Abstract

The coordination complexes of trivalent f-element pertechnetates and perrhenates with some N-donor ligands were determined by using X-ray structural analysis: Nd^{3+} perrhenate with 2,6-bis(tetramethylfurano)-1,2,4-triazin-3-yl)-pyridine ($[Nd(FBTP)_3ReO_4](ReO_4)_2 \cdot 2H_2O$ (**I**)), tris(2-pyridylmethyl)amine ($[Nd(TPA)(ReO_4)_3]$ (**II**)) and *N*,*N*′-tetraethylmalonamide ($[Nd(TEMA)_4](ReO_4)_3$ (**III**)). The coordination number of Nd is 10 in **I**, 9 in **II** and 8 in **III**. The complexes of Nd^{3+} pertechnetate and Am^{3+} pertechnetate with TPA have been also synthesized ($Nd(TPA)(TcO_4)_3$ (**IV**) and $Am(TPA)(TcO_4)_3$ (**V**)). The structure **II** does not change on replacement of perrhenate by pertechnetate and neodymium by americium.

Keywords: Trivalent f-element; Pertechnetates; Perrhenates; Coordination complexes; N-donor ligands

1. Introduction

Interactions between the pertechnetate anion and actinide cations can occur in the course of nuclear fuel processing and nuclear waste treatment and can interfere with some stages of nuclear fuel processing. Structural characterization of actinide compounds with the pertechnetate anion could clarify to some extent the role of such interactions in technology. Complexes of uranyl [1,2], neptunyl [3] and thorium [1] with pertechnetate have been prepared and structurally characterized. Complexes of uranyl [2,4], neptunium(V) [5] and uranium(IV) [6] with the perrhenate anion, an excellent analogue of the pertechnetate anion, have also been investigated. In these complexes, both the pertechnetate and the perrhenate anions directly coordinate to the actinide metal center, demonstrating the high affinity of these tetraoxoanions toward ions of actinides with different oxidation states.

We have investigated coordination complexes of trivalent f-element pertechnetates and perrhenates with some N-donor ligands which are considered as promising agents for new separation processes such as SANEX and related projects. Such complexes could be useful as precursors for ceramic–metallic (cermet) composite preparations. Regarding targets for minor actinide incineration, cermet composites have been identified [7,8] as the materials with the best thermal conductivity that can help to reduce the operating temperature.

2. Experimental

2.1. Synthesis of Nd^{3+} and Am^{3+} perrhenate and pertechnetate complexes with N-bearing neutral ligands

Nd^{3+} perrhenate complexes with 2,6-bis(tetramethylfurano)-1,2,4-triazin-3-yl)-pyridine (FBTP), tris(2-pyridylmethyl)amine (TPA) and *N*,*N*′-tetraethylmalonamide (TEMA) were synthesized and their structures were determined by X-ray structural analysis. The compositions of the new complexes were $[Nd(FBTP)_3ReO_4](ReO_4)_2 \cdot 2H_2O$ (**I**), $[Nd(TPA)(ReO_4)_3]$ (**II**) and $[Nd(TEMA)_4](ReO_4)_3$ (**III**). Nd^{3+} pertechnetate and americium pertechnetate complexes with TPA were also synthesized ($Nd(TPA)(TcO_4)_3$ (**IV**) and $Am(TPA)(TcO_4)_3$ (**V**)). All compounds were formed during the isothermal evaporation ($T \sim 20$ °C) of solutions, prepared in the following manner: freshly prepared $Nd(OH)_3$ or $Am(OH)_3$ was dissolved in a calculated amount of 0.01 M $HReO_4$ or $HTcO_4$ in H_2O and this solution was evaporated to dryness at $T \leqslant 100$ °C. The residue was dissolved in a minimal quantity of ethanol and a solution of the ligand in ethanol was added to obtain a 1:3 Nd:ligand molar ratio.

2.2. X-ray analysis

Data for $[Nd(FBTP)_3ReO_4](ReO_4)_2 \cdot 4H_2O$ (**I**) and $[Nd(TPA)(ReO_4)_3]$ (**II**) were collected on a Nonius Kappa CCD area detector diffractometer (Mo $K\alpha$ radiation, graphite monochromator). The lattice parameters were determined from 10 images recorded with 1° ϕ-scans and later refined on all data. A hemisphere of the reciprocal space was measured. The crystal-to-detector distance was fixed at 30 mm. The data were processed with the HKL package [9]. Absorption effects were empirically corrected with the MULABS routine in PLATON [10]. The structures were solved by the heavy-atom method with SHELXS97 [11] and subsequent difference Fourier-syntheses and refined by full-matrix least-squares on F^2 with SHELXL97 [11]. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms of organic ligands were placed in idealized calculated positions and refined as riding atoms with displacement parameters equal to 1.2 (CH and CH_2) or 1.5 (CH_3) times that of the attached carbon atom. The hydrogen atoms of crystallization water molecules in **I** were not located. The value of the Flack parameter [12] for **II** was −0.014(9) showing the correctness of the determination

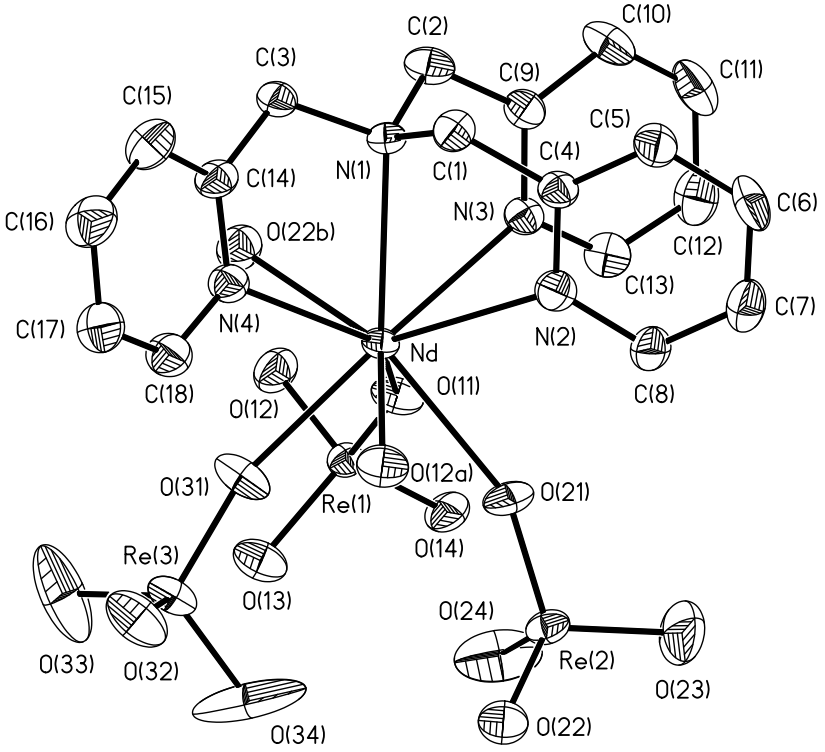

Fig. 4. A view of **II**, showing the atom labelling scheme. Displacement ellipsoids are drawn at the 30% probability level and H atoms are omitted.

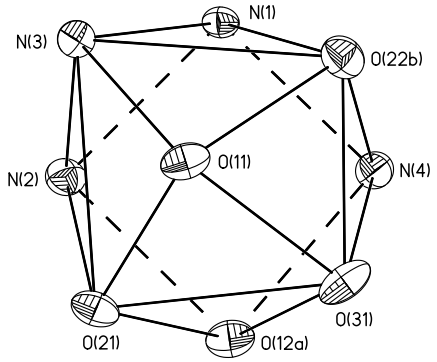

Fig. 5. Coordination polyhedron of the Nd atom in **II**.

of the absolute structure. Crystal data for the structures are given in Table 1.

X-ray diffraction analysis of $[Nd(TEMA)_4](ReO_4)_3$ (**III**) was performed with a single-crystal fragment. The main crystal data, data collection, and refinement for **III** are presented in Table 1. Experimental data were collected on a Bruker AXS SMART 1000 CCD automated diffractometer (Mo Kα radiation, graphite monochromator). The experimental intensities were empirically corrected for absorption using SADABS [13]. The structure was solved by direct methods (SHELXS97) and refined by full-matrix least-squares procedure on F^2 (SHELXL97) in an anisotropic approximation for all the non-hydrogen atoms. The perrhenate anions are partially disordered. This disordering was indicated by the shape and size of the thermal vibration ellipsoids. Attempts to refine the structure with the perrhenate anions disordered over two positions failed. The $Re(1)O_4$, $Re(2)O_4$ and $Re(3)O_4$ groups were restrained using DFIX (free variable 3) and refined as regular tetrahedra. The $Re(2)O_4$ group was refined with the same anisotropic displacement parameters for all atoms. The positions of the hydrogen atoms in TEMA were added in calculated positions and refined using a riding model. The H atoms of CH_2 groups were refined with $U_{iso}(H) = 1.2U_{eq}(C)$. The H atoms of CH_3 groups were refined including free rotation about C–C bonds with $U_{iso}(H) = 1.5U_{eq}(C)$.

The molecular drawings for **I**, **II** and **III** were done with SHELXTL [14].

The X-ray powder patterns were measured with a model XDC-700 focusing Guinier-Hägg camera (Jungner Instrument, Sweden) using Cu Kα1 radiation, with Si as an internal standard. The X-ray patterns were indexed and cell parameters were refined using the CRYSFIRE program suite [15].

The IR spectra were recorded in the range 4000–400 cm^{-1} using a Specord M80 spectrophotometer at room temperature in the NaCl matrix.

3. Results and discussion

One of three FBTP ligands in the structure of **I** is shown in Fig. 1. Three tridentate ligands linked to a Nd atom together with a monodentate perrhenate anion form the complex cation $[Nd(FBTP)_3ReO_4]^{2+}$ (Fig. 2). Interatomic distances for the Nd atom environment are given in Table 2. The complex cation is close to (non-crystallographic) C_3 symmetry (Fig. 2). The Nd, Re(1) and O(1) atoms are on a pseudo-threefold axis. Symmetric coordination of the FBTP ligands results in the formation of a rather unusual coordination polyhedron (coordination number 10) having three quadrilateral faces (Fig. 3). A similar coordination

polyhedron can be found in La^{3+} complexes containing three terpyridine molecules and coordinated water or acetonitrile [16], but the authors of that work did not discuss the coordination polyhedra. Two ReO_4 groups in **I** are outer sphere anions. Four crystallization water molecules are, possibly, partially disordered.

The Nd atom in **II** is nine-coordinated. All four N atoms of the TPA ligand enter the coordination sphere of the Nd atom. Such coordination is typical of TPA with Ln^{3+}, U^{3+} or U^{4+} [17–19]. In contrast to **I**, all three perrhenate anions in **II** are involved in coordination with the Nd atom (Fig. 4). One anion acts as a monodentate ligand, whilst two others are bidentate-bridging ones. The Nd–N and Nd–O distances are given in Table 2. The coordination polyhedron of the Nd atom in **II** can be described as a distorted capped square antiprism (Fig. 5). The bridging function of the two perrhenate anions results in the formation of chains along the [0 0 1] direction (Fig. 6).

Two crystallographically independent Nd(1) and Nd(2) atoms in **III** have coordination environments formed by oxygen atoms of four TEMA ligands (coordination number 8) (Fig. 7). Each TEMA ligand links to the Nd atom in a

Table 4
Probable assignment of some characteristic absorption bands of $[Nd(FBTP)_3ReO_4](ReO_4)_2 \cdot 4H_2O$ (**I**), $[Nd(TPA)(ReO_4)_3]$ (**II**) and $[Nd(TEMA)_4](ReO_4)_3$ (**III**)

Assignment	The maxima of the absorption bands (cm^{-1})

ν(CC); ν(NC); δ(CCN); $\Delta(CH_3)$;	1636, 1588, 1556, 1540, 1528, 1496, 1476, 1456,1436, 1364, 1300, 1268, 1212, 1178, 1128, 1092, 1022	1624, 1604, 1446, 1396, 1380, 1156, 1100, 1088	1608, 1580, 1508, 1476, 1460, 1382, 1360, 1264, 1212, 1152, 1100, 1076
$\nu(ReO_4^-)$	932, 909	952, 936, 922	908, 904
$\rho(CH)_{Pyr}$	616	634	622

bidentate mode. Structure **III** contains $[Nd(TEMA)_4]^{3+}$ complex cations. The perrhenate anions are not involved in the coordination sphere of the Nd(1) and Nd(2) atoms. Interatomic distances in the Nd(1) and Nd(2) atom environments are given in Table 2. The coordination polyhedra of the Nd(1) and Nd(2) atoms can be described as distorted square antiprisms. The average bond distance in the coordination sphere of Nd(1) is 2.424 Å, the largest deviation of oxygen atoms from the square faces is 0.109(4) Å. The average Nd(2) bond length is 2.418 Å, both square faces are planar within the 0.096(4) Å limit.

There are three different ways of arranging bidentate ligands along the various edges of a tetragonal antiprism and two of them result in D_{2d} molecular symmetry [20]. In **III** both possibilities of the TEMA fitting are realized, as shown in Fig. 8.

FBTP with neodymium pertechnetate gives a crystalline complex, but its X-ray powder diffraction pattern differs from that of complex **I**. In contrast to **I** and **III**, structure **II** does not change due to replacement of perrhenate by pertechnetate and neodymium by americium. Thus the corresponding compounds can be given the formulas $[Nd(TPA)(TcO_4)_3]$ (**IV**) and $[Am(TPA)(TcO_4)_3]$ (**V**). X-ray pattern indexing gives the unit cell constants indicated in Table 3 for **IV** and **V**.

The conditions under which complex **III** was prepared using neodymium pertechnetate yielded only amorphous products.

The IR spectra of complexes **I**–**III** consist of numerous bands due to the large organic ligands containing different functional groups which are active in the spectra. Table 4 indicates the probable assignments for some characteristic absorption bands that should be taken into account; in the 1700–1000 cm^{-1} range are situated vibration frequencies of the furan and pyridine rings, which are hardly mixed ν(CC), ν(NC), δ(CCN) and δ(CH) [21].

In the range of valent vibrations of the perrhenate ion, in all the spectra high-intensity split $\nu(ReO_4^-)$ absorption bands are observed, for which the maxima are largely shifted towards the low-frequency region in comparison with the non-coordinated ion [22].

4. Conclusions

1. The complexes $[Nd(FBTP)_3ReO_4](ReO_4)_2 \cdot 2H_2O$ (I), $[Nd(TPA)(ReO_4)_3]$ (**II**) and $[Nd(TEMA)_4](ReO_4)_3$ (**III**) were synthesized and their structures were determined by X-ray diffraction [FBTP is 2,6-bis(tetramethylfurano)-1,2,4-triazin-3-yl)-pyridine, TPA is tris(2-pyridylmethyl)amine and TEMA is *N*,*N*′-tetraethylmalonamide.
2. Pertechnetate analogue complexes were synthesized with Nd or Am, and only $[M(III)(TPA)(TcO_4)_3]$ are isostructural to **II**.

ABSTRACT

Reaction of phosphorus ylide $Ph_3PCHC(O)C_6H_4Cl$ ($\mathbf{Y}_1$) with HgX_2 (X = Cl, Br and I) and ylide $(p\text{-tolyl})_3PCHC(O)CH_3$ ($\mathbf{Y}_2$) with HgI_2 in equimolar ratios using methanol as solvent leads to binuclear products. The bridge-splitting reaction of binuclear complex $[(Y_1)\cdot HgCl_2]_2$ by DMSO yields a mononuclear complex containing DMSO as ligand. O-coordination of DMSO is revealed by single crystal X-ray analysis in mononuclear complex of $[(Y_1)\cdot HgCl_2\cdot DMSO]$. C-coordination of ylides is confirmed by X-ray structure of binuclear complex $[(Y_2)\cdot HgI_2]_2$. Characterization of the obtained compounds was also performed by elemental analysis, IR, ^1H, ^{31}P, and ^{13}C NMR. Theoretical studies on mercury(II) complexes of Y_1 show that formation of mononuclear complexes in DMSO solution in which DMSO acts as a ligand, energetically is more favorable than that of binuclear complexes.

1. Introduction

The utility of metalated phosphorus ylides in synthetic chemistry has been well documented [1,2]. Synthesis of complexes derived from phosphorus ylides and Hg(II) halides was started in 1965 by Nesmeyanov et al. [3]. In 1975, Weleski et al. [4] proposed a symmetric halide-bridged dimeric structure for Hg(II) halide complexes whereas Kalyanasundari et al. [5] reported an asymmetric halide-bridged dimeric structure in 1995. In 1985, Sanehi et al. [6] reported a mononuclear Hg(II) complex of phosphorus ylides without any structural characterization. We have recently focused on the synthesis of binuclear and polynuclear complexes derived from mercury(II) salts and phosphorus ylides [7–9]. The α-keto-stabilized phosphorus ylides $R_3P{=}C(R')COR''$ show interesting properties such as their high stability and their ambidentate character as ligands (C- versus O-coordination) [10]. This ambidentate character can be rationalized in terms of the resonance forms A–C, together with the isomeric form D (Chart 1).

Form B can be considered as leading to coordination by the carbon atom to give a complex of form E, whereas isomers C and D would both lead to coordination by the oxygen atom, affording structures F (*transoid*) and form G (*cisoid*), respectively. Although many coordination modes are possible for keto ylides [11], coordination through carbon is more predominant and observed with soft metal ions, *e.g.*, Pd(II), Pt(II), Ag(I), Hg(II), Au(I) and Au(III) [5,12–15], whereas, O-coordination dominates when the metals involved are hard, *e.g.*, Ti(IV), Zr(IV), and Hf(IV) [16]. Only W(0) complexes of the type $W(CO)_5L$ (L = ylide) [17] and Pd(II) complexes of stoichiometry $[Pd(C_6F_5)(L_2)(APPY)](ClO_4)$ [12] [APPY = $Ph_3PCHCOMe$; L = PPh_3 and PBu_3; L_2 = bipy] contain stable ylides O-linked to a soft metal centre.

2. Experimental

2.1. Materials

All reactions were performed in air. Starting materials were purchased from commercial sources and used without further purification. The ligands were synthesized by the reaction of related phosphine with 2-bromo-4′-chloroacetophenone or chloroacetone and concomitant elimination of HBr by NaOH [18].

2.2. Physical measurements

Melting points were measured on a SMPI apparatus. Elemental analysis for C and H atoms were performed using a Perkin–Elmer 2400 series analyzer. IR spectra were recorded on a Shimadzu 435-U-04 FT spectrophotometer from KBr pellets. ^1H, ^{13}C, and ^{31}P NMR spectra were recorded on a 300 MHz Bruker spectrometer in DMSO-d_6 or $CDCl_3$ as solvent at 25 °C. Chemical shifts (ppm) are reported according to internal TMS and external 85% phosphoric acid. Coupling constants are given in Hz. The single crystal X-ray diffraction analyses were performed on a STOE IPDS-II two

circle diffractometer at 293(2) K, using graphite monochromated Mo Kα X-ray radiation ($\lambda = 0.7107$ nm). The data collection were performed at room temperature using the ω-scan technique and using the STOE X-AREA software package [19]. The crystal structures were solved by direct methods and refined by full-matrix least-squares on F^2 by SHELX [20] and using the X-STEP32 crystallographic software package [21]. All non-hydrogen atoms were refined anisotropically using reflections $I > 2\sigma(I)$. Hydrogen atoms were located in ideal positions.

2.3. Theoretical studies

The geometries of compounds were fully optimized at the Hartree–Fock (HF) level of theory using the GAUSSIAN98 program [22] on a Pentium-PC computer with 3600 MHz processor. The standard LanL2mb basis set was used for all complexes [23]. This basis set includes effective core potentials (ECP) for both the mercury and phosphorus as well as halide (Cl, Br and I) ions. Vibrational frequency analyses, calculated at the same level of theory, indicate that optimized structures are at the stationary points corresponding to local minima, without any imaginary frequency. Atomic coordinates for ab initio calculations were obtained from the data of the X-ray crystal structure analyses.

2.4. Preparation of $Ph_3PCHCOC_6H_4Cl$ (Y_1), general procedure for ylides [24]

A solution of triphenylphosphine (0.131 g, 0.5 mmol) and 2-bromo-4′-chloroacetophenone (0.117 g, 0.5 mmol) in acetone (15 ml) was stirred at room temperature for 4 h. The resulting white precipitate was filtered off, washed with diethylether and dried. Further treatment with aqueous solution of NaOH (0.5 M, 50 ml) led to elimination of HBr, giving the free ligand Y_1. IR (KBr, cm^{-1}): ν 1579 (C=O), 1522, 1480, 1435, 1404, 1383, 1175, 1104, 1085, 1009, 882 (P–C), 848. ^{1}H NMR ($CDCl_3$) δ_H: 4.38 (d, $^2J_{PH}$ = 23.75 Hz, 1H, C*H*); 7.25–7.94 (m, 19H, Ph). ^{31}P NMR ($CDCl_3$) δ_P: 14.19 (s). ^{13}C NMR ($CDCl_3$) δ_C: 50.65 (d, $^1J_{PC}$ = 110.3 Hz, *C*H); 126.0 (d, $^1J_{PC}$ = 91.40 Hz, PPh_3 (*i*)); 127.31 (COPh (*m*)); 128.03 (PPh_3 (*p*)); 128.48 (d, $^3J_{PC}$ = 12.41 Hz, PPh_3 (*m*)); 131.80 (d, $^4J_{PC}$ = 2.73 Hz, COPh (*o*)); 132.60 (d, $^2J_{PC}$ = 10.25 Hz, PPh_3 (*o*)); 134.71 (COPh (*p*)); 139.15 (d, $^2J_{PC}$ = 14.69 Hz, COPh (*i*)); 182.84 (d, $^2J_{PC}$ = 3.1 Hz, CO).

2.6. Synthesis of the complexes

The binuclear complexes **1**–**4** were prepared based on a general procedure as follows (Scheme 1). According to various papers [5,7,8,25], the binuclear structures are suggested for above compounds, as shown in Scheme 1. X-ray quality crystals of the complexes **4** and **5** (Schemes 1 and 2) were grown from a

3. Results and discussion

3.1. Spectroscopy

The ν (CO) band, which is sensitive to complexation, is observed for complexes at higher frequencies compared to the parent ylides, indicating coordination of the ylide thorough carbon atom in each case [26]. The ν (P^+–C^-) band, (823, 819 and 820 cm^{-1} for complexes **1**–**3**, respectively) which is also diagnostic of the coordination modes, occurs at lower frequencies (882 cm^{-1}) in comparison to the parent ylide (Y_1), consistent with some removal of electron density in the P–C bonds [7–9]. C-coordination causes an increase in ν (CO) and decrease in ν (P^+–C^-) while for O-coordination a lowering for both frequencies is expected [15]. It should be noted that there is not any significant difference in the IR absorption bands for binuclear complex **1** and related mononuclear complex **5**.

In the ^{1}H NMR spectra, the signals due to the methinic protons for complexes are doublet or broad. Similar behavior was observed earlier in the case of ylide complexes of platinum(II) chloride [27]. The expected downfield shifts of ^{31}P and ^{1}H signals for the PCH group upon complexation in the case of C-coordination were observed in their corresponding spectra. The proton decoupled ^{31}P NMR spectra show only one sharp singlet between 20.63 and 22.72 ppm in the complexes. The appearance of a single signal for the PCH group in each of the ^{31}P and ^{1}H NMR spectra indicates that all ligands are in the same environment in these complexes, as expected for C-coordination. It must be noted that O-coordination of the ylide generally leads to the formation of a mixture of *cisoid* and *transoid* isomers, giving rise to two different signals in ^{31}P and ^{1}H NMR spectra (Chart 1) [12]. The ^{31}P chemical shift values for the complexes appear to be shifted downfield by about 6.5–10 ppm with respect to the parent ylides also indicating that coordination of the ylide has occurred [5,7–9,25]. Satellites due to coupling to ^{199}Hg for ylidic complexes of Hg(II) are only observed at low temperature [7,25] or by solid-state ^{31}P NMR [25] and also in the case of $Hg(NO_3)_2 \cdot H_2O$ as metal source [9]. Failure to observe satellites

in above spectra was previously noted in the complexes of Hg(II) [28] and Ag(I) [15] and was assigned to fast exchange of the ylide with the metal at higher temperatures.

The most interesting aspect of the ^{13}C NMR spectra of the complexes is the upfield shift of the signals due to the ylidic carbon atoms. Such an upfield shift was observed in [PdCl(η^3-2-XC_3H_4)$(C_6H_5)_3$PCHCOR] (X = H, CH_3; R = CH_3, C_6H_5), and is due to the change in hybridization of the ylidic carbon atom on coordination [29]. Similar up field shifts of 2–3 ppm with reference to the parent ylide were also observed in the case of $[(C_6H_5)_3PC_5H_4HgI_2]_2$ [28]. The downfield shifts of the carbonyl C atom in the complexes compared to the same carbon atom in the parent ylides, indicate a much lower shielding of the CO group in these complexes.

3.2. X-ray crystallography

Table 1 provides the crystallographic results and refinement information for complexes **4** and **5**. The molecular structures are shown in Figs. 1 and 2. Pertinent bond distances and angles for **4** and **5** are given in Tables 2 and 3, respectively. Packing diagrams, fractional atomic coordinates and equivalent isotropic displacement coefficients (Ueq) for the non-hydrogen atoms of complexes are shown in Supplementary materials.

The Hg(II) centre in complex **4** forms four-coordinate with sp^3 hybridization. This environment is contained of one short terminal Hg–I bond, one Hg–C bond and two asymmetric bridging Hg–I bonds. The Hg–C and terminal Hg–I bond lengths in **4** (2.279(8) and 2.7036(8) Å) are comparable to analogous distances in $[(Ph_3PCHCOPh)\cdot HgI_2]_2$ (2.312(13) and 2.705(1) Å, respectively) [5].

The angles subtended by the ligands at the Hg(II) centre in **4** vary from 95.53(3) to 121.7(2) indicating a much distorted tetrahedral environment. The widening of the IHgC angle from the tetrahedral angle must be due to the higher s character of the sp^3 hybrid mercury orbitals involved in the above bonds and the formation of a strong halide-bridge between Hg atoms which requires the internal IHgI angle (95.53(3)) to be considerably smaller. The two mercury atoms and two bridging halides are perfectly coplanar. The internuclear distance between mercury atoms in complex **4** were found to be 3.926 Å, which is much longer than the sum of Van der Waals radii (3 Å) of the two mercury atoms [30], indicating the absence of significant bonding interactions between the mercury atoms in the molecular structures.

The Hg(II) centre in complex **5** is coordinated by one carbon, one oxygen and two chloro atoms in a distorted tetrahedral geometry. The two different Hg–Cl distances in **5** (2.3986(13) and 2.5106(12) Å) are less than those of found in mononuclear complex of $[HgCl_2(PPh_3)_2]$ [31] (2.559(2) and 2.545(3) Å), indicating relatively strong Hg–Cl bonds in **5**. Difference between two distances in these complexes might be arising from steric effects of the large ylidic groups. The angles around mercury in complex **5** vary from 87.39(13) to 139.45(11), indicating a much distorted tetrahedral environment. This distortion must be due to the higher s character of the sp^3 hybrid mercury orbitals involved in the above bonds and the steric effects of phosphine group needing the C–Hg–Cl angle to be larger.

The stabilized resonance structure for the parent ylides are destroyed by the complex formation, thus, the C(H)–C bond lengths, 1.473(12) Å (**4**) and 1.491(5) Å (**5**) are significantly longer than the corresponding distances found in the uncomplexed similar phosphoranes (1.407(8) Å [32] and 1.401(2) Å [33]). On the other hand, the bond length of P–C(H) in the similar ylide is 1.7194(17) Å [33] which shows that the corresponding bonds are considerably elongated to 1.786(8) Å (**4**) and 1.787(4) Å (**5**).

The C-coordination of the title ylides is in contrast to the O-coordination of the phosphorus ylide $Ph_3PC(COMe)(COPh)$ (ABPPY) in a different Hg(II) complex [34]. The difference in coordination mode between ABPPY and present ylides to Hg(II) can be rationalized in terms of the electronic properties, steric requirements and size and shape of the ligand in the final bonding mode. This may also explain by the electronic nature of the metal (Pd, Pt, Ru, Au, etc.) and even the position of the coordination site (*trans* to a C atom, *trans* to a N atom, *trans* to an O atom, and so on). The nucleophilicity of the carbanion in ABPPY is less than in our ylides; this is due to the additional delocalization of the ylide electron density in ABPPY which is facilitated by the second carbonyl group. This will reduce the ability of ABPPY to bind via the ylidic carbon. Belluco et al. have studied steric influences on the coordination modes of ylide molecules to Pt(II) systems [35]. These authors concluded that the preferred coordination mode is via the ylidic carbon, but that steric hindrance around the metal centre or the ylidic carbon will necessitate O-coordination. Indeed, this trend is reflected here, these ylides are slightly less sterically demanding than ABPPY and are C-coordinated to Hg(II).

3.3. DMSO as ligand

Literature data show that the coordination mode of dimethylsulfoxide (DMSO) to relatively soft metal atoms depends on both electronic and steric factors deriving from the DMSO moderate π-acceptor properties and its greater steric demand in the case of S-bonding [36]. In the case of ruthenium(II) complexes, coordination through sulfur (DMSO–S) seems to be preferred over

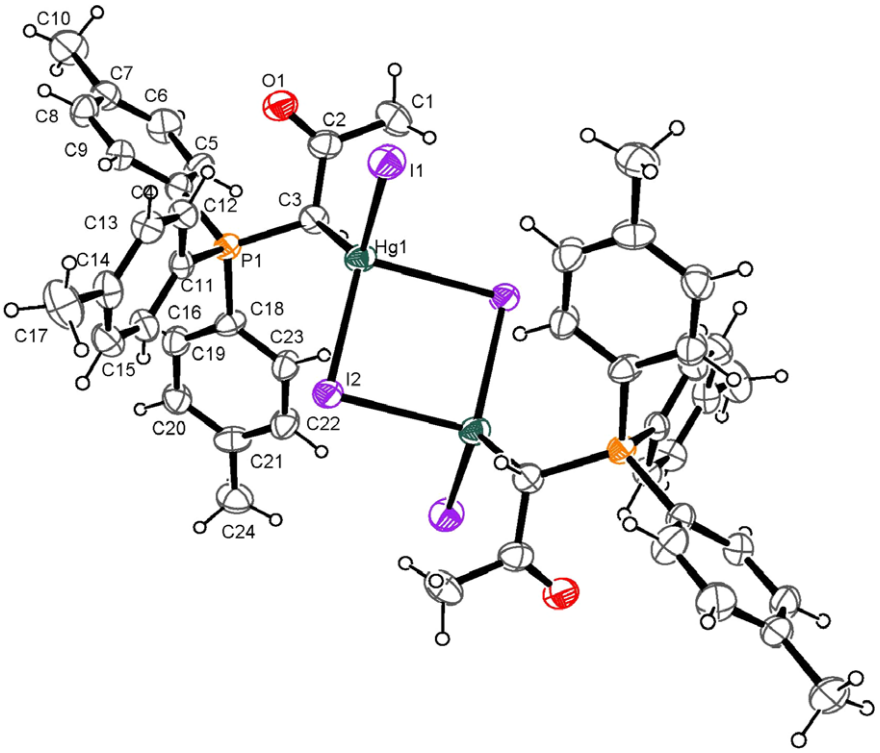

Fig. 1. ORTEP view of X-ray crystal structure of $[(Y_2) \cdot HgI_2]_2$ (**4**).

coordination through oxygen (DMSO–O) to get stable species, unless ligand overcrowding occurs [37] or DMSO is trans to strong π-acceptors like CO [38] and NO [39,40]. A similar overestimate is found for the calculated S–O distance in 'free' DMSO (1.509 Å), which results 0.018 Å longer than the experimental reference value of 1.492(1) Å [41]. The significant elongation of the S–O distance upon O-coordination is further confirmed by the recent X-ray structure determination of a disulfoxide and related copper(II) complexes, where the average S–O distances are of 1.487(4) Å (free) and 1.520(3) Å (O-bonded) [42]. This work reports the example of

a mercury(II) complex containing DMSO as ligand with an O-coordination mode. It is worth noting that in **5**, the S–O bond distance of 1.507(3) Å, is about 0.015 Å longer than the experimental reference value of 1.492(1) Å for free DMSO ligand [41].

3.4. Theoretical studies

We were interested to determine whether the formation of mononuclear complexes in the gas phase in which DMSO acts as ligand, energetically is more favorable than those of binuclear complexes. The analytical and spectroscopic data for compound **5** can be similar to those of the other complexes synthesized here containing ylide Y_1. Thus the observed geometry of compound **5** was considered for ab initio calculations. The optimized structure of compounds **5** is shown in Fig. 3. A comparison between the calculated bond lengths (Å) and bond angles (°) for this compound with corresponding experimental values are presented in Table 4. A list of calculated key bond lengths and bond angles and the optimized structure of compounds $[(Y_1)\cdot HgX_2\cdot DMSO]$ (where X = Br and I) are presented in Supplementary materials.

As can be seen, the calculated bond lengths are slightly longer than measured ones but the similarity of calculated and measured bond angles reflects the similar geometrical structures for these compounds in both the solid state and gas-phase. The results of calculations (Table 5) show that the products of following proposed reaction (Eq. (1)) are more stable than reactants. These stabilities are about 32, 34 and 40 kcal/mol where X is Cl, Br and I, respectively.

$$[(Y_1)\cdot HgX_2]_2 + 2DMSO \xrightarrow{rt} 2[(Y_1)\cdot HgX_2\cdot DMSO] \quad (1)$$

The similarity of calculated energies for latter reaction of Y_1 complexes indicate that the reaction energy mainly depends on the bridging halide atom. Therefore it is clear that for all compounds synthesized here, the gas-phase reaction shown in Eq. (1) is an exothermic reaction, thus it seems that the bridge-splitting reaction in

Table 5

X = I	−2285.2766229	−161.8305649	−1304.5010169	40.337

DMSO solution is potentially possible for all dimeric complexes of Y_1 in which DMSO acts as a ligand. The data show that in the case of iodine complex, the formation of mononuclear complexes is relatively more favorable than corresponding chlorine and bromine complexes (Table 5).

4. Conclusions

Present study describes the synthesis and characterization of mononuclear and binuclear Hg(II) complexes of phosphorus ylides. On the basis of the physico-chemical and spectroscopic data we propose that ligands herein exhibit monodentate C-coordination to the metal centre, which is further confirmed by the X-ray crystal structure of the complexes. This study also presents a method for synthesis of mononuclear Hg(II) complexes of phosphorus ylides via bridge-splitting reaction using DMSO as ligand. Theoretical studies on the gas-phase structure of the complexes, confirm that, the bridge-splitting reaction in DMSO solution is potentially possible for all dimeric complexes in which DMSO acts as a ligand.

ABSTRACT

The photoluminescent properties of 17 zinc(II) chelates [Zn(RC(S)NP(O)(O*i*Pr)$_2$-*O*,*S*)$_2$] (R = Ph (**1a**), PhNH (**1b**), *p*-BrPh (**1c**), *p*-MeOC$_6$H$_4$NH (**1d**), *p*-BrC$_6$H$_4$NH (**1e**), NH_2 (**1f**), *i*PrNH (**1g**), *t*BuNH (**1h**), Et_2N (**1i**), *c*-$C_5H_{10}N$ (**1j**), *c*-OC_4H_8N (**1k**), *c*-$C_6H_{11}NH$ (**1l**), aminobenzo-15-crown-5 (**1m**)) and [Zn(B)(RC(S)NP(O)(O*i*Pr)$_2$-*O*,*S*)$_2$] (R = Ph, B = 2,2′-bipyridine (**2a**); R = Ph, B = 1,10-phenanthroline (**2b**); R = PhNH, B = 2,2′-bipyridine (**2c**); R = PhNH, B = 1,10-phenanthroline (**2d**)), are reported. Colorless and air/moisture stable chelate complexes of divalent zinc show blue emission in the solid state when excited with UV light. Complexes **1f**, **1h**, **1l** were investigated by single crystal X-ray diffraction. The zinc(II) atom in complexes **1f**, **1h**, **1l** is in a distorted tetrahedral O_2S_2 environment formed by the C=S sulphur atoms and the P=O oxygen atoms of two deprotonated ligands.

1. Introduction

Up to now, large numbers of coordination complexes of the Zn(II) cation have been prepared by taking certain factors into account, such as the functionality, flexibility, symmetry and nature of donor centers of organic ligands and the coordination ability of the metal ion [1]. Among these, the construction of complexes with changeable geometry and structure, to the best of our knowledge, has become a widely propagated and popular subject. Such complexes are important in advanced materials such as optical devices, especially with luminescence properties [2]. One of the effective strategies to vary luminescent activity is to change the geometry and structure. This requires the synthesis of complexes by addition of a heteroligand to homoligand luminescence active complexes. These compounds might find applications as receptors with optical detecting properties.

The late transition metal ion complexes of *N*-acylthioureas $R_2NC(S)NHC(O)R'$ [3] and their phosphoryl analogues based on thioureas $R_2NC(S)NHP(O)(OR')_2$ and thioamides $RC(S)NHP(O)(OR')_2$ [4,5, and references therein] are of interest due to their magnetic and photophysical properties. The 1,5-*X*,*S*-coordination of these ligand anions is typical for chelate complexes (e.g. [4–6]).

However, recent investigations have shown that the coordination mode of these ligands containing the RNH group towards Ni(II), Pd(II), Pt(II) [7,8], Cu(II) [9] and Cd(II) [10] cations depends on the presence of strong intramolecular NH···O=P or NH···O=C bonds. The thiourea ligands of common formula $RNHC(S)NHP(O)(OR')_2$ (NPTU) [8,9] are able to bind Ni(II), Pd(II) and Cu(II) cations through the C=S sulfur and P–N nitrogen atoms. The thiourea *n*PrNHC(S)NHC(O)*n*Pr [7] forms similar 1,3-*N*,*S*-chelate with the Pt(II) cation through the C=S sulfur and NC(O) nitrogen atoms.

Interestingly, the *N*-(*o*-nitrophenyl)-*N*′-(methoxycarbonyl)thiourea (HQ) in complex of formula [Cd(2,2′-bpy)Q_2] is also bound in the 1,3-*N*,*S*-fashion via the C=S sulfur and NC(O) nitrogen atoms [10]. However, the sulfur atom of the thiourea HQ does not coordinate to the Zn(II) ion. A monodentate coordination through the deprotonated nitrogen atom of the C(S)NC(O) moiety occurs in the chelate [Zn(2,2′-bpy)Q_2].

In the literature there is no information on crystal structure of NPTU complexes with the Zn(II) cation. In this connection it was interesting to investigate the structure and properties of some complexes of phosphorylated thioureas and thioamides and compares these with heteroligand analogues with participation of 2,2′-bipyridine (bpy) and 1,10-phenanthroline (phen) as additional donor ligands.

In this paper, we report on the photoluminescence properties at room temperature of thirteen solid zinc-containing chelating complexes with HL of composition Zn[RC(S)NP(O)(O*i*Pr)$_2$-*O*,*S*]$_2$ (R = Ph **1a**, PhNH **1b**, *p*-BrPh **1c**, *p*-MeOC$_6$H$_4$NH **1d**, *p*-BrC$_6$H$_4$NH **1e**, NH$_2$ **1f**, *i*PrNH **1g**, *t*BuNH **1h**, Et$_2$N **1i**, *c*-C$_5$H$_{10}$N **1j**, *c*-OC$_4$H$_8$N **1k**, *c*-C$_6$H$_{11}$NH **1l**, aminobenzo-15-crown-5 **1m**) and four novel heteroligand complexes of composition Zn(B)[RC(S)NP(O)(O*i*Pr)$_2$-*O*,*S*]$_2$ (R = Ph, B = 2,2′-bipyridine **2a**; R = Ph, B = 1,10-phenanthroline **2b**; R = PhNH, B = 2,2′-bipyridine **2c**; R = PhNH, B = 1,10-phenanthroline **2d**).

2. Experimental

2.1. Physical measurements

Infrared spectra (Nujol) were recorded on a Specord M-80 spectrometer in the range 400–3600 cm^{-1}. NMR spectra were obtained on a Varian Unity-300 NMR spectrometer at 25 °C. ^{1}H and ^{31}P{^{1}H} spectra were recorded at 299.948 and 121.420 MHz, respectively. Chemical shifts are reported with reference to $SiMe_4$ (^{1}H) and H_3PO_4 (^{31}P{^{1}H}). Electron ionization mass spectra were measured on the TRACE MS Finnigan MAT instrument. Ionization energy was 70 eV. The substance was injected directly into the ion source at 150 °C. Heating was carried out in a programmed mode from 35 to 200 °C at a rate of 35 °C/min. Electrospray ionization mass spectra were measured with a Finnigan-Mat TCQ 700 mass spectrometer on a 10^{-6} M solution in CH_3OH. The speed of a sample submission was 2 μL/min. The ionization energy was 4.5 kV. The capillary temperature was 200 °C. Fluorescence measurements were made on a SLM Aminco 500 spectrofluorometer at room temperature. Elemental analyses were performed on a Perkin–Elmer 2400 CHN microanalyser. An ENRAF NONIUS four circle diffractometer, operating with Mo Kα radiation and a graphite monochromator was used for determining the crystallographic parameters and collecting the data sets.

2.2. Synthesis of [ZnL$_2$] (**1a**–**1m**)

Complexes **1a**, **1b**, **1d**, **1e**, **1g**–**1l** were prepared according to the previously described techniques [4,5,11].

Complexes **1c** and **1f** were synthesized for the first time by the method used in [4,5]. A suspension of HL, R = *p*-BrC$_6$H$_4$ (1.900 g, 5 mmol) or R = NH$_2$ (1.200 g, 5 mmol) in aqueous ethanol (20 mL) was mixed with an ethanol solution of potassium hydroxide (0.28 g, 5 mmol). An aqueous (20 mL) solution of $ZnCl_2$ (0.381 g, 2.8 mmol) was added dropwise under vigorous stirring at room temperature for a further 3 h and left overnight. The resulting complex was extracted with dichloromethane, washed with water and dried with anhydrous $MgSO_4$. The solvent was then removed in vacuo. A colourless precipitate was isolated from dichloromethane by *n*-hexane.

2.2.1. [Zn(*p*-BrC$_6$H$_4$C(S)NP(O)(O*i*Pr)$_2$)$_2$] (**1c**)

Yield: 1.73 g (84%), m.p. 143 °C. ^{1}H NMR ($CDCl_3$): δ (ppm) = 1.35 (d, $^3J_{H,H}$ = 5.6 Hz, 12 H, CH_3), 1.36 (d, $^3J_{H,H}$ = 5.6 Hz, 12H, CH_3), 4.71 (d. sept, $^3J_{POCH} \approx {}^3J_{H,H} \approx 6.2$ Hz, 4H, OCH), 7.50 (m, 4H, *o*-H, C$_6$H$_4$), 8.14 (m, 4H, *m*-H, C$_6$H$_4$). ^{31}P{^{1}H} NMR ($CDCl_3$): 6.9 ppm. IR (cm^{-1}): 1000 (b, vs) (POC); 1152 (vb, s) (P═O); 1544 (s) (SCN). *Anal.* Calc. for $C_{26}H_{36}Br_2N_2O_6P_2S_2Zn$ (823.85): C, 37.90; H, 4.40; N, 3.40. Found: C, 37.86; H, 4.45; N, 3.38%.

2.2.2. [Zn(NH$_2$C(S)NP(O)(O*i*Pr)$_2$)$_2$] (**1f**)

Yield: 1.24 g (91%), m.p. 182 °C. ^{1}H NMR ($CDCl_3$): δ (ppm) = 1.29 (d, $^3J_{H,H}$ = 6.2 Hz, 12H, CH_3), 1.30 (d, $^3J_{H,H}$ = 6.2 Hz, 12H, CH_3), 4.58 (d. sept, $^3J_{POCH}$ = 7.6 Hz, $^3J_{H,H}$ = 6.2 Hz, 4H, OCH), 5.81 (br. s, 1H, NH$_2$), 5.97 (br. s, 1H, NH$_2$). ^{31}P{^{1}H} NMR ($CDCl_3$): 6.2 ppm. IR (cm^{-1}): 992 (b, vs) (POC); 1132 (vb, s) (P═O); 1512 (s) (SCN); 1620 (s), 3136 (b, s), 3272 (s); 3496 (s) (NH$_2$). *Anal.* Calc. for $C_{14}H_{32}N_4O_6P_2S_2Zn$ (542.05): C, 30.92; H, 5.93; N, 10.30. Found: C, 30.90; H, 5.91; N, 10.33%.

2.3. Synthesis of [Zn(B)L$_2$] (**2a**–**2d**)

A solution of complexes **1a** (0.30 g, 0.45 mmol) or **1b** (0.31 g, 0.45 mmol) in benzene (10 mL) was added dropwise whilst stirring to a solution of 2,2′-bipyridine (0.07 g, 0.45 mmol) or 1,10-phenanthroline (0.08 g, 0.45 mmol) in benzene (10 mL). After complete addition, the solution was stirred for an hour. The solvent was then removed in vacuo. The residue was recrystallized from a methylene chloride/*n*-hexane mixture. The complexes **2a**-**2d** were isolated as colorless powders.

2.3.1. [Zn(2,2′-bpy)(PhC(S)NP(O)(OiPr)$_2$)$_2$] (**2a**)

Yield: 0.28 g (75%), m.p. 102 °C. ^{1}H NMR ($CDCl_3$): δ (ppm) = 1.36 (d, $^3J_{H,H}$ = 6.1 Hz, 24H, CH_3), 4.74 (d. sept, $^3J_{POCH} \approx {}^3J_{H,H} \approx 6.5$ Hz, 4H, OCH), 7.21–8.76 (m, 18H, C$_6$H$_5$ + bpy). ^{31}P{^{1}H} NMR ($CDCl_3$): 5.9 ppm. IR (cm^{-1}): 996 (b, vs) (POC); 1168 (b, s) (P═O); 1464 (s) (SCN). EI-MS: *m*/*z* (%) = 665 (73) [ZnL$_2$]$^+$, 301 (61) [HL]$^+$, 156 (13) [bpy]$^+$. ES (positive ion): *m*/*z* (%) = 522.2 (100) [M−PhC(S)NP(O)(O*i*Pr)$_2$]$^+$. *Anal.* Calc. for $C_{36}H_{46}N_4O_6P_2S_2Zn$ (820.16): C, 52.59; H, 5.64; N, 6.81. Found: C, 52.62; H, 5.60; N, 6.78%.

2.3.2. [Zn(1,10-phen)(PhC(S)NP(O)(OiPr)$_2$)$_2$] (**2b**)

Yield: 0.31 g (82%), m.p. 154 °C. ^{1}H NMR ($CDCl_3$): δ (ppm) = 1.32 (d, $^3J_{H,H}$ = 6.0 Hz, 24H, CH_3), 4.72 (d. sept, $^3J_{POCH} \approx {}^3J_{H,H} \approx 6.5$ Hz, 4H, OCH), 7.28–8.42 (m, 18H, C$_6$H$_5$ + phen). ^{31}P{^{1}H} NMR ($CDCl_3$): 6.1 ppm. IR (cm^{-1}): 996 (b, vs) (POC); 1172 (b, s) (P═O); 1492 (s) (SCN). EI-MS: *m*/*z* (%) = 665 (100) [ZnL$_2$]$^+$, 301 (29) [HL]$^+$, 180 (54) [phen]$^+$. ES (positive ion): *m*/*z* (%) = 546.3 (100) [M−PhC(S)NP(O)(O*i*Pr)$_2$]$^+$. *Anal.* Calc. for $C_{38}H_{46}N_4O_6P_2S_2Zn$ (844.16): C, 53.93; H, 5.48; N, 6.62. Found: C, 53.96; H, 5.51; N, 6.59%.

2.3.3. [Zn(2,2′-bpy)(PhNHC(S)NP(O)(OiPr)$_2$)$_2$] (**2c**)

Yield: 0.25 g (65%), m.p. 101 °C. ^{1}H NMR ($CDCl_3$): δ (ppm) = 1.15–1.33 (m, 24H, CH_3), 4.48–4.65 (m, 4H, OCH), 6.89–8.46 (m, 18H, C$_6$H$_5$ + bpy), 8.58–8.63 (m, 2H, PhNH). ^{31}P{^{1}H} NMR ($CDCl_3$): 6.5 ppm. IR (cm^{-1}): 1008 (b, vs) (POC); 1140 (b, s) (P═O); 1560 (s) (SCN); 3312 (NH). EI-MS: *m*/*z* (%) = 695 (22) [ZnL$_2$]$^+$, 316 (100) [HL]$^+$, 56 (74) [bpy]$^+$. ES (positive ion): *m*/*z* (%) = 537.3 (100) [M−PhNHC(S)NP(O)(O*i*Pr)$_2$]$^+$. *Anal.* Calc. for $C_{36}H_{48}N_6O_6P_2S_2Zn$ (850.18): C, 50.73; H, 5.68; N, 9.86. Found: C, 50.70; H, 5.72; N, 9.84%.

2.3.4. [Zn(1,10-phen)(PhNHC(S)NP(O)(OiPr)$_2$)$_2$] (**2d**)

Yield: 0.31 g (82%), m.p. 104 °C. ^{1}H NMR ($CDCl_3$): δ (ppm) = 0.96–1.32 (m, 24H, CH_3), 4.39–4.66 (m, 4H, OCH), 6.85–8.45 (m, 18H, C$_6$H$_5$ + phen), 9.18–9.40 (m, 2H, PhNH). ^{31}P{^{1}H} NMR ($CDCl_3$): 6.6 ppm. IR (cm^{-1}): 1020 (b, vs) (POC); 1144 (b, s) (P═O); 1504 (s) (SCN); 3288 (NH). EI-MS: *m*/*z* (%) = 695 (34) [ZnL$_2$]$^+$, 316 (57) [HL]$^+$, 180 (91) [phen]$^+$. ES (positive ion): *m*/*z* (%) = 561.2 (100) [M−PhNHC(S)NP(O)(O*i*Pr)$_2$]$^+$. *Anal.* Calc. for $C_{38}H_{48}N_6O_6P_2S_2Zn$ (874.18): C, 52.08; H, 5.52; N, 9.59. Found: C, 52.04; H, 5.47; N, 9.64%.

2.4. Crystal structure determination and refinement

The selected crystal was coerced with lithelene and mounted on a glass fibre. It was then cooled to −60 °C on the goniometer head of a Kappa Nonius diffractometer operated with a rotating anode. After alignment the unit cell parameters were calculated from a se-

lected data set, and data collection was performed by using an area detector. For data reduction the program SMART was used, and for structure solution and refinement the program package SHELXTL PLUS. All plots of the molecules are shown with a 50% probability for the thermal ellipsoids. The numbering of the atoms is shown in Figs. 1–3 (ORTEP) [12] (see Table 1).

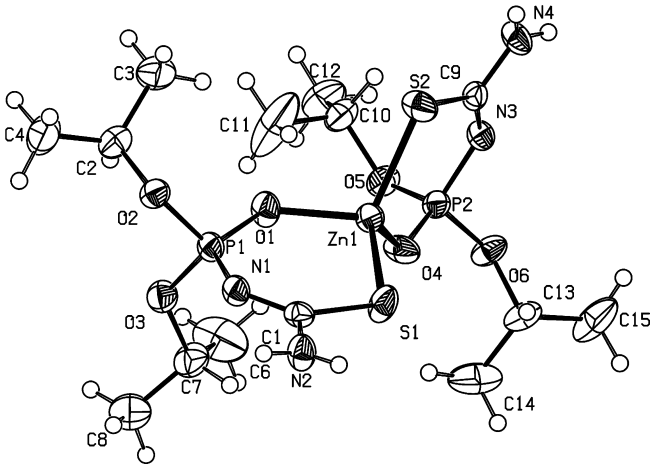

Fig. 1. An ORTEP view of $[Zn(H_2NC(S)NP(O)(OiPr)_2)_2]$ (**1f**). Displacement ellipsoids are drawn at the 50% probability level.

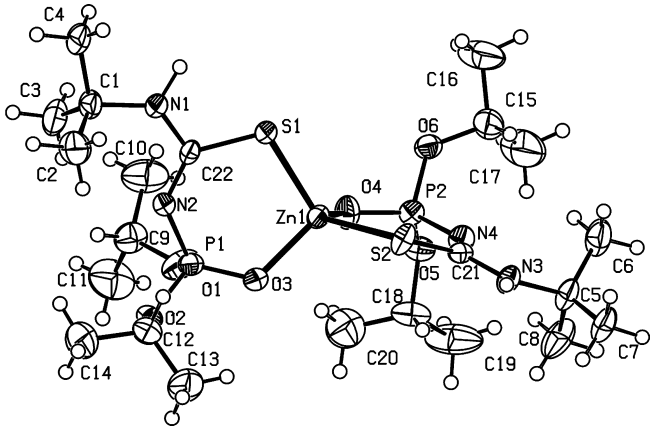

Fig. 2. An ORTEP view of $[Zn(t\text{BuNHC}(S)NP(O)(OiPr)_2)_2]$ (**1h**). Displacement ellipsoids are drawn at the 50% probability level.

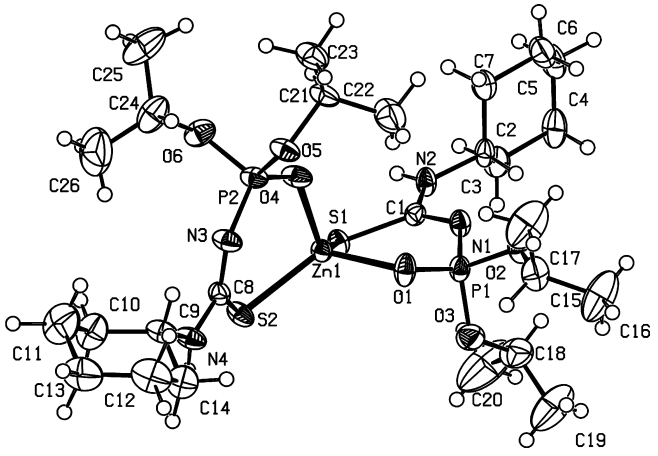

Fig. 3. An ORTEP view of $[Zn(c\text{-}C_6H_{11}NHC(S)NP(O)(OiPr)_2)_2]$ (**1l**). Displacement ellipsoids are drawn at the 50% probability level.

3. Results and discussion

3.1. Synthesis

Complexes **1a**–**1m** were prepared by the following procedure: the ligand was converted to the potassium salt, followed by reaction with $ZnCl_2$ (Scheme 1). The compounds obtained are crystalline solids soluble in most polar solvents.

Unsaturation of the ZnO_2S_2 coordination environment opens up possibilities for the synthesis of a large number of heteroligand complexes. They are obtained by the interaction of these complexes with various donor agents.

In order to obtain the heteroligand complexes, we have combined HL and two aromatic chelate ligands, (2,2′-bipyridine or 1,10-phenanthroline) in experiments based on the following considerations: (i) the steric hindrance at the metal center will be increased when the aromatic 1,4-donor ligand binds to the metal ion; this ensures the formation of the lower dimensional structure and on the other hand (ii) metal complexes of 2,2′-bipyridine or 1,10-phenanthroline and their derivatives exhibit excellent luminescent properties [13], which can be used not only as efficient blue emitters in electroluminescent devices but also as chemical sensors for specific organic molecules [14].

Complexes **2a**–**2d** were prepared by the following procedure: a benzene solution of 2,2′-bipyridine or 1,10-phenanthroline was added dropwise to a benzene solution of **1a** or **1b** (Scheme 1). The compounds obtained **2a**–**2d** are crystalline solids soluble in most polar solvents.

3.2. IR and NMR spectroscopy

It is shown that all listed complexes **1a**–**1m** have a similar coordination environment at the zinc atom. The IR, ^1H, $^{31}P\{^1H\}$ NMR [4,11] and X-ray [4] data confirm that in a $CDCl_3$ solution and in the solid state only $[ZnL_2]$ chelates with a tetrahedral ZnO_2S_2 core exist. The 1,5-*O*,*S*-coordination appears to be the most steric favorable in this case because it provides a maximal bite angle for the ligand's anionic form L^-.

The additional ligands bpy or phen in a molecule of complex could affect on the coordination mode of the anionic thiourea ligands. The bond angles in the cation environment decrease in comparison with the tetrahedral core and requirements to the bite angle are softened, thus the situation becomes ambiguous. The structures of the thiourea HQ chelates with the Zn(II) and Cd(II) cations demonstrate the examples of such changes in the coordination modes [10].

There is a strong (20–25 kJ/mol) hydrogen bond of type PhNH···O=P in the thiourea $PhNHC(S)NHP(O)(OiPr)_2$ and its complexes [8,9]. It prevents the coordination through the P=O group in square planar complexes of the Ni(II), Pd(II) and Cu(II) cations.

Thus, the presence the bpy or phen in the coordination sphere of Zn(II) makes possible the three coordination modes of $PhNHC(S)NHP(O)(OiPr)_2$ (HL): (i) preservation of the 1,5-*O*,*S*-coordination for L^- (Scheme 2A); (ii) 1,3-*N*,*S*-coordination of L^- (Scheme 2B); (iii) monodentate *N*-coordination (Scheme 2C). Neither of them could be discarded *a priori*.

The 1,5-*O*,*S*-coordination (Scheme 2A) is a unique variant is for complexes of the thioamide $PhC(S)NHP(O)(OiPr)_2$ due to absence of the intramolecular H-bonds.

Unfortunately, we could not get suitable crystals of complexes **2a**–**2d**, for X-ray structure analysis. However, according to the IR, ^1H, $^{31}P\{^1H\}$ NMR and luminescence data, obtained in a $CDCl_3$ solution and in the solid state, complexes **2a**–**2d** have a $ZnO_2S_2N_2$ core (Scheme 2A). The comparative analysis of IR spectra of the initial ligands $RC(S)NHP(O)(OiPr)_2$ (R = Ph and PhNH), their complexes

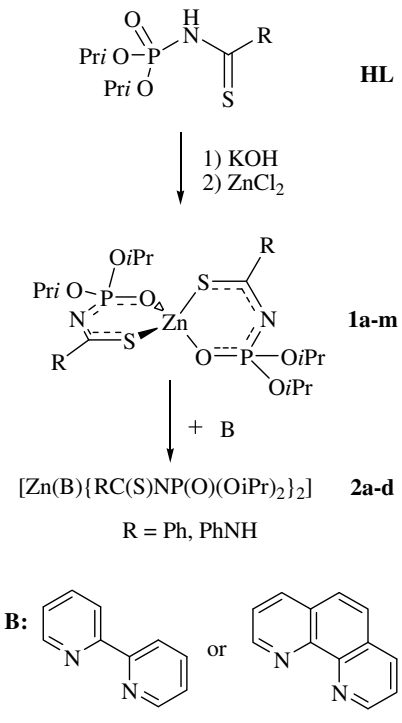
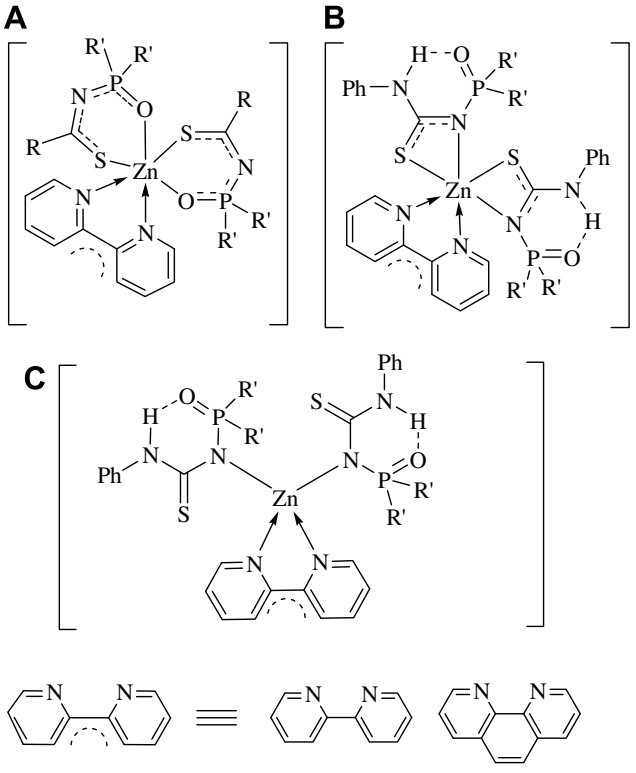


Scheme 1.



Scheme 2. Proposed modes of the ligand coordination in complexes [Zn(B)L_2] (2). R′ = O*i*Pr.

with the Zn(II) cation **1a** and **1b**, and adducts **2a**–**2d** confirms the preservation of the 1,5-*O*,*S*-coordination in the [ZnL_2] core of **2a**–**2d**.

There is a series of the P═O group absorption bands in the IR spectra of complexes **2a**–**2d** in the area close to the appropriate 1,5-*O*,*S*-chelate complexes of type [ML_2] [4–6], and there is also an intense absorption band of the SCN fragment. This confirms the 1,5-*O*,*S*-coordination of the ligand anions.

It is important to note, that the band of the PhNH group in **2c**, **2d** is in the field of 3288–3312 cm^{-1}, which is characteristic for

1,5-*O*,*S*-isomers, showing the weak intermolecular H-bonding in the solid state [5,8]. The isomers B and C must have the NH-group absorption band up to 3100–3160 cm^{-1} [8] due to formation of the strong intramolecular hydrogen bond (Scheme 2).

The $^{31}P\{^1H\}$ NMR signals of complexes **2a**–**2d** appear at δ = 5.9–6.7 ppm, i. e. there is a down-field shift relative to that of the free ligand RC(S)NP(O)(O*i*Pr)$_2$ (R = Ph, δ = −5.6 ppm and PhNH, δ = −5.3 ppm). Full width at half peak heights is in the range 3.0–9.0 Hz. However, the shift of the signals in **2a**–**2d** is more than 0.2–0.4 ppm, compared to the complexes **1a** and **1b** [11]. The signals are in the region that is characteristic to the amidophosphate environment in complexes of *N*-acylamidophosphate anions.

The ^1H NMR spectra of complexes **2a**–**2d** contain a set of signals for the (*i*PrO)$_2$P(O) and C_6H_5 protons. There are also signals corresponding to the polyaromatic chelate ligand. Analysis of the integral intensities of the proton signal testifies about complexes **2a**–**2d** structure of [Zn(2,2′-bpy)L_2] (**2a**, **2c**) or [Zn(1,10-phen)L_2] (**2b**,**2d**).

Thus, IR and NMR spectroscopy data confirm the structure of the adducts **2a**–**2d** in solution and solid state. The donor polyaromatic ligands, as well as anionic ligands, are coordinated to the Zn(II) cation.

3.3. EI mass spectrometry

Molecular ions of complexes **2a**–**2d** are unstable under the conditions of measurement, and the heaviest molecular ion, observed in the spectra of **2a**–**2d**, corresponds to the neutral [ZnL_2] complex core. In the EI mass spectra there are also peaks of the parent amidophosphate ligands, 2,2′-bipyridine and 1,10-phenanthroline, respectively.

3.4. Molecular structure of ZnL_2 complexes *1f*, *1h*, *1l*

According to the X-ray data complexes **1f**, **1h**, **1l** are spirocycling bis-chelates with a distorted-tetrahedral ZnO_2S_2 core. All complexes contain structurally independent ligand moieties. The selected bond lengths and torsion angles are given in Table 2. Intermolecular hydrogen bond parameters are given in Table 3.

Bond lengths (S)C–N and P–N in complexes are shortened (Table 2) and the C=S and P=O(Zn) distances are considerably lengthened in comparison with typical interatomic distances reported for *N*-phosphorylated thioureas [6]. The bond lengths distribution in the ligand moieties confirms the superiority of *S*-enolic tautomeric form S–C=N–P=O for all compounds.

Six-membered Zn–O–P–N–C–S cycles have the asymmetrical boat conformation. The maximal deviation of atoms from the least square plane (LSP) of the cycles is observed for the phosphorus, sulphur and zinc atoms. Chelate cycles in **1f** are almost planar; the deviation from LSP is the smallest among the presented structures.

Complexes **1f**, **1l** show a remarkably different H-bonding pattern in the crystal (Scheme 3). Molecules of **1f** are connected to endless chains by H-bonds between the NH_2 group proton and the nitrogen atom of the N–P group. The chelates **1h** and **1l** form hydrogen-bonded chains with the RNH proton and the sulphur atom of neighbor chelate molecule.

3.5. Photoluminescent properties

The data of the emission spectra for complexes **1a**–**1m** and **2a**–**2d** in the solid state at room temperature are listed in Table 4 (note that the parent ligands have no emission). Interestingly, they exhibit practically the same fluorescent properties.

Complexes **1a**–**1m** show a blue emission band with the maximum intensity at 394–399 nm upon excitation at 249 nm (Table 4 and Fig. 4). Complexes **2a**–**2d** give a strong blue emission band at 413–419 nm when irradiated at wavelength 249 nm (Table 4 and Fig. 4). In order to understand the nature of these emission bands, we analyzed the photoluminescence properties of free HL. For excitation wavelengths between 300 and 500 nm, there is no obvious emission observed for free HL under the same experimental conditions. Therefore, the fluorescent emissions in the compounds **1a**–**1m** are proposed to originate from the coordination of two L^- to the zinc atom and according to the literature [15], these emission bands can be assigned to the emission of ligand-to-metal charge transfer (LMCT).

1e	398	**2a**	415
1f	397	**2b**	418
1g	398	**2c**	413
1h	399	**2d**	419
1i	398		

[a] Excitation at 249 nm.

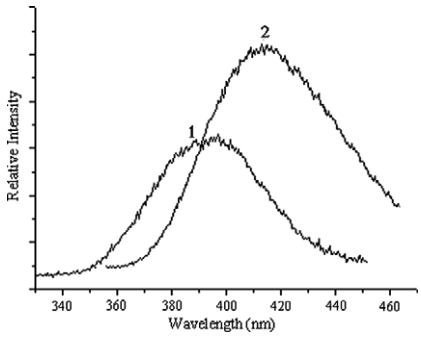

Fig. 4. Fluorescent emission spectra of complexes **1a** (curve 1; spectra of complexes **1b**–**1m** are similar) and **2a** (curve 2; spectra of complexes **2b**–**2d** are similar).

In the solid state, the emission bands increase in intensity and with a notable shift in energy. As it has been told above, there are no emission bands of HL found at 300–500 nm and it is known that the free 2,2′-bipyridine molecule displays a very weak luminescence at 530 nm in the solid state at room temperature [15b]. Thus, compared with **1a**, **1b**, the emission peaks of **2a**–**2d** exhibit a clear bathochromic shift, which may be due to σ-donations from both the L^- and 2,2′-bipyridine or 1,10-phenanthroline ligands to the Zn(II) ion.

Easily synthesized *N*-thioacylamidophosphates HL do not have absorption in the visible region and their Zn(II) chelates are colourless. Therefore they could be excited with UV light that has been shown by us during the experiment. The presence of the bpy or phen ligands in the coordination sphere of the Zn(II) cation allows increasing the emission that might be easily used in non-linear optical devices.

4. Conclusion

N-Phosphorylated thioamides and thioureas HL form with the Zn(II) cation only [ZnL_2] chelates with a tetrahedral ZnO_2S_2 core. 1,5-*O*,*S*-Coordination of the deprotonated form of the ligand, generating a maximal bite angle for L^-, appears as much as possible favorable on the steric reasons.

The ZnO_2S_2 core in these complexes shows a coordination unsaturation. The [ZnL_2] complexes tends to increase the coordination number of the central atom with neutral donor ligands like 2,2′-bipyridine or 1,10-phenanthroline. The adducts of common formula [Zn(bpy)L_2] and [Zn(phen)L_2] have been obtained and characterized. The preservation of the 1,5-*O*,*S*-coordination mode of L^- in the adducts have been established on the basis of the IR and NMR data comparison.

Luminescent zinc *N*-thioacylamidophosphates can be used as new light-converting molecular devices since they (i) are air/moisture stable, (ii) show luminescent properties in the solid state, and at the same time (iii) ligands can be easily prepared from widely used amines and isothiocyanates [4,11].

Received 21 January 2008; accepted 21 January 2008
Available online 10 March 2008

The authors regret that in the experimental section, everywhere where they occurred, complex $Cu_2(H_2O)_2(L^6)_2 \cdot 2DMF$ should be numbered as **3** and not **2**, and complex $Cu_2(OAc)_2(H_2O)_2\ (L^3)_2$ has to be numbered as **2** and not **3**. The same correction is needed in the column headings (Compound) of Tables 1 and 2. The correct column headings should be: Compound **1 3 2 4** (instead of "Compound **1 2 3 4**").

A revised experimental section is appended.

2.2.2. $Cu_2(H_2O)_2(L^6)_2 \cdot 2DMF$ (**3**)

A solution of $Cu(OAc)_2 \cdot H_2O$ (130 mg, 0.66 mmol) in water (2 ml) was added to a solution of nitronyl nitroxide **HL**^{2} (100 mg, 0.33 mmol) in MeOH (3 ml). The resulting solution was stored for 12 h; then the solvent was distilled off in vacuum at room temperature. The residue was crystallized as described for **1**. Compound **3** was obtained as greenish blue crystals suitable for an X-ray analysis. Yield 110 mg (77%). IR: $\tilde{\nu}_{max}$ = 481, 548, 607, 662, 798, 848, 875, 1026, 1074, 1101, 1138, 1170, 1298, 1324, 1351, 1379, 1403, 1467, 1510, 1627, 1666, 2993, 3393 cm^{-1}. Elemental *Anal.* Calc. for $C_{28}H_{44}Cu_2N_{10}O_{12}$: C, 40.1; H, 5.3; N, 16.7. Found: C, 39.9; H, 5.3; N, 16.7%. When conducted in DMF, the reaction also gave compound **3** in ~85% yield.

2.2.3. $Cu_2(OAc)_2(H_2O)_2(L^3)_2$ (**2**)

A solution of $Cu(OAc)_2 \cdot H_2O$ (80 mg, 0.39 mmol) in water (1.5 ml) was added to a solution of imino nitroxides **HL**^{3} (80 mg, 0.39 mmol) in a mixture of water (1.5 ml), MeOH (1 ml), and EtOH (1.5 ml). The resulting solution was stored for 12 h; then the solvent was distilled off in vacuum at room temperature. The residue was processed as described for **1**. Complex **2** was obtained as dark green crystals suitable for an X-ray analysis. Yield 40 mg (30%). IR: $\tilde{\nu}_{max}$ = 422, 468, 567, 611, 633, 684, 723, 795, 891, 935, 968, 1020, 1077, 1137, 1188, 1260, 1340, 1369, 1400, 1482, 1593, 1676, 2928, 2972, 3248, 3454 cm^{-1}. Elemental *Anal.* Calc. for $C_{24}H_{40}Cu_2N_8O_8$: C, 41.4; H, 5.8; N, 16.1. Found: C, 41.6; H,5.7; N, 16.1%.

Monodentate coordination

ABSTRACT

A polypyridyl ruthenium complex monodentately coordinated by 2-mercaptopyridine *N*-oxide was prepared as a candidate for showing linkage isomerisation. [Ru(bpy)(tpy)(2-OpyS)]PF_6 (bpy: 2,2′-bipyridine; tpy: 2,2′:6′,2″-terpyridine; 2-OpyS$^-$: anion of 2-mercaptopyridine *N*-oxide) was synthesised and structurally characterised. The complex contains a 2-OpyS$^-$ ligand coordinating only with the sulphur atom. Electrochemically induced linkage isomerisation was examined for this complex.

© 2008 Elsevier Ltd. All rights reserved.

1. Introduction

Linkage isomerisation is known to occur in complexes of which the metal atom is bound to an ambidentate ligand that has two or more different donor atoms [1–17]. In general, metal ions act as Lewis acids and coordination atoms of ligands serve as Lewis bases. According to the hard and soft acids and bases (HSAB) principle, soft coordination atoms preferentially bind to Ru(II) ions and hard coordination atoms bind to Ru(III) ions, because Ru(II) ions are softer than those of Ru(III). Therefore, if a ruthenium complex is designed to contain a monodentately coordinated ligand with coordination atoms of different softness (or hardness), the linkage isomerisation between Ru(II)–[soft coordination atom] and Ru(III)–[hard coordination atom] should be observed on oxidation or reduction of ruthenium. Many ruthenium–dimethylsulfoxide (dmso) complexes, which exhibit electrochemically induced linkage isomerisation, have been reported [8–17]. For example, $[Ru^{II}(NH_3)_5(dmso)]^{2+}$ [8] is one of the most well-known molecules. In this complex, the S atom of dmso coordinates to the Ru(II) and the O atom does not coordinate. After oxidation of Ru(II) to Ru(III), the complex isomerises to the other isomer in which Ru(III) is coordinated to the O atom.

In this study, a ruthenium complex was designed as a candidate for showing linkage isomerisation as follows. The anion of 2-mercaptopyridine *N*-oxide (2-OpyS$^-$) is an ambidentate ligand that has different types of coordination atoms in one molecule. So far, some studies have reported that 2-OpyS$^-$ monodentately coordinates to a metal ion [18], although complexes with an ambidentate ligand are largely unexplored [19]. Therefore, the ruthenium complex monodentated by 2-OpyS$^-$ is designed to contain 2,2′-bipyridine(bpy) and 2,2′:6′,2″-terpyridine(tpy) as ancillary ligands. We report here the synthesis, characterisation and electrochemical investigation of the ruthenium complex $[Ru^{II}(bpy)(tpy)(2\text{-}OpyS)]PF_6$ (**1**).

