2b) atoms exhibit two relatively short $Cl\cdots K$ contacts (3.247(2) and 3.371(2) Å) and one much longer (3.662(2) Å). The most adjacent potassium cations are distant from one another by 4.521(2) or 4.525(1) Å. No interactions between K^+ and H_2O are present, the shortest $K\cdots O$ distance being as much as 5.619(5) Å.

The similarity of the unit cell parameters for $K_2[Ir(H_2O)Cl_5]$ and $Rb_2[Ir(H_2O)Cl_5]$ [5], as well as of the single crystal X-ray data for $K_2[Ir(H_2O)Cl_5]$ and $Cs_2[Ir(H_2O)Cl_5]$ [5] suggests that all concerned alkali metal salts have analogous molecular structures (despite a variable packing). The same conclusion concerns $(NH_4)_2[Ir(H_2O)Cl_5]$, owing to its analogy with $(NH_4)_2[Ir(NH_3)Cl_5]$ [9] (isostructural to $K_2[Ir(NH_3)Cl_5]$ [7] and $K_2[Ir(H_2O)Cl_5]$ [8]). Hence, the presently described X-ray structure of potassium aquapentachloroiridate(III) can be regarded as typical for the whole class of the $M_2[IrLCl_5]$ compounds (M = K, NH_4, Rb, Cs; L = H_2O, NH_3).

3.2. Far-IR spectroscopy

The far-IR spectra of both $K[Ir(LL)Cl_4]$ complexes reveal four ν_{IrCl} stretching modes, what is consistent with the $2A_1 + B_1 + B_2$ pattern (predicted by the group theory for such a MX_2Y_4 octahedral species of the C_{2v} symmetry [55]) – 334, 315, 310, 299 cm^{-1} (for LL = bpy) and 341, 315, 305, 290 cm^{-1} (for LL = phen). These wave numbers are nearly identical with those reported for $(bpyH)[Ir(bpy)Cl_4]$ (333, 316, 309, 300 cm^{-1}) and $(phenH)[Ir(phen)Cl_4]$ (340, 304, 291 cm^{-1} [10] or 340, 313, 303, 290 cm^{-1} [11]). They are, however, *ca.* 10–25 cm^{-1} smaller comparing to the analogous Ir(IV) species ($[Ir(bpy)Cl_4]$ – 344, 336, 320, 314 cm^{-1}; $[Ir(phen)Cl_4]$ – 365, 338, 330, 318 cm^{-1} [10] or 364, 339, 330, 317 cm^{-1} [11]), what is an obvious consequence of a lower oxidation state [55].

The analogous measurements for both *cis*-$[Ir(LL)_2Cl_2]Cl\cdot nH_2O$ compounds exhibit two ν_{IrCl} vibrations ($A_1 + B_1$ [55]) – 333, 309 cm^{-1} (for LL = bpy) and 337, 313 cm^{-1} (for LL = phen). These values are close to those published for *cis*-$[Ir(phen)_2Cl_2]Cl$ (338, 313 cm^{-1} [11] or 340, 310 cm^{-1} [22]) and *cis*-$[Ir(phen)_2Cl_2]BF_4$ (336, 319 cm^{-1} [10]), as well as for some Ir(III)–chloride–pyridine complexes containing a similar IrN_4Cl_2 chromophore (338 cm^{-1} for *trans*-$[Ir(py)_4Cl_2]Cl$, and 332, 325 cm^{-1} for *cis*-$[Ir(py)_4Cl_2]Cl$] [56]).

3.3. ^1H NMR spectra

The ^1H NMR spectra of $K[Ir(bpy)Cl_4]$ and $K[Ir(phen)Cl_4]$ have been measured in D_2O and DMSO-d_6, *cis*-$[Ir(bpy)_2Cl_2]Cl$ – in D_2O, *cis*-$[Ir(phen)_2Cl_2]Cl$ – in DMSO-d_6. The δ^{1H} chemical shifts and the Δ^{1H}_{coord} coordination shifts (determined in respect to free bpy or phen in DMSO-d_6) are listed in Table 3.

$K[Ir(bpy)Cl_4]$ is well soluble and relatively stable in D_2O, what has allowed to detect also its ^{13}C and ^{15}N NMR spectra (*vide infra*). Nevertheless, in the aqueous medium a slow hydrolysis occurs as gradually some new ^1H signals appear at *ca.* 9.5, 8.5, 8.0, 7.7 ppm (being of *ca.* 20% and *ca.* 50% total intensity, respectively, after 24 and 120 h). Because no liberation of free bpy is observed, one can assume the substitution by the water molecules concerns only the chlorides and not the azine ligands. The solubility of $K[Ir(bpy)Cl_4]$ in DMSO-d_6 is even better but its decomposition, resulting from a well-known ligating ability of this NMR solvent, is much faster; hence, the simple ^1H NMR studies have been done but not the time-consuming $^1H–^{13}C$ or $^1H–^{15}N$ HMBC/HSQC/HMQC experiments.

$K[Ir(phen)Cl_4]$ is more inert and can be studied in both solvents, the content of the formed by-products, after 24 h, not exceeding 5–10%. However, it is sparingly soluble in D_2O and only its ^1H NMR spectrum has been successfully measured, whereas in DMSO-d_6 the ^{13}C and ^{15}N NMR signals have been detected as well using heteronuclear correlation methods (*vide infra*).

cis-$[Ir(bpy)_2Cl_2]Cl$ is easily dissolved in both D_2O and DMSO-d_6, but in the latter solvent it decomposes and thus its ^1H, ^{13}C and ^{15}N NMR measurements have been performed only in the aqueous medium. In contrast, *cis*-$[Ir(phen)_2Cl_2]Cl$ is too weakly soluble in water even for the ^1H NMR studies, while its solubility and stability in DMSO-d_6 has been sufficient to detect all types of the NMR spectra.

Table 3
^{1}H NMR chemical shifts (δ^{1H}, ppm) of Ir(III) chloride complexes with bpy or phen, in D_2O (A) or DMSO-d_6 (B); ^{1}H coordination shifts (Δ^{1H}_{coord}, ppm) are in parentheses

Compound	H(3)	H(4)	H(5)	H(6)

In the *cis*-[Ir(LL)$_2Cl_2$]$^+$ cations: the protons denoted as H and H′ correspond to these halves of each LL ligand which are positioned *trans* to chlorine and *trans* to another nitrogen, respectively.

[a] Δ^{1H}_{coord} determined for complexes in D_2O *versus* free ligands in DMSO-d_6.

[b] ^{1}H literature data for *cis*-[Ir(bpy)$_2Cl_2$]CF_3SO_3, in CD_3CN: 9.77, 8.56, 2 × 8.42, 8.08, 7.98, 7.72, 7.39 (unassigned) [24]; for *cis*-[Ir(bpy)$_2Cl_2$]PF_6, in DMSO: H(3′) 8.91, H(4′) 8.50, H(5′) 8.15, H(6′) 9.65, H(3) 8.82, H(4) 8.20, H(5) 7.51, H(6) 7.85 [25].

[c] ^{1}H NMR spectrum of [Ir(bpy)(bpy**)Cl]$_2Cl_2$, in unspecified solvent: 15 signals within 7.0–9.7 ppm range [34].

[d] ^{1}H literature data for *cis*-[Ir(bpy)(phen)Cl_2]Cl, in DMSO-d_6: 7.35, 7.70, 7.85, 8.16, 2 × 8.21, 4 × (8.38–8.60), 2 × 8.83, 8.97, 9.14, 9.73, 9.86 (unassigned) [12].

Both K[Ir(LL)Cl_4] coordination compounds exhibit the same orders of the proton signals like the free ligands (H(6) > H(3) > H(4) > H(5) for LL = bpy; H(2) > H(4) > H(5) > H(3) for LL = phen; see also Supplementary Figs. 1S and 3S). So simple spectral patterns unambiguously indicate the symmetric N(1),N(1′) bidentate coordination modes of both azines, excluding either the N(1) monodentate bonding or the N(1),C(3') chelation (possible for bpy). Thus, the [Ir(LL)Cl_4]$^-$ anions have the same structures as assumed by other authors [10,11,13].

All protons in the bpy and phen ligands are noticeably deshielded, the magnitudes of the Δ^{1H}_{coord} parameters decreasing in the orders H(6) > H(5) > H(4) > H(3) for [Ir(bpy)Cl_4]$^-$ and H(2) > H(3) > H(5) > H(4) for [Ir(phen)Cl_4]$^-$. Particularly, the largest Δ^{1H}_{coord} values are noted for H(6) in bpy (*ca.* 0.9 ppm in D_2O, *ca.* 1.0 ppm in DMSO-d_6) and H(2) in phen (*ca.* 0.55 ppm in D_2O, *ca.* 0.75 ppm in DMSO-d_6), *i.e.* in case of the hydrogens mostly adjacent to the N(1) coordination sites. It should be noted here that also for the aqueous solutions the ^{1}H coordination shifts have been determined in respect to the uncoordinated azines in DMSO-d_6; obviously, the ^{1}H chemical shifts of free bpy or phen could not have been measured in D_2O, as these heterocycles are insoluble in water.

The deshielding of the other protons is much smaller (*max. ca.* 0.35–0.45 ppm). Generally, in case of each ^{1}H signal, for both bpy and phen, the shifts to higher frequency are more enhanced in DMSO-d_6 than D_2O; the differences between the respective δ^{1H} parameters, found for the same ^{1}H nucleus but in various solvents, are again mostly expressed for H(6) in bpy (*ca.* 0.1 ppm) and H(2) in phen (*ca.* 0.2 ppm).

The increase of the δ^{1H} values for the [Ir(LL)Cl_4]$^-$ anions is generally similar to that noted upon complexation of the same or derived azines by some other transition metal chlorides, in which this phenomenon also concerned mainly the protons adjacent to the nitrogen [26–28]. Also the fact that in both Ir(III) complexes the deshielding of H(6) in bpy is larger than of H(2) in phen resembles an analogous dependency described for several Au(III), Pd(II), Pt(II) and Pt(IV) chloride coordination compounds having the general [Au(LL)Cl_2]$^+$, [Pd(LL)Cl_2], [Pt(LL)Cl_2] and [Pt(LL)Cl_4] formulae (LL = bpy, phen) [26–28]. However, the magnitude of the Ir(III)-induced ^{1}H high-frequency coordination shifts is even larger: $\Delta^{H(6)}_{coord}$ = 1.01 ppm for [Ir(bpy)Cl_4]$^-$ *versus* 0.43 ppm for [Pd(bpy)Cl_2], 0.81 ppm for [Pt(bpy)Cl_2], 0.82 ppm for [Pt(bpy)Cl_4], 0.70 ppm for [Au(bpy)Cl_2]$^+$; $\Delta^{H(2)}_{coord}$ = 0.77 ppm for [Ir(phen)Cl_4]$^-$ *versus* 0.23 ppm for [Pd(phen)Cl_2], 0.58 ppm for [Pt(phen)Cl_2], 0.63 ppm for [Pt(phen)Cl_4], 0.58 ppm for [Au(phen)Cl_2]$^+$; all data in DMSO-d_6 [26,27]). Furthermore, the large ^{1}H deshielding in the [Ir(LL)Cl_4]$^-$ anions strongly contrasts to a very small effect for the analogous H(2), H(6) nuclei in *cis*-[Pt(py)$_2Cl_4$] ($\Delta^{H(2),H(6)}_{coord}$ = 0.14 ppm [26]), although the geometry of the compared species is quite similar (in both types of such a coordination polyhedron the metallated nitrogen atoms are located *trans*- to chlorides, while the azine rings are *cis*-positioned to each other).

A high similarity of the [Ir(LL)Cl_4]$^-$ and [Pt(LL)Cl_4] species allows for a more detailed comparison. The respective coordination compounds (containing a given azine ligand) are isoelectronic (as the Ir(III) and Pt(IV) central ions have the same 6d^6 electron configuration), reveal a similar geometry (octahedral with the C_{2v} symmetry), and have a nearly identical atomic mass of the platinide (Ir 192.2, Pt 195.1). In fact, the analogous complexes of Ir(III) and Pt(IV) differ only in the overall electric charge, and, apparently, in the metal oxidation state. Thus, it can be seemingly surprising that the corresponding H(6) (in bpy) or H(2) (in phen) protons are more deshielded in the [Ir(LL)Cl_4]$^-$ anions than in the [Pt(LL)Cl_4] neutral molecules, although one could expect a weaker deshielding effect in the former case, owing to the presence of the (−1) negative charge, and, in consequence, a higher electron density within the whole azine ring system.

Such a relation between the $\Delta^{H(6)}_{coord}$ (for bpy) or $\Delta^{H(2)}_{coord}$ (for phen) parameters, in [Ir(LL)Cl_4]$^-$ *versus* [Pt(LL)Cl_4], however, is true for these protons only; in contrast, for all others the ^{1}H deshielding effect decreases upon the Pt(IV) → Ir(III) replacement: $\Delta^{H(3)}_{coord}$ = 0.58 ppm → $\Delta^{H(3)}_{coord}$ = 0.11 ppm; $\Delta^{H(4)}_{coord}$ = 0.65 ppm → $\Delta^{H(4)}_{coord}$ = 0.25 ppm; $\Delta^{H(5)}_{coord}$ = 0.70 ppm → $\Delta^{H(5)}_{coord}$ = 0.44 ppm (for the [Pt(bpy)Cl$_4$] → [Ir(bpy)Cl_4]$^-$ transition), as well as: $\Delta^{H(3)}_{coord}$ = 0.68 ppm → $\Delta^{H(3)}_{coord}$ = 0.29 ppm; $\Delta^{H(4)}_{coord}$ = 0.73 ppm → $\Delta^{H(4)}_{coord}$ = 0.06 ppm, $\Delta^{H(5)}_{coord}$ = 0.54 ppm → $\Delta^{H(5)}_{coord}$ = 0.23 ppm (for the [Pt(phen)Cl_4] → [Ir(phen)Cl$_4$]$^-$ transition) [26]. In our opinion, an overall metal-induced ^{1}H deshielding can be better characterised by a mean value of Δ^{1H}_{coord}, determined for all hydrogen atoms in a given LL ligand: 0.45 ppm for [Ir(bpy)Cl_4]$^-$ *versus* 0.68 ppm for [Pt(bpy)Cl_4], and 0.33 ppm for [Ir(phen)Cl_4]$^-$ *versus* 0.64 ppm for [Pt(phen)Cl_4]. Thus, each [Pt(LL)Cl_4] → [Ir(LL)Cl_4]$^-$ transition weakens an average deshielding effect for the whole set of protons, such a dependency being now consistent with the increased electron density.

The increase of the ^{1}H chemical shifts following Ir(III) chloride complexation seems to be a more general phenomenon, as it was already described for several coordination compounds of some other

azines and azoloazines, being again mostly pronounced for the nitrogen-adjacent protons: $\delta^{H(2)}$ = 8.21 ppm, $\delta^{H(4)}$ = 7.51 ppm, $\delta^{H(5)}$ = 7.20 ppm for *trans*-[Ir(imidazole-N(1))$_2$Cl$_4$]$^-$ in D$_2$O (imidazoleH$^+$ counterions) [57] *versus* $\delta^{H(2)}$ = 7.73 ppm, $\delta^{H(4)/H(5)}$ = 7.13 ppm for free imidazole in CDCl$_3$ [58]; $\delta^{H(6),H(6'')}$ = 9.23 ppm for [Ir(2,2′:6′,2″-terpyridine-N(1),N(1′),N(1″))Cl$_3$] in DMSO-d_6 [59] *versus* $\delta^{H(6),H(6'')}$ = 8.68 ppm for free 2,2′:6′,2″-terpyridine in CDCl$_3$ [58]).

The discussed deshielding phenomenon, in the presently studied [Ir(LL)Cl$_4$]$^-$ anions, seems to be primarily caused by an inductive effect of the electron-acceptor IrCl$_4$ moiety, related to a strongly electronegative character of four chlorine atoms (while iridium is weakly electropositive – 2.20 electronegativity [53]); as already mentioned, the magnitude of this effect is probably partially decreased by the presence of the negative electric charge. Anisotropic phenomena, potentially deriving from the adjacency of some other azine ligands, are principally absent here because both [Ir(LL)Cl$_4$]$^-$ species contain exactly one bpy or phen molecule. Relativistic contributions, characteristic for heavy metal complexes, must be also taken into account. Finally, solvation effects are important, as indicated by the earlier described dependency of the δ^{1H} and Δ^{1H}_{coord} parameters on the solvent type.

The ^{1}H NMR spectra of both *cis*-[Ir(LL)$_2$Cl$_2$]Cl complexes are much more complicated as they reveal a double number of peaks due to the magnetic inequivalency of the two halves of each coordinated azine ligand (although the two bpy or phen molecules, treated as the whole, remain equivalent to each other). Such NMR patterns, consistent with the literature data for *cis*-[Ir(bpy)$_2$Cl$_2$]CF$_3$SO$_3$ or *cis*-[Ir(bpy)$_2$Cl$_2$]PF$_6$ (in CD$_3$CN or DMSO, respectively; 8 signals) [24,25] and *cis*-[Ir(bpy)(phen)Cl$_2$]Cl (in DMSO-d_6; 16 signals) [12] were already described for the analogous *cis*-[Co(LL)$_2$Cl$_2$]Cl and *cis*-[Rh(LL)$_2$Cl$_2$]Cl species [27]. The presence of only eight proton resonances unambiguously proves the symmetric N(1),N(1′) bidentate coordination modes of bpy or phen, excluding the N(1) monodentate bonding or the N(1),C(3′) chelation (possible in case of bpy) for any of the two coordinated molecules; otherwise, we could expect 16 (bpy + bpy* or phen + phen*) or 15 (bpy + bpy**) ^{1}H peaks, by analogy to the spectrum of [Ir(bpy)(bpy**)Cl]$_2$Cl$_2$ [34]). Hence, both *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ cations have, at least in the studied solutions, the analogous structures as in crystalline *cis*-[Ir(phen-κ^2N(1),N(1′))$_2$Cl$_2$]PF$_6$ (AMIPIV) [30], *cis*-[Ir(4,4′-dimethyl-bpy-κ^2N(1),N(1′))$_2$Cl$_2$]PF$_6$ (WABDEJ) [60] and *cis*-[Ir(2,2′-biquinoline-κ^2N(1),N(1′))$_2$Cl$_2$]PF$_6$ (AJUKAR) [61].

Further we will denote as N atoms these positioned (within the IrN$_2$Cl$_4$ chromophore) *trans* to chlorine, while as N′ – those *trans* to another nitrogen – Fig. 3. For each pair of the corresponding protons in the two inequivalent halves of bpy or phen rings, the peak appearing at the higher frequency can be assigned to H′, while that at the lower chemical shift – to H. Such an attribution follows an obvious fact that the former hydrogens (located approximately within the plane determined by the adjacent bpy/phen ring) are more deshielded than the latter ones (far-distanced from that plane), owing to the additional magnetic field generated by the neighbouring heterocyclic molecule.

The orders of the proton signals for *cis*-[Ir(bpy)$_2$Cl$_2$]$^+$ and *cis*-[Ir(phen)$_2$Cl$_2$]$^+$ are H(6′) > H(3′) > H(3) > H(4′) > H(4) > H(5′) > H(6) > H(5) and H(2′) > H(4′) > H(4) > H(5′) > H(3′) > H(5) > H(2) > H(3), respectively (see also Supplementary Figs. 2S and 3S); the former sequence is identical with that suggested for *cis*-[Ir(bpy)$_2$Cl$_2$]PF$_6$ [25]. We observe the highly positive Δ^{1H}_{coord} values for the H′ atoms (*ca.* 0.25–0.95 ppm for bpy, *ca.* 0.5–0.85 ppm for phen) and much smaller (*max ca.* 0.15 ppm for bpy, *max ca.* 0.4 ppm for phen) or even negative (down to *ca.* −1.0 ppm for both ligands) for those of H. The largest absolute magnitudes of the ^{1}H coordination shifts are again noted for H(6)/H(6′) in bpy ($\Delta^{H(6)\prime}_{coord}$ = +0.94 ppm, $\Delta^{H(6)}_{coord}$ = −0.97 ppm) and H(2)/H(2′) in phen ($\Delta^{H(2)\prime}_{coord}$ = +0.84 ppm, $\Delta^{H(2)}_{coord}$ = −1.04 ppm). The same phenomenon

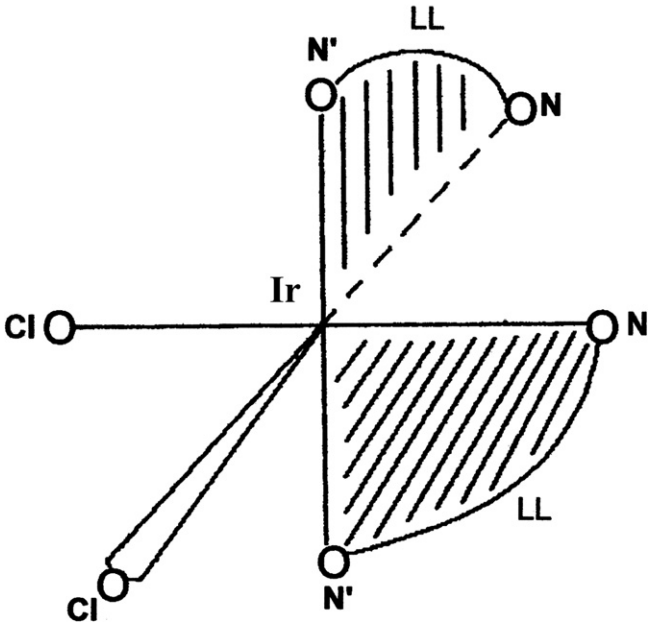

Fig. 3. Geometry of *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ cations (LL = bpy, phen).

was already observed for the *cis*-[Co(LL)$_2$Cl$_2$]$^+$ and *cis*-[Rh(LL)$_2$Cl$_2$]$^+$ cations; however, the Δ^{1H}_{coord} parameters for the Ir(III) complexes are more similar to those for the Rh(III) than Co(III) species (*cis*-[Rh(bpy)$_2$Cl$_2$]$^+$ – $\Delta^{H(6)\prime}_{coord}$ = +0.99 ppm, $\Delta^{H(6)}_{coord}$ = −0.91 ppm and *cis*-[Co(bpy)$_2$Cl$_2$]$^+$ – $\Delta^{H(6)\prime}_{coord}$ = +1.11 ppm, $\Delta^{H(6)}_{coord}$ = −1.36 ppm; *cis*-[Rh(phen)$_2$Cl$_2$]$^+$ – $\Delta^{H(2)\prime}_{coord}$ = +0.88 ppm, $\Delta^{H(2)}_{coord}$ = −1.06 ppm and *cis*-[Co(phen)$_2$Cl$_2$]$^+$ – $\Delta^{H(2)\prime}_{coord}$ = +0.92 ppm, $\Delta^{H(2)}_{coord}$ = −1.56 ppm; all data for the chloride salts in DMSO-d_6 [27]). Most likely, this dependency reflects a larger similarity of the Ir(III) ionic radius to that of Rh(III) than Co(III) (0.68 Å *versus* 0.67 Å and 0.55 Å, respectively [53]), and, in consequence, of the relevant distance between the H(6) (bpy) or H(2) (phen) proton and the metal atom.

The differences between the δ^{1H} parameters for the H′ and H atoms are always positive and increase in the orders H(3) < H(4) < H(5) < H(6) (*cis*-[Ir(bpy)$_2$Cl$_2$]$^+$) or H(5) < H(4) < H(3) < H(2) (*cis*-[Ir(phen)$_2$Cl$_2$]$^+$), having their maxima for the nitrogen-adjacent hydrogens (1.91 ppm for H(6) in bpy, 1.88 ppm for H(2) in phen). Exactly the same dependencies were reported for the respective Co(III) and Rh(III) complexes, the separations between the H(6′) and H(6) (*cis*-[Co(bpy)$_2$Cl$_2$]$^+$: 2.47 ppm, *cis*-[Rh(bpy)$_2$Cl$_2$]$^+$: 1.90 ppm), as well as the H(2′) and H(2) (*cis*-[Co(phen)$_2$Cl$_2$]$^+$: 2.48 ppm, *cis*-[Rh(phen)$_2$Cl$_2$]$^+$: 1.94 ppm) signals being again more similar for Ir(III) and Rh(III) than Co(III) [27].

An overall ^{1}H deshielding, for each of the discussed *cis*-[M(LL)$_2$Cl$_2$]$^+$ cations (M = Ir, Rh, Co; LL = bpy, phen), can be again described by a mean Δ^{1H}_{coord} parameter, determined for all hydrogen atoms in the two coordinated azine molecules: 0.19 ppm in *cis*-[Ir(bpy)$_2$Cl$_2$]$^+$ *versus* 0.37 ppm in *cis*-[Rh(bpy)$_2$Cl$_2$]$^+$ and 0.32 ppm in *cis*-[Co(bpy)$_2$Cl$_2$]$^+$, as well as 0.27 ppm in *cis*-[Ir(phen)$_2$Cl$_2$]$^+$ *versus* 0.32 ppm in *cis*-[Rh(phen)$_2$Cl$_2$]$^+$ and 0.27 ppm in *cis*-[Co(phen)$_2$Cl$_2$]$^+$ [27]. Thus, in both series of the compared complexes we observe the increase of an average ^{1}H deshielding effect from cobalt to rhodium, and then its decrease from rhodium to iridium.

In case of the *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ cations a combination of several factors affects the ^{1}H shielding constants: a general deshielding tendency caused by an inductive effect of the electron-acceptor IrCl$_2$ moiety and the presence of the positive (+1) electric charge; anisotropic phenomena of variable sign and magnitude deriving from the adjacent π-electron ring systems; relativistic contribu-

tions; solvation effects. As all of them are noticeably dependent on the proton position, the ^{1}H resonances appear in the relatively broad spectral ranges (*cis*-[Ir(bpy)$_2$Cl$_2$]Cl: *ca.* 7.4–9.7 ppm; *cis*-[Ir(phen)$_2$Cl$_2$]Cl: *ca.* 7.7–10.0 ppm); quite similar intervals were reported for *cis*-[Ir(bpy)$_2$Cl$_2$]CF$_3$SO$_3$ in CD$_3$CN (*ca.* 7.4–9.8 ppm) [24] and *cis*-[Ir(bpy)$_2$Cl$_2$]PF$_6$ in DMSO (*ca.* 7.5–9.65 ppm) [25]. Comparable or even larger expanses were occupied by the proton peaks in the spectra of *cis*-[Co(bpy)$_2$Cl$_2$]Cl (*ca.* 7.3–9.8 ppm), *cis*-[Rh(bpy)$_2$Cl$_2$]Cl (*ca.* 7.5–9.7 ppm), *cis*-[Co(phen)$_2$Cl$_2$]Cl (*ca.* 7.5–10.1 ppm), *cis*-[Rh(phen)$_2$Cl$_2$]Cl (*ca.* 7.7–10.0 ppm) [27], as well as *cis*-[Ir(bpy)(phen)Cl$_2$]Cl (*ca.* 7.3–9.9 ppm, in DMSO-d_6 [12]) and [Ir(bpy)(bpy**)Cl]$_2$Cl$_2$ (*ca.* 6.9–9.7 ppm, in an unspecified solvent [34]), whereas in case of uncoordinated bpy or phen they were much more narrow (*ca.* 7.4–8.7 ppm and *ca.* 7.8–9.1 ppm).

The other salts containing the *cis*-[Ir(bpy)$_2$Cl$_2$]$^+$ cations exhibits a moderate dependence of the δ^{1H} values on the type of counterions or a solvent. Particularly, for *cis*-[Ir(bpy)$_2$Cl$_2$]CF$_3$SO$_3$ (9.77, 8.56, 2 × 8.42, 8.08, 7.98, 7.72, 7.39 ppm, in CD$_3$CN [24]) and *cis*-[Ir(bpy)$_2$Cl$_2$]PF$_6$ (9.65, 8.91, 8.82, 8.50, 8.20, 8.15, 7.85, 7.51, in DMSO [25]) the ^{1}H chemical shifts differed from ours for *cis*-[Ir(bpy)$_2$Cl$_2$]Cl (in D$_2$O) by *max. ca.* ±0.3 ppm. In contrast, the change of auxiliary ligands within the Ir(III) coordination sphere results in much larger δ^{1H} variations. As an example may serve the replacement of chlorides by trifluoromethylsulfonates (leading to even larger proton deshielding: *cis*-[Ir(bpy)$_2$(OSO$_2$CF$_3$)$_2$]CF$_3$SO$_3$ – 3 × 9.65, 9.52, 9.42, 9.22, 2 × 9.13 ppm, in CD$_3$CN [24]) or hydrides (the majority of protons was shielded: *cis*-[Ir(bpy)$_2$H$_2$]PF$_6$ – 9.37, 2 × 8.34, 8.06, 7.96, 7.76, 7.45, 7.33 ppm, in CD$_3$CN [24]). We do not compare the δ^{1H} parameters of the particular protons in *cis*-[Ir(bpy)$_2$Cl$_2$]$^+$ or *cis*-[Ir(phen)$_2$Cl$_2$]$^+$ to those in *cis*-[Ir(bpy)(phen)Cl$_2$]$^+$, [Ir(bpy)(bpy**)Cl]$_2^{2+}$, *cis*-[Ir(bpy)$_2$(OSO$_2$CF$_3$)$_2$]$^+$ or *cis*-[Ir(bpy)$_2$H$_2$]$^+$ because the ^{1}H signals reported in the literature generally remained unassigned [12,24,34].

The ^{1}H NMR spectral patterns for the Ir(III)-coordinated bpy or phen molecules are also heavily dependent on the presence of another heterocyclic ligand. Particularly, for some mixed Ir(III) chloride complexes with bpy/phen and 2,2′-dipyridylamine ((C$_5$H$_4$N)$_2$NH), a large deshielding of the H(6′)/H(2′) nuclei contrasted to the variable in sign and very slight in magnitude coordination shifts of H(6)/H(2) protons: *cis*-[Ir(bpy)(2,2′-dipyridylamine)Cl$_2$]Cl – $\delta^{H(6')}$ = *9.71 ppm (thus* $\Delta^{H(6')}_{coord} = +1.02$ ppm*) versus* $\delta^{H(6)}$ = 8.73 ppm (thus $\Delta^{H(6)}_{coord}$ = +0.04 ppm); *cis*-[Ir(phen)(2,2′-dipyridylamine)Cl$_2$]Cl – $\delta^{H(2')}$ = 9.95 ppm (thus $\Delta^{H(2')}_{coord} = +0.84$ ppm) *versus* $\delta^{H(2)}$ = 8.76 ppm (thus $\Delta^{H(2)}_{coord}$ = -0.35 ppm); both compounds in DMSO-d_6 [13]. On the other hand, the influence of an additional aromatic ring was sometimes very limited, *e.g.* in some Ir(III) complexes containing one bpy/phen molecule and the pentamethylcyclopentadienyl anion the H(6)/H(2) signals were nearly unaffected: [Ir(bpy)(C$_5$(CH$_3$)$_5$)Cl]ClO$_4$ – $\delta^{H(6)}$ = 8.65 ppm (thus $\Delta^{H(6)}_{coord} = -0.04$ ppm); [Ir(phen)(C$_5$(CH$_3$)$_5$)Cl]ClO$_4$ – $\delta^{H(2)}$ = 9.02 ppm (thus $\Delta^{H(2)}_{coord} = -0.09$ ppm); both compounds in CD$_3$CN [62]. In this case, however, one must take into account the presence of one Cl ligand only, and another character of the pentamethylcyclopentadienyl bonding (ferrocene-like), modifying either inductive or anisotropic effects.

As other examples illustrating the significance of anisotropic phenomena can serve the trischelated [Ir(LL)$_3$]$^{3+}$ cations, which exhibited very low δ^{1H} parameters (unassigned): [Ir(bpy)$_3$](PF$_6$)$_3$ – 8.67, 8.40, 2 × 7.69 ppm, in CD$_3$CN [24]; [Ir(phen)$_3$](ClO$_4$)$_3$ – 9.04, 8.47, 8.16, 7.96 ppm, in CD$_3$OD [63]. In these highly symmetric complexes inductive effects were entirely absent due to the lack of any electronegative elements, while those anisotropic probably balanced one another. In contrast, the unsymmetric [Ir(bpy)$_2$(bpy*)]$^{3+}$ and [Ir(bpy)$_2$(bpy**)]$^{2+}$ cations revealed a much larger variability of the unassigned δ^{1H} values ([Ir(bpy)$_2$(bpy*)](ClO$_4$)$_3$: *ca.* 6.7–9.1 ppm, in DMSO-d_6 [36]; [Ir(bpy)$_2$(bpy**)](ClO$_4$)$_2$: *ca.* 6.7–8.8 ppm, in DMSO-d_6 + D$_2$O (1:1) [16]; [Ir(bpy)$_2$(bpy**)](BF$_4$)$_2$: *ca.* 7.3–9.0 ppm, in CD$_3$OD [38]). A similar situation was in case of [Ir(bpy)$_2$(bpy***)(H$_2$O)]Cl$_3$ and [Ir(bpy)$_2$(bpy · H$_2$O)]Cl$_3$: *ca.* 6.5–9.0 ppm, in DMSO-d_6 [40,41]. So large differences between various types of Ir(III) cations containing three bpy ligands (differing in the complexation mode and/or electric charge) reflect a high dependence of anisotropic effects on the type and orientation of the coordinated heterocycles. Even more complicated and thus unassigned (due to the presence of some other azine ligands) were the ^{1}H NMR patterns reported for [Ir(bpy)$_2$(2-phenylpyridyl)](PF$_6$)$_2$, in DMSO-d_6 [64] and [Ir(bpy)(phen)(9,10-phenanthrenequinonedimine)](CF$_3$SO$_3$)$_3$, in DMSO-d_6 [12].

Mixing of equimolar K[Ir(bpy)Cl$_4$] + *cis*-[Ir(bpy)$_2$Cl$_2$]Cl (in D$_2$O) or K[Ir(phen)Cl$_4$] + *cis*-[Ir(phen)$_2$Cl$_2$]Cl (in DMSO-d_6) solutions results in the appearance of distinct, neither broadened nor averaged, ^{1}H peaks for the cations and the anions (see also Supplementary Fig. 3S). This observation excludes an exchange of the bpy or phen ligands between the coordination spheres of the respective complex ions, reflecting a large strength of the N(1),N(1′)-chelation of both azines, and a well-known kinetic inertness of Ir(III). The formed *cis*-[Ir(bpy)$_2$Cl$_2$][Ir(bpy)Cl$_4$] ionic pair is partially precipitated in D$_2$O, whereas that of *cis*-[Ir(phen)$_2$Cl$_2$][Ir(phen)Cl$_4$] in DMSO-d_6 remains well soluble, allowing for detection also its ^{1}H–^{13}C and ^{1}H–^{15}N NMR spectra (*vide infra*).

3.4. ^{13}C NMR spectra

During the present work, the ^{13}C NMR spectra of both bpy complexes have been measured in D$_2$O, while those of the phen

Table 4
^{13}C NMR chemical shifts (δ^{13C}, ppm) of Ir(III) chloride complexes with bpy or phen, in D$_2$O (A) or DMSO-d_6 (B); ^{13}C coordination shifts (Δ^{13C}_{coord}, ppm) are in parentheses

Compound	C(2)	C(3)	C(4)	C(5)	C(6)

In the *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ cations: the carbons denoted as C and C′ correspond to these halves of each LL ligand which are positioned *trans* to chlorine and *trans* to another nitrogen, respectively.

[a] Δ^{13C}_{coord} for bpy complexes determined in D$_2$O *versus* free bpy in DMSO-d_6.

ones – in DMSO-d_6. The respective δ^{13C} chemical shifts and the Δ^{13C}_{coord} coordination shifts are listed in Table 4.

The ^{13}C NMR signal patterns follow those noted upon the ^{1}H measurements, thus in case of the $[Ir(bpy)Cl_4]^-$ and $[Ir(phen)Cl_4]^-$ anions only 5 and 6 peaks are observed, while for the *cis*-$[Ir(bpy)_2Cl_2]^+$ and *cis*-$[Ir(phen)_2Cl_2]^+$ cations their number is again double, being 10 and 12, respectively. It confirms the equivalency of the two bpy or phen molecules (whose halves, however, become inequivalent to each other) in both *cis*-$[Ir(LL)_2Cl_2]^+$ ions, in contrast to the $[Ir(bpy)(bpy^{**})Cl]_2^{2+}$, $[Ir(bpy)_2(bpy^{*})]^{3+}$, $[Ir(bpy)_2(bpy^{**})]^{2+}$ and $[Ir(bpy)_2(bpy^{***})(H_2O)]^{3+}$ species, for which the ^{13}C NMR spectra were more complicated [34,36,38].

The influence of Ir(III) chloride complexation on the δ^{13C} parameters of both azines is relatively limited, the signal orders for the $[Ir(LL)Cl_4]^-$ and *cis*-$[Ir(LL)_2Cl_2]^+$ ions remaining the same like for uncoordinated bpy (C(2) > C(6) > C(4) > C(5) > C(3)) or phen (C(2) > C(1a) > C(4) > C(4a) > C(5) > C(3)). Comparing to the free ligands, all ^{13}C nuclei are moderately deshielded. This phenomenon is more pronounced for bpy (*ca.* 4–7 ppm) than phen (*ca.* 1–5 ppm), with no clear correlation to the carbon position. In contrast to ^{1}H NMR, the Δ^{13C}_{coord} parameters for the $[Ir(LL)Cl_4]^-$ and *cis*-$[Ir(LL)_2Cl_2]^+$ ions containing the same azine ligand are comparable (the variations up to ±2 ppm), with very small differences (always positive: *ca.* 0.1–0.8 ppm) between the C′ and C atoms in the latter species. So slight dependencies, similar in sign and magnitude to those for the analogous Co(III) and Rh(III) complexes [27], allow for a general conclusion that a high invariability of the δ^{13C} parameters on the affiliation of a carbon atom to one of the two halves of the bpy or phen ring systems (C′ *versus* C) reflects, unlike in ^{1}H NMR, a negligible contribution of anisotropic phenomena into the ^{13}C shielding constants.

3.5. ^{15}N NMR spectra

Like during the ^{13}C NMR measurements, the ^{15}N NMR spectra of both bpy complexes have been recorded in D_2O, while those of the phen ones and of the free ligands – in DMSO-d_6. The respective δ^{15N} chemical shifts and the Δ^{15N}_{coord} coordination shifts are listed in Table 5.

Generally, Ir(III) chloride complexation of both azines results in *ca.* 105–120 ppm low-frequency shifts of the ^{15}N signals of the pyridine-like nitrogens, thus the $\Delta^{N(1)}_{coord}$ parameters are strongly negative. No really significant differences are observed between the $[Ir(LL)Cl_4]^-$ and *cis*-$[Ir(LL)_2Cl_2]^+$ ions ($\Delta^{N(1)}_{coord}$ varying from *ca.* −107 ppm to *ca.* −116 ppm, and from *ca.* −111 ppm to *ca.* −120 ppm, respectively) although these species differ in such important structural features as the number of chloride and azine ligands, and the electric charge. Hence, neither inductive effects nor anisotropic phenomena, important in case of ^{1}H NMR, have a noticeable influence on the ^{15}N chemical shift. This is consistent with a well-known fact that the above factors determine rather the diamagnetic and not the paramagnetic contribution in a given shielding constant, while for the ^{15}N nuclei the former term is less significant than the latter one.

Table 5
^{15}N NMR chemical and coordination shifts (δ^{15N}, Δ^{15N}_{coord}; ppm) of Ir(III) chloride complexes with bpy or phen, in D_2O (A) or DMSO-d_6 (B).

Compound	$\delta^{N(1)}$	$\Delta^{N(1)}_{coord}$

Average for N and N′	−186.85	−117.55
Difference between N′ and N	+2.7	+2.7

In the *cis*-$[Ir(LL)_2Cl_2]^+$ cations: the nitrogens denoted as N and N′ are positioned *trans* to chlorine and *trans* to another nitrogen, respectively.

[a] $\Delta^{N(1)}_{coord}$ for bpy complexes determined in D_2O *versus* free bpy in DMSO-d_6.

The $|\Delta^{N(1)}_{coord}|$ absolute magnitudes for the $[Ir(LL)Cl_4]^-$ anions (*ca.* 107–116 ppm) are larger than those previously reported for the $[Au(LL)Cl_2]^+$ cations (*ca.* 78–82 ppm) [27] and the $[Pd(LL)Cl_2]$ (*ca.* 90–95 ppm), $[Pt(LL)Cl_2]$ (*ca.* 105–111 ppm), $[Pt(LL)Cl_4]$ (*ca.* 99–105 ppm) neutral molecules [26] (all data in DMSO-d_6). They are also much higher than the relevant $|\Delta^{N(1)}_{coord}|$ absolute values found in case of some Ge(IV) compounds having the general $[Ge(bpy)Cl_x(NCS)_{4-x}]$ (x = 0–4) formulae, for which $\delta^{N(1)}$ ranged from *ca.* −123 to *ca.* −130 ppm (in DMSO-d_6) [65], and thus $\Delta^{N(1)}_{coord}$ varied from *ca.* −50 ppm to *ca.* −57 ppm. So a huge difference between the ^{15}N shielding effects may result from the fact that, in contrast to iridium, gold, palladium and platinum, the germanium element is not a transition metal and has only semi-metallic properties.

The detailed comparison of the $\Delta^{N(1)}_{coord}$ parameters for $[Ir(bpy)Cl_4]^-$ and $[Pt(bpy)Cl_4]$ (−116.4 ppm *versus* −99.5 ppm [26]), as well as for $[Ir(phen)Cl_4]^-$ and $[Pt(phen)Cl_4]$ (−106.8 ppm *versus* −105.1 ppm [26]) exhibits a more enhanced ^{15}N shielding effect in case of the Ir(III) than Pt(IV) complexes, although, as we have mentioned upon the ^{1}H NMR discussion, both types of compounds have quite similar molecular structures. In our opinion, the negative differences between the δ^{15N} (or Δ^{15N}_{coord}) values for the $[Ir(LL)Cl_4]^-$ and $[Pt(LL)Cl_4]$ species (which are, however, of a variable magnitude: *ca.* −17 ppm for LL = bpy and *ca.* −2 ppm for LL = phen) may reflect another scale of the diamagnetic contribution in the relevant ^{15}N shielding constants; since this factor is related mainly to the electron density at the nitrogen, it should be larger for anions than neutral molecules, *i.e.* it must increase upon the $[Pt(LL)Cl_4] \rightarrow [Ir(LL)Cl_4]^-$ transitions. Obviously, the major part of the ^{15}N shielding effect results, most likely, from the decrease of the paramagnetic contribution (*via* the replacement of the main $n_N \rightarrow \pi^*$ electronic transition by a more energetic $\sigma_{N-M} \rightarrow \pi^*$ [26–28]) and from the appearance of relativistic phenomena (associated to the presence of the heavy metal ions); nevertheless, these factors are probably of a comparable magnitude in the corresponding Ir(III) and Pt(IV) complexes, due to their structural similarity.

Such a hypothesis, *i.e.* that the variations in the diamagnetic contribution (which itself is, principally, of a minor significance in determining the ^{15}N shielding constants) are mainly responsible for the final differences in the Δ^{15N}_{coord} values, noted for analogous coordination compounds having nearly the same structure but another electric charge, is supported by the fact that a similar enhancement of the ^{15}N low-frequency coordination shifts was observed upon the $[Au(LL)Cl_2]^+ \rightarrow [Pt(LL)Cl_2]$ transitions (for LL = bpy: $\Delta^{N(1)}_{coord}$ = −78.1 ppm → −105.3 ppm; for LL = phen: $\Delta^{N(1)}_{coord}$ = −81.8 ppm → −110.7 ppm [26,27]). In fact, the corresponding cationic Au(III) and neutral Pt(II) species were also very similar to each other, as they had the same $6d^8$ electron configuration of the central atom and the square-planar *cis*-geometry, as well as a very close metal atomic mass (Au 197.0, Pt 195.1), again differing mainly in the electron densities within the whole azine ring systems, and, in consequence, around the nitrogen atoms. Hence, the relation between $[Au(LL)Cl_2]^+$ and $[Pt(LL)Cl_2]$ is more or less like between $[Pt(LL)Cl_4]$ and $[Ir(LL)Cl_4]^-$. In our opinion, both comparisons lead to the same dependencies: the decrease of the central atom oxidation number and the overall electric charge by +1 results in the increase of the diamagnetic term in the expression for the ^{15}N shielding constant, what, owing to comparable magnitudes of the paramagnetic contributions, finally diminishes the respective δ^{15N} (or Δ^{15N}_{coord}) parameter.

Surprisingly, the ^{15}N shielding effect is *ca.* 9 ppm more pronounced for $[Ir(bpy)Cl_4]^-$ than $[Ir(phen)Cl_4]^-$ ($|\Delta^{N(1)}_{coord}|$ being *ca.* 116 ppm and *ca.* 109 ppm, respectively), although for the analogous Au(III), Pd(II), Pt(II) and Pt(IV) complexes the opposite relation was observed (with *ca.* 4–6 ppm smaller $|\Delta^{N(1)}_{coord}|$ parameters for LL = bpy than LL = phen [26,27]). This anomaly may be partially caused by the fact that the ^{15}N signals of $K[Ir(bpy)Cl_4]$ and bpy have been detected in various solvents (D_2O *versus* DMSO-d_6), so the difference between their $\delta^{N(1)}$ chemical shifts cannot be regarded as an accurate $\Delta^{N(1)}_{coord}$ coordination shift.

The comparison of the ^{15}N NMR spectra for *cis*-$[Ir(LL)_2Cl_2]^+$ to *cis*-$[Co(LL)_2Cl_2]^+$ and *cis*-$[Rh(LL)_2Cl_2]^+$ exhibits the increase of the mean $|\Delta^{N(1)N(1')}_{coord}|$ absolute magnitude (we have averaged it for N(1) and N(1′)) in the order: Rh(III) (*ca.* 88–95 ppm) < Co(III) (*ca.* 95–103 ppm) < Ir(III) (*ca.* 115–118 ppm). The enhancement of the ^{15}N shielding effect following the Rh → Co transition (by *ca.* 7–8 ppm) probably results from the shortening of the respective metal–nitrogen bonds, as usually Rh–N > Co–N: 2.011(5)–2.037(6) Å in *cis*-$[Rh(bpy\text{-}\kappa^2N(1),N(1'))_2Cl_2]Cl \cdot 2H_2O$ (KIKPEZ) [66] *versus* 1.933(3)–1.940(3) Å in *cis*-$[Co(bpy\text{-}\kappa^2N(1),N(1'))_2Cl_2]Cl \cdot 2H_2O$ (QQQEQG01) [67], and 2.022(8)–2.049(7) Å in *cis*-$[Rh(phen\text{-}\kappa^2N(1),N(1'))_2Cl_2]ClO_4$ (GOLHOE) [68] *versus* 1.94–2.03 Å in *cis*-$[Co(phen\text{-}\kappa^2N(1),N(1'))_2Cl_2]Cl \cdot 3H_2O$ (CPHCOC) [69], what is again a consequence of the smaller ionic radius of Co(III) than Rh(III). In contrast, a further increase of the mean $|\Delta^{N(1)N(1')}_{coord}|$ absolute value upon the Rh(III) → Ir(III) replacement (by *ca.* 23–27 ppm), analogous to that reported during the Pd(II) → Pt(II) change (by *ca.* 15–16 ppm [26]) cannot be explained in this way, because the typical Ir–N bond lengths (*e.g.* 2.046(4)–2.053(5) Å in *cis*-$[Ir(phen\text{-}\kappa^2N(1),N(1'))_2Cl_2]PF_6$ (AMIPIV) [30]; 2.015(5)–2.131(5) Å in *cis*-$[Ir(4,4'\text{-dimethyl-bpy-}\kappa^2N(1),N(1'))_2Cl_2]PF_6$ (WABDEJ) [60]; 2.058(4)–2.070(4) in *cis*-$[Ir(2,2'\text{-biquinoline-}\kappa^2N(1),N(1'))_2Cl_2]PF_6$ (AJUKAR) [61]) are usually very close to the corresponding Rh–N ones, due to nearly the same ionic radii of Rh(III) and Ir(III). As also the other atomic properties of the rhodium and iridium elements are comparable (their electronegativities being 2.28 and 2.2; the electronic polarisabilities being 8.6±25% and 7.6±25%, respectively [53]), most likely relativistic phenomena (much more pronounced for Ir than Rh) may be of a major significance.

In both *cis*-$[Ir(LL)_2Cl_2]^+$ cations the N(1) atoms are more shielded than N(1′) ($\delta^{N(1')} > \delta^{N(1)}$; the $\delta^{N(1')} - \delta^{N(1)}$ difference being *ca.* +8 ppm for LL = bpy, and *ca.* +3 ppm for LL = phen). The same dependency (but with smaller separations of the N(1′) and N(1) signals: $\delta^{N(1')} - \delta^{N(1)}$ = *ca.* +3 ppm for LL = bpy, $\delta^{N(1')} - \delta^{N(1)}$ = *ca.* +1 ppm for LL = phen) was noted for the similar *cis*-$[Rh(LL)_2Cl_2]^+$ ions [27]. A more expressed ^{15}N shielding effect for the nitrogens *trans* to chlorine (N(1)) comparing to those *trans* to another nitrogen (N(1′)) can be again related to the fact that the Ir–N(1) or Rh–N(1) bonds are shorter than Ir–N(1′) or Rh–N(1′) (*cis*-$[Ir(phen\text{-}\kappa^2N(1),N(1'))_2Cl_2]PF_6$ (AMIPIV) – 2.046(4) Å *versus* 2.053(5) Å [30]; *cis*-$[Rh(bpy)_2Cl_2]Cl \cdot 2H_2O$ (KIKPEZ) – 2.016(5) Å *versus* 2.032(6) Å [66]; *cis*-$[Rh(phen)_2Cl_2]ClO_4$ (GOLHOE) – 2.036(8) Å *versus* 2.044(8) Å [68]; the mean lengths for both coordinated azine molecules). This hypothesis can also explain the opposite order of the N(1) and N(1′) peaks in the *cis*-$[Co(LL)_2Cl_2]^+$ cations ($\delta^{N(1')} - \delta^{N(1)}$ = *ca.* −0.1 ppm for LL = bpy, $\delta^{N(1')} - \delta^{N(1)}$ = *ca.* −2 ppm for LL = phen [27]), because, in contrast to the corresponding Rh(III) and Ir(III) complexes, in both Co(III) species the Co–N(1) bonds are longer than Co–N(1′) (*cis*-$[Co(bpy)_2Cl_2]Cl \cdot 2H_2O$ (QQQEQG01) – 1.939(3) Å *versus* 1.936(3) Å [67]; *cis*-$[Co(phen)_2Cl_2]Cl \cdot 3H_2O$ (CPHCOC) – 2.00 Å *versus* 1.96 Å [69]; the mean lengths for both coordinated azine molecules). Summing up, the interatomic metal-nitrogen distance seems to be an important factor determining the $\Delta^{N(1)}_{coord}$ parameter.

The ^{15}N NMR low-frequency coordination shifts, observed for the sp^2-hybridised pyridine-like nitrogens in bpy or phen, are analogous to those reported for some anionic (deprotonated) ligands deriving from pyrazole. Particularly, in the mixed Ir(III)–pyrazolate–pentamethylcyclopentadienyl-triphenylphosphine complex of the $[Ir(pyrazolate\text{-}N(1))_2(C_5(CH_3)_5)(P(C_6H_5)_3)]$ formula, the signal of the iridium-bonded N(1) atom was shifted to the lower frequency by as much as *ca.* 150 ppm, comparing to the uncoordinated N(2) nitrogen ($\delta^{N(1)-Ir}$ = −203.5 ppm *versus* $\delta^{N(2)}$ = −53.7 ppm; in $CDCl_3$ at −80 °C [70]). Furthermore, in the mixed triphenylphosphine–chloride–hydride Ir(III) complexes with L = pyridine, benzoimidazole, purine or adenine (*trans*(H,N)(H,Cl)–$[IrL(P(C_6H_5)_3)_2Cl(H)_2]$) the ^{15}N signals were also noticeably low-frequency shifted (*e.g.* for py from $\delta^{N(1)}$ = −60.6 ppm to $\delta^{N(1)-Ir}$ = *ca.* −131 ppm, in toluene-d_8; those of benzoimidazole, purine and adenine complexes appeared at *ca.* −137 ppm, *ca.* −177 ppm and *ca.* −105 ppm, respectively, all in toluene-d_8) [71]. For *trans*(H,N)(H,Cl)–$[Ir(py)(P(C_6H_5)_3)_2Cl(H)_2]$ such relatively small *ca.* 70 ppm ^{15}N shift probably reflected a smaller *trans* influence of H than N or Cl atoms; for the other cases some equilibria between the coordination species containing variously coordinated ligands (being ambidentate N-donors) must be considered.

Negative in sign (although smaller in the absolute magnitude) were also the Δ^{15N}_{coord} parameters for the sp^3 nitrogens in the NH_3 molecules, present in several Ir(III) complexes with such auxiliary groups as hydrides, chlorides, triethylphosphine or cyclooctene. Comparing to the liquid ammonia (δ^{NH3} = −381.7 ppm [72]), the ^{15}N signals were *ca.* 20–90 ppm low-frequency shifted as their δ^{Ir-NH3} values ranged from −403 ppm to −473 ppm [73,74]. This ^{15}N shielding effect was surprisingly opposite to the well-known *ca.* 20–25 ppm deshielding caused by ammonia protonation (as for NH_4^+: $\delta^{NH_4^+}$ = *ca.* − 358 ppm to *ca.* −361 ppm [72]), being noticeably dependent on the type of auxiliary ligands and the arrangement of the NH_3 molecules within the Ir(III) coordination sphere. Particularly, the ^{15}N low-frequency coordination shifts were more expressed for the ammonia ligands positioned *trans* to each other than for those *trans* to some other groups, as illustrated by the following δ^{15N} parameters: $[Ir(C_8H_{14})(NH_3)_4H]^{2+}$ – δ^{Ir-NH3} = −447.2 ppm (2 × N *trans* to NH_3) *versus* −420.0 ppm and −403.2 ppm (1 × N + 1 × N *trans* to H or cyclooctene); $[Ir(C_8H_{14})(NH_3)_3HCl]^+$ – δ^{Ir-NH3} = -442.8 ppm (2 × N *trans* to NH_3) *versus* -411.8 ppm (1 × N *trans* to cyclooctene); $[Ir(P(C_2H_5)_3)_3(NH_3)_2H]^{2+}$ – δ^{Ir-NH3} = -473.0 ppm (2 × N *trans* to NH_3); $[Ir(P(C_2H_5)_3)_2(NH_3)_3H]^{2+}$ – δ^{Ir-NH3} = −466.1 ppm (2 × N *trans* to NH_3) *versus* −425.3 ppm (1 × N *trans* to H); $[Ir(P(C_2H_5)_3)_2(NH_3)_2HCl]^+$ – δ^{Ir-NH3} = −461.2 ppm (2 × N *trans* to NH_3); PF_6^- salts in THF/THF-d_8 [73,74]. Such a dependency reflects the importance of some geometric factors in determining the ^{15}N coordination shielding effect.

The ^{15}N shielding phenomenon was described as well for the sp^3 nitrogens in the Ir(III)-coordinated –NH_2 and –NH–CO– moieties, present in 8-aminoquinoline and its trimethylacetamide. In the $[Ir(quinoline\text{-}8\text{-}NH_2)(P(C_6H_5)_3)_2H_2]^+$ and $[Ir(quinoline\text{-}8\text{-}NHCOC(CH_3)_3)(P(C_6H_5)_3)_2H_2]^+$ cations (SbF_6^- salts in CD_2Cl_2), the ^{15}N resonances were *ca.* 40 ppm low-frequency shifted, comparing to the free ligands: δ^{Ir-NH2} in quinoline-8-NH_2 – from −329.2 to −372.6 ppm, δ^{Ir-NH} in quinoline-8-$NHCOC(CH_3)_3$ – from −263.2 to −304.6 ppm [75].

The Ir(III)-induced ^{15}N low-frequency coordination shifts were reported also for many other types of nitrogen atoms, *e.g.* for nitro groups (sp^2) and cyanides (sp). As examples may serve: (a) *ca.* 180–220 ppm decrease of the δ^{15N} values in various nitro-, nitro-chloride- and nitro-aqua-iridate(III) anions ($[Ir(NO_2)_6]^{3-} - \delta^{Ir-NO2}$ = *ca.* +52 ppm, *trans*-$[Ir(NO_2)_4Cl_2]^{3-} - \delta^{Ir-NO2}$ = *ca.* +50 ppm, *fac*-$[Ir(NO_2)_3Cl_3]^{3-} - \delta^{Ir-NO2}$ = *ca.* +32 ppm, *fac*-$[Ir(NO_2)_3(H_2O)_3] - \delta^{Ir-NO2}$ = *ca.* +11 ppm (in 2 M NaCl aqueous solutions) comparing to free NO_2^- ($\delta^{NO2(-)}$= *ca.* +230 ppm) [76,77]); the original ^{15}N chemical shifts were primarily referenced to 1 M $NaNO_3$ and then recalculated by us to the neat nitromethane by adding *ca.* −4 ppm [78];

(b) *ca.* 110 ppm lower δ^{15N} parameters for the bridged –CN– than terminal –CN ligands in the two Ir(III) cyanide–chloride–dimethylphenylphosphine complexes ($\delta^{Ir-CN-Ir}$ = −204.6 ppm in [(P(C$_6$H$_5$)-(CH$_3$)$_2$)$_3$Cl$_2$Ir(μ-CN)IrCl$_2$(P(C$_6$H$_5$)(CH$_3$)$_2$)$_3$]ClO$_4$ *versus* δ^{Ir-CN} = −95.9 ppm in [Ir(P(C$_6$H$_5$)(CH$_3$)$_2$)$_3$Cl$_2$(CN)] (both in CD$_2$Cl$_2$) [79]).

Summing up, this short review exhibits that generally the formation of the iridium-nitrogen coordination bonds results in the ^{15}N shielding effect (*i.e.* in the low-frequency shifts of the ^{15}N resonances), such a phenomenon being observed for a large variety of N atoms.

The presently studied Ir(III) complexes reveal no ^{15}N chemical shift isotopomerism associated with the natural abundance of the ^{191}Ir (37.3%) and ^{193}Ir (62.7%) nuclei [53]. Furthermore, all ^{15}N signals appear as singlets, the absence of ^{15}N–^{191}Ir or ^{15}N–^{193}Ir couplings being probably caused by a quadrupolar character of both iridium isotopes (their spin numbers are 3/2, their electric quadrupol moments are +0.82 and +0.75 barn (10^{-28} m^2) [53]). Such a behaviour is analogous to that noted for the respective Co(III) species [27,80] (the 100% abundant ^{59}Co nucleus has the 7/2 spin number and the electric quadrupol moment of +0.41 barn [53]) but entirely different from the one observed for similar Rh(III) compounds (the only ^{103}Rh isotope has the 1/2 spin number [53]), where the intense ^{15}N–^{103}Rh spin–spin interactions were detected [27].

3.6. Calculated ^{1}H NMR chemical shifts

The δ^{1H}_{calc} parameters, calculated for free bpy and phen, as well as for the [Ir(LL)Cl$_4$]$^-$ and *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ ions, by B3LYP/LanL2DZ+6-31G**//B3LYP/LanL2DZ+6-31G* (as isolated species, *i.e. in vacuo*; method (a)) or by B3LYP/LanL2DZ+6-31G**(PCM)//B3LYP/LanL2DZ+6-31G* (as solvated species, assuming as medium: H$_2$O for the bpy complexes, DMSO for the free ligands and the phen complexes; method (b)), are listed in Table 6.

The reproducibility of the calculated ^{1}H chemical shifts has been significantly improved after the inclusion of solvation effects, as exhibited by the large decrease of the rmsd values, observed for each studied compound (for all species: 0.51→0.11); this is why we will focus at the results obtained by the method (b). Upon its application, the respective rmsd parameters for the complexes are comparable or even smaller than those in case of the free ligands.

For both [Ir(LL)Cl$_4$]$^-$ anions the order of the ^{1}H resonances has been correctly predicted: H(6) > H(3) > H(4) > H(5) for LL = bpy, H(2) > H(4) > H(5) > H(3) for LL = phen. Furthermore, the most expressed deshielding effects of *ca.* 0.6–0.9 ppm have been forecasted for H(6) in bpy and H(2) in phen, *i.e.* in accordance with the actual NMR measurements.

For both *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ cations a larger deshielding of the corresponding H′ than H atom has been reproduced for all protons; moreover, the separation of these signals (*i.e.* the $\delta^{H'}_{calc} - \delta^{H}_{calc}$ difference) increases in the same order like in the real NMR spectra: H(3) < H(4) < H(5) < H(6) for LL = bpy, H(5) < H(4) < H(3) < H(2) for LL = phen, reaching *ca.* 2.0–2.1 ppm for the nitrogen-adjacent protons. In consequence, H(6′) in bpy and H(2′) in phen are predicted to be deshielded by *ca.* 0.9–1.1 ppm, whereas those of H(6) in bpy and H(2) in phen – to be shielded by *ca.* 1.0–1.3 ppm, comparing to the same protons in the free ligands, also in a qualitative agreement with the experimental results.

Table 6
Quantum-chemically calculated, by B3LYP/LanL2DZ+6-31G**//B3LYP/LanL2DZ+6-31G* – (a), or B3LYP/LanL2DZ+6-31G** (PCM)//B3LYP/LanL2DZ+6-31G* – (b), ^{1}H NMR chemical shifts (δ^{1H}_{calc}, ppm) for bpy, phen and their Ir(III) chloride complexes

Compound	H(3)	H(4)	H(5)	H(6)	rmsd
Bpy (a)[C]	9.06	7.87	7.32	8.93	0.32
Bpy (b)[B]	8.72	7.89	7.38	8.70	0.17
[Ir(bpy)Cl$_4$] - (a)[C]	7.56	7.22	7.13	10.70	0.84
[Ir(bpy)Cl$_4$]$^-$ (b)[A]	8.29	8.08	7.66	9.64	0.09
cis-[Ir(bpy)$_2$Cl$_2$]$^+$ (H) (a)[C]	8.41	8.21	7.55	7.87	0.30
cis-[Ir(bpy)$_2$Cl$_2$]$^+$ (H′) (a)[C]	8.47	8.49	8.19	10.51	
cis-[Ir(bpy)$_2$Cl$_2$]$^+$ (H) (b)[A]	8.54	8.20	7.58	7.74	0.07
cis-[Ir(bpy)$_2$Cl$_2$]$^+$ (H′) (b)[A]	8.63	8.43	8.02	9.79	
	H(2)	H(3)	H(4)	H(5)	rmsd
Phen (a)[C]	9.55	7.73	8.21	7.89	0.27
Phen (b)[B]	9.21	7.81	8.36	7.95	0.09
[Ir(phen)Cl$_4$]$^-$ (a)[C]	10.75	7.56	7.63	7.55	0.70
[Ir(phen)Cl$_4$]$^-$ (b)[B]	9.81	8.03	8.55	8.15	0.03
cis-[Ir(phen)$_2$Cl$_2$]$^+$ (H) (a)[C]	8.06	7.81	8.61	8.37	0.30
cis-[Ir(phen)$_2$Cl$_2$]$^+$ (H′) (a)[C]	10.80	8.59	8.94	8.53	
cis-[Ir(phen)$_2$Cl$_2$]$^+$ (H) (b)[B]	7.91	7.86	8.70	8.36	0.11
cis-[Ir(phen)$_2$Cl$_2$]+ (H′) (b)[B]	10.11	8.46	8.99	8.46	

The overall rmsd value is 0.51 (method (a)) and 0.11 (method (b)).
In the *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ cations: the protons denoted as H and H′ correspond to these halves of each LL ligand which are positioned *trans* to chlorine and *trans* to another nitrogen, respectively.
[A] Calculated in H$_2$O.
[B] Calculated in DMSO.
[C] Calculated *in vacuo*.

3.7. Calculated ^{13}C NMR chemical shifts

The δ^{13C}_{calc} parameters, calculated for free bpy and phen, as well as for the [Ir(LL)Cl$_4$]$^-$ and *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ ions, by B3LYP/LanL2DZ+6-31G**//B3LYP/LanL2DZ+6-31G* (as isolated species, *i.e. in vacuo*; method (a)) or by B3LYP/LanL2DZ+6-31G**(PCM)//B3LYP/LanL2DZ+6-31G* (as solvated species, assuming as medium: H$_2$O for the bpy complexes, DMSO for the free ligands and the phen complexes; method (b)), are listed in Table 7.

The quality of these ^{13}C NMR calculations is again better in case of the method (b) than (a), although the decrease of the rmsd parameters is much less pronounced than in case of ^{1}H NMR (3.5→2.6, for all species), probably due to a smaller impact of solvation effects on the δ^{13C} parameters. The rmsd values for the complexes are always larger than in case of the free ligands. Nevertheless, the orders of the ^{13}C signals have been correctly predicted: C(2) > C(6) > C(4) > C(5) > C(3) for LL = bpy, C(2) > C(1a) > C(4) > C(4a) > C(5) > C(3) for LL = phen, with rather slight differences (being, however, of variable sign) between the corresponding C′ and C carbons in both *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ cations.

3.8. Calculated ^{15}N NMR chemical shifts

The δ^{15N}_{calc} parameters, calculated for all [Ir(LL)Cl$_4$]$^-$ and *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ ions by B3LYP/LanL2DZ+6-31G**//B3LYP/LanL2DZ+6-31G* (as isolated species, *i.e. in vacuo*; method (a)) or by B3LYP/LanL2DZ+6-31G**(PCM)//B3LYP/LanL2DZ+6-31G* (as solvated species, assuming as medium: H$_2$O for the bpy complexes, DMSO for the phen ones; method (b)), are listed in Table 8.

The introduction of solvation effects has generally improved the quality of the ^{15}N NMR calculations (rmsd for all complexes: 13.6→5.7). Nevertheless, in contrast to the actual experiments, the calculated ^{15}N chemical shifts are noticeably lower for *cis*-[Ir(LL)$_2$Cl$_2$]$^+$ than [Ir(LL)Cl$_4$]$^-$ (by *ca.* 10 ppm for LL = bpy and by *ca.* 12 ppm for LL = phen). Furthermore, the δ^{15N}_{calc} parameters are smaller for the nitrogen atoms in bpy than phen, differing by *ca.* 1 ppm for [Ir(LL)Cl$_4$]$^-$ and by *ca.* 3 ppm for *cis*-[Ir(LL)$_2$Cl$_2$]$^+$, what is again inconsistent with the experimental dependencies. On the other hand, a more pronounced shielding of the nitrogens *trans* to chlorine (N(1)) comparing to those *trans* to another nitrogen (N(1′)) has been well reproduced by the method (b), although the computed $\delta^{N(1')}_{calc} - \delta^{N(1)}_{calc}$ differences are slight (*ca.* 1–2 ppm). It is worth noting that analogous calculations performed by the method

Table 7
Quantum-chemically calculated, by B3LYP/LanL2DZ+6-31G**//B3LYP/LanL2DZ+6-31G* – (a), or B3LYP/LanL2DZ+6-31G** (PCM)//B3LYP/LanL2DZ+6-31G* – (b), ^{13}C NMR chemical shifts (δ^{13C}_{calc}, ppm) for bpy, phen and their Ir(III) chloride complexes

Compound	C(2)	C(3)	C(4)	C(5)	C(6)	rmsd

(a) have lead to the opposite, erroneous relations, *i.e.* to negative $\delta^{N(1')}_{calc} - \delta^{N(1)}_{calc}$ differences. The change of sign of such $\delta^{N(1')}_{calc} - \delta^{N(1)}_{calc}$ expressions upon the solvent introduction may suggest an importance of solvation effects in determining the δ^{15N} chemical shifts.

4. Conclusions

The molecular structure of potassium aquapentachloroiridate(III) is typical for the whole class of the $M_2[IrLCl_5]$ compounds (M = K, NH_4, Rb, Cs; L = H_2O, NH_3), although the crystal packing of these inorganic salts is variable. Particularly, $K_2[Ir(H_2O)Cl_5]$ is crystallographically nearly isostructural with $K_2[Ir(NH_3)Cl_5]$, a distorted octahedral geometry of the $[Ir(H_2O)Cl_5]^{2-}$ anions being similar to those in $Cs_2[Ir(H_2O)Cl_5]$ and $[Pt(NH_3)_4][Ir(H_2O)Cl_5] \cdot 2H_2O$.

The ^1H, ^{13}C, ^{15}N NMR spectral patterns correspond well to the assumed structures of the $[Ir(LL)Cl_4]^-$ and *cis*-$[Ir(LL)_2Cl_2]^+$ ions. They confirm the N(1),N(1′)-chelation of both azines, excluding either the monodentate N(1)-bonding or the unsymmetric N(1), C(3′)-coordination.

The ^1H NMR spectra are heavily affected by Ir(III) chloride complexation, this effect being noticeably dependent on the composition and geometry of the coordination sphere, as well as on the proton position. In the $[Ir(LL)Cl_4]^-$ anions, the ^1H signals are high-frequency shifted, the Δ^{1H}_{coord} parameters decreasing in the orders H(6) > H(5) > H(4) > H(3) for LL = bpy, and H(2) > H(3) > H(5) > H(4) for LL = phen; the largest values are noted for the hydrogens directly adjacent to the coordination sites, *i.e.* H(6) in bpy (*ca.* 0.9–1.0 ppm) and H(2) in phen (*ca.* 0.5–0.8 ppm). In the *cis*-$[Ir(LL)_2Cl_2]^+$ cations, the magnetic inequivalency of the two halves of each coordinated azine molecule results in a double number of the ^1H resonances; for each pair of the corresponding protons, the peak appearing at the higher frequency (H′) can be assigned to the ligand moiety positioned *trans* to N, while its counterpart at the lower frequency (H) – to that *trans* to Cl. In consequence, the highly positive Δ^{1H}_{coord} parameters (*ca.* 0.2–1.0 ppm) are noted for H′ protons, whereas much smaller (up to *ca.* 0.4 ppm) or even negative (down to *ca.* −1.0 ppm) for the H ones; the respective absolute values ($|\Delta^{1H}_{coord}|$) as well as the separations of the corresponding H′ and H signals ($\delta^{(H')} - \delta^{(H)}$) are again the largest for H(6)/H(6′) in bpy and H(2)/H(2′) in phen. This δ^{1H} patterns variability reflects an importance of several factors influencing the σ^{1H} shielding constants: an inductive effect of the electron-acceptor $IrCl_4$ or $IrCl_2$ moiety, anisotropic phenomena deriving from the adjacency of some additional π-electron ring systems and relativistic contributions.

The ^{13}C NMR spectra are only moderately influenced, the orders of resonances remaining the same like in the free ligands. The carbon deshielding is generally observed, the Δ^{13C}_{coord} parameters not exceeding 8 ppm. In contrast, the formation of Ir–N bonds results in the large ^{15}N low-frequency shifts (the Δ^{15N}_{coord} values ranging from *ca.* −105 ppm to *ca.* −120 ppm), even more expressed than in the similar Pd(II), Pt(II), Pt(IV), Au(III), Co(III) and Rh(III) species. In the *cis*-$[Ir(LL)_2Cl_2]^+$ cations the nitrogens positioned *trans* to chlorine (N(1)) are *ca.* 3–8 ppm more shielded than those *trans* to another nitrogen (N(1′)), this relation being the same as in the analogous Rh(III) complexes, but opposite to that in the relevant Co(III) species.

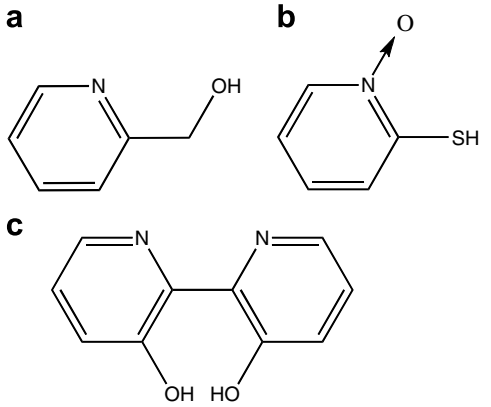

Fig. 1. Schematic of ligands (a) H-OPy, (b) H-2MPO, and (c) H_2-OBPy.

2. Experimental

All compounds described below were handled under an argon atmosphere with rigorous exclusion of air and water using standard Schlenk line and glove box techniques. All solvents were stored under argon and used as received (Aldrich) in Sure/Seal™ bottles, including toluene (tol) and pyridine (py). The following chemicals were used as received (Aldrich and Alfa Aesar): $Ti(OPr^i)_4$, $Zr(OBu^t)_4$, H-ONep, H-2MPO, and (*R*,*S*) H_2-OBPy. [Ti(μ-ONep)(O-Nep)$_3$]$_2$was prepared according to the literature procedure [7].

FT-IR data were obtained on a Bruker Vector 22 Instrument using KBr pellets under an atmosphere of flowing nitrogen. Elemental analysis was performed on a Perkin–Elmer 2400 CHN–S/O Elemental Analyzer. All NMR samples were prepared from dried crystalline materials that were handled and stored under an argon atmosphere and redissolved in toluene-d_8.

2.1. General synthesis

Due to the similarity of synthesis of **1**–**5**, a general description is supplied with specific details listed for each compound below. The desired ligand was slowly added to a stirring solution of the $M(OR)_4$ dissolved in toluene (~5 mL). After 12 h, the resultant clear reaction mixtures were concentrated by rotary evaporation and then either cooled at −35 °C or left at room temperature uncapped until X-ray quality crystals formed.

2.1.1. $(2MPO)_2Ti(OCHMe_2)_2$ (**1**)

Used $Ti(OCHMe_2)_4$ (1.00 g, 3.52 mmol), H-2MPO (0.895 g, 7.04 mmol), and tol (~10 mL). Yield 1.26 g (85.7%). FT-IR (KBr, cm^{-1}) 3081(w), 3053(w), 2966(s), 2926(s), 2855(s), 1595(m), 1546(m), 1461(s), 1419(m), 1372(m), 1324(m), 1255(m), 1208(s), 1162(s), 1116(s), 983(s), 850(s), 764(s), 713(s), 608(s), 488(m). ^{1}H NMR (399.9 MHz, tol-d_8) δ 8.01–7.99 (4H, mult, ONC_5H_4S, J_{H-H} = 6.0 Hz), 5.04 (0.97H, $OCH(CH_3)_2$, J_{H-H} = 6.2 Hz), 1.23 (8.8H, d, $OCH(CH_3)_3$, J_{H-H} = 8.0 Hz). Elemental *Anal.* Calc. for $C_{16}H_{22}N_2O_4S_2Ti$: C, 45.93; H, 5.30; N, 6.70. Found: C, 45.85; H, 5.31; N, 6.30%.

2.1.2. $(2MPO)_2Ti(OCH_2CMe_3)_2$ (**2**)

Used $Ti(OCH_2CMe_3)_4$ (1.00 g, 2.52 mmol), H-2MPO (0.642 g, 5.05 mmol), and tol (~10 mL). Yield 1.14 g (95.2%). FT-IR (KBr, cm^{-1}) 3105(w), 2950(s), 2903(m), 2865(s), 2828(s), 2687(w), 1601(m), 1543(m), 1460(s), 1419(m), 1395(m), 1375(m), 1207(s), 1142(s), 1090(s), 1059(s), 1023(s), 812 (m), 800(w), 755(m), 710(w), 670(s), 612(m), 578(m), 480(m). ^{1}H NMR (399.9 MHz, $CDCl_3$) δ 8.01 (1H, d, ONC_5H_4S, J_{H-H} = 6.8 Hz), 7.45 (1.1H, d, ONC_5H_4S, J_{H-H} = 6.8 Hz), 7.21 (1.3H, t, ONC_5H_4S, J_{H-H} = 7.6 Hz), 6.81 (1.1 H, t, ONC_5H_4S, J_{H-H} = 6.8 Hz) 4.34 (2.2H, s, $OCH_2C(CH_3)_3$), 0.86 (13.2H, s, $OCH_2C(CH_3)_3$). Elemental *Anal.* Calc. for $C_{20}H_{30}N_2O_4S_2Ti$: C, 50.60; H, 6.37; N, 5.90. Found: C, 51.31; H, 6.64; N, 5.69%.

2.1.3. $(2MPO)_2Ti(OCMe_3)_2$ (**3**)

Used $Ti(OCMe_3)_4$ (1.00 g, 2.94 mmol), H-2MPO (0.747 g, 5.88 mmol), and tol (~10 mL). Yield 1.22 g (93.1%). FT-IR (KBr, cm^{-1}) 3078(m), 3032(w), 2972(s), 2924(s), 2859(m), 1595(m), 1545(m), 1460(s), 1418(m), 1389(w), 1354(m), 1257(m), 1188(m), 1167(m), 1139(m), 1091(m), 1015(s), 983(s), 840(m), 782(m), 736(m), 708(m), 602(m), 583(m). ^{1}H NMR (399.9 MHz, tol-d_8) δ 7.99 (1H, d, ONC_5H_4S, J_{H-H} = 6.4 Hz), 7.43 (1H, d, ONC_5H_4S, J_{H-H} = 6.8 Hz), 7.15 (1.2H, t, ONC_5H_4S, J_{H-H} = 7.8 Hz), 6.77 (1H, t, ONC_5H_4S, J_{H-H} = 7.0 Hz), 1.31 (11H, s, $OC(CH_3)_3$). Elemental *Anal.* Calc. for $C_{18}H_{26}N_2O_4S_2Ti$: C, 48.43; H, 5.87; N, 6.28. Found: C, 48.19; H, 5.87; N, 6.26%.

2.1.4. $[(ONep)_2Ti(\mu_c\text{-}OBPy)]_3$ (**4**)

Used $Ti(ONep)_4$ (0.11 g, 0.27 mmol) and H_2-OBPy (0.05 g, 0.27 mmol). FT-IR: (KBr, cm^{-1}) 2952(s), 2865(s), 2829(m), 1574(m), 1442(m), 1411 (s), 1362(w), 1316(s), 1261(w), 1227(w), 1206(w), 1098(s), 1074(s), 1024(s), 871(m), 805(m), 731(m), 659(s), 490(w), 471(w). ^{1}H NMR (400.1 MHz, tol-d_8) δ 8.27 (1.0H, dd, $(NC_5H_3O)_2$), 6.82 (1.1H, dd, $(NC_5H_3O)_2$), 6.55 (1.1H, mult, $(NC_5H_3O)_2$), 4.29 4.16 (1.8H, dd, $OCH_2(CH_3)_3$), 0.95 (9H, s, $OCH_2(CH_3)_3$). Elemental *Anal.* Calc. for $C_{60}H_{84}N_6O_{12}Ti_3$: C, 58.87; H, 6.83; N, 6.86. Found: C, 58.79; H, 6.58; N, 6.79%.

2.1.5. $[(OBu^t)_2Zr(\mu_c\text{-}OBPy)]_3$ (**5**)

Used $Zr(OBu^t)_4$ (0.075 g, 0.27 mmol) and H_2-OBPy (0.05 g, 0.27 mmol). FT-IR: (KBr, cm^{-1}) 2968(s), 2928(m, sh), 2866(m, sh), 2813(w, sh), 1577(m), 1449(s), 1413(s), 1359(m), 1322(s), 1260(w), 1227(m, sh), 1198(s), 1115(m), 1073(w), 1024(s, br), 906(m), 869(s), 787(m, sh), 752(m, sh), 733(m), 647(s), 623(s), 538(m, br), 480(m,br). ^{1}H NMR (400.1 MHz, tol-d_8) δ 8.23 (1.0H, dd, $(NC_5H_3O)_2$), 6.91 (1.0H, dd, $(NC_5H_3O)_2$), 6.58 (1.0H, mult, $(NC_5H_3O)_2$) 1.31 (9.4H, s, $OC(CH_3)_3$). Elemental *Anal.* Calc. for $C_{68}H_{89}N_6O_{12}Zr_3$: C, 56.09; H, 6.16; N, 5.77. Found: C, 52.25; H, 6.53; N, 4.48%.

2.2. General X-ray crystal structure information [8,9]

Crystals were mounted onto a glass fiber from a pool of Fluorolube™ and immediately placed in a cold N_2 vapor stream, on a Bruker AXS diffractometer equipped with a SMART 1000 CCD detector using graphite monochromatized Mo Kα radiation (λ = 0.7107 Å). Lattice determination and data collection were carried out using SMART Version 5.054 software. Data reduction was performed using SAINTPLUS Version 6.01 software and corrected for absorption using the SADABS program within the SAINT software package.

Structures were solved by direct methods that yielded the heavy atoms, along with a number of the lighter atoms or by using the PATTERSON method, which yielded the heavy atoms. Subsequent Fourier syntheses yielded the remaining light-atom positions. The hydrogen atoms were fixed in positions of ideal geometry and refined using SHELXS software. The final refinement of each compound included anisotropic thermal parameters for all non-hydrogen atoms. It is of note that crystal structures of $M(OR)_x$ often contain disorder within the atoms of the ligand chain causing higher than normal final correlations [10–15]. All final CIF files were checked at http://www.iucr.org/. Additional information concerning the data collection and final structural solutions can be found in the Supplementary data or by accessing CIF files through the Cambridge Crystallographic Data Base [8]. Data collection parameters for **1**–**6** are

given in Table 1. The problems associated with particular crystal structures are listed below.

*2.2.1. Compound **2***

For **2**, the 2MPO ring was found to be distorted away from normal in the final refinement efforts due to disordering which was successfully modeled as two environments based on the coordination of the ring (see Fig. 2). The modeling of the disordered 2MPO ligand proceeded first by locating sites for both the O and S atoms for each of the octahedral positions about the Ti atom (4 sites total). These sites were assigned as S(2), O(2), S(2′), or O(2′) based on the approximate bond distance from the Ti atom. Each of the S and O sites were assigned 0.5 occupancy and their positional and thermal ellipsoid parameters were refined. In similar fashion, N and C atoms in the 2MPO ring also required partial occupancy assignment and refinement. Finally, all similar bonds (i.e., S(1)–Ti(1) bond equal to S(1′)–Ti(1) bond, etc.) for the disordered configurations of the 2MPO ligand were restrained to be equivalent at appropriate bond lengths. The final refinement revealed stable atom positions and reasonable thermal ellipsoids for all of the disordered 2MPO sites. Due to the disorder, H atoms were not modeled on this ligand, but were added to the chemical formula during the final refinement to generate appropriate crystal data values.

*2.2.2. Compound **4***

In the host lattice of structure **4** several disordered toluene (tol) solvent molecules were observed. These were modeled using the PLATON/SQUEEZE program (Ver. 251005) and were located at: (1/2,0,0) (0,1/2,0) (0,0,0) (0.663,0.127,1/2) (0.337,0.873,1/2) (0.151,0.261,0.881) (0.849,0.739,0.119) (0,0.280,0.859) (0,0.720,0.141). The SQUEEZE program calculated a potential volume of 1405.4 Å^3 and an electron count of 266 electrons/cell, consistent with ~6 toluene molecules/unit cell which implied partial occupancy for most of the toluene solvent molecules. Based on the determined electron density obtained via SQUEEZE, 6 tol molecules were added to the contents of the unit cell during the final refinement series so that the proper crystal data could be calculated. In addition, a number of the terminal ONep groups were found to display rotational and/or displacement disorder, which is often noted for metal alkoxides [10–15]. For the dominant configuration, the C atoms were refined with anisotropic atomic displacement parameters, whereas for the minor orientation, the ONep group was refined using isotropic atomic displacement parameters. The disordered ONep groups were restrained (37 restraints total) to have equivalent C–C bond lengths for the two differing orientations (e.g., all C–CH_3 bond lengths for both ONep orientations were restrained to be equal). This aided in convergence of the refinement. Disordered C atoms on ONep ligands were refined without H atoms; however, the H

atoms were included in the formula unit during the final refinement for proper crystal data calculation.

3. Results and discussion

A search of the literature reveals that the 2MPO ligand (or derivatives) will bind to numerous metal centers (46 by CDCC search V 1.7), [8,9] with the late transition metals Co (13 derivatives) [16–23] or Zn (6 derivatives) being the most common metals [16,24–27]. For these compounds, the 2MPO acts in a chelating mode to form disubstituted monomers [16,26,27] or chelating unidentate bridged dinuclear [24,25] species. There are no reports of group 4 2MPO derivatives or OR/2MPO systems. For the OBPy ligand, only a single Ru species, $[(bipy)_2Ru(\mu\text{-}OBPy)]_2[PF_6]$ [28] has been reported wherein the OBPy moiety acts as a bridge in a twist conformation where the N atom on one ring and the O on the other bind to the same metal. As can be determined, these ligands offer the potential to generate controlled structures acting as chelates in the case of the 2MPO or as bridges as observed for the OBPy ligand. Since there were no group 4 cations that employ these ligand, we initiated our investigation with $Ti(OR)_4$ (Eqs. (1) and (2)).

3.1. Synthesis

Whether using the 2MPO or OBPy ligand, the alcohol exchange proceeds smoothly with toluene as a solvent. For each reaction, there is a significant intense color change associated with the binding of the ligand, turning from colorless to intense yellow-orange colors. Due to the minimum amount of solvent used, several of the reactions precipitated after stirring but a clear solution was easily produced upon heating. X-ray quality crystals were isolated upon cooling of the reaction mixture to room temperature or through slow evaporation of the volatile component. Dried crystalline materials were used for all remaining analyses.

The FT-IR spectrum of the H-2MPO ligand has a sharp stretch at 754 cm^{-1}, which is consistent with the N–O interaction. After binding to the $Ti(OR)_4$ (**1**–**3**, Eq. (1)), the N–O stretch of the 2MPO has been significantly reduced in intensity and slightly shifted for each of the compounds (**1**, 764; **2**, 755; **3** 782 cm^{-1}). Interestingly, the SH stretch (reportedly present at 2600–2550 cm^{-1}) is not observed with any intensity in the IR spectrum of the free ligand and therefore, not unexpectedly it was not found in the spectra of **1**–**3**. For each compound a stretch around 3100 cm^{-1} is observed which may represent the C–S stretch of the 2MPO ligand which is much more intense in **1**–**3** versus the free ligand. The remainder of the stretches and bends are associated with the 2MPO ligand or the OR ligands of **1**–**3**. Combined, these data indicate that the 2MPO has reacted and bound through the S and O atoms of the ligand.

The FT-IR spectrum of the H_2-OBPy ligand displays a broad OH stretch around 3000 cm^{-1} with the majority of stretches and bends of the py ring below 1500 cm^{-1}. Upon reacting, the spectrum of **4** or **5** (Eq. (2)) no longer displays an OH stretch but does show stretches below 1500 cm^{-1} similar to those noted for the free ligand. In addition, there are a number of stretches and bends from 3000 to 2700 cm^{-1} that represent the aliphatic pendant chains of the OBu^t and ONep ligands of **4** and **5**, respectively. Again, it appears the alcoholysis exchange had successfully occurred for Eq. (2).

3.2. Structures

Single crystal X-ray diffraction studies were undertaken to assist in identifying the structure of the final products of Eq. (1) (**1**–**3**) and Eq. (2) (**4**–**5**). The structures of **1**–**3** were found to be similar in constructs where Fig. 2 is the representative structure plot of **2**. Table 2 lists the selected average metrical data for **1**–**3**. For each of these compounds, two bidentate 2MPO ligands use their O and S atoms to fill 4 of the octahedrally (Oh) bound Ti metal center. The final 2 sites are filled by two parent alkoxides. Due to the bidentate nature of the 2MPO ligand two binding modes are available however, this only led to disorder in the final structure of **2**. Fig. 2 shows the *trans* S and Fig. 2b shows the *cis* S arrangement that were successfully modeled for **2**. The Ti–O and Ti–S distance for **1**–**3** are self-consistent (av 1.80 Å and 2.46 Å, respectively) and are in agreement with literature reported distances [16,24–27]. The bite angle of the 2MPO ligand was found to be av 78.2 ° which is on the short end of the range (72.8–89.7°) noted for 2MPO ligated compounds [29,30]. This imparts a slight distortion to the semi-regular Oh geometry around each of the Ti metal. The av Ti–O–N angle (118.8°) is significantly larger in comparison to the Ti–S–C angle (98.4°). The remainder of angles and distances are consistent with each other and literature model compounds [16,24–27].

Table 2
Selected averaged metrical data for **1**–**3**

	1	2	3
Distances (Å)			
Ti–OR	1.80	1.81	1.79
$Ti–O_{2MPO}$	2.05	2.22	2.07
Ti–S	2.48	2.43	2.47
C–S	1.72	1.64	1.72
N–O	1.34	1.40	1.34
Angles (°)			
OR–Ti–OR	98.1	94.8	98.8
$S_{2MPO}–Ti–O_{2MPO}$	77.4	79.8	77.4
$RO–Ti–O_{2MPO}$	92.1, 162.5	90.2, 163.7	91.3, 164.8
RO–Ti–S	85.8, 108.6	83.9, 108.5	88.9, 105.6
S–Ti–S	158.3	161.9	157.9

Ti–S–C	97.3	100.2	97.8
N–C–S	118.1	121.1	188.1

Switching to the heterocyclic OBPy ligand, compounds **4** (see Graphical Abstract) and **5** (Fig. 3) were isolated. The μ_c-OBPy ligand is found to act in a tetradentate chelating bridging manner, forming a trinuclear species with C_{3v} symmetry wherein each metal center adopts an Oh geometry with two terminal OR, two O and two N from the three bridging OBPy ligand. While the OBPy ligands use both the N and O to bind to the metal centers, due to the free

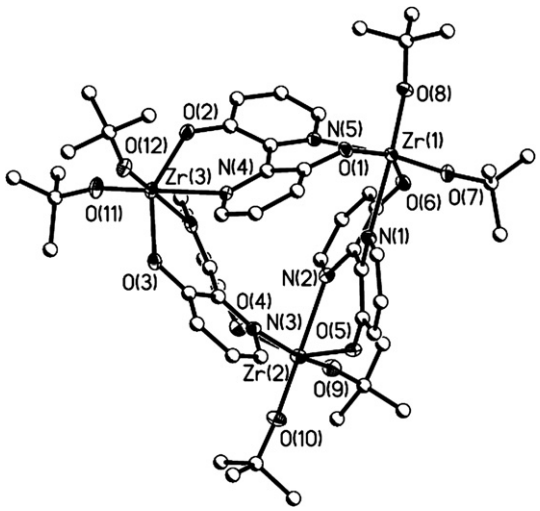

Fig. 3. Structure plot of **5**. Heavy atom thermal ellipsoids drawn at 30% level and carbon and hydrogen atoms drawn as ball and stick for simplicity.

rotation of the rings, the N and O atoms of one ring bind to different metal centers. This structure forms independent of the metal or pendant hydrocarbon chain. The metrical data for **4** and **5** are listed in Table 3. For 4, the av Ti–O distance was found to be 1.86 Å from a range of 1.78–1.92 Å and an av Ti–N distance of 2.31 Å with a range of (2.30–2.33 Å). The Ti–N distance for **4** are long in comparison to other $Ti(OR)_4$ that possess a bound py (range 2.17–2.34 Å; av 2.26 Å) [5,31–33]. The forced interaction by the OBPy constructs may account for the longer interaction. In comparison, the av Zr–O distances of **5** were found to be 1.99 Å and Zr–N av distance of 2.44 Å. In contrast to the Ti system, the Zr–N distances are in agreement with the few zirconium alkoxy pyridine compounds present in the literature (range 2.34–2.53 Å; av 2.44 Å) [5,34–37]. The larger Zr cation may allow for a less forced interaction with the distance variations between 4 and 5 being attributed to the size change from 6-coordinated Ti (0.745 Å) to Zr (0.86 Å) [38]. Not surprisingly, the geometries noted around the metals are distorted octahedrons.

Elemental analyses of the bulk powder of **1**–**5** were found to be in agreement with the solved crystal structures. The analyses of the 2MPO species are surprisingly accurate even though $M(OR)_x$ often give unreliable elemental analyses due to ligand decomposition, volatility, or high reactivity with the circumjacent atmosphere. The reproducibility of **1**–**3** indicates the stability of these compounds. In fact, air exposed samples unexpectedly also had acceptable elemental analysis consistent with the single crystal structures. For **4**, the elemental analysis is within agreement but **5** differs slightly from expected values. This may be attributed to the problems discussed above with a slightly reduced stability of the larger congener.

3.2.1. Solution behavior

In order to determine if the structures were retained in solution, the crystals of **1**–**5** were individually dissolved in tol-d_8 at as concentrated levels as possible. The ^{1}H NMR spectra were collected at room temperature and are discussed in terms of the different alkoxides below.

For **1**–**3**, the spectra in tol-d_8 showed the expected 4 resonances for the 2MPO ligand and the respective alkoxide ligands. However, the expected doublets and triplets of the 2MPO were further complicated by additional H–H splittings. In order to investigate solvent interaction effects, the samples were redissolved in $CDCl_3$ and the NMR spectra collected with no change in the multiple resonances noted. Variable temperature NMR (−40 to +45 °C) investigations also showed no change in the alkoxide resonances and only a slight decrease in the splittings noted previously. This eliminates the idea that the bidentate ligand is reversibly binding/unbinding to the metal center; however, cross-ligand H interactions or isolation of diastereomers based on the binding nature of the 2MPO ligand with four potential arrangements of the 2MPO ligand around the metal center (2 meso and 2 enantiomers) may result. Computational simulation of the expected spectra and the experimentally observed samples were identical. This indicates that the multiplet and fine structure observed in ^{1}H NMR of **1**–**3** and the H-2MPO ligand itself, result from the ^{1}H–^{1}H *J* couplings which ranged from 6.8 to 8.5 Hz, 1.3 to 1.6 Hz and 0.3 to 0.5 Hz for the ^1J, ^2J and ^3J couplings, respectively. Therefore, it can be concluded that the solid-state constructs of **1**–**3** are retained in solution.

The OBPy ligand is sold as a mixture of *R* and *S* due to the hindered rotation of the OH moieties. Therefore the ^{1}H NMR spectrum of the ligand reflects two complete sets of resonances for the *R* and *S* derivatives with significant overlap occurring. Upon binding to form either **4** or **5**, the ^{1}H NMR spectra revealed a significant change in the chemical shift but not the splittings. In comparison to the bound species, compound **5** displays greater resolution of the peaks than what was observed for **4**. The simplicity of these spectra and similarity to starting racemic mixture indicates that there is a handedness to the binding of the OBPy ligand to the metal centers. If there was a mixture of *R* and *S* to each metal center, more diastereomers would be observed, the OBPy resonances would therefore would be much more complex since the *R*/*S* ratio would range from 3:0, 2:1, 1:2 and 0:3 and each would be present in the NMR. Consequently, each molecule of **4** or **5** is either completely bound by *R* or *S* OBPy ligand which is has been observed previously for chiral alkoxide ligands [39]. For 4 and **5**, only one Bu^t resonance is observed for either compound; however, for the aromatic protons, doublets of the expected resonances are observed since these protons are now diastereotopic due to the handedness of the central core induced by the OBPy ligand.

Table 3
Selected averaged metrical data for **4**–**5**

Compound	M–OR (Å)	$M–O_{OBPy}$ (Å)	M–N (Å)
4	1.82	1.90	2.31
5	1.93	2.05	2.44
	O–M–O (°)	N–M–N (°)	$N–M–O_{OBPy}$ (°)
4	98.8, 152.3	91.5	82.1, 176.5
5	100.6, 146.3	87.4	80.7, 172.6

4. Summary and conclusion

We have continued our exploration of potential ceramic materials precursors using group 4 $M(OR)_x$ and the heterocyclic modifying ligands H-2MPO and H_2-OBPy which have led to the isolation of **1**–**3** and **4**–**5**, respectively. The products were isolated and characterized by single crystal X-ray diffraction as the first examples of these ligands and group 4 $M(OR)_x$. The 2MPO ligand was found to chelate to the Ti metal center through the N and the S forming $(2MPO)_2Ti(OR)_2$ independent of the hydrocarbon chain present. This species is reminiscent of '$(OPy)_2$Ti' [6] and '$(CP)_2$Ti' species and the potential rich chemistry associated with the '$(2MPO)_2$Ti' system is being explored. In contrast, the OBPy ligand was found to act as a tetradentate chelating bridging ligand only forming $[(\mu_c\text{-OBPy})M(OR)_2]_3$. With the unique trinuclear constructs, controlled manipulation of the terminal alkoxides is possible and is currently under exploration. Combined, these new N-based heterocycles motifs allow for controlled construction of $M(OR)_x$ and their utility in materials applications are also being explored.

Appendix A. Supplementary data

CCDC 683997, 683998, 683999, 6834000 and 684001 contain the supplementary crystallographic data for **1**–**5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

The authors would like to thank Dr. Todd M. Alam for his simulation of the NMR data. For support of this research, the authors thank the Office of Basic Energy Science and the US Department of Energy under Contract DE-AC04-94AL85000. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy.

reducing $HAuCl_4$ self-assembled into uniform spherical aggregates when a low concentration of compound **1** is used, but spherical Au nanoparticles are obtained with relatively higher concentration of the reducing agent. The suitable chemical environment permits reduction at more moderate conditions and results in higher colloid uniformity than the usual methods. It is noteworthy that Au nanoparticles have been prepared earlier by using many benzenethiol-derivatives [18,19]. Our objective is to synthesize such nanoparticles of varied morphologies by using a benzene diol derivative.

2. Experimental

2.1. Materials and physical methods

All aqueous solutions were prepared from Millipore water (resistivity, 18 MΩ; Millipore Systems). Gold chloride trihydrate ($HAuCl_4 \cdot 3H_2O$) was purchased from Aldrich and used without purification. Other reagents were purchased from commercial sources and used without further purification. Solvents used for spectroscopic studies were purified and dried by standard procedures before use [20]. Elemental analysis was carried out in a 2400 Series-II CHN analyzer, Perkin Elmer, USA. FT-IR spectra were obtained on a Nicolet MAGNA-IR 750 spectrometer with samples prepared as KBr pellets. Absorption spectra were studied on a Shimadzu UV2100 UV–Vis recording spectrophotometer. The ESI-MS was recorded on Qtof Micro YA263 mass spectrometer. Morphology of all the samples was investigated by Transmission Electron Microscope (TEM). TEM images were recorded in a Jeol JEM 2010 transmission electron microscope operated at an accelerated voltage of 200 kV. A drop of dilute solution of the sample in water–methanol on a 300 mesh carbon coated copper grids was dried in vacuum and directly observed in the TEM.

2.2. Synthesis of 2,3,5,6-tetrakis(morpholinomethyl)hydroquinone (*1*)

The mixture of hydroquinone (1.1 g, 10 mmol), morpholine (3.48 g, 40 mmol) and paraformaldehyde (2 g, 66.67 mmol) in 1,4-dioxane (20 mL) was heated to reflux and kept at this temperature for 24 h. The resulting solution was cooled to room temperature. The solution was filtered, concentrated on a rotary evaporator to dryness and kept overnight at 4 °C. The resulting compound is solid. Colorless prismatic single crystals of **1** suitable for X-ray crystallography were obtained on recrystallization with toluene (yield = 0.58 g, 65%). Data for **1**: *Anal.* Calc. for $C_{26}H_{42}N_4O_6$: C, 61.66; H, 6.94; N, 11.06. Found: C, 61.54; H, 6.81; N, 10.93%. FT-IR (KBr phase) ν/cm^{-1} 3433, 2852, 1650. ^1H NMR ($CDCl_3$, 300 MHz), δ = 10.4 (br s, 2H), 3.68 (s, 16H), 2.51 (s, 8H), 1.58 (s, 16H). ^{13}C NMR ($CDCl_3$, 75 MHz), δ = 149.7 (2C), 121.5 (4C), 67.0 (8C), 54.7 (4C), 52.9 (8C). HR-MS (ESI): ($C_{26}H_{42}N_4O_6 + H^+$) Calc. 507.64, found 507.64.

2.3. Synthesis of gold nanoparticle

The synthesis of Au nanoparticles was achieved by the chemical reduction of $HAuCl_4$ in methanol–water medium with compound **1** without using any stabilizer. The following reduction methods with different concentrations of compound **1** were employed.

2.3.1. Method I

To 20 mL of a 10^{-3} M methanolic solution of compound **1**, a total of 1 mL of a 2.23×10^{-5} M $HAuCl_4$ aqueous solution was added dropwise over a period of 60 s at room temperature. Stirring was stopped 20 s after the addition was completed. During this period, the color of the solution changed from pale yellow to purple.

Goodness-of-fit	1.056

2.3.2. Method II

The method is similar to method I except that 60 mL of compound **1** was used and the color of the solution changed from pale yellow to blue.

2.4. X-ray data collection and structure determination

Crystal data of **1** are summarized in Table 1. The diffraction experiment was carried out on a Bruker SMART CCD area-detector diffractometer at 150 K. No crystal decay was observed, so that no time-decay correction was needed. The collected frames were processed with the software SAINT [21], and an empirical absorption correction was applied (SADABS) [22] to the collected reflections. The calculations were performed using the Personal Structure Determination Package [23] and the physical constants tabulated therein [24]. The structure was solved by direct methods (SHELXS) [25] and refined by full-matrix least-squares using all reflections and minimizing the function $\sum w(F_o^2 - kF_c^2)^2$ (refinement on F^2). All the non-hydrogen atoms were refined with anisotropic thermal factors. All the other hydrogen atoms were placed in their ideal positions (C–H or O–H = 0.97 Å), with the thermal parameter U 1.10 times that of the atom to which they are attached, and not refined.

3. Results and discussion

3.1. Description of the structure of 2,3,5,6-tetrakis(morpholinomethyl)-hydroquinone (*1*)

2,3,5,6-Tetrakis(morpholinomethyl)hydroquinone (**1**) has been synthesized by the aminomethylation of hydroquinone with morpholine. An ORTEP view of **1** is shown in Fig. 1. Selected bond lengths and bond angles are listed in Table 2. As shown in Fig. 1, the asymmetric unit of **1** contains one-half molecule with the other half generated by a center of inversion which lies at the center of the benzene ring. The benzene rings in the molecules do not show any unusual features, and the bond lengths and bond angles are within the normal ranges. The shorter bond distance O1–C1 of 1.3763(14) Å [26] in the molecular unit indicates the p–π conjugation of O1 with the benzene ring. The morpholino rings adopt the usual chair conformation similar to those of 2,6-bis-(*N*-methylenemorpholino)-4-methylphenol [27] and 2,5-bis(morpholinomethyl) hydroquinone [26], but the two morpholine pendant arms in *para*

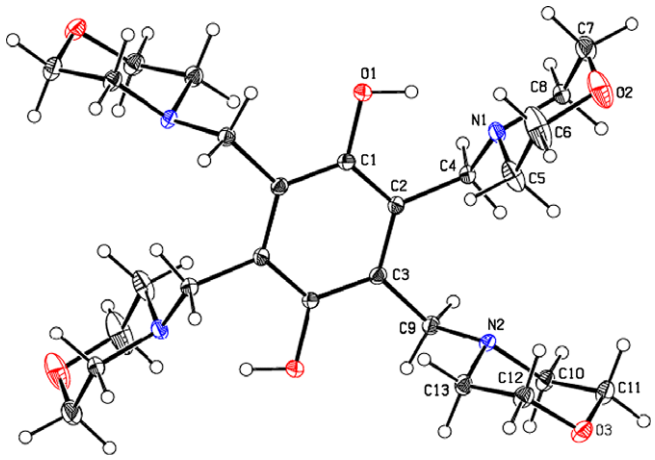

Fig. 1. ORTEP drawing and atom numbering scheme for compound (**1**).

positions display *trans*-configuration as regards the parent phenol ring with atoms N1, O2, N2 and O3 deviating from the phenol moiety by 0.897, 3.029, 1.343 and 3.753 Å, respectively. The bond distances N1–C5 (1.4610(14) Å) and N2–C9 (1.4673(13) Å) are in accordance with that of reported one [26]. There exists the intramolecular O1–H ··· N1 hydrogen bond between the phenolic O atom and the morpholine N donor, and the distance (1.811(13) Å) between the proton and acceptor nitrogen atom is obviously shorter than the sum of their Van der Waals' radii (2.6615(11) Å), all being normal weak hydrogen bond interactions [28]. It is worthy of being noted that the two six-membered hydrogen-bonded rings in one unit can stabilize the crystal structure. No significant π–π interaction between the phenyl rings of the molecules packing together in the solid state exists.

3.2. Preparation and characterization of gold nanoparticles by method I

Au colloids have been obtained through reduction of $HAuCl_4$ by 2,3,5,6-tetrakis-(morpholinomethyl)hydroquinone at room temperature. The characteristic UV–Vis absorption spectrum of the Au nanoparticles prepared by this method is shown in Fig. 2. On mixing $HAuCl_4$ and **1**, the plasmon band of gold nanoparticles at 535 nm is observed. This indicates that the reduction of $AuCl_4^-$ occurs by compound **1** to produce the nanoparticles. A broad and well defined absorption band at 744 nm is also found, and could be assigned to the aggregative states of gold nanoparticles [29]. The coupling of the plasma resonance modes of the Au nanoparticles is caused by aggregation, and this is reflected in the red shift of

Table 2
Selected bond lengths (Å) and bond angles (°)

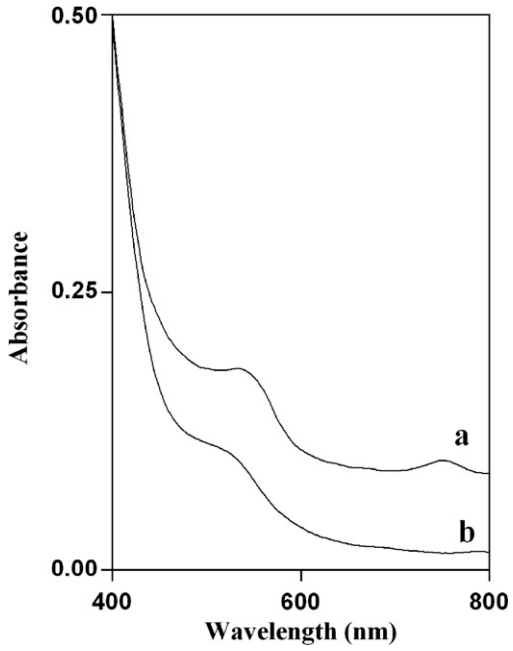

Fig. 2. UV–Vis spectra for the gold nanoparticles synthesized by method I before (a) and after (b) ultrasonic treatment.

the surface plasma resonance in the optical spectrum. Such red shift is supported by the well-known Mie scattering theory [30]. The essence of this theory is that a shift in surface plasma resonance is caused by deviation of the particles from the spherical geometry, such as that occurring in aggregates. In the circumstances, equivalent resonances are no longer produced by transverse and longitudinal dipole polarizability. As a result, there appear two plasma resonances: (i) a broadened and red-shift longitudinal plasma resonance and (ii) a transverse plasma resonance whose absorbance remains centered at *ca.* 540 nm. The electron spray ionization mass spectrum of the mixture of compound **1** and $HAuCl_4$ shows a peak at $m/z = 527.62$ along with the peak at $m/z = 507.64$ (for compound **1**) that can be assigned to the formation of 2,3,5,6-tetrakis-(morpholinomethyl)quinone ($C_{26}H_{40}N_4O_6$). The isotropic distributions for the above molecular species obtained experimentally (at $m/z = 527.62$) correspond to the simulated patterns (see Supplementary data, Fig. S1). In this spectrum the peak at $m/z = 527.62$ assigned to ($C_{26}H_{40}N_4O_6 + Na^+$) species corroborate the presence of 2,3,5,6-tetrakis-(morpholinomethyl)quinone, the oxidized product of **1**.

We have then characterized the gold colloids by transmission electron microscopy (TEM). A representative one is shown in Fig. 3. Spherical aggregates having diameter of *ca.* 170 ± 17 nm were observed. The enlarged view (Fig. 3, inset) clearly shows the edge of a randomly selected spherical aggregate which consists of individual particles with a size of *ca.* 10 nm. It should be noted that the interaction between individual particles is relatively weak and the spherical aggregates could be destroyed by ultrasonic treatment. The spherical aggregates disappeared and individual nanoparticles were monodispersed after ultrasonic treatment (30 min at 10 kHz), as shown in Fig. 4. The results indicate that the spherical aggregates might be formed through intermolecular interaction between nanoparticles. Fig. 2 shows the UV–Vis absorption spectra of the spherical aggregates before and after ultrasonic treatment. The plasmon absorption band of the gold nanoparticles at 535 nm is retained, but the absorption of the spherical aggregates at 744 nm disappears on ultrasonic treatment. These results also indicate that the spherical aggregates are composed of individual nanoparticles [31].

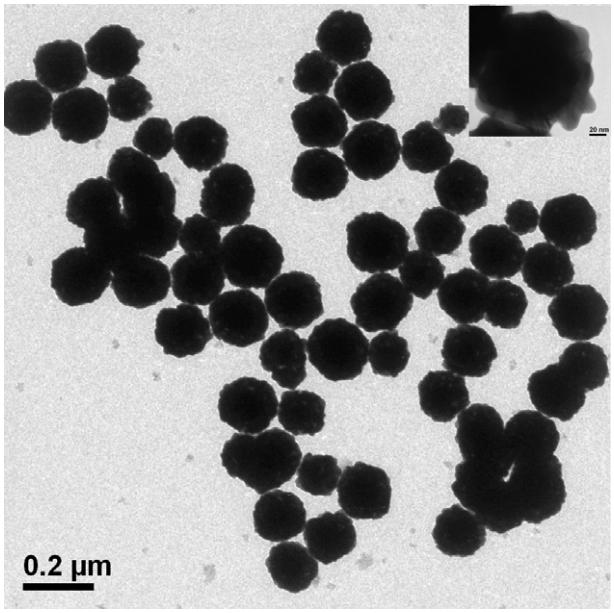

Fig. 3. Representative TEM image of gold nanoparticles prepared by method I.

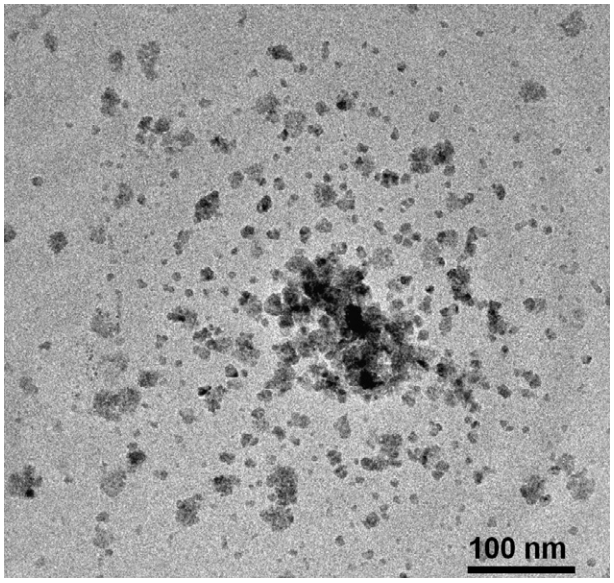

Fig. 4. TEM image of gold nanoparticles synthesized by method I after ultrasonic treatment.