2. Experimental

2.1. Materials

All materials were purchased from commercial suppliers (Wako Pure Chemical Industries Ltd., Kanto Chemical Co. Inc. and Acros Organics) and were used without further purification.

2.2. Instrumentation

The crystal structure measurement was made on a Rigaku AFC-5 diffractometer with graphite-monochromated Mo Kα (λ = 0.71069 Å) radiation. The psi-scan correction was applied. The structure was solved by the direct method (SHELXS-97 [20]), and was refined by the full matrix least-square method on F^2 (SHELXL-97 [20]). Hydrogen atoms were included in the calculated positions and refined as a riding model. The ^{1}H NMR spectrum was measured on a Varian Inova 400WB NMR spectrometer at room temperature. Chemical shifts were referenced to the acetonitrile signal at δ 1.93 ppm, corresponding to TMS at δ 0.00 ppm. The absorption spectrum was measured using a SIMADZU UV-3600 UV–Vis–NIR spectrophotometer and 10-mm quartz cell at a concentration of 3.49×10^{-5} mol dm^{-3}. Cyclic voltammetry was performed on a BAS BAS100B/W using three electrode cells (glassy

doi:10.1016/j.poly.2008.03.013

carbon electrode as working electrode, Pt coil electrode as counter electrode and homemade Ag^+/Ag electrode as reference electrode). The medium was 0.1 mol dm^{-3} n-Bu_4NPF_6/CH_3CN. The concentration of the complex was 1×10^{-3} mol dm^{-3}. $E_{1/2}$ of the ferrocenium/ferrocene couple was 0.10 V versus Ag^+/Ag. Scan rate was 50 mV s^{-1}. C, H and N analysis was furnished by Service center of the elementary analysis of organic compound of Kyushu University. ESI-Mass spectrum was recorded on a JEOL JMS-T100CS mass spectrometer.

2.3. Synthesis

A mixture of a suspension of $[Ru(bpy)(tpy)Cl]Cl \cdot 2.5H_2O$ [21] (0.50 g, 0.82 mmol) in H_2O (30 cm^3) and a solution of $AgCF_3COO$ (2 equiv.) in H_2O (20 cm^3) was heated at 80 °C for 30 min. The precipitate was filtrated off after cooling the mixture to room temperature. 2-OpySNa (0.69 g, 4.1 mmol) was added to the filtrate, and the solution was allowed to stand for 2 days. KPF_6 (1.84 g, 10 mmol) was added to the solution, and the resulting precipitate was filtrated (0.48 g). The crude product (0.20 g) was purified by recrystallization from H_2O/acetone with a yield of 0.047 g (8.2%). *Anal.* Calc. for $C_{30}H_{23}N_6O_1S_1Ru_1P_1F_6 \cdot 0.5H_2O$: C, 46.76; H, 3.14; N, 10.91. Found: C, 46.78; H, 3.06; N, 10.96%. ESI-MS: m/z 617 (calc(M−PF_6) = 617).

Absorption data (CH_3CN) λ/nm (ε/dm^3 mol^{-1} cm^{-1}): 585sh (3670), 494 (5670), 444sh (5070), 362sh (6880), 304 (28 500), 292 (37 700), 278sh (32 800), 249 (43 100).

^1H NMR (400 MHz, CD_3CN) δ/ppm: 6.31 (d, 7.8 Hz, 1H, 2-OPyS$^-$), 6.38 (t, 7.5 Hz, 1H, 2-OPyS$^-$), 6.58 (t, 5.8 Hz, 1H, 2-OPyS$^-$), 6.94 (t, 5.7 Hz, 1H, bpy), 7.09 (t, 5.6 Hz, 2H, tpy), 7.20 (d, 5.6 Hz, 1H, bpy), 7.31 (d, 6.4 Hz, 1H, 2-OPyS$^-$), 7.69 (d, 5.0 Hz, 2H, tpy), 7.74 (m, 1 H+2H, bpy+tpy), 7.97 (t, 5.6 Hz, 1H, bpy), 8.02 (t, 8.1 Hz, 1H, tpy), 8.13 (d, 8.1 Hz, 2H, tpy), 8.25 (t, 7.9 Hz, 1H, bpy), 8.33 (d, 8.1 Hz, 1H, bpy), 8.36 (d, 8.1 Hz, 2H, tpy), 8.56 (d, 8.1 Hz, 1H, bpy), 11.33 (d, 5.8 Hz, 1H, bpy).

Crystallographic data: crystal colour black, crystal habit plate, crystal dimensions 0.50 mm × 0.50 mm × 0.08 mm, empirical formula $C_{30}H_{23}F_6N_6OPRuS$, M = 761.64, crystal system monoclinic, space group $P2_1/n$, a = 9.0777(11), b = 18.866(2), c = 16.8965(13) Å, β = 97.833(9)°, V = 2866.6(5) Å^3, Z = 4, D_{calc} = 1.765 g cm^{-3}, T = 296(2) K, parameters 415, reflections collected 6977, independent reflections 6572, reflections used 5114 for $I > 2\sigma(I)$, R_{int} = 0.0830, R_1 and wR_2 were 0.0326 and 0.0840 for $I > 2\sigma(I)$, respectively ($R_1 = \sum||F_o| - |F_c||/\Sigma|F_o|$ $wR_2 = ((\sum(w(F_o^2 - F_c^2)^2))/\sum(wF_o^4))^{0.5}$).

3. Results and discussion

3.1. Synthesis and identification

The reaction of $[Ru(bpy)(tpy)Cl]^+$ and Ag^+ produced $[Ru(bpy)(tpy)(H_2O)]^{2+}$. In the resulting complex $[Ru(bpy)(tpy)(H_2O)]^{2+}$, the Ru atom is coordinated to five inert N atoms of bpy/tpy and one labile O atom of water. Since the five positions are protected from coordination, 2-OpyS$^-$, which is a bidentate ligand, can coordinate to ruthenium through only one atom. Complex **1** was prepared by the reaction of $[Ru(bpy)(tpy)(H_2O)]^{2+}$ and excess 2-mercaptopyridine N-oxide sodium salt at room temperature. The complex cation was precipitated from the reaction mixture as its PF_6 salt. The crude product was purified as black crystals by recrystallisation from H_2O/acetone. Complex **1** is soluble in polar solvents such as CH_3CN and acetone and is insoluble in nonpolar solvents such as benzene and chloroform.

Single crystals of **1** suitable for single-crystal X-ray analysis were obtained by slow recrystallisation from a H_2O/acetone solution at room temperature. The crystal structure of **1** is shown in Fig. 1. As mentioned above, 2-OpyS$^-$ has two different types of coordination atoms in one molecule; it is interesting that the Ru atom is coordinated by either the S atom or the O atom of 2-OpyS$^-$. Fig. 1 shows that the 2-OpyS$^-$ ligand coordinates to the Ru atom through only the S atom, and this coordination environment is a reasonable example of the HSAB principle being obeyed. Each **1** molecule contains one PF_6 anion and the ruthenium is of the Ru(II) species (see ^1H NMR discussion below); therefore, the 2-OpySH ligand is deprotonated and coordinates to Ru as an anion form. The S(1)–C(26) and N(6)–O(1) bond lengths are 1.733(4) and 1.308(4) Å, respectively. These indicate that 2-OpyS$^-$ may coordinate to the Ru in the thione form rather than the thiolate form and that the negative charge of the 2-OpyS$^-$ ligand is mainly localised on the O atom [18,22,23]. Tridentated tpy coordinates in meridional fashion with the central nitrogen closest to the Ru atom, the *cis*-position of tpy is filled by the S atom of the monodentate 2-OpyS$^-$ ligand, and the remaining coordination positions are coordinated by the N atoms of bpy. This coordination environment forms a distorted octahedral structure on the Ru. Bpy plane and tpy plane are almost orthogonal (83.97(5)°); however, the angles between 2-OpyS$^-$ plane and bpy plane and between 2-OpyS$^-$ plane and tpy plane are 63.77(7)° and 70.24(6)°, respectively. The steric repulsion between 2-OpyS$^-$ and the other ligands forces 2-OpyS$^-$ into this arrangement, and therefore, the O atom is kept away from the Ru atom in the crystal.

^1H NMR spectrum of **1** in CD_3CN is a complicated spectrum, and almost all peaks are in the narrow range of δ 6 to δ 9 ppm (Fig. 1S in Supplementary material). The complex contains 18 non-equivalent pyridyl protons, which have considerably similar electronic environments. We have assigned all peaks to the individual protons of the ligands by the ^1H correlation spectroscopy (COSY) experiment; therefore, single-crystal X-ray analysis of **1** should also reveal a unique structure in CH_3CN solution. The signals for the tpy indicate that there is twofold symmetry, which suggests rotation of the 2-OpyS$^-$ around the Ru–S bond. Sharp signals in the normal region reveal that **1** is diamagnetic, i.e., the ruthenium species is Ru(II).

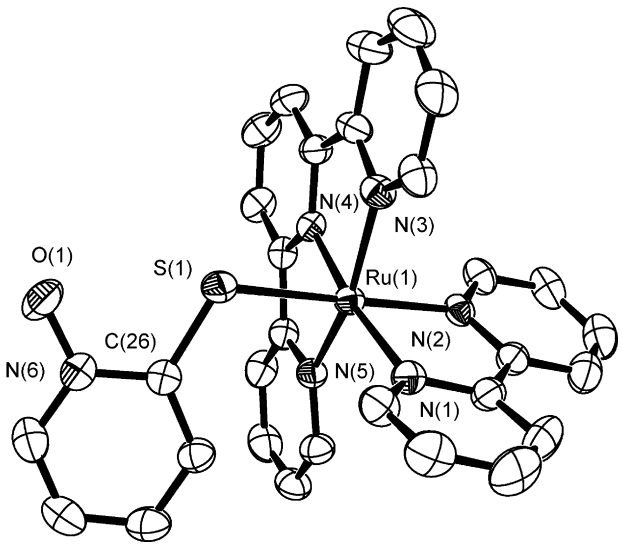

Fig. 1. Molecular structure of the complex cation of **1**. Thermal ellipsoids are drawn at the 50% probability level, and hydrogen atoms are omitted. Selected bond lengths (Å) and angles (°): Ru(1)–N(1) = 2.095(3), Ru(1)–N(2) = 2.064(3), Ru(1)–N(3) = 2.079(3), Ru(1)–N(4) = 1.961(3), Ru(1)–N(5) = 2.099(3), Ru(1)–S(1) = 2.4194(10), S(1)–C(26) = 1.733(4), N(6)–O(1) = 1.308(4), N(2)–Ru(1)–N(1) = 77.82(12), N(4)–Ru(1)–N(3) = 79.76(12), N(4)–Ru(1)–N(5) = 78.98(11), N(2)–Ru(1)–S(1) = 175.00(8), N(4)–Ru(1)–N(1) = 172.40(12) and N(3)–Ru(1)–N(5) = 158.63(12).

The absorption spectrum of **1** was measured in acetonitrile (Fig. 2S in Supplementary material). Four weak broad bands are seen in the visible region and four intense sharp bands are in the UV region. The former bands are assigned to metal-to-ligand charge transfer (MLCT), and the latter bands are assigned to a ligand centred π–π^* transition. Various MLCT and π–π^* transitions are caused by three pyridine-derivative ligands.

3.2. Electrochemical properties

One anion of 2-OpyS$^-$ contains one O and one S atom, and the S atom is softer than the O atom. Therefore, this complex might exhibit electrochemically induced linkage isomerisation of Ru(II)–S to Ru(III)–O upon oxidation, such as in $[Ru(NH_3)_5(dmso)]^{2+}$ [8] and $[Ru(bpy)(tpy)(dmso)]^{2+}$ [14]. To investigate electrochemically induced linkage isomerisation of **1**, cyclic voltammograms were obtained. For anodic scan starting at −1.50 V versus Ag^+/Ag (Fig. 2a), one reversible redox couple was observed at $E_{1/2}$ = 0.72 V versus Ag^+/Ag. A cathodic peak at E_c = −0.76 V and an anodic peak at E_a = 0.19 V versus Ag^+/Ag were also observed. After oxidising at 1.00 V for 3 min, almost the same voltammogram was observed with a cathodic scan starting at 1.00 V versus Ag^+/Ag ($E_{1/2}$ = 0.72 V, E_c = −0.71 V and E_a = 0.19 V versus Ag^+/Ag). This irreversible redox behaviour at E_c and E_a might imply that **1** showed linkage isomerisation caused by the redox of the ruthenium [5,8,15].

Cyclic voltammograms of **1** and the ligands were compared due to confirm whether the metal centre is responsible for the irreversible redox behavior. Fig. 2b is the cyclic voltammogram of 2-OpySH in 1 equiv. Et_3N/CH_3CN, where 2-OpySH is in the deprotonated form (2-OpyS$^-$). Regardless of scan direction, 2-OpyS$^-$ has approximately the same irreversible redox behavior as **1** (anodic scan: E_c = −1.38 V and E_a = 0.03 V versus Ag^+/Ag; cathodic scan:E_c = −1.37 V and E_a = −0.04 V versus Ag^+/Ag). Therefore, the ligand and not the metal centre is responsible for the irreversible redox behavior, which might imply electrochemically induced linkage isomerisation. The reversible redox couple at $E_{1/2}$ = 0.72 V versus Ag^+/Ag is associated with Ru(III/II), and this complex does not show electrochemically induced linkage isomerisation.

The short distance between the Ru and O atoms should be important for electrochemically induced linkage isomerisation from Ru(II)–S to Ru(III)–O. For example, $[Ru(bpy)(tpy)(dmso)]^{2+}$ [14], which has almost the same local coordination environment as the Ru of **1**, exhibits linkage isomerisation. The distances of Ru–S and Ru···O in $[Ru(bpy)(tpy)(dmso)]^{2+}$ are 2.282(1) and 3.204(2) Å, respectively. In the case of **1**, the Ru–S and Ru···O distances are 2.4194(10) and 5.1917(30) Å, respectively. Complex **1** might have too long Ru···O to form a Ru–O bond by comparison with Ru···O distance of $[Ru(bpy)(tpy)(dmso)]^{2+}$; however, 2-OpyS$^-$ ligand is able to rotate around the Ru–S bond (see ^{1}H NMR discussion). The rotation around Ru–S and C–S bond on the computer obtained the closest distance as ca. 3.5 Å, which seems not to be long. Therefore, isomerisation is not affected by the structure. On the other hand, Rack and co-workers mention the importance of ancillary ligands. They remark that weak-field π-basic ligands do not allow the Ru(III) centre to appear hard enough to favor the hard O-donor over the soft S-donor in [Ru(tpy)(ancillary ligand)(dmso)]$^{n+}$ [12,16,17]. Their discussion is in the case of dmso complex instead of 2-OpyS$^-$ complex; however, we think that the Ru(III) in **1** also might prefer to make Ru–S bond instead of Ru–O due to the electron density.

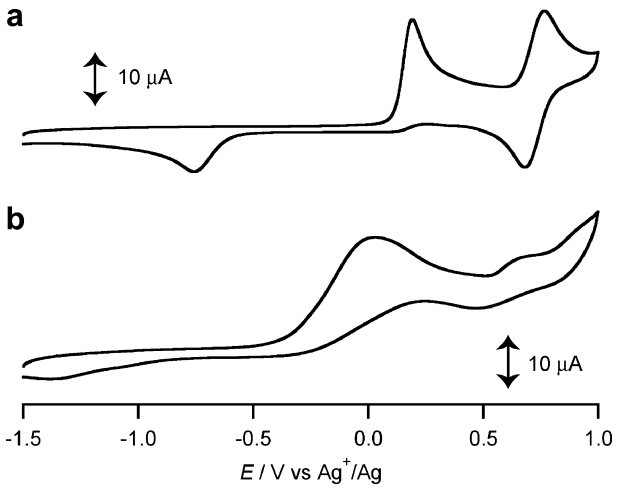

Fig. 2. Cyclic voltammograms of (a) **1** in CH_3CN and (b) 2-OpySH in 1 equiv. Et_3N/CH_3CN.

4. Conclusion

$[Ru(bpy)(tpy)(2\text{-}OpyS)]PF_6$ was prepared, crystallographically characterised and electrochemically investigated. The 2-OpyS$^-$ ligand coordinates to the Ru(II) only through the S atom in the isolated complex. To the best of our knowledge, **1** is the first structurally characterised example of a monodentate κS bound 2-OpyS$^-$ ligand in the ruthenium complex reported so far.

The 2-OpyS$^-$ ligand is also possible to coordinate to central metal with O atom; however, the complex does not show linkage isomerisation from Ru(II)–S to Ru(III)–O under the condition in this study. The reason why the complex shows no isomerisation might come from the electron density on the Ru centre. In future studies, we would investigate a family of $[Ru^{II}(ancillary\ ligand)(2\text{-}OpyS)]^{n+}$ complexes, and we will address the relationship among the electron density of the Ru, the property of ancillary ligand and electrochemically induced linkage isomerisation.

ABSTRACT

Three novel supramolecules of the Ag(I) complexes of $[Ag_4(pyapa)_4(SO_4)_2 \cdot 6H_2O]_n$, **1**, $\{[Ag_2(pyapa)_2][ClO_4]_2\}_n$, **2** and $\{[Ag_2(pyapa)_2(H_2O)][NO_3]_2\}_n$, **3**, (pyapa = 1-(2-pyrazinyl)piperazine) have been prepared by self-assembly of Ag(I) salts with 1-(2-pyrazinyl)piperazine (pyapa) in MeOH/H_2O system. The IR, TGA and elemental analysis have been recorded and all the complexes have been structurally characterized by X-ray crystallography confirming that complexes **1**–**3** are one-dimensional coordination polymers. The pyapa ligands in complexes **1**–**3** bind soft acid Ag(I) ions through the pyrazinyl and piperazinyl groups forming the 1-D polymeric chains. The anions SO_4^{2-} in complexes **1** shows the disordered geometries and bridging the Ag(I) atoms, while the anions ClO_4^- and NO_3^- in complexes **2**–**3** are not coordinated to the Ag(I) atoms, and all of them play an important roles in linking cationic chains into 3-D supramolecular structures. Thermal gravimetric analyses (TGA) were carried out to investigate their thermal properties.

1. Introduction

Recently, a great effort has been devoted to the self-assembly of organic and inorganic molecules in the solid state, because it extends the range of designing new solids with desired physical and chemical properties [1,2]. The range and variety of self-assembled inorganic structures that can be constructed relies on the suitable metal-ligand interactions and supramolecular contacts, i.e., hydrogen bondings and other weak interactions [3]. The self-assembly of supramolecular structures using metal coordination has become the focus of intense interest over the past decade [4]. This is largely due to the range of potential applications in electrical, magnetic, optical devices [5] and porous zeolite mimics [6]. The specific properties of each coordination network are directly related to its atomic structure, which is a function of both the ligand and the metal. There has been a resurgent interest on extended organic or organometallic crystals based on hydrogen bonds and metal coordination bonds [7–9].

It is, therefore, important to try to understand, and control, the interplay between the coordination characteristics of the ligands and the metals, and the ultimate shape of the self-assembled superstructure. Much study has centered upon the use of supramolecular contacts between suitable molecules to generate multidimensional arrays or networks. The design of supramolecular assemblies via ligand design, the coordination characteristics of the metal ion, and the length of the spacer has resulted in a variety of structural motifs [10]. Many topologically promising architectures have been constructed for the silver(I) ion with bidentate building blocks containing nitrogen donor. The various types of polymeric structure include 1-D, 2-D and 3-D network structures [11]. Despite some recent progress, the ability to predict and control the supramolecular assembly of molecules remains elusive, and much more work is required to understand the inter- and intra-molecular forces that determine the patterns of molecular structure and crystal packing in the solid state. So far, various ligands, such bipyridine-type and biphenyl cyanide-type ligands, have been used for supramolecular building blocks [12–14].

Various ligands have been used for supramolecular building blocks, but exploitation of the polydentate 1-(2-pyrazinyl)piperazine (pyapa) has until recently unprecedented. The ligand process two functionalities with pyrazinyl and the piperazinyl groups. The affinity of Ag^+ for N-donor ligands, especially pyrazinyl and the piperazinyl group, is well known. In this paper, we report three novel supramolecular Ag(I) complexes of $[Ag_4(pyapa)_4(SO_4)_2 \cdot 6H_2O]_n$, (pyapa = 1-(2-pyrazinyl)piperazine) **1**, $\{[Ag_2(pyapa)_2][ClO_4]_2\}_n$, **2** and $\{[Ag_2(pyapa)_2(H_2O)][NO_3]_2\}_n$, **3**.

2. Experimental

2.1. General procedures

All manipulations were carried out under air. IR spectra were obtained from a Jasco FT/IR-460 plus spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer or a HERAEUS VaruoEL analyzer. Thermogravimetric analyses (TGA) were conducted on a SDT 2960 using a heating rate of 20 C/min in a nitrogen atmosphere.

2.2. Materials

The reagents 1-(2-pyrazinyl)piperazine (pyapa), Ag_2SO_4, $AgClO_4$ and $AgNO_3$ were purchased from Acros Co.

2.3. Preparation of complex *1*

1-(2-Pyrazinyl)piperazine (pyapa) (0.328 g, 0.20 mmol) in 5 ml EtOH was layered onto a solution of Ag_2SO_4 (0.311 g, 0.10 mmol) in 5 ml H_2O. The resulting solution was slowly diffused for several weeks to give colorless crystal. Yield: 0.0372 g, 27.0% *Anal.* Calc. for **1** ($C_{32}H_{48}Ag_4N_{16}O_{14}S_2$): C, 27.92; H, 3.51; N, 16.28. Found: C, 27.88; H, 3.51; N, 16.22%. IR (KBr disk, cm^{-1}): 3435 (w), 3205 (br), 3106 (m), 2955 (m), 2920 (m), 2487 (m), 1638 (m), 1580 (m), 1518 (m), 1490 (m), 1436 (m), 1313 (m), 1259 (m), 1201 (m), 1119 (m), 995 (m), 944 (m), 829 (m), 619 (m).

2.4. Preparation of complex *2*

Complex **2** was prepared as for **1**. Yield: 0.0416 g (28%). *Anal.* Calc. for **2** ($Ag_2C_{16}H_{24}Cl_2O_8N_8$): C, 25.86; H, 3.25: N; 15.08. Found: C, 25.82; H, 3.20; N, 15.11%. IR (KBr disk, cm^{-1}): 3436 (w), 3244 (br), 3099 (m), 2960 (m), 2840 (m), 1631 (m), 1583 (m), 1519 (m), 1486 (m), 1433 (m), 1205 (m), 1107 (m), 1090 (m), 995 (m), 937 (m), 822 (m), 626 (m).

2.5. Preparation of complex *3*

Complex **3** was prepared as for **1**. Yield: 0.0213 g (31%). *Anal.* Calc. for **3** ($Ag_2C_{16}H_{26}O_7N_{10}$): C, 28.00; H, 3.82; N, 20.41. Found: C, 28.14; H, 3.85; N, 20.36%. IR (KBr disk, cm^{-1}): 3399 (w), 3246 (br), 3108 (m), 2956 (m), 2920 (m), 2804 (m), 1652 (m), 1518 (m), 1439 (m), 1439 (m), 1366 (m), 1309 (m), 1261 (m), 1201 (m), 1176 (m), 1139 (m), 1078 (m), 1002 (m), 948 (m), 832 (m), 767 (m), 739 (m), 641 (m), 543 (m).

2.6. X-ray crystallography

The diffraction data of **1** was collected on a Bruker AXS Smart 1000 CCD diffractometer, which was equipped with graphite-monochromated Mo Kα (Kα = 0.71073 Å) radiation. Data reduction was carried by standard methods with use of well-established computational procedures [15]. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1. The structure factors were obtained after Lorentz and polarization corrections. The positions of the heavy atoms, including the silver atoms, were located by the direct method. The oxygen atoms (O(5), O(6) and O(8)) of sulfate anions in complex **1** are disordered and thus with the ratio of 0.5:0.5 occupancy were found. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements [16]. The final residuals of the first refinement were $R_1 = 0.0418$, $wR_2 = 0.1062$. The crystallographic procedures for **2** and **3** were similar to those for **1**. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1.

2.7. Syntheses and spectroscopics studies

Complexes of $[Ag_4(pyapa)_4(SO_4)_2 \cdot 6H_2O]_n$, (pyapa=1-(2-pyrazinyl)piperazine) **1**, $\{[Ag_2(pyapa)_2][ClO_4]_2\}_n$, **2** and $\{[Ag_2(pyapa)_2(H_2O)][NO_3]_2\}_n$, **3** were prepared by reactions of Ag_2SO_4, $AgClO_4$ and $AgNO_3$ with pyapa in $MeOH/H_2O$ system. All these complexes were structurally characterized by X-ray crystallography. Crystals suitable for X-ray diffraction studies were obtained

by pyapa in methanolic solution was layered onto a solution of Ag(I) salts in H_2O. The IR spectrum of the complex **1** clearly shows the bands of SO_4^{2-} anions at 1119, 995 and 687 cm^{-1}, indicating the mondendate coordination mode (C_{3v} symmetry). For **2** clearly indicated the presence of ClO_4^- bands at 1090 and 624 cm^{-1}.

2.8. Structure of complex *1*

A single crystal X-ray structural analysis of crystals of **1**, obtained by layer the pyapa methanolic solution on the top of Ag_2SO_4 aqua-solution, revealed the formation of a complex of $[Ag_4(pyapa)_4(SO_4)_2 \cdot 6H_2O]_n$. Colorless crystals of **1** conform to the space group $P2_1$ with two molecules in a unit cell Fig. 1 shows the asymmetric unit ORTEP diagrams for **1**. Selected bond distances and angles are listed in Table 2. The sulfate anion is disordered such that two different molecules, each possessing 50% occupancy, can be solved. Fig. 1a and b show the asymmetry unit ORTEP diagrams of these two disordered anions, while Fig. 1c shows their overlap and the relationship

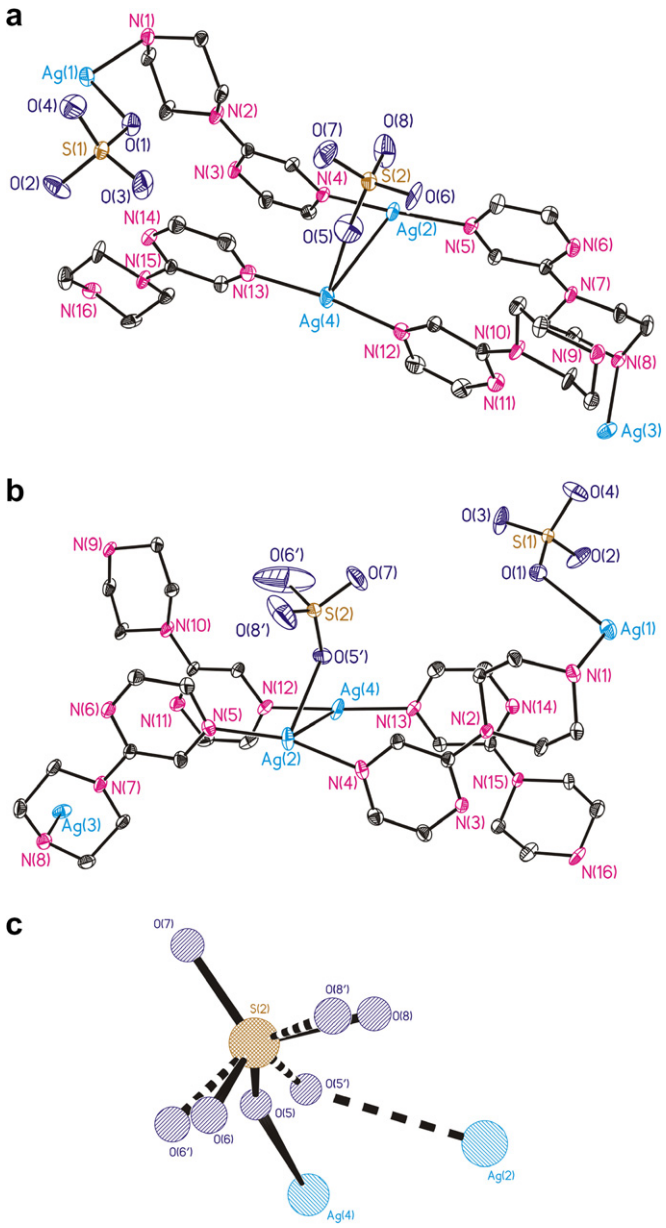

Fig. 1. An ORTEP diagrams of **1**, showing the two disordered asymmetric units, (a) and (b), and the overlap of the two sulfate anions, (c).

between the Ag(2), Ag(4) and the SO_4^{2-} anion. The asymmetry units contain four Ag atoms, two sulfate anions and four pyapa groups. All the sulfate anions in complex **1** are coordinated to the silver centers in monodentate fashion. Fig. 2a shows the coordination geometry about the Ag metal center. The Ag metal centers possess two types of geometries. The Ag(1), Ag(2) and Ag(4) centers adopt a slightly distorted triangular planar coordination geometries, while Ag(3) adopts a linear geometry. The selected bond distances and angles are listed in Table 2. The Ag(2) and Ag(4) atoms are bonded to four pyrazinyl nitrogen atoms (Ag–N = 2.133(6)–2.158(5) Å) from the four different pyapa groups and one sulfate oxygen atom (Ag–O = 2.473(3) and 2.502(2) Å). The Ag(1) bonded to two piperazinyl nitrogen atoms (Ag–N = 2.235(5) and 2.234(6) Å) and a monodentate SO_4^2 oxygen atom to complete the disorder triangular planar geometry, while Ag(3) bonded to two piperazinyl nitrogen atoms (Ag–N = 2.179(6) and 2.196(6) Å) in the linear geometry [N(8)–Ag(3)–N(16B) = 167.7(2)°]. Each Ag(I) coordinated to two pyapa ligands and each pyapa bridged two Ag(I) atoms in complex **1**. Fig. 2b and c shows the pyapa ligand bridging each Ag atoms through pyrazinyl and piperarzinyl nitrogen atoms and formed the helical chains, which the Ag(1) and Ag(2) centers forming the blue one and Ag(3) and Ag(4) centers forming the purple one. The helixes interlink each through Ag···Ag interactions (Ag···Ag = 3.0477(10) Å) and the π–π stacking between the pyrazinyl rings (3.688 and 3.798 Å). The Ag···Ag distances in the helical chains separated by the bridging pyapa are 8.836 and 8.970 Å. The dihedral angles between the two pyrazinyl rigns that coordinated to the Ag atom through the nitrogen atoms are 9.5° and 10.0°. Some few double helical motifs are related, especially if there are several kinds of donor groups in ligand molecular or with flexible ligands. For instances, the ligand 1,3-bis(4-pyridyl)propane (bpp) reacts with $AgCF_3SO_3$ afforded $\{[Ag(bpp)](CF_3SO_3)\}_n$ double helical chains which are also interlinking through Ag···Ag interactions [17] and π–π stacking [18].

Fig. 3 shows the 1-D polymeric helices interlinked each through the weak O···Ag interactions (O···Ag = 2.783–3.086 Å). In complex **1**, the 1-D helices are further linked by the anions through Ag···O interactions (O···Ag = 2.783, 2.826, 3.086 and 3.210 Å), the rare CH···Ag interactions (H···Ag = 2.988–3.348 Å, ∠C–H···Ag = 122.3–147.1°) and CH···O interactions (H···O = 2.486–2.523 Å, ∠C–H···O = 146.6–170.5°) hydrogen bonds to form the 3-D supramolecular structure, Fig. 3.

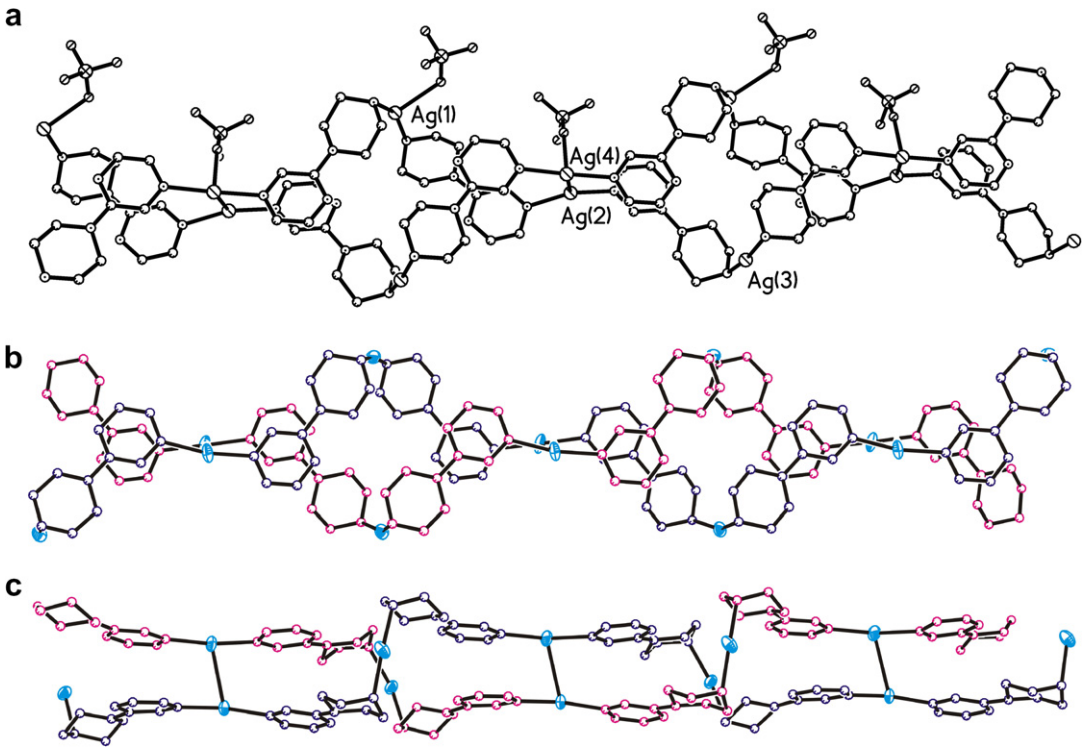

Fig. 2. (a) The structure drawing of complex **1** showing the metal center coordination location, (b) and (c) two fashions of the double helical chains.

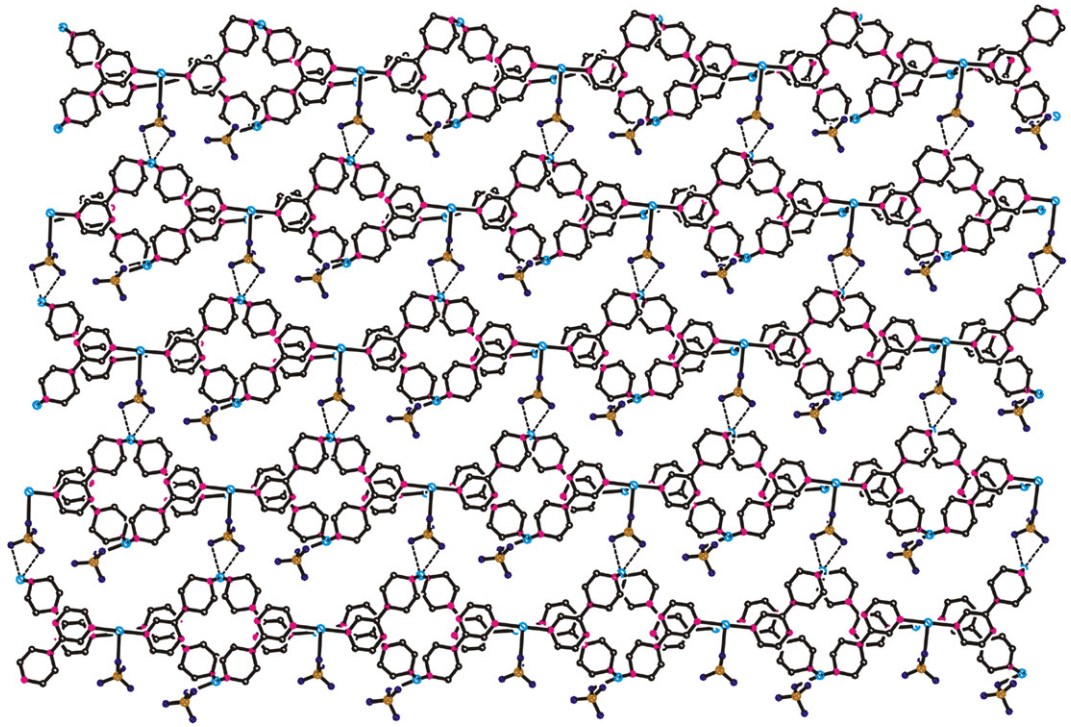

Fig. 3. The packing diagram of complex **1** shows the 2-D sheets forming by weak Ag···O interactions.

2.9. Structure of complex **2**

The crystal structure of complex **2** belongs to the space group $P2_1/c$. A representative ORTEP diagram shows the asymmetric unit of complex **2**, which containing four silver atoms, four perchlorate anions and four bidentate pyapa groups (Fig. 4a). Table 2 list the bond distances and angles around silver atoms for complex **2**. The Ag(I) atoms which are coordinated by two pyrazinyl nitrogen atoms of different pyapa ligands [Ag–N = 2.110(10)–2.186(8) Å] or two piperarzinyl nitrogen atoms of pyapa groups [Ag–N = 2.118(9)–2.180(9) Å] are linear geometries in Ag(1), Ag(2), Ag(3) and Ag(4) [∠N(1)–Ag(1)–N(8A) = 173.0(4)°, ∠N(5)–Ag(2)–N(4) = 174.9(4)°, ∠N(9)–Ag(3)–N(16B) = 176.8(5)°, ∠N(13)–Ag(4)–N(12) = 177.2(3)°]. Fig. 4b shows the silver atoms of Ag(1) and

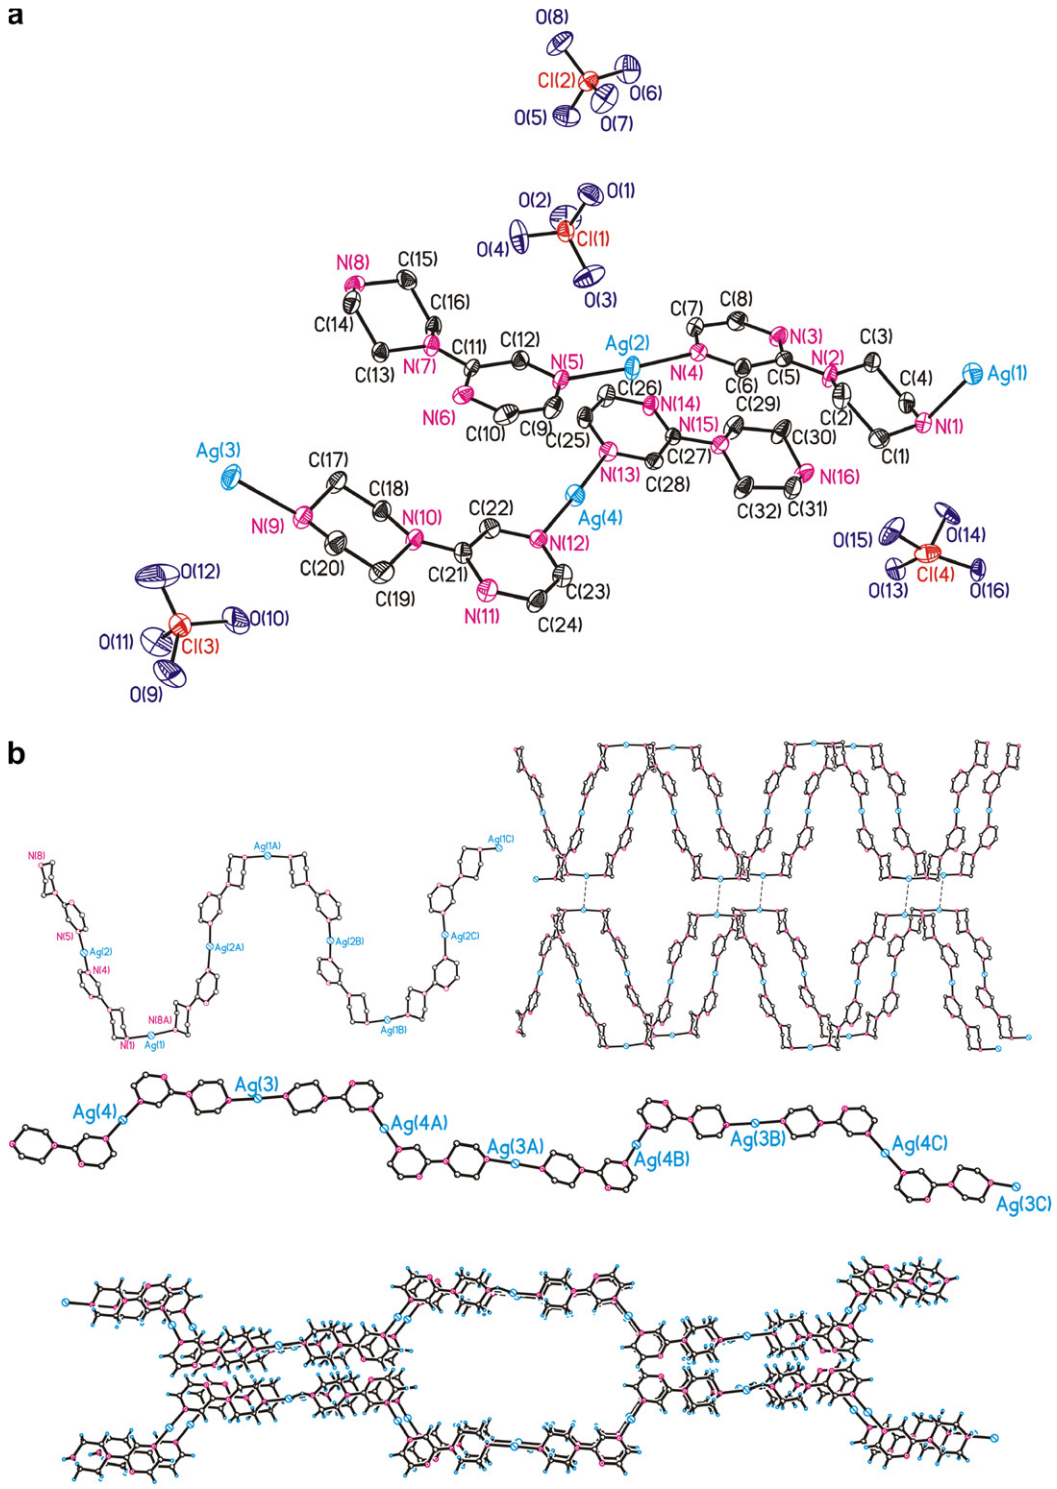

Fig. 4. (a) An asymmetry unit ORTEP drawing of **2**. (b) Two types of $[Ag(pyapa)]_n^{n+}$ cationic chains in **2**.

Ag(2) coordinated to pyapa ligands forming a zig-zag chain that is different from the chain forming by Ag(3), Ag(4) and pyapa groups. The dihedral angles between the two pyrazinyl rings that coordinated to the Ag atoms through the nitrogen atoms are almost coplanar in the degrees of 2.5° and 3.7°. The Ag···Ag distances in the zig-zag chains separated by the bridging pyapa are 9.000 Å.

The packing diagrams (Fig. 5top) show two fashions of the polymeric chains containing Ag(1) and Ag(2) or the one containing Ag(3) and Ag(4) interlink each through weak Ag···Ag interactions (Ag···Ag = 4.004 Å), while the view along the *c*-axis shows two types chains packing through series Ag···Ag (Ag···Ag = 3.892 Å) and Ag–N (Ag–N = 3.167–3.431 Å) interactions (Fig. 5bottom). When looking along the *a*-axis, complex **2** forms the 3-D open-channel supramolecular structure, which are linking by the anions and cationic chains through Ag···O, Ag···N interactions and N–H···N, CH···Ag hydrogen bonds (Ag···O = 3.275 and 3.359 Å, CH···Ag = 3.307 Å, N–H···N = 2.591 Å).

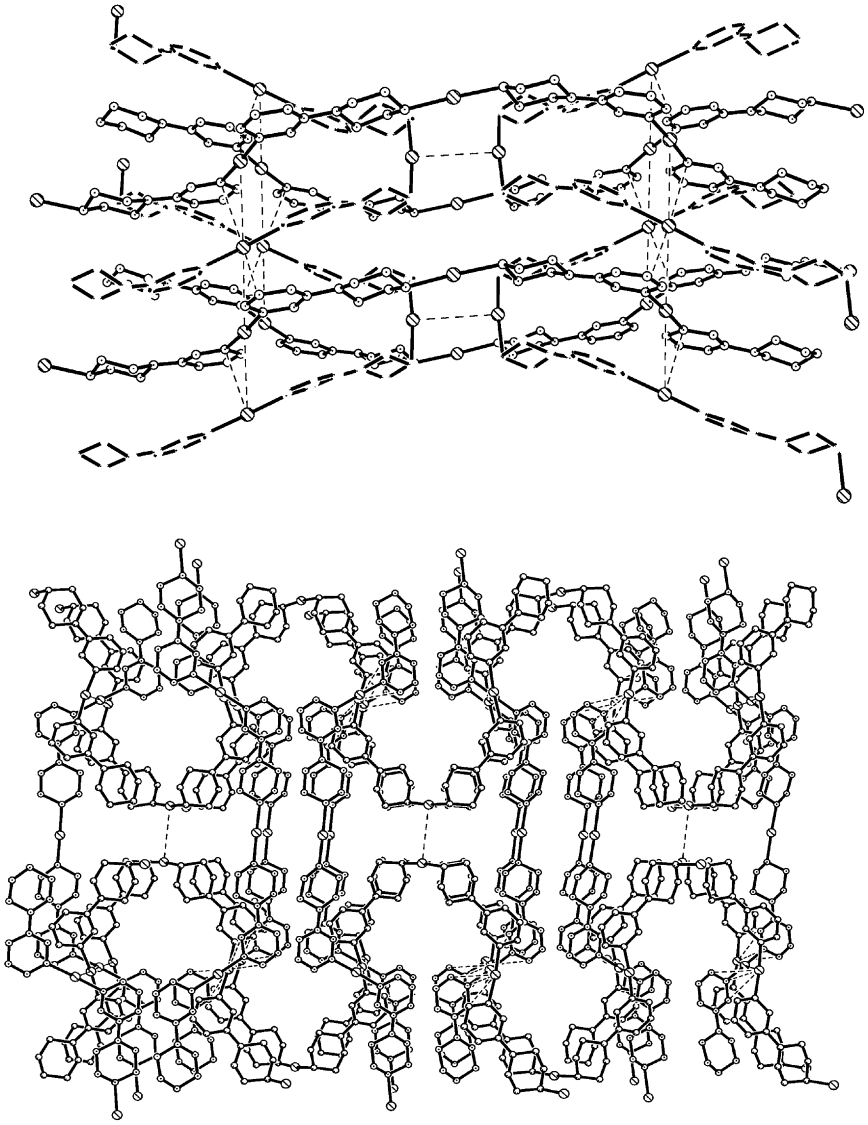

Fig. 5. Packing diagrams of **2**.

2.10. Structure of complex **3**

The structure **3** was solved in the space group $P2_1/c$. Fig. 6a shows the asymmetric unit of complex **3**, which contains two Ag(I) atom, two pyapa groups, two nitrate anions and a bonded water molecule. Fig. 6b shows the local coordination of the Ag(I) centers in complex **3** forming the zig-zag polymeric chain. Table 2 list the bond distances and angles around Ag(1) and Ag(2) for complex **3**. The Ag(1) atom bond two piperazinyl nitrogen atoms (Ag–N = 2.188(3)–2.217(3) Å) and the silver metal center adopts slightly linear geometry (N–Ag–N = 165.41(14)°), while Ag(2) atom bond two pyrazinyl nitrogen atoms (Ag–N = 2.167(4)–2.175(3) Å), one bound water molecule (Ag–O = 2.577(4) Å) and the silver metal center adopts slightly disorder T-shaped geometry [∠N(4)–Ag(2)–N(5) + ∠N(4)–Ag(2)–O(7) + ∠N(5)–Ag(2)–O(7) = 359.7°]. Each Ag(I) coordinated to two pyapa ligands and each pyapa bridged two Ag(I) atom in **3**. The dihedral angle between the two pyrazinyl rings that coordinated to the Ag atom through the nitrogen atoms is almost coplanar in the degree of 3.5°. The Ag···Ag distances in the zig-zag chains separated by the bridging pyapa are 9.124 Å.

Fig. 7a shows the cationic molecules in complex **3** linking each through the Ag···N and Ag···Ag weak interactions to form the 2-D

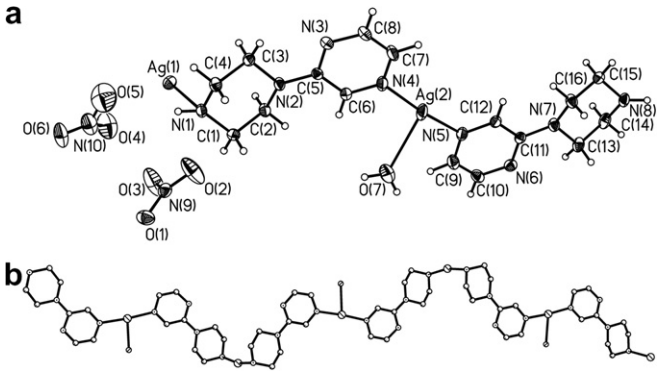

Fig. 6. (a) An ORTEP drawing of complex **3**. (b) The structure drawing of Ag(I) centers coordination location.

pleated layers. The Ag···N distances are in the range from 3.257 to 3.442 Å, and the distances of Ag···Ag between two zig-zag chains is 3.682 Å. In complex **3**, Fig. 7b, the 2-D pleated sheets are further linked by the anions and solvent molecules and through Ag···O

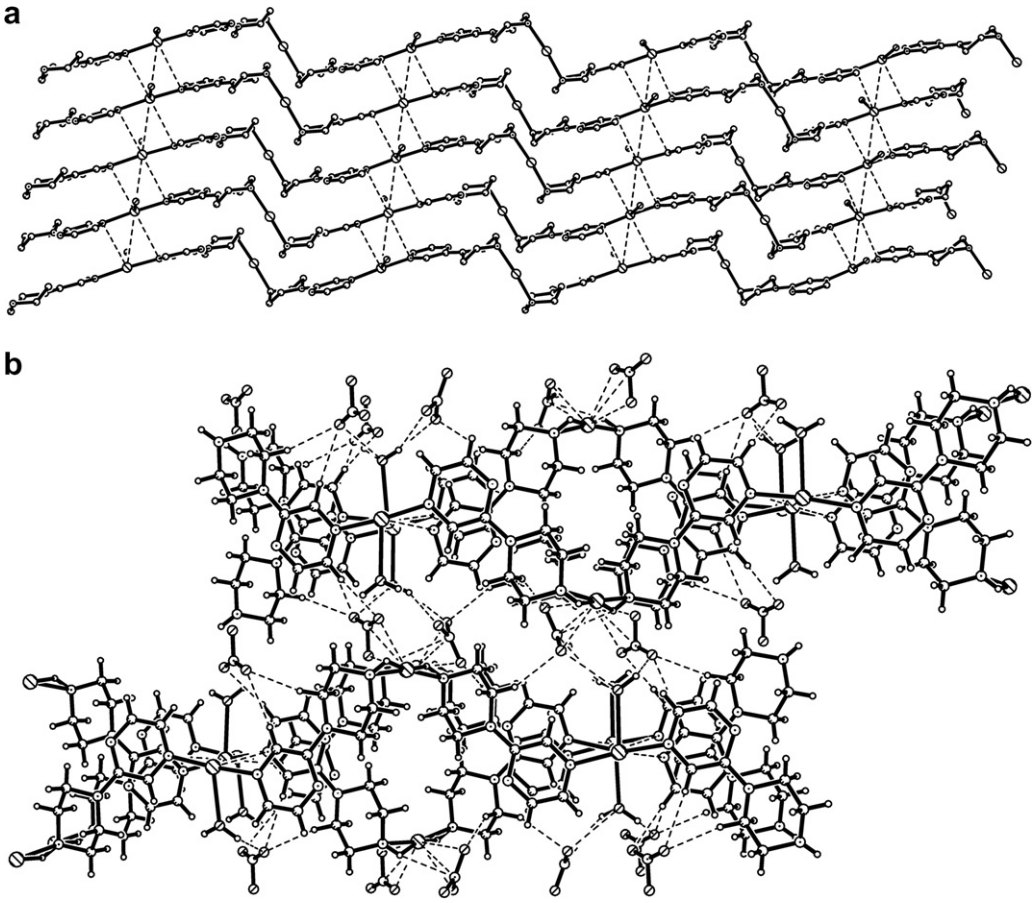

Fig. 7. (a) The 2-D sheet showing the weak Ag···Ag and Ag···N interactions among the 1-D zig-zag chains. (b) Packing diagram of **3** shows the anions and solvent molecules interlinking cationic layers through serious hydrogen bonds.

interactions, C–H···O and/or O–H···O hydrogen bonds to form 3-D supramolecular structures (Ag···O = 2.677–3.292 Å, C–H···O = 2.431–2.527 Å, ∠C–H···O = 135.4–172.5°, O–H···O = 2.159–2.536 Å, ∠O–H···O = 103.0–159.7°).

3. Thermal properties

Thermal gravimetric analyses (TGA) were carried out to examine the thermal stability of **1**–**3**. The samples were heated up in air at 1 atm pressure with the heating rate of 10 °C min^{-1}. The TGA curve shows that **1**is the first loss took place between 150 and 220 °C and was associated with the loss of the H_2O molecules (calculated 7.8%, observed 7.6%). The second loss took place between 220 and 250 °C, corresponding to the loss SO_4^{2-} anions and pyapa ligands (calculated 61.6%, observed 61.2%). The TGA for **2** showed the loss of ClO_4^- anions in range 150–220 °C (calculated 26.8%, observed 26.7%), followed by the loss of pyapa ligands (calculated 44.1%, observed 44.3%). The TGA curve shows that **3**is the first loss took place between 95 and 135 °C and was associated with the loss of the H_2O molecules (calculated 2.6%, observed 2.5%). The second loss took place between 135 and 230 °C, corresponding to the loss NO_3^- anions and pyapa ligands (calculated 56.8%, observed 57.1%).

4. Conclusions

In this study, the coordination chemistry of Ag(I) salts with 1-(2-pyrazinyl)piperazine (pyapa) was investigated. The synthesis and structures of three novel complexes $[Ag_4(pyapa)_4(SO_4)_2 \cdot 6H_2O]_n$, **1**, $\{[Ag_2(pyapa)_2][ClO_4]_2\}_n$, **2** and $\{[Ag_2(pyapa)_2(H_2O)][NO_3]_2\}_n$, **3**, have been successfully accomplished. The double helices 1-D polymeric chain structures was seen in complex **1**, and the pyapa acted as the bidentate ligand that bonded Ag(I) atoms. The helices interlinks each through strong Ag···Ag interactions and π–π stacking. In complexes **2** and **3** show the zig-zag polymeric chains, which interact through the weak Ag···O and Ag···N interactions between Ag(I) atoms and the pyrazinyl groups of pyapa ligands that formed the pleated 2-D supramolecular layers, respectively. In complexes **1**–**3**, the same ratio of Ag(I) atom to pyapa ligand is 1–1, but display the different supramolecular architectures.

ABSTRACT

A new 24-membered octaaza macrocyclic ligand (**L**) containing two methoxybenzyl pendant arms has been synthesized. While its complexation with $MnCl_2$ in the presence of perchlorate anion yielded a mononuclear complex, $[Mn\mathbf{L}](ClO_4)_2$, a similar reaction in the absence of perchlorate anion led to an endocyclic dinuclear complex, $[Mn_2\mathbf{L}Cl_4]$. In $[Mn\mathbf{L}](ClO_4)_2$, the Mn(II) ion was tightly surrounded by the N8-macrocyclic ligand to form a distorted bicapped octahedral geometry. In $[Mn_2\mathbf{L}Cl_4]$, the endomacrocyclic bound two manganese ions are bridged via two chloro ligands to form a bis-(μ-chloro) Mn_2Cl_2 diamond core. Each Mn(II) ion in the dinuclear complex is additionally ligated with a diaminomethyl pyridinyl nitrogen donor atom of the ligand and a terminal chloride, which leads to a distorted octahedral geometry of the N_3Cl_3 donor set. An EPR study of $[Mn\mathbf{L}](ClO_4)_2$ in DMSO or DMF showed an unprecedented Mn(II) EPR signal spreading from ~100 G over ~7000 G with ^{55}Mn nuclear hyperfine structures at 600–1800 G. For $[Mn_2\mathbf{L}Cl_4]$, a typical high-spin Mn(II) signal was observed near $g = \sim 2$ with an average ^{55}Mn nuclear hyperfine coupling constant of 91 G and small ZFS.

1. Introduction

The synthesis and coordination chemistry of polyaza macrocyclic ligands bearing pendant arms has attracted much interest in the last few decades [1,2]. The incorporation of pendant arms on polyaza macrocyclic ligands can change the complexation capability of the ligands, and can increase the stability of their complexes with multiple metal ions. Among the transition metals that form complexes with polyaza macrocycles, manganese is well known to have an important role in many biological reactions [3], such as water oxidation (photosystem II) [4], decomposition of hydrogen peroxide (catalase), and dismutation of the superoxide anion radical (superoxide dismutase). Therefore, studies on manganese complexes with various geometries would expand our understanding of the coordination geometries and the mechanisms of manganese enzymes.

The octaaza macrocycle containing two pyridyl groups, specifically 3,6,9,17,20,23,29,30-octaazatricyclo[23,3,1,1]triaconta-1(29),-11,13,15,25,27-hexaene (BPBD) shown in Scheme 1, has been studied as a host for phosphate and transition metal ions [5,6]. Its Cu(II), Ni(II) and Zn(II) complexes have been prepared and the structure determined [6–8]; all of them were dinuclear and each metal ion in the complexes was coordinated to the equatorial four nitrogen atoms of the macrocycle. We have prepared a new 24-membered octaaza macrocycle that contains two methoxybenzyl substituents as pendant arms (Fig. 1). When a Mn(II) ion was complexed with the ligand, two different species were obtained, depending on conditions, one is the mononuclear Mn(II) complex in the presence of perchlorate anion and the other is a dinuclear Mn(II) endomacrocyclic complex with a bis-μ-chloro bridge in the absence of perchlorate anion. The latter structure is an attractive model for the study of the role of chloride anions in the manganese assembly found in photosynthetic water oxidation systems [9]. Here, we present the synthesis of a new ligand and its manganese complexes (Scheme 1), the solid-state characterizations of the complexes using single-crystal structure analysis, and studies on the solution characteristics using EPR spectroscopy.

2. Experimental

2.1. General procedures and methods

All reagents were obtained from commercial suppliers and used without purification unless specified otherwise. ^1H and ^{13}C NMR spectra were collected on a Bruker AVANCE II 500 spectrometer at resonance frequencies of 500.1 MHz and 125.7 MHz, respectively. The solvents used were $CDCl_3$ and D_2O. The chemical shifts (in ppm) are reported from tetramethylsilane or referenced to

solvent on the δ scale. LRMS (ESI) spectra were recorded on an Agilent 1100 LC/MSD instrument. The ATR-FTIR spectra of the manganese complexes were measured from 4000 cm^{-1} to 650 cm^{-1} with a Spectrum 100 spectrometer (Perkin–Elmer).

2.2. Synthesis of the macrocycle *L*

2.2.1. 4-(2-Methoxy-benzyl)-1,7-bis(2-nitrophenylsulfonyl)-1,4,7-triazaheptane (*2*)

Compound **1** (in Scheme 1) [10] (1.0 g, 2.11 mmol) and a 2-methoxybenzaldehyde (0.35 g, 2.53 mmol) were mixed in MeOH (30 mL) at room temperature. Sodium cyanoborohydride (0.20 g, 3.17 mmol) and glacial acetic acid (0.13 g, 2.11 mmol) were added, and the mixture was stirred for 6 h at room temperature. The reaction mixture was quenched with saturated aqueous $NaHCO_3$ solution, and the product was extracted with CH_2Cl_2. The solvent was removed in vacuo, and the crude product was purified by chromatography on a silica gel column (1:2 hexane/EtOAc) to give a light yellow solid. Yield, 1.14 g (91%). ^{1}H NMR (500 MHz, $CDCl_3$); δ 7.99–7.98 (m, 2H), 7.70–7.75 (m, 2H), 7.69–7.66 (m, 4H), 7.20 (t, 1H, J = 7.8 Hz), 7.04 (d, 1H, J = 7.3 Hz), 6.88 (d, 1H, J = 8.2 Hz), 6.79 (t, 1H, J = 7.4 Hz), 3.89 (s, 4H), 3.54 (s, 2H), 3.01 (t, 4H, J = 5.7 Hz), 2.56 (t, 4H, J = 4.7 Hz); ^{13}C NMR (125.76 MHz, $CDCl_3$); δ 158.05, 148.08, 133.49, 133.43, 132.58, 131.17, 130.69, 129.25, 125.46, 125.39, 120.28, 110.93, 55.53, 54.27, 53.82, 41.43. ESI-MS $[M+H]^+$: 594.3.

2.2.2. N^1-(2-amino-ethyl)-N^1-(2-methoxy-benzyl)-ethane-1,2-diamine (*3*)

Thiophenol (0.46 g, 4.2 mmol) was added to a stirred solution of compound **2** (1.0 g, 1.68 mmol) and anhydrous potassium carbonate (0.70 g, 5.05 mmol) in dimethyl formamide (DMF). The resulting mixture was stirred for 4 h at room temperature and then the solvent was removed in vacuo. The residue was dissolved in a mixture of EtOAc (50 mL) and 1 N-HCl (20 mL). The aqueous layer was washed with EtOAc until the by-product was removed, and then basified with 2 N-KOH. The aqueous solution was extracted with CH_2Cl_2, dried over Na_2SO_4 and concentrated in vacuo to give a colorless viscous oil. Yield, 0.38 g (85%). ^{1}H NMR (500 MHz, D_2O) as a HCl salt; δ 7.35 (t, 1H, J = 7.9 Hz), 7.25 (m, 1H, J = 7.4 Hz), 7.06 (d, 1H, J = 8.3 Hz), 6.98 (t, 1H, J = 7.4 Hz), 3.81 (s, 3H), 3.59 (s, 2H), 3.07 (t, 4H, J = 5.7 Hz), 2.75 (t, 4H, J = 5.8 Hz); ^{13}C NMR (125.76 MHz, D_2O); δ 157.70, 131.91, 129.82, 125.10, 120.92, 111.82, 55.55, 51.50, 50.37, 36.90. ESI-MS $[M+H]^+$: 224.3.

2.2.3. 6,20-Bis-(2-methoxy-benzyl)-3,6,9,17,20,23,29,30-octaaza-tricyclo[23.3.1.111,15]triaconta-1(29),11,13,15(30),25,27-hexaene (*4*)

A solution of compound **3** (0.30 g, 1.34 mmol) in MeOH was added dropwise over 15 min to 2,6-diformylpyridine (0.18 g, 1.34 mmol) and $BaCl_2 \cdot 2H_2O$ (0.16 g, 0.67 mmol) in MeOH. The resulting mixture was refluxed for 4 h. After the yellow solution was allowed to cool to room temperature, solid $NaBH_4$ (0.25 g, 6.7 mmol) was added slowly and stirred for 30 min, and then the solvent was removed in vacuo. The residue was dissolved in a mixture of CH_2Cl_2 (50 mL) and 1 N-HCl (20 mL). The aqueous layer was washed with CH_2Cl_2 until the by-product was removed, and then basified with 2 N-KOH. The aqueous solution was extracted with CH_2Cl_2 and the organic layer was dried over Na_2SO_4 and concentrated. The crude product was purified by chromatography on a silica gel column (10:1 MeOH/NH_4OH) to give a light yellow viscous oil. Yield, 0.66 g (75%). ^{1}H NMR (500 MHz, D_2O) as a HCl salt: 7.88 (dt, 2H, J = 1.5 and 7.8 Hz), 7.45 (dt, 1H, J = 1.4 and 8.1 Hz), 7.39 (d, 4H, J = 7.9 Hz), 7.36 (dd, 2H, J = 1.4H and 7.4 Hz), 7.04-6.99 (m, 4H), 4.42 (s, 6H), 4.39 (s, 4H), 3.74 (s, 4H), 3.72 (m, 8H), 3.64 (m, 8H); ^{13}C NMR (125.76 MHz, D_2O): 157.95, 149.95, 139.66, 132.70, 132.62, 123.16, 121.30, 116.90, 111.75, 55.61, 53.93, 50.75, 50.04, 42.15. ESI-MS $[M+H]^+$: 653.6.

2.2.4. $[MnL](ClO_4)_2$

$Mn(OAc)_2 \cdot 4H_2O$ (28 mg, 0.16 mmol) was added to a stirred solution of macrocyclic ligand **L** (50 mg, 0.08 mmol) in MeOH (5 mL) and the resulting mixture was stirred at room temperature for 2 h. Sodium perchlorate (20 mg, 0.16 mmol) was added and the mixture was stirred for another 30 min. The crude product was dissolved in H_2O (10 mL), extracted with CH_2Cl_2, and dried over Na_2SO_4. The solvent was removed in vacuo to give a light yellow solid. Yield, 61 mg (84%). Colorless single-crystals suitable for X-ray diffraction studies were obtained by slow evaporation of CH_2Cl_2 solution of Mn complex. IR (powder, cm^{-1}): 3319 (w), 2856 (w), 1601 (m), 1583 (m), 1492 (m), 1466 (m), 1451 (m), 1248 (m), 1165 (m), 1081 (s). ESI-MS $[MnLClO_4]^+$: 806.5.

2.2.5. $[Mn_2LCl_4] \cdot CH_3OH$

Anhydrous $MnCl_2$ (38 mg, 0.3 mmol) was added to a stirred solution of macrocyclic ligand **L** (100 mg, 0.15 mmol) in MeOH (10 mL) and the resulting mixture was stirred for 1 h at room temperature. The white precipitate was collected by filtration and washed with cooled MeOH and ether, and dried in vacuo. Yield, 0.12 g (92%). Colorless single crystals suitable for X-ray diffraction studies were obtained by vapor diffusion of diethyl ether into a solution of the Mn complex in methanol. IR (powder, cm^{-1}): 3243 (w), 3221 (w), 2801 (w), 1601 (m), 1582 (m), 1494 (m), 1467 (m), 1434 (m), 1244 (m), 1152 (m). ESI-MS $[Mn_2LCl_4–MnCl_3]^+$: 742.5.

2.3. Crystallography

Crystals were coated with paratone oil to prevent loss of crystallinity on exposure to air. Data were collected at −100 °C using Mo-Kα radiation (λ = 0.71073 Å) employing a Bruker SMART CCD equipped with a graphite crystal, incident-beam monochromator. The SMART and SAINT software packages [11] were used for data collection and integration, respectively. The data were corrected for absorbance using SADABS [12] based upon Laue symmetry using equivalent reflections. Structures were solved by direct methods, and refined using full-matrix, least-squares calculations employing the SHELXTL–PLUS software package [13]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms in the crystal of $[MnL](ClO_4)_2$ were found by difference Fourier peaks, and refined isotropically, but hydrogen atoms in the crystal of $[Mn_2LCl_4] \cdot CH_3OH$ were assigned isotropic displacement coefficients U(H) = 1.2U (C, N) or 1.5U (C_{methyl}, O), and their coordinates were allowed to ride on their respective atoms. Crystal and intensity data are given in Table 1.

2.4. EPR spectroscopy

X-band (9 GHz) EPR spectra were recorded on a Jeol JES-TE300 ESR spectrometer using 100 kHz field modulation. Low-temperature spectra were obtained using a Jeol ES-DVT3 variable temperature controller for liquid nitrogen temperature and an Oxford continuous-flow cryostat ESR900 for liquid helium temperature.

3. Results and discussion

3.1. Synthesis

The synthesis of ligand **L** is described in Scheme 1. Bis-nosylated diethylenetriamine **1** was prepared as described [10], and the secondary amine was reductively alkylated with 2-methoxybenzaldehyde to give compound **2** with 91% yield in the presence of sodium cyanoborohydride. Two nosyl groups of compound **2** were removed under basic conditions in 85% yield, and then cyclized with 2,6-diformylpyridine under reducing conditions in a 2 + 2 manner, yielding the disubstituted octaaza macrocycle **L**. The ligand was complexed with Mn(II) ion under different conditions (see Section 2) to afford the two complexes $[MnL](ClO_4)_2$ and $[Mn_2LCl_4]$, respectively.

3.2. Description of the crystal structures

The molecular structure of $[MnL](ClO_4)_2$ is shown in Fig. 2. In the crystal structure of the complex, the Mn(II) ion is encapsulated by the N8-macrocyclic ligand, resulting in an overall distorted bicapped octahedral geometry. The planes of a typical meridional tridentate, two 2,6-diaminomethyl pyridine moiety of the ligand [N(2), N(1), and N(8) and N(6), N(5), and N(7) with Mn ion] are

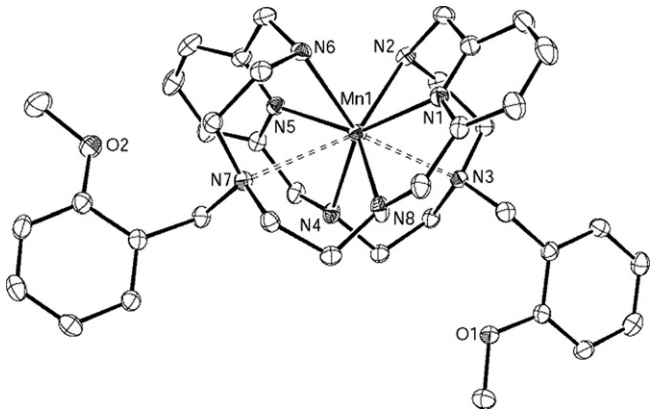

Fig. 2. ORTEP view of the cation of $[MnL](ClO_4)_2$ complex with 30% probability. Hydrogen atoms are omitted for clarity.

Table 2
Selective bond distances (Å) and angles (°) for [Mn**L**](ClO$_4$)$_2$

Mn(1)–N(1)	2.261(2)	Mn(1)–N(8)	2.340(2)

N(5)–Mn(1)–N(2)	83.71(7)		

slightly bent [i.e. the torsional angles of N(2), Mn(1), N(1), and N(8) and N(6), Mn(1), N(5), and N(7) are −161.89° and 155.80°, respectively]. The two pyridine planes are twisted about −71° and wrap round the Mn ion, and the remaining "open" spaces are capped with two weakly coordinated tertiary nitrogen atoms. The distances of Mn–N(3) and Mn–N(7) are 2.838 Å and 2.989 Å, respectively.

Selected bond distances and angles are given in Table 2. The average distance between Mn and pyridyl nitrogen atoms [N(1) and N(5)] is 2.262 Å, while that of Mn secondary amines is 2.367 Å, reflecting the stronger coordination ability of the pyridyl nitrogen. These average distances are similar to those found in other manganese complexes of acyclic ligands [14–16].

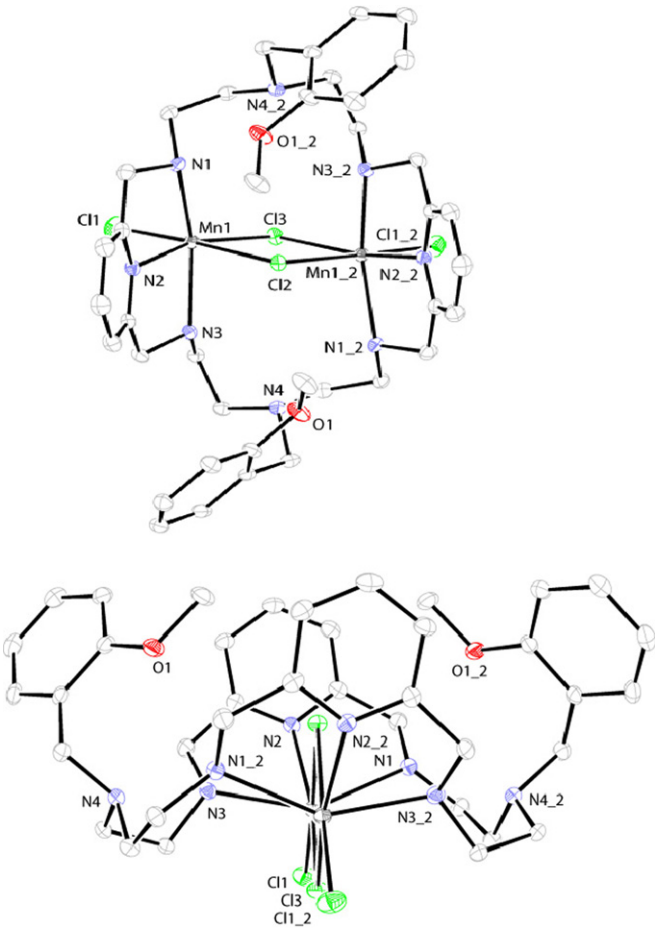

Fig. 3. ORTEP view (top and side) of [Mn$_2$**L**Cl$_4$] with 30% probability. The complex is on the crystallographic 2-fold axis. Hydrogen atoms are omitted for clarity.