In order to confirm the formation of a crystal phase and calculate the mean size of the nanoparticles, X-ray diffraction (XRD) analysis was performed. Fig. 5 shows the XRD pattern of the nanoparticles obtained by method I. The diffraction features appearing at $2\theta = 38.37°$, 44.49°, 64.62°, 77.72° and 81.52° correspond to the (111), (200), (220), (311) and (222) planes of the standard cubic phase of Au, respectively. As expected, the XRD peaks of the nanocrystallites were considerably broadened compared to those of the bulk Au because of the finite size of these crystallites.

3.3. Preparation and characterization of gold nanoparticles by method II

Au colloids were obtained through the reduction of $HAuCl_4$ by compound **1** under similar condition as that for Method I. Aqueous $HAuCl_4$ solution showed a very pale yellow color. Reduction of

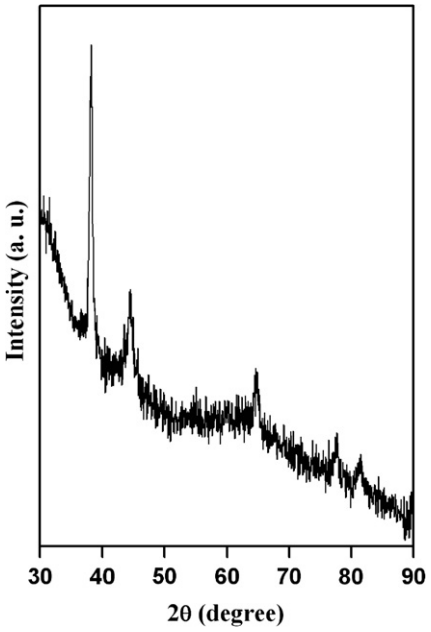

Fig. 5. XRD pattern of aggregate of gold nanoparticles.

$HAuCl_4$by compound 1 in methanol changed the color of the solution to blue. Gold nanoparticles exhibit strong plasmon resonance absorption that is dependent on the particle size and shape. For roughly spherical gold nanoparticles, the plasmon band maximum falls between 520 and 530 nm [32]. Fig. 6 shows the UV–Vis absorption spectrum of gold nanoparticles generated by method II. The spectrum was taken for freshly prepared samples. The absorption band for the nanoparticles is centered at 527 nm.

Fig. 7 shows the TEM image of prepared gold nanoparticles following method II in methanol–water medium. The micrograph clearly indicates the formation of nearly spherical nanoparticles with an average diameter of 12 nm. The diameter of these nanoparticles is shorter than those prepared by method I. The particles

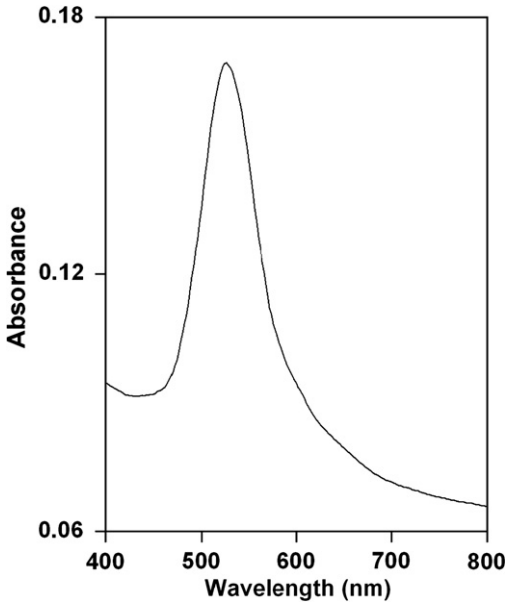

Fig. 6. UV–Vis spectrum of the spherical gold nanoparticles prepared by method II.

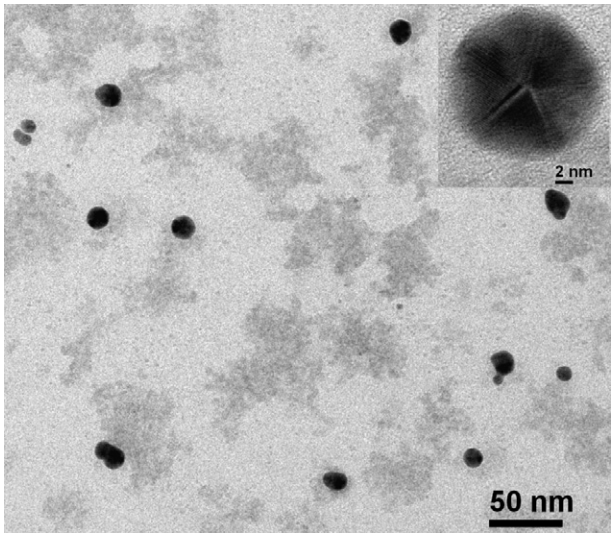

Fig. 7. Representative TEM image of spherical gold nanoparticles prepared by method II.

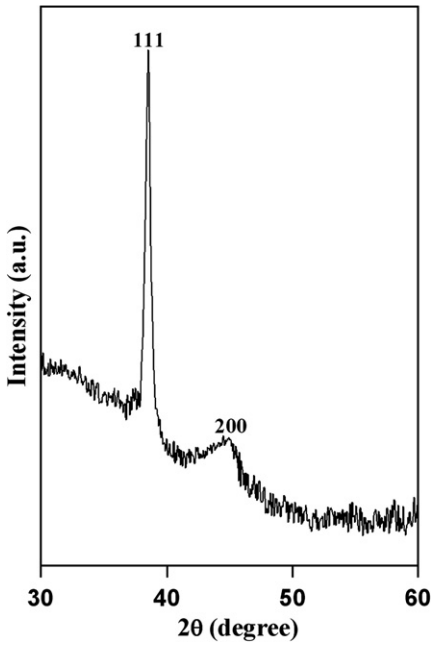

Fig. 8. XRD pattern of spherical gold nanoparticles.

do not get self-assembled unlike that of method I where compound **1** acting as a capping agent too was lesser in amount compared to that in method II. Thus self-assembly can be regulated smoothly, and the growth is limited to the aforementioned sizes by controlling the critical $AuCl_4^-$/compound **1** ratio. However, the TEM micrograph shows randomness of the particles, depicting crystalline assembly with the individual clusters placed in random locations. The high-resolution TEM image of these nanoparticles has been shown in the inset given in Fig. 7. The inset of the figure clearly indicates the presence of twin boundaries [33]. Further, the crystalline nature of these particles has been confirmed from the XRD analysis. XRD pattern of the gold nanoparticles prepared by method II is given in Fig. 8. Fig. 8 shows the peaks at 38.51° and 44.85° corresponding to (111) and (200) planes.

4. Conclusion

We have prepared a new compound, 2,3,5,6-tetrakis-(morpholinomethyl) hydroquinone, which can form gold nanoparticles from Au(III) solution. This compound also behaves as the capping agent for the nanoparticles synthesis. Gold nanoparticles with two different shapes and sizes have been prepared by simply altering the ratio of $AuCl_4^-$ and compound **1** which has been prepared by Mannich-type aminomethylation of hydroquinone with morpholine and characterized by single crystal X-ray diffraction analysis. These nanoparticles are stable and remain suspended for about three months, and may find potential applications such as catalysis, optical coatings.

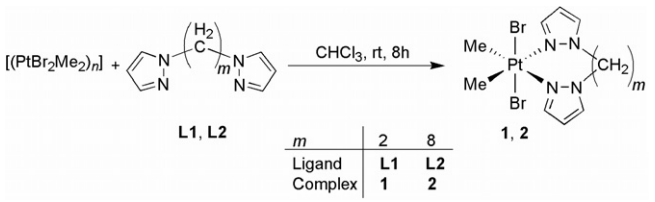
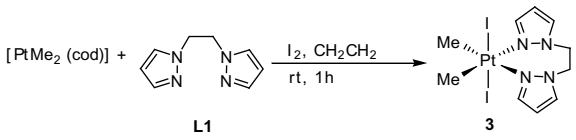
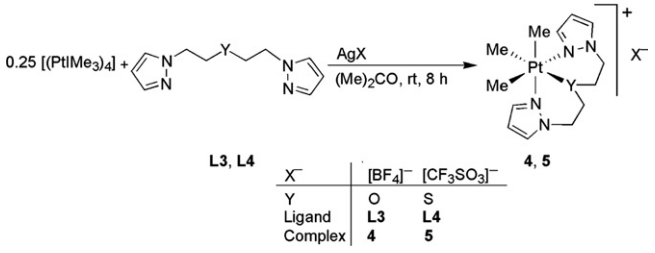


Scheme 1.



Scheme 2.



Scheme 3.

the presence of minor impurities but was fully characterized in solution as an analogue of **4**, with a triflate rather than tetrafluoroborate counterion, as discussed below.

2.2. Characterization

Complexes **1**–**5** have good solubility in common organic solvents such as acetone and chloroform and were characterized by NMR spectroscopy. As can be seen from the data given in Table 1, the ^{195}Pt NMR spectra contain a single resonance between −3409 and −2195 ppm with the diiodo substituted complex **3** the most high-field shifted, as may be expected [11]. A single resonance is found for the methyl ligands in the ^{1}H and ^{13}C NMR spectra of **1**–**3**. The $^{2}J_{Pt,H}$ (70–75 Hz) and $^{1}J_{Pt,C}$ (526.6 and 543.7 Hz) coupling constants confirm the *trans* coordination of the nitrogen donor ligands to the methyl ligands with the halo ligands occupying mutually *trans* positions (configuration index: *OC*-6-13), as may be expected [10,12]. In addition, the ^{1}H NMR spectrum of **2** shows a broadening of the signals assignable to the CH_2 groups of the spacer, relative to those of the free ligand, whereas the resonance of the methyl ligands are sharp.

The ^{1}H and ^{13}C NMR spectra of **4** and **5** share a number of similarities. Comparing the ^{1}H NMR spectrum of **4** to that of the corresponding free ligand **L3** (Fig. 1), the AA′XX′ spin system of the protons on the **L3** backbone ($C^6H_2C^7H_2$) becomes an ABCD spin system in **4** (δ_H 4.2–4.6 ppm; assignment by correlation spectroscopy). The three methyl ligands have two sets of resonances in a 2:1 intensity ratio and the corresponding $^{2}J_{Pt,H}$ (69.9 and 80.7 Hz) and $^{1}J_{Pt,C}$ (692.5 and 773.3 Hz) coupling constants confirm the coordination of two of the methyl ligands *trans* configured to the ligating nitrogen atoms and the third methyl ligand *trans* configured to the ligating oxygen atom (sulfur atom in **5**) giving a configuration index of *OC*-6-33. Due to the C_s point group symmetry of **4**, one resonance for C^6 atoms and one resonance for C^7 atoms are observed in the ^{13}C NMR spectrum. Similar findings are observed in the ^{1}H and ^{13}C NMR spectra of **5** (see Section 4).

Complexes **4** and **5** were also characterized by high resolution ESI-MS. The $[PtMe_3(pzCH_2CH_2OCH_2CH_2pz)]^+$ ($[M]^+$) cation at *m*/*z* 446.15124 is the only peak observed in the positive mode spectrum of **4** and the isotopic pattern is in satisfactory agreement with the calculated values (see Section 4). The most intensive peak in the positive mode spectrum of **5** is found to be the $[PtMe_3(pzCH_2CH_2SCH_2CH_2pz)]^+$ ($[M]^+$) cation at *m*/*z* 462.12835 (Fig. 2a). Enlargement of the peak assignable to $[M]^+$ shows an isotopic pattern consistent with the calculated values expected for a cation of this composition (Fig. 2b and Section 4). The second most intensive peak in the spectrum at *m*/*z* 1071.19950 is attributed to the dication + anion cluster ($[2M+CF_3SO_3]^+$). The signal at *m*/*z* 431.07891 agrees with the elimination of two methyl fragments from $[M]^+$.

2.3. Crystal structures

Complex **1** crystallized as **1** · $CHCl_3$ in the monoclinic space group $P2_1/c$ (Fig. 3). As the data collected in Table 2 confirm, the molecule has a distorted octahedral geometry. There is no evidence of any unusual intra- or intermolecular interactions.

The chelating ligand **L1** is *trans* configured to the methyl ligands. A large N1–Pt–N3 bite angle (97.3(1)°) is created by the chelating ligand due to geometrical constraints and is a common feature in the small number of reported platinum(IV) complexes with N,N′-bidentate ligands giving seven-membered chelate rings [13]. Although the C1–Pt–C2 bond angle is 86.4(2)° it is similar to other C–Pt–C bond angles observed for related dihalodimethylplatinum(IV) structures (86.8(4)–96.6(3)°) [10,14]. Other than the Pt–N3 bond length (2.235(3) Å) which is longer than expected for a Pt(IV)–N bond *trans* to a carbon ligator atom (median 2.163 Å; lower/upper quartile 2.142/2.198 Å; *n* = 351; *n* = number of observations) no peculiarities are found for the bond lengths of **1** [15]. Both pyrazolyl rings are twisted out of the $[PtC_2N_2]$ coordination plane (γ = 8.9(2)° and 34.5(2)°). The C6 and C7 atoms of the

γ: Interplanar angle between least squares planes of the $[PtC_2N_2]$ atoms (carbon atoms *trans* to *N*-donors) and the pyrazolyl rings (coordinating *N*-donor atom specifies the pyrazolyl ring).

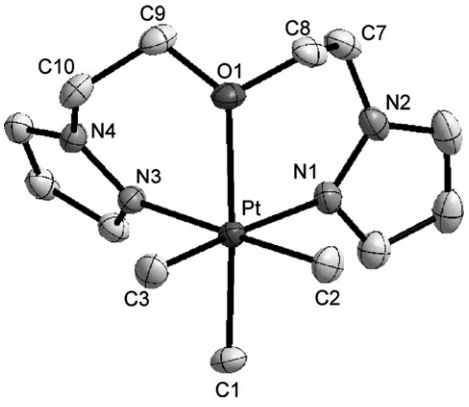

Fig. 4. Molecular structure **4**, $[BF_4]^-$ counterion and hydrogen atoms omitted. Displacement ellipsoids at 30% probability.

forming two six-membered chelate rings (Fig. 4). The ligand **L3** adopts a facial arrangement with the methyl ligands occupying the three remaining coordination sites resulting overall in an approximate octahedral arrangement of the ligator atoms around the platinum atom. Thus two diazaoxaplatina six-membered chelate rings result form the tridentate coordination of **L3**.

The Pt–C bond lengths of **4** do not differ significantly from one another or indeed from the range typical for Pt(IV)–C bond lengths *trans* to nitrogen (median 2.053 Å; lower/upper quartile 2.040/2.069 Å; $n = 351$) or oxygen donor atoms (median 2.024 Å; lower/upper quartile 2.003/2.044 Å; $n = 109$), respectively. As seen from the Pt(IV)–N range given above in the discussion of **1** · $CHCl_3$ the Pt(IV)–N bond length values are within the expected range. A very small number of structures have been reported with Pt(IV)–O bonds in which the oxygen atom is part of a C–O–C fragment and the equivalent bond length in **4** compares well with these [16]. Several of the angles around the platinum atom deviate from the ideal values; the greatest deviation is found for the C3–Pt–N1 bond angle (175.0(2)°). Two other trimethylplatinum(IV) structures with tridentate $\kappa^2N,N',\kappa O$ ligands are known [14a,17]. While the respective bond lengths in all three structures are similar, the arrangement of the ligating atoms around the platinum atom in **4** is closer to the ideal geometry as demonstrated by comparison of the most distorted angle in each of the three structures (C–Pt–O: 168.8 and C–Pt–O: 172.2, [14a,17] respectively). A further

feature of **4** is the twisting of the pyrazolyl ring coordinated via N3 relative to the $[PtC_2N_2]$ plane as given by the interplanar angle $\gamma = 59.9(3)°$. In contrast, the pyrazolyl ring coordinated via N1 is approximately perpendicular ($\gamma = 88.2(3)°$) to the $[PtC_2N_2]$ plane. Although three of the four fluorine atoms of the $[BF_4]^-$ anion of **4** are disordered, a number of short C···F distances (3.01–3.29 Å) and F···H contacts (2.37–2.40 Å; hydrogen atoms calculated) indicate the formation of weak hydrogen bonding interactions between each cation and three of the surrounding tetrafluoroborate anions [18].

3. Summary and conclusions

The preparation of several platinum(IV) complexes with simple α,ω-bis(pyrazol-1-yl) alkanediyl and diethyl ether/thioether ligands was described. The ethylene linked bis(pyrazol-1-yl) **L1** yielded platinum(IV) complexes with seven-membered chelate rings. Bis[2-(pyrazol-1-yl)ethyl]ether (**L3**) can behave as a tridentate ligand, as can bis[2-(pyrazol-1-yl)ethyl]thioether (**L4**), thus being $\kappa^2N,N',\kappa O$ and $\kappa^2N,N',\kappa S$ ligands respectively. The solid state structures of **1** · $CHCl_3$ and **4** reveal in each case a distorted octahedral arrangement adopted by the ligating atoms around the platinum atom, owing to geometrical constraints of the respective ligands, **L1** and **L3**. Furthermore, a small number of structures with substituted bis[2-(pyrazol-1-yl)ethyl]ether ligands are reported for Rh(I) [8a], Cu(I)/(II) [8c,19] Zn(II), Co(II) [8b] and Cd (II) [8d] complexes. In addition, only one of these structures (Rh(I) complex) demonstrates a facial binding mode of the bis[2-(3,5-dimethylpyrazol-1-yl)ethyl]ether ligand [8a]. The structure of **4** with a facial arrangement of the tridentate **L3** is of interest since structures of any *d*-block element hexacoordinated with a neutral $\kappa^2N,N',\kappa O$ ligand are unknown. The structure of **4** verifies the applicability of **L3** as new neutral κ^2N,N', κO type ligand for hexacoordinated complexes.

4. Experimental

4.1. General comments

Preparative centrifugal thin layer chromatography was performed using a Chromatotron (Harrison Research). ^1H and ^{13}C NMR spectra were recorded on Varian Gemini 2000 (200 and 400 MHz) and Varian Unity 500 (500 MHz) spectrometers. Chemical shifts are relative to solvent signals ($CDCl_3$ δ_H 7.24, δ_C 77.0; $(CD_3)_2CO$ δ_H 2.04, δ_C 29.8). ^{195}Pt NMR data were referenced to $H_2[PtCl_6]$ in D_2O (δ_{Pt} 0). Assignment of NMR signals was revealed by COSY and HMBC experiments. IR spectra were recorded on a Galaxy Mattson 5000 FT-IR spectrometer using KBr pellets. Microanalyses were performed at the microanalytical laboratory of Martin-Luther-Universität Halle-Wittenberg using CHNS-932 (LECO) and Vario EL (Elementaranalysensysteme) elemental analyzers. EI-MS was determined by slow heating of **L4** to a maximum of 350 °C and application of an ionization energy of 70 eV on an AMD 402 (AMD Intectra GmbH). GC-EI-MS for **L2** was preformed using an HP 5890 Series II/HP-5972 MSD (Hewlett–Packard) (column: HP5-MS 30 m). The method used: injector port 250 °C; helium flow rate 1.10 ml/min; oven temperature was 70 °C for 1 min and ramped to 250 °C over 10 min. High resolution (HR) positive mode ESI-MS were obtained using a Bruker Apex III Fourier transform ion cyclotron resonance (FT-ICR) mass spectrometer (Bruker Daltonics, Billerica, USA) equipped with an Infinity™ cell, a 7.0 T superconducting magnet (Bruker, Karlsruhe, Germany), an RF-only hexapole ion guide and an external electrospray ion source (Agilent, off axis spray, voltages for positive ion: endplate, −3.700 V; capillary, −4.200 V; capillary exit, +100 V; skimmer 1, +15.0 V; skimmer 2, +6.0 V). Nitrogen was used as drying gas at 150 °C. The sample solution were introduced continuously via a syringe pump at a flow rate of 120 μl h^{-1}. The data were acquired with 512 k data points and zero filled to 2048 k by averaging 32 scans. All starting materials necessary for the preparation of the ligands were obtained commercially (Acro, Fluka and Aldrich) and were used as received. The ligands **L1**–**L4** were prepared by analogy to a known procedure [7]. Characterization of **L1** and **L3** agreed with reported data [20,9]. $[(PtBr_2Me_2)_n]$, $[PtMe_2(cod)]$ and $[(PtIMe_3)_4]$ were prepared according to reported procedures [21–23].

4.2. General procedure for the synthesis of L2 and L4

As per [7]. In brief, pyrazole (1.50 g, 22 mmol) and NaH (37 mmol) suspended in paraffin were added to a flask fitted with a reflux condenser. At 0 °C under anaerobic conditions DMF (15 ml) was slowly added and the reagents were stirred until no further H_2 evolved. A DMF solution (ca. 15 ml) of the appropriate glycol ditosylate (11 mmol) was added over 4–5 min and allowed to stir for 15 min at ambient temperature before stirring at 82 °C for ca. 12 h. The reaction was then stopped and the solvent was removed under vacuum. The crude product was washed from reaction residue with ether (100 ml). **L2** was purified by preparative centrifugal thin layer chromatography using *n*-pentane, *n*-pentane/ether 90/10 and finally *n*-pentane/ether 50/50 to elute the product. **L4** was used without further purification.

4.2.1. $pzC^6H_2C^7H_2C^8H_2C^9H_2CH_2CH_2CH_2CH_2pz$ (**L2**)

Yellow oil/crystalline mix 1.89 g (70%). ^1H NMR (400 MHz, $CDCl_3$): δ 1.22 (m(br), 8H, $C^{8,9}H_2$), 1.82 (m, 4H, C^7H_2), 4.08 ('t', 4H, C^6H_2), 6.20 ('t', $^3J_{H,H}$ = 2.1 Hz, 2H, C^4H), 7.32 (d(br), 2H, C^5H), 7.46 (d(br), 2H, C^3H). ^{13}C NMR (101 MHz, $CDCl_3$): δ 26.5 (s, C^9H_2), 28.9 (s, C^8H_2), 30.3 (s, C^7H_2), 52.0 (s, C^6H_2), 105.1 (s, C^4H), 128.6 (s, C^5H), 138.9 (s, C^3H). RT = 16.91 min; EI-MS (*m*/*z*, rel. int. (%)): 246 ($M^{+\cdot}$, 23), 179 (7), 165 (53), 151 (23), 137 (30), 123 (28), 109 (13), 96 (17), 81 (100), 69 (41).

4.2.2. $pzC^6H_2C^7H_2SCH_2CH_2pz$ (**L4**)

Viscous orange oil. Yield 50% (0.80 g) ^1H NMR (400 MHz, $CDCl_3$): δ 2.79 ('t', 4H, C^7H_2), 4.21 ('t', 4H, C^6H_2), 6.22 ('t', $^3J_{H,H}$ = 2.1 Hz, 2H, C^4H), 7.36 (d(br), 2H, C^5H), 7.45 (d(br), 2H, C^3H). ^{13}C NMR (125 MHz, $CDCl_3$): δ 32.4 (s, C^6H_2), 52.2 (s, C^7H_2), 105.4 (s, C^4H), 129.6 (s, C^5H), 139.7 (s, C^3H). EI-MS (*m*/*z* (rel. int. (%)): 222 ($M^{+\cdot}$, 2), 154 (100), 141 (4), 127 (17), 95 (13), 86 (96), 81 (36), 68 (32).

4.3. Synthesis of 1–5

4.3.1. $[PtBr_2Me_2(pzC^6H_2CH_2pz)]$ (**1**)

As per [12a,b]. In brief, using standard Schlenk techniques $[(PtBr_2Me_2)_n]$ (30 mg, 0.08 mmol) and **L1** (13 mg, 0.08 mmol) were stirred in $CHCl_3$ (5 ml) for ca. 8 h after which time the solution became transparent yellow. The solvent was removed under vacuum. The residue was taken up in $CHCl_3$ (2 ml) and the product, a yellow powder, precipitated upon addition of pentane (10 ml). Yield: 40 mg (98%). T_{dec}: 125 °C. *Anal.* Calc. for $C_{10}H_{16}Br_2N_4Pt$ (547.15): C, 21.95; H, 2.95; N, 10.24. Found: C, 22.32; H, 3.17; N, 10.14%. IR [cm^{-1}]: *ν* 3429 (s), 2915 (m), 1560 (w), 1508 (w), 1448 (s), 1449 (s), 1275 (m), 1227 (w), 1165 (w), 1072 (m), 760 (s), 669 (m), 619 (w). ^1H NMR (400 MHz, $CDCl_3$): δ 2.31 (s + d, $^2J_{Pt,H}$ = 73.3 Hz, 6H, CH_3), 4.82 (s, 4H, C^6H_2), 6.40 (m, 2H, C^4H), 7.49 (m, 2H, C^5H), 7.98 (m, 2H, C^3H). ^{13}C NMR (125 MHz, $CDCl_3$): δ −3.8 (s + d, $^1J_{Pt,C}$ = 543.7 Hz, CH_3), 51.5 (s, C^6H_2), 107.1 (s, C^4H), 133.8 (s, C^5H), 142.8 (s + d, $^2J_{Pt,C}$ = 73.3 Hz, C^3H). ^{195}Pt NMR (107 MHz, $CDCl_3$): δ −2319 (s).

4.3.2. [PtBr$_2$Me$_2$(pzC^{6}H$_2$C^{7}H$_2$C^{8}H$_2$C^{9}H$_2$CH$_2$CH$_2$CH$_2$CH$_2$pz)] (**2**)

As for **1** except **L2** instead of **L1** and the final product was isolated after the solvent was removed. Bright yellow residue. T_{dec}: 110 °C. IR [cm^{-1}]: *ν* 3997 (m), 3103 (m), 2920 (s), 2854 (s), 1625 (w), 1458 (w), 1420 (m), 1275 (w), 1215 (w), 1105 (w), 1065 (m), 985 (w), 889 (w), 755 (s), 616 (w). ^{1}H NMR (400 MHz, $CDCl_3$): *δ* 1.26 (m(br), 8H, C^{8,9}H$_2$), 1.77 (s(br), 4H, C^{7}H$_2$), 2.31 (s + d, $^2J_{Pt,H}$ = 73.3 Hz, 6H, C*H*$_3$), 4.13 (m(br), 4H, C^{6}H$_2$), 6.40 (s, 2H, C^4*H*), 7.48 (s(br), 2H, C^5*H*), 7.84 (s(br), 2H, C^3*H*). ^{13}C NMR (101 MHz, $CDCl_3$): *δ* −5.8 (s + d, $^1J_{Pt,C}$ = 526.6 Hz, *C*H$_3$), 26.3 (s, *C*^{9}H$_2$), 28.8 (s, *C*^{8}H$_2$), 30.6 (s, *C*^{7}H$_2$), 51.6 (s, *C*^{6}H$_2$), 106.7 (s(br), *C*^{4}H), 131.2 (s(br), *C*^{5}H), 142.9 (s(br), *C*^{3}H). ^{195}Pt NMR (107 MHz, $CDCl_3$): *δ* −2320 (s).

4.3.3. [PtI$_2$Me$_2$(pzCH$_2$CH$_2$pz)] (**3**)

By analogy to a known procedure [10]. In brief, to a stirring solution of [PtMe$_2$(cod)] (33 mg, 0.10 mmol) and **L1** (16 mg, 0.10 mmol) in CH_2Cl_2 (10 ml) a solution of I_2 (ca. 50 mg in 5 ml) was added dropwise until the red-purple color of the I_2 persisted. After stirring for ca. 1 h the solvent was removed under vacuum. The residue was washed with small portions of CH_2Cl_2 (5 × 2 ml) and decanted to a separate flask. The solvent was removed. The residue was taken up in CH_2Cl_2 (4 ml) and the product precipitated upon addition of pentane (10 ml) at −18 °C. The latter step was repeated three times to afford the product, an orange powder. Yield 51 mg (81%). T_{dec}: 133 °C. *Anal.* Calc. for [C$_{10}$H$_{16}$I$_2$N$_4$Pt] (641.15): C, 18.73; H, 2.52; N, 8.74. Found: C, 18.96; H, 2.90; N, 8.29%. IR [cm^{-1}]: *ν* 3404 (m), 3108 (w), 2915 (m), 1521 (w), 1419 (s), 1281 (m), 1165 (w), 1111 (m), 1074 (m), 1005 (w), 984 (w), 758 (s), 613 (m). ^{1}H NMR (400 MHz, $CDCl_3$): *δ* 2.66 (s + d, $^2J_{Pt,H}$ = 75.5 Hz, 6H, C*H*$_3$), 4.76 (s, 4H, C^6*H*$_2$), 6.40 (t, $^3J_{H,H}$ = 2.4 Hz, 2H, C^4*H*), 7.47 (d, $^3J_{H,H}$ = 2.1 Hz, 2H, C^5*H*), 7.98 (d, $^3J_{H,H}$ = 2.5 Hz, 2H, C^3*H*). ^{13}C NMR (100 MHz, $(CD_3)_2CO$): *δ* −13.5 (s, *C*H$_3$), 51.9 (s, *C*^{6}H$_2$), 106.3 (s, *C*^{4}H), 135.1 (s, *C*^{5}H), 142.5 (s, *C*^{3}H). ^{195}Pt NMR (107 MHz, $(CD_3)_2CO$): *δ* −3409 (s).

4.3.4. [PtMe$_3$(pzC^{6}H$_2$C^{7}H$_2$OCH$_2$CH$_2$pz)][BF$_4$] (**4**)

To a flask **L3** (36 mg, 0.18 mmol), [(PtIMe$_3$)$_4$] (64 mg, 0.18 mmol), an excess of $AgBF_4$ (ca. 49 mg, 0.25 mmol) and acetone (10 ml) were added. The reagents were stirred 24 h in darkness before the reaction mixture was filtered and the transparent filtrate was evaporated to dryness. The residue was taken up in $CHCl_3$ (ca. 2 ml) and **4** precipitated upon addition of pentane (10 ml). White microcrystalline solid. Yield: 84 mg (90%). T_{dec}: 192 °C. IR [cm^{-1}]: ν 3441 (s), 3148 (m), 2970 (s), 2901 (s), 2819 (w), 1636 (w), 1520 (w), 1415 (s), 1299 (m), 1237 (m), 1190 (m), 1054 (s), 787 (s), 618 (m), 522 (w). ^{1}H NMR (400 MHz, $(CD_3)_2CO$): *δ* 1.02 (s + d, $^2J_{Pt,H}$ = 69.9 Hz, 6H, C*H*$_3$–Pt–N), 1.50 (s + d, $^2J_{Pt,H}$ = 80.7 Hz, 3H, C*H*$_3$–Pt–O), 4.31 (m, 2H, C^7*H*$_2$), 4.40 (m, 4H, C^{6,7}*H*$_2$), 4.59 (m, 2H, C^6*H*$_2$), 6.42 (m, 2H C^4*H*), 7.50 (m, 2H, C^3*H*), 7.76 (m, 2H, C^5*H*). ^{13}C NMR (125 MHz, $(CD_3)_2CO$): *δ* −7.1 (s + d, $^1J_{Pt,C}$ = 773.3 Hz *C*H$_3$–Pt–O), −6.7 (s + d, $^1J_{Pt,C}$ = 692.5 Hz, *C*H$_3$–Pt–N), 49.6 (s, C^{6}H$_2$), 53.0 (s, C^{7}H$_2$), 107.0 (s + d, $^3J_{Pt,C}$ = 12.4 Hz, C^{4}H), 135.2 (m, C^{5}H), 139.3 (m, CH^3). ^{195}Pt NMR (107 MHz, $(CD_3)_2CO$): *δ* −2195 (s). Positive mode ESI-FTICR-MS (MeOH): *m*/*z* 446.15124, calc. for [C$_{13}$H$_{23}$N$_4$O^{195}Pt]$^+$ 446.15141; *m*/*z* (intensity calc./found for cation [C$_{13}$H$_{23}$N$_4$OPt]$^+$, %) 445 (85/75), 446 (100/100), 447 (79/87), 448 (12/12), 449 (19/25), 450 (3/3).

4.3.5. [PtMe$_3$(pzC^{6}H$_2$C^{7}H$_2$SCH$_2$CH$_2$pz)][CF$_3$SO$_3$] (**5**)

As for **4** except **L4** instead of **L3**, $AgCF_3SO_3$ instead of $AgBF_4$ and the final product was isolated in the presence of minor impurities after evaporation of the filtrate. A clear residue. Yield (crude, ca. 10% impurities): 82 mg. ^{1}H NMR (400 MHz, $(CD_3)_2CO$): *δ* 0.95 (s + d, $^2J_{Pt,H}$ = 70.9 Hz, 6H, C*H*$_3$–Pt–N), 1.38 (s + d, $^2J_{Pt,H}$ = 66.8 Hz, 3H, C*H*$_3$–Pt–S), 3.54 (m, 4H, C^{7}H$_2$), 4.14 (m, 2H, C^{6}H$_2$), 4.70 (m, 2H, C^{6}H$_2$), 6.39 (t, $^3J_{H,H}$ = 2.4 Hz, 2H, C^4*H*), 7.42 (d, $^3J_{H,H}$ = 2.4 Hz, 2H, C^3*H*), 7.70 (d, $^3J_{H,H}$ = 2.5 Hz, 2H, C^5*H*). ^{13}C NMR (125 MHz, $(CD_3)_2CO$): *δ* −7.8 (s + d, $^1J_{Pt,C}$ = 669.5 Hz, *C*H$_3$–Pt–N), 9.3 (s + d, $^1J_{Pt,C}$ = 662.0 Hz, *C*H$_3$–Pt–S), 34.1 (s, *C*^{7}H$_2$), 50.2 (s + d, $^3J_{Pt,C}$ = 13.1 Hz, C^{6}H$_2$), 107.7 (s + d, $^3J_{Pt,C}$ = 12.4 Hz, C^{4}H), 135.8 (s, *C*^{5}H), 140.9 (s + d, $^2J_{Pt,C}$ = 12.4 Hz, *C*^{3}H) 160.5 ('m', *C*F$_3$). ^{195}Pt NMR (107 MHz, $CDCl_3$): *δ* −2874 (s). Positive mode ESI-FTICR-MS (MeOH): *m*/*z* 431.07891, calc. for [C$_1$^{1}H$_{17}$N$_4$^{194}Pt^{32}S]$^+$ 431.07951; *m*/*z* 461.12599, calc. for [C$_{13}$H$_{23}$N$_4$^{194}Pt^{32}S]$^+$ 461.12646; *m*/*z* 462.12835, calc. for [C$_{13}$H$_{23}$N$_4$^{195}Pt^{32}S]$^+$ 462.12857; *m*/*z* 1071.19950, calc. for [C$_{27}$H$_{46}$F$_3$N$_8$O$_3$^{194}Pt$_2$^{32}S$_3$]$^+$ 1071.20549; *m*/*z* (intensity calc./found for cation [C$_{13}$H$_{23}$N$_4$PtS]$^+$, %) 461 (84/82), 462 (100/100), 463 (83/73), 464 (16/9), 465 (23/21), 466 (4/4).

4.4. X-ray crystal structure determination

Single crystals of **1** · $CHCl_3$ and **4** were obtained by slow evaporation of a chloroform solution of the respective compound at room temperature. Table 3 shows crystallographic and data collection parameters. Intensity data were collected on either a CCD Xcalibur S diffractometer (**1** · $CHCl_3$) at 130(2) K or a Stoe-IPDS (**4**) at 293(2) K both with Mo Kα radiation (*λ* = 0.7103 Å, graphite monochromator). The absorption correction for **4** was made using the IPDS software package and a semi-empirical correction was made for **1** · $CHCl_3$ with SCALE3 ABSPACK [24]. Both structures were solved by direct methods using SHELXS-97 and refined using full-matrix least-squares routines against F^2 with SHELXL-97 [25]. Non-hydrogen atoms were refined with anisotropic displacement parameters. Three of the four fluorine atoms of $[BF_4]^-$ in the structure of **4** (F2, F3 and F4) are disordered with refined occupancy factors (70/30%). Hydrogen atoms were included in the models by calculating the positions using the riding model and refined with isotropic displacement parameters. Illustrations were generated using DIAMOND 3.0 software [26].

5. Supplementary data

CCDC 684953 and 684952 contain the supplementary crystallographic data for **1** · $CHCl_3$ and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

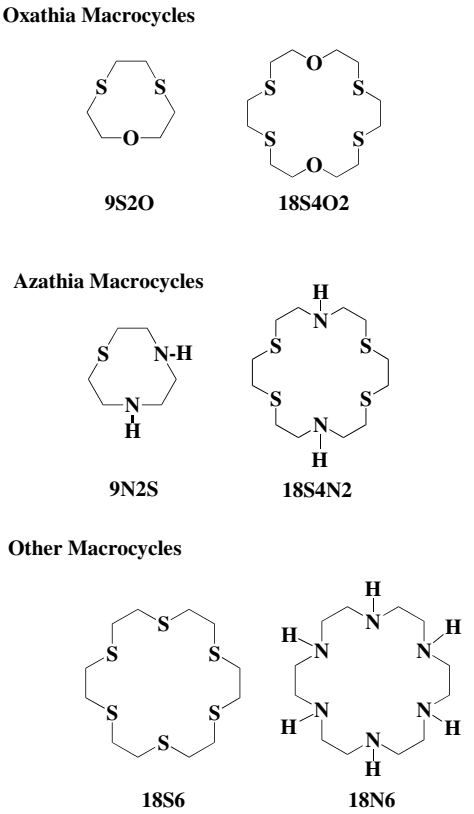

Scheme 1. Macrocyclic ligands discussed in this report.

2. Experimental

2.1. Materials and measurements

The ligands 9S2O, 18S4O2, and 9N2S were prepared by their respective literature methods [21–24]. All other reagents and solvents were purchased commercially and used as received. An aqueous solution containing 45% by weight of $Cd(BF_4)_2$ was used as the source of that reagent in aqueous syntheses. *Caution!!! Although the perchlorate salts prepared in this report do not appear to be shock-sensitive, they should be handled with caution and only in very small quantities.* Mercury and cadmium are toxic metals, and their compounds should be handled accordingly.

Elemental analyses were performed by Atlantic Microlab, Inc., of Atlanta, Georgia. Fourier Transform Infrared spectra were obtained on a Nicolet FT-IR using dry pre-weighed KBr powder and an ATR accessory. All $^{13}C\{^1H\}$ and ^1H NMR spectra were recorded on a JEOL ECX-400 NMR spectrometer using either the residual deuterated organic solvent (CD_3NO_2, CD_3CN, etc.) peaks for the internal reference or an internal reference of d-6-acetone for $^{13}C\{^1H\}$ NMR spectra obtained in D_2O. The $^{113}Cd\{^1H\}$ NMR spectra were collected at 25 °C and 88.66726 MHz using a 75° pulse, a 0.5 s acquisition time, and a relaxation delay time of 5.0 s. Referencing was done using a 0.10 M solution of $Cd(ClO_4)_2$ in D_2O at 0 ppm. The $^{113}Cd\{^1H\}$ NMR spectra were collected until a minimum signal/noise ratio of 20/1 was obtained. Data collection on one sample typically required 10 000–12 000 transients and took 24–30 h to complete.

2.2. Complexes with oxathiacrown ligands

2.2.1. Synthesis of $[Hg(9S2O)_2](ClO_4)_2$

A solution containing 107 mg of $Hg(ClO_4)_2 \cdot 3H_2O$ (0.236 mmol) and 10 drops of acetic anhydride in 10 mL of CH_3NO_2 was added dropwise to a solution containing a mass of 76.9 mg of 9S2O (0.468 mmol) in 5 mL of CH_3NO_2 and cooled at 0°C for about 15 min. A volume of 40 mL of diethyl ether was added dropwise to the cold solution which was left at 0° overnight. White crystals of $[Hg(9S2O)_2](ClO_4)_2$ had formed which were filtered, washed with diethyl ether (3×15 mL) to yield 126 mg of product (73.9%). *Anal.* calc. for $C_{12}H_{24}Cl_2HgO_{10}S_4$: C, 19.80; H, 3.32; S, 17.62; Cl, 9.74. Found: C, 19.63; H, 3.27; S, 17.34, Cl, 9.73%. FT-IR (cm^{-1}): 2991 (C–H), 2939 (C–H), 2904(C–H), 2866 (C–H), 1628, 1543, 1469, 1409, 1297, 1111–1081 s, (ClO_4^-), 904, 813, 624, 409. ^1H NMR (CD_3NO_2) δ (ppm): complex AA′BB′ symmetrical pattern at 4.09–4.01 (4H) and 3.86–3.78 (4H) (–O–C*H*$_2$–CH$_2$–S–); broad, overlapping multiplets at 3.49–3.26 (16H, –O–CH$_2$–C*H*$_2$–S– and –S–C*H*$_2$–C*H*$_2$–S–). $^{13}C\{^1H\}$ NMR (CD_3CN) δ (ppm): 62.11 (4C, –O–*C*H$_2$–CH$_2$–S–), 32.94 (4C, –O–CH$_2$–*C*H$_2$–S–), 29.87 (–S-(*C*H$_2$)$_2$–S–). No ^{199}Hg NMR signal in CD_3NO_2 was observed after 12 000 transients. Slow evaporation of a nitromethane solution produced large rods suitable for single crystal X-ray analysis.

2.2.2. Synthesis of $[Hg(18S4O2)](ClO_4)_2$

A mixture containing 88.8 mg of $Hg(ClO_4)_2 \cdot 3H_2O$ (0.196 mmol), 10 drops of acetic anhydride, and 57.5 mg of 18S4O2 (0.175 mmol) in 15 mL of CH_3NO_2 was refluxed for 1.5 h. After cooling in an ice bath, 20 mL of diethyl ether was slowly added to precipitate a white crystalline solid. The solid was isolated by filtration and washed with diethyl ether (3×15 mL) to yield 57.7 mg (45.3%) of $[Hg(18S4O2)](ClO_4)_2$. *Anal.* calc. for $C_{12}H_{24}Cl_2HgO_{10}S_4$: C, 19.80; H, 3.32; S, 17.62; Cl, 9.74. Found: C, 19.78; H, 3.29; S, 17.40; Cl, 9.59%. FT-IR (cm^{-1}): 2987 (C–H), 2939 (C–H), 2870 (C–H), 2793 (C–H), 1559, 1464, 1409, 1357, 1271, 1111–1081 s, (ClO_4^-), 1020, 913, 775, 693, 624. ^1H NMR (CD_3CN) δ (ppm): sharp multiplet at 3.73 (8H, –O–C*H*$_2$–CH$_2$–S–), broad mutliplet at 3.33–3.05 (16H, –O–CH$_2$–C*H*$_2$–S– and –S–C*H*$_2$–C*H*$_2$–S–). $^{13}C\{^1H\}$ NMR (CD_3CN) δ (ppm): 66.21 (4C, –O–*C*H$_2$–CH$_2$–S–), 34.24 (4C, –O–CH$_2$–*C*H$_2$–S–), 31.76 (4C, –S-(*C*H$_2$)$_2$–S–). No ^{199}Hg NMR signal in CD_3CN was observed after 40 000 transients. Two consecutive crystallizations using diethyl ether diffusion into acetonitrile resulted in X-ray quality colorless prisms.

2.2.3. Synthesis of $[Cd(9S2O)_2](ClO_4)_2$ and $[Cd(18S4O2)](ClO_4)_2$

The two known Cd(II) complexes $[Cd(9S2O)_2](ClO_4)_2$ and $[Cd(18S4O2)](ClO_4)_2$ were prepared by the published methods [25]. Verification of complex formation was accomplished by ^1H and $^{13}C\{^1H\}$ NMR spectra which matched the prior results.

For $[Cd(9S2O)_2](ClO_4)_2$: ^1H NMR (CD_3NO_2), δ (ppm): multiplet at 3.99 (8H, –OC*H*$_2$–CH$_2$S–), singlet at 3.29 (8H, –SC*H*$_2$–C*H*$_2$S–), multiplet at 3.24 (8H, –OCH$_2$–C*H*$_2$S–). $^{13}C\{^1H\}$ NMR (CD_3NO_2) δ (ppm): 63.91, 31.37, 29.52. Data collection for the $^{113}Cd\{^1H\}$ NMR spectrum of the complex was attempted, but no ^{13}Cd NMR peak was observed. Data collection on one sample typically required 10 000–12 000 transients and 24–30 h to complete. Colorless plates of the complex, suitable for X-ray diffraction studies, were obtained from diethyl ether diffusion into a nitromethane solution.

For $[Cd(18S4O2)](ClO_4)_2$: ^1H NMR (CD_3NO_2), δ (ppm): multiplets at 3.97 (8H, –OC*H*$_2$–CH$_2$S–), 3.41 (8H, –OCH$_2$–C*H*$_2$S–), 3.28 (8H, –SC*H*$_2$–C*H*$_2$S–). $^{13}C\{^1H\}$ NMR (CD_3NO_2) δ (ppm): 66.89, 32.79, 31.28. The $^{113}Cd\{^1H\}$ NMR spectra were collected, but again no ^{113}Cd NMR peak for the complex was observed. Data collection on one sample typically required 10 000–12 000 transients and 24–30 h to complete. Colorless plates of the complex were obtained from diethyl ether diffusion into a nitromethane solution.

2.3. Complexes with azathiacrown ligands

2.3.1. Synthesis of $[Cd(9N2S)_2](ClO_4)_2$

A solution containing 91.0 mg of $Cd(ClO_4)_2 \cdot 6H_2O$ (0.217 mmol) dissolved in 10 mL of MeOH was slowly added to a stirred solution

containing 65.9 mg of 9N2 S (0.451 mmol) in 5 mL of MeOH. A white precipitate formed immediately. The precipitate was filtered, washed with cold MeOH (3 × 15 mL), diethyl ether (3 × 15 mL), and air-dried. A mass of 58.0 mg of $[Cd(9N2S)_2](ClO_4)_2 \cdot 3H_2O$ was obtained in a 40.7% yield. *Anal.* calc. for $C_{12}H_{36}Cl_2CdN_4O_{11}S_2$: C, 21.98; H, 4.92; S, 9.78; Cl, 10.81; N, 8.54. Found: C, 21.73; H, 5.26; S, 9.55; Cl, 10.45; N, 8.44%. FT-IR (KBr, cm^{-1}): 3283 (N–H), 2938 (C–H), 2876 (C–H), 1462, 1414, 1359, 1290, 1228, 1117 (ClO_4^-), 917, 779, 634. ^1H NMR (CD_3NO_2) δ (ppm): broad singlet at 3.49–3.40 (4H, –N*H*–CH_2CH_2–), multiplet at 3.27–3.15 (8H, –N–CH_2CH_2-N–), multiplet at 3.07–2.95 (8H, –N–CH_2CH_2–S), and multiplet at 2.91–2.77 (8H, –N–CH_2CH_2–S–). $^{13}C\{^1H\}$ NMR (CD_3NO_2) δ (ppm): 44.69 (2C, –N–CH_2CH_2-N–), 44.58 (2C, –N–CH_2CH_2-N–), 43.56 (2C, –N–CH_2CH_2–S–), 43.46 (2C, –N–CH_2CH_2–S–), 30.59 (4C, -CH_2–S–CH_2–). ^{113}Cd NMR (CD_3NO_2): δ ($\nu_{1/2}$) 521 ppm (34 Hz). Colorless rods suitable for X-ray diffraction were obtained by slow evaporation of a nitromethane solution.

2.4. Preparation of Cd(II) complexes with other macrocyclic ligands

2.4.1. Synthesis of $[Cd(18N6)](BF_4)_2$

A mass of 18N6 · $3H_2SO_4$ (151 mg, 0.273 mmol) was placed in 15 mL of H_2O and heated to 60 °C to completely dissolve the ligand. A mass of $BaCO_3$ (162 mg, 0.821 mmol) was added, and the reaction mixture was then heated to 75 °C and stirred for 1.5 h. The reaction solution was filtered to remove the white solid of precipitated $BaSO_4$. A mass of $Cd(BF_4)_2$ (77.9 mg, 0.272 mmol) was then added to the filtrate, and the reaction heated to 75 °C and stirred for 2 h. The solution was evaporated to dryness giving an off-white solid. The solid was crystallized from water to yield colorless, hygroscopic crystals. These were dried *in vacuo* to produce 50.2 mg (33.9% yield) of $[Cd(18N6)](BF_4)_2$. *Anal.* calc. for $C_{12}H_{30}B_2CdN_6F_8$: C, 26.46; H, 5.55; N, 15.44. Found: C, 26.73; H, 5.26; N, 15.44%. FT-IR (KBr, cm^{-1}): 3428 (b, N–H), 3235(b, N–H), 2910 (C–H), 2855 (C–H), 2076, 1621, 1455, 1366, 1338, 1283, 1214, 1083 s, (BF_4^-), 1028, 938, 821, 621, 517. ^1H NMR (CD_3OD) δ (ppm): 4.86 (b, s, N*H*, 6H), 2.99 (m, 8H), 2.69 (m, 8H). 2.57 (m, 8H). $^{13}C\{^1H\}$ NMR (D_2O) δ (ppm): approximately equal intensity singlets at 45.82, 45.65, 44.96. ^{113}Cd NMR (D_2O): δ ($\nu_{1/2}$) 277 ppm (57 Hz).

2.4.2. Synthesis of $[Cd(18S6)](BF_4)_2$

A mass of 18S6 (53.1 mg, 0.147 mmol) was added to 10 mL of CH_3NO_2. Solid $Cd(BF_4)_2 \cdot 6H_2O$ (57.7 mg, 0.146 mmol) followed by 5 drops of acetic anhydride was then added, and the mixture was stirred at room temperature for 30 min. A white precipitate had formed which was filtered and washed with CH_3NO_2 (3 × 25 mL) and $CHCl_3$ (3 × 25 mL) to remove any unreacted ligand and starting Cd(II). The product was air dried to yield 71 mg (75% yield) of $[Cd(18S6)](BF_4)_2$. *Anal.* calc. for $C_{12}H_{24}B_2CdF_8S_6$: C, 22.29; H, 3.74; S, 29.74. Found: C, 22.39; H, 3.82; S, 29.55%. FT-IR (cm^{-1}): 2979 (C–H), 2938 (C–H), 1421, 1276, 1097, 1062 (ClO_4^-), 1028, 931, 903, 855, 710, 676 (C–S), 524. ^1H NMR (DMSO-d_6) δ (ppm): 2.80(s). $^{13}C\{^1H\}$ NMR (DMSO-d_6) δ (ppm): 31.56(s). The $^{113}Cd\{^1H\}$ NMR spectra were collected on a solution in DMSO-d_6, but no ^{113}Cd NMR peak for the complex was observed. Data collection on one sample typically required 10 000–12 000 transients and took 24–30 h to complete.

2.5. Data collection and processing

Table 1 contains crystal data, collection parameters, and refinement criteria for the structures of all four compounds. For all structures, X-ray intensity data were measured at low temperature (153(2) K) with graphite-monochromated radiation (λ = 0.71073 Å) on a Rigaku AFC8S diffractometer equipped with a 1 K Mercury CCD detector [26]. The structure was solved using direct methods and refinement was done using full-matrix least-squares techniques (on F^2). Data were corrected for absorption, using semi-empirical methods. Structure solution, refinement and the calculation of derived results were performed with the SHELXTL package of computer programs [27]. All H atoms were geometrically fixed and allowed to ride on the corresponding non-H atom with C–H = 0.96 Å and $U_{iso}(H) = 1.5U_{eq}(C)$ of the attached C atom for methyl H atoms and $1.2U_{eq}(C)$ for other H atoms. Larger

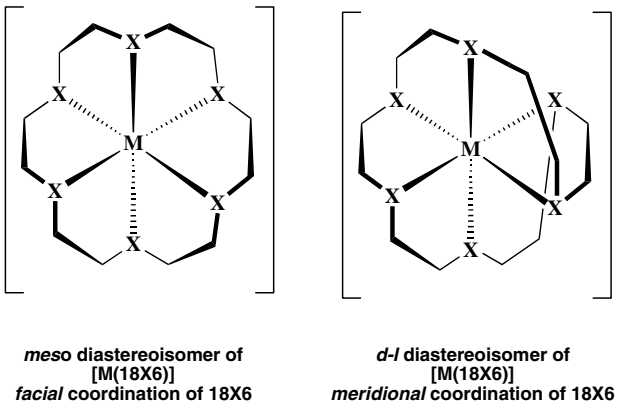
than expected residual peaks of electron density were observed in the Compounds **1**, **2**, and **4**. This arises due to the presence of the large Hg and Cd ions, and the remaining electron peak density ranges from 1.78 to 3.07 in Compounds **1**, **2** and **4**. The location of the peak density in these three structures is as follows: Compound **1**, 1.39 Å from S16; Compound **2**, 1.39 Å from O10; Compound **4**, 1.51 Å from H3B.

We have isolated single crystals of $[Cd(18S4O2)](ClO_4)_2$ and obtained a partial structure of the complex. Using Space Group *P1* yielded a structure with $R_1 = 0.119$ and GOF = 1.08. However, there were disorder problems within the macrocycle for the thioether(S) and ether(O) positions as well as the perchlorate ion. Nevertheless, the structure clearly shows a six-coordinate environment around the Cd(II) center involving the hexadentate 18S4O2 ligand.



Scheme 2. Possible diastereoisomers of hexacoordinate macrocycles.

3. Results and discussion

3.1. Synthesis and spectra

The homoleptic macrocyclic complexes of Cd(II) and Hg(II) are prepared by substitution of the macrocyclic ligand on the metal ion in the presence of a non-coordinating anion. The formulae of all five new complexes have been confirmed by elemental analyses. Infrared spectra of the complexes show the presence of bands associated with the particular macrocyclic ligand and non-coordinating anion. The proton and ^{13}C NMR spectra for the complexes show all methylene resonances and NH peaks (if present) in the correct ratios, chemical shifts, and splittings. Four new X-ray crystal structures further characterize several of the complexes.

As expected in both the proton and ^{13}C NMR spectra, the methylene groups within the macrocyclic ring that are closer to the more electronegative oxygen or nitrogen appear more downfield compared to the methylene groups attached to the sulfur. In the proton spectrum of $[Hg(9S2O)_2](ClO_4)_2$ we observe a characteristic AA′BB′ splitting pattern of the four methylene protons adjacent to the oxygen donor which split into a symmetrical pattern with a dispersion of 0.2 ppm (see Experimental Supplementary data). This is commonly observed in related 9S3 complexes of transition metals and arises from the non-equivalency of the methylene protons upon complexation [28]. Curiously, none of the other oxa thioether macrocyclic complexes exhibit this distinctive feature, but rather they show other non-first order couplings (see Experimental Supplementary data). As we have noted previously for other Hg(II) and Cd(II) complexes involving thiacrown ligands, all ^{13}C NMR methylene resonances in the ligand show unusual upfield chemical shifts (over 10 ppm in some cases) upon complexation rather than the expected downfield ones [6]. For all Hg(II) and Cd(II) complexes with the two cyclononane macrocycles, we again observe these upfield chemical shifts for several methylene resonances, in some cases 10 ppm relative to free ligand. The methylene resonances in both 18S4O2 complexes also show upfield ^{13}C NMR chemical shifts, but not to the same degree. We have argued that these arise from distortions of the methylene carbons from tetrahedral environments, and again, a similar trend is seen. All four of the structurally characterized complexes show X–C–C angles that average 112°, larger than an ideal tetrahedral value.

For homoleptic hexathia or hexaaza 18X6 complexes (X = S or N–H), two possible diastereoisomers are possible as seen in Scheme 2, a *meso* and a *d-l racemic (*rac) isomer. Based upon the known preference of C–S bonds to adopt *gauche* conformations, the *meso* is the preferred stereoisomer in octahedral 18S6 complexes [29]. A single resonance in the ^{13}C NMR spectrum for the Cd(II) of 18S6 complex is consistent with exclusive presence of the *meso* diastereoisomer. In that regard, we also note our prior work with the related complex $[Hg(18S6)](PF_6)_2$ whose multinuclear NMR spectra as well as its X-ray crystal structure show exclusive *meso* formation [6]. In contrast, the ^{13}C NMR spectrum for the Cd(II) complex with 18N6 shows three equal intensity resonances. This again is consistent with the known contrasting preference of C–N bonds to adopt *anti* conformations, resulting in a preferred *rac* stereoisomer for the azacrown [7,15,30]. Thus, ^{13}C NMR spectroscopy provides an effective tool for diastereoisomer identification for octahedral complexes involving hexadentate macrocycles.

For the *trans* diastereoisomer of $[Cd(9N2S)_2]^{2+}$, a three-line carbon ^{13}C NMR spectrum would be anticipated. In contrast, the *cis* stereoisomer would yield an equal intensity six-line ^{13}C NMR spectrum [31]. For the aza thiacrown complex in CD_3NO_2, we obtain a ^{13}C NMR spectrum best described as a three-line spectrum which is consistent with the crystal structure which shows the *trans* stereoisomer. However, there is an unusual feature. Two near equal intensity singlets appear for the methylene carbons adjacent to each of the two nitrogen donors while the methylene carbons next to the sulfur show a single, more intense peak (see Experimental Supplementary data). As the temperature is raised from 25° to 75°, the peaks broaden resulting in a three-line carbon spectrum and suggesting some type of exchange process involving the ligand is occurring. We propose that there is a modification in the Cd–N bond (possibly through bond rupture and reformation), resulting in a more complex spectrum than would normally be anticipated based upon a simple *trans* positioning of the two sulfur donors. However, an exchange involving the secondary amine protons is also a possible source of the complex NMR pattern.

We have been unsuccessful in our attempts to observe a ^{199}Hg NMR signal in either Hg(II) complex. This failure occurs despite long acquisition times, and our prior experience in making successful ^{199}Hg NMR measurements for these types of complexes [6]. We suggest that ligand exchange of the 9S2O and 18S4O2 macrocycles is the source of the problem. Similarly, we cannot observe a ^{113}Cd NMR signal for either of the two related Cd complexes with oxathia macrocycles, again despite long acquisition times and successful prior measurements [7]. We also do not observe a ^{113}Cd NMR signal for the 18S6 complex. Low solubility might be a possible cause although we would also note our inability to observe a ^{199}Hg NMR signal for the mercury(II) analog [6]. In that case, we proposed that the unusual hexagonal structure of the ligand binding (all six Hg–S bond distances are identical by symmetry restrictions) was the source of the lack of an NMR signal. It is possible that a similar situation may be occurring with the Cd(II) 18S6 complex, but this cannot be confirmed until a crystal structure is obtained. In contrast, we readily were able to measure ^{113}Cd NMR resonances for the two Cd(II) complexes involving amine donors, $[Cd(9N2S)_2]^{2+}$ and $[Cd(18N6)]^{2+}$. These show single peaks with chemical shifts at 521 ppm and 277 ppm, respectively. Combined with our prior

^{113}Cd NMR data for $[Cd(9S3)_2]^{2+}$ (731 ppm, S6 environment) and $[Cd(18S4N2)]^{2+}$ (560 ppm, S4N2 environment), a discernible trend emerges. Each time a secondary amine donor replaces a thioether sulfur donor, there is a progressive upfield chemical shift. Thus, ^{113}Cd NMR can be used as a powerful probe in elucidating coordination environment around a cadmium center.

3.2. X-ray crystal structures

Crystallographic data for the four complexes are presented in Table 1, selected bond distances and angles appear in Table 2, and thermal ellipsoid plots of all four structures are presented in Figs. 1–4.

3.2.1. $[Hg(9S2O)_2](ClO_4)_2 \cdot 2CH_3NO_2$ (**1**)

The complex $[Hg(9S2O)_2](ClO_4)_2 \cdot 2CH_3NO_2$ crystallizes in the monoclinic space group $P2_1/n$ and contains four complex formula units per unit cell which also includes eight perchlorate counter anions and eight nitromethane solvate molecules. The asymmetric unit consists of the mercury(II) ion, situated at an inversion center,

one 9S2O ligand, one anion, and one nitromethane, each occupying general positions within the cell. The four sulfur donors (two each

per macrocycle) form a distorted tetrahedral environment around the four-coordinate mercury center. The Hg–S bond distances range from 2.547(3) Å to 2.649(3) Å with an average of 2.596(3) Å. These are typical bond lengths for a mercury-thioether sulfur in a four-coordinate complex [32,33]. For higher coordination number complexes, longer Hg–S bonds are observed. For example, in the octahedral $[Hg(9S3)_2]^{2+}$ complexes, the Hg–S bond distances average 2.68 Å [34–37]. The two Hg–O distances (2.705(3) and 2.733(3) Å) are longer than any of these Hg–S bonds indicating the lack of oxygen coordination to the Hg center. Indeed, the mean Hg–O bond distance in six-coordinate mercury complexes is reported at 2.39 Å, significantly shorter than what we observe in the complex [32]. Our structural data are also consistent with other reported crystal structures involving oxathia crown complexes with a variety of soft metal ions including Hg(II) [38–40], Ru(II) [41], Pd(II) [42,43], and Ag(I) [44]. Coordination by the ether oxygens to the metal center is never observed in any of these cases. Although the two oxygen atoms are oriented in an *endodentate* fashion in the Hg(II) 9S2O structure, we believe that this a consequence of the ligand conformation and not due to bond formation between the mercury(II) and the hard oxygen donor. The 9S2O ligand adopts the [333] conformation [45], and this particular conformation of the ligand had only been observed previously in the Jahn–Teller distorted bis Cu(II) complex [25]. Interestingly, molecular mechanics calculations on mixed donor tridentate cyclononane ligands have suggested that the [333] conformation is less strained than the [234] conformation by 12–20 kJ/mol [46].

The tetrahedral environment is further demonstrated through the S–Hg–S bond angles (six total). Although these angles range widely from 85.27(10)° to 141.68(10)°, the median of the six is 109.19(10)°, very close to an ideal tetrahedral value. Sulfur atoms S4 and S16 are located 0.928 Å and 0.892 Å, respectively, above the mean tetrahedral plane (defined by the mercury and four sulfur donors) while S7 and S13 lie 0.902 Å and 0.964 Å, respectively, below the plane. Consistent with the difference in complexation behavior between 9S2O and the trithiacrown 9S3, octahedral complexes of $[Hg(9S3)_2]^{2+}$ show S–Hg–S chelate angles no larger than 83°, smaller than the values exhibited here [35]. The O–Hg–O angle is 77.68(10)° which is closer to a *cis* positioning of the oxygen donors and would result in a six line ^{13}C NMR spectrum. However, we obtain a three line ^{13}C NMR spectrum for the complex. The simplicity of that spectrum would be expected only with an exclusive *trans* positioning of the two O donors unless a ligand exchange process were occurring. The combination of the NMR data and the X-ray structure suggest that a ligand exchange of the 9S2O in the mercury complex is indeed occurring in solution.

3.2.2. [Hg(18S4O2)](ClO4)2 (2)

The complex $[Hg(18S4O2)](ClO_4)_2$ crystallizes in the monoclinic space group $P2_1/c$ and contains four complex formula units including eight perchlorate anions, but unlike **(1)**, without any solvate molecules. The asymmetric unit consists of one entire complex along with two anions, occupying general positions within the unit cell. The overall structure is similar to the above bis 9S2O complex in that the four sulfur donors from the macrocycle again form a distorted tetrahedral S4 environment around the Hg(II). The two oxygen donors are at too great of a distance (2.872(6) Å, 2.770(6) Å) to bond with the mercury. The Hg–S bond distances are essentially the same as in the 9S2O complex, ranging from 2.558(6) Å to 2.605(4) Å with an average of 2.596(5) Å. These Hg–S bond distances are again consistent with an S4 mercury(II) coordination environment. Sulfur atoms S4 and S16 lie 0.966 Å and 0.928 Å, respectively, above the mean tetrahedral plane (defined by the mercury and four sulfur donors) while S7 and S13 lie 0.947 Å and 0.987 Å, respectively, below the plane. The tetrahedral structure around the Hg center is best seen in the S–Hg–S angles which range widely from 85.96(15)° to 138.96(14)°, but again show a median value close to an ideal tetrahedral value at 110.04(14)°. The angles again contrast those found in the related octahedral $[Hg(18S6)]^{2+}$ structure where the S–Hg–S angle is 82.21(6)° [6]. It is interesting to note that the *trans* annular oxygen–oxygen distance within the 18S4O2 macrocyclic ring has increased upon complexation, from 5.294 Å in the reported structure of the free ligand to 5.638(9) Å in the Hg(II) structure [21]. We believe that the increase is a consequence of coordination by the macrocycle to the mercury through all four sulfur donors which pushes the oxygen donors further apart. Unlike the bis 9S2O Hg(II) complex which showed *cis* positioning of the two oxygen atoms, the O–Hg–O angle here is *trans* at 174.41(15)° due to the rigid environment of the larger 18-membered ring macrocycle,

3.2.3. [Cd(9S2O)2](ClO4)2 · 2CH3NO2 (3)

The complex $[Cd(9S2O)_2](ClO_4)_2 \cdot 2CH_3NO_2$ crystallizes in the triclinic space group *P-1* and contains two complex formula units per unit cell with four perchlorate anions and four nitromethane solvate molecules. The structure consists of two 9S2O macrocyclic ligands bonded to a Cd^{2+} center, and the asymmetric unit consists of one entire $[Cd(9S2O)_2]^{2+}$ cation, two perchlorates, and two nitromethanes. Unlike the above Hg(II) analog (**1**) or the 18S4O2 Hg complex (**2**), all six donor atoms, four sulfur and two oxygen donors from both 9S2O ligands, are coordinated to the Cd(II) in a highly distorted octahedral structure. To our knowledge, this is the first example of a crystal structure involving a neutral S4O2 environment around a Cd(II) center [47]. The Cd–O bond distances average 2.427(2) Å, significantly shorter than the Hg–O distances in (**1**) and (**2**), respectively. The Cd–S distances do not show large differences, ranging from 2.6039(9) to 2.6370(11) Å, and are slightly longer than the Hg–S distances in the two mercury structures, consistent with a higher coordination number. Thus, there is an interesting contrast between Hg(II) and Cd(II) with regards to how these oxathia ligands are complexing the two heavy metal ions.

The orientation of the coordinated oxygen atoms lies closer to *cis* and not *trans*, but the O1-Cd1-O2 angle is significantly less than 90° (84.78(8)°). There are also other significant deviations overall from an octahedral geometry as pronounced through certain *cis* S–Cd–S angles (S1-Cd1-S4 122.06(3)°, S1–Cd1–S3 106.63(3)°, S2–Cd1–S4 109.94(3)°) as well as the difference in the least-squares planes formed by the ligating atoms of each 9S2O ligand (25.05°). The distortions of the Cd–S4 environment are towards a tetrahedral structure, similar to those observed previously in the six-coordinate Cd(II) 18N2S4 complex [7]. The cyclononane macrocycle adopts the [333] conformation which now appears to be the more common one for 9S2O complexes structures and consistent with the prior molecular mechanics calculations. The open face of the Cd coordination sphere has an interesting approach of a perchlorate (Cl2, O7-O10). This perchlorate is 3.595 Å from Cd center (Cd1-O9), which is the sum of the van der Waals radii plus 0.495 Å. While the perchlorate and Cd obviously do not form a Cd–O bond, a perchlorate–Cd interaction may be important in solution. We have also isolated single crystals of $[Cd(18S4O2)](ClO_4)_2$, but disorder problems prevented a full structural solution. Although not crystallographically acceptable, the partial structure shows a six-coordinate S4O2 environment around the Cd(II) center containing a hexadentate 18S4O24 ligand. This is consistent with the complexation behavior of the 9S2O macrocycle towards Cd(II).

3.2.4. [Cd(9N2S)2](ClO4)2 (4)

The complex $[Cd(9N2S)_2](ClO_4)_2$ crystallizes in the monoclinic space group $P2_1/c$ and contains two complex formula units including four perchlorate anions. No solvent molecules are present, and the two tridentate 9N2S macrocycles are centrosymmetrically oriented around the octahedral Cd center. The asymmetric unit con-

sists of the cadmium(II) ion, situated at an inversion center, one 9N2S ligand and one anion, each occupying general positions within the cell. In contrast to the previous three structures, the complex is octahedral with only a small degree of distortion. Several crystal structures for homoleptic bis complexes with this ligand have been reported including Ni(II) [48], Zn(II) [49], Hg(II) [12], Mn(II) [50], Fe(II) [49,51], and Co(III) [52]. These are generally octahedral as we observe here for Cd(II). However, metal ions such as Cu(II) [53], Pd(II) [54], and Pt(II) [55], which have electronic preferences for other geometries, exhibit bis 9N2S structures which are not octahedral. The 9N2S ligand adopts the [333] conformation, the predominate one that is seen in its complexes. Unlike other tridentate cyclononane ligands such as 9S3 and 9N3, the 9N2S macrocycle is not sufficiently rigid to force a particular stereochemistry on the metal ion, but nevertheless Cd(II) forms an octahedral structure.

The four nitrogen donors and the Cd ion are co-planar, and the *trans* N–Cd–N and S–Cd–S angles are 180° due to symmetry requirements. The *cis* N–Cd–N angle is 74.9(2) ° which is comparable to the N–Cd–N values (75.7(4)°) seen in the structure of the bis Cd(II) complex for the triazacyclononane macrocycle 9N3 [56]. The Cd–S distance is 2.6994(17) Å, the longest metal-sulfur distance among the four structures in our report. The Cd–N distances average 2.356(6) Å, but vary by over 0.03 Å. The longer Cd–N bond (2.371(6) Å) involves the smaller S–Cd–N chelate angle (78.261(14)° versus 79.641(14)°). We believe that the less distorted octahedral structure obtained for the azathia crown is a reflection of the donor properties of the ligand, in particular the Cd–N bond. The weaker Cd–O bonds for the oxathiacrown complex are seen in the distortions as well as in the exchange seen in solution NMR. To our knowledge, this is only the second reported Cd(II) structure containing a N4S2(thioether) coordination environment [47]. Bebout and co-workers have recently reported the structure for the bis Cd(II) complex of bis(2-methylpyridyl)sulfide [57]. Their structure also shows a six-coordinate Cd(II), but it is much more distorted with the two thioether sulfur atoms (from two different ligands) arranged in a *cis*, not *trans* orientation, with a S–Cd–S angle of 126.264(19)°. We propose that the difference in complexation behavior between the two ligands arises from the different types of nitrogen donors (sp^2 N in the pyridyl ligands versus sp^3 N in 9N2S) as well as the rigidity of the cyclononane macrocycle.

4. Conclusions

The mixed oxathia macrocycles 9S2O and 18S4O2 complex Hg(II) and Cd(II) to form homoleptic complexes, but different coordination behavior is seen between the two heavy metals. For Hg(II), S4 tetrahedral structures are obtained which do not involve oxygen coordination, but for Cd(II), all six donor atoms coordinate in highly distorted structures. All four of the heavy metal complexes with oxathia macrocycles exhibit fluxional ligands in solution. We also report the structure of bis(9N2S (1,4-diaza-7-thiacyclononane))cadmium(II) which shows octahedral coordination in a *trans*-N4S2 environment. The macrocycles 18N6 and 18S6 show hexadentate coordination to Cd(II) with stereoisomer preference determined by the conformations of the individual C–X bonds for the ligand. Lastly, we note a trend in ^{113}Cd NMR chemical shifts that shows progressive upfield shifts as secondary amine N donors replace thioether S donors.

groups through such substitution reactions, this offers an attractive method for the synthesis of novel receptors of higher complexity.

The "sandwich compound", ferrocene (Fc), and its derivatives are today universally being studied in the fields of medicine [35], biosensors [36], asymmetric catalysts [37], redox agents [38], photoactive agents [39] and so on for their favorable electrochemical properties. Our attention has been directed towards the synthesis of ferrocene derivatives of Nitmtaa for the addition of extended functionality. In order to study the electrochemistry behaviors between the completely conjugated system of tmtaa and electroactive ferrocene, we grafted one and two ferrocenes on the γ,γ' positions of Nitmtaa through carbonyl groups to acquire two complexes {[(η-C_5H_5)Fe(η-C_5H_4)(CO)](\(C_{22}H_{21}N_4\))Ni} (**1**) and {[(η-C_5H_5)Fe(η-C_5H_4)(CO)]$_2$-(\(C_{22}H_{20}N_4\))Ni} (**2**), respectively (Fig. 2). The electrochemical properties of complexes **1** and **2** have been studied using cyclic voltammetry (CV). The X-ray crystal structure of **1** is also presented here.

2. Experimental

2.1. Reagents and physical measurements

All solvents were distilled and all chemicals were of reagent grade. Nitmtaa [3] and ferrocenoyl chloride (FcCOCl) [40] were prepared according to the literature methods. Thin-layer chromatography (TLC) was performed on commercial Merck plates coated with a 0.20 mm layer of an alumina gel (Wako Pure Chemical Industries Ltd.: B-10) to separate and purify the products.

Elemental analyses were performed on a Yanaco CHN corder MT-3. IR spectra (4000–400 cm^{-1}) were recorded on a JASCO FT/IR-400 spectrophotometer in KBr pellets at room temperature (r.t.). FAB^+ mass spectra were carried out with a JEOL JMSSX102A gas chromatograph–mass spectrometer in a 2-nitrophenyloctylether matrix. Ultraviolet and visible spectra were recorded on a Shimadzu UV-200S double beam spectrophotometer in chloroform at r.t. DSC data were obtained using a Shimadzu DSC-50 differential calorimeter. ^{1}H NMR measurements were taken on a BRUKER AVANCE-400 in chloroform-*d* and chemical shifts are given in ppm relative to tetramethylsilane as an internal reference standard.

2.2. Syntheses of complexes *1* and *2*

After the solution of Nitmtaa (0.626 g, 1.56 mmol) and triethylamine (2 mL) in dry toluene (50 mL) was stirred at r.t. under nitrogen atmosphere for 10 min, a solution of FcCOCl (0.384 g, 1.55 mmol) in dry toluene (50 mL) was slowly added dropwise and the reaction mixture was further stirred at 80 °C for 12 h. After being cooled to r.t., the solution was filtered to eliminate the hydrochloride of triethylamine. Evaporating the filtrate resulted in a dark green powder. The powder was purified and separated on a large-scale alumina gel TLC using dichloromethane–hexane (4:1 v/v) as the developing solution. The products were recrystallized from dichloromethane and hexane to give green micro-crystals of **1** and **2**, respectively.

Complex **1**, yield: 0.213 g (22.3%). *Anal.* Calc. for \(C_{33}H_{30}FeN_4NiO\) (613.16): C, 64.64; H, 4.93; N, 9.14. Found: C, 64.58; H, 4.88; N, 9.19%. M.p.: 333–336 °C (DSC). 2.3. Electrochemical measurements

Cyclic voltammograms were collected using a Yanaco POLAROGRAPHIC ANALYZER P-1100 potentiostat at r.t. A typical three-electrode configuration was used, where the working electrode was glass carbon, a platinum wire was used as the counter electrode and a Saturated Calomel Electrode (SCE, Hg/Hg_2Cl_2, KCl-saturated) was the reference electrode. All samples for electrochemical analysis were prepared in CH_2Cl_2 (being refined in accordance with the standard method) at a concentration of 2×10^{-4} M. The supporting electrolyte was tetra-*n*-butylammonium perchlorate (*n*-Bu_4NClO_4) and its concentration was 1×10^{-1} M. The scan rate was 200 mV s^{-1} and the scanning scope was from 0 to 1.6 V.

2.4. X-ray crystal structure analysis

Crystals of **1** are stable in air. A dark green crystal of **1** was measured on a Rigaku AFC7R diffractometer equipped with a rotating anode generator using monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). The structure of **1** was solved by direct methods [41] and expanded using the Fourier technique [42]. The non-hydrogen atoms were refined with anisotropic thermal parameters. Crystal data and details associated with data collection of **1** are summarized in Table 1.

3. Results and discussion

3.1. Syntheses and spectra

One and two [(η-C_5H_5)Fe(η-C_5H_4)(CO)] grafted tmtaa Ni(II) complexes **1** and **2** were simultaneously synthesized from the reaction of FcCOCl and Nitmtaa in a 1:1 molar ratio and the yields were 22.3% and 17.9%, respectively. In order to obtain the one [(η-C_5H_5)Fe(η-C_5H_4)(CO)] substituted complex **1** in a higher yield, the reaction was performed with a 1:2 molar ratio of FcCOCl and Nitmtaa, in which the yield of **1** increased to 30.3%. Since the spots of the products and the starting reactant, Nitmtaa, were very close in the column chromatography, purification of **1** and **2** could not be achieved favorably by using column chromatograph. Thus, the purification was carried out by large-scale TLC. However, if the molar ratio of the reactants, FcCOCl and Nitmtaa, was changed to 4:1, the two [(η-C_5H_5)Fe(η-C_5H_4)(CO)] substituted complex **2** could be obtained separately in a higher yield and the purification could be achieved by short column chromatography. Crystals of **1** suitable for X-ray structure analysis were grown in a dichloromethane–hexane (1:1 v/v) solution at r.t. Unfortunately a single crystal of **2** was not obtained.

Complexes **1** and **2** were characterized by ^1H NMR, IR, MS spectra, element analyses and DSC measurements. The electronic absorption spectra for Nitmtaa, **1** and **2** were measured in chloroform solution at r.t. The spectrum of Nitmtaa showed two absorption bands at ca. 393 and 581 nm (shoulder), attributed to a $\pi \rightarrow \pi^*$ transition within the ligand and a $d \rightarrow d^*$ transition from the central metal to the ligand, respectively. After the Fc groups were introduced to Nitmtaa, great changes of the electronic absorption spectra should be observed because of the distinctive electronic characteristics of Fc. Nevertheless, comparing the electronic absorption spectra of **1** [ca. 390 and 583 nm (shoulder)] and **2** [ca. 391 and 584 nm (shoulder)] with that of Nitmtaa, almost no changes were observed. Hence, only judging from the electronic absorption spectra, there was almost no influence to the ligand and the central metal when the Fc groups were introduced to Nitmtaa.

This may be due to the spatial structures of complexes **1** and **2**. In complex **1**, the symmetry axis of ferrocene is almost parallel to the cyclic tmtaa (see Section 3.2) and the impact to this conjugated system is extraordinarily small. Because almost no new charge transition bands were observed, it is difficult to appraise the interaction of Fc and the tmtaa ring or central metal from the electronic absorption spectra.

3.2. Crystal structure of complex 1

A structural representation of **1** is shown in Fig. 3. Selected bond lengths and bond angles are given in Table 2. In the molecular structure of **1**, the non-planar, saddle-shaped geometry reported for the free ligand, H_2tmtaa, is almost retained in the tmtaa moiety of the complex. Ni(II) coordinates to four nitrogen atoms of tmtaa to form a four-coordinated complex. The N1–Ni1–N3 and N2–Ni1–N4 angles are 176.34(10)° and 178.06(9)°, respectively, showing that the Ni atom is almost in the same plane as that of N_4. The displacement of the nickel center out of the N_4 plane is only 0.061(5) Å. The mean Ni–N bond distance is 1.866 Å. In **1**, the C–N and C–C bond distances in the chelate ring are from 1.336(4) to 1.419(4) Å and from 1.400(5) to 1.416(4) Å, respectively, showing obvious differences from those in Nitmtaa, in which the C–N and C–C bond distances range from 1.324 to 1.342 Å and from 1.394 to 1.408 Å, respectively [43]. This may be due to the spatial interaction between the nickel complex and ferrocene.

Ferrocene was grafted onto the methine of the tmtaa nickel complex through a carbonyl group. The two cyclopentadieny (Cp) rings are virtually parallel to each other. The average distances of Fe to the C atoms of the Cp rings (2.041(4) Å in the substituted Cp ring and 2.043(4) Å in the unsubstituted Cp ring) are normal and compare well with those of other ferrocenoyl structures [44]. The average C–C–C angles in two Cp rings are the same (108.0(3)°). Interestingly, the Cp internal average C–C bond distance in the substituted Cp ring (1.417(5) Å) is longer than that in the unsubstituted Cp ring (1.407(5) Å). The distance of the carbonyl carbon to the Cp ring (C(23)–C(24): 1.479(4) Å) is a normal C–C single bond distance. The carbonyl C═O distance (1.220(4) Å) compares well with those of other ferrocenoyl structures. The symmetry axis of the ferrocene is almost parallel to the nickel tmtaa complex moiety. The dihedral angle between the N_4 plane in the nickel complex and the grafted Cp ring (C24–C25–C26–C27–C28) in the ferrocene is 98.5°, while the dihedral angle between the iminato fragment in the Nitmtaa moiety and the Cp ring is 71.6°. Apparently, this difference is caused by the non-planar, saddle-shaped geometry of the Nitmtaa moiety.

3.3. Electrochemical properties of complexes *1* and *2*

The electrochemical behaviors of related compounds including **1** and **2** were investigated by the cyclic voltammetric technique in $CH_2Cl_2/1 \times 10^{-1}$ M n-Bu_4NClO_4 using a glass carbon working electrode. The scan rate

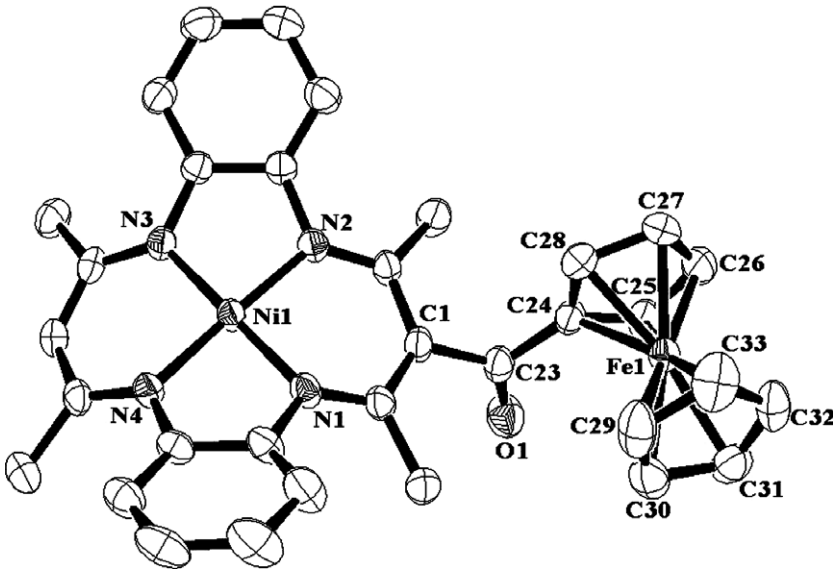

Fig. 3. ORTEP drawing of **1**. The thermal ellipsoids are drawn at the 50% probability level. The H atoms are omitted for clarity.

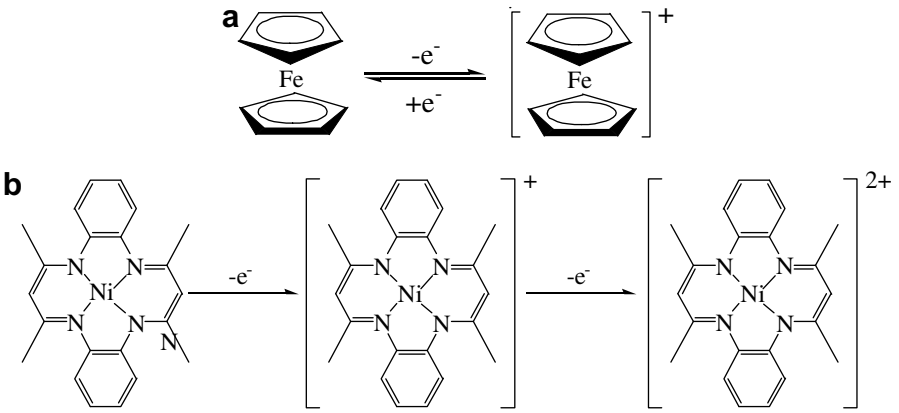

Scheme 1. The redox processes with a scanning scope from 0 to 1.6 V in the CV experiments. (a) The redox process of Fc. (b) The oxidation process of Nitmtaa.

was 200 mV s^{-1} and the scanning scope was from 0 to 1.6 V. As a contrast, cyclic voltammetries of the free Fc and Nitmtaa were also carried out under similar conditions. The CV experiments in CH_2Cl_2/*n*-Bu_4NClO_4 indicate a totally reversible one-electron oxidation–reduction of Fc ($E_{Pa} = 0.61$ V, $E_{Pc} = 0.38$ V versus SCE, $\Delta E_p = 0.23$ V). While the cyclic voltammogram of Nitmtaa shows an irreversible two-electron oxidation. The first and second oxidation potentials are 0.61 and 1.20 V versus SCE, respectively. The oxidation–reduction process of Fc and the oxidation process of Nitmtaa are shown in Scheme 1. Under our experiment conditions, free Fc shows a good reversible one-electron oxidation–reduction process. The oxidation wave corresponds to the Fe(II) → Fe(III) process and the reduction wave corresponds to the Fe(III) → Fe(II) process. However, in the cyclic voltammogram of free Nitmtaa, two oxidation potential peaks ($E^1_{Pa} = 0.61$ V, $E^2_{Pa} = 1.20$ V) were observed, while no reduction potential peaks were observed. To the best of our knowledge, central metals in tmtaa complexes may not be oxidized or reduced easily because of the π electron conjugated system of tmtaa ring. Up until now, no literature has conclusively proved that the central metals in tmtaa complexes can be oxidized or reduced. Thus, we consider that the π electron conjugated system of the tmtaa ring is oxidized in the CV experiments. The oxidation waves correspond to $tmtaa^{2-} \rightarrow tmtaa^{-}$ and $tmtaa^{-} \rightarrow tmtaa$ processes, respectively.

Table 3
Electrochemical parameters[a] of **1**, **2** and CH_3COFc at r.t. in CH_2Cl_2 with a concentration of 2×10^{-4} M, supporting electrolyte *n*-Bu_4NClO_4 with a concentration of 1×10^{-1} M

Compound	E_{Pa}		E_{Pc}		ΔE^1_{Pa} (V)[c]
	E^1_{Pa} (V)	E^2_{Pa} (V)	E^1_{Pc} (V)	E^2_{Pc} (V)	
1	0.85	1.50	0.63	1.20	−0.05
2	0.84	1.33	0.62	1.14	−0.06
CH_3COFc	0.90[b]		0.60[b]		

[a] Maximum error ±6%; all potentials are measured against SCE reference electrode.
[b] The cyclic voltammogram of CH_3COFc shows a reversible one-electron oxidation reduction, thus, only E_{Pa} and E_{Pc} data are listed in the table.
[c] $\Delta E^1_{Pa} = E^1_{Pa,complex} - E_{Pa,CH_3COFc}$.

In **1** and **2**, one and two ferrocenes connect with Nitmtaa through carbonyl groups, respectively. In order to investigate the electrochemical behaviors between the completely conjugated system of Nitmtaa and ferrocene-containing substituted groups in **1** and **2**, cyclic voltammetries of **1**, **2** and acetylferrocene (CH_3COFc), an analogue of the substituted groups (–COFc) in **1** and **2**, were carried out under similar conditions. Because CH_3COFc and the

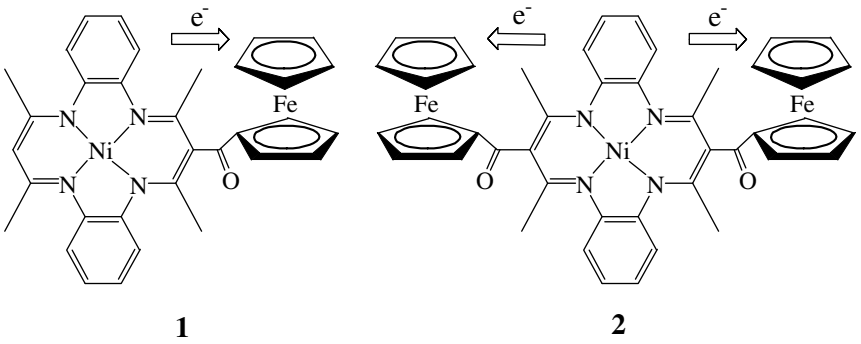

Fig. 4. The proposed electron flows in **1** and **2**.

substituted groups (–COFc) in **1** and **2** all contain electron withdrawing carbonyl groups and electroactive Fc, we consider it is significant to investigate the electrochemical property of CH_3COFc instead of the –COFc groups in **1** and **2**. All the electrochemical data are summarized in Table 3. Both **1** and **2** show a reversible two-electron oxidation–reduction, which is different from those of free Nitmtaa and Fc. Furthermore, the cyclic voltammogram of CH_3COFc shows a totally reversible one-electron oxidation–reduction, which is similar to that of free Fc. However, its oxidation and reduction potentials are higher than those of free Fc. The differences of the first oxidation potentials of **1** and **2** to the oxidation potential of CH_3COFc are −0.05 and −0.06 V, respectively. Although these potential differences are very tiny, the minus values still hint that electrons flow from the π electron conjugated system of the tmtaa ring to the ferrocenes in **1** and **2** (Fig. 4), which means that the ferrocenes act as electron acceptors in **1** and **2**. This is reverse to the fact that Fc is often used as an electron donator. In **1** and **2**, Nitmtaa and Fc are connected through carbonyl groups. The carbonyl group is an electron withdrawing group and perhaps it facilitates electrons flowing from Nitmtaa to Fc.

4. Conclusions

In summary, two ferrocene-containing tmtaa nickel complexes, $\{[(\eta\text{-}C_5H_5)Fe(\eta\text{-}C_5H_4)(CO)](C_{22}H_{21}N_4)Ni\}$ (**1**) and $\{[(\eta\text{-}C_5H_5)Fe(\eta\text{-}C_5H_4)(CO)]_2(C_{22}H_{20}N_4)Ni\}$ (**2**), were simultaneously synthesized from the reaction of FcCOCl and Nitmtaa in a 1:1 molar ratio. **1** and **2** are the first examples of tmtaa complexes in which ferrocenes are introduced. The single crystal structure of **1** was determined. In **1**, the symmetry axis of ferrocene is almost parallel to the tmtaa nickel complex moiety. The electrochemical properties of **1** and **2** were investigated using the cyclic voltammetric technique and the results suggest that the ferrocenes act as electron acceptors in the complexes.

planar moiety and also the reluctance to axial binding arising out of the Jahn–Teller effect.

In a continuation of our studies in this field [7], here we have strategically selected an N_4-donor copper(II) synthon, [Cu(nelin)]-$(ClO_4)_2$ (**1**) (nelin = 1,9-diamino-5-methyl-5-nitro-3,7-diazanonane) with a nitroalkyl pendant attached to the main ligand frame.

The utilization of such a precursor deserves special attention since nitro compounds are used extensively as antibacterial, antiprotozoal and anticancer agents [8]. Again, such compounds in metabolic pathways undergo a one-electron reduction to generate nitro-radical anions that exhibit cytotoxicity towards cellular systems [9], causing DNA damage within the cell. Furthermore, several nitro compounds [10] and some of their metal complexes [11] are potent radio-sensitizers towards hypoxic tumour cells, and the efficiency of these drugs is related to the one-electron reduction potential of these compounds [12]. It is therefore important to study the redox behavior of these nitro compounds and the reactivity of the corresponding one-electron reduced nitro-radical anions. So far, the reactivity of these nitro-radical anions has been studied mainly by pulse radiolysis [13] and in few cases by cyclic voltammetry [14], mostly in a mixed solvent medium. The cyclic voltammetric reduction of **1** [15] and other nitro compounds [16] in protic solvents at neutral pH resulted in a single irreversible cathodic wave corresponding to the four-electron reduction of the nitro group to the hydroxylamine derivative. Recently, cyclic voltammetric reduction of a heterocyclic drug, metronidazole, in aqueous solution and aqueous DMF [17] produced the nitro-radical anion successfully. However, monitoring of the redox behavior of copper(II) complexes containing a nitro group on a ligand fragment in vivo-friendly pure aqueous medium is absolutely a new era in this dimension.

In this paper attempts have been made to highlight two relevant aspects in a justified way. First we report the syntheses, crystal structures and other physical characterizations of two new cyano complexes viz. ionic $[Cu(nelin)(H_2O)_2]_2[Fe(CN)_6]\cdot 6H_2O$ (**2**) and bridged $[\{Cu(nelin)\}_2Ni(CN)_4](ClO_4)_2\cdot 2H_2O$ (**3**), by taking $[Cu(nelin)]^{2+}$ as the strategically starting synthon. It is noteworthy to mention here that cyanometallate incorporated copper(II) complexes in an N_4-donor diaza-diamine environment containing an $-NO_2$ pendant group has been scarcely studied [6e]. Here, the supramolecular view not only provides an aesthetically pleasing architecture, the simultaneous transformation of **2** to a quasi-glass phase on dehydration warrants special attention in material science. In the next part, we report the detailed comparative cyclic voltammetric studies of these compounds as well as the parent complex $[Cu(nelin)](ClO_4)_2$ (**1**), especially giving emphasis on the generation of the nitro-radical anion and its effects on the subsequent redox processes in pure aqueous and in MeCN media. In this regard, it is mentionable that the nitroalkyl-substituted $Cu^{II}N_4$ precursor and the cyanometallate incorporated complexes deserve further exploration in the context of the possibility of their potential application as radio-sensitizers in the treatment of cancer, as they are expected to serve in a better way than other organic drugs having poor solubility and high toxicity in physiological conditions compared to the macro-cyclic and acyclic complexes.

2. Experimental

2.1. Materials and methods

Materials such as aqueous formaldehyde (37%) (E-Merck, India), nitroethane (Aldrich), $HClO_4$, and $K_4[Fe(CN)_6]$ (E-Merck, India) were of reagent grade and were used as received. Ethylenediamine (E-Merck, India) and triethylamine (Ranbaxy, India) were distilled over sodium metal before use. Single distilled HPLC grade MeCN (Merck Germany) was used for the electrochemical studies. All the solutions of the complexes for the electrochemical studies were prepared freshly with double distilled water.

Elemental analyses were carried out using a Perkin–Elmer 240 elemental analyzer. Infrared spectra (400–4000 cm^{-1}) were recorded from KBr pellets on a Nicolet Magna IR 750 series-II FTIR spectrophotometer. EPR spectra of polycrystalline samples were recorded using a Varian Century Series X-band EPR spectrophotometer having 100 KHz magnetic field modulation (model E 109) and equipped with a low-temperature quartz Dewar for low-temperature measurements. Room temperature magnetic susceptibilities were recorded on a PAR vibrating sample magnetometer using $Hg[Co(NCS)_4]$ as the calibrant. Diamagnetic corrections were estimated from Pascal's constants. TGA and DTA curves were recorded simultaneously on a Perkin–Elmer, Model Pyris Dimond TG/DTA in static dry nitrogen at a heating rate of 5 °C min^{-1}. Electrochemical measurements were carried out using a computer controlled PAR model 263A VERSASTAT electrochemical instrument with a glassy carbon disk (4 mm diameter, EG&G instrument) as the working electrode. All the results were collected at 25 ± 0.5 °C with reference to the Ag/AgCl electrode. All the solutions were purged with pure argon gas for at least 10 min prior to each experiment. Junction potentials were not corrected. Electronic spectra was recorded on an Agilent 8453 UV–Vis diode array spectrophotometer with a Peltier thermostatic temperature control facility at 25 ± 0.10 °C.

2.2. Syntheses

Caution! Since perchlorate salts are potentially explosive, only small amounts of the materials should be handled with care.

Preparation of $Cu(ClO_4)_2\cdot 6H_2O$, $[Cu(en)_2](ClO_4)_2$, $Na_2[Ni(CN)_4]\cdot 3H_2O$ and the starting material $[Cu(nelin)](ClO_4)_2$ (**1**) have been mentioned elsewhere [7,18] and the purity of each was checked by CHN analysis.

2.2.1. Synthesis of $[Cu(nelin)(H_2O)_2]_2[Fe(CN)_6]\cdot 6H_2O$ (*2*)

To an aqueous solution of $[Cu(nelin)](ClO_4)_2$ (0.576 g, 1.0 mmol), $K_4[Fe(CN)_6]$ (0.375 g, 1.0 mmol) dissolved in a minimum volume of water was added dropwise with constant stirring over 5 min. The precipitate that appeared initially was filtered off and the deep blue filtrate was kept in a refrigerator at 4 °C for several weeks, during which time dark brown block shaped crystals of **2** suitable for X-ray study were obtained. These were washed with cold water and dried in air at room temperature. Yield: 62% based on $[Cu(nelin)](ClO_4)_2$. *Anal.* Calc. for $C_{22}H_{62}Cu_2FeN_{16}O_{14}$: C, 27.56; H, 6.47; N, 23.39. Found: C, 27.92; H, 6.88; N, 23.06%.

IR in cm^{-1} (KBr): 3582 (s,br), 3495 (w,br), 3287 (w), 3227 (w,m), 3173 (w,sh), 2959 (w), 2886 (w), 2045 (vs), 1604 (s), 1548 (s), 1346 (s). μ_{eff} (per monomer): 1.67 μ_B at 27 °C. Electronic spectrum (water): λ_{max} = 532 nm (ε: 61.2 M^{-1} cm^{-1}).

2.2.2. Synthesis of $[\{Cu(nelin)\}_2Ni(CN)_4](ClO_4)_2\cdot 2H_2O$ (*3*)

To an aqueous solution of $[Cu(nelin)](ClO_4)_2$ (0.576 g, 1.0 mmol), $Na_2[Ni(CN)_4]\cdot 3H_2O$ (0.158 g, 0.6 mmol) dissolved in a minimum volume of water was added dropwise with constant stirring over 5 min. The precipitate that appeared initially was filtered off and the deep blue colored filtrate was allowed to undergo slow evaporation at ambient temperature in the open air. After several weeks, dark blue needle shape shiny crystals of **3** suitable for an X-ray study were obtained from the filtrate, which were filtered and washed with cold water followed by diethyl ether and dried in air at room temperature. Yield: 49%. based on $[Cu(nelin)](ClO_4)_2$. *Anal.* Calc. for $C_{20}H_{46}Cl_2Cu_2N_{14}NiO_{14}$: C, 24.91; H, 4.77; N, 20.34. Found: C, 25.01; H, 4.41; N, 20.06%.

IR in cm^{-1} (KBr): 3609 (w), 3383 (w), 3287 (w), 3225 (w), 3151 (w), 2959 (w), 2923 (w), 2893 (w), 2141 (vs), 2124 (s), 1604 (s),

2.3. Crystal data collection and refinement

Intensity data for **2** and **3** were collected at 293(2) K on a Siemens P4 diffractometer using graphite monochromatized Mo Kα radiation (λ = 0.71073 Å) and the ω–2θ scan mode in the range $2.44 \leqslant \theta \leqslant 26.47^{o}$ and $2.47 \leqslant \theta \leqslant 24.00^{\circ}$, respectively. The intensities were corrected for Lorentz-polarization effects and for absorption using ψ-scans. The minimum and maximum transmission factors were 0.357 and 0.596 for **2** and 0.122 and 0.142 for **3**. The structures were solved by direct methods and all non-hydrogen atoms refined anisotropically by full matrix least squares on F^2 using the SHELXTL PLUS-PC version [25,19] and hydrogen atoms were included geometrically and refined isotropically except those of water hydrogens. Other additional information concerning the data collection and refinement of the structure are compiled in Table 1.

2.4. PXRD data collection

Powder X-ray diffraction data were collected on a Bruker D8 Advance powder diffractometer in the Bragg-Brentano geometry using monochromatic Cu Kα1 radiation (λ = 1.5406 Å) selected with an incident beam germanium monochromator.

3. Results and discussion

Description of the structure of $[Cu(nelin)(H_2O)_2]_2[Fe^{II}(CN)_6] \cdot 6H_2O$ (**2**). Complex **2** crystallizes in the monoclinic space group $P2_1/n$. The asymmetric unit contains half of the formula unit along with three water molecules (Fig. 1). The molecular structure of complex **2** consists of two cationic $[Cu(nelin)(H_2O)_2]^{2+}$ fragments

[*] Symmetry transformation used to generate equivalent atoms: #1 $-x, -y, -z$; #2 $-x+1, -y, -z$.

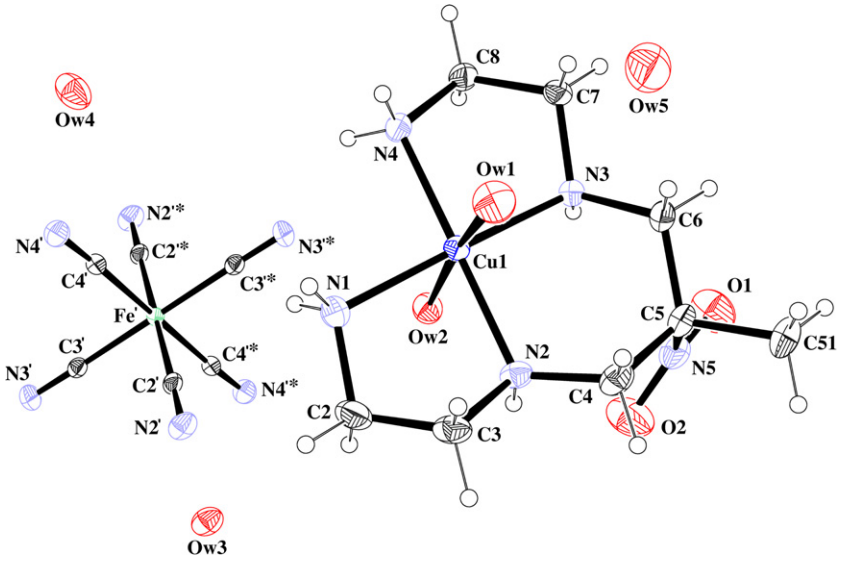

Fig. 1. ORTEP diagram (30% ellipsoidal probability) with the atom numbering scheme for complex **2** ([*] = $-x+1, -y, -z$).

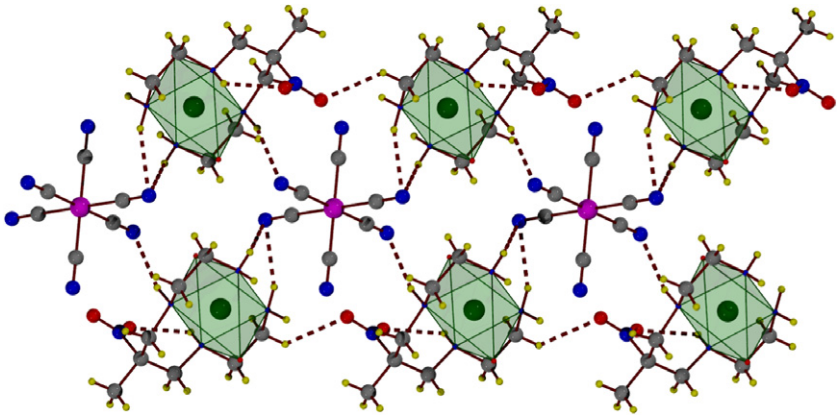

Fig. 2. H-bonded supramolecular 1D chain of anions and cations for complex **2** along the *a*-axis.

the charges of which are counter-balanced by the $[Fe^{II}(CN)_6]^{4-}$ anion along with six water molecules. The coordination geometry of each copper(II) atom is best described as distorted octahedral. The square plane is constructed by the four nitrogen atoms (N1, N2, N3 and N4) of the diaza-diamine ligand and the axial sites are occupied by two more distant oxygen atoms of two water molecules. The N(4)–Cu–N(2) (177.3(1)°) and N(1)–Cu–N(3) (174.2(1)°) angles in the equatorial plane slightly deviate from 180° and the average of the four OW_1–Cu–N angles (92.1°) (Table 2) is slightly higher than 90°. All these indicate a slight distortion from a regular octahedral geometry with the copper center situated at 0.100(4) Å above the mean plane towards the axial OW1 water molecule. In the equatorial plane, the Cu–N bond distances vary from 2.009(2) to 2.027(2) Å (avg. 2.017(2) Å) and are comparable with the previously reported values [18]. It is noteworthy that the two axial Cu–OW bond distances are not identical; Cu–OW_1 2.413(2) and Cu–OW_2 2.722(2) Å; probably due to a different extent of H-bonding. On the other hand, $[Fe^{II}(CN)_6]^{4-}$ retains its perfect octahedral geometry (Table 2).

Hydrogen bonds play a pivotal role in assembling the discrete cationic and anionic entities towards higher dimensionality. The packing diagram clearly indicates that all the ferrocyanide ions occupy special positions and the participation of the cyano nitrogen in extensive intermolecular H-bonding. The $[Fe(CN)_6]^{4-}$ unit act as a template for the organization of four $[Cu(nelin)]^{2+}$ units around it and due to successive hydrogen bonding this gives rise to a supramolecular chain along the crystallographic *a*-axis (Fig. 2, Table 3). The H-bonded polymeric chains are three dimensionally interlinked through hydrogen bonding (N4–H44···O2) to form irregular honeycomb-like channels (Fig. 3), which accommodate a one dimensional helical water chain as shown in Fig. 4. Three lattice water molecules (OW3, OW4, OW5), by hydrogen bonding association with themselves together with the coordinated water molecule (OW1), give rise to this helical assembly. The hydrogen bonding distances are OW1···OW3 = 2.818(4) Å; OW3···OW4 = 2.889(4) Å; OW4···OW5 = 2.807(4) Å; OW5···OW1 = 2.724(4) Å. The pitch of the helical water chain is 9.3 Å and it is supported within the channel by three more hydrogen bonding contacts OW3···OW2 = 2.804(4) Å; OW3···N2′ = 2.729(4) Å and OW3···N4′ = 2.887(4) with the wall as it propagates along the *a*-axis. Each of the channels is symmetric and it is divided

into two halves. Each half accomodates a helical water chain which run in opposite directions to each other (Fig. 5).

3.1. Description of structure of $[\{Cu(nelin)\}_2Ni(CN)_4](ClO_4)_2.2H_2O$ (3)

The molecular structure of **3** consists of a trinuclear $[\{Cu(nelin)\}_2Ni(CN)_4]^{2+}$ cation, two perchlorate anions and two water molecules (Fig. 6). The asymmetric unit consists of one half of the formula unit with the inversion center located at the nickel atom. The $[Ni(CN)_4]^{2-}$ anion is coordinated to two $[Cu(nelin)]^{2+}$ cations through two cyano groups bridging in a di-*trans* fashion, leaving the two other *trans*-CN groups uncoordinated, and complex **3** in this sense is comparable to $[Cu(HL)]_2[Ni(CN)_4]\cdot 4H_2O$ [7b] (H_2L = 3,9-dimethyl-4,8-diazaundec-3,8-diene-2,10-dione-dioxime). The bonding arrangement of this trinuclear unit is shown in Fig. 6 and selected bond distances and angles are given in Table 2.

The coordination geometry around the copper center is best described by a square pyramid with the geometrical factor $\tau = 0.03$ [7a]. The basal plane is constructed by the four nitrogen atoms of the diaza-diamine ligand and the apical position is occupied by the nitrogen atom of the bridging cyanide. In the basal plane the Cu–N bond distances vary from 2.012(7) to 2.032(6) Å, whilst that of the apical Cu–N(6) is 2.294(6) Å, which is significantly longer than the basal Cu–N bond lengths. The N(1)–Cu–N(3), 169.4(2)° and N(2)–Cu–N(4), 167.8(3)° angles in the basal plane deviate significantly from 180° and the four N(6)–Cu–N(x) [x = 1, 2, 3 and 4] angles are larger than 90° (avg. 95.6(3)°), indicating that the coordination geometry around each copper(II) center is a distorted square pyramid. The copper center is situated 0.199 Å above the plane towards the apical direction. It is interesting to mention here that one oxygen atom from the perchlorate anion, O(1′), is at an elongated contact distance 2.936(15) Å to the copper(II) center. The bridging cyanide coordinates to the copper ion in a bent fashion with a C(6)–N(6)–Cu bond angle of 165.3(6)°. The intramolecular Cu···Cu separation is 10.497 Å. Like the earlier trends [7b] no significant difference has been observed here between the bridging (C(6)–N(6) = 1.143(9) Å) and terminal (C(7)–N(7) = 1.136(10) Å) cyano groups and $[Ni(CN)_4]^{2-}$ retains its square planer(SP) geometry (Table 2).

As shown in Fig. 7, the trinuclear units are arranged in successive rows in a herringbone fashion and the bifurcated hydrogen bonding (N3–H31···N7 and N4–H42···N7) (Table 3) through the uncoordinated terminals of the $[Ni(CN)_4]^{2-}$ units give rise to a supramolecular (4,4) network in the (202) plane. In this arrangement the $[Ni(CN)_4]^{2-}$ units act as a template for a (4,4) net architecture. Perchlorate anions and lattice water molecules occupy the void spaces within this network and bind to the cationic part of the trinuclear units through hydrogen bonding (Table 3). Successive (202) planes are stacked along the [101] direction through C–H···O hydrogen bonding (Fig. 8).

3.2. IR study

The positions of the relevant IR bands of complexes **2** and **3** are given in Section 2. The IR active bands fall in the region of *ca.* 3151–3600 cm^{-1} for both complexes which is characteristic for ν(O–H) and ν(N–H) groups. For cyano complexes, absorption bands due to ν_{CN} stretching vibrations are very characteristic. In $K_4[Fe^{II}(CN)_6]$ the ν_{CN} band appears at 2042 cm^{-1} [20] and in complex **2** a sharp peak at *ca.* 2045 cm^{-1} clearly indicates that all the cyano groups of the ferrocyanide ion are terminal. For the tetracyanonickelate anion this absorption band appears at 2128 cm^{-1} [20]. On bridging

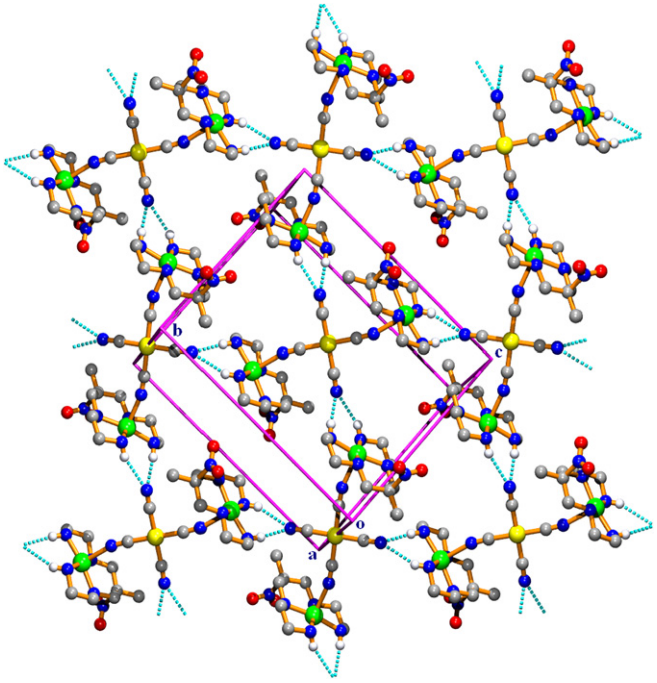

Fig. 7. The (4,4) supramolecular network in the (202) plane of complex **3**. $[Ni(CN)_4]^{2-}$ units act as a template for this network. Perchlorate ions and water molecules, which are omitted for clarity, occupy the void space within the network.

via N atoms this band shifts to a higher wave number. The two ν_{CN} IR bands appearing at 2124 (vs) and 2141 (s) cm^{-1} for **3** can be assigned to the terminal and bridging cyanide groups, respectively [20a]. The characteristic IR bands corresponding to the nitro group appear for **2** at 1548 cm^{-1} (s, ν_{as}) and 1346 cm^{-1} (m, ν_s) and that for **3** at 1556 cm^{-1} (s, ν_{as}) and 1350 cm^{-1} (w, ν_s) [1g]. Additionally, a strong band near 1115 cm^{-1} and a sharp band near 623 cm^{-1} indicate the presence of an uncoordinated perchlorate anion for complex **3** [20b]. All other bands appear at their usual positions.