The crystal structure of [Mn$_2$**L**Cl$_4$] is displayed in Fig. 3. The complex consists of two endo-encapsulated Mn(II) centers bridged by two chloro ligands, which leads to a bis-μ-chloro Mn$_2$Cl$_2$ diamond core. Each Mn(II) atom is coordinated additionally with a diaminomethyl pyridine and a terminal chloride, giving a six-coordinated N$_3$Cl$_3$ ligand donor set with distorted octahedral geometry. This type of dinuclear chloro-bridged Mn(II) compound with N/O ligands is relatively rare [17–27] and, as far as we know, this is the first example of a structurally defined Mn(II) endomacrocyclic complex with a bis-μ-chloro bridge.

The selected bond lengths and bond angles for [Mn$_2$**L**Cl$_4$] are given in Table 3. As in the mononuclear manganese complex above, the bond distances to the Mn(II) ion are shorter for the pyridyl nitrogen atoms N(2) (2.230 Å) than for the secondary nitrogen atoms N(1) (2.343 Å) and N(3) (2.296 Å). The two Mn–Cl bond distances in the Mn$_2$Cl$_2$ diamond core are slightly different (2.5261 Å and 2.6608 Å), and are longer than the terminal Mn–Cl bond distances (2.4135 Å), as expected for the chloride in bridging mode. The Mn–Mn distance is 3.886 Å, which is comparable to that found in other bis-μ-chloro-bridged Mn(II) complexes [17–27]. The bond angles in the diamond core are 82.80° [Cl(3)–Mn(1)–Cl(2)], 82.81° [Cl(3)–Mn(1)#1–Cl(2), #1: $-x+3/2$, $-y+1/2$, z], 93.82° [Mn(1)–Cl(2)–Mn(1)#1], and 100.57° [Mn(1)#1–Cl(3)–Mn(1)]. The significant difference between the two chloride-centered bridging angles (93.82° and 100.57°) may arise from the different bridging chloride environments caused by the conformational restriction on the ligand in a 2-fold symmetric environment. The structural feature of our bis-μ-chloro-bridged Mn(II) complex, in comparison to other dinuclear BPBD complexes on which no significant interaction between two metal ions is found [7,8], seems to arise from the attractive hydrophobic interaction between the pendant arm and the pyridine moiety of the ligand.

3.3. EPR spectra

Fig. 4 displays frozen-solution EPR spectra obtained from [Mn**L**](ClO$_4$)$_2$ and [Mn$_2$**L**Cl$_4$] dissolved in DMSO and DMF at 110 K. The overall shape of each spectrum is unchanged at helium temperature, but the signal intensities are increased. [Mn**L**](ClO$_4$)$_2$ exhibits an unprecedented Mn(II) EPR spectrum. The EPR signal obtained from the sample in DMSO spreads from ~100 G over ~7000 G, while that in DMF shows almost the same feature as in DMSO, with ^{55}Mn nuclear hyperfine structures at 600–1800 G.

EPR of the high-spin Mn(II) (d^5, $S = 5/2$) complex can be described by the Hamiltonian [28]:

$$\boldsymbol{H} = D\left[S_z^2 - \frac{1}{3}S(S+1)\right] + E(S_x^2 - S_y^2) + \beta \boldsymbol{B}\cdot\boldsymbol{g}\cdot\boldsymbol{S} + \boldsymbol{S}\cdot\boldsymbol{A}\cdot\boldsymbol{I}$$

[a] Due to the C_2 symmetric nature of the complex, only half of the data is displayed. #1: $-x+3/2$, $-y+1/2$, z.

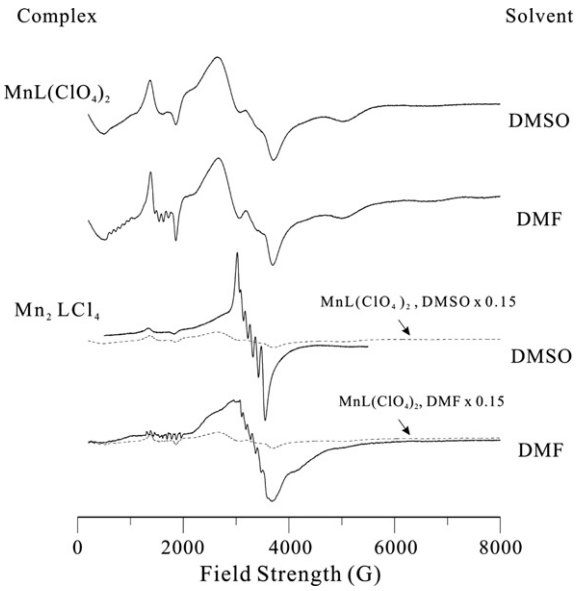

Fig. 4. EPR spectra of the complexes $[MnL](ClO_4)_2$ and $[Mn_2LCl_4]$ dissolved in DMSO and DMF. Numerically reduced $[MnL](ClO_4)_2$ EPR spectra (broken line) are inserted for comparison. *Experimental conditions*: microwave frequency, 9.221 GHz; microwave power, 1.2 mW; modulation width, 10 G for $[MnL](ClO_4)_2$ and 5 G for $[MnL](ClO_4)_2$; time constant, 0.3 s; scan time, 4 min; temperature, 110 K.

where D and E are the axial and rhombic zero-field splitting (ZFS) parameters, $\boldsymbol{B}\cdot\boldsymbol{g}\cdot\boldsymbol{S}$ represents the electron Zeeman interaction, and $\boldsymbol{S}\cdot\boldsymbol{A}\cdot\boldsymbol{I}$ is the nuclear hyperfine coupling term. High-spin Mn(II) in the octahedral field of the $^6A_{1g}$ state generally has small ZFS parameters (D and E) and its X-band EPR signal is readily interpretable. However, as revealed by the single-crystal study of the complex, where Mn–N bond lengths are in the range of 2.26–2.41 Å and N–Mn–N bond angles are 71.6–144.6°, the Mn–N coordination structure is severely distorted from the octahedral geometry, which would give rise to strong ZFS and hamper the quantitative analysis of the spectra at the X-band. The previous multifrequency EPR experiment on a high-spin Mn(II) complex with an N_6 donor set consisting of two tridentate 1,4,7-triazacyclononane ligands showed that the D value of the complex is 0.090 cm^{-1} and E/D is 0.1 [29]. The X-band spectrum of $[MnL](ClO_4)_2$ is similar to but not identical with that reported. We performed numerical simulations to fit the observed spectra using the parameters reported previously for four to six-coordinated high-spin Mn(II) complexes [30,31]. None provides a good explanation of the X-band EPR of $[MnL](ClO_4)_2$. Further investigation using high-field high-frequency EPR to elucidate the details of the electronic structure of this highly distorted $Mn(II)N_6$ compound exhibiting an unprecedented X-band EPR spectra is needed and is being planned [30].

The EPR of $[Mn_2LCl_4]$ in DMF (Fig. 4) shows a typical high-spin Mn(II) feature near $g \sim 2$ with an average ^{55}Mn nuclear hyperfine coupling constant of 91 G and small ZFS, and shows weak signals at $g = 4.91$ (1343 G) and $g = 3.60$ (1830 G). The EPR in DMF displays a richer signal from low field up to ~6000 G with some ^{55}Mn nuclear hyperfine structures. Though the crystal structure tells us that $[Mn_2LCl_4]$ has a bis-μ-Cl bridged Mn(II)Mn(II) dinuclear center, the spectra do not resemble previously reported EPR of spin-coupled Mn(II)Mn(II) complexes [32–34]. Closer examination of the spectra reveals some signal intensity that resembles the EPR features of $[MnL](ClO_4)_2$, represented by a broken line (EPR of $[MnL](ClO_4)_2 \times 0.15$), implying that the $[Mn_2LCl_4]$ solution contains the mononuclear species, $[MnL]^{2+}$. A plausible explanation can be derived from the crystal structure of $[Mn_2LCl_4]$. The Mn_2 dinuclear center of $[Mn_2LCl_4]$ is exposed to the outside of the ligand pocket along the molecular C_2 axis toward the face consisting of terminal chloride ions and one of the bridging chloride ions, whereas the Mn site of $[MnL](ClO_4)_2$ is buried inside the chelating ligand. The structural characteristics of $[Mn_2LCl_4]$ make the Mn_2 center vulnerable to attack by basic solvents, and changes the dinuclear complex to a more stable mononuclear species, $[MnL]^{2+}$. But the signal from $[MnL]^{2+}$ is not fully responsible for the observed intensity of $[Mn_2LCl_4]$ in both DMSO and DMF. The hyperfine structure near $g \sim 2$ indicates that a solvated mononuclear Mn(II) species also exists in the solution. The remaining intensities may arise from the dinuclear Mn_2 center of $[Mn_2LCl_4]$. Hence, the observed EPR spectra suggest that $[Mn_2LCl_4]$ in the solvent is in an equilibrium in the forms of $[Mn_2LCl_4]$, $[MnL]^{2+}$, and solvated mononuclear Mn(II).

4. Conclusions

The complexation of new ligand **L**, a 24-membered octaaza macrocyclic ligand containing two non-coordinating pendant arms, with Mn(II) gave a mononuclear $[MnL](ClO_4)_2$ in the presence of perchlorate ion, but an endocyclic dinuclear $[Mn_2LCl_4]$ in the absence of perchlorate ion. The crystal structure analysis of $[MnL](ClO_4)_2$ revealed that a Mn(II) ion is encapsulated with the N8-macrocyclic ligand, resulting in an overall distorted bicapped octahedral geometry. In the crystal structure of $[Mn_2LCl_4]$, an endomacrocyclic dinuclear bis-μ-Cl-bridged center was observed, where two Mn(II) ions formed a Mn_2Cl_2 diamond core with two bridging chloro ligands. Each Mn(II) ion is coordinated additionally with a diaminomethyl pyridine of the ligand and terminal chloride, giving a six-coordinated N_3Cl_3 ligand donor set with distorted octahedral geometry. An EPR study of $[MnL](ClO_4)_2$ exhibited an unprecedented Mn(II) EPR signal in DMSO and DMF, spreading from ~100 G over ~7000 G with ^{55}Mn nuclear hyperfine structures at 600–1800 G. For the $[Mn_2LCl_4]$ complex, a typical high-spin Mn(II) signal appeared near $g \sim 2$ with an average ^{55}Mn nuclear hyperfine coupling constant of 91 G and small ZFS, and weak signals were found at $g = 4.91$ (1343 G) and $g = 3.60$ (1830 G).

ABSTRACT

The interaction of ZrO_2/HfO_2 or Nb_2O_5/Ta_2O_5 with an aqueous solution of hydrofluoric acid in the presence of aza-crown ether resulted in novel organically templated metal oxyfluorides of the compositions $[(HA15C5)_2][Ta_2F_{10}O]$ (**1**), $[(HA18C6\cdot H_2O)(A18C6\cdot H_2O)][(H_2O)Nb_2F_9O]\cdot H_2O$ (**2**), $[(HA18C6\cdot H_2O)(M_2F_{10}\cdot 2H_2O)\cdot(H_3O)\cdot H_2O]$ (**3**, **4**) and $[(H_2DA18C6)(M_2F_{10}\cdot 2H_2O)\cdot 2H_2O]$ (**5**, **6**) (M = Zr, Hf, A15C5 = aza-15-crown-5, A18C6 = aza-18-crown-6, DA18C6 = diaza-18-crown-6). Complexes **1**–**6** were identified by single crystal X-ray diffraction. In **1**, the negative charge of the $[(TaF_5)_2O]^{2-}$ centrosymmetric dianion is balanced by two azonia-15C5 cations, while in **2** the charge of asymmetric $[(H_2O)NbF_4ONbF_5]^-$ monoanion is compensated by azonia-18C6 cation. The crystal of **2** revealed an extensive hydrogen bonding between the anions, protonated and neutral macrocycles and water molecules that combine the components into 2D sheet. Complexes **3**–**4** and **5**–**6** are isostructural in pairs; in all of them the rigid 2D inorganic motif is formed through the association of the$[(M_2F_{10}\cdot 2H_2O)]^{2-}$ anions by means of OH···F hydrogen bonds. The similar 3D supramolecular architecture in **3**–**6** represents an alternation of the negatively-charged inorganic sheets and the columns of $(HA18C6)^+$ or $(DA18C6)^{2+}$ organic cations glued by oxonium cations or water molecules.

1. Introduction

The successful efforts undertaken by Atwood to stabilize the Lewis acidic species by the complexation with crown ethers [1], initiated our long-standing interest to the fluoro-containing Lewis acids (BF_3, SiF_4, GeF_4, SbF_3, etc.) and the products of their transformations in aqueous solutions in the presence of crown ether macrocyclic molecules as organic-templating species. Following to Atwood and Selig [1,2], we have discovered the possibility to retain the rather unstable neutral adducts of the composition $BF_3\cdot H_2O$ [3] and $SiF_4\cdot 2H_2O$ [4] in the complexes with *classic all O-containing crown ethers* (18-crown-6, *cis–anti–cis*-dicyclohexyl-18-crown-6) stabilised by the OH···O hydrogen bonding between the intermediate water molecule and crown oxygen atoms. In the case of SbF_3 interaction with the macrocyclic molecule (18C6, B18C6, *cis*-isomers of DCH18C6, thia-[1.5]DB18C6) [5], the electronic effects are crucial, and the anhydrous adducts of the 1:1 ratio are held together through the interaction of the antimony atom lone pair with O-collective electronic system.

The interaction of the fluorosilicic acid (H_2SiF_6, FSA) solution with aza-containing macrocycles has resulted in ionic crystalline complexes of the compositions $(HA18C6\cdot H_2O)$ $[SiF_5(H_2O)]\cdot H_2O$, $(H_2DA18C6)[SiF_5(H_2O)]_2$, $(HA12C4)_2[SiF_5(H_2O)]_2\cdot 3H_2O$ [6], (A18C6, aza-18-crown-6; DA18C6, diaza-18-crown-6; A12C4, aza-12-crown-4), which have represented the structural evidence for the existence in the solid state of the $[SiF_5(H_2O)]^-$ anion, the labile product of the hydrolytic transformations of $[SiF_6]^{2-}$ anion. So far these three complexes remain the only known examples of the crystallographically proven existence of the $[SiF_5(H_2O)]^-$ anion in the solid state. The major role in stabilisation of the asymmetric and labile $[SiF_5(H_2O)]^-$ species plays the multiple H-bonding interactions between 'organic' and 'inorganic' components.

The problem of concentration and extraction of such elements as Zr, Hf, Nb, Ta encouraged us to apply the macrocyclic molecules

doi:10.1016/j.poly.2008.03.023

with the aim to obtain new supramolecular complexes involving these elements in the form of neutral or anionic fluoro-containing species and crown ethers. In the previously reported system ZrO_2/HfO_2–HF–H_2O–18C6, the crystals suitable for X-ray diffraction have been obtained only for Hf, and the crystalline complex of the composition $[(18C6)(H_3O)_2(Hf_2O_{10}\cdot 2H_2O)\cdot 4H_2O]$ has been studied [7]. Although the *neutral* 18C6 molecule has been used in synthesis, the resulting supramolecular complex combines both neutral and ionic species. The $(Hf_2O_{10}\cdot 2H_2O)^{2-}$ anions form inorganic 2D sheet through the OH···F hydrogen bonds and is adjusted to the 18C6 molecules *via* oxonium clusters of the composition $(H_7O_3)^+$. The 3D supramolecular architecture represents an alternation of the inorganic sheets and columns of H-bonded crown-ethers and water molecules.

Our recent study of the systems Nb_2O_5/Ta_2O_5 (NbF_5/TaF_5)–HF–H_2O–CE for a wide range of oxygen-containing crown ethers showed that in the crystalline ionic complexes of the compositions $[CE\cdot H_3O][MF_6]$ for 18C6, B18C6, *cis–syn–cis*-DCH18C6 and diphenyl-20C6, $[(CE)_2\cdot H_7O_3][MF_6]$ for [1.5]DB18C6 [6], $[CE\cdot H_5O_2][MF_6]$ for 15C5 and tetrabenzo-30C10, $[(CE)_2\cdot H_5O_2][(CE)_2\cdot H_3O][MF_6]_2$ for B15C5 and $[(CE)_2\cdot H_3O][MF_6]$ for B12C4, the negative charge of NbF_6^-/TaF_6^- anions is balanced by the oxonium ions [8]. Thus, the general feature for these complexes is a retention of metal-containing *anionic species* by neutral O-containing crown molecules due to the acidity of the reaction medium introduced by the presence of hydrofluoric acid. We also showed that in spite of either the MF_5 pentafluorides or the corresponding M_2O_5 oxides were used as starting materials, all-O-containing CEs extract NbF_6^-/TaF_6^- hexafluoroniobate/hexafluorotantalate anions in the form of crystalline complexes.

Keeping in mind the disclosed ability of aza-containing crown ethers to extract the hydrolytically unstable species from FSA solutions [7], we have used the aza-containing crown ethers, A15C5, A18C6 and DA18C6 with the aim to extract the products of interaction of ZrO_2/HfO_2 and Nb_2O_5/Ta_2O_5 with an aqueous solution of hydrofluoric acid. Six new complexes, $[(HA15C5)_2][Ta_2F_{10}O]$ (**1**), $[(HA18C6\cdot H_2O)(A18C6\cdot H_2O)][(H_2O)\ Nb_2F_9O]\cdot H_2O$ (**2**), $[(HA18C6\cdot H_2O)(Zr_2F_{10}\cdot 2H_2O)\cdot(H_3O)\cdot H_2O]$ (**3**), $[(HA18C6\cdot H_2O)$-$(Hf_2F_{10}\cdot 2H_2O)\cdot(H_3O)\cdot H_2O]$ (**4**), $[(H_2DA18C6)(Zr_2F_{10}\cdot 2H_2O)\cdot 2H_2O]$ (**5**), $[(H_2DA18C6)(Hf_2F_{10}\cdot 2H_2O)\cdot 2H_2O]$ (**6**) were obtained and studied by single crystal X-ray diffraction.

2. Experimental

2.1. Materials and apparatus

Caution! Hydrofluoric acid is toxic and corrosive, and must be handled with extreme caution and the appropriate protective gear! If contact with the liquid or vapor occurs, proper treatment procedures should immediately be followed [9]. Crown ethers were purchased from ACROS, ZrO_2, HfO_2, Nb_2O_5 and Ta_2O_5 were purchased from Aldrich and were used without further purification. Complexes **1**–**6** were obtained by an interaction of the corresponding oxides with the 40% aqueous HF followed by treatment of the resulting solution with the corresponding crown ether and were analyzed for C, H and N in a Perkin Elmer 240 °C instrument.

2.2. Synthesis

2.2.1. $[(HA15C5)_2][Ta_2F_{10}O]$ (**1**)

Crystals of complex **1** separated in a quantitative yield, and are colorless transparent prisms, soluble in methanol, ethanol; m.p. 152–153 °C. *Anal.* Calc. for $C_{20}H_{44}F_{10}N_2O_9Ta_2$: C, 23.82; H, 4.40; F, 18.84; N, 2.78. Found: C, 23.80; H, 4.43; F, 18.86; N, 2.81%.

2.2.2. $[(HA18C6\cdot H_2O)(A18C6\cdot H_2O)][(H_2O)Nb_2F_9O]\cdot H_2O$ (**2**)

Crystals of complex **2** separated in a quantitative yield, and are colorless transparent prisms, soluble in methanol, ethanol; m.p. 115–117 °C. *Anal.* Calc. for $C_{24}H_{59}F_9N_2Nb_2O_{15}$: C, 29.64; H, 6.11; F, 17.58; N, 2.88. Found: C, 29.69; H, 6.13; F, 17.63; N, 2.84%.

2.2.3. $[(HA18C6\cdot H_2O)(Zr_2F_{10}\cdot 2H_2O)\cdot(H_3O)\cdot H_2O]$ (**3**)

Crystals of complex **3** separated in an approximately quantitative yield, and are colorless transparent prisms, soluble in methanol; m.p. ≫250 °C. *Anal.* Calc. for $C_{12}H_{37}F_{10}NO_{10}Zr_2$: C, 19.80; H, 5.12; F, 26.10; N, 1.92. Found: C, 19.7; H, 5.15; F, 26.14; N, 1.90%.

2.2.4. $[(HA18C6\cdot H_2O)(Hf_2F_{10}\cdot 2H_2O)\cdot(H_3O)\cdot H_2O]$ (**4**)

Crystals of complex **4** separated in an approximately quantitative yield, and are colorless transparent prisms, soluble in methanol; m.p. ≫250 °C. *Anal.* Calc. for $C_{12}H_{37}F_{10}Hf_2NO_{10}$: C, 15.97; H, 4.13; F, 21.05; N, 1.55. Found: C, 15.94; H, 4.15; F, 21.08; N, 1.57%.

2.2.6. $[(H_2DA18C6)(Hf_2F_{10}\cdot 2H_2O)\cdot 2H_2O]$ (**6**)

Crystals of complex **6** separated in an approximately quantitative yield, and are colorless transparent prisms, soluble in methanol; m.p. ≫250 °C. *Anal.* Calc. for $C_{12}H_{36}F_{10}Hf_2N_2O_8$: C, 16.32; H, 4.11; F, 21.51, N, 3.17.Found: C, 16.30; H, 4.15; F, 21.54, N, 3.15

2.3. X-ray diffraction study

The experimental data for complexes **1**, **2** were recorded on a Xcalibur S with a CCD detector (Mo Kα radiation (λ = 0.71073 Å), graphite monochromator, ω scan mode). The X-ray intensity data for complexes **3**–**6** were recorded on a Nonius CCD area detector diffractometer employing graphite monochromatized Mo Kα radiation in ϕ and ω scan mode. Final unit cell dimensions were obtained and refined on the entire data set. Integration and scaling resulted in a data set corrected for Lorentz and polarization effects using DENZO [10]. The scaling as well as the global refinement of crystal parameters were performed by SCALEPACK [10]. The absorption correction for **1**–**6** was applied using SADABS [11] The structure solution and refinement proceeded similarly using SHELX-97 program package [12] for all structures. The non-hydrogen atoms were treated anisotropically (full-matrix least-squares method on F^2). In complexes **3** and **4**, the macrocycle, water molecules and oxonium ions are disordered over two positions with equal occupancies. In **3**–**4**, the H–O atoms of the disordered water molecules and oxonium ions were not localized. N–H atoms were found from geometric considerations. The X-ray study for complexes **5**–**6** revealed their lamellar structure and the disorder due to the shift of the layers being parallel to the crystallographic plane (101). The major crystal component corresponds to 86% and 85% in the crystals of **5** and **6**, correspondingly. Two minor shifted components with the contributions of 11% and 2% for **5** and 11% and 3 % for **6** were detected. For minor components only position of inorganic anions were localized. The crown and water molecules were refined with the occupancies that correspond to the major component. In all complexes, C-bound H atoms were placed in calculated positions, with C–H distances of 0.97 Å, and were treated using a riding-model approximation, with $U_{iso}(H) = 1.2U_{eq}(C)$. In **2**, H-atoms of water molecules and NH-groups were determined from a difference Fourier map and were then allowed to refine isotropically with $U_{iso}(H) = 1.5U_{eq}(O)$ and O–H and N–H distances subjected to DFIX restraints. The X-ray data and the details of the refinement for **1**–**6** are summarized in Table 1, the selected geometric parameters are given in Table 2, the hydrogen bonding geometry is given in Table 3.

3. Results and discussion

3.1. Description of the structures

3.1.1. $[(HA15C5)_2][Ta_2F_{10}O]$ (**1**)

The ORTEP view for complex **1** is shown in Fig. 1. Compound **1** crystallises in the triclinic space group $P\bar{1}$. The formula unit comprises of the $[(TaF_5)_2O]^{2-}$ dianion which resides on an inversion center, and two azonia-15C5 monocations which compensate the negative charge and are bound with the anion *via* NH···F hydrogen bond, N(1)–H(1N1)···F(3) ($x+1$, y, z), H···F 2.07(4), N···F 2.886(4) Å, NHF angle 165(3)°. The Ta(1) atom has a distorted octahedron surrounding (Table 2) with the Ta–F distances falling in the range 1.847(3)–1.908(2) Å, the maximal deviations of the F–Ta–F bond angles from the straight and right angles being 5.83(10)° and 3.9(10)°, correspondingly, and the deviation for the O–Ta–F angle from the right angle being 3.76(8)°. The geometry of the $[(TaF_5)_2O]^{2-}$ dianion coincides with that in the structure of bis(tetraethylammonium)μ-oxo-bis(pentafluorotantalum(v)) [13]. The

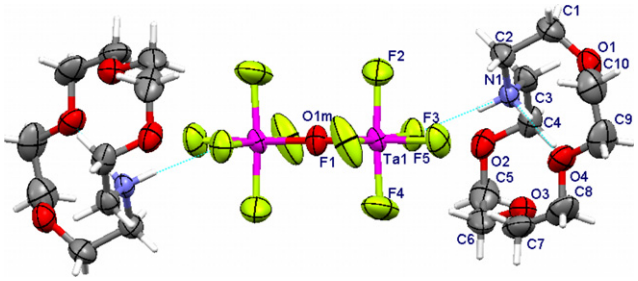

Fig. 1. ORTEP drawing of **1** with the numbering scheme and hydrogen bonding distances shown by dashed lines. Thermal ellipsoids are shown at the 50% probability level.

$(HA15C5)^+$ cation has a distorted shape fixed by the intramolecular N(1)–H(2N1)···O(4) hydrogen bond, H···O 1.94(5), N···O 2.835(5) Å, NHO angle 159(4)°. The similar macrocycle conformation (N···O 2.858 Å) was found in the structure of N-(2-methoxy-4-((4-nitrophenyl)azo)phenyl)-1,4,7,10-tetraoxa-13-azoniacyclopentadecane hexafluorophosphate [14]. It is noteworthy that **1** represents the only second after [13] known example of the organically templated tantalum oxofluoride and the first compound where the macrocycle is used in this function.

3.1.2. *[(HA18C6 · H_2O)(A18C6 · H_2O)][$(H_2O)Nb_2F_9O$] · H_2O (**2**)*

Compound **2** crystallizes in the space group $Pna2_1$. The content of the asymmetric unit is shown in Fig. 2. It comprises of $[(H_2O)NbF_4O\ NbF_5]^-$ anion, two macrocycles (designated A and B; cycle A represents monocation, cycle B represents neutral molecule) centered by two water molecules, and bridging water molecule O(3w). The X-ray data unambiguously showed that $[(H_2O)NbF_4ONbF_5]^-$ is built of $(H_2O)NbF_4O$ and $ONbF_5$ moieties joined *via* common oxygen atom. Complex **2** is the first known example of non-symmetric binuclear aqua niobium oxofluoride and only the second example after bis(ethylenediaminium) μ-oxo-bis[tetrafluorooxoniobium(V)], $(C_2H_{10}N_2)_2[(NbF_5O)_2O]$ [15] dimeric unit. The anion has an angular shape with the Nb(1)–O(1)–Nb(2) angle equal to 158.4(2)° and the Nb(1)···Nb(2) distance of 4.008 Å. The geometry of two octahedral units is rather similar: the longest Nb(1)–O(1w) distance of 2.310(3) Å corresponds to the longest Nb(2)–O(1m) distance of 2.346(3) Å in the second octahedron, while the shortest Nb(1)–O(1m) distance of 1.732(3) Å corresponds to the shortest Nb(2)–F(9) distance of 1.709(3) Å in the second octahedron, etc. The conclusions made by Poeppelmeier et al. [16] about out-of-center distortions observed in Group 5 and 6 metal oxide fluoride octahedra with the general formula of $[MO_xF_{6-x}]^{n-}$ ($x = 1$, $M = V^{5+}$, Nb^{5+}, Ta^{5+}, $n = 2$) that arise from the inherent differences between M=O and M–F bonding and allow for the strong dπ–pπ metal–oxide orbital interactions, are manifested themselves either in purely inorganic niobium oxyfluorides, e.g., Li_2NbOF_5, $Rb_5Nb_3OF_{18}$ [17] or in mixed inorganic–organic compounds, $[4\text{-apyH}]_2[Cu(4\text{-apy})_4(NbOF_5)_2]$ (4-apy = 4-aminopyridine), $Cd(3\text{-apy})_4(NbOF_5)$ (3-apy = 3-aminopyridine), $Cd(py)_4NbOF_5$ (py = pyridine) [16], $[NEt_3H][NbOF_4(H_2O)]$ [18] and can be extrapolated to the reported here new anion, $[(H_2O)NbF_4ONbF_5]^-$ (Table 3).

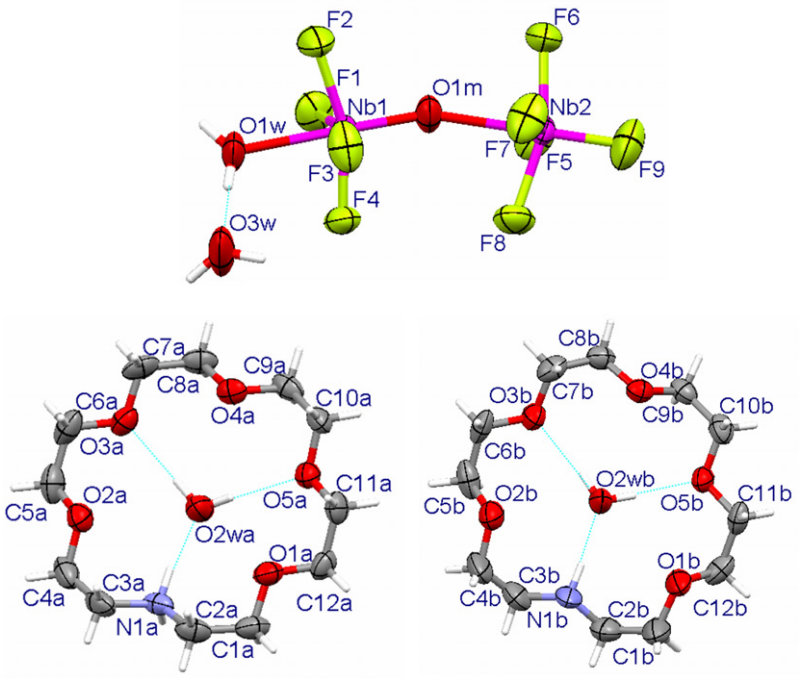

Fig. 2. ORTEP drawing of **2** with the numbering scheme and hydrogen bonding distances shown by dashed lines. Thermal ellipsoids are shown at the 50% probability level.

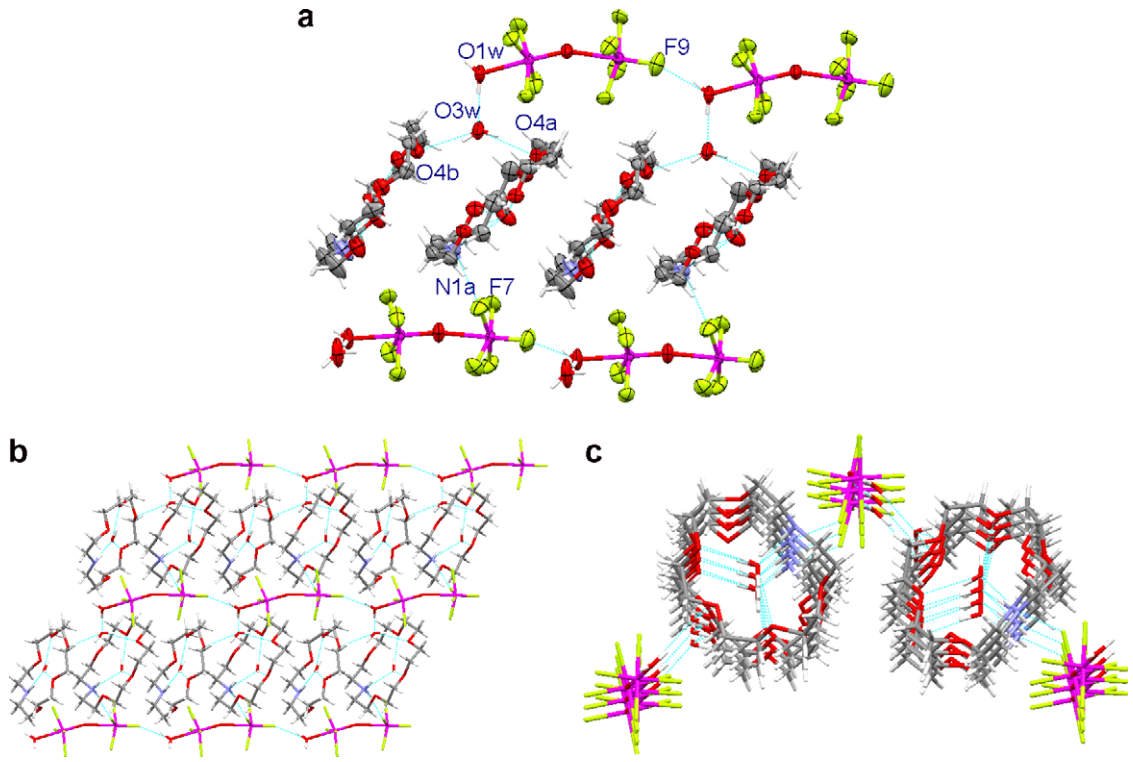

Fig. 3. View of the layer in **2**. (a) Fragment of layer with the numbering of the atoms participating in hydrogen bonding. (b) View along *a* direction. (c) View along *b* direction.

The specific feature of this anion is a *trans*-arrangement of water molecule referring to μ-oxoatom. As it is known, in the hetero-ligand metal complexes with the d^0 configuration of the central atom the mutual ligand influence is manifested in the form of *trans*-effect [19], while the relative stabilization of either *cis*- or *trans*-isomers of the complexes MF_4XO is dictated by the difference in σ- and π-donor characteristics of X and Y ligands [20]. For the oxo-bridge and water molecule arranged in the opposite points of the row of static trans-influence and being essentially different by their σ-, π-donor properties, the approaches [20] indicate the stabilization of the *trans*-form that is agreed with experimental data. It is interesting to note that in formally similar dimeric anion $[Nb_2F_8O_3]^{4-}$ [15] the double-bonded oxygen atoms are arranged in a *cis*-position to the oxo-bridge that is typical for the octahedral

fluorocomplexes of d^0-metals with multiple-bound ligands [20].

In the crystal, the anions translated along *a* direction form OH···F hydrogen bond chain (Fig. 3, Table 3). The analysis of the system of hydrogen bonding as well as the pronounced distinctions in A and B crown ethers' conformations (see Table 2) permit to conclude that in the crystal both monoprotonated and neutral forms of A18C6 co-exist. Water molecules center both macrocycles and act in a similar way, as a double H-donor towards two crown oxygen atoms and as a single H-acceptor towards nitrogen atom (Fig. 2, Table 3). In molecule A, the hydrogens of $>H_2N^+$ group are *endo*,*exo*-oriented that facilitates for the *exo*-oriented hydrogen atom its participation in $NH^+\cdots F$ hydrogen bonding with the anion. Water molecule O(3w) occupies an intermediate position between the negatively charged inorganic chain and rows of macrocyclic molecules and bridges A and B crown molecules *via* OH···O hydrogen bonds. Thus, the supramolecular architecture in **2** represents a 2D sheet built of the alternating negatively-charged inorganic chains and rows of crown molecules, where A and B macrocyclic molecules arranged in approximately parallel planes (the dihedral angle between the planes (A/B) of NO_5 atom set is equal to 13.8(1)°) alternate (Fig. 3).

3.1.3. *[(HA18C6 · H_2O)(M_2O_{10} · 2H_2O) · (H_3O) · (H_2O)] (M = Zr, Hf) (**3**, **4**)*

The system ZrO_2/HfO_2–HF–H_2O–aza18C6 resulted in two isostructural crystalline complexes of the composition [(HA18C6 · H_2O)(M_2O_{10} · 2H_2O) · (H_3O) · (H_2O)] (**3**, **4**), so the only complex **3** is further discussed. Complexes crystallize in the orthorhombic space group $Pca2_1$. The asymmetric unit for **3** is shown in Fig. 4. It comprises of the $(Zr_2F_{10} \cdot 2H_2O)^{2-}$ dianion, azonia-18C6 cation, oxonium ion, and two water molecules. In the dimeric $(Zr_2F_{10} \cdot 2H_2O)^{2-}$ anion, the coordination environment of each Zr atom represents a pentagonal bipyramid. In the equatorial plane of the anion, the bridging F(1m) and F(2m) atoms form a double bridge, with the Zr–F distances being in the range 2.135(7)–2.150(7) Å, and coordinated to Zr water molecules located along the Zr(1)···Zr(2) line, Zr···O distances being 2.207(6) and 2.208(7) Å, Zr(1)···Zr(2) separation being 3.604(1) Å. Our survey of the CSD [21] revealed no examples of such organically templated zirconate anion. The only known relative example with the same Brutto formula of the anion is a tetramethylammonium pentafluoro-zirconium monohydrate, $(C_4H_{12}N)_2(Zr_2F_{10} \cdot 2H_2O)$ [22], where the coordinated to Zr water molecules are arranged perpendicular to the Zr···Zr line.

The monoprotonated macrocyclic molecule in the complex is disordered over two positions (A and B) with equal probabilities. Similar to complex **2**, water molecule O(3w) centers the macrocyclic cation and acts as a double H-donor towards two crown oxygens and as a single H-acceptor towards *endo*-oriented H-atom of NH_2-group. It was impossible to unambiguously find the positions of hydrogen atoms in water molecule due to the severe disorder of the macrocycle and the proposition of the possible hydrogen bonding was assumed from consideration of the shortest O(3w)···N(O) crown distances which adopt the following values in two (A and B) systems: 2.91(2), 2.97(2) and 2.74(2) Å to atoms O(1A), O(3A) and O(5A), respectively and 2.86(3), 3.03(2) and 2.72(2) Å to atoms O(1B), O(2B) and O(5B), respectively.

The anions form in the crystal an inorganic layer due to OH···F hydrogen bonds between the coordinated to Zr water molecules and four equatorial fluorine atoms (Fig. 5, Table 3), in such a way, that every anion is surrounded by four closest neighbors, the association of the anions occurs *via* alternation of $R_2^2(8)$ and $R_4^4(16)$ hydrogen-bonded rings. The similar inorganic sheet is generated in structures containing $(Hf_2F_{10} \cdot 2H_2O)^{2-}$ anion, hexamethyldiammonium pentafluorohafnate tetrahydrate $(C_6N_2H_{18})[Hf_2F_{10}(H_2O)_2] \cdot 4H_2O$, tetramethylenediammonium pentafluorohafnate hexahydrate $(C_4N_2H_{14})[Hf_2F_{10}(H_2O)_2] \cdot 4H_2O$ [23] as well as in the complex $[(18C6)(H_3O)_2(Hf_2O_{10} \cdot 2H_2O) \cdot 4H_2O]$ [7].

The disorder of the macrocycle causes the disordering of the oxonium ion labelled O5o(a,b) and solvated water molecule O4w(a,b) which are bound in a slightly different mode with the macrocycle and inorganic layer (Fig. 4). The 3D supramolecular architecture in **3** is formed *via* alternation of the inorganic layers and rows of macrocyclic molecules held together via oxonium

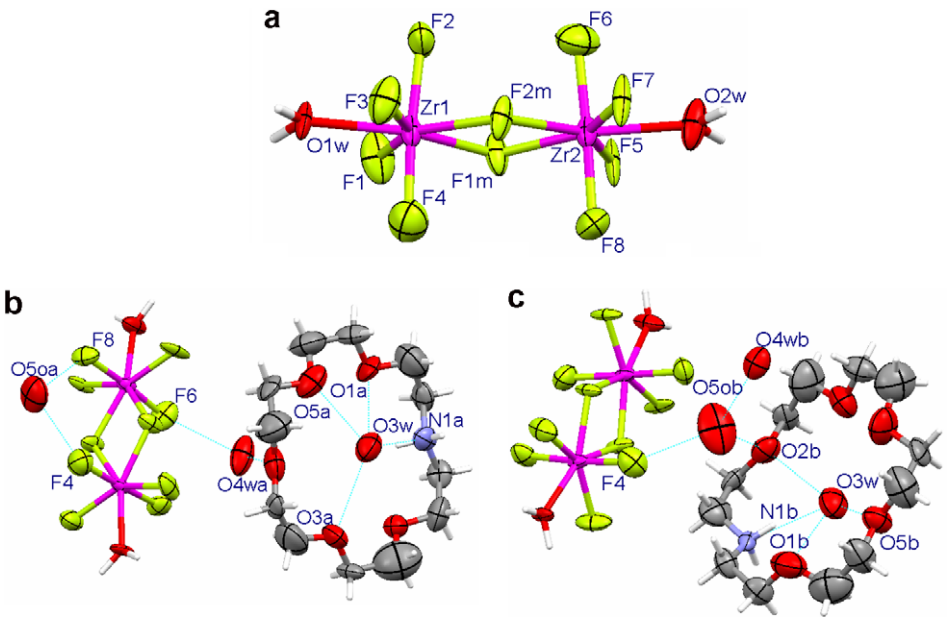

Fig. 4. ORTEP drawing of **3**. (a) View of the $(Zr_2F_{10} \cdot 2H_2O)^{2-}$ anion with the numbering scheme. and water molecules. Besides these indirect interactions, the direct $NH^{+}\cdots F^{-}$ contacts between charged units also exist (Table 3, Fig. 6).

*3.1.4. $[(H_2DA18C6)(M_2O_{10}\cdot 2H_2O)\cdot 2H_2O]$ (M = Zr, Hf) (**5**, **6**)*

The interaction in the system ZrO_2/HfO_2–HF–H_2O–1,10-diaza18C6 resulted in two isostructural complexes $[(H_2DA18C6)(M_2O_{10}\cdot 2H_2O)\cdot 2H_2O]$ (**5**, **6**), and only complex **5** is further discussed. Complexes crystallize in the triclinic space group $P\bar{1}$. The content of the asymmetric unit is shown in Fig. 7. It comprises of the $(Zr_2F_{10}\cdot 2H_2O)^{2-}$ anion and two water molecules in general positions and two halves of two crystallographically different diazonia-18C6 cations (A and B), which reside on inversion centers. The structure of the dimeric anion is the same as in **3** and in its Hf analogue in **4** and **6**, the coordination environment of each Zr atom represents a pentagonal bipyramid (Table 2).

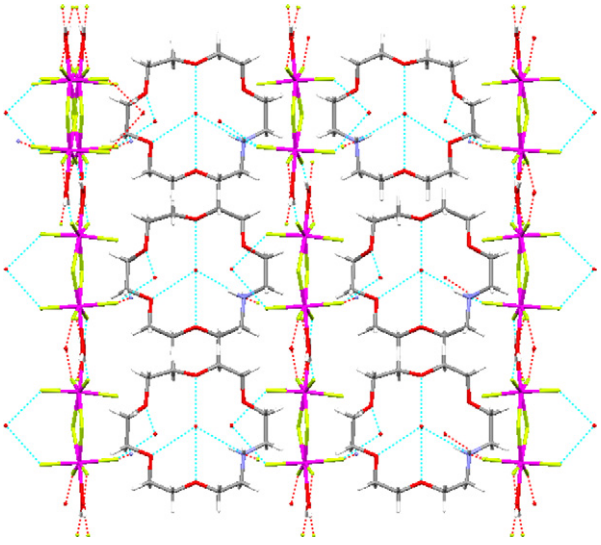

Fig. 6. Fragment of the crystal packing in **3**.

Similar to **3**, the anions in **5** formulate a rigid inorganic negatively charged 2D sheet sustained by OH···F hydrogen bonds (Table 3). Two water molecules O(3w) and O(4w) in an identical mode are bridging two pairs of the anion's axial fluorine atoms (Table 3). Further, these two water molecules in different modes act as intermediates between the inorganic anion and macrocyclic cations. Fig. 8a demonstrates interactions between the components in the complex. Water molecule O(3w) acts in a 'side' mode, and as a single H-acceptor forms N(1a)H···O(3w) hydrogen bond with the A macrocycle, while the second H-atom of the same $\geqslant NH_2^{+}$ group is involved in a single charged-assisted N(1a)H···F(2) hydrogen bond, it is a unique such contact (between the charged species) in this structure. Water molecule O(4w) is situated above the macrocyclic cation B and, acting as a double H-acceptor across the cavity, binds both protons of $\geqslant N(1b)H_2$ ammonia group. It explains, why this macrocycle does not have any direct contacts with the anionic layer. The different modes of water inclusion as well as the distinctions in the interaction with the anionic component, determine the different conformations of A and B macrocyclic cations (Fig. 7, Table 2). Nevertheless, the 3D supramolecular architecture still remains very similar to that one described for **3** (**4**) and for the aforementioned complex $[(18C6)(H_3O)_2(Hf_2O_{10}\cdot 2H_2O)\cdot 4H_2O]$ [7] (Fig. 8b) and represents the alternation of inorganic layers and rows of macrocyclic cations attached, where the A and B macrocycles alternate.

Summarizing these two sections, the following general remarks can be given. Complexes **3**–**6** have enriched a rather restricted family of the aqua, fluoro-containing zirconates [22] and hafnates [23]. For the compounds containing the anions of the similar composition $(M_2O_{10}\cdot 2H_2O)^{2-}$ (M = Zr, Hf), the different arrangement of the coordinated to the central atom water molecules is observed: they are always displayed in the equatorial plane and either lie along the M–M line (complexes **3**–**6**, $[(18C6)(H_3O)_2(Hf_2O_{10}\cdot 2H_2O)\cdot 4H_2O]$ [7]) or perpendicular to it. Besides the discussed here crown-templated complexes, the similar inorganic 2D motif also has been recorded in hexamethyldiammonium pentafluorohafnate tetrahydrate, tetramethylenediammonium pentafluorohafnate hexahydrate [23] and can be considered as a reproducible supramolecular motif. The type of bridging of axial fluorine atoms *via* coordinated or solvated water molecule or oxonium ion found in **3**–**4**, and **5**–**6**, was also registered in Refs. [22,23]. Moreover, this bridge can also represent two-membered H_5O_2 oxonium cluster as in $[(18C6)(H_3O)_2(Hf_2O_{10}\cdot 2H_2O)\cdot 4H_2O]$

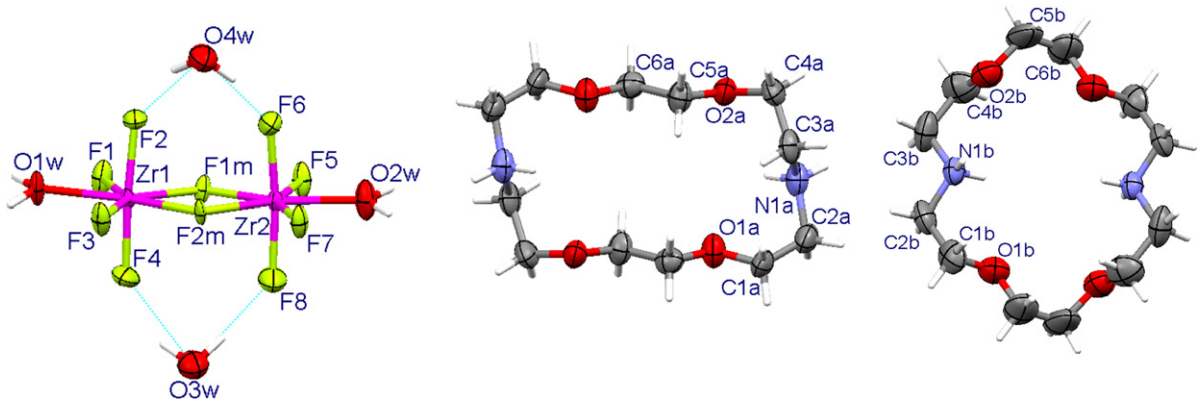

Fig. 7. ORTEP drawing of **5** with the numbering scheme and hydrogen bonding distances shown by dashed lines. Thermal ellipsoids are shown at the 50% probability level.

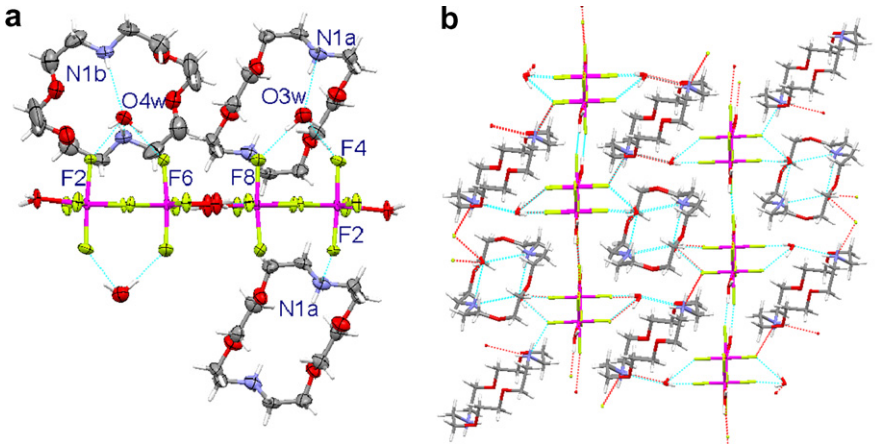

Fig. 8. Fragment of crystal packing in **5**. (a) Fragment of the structure demonstrating the interactions between the inorganic layer and macrocyclic cations, only atoms participating in hydrogen bonding are labeled. (b) 3D network in **5**.

[7] or association of water molecule and ammonium group of templated amine. For **3**–**6**, we conclude the reproduction of 3D supramolecular architecture, which represents the alternation of 2D inorganic sheets and columns of 18-membered crown ethers glued by the different number of water molecules. We also observe the gradual decrease of water content in the complexes with the increase of the positive charge of the macrocyclic cation.

4. Conclusion

The interaction of ZrO_2/HfO_2 or Nb_2O_5/Ta_2O_5 with an aqueous solution of hydrofluoric acid in the presence of aza-crown ether resulted in novel organically templated metal oxofluorides of the compositions $[(HA15C5)_2][Ta_2F_{10}O]$ (**1**), $[(HA18C6\cdot H_2O)$-$(A18C6\cdot H_2O)][(H_2O)\ Nb_2F_9O]\cdot H_2O$ (**2**), $[(HA18C6\cdot H_2O)(M_2F_{10}\cdot 2H_2O)\cdot(H_3O)\cdot H_2O]$ (**3**, **4**) and $[(H_2DA18C6)(M_2F_{10}\cdot 2H_2O)\cdot 2H_2O]$ (**5**, **6**) (M = Zr, Hf, A15C5 = aza-15-crown-5, A18C6 = aza-18-crown-6, DA18C6 = diaza-18-crown-6). The unique ability of crown macrocyclic molecules to form the complexes with novel or rarely observed anions has been demonstrated. So far **1**–**6** represent the exclusive examples of *crown-templated* mixed O,F-containing anions for Zr, Hf, Nb and Ta. The Ta complex **1** represents the second example of such organically templated anion alongside with [9] and the first example of the macrocyclic molecule used in this function. For the first time, the structural information has been obtained for the anion $[(H_2O)NbF_4ONbF_5]^-$ in the complex with macrocyclic molecule. Complex **2** represents a perspective example of the non-centrosymmetric solid with the local ordered anion, thus being crystallized in an acentric space group with an ordered inorganic unit, it might give rise to the new NLO materials. Complexes **3**–**6** give bright examples of the reproducible supramolecular motifs where the factors of domination of inorganic framework and dimensionality of crown molecule are decisive ones. We concluded, that the substitution of one or two oxygen atoms in 18C6 molecule by nitrogen atom did not crucially change the composition of the negatively-charged framework for Zr and Hf in particular and the 3D supramolecular architecture in a whole in the row 18C6–A18C6–DA18C6. The isostructural products have been obtained for Zr and Hf.

ABSTRACT

Crystals of $Co(H_2O)_6K_2V_2W_4O_{19}$ (**1**) and $[Co(H_2O)_6]_2V_2W_4O_{19}$ (**2**) were obtained from aqueous solution of $[V_2W_4O_{19}]^{4-}$ and cobalt(II) nitrate. The structure of $[V_2W_4O_{19}]^{4-}$ is that of the Lindqvist anion in which the two vanadium and four tungsten atoms are statistically distributed over the six metallic positions. The $[V_2W_4O_{19}]^{4-}$ and the $[Co(H_2O)_6]^{2+}$ octahedra are arranged alternately with their faces parallel to each other for maximal interactions (face-to-face interaction). The structure of **1** shows the presence of large mono-directional channels along *c*-axis with a quasi hexagonal section of 8.52×6.35 Å^2 which are filled by cobalt. The structure of **2** can be viewed as a pillar arrangement of $[Co(H_2O)_6]_2V_2W_4O_{19}$ units along *c*-axis.

1. Introduction

Polyoxometalates represent a class of compounds that show a great variety of structural building blocks. In addition to their remarkable chemical and physical properties they have various fields of applications such as catalysis [1–4], medicine [5,6] and material science [7–9]. Vanadium–tungsten mixed isopolyanions were firstly described by Finkener [10] and Rosenheim [11], then in 1894 by Friedheim [12,13] and in 1915 by Prandtl [14]. In 1963, Chauveau and Souchay [15] confirmed the V/W = 2:4 stoichiometry and determined the pH range for the stability of this species. In 1971, Flynn and Pope [16], gave efficient methods to prepare the complexes $[V_xW_{6-x}O_{19}]^{-2-x}$ ($x = 1, 2$). IR and Raman spectroscopic studies in solution and in the solid state have shown that these anions have likely the Lindqvist structure [17,18] with respectively one and two tungsten atoms being replaced by vanadium. The stability in aqueous solution of such species depends strongly on the pH [19,20]. The high charge and large size of the isopolyanions make them nice building units for self assembly in variable clusters packing and to form various internal structures and functionalities [21]. Different modes of interactions govern ionic clusters packing, such as coordination bonds, hydrogen bonds and ionic interactions. As recently shown by Son et al. in the complex $[Al_{13}O_4(OH)_{24}(H_2O)_{12}]_2[V_2W_4O_{19}]_3(OH)_2 \cdot 27H_2O$ [22], electrostatic interactions between oppositely charged polyhedra reinforced by hydrogen bonds, result in face-to-face arrangement of these ionic clusters. The resulting species show bi-dimensional honeycomb layers of clusters. The present work constitutes a contribution to this domain by the synthesis and the structural characterization of two new salts of substituted isopolyanions $Co(H_2O)_6K_2V_2W_4O_{19}$ and $[Co(H_2O)_6]_2V_2W_4O_{19}$ which present face-to-face clusters arrangement.

2. Experimental

Reagent grade cobaltous nitrate $Co(NO_3)_2 \cdot 6H_2O$, was purchased from Acros and used as received. $K_4V_2W_4O_{19} \cdot 8H_2O$ was prepared according to the literature [16]. The IR spectra have been recorded from KBr pellets on a FT-IR Bio-Rad FTS 165 spectrometer with a resolution of 4 cm^{-1}.

2.1. Synthesis

2.1.1. Preparation of $Co(H_2O)_6K_2V_2W_4O_{19}$ (**1**)

An orange solution of divanado-tetratungstate was prepared by dissolving $K_4V_2W_4O_{19} \cdot 8H_2O$ (1 g, 0.69 mmol) in 25 mL of distilled water (pH ≈ 5). Violet solution of cobalt(II) nitrate was obtained by dissolving $Co(NO_3)_2 \cdot 6H_2O$ (0.40 g, 1.38 mmol) in 25 mL of distilled water (pH ≈ 5.4). After mixing the resulting dark orange solution (pH ≈ 5) was stirred and heated for 10 min at 50 °C then

doi:10.1016/j.poly.2008.03.020

left at room temperature until evaporation to dryness (*ca.* 1 week). The crude product was purified by crystallization: it was redissolved in a minimum amount (*ca.* 10 mL) of distilled water, then the solution was filtered by suction filtration (in glass frit No. 4) to eliminate some insoluble residues. Crystals obtained by evaporation at room temperature were collected before dryness, washed successively with water/ethanol mixture (50/50 v/v) and by diethylic ether. Yield of $Co(H_2O)_6K_2V_2W_4O_{19}$: 0.67 g, 67% based on polyoxoanion. IR (KBr pellets 300–1000 cm^{-1}): 364 (m), 368 (m), 436 (s), 455 (s), 592 (m), 596 (m), 787 (vs), 941 (s), 956 (vs), 989 (m). Well-shaped dark orange prismatic crystals suitable for X-ray data collection were obtained after slow recrystallization in distilled water.

2.1.2. Preparation of $[Co(H_2O)_6]_2V_2W_4O_{19}$ (**2**)

To 5 mL of a dark orange aqueous solution of **1** (0.5 g, 0.34 mmol, pH ≈ 5) was added 5 mL of an aqueous solution of $Co(NO_3)_2 \cdot 6H_2O$ (0.10 g, 0.34 mmol, pH ≈ 5.4). The subsequent treatment was the same as that used for **1**. Yield of $[Co(H_2O)_6]_2V_2W_4O_{19}$: 0.17 g, 34%. IR (KBr pellets 300–1000 cm^{-1}): 369 (m), 372 (m), 441 (s), 452 (s), 587 (m), 591 (m), 793 (vs), 946 (s), 962 (vs), 991 (m). After recrystallization in distilled water well-shaped orange prismatic crystals suitable for X-ray data collection were obtained.

2.2. X-ray single-crystal structure determination

An orange prismatic crystal (0.10 × 0.12 × 0.12 mm^3) of **1** was mounted on a four-circle CAD-4 Enraf Nonius diffractometer using graphite-monochromated Mo Kα radiation (0.71073 Å). Intensity data were collected at 293 K. Treatment of data and refinement of cell parameters have been performed using Express program CAD-4 [23,24]. The data reduction has been assured by the program RC93 (Watkin et al., 1994).

An orange parallelepipedic crystal (0.10 × 0.11 × 0.12 mm^3) of **2** was mounted on a Kappa-CCD Bruker AXS diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). Data were collected at 293 K. Refinement of cell parameters has been performed by Dirax/lsq (Duisenberg and Schreurs, 1989–2000) and data reduction by EvalCCD (Duisenberg and Schreurs 1990–2000).

Reflection collected	1407	1396
Data completeness	99.9%	99.5%
Data used/restraints/parameters	1104/2/110	925/85/36
Goodness-of-fit on *F*	1.0541	1.0744
Final R_1, wR_2 [$I > 3\sigma(I)$]	0.0443, 0.0484	0.0397, 0.0425
Largest differential peak and hole (e Å)$^{-3}$	−1.62, 1.37	−1.93, 1.98

The positional parameters of metal and of most oxygen atoms of the clusters were obtained by direct methods and refined with full-matrix least-squares technique on *F* using SHELXS86 [25]. The crystallographic software CRYSTALS [26] was used for the refinement of the structure and the preparation of data for the publication. The structure representations were drawn with DIAMOND program [27]. The crystal data and details of data collection and refinement for crystals of **1** and **2** are summarized in Table 1.

3. Results and discussion

3.1. Synthesis

It is well known that stability of polyoxoanion in aqueous solution dramatically depends on the pH. Obtaining polyanions as crystalline material from their aqueous solution require the use of an appropriate counterion which does not strongly affect the pH. Stability range of $[V_2W_4O_{19}]^{4-}$ is $4 \leqslant pH \leqslant 7$ [20]. For the obtainment of transition metal salts of this anion it is therefore important to maintain the pH of the solution between 4 and 7 during the addition of counterion; e.g. Co^{2+} aqueous solutions (pH = 5.4) are therefore appropriate for that purpose. All attempts to obtain the all-cobalt species $[Co(H_2O)_6]_2V_2W_4O_{19}$ (**2**) directly from $K_4V_2W_4O_{19}$ and cobalt nitrate failed even with a large excess of the later. The mixed potassium cobalt salt **1** crystallizes instead from the solution. Potassium-free **2** was ultimately obtained by addition of cobalt nitrate to a solution of **1**.

3.2. Infrared spectroscopy

The infrared spectra of $K_4V_2W_4O_{19} \cdot 8H_2O$, **1** and **2** are very similar and characteristic of the substituted Lindqvist structure: the stretching modes of the M–O_t bonds appear at relatively high wavenumbers (900–1006 cm^{-1}) and those implying the bridging oxygen atoms at ca 800 cm^{-1}. Low-wavenumber bands were assigned to bending vibrations of the oxocluster (see Table 2). It should be noted that the two high frequency modes are shifted to low wavenumbers by 10–15 cm^{-1} in the cobalt-containing species (with respect to the potassium salt); such a shift has been already reported for the guanidinium salt [28] and also for Keggin derivatives [29]. This could originate from specific cation–anion interactions implying the external oxygen atoms of the polyoxometallates.

3.3. Structural analysis

3.3.1. Structural determination

Crystals of $Co(H_2O)_6K_2V_2W_4O_{19}$ (**1**) were obtained from an aqueous solution of potassium salt of $[V_2W_4O_{19}]^{4-}$ and cobalt(II) nitrate. Crystals of $[Co(H_2O)_6]_2V_2W_4O_{19}$ (**2**) were obtained from an aqueous solution of **1** and cobalt(II) nitrate.

Both compounds **1** and **2** contain $[V_2W_4O_{19}]^{4-}$ oxocluster. This anion is isostructural with $W_6O_{19}^{2-}$ [30], $Nb_6O_{19}^{8-}$ [31], $Ta_6O_{19}^{8-}$

[32], $Mo_6O_{19}^{2-}$ [33] and has the so-called Lindqvist structure with general formula $M_6O_{19}^{n-}$. This structure is based on the arrangement of six edge-sharing octahedra with overall O_h symmetry. It contains three types of oxygen atoms: six terminal oxygen atoms O_t (M–O_t ~ 1.7 Å), twelve oxygen atoms O_b bridging two metals (M–O_b ~ 1.9Å) and one central oxygen atom O_c common to the six MO_6 octahedra (M–O_c ~ 2.3Å).

As was already observed for the guanidinium $(CN_3H_6)_4V_2W_4O_{19}$ [28] and Al_{13} [22] salts, compounds **1** and **2** exhibit a random V/W distribution over the metal sites. This orientational disorder of the $[V_2W_4O_{19}]^{4-}$ anion is a consequence of a regular distribution of the anionic charge over the external oxygen atoms. The problem of statistical disorder is frequently encountered in the structural resolutions of substituted and lacunary polyoxometalates for which it is impossible to derive specific metrical parameters [34]. Refinements of the structures were performed by forcing the vanadium and tungsten atoms to occupy the same crystallographic sites. In both cases refinement converged to statistical occupancies of 1/3 and 2/3 for V and W respectively in agreement with $[V_2W_4O_{19}]^{4-}$ formula. For both compounds the Co–O_w (O_w: water oxygen) average distance of 2.1 Å is typical for those found in related Co–O complexes as seen in Table 3. Valence sum calculations according to Brown's method using VALIST program [35] show that in both compounds **1** and **2** the oxidation state of cobalt is close to +2.

*3.3.1.1. Crystal structure description of $Co(H_2O)_6K_2V_2W_4O_{19}$ (**1**).* The asymmetric unit is composed of fifteen independent non-hydrogen atoms, corresponding to one potassium atom, one cobalt atom linked to four oxygen atoms (water oxygen) and nine atoms generating the $V_2W_4O_{19}$ anion. In $V_2W_4O_{19}$ the nine atoms are divided in two metallic atoms (M = 2/3 W and 1/3 V) and seven oxygen atoms labelled according to their position in the structure: 1 O_c, 2 O_t and 4 O_b are central, terminal and bridging oxygen atoms respectively. The reduction in the atom numbers in the asymmetric unit is due to the high symmetry of the orthorhombic system in which crystallizes the compound **1**.

The cobalt octahedra are disordered over two positions. In the asymmetric unit all representative atoms of cobalt octahedra (labelled Co13, O14, O15, O16 and O17) are located at special positions and some of them occupy partially their positions: the cobalt and two oxygen atoms (Co13, O16 and O17) occupy their positions at 50% and the two other oxygen atoms (O14 and O15) occupy fully their positions. The atomic parameters and selected bonds are reported in Tables 4 and 5. The anisotropic displacement and the full refinement data are available as supplementary materials.

The X-ray observed structure for cobalt cation is a face sharing dimeric species (Fig. 1) statistically disordered over two position with 50% occupancy of each position; this crystallographic solution is consistent with electroneutrality of the whole molecule. The refinement of the cobalt occupancy (at Wyckoff position f) without constraint reveals that its real value is 50%. The refinement converges and the thermal displacement of the oxygen atoms is considerably reduced when occupancies of the oxygen atoms located out of the shared face is reduced by half.

The structure of compound **1** can be viewed as stacking of isopolyanion layers along *c*-axis. The cohesion between these layers is ensured by electrostatic interactions between the cluster anions and the potassium atoms (Fig. 2). The potassium atoms are coordinated to four V_2W_4 units belonging to two adjacent layers. In each layer, the potassium atom is linked to one terminal oxygen of one polyanion and one bridging oxygen atom of the other, with an average distance of about 2.836 Å (Fig. 3).

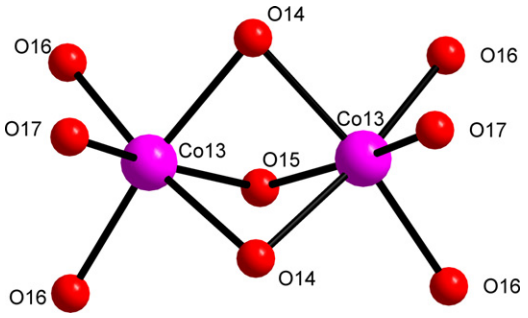

Fig. 1. Dimeric face-sharing cobalt octahedra in **1** with 50% occupancy on each position.

The resulting network generates large one-dimensional channels with cross sectional area of 8.5 × 6.3 Å^2 along *c*-axis, in which are located the cobalt octahedra $Co(H_2O)_6^{2+}$. These channels constitute ca. 70% of unit cell volume.

*3.3.1.2. Crystal structure description of $[Co(H_2O)_6]_2V_2W_4O_{19}$ (**2**).* The high symmetry of the space group $R\bar{3}m$ in which crystallizes the compound **2** reduces to eight the number of independent non-hydrogen atoms in the asymmetric unit. The polyoxoanion $V_2W_4O_{19}^{4-}$ is generated by five atoms: one metallic atom (2/3 W and 1/3 V) and four oxygen atoms (1 O_c, 2 O_b and 1 O_t). The cobalt octahedron $Co(H_2O)_6^{2+}$ is represented by cobalt and two oxygen atoms (water oxygen).

The basic motif of **2** consists of one $V_2W_4O_{19}^{4-}$ and two $Co(H_2O)_6^{2+}$ forming neutral molecules. The isopolyanion and cobalt octahedra are arranged alternately with their faces parallel to each other. Crystal structure of **2** can be described by the pillar packing of $[Co(H_2O)_6]_2V_2W_4O_{19}$ along the *c*-axis. The spacing distance between $[Co(H_2O)_6]_2V_2W_4O_{19}$ entities along *c*-axis is ca. 4 Å, (Fig. 4). Cohesion of the pillar structure is ensured by electrostatic forces and hydrogen bonds as discussed below. The atomic parameters and selected bonds are reported in Tables 6 and 7.

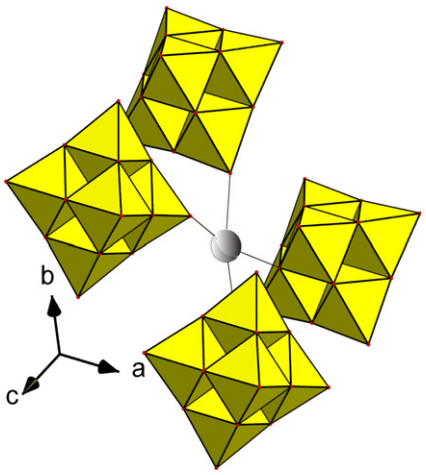

Fig. 3. Coordination of the potassium cation in **1**.

The anisotropic displacement and the full refinement data are available as supplementary materials.

3.4. Face-to-face interaction

For both compounds hydrogen bonds ensure the cohesion between $V_2W_4O_{19}^{4-}$ faces and those of $[Co(H_2O)_6]^{2+}$ octahedra. Hydrogen bond lengths O···O between the oxygen atoms of the V_2W_4 cluster, and water molecules coordinated to cobalt vary between 2.70 and 2.90 Å. The triangular contacting faces for both title compounds are nearly parallel to each other with an angular shift of 0.81° and 0.51°, respectively for **1** and **2** (Fig. 5).

4. Conclusion

The reaction of $V_2W_4O_{19}^{4-}$ with $[Co(H_2O)_6]^{2+}$ in aqueous solution at adequate pH results in complexes $Co(H_2O)_6K_2V_2W_4O_{19}$ (**1**)

ABSTRACT

Two complexes of silver(I) with 4,5-diazafluoren-9-one (dafone) which are the first examples of Ag-dafone complexes were synthesized and structurally characterized. Crystals of $[Ag(dafone)_2]NO_3 \cdot H_2O$ (**1**) contain two strictly planar four-coordinate Ag(I) complexes. The silver coordination polyhedron in $[Ag_2(4,4'\text{-bpy})(dafone)_4]BF_4$ (**2**) is a highly distorted tetrahedron. Its crystal structure is built by a two-fold interpenetration of identical porous networks. The unusual coordination in the two compounds (planar four-coordinate d^{10} ion in **1**, chelation with two long Ag–N bonds in **2** and low bond valence sums in both complexes) is in part due to the large chelate bite of dafone, and in part due to the stacking and other intermolecular interactions influencing the coordination geometry of Ag(I). This was further probed through molecular simulation of $[Ag(N\text{–}N)_2]^+$ complexes using DFT calculations.

1. Introduction

4,5-Diazafluoren-9-one (dafone) is a derivative of 1,10-phenanthroline (phen), having an exocyclic keto function [1]. Even though silver(I) complexes of other diimine ligands like 2,2′-biyridine (bpy) and phen are known [2–6], little is known about the dafone complexes. Silver, due to its d^{10} configuration has no electronically imposed preference for any particular coordination geometry. The observed stereochemistry and crystal structures are influenced by several factors like steric interactions between ligands, π–π stacking interaction between aromatic rings, Ag ... Ag interactions and counter anions [7,8]. Recent reports of silver(I) complexes of derivatives of bpy and pyridine ligands further substantiate the above factors [2,9]. Unlike phen and bpy, dafone has a large N–N bite distance (2.99 Å) enforced by the rigid five-membered centre ring, which makes it unique among the diimine ligands [10]. In order to explore the effect of the geometry of dafone on silver coordination, we have synthesized two complexes of silver(I) with dafone having nitrate and tetraflouroborate anions.

2. Experimental

2.1. Materials and physical measurements

All chemicals were of reagent grade obtained from commercial sources and were used without further purification. Dafone was prepared using a reported procedure [1]. IR spectra were recorded using KBr discs on a Jasco FT/IR 5300 spectrometer in the range 4000–400 cm^{-1}. Elemental analysis for C, H and N was performed on a Perkin–Elmer 240C elemental analyzer.

2.2. Synthesis

2.2.1. Synthesis of $[Ag(dafone)_2]NO_3 \cdot H_2O$ (*1*)

Dafone (0.181 g, 1.00 mmol) dissolved in acetonitrile (15 mL) was added to an aqueous solution (15 mL) of $AgNO_3$ (0.085 g, 0.50 mmol), with constant stirring. It was filtered and kept for crystallization at room temperature to yield yellow needle shaped crystals suitable for X-ray data collection. Yield 0.250 g, (0.453 mmol, 90%). *Anal.* Calc. for $C_{22}H_{14}AgN_5O_6$ (M.W. 552.25 g): C, 47.85; H, 2.56; N, 12.68. Found: C, 47.72; H, 2.52; N, 12.93%. Important IR absorptions (KBr disk, cm^{-1}): 3576, 3425, 3034, 1834, 1718, 1593, 1462, 1259, 916 and 758.

2.2.2. Synthesis of $[Ag_2(4,4'\text{-bipyridine})(dafone)_4](BF_4)_2$ (*2*)

4,4′-Bipyridine (0.039 g, 0.25 mmol) and dafone (0.181 g, 1.00 mmol) were dissolved in acetonitrile (20 mL) and slowly added to an acetonitrile solution (10 mL) of $AgBF_4$ (0.098 g, 0.50 mmol) while stirring. It was filtered and kept for crystallization at room temperature to yield yellow block shaped crystals. Yield 0.295 g (0.232 mmol, 93%). *Anal.* Calc. for $C_{54}H_{32}Ag_2B_2F_8N_{10}O_4$ (M.W. 1274.25 g): C, 50.90; H, 2.53; N, 10.99. Found: C, 50.84; H, 2.58; N, 10.73%. (λ = 0.71073 Å) at 298 K. Data were reduced using SAINTPLUS [11] and a multi-scan absorption correction using SADABS [12] was performed. The structures were solved by direct method using SHELXS-97 and full-matrix least-square refinement was carried out using SHELXL-97 [13]. All ring hydrogen atoms were assigned on the basis of geometrical considerations and were allowed to ride upon the respective carbon atoms. Hydrogen atoms on the water molecules were located from the difference maps and geometrical constraints were applied. Drawings were made using ORTEP3 for windows [14] and Mercury [15]. Crystallographic data are in Tables 1 and 2.

2.4. Computational details

DFT calculations were done by using B3LYP [16] exchange correlation function as implimented in the GUASSIAN-03 [17]. Ag(I) ion was described with the LANL2DZ basis set, including effective core potential, whereas 6-31G(d) basis set was used for C, N, O and H atoms.