3.3. Thermal analyses

Complex **2** remains unchanged at room temperature (27 °C) for an indefinite period. TGA studies show that total water loss occurs in two narrow temperature regions: an 8.57% weight loss was observed in between 40 and 90 °C, which is almost equivalent to a loss of 4.5 water molecules. This is accompanied by a small *endo*-effect on the DTA curve at *ca.* 80 °C. Obviously these are due to non-coordinated lattice water molecules present in the cavities. On gradual heating a further 8.51% weight loss was monitored in between 100 and 130 °C and the total weight loss is equivalent to 4.46 water molecules. These are partially lattice as well as coordinated water molecules. The corresponding endo-therm was observed at *ca.* 122 °C. The remaining water molecules are retained up to 140 °C, after which the complex undergoes an immediate decomposition with a large exothermal peak at *ca.* 145 °C in the DTA curve. Losses of water molecules in different stages are due to the different extent of H-bonding. For example, some water mol-

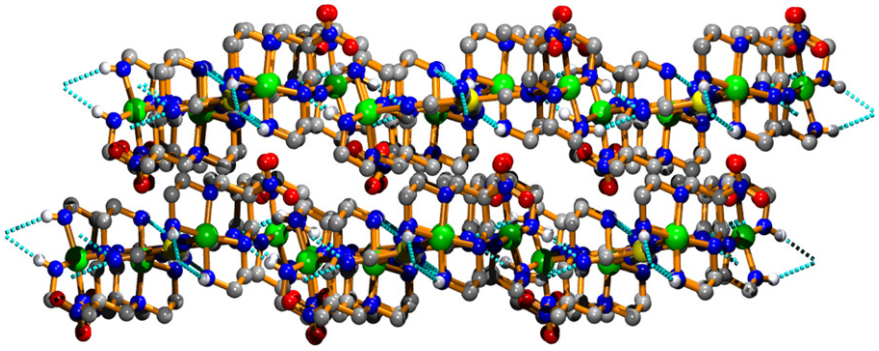

Fig. 8. The disposition of successive (202) layers in complex **3**.

ecules are doubly H-bonded with two neighbouring water molecules while some water molecules are triply H-bonded with an additional H-bond to a cyano nitrogen atom. As it is envisaged that the network is purely built up of strong H-bonding, complete removal of all the water molecules ultimately results in collapse of the structural morphology. This is evident from the powder X-ray diffraction (PXRD) pattern (Fig. 9).

Thermal decomposition of complex **3** starts at *ca.* 65 °C and consequently the complex eliminates its two uncoordinated water molecules, and the process continues up to *ca.* 100 °C (found/calc.: 3.70%/3.74% with respect to loss of weight%). This is accompanied by a small *endo*-effect on the DTA curve at *ca.* 90 °C. The anhydrous complex, having the formula $[\{Cu(nelin)\}_2Ni(CN)_4](ClO_4)_2$, maintains its thermal stability up to *ca.* 180 °C. After that the complex undergoes an immediate decomposition with a small exothermal peak at *ca.* 190 °C in the DTA curve. Since the complex contains the perchlorate anion, we have not carried out the experiment beyond 200 °C.

3.4. PXRD analysis

To study the effect of dehydration on the structure, a PXRD pattern of complex **2** was recorded at 27 °C (Fig. 9a). It was then heated to (130 ± 2) °C in a stream of nitrogen and was kept at this temperature for 30 min. An X-ray powder diffraction pattern (Fig. 9b) was recorded almost immediately on cooling the compound to room temperature (27 °C), which showed marked changes in the diffraction pattern compare to that of the original phase (Fig. 9a). The PXRD pattern of the dehydrated species clearly indicates that in addition to water removal from the original crystalline structure, it has transformed into a quasi glassy material. Dehydration of the hydrated species to generate a glassy state is most unusual, since up until now only hydrated trehalose [21], raffinose [22] and magnesium acetate [23] have been reported to have this property. Such a finding may be explored by crystal engineers in a more applied way.

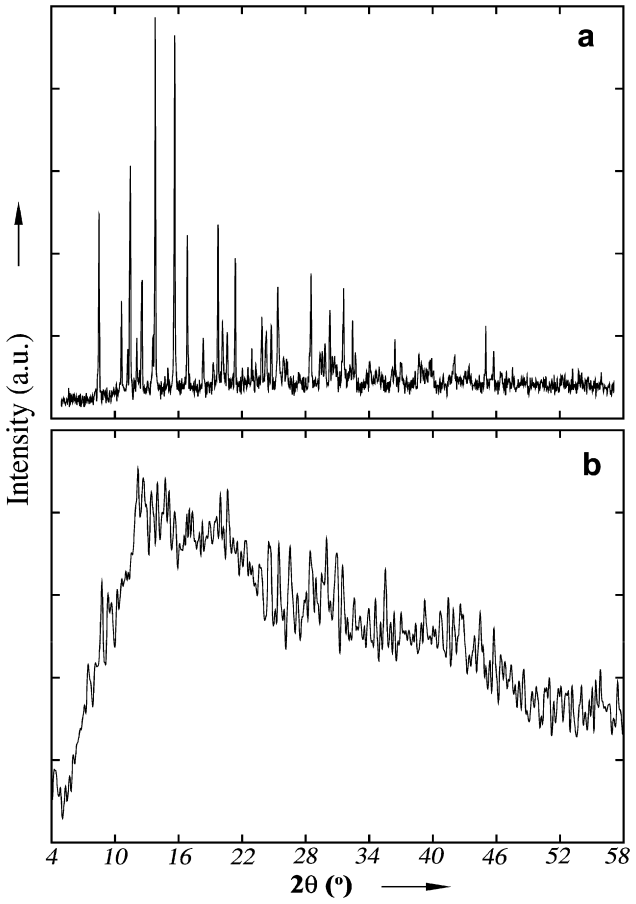

Fig. 9. (a) PXRD pattern (complex **2**); (b) PXRD patten (complex **2** after heating).

3.5. EPR studies

Room temperature solid state EPR of a polycrystalline sample of **2** is typical for a mononuclear copper(II) complex with axial distortion, and the elongation of the axis is characterized by $g_{||} = 2.21$ and $g_{\perp} = 2.01$. An almost identical spectrum for **3** is characterized by $g_{||} = 2.11$ and $g_{\perp} = 2.04$. The observed values ($g_{||} > g_{\perp}$) confirm that the unpaired electron resides in the $d_{x^2-y^2}$ orbital. In the water–alcohol glass phase at 77 K complex 2 exhibits a typical four-line hyperfine spectra with $g_{||} = 2.11$, $g_{\perp} = 2.02$, $A_{||} = 150$ Oe and $A_{\perp} = 5$ Oe at $V = 9.45$ MHz. On standing the solution for 2–5 days a moderately strong signal at $g = 4.3$ indicates the presence of Fe^{III} species in the system [24]. This may be attributed to the oxidation of a portion of $[Fe^{II}(CN)_6]^{4-}$ to $[Fe^{III}(CN)_6]^{3-}$ in aqueous solution, as indicated by the slow disappearance of the color of the complex with time.

3.6. Electrochemical studies

The electrochemical properties of the complexes $[Cu(nelin)(H_2O)_2]_2[Fe^{II}(CN)_6] \cdot 6H_2O$ (**2**) and $[\{Cu(nelin)\}_2Ni(CN)_4](ClO_4)_2 \cdot 2H_2O$ (**3**) were investigated using the cyclic voltammetric technique in aqueous and in MeCN solutions, respectively, with Ag/AgCl as the reference electrode. The cyclic voltammetric behavior of the parent complex $[Cu(nelin)](ClO_4)_2$ (**1**) was also studied under similar conditions in aqueous and in MeCN media to compare the results. All the electrochemical data are summarized in Table 4.

The electrochemical responses of complex **1** in aqueous solution were found to be highly influenced by the scan rate. At a scan rate of $\sim$1.0 V s^{-1}, a single irreversible reduction peak at a potential of *ca.* −0.94 V was found and attributed to a four-electron reduction process (Eq. (1)), as generally observed for nitro compounds in protic solvents [15,16]:

$$-NO_2 + 4H^+ + 4e^- \rightarrow -NHOH + H_2O \quad (1)$$

At appreciably lower scan rates, the situation is quite different. Thus, at a scan rate of 0.05 V s^{-1}, two irreversible reduction waves having peaks *viz.* A and B at potentials of *ca.* −0.69 V and −1.0 V, respectively, were observed, and on the reverse sweep an anodic peak (D) at *ca.* −0.31 V was monitored. After a second sweep, another reduction peak C at *ca.* −0.49 V in addition to peaks A and B appeared, while the anodic peak D remained invariant with respect to its position (Fig. 10). However, it is important to note that after the first sweep the peak intensities for A and B were greatly diminished while that of D remained almost unchanged. In order to assess the number of electron transfers involved in these processes, peak A was assigned to be a one-electron reduction of a nitro group to a nitro-radical anion followed by a three-electron reduction of the nitro-radical anion (peak B) to the hydroxylamine derivative (Scheme 1). These are comparable with the nitro-containing heterocyclic drug metronidazole [17].

Surprisingly, no cathodic wave (peak C), for a $Cu^{II} \rightarrow Cu^{I}$ reduction was observed during the first scan. However, if we assume that the anodic oxidation peak D observed in the reverse sweep in the first scan is due to oxidation of $Cu^{I} \rightarrow Cu^{II}$, then it is likely to assume that the nitro-radical anion generated in the first sweep is responsible for initiation of the reduction of the Cu^{II} center, which in the reverse sweep undergoes oxidation. Thus keeping

Scheme 1.

the copper(II) to copper(I) reduction silent in the first scan and its appearance from the second scan (peak C) may be thought of that the original Cu^{II} complex remains silent towards the redox transformation. The above proposition is supported by the following observations:

(1) When the scan was reversed just before the generation of the nitro-radical anion (peak A), the anodic peak D was absent.
(2) When the scan was reversed just after the appearance of peak A, the anodic peak D was observed.
(3) If the scan is reversed just after the appearance of peak A and is delayed for 5 min at the same potential the intensity of the anodic peak (D) is increased (Fig. 11).

Thus the copper(II) center in complex **1** is found to be silent towards redox transformation in the experimental scan rate at the first scan. Now the question arises, why is the copper(II) center in **1** silent towards this redox process. A reasonable argument can be made as follows: the copper(II) center is deeply buried in the ligand environment while the NO_2 group on the ligand fragment is well exposed in space for redox processes. Thus, it is the NO_2 group which first undergoes reduction to give the nitro-radical anion $Cu^{II}RNO_2^-$. The highly reactive nitro-radical anion thus generated electrochemically from the nitro group, in close proximity towards the metal center due to conformational puckering, [15] immediately transmits its electron to facilitate the copper(II) reduction to copper(I), which concomitantly undergoes some kind of structural modification to give $Cu^{I}R^{*}NO_2$. This modified species, only after oxidation to $Cu^{II}R^{*}NO_2$, can initiate its second time reduction without the assistance from a nitro-radical anion; and by this way $E_{1/2}$ for Cu^{II}/Cu^{I} was estimated as −0.40 V. All these transformations are given in Scheme 2.

Considering the overall cyclic voltammetric pattern of **1** in aqueous solution in the above mentioned slow scan rate, a

$$Cu^{II}(R\text{-}NO_2)^{+} \xrightarrow{e^-} Cu^{II}(R\text{-}NO_2^{\bullet-}) \xrightarrow{iet} Cu^{I}(R\text{-}NO_2) \xrightarrow{cm} Cu^{I}(R^{*}\text{-}NO_2)$$

$$\xrightarrow{-e^-} Cu^{II}(R^{*-}NO_2) \longrightarrow Cu^{I}(R^{*}\text{-}NO_2)$$

iet = intramolecular electron transfer; cm = conformational modification

Scheme 2.

speculative explanation may be furnished: peak A is just due to the irreversible reduction of $[Cu^{II}(nelin)]^{2+}$ to $[Cu^{I}(nelin)]^{+}$; which subsequently undergoes decomposition to generate the free Cu^{+} ion, which in turn is reoxidized to the Cu^{2+} ion (peak D) and re-reduced to the bare Cu^{+} ion (peak C). However, a serious problem for such a proposition arises from the $E_{1/2}$ value for the Cu^{II}/Cu^{I} couple (−0.40 V *versus* Ag/AgCl). The observed potential (−0.18 V *versus* NHE) is much more negative than the corresponding standard electrode potential for the free Cu^{II}/Cu^{I} couple (0.15 V). Moreover, the free Cu^{+} ion is too susceptible for disproportionation in aqueous solution, but no such indication was observed in the back scan, either through the appearance of an anodic stripping peak or through elemental copper deposition in the experimental solution during and after the completion of the cyclic voltammetric process. Thus the speculation of the transformation of $[Cu^{I}(nelin)]^{+}$ to $[Cu^{0}$-$(nelin)]^{0}$, or put in a better way Cu^{0}, (peak B) can be discarded safely.

The electrochemical behavior of complex **1** at the same scan rate (0.05 V s^{-1}) in MeCN (Fig. 12) was completely different from that which was observed in aqueous solution. Here, from the beginning a cathodic peak (E) for $Cu^{II} \rightarrow Cu^{I}$ reduction was observed at a potential of *ca.* −0.62 V; for which the reverse scan showed an anodic wave (H) at *ca.* −0.36 V and the corresponding $E_{1/2}$ was estimated as −0.49 V *versus* Ag/AgCl. It is important to note that after formation of the Cu^{I} complex (peak E), it subsequently undergoes slow disproportionation to Cu^{II} and Cu^{0}, and a well defined anodic stripping peak at *ca.* −0.16 V was observed for Cu^{0}. As a consequence the anodic peak (peak H) for oxidation of $Cu^{I} \rightarrow Cu^{II}$ was greatly diminished. To support this proposition two separate CV profiles were recorded, inverting the scan immediately after traversing peak E and peak F, respectively, under same scan rate (0.05 V s^{-1}). The great increment of the anodic stripping peak after traversing peak F compare to peak E, not only certified the disproportionation of the $[Cu^{I}(nelin)]^{+}$ complex but simultaneously helped to assign peak F as $Cu^{I} \rightarrow Cu^{0}$. At a comparatively higher scan rate (0.8 V s^{-1}) no such anodic stripping peak in the back scan after traversing peak E indicates the slower nature of the disproportionation reaction. Here peak G is conceivably assign to the irreversible $NO_2/-NO_2^{-}$ reduction. The cathodical fluctuation of the nitro-radical anion peak from solvent to solvent is a common feature for nitro-containing compounds [25].

In conclusion, it is clear that the nitro-radical induced reduction of $[Cu^{II}(nelin)]^{2+}$ and the reluctancy of the disproportionation reaction of the modified $Cu^{I}R^{*}NO_2$ is the main feature in aqueous medium, while the normal reduction (without any assistance of a nitro group) of $[Cu^{II}(nelin)]^{2+}$ to $[Cu^{I}(nelin)]^{+}$ followed by slow disproportionation to Cu^{II} and Cu^{0} are the mentionable characteristics in MeCN for complex 1. It also further indicates that the initial environment of $[Cu^{II}(nelin)]^{2+}$ in aqueous and in MeCN solution are to some extent different.

The electrochemical behavior of complex **2** was monitored at a slow scan rate (0.05 V s^{-1}) in aqueous medium (Fig. 13). A well defined anodic wave at *ca.* 0.40 V and a corresponding cathodic wave at *ca.* 0.22 V appeared. It was assigned to the $[Fe^{III}(CN)_6]^{3-}/[Fe^{II}(CN)_6]^{4-}$ couple and the corresponding $E_{1/2}$ was estimated as 0.31 V *versus* Ag/AgCl. From the peak height and intensity it is evident that the concentration of iron(II) is higher than that of the iron(III) species. When the scan was continued further to negative potential, two irreversible reduction peaks at potentials of *ca.* −0.72 V and −0.95 V were observed, and these are assigned to the corresponding nitro group reduction (*vide infra*). It is surprising that no Cu^{II}/Cu^{I} couple was observed even after a second sweep, as compared to that observed in the parent complex **1**. On the

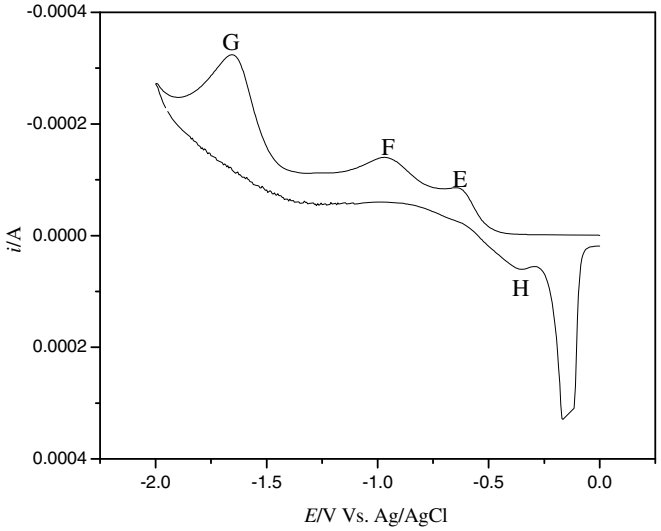

Fig. 12. Cyclic voltammogram of **1** in MeCN at a scan rate of 0.05 V s^{-1}.

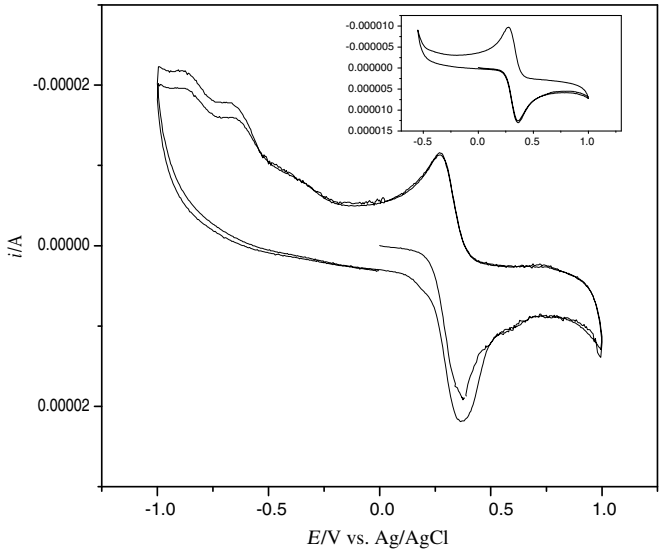

Fig. 13. Cyclic voltammograms of **2** in water at a scan rate of 0.05 V s^{-1}. The scan is reversed before nitro-radical anion formation (inset).

other hand, on the reverse sweep, the peak height of the anodic wave was markedly enhanced in comparison to that of the cathodic wave in the positive potential range, indicating the conversion of $Fe^{II} \rightarrow Fe^{III}$ increases after the nitro group reduction. Since the reduction potential of the $[Fe^{III}(CN)_6]^{3-}/[Fe^{II}(CN)_6]^{4-}$ couple is much more than that of Cu^{II}/Cu^{I} (−0.40 V *versus* Ag/AgCl for complex **1**), most probably the nitro-radical anion transfers its electron to the Fe^{III} instead of the Cu^{II} center and that is why nitro-radical induced copper(II) reduction does not take place as observed in complex **1**. Consequently the Cu^{II}/Cu^{I} couple remains silent towards redox transformation. To check whether the nitro group has any influence upon the iron center, a number of CV profiles were recorded starting from 0.0 V to 1.0 V, 1.0 V to −0.60 V (*i.e.* before nitro-radical anion generation) (Fig. 13, inset) under the same scan rate and it was observed that the peak height and intensity for the anodic and cathodic waves responsible for the $[Fe^{III}(CN)_6]^{3-}/[Fe^{II}(CN)_6]^{4-}$ couple remain invariant even after a second successive sweep. It is well known [25] that the nitro-radical anion is not generated particularly with a platinum working electrode. To confirm whether the reduction peaks arise due to nitro group reduction or for copper (II) reduction, a cathodic CV profile starting from 0.0 V to −1.2 V was recorded using platinum working electrode under same scan rate, but no peak responsible for the nitro-radical anion was observed. In conclusion, it may be assumed that only a portion of the ferrocyanide ion may coordinate to the copper(II) center, facilitating a lower energy pathway for electron transfer. This chemically generated ferricyanide ion on electrochemical processing is reduced to the ferrocyanide by capturing the electron from the nitro-radical anion. In cyclic voltammetry, such a coordinated ferrocyanide ion reduced by a generated nitro-radical, as well as the non-coordinated ferrocyanide ion, enhances the peak height for the $Fe^{II} \rightarrow Fe^{III}$ conversion in the reverse sweep.

The electrochemical behavior of complex **3** warrants special features in comparison to that of the parent complex **1** in MeCN (Fig. 14). The quasi-reversible reduction process for $Cu^{II} \rightarrow Cu^{I}$ (peak I/L) appeared at a slightly more positive potential than that in complex **1** under similar conditions and the corresponding $E_{1/2}$ was estimated as −0.45 V *versus* Ag/AgCl. It is noteworthy that compared to complex **1**, both electrochemical reduction and oxidation for the Cu^{II}/Cu^{I} couple in complex **3** are more facile and this is attributed to the axial ligation of $[Ni(CN)_4]^{2-}$ to the $[Cu(nelin)]^{2+}$ precursor [7b]. Another interesting aspect of complex **3** compared to **1** is that after formation of the Cu^{I} complex (peak I) it does not undergo any disproportionation reaction like 1 at either high or slow scan rates. This is also due to the axial attachment of $[Ni(CN)_4]^{2-}$ to the $[Cu^{II}(nelin)]^{+2}$ moiety which ultimately stabilizes the $[Cu^{I}(nelin)]^{+}$ species. No anodic stripping peak was observed during the back scan after traversing from peak I. Peak J is certainly for $[Cu^{0}(nelin)]^{0}$, or put in better way Cu^{0}, which on back scanning produces an anodic stripping peak at *ca.* 0.0 V.

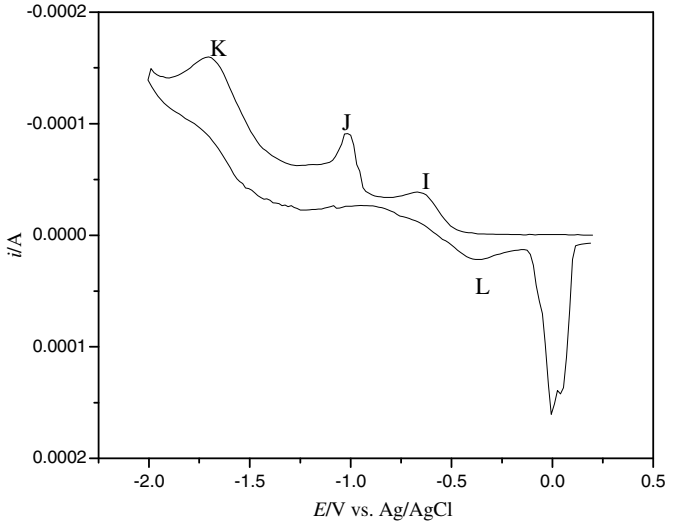

Fig. 14. Cyclic voltammogram of **3** in MeCN at a scan rate of 0.05 V s^{-1}.

4. Conclusions

Two new complexes, $[Cu(nelin)(H_2O)_2]_2[Fe(CN)_6] \cdot 6H_2O$ (**2**) and $[\{Cu(nelin)\}_2Ni(CN)_4](ClO_4)_2 \cdot 2H_2O$ (**3**), have been synthesized using a nitroalkyl-substituted $Cu^{II}N_4$ precursor and have been characterized using the single crystal X-ray diffraction technique. The H-bonded 1D chains of 2 along the *a*-axis, generated from supramolecular synthons using cations and anions, are further propagated into a 3D array to form irregular honeycomb-like channels which are divided into two halves, in each half there is a helical water chain which runs in opposite directions to each other. In complex **3** trinuclear units are arranged in successive rows in a herringbone fashion and bifurcated hydrogen bonding through the uncoordinated terminals of the $[Ni(CN)_4]^{2-}$ units give rise to a supramolecular (4,4) network. Complex **2** exhibits a quasi-glass nature on dehydration, which is important in material science. The electrochemical properties of **1**, 2 and **3** have been investigated in comparative ways using the cyclic voltammetric technique in aqueous and in MeCN solutions with Ag/AgCl as the reference electrode. Electrochemical studies in aqueous medium generate the one-electron reduced nitro-radical anion which is highly important and may find application as a radio-sensitized drug in cancer treatment. Although organic, especially aromatic, nitro compounds have widespread application in medicine and cancer therapy, there is direct proof that nitro-radical anions are involved as an obligate intermediate but in many cases they act as a direct damaging toxin. The corresponding use of coordination complexes bearing a nitro group on a side arm of a ligand fragment has not yet been reported. Inorganic macrocyclic or macrocyclic complexes of transition metals may serve in a better way than the aromatic nitro compounds as drugs, as they may have comparatively better solubility and show a lesser toxic effect.

meso-cis-1,3-cyclohexanedicarboxylic acid and chiral *cis*-(1*R*,3*S*)-(+)-camphoric acid with trimethyltin chloride under hydrothermal conditions.

2. Results and discussion

2.1. Syntheses

Reactions of 5-nitroisophthalic acid, 4-cyclohexene-1,2-dicarboxylic acid, 1,4-cyclohexanedicarboxylic acid, 1,3-cyclohexanedicarboxylic acid, and camphoric acid with trimethyltin chloride in 1:2 stoichiometry afford air-stable complexes **1**–**5**. The syntheses procedures are shown in Scheme 1a–e.

2.2. Spectroscopic studies

The stretching frequencies of interest are those associated with the acid COO, Sn–C and Sn–O groups. The strong absorption appearing at 442–454 cm^{-1} in the respective IR spectra of the complexes **1–5**, which is absent in the spectra of the free ligand, is assigned to the Sn–O stretching mode of vibration. Also strong absorption appearing at 1574–1615 and 1433–1469 cm^{-1} in the respective spectra of complexes **1–5** is assigned to the asymmetric and symmetric vibrations, respectively, of the COO moiety; moreover, the strong peaks at 649–669 cm^{-1} are assigned to *ν(O–Sn–O)*, indicating O–Sn–O bridging structures. All these values are consistent with that detected in a number of organotin(IV) derivatives [7].

The ^{1}H NMR spectra show the expected integration and peak multiplicities. The single resonance of –OH in the spectra of the free ligands are absent in the spectra of complexes **1–5** indicating the replacement of the carboxylic acid protons by a dimethyltin moiety on the complexes formation. The ^{13}C NMR spectra of all complexes show a significant downfield shift of all carbon resonances compared with the free ligands, the shift is a consequence of an electron density transfer from the ligand to the acceptor. The single resonances at 167.3–171.4 are attributed to the COO groups in complexes **1–5**. The ^{119}Sn NMR spectra of complexes **1–5** show resonances between –116.9 and –259.3 ppm. As reported in the literature [8], values of δ (^{119}Sn) in the ranges −210 to −400, −90 to −190 and 200 to −60 ppm have been associated with six-, five-, and four-coordinated tin centers, respectively. On this basis we can conclude that complexes **1, 2** and **4** have two different coordination environments around the tin atoms, these are confirmed by the X-ray crystal structures of complexes **1, 2** and **4**. Complex **3** as well as complex **5** has only one signal in −138.7 and −116.9 ppm, respectively, thus indicating only existence of five-coordinated atoms for complexes **3** and **5**, which are not completely accordance with the structure in the solid state. Some Sn–O bonds about the six-coordinated tin atoms in complexes **3** and **5** are much longer than the covalent radii of tin and oxygen, maybe these weak Sn–O bonds rupture in solution and the six-coordinated tin atoms become five-coordinated, so only the five-coordinated tin atoms are found in the ^{119}Sn NMR spectra.

2.3. Description of crystal structures

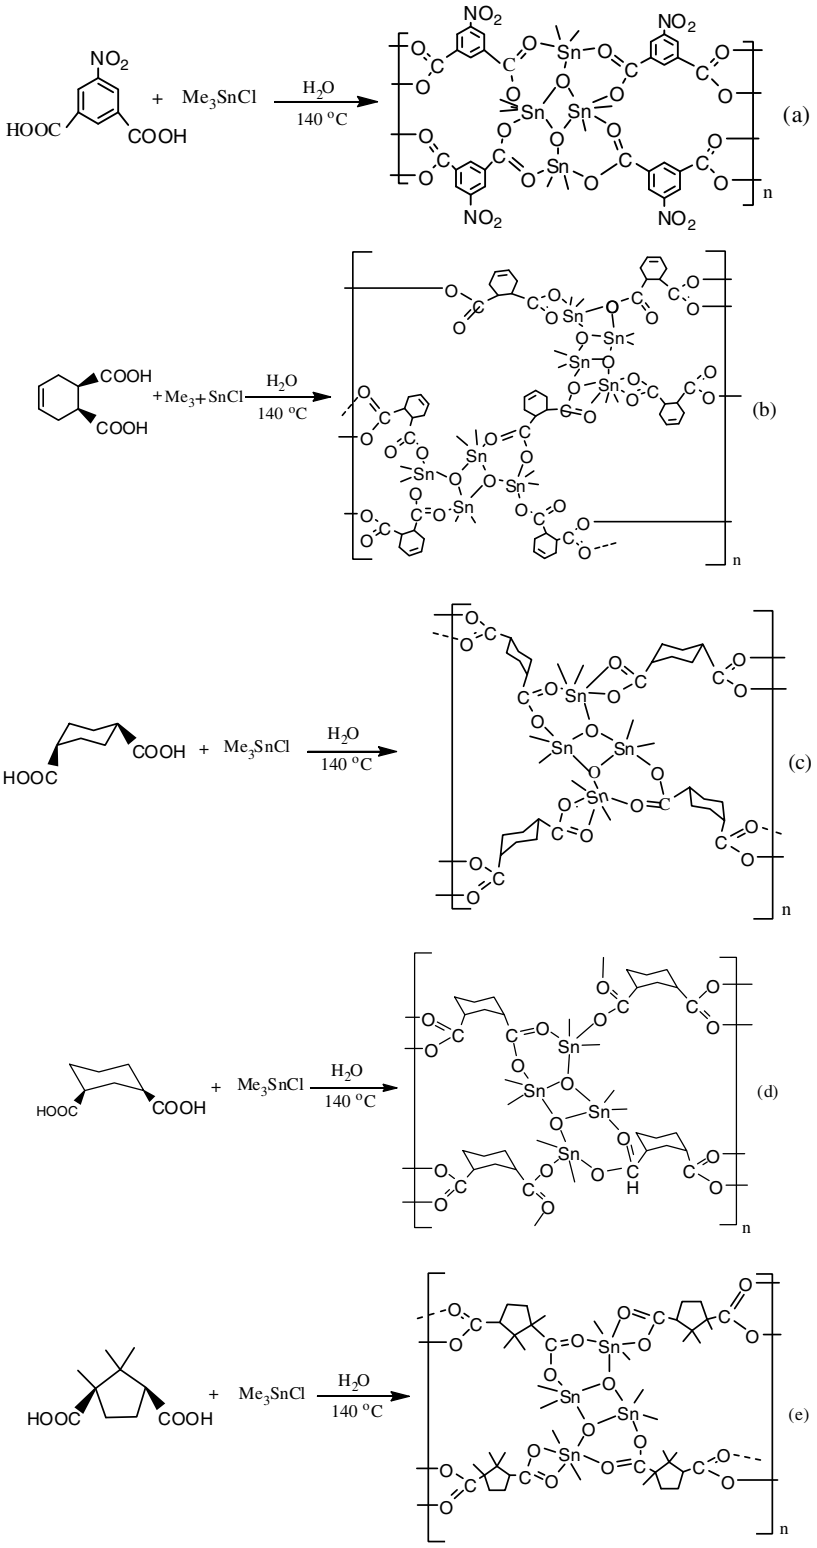
2.3.1. $\{(Me_2Sn)_2[\mu_4\text{-}(C_8H_3NO_6)](\mu_3\text{-}O)\}_n$ (**1**)

The repeating unit and 1D infinite chain structure of complex **1** are illustrated in Figs. 1 and 2, respectively, and selected bond lengths and bond angles are given in Table 2. As shown in Fig. 1, the predominant structural form of complex **1** is dimeric dicarboxylatotetraorganodistannoxane which consists of a central planar $(Me_2Sn)_2O_2$ four-membered ring and two peripheral Me_2Sn units, each bridging oxygen atom in the Sn_2O_2 ring is attached to three Me_2Sn units and as a result these oxygen atoms are three-coordinated. The geometries of all the tin atoms in complex **1** can be classified into two types: pentacoordinated tin (Sn1), and hexacoordinated tin (Sn2). Each of the pentacoordinated tin atoms – Sn1, for example – forms three short Sn–O bonds with three oxygen atoms: one from the Sn_2O_2 moiety and the other two from two different carboxylate groups. Together with the two bonds to methyltin groups, the Sn1 atom may be viewed as a slightly distorted trigonal bipyramid with the axial site occupied by the O(1)#1 and O(1) atoms O(1)#1–Sn(1)–O(1) 168.2(4)). Each of the hexacoordinated tin atoms – Sn2, for example – has an octahedral geometry with four equatorial oxygen atoms and two axial carbon atoms, the geometry being somewhat distorted by the small angles in the stannoxane rings, affecting the equatorial angles. Steric effects between the methyl groups across the stannoxane ring cause the rings to bend away from the center of molecule C(7)–Sn(2)–C(7)#2 154.0(7)°) and also to twist relative to each other.

As shown in Fig. 2, complex **1** has a one-dimensional infinite chain structure constructed from approximately hexagon rings. Each ring is composed of two deprotoned 5-nitroisophthalic acid ligands and two dimeric tetraorganodistannoxane units. 5-Nitroisophthalic acid in a μ_4-bridging mode links two dimeric tetraorganodistannoxane units are shared by the approximately hexagon rings to form a one-dimensional chain coordination polymer. This structural feature of **1** is quite different from that of $\{(Me_2Sn(OAc)_2O)_2\}_n$, a one-dimensional organotin polymer; in which the acetate links the dimeric tetraorganodistannoxane units in a tetradentate mode [9].

2.3.2. $\{(Me_2Sn)_2[\mu_3\text{-}(C_8H_8O_4)](\mu_3\text{-}O)\}_n$ (**2**), $\{(Me_2Sn)_2[\mu_4\text{-}(C_8H_{10}O_4)](\mu_3\text{-}O)\}_n$ (**3**) and $\{(Me_2Sn)_2[\mu_4\text{-}(C_8H_{10}O_4)](\mu_3\text{-}O)\}_n$ (**4**)

The repeating units and 2D polymeric structures of complexes **2, 3** and **4** are illustrated in Figs. 3–8, respectively, and selected bond lengths and bond angles are given in Tables 3–5, respectively. Complexes **2–4** are all 2D organotin polymers made up of the dimeric tetraorganodistannoxane and bridging dicarboxylate units. Complex **2** is a 2D corrugated sheet polymer made up of two types of typical ladder tetraorganodistannoxane units and bridging deprotoned 4-cyclohexene-1,2-dicarboxylic acid ligands. In the first type of the ladder tetraorganodistannoxane units each Sn atom is a five-coordinate geometry, it consists of a central planar $(Me_2Sn)_2O_2$ four-membered ring and two peripheral Me_2Sn units attached to two μ_3-oxygen atoms. Deprotoned 4-cyclohexene-1,2-dicarboxylic acid acts as a tridentate ligand which coordinates to an outer Sn atom through an oxygen atom of the carboxylate and chelates between exocyclic and endocyclic Sn atoms forming a stable six-membered ring through the other carboxylate oxygen atoms. Thus, all the Sn atoms adopt distorted trigonal bipyramidal geometry. The exocyclic and endocyclic Sn atoms lie 0.2539 and 0.0789 Å out of the plane defined by the three-coordinated oxygen atoms, respectively. In the second type of the ladder tetraorganodistannoxane units all the tin atoms can be classified into two types: pentacoordinated tin (Sn4), and hexacoordinated tin (Sn3). Each of the pentacoordinated tin atoms – Sn4, for example – in this complex each have five primary bonds, two to the methyl groups and the others to the μ_3-oxygen atoms, thus adopting a distorted trigonal bipyramid geometry similar to that found in $[(n\text{-BuSn(O)}O_2CR)_2\text{-}n\text{-BuSn}(O_2CR)_3]_2$ (R = Ph and Me) [10]. Each of the hexacoordinated tin atoms – Sn3, for example – forms six primary bonds: two to the methyl groups, two to the μ_3- oxygen atoms and the others to the bidentate carboxylate groups, and the geometry around Sn2 is similar to that found in $\{([Me_2Sn(VA)_{0.5}]_2O)_2{\cdot}2H_2O\}_n$ [VA = 4-hydroxy-3-methoxybenzoic acid] [11] The ladder core can be viewed as four-rung ladder frameworks have found in $[(n\text{-Bu–Sn(O)}O_2CC_6H_{11})_3]_2$ [10], the central Sn(4)–O(10)–Sn(4)#2–O(10)#2 ring is strictly planar, with the terminal tins and terminal oxygen atoms have no deviation out of the ladder plane, the ladder



Scheme 1.

does not have linear sides but is bent, with the angles Sn(3)–O(10)–Sn(4)#2 and O(3)–Sn(4)–O(10)#2 being 130.7° and 149.7°, respectively. As shown in Fig. 4, each deprotoned 4-cyclohexene-1,2-dicarboxylic acid as a tridentate ligand connecting two different ladders to give rise to a 2D corrugated structure which consists of 28-membered organotin rings, and the width of 28-ring channel is 10.71 × 9.52 Å (transannular Sn3···Sn3′ and Sn1···Sn1′), the structure is similar to that found in $[(Me_2Sn)_4(\mu_3\text{-DPA})(\mu_4\text{-DPA})(\mu_3\text{-O})_2]_n$ [12], which also was a 2D corrugated sheet polymer made up of the dimeric tetraorganodistannoxane units and bridging DPA ligands (Table 6).

Different from complex **2**, complex **3** is a 2D network polymer made up of only one type of typical ladder tetraorganodistannoxane units and bridging deprotoned 1,4-cyclohexanedicarboxylic

acid ligands. This ladder tetraorganodistannoxane units is a tetranuclear centrosymmetric dimeric structure with one four-membered planar Sn(2)–O(1)–Sn(2)#1–O(1)#1 ring and two six-membered planar Sn(1)–O(1)–Sn(2)–O(3)–C(7)–O(2) and Sn(1)#1–O(1)#1–Sn(2)#1–O(3)#1–C(7)#1–O(2)#1 rings. The four Me_2Sn moieties are linked by two bridging carboxylate groups, while the remaining two carboxylate groups are attached to each of the exocyclic Me_2Sn moieties. Similar tetraorganodistannoxane units have been documented in the arrangement of $[Bu_2SnLOLSnBu_2]_2$ (L = *o*-methylbenzoic acid) and $[(n\text{-}Bu_2SnO_2CC_6H_4\text{–}o\text{-}Cl)_2O]_2$ [13]. The geometries of all the tin atoms in complex **3** can also be classified into two types: pentacoordinated tin (Sn2), and hexa-

coordinated tin (Sn1). The pentacoordinated tin atoms –Sn2, for example, also form three short Sn–O bonds with three oxygen atoms: two from the Sn_2O_2 moiety and the other one from the carboxylate group, together with the two bonds to methyltin groups, the Sn2 atom may be viewed as slightly distorted trigonal bipyramid with the axial site occupied by the O(1)#1 and O(3) atoms ((O1)#1–Sn(2)–O(3) 166.8(3)°). Each of the hexacoordinated tin atoms – Sn1, for example – forms four short Sn–O bonds with four oxygen atoms: one from the Sn_2O_2 moiety and the other three from two different carboxylate groups. Together with the two bonds to methyltin groups, the Sn1 atom may be viewed as distorted octahedral geometry. Thus, each deprotoned 1,4-cyclohexanedicarboxylic acid affords its four O atoms as a tetradentate ligand connecting two adjacent ladders to give rise to a 2D network polymer (Fig. 7), which is different from that found in other related organotin complexes [14].

Similar to complex **3**, complex **4** is also a 2D network polymer made up of only one type of typical ladder tetraorganodistannoxane units and bridging deprotoned 1,3-cyclohexanedicarboxylic acid ligands. This ladder tetraorganodistannoxane units is also a tetranuclear centrosymmetric dimeric structure with a central planar $(Me_2Sn)_2O_2$ four-membered ring and two peripheral Me_2Sn units. each bridging oxygen atom in the Sn_2O_2 ring is attached to three Me_2Sn units and as a result these oxygen atoms are three-coordinated. The geometries of all the tin atoms in complex **4** can also be classified into two types: pentacoordinated tin (Sn2), and hexacoordinated tin (Sn1). Each of the pentacoordinated tin atoms – Sn2, for example – forms three short Sn–O bonds with three oxygen atoms: two from the Sn_2O_2 moiety and the other two from dicarboxylate groups. Together with the two bonds to methyltin groups, the Sn2 atom may be viewed as a slightly distorted trigonal bipyramid with the axial site occupied by the O(5A) and O(2) atoms O(5)#1–Sn(2)–O(2) 168.2(4)°). Each of the hexacoordinated tin atoms – Sn1, for example – forms four short Sn–O bonds with four oxygen atoms: one from the Sn_2O_2 moiety and the other three from three different dicarboxylate groups. Together with the two bonds to methyltin groups Sn1 forms an octahedral geometry. The geometry being somewhat distorted by the small angles in the stannoxane rings, affecting the equatorial angles. Steric effects between the methyl groups across the center of the molecule ((C(10)–Sn(1)–C(9) = 148.8(10)°) and also to twist relative to each other. As shown in Fig. 9, each deprotoned 1,3-cyclohexanedicarboxylic acid as a tetradentate ligand connecting two adjacent ladders to give rise to a 2D network polymer which consists of 20-membered organotin rings, and the width of 20-ring channel is 12.429×7.439 Å (transannular Sn1···Sn1′and Sn2···Sn2′), which is larger than other organotin complexes we have been reported [15] (Fig. 10).

*2.3.3. {(Me_2Sn)$_2$[μ_3-($C_8H_8O_4$)](μ_3-O)}$_n$ (**5**)*

X-ray diffraction study reveals that complex **5** crystallizes in the tetragonal chiral space group *P*4(3)2(1)2. the molecular of complex **5** also is a tetranuclear centrosymmetric dimeric structure with one four-membered planar Sn(2)–O(5)–Sn(2)#2–O(5)#2 ring and two six-membered planar Sn(2)–O(4C)–C(7C)–O(3C)–Sn(1)#2–O(5)#2 and Sn(1)–O(5)–Sn(2)#2–O(4)#1–C(7)#1–O(3)#1 rings, The four Me_2Sn moieties are linked by two bridging carboxylate groups, while the remaining two carboxylate groups are attached to each of the exocyclic Me_2Sn moieties, the central Sn(2)–O(5)–Sn(2)#2–O(5)#2 ring is strictly planar, with the terminal tins being 0.0013 Å out of the ladder planar. The geometries of all the tin atoms in complex **5** can also be classified into pentacoordinated tin (Sn2) and hexacoordinated tin (Sn1). Each of the pentacoordinated tin atoms – Sn2, for example – forms five primary bonds, and the geometry around Sn2 is similar to that in complexes **1–4**, Each of the hexacoordinated tin atoms – Sn1, for example – forms six primary bonds and its coordinate environment is essentially the same as its counterpart in complex **3** except for little short of the O(1)–Sn(1) distance (2.152 Å) and O(2)–Sn(1) distance (2.717 Å). The polymeric structure of complex **5** is different from complexes **1–4**. Each deprotoned camphoric acid affords its four carboxylate O atoms as a tetradentate ligand connecting two adjacent ladders to give rise to a 3D organotin framework, which is an irregular 3D polymer and to the best of our knowledge, similar organotin structures have so far not been reported by any other people.

In summary, through the hydrothermal reaction, we have obtained five new organotin polymers consisting of dimeric dicarboxylatotetraorganodistannoxane derived from the trimethyltin chloride and dicarboxylate acids, in all complexes **1–5** the trimethyltin groups became dimethyltin groups due to the Sn–C cleavage on the condition of high temperature. The results suggest that hydrothermal reaction is a potent synthetic route to prepare

discrete dimeric dicarboxylatotetraorgandistannoxane that hardly arise from the common synthetic methods.

3. Experimental details

3.1. Materials and methods

Trimethyltin chloride, 5-nitroisophthalic acid, 4-cyclohexene-1,2-dicarboxylic acid, 1,4-cyclohexanedicarboxylic, 1,3-cyclohexanedicarboxylic acid and camphoric acid are commercially available and they are used without further purification. The melting points were obtained with an X-4 digital micro melting-point apparatus and were uncorrected. Infrared-spectra were recorded on a Nicolet-5700 spectrophotometer using KBr discs and sodium chloride optics. ^{1}H and ^{13}C NMR spectra were recorded on Varian Mercury Plus 400 spectrometer operating at 400, 100.6 and 149.2 MHz, respectively. The spectra were acquired at room temperature (298 K) unless otherwise specified; ^{13}C NMR spectra are broadband proton decoupled. The chemical shifts were reported in ppm with respect to the references and were stated relative to external tetramethylsilane (TMS) for ^{1}H and ^{13}C NMR and Me_4Sn for ^{119}Sn NMR. Elemental analyses (C, H, N) were performed with a PE-2400II apparatus.

3.2.4. $\{(Me_2Sn)_2[\mu_4\text{-}(C_8H_{10}O_4)](\mu_3\text{-}O)\}_n$ (**4**)

Complex **4** was synthesized by the hydrothermal reaction of 1,3-cyclohexanedicarboxylic acid (0.172 g, 1 mmol), trimethyltin chloride (0.398 g, 2 mmol) and H_2O (20 ml) in a Teflon-lined autoclave at 140 °C for 3 days. Yield: 81%. M.p. 182–184 °C. *Anal.* Calc. for $C_{12}H_{22}O_5Sn_2$: C, 29.80; H, 4.58. Found: C, 29.55; H, 4.32%. IR (KBr, cm^{-1}): ν_{as}(COO), 1597; ν_s(COO), 1468; ν(Sn–C), 549; ν(Sn–O), 452; ν(O–Sn–O), 653. ^{1}H NMR [$(CD_3)_2SO$, ppm]: δ 0.81 (12H, Sn–CH_3, $^2J_{Sn,H}$ = 86 Hz), 4.01–4.32 (8H, CH_2), 4.94 (2H, CH). ^{13}C NMR [$(CD_3)_2SO$, ppm]: 170.3, 47.6, 29.7, 8.36 ($^1J_{Sn,C}$ = 812 Hz). ^{119}Sn NMR: −235.6, −117.8 ($^2J_{Sn,Sn}$ = 108 Hz).

3.2.5. $\{(Me_2Sn)_2[\mu_4\text{-}(C_{10}H_{14}O_4)](\mu_3\text{-}O)\}_n$ (**5**)

Complex **5** was synthesized by the hydrothermal reaction of camphoric acid (0.200 g, 1 mmol), trimethyltin chloride (0.398 g, 2 mmol) and H_2O (20 ml) in a Teflon-lined autoclave at 140 °C for 3 days. Yield: 80%. M.p. 201–202 °C. *Anal.* Calc. for $C_{14}H_{26}O_6Sn_2$: C, 31.86; H, 4.97. Found: C, 31.61; H, 4.78%. IR (KBr, cm^{-1}): ν_{as}(COO), 1615; ν_s(COO), 1460; ν(Sn–C), 574; ν(Sn–O), 454; ν(O–Sn–O), 649. ^{1}H NMR [$(CD_3)_2SO$, ppm]: δ 0.80 (12H, Sn–CH_3, $^2J_{Sn,H}$ = 89 Hz), 4.01–4.18 (4H, CH_2), 4.46 (1H, CH) 1.37 (9H, ring-CH_3). ^{13}C NMR [$(CD_3)_2SO$, ppm]: δ 176.8, 174.4, 57.5, 52.7, 41.1, 39.8, 34.9, 22.3–23.7, 12.3 ($^1J_{Sn,C}$ = 748 Hz). ^{119}Sn NMR: −116.9 ($^2J_{Sn,Sn}$ = 114 Hz).

3.3. X-ray structure analyses of **1–5**

Diffraction data were collected on a Smart CCD area-detector with graphite monochromated Mo Kα radiation (λ = 0.71073 Å). A semiempirical absorption correction was applied to the data. The structure was solved by direct methods using SHELXS-97 and refined against F^2 by full matrix least-squares using SHELXL-97. Hydrogen atoms were placed in calculated positions. Crystal data and experimental details of the structure determinations are listed in Table 1.

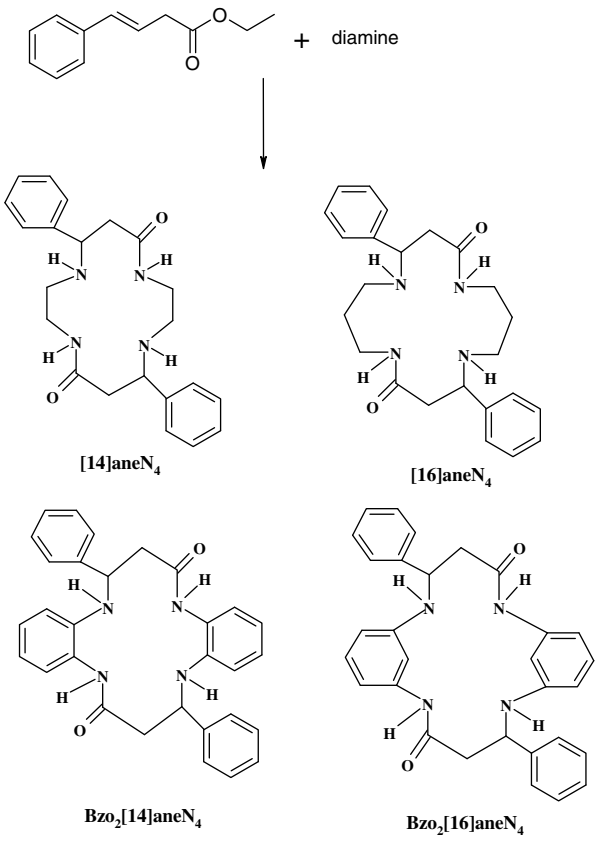


Scheme 1.

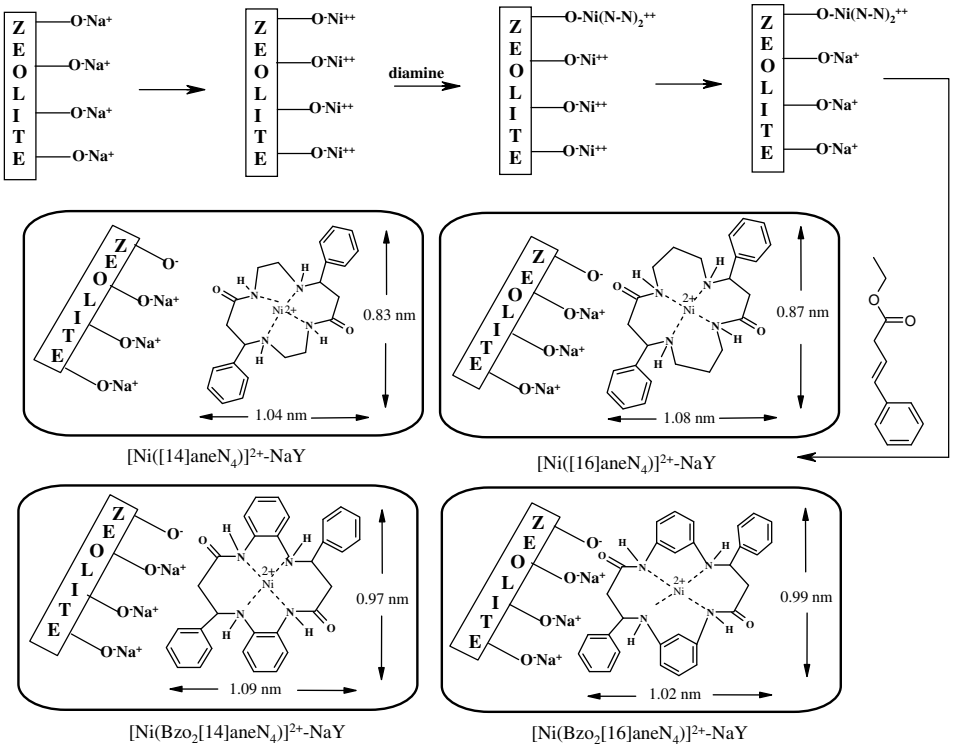
both the reactants and products when involved in chemical reactions and processes. The large internal surface area and void volumes with extremely narrow pore size distribution as well as functional centers homogeneously dispersed over the surface make nanoporous solids highly active materials. Over the last decade, there has been a dramatic increase in the synthesis, characterization and application of novel nanoporous materials [1–15].

In this work tetraaza dioxo diphenyl ligands and their encapsulated complexes were chosen (Schemes 1 and 2) for the oxidation reaction because, so far, encapsulated tetraaza dioxo diphenyl nickel(II) complexes have not been used within the nanopores of zeolite-Y for the oxidation of cyclohexene. The use of these encapsulated complexes as nanocatalysts can enhance and increase the selectivity in the oxidation reaction. The HGNM can act as windows for the selection of a suitable nanocatalyst for the oxidation reaction. In this paper the synthesis and characterization of nickel(II) complexes of 14- and 16-membered tetraaza dioxo diphenyl macrocyclic ligands, [14]aneN$_4$: 1,5,8,12-tetraaza-2,9-dioxo-4,11-diphenylcyclotetradecane; [16]aneN$_4$: 1,5,9,13-tetraaza-2,10-dioxo-4,12-diphenylcyclohexadecane; Bzo$_2$[14]aneN$_4$: dibenzo-1,5,8,12-tetraaza-2,9-dioxo-4,11-diphenylcyclotetradecane and Bzo$_2$[16]aneN$_4$: dibenzo-1,5,9,13-tetraaza-2,10-dioxo-4,12-diphenylcyclohexadecane, are reported and these complexes are encapsulated within the nanopores of zeolite-Y by the template condensation of ethylcinnamate and [bis(diamine)nickel(II)], producing [Ni([14]aneN$_4$)]$^{2+}$–NaY, [Ni([16]aneN$_4$)]$^{2+}$–NaY, [Ni(Bzo$_2$[14]aneN$_4$)]$^{2+}$–NaY and [Ni(Bzo$_2$[16]aneN$_4$)]$^{2+}$–NaY, as shown in Schemes 1 and 2 and used in the oxidation of cyclohexene with molecular oxygen.

2. Experimental

2.1. Materials and physical measurements

Cyclohexene was distilled under nitrogen and stored over molecular sieves (4 Å). Cyclohexanone was used as an internal standard for the quantitative analysis of the product using gas chromatography. Reference samples of 2-cyclohexene-1-ol and 2-cyclohexene-1-one



Scheme 2.

(Aldrich) were distilled and stored in a refrigerator. NaY with a Si:Al ratio of 2.53 was purchased from Aldrich (Lot No. 67812). The complex $[Ni(N–N)_2](ClO_4)_2$ was prepared according to the published procedures [16]. FAB mass spectra were recorded on a Kratos MS50TC spectrometer. FT-IR spectra were recorded on a Shimadzu Varian 4300 spectrophotometer in KBr pellets. The electronic spectra of the neat complexes were taken on a Shimadzu UV–Vis scanning spectrometer (Model 2101 PC). The stability of the encapsulated catalyst was checked after the reaction by UV–Vis spectroscopy, as was the possible leaching of the complex in the reaction solution after filtration of the zeolite. The amounts of metallocomplexes encapsulated in the zeolite matrix were determined by elemental analysis and by subtracting the amount of metallocomplex left in the solution after the synthesis of the catalysts, as determined by UV–Vis spectroscopy, from the amount taken for the synthesis. Atomic absorption spectra (AAS) were recorded on a Perkin–Elmer 4100–1319 spectrophotometer using a flame approach, after acid (HF) dissolution of known amounts of the zeolitic material, and SiO_2 was determined by gravimetric analysis. Diffuse reflectance spectra (DRS) were registered on a Shimadzu UV/3101 PC spectrophotometer the range 1500–200 nm, using MgO as a reference. The elemental analysis (carbon, hydrogen and nitrogen) of the materials was obtained from a Carlo ERBA Model EA 1108 analyzer. XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Nitrogen adsorption measurements were performed at 77 K using a Coulter Ofeisorb 100CX instrument. The samples were degassed at 150 °C until a vacuum better than 10^{-3} Pa was obtained. Micropore volumes were determined by the *t*-method, a "monolayer equivalent area" was calculated from the micropore volume [17,18]. The electrochemical data was obtained in acetonitrile with 0.1 M $(n\text{-}Bu)_4NClO_4$ as the supporting electrolyte. The working electrode was a platinum disk, the auxiliary electrode was a coiled platinum wire and the reference electrode was $Ag/AgClO_4$ (0.1 M in CH_3CN), which showed +0.24 V versus SCE.

2.2. Synthesis of the 14-, and 16-membered tetraaza dioxo diphenyl macrocyclic ligands

The tetraaza dioxo diphenyl macrocyclic ligands ([14]aneN$_4$, [16]aneN$_4$, Bzo$_2$[14]aneN$_4$ or Bzo$_2$[16]aneN$_4$) were prepared by following the procedures reported in Ref. [19]. A hot ethanolic solution (20 ml) of ethylcinnamate (3.52 g, 0.02 mol) and a hot ethanolic solution (20 ml) of diamine (0.02 mol), 1,2-diaminoethane (1.20 g), 1,3-diaminopropane (1.48 g), 1,2-diaminobenzene (2.16 g) or 1,3-diaminobenzene (2.16 g) were mixed slowly with constant stirring. This mixture was refluxed at 80 °C for 12 h in the presence of a few drops of concentrated hydrochloric acid. On cooling, a white precipitate was formed which was filtered, washed with cold ethanol, and dried under vacuum over P_4O_{10}. The purity was checked by the HPLC technique.

2.3. Preparation of the [Ni([14 or 16]aneN$_4$)](ClO$_4$)$_2$ and [Ni(Bzo$_2$[14 or 16]aneN$_4$)](ClO$_4$)$_2$complexes

Nickel(II) perchlorate hexahydrate (0.01 mol) dissolved in ethanol (20 ml) was reacted with an ethanolic (20 ml) solution of the tetraaza dioxo diphenyl ligands ([14]aneN$_4$, [16]aneN$_4$, Bzo$_2$[14]aneN$_4$ or Bzo$_2$[16]aneN$_4$) (0.01 mol) by refluxing for 4 h under a nitrogen atmosphere. The mixture was heated at reflux for 6 h until an orange solution resulted. The solution was cooled to room temperature and filtered to remove nickel hydroxide. Excess lithium perchlorate dissolved in methanol was added to the filtrate, and the mixture was kept in the refrigerator until an orange solid formed. The solids were filtered, washed thoroughly with cold ethanol and dried in vacuum.

2.4. Preparation of Ni(II)–NaY

Two grams of NaY zeolite were suspended in 100 ml distilled water, which contained nickel(II) nitrate (0.025 M). The mixture was then heated while stirring at 90 °C for 24 h. The solid was filtered, washed with hot distilled water until the filtrate was free from any nickel(II) ion (by AAS of filtrate) content and dried for 10 h at 80 °C under vacuum. The ionic exchange degree was determined by atomic absorption spectrophotometry.

2.5. Preparation of [Ni(N–N)$_2$]$^{2+}$–NaY

Typically a 4 g sample of NaY zeolite was mixed with 0.37 g of [bis(diamine)nickel(II)] perchlorate, the diamine 1,2-diaminopropane, 1,3-diaminopropane, 1,2-diaminobenzene or 1,3-diaminobenzene suspended in 100 ml of methanol, and then refluxed for 8 h. The pale yellow solid consisting of $[Ni(N–N)_2]^{2+}$, exchanged with Na^+ in NaY and denoted as $[Ni(N–N)_2]^{2+}$–NaY, was collected by filtration, and then washed with ethanol. The resulted zeolites, were Soxhlet extracted with *N*,*N*′-dimethylformamide (for 4 h) and then with ethanol (for 3 h) to remove excess unreacted diamine and any Ni(II) complexes adsorbed onto the external surface of the crystalline zeolite. The resulting light blue solids were dried at 60 °C under vacuum for 24 h.

2.6. Preparation of host–guest nanocomposite materials, [Ni([14 or 16]aneN$_4$)]$^{2+}$–NaY and [Ni(Bzo$_2$ [14 or 16]aneN$_4$)]$^{2+}$–NaY

To a stirred methanol suspension (100 ml) of $[Ni(N–N)_2]^{2+}$–NaY (2 g) was slowly added ethylcinnamate (under N_2 atmosphere). The mixture was heated under reflux conditions for 24 h until a pale yellow suspension resulted. The solution was filtered and the resulting zeolites, were Soxhlet extracted with *N*,*N*′-dimethylformamide (for 6 h) and then with ethanol (for 5 h) to remove excess unreacted products from the amine-ester condensation and any nickel(II) complexes adsorbed onto the external surface of the crystalline zeolite. The resulting pale yellow solids were dried at 70 °C under vacuum for 12 h. The remaining [bis(diamine)nickel(II)] ions in the zeolite were removed by exchanging with aqueous 0.1 M NaCl solution. The stability of the encapsulated catalyst was checked after the reaction by UV–Vis spectroscopy, as was the possible leaching of the complex into the reaction solution after filtration of the zeolite.

2.7. Oxidation of cyclohexene, general procedure

General procedure for oxidation of cyclohexene with molecular oxygen: 10 ml of cyclohexene and 1.2×10^{-5} mol of heterogeneous catalyst were added to a glass reactor with a gas inlet tube connected to a gas burette and an oxygen storage bottle. The mixture was heated to 70 °C in a water bath and stirred with a magnetic stirring bar. The oxidation reactions were performed under atmospheric pressure of molecular oxygen in the absence of solvent, and 2-cyclohexene-1-ol and 2-cyclohexene-1-one were the major products.

3. Results and discussion

3.1. Synthesis of [Ni([14 or 16]aneN$_4$)] (ClO$_4$)$_2$ and [Ni(Bzo$_2$ [14 or 16]aneN$_4$)](ClO$_4$)$_2$

The deep yellow complexes [Ni([14 or 16]aneN$_4$)](ClO$_4$)$_2$ and [Ni(Bzo$_2$[14 or 16]aneN$_4$)](ClO$_4$)$_2$ readily dissolve in polar solvents such as H_2O, CH_3CN, CH_3NO_2 and Me_2SO_2. The nickel(II) complexes are extremely stable in the solid state and in solution and are

Table 1
Elemental analysis, vibrational parameters and molecular ion peaks for the ligands and the tetraaza dioxo diphenyl macrocyclic nickel(II) complexes

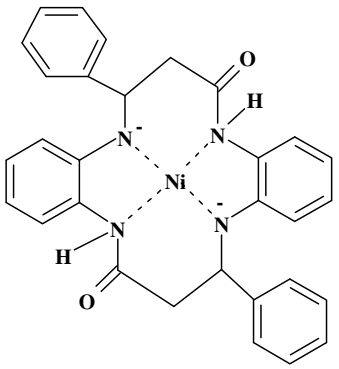
$[Ni(Bzo_2[14]aneN_4)](ClO_4)_2$	49.08 (48.83)	3.84 (3.69)	7.63 (7.82)	6.43 (6.24)	8.00 (7.82)	1632	1594	1250	782	3260	350	635	535
$Bzo_2[16]aneN_4$	75.61 (75.43)	5.92 (5.71)	11.76 (11.88)	6.43 (6.35)		1627	1594	1250	782	3288			
$[Ni(Bzo_2[16]aneN_4)](ClO_4)_2$	49.08 (48.80)	3.84 (3.72)	7.63 (7.79)	6.43 (6.26)	8.00 (7.79)	1628	1592	1253	781	3257	346	635	535

relatively stable against ligand dissociation even in highly acidic solutions. The molecular formulae of the complexes have been assigned on the basis of the results of their elemental analyses and the molecular ion peaks in the mass spectra (Table 1). All the mass spectra showed molecular ion peaks for the 1:1 metal-to-ligand stoichiometry, with no further peaks above them. A preliminary identification of the metal complexes was made on the basis of their IR spectra, which exhibited no bands characteristic of free primary amine, thus supporting the proposed macrocyclic skeleton (Scheme 1). The EI mass spectra of the free ligands confirm the proposed formula by showing a peak at 381 amu ($C_{22}H_{28}N_4O_2$), 409 amu ($C_{24}H_{32}N_4O_2$) and 477 amu ($C_{30}H_{28}N_4O_2$) corresponding to the macrocyclic moiety.

The molar conductance values of the complexes (~220 Ω^{-1} mol^{-1} cm^2), measured in nitromethane, correspond to 1:2 electrolytes. The overall geometries of all the macrocycles have been deduced on the basis of the observed values of the magnetic moments and the band positions in the electronic spectra. The magnetic moments (−0.08 to −0.12 μ_B) of the nickel(II) complexes measured in the solid state correspond to the square-planar coordination geometry of the complexes (Table 2).

The 14- and 16-membered tetraaza dioxo diphenyl macrocyclic nickel(II) complexes undergo intense color changes due to deprotonation of the macrocyclic ligand in the presence of amine bases such as pyridine and Et_3N. Similar N–H deprotonations have been observed with other metal complexes containing N–H linkages. For the nickel(II) complexes, Et_3N is sufficiently basic to facilitate formation of the molecular complexes. For the preparation of the deprotonated form of $[Ni(Bzo_2[14]aneN_6)](ClO_4)_2$, Et_3N (0.5 ml) was added to a solution of 200 mg of $[Ni(Bzo_2[14]aneN_6)](ClO_4)_2$ in 15 ml of CH_3CN. The shiny-brown product, which began precipitating within minutes, was filtered after 0.5 h under a N_2 atmosphere, washed with anhydrous EtOH, and dried in a vacuum. The product was characterized by elemental analysis and IR spectroscopy. The elemental analysis data support formula (I). IR (KBr, cm^{-1}): 3204 (ν_{N-H}). *Anal.* Calc. for $[Ni(C_{30}H_{26}N_4)]$: Ni, 11.00; C, 67.58; H, 4.92; N, 10.50. Found: Ni, 10.82; C, 67.39; H, 4.80; N, 10.63%. The N–H stretching frequency of this compound $[Ni(C_{30}H_{26}N_4)]$, 3204 cm^{-1}, is reduced significantly from its dicationic precursor, $[Ni(Bzo_2[14]aneN_4)](ClO_4)_2$, 3260 cm^{-1}.



(I)

3.2. ^{1} H NMR spectral study

The ^{1}H NMR spectra of the tetraaza dioxo diphenyl ligands ([14]$aneN_4$, [16]$aneN_4$, Bzo_2[14]$aneN_4$, Bzo_2[16]$aneN_4$) do not give any signal corresponding to primary amine and alcoholic protons. They give a doublet in the region 8.60–8.73 ppm, which is due to

[a] In nitromethane.

the amide group (–NH–CO–, 4H) protons [20]. Signals appear in the region ~1.57, ~2.38 and ~7.26 ppm, which correspond to methyne (–CH–CH_2–), methylene (–CH_2–CO–) and benzenoid protons, respectively. The presence of another signal at δ5.17–5.22 ppm is due to the protons of the –NH group (Table 3). The diamagnetic nature of the Ni(II) complexes of $[Ni(Bzo_2[14\ or\ 16]aneN_6)](ClO_4)_2$ has allowed their characterization by NMR spectrometry. ^1H NMR spectra of the Ni(II) complexes exhibit very broad peaks in D_2O, CH_3CN-d_3 and Me_2SO-d_6 but sharp resolvable peaks in CH_3NO_2-d_3. This indicates that a considerable amount of paramagnetic octahedral species of $[Ni(Bzo_2[14]aneN_4)(Solvent)_2]^{2+}$ exists in donating solvents, where as the Ni(II) complexes of $Bzo_2[14]aneN_4$ exist primarily as diamagnetic square-planar species in CH_3NO_2-d_3. The ^1H NMR spectra of the nickel complex $[Ni(Bzo_2[14]aneN_4)](ClO_4)_2$ gave a singlet at 7.27 ppm corresponding to the C_6H_5 (10H) protons. However, the ^1H NMR spectra of the complexes $[Ni(Bzo_2[14\ or\ 16]aneN_4)](ClO_4)_2$ showed a multiplet in the region 7.35–7.45 ppm, corresponding to the –C_6H_4– ring protons (8H). The ^1H NMR spectra of all the complexes showed a broad signal at ~6.95 ppm which can be assigned to secondary amine protons (4H). A singlet for the complexes at 2.38 ppm corresponds to the CH_2 (4H) protons adjacent to nitrogen. However, none of the spectra show any signal corresponding to free primary amine protons for any of the complexes.

3.3. Synthesis of host–guest nanocomposite materials

The synthesis of tetraaza dioxo diphenyl nickel(II) complexes encapsulated in the nanocavity of zeolite-Y involves two steps: (i) exchange of $[Ni(N–N)_2]^{2+}$ (diamine = 1,2-diaminopropane, 1,3-diaminopropane, 1,2-diaminobenzene or 1,3-diaminobenzene) ions with NaY in methanol solution and (ii) reaction of $[Ni(N–N)_2]^{2+}$–NaY with excess ethylcinnamate in methanol where ethylcinnamate slowly enters into the nanocavity of zeolite-Y due to its template nature and interacts with [bis(diamine)nickel(II)] ions. Soxhlet extraction using methanol finally purified the impure complexes. The remaining uncomplexed metal ions in the zeolite were removed by exchange with aqueous 0.01 M NaCl solution. As one extra anionic ligand would be required to balance the overall charge on the Ni(II), Cl^- of NaCl used during the exchange process fulfills this requirement. Thus, the formula of the nickel(II) complexes may be written as $[Ni([14]aneN_4)]^{2+}$–NaY, $[Ni([16]aneN_4)]^{2+}$–NaY, $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY and $[Ni(Bzo_2[16]aneN_4)]^{2+}$–NaY. The percentage metal content determined before and after encapsulation by inductively coupled plasma (ICP), along with their expected formula, is presented in Table 4. As crude mass was extracted with methanol, the metal ion content found after encapsulation is only due to the presence of metal complexes in the nanopores of the zeolite-Y. The molecular formula of the complexes are based on the neat complexes $[Ni([14]aneN_4)]^{2+}$,

$[Ni([16]aneN_4)]^{2+}$, $[Ni(Bzo_2[14]aneN_4)]^{2+}$ and $[Ni(Bzo_2[16]aneN_4)]^{2+}$ that have also been prepared and characterized.

3.4. IR spectral study

The IR spectra of the ligands do not exhibit any band corresponding to the free primary diamine and hydroxyl group. The absorption in IR spectra of the tetraaza dioxo diphenyl ligands in the range 730–770 and 1415–1645 cm^{-1} [21] is due to the presence of the phenyl groups. Four new bands appear in the spectra of the free ligands in the regions ~1620, ~1590, ~1248 and ~780 cm^{-1}, corresponding to amide I [ν(C=O)], amide II [ν(C–N) + δ(N–H)], amide III [δ(N–H)] and amide IV [ϕ(C=O)] bands, respectively, [22]. A sharp band observed at ~3287 cm^{-1}, may be due to [ν(N–H)] of the secondary amino group [23]. The IR spectra of all the complexes (Table 1) showed a single sharp absorption around ~3250 cm^{-1} which may possibly arise from a secondary amine, ν_{N-H}, although its position has been found to be lower by ~30 cm^{-1} than the analogous metal-free tetraaza ligands [24]. This suggests that the secondary amine nitrogens take part in coordination to the metal ions, which has been further confirmed by the appearance of bands in the 340–350 cm^{-1} region in all the complexes, corresponding to ν_{M-N} vibrations. The absorption bands in the 2850–3050 and 1400–1450 cm^{-1} regions observed in the complexes may reasonably correspond to CH stretching and CH bending vibrational modes. The IR bands of all the encapsulated complexes are weak in comparison with the neat complexes due to their low concentrations in zeolite nanocages. The four entrapped complexes exhibit very similar IR spectra, with bands in all regions that are shifted by ~10 cm^{-1} relative to those of the corresponding free complexes (Table 4).

3.5. Elemental analyses of neat and HGNM

The C, H, N analysis results of the neat nickel(II) complexes show close similarity to the theoretical values. The molecular formulae of the tetraaza dioxo diphenyl complexes have been assigned on the basis of the results of their elemental analyses. A preliminary identification of the metal complexes was made on the basis of their IR spectra, which exhibited no bands characteristic of free primary amine, thus supporting the proposed macrocyclic skeleton (Scheme 1). The nickel contents of the HGNM catalysts were estimated by dissolving known amounts of the catalyst in *conc*. HCl and from these solutions, the nickel contents were estimated by using atomic absorption spectrometry (AAS). The chemical compositions (Tables 1 and 4) confirm the purity and stoichiometry of the neat and encapsulated complexes. The chemical analyses of the samples revealed the presence of organic matter with a C/N ratio roughly similar to that for the neat complexes. In Table 5 the molar ratios Si/Al obtained by chemical analysis for the zeolites have been presented. The Si and Al contents in Ni(II)–NaY and the zeolite complexes were almost in the same ratio as in the parent zeolite. This indicates little change in the zeolite framework due to the absence of de-alumination in the metal ion exchange. The parent NaY zeolite has Si/Al molar ratio of 2.53 which corresponds to a unit cell formula $[Na_{56}[(AlO_2)_{56}(SiO_2)_{136}]$. The unit cell formula of metal-exchanged zeolites showed a nickel dispersion of 11.2 moles per unit cell $[(Na_{33.8}Ni_{11.2}[(AlO_2)_{56}(SiO_2)_{136}] \cdot nH_2O)$. The analytical data of each complex indicated Ni:C:N molar ratios very close to those calculated for the mononuclear structure. However, the presence of minute traces of free $[Ni(N–N)_2]^{2+}$ in the lattice can be assumed as the $[Ni(N–N)_2]^{2+}$ content, which is slightly higher than the stoichiometric requirement, only a portion of $[Ni(N–N)_2]^{2+}$ in the exchanged zeolite has undergone complexation and the rest is expected to be removed on re-exchange with NaCl solution.

3.6. Electronic spectral studies

Nickel(II) complexes with 14- and 16-membered tetraaza dioxo macrocyclic ligands exist in aqueous solution as an equilibrium mixture of a yellow, square-planar, diamagnetic, low-spin species and a blue, octahedral, paramagnetic, high-spin species. Solutions of the tetraaza dioxo macrocyclic nickel(II) complexes in non-coordinating solvents show an absorption maximum at 14320, 21930 and 25440 cm^{-1}, characteristic for square-planar yellow species, and at 14050, 21640 and 25190 cm^{-1}, characteristic for blue octahedral species. Table 2 shows that the molar absorption coefficient of the ligand field transition band for the complexes measured in a coordinating solvent is smaller than that in nitromethane, a non-coordinating solvent. These results are quite similar to those reported for other related polyaza macrocyclic complexes, indicating that the complexes dissolve in water or acetonitrile to produce an equilibrium mixture of square-planar $[Ni(Bzo_2[14]aneN_4)]^{2+}$ and octahedral *trans*-$[Ni(Bzo_2[14]aneN_4)(solvent)_2]^{2+}$ [25,26]. Generally, the ligand structure, the nature of the solvent and the concentration of added electrolyte affect the equilibrium. The molar absorption coefficient of the ligand field transition band for $[Ni(Bzo_2[14]aneN_4)]^{2+}$ measured in 3.0 M NaCl aqueous solution is somewhat higher than that in pure water (Table 2). A similar result was also observed in the solutions containing NaBr, $NaNO_3$ or $NaClO_4$. This corresponds to the generally observed trend that neutral salts such as NaCl dissolved in water from their hydrate, reduce the effective concentration of free water, and then increase the concentration of the square-planar species [27]. The electronic spectra (Table 2) of the Ni(II) complexes are comparable to other square-planar tetraaza macrocyclic nickel(II) complexes, indicating that the tetraaza ligands of this study do not differ significantly from these other tetraaza ligands with respect to the ligand field strength [25–32].

At room temperature these complexes show a diamagnetic behavior, indicating the square-planar environment around the Ni(II) ion (Scheme 2). The electronic spectra of the Ni(II) complexes in Table 2 exhibit three absorption bands in the range 13640–13980 (ε = 53–58 l mol^{-1} cm^{-1}), 21200–21640 (ε = 88–97 l mol^{-1} cm^{-1}), and 24800–25190 cm^{-1} (ε = 130–140 l mol^{-1} cm^{-1}), corresponding to a square-planar geometry. These bands may be assigned to the three spin allowed transitions: $1A_{1g}(D) \rightarrow 1A_{2g}(G)$ (ν_1), $1A_{1g}(D) \rightarrow 1B_{2g}(G)$ (ν_2) and $1A_{1g}(D) \rightarrow 1E_g(G)$ (ν_3), respectively, [33]. When the complexes were encapsulated in zeolite-Y, the d ↔ d band shifted again to the higher energy side. The stability of the complexes apparently increases when they are encapsulated in zeolite-Y. The position of the d ↔ d band corresponds to a square-planar geometry for the tetraaza macrocyclic nickel(II) complexes [25–32].

3.7. Cyclic voltammetry studies

Cyclic voltammetric data are summarized in Table 4. Table 4 shows that the oxidation and reduction potentials of the Ni(II) complexes of tetraaza dioxo diphenyl do not differ significantly from other $[14]aneN_4$ complexes. This suggests that the tetraaza dioxo diphenyl macrocycles have Lewis basicities and hole sizes similar to the $[14]aneN_4$ ligand, in spite of the structural differences. A pronounced shift in the oxidation state stability occurs when there is a change in the macrocyclic ring size. An increase in ring size promotes the ease of formation of Ni(I), whilst rendering the oxidation to Ni(III) more difficult. The difference in potential between the $[Ni([14]aneN_4)]^{2+}$ and $[Ni((CH_3)_6[16]1,4,12\text{-}trieneN_4)]^{2+}$ complexes is 0.3 V. Busch and co-workers suggested that this difference is primarily due to deviations from the ideal metal-donor atom distances accompanying the redox changes [34]. This concept of an optimum fit between the coordi-

Surface area and pore volume data of host (nanopores of zeolite-Y) guest (tetraaza dioxo diphenyl macrocyclic nickel(II) complexes) nanocomposite materials

Sample	Surface area [a] (m^2/g)	Pore volume[b] (ml/g)
NaY	545	0.31
Ni(II)–NaY	528	0.31
$[Ni([4]aneN_4)]^{2+}$–NaY	430	0.18
$[Ni([16]aneN_4)]^{2+}$–NaY	422	0.16
$[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY	386	0.14
$[Ni(Bzo_2[16]aneN_4)]^{2+}$–NaY	370	0.13

[a] Surface area is the "monolayer equivalent area" calculated as explained in Refs. [17,18].
[b] Calculated by the *t*-method.

nated metal ion and the "hole size" provided by the macrocyclic ligand is also in accord with theoretical conclusions and electronic spectral studies. The more common effect of ligand unsaturation also favors the formation of the lower valent states of the complexes and causes the Ni(II) to Ni(III) process to occur at higher energy. The effect of the Bzo function on the reduction reactions of the nickel macrocycles is very pronounced and the structures containing this moiety form the stable complexes in the lower valence states under the influence of relatively mild potentials.

3.8. X-ray diffraction

The X-ray powder diffraction (XRD) patterns of NaY, Ni(II)NaY and the encapsulated metal complexes along with the simple complexes $[Ni(Bzo_2[14]aneN_4)]^{2+}$ were recorded at 2θ values between 5° and 70° to study the crystallinity and to ensure encapsulation. The XRD patterns of the nickel exchanged zeolite and the respective encapsulated complexes are essentially similar to that of NaY, though a slight change in the intensity of the bands has been noticed. These observations indicate that the framework of the zeolite has not undergone any significant structural changes during incorporation of the catalysts i.e. the crystallinity of zeolite-Y is preserved during the encapsulation. A new band with a 2θ value of 25.3° was located in Ni(II)NaY, $[Ni([14]aneN_4)]^{2+}$–NaY, $[Ni([16]aneN_4)]^{2+}$–NaY, $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY and $[Ni(Bzo_2[16]aneN_4)]^{2+}$–NaY while another band with a 2θ value of 17.3° could be located only in Ni(II)NaY and $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY. This clearly suggests the presence of metal complexes in the zeolite matrix.

3.9. Surface area and pore volume studies

The surface area and pore volume of the catalysts is presented in Table 6. The encapsulation of $[Ni([14]aneN_4)]^{2+}$–NaY, $[Ni([16]aneN_4)]^{2+}$–NaY, $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY and $[Ni(Bzo_2[16]aneN_4)]^{2+}$–NaY complexes in zeolite reduced the adsorption capacity and the surface area of the zeolite. The lowering of the pore volume and surface area indicated the presence of complexes $(Ni([14]aneN_4)]^{2+}$, $[Ni([16]aneN_4)]^{2+}$, $[Ni(Bzo_2[14]aneN_4)]^{2+}$ and $[Ni(Bzo_2[16]aneN_4)]^{2+})$ within the zeolite nanocages and not on the external surface.

3.10. Catalytic activity

The tetraaza dioxo diphenyl macrocyclic nickel(II) complexes exhibited good activity in the oxidation of cyclohexene using molecular oxygen (Table 7). Blank reactions performed over NaY zeolite under identical conditions show only negligible conversion indicating that the zeolite host is inactive for oxidation. Furthermore, O_2 alone is unable to oxidize the substrates in the absence of any catalyst. In representative tests, HGNM was filtered out

Table 7
Oxidation of cyclohexene with molecular oxygen catalyzed by "neat" 14- and 16-membered tetraaza dioxo diphenyl macrocyclic nickel(II) complexes (reaction conditions: 1 atm of O_2; time 8 h; catalyst 1.2×10^{-5} mol; substrate, cyclohexene 10 ml, temperature (70° C))

Catalyst	Conversion (%)	Selectivity (%)	
		2-Cyclohexene-1-ol	2-Cyclohexene-1-one
$[Ni([14]aneN_4)](ClO_4)_2$	44.7	52.5	47.5
$[Ni([16]aneN_4)](ClO_4)_2$	40.3	54.8	45.2
$[Ni(Bzo_2[14]aneN_4)](ClO_4)_2$	53.8	61.5	38.5
$[Ni(Bzo_2[14]aneN_4)](ClO_4)_2$[a]	30.4	70.2	29.8
$[Ni(Bzo_2[14]aneN_4)](ClO_4)_2$[b]	50.1	58.4	41.6
$[Ni(Bzo_2[14]aneN_4)](ClO_4)_2$[c]	39.6	51.3	48.7
$[Ni(Bzo_2[16]aneN_4)](ClO_4)_2$	42.1	64.7	35.3

[a] Catalyst = 0.5×10^{-5} mol.
[b] Catalyst = 2.04×10^{-5} mol.
[c] Catalyst = 4.08×10^{-5} mol.

and the filtrate was analyzed for nickel content. The absence of nickel ions in the solution phase indicates that no leaching of the complexes occurred during the reaction, as they are too intact in the nanopores. These observations suggest that the oxidations occur due to the catalytic nature of the encapsulated macrocyclic complexes and no significant role is played by either the zeolite support or the free complexes.

2-Cyclohexene-1-ol is the major product and 2-cyclohexene-1-one is also formed in small quantities (Table 7). The type of macrocyclic ring and encapsulation affected the activity and product selectivity. Conversion for the nickel(II) complexes with different macrocyclic ligands decreased in the order: $Bzo_2[16]\ aneN_4 > Bzo_2[14]aneN_4 > [16]aneN_4 > [14]aneN_4$ (for "neat" and encapsulated complexes) (Tables 7 and 8).

A comparison between the "neat complexes" and "HGNM" as catalysts evidenced that the "neat complexes" gave higher conversion of cyclohexene than their corresponding HGNM. For homogeneously catalysis reactions, the termination of a catalytic cycle may occur because of two factors, due to the formation of Ni–O–Ni species, which have poor catalytic activity, or due to the oxidative degradation of the metal complexes (Tables 7, 8 and Schemes 1 and 2). This was confirmed by taking the IR spectra of the solid after the catalytic reaction. The IR spectra of these solids are very different from the IR spectra of the parent compounds. To improve the stability of the metal complexes under the reaction conditions we have heterogenized the complexes by preventing the catalytic species from dimerizing or aggregating, and to tune the selectivity of the reaction using the walls of the nanopores of the solid via steric effects.

As mentioned before [6,23,31,32], the higher activity of the $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY complex might be attributed to the

Table 8
Oxidation of cyclohexene with molecular oxygen catalyzed by host/guest nanocomposite materials (reaction conditions: 1 atm of O_2; time 8 h; catalyst 1.2×10^{-5} mol; substrate, cyclohexene 10 ml, temperature (70 °C))

Catalyst	Conversion (%)	Selectivity (%)	
		2-cyclohexene-1-ol	2-cyclohexene-1-one
$[Ni([14]aneN_4)]^{2+}$-NaY	40.3	54.3	45.7
$[Ni([16]aneN_4)]^{2+}$-NaY	35.1	58.6	41.4
$[Ni(Bzo_2[14]aneN_4)]^{2+}$-NaY	49.6	75.4	24.6

$[Ni(Bzo_2[14]aneN_4)]^{2+}$-NaY[b]	48.2	73.8	26.2
$[Ni(Bzo_2[14]aneN_4)]^{2+}$-NaY[c]	47.9	78.9	26.9
$[Ni(Bzo_2[16]aneN_4)]^{2+}$-NaY	38.2	78.9	21.1

[a] First reuse.
[b] Second reuse.
[c] Third reuse.

higher activity of the aromatic ligand and its more active cation radical intermediate with respect to the aliphatic ligand system. Lower activity (35.1%) of $[Ni([16]aneN_4)]^{2+}$–NaY and can be accounted for by the substantial steric hindrance of the propylene groups that prevent the approaching oxidant from reaching the central metal of the catalyst.

Homogeneous catalysts are more prone to deactivation by dimerization of the active centers, which is expected to be reduced by encapsulating them in zeolites. $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY was recycled for the oxidation of cyclohexene with molecular oxygen with a view to establish the effect of encapsulation on stability. The initial run showed a conversion of 49.6% and it is only marginally reduced to 49.1% on recycling the catalyst. These results indicate that the $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY complex is almost stable enough to be recycled for the oxidation of cyclohexene without much loss in activity. Thus, the encapsulation of the complexes in zeolites is found to increase the life of the catalyst by reducing dimerization due to the restriction of the internal framework structure. The IR spectrum of the recycled sample is quite similar to that of the fresh sample, indicating little change in the coordination of $Bzo_2[14]aneN_4$ after the oxidation reactions.

The results clearly suggest that $[Ni(Bzo_2[14]aneN_4)]^{2+}$–NaY efficiently catalyses the conversion of cyclohexene to 2-cyclohexene-1-ol with 75.4% selectivity. Greater activity of the $Bzo_2[14]aneN_4$ system has clearly arisen from the existence of the electron donating ligand which facilitates the electron transfer rate, a process that has previously been observed by us in other oxidation reactions [31,32]. All conversion efficiencies with high selectivity obtained in this study are significantly higher than those obtained using metal containing porous and non-porous materials [31,32].

4. Conclusion

In summary, the results show that the "neat" complexes can be encapsulated in the nanopores of zeolite by a template condensation between the pre-entrapped $[Ni(N–N)_2]^{2+}$ complexes and ethylcinnamate. The "neat" and zeolite-Y-encapsulated nickel(II) tetraaza dioxo diphenyl macrocyclic complexes exhibit efficient catalytic activity in the oxidation of cyclohexene using O_2. The encapsulated complexes exhibit enhanced selectivity in the oxidation reaction. The size of the macrocyclic ring and substitution also influence the catalytic activity. These encapsulated systems offer structural integrity by having a uniform distribution of the metal complex in the pore structure of the support. The zeolite framework keeps the guest complexes dispersed and prevents their dimerization leading to retention of the catalytic activity. Future work on this system is expected to envisage its industrial applications for partial oxidation reactions.

2.2. Physical measurements

Infrared spectra (Nujol) were recorded with a Specord M-80 spectrometer in the range 400–3600 cm^{-1}. NMR spectra were obtained on a Varian Unity-300 NMR spectrometer at 25 °C. ^{1}H and ^{31}P NMR spectra were recorded at 299.948 and 121.420 MHz, respectively. Chemical shifts are reported with reference to $SiMe_4$ (^{1}H) and H_3PO_4 (^{31}P). Elemental analyses were performed on a Perkin–Elmer 2400 CHN microanalyser.

2.3. Crystal structure determination and refinement

Data for both structures were collected on a STOE IPDS-II diffractometer with graphite-monochromated Mo Kα radiation. The images were indexed, integrated and scaled using the X-AREA package [11]. Data were corrected for absorption using the PLATON [12] program. The structures were solved by direct methods using the SHELXS [13] program and refined first isotropically and then anisotropically using SHELXL97 [14]. Hydrogen atoms were revealed from $\Delta\rho$ maps and refined using a riding model. All figures were made using the program XP [15].

3. Results and discussion

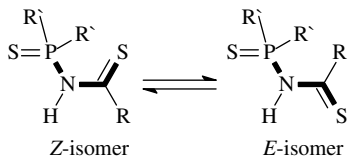
The thioureas $\mathbf{H_2L}^a$ and $\mathbf{H_2L}^b$ were synthesized by the treatment of *N,N'*-diphenyl-1,2-diaminoethylene or hydrazine hydrate with the isothiocyanate $(i\text{PrO})_2\text{P(S)NCS}$. Their compositions were successfully proved by the microanalysis data.

The ^{31}P NMR spectrum of $\mathbf{H_2L}^a$ in $CDCl_3$ contained a singlet at 58.8 ppm, which is typical for *N*-thiophosphoryl thioureas with a *tert*-nitrogen group $R_2NC(S)$ [7]. The IR and ^{1}H NMR spectra confirm the structure.

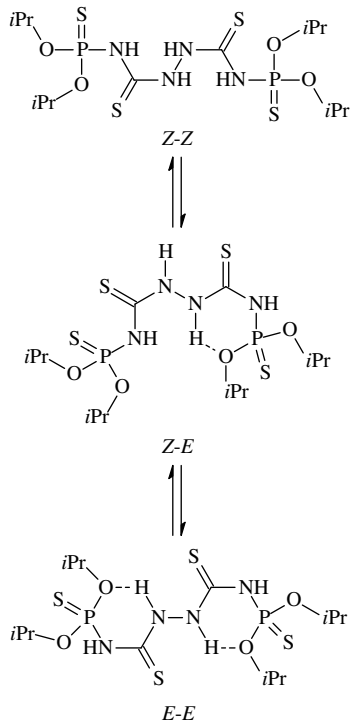
Surprisingly, there are two signals in the ^{31}P NMR spectrum of $\mathbf{H_2L}^b$: a major signal at 54.1 and a minor low-field peak at 66.2 ppm in $CDCl_3$ solution. A similar picture was observed in acetone-d_6 solution: the peaks appeared at 56.3 (major form) and 58.6 ppm. The integral intensity ratio changes from 3.9:1 to 1.9:1 for the high- and low-field signals, respectively.

Doubling of signals is also observed in the ^{1}H NMR spectra. The signals of the alkyl protons are overlapped, but the NH-groups show independent sets of different intensities. Phosphorus–proton coupling, $^2J_{PNH}$, allows the separation of the signals of the PNH groups and the NHNH moiety.

It is known that in these compounds processes of complicated rotation along the CN bond in the fragment CNP may show an essential influence on the chemical shifts of the phosphorus signals [7,16–18]. It was established that for compounds of the common formula $RC(S)NHP(S)(OR')_2$ (R = Ar, Me, NR^1R^2) in solutions the formation of conformers, caused by a complicated rotation along the C–N(P) bond, is observed (Scheme 3). The chemical shifts in the ^{31}P NMR spectra depend on the conformation balance in solutions. The activation energy of the rotation around the CN bond, established on the basis of the NMR data, is $\Delta G^{\neq}$ = 49–60 kJ/mol [17]. For example, in the case of *N*-phosphorylated thioacetamide $CH_3C(S)NHP(O)(O\text{i}Pr)_2$ there is a rather slow conformation exchange between the *Z*- and *E*-rotamers in solutions, whose signals



Scheme 3.



Scheme 4.

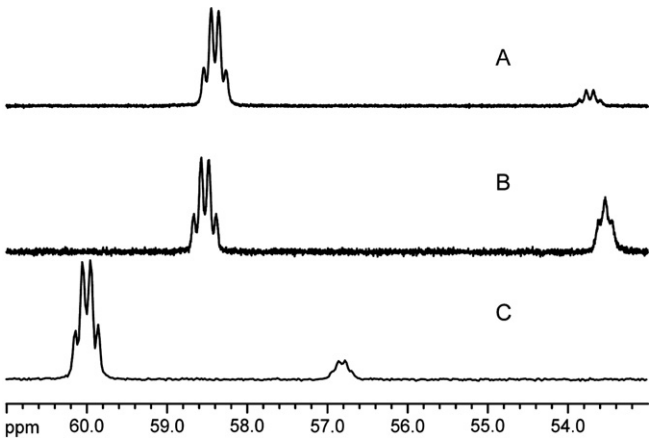


Fig. 1. ^{31}P NMR spectra of **HL**^{c} in $CDCl_3$ (−50 °C, A; 25 °C, B) and in acetone-d_6 (25 °C, C).

are managed to be observed at room temperature by ^{31}P NMR spectroscopy [18].

The conformation describing a *Z*-arrangement of the N–P and C=S bonds (Scheme 3), is prevailing for the majority of *N*-thiophosphorylated thioamides and *N*-thiophosphorylated thioureas of the common formula $Alk_2NC(S)NHP(S)(OAlk)_2$, containing a tertiary nitrogen atom of the $R_2NC(S)$ fragment [7]. As well as for **H$_2$L**^{a}, they show chemical shifts in the range 57–60 ppm in the ^{31}P NMR spectra.

The ^{31}P NMR spectra of the compounds $RNHC(S)NHP(S)(OiPr)_2$ in non-polar solvents contain signals in the characteristic area of 52–54 ppm [7]. This is caused by the formation of intramolecular hydrogen bonds between the RNH fragment and the oxygen or sulfur atoms of the (thio)phosphoryl group [7]. Formation of these bonds stabilizes the *E*-conformer (Scheme 3). In polar solvents (acetone-d_6) the signals in the ^{31}P NMR spectra are shifted by up to 60 ppm [16].

The doubling of signals in the NMR spectra of **H$_2$L**^{b} could be explained by the similar *E*-, *Z*-conformation isomerism or by the unequivalence of the two $-C(S)NHP(S)(OR)_2$ moieties in the bifunctional molecule. To eliminate the latter reason we decided to compare the obtained data to the simpler monofunctional analogue. This allowed us to avoid the complication caused by the multiple isomeric forms in the bifunctional 2,5-dithiobiurea (Scheme 4) and gives evidence that the observed signals are provided by the conformation isomers of the $RC(S)NHP(S)(OR)_2$ moiety.

The thiophosphorylated thiosemicarbazide **HL**^{c} was synthesized by the addition of phenylhydrazine to the isothiocyanate $(iPrO)_2P(S)NCS$. There are no absorption bands for the NH_2 group in the IR spectrum of **HL**^{c}. This confirms the isothiocyanate addition to the non-substituted nitrogen atom of the parent hydrazine. The ^{31}P NMR spectra of **HL**^{c} contain two signals (Fig. 1). The ratio of the integrated intensities depends on the temperature. At 25 °C (Fig. 1 B) this ratio is approximately 1:2, whereas at −50 °C (Fig. 1 A) it is 1:7 for the high-field and low-field signals, respectively. In the acetone-d_6 medium (25 °C), the integrated intensities ratio is 6.4:1 in favour of the high-field signal (Fig. 1 C). Thus, in contrast to **H$_2$L**^{b}, the ^{31}P spectra of **HL**^{c} shows the superiority of the low-field signal.

We suppose that in solution, both *Z*- and *E*-forms of **HL**^{c} are present, and they are stabilized by the intramolecular hydrogen bonds (Scheme 5). The bond of the basic nitrogen atom of the PhNH group should surpass on durability the bond in the *E*-isomer, which is in agreement with the ^{31}P NMR spectroscopy data. The chemical shifts of phosphorus are in the area which is characteristic for the *Z*- and *E*-isomers of *N*-thiophosphorylthioureas, which are related by structure to the investigated compounds [7].

The signals in the ^{31}P NMR spectrum of **HL**^{c} at −50 °C (Fig. 1A) are shown as quartets. This spin–spin coupling is typical for the $NHP(S)(OiPr)_2$ group. The phosphorus spectrum at 25 °C (Fig. 1B) shows less coupling, with $^{2}J_{PNH}$ being constant for the labile proton of the PNH group. The data obtained show that the speed of the proton exchange in the *E*-isomer (high-field signal) is higher than for the *Z*-form, in which the PNH proton participates in the intramolecular hydrogen bond formation.

In the acetone medium, the picture changes again (Fig. 1C). A significant low-field shift and increasing in intensity for the *E*-isomer is observed at 25 °C. This is in agreement with the assumption of the weak hydrogen bonds destruction in the *E*-form. Suppression of a proton exchange in the acetone medium leads to the appearance of the $^{2}J_{PNH}$ constant. A similar shift is also observed for the signal of the *Z*-form.

In the compound **H$_2$L**^{b}, the nitrogen atoms of the NHNH group are not basic, which makes the stabilization of the *Z*-isomer impossible by an intramolecular hydrogen bond (Scheme 5). As a result the accumulation of the *E,E*-isomer (high-field signal) is observed in solution.

Crystals of **H$_2$L**^{a} and **H$_2$L**^{b} were obtained by recrystallization from a 1:5 (v/v) mixture of methylene chloride and *n*-hexane (Table 1). The NMR probes and the crystals for the X-ray

determination were taken from the same samples. The parameters of the C=S, C–N, P–N and P=S bonds observed for both compounds (Tables 2 and 3) are in the typical range for *N*-thiophosphorylated thiourea derivatives [7,19].

The bifunctional thiourea $\mathbf{H_2L}^a$ has a centrosymmetrical conformation in the crystal (Fig. 2). Two N2–C1(S2)–N1–P1–O2 moieties are significantly flattened. These planes are placed orthogonal to the 1,2-diaminoethylene spacer backbone N2–C2–C2#1–N2#1 which possesses an anti-planar conformation (Table 2). As expected, the S2–C1–N1–P1 moieties in the crystal phase have a *Z*-conformation (Scheme 3), typical for *N*-thiophosphoryl thioureas with a *tert*-amide group $R_2NC(S)$.

The 2,5-dithiobiurea $\mathbf{H_2L}^b$ molecules consist of two independent NHC(S)NHP(S)(O*i*Pr)$_2$ groups with a similar conformation (Fig. 3). The 2,5-dithiobiurea backbone together with the thiophosphoryl substituents are in an anti-planar displacement (Table 3). Contrary to the thiourea $\mathbf{H_2L}^a$, the 2,5-dithiobiurea $\mathbf{H_2L}^b$ has an *E*,*E*-conformation of the S–C–N–P backbones. The conformation is supported by intramolecular H-bonding of the type C(S)NH···O(*i*Pr)P. The

molecules in the crystal are paired by two weak intermolecular NH···S=C hydrogen bonds (Table 4).

4. Conclusions

A *Z,Z*-arrangement of the C=S and P–N bonds in the SCNPS backbone was found both in the crystal phase and in $CDCl_3$ solution for the bis-thiourea $\mathbf{H_2L}^a$. The 2,5-dithiobiurea $\mathbf{H_2L}^b$ and the thiosemicarbazide $\mathbf{HL}^c$ are presence as a mixture of *E*- and *Z*-conformation isomers, stabilized by H-bonds in acetone-d_6 and $CDCl_3$ solutions. Comparison of the ^{31}P NMR data allows the superiority of the *Z*-isomer for the thiosemicarbazide $\mathbf{HL}^c$, which is stabilized by the H-bond PhN···H–NP, to be determined. The superiority of the *E,E*-isomer of the 2,5-dithiobiurea $\mathbf{H_2L}^b$ was found both in the crystal phase and in solution.

$$\sigma = -\frac{8}{3}\mathrm{Im}\left\{\sum_{L,L',m_c} \mathrm{i}^{l-l'} \exp\{\mathrm{i}(\delta_l^A + \delta_{l'}^A)\}\rho_c(l)\rho_c(l') \times G(L_c 10|L)G(L_c 10|L')(t^{-1})_{LL}^{AA}[(1-X)^{-1}]_{LL'}^{AA}\right\},$$

where $G(LL'|L'')$ is Gaunt's integral and $\rho_c(l)$ is the radial dipole integral between the radial part of $\phi_c(\mathbf{r})$ and the lth partial wave of photoelectrons $R_l(r)$ at site A. The phase shift of the lth partial wave at site A is represented by δ_l^A. We introduce the matrix X specified with site index α and angular momentum L and so on; it is defined as

$$X_{LL'}^{\alpha\beta} = t_l^{\alpha} G_{LL'}(\mathbf{R}_\alpha - \mathbf{R}_\beta)(1-\delta_{\alpha\beta}), \quad (2)$$

where t_l^{α} and $G_{LL'}$ represent the T-matrix at site α and the Green's function in an angular momentum representation. The inverse matrix $(1-X)^{-1}$ includes an infinite order of the full multiple-scattering inside the cluster we are considering. The phase shifts in $t_l^{\alpha}(= -[\exp(2\mathrm{i}\delta_l^{\alpha}) - 1]/2\mathrm{i}k)$ are one of the most important features and reflect the electronic structure of the surrounding atoms, which are calculated within the Hartree–Fock approximation. The Green's function $G_{LL'}$ reflects the geometrical structure.

3. Results and discussion

3.1. Experimental results

Figs. 1–3 show the observed Sn L_3-edge XANES spectra for methyl (Fig. 1), butyl (Fig. 2) and phenyl (Fig. 3) compounds measured by Takahashi et al. [6]. The XANES spectra depend on the organic extent. The white-line region sometimes reflects bound unoccupied levels localized on Sn in addition to the transition to continuum: the latter is sensitive to the local structures. We rather pay attention to the region A (well above the edge, 3940–3980 eV) which mainly reflects the local structure. In recent study of Sn L_3-edge XANES of gas-phase $SnCl_4$ molecule, the continuum edge is observed at 3940 eV [7]. The extended spectra are also shown in Figs. 1–3b, which show the systematic change depending on the

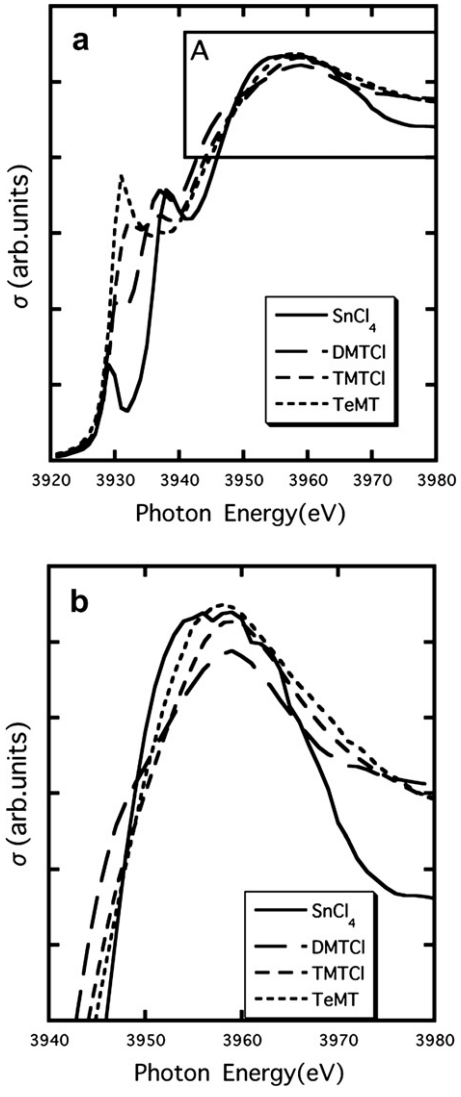

Fig. 1. (a) The observed Sn L_3-edge XANES spectra of methyl compounds (b) Extended spectra in the region A. DMTCl is dimethyltin chloride (n = 2), TMTCl is trimethyltin chloride (n = 3), TeMT is tetramethyltin (n = 4), respectively.

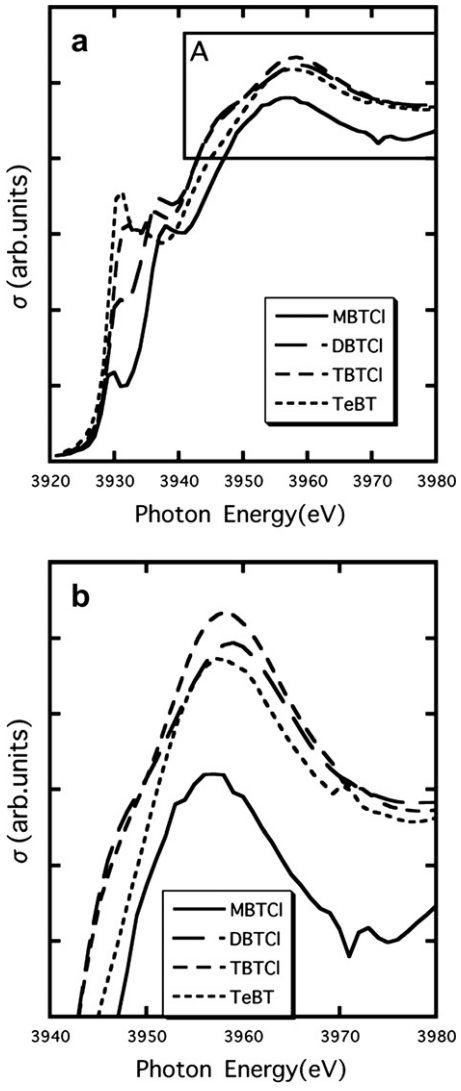

Fig. 2. (a) The observed Sn L_3-edge XANES spectra of butyl compounds. (b) Extended spectra in the region A. MBTCl is monobutyltin chloride (n = 1), DBTCl is dibutyltin chloride (n = 2), TBTCl is tributyltin chloride (n = 3), TeBT is tetrabutyltin (n = 4), respectively.

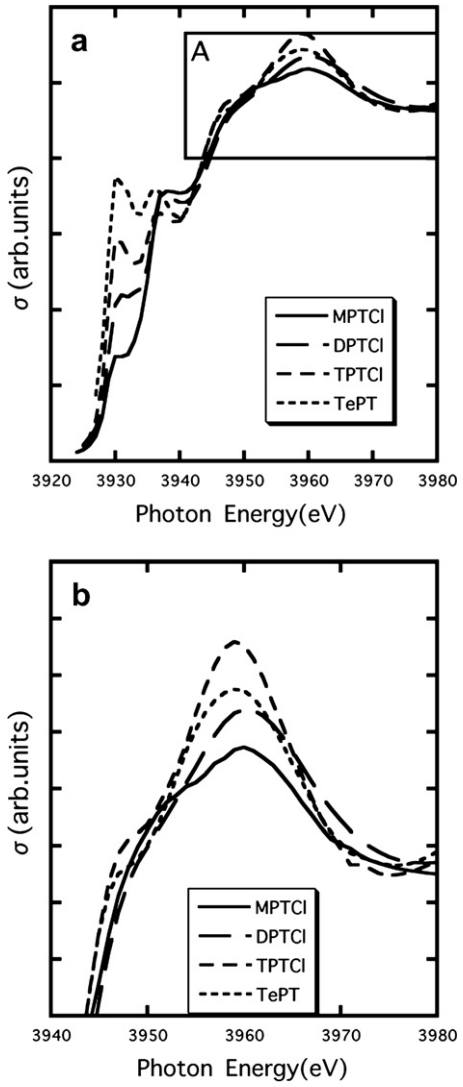

Fig. 3. (a) The observed Sn L_3-edge XANES spectra of phenyl compounds. (b) Extended spectra in the region A. MPTCl is monophenyltin chloride ($n = 1$), DPTCl is diphenyltin chloride ($n = 2$), TPTCl is triphenyltin chloride ($n = 3$), TePT is tetraphenyltin ($n = 4$), respectively.

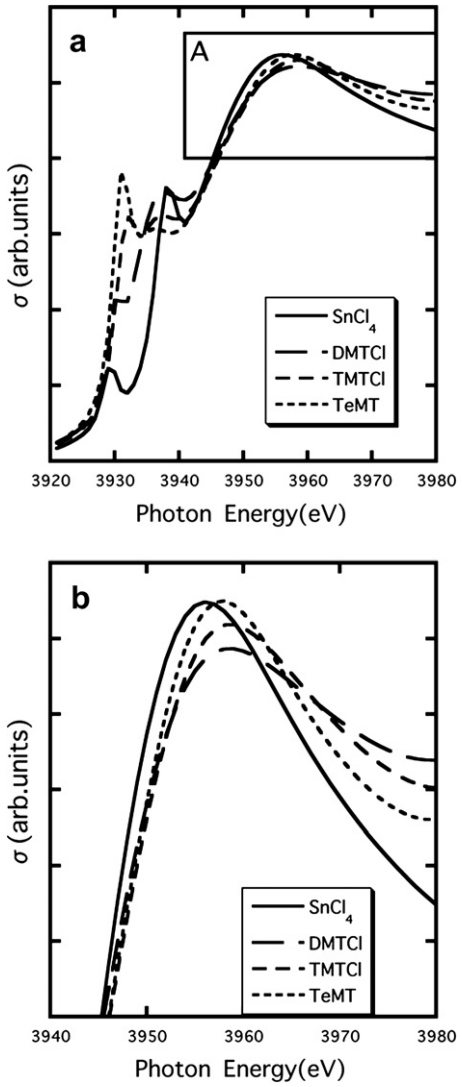

Fig. 4. (a) The calculated Sn L_3-edge XANES spectra of methyl compounds. (b) Extended spectra in the region A. DMTCl is dimethyltin chloride ($n = 2$), TMTCl is trimethyltin chloride ($n = 3$), TeMT is tetramethyltin ($n = 4$), respectively.

organic extent n, $SnCl_{4-n}X_n$ (X = Me, Bt, Ph). The peak position shifts to left and its intensity grows with the organic extent n. We thus expect that these systematic changes can be related to the structural changes, which of course cause changes in electronic structures.

3.2. Structural models and DF calculations

No experimental attempt to obtain structural information has been undertaken except $SnCl_4$ for which electron diffraction measurement gives the information on the Sn–Cl distance, Sn–Cl = 2.31 Å [13].

In order to obtain useful information about the electronic and geometric structures, we thus apply *ab initio* molecular-orbital approaches to these organotin compounds [14], where a density functional theory employs the B3LYP type exchange-correlation potential with LanL2DZ basis set. All the optimized structures are tetrahedral whose Sn–C and –Cl distances are shown in Table 1. The optimized Sn–Cl distance 2.37 Å is quite close to the observed one 2.31 Å. We thus can put trust in the calculated results. The Sn–Cl distance increases with the organic extent n, while Sn–C distances are nearly constant. These structural changes are related to the changes in bond order. The Sn–C bond order is nearly constant, whereas the Sn–Cl bond order decreases with n.

Table 1
Calculated Sn–C, Sn–Cl distances in organic tin molecules

	Sn–C/Å	Sn–Cl/Å		Sn–C/Å	Sn–Cl/Å		Sn–C/Å	Sn–Cl/Å
$SnCl_4$		2.37	MBTCl	2.13	2.39	MPTCl	2.10	2.39
DMTCl	2.12	2.41	DBTCl	2.13	2.42	DPTCl	2.11	2.41
TMTCl	2.13	2.45	TBTCl	2.15	2.45	TPTCl	2.12	2.44
TeMT	2.15		TeBT	2.16		TePT	2.14	

3.3. Sn L_3-edge XANES analyses

Our multiple-scattering calculations describe core to continuum transitions, so that purely core to localized bound state transitions are taken into account by use of several Voigt functions. Fig. 4 shows the calculated Sn L_3-edge XANES spectra for $SnCl_{4-n}Me_n$ (n = 0–4). The calculated results also show that the specific peak shifts to high-energy side in the region A with n from $SnCl_4$ to $SnClMe_3$. The peak A is caused by the multiple-scattering, which suggests that the peak shift can be explained on the basis of Natoli's rule [15],

$$(E_p - E_0)R^2 = \text{const.}, \quad (3)$$

where $E_p - E_0$ is the energy of the peak A measured from E_0 (muffin-tin constant), and R is Sn–Cl distance. Of course Sn → C scattering paths contribute to the XANES spectra, but Cl is stronger scatterer than C. With increase of n the Sn–Cl distance gets shorter, which gives rise to the energy shift to low energy side. Both the observed and the calculated results support this rule. The calculated results also explain the intensity change depending on the organic extent n, which cannot be explained on the basis of the Natoli's rule.

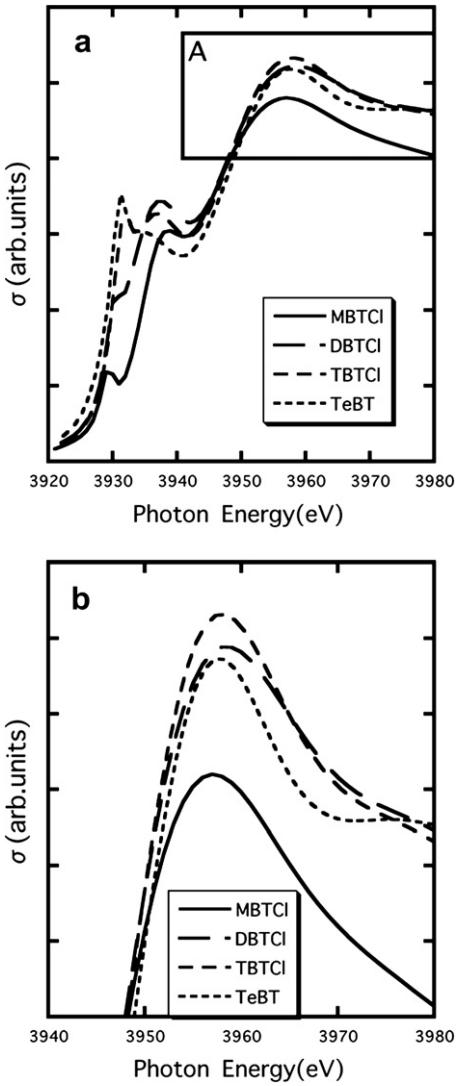

Fig. 5. (a) The calculated Sn L_3-edge XANES spectra of butyl compounds. (b) Extended spectra in the region A. MBTCl is monobutyltin chloride (n = 1), DBTCl is dibutyltin chloride (n = 2), TBTCl is tributyltin chloride (n = 3), TeBT is tetrabutyltin (n = 4), respectively.

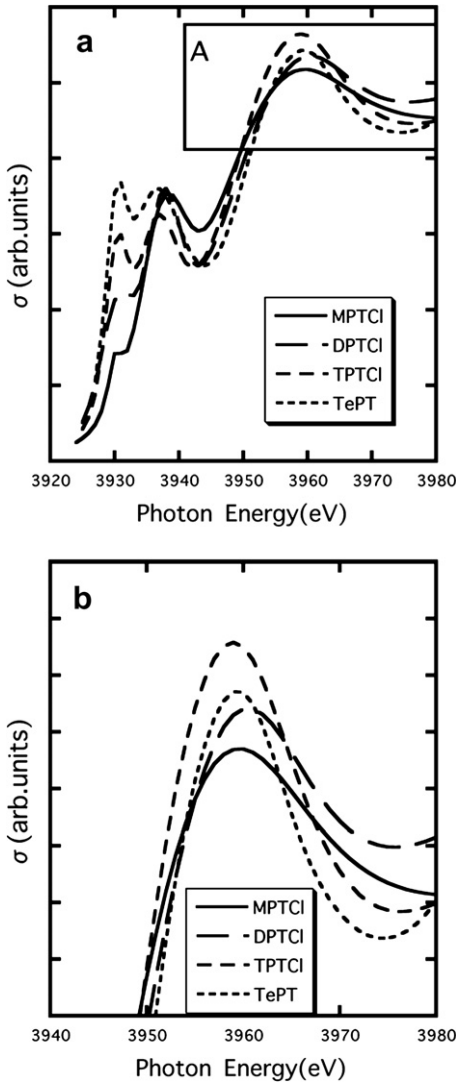

Fig. 6. (a) The calculated Sn L_3-edge XANES spectra of phenyl compounds. (b) Extended spectra in the region A. MPTCl is monophenyltin chloride (n = 1), DPTCl is diphenyltin chloride (n = 2), TPTCl is triphenyltin chloride (n = 3), TePT is tetraphenyltin (n = 4), respectively.

Fig. 5 shows the calculated Sn L_3-edge XANES spectra for $SnCl_{4-n}Bt_n$ (n = 0–4), which are quite similar to the previous results. The peak shifts again follow the Natoli's rule, and the calculated peak intensities well explain the observed result. Fig. 6 shows the same ones for $SnCl_{4-n}Ph_n$. In contrast to the previous results, the observed peak shifts and the intensity changes cannot be explained by the present calculations. This should be due to the difficulty in optimizing the structures by DFT calculations because large phenyl groups can easily rotate around Sn–C bonds.

Fig. 7 shows the calculated Sn L_3-edge XANES spectra for different Sn–Cl distances in $SnCl_4$ (a) and Sn–C distances in $SnMe_4$ (b). For the larger Sn–Cl or Sn–C distance we observe the energy shift of the peak A to low energy side in consistent with the Natoli's rule [15]. For $SnCl_4$, $(E_p - E_0)R^2$ = 204 eV Å^2 at R = 2.27 Å, 202 eV Å^2 at 2.37 Å whereas 180 eV Å^2 at 2.47 Å: the peak at 3938 eV is lost because of the XANES peak at ~3940 eV shifts to low energy side. For $SnMe_4$ we find similar behavior, 183 eV Å^2 at R = 2.05 Å, 174 eV Å^2 at 2.15 Å and 162 eV Å^2 at 2.25 Å. We thus find that Natoli's rule is not quantitative but qualitative.

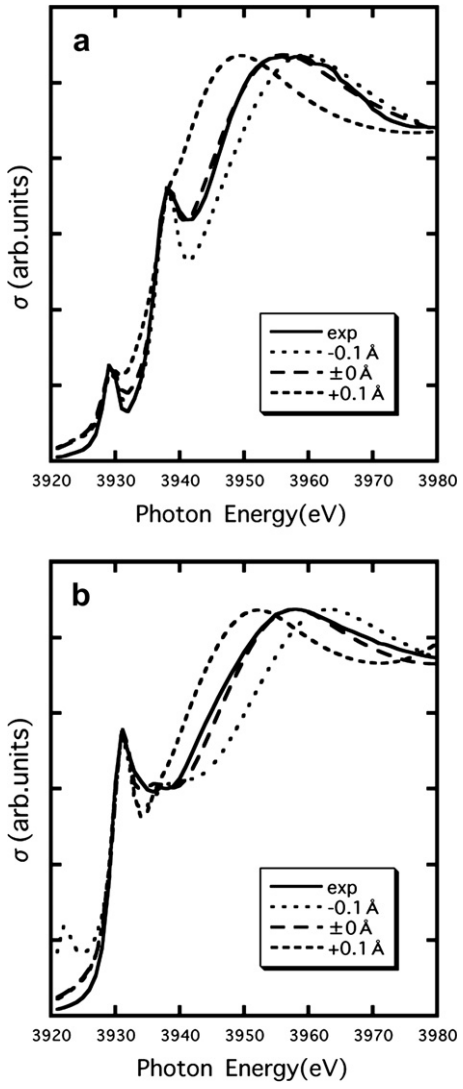

Fig. 7. The calculated Sn L_3-edge XANES spectra for different Sn–Cl distances in $SnCl_4$ (a), and Sn–C distances in $SnMe_4$(TeMT) (b).

4. Concluding remarks

The multiple-scattering XANES analyses for Sn L_3-edge spectra have been applied to organotin compounds $SnCl_{4-n}Me_n$, $SnCl_{4-n}Bt_n$, and $SnCl_{4-n}Ph_n$ (n = 0–4). The white-lines are ascribed to $2p_{3/2} \rightarrow$ bound unoccupied state transitions, which are sensitive to the electronic structure on Sn. The spectral changes are clearly related to the changes in electronic structures. On the other hand, the peak A at ~3960 eV is sensitive to the local geometry around the central Sn. With aid of Natoli's rule we can easily obtain qualitative structural information. The present XANES analyses support the optimized structures obtained on the basis of DFT calculations.

3. Analyses and physical measurements

Carbon, hydrogen, nitrogen and sulfur contents were estimated on a CHN Model CE-440 Analyser and on an Elementar Vario EL III Carlo Erbo 1108. By following standard procedures, the complexes were analyzed for their metal content, after decomposition with a mixture of conc. HNO_3 and HCl, followed by conc. H_2SO_4 [20]. Magnetic susceptibility measurements were performed at room temperature on a Cahn Faraday balance using $Hg[Co(NCS)_4]$ as the calibrant and electronic spectra were recorded on an UV-1700 Pharmaspec spectrophotometer. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a Varian Excalibur 3100 FT-IR spectrophotometer. ^{1}H and ^{13}C NMR spectra were recorded in DMSO-d_6 on a JEOL AL300 FT NMR spectrometer using TMS as an internal reference.

4. Crystal structure determination and structure refinement

Data for the structures were obtained at 173(2) K on a Bruker three-circle diffractometer equipped with a SMART 6000 CCD diffractometer using a graphite monochromated Mo Kα (0.71073 Å) radiation source. Intensity measurements were performed on a rapidly cooled crystal. The spectra were solved by direct methods (SHELXL-97) and refined against all data by full matrix least-squares on F^2 using anisotropic displacement parameters for all non-hydrogen atoms. All the hydrogen atoms were included in the refinement at geometrically ideal positions and refined with a riding model [21,22]. The MERCURY package was used for molecular graphics [23]. Crystal structure diagrams were generated by use of the ORTEP-3 for windows program [24].

5. Results and discussion

As a part of our study on metal complexes of pyridyl-1,3,4-oxadiazole-2-thione and 5-phenyl-1,3,4-oxadiazole-2-thiol [10,13], we report herein the preparation, spectroscopic and X-ray studies of two new Ni(II) and Cu(II) complexes based on 5-(3-pyridyl)-1,3,4-oxadiazole-2-thione $(3\text{-pyt})^-$. A methanol solution of $Ni(en)_2(NCS)_2$ reacts with $[K^+(H_2L)^-]$ to produce $[Ni(en)_2(3\text{-pyt})_2]$ (**1**). $[K^+(H_2L)^-]$ reacts with $CuCl_2 \cdot 2H_2O$ to give a green precipitate which dissolves in methanolic en to form $[Cu(en)2](3\text{-pyt})_2$ (**2**). The single crystal X-ray diffraction studies indicate that the ligand $(3\text{-pyt})^-$ adopts the thione form in **1** but is present as the thiolato form in **2** (as shown in Fig. 2). The complexes are stable towards air and moisture for several days. Scheme 1 shows the formation of the Ni(II) and Cu(II) complexes with $[K^+(H_2L)^-]$ as the ligand and en as a co-ligand. Both complexes are soluble in MeOH and other polar solvents such as DMF and DMSO.

5.1. ^{1}H and ^{13}C NMR spectra

The ^{1}H NMR spectrum of $[K^+(H_2L)^-]$ in DMSO-d_6 shows a signal at δ 10.01 ppm for the two NH protons. The pyridine ring protons

N(12B)–H(12H)···N(2B)	0.92	2.59	3.178(2)	122.2

#1: $x-1, -y+2, z$; #2: $x+1/2, -y+1, z$.

appear at δ 9.05, 8.73, 7.51 and 8.23 ppm. ^{13}C NMR signals at δ 214.76 (>C=S), 161.99 (>C=O), 128.96 (C3), 151.99 (C7), 148.45 (C6), 123.52 (C5) and 135.06(C4) ppm suggest the presence of a dithiocarbazate moiety in the potassium salt. We were unable to record the NMR spectra of the Ni(II) and Cu(II) complexes due to their paramagnetic nature.

5.2. IR spectra

The IR spectrum of $[K^+(H_2L)^-]$ is expected to give rise to characteristic bands due to ν(NH), ν(C=O), thioamide I, thioamide II, ν(C=S) and ν(N–N), which occur at 3218, 3148, 1665, 1470, 1329, 989 and 1087 cm^{-1}, respectively. The band at 691 cm^{-1} is due to the pyridine ring.

A comparative study of the IR spectra of complexes **1** and **2** with that of $[K^+(H_2L)^-]$ indicate very surprising results, the bands due to the –C(O)NHNHC(S)– moiety i.e. ν(C=O), thioamide I, thioamide II and ν(C=S) are found to be absent. In addition to this, the IR spectra of both complexes are devoid of any peak due to ν(NH), which

C(1)–S–Cu	102.66(4)		

is present in the ligand. Further, the disappearance of bands related to ν(C=O) and ν(C=S) and the appearance of new bands at 1584 and 1604 cm^{-1} (endocyclic C=N), 1273–1277 for ν_{as}(C–O–C) and 1187–1190 for ν_s(C–O–C) cm^{-1}, suggest cyclization of the acyclic dithiocarbazate moiety. The IR data are thus consistent with the presence of a 1,3,4-oxadiazole moiety [25]. The slight negative shift in the ν(C=S) band in complex **1** may be due to the presence of N–H···S bonding. The absorption appearing in the region 3247–3284 cm^{-1} due to NH stretching vibrations of en is found to be shifted to lower frequency than those encountered in free en due to the presence of N–H···S and N–H···O hydrogen bonding in **1** and **2** [26]. The appearance of new bands at 426 and 470 cm^{-1} for complexes **1** and **2**, respectively, suggests the formation of a chelate ring in both complexes.

5.3. Electronic spectra and magnetic moment

The magnetic moment of 2.83 B.M. for $[Ni(en)_2(3\text{-pyt})_2]$ and the presence of two d–d bands at 670 and 450 nm assigned to the $^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)$ and $^3T_{1g}(P)$ transitions, respectively, suggest an octahedral geometry around Ni(II) in the complex [27]. Another two bands at 299 and 226 nm may be due to charge transfer/intraligand transitions.

$[Cu(en)_2](3\text{-pyt})_2$ shows a magnetic moment of 1.78 B.M., which indicates the presence of one unpaired electron. The presence of a broad band around 645 nm assigned to the envelope of the $^2B_{1g} \rightarrow {}^2A_{1g}$, $^2B_{2g}$, ^2E_g transitions suggests a square planar geometry for the complex [27]. Two other high energy bands observed at 305 and 268 nm may be due to charge transfer/intraligand transitions.

5.4. Crystal structure description of $[Ni(en)_2(3\text{-pyt})_2]$ (**1**)

The crystal structure refinement data related to complex **1** are given in Table 1 and selected bond length and angles are given in Table 2. The X-ray crystal structure of **1** shows the presence of two bidentate ethylenediamines as a co-ligand and two $(3\text{-pyt})^-$ as ligands coordinated to Ni(II), resulting in a somewhat distorted NiN_6 octahedral geometry (Fig. 3). The monomeric unit $[Ni(en)_2(3\text{-pyt})_2]$ possesses a centrosymmetry nickel at the inversion center. Its coordination environment is fulfilled by two axial $(3\text{-pyt})^-$ anions at trans positions, bonded through nitrogen atoms at distances of 2.1090(14) and 2.1150(14) Å, and the four equatorial sites are occupied by the two bidentate *N,N′* ethylenediamine co-ligands. The binding of the en co-ligands, Ni–N(11A), Ni–N(11B) with a distance of 2.0930(14) and 2.0918(14) Å and Ni–N(12A), Ni–N(12B) with a distance of 2.1127(13) and 2.1059(13) Å, involves two five-membered chelate rings Ni–N12A–C12A–C11A–N11A and Ni–N11B–C12B–N11B with bite angles of 83.27(5)° and 83.06 (5)°, which represent a major deviation from the octahedral geometry. Although all the N(11A), N(11B), N(12A) and N(12B) atoms of

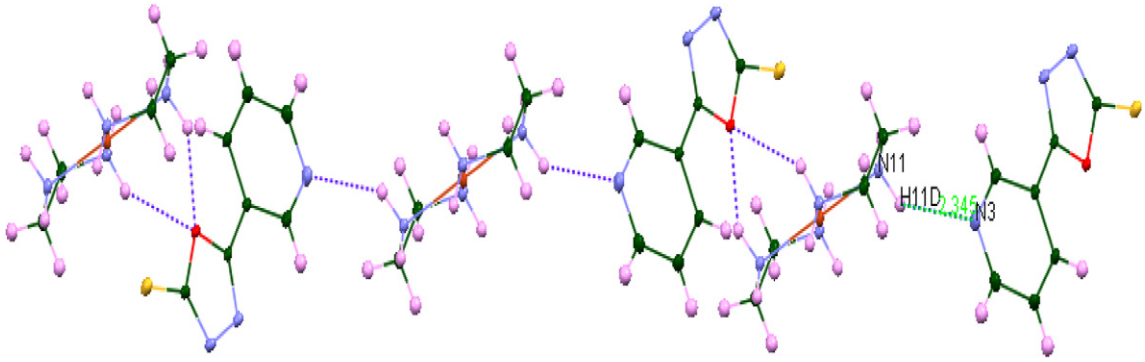

Fig. 7a. One-dimensional chain due to N–H···N hydrogen bonding.

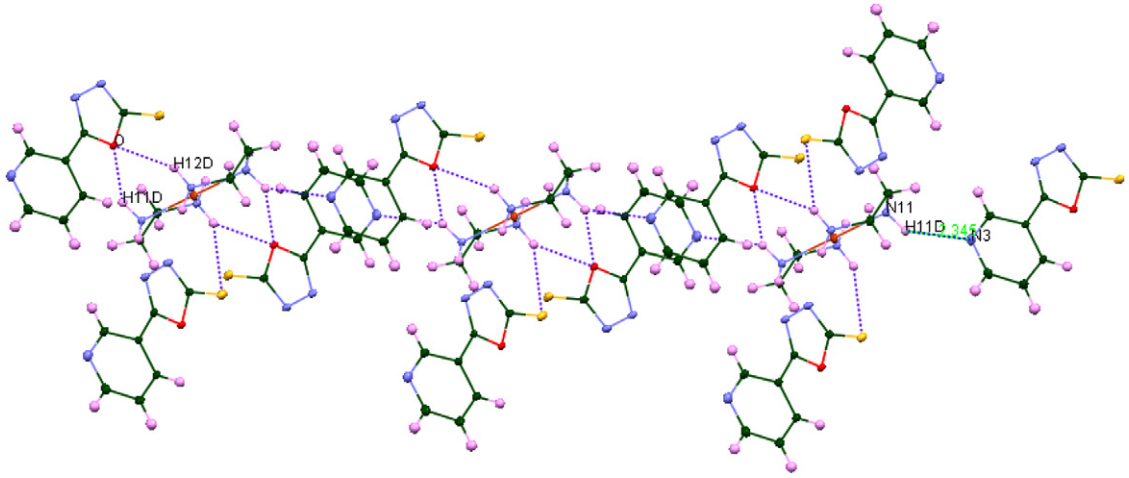

Fig. 7b. Two-dimensional network via N–H···O hydrogen bonding and face to face (π···π) interactions between two pyridine rings ($Cg_{py}\cdots Cg_{py}$).

en involved in bonding lie in a plane, the $Ni(en)_2^{2+}$ core is non-planar due to typical out of plane deviation of the methylene groups.

The geometry and bonding parameters within the en molecule agree with those of related compounds, e.g. $[Ni\{trans\text{-}(L)_2(en)_2\}${L = N-(5-chlorouracilato) [28], isothiocyanato [29] and salicylato [30]}. Similarly, the almost planar $(3\text{-pyt})^-$ ligands in **1**, bound via Ni–N(1A) = 2.1090(14) and Ni–N(1B) = 2.1150(14) Å, are significantly lengthened in comparison to the corresponding

Hydrogen bonds for $[Cu(en)_2](3\text{-pyt})_2$ (Å and °)

D–H···A	*d*(D–H)	*d*(H···A)	*d*(D···A)	∠(DHA)
N(11)–H(11C)···N(2)$^{\#2}$	0.92	2.11	3.0307(15)	174.5
N(11)–H(11D)···O$^{\#1}$	0.92	2.46	3.1623(14)	133.5
N(12)–H(12C)···N(1)$^{\#3}$	0.92	2.18	3.0954(16)	173.6
N(12)–H(12D)···O	0.92	2.40	3.1238(14)	135.2
N(12)–H(12D)···S$^{\#4}$	0.92	2.97	3.7434(12)	143.2

#1: $-x+1/2, -y+1/2, -z$; #2: $-x+1/2, y-1/2, -z+1/2$; #3: $x, -y+1, z-1/2$; #4: $-x+1/2, y+1/2, -z+1/2$.

bonds of 1.907(3) and 1.895(4) Å in [Ni{^{5}-(2-dimethylaminoethyl)cyclopentadienyl}(pti)]0.5(C_7H_8) [31] and [Ni{^{5}-(1-methylindene)(pti)(PPh_3)] [32], respectively, but are comparable to that of ca. 2.102 Å encountered in the related *N*-succinimido compound [Ni(succinimido)$(H_2O)_4$] · $2H_2O$[33]. The binding of en and (3-pyt)$^-$ in **1** is further stabilized by extensive intramolecular hydrogen bonding interactions (Fig. 5). The remaining atoms of the (3-pyt)$^-$ groups participate in hydrogen bonding interactions with the ethylenediamine present as a co-ligand. Hence, all the hydrogens of the NH_2 groups are involved in H-bonding to the oxygen, nitrogen and sulfur atoms of the oxadiazole ring of (3-pyt)$^-$, thus providing multiple N–H···O, linkages with D···A distances ranging from 2.578 to 2.634 Å and ∠DHA angles of 128.36–129.27° (Fig. 5). In addition, the monomeric $[Ni(en)_2(3\text{-pyt})_2]$ units are held together through N–H···S/N intermolecular hydrogen bonding, listed in Table 3, leading to the formation of wave-like metal–organic chains along the *a*-axis (Fig. 4). The shortest intra and inter chain Ni···Ni separations within these chains are 8.095 and 9.896 Å, respectively (Fig. 4). The arrangement of the monomeric $[Ni(en)_2(3\text{-pyt})_2]$ units

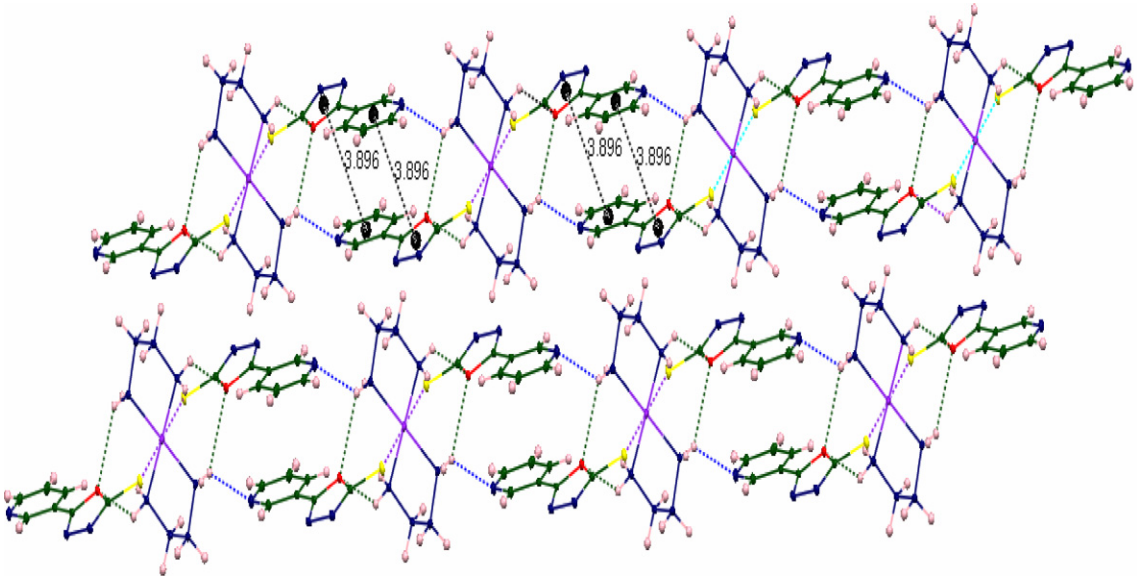

Fig. 8. MERCURY view of the crystal packing of $[Cu(en)_2](3\text{-pyt})_2$ showing face to face (π···π) interactions between the pyridine ring (Cg_{py}) and the oxadiazole ring (Cg_{oxa}).

in the three-dimensional architecture along the *a*-axis provide a supramolecular network.

5.5. Crystal structure description of $[Cu(en)_2](3\text{-pyt})_2$ (**2**)

The crystal structure refinement data related to complex **2** are given in Table 1 and selected bond length and angles are given in Table 4. The structure of complex **2** is presented in Fig. 6 and packing diagrams are presented in Fig. 7. The X-ray crystal structure analysis of **2** has a composition $[Cu(en)_2]^{2+}$ cation surrounded by two $(3\text{-pyt})^-$ anions. In the centrosymmetric unit of $[Cu(en)_2](3\text{-pyt})_2$ the metal ion has a square planar geometry where Cu(II) is bonded with four symmetry related N-atoms of two en molecules and is ionically bonded with two $(3\text{-pyt})^-$ anions. The complex cation consists of two en molecules which chelate Cu(II) in equatorial positions and two $(3\text{-pyt})^-$ occupy apical positions in a trans manner (Fig. 6). The Cu–N distances in complex **2** are in the range 2.0144(11)–2.0327(11) Å, which is almost normal for Cu–N (amine) bonds. The bite angles for the CuN_4 core are 84.18(4)° and 95.82(4)°, indicating a substantial distortion in the molecule with two five-membered CuC_2N_2 chelate rings around the Cu(II) ion. Similar geometrical parameters for the coordination sphere have been reported for diaquao-bis(ethylenediamine)copper(II) salts [34–37]. In $[Cu(en)_2]^{2+}$, the copper(II) and ethylenediamine lie in the same plane. Each $[Cu(en)_2]^{2+}$ forms a pair of weak intermolecular Cu···S interactions with a distance of 3.0585(5) Å. This distance is well within the distance of 3.2 Å, the sum of van der Waals' radii of Cu and S [38], and suggests a comparatively strong interaction. The propensity towards such an interaction is probably due to the tendency of Cu(II) to increase its coordination number. The Cu(II) in D_{4h} symmetry is bonded to four nitrogen atoms of en groups which offer interesting hydrogen bonding packing. The elements of the structure are joined to each other in the crystal packing by means of an extended system of hydrogen bonding and weak π···π interactions present (i) between the adjacent pyridine ring (Cg_{py}) and oxadiazole ring (Cg_{oxa}) with a distance of 3.896 Å (ii) between two adjacent pyridine rings (Cg_{py}) with a distance of 4.029 Å (Fig. 7b and Fig. 8).

In the molecular packing of complex **2**, the ligand $(3\text{-pyt})^-$ has formed one-dimensional chains via intermolecular N11–H11D···N3 (2.345 Å) hydrogen bonding along the *b*-axis (Fig. 7a). The π···π stacking interactions between two adjacent pyridine rings of $(3\text{-pyt})^-$ and intermolecular N11–H11D···O and N12–H12D···O hydrogen bonding connect the one-dimensional chains into a two-dimensional network (Fig. 7b). Further, $(3\text{-pyt})^-$ has formed intermolecular hydrogen bonding with the hydrogen atoms of en, viz. N(11)–H(11C)···N1#3 and N(12)–H(12D)···S#4. All these hydrogen bondings, together with weak π···π interactions, grow the chains into a three-dimensional framework (Fig. 7c). The hydrogen bonding parameters are listed in Table 5. The arrangement of $[Cu(en)_2]^{2+}$ at a dihedral angle of 84.44° with respect to $(3\text{-pyt})^-$ provides a network of intermingled chains giving the shortest intra and inter chain Cu···Cu separations within these chains of 11.744 and 12.990 Å, respectively (Fig. 8).

6. Conclusion

This paper reports the $[Ni(en)_2(3\text{-pyt})_2]$ and $[Cu(en)_2](3\text{-pyt})_2$ complexes of 5-(3-pyridyl)-1,3,4-oxadiazole-2-thione/thiol $(3\text{-pyt})^-$, containing en as a co-ligand. Both complexes contain extended hydrogen bonding, providing a three-dimensional supramolecular framework. $[Cu(en)_2](3\text{-pyt})_2$ shows weak π···π interactions.

7 Supplementary data

CCDC 656004 and 656003 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

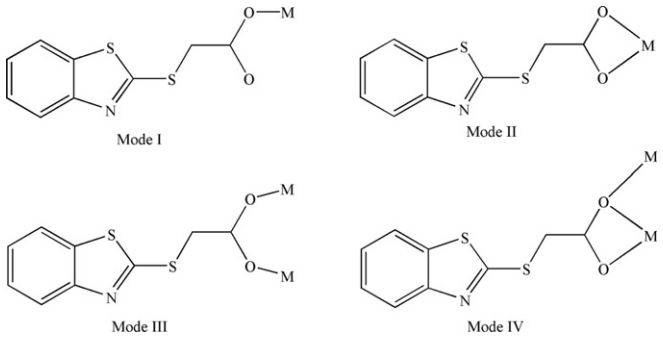

Scheme 1. Different coordination modes of the BTTAA ligand in the six complexes.

2.2. Syntheses of the complexes

2.2.1. Synthesis of **1**

A mixture of HBTTAA (225 mg, 1.00 mmol), $Mn(ClO_4)_2 \cdot 6H_2O$ (362 mg, 1.00 mmol) and 4,4′-bipyridine (312 mg, 2.00 mmol) were dissolved in an ethanol solution (15 mL) and the solution was stirred for 3 h at room temperature and then filtered. Orange block-shaped crystals of **1** were obtained from the filtrate after several days. Yield: 30% (on the basis of HBTTAA). *Anal.* Calc. for $C_{76}H_{60}Cl_2Mn_3N_{12}O_{18}S_8$: C, 47.50; H, 3.15; N, 8.75; S, 13.35. Found: C, 47.23; H, 3.12; N, 8.58; S, 13.58%. IR (KBr, cm^{-1}): 3460w, 1606s, 1591s, 1560s, 1536m, 1519w, 1490m, 1457m, 1421s, 1392s, 1221m, 1108s, 994s, 807m, 722w.

2.2.2. Synthesis of **2**

This complex was prepared by a similar procedure as that for **1**, but with a higher molar ratio (2:1:2) of HBTTAA to $Mn(ClO_4)_2 \cdot 6H_2O$ and 4,4′-bipyridine. Yield: 70% (on the basis of HBTTAA). *Anal.* Calc. for $C_{28}H_{20}MnN_4O_4S_4$: C, 55.94; H, 3.46; N, 10.30; S, 15.72. Found: C, 55.69; H, 3.12; N, 10.58; S, 5.58%. IR (KBr, cm^{-1}): 3445w, 1581s, 1530m, 1489w, 1462m, 1427s, 1385s, 1222m, 995s, 807w, 723w.

2.2.3. Synthesis of **3**

A mixture of HBTTAA (450 mg, 2.00 mmol), NaOH (80 mg, 2.00 mmol), $Cd(NO_3)_2 \cdot 4H_2O$ (309 mg, 1.00 mmol), 4,4′-bipyridine (156 mg, 1.00 mmol) and water (17 mL) was placed in a 25 mL Teflon-lined stainless autoclave and heated under autogenous pressure at 100 °C for 5 days. It was then slowly cooled to room temperature over 24 h. Colorless block-like crystals of **3** were separated from the reaction mixture in about 54% yield (on the basis of HBTTAA). *Anal.* Calc. for $C_{28}H_{20}CdN_4O_4S_4$: C, 46.89; H, 2.81; N, 7.81; S, 17.88. Found: C, 46.57; H, 3.12; N, 7.58; S, 17.58%. IR (KBr, cm^{-1}): 3444w, 1584s, 1532m, 1490w, 1460m, 1426s, 1401s, 1220m, 994m, 806m, 728w.

2.2.4. Synthesis of **4**

A mixture of HBTTAA (255 mg, 1.00 mmol), $Cd(NO_3)_2 \cdot 4H_2O$ (309 mg, 1.00 mmol) and 4,4′-bipyridine (156 mg, 1.00 mmol) were dissolved in methanol (15 mL) and the solution was stirred for 3 h at room temperature and filtered. Colorless block-shaped crystals of **4** were obtained from the filtrate after several days. Yield: 37% (on the basis of HBTTAA). *Anal.* Calc. for $C_{19}H_{16}CdN_4O_6S_2$: C, 39.83; H, 2.81; N, 9.78; S, 11.19. Found: C, 39.56; H, 3.17; N, 9.58; S, 11.58%. IR (KBr, cm^{-1}): 3436w, 1602m, 1585s, 1534w, 1489w, 1454m, 1426m, 1384vs, 1220w, 1006m, 806m, 727w.

2.2.5. Synthesis of **5**

A mixture of HBTTAA (450 mg, 2.00 mmol), NaOH (80 mg, 2.00 mmol), $Co(NO_3)_2 \cdot 6H_2O$ (291 mg, 1.00 mmol), 4,4′-bipyridine (312 mg, 2.00 mmol) and ethanol (15 mL) was placed in a 25 mL Teflon-lined stainless autoclave and heated under autogenous pressure at 100 °C for 5 days. It was then slowly cooled to room temperature over 24 h. Red block-like crystals of **5** were separated from the reaction mixture. Yield: 11% (on the basis of HBTTAA). *Anal.* Calc. for $C_{28}H_{24}CoN_4O_6S_4$: C, 48.06; H, 3.46; N, 8.01; S, 18.33. Found: C, 48.23; H, 3.17; N, 8.38; S, 18.47%. IR (KBr, cm^{-1}): 3405s, 1607s, 1577s, 1491w, 1450m, 1423s, 1374s, 1222m, 1008m, 811m, 752m.

2.2.6. Synthesis of **6**

A mixture of HBTTAA (450 mg, 2.00 mmol), NaOH (80 mg, 2.00 mmol), $CuCl_2 \cdot 2H_2O$ (171 mg, 1.00 mmol), 4,4′-bipyridine (312 mg, 2.00 mmol) and ethanol (15 mL) was placed in a 25 mL Teflon-lined stainless autoclave and heated under autogenous pressure at 110 °C for 5 days. It was then slowly cooled to room temperature over 24 h. Blue block-like crystals of **6** were separated from the reaction mixture. Yield: 70% (on the basis of HBTTAA). *Anal.* Calc. for $C_{28}H_{20}CuN_4O_4S_4$: C, 50.32; H, 3.02; N, 8.38; S, 19.19. Found: C, 50.49; H, 3.23; N, 8.57; S, 19.48%. IR (KBr, cm^{-1}): 3443w, 1611s, 1598s, 1495w, 1454m, 1424s, 1385m, 1222w, 1009m, 758w.

CAUTION! Although we have experienced no problems in handling perchlorate compounds, these should be handled with great caution due to the potential for explosion.

2.3. Crystal structure determination

X-ray crystal data collection for the six complexes was performed on a Bruker Smart 1000 CCD diffractometer with monochromated Mo-Kα radiation ($\lambda = 0.71073$ Å) at 298 K (Table 1). Semi-empirical absorption corrections were applied using the SADABS program. All calculations were carried out with SHELXS-97 and SHELXL-97 [10,11]. The structures were solved by direct methods and refined on $|F|^2$ by full-matrix least squares methods.

3. Results and discussion

3.1. Description of the crystal structures

The X-ray diffraction analysis of **1** reveals a novel 2D coordination polymer with a linear trinuclear manganese(II) unit bridged by 4,4′-bipy ligands (Fig. 1a). In the trinuclear unit, the Mn2 atom is located on a crystallographic inversion center and is coordinated octahedrally by two 4,4′-bipy nitrogen atoms and four BTTAA carboxylato oxygen atoms (Table 2). Mn2 is bridged to Mn1 through the two BTTA anions. One is in a *syn–syn* mode (μ_2,η_2-carboxylato), and the other coordinates through one oxygen atom (μ_2,η_1-carboxylato). In short, BTTAA links the metal centers in two different coordinated modes (III and IV). The coordination environment of Mn1 is completed by three carboxylato oxygen atoms and three N atoms from three 4,4′-bipy ligands to form a distorted MnN_3O_3 octahedron while Mn2 has a distorted MnN_2O_4 octahedral geometry. The $Mn_3(BTTAA)_4$ core is similar to those found in Refs. [12–18]. The Mn···Mn distance (3.853(2) Å) linked by the carboxylato group in the Mn_3 core is slightly longer than those observed in $[Mn_3(bipy)_2(O_2CPh)_6]$ (3.588 Å) [12] and $[Mn_3(bipy)_2(OAc)_6]$ (3.614 Å) [16]. Interestingly, these Mn_3 subunits are linked via 4,4′-bipy ligands with Mn···Mn separations of 11.462(2) and 11.632(2) Å, respectively, to form a novel two-dimensional network in the *ab* plane, as well as uncoordinated ClO_4^- anions and water molecules that fill in the network (Fig. 1b). The 4,4′-bipy ligands act as bridges between the trimers such that the structure forms two different perfect 4^4 square grid networks [19] and adjacent layers are packed with an ABAB mode as shown in Fig. 1c.

When we change the molar ratio of HBTTAA to 4,4′-bipy and metal salt, compound 2, with a layered structure, was isolated. Compounds **2** and **3** are isostructural, so only the structure of **2** will

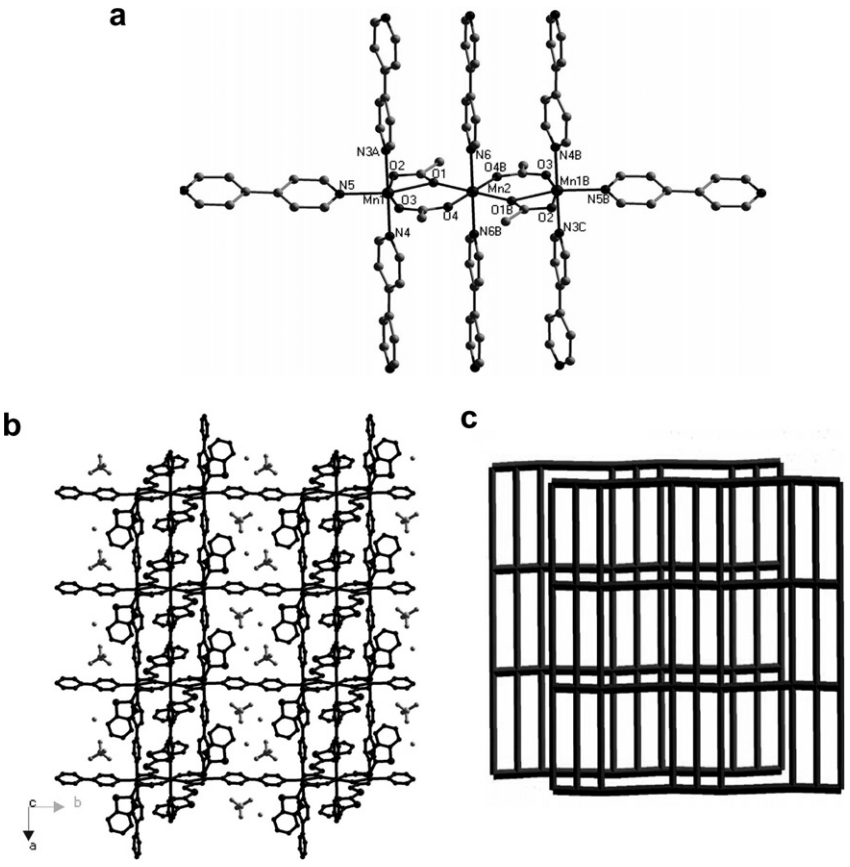

Fig. 1. (a) The asymmetric unit of **1**, the BTTAA ligands are reduced to the acetic ligand for clarity. (b) The two different 4^4 grid networks. (c) Schematic representation of the mode of ABAB packing.

be discussed in detail as a representative example. The Mn(II) atoms in **2** lie at a crystallographic inversion center and each of them is six-coordinated by four carboxylato oxygen atoms in the equatorial plane and two N atoms from two disordered 4,4′-bipy ligands (a similar "disordered" phenomenon appears in **3**) at axial sites, as shown in Fig. 2a (Table 2). Each Mn(II) is connected by two *syn–anti* (μ_2,η_2-BTTAA) carboxylato bridges (mode III) with a Mn···Mn separation of 4.985(5) Å, and Cd···Cd separation of 5.063(1) Å for **3**. This leads to the formation of an infinite 1D chain which is further connected by the coordination of 4,4′-bipy molecules to adjacent chains with an interchain Mn···Mn separation of 11.763(3) Å (interchain Cd···Cd separation of 11.833(2) Å for **3**),

resulting in the construction of a 2D 4^4 grid network in the ac plane, as shown in Fig. 2b.

Compounds **4**, **5** and **6** all have a one-dimensional polymeric structure with neutral $[Cd(BTTAA)(4,4'\text{-bipy})(NO_3)(H_2O)]$, $[Co(BTTAA)_2(4,4'\text{-bipy})(H_2O)_2]$ and $[Cu(BTTAA)_2(4,4'\text{-bipy})]$ as repeating units, respectively. In **4**, the Cd(II) atom is coordinated by two carboxylato O atoms (O1, O2) from a BTTAA ion (in mode II), two O atoms (O3, O4) from NO_3^-, two N atoms (N1, N2) from two different 4,4′-bipy ligands and one water molecule (Fig. 3a). The geometry around the metal center is a slightly distorted pentagonal-bipyramidal, with two N atoms lying in the axial positions. The Cd–O bond distances lie in the 2.324(3)–2.480(3) Å range, and Cd–N distances are between 2.309(3) and 2.349(3) Å, which is similar to that observed in the complex we reported previously [20]: $[Cd(BTTAA)(phen)_2(H_2O)] \cdot NO_3 \cdot H_2O$. The 4,4′-bipy spacers bridge the Cd(II) atoms with a Cd···Cd separation of 11.729(5) Å, leading to a 1D chain along the crystallographic *c* axis. The most important interchain interaction in the crystal packing is hydrogen bonds (O6–H6A···O1^{i}, O6–H6B···O5^{ii}, Symmetry codes: i $-x+2, -y, -z+1$; ii $x+2, -y-3/2, z-1/2$) among the coordinated carboxylate oxygen atoms, the uncoordinated NO_3^- oxygen atoms and coordinated water molecules. The hydrogen bonds in the structure

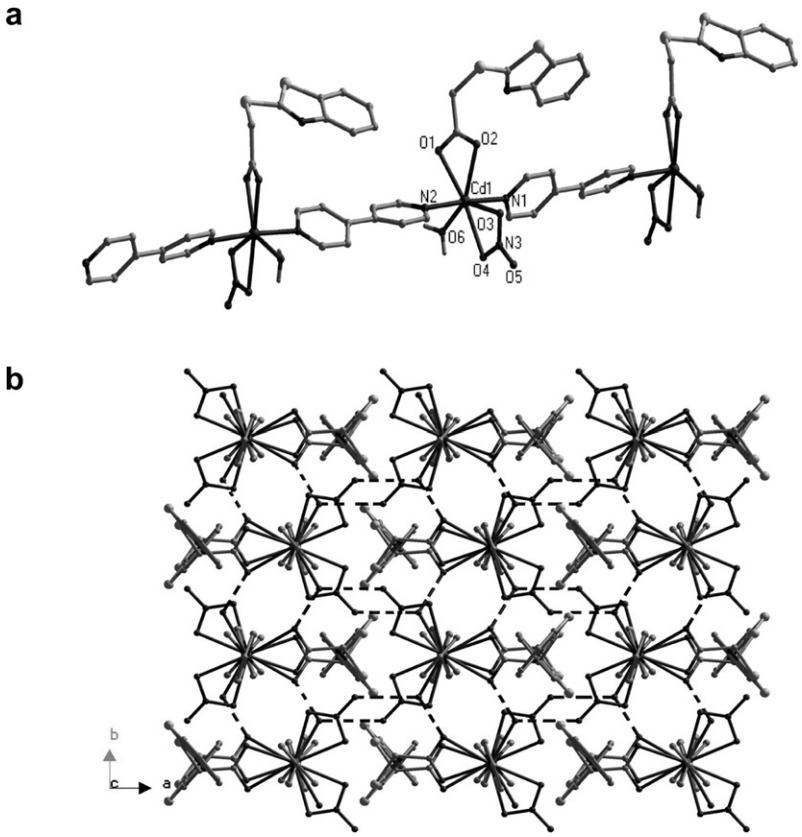

Fig. 3. (a) The coordination environment of the Cd(II) ion in **4**. (b) The 3D supramolecular structure of **4**.

allow the formation of an extended 3D supramolecular framework as shown in Fig. 3b.

As shown in Fig. 4, Co1 in **5** was located on a crystallographic inversion center and coordinated octahedrally by two 4,4′-bipy nitrogen atoms, two BTTAA carboxylato oxygen atoms and two water molecules, giving a CoN_2O_4 octahedron. The 4,4′-bipy spacers bridge adjacent Co(II) atoms with a Co···Co separation of 11.437(3) Å, leading to a 1D chain along the crystallographic *c* axis.

In **6** (Fig. 5), the Cu(II) center is coordinated by two carboxylato O atoms (O1, O3) from two different BTTAA ions and two N atoms (N3, N4) from two 4,4′-bipy ligands. The geometry around the metal center is a slightly distorted square. The 4,4′-bipy spacers bridge adjacent Cu(II) atoms with a Cu···Cu separation of 11.061(1) Å, leading to a 1D chain along the crystallographic c axis. It should be summarized that the carboxylato groups coordinating to the metal atoms in **5** and **6** are all in mode I.

3.2. Magnetic properties

The magnetic properties of the complexes **1**, **2**, 5 and **6** were investigated over the temperature range 2.0–300.0 K and the

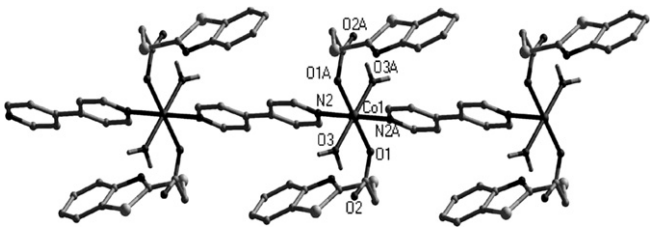

Fig. 4. The coordination environment of Co(II) in **5**.

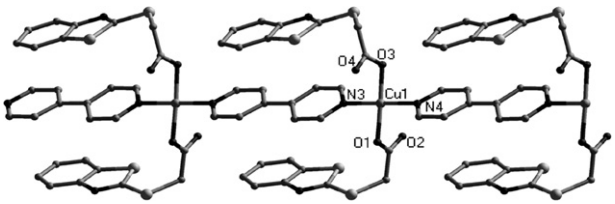

Fig. 5. The coordination environment of the Cu(II) ion in **6**.

resulting data are shown in Fig. 6. For **1**, the μ_{eff} value at 300.0 K is 10.18 B.M., which is characteristic of three independent d^5 ions. As the temperature decreases, μ_{eff} decreases continuously to a value of 5.03 B.M. at 2.0 K (Fig. 6a). This behavior indicates a dominant antiferromagnetic interaction between the Mn(II) ions. As the shortest Mn···Mn distance across the 4,4′-bipy bridge is 11.462(2) Å in **1**, the magnetic exchange coupling through the bridge is expected to be very weak [21]. The observed antiferromagnetic interaction, therefore, should mainly arise from the magnetic superexchange through the carboxylato bridges in the linear trinuclear subunit. For a linear trinuclear compound, the magnetic susceptibility can be calculated using the Hamiltonian $H = -2J(S_1S_2 + S_2S_3) - 2J_{13}S_1S_3$, where J and J_{13} represent the exchange constants between neighboring metal ions bridged by carboxylato groups and between the terminal metal ions, respectively. In the absence of a clearly defined exchange pathway between the terminal metal ions, J_{13} was taken as zero [22]. The best fit to the magnetic susceptibility data yielded $g = 2.02$, $J = -1.33\ cm^{-1}$, $zJ' = -0.08\ cm^{-1}$ and agreement factor $R = 8.77 \times 10^{-4}$.

For **2** (Fig. 6b), when the temperature decreases, μ_{eff} decreases slightly from a value close to 5.88 B.M. at 300.0 K, which is close to the spin-only value for two magnetically isolated high-spin

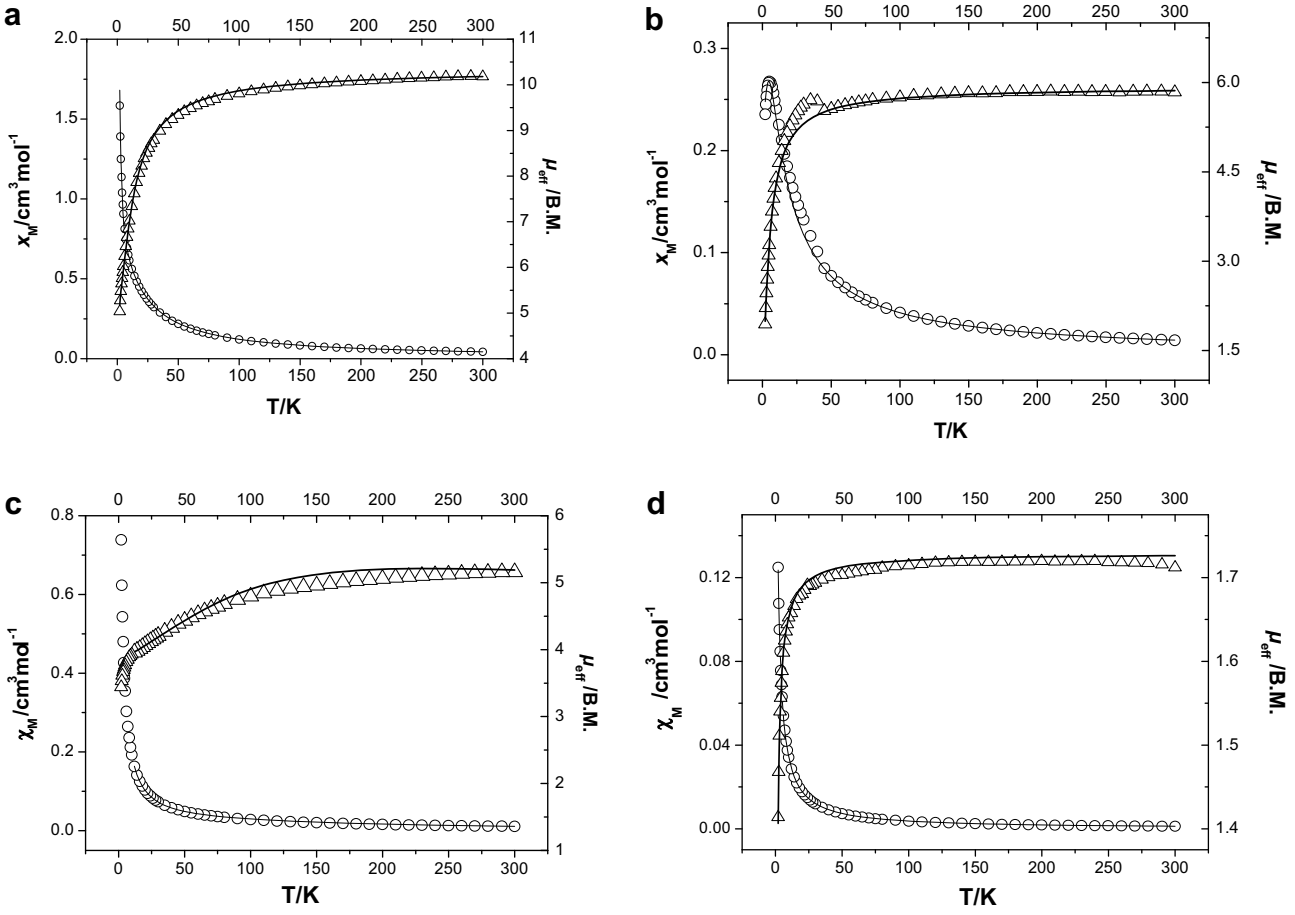

Fig. 6. Plots of the μ_{eff} product (Δ) and χ_M (○) vs. T for the complexes: (a) **1**, (b) **2**, (c) **5** and (d) **6**. The solid lines show the best fit of the data (see text).

Mn(II) ions (μ_{eff} = 5.86 B.M.), to 5.52 B.M. at 47.3 K, indicating a weak antiferromagnetic exchange interaction. From 47.3 to 34.7 K, there is a slight increase in μ_{eff}, with a maximum at 5.71 B.M. [23,24], then μ_{eff} decreases steeply below 34.7 K to a value of 1.94 B.M. at 2.0 K. In **2**, it can be considered that chains, made by the Mn(II) ions bridged by carboxylato bridging ligands, link to each other through 4,4′-bipy ligands. To simulate the experimental magnetic behavior, we used the expression derived by Fisher [25] with an interchain interaction (zJ'). The best fit parameters to reproduce satisfactorily the experimental data are g = 2.00, $J = -0.77$ cm^{-1}, $zJ' = -0.05$ cm^{-1}, $R = 2.6 \times 10^{-3}$.

In the previous literatures, polynuclear Mn(II) complexes bridged by carboxylato groups show weak coupling which is usually antiferromagnetic. In general, the magnitude of $|J|$ increases with the number of carboxylato bridges [26]. In addition, the exchange coupling is highly dependent on the conformation modes of the bridge between the metal centers. The *syn–syn* mode causes the larger $|J|$ value than other tri-atomic carboxylato bridges. In our case, complex **1** shows one *syn–syn* and one μ_2,η_1-carboxylato bridge. Thus the exchange ($J = -1.44$ cm^{-1}) is smaller than that of complexes with double *syn–syn* bridges [27] ($J = -3.5$ to -4.4 cm^{-1}), while it is larger than the values of complexes with double μ_2,η_1-carboxylato bridges [26]. In **2**, the Mn(II) ions are linked through double *syn–anti* mode bridges. The exchange ($J = -0.77$ cm^{-1}) is comparable to those reported for other similar Mn(II) complexes [28].

For **5**, the μ_{eff} value is close to 5.07 B.M. at 300.0 K, which is much larger than the expected spin-only value (3.87 B.M.) of one magnetically isolated high-spin Co(II) ion (S = 3/2). Upon cooling, the μ_{eff} value decreases slightly to 3.44 B.M. at 2 K (Fig. 6c). As the Co···Co distance through the 4,4′-bipy bridge is 11.437(3) Å in **5**, the magnetic exchange coupling through the bridge is expected to be very weak. Therefore, the magnetic behavior should be due to a larger orbital contribution arising from the $^4T_{1g}$ ground state of Co(II) [29]. Taking into account the contribution of the orbital momentum of the Co(II) ion, and considering the very weak magnetic interactions between the paramagnetic ions through 4,4′-bipy bridges, we tried to analyze the experimental data using a magnetic susceptibility equation derived by Miller [30]. The best fit parameters for reproducing satisfactorily the experimental data are g = 2.21, $zJ' = -0.08$ cm^{-1}, $\lambda = -115.6$ cm^{-1} and $R = 1.83 \times 10^{-4}$, where λ is the spin–orbit coupling constant ($\lambda = -176$ cm^{-1} is the free-ion value for Co(II)). The value of zJ' indicates a very weak antiferromagnetic exchange interaction between the metal ions through the 4,4′-bipy bridges.

As shown in Fig. 6d, for **6**, when the temperature decreases, μ_{eff} decreases slightly from a value close to 1.71 B.M. at 300.0 K, which is close to the spin-only value (μ_{eff} = 1.73 B.M.) for one magnetically isolated Cu(II) ion (S = 1/2), to 1.41 B.M. at 2.0 K. This behavior indicates a very weak antiferromagnetic interaction between the Cu(II) ions through the 4,4′-bipy bridges in the structure [31]. Keeping in mind the structure of 6 we have analyzed its magnetic data through the expression derived by Hall [32], which describes well the results of Niclós-Gutiérrez and coworkers [33] on a uniformly-spaced linear chain of local spin S = 1/2. The best fit parameters for reproducing satisfactorily the experimental data are g = 2.00, $J = -0.99$ cm^{-1} and $R = 3.3 \times 10^{-5}$. The value of J is small, as expected for this type of compound, indicating a weak antiferro-

magnetic exchange interaction between the metal ions through the 4,4′-bipy bridges.

4. Conclusion

In this paper, we have presented the synthesis and crystal structures of six low-dimensional coordination polymers using 2-benzothiazolylthioacetic acid and 4,4′-bipyridine as mixed ligands, reacted with Mn(II), Cd(II), Co(II) and Cu(II) ions. There are four coordination modes (monodentate, chelating, bridging and bridging-chelating) in the six complexes. As a result of different reaction conditions, Mn(II) and Cd(II) coordinate with the ligands to form two different complexes. The metal centers are bridged by carboxylato groups as well as 4,4′-bipy molecules in the 2D complexes **1**–**3**. However, only 4,4′-bipy ligands link the metal centers to form 1D complexes in **4**–**6**. Weak antiferromagnetic interactions were observed between the Mn(II) atoms bridged by μ_2,η_2-carboxylato and μ_2,η_1-carboxylato groups in **1** and by μ_2,η_2-carboxylato groups in **2**. There are weak antiferromagnetic interactions between the metal centers bridged by 4,4′-bipy in **1**, **2**, 5 and **6**.

5 Supplementary data

CCDC 665657, 665658, 680195, 680201, 680196 and 680202 contain the supplementary crystallographic data for **1**–**6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

[a] Since the complexes $[Re_{12}CS_{17}(CN)_6]^{n-}$ in the synthesized compound $Cs_6[Re_{12}CS_{17}(CN)_6] \cdot 20H_2O$ and $K_8[Re_{12}CS_{17}(CN)_6]$ are not of the ideal point symmetry D_{3h}, we cite only average characteristic interatomic distances [5].

3. Results

Table 1 shows interatomic distances of the complexes. As is seen, both computed and experimental distances change strongly as functions of the redox state. Table 2 lists predicted charges on the atoms of complexes $[Re_{12}CS_{17}(CN)_6]^{n-}$. Note that the effective charge on the μ_6-C atoms remains almost invariable when the redox state changes. $[Re_{12}CS_{17}(CN)_6]^{6-}$ has a larger absolute bond energy (−309.1 eV) than $[Re_{12}CS_{17}(CN)_6]^{8-}$ (−285.0 eV) and is thus more stable. This result is in a good accordance with experimental data which show that $K_8[Re_{12}CS_{17}(CN)_6]$ is not stable in aqueous solutions and rapidly transforms into $[Re_{12}CS_{17}(CN)_6]^{6-}$ anion [5].

Table 2
Calculated atomic charges in cluster units $[Re_{12}CS_{17}(CN)_6]^{n-}$

The electronic structure of the studied systems stands out by strong redox dependence of the energy level of MO 77a″2 (fig. 2). The splitting ΔE between 30a′2 and 77a″2 is ∼1.07 eV for n = 6 and ∼0.06 eV for n = 8. The molecular orbital 30a′2 consists of 5d

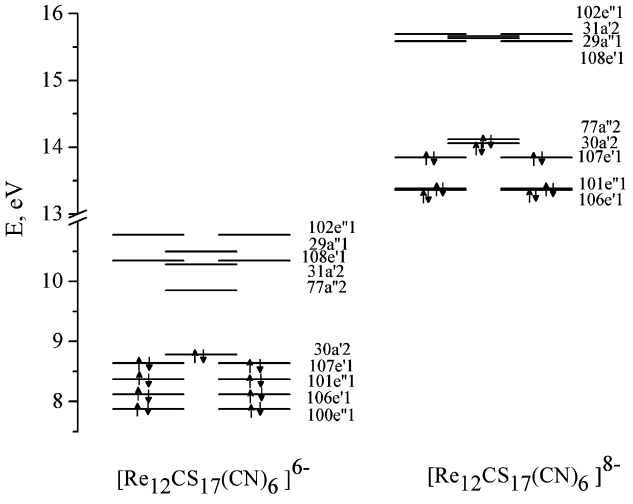

Fig. 2. Energy levels of molecular orbitals for $[Re_{12}CS_{17}(CN)_6]^{n-}$ (n = 6, 8).

valence orbitals of Re (~20%) and 3p orbitals of μ_2-S (~50%) 3p orbitals of μ_3-S^{in} (~30%) with no contribution from the carbon μ_6-C. d-Orbitals of Re^{in} atoms and 3p orbitals of μ_3-S^{in} show a weak bonding interaction between two symmetric groups $\{Re_6S_7\}$. MO 77a″2 consists of valence 5d- and vacant 6d-orbitals of Re (~45%), valence 3p- and vacant 4p-orbitals of μ_2-S (~25%), valence 3p- and vacant 4p-orbitals of μ_3-S^{out} (~17%) and with considerable contribution (~10%) of 2p and 3p orbitals from μ_6-C, but no direct overlap of atomic shells between Re^{in} in two symmetrical groups $\{Re_6S_7\}$ (fig. 3). Comparison of measured and computed interatomic distances suggests that the singularity in interatomic interactions on the redox state changes is "localized" in the vicinity of μ_6-C (Table 1). However, the structure of the molecular orbitals alone cannot clarify the behaviour of interatomic interactions with μ_6-C. Therefore we studied the electronic density in $[Re_{12}CS_{17}(CN)_6]^{n-}$ (n = 6, 8) by the method of electron localisation function.

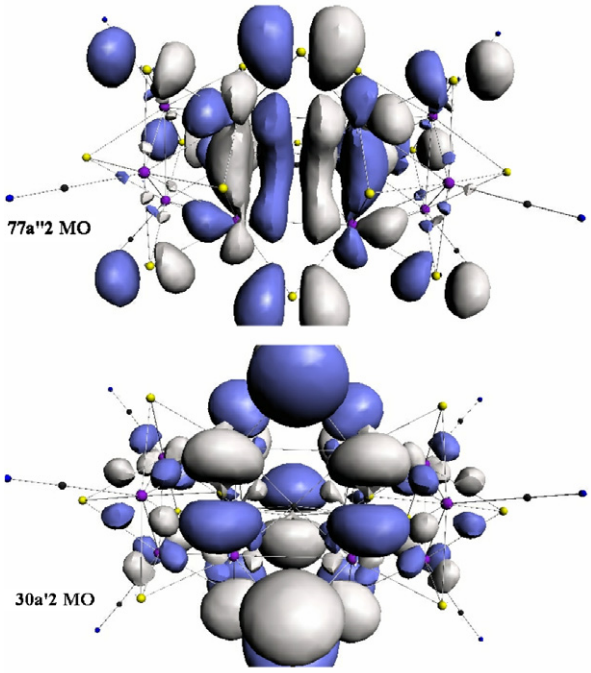

Fig. 3. Schematic 77a″2 and 30a′2 molecular orbitals for $[Re_{12}CS_{17}(CN)_6]^{n-}$ (n = 6, 8).

Figs. 4 and 5 show the results of the topological analysis of the electron density in $[Re_{12}CS_{17}(CN)_6]^{n-}$ (n = 6, 8) in the vicinity of μ_6-C. At ELF ≈ 0.78, the μ_6-C atom has three identical attractors (lone pairs) in the $[(\mu_6\text{-C})(\mu_2\text{-S})_3]$ plane for both complexes $[Re_{12}CS_{17}(CN)_6]^{n-}$ (n = 6, 8). The monosynaptic attractors are directed from the centre μ_6-C of the triangle towards its apexes made by μ_2-S atoms to form the angles 120°. In the vicinity of μ_6-C along the triad axis in the plane perpendicular to the $[(\mu_6\text{-C})(\mu_2\text{-S})_3]$ plane there is yet another region of electron localization (ELF ≈ 0.78) that can be also interpreted as a lone pair. The observed pattern of electron localization suggests that the electron configuration of μ_6-C is made by sp^2-hybrids. Since ELF is close to 0.8 at each of the four attractors corresponding to the three sp^2 hybrid orbitals and the remaining nonhybrid p orbital, the redox state is close to −4 in both complexes (this is in general agreement with the invariant charges of μ_6-C, Table 2).

When the redox state of $[Re_{12}CS_{17}(CN)_6]^{n-}$ changes, the only result is the change in interaction within the systems $[(\mu_6\text{-C})(\mu_2\text{-S})_3]$ and $[(\mu_6\text{-C})\{Re_6\}_2]$. A bonding attractor, or V(Re,Re) disynaptic basin, is seen between each pair of Re atoms at ELF ≈ 0.5. Though ELF is not so high here, it is known that low ELF values associated with covalent bonding between d elements are explained by the fact that electron localization is greatly reduced due the Pauli repulsion exerted by the electron density concentrated in core

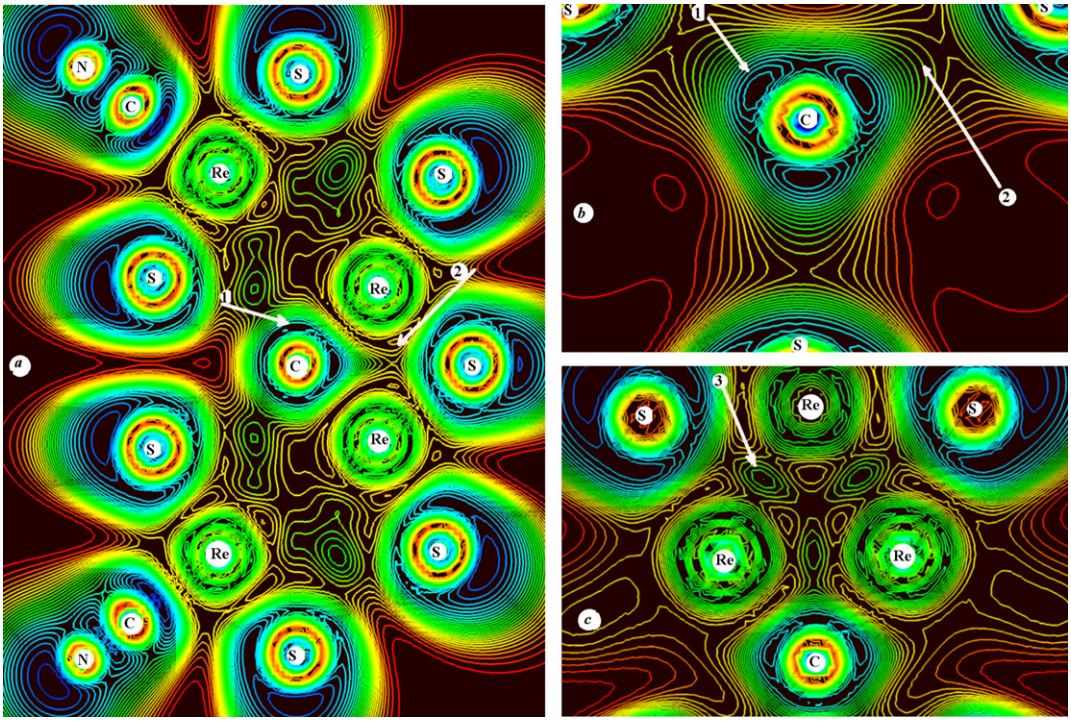

Fig. 4. ELF distribution maps for $[Re_6CS_{17}(CN)_6]^{6-}$ complex: (a) cutting plane Re–(μ_2-S)–Re–(μ_6-C), the Re atoms belong to different symmetry groups $\{Re_6S_7\}$; (b) cutting plane through three atoms μ_2-S and the atom μ_6-C; (c) cutting plane through the atoms Re–(μ_6-C)–Re (the rheniums belong to the same group $\{Re_6S_7\}$). Arrows 1 point to the attractors of sp^2-hybridization, arrows 2 point to the bonding between μ_6-C and μ_2-S, arrows 3 point to the disynaptic V(Re,Re) basins of covalent bond Re–Re.

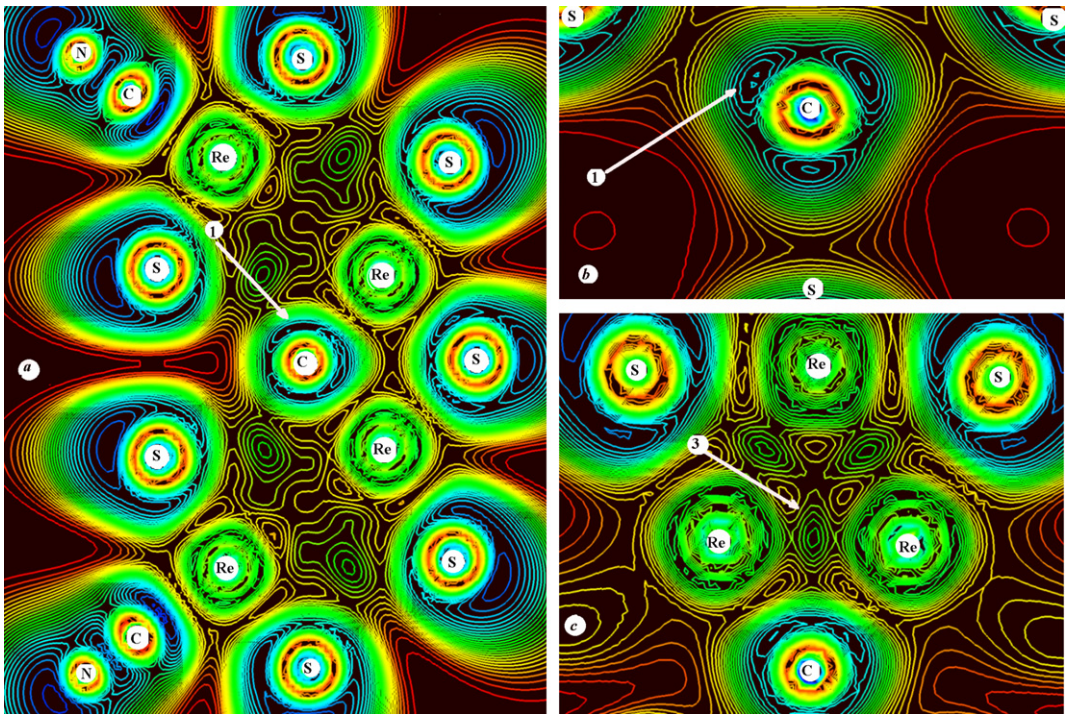

Fig. 5. ELF distribution maps for $[Re_6CS_{17}(CN)_6]^{8-}$ complex: (a) the plane crossing the atoms Re–(μ_2-S)–Re–(μ_6-C), the Re atoms belong to different symmetric groups $\{Re_6S_7\}$; (b) the plane crossing three atoms μ_2-S and the atom μ_6-C; (c) the plane crossing the atoms Re–(μ_6-C)–Re (the rheniums belong to the same group $\{Re_6S_7\}$). Arrows 1 point to the attractors of sp^2-hybridization, arrow 3 point to the disynaptic V(Re,Re) basins of covalent bond Re–Re.

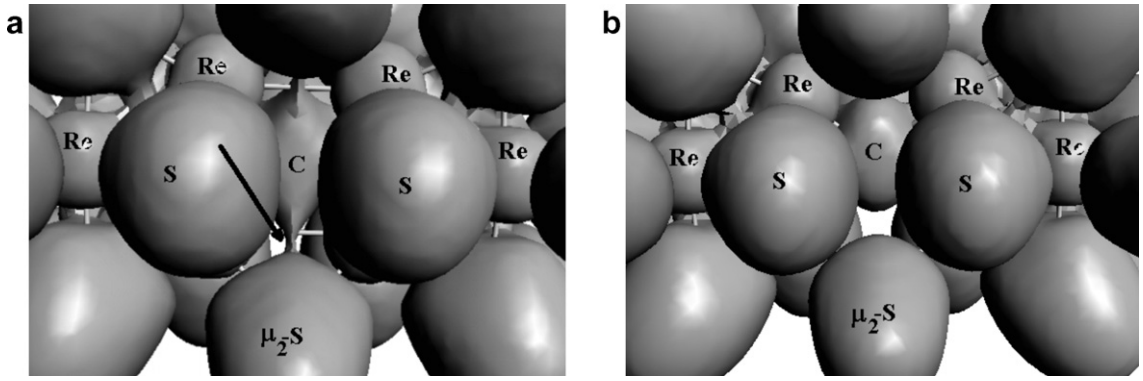

Fig. 6. Isosurfaces ELF = 0.3 for $[Re_{12}CS_{17}(CN)_6]^{6-}$ (a) and $[Re_{12}CS_{17}(CN)_6]^{8-}$ (b). The arrow depicts the bonding between μ_6-C and μ_2-S in $[Re_{12}CS_{17}(CN)_6]^{6-}$, the bonding disappears in $[Re_{12}CS_{17}(CN)_6]^{8-}$.

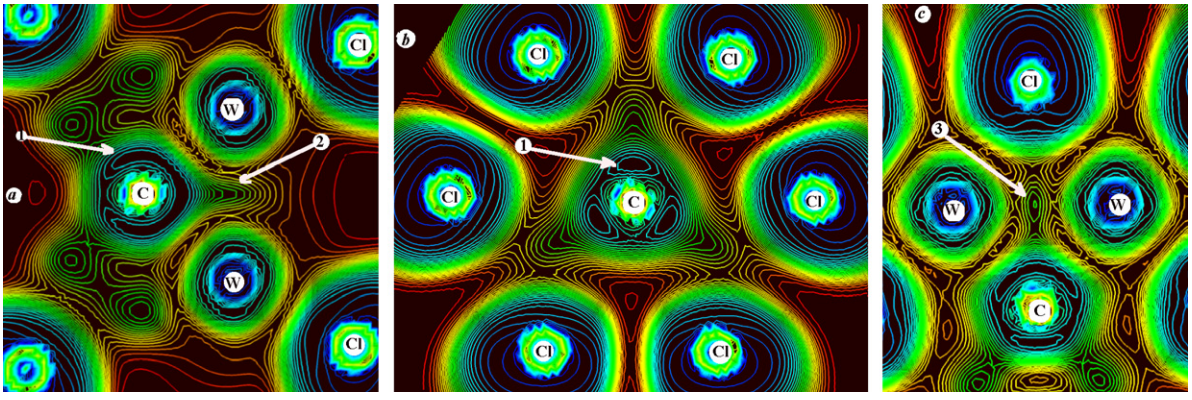

Fig. 7. ELF distribution maps for W_6CCl_{18} molecule: (a) cutting plane through W–(μ_6-C)–W atoms; (b) cutting plane through Cl atoms and the atom μ_6-C; (c) cutting plane crossing the atoms W–(μ_6-C)–W (the W belong to the same fragment $[W_3]$). Arrows 1 point to the attractors of sp^2-hybridization, arrows 2 point to the region between W, arrow 3 points to the disynaptic V(W,W) basins of the covalent bond W–W.

regions [16,18]. The bonding between μ_6-C and Re^{in} in the fragments $[(\mu_6\text{-C})\{Re_6\}_2]$ results from electron exchange that binds the valent area μ_6-C with the V(Re,Re) associated with different levels of electron density localization (ELF ≈ 0.36 for $[Re_{12}CS_{17}(CN)_6]^{6-}$ and ELF ≈ 0.32 for $[Re_{12}CS_{17}(CN)_6]^{8-}$). We characterize this interaction as a multicentered shared electron interaction. At $[Re_{12}CS_{17}(CN)_6]^{6-}$ an unexpected bonding (ELF ≈ 0.3) is seen between μ_6-C and μ_2-S in the group $[(\mu_6\text{-C})(\mu_2\text{-S})_3]$ which is not observed in $[Re_{12}CS_{17}(CN)_6]^{8-}$ (Figs. 4–6).

To compare our results for $[Re_{12}CS_{17}(CN)_6]^{n-}$ with the analysis of the carbon μ_6-C in trigonal prismatic environment of tungsten atoms in $[W_6CCl_{18}]^{n-}$ [3], we studied the electron localization function in diamagnetic W_6CCl_{18} ($n = 0$ and $2S + 1 = 1$) in the vicinity of μ_6-C with ELF function (all quantum-chemical calculations were made in the same manner as for $[Re_{12}CS_{17}(CN)_6]^{n-}$). In isolated molecular clusters W_6CCl_{18}, the atom C was hypothesized to be characterized by sp^2p_z-state with the sp^2 lobes directed to the prism edges, increasing the Cl–Cl distances of the bridges [3]. As is seen in Fig. 7 of the ELF distribution map, the attractors of the lone pairs of μ_6-C atom are indeed directed to the prism edges.

4. Conclusion

The obtained results indicate that the electronic state of μ_6-C in the trigonal-prismatic environment can be interpreted as the one formed by filled sp^2 hybrid orbitals and having the oxidation state ~−4 independently on the redox state of the complexes. It is thus shown that C^{4-} carbide anion can be viewed as a strong electron donor ligand in the trigonal prismatic environment of transition metals, which is in agreement with [3]. The obtained evidence of very weak long-distant (3.454 Å) interactions between μ_6-C and μ_2-S (ELF ≈ 0.3) in the $[(\mu_6\text{-C})(\mu_2\text{-S})_3]$ of $[Re_{12}CS_{17}(CN)_6]^{6-}$ and the absence of such interactions in $[Re_{12}CS_{17}(CN)_6]^{8-}$ is an unexpected result. The discovered interaction between μ_6-C and μ_2-S cannot be of covalent nature since it occurs at the distance ~3.454 Å in complex $[Re_{12}CS_{17}(CN)_6]^{6-}$ and disappears at shorter distances ~3.330 Å in $[Re_{12}CS_{17}(CN)_6]^{8-}$ (a disynaptic attractor could be expected to appear at a covalent bonding when the interatomic distance decreases). According to the classification [13] the observed bonding belongs to the unshared electron interaction. Since the charges on μ_6-C and μ_2-S are negative (Table 2), the interaction between them can be characterized only as an exchange-correlation interaction between closed-shell atoms [20]. We think that the weak electron bonding between μ_6-C and μ_2-S is responsible for shortened Re^{in}–Re^{in} distances in the system $[Re_{12}CS_{17}(CN)_6]^{6-}$. This interaction seems to be substantially weakened when the antibonding MO 77a″2 in $[Re_{12}CS_{17}(CN)_6]^{8-}$ is filled by two electrons and is absent at ELF = 0.3 (Fig. 6) which results in a strong increase of interatomic distances Re^{in}–Re^{in} and a significant change in MO 77a″2 energy (Fig. 2).

The obtained results appear to have important implications for the carbon coordination behaviour in the complexes of transition metals.

Scheme 1. The template condensation between 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde and two linear tetraamines with piperazine moiety in the presence of Mn(II).

In all cases, the [1+1] template cyclocondensation occurs and the metal complexes of the 16-, and 17-membered pentaaza macrocycles L^1–L^4 were obtained.

The template cyclocondensation involving the *N,N′*(2-aminoethyl)(3-aminopropyl)piperazine precursor give rise to Mn(II) complexes of the asymmetrical macrocycles L^1 and L^2, whilst with the 1,4-bis(3-aminopropyl)piperazine amine, the Mn(II) complexes of L^3 and L^4 were obtained. The Mn(II) complexes recorded in Scheme 1 have been obtained. The crystal structures of $[MnL^2Cl(CH_3OH)](ClO_4)$ and $[MnL^4Cl](PF_6)$ are also reported.

2. Experimental

2.1. Chemical and starting materials

2,6-Pyridinedicarbaldehyde was prepared according to the literature method [27]. 2,6-Diacetylpyridine, 1,4-bis(3-aminopropyl)piperazine and the metal salts were commercial products (from Merck, Aldrich and Fluka, respectively) and were used without further purification. Solvents were of reagent grade purified by the usual methods.

Caution: Perchlorate salts are potentially explosive. While we have not experienced any problems with the compounds described, they should be treated with caution and handled in small quantities.

2.2. Synthesis of N,N′(2-aminoethyl)(3-aminopropyl)piperazine

2-Aminoethylpiperazine (2.58 g, 20 mmol) and phthalic anhydride (2.96 g, 20 mmol) were mixed in appropriate beaker and fused at 180 °C with constant stirring for 15 min. After lowering the temperature (at about 160 °C), *N*-(3-bromopropyl) phthalimide (5.36 g , 20 mmol) was also added and fused together at with constant stirring for 30 min. The resulting solid was washed two steps with hot ethanol, pulverized and heated under reflux with HCl (300 ml, 25%) for 12 h. The phthalic acid which formed on cooling was filtered off and the filtrate evaporated to small bulk and poured into absolute ethanol. The resulting viscous precipitate was recrystallized from $EtOH/H_2O$, washed with a small amount of cooled absolute ethanol and diethyl ether, and the resulting yellow powder was dried and characterized as the pure compound (Scheme 2). Yield: 3.15 g (45%). *Anal.* Calc. for $C_9H_{28}Cl_4N_4O$ (MW: 348.1): C, 30.9; H, 8.1; N, 16.0. Found: C, 30.7; H, 8.2; N, 16.1%. FAB-MS (*m/z*): 187 $[M+1]^+$.

2.3. Synthesis of the metal complexes – general procedure

All macrocyclic complexes were prepared according to the literature method [28]. A solution of NaOH (2 mmol) in absolute ethanol (10 ml) was added to a suspension of the appropriate tetramine salt (0.5 mmol) in absolute ethanol (10 ml). The mixture was stirred at room temperature for a few minutes then filtered, and the precipitate was washed well with absolute ethanol (10 ml). The washings and the filtrate were combined and this solution was added dropwise to a hot solution of $Mn(ClO_4)_2 \cdot xH_2O$ (0.5 mmol) and 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde (0.5 mmol) in absolute methanol (20 ml), over a period of 2 h. After refluxing the solution for 24 h it was filtered. Crystalline compound was obtained by slow diffusion of diethyl ether vapour into the MeOH/MeCN solution of the above solid.

Recrystallization of 0.5 g of the above compound in methanol in the presence of an excess of NH_4PF_6 gave brown needle orange crystals of $[MnL^4Cl](PF_6)$. *Anal.* Calc. for $C_{19}H_{31}ClF_6MnN_5OP$ (MW: 580.12): C, 39.3; H, 5.4; N, 12.1. Found: C, 39.5; H, 5.3; N, 11.9%. Yield: 75%.

2.4. Physical measurements

Elemental analyses were performed in a Carlo-Erba EA microanalyser. FT-IR spectra in the 4000–400 cm^{-1} region were recorded from KBr pellets on Bruker VECTOR 22 and Perkin–Elmer GX spectrophotometers. FAB mass spectra were recorded using a Kratos-MS-50T spectrometer connected to a DS90 data system using 3-nitrobenzyl alcohol as the matrix. Magnetic susceptibility measurements were performed at 25 °C using a Johnson Matthey Alfa MSBMKI Gouy balance. Conductivity measurements were carried out in 10^{-3} mol dm^{-3} dimethylformamide solutions at 20 °C using a CARISON GLP32 conductivimeter. ^1H and ^{13}C NMR spectra were recorded on a Bruker 500 MHz using D_2O as solvent.

2.5. X-ray crystal structure determination

Vapour diffusion of diethyl ether into a solution of $[MnL^nCl]^+$ (n = 2 and 4) in mixture of acetonitrile and methanol, afforded crystal suitable for study by X-ray crystallography. The details of the X-ray crystal data, and of the structure resolution and refinement, are given in Table 1. Measurements were made on a Bruker SMART CCD area diffractometer. All data were corrected for Lorentz and polarization effects. Empirical absorption corrections were also applied for all the crystal structures obtained [29]. Complex scattering factors were taken from the program package SHELXTL [30]. The structures were solved by direct methods which revealed the position of all non-hydrogen atoms. All the structures were refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters for all non-hydrogen atoms. The hydrogen atoms were located in their calculated positions and refined using a riding model. Molecular graphics were generated using ORTEP-3 [31].

3. Results and discussion

The new asymmetric amine *N*,*N*′(2-aminoethyl)(3-aminopropyl)piperazine was readily prepared starting from *2*-aminoethylpiperazine, phthalic anhydride and *N*-(3-bromopropyl) phthalimide in a 45% yield.

The FAB mass spectra confirm the presence of the desired final product as it shows a peack at *m/z* 187 belonging to the protonated amine.

The Schiff-base macrocyclic complexes $[MnL^nCl]^+$ (n = 1–4) were prepared from [1+1] cyclocondensation of 2,6-diacetypyridine or 2,6-pyridinedicarbaldehyde and the amine salts of 1,4-bis(3-aminopropyl)piperazine or *N*,*N*′(2-aminoethyl)(3-aminopropyl)piperazine. The complexes were characterised by elemental analyses, IR, FAB-MS, magnetic properties and conductivimetry measurements. The solid compounds are air stable and elemental analyses are consistent with the formulations given in Section 2.

All of the complexes exhibit a ν(C=N) vibration in the range 1633–1650 cm^{-1} and also bands at approximately 1600 and 1450 cm^{-1} associated with $\nu(C=N)_{py}$ and ν(C=C) vibrations from the pyridine and phenyl rings [32]. However no bands are observed for the free carbonyls or primary diamines, indicating that complete condensation has occurred. The IR spectrum of $[MnL^4Cl](ClO_4) \cdot 2H_2O$ is consistent with the presence of water molecules accordingly with the microanalytical data. For the perchlorate complexes, absorptions attributable to perchlorate ions were found at approximately 1100 and 625 cm^{-1} [33]. The lack of splitting of these bands suggests that the perchlorate anions are not coordinated [34].

The molar conductance values of the complexes measured in dimethylformamide lie in the range reported for 2:1 electrolytes in this solvent [35].

Positive-ion FAB mass spectrometry provided further evidence for cyclocondensation and the formation of di-imine complexes. The spectra show that most intense peaks are observed at *m/z* 375, 403, 389 and 477 a.m.u. corresponding to $[MnL^n(Cl)]^+$ (n = 1–4), respectively.

The values of the room temperature magnetic moment of the complexes, 5.44, 5.53, 5.59 and 5.54 BM for $[MnL^1Cl]^+$, $[MnL^2Cl]^+$, $[MnL^3Cl]^+$and $[MnL^4Cl]^+$, respectively are indicative of high-spin Mn(II) in all cases [36]. The high-spin Mn(II) ion possesses a half-filled 3d-shell and thus the coordination geometries of its complexes are not subject to ligand field effects and are determined mainly by the chelating power and geometrical arrangement of the ligands.

3.1. Crystal structures

The crystal structure of the two Mn(II) complexes with formula $[MnL^2Cl(CH_3OH)](ClO_4)$ and $[MnL^4Cl](PF_6)$ have been determined by X-ray diffraction. The projection view of the molecular structures of the cationic unit present in the complexes with non-hydrogen atoms represented by 50% thermal ellipsoids are shown in Figs. 1 and 2, respectively, together with selected bond lengths and angles relating to the coordination environment of the metal (Table 2).

The $[MnL^2Cl(CH_3OH)](ClO_4)$ complex crystallizes in the triclinic $P\bar{1}$ space group and shows that the metal atom is seven coordinated in a pentagonal bipyramidal geometry, arising from coordination by the five N atoms of the macrocycle, one chloride ion and one oxygen atom from a methanol molecule. A similar seven coordinate geometry has been found for other Mn(II) complexes with N5 macrocyclic ligands [37,38]. The ligand shows a nearly plane conformation, and the rms of the plane formed by the five N atoms is 0.0756, showing that these atoms are almost coplanar, with the Mn(II) ion 0.0942 Å out of this plane. The sum of the five N–Mn–N chelate angles (359.96°) is almost 360° for an ideal planar structure. The Cl and O donor atoms are sited *trans* to the macrocyclic plane, with an angle Cl–Mn–O of 170.19(13)°, near to 180°. The five Mn–N bond lengths are in the range 2.246–2.346 Å, affording an average Mn–N bond distance of 2.321 Å. The Mn–Cl and Mn–O distances of 2.5214 and 2.332 Å, respectively, are within the range observed previously for this sort of complexes.

N(5)–Mn(1)–Cl(1)	90.18(13)		

The perchlorate ion is non-coordinating reflecting the low coordination ability of this anion.

No intra- or intermolecular π,π-interactions have been observed in the net.

The $[MnL^4Cl](PF_6)$ complex crystallizes in the monoclinic $P2(1)/c$ space group, and the $[MnL^4Cl]^+$ cation shows the Mn(II) ion in a six coordinated environment into the macrocycle hole interacting

with the five N donor atom of the ligand, whilst the sixth coordination position is occupied by one chloride ion. The geometry can be described as highly distorted octahedral, where the equatorial plane is comprised by N(1) N(2) N(3) N(5) donor atoms, being the apical positions occupied by the chloride ion and the N(4) donor atom. In this case, the $[MnL^4Cl]^+$ cation shows that the ligand is folded due to the presence of two propylene chains between the tertiary amine groups of the molecule, which give rise to a higher flexibility of L^4 compared with L^2. The rms of the equatorial plane is 0.4716 and the Mn(II) ion is 0.6838 Å out of this plane. The five Mn–N bond lengths vary from 2.250 to 2.286 Å, with average Mn-N bond distance of 2.310 Å, similar to previously reported six-coordinate manganese(II) complexes with this kind of ligands, and only 0.01 Å shorter than the average distance in the seven-coordinate complex [39].

The Mn(II) to chlorine distance [Mn(1)–Cl(1) 2.3646 Å], is slightly shorter than the Mn–Cl distances found previously in this sort of complex. The PF_6^- anion is disordered in four of the six fluoride ions of the counter ion with occupancies of 65% and 35% for the two components present.

As in the previous complex no intra- or intermolecular π,π-interactions have been observed.

4. Conclusion

The Mn(II) ion is effective as a template for the Schiff-base condensation of 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde with two different tetraamines having a piperazine moiety. In spite of presence of steric hindrance due to structural restriction of piperazine, cyclocondensation has occurred and pentaaza macrocyclic complexes based on the [*X*]piperazine N_5 rings (*X* = 16 and 17) were obtained. The crystal structures of $[MnL^2Cl(CH_3OH)](ClO_4)$ and $[MnL^4Cl](PF_6)$ were determined and indicate that in the solid state the complexes adopt a pentagonal bipyramidal and a highly distorted octahedral geometry, respectively.

5 Supplementary data

CCDC 649842 and 686394 contain the supplementary crystallographic data for $[MnL^2Cl(CH_3OH)](ClO_4)$ and $[MnL^4Cl](PF_6)$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

(aldehyde/alcohol) and potentially stereoselectivity of the products. Carbon monoxide is a competing ligand in hydroformylation reactions and, since CO is present in high concentration, excess phosphine is often required to avoid the formation of species such as **A** in Scheme 1. An example of this phenomenon was presented by Pruett and Smith [43]. They showed that the yield of the linear aldehyde product increased from 31% to 89% when the number of equivalents of triphenylphosphite was increased from 0 to 60 during the rhodium catalyzed hydroformylation of 1-pentene. The goal is to manipulate the equilibrium in Scheme 1 such that the predominant species is **D**. To this end, CO concentration, ligand concentration, and the nature of PR_3 can be varied. A logical extension is that if the correct NHC is chosen to stabilize **D**-type intermediates, then high selectivities should be achievable without excess ligand.

In a 1997 patent, Herrmann et al. [44] claimed catalytic hydroformylation activity using (COD)RhCl(NHC) (where NHC = 1,3-dimethylimidazolin-2-ylidine) as the catalyst. With 1-hexene as substrate 33.8% *n*-heptanal and 66.2% 2-methylhexanal were formed. Crudden and coworkers [45] followed this patent in the chemistry literature in 2000. Scheme 2 depicts the synthesis of two precatalysts (**1** and **2**) Crudden used in the hydroformylation of styrene derivatives. To form complex **1**, PPh_3 is displaced from Wilkinson's complex with 1,3-bis(2,4,6-trimethylphenyl)imidazol-2-ylidene (**IMes**). Conversion to complex **2** demonstrates the lability of phosphines towards substitution with CO, and is the primary reason for the need for excess phosphine. Once CO is installed, complex **2** is rendered stable to oxygen, but **1** decomposes and must be manipulated under inert conditions. Presumably the first step under hydroformylation conditions (CO atmosphere) is to convert **1** into **2**. The expectation then is **1** and **2** should perform uniformly in hydroformylation reactions but that is not the case; compare entries 1 and 2 in Table 1. Instead, **1** is twice as reactive as **2**. Surprisingly, if one equivalent of PPh_3 is added to **2** then the activity is again equal to **1** (entry 3). This raises questions as to the true identity of the catalytically active species. If the NHC ligand is displaced during hydroformylation then $Rh(CO)Cl(PPh_3)_2$ could be formed, but when tested under similar conditions, the branched to linear ratio was much different (88:12 compared to 96:4 for **2**).

It is still unclear what role the additional phosphine plays, but regardless of the conditions, the precatalyst, or the substrate used, the branched to linear ratio is consistently very high 95:5 (±2).

A report by Crudden and coworkers [46] that describes the clean displacement of **IMes** from complex **1** further complicates the question of active catalyst identity. The implication is the NHC ligands used in hydroformylation reactions are not substitutionally inert. Treating complex **1** with one equivalent of PPh_3 cleanly forms Wilkinson's complex at 60 °C in dichloroethane (Scheme 3). The carbonyl substituted derivative **2** depicted is less reactive towards NHC displacement but eventually loses **IMes** at 80 °C with a $t_{1/2}$ of three weeks. In hydroformylation studies performed by Crudden, the most efficient reactions always have at least one equivalent of PPh_3. Confirmation of detrimental solvent reactivity was demonstrated by simply dissolving **IMes** in dichloroethane to irreversibly form the diimidazolium salt (77% yield), which was characterized by single-crystal X-ray diffraction, and IMesHCl (18%).

The consistent b:l ratios are strikingly similar to those originally obtained by simply using hydridocarbonyltris(triphenylphosphine)rhodium(I) $RhH(CO)(PPh_3)_3$, studied extensively by Wilkinson [47–53]. Under CO atmosphere at 273 K, $RhH(CO)(PPh_3)_3$ quickly converts to the hydridodicarbonylbistriphenylphospine-rhodium(I) complex $RhH(PPh_3)_2(CO)_2$. Addition of one equivalent of styrene results in the detectable formation of two distinct acyl b:l isomers in a 91:9 ratio, which is similar to the ratios of aldehyde products obtained under catalytic conditions [54].

Crudden and coworkers [55] continued to explore hydroformylation, and reported the synthesis of complexes bearing the saturated carbene 1,3-dimesitylimidazolium-2-ylidene (**SIMes**) and various trialkyl phosphines (**3-R**, Scheme 4). Entries 16 and 17 (Table 1) provide a direct comparison of two different NHCs while retaining the same phosphine, namely PPh_3. The catalyst **3-Ph** (TOf = 14) has a TOF twice that of **1** (TON = 8) and the b:l ratios of the resulting styrenic aldehydes are statistically identical. Certainly this rate difference, though small, suggests the active species retains the NHC ligand. A greater spread of steric and electronically adjusted NHCs will provide conclusive evidence.

Clear evidence is presented that the trialkyl phosphine is important during the rate determining step. A one order of magnitude dif-

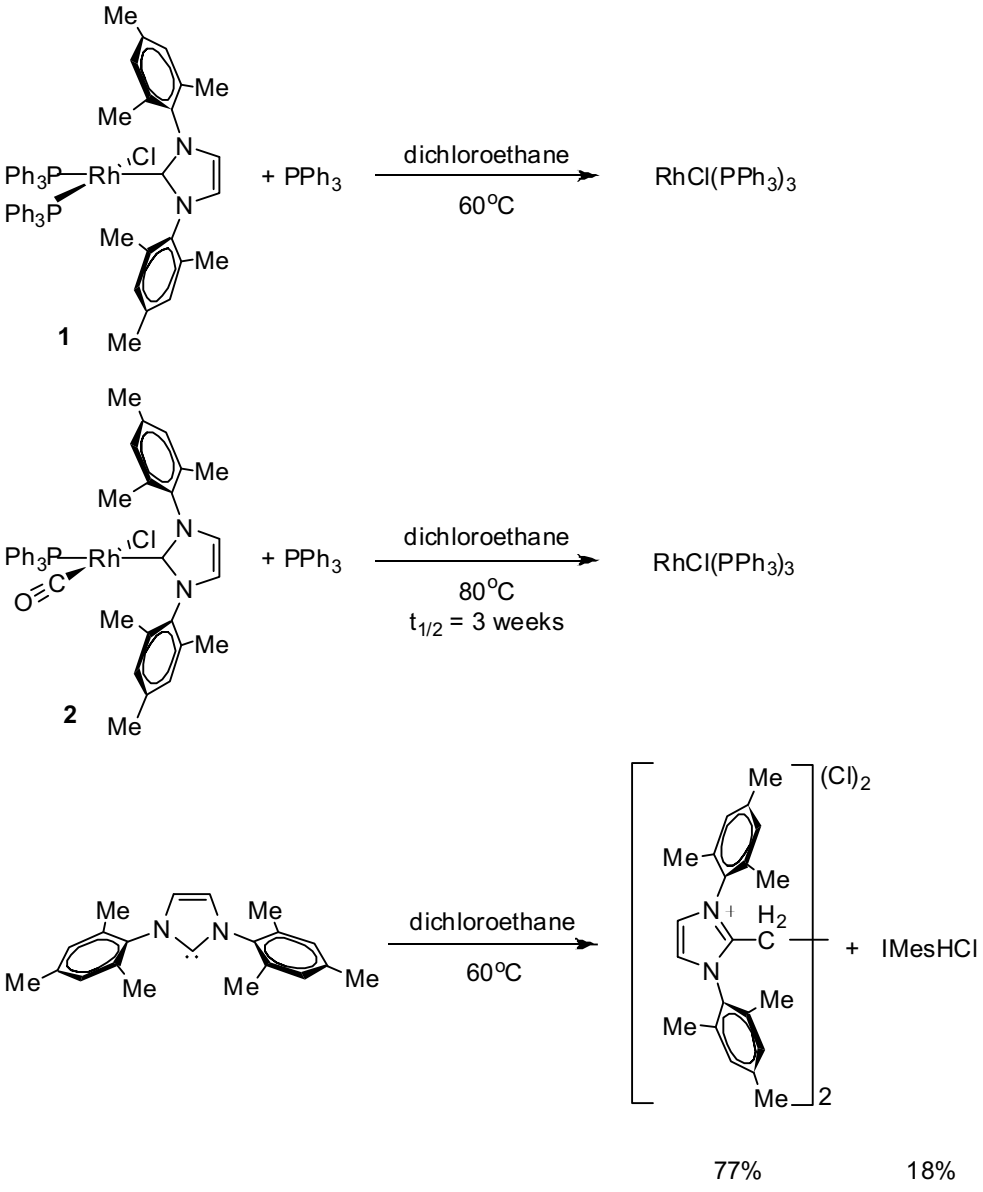
[a] Reaction conditions: substrate (0.8 mmol) in 5 mL benzene under 1000 psi H_2/CO at 60 °C.
[b] DBP = phenyldibenzophosphole.
[c] Catalyst = $Rh(CO)Cl(PPh_3)_2$.

ference in TOF is reported between the electron-withdrawing substituted **3-*p*-FPh** catalyst and the bulky orthomethyltolyl derivative **3-*o*-tolyl**. Switching the *para*-substituent to electron-donating –OMe (**3-*p*-OMePh**) resulted in a less reactive species (compare entries 19 and 20). A peculiar result was observed when **3-OPh** featuring a trialkylphosphite $P(OPh)_3$ was used: the branched to linear ratio dropped to 65:35, though no explanation was provided. Though Crudden et al. state preparation of asymmetric versions of their Rh–NHC complexes is underway, no report of enantioselective hydroformylation has emerged since 2000. This is odd considering the availability of chiral NHCs and chiral Rh–NHC complexes [4,8,10,56]. Surely any amount of enantioselectivity obtained would be conclusive evidence that the NHC remains bound.

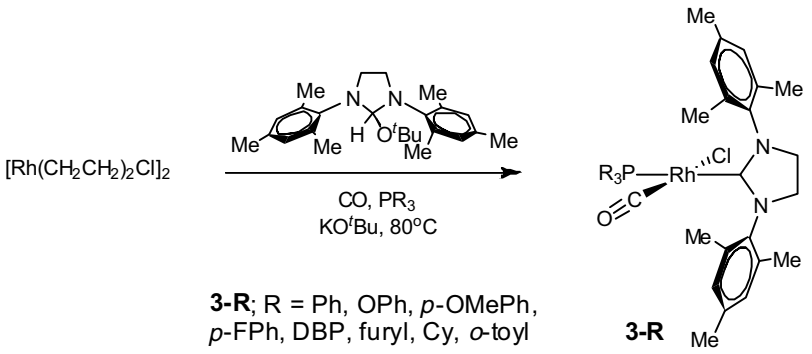
The authors were able to drastically increase the TOF for styrene hydroformylation using the carboxylato derivative **7** described in Scheme 5 [57]. Complex **7** contains one NHC and can be converted to the *bis*-NHC complex **8** by adding an additional equivalent of IPr. Both **7** and **8** were characterized by X-ray crystallography. In this case, when **7** is used as the catalyst under a variety of conditions, a distribution of b:l ratios is observed instead of the consistent 95:5 (±2) discussed above. The authors were able to optimize the conditions for which benzene was solvent: 80 °C, 0.5 mol% **7**, 0.5 mol% PPh_3, and 1000 psi H_2/CO. Again, excellent branched to linear ratios were obtained, but in this case the TOF's were much higher, the best being 515 h^{-1} in the case of 4-chlorostyrene. The authors also examined hydroformylation of the α-olefins 4-phenyl-1-butene and 1-decene and observed b:l ratios of 30:70 and 25:75, respectively (Table 2).

Catalyst **7** is touted as the first example of a square-planar catalytically active rhodium carboxylato complex bearing an NHC ligand. The analogous acetylacetonate complexes **9** and **10** displayed in Fig. 1 do not exhibit hydroformylation activity. Instead, Otto and coworkers [58] tested the stability of **10** using high pressure ^{31}P NMR spectroscopy to simulate real hydroformylation conditions. ^{31}P resonances attributed to **10** quickly disappear under 20 bar CO/H_2 gas and are replaced with two new doublets at 36.9 ppm ($^{1}J_{Rh-P}$ = 140 Hz) and 44.3 ppm ($^{1}J_{Rh-P}$ = 151 Hz), respectively. The authors attribute the resonances at 36.9 and 44.3 ppm to the well-known hydroformylation catalyst precursor $[HRh(CO)_2(PPh_3)]$ and the non-active compound $[Rh(CO)_3(L_2)(PPh_3)]^+$, [59], respectively. The key finding is that complex **10** does not exhibit any hydroformylation activity. However, if PPh_3 is added, then the hydroformylation activity is turned on. The resultant activity is identical to simply using $[Rh(acac)(CO)_2]$ with PPh_3, and no benefit was realized by the preinstalled NHC ligand. Is Crudden's catalyst retaining the NHC ligand? Crudden admits they cannot rule out NHC-free catalytically active species, but also note their yields and selectivities do not match those for $Rh(CO)(acac)(PPh_3)/PPh_3$ mixtures reported by Trzeciak and coworkers [60].

If keeping the NHC ligand bound to the metal center is problematic, then a multidentate NHC ligand may be a solution. Crabtree and coworkers [61–63] synthesized the pincer-type diimidizolium salt **11** (Scheme 6). The dinuclear complex **12** is easily prepared by deprotonating **11** with a mild base (NEt_3) followed by addition of $[Rh(COD)Cl]_2$ at 40 °C. The tridentate Rh(III) complex **13** can be prepared either from **12** by adding an additional equivalent of **11**, or by simply refluxing the initial reaction mixture in aerated CH_3CN in the presence of excess KBr. Additionally, the authors report the synthesis of the chelating bis-NHC rhodium complex **14**. These complexes exhibited high activity for the hydrosilylation of alkynes and olefins, and in the hydrogen transfer from alcohols to ketones. Subsequently, Peris and coworkers [63] tested **12** and

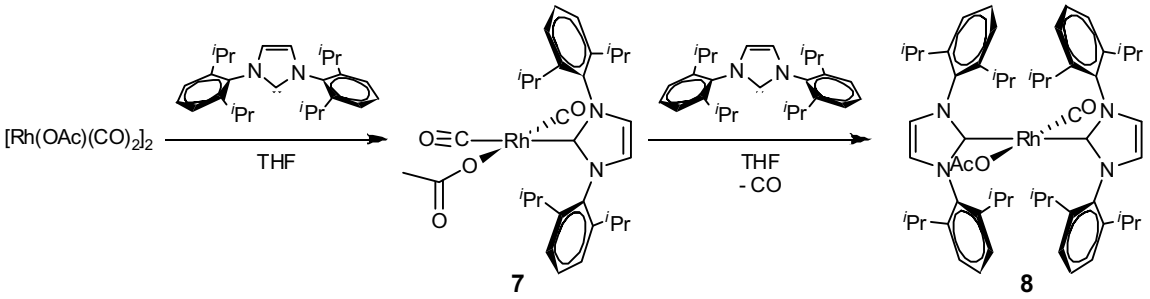


Scheme 3.



Scheme 4.

14 as hydroformylation precatalysts and obtained branched aldehyde in quantitative yield when complex **12** was used. Boosting the temperature and pressure to 40 °C and 80 atm provided 100% conversion and maintained a very high b:l ratio of 97:3 (Table 3, entry 5). Catalyst **12** is not particularly selective for linear alkenes and only provided 43% branched aldehyde for 1-octene.



Scheme 5.

Table 2
Hydroformylation of alkenes catalyzed by **7**[a]

Entry	Alkene	TOF (h^{-1})[b]	b:l
1	Styrene	338	96:4

[a] Reaction conditions: 0.5 mol% of 7, 0.05 mol% of PPh_3 in ca. 1.0–1.2 M benzene solution of substrate under 1000 psi (CO/H_2).
[b] TOF's determined after 1 h by ^1H NMR using an internal standard.

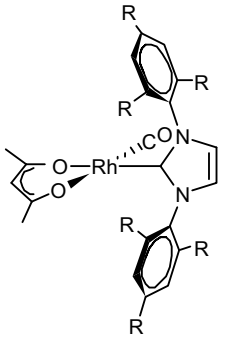

Fig. 1.

Surprisingly, the bis-NHC complex **14** showed zero activity towards hydroformylation of styrene even under harsh reaction conditions (80 °C and 80 atm).

Another approach to stabilizing active Rh(I) hydroformylation catalysts is to use a hemilabile ligand. Green and coworkers [64,65] prepared the first example of a stable crystalline noncyclic imino NHC according to Scheme 7. The stable carbene was structurally characterized and is a significant achievement, considering an earlier report indicated these ligands can undergo [1,2]-rearrangement prior to metallation [66,67]. Access to the free carbene enabled the synthesis of complex **17** according to Scheme 6. Complex **17** was tested for activity in the hydroformylation of 1-octene. The yields of aldehydes reached >99% but l:b ratios were unremarkable (1.2) at high pressure and temperature. Under milder conditions (60 °C, 10 bar) a l:b ratio of 2.5 was observed but only 30% of the olefin was converted to aldehyde products.

Raubenheimer and coworkers [68] pursued the hydroformylation of 1-hexene using Rh(I) precursors with particular focus on the potential activity when thione ligands (C = S, Chart 1) were employed. The authors prepared numerous complexes by varying the combinations of ligands presented in Chart 1. Several of the combinations included either monodentate NHC_R (R = Me, ^{i}Pr) or bidentate NHC–NHC ligands. The composition of Rh catalysts containing at least one NHC ligand combination are as follows: $Rh(COD)NHC_{Me}Cl$, $[Rh(NHC_{Me})_2]Cl$, *cis*-$Rh(CO)_2NHC_{Me}Cl$, *trans*-$Rh(CO)(NHC_{Me})_2Cl$, $[Rh(COD)(NHC–NHC)]PF_6$, $[Rh(CO)_2(NHC–NHC)]PF_6$, $Rh(CO)(C=S)NHC_{Me}Cl$, $[Rh(COD)(thione)NHC_{iPr}]BF_4$, $[Rh(CO)_2(thione)NHC_{iPr}]BF_4$, $Rh(CO)(PPh_3)NHC_{iPr}Cl$, $Rh(CO)[P(thiazole)_3]NHC_{iPr}Cl$. The authors present hydroformylation results obtained under a variety of conditions, but it is apparent that no benefit is obtained by including the NHC ligand in the catalyst precursor. The percent conversion, yield of aldehyde, and b:l ratio are all similar to those obtained by simply using Wilkinson's complex.

Buchmeiser, Nuyken, Weberskirch and coworkers [69,70] examined the hydroformylation activity of a series of compounds in which the NHC heterocycle is 1,3-R-3,4,5,6-tetrahydropyrimidin-2-ylidene (R = ^{i}Pr, and Mes; see Fig. 2.). Not surprisingly, the chloro (**18-Cl, 19-Cl**) and bromo (**18-Br, 19-Br**) derivatives displayed identical reactivity, implying an active catalyst of the general formula $Rh(CO)_2(H)NHC$. Gratifyingly, significant differences were observed in the initial TOF between catalyst **18-Cl** and **19-Cl** bearing *N*-^{i}Pr and *N*-Mes groups, respectively. Complex **19-Cl** exhibited a TOF of 1500 h^{-1}, whereas under identical conditions **18-Cl** only turned over at a pace of 520 h^{-1}. None of the catalysts were particularly selective for the formation of aldehydes, but convincing evidence for an NHC-bound active catalyst was finally realized.