3. Results and discussion

3.1. Structure of [Ag(dafone)$_2$]NO$_3$ · H$_2$O (**1**)

There are two crystallographically independent, but chemically similar Ag(dafone)$_2^+$ cations in the unit cell of **1** (Fig. 1). Each four-coordinate silver atom is situated on a crystallographic inversion centre. The coordination is, therefore, strictly planar even though the dafone ligands deviate slightly (4.3° Ag(1); 5.2° Ag(2)) from the AgN4 plane. There is a large asymmetry in the chelating bond distances of dafone with two short and two long bonds (2.22 and 2.69 Å for Ag(1); 2.25 and 2.65 Å for Ag(2)). Most previously reported [Ag(N–N)$_2$]$^+$ complexes are near-symmetric chelates exhibiting a flattened tetrahedral coordination with dihedral angles in the range 18–80° [2–6,18–25]. The two complex cations in **1** inter-

act through π-stacking (3.36–3.50 Å) leading to an interdigitized packing. The nitrate ion and the lattice water molecule participate in H-bonding (O–H···O, C–H···O) and O···π interactions (Fig. 2).

As early as 1986, Goodwin et al. [26] after considering electronic as well as steric factors, concluded that the flattening distortion in bis-chelate complexes of Ag(I) with hetero-aromatic ligands is imposed by π-stacking interactions in the lattice. The wide range of the observed torsion angles reveal that there is considerable plasticity in the coordination polyhedron of this class of four-coordinate Ag(I) complexes. Compound **1**, represents the extreme situation of perfect planarity. However, it should be noted that the flattening is accompanied by a highly unsymmetrical (to the extent of 15–20%) chelate bonds. Further, Ag(I) in this compound has an abnormally low bond valence sum [27] of 0.78–0.81 (expected value 1.0). Other complexes, for example $Ag(bpy)_2^+$, typically have a bond valence sum of 0.98. It appears that the relatively weak metal–ligand interaction is compensated by intermolecular interactions, especially π-stacking. The dominant role of lattice interactions in controlling the coordination geometry of Ag(I) complexes has been previously noted [28].

3.2. Structure of $[Ag_2(4,4'\text{-bipyridine})(dafone)_4](BF_4)_2$ (**2**)

The cation in **2** is dinuclear with a crystallographic inversion centre (Fig. 3). The coordination polyhedron at each silver atom is a highly distorted tetrahedron with two short (2.24 and 2.25 Å), and two long (2.59 and 2.64 Å) bonds. Of the two-coordinated dafone molecules, one forms a single short bond, while the other forms 2-weak chelating bonds. The fourth coordination position of each silver atom is occupied by a nitrogen atom of the bridging 4,4′-bipyridine. The cations are assembled into porous two-dimensional sheets by C–H···F and C–H···O interactions. However, the pores are blocked by the two-fold interpenetration of identical networks with the adjacent networks connected by π···π stacking (3.30–3.48 Å) interactions (Fig. 4). Compound **2** further illustrates the weakness of Ag-dafone interaction. The chelating dafone in this complex presents the unusual picture of two long Ag–N bonds, while the singly bonded dafone forms a normal Ag–N bond. Even in this compound, the bond valence sum is only 0.82.

3.3. Geometry optimizations

Geometry optimization using DFT for $[Ag(N\text{-}N)_2]^+$ ion, with N–N = bpy, phen, or dafone, resulted in a tetrahedral structure for all the three complexes with the following bond distances (Å) and dihedral angles (°): bpy, 2.38, 87.6; phen, 2.39, 90.0; dafone, 2.41–2.52, 89.8. The optimized bond distances for the bpy and phen complexes are within 0.14 Å of the crystallographic values (CSD REFCODE for the bpy complex MAYCIZ; for the phen complex IGULOL01). However, the dihedral angles in the crystal structures are 39.5° in both structures, corresponding to flattened tetrahedral coordination. There are also local minima in the case of dafone, within about 0.2 eV, in which the complex ion is planar or nearly planar with two short and two long bonds. However, the long

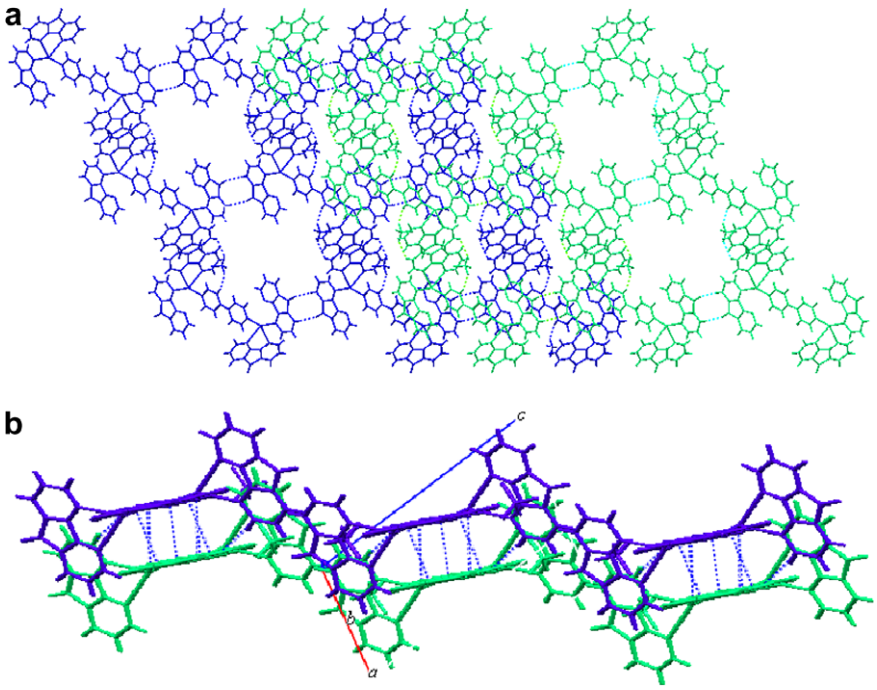

Fig. 4. (a) Two-fold interpenetrating layers of **2** viewed in the *bc*-plane. (b) Side view showing stacking interactions between the interpenetrating layers.

bonds were so long (2.8 Å) that the complex is actually two-coordinate. It may be recalled that bis-chelates with *trans*-geometry having four short bonds are not possible for these ligands due to α-hydrogen strain (bulk effect). In summary, the simulations show that the "gas-phase" ion will have a regular tetrahedral geometry for all the three ligands even though in the case of dafone the Ag–N bond distances will be considerably longer compared to bpy or phen. Therefore, the flattened structures observed in crystals must be due to lattice effects.

4. Conclusion

Like in the case of $Cu(dafone)_2X_2$ [10] complexes, dafone prefers a *trans* bis-chelate configuration with two short and two long bonds in $[Ag(dafone)_2]^+$. If it is the Jahn–Teller effect which uses the unfavorable chelate bite as a handle to distort the molecular structure in the case of Cu(II), it is the intermolecular interaction in the crystal lattice which plays this role for Ag(I). The above silver(I) complex ion is perfectly planar in the crystal though the coordination plane is far from square. A recent review [29] on "square planar" silver(I) complexes lists about 65 such complexes which form about 2% of the crystallographically characterized silver(I) complexes. Even this small number includes those whose coordination is best described as planar [2 + 2] as well as those in which a significant tetrahedral distortion and/or distant axial interactions are present. As stated in the above review, while square planar complexes will be sought after for use as four-connected nodes or secondary building blocks for the design of silver(I) coordination networks, there is no simple way to predict the precise circumstances that will lead to a square planar geometry.

Dafone forms much weaker bonds with silver compared to bpy or phen, so much so that in mixed ligand complexes it may even act as a mono-dentate ligand or as a weak chelating ligand. Even though the mono-dentate mode and the asymmetric chelating mode have been observed in many other complexes [10,30–37] with different metal ions, the weak chelate with two long bonds seen in the crystals of **2** is unusual.

Acknowledgements

We thank a referee for bringing to our notice a recent review on square planar silver(I) complexes. This work was supported by CSIR, India. A.R.B thanks UGC for a research fellowship. Infrastructure support from UGC (UPE program) and DST (X-ray diffractometer facility) is also acknowledged. The DFT calculations were performed using the CMSD facility.

Appendix A. Supplementary data

CCDC 668064 and 668065 contain the supplementary crystallographic data for **1** and **2**. ABSTRACT

The approach to remove green house gases by pumping liquid CO_2 several kilometres below the ground implies that many carbonate containing minerals will be formed. Among these minerals the formation of dypingite and artinite are possible; thus necessitating a study of such minerals. Two carbonate bearing minerals dypingite and artinite with a hydrotalcite related formulae have been characterised by a combination of infrared and near-infrared spectroscopy. The infrared spectra of both minerals are characterised by OH and water stretching vibrations. Both the first and second fundamental overtones of these bands are observed in the NIR spectra in the 7030–7235 cm^{-1} and 10490–10570 cm^{-1}. Intense $(CO_3)^{2-}$ symmetric and antisymmetric stretching vibrations confirm the distortion of the carbonate anion. The position of the water bending vibration indicates water is strongly hydrogen bonded to the carbonate anion in the mineral structure. Split NIR bands at around 8675 and 11100 cm^{-1} indicates that some replacement of magnesium ions by ferrous ions in the mineral structure has occurred.

1. Introduction

The ability to be able to easily and readily detect minerals is of importance [1,2]. This is especially so where carbonate minerals are concerned. The technique of NIR spectroscopy does meet these requirements. What is probably not appreciated is that many carbonate containing minerals especially the secondary minerals are soluble and can translocate. The proposal to remove green house gases by pumping liquid CO_2 several kilometres below the ground requires formation of many carbonate containing minerals [3–5]. Two magnesium carbonate minerals which may form under such conditions of high CO_2 partial pressure are dypingite $Mg_5(CO_3)_4(OH)_2 \cdot 5H_2O$ [6–10] and artinite $Mg_2(CO_3)(OH)_2 \cdot 3H_2O$ [11–20].

The study of the magnesium carbonates is of extreme importance in the development of technology for the removal of green house gases. Magnesium minerals such as brucite, periclase and hydrotalcites have the potential for the sequestration of carbon dioxide. The formation and reaction pathways of hydroxy and hydrous carbonates of magnesium are essential for the understanding of this sequestration. The hydration–carbonation reaction path in the $MgO–CO_2–H_2O$ system at ambient temperature and atmospheric CO_2 is of essential significance from the standpoint of carbon balance and the removal of green house gases from the atmosphere. A better understanding of the global masses of Mg and CO_2 and the thermal stability of the hydrated carbonates of magnesium will provide fundamental knowledge of carbon dioxide removal. From a practical point of view, the exact knowledge of the reaction path in $MgO–CO_2–H_2O$ system is of great significance to the performance of brucite and related minerals for green house gas removal. The reaction path involving carbonation of brucite ($Mg(OH)_2$) is particularly complex, as Mg has a strong tendency to form a series of metastable hydrous carbonates. These metastable hydrous carbonates include hydromagnesite ($Mg_5(CO_3)_4(OH)_2 \cdot 4H_2O$, or $Mg_4(CO_3)_3(OH)_2 \cdot 3H_2O$), artinite ($Mg_2CO_3(OH)_2 \cdot 3H_2O$), nesquehonite ($MgCO_3 \cdot 3H_2O$), and lansfordite ($MgCO_3 \cdot 5H_2O$). The free energy of formation for these hydroxy and hydrous carbonates differs and their formation depends on the partial pressure of CO_2.

There are many applications of near infrared spectroscopy [21–29]. Many of these studies have been applied to minerals and soils [1,2,29–32]. One means of studying the distant planets and comets is the use of NIR spectroscopy [23,24,26,27,33–35]. Recently, Frost et al. used NIR spectroscopy to study some hydroxyl phosphated minerals [36,37] and some autunites [38,39]. The technique of NIR spectroscopy can be used at distances away from the spectrometer using a fibre optic probe and the NIR technique does have the possibility of detecting carbonate minerals. Many carbonate minerals contain both bonded water and adsorbed water; several minerals contain hydroxyl groups. NIR spectroscopy has often been referred to as 'proton' spectroscopy. This means that any mineral

doi:10.1016/j.poly.2008.03.019

or compound containing protons will be able to be determined using NIR spectroscopy. Thus because of the presence of water and OH units, the hydroxyl and hydrated carbonate minerals lend themselves to analyses by NIR spectroscopy. Near-IR spectral regions may be conveniently divided into three spectral regions: (a) the high wavenumber region above 7500 cm^{-1} attributed to electronic bands, (b) between 5400 and 7500 cm^{-1} attributed to the first overtone of the fundamental hydroxyl stretching modes and (c) the 4000–5400 cm^{-1} region attributed to water combination modes [36,39–42]. This paper reports the detection of selected carbonate minerals using NIR spectroscopy with a fibre optic probe.

2. Experimental

2.1. Minerals

The following minerals were used in this research: (a) dypingite – Yoshikawaite, Shinshiro Shi, Aichi Prefecture, Japan, (b) Sample 4 dypingite – Clear Creek District, Southern San Benito County, CA, (c) Sample 3 artinite – Clear Creek District, Southern San Benito County, CA and (d) Sample 7 artinite – Higasi-Kuroda-Guchi, Inasa-Cho, Inasa-Gun, Aichi Prefecture, Japan. The phase purity of the minerals was checked by X-ray diffraction and the chemical composition by EDX measurements.

2.2. Near-infrared (NIR) spectroscopy

NIR spectra were collected on a Nicolet Nexus FT-IR spectrometer with a Nicolet Near-IR Fibreport accessory (Madison, WI). The reason for using a fibre optic probe is the ease of operation and the fact that the probe can be brought to the mineral and can be used at some distance from the spectrometer. A white light source was used, with a quartz beam splitter and TEC NIR InGaAs detector. Spectra were obtained from 13 000 to 4000 cm^{-1} (0.77–2.50 μm) by the co-addition of 256 scans at a spectral resolution of 8 cm^{-1}. A mirror velocity of 1.266 m s^{-1} was used. The spectra were transformed using the Kubelka-Munk algorithm to provide spectra for comparison with published absorption spectra. Spectral manipulations, such as baseline correction, smoothing and normalisation, were performed using the software package GRAMS (Galactic Industries Corporation, NH, USA).

2.3. Mid-IR spectroscopy

Infrared spectra were obtained using a Nicolet Nexus 870 FT-IR spectrometer with a smart endurance single bounce diamond ATR cell over the 4000–525 cm^{-1} range obtained by the co-addition of 64 scans with a resolution of 4 cm^{-1} and a mirror velocity of 0.6329 cm/s. Spectra were co-added to improve the signal to noise ratio.

Band component analysis was undertaken using the Jandel 'Peakfit' (Erkrath, Germany) software package which enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. The Lorentz–Gauss ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations (r^2) greater than 0.995. Band fitting of the spectra is quite reliable providing there is some band separation or changes in

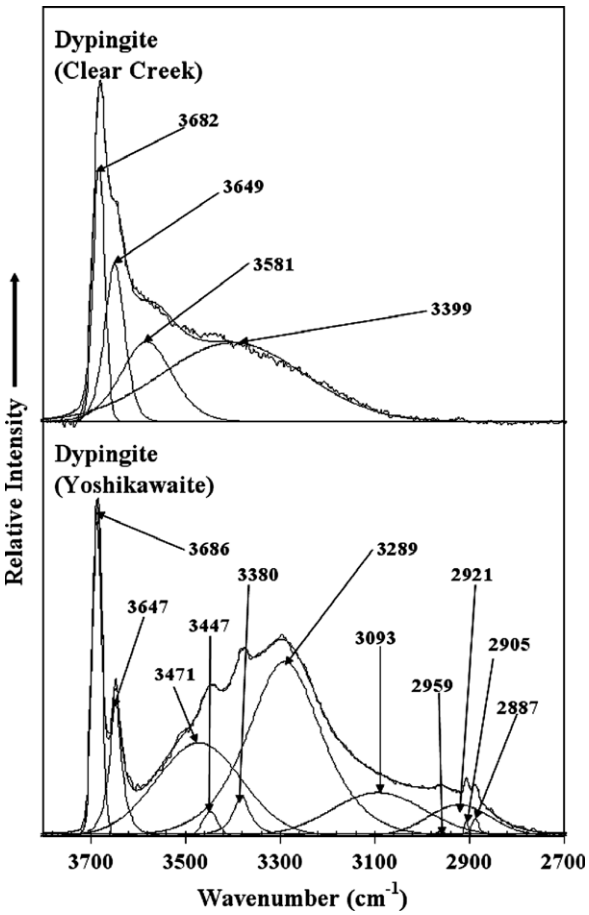

Fig. 1. Infrared spectra of artinite in the 2700–3800 cm^{-1} region.

the spectral profile. The band intensities were calculated as a percentage of the total normalised band intensity.

3. Results and discussion

3.1. Mid-infrared spectroscopy

The infrared spectrum of dypingite and artinite are shown in Figs. 1 and 2. The results of the infrared spectral analysis are reported in Table 1. The infrared spectra of dypingite in the OH stretching region displays two features: (a) two sharp bands at 3647 and 3686 cm^{-1} and (b) a number of broad overlapping bands centred upon 3289, 3380 and 3447 cm^{-1} (Yoshikawaite). The first two bands are assigned to the hydroxyl stretching vibrations of OH units whereas the broad bands are assigned to water stretching bands. The infrared bands at 2887, 2995, 2921 and 2959 cm^{-1} in Yoshikawaite dypingite is ascribed to adsorbed organics on the surface of the dypingite. The variation in intensity of the water stretching bands shows that some variation in the formula of dypingite may occur and is a function of the water partial pressure. This variation in intensity is readily observed in Fig. 1. Such variation in intensity of the bands assigned to water stretching vibrations may be complicated by the adsorption of water on the mineral surface. The same explanation is suitable for the mineral artinite. Two sharp bands at 3649 and 3685 cm^{-1} are observed for the Clear creek artinite and three bands at 3651, 3685 and 3696 cm^{-1} for the Aichi artinite. These bands are attributed to the stretching vibrations of the OH units. The other bands in the spectra are assigned to water stretching bands.

The infrared spectra of dypingite and artinite in the 525–1625 cm^{-1} region are shown in Figs. 3 and 4 respectively. The sharp bands at 1071 (Yoshikawaite) and the shoulder at 1078 cm^{-1} (Clear Creek) are attributed to the $(CO_3)^{2-}$ carbonate symmetric stretching mode. The observation of this mode in the infrared spectra provides evidence for the distortion of the carbonate anion and consequential loss of symmetry. Such a band should be not observed in the infrared spectrum but would be intense in the Raman spectrum. The band is observed at 1076 cm^{-1} for

artinite (Clear Creek) and 1083 cm^{-1} for the Aichi artinite. The $(CO_3)^{2-}$ symmetric stretching mode is complimented with the antisymmetric stretching modes found in the 1300–1450 cm^{-1} region where a series of overlapping bands may be observed providing a complex spectral profile. For the dypingite from Clear Creek, these $(CO_3)^{2-}$ symmetric stretching bands are observed at 1312, 1438, 1534 and 1585 cm^{-1}. These bands appear better defined for the Yoshikawaite dypingite with clearly resolved bands at 1380, 1405, 1479 and 1509 cm^{-1}. For the artinite minerals these $(CO_3)^{2-}$ antisymmetric stretching modes are observed at 1325, 1381, 1439 cm^{-1} (Aichi) and 1376, 1441, 1535 cm^{-1} (Clear Creek).

In the spectrum of the Yoshikawaite dypingite two bands are observed at 1599 and 1682 cm^{-1}. The probable assignment of these two bands is to the water HOH bending mode. The fact that two bands are observed suggests that there are two types of water present in the dypingite structure. The band at 1599 cm^{-1} is attributed to non-hydrogen bonded water and corresponds to the position of the water bending mode of water vapour. Whereas the band at 1682 cm^{-1} corresponds to water not bonded by hydrogen bridges. For artinite, two bands are observed at 1578 and 1643 cm^{-1}. This latter band shows that the water is very strongly hydrogen bonded. This band corresponds to the water stretching vibration at low wavenumber whereas the 1595 cm^{-1} band is reflected in the OH stretching region by the bands in the 3200–3450 cm^{-1} region.

Two intense infrared bands are observed at 948 and 1008 cm^{-1} (Yoshikawaite dypingite) and 947 and 1012 cm^{-1} (Clear Creek). These bands are observed at 947 and 1017 cm^{-1} for the Clear Creek sample and at 952 and 995 cm^{-1} for the Aichi mineral. One possible assignment of these bands is to the OH deformation modes of the MgOH units. For the Yoshikawaite dypingite infrared spectrum low intensity infrared bands are observed at 755 and 799 cm^{-1}. For the Aichi artinite these bands are observed at 722 and 762 cm^{-1}. These bands are assigned to the $(CO_3)^{2-}\nu_4$ bending modes. The observation of more than one band supports the concept that there are multiple $(CO_3)^{2-}$ bending modes as a result of the distortion of the $(CO_3)^{2-}$ units in the dypingite and artinite structures. For the Yoshikawaite dypingite infrared spectrum, two bands are observed at 852 and 882 cm^{-1}. These bands are assigned to the $(CO_3)^{2-}\nu_2$ bending modes. A very low intensity band is observed for the Clear Creek artinite at 844 cm^{-1} which may correspond with this assignment.

Two bands are observed at 548 and 618 cm^{-1} for the Clear Creek dypingite and at 546 and 600 cm^{-1} for the Yoshikawaite dypingite. For the clear Creek artinite the bands are observed at 552 and 610 cm^{-1} and at 568 and 638 cm^{-1} for the Aichi artinite. These bands are too low in position to be interpreted as $(CO_3)^{2-}$ bending modes. One possible assignment of these bands is to the water librational modes.

3.2. Near-infrared (NIR) spectroscopy

Spectra are divided into: (a) the spectral region between 5500 and 8000 cm^{-1}, corresponding to the first fundamental overtone of the mid-infrared OH stretching vibration; (b) the spectral region between 4000 and 5500 cm^{-1} attributed to the water OH overtones, carbonate combination bands and (c) the spectral region between 8000 and 12 000 cm^{-1} corresponding to the second

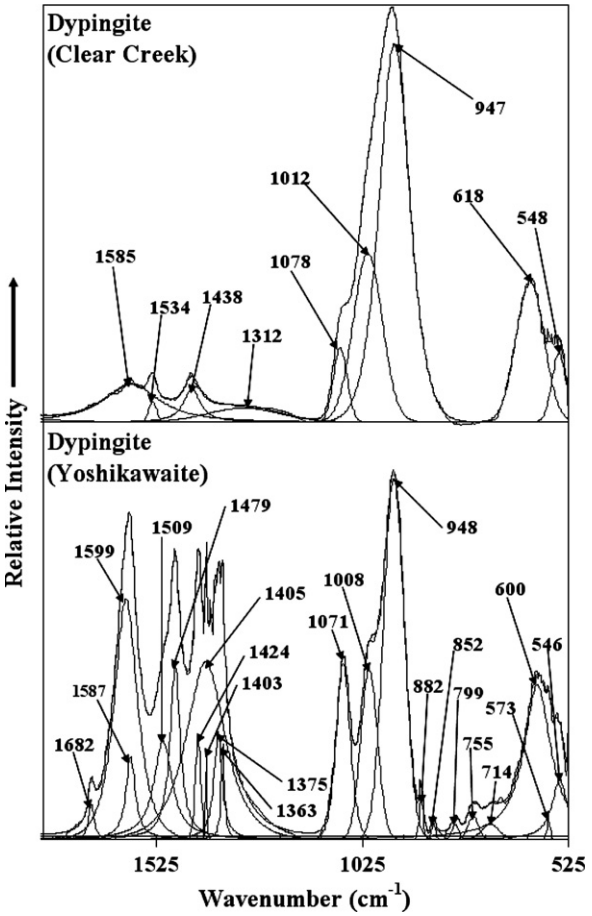

Fig. 3. The infrared spectra of dypingite in the 525–1625 cm^{-1} region.

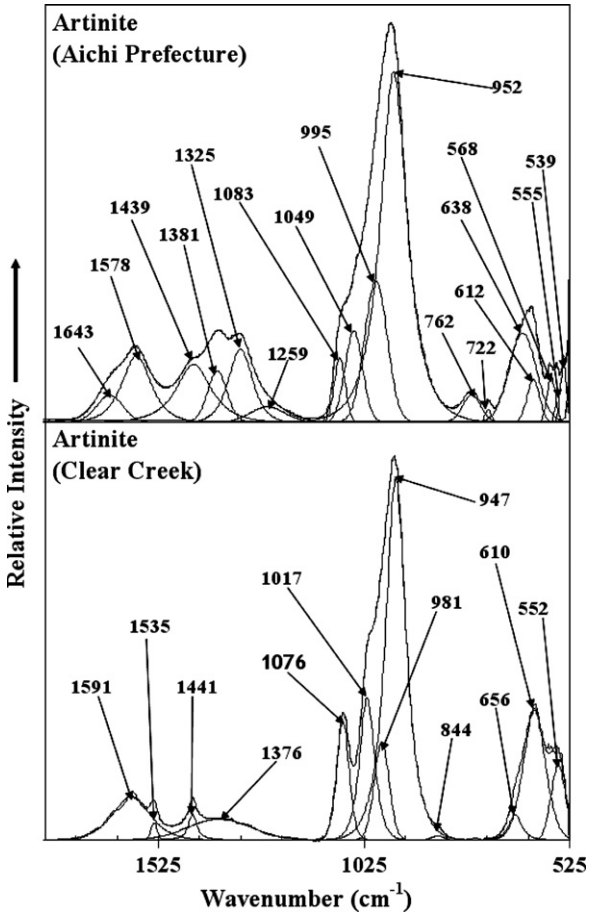

Fig. 4. The infrared spectra of artinite in the 525–1625 cm^{-1} region.

fundamental overtone of the OH stretching vibrations and also includes electronic bands resulting from transition metal ions in the structure [43–51].

The NIR spectra in the 5500–8000 cm^{-1} region of dypingite and artinite are shown in Figs. 5 and 6. The results of the NIR spectral analysis are reported in Table 2. The distinct feature of the NIR spectra of dypingite is the very sharp bands in this spectral region. For the Clear Creek dypingite a sharp intense band at 7127 cm^{-1} is observed with other lower intensity bands at 6914 and 7200 cm^{-1}. The NIR spectrum of the Yoshikawaite dypingite shows more complexity with bands at 7128, 7179, 7210 and 7237 cm^{-1}. These bands are attributed to the first fundamental overtone of the OH stretching vibrations. Similar spectra are observed for the artinite mineral samples. The Aichi artinite shows three sharp bands at 7166, 7207 and 7234 cm^{-1}. Lower intensity bands are observed at 7060, 7355 and 7760 cm^{-1}. The NIR spectrum of the Clear Creek dypingite shows broader bands with peaks at 6991, 7098, 7192 cm^{-1}. The sharp bands are the first fundamental overtone of the OH stretching bands (i.e. $2\nu_1$). It must be remembered that there are no selection rules for the NIR spectra and fundamentally all combinations of the OH stretching vibrations are allowed, i.e. Raman bands and infrared bands can combine as well as the doubling of the wavenumbers of the bands. It is probable the bands in this spectral region result from the addition or subtraction of the OH deformation mode and the doubling of the first overtone of the OH stretching vibration (i.e. $2\nu_1 \pm \delta\nu$).

The NIR spectra in the 4000–5500 cm^{-1} region for dypingite are shown in Fig. 7 and for artinite in Fig. 8. For the Clear Creek dypingite two bands are observed at 4987 and 5147 cm^{-1}; for the Yoshikawaite dypingite three bands are observed at 4732, 5052 and 5201 cm^{-1}. These bands are probably a combination of water and carbonate bands. Carbonate bands are normally found in this spectral region resulting from the doubling of the symmetric and antisymmetric carbonate stretching bands $2(\nu_1 + \nu_3)$. A number of bands are observed in the 4000–4500 cm^{-1} region. These may be simply described as combination bands resulting from combination of bands in the mid-IR spectral region. The spectrum in this spectral region of artinite shows similarity to that of dypingite; however the ratio of the intensity of the bands appears different. The Aichi artinite NIR spectrum displays bands at 4702, 4766, 5051 and 5212 cm^{-1}. The Clear Creek artinite NIR spectrum shows bands at 4747, 5035 and 5208 cm^{-1}.

For the Clear Creek dypingite, a number of bands are observed at 4109, 4233, 4300 and 4409 cm^{-1}; for the Yoshikawaite dypingite three bands are observed at 4103, 4179, 4300 and 4387 cm^{-1}. For the artinite mineral samples greater complexity in the 4000 to 4500 spectral region is observed. Prominent NIR bands are observed for the Clear Creek artinite are observed at 4300, 4386 and 4461 cm^{-1}; for Aichi artinite NIR bands are found at 4294, 4377 and 4461 cm^{-1}. Bands in this spectral region result from the combination of bands in the mid-IR spectral region.

The NIR spectra in the 8000–12000 cm^{-1} region of artinite and dypingite are shown in Figs. 9 and 10. There are two features in this spectral region that are noteworthy: firstly there are bands at around 10446 cm^{-1} for Clear Creek dypingite and 10536, 10611 and 10999 cm^{-1} for the Yoshikawaite dypingite; these bands are assigned to the second overtone of the OH stretching vibrations (i.e. $3\nu_1$ and $3\nu_3$). Secondly there is a broad feature centred upon

around 8598 and 10999 cm^{-1}. These bands are attributed to electronic bands of the ferrous ion. There is an important implication based upon this observation: namely that according to the formula no ferrous ion is in the structure dypingite $Mg_5(CO_3)_4(OH)_2 \cdot 5H_2O$ and artinite $Mg_2(CO_3)(OH)_2 \cdot 3H_2O$. The intensity of the bands suggests that a significant amount of Fe^{2+} has replaced some of the Mg^{2+} in the structure. The intensity of the bands for the Clear Creek dypingite is very low for the Fe^{2+} electronic band. The intensity is higher for the Yoshikawaite dypingite. Some replacement of the Mg^{2+} by Fe^{2+} is likely. Thus the formula is more likely to be $(Fe^{2+},Mg)_5(CO_3)_4(OH)_2 \cdot 5H_2O$. In other words the formula of artinite is more likely to be $(Fe^{2+},Mg)_2(CO_3)(OH)_2 \cdot 3H_2O$. Sharp bands for artinite are found at 10523 and 10604 cm^{-1} and are assigned to the second overtone of the OH stretching vibrations.

4. Conclusions

The concept of geosequestration involves the pumping of liquefied green house gases to significant depths below the surface of the earth. The high partial pressure of CO_2 is significant in that many different types of carbonates will be formed. Among these minerals there is the possibility of the formation of dypingite and artinite which are related at least in chemical formula to the hydrotalcite or layered double hydroxide minerals. A combination of infrared and near infrared spectroscopy has been used to characterise these two minerals and the bands related to the mineral structure. Importantly the observation of split broad bands in the 8000–12000 cm^{-1} region is evidence for the partial replacement of Mg^{2+} by Fe^{2+} in the mineral structure.

Crystal and molecular structure

ABSTRACT

The reactions of hexachloro-*cyclo*-triphosphazene $P_3N_3Cl_6$ (**1**) with 1-aminoadamantane (amantadine, Ad-NH_2) and 1-amino-3,5-dimethyladamantane (memantine, Mem) were studied. New geminally substituted phosphazene derivatives, $P_3N_3Cl_4$(NH-Ad)$_2$ (**2**), $P_3N_3Cl_2$(NH-Ad)$_4$ (**3**) and $P_3N_3Cl_2$(Mem)$_4$ (**4**), were prepared. The substances **3** and **4** were fully characterized by ^{31}P NMR and IR spectroscopies and elemental analysis. Molecular and crystal structures of **2**–**4** were determined by X-ray diffraction. The compounds are triclinic, space group $P\bar{1}$. Compound **3** crystallized from dichloromethane as a solvate.

1. Introduction

Phosphazenes, compounds having –P=N– group in their molecules, constitute one of the important class of compounds in the chemistry of phosphorus and nitrogen. First heterocyclic compounds of the composition $(PNCl_2)_3$ and $(PNCl_2)_4$ were isolated in the 1830s [1–3] from the reaction of PCl_5 with NH_4Cl. Since that time, a diverse class of phosphazene ring and linear species has been investigated [4–7]. Hexachloro-*cyclo*-triphosphazene, $P_3N_3Cl_6$, being easily prepared, is commonly used as a starting material for many substitutions [8].

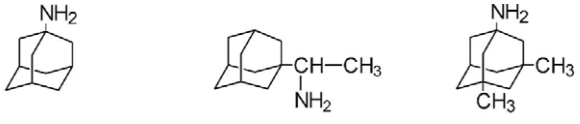
Within the context of biological and pharmacological properties of some amido- and aminophosphazenes, nucleophilic substitutions (ammonolysis and aminolysis) belong to the two main reaction types. In the course of these reactions, a lone electron pair of the reagent nitrogen atom attacks a phosphorus atom of the phosphazene cycle, and amido- or amino-*cyclo*-triphosphazene derivatives are formed under release of HCl [2,3].

The result of the reaction of phosphazene derivative with nucleophile reagent strongly depends on reaction conditions whereas a series of various substitution derivatives can be formed [5,9–14].

The interest in these reactions does not subside even at present. Many research groups focus their effort on the study and comparison of individual reactions, collecting all possible structural and chemical data of new compounds with the aim of their practical utilization [15–17]. However, only two articles dealing with reactions of $P_3N_3Cl_6$ with cycloalkylamino substituents have been published so far [18,19]. Allcock and co-workers [18] studied the reaction of $P_3N_3Cl_6$ with 1-aminoadamantane in molar ratio 1:12 (Scheme 1). Gem-*tetrakis*(adamantanamino)dichloro-*cyclo*-triphosphazene (**3**) (in major yield) and *hexakis*(adamantanamino)-*cyclo*-triphosphazene (**5**) were prepared in this reaction, but only crystal and molecular structures of **5** were determined.

Another paper summarized results of the study of reactions of $P_3N_3Cl_6$ with some cycloalkylamines [19] where geminal tetrakis derivatives $P_3N_3Cl_2(NHR)_4$, R = $-C_6H_{11}$, $-C_5H_9$, $-C_3H_5$ were identified as major products.

It is worth mentioning that some aminoadamantane derivatives themselves are used as pharmaceuticals, such as anti-virals, anti-diabetics, anti-parkinsonians, anti-tuberculosis, and analgesics. The most important pharmacologically effective representatives based on adamantane are 1-aminoadamantane (amantadine, Ad-NH_2) and *N*-ethylaminoadamantane (rimantadine, Rim) that were tested in the treatment of viral diseases [20,21]. Amantadine can also cause palliation of Parkinsonic symptoms. 1-Amino-3,5-dimethyladamantane (memantine, Mem) improves capillary blood return of the brain and can be used in the treatment of dementia [22].



amantadine (Ad-NH_2) rimantadine (Rim) memantine (Mem)

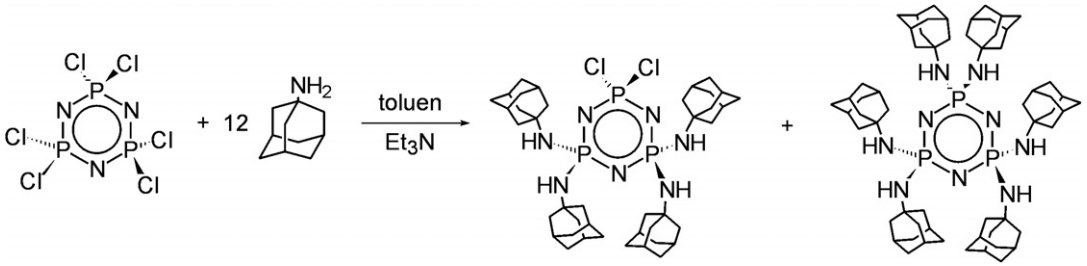


Scheme 1. Reaction of hexachloro-*cyclo*-triphosphazene with aminoadamantane (1:12) by Allcock [18].

Table 1
Amount of starting compounds and solvents used in the reactions

Synthesized compound	$P_3N_3Cl_6$ (g/mmol)	Aminoadamantane reagent (g/mmol)		Et_3N (g/mmol)	Solvent (cm^3)		Time of heating (h)
2	0.298/0.857	Ad-NH_2	1.037/6.856		diethyl ether	20	12
3	0.216/0.621	Ad-NH_2	1.127/7.452	0.754/7.452	toluene	24	48
4	0.216/0.621	Mem	1.336/7.452	0.754/7.452	toluene	24	48

We suppose that derivatives of chlorophosphazenes bearing aminoadamantane group could be very promising from the point of their biological activity and potential practical use. Therefore it is surprising that only one paper [18] deals with the reaction of chlorophosphazene with aminoadamantane derivative.

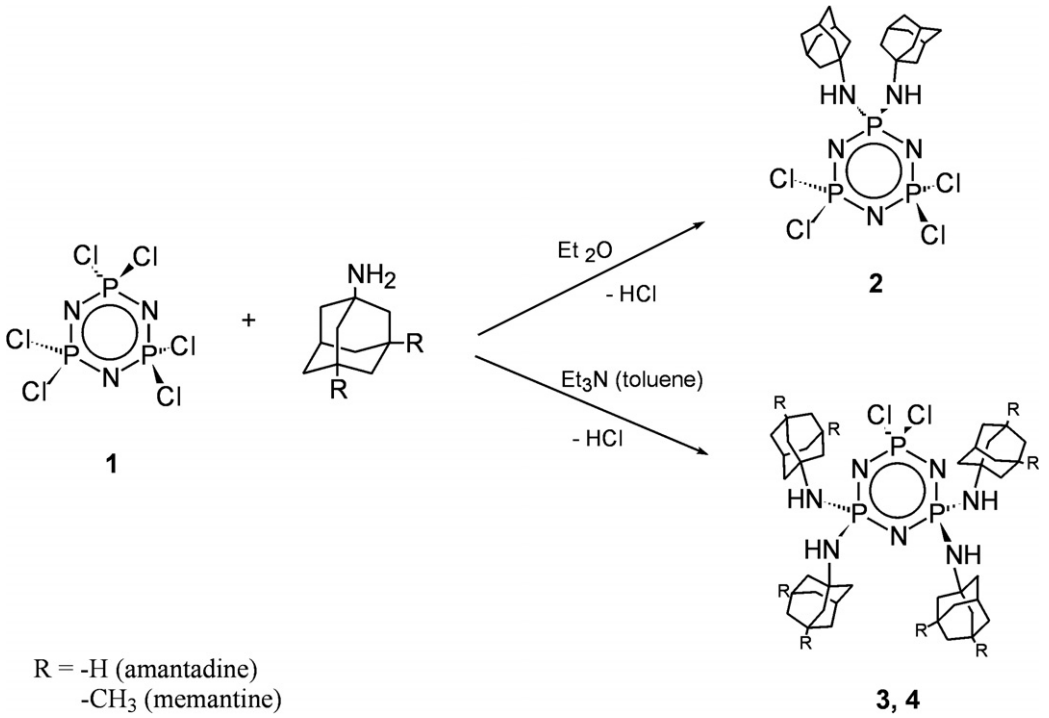
Results of our investigations of the course of reactions of hexachloro-*cyclo*-triphosphazene with amantadine and memantine are summarized in this article.

2. Experimental

2.1. Reagents and general procedures

All procedures, syntheses and sample preparations were performed using Schlenk technique under dry nitrogen atmosphere. Solvents, such as toluene, dichloromethane, diethyl ether, and *n*-hexane (all Aldrich, p.a.) were purified and dried according to procedures described by Perrin and Armarego [23]. Pure hexachloro-*cyclo*-triphosphazene (**1**) (BASF) was obtained from its mixture with octachloro-*cyclo*-tetraphosphazene by crystallization from *n*-hexane and subsequent sublimation in vacuum at 60 °C. The purity of **1** was proved by MS spectrometry and ^{31}P NMR spectroscopy.

Amantadine (Ad-NH_2) and memantine (Mem) were prepared from the corresponding hydrochlorides (Aldrich, p.a.) by neutralization with 1.5-fold excess of KOH. This procedure was carried out in a separatory funnel and "free" amantadine and memantine were extracted with three portions of dichloromethane. The organic phases were combined, dried with anhydrous $MgSO_4$, and amantadine and memantine were obtained from the filtrate by evaporation of the solvent. Their purity was proved by IR and Raman spectroscopies.



Scheme 2. Reaction of **1** with aminoadamantanes; R = –H (amantadine) or $–CH_3$ (memantine).

Triethylamine (Et_3N) was purified according to [23] and distilled before use.

2.2. Instrumentation

^{31}P NMR spectra were recorded on a 500 MHz Bruker DRX AVANCE spectrometer and were referenced to 85% H_3PO_4 (external standard). The samples were sealed in Simax® tubes (diameter 4 mm) and inserted in original Wilmad® NMR cuvettes (diameter 5 mm), the space between the two cuvettes was filled with D_2O (external lock), and samples were measured in the coaxial NMR cuvette system.

Mass spectra were measured using the MAT Trio 1000, Series II, Finnigan, excitation energy 70 eV, connected to a gas chromatograph GC 8000 with DB-5 column. The sample (1–2 μl) in a suitable solvent was injected onto the column, the temperature of the heated zone was 50–280 °C, and the heating rate 10 °C min^{-1}. Nitrogen was used as carrier-gas.

IR spectra were measured by a Bruker IFS 28 spectrometer either in KBr disks containing 1.0–1.7 mg of the sample and 100 mg KBr. Raman spectra of solid samples were measured in Raman capillaries using a Bruker IFS 55 Equinox apparatus, equipped with a FRA 106/S adapter, (Nd:YAG laser, λ = 064 nm, W = 150–400 mW).

Elemental analyses (C, H and N) were performed on a Fisons Instruments EA-1108 elemental analyzer.

Diffraction data were collected using the KUMA KM-4 κ-axis diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71069 Å) equipped with a CCD detector. All structures were solved by direct methods, and refined by full-matrix least-squares methods using anisotropic thermal parameters for the non-hydrogen atoms. The software XCALIBUR CCD system [24] was used for data collection/reduction and the SHEXTL software [25] was used for the structure solution, refinement, and drawing preparation. Thermal ellipsoids are drawn at the 50% probability level.

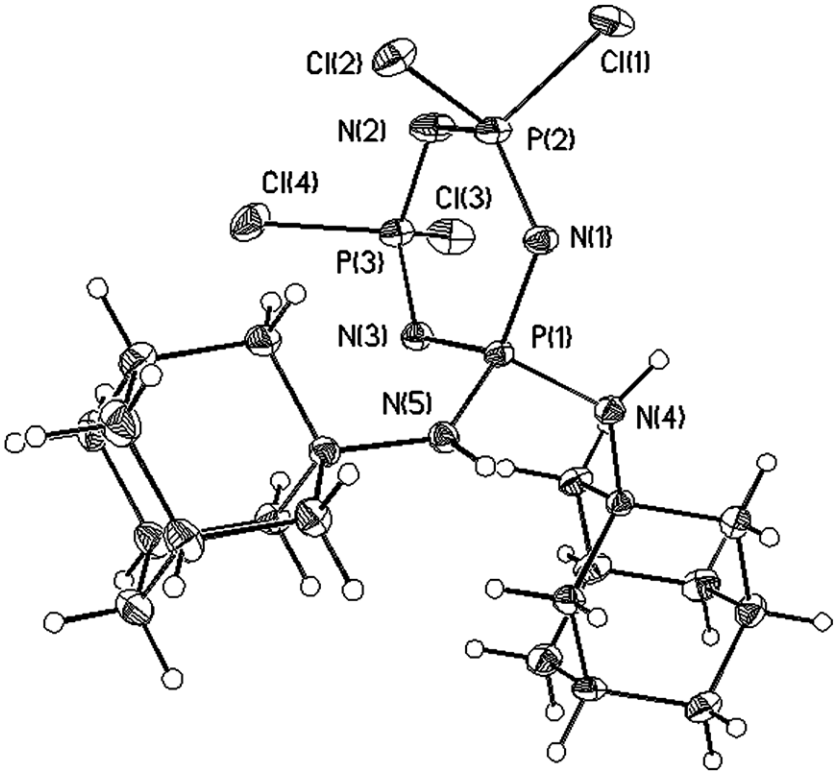

Fig. 1. The ORTEP drawing of **2**. The thermal ellipsoids of non-hydrogen atoms are drawn at 50% probability level.

Crystals of **2** for X-ray determination were obtained directly from the reaction mixture. Single crystals of **3** and **4** were grown from concentrated dichloromethane solutions at room temperature over few days.

2.3. Synthesis

The reaction of $P_3N_3Cl_6$ (**1**) with aminoadamantanes was carried out simply by mixing the solutions of **1** and aminoadamantane derivatives under permanent stirring in the corresponding molar ratios (see Table 1). The excess of Ad-NH_2 (for compound **2**) or triethylamine (for **3** and **4**) played the role of HCl acceptor. The reaction mixture was placed in a tube and heated on oil bath for several hours. The temperature of the bath depended on the boiling point of the solvent. After cooling, the amine hydrochloride was filtered off. Reaction products were obtained after partial (**2**) or complete (**3** and **4**) evaporation of the solvent. Compound **2** was isolated in the crystalline form, while **3** and **4** were obtained as white solid powders and were purified by recrystallization from toluene.

2.3.1. $P_3N_3Cl_4(NH\text{-}Ad)_2$ (**2**)

The yield of **2** was very small, only few crystals were isolated that were used for X-ray study. M.p.: ≫300 °C. $^{31}P\{^1H\}$ NMR (CH_2Cl_2): δ = 19.0 ppm (d), 1.7 ppm (t), $^2J_{P-N-P}$ = 45.6 Hz.

2.3.2. $P_3N_3Cl_2(NH\text{-}Ad)_4$ (**3**)

Yield: 0.355 g (63% with respect to **1**). M.p.: ≫300 °C. $^{31}P\{^1H\}$ NMR (CH_2Cl_2): δ = 20.0 ppm (t), 4.1 ppm (d), $^2J_{P-N-P}$ = 51.5 Hz. *Anal.* Calc. for $P_3N_3Cl_2(NH\text{-}Ad)_4$: C, 59.54; H, 8.00; N, 12.16. 3. Results and discussion

The formation of compounds **2**–**4** in the course of reaction between **1** and aminoadamantane derivatives is described in Scheme 2.

The $^{31}P\{^1H\}$ NMR spectra of **2**–**4** are very simple. They consist of the characteristic system of multiplets (doublet and triplet, AX_2 spin system) [18,19,26] which corresponds to the suggested structures of geminally substituted derivatives (see Table 2).

The attempt to assign some bands in IR spectra of **3** and **4** was done [27–30]. The absorption bands in region 3200–3400 cm^{-1} can be ascribed to the valence vibrations of N–H groups. Valence vibrations (υ_{as} and υ_s) of CH_x groups (x = 1–3) were found between 2849 and 2932 cm^{-1} for **3** and 2840 and 2944 cm^{-1} for **4**. Bands of deformation vibrations δ_{as} of CH_x groups (x = 1–3) occurs in region 1308–1453 cm^{-1} for **3**, between 1332 and 1455 cm^{-1} for compound **4**, respectively. Signals between 1221 and 1285 cm^{-1} (for **3**) and 1230 and 1248 cm^{-1} (for **4**) correspond to valence vibrations of "endocyclic" P–N bonds or deformation vibrations δ_s of CH_3 groups. Valence vibrations υ_s, υ_{as}, of exocylic P–N bonds, possi-

[1] In this case the lower carbon content was found. According to our experience, very stable phosphorus nitrides are formed during combustion of chlorophosphazene samples and carbon is partially absorbed in these nitrides. Therefore carbon cannot be completely determined.

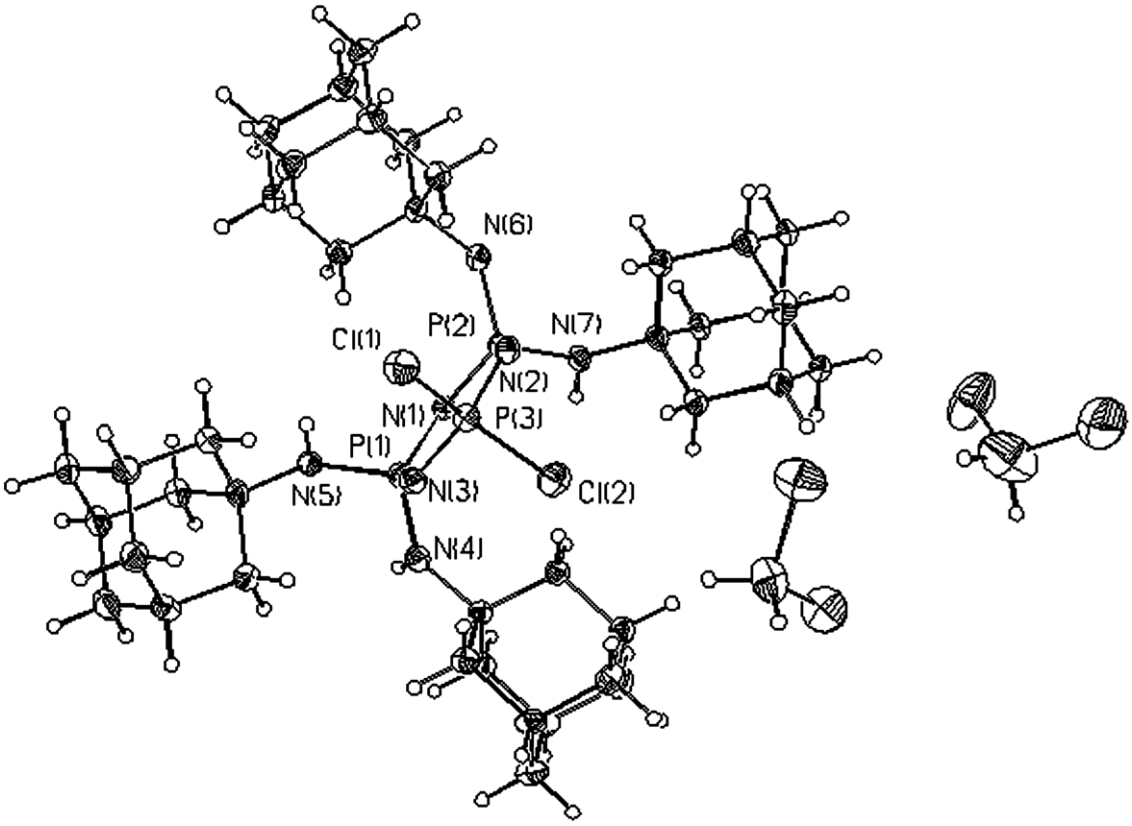

Fig. 2. The ORTEP drawing of **3**. The thermal ellipsoids of non-hydrogen atoms are drawn at 50% probability level.

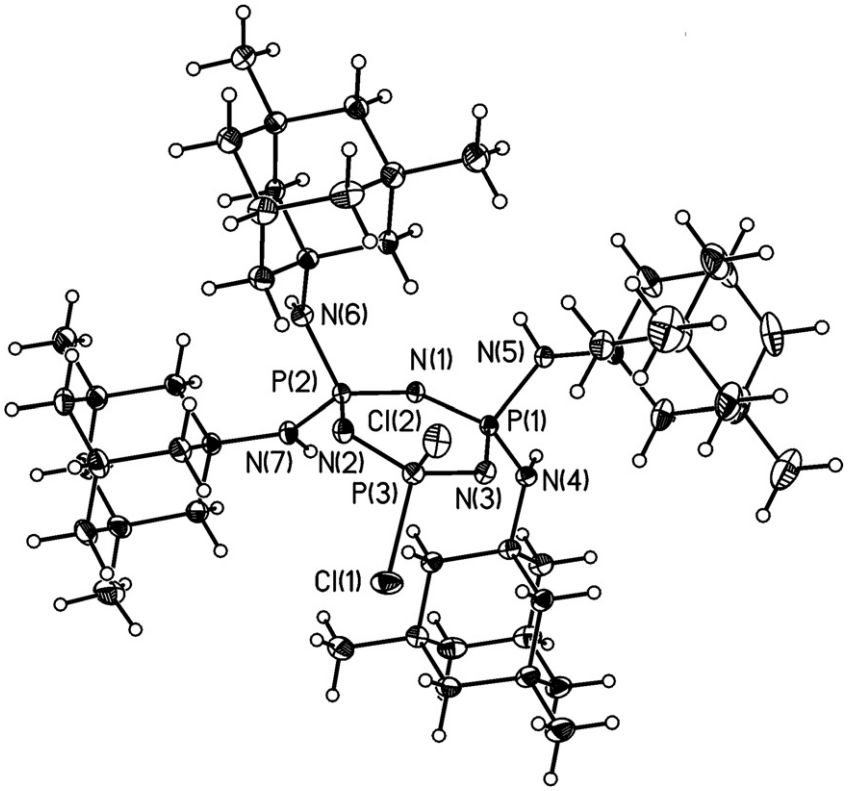

Fig. 3. The ORTEP drawing of **4**. The thermal ellipsoids of non-hydrogen atoms are drawn at 50% probability level.

Table 5
Hydrogen bonding parameters (Å, °) for compounds **2** and **4**

D–H	d(D–H)	d(H···A)	∠DHA	d(D···A)	A
Compound **2**					
N5–H11	0.652	2.604	171.55	3.251	N1 [$-x+2, -y+1, -z+1$]
Compound **4**					
N4–H1	0.810	2.501	170.37	3.302	N2 [$-x+1, -y+2, -z$]

Hydrogen bonds with H···A < r(A) + 2.000 Å and ∠DHA > 110°.

bly also υ_{as} P–N–C vibrations, were observed at wavenumbers 1124–1192 cm^{-1} for **3** and 1142–1198 for **4**. The bands of valence vibrations at 549 cm^{-1} for **3** and 551 cm^{-1} for **4** in spectrum correspond to υ_{as} vibrations of P–Cl groups.

Molecular and crystal structures of **2**–**4** were determined by using X-ray diffraction. The basic crystallographic data are given in Table 3 and selected bond lengths and angles in Table 4.

X-ray determinations proved that all three compounds are triclinic, space group $P\bar{1}$, compound **3** crystallized with two molecules of dichloromethane (Figs. 1–3).

The asymmetric unit of **2**–**4** consists of one symmetric independent molecule. All molecules lie on the common position.

Comparison of molecules **2**–**4** with **1** [31] shows a significant elongation of P–Cl bonds (2.010–2.045 in **2**–**4** to 1.985 Å in **1**) while the length of P–N(H) bond is very similar to other aminophosphazenes (1.621–1.657 Å) [19,32,33]. The substitution of chlorine atoms led to changes in P[N(H)]–N bond lengths of the phosphazene ring (1.598–1.620) when compared with other P(Cl)–N bonds (1.559–1.575 Å).

Crystal structures of **2** and **4** show relevant short contacts. Two molecules of **2** and **4** are bonded together by two N–H···N hydrogen bonds (see Table 5), while **3** contains no H-bridges probably due to the solvation effect of dichloromethane.

The six-membered phosphazene ring in **2** is not strictly planar. All N atoms are slightly distorted from the P1, P2, P3 plane (0.10–0.21 Å). Phosphazene rings of **3** and **4** are situated in a plane and distortions of N atoms are very small. The angles between the phosphazene ring (def. P1, P2, P3 plane) and the planes formed by PCl_2 or $P(NH)_2$, respectively, are in the range of 84.18–89.99°.

ABSTRACT

A long, flexible bipyridyltype linking ligand **L** [(4py)–CH_2–NH–$(CH_3)C_6H_3$–$C_6H_3(CH_3)$–NH–CH_2–(4-py)], which possesses two terminal 4-pyridyl groups, was prepared by reducing its parent diimine ligand (4-py)–CH=N–$(CH_3)C_6H_3$–$C_6H_3(CH_3)$–N=CH–(4-py). Four novel polymeric species based on **L**, $[Co(\mathbf{L})(NO_3)_2]$ (**1**), $[Zn(\mathbf{L})(NO_3)_2]$ (**2**), $[CdL_2(NO_3)_2]$ (**3**) and $[CdL_2(NO_3)_2](C_6H_6)_2$ (**4**), could be synthesized under solvothermal conditions. Whereas polymers **1** and **2** have a 1D zigzag-chain structure, polymers **3** and **4** have a 2D network structure. The N···N separation between the two pyridyl groups in **L** (the free ligand) is 19.871(3) Å, whereas this distance varies from 11.934(4) to 16.373(8) Å in its coordination polymers.

1. Introduction

Construction of coordination polymers, also called metal–organic frameworks, by combining appropriate linking ligands and transition metals is currently under intensive study due to their desirable properties applicable to magnetism, photoluminescence, catalytic properties and gas storage [1–6]. Relatively short bipyridyl-type ligands have been used extensively in preparing various metal–organic networks [7–10] as well as pure organic networks [11]. Very long linking ligands containing terminal pyridyls, however, were recently employed in preparing coordination polymers with various topologies [12–19]. We also prepared several long bipyridyl-type ligands $\mathbf{L}^1$–$\mathbf{L}^6$ (Chart 1) and their coordination polymers [20–25].

In controlling the network topologies of coordination polymers, several experimental parameters are known, including the size or polarity of the counterion [26–28], the length of the spacer [29], the pH value of the reaction solution [30], and the nature of the solvents used [31]. Furthermore, it is also known that ligands containing a flexible backbone provide conformational freedom to create greater structural diversity [31,32]. Among the ligands $\mathbf{L}^1$–$\mathbf{L}^6$, ligands $\mathbf{L}^5$ and $\mathbf{L}^6$ turned out to be flexible due to the ring flip of the intervening cyclohexyl fragment in these ligands [24]. On the other hand, ligands $\mathbf{L}^1$–$\mathbf{L}^4$ are structurally rigid because of the presence of the diimine fragments (–CH=N–) in their backbones, that is, a complete conjugated π system. Considering our previous works related to ligands $\mathbf{L}^1$–$\mathbf{L}^6$, we decided to reduce this type of ligands to enhance their structural flexibility that would lead to the creation of novel coordination polymers, which cannot be obtained from their parent diimine ligands. With this aim in mind, we reduced the diimine ligand **L′** [(4-py)–CH=N–$(CH_3)C_6H_3$–$(CH_3)C_6H_3$–N=CH–(4-py)] with sodium borohydride to produce the corresponding flexible ligand **L** [(4-py)–CH_2–NH–$(CH_3)C_6H_3$–$(CH_3)C_6H_3$–NH–CH_2–(4-py)], in which free rotations about the Ar–NH, NH–CH_2 and CH_2–(4-py) bonds may be possible. Herein we report the preparation of this flexible ligand (**L**) and its coordination polymers, $[Co(\mathbf{L})(NO_3)_2]$ (**1**), $[Zn(\mathbf{L})(NO_3)_2]$ (**2**), $[CdL_2(NO_3)_2]$ (**3**) and $[CdL_2(NO_3)_2](C_6H_6)_2$ (**4**).

2. Experimental

All the solid chemicals were purified by recrystallization, and all solvents were distilled and stored over molecular sieves. Infrared (IR) samples were prepared as KBr pellets, and their spectra were obtained in the range 400–4000 cm^{-1} on a Nicolet 320 FTIR spectrophotometer. Elemental analyses were performed with EA1110 (CE instrument, Italy) at the Korea Basic Science Institute. Thermogravimetric analysis (TGA) was conducted on a TA4000/SDT 2960 instrument at the Cooperative Center for Research Facilities (CCRF) in Sungkyunkwan University. ^1H and $^{13}C\{^1H\}$ NMR data were collected on a 500 MHz Varian Inova spectrometer.

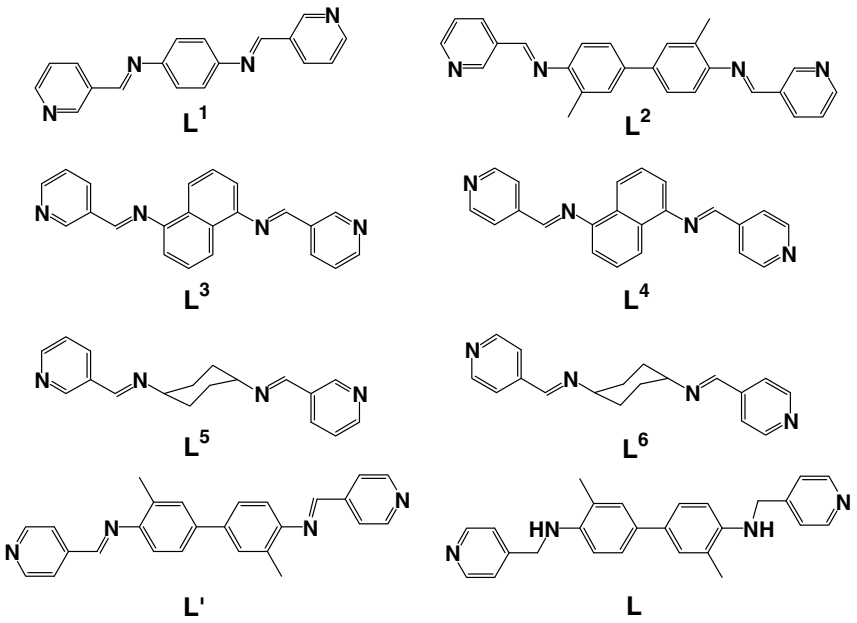

Chart 1.

2.1. Preparation of [(4-py)–CH=N–$(CH_3)C_6H_3$–$C_6H_3(CH_3)$–N=CH–(4-py)] (**L′**)

To 4-pyridine carboxaldehyde (6.30 ml, 66.8 mmol) in methanol (200 ml) was added *o*-tolidine dihydrochloride hydrate {[–$C_6H_3(CH_3)$-4-$NH_2]_2 \cdot 2HCl \cdot H_2O$, 9.52 g, 33.4 mmol)} at room temperature. After the addition of dichlomethane (400 ml) and then several drops of formic acid, the mixture was stirred at room temperature for 24 h. The solvent was removed under vacuum, and the residue was extracted with dichloromethane (500 ml), and washed with a saturated Na_2CO_3 solution (500 ml) and then with water (500 ml × 2). The organic phase was dried over $MgSO_4$ and filtered. Upon removal of the solvent, an analytically pure yellow crystalline solid was obtained in 86% yield. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 8.77 (m, 4H), 8.46 (m, 2H), 7.80 (m, 2H), 7.54–7.32 (m, 4H), 7.07 (m, 2H), 2.49 (s, 6H). $^{13}C\{^1H\}$ NMR (125 MHz, $CDCl_3$) δ: 157.0, 150.8, 149.2, 143.2, 139.3, 133.5, 129.3, 125.5, 122.5, 118.0, 18.7. IR (KBr, cm^{-1}): 1622 (s), 1595 (s), 1546 (w), 1484 (w), 1414 (w), 1322 (w), 1220 (w), 1124 (s), 1059 (s), 989 (s), 822 (s), 645 (s), 556 (s), 518 (s), 486 (s). *Anal.* Calc. for $C_{26}H_{22}N_4$: C, 78.97; H, 5.68; N, 14.35. Found: C, 78.94; H, 6.07; N, 14.82%.

2.2. Preparation of [(4-py)–CH_2–NH–$(CH_3)C_6H_3$–$C_6H_3(CH_3)$–NH–CH_2–(4-py)] (**L**)

To compound **L′** (7.0 g, 17.9 mmol) in methanol (200 ml) and dichlomethane (300 ml) was added sodium borohydride (6.78 g, 179 mmol) in small portions with stirring at room temperature. The resulting mixture was stirred at room temperature for 12 h. The solvent was removed under vacuum, and the residue was extracted with dichloromethane (300 ml), and washed with water (300 ml × 3). The organic phase was dried over $MgSO_4$ and filtered, and upon removal of the solvent, an analytically pure yellow crystalline solid was obtained (6.22 g, 15.8 mmol, 88% yield). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 8.58 (m, 4H), 7.34–7.21 (m, 10H), 6.47 (dd, 2H), 4.47 (s, 4H), 4.07 (br s, 2H), 2.28 (s, 6H). ^{13}C NMR (125 MHz, $CDCl_3$)δ: 150.2, 149.4, 144.2, 131.3, 128.8, 125.3, 122.6, 122.3, 110.7, 47.4, 18.0. IR (KBr, cm^{-1}): 3322 (w), 1603 (s), 1503 (s), 1470 (w), 1440 (w), 1414 (w), 1308 (s), 1254 (s), 1140 (w), 1065 (w), 992 (w), 804 (w). *Anal.* Calc. for $C_{26}H_{26}N_4$: C, 79.16; H, 6.64; N, 14.20. Found: C, 79.30; H, 6.62; N, 14.70%.

2.3. Preparation of [$Co(L)(NO_3)_2$] (**1**)

A mixture of $Co(NO_3)_2 \cdot 6H_2O$ (29.7 mg, 0.10 mmol), ligand **L** (39.4 mg, 0.1 mmol), methanol (10 ml) and benzene (3 ml) was heated in a vial at 70 °C for 3 days and then cooled to room temperature by air-cooling. The crystalline product was collected by filtration, washed with methanol, and air-dried to give violet crystals of polymer **1** (25 mg, 0.043 mmol, 43%). IR (KBr, cm^{-1}): 3427 (w), 1618 (s), 1502 (s), 1429 (w), 1382 (w), 1292 (s), 1261 (s), 1145 (w), 1018 (w), 806 (w). *Anal.* Calc. for $C_{26}H_{26}CoN_6O_6$: C, 54.18; H, 4.54; N, 14.55. Found: C, 54.06; H, 4.58; N, 14.18%.

2.4. Preparation of [$Zn(L)(NO_3)_2$] (**2**)

Polymer **2** was prepared similarly to polymer **1**. A mixture of $Zn(NO_3)_2 \cdot 6H_2O$ (29.7 mg, 0.10 mmol), ligand **L** (39.4 mg, 0.10 mmol), methanol (10 ml) and benzene (5 ml) was heated at 70 °C for 10 days. Yield: 5.1%. IR (KBr, cm^{-1}): 3426 (w), 1622 (s), 1505 (s), 1494 (s), 1432 (s), 1383 (s), 1305 (s), 1263 (s), 1146 (w), 1063 (w), 1031 (w), 805 (w). *Anal.* Calc. for $C_{26}H_{26}ZnN_6O_6$: C, 53.48; H, 4.49; N, 14.39. Found: C, 53.31; H, 4.70; N, 14.60%.

2.5. Preparation of [$CdL_2(NO_3)_2$] (**3**)

A mixture of $Cd(NO_3)_2 \cdot 4H_2O$ (30.0 mg, 0.10 mmol), ligand **L** (39.0 mg, 0.10 mmol) and methanol (10 ml) was heated in a vial at 70 °C for 3 days and then cooled to room temperature by air-cooling. The crystalline product was collected by filtration, washed with methanol, and air-dried to give yellow crystals of polymer **3** (25 mg, 0.0244 mmol, 49%). IR (KBr, cm^{-1}): 3434 (w), 3408 (w), 1611 (s), 1584 (w), 1506 (s), 1425 (s), 1383 (s), 1309 (s), 1268 (s), 1145 (w), 1102 (w), 1013 (w), 876 (w), 823 (w), 801 (w). *Anal.* Calc. for $C_{52}H_{52}CdN_{10}O_6$: C, 60.91; H, 5.11; N, 13.66. Found: C, 60.12; H, 4.98; N, 14.01%.

2.7. X-ray structure determination

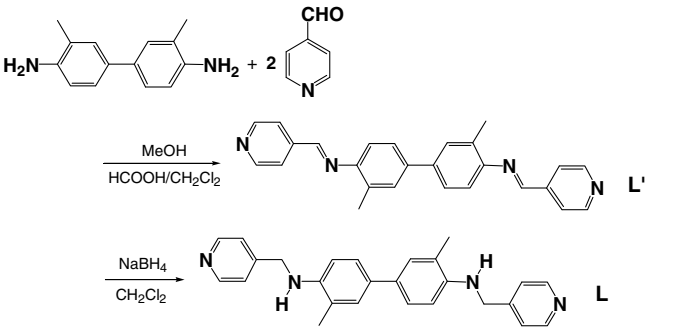
All X-ray data were collected with a Siemans P4 diffractometer (**1**, **2** and **4**) or a Bruker Smart APEX2 diffractometer (**L** and **3**) equipped with a Mo X-ray tube. No absorption corrections were made for the ligand **L**, but intensity data were empirically corrected for absorption with ψ-scan data (**1**, **2**, **4**) or SADABS (**3**) [33]. All calculations were carried out with SHELXTL programs [34]. All structures were solved by direct methods. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were generated in idealized positions and refined using the riding model.

A colorless crystal of **L** of approximate dimensions 0.18 × 0.12 × 0.10 mm^3, shaped as a block, was used for crystal and intensity data collection. A violet crystal of **1** (a block, 0.36 × 0.28 × 0.10 mm^3), a yellow crystal of **2** (a block, 0.26 × 0.24 × 0.06 mm^3), a yellow crystal of **3** (0.22 × 0.12 × 0.04 mm^3) and a yellow crystal of **4** (a block, 0.42 × 0.12 × 0.10 mm^3) were used. Details of the crystal data, intensity collection and refinement details are given in Table 1. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

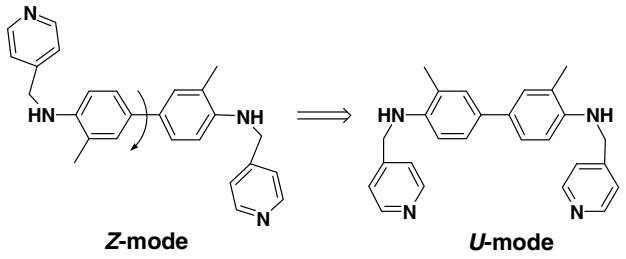
3.1. Synthesis

A long, flexible bis(monodentate) linking ligand $C_{26}H_{26}N_4$ (**L**), which possesses two terminal pyridyl groups with their nitrogen atoms in the 4,4′-positions, was prepared in two steps on a relatively large scale (Eq. (1)). In the first step, the diimine species [(4-py)–CH=N–$(CH_3)C_6H_3$–$C_6H_3(CH_3)$–N=CH–(4-py)] (**L′**), a positional isomer of the ligand **L**[2] (Chart 1), was prepared in 86% yield by the condensation of a diamine (*o*-tolidine dihydrochloride hydrate) and a pyridinealdehyde (4-pyridine carboxaldehyde) at room temperature. In the second step, **L′** was reduced with sodium borohydride to give [(4-py)–CH_2–NH–$(CH_3)C_6H_3$–$C_6H_3(CH_3)$–NH–CH_2–(4-py)] (**L**) in 88% yield.



(1)

Because of the possible rotations about the Ar–NH, NH–CH_2 and CH_2–(4-py) single bonds, the ligand **L** is expected to be considerably more flexible than $\mathbf{L}^1$–$\mathbf{L}^4$ [20–23]. However, X-ray structural analysis of ligand **L** and its coordination polymers **1**–**4** revealed that this ligand exhibits only two out of several possible conformations, in which the two terminal 4-pyridyl groups (or two central methyl groups) are located on either the opposite (*Z*-mode) or the same (*U*-mode) side of the central biphenyl fragment [35]. The *Z*-mode conformer can be transformed to the *U*-mode one by rotation about the central C–C bond, and vice versa.



Solvothermal treatment of cobalt(II) nitrate and zinc(II) nitrate with the ligand **L** in methanol–benzene at 70 °C produced a 1D cobalt $[Co(\mathbf{L})(NO_3)_2]$ (**1**) and a 1D zinc coordination polymer $[Zn(\mathbf{L})(NO_3)_2]$ (**2**), respectively (Eqs. 2 and 3). In addition, a 2D grid cadmium polymer $[Cd\mathbf{L}_2(NO_3)_2]$ (**3**) was prepared from cadmium(II) nitrate and the ligand **L** in methanol at 70 °C (Eq. (4)). Interestingly, when the last reaction was carried out in a mixed solvent (methanol–benzene), a guest-containing cadmium polymer, $[Cd\mathbf{L}_2(NO_3]_2](C_6H_6)_2$ (**4**), was prepared (Eq. (5)).

$$Co(NO_3)_2 + \mathbf{L} \xrightarrow{MeOH/C_6H_6} [Co(\mathbf{L})(NO_3)_2]\ (\mathbf{1}) \quad (2)$$

$$Zn(NO_3)_2 + \mathbf{L} \xrightarrow{MeOH/C_6H_6} [Zn(\mathbf{L})(NO_3)_2]\ (\mathbf{2}) \quad (3)$$

$$Cd(NO_3)_2 + \mathbf{L} \xrightarrow{MeOH} [Cd\mathbf{L}_2(NO_3)_2]\ (\mathbf{3}) \quad (4)$$

$$Cd(NO_3)_2 + \mathbf{L} \xrightarrow{MeOH/C_6H_6} [Cd\mathbf{L}_2(NO_3)_2](C_6H_6)\ (\mathbf{4}) \quad (5)$$

It would be meaningful to consider the preparation of polymers **1** and **2**. Our initial goal was to prepare coordination polymers that contained guest (benzene) molecules, which might be able to act as a template to enhance the dimensionality of the target polymers. Inconsistent with our expectation, reactions only in methanol did not produce suitable crystals for X-ray diffraction. Only the reactions in the presence of benzene led to the formation of single crystalline products, which do not contain the benzene molecules. Although we do not know the exact function of benzene in our reaction system, benzene appears to have promoted the formation of good crystals. Similar observations were previously reported in the preparation of $[Cu_3(C_6H_8O_4)_3(H_2O)_2(C_6H_{11}OH)]$ [36], $[M_3(2,6\text{-}NDC)_3(bipy)_{1.5}]$ (M = Ni, Co; 2,6-NDC = 2,6-naphthalenedicarboxylate; bipy = 4,4′-bipyridyl) [37] and $[Cu(1,3\text{-}BDC)(H_2O)]\cdot 2H_2O$ (1,3-BDC = 1,3-benzenedicarboxylate) [38].