Immobilization of well-defined, air-stable, and recyclable polymer-supported NHC catalysts and their application in Heck reactions was first reported in 2000 [71]. Following this approach, Weberskirch and coworkers [72] synthesized the unsymmetrical, monohydroxy-functionalized rhodium NHC complex **20** with the intent to attach an amphiphilic polymer to enable biphasic hydroformylation catalysis (Scheme 8). Complex **20** catalyzes the hydroformylation of 1-octene in benzene with a inspiring TOF of 2400 h^{-1}, the fastest to date, however selectivity was unremarkable (l:b = 0.67). However, when the supported complex **21** is employed under biphasic conditions (water/1-octene) the ratio increases to 2.6 and the initial TOF is 1100 h^{-1}, which indicates a definite change in the steric environment of the active metal center once supported. The authors demonstrated that **21** was easily recyclable and the TOF increased to 2320–2360 h^{-1} after recycling twice, identical to the unbound catalyst, but the l:b ratio declined to 1.2 and then remained constant. The pronounced increase in TOF was attributed to slow catalyst activation which requires approximately 4 h to fully activate each metal center. To summarize this work, NHC–Rh(I) precatalysts can be attached to polymer supports and retain their activity. More importantly, the supported Rh(I) catalyst is *air* and *water* stable, thereby enabling catalysis under biphasic conditions to facilitate product separation and catalyst recycling.

Co–NHC complexes have received considerably less attention than Rh–NHCs despite the fact NHCs may actually be better suited to cobalt. That is, basic phosphines work well with Co whereas less basic phosphines and phosphites provide the best Rh catalysts [38]. If the purported electronic correlation between NHCs and trialkylphoshines is true, then Co–NHC catalysts should prove effec-

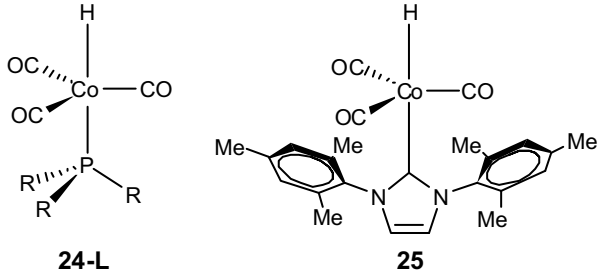

Fig. 3.

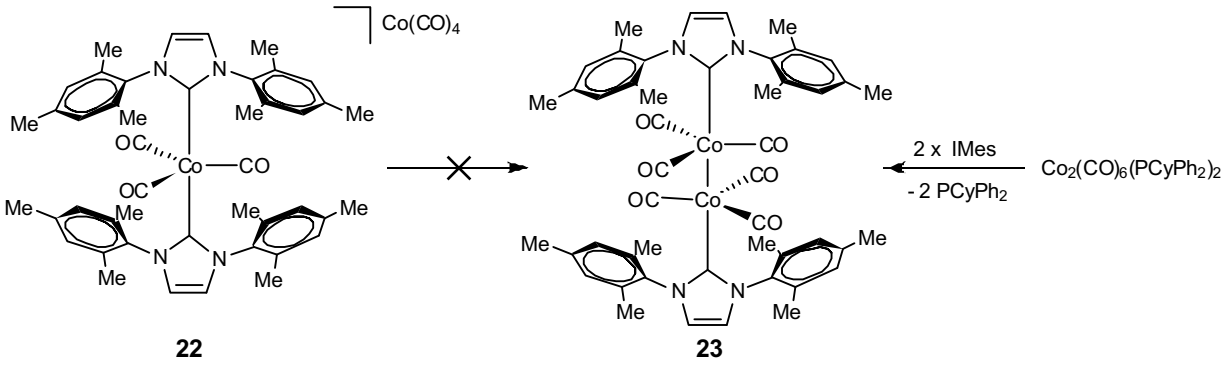
tive as hydroformylation catalysts. van Rensburg et al. [73,74] synthesized the disproportionation salt **22** by treating Co_2CO_8 with two equivalents of **IMes** (Scheme 9). The salt is surprisingly stable and does not spontaneously convert to dimer **23**, as do the phosphine derivatives $[Co(CO)_3P_2][Co(CO)_4]$. The authors note the strong σ-donor phosphine derivative, where P = P^{n}Bu$_3$, converts to the dimer much more slowly than when P = PPh$_3$. Thus, the apparent stability of **22** may be due to the exceptionally strong σ-donor capability of **IMes**. Regardless, the dimer can be synthesized by treating $Co_2CO_6(PCyPh_2)_2$ with two equivalents of **IMes**. However, when **23** is treated with 1-octene and syngas (H_2:CO = 2:1) at 60 bar and 170 °C, a dark brown oily compound precipitated which was identified as the imidazolium salt [1,3-bis(2,4,6-trimethylphenyl)imidazolium][$Co(CO)_4$].

Despite detrimental decomposition Llewellyn, Green, and Cowley [75] were able to isolate the Co–H complex $Co(CO)_3$HIMes (**25**) by treating the corresponding acyl species $Co(CO)_3$(COMe)IMes with hydrogen (Fig. 3). The authors note **25** is solid-state stable in the absence of oxygen and moisture and only 15% decomposition occurs after 7 d in solution. This is in contrast to the phosphine versions Co(L)$(CO)_3$H (**24-L**; L = P^{n}Bu$_3$, PPh$_3$, P(OPh)$_3$, and PF$_3$) which dimerize at room temperature. The Co-hydride complex **25** was examined for activity in the hydroformylation of 1-octene. With 8 atm of syngas (H_2/CO) at 50 °C for 17 h and 1 mol% **25**, 47% conversion to aldehyde products was achieved. Surprisingly 83% of the product was the internal aldehyde 2-methyl-octanal. Presumably 1-octene is rapidly isomerized to 2-octene followed by hydroformylation. The authors only present one catalytic result, but if the improved stabilization is indeed due to better σ-donation of NHCs over phosphines, then more Co–NHC catalysts should be forthcoming.

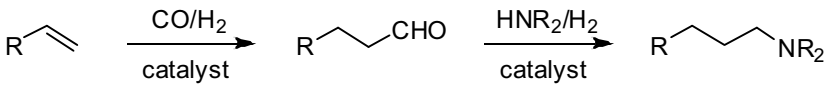
3. Hydroaminomethylation

Hydroaminomethylation is a direct and efficient method of generating higher value amines from inexpensive feedstock alkenes and syngas [76–78] (Scheme 10). Application of this reaction has procured key pharmaceuticals, agrochemicals, and natural products, most notably the 3,3-diarylpropylamines depicted in Fig. 4 [79–86]. Hydroaminomethylation is essentially hydroformylation coupled to amine-aldehyde condensation followed by hydrogenation. The key reaction is hydroformylation, since this reaction establishes the regiochemistry, and the hydrogenation step determines the chemoselectivity between amine and eneamine products. Once the aldehyde is formed and as long as the catalyst can serve a dual role to catalyze hydrogenation, the amine product forms. Considering the discussion above regarding hydroformylation, hydroaminomethylation is a logical reaction to try with Rh and Co based NHC complexes.

Beller and coworkers [87,88] are the first to report hydroaminomethylation with an NHC supported catalyst. The authors screened a series of catalysts depicted in Fig. 5. Initially catalyst **26** was used in the hydroaminomethylation of 1- and 2-pentene with piperidine. The results varied dramatically with changes in



Scheme 9.



Scheme 10.

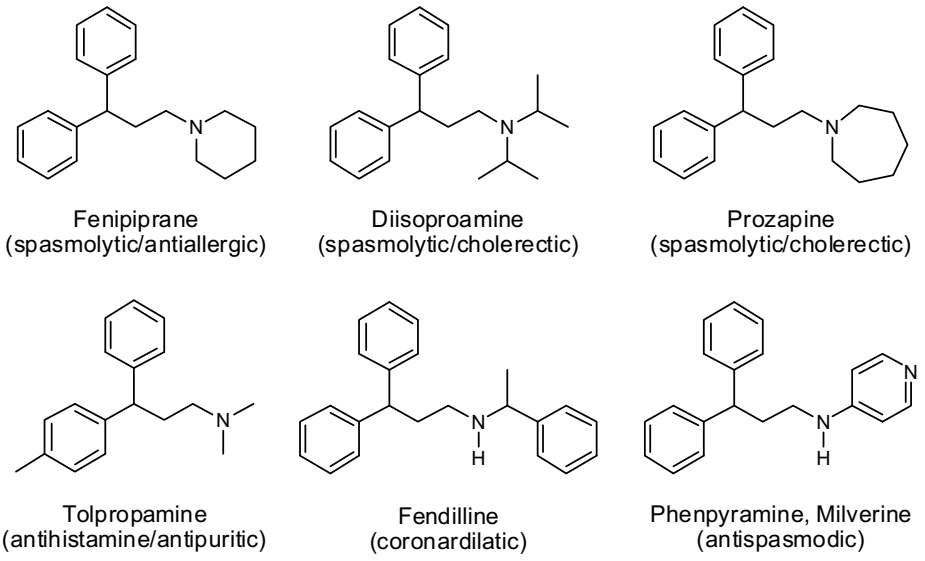


Fig. 4. Pharmaceutically active 3,3-diarylpropylamines (pheniramines) [87].

pressure of H_2/CO, temperature, and solvent. The best result obtained converted 99% of 1-pentene into 99% amine with a l:b ratio of 62:38, which is fairly typical for the Rh-NHC hydroformylation catalysts discussed above. $[Rh(COD)Cl]_2$ will catalyze the reaction faster, but unselectively, and decomposes to Rh(0) during catalysis.

When 1,1-diarlyethylenes are used, only linear products are formed due to the sterics of the substrate, not the catalyst. The authors optimized conditions for the general reaction of 1,1-diphenylethylene and piperidine displayed in Scheme 11 and note that the highest TOF (288 h^{-1}) for this specific reaction is obtained using complex **29**, syngas (H_2:CO = 5:1), at 125 °C for 24 h. Similarly, prozapine, fendilline, and diisopromine were obtained in 85%, 91%, and 88% yield, respectively, using the one-pot method. The authors were able to demonstrate that Rh–NHC-catalyst activities compare favorably with the established the Rh-Xantphos system [89]. The authors also note the first one-step synthesis of Milverine (an important antispasmodic agent) was achieved, which was previously unattainable since the aldehyde intermediate is susceptible to reduction [90]. This represents a clear example of the potential benefit of Rh–NHC catalysts over Rh-PR_3 complexes.

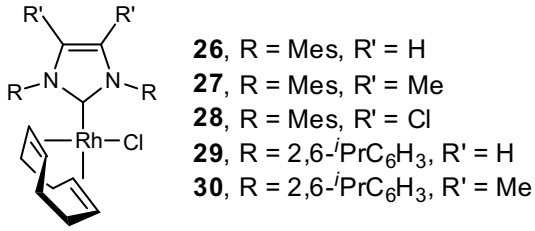

Fig. 5.

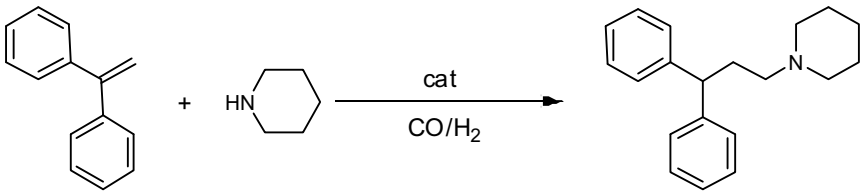
4. Carbonylation of aryl halides

Incorporating CO as a one-carbon synthon to form organic acids from organic halides is routinely catalyzed by Pd catalysts bearing



Scheme 11.

ubiquitous trialkylphosphine ligands [91–95]. The problem, or opportunity to improve, occurs when harsh conditions are required to carbonylate less reactive C–X bonds such as aryl-chlorides. Catalyst degradation via P–C [39–42] bond cleavage typifies the need for more robust ligands. Benzothiazole carbene ligated Pd complexes are stable to high temperatures, oxygen and moisture and exhibit activity in C–C coupling reactions. Complex **31** was first reported in 2000 [96] and was subsequently tested as a catalyst in the carbonylation of aryl halides [97]. When complex **31** is used as the precatalyst, activated aryl halides are carbonylated in good yield under 1 atm pressure of CO (Table 4). The less reactive bromobenzene required additional additives to achieve reasonable conversion (Fig. 6).

Some questions regarding the identity of the active catalyst remain. That is, the best results are always obtained when PPh_3 is present during catalysis, suggesting the benzothiazole carbene may be substituted. However, when just $Pd(OAc)_2$ and PPh_3 are used, the system loses reactivity when recycled, and Pd(0) forms. In contrast, complex **31** can be recycled seven times with only a 10% drop in product yield, and no Pd(0) is observed. In addition to the above study, a few reports have appeared describing the Pd catalyzed methoxycarbonylation of aryl and alkyl iodides in ionic liquids (IL). The ionic liquids are imidazolium salts, and NHC–Pd species have been proposed as the active species, though conclusive evidence remains elusive [98,99].

5. Oxidative carbonylation of amino compounds

The formation of *N*-containing carbonyl compounds such as ureas, carbamates, and 2-oxazolidinones (Scheme 12) traditionally requires the use of phosgene or its derivatives [100]. These toxic pollutants have been replaced by the direct metal-catalyzed carbonylation of amino compounds, most notably $W(CO)_6$ [101]. Some of the catalytic reactions require harsh conditions to obtain reasonable yields and often require the additives KI or I_2. If high pressures of CO are required and water is a byproduct, then strong σ-donating NHCs may be well-suited ancillary ligands.

The NHC–Cu complexes **31-X** (X = Cl, Br, I) [102] were tested as catalysts for the oxidative carbonylation of amino alcohols (Fig. 7). The authors note that **31-I** is the first catalyst to selectively prepare the three different *N*-containing carbonyl derivative types displayed in Scheme 12, and furthermore, no additive was required. Table 5 shows the counterion is critical to achieving complete conversion and the NHC ligand improves upon the use of CuI alone. **31-I** will also catalyze the oxidative carbonylation of primary amines to yield ureas and carbamates. *N*-Propylamine, *n*-butylamine, and *t*-butylamine were transformed to the corresponding ureas, and when CH_3OH was used, the carbamates were isolated in yields ranging from 86% to 98%. **31-I** will not convert aromatic amines, presumably due to their lower basicity.

Subsequently, the authors prepared the series of Pd(II)–NHC complexes depicted in Fig. 8 [103]. These complexes also catalyze the oxidative carbonylation of amino compounds and exhibit high TOFs (Table 6). Unlike the Cu–NHC-catalyst **31-X**, **32-L** will catalyze the oxidative carbonylation of a variety aromatic amines. For example, 4-Me–C_6H_4–NH_2, 4-Cl–C_6H_4–NH_2, 4-Me–C_6H_4–NH_2, 2,4-Me_2–C_6H_3–NH_2, 2,6-Me_2–C_6H_3–NH_2, and 4-Ac–$C_6H_3NH_2$ are converted to the corresponding ureas after 1 h at 150 °C, with only 0.02 mol% **32-an** in 99%, 87%, 85%, 72%, and 60% isolated yields, respectively (P_{CO/O_2} = 3.2/0.8 MPa).

6. Oxidative carbonylation of phenolic compounds

Metal catalyzed oxidative carbonylation can also be used to synthesize aromatic polycarbonates (PCs) which are desirable materials [104]. The motivation in PC synthesis is to avoid the

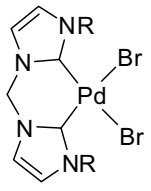
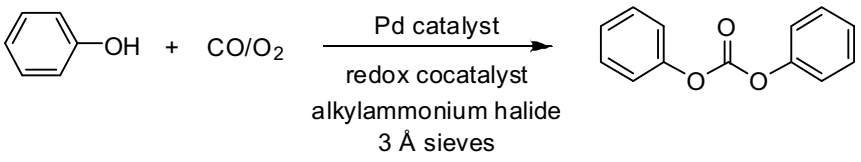
conventional employment of phosgene, which is normally treated with bisphenol A under interfacial polycondesation conditions. Transesterification from diphenyl carbonate (DPC) is advantageous but DPC is itself synthesized using phosgene and sodium phenolate or dimethyl carbonate with phenol. Catalysts that can directly car-



33-R

R = Me, Et, ^{n}Bu, ^{t}Bu, ^{c}Hex, Ph, Mes

Fig. 9.



Scheme 13.

bonylate bisphenol A to efficiently provide DPC or PCs with high molecular weights would be advantageous. Simple metal salts such as PdX_2 (X = Cl, Br) produce PCs with low molecular weights, and some improvements are made by utilizing bipyridyl ancillary ligands, but none provide materials deemed useful for industry.

Sugiyama and coworkers [105] explored the synthesis of DPC using the catalysts in Fig. 9 which were synthesized according to or adapted from known procedures. The premise for using NHCs is to take advantage of their strong σ-donation capability to create longer-lived catalysts which may lead to longer chained polymers. The authors attempted to directly carbonylate phenol to form DPC which is then converted to PCs, without phosgene. The catalyst system is complicated and requires an inorganic redox active cocatalyst, alkylammonium halide, sieves and the NHC-catalyst **33-R** (Scheme 13). The best results were obtained with **33-^{t}Bu**, $Ce(TMHD)_4$ (TMHD = 2,26,6-tetramethyl-3,5-heptanedionate), hydroquinione, $^n Bu_4NBr$ and 3 Å molecular sieves which provided DPC in 45% yield with a TOF of 50.7 (mol-DPC/mol-Pd h).

Eventually the authors discovered they could catalyze the formation of polycarbonate with **33-R** via oxidative carbonylation of bisphenol A [106]. Using similar conditions and **33-^{t}Bu** a polycarbonate with M_w = 24 000 and M_n = 9400 was obtained in 80% yield. The authors note the polymer obtained has the highest molecular weight synthesized directly from PC via oxidative carbonylation of bisphenol A and is comparable to commercially available PC.

The properties and yield of the polymer product are directly related to the NHC used, providing clear evidence the NHC ligand is bound and influencing the reaction. Smaller R groups (Me, Et) on **33-R** provided low molecular weights and yields, and detectable amounts of cross-linked salicylate byproduct were observed. The above study only examined the influence of sterics on the formation of polycarbonate. Considering the copious NHCs now available and the ability to dramatically change their electronic and steric properties, this reaction is ripe for further optimization. Clearly this reaction exemplifies the general thought that creating a stable catalyst by incorporating an NHC ligand will lead to longer catalyst lifetimes. Extension of this technology has already been applied to NHC ligands tethered to a styrene bead [107].

7. Copolymerization of alkenes and CO

Guided by the principle that switching to NHC ligands may improve catalyst lifetimes and enhance reactivity, Herrmann and coworkers [108,109] examined the copolymerization of CO and ethylene. Their catalyst design was based upon the exceptional work by Drent and Budzelaar who demonstrated monocationic and dicationic *cis*-chelating phosphine complexes of the general formula $[L_2Pd(solvent)Me]^+$ and $[L_2Pd(solvent)_2]^{2+}$ are active catalysts for copolymerization [110]. By analogy then, a *cis*-chelating NHC complex of the form $[NHC_2Pd(solvent)Me]^+$ or $[NHC_2Pd(solvent)_2]^{2+}$ should also catalyze this polymerization. Accordingly, the complexes **36-R$_X$** (R = Me, X = BF_4, and R = Mes, X = PF_6) were synthesized using standard procedures in CH_3CN (Scheme 15). Table 7 highlights some of the results from the study and entry 2 in particular, shows the best conditions. Under identical conditions (entries 2 and 6) catalyst **36-Mes$_{PF6}$** performed better than **36-Mes$_{BF4}$** by providing 810 and 324 g polymer/g Pd, respectively. Apparently three equivalents of *p*-benzoquinone was the ideal amount of oxidant required as any more or less was detrimental. The authors were unable to determine the identity of the active catalyst but did note that not all of the Pd metal centers were activated. The polymer obtained melted between 250 and 260 °C indicating high purity. The estimated average molecular weight of the copolymer is exceedingly high, even higher than that obtained by Drent. The catalysts are inactive for CO/propene and CO/styrene copolymerization.

Surprisingly, only one other report has surfaced for M–NHC catalyzed copolymerization of CO/alkenes since 1999. Again, by analogy to known pyridylphosphine hemilabile ligands, Chen and Lin [111] synthesized the imidizaolium salt **37**. Subsequent metallation with $Pd(OAc)_2$ generated the bis-NHC dication **38** that features a hemilabile pyridyl-NHC ligand (Scheme 16). Indeed, spectroscopic and reactivity studies indicate the pyridyl arms are fluxional and labile enabling the catalyst to copolymerize CO and norbornene. The copolymer can be synthesized in 87% yield by employing 0.5 mol%

38, and 750 psi CO gas after 3 d at 60 °C. The polymer formed contained ~37 repeat units and M_w = 4660 and M_n = 3790.

8. Conclusions

Tremendous economic and environmental benefit can be realized if CO is efficiently and catalytically incorporated into organic substrates to create higher value products. Exemplary cases presented herein include the hydroaminomethylation of simple vinylic arenes to produce a variety of useful pharmaceuticals in a one-pot reaction (Fig. 4), and the phosgene-free carbonylation of amino and phenolic compounds (Schemes 12 and 14). The purpose of this review was to examine the extent M–NHC catalysts will promote reactions that use CO as a C1-carbon source. Though the first catalytic reaction incorporating CO by a M–NHC was reported in 1997, only a small set of reactions have emerged that clearly benefit from the presence of a NHC ligand. Certainly, a case can be made that M–NHCs can compete with traditional M–PR_3 catalysts, and can in some instances out-perform them. However, this review reveals, or at least adds to, growing evidence that NHCs are not substitutionally inert. The notion that NHCs are stronger σ-donors than even the most basic phosphine does not, in all cases, translate into better catalysts. Hydroformylation is the most extensively studied reaction involving CO, and the results are somewhat mixed. Exceptionally high b:l ratios for vinylic arenes are achieved for a variety of M–NHC precatalysts but the identity of the active species is still unclear. Non-aromatic 1-alkenes are hydroformylated with only average b:l ratios, and no clear benefit is obtained by the presence of an ancillary NHC. Surprisingly, after nearly one decade, no enantioselective hydroformylation has been achieved by M–NHCs. These results are perhaps symptomatic of the glaring omission of a singular experimental mechanistic investigation. The activity of NHC versus PR_3 ligands in metal-catalyzed hydroformylation has been explored by computation [112] but focused mechanistic work is sadly absent.

Acknowledgments

collected at 298 K. The reported results are referenced to SCE in MeCN and are uncorrected for junction potential. [*n*-Bu_4N][ClO_4] was used as supporting electrolyte.

2.3. Synthesis of [Ni(β-NaiEt)$_2$(NCS)$_2$] (**6b**)

In methanolic solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.25 g, 0.68 mmol) (10 ml) solid ammonium thiocyanate (NH_4SCN) (1.04 g, 1.38 mmol) was added under stirring at 298 K. To this solution 1-ethyl-2-(naphthyl-β-azo)imidazole (β-NaiEt) (**2b**) (0.37 g, 1.48 mmol) in the same solvent (20 ml MeOH) was added dropwise. The resulting brown solution was stirred for 15 min. The solid product was separated from the solution. The orange crystalline products were collected, washed with aqueous methanol and finally with ether. It was dried in vacuo. Yield was 0.19 g (54%).

All other complexes were prepared by the same procedure. Crystalline products were obtained in the yield of 50–70%.

Elemental analysis data were as follows: [Ni(α-NaiMe)$_2$(N_3)$_2$], **3a**: $C_{28}H_{24}N_{14}Ni$: *Anal.* Calc.: C, 54.65; H, 3.94; N, 31.87. Found: C, 54.73; H, 3.90; N, 31.77%. 2.4. X-ray crystal structure analysis

X-ray quality red colored cubic crystals of [Ni(β-NaiEt)$_2$(NCS)$_2$] (**6b**) were isolated by diffusion of 2-methoxy-ethanol solution of the complex to methanol at room temperature. Data were collected (Table 1) with Siemens SMART CCD diffractometer using graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å) at 293 (2) K. Unit cell parameters were determined from least-squares refinement of setting angles of 3810 reflections ($I > 2\sigma(I)$) out of 10336 collected data with 2θ in the range $3.88° \leqslant 2\theta \leqslant 56.64°$. A summary of the results were recorded using the ω scan technique in the *hkl* range of $-22 \leqslant h \leqslant 26$, $-18 \leqslant k \leqslant 18$, $-19 \leqslant l \leqslant 11$. Data were corrected for Lorentz polarization effects and for linear decay. Semi-empirical absorption corrections were applied using SADABS programme. The structure was solved by direct method and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed geometrically and refined using the riding model. In the final difference Fourier map the residual minima and maxima were −0.195 and 0.604 (e/Å^3) respectively, carried out using SHELXL-97. All calculations were carried out using SHELXL-97 [33], ORTEP-32 [34], PLATON-99 [35] programs.

3. Results and discussion

3.1. Synthesis and formulation

1-Methyl-2-(naphthyl-α-azo)imidazole (α-NaiMe, **1a**), 1-ethyl-2-(naphthyl-α-azo)imidazole (α-NaiEt, **2a**), 1-methyl-2-(naphthyl-β-azo)imidazole (β-NaiMe, **1b**), 1-ethyl-2-(naphthyl-β-azo)imidazole (β-NaiEt, **2b**) are used as bidentate N, N′ (where N and N′ refer to N(imidazole) and N(azo) centres) (Scheme 1). Pseudohalides, azide (N_3^-) and thiocyanate (SCN^-), are used to balance charge of the complexes. To methanolic solution of $Ni(ClO_4)_2 \cdot 6H_2O$ solid NaN_3 or NH_4NCS (2 equiv) was added under stirring at 298 K. To this solution α/β-NaiR in methanol in 1:2 mole ratio of Ni:ligand was added. Solution colour immediately turned to brown red and orange precipitate slowly separated from the solution. The product was isolated by filtration in the yield of >50%. The composition of the complex, [Ni(α/β-NaiR)$_2$(X)$_2$] (**3–6**) was supported by microanalytical data.

The complexes in this paper are non-electrolyte in MeCN solution. The are soluble in common organic solvents like $CHCl_3$, CH_2Cl_2. Bulk room temperature magnetic moment with correction incorporating Pascal's diamagnetic constant show two electron paramagnetic nature of Ni(II) ($\mu_{av} = 2.6–2.8$ B.M.) suggesting $t_{2g}^6e_g^2$ electronic configuration in octahedral geometry.

Table 1
Summarised crystallographic data for [Ni(β-NaiEt)$_2$(NCS)$_2$] (**6b**)

Empirical formula	$C_{32}H_{28}N_{10}S_2Ni$
Formula weight	675.47
Temperature (K)	295 (2)
Crystal system	monoclinic
Space group	*C*2/*c*
Crystal size (mm)^3	0. 25 × 0.20 × 0.20
Unit cell dimensions	
a (Å)	19.863(4)
b (Å)	13.847(3)
c (Å)	14.237(3)
β (°)	125.47(3)
V (Å)^3	3189.3(11)
Z	4
λ (Å)	0.71073
μ (Mo Kα) (mm^{-1})	0.780
D_{calc} (mg m^{-3})	1.407
Refine parameters	204
Reflection number total	10336
Reflection number get	3810
R_1[a] [$I > 2\sigma(I)$]	0.0522
wR_2[b]	0.0687
Goodness-of-fit	0.971

[a] $R = \sum|F_o - F_c|/\sum F_o$.
[b] $wR = [\sum w(F_o^2 - F_c^2)/\sum wF_o^4]^{1/2}$ $w = 1/[\sigma^2(F_o^2) + (0.0250P)^2]$ where $P = (F_o^2 + 2F_c^2)/3$.

Table 2
Bond distance and bond angle of [Ni(β-Nai-Et)$_2$(NCS)$_2$] (**6b**)

Bond distance	(Å)	Bond angle	(°)
Ni–N(1)	2.0181(19)	N(2)–Ni –N(1*)[a]	91.82(11)
Ni–N(2)	2.3109(15)	N(1)–Ni–N(2)	96.39(7)

		N(2)–Ni–N(2*)[a]	78.68(7).

[a] Symmetry: $-x, y, 1/2 - z$.

3.2. Molecular structure of [Ni(β-Nai-Et)$_2$(NCS)$_2$] (**6b**)

The molecular structureof [Ni(β-Nai-Et)$_2$(NCS)$_2$] (**6b**) is shown in Fig. 1. In this molecule Ni(II) is surrounded by two β-Nai-Et and two thiocyanates. β-NaiEt serves as unsymmetric N,N′-chelat-

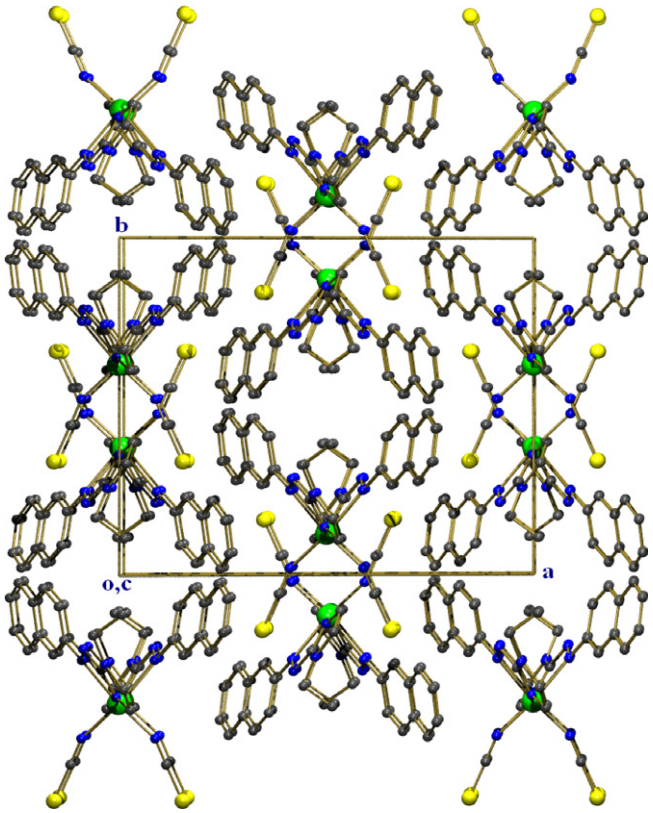

Fig. 2. Packing viewed along *c*-axis of [Ni(β-Nai-Et)$_2$(NCS)$_2$] (**6b**).

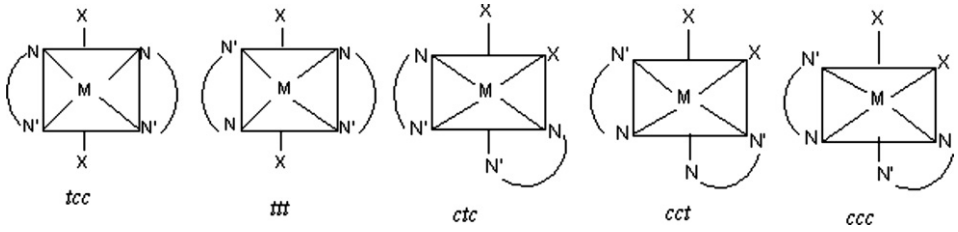
ing agent (N refers to imidazole-N and N/ refers to azo-N donor centres) and the coordination disposition of N and N/ has identified an arrangement of *trans*-N,N and *cis*-N/,N/ stereochemistry. Pseudooctahedral complexes of formula, $M(N,N^{/})_2X_2$ may exist in five stereoisomeric forms referring to sequence of the coordination pairs of X,X; N,N; N/, N/; the isomers are abbreviated as *trans–cis–cis* (*tcc*); *trans–trans–trans* (*ttt*); *cis–trans–trans* (*ctc*); *cis–cis–trans* (*cct*) and *cis–cis–cis* (*ccc*) (see Table 1).



In these complexes NCS^- is N-donor ligand and two NCS^- coordinate in a *cis*-fashion around Ni(II). Thus, coordination sequence of thiocyanato-N, imidazole-N(N) and azo-N(N/) describe *cis–trans–cis* (ctc) stereochemical orientation [7–10]. Selected bond lengths and angles are given in Table 2. The N–Ni–N/ bond angles subtended by the chelating ligand is N(2)–Ni–N(5), 73.08(6)°. The deviation of the angle from ideal 90° for a regular octahedron is the result of steric requirements of the ligand [36–41]. Other angles in the chelated motif are also deviated in either direction from the regular five member ring. The pendant naphthyl ring makes dihedral 27.84(8)° with chelate plane. Out of N(imidazole), N(azo) and N(thiocyanato) donor centres the N(azo) requires considerably more space than other two types N-donors. The N(azo) is exocyclic N=N in a pendant naphthyl group; thus the van der Waals repulsion will be greater than N(imidazole) and thus N(azo) is more space demanding. The Ni–N(azo) distance, 2.3109(15) Å is less than that of the sum of the van der Waals radii of Ni(II) (1.63 Å) and N(azo) (1.55 Å) [42]. This implies covalent interaction of N(azo) and Ni(II).

In the equatorial plane the trans angle is 164.78(6)° [N(1*)–Ni–N(2)]. The large deviation (~15°) from 180° is undoubtedly from the combined contribution of short chelate angle and steric

requirement of azo-N centres. The azo, N=N, distances is 1.2671(19) Å which is longer than the free ligand value (1.250(1) Å) [18]. A small extension of azo bond may come from the structural strain arises out of small chelate bite angle and steric requirement of the chelated azoimine fragment. Packing viewed along *c*-axis (or along *a*- or *b*-axes) does not show any reasonable noncovalent interaction; however, the packing shows proper disposition of naphthyl groups so that they may have a trend of noncovalent interaction. Packing structure along *c*-axis is shown in Fig. 2.

3.3. Spectral studies

[Ni(α/β-Nai-R)$_2$(N$_3$)$_2$] show characteristic strong transmission at 2118–2042 cm^{-1} along with a weak band at 2045–2047 cm^{-1} in infrared spectra. These are corresponding to $\nu_{asym}(N_3)$. This supports mononuclear mono-dentate N_3^- bonding in **3** and **4**. The [Ni(α/β-Nai-R)$_2$(NCS)$_2$] (**5** and **6**) complexes show band at 2098–2105 cm^{-1} along with a weak band at 2090–2093 which correspond to ν(CN) of bounded NCS. Medium to strong bands observe at 760–770 and 680–695 cm^{-1} have been assigned to ν(CS) for [Ni(α/β-NaiR)$_2$(NCS)$_2$]. The chelated ligand α/β-Nai-R shows characteristic transmission at 1600–1200 cm^{-1}. Moderately intense stretching at 1585–1600 and 1435–1440 cm^{-1} are due to ν(C=N) and ν(N=N), respectively.

The absorption spectrum of free ligands show characteristics structured absorption band around 350–370 nm with a molar absorption coefficient on the order of 10^4 M^{-1} cm^{-1} and a tail extending into 400–420 nm. The large absorption band around below 400 nm corresponds to $\pi \rightarrow \pi^*$ transitions, while the tail corresponds to $n \rightarrow \pi^*$ transition [18]. These bands suffer marginal shifts to longer wavelength region on complexation. The solution spectra were recorded in MeCN and data are listed in Table 3. Intense band ($(\varepsilon \sim 10^4$ dm^3 mol^{-1} cm^{-1}) appear in the range 430–445 nm may be assigned to $d\pi(Ni) \rightarrow \pi^*$ (ligand) charge transfer transitions. Two broad bands at longer wavelengths (710–730 and 620–650 nm) are observed and the molar extinction coefficient data warrant to consider them not only d–d bands rather admixture of d–d and MLCT transitions. The azoimine (–N=N–C=N–) function is π-acidic enough to insist such MLCT transitions. The assignment is also supported by theoretical calculations [18]. DFT analyses show that HOMO, HOMO − 1 of [Ni(β-Nai-Et)$_2$(NCS)$_2$] (**6b**) have small contribution from Ni (Scheme 2) (HOMO, 4% (Ni); HOMO-1, 1% (Ni)) and also the LUMO (3% Ni) and LUMO + 1 (nil, Ni) while HOMO, HOMO-1 bear ⩾95% contribution from NCS group. β-Nai-Et dominates (⩾95%) in LUMO and LUMO+1. The calculated transitions are (wavelength λ, nm and oscillator strength, $f \times 10^3$), (% contribution) recommended transition (assignment): (855 (0.0367), (46%) H-3 → L + 2 (XLCT); 509 (0.0046), (62%) H-6 → LUMO (MLCT).; 461 (0.0444), (20%) H-7 → L + 1, (61%) H-5 → LUMO (LLCT) (where XLCT: NCS to β-Nai-Et charge transfer; MLCT: Ni(II) to β-Nai-Et charge transfer; LLCT: β-Nai-Et to β-Nai-Et charge transfer). A plot of oscillator strength (*f*) *versus wavelength* (λ) is given in Fig. 3. The correlation between theoretical and experimental spectra exhibit widely different transition region which may be due to influence of solvent polarity on the stabilization of polar ground and excited states. Calculation is carried out in gas phase while spectra are recorded in MeCN solution. We cannot perform calculation using solvent system due to some infrastructural problem with computational facilities.

3.4. Cyclic voltammetry

During voltammetric study the anodic current increases progressively above 0.5 V and ill-defined anodic response is observed in the potential range 0.3–0.4 V but no cathodic counterpart is observed on scan reversal. The anodic response may be assigned to unstable oxidized Ni(III) species [43,44]. Redox couples negative to SCE are reductive in nature and have been assigned to reductions of chelated azo-ligand. Arylazoheterocycles accommodate two electrons at LUMO which is mostly azo in character: [–N=N]/[–N⁻⁻⁻⁻N–]$^-$ and [–N⁻⁻⁻⁻N]$^-$/[–N–N–]$^{2-}$. Voltammetric data are set out in Table 3 and a representative figure is shown in Fig. 4. The DFT calculation suggests 95% contribution of β-Nai-Et to LUMO and thus the reduction is explained as electron feeding into the azo-dominated LUMO. We find that the HOMO has 4% from Ni and 95% from thiocyanate group. It is not expected that the oxidation of coordinated NCS at 0.3–0.4 V [45] and Ni(II) → Ni(III) oxidation is recommended.

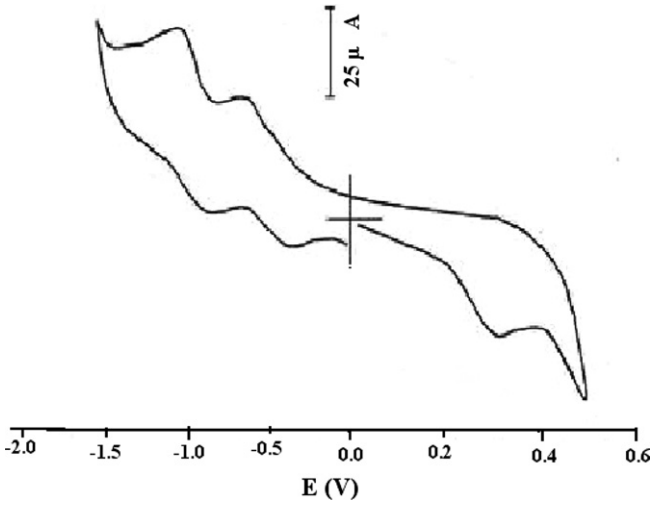

Fig. 4. Cyclic voltammogram of [Ni(β-Nai-Et)$_2$(SCN)$_2$] (**6b**) in MeCN using Pt working electrode, SCE reference and [nBu$_4$N][ClO$_4$] supporting electrolyte.

4. Conclusion

Ni(β-NaiR)$_2$(X)$_2$ (X = N$_3$, NCS) complexes are reported in this work. The structure supports this composition. Distorted octahedral geometry supports mixed electronic transition of MLCT, LLCT, XLCT type. Electrochemistry of the complexes show irreversible Ni(III)/Ni(II) response with azo reduction of coordinated azoimine function. The electronic configuration, spectra and redox property have been attempted to explain by DFT calculation.

dinated by the incorporation of one methanol (solvent) molecule [7,10–12] in its coordination sphere or remains penta-coordinated [8,12] (where the coordination of the solvent molecule is inhibited probably due to steric repulsion between the methyl group attached to the carbonyl carbon instead of a hydrogen atom in the aryloxy ring of the hydrazone ligand and the OH group of the solvent alcohol).

Such an observation indicates that there should be ligands of intermediate basicity, which would be able to form both the penta-coordinated monomeric and the hexa-coordinated methoxy-bridged dimeric complexes. For this purpose, a family of tridentate ligands with varying basicity will be ideal and on this ground, the hydrazone ligands derived from the condensation of aliphatic/aromatic acid hydrazide with aromatic 2-hydroxycarbonyl compound containing a substitution in the aromatic ring may be suitable, where, the basic property of the ligands can be finely tuned through the incorporation of suitable substituent. With a view to searching for suitable ligand(s) of borderline basicity, we have chosen the benzoyl hydrazones of 2-hydroxyacetophenone and its 5-substituted derivatives (H_2L^{1-4}, general abbreviation H_2L, Scheme 1) for this study. There are two reasons behind the selection of this family of ligands: (i) these hydrazone ligands contain two intermediate basic phenolic and amide (which binds through their enol forms) groups, which are very suitable for the stabilization of +V state of vanadium [13–15] and (ii) due to presence of one methyl group with the carbonyl carbon (in stead of hydrogen in 2-hydroxybenzaldehyde), the coordination of solvent molecule is inhibited for steric reason. Utilizing this family of ligands we have been able to identify three suitable hydrazone ligands which are able to form both the methoxy bonded monomeric complexes and their dimethoxy-bridged dimeric analogues, which, to the best of our knowledge, represent the first report in this area. We also report the procedure for the transformation of these complexes to the corresponding complexes with $V_2O_3^{4+}$ and VO_2^+ motifs, which is important in connection with their catalytic activities. Such type of oxidovanadium(V)–alkoxide complexes are important due to their biological relevance [16] and also for their catalytic activities [17,18].

H_2L^1	H
H_2L^2	CH_3
H_2L^3	OCH_3
H_2L^4	Cl

Scheme 1.

2. Experimental

2.1. Materials

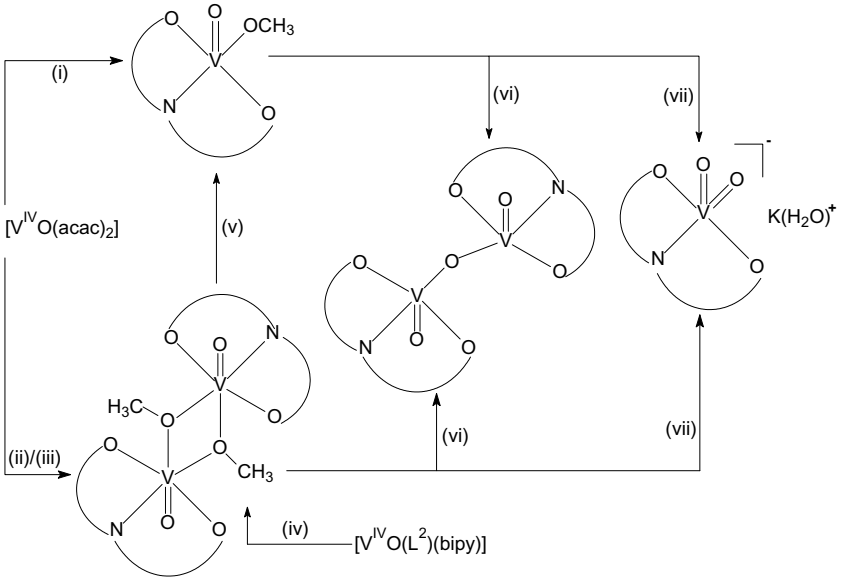
$[V^{IV}O(acac)_2]$ [19] and the hydrazone ligands (H_2L^{1-4}) [20] (Scheme 1) were prepared by the reported methods. Reagent grade solvents were dried and distilled prior to use. All other chemicals were reagent grade, obtained from commercial sources and used without further purification. Spectroscopic grade solvents were used for spectral measurements.

2.2. Synthesis of the complexes $[VO(L)(OCH_3)]$, (**1**)–(**4**)

All these complexes except **3** were synthesized by a simple general method using $[V^{IV}O(acac)_2]$ (where $acac^-$ represents the acetyl acetonate ion) as the starting material (Scheme 2).

2.2.1. $[VO(L^1)(OCH_3)]$ (**1**)

A total of 0.254 g (1.0 mmol) of H_2L^1 was dissolved in 30 ml of methanol and 0.265 g (1.0 mmol) of $[V^{IV}O(acac)_2]$ was added to the ligand solution. The mixture was then heated under reflux for 2 h. A reddish brown solution was obtained which was kept



Scheme 2. (i) Heated under reflux in methanol with one equivalent H_2L^1 or H_2L^2 or H_2L^4; (ii) on heating under reflux in methanol with one equivalent H_2L^3; (iii) on heating under reflux in methanol with one equivalent H_2L^1 in presence of half-equivalent 4,4′-bipyridine; (iv) on keeping its methanol solution for ~7 days; (v) heated under reflux with the excess amount of imidazole in methanol; (vi) on heating under reflux in acetone; (vii) on reaction with the methanolic solution of KOH at slightly warm condition.

for slow evaporation at room temperature. Shiny black crystalline compound, suitable for X-ray diffraction analysis were obtained after one week. Yield: 0.30 g (86%). *Anal.* Calc. for $C_{16}H_{15}N_2O_4V$: C, 54.82; H, 4.28; N, 7.99. Found: C, 54.79; H, 4.25; N, 7.97%. Selected IR data (cm^{-1}): ν = 1590 (s, C=$N_{azomethine}$); 1238 (s, C–$O_{enolate}$); 1041 (m, N–N); 992 (s, V=O). ^1H NMR (300 MHz; $CDCl_3$): δ = 7.28–7.32 (m, 2H, H-3, H-13); 7.36 (dd, 1H, H-4, J = 8.4, 0.8 Hz); 7.16–7.21 (m, 1H, H-5); 7.75 (dd, 1H, H-6, J = 8.2, 0.8 Hz); 2.26 (s, 3H, 3 × H-8); 7.66 (dd, 2H, H-11, H-15, J = 7.9, 1.0 Hz); 7.05 (t, 2H, H-12, H-14, J = 7.8 Hz); 3.49 (s, 3H, 3 × H-16) ppm. λ_{max} (ε, $dm^3\ mol^{-1}\ cm^{-1}$) = 384^{sh} nm (10845), 323 nm (26228).

2.2.2. $[VO(L^2)(OCH_3)]$ (**2**)

Compound **2** was also prepared analogously to **1** and was obtained as shiny black crystalline solid (suitable for X-ray diffraction analysis). Yield: 0.30 g (82%). *Anal.* Calc. for $C_{17}H_{17}N_2O_4V$: C, 56.00; H, 4.67; N, 7.69. Found: C, 55.97; H, 4,64; N, 7.68%. Selected IR data (cm^{-1}): ν = 1585 (s, C=$N_{azomethine}$); 1237 (s, C–$O_{enolate}$); 1031 (m, N–N); 1000 (s, V=O). ^1H NMR (300 MHz; $CDCl_3$): δ = 7.25 (d, 1H, H-3, J = 8.3 Hz); 7.50 (dd, 1H, H-4, J = 8.3, 0.8 Hz); 7.52 (d, 1H, H-6, J = 0.8 Hz); 2.26 (s, 3H, 3 × H-8); 7.65 (dd, 2H, H-11, H-15, J = 7.6, 0.7 Hz); 7.06 (dt, 2H, H-12, H-14, J = 7.6, 7.4 Hz); 7.32 (dt, 1H, H-13, J = 7.4, 0.8 Hz); 3.49 (s, 3H, 3 × H-16); 2.46 (s, 3H, 3 × H-17) ppm. λ_{max} (ε, $dm^3\ mol^{-1}\ cm^{-1}$) = 380^{sh} nm (10523), 323 nm (19636).

2.2.3. $[VO(L^3)(OCH_3)]$ (**3**)

Compound **3** was obtained as shiny black crystalline solid (suitable for X-ray diffraction analysis) by the reaction with **3A** (vide infra) with an excess (~3 times) amount of imidazole in methanol. A total of 0.200 g of $[V^{V}O(L^3)(OCH_3)]_2$ **(3A)** and 0.05 g of imidazole were dissolved in 40 ml methanol on warming. The resulting mixture was heated under reflux for ½ h and then kept for slow evaporation at room temperature. A shiny black crystalline compound was obtained after 3 days. Yield: 0.18 g (90%). *Anal.* Calc. for $C_{17}H_{17}N_2O_5V$: C, 53.68; H, 4.47; N, 7.37. Found: C, 53.63; H, 4.45; N, 7.36%. Selected IR data (cm^{-1}): ν = 1588 (s, C=$N_{azomethine}$); 1228 (s, C–$O_{enolate}$); 1034 (m, N–N); 995 (s, V=O). ^1H NMR (300 MHz; $CDCl_3$): δ = 7.30–7.33 (m, 3H, H-3, H-4, H-13); 7.19 (d, 1H, H-6, J = 0.7 Hz); 2.26 (s, 3H, 3 × H-8); 7.65 (dd, 2H, H-11, H-15, J = 7.3, 0.5 Hz); 7.07 (dt, 2H, H-12, H-14, J = 7.3, 7.7 Hz); 3.49 (s, 3H, 3 × H-16); 3.91 (s, 3H, 3 × H-17) ppm. λ_{max} (ε, $dm^3\ mol^{-1}\ cm^{-1}$) = 378^{sh} nm (14766), 324 nm (26502).

2.2.4. $[VO(L^4)(OCH_3)]$ (**4**)

Compound **4** was obtained as microcrystalline shiny black solid by using a protocol very similar to that for **1**. Yield: 0.35 g (91%). *Anal.* Calc. for $C_{16}H_{14}N_2O_4ClV$: C, 49.93; H, 3.64; N, 7.28. Found: C, 49.90; H, 3.61; N, 7.26%. Selected IR data (cm^{-1}): ν = 1580 (s, C=$N_{azomethine}$); 1236 (s, C–$O_{enolate}$); 1025 (m, N–N); 997 (s, V=O). ^1H NMR (300 MHz; $CDCl_3$): δ = 7.31 (d, 1H, H-3, J = 8.9 Hz); 7.44 (dd, 1H, H-4, J = 8.9, 1.5 Hz); 7.70 (d, 1H, H-6, J = 1.5 Hz); 2.25 (s, 3H, 3 × H-8); 7.64 (dd, 2H, H-11, H-15, J = 7.4, 0.6 Hz); 7.10 (dt, 2H, H-12, H-14, J = 7.4 Hz); 7.37 (dt, 1H, H-13, 7.4, 7.2 Hz); 3.49 (s, 3 × H-16) ppm. λ_{max} (ε, $dm^3\ mol^{-1}\ cm^{-1}$) = 388^{sh} nm (6465), 321 nm (15043).

2.3. Synthesis of the complexes $[VO(L)(OCH_3)]_2$, (**1A**)–(**3A**)

2.3.1. $[VO(L^1)(OCH_3)]_2$ (**1A**)

A total of 0.254 g (1.0 mmol) of H_2L^1 and 0.08 g (~0.5 mmol) of 4,4′-bipyridine were dissolved in 30 ml of methanol and 0.265 g (1.0 mmol) of $[V^{IV}O(acac)_2]$ was added to this solution. The mixture was then heated under reflux for 2 h. A reddish brown solution was obtained which was kept for slow evaporation at room temperature. Shiny black crystalline compound, suitable for X-ray diffraction analysis were obtained after one week. Yield: 0.32 g (91%). *Anal.* Calc. for $C_{16}H_{15}N_2O_4V$: C, 54.82; H, 4.28; N, 7.99. Found: C, 54.79; H, 4.25; N, 7.97%. Selected IR data (cm^{-1}): ν = 1597 (s, C=$N_{azomethine}$); 1244 (s, C–$O_{enolate}$); 1040 (m, N–N); 982 (s, V=O). ^1H NMR (300 MHz; $CDCl_3$): δ = 7.28–7.37 (m, 2H, H-3, H-13); 7.45 (dd, 1H, H-4, J = 7.6, 1.0 Hz); 7.15–7.22 (m, 1H, H-5); 7.90 (dd, 1H, H-6, J = 8.1, 0.9 Hz); 2.26 (s, 3H, 3 × H-8); 7.73 (dd, 2H, H-11, H-15, J = 8.2, 0.9 Hz); 7.04 (t, 2H, H-12, H-14, J = 7.6 Hz); 3.48 (s, 3H, 3 × H-16); 5.20 (s, 3H, 3 × H-16(bridged)) ppm. λ_{max} (ε, $dm^3\ mol^{-1}\ cm^{-1}$) = 381^{sh} nm (11550), 323 nm (28240).

2.3.2. $[VO(L^2)(OCH_3)]_2$ (**2A**)

0.100 g of $[V^{IV}O(L^2)(bipy)]$ [21] was dissolved in 40 ml methanol on warming. The resulting orange red solution was kept at room temperature for slow evaporation. A black crystalline compound of **2A** (suitable for X-ray diffraction analysis) was obtained after 7 days. Yield: 0.063 g (85%). *Anal.* Calc. for $C_{34}H_{34}N_4O_8V_2$: C, 56.00; H, 4.67; N, 7.69. Found: C, 55.96; H, 4.64; N, 7.67%. Selected IR data (cm^{-1}): ν = 1582 (s, C=$N_{azomethine}$); 1239 (s, C–$O_{enolate}$); 1026 (m, N–N); 976 (s, V=O). ^1H NMR (300 MHz; $CDCl_3$): δ = 7.24 (d, 1H, H-3, J = 8.1 Hz), 7.39 (dd, 1H, H-4, J = 8.1, 0.7 Hz), 7.51 (d, 1H, H-6, J = 0.7 Hz), 2.25 (s, 3H, 3 × H-8), 7.64 (dd, 2H, H-11, H-15, J = 7.6, 1.0 Hz), 7.05 (dt, 2H, H-12, H-14, J = 7.6, 7.3 Hz), 7.31 (dt, 1H, H-13, J = 7.3, 1.0 Hz), 3.48 (s, 3H, 3 × H-16), 5.18 (s, 3H, 3 × H-16(bridged)), 2.45 (s, 3H, 3 × H-17) ppm. λ_{max} (ε, $dm^3\ mol^{-1}\ cm^{-1}$) = 378^{sh} nm (25115), 324 nm (46476).

2.3.3. $[VO(L^3)(OCH_3)]_2$ (**3A**)

Compound **3A** was also obtained as shiny black crystalline solid (suitable for X-ray diffraction analysis) by using the same method as that of **1**. Yield: 0.33 g (87%). *Anal.* Calc. for $C_{34}H_{34}N_4O_{10}V_2$: C, 53.68; H, 4.47; N, 7.37. Found: C, 53.64; H, 4.44; N, 7.36%. Selected IR data (cm^{-1}): ν = 1588 (s, C=$N_{azomethine}$); 1235 (s, C–O_{enolic}), 1032 (m, N–N), 974 (s, V=O). ^1H NMR (300 MHz; $CDCl_3$): δ = 7.12–7.20 (m, 2H, H-3, H-4); 7.28 (d, 1H, H-6, J = 0.8 Hz); 2.25 (s, 3H, 3 × H-8); 7.65 (dd, 2H, H-11, H-15, J = 7.5, 0.6 Hz); 7.06 (dt, 2H, H-12, H-14, J = 7.5, 7.4 Hz); 7.47 (dt, 1H, H-13, J = 7.4, 0.6 Hz); 3.47 (s, 3H, 3 × H-16); 5.18 (s, 3H, 3 × H-16(bridged)); 3.88 (s, 3H, 3 × H-17) ppm. λ_{max} (ε, $dm^3\ mol^{-1}\ cm^{-1}$) = 376^{sh} nm (23272), 325 nm (41066).

2.4. Conversion of these VO^{3+} complexes to the complexes with $V_2O_2^{4+}$ motif

The conversion of these VO^{3+} complexes to the complexes with $V_2O_3^{4+}$ motif can be done by a simple general method and for this reason only one representative method is described here.

2.4.1. Conversion to $[V_2O_3(L^1)_2]$

0.100 g of $[VO(L^1)(OCH_3)]$ (**1**) was dissolved in 40 ml acetone on warming. The solution was then heated under reflux for 2 h and the resulting red-brown solution was then kept for slow evaporation at room temperature. A deep brown microcrystalline compound was obtained. Yield: 89%. This compound was found to be identical in all respects with the $[V_2O_3(L^1)_2]$ complex reported earlier [15].

2.5. Conversion of these VO^{3+} complexes to the complexes with VO_2^+ motif

This conversion has also been done by a simple general method. So, one representative method is described here.

2.5.1. Conversion to $K^+(H_2O)[VO_2(L^1)]^-$

To a methanol solution (30 ml) of KOH (0.025 g), a total of 0.150 g of $[VO(L^1)(OCH_3)]$ (**1**) was added and dissolved on warming. The reddish-yellow solution was then stirred at room temperature for 2 h and the resulting solution was then kept for slow evaporation at room temperature. A yellow crystalline compound was obtained. Yield: 72%. This compound was found to be identical in all respects with the $K^+(H_2O)[VO_2(L^1)]^-$ complex reported earlier [15].

2.6. Physical measurements

Elemental analyses were performed on a Perkin-Elmer 2400 CHNS/O analyzer. Electronic spectra (in CH_2Cl_2) were recorded on a Hitachi U-3501 spectrophotometer and IR spectra (as KBr pellets) were taken on a Perkin-Elmer 782 spectrophotometer. The ^1H NMR spectra were recorded in $CDCl_3$ on a Bruker AM 300L (300 MHz) superconducting FT NMR spectrophotometer. Electrochemical measurements were performed at 298 K in CH_2Cl_2 solution for *ca.* 10^{-3} M using Et_4NClO_4 as supporting electrolyte under a dry N_2 atmosphere on a PC controlled PAR model 273 A electrochemistry system. A Pt disk, a Pt wire auxiliary electrode and an aqueous saturated calomel electrode (SCE) were used in a three-electrode configuration. All the potential values reported here are uncorrected for junction contribution. The ferrocene/ferrocinium (Fc/Fc^+) couple was used as the internal standard.

2.7. Crystallographic data collection and refinement

Data were measured with Mo Kα radiation at 150 K using the Oxford Diffraction X-Calibur CCD System. Data analysis was carried out with the Crysalis [22] program and the structures were solved with the SHELXS97 program [23]. For all six structures, the non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. Absorption corrections were carried out with the ABSPACK program [24]. The structures were refined on F^2 using SHELXL-97 program [23] and molecular graphics were computed using PLATON [25]. Crystallographic data are given in Tables 1 and 2. The somewhat high R values obtained, particularly for structure **1A**, from the refinements are due to the poor quality of the crystals and resulting diffraction data.

3. Results and discussion

3.1. Synthesis of methoxy bonded monomeric and methoxy-bridged dimeric VO^{3+}-hydrazone complexes and their conversion into the complexes with $V_2O_3^{4+}$ and VO_2^+ motifs

In the attempt to prepare the methoxy bonded mixed-ligand oxidovanadium(V)-hydrazone complexes of the type $[V^VO(L)(OCH_3)]$ [where L^{2-} is the general abbreviation of the deprotonated form of tridentate dinegative hydrazone ligands (H_2L^{1-4}) derived from the condensation of benzoyl hydrazine with 2-hydroxyacetophenone and its five-substituted derivatives] led to an interesting observation which encouraged us to make a systematic study on the role of ligands' basicity (as the steric factor is almost constant) regarding the structure of these complexes. It was found that the methanol solution of $[V^{IV}O(acac)_2]$ on reaction with H_2L^1, H_2L^2 (containing an electron donor methyl group at the 5-position of the aryloxy ring with σ (Hammett parameter [26]) = −0.17) and H_2L^4 (containing an electron withdrawing chlorine atom at the 5-position with σ = +0.23) produced only the monomeric complexes $[V^VO(L^1)(OCH_3)]$ (**1**), $[V^VO(L^2)(OCH_3)]$ (**2**) and $[V^VO(L^4)(OCH_3)]$ (**4**), respectively, while the similar reaction with H_2L^3 (containing a relatively stronger electron donor OCH_3 group at the 5-position with σ = −0.27) ligand yielded only the dimethoxy-bridged dimeric $[V^VO(L^3)(OCH_3)]_2$ (**3A**) complex. Such observations suggest that the basicity of H_2L^1 and H_2L^2 ligands should be of borderline nature and they should also form the dimethoxy-bridged dimeric analogue of, respectively, **1** and **2** and ultimately we have been able to synthesize the desired dimeric forms **1A** and **2A** from the reaction of $[V^{IV}O(acac)_2]$ with the H_2L^1 ligand in presence of half-equivalent 4,4′-bipyridine in methanol and from the decomposition of $[V^{IV}O(L^2)(bipy)]$ complex [21] in methanol, respectively, though the specific role of 4,4′-bipyridine and 2,2′-bipyridine (bipy) is not clear. But such type of dimeric complex with H_2L^4 ligand was not obtained by any of these methods indicating the borderline basicity of H_2L^1 and H_2L^2 ligands. Interestingly, when these dimeric compounds **1A**–**3A** were allowed to react with an excess (~3 times) amount of imidazole in methanol the respective monomeric form **1**–**3** was obtained. The oxidizing agent for the formation of pentavalent state of vanadium is the

aerial oxygen and all the stated reactions can be represented as

$$2[V^{IV}O(acac)_2] + 2H_2L + 2CH_3OH + 1/2O_2 \rightarrow 2[V^{V}O(L)(OCH_3)] + 4Hacac + H_2O \quad (1)$$

where $H_2L = H_2L^1$ (for **1**) or H_2L^2 (for **2**) or H_2L^4 (for **4**).

$$2[V^{IV}O(acac)_2] + 2H_2L^3 + 2CH_3OH + 1/2O_2 \rightarrow [V^{V}O(L^3)(OCH_3)]_2\ (\mathbf{3A}) + 4Hacac + H_2O \quad (2)$$

$$2[V^{IV}O(acac)_2] + 2H_2L^1 + 2CH_3OH + 1/2O_2 + 4,4'\text{-bipy} \rightarrow 2[V^{V}O(L^1)(OCH_3)]_2\ (\mathbf{1A}) + 4Hacac + H_2O + 4,4'\text{-bipy} \quad (3)$$

$$2[V^{IV}O(L^2)(bipy)] + 2CH_3OH + 1/2O_2 \rightarrow [V^{V}O(L^2)(OCH_3)]_2\ (\mathbf{2A}) + 2bipy + H_2O \quad (4)$$

$$[V^{V}O(L)(OCH_3)]_2 + 3Im \rightarrow 2[V^{V}O(L)(OCH_3)] + 3Im \quad (5)$$

where $H_2L = H_2L^1$ (for **1A**) or H_2L^2 (for **2A**) or H_2L^3 (for **4A**).

Where Hacac, 4,4′-bipy, bipy and Im represent the acetyl acetone, 4,4′-bipyridine, 2,2′-bipyridine and imidazole molecule, respectively.

These complexes can be easily transformed into the corresponding complexes with $V_2O_3^{4+}$ motif simply on refluxing them in wet acetone and to the corresponding complexes with VO_2^+ motif by the reaction with one equivalent KOH in methanol at slightly warm (∼60 °C) condition. These conversions can be represented as

$$2[VO(L)(OCH_3)] + H_2O \xrightarrow{\text{wet acetone}} [V_2O_3(L)_2] + 2CH_3OH \quad (6)$$

$$[VO(L)(OCH_3)] + KOH \xrightarrow{\text{wet acetone}} K^+(H_2O)[VO_2(L)]^- + CH_3OH \quad (7)$$

The properties of these complexes are very much identical with the reported complexes, which we have synthesized by other methods and reported [15] very recently.

3.2. IR spectra of the complexes

IR spectra of the complexes exhibit all the characteristic bands of the enol forms of the coordinated tridentate dianionic ligands and these are described in Section 2. In addition, the monomeric complexes **1–4** exhibited a strong band near 1000 cm^{-1} which are attributed to ν(V=O) band and for the dimeric complexes **1A**, **2A** and **3A**, this band was observed near 975 cm^{-1} (which is significantly lower than **1–4**) indicating, respectively, the penta- and hexa-coordinated environment around the vanadium center [10–14,20].

3.3. Structure of the complexes

3.3.1. Structure of $[VO(L^1)(OCH_3)]$ (**1**)

The crystals of complex **1** belong to the orthorhombic crystal system with $P2_1ab$ space group. Fig. 1 displays a perspective view of the complex **1** and the bond parameters are collected in Table 2. The vanadium atom in the molecule is penta-coordinated existing in a distorted square-pyramidal environment in which the basal plane consists of a phenolic oxygen O(2), an enolic oxygen O(3)

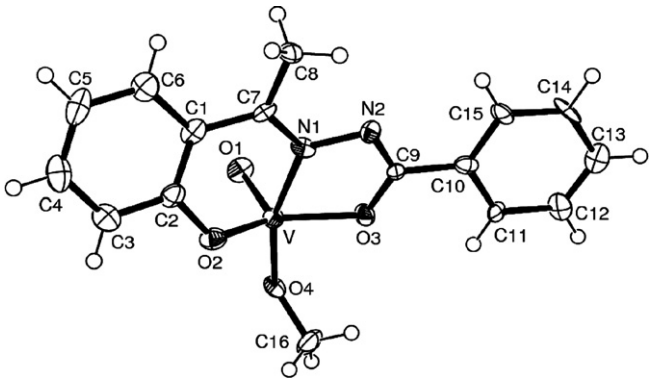

Fig. 1. Molecular structure of **1** showing the atom-numbering scheme with ellipsoid at 50% probability.

and an imine nitrogen N(1) from the fully deprotonated H_2L^1 ligand in its enol form and O(4) from the methoxide oxygen. The r.m.s. deviation of the four contributing atoms is 0.08 Å. The vanadium atom is displaced from this plane by 0.548 Å towards the axial oxido oxygen O(1). The unequal bond lengths of V–O(1), V–O(2), V–O(3), V–O(4) and V–N(1) bonds as well as unequal bond angles generated by these bonds at the V-acceptor center indicate a significant distortion from the perfect square-pyramidal geometry. The amount of distortion can be quantitatively estimated from the average O(axial)–V–O/N(basal) angle [27] and also from the τ parameter [28] (equal to $\Delta/60$, where Δ is the difference between the largest and next-to-largest ligand–metal–ligand angles). These values are, respectively, 104.6° (for idealized square-pyramid this value is 102°) and 0.358 ($\Delta = 0$, $\tau = 0$, for idealized square-pyramid) indicating appreciable distortion.

In this molecule, the H_2L^1 hydrazone ligand in its dinegative form $(L^1)^{2-}$, forms one six-membered and one five-membered chelate ring at the V(V) acceptor center with the corresponding bite angles being 83.1(2)° and 74.7(2)°. The atoms in the five-membered ring are coplanar with an r.m.s. deviation of 0.03 Å and the six-membered ring is folded. The C–O, C–N and N-N distances of the five-membered chelate ring are consistent with the enolate form of the amide. The four V–O bond lengths present in the molecule are unequal and follow the order: V–O(oxido) < V–O(alkoxide) < V–O(phenoxide) < V–O(enolate), which can be explained on the basis of π-bonding ability and the basicity of the O-donor moieties. The short V–O(1) distance of 1.580(4) Å indicates the presence of a vanadium-oxygen double bond which is commonly found in the VO^{3+} complexes.

3.3.2. Structure of $[VO(L^1)(OCH_3)]_2$ (**1A**)

Like the complex **1**, the crystals of complex **1A** also belong to the orthorhombic crystal system but with *Pbca* space group. The dimeric structure of **1A** is illustrated in Fig. 2. The dimensions in the metal coordination sphere are collected in Table 2. The dimer, which lies on a crystallographic center of symmetry is formed by two bridging methoxide-O atoms with V–O(4) and V–O(4)$1 [Symmetry code $1 = 1 − x, −y, 1 − z] bond lengths of 1.838(5) and 2.400(5) Å, respectively. This symmetry is also reflected in its electrochemical behaviour. The V···V separation is 3.373(2) Å and the V–O(4)–V$1 angle is 104.7(2)° which is very similar with the other hydrazone complexes [8,9]. The V···V separation is longer than in **2A** (by ~0.04 Å) and **3A** (by ~0.06 Å) indicating less effective bridging which is expected from the ligand's basicity point of view. Like **1**, the H_2L^1 ligand also binds the vanadium meridionally in its fully deprotonated $(L^1)^{2-}$ form through the phenolate-O, imine-N and deprotonated amide-O in its enol form generating a folded six-membered and an almost planar (with an r.m.s. deviation of 0.0735 Å) five-membered chelate ring. The corresponding bite angles are 82.8(2)° and 75.7(2)° which are very similar with the other four complexes and also other reported hydrazone complexes [7–10,12]. So, the phenolate-O, enolate-O and the imine-N atoms of $(L^1)^{2-}$ species and the methoxide-O atom (lying *trans* to the imine-N) form the square plane with an r.m.s. deviation of 0.0324 Å. Two axial positions are occupied by the oxido-O(1) atom and a bridging methoxide-O(4$1) atom of the neighbouring molecule. The displacement of the V(V) center towards the O(1) atom from the square plane is 0.349(3) Å which is significantly lower than the complex **1** (*vide supra*) and the atoms of the ligands are also symmetrically disposed relative to the center of the $[VO(\mu_2\text{-}OCH_3)_2VO]^{4+}$ core and the disposition of the oxidovanadium groups is anti-coplanar which is also observed in other dimeric oxidovanadium complexes [7–9]. The V=O distance is only 1.569(5) Å which is very closed to **3A** (*vide infra*) and another complex reported by Moon et al. [29] (in a pentacoordinated ethoxy bonded oxidovanadium(V)-hydrazone complex derived from salicyl hydrazide and acetyl acetone) but shorter than the other four complexes and also other similar type of reported complexes (~1.580 Å) [7–10,12]. Due to the formation of bridge, the V–O(4) (methoxide) bond increases significantly (by ~0.08 Å) in comparison to its monomer **1** and it becomes longer than the V–O(2) (phenolate) bond. The five V–O bond lengths follow the order: V–O(oxido) < V–O(phenoxide) < V–O(methoxide)^e (e = equatorial) < V–O(enolate) < V–O(methoxide)^a (a = axial).

3.3.3. Structure of $[VO(L^2)(OCH_3)]$ (**2**)

The molecular structure of **2** is very similar to the structure of **1** with the hydrogen atom at the 5-position of the aryloxy ring replaced by a methyl group and its crystals belong to the monoclinic crystal system with $P2_1ab$ space group. The molecular structure and the atom-numbering scheme are illustrated in Fig. 3 and the dimensions are provided in Table 2.

In **2**, the equatorial positions of vanadium atom are occupied by phenolate-O, imine-N and the enolate-O atoms of the fully deprotonated H_2L^2 ligand in its enol form along with a methoxy oxygen (with an r.m.s. deviation of 0.13 Å) and one axial position is occupied by the oxido oxygen atom. Thus, a distorted square-pyramidal geometry is formed at the vanadium center. The vanadium atom is 0.504 Å from the mean equatorial plane towards the oxido oxygen atom O(1). The $(L^2)^{2-}$ species binds meridionally generating a six-membered ring (which is folded) and a almost planar five-membered ring (with an r.m.s. deviation of 0.04 Å), the corresponding bite angles being 82.36(7)° and 74.59(7)°. Significant distortion from the perfect square-pyramidal geometry can be estimated from the value of average O(axial)–V–O/N(basal) angle (105.3°)

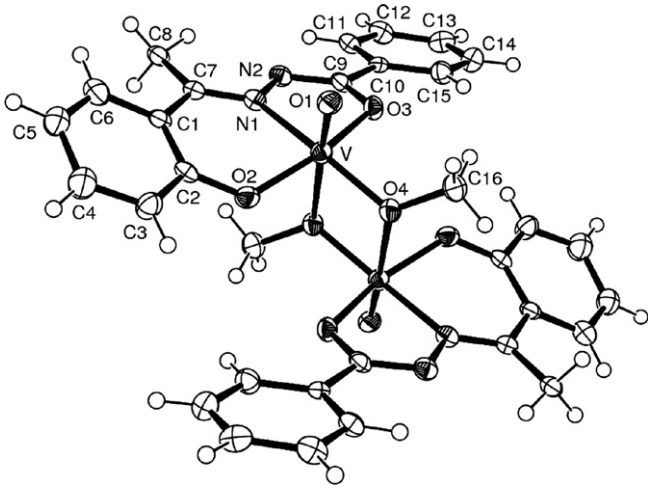

Fig. 2. Molecular structure of **1A** showing the atom-numbering scheme with ellipsoid at 50% probability.

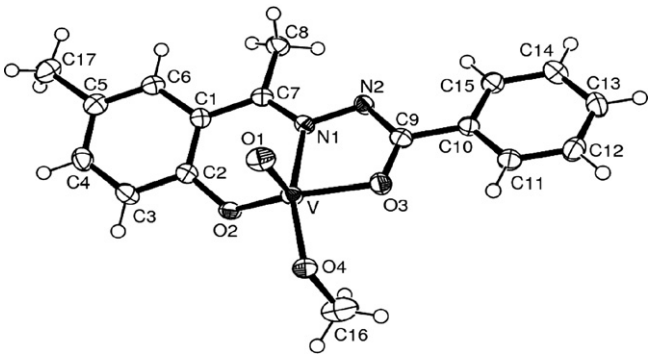

Fig. 3. Molecular structure of **2** showing the atom-numbering scheme with ellipsoid at 50% probability.

and also from the τ value (0.316). The four bond lengths follow the similar order as that in **1**.

3.3.4. Structure of $[VO(L^2)(OCH_3)]_2$ (**2A**)

Like **2**, the crystals of complex **2A** also belong to the monoclinic crystal system but with *C2/c* space group. The molecular structure of **2A** is illustrated in Fig. 4 and the bond parameters are listed in Table 2. The dimer, which lies on a crystallographic center of symmetry is formed by two bridging methoxide-O atoms with V–O(4) and V–O(4)$2 [Symmetry code $2 = $-x + ½, -y + ½, -z$] bond lengths of 1.8248(18) and 2.311(2) Å, respectively. The V···V separation is 3.329(1) Å and the angle V–O(4)–V$2 is 106.35(13)° which is very similar to **1A** and **3A** (*vide infra*) and also other reported dimethoxy-bridged hydrazone complexes [8,9]. The V···V separation is shorter (by ~0.04 angle Å) than **1A** indicating more effective bridging due to the higher basic property of $(L^2)^{2-}$ ligand in comparison to $(L^1)^{2-}$ ligand but it is longer (by ~0.02 Å) than **3A** indicating less effective bridging arising from lower basic property of $(L^2)^{2-}$ ligand in comparison to $(L^3)^{2-}$ ligand. The binding nature of $(L^2)^{2-}$ ligand in this complex is very similar to **2** forming a folded six-membered and an almost planar five-membered chelate ring with the corresponding bite angles being 82.19(9)° and 74.86(8)°. The displacement of the V atom towards the O(1) atom from the mean square plane [formed by O(2), N(1), O(3) and O(4) atoms] is 0.330 Å, which is lower than **1**, **1A**, **2** and **3** but higher than **3A**. Due to hexa-coordination, there is a significant change in equatorial V–O/N bond lengths in comparison to its monomeric analogue **2**: V–O(2) and V–N(1) bonds are shortened by ~0.01 Å while V–O(3) and V–O(4) bonds are lengthened by ~0.02 and ~0.06 Å, respectively. Like **1A**, the V–O(4) (methoxide) bond in this complex, is also longer than V–O(2) (phenolate) bond by ~0.01 Å, which is not usual. Hence, the five V–O bond lengths follow the similar order to **1A**.

3.3.5. Structure of $[VO(L^3)(OCH_3)]$ (**3**)

The crystals of complex **3** belong to the monoclinic crystal system with $P2_1/c$ space group and its crystallographic data are collected in Table 1. Fig. 5 displays a perspective view of this complex and the bond parameters are listed in Table 2. The molecular structure of **3** is also very much similar to **1** and **2** with the 5-position occupied by a methoxy group and the geometry around the vanadium center is also distorted square-pyramidal. The basal plane is occupied by the phenolate-O, enolate-O and the imine-N atoms of the meridionally disposed $(L^3)^{2-}$ ligand [forming one six-membered (folded) and one five-membered (atoms are coplanar with an r.m.s. deviation of 0.080 Å) chelate ring at the V(V) acceptor center with the corresponding bite angles being 82.40(14)° and 74.34(15)°] together with a methoxy oxygen atom. The r.m.s. deviation of the four contributing atoms of the basal plane is 0.054 Å. The vanadium atom is displaced from this plane by 0.475(2) Å towards the axial oxido oxygen O(1). The values of average O(axial)–V–O/N(basal) angle and τ parameter are, respectively, 104.1° and 0.186 indicating appreciable distortion but to a lesser extent than the complexes **1** and **2**. The four V–O bond lengths present in the molecule are unequal and also follow the similar order as that in **1** and **2**.

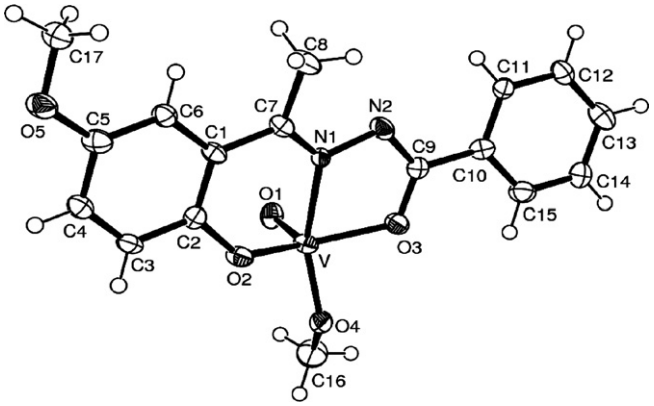

Fig. 5. Molecular structure of **3** showing the atom-numbering scheme with ellipsoid at 50% probability.

3.3.6. Structure of $[VO(L^3)(OCH_3)]_2$ (**3A**)

The crystals of complex **3A** belong to the triclinic crystal system with $P\bar{1}$ space group. The molecular structure of **3A** is illustrated in Fig. 6, which is very similar to the structure of **1A** and **2A** with the hydrogen atom and the methyl group, respectively, at the 5-position in the aryloxy ring replaced by a methoxy group. The molecular dimensions in the coordination sphere are collected in Table 2. Like **1A** and **2A**, this dimer also lies on a crystallographic center of symmetry, formed by two methoxide-O atoms with V–O(4) and V–O(4)$3 [Symmetry code $3 = $-x, -y, -z$] bond lengths of 1.838(3) and 2.282(3) Å, respectively. The V···V separation is 3.309(1) Å and the angle V–O(4)–V$3 is 106.35(13)° which is very similar with

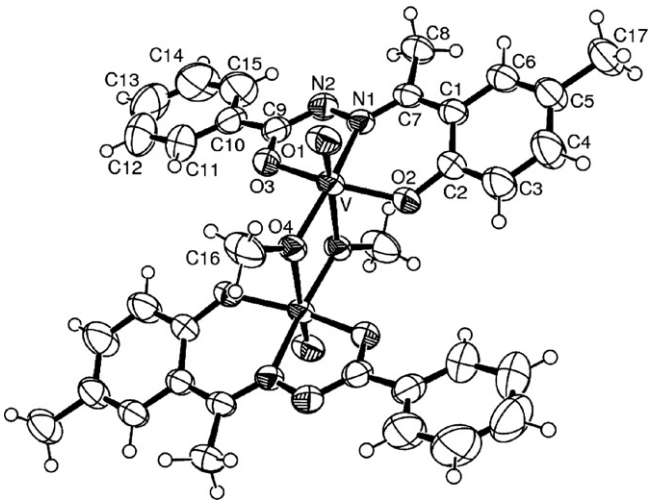

Fig. 4. Molecular structure of **2A** showing the atom-numbering scheme with ellipsoid at 50% probability.

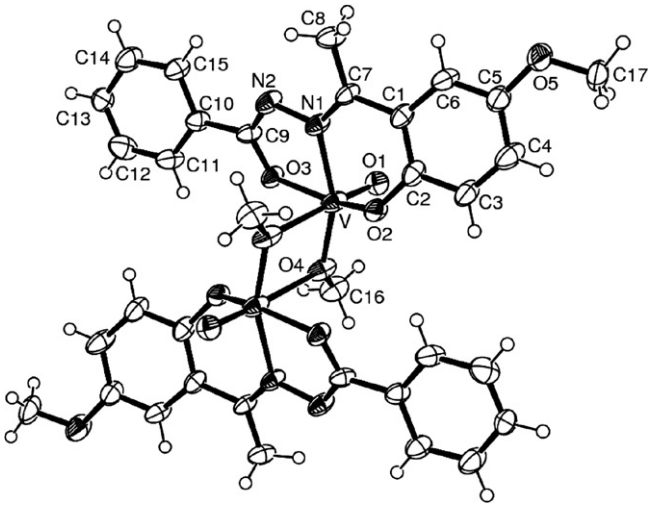

Fig. 6. Molecular structure of **3A** showing the atom-numbering scheme with ellipsoid at 50% probability.

the other two dimeric hydrazone complexes reported here The V···V separation is shorter than in **1A** and **2A**, respectively, by 0.06 Å and 0.02 Å, indicating more effective bridging which is expected from the ligand's basicity point of view. Like **3**, the H_2L^3 ligand binds the vanadium meridionally through the phenolate-O, imine-N and deprotonated amide-O in its enol form generating a folded six-membered and an almost planar (with an r.m.s. deviation of 0.05 Å) five-membered chelate ring with the corresponding bite angles being 82.90(14)° and 74.67(13)°. So, the fully deprotonated ONO donor moieties of the $(L^3)^{2-}$ species and the methoxide-O (lying *trans* to the imine-N) form the square plane with an r.m.s. deviation of 0.01 Å. Two axial positions are occupied by the oxido-O(1) atom and a bridging methoxide-O(4$3) atom of the neighbouring molecule. The displacement of the V(V) center towards the O(1) atom from the square plane is 0.322 Å which is significantly lower than the complexes **1**, **1A**, **2**, **2A** and **3** (*vide infra*). Like **1A** and **2A**, the atoms of the ligands are also symmetrically disposed relative to the center of the $[VO(\mu_2\text{-}OCH_3)_2VO]^{4+}$ core and the disposition of the oxidovanadium groups is anti-coplanar. The V=O distance is only 1.558(3) Å which is very closed to **1A** and shorter than the other four complexes and also other similar type of reported complexes (~1.580 Å) [7–10,12]. To the best of our knowledge, this V=O bond length represents the shortest V=O distance in the family of complexes with VO^{3+} motif both in penta- and hexa-coordinated environment. Due to the formation of bridge, the V–O(4) (methoxide) bond increases significantly in comparison to its monomeric form **3** and is almost equal in length to the V–O(2) (phenolate) bond and hence, the five V–O bond lengths follow the order: V–O(oxido) < V–O(methoxide)^e (e = equatorial) ≈ V–O(phenoxide) < V–O(enolate) < V–O(methoxide)^a (a = axial).

From the structural analysis discussed above, it is evident that the extent of displacement of the vanadium atom from the mean square plane decreases with the increase of electron donating property of the substituent in both the monomeric and dimeric complexes. Furthermore, the V=O bond distance in **3A** represents the shortest V=O bond in the complexes with VO^{3+} motif present in either penta- or hexa-coordinated environment while in the complexes **1A** and **2A**, the V–O(methoxide) bond represents the unusually long bond which is even longer than V–O(phenolate) bond.

3.4. Proton NMR spectra of the complexes

^{1}H NMR data of all the complexes are given in Section 2. Complex $[VO(L^4)(OCH_3)]$ (**4**) was identified by its NMR spectra in $CDCl_3$ solution. Apart from all the proton signals of the coordinated ligand $(L^1)^{2-}$, $(L^2)^{2-}$ and $(L^3)^{2-}$, the spectrum of **1A**, **2A** and **3A** exhibited one singlet at ~5.18 ppm corresponds to protons of the bridging OCH_3 group in addition to another singlet (with different intensity) at 3.48 ppm attributed to the coordinated terminal OCH_3 group (observed in the NMR spectra of monomeric **1**–**4** complexes). These two peaks indicate that these dimeric species **1A**, **2A** and **3A** are decomposed to the corresponding monomeric species significantly (the ratio of dimeric species to monomeric being ~1:1 for **1A** and **2A** and ~10:7 for complex **3A**) in $CDCl_3$ solution.

3.5. Electronic spectra of the complexes

The electronic spectral data of all the complexes are described in the Section 2. The electronic spectra of the monomeric complexes **1**–**4** in CH_2Cl_2 solution exhibit two intense absorption bands: one in the 378–388 nm region, which is assigned to L→V(dπ) LMCT transition and another in the 321-326 nm region attributed to intra-ligand π→π* transition of C≡N bond. Such type of LMCT transition band for the complexes **1A**, **2A** and **3A** was observed at 381 nm, 378 nm and 376 nm, respectively, and the intra-ligand π→π* transition at *ca.* 325 nm.

3.6. Electrochemistry of the complexes

All the complexes exhibit one quasi-reversible reduction peak in the +0.19 V to +0.31 V versus SCE region in CH_2Cl_2 solution due to VO^{3+}/VO^{2+} couple. Cyclic voltammetric data for all the complexes are collected in Table 3 and the Fig. 7 displays a representative cyclic voltammogram of **2**. The dinuclear V(V) complexes are usually expected to undergo a two step one electron reduction, with the first step leading to the formation of mixed-valence V(V)–V(IV) species. But contrary to such an expectation, all the dinuclear complexes **1A**, **2A** and **3A** were found to undergo only one-step quasi-reversible reduction in CH_2Cl_2 solution in the potential +0.19–0.25 V region. On changing from the penta- to hexa-coordinated environment around the vanadium in the respective dimeric form, the redox potential value is decreased by only 0.01 V. The appearance of one reduction peak for these dinuclear complexes is probably due to their conversion to the monomeric species in solution (which have almost identical redox potential value) to a significant extent as evident in their ^{1}H NMR specta. The $E_{½}$ values of the complexes have been found to follow a linear trend with the Hammett parameter (σ) of the substituent in the ligands (*vide supra*).

Table 3
Electrochemical[a] data of the complexes **1**–**4** in CH_2Cl_2 solution at 298 K

Compound	E_p^c (V)	E_p^a (V)	$E_{½}$[b]/V (ΔE_P/mV)
$[VO(L^1)(OCH_3)]$ (**1**)	+0.215	+0.305	+0.26(90)
$[VO(L^1)(OCH_3)]_2$ (**1A**)	+0.21	+0.29	+0.25(80)
$[VO(L^2)(OCH_3)]$ (**2**)	+0.17	+0.27	+0.22(100)
$[VO(L^2)(OCH_3)]_2$ (**2A**)	+0.16	+0.26	+0.21(100)
$[VO(L^3)(OCH_3)]$ (**3**)	+0.15	+0.25	+0.20(100)
$[VO(L^3)(OCH_3)]_2$ (**3A**)	+0.14	+0.24	+0.19(100)
$[VO(L^4)(OCH_3)]$ (**4**)	+0.27	+0.35	+0.31(80)

[a] At a Pt disk electrode; supporting electrolyte: Et_4NClO_4 (TEAP, 0.1 M), scan rate 50 mV s^{-1}, reference electrode SCE, solute concentration ~10^{-3} M.
[b] $E_{½}$ is calculated as the average of anodic (E_p^a) and cathodic (E_p^c) peak potential values; ΔE_p = difference of cathodic and anodic peak potential values.

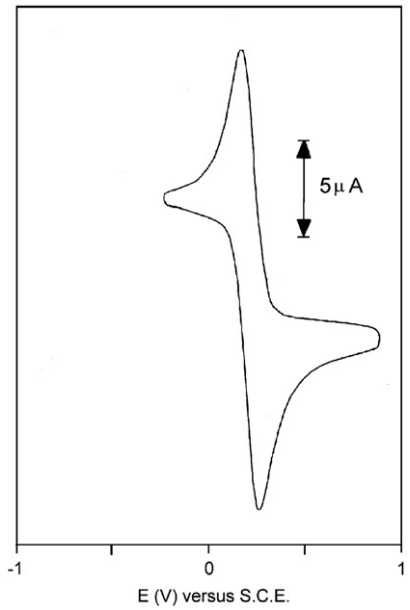

Fig. 7. Cyclic voltammogram of **2** in CH_2Cl_2 solution.

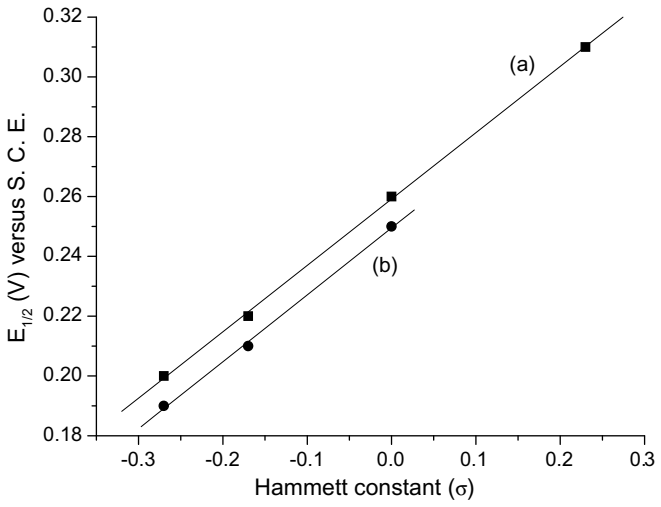

Fig. 8. (a) Plot of $E_{½}$ vs. Hammett constant (σ) of the monomeric complexes **1**–**4**; (b) Plot of $E_{½}$ vs. Hammett constant (σ) of the dimeric complexes **1A**–**3A**.

3.7. Influence of ligand substituents on $E_{½}$ values of the complexes

An analysis of the $E_{½}$ values of the complexes **2**, **2A**, **3** and **3A** indicate that for the complexes with an electron donating substituent at 5-position, a decrease in $E_{½}$ values occurs compared to complex **1** and **1A** while, for the complex **4** with an electron withdrawing substituent, the opposite is true. For finding out the quantitative relation with the electronic effect of the substituent at the 5-position on the vanadium center, the redox potential ($E_{½}$) value of both monomeric and dimeric complexes are plotted against the respective Hammett constant (σ) (Fig. 8a and b, respectively).

These two plots show linear relations [20,21,30–32] and statistical analysis gives the following relations describing the dependence on σ:

For monomeric complexes:

$$E_{1/2}\ (\mathrm{V}) = 0.26 + 0.22 \times \sigma \quad (8)$$

For dimeric complexes:

$$E_{1/2}\ (\mathrm{V}) = 0.25 + 0.22 \times \sigma \quad (9)$$

These correlations have r-values of ~1.00 with a standard deviation 0.0013 and 0.0018, respectively, for monomeric and dimeric complexes. The estimated error in the intercept of Fig. 8a is 6.74×10^{-4} and in the $dE_{½}/d\sigma$ value is 3.43×10^{-3} while those of Fig. 8b are, respectively, 0.0017 and 0.0093.

4. Conclusion

The basic property of a family of hydrazone ligands has been nicely exploited in the syntheses of mixed-ligand methoxy bonded monomeric and methoxy-bridged dimeric oxidovanadium(V)-hydrazone complexes. Six of the seven complexes (except **4**) reported here, have been structurally characterized. This study indicates that the lower basic hydrazone ligands (e.g., H_2L^1, H_2L^2 and H_2L^4) have the normal tendency to form monomeric complex (**1**, **2** and **4**, respectively), while the higher basic ligand (e.g., H_2L^3) has a tendency to form methoxy-bridged dimeric complexes **3A**. The intermediate basic H_2L^1 and H_2L^2 ligands can form the dimeric species **1A** and **2A** in the presence of 4,4′-bipyridine and 2,2′-bipyridine, respectively, while the strong basic H_2L^3 ligand can form the monomeric species **3** only by the decomposition of **3A** with the influence of imidazole (a monodentate intermediate basic N-donor ligand). These VO^{3+} complexes are easily interconvertible to the complexes with $V_2O_3^{4+}$ and VO_2^{+} motifs.

5. Supplementary data

CCDC 681054, 689347, 681055, 681056, 681057 and 681058 contain the supplementary crystallographic data for **1**, **1A**, **2**, **2A**, **3** and **3A**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. Materials

Safety note: cobalt perchlorate salt with organic ligands is often explosive and should be handled with caution.

All other reagents and solvent were purchased from Merck (pro-analysis) and dried using molecular sieves (Linde 4 Å). NaY with the Si:Al ratio of 2.53 was purchased from Aldrich (Lot No. 67812). Thiodiglycolic acid also obtained from Aldrich. 1,2-Diaminoethane, 1,3-diaminopropane, 1,2-diaminobenzene, 1,3-diaminobenzene was obtained from Merck. Solvents were dried before used.

2.2. Physical measurements

The elemental analysis (CHN) of the materials was obtained from Carlo ERBA Model EA 1108 analyzer. XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Nitrogen adsorption measurements were performed at 77 K using a Coulter Ofeisorb 100CX instrument. The samples were degassed at 150 °C until a vacuum more than 10^{-3} Pa was obtained. Micropore volumes were determined by the *t*-method, a "monolayer equivalent area" was calculated from the micropore volume [22,23]. The stability of the encapsulated complexes was checked after the reaction by UV–Vis and possible leaching of the complex was investigated by UV–Vis in the reaction solution after filtration of the zeolite. The amounts of metallocomplexes encapsulated in zeolite matrix were determined by the elemental analysis and followed by subtracting the amount of metallocomplex left from the solutions after the synthesis of the complexes as determined by UV–Vis spectroscopy, from the amount taken for the synthesis. Atomic absorption spectra (AAS) were recorded on a Perkin–Elmer 4100-1319 Spectrophotometer using a flame approach, after the acid (HF) dissolves the known amounts of the zeolitic material. SiO_2 was determined by gravimetric analysis. Magnetic moments were calculated from magnetic susceptibility data obtained using a Johnson Matthey MK-1 magnetic susceptibility balance and conductance measurements with a Metrohm Herisau conductometer E 518. FT-IR spectra were recorded on Shimadzu Varian 4300 spectrophotometer in KBr pellets. The electronic spectra of the neat complexes were taken on a Shimadzu UV–Vis scanning spectrometer (Model 2101 PC). Diffuse reflectance spectra (DRS) were registered on a Shimadzu UV/3101 PC spectrophotometer over the range 1500–200 nm, using MgO as reference. FAB mass spectra were recorded on a Kratos MS50TC spectrometer.

2.3. Synthesis of tetraoxodithiatetraaza macrocyclic ligand

Tetraoxodithiatetraaza macrocyclic ligands ([18]aneN$_4$S$_2$, [20]aneN$_4$S$_2$, Bzo$_2$[18]aneN$_4$S$_2$ or Bzo$_2$[20]aneN$_4$S$_2$) were prepared by following the procedures reported in Ref. [24]. The ligand has been synthesized by the condensation reaction of the thiodiglycolic acid (0.02 mol) and diamine (0.02 mol); diamine = 1,2-diaminoethane (1.20 g), 1,3-diaminopropane (1.48 g), 1,2-diaminobenzene (2.16 g), 1,3-diaminobenzene (2.16 g). Both reagents were taken in equimolar ratio in a round bottom flask, in the presence of few drops of concentrated hydrochloric acid (∼pH 4–5) and were refluxed on a water bath up to the completion of reaction. After completion of the reaction mixture was kept in a refrigerator at 0 °C, over night. The cream colored crystals separated out, which were filtered, washed with cold EtOH and dried in vacuum over P_4O_{10}. The purity was checked by HPLC technique.

2.4. Preparation of [Co([18 or 20]aneN$_4$S$_2$)](ClO$_4$)$_2$ and [Co(Bzo$_2$[18 or 20]aneN$_4$S$_2$)](ClO$_4$)$_2$ complexes

Cobalt(II) perchlorate hexahydrate (3.66 g, 0.01 mol) dissolved in ethanol (20 ml) was reacted with an ethanolic (20 ml) solution of tetraoxodithiatetraaza ligands ([18]aneN$_4$S$_2$, [20]aneN$_4$S$_2$, Bzo$_2$[18]aneN$_4$S$_2$ or Bzo$_2$[20]aneN$_4$S$_2$) (0.01 mol) by refluxing for 1 h under nitrogen atmosphere. The mixture was heated at reflux for 6 h until an orange solution resulted. The solution was cooled to room temperature and filtered to remove cobalt hydroxide. Excess lithium perchlorate dissolved in methanol was added to the filtrate, and the mixture was kept in the refrigerator until orange solid formed. The solids were filtered, washed thoroughly with cold ethanol and dried in vacuum.

2.5. Preparation of [Co(N–N)$_2$]$^{2+}$–NaY

Typically a 4 g sample of NaY zeolite was mixed with 0.37 g of bis(diamine)cobalt(II) perchlorate; diamine = 1,2-diaminopropane, 1,3-diaminopropane, 1,2-diaminobenzene or 1,3-diaminobenzene; suspended in 100 ml of methanol and then refluxed for 8 h. The pale orange solid consisting of [Co(N–N)$_2$]$^{2+}$ exchanged with Na^+ in NaY and denoted as [Co(N–N)$_2$]$^{2+}$–NaY was collected by filtration, washed with ethanol. The resulted zeolites, were Soxhlet extracted with *N*,*N*′-dimethylformamide (for 4 h) and then with ethanol (for 3 h) to remove excess unreacted diamine and any Co(II) complexes adsorbed onto the external surface of the zeolite crystallines. The resulting light orange solids were dried at 60 °C under vacuum for 24 h.

2.6. Preparation of [Co([18 or 20]aneN$_4$S$_2$)]$^{2+}$–NaY and [Co(Bzo$_2$[18 or 20]aneN$_4$S$_2$)]$^{2+}$–NaY

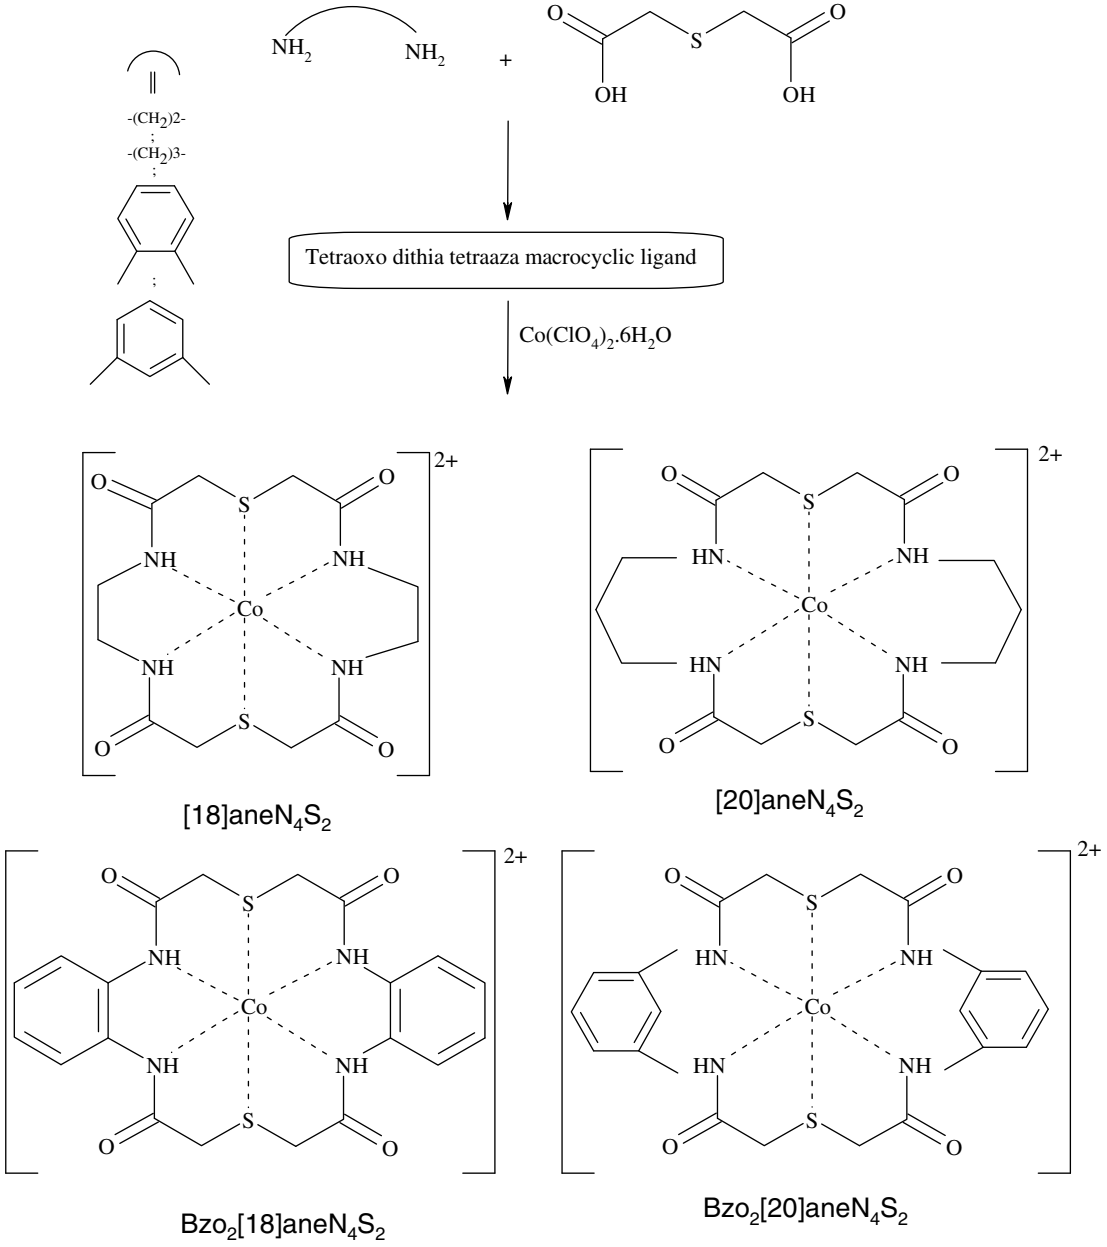
To a stirred methanol suspension (100 ml) of [Co(N–N)$_2$]$^{2+}$–NaY (2 g) was slowly added thiodiglycolic acid (under N_2 atmosphere). The mixture was heated under reflux condition for 24 h until a pale pink suspension resulted. The solution was filtered and the resulting zeolites, were Soxhlet extracted with *N*,*N*′-dimethylformamide (for 6 h) and then with ethanol (for 5 h) to remove excess unreacted products from amine-ester condensation and any cobalt(II) complexes adsorbed onto the external surface of the zeolite crystallines. The resulting pale pink solids were dried at 70 °C under vacuum for 12 h. The remaining [bis(diamine)cobalt(II)] ions in zeolite were removed by exchanging with aqueous 0.1 M $NaNO_3$ solutions. The stability of the encapsulated complexes was checked after the reaction by UV–Vis and possible leaching of the complex was investigated by UV–Vis in the reaction solution after filtration of the zeolite. The amount of cobalt(II) complexes encapsulated in zeolite matrix were determined by the elemental analysis and subtracting the amount of Co(II) complex left from the solutions after the synthesis of the complexes is determined by UV–Vis spectroscopy, from the amount taken for the synthesis.

3. Results and discussion

Cobalt(II) reacted with 18- and 20-membered tetraoxodithiatetraaza macrocyclic ligands ([18]aneN$_4$S$_2$, [20]aneN$_4$S$_2$, Bzo$_2$[18]aneN$_4$S$_2$ and Bzo$_2$[20]aneN$_4$S$_2$) in presence of $LiClO_4$ to yield the cationic complexes; [Co([18]aneN$_4$S$_2$)](ClO$_4$)$_2$, [Co([20]aneN$_4$S$_2$)](ClO$_4$)$_2$, [Co(Bzo$_2$[18]aneN$_4$S$_2$)](ClO$_4$)$_2$ and [Co(Bzo$_2$[20]aneN$_4$S$_2$)](ClO$_4$)$_2$ (Scheme 1).

3.1. ^{1}H NMR studies

The ^{1}H NMR a spectrum of all tetraoxodithiatetraaza macrocyclic ligands in $CDCl_3$ does not give any signal corresponding to primary amine and alcoholic protons. It shows a multiplet at



Scheme 1.

~8.60 ppm corresponding to amide CO–NH (4H) protons and does not show any signal corresponding to primary amine and alcoholic protons. A multiplet signal corresponding to methylene proton CO–N–CH_2 (8H) that are adjacent to the nitrogen atom appeared at ~3.40 ppm. NMR spectrum also shows a singlet at ~2.35 ppm corresponding to CO–CH_2–S (8H) that is close to sulphur atom.

For more investigation of structure, were synthesized the diamagnetic zinc(II) complexes (Table 1). The diamagnetic nature of the zinc(II) complexes has allowed its characterization by NMR spectrometry. The ^{1}H NMR spectrum of zinc complexes has been recorded in DMSO-d_6 as it is insoluble in $CHCl_3$-*d*. The ^{1}H NMR spectra of all the zinc(II) complexes does not show any signal corresponding to primary amino and alcoholic protons. However, show multiplet in the region 8.50–8.68 ppm, which is assigned to amide (HN–CO, 4H) protons [25]. Another multiplet appeared in the region 3.37 ppm ($[Zn([18]aneN_4S_2)]^{2+}$) and 3.35 ppm ($[Zn([20]aneN_4S_2)]^{2+}$), corresponding to the methylene protons [26] (CO–N–CH_2, 8H) which are adjacent to the nitrogen atoms. The multiplet appearing in the region δ 7.1–7.6 ppm has been assigned to phenyl protons ($[Zn(Bzo_2[18]aneN_4S_2)]^{2+}$ and $[Zn(Bzo_2[20]aneN_4S_2)^{2+}$). Furthermore, a singlet in the region 2.43–2.46 ppm was observed assignable to methylene protons (CO–CH_2–S, 8H) which are adjacent to the sulfur atom.

3.2. Co content and textural analysis

The molecular formulae of the complexes "$[Co([18]aneN_4S_2)](ClO_4)_2$, $[Co([20]aneN_4S_2)](ClO_4)_2$, $[Co(Bzo_2[18]aneN_4S_2)](ClO_4)_2$ and $[Co(Bzo_2[20]aneN_4S_2)](ClO_4)_2$" have been assigned on the basis of the results of their elemental analysis and the molecular ion peaks in the mass spectra. All mass spectra showed molecular ion peaks for the 1:1 metal-to-ligand stoichiometry with no further peaks above them. A preliminary identification of the metal complexes was made on the basis of their IR spectra, which exhibited no bands characteristic of free primary amine, thus supporting the proposed macrocyclic skeleton (Scheme 1).

DMSO solutions of these complexes were conductive (Table 2). Unfortunately, I could not grow any single crystals suitable for

Table 1

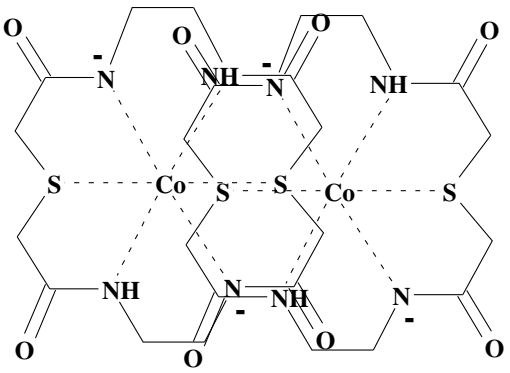
[a] In DMSO solutions.

X-ray crystallographic studies. The molar conductance values ($\sim$170 Ω^{-1} mol^{-1} cm^2) and measured of tetraoxodithiatetraaza macrocyclic complexes correspond to 1:2 electrolytes. Comparing the obtained magnetic measurement at room temperature and the results of electronic spectra (Table 2) of metal complexes with octahedral Co(II) tetraoxodithiatetraaza macrocycle complexes indicated that the tetraoxodithiatetraaza ligands of this study do not differ significantly from the dithiatetraaza ligands respect to the ligand field strength. The results of elemental analysis (Table 1) support the proposed macrocyclic structure.

The 18- and 20-membered tetraoxodithiatetraaza macrocyclic cobalt(II) complexes undergo intense color changes due to deprotonation of the macrocyclic ligand in the presence of amine bases such as pyridine and Et_3N. Similar N–H deprotonations have been observed with other metal complexes containing N–H linkages. For the cobalt(II) complex, Et_3N is sufficiently basic to facilitate formation of the molecular complex. For preparation of the deprotonation form of $[Co([18]aneN_4S_2)](ClO_4)_2$; triethyleneamine (0.5 ml) was added to a deaerated solution of 200 mg of $[Co([18]aneN_4S_2)](ClO_4)_2$in 15 ml of MeCN. The deep-pink product, which began precipitating within minutes, was filtered after 0.5 h under a N_2 atmosphere, washed with anhydrous EtOH, and dried in a vacuum. IR (KBr, cm^{-1}): 3120 (ν_{N-H}). *Anal.* Calc. for $[Co(C_{12}H_{18}O_4N_4S_2)]$ (I): Co, 14.33; C, 35.40; H, 4.25; N, 13.94. Found: Co, 14.55; C, 35.57; H, 4.48; N, 13.82%. The N–H stretching frequency of this compound $[Co(C_{12}H_{18}O_4N_4S_2)]$, 3120 cm^{-1}, is reduced significantly from its dicationic precursor, $[Co([18]aneN_4S_2)](ClO_4)_2$, 3200 cm^{-1}.



The CHN analysis results of the neat cobalt complexes showed near similarity to the theoretical values. The cobalt contents of the zeolite encapsulated complexes were estimated by dissolving known amounts of the complex in concentric HCl and using AAS. The analytical data of each complex indicate molar ratios of Co:C:H almost close to those calculated for the mononuclear structure (Table 1). However, the presence of minute traces of free metal ions in the lattice could be assumed as the metal content which is slightly higher than the stoichiometric requirement. Only a portion of metal ions in metal-exchanged zeolite has undergone complexation and the rest is expected to be removed on re-exchange with sodium nitrate solution. The Si and Al contents in the metal-exchanged zeolites and the zeolite complexes are almost the same ratio as in the parent zeolite (Table 3). This indicates little changes in the zeolite framework due to the absence of dealumination in metal ion exchange.

The flexible ligand synthesis scheme leads to the encapsulation of Co(II) complexes of tetraoxodithiatetraaza macrocyclic ligands ($[18]aneN_4S_2$, $[20]aneN_4S_2$, $Bzo_2[18]aneN_4S_2$ and $Bzo_2[20]aneN_4S_2$) inside the nanopores of zeolite (Scheme 2). The results of chemical analysis of the samples are given in Table 3. The parent NaY zeolite has Si/Al molar ratio of 2.53 which corresponds to a unit cell formula $Na_{56}[(AlO_2)_{56}(SiO_2)_{136}]$. The unit cell formula of metal-exchanged zeolites shows 11 moles of cobalt dispersion per unit cell ($Na_{34}Co_{11}[(AlO_2)_{56}(SiO_2)_{136}] \cdot nH_2O$). The cobalt contents of all the encapsulated samples very little in the range of 2.5–2.6 wt%. On that basis of these results, along with elemental analysis, the average number of encapsulated Co complexes per nanocavity was determined to be 0.33 for the Co complexes–NaY.

3.3. Powder X-ray diffraction studies

The X-ray diffraction (XRD) patterns of encapsulated complexes are shown in Fig. 1. The encapsulated complex exhibit similar peaks to those of zeolite Y; except for a slight change in the intensity of the peaks, no new crystalline pattern emerges. These facts confirmed that the framework and crystallinity of zeolite were not destroyed during the preparation, and that the complexes were well distributed in the cages. The relative peak intensities of the 220, 311 and 331 reflections have been thought to be correlated to the locations of cations. In zeolite Y, the order of peak intensity is

in the order: $I_{331} > I_{220} > I_{311}$, while in encapsulated complexes, the order of peak intensity became $I_{331} > I_{311} > I_{220}$. The difference indicates that the ion-exchanged Co^{2+}, which substitutes at the location of Na+, undergoes rearrangement during complexation.

3.4. Scanning electron micrograph study

The SEM photographs of the samples taken before Soxhlet extraction show the deposition of complexes on the external surface. However, the absence of extraneous materials in the SEM photographs of finished products indicates the complete removal of complexes surface which could be accomplished by extended extraction procedures.

3.5. Electronic spectral studies

The electronic spectra of all tetraoxodithiatetraaza macrocyclic cobalt(II) complexes exhibit absorption in the region 15580–15800 and 19050–19700 cm^{-1} which may be assigned to the $4T_{1g}(F) \rightarrow 4A_{2g}(F)$ and $4T_{1g}(F) \rightarrow 4T_{1g}(P)$ transitions, respectively [27], suggesting an octahedral environment around the cobalt ions in these complexes. Furthermore, magnetic moments measurements in the range 4.87–4.93 BM (Table 2) support the above octahedral geometry [28]. Comparing the obtained magnetic measurement and the results of electronic spectra (Table 1) of metal complexes with octahedral Co(II) macrocycle complexes indicated that the N_4S_2 ligands of this study do not differ significantly from the tetraoxodithiatetraaza ligands respect to the ligand field strength. The diffuse reflectance spectra of Co(II) complexes contain dithiatetraaza macrocycle were almost identical before and after encapsulation, indicating the complexes maintain their geometry even after supported without significant distortion. The UV–Vis spectrum of Co(II)–NaY does not show any absorption band appear in the near-UV region, while spectrum of encapsulated complexes display two broad band at near-UV region, which is probably due to a symmetry forbidden ligand to metal charge transfer transition (Fig. 2). These data compare closely with that of pure complexes as well as of encapsulated complexes and are indicative of an octahedral structure present within the nanodimensional pores of zeolite. Bands due to zeolite encapsulated Co(II) complex appeared in the visible, and charge transfer bands appeared in the near-UV region; these values were very similar to the obtained values for the discrete neat complex [27,28].

3.6. IR spectral study

The infrared spectra of the complexes (Table 1) does not exhibit any band corresponding for the free –NH and –OH groups. Four new bands appear in the spectrum of free ligand in the regions 1637–1650, 1567–1573, 1243–1248 and 660–664 cm^{-1}, assignable to amide **I** [ν(C=O)], amide **II** [ν(C–N)+δ(N–H)], amide **III** [δ(N–H)], and amide **IV** [ϕ(C=O)] bands, respectively, which support the

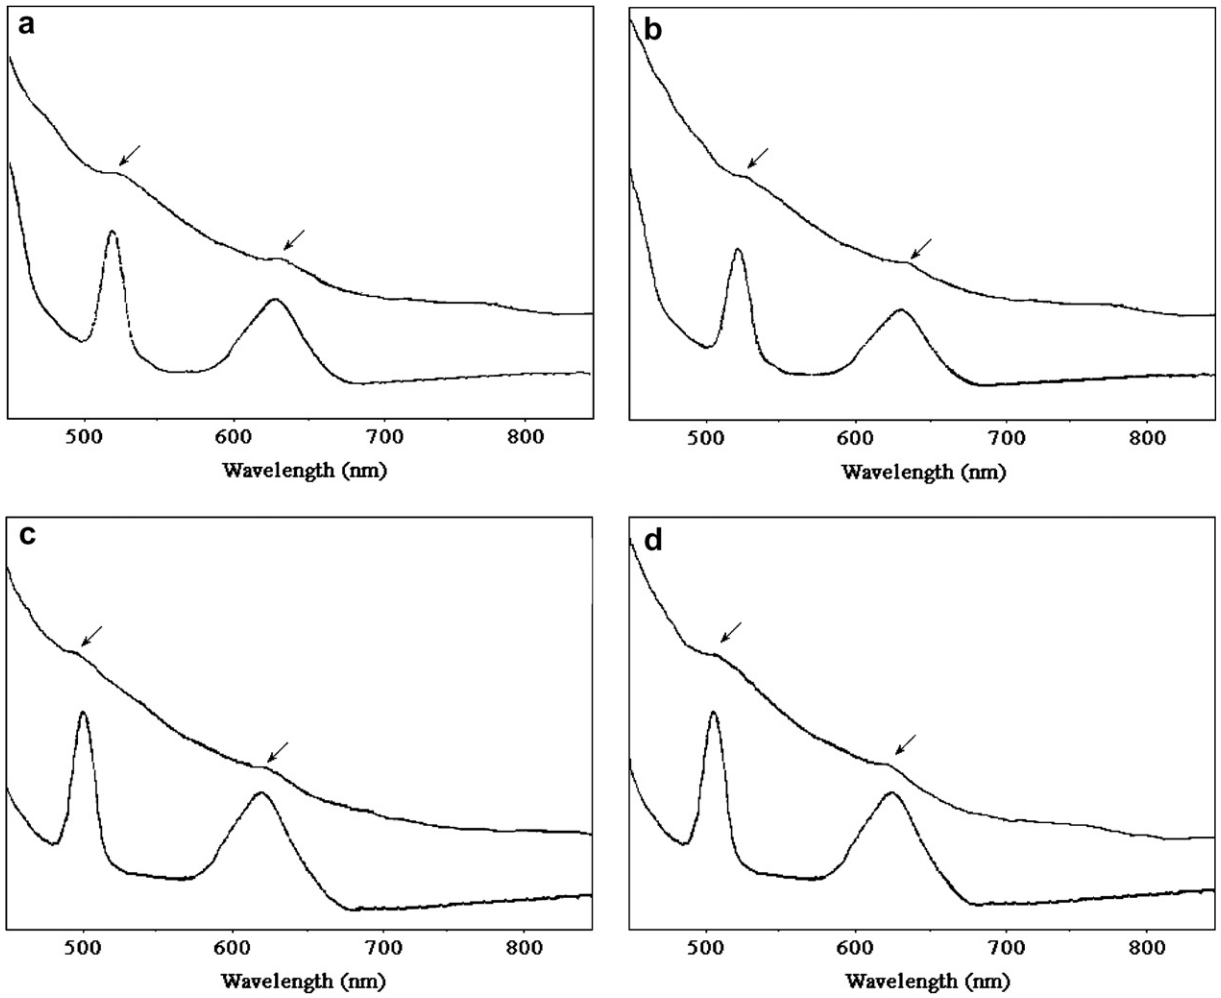

Fig. 2. UV–Vis and DRS spectra of (a) $[Co([18]aneN_4S_2)](ClO_4)_2$, $[Co([18]aneN_4S_2)]^{2+}$–NaY; (b) $[Co([20]aneN_4S_2)](ClO_4)_2$, $[Co([20]aneN_4S_2)]^{2+}$–NaY; (c) $[Co(Bzo_2[18]aneN_4S_2)](ClO_4)_2$, $[Co(Bzo_2[18]aneN_4S_2)]^{2+}$–NaY and (d) $Co(Bzo_2[20]aneN_4S_2)](ClO_4)_2$, $[Co(Bzo_2[20]aneN_4S_2)]^{2+}$–NaY.

macrocyclic structure. A single sharp band observed in the region 3100–3295 cm^{-1}may be assigned to ν(N–H) of the secondary amino group [29,30]. An important feature is the appearance of a new medium intensity band at 403–414 cm^{-1}attributable to ν(M–N) which provide strong evidence for the involvement of nitrogen in coordination [31].

IR spectra of the encapsulated complexes were obtained (Table 3). The intensity of the peaks of encapsulated complex is, though, weak due to low concentration of the complex in zeolite, the IR spectrum of encapsulated complex is essentially similar to that of the free metal complex. No significant broadening or shift of the structure-sensitive zeolite vibrations at 1130 cm^{-1} (due to asymmetric T–O stretch) on encapsulation indicates that there is no significant expansion of the zeolite cavity or dealumination during the encapsulation process. This further indicates that structure of metal complex fit nicely within the nanocavity of the zeolite. The entrapped complexes exhibit very similar IR data that are shifted 2–4 cm^{-1} relative to those of the corresponding free complexes (Table 1). These variations in band frequency can also be attributed to (i) distortions of the complexes, or to (ii) interactions with the zeolitic matrix (by electrostatic effects or co-ordination-the higher negative charge of the zeolite host makes it a stronger ligand). Thus, IR and UV–Vis data indicates the encapsulation of tetraoxodithiatetraaza macrocyclic complexes in the zeolite nanocavity.

3.7. Surface area and pore volume studies

The surface area and nanopore volume of the host–guest nanocomposite materials are presented in Table 4. The encapsulation of cobalt ions and cobalt tetraoxodithiatetraaza macrocyclic complexes reduced the surface area and adsorption capacity of nanopores of zeolite. The lowering of the nanopore volume and surface area supported the fact that cobalt(II) tetraoxodithiatetraaza macrocyclic complexes are present within the zeolite cages and not on the external surface.

3.8. XPS studies

The Co ($2p_{3/2}$) binding energy (E_b) is 857.7 and 856.3 eV in the Co complex in cobalt(II) perchlorate, respectively. The Co ($2p_{3/2}$) binding energy of the cobalt(II) complex has been increased 1.5 eV compared with that of the cobalt(II) chloride. The results indicate that the charge on the metals decreases when complexes were formed. The encapsulated complexes are referenced to the binding energy of 102.7 eV for the Si 2p core level due to its extensive use of this binding energy in NaY system [32–34]. However, the neat complexes are referenced to the binding energy of 292.7 eV for the K $2p_{3/2}$ core level. Table 5 shows the Co 2p core levels of the neat and the encapsulated complexes. Cobalt remains in the +2 oxidation states in both the neat and the encapsulated complexes and it matches well with the reported values for similar systems [35]. There is a high increase in satellite intensity for Co 2p levels and a large energy gap (~16.0 eV) in the encapsulated complex which show the higher stability than the neat complex.

Table 4
Surface area and pore volume data of host (nanopores of zeolite Y) guest (tetraoxodithiatetraaza macrocyclic cobalt(II) complexes) nanocomposite materials

Sample	Surface area[a] (m^2/g)	Pore volume[b] (ml/g)
NaY	545	0.31
Co(II)–NaY	532	0.30
$[Co([18]aneN_4S_2)]^{2+}$–NaY	395	0.18
$[Co([20]aneN_4S_2)]^{2+}$–NaY	388	0.17
$[Co(Bzo_2[18]aneN_4S_2)]^{2+}$–NaY	367	0.14
$[Co(Bzo_2[20]aneN_4S_2)]^{2+}$–NaY	355	0.12

[a] Surface area is the "monolayer equivalent area" calculated as explained in Ref. [22,23].
[b] Calculated by the *t*-method.

Table 5
XPS data of neat and host (nanopores of zeolite Y) guest (tetraoxodithiatetraaza macrocyclic cobalt(II) complexes) nanocomposite materials

Sample	BE, Co $2p_{3/2}$ (eV)	$2p_{3/2}$ and $2p_{1/2}$ separation (eV)
$[Co([18]aneN_4S_2)](ClO_4)_2$	782.1	15.5
$[Co([18]aneN_4S_2)]^{2+}$–NaY	782.9	16.8
$[Co([20]aneN_4S_2)](ClO_4)_2$	782.0	15.4
$[Co([20]aneN_4S_2)]^{2+}$–NaY	782.7	16.7
$[Co(Bzo_2[18]aneN_4S_2)](ClO_4)_2$	782.8	15.8
$[Co(Bzo_2[18]aneN_4S_2)]^{2+}$–NaY	783.4	17.3
$[Co(Bzo_2[20]aneN_4S_2)](ClO_4)_2$	782.6	15.6
$[Co(Bzo_2[20]aneN_4S_2)]^{2+}$–NaY	783.2	17.4

4. Conclusions

By combining surface analysis and spectroscopic data, it was possible to prove that $[Co([18]aneN_4S_2)]^{2+}$, $[Co([20]aneN_4S_2)]^{2+}$, $[Co(Bzo_2[18]aneN_4S_2)]^{2+}$ and $[Co(Bzo_2[20]aneN_4S_2)^{2+}$ can be encapsulated in the FAU nanopores of zeolite NaY by template condensation between preadsorbed; [bis(diamine)cobalt(II)]; (diamine = 1,2-diaminoethane, 1,3-diaminopropane, 1,2-diaminobenzene, 1,3-diaminobenzene); $[Co(N–N)_2]^{2+}$–NaY; and the corresponding thiodiglycolic acid, without damage of the main framework of the zeolite or loss of its crystallinity. The data indicate that all cobalt(II) complexes in NaY zeolite exhibit structural and electronic properties that are different from those of the same complexes encapsulated in NaY, which have been shown to be mainly physically entrapped in the FAU supercages, with no significant interaction with the zeolite matrix. Spectroscopic data (FT-IR, XRD, XPS and DRS) and BET technique for the encapsulated complexes in NaY suggest host/guest interactions within the zeolite.

Although the coordination chemistry of *S*-alkyl and *S*-benzyldithiocarbazate Schiff bases derived from orthohydroxy aldehydes and ketones [16–18], β-diketones [19–21] as well as β-*N*-heterocyclic aldehydes and ketones [22–25] have been extensively studied, less attention, however, was paid for Schiff bases obtained from the condensation of *S*-methyl and *S*-benzyldithiocarbazate with diacetylmonoxime (**1**) [26]. In the present work, the synthesis, characterization and X-ray crystal and molecular structures of some nickel(II) complexes derived from diacetylmonoxime *S*-benzyldithiocarbazonate have been studied aiming to search for new building blocks capable to form extended supramolecular assemblies via interligand or ligand–solvent hydrogen bonding.

2. Experimental

2.1. Materials

Diacetylmonoxime was obtained from Sigma, while pyrazole and imidazole were obtained from Aldrich and used without further purification.

2.2. Preparation of diacetylmonoxime S-benzyldithiocarbazonate (H_2L) (**1**)

A solution of *S*-benzyldithiocarbazate (1.98 g, 10 mmol) in ethanol (50 ml) was added to a solution of diacetylmonoxime (1.01 g, 10 mmol) in the same solvent (50 ml). The reaction mixture was heated under reflux for 2 h during which a white precipitate was formed. After cooling to room temperature, the solid product was isolated by filtration. The crude product was crystallized from ethanol then dried in vacuo. Yield: 75%. M.p. 210 °C, *Anal.* Calc. for $C_{12}H_{15}N_3OS_2$: C, 51.22; H, 5.37; N, 14.93, Found: C, 51.34; H, 5.42; N, 14.85%. IR (KBr) (cm^{-1}): 3412m ν(O–H); 3288m ν(N–H); [3155m, 2924m ν(C–H)]; 1641m,1606m $\nu(C{=}N)_{hy}$; 1485s,1449m,1419s, 1366m, 1281s, 1232m, 1140m, 1072s, 975m, 928m, 714m, 702m. UV–Vis (EtOH, λ_{max}/nm ($\log\varepsilon$)): 289(4.10); 322(4.50); 0.007 M KOH (EtOH): 273(4.06); 325(4.04); 370sh. ^{1}H NMR (DMSO-d_6, TMS, ppm): 12.47 (1H, oxime OH); 11.79 (1H, CONH); 7.40 (2H, m, aromatic); 7.30 (2H, m, aromatic); 7.24 (1H, m, aromatic); 4.46 (2H, s, SCH_2); 2.19 (3H, s, $CH_3C{=}NN$), 1.95 (3H, s, $CH_3C{=}NO$). $^{13}C\{^1H\}$ NMR (DMSO-d_6, TMS, δ): 198.68 (C=S); 154.11 (C=N-OH); 150.76 (C=N–NH); 136.77, 129.13, 128.38, 127.08 (CH- aromatic); 12.23 (CH_3–C=NOH); 9.16 (CH_3–C=N · N).

2.3. Preparation of nickel(II) complexes

2.3.1. Preparation of $[Ni(L)]_2$ (**2**)

A solution of nickel(II) acetate tetrahydrate (1.0 mmol, 0.281 g) in ethanol (30 ml) was added to a suspension of diacetylmonoxime-*S*-benzyldithiocarbazonate (1.0 mmol, 0.248 g) in ethanol (50 ml). The resulting mixture was treated with a solution of KOH (0.02 mol) in ethanol (20 ml). On refluxing the reaction mixture with stirring for 1 h a red precipitate was formed. It was then filtered, washed with hot ethanol (3 × 5 ml) and dried in vacuo, over anhydrous calcium chloride. *Anal.* Calc. for $C_{24}H_{26}N_6O_2S_4Ni_2$: C, 42.63; H, 3.88; N, 12.34, Found: C, 42.33; H, 3.85; N, 21.46%. IR (KBr) (cm^{-1}): 3059m, 3027m, 2915m, 1644m, 1627m,1600m $\nu(C{=}N)_{hy}$; 1571m, 1522m, 1535m, 1518m $\nu(C{=}N)_{ox}$; 1458s, 1429s, 1386s, 1350m, 1255m, 1214vs, 1186s, 1136s, 1136s, 1099s, 1070m, 1039vs, 990m, 940m, 787m, 769m, 720. Electronic spectrum ($CHCl_3$, λ_{max}/nm ($\log\varepsilon$)): 271(4.16), 315(4.22), 350(4.06), 366sh, 425sh, 445sh, 615sh, 660(2.47). ^{1}H NMR (DMSO-d_6, TMS, ppm), 7.10–7.30 (5H, m, aromatic), 4.20 (2H, s, SCH_2), 1.90 (3H, s, $CH_3C{=}NN$), 1.72 (3H, s, $CH_3C{=}NO$). FD MS, m/z = 674 (100%).

2.3.2. Preparation of [NiL · HPyr] (**3**)

To a suspension of dimeric $[Ni(L)]_2$ complex (1.0 mmol, 0.338 g) in ethanol (50 ml), a sufficient amount of solid pyrazole (5.0 mmol, 0.34 g) was added and the reaction mixture was heated under reflux until complete dissolution. The reaction mixture was filtered to remove any unreacted starting material and the filtrate was evaporated to half its volume. On cooling, the pyrazole nickel complex which separated out was filtered, washed with diethyl ether (3 × 5 ml) and dried in vacuo over anhydrous calcium chloride.

Anal. Calc. for $C_{15}H_{17}N_5OS_2Ni$: C, 44.36; H, 4.22; N, 17.24, Found: C, 44.78; H, 4.35; N, 16.45%. IR (KBr) (cm^{-1}): 3145w ν(N–H), 3119s, 3060, 3033w, 3007w, 2928m, 2851w [ν(N–H) + ν(C–H)]; 1642m, 1624m, 1598w; 1570m; 1450s, 1390m, 1342s, $NCSSCH_2C_6H_5$: 1220s, 1174s, 1130vs, 1067s, 1040vs, 945m, 925m, 850m, 815m, 777s, 759s, 710m. FD MS, m/z = 676 (100%).

2.3.3. Preparation of [NiL · HIm] (**4**)

The imidazole complex [NiL · HIm] was prepared from the reaction of $[Ni(L)]_2$ complex with excess imidazole using the same procedure described for the corresponding pyrazole complex.

Anal. Calc. for $C_{15}H_{17}N_5OS_2Ni$: C, 44.36; H, 4.22; N, 17.24, Found: C, 44.04; H, 4.24; N, 17.45%. Electronic spectrum (saturated solution in $CHCl_3$, λ_{max}/nm): 322, 380, 600sh, 650sh. ^{1}H NMR (DMSO-d_6, TMS, ppm), 12.60 (1H, CONH), 7.87 (1H, N=C*H*–NH, imidazole), 7.28–7.31(5H, m, aromatic), 7.0 (2H, CH=CH, imidazole) 4.27 (2H, s, SCH_2), 2.17 (3H, s, $CH_3C{=}NN$), 1.70 (3H, s, $CH_3C{=}NO$). FD MS, m/z = 674 (100 %).

2.3.4. Preparation of $[Ni(HL)_2] \cdot H_2O$ (**5**)

A solution of nickel(II) acetate tetrahydrate (1.0 mmol, 0.248 g) in ethanol (30 ml) was added dropwise, with constant stirring, to a suspension of diacetyl-*S*-benzyldithiocarbazonate (2.0 mmol, 0.562 g) in ethanol (50 ml). The reaction mixture was then refluxed with constant stirring for 30 min. The dark green crystals which were separated on cooling were filtered off, washed several times with hot ethanol (3 × 5 ml) then dried over anhydrous calcium chloride. *Anal.* Calc. for $C_{24}H_{30}N_6O_3S_4Ni$: C, 44.98; H, 4.92; N, 12.82, Found: C, 44.66; H, 4.43; N, 12.76%. IR (KBr) (cm^{-1}): 3175m, 3060m, 3029m, 2970m, 2923m, 2848m, 1624m, 1600m, 1535m, 1491m, 1448s, 1407vs, 1371vs, 1292vs,1233m, 1180s, 1158m, 1060s, 1017vs, 981s, 928m, 822m, 769m, 706m. Electronic spectrum (in $CHCl_3$, λ_{max}/nm ($\log\varepsilon$)): 325 (4.49), 375 (4.21), 466sh,565 (1.1) 655sh, 750 (0.70), 890 (0.50).

2.4. Physical measurements

The infrared spectra were recorded on a Perkin–Elmer 1430 Data system and/or a Perkin–Elmer (FT-IR) Paragon 1000 PC spectrophotometer. Calibrations of frequency reading were made with polystyrene film. Solid samples were examined as KBr discs. The ultraviolet and visible absorption spectra were recorded on double beam ratio recording Lambada 4B Perkin–Elmer spectrophotometers. ^{1}H NMR and ^{13}C NMR were recorded on Brucker WM 300 (300 MHz) instrument. Mass spectra were recorded on Esquire-LC from Bruker Daltonic Nebulizer 10 psi (dry gas 8 L/min., dry temp. 250 °C). Magnetic susceptibilities of powdered dried samples were recorded on a Faraday-type magnetometer using a sensitive computer controlled D-200 Cahn RG microbalance. The magnetic field applied was ~1.5 T. Experimental susceptibility

data were corrected for the underlying diamagnetism using Pascal's constants.

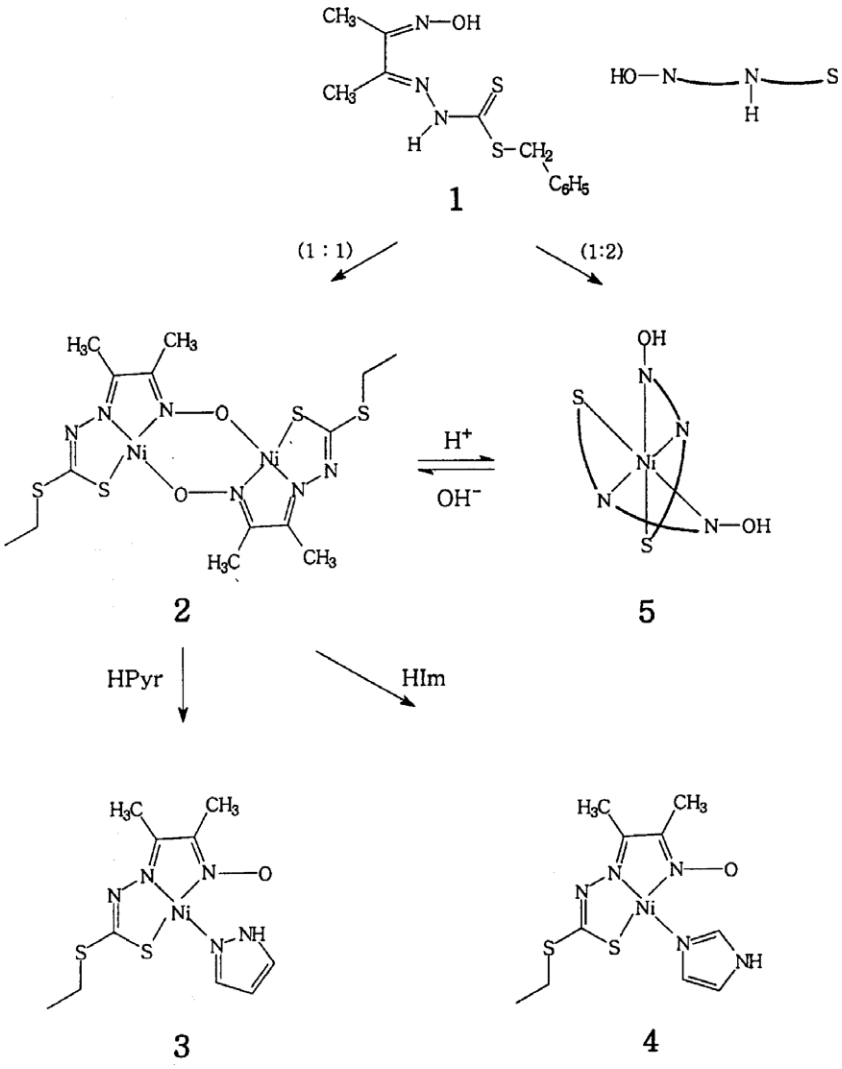
X-ray diffraction data were collected on CRYSALIS CCD, Oxford Diffraction limited, version 1.70.14 (2002), using graphite monochromated Mo Kα radiation ($\lambda = 0.71013$ Å). The structures were solved by direct method with SHELXS-97 [27]; refinement was done by full-matrix least squares on F^2 using the SHEXL-97 [27]. Drawings of the molecules were produced with ORTEP 3 [28] or PLATON [29].

3. Results and discussion

3.1. Synthesis and characterization

Similar to other NNO and NNS tridentate hydrazoneoximes [13–15,30], the reaction of diacetylmonoxime-*S*-benzyldithiocarbazonate (H_2L) (**1**) with nickel(II) acetate tetrahydrate, using 1:1 molar ratio, in presence of KOH proceeded with the deprotonation of both oxime and thiolimine residues and eventually gave the dinuclear complex [{NiL}$_2$] (**2**). Both electron impact and field desorption mass spectra of [{NiL}$_2$] show a base peak at $m/z = 676$, confirming dimerization via oximate bridges [31]. The absence of both oxime ν(O–H) and hydrazone ν(N–H) from the IR spectrum of **2** is in agreement with this assignment. The dinuclear [{NiL}$_2$] was found to be diamagnetic indicating square planar arrangement with $^1A_{1g}$ ground state. The solution absorption electronic spectrum in $CHCl_3$ is also diagnostic of square planar environment around each Ni(II) ion. The spectrum shows absorptions at 270, 315 and 350 nm originated from different L–L* transitions of the dinegative hydrazoneoxime ligand, while absorptions at 360 and 400 nm can be assigned to LMCT transitions. The d–d transitions ($^1A_{1g}$–$^1B_{1g}$, $^1B_{3g}$) appear at 425 and 445 nm. The absorptions at low energy side at 615sh and 660sh nm can be safely related to MLCT transitions [32–34]. The ^{1}H NMR spectrum of **2** in DMSO-d_6 displays two singlets at 1.72 and 1.90 ppm, respectively, due to two non-equivalent (CH_3–C=N) and (CH_3–C=NO) methyl groups, in addition to a CH_2 singlet at 4.21 ppm. The NH and OH singlets, which appear at 11.798 and 12.47 ppm in the spectrum of the metal free ligand, disappeared from the spectrum of the **2**, confirming the deprotonation of both oxime and enolimine groups.

Reaction of [{NiL}$_2$] (**2**) with excess pyrazole (HPyr) or imidazole (HIm) in methanol proceeds with the rupture of the oximate bridges and eventually gives the monomeric [NiL · HPyr] (**3**) or [NiL · HIm] (**4**) complexes. The IR spectra of both **3** and **4** lack absorptions attributable to oxime ν(O–H) and hydrazone ν(N–H) but show a medium absorption at 3145 and 3100 cm^{-1}, respectively, due to pyrazole and imidazole ν(N–H), implying the deprotonation of both oxime (O–H) and thiol SH of the thiolimine tautomer. Both **3** and **4** were found to be dia-



magnetic, implying square planar arrangement around the Ni(II) ion. The electronic absorption spectrum of **3**, in $CHCl_3$, shows absorptions at 315 and 370 nm originating from different L–L* transitions, besides relatively lower intense absorption at 385 nm due to LMCT transition. The d–d* transitions ($^1A_{1g} \rightarrow {}^1B_{1g}$, $^1B_{3g}$) appears at 440 and 445 nm. The two broad unresolved bands at lower energies 552 and 625 nm can be related to MLCT transitions usually observed in the spectra of square planar Ni(II) complexes with sulphur containing ligands [35]. The spectrum of **4** also displays the L–L* and MLCT bands at 322 and 380 nm, respectively. The d–d transitions cannot be observed, most probably hidden under the relatively intense LMCT band at 380 nm. Here again, the spectrum displays the MLCT transitions at 600 and 650 nm. The ^1H NMR spectra of both **3** and **4** are more or less similar and display the two non-equivalent methyl signals at *ca* 2.00 and 2.18 ppm, besides the methylene protons at *ca* 4.30 ppm. The pyrazole and imidazole N–H protons appear at 6.22 and 6.29 ppm, respectively.

Careful acidification of the dimeric $[\{NiL\}_2]$ resulted in the formation of bisligand complex $[Ni(HL)_2]\cdot H_2O$ (**5**). This bisligand complex can be also prepared by reacting the hydrazoneoxime (H_2L) (**1**) with nickel(II) acetate tetrahydrate in methanol, using (2:1) molar ratio. Deprotonation of $[Ni(HL)_2]$ (**5**) with KOH in methanol afforded the dimeric $[\{NiL\}_2]$ (**2**) complex. The prepared bisligand Ni(II) complex is paramagnetic with $\mu = 3.32\ \mu_\beta$ suggesting octahedral structure. The electronic absorption spectrum is in agreement with this assignment. In $CHCl_3$ the spectrum shows the L–L* absorptions at 325 and 375 (sh) nm, besides a broad band centered at 560 nm, most probably, due to MLCT transitions. The spectrum also shows a series of weak broad absorptions at *ca* 750 and 890 nm corresponding to $^3A_{2g}$–$^3T_{1g}$(F), $^3T_{2g}$ transitions in octahedral symmetry [34].

3.2. Electrospray ionization mass spectra (ESI MS)

The positive mode ESI MS of the prepared nickel(II) complexes can assist for better understanding the behaviour of these complexes in solutions, since the generated ions in the gas phase closely reflect those in solution [36,37]. The cations displayed in the recorded ESI MS of $[\{Ni(L)\}_2]$, $[Ni(HL)_2]$, [NiL · HPyr] and [NiL · HIm] together with their assignments are listed in Table 1. The *m*/*z* values are given for the most intense peak in the isotope mass distribution. In all cases the observed isotope distribution patterns are well matched with the simulated patterns [38]. The observed association of Na^+ with many cations came from traces of Na^+ often present even in HPLC grade solvents or from the instrument [37].

The ESI mass spectrum of $[\{NiL\}_2]$ (**2**) display peaks at *m*/*z* = 339, 677 and 698, corresponding to $[\{NiL\}_2 + 2H]^{2+}$, $[\{NiL\}_2 + H]^{1+}$ and $[\{NiL\}_2 + Na]^{1+}$ species, confirming the dimeric structure (**2**). The spectrum also shows a peak at *m*/*z* = 412 attributed to the presence of a solvated cation $[NiL \cdot DMF + H]^{1+}$ originating from the rupture of the oximate bridges in the coordinating solvent DMF.

The positive ion ESI MS spectrum of [NiL · HPyr] (**3**) lacks any peak attributable to the monomeric $[NiL \cdot HPyr + H]^{1+}$ cation. The spectrum, however, shows a base peak at *m*/*z* = 643 corresponding to the dipositive cyclic trimeric cation, $[Ni_3L_3Pyr_3 + 2H + 3Na]^{2+}$ ($[\mathbf{6} + 2H]^{2+}$). The formation of ($[\mathbf{6} + 2H]^{2+}$) may initially proceed by the deprotonation of the pyrazole NH proton followed by self assembly which ultimately gives the cyclic trimeric species where the oximate groups are associated with protons or Na^+ ions. This is in quite agreement with the coordination chemistry of metal(II) complexes with pyrazole and pyrazole containing ligands [7,15,39–42]. The spectrum also displays two peaks at *m*/*z* = 677 and 699 which can be assigned as $[\{NiL\}_2 + H]^{1+}$ and $[\{NiL\}_2 + Na]^{1+}$, respectively. The formation of these dinuclear cations initially pro-

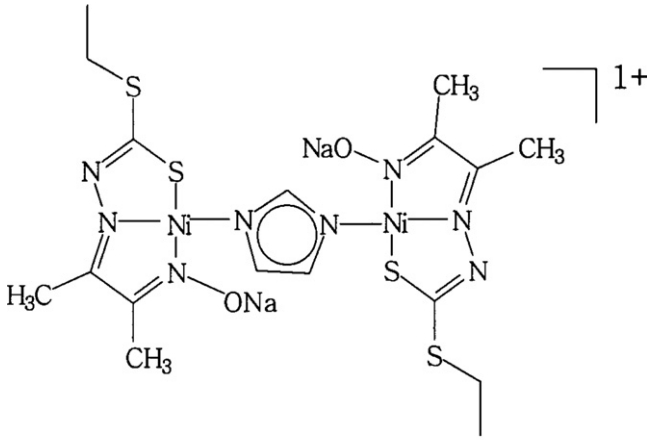
ceeds by the expulsion of the pyrazole from **3** followed by dimerization. Furthermore, expulsion of pyrazolate anion from **4** followed by the disproportionation of the generated $[Ni(HL).solvent]^{1+}$ or $[Ni(HL)]^{1+}$ gives rise to the partially deprotonated [Ni(HL)(L)]

species which readily recombine with either $[Ni(HL).solvent]^{1+}$ or $[Ni(HL)]^{1+}$ giving ultimately the dinuclear $[Ni_2(HL)_2L + Na]^{1+}$ ($[\mathbf{7} + Na]^{1+}$) and $[Ni_2(HL)_2L + DMSO + H]^{1+}$ ($[\mathbf{7} + DMSO + H]^{1+}$), which appear at $m/z = 980$ and 1036, respectively.

The ESI mass spectrum of **4**, Table 1, displays a series of peaks at $m/z = 396$ (base peak), 763 and 791, respectively, due to the dinuclear imidazole containing cations, $[Ni_2L_2 \cdot Im + 2Na + H]^{2+}$ ($[\mathbf{9} + H]^{2+}$), $[Ni_2L_2 \cdot Im + Na + H]^{1+}$ and $[Ni_2L_2.Im + 2Na]^{1+}$, besides a less intense peak at $m/z = 424$ due to the tetranuclear cation $[\{Ni(HL) \cdot Im\}_4 + DMF + 4H]^{4+}$ ($[\mathbf{10} + DMF + 4H]^{4+}$). The formation of these dinuclear or tetranuclear cations may proceed via the initial deprotonation of the imidazole N–H proton followed by self-assembly. It is not uncommon that self assembly of deprotonated imidazolate complexes leads to the formation of either linear or cyclic polynuclear imidazolate species, where the imidazolate anion acts as a bridge [6,8,43]. On the other hand, expulsion of imidazole from **4**, followed by self-assembly also gives rise to the dinuclear, $[\{NiL\}_2 + 2H]^{2+}$ and $[\{NiL\}_2 + H]^{1+}$, as well as the tetranuclear $[\{NiL\}_4 + DMF + 4H]^{4+}$ ($[\mathbf{11} + DMF]^{4+}$) and $[\{NiL\}_4 + DMF + 2H + 2Na]^{4+}$ imidazole free cations. In these cations, the oximate N–O acts as a bridge between the Ni(II) ions. The generation of di-, tri, and tetranuclear cation during electro spray ionization was also reported for other hydrazoneoxime copper(II) and nickel (II) complexes [13–15].



9

The spectrum of the bisligand complex $[Ni(HL)_2] \cdot H_2O$ (**5**) shows the parent cationic species $[Ni(HL)_2 + H]^{1+}$ ($m/z = 620$) which is transformed from the solution to the gas phase. The spectrum also displays the dimeric cation $[\{NiL\}_2 + H]^{1+}$ ($m/z = 677$) besides other polynuclear cations $[Ni_3(HL)_2L_2 + H + Na\ ]^{2+}$ ($m/z = 659$), $[Ni_2(HL)_2L + H]^{1+}$ ($m/z = 958$) and $[Ni_3(HL)_2L_2 + H]^{1+}$ ($m/z = 1296$). The formation of $[\{NiL\}_2 + H]^{1+}$ is suggested to occur in the electro spray ion source via complete deprotonation of the two oxime groups of $[Ni(HL)_2]$ (**5**). This is in agreement with the observed chemical deprotonation of **5** (using methanolic KOH) which eventually gives the dimeric complex (**2**). The formation of the other polynuclear cations proceeds by the initial partial deprotonation of $[Ni(HL)_2]$ to give $[Ni(HL)(L)]$ which readily reacts with one or two solvated mononuclear $[NiL \cdot DMF + H]^{1+}$, generated from the dissociation of $[\{NiL\}_2]$ in DMF, giving ultimately $[Ni_2(HL)_2L + H]^{1+}$ ($[\mathbf{7} + H]^{1+}$) and $[Ni_3(HL)_2L_2 + H]^{1+}$ ($[\mathbf{8} + H]^{1+}$), respectively.

3.3. X-ray crystal and molecular structures of *3*, *4* and *5*

The crystal data and structural refinement parameters for **3**, **4** and **5** are listed in Table 2. Selected bond distances (Å) and bond angles (°) for **3** and **4** are collected in Table 3, while those of **5** are listed in Table 4. The structures of **3** and **4** together with the atomic numbering scheme are, respectively, shown in Figs. 1 and 2. The crystal structure of **3** consists of one type of discrete molecular units, while that of **4** consists of two molecular units, namely Ni1 and Ni2 molecular units which are crystallographically independent but chemically similar. In either **3** or **4**, the Ni(II) is in a distorted square planar environment and is coordinated to the dianionic NNS tridentate hydrazoneoxime ligand via deprotonated oximate nitrogen N2, hydrazone imine nitrogen N1, and thiolate sulphur S1. The fourth coordination sites in **3** and **4** are occupied, respectively, by the pyrazole N3 and imidazole N3 or N8 nitrogens. Deviation from idealized square planar arrangement in either **3** or **4** is evident from the values, Table 3, of both cis- and trans bond angles around the central Ni(II). The pyrazole plane (C4, C5, C6, N4, N3) in **3** is almost coplanar with the nickel coordination plane (N1, N2, N3, S1, Ni1) as the dihedral angle between these two planes is only 3.15°. However, in **4** the imidazole planes (N3, C4, N4, C5, C6) and (N8, C19, N9,C20, C21) deviate from the Ni1(N1, N2, N3, S1, Ni1) and Ni2 (N6, N7, N8, S3, Ni2) coordination planes by 52.30° and 50.47° angles, respectively. The phenyl plane in **3**

also forms a dihedral angle of 74.73° with the Ni coordination plane while the Ni1 and Ni2 coordination planes of **4** form 78.14° and 79.21° angles with the corresponding phenyl planes.

The Ni–N (oximate) bond distances in both **3**[Ni1–N2 = 1.923(5) Å] and **4**[Ni1–N2 = 1.906(4) Å, Ni2–N7 = 1.900(4) Å], are within the range (1.93–1.87 Å) reported for other Ni(II) hydrazoneoxime complexes [15,30]. The Ni–N (hydrazone imine) bond distances of **3** [Ni1–N1 = 1.836(6) Å] and **4** [Ni1–N1 = 1.843(4) Å, Ni2–N6 = 1.831(4) Å] are shorter than the Ni–N (oximate), but still within the normal range (1.84–1.88 Å) reported for other Ni(II) complexes derived from dianionic NNS [44–47] and ONS tridentate hydrazones [48–54]. The Ni–S bond distances in the pyrazole complex **3** [Ni1–S1 = 2.1740(17) Å] and imidazole complex **4** [Ni1–S1 = 2.1665(16) Å, Ni2–S3 = 2.1795 Å] are also comparable with those reported for square planar Ni(II) complexes derived of NNS- and ONS-tridentate thiosemicarbazonates [44–54] and dithiocarbazates [55,56].

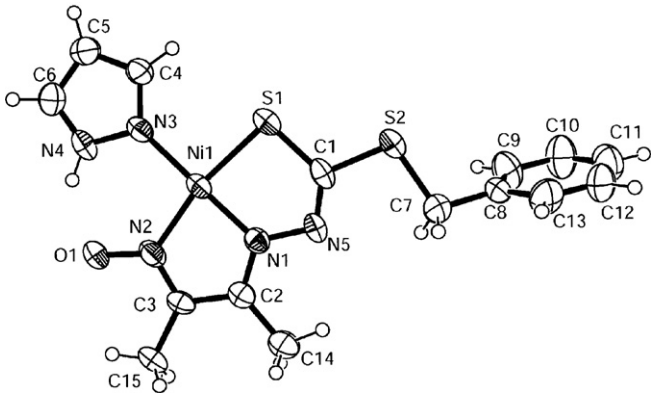

Fig. 1. ORTEP representation of [NiL · HPyr] (**3**) with labeling atoms.

The oximate O1 of **3** is involved in intramolecular hydrogen bond with the pyrazole N4H proton (N4···O1 = 2.557(9) Å). This hydrogen bond motif of graph set descriptor **S**(**6**) [57,58], Fig. 3, forms a six membered ring which is almost coplanar with the two five membered chelate rings as well as the pyrazole ring.

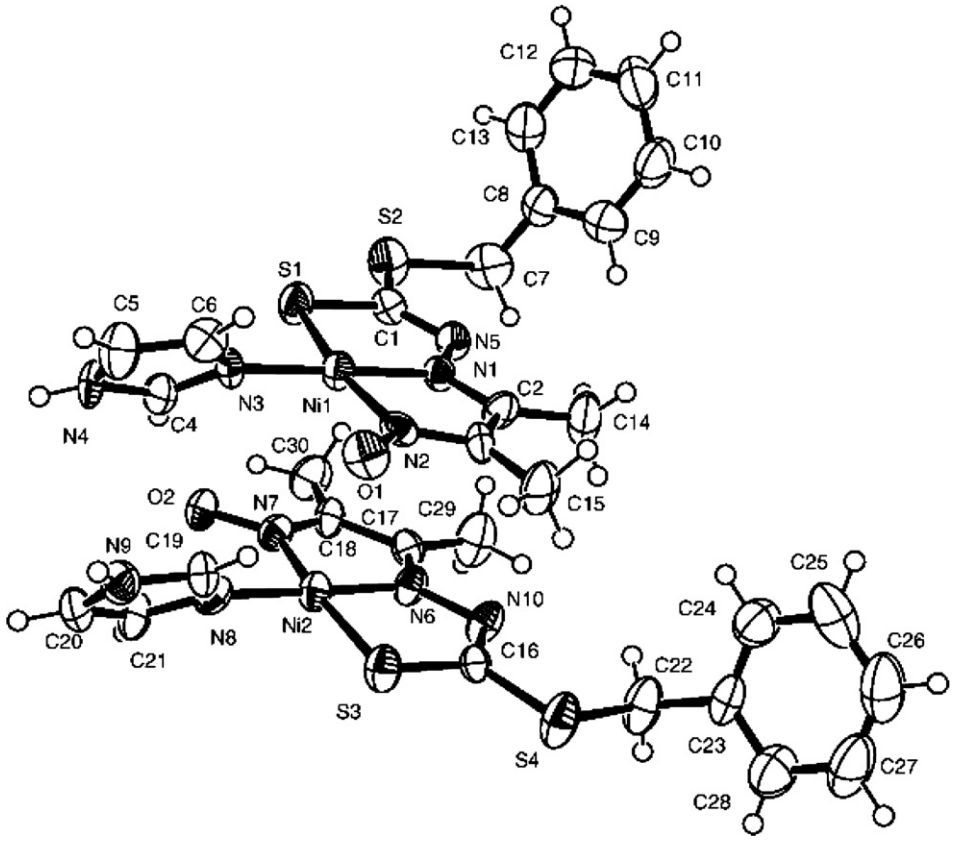

Fig. 2. ORTEP representation of [NiL · HIm] (**4**) with labeling atoms.

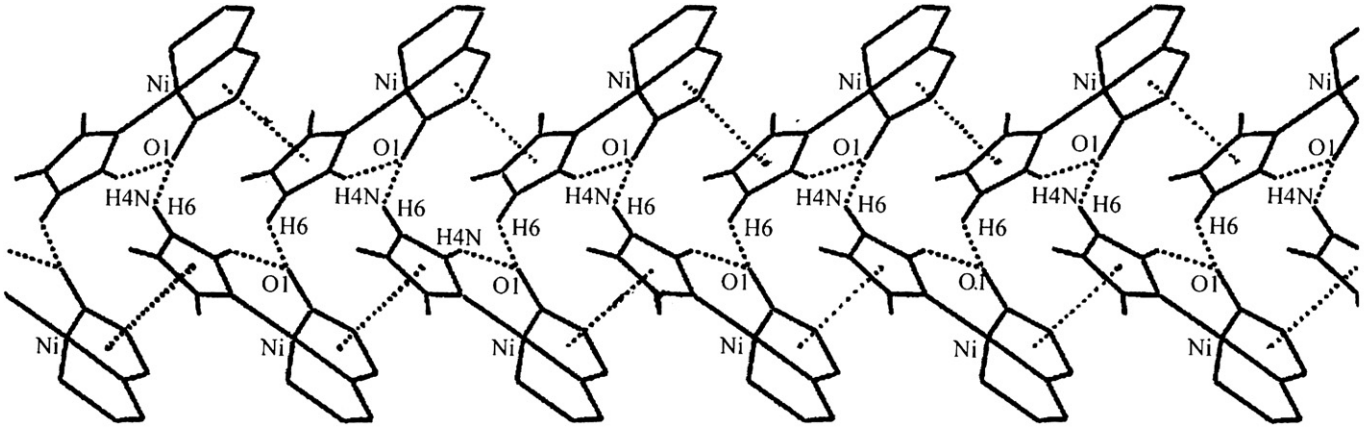

Fig. 3. Intramolecular N4H···O1, C6H···O1 and π···π non-covalent bond interactions in helical chains of [NiL · HPyr] (**3**), Methyl and *S*-benzyl groups are omitted for clarity.

The oximate O1 is also involved in weak (CH···O) intermolecular hydrogen bond formation with the pyrazole H6 proton of the neighboring molecular unit. This hydrogen bond of the graph set descriptor **C7** [57,58] forms a helical chain propagating along the *b*-axis as shown in Fig. 3. The existence and structural importance of weak CH···O hydrogen bonding interactions are now well established and are observed in other metal complexes [59,60]. The Ni coordination planes on each side of the helical chain are arranged parallel to each other, but make an angle of 71.53° with the corresponding Ni coordination plane on the other side. The parallel arrangement of the molecular units on both sides of the helical chain is stabilized by π···π interactions between the delocalized diimine chelate ring, which acts as an aromatic ring [61,62], and the aromatic heterocyclic pyrazole ring of the adjacent molecular unit (Cg1···Cg2 = 3.330 Å). The mean plane of the diimine ring is almost parallel to that of the pyrazole plane and the dihedral angle between these planes is 3.89°. The intra and intermolecular non-covalent bond interactions within the helical chain are listed in Table 5. The pyrazole rings of each chain are interconnected to the pyrazole rings of two neighboring chains by two reciprocal edge to face CH···π interactions (H5···Cg1 = 2.768 Å) [63,64], where Cg1 refers to pyrazole ring centroid. Such interactions give rise to short contacts between the pyrazole H4 and methyl C15 carbon. Similarly, the phenyl rings of the benzyl residues in this chain

Table 5

Cg1 pyrazole ring (C4, C5, C6, N3, N4) centroid.
Cg2 diimine chelate ring (C2, C3, N2, Ni, N1) centroid.
Cg3 phenyl ring (C8, C9, C10, C11, C12, C13) centroid.
Cg4 imidazole ring (N3, C4, N4, C5, C6) centroid.
Cg5 imidazole ring (N8, C19, N9, C20, C21) centroid.
Cg6 phenyl ring (C15, C16, C17, C18, C19, C20) centroid.

are also interconnected to the phenyl rings of other two helical chains via a pair of reciprocal edge to face CH···π interactions (CH9···Cg3 = 3.303 Å). In these interactions, both pyrazole and phenyl rings act as proton donor as well as π acceptor. Thus each helical chain is interconnected to four different chains giving rise to two dimensional arrays of helical chains.

Each Ni1 molecular unit in **4** are linked to the two adjacent Ni2 molecular units via N4H···O2 (N4···O2 = 2.735 Å) and O1···H9N

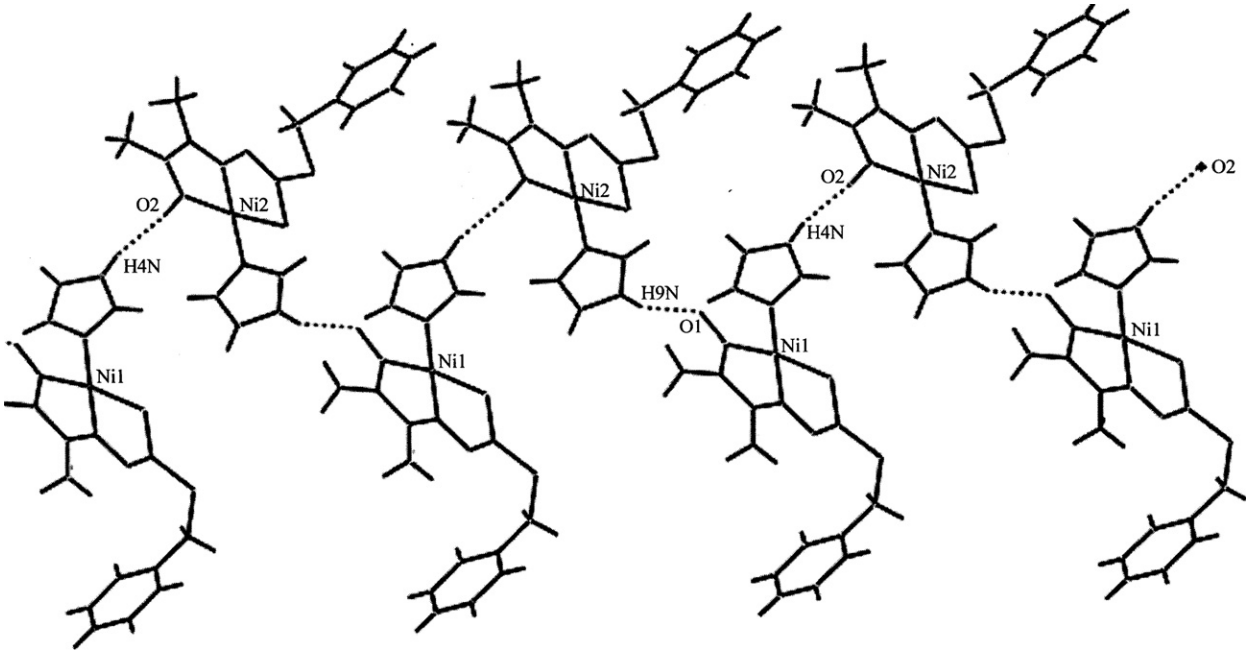

Fig. 4. Intermolecular N4H···O2 hydrogen bonding in the zigzag chain of [NiL · HIm] (**4**) extending along *a*-axis.

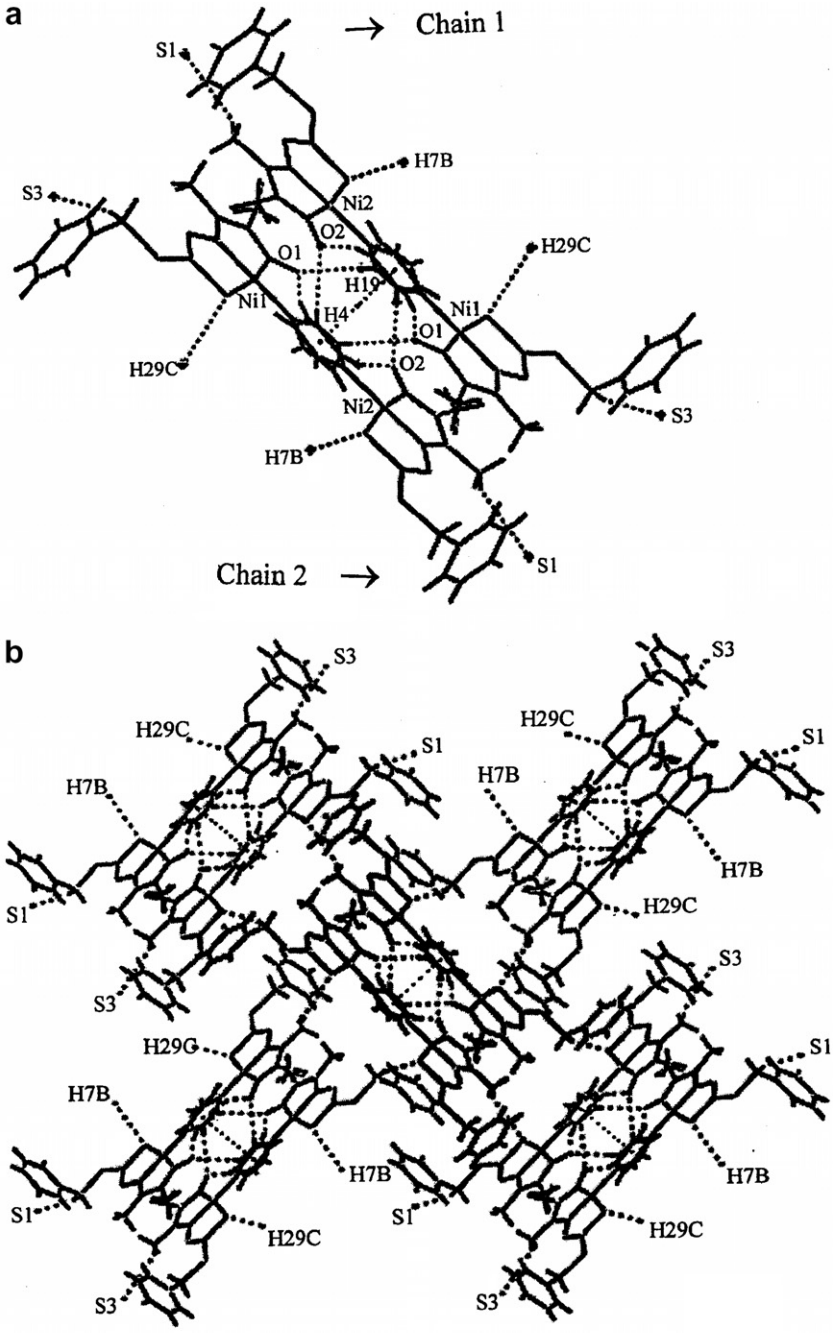

Fig. 5. Diagrammatic representation of (a) the double chain of [NiL · HIm] (**4**) viewed along *a*-axis and (b) the interaction a double chain with four neighboring chains via C29H···S1 and C7H···S3 interactions.

(N9···O1 = 2.687 Å) hydrogen bonds of graph set descriptor **C7**, forming an infinite zigzag chain (chain 1) extended along the *a*-axis as shown in Fig. 4. Similarly, the other crystallographically independent Ni2 molecular unit also forms another chain (chain 2) which propagates parallel to chain1. The two chains are interconnected by π···π and CH···O non-covalent bond interactions, Table 5, forming a double chain structure as shown in Fig. 5. The π···π interactions involve the imidazole rings [N8, C19,N9, C20, C21 (Cg5)] of Ni2 molecular units in Chain 1 and the imidazole rings Ni1 [N3, C4, N4, C5, C6 (Cg4)] of molecular units in chain 2 where Cg4–Cg5 = 3.586 Å. Both O1 and O2 oximate oxygens are also involved in two CH···O weak hydrogen bond formation with the imidazole C19H and C4H protons, respectively. Each double chain is interconnected to four neighboring double chains via four pairs of reciprocal S1···H29C and S3···H7C [S1···H29 = 3.796 Å and S3···H7 = 3.761 Å] interactions, Fig. 5a and b, giving rise to two dimensional arrays of double chains.

Selected bond distances and bond angles for **5** are given in Table 4. The crystal structure of **5**, Fig. 6, shows that the Ni(II) is in a distorted octahedral environment. The two mononegative hydrazoneoxime ligands are coordinated in the meridional configuration where the two thiol sulphur atoms (S1 and S2) and the two oxime nitrogen atoms (N3 and N6) are cis to each other, while the imine nitrogen atoms (N1 and N4) are trans. Similar

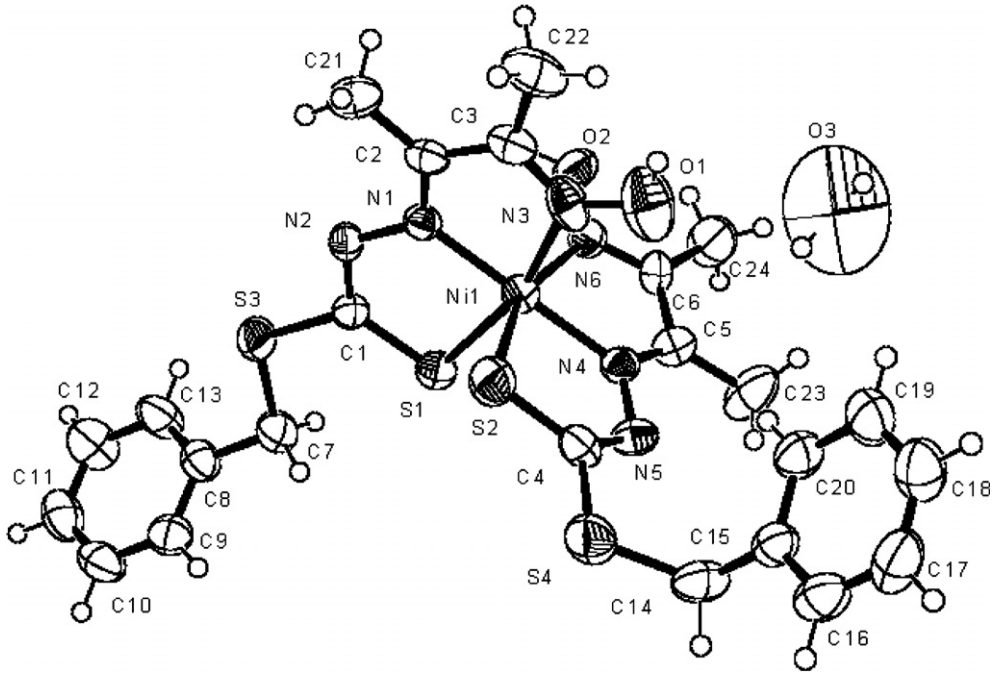

Fig. 6. ORTEP representation of $[Ni(HL)_2] \cdot 1/2H_2O$ (**5**) with labeling atoms.

meridional configurations have also been reported for other octahedral Ni(II) complexes with NNS tridentate ligands [65–71]. Each ligand is bounded to the Ni(II) via oxime nitrogen [Ni1–N3 = 1.987 Å, Ni1–N6 = 2.142 Å], imine nitrogen [Ni1–N1 = 1.9341 Å, Ni1–N4 = 1.959 Å] and deprotonated thiol sulphur [Ni1–S1 = 2.3034 Å, Ni–S2 = 2.3883 Å]. The bond distances between the Ni and the set of ligand donor atoms are within the range reported for other octahedral Ni(II) complexes with NNS tridentate thiosemicarbazones [65–67], dithiocarbazonates [68–70] and thiosemicarbazoneoximes [71].

The oxime proton O2H is involved in a reciprocal bifurcated hydrogen bond formation with both N2 and S3 of the adjacent molecule giving rise to hydrogen bonded dimer. This dimeric structure is further stabilized by a pair of reciprocal C21H···O2 and O2H···C interactions. A one dimensional chain of alternating dimeric unit and water molecule propagating along the *c*-axis is formed via hydrogen bond formation between the oxime O1 oxygen and the bridged water molecule proton O3H (O1···O3 = 3.175 Å).

The chains are packed together through a combination of several CH···π interactions involving the (C8–C13) and (C15–C20) phenyl rings of the benzyl residues. The acidic methylene H7A protons of the molecular units of one chain are involved in reciprocal CH···π interactions with the (C8– C13) phenyl rings of the adjacent chain (C7H···Cg6 = 2.824 Å). The (C8–C13) phenyl rings are also involved in an edge to face interactions with the H17 proton of (C15–C20) phenyl rings of another adjacent chain (C17H···Cg6 = 4.347). Both H22C and H23B methyl proton of two different chains are directed towards the (C15–C20) phenyl ring centroid, thus forming two non-equivalent CH···π interactions. Reciprocal CH21···C2 interactions connecting two neighboring chains are also observed. Moreover, the two dithiocarboxylate S2 sulphur atoms of each hydrogen bonded dimeric unit are involved in weak hydrogen bond formation with phenyl C11H protons of two neighboring dimers, thus each chain is interconnected by two other neighboring chains via C11H···S2 hydrogen bonds (C11···S2 = 3.686 Å). These non-covalent bond interactions, Table 5, combine to form an entangled multidimensional supramolecular network.

4. Supplementary data

CCDC 684840, 684841 and 684842 contain the supplementary crystallographic data for [NiL · HPyr], [NiL · HIm] and $[Ni(HL)_2] \cdot H_2O$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

determined by HPLC analysis using a chiralcel OD-H column. Optical rotation was measured on JASCO polarimeter. Elemental analyses were carried on EA 1108-Elemental Analyzer at the Chemical Analysis Laboratory of the Center for Scientific Instruments of Kyungpook National University.

2.2. Syntheses of Cu(**L**)Cl_2 and Zn(**L**)Cl_2

A solution of **L** (1.0 g, 3.40 mmol) in methanol (5 ml) was added dropwise to a solution of $CuCl_2 \cdot 2H_2O$ (0.58 g, 3.37 mmol) or $ZnCl_2$ (0.46 g, 3.37 mmol) in methanol (10 ml). The mixture was stirred overnight at ambient temperature. The solvent was removed to yield blue or white solid, respectively. The yield of blue solid was 87% (1.26 g). *Anal.* Calc. for $C_{20}H_{26}Cl_2N_2Cu$: C, 56.01; H, 6.11; N, 6.53. Found: C, 55.90; H, 6.21; N, 6.51%.

The yield of white solid was 85% (1.23 g). *Anal.* Calc. for $C_{20}H_{26}Cl_2N_2Zn$: C, 55.77; H, 6.08; N, 6.50. Found: C, 55.67; H, 6.02; N, 6.52%. ^{1}H NMR (400 Hz, CD_3CN) δ 7.54 (t, 4H, Ph), 7.36 (m, 6H, Ph), 4.06 (dd, 2H, CH_2), 3.92 (t, 2H, CH_2), 2.86 (m, 2H, CHA), 2.58 (s, 2H, NH), 2.52 (m, 2H, CHA), 1.83 (m, 2H, CHA), 1.32 (m, 4H, CHA).

2.3. Crystal structures of Cu(**L**)$Cl_2 \cdot 2CH_3OH$ and Zn(**L**)Cl_2

Single crystals suitable for X-ray analysis were grown from methanol solutions and sealed in thin walled glass capillaries and mounted on an Enraf-Nonius CAD-4 diffractometer equipped with monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. The intensity data were corrected for Lorentz-polarization effect. Data reductions were carried out using an XCAD program package and empirical absorption corrections with ABSCAL program were applied based on ψ scans [22]. Crystal data and structure refinement for these complexes are listed in Table 1. The structures were determined by direct methods and refined by full-matrix least-squares using SHELXS-97 and SHELXL-97 program packages [23]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were constrained by riding models except H atoms at OH of solvated molecules in Cu(**L**)Cl_2. Selected bond lengths and bond angles are given in Table 2.

5	**L**	(i-Pr)$_2$NEt	70	~0	~0

[a] Values are isolated yields after chromatographic purification.

2.4. Asymmetric nitroaldol reactions

Reactions were carried out at room temperature. At first 10% equivalent of Cu(**L**)Cl_2 or Zn(**L**)Cl_2 was dissolved in 25 ml methanol. Then 6% equivalent of diisopropylethylamine or triethylamine was added after the addition of 1.1 ml nitromethane (2 equiv.) and 1.0 ml benzaldehyde. Reactions were monitored by TLC. After stirring for a week at room temperature, reaction was quenched with 1 ml of 1 N HCl solution and then evaporated. The mixture was extracted by CH_2Cl_2 (3 times × 20 ml) and dried with anhydrous $MgSO_4$, then filtered and the solvent was removed by evaporation. The crude product was purified by column chromatography to afford 1-phenyl-2-nitroethanol with yields of 51–57% (Table 3). Ee was determined by HPLC with a Chiralcel OD-H column at 20 °C, 15% isopropyl alcohol in hexane, flow rate 0.5 ml/min, *R* enantiomer t_r = 18.3 min, *S* enantiomer t_r = 22.1 min. $[\alpha]_D$ = (−)1.5–(+)24 (c = 1, CH_2Cl_2, at 25 °C) (Table 3).

3. Results and discussion

3.1. Syntheses and X-ray crystal structures of Cu(**L**)Cl_2 and Zn(**L**)Cl_2

The complexes were obtained from the reaction of the ligand with $ZnCl_2$ and $CuCl_2 \cdot 2H_2O$ using methanol as solvent. Zn(II) or

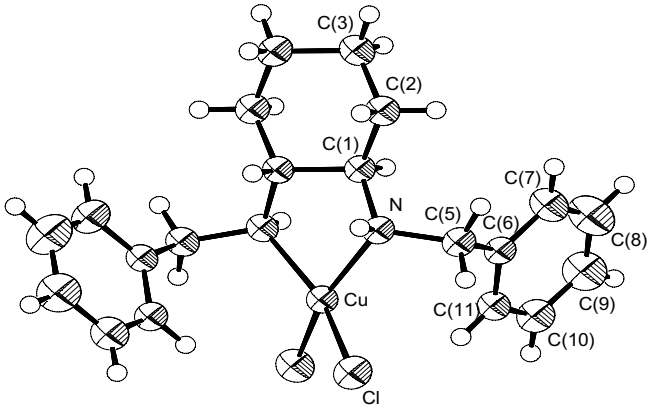

Fig. 1. An ORTEP drawing of Cu(***L***)Cl_2. Displacement ellipsoids are shown at the 40% probability level.

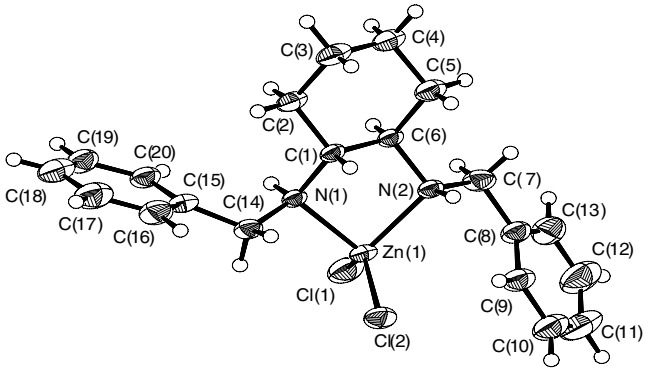

Fig. 2. An ORTEP drawing of Zn(***L***)Cl_2. Displacement ellipsoids are shown at the 40% probability level.

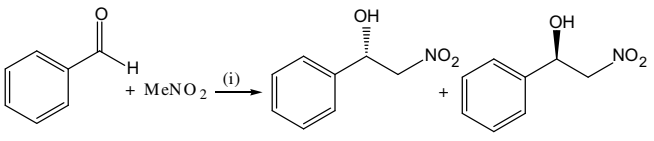
Cu(II) complex is soluble in polar organic solvents such as acetonitrile, methanol and dichloromethane. The crystal structures of the chiral Cu(***L***)Cl_2 and Zn(***L***)Cl_2 are shown in Figs. 1 and 2, respectively. The central Cu ion is coordinated by two nitrogen atoms of ***L*** and two chlorine atoms in distorted square-planar geometry while Zn ion is also coordinated by two nitrogen atoms of ***L*** and two chlorine atoms in a nearly tetrahedral arrangement. The average bond distance of Zn–N is 2.085(3) Å, which are close to those in a similar complex of Zn(*R,R*-bmbcd)Cl_2 [bmbcd: *N,N′*-bis(4-methoxy-benzyl)-cyclohexane-1,2-diamine] [8], but longer than Cu–N 2.017(2) Å. The mean bond distances of Zn–Cl is 2.216(1) Å, also close to those in the similar complex of Zn(*R,R*-bmbcd)Cl_2, 2.2289(2) and 2.2036(8) Å, respectively, but shorter than Cu–Cl 2.2448(7) Å. The bond angle of N–Cu–$N^{\#1}$ is 84.77(6)° similar to N(1)–Pd–N(2), 84.8(1)° [25]. However, Cl–Cu–$Cl^{\#1}$ is 97.84(4)° larger than Cl(1)–Pd–Cl(2), 92.95(4)°. The bond angles of N–Zn–N and Cl–Zn–Cl are similar to those in Zn(*R,R*-bmbcd)Cl_2, respectively. The coordination of ligand to Cu or Zn leads to 5-membered heterocyclic rings which block nitrogen atoms and induces chirality in (*S,S*)-configuration which is similar to the coordination in the compounds of Zn(*R,R*-bmbcd)Cl_2 and Ni-complex [9], but entirely different from that in Pd-complex [24] of (*R,S*)-configuration.

3.2. Asymmetric nitroaldol reaction

10 mol% of Cu(***L***)Cl_2 or Zn(***L***)Cl_2 as the chiral Lewis acid and 6 mol% of bases as promoters were used for nitroaldol reaction at room temperature, (Scheme 1), herein methanol used as the solvent.



Scheme 1. (i) Cu(***L***)Cl_2 or Zn(***L***)Cl_2 10 mol%, (*i*-Pr)$_2$Net or Et_3N 6 mol%, MeOH.

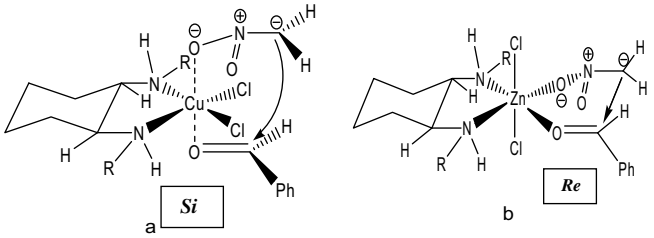


Fig. 3. Proposed transition states for the catalyzed enantioselective nitroaldol reactions with Cu and Zn complexes.

The reaction took place in a slow rate in the case of both conditions. After a week, the conversion was in the range of 51–57% (Table 3). However, in the case of the Zn-complex as chiral catalyst, ee(s) are low, 3% for Et_3N and 5% for (*i*-Pr)$_2$NEt and (*R*)-enantiomer is preferential. Ee(s) in the case of Cu-complex as catalyst are 39% for Et_3N and 23% for (*i*-Pr)$_2$NEt and (*S*)-enantiomer is preferential. In addition, a sample without chiral complex was also carried out (Table 3, entry 5). Although a higher conversion obtained because of organic base catalyst the selectivity is almost zero. So the selectivity observed (entries 1–4) clearly thanks to the chiral complexes. The reason of (*R*) or (*S*) selectivity may be the geometrical difference around the metals, distorted square-planar for Cu whereas nearly tetrahedral for Zn.

As we have seen, these complexes have the same ligand however in different stereochemical patterns so they lead to different major enantiomers. Based on our experimental observation, X-ray structure data and the previous reported steric and electronic considerations [11b,13b,19,25], we propose two transition states, which can account for the absolute configuration of the products obtained with the chiral Cu and Zn complexes. Because the metal center geometry of Cu complex is distorted square-planar therefore in the transition state for nitroaldol reaction oxygen atoms of the two reactants may be coordinated to Cu complex at axial positions of the distorted octahedron (Fig. 3a). The attack of the nitronate would take place preferentially to *si*-face of carbonyl group giving the nitroaldol product with the (*S*)-configuration. In the case of Zn complex, the metal center geometry of Zn complex is nearly tetrahedral so in the transition state for nitroaldol reaction oxygen atoms of the substrates may be coordinated to Zn at equatorial positions resulted the distorted octahedron (Fig. 3b). The attack of the nitronate would take place preferentially to *re*-face of carbonyl group giving the nitroaldol with (*R*)-configuration, respectively.

4. Conclusions

We have synthesized and determined X-ray crystal structures of chiral Lewis acids, Cu(***L***)Cl_2 and Zn(***L***)Cl_2, successfully. Zn(II) was in a nearly tetrahedral geometry while Cu was coordinated in distorted square-planar. In both cases, (*S,S*)-coordination of nitrogen atoms was induced. Application as enantioselective catalysts to nitroaldol reaction was carried out. Although the enantioselectivities are low, the geometrical difference between Cu and

Zn may be the main reason for (*S*) or (*R*) enantiomer selectivity, respectively.

5. Supplementary data

CCDC 682511 and 682512 contains the supplementary crystallographic data for Cu(***L***)$Cl_2 \cdot 2CH_3OH$ and Zn(***L***)Cl_2. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

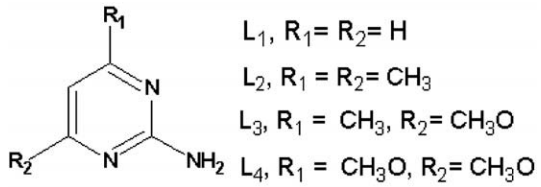

Chart 1. Structural drawings of ligand L_1–L_4.

6-methylpyrimidine; L_4 = 2-amino-4,6-dimethoxypyrimidine]. The research results indicate that difference of steric hindrance from substituted groups in ligands and the choice of solvent all have great impact on the structure of the complexes.

2. Experimental

2.1. Materials

All reagents and solvents in the synthesis were of reagent grade, and they were used without further purification. Infrared spectra were recorded on a Nicolet AVATAT FT-IR360 spectrometer as KBr pellets in the frequency range 4000–400 cm^{-1}. The elemental analyses (C, H, N contents) were determined on a CE instruments EA 1110 analyzer. Photoluminescence measurements were performed on a Hitachi F-4500 fluorescence spectrophotometer with solid powder on a 1 cm quartz round plate at room temperature.

2.2. Synthesis of complexes

2.2.1. Synthesis of complex $[Ag(L_1)(NO_3)]_n$ (**1**)

To a solution of $AgNO_3$ (170 mg, 1 mmol) in distilled water (3 ml) was added a solution of L_1 (94 mg, 1 mmol) of in distilled water–CH_3OH (5:5 v/v, 10 mL) at 60 °C. A small amount of white precipitate was removed from the resulting solution. Colorless crystals of **1** were obtained in 50% yield by slow evaporation at room temperature after one week. They were washed with a small volume of cold CH_3OH and diethyl ether. *Anal.* Calc. for $AgC_4H_5N_4O_3$: C, 18.13; H, 1.90; N, 21.14. Found: C, 18.20; H, 1.86; N, 21.18%. IR (cm^{-1}): 3396 (s), 3302 (m), 3188 (m), 1762 (m), 1625 (s), 1570 (s), 1529 (m), 1477 (s), 1459 (m), 1384 (s), 1223 (m), 1187 (m), 976 (w), 871 (m), 825 (m), 788 (m), 658 (m), 515 (m), 465 (m).

2.2.2. Synthesis of complex $[Ag_4(L_2)_6(NO_3)_4]$ (**2**)

The synthesis of **2** was similar to that of **1**, but with ligand L_2 (123 mg, 1 mmol) in place of ligand L_1. Colorless crystals were obtained in 66% yield. *Anal.* Calc. for $Ag_4C_{36}N_{22}H_{54}O_{12}$: C, 30.48; H, 3.84; N, 21.72. Found: C, 30.47; H, 3.81; N, 21.78%. IR (cm^{-1}): 3396 (s), 3313 (m), 3138 (br), 1654 (s), 1594 (m), 1568 (m), 1475 (m), 1453 (m), 1384 (s), 1233 (m), 1026 (m), 961(m), 834 (m), 825 (m), 788 (m), 729 (m), 567 (m), 547 (m), 474 (m).

2.2.3. Synthesis of complex $[Ag(L_3)(NO_3)]_n$ (**3**)

The synthesis of **3** was similar to that of **1**, but with ligand L_3 (139 mg, 1 mmol) in place of ligand L_1. Colorless crystals were obtained in 60% yield. *Anal.* Calc. for $AgC_6H_9N_4O_4$: C, 23.32; H, 2.94; N, 18.13. Found: C, 23.35; H, 2.90; N, 18.09%. IR (cm^{-1}): 3367 (s), 3314 (w), 3183 (m), 3023 (m), 1637 (s), 1585 (s), 1458 (m), 1384 (s), 1346 (m), 1204 (m), 1152 (m), 1023 (m), 938(m), 839 (w), 798(m), 782 (m), 646(m), 585 (w), 546 (w).

2.2.4. Synthesis of complex $[Ag_3(L_4)_3(NO_3)_3]_n$ (**4**)

The synthesis of **4** was similar to that of **1**, but with ligand L_4 (155 mg, 1 mmol) in place of ligand L_1. Colorless crystals were obtained in 55% yield by the slow evaporation at room temperature after one week. They were washed with a small volume of cold CH_3OH and diethyl ether. *Anal.* Calc. for $Ag_3C_{18}H_{27}N_{12}O_{15}$: C, 22.17; H, 2.79; N, 17.24. Found: C, 22.07; H, 2.65; N, 17.30%. 2.2.5. Synthesis of complex $[Ag(L_4)(NO_3)]_n$ (**5**)

To a solution of $AgNO_3$ (170 mg, 1 mmol) in distilled water (3 ml) was added a solution of L_4 (155 mg, 1 mmol) of in distilled water–CH_3CH_2OH (5:5 v/v, 10 mL) at 60 °C. A small amount of white precipitate was removed from the resulting solution.

2.3. X-ray crystallography

Single crystals of these complexes with appropriate dimensions were mounted on a glass fiber and used for data collection. Data were collected on a Bruker-AXS CCD diffractometer equipped with a graphite-monochromated Mo Kα radiation source ($\lambda = 0.71073$ Å) at 298 K for **1**–**5**. All absorption corrections were performed with the SADABS program [26a]. All the structures were solved by direct methods using SHELXS-97 [26b] and refined by full-matrix least-squares techniques using SHELXL-97 [26c]. All the non-hydrogen atoms were treated anisotropically. The positions of hydrogen atoms were generated geometrically. The crystallographic details of **1**–**5** are summarized in Table 1. Selected bond lengths and bond angles of **1**–**5** are displayed in Table 2.

3. Results and discussion

3.1. Synthesis of the complexes

The synthesis of complexes **1–5** is readily prepared by the reactions of $AgNO_3$ with a family of 2-aminopyrimidyl ligands and is

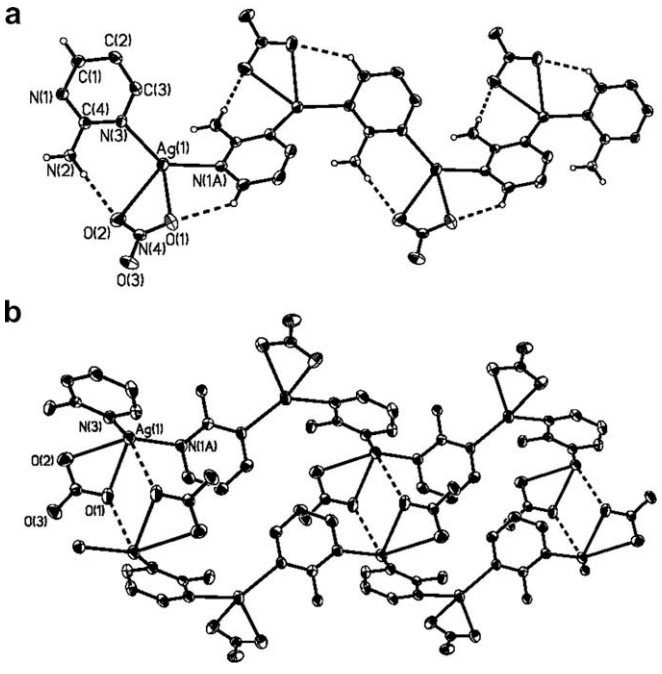

Fig. 1. (a) Perspective drawing of a fragment of the chain of **1** growing along the *a* axis. The dashed lines correspond to the hydrogen bonds. The thermal ellipsoids are drawn at the 35% probability level. Hydrogen atoms in pyrimidyl groups partially omitted for clarity. (b) The 1-D ladder structure formed through Ag···O weak interactions (indicated by dashed lines) between the adjacent chains. All hydrogen atoms omitted for clarity.

summarized in the Supplementary data. The formation of the products is not significantly affected by changes of the reaction mole ratio of ligands to metal ions, and the resultant crystals are insoluble in water and common organic solvents. Three complexes (**1** with 1-D zigzag chain, **2** with 0-D tetramer, and **3** with 2-D grid network) are obtained by using the same silver(I) nitrate but different ligands to investigate the effect of substituted groups of ligands on the structure of the complexes. On the other hand, **4** and **5** are isolated by using the same silver salt and ligand but different solvent systems to investigate the influence of reaction solvents on the structure of the complexes. Complex **4** has a 1-D polymeric ribbon further connected by hydrogen bonds to generate a 2-D layer structure. While Complex **5** shows a 2-D honeycomb-like layer consisting of 24-membered metallocycles. In **1**–**5**, 2-aminopyrimidine and its derivatives adopt similar coordination modes, bidentate N,N′-donor ligands binding with silver atoms, while the different substitutions of 2-aminopyrimidyl ligands in the same substitutional positions in these complexes result in distinct structural motifs. Thus, we have reason to believe that subtle structural changes of ligands might create a tuning effect on the formation of crystal structures. Additionally, as far as certain ligand such as L_4 concerned, the structure of complexes (**4**–**5**) can be controlled by choosing different solvent systems. In addition, the secondary forces such as intramolecular and intermolecular hydrogen bonds also play important role in the overall architecture and stabilization of the complexes. The hydrogen bond geometries **1**–**5** are summarized in Table S1.

3.2. Description of the crystal structures of *1*–*5*

3.2.1. Crystal structure of $[Ag(L_1)(NO_3)]_n$ (*1*)

X-ray analysis reveals that **1** has an infinite 1-D zigzag chain structure. As depicted in Fig. 1a, the basic repeat is a distorted tetragonal four-coordinate AgO_2N_2 unit, which comprises two oxygen atoms from one nitrate anion and two independent pyrimidine hetero-nitrogens in a distinctly nonlinear geometry forming zigzag chains. The average Ag–N distance in **1** is agreement with those reported in the literature, such as $[\{Ag(pts)\}_2(L_2)_3]_n$ [24b] and $[Ag(L_2)(NO_3)]_n$ [24h] (pts = *p*-toluenesulfonate; L_2 = 2-amino-4,6-dimethylpyrimidine). The acute angle at the chelate site of nitrate [47.9(1)° for O(1)–Ag(1)–O(2)] accounts for the obviously distorted surrounding of silver ions. In **1**, each ligand L_1 links two Ag atoms to form a 1-D zigzag chain. In the 1-D chain, two kinds of intramolecular hydrogen bonds are observed including $C_{(pyrimidyl)}$–H···O and N–H···O [3.238(4) and 2.979(4) Å for C(1A)···O(1) and N(2)···O(2), respectively, symmetry code: (A) = $x + 1/2$, $-y + 1/2$, $z - 1/2$], which contribute to the stabilization of the crystal packing. The adjacent chains in **1** are further interlinked by means of Ag···O weak interactions with Ag–O distance of 2.832 Å to generate 1-D ladder structure (Fig. 1b). In the 1-D ladder, the value of

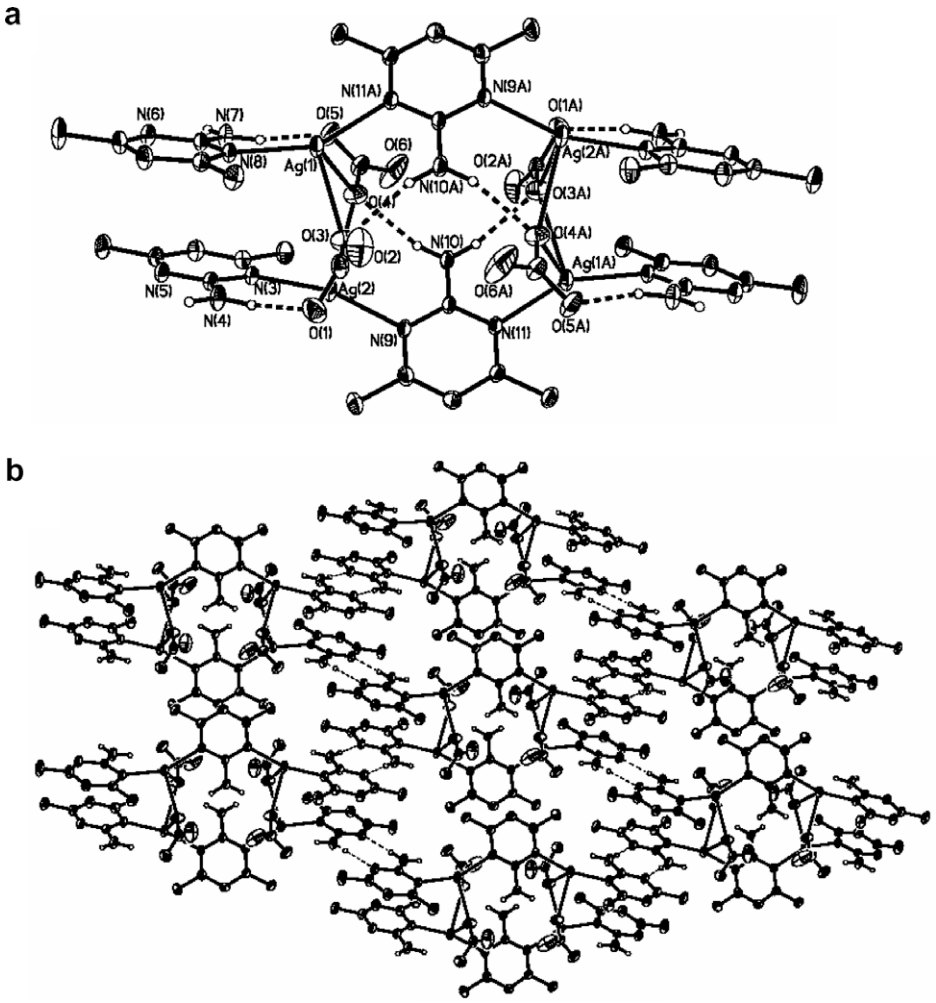

Fig. 2. (a) ORTEP drawing of **2** showing the coordination environment around Ag(I) centers at 30% probability level. The hydrogen atoms in pyrimidyl groups were omitted for clarity. (b) Hydrogen-bonding indicated by dashed lines in crystals of **2** showing tetramers further linked into layers. The hydrogen atoms in pyrimidyl groups were omitted for clarity.

the intrachain silver–silver separation is 6.463 Å whereas that of the shortest interchain distance is 4.394 Å.

3.2.2. Crystal structure of $[Ag_4(L_2)_6(NO_3)_4]$ (**2**)

When the L_2 ligand reacts with $AgNO_3$ under the same reaction conditions, a new complex **2** is obtained. X-ray analysis shows that **2** consists of the neutral tetranuclear $[Ag_4(L_2)_6(NO_3)_4]$ unit. As depicted in Fig. 2a, the overall molecular structure of **2** is centrosymmetric, having two independent Ag^I ions with similar coordination environments linked together through nitrate groups and N donors of L_2. Each Ag center is four-coordinate by two N atoms from two different L_2 ligands and two O atoms form two bridging ONO_2^- anions. The Ag–N and Ag–O bond distances are all within normal range. In tetramer **2**, four Ag atoms (Ag1, Ag2, Ag1A and Ag2A) are approximately coplanar with the average Ag–Ag separation is 5.076 Å, preclusive of any direct metal–metal interaction.

Hydrogen bonds play a key role in stabilizing and assembling 2-D supramolecular architectures in **2**. Intramolecular N–H···O hydrogen bonds in the tetramer occur where oxygen atoms of nitrate anions serve as acceptors while the uncoordinated amino group of the L_3 ligand act as donors [H···O, 2.13 to 2.60 Å, N···O, 2.932(5) to 3.361(6) Å, ∠N–H···O, 147.0–155.0°]. Interestingly, an extended 2-D supramolecular network arises from self-complementary intermolecular N–H···N hydrogen bonds from the syn-amino proton to a nitrogen atom of the pyrimidine ring [H···N, 2.14–2.17 Å, N···N, 2.997(5)–3.029(5) Å, ∠N–H···N, 176.5–178.5°] (see Fig. 2b).

3.2.3. Crystal structure of $[Ag(L_3)(NO_3)]_n$ (**3**)

To evaluate the effect of the substituting group of the 2-aminopyrimidyl ligands on the framework formation of their complexes, the L_3 ligand is chosen to react with $AgNO_3$ under the same reaction conditions and a new complex **3** is obtained. X-ray analysis shows that **3** features a 2-D grid structure. As shown in Fig. 3a, the central Ag atom has distorted trigonal-bipyramidal geometry, and is confined by two N atoms from two pyrimidine rings, three O atoms from two individual nitrate groups. N1 and N3 and O2 define the trigonal equatorial plane, while O2B and O3B occupy the axial positions. The average Ag–N distance in **3** is in agreement with that of **1**. Additionally, the distance between the silver atom and the oxygen atom from methoxy group in pyrimidyl ring is 3.014(2) Å, a value which is smaller than the sum of the van der Walls radii [27,28], revealing the weak interaction of the silver(I) ions with CH_3O groups. As shown in Fig. 3b, each L_3 ligand as a bidentate ligand links two Ag atoms to form a 1-D zigzag chain and the adjacent chains are further connected by the atoms from nitrate anions to generate a 2-D grid structure in the *ac* plane. The intramolecular nonbonding metal–metal distances of Ag1···Ag1A and Ag1···Ag1B in **3** are 6.373 and 4.559 Å, which are longer than those in **2**. It is noticeable that the 2-D grid network is further stabilized by two kinds of intermolecular N–H···O hydrogen bonds where oxygen atoms of nitrate anions and CH_3O groups serve as acceptors while hydrogen atoms of the uncoordinated amino group of the L_3 ligand act as donors [N(2)–H(2A)···O(2), 2.846 Å, N–H···O, 156.2°; N(2)–H(2B)···O(1), 2.976 Å, N–H···O, 159.4°]. Obvious changes are observed from the structures of **2** and **3**, and the dimension of the complexes increase from 0-D (**2**) to 2-D (**3**). Striking structural difference between **2** and **3** simply is caused by a subtle difference in the ligand structure, *i.e.*, the replacement of 4-position of methyl group by methoxy group. On the basis of the above results, it may be concluded that structural major transformation between **2** and **3** may partially be attributed to steric effect of substituted groups of ligands.

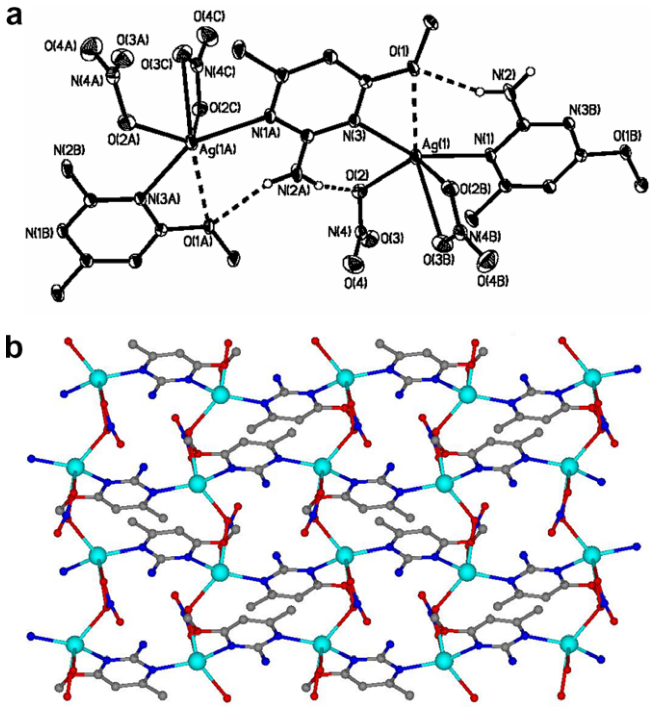

Fig. 3. (a) ORTEP drawing of **3** showing the coordination environment around Ag(I) centers at 30% probability level. The hydrogen atoms in pyrimidyl, methyl, and methoxy groups were omitted for clarity. (b) A view along the *a* axis of 2-D grid network structure in **3**. Hydrogen atoms are omitted for clarity. Ag stressed in bigger ball.

3.2.4. Crystal structure of $[Ag_3(L_4)_3(NO_3)_3]_n$ (**4**)

To evaluate the effect of the reaction solvent systems on the structure of the complexes, reactions of ligand L_4 with $AgNO_3$ are carried out under different mixed solvents (methanol–water and ethanol–water, respectively) and complexes **4** and **5** are successfully isolated. X-ray analysis shows the asymmetric unit in **4** contains three Ag^I atoms, three L_4 ligands and three nitrate anions. As depicted in Fig. 4a, there are three metal atoms with different coordination environments in **4**. The Ag(1) atom adopts the distorted triangular geometry, in which the metal is coordinated by the nitrogen atoms of two L_4 ligands and one oxygen atom of the nitrate anion. The Ag(2) atom displays a distorted tetrahedral geometry, being coordinated by two nitrogen atoms from two different L_4 ligands, one μ_2-O atom from one bridging nitrate anion, and one terminated μ_1-O atom from another nitrate anion. The Ag(3) atom adopts the distorted trigonal-bipyramidal geometry in which two nitrogen atoms of two L_4 and three O atoms of separate nitrate anions coordinate the metal silver center. Three types of NO_3^- anions are found in **4**. The first type adopts the μ_1-O, μ_2-O′ bonding mode to bridge two Ag(I) ions. The second adopts the μ_1-O bonding mode to coordinate weakly to one Ag(I) ion. While the third type adopts the μ_2-O bonding mode to bridge two Ag(I) atoms. Fig. 4b shows that **4** forms a 1-D polymeric ribbon arrangement by the continual symmetry operations including twofold screw axis and inversion center. In the 1-D ribbon, intramolecular hydrogen bonds are observed involving the free amino group of the L_4 with the oxygen atoms on the mono-coordinated NO_3^- anion and on the methoxy groups, respectively [2.996(7) and 3.172(7) Å for N(2)···O(10) and N(2)···O(1)], and one kind of non-classical hydrogen bonds where oxygen atoms of NO_3^- anions serve as acceptors while hydrogen atoms of methoxy groups of the pyrimidine rings act as donors [3.339(9) Å for C(8)···O(12)]. The adjacent ribbons in **4** are interlinked to form 2-D layer structure by means of intermolecular hydrogen bonds in which oxygen atoms of nitrate anions serve as acceptors while hydrogen atoms of NH_2 groups of the pyrimidine rings act as donors [H···O = 2.06–2.64 Å, N···O = 2.883(7)–3.172(7) Å, ∠N–H···O = 123.2–170.3°] (Fig. 4b).

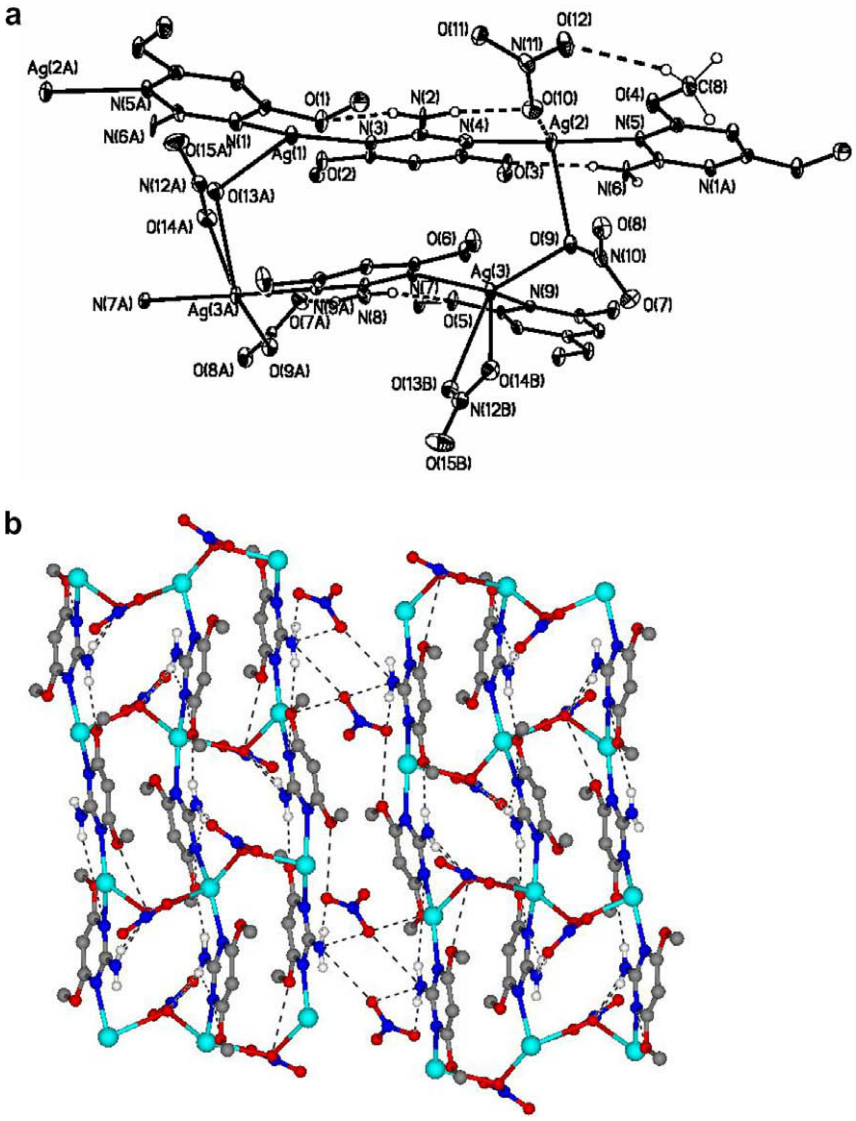

Fig. 4. (a) ORTEP drawing of **4** showing the coordination environment around Ag(I) centers at 30% probability level. Hydrogen atoms in pyrimidyl and methoxy groups were omitted for clarity. (b) A view along the *a* axis of 2-D layer structure in **4**. The dashed lines correspond to the hydrogen bonds. Ag stressed in bigger ball.

*3.2.5. Crystal structure of $[Ag(L_4)(NO_3)]_n$ (**5**)*

It is interesting that complex **5** has a different space group *C*2/*c* and structure from that of **4**, caused by different mixed solvent. The repeat unit of **5** consists of one Ag^I atoms, one L_4 ligands, and one nitrate anion. It is clear that the metal-to-ligand ration is 1 in **5**, which is the same as **4** or **3**. As shown in Fig. 5a, the silver metal centers only possess one type of geometry different from that of **4**. Each four-coordinate Ag which adopts a distorted tetrahedral geometry is coordinated by two μ_1-O donors from two individual nitrate anions, and two bridging L_4 pyrimidine nitrogen atoms. The angle of O–Ag–O [82.53(8)° for O(1)–Ag(1)–O(2B)] is responsible for the distorted tetrahedral geometry of Ag^+ ions. The average Ag–O distance in **5** is slightly shorter than that of **4**. X-ray analysis shows that **5** is a 2-D honeycomb-like layer consisting of 24-membered metallocycles different from 1-D ribbon of **4**, implying that the choice of solvent has a great influence on the overall structure of the complexes in this system (Fig. 5b). The metallocycles involve two sorts of Ag(I) ions. One type Ag(I) ions are bridged by four L_4 ligands through the pyrimidyl nitrogen atoms, while the other Ag(I) ions are not only bridged by four L_4 ligands *via* the pyrimidyl nitrogen atoms, but by four NO_3^- anions by μ_1-O, μ_1-O′ bonding modes (Fig. 5b). It is noteworthy that inside the 24-membered metallocycles, intramolecular hydrogen bonds are observed between bridging nitrate anions, methoxy groups and NH_2 groups of the pyrimidyl rings, respectively: N(3)···O(5A) = 3.050(3), N(3)···O(2B) = 2.932(3) Å [symmetry codes: (A), x, $-y+1$, $z-1/2$; (B), $-x+1/2$, $-y+3/2$, $-z+1$].

3.3. Photoluminescence properties

The mixed inorganic–organic hybrid coordination polymers have been investigated for fluorescence properties and for potential applications. However, owing to the intense spin–orbital coupling of Ag(I), most of luminescent Ag(I) complexes exhibit luminescence at low temperature [29] and Ag(I) complexes which exhibit luminescence at room temperature are few [30]. The complexes **1**–**5** reported herein represent room temperature luminescent Ag-containing polymeric complexes [31].

The solid-state fluorescence data for both free ligands and the complexes **1–5** at room temperature are shown in Table 3. As

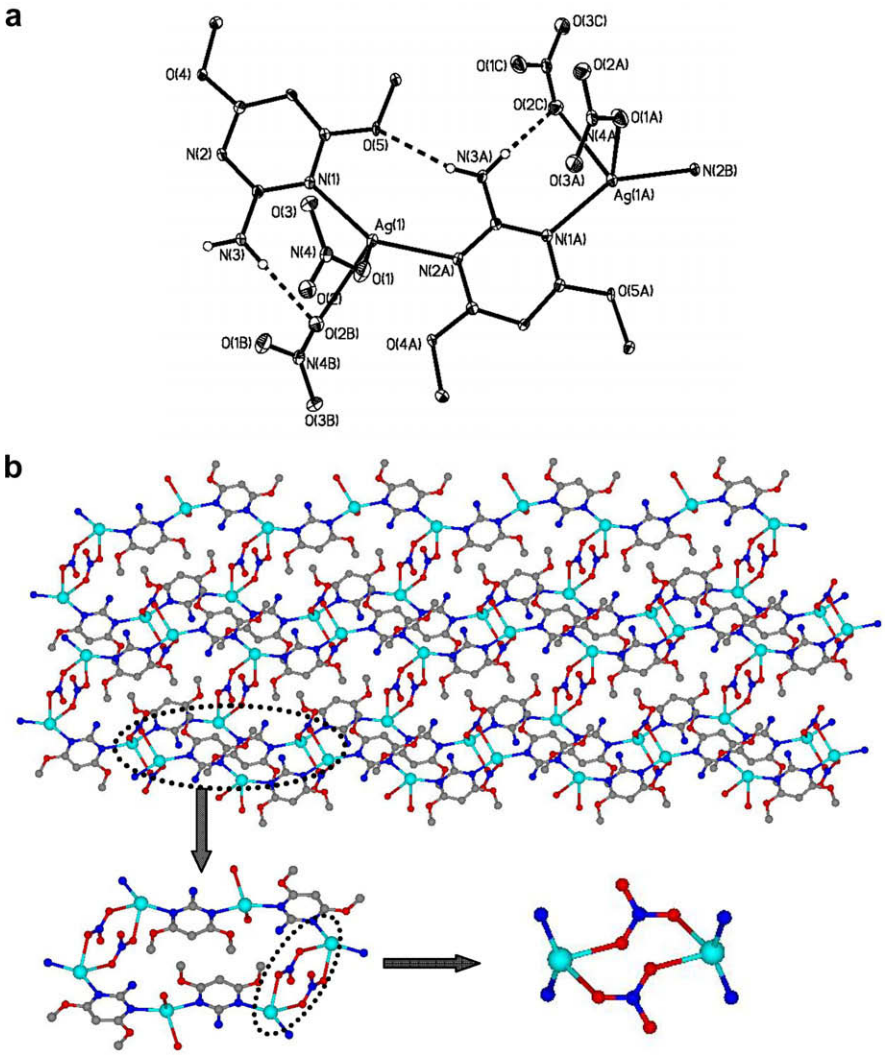

Fig. 5. (a) ORTEP drawing of **5** showing the coordination environment around Ag(I) centers at 30% probability level. Hydrogen atoms in pyrimidyl and methoxy groups were omitted for clarity. (b) A view along the *a* axis of 2-D honeycomb structure in **5**. Hydrogen atoms are omitted for clarity. Ag stressed in bigger ball.

Table 3
Comparison of emission peaks between the complexes and free ligands

Ligands	$\lambda_{em\ (ligand)}$ (nm)	Complexes	$\lambda_{em\ (complex)}$ (nm)	Red-shifted wavelength comparable with ligands (nm)
L_1	345	1	360	15
L_2	340	2	352	12
L_3	331	3	338	7
L_4	327	4	336	9
L_4	327	5	335	8

can be seen, **1** shows a main peak at 360 nm upon photo-excitation at 280 nm. And **2** and **3** exhibit an intense emission band with the maximum intensity at 352 nm and 338 nm, respectively. Here the presence of the silver only causes minor change in the emission spectra of the ligands. The emission spectrum of L_4 shows a peak at 327 nm upon excitation at 280 nm, and this emission is probably attributed to the aromatic π–π^* transition of L_4. By comparison, both of complexes **4** and **5** exhibit similar red-shift values for emission maxima as compared to the corresponding free ligand values. All the complexes **1**–**5** exhibit some low-energy emission bands, which have shapes and positions similar to the free ligands L_1–L_4. The emissions are neither metal-to-ligand charge (MLCT) nor ligand-to-metal charge transfer (LMCT) in nature and probably can be assigned to the intraligand π_L—π_L^* transitions fluorescent emission (LLCT) because very similar emissions are also observed for the free ligands.

4. Conclusions

In this study, five new silver(I) complexes with interesting structural motifs have been successfully synthesized from the various rigid ligands L_1, L_2, L_3 and L_4 with silver(I) nitrate. The analysis of the crystallographic data of **1–5** clearly shows that the overall architecture of the crystals is not only controlled by the nature of the rigid ligands present in the moiety, but by different solvent systems. Table S2 shows the cation–anion interaction, metal geometry and structure in complexes **1–5**. Moreover, the photoluminescent properties of free ligands L_1–L_3, and complexes **1**–**5** have been examined.

The spectral studies, redox properties and single crystal X-ray structures (for two representative examples) of this family are described in this work. The electrochemical parameters (E_L(L)) of the substituted diimine ligands (L) are reported. These values have broad utilization across both organometallic and coordination chemistry and can be used to predict M^n/M^{n-1} redox potentials by assuming that all ligand contributions are additive.

2. Experimental

2.1. Materials

The reagents: aniline-, bipyridine- and phenanthroline-derivatives, lithium chloride and ruthenium trichloride hydrate, and solvents (reagent grade) were purchased from Aldrich and were used as received. Tetrabutylammonium hexafluorophosphate (TBAH), was recrystallized twice from 1:1 ethanol/water solution and then vacuum dried at 110 °C. The synthesis and the physical characterization of the ligand, 1-(4-phenylimino)-1-(phenylhydrazono)-propan-2-one (Az) and the complex *trans*-[Ru(bpy)(L)Cl_2] have been prepared as described in the literature [6].

2.2. General procedure for the preparation of trans-[Ru(Az)(L)Cl_2] **2–8**

A suspension of ruthenium trichloride trihydrate (0.26 g, 1.00 mmol) and the 1-(4-phenylimino)-1-(phenylhydrazono)-propan-2-one (Az) (0.023 mmol) in 100 mL absolute ethanol were reacted under reflux conditions. After 1 h, 1.0 mmol of the corresponding ligand and excess amount of LiCl (0.50 g, 11.8 mmol) were added. The reaction was heated for an additional 3 h, after which the solvent was removed by using a rotary evaporator. The crude product was dissolved in dichloromethane, filtered and washed with water to remove the unreacted ruthenium trichloride and lithium chloride. The filtrate was reduced to 20 mL and purified by chromatography (50 × 3 cm) on alumina grade (III). Elution with acetone gave a yellow band which was discarded followed by a dark-red band of the product. The products were recrystallized from slowly evaporating solution of dichloromethane.

2.2.1. trans-[Ru(Az)(dmb)Cl_2] (**2**)

Yield (0.28 g, 46%). *Anal.* Calc. for $C_{27}H_{25}N_5ORuCl_2$: C, 53.38; H, 4.15; N, 11.53. Found: C, 53.70; H, 4.27; N, 11.47%. UV–Vis in acetonitrile: λ_{max} ($\varepsilon_{max}/M^{-1}\,cm^{-1}$): 370 ($6.688 \times 10^3$), 504 ($5.146 \times 10^3$). IR: ν(N=N) 1486, ν(C=N) 1616, ν(C=O) 1717 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 2.44 (6H, s, dmb), 2.73 (3H, s, $COCH_3$), 6.71 (1H, d, dmb), 7.05 (2H, d, H4), 7.31 (1H, d, dmb), 7.48 (1H, t, H6), 7.52 (2H, t, H5), 7.57 (1H, t, dmb), 7.62 (2H, t, H2), 7.80 (1H, t, H3), 7.95 (2H, d, H1), 8.30 (1H, s, dmb), 8.40 (1H, s, dmb).

2.2.2. trans-[Ru(Az)(dmeb)Cl_2] (**3**)

Yield (0.31 g, 47%). *Anal.* Calc. for $C_{27}H_{25}N_5O_3RuCl_2 \cdot H_2O$: C, 49.32; H, 4.14; N, 10.65. Found: C, 49.41; H, 4.18; N, 10.51%. UV–Vis in acetonitrile: λ_{max} ($\varepsilon_{max}/M^{-1}\,cm^{-1}$): 378 ($7.449 \times 10^3$), 500 ($6.55 \times 10^3$). IR: ν(N=N) 1490, ν(C=N) 1612, ν(C=O) 1705 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 2.66 (3H, s, $COCH_3$), 3.97 (6H, s, dmeb), 6.67 (1H, d, dmeb), 6.75 (1H, d, dmeb), 6.83 (1H, d, dmeb), 7.30 (1H, t, H6), 7.34 (2H, d, H4), 7.45 (2H, t, H5), 7.49 (1H, d, dmeb), 7.59 (2H, t, H2), 7.80 (1H, t, H3), 8.96 (2H, d, H1), 8.09 (1H, s, dmeb), 8.16 (1H, s, dmeb).

2.2.3. trans-[Ru(Az)(dtb)Cl_2] (**4**)

Yield (0.36 g, 55%). *Anal.* Calc. for $C_{33}H_{37}Cl_2N_3ORu \cdot CH_2Cl_2$: C, 63.07; H, 6.07; N, 6.49. Found: C, 63.29; H, 6.39; N, 6.56%. UV–Vis in acetonitrile: λ_{max} ($\varepsilon_{max}/M^{-1}\,cm^{-1}$): 368 ($6.40 \times 10^3$), 506 ($5.684 \times 10^3$). IR: ν(N=N) 1480, ν(C=N) 1611, ν(C=O) 1701 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 1.34 (18H, s, dtb), 2.73 (3H, s, $COCH_3$), 6.84 (1H, d, dtb), 7.12 (1H, d, dtb), 7.17 (1H, d, dtb), 7.32 (2H, d, H4), 7.49 (1H, d, dtb), 7.50 (2H, t, H5), 7.54 (1H, t, H3), 7.61 (2H, t, H2), 7.83 (1H, t, H6), 7.96 (2H, d, H1), 8.47 (1H, s, dtb), 8.40 (1H, s, dt*b*).