3.2. Structure

The molecular structure of **L**, with the atom-numbering scheme, is shown in Fig. 1, in which two terminal pyridyl groups are linked by a diamide moiety (–CH_2–NH–$(CH_3)C_6H_3$–$(CH_3)C_6H_3$–NH–CH_2–) and have their pyridyl nitrogen atoms at the *para* positions (4,4′). Ligand **L** has a *Z*-conformation, in which two methyl substituents are directed to opposite directions (*anti* orientation). The N···N separation between the two terminal pyridyl rings is 19.871(3) Å, and these rings are essentially parallel to each other with a dihedral angle of 3.7(2)°. The two phenyl rings in the central biphenyl fragment are significantly twisted from each other by 39.17(6)°. The N2–C6 (1.438(3) Å) and N3–C21 (1.425(3) Å) bond lengths indicate N–C single bonds.

A monomer unit of polymer **1** is shown in Fig. 2, which shows that the Co(II) metal is 6-coordinate and its coordination sphere consists of two pyridyl nitrogens and four η^2-nitrato oxygen atoms. The Co metal lies on the crystallographic C_2-axis, which explains the *Z* value of **4** rather than **8** (Table 1). The N–H hydrogen is involved in intermolecular N–H···O hydrogen bonding: N2–H2 = 0.73 Å; N2···O1 ($-x$, $y+1$, $-z+1/2$) = 2.66 Å; N2–H2···O1 = 136°. The projection of polymer **1** along the *b*-axis demonstrates its one-dimensional zigzag structure (Fig. 3). This chain is formed by the bridging **L** ligands linking Co metals in the [1 0 1] direction, with a N···N separation of 16.112(6) Å and a Co···Co separation of 19.275(4) Å. The **L** ligands adopt the *Z*-conformation, which is quite similar to that found in the molecular ladder prepared from $Cd(NO_3)_2$ and 1,4-bis(4-pyridylmethyl)benzene in a 2:3 molar ratio [39].

Polymer **2** is isostructural with polymer **1**, and its monomer unit and projection along the *b*-axis are presented in Figs. 4 and 5, respectively. The Zn metal lies on the crystallographic C_2-axis, and the nitrato ligand η^2-coordinates in an asymmetric mode (Zn1–O1 = 2.039(7) Å; Zn1–O3 = 2.492(9) Å). The N···N separation in the one-dimensional zigzag chain is 16.083(11) Å, and the Zn···Zn separation is 19.302(4) Å.

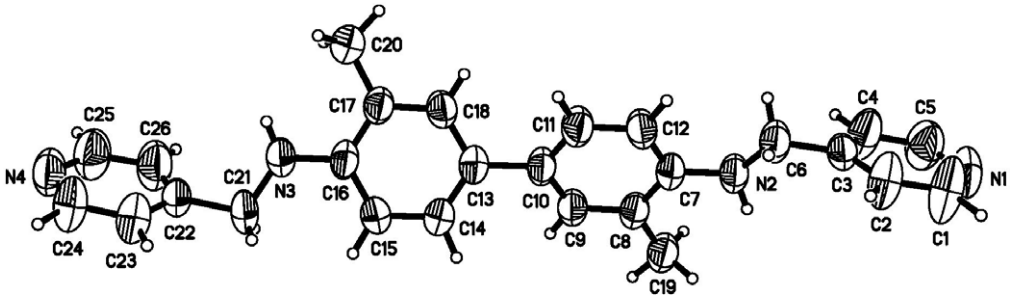


Fig. 1. ORTEP drawing of ligand **L** with 50% probability thermal ellipsoids.

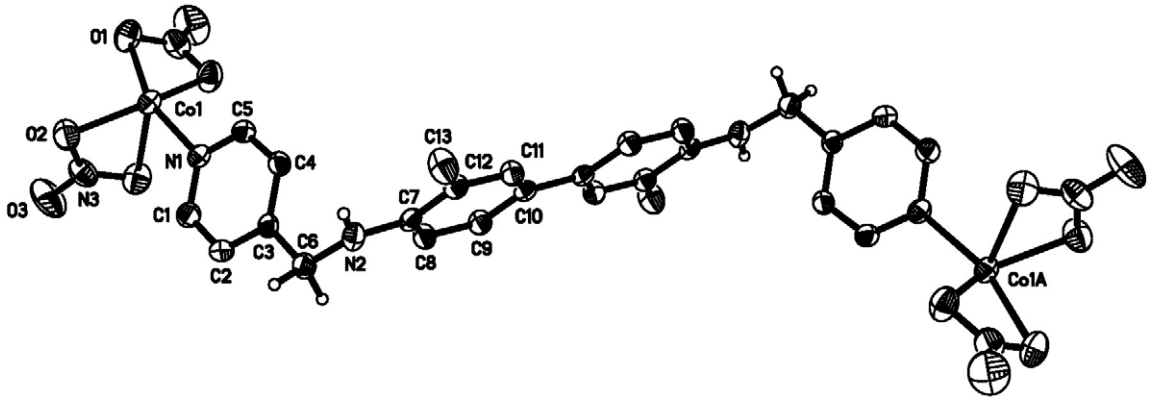

Fig. 2. Local coordination environment around the cobalt atom in polymer **1**. Unlabelled atoms are related to labelled atoms by the inversion symmetry.

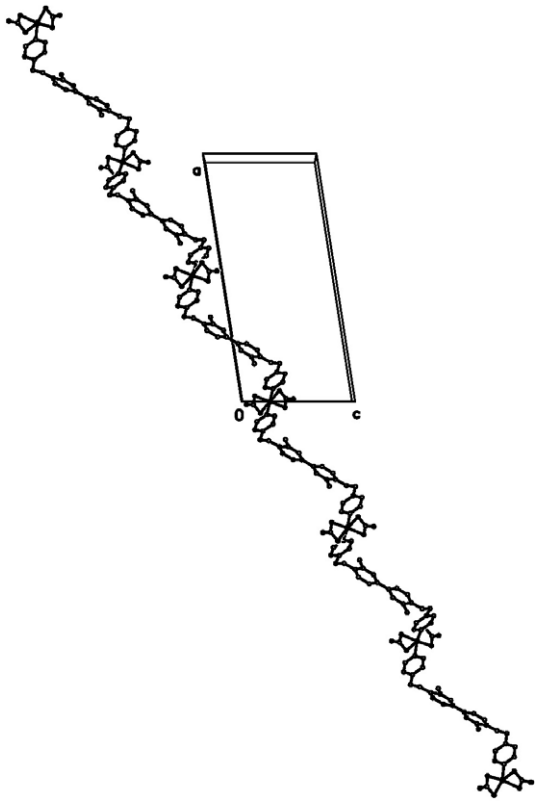

Fig. 3. Projection of polymer **1** along the *b*-axis, showing a linear zigzag chain structure.

A monomer unit of polymer **3** is given in Fig. 6, which shows that the Cd(II) metal is 6-coordinate and its coordination sphere consists of four pyridyl nitrogens and two oxygens of two η^1-NO_3 ligands. The Cd metal is located on the crystallographic inversion center. The N2–C6 and N2–C7 bond lengths are 1.427(6) and 1.381(6) Å, respectively. Fig. 7 shows a projection along the *a*-axis. Polymer **3** has a 2D structure that extends approximately in the [0 1 1] direction, and consists of layers of grids. Each grid consists of four Cd metals and four **L** ligands, forming a large 84-membered (80 ligand atoms and 4 Co metals) ring with dimensions of ca. 20.2×20.3 Å^2 (based on the Cd···Cd separations). Despite the presence of large repeating rings, polymer **3** does not exhibit the interpenetration phenomenon and does not contain guest molecules, either. In polymer **3**, the ligands have practically the same N···N separation [16.363(8) and 16.373(10) Å]. In addition, the metals also have practically the same Cd···Cd separation [20.274(3) and 20.201(3) Å].

A monomer unit of polymer **4** is shown in Fig. 8. The Cd(II) metal is 6-coordinate with a $[CdN_4O_2]$ core, and its coordination sphere consists of four pyridyl nitrogens and two oxygens of two η^1-NO_3 ligands. The N···N separation between the terminal pyridyl rings is 11.934(8) Å. The N3–H3 hydrogen is involved in intermolecular N–H···O hydrogen bonding: N3–H3 = 0.72 Å; N2···O3 $(-x+2, -y, -z+2)$ = 2.46 Å; N3–H3···O3 = 163°.

Fig. 9 shows a projection of polymer **4** approximately perpendicular to the (0 1 1) plane, which shows a 2D compact network containing benzene guest molecules. It is worth noting that all the **L** ligands in polymer **4** adopt the *U*-conformation (*syn*-orientation of pyridyl groups). This type of coordination of bipyridyl-based ligands is rather unusual and was previously reported for [Cd(3-pmpmd)$_{1.5}$(NO$_3$)$_2$] · EtOH and [Zn(3-pmpmd)$_{1.5}$(NO$_3$)$_2$] · MeOH (3-

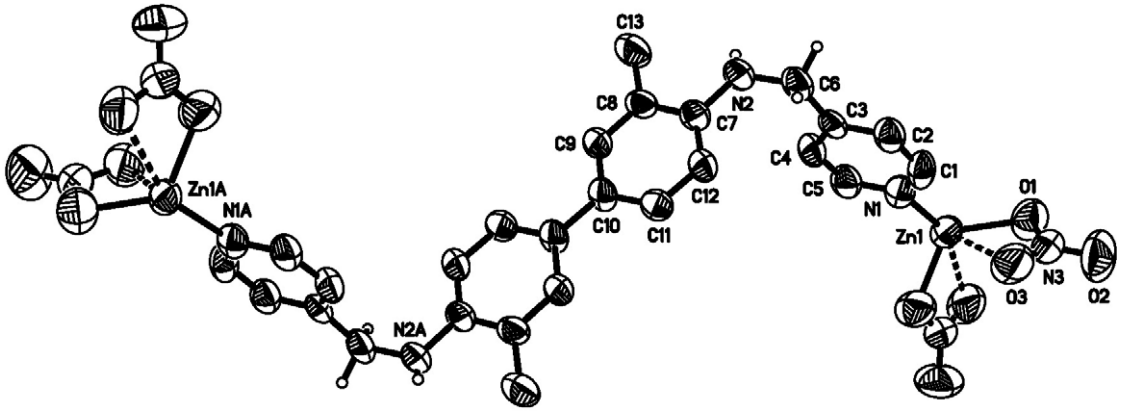

Fig. 4. ORTEP drawing of local environment of zinc in polymer **2**.

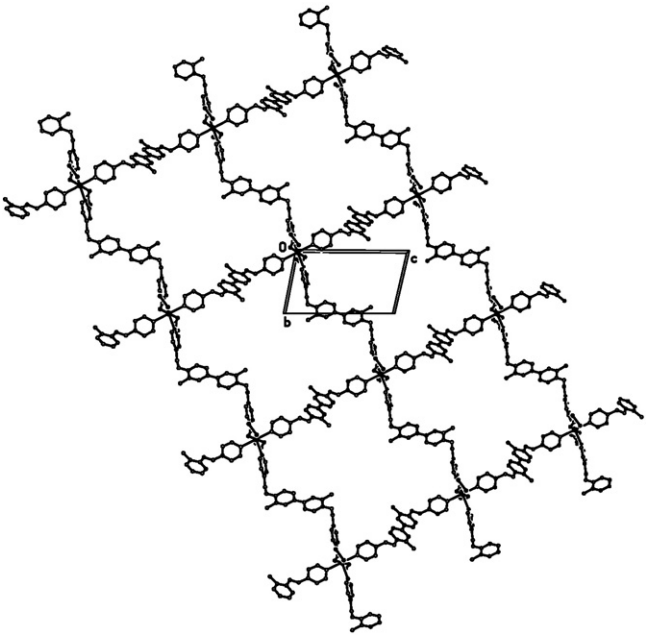

Fig. 7. Projection of polymer **3** along the *a*-axis, showing a 2D grid network.

pmpmd = *N*,*N*′-bis(3-pyridylmethyl)pyromellitic diimide) [35]. The benzene guest molecules are located inside the cavities of the 2D framework. Each cadmium metal is linked by four ligands that approximately form a square plane with 90° to one another. If the four ligands are taken as two independent sets of two ligands,

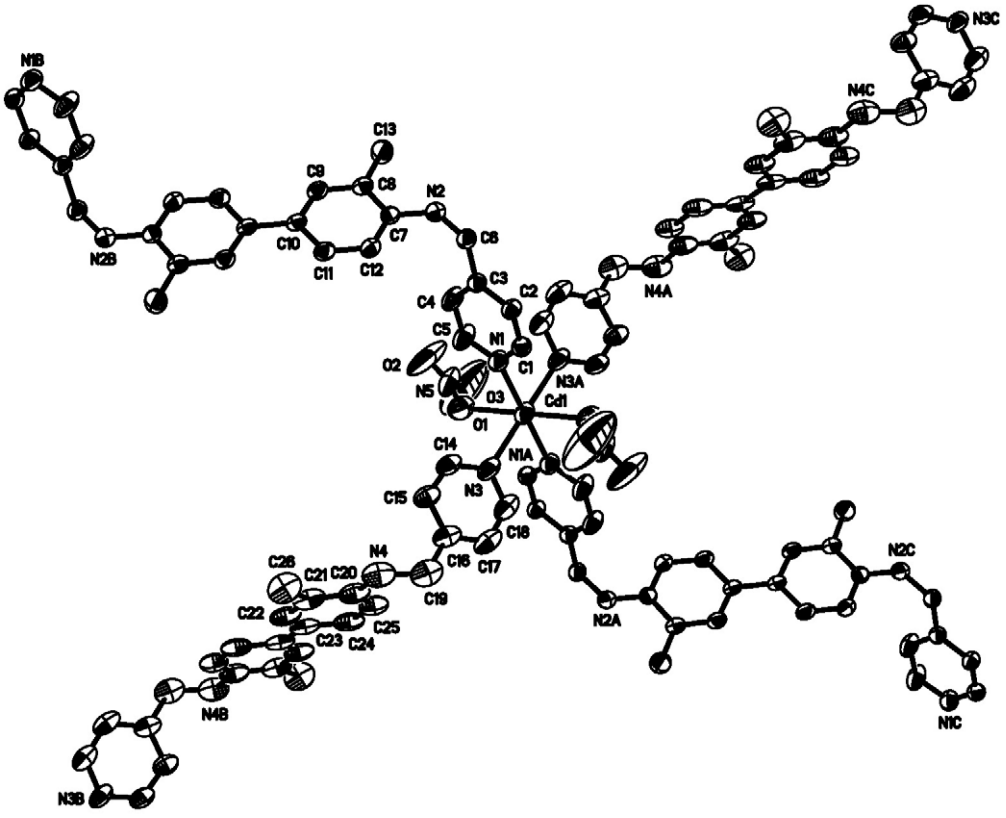

Fig. 6. Local coordination environment of cadmium in polymer **3**.

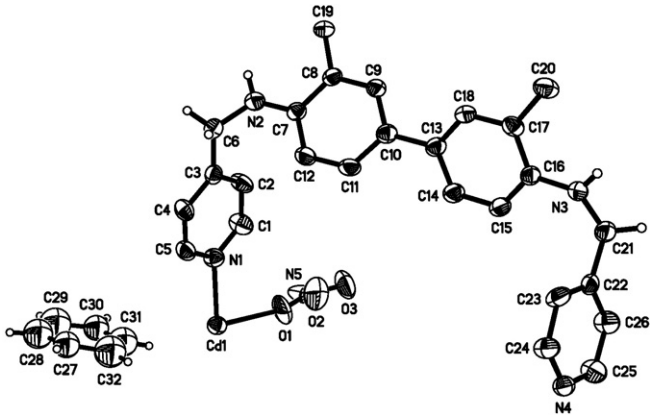

Fig. 8. Local coordination environment around the cadmium atom in polymer **4**.

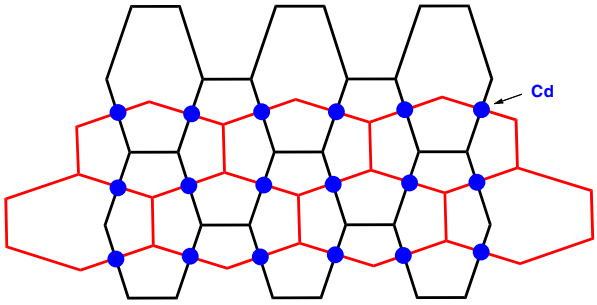
Fig. 6 looks like a combination of two honeycombs (red and black), each of which is generated by each ligand set. Nevertheless, in fact, the actual unit in polymer **4** is a 84-membered ring, composed of four Cd atoms and four ligands (M_4L_4). Although polymers **3** and **4** have the same framework formula {[Cd**L**$_2$(NO_3)$_2$]}, their framework structures are essentially different, depending on the absence (**3**) or presence (**4**) of guest molecules.



3.3. Thermogravimetric analyses

Thermogravimetric analyses (TGA) were performed on polymers **1**–**4** by heating them up to 800 °C. The framework of polymer **1** is stable up to 202 °C, above which an abrupt weight loss occurs between 202 and 275 °C, followed by another abrupt weight loss between 373 and 416 °C, which corresponds to the breakdown of its framework. Polymer **2** is stable up to 261 °C, and two subsequent weight losses occur at 261–264 and 373–449 °C. These data indicate that the thermal stability of the framework of polymer **2** is higher than that of polymer **1**. The TGA of polymer **3** displays two steps of weight loss: an abrupt weight loss at 256–523 °C and a gradual weight loss above 582 °C. The guest-containing polymer **4** exhibits a gradual weight loss (about 16%) in the range 178–215 °C, corresponding to the loss of the guest benzene molecules. The framework of polymer **4** decomposes above 273 °C. When heated at 220 °C for 2 h, polymer **4** gave its guest-free form, which is amorphous. Therefore, we gave up desorption–resorption experiments for this polymer.

4. Conclusion

In summary, we prepared a long, flexible (4,4′-bipyridyl)-type linking ligand **L** [(4-py)–CH_2–NH–(CH_3)C_6H_3–C_6H_3(CH_3)–NH–CH_2–(4-py)] by reducing its parent diimine species (4-py)–CH═N–(CH_3)C_6H_3–C_6H_3(CH_3)–N═CH–(4-py) (**L**′). Novel zinc (**1**), cobalt (**2**) and cadmium (**3** and **4**) coordination polymers were prepared from the corresponding metal nitrates and the ligand **L** under solvothermal conditions. The N···N separation between the two pyridyl groups in **L** (in the free state) is 19.871(3) Å, and this distance varies from 11.934(4) to 16.373(8) Å in the polymers **1**–**4**. In addition, **L** coordinates to the metal via its terminal pyridyl nitrogen atoms either in the *Z*-mode (in polymers **1**–**3**) or in the *U*-mode (in polymer **4**). Whereas polymers **1** and **2** have a 1D zigzag-chain structure, polymers **3** and **4** have a 2D network structure. Several conclusions may be drawn from our work: (1) Reduction of diimine with $NaBH_4$ to give its reduced form proceeds readily at room temperature in high yield. (2) Benzene promoted the formation of high-quality crystals of polymers **1** and **2**. (3) The various N···N separations and two conformation modes in

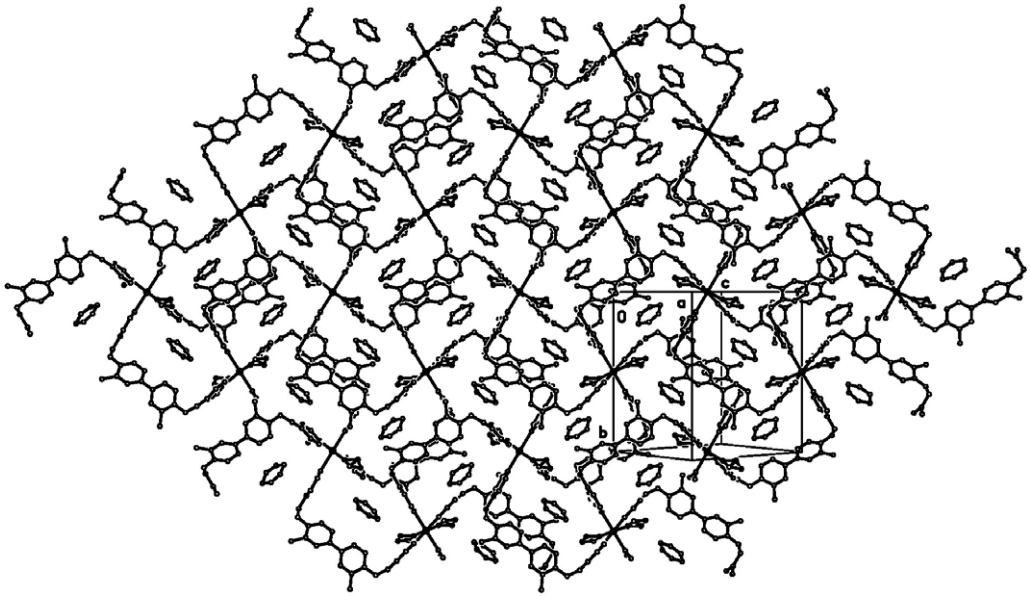


Fig. 9. Projection of polymer **4**, showing the *U*-mode of ligand **L**.

the coordination polymers indicate the high flexibility of ligand **L**. (4) The amine nitrogen atoms in **L** do not bind to the metal in all the polymers.

5. Supplementary data

CCDC 672275, 672276, 672277, 672278 and 672279 contain the supplementary crystallographic data for **L**, **1**, **2**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ,UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

1-(1*H*-Benzoimidazol-2-yl)-ethanone thiosemicarbazone (H_2L) (**1**) was obtained by the condensation reaction of 2-acetylbenzimidazole, thiosemicarbazide and acetic acid in ethanol. The novel cobalt(III) complex [Co(L)(HL)] **2** was prepared by the direct reaction of $CoCl_2 \cdot 6H_2O$ with the ligand H_2L. The reaction products were characterized by elemental analysis, thermogravimetric analysis (TGA), FT-IR and mass spectrometry for H_2L, and magnetic measurement for the Co(III) complex. The crystal and molecular structures of complex **2** and the free ligand **1** were also determined by single-crystal X-ray structure analysis. The crystal structure data suggests that in compound **2**, two ligands (H_2L) coordinate to cobalt in a N_2S tridentate fashion, giving a distorted octahedral geometry. Furthermore, compounds **1** and **2** were evaluated for their antimicrobial properties using a broth microdilution assay against various human pathogenic bacteria and the yeast *Candida tropicalis*, resulting in moderate minimum inhibitory concentrations (MIC = 0.25–1 mg/mL) when compared to standard antimicrobial agents. The free radical scavenging activity of the compounds against 1,1-diphenyl-2-picrylhydrazyl hydrate (DPPH) was also investigated.

1. Introduction

The benzimidazoles are a subject of interest to medicinal chemistry because of the broad spectrum of their biological and pharmaceutical properties. Benzimidazole complexes have been previously investigated for their antifungal [1,2], antibacterial [3,4], antimicrobial [5,6], antiamoebic [7,8], antiparasitic [9] and antitumor activities [10,11]. Although many thiosemicarbazones and their transition metal ion complexes have been studied extensively, due to their wide range of biological activities [12–16], there is very limited information about the structural characterization of benzimidazole thiosemicarbazone derivatives. The pharmacological or coordinative information about imidazole thiosemicarbazone derivatives and some of their complexes are limited in the literature [17–19].

In this present study, the synthesis, structural characterization and crystal structures of the free ligand and its cobalt(III) complex is reported (to the best of our knowledge it is the first X-ray study of H_2L and one of its complexes). Furthermore, the antimicrobial and radical scavenging activity of complex **2** and the free ligand **1** against various pathogenic microorganisms and the 1,1-diphenyl-2-picrylhydrazyl hydrate (DPPH) radical were evaluated.

2. Experimental

2.1. General procedures and materials

All the chemicals used were spectroscopic and analytical grade. They were used as received from commercial sources (Sigma–Aldrich, and AlfaEaser). The IR spectra were recorded on a Perkin Elmer BX-II FT–IR spectrophotometer, using a KBr disk, in the range 4000–400 cm^{-1}. Thermogravimetric analyses were performed on a Linseis Thermowaage L81 Series thermal analysis system by heating (increases of 20 °C/min) *ca.* 8 mg of the samples under an air atmosphere in the temperature range 25–150 °C. Elemental analyses for C, N, S and H were performed on Elementar Vario III EL. Magnetic susceptibility measurements were performed on pulverised samples at room temperature on a Sherwood Magway MSB Mk1 balance.

2.2. Synthesis of the 1-(1H-benzoimidazol-2-yl)-ethanone thiosemicarbazone ligand (*1*)

A slightly modified procedure was applied to prepare the thiosemicarbazone derivative [20]. Thus, a mixture of 2-acetylbenzimidazole (5 mmol), thiosemicarbazide (5 mmol) and 1 mL acetic acid in 50 mL ethanol was refluxed for 6 h. The raw product precipitated in a cooled solution, and was then filtered and recrystallised

2.3. Synthesis of [1-(1H-benzoimidazol-2-yl)-ethanone thiosemicarbazone]$_2$ cobalt

A solution of the crystalline ligand (0.125 g, 0.538 mmol) in ethanol (40 mL) was added to a solution of $CoCl_2 \cdot 6H_2O$ (0.0635 g, 0.267 mmol) in 20 mL wet ethanol. The resulting mixture was stirred under reflux at least for 40 h. The solution was left for slow evaporation at room temperature. The resulting crystals of the complex were separated from the solution after few days (30% yield, w/w). The oxidation of Co(II) occurred during the reaction and the Co(III) complex was obtained. This was due to air oxidation during evaporation of solvent as observed in the synthesis of a similar compound in the literature [19]. Elemental *Anal.* Calc. for $C_{20}H_{19}N_{10}S_2Co \cdot H_2O$: C, 44.44; H, 3.92; N, 25.91; S, 11.86. Found: C, 44.52; H, 4.02; N, 25.48; S, 11.55%. 2.4. X-ray structure determinations of [$C_{12}H_{18}N_5O_2S$] (**1**) and [$C_{20}H_{21}CoN_{10}S_2$] (**2**)

Measurements of **1** and **2** were made on a Stoe IPDS II CCD X-ray diffractometer employing plane graphite Mo Kα monochromatized radiation (λ = 0.71073 Å), using the ω–2θ scan mode. Unit cell parameters were refined from the setting angles of 25 centered reflections in the range of (**1**) $2.33 \leqslant \theta \leqslant 25.00$ and (**2**) $1.69 \leqslant \theta \leqslant 25.25$. The structures were solved by direct methods and refined by full-matrix least-squares techniques on F^2 using the solution program SHELXS-97 and refined using SHELXL-97 [21]. Empirical absorption corrections were applied by the integration method via X-RED software [22]. All non-hydrogen atoms were refined with anisotropic displacement parameters and hydrogen atoms were included in their idealized positions and refined isotropically except for the water hydrogen atoms which were located from difference maps and refined with isotropic thermal parameters. The crystal data and structure refinement details for complex **1** and **2** are given in Table 1. ORTEP drawings [23] of the molecules with 40% probability displacement thermal ellipsoids and the atom labelling scheme are shown in Figs. 1 and 2, respectively.

2.5. Biological evaluation

2.5.1. Antimicrobial activity

A modified broth microdilution susceptibility assay was used [24,25]. Stock solutions of the test samples (2 mg/mL) were prepared in 25% (v/v) dimethylsulfoxide (DMSO, Carlo Erba), which were used as the initial concentration and later serially diluted in an equal volume of Mueller–Hinton broth (MHB, Merck, Germany) up to 0.98 μg/mL in a 96-well microtiter plate format. Microbial suspensions were grown as previously described [24], which were standardized to 10^8 CFU mL^{-1} using the McFarland No. 0.5 standard, also in MHB. Each microbial suspension (100 μL) was then added to the dilutions under sterile conditions. The last row, which contained only the dilutions of the test samples without the microorganism, was used as a negative control. To eliminate solvent effects, DMSO dilutions were considered as another control, separately. After incubation at 37 °C for 24 h the first well without turbidity was determined as the minimum inhibition concentration (MIC, mg/mL). Chloramphenicol and Ketoconazole were used as standard antimicrobials. Strain sources and activity results are given in Table 2.

2.5.2. Quantitative free radical scavenging activity using DPPH

The test substances were subjected to a quantitative UV-spectroscopic microdilution assay [26], where inhibitory concentrations (IC) were determined in comparison with standard substances. Stock solutions of each test sample were prepared to obtain a final concentration of 0.5 mg/mL in methanol, which were transferred in aliquots of 100 μL of each test solution to the first row of the 96-well plate. Ten-fold serial dilutions in an equal amount of MeOH were prepared and vortexed for 5 min. DPPH was dissolved in methanol to obtain a stock reagent solution with a final concentration of 80 μg/mL. To initiate the reaction, 100 μL of DPPH solution was added into each well and left for 30 min in the dark. Vitamin C, BHT (butylated hydroxytoluene) and quercetin were used as positive controls at the same concentration, DPPH + MeOH served as a negative control and only MeOH was used as a blank on the same test plate. The UV absorbance was read at 517 nm using a microplate spectrophotometer (BioTek, Powerwave) at room temperature. All experiments were performed on quadruplets in two different plates. The results were expressed as mean ± standard deviation (n = 8). For statistical evaluations and calculations Gen5 Data Analysis Software (BioTek) was used. The antioxidant activity was expressed as half maximal of the inhibitory concentration (IC_{50}) required to inhibit DPPH radical formation, as determined from the log-dose inhibition curve. The value was calculated using the formula $IC_{50} = [(A_0 - A_1)/A_0] \times 100$ where A_0 is the absorbance of the control and A_1 the absorbance of the test sample. Comparative results of the test samples and standards are given in Table 3.

3. Results and discussion

3.1. Description of the structures

3.1.1. Solid-state structure of [1-(1*H*-benzoimidazol-2-yl)-ethanone] (**1**)

The free ligand, 1-(1*H*-benzoimidazol-2-yl)-ethanone, crystallizes into a triclinic lattice with the space group $P\bar{1}$. The molecular structure of **1** with the atomic numbering scheme is given in Fig. 1 and selected bond distances and angles are presented in Table 4. The ligand adopts an (*E*)-configuration about the C1–N2 and C4–N4 bonds with both the azomethine nitrogen atoms. As illustrated in Fig. 1, the asymmetric unit of the free ligand consists of one molecule of ethanol and one molecule of water. The C1–S1 [1.697(4) Å], C1–N2 [1.351(5) Å], N2–N3 [1.367(4) Å] and C2–N3

Table 4
Selected bond distances (Å) and angles (°) for compound **1**

C1–N1	1.312(6)	C4–N5	1.359(5)
C1–N2	1.351(5)	C5–N4	1.371(5)
C1–S1	1.697(4)	C10–N5	1.387(5)
C2–N3	1.286(5)	N2–N3	1.367(4)
C4–N4	1.320(5)	O2–C12	1.409(8)
N1–C1–N2	117.5(4)	N4–C4–N5	112.6(3)
N1–C1–S1	123.3(3)	C1–N2–N3	117.9(4)
N2–C1–S1	119.2(3)	C4–N4–C5	105.7(3)
N3–C2–C4	112.9(4)		

[1.286(5) Å] bond distances are comparable with those of related ligands [27–29]. The above bond distances indicate that there is some electron delocalization in the thiosemicarbazide side chain. The thiosemicarbazone skeleton comprising of atoms N3, N4, C1, S1 and N1 has a maximum deviation of 0.010 (2) Å from the mean plane. The C2–N3 bond distance [1.286(5) Å] is appreciably close to that of a C=N double bond (1.28 Å) [30], confirming the azomethine bond formation. Intermolecular N–H···O and N–H···S hydrogen bonds link the molecules, helping to stabilize the crystal structure. The parameters for the hydrogen bonding interaction in ligand **1** are as follows: H(4)···O(2) 1.94 Å, N(4)···O(2) 2.778(5) Å, N(4)–H(4)···O(2) 164°; H(2)···N(4) 2.06 Å, O(2)···N(4) 2.777(5) Å, O(2)-H(2)···N(4) 146°.

3.1.2. Solid-state structure of $[C_{20}H_{21}CoN_{10}OS_2]$ (**2**)

The crystal of **2** is triclinic and the asymmetric unit consists of two independent and similar molecules (A and B), $[C_{20}H_{21}CoN_{10}OS_2]$. The coordination environment of the cobalt atom may be considered as a distorted octahedral geometry with the thiosemicarbazone ligand (H_2L) **1** coordinated to the cobalt ion as a tridentate N_2S chelate via the four azomethinic nitrogen atoms and two thioamide sulfur atoms. Structurally there are a few significant differences between the (H_2L) (**1**) ligand and the novel cobalt(III) complex [Co(L)(HL)] (**2**). The C1–S1 bond distance has been increased from 1.697(4) Å (**1**) to [1.734(5)–1.727(6) Å] in complex (**2**). The C–S bond distances still have an intermediate value between a single (1.82 Å) and double (1.56 Å) C–S bond [29]. This is an indication that there is some electron delocalization in the thiosemicarbazide chain, but that it is independent of coordination. Selected bond distances and angles are listed in Table 5.

In the Co complex, two ligands coordinate in the expected meridional conformation via azomethinic nitrogens [N(3) and N(8)] and sulfur atoms. The *trans* angle involving the azomethinic nitrogens of the two ligands is 177.02(16)°, showing less distortion from octahedral symmetry than in $[[Ni(HAm4M)_2](ClO_4)_2 \cdot 2H_2O]$, in which this angle is 173.1(3)° [31]. The other two *trans* angles, each of which involves the terminal donors of one of the tridentate ligands are approximately 167.2°. As expected the sulfur and imine nitrogen atoms in both molecules (A and B) of the ligand are in the *cis* conformation with respect to the C20–N9 bonds [12]. The two donor nitrogen atoms, N1 and N3, in A and B also lie *cis* to each other. The oxidation state of three for cobalt is shown by its coordination bond distances Co–S and Co–$N_{azomethine}$ (Table 5), which are in the expected range ranges of 2.2278(14)–2.2305(14), 1.909(4)–1.950(4) Å, respectively, as noted for several Co(III) complexes [32–34]. The loss of the proton originally bound to N(9) produces a negative charge which is delocalized in the N8–N9–C20 system, as indicated by the bond distances and in particular S(1)–C(20) (1.735(5) Å) and C(20)–N(9) (1.323(6) Å). The other ligand, not deprotonated on N(4), is in the thione form [S(2)–C(10) 1.725(6), C(10)–N(4) 1.348(5) Å]. The coordination of the cobalt ion is not completely regular; the bond angles at the Co1A atom range from 82.55(15)° to 97.84(12)°. The two molecules of the ligand are practically planar [maximum deviations of 0.037(2) and

S1–Co1a–S2	90.59(5)	S4–Co2b–S3	89.84(6)

−0.022(2) Å, respectively]. The angles generated at the cobalt centre by the chelating donor points (N and S) differ slightly in the two coordinating ligands. It appears that the angles at the cobalt centre in the chelate rings are controlled to some extent by the ligand geometry. The bond distances and angles around the cobalt atom are in agreement with literature values [35–37].

3.2. Spectral studies, thermogravimetric analysis (TGA), magnetic measurement

The thermal analytical data of the ligand show that when the temperature was raised up to 377 K, the weight loss was 21%, indicating loss from the crystal of one water molecule and one ethanol molecule. The thermal analytical data of the Co(III) complex show that when the temperature was raised to 377 K, the weight loss was 3.3%, indicating loss from the crystal of one water molecule. The crystalline complex lost H_2O molecules of hydration below 100 °C, and lost coordinated H_2O molecules above 100 °C. Magnetic susceptibility data indicate that the Co(III) complex is diamagnetic (at ~300 K) as expected for a spin-paired d^6 ion.

3.3. IR spectra

(i) The disappearance of the ν(NH) bands is verified in the complex which contains the ligand in its bideprotonated form. (ii) The coordination of the azomethine nitrogen atom to the metal ion is suggested by the shifting of the band of ν(C=N) at 1612 cm^{-1} to a lower wavenumber. (iii) The coordination of the sulfur atom causes, in the spectra of the complex, the shift of the band at 839 cm^{-1} to a lower frequency value. (iv) The coordination of the deprotonated imidazole nitrogen is shown by the shift of the δ(ring) in complex to higher frequency values [19].

3.4. Antimicrobial and free radical scavenging activity

A selection of human pathogenic Gram positive and Gram negative bacteria and the yeast *C. tropicalis* were interacted under in vitro conditions with the synthesized **2** (complex) and **1** (ligand). A modified broth microdilution assay [24] was used to evaluate their antimicrobial properties. Compound **1** was more effective against *E. coli* and *S. aureus* among the tested bacteria and the yeast *Candida tropicalis* when compared to the other tested compounds. Interestingly, compound **2** showed the best inhibitory activity against the yeast *C. tropicalis*, like compound **1**, with a MIC value of 0.25 mg/mL at the same level as the standard antifungal agent Ketoconazole. Overall, good to moderate inhibitions (0.25–1 mg/mL) were observed against the tested microorganisms, when compared to standard antimicrobial agents. Compounds **1** and **2** were also evaluated for their free radical scavenging activity using the DPPH radical. When compared to standard antioxidant compounds such as Vitamin C, and BHT with IC_{50} values of 0.008 and 0.020 mg/mL, respectively, both **1** and **2** displayed IC_{50} values more than 0.5 mg/mL and are rated rather inactive.

In vitro biological evaluations using standard methods may have correlations to in vivo results, which are practical and fast in obtaining bioactivity results of individual compounds. Also standard bioassay methods can produce comparable results to other similar studies. Previous antimicrobial studies [1–9] support that such complexes can exhibit remarkable biological and pharmacological effects.

4. Conclusion

To the best of our knowledge the crystal structures of compounds **1** and **2** are obtained for the first time and evaluated for their physicochemical and biological activities. Preliminary biological activity screens of the compounds showing antifungal activity suggest further evaluations of derivatives of the tested substances, also in other bioassays.

Stacking interactions

ABSTRACT

The crystal structures of two Mg(II) complexes of 3-hydroxy-4-nitrobenzoic acid have been reported. The first complex, **2** ($C_{14}H_{20}N_2O_{16}Mg$), consists of ionic entities comprising one hexaaquamagnesium cation and two organic carboxylate anions. The second complex, **3** ($C_7H_{15}NO_{11}Mg$) consists of zwitterionic entities comprising one organic ligand per Mg atom. In both cases, the complexes are linked through an extensive hydrogen bonding network. The 3D supramolecular architectures of these complexes are also stabilized by two types of stacking interactions. An interesting interconversion between the two complexes was observed in aqueous solution.

1. Introduction

Besides their relevance to solid state structures and supramolecular design [1–3], (salicylato)-metal complexes have attracted considerable attention because of their promising anti-inflammatory and anticonvulsant activities [4–10]. As part of a systematic program devoted to the study of the structure–activity relationships of (salicylato)-metal complexes, we recently reported the preparation, crystal structures and anticonvulsant activities of Zn(II) and Co(II) tetraaqua(3-nitro-4-hydroxybenzoato) complexes [11]. Interestingly, promising pharmacological responses were obtained for these complexes as anticonvulsants. An exciting feature in this series is the possibility of modifying the original structure by moving groups attached to the aromatic nucleus. Herein we report the crystal structures of two Mg(II) complexes of 3-hydroxy-4-nitrobenzoic acid, the latter corresponding to the formal permutation of the hydroxyl and nitro groups in the above ligand [11].

2. Experimental

2.1. Materials

High purity 3-hydroxy-4-nitrobenzoic acid (ligand **1** in Fig. 1) and anhydrous magnesium chloride were purchased from Acros (USA) and were used without further purification.

2.2. Physical measurements

Characterization of the complexes: Elemental analyses (C, H and N) were performed on a Perkin–Elmer 2400 analyzer. The IR spectra were recorded with a Bruker Vector 22 spectrometer. The UV spectra were recorded with a Gasco V550 spectrometer. Thermogravimetric analysis (TGA) was carried out on a TA Instruments TGA Q500 apparatus. Calibration was performed at different

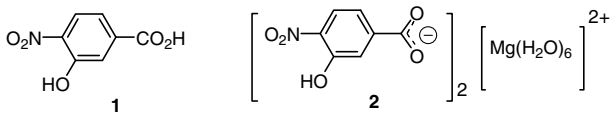

Fig. 1. Canonical representations of ligand **1** and salt $[(C_7H_4NO_5)^-]_2[Mg(H_2O)_6]^{2+}$ (**2**).

temperatures using Curie magnetic transitions for the recommended materials: alumel (163 °C), nickel (354 °C); calibration (mass) was carried out using a standard mass of 100 mg, calibration of the furnace was made between 100 and 900 °C to verify the thermocouple operation. All the experiments were performed under dry nitrogen, with a flow rate of 6×10^{-2} l min^{-1}. Analysis of the compounds out of nitrogen purging was conducted at a heating rate of 20 °C min^{-1}, in order to determine the percentage of mass loss with the best precision. A differential scanning calorimetry (DSC) experiment has been carried out with a TA Instruments Universal V4.2E apparatus under nitrogen flow. The samples were introduced in aluminum pans and covered with holed caps in order to avoid an uncontrolled variation of pressure. Calibration of the temperature was performed with indium (156.6 °C) and tin (231.9 °C) of quality 5 N at a heating rate of 10 °C min^{-1}. Impedance measurements of aqueous solutions were performed using a VoltaLab 80 (Radiometer Analytical) with a 2-pole cell with two platinum plates. The signal amplitude was 100 mV. A continuous potential of 0 mV was imposed. Measurements were obtained at 20 °C at 1 kHz frequency.

Potentiometric measurements of the ligand **1**: The experimental conditions of the reactant concentrations and pH were chosen from speciation calculations so that all species characterized from the potentiometric investigations and being of spectroscopic interest could be made successively predominant in solution. The different pH values investigated were imposed on test solutions by adding negligible volumes of concentrated NaOH or HCl. UV–Vis absorption spectra were recorded at room temperature in the 200–800 nm range using a double beam Lambda 2 Perkin–Elmer (equipped with 1 mm quartz cells). A water blank was used as a reference. The results were expressed as ε (molar absorption coefficient) with respect to the molar concentrations of the ligand.

2.3. Preparation of the complexes

2.3.1. $C_{14}H_{20}N_2O_{16}Mg$ (*2*)

The monosodium salt of ligand **1** was prepared by neutralizing **1** (0.915 g, 5 mmol) with 5 ml of 1 M NaOH. To this solution was added anhydrous $MgCl_2$ (0.238 g, 2.5 mmol) in 5 ml of water. After a few days **2** was filtered, crystallized from water and dried over magnesium sulfate. Yield: 0.903 g (73%). *Anal.* Calc. for $C_{14}H_{20}N_2O_{16}Mg$ (**2**): C, 33.86; H, 4.06; N, 5.64. Found: C, 33.25; H, 3.85; N, 5.44%. IR (neat, cm^{-1}): 3585(m), 3557(m), 3229(m), 2951(m), 1670(m), 1601(m), 1557(s), 1475(m), 1430(m), 1380(s), 1348(s), 1316(s), 1273(m), 1239(s), 1170(s), 1070(m), 957(m), 910(m), 839(s), 786(s), 750(s), 671(s), 632(s), 607(s). UV spectrum (in water): λ_{max} = 283 nm, ε = 14700; λ_{max} = 354 nm, ε = 5200. The conductance and pH of the 2×10^{-2} M solution in water were found to be 2.05×10^{-3} Ω^{-1} cm^{-1} and 4.85, respectively. TGA analysis of **2** revealed a mass loss of 21.4% on heating from 70 to 195 °C, corresponding to a loss of six water molecules (Calc. 21.8%). The DSC study of **2** revealed, as the main events, two endotherms centered at 122 and 181 °C corresponding to loss of water.

2.3.2. $C_7H_{15}NO_{11}Mg$ (*3*)

Ligand **1** (1.07 g, 5.85 mmol) and $Mg(OH)_2$ (0.450 g, 7.76 mmol) were heated under reflux in a mixture of acetone (30 mL) and water (5 mL) for 3 days. A red solid was obtained which was filtered and crystallized from water. Yield: 1.34 g (73%). *Anal.* Calc. for $C_7H_{15}NO_{11}Mg$ (**3**): C, 26.82; H, 4.82, N, 4.49. Found: C, 26.79; H, 4.82; N, 4.55%. IR (neat, cm^{-1}): 3187(m), 1665(m), 1534(s), 1441(s), 1396(s), 1329(s), 1251(s), 1218(s), 1065(s), 970(m). UV–Vis spectrum (in water): λ_{max} = 284 nm, ε = 8370; λ_{max} = 358 nm, ε = 3370; shoulder centered at ca 430 nm, ε = ca 1500. The conductance and pH of the 2×10^{-2} M solution in water were found to be 1.82×10^{-3} Ω^{-1} cm^{-1} and 6.42, respectively. TGA analysis of **3** revealed a mass loss of 33.9% on heating from 60 to 340 °C, corresponding to a loss of six water molecules (Calc. 34.4%). The DSC study of **3** revealed, as the main event, an endotherm centered at 147 °C corresponding to loss of water.

2.4. X-ray diffraction study

Diffraction data for salt **2** were collected on a Bruker-SMART three axis diffractometer equipped with a SMART 1000 CCD area detector using graphite monochromated Mo Kα X-radiation (wavelength λ = 0.71073 Å) at 100.0(1) K. The low temperature was reached by an evaporated liquid nitrogen stream over the crystal, provided by the Oxford Cryosystem device. Data collection and processing were carried out using the Bruker SMART programs [12] and empirical absorption correction was applied using the SADABS computer program [12]. The structure was solved by direct methods SIR97 [13], and refined by full-matrix least-squares based on F^2 using CRYSTALS software [14]. Structural data for complex **3** were obtained with monochromated Mo Kα radiation (λ = 0.71073 Å) on a Nonius Kappa detector at 293 K, with data collection and reduction using the HKL package [15]. The structure was solved by direct methods in the space group $P\bar{1}$ using SHELXS-97 [16] and refined by least-squares methods on F using CRYSTALS software [14]. All non-hydrogen atoms were anisotropically refined. The hydrogen atoms were located in difference Fourier maps. H atoms were refined isotropically with U_{iso} = 1.20 U_{eq}, where U_{eq} is the equivalent isotropic atomic displacement parameter of the attached atom. The

crystal parameters, data collection and the refinement details of compounds **2** and **3** are reported in Table 1.

3. Results and discussion

3.1. Description of the crystal structure of salt 2

Salt **2** can be represented by the general formula $[(C_7H_4NO_5)^-]_2[Mg(H_2O)_6]^{2+}$. The canonical drawing of this complex is represented in Fig. 1 and the CAMERON [17] molecular structure in Fig. 2, with the atom numbering system used in Table 2, which lists the most relevant bond distances and angles.

Compound **2** belongs to a well-documented family of ionic metal carboxylates [1,18–25]. The formula unit consists of a Mg^{++} cation located on an inversion center and two 3-hydroxy-4-nitrobenzoate anions related by symmetry. The Mg^{++} atom is octahedrally coordinated by six water molecules, with a slightly irregular geometry. The two Mg–O distances are rather similar [Mg–O(10) and Mg–O(12) are equal to 2.094 and 2.105 Å, respectively], while the third one, Mg–O(11), is much shorter (2.005 Å) (Fig. 3). These distances are comparable to those found in related compounds [26].

Regarding the ligand geometry, it is noteworthy that the $C(26)_{carboxylato}$ and $N(23)_{nitro}$ atoms deviate significantly from the aromatic mean plane [$\Delta C(26)_{carboxylato}$ and $\Delta N(23)_{nitro}$: +0.156 and +0.090 Å, respectively].

The two 3-hydroxy-4-nitrobenzoate anions are not directly coordinated to magnesium, but there are important hydrogen-bonded interconnections between the cations and anions. Thus, from a total of seven hydrogen bonds found in the asymmetric unit, four are involved in connections with the carboxylato groups: Mg–O(10)–H(101)···O(26)^{i}–C=O, Mg–O(11)–H(111)···O(26)^{iii}–C=O, Mg–O(10)–H(102)···O(27)^{iii}–C=O, Mg–O(12)–H(122)···O(27)^{v}–C=O, and two with the nitro groups: Mg–O(11)–H(112)···O(22)^{ii}–N=O, Mg–O(12)–H(121)···O(23)^{iv}–N=O. It is noteworthy that the lengths of the bridges involved in these interconnections are highly dissimilar. In this respect, the bond set connecting the carboxylato group O(26)^{iii}–C=O to the Mg atom incorporates two exceptionally short bridges: Mg–O(11) [2.005 Å, while the related Mg–O(10) and Mg–O(12) coordination distances are 2.094 and 2.105 Å, respectively] and H(111)···O(26)^{iii} [1.813 Å, while the related H(101)···O(26)^{i}, H(102)··· O(27)^{iii} and H(122)···O(27)^{v} H-bond distances are 1.906, 1.931 and 1.940 Å, respectively], making it an energetically favored pathway for the joining of the anions to the cations. On the other hand, the phenol and nitro groups found in the 3-hydroxy-4-nitrobenzoate anions of salt **2** are linked together through a conventional internal hydrogen bond: O(22)–H(22)···O(23). In sharp contrast, the *ortho*-nitrophenol moieties found in the Zn(II) and Co(II) (3-nitro-4-hydroxybenzoato) complexes take part in an original parallelogram–shaped structure consisting of alternate intra- and inter-molecular hydrogen bonds [11] (Fig. 4 and Table 3).

The individual zero-dimensional units (0D) of salt **2** are further engaged in alternate layers of $[Mg(H_2O)_6]^{2+}$ cations and stacked organic anions, resulting in 2D and 3D supramolecular architectures

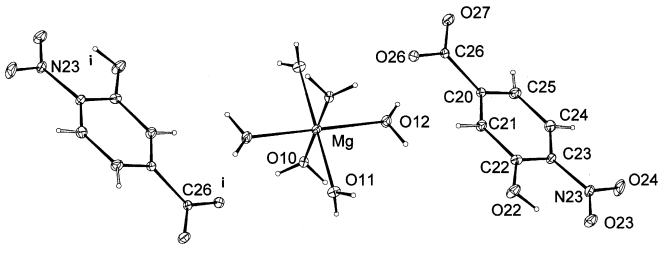

Fig. 2. Labelled CAMERON diagram of $[(C_7H_4NO_5)^-]_2[Mg(H_2O)_6]^{2+}$ (**2**). Ellipsoids are drawn at the 50% probability level. Symmetry code: i, $-x$, $-y$, $-z+2$.

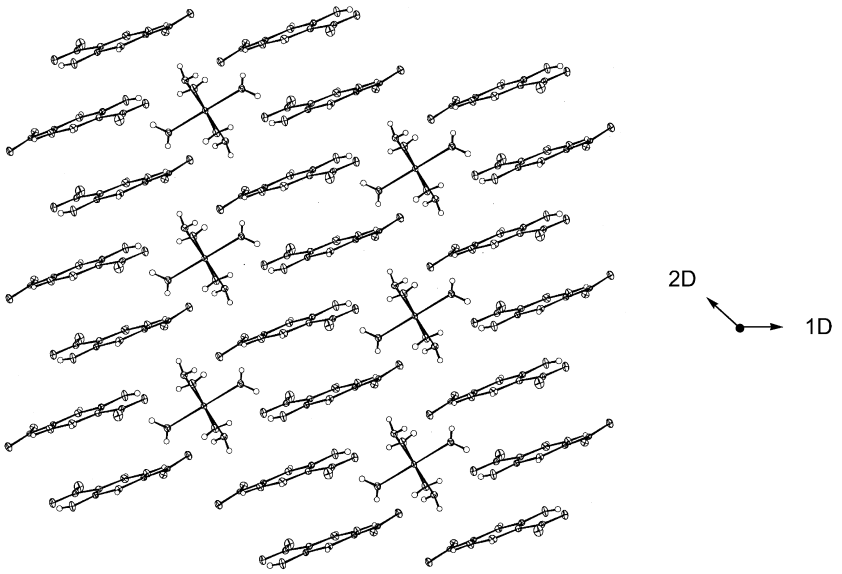

Fig. 5. 2D perspective diagram of $[(C_7H_4NO_5)^-]_2[Mg(H_2O)_6]^{2+}$ (**2**) viewing the alternate stacking of planar layers of 3-hydroxy-4-nitrobenzoate anions in between slabs of hexaaquamagnesium(II) cations. Hydrogen bonds are omitted for clarity.

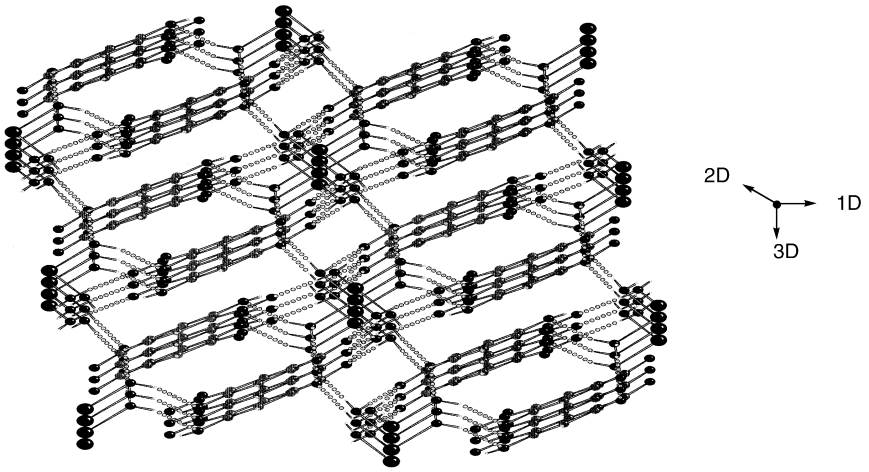

Fig. 6. Packing of $[(C_7H_4NO_5)^-]_2[Mg(H_2O)_6]^{2+}$ (**2**) showing the H-bonded 3D continuum as broken lines. Mg(II) centers are symbolized by large circles.

(Figs. 5 and 6). The most salient feature of the 3D architecture is the extensive coordination of the Mg(II) centers to the aromatic ligands through a complex hydrogen bond network. Four types of alternate channels are thus generated in the *b*-direction, the two larger ones measuring ca 3.1 × 7.7 and 3.5 × 4.0 Å^2 (Fig. 6).

The crystal packing of **2** is also governed by π–π stacking interactions involving the anionic aromatic moieties in a head-to-tail, *anti*-facial arrangement of the aromatic nuclei planes P(1) [C(20) until C(25)] and P(2) [C(20) until C(25); symmetry: $-x+1$, $-y+1$, $-z+1$]. The values of the mean interplanar spacing, the ring-centroid separation and the ring-centroid offset are, respectively, 3.534, 3.740 and 1.224 Å.

3.2. Description of the crystal structure of complex **3**

Complex **3** can be represented by the general formula $C_7H_3NO_5Mg(H_2O)_4 \cdot 2H_2O$. The canonical drawing of this complex is represented in Fig. 7 and the CAMERON [8] molecular structure in Fig. 8, with the atom numbering system used in Table 4, which lists the most relevant bond distances and angles.

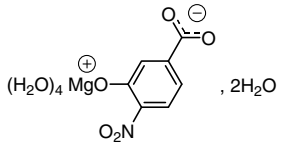

Fig. 7. Canonical representation of $C_7H_3NO_5Mg(H_2O)_4 \cdot 2H_2O$ (**3**).

The asymmetric unit of complex **3** consists of a zwitterion comprising of one organic ligand in its dianionic state and one magnesium cation. This type of structure is rather unusual [1,27–31]. One of the most salient features in **3** is the direct ligation of the magnesium cation to the phenoxo group. This can be interpreted by referring to the two acidities of ligand **1** (see Section 3.4.1). With the carboxylic acid in **1** ($pK_a = 3.11$) being ca 3×10^3 more acidic than the phenol group ($pK_a = 6.59$), the highest negative charge in the zwitterion **3** resides necessarily at the phenoxo site bonded to the Mg^{2+} cation. The Mg atom of **3** is octahedrally coordinated by four water molecules, one phenoxo group and one nitro group of

Mg–O(23)	2.164(2)	O(23)–N(23)–O(24)	119.10(2)
O(24)–N(23)	1.229(2)	O(22)–C(22)–C(23)	125.93(2)
O(26)–C(26)	1.258(2)	O(24)–N(23)–C(23)	120.09(2)
O(27)–C(26)	1.260(2)	O(26)–C(26)–O(27)	122.92(2)

the aromatic ligand. Two additional water molecules, although not directly coordinated with the Mg atom, are involved in an extensive H-bonding network (see below). The octahedron around the Mg atom exhibits an irregular geometry. The four Mg–O (water) distances are rather similar [2.036(2)–2.071(2) Å], while the Mg–$O(22)_{phenoxo}$ distance [1.998(2) Å] is much shorter than the Mg–$O(23)_{nitro}$ distance [2.164(2) Å] (Fig. 9).

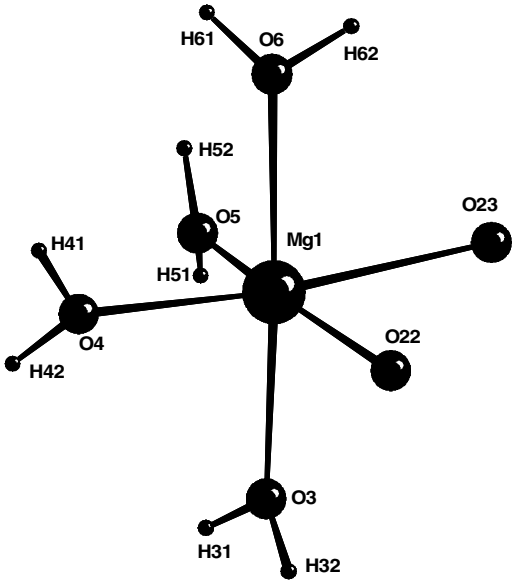

Fig. 9. Coordination octahedron around the Mg center in $C_7H_3NO_5Mg(H_2O)_4 \cdot 2H_2O$ (**3**).

Regarding the ligand geometry, it must be emphasized that the $C(26)_{carboxylato}$ atom is nearly located on the aromatic mean plane [$\Delta C(26)_{carboxylato}$: +0.004 Å], while the $N(23)_{nitro}$ and $O(22)_{phenoxo}$ atoms deviate slightly from this plane [$\Delta N(23)_{nitro}$: −0.054 Å, $\Delta O(22)_{phenoxo}$: +0.064 Å].

In other respects, it should be noted that the $O(23)_{nitro}$–Mg(1) coordination bond (length: 2.164 Å) takes part in a six-membered ring involving O(23), Mg(1), O(22), C(22), C(23) and N(23) atoms. The peculiar flattened boat-shaped conformation of this ring was highlighted through the orthogonal deviations of the ring atoms from the ring mean plane (in Å): −0.010 for ΔO(23), −0.063 for ΔMg(1), +0.119 for ΔO(22), −0.060 for ΔC(22), −0.061 for ΔC(23) and +0.075 for ΔN(23).

The carboxylate anion of complex **3** is not directly coordinated to the magnesium cation, but there are important hydrogen bonds joining the zwitterionic species. In particular, there are six interconnections between the carboxylato groups and each magnesium cation, involving either a single water molecule: O=C–$O(26)^{ii}\cdots$H(42)–O(4)–Mg, O=C–$O(27)^{iii}\cdots$H(51)–O(5)–Mg, O=C–$O(27)^{v}\cdots$H(61)–O(6)–Mg, O=C–$O(27)^{vi}\cdots$H(62)–O(6)–Mg, or two water molecules: O=C–$O(26)^{v}\cdots$H(82)–O(8)$\cdots$H(41)–O(4)–Mg, O=C–$O(26)^{vii}\cdots$H(81)–O(8)$\cdots$H(41)–O(4)–Mg (Fig. 10 and Table 5).

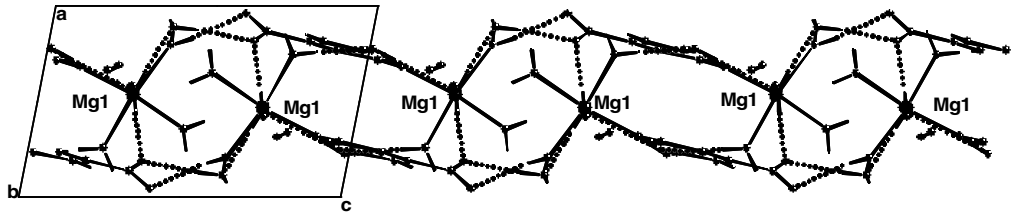

Fig. 11. Structural of part of $C_7H_3NO_5Mg(H_2O)_4 \cdot 2H_2O$ (**3**) indicating the 1D chain structure. The H-bonded continuum is symbolized as broken lines.

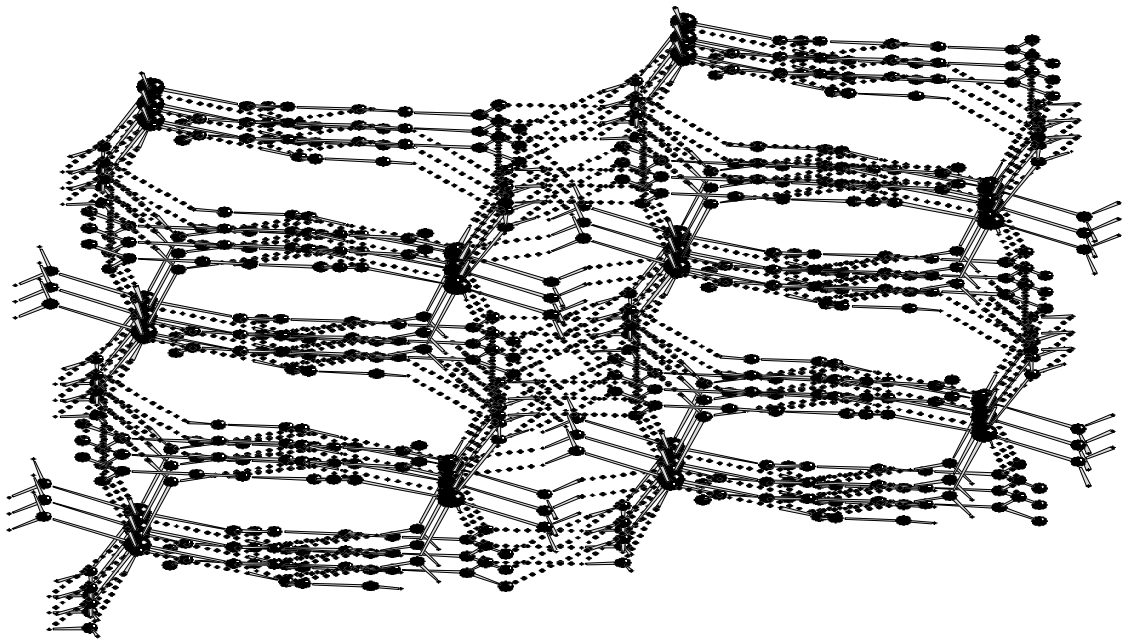

Fig. 12. Packing of $C_7H_3NO_5Mg(H_2O)_4 \cdot 2H_2O$ (**3**) showing the H-bonded 3D continuum as broken lines. Mg centers are symbolized by large circles.

The individual units of complex **3** are further engaged in a complicated hydrogen bond network, forming infinite chains along the *b*-axis (Fig. 11). These, in turn, self-assemble via hydrogen bonds, resulting in a 3D supramolecular architecture. Two types of alternate channels are thus generated in the *b*-direction, measuring ca 3.3×6.1 and 3.6×8.8 Å^2 (Fig. 12).

The crystal packing of **3** is also governed by π–π stacking interactions involving the anionic aromatic moieties. The type I-stacking involves a head-to-tail *anti*-facial arrangement of the aromatic nuclei planes P1, [P1: C(20) until C(25)] and P(2) [P2: C(20) until C(25); symmetry: $-x, -y + 2, -z + 2$] with a mean interplanar spacing of 3.345 Å. The two rings have a centroid separation of 3.534 Å, corresponding to a ring-centroid offset of 1.139 Å.

3.3. Interconversion of complexes *2* and *3* in aqueous solution

The identification of the ultimate entity that crosses the blood–brain barrier is of the highest importance for understanding the mode of action of anticonvulsant drugs of the (salicylato)-metal complexes family [32]. In this regard, the behavior of complexes **2** and **3** in aqueous solution was investigated, revealing a facile interconversion between the two compounds.

The conversion of **2** to **3** was revealed through the following water/1-octanol extraction experiment [11,33]. Salt **2** (300 mg, 6.1×10^{-4} mol) was dissolved in deionized water (30 ml). This solution was extracted with 1-octanol (30 ml) at room temperature. The extraction was repeated four times and the 1-octanol extracts combined. After removal of 1-octanol by vacuum distillation at 1 Torr, ligand **1** (71 mg), was obtained as a pale yellow solid, which was unambiguously identified by comparison with an authentic sample using R_f values in thin layer chromatography and ^{1}H NMR spectroscopy. During this experiment, the color of the aqueous phase changed from pale yellow to bright orange. Evaporation of this solution at room temperature under vacuo gave complex **3** as a microcrystalline bright red solid (174 mg, 93% yield). The above outcome can be interpreted on the basis of two-step equilibrium of salt **2** in aqueous medium, depicted in Fig. 13. The first step of this process involves the dissociation of the salt into the 3-hydroxy-4-nitrobenzoate anion and the magnesium(II) cation. These, in turn, may interconvert through proton transfer into ligand **1** and complex **3** (in which one metal atom is coordinated to one ligand molecule acting as a bidendate linker through its carboxylato and phenoxo groups). Because of its

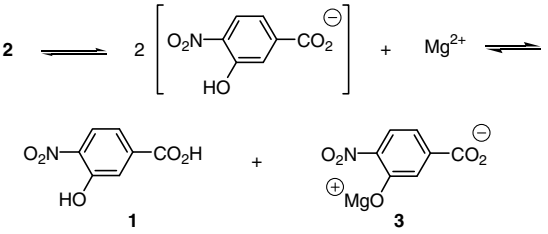

Fig. 13. Equilibrium of salt **2** in aqueous solution. The water molecules coordinated to the metal atom have been omitted for clarity.

marked lipophilicity (calculated log*P* = 1.78) [31], ligand **1** is extractable with 1-octanol (an operation that drives the equilibrium toward partners **1** and **3**), while the hydrophilic complex **3** remains in the aqueous phase.

The conversion of **3** to **2** was revealed through the following experiment. To a solution of complex **3** (0.157 g, 0.5×10^{-3} mol) in 2 ml of water was added a solution of ligand **1** (0.092 g, 0.5×10^{-3} mol) in 2 ml of ethanol at room temperature. The bright orange color of the solution changed instantaneously to pale yellow. After evaporation of the solvents, salt **2** was obtained in quantitative yield.

3.4. Potentiometric measurements of ligand *1*

Since the magnesium(II) complexes **2** and **3** correspond to ligand **1** (3-hydroxy-4-nitrobenzoic acid) in its mono– and dianionic states, respectively, the protonation constants and UV–Vis spectra of **1** as a function of the pH were determined. The distribution of species as a function of pH were also investigated, involving potentiometric measurements and simulation studies.

3.4.1. Determination of the protonation constants of *1*

The protonation constants (p*K*a) of the acidic functions of 3-hydroxy-4-nitrobenzoic acid (**1**) have been calculated. The carboxylic group (p*K*a = 3.106 ± 0.003) is more acidic than benzoic acid (4.20), in agreement with the acid-strengthening effect of the electron-withdrawing nitro group in the *para* position (3.44 for 4-nitrobenzoic acid) and of the phenol function in the *meta* position (4.08 for 3-hydroxybenzoic acid). Concerning the phenol function, the lowest value observed ($pK_a = 6.590 \pm 0.002$), compared to phenol itself (9.96), is in agreement with the electron-withdrawing effect of both the nitro (7.22 for 2-nitrophenol) and carboxylic groups.

3.4.2. UV–Vis spectra of *1* as a function of pH

In the 200–600 nm region, at high acidic pH values, 3-hydroxy-4-nitrobenzoic acid (**1**) displays three absorption bands centered at around 211, 276 and 353 nm (Fig. 14 and Table 6). These are all $\pi \rightarrow \pi^*$ transitions corresponding to $A_{1g} \rightarrow E_{1u}$ (E_1-band), $A_{1g} \rightarrow B_{1u}$ (E_2-band) and $A_{1g} \rightarrow B_{2u}$ (B–band) transitions in the benzene ring, corrected by the bathochromic shift due to the auxochromic 3,4-substituted groups [34]. The shoulder present at 244 nm could be assigned to the $n \rightarrow \pi^*$ transitions of the carboxyl function whereas the weak $n \rightarrow \pi^*$ transition of the nitro function is submerged by the E_2 band at 276 nm. As the pH is increased, the deprotonation of the carboxyl function induces a bathochromic shift in the $A_{1g} \rightarrow B_{1u}$ transition. Above pH 8.0, the deprotonation of the phenol function results in a general bathochromic shift of all the bands, being stronger for the E_1-band and the B-bands, the last one being responsible of the color change from pale yellow to bright orange. Isosbestic points are present at 199, 235, 318 and 362 nm.

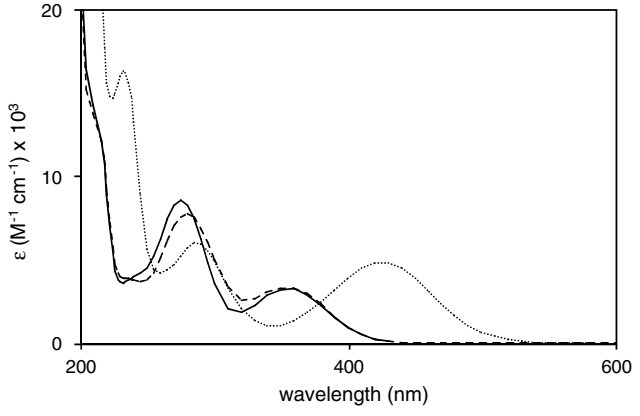

Fig. 14. UV–visible spectra of 3-hydroxy-4-nitrobenzoic acid (**1**) in aqueous solution as a function of pH: pH 2.0 (——); 4.0 (– – –); 10.2 (. . .); $[LH_2] = 1.0 \times 10^{-3}$ M, [NaCl] = 0.15 M.

Table 6
λmax and ε in the UV–Vis spectra of 3-hydroxy-4-nitrobenzoic acid (**1**) (LH_2) in aqueous solution as a function of the pH[a]

Species	pH	$\pi \rightarrow \pi^*$	$n \rightarrow \pi^*$	$\pi \rightarrow \pi^*$	$\pi \rightarrow \pi^*$
		E_1	(COOH)	E_2	B

LHNa	4.0	211 sh (14000)	235 sh (3815)	279 (7763)	353 (3290)
LNa_2	10.2	232 (16250)	submerged	285 (6000)	422 (4845)

[a] λ_{max} in nm, ε in $M^{-1}\,cm^{-1}$.

3.4.3. Distribution of species as a function of pH

Potentiometric measurements of the system, ligand **1** and $MgCl_2$ in the presence of NaOH were first recorded according to a previously reported procedure [35,36] (data not shown). Formation constants of species were subsequently calculated by means of ESTA [37] and MINIQUAD [38] programs. Regarding the ligand **1** (LH_2)/NaOH system, increasing the pH from 1 to 8 results in the successive formation of LHNa and LNa_2 species, as expected (Fig. 15). Regarding the ligand **1** (LH_2)/$MgCl_2$/NaOH system, increasing the pH from 2 to 8 results in the successive formation of $(LH)_2Mg$ (complex **2**), LMg (complex **3**) and $Mg(OH)_2$ species (Fig. 16). It is noteworthy that the optimal pH values for the formation of Mg(II) complexes **2** and **3** (ca 4.7 and 7.0, respectively) are

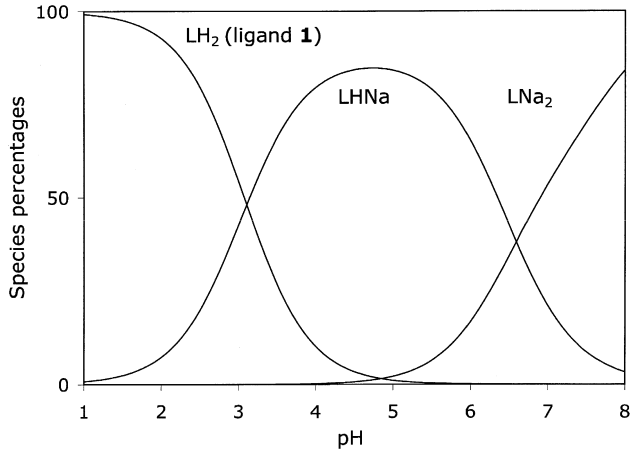

Fig. 15. Distribution of species as a function of pH in the ligand **1**/NaOH system (ligand speciation) ($[LH_2] = 10^{-3}$ M).