2.2.4. trans-[Ru(Az)(phen)Cl_2] (**5**)

Yield (0.23 g, 40%). *Anal.* Calc. for $C_{27}H_{21}Cl_2N_3ORu$: C, 56.35; H, 3.68; N, 7.30. Found: C, 56.51; H, 3.87; N, 7.48%. UV–Vis in acetonitrile: λ_{max} ($\varepsilon_{max}/M^{-1}\,cm^{-1}$): 372 ($9.015 \times 10^3$), 505 ($6.321 \times 10^3$). IR: ν(N=N) 1495, ν(C=N) 1606, ν(C=O) 1711 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 2.83 (3H, s, $COCH_3$), 7.24 (1H, d, phen), 7.33 (1H, dd, phen), 7.38 (1H, dd, phen), 7.53 (1H, t, H6), 7.58 (2H, d, H2), 7.50 (2H, t, H5), 7.75 (1H, t, H3), 7.84 (2H, d, H4), 7.95 (1H, d, phen), 8.12 (2H, d, H1), 8.25 (1H, d, phen), 8.29 (1H, d, phen),

2.2.5. trans-[Ru(Az)(aphen)Cl_2] (**6**)

Yield (0.30 g, 48%). *Anal.* Calc. for $C_{27}H_{22}Cl_2N_6ORu \cdot 0.5H_2O$: C, 51.68; H, 3.69; N, 13.39. Found: C, 51.34; H, 3.63; N, 13.70%. UV–Vis in acetonitrile: λ_{max} ($\varepsilon_{max}/M^{-1}\,cm^{-1}$): 378 ($7.343 \times 10^3$), 507 ($6.464 \times 10^3$). IR: ν(N=N) 1490, ν(C=N) 1637, ν(C=O) 1705 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 2.70 (3H, s, $COCH_3$), 5.76 (2H, s, NH_2), 6.73 (1H, s, aphen), 6.94 (1H, d, aphen), 7.14 (1H, d, aphen), 7.29 (1H, t, H6), 7.42 (2H, t, H5), 7.58 (2H, d, H4), 7.63 (1H, d, aphen), 7.65 (1H, t, aphen), 7.77 (2H, t, H2), 7.86 (1H, t, H3), 8.06 (2H, d, H1), 8.21 (1H, d, aphen), 8.80 (1H, d, aphen).

2.2.6. trans-[Ru(Az)(chphen)Cl_2] (**7**)

Yield (0.36 g, 50%). *Anal.* Calc. for $C_{27}H_{20}Cl_3N_5ORu \cdot CH_2Cl_2$: C, 46.53; H, 3.07; N, 9.69. Found: C, 46.82; H, 3.19; N, 9.92%. UV–Vis in acetonitrile: λ_{max} ($\varepsilon_{max}/M^{-1}\,cm^{-1}$): 374 ($9.277 \times 10^3$), 500 ($8.62 \times 10^3$). IR: ν(N=N) 1487, ν(C=N) 1632, ν(C=O) 1704 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 2.73 (3H, s, $COCH_3$), 7.13 (1H, d, chphen), 7.43 (2H, d, H4), 7.59 (2H, t, H5), 7.60 (1H, t, chphen), 7.68 (2H, d, H2), 7.73 (1H, t, chphen), 7.74 (1H, d, chphen), 7.76 (1H, t, H6), 7.88 (1H, t, H3), 7.99 (2H, d, H1), 8.50 (1H, s, chphen), 8.65 (1H, d, chphen) , 8.90 (1H, d, chphen).

2.2.7. trans-[Ru(Az)(tmphen)Cl_2] (**8**)

Yield (0.30 g, 46%). *Anal.* Calc. for $C_{31}H_{29}Cl_2N_5ORu$: C, 56.45; H, 4.43; N, 10.62. Found: C, 56.61; H, 4.10; N,10.87%. UV–Vis in acetonitrile: λ_{max} ($\varepsilon_{max}/M^{-1}\,cm^{-1}$): 372 ($8.343 \times 10^3$), 509 ($6.195 \times 10^3$). IR: ν(N=N) 1443, ν(C=N) 1623, ν(C=O) 1702 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 2.04 (3H, s, tmphen), 2.10 (3H, s, tmphen), 2.70(3H, s, $COCH_3$), 6.69 (2H, s, tmphen), 7.40 (1H, t, H6), 7.45 (2H, d, H4), 7.59 (2H, t, H5), 7.72 (2H, t, H2), 7.89 (1H, t, H3), 7.97 (2H, d, H1), 8.3 (1H, d, tmphen).

2.3. Instrumentation

Cyclic voltammetric studies were performed in acetonitrile (Aldrich, HPLC grade) using a voltalab 21 (PGP201). Three electrodes were utilized in this system, two platinum-disk working and counter (auxiliary) electrodes (platinum electrode, 2-mm diameter),

and a silver wire pseudo-reference electrode with ferrocene (0.665 V versus NHE) as an internal reference [7]. To maintain the cell temperature at 25.0 ± 0.1 °C, a Haake D8-G refrigerated bath and circulator was used. Tetrabutylammonium hexafluorophosphate was twice recrystallized and vacuum dried at 120 °C, and used as the supporting electrolyte. Spectroscopic data were obtained using Cary 5 spectrophotometer. IR spectra were measured by FT-IR JASCO model 420. Nuclear magnetic resonances (^{1}H NMR) spectra were measured on a Bruker-Avance 400 MHz spectrometer. Elemental analyses were carried out on an Eurovector E.A.3000 instrument using copper sample-tubes.

Table 1
Crystallographic data and structure refinement parameters for **2** and **5**

	Complex **2**	Complex **5**

2.4. Computational methods

The crystallographic geometries of **2** and **5** were used as examples for our calculations. All theoretical calculations were carried out using a Becke's three-parameter hybrid function [8] with LYP correlation function [9] (B3LYP), as implemented in the GAUSSIAN 03 program package [10]. LanL2DZ effective core potential basis set was employed for all atoms in acetonitrile solution [11]. The theoretical electronic spectra were simulated from the energy of the excited states and transition oscillator strengths calculated by the TD-DFT formalism as implemented in the GAUSSIAN 93 program [10]. A value equal to 3000 cm^{-1} for the bandwidth at half height has been used in these simulations with Gaussian line shapes because this value often provides us with molar extinction coefficient values close to experimental data.

2.5. Crystallography

Crystals of compounds **2** and **5** were removed from the flask, a suitable crystal was selected, attached to a glass fiber and data were collected at 90(2) K using a Bruker/Siemens SMART APEX instrument (Mo Kα radiation, λ = 0.71073 Å) equipped with a Cryocool NeverIce low temperature device. Data were measured using omega scans 0.3° per frame for 5 s, and a full sphere of data was collected. A total of 2400 frames were collected with a final resolution of 0.77 Å. Cell parameters were retrieved using SMART [12] software and refined using SAINTPLUS on all observed reflections [13]. Data reduction and correction for Lp and decay were performed using the SAINTPLUS software. Absorption corrections were applied using SADABS [14]. The structure was solved by direct methods and refined by least squares method on F^2 using the SHELXTL program package [15]. The structure was solved in the space group $P\bar{1}$ for complex **5** and $P21/n$ for complex **2** by analysis of systematic absences. The ketone group was disordered in two positions with occupancies of 84:16% and all non-hydrogen atoms were refined anisotropically. No decomposition was observed during data collection. Details of the data collection and refinement are given in Table 1. Further details are provided in the Supporting Information.

3. Results and discussion

3.1. Synthesis

The new complexes *trans*-[Ru(Az)(L)Cl$_2$] **(2–8)** used in this study were prepared by stepwise equimolar addition of RuCl$_3$, 1-(phenylimino)-1-(phenylhydrazono)-propan-2-one (Az), substi-

tuted bipyridine or phenanthroline ligands ($\mathbf{L_1}$–$\mathbf{L_8}$) and then an excess of lithium chloride according to Scheme 1.

These neutral complexes are air stable, diamagnetic and their structures were confirmed by ^{1}H NMR spectra and X-ray diffraction for complexes **2** and **5**. The ^{1}H NMR spectra of complexes **2–8** show featureless multiplets due to aromatic protons of the phenyl rings of the ligands. In their IR-spectra, all complexes show bands in the range of 1660–1712 cm^{-1} assignable to C=O stretching frequency of the acetyl group and intense bands in the ranges of 1560–1590 and 1430–1500 cm^{-1} which are assigned to the C=N and N=N stretching bands of azoimine ligands, respectively.

3.2. Crystal structures

The X-ray structures of (**2**) and (**5**) were determined and the perspective molecular views for the asymmetric units are shown in Figs. 1 and 2, respectively. The selected bond parameters are listed in Table 2. The ORTEP geometry of complex **5** as representative example for phenanthroline family is shown in Fig. 2. This complex crystallizes in the $P\bar{1}$ space group, which is different from $P21/n$ of complex **2**. The coordination geometry of the complexes is distorted from regular octahedral as a consequence of the small bite angles of bidentate phen (77.31°) and bpy ligands (78.9°), which deviate very much from the ideal octahedral angle of 90°. For both complexes (**2** and **5**) the chloride ligands are *trans* to each other and the azomethine and diimine nitrogen donor atoms are equatorially coordinated. Most bis bipyridine or phenanthroline complexes prefer a *cis* geometry because of steric hindrance between α protons in the *trans* geometry [16]. Steric hindrance is evidently not as great for the complexes of this study because the Az ligand phenyl rings can twist away from the α protons as shown in Figs. 1 and 2. The *trans* complexes of this study appear to be thermally stable in solution and we hope to explore their photochemical properties in the future. For complex **5**, the N(7)–Ru(1)–N(13) angle of the azomethine ligand has a value of 76.33. The azomethine ligand is known to participate strongly in dπ–π^* interactions with Ru(II). This has been reflected in the Ru–N(bpy), Ru–N(phen) and Ru–N(Az) bond distance data. The Ru–N(py) bond distances for complex **5** and **2** fall within a narrow range of 2.121–2.146 Å. The Ru–N(bpy) and Ru–N(phen) distances are longer than those in the

corresponding $[Ru(bpy)_3]^{2+}$ and $[Ru(phen)_3]^{2+}$ complexes, respectively [17]. For complex **2,** the Ru–N(bpy) distances (average, 2.121(3) Å) are shorter than Ru–N(phen) distances (average, 2.146(3) Å) revealing that bpy is more strongly coordinated than phen. For complex **5**, the average Ru–N(azo) and Ru–N(methine) distances of the azoimethine ligand is 1.971(3) Å which is shorter than Ru–N(phen) lengths (average, 2.146(3) Å). This shortening may be due to greater π-back donation from Ru-d orbital to the empty π^* orbital of the azoimine ligand, and this comes as an indication that the M–(Az) π interaction is localized in the M–azo fragment [18]. Reported Ru–Cl distances in chloro-Ru(II) complexes lie in the range 2.389–2.401 Å [19]. The average Ru–Cl bond lengths in **5** (2.364) is comparable to similar reported systems [19].

3.3. Electrochemistry

Formal oxidation and reduction potentials versus NHE were obtained from cyclic voltammograms recorded at a platinum elec-

trode in acetonitrile containing 0.1 M tetrabutylammonium hexafluorophospate. These data are listed in Table 3. Ru(III/II) values were obtained from an average of anodic and cathodic peak potentials. Complex **5**, as a representative example (Fig. 3), displays a reversible oxidation peak at 1.18 V, being attributed to the metal-centered Ru(III/II) couple. The two reduction waves at −0.43 and −0.77V are assigned to azo(0/−) and azo(−/−2) ligand-centered processes. This reduction couples are shifted to more positive potentials by the electron withdrawing group attached to bipyridine and phenanthroline ligands. The electrochemical properties of Ru(II) complexes containing substituted phenanthroline ligand were quite similar to those of substituted bipyridine complexes. However, the half-wave potential of earlier complex was shifted anodically by 20 mV compared to those observed with later complexes. This relationship indicates that the donor ability of the phenanthroline ligand is slightly weaker than that of the bipyridine ligand [19]. The Ru(III/II) couple is slightly affected by changing the substituent on the phenanthroline ligand and is shifted to more positive potentials upon replacing the donating methyl group with the more withdrawing chloro group. Lever has developed an electrochemical parameterization method to calculate ruthenium(III/II) couples of complexes with octahedral geometry as shown in Eq. (1) [4].

$$E_{\mathrm{Ru(III/II)}} = 0.97\left[\sum E_{\mathrm{L}}\right] + 0.04 \text{ in V versus NHE} \quad (1)$$

where $\sum E_{\mathrm{L}}$ is the sum of electrochemical parameters for each ligand in the complex. The parameter E_{L} is a measure of the stabilizing effect a ligand has on the Ru(II) state and so the greater the magnitude of positive E_{L} the more positive the Ru(III/II) couple. Based on the previously found (E_{L}(Az) = 0.42) [6], E_{L}(Cl) = −0.24 [4]) and assuming ligand additivity, the Ru(III/II) couple for these octahedral complexes was used to find the ligand electrochemical parameters (E_{L}(L)) for unreported diimine ligands (L) using Eq. (1) and the data are listed in Table 3.

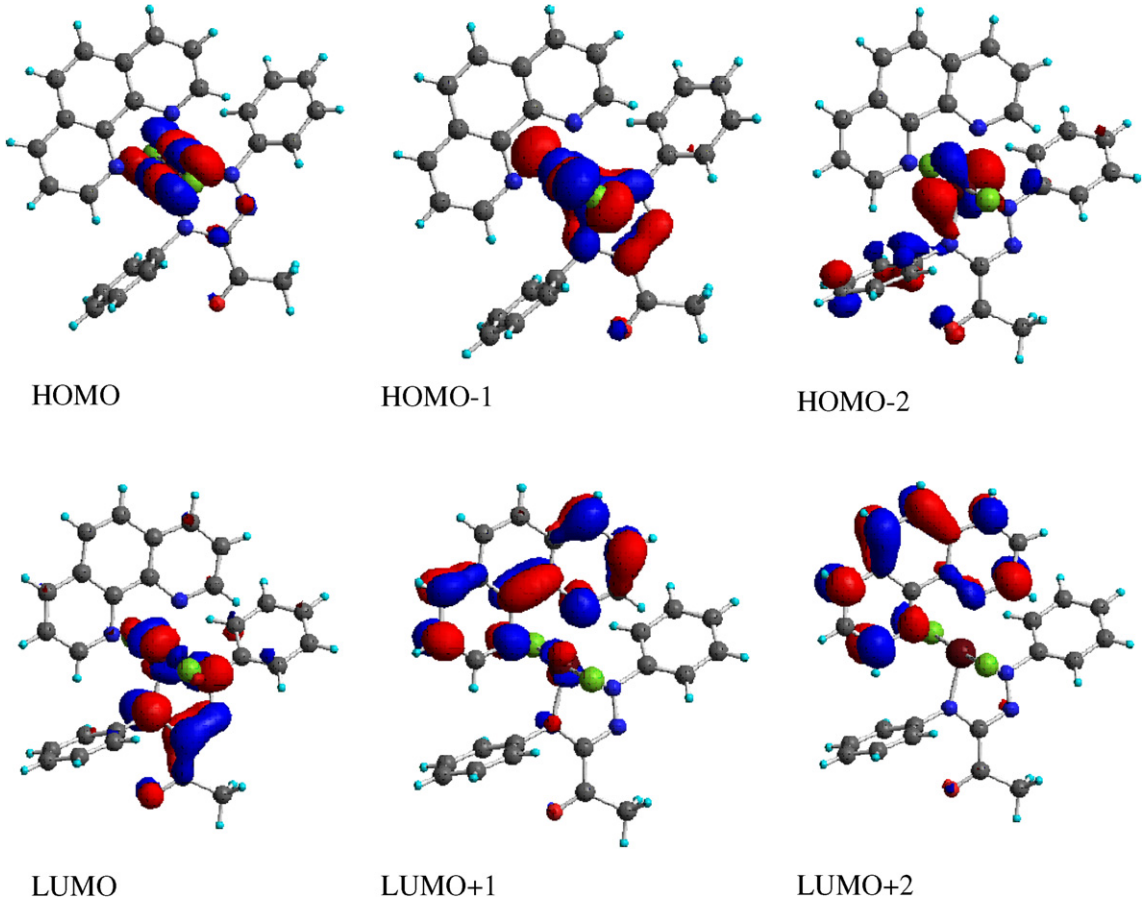

Fig. 4. Isodensity plots of the HOMO and LUMO orbitals of **5**.

mostly of a series of antibonding π^* orbital of azoimine together with a small contribution from π^* orbital of phenanthroline. Results indicate that the LUMO is constructed mainly from the π^* orbital of azoimine (60%) and has 26% metal d-orbital character which suggests significant back donation [20]. The other group of HOMOs, can be described as t_2g Ru orbitals (HOMO to HOMO − 2) with small contributions from the azomethine ligands. Moreover, results indicate that π orbital of azoimine ligand contributes significantly to HOMO − 3.

The lowest 20 singlet-to-singlet spin-allowed excitation states were taken into account for the calculation of the electronic absorption spectrum of complex **5** using TD-DFT method. Excitation energies, oscillator strengths and corresponding transitions compositions for the simulated absorption bands in acetonitrile solution are listed in Table 5. Each excited state was interpolated by a Gaussian convolution with the full width at half-maximum (fwhm) of 3000 cm^{-1}. Both the experimental UV–Vis spectrum for complex **5** (as a representative example) and its simulated absorption spectrum reported in acetonitrile, shown in Fig. 5, were in good agreement. Experimentally, complex **5** has a maximum centered at 504 nm and a shoulder peak at 390 nm. Contrary to the experimental information, the simulated near-UV band is much higher than the visible one. Assuming that the appropriate fwhm values are chosen, the molar absorptivity of the band maximum in visible region is slightly underestimated, while the one in the near-UV region is significantly overestimated. Similar results in simulation of N3-type dye also exist [21]. The study of Tozer et al. also revealed that TD-DFT has difficulty in distributing intensity properly [22]. For the absorption band in visible region, TD-DFT calculations shows that the band centered at λ_{max} = 504 nm (≈550 nm (calculated)) resulted from HOMO − 1 orbital, which have sizable contributions of Ru(dπ) orbitals mixed with azomethine to LUMO which has a significant contribution from the π^* orbital of azomethine. Thus this band is assigned to MLCT (Ru(dπ) → π^* azomethine). For the band in the near-UV region, the band centered at 390 nm (≈388 nm (calculated)) arises from the overlap of several transitions, MLCT and $\pi \rightarrow \pi^*$. The MLCT band centered at 395 resulted from HOMO (mainly Ru) → LUMO + 3 (azomethine in character), while the $\pi \rightarrow \pi^*$ transition is at centered 388 nm and resulted from the HOMO − 6 (azomethine

Table 5
Computed excitation energies (eV), electronic transition configurations and oscillator strengths (*f*) for the optical transitions in the visible region of **5** (transitions with $f > 0.01$ are listed)

375 (3.313)	0.0111	78.1% HOMO − 10 → LUMO

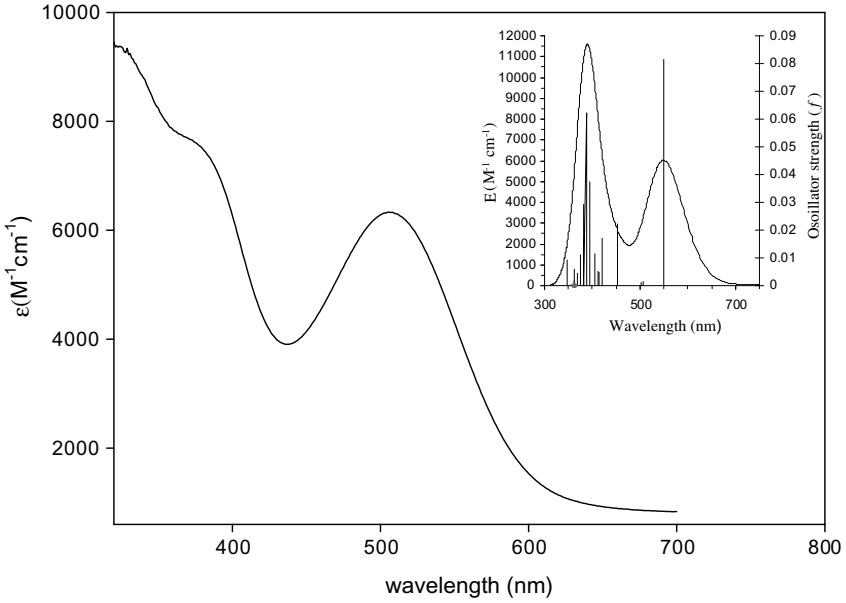

Fig. 5. UV–Vis spectrum for **5** in acetonitrile. Inset shows simulated absorption spectrum. (black line) based on TD-DFT calculations, compared to excitation energies and oscillator strengths.

in character) → LUMO. The observation of two MLCT transition may be explained by the low symmetry of this distorted octahedral Ru complexes [23–25].

The difference in the two successive redox responses at potentials positive and negative to NHE [$\Delta E^\circ = E^\circ_{1/2M} - E^\circ_{L^*}(0/-)$] may be correlated with the low energy MLCT [t(Ru) → π*(azomethine)] transition [25]. Charge transfer transitions may be considered an intramolecular redox process [26–29] and the intense spin-allowed MLCT transition is expected to be linearly related to ΔE° with slope equal to unity. A least-squares plot of ΔE° versus lower energy MLCT (Fig. 6) gave a linear correlation ($E_{MLCT} = 0.39\ \Delta E^\circ + 1.829$) however the slope of the line is only 0.39. This may result from solvent effects that become important for the small changes in energy that are seen in this group of complexes [26].

4. Conclusions

A series of complexes of general formula *trans*-[Ru(II)(Az)(L)Cl_2] where Az = $C_6H_5N{=}NC(COCH_3){=}NC_6H_5$, and L is nitrogen substituted bipyridine and phenanthroline ligands have been prepared and their redox chemistry and UV–Vis spectroscopy examined. The structures for complex **2** and **5** have been further characterized by X-ray diffraction analysis. Crystallographic studies shows that bidentate azomethine ligands are strong π-acceptor that coordinate via imine and azo nitrogens. Electrochemical and photophysical data in acetonitrile showed that electron-donating groups in the bipyridine and phenanthroline ligands shifts the redox potentials to more negative values than those observed for the parent ligands. Assuming ligand additivity, the Ru(III/II) couple for these octahedral complexes was used to find the ligand electrochemical

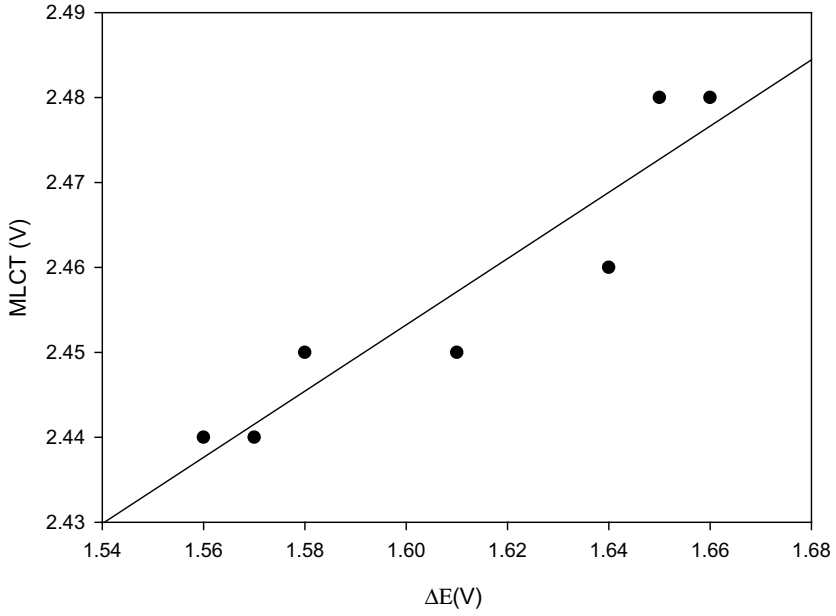

Fig. 6. Linear correlation between MLCT band energies and ΔE° (ΔE° = Ru(III/II) − Azo(0/−)) in volts. The equation of the line is ($E_{MLCT} = 0.39\Delta E^\circ + 1.829$).

parameter (E_L(L)) for unreported diimine ligands (L). The electronic absorption spectra of these complexes show two strong MLCT band in the visible region and near UV–Vis region in acetonitrile solution. These two bands are assigned to a (Ru(II)-to-azomethine) MLCT transition based on TD-DFT calculations. Good agreement between computed and experimental absorption spectra was obtained.

5 Supplementary data

CCDC 690081 and 690082 contain the supplementary crystallographic data for **2** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

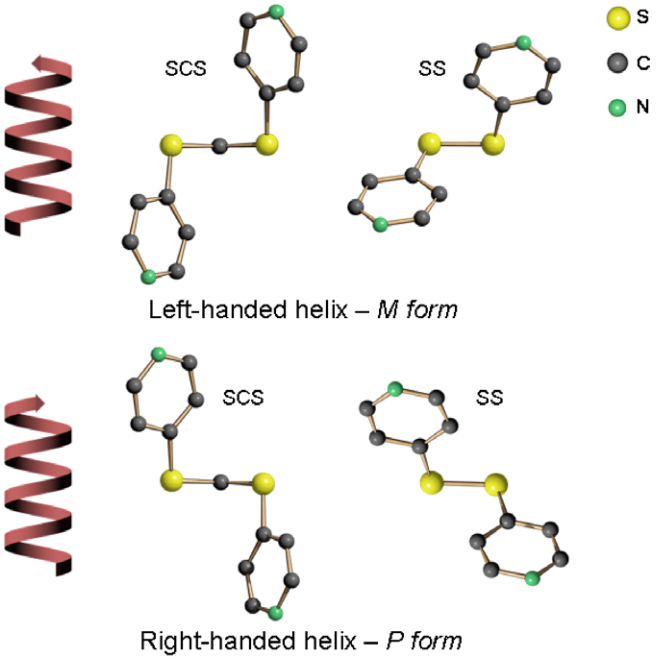

Scheme 1.

Vector 22 spectrophotometer. A Shimadzu UV-3101PC spectrophotometer was used to obtain electronic spectra in the solid state. Magnetic susceptibility measurements were performed at room temperature using a Johnson-Matthey Alfa MSB-MK1 Gouy balance. TGA analysis was carried out using a TA Instruments Hi-Res TGA2950 Thermobalance coupled to an FT-IR Bruker Tensor 27 apparatus.

2.2. Synthesis of the complexes

2.2.1. $[Cu(SO_4)(4\text{-bpytm})(H_2O)_3] \cdot H_2O$ (**1** · **H_2O**)

Compound **1** · **H_2O** was obtained by reaction of bis(4-pyridylthio)methane (4-bpytm) (0.86 mmol) in EtOH (10 mL) and $CuSO_4 \cdot 5H_2O$ (0.86 mmol) in a 1:1 mixture EtOH:H_2O (20 mL). The resulting mixture was heated under reflux for 48 h and was left to cool down to room temperature. The resulting blue precipitate was filtered off, washed with EtOH and dried under vacuum. Single crystals were obtained by recrystallization of the precipitate from water.

Data: Yield: 73%. *Anal.* Calc. for $C_{11}H_{18}N_2O_8S_3Cu$: C, 28.3; H, 3.9; N, 6.0. Found: C, 28.8; H, 3.9; N, 5.9%. IR (KBr, cm^{-1}): 3500–2959s,b, 1597s, 1541m, 1484m, 1421s, 1232m, 1167s, 1112s, 1065m, 1032m, 970m, 800m, 732m, 463m, 657w, 618s. UV–Vis (λ_{max}, cm^{-1}): 14500. μ (R.T.): 2.0 B.M.

2.2.2. $[Cu(NO_3)_2(4\text{-bpytm})_2] \cdot H_2O$ (**2** · **H_2O**)

A solution of bis(4-pyridylthio)methane (4-bpytm) (0.92 mmol) in EtOH (10 mL) was slowly added to a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.46 mmol) in EtOH (10 mL). The resulting mixture was heated under reflux for 21 h and was left to cool down to room temperature. The resulting blue-lilac precipitate was filtered off, washed with EtOH and dried under vacuum. Single crystals of **2** · **H_2O** were obtained by slow diffusion of $Cu(NO_3)_2 \cdot 3H_2O$ (2.25 mmol) in water into a solution of 4-bpytm (0.25 mmol) in CH_3CN. The elemental analysis and the spectroscopic data for the single crystal and the powder phase were coincident.

Data: Yield: 98%. *Anal.* Calc. for $C_{22}H_{20}S_4O_7N_6Cu$: C, 39.2; H, 3.3; N, 12.5. Found: C, 39.9; H, 3.1; N, 12.8%. IR (KBr, cm^{-1}): 3446m, 1597s, 1536m, 1487m, 1385s, 1311m, 1223m, 1064m, 1023w, 810m, 733m, 501m. UV–Vis (λ_{max}, cm^{-1}): 17700. μ (R.T.): 1.7 B.M.

2.2.3. $[Cu(NO_3)2(4\text{-bpytm})_2] \cdot Solv$ (2 · ***Solv***)

4-bpytm (0.213 mmol), $Cu(NO_3)_2 \cdot 3H_2O$ (0.107 mmol), dmf (4 mL) and EtOH (2 mL) were added to a Schlenk tube, which was then placed in a microwave oven. The mixture was irradiated for 90 s at 700 W. The resulting blue solution was allowed to cool down to room temperature and immediately yielded blue crystals of **2** · **Solv**.

Data: Yield: 69%. *Anal.* Calc. for $C_{25}H_{31}S_4O_{10}N_7Cu$ (781.4; Solv = $2H_2O$ + dmf): C, 38.4; H, 4.0; N, 12.6. Found: C, 38.0; H, 3.8, N, 12.3%. IR (KBr, cm^{-1}): 3443m, 1658s, 1595s, 1485m, 1421m, 1385m, 1290m, 1219m, 1110m, 1066m, 1026w, 810m, 732m, 664m, 503m. μ (R.T.): 1.6 B.M.

2.3. Crystallography

Crystallographic data were collected on a Bruker Smart 1000 CCD diffractometer at 293 K using graphite monochromated Mo K_α radiation (λ = 0.71073 Å) and were corrected for Lorentz and polarisation effects. The frames were integrated with the Bruker SAINT [20] software package and the data were corrected for absorption using the program SADABS [21]. The structures were solved by direct methods using the program SHELXS97 [22]. All non-hydrogen atoms were refined with anisotropic thermal parameters by full-matrix least-squares calculations on F^2 using the program SHELXL97 [23]. Hydrogen atoms were inserted at calculated positions and constrained with isotropic thermal parameters, except for the hydrogen atoms of the water molecules in **1**, which were located from a difference Fourier map and refined isotropically. For **2** · **H_2O** disorder was observed in nitrate ions and in the refinement the N–O distance was restrained to values around 1.2 Å (DFIX 1.2). In the structures of **2** · **H_2O** and **2** · **Solv** the contribution of the disordered solvents to the diffraction pattern could not be rigorously included in the crystallographic calculations and these were consequently removed by the SQUEEZE routine of PLATON [24]. The *R* values before SQUEEZE application were 0.1128 [$I > 2\sigma(I)$] and 0.3030 (all data) for **2** · **H_2O** and 0.1770 [$I > 2\sigma(I)$] and 0.4876 (all data) for **2** · **Solv**. Drawings were produced with MERCURY [25] and special computations for the crystal structure discussions were carried out with PLATON. Crystal data and structure refinement data are listed in Table 1.

3. Results and discussion

The reaction of 4-bpytm with $CuSO_4 \cdot 5H_2O$ and $Cu(NO_3)_2 \cdot 3H_2O$ in metal/ligand molar ratios of 1:1 and 1:2, respectively, under reflux conditions yielded the polymeric compounds **1** · **H_2O** and **2** · **H_2O** (Scheme 2). Single crystals of **1** · **H_2O** and **2** · **H_2O** were obtained by recrystallization from EtOH and by diffusion, respectively. The microwave synthesis was an interesting method due to its high efficiency, leading to a reduction in reaction times, purer products and also acceleration of the crystallization process. As a result, we performed the synthesis with $Cu(NO_3)_2 \cdot 3H_2O$ using dmf and EtOH under microwave irradiation. In this way we isolated the pseudo-polymorph **2** · **Solv**.

Compounds **1** · **H_2O** and **2** · **H_2O** proved to be stable in air but this was not the case for **2** · **Solv**, which slowly loses the solvent component in air, leading to slight changes in the initial blue colour. The solvent component of **2** · **Solv** could not be accurately determined; the analytical data agree with the solvent component being $2H_2O$ and dmf but the X-ray structural resolution shows a highly disordered solvent area, which seems to contain dmf, H_2O and probably also EtOH.

The IR spectrum of **1** · **H_2O** exhibit a medium intensity, very broad band centred at 3230 cm^{-1} assignable to ν(OH) vibrations of the coordinated and lattice water molecules. The broadness

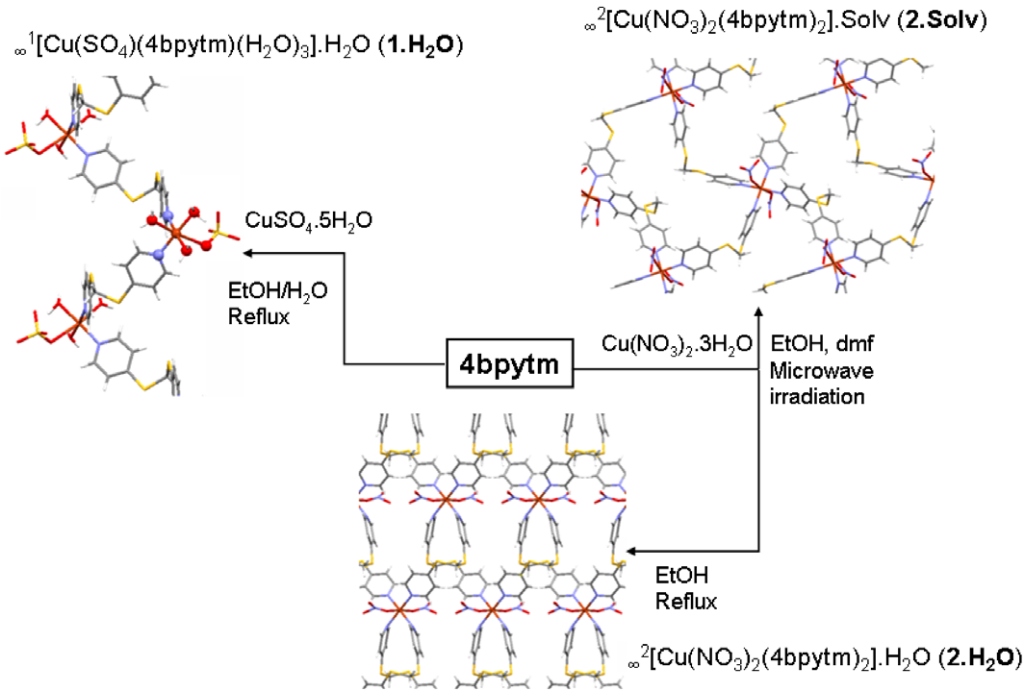

Scheme 2.

and relatively low frequency of this band are indicative of extensive hydrogen bonding. In **2 · H$_2$O** and **2 · Solv** the bands corresponding to the ν(OH) vibrations are located at about 3440 cm^{-1} and are narrow, suggesting that the water lattice molecules are weakly involved in hydrogen bonding. The IR spectrum of **1 · H$_2$O** exhibits two strong peaks at 1112 and 618 cm^{-1}, indicating the implication of the SO_4^{2-} group in the coordination to the Cu(II) centre. Compounds **2 · H$_2$O** and **2 · Solv** shows bands corresponding to the NO_3^- anions at 1311 cm^{-1} (**2 · H$_2$O**) and 1219 cm^{-1} (**2 · Solv**) for $\nu_a(NO_2)$ and at 1023 cm^{-1} (**2 · H$_2$O**) and 1026 cm^{-1} (**2 · Solv**) for $\nu_s(NO_2)$. Also in the spectrum of **2 · Solv** a strong peak at 1658 cm^{-1} is attributed to the amide I band of the dmf solvent.

The thermal decomposition of the complexes was studied using thermogravimetric analysis. In compound **1 · H$_2$O**, an initial mass loss of 15.2% was observed between room temperature and 109 °C, which corresponds to the release of the lattice H_2O molecule and the three aqua ligands (calc. 15.4%). A plateau was then reached up to 244 °C, suggesting that the anhydrous species is thermally stable. The second weight loss of 52%, between 244 and 270 °C, corresponds to the escape of the 4-bpytm ligand (calc. 50%). For compound **1 · H$_2$O** the release of the water lattice molecule occurs between RT and 58 °C and in the two following steps, between 58 and 393 °C, a complicated degradation occurs with a total weight loss of 72%. In **2 · Solv**, an initial step with a loss of about 1.5%, between R.T. and 120 °C, is consistent with the escape

of 0.7 water molecules and a second release of about 7.9%, in the range 120–220 °C, could corresponds to the loss of one dmf molecule (calc. 8.4%) and the final release, in the range 220–340 °C, corresponds to the total decomposition of the sample.

3.1. Structure of $[Cu(SO_4)(4\text{-bpytm})(H_2O)_3] \cdot H_2O$ (**1** · **H_2O**)

The coordination environment of the copper atom in **1** · **H_2O** is represented in Fig. 1, together with the atom numbering scheme for coordinating atoms, and selected bond distances and angles are listed in Table 2. The structure is based on 1D helical chains and water of crystallization. The metal centre adopts a distorted octahedral coordination geometry that can be described as a 4 + 1 + 1′ type, with two *cis* pyridyl nitrogen atoms and two *cis* oxygen atoms of aqua molecules in the equatorial plane (Cu–N = 2.020; 1.987 and Cu–O = 1.976; 1.965 Å). The copper atom is also bonded to one oxygen atom of an aqua molecule (Cu–O3 = 2.305 Å) and one oxygen atom of the sulfate ion (Cu–O11 = 2.635 Å) in the axial positions. The Cu···Cu distance in the chain separated by the bridging 4-bpytm is 13.0098(14) Å. The helices run along the *b* axis and in the 4-bpytm ligand the C–S–C–S torsion angles are 75.5(4)° and 74.4(4)°, which are in the range reported for other polymeric metal complexes [15]. The data for some very similar one-dimensional copper(II) polymers containing different N,N′-bridging ligands [26–29] are listed in Table 3 for the sake of comparison. In all cases the equatorial Cu–N and Cu–Ow distances are around 2 Å, but the axial Cu–Ow and Cu–OSO_3 distances have values in the ranges 2.207–2.594 and 2.378–2.673 Å, respectively. When a rigid N,N′-ligand is used the N *trans* disposition is obtained, but when the ligand has some degree of flexibility the N *cis* arrangement is preferred. Some other similar 1D metal polymers, such as $[M(SO_4)(44bipy)(H_2O)_3] \cdot C_2H_6O_2$, M = Co(II) [30] and M = Zn(II) [31], also show an N *trans* disposition for the rigid ligand 4,4′-bipyridine.

involving the coordinated water molecules and the sulfate anions are responsible for the association of the chains to form this layer.

The layers with opposite helicity are connected to give a 3D architecture (Fig. 2, left) through hydrogen bonding involving the water molecule of crystallization, one oxygen (O14) of the sulfate anion and two –CH (C3 and C13) units of the two pyridine rings (Table 4). So, each unit, by means of two $CH_{py}\cdots OSO_3$ hydrogen bonds, connects along the *b* axis each helix with two others of opposite helicity (Fig. 2, right top) and the hydrogen bonds involving the water of crystallization and the coordinated oxygen atom (O11) of the sulfate connect the helices along the *a* axis (Fig. 2, right bottom). The final 3D supramolecular architecture is racemic due to the existence of equal amounts of P- and M-helices. The crystallization water (O4) is involved in four hydrogen bonds: as an acceptor with two coordinated water molecules (O2 and O3) from two different chains and as a donor with two of the oxygen atoms (O11 and O12) of the sulfate anions of another two chains.

*3.2. Structure of $[Cu(NO_3)_2(4\text{-}bpytm)_2]\cdot H_2O$ (**2 · H_2O**) and $[Cu(NO_3)_2(4\text{-}bpytm)_2]\cdot Solv$ (2 · **Solv**)*

The 2D coordination polymers **2 · H_2O** and **2 · Solv** are pseudo-polymorphs. The different solvents and probably the different synthetic methodologies used play a determinant role in the formation of the 2D coordination network and also, consequently, in the supramolecular organization in both compounds. The 2D coordination networks are represented in Figs. 3 and 4 together with the atom numbering scheme for coordinating atoms and a schematic representation showing the different patterns of the layers of **2 · H_2O** and **2 · Solv**, respectively. Selected interatomic distances and angles and the main hydrogen bonds are listed in Tables 2 and 4, respectively.

In both compounds, as in other tetrakis-bipyridyl based structures with $M(NO_3)_2$ [32], the four bridging bipyridyl ligands occupy equatorial coordination sites of the metal centre, leading to the propagation of a 2D sheet structure. The Cu–N distances are all about 2 Å but in **2 · Solv** one of the Cu–N distances has a value of 2.212 Å, which is clearly longer than the others.

The remaining axial sites are occupied by the monodentate nitrate ions. In **2 · H_2O**, the Cu–O distance of 2.765 Å is indicative of a very weak coordination so the coordination geometry around the copper centre corresponds to an elongated octahedron (4+2 type). In **2 · Solv** there are two different Cu–O distances, one short (2.367 Å) and one long (2.604 Å), although both of these are shorter than those observed in **2 · H_2O**. The 2D layer in **2 · H_2O** can be described as a rhombic-grid with a Cu···Cu distance of 11.08 Å through the bridging ligand, a major diagonal Cu···Cu distance of 20.44 Å and a minor diagonal Cu···Cu distance of 8.55 Å (Fig. 3).

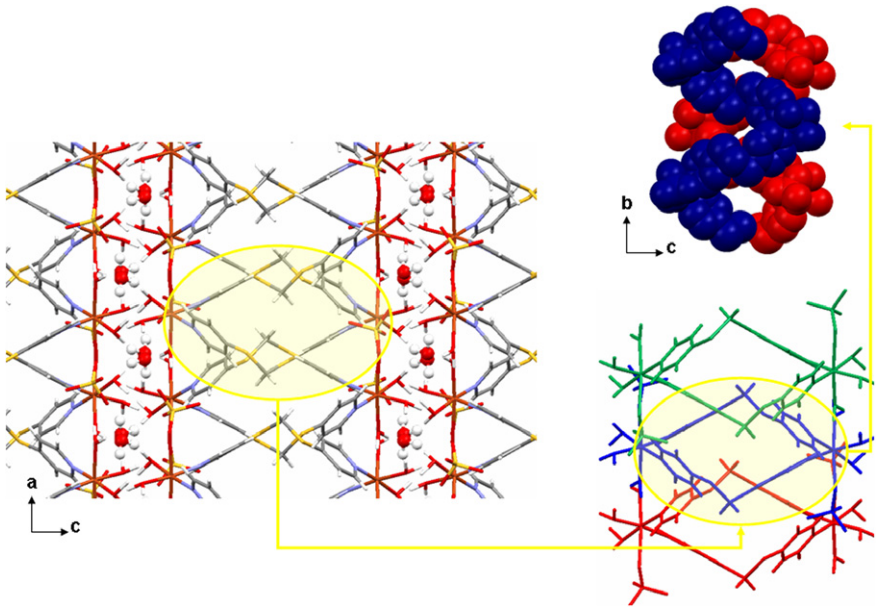

Fig. 2. View in the *ac* plane of the 3D organization in **1** · **H_2O**, showing details of the arrangement of the helices with different handedness (right) marked with different colours.

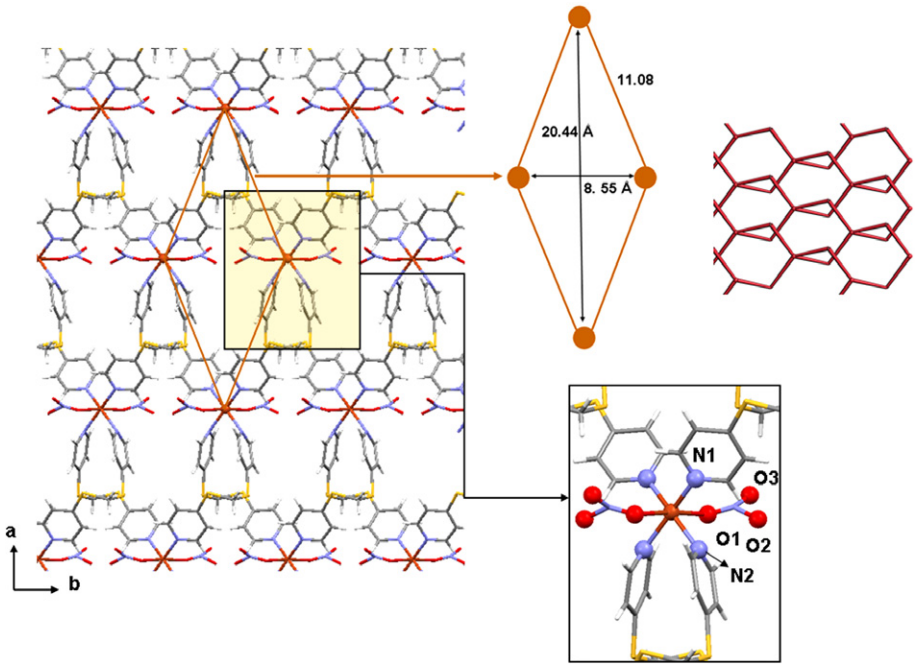

Fig. 3. View of the 2D coordination polymer $[Cu(NO_3)_2(4\text{-bpytm})_2] \cdot H_2O$ (**2** · **H_2O**) together with the coordination environment of copper ions, a topological representation of the layer and a metrical representation of the rhombic-grid showing the Cu···Cu distances.

The 2D layer in **2.Solv** presents a parquet motif with Cu···Cu distances through the bridging ligands of about 12 Å and diagonal Cu···Cu distances of 16.13 and 17.43 Å (Fig. 4).

In the 4-bpytm ligands the values for the C–S–C–S torsion angles of 73.3(6)/62.8(6)° in **2** · **H_2O** and 67.1(4)/63.3(4)° and 69.2(4)/67.3(4)° in **2** · **Solv** are lower than those found in **1** · **H_2O**, but all fall within the range 63.2–76.9° observed in the free 4-bpytm ligand and in the 2D polymeric complexes $[CuX_2(4\text{-bpytm})_2]$ (X = Cl, Br) [15]. However, all of these values are lower than 82.4°, which was recently observed in the 1D compound $[Cu(HCOO)_2(4\text{-bpytm})]$ [16]. An interesting point is that in both compounds each sheet incorporates molecules of the 4-bpytm with the same helicity, and then each sheet is homochiral and connects through weak interactions to sheets of opposite chirality to generate racemic supramolecular arrays.

Both compounds exhibit an AB stacking mode of the layers (Figs. 5 and 6) with a linkage by means of weak CH···O hydrogen bonds (Table 4) between layers of opposite chirality. The shorter Cu···Cu distances between adjacent layers are 9.61 Å in **2** · **H_2O** and 8.61 Å in **2** · **Solv**, with the latter value lower than all the intralayer Cu···Cu distances.

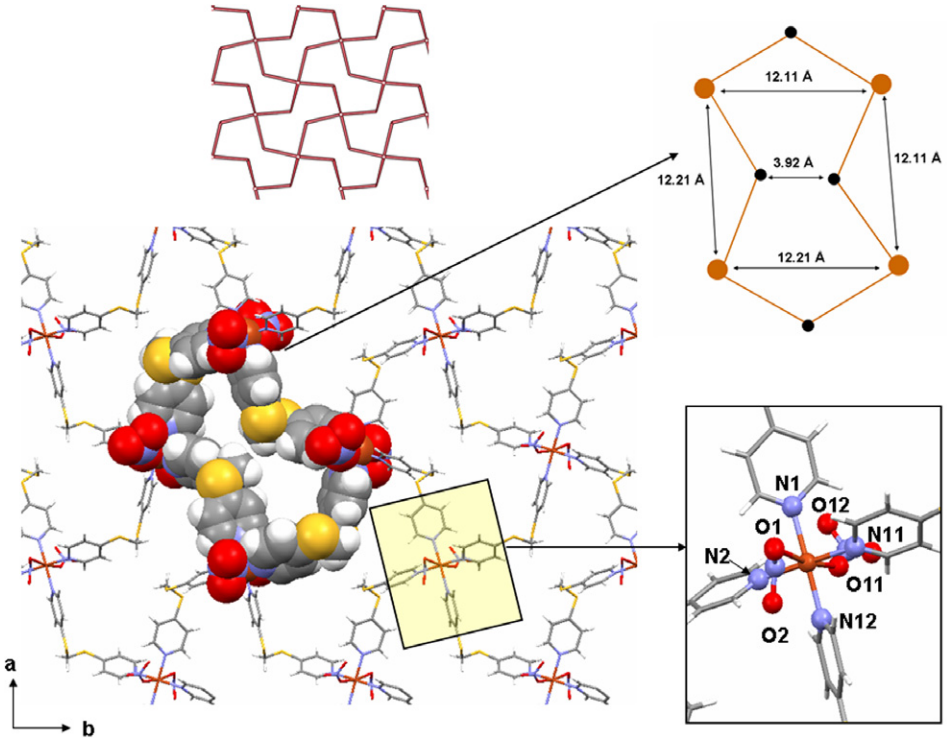

Fig. 4. View of the 2D coordination polymer $[Cu(NO_3)_2(4\text{-bpytm})_2]$ · Solv (**2** · **Solv**) together with the coordination environment of copper ions, a topological representation of the layer and a metrical representation (black circle represents the $-CH_2$ groups of the ligands) of the hole showed also as space filling representation.

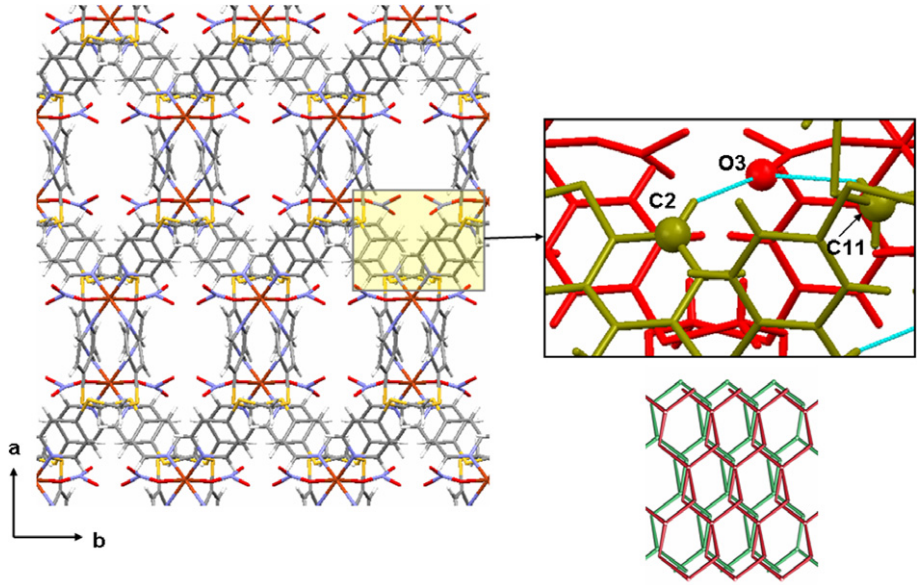

Fig. 5. View of the 3D supramolecular structure and 3D topological representation of **2** · $\mathbf{H_2O}$ showing detail of the CH···O linkage between sheets of opposite chirality.

Since the solvent component for both structures could not be successfully determined in the crystallographic calculations, the analysis of the supramolecular organization is based on the study of the weak interactions in the metal-organic framework. However, the analysis of the corresponding solvent areas showed marked differences between the two compounds. For **2** · $\mathbf{H_2O}$ the solvent area corresponds to a volume of 370.5 $Å^3$, which represents 12.8% of the unit cell, and corresponds to a total of 64 electrons per unit cell which is assigned to 6.4 molecules of water. In **2** · **Solv** the situation is clearly different with a solvent area volume of 1978 $Å^3$ (46.4% of the unit cell) and a total of 470 electrons per unit cell, assigned to two water, one dmf and two ethanol molecules. These differences are also evident in the corresponding values for the Kitaigorodskii packing index [33]: 64.7% for **2** · $\mathbf{H_2O}$ and 44% for **2** · **Solv**. This analysis suggests that the solvent mixture used (dmf + EtOH) under microwave irradiation plays a key role in the preparation and crystallization of **2** · **Solv**, meaning that it is not unreasonable to consider a template function of the solvent mixture.

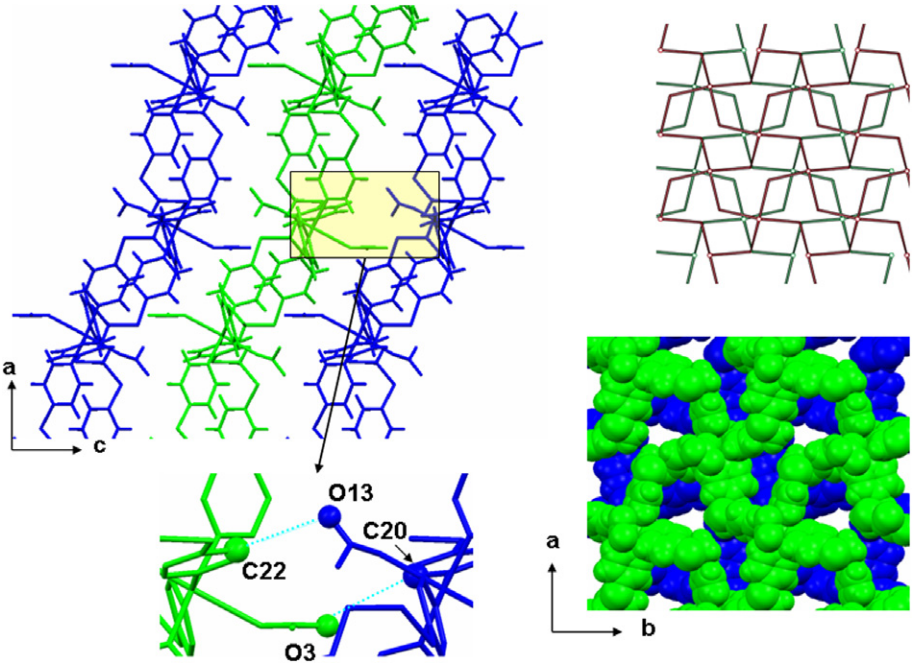

Fig. 6. View of the 3D supramolecular structure and 3D topological representation of **2** · **Solv** showing detail of the CH···O linkage between sheets of opposite chirality and a space filling representation.

4. Conclusions

The reaction of 4-bpytm with $CuSO_4 \cdot H_2O$ afforded a helical chain for **1** · **H_2O**. The reaction with $Cu(NO_3)_2 \cdot 3H_2O$ under different synthetic conditions afforded two 2D pseudo-polymorphs with different (4,4) topology: the rhombic-grid in **2** · **H_2O** and the parquet motif in **2** · **Solv**. The non-rigid 4-bpytm spacer is responsive to the nature of the anion, so that the anion effect seems to control the dimensionality and topology of the resulting coordination polymer. The microwave synthesis has proven to be very efficient for the preparation and crystallization of **2** · **Solv** and the mixture of solvents used seem to play a template role.

5. Supplementary data

CCDC 675465, 675466 and 675467 contains the supplementary crystallographic data for **1** · **H_2O**, **2** · **H_2O** and **2** · **Solv**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

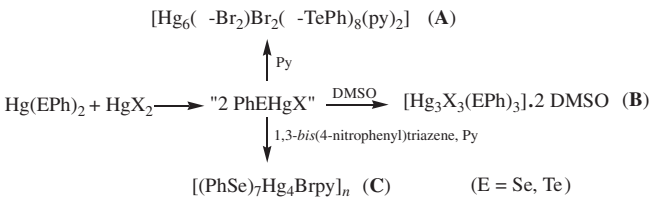

Scheme 1. Reactions attained from the intermediary PhTeHgX (X = halogenide).

and of the cluster $[(PhTe)_{16}Ag_4Hg_6Py_4] \cdot H_2O$ (**2**) are given in Table 1. The polymeric structure of **1** is represented in Fig. 1, and the high symmetric structure of **2** is shown in Fig. 2, for clarity, without the H_2O solvate molecule.

The asymmetric unit of **1** corresponds to its empirical formula, $[(PhTe)_4Ag_2Hg_2(Cl)_2]$. The association of the asymmetric units through "intermolecular" Ag–Te, Hg–Te, Hg–Cl, and Ag–Cl bonds leads to the assembly of polymeric, bidimensional and polycyclic layers in the *ab*-plane. The mean Hg–Cl bond distance within the monomeric unit is 2.66 Å, but this bond becomes noticeably longer (2.95 Å) for Hg and Cl atoms belonging to different units. The layers of the coordination polymer **1** stack in the *c*-plane at a distance of 9.6 Å from each other (distance between the closest Te atoms belonging to vicinal layers).

Cluster **2** stands in bold relief due to two main characteristics: first, its high symmetry; and second, the occupational disorder related to the Hg and Ag atoms [5,25]. A minor, but also interesting feature is the coordination of pyridine molecules to the terminal Hg atoms. The occupational relationship was set up in 40%/60%

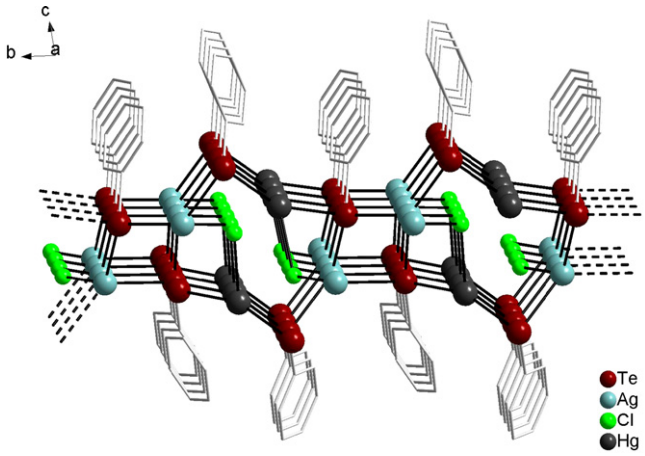

Fig. 1. Polymeric, bidimensional structure of $[(PhTe)_4Ag_2Hg_2(Cl)_2]_n$ (**1**).

for Ag and Hg, respectively. Occupational relationships define the rate of occupation of the same spatial position by two different atoms.

The occupational disorder of the metal ions in cluster **2** was calculated by restraints on the linear combinations of free variables [26],[1] which provide a way of restraining the sum of the occupancies of a multi-component disorder to be unity, also in order to fit the charge balances and chemical analysis of a mineral with several sites occupied by a mixture of cations. Occupation disorders, which occur with the ions with different charges (as in the case of compound **2**), have been reported also in high symmetric compounds, for example, supertetrahedral clusters [27].

The asymmetric unit of the cluster **2** represents 1/4 of the empirical formula. The other ¾ are generated by the symmetry operations $z + 3/4$, $-y + 1/4$, $-x + 3/4$; $-z + 3/4$, $-y + 1/4$, $x - 3/4$; $x + 3/2$, $y + 0$, $-z + 0$. The cluster is composed overall by 10 metal atoms (with an occupational relationship of 40%/60% for Ag and Hg, respectively), which are connected through PhTe groups attaining μ_2 bridges. The Te–metal bond distances are situated between 2.739(0) and 2.819(0) Å, which are the standard values for these compound types [5,24,25,28].

2.2. Synthetic considerations and inherent possibilities

In an early report, we have pointed out that the reaction of $[Hg(TePh)_2]$ and metal salts stabilized by different phosphine ligands and (coordinative) solvent molecules should lead to different redistribution reactions [24]. In the present case, these reactions would comprise the simultaneous formation of PhTeHgX, $[(TePh)_2HgX]^-$, and $(TePh)[M(L)_n]$ (M = Ag; L = PMe_2Ph, PPh_3, DMSO, pyridine; X = Cl^-) moieties [17,20,22].

The symmetric structures of the clusters $[Hg_6Ag_4(TePh)_{16}]$ and $[Hg_6Ag_4Te(TePh)_{14}]_n$ [24] obtained through the reaction of $[Hg(TePh)_2]$ with AgCl or $AgNO_3$ in the presence of $PMePh_2$, PPh_3, or DMF – arising actually from the correspondent adducts $[Ag(L)_n]X$ (X = Cl^-, NO_3^-; L = $PMePh_2$, PPh_3, DMF) – can also be attributed to the prevalence of some order of aggregation of the Ag^+ ions into the cluster frame, since this metal occupies very symmetrical equatorial positions, practically dividing the clusters into two halves. We think that this "entry selectivity" is highly dependent on the coordinative character of the counterion of the silver salt. Both ions Cl^- and NO_3^- have good coordinative characters, although Cl^- is somewhat better. In the presence of other ligands such as phosphines, or coordinative solvents such as DMF, DMSO

[1] The SHELX-97 Manual, p. 5-4.

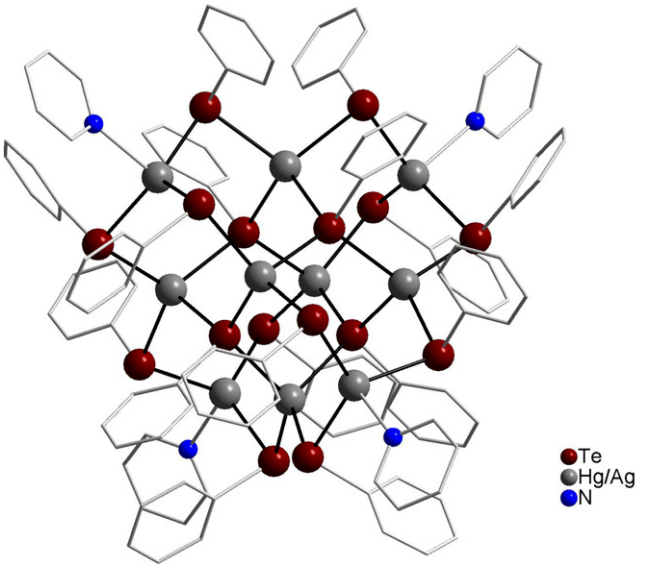

Fig. 2. Structure of $[(PhTe)_{16}Ag_4Hg_6Py_4] \cdot H_2O$ (**2**). For clarity the solvate molecule is not displayed.

or pyridine, an exchange should occur between the more or less coordinative counterion and solvent/ligand molecules. We believe that the lower the exchange velocities (for good coordinating counterions), the better the entry selectivity of the silver ions in the assembling process of the cluster.

One of the differences in the synthesis of clusters **1** and **2**, in the present work, is the use of different silver salts, AgCl (**1**) and $AgClO_4$ (**2**). It is known that the perchlorate anion is a very poor coordinative species, and when we assume that the entry selectivity of the silver ion into the skeleton of a cluster is proportional to the coordinative character of the counterion of the salt, this selectivity should increase in the series $ClO_4^- < NO_3^- < Cl^-$. This should mean that for the perchlorate salt the entry selectivity of the silver ion is practically null, and this can be related to the occupational disorder of the metal ions in the frame of cluster **2**: the – very probable – high velocity of formation of **2** allows inferring that the relatively "free" metal ions are also free to occupy any space in any point thermodynamically possible, during the cluster formation.

However, since the synthesis of **2** was carried out with the initial addition of an excess of triphenylphosphine to $AgClO_4$, our assumption that the failed coordinative character of the ClO_4^- ion would determine the low entry selectivity of the silver ions into the cluster could be a *nonsense*, because the Ag^+ species should be coordinated to the PPh_3 molecules (thus, with less freedom degrees). The evident autonomy of the silver ions in solution, together with the absence of triphenylphosphine in the cluster, leads us to consider the selective oxidation of the Lewis π-acid triphenylphosphine to triphenylphosphine oxide by the perchlorate anions.

3. Experimental

3.1. Synthesis of $[(PhTe)_4Ag_2Hg_2(Cl)_2]_n$ (**1**)

To a mixture of AgCl (0.036 g, 0.25 mmol) and dimethylphenylphosphine (0.070 g, 0.5 mmol) in 10 mL of dimethyl sulfoxide (DMSO), $Hg(TePh)_2$ (0.158 g, 0.26 mmol) was added. The solution was warmed up at 75 °C under stirring for 1 h, and then was kept still for one month at room temperature. Thereafter, yellow crystals were formed, and were washed with anhydrous ethanol. Yield: 56.3% based on $Hg(TePh)_2$.

Properties: yellow, tabular crystals. *Anal.* Calc. for $C_{24}H_{20}Ag_2Cl_2Hg_2Te_4$ (1506.62): C, 19.13; H, 1.32. Found: C, 19.2; H, 1.29%. Melting point: 165 °C.

3.2. Synthesis of $[(PhTe)_{16}Ag_4Hg_6Py_4] \cdot H_2O$ (**2**)

To a mixture of $AgClO_4$ (0.025 g, 0.125 mmol) and triphenylphosphine (0.066 g, 0.25 mmol) in 10 mL of CH_2Cl_2, $Hg(TePh)_2$ (0.182 g, 0.3 mmol) was added. After 1 h stirring at room temperature, 0.5 mL pyridine was added. In the solution which was kept still, after one week red crystals were formed. Yield: 71% based on $Hg(TePh)_2$.

Properties: red, cubic crystals. *Anal.* Calc. for $C_{116}H_{102}Ag_4Hg_6N_4OTe_{16}$ (5244.64): C, 26.58; H, 1.94; N, 1.04. Found: C, 26.3; H, 1.92; N, 0.09%. Melting point: 127.5 °C.

3.3. X-ray structure determinations

Data were collected with a Bruker APEX II CCD area-detector diffractometer and graphite-monochromatized Mo Kα radiation. The structures were solved by direct methods using SHELXS [26]. Subsequent Fourier-difference map analyses yielded the positions of the non-hydrogen atoms. Refinements were carried out with the SHELXL package [26]. All refinements were made by full-matrix least-squares on F^2 with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were included in the refinement in the calculated positions. Crystal data and more details of the data collections and refinements are given in Table 1.

4. Supplementary data

CCDC 685648 and 685649 contains the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

solvated 2 · CH_2Cl_2 (first fraction, 12 mg) and of $[Re(CO)_3(H_2O)_3][Re_5(CO)_{18}(Se_2)_3]$ (**1**) (second fraction, 30 mg). IR (ν (CO), CH_2Cl_2): 2108, 2098, 2055, 2035, 2012, 1967 cm^{-1} (**1**) and 2129, 2089, 2022, 1949, 1922 cm^{-1} (**2**).

2.2. X-ray crystallography

Slow evaporation of the respective solutions in dichloromethane yielded red-orange crystals of **1**, and a mixture of **2** and **2** · CH_2Cl_2, suitable for X-ray analysis. Crystallographic data and structure refinement details for the compounds are given in Table 1. All diffraction data were collected on a Bruker X8Apex CCD diffractometer with Mo Kα radiation (λ = 0.71073 Å) using φ and ω scans of narrow (0.5°) frames. All structures were solved by direct methods and refined by full-matrix least-squares method against $|F|^2$ in anisotropic approximation using SHELXTL programs set [12]. Absorption corrections were applied empirically using SADABS program [13]. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

Hydrogen selenide H_2Se (pK_{a1} = 3.89; pK_{a2} = 11.0 at 25 °C) is a very reactive compound used for dosage of semiconductors with Se and in the synthesis of organoselenium compounds, which is, however, usually avoided by the synthetic inorganic chemists because of its well-known disadvantages including the nasty smell, a high toxicity (exposure limit 0.3 ppm over an 8 h period) and low stability [14]. The dosage of H_2Se in an open-flow system is difficult. To avoid the use of free H_2Se in an open system, we used in situ generated H_2Se, which is quantitatively generated from ZnSe powder with 4 M HCl. As the reaction of ZnSe with HCl of this concentration takes place only at high temperature, a mixture of a reagent, ZnSe and 4 M HCl can be safely placed in a glass tube at room temperature. The tube is then evacuated and sealed, and exactly known amount of H_2Se is then released upon heating. In this way the problem of dosage and disposal of unreacted H_2Se is circumvented [15]. The reaction gives two products, a pentanuclear complex $[Re(CO)_3(H_2O)_3][Re_5(CO)_{18}(Se_2)_3]$ (**1**) (Fig. 1) and a tetranuclear complex $[Re_4(CO)_{14}(Se_2)(Se_5)]$ (**2**) (Fig. 2), which are structurally related. Increasing the Re/Se ratio from 2/3 to 1/3 does

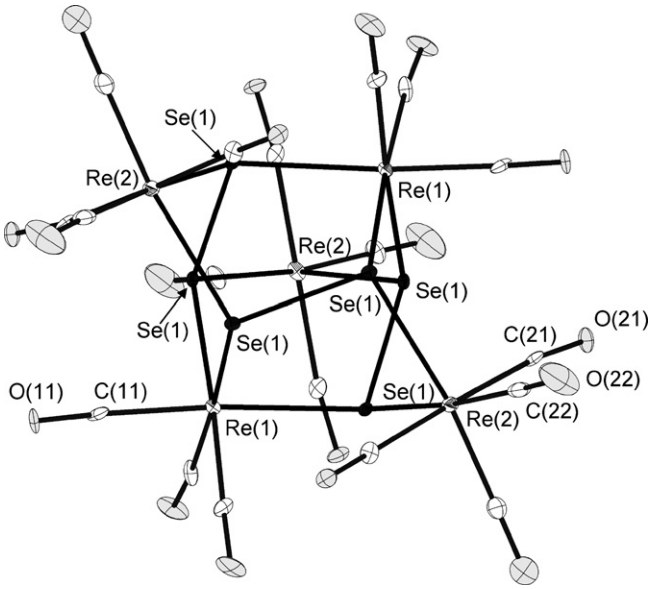

Fig. 1. The anion $[Re_5(Se_2)_3(CO)_{18}]^-$ in crystal structure of **1**, a.d.p. ellipsoids (50% probability). The distances (Å) in Re/Se core are (at 90 K): Re(1)–Se(1) 2.5842(14), Re(2)–Se(1) 2.6206(14), Se(1)–Se(1) 2.430(3).

not influence the yields in this reaction and does not lead to new products.

The first step in the formation of both **1** and **2** is probably substitution of water ligands in $[Re(CO)_3(H_2O)_3]^+$ with H_2Se, followed by deprotonation of coordinated H_2Se to give transient $[Re(CO)_3(SeH)_3]^{2-}$ species. Taking into account that Se^{2-} is strongly reducing even toward protons (E^0 for the Se/H_2Se couple is –0.399 V) [27], it is not difficult to explain oxidative dimerization of two such species into the $[Re_2(CO)_6(Se_2)_3]^{4-}$ central unit, which then acts as centre of coordination for three *cis*-$\{Re(CO)_4\}^+$ groups to give **1**. A deviation from this route gives **2** by incorporation of liberated Se between two of the three Se_2 bridges. Fig. 3 illustrates this putative reaction route. Reaction of $Re_2(CO)_{10}$ with K_2Se_3 was reported to yield a binuclear tetraselenide complex, $[Re_2(CO)_6(Se_4)_2]^{2-}$, where each bridging Se_4^{2-} ligand is chelating bidentate toward one Re and monodentate to the other [28].

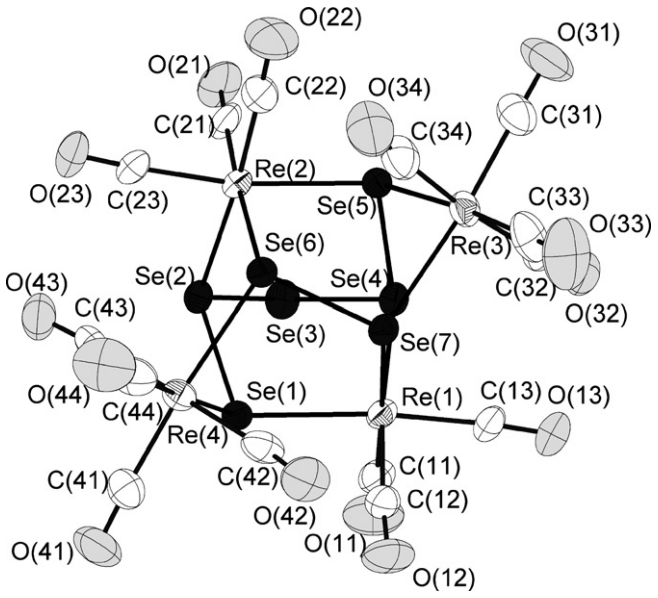

Fig. 2. Molecular fragment $[Re_4(Se_5)(Se_2)(CO)_{14}]$ in crystal structure of **2** · CH_2Cl_2, a.d.p. ellipsoids (50% probability). The numeration scheme is the same in **2** and **2** · CH_2Cl_2. The distances (Å) in Re/Se core are listed for **2** · CH_2Cl_2 (at 100 K): Re(1)–Se(4) 2.5360(6), Re(1)–Se(1) 2.5701(7), Re(1)–Se(7) 2.5888(6), Re(2)–Se(2) 2.5566(7), Re(2)–Se(5) 2.5734(7), Re(2)–Se(6) 2.5863(7), Re(3)–Se(5) 2.6085(6), Re(3)–Se(7) 2.6183(7), Re(4)–Se(6) 2.6002(8), Re(4)–Se(1) 2.6130(7), Se(3)–Se(4) 2.3332(8) Se(3)–Se(2) 2.3463(8) Se(6)–Se(7) 2.4125(8) Se(2)–Se(1) 2.4388(9) Se(5)–Se(4) 2.4430(8).

The structure of **1** contains the well-known *fac*-$[Re(CO)_3(H_2O)_3]^+$ cations [16] (disordered over two positions) and unusual pentanuclear anions $[Re_5(CO)_{18}(Se_2)_3]^-$ (Fig. 1), which can be represented as a distorted trigonal bipyramid of five Re atoms as *fac*-$\{Re(CO)_3\}^+$ and $\{cis$–$Re(CO)_4\}^+$ groups, connected together by three μ_4-Se_2^{2-} bridges (Re(CO)$_3$–Se 2.584 Å, Re(CO)$_4$–Se 2.621 Å, Se–Se 2.430 Å). In $[Cp^*Re(Se_3)(\mu\text{-}Se_2)]_8$ the Se–Se distance in the Re–Se–Se–Re unit is shorter, 2.36–2.38 Å. The difference may reflect the increasing population of the π^*–Se_2 orbital through increasing back donation in the case of the μ_4-Se_2^{2-} binding mode. The 18-electrons rule is satisfied at each Re atom without involving metal-metal bonding, and Re···Re distance are large, about 6 Å between the equatorial atoms, and 4 Å between polar and equatorial Re atoms. The structure of the other product, tetranuclear complex **2** is very similar (the geometrical parameters of the complex in the unsolvated crystal (**2**) and in the solvate (**2** · CH_2Cl_2) is virtually identical), except that one of the $\{Re(CO)_4\}$ groups is replaced with a Se^{2+} so that a pentaselenide Se_5^{2-} ligand results (Fig. 2). In this ligand the two peripheral Se–Se bonds are much longer than the two central ones (2.41, 2.44 Å vs. 2.33, 2.34 Å). While this situation is typical for the coordinated Se_5^{2-} ligand (as, for example, in $[V_2Se_{13}]^{2-}$ [17]), in free Se_5^{2-} the reverse is true: the two central Se–Se bonds are longer than the two peripheral ones [18–20]. This is the first example of a Se_5^{2-} ligand bridging four metal centers.

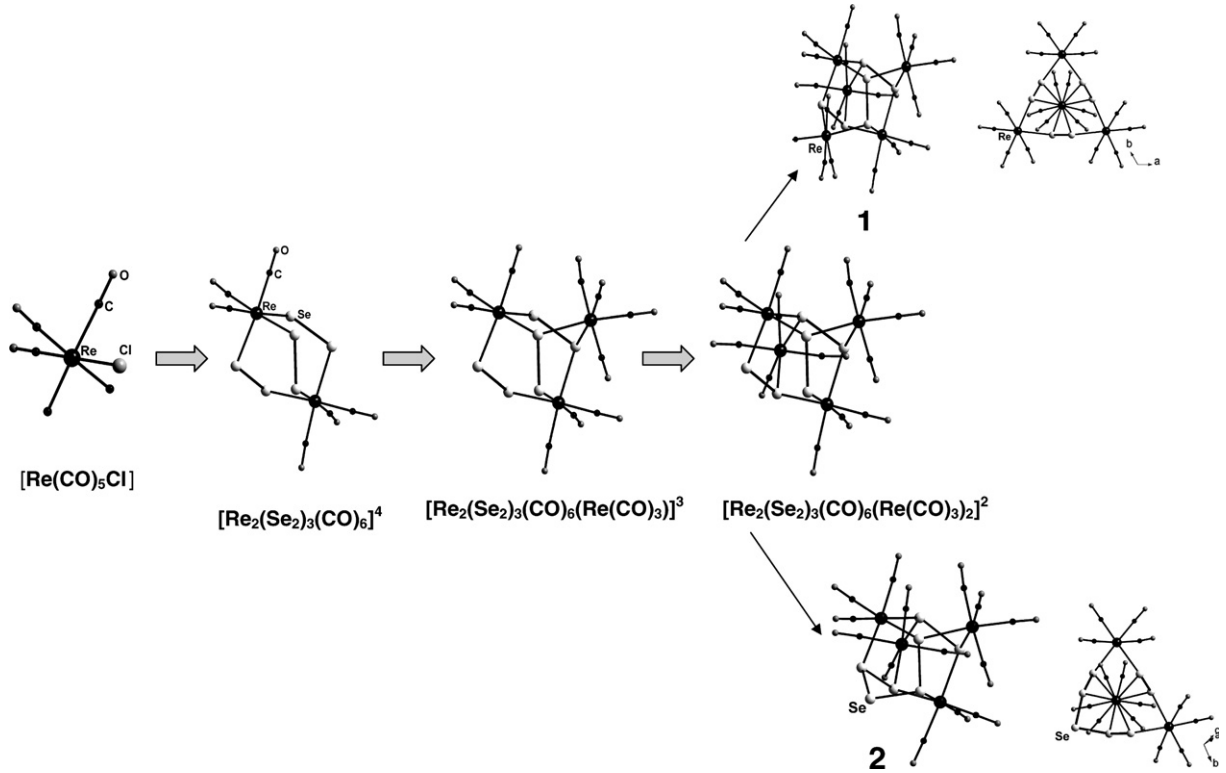

Fig. 3. Tentative scheme fro the formation of $[Re_5(Se_2)_3(CO)_{18}]^-$.

Bridging of three metal atoms is achieved in $[Cu_4Se_{13}]^{2-}$ [20,21]. A similar way of coordination is found, however, for S_5^{2-} in the copper clusters $[Cu_4(\mu_4\text{-}S_5)_2(L)_4]$ (L = Py, 4-Mepy) [22,23]. The Se–Se distance in the diselenide ligand in **2** is also long, 2.41 Å. It is remarkable that the Re and Se framework of **1** and **2**, taken as whole, has exactly the same geometry and connectivity as Zintl anions E_{11}^{3-} (E = As, Sb) which can be explained by taking into account equal number of the cluster skeletal electrons (30) in these species (electronic contributions are zero for $\{Re(CO)_3\}^+$, two for both $\{Re(CO)_4\}^+$ and Se^{2+}, four for E^- and E_2 units in the Zintl anion, and six for Se_2^{2-} [24,25]. Cluster $[Cp_2Ni_2Mn_2(CO)_6(\mu_4\text{-}S_2)(\mu_4\text{-}S_5)]$ has similar structure because the $\{Re(CO)_4\}$ and $\{CpNi\}$ groups contribute the same number of electrons [26].

Thus, a new method of self-assembly of polynuclear selenides based on reaction with in situ generated H_2Se has been introduced. Testing its applicability to other metal carbonyls is under way.

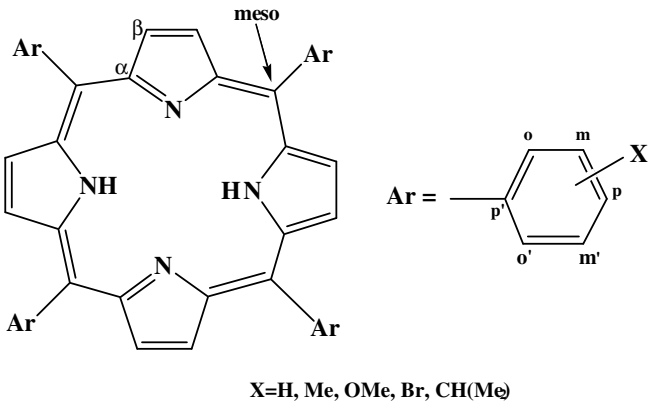

Fig. 1. *Meso*-tetraarylporphyrins, H_2tap.

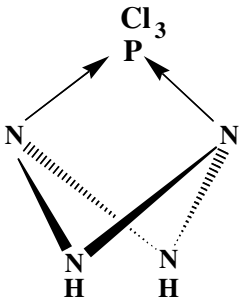

Fig. 2. Only the nitrogens of the distorted porphyrin core are shown.

2.2. Physical measurements

The NMR spectra (^{1}H, ^{13}C) were recorded on a Bruker 400 Ultrashield spectrometer in $CDCl_3$. The ^{31}P NMR spectra were recorded on a Bruker 250 Ultrashield spectrometer in $CDCl_3$ with H_3PO_4 as the reference. The residual $CHCl_3$ in the conventional 99.8% atom $CDCl_3$ gives a signal at δ = 7.26 ppm, which was used for calibration of the chemical shift scale. The UV–Vis measurements were obtained with a GBC cintra 6 UV–Vis spectrophotometer. FT-IR spectra were recorded on a Magna 550 Nicolet spectrometer using KBr pellets. The molar conductance of the complexes and the diprotonated species were measured on a METROHM 644 conductometer.

2.3. Preparation of the i-SAT complexes

To H_2tap (1 mmol) in a mortar, PCl_3 (1 mmol) was added with grinding at ambient temperature for 20 min, without addition of any solvent until complexation was completed. The porphyrins were completely converted to the i-SAT complexes. The completion of the reactions was determined by UV–Vis and ^{1}H NMR spectroscopies. The 1:1 mixture of the porphyrins with PCl_3 did not show the absorption bands or ^{1}H NMR signals due to the free base porphyrins. The results of elemental analysis for the i-SAT complexes are presented in Table 1.

Table 1
The results of elemental analyses for the i-SAT complexes

i-SAT complexes	Found (calculated)		
	%C	%H	%N
[PCl_3(H_2tpp)]	69.9 (70.3)	3.8 (3.4)	7.4 (7.4)
[PCl_3(H_2t(4-OMep)p)]	65.7 (66.1)	4.3 (4.4)	6.4 (6.4)
[PCl_3(H_2t(4-Mep)p)]	71.0 (71.4)	4.5 (4.7)	6.9 (6.9)
[PCl_3(H_2t(4-Brp)p)]	61.2 (61.5)	2.8 (3.0)	6.3 (6.5)
[PCl_3(H_2t(4-CH(Me)$_2$p)p)]	72.6 (73.1)	5.6 (5.9)	5.9 (6.1)
[PCl_3(H_2t(3-OMep)p)]	65.8 (66.1)	4.1 (4.4)	6.3 (6.4)
[PCl_3(H_2t(3-Mep)p)]	70.9 (71.3)	4.5 (4.7)	6.7 (6.9)
[PCl_3(H_2t(3-Brp)p)]	61.1 (61.5)	2.8 (3.0)	6.4 (6.5)

3. Results and discussion

The SAT complexation was followed by monitoring the changes in the ^{1}H NMR and UV–Vis spectra. These changes are due to adduct formation between different equivalents (0.25, 0.5, 0.75, 1.0, 1.5 and 2.0) of PCl_3 and H_2tpp until a 1:1 (PCl_3:H_2tpp) molar ratio, where addition of an excess amount of PCl_3 caused no changes in the spectra of the [PCl_3(H_2tpp)] complex. Consequently the reactants have a 1:1 molar ratio in the i-SAT complexes. This subject also was confirmed by elemental analysis.

In the free base H_2tap, the N–H protons are upfield (−2.74 to −2.82 ppm, singlet) and the β-protons appear in the range of 8.85–8.90 ppm (singlet) (Table 2). The i-SAT complexation of *meso*-tetraarylporphyrins with PCl_3, similar to the molecular complexation of the porphyrins with various acceptors, caused downfield shifts for the proton signals of N−H and the aryl rings, and an upfield shift of the β-hydrogens [16–23]. These observations indicate that binding of phosphorus(III) to the pyrrolenine nitrogen atoms distorts the porphyrin ring and as a result the ring current is lost in the i-SAT complexes. Distortion of the porphyrin ring leads to an extension of the aryl π-system whereupon there are downfield shifts of the proton signals of the aryl rings. The presence of a singlet signal for the β-protons in the ^{1}H NMR spectra of the complexes do not corresponded the unsymmetrical pyrrole rings in the proposed structure. This shows that ring inversion of the tilted core conformation of the porphyrin is probably fast on the NMR timescale [16,17,23]. The results of the ^{1}H NMR spectral data for NH and H_β of the *meso*-tetraarylporphyrins and the complexes are listed in Table 2.

In the ^{13}C NMR spectrum of H_2tpp six sharp signals for the porphine core and aryl rings are observed (120.5 (C_{meso}), 127.1 ($C_{m,m'}$), 128.1 (C_p), 131.5 (C_β), 135.0 ($C_{o,o'}$), *142.6* ($C_{p'}$) ppm), along with very broad signal (145 ppm) for the α-carbon [20,21]. The i-SAT complexation of H_2tpp with PCl_3 leads to changes in the ^{13}C NMR spectrum of the porphyrin. After complexation peaks were revealed at 122.6 (C_{meso}), 128.0 (C_β), 128.4 ($C_{m,m'}$), 130.0 (C_p), 139.0 ($C_{o,o'}$), *139.9* ($C_{p'}$) and 146.0 (C_α) ppm. The observed changes upon the i-SAT complexation of the *meso*-tetraarylporphyrins with PCl_3 are very similar to the molecular complexation of the porphyrins with different acceptors [16,17,20,21].

The UV–Vis spectrum of H_2tpp has absorption bands at 416.7(S), 516.8, 551.5, 592.0, 648.0 nm, whereas the related complex with PCl_3 shows two new absorption bands at 444.5 (soret) and 660.0 nm. Upon addition of PCl_3 to the free base H_2tpp, the UV–Vis spectrum of the porphyrin is 12–28 nm red shifted. This is interpreted as evidence for the increased resonance interaction of the aryl rings with the porphyrin nucleus in going from the free base to the i-SAT complex, which would be allowed by the deformation of the pyrroles [16,17]. The results of UV–Vis spectra for the other complexes are shown in Table 3.

UV–Vis, ^{1}H NMR and ^{13}C NMR correspondences between spectral data of the molecular complexes of σ- or π-acceptors with *meso*-tetraarylporphyrins and [PCl_3(H_2tap)] complexes suggest similar structures for the porphyrin core in all of the species [16–23]. In this conformation the lone pairs of two pyrrolenine nitrogens act as electron donors to the phosphorus atom of PCl_3, and so two hydrogen atoms of the pyrrole groups (N–H) still remain on the macrocycle (Fig. 2).

The UV–Vis and ^{1}H NMR spectral data of the complexation of substituted *meso*-tetraarylporphyrins with PCl_3 (Tables 2 and 3) showed that the π-resonance is greater than σ-induction effects,

[a] $\Delta\lambda$: red shifts for the bands of the porphyrins upon i-SAT complexation.

and so the trend in electron donating ability for the substituted *meso*-tetraarylporphyrins is *para* > *meta*. This trend corresponds to lower steric hindrance from the *meta* substituents compared to the *para* substituents. On the other hand, halogens are σ-electron withdrawing and π-donor groups. With these substituents the π-effect is more efficacious than the σ-effect. Further, the 4-isopropyl group is a greater electron donor than the 4-methyl group.

The ^{31}P NMR spectra were used to confirm the coordination of phosphorus(III) chloride to the porphyrins. The proton-decoupled ^{31}P NMR spectra (85% H_3PO_4 external reference) gave signals at 220 ppm and 5.5 ppm for PCl_3 and the [PCl_3(H_2t(4-Mep)p)] complex, respectively. The produced upfield shift upon the i-SAT complexation of PCl_3 with H_2t(4-Mep)p demonstrates the proposed structure for the new complex (a five-coordination number for the phosphorus atom), (Fig. 2).

The FT-IR spectrum of the free base (H_2tap) shows an N–H stretching band at 3320 cm^{-1} [24], that upon i-SAT complexation with PCl_3 does not shift considerably. This indicates that two protons remain on the complexed porphyrins and this completely corresponds to the proposed structure, (Fig. 2).

The UV–Vis and (^{1}H, ^{13}C) NMR spectra of the i-SAT complexes of *meso*-tetraarylporphyrins with PCl_3 are similar to those of the related porphyrin diprotonated species [16,17,25–27]. However, the molar conductivity results for the i-SAT complexes and those diprotonated species were completely different. For example, the molar conductance of [PCl_3(H_2tpp)] (in acetone) shows that the complex is not an electrolyte, whereas the molar conductance of [H_4tpp]Cl_2 is in accord with a 1:2 electrolyte (Λ (in methanol) = 213.3 Ω^{-1} cm^2 mol^{-1}) [28]. The remarkable spectral correspondence between the i-SAT complexes and the diprotonated species thus suggest only an analogous tilted porphyrin core structure in these species.

4. Conclusion

An investigation of the sitting-atop complexation between *meso*-tetraarylporphyrins and phosphorus(III) chloride has been carried out in this study. Using phosphorus(III) chloride and free solvent conditions has led to the formation of i-SAT complexes, $[PCl_3(H_2tap)]$. Two pyrrolic protons of the porphyrins prohibit the phosphorus atom from going into the centre of the porphyrin plane and in result it resides above the ring plane.

as well as in their conformations. It is important to note that in 'unit A' V(V) is hexa-coordinated, while in 'unit B' it is penta-coordinated. Again, when HL_2 reacts with $Cu(ClO_4)_2 \cdot 6H_2O$ in 1:1 molar ratio, complex $[Cu(L_2)ClO_4]$ (**3**) is formed. All attempts to prepare X-ray quality crystals produced micro crystals which were not suitable for X-ray diffraction. The elemental analyses and spectral data fit with the composition $[Cu(L_2)ClO_4]$ (**3**). Upon reaction with $VO(acac)_2$ in 1:1 molar ratio HL_2 produced the hexa-coordinated V(V) $[VO(L_2)(OCH_3)(CH_3OH)]$ (**4**) complex.

2. Experimental

2.1. Materials

All chemicals were of reagent grade, purchased from commercial sources and used without further purification. Tetraethyl ammonium perchlorate (TEAP) used for electrochemical work was prepared as reported in the literature [23]. Salicylaldehyde was purchased from Aldrich Chemical Company, USA and used without further purification.

Caution! Although we have not encountered any problem, it should be kept in mind that perchlorate compounds of metal ions are potentially explosive especially in the presence of organic ligands. Only a small amount of the material should be prepared and it should be handled with care.

2.2. Physical measurement

Elemental analyses (carbon, hydrogen and nitrogen) of the ligand and the metal complexes were determined with a Perkin–Elmer CHN analyzer 2400 at the Indian Association for the Cultivation of Science, Kolkata. The molar conductance values of the complexes were measured in purified CH_3OH with a Systronic model 304 digital conductivity meter. The electronic spectra of the complexes in methanolic solution were recorded on a Hitachi model U-3501 spectrophotometer. IR spectra (KBr pellet, 400–4000 cm^{-1}) were recorded on a Perkin–Elmer model 883 infrared spectrophotometer. ^1H NMR spectra of the ligands were recorded in $CDCl_3$ with a Bruker AM 300L (300 MHz) superconducting FTNMR. Cyclic voltammetry was carried out with a Sycopel model AEW2 1820F/L instrument. The measurements were carried out at 293 K in CH_3OH solution containing 0.2 M TEAP as supporting electrolyte and 10^{-3}–10^{-4} M solution of the respective complexes deoxygenated by bubbling with nitrogen. The working, counter and reference electrodes used were a Pt wire, platinum coil and an SCE, respectively.

2.3. Synthesis of ligands

Ethyl-5-methyl-1-(2-pyridyl)pyrazole-3-carboxylate was prepared following a literature method [24]. Methyl-5-methyl-1-(4,6-dimethyl-2-pyrimidyl)pyrazole-3-carboxylate has been synthesized by passing dry HCl gas into the solution of 5-methyl-1-(4,6-dimethyl-2-pyrimidyl)pyrazole-3-carboxylic acid [25] in dry methanol following the usual procedure. The corresponding carbohydrazides were prepared by the reaction between hydrazine hydrate and the respective ester in methanol taken in a 1:1 molar ratio. Salicylaldehyde was condensed with the synthesised carbohydrazides taken in 1:1 molar ratio (Scheme 1). Details are described below.

The two ligands HL_1 and HL_2 were synthesized in a similar way by refluxing a methanolic solution (30 cm^3) of ethyl-5-methyl-1-(2-pyridyl)pyrazole-3-carbohydrazide (2.17 g, 10 mmol) and methyl-5-methyl-1-(4,6-dimethyl-2-pyrimidyl)pyrazole-3-carbohydrazide (2.46 g, 10 mmol), respectively, with salicylaldehyde (1.22 g, 10 mmol), also taken in methanol (10 cm^3). Reflux was continued for ca. 30 min at water bath temperature. After slow evaporation of the respective reaction mixture a solid microcrystalline compound separated. It was filtered off, washed several times with cold methanol and dried in vacuo over fused $CaCl_2$.

Single crystals of HL_1 and HL_2, suitable for X-ray diffraction were obtained by slow evaporation of the respective methanolic solution of the ligands.

HL_1: Yield: 2.71 g (80%); M.p. (°C) 140; *m*/*z* 321 (M^+, 100%); *Anal.* Calc. for $C_{17}H_{15}N_5O_2$: C, 63.50; H, 4.67; N, 21.80. (s, 1H, ring pym-H), 8.69 (s, 1H, –CH=N–), 12.15 (s, 1H, aromatic-OH). IR (KBr, cm^{-1}): 1606 (pym $\nu_{C=N}$), 1460 (pz $\nu_{C=N}$), 3175 (ν_{OH}), 1650 ($\nu_{C=O}$), 1546 ($\nu_{C=C}$).

2.4. Preparation of the complexes

2.4.1. Preparation of complex **1**

To a solution of HL_1 (0.321 g, 1 mmol) in methanol (10 cm^3), $Cu(ClO_4)_2 \cdot 6H_2O$ (0.371 g, 1 mmol) taken in the same solvent was added dropwise with constant stirring. Immediately, the solution turned deep green and stirring was continued for ca. 15 min. A green coloured compound separated out from the reaction mixture. This was filtered under suction, washed with methanol and dried over fused $CaCl_2$. X-ray quality crystals were obtained by slow evaporation of acetonitrile solution of the complex. Yield, 0.484 g (70%). *Anal.* Calc. for $C_{19}H_{17}N_6O_6ClCu$: C, 43.48; H, 3.24; N, 16.02. Found: C, 43.50; H, 3.19; N, 16.01%. IR (KBr, cm^{-1}): 1567 (py $\nu_{C=N}$), 1465 (pz $\nu_{C=N}$), 1660 ($\nu_{C=O}$), 1540 ($\nu_{C=C}$), 1092 ($\nu_{ClO_4^-\ coordinated}$). UV–Vis ($CH_3OH$): $\lambda_{max/nm}$: 406, 669. λM (MeOH, $ohm^{-1}\ cm^2\ mol^{-1}$): 22. μ_{eff} (at 298 K): 1.70 B.M.

2.4.2. Preparation of complex **2**

To a solution of HL_1 (0.321 g, 1 mmol) in methanol (10 cm^3), $VO(acac)_2$ (0.265 g, 1 mmol) taken in the same solvent was added with continuous stirring. The resulting colour of the solution was violet and stirring was continued for ca. 1 h. The solution was filtered and the filtrate was kept for slow evaporation. After two days, X-ray quality crystals of the complex were separated and they are collected by usual technique. Yield: 0.381 g (65%). *Anal.* Calc. for $C_{37}H_{36}N_{10}O_9V_2$: C, 51.23; H, 4.15; N, 16.15. Found: C, 51.15; H, 4.01; N, 16.12%. IR (KBr, cm^{-1}): 1560 (py $\nu_{C=N}$), 1463 (pz $\nu_{C=N}$), 970 ($\nu_{V=O}$). UV–Vis (CH_3OH): $\lambda_{max/nm}$: 398. λM (MeOH, $ohm^{-1}\ cm^2\ mol^{-1}$): 20. μ_{eff} (at 298 K): 0 B.M.

2.4.3. Preparation of complex **3**

A methanolic solution of (5 cm^3) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.371 g, 1 mmol) was added dropwise to a solution of HL_2 (0.350 g, 1 mmol) in the same solvent (10 cm^3) with constant stirring. The solution became deep green and it was filtered and the filtrate was kept for slow evaporation. After a few days a green microcrystalline compound was isolated. All attempts to prepare X-ray quality crystals were futile. Yield: 0.484 g (70%). *Anal.* Calc. for $C_{18}H_{17}N_6O_6ClCu$: C, 42.10; H, 3.50; N, 16.37. Found: C, 42.15; H, 3.58; N, 16.35%. IR (KBr, cm^{-1}): 1611 (pym $\nu_{C=N}$), 1535 (pz $\nu_{C=N}$), 1650 ($\nu_{C=O}$), 1095 ($\nu_{ClO_4^-\ coordinated}$). UV–Vis ($CH_3OH$): $\lambda_{max/nm}$: 398. λM (MeOH, $ohm^{-1}\ cm^2\ mol^{-1}$): 25. μ_{eff} (at 298 K): 1.72 B.M.

2.4.4. Preparation of complex **4**

To a solution of HL_2 (0.350 g, 1 mmol) in methanol (10 cm^3), $VO(acac)_2$ (0.265 g, 1 mmol) taken in the same solvent was added with stirring. A deep violet solution was obtained and stirring was continued for ca. 1 h. The solution was filtered and kept for slow evaporation. After a few days, crystals suitable for X-ray diffraction were obtained. Yield: 0.461 g (75%). *Anal.* Calc. for $C_{20}H_{23}N_6O_5V$: C, 50.17; H, 4.81; N, 17.56. Found: C, 50.10; H, 4.75; N, 17.58%. IR (KBr, cm^{-1}): 1610 (pym $\nu_{C=N}$), 1547 (pz $\nu_{C=N}$), 970 ($\nu_{V=O}$). UV–Vis (CH_3OH): $\lambda_{max/nm}$: 399. λM (MeOH, $ohm^{-1}\ cm^2\ mol^{-1}$): 21. μ_{eff} (at 298 K): 0 B.M.

2.5. Single crystal X-ray crystallography

Crystal data of HL_1, HL_2, **1**, **2** and **4** have been deposited in CCDC. Selected crystal data for HL_1, HL_2, **1**, **2** and **4** are given in Table 1 and selected metrical parameters of these complexes are given in Table 2. Oxford Diffraction Gemini (for HL_1, **1** and **2**) and CCD area detector (for HL_2, **4**) equipped with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) source in φ and ω scan mode were

used for data collection. Cell parameters refinement and data reduction were carried out using the CRYSALIS RED, Oxford Diffraction Ltd., [Version 1.171.32.5 (release 08-05-2007 CRYSALIS171 .NET) and Version 1.171.31.8 (release 12-01-2007 CrysAlis171.NET)] [26a] for HL_1, **1** and **2**, respectively. Bruker SMART [26b] and Bruker SAINT softwares [27] were used for cell parameters refinement and data reduction of HL_2 and complex **4**. All the structures were solved by conventional direct methods and refined by full-matrix least square methods using F^2 data. SHELXS-97 and SHELXL-97 programs [28] were used for structure solution and refinement, respectively. Positions of H-atoms were treated as riding on their parent atoms.

3. Results and discussion

3.1. Syntheses

Two new ligands HL_1 and HL_2 were synthesized by the 1:1 condensation reaction of Salicylaldehyde with ethyl-5-methyl-1-(2-pyridyl)pyrazole-3-carbohydrazide/methyl-5-methyl-1-(4,6-dimethyl-2-pyrimidyl)pyrazole-3-carbohydrazide in methanol, respectively. The complexation behaviour of these ligands towards Cu(II) and V(V) were investigated. All the complexes (**1**–**4**) of these ligands were obtained from a refluxing mixture of the respective ligand and the appropriate metal salts, taken in a 1:1 molar proportion in methanol. X-ray quality crystals of these complexes (**1**, **2** and **4**) were obtained upon slow evaporation of the respective reaction mixture at room temperature. The ligands were characterized primarily by X-ray crystallography along with the elemental analyses, IR and ^{1}H NMR spectroscopy. The metal complexes were characterized by elemental analyses, solution electrical conductivity, magnetic susceptibility, IR, UV–Vis spectroscopy. X-ray crystallographic studies are made for **1**, **2** and **4**. The results are consistent with the proposed mononuclear formulations. The complexes were found to be fairly soluble in most common organic solvents. Molar conductivity values of the complexes are in accord with non-electrolytic behaviour of the complex species.

3.2. Description of crystal structure

3.2.1. Structural descriptions of HL_1 and HL_2

Perspective view of the asymmetric units of the ligands HL_1, HL_2 and the complexes **1**, **2** and **4** with the atom numbering schemes are shown in Figs. 1–5, respectively. Selected metrical parameters are listed in Table 2. The ligands HL_1 and HL_2 crystallize with the space groups $I4_1/a$ and $P2_1/c$, respectively. In the molecular structure, pyridyl/pyrimidyl–pyrazole and salicylaldehyde moieties adopt a trans orientation to each other leaving the O2 and O1 atoms in cis position. In the free ligand moiety HL_1, pyridine nitrogen (N5) and pyrazole nitrogen (N3) are trans to each other. During chelation, they rearrange to cis fashion in complex **1**. In HL_1 the dihedral angle between pyridine and pyrazole plane is 4.93°, whereas in HL_2 that between pyrimidine and pyrazole plane is 4.60° showing that the pyridyl–pyrazole part in HL_1 and pyrimidyl–pyrazole part in HL_2 are almost planar. The planarity is almost retained after complexation in the 'unit B' of complex **2** (dihedral angle 10.16°) and in complex **4** (dihedral angle 10.75°). However, in the 'unit A' of complex **2** a marked deviation from planarity (dihedral angle 33.56°) in the same portion of the ligand is noted.

Both HL_1 and HL_2 are stabilized through a network of weak H-bond interactions (Figs. 6 and 7, respectively). Relevant H-bond parameters are listed in Table 3.

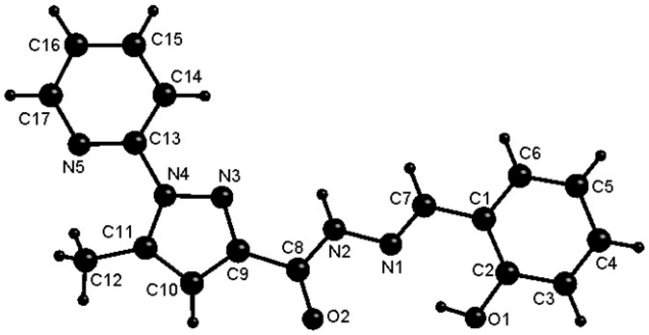

Fig. 1. Structural representation with atom numbering scheme of HL_1.

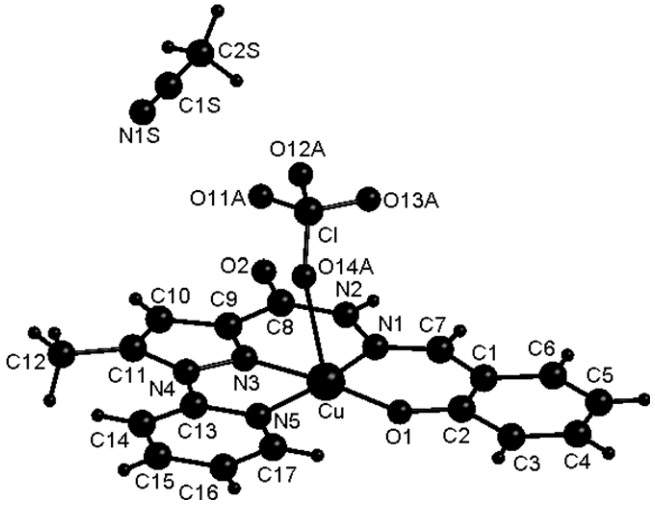

Fig. 3. Structural representation with atom numbering scheme of **1**.

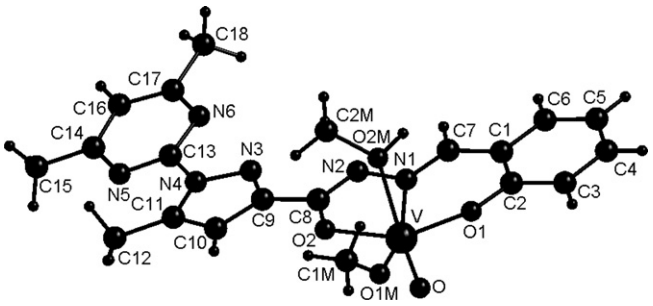

Fig. 5. Structural representation with atom numbering scheme of **4**.

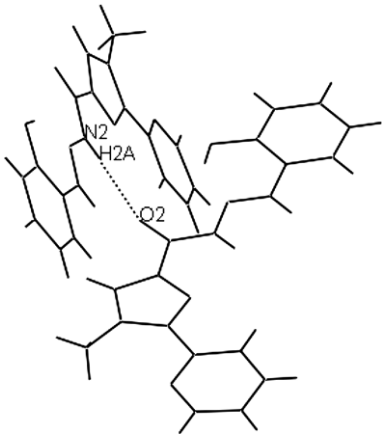

Fig. 6. H-bonding in HL_1.

3.2.2. Structural description of ***1***

Complex **1** crystallizes in space group $P\bar{1}$. The coordination geometry around Cu(II) atom is slightly distorted square pyramidal, where four equatorial positions are occupied by three nitrogen atoms (N5 of pyridine, N3 of pyrazole and N1 of azomethine nitrogen) and one phenoxide oxygen (O1) of salicylaldehyde part while the axial position is occupied by one oxygen atom (O14A) of perchlorate anion. The unit cell of **1** comprises of two molecules. HL_1 ligand forms one five membered and two six membered chelate rings with the Cu(II) metal centre. The bond angle of N3–Cu–N5 deviates maximum [78.76(5)°] from the ideal bond angle of 90°, due to formation of five membered chelate ring, where as least deviation is observed for the angle N3–Cu–N1 [89.69(5)°]. Among the four equatorial bonds Cu–O1 is the shortest [1.8462(10) Å] whereas Cu–N5 is the longest [2.0246(14) Å]. The shortest distance is due to the formation of strong bond between Cu(II) and negatively charged oxygen atom. The axial Cu–O14A bond is 2.606 Å which is much longer than the Cu–O1 equatorial bonds although both oxygen atoms are uninegative. This proves that the phenoxide oxygen is stronger donor centre than the perchlorate oxygen. The Cu-atom is shifted through a distance of 0.052 Å upward beyond the basal plane towards the ClO_4^- unit. The τ-value (0.08) [29] for complex **1** implies that the central copper atom sits in an almost square pyramidal geometry.

The complex **1** is stabilized through a network of hydrogen bonding (Fig. 8). It shows that there is a weak H-bond interaction between H2A and O2 atoms [d(D···A) 2.8012(19) Å] of the two adjacent molecules lying parallel.

3.2.3. Structural descriptions of ***2*** and ***4***

Complex **2** crystallizes in space group $P\bar{1}$ while **4** in space group $P2_1/c$. Unit cells of both **2** and **4** comprise of four molecules. The

#1: $y + 3/4, -x + 3/4, z - 1/4$ for HL_1.
#1: $-x + 2, -y + 1, -z - 1$ for **1**.
#1: $-x, -y + 1, -z + 1$ for **2**.
#1: $-x, -y, -z + 1$ for **4**.

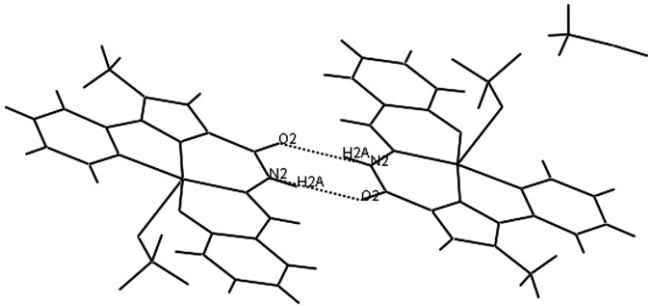

Fig. 8. H-bonding in **1**.

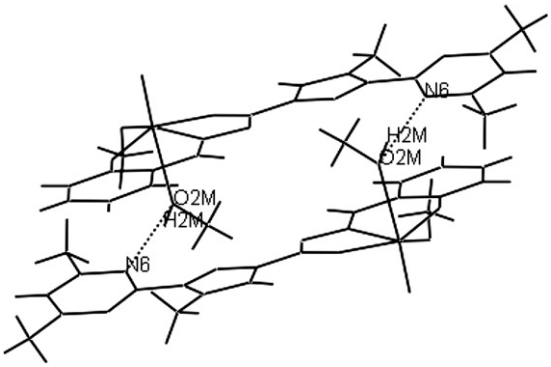

Fig. 10. H-bonding in **4**.

asymmetric unit of **2** contains two independent molecules. Here it is interesting to note that in 'unit A', V(V) is hexa-coordinated while in 'unit B', it is penta-coordinated. The vanadium atoms in the two units (A and B) are separated by a distance of 13.632 Å. For 'unit A', the vanadium atom is in distorted octahedral geometry, where four equatorial positions are satisfied by three oxygen atoms (deprotonated enol oxygen O5A, phenoxide oxygen O1A and methoxy oxygen O3A) and one azomethine nitrogen (N1A) atom, while two axial positions are occupied by two oxygen atoms (one terminal oxo group (O2A) and one methanol oxygen atom (O4A)). In 'unit B', the vanadium atom like copper atom in **1** is also in distorted square pyramidal geometry. Here four equatorial positions are occupied by three oxygen atoms (deprotonated enol oxygen O3B, phenoxide oxygen O1B and methoxy oxygen O4B) and one azomethine nitrogen (N1B) and the axial coordination is completed by one terminal oxo group (O2B). Thus the two vanadium atoms in the same asymmetric unit face the same donor environment with the exception of one extra coordinated methanol moiety in 'unit A' which is absent in 'unit B'. The methanol moiety accounts for the different coordination geometry around the two vanadium atoms. However, compared to penta-coordinated copper atom in **1**, the penta-coordinated V-atom in 'unit B' of **2** experiences a greater extent of deviation from the ideal square pyramidal geometry. This is evidenced by the calculation of τ-value ($\tau = 0.35$ compared to 0.08 in **1**). In complex **4**, vanadium(V) atom is in distorted octahedral environment similar to that in 'unit A' of **2**. The vanadium atom is displaced almost equally out of the mean basal plane in 'unit A' of **2** and in **4** (0.290 Å for 'unit A' of **2** and 0.285 Å for **4**) but the displacement is almost doubled for 'unit B' of **2** (0.508 Å). The V=O distances are 1.5856(14) Å for 'unit A', 1.5762(15) Å for 'unit B' of **2** and 1.600(3) Å for **4**, which are same as normal V=O distance of 1.595 Å. The V1–N1A distance 2.1435(13) Å in 'unit A' and V2–N1B distance 2.0860(14) Å in 'unit B' of **2** and V–N1 distance 2.113(3) Å in **4** are in accordance with literature values for V–N distances [30,31].

In 'unit A' of **2** there is a weak intermolecular H-bond interaction through H(4S) and N(2A) between two molecules (Fig. 9). In complex **4**, a weak intermolecular H-bond exists between H(2M) atom of one molecule and N(6) of another (Fig. 10). The details are presented in Table 3.

4. Characterization of the complex species

The V(V) complexes have been prepared employing a V(IV) starting material such as $VO(acac)_2$. Molecular dioxygen from air serves as the oxidant during the course of the reaction. The V-complexes (**2** and **4**) are diamagnetic in nature.

Table 4
Summary of electrochemical data for complexes **1**, **2**, **3** and **4**

Complex	E_{pc} (V) (Cu^{II}/Cu^{I})	E_{pa} (V) (Cu^{II}/Cu^{III})	E_{pc} (V) (Cu^{III}/Cu^{II})	ΔE (V)	E_{pc} (V) (V^{V}/V^{IV})	E_{pa} (V) (V^{V}/V^{IV})
1	−0.467	0.480	0.367	0.113		
2				0.196	−0.172	−0.024
3	−0.623	0.466	0.291	0.175		
4				0.394	−0.302	−0.092

4.1. Electronic spectra

The electronic solution spectra of the complexes were recorded in CH_3OH solution. Complex **1** shows a pyridine → Cu charge transfer band at 406 nm. A broad characteristic band at 669 nm may be due to the slightly distorted square pyramidal environment around Cu(II) centre [32]. Complex **3** shows $N_{(pym)}$ → Cu charge transfer band at 398 nm. The spectral feature of **3** is quite similar to that of **1**. This implies that like **1**, **3** also bear the central Cu atom in almost square pyramidal geometry. The electronic spectra of the vanadium complexes (**2** and **4**) exhibit one intense band near 400 nm, which is assigned to L–V(dπ) LMCT transition [33].

5. Electrochemistry

The cyclic voltammetry of the Cu(II) complexes **1** and **3** are studied in CH_3OH solution in the potential range −1.5 to +1.5 V. For all the complexes, the most important electrochemical data associated with the metal centres are listed in the Table 4. Complex **1** shows an irreversible reductive response associated with Cu(II)/Cu(I) at −0.46 V. In case of complex **3** the same peak is obtained at −0.62 V. None of the complexes shows the characteristic reduction peak for Cu(I)/Cu(0) in the same potential window. In the anodic scan of complex **1**, couple of quasireversible nature is obtained for Cu(II)/Cu(III) process at 0.42 V. For complex **3**, the irreversible peak for Cu(II)/Cu(III) is obtained at 0.38 V (for complex **1** ΔE = 0.113 V and for complex **3** ΔE = 0.175 V). Complex **2** shows an irreversible one-step, one-electron response at −0.098 V (ΔE = 0.196V), corresponding to V(V)/V(IV) reduction. Although two different peaks are expected in the same direction of the scan due to the different coordination environment around the two V(V) centres, the appearance of only one cathodic peak and one anodic peak infer that $E_{1/2}$ value is coordination insensitive. The mono oxo alkoxo V(V) complex **4** shows an irreversible one electron reductive response at −0.197 V (ΔE = 0.394 V).

6. Concluding remarks

We have prepared Cu(II) and V(V) complexes of HL_1 and HL_2 where HL_1 and HL_2 are pyridyl/pyrimidyl–pyrazole derived Schiff base ligands, respectively. In complex **1** the HL_1 ligand in its 'keto-imine' form behaves as mononegative NNNO tetradentate one utilizing all the possible nitrogen donor centres (pyridine N, pyrazole N and azomethine N). In complex **2**, HL_1 ligand in its 'imineol' form acts as tridentate dianionic ONO donor where the heterocyclic nitrogen atoms remain non-coordinated, instead the deprotonated enol oxygen atom participates in the game. This is to fulfill the differential preference for donor sites by the two different metal atoms. Cu(II) being a borderline acid prefers relatively less harder N-donor centre while O-donor centre being the harder one is preferred by hard V(V) cation. Thus to avail the oxygen as donor centre, HL_1 undergoes tautomerisation to its 'imineol' form followed by deprotonation during complexation with V(V). Further, in the asymmetric unit of complex **2**, two different coordination geometry around two V(V) centres have been observed with the same ligand HL_1. In 'unit A', V(V) is hexa-coordinated employing a methanoate species, a methanol moiety and one oxo group apart from the tridentate ligand unit, whereas in 'unit B' the same metal atom is penta-coordinated using the same donor environment except the coordinated methanol moiety. In **4**, the vanadium(V) atom sits in the distorted octahedral coordination pocket formed by one tridentate ONO binegative ligand molecule (HL_2), one oxo group, one methoxy group and one methanol moiety. Likewise HL_1, the HL_2 ligand is expected to behave similarly regarding its donor sites towards Cu(II) centre in **3** which is concluded from the similar spectral features of **1** and **3**. As a concluding remark, it is stated that the two similar ligands produce the identical coordination environment towards Cu or V, but these similar environments for these two different metal atoms differ from each other.

3. Results and discussion

3.1. Spectroscopy

The ν(CO) band, which is sensitive to complexation, occurs at 1600 and 1610 cm^{-1} in the parent ylides Y^1 and Y^2, respectively [30,31]. Coordination of ylide through the carbon atom causes an increase in the ν(CO) band, whereas for O-coordination a lowering of the ν(CO) band is expected [32]. Thus the IR absorption bands for the complexes at higher frequencies indicate that C-coordination has occurred. The ν(P–C) band frequencies, which are also diagnostic of the coordination mode, occur at 848 and 887 cm^{-1} in the parent ylides Y^1 and Y^2, respectively, and are shifted to lower frequencies for the complexes, suggesting some removal of the electron density of the P–C bonds [33].

The presence of two chiral C centres (forming diastereoisomers) in **1b** (Scheme 1) is shown in the ^1H, ^{31}P and ^{13}C NMR spectra by two sets of signals with unequal populations for CH_2, CH, CO and PCH groups. The geometry of cis and trans may leads to the further peaks in the ^{31}P NMR spectra: 19.83, 20.80, 27.84 and 28.09 ppm for **1b** and 23.38 and 23.52 ppm at 25 °C for **1a** [34,35].

The two geometries for **1a** equilibrate rapidly at higher temperatures, leading to one signal for phosphorus centre (δ_P = 23.50 ppm at 55 °C) (Fig. 1).

Scheme 1.

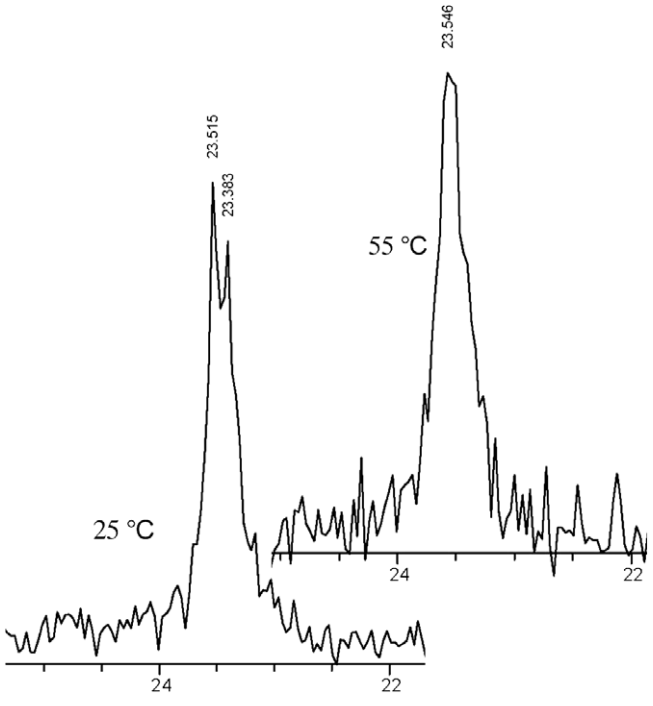

Fig. 1. Variable temperature ^{31}P NMR study on **1a**.

In the ^1H NMR spectra for **1a** and **1b**, the signals due to the methinic proton are broad (**1a**) or are a broad doublet (**1b**). This broadening is probably due to the presence of different geometries and the above mentioned diastereoisomers. A related insoluble complex, $[PdCl_2\{CH(PPh_3)CO_2Me\}_2]$, has been reported to be of a trans geometry on the basis of IR data [20]. An NMR study could not be performed on complexes **2a** and **2b** because they are very insoluble in the most common solvents. However their elemental analysis, IR spectra and the synthesis of **3a** and **4b** from complexes **2a** and **2b** adequately establish their identity, thus we propose for **2a** and **2b** the same structure as reported for the related complexes [17,20,22–26] (see Scheme 1). The bridge-splitting reaction of **2a** and **2b** with PPh_3 and P(*p*-tolyl)$_3$ is highly selective, affording exclusively the corresponding mononuclear compounds **3a, 4a**, **3b** and **4b**, respectively (Scheme 1). The ^1H and ^{31}P signals for the PCH group of complexes **3a**–**4b** are shifted downfield compared to that of the free ylide, as a consequence of the inductive effect of the metal centre. The ^1H NMR spectra of complexes **3a**–**4b** show one doublet of doublets signal for the CH group that must

arise from the simultaneously coupling with two phosphorus centres.

In ^{13}C NMR spectra, a higher shielding of the ylidic carbon atoms compared to those of the parent ylides is expected and we observed this for **3a**, **4a** and **1b**. Such a higher shielding was observed in $[PdCl(\eta^3\text{-}2\text{-}XC_3H_4)(C_6H_5)_3PCHCOR]$ (X = H, CH_3; R = CH_3, C_6H_5), and is due to the change in hybridization of the ylidic carbon atom on coordination [36]. Similar upfield shifts of 2–3 ppm with reference to the parent ylide were also observed in the case of $[(C_6H_5)_3PC_5H_4 \cdot HgI_2]_2$ [37] and in our synthesized complexes [30,38]. The downfield shift of the carbonyl C atom in **1a**, **3a**, **3b**, **4a** and **4b** compared to the same carbon atom in the parent ylides (190.38 ppm (Y^1) and 170.46 ppm (Y^2)), indicate a much lower shielding of the CO group in these complexes [30,38–40]. In this work, it is interesting that the expected upfield shift of the ylidic C atoms in **3b** and **4b** and downfield shift of the carbonyl C atom in **1b** are not in accordance with the expected process. This is probably due to the steric nature of Y^2, which is different from ketonic ylides.

3.2. X-ray crystallography

Table 1 provides the crystallographic results and refinement information for complex **4a**. The molecular structure and pertinent bond distances and angles are presented in Fig. 2.

Suitable crystals of **4a** were grown by the slow diffusion of diethyl ether into a chloroform solution. The Pd atom is located in a distorted square-planar environment, surrounded by one ylidic carbon (C3) and one metallated carbon (C12) that form a five-membered cycle, one chlorine (Cl1) and one phosphorus (P2) atom. The angles subtended by the ligands at the Pd(II) centre in **4a** vary from 86.8(2)° to 93.33(5)° and 168.19(16)° to 170.58(14)° indicating the distorted square-planar environment. The C(3)–Pd(1)–P(2) (168.19(16)°) and C(12)–Pd(1)–Cl(1) (170.58-(14)°) bond angles deviate a little from linearity. The Pd(1)–C(12) bond distance (2.021(5) Å) is statistically identical to those found in the orthopalladated complexes $[Pd\{\kappa^2\text{-}C,N\text{—}C_6H_4\text{-}1\text{-}[(3,5\text{-}Me_2\text{—}C_3N_2)\text{—}CH_2\text{—}(\eta^5\text{-}C_5H_4Fe(\eta^5\text{-}C_5H_5)]\}Cl(PPh_3)]$ (2.035(5) Å) [41] and $[Pd\{\kappa^2\text{-}C,O\text{—}C_6H_4\{C(O)Me\}\text{-}2\}Br\{P(o\text{-}To)_3\}]$ (2.021(2) Å) [42]. The distances Pd(1)–C(12) [2.021(5) Å] and Pd(1)–C(3) [2.166(5) Å] are different, probably reflecting the different trans effect of the phosphorus and chlorine atoms. The stabilized resonance structure for the parent ylide is destroyed by the complex formation, thus the C(2)–C(3) bond length (1.478(8) Å) is significantly longer than the corresponding distance found in the similar uncomplexed phosphoranes (1.407(8) Å [43] and 1.401(2) Å [44]). Likewise the C(3)–P(1) bond length in a similar ylide is 1.7194(17) Å [44], which shows that the corresponding bond in **4a** is considerably elongated to 1.780(5) Å.

4. Conclusion

The present study describes the synthesis and characterization of orthometallated Pd(II) complexes of phosphorus ylides. On the basis of the physico-chemical and spectroscopic data we propose that these ligands herein exhibit C-coordination to the metal centre, which is further confirmed by the X-ray crystal structure of complex **4a**. The structural study involved in this work demonstrates that phosphorus ylides can show transition metal induced activation of C–H bonds.

Acknowledgement

We are highly grateful to Mr. Zebarjadian for recording the NMR spectra.

Appendix A. Supplementary data

CCDC 684309 contains the supplementary crystallographic data for **4a**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.07.017.

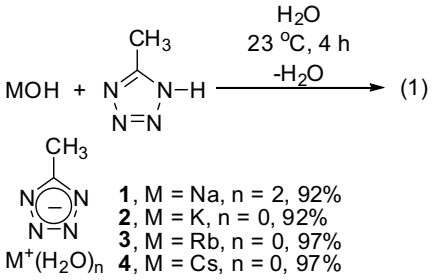
ligand adopts a μ_2-1,2-bridging coordination mode, which has been widely observed in other metal tetrazolate complexes. By contrast, the potassium, rubidium, and cesium Metetz complexes contain new coordination modes that entail bonding of two or more metal atoms to each nitrogen atom in the tetrazolate ligand. These new coordination modes lead to high solid state densities through extremely efficient packing. Achievement of high solid state densities in energetic materials is very important, since the detonation pressure and thus explosive performance of a compound is related to the square of the density [51].

2. Results and discussion

2.1. Preparation and characterization of sodium, potassium, rubidium, and cesium methyl tetrazolate complexes

Several group 1 Metetz complexes have been previously described, with varying levels of characterization. Na(Metetz) has been generated in solution by treatment of MetetzH with several different bases, and has been used as a nucleophilic tetrazolate transfer reagent [52,53]. The X-ray crystal structure of Na(Metetz)$(H_2O)_2$ was recently reported, although it was not described [38b]. K(Metetz) has been generated in solution by deprotonation of MetetzH and was used as an intermediate in the synthesis of functionalized tetrazoles [54,55]. Neither Rb(Metetz) nor Cs(Metetz) has been previously described. In the present work, MetetzH was treated with MOH or MOH · H_2O (M = Na, K, Rb, Cs) in water at room temperature, which afforded 92–97% isolated yields of Na(Metetz)$(H_2O)_2$ (**1**), K(Metetz) (**2**), Rb(Metetz) (**3**), and Cs(Metetz) (**4**) as colorless solids after workup (Eq. (1)). Complex **1** was isolated as the dihydrate, and the waters of hydration were not lost upon extended storage at room temperature. By contrast, **2**–**4** crystallized from concentrated aqueous solutions (**2**, **3**) or methanol/diethyl ether (**4**) as the anhydrous Metetz complexes. The crystal structures of **1**–**4** are described below. Several precautions were required during the synthetic procedures. To avoid formation of carbonates, reactions involving the metal hydroxides were conducted under argon in degassed, distilled water. A slight excess of MetetzH was employed in each synthesis, to assure complete consumption of the metal hydroxide starting materials. The excess MetetzH was subsequently removed by washing the crude reaction mixtures with tetrahydrofuran, since **1**–**4** are rigorously insoluble in this solvent, whereas MetetzH is very soluble. A small portion of each crude reaction product was also dissolved in water, and several drops of phenolphthalein solution were added. Formation of a light pink color indicated the presence of hydroxide ion, and thus incomplete reaction. Only products that afforded colorless solutions with the phenolphthalein test were employed further. Finally, although **2**–**4** crystallized as anhydrous materials, the crystals themselves were hygroscopic and formed gelatinous blobs upon standing in ambient atmosphere (0.25–2 h, depending on the humidity levels). Crystals of **2**–**4** were obtained upon slow evaporation of aqueous (**2**, **3**) or methanol/diethyl ether (**4**) solutions, but the crystals themselves were encased in greasy coatings that could not be removed without dissolving the crystals. In addition, only small amounts of crystals were obtained in each evaporation, with most of the product forming microcrystalline or syrupy materials. As a result, it was not possible to obtain analytical samples by crystallization. Infrared spectra of **2**–**4** obtained on the powders obtained after tetrahydrofuran washing and vacuum drying at ambient temperature for 18 h showed absorptions at ~3400 and ~1645 cm^{-1} that corresponded to vibrations from water molecules, indicating that these materials were hydrates. Carbon, hydrogen, and nitrogen microanalyses of these hydrated powders gave variable results, but generally suggested formulations of **2** · $(H_2O)_{0.5}$, **3** · $(H_2O)_{0.5}$, and **4** · $(H_2O)_{0.5}$. The waters of hydration could be removed by drying for 18 h at 111 °C/0.05 Torr in a drying pistol using refluxing toluene. Infrared spectra of **2**–**4** after this drying protocol did not show the absorptions at ~3400 and ~1645 cm^{-1}, demonstrating that these materials were anhydrous. The carbon, hydrogen, and nitrogen microanalysis values were consistent with analytically pure material for **2**. However, carbon, hydrogen, and nitrogen microanalysis values within 0.4% of the calculated values could not be obtained for **3** and **4**, despite three analyses for each compound. It has been previously established that the high nitrogen contents in tetrazoles can lead to difficulties in obtaining correct microanalyses [56].



The ^1H NMR resonances for the methyl group hydrogen atoms in **1**–**4** appeared at δ 2.41 in methanol-d_4, while the $^{13}C\{^1H\}$ NMR spectra in the same solvent showed resonances between 159.14 and 159.17 ppm for the tetrazolate ring carbon atom and between 10.14 and 10.20 ppm for the methyl group carbon atom. These resonances suggest very similar solution structures that probably involve solvated, separated metal and methyl tetrazolate ions. The infrared spectrum of **1** showed absorptions due to the methyl tetrazolate ligand, as well as a strong, broad absorption at 3420 cm^{-1} and a sharp, medium intensity absorption at 1645 cm^{-1}. These latter absorptions correspond to the symmetric and asymmetric stretches of water and the bending of the water O–H bonds, respectively. The infrared spectra of dried samples of **2**–**4** revealed absorptions for the methyl tetrazolate ligand, and the water absorptions were absent.

Complexes **1** and **2** have melting points above 300 °C, while **3** and **4** melt at 254 and 257 °C, respectively. There was no evidence for detonation of **1**–**4** during the melting point experiments. Small samples of **1**–**4** (~5 mg) were placed on an iron anvil and were struck hard with a hammer. No detonations occurred during these procedures. Small samples (~10 mg) of **1**–**4** were placed on laboratory tissues in a large ceramic dish, and the tissues were lit with a match. No noise was heard upon burning **1**–**4**, and normal burning was observed (no deflagration). Passing sparks from a Tesla coil through ~5 mg samples of **1**–**4** on an iron anvil did not lead to detonation or even deflagration. These experiments suggest that **1**–**4** are not primary energetic materials, although they may still contain considerable energy. The thermal decomposition of **1**–**4** was further investigated by thermogravimetric analysis under a nitrogen atmosphere between 25 and 450 °C with a heating rate of 10 °C/min. The thermogravimetric analysis of **1** showed two events: loss of coordinated water with the onset at 92 °C (weight loss = 26.2% versus 25.4% expected for loss of two water molecules) and two step loss of dinitrogen with onsets at 352 and 395 °C (weight loss = 41.2% versus 39.4% expected for loss of 2 equiv. of dinitrogen). Complexes **2**–**4** showed single weight loss events with onsets at 350, 377, and 362 °C with total weight loss of 38.7%, 31.5%, and 21.9%, respectively. The weight losses for **2**–**4** are consistent with 85%, 95%, and 84%, respectively, of the mass losses expected for 2 equiv. of dinitrogen.

2.2. X-ray crystal structures of 1–4

Complexes **1**–**4** were subjected to X-ray crystal structure analyses to determine the bonding modes of the methyl tetrazolate ligands, the geometries around metal centers, and solid state densities. The X-ray crystal structure of **1** was reported recently [38b], but was not described in the publication. We describe the structure of **1** herein to allow comparison with **2**–**4**. Crystallographic data for **1**–**4** are summarized in Table 1, selected bond lengths and bond angles are listed in Tables 2–5, while perspective views are given in Figs. 1–4. In the structure discussion and throughout the paper, N_1–N_4 refer to the atom numbers within the tetrazolate ligand CN_4 core (Chart 1), whereas N(1) and N(2) refer specifically to the crystallographically unique nitrogen atoms within each structure.

The molecular structure of **1** is shown in Fig. 1. The structure consists of approximately octahedrally coordinated sodium ions that form infinite chains built up by two μ_2-aqua ligands and two μ_2-N_1,N_2-tetrazolate ligands between each sodium atom. The tetrazolate ligand nitrogen atoms are *trans* within the octahedron, and occupy the crystallographic mirror along with the sodium ion. The four oxygen atoms lie in an approximate plane containing the sodium ion. The sodium–nitrogen distances are 2.523(1) and 2.533(1) Å, while the nitrogen–sodium–nitrogen angle is 168.63(3)°. The nitrogen–sodium–oxygen angles range between 77.56° and 110.52°, which illustrate the distorted octahedral geometry. The sodium–oxygen distances are 2.422(1) and 2.435(1) Å, the *cis* oxygen–sodium–oxygen angles are between 84.74° and 93.36°, while the *trans* oxygen–sodium–oxygen angle is 166.40(2)°. The sodium–oxygen–sodium angle is 92.30(2)°. The linear chains containing the NaN_2O_4 octahedra form a larger structure that is cross-linked by O–H···N hydrogen bonds between the bridging aqua ligand hydrogen atoms and the uncoordinated N_3 and N_4 atoms of each Metetz ligand. These hydrogen bonds are characterized by oxygen-hydrogen distances of 0.843 and 0.847 Å, hydrogen–nitrogen distances of 2.078 and 2.132 Å, oxygen–nitrogen separations of 2.925 and 2.966 Å, and oxygen–hydrogen–nitrogen angles of 169.69° and 179.00°.

Complexes **2** and **3** are isostructural and have similar bonding interactions (Figs. 2 and 3). The metal ions in each complex are eight coordinate, and each has bonds to one η^2-N_1,N_2-tetrazolate ligand, one η^2-N_2,N_3-tetrazolate ligand, one η^2-N_3,N_4-tetrazolate ligand, one η^1-N_1-tetrazolate ligand, and one η^1-N_4-tetrazolate ligand. The η^2-N_1,N_2- and η^2-N_3,N_4-tetrazolate interactions are *syn* to each other within each Metetz ligand. Through these bonding motifs, each nitrogen atom in the Metetz ligand forms bonds to two potassium or rubidium ions. In **2**, the potassium–nitrogen distances range from 2.89 to 2.97 Å, while the rubidium–nitrogen distances in **3** are between 3.01 and 3.07 Å. There are no close contacts between the metal ions and the Metetz ligand core carbon atom in either **2** or **3**. In **2**, the nitrogen–potassium–nitrogen bite angle associated with the η^2-tetrazolate interactions are 26.00(5)° and 26.73(3)°. For **3**, the corresponding angles are 25.13(4)° and 25.65(2)°. The slightly smaller bite angles in **3** are consistent with the longer metal–nitrogen distances, compared to **2**.

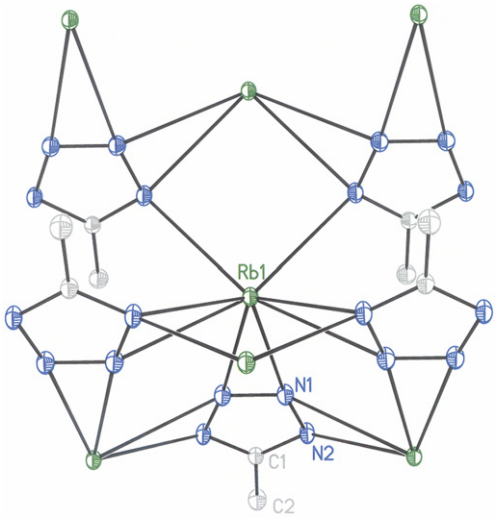

Fig. 3. Perspective view of **3** with thermal ellipsoids at the 50% probability level.

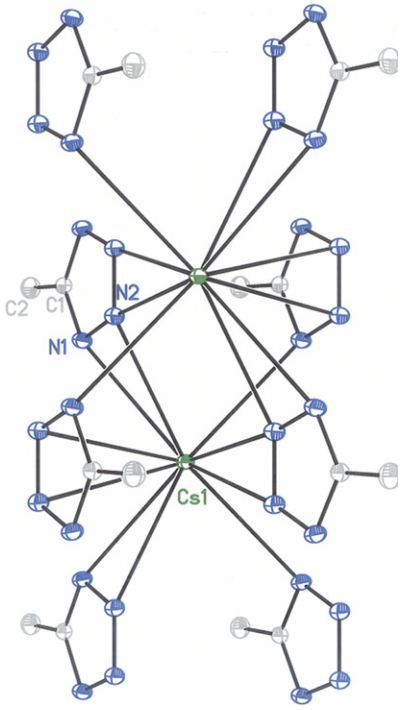

Fig. 4. Perspective view of **4** with thermal ellipsoids at the 50% probability level.

The cesium ions in **4** are 10-coordinate, and form bonds to one η^2-N_1,N_2-tetrazolate ligand, two η^2-N_2,N_3-tetrazolate ligands, one η^2-N_3,N_4-tetrazolate ligand, one η^1-N_1-tetrazolate ligand, and one η^1-N_4-tetrazolate ligand (Fig. 4). The cesium atoms lie slightly out of the CN_4 planes of the η^2-N_1,N_2- and η^2-N_3,N_4-tetrazolate ligands, but the CsN_2/CN_4 angles are small (21.3°). By contrast, the CsN_2/CN_4 angles associated with the two η^2-N_2,N_3-tetrazolate ligands are 95.6° and 0.9°. The cesium ion bonding vector makes an angle of 71.5° with the CN_4 planes of the η^1-N_1- and η^1-N_4-tetrazolate ligands. Through these cesium–nitrogen interactions, the two N(1) atoms of the Metetz ligands (adjacent to the core carbon atom) each form bonds with two cesium ions, whereas the two N(2) atoms (remote from the core carbon atom) each form bonds to three cesium ions. The cesium–nitrogen distances in **4** range between 3.14 and 3.50 Å. The η^2-1,2-N_1,N_2- and η^2-N_3,N_4-tetrazolate ligands have cesium–nitrogen distances of 3.337(1) Å to N(1) and 3.139(1) Å to N(2), and thus have a distorted η^2-interaction. The η^2-N_2,N_3-tetrazolate ligands are characterized by cesium–nitrogen distances of 3.207(1) Å for the in-plane interaction and 3.497(1) Å for the out-of-plane interaction. The latter interaction is the longest cesium–nitrogen bond in the complex, consistent with the presumably lower basicity of the out-of-plane π-orbitals, compared to the in-plane nitrogen-based lone pairs. The η^1-interactions have a cesium–nitrogen distance of 3.333(1) Å. The nitrogen–cesium–nitrogen bite angles associated with the η^2-tetrazolate interactions are 23.94(2)°, 23.65(4)°, and 21.66(4)°. These angles are smaller than those found in **2** and **3**, due to the longer cesium–nitrogen bond lengths in **4**. In addition, the latter bite angle in **4** (21.66(4)°) is associated with the out-of-plane η^2-N_2,N_3-tetrazolate interaction, and is smaller than the other two bite angles because of the longer cesium–nitrogen distances.

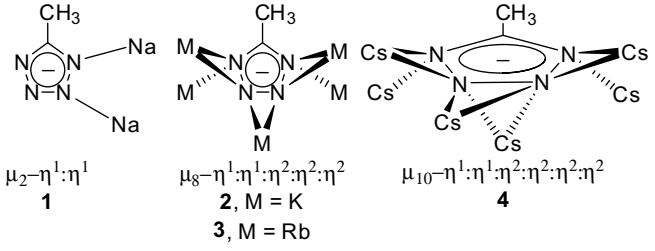
Chart 1. Numbering scheme for tetrazolate ligand core nitrogen atoms.

We have recently reported examples of intramolecular and intermolecular C-H···N hydrogen bonding between 18-crown-6 C–H bonds and the nitrogen atoms of tetrazolate ligands in group 1 and 2 complexes [48–50]. These interactions are important, since the metal–tetrazolate bonding interactions were distorted to facilitate the hydrogen bonding and because this weak hydrogen bonding possibly promotes higher densities through more efficient packing. The sum of the van der Waals radii for N and H is about 2.7–3.0 Å [57,58], so interactions in this range or shorter are diagnostic of C–H···N hydrogen bonding. The structure of **1** contains intermolecular C–H···N hydrogen bonding interactions with an H···N separation of 2.905 Å. Complexes **2** and **3** exhibit intermolecular C–H···N hydrogen bonding interactions with H···N separations of 2.551 and 2.693 Å, respectively. Complex **4** exhibits close H···N distances of 2.797, 2.896, and 2.901 Å.

2.3. Discussion

Chart 2 depicts the metal atom coordination modes to the Metetz ligands in **1**–**4**. Complex **1** contains N_1,N_2-μ_2-η^1:η^1-Metetz ligands, which is a common coordination mode for tetrazolate ligands. The same coordination mode has been observed in $[Cd[Cd(py)(H_2O)]_2(1,3\text{-BTB})_2]$ (1,3-BTB = 1,3-benzeneditetrazolate, py = pyridine) [16f]. One of the tetrazolate moieties within sodium *trans*-5,5′-ethylenetetrazolate [38d] and sodium 5,5′-azotetrazolate pentahydrate [38g] also exhibits the N_1,N_2-μ_2-η^1:η^1-coordination mode. The N_1,N_2-μ_2-η^1:η^1-coordination mode is also a common motif within more complex tetrazolate bridging ligand modes [1,16c,16e]. Complexes **2** and **3** contain the μ_8-η^1:η^1:η^2:η^2:η^2 coordination mode. A very similar coordination mode was observed in cesium cyanotetrazolate [38h], where η^1-cesium–nitrogen bonds occurred to N_1 and N_4 of the tetrazolate core, and η^2-interactions were observed to N_1–N_2, N_2–N_3, and N_3–N_4. The only difference between the coordination mode of the tetrazolate ligand cores in **2** and **3** and that in cesium cyanotetrazolate is that the η^2-interactions to N_1–N_2 and N_3–N_4 are *syn* within each tetrazolate ligand in the former two examples, but are anti in the last example. Interestingly, the tetrazolate moieties in rubidium 5,5′-azotetrazolate dihydrate exhibit a novel bridging coordination mode that entails η^1-coordination of N_1, two η^2-interactions to N_1 and N_2, and an η^2-interaction to N_2 and N_3 [38g]. This coordination pattern is very similar to that in **2** and **3**. However, N_3 and N_4 engage in hydrogen bonding to the water molecules, which interrupts coordination of the rubidium ion to all of the ligand core nitrogen atoms. Complex **4** contains the μ_{10}-η^1:η^1:η^2:η^2:η^2:η^2-Metetz ligand, which is a new coordination mode for a tetrazolate ligand. Interestingly, the Metetz ligand nitrogen atoms in **4** form bonds to 10 cesium ions, whereas the core nitrogen atoms in cesium cyanotetrazolate form bonds to only 8 cesium ions [38h]. This difference occurs because the cyano group nitrogen atom in cesium cyanotetrazolate bonds to three cesium ions, thereby reducing the overall number of cesium–nitrogen bonds to the cyanotetrazolate core nitrogen atoms. The X-ray crystal structure of cesium aminotetrazolate has also been reported [38d]. Each cesium ion is 9-coordinate, with eight cesium–nitrogen bonds to tetrazolate ring core nitrogen atoms and one cesium–nitrogen bond to the amino nitrogen atom. The core nitrogen atoms of the tetrazolate ligand are bonded to six cesium atoms, with two η^1-N_1, two η^1-N_4, and two η^2-N_2,N_3 interactions. Apparently, the coordination number at the cesium ion and the number of cesium atoms bonded to each tetrazolate core nitrogen atom are reduced in cesium aminotetrazolate, due to the formation of the cesium–nitrogen bond to the amino group as well as the N–H···N hydrogen bonding that is associated with the amino group hydrogen atoms. The X-ray crystal structure of the cesium salt of the dianion 5-cyanoiminotetrazoline has been described [38e]. In this structure, each CN_4 core nitrogen atom is bonded to three cesium ions with two η^1-N_1, two η^1-N_4, and two η^2-N_1,N_2, one η^2-N_2,N_3, and one η^2-N_3,N_4 interactions. However, the presence of two cesium ions per tetrazolate ring and the Lewis basic cyanoimino group makes the overall coordination spheres of the cesium ions very complex.

The X-ray crystal structure of Na(Htetz)(H_2O) has been determined [38i], and its coordination sphere consists of four nitrogen atoms from four tetrazolate ligands lying in an approximate plane and two *trans* oxygen atoms of the aqua ligands. Each tetrazolate ligand has four sodium–nitrogen bonds, and forms two η^1-N_1 and two η^1-N_4 interactions. The uncoordinated N_2 and N_3 atoms of each tetrazolate ligand are engaged in hydrogen bonding to the hydrogen atoms of the aqua ligands. Interestingly, the carbon-bound hydrogen atom has an intermolecular close contact of 2.782 Å to N_2 of an adjacent tetrazolate ion, which demonstrates that weak C–H···N hydrogen bonding is also present in the solid state. The thermal decomposition of Na(Htetz)(H_2O) was reported [59], and it exhibits water loss between 120 and 170 °C and loss of 1 equiv. of dinitrogen as a single event between 323 and 337 °C. For comparison, **1** underwent dehydration beginning at 92 °C, but lost 2 equiv. of dinitrogen in a two step process beginning at 352 °C. Complexes **2**–**4** lost 2 equiv. of dinitrogen in single step events at onset temperatures between 350 and 377 °C. Detonations of **1**–**4** were not observed in any of the thermogravimetric analysis experiments. By contrast, it was reported that thermogravimetric analyses with more than 10 mg of Na(Htetz)(H_2O) resulted in detonation [59]. It is likely that the Metetz complexes are less energetic than Na(Htetz)(H_2O), due to the lower nitrogen contents associated with the presence of the methyl groups in **1**–**4**.



μ_2–η^1:η^1 **1**

μ_8–η^1:η^1:η^2:η^2:η^2 **2**, M = K; **3**, M = Rb

Chart 2. Tetrazolate ligand coordination modes in 1–4.

3. Experimental

3.1. Caution

The compounds described herein have high nitrogen contents, and are potentially energetic. While **1**–**4** showed no evidence for detonation or shock sensitivity in our studies, safety precautions

such as a face shields, a leather apron and gloves, and hearing protection should be employed.

3.2. General considerations

The syntheses of **1**–**4** were conducted under an argon atmosphere using Schlenk line techniques, to avoid the formation of metal carbonates in the reaction solutions. Once isolated, **2**–**4** were handled under a dry argon atmosphere in a glove box to avoid the formation of hydrates. Methyl tetrazole, NaOH, KOH, $RbOH \cdot H_2O$, $CsOH \cdot H_2O$, and methanol were purchased from Aldrich Chemical Company and were used without further purification. ^1H and $^{13}C\{^1H\}$ NMR spectra were obtained at 300 and 75 MHz, respectively, in methanol-d_4. Infrared spectra were obtained as Nujol mulls on NaCl plates. Elemental analyses were performed by Midwest Microlab, Indianapolis, IN. Melting points were obtained on a Haake–Buchler HBI digital melting point apparatus and are uncorrected. Thermogravimetric analyses were conducted on a Perkin Elmer Pyris 1 TGA system between 25 and 450 °C, using nitrogen as the flow gas with a heating rate of 20 °C/min.

3.3. General procedure for the preparation of *1*–*4*

A 100-mL Schlenk flask was charged with the metal hydroxide, a stir bar, and degassed, distilled water (20 mL). To the stirred solution at ambient temperature, the methyl tetrazole (1.1 molar equiv.) was slowly added as a solution in 20 mL of degassed, distilled water. The resultant mixture was stirred for 4 h at ambient temperature. The volatile components were then removed under reduced pressure to afford colorless solids. The crude solids were washed with two 20 mL portions of tetrahydrofuran to remove the excess methyl tetrazole. A small sample of each complex was dissolved in dry, degassed water. To this solution was added a few drops of an aqueous phenolphthalein solution. A pink color at this stage indicated the presence of hydroxide ion, and thus an incomplete reaction. Only products that afforded colorless solutions upon addition of phenolphthalein were deemed successful. With **2**–**4**, the solids were dried for 18 h at 0.05 Torr in a drying pistol, using refluxing toluene (111 °C). Single crystals for the X-ray crystallographic analyses were obtained by slow evaporation of water at 23 °C for **1**–**3**, and by diffusion of diethyl ether into a methanol solution of **4** at 23 °C.

3.4. Sodium methyl tetrazolate dihydrate (*1*)

Prepared from sodium hydroxide (0.182 g, 4.55 mmol) and methyl tetrazole (0.421 g, 5.01 mmol) to afford **1** in 92% yield as a colorless solid: mp >300 °C; IR (Nujol, cm^{-1}) 3435 (vs), 1645 (s), 1302 (s), 1259 (m), 1169 (m), 1153 (m), 1125 (s), 1103 (s), 1068 (s), 1028 (s), 721 (s), 700 (s); ^1H NMR (CD_3OD, 23 °C, δ) 2.41 (s, 3H, CN_4CH_3); $^{13}C\{^1H\}$ NMR (CD_3OD, 23 °C, ppm) 159.14 (s, CN_4CH_3), 10.15 (s, CN_4CH_3).

Anal. Calc. for $C_2H_7N_4NaO_2$: C, 16.91; H, 4.97; N, 39.43. Found: C, 16.78; H, 5.15; N, 39.67%.

3.5. Potassium methyl tetrazolate (*2*)

Prepared from potassium hydroxide (0.216 g, 3.84 mmol) and methyl tetrazole (0.356 g, 4.23 mmol) to afford **2** in 92% yield as a colorless solid: mp >300 °C; IR (Nujol, cm^{-1}) 1305 (m), 1261 (m), 1200 (s), 1115 (s), 1108 (s), 1054 (s), 1018 (s), 799 (m), 716 (s), 696 (s); ^1H NMR (CD_3OD, 23 °C, δ) 2.41 (s, 3 H, CN_4CH_3); $^{13}C\{^1H\}$ NMR (CD_3OD, 23 °C, ppm) 159.16 (s, CN_4CH_3), 10.15 (s, CN_4CH_3).

Anal. Calc. for $C_2H_3N_4K$: C, 19.66; H, 2.48; N, 45.86. Found: C, 19.77; H, 2.57; N, 45.56%.

3.6. Rubidium methyl tetrazolate (*3*)

Prepared from rubidium hydroxide hydrate (0.394 g, 3.27 mmol) and methyl tetrazole (0.302 g, 3.60 mmol) to afford **3** in 97% yield as a colorless solid: mp 254–256 °C; IR (Nujol, cm^{-1}) 1306 (m), 1194 (s), 1117 (s), 1055 (s), 1019 (s), 997 (m), 716 (s), 694 (s); ^1H NMR (CD_3OD, 23 °C, δ) 2.41 (s, 3H, CN_4CH_3); $^{13}C\{^1H\}$ NMR (CD_3OD, 23 °C, ppm) 159.17 (s, CN_4CH_3), 10.14 (s, CN_4CH_3).

Anal. Calc. for $C_2H_3N_4Rb$: C, 14.25; H, 1.79; N, 33.24. Found: C, 13.61; H, 1.82; N, 32.64%.

3.7. Cesium methyl tetrazolate (*4*)

Prepared from cesium hydroxide hydrate (0.362 g, 2.16 mmol) and methyl tetrazole (0.199 g, 2.37 mmol) to afford **4** in 97% yield as a colorless solid: mp 257 °C; IR (Nujol, cm^{-1}) 1305 (m), 1261 (m), 1194 (s), 1114 (s), 1103 (m), 1049 (s), 1015 (s), 722 (s), 715 (s), 693 (s); ^1H NMR (CD_3OD, 23 °C, δ) 2.41 (s, 3H, CN_4CH_3); $^{13}C\{^1H\}$ NMR (CD_3OD, 23 °C, ppm) 159.17 (s, CN_4CH_3), 10.20 (s, CN_4CH_3).

Anal. Calc. for $C_2H_3CsN_4$: C, 11.12; H, 1.40; N, 25.94. Found: C, 10.49; H, 1.93; N, 25.52%.

3.8. X-ray crystallographic structure determinations of *1*–*4*

Diffraction data were measured on a Bruker *X8* APEX-II kappa geometry diffractometer with Mo radiation and a graphite monochromator. Frames were collected at 100 K as a series of sweeps with the detector set at 40 mm and 0.3° between each frame and were recorded for 5 or 10 s. APEX-II [60] and SHELX-97 [61] software were used in the collection and refinement of the models. Crystals of **1** grew as colorless plates. 15762 reflections were measured, yielding 1663 unique data. Hydrogen atom positions were placed in calculated and observed positions. The sodium, nitrogen, and carbon atoms all occupy crystallographic mirrors; the methyl hydrogen atoms are necessarily disordered through the mirror. The lattice contains a two-dimensional polymeric structure that is cross-linked by hydrogen bonds. Crystals of **2** were obtained as colorless rods. 6630 reflections were counted, which averaged to 1310 independent data. Hydrogen atoms were placed in observed positions. The atoms K(1), C(1), and C(2) occupy a crystallographic mirror plane. The structure consists of a three-dimensional polymer in which each nitrogen atom is bound to two potassium atoms, and every potassium atom is bound to 8 nitrogen atoms. Crystals of **3** were colorless plates. 10496 data were integrated, which averaged into 1256 independent data. The Rb(1), C(1), and C(2) atoms occupy the crystallographic mirror. Complex **3** is isostructural with **2**, although the unit cell is slightly larger in **3** due to the longer Rb–N distances compared to the K–N distances in **2**. Complex **4** crystallized as colorless rods. 5514 data were averaged into 1370 unique data. Hydrogen atoms were placed in calculated positions. The Cs, C(1), and C(2) atoms all occupy a crystallographic mirror. The structure consists of an extended three-dimensional ionic polymer.

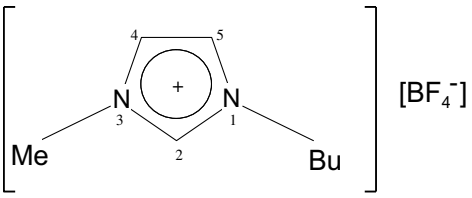

Chart 1. The ionic liquid used in this study.

ppm relative to tetramethylsilane (TMS) as external standard. The synthesized [BMIm][BF_4] has the following spectral characteristics: ^{1}H NMR ($CDCl_3$): 8.54 [s, 1H, H(2)]; 7.45 [s, 1H, H(4)]; 7.40 [s,1H, H(5)]; 4.07 [t, 2H, $^3J_{HH}$ = 6.6 Hz, H(6)]; 3.79 [s, 3H, H(10)]; 1.70 and 1.13 [2m, 4H, H(7) and H(8)]; 0.69 [t, 3H, $^3H_{HH}$ = 7.2 Hz, H(9)]. ^{13}C NMR ($CDCl_3$): 136.48 [C(2)]; 123.33 [C(4)]; 122.01 [C(5)]; 48.95 [C(6)]; 35.36 [C(10)]; 31.48 [C(7)]; 18.83 [C(8)]; 12.61 [C(9)].

Infrared spectra (IR) were recorded on ABB BOMEM model FTLA 2000-100 FTIR spectrometer using an Axiom Analytical DPR 207 immersion probe.

2.3. Water content analysis

The water content in the synthesized ILs was determined using a coulometric Karl–Fischer titration (Titrino 756 KF Metrohm) and duplicate measurements were performed with results agreeing to within 5%.

All aqueous solutions were prepared with deionized water that was purified using a LAB-UPW water purification system. The water employed has a conductivity value of less than 1.2 μS cm^{-1}.

2.4. Density measurements

All densities were determined by gravimetric analysis using a calibrated 10 mL volumetric pipette. Deionized water was employed as reference for calibration. All measurements were taken at 25.00 ± 0.01 °C using a thermostated water bath and repeated at least three times.

2.5. Viscosity measurements

The viscosities were determined using an Ubbelohde capillary viscosimeter. A 10 mL sample was used and the temperature was maintained at 25.00 ± 0.01 °C. The absolute viscosity (η) for each [BMIm][BF_4]/H_2O mixture was calculated using

$$\eta = \rho k t$$

where ρ is the density measured for each mixture, k is the constant of the viscosimeter and t is the mean flow time.

2.6. Surface tension measurements

The surface tension (γ) was measured by capillary ascension using

$$\Delta h \rho g = 2\gamma / r$$

where Δh is the capillary ascension, ρ is the density of the analyzed solution, g is the acceleration due to gravity and r is the radius of the capillary employed. The temperature was maintained constant at 25.00 ± 0.01 °C during the measurements.

2.7. Conductivity measurements

All the conductivity measurements were carried out with a Digimed DM-31 digital conductimeter equipped with a platinum electrodes cell calibrated at 25 °C by using aqueous KCl solution. The temperature of the sample was maintained at 25.00 ± 0.01 °C during the measurements.

3. Results and discussion

3.1. Water absorption by [BMIm][BF_4]

Atmospheric water is slowly absorbed by [BMIm][BF_4] as shown in Fig. 1 [room temperature and 80% air humidity]. It can be observed that the [BMIm][BF_4] absorbs water continuously and that the absorption rate decreases with time of exposure. After a 1 day exposure of [BMIm][BF_4] to an environment with 80% humidity, the water content attains only ca. 0.5 weight% and a composition of 4.0 weight% is obtained after 20-day exposure.

3.2. Physico-chemical properties

The physico-chemical properties studied in the present work (density, viscosity, excess molar volume, surface tension and conductivity) are summarized in Tables 1 and 2.

3.2.1. Density

Increasing the water content causes a decrease in solution density. Fig. 2a shows that the density depends linearly on the molar

concentration (d = 0.0376 C + 1.009), which can be useful to predict water concentrations in this class of ILs.

On the other hand, the dependence of the density with the mole fraction is not linear, as shown in Fig. 2b. Two regions are shown: a water-rich and a salt-rich region. When water is added to the IL in the salt-rich region, ($x_{[BMIm][BF_4]}$ = 1 to ca. 0.3), the density decreases slowly, but in the water-rich region, ($x_{[BMIm][BF_4]}$ = ca. 0.3 to 0) the density decreases rapidly with small additions until the value of pure water. Similar results have been described by Liu et al. [53] and Zhou et al. [54].

3.2.2. Viscosity

The viscosity of the IL solutions depends strongly on their concentration as shown in Figs. 3a and b. Table 1 shows that the viscosity for pure [BMIm][BF_4] (106.82 cP) is comparable to the density of a typical oil. The addition of water, whose viscosity is 0.959 cP, decreases solution viscosity as shown in Fig. 3. When the concentration is expressed as molarity (Fig. 3a) two regions can be observed, similarly to the previously described behavior of the density (Fig. 2b). Increasing the IL content of the mixture in the dilute region does not have much effect on increasing mixture viscosity. On the other hand, for the concentrated region, the viscosity increases rapidly with the IL concentration.

The viscosity of an IL solution can be correlated with the supramolecular structure of the liquid network. The experimental findings indicate that a small addition of water is enough to drastically change the intermolecular interactions and to affect the dependence between viscosity and concentration.

The curve viscosity versus concentration expressed in molar fraction, shown in Fig. 3b, can be fitted by an exponential function as

$$\eta = \eta_{IL}\exp(-x_{H_2O}/a)$$

where η is the viscosity of the system, η_{IL} is the viscosity of the pure IL, x_{H_2O} is the molar fraction of water and a is a constant with value of 0.212 for the [BMIm][BF_4]. This function enable the prediction of the viscosity at different water contents and also to determine water content through viscosity experiments.

The viscosity of the ILs has been described as decreasing with the addition of co-solvents proportionally to its dielectric constant [52,57,58]. Nevertheless, the viscosity of a mixture with a known IL concentration can be predicted, in general, by the exponential relationship, regardless of the co-solvent polarity [52].

3.2.3. Conductivity

Figs. 4a and b show the dependence of the specific conductivity of IL/water solutions on the concentration. The plots exhibit a maximum conductivity around 48 mS cm^{-1} at a concentration of 2.7 mol L^{-1} (Fig. 4a), corresponding to a 0.09 mole fraction (Fig. 4b).

Once again the system properties show a water-rich and a salt-rich region, shown by a maximum of the abovementioned specific conductivity. This maximum appears for a solution with an IL molarity ca. 2.7 mol L^{-1} or a mole fraction of 0.09. Fig. 4b shows that the conductivity increases rapidly in the water-rich region and decreases linearly in the salt-rich region, as IL concentration increases.

Thus, in the water-rich region, increasing conductivity may be attributed to the dissociation increase of the [BMIm][BF_4] ionic li-

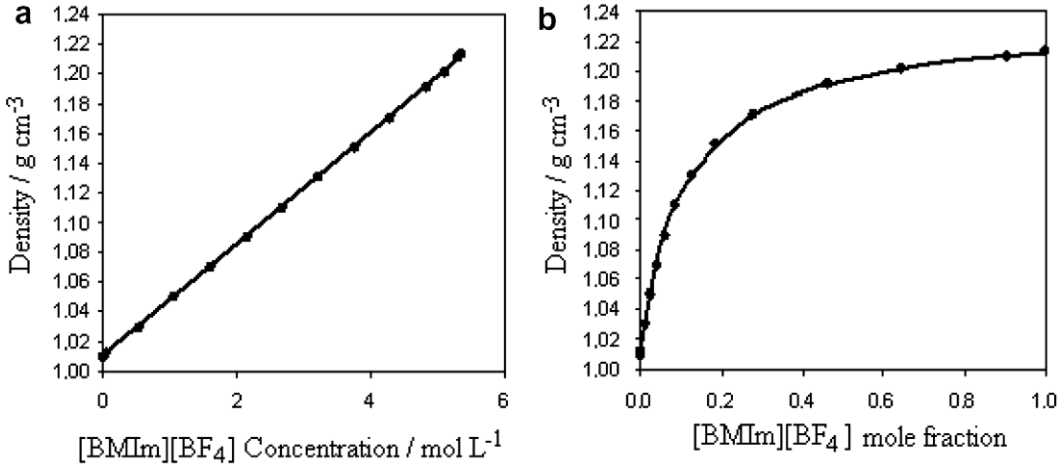

Fig. 2. Concentration dependence {molar concentration (a) and mole fraction (b)} of the density for aqueous [BMIm][BF_4] solutions.

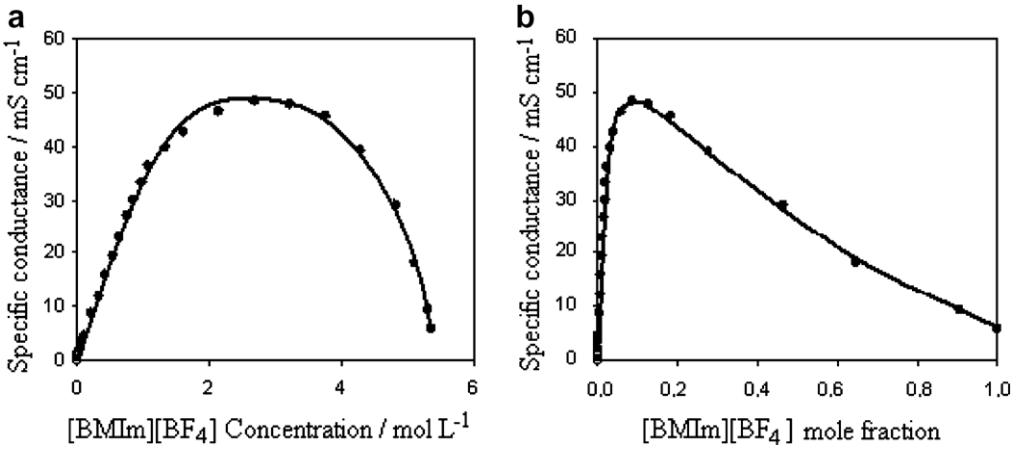

Fig. 4. Concentration dependence {molar concentration (a) and mole fraction (b)} of the specific conductance for aqueous [BMIm][BF_4] solutions.

quid. In this region, water acts as a solvent, interacting with the IL cations and anions. This interaction leads to the weakening and even breaking of the strong Coulombic forces involved in keeping ions dissociated. Therefore, in this region, solvated cations and anions are present and also water molecules that are not hydrogen bonded to the salt (the so-called "free water" [58]).

It is worthwhile pointing out that ILs may form contact ion-pairs and aggregates in solution, which cannot contribute to the ionic conduction as well as dissociated ions, responsible for conduction [59,60]. Moreover, ionic conductivity is proportional to the number of charge carrier ions and their mobility. Therefore it can be pointed out that the solvation effect of the water on the [BMIm][BF_4] has two important consequences. The first involves a reduction of the [BMIm][BF_4]$_{aq}$ structure size. In this respect, it was demonstrated that the structure of pure dialkylimidazolium ionic liquids can be considered as a highly ordered three-dimensional network of anions e cations, linked by hydrogen bonds [61–65]. The addition of water molecules to IL progressively reduces the electrostatic attractions between the ions, promoting its separation with a disruption of the hydrogen bond network leading to the formation of ionic aggregates, contact ions pairs and finally, in infinite dilution, solvated separated ion pairs. This process is expressed by the consequent increase of the ionic mobility of the ionic species. Moreover, the overall cohesive energy of the system is lowered and hence its viscosity is lowered too, as observed in Figs. 3a and b more specifically for the mixtures belonging to the water-rich region. The second immediate consequence of the dissociation of the ionic structure is the increasing number of charge carrier species responsible for electrical conduction of the system. In this way, both consequences are beneficial to increase the ionic conductivity, in agreement with experimental results obtained in this concentration region.

Another point to be considered is that the reduced cohesive energy is a likely cause of the volumetric expansion of the system from the pure IL, as will be demonstrated later.

In the salt-rich region, increasing concentration of [BMIm][BF_4] results in decreasing ionic specific conductivity. It is suggested that this is due to the exponential increase of the viscosity of the solutions in this region, as shown in Fig. 3b. Such behavior can be explained by Walden's rule [66], which is derived from the Stokes–Einstein equation, in which the diffusion coefficient of a fluid particle in a solution is inversely proportional to solution viscosity and from the Nernst–Einstein law, in which this diffusion coefficient is directly proportional to molar conductivity of the solution [67]. The resulting empirical rule is given by

$$\Lambda\eta = \text{constant}$$

which states that the product of molar conductivity (Λ) and viscosity (η) of hydrodynamic systems having moving conducting entities is a constant at a given temperature.

Thus, in the salt-rich region, the [BMIm][BF_4] solutions exhibit a decrease in the conductivity parallel to the increase in viscosity.

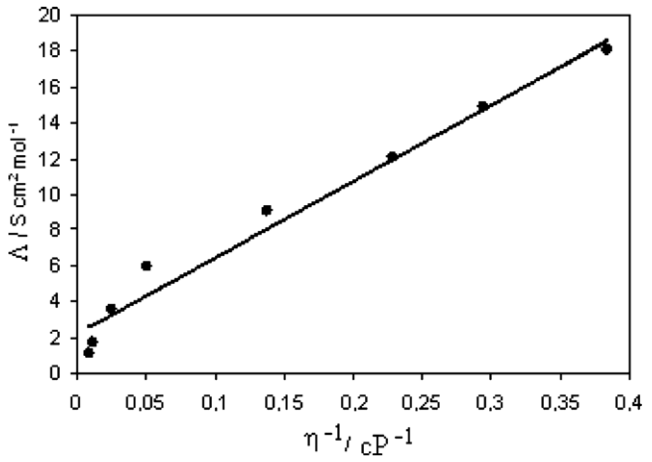

Fig. 5. Walden's plot: a plot of the molar conductivity (Λ) against the reciprocal of the viscosity (η^{-1}) for [BMIm][BF_4]. Data collected at 25 °C. — Linear plot corresponding to Walden's law.

Fig. 5 represents Walden's plot of the [BMIm][BF_4]/H_2O system for this region. The use of Walden's rule in the system studied evidence that, in the salt concentrated region, conductivity is related to the viscosity of the media i.e., in this region transport of the charge is controlled by the viscosity.

Another point that must be considered to explain the behavior observed in this region involves the reduction of the degree of dissociation of [BMIm][BF_4] because of the decreased water content, leading to a lower concentration of ionic mobile species in solution and hence decreasing the ionic conductivity. This result agrees with the general recognition that a lower degree of dissociation of a salt leads to lower conductivity due to the reduction of the charge carrier concentration.

In order to determine the limiting molar conductivity (Λ_o), the molar conductivity ($\Lambda = \kappa/C$) was plotted against the square root of the IL concentration and the Λ values in the low concentration domain were extrapolated to infinite dilution, as shown in Fig. 6. The extrapolated value found was 142.05 S cm^2 mol^{-1}. Similar results were found for other aqueous systems involving [DMIm]Br, [BMIm]Br and [EMIm]Cl [28,64].

The value of the limiting molar conductivity for solutions of [BMIm][BF_4] in water is in the same range as other classical salts like tetraalkylammonium salts [68], characteristic for 1:1 electrolytes. Thus, the solvation of [BMIm][BF_4] in water can be described by the equilibrium between the solvated contact ion pairs and the solvated unassociated ions, according to the following equation:

$$([BMIm^+ \cdots [BF_4]^-)_{H_2O} \leftrightarrow ([BMIm]^+)_{H_2O} + ([BF_4]^-)_{H_2O}$$

The specific conductivity behavior of the [BMIm][BF4]/H_2O system for low IL concentrations was studied in order to elucidate whether this IL can show association forming aggregates, i.e., micelles. A representative result is shown in Fig. 7.

It is apparent that the gradual increase of the IL concentration leads to two readily distinguishable linear dependencies. In the low concentration domain the increase of specific conductivity is due to the increasing number of $[BMIm]^+$ and $[BF_4]^-$ moieties. In this region the IL behaves like a strong electrolyte, suffering complete dissociation and behaving like a usual 1:1 electrolyte, as demonstrated by the use of Kohlrausch's law (Fig. 6). However, the abrupt change of the slope in the specific conductivity versus concentration plot indicates that micelles, start to form at the concentration corresponding to the break point, suggesting a structural resemblance of imidazolium IL to conventional cationic surfactants. The polar or hydrophilic group (the "head") is constituted by imidazolium cations, and the hydrophobic group (the "tail") is formed by nonpolar alkyl side chains. The tetrafluoroborate is the counter-ion, which has a fundamental role: when in adequate concentration, surrounding the positive charge of the aggregates, decreasing the repulsion of the head-groups. Micelles are not completely dissociated, i.e., only a small fraction remains free in solution, assuming the behavior of a weak electrolyte. The critical micellar concentration (cmc) determined is an intrinsic property and characteristic of each surface-active species.

The value obtained for the cmc for the [BMIm][BF_4]/H_2O system (around 1.0 mol L^{-1}) is considerably higher than those for typical cationic surfactants. This behavior is a consequence of the short, length of the alkyl substituents (methyl and butyl). It is well known [24–28] that, for single alkyl chain surfactants, the cmc value depends primarily on the number of carbon atom substituents incorporated in the IL structure. Above the critical micellar concentration (cmc) the increase of the specific conductivity has a smaller slope due to two reasons: (i) the association of a fraction of the counter-ion with the micellar surface results in an effective decrease in the number of ionic charge carriers and (ii) the micelles can contribute to the charge transport to a lesser extent than the free ions owing to their lower mobility. As the concentration of the surfactant ([BMIm][BF_4]) increases, the association between

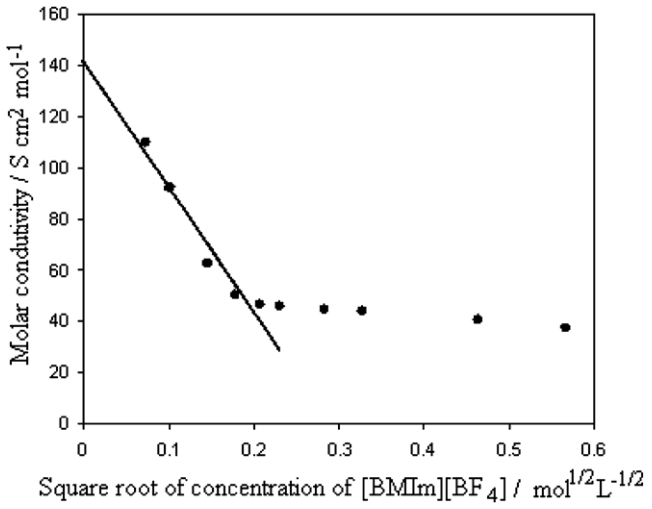

Fig. 6. Molar conductivity vs square root of concentration for aqueous [BMIm][BF_4] solutions. Data collected at 25 °C. — Linear plot corresponding to Kohlrausch's law.

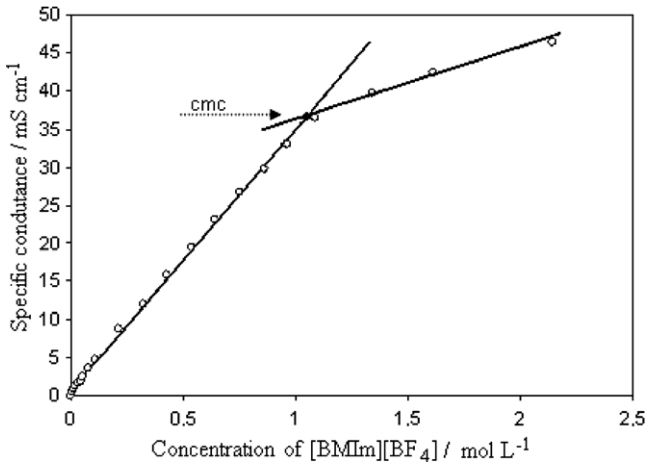

Fig. 7. Specific conductance vs concentration for aqueous [BMIm][BF_4] solutions.

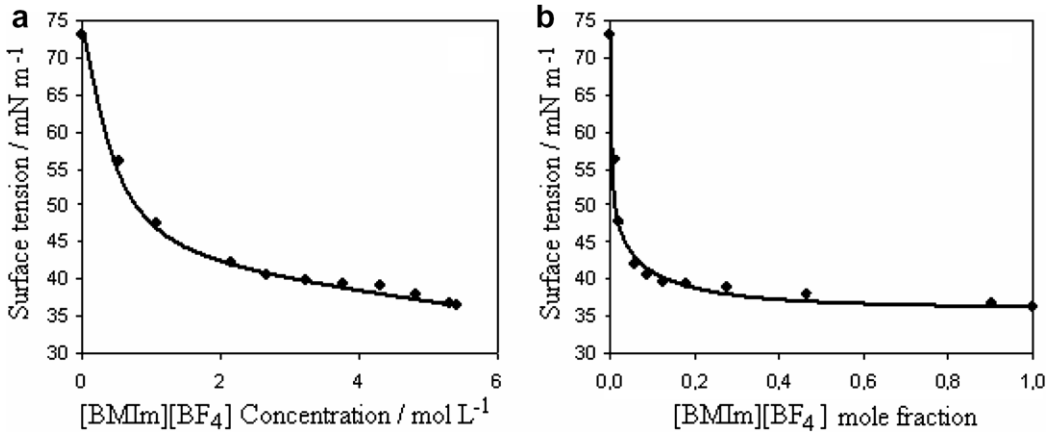

Fig. 8. Concentration dependence {molar concentration (a) and mole fraction (b)} of the surface tension for aqueous [BMIm][BF_4] solutions.

cations and anions is favored, thus resulting in a higher number of nonconducting aggregates of IL dispersed in water and a second interpenetrated phase is created within the first. The conductivity of the system, then, decreases until it reaches the low value of the pure IL, as previously explained.

3.2.4. Surface tension

As shown in Figs. 8a and b, the surface tension of the [BMIm][BF_4]/H_2O system reveals two distinct tendencies: it decreases rapidly in the water-rich region and becomes almost constant in the salt-rich region. This behavior is typical of surface active molecules showing that [BMIm][BF_4] acts as a surfactant in aqueous solution. The surface tension value obtained for pure [BMIm][BF_4] (36.43 mN m^{-1}) is somewhat higher than traditional organic solvents [69], whose values are in the 20–30 mN m^{-1} range and lower than water, which has a high surface tension, in the range of 72 mN m^{-1}, in accordance with Huddleston et al. [70].

An excess property of a solution is defined as the difference between the actual property of the mixture and that which would be obtained for an ideal solution at the same temperature, pressure and composition. So, the excess molar properties represent the deviation from ideal behavior of the mixtures and are very important for understanding the nature of the interactions and of the molecular aggregations existing in binary mixtures. The excess molar volumes (V_{exc}) were calculated from our measurements according to the following equation [71]:

$$V_{exc} = [x_1M_1 + x_2M_2/\rho] - [x_1M_1/\rho] - [x_2M_2/\rho_2]$$

where ρ is the viscosity of the mixtures, x_1 and x_2 are mole fractions, M_1 and M_2 are molar masses and ρ_1 and ρ_2 are densities of [BMIm][BF_4] and water, respectively. The plot of the excess molar volume in function of the [BMIm][BF_4] concentration is shown in Fig. 9.

From Fig. 9, it can be seen that the values of V_{exc} are positive throughout the range of composition, indicating a positive deviation from ideal behavior and suggesting that water reduces and even breaks the strong electrostatic attractions between cations and anions of the pure IL during the mixing process. This assumption was investigated using infrared spectroscopy for the [BMIm][BF_4]/H_2O system.

The IR spectra obtained for the [BMIm][BF_4] identified the characteristic C–H···F hydrogen bonding bands in the region of 3100–3200 cm^{-1} concerning the interactions of the H2, H4 and H5 of the imidazolium ring with the BF_4 anion [62,63]. The bands at 2800–3000 cm^{-1} are due to C–H stretches of methyl and butyl groups. It was observed that the bands at 3128 cm^{-1} and at 3166 cm^{-1}, ascribed to the C2 and C4, C5 hydrogen stretching,

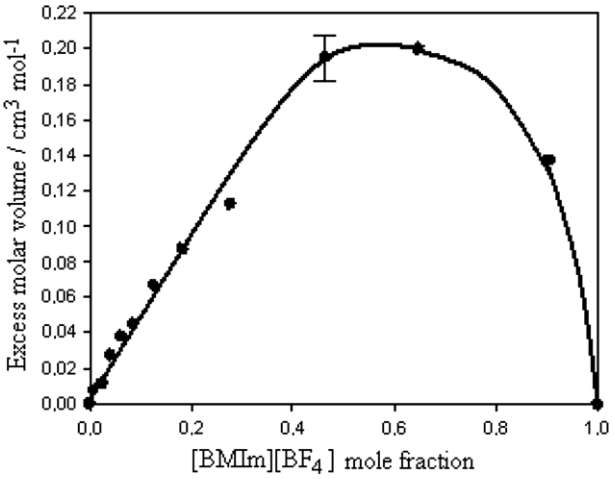

Fig. 9. Excess molar volume for [BMIm][BF_4]/H_2O mixtures at 25 °C vs mole fraction of [BMIm][BF_4].

respectively, both observed in the pure IL, are shifted as the water content increases, to 3142 cm^{-1} and 3198 cm^{-1}, respectively. This tendency suggests a weakening and even a breaking of the strong attraction forces involved between cations and anions. These results are in agreement with the conductivity measurements and excess molar volume values. The shift of the C–H stretching value can be observed until a concentration of 2.68 mol L^{-1}. For higher concentrations values, the bands pertaining to the water molecule completely overlapped the [BMIm][BF_4] bands.

4. Conclusions

The density, viscosity, and surface tension of the [BMIm][BF_4]/H_2O system depends on the molar fraction of the mixtures. It is clear that there are a water-rich and a salt-rich region in which the effect of water addition is drastically different. The presence of water strongly affects (i) the density and the surface tension of water-rich solutions and (ii) the viscosity of salt-rich solutions. Such behavior, characterized by an exponential dependence of the viscosity with the molar fraction, provides a practical method for the quantitative determination of the amount of water in the solution using simple measures of this physico-chemical property.

Specific conductivity of the IL solutions increases in the water-rich region and decreases in the salt-rich region, exhibiting a maximum at IL mole fraction ca. 0.09. Increasing specific conductivity

has been attributed to the weakness of the intermolecular interaction of the [BMIm][BF_4] structure provoked by adding water, increasing the dissociation and, consequently, increasing the ionic mobility of the ionic species. The decrease in the intermolecular interaction between the anionic and cationic species of [BMIm][BF_4] due to the addition of water has been shown by IR. The decrease of the specific conductivity in the salt-rich region has been explained taking into account the viscosity increase, which follows the empirical Walden's rule, and also considering the reduction of the dissociation degree of the IL.

Applying Kohlrausch's equation to specific conductivity for low IL concentration solutions (lower than 0.04 IL mol^{-1}) allows the determination of the [BMIm][BF_4] limiting molar conductivity. The observed value of 142.05 S cm^2 mol^{-1} is characteristic of a 1:1 electrolyte.

Conductivity and surface tension measurements, herein reported, shows that [BMIm][BF_4] IL displays cationic surfactant properties characteristic of micelles. The critical micellar concentration (cmc) of 1.07 mol L^{-1} determined through conductivity measurements indicates that [BMIm][BF_4] behaves like a weak electrolyte above this value.

Finally, the excess molar volume values of the water content IL solutions indicated a positive deviation from ideal behavior. These measures confirmed that added water in IL solution is responsible for a progressive weakness of the intermolecular interaction of IL molecules.

Thus, this study demonstrates that addition of water to [BMIm][BF_4] solutions affects density, viscosity, surface tension, specific conductivity and excess volume values which can be explained by change in the molecular organization of the solution. These results are helpful for a variety of different technological applications and in particular for electrochemical applications.

Acknowledgements

Financial support by PRONEX/FAPERGS, CNPq and the LAPPS – UFRGS for the water contents determination are gratefully acknowledged.

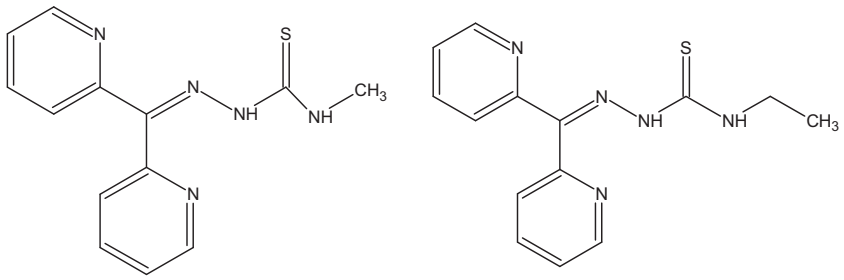

Scheme 1.

solution was heated at reflux for 3 hours and then kept at room temperature. The complex formed was filtered, washed thoroughly with ether and dried *in vacuo* over P_4O_{10}.

*2.3.3. Synthesis of [Mn(HDpyMeTsc)$_2$](ClO$_4$)$_2$ · H$_2$O (**3**)*

To a solution of HDpyMeTsc (0.271 g, 1 mmol) in hot ethanol was added $Mn(ClO_4)_2 \cdot 6H_2O$ (0.361 g, 1 mmol), and the resulting solution was heated at reflux for 3 hours and then kept at room temperature. The complex formed was filtered, washed thoroughly with ether and dried *in vacuo* over P_4O_{10}.

Single crystals of compound **1** suitable for X-ray diffraction were grown from a 1:1 (v/v) mixture of ethanol and methanol. Attempts were made to crystallize other complexes also, but unfortunately we could not isolate single crystals of suitable quality for single crystal XRD.

2.4. Physical measurements

Elemental analyses of the ligands and the complexes were done on a Vario EL III CHNS analyzer at SAIF, Kochi, India. The IR spectra were recorded on a Thermo Nicolet AVATAR 370 DTGS model FT-IR Spectrophotometer with KBr pellets at SAIF, Kochi. Electronic spectra in DMF solution were recorded on a Spectro UV–Vis Double Beam UVD-3500 spectrometer in the 200–900 nm range. The EPR spectra of the complexes were recorded on a Varian E-112 spectrometer using TCNE as the standard at the SAIF, IIT, Bombay, India. The molar conductance measurements of the complexes in dimethylformamide solutions (10^{-3} M) at room temperature were measured using a direct reading conductivity meter.

2.5. X-ray crystallography

Reddish brown crystals for the single crystal X-ray diffraction were grown by slow evaporation of the complex in ethanol/methanol (1:1) mixture. The crystallographic data and structure refinement parameters are given in Table 1. The data reduction and cell refinement were carried out using a CRYSALIS RED, Oxford Diffraction Ltd. at the National Single Crystal X-ray Diffraction facility, IIT, Bombay, India. The trial structure was solved using SHELXS-97 [16] and refinement was carried out by full-matrix least squares on F^2 (SHELXL-97) [16]. The molecular graphics employed were PLATON [17] and MERCURY [18].

Table 1
Crystal refinement parameters of [Mn(DpyMeTsc)$_2$]

Empirical formula	$C_{26}H_{24}Mn_1N_{10}S_2$
Formula weight (M)	595.63
Temperature (T) (K)	120(2)
Wavelength (Mo Kα) (Å)	0.71073
Crystal system	monoclinic
Space group	$P2_1/n$
Lattice constants	
a (Å)	10.6433(7)
b (Å)	15.1466(9)
c (Å)	17.2816(10)
α (°)	90.00
β (°)	92.179(6)
γ (°)	90.00
Volume V (Å^3)	2784.0(3)
Z	4
D_{calc} (ρ) (Mg m^{-3})	1.421
Absorption coefficient, μ (mm^{-1})	0.660
F(000)	1228
Crystal size (mm^3)	0.19 × 0.15 × 0.13
θ Range for data collection	2.94–25
Limiting indices	$-12 \leqslant h \leqslant 12$, $-18 \leqslant k \leqslant 18$, $-20 \leqslant l \leqslant 20$
Reflections collected	21 200
Unique reflections (R_{int})	4883 (0.1276)
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	4883/0/362
Goodness-of-fit on F^2	1.026
Final R indices [$I > 2\sigma(I)$]	$R_1 = 0.0636$, $wR_2 = 0.0869$
R indices (all data)	$R_1 = 0.1463$, $wR_2 = 0.1142$
Largest difference peak and hole (e Å^{-3})	0.43 and −0.427

$R_1 = \sum||F_o| - |F_c||/\sum|F_o|$.
$wR_2 = [\sum w(F_o^2 - F_c^2)^2/\sum w(F_o^2)^2]^{1/2}$.

3. Results and discussion

All the four compounds are soluble in polar organic solvents like chloroform, DMF, DMSO, etc. In compounds **1** and **4**, the thiosemicarbazones deprotonate and chelate in the thiolate form, as proved by the IR spectral data. In **2** and **3**, the ligands are in the thione form. Elemental analyses and conductivity data are in agreement with the general empirical formula [Mn(DpyMeTsc)$_2$] for the complex part of compound **1** and [Mn(DpyETsc)$_2$] for compound **4**. Compounds **2** and **3** are [Mn(DpyMeTsc)Cl$_2$] and [Mn(DpyMeTsc)$_2$](ClO$_4$)$_2$, respectively. The colors, partial elemental analyses and molar conductivities of the metal complexes are shown in Table 2. The molar conductivity measurements in 10^{-3} M DMF solutions indicate that complexes **1**, **2**, and **4** are non-electrolytes and complex **3** is probably 1:2 electrolyte [19].

*3.1. Crystal structure of [Mn(DpyMeTsc)$_2$] (**1**)*

The molecular structure of the compound along with atom numbering scheme is given in Fig. 1. The compound crystallizes into a monoclinic lattice with $P2_1/n$ space group. The two molecules of monodeprotonated ligand, coordinate to manganese *via* pyridyl nitrogen, azomethine nitrogen and thiolato sulfur atoms to form four five membered chelate rings. The coordination of sulfur occurs through deprotonation after enolization, and was confirmed by the partial single and double bond nature of C1–S1 [1.728(5) Å] and N1–C1 [1.323(6) Å] bonds. There is a slight

Table 2
Colors, partial elemental analyses and molar conductivities of the complexes

Complex	Color	λ^{a}_{m}	Found (Calc.) (%)		
			C	H	N
$[Mn(DpyMeTsc)_2]$ (**1**)	Brown	8	52.18 (52.43)	4.17 (4.06)	23.06 (23.52)

[a] Molar conductivity of 10^{-3} M DMF solution, in ohm^{-1} cm^2 mol^{-1}.

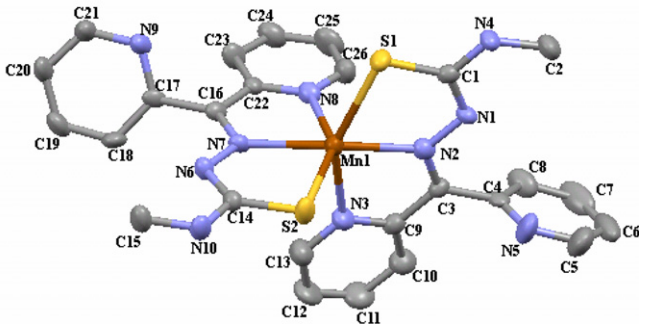

Fig. 1. The molecular structure of $[Mn(DpyMeTsc)_2]$ (**1**) along with the atom numbering scheme. The hydrogen atoms are omitted for clarity.

shortening of Mn–$N_{azomethine}$ bond distance compared to Mn–N_{py} distances; this may be attributed to the fact that the azomethine nitrogen is a stronger base compared with the pyridyl nitrogen. The ligands with their donor atoms are arranged around the manganese ion in a meridional fashion. In this compound, while S1, S2, N3 and N8 lie in the equatorial plane, N2 and N7 occupy the axial positions of the distorted octahedron. The MnN_2S_2 fragment is distorted from the mean plane by 0.013 Å. Each thiosemicarbazone fragment is subtending an angle of 147.38 and 148.41° at the Mn center, which is smaller than 180° that is expected for an ideal octahedron. The planes containing Mn, S1, N2, N3, N7 and Mn, S2, N2, N8, N7 are deviated from the mean plane by 0.179 and 0.166 Å (Mn), respectively. These factors suggest considerable distortion from an octahedral geometry around the Mn(II) center. The significant deviation from regular octahedron coordination geometry around the central metal is evident from the observed values of bond distances and angles as summarized in Table 3.

The molecules are connected in the crystal lattice through weak intermolecular hydrogen bonds; N4(H) of one molecule with S1 of another molecule [symmetry code: $2 - x$, $-y$, $1 - z$; with a H···S distance of 2.60(6) Å and angle 166(5)°] and vice-versa and N10(H) of same molecule with N(9) of another [symmetry code: $5/2 - x$, $1/2 + y$, $1/2 - z$; with a H···N distance of 2.28(6) Å and angle 169(5)°] leading to a three-dimensional network (Fig. 2). The network of electron delocalization brought about by the aromatic and metallo-aromatic [20] rings gives rise to diverse π–π and C–H···π interactions, invoking stable molecular arrangement in the unit cell. The interaction parameters are listed in Table 4.

Table 3
Selected bond lengths (Å) and bond angles (°) of $[Mn(DpyMeTsc)_2]$

Bond lengths (Å)		Bond angles (°)	
Mn(1)–N(2)	2.231(4)	N(2)–Mn(1)–N(7)	160.60(14)

N(6)–C(14)	1.342(5)	S(2)–Mn(1)–S(1)	06.23(5)
N(10)–C(14)	1.335(6)		

3.2. Infrared and electronic spectra

To clarify the mode of bonding, the IR spectra of the free ligands and manganese(II) complexes were studied and assigned on the basis of a careful comparison of the latter with the free ligand. The tentative IR spectral assignments are listed in Table 5. The IR spectra of the ligands exhibit a medium band at *ca.* 3050 cm^{-1} assigned to ν(N–H) vibration, disappears in the spectra of complexes **1** and **4**, providing strong evidence for ligand coordination to the manganese(II) ion in the deprotonated thiolate form [12]. In complexes **2** and **3**, the ν(N–H) bands are shifted slightly but are indicative of the ligands in the thione form. The ν(C=N) bands of thiosemicarbazones are found to be shifted to lower frequencies in all the complexes indicating coordination *via* the azomethine nitrogen. The involvement of this nitrogen in bonding is also supported by a shift in ν(N–N) to higher frequencies. The appearance of new bands at *ca.* 1510 cm^{-1} in complexes **1** and **4** due to the newly formed ν(N=C) support the above observation. Coordination

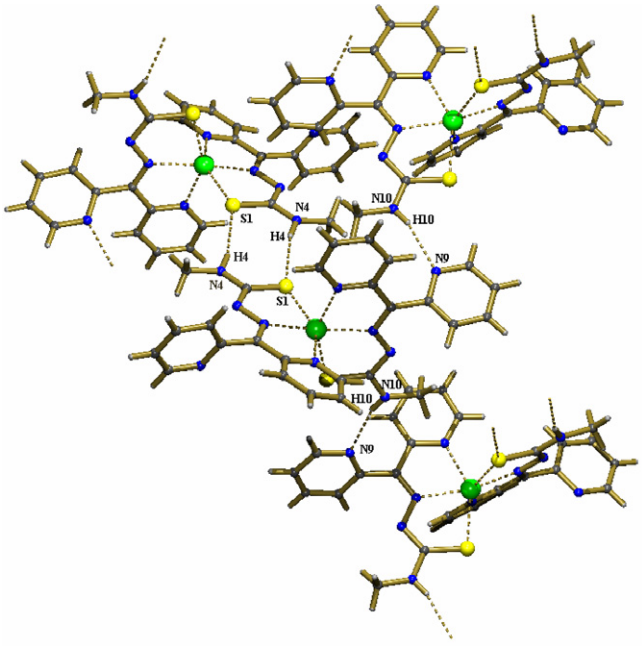

Fig. 2. Packing diagram of compound **1** showing H-bonding.

Table 4
H-bonding, π–π and C–H···π interaction parameters of the compound [Mn(DpyMeTsc)$_2$]

Donor···H···A (Å)	D–H	H···A	D···A	D–H···A
H-bonding				
N4(H)···S(1)	0.97	2.60	3.550	166
N10(H)···N(9)	0.83	2.28	3.100	169

C(19)–H(19) [1] ⩾ Cg(1)[a]	2.57	160	3.476	
Equivalent position code				
a = ½ + *x*, ½ − *y*, −1/2 + *z*		Cg(1) = Mn(1), S(1), C(1), N(1), N(2)		

D, donor; A, acceptor; Cg, centroid; α, dihedral angles between planes *I* and *J*; β, angle Cg(1)–Cg(J).

via the thiolate sulfur is indicated by the negative shift of the two bands assigned to ν(C=S) and δ(C=S) vibrations. The out-of-plane bending vibrations of the pyridine ring in uncomplexed ligands shift to higher frequencies on complexation, confirming the coordination of the ligands to the metal *via* the pyridine nitrogen [21].

The perchlorate complex shows a single broad band at 1098 cm^{-1} and a band at 637 cm^{-1}, indicating the presence of ionic perchlorate. The band at 1098 cm^{-1} is assignable to $\nu_3(ClO_4)$ and the unsplit band at 637 cm^{-1} is assignable to $\nu_4(ClO_4)$.

The ground state of the high spin octahedrally coordinated Mn^{2+} ion is $^6A_{1g}$. Since there are no other terms of sextet spin multiplicity, all the d-d transitions in high spin d^5 complexes are not only Laporte forbidden but also spin forbidden. The absorptions of the organic ligands tailing into the visible region obscure the very weak d–d absorption bands of the manganese(II) complexes. The broad band at *ca.* 24000 cm^{-1}, due to the $^4E_g \leftarrow {}^6A_{1g}$ transitions, is observed for all the complexes. The very weak bands at *ca.*18000 cm^{-1} are assigned to $^4T_{1g} \leftarrow {}^6A_{1g}$ transitions. The electronic spectral assignments are summarized in Table 6.

3.3. EPR spectra

The EPR spectra of Mn(II) may be described by the spin Hamiltonian

$$\hat{H} = g\beta HS + D[S_z^2 - S(S+1)/3] + E(S_x^2 - S_y^2)$$

where *H* is the magnetic field vector, *g* is the spectroscopic splitting factor, β is the Bohr magneton, *D* is the axial zero field splitting term, *E* is rhombic zero field splitting parameter and *S* is the electron spin vector [22]. If *D* and *E* are very small compared to *gβHS*, five EPR transitions are expected. The solid state EPR spectra of complexes **2** and **4** at 298 K are characterized by broad signals with *g* values of 2.031 and 2.097 respectively, broadening is due to dipolar interactions and random orientation of the Mn^{2+} ions [21]. Compound **3** is characterized by two *g* values at 2.073 and 5.241. The solid state EPR spectrum of complex **1** consists of five *g* values due to zero field splitting and Kramers degeneracy. The solution spectra in DMF at 77 K displayed a hyperfine sextet with *g* values 1.999 and 1.997, and *A* values 99 and 96 G, respectively for complexes **2** and **3** (Figs. 3 and 4). For complex **3,** a broad signal in the low field region is also observed with *g* value 4.642. The six hyperfine lines are due to the interaction of electron spin with the nuclear spin (^{55}Mn, *I* = 5/2). The frozen solution spectra of the complexes **1** and **4** in DMF, displayed two *g* values. The EPR spectral data of the complexes are summarized in Table 7.

The observed *g* values are very close to the free electron spin value, suggestive of the absence of spin orbit coupling in the ground state. The A_{iso} values are somewhat lower than pure ionic compounds, which reflects the covalent nature of the metal–ligand bond in the complexes. The mixing of the nuclear hyperfine levels with the zero field splitting factor produces low intensity

of the 4-nitrobenzoates of the alkaline-earths [24–28]. The triad of compounds $[Mg(H_2O)_6](4\text{-nba})_2 \cdot 2H_2O$, $[Mg(H_2O)_2(Im)_2(\eta^1\text{-}4\text{-nba})_2]$ (Im = imidazole) and $[Mg(H_2O)(N\text{-MeIm})_2(\eta^1\text{-}4\text{-nba})(\mu_2\text{-}\eta^1\text{:}\eta^1\text{-}4\text{-nba})]_2$ (*N*-MeIm = *N*-methylimidazole) demonstrate a rich and variable chemistry of 4-nitrobenzoates of Mg in terms of the binding modes of 4-nba anions as well as secondary H-bonding interactions. For calcium we reported on the structure and properties of a seven coordinated monomeric complex $[Ca(H_2O)_4(\eta^1\text{-}4\text{-nba})(\eta^2\text{-}4\text{-nba})]$ **1** [24], which exhibits both mono (η^1) and bidentate (η^2) coordination of 4-nba and $[Ca(H_2O)_3(Im)(\eta^1\text{-}4\text{-nba})_2] \cdot Im$ [25] which shows η^1 ligation of 4-nba and contains coordinated as well as free imidazole. In this paper, we present the details of the investigation of the thermal reaction of the seven coordinated Ca compound **1** in the presence of *N*-methylimidazole (*N*-MeIm) and imidazole (Im), resulting in the formation of the anhydrous mixed ligand complexes of composition $[Ca(L)(4\text{-nba})_2]$ (L = *N*-MeIm **2**; L = Im **3**).

2. Experimental

2.1. Materials and methods

All the chemicals used in this study were of reagent grade and were used as received. The starting materials and reaction products are air stable and hence were prepared under normal laboratory conditions. The complex $[Ca(H_2O)_4(\eta^1\text{-}4\text{-nba})(\eta^2\text{-}4\text{-nba})]$ **1** was prepared as described earlier [24]. Infrared (IR) spectra were recorded on a Shimadzu (IR Prestige-21) FT-IR spectrometer in the range 4000–400 cm^{-1}. The samples for the IR spectra were diluted with KBr in the solid state and the signals referenced to polystyrene bands. Electronic spectra were recorded using matched quartz cells on a Shimadzu (UV-2450) spectrophotometer. ^1H NMR spectra were recorded in DMSO-d_6 on a Bruker 400 MHz FT-NMR spectrometer. TG-DSC measurements were performed in Al_2O_3 crucibles on a STA-409PC simultaneous thermal analyzer from Netzsch in flowing air. A heating rate of 10 K min^{-1} was employed for all measurements. X-ray powder pattern were recorded on a Phillips PW-3710 diffractometer using Cu K_α radiation over 2θ range of 15–75° at a scan rate of 3° min^{-1}. The insoluble 4-nbaH obtained on acid treatment of the complexes was weighed as described earlier [15] and metal analysis was performed titrimetrically following a standard procedure. Isothermal weight loss studies were performed in an electric furnace fitted with a temperature controller.

2.2. Preparation of $[Ca(H_2O)(4\text{-nba})_2]$ **1a**

A powdered sample of **1** (0.444 g) was heated on a steam bath for ~30 min. The heat-treated sample was kept in a desiccator and allowed to cool to room temperature and weighed to obtain **1a**. The observed decrease in weight (12.15%) corresponds to the removal of three moles of water. The yield was quantitative. The compound is insoluble in MeOH, CH_3CN, etc.

Anal. Calc. for $C_{14}H_{10}CaN_2O_9$: Ca, 10.25; 4-nbaH, 85.68; CaO, 14.35. Found: Ca, 10.01; 4-nbaH, 84.8, CaO, 14.0%.

2.3. Preparation of $[Ca(N\text{-MeIm})(4\text{-nba})_2]_n$ **2**

2.3.1. Method 1

N-Methylimidazole (0.082 g, 1 mmol) was added into a freshly prepared sample of **1a** and the reaction mixture was left in a desiccator for ~30 min. The reaction mixture was washed with ether and dried to obtain **2**. Alternatively **2** can also be prepared by directly heating a mixture of a finely powdered sample of **1** (0.45 g, 1 mmol) and *N*-MeIm (0.082 g, 1 mmol) in a steam bath for ~30 min. The hot reaction mixture was cooled and washed well with ether and dried in air. Yield: (quantitative).

Anal. Calc. for $C_{18}CaH_{14}N_4O_8$ (454.43) **2**: Ca, 8.8; 4-nbaH, 73.11; CaO, 12.34; C, 47.53; H, 3.0; N, 12.32. Found: Ca, 8.8; 4-nbaH, 73, CaO, 12.2; C, 47.6; H, 3.03; N, 11.81%.

IR data: 3121(s), 2967(s), 2855(w), 1614(s), 1584(s), 1520(m), 1402(s), 1375(s), 1344(s), 1321(s), 1279(s), 1230(m), 1107(s), 1014(s), 1082(m), 934(s), 878(s), 822(s), 800(s), 752(s), 727(s), 667(s), 621(s), 559(s), 509(s) cm^{-1}.

UV–Vis 274 nm (23 775 L mol^{-1} cm^{-1}).

^1H NMR (DMSO-d_6) δ (in ppm): 3.63 (s, 3H); 6.86 (s, 1H); 7.09 (s, 1H); 7.55 (s, 1H); 8.16 (m, 4H).

DSC data (in °C): 188 (*endo*), 412 (*exo*), 558 (*exo*).

2.3.2. Method 2

A powdered sample of **1** (1.78 g, 4 mmol) was heated with *N*-MeIm (1.4 ml, 17 mmol) on a steam bath for ~1 h to obtain a light yellow solid. To this hot mass distilled water (~8 ml) was added and the mixture reheated to obtain a pale yellow solution. The hot solution was quickly filtered and kept aside for crystallization. Fine colorless blocks of crystals suitable for X-ray study, which separated were washed with ether (5 ml) and dried in air. Yield: 60%. The use of reduced amounts of *N*-MeIm in the thermal reaction or excess water for recrystallisation results in the formation of the tetraaqua compound **1** in accordance with its hydration characteristics (*vide infra*). The infrared spectrum and the DSC thermogram of this product is identical with that of the product obtained in the thermal reaction.

2.4. Preparation of $[Ca(Im)(4\text{-nba})_2]$ **3**

Imidazole (0.068 g, 1 mmol) was added into a freshly prepared sample of **1a** and the reaction mixture was left in a desiccator for ~30 min. The reaction mixture was washed with ether and dried to obtain **3**. Alternatively **3** can also be prepared by directly heating a mixture of a finely powdered sample of **1** (0.45 g, 1 mmol) and Im (0.068 g, 1 mmol) in a steam bath for ~30 min. The hot reaction mixture was cooled and was washed well with ether and dried in air. Yield: (quantitative).

Anal. Calc. for $C_{17}CaH_{12}N_4O_8$ **3**: Ca, 9.08; 4-nbaH, 75.88; CaO, 12.73; C, 46.31; H, 2.72; N, 12.71. Found: Ca, 8.9; 4-nbaH, 74.28; CaO, 12.3; C, 45.95; H, 3.13; N, 10.94%.

IR data: 3381(s), 3223(s), 3061(w), 2941(w), 1604(w), 1570(s), 1516(s), 1490(m), 1402(s), 1348(s), 1321(s), 1261(s), 1171(m), 1142(m), 1107(s), 1066(s), 1014(s), 935(s), 918(s), 860(s), 825(s), 802(s), 752(s), 740(s), 723(s), 659(s), 617(s), 497(s), 511(s) cm^{-1}.

^1H NMR (DMSO-d_6) δ (in ppm): 7.00 (s, 2H); 7.63 (s, 1H); 8.13 (m, 4H).

DSC data (in °C): 198 (*endo*), 415 (*exo*), 547 (*exo*).

2.5. Rehydration studies

A powdered sample of **2** (200 mg) was suspended in water (~5 ml) and the reaction mixture left undisturbed overnight. The reaction mixture was filtered and the residue was washed with alcohol followed by ether and dried to obtain **1** in quantitative yields. The formation of **1** is evidenced by its characteristic IR spectrum and DSC thermogram. Alternatively **2** can be transformed to **1** by suspending an amount (200 mg) of **2** in water (5 ml) and heating the solution till dissolution of the solid. The hot solution is cooled to obtain **1** in quantitative yield. The equilibration of a powdered sample of **3** over water vapour, resulted in the

formation of the starting compound **1** in quantitative yield in about a day as evidenced by its characteristic IR spectrum and DSC thermogram.

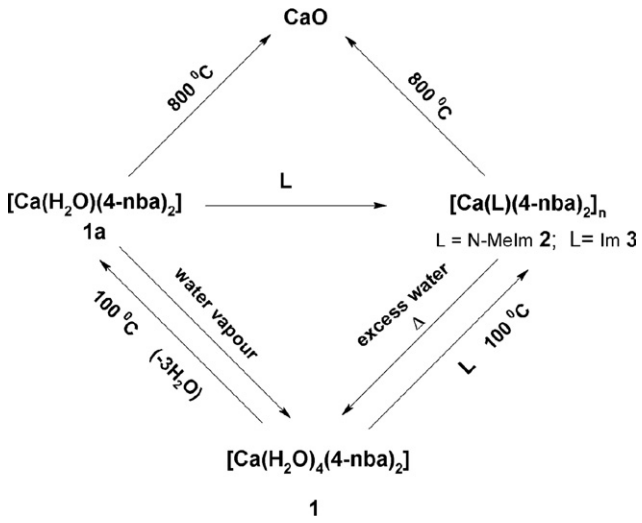
2.6. X-ray crystallography

Intensity data for **2** were collected on a Bruker Smart Apex CCD diffractometer using graphite-monochromated Mo Kα radiation. The data integration and reduction were processed with SAINT software [29]. An empirical absorption correction was applied to the collected reflections with SADABS [30]. The structure was solved with direct methods using SHELXS-97 and refinement was done against F^2 using SHELXL-97 [31]. All non-hydrogen atoms were refined anisotropically. Aromatic hydrogens were introduced on calculated positions and included in the refinement riding on their respective parent atoms. The technical details of data acquisition and some selected refinement results for **2** are listed in Table 1.

3. Results and discussion

3.1. Synthesis and spectroscopy

Heating of a solid sample of the tetrahydrate **1** at 100 °C resulted in the loss of three moles of water leading to the formation of a monohydrate $[Ca(H_2O)(4\text{-nba})_2]$ **1a** (Scheme 1). The presence of water in **1a** is evidenced by the strong and broad absorption around 3500 cm^{-1} in its infrared spectrum assignable to O–H vibration. It is to be noted that the profile of the O–H signal of compound **1a** is quite different as compared to that of the tetrahydrate compound **1**. In addition the IR signals of the nitro and carboxylate functionalities, which occur between 1300 and 1650 cm^{-1} are broadened in **1a** as compared to the spectrum of **1** (Fig. 1). On exposure to moisture the monohydrate rapidly transforms into the seven coordinated starting material **1.** Interestingly, the reaction of *N*-MeIm or Im with the monohydrate **1a** results in the displacement of water by the N-donor ligands and the formation of anhydrous mixed ligand compounds **2** or **3** having molar composition of Ca:4-nba:*N*-MeIm(Im) 1:2:1 (Scheme 1). The use of excess *N*-MeIm or Im in the thermal reaction did not result in the formation of new products containing additional N-donor ligands. The anhydrous mixed ligand compounds **2** or **3** can also be synthesized in a single step by directly heating a mixture of powdered sample of **1** and *N*-MeIm in a 1:1 mole ratio. The presence of the N-donor ligands in compounds **2** and **3** can be readily confirmed by their NMR spectra which exhibit the characteristic signals of 4-nba, *N*-MeIm or Im. The formation of the anhydrous compounds **2** or **3** is evidenced by their IR spectra, which are devoid of the signals for O–H vibrations of water and is further confirmed by the appearance of additional bands due to the incorporation of the N-donor ligand in its mid IR spectrum (Fig. 1). Compounds **2** and **3** are relatively stable compared to the moisture sensitive monohydrate **1a**. However, both **2** and **3** can be transformed to **1** by suspending them in water overnight or alternatively by heating **2** or **3** in water (Scheme 1). Crystals of **2** suitable for structure determination were prepared by heating a mixture of **1** and excess *N*-MeIm at 100 °C followed by recrystallisation from minimum water. Similar attempts to prepare compound **3** in crystalline form suitable for



Scheme 1.

X-ray structure determination by solution method always resulted in the formation of the known monomeric compound $[Ca(H_2O)_3(Im)(\eta^1\text{-4-nba})_2]\cdot Im$. The compounds **1a**, **2** and **3** were formulated based on the elemental analysis and the mass loss leading to the formation of CaO on pyrolysis in a Bunsen flame. All the compounds exhibit several signals in the mid IR region indicating the presence of the organic moieties. However, based only on the infrared data the exact nature of the binding of the 4-nba ligand cannot be confirmed. The UV–Vis spectra of all compounds exhibit an absorption in the UV region around 274 nm assignable to the charge transfer of the aromatic 4-nba ligand.

3.2. Crystal structure description of **2**

Compound **2** crystallises in the triclinic space group $P\bar{1}$ and all atoms are situated in general positions. The structure reveals that **2** is a polymer and can be formulated as *catena*-poly[[(*N*-methylimidazole)calcium(II)](μ_2-η^1:η^1-4-nitrobenzoato)(μ_3-η^2:η^1-4-nitrobenzoato)]. The structure of $[[Ca(N\text{-MeIm})](\mu_2\text{-}\eta^1\text{:}\eta^1\text{-4-nba})(\mu_3\text{-}\eta^2\text{:}\eta^1\text{-4-nba})]_n$ **2** consists of a central Ca(II) ion, a terminal *N*-MeIm ligand and two crystallographically independent 4-nba ligands. In the crystal structure, each Ca(II) is bonded to a nitrogen atom of *N*-MeIm and five oxygen atoms from five symmetry related 4-nba ligands resulting in a distorted $\{CaO_5N\}$ octahedron (Fig. 2). The geometric parameters of the 4-nba anions and *N*-MeIm are in the normal range and are comparable with literature values [24–27]. The Ca–O distances in **2** range from 2.2823(12) to 2.4507(11) Å (Table 2) and are in agreement with literature values [24,25]. The Ca–N bond is longer at 2.5088(14) Å. The *cis* O–Ca–O and O–Ca–N angles range from 73.71(4)° to 107.39(4)° while the trans O–Ca–O and O–Ca–N angles range from 163.97(4)° to 175.54(4)° indicating a distorted octahedron. It is interesting to note that both 4-nitrobenzoates in each formula unit are coordinated to the central Ca(II) in different bridging modes (Fig. 2). One of the two 4-nba anions in each formula unit functions as a bridging bidentate ligand (μ_2-η^1:η^1-4-nba) (Supplementary data, Fig. 1) and is linked to two symmetry related Ca(II) ions via O5 and O6 atoms resulting in the formation of an infinite chain extending along *a* axis with a Ca···Ca separation of 5.531(1) Å. The second independent ligand (μ_3-η^2:η^1-4-nba) is coordinated to three different Ca(II) ions with both the carboxylate oxygen atoms O1 and O2 linked to the same infinite chain formed earlier and one of the carboxylate oxygen atoms (O1) functioning as a monoatomic bridge between two symmetry related Ca(II) ions (Supplementary data, Figs. 2 and 3). This monoatomic bridge serves to link the two infinite chains with a shorter Ca···Ca separation of 3.8585(7) Å resulting in the formation of a one-dimensional ladder structure (Fig. 3).

It is to be noted that Ca(II) forms a polymeric compound with 4-nba in the presence of *N*-MeIm unlike Mg(II) which forms a centrosymmetric dimeric complex $[Mg(H_2O)(N\text{-MeIm})_2(\eta^1\text{-4-nba})(\mu_2\text{-}\eta^1\text{:}\eta^1\text{-4-nba})]_2$ [26]. The coordination polymer **2** and the previously reported monomeric compounds $[Ca(H_2O)_4(\eta^1\text{-4-nba})(\eta^2\text{-4-nba})]$ **1** [24] and $[Ca(H_2O)_3(Im)(\eta^1\text{-4-nba})_2]\cdot Im$ [25] constitute a triad of Ca(II) compounds having Ca:4-nba in a 1:2 mole ratio and showing different binding modes of the 4-nba ligand. In terms of secondary interactions **1** shows only O–H···O interactions while the monomeric imidazole compound is involved in three varieties of H-bond-

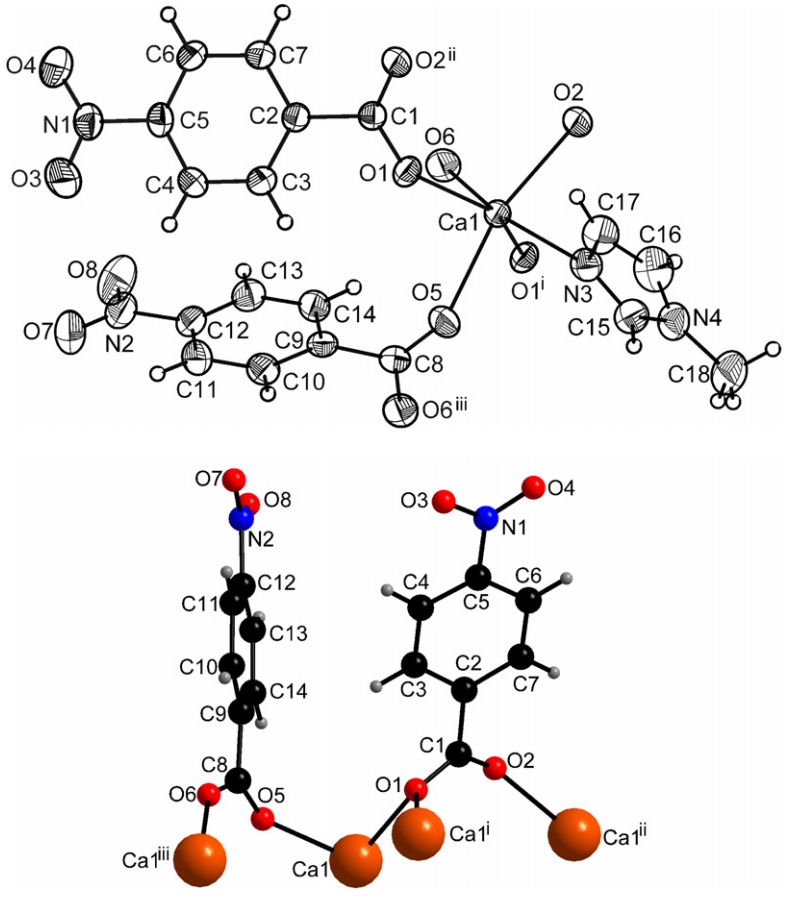

Fig. 2. The coordination sphere of Ca(II) in **2** showing the atom-labeling scheme. Displacement ellipsoids are drawn at the 50% probability level except for the H atoms, which are shown as circles of arbitrary radius (top). The μ_2-η^1:η^1 (O5,O6) and μ_3-η^2:η^1 (O1, O1, O2) bridging binding modes of the 4-nitrobenzoate ligands in **2** (bottom). Symmetry code: (i) $-x+1, -y+1, -z+1$; (ii) $-x+2, -y+1, -z+1$; (iii) $x-1, y, z$.

ing interactions namely O–H···O, N–H···O and O–H···N. The absence of coordinated water as well as methylation of the nitrogen atom in *N*-MeIm in **2** blocks the O–H···O, N–H···O and O–H···N interactions. An analysis of the structure of **2** reveals that the anhydrous compound is involved in only C–H···O interactions (Supplementary data, Fig. 4) with the oxygen atoms of the nitro groups functioning as H-acceptors and the methyl group of imidazole as well as H atoms on the aromatic ring functioning as H-donors. The geometric parameters of these hydrogen bonds are listed in Table 3.

3.3. Comparative study of Ca(II) coordination polymers

A survey of the reported structures of Ca(II) carboxylates reveals that formation of a polymeric chain due to the bridging nature of the carboxylate ligand is a characteristic structural feature of many Ca(II) carboxylates. Several polymeric Ca(II) carboxylates of varying dimensionalities (D) [17–23,32–52] have been reported in the literature many of which are 1-D polymers (Table 4). A comparative study of 30 different Ca(II) 1-D polymers reveals that the coordination number of Ca(II) in these compounds varies from 6 to 10, with eight coordination observed in many cases. Hexacoordination around Ca(II) is observed in compound **2** as well as $[Ca(Sa)_2(Phen)]_n$ and $[Ca(H_2O)_2(C_9H_8NO_4)_2]\cdot 2.5H_2O]_n$ (for abbreviations see Table 4). Of the several Ca(II) coordination polymers reported in the literature using substituted benzene carboxylic acids, compound **2** constitutes the first example of a Ca(II) coordination polymer derived from 4-nba ligand as the two other known Ca(II) compounds of 4-nba are monomeric in nature. A wide range of Ca···Ca distances between 3.612(1) and 9.816(1) Å are observed for the different Ca(II) 1-D polymeric compounds listed in the comparative table. The Ca···Ca separation of 3.8585(7) Å between the chains in the ladder compound is comparable with the Ca–Ca distance of around 4.0 Å observed in several coordination polymers listed in Table 4 while the Ca···Ca separation of 5.531(1) Å across the chains in **2** is relatively longer. A very long Ca···Ca distance of 9.816(1) Å is observed in the one-dimensional polymer $[[Ca(H_2O)_4(AlP)_2](H_2O)]_n$ containing the 5-aminoisophthalate dianion. Interestingly in the related 1-D Ca(II) polymer derived from isophthalic acid which exhibits a triple helix structure, Ca···Ca separations of 3.6402(3) and 3.8705(4) Å are reported. These observations indicate that the Ca···Ca distances across the polymeric chain in the coordination polymers are determined by a combination of several factors, which include the electronic and steric requirements of the central metal, the denticity, flexibility, bridging behavior, H-bonding characteristics of the carboxylate ligand, presence of ancillary ligands, etc.

3.4. Thermal studies

The temperature for the thermal synthesis of compounds **2** and **3** was chosen based on the thermal characteristics of compound **1**. A comparison of the thermal behavior of the tetrahydrate **1** and the monohydrate **1a** reveals that the DSC thermograms of **1a** is identical to that of compound **1** above 100 °C when the tetrahydrate **1** emits three moles of water forming the monohydrate (see Supple-

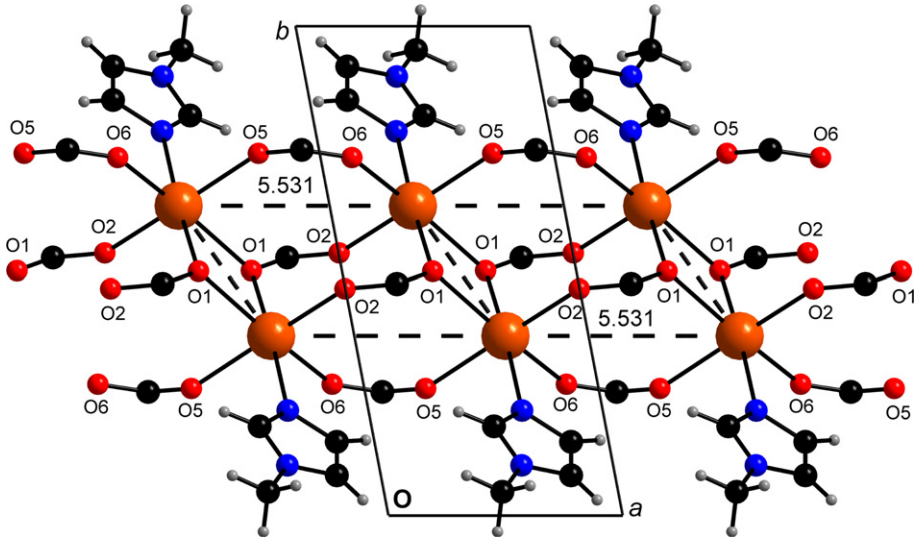

Fig. 3. A view of the bridging bidentate coordination (μ_2-η^1:η^1) of 4-nba through O5 and O6 leading to a one-dimensional polymeric Ca(II) chain extending along *a* with Ca···Ca separation of 5.531(1) Å. The monoatomic bridging mode of O1 in the second 4-nba ligand results in the linking of two infinite chains. In the chains each Ca(II) is bonded to five O atoms and one N atom. For clarity only the carboxylate groups are shown.

Table 4
Ca···Ca distances across the chain in reported one-dimensional (1-D) Ca(II) coordination polymers

Compound	C.N.	Ca···Ca distance (Å)	Reference
$[[Ca(H_2O)_3(4\text{-fba})](4\text{-fba})]_n$	8	3.612(1)	[32]
$[Ca(H_2O)_3(benz)_2]_n$	8	3.6146(4)	[33]