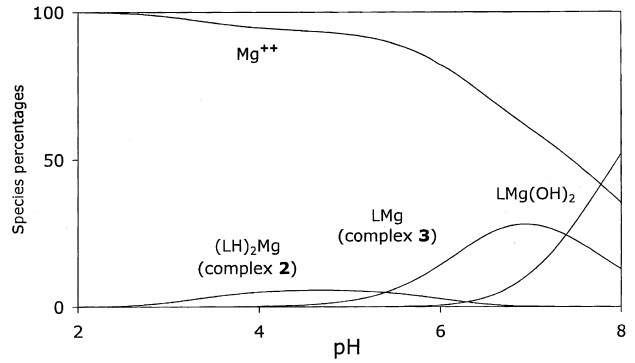

Fig. 16. Distribution of species as a function of pH in the ligand **1**/$MgCl_2$/NaOH system (metal speciation) ($[LH_2] = [MgCl_2] = 10^{-3}$ M).

close to the pH values of the 2×10^{-2} M water solutions of these complexes (4.85 and 6.42 for **2** and **3**, respectively, see Sections 2.3.1 and 2.3.2).

4. Conclusion

The crystal structures of two magnesium(II) complexes of 3-hydroxy-4-nitrobenzoic acid (**1**) have been reported. The first complex (**2**) is comprised of two organic anions and one hexaaquamagnesium cation. In these ionic entities, the anions do not coordinate directly to magnesium, but there are important hydrogen-bonded interconnections between the cations and anions. The second complex (**3**) consists of an original zwitterionic structure comprising one organic ligand in its dianionic state and one magnesium cation. One of the most salient features in this structure is the direct ligation of the magnesium to the phenoxo group. The carboxylate anion of this zwitterion is not directly coordinated to the magnesium cation, but there are important hydrogen bonds joining the zwitterionic units. The 3D supramolecular architectures of complexes **2** and **3** are also stabilized by two types of stacking interactions involving the aromatic part of ligand **1**.

An interesting interconversion between the two complexes was observed in aqueous solution, involving the addition/release of one ligand molecule. This phenomenon was supported by potentiometric measurements of ligand **1** in the presence of Na^+ and Mg^{++} cations. The distributions of species as a function of pH were also determined through simulation studies.

Appendix A. Supplementary data

CCDC 655902 and 675372 contain the supplementary crystallographic data for **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.03.027.

ABSTRACT

A set of three copper(II) complexes, $[Cu^{II}(dpq)_2Cl_2]$ (**1**), $[\{Cu^{II}(dpq)_2(SCN)\}\{Cu^{II}(dpq)(SCN)_3\}]$ (**2**) and $[Cu^{II}(dpq)_2(N_3)](ClO_4)$ (**3**), derived from the ligand dipyrido[3,2-f: 2′,3′-h]-quinoxaline (dpq) have been reported. The molecular and the crystal structures of all the complexes have been determined by X-ray crystallography. The structural results confirm that depending on the selected anions, a great variety of geometries are observed with copper(II). The light blue compound **1** has a distorted octahedral geometry with a $[CuN_4Cl_2]$ core. Compound **2** consists of a cationic part, $\{Cu^{II}(dpq)_2(SCN)\}^+$, and an anionic part, $\{Cu^{II}(dpq)(SCN)_3\}^-$. In both the cationic and anionic part, the geometry around the copper(II) ion is distorted square pyramidal. In compound **3**, one azide anion is coordinated to the metal centre providing a distorted square pyramidal geometry. The quinoxaline ring in **1** and **2** is involved in intermolecular π–π interactions leading to the generation of a sinusoidal chain in **1** and a zigzag chain in **2**. The electronic absorption spectra and the redox behaviour of all the complexes have been studied in dimethyl sulfoxide.

1. Introduction

Metal ion complexes with bidentate ligands continue to be of strong interest in many areas of chemistry. 2,2′-Bipyridine (bpy) and 1,10-phenanthroline (phen) have been extensively used as chelating ligands in both analytical and preparative coordination chemistry [1]. More recently, systematic studies of substituted bipyridines, phenanthrolines and other α-diimine derivatives have been undertaken [2–9]. Ligands based on the 2,2′-bipyridine (bpy) and 1,10-phenanthroline (phen) frameworks have played a particularly important role because of the imbedded π electron system present. Their complexes with metal ions spanning much of the periodic table have led to a wide variety of systems with interesting structural, spectroscopic, catalytic, biomimetic, DNA binding and cleavage properties [10,11]. A key feature of these six-membered heterocyclic rings is their π-electron deficiency, which make them excellent π-acceptor ligands. Consequently, they have been used to stabilize various metal complexes in lower oxidation states [12,13].

Of particular interest, copper complexes of these ligands have been studied for a variety of reasons, including intense interest in their catalytic properties in organic synthesis, control in polymerization reactions and biomimetic behaviour. These types of copper complexes have also been studied for their relevance to the active-site structures of metalloproteins [14]. The redox chemistry of copper polypyridines is of particular interest as they undergo significant changes in their coordination geometry during the redox process. The influence of the inner coordination-sphere upon the redox properties of the copper(II/I) couple has received considerable attention, being stimulated, to a large part, by the importance of this redox couple in enzymes. The ability to deliberately control the microstructure of a coordination polymer by using macroscopic principles, through dissociation/binding ligands from/to metal centres by an applied potential can have numerous material applications [15].

Phenanthroline-based ligands such as dipyrido[3,2-f: 2′,3′-h]-quinoxaline (dpq), dipyridophenazine (dppz) and 7,8-dimethylpyridophenazine (dppx) with an extended planar quinoxaline moiety, can act as good bidentate ligands as well as good binders to DNA. Several ruthenium(II) complexes, such as $[RuL_2(dpq)]^{2+}$ (L = bpy or phen), have been synthesized because they bind to DNA strongly by intercalating the aromatic dpq ligand between the base pair. Moreover, on binding to DNA they strongly luminesce to act as "light switches" [16]. More recently it has also been shown that copper(II) complexes having photoactive and DNA binding ligands cleave DNA on irradiation with red light [17]. Ternary copper(II) complexes derived from tridentate ONO and ONS ligands and the DNA binding ligand dpq cleave DNA on exposure to red light [18]. We have earlier reported the syntheses, X-ray crystal structures, spectroscopic properties and redox activities of zinc(II), copper(I), copper(II), nickel(II), cobalt(II), cobalt(III), iron(II) and

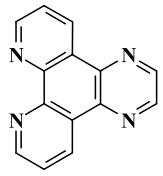
manganese(II) complexes of dpq [19]. In this present study, we have reported the influence of various anions such as Cl^-, SCN^- and N_3^- on the structural, spectroscopic and electrochemical properties of copper(II) complexes of the dpq ligand.



dpq

2. Experimental

2.1. Materials

All the chemicals were obtained from commercial sources and were used as received. The solvents were dried and purified according to standard methods [20]. 1,2-Diaminoethane was dried over potassium hydroxide before vacuum distillation. 1,10-Phenanthroline-5,6-dione and dipyrido[3,2-f: 2′,3′-h]-quinoxaline (dpq) were prepared according to the reported methods [19,21].

Caution: The perchlorate salts reported here are potentially explosive and should be handled with care.

2.2. Preparation of metal complexes

2.2.1. $[Cu^{II}(dpq)_2Cl_2]$ (**1**)

To a stirred suspension of dpq (0.23 g, 1 mmol) in acetonitrile (20 mL) was added an acetonitrile solution (5 mL) of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.19 g, 0.5 mmol) followed by an excess NaCl solution (5 mL) in water (0.12 g, 2 mmol). The light blue crystalline product that deposited after 15 min of stirring was collected by filtration and washed with a little acetonitrile-water (1:1) mixture. The filtrate was kept for an overnight period, during which time light blue single crystals suitable for X-ray crystallography appeared. Yield: 0.15 g (50%). *Anal.* Calc. for $C_{28}H_{16}N_8Cl_2Cu$: C, 56.15; H, 2.69; N, 18.70. Found: C, 56.24; H, 2.72; N, 18.65%. UV–Vis–NIR (λ_{max}, nm/ε, $M^{-1}\,cm^{-1}$): 250(100000), 295(35000), 350(10000), 450(880), 740(125), 925(95).

2.2.2. $[\{Cu^{II}(dpq)_2(SCN)\}\{Cu^{II}(dpq)(SCN)_3\}]$ (**2**)

This compound was prepared in the same way as described for **1**, using NaSCN solution in water instead of NaCl. Yield: 0.20 g (74%). *Anal.* Calc. for $C_{46}H_{24}N_{16}S_4Cu_2$: C, 52.31; H, 2.29; N, 21.22. Found: C, 52.40; H, 2.35; N, 21.15%. IR (KBr): νSCN^- = 2098s, 2071s cm^{-1}. UV–Vis–NIR (λ_{max}, nm/ε, $M^{-1}\,cm^{-1}$): 260(120000), 300(44000), 340(13000), 405(1300), 710(140), 940(sh).

2.2.3. $[Cu^{II}(dpq)_2(N_3)](ClO_4)$ (**3**)

This compound can be obtained following the same method described above for **1** and **2** using NaN_3 solution in water. Yield: 0.60 g (75%). *Anal.* Calc. for $C_{28}H_{16}N_{11}O_4ClCu$: C, 50.23; H, 2.40; N, 23.01. Found: C, 50.30; H, 2.42; N, 22.95%. IR (KBr): ν_{as} N_3^- = 2036s, $\nu_s N_3^-$ = 1338m, $\nu_s ClO_4^-$ = 1120s, 1081s, 622m cm^{-1}. UV–Vis–NIR (λ_{max}, nm/ε, $M^{-1}\,cm^{-1}$): 260(105000), 290(33000), 340(9000), 400(2000), 680(110), 1050(sh).

2.3. Physical measurements

The C, H and N analyses were performed on a Perkin–Elmer 2400 II elemental analyzer. IR spectra were recorded using KBr disks on a Shimadzu FTIR 8400S spectrometer. The electronic absorption spectra were obtained with a Perkin–Elmer 950 UV/Vis/NIR spectrophotometer. The electrochemical measurements were carried out with a BAS 100 B electrochemistry system using a three-electrode assembly comprising a glassy carbon working electrode, Pt auxiliary electrode and an aqueous Ag/AgCl reference

electrode. The cyclic voltammetric (CV) and square wave voltammetric (SWV) measurements were carried out at 25 °C under a nitrogen atmosphere at room temperature. The solutions were 1 mmol dm^{-3} in complexes and 0.1 mol dm^{-3} in tetraethylammonium perchlorate (TEAP) as the supporting electrolyte. All CV experiments were carried out at a scan rate of 100 mV/s. The reference electrode was separated from the bulk electrolyte by a salt bridge containing the supporting electrolyte in nitromethane solution. IR compensation was made automatically during each run. Under the experimental conditions the $E_{1/2}$ values of the ferrocene/ferrocenium couple was observed at 390 mV in dimethyl sulfoxide.

2.4. Crystallography

For complexes **1**–**3** single crystals suitable for X-crystallography were obtained by slow evaporation of the filtrate of the reaction mixture. The crystals were mounted on glass fibres using perfluoropolyether oil. Intensity data were collected on a Bruker-AXS SMART APEX II diffractometer at 293(2) K using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The data were processed with SAINT [22] and absorption corrections were made with SADABS [22]. The structures were solved by direct and Fourier methods and refined by full-matrix least-squares methods based on F^2 using SHELX-97 [23]. For the structure solutions and refinements, the SHELX-TL software package [24] was used. The non-hydrogen atoms were refined anisotropically, while the hydrogen atoms were placed at geometrically calculated positions with fixed thermal parameters. Crystal data and details of data collection are listed in Table 1.

3. Results and discussion

3.1. Synthesis

The ligand dipyrido[3,2-f: 2′,3′-h]-quinoxaline, abbreviated as dpq, has been obtained by the [1+1] cyclocondensation between 1,10-phenanthroline-5,6-dione and 1,2-diaminoethane. All the complexes **1**–**3** are obtained by the direct reaction between the ligand dpq, $Cu(ClO_4)_2 \cdot 6H_2O$ and NaX [X = Cl (**1**), SCN (**2**), N_3 (**3**)] in a 2:1:4 ratio. The single crystals were grown by slow evaporation of the filtrate after collecting the precipitated bulk compound.

3.2. Infrared spectra

The characteristic IR spectral bands for the anions of complexes **2** and **3** are given in the Section 2, while full details are given in the supplementary material. The ligand dpq has four strong bands at around 1575, 1465, 1392 and 740 cm^{-1} due to the phenanthroline moiety. In all the complexes **1**–**3**, these four characteristic bands have undergone shifts in energy. The band of dpq at 1392 cm^{-1} is split into bands at 1405 and 1385 cm^{-1} in all the compounds.

In the thiocyanate complex [{$Cu^{II}(dpq)_2(SCN)$}{$Cu^{II}(dpq)(SCN)_3$}] (**2**), in addition to the above discussed features observed for dpq, two strong sharp bands due to the thiocyanate are observed at 2098 and 2071 cm^{-1}, the positions of which are normally considered [25] to be due to terminally N-coordinated NCS^- ligands. Two bands are observed due to the thiocyanate because both the cationic and anionic parts in compound **2** possess thiocyanate ligands, which gives rise to two bands. In the azide complex [$Cu^{II}(dpq)_2(N_3)$](ClO_4) (**3**), a strong band due to the $\nu_{as}N_3^-$ vibration is observed at 2036 cm^{-1} and a medium band due to the $\nu_sN_3^-$ vibration is observed at 1338 cm^{-1}. Complex **3** also exhibits characteristic bands due to the perchlorate ion at *ca.* 1100 cm^{-1} and *ca.* 622 cm^{-1}.

3.3. Crystal structures

3.3.1. [$Cu^{II}(dpq)_2Cl_2$] (**1**)

The molecular structure of the complex [$Cu^{II}(dpq)_2Cl_2$] (**1**) is shown in Fig. 1 and the relevant bond distances and angles are given in Table 2. A two-fold axis passes mid-way through the metal-bound chloride atoms Cl(1) and Cl(1A). The coordination environment around the six-coordinated metal centre [CuN_4Cl_2] may be considered as distorted octahedral. The atoms N(2), N(2A), Cl(1) and Cl(1A) form the best plane, although the atoms N(2)/N(2A) are displaced from the mean plane by ±0.195(2) Å and Cl(1)/Cl(1A) by ±0.164(2) Å. The metal atom lies exactly on the mean plane. The nitrogen atoms N(1) and N(1A) are *trans*-axially disposed to the metal centre, the equatorial Cu–N distances [2.1731(18) Å] are somewhat longer than the axial Cu–N distances [2.0475(16) Å], while the equatorial Cu–Cl distances [2.5456(8) Å] are much longer. The *trans*-axial N(1)–Cu–N(1A) angle is 168.14(7)°, while the *trans*-equatorial N(2)–Cu–Cl(1) angle is 171.09(5)°.

Another interesting structural feature of this compound is the presence of two types of π–π interaction. First one is between the pyrazine ring C(13)C(14)N(3)C(11)C(12)N(4) and the aromatic ring C(11)C(12)C(9)C(10)C(5)C(4) [the distance between the two centroids is 3.513 Å] and second one is between two pyrazine rings of adjacent molecules [the distance between the two centroids is 3.732 Å]. These two π–π interactions give rise to a sinusoidal pattern in the molecule as shown in Fig. 2.

3.3.2. [{$Cu^{II}(dpq)_2(SCN)$}{$Cu^{II}(dpq)(SCN)_3$}] (**2**)

In complex **2**, the asymmetric unit contains one complex cation and one complex anion species *viz.* $\{Cu^{II}(dpq)_2(SCN)\}^+$ and $\{Cu^{II}(dpq)(SCN)_3\}^-$. An ORTEP projection of the cation and anion in **3** is shown in Fig. 3a and b.

In the five-coordinated copper(II) cationic part, $\{Cu^{II}(dpq)_2(SCN)\}^+$, the metal centre adopts a distorted square pyramidal geometry (Fig. 3a) with the atoms N(5)N(9)N(10)N(16) forming the basal plane, while the pyridyl nitrogen N(6) occupies the apical position. The atoms N(5), N(9), N(10) and N(16) are deviated from their least-squares plane by *ca.* ±0.152(9) Å. The copper(II) centre is displaced from the basal mean plane by 0.069 Å towards the N(6)

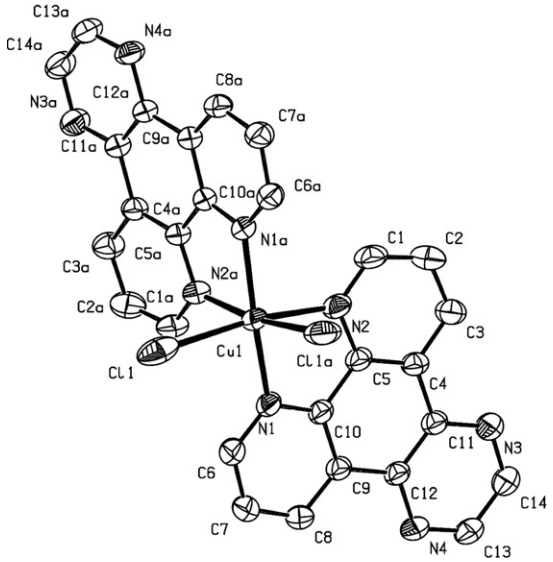

Fig. 1. An ORTEP representation of the molecule [$Cu^{II}(dpq)_2Cl_2$] (**1**) showing 50% probability displacement ellipsoids. 'A' indicates symmetry operation: (−*x*, *y*, 1/2 − *z*).

[a] For **1** 'A' indicates: $-x, y, 1/2 - z$.

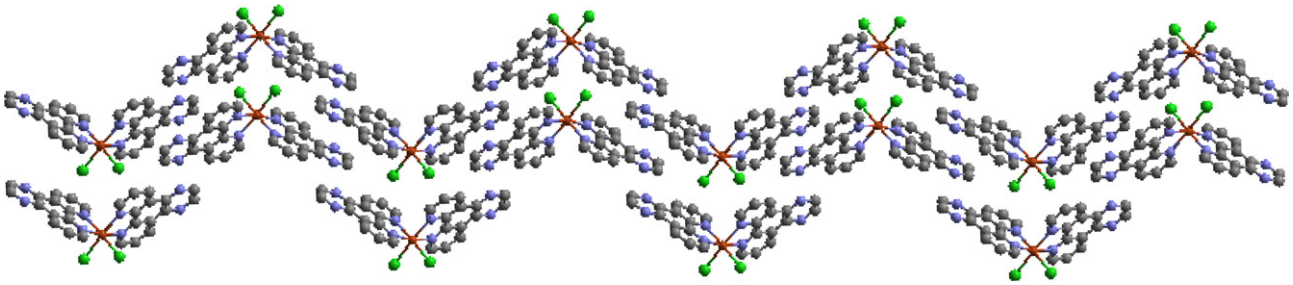

Fig. 2. Sinusoidal growth of the molecule $[Cu^{II}(dpq)_2Cl_2]$ (**1**) through π–π stacking interactions.

atom. The distortion of the geometry from a square pyramidal or trigonal bipyramidal geometry can be described in terms of the parameter τ [26] (the parameter $\tau = (\varphi_1 - \varphi_2)/60$, where φ_1 and φ_2 are the largest and second largest N–Cu–N angles; the value of $\tau = 1$ corresponds to trigonal bipyramidal and $\tau = 0$ to square pyramidal geometry, respectively), which in this case is 0.114. The three Cu(1)–N(pyridyl) distances [Cu(1-)-N(5) = 2.044(4) Å, Cu(1)–N(9) = 2.021(3) Å and Cu(1)–N(10) = 2.031(3) Å] in the basal plane are longer than Cu(1)–N(thiocyanate) distance [Cu(1)–N(16) = 1.935(4) Å]. On the other hand, the axial Cu(1)–N(pyridyl) distance [Cu(1)–N(6) = 2.266(3) Å] is significantly longer relative to the Cu(1)–N(pyridyl) distances in the basal plane.

In the five-coordinated anionic part, $\{Cu^{II}(dpq)(SCN)_3\}^-$, the metal centre $[CuN_5]$ also adopts a distorted square pyramidal geometry (Fig. 3b), which is evident from its τ value of 0.13. The donor atoms N(1), N(2), N(14) and N(15) around copper(II) form a basal plane from which the metal atom is displaced towards the apical coordination site N(13) by 0.199(3) Å. In the basal plane, the two Cu(2)–N(pyridyl) distances [Cu(2)–N(1) = 2.030(4) Å, Cu(2)–N(2) = 2.028(4) Å] are almost the same, whereas the two Cu(2)–N(thiocyanate) distances [Cu(2)–N(14) = 1.939(4) Å, Cu(2)–N(15) = 1.950(4) Å] vary to some extent. The apical Cu(2)–N(thiocyanate) distance [Cu(2)–N(13) = 2.293(4) Å] is considerably longer relative to the Cu(2)–N(thiocyanate) distances in the basal plane. The relevant bond distances and bond angles are given in Table 2.

Similar to complex **1**, complex **2** also possesses three types of extensive π–π interactions which produce a zigzag chain in the molecule, as shown in Fig. 4. The first one is between N(8)C(41)C(40)N(7)C(35)C(43) of the pyrazine ring in the cationic part with the C(31)C(30)C(29)C(28)C(35)C(43) aromatic ring of an adjacent cationic part, for which the distance between the two centroids is 3.586 Å. In the second case, the N(3)C(44)C(45)N(4)C(8)C(9) pyrazine ring of the anionic part interacts with the N(12)C(48)C(49)N(11)C(23)C(47) pyrazine ring of the adjacent cationic part [the distance between the two centroids is 3.554 Å]. This π–π interaction also exists between two adjacent anionic parts. The N(3)C(44)C(45)N(4)C(8)C(9) pyrazine ring in the anionic part is involved in a π–π interaction with the pyrazine ring of the adjacent anionic part. In this case, the distance between the two centroids is 3.822 Å.

3.3.3. $[Cu^{II}(dpq)_2(N_3)](ClO_4)$ (**3**)

The ORTEP representation of the cation $[Cu(dpq)_2(N_3)]^+$ in **3** is shown in Fig. 5 and the pertinent bond distances and angles are given in Table 2. The five-coordinated copper(II) centre $[CuN_5]$ appears to be lying between trigonal bipyramidal and square pyramidal geometries. In complex **3** $\tau = 0.224$, that is the coordination polyhedra can be considered as a distorted square pyramid. The distorted square pyramidal geometry of the copper centre is based on consideration of the N(1), N(2), N(6) and N(9) atoms forming the basal plane, which, however, are displaced from the mean plane by *ca.* ±0.164(11) Å. In this description, the metal centre is displaced from the basal plane by 0.124(2) Å towards the axial donor N(5). The distances of the copper centre from the donor atoms in the square plane are unequal; the Cu–N(1) [2.015(2) Å], Cu–N(2) [2.034(3) Å] and Cu–N(6) [2.028(2) Å] distances are considerably

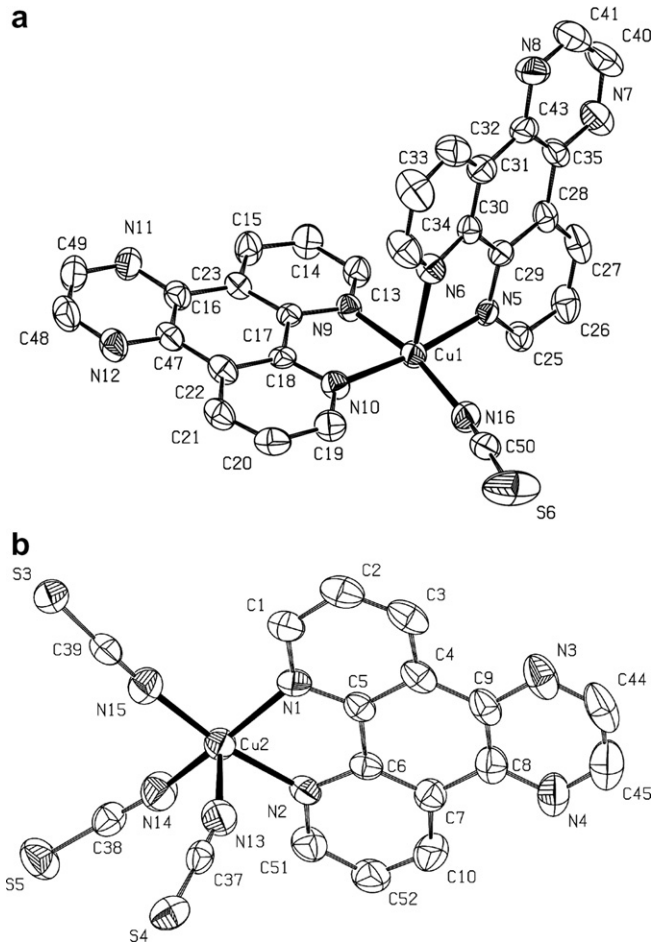

Fig. 3. (a) An ORTEP representation of the complex cation $[Cu^{II}(dpq)_2(SCN)]^+$ and (b) complex anion $[Cu^{II}(dpq)(SCN)_3]^-$ in the complex **2** showing 50% probability displacement ellipsoids.

longer than the Cu–N(9) distance [1.972(3) Å]. The axial distance Cu–N(5) [2.193(2) Å], however, is somewhat longer than the equatorial bond lengths.

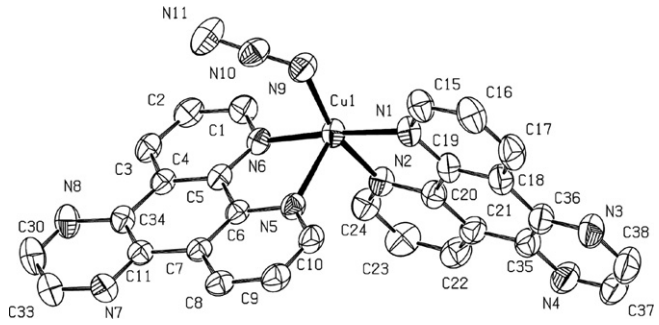

Fig. 5. An ORTEP representation of the cation of the complex $[Cu^{II}(dpq)_2N_3](ClO_4)$ (**3**) showing 50% probability displacement ellipsoids.

In the basal plane, the distances N(2)···N(6) = 3.005 Å, N(6)···N(9) = 2.875 Å and N(1)···N(9) = 2.876 Å are longer relative to N(1)···N(2) = 2.631 Å, which indicates deviations from a regular square plane. Again, considerable departure of the relevant angles in the basal plane [N(1)–Cu–N(2) = 81.04(10)°, N(1)–Cu–N(9) = 92.30(12)°, N(2)–Cu–N(6) = 95.44(10)° and N(6)–Cu–N(9) = 91.88(12)°] from the desired angle of 90° are also indicative of deviation from an ideal square pyramidal geometry.

Like compounds **1** and **2**, the N(3)C(36)C(35)N(4)C(37)C(38) pyrazine ring of compound **3** is involved in an intermolecular π–π interaction with the C(21)C(35)C(36)C(18)C(19)C(20) aromatic ring [the distance between the two centroids is 3.804 Å] of an adjacent molecule. But, unlike **1** and **2**, this π–π interaction does not give rise to any specific pattern in compound **3**. This may be due to the presence of the tetrahedral perchlorate anion, which in turn inhibits the close approach of the adjacent molecules for the strong π–π interaction required for the formation of a polymeric pattern.

3.4. Electronic spectra

The absorption spectroscopic behaviour of compounds **1**–**3** have been studied in dimethyl sulfoxide. The UV–Vis–NIR spectral data for these compounds in dimethyl sulfoxide are given in Section 2.

All of the complexes exhibit three very strong absorption bands at 250–260, 290–300 and 340–350 nm due to the ligand centred π–π* transitions.

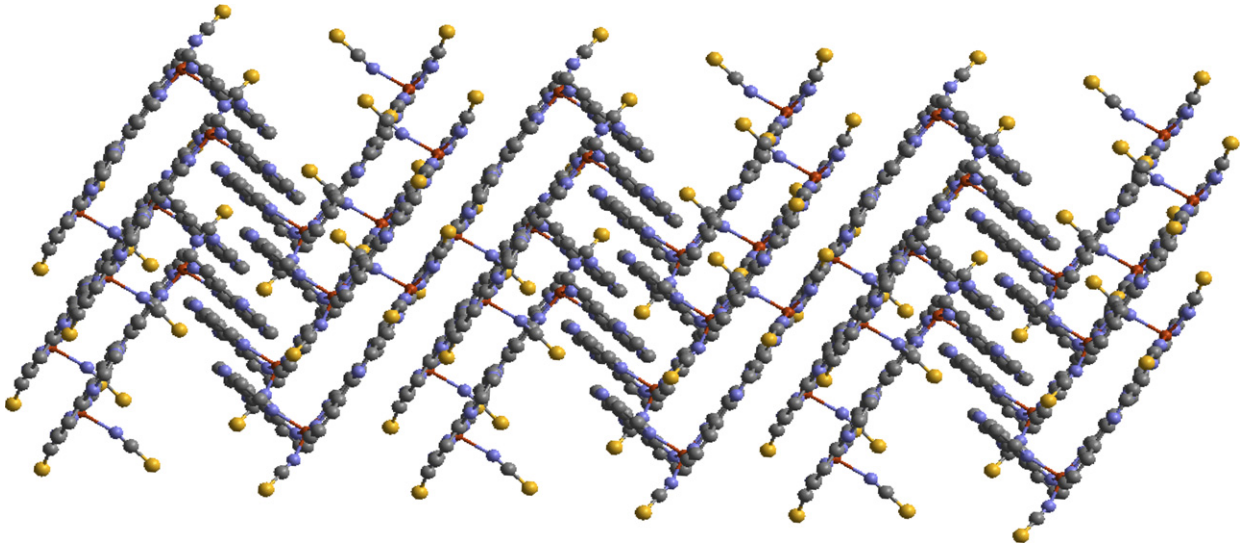

Fig. 4. Zigzag chain in the molecule $[\{Cu^{II}(dpq)_2(SCN)\}\{Cu^{II}(dpq)(SCN)_3\}]$ (**2**) through π–π stacking interactions.

The six-coordinated octahedral copper complex exhibits three bands in the visible range at 450 nm ($\varepsilon = 880\ M^{-1}\ cm^{-1}$), 740 nm ($\varepsilon = 120\ M^{-1}\ cm^{-1}$) and 925 ($\varepsilon = 95\ M^{-1}\ cm^{-1}$). The well-resolved peak at 450 nm is most likely due to a $Cl^- \rightarrow Cu^{II}$ ligand-to-metal charge transfer (LMCT) [27] transition, while the other two bands observed are due to d–d transitions.

Both compounds **2** and **3** exhibit a peak at around 400 nm and an unresolved broad band between 600 and 1300 nm. Clearly, the peak at around 400 nm in both compounds is due to a ligand-to-metal charge transfer. It is of interest to note that although for both compounds the ligand-to-metal charge transfer (LMCT) transitions $SCN^- \rightarrow Cu^{II}$ (**2**) and $N_3^- \rightarrow Cu^{II}$ (**3**) occur at almost same energy 25 000 cm^{-1}, their intensities are very different. It is documented, especially for copper(II) complexes, that a single d–d band with a high energy shoulder is indicative of a trigonal bipyramidal stereochemistry around the metal centre, while an absorption envelop with a low energy shoulder is characteristic of a square pyramidal geometry. Some pentacoordinated copper(II) complexes with two d–d bands of equal intensity appear to possess an intermediate distorted geometry [27]. The broadness of these bands with a low energy shoulder are indicative of the presence of more than two transitions at lower energies, as expected for copper(II) in a distorted square pyramidal environment. Indeed, deconvolution of the absorption spectrum of **3** in dimethyl sulfoxide by Gaussian line-shape analysis gives rise to three peaks (shown in Fig. 6), which are due to the $d_{xz}, d_{yz} \rightarrow d_{x^2-y^2}$ ($\lambda = 670$ nm, $\varepsilon = 70\ M^{-1}\ cm^{-1}$), $d_{xy} \rightarrow d_{x^2-y^2}$ ($\lambda = 705$ nm, $\varepsilon = 52\ M^{-1}\ cm^{-1}$) and $d_{z^2} \rightarrow d_{x^2-y^2}$ ($\lambda = 1060$ nm, $\varepsilon = 20\ M^{-1}\ cm^{-1}$) transitions in a descending order of energy.

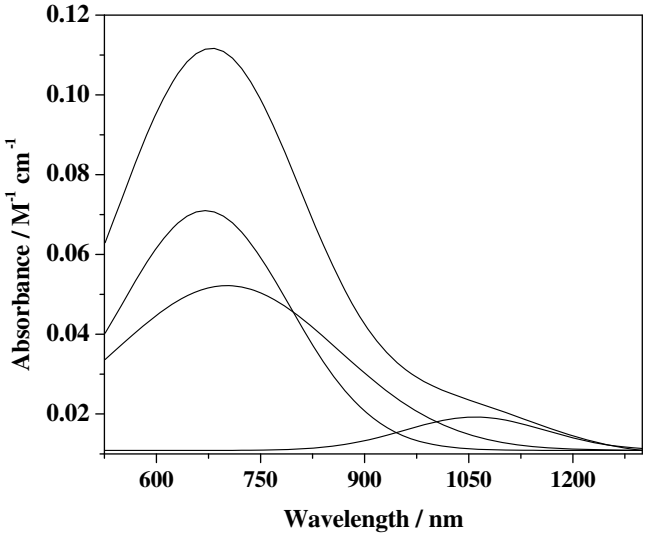

Fig. 6. Visible and near infrared absorption spectra of the complex $[Cu^{II}(dpq)_2N_3](ClO_4)$ (**3**) in dimethyl sulfoxide (10^{-3} M). The three bands below the spectrum are obtained by Gaussian line-shape analysis and added together give the experimental line.

Table 3
Electrochemical data[a] for complexes **1**–**3** in dimethyl sulfoxide

Compound	$E_{1/2}$[b] (mV)	ΔE_p[c]
$[Cu^{II}(dpq)_2Cl_2]$ (**1**)	90	75
$[\{Cu^{II}(dpq)_2(SCN)\}$	125, −1070 ($E_{p,c}$)	70
$\{Cu^{II}(dpq)(SCN)_3\}]$ (**2**)	−245 ($E_{p,a}$)	
$[Cu^{II}(dpq)_2(N_3)](ClO_4)$ (**3**)	50	120

[a] All the potentials are against the Ag/AgCl reference electrode.
[b] $E_{1/2}$ values are the average of those obtained from cyclic voltammetric and square wave voltammetric measurements, which are within ±5 mV.
[c] ΔE_p Refers to peak-to-peak separation at a scan rate of 100 mV/s.

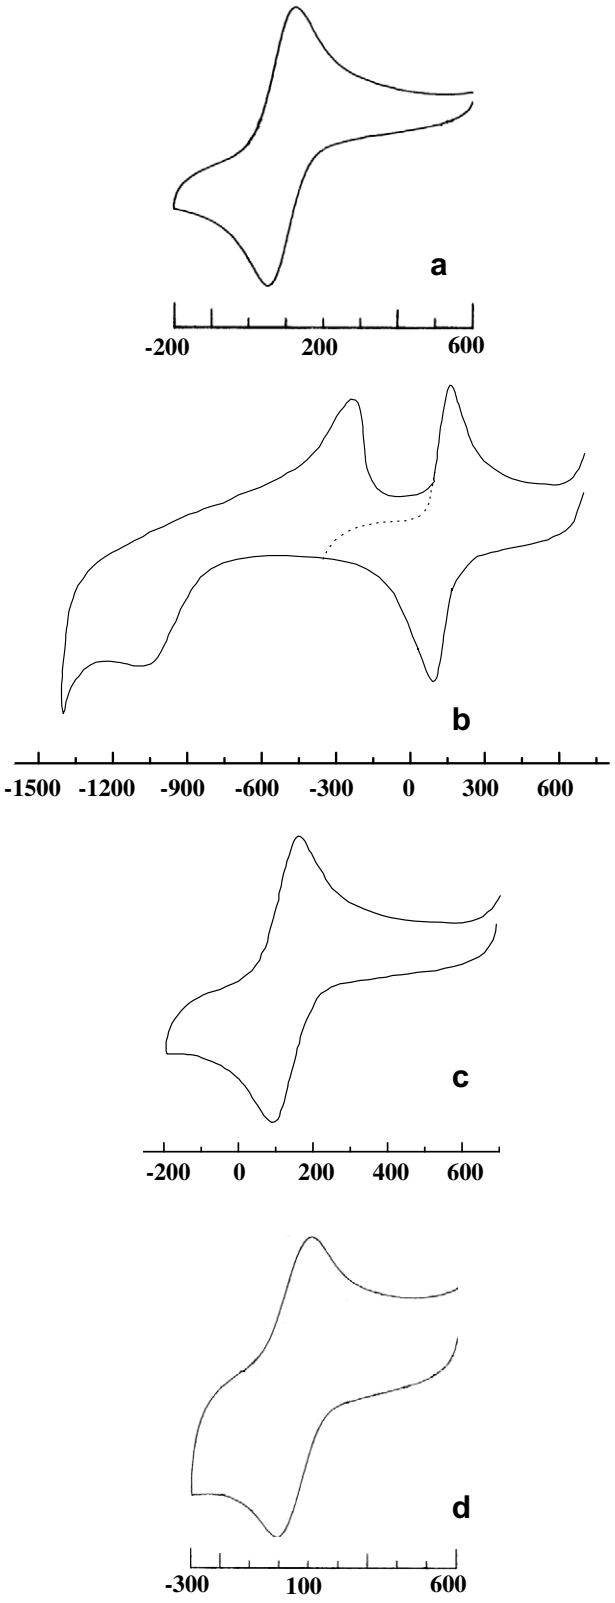

Fig. 7. Cyclic voltammograms of complexes (a) $[Cu^{II}(dpq)_2Cl_2]$ (**1**), (b) $[\{Cu^{II}(dpq)_2(SCN)\}\{Cu^{II}(dpq)(SCN)_3\}]$ (**2**) in the range 700 to −1400 mV, (c) $[\{Cu^{II}(dpq)_2(SCN)\}\{Cu^{II}(dpq)(SCN)_3\}]$ (**2**) in the range 700 to −200 mV and (d) $[Cu^{II}(dpq)_2N_3](ClO_4)$ (**3**) in dimethyl sulfoxide. Scan rate was 100 mV/s for all experiments.

3.5. Electrochemistry

The electrochemical characteristics of complexes **1**, **2** and **3** in dimethyl sulfoxide have been examined by cyclic voltammetry (cv) and square wave voltammetry (swv) and the observed redox potentials are given in Table 3.

As shown in Fig. 7a, the copper(II) complex $[Cu^{II}(dpq)_2Cl_2]$ (**1**) undergoes one electron reversible ($\Delta E_p = 75$ mV) reduction at $E_{1/2} = 90$ mV. As shown in Fig. 7b, in the potential range +700 to −1400 mV, complex **2** exhibits two cathodic responses at +90 and −1070 mV, while in the return sweep two anodic peaks are observed at −245 and +160 mV. The two cathodic peaks are evidently due to the one electron reduction processes $[Cu^{II}(dpq)_2(SCN)]^+ \rightarrow [Cu^{I}(dpq)_2(SCN)]$ (+90 mV) and $[Cu^{II}(dpq)(SCN)_3]^- \rightarrow [Cu^{I}(dpq)(SCN)_3]^{2-}$ (−1070 mV). However, the reduced species $[Cu^{I}(dpq)(SCN)_3]^{2-}$, being unstable in solution, undergoes decomposition and consequently in the return sweep the observed anodic peak at −245 is not related to the original species. To verify this, the cyclic voltammogram shown in Fig. 7c was recorded in the spectral window +700 to −200 mV. It may be noted that in this case a single reversible voltammogram with $E_{1/2} = 125$ mV and $\Delta E_p = 70$ mV is obtained with $E_{p,c} = 90$ mV and the corresponding $E_{p,a} = 160$ mV. The copper(II) complex $[Cu^{II}(dpq)_2(N_3)](ClO_4)$ (**3**) undergoes a one electron quasireversible ($\Delta E_p = 120$ mV) reduction at $E_{1/2} = 50$ mV (Fig. 7d). The variation in reduction potential of the Cu^{2+}/Cu^{+} couple for complexes **1**–**3** may be attributed to the variation of electronic contribution of the different anions over the copper centre.

4. Conclusion

Copper(II) complexes (**1**–**3**) of dipyrido[3,2-f: 2′,3′-h]-quinoxaline (dpq) have been synthesized and structurally characterized. Various spectroscopic and electrochemical properties of these compounds have been studied.

The most significant aspect of the study is the isolation and structural characterization of three copper(II) complexes of dpq. The structure determination of compound $[Cu^{II}(dpq)_2Cl_2]$ (**1**) has revealed that copper(II) has a hexacoordinated geometry and can be best described as a slightly distorted octahedral geometry with a $[CuN_4Cl_2]$ core around the copper ion. The structure determination of compound **2** has established the presence of one complex cation and one complex anion in the asymmetric unit, *viz.* $\{Cu^{II}(dpq)_2(SCN)\}^+$ and $\{Cu^{II}(dpq)(SCN)_3\}^-$. In both the cationic and anionic part, the geometry around copper(II) is distorted square pyramidal with $\tau = 0.114$ [for $\{Cu^{II}(dpq)_2(SCN)\}^+$] and $\tau = 0.13$ [for $\{Cu^{II}(dpq)(SCN)_3\}^-$]. In the crystal lattice of complexes **1** and **2**, the quinoxaline and aromatic rings of the complex unit are involved in intermolecular π–π interactions which leads to the generation of a sinusoidal chain in complex **1** and a zigzag chain in complex **2**. The compound $[Cu^{II}(dpq)_2(N_3)](ClO_4)$ (**3**) also shows a distorted square pyramidal geometry ($\tau = 0.224$) with a $[CuN_5]$ core around the copper cation. Electrochemical studies carried out for **1** and **3** in dimethyl sulfoxide show that while **1** undergoes a reversible reduction at $E_{1/2} = 90$ mV, **3** undergoes a quasireversible reduction at $E_{1/2} = 50$ mV. The electrochemical behaviour reveals that complex **2** exhibits a reversible one electron reduction at $E_{1/2} = 125$ mV and one irreversible one electron reduction at $E_{p,c} = -1070$ mV.

ABSTRACT

The unknown complex formation of Cm(III) with two hydroxamic acids, salicylhydroxamic (SHA) and benzohydroxamic acid (BHA) was studied by time-resolved laser-induced fluorescence spectroscopy (TRLFS). Hydroxamate containing chelating substances have the potential to enhance the solubility and mobility of metals and radionuclides by forming complexes. We explored the fluorescence properties, lifetimes and individual fluorescence emission spectra of the formed Cm(III) hydroxamate species. In both Cm(III)–hydroxamic acid systems a 1:1 and a 1:2 complex of the type $M_pL_qH_r$ could be identified from the fluorescence emission spectra having peak maxima at 600 and 609 nm, respectively. An indirect excitation mechanism of the Cm(III) fluorescence was observed in the presence of the hydroxamic acids. Consistent stability constants were determined by using either indirect or direct excitation mode of the Cm(III) fluorescence. In the Cm(III)–SHA system, the stability constants are $\log\beta_{111} = 16.52 \pm 0.14$ and $\log\beta_{121} = 24.09 \pm 0.62$. The complex formation constants of the Cm(III)–BHA species result to $\log\beta_{110} = 6.52 \pm 0.19$ and $\log\beta_{120} = 11.60 \pm 0.50$. The stability constants were compared to those of natural pyoverdins.

1. Introduction

The migration and mobilization of actinides by various environmental compounds is very important for the long-term risk assessment of nuclear waste disposal sites. The influence of microbes and bioligands secreted by microbes on the mobilization of trivalent actinides is little investigated [1–4]. To understand the complex interaction processes of actinides in biological systems on a molecular level, it is necessary to explore the complexation behavior of actinides with selected bioligands of relevant functionalities as model compounds. A special group of natural bioligands with a high potential to bind actinides are siderophores of the pyoverdin-type [4–11]. Pyoverdins are secreted under iron limited conditions from *Pseudomonas* ssp., which are ubiquitous aerobic soil bacteria. The preferred binding places for metals at the pyoverdin molecule are the hydroxamic acid group at the peptide chain and the catechol functionality of the chromophor [4,5]. In this study, we simulate the hydroxamic acid function identified in pyoverdins with simple model ligands, salicylhydroxamic (SHA) and benzohydroxamic acid (BHA) (Fig. 1). Of special importance is the investigation of the interaction of bioligands with long-lived actinides like uranium and curium. In previous studies [12,13], we used UV–Vis spectroscopy and time-resolved laser-induced fluorescence spectroscopy (TRLFS) to determine the stability constants of the complex formation between uranium(VI) and hydroxamic acids. Furthermore, we determined the absorption and fluorescence properties of the formed uranium(VI) species with SHA and BHA. At present, no results are available about the complex formation of hydroxamic acids with trivalent actinides, e.g., curium(III). Recently, the complexation of ^{248}Cm(III) with pyoverdins was studied by Moll et al. in 2007 [4]. Three 1:1 complexes were identified with stability constants of $\log\beta_{121} = 32.50 \pm 0.06$, $\log\beta_{111} = 27.40 \pm 0.11$, and $\log\beta_{101} = 19.30 \pm 0.17$. These large formation constants compared to other chelating agents illustrate the unique complexation properties of hydroxamate containing pyoverdin-type siderophores.

To address the lack of studies of the complexation of aromatic hydroxamic acids with Cm(III), we thus present findings regarding the complex formation of Cm(III) with two hydroxamic acids using TRLFS. Due to the excellent fluorescence properties of Cm(III), this method enabled the working at trace Cm(III) concentrations (3×10^{-7} M). We explored the fluorescence properties, lifetimes and individual fluorescence emission spectra of the formed Cm(III) species. An indirect excitation mechanism for the Cm(III) fluorescence was observed in the presence of the hydroxamic acids. The stability constants determined either by indirect (360 nm) or direct (395 nm) excitation of the Cm(III) fluorescence were compared. The determination of stability constants by indirect fluorescence excitation is a new possibility to study and validate the complexation of fluorescent actinides with ligands. The determined stability constants of the identified complexes were compared to those of

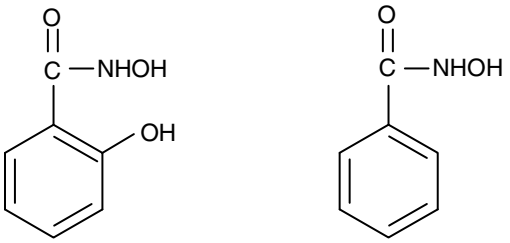

Fig. 1. Structures of the hydroxamic acids considered in this paper.

the pyoverdins [4]. The results of this study increase our understanding of the mobilization of trivalent actinides with hydroxamic acids.

2. Experimental

2.1. Solutions and reagents

A stock solution of the long-lived curium isotope ^{248}Cm ($t_{1/2} = 3.4 \times 10^5$ years) was used. The solution had the following composition: 97.3% ^{248}Cm, 2.6% ^{246}Cm, 0.04% ^{245}Cm, 0.02% ^{247}Cm, and 0.009% ^{244}Cm in 1.0 M $HClO_4$. All experiments were made in a glove box under nitrogen atmosphere at 25 °C. The sodium perchlorate, salicylhydroxamic (SHA) and benzohydroxamic (BHA) acids used were of analytical grade. Salicylhydroxamic acid was provided by Sigma–Aldrich, Germany and the other chemicals were ordered from Merck, Germany. The stock solutions of the ligands were freshly prepared for each experiment. To avoid carbonate complexation of Cm(III), carbonate free water and NaOH solution were used. The Cm(III) concentration was fixed to 3×10^{-7} M in all TRLFS measurements. The concentration of the ligands was varied between 1×10^{-5} M and 1×10^{-3} M. The pH was measured using an InLab 427 combination pH puncture electrode (Mettler-Toledo Giessen, Germany) calibrated in H^+ concentration units. The pH was changed between 2.0 and 9.0 by adding analytical grade NaOH or $HClO_4$ with an accuracy of ±0.02 units. All experiments were made in an ionic medium where the sodium concentration was kept constant at 0.1 M by adding $NaClO_4$.

In the Cm(III)–SHA system four series of experiments were made; in the first three series we investigated the complexation of Cm^{3+} and the ligand at three different ligand concentrations, 1.5×10^{-5}, 1.5×10^{-4} and 3.26×10^{-4} M, by varying the pH between 2 and 9. In the fourth run, we varied the ligand concentration between 1×10^{-5} and 1×10^{-4} M at pH 8. In the Cm(III)–BHA system three series of experiments were made with constant ligand concentrations of 1.5×10^{-4} M, 3.65×10^{-4} M and 1×10^{-3} M by varying the pH between 2 and 9.

2.2. TRLFS measurements: experimental setup

The time-resolved laser-induced fluorescence spectra were recorded at 25 ± 2 °C using a flash lamp pumped Nd:YAG-OPO laser system (Powerlite Precision II 9020 laser and Green PANTHER EX OPO from Continuum, Santa Clara, CA, USA). Further details about the laser system can be found in [4]. The system consists of an Oriel MS 257 monochromator and spectrograph with a 300 or 1200 lines mm^{-1} grating and an Andor iStar ICCD camera (Lot-Oriel Group, Darmstadt, Germany). The emission spectra were recorded in the 570–659 nm (1200 lines mm^{-1}) and 500–700 nm (300 lines mm^{-1}) ranges, respectively. The laser pulse energy was monitored using a photodiode and was between 3 and 7 mJ depending on the used excitation wavelength. A constant time window of 1 ms was applied, and two excitation wavelengths of 360 and 395 nm were used. For measuring the time-dependent emission decay, the delay time between laser pulse and camera grating was scanned with time intervals between 10 and 20 μs.

2.3. TRLFS measurements: evaluation of the fluorescence spectra

The fluorescence spectra were evaluated using the ORIGIN 7.5G (OriginLab Corporation, USA) code. The stability constants were determined using the factor analysis program SPECFIT [14]. SPECFIT calculates the complex formation constants and the single component spectra at both excitation wavelength of 395 and 360 nm based on the observed changes in the fluorescence emission spectra by varying a given physico-chemical parameter, e.g., pH or ligand concentration. We could demonstrate the successful application of SPECFIT to describe the coordination chemistry of Cm(III) in different organic systems [4,15–17]. Input parameters for the calculations with SPECFIT were the known total concentrations of Cm^{3+} and the ligand, the pH of each sample and the protonation constants of

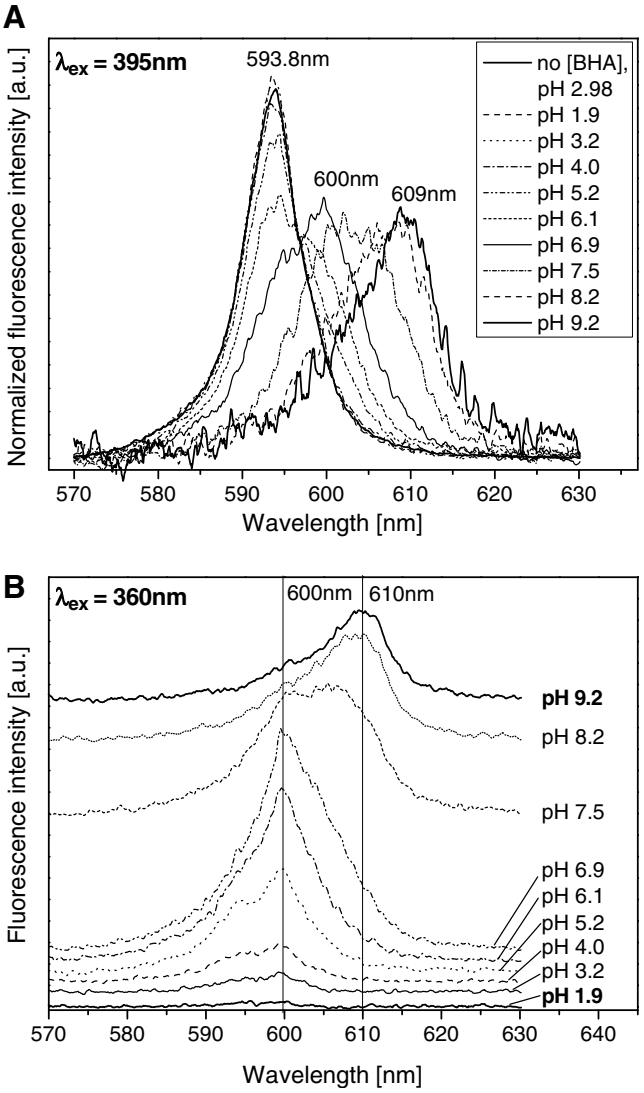

Fig. 2. Fluorescence emission spectra of 3×10^{-7} M Cm^{3+} and 1.5×10^{-4}M BHA as a function of pH at an excitation wavelength of (A) 395 nm (direct excitation mode) and (B) 360 nm (indirect excitation mode). The spectra at an excitation wavelength of 395 nm are scaled to the same peak area and the spectra at excitation wavelength of 360 nm are energy corrected.

SHA ($\log\beta_{011} = 10.05 \pm 0.03$, $\log\beta_{012} = 17.72 \pm 0.09$) and BHA ($\log\beta_{011} = 8.76 \pm 0.05$) [12]. As well, the known emission spectrum of the Cm^{3+} aquo ion was used in the SPECFIT calculations.

3. Results and discussion

3.1. Benzohydroxamic acid

The fluorescence emission spectra of 3×10^{-7} M Cm(III) with 1.5×10^{-4} M BHA in the pH range 2–9 are shown in Fig. 2. The spectra are recorded at two different excitation wavelengths. The spectra with an excitation wavelength of 395 nm are shown in Fig. 2A, the spectra with an excitation wavelength of 360 nm are summarized in Fig. 2B. The Cm^{3+} aquo ion has a characteristic fluorescence emission band maximum of 593.8 nm at an excitation wavelength of 395 nm. In Fig. 2A we observed a pronounced red shift of the emission maximum with increasing pH. This indicates the complex formation between Cm(III) and BHA. At an excitation wavelength of 360 nm (Fig. 2B) we identified an increasing fluorescence intensity and red shift of the emission maximum with increasing pH. From this we can conclude that the concentration of the Cm(III)–hydroxamate species increased with increasing pH. The complexation is accompanied by an increase of the fluorescence emission lifetime. At pH values equal to or less than 7, the fluorescence lifetime increased from 65 μs for the Cm^{3+} aquo ion to 85 μs showing monoexponential decay. At pH values greater than 8, a biexponential decay was measured with lifetimes of 75 and 150 μs. In the pH range 4–7, a second Cm(III) species besides the Cm^{3+} aquo ion with a peak maximum at 600 nm dominates more and more the sum fluorescence spectrum. Above pH 7 a third Cm(III) species appeared with a peak maximum at 609 nm. These experimental findings, the two identified peak maxima and the two identified lifetimes give clear evidence for the formation of two different Cm(III)–BHA species.

Previous studies [4,18–20] have shown that fluorescence emission of complexes between Cm(III) and organic ligands like pyoverdins and humic acids can be generated either by direct excitation of the Cm(III) fluorescence or by excitation of the ligand followed by an energy transfer from the ligand molecule to the Cm(III) ion (indirect excitation). So, the fluorescence properties of the Cm(III)–BHA complex species can be also determined by an excitation at 360 nm (spectra shown in Fig. 2B) via the discussed energy transfer from the BHA molecule to the Cm(III). A comparison of the spectra at the two excitation wavelengths in dependence of the pH is shown in Fig. 3. At an excitation wavelength of 395 nm and pH 4, the spectrum shows no influence of the beginning complex formation. In contrast to this, the spectrum measured at an excitation wavelength of 360 nm exhibits clearly a peak at 600 nm corresponding to the formation of the first complex. Also at pH 6 and 7, the formation of Cm(III)–BHA species influences strongly the measured sum fluorescence spectra using the indirect excitation mode in contrast to the spectra at 395 nm. At pH 8, where no uncomplexed Cm(III) species exist, the measured spectra exhibit the same peak maxima at both excitation wavelengths.

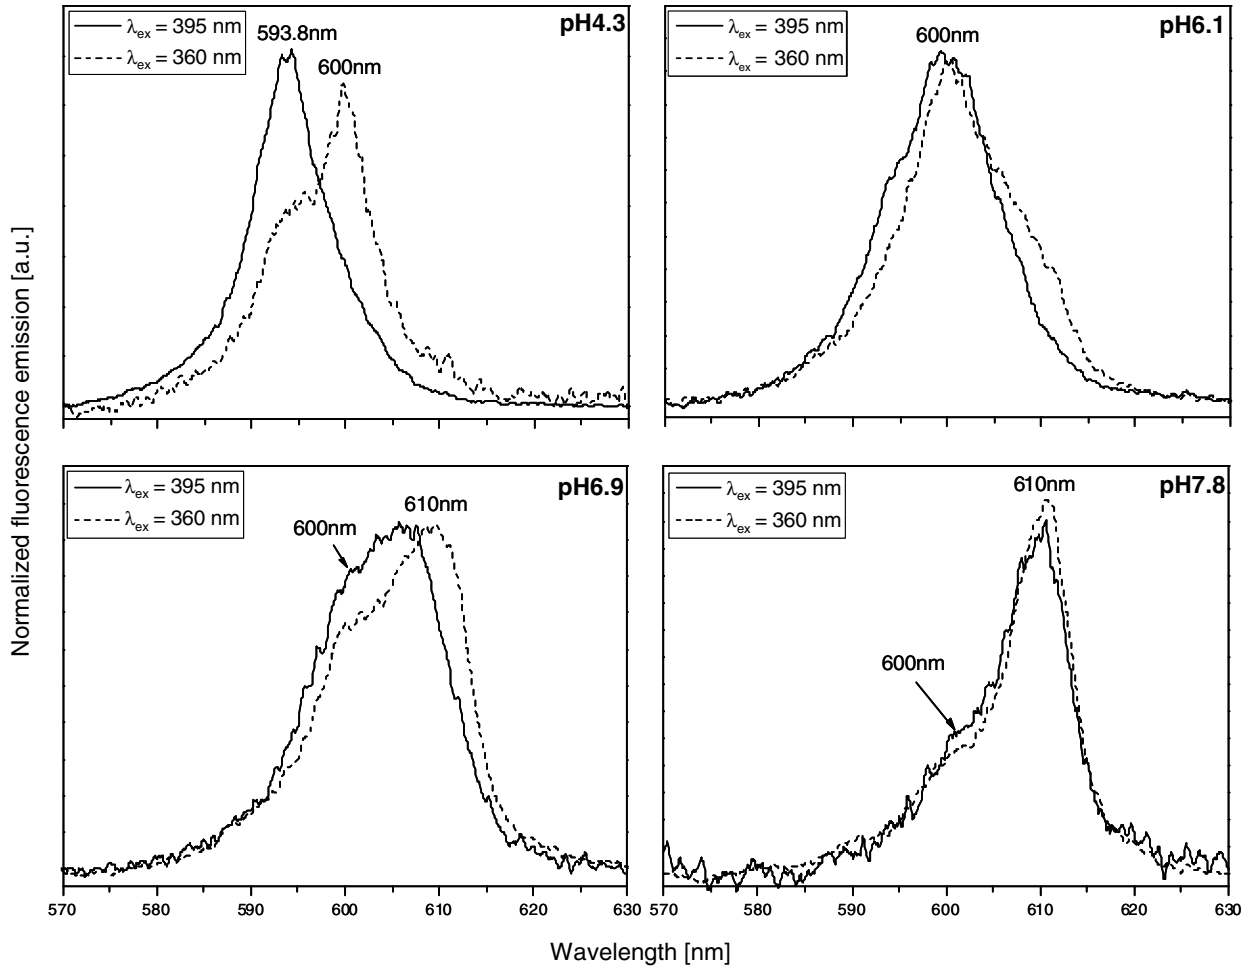

Fig. 3. Direct comparison of fluorescence emission spectra of the curium(III)–benzohydroxamate system measured at excitation wavelengths of 360 (indirect excitation mode) and 395 nm (direct excitation mode).

To describe the complex formation reactions the factor analysis program SPECFIT was used. As a result of the SPECFIT calculations, the variations observed in the fluorescence emission spectra can be described by the following equilibria:

$$Cm^{3+} + C_6H_4CONHO^- \rightleftharpoons Cm[C_6H_4CONHO]^{2+} \qquad \log\beta_{110} \qquad (1)$$

$$Cm^{3+} + 2C_6H_4CONHO^- \rightleftharpoons Cm[C_6H_4CONHO]_2^{+} \qquad \log\beta_{120} \qquad (2)$$

The stability constants were determined at both excitation wavelengths. At an excitation wavelength of 395 nm the stability constant for the 1:1 complex, $Cm[C_6H_4CONHO]^{2+}$, was determined to be $\log\beta_{110} = 6.42 \pm 0.11$ and for the 1:2 complex, $Cm[C_6H_4CONHO]_2^{+}$, $\log\beta_{120} = 11.25 \pm 0.36$ at an ionic strength of 0.1 M. The stability constants at an excitation wavelength of 360 nm are $\log\beta_{110} = 6.61 \pm 0.21$ and $\log\beta_{120} = 11.95 \pm 0.35$. The stability constants determined either by indirect (360 nm) or direct (395 nm) excitation of the Cm(III) fluorescence are consistent and show the applicability of the indirect excitation to determine complex formation equilibria. The corresponding single component spectra of the curium–benzohydroxamate species at both wavelengths are shown in Fig. 4. The emission maxima of both benzohydroxamate species are in agreement measured either with direct or indirect excitation.

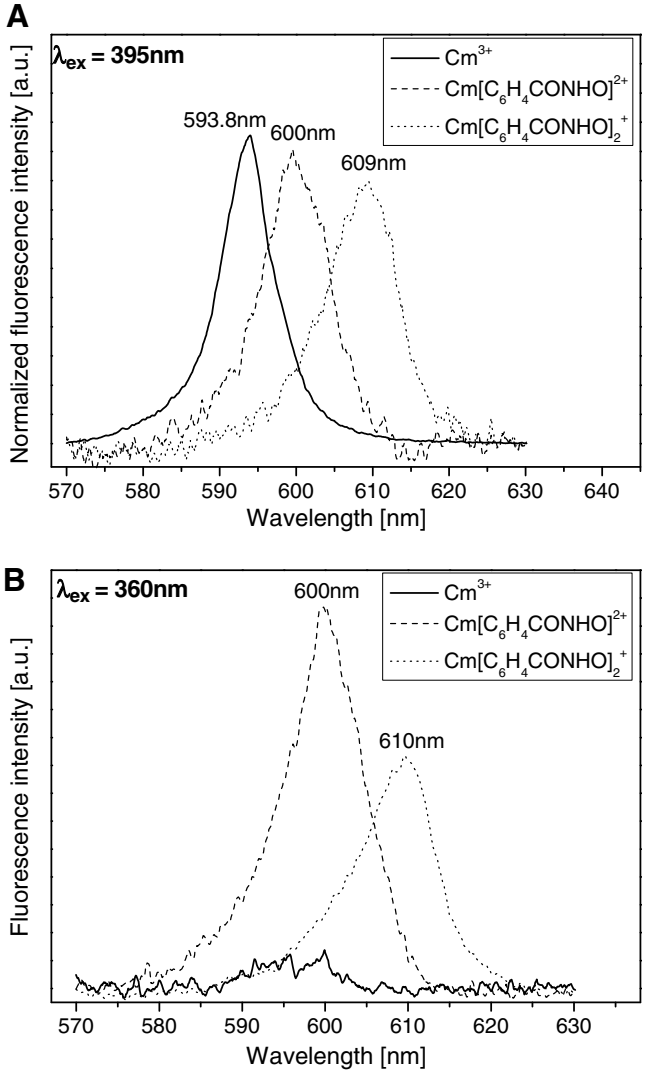

Fig. 4. Fluorescence emission spectra of the single components in the Cm^{3+}–BHA system at an excitation wavelength of (A) 395 nm and (B) 360 nm.

3.2. Salicylhydroxamic acid

The measured fluorescence emission spectra of Cm(III) with SHA in the pH range 4–8 (spectra not shown here) at an excitation wavelength of 395 nm show a red shift of the emission maxima with increasing pH from the characteristic emission maximum of Cm(III) at 593.8 nm via 600 nm to an emission maximum at 608 nm indicating the complex formation between Cm(III) and SHA. Two different Cm(III)–SHA species are formed. The first complex species appears in the pH range 4–7 with a peak maximum of 600 nm and a lifetime of 80 μs and the second species with a lifetime of 200 μs and a peak maximum of 608 nm occurs at pH values greater than 7.

The fluorescence emission spectra at both excitation wavelength of 395 and 360 nm were analyzed with the factor analysis program SPECFIT. The calculated single component spectra of the Cm(III)–SHA complex species are similar to those of the Cm–BHA system and are not shown here. The complexation reactions can be expressed as follows:

$$Cm^{3+} + OC_6H_4CONHO^{2-} + H^+ \rightleftharpoons Cm[HOC_6H_4CONHO]^{2+} \qquad \log\beta_{111} \qquad (3)$$

$$Cm^{3+} + 2OC_6H_4CONHO^{2-} + H^+ \rightleftharpoons Cm[HOC_6H_4CONHO,OC_6H_4CONHO] \qquad \log\beta_{121} \qquad (4)$$

The stability constant for the 1:1 complex, $Cm[HOC_6H_4CONHO]^{2+}$, and the 1:2 complex, $Cm[HOC_6H_4CONHO, OC_6H_4CONHO]$, are $\log\beta_{111} = 16.52 \pm 0.14$ and $\log\beta_{121} = 24.09 \pm 0.62$ at an ionic strength of 0.1 M, respectively. The 1:2 complex is a mixed complex consisting of two different deprotonated ligand molecules ($HOC_6H_4CONHO^-$ and $OC_6H_4CONHO^{2-}$) and a Cm^{3+} ion. There are evidences that the phenolic OH-group of one of the ligand molecules is deprotonated through the complexation. The longer lifetime of the 1:2 complex of SHA (200 μs) in comparison to the lifetime of the 1:2 complex of BHA (150 μs) could indicate an involvement of the phenolic OH-group during the complexation.

4. Conclusions

Table 1 gives a summary of the determined emission maxima, lifetimes and complex formation constants of the Cm(III)–hydroxamic acid complexes in comparison to those of the Cm(III)-*Pseudomona fluorescens* pyoverdin species. For a better direct comparison of the strength of the formed species the determined $\log\beta$ values were recalculated in $\log K$ values using the involved aqueous ligand species. The $\log K$ values of the 1:1 complexes of BHA and SHA show that SHA and BHA form 1:1 complexes with similar stability. In case of the 1:2 complexes BHA has a lower stability constant than SHA which indicates a stronger complex formation of Cm(III) with salicylhydroxamic acid. This is in agreement with the results obtained with uranium(VI) [12,21] and other metals like Fe(III) and Cu(II) [22–25]. The larger stability constants of SHA are probably caused by the influence of the additional phenolic OH group, which was also described by Khairy [26] and O'Brien [24]. The complex formation constants of the three Cm(III)-pyoverdin species identified by Moll et al. [4] are larger than the constants of the hydroxamic acids. One reason could be the different structure of the pyoverdins and the larger number of functional groups in these molecules. The model ligands simulate only one functional group of the pyoverdins. The functional groups in the pyoverdin molecule that participate in the metal binding are the catechol group of the chromophore and hydroxamate and α-hydroxy acid moieties at the peptide chain. The complexation of metals with the pyoverdins is influenced by all these functional groups and the structure of the molecule itself. There-

fore, pyoverdins form stronger complexes with Cm(III) than the model ligands with one hydroxamic acid functionality.

Fluorescence lifetime measurements were used to obtain information about the composition of the first coordination sphere of curium(III). In 1994, Kimura and Choppin [27] found a linear relationship between the lifetime and the number of water molecules in the first coordination sphere of Cm(III). The Cm^{3+} aquo ion is characterized by a measured lifetime of 68 μs, which corresponds to nine water molecules, while the value of 1370 μs measured in D_2O [28] corresponds to zero water molecules in the first coordination sphere of curium(III). In case of a complex formation of the Cm^{3+} aquo ion, the lifetimes of the Cm(III) species increase indicating the exclusion of water molecules out of the first coordination sphere. In all samples with pH values up to 5, a mono-exponential decay was measured with an averaged lifetime of 80 μs in the Cm(III)–SHA system and 85 μs in the Cm(III)–BHA system. This lifetime might correspond to the 1:1 Cm(III)–hydroxamic acid complexes. In samples with pH values above 5, a bi-exponential decay was detected with average lifetimes of 80 and 200 μs for SHA and 85 and 150 μs for BHA, respectively. The second larger lifetime could correspond to the 1:2 complexes. The average number of water molecules in the first coordination sphere calculated with the determined fluorescence lifetimes is 7.3 (SHA) and 6.8 (BHA) for the 1:1 complex and 2.4 (SHA) and 3.5 (BHA) for the 1:2 complex, respectively. During the formation of the 1:1 complex with both hydroxamic acids two water molecules are excluded out of the first coordination sphere. This is in good agreement with the complex stoichiometry found with SPECFIT in the two Cm(III)–hydroxamic acids systems. In a first assumption also caused by the lack of information regarding the structure of Cm(III)–hydroxamate compounds, we assume that the complex stoichiometry and structure of the 1:1 Cm(III)–SHA and Cm(III)–BHA complexes are similar to the U(VI)-SHA and -BHA complexes. The coordinating atoms in the complexes are the hydroxamic acid oxygens ([O,O]-mode), the other reasonable coordination mode via the phenolic oxygen and the nitrogen atom ([N,O′]-mode) could be excluded according to Ref. [29]. So, the Cm^{3+} aquo ion binds like the UO_2^{2+}-ion to the hydroxamic acids via the two hydroxamate oxgens. As a result of the formation of the 1:2 complex of Cm(III)–SHA 6–7 water molecules leave the first coordination sphere. The outcome of the SPECFIT calculation points to a five- or six- coordinated Cm(III)-atom depending if the phenolic OH-groups are involved in the complex formation or not. Six released water molecules suggest that the protonated OH-group is concerned in the complexation. In the Cm(III)–BHA system the fluorescence lifetime of the 1:2 complex suggest that five water molecules are released due to the complex formation. The bidentate coordination of two hydroxamate groups of BHA to Cm(III) would result in five remaining water molecules. The observed difference could be explained by additional interactions with the π-system of the ring. In case of the 1:1 complexes with the hydroxamic acids the relationship between the lifetime and the number of released water molecules agree well with the stoichiometry of the complexes found with SPECFIT. However, we cannot exclude quench mechanism during the complexation via the organic ligands, which might cause that the linear relationship of Kimura and Choppin would be inapplicable. On that account the fluorescence decay was used for comparison and to give evidences for the structure of the formed complexes.

To summarize we studied the until now unknown interaction of Cm(III) with hydroxamic acids using TRLFS. We determined the stability constants of the Cm(III)–SHA and Cm(III)–BHA species by direct (395 nm) and indirect (360 nm) excitation of the fluorescence. The stability constants were compared to those of natural pyoverdins. The stability constants determined by indirect excitation of the Cm(III) agree well with the constants determined by direct excitation of the Cm(III) fluorescence. Therefore, the investigation of complex formation equilibria by indirect excitation points to a new possibility to study the complex formation of fluorescent actinides with organic ligands. The results presented also in comparison with the constants of the natural pyoverdins [4], contribute to a better understanding of the speciation and mobilization of trivalent actinides by hydroxamate compounds by exploring their fluorescence properties.

ABSTRACT

Two series of new three-dimensional (3D) hybrid organic–inorganic frameworks $[Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]_n$ [I, Ln = Nd (**1**), Y (**2**)] and $\{[Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]\cdot 2H_2O\}_n$ [II, Ln = Pr (**3**), Ce (**4**) and Eu (**5**)] (where H_2dpa = 1,4-piperazinediacetic acid) have been synthesized by the reactions of H_2pda, lanthanide oxides and H_2SO_4 under similar hydrothermal conditions. All compounds are constructed by two-dimensional hybrid organic–inorganic layers, which originate from different lanthanide(III) sulfate chains and *in situ* generated μ_4-oxalates, and organic H_2dpa pillars. The coordination modes of sulfate in I and II are, respectively, η^4,μ_3-pentadentate and η^3,μ_3-tridentate, resulting in the different inorganic $[Ln(SO_4)(H_2O)]_\infty$ chains that have not been documented so far. In I, each organic H_2dpa pillar is connected with two Ln(III) ions in a bis-monodentate fashion, while it is linked to four Ln(III) ions in a bis-bidentate *syn–anti* mode in II. Meanwhile, each Ln(III) ion in I and II is linked by one and two H2pda ligands, respectively. The observations hint that application of lanthanide(III) sulfate chains and flexible spacer pillars can self-assemble into interesting hybrid organic–inorganic framework solids. Compounds **1** and **3** are air stable and both the three-dimensional frameworks can be retained below 180 °C. The variable-temperature magnetic studies show that the χ_M values of **1** and **3** increase on the falling temperature, which may be attributed to the depopulation of Stark levels and/or intramolecular antiferromagnetic coupling between the metal centers.

1. Introduction

Recent years have witnessed an explosion of great interest in hybrid organic–inorganic framework solids not only for their intriguing architectures and topologies, but also for their potential applications in optical, electrical, magnetic, and microporous materials [1–4]. A powerful strategy for constructing such organic–inorganic aggregates is directed self-assembly of designed organic ligands and inorganic skeletons. The inorganic skeletons are built up from two parts: metallic cations and oxoanions. The metal elements range from main group elements to transition metal elements. And most of "oxo-anion part" works have often been involved in tetrahedral anions as $[TO_4]$ units (T = tetrahedrally coordinated element), such as phosphates [5], germanites [6], arsenates [7], and selenites [8]. Recently, there has been growing interest in the study of open-framework architectures containing tetrahedral oxo-anions of sulfurs not only due to their versatile coordination modes such as monodentate, μ_2-, μ_3-, μ_4- and μ_5-bridges and so on, but also due that they have been known to promote a diversity of structural arrangements in inorganic solids [9]. And that the materials including metal sulfates are usually much thermally stable [10]. However, it is noted that such sulfate-based compounds reported mainly focus on the d-block transition metals. So far, there are only several examples of lanthanide sulfates [11–13] published in the CCDC [14], and most of them are based on simple lanthanide sulfates in the presence of templating amines as balance cations [12]. Hence, hybrid organic–inorganic frameworks including inorganic skeletons formed by lanthanide sulfate and bridging organic pillars have been rarely reported [13].

In the past study, rigid spacer ligands such as benzene di-, and tri-carboxylates have been successfully used to produce various extended structures with metal ions, but flexible spacer ligands turn out to be much difficult to control their conformations in the architecture of the products. Recent interest in design of polydentate flexible ligands has propagated a family of piperazine-based ligands, because the chair configuration of piperazine can reduce their coordination modes, which makes piperazine or its related species structurally or functionally directing polymeric constructions [15–19], compatible to its analogue-cyclohexane-based organic species such as 1,4-cyclohexanedicarboxylate with (*a*,*a*), (*a*,*e*) and (*e*,*e*) conformers [20]. However, most of the published

piperazine-based examples are concentrated on organic phosphates [16,17] or bipyridyl substituents [18,19]. To the best of our knowledge, there has been no coordination polymers reported, being constructed by piperazine-based carboxylates [14].

Herein, based on bridging 1,4-piperazinediacetic acid and different inorganic lanthanide sulfate chains, we report two series of hybrid organic–inorganic frameworks, $[Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]_n$ [I, Ln = Nd (**1**), Y (**2**)] and $\{[Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]\cdot 2H_2O\}_n$ [II, Ln = Pr (**3**), Ce (**4**) and Eu (**5**)] (H_2dpa = 1,4-piperazinediacetic acid), which have been structurally characterized.

2. Experimental section

2.1. Materials and methods

All solvents and reagents were obtained commercially and used without further purification. Infrared (IR) spectra were recorded on a Bruker Vector 22 FT-IR spectrophotometer. C, H, N and S microanalyses were carried out with a Perkin-Elmer 1400C analyzer. Thermal analysis (TG) was performed on a TGA Q500 thermal analyzer under nitrogen atmosphere at a scan rate of 10 °C min^{-1}. Magnetic susceptibility data of powder samples were collected in the temperature range of 1.8–300 K with the use of a Quantum Design MPMS XL-7 SQUID magnetometer. $H_2pda\cdot 2H_2O$ was prepared according to the reported procedures [21] and confirmed with elemental analysis and single crystal X-ray diffraction.

2.2. Synthesis of compounds

2.2.1. Synthesis of $[Nd_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]_n$ (*1*)

A mixture of $H_2pda\cdot 2HCl$ (0.019 g, 0.1 mmol), Nd_2O_3 (0.034 g, 0.1 mmol), 50% H_2SO_4 (0.1 mL), and water (6 mL) were heated in a 15-mL Teflon-lined vessel at 160 °C for 3 days, followed by slow cooling (5 °C h^{-1}) to room temperature. After filtration and washing with H_2O, pink block crystals were collected and dried in air (0.012 g, yield ca. 35% based on H_2pda). *Anal.* Calc. for $C_{10}H_{18}N_2Nd_2O_{18}S_2$: C, 14.89; H, 2.25; N, 3.47; S, 7.95. Found: C, 14.87; H, 2.29; N, 3.45; S, 7.93%. FT-IR (KBr, cm^{-1}): 3508b, 3404m, 2987w, 2785w, 2638w, 1622s, 1463m, 1376w, 1339w, 1143vs, 1106vs, 1067vs, 985m, 713w, 611m.

2.2.2. Synthesis of $[Y_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]_n$ (*2*)

The reaction was carried out in a method similar to that for **1**, using Y_2O_3 (0.023 g, 0.1 mmol) instead of Nd_2O_3. After filtration and washing with H_2O, colorless block crystals were collected and dried in air (0.018 g, yield ca. 46% based on H_2pda). *Anal.* Calc. for $C_{10}H_{18}N_2O_{18}S_2Y_2$: C, 17.25; H, 2.61; N, 4.02; S, 9.21. Found: C, 17.28; H, 2.57; N, 4.00; S, 9.18%. FT-IR (KBr, cm^{-1}): 3422b, 3028 s, 3010s, 2977w, 2783w, 2636w, 1724vs, 1673s, 1468m, 1403vs, 1324w, 1146w, 1122 m, 1062m, 988m, 977m, 670m.

2.2.3. Synthesis of $[[Pr_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2].2H_2O]_n$ (*3*)

Compound **3** was prepared in an analogous way to that for **1**, using Pr_6O_{11} (0.036 g, 0.035 mmol) instead of Nd_2O_3. After filtration and washing with H_2O, dark-green block crystals were collected and dried in air (0.023 g, yield ca. 55% based on H_2pda). *Anal.* Calc. for $C_{10}H_{22}N_2O_{20}Pr_2S_2$: C, 14.36; H, 2.65; N, 3.35; S,

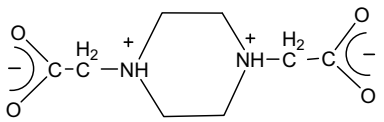
2.3. X-ray crystallography

Diffraction intensities for the compounds were collected on a Bruker SMART CCD area-detector diffractometer (Mo Kα, 0.71073 Å). Absorption corrections were applied by using multi-scan program SADABS [22]. The structures were solved by direct methods and refined with full-matrix least-squares technique with the SHELXTL program package [23]. Anisotropic thermal parameters were applied to all the non-hydrogen atoms. Organic hydrogen atoms were generated geometrically (C–H 0.96 Å) and refined with isotropic temperature factors. Hydrogen atoms on oxygen and nitrogen atoms were located from difference maps and refined isotropically with geometric AFIX restraints of 0.85–0.95 Å. Crystallographic data are summarized in Table 1. Selected bond distances are listed in Table 2, and hydrogen bonding parameters are given in Table 3.

3. Results and discussion

3.1. Synthesis

The syntheses exploit hydrothermal conditions, which have been demonstrated to be particularly effective for the fabrication of interesting organic–inorganic hybrid materials. The reaction conditions employed for the preparations of **1**–**5** were relatively simple. Thus, all the compounds were prepared from mixtures of the appropriate lanthanide oxide, $H_2pda \cdot 2HCl$, 50% H_2SO_4 and H_2O at 160 °C for 3 days. After the reactions, the pH values were between 2 and 3. Surprisingly, compounds **1** and **2** have different inorganic chains of lanthanide sulfate and different frameworks from those of **3**, **4** and **5**, under the similar conditions, which may be attributed to the inherent coordination characteristic of different lanthanide cations. Meanwhile, oxalates were unexpectedly *in situ* generated as a μ_4-oxobridged ligand in these coordination polymers, which may come from the decomposition of the cayboxylic groups of the ligand in the hydrothermal synthesis with high temperature and pressure [24]. It is noted that H_2pda exists as a zwitterionic ligand in all the complexes as shown in Scheme 1. The reaction scheme is shown in Scheme 2. All the products are



H_2pda

Scheme 1. Structural formula of H_2pda.

$$H_2pda + Ln_2O_3 + H_2SO_4 \xrightarrow{160\,^{\circ}C} [Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]_n \quad (Ln = Nd, Y)$$

$$H_2pda + Ln_xO_y + H_2SO_4 \xrightarrow{160\,^{\circ}C} \{[Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2].2H_2O\}_n \quad (Ln = Pr, Ce, Eu)$$

Scheme 2. Reaction scheme.

not soluble in H_2O and common organic solvents such CH_3OH, CH_3CN, and CH_3COCH_3.

3.2. Type I structure of **1** and **2**

Single-crystal XRD study has revealed that both complexes **1** and **2** crystallize in the monoclinic system, *C*2/*c* space group. Since the crystals of **1** and **2** are isomorphous, only the structure of **1** is depicted in detail. Compound **1** is a three-dimensional framework consisting of two-dimensional hybrid organic–inorganic layers, which originate from inorganic $[Nd(SO_4)(H_2O)]\infty$ chains and *in situ* generated μ_4-oxalates, and organic H_2pda pillars. As shown in Fig. 1a, each Nd(III) ion is surrounded by nine oxygen atoms, in which five oxygen atoms are from three sulfates, two from one oxalate ($C_2O_4^{2-}$), one carboxylate oxygen atom from one H_2pda, and one from a water molecule, forming a NdO_9 polyhedron of distorted mono capped square antiprism. The average Nd–O bond distance of NdO_9 polyhedra is 2.50 Å, comparable with that in a Nd(III) compound coordinated by nine oxygen atoms from two terminal water molecules, three chelating and one monodentate sulfates (2.51 Å) [12g]. The shortest Nd–O separation is 2.34(5) Å, resulting from the Nd1–O2 bond of carboxylate, and the longest is 2.71(6) Å of Nd1–O6 from the sulfate. Other distances of Nd–O(sulfate) vary in the range of 2.48(4)–2.66(4) Å. Also, Nd–O3c and Nd–O4 bonds from oxalate are 2.46(6) and 2.43(6) Å, respectively. The distance of Nd(III) and the coordinated water is 2.46(5) Å.

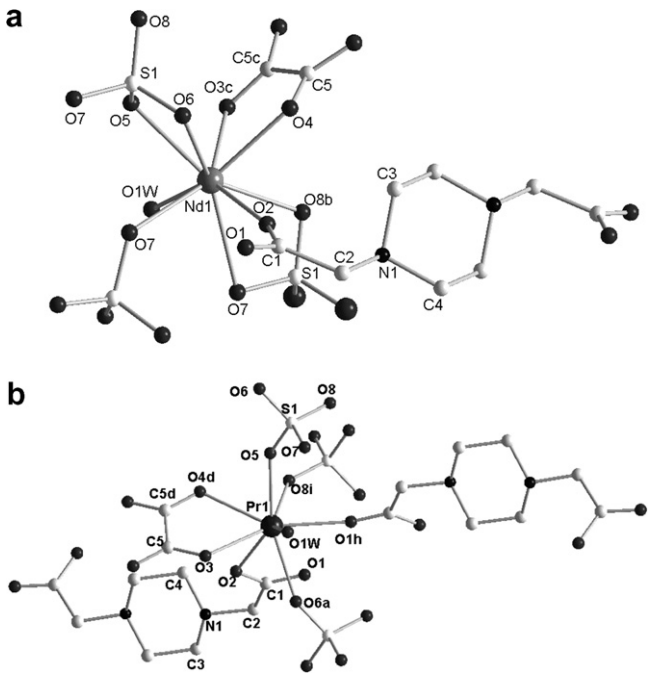


Fig. 1. Local coordination environment of compounds **1** (a) and **3** (b) with 30% thermal ellipsoids. All the hydrogen atoms are omitted for clarity. Symmetry codes for **1**, b: *x*, 1 + *y*, *z*; c: 1 − *x*, *y*, 1/2 −*z*; for **3**, a: *x*, −1 + *y*, *z*; d: 1 − *x*, 2 − *y*,1 − *z*; h: 3/2 − *x*, 3/2 − *y*, 1 − *z*.

The 3D framework can be considered as hybrid organic–inorganic layers pillared by organic H_2pda ligands. The layers consist of inorganic $[Nd(SO_4)(H_2O)]\infty$ chains running along the *b*-axis and μ_4-oxobridged $C_2O_4^{2-}$ derived from the decomposition of carboxylates. Within the chain, Nd(III) ions are arranged zigzag-like, with the shortest intrachain Nd···Nd distance of 4.77 Å, and each pair of Nd ions is bridged by a μ_2-O bridge of one SO_4^{2-} to form a $[Nd_2O]$ triangular unit. These units form the chains by sharing their two apexes (Nd^{3+} ions). Meanwhile, SO_4^{2-} anions are also in a zigzag-like arrangement complementary to the zigzag array of Nd ions, and adopt five-coordinated modes with one μ_2-O and three monodentate oxygen atoms to bridge three Nd(III) ions of an isosceles triangle in the chains (Figs. 2c and 3a). The Nd···Nd distance along the larger bottom edge of these $[Nd_3]$ triangles is 6.35 Å. This chain-like structure is different from those of reported lanthanide sulfates in the literatures [11a,12a,12b,12c,12d]. The adjacent chains are linked *via* μ_4-oxalate to form a 2D hybrid organic–inorganic layer with the shortest interchain Nd···Nd distance 6.29 Å (Fig. 3c). Finally, these 2D layers, parallel to the *ab* plane, are further pillared by organic H_2pda ligands in a bis-monodentate fashion, resulting in an interesting three-dimensional pillared-layer framework, as shown in Fig. 3d. The interlayer distance is *ca.* 8.7 Å. The H_2pda pillars also interact with the adja-

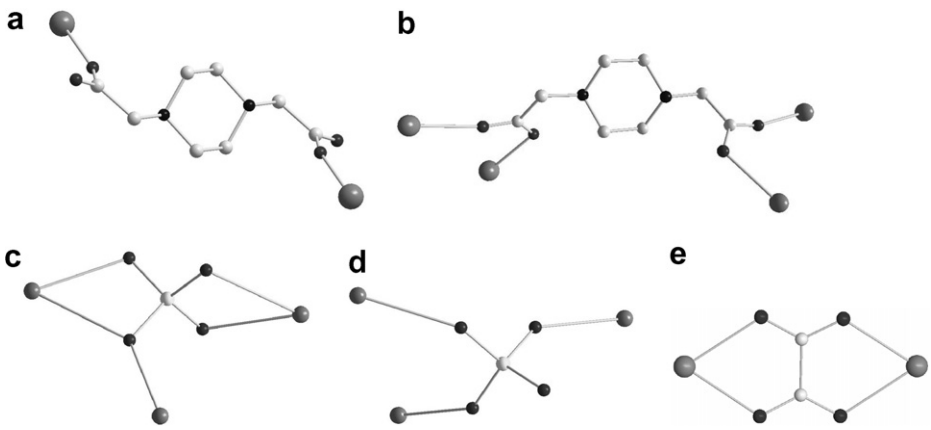

Fig. 2. Coordination modes of H_2pda, SO_4^{2-} and $C_2O_4^{2-}$ anions observed in **1**–**5**.

cent layers *via* O–H···O, N–H···O and C–H···O hydrogen bonds (Table 3), which contributes to the additional stability of the structure. The O–H···O hydrogen bonds originate from the coordinated waters from the layers and the uncoordinated carboxylate oxygens from the adjacent pillars with the O···O distances 2.70(8) and 2.84(7) Å. The N–H···O hydrogen bond comes from the protonated N atom of the pillar and the O atom of SO_4^{2-}, and the N···O distance is 2.96(7) Å. The C–H···O hydrogen bonds involve the piperazine C–H and the oxygen atoms of $C_2O_4^{2-}$, the C···O distances being 2.95(9) and 3.36(8) Å.

3.3. Type II structure of **3**, **4** and **5**

The structure of type II, represented by compound **3**, is different from those of type I, though it can also be described as a three-dimensional framework consisting of hybrid organic–inorganic layers of Pr(III), $C_2O_4^{2-}$ and SO_4^{2-}, and organic H_2pda pillar. First of all, the local coordination environment around a Ln(III) ion is significantly different. As shown in Fig. 1b, each Pr(III) ion is eight-coordinated and exhibits a distorted dodecahedral geometry with three sites occupied by three oxygen atoms of three SO_4^{2-} and two sites by $C_2O_4^{2-}$. The last sites are completed by one water molecule and one carboxylate oxygen atom from a H_2pda ligand. The Pr-O distances range from 2.41(4) to 2.52(4) Å with the average value 2.47 Å, comparable with those in Pr(III) complexes coordinated by eight oxygen atoms (2.46 and 2.49 Å) [25].

Compared with the extended inorganic moieties of type I, the inorganic parts of **3** are different from $[Ln(SO_4)(H_2O)]\infty$ chains along the *b*-axis. In the chains, each pair of Pr(III) ions is bridged by a pair of SO_4^{2-} anions to form an inorganic $[Pr_2(O–S–O)_2]$ eight-membered ring, as shown in Fig. 4a. There are two kinds of eight-membered rings in one chain, one is that the bridges

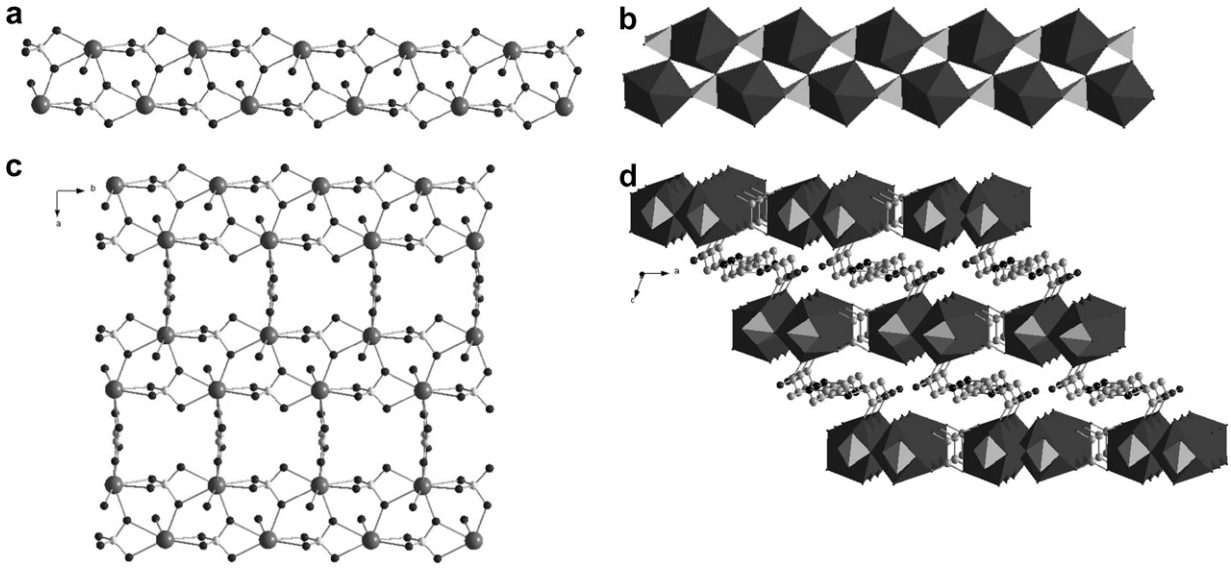

Fig. 3. Structures of 1D inorganic $[Nd(SO_4)(H_2O)]\infty$ chain (a), its polyhedral form (b, grey: SO_4 polyhedra; black: NdO_9 polyhedra), 2D hybrid organic–inorganic layer linked *via* $C_2O_4^{2-}$ anions (c), and 3D framework pillared by H_2pda (d).

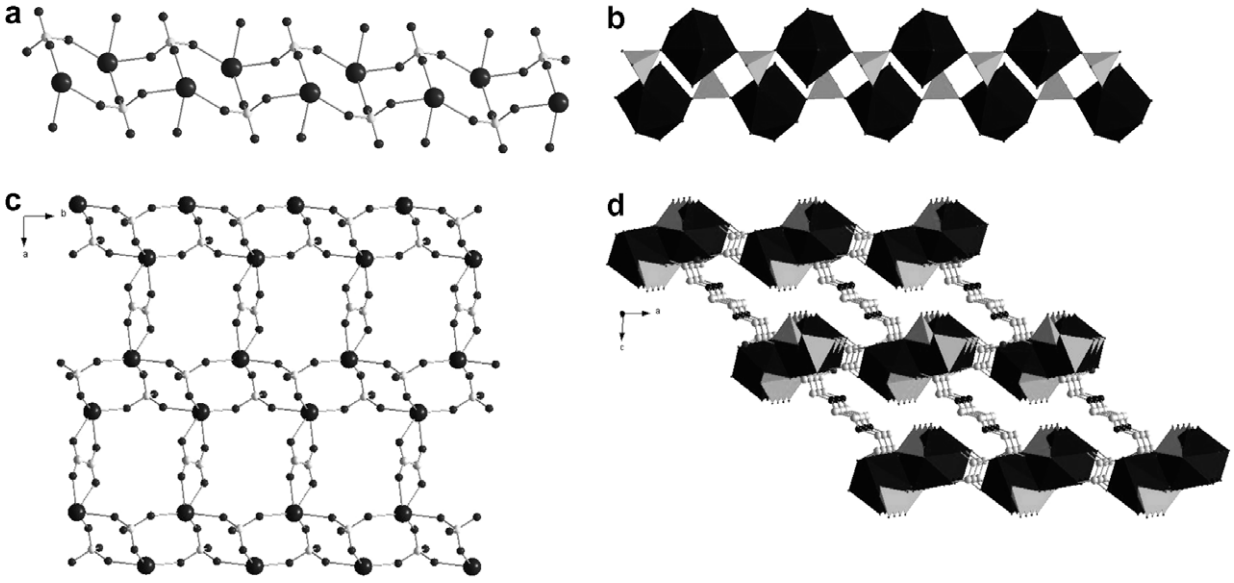

Fig. 4. Structures of 1D $[Pr(SO_4)(H_2O)]\infty$ inorganic chain (a), its polyhedral form (b, grey: SO_4 polyhedra; black: PrO_8 polyhedra), 2D hybrid organic–inorganic layer linked *via* $C_2O_4^{2-}$ anions (c), and the 3D framework pillared by H_2pda (d).

between the Pr ions are only two SO_4^{2-} anions; the other is that the bridges are two *syn–anti* carboxylates, respectively, coming from two H_2pda ligands, apart from two bridging SO_4^{2-} anions. The Pr···Pr distances in the rings are 5.66 and 4.38 Å, respectively. These two inorganic rings are alternately arranged into an inorganic $[Pr(SO_4)(H_2O)]_\infty$ chain by sharing their two apexes (Pr^{3+} ions) with the coordinated H_2O molecules. The Pr(III) ions are arranged as an unequal zigzag-like chain. Moreover, just like **1**, SO_4^{2-} anions are also in a zigzag-like arrangement and each SO_4^{2-} bridges three Ln(III) ions of an isosceles triangle in one chain with a larger Pr···Pr distance 6.81 Å (Fig. 4a). However, the sulfates in **3** adopt η^3,μ_3- tridentate coordination modes, different from those (η^4,μ_3-pentadentate coordination modes) of **1** (Figs. 2d and 4a). Meanwhile, intrachain strong hydrogen bonds are found between the coordinated water molecules and the oxygen atoms of SO_4^{2-} groups [O1w···O7n 2.77(5) and O1w···O7 2.72(5) Å] to stabilize the chain. To the best of our knowledge, such a lanthanide sulfate chain has not been reported so far [14].

The adjacent chains are linked *via* μ_4-oxalate to form a 2D hybrid organic–inorganic layer (Fig. 4c). The shortest interchain Pr···Pr distance is 6.41 Å, which is a little longer than that of **1** (6.29 Å). The 3D structure is generated by the connections of the layers *via* the H_2pda ligands, as shown in Fig. 4d. Each carboxylate of H_2pda links two Pr(III) ions from one chain in a bidentate *syn–anti* mode. Therefore, each organic pillar is connected with four Pr(III) ions from two adjacent layers (Fig. 2b). Meanwhile, each Pr(III) ion is connected by two H_2pda pillars from the above and below the layers, respectively. The 3D structure is sustained by extensive weak C–H···O hydrogen bonds, which originate from the carbon atoms of H_2pda pillars and the oxygen atoms from the SO_4^{2-} [C2···O8h 3.36(6) and C2···O7r 3.28(6) Å] and $C_2O_4^{2-}$ anions [C2···O4k 3.24(6), C3···O3s 3.19(6) and C3···O4d 3.29(6) Å] of the adjacent layers. It is noted that there are "empty" spaces in the 3D network, which are filled with dinuclear water molecules with a distance of 2.82(7) Å. These $(H_2O)_2$ clusters are stabilized in the apertures of this 3D construction by the hydrogen bonds, which involves the oxygen atom from SO_4^{2-} [O2w···O5d 3.00(7) Å] and $C_2O_4^{2-}$ anions [O2w···O3k 3.01(6) and O2w···O4 3.20(6) Å] of the $[Pr(SO_4)(H_2O)(C_2O_4)]$ layers, and the carboxylate oxygen atoms [O2w···O2k 3.18(6) Å] from the bridging H_2pda ligands.

3.4. Thermogravimetric properties

All compounds are air stable and can retain their structural integrity at room temperature for a considerable length of time. The thermogravimetric analyses of powder samples **1** and **3** were carried out from 24 to 780 °C under nitrogen atmosphere at the heating rate of 10 °C min^{-1}, as shown in Fig. 5. For compound **1**, it is stable below 180 °C, which shows that the materials including metal sulfates are rather thermally stable. An initial weight loss of 4.5% occurred between 180 and 220 °C corresponds to the removal of the coordinated water molecules (4.5% calculated). The weight loss of 50% in a range of 220–780 °C indicates the decomposition of the whole structure. The TGA curve of **3** shows a weight loss of 2.1% in the temperature range of 24–213 °C, which is in agreement with the removal of the encapsulated water molecules (4.3% calculated). The second weight loss of 4.1% between 213 and 248 °C corresponds to the removal of two coordinated water molecules per formula unit (4.3% calculated). The decomposition of the whole framework occurs from 248 to 780 °C.

3.5. Magnetic properties

The magnetic susceptibility of **1** has been measured in the temperature range of 1.8–300 K at an applied field of 2000 Oe and the plots of χ_M and $\chi_M T$ versus T are shown in Fig. 6. When the temperature decreases from 300 K, the χ_M value gradually increases from 0.005 cm^3 mol^{-1} to 0.400 cm^3 mol^{-1} at 1.8 K. Meanwhile, the $\chi_M T$ value per Nd(III) ion is 1.45 cm^3 K mol^{-1} at 300 K, which is slightly less than the theoretical value of 1.64 cm^3 K mol^{-1} for magnetically isolated Nd(III) ions, then decreases to 0.72 cm^3 K mol^{-1} at 1.8 K on falling. The variable-temperature magnetic properties of a free rare earth ion generally shows strong deviations from the Curie–Weiss law, and $\chi_M T$ decreases with the cooling temperature owing to the

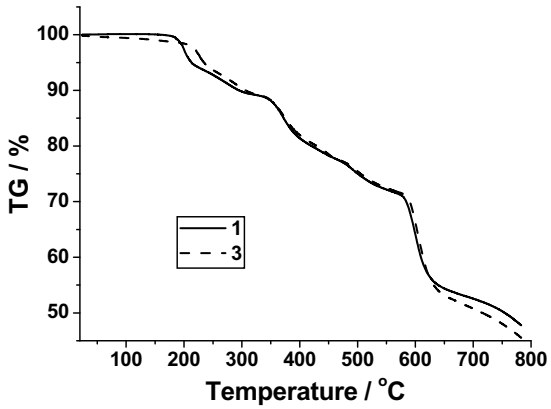

Fig. 5. TG plots for **1** and **3**.

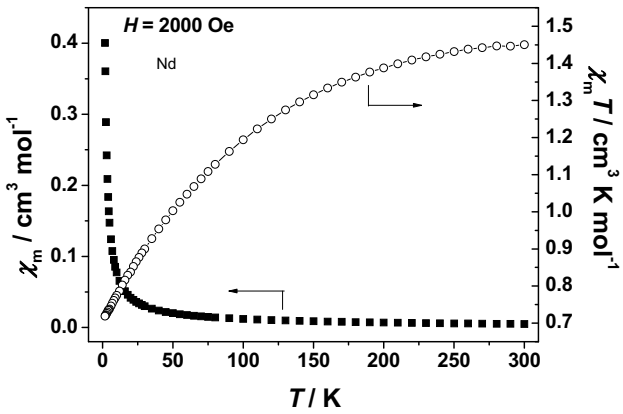

Fig. 6. Temperature dependence of χ_M (■) and $\chi_M T$ (○) for **1**.

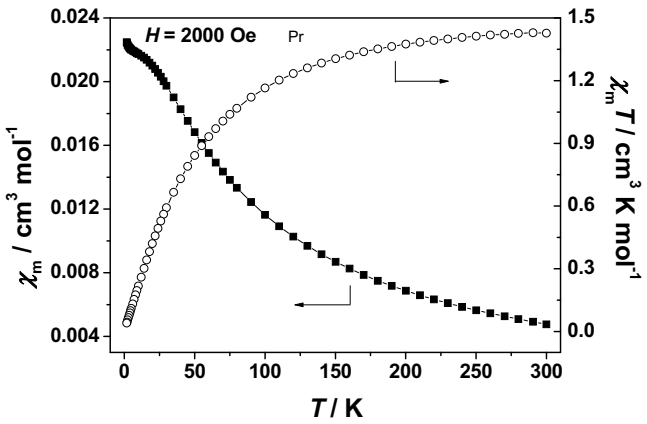

Fig. 7. Temperature dependence of χ_M (■) and $\chi_M T$ (○) for **3**.

depopulation of Stark levels [26]. Therefore, the magnetic behavior of **1** may be ascribed to intramolecular antiferromagnetic coupling between the metal centers and/or the orbital coupling contribution.

Compound **3** shows a similar profile of $\chi_M T$ in the temperature range of 1.8–300 K (Fig. 7). The $\chi_M T$ value (1.43 $cm^3\,K\,mol^{-1}$) per Pr(III) ion at 300 K is somewhat lower than that expected for an isolated Pr(III) ion (1.60 $cm^3\,K\,mol^{-1}$). On cooling, $\chi_M T$ falls to 0.04 $cm^3\,K\,mol^{-1}$ at 1.8 K, and the χ_M (0.005 $cm^3\,mol^{-1}$ at 300 K) exhibits an increase to 0.022 $cm^3\,mol^{-1}$ at 1.8 K. This may also be attributed to the depopulation of Stark levels and/or intramolecular antiferromagnetic coupling between the metal centers.

4. Conclusion

Among the two series of complexes $[Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]_n$ [I, Ln = Nd (**1**), Y (**2**)] and $\{[Ln_2(H_2pda)(C_2O_4)(SO_4)_2(H_2O)_2]\cdot 2H_2O\}_n$ [II, Ln = Pr (**3**), Ce (**4**) and Eu (**5**)] prepared by the solvothermal reactions of H_2pda, lanthanide oxides and H_2SO_4 under similar conditions, the structures are all based on organic H_2pda pillars and two-dimensional hybrid organic–inorganic layers, which come from different $[Ln(SO_4)(H_2O)]\infty$ chains and *in situ* generated μ_4-oxalates. Corresponding to the different coordination polyhedra of different lanthanide(III) ions, sulfate anions adopt different coordination modes in the chains, which results in the difference of inorganic $[Ln(SO_4)(H_2O)]\infty$ chains. This work demonstrates that use of lanthanide(III) sulfate chains and flexible spacer pillars can generate interesting hybrid organic–inorganic framework solids.

5. Supplementary data

CCDC 675193, 675194, 675195, 675196, 675197 contain the supplementary crystallographic data for compounds **1**, **2**, **3**, **4** and *5*. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Tantalum(V) complexes
Oxazoline
Chelating-diamide ligand

ABSTRACT

Two six coordinate tantalum(V) oxazoline complexes, $[Ta(OX)(NMe_2)_4]$ (**1**) and $[Ta(OX)_2(NMe_2)_3]$ (**2**), formed by the reaction of $[Ta(NMe_2)_5]$ with the chelating di-nitrogen ligand 4,4-dimethyl-2-pyrrole-2-oxazoline in 1:1, 1:2 and/or 1:3 molar ratios have been investigated. The structural study of **1** and **2** by X-ray crystallography shows that they both adopt geometries best described as distorted octahedral with N–Ta–N angles of 172.6(3)° and 169.4(2)°, respectively. The nitrogen atoms of the oxazoline are bound directly to the tantalum, leading to a five-membered metallacycle in the basal plane. The N–Ta–N and Ta–N–C angles of the basal five-membered oxazoline ring are 71° and 113–117°, respectively.

1. Introduction

Metal–organic complexes of early transition metals bearing nitrogen containing ligands have received increasing attention over the last couple of years [1–3]. Significant attention has been focused on metal complexes supported by cyclopentadienyl-based ligand sets [4,5], but there is also growing interest in the use of complexes with dialkoxide [6,7] or diamide ligands [8–16]. Interest in studying chelating-diamide supported Group 4 complexes is due to their easily preparation together with the fact their the steric and electronic properties can be tuned by varying the nitrogen substituents. d^0 Group 4 metal complexes (Ti, Zr, Hf) of diamide ligands show good catalytic activity for the polymerization of α-olefins [9–23]. In response to the growing interest in alternatives to classical metallocene-based catalysts, we have become interested in examining the chemistry of a relatively unexplored class of mixed amido ligands (Scheme 1).

Typically, the synthesis of these compounds is one-step process involving the reaction between $Ta(NMe_2)_5$ and oxazoline. In this paper, we describe the first six coordinate tantalum(V) complexes to contain two types of oxazoline binding by the reactions of $Ta(NMe_2)_5$ with 4,4-dimethyl-2-pyrrole-2-oxazoline (OX) in 1:1, 1:2 and 1:3 molar ratios. The molecular structure of $[Ta(OX)(NMe_2)_4]$ (**1**) and $[Ta(OX)_2(NMe_2)_3]$ (**2**) are also reported.

2. Experimental

2.1. Materials and methods

All experimental procedures were conducted under an inert atmosphere, either in a N_2 filled dry box or by using standard Schlenk techniques. Diethyl ether was distilled from sodium benzophenone ketyl; toluene, hexanes and pentane were distilled from sodium; dichloromethane was distilled from CaH_2. The distilled solvents were stored under an argon atmosphere and over 4 Å molecular sieves. All NMR solvents were degassed and stored over 4 Å molecular sieves in a N_2 filled drybox. $Ta(NMe_2)_5$ was synthesized according to the improved procedure for the preparation of homoleptic metal amide complexes reported by Jordan et al. [24]. The 4,4-dimethyl-2-pyrrole-2-oxazoline was synthesized according to previously published procedures [25,26].

^{1}H NMR spectra were measured on a Varian Gemini 200 spectrometer using sealed NMR tubes. The chemical shifts are reported in parts per million (ppm) downfield from tetramethyl-silane and referenced to residual proton peaks of the NMR solvents. Electronic Ionization Mass spectra were recorded using a Varian MAT spectrometer. *m*/*z* values were referenced to ^{35}Cl, ^{90}Zr, ^{180}Hf and ^{181}Ta. Elemental analysis was performed by a 2400 Analyzer, series II CHN/O Perkin-Elmer. X-ray diffraction data were collected using a Bruker Ax SMART 1K CCD and refined with the SHELXL and SHELXS program suite.

2.2. Synthesis of $[Ta(OX)(NMe_2)_4]$ (**1**)

To a toluene solution of $Ta(NMe_2)_5$ (0.55 g, 1.37 mmol) at room temperature (r.t.) was added a toluene solution of 4,4-dimethyl-2-pyrrole-2-oxazoline (0.2255 g, 1.37 mmol). A change of color to

2.3. Synthesis of $[Ta(OX)_2(NMe_2)_3]$ (**2**)

To a toluene solution of $Ta(NMe_2)_5$ (0.55 g, 1.37 mmol) at room temperature (r.t.) was added a toluene solution of 4,4-dimethyl-2-pyrrole-2-oxazoline (0.451 g, 2.74 mmol or 0.676 g, 4.11 mmol). The solution color slowly changed to yellow. The mixture was allowed to stir for 48 h at r.t. (connected to an oil bubbler to release the $HNMe_2$ produced during the reaction). After removal of the reaction solvent under reduced pressure and leaving for one week at −37 °C, bright red crystals were obtained, which were washed with several portions of hexane to yield 0.454 g (71%) of $[Ta(OX)_2(NMe_2)_3]$ (**2**). Elemental analysis Calc. for $C_{24}H_{40}N_7O_2Ta$: C, 45.07; H, 6.30; N, 15.33. Found: C, 45.20; H, 6.23; N, 15.44%. Mass Spec. Calc.: 639.2723 *m*/*e*, found: (FAB) 639.2723 *m*/*e*.

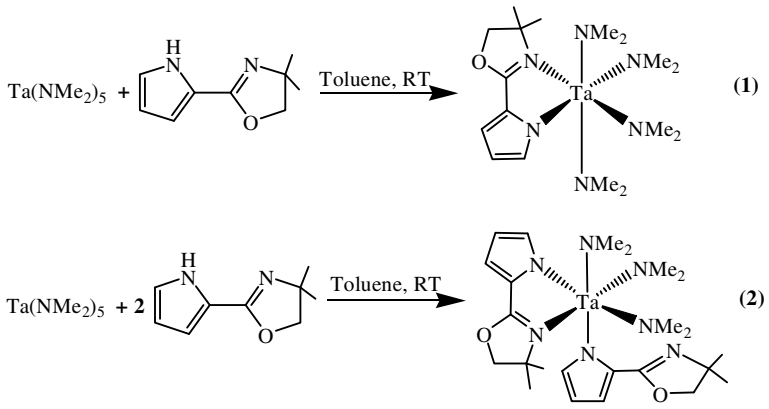
2.4. X-ray crystal structure analysis

Single-crystal diffraction experiments were carried out at 203 K on a Bruker-AXS-SMART (CCD 1000) diffractometer with



Scheme 2. Synthesis reaction map of **1** and **2**.

monochromated Mo Kα radiation (0.71073 Å). The structures were solved by direct methods and refined anisotropically with the SHELXL-97 program suite [27,28]. The crystals were mounted on capillary using inert oil and transferred immediately to the cold gas stream (203 K) of the diffractometer. Crystallographic data is presented in Table 1. The molecular structures of **1** and **2** in the solid state are shown in Figs. 1 and 2.

3. Results and discussion

Herein, we describe the synthesis and structural characterization of tetrakis(dimethylamido)(4,4-dimethyl-2-pyrrole-2-oxazoline)tantalum(V) and tris(dimethylamido)bis(4,4-dimethyl-2-pyrrole-2-oxazoline)tantalum(V). The later compound contains one anchoring oxazoline ligand and is the first complex to contain two types of oxazoline binding. The reaction of $[Ta(NMe_2)_5]$ with the chelating di-nitrogen ligand 4,4-dimethyl-2-pyrrole-2-oxazoline*(OX)* in 1:1, 1:2 and/or 1:3 molar ratios yielded the tantalum(V) oxazoline complexes $[Ta(OX)(NMe_2)_4]$ (**1**) and $[Ta(OX)_2(NMe_2)_3]$ (**2**) in high yield (71% and 76%) (Scheme 2). Their structures have been characterized by X-ray crystallography. In the 1:2 and 1:3 ratio cases, only displacement of 2 equiv. of dimethylamine occurs, yielding (**2**) while in the case of the 1:1 reaction, displacement of 1 equiv. of dimethylamine occurs, yielding $[Ta(OX)(NMe_2)_4]$ (**1**). In fact treatment of pentakis(dimethylamido)tantalum with more than 2 equiv. of 4,4-dimethyl-2-pyrrole-2-oxazoline did not lead to substitution of more dimethylamido groups, and only **2** was isolated. Similar results have reported by Darrin S. Richeson with a symmetrical chelating bidentate guanidinate anion to give $[CyNC(NMe_2)NCy]Ta(NMe_2)_4$ [29] or Charles H. Winter with the 3,5-di-*tert*-butylpyrazolato ligand to give tris(dimethylamido)bis(3,5-di-*tert*-butylpyrazolato) tantalum(V) [30]. But multiple insertion products have been observed in the analogous reactions of Me_xTaCl_{5-x}; ($x = 1,2,3$) with carbodiimides RNCNR; (R = isopropyl, cyclohexyl, *p*-tolyl) to give acetamidinate complexes $MCl_4[RN–C(Me)=NR]$, $MeMCl_3[RN–C(Me)=NR]$ and $MCl_3[RN–C(Me)=NR]_2$; M = Ta, Nb [31–33].

These observations and also the Soft Chemistry Approach [34] revealed both steric and electronic factors play a central role in determining the overall structure. In the most fascinating observation, the size and number of ligands are definitely more important than their chemical nature [34]. Another possibility for the decreased reactivity of **2** towards further insertion may arise from the increased π-donating ability of the amido group and the consequent reduction in the acidity of the Ta center. In compound **2**, the values for the Ta–NMe_2 distances are short enough to establishment this π-interaction [35] (Ta–N(5), Ta–N(6) and Ta–N(7) are 2.007, 2.005 and 1.978 Å, respectively) and the orientation of the amido groups is consistent with d–p interactions between the nitrogen p orbitals and metal d_{xy}, d_{xz}, d_{yz} orbitals of the distorted octahedral geometry.

The room temperature ^1H NMR spectrum of **1** displays two singlets at 3.10 and 3.38 ppm in a 2:2 ratio, that are assigned to the NMe_2 groups. Also two singlets at 3.14 and 3.49 ppm (1:2 integration ratio) were observed for **2**, corresponding to the NMe_2 groups, whilst three equal intensity resonances were expected. The observed equivalency of the equatorial NMe_2 groups, even at −30 °C, may imply the presence of a fast exchange process which equilibrates the NMe_2 groups on the NMR timescale.

The X-ray diffraction studies of **1** and **2** show that octahedral coordination geometries are found in the solid state with N–Ta–N angles of 172.6° and 169.4°, respectively. Molecular drawings of **1** and **2** and their selected bond lengths and angles are presented in Figs. 1 and 2. The nitrogen atoms of the oxazoline are bound directly to the tantalum center, leading to a five-membered metallacycle in the basal plan. The compound $[Ta(OX)_2(NMe_2)_3]$ (**2**) adopts a distorted octahedral geometry about the tantalum center with one bidentate oxazoline ligand occupying two equatorial sites and another oxazoline ligand anchored by an amido N-bond in an axial position. The dimethylamido ligands occupy two equatorial and one axial site. The bite angle of the ligand (N(1)–Ta–N(2): 71.68°) is smaller than that observed for other bidentate amido complexes reported in the literature, due to the five-membered chelate ring, but is bigger than that reported by D.S. Richeson for the four-membered carbodiimide-Ta chelate ring in $Ta(NMe_2)_4$-$[CyNC(NMe_2)NCy]$ (58.66°) [29].

This is an extremely tight bite angle and the tightest observed in compounds of this nature [36,37]. Related complexes display similar tight chelate angles. The reason for such a tight bite angle is unclear but it would appear to be attributable to the need for some sort of adjustment in the chelate ring shape to allow for the size of the tantalum and the high coordination number of 6 that is achieved. The Ta–N(1)–C(5) and Ta–N(2)–C(4) angles of the basal five-membered oxazoline ring are 113° and 117°, respectively. The Ta–N(1) and Ta–N(2) bond lengths of the oxazoline ligand, 2.250(6) and 2.344(7) Å, are longer than the Ta–N bond distances of the Ta–NMe_2 units (1.977(7), 2.005(6) and 2.007(6) Å). The torsion angle around N(1), N(2), N(6) and N(7) is 2.83° indicating a pseudo-octahedral geometry.

In $[Ta(OX)(NMe_2)_4]$ (**1**), the six octahedral positions are occupied by two axial dimethylamido, two equatorial dimethylamido and two N-bonded oxazoline ligands. The torsion angle of **1** around N(1), N(2), N(5) and N(5) is 1.04°, indicating an octahedral geometry. The N(1)–Ta–N(2) angle of 71.57° is almost the same as that

observed for **2**. The Ta–N(1) and Ta–N(2) bond lengths of the oxazoline ligand, 2.350(5) and 2.272(6) Å, are longer than the Ta–N bond lengths of the NMe_2 ligands (equatorial: 2.002(6), 2.009(6) Å and axial: 2.038(6), 2.033(6) Å). In both compounds **1** and **2**, the angles between the mean planes of the axial amides are nearly orthogonal, an alignment appropriate for these two amides to interact with two orthogonal tantalum d_{xz} and d_{yz} orbitals. The two equatorial amido ligands also exhibit a preferred orientation for maximum π-overlap with the remaining tantalum d_{xy} orbital, because the angles of 90° would be achieved. Opposing this orientation are the steric interactions between the axial and equatorial amido ligands and the fact that the two amido ligands are competing for donation to a single orbital.

4. Summary

In conclusion, we have demonstrated 4,4-dimethyl-2-pyrrole-2-oxazoline compounds have been successfully employed as chelating amido-imine ligands in the synthesis of the air and moisture sensitive tantalum amido complexes $[Ta(OX)(NMe_2)_4]$ (**1**) and $[Ta(OX)_2(NMe_2)_3]$ (**2**) in high yield via the amide elimination method. In addition, the first example of the reactions of tantalum pentakis amido complexes with oxazoline has been reported. Structural studies of **1** and **2** show they both adopt geometries best described as distorted octahedral with N–Ta–N angles of 169.4(2)° and 173.6(3)°, respectively. The nitrogen atoms of the oxazoline are bound directly to the tantalum center, leading to a five-membered metallacycle in the basal plan. In $[Ta(OX)(NMe_2)_4]$ (**1**), six octahedral positions are occupied with two axial dimethylamido, two equatorial dimethylamido and two N-bonded oxazoline ligands. $[Ta(OX)_2(NMe_2)_3]$ (**2**) adopts a geometry with an axial dimethylamido, two equatorial dimethylamido, an equatorial amido-imine oxazoline and finally an anchored N-bonded amido oxazoline ligand at an axial position. We have shown that the oxazoline ligand can be inserted into Ta-amido functions. The structure of complex **2** indicates some of the steric and electronic features by providing initial details on the role of the ligand. But in the case of our study it seems that steric hindrance may play a more important role in these reactions. Our future researches will be directed at clarifying these issues through manipulation of ancillary ligands.

ABSTRACT

The use of the maleamic acid (H_2L)/1,10-phenathroline "blend" in copper(II) chemistry has yielded mononuclear and dinuclear complexes, and one coordination polymer. The chemical and structural identity of the products depends on the solvent, the absence or presence of external hydroxides in the reaction mixtures, the nature of the inorganic anion present in the copper(II) starting material and the molar ratio of the reactants. The maleamato(-1) complexes $[Cu_2(HL)_3(phen)_2](NO_3)$ (**2**, **7**), $[Cu(HL)(phen)_2](OH)$ (**3**), $[Cu(HL)_2(phen)]$ (**4**) and $[Cu(HL)(NO_3)(phen)]_n$ (**8**) have been prepared and structurally characterized. The dinuclear cations **2** and **7** are structurally similar to the cation of complex $[Cu_2(HL)_3(phen)_2](ClO_4)$ (**1**) which was previously communicated. The maleamato(-1) ligand adopts a variety of coordination modes in the above complexes, ranging from the familiar *syn,syn* $\eta^1:\eta^1:\mu_2$ bridging mode and the rare monoatomic bridging ($\eta^1:\mu_2$) mode in the structures of **2** and **7**, to the terminal monodentate in the structures of **3** and **4**. Complex **8** is a 1D, zigzag coordination polymer in which the carboxylato group of the HL^- ligand is asymmetrically coordinated to two Cu^{II} ions adopting the *syn,anti* $\eta^1:\eta^1:\mu_2$ mode; the amide O atom is also coordinated, thus forming an unusual 7-membered chelating ring. The crystal structures of the complexes are stabilized by a variety of H-bonding patterns which lead to interesting supramolecular architectures. Characteristic IR bands of the complexes are discussed in terms of the known structures, and the coordination modes of the HL^- ligand.

1. Introduction

There continues to be great interest by inorganic chemistry groups around the world in the synthesis and characterization of polynuclear (also known as clusters) and polymeric (also known as coordination polymers, metal–organic frameworks or organic–inorganic hybrid coordination polymers in the case where the metal–organic connectivity is interrupted by "inorganic" bridges) 3d-metal molecular complexes. Among the diverse reasons for the interest for new clusters are the search for models of metal-containing biological sites [1], and new high-spin molecules [2] and single-molecule magnets [3,4]. Coordination polymers have various applications in catalysis, electrical conductivity, magnetism, luminescence, non-linear optics, molecular electronics, medicine, sensing and zeolitic behaviour [5]. There thus continues to be a need for new synthetic methods to clusters and coordination polymers.

The success of organic chemists in establishing methods for making large, complicated molecules and organic polymers in a systematic and controlled manner is one of the great collective achievements of 20th-century science. The attitude of mind involved in such processes has become inculcated in all synthetic chemists. By comparison, transition metal chemists have made little progress in discovering general approaches to preparing compounds containing large or infinite numbers of metal centers. This is because until recently means for routine characterization of such compounds did not exist, and because the obvious biological relevance and commercial applications of large organic molecules and organic polymers were not matched by properties of polynuclear and polymeric metal complexes. The lack of control in transition metal chemistry has led to the neologism "self-assembly" being coined [6]. In the last decade, several groups have been introducing an element of design into the assembly process by choosing rigid ligands which have strong preferences for specific bonding modes and metal ions with preferred coordination geometries. This "designed assembly" approach has produced many beautiful clusters [7] and coordination polymers [8]. The structures of such compounds are moderately predictable, based on the preferred coordination geometry of the metal ion, the number of pre-organized donor sites presented by the ligand and on the limited flexibility of the ligand. Other researchers, including our group, use much less well-behaved *bridging* organic ligands for the preparation of clusters [9] and coordination polymers [10].

Once formation of a five- or six-membered chelate ring is excluded, the coordinative flexibility of any polydentate ligand increases enormously. This flexibility in turn allows stabilization of many unpredictable structures, almost invariably incorporating further ligands such as oxide, hydroxide, alkoxides, inorganic anions or organic coligands. In the case of clusters, this approach has been termed "serendipitous assembly" [11]. The advantages of serendipidous assembly in cluster chemistry and of less-designed (or "non-programmed") assembly in the chemistry of coordination polymers are considerable. Most often designed assembly requires similar coordination at each metal site, and this restricts the number of accessible structures, e.g. to Platonic solids, rings and grids in the case of cluster chemistry. On the other hand, serendipitous or less designed assembly vastly increases the range of compounds available for study. The unusual structures of some of these compounds can lead to novel properties.

A frequently used family of organic ligands, often in combination with terminal aromatic N-donors, for the construction of clusters [12] and coordination polymers [13] consists of aliphatic α,ω-dicarboxylates, $^{-}OOC\text{-}(CH_2)_n\text{-}COO^{-}$ (**I** in Fig. 1; $n = 2,3,4\ldots$), $^{-}OOC\text{–}CH{=}CH\text{–}COO^{-}$ (**II** in Fig. 1, fumarate; **III** in Fig. 1, maleate) and $^{-}OOC\text{–}C{\equiv}C\text{–}COO^{-}$ (**IV** in Fig. 1, acetylene dicarboxylate), which are capable of bridging metal ions at various distances [14]. In contrast to the large body of knowledge in this area, *practically nothing is known about the metal complexes of the monoanionic monoamides of α,ω-dicarboxylates*, $^{-}OOC\text{–}(CH_2)_n\text{–}CONH_2$ (**V** in Fig. 1; $n = 2,3,4,\ldots$), $^{-}OOC\text{–}CH{=}CH\text{–}CONH_2$ (**VI** in Fig. 1, fumarate monoamide; **VII** in Fig. 1, maleate monoamide or maleamate) and $^{-}OOC\text{–}C{\equiv}C\text{–}CONH_2$ (**VIII** in Fig. 1, acetylene dicarboxylate monoamide). The presence of an amide functionality, instead of a carboxylate group, is expected – due to different charge (neutral versus ionic), electronic properties and hydrogen bonding effects – to alter the coordination behaviour of these ligands (and hence the identity of the resultant metal complexes) in comparison with that of aliphatic α,ω-dicarboxylates.

With the above considerations in mind, we have explored "ligand blend" reaction systems involving the succinamate(-1) ligand, $^{-}OOC\text{–}CH_2\text{–}CH_2\text{–}CONH_2$ ($n = 2$ in **V** of Fig. 1; $Hsucm^{-}$) and various aromatic *N*,*N*′-donors as a means to dinuclear and polymeric copper(II) compounds [15]. Thus, several reaction schemes involving various copper(II) sources, $Hsucm^{-}$ and 4,4′-dimethyl-2,2′-bipyridine (dmbpy) or 2,2′-bipyridine (bpy) afforded [15] the complexes $[Cu_2(Hsucm)_3(dmbpy)_2](OH)$, $[Cu_2(Hsucm)_2(dmbpy)_2(H_2O)_2](ClO_4)_2$, $[Cu_2(OH)(H_2O)(Hsucm)(bpy)_2](ClO_4)_2$ and $\{[Cu_4(Hsucm)_5(dmbpy)_4](ClO_4)_3\}_n$. The dinuclear complexes contain extremely rare cores, while the novel cationic coordination polymer consists of alternating $\{Cu_2(Hsucm)_2(dmbpy)_2\}^{2+}$ and $\{Cu_2(Hsucm)_3(dmbpy)_2\}^{+}$ dinuclear units. We also reported the *binary* 1D coordination polymers $[Ln(Hsucm)_3(H_2O)]_n$ which feature only $Hsucm^{-}$ ligands that exhibit three different coordination modes [16].

We illustrate herein how the use of the maleamate(-1) (**VII** in Fig. 1; HL^{-})/1,10-phenanthroline(phen) ligand combination in copper(II) chemistry leads to interesting mononuclear, dinuclear and polymeric complexes that contain the intact HL^{-}. The aromatic donor is necessary for the successful crystallization of the complexes (vide infra) and its use allows direct structural comparison with the complexes featuring the corresponding α,ω-dicarboxylate(-2) (**III** in Fig. 1; maleate) and the succinamate(-1) ligand, i.e., the $Cu^{II}/^{-}OOC\text{–}CH{=}CH\text{–}COO^{-}$/phen and $Cu^{II}/Hsucm^{-}$/phen complexes. The coordination chemistry of maleamic acid (H_2L) is almost unknown. The present work can be considered as continuation of our research efforts on the oxamate(-1) or its derivatives (**X** in Fig. 1) [17] and malonamate(-1) (**XI** in Fig. 1) [18] 3d-metal complexes.

The structure of the copper(II) maleamate(-1) complex $[Cu_2(HL)_3(phen)_2](ClO_4)\cdot 1.5MeCN\cdot 0.5H_2O$ (**1** $\cdot 1.5MeCN\cdot 0.5H_2O$) has been communicated by our group [19]. We also reported in the preliminary communication [19] of this work that the $Cu(ClO_4)_2\cdot 6H_2O/H_2L$/phen reaction system in MeOH, in the absence of external hydroxide ions, affords the remarkable complex $[Cu_2(L')_2(ClO_4)(phen)_2(MeOH)](ClO_4)$ (**5**) in which the maleamate(-1) ion has been transformed to the monomethyl maleate(-1) ligand L'^{-} (**IX** in Fig. 1) via a novel, metal-ion assisted/promoted process and through the formation of the HL^{-}-free coordination polymer $[Cu(ClO_4)(phen)(MeOH)_2]_n$ (**6a**); the structure of the latter was assigned on the basis of its spectral similarity with the structurally characterized 1D compound $[Cu(ClO_4)(phen)(MeCN)_2]_n(ClO_4)_n$ (**6b**) [19].

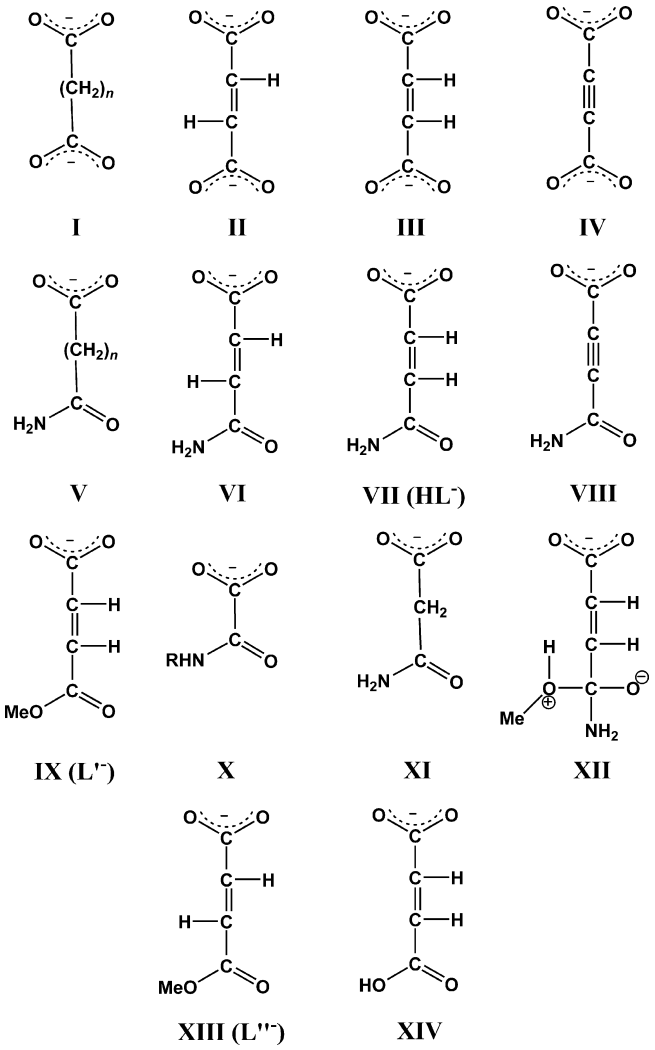

Fig. 1. Some of the dicarboxylate(-2) and amide-carboxylate(-1) ligands discussed in the text. The ligand used in this work is the maleamate(-1) ion (**VII**, HL^{-}). The succinamate(-1) ligand used in our previous studies is ligand **V** with $n = 2$ ($Hsum^{-}$). **XII** is the *possible* intermediate formed during the Cu^{II}-assisted transformation of HL^{-} to L'^{-}[19]. R = H (oxamate), Me, Et, ...

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. Microanalyses (C,H,N) were performed by the University of Ioannina

(Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer.

IR spectra (4000–450 cm^{-1}) were recorded on a Perkin-Elmer 16 PC FT-spectrometer with samples prepared as KBr pellets.

Safety note: Perchlorate salts are potentially explosive; such compounds should be synthesized and used in small quantities, and treated with utmost care at all times.

2.2. Compound preparation

Since the detailed syntheses and full characterized data of complexes **1**, **5**, **6a** and **6b** were not reported of this work [19], we incorporate these details below.

2.2.1. $[Cu_2(HL)_3(phen)_2](ClO_4) \cdot 1.5MeCN \cdot 0.5H_2O$ (**1** $\cdot 1.5MeCN \cdot 0.5H_2O$)

A colourless aqueous solution (1.5 ml) of $LiOH \cdot H_2O$ (0.018 g, 0.44 mmol) was added to a colourless solution of H_2L (0.049 g, 0.43 mmol) in MeCN (20 ml) to give a white suspension. Solid phen $\cdot H_2O$ (0.044 g, 0.22 mmol) was then added and the resulting colourless solution was stirred for 20 min. A light blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.080 g, 0.22 mmol) in MeCN (10 ml) was finally added to obtain a blue solution. X-ray quality blue prismatic crystals of the product were obtained by layering of the blue solution with a mixture of Et_2O/*n*-hexane (30 ml, 1:1 v/v). The crystals were collected by filtration under vacuum, washed with cold MeCN (5 ml), Et_2O (5 ml) and dried in air. Typical yields were in the 55–60% range. FT-IR (KBr pellet, cm^{-1}): 3422m, 3350m, 3190w, 3066w, 1692s, 1628s, 1586s, 1554s, 1520m, 1432s, 1370sh, 1304m, 1280m, 1220w, 1146sh, 1090s, 852m, 814w, 784w, 722m, 656sh, 622m. The dried solid analysed as solvent-free. *Anal.* Calc. for $C_{36}H_{28}N_7O_{13}ClCu_2$ (929.25): C, 46.53; H, 3.04; N, 10.55%. Found: C, 46.30; H, 2.92; N, 10.70%.

2.2.2. $[Cu_2(HL)_3(phen)_2](NO_3) \cdot 2.5MeCN \cdot 2H_2O$ (**2** $\cdot 2.5MeCN \cdot 2H_2O$)

A colourless aqueous solution (2 ml) of $LiOH \cdot H_2O$ (0.018 g, 0.44 mmol) was added to a solution of H_2L (0.049 g, 0.43 mmol) in MeCN (20 ml) to give a white suspension. Solid phen $\cdot H_2O$ (0.044 g, 0.22 mmol) was then added and the resulting colourless solution was stirred under heating for 20 min. A turquoise solution of $Cu(NO_3)_2 \cdot 2.5H_2O$ (0.051 g, 0.22 mmol) in MeCN (10 ml) was finally added to obtain a blue mixture, which was filtered to give a clear blue solution. X-ray quality light blue, needle-like crystals of the product formed in a closed vial after four days. The crystals were collected by filtration under vacuum, washed with Et_2O (2×2 ml) and dried in air. Typical yields were in the 55–60% range. FT-IR (KBr pellet, cm^{-1}): 3375sb, 3184mb, 3091w, 3062w, 1676m, 1643s, 1575vs, 1548sh, 1520m, 1493w, 1431s, 1383vs, 1312wb, 1225w, 1203w, 1189w, 1143w, 1107w, 1045wb, 994vw, 962wb, 902w, 873w, 850m, 823w, 739w, 720m, 673w, 650m, 630w, 476vw. The dried solid analysed as **2** $\cdot 2H_2O$. *Anal.* Calc. for $C_{36}H_{32}N_8O_{14}Cu_2$ (927.85): C, 46.60; H, 3.48; N, 12.08. Found: C, 46.47; H, 3.21; N, 12.27%.

2.2.3. $[Cu(HL)(phen)_2](OH) \cdot 0.5MeCONH_2 \cdot 0.75H_2O$ (**3** $\cdot 0.5MeCONH_2 \cdot 0.75H_2O$) and $[Cu(HL)_2(phen)]$ (**4**) in a mixture

A colourless aqueous solution (1.5 ml) of $LiOH \cdot H_2O$ (0.014 g, 0.34 mmol) was added to a solution of H_2L (0.038 g, 0.33 mmol) in MeCN (25 ml) to give a white suspension. Solid $CuCl_2 \cdot 2H_2O$ (0.038 g, 0.22 mmol) was then added to obtain a light blue slurry. A colourless solution of phen $\cdot H_2O$ (0.044 g, 0.22 mmol) in MeCN (10 ml) was added to the above light blue slurry under stirring yielding a darker light blue mixture, which was stirred for ~1 h. The final "solution" was filtered off and the light blue solution was layered with Et_2O (60 ml). X-ray quality blue prismatic and purple needle-like crystals in an approximate ratio of 1:1 formed, which were separated manually and dried in air. X-ray crystallography revealed that blue prisms correspond to complex **3** $\cdot 0.5 MeCONH_2 \cdot 0.75H_2O$ and purple needles correspond to complex **4**. FT-IR for **3** $\cdot 0.5 MeCONH_2 \cdot 0.75H_2O$ (KBr pellet, cm^{-1}): 3425sb, 3275wb, 1681m, 1628m, 1596m, 1519m, 1431s, 1384s, 1305m, 1227vw, 1146w, 1106w, 872w, 850m, 778vw, 722m, 668w, 621w, 460vw. *Anal.* Calc. for $C_{29}H_{25}N_{5.5}O_{5.25}Cu$ (598.14): C, 58.23; H, 4.22; N, 12.88. Found: C, 57.95; H, 4.03; N, 12.96%. FT-IR for **4** (KBr pellet, cm^{-1}): 3510sh, 3376mb, ~3200wb, 1676m, 1654w, 1628w, 1576s, 1521m, 1432vs, 1304m, 1202w, 1148vw, 1108vw, 874m, 850m, 821w, 718m, 668m, 652w, 608vw, 530vw, 489vw, 471vw. *Anal.* Calc. for $C_{20}H_{16}N_4O_6Cu$ (471.95): C, 50.90; H, 3.42; N, 11.87. Found: C, 50.72; H, 3.38; N, 11.99%.

2.2.4. $[Cu(HL)(phen)_2](OH) \cdot 0.5MeCONH_2 \cdot 0.75H_2O$ (**3** $\cdot 0.5MeCONH_2 \cdot 0.75H_2O$)

A colourless aqueous solution (3 ml) of $LiOH \cdot H_2O$ (0.032 g, 0.78 mmol) was added to a solution of H_2L (0.046 g, 0.40 mmol) in MeCN (25 ml) to give a white suspension. Solid $CuCl_2 \cdot 2H_2O$ (0.068 g, 0.40 mmol) was then added and the obtained light blue slurry turned into green during 45 min of stirring. A colourless solution of phen $\cdot H_2O$ (0.159 g, 0.80 mmol) in MeCN (10 ml) was then added to the above mixture, which was further stirred for 30 min. The final clear turquoise solution of the product was layered with Et_2O. Slow mixing gave X-ray quality, blue prismatic crystals, which were collected by filtration under vacuum and dried in air. Typical yields were in the 65-70% range. FT-IR spectroscopy and microanalytical data showed that the blue prismatic crystals correspond to complex **3** $\cdot 0.5MeCONH_2 \cdot 0.75H_2O$.

2.2.5. $[Cu_2(L')_2(ClO_4)(phen)_2(MeOH)](ClO_4)$ (**5**)

Solid phen $\cdot H_2O$ (0.057 g, 0.28 mmol) was dissolved in a colourless solution of H_2L (0.050 g, 0.43 mmol) in MeOH (20 ml). A blue solution of $Cu(ClO)_2 \cdot 6H_2O$ (0.107 g, 0.29 mmol) in MeOH (10 ml) was then added to obtain a turquoise solution which was layered with a mixture of Et_2O/*n*-hexane (35 ml, 1:1 v/v). Slow mixing initially gave a turquoise polycrystalline solid (**6a**). Upon storage of the closed layering tube at room temperature for one week, the polycrystalline powder was transformed into blue, X-ray quality crystals of the product. The crystals were collected by filtration under vacuum and dried in air. Typical yields were >60%. FT-IR (KBr pellet, cm^{-1}): 3461mb, 3356m, 3093wb, 2953w, 1719s, 1697m, 1644w, 1583vs, 1520m, 1495w, 1445s, 1432s, 1358w, 1346w, 1302vw, 1234s, 1174m, 1150sh, 1116vs, 1106vs, 1053sh, 930w, 875w, 846m, 825w, 774vw, 742vw, 720s, 683vw, 652w, 624s, 546vw, 458vw, 432w, 405vw. The IR spectrum of the turquoise powder (see spectrum of **6a**) is completely different compared to that of **5**. *Anal.* Calc. for $C_{35}H_{30}N_4O_{17}Cl_2Cu_2$(976.68): C, 43.04; H, 3.10; N, 5.74. Found: C, 42.98; H, 2.94; N, 5.82%.

2.2.6. $[Cu(ClO_4)(phen)(MeOH)_2]_n(ClO_4)_n$ (**6a**)

A colourless solution of phen $\cdot H_2O$ (0.170 g, 0.86 mmol) in MeOH (15 ml) was added to a light blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.319 g, 0.86 mmol) in the same solvent (20 ml). The resultant blue solution was layered with Et_2O (55 ml). Slow mixing gave a turquoise polycrystalline powder, which was collected by filtration, washed with Et_2O (3×2 ml) and dried in air. The yield was ~65%. FT-IR (KBr pellet, cm^{-1}): 3440 mb, 3070vw, 1629vw, 1585m, 1521m, 1494w, 1430s, 1406w, 1388w, 1342w, 1225w, 1148m, 1088vs, 874m, 847s, 777w, 738w, 720s, 687vw, 668w, 652w, 623w. This IR spectrum is identical to that of the turquoise polycrystalline solid which was initially isolated during the preparation of **5** (paragraph 2.2.5) and very similar to the IR spectrum of **6b** (see below). *Anal.* Calc. for $C_{14}H_{16}N_2O_{10}Cl_2Cu$ (506.77): C, 33.18; H, 3.19; N, 5.53. Found: C, 32.90; H, 3.21; N, 5.68%.

*2.2.7. $[Cu(ClO_4)(phen)(MeCN)_2]_n(ClO_4)_n$ (**6b**)*

A solution of phen · H_2O (0.087 g, 0.44 mmol) in MeCN (15 ml) was added to a light blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.163 g, 0.44 mmol) in the same solvent (40 ml) to give a turquoise solution. X-ray quality, turquoise crystals of the product formed by vapour diffusion of Et_2O onto the turquoise solution. The crystals were collected by filtration under vacuum, washed with cold MeCN (1 ml), Et_2O (2 ml) and dried in air. Typical yields were in the 55–60% range. FT-IR (KBr pellet, cm^{-1}): 3450mb, 3050vw, 1628w, 1608w, 1586m, 1516m, 1496w, 1349m, 1147vs, 1107vs, 1093vs, 940w, 870m, 852s, 776m, 734m, 720s, 636sh, 627s. *Anal.* Calc. for $C_{16}H_{14}N_4O_8Cl_2Cu$ (524.79): C, 36.62; H, 2.69; N, 10.68. Found: C, 36.18; H, 2.61; N, 10.83%.

*2.2.8. $[Cu_2(HL)_3(phen)_2](NO_3) \cdot MeOH \cdot H_2O$ (**7** · MeOH · H_2O)*

Solid LiOH · H_2O (0.018 g, 0.44 mmol) was added to a colourless solution of H_2L (0.049 g, 0.43 mmol) in MeOH (20 ml). The resultant solution was refluxed for 2 h and solid $Cu(NO_3)_2 \cdot 2.5\,H_2O$ (0.067 g, 0.29 mmol) was added. The colour of the solution immediately turned to light blue-turquoise. A solution of phen · H_2O (0.057 g, 0.28 mmol) in MeOH (10 ml) was then added yielding a final blue solution. X-ray quality blue prismatic crystals of the product formed by vapour diffusion of Et_2O onto the reaction solution. The crystals were collected by filtration under vacuum, washed with cold MeOH (1 ml), Et_2O (5 ml) and dried in air. Typical yields were in the 45–50 % range. FT-IR (KBr pellet, cm^{-1}): 3400mb, 3173w, 2927w, 2805w, 1678m, 1620sh, 1598vs, 1516m, 1493w, 1427m, 1384s, 1336m, 1311m, 1223w, 1203w, 1181vw, 1144w, 1106w, 1025wb, 871w, 850m, 829w, 775w, 737w, 722s, 647w, 613m, 561w, 515w, 484w, 453vw. The dried solid analysed as **7** · H_2O. *Anal.* Calc. for $C_{36}H_{30}N_8O_{13}Cu_2$ (909.83): C, 47.52; H, 3.33; N, 12.32. Found: C, 47.85; H, 3.24; N, 11.97%.

*2.2.9. $[Cu(HL)(NO_3)(phen)]_n$ (**8**)*

Solid phen · H_2O (0.057 g, 0.28 mmol) was dissolved in a colourless solution of H_2L (0.050 g, 0.43 mmol) in MeOH (20 ml). The obtained solution was mixed with a light blue solution of $Cu(NO_3)_2 \cdot 2.5\,H_2O$ (0.067 g, 0.29 mmol) in MeOH (8 ml). The final blue solution was layered with Et_2O. Slow mixing gave X-ray quality blue-turquoise crystals, which were collected by filtration under vacuum, washed with cold MeOH (1 ml), Et_2O (4 ml) and dried in air. Typical yields were >60%. FT-IR (KBr pellet, cm^{-1}): 3284mb, 3060s, 1748w, 1609s, 1588s, 1564s, 1519m, 1492m, 1456w, 1431s, 1385vs, 1344s, 1313vs, 1257m, 1225m, 1142w, 1106w, 1042w, 1001vw, 971m, 875m, 850s, 828w, 803w, 761vw, 740m, 721s, 651s, 618m, 560w, 509vw, 432m. *Anal.* Calc. for $C_{16}H_{12}N_4O_6Cu$ (419.87): C, 45.77; H, 2.89; N, 13.35. Found: C, 45.95; H, 2.85; N, 13.09 %.

2.3. Single-crystal X-ray crystallography

Details for the crystallographic characterization of **1** · 1.5MeCN · 0.5H_2O, **5** and **6b** have been reported earlier [19]. Light blue prismatic crystals of **2** · 2.5MeCN · 2H_2O (0.10 × 0.20 × 0.65 mm) were mounted in capillary. Diffraction measurements were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Cu Kα radiation at room temperature. Data collection (ω-scans) and processing (cell refinement, data reduction and empirical absorption correction) were performed using the CRYSTALCLEAR program package [20]. The crystals of **2** · 2.5MeCN · 2H_2O had poor diffraction ability, despite their sufficient size. Data were collected to $2\theta_{max} = 143.8°$ ($\sin\theta/\lambda = 0.6165$), but only the data to $2\theta_{max} = 118°$ were used, because at higher 2θ values more than half of the data collected were unobserved. Blue prismatic crystals of **3** · 0.5$MeCONH_2$ · 0.75H_2O (0.15 × 0.30 × 0.60 mm), blue-purple dichroic crystals of **4** (0.04 × 0.05 × 0.55 mm) and blue-turquoise crystals of **8** (0.20 × 0.40 × 0.85 mm) were mounted in air. Blue crystals of **7** · MeOH · H_2O (0.15 × 0.50 × 0.85 mm) were mounted in capillary. The crystals of **7** · MeOH · H_2O had poor diffraction ability (despite their sufficient size) showing large ω-widths with shoulders on each side. The data collected to only $2\theta_{max} = 29°$ were adequate to solve the structure, which is very similar to the structure of the well characterized compound **2**. Thus, we felt that the complete structural characterization was not crucial. Diffraction measurements were made on a Crystal Logic Goniometer diffractometer using graphite monochromated Mo Kα radiation for **3** · 0.5$MeCONH_2$ · 0.75H_2O, **7** · MeOH · H_2O and **8**, and on a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic using graphite monochromated Cu Kα radiation for **4**. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$ for **3** · 0.5$MeCONH_2$ · 0.75H_2O, **7** · MeOH · H_2O and **8**, and $22° < 2\theta < 54°$ for **4**. Intensity data were recorded using a θ-2θ scan. Three standard reflections monitored every 97 reflections showed less than 3% intensity fluctuation and no decay. Lorentz, polarization and psi-scan absorption corrections (for **8** only) were applied using Crystal Logic software. Important crystal data and parameters for data collection for **2** · 2.5MeCN · 2H_2O, **3** · 0.5$MeCONH_2$ · 0.75H_2O, **4** and **8** are reported in Table 1.

The structures were solved by direct methods using SHELXS-97 [21] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [22]. Further experimental crystallographic details for **2** · 2.5MeCN · 2H_2O: $2\theta_{max} = 118°$, reflections collected/unique/used 28955/6354 [R(int) = 0.0731]/6354, 603 parameters refined, $(\Delta/\sigma)_{max} = 0.006$, $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.586/-0.644$ e/Å^3, R_1/wR_2 (for all data) 0.1457/0.2706. All hydrogen atoms were introduced at calculated positions as riding on their bonded atoms. All non-H atoms were refined anisotropically, except those of the solvate acetonitrile molecules which were refined isotropically. No H atoms for the solvate molecules were included in the refinement. Further experimental crystallographic details for **3** · 0.5$MeCONH_2$ · 0.75H_2O: $2\theta_{max} = 50°$, reflections collected/unique/used 5490/5240 [R(int) = 0.0167]/5240, 460 parameters refined, $(\Delta/\sigma)_{max} = 0.004$, $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.910/-0.333$ e/Å^3, R_1/wR_2 (for all data) 0.0823/0.1893. Hydrogen atoms were located by difference maps and refined isotropically. All non-H atoms were refined anisotropically, except those of the water solvate molecules which were refined isotropically. There is also a disordered, over a centre of symmetry, acetamide solvate molecule, which is the hydrolysis product of the MeCN reaction solvent. No H atoms for the solvate molecules were included in the refinement. Further experimental crystallographic details for **4**: $2\theta_{max} = 118°$, reflections collected/unique/used 2885/2641 [R(int) = 0.0281]/2641, 345 parameters refined, $(\Delta/\sigma)_{max} = 0.000$, $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.416/-0.650$ e/Å^3, R_1/wR_2 (for all data) 0.0370/0.0968. Hydrogen atoms were located by difference maps and refined isotropically. All non-H atoms were refined anisotropically. Further experimental crystallographic details for **7** · MeOH · H_2O: $C_{37}H_{34}N_8O_{14}Cu_2$, fw = 941.81, a = 11.80(3), b = 12.21(3), c = 15.75(3) Å, $\alpha = 69.52(6)°$, $\beta = 76.47(7)°$, $\gamma = 77.21(7)°$, $V = 2042.41(2)$ Å^3, $Z = 2$, space group $P\bar{1}$, $2\theta_{max} = 29°$, reflections collected/unique/used 1640/1505 [R(int) = 0.0264]/1505, 255 parameters refined, $(\Delta/\sigma)_{max} = 0.370$, $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.997/-1.421$ e/Å^3, R_1/wR_2 (for 1311 refs with $I > 2\sigma(I)$) 0.1566/0.4009, R_1/wR_2 (for all data) 0.1662/0.4179. Only the copper atoms were refined anisotropically, the rest were refined isotropically. No H atoms were included in the refinement. Further experimental crystallographic details for **8**: $2\theta_{max} = 50°$, reflections collected/unique/used 2851/2851 [R(int) = 0.0000]/2851, 292 parameters refined, $(\Delta/\sigma)_{max} = 0.001$, $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.688/-0.863$ e/Å^3, R_1/wR_2 (for all data) 0.0724/0.1807. Hydrogen atoms were located

3. Results and discussion

3.1. Syntheses

Our efforts to prepare *binary* Cu^{II}/HL^- complexes were both successful and unsuccessful. The 1:2 reactions between $Cu(NO_3)_2 \cdot 2.5H_2O$ or $Cu(ClO_4)_2 \cdot 6H_2O$ and H_2L in H_2O, H_2O/MeCN or MeCN *in the absence of an external base* give polycrystalline blue solids in almost quantitative yields which have identical IR spectra. Analytical data repeatedly confirmed the empirical formula $Cu(HL)_2$ (**9**). The IR spectrum of **9** reveals the presence of coordinated amide group and bidentate carboxylate groups (vide infra). The same compound is readily isolated from the reaction of $[Cu_2(O_2CMe)_4(H_2O)_2]$ and four equivalents of H_2L in H_2O, H_2O/MeCN or MeCN. The 1:2:2 $Cu(ClO_4)_2 \cdot 6H_2O/H_2L/LiOH \cdot H_2O$ or NaOMe reaction systems in the same solvents or solvent mixtures, i.e. in the presence of an external base, lead to greenish-blue polycrystalline powders with identical IR spectra; the yields of these reactions are moderate. The same product is also isolated from MeOH or EtOH. Analytical data repeatedly confirmed the empirical formula $Cu(HL)_2 \cdot H_2O$ (**10**) for this solid. The IR study (vide infra) of this compound reveals the presence of "free", i.e. uncoordinated, amide groups and bridging carboxylate groups. Despite our numerous efforts (more than fifty samples were examined), we could not grow crystals of **9** and **10** suitable for single-crystal X-ray crystallography and thus their structures remain unknown. Based on the analytical data and IR spectra, we tentatively propose a polymeric structure for **9** with an O(amide),O(carboxylate), O′(carboxylate) bridging behaviour of HL^- resulting in six-coordinate Cu^{II} centres and a dinuclear, $[Cu_2(HL)_4(H_2O)_2]$, structure of the common paddle-wheel type for **10** with a bidentate bridging O(carboxylate), O′(carboxylate) coordination of HL^- and a five-coordinate (most probably square pyramidal) coordination geometry about the metal ions. Since compounds **9** and **10** have not been crystallographically characterized, their preparations are not given in the experimental (Section 2.2).

The synthetic investigation of the Cu^{II}/H_2L/phen reaction system leads to interesting mononuclear, dinuclear and polymeric complexes. We have studied the influence of four synthetic parameters on the chemical and structural identity of the products; these are the solvent, the absence or presence of external OH^-s in the reaction mixtures, the nature of the inorganic anion present in the copper(II) starting material and the molar ratio of the reactants.

Having obtained and identified complex **1** (see Section 2.2.1) [19], the next question addressed was whether, and in what manner, changes in the inorganic anion of the copper(II) starting material (keeping the same solvent mixture, i.e. MeCN/H_2O) might affect the product identity. The reaction of $Cu(NO_3)_2 \cdot 2.5H_2O$ with a mixture of H_2L and phen · H_2O, in the presence of LiOH · H_2O (1:2:1:2 molar ratio), in a solvent mixture comprising MeCN and H_2O (20:1 v/v) under slight heating led to a blue solution, from which were subsequently isolated light blue crystals of $[Cu_2(HL)_3(phen)_2](NO_3) \cdot 2.5MeCN \cdot 2H_2O$ (**2** · 2.5MeCN · $2H_2O$) in satisfactory yield. The molecular structures of the cations $[Cu_2(HL)_3(phen)_2]^+$ present in **1** and **2** are identical (vide infra). This, combined with the stronger coordination tendency of the NO_3^- ion (compared with that of the ClO_4^- ion) [23] indicates the great thermodynamic stability of this cation.

The use of $CuCl_2$ as starting material led to completely different chemistry. The 1:1.5:1:1.5 $CuCl_2 \cdot 2H_2O/H_2L$/phen · H_2O/LiOH · H_2O reaction mixture in MeCN/H_2O (20:1 v/v) gave a light blue solution, which upon layering with Et_2O yielded crystals that were obviously a mixture of two products. Microscopic examination showed both blue prisms and purple needles to be present in a visual ratio of roughly 1:1. Their not-too-dissimilar solubility prevented chemical separation. However, the extreme differences in colour and in crystal shape were fortuitous and allowed easy manual separation of the two materials. The prismatic and needle-like crystals were crystallographically characterized as complexes $[Cu(HL)(phen)_2](OH) \cdot 0.5MeCONH_2 \cdot 0.75H_2O$ (**3** · 0.5$MeCONH_2$ · 0.75H_2O) and $[Cu(HL)_2(phen)]$ (**4**), respectively.

With the identities of **3** and **4** established, convenient syntheses of pure materials were sought under alternative reaction conditions. Complex **3** has a Cu^{II}/HL^-/phen ratio of 1:1:2 and contains a hydroxide counterion, whereas the initial reaction solution had a Cu^{II}/HL^-/phen/OH^- ratio of 1:1.5:1:1.5. Thus, attempts to obtain pure **3** were made by adjusting the Cu^{II}/H_2L/phen/OH^- reaction ratio to 1:1:2:2. Using this modified reaction ratio, we were lucky enough to isolate the blue prisms of **3** as the only product, see paragraph 2.2.4 of Section 2. Complex **4** has a Cu^{II}/HL^-/phen ratio

of 1:2:1, whereas this ratio in the initial reaction solution was 1:1.5:1:1.5. In seeking to prepare the pure complex **4**, it was logical to carry out reactions employing the 1:2:1:2 $Cu^{II}/H_2L/phen/OH^-$ ratio. This reaction mixture in $MeCN/H_2O$ led to the isolation of *almost* pure purple needles of **4** in good yields (typically higher than 50%). However, careful examination of the purple material revealed trace amounts of blue microcrystals and/or specks which were shown to be complex **3** by IR spectroscopy. Thus, the manual separation of purple crystals from their above described mixture with **3** remains the only source of **4** to date for further measurements. It is likely that every reaction solution contains a mixture of $[Cu(HL)(phen)_2]^+$(the cation of **3**) and $[Cu(HL)_2(phen)]$ (**4**) in equilibrium, with factors such relative solubility, hydroxide concentration, lattice energy and crystallization kinetics, amongst others, determine the identity of the isolated products.

Somewhat to our surprise, the crystal structure of **3** contains lattice acetamide ($MeCONH_2$) molecules. The $MeCONH_2$ molecule is the hydrolysis product of the MeCN solvent, which is favoured in the presence of the metal ion [24]. The initial formed hydroxyimine, MeC(=NH)OH, tautomerizes to the amide, the hydrolysis in this particular case not proceeding to the formation of $MeCO_2H$ or $MeCO_2^-$. The formation of $MeCONH_2$ in an MeCN-containing reaction mixture and its incorporation in a complex (albeit as a ligand) were recently observed during the preparation of the cluster $[Fe_6(\mu_3\text{-}O)_2(O_2CPh)_{10}(salox)_2(MeCONH_2)_2] \cdot 6MeCN$ [25], where $salox^{2-}$ is the salicylaldehyde oximate(-2) ligand.

Having confirmed [19] that the $HL^- \rightarrow L'^-$ transformation takes place in OH^--free methanolic reaction mixtures (see also preparation of complex **5** in Section 2.2.5), the next question addressed was whether, and in what manner, addition of external base might affect the product identity. The 1:2:1:2 $Cu(ClO_4)_2 \cdot 6H_2O/H_2L/phen \cdot H_2O/LiOH \cdot H_2O$ reaction mixture in MeOH led to a pale blue solution, which upon layering with Et_2O or Et_2O/*n*-hexane gave a turquoise polycrystalline solid (**11**) in high yield (~70%). Analytical data are consistent with the empirical formula $Cu(HL)_{1.5}(phen)\text{-}(ClO_4)_{0.5} \cdot xMeOH$ ($x = 0.5$–1.0), while its IR spectrum indicates the presence of ionic perchlorates. Based on the structure of **7** · MeOH · H_2O (vide infra), we believe that **11** is a dinuclear complex possessing the cation $[Cu_2(HL)_3(phen)_2]^+$ with a molecular structure akin to the structures of the cations that are present in **1**, **2** and **7**. Seeking for the structural characterization of a product from the $Cu^{II}/H_2L/phen/OH^-$ reaction system in MeOH, we carried out an analogous reaction using $Cu(NO_3)_2 \cdot 2.5H_2O$ as starting material. We were lucky to easily crystallize and roughly solve the structure of $[Cu_2(HL)_3(phen)_2](NO_3) \cdot MeOH \cdot H_2O$ (**7** · MeOH · H_2O); as mentioned in Section 2.3, the quality of the structure is not particularly good, but we were able to reveal the gross structural features of this compound. Thus, the presence of external OH^-s in MeOH does *not* favour the formation of a Cu^{II}/L'^-/phen complex.

We came across complex $[Cu(HL)(NO_3)(phen)]_n$ (**8**) when we tried to prepare the nitrate analogue of complex $[Cu_2(L')_2(ClO_4)\text{-}(phen)_2(MeOH)](ClO_4)$ (**5**) [19]. Our desire was to investigate whether the nature of the inorganic anion plays any role in the $HL^- \rightarrow L'^-$ transformation. These at first glance trivial efforts led to an interesting coordination polymer. The reaction explored was that between $Cu(NO_3)_2 \cdot 2.5H_2O$, one and a half equivalents of H_2L and one equivalent of phen · H_2O in MeOH *in the absence* of external OH^-s. The blue solution obtained was layered with Et_2O to give blue-turquoise, X-ray quality crystals of **8** in higher than 60% yield. If the layering tube remains undisturbed for 4–5 days, few (3–4) small dark blue crystals of the known [26] 1D coordination polymer $[Cu(NO_3)_2(phen)]_n$ (**12**) appear; the identity of **12** was confirmed by single-crystal, X-ray crystallography, because we had not suspected that this compound does not contain HL^- or L'^- (we neglected to look carefully at the IR spectrum!). With the identities of **8** and **12** established, a convenient preparative route for the former was sought by increasing the H_2L/Cu^{II} ratio from 1.5:1 to 3:1. Our attempts were in vain because we could not avoid the *slow* precipitation of a small amount of **12**. However, taking advantage of the different rate of crystallization, we could obtain an analytically pure batch of crystals of **8** which were used for further characterization; for this reason, the slow appearance of few small, dark blue crystals of **12** is not mentioned in Section 2.2.9.

We were disappointed at not observing the Cu^{II}-assisted/promoted $HL^- \rightarrow L'^-$ transformation [19] during the investigation of the $Cu(NO_3)_2 \cdot 2.5H_2O/H_2L/phen$ reaction system in MeOH. The obvious, initial conclusion was that this transformation is anion-dependent and it is not favoured in the presence of NO_3^- ions! However, prolonged storage (e.g. for 45 days) of $Cu(NO_3)_2 \cdot 2.5H_2O/H_2L/phen \cdot H_2O$ (1:1:1) reaction mixtures in MeOH or EtOH in closed flasks or layering tubes (with Et_2O) leads to solids with no reproducible analytical data, but with IR spectra that exhibit a strong band at 1720 cm^{-1} attributable to the $\nu(C{=}O)_{ester}$ vibration. Experimental work at the time of submission of this work has allowed access to complex $[Cu(L'')_2(NO_3)(phen)_2(EtOH)](NO_3)$, where L''^- is the monoethyl maleate(-1) ligand. Further synthetic studies on the general $CuX_2/H_2L/phen$ reaction system in alcohols (ROH) are in progress; we have been investigating the effects of the nature of X^-, the nature of R, the reactants' concentration and the crystallization rate on the chemical and structural identity of the products.

3.2. Description of structures

The crystallographically established coordination modes of HL^- in complexes **2**–**4**, **7** and **8** are shown in Fig. 2. Aspects of the molecular and crystal structures of representative complexes are presented in Figs. 3–10, while selected interatomic distances and angles are listed in Tables 2–4.

The molecular structures of the dinuclear cations that are present in complexes **1** · 1.5MeCN · $0.5H_2O$, **2** · 2.5MeCN · $2H_2O$ and

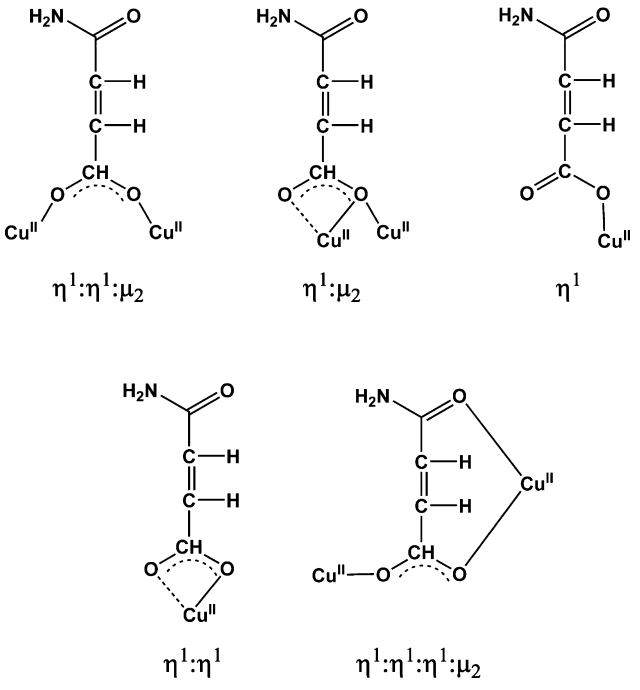

Fig. 2. The crystallographically established coordination modes of the maleamate-(-1) (HL^-) ligand in the copper(II) complexes **2**–**4**, **7** and **8**.

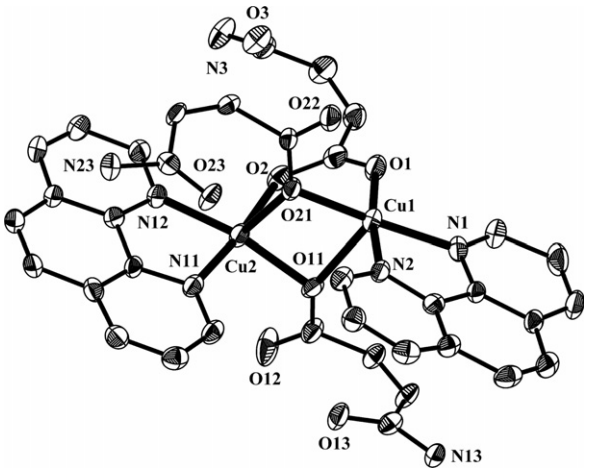

Fig. 3. Partially labeled ORTEP plot of the cation of **2** · 2.5MeCN · $2H_2O$ with ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity.

7 · MeOH · H_2O are very similar. We give below a comparative structural description for the cations of **1** (Fig. S1) [19] and **2** (Fig. 3, Table 2). The structure of the cation in both complexes consists of two Cu^{II} ions bridged by the carboxylate groups of the three HL^- ligands; one carboxylate group is in the familiar $\eta^1{:}\eta^1{:}\mu_2$ mode and the other two in the relatively rare monoatomic bridging mode ($\eta^1{:}\mu_2$), see Fig. 2. A chelating phen molecule completes five-coordination at each metal center. The neutral primary amide groups of the HL^- ligands remain uncoordinated. As is sometimes [27] (but not always [28]) observed for monoatomic bridging carboxylate groups, there is evidence for weak interactions between the metal ions and the "free" carboxylate oxygen atoms. For example, the Cu(1)···O(22) and Cu(2)···O(12) distances in **2** are only 2.989(5) and 2.882(5) Å, respectively. The coordination geometry about each metal ion in both complexes is well described as square pyramidal with the bridging carboxylate oxygen atoms occupying the apical positions for the two Cu^{II} centers; for example, atoms O(11) and O(21) occupy the apical positions for Cu(1) and Cu(2), respectively. Analysis of the shape-determining angles using the

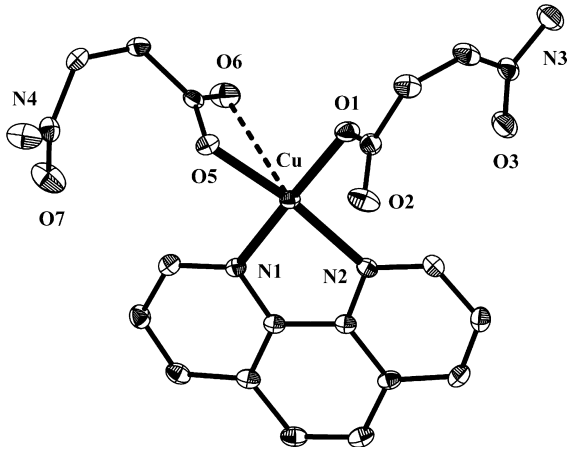

Fig. 7. Partially labelled ORTEP plot of **4** with ellipsoids drawn at the 30% probability level. The dashed line indicates a weak bonding interaction. H atoms have been omitted for clarity.

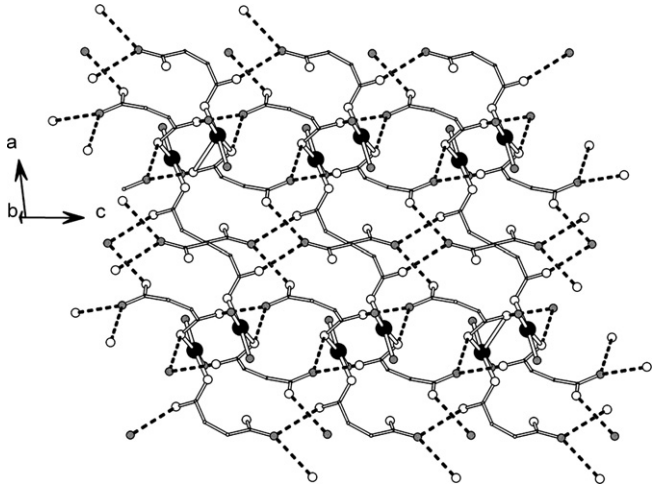

Fig. 8. A part of the 3D H-bonded network that stabilizes the crystal structure of **4**. Colour code as in Figs. 4 and 5. The dashed lines represent H bonds. Only the N atoms of the phen ligands are shown.

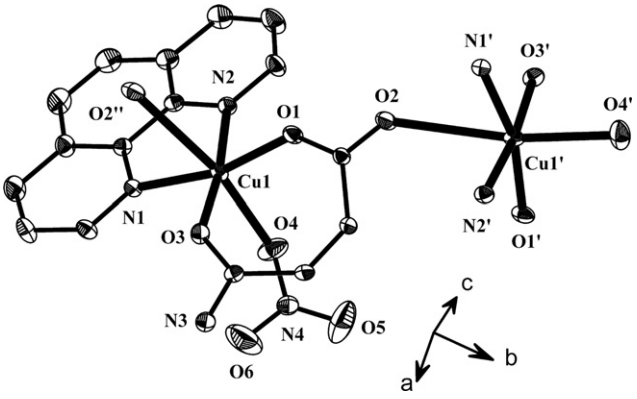

Fig. 9. Partially labelled ORTEP plot of a very small fragment of one chain of complex **8** with ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity. *Symmetry codes*: (′) $1-x$, $0.5+y$, $1.5-z$; (″) $1-x$, $-0.5+y$, $1.5-z$.

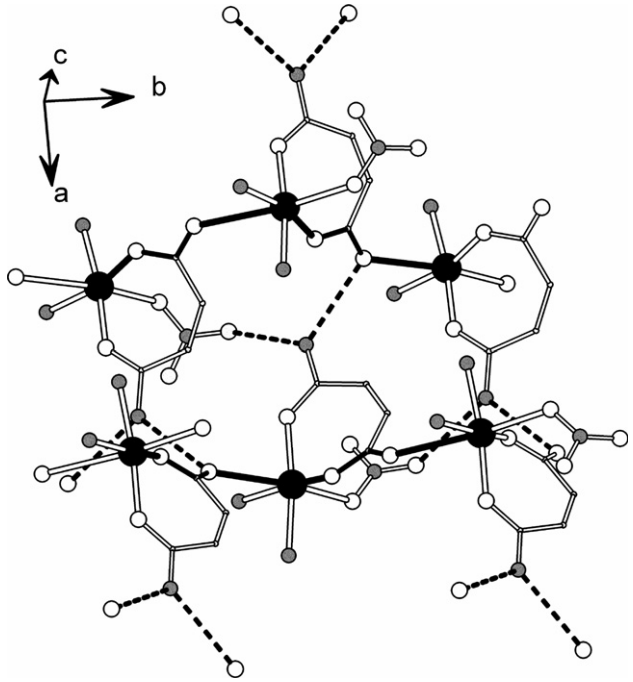

Fig. 10. A plot of the 2D H-bonded network in the crystal structure of **8**. Colour code as in Figs. 4, 5 and 8. The dashed lines represent H bonds along the chains. Only the N atoms of the phen ligands are shown.

approach of Reedijk, Addison and co-workers [29] yields trigonality index, τ, values of 0.025 and 0.042 for Cu(1) and Cu(2), respectively, in **1**, and 0.033 and 0.106 for Cu(1) and Cu(2), respectively, in **2** ($\tau = 0$ and 1 for perfect *sp* and *tbp* geometries, respectively). As expected, the axial bonds are the longest. For **1**, the dihedral angle between the two least-squares basal planes is 21.5°, and the angle between the two phen planes is 23.2°. The corresponding angles for **2** are 17.8° and 9.0°, respectively.

In the crystal structure of **2**, the cations are associated through two N(3)···O(3) ($2-x$, $-y$, $2-z$), as well as through N(23)···O(13) ($0.5+x$, $0.5-y$, $0.5+z$) H bonds forming loops of six H-bonded cations (Fig. 4, Table S1); the loops are adjacent to each other, thus creating layers that extend parallel to the (101) plane (Fig. 5).

Complexes **1**, **2** and **7** are new welcome additions in the very small family of complexes containing the extremely rare $\{Cu^{II,II}_2(\eta^1{:}\mu_2\text{-}O_2CR)_2(\eta^1{:}\eta^1{:}\mu_2\text{-}O_2CR)\}^+$ core [15,30], where RCO_2^-

is a simple carboxylate (R = H, Me, Ph, ..., i.e. R is a non-coordinating group).

The structure of **3** · $0.5MeCONH_2$ · $0.75H_2O$ consists of the mononuclear cation $[Cu(HL)(phen)_2]^+$ (Fig. 6, Table 3), a hydroxide counteranion, and acetamide and water solvate molecules; the latter three will not be further discussed. The coordination sphere of the complex cation consists of four N atoms belonging to the two chelating phen molecules and one carboxylate oxygen from the terminal monodentate (η^1, Fig. 2) HL^- ligand. The metal coordination geometry may be described as distorted square pyramidal with the N(2) atom occupying the apical position at Cu(1). As a result, the Cu(1)–N(2) bond length (2.198(4) Å) is longer than the Cu(1)–N(1,11,12) bond distances (1.995(3)–2.057(4) Å). The τ value is 0.31 and thus the geometry about the metal ion is significantly distorted. The cations of **3** are held together through two N(3)···O(3) ($-x$, $1-y$, $1-z$) H bonds to form dimers, dimensions being N(3)···O(3) = 2.992 Å, HN(3A)···O(3) = 2.072 Å and N(3)–HN(3A)···O(3) = 168.0° (Table S2). The intermolecular distance of 2.896 Å between the hydroxide O atom and the carboxylato oxygen atom O(1) is a strong evidence of the presence of a H bond between the two atoms.

Complex **3** joins a family of structurally characterized complexes of the general formula $[Cu(O_2CR)(phen)_2]^+$ [31], where R is a non-coordinating group; however, in most of these complexes the carboxylate group of RCO_2^- is chelating, notable exceptions being complexes $[Cu(O_2CMe)(phen)_2](BF_4)$ [31e], $[Cu(O_2CMe)(phen)_2](O_2CMe)\cdot A$ [31f], where A is the neutral lattice molecule 2-(ethylthio)-4-oxopteridine, and $[Cu(HCO_2)(phen)_2](BF_4)$ [31g].

The structure of **4** (Fig. 7, Table 3) consists of mononuclear $[Cu(HL)_2(phen)]$ molecules. Two carboxylate oxygen atoms from the two terminal monodentate HL^- ligands (η^1, Fig. 2) and two phen nitrogen atoms create the coordination environment around the Cu^{II} atom. The metal coordination geometry is well described as square planar, the two *trans* coordination angles being 171.9(1)° (O(5)–Cu–N(2)) and 173.9(1)° (O(1)–Cu–N(1)). The carboxylato group of one HL^- ligand can be alternatively considered as asymmetric chelating (η^1:η^1, Fig. 2) as evidenced by the Cu–O distances of 1.947(2) (Cu–O(5)) and 2.805(2) (Cu–O(6)) Å; on the other hand, the carboxylato group of the second HL^- ligand is undoubtedly considered as monodentate due to the large Cu–O(2) distance of 3.050(2) Å. Adopting this alternative description of the carboxylate coordination mode, the metal coordination geometry may be described as distorted square pyramidal with the weakly bonding O(6) atom occupying the apical position at Cu; this view is emphasized in Fig. 7. The primary amide groups of the two HL^- ligands remain uncoordinated in **4**; instead, both participate in hydrogen bonding interactions that lead to the formation of a 3D framework (Fig. 8, Table S2).

Complex **4** is only the second structurally characterized example of a mononuclear complex with the formula $[Cu(RCO_2)_2(phen)]$, the first being the bis(3-methylbenzoato-O,O′)(phenanthroline-N,N′)copper(II) [32]; however, in the latter both carboxylate groups are chelating resulting in a six-coordinate species. It should be mentioned at this point that two other, mononuclear copper(II) complexes containing two (monodentate) carboxylate ligands and one phen ligand have been crystallographically characterized. These are $[Cu(Cl_3CCO_2)_2(phen)(H_2O)]$ [33a] and $[Cu(O_2CPh)_2(phen)(H_2O)]$ [33b]; both contain one aquo ligand resulting in a true 5-coordination at the metal centre.

Complex **8** in a 1D coordination polymer comprising neutral $[Cu(HL)(NO_3)(phen)]_n$ chains (Fig. 9, Table 4). The carboxylato group of the HL^- ligand is asymmetrically coordinated to two neighbouring Cu^{II} ions adopting the *syn,anti* η^1:η^1:μ_2 mode, thus promising the formation of zigzag chains which extend parallel to the (1 0 0) plane. Two carboxylate oxygen atoms (from different HL^- ligands), two N atoms from the phen ligand, one oxygen atom (O(4)) from the monodentate nitrato group and the amide oxygen (O(3)) of HL^- create a distorted octahedral environment around the Cu^{II} centre. The Jahn–Teller sites are atoms O(4) and the carboxylate oxygen atom O(2″) ($1-x$, $-0.5+y$, $1.5-z$); the Cu(1)–O(4) and Cu(1)–O(2) ($1-x$, $-0.5+y$, $1.5-z$) distances are 2.398(5) and 2.751(5) Å, respectively. As a result of the orientation of the Jahn–Teller axis, the two $Cu–O_{carboxylato}$ bond lengths differ about

Symmetry codes: (′) $1-x$, $0.5+y$, $1.5-z$; (″) $1-x$, $-0.5+y$, $1.5-z$.

0.8 Å (Cu(1)–O(1) 1.919(4) Å, Cu(1)–O(2″) 2.751(5) Å); this significant difference is reflected on the C–O carboxylate bond distances which also differ (C–O(1) 1.270(6) Å, C–O(2) 1.231(6) Å). The maleamate(-1) ligand adopts the η^1:η^1: η^1:μ_2 coordination mode (Fig. 2) in **8** and this is the first case in which amide coordination of HL^- is realized; **8** is the first example of a polymeric metal complex involving the HL^- ligand. Of remarkable interest is the formation of the 7-membered $CuO_{amide}C{=}C{-}CO_{carboxylate}$ chelating ring.

There are two H bonding interactions in the crystal lattice of **8**, which result in the formation of a 2D network that extends parallel to the (0 0 1) plane, see Fig. 10. Their dimensions are: N(3)···O(5) $(1.5-x,\ -0.5+y,\ z)$ = 2.927 Å, HN(3A)···O(5) = 2.077 Å, N(3)–HN(3A)···O(5) = 151.5° and N(3)···O(2) $(0.5+x,\ y,\ 1.5-z)$ = 2.896 Å, HN(3B)···O(2) = 2.149 Å, N(3)–HN(3B)···O(2) = 159.2°.

If we ignore the preliminary communication of this work [19], complexes **1**, **2**, **3**, **4**, **7** and **8** are the first structurally characterized maleamate complexes of *any* metal. However, it should be mentioned at this point that few metal complexes of N-substituted maleamate ligands have been structurally characterized [34]. These are $[Bu^n{}_3Sn^{IV}(L1)]_n$[34a], where $L1^-$ is the N-(1-naphthyl)maleamato(-1) ligand, and $[Mo^{II}(\eta^3\text{-}C_3H_4\text{-Me-2})(L2)(CO)_2\text{-}(phen)]$ [34b], where $L2^-$ is the N-(*p*-tolyl)maleamato(-1) ligand. $L1^-$ behaves as an $O_{carboxylate}$, O_{amide} bidentate bridging ligand leading to polymeric chains, while $L2^-$ acts as a terminal $O_{carboxylate}$ monodentate ligand. The Mo^{II} complex was prepared from the reaction of $[Mo^{II}(\eta^3\text{-}C_3H_4\text{-Me-2})\{NH(p\text{- tolyl})(CO)_2(phen)\}]$ with maleic anhydride in THF and the $L2^-$ ligand resulted from the coupling between maleic anhydride and the coordinated amido group of the starting material.

3.3. IR spectra

Complexes **2**–**4** and **7**–**11** were characterized by IR spectroscopy. Complexes **2**, **3**, **7**, **10** and **11** exhibit a variable intensity, very broad band above 3100 cm^{-1}, assignable to ν(OH) vibrations of coordinated or/and lattice MeOH/H_2O [10a], and to $\nu(OH)_{hydroxo}$ mode (only in **3**). The broadness and relatively low frequency of this band are both indicative of H bonding.

Absorptions of free phen in the 1600–1400 cm^{-1} region, attributed to ring stretching vibrations, shift to higher frequencies upon chelation in **2**–**8** and **11**. The 854 and 738 cm^{-1} bands of free phen, assigned to out-of-plane C–H deformations, shift to lower frequencies, sometimes with splitting of the former [35].

In the spectrum of **11**, the strong band at around 1090 cm^{-1} and the medium band at 620–625 cm^{-1} are attributed to the $\nu_3(F_2)$ and $\nu_4(F_2)$ modes (ν_d(ClO) and δ_d(OClO), respectively) of the uncoordinated T_d perchlorate ions, respectively [36a].

The IR spectra of **2** and **7** are indicative of the presence of ionic nitrates; their – crystallographically established – existence is deduced from the appearance of the $\nu_3(E')$ ν_d(NO) mode of the D_{3h} ionic nitrate at ~1385 cm^{-1} [36a]. The IR spectrum of **8** in KBr (Section 2.2.9) exhibits the strong $\nu_3(E')$ band at 1385 cm^{-1}; it is thus indicative of the presence of ionic nitrates, although the structure of the complex (Section 3.2) revealed no NO_3^- counterions! This suggest [36b] that a certain amount of nitrato ligands are replaced by bromides (thus generating ionic nitrates) in the KBr matrix. It is well known that pressing a pellet affects the nitrate coordination [36b,36c], and this consequently affects the nitrate vibrations [36b,36c,36d]. In the Nujol and hexachlorobutadiene mull spectra of **8** (not cited in Section 2.2.9), the bands at 1455 and 1320 cm^{-1} are assigned to the $\nu_5(B_2)$ ($\nu_a(NO_2)$) and $\nu_1(A_1)$ ($\nu_s(NO_2)$) stretching modes (under C_{2v} symmetry), respectively, of the nitrato ligand [36a]; their separation is small (135 cm^{-1}) in accordance with the monodentate character of the nitrate group [36a].

The spectra of **2**–**4** and **7**–**11** exhibit the typical bands of the primary amide and carboxylate groups [37]. Tentative IR assignments of few diagnostic bands attributed to these groups are given in Table 5. The assignments have been given in comparison with the data obtained for sodium maleamate (Na(HL)), assumed to contain a "free" carboxylate group [37b], oxamato(-1) (**X** in Fig. 1; R = H) [17b], malonamato(-1) (**V** in Fig. 1; n = 1) [18] and succinamato-(-1) (**V** in Fig. 1; n = 2) [15,16] metal complexes, and taking into account literature reports [37]. As a general remark, we must emphasize that some of the vibrational modes shown in Table 5 are strongly coupled and thus the proposed assignments must be regarded as approximate descriptions of the vibrations. The typical bands of the neutral amide group ($\nu_{as}(NH_2)$, $\nu_s(NH_2)$, $\delta(NH_2)$, ν(CN)) in the spectra of **2**–**4**, **7**, **10** and **11** are situated at approximately the same wavenumbers to those in the spectrum of Na(HL), confirming (**2**–**4**, **7**) or suggesting (**10**, **11**) the non-participation of the amide group in coordination. In the spectrum of **8**, the ν(CN) mode shifts to higher frequencies compared to Na(HL), whereas the $\nu(C{=}O)_{amide}$ band shows a frequency decrease. These shifts confirm the amide-O coordination [16,18]. Upon coordination via oxygen, the positively charged Cu^{II} ion stabilizes the negative charge on the O atom; the amide function now occurs in its polar resonance form and thus the double bond character of the CN bond increases (hence the shift of ν(CN) to higher wavenumbers), while the double bond character of the CO bond decreases (hence the shift of ν(CO) to lower wavenumbers). For **9**, only the $\nu(C{=}O)_{amide}$ band shows a frequency decrease. The difference $\Delta(\Delta = \nu_{as}(CO_2)-\nu_s(CO_2))$ for **3** is more than that of Na(HL), as expected for the crystallographically confirmed monodentate mode of the carboxylate

ligation [37b]. Owing to the presence (confirmed for **2**, **7** and proposed for **11**) of two different types of carboxylate bridges in the complexes containing the cation $[Cu_2(LH)_3(phen)_2]^+$, two $\nu_{as}(CO_2)$ bands are observed [15]. The difference Δ for **8**, **9** and **10** is less than that of Na(HL), as expected for the crystallographically confirmed (**8**) or suggested (**9**, **10**) bidentate bridging mode of the carboxylate ligation [37b].

4. Concluding comments and perspectives

The initial use of the HL^-/phen "ligand blend" in Cu(II) chemistry has yielded complexes (**3**, **4**, **8**) or a group of complexes (**1** [19], **2**, **7**), each of which promises to be a new family of copper(II) compounds. The dinuclear complexes **1**, **2** and **7** have bridging units that rarely appear in $Cu^{II,II}_2$ chemistry, while **8** is an interesting 1D polymer where polymerization is solely achieved by the carboxylate group of the HL^- ligand. Complexes **3** and **4** are new members in the $[Cu(RCO_2)(N,N'\text{-donor})_2]^+$ and $[Cu(RCO_2)_2(N,N'\text{-donor})]$ families of complexes, respectively. The structural diversity of the maleamato(-1) complexes described stems in part from the ability of HL^- to exhibit a variety of distinct coordination modes; no less than five ligation modes were observed in complexes **2**–**4**, **7** and **8**. We do believe that HL^- is also capable of acting as μ_3 and μ_4 ligand, thus increasing the possibilities for polynuclear complex and/or coordination polymer formation. Preliminary results in our group indicate that "fine-tuning" of the synthetic and crystallization conditions can bring remarkable changes in the ligation modes of HL^-, and in the structures of the resulting metal complexes.

The structural chemistry of the Cu^{II}/ HL^-/phen system, as detailed in the above discussion for **2**–**4**, **7** and **8**, does not show similarities to that of the $Cu^{II}/^-OOC–CH{=}CH–COO^-$/phen system [38,39], due to the different nature (charge, donor groups) of HL^- and the maleate(-2) (**III** in Fig. 1) or fumarate(-2) (**II** in Fig. 1) ligands. Even the hydrogenmaleate(-1) ion, $Hmal^-$ (**XIV**, Fig. 1), which can be considered as a "structural analogue" of HL^-, forms the complex $[Cu(Hmal)(phen)(H_2O)_2]^+(Hmal^-)$ [40], which is different from the mononuclear complexes **3** and **4**. A direct comparison of the chemistry of the $Cu^{II}/HL^-/N,N'$-donor system with that of the $Cu^{II}/^-OOC–CH_2–CH_2–CONH_2$ (**V** with $n = 2$ in Fig. 1; Hsucm)/N,N′-donor system is not feasible, because phen has not yet been used in the latter. However, complexes $[Cu_2(Hsucm)_3(dmbpy)_2](OH)$ [15], **2** and **7** have structurally similar cations, the only difference being the different nature of the aromatic bidentate N,N′-chelate (dmbpy = 4,4′-dimethyl-2,2′-bipyridine). It should be mentioned that no transformation of the amide group to the methyl ester group was observed during the investigation of the Cu^{II}/Hsucm$^-$/bpy or dmbpy system in MeOH [15].

Complexes of other 3d- or 4f-metal ions with the HL^-/phen ligand combination are not known to date, and it is currently not evident whether the chemical identity and structure of such compounds, and the $HL^-\rightarrow L'^-$ transformation [19] are dependent on the particular nature of the metal ion. It is also clear that the metal ion/LH^- chemistry warrants expansion to other bidentate and *tridentate* aromatic N-heterocycles. We are studying these matters. In the preliminary communication of this work [19], we have reported that the tridentate chelating ligand 2,6-bis(pyrazol-1-yl)pyridine(bppy) gives complexes $[Cu_2(HL)_2(bppy)_2](ClO_4)_2$ and $[Cu_2(L')_2(bppy)_2](ClO_4)_2$ in MeCN and MeOH, respectively.

ABSTRACT

Nickel(II) complexes of the type $Ni[(XPR_2)(YPR'_2)N]_2$ [X = S (**1**) or O (**2**), Y = O, R = Ph, R′ = OEt] and $Ni_2[(OPPh_2)_2N]_4$ (**3**) were prepared by reacting either anhydrous $NiCl_2$ or $NiCl_2 \cdot 6H_2O$ with the potassium salt of the appropriate tetraorganodichalcogenoimidodiphosphinic acid, in 1:2 molar ratio. Recrystallization of **3** from dimethylformamide resulted in $Ni[(OPPh_2)_2N]_2(DMF)$ (**4**). Reaction between $NiCl_2$ and $K[(SPPh_2)\{OP(OEt)_2\}N]$ in an 1:3 molar ratio resulted in the ionic species $KNi[(SPPh_2)\{OP(OEt)_2\}N]_3$ (**5**). Compounds **1**–**5** were characterized by IR, electronic spectroscopy and mass spectrometry. The molecular structures of $\mathbf{3} \cdot CH_2Cl_2$, $\mathbf{4} \cdot 2H_2O$ and **5** were determined by single-crystal X-ray diffraction. A dimeric structure was found in case of complex $\mathbf{3} \cdot CH_2Cl_2$, with both monometallic biconnective and homobimetallic triconnective $[(OPPh_2)_2N]^-$ units, while an octahedral environment around nickel was established in the monomeric complex $\mathbf{4} \cdot 2H_2O$ by monometallic biconnective $[(OPPh_2)_2N]^-$ and DMF ligands, respectively. The crystal of the ionic species **5** contains discrete tetranuclear units in which the phosphorus ligands act heterobimetallic, either (*O*,*O*,*S*)-triconnective or (*S*,*O*,*O*,O_{Et})-tetraconnective, and (*N*,*O*,*O*,*S*)-heterotrimetallic tetraconnective, resulting in an octahedral environment around nickel and a square-pyramidal one around potassium, respectively. Powder X-ray diffraction studies on **5** are in agreement with the single-crystal investigation.

1. Introduction

Metal complexes of tetraorganodichalcogenoimidodiphosphinato ligands, $[(XPR_2)(YPR'_2)N]^-$, attracted an increased interest for many years, due to their properties and potential applications as catalysts in organic synthesis, components in optical or electronic devices and sensors, NMR shift reagents, as well as derivatives with biological activity. Inorganic and organometallic derivatives either of Main Group [1] or transition metal complexes [2] were previously described. Several nickel(II) complexes of type $Ni[(XPR_2)(YPR'_2)N]_2$ were reported so far. For compounds containing the same chalcogen atoms, *e.g.* $Ni[(SPR_2)_2N]_2$ (R = Me [3,4], Ph [5,6]) and $Ni[(SePPh_2)_2N]_2$ [7], monomeric structures with a tetrahedral NiE_4 core (E = S, Se) were found by single-crystal X-ray diffraction, while in the case of the derivative $Ni[(SPMe_2)(SPPh_2)N]_2$ [5] a square-planar NiS_4 core was observed. The monothio derivatives $Ni[(OPPh_2)(SPR_2)N]_2$ (R = Me, Ph) are also monomeric, with chelating monometallic biconnective ligands, resulting in tetrahedral NiO_2S_2 cores [8]. For the dioxo derivative $Ni[(OPPh_2)_2N]_2$, a dimeric structure was previously proposed in benzene solution according to the molecular mass measurements [9].

Here we report on the synthesis and spectroscopic characterization of the new derivatives $Ni[(SPPh_2)\{OP(OEt)_2\}N]_2$ (**1**) and $Ni[(OPPh_2)\{OP(OEt)_2\}N]_2$ (**2**), the ionic species $KNi[(SPPh_2)\{OP(OEt)_2\}N]_3$ (**5**) as well as the adduct $Ni[(OPPh_2)_2N]_2(DMF)_2 \cdot 2H_2O$ ($\mathbf{4} \cdot 2H_2O$). The crystal and molecular structure of the dimeric $Ni_2[(OPPh_2)_2N]_4 \cdot CH_2Cl_2$ ($\mathbf{3} \cdot CH_2Cl_2$), its adduct $\mathbf{4} \cdot 2H_2O$ and the ionic derivative **5** are also discussed.

2. Experimental

The organophosphorus ligands were prepared according to literature methods: $K[(SPPh_2)\{OP(OEt)_2\}N]$, $K[(OPPh_2)\{OP(OEt)_2\}N]$

[10]. K[(OPPh$_2$)$_2$N] was obtained by stirring the free acid with KOBu^t in diethyl ether. NiCl$_2$ was dehydrated by keeping NiCl$_2 \cdot 6H_2O$ for two weeks in the oven at 120 °C and subsequently stored under argon. Solvents were dried (THF on potassium, EtOH and MeOH on magnesium and CH_2Cl_2 on $CaCl_2$) and distilled under argon prior to be used. IR spectra were recorded in the range 4000–400 cm^{-1} in KBr pellets on a Jasco FT/IR-615 equipment, while the electronic spectra were recorded on a Jasco V-550 spectrometer. Mass spectra were recorded on a FINNIGAN MAT 8200 (CI), a FINNIGAN MAT 8222 (FAB) and a Bruker Esquire LC instrument (ESI), respectively. Magnetic moments were determined on a Sherwood MSB AUTO instrument and elemental analysis were performed on a VarioEL analyzer. The experimental powder diffraction pattern was obtained with a Shimadzu XRD-6000 diffractometer using a Cu Kα X-ray radiation, while the simulated X-ray powder diffraction pattern was obtained with the MERCURY CSD 2.0 program [11].

2.1. Preparation of bis[P,P-diethoxi-P′,P′-diphenyl-P′-thioimidodiphosphinato]nickel, Ni[(SPPh$_2$){OP(OEt)$_2$}N]$_2$ (**1**)

A mixture of K[(SPPh$_2$){OP(OEt)$_2$}N] (0.511 g, 1.25 mmol) and NiCl$_2$ (0.148 g, 0.62 mmol) was stirred for 8 h in a mixture of THF (40 ml) and ethanol (10 ml) at reflux. The solvent was removed in vacuum and the solid was treated with CH_2Cl_2. KCl was filtered off and the solution was concentrated in vacuum. A yellow-brown solid product was isolated. Yield: 0.39 g (78%), M.p. 99 °C. *Anal.* Calc. for $C_{32}H_{40}N_2O_6P_4S_2Ni$: C, 48.33; H, 5.03; N, 3.52. Found: C, 47.98; H, 5.16; N, 3.48%. IR (cm^{-1}): 1255vs [ν_{as}(P$_2$N)], 1105s [ν(PO)], 1043vs, br [ν(POC)], 596s [ν(PS)]. λ_{max} (cm^{-1}), CH_2Cl_2 (blue): 14620, 16129, 17921, 21209; THF (yellow): 12048, 22026. CI$_{neg}$ MS (*m*/*z*, %): 794 (85) [M$^-$], 368 (100) [{(SPPh$_2$){OP(OEt)$_2$}N}$^-$], 336 (38) [{(PPh$_2$){OP(OEt)$_2$}N}$^-$]. μ = 1.88 BM.

2.2. Preparation of bis[P,P-diethoxi-P′,P′-diphenyl-imidodiphosphinato]nickel, Ni[(OPPh$_2$){OP(OEt)$_2$}N]$_2$ (**2**)

A mixture of K[(OPPh$_2$){OP(OEt)$_2$}N] (0.720 g, 1.84 mmol) and NiCl$_2$ (0.119 g, 0.92 mmol) was stirred for 8 h in a mixture of THF (40 ml) and ethanol (10 ml) at reflux, under argon atmosphere. The solvent was removed in vacuum and the solid was treated with CH_2Cl_2. KCl was filtered off and the solution was concentrated in vacuum. A pale yellow solid product was isolated. Yield: 0.63 g (90%), M.p. 108–110 °C. *Anal.* Calc. for $C_{32}H_{40}N_2O_8P_4Ni$: C, 50.36; H, 5.25; N, 3.67. Found: C, 5.31; H, 5.17; N 3.52%. IR (cm^{-1}): 1261vs [ν_{as}(P$_2$N)], 1103vs [ν(PO)], 1041vs, 1028vs [ν(POC)]. λ_{max} (cm^{-1}), CH_2Cl_2 (blue): 14652, 16181, 18099, 21276; THF (yellow): 12706, 22321. CI$_{neg}$ MS (*m*/*z*, %): 762 (92) [M$^-$], 352 (100) [{(OPPh$_2$){OP(OEt)$_2$}N}$^-$], 336 (23) [{(PPh$_2$){OP(OEt)$_2$}N}$^-$]. μ = 2.19 BM.

2.3. Preparation of tetrakis[tetraphenylimidodiphosphinato]dinickel, Ni$_2$[(OPPh$_2$)$_2$N]$_4$ (**3**) and bis(dimethylformamide)bis(tetraphenyl-imidodiphosphinato)nickel, Ni[(OPPh$_2$)$_2$N]$_2$(DMF)$_2$ (**4**)

A solution of NiCl$_2 \cdot 6H_2O$ (0.24 g, 1.0 mmol) in methanol (15 ml) was added to a solution of K[(OPPh$_2$)$_2$N] (0.88 g, 2.0 mmol) in methanol (15 ml). The reaction mixture was stirred at room temperature for 12 h. The solvent was removed in vacuum and the solid was extracted with benzene (20 ml). The benzene solution was concentrated in vacuum to ca. 10 ml and layered with hexane. Yellow crystals of **3** were isolated by filtration. Yield 0.80 g (86%), M.p. 290 °C. *Anal.* Calc. for $C_{48}H_{40}N_2O_4P_4Ni$: C, 64.66; H, 4.53; N, 3.14. Found: C, 64.58; H, 4.37; N, 3.16%. IR (cm^{-1}): 1232vs [ν_{as}(P$_2$N)], 1136vs [ν(PO)], 1097vs [ν(PO)]. λ_{max} (cm^{-1}), CH_2Cl_2 (yellow): 11904, 18182, 22727; THF (yellow): 12670, 23614. CI$_{neg}$ MS (*m*/*z*, %): 890 (100) [Ni{(OPPh$_2$)$_2$N}$_2^-$], 416 (7) [{(OPPh$_2$)$_2$N}$^-$], 216 (5) [{(OPPh$_2$)N}$^-$]. FAB + MS (*m*/*z*, %): 1783 (15) [{Ni$_2$[(OPPh$_2$)$_2$N]$_4$ + 2H}$^+$], 1366 (38) [{Ni$_2$-[(OPPh$_2$)$_2$N]$_3$ + 2H}$^+$], 891 (100) [{Ni[(OPPh$_2$)$_2$N]$_2$ + H}$^+$]. μ = 3.26 BM.

Compound **3** was dissolved at room temperature in dimethylformamide. The yellow solution was concentrated in vacuum. Yellow-green crystals of **4** quantitatively formed at −5 °C. M.p. 115 °C (dec.). *Anal.* Calc. for $C_{54}H_{54}N_4O_6P_4Ni$: C, 62.52; H, 5.21; N, 5.40. Found: C, 62.83; H, 5.32; N, 5.28%. IR (cm^{-1}): 1643vs [ν(CO)], 1230vs, br [ν_{as}(P$_2$N)], 1130vs [ν(PO)], 1105vs [ν(PO)]. λ_{max} (cm^{-1}), CH_2Cl_2 (yellow): 11904, 14706, 18248, 22727; THF (yellow): 12658, 23809. CI$_{neg}$ MS (*m*/*z*, %): 890 (100) [{Ni-[(OPPh$_2$)$_2$N]$_2$}$^-$], 416 (7) [{(OPPh$_2$)$_2$N}$^-$], 216 (5) [{(OPPh$_2$)N}$^-$]. μ = 3.10 BM.

2.4. Preparation of potassium [tris{P,P-diethoxi-P′,P′-diphenyl-P′-thioimidodiphosphinato}nickel], KNi[(SPPh$_2$){OP(OEt)$_2$}N]$_3$ (**5**)

(a) A mixture of K[(SPPh$_2$){OP(OEt)$_2$}N] (0.766 g, 1.86 mmol) and NiCl$_2$ (0.148 g, 0.62 mmol) was stirred for 16 h in methanol (40 ml) at room temperature. The solvent was removed in vacuum and the solid was treated with CH_2Cl_2. KCl was filtered off and the solvent was removed in vacuum, resulting in a yellow-brown solid product. Yield: 0.58 g (77%). M.p. 118–119 °C. *Anal.* Calc. for $C_{48}H_{60}N_3O_9P_6$ S_3KNi: C, 47.94; H, 4.99; N, 3.50. Found: C, 48.21; H, 4.82; N, 3.24%.

(b) Alternatively, **5** was obtained by stirring a 1:1 mixture of **1** (0.794 g, 1 mmol) and K[(SPPh$_2$){OP(OEt)$_2$}N] (0.407 g, 1 mmol) in methanol (50 ml) at room temperature, for 24 h. The solvent was removed in vacuum from the blue-green solution, resulting quantitatively in a yellow-brown solid. M.p. 118–119 °C. *Anal.* Calc. for $C_{48}H_{60}N_3O_9S_3P_6KNi$: C, 47.94; H, 4.99; N, 3.50. Found: C, 47.82; H, 4.92; N, 3.53%. 2.5. Crystal structure determinations

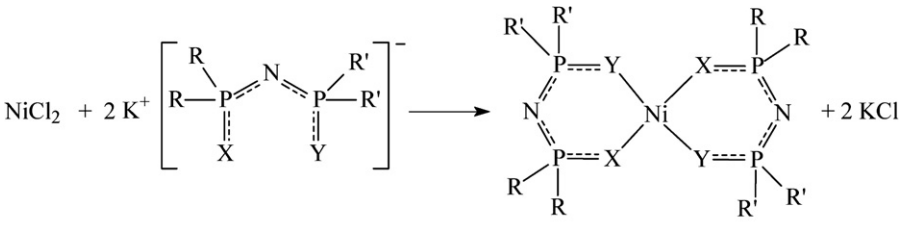
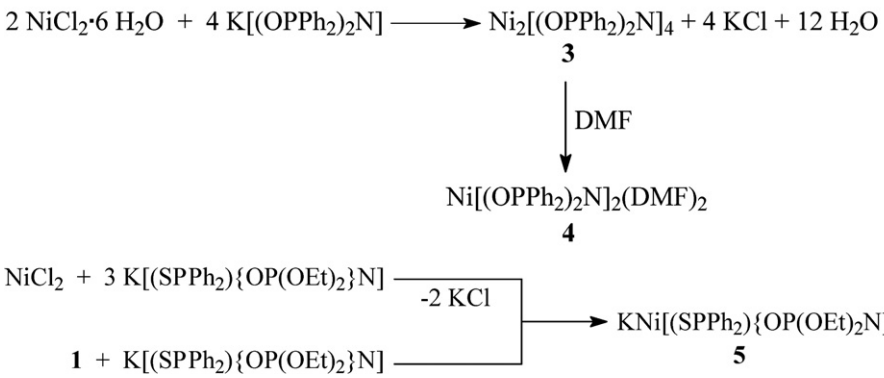
Block crystals of Ni$_2$[(OPPh$_2$)$_2$N]$_4 \cdot CH_2Cl_2$ (**3** $\cdot CH_2Cl_2$) (yellow), Ni[(OPPh$_2$)$_2$N]$_2$(DMF)$_2 \cdot 2H_2O$ (**4** $\cdot 2H_2O$) (yellow-green) and KNi[(SPPh$_2$){OP(OEt)$_2$}N]$_3$ (**5**) (yellow-brown) were attached with epoxy glue on cryoloops. The data were collected at room temperature on a Bruker SMART APEX CCD diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The details of the crystal structure determination and refinement are given in Table 1.

The structures were refined with anisotropic thermal parameters. The hydrogen atoms were refined with a riding model and a mutual isotropic thermal parameter. For structure solving and refinement the software package SHELX-97 was used [12]. The drawings were created with the DIAMOND program [13].

3. Results and discussion

The title nickel(II) complexes were obtained by salt metathesis reactions between anhydrous NiCl$_2$ or NiCl$_2 \cdot 6H_2O$ and the potassium salt of the corresponding tetraorganodichalcogenoimidodiphosphinic acid, according to the following equations:





The reactions between $K[(XPR_2)(YPR'_2)N]_2$ and nickel dichloride were performed using either dehydrated $NiCl_2$ or $NiCl_2 \cdot 6H_2O$ in a tetrahydrofurane/ethanol mixture (**1** and **2**), or methanol as solvent (**3** and **5**), respectively. The use of anhydrous $NiCl_2$ and argon atmosphere resulted in a considerable increase in the yields of compounds **1** and **2**. The formation of the ionic species **5** through both methods of preparation was confirmed by powder X-ray diffraction studies. The experimental spectrum is in a good agreement with the simulated one based on the single-crystal X-ray diffraction data (Fig. 1).

All isolated compounds are stable as solids in open atmosphere for weeks. They are paramagnetic in solid state. Attempts to characterize these compounds as $CDCl_3$ solutions by NMR spectroscopy failed suggesting their paramagnetic nature in solution too.

The CI_{neg} mass spectra of compounds **1** and **2** show the molecular ion with high intensity (85% for **1** and 92% for **2**, respectively). In case of compounds **3** and **4** the $[Ni\{(Ph_2PO)_2N\}_2]^-$ ion appeared with 100% intensity in CI_{neg} mass spectra. The dimeric species **3** was confirmed by FAB mass spectroscopy, while the formation of **5** was revealed by ESI mass spectra.

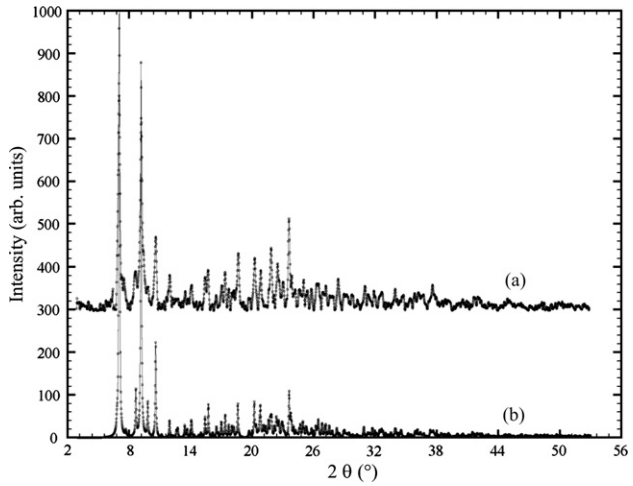

Fig. 1. (a) Experimental powder diffraction pattern and (b) the simulated X-ray powder diffraction spectrum obtained from the single-crytal cif file of **5**.

Strong infrared absorptions were observed for all complexes in the region 1260–1230, 1140–1100, 1050–1030 and about 600 cm^{-1} and they were assigned to $\nu_{as}(P_2N)$, $\nu(PO)$, $\nu(POC)$ and $\nu(PS)$ stretching vibrations, respectively, by comparison with the IR spectra of the free acids and their alkali metal salts [1,10,14], thus suggesting the coordination of the ligand units through both chalcogen atoms. For the adduct **4** the coordination of the DMF molecules to the metal atom is reflected in a shift of the C=O vibration from 1675 cm^{-1} in the free DMF to 1643 cm^{-1} in the adduct spectrum.

All derivatives are well soluble in CH_2Cl_2, resulting in blue-green (**1**, **2** and **5**) or yellow (**3** and **4**) solutions, respectively. The solutions of all compounds in coordinating solvents, *i.e.* tetrahydrofurane or methanol, are yellow. The electronic spectra of compounds **1**, **2** and **5** exhibit four absorption maxima in CH_2Cl_2 solutions, around 21 000, 18 000, 16 000 and 14 600 cm^{-1}, assignable to tetracoordinate species [5,8]. According to the magnetic moments (about 2.0 BM) found for compounds **1** and **2** in solid state, the formation of a mixture of tetrahedral and square-planar species might be suggested [15]. It can be mentioned here that the crystal of the related copper(II) complex, $Cu[(OPPh_2)(SPPh_2)N]_2$, was reported to contain both tetrahedral and square-planar isomers [16].

For the derivative **3** in CH_2Cl_2 solution the observed absorptions (22 727, 18 182 and 11 904 cm^{-1}) are similar to those reported previously for the dimeric $Ni_2[(OPPh_2)_2N]_4$ species in benzene solution [9], while in case of its adduct with dimethylformamide (**4**) a fourth absorption appeared around 14 700 cm^{-1}. This behavior might be consistent with a mixture of octahedral and pentacoordinate species in solution. The magnetic moments recorded in solid state for compounds **3**–**5** (3.26, 3.10 and 3.36 BM, respectively) are consistent with paramagnetic species with two unpaired electrons. In THF all compounds gave strong absorptions in the region 22 000–24 000 cm^{-1} accompanied by weaker absorptions in the region 12 000–13 000 cm^{-1}.

*3.1. Crystal and molecular structure of $Ni_2[(OPPh_2)_2N]_4 \cdot CH_2Cl_2$ (**3** $\cdot CH_2Cl_2$) and $Ni[(OPPh_2)_2N]_2(DMF)_2 \cdot 2H_2O$ (**4** $\cdot 2H_2O$)*

Single crystals of $Ni_2[(OPPh_2)_2N]_4 \cdot CH_2Cl_2$ (**3** $\cdot CH_2Cl_2$), suitable for X-ray diffraction studies, were obtained from CH_2Cl_2/*n*-hexane (1:4, v:v).

The crystal of **3** consists of distinct dinuclear units separated by normal van der Waals distances between heavy atoms. An ORTEP-like view with the atoms numbering scheme is given in Fig. 2. Selected bond lengths and angles are listed in Table 2.

Three of the phosphorus ligands act as homobimetallic triconnective units, bridging the two metal centers, while the fourth one acts monometallic biconnective. The result is a fused polycyclic system formed by three six-membered NiO_2P_2N rings and three non-planar four-membered Ni_2O_2 rings [dihedral angles:

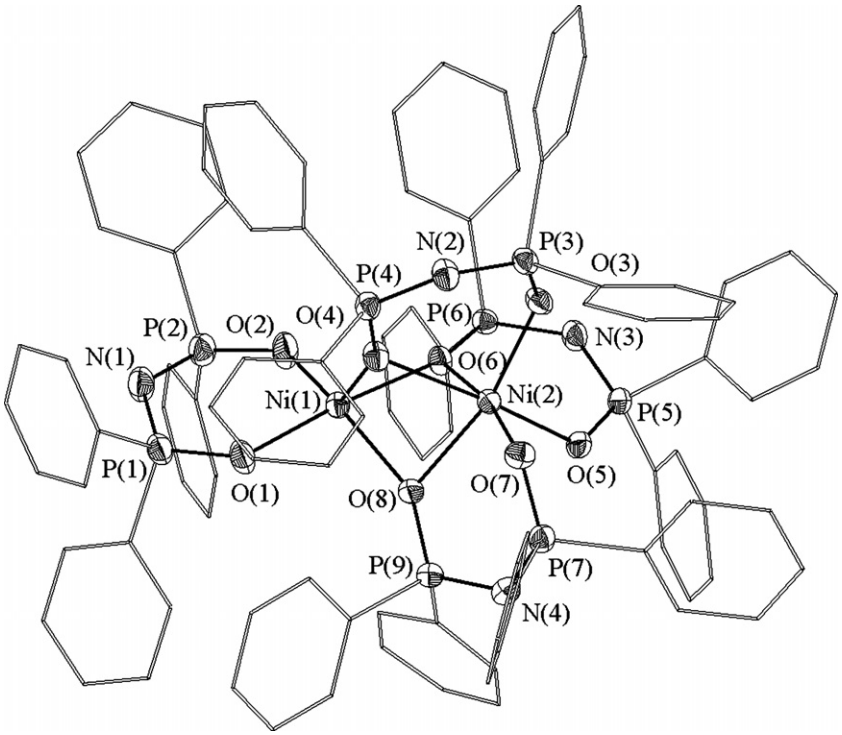

Fig. 2. ORTEP plot of the dinuclear unit in the crystal of **3** $\cdot CH_2Cl_2$. The atoms are drawn with 40% probability ellipsoids. Hydrogen atoms and CH_2Cl_2 are omitted.

O(4)Ni(1)O(6)/O(4)Ni(2)O(6) 54.6°; O(4)Ni(1)O(8)/O(4)Ni(2)O(8) 57.8°; O(4)Ni(1)O(8)/O(4)Ni(2)O(8) 54.2°]. The two nickel atoms are in different environments: Ni(1) has a distorted square-pyramidal coordination geometry, with O(4) atom in apical position and the nickel atom out of the best O(1)O(2)O(6)O(8) plane (0.29 Å), while Ni(2) has a distorted octahedral geometry being surrounded by six oxygen atoms. The Ni_2O_8 core may be considered as resulted from a $Ni(1)O_5$ square pyramid and a $Ni(2)O_6$ octahedron, with a common trigonal face described by the O(4), O(6) and O(8) atoms (Fig. 3). The two nickel atoms are brought very close each other, at a distance less than the sum of their van der Waals radii [Ni(1)···Ni(2) 2.8552(8) Å *versus* $\sum_{vdW}$(Ni, Ni) 3.20 Å [17]. This compound displays a different structure compared with the related dimeric manganese(II) derivative, $[Mn\{(OPPh_2)_2N\}_2]_2$, where both metal centers have the same coordination geometry, *i.e.* trigonal bipyramidal, with two of the imidodiphosphinato ligands acting as monometallic biconnective units, with a *cis* orientation with respect to the four-membered Mn_2O_2 ring; the other two phosphorus ligands are homobimetallic triconnective, the result being a fused tricyclic $Mn_2O_4P_4N_2$ system [18].

The nickel–oxygen distances are different. The shorter bonds [Ni(1)–O(1) 1.982(3), Ni(1)–O(2) 1.970(3) Å] are established by

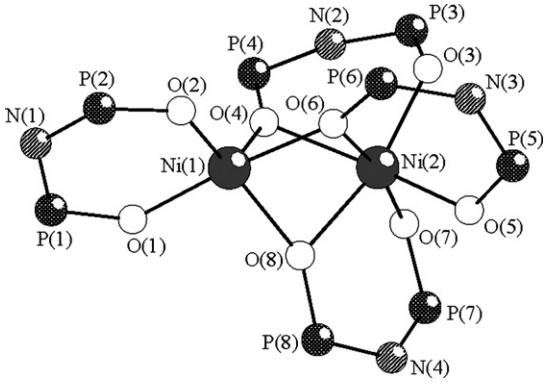

Fig. 3. View of the $Ni_2O_8P_8N_4$ core in the crystal of $\mathbf{3} \cdot CH_2Cl_2$.

the isobidentate, monometallic biconnective ligand which coordinate the Ni(1) atom. They are considerably shorter than the corresponding metal–oxygen bonds in the adduct $\mathbf{4} \cdot 2H_2O$ in which the phosphorus ligands exhibit an anisobidentate, monometallic biconnective pattern [Ni(1)–O(1) 2.1133(17), Ni(1)–O(2) 2.0542(17) Å]. The bridging Ni–O–Ni systems are not symmetric (Table 2), with Ni(1)–O distances shorter than Ni(2)–O distances. The remaining, terminal, Ni(2)–oxygen bond distances are of intermediate magnitude between the bridging metal–oxygen and Ni(1)–O bonds established by the monometallic biconnective ligand, respectively.

The phosphorus–nitrogen [1.570(3)–1.592(3) Å] and phosphorus–oxygen [1.499(2)–1.524(2) Å] distances are intermediate between single and double bonds [cf. $Ph_2P(=S)–N=P(–SMe)Ph_2$ [19]: P=N 1.562(2) Å, P–N 1.610(2) Å, $Ph_2P(O)OH$ [20]: P=O 1.486(6) Å, P–O 1.526(6) Å], thus suggesting some delocalization of the π electrons. However the resulting NiO_2P_2N rings are not planar. All ligands acting as homobimetallic triconnective units establish six-membered NiO_2P_2N rings which exhibit distorted boat conformation, with Ni(2) and nitrogen atoms in apices. The fourth six-membered NiO_2P_2N ring, established by the monometallic biconnective ligand, has an envelope conformation, folded on the imaginary P(1)···P(2) axis, with the nitrogen atom −0.31 Å out of the almost planar NiO_2P_2 skeleton.

Recrystallization of **3** from dimethylformamide led to isolation of the adduct $Ni[(OPPh_2)_2N]_2(DMF)_2 \cdot 2H_2O$ ($\mathbf{4} \cdot 2H_2O$). Its crystal consists of discrete molecules with Ni atom as inversion center, separated by normal van der Waals distances. An ORTEP-like view with the atoms numbering scheme is given in Fig. 4 and selected bond lengths and angles are listed in Table 3.

The two imidodiphosphinato ligands act as monometallic biconnective units, chelating the metal center through both oxygen atoms. This results in a *spiro*-bicyclic system with Ni as *spiro* atom, occupying an inversion center. The NiO_4 system is planar, with different Ni–O distances [Ni–O(1) 2.1134(16) Å, Ni–O(2) 2.0541(16) Å]. The six-membered NiO_2P_2N rings are of boat conformations [with Ni(1) and nitrogen atoms in apices] and folded along the imaginary O(1)···O(2a) and O(1a)···O(2) axis [dihedral angle of 16.4° between the best P_2O_2 and NiO_4 planes] on opposite sides of the planar NiO_4 core [deviations from NiO_4 plane: P(1) −0.462, P(2a) −0.385, N(1a) −0.703 Å, and P(1a) 0.462, P(2) 0.385, N(1) 0.703 Å, respectively]. The phosphorus–oxygen [P(1)–O(1) 1.5106(18), P(2)–O(2) 1.5088(17) Å] and phosphorus–nitrogen [P(1)–N(1a) 1.593(2), P(2)–N(1) 1.582(2) Å] distances, respectively, are equivalent and intermediate between single P–E and double P=E (E = O, N) bonds. The two dimethylformamide groups complete the axial position of the octahedral environment around the metal center and the $Ni–O_{DMF}$ bond lengths are intermediate between the short and the long metal–oxygen bonds established by

Symmetry equivalent positions ($-x$, $-y$, $1-z$) are given by "a".

which describe a triangular face of the distorted octahedral environment. The oxygen atoms of the SPNPO skeletons are involved in bridges between metal centers, *i.e.* O(4) and O(7) atoms bridge the metal atoms of a $KNi[(SPPh_2)\{OP(OEt)_2\}N]_3$ unit, while O(1) atom is involved in a bridge between the two potassium atoms of the $[KNi[(SPPh_2)\{OP(OEt)_2\}N]_3]_2$ dimer. The N(1) atom completes the octahedral coordination of the nickel atom ($NiNO_2S_3$ core), while the coordination sphere around the potassium atom is completed by an oxygen atom from an ethoxy group belonging to the $KNi[(SPPh_2)\{OP(OEt)_2\}N]_3$ unit [K(1)–O(8) 2.540(6) Å]. Thus phosphorus ligands can be described as (*O*,*O*,*S*)-heterobimetallic triconnective, (*S*,*O*,*O*,O_{Et})-heterobimetallic tetraconnective and (*N*,*O*,*O*,*S*)-heterotrimetallic tetraconnective, respectively. As far very few examples of complexes are known in which the nitrogen atom of the imidodiphosphinato ligand is involved in interaction with the metal center, *i.e.* *S*,*N*-monometallic biconnective in $Pd[(SPR_2)\{OP(OPh)_2\}N]_2$ (R = Ph, Pr^i) [21], *O*,*N*-monometallic biconnective in the dimeric $[PhHg\{OP(OPh)_2\}_2N]_2$ [22] and *X*,*X*,*N*-monometallic triconnective coordination in $[2\text{-}(Me_2NCH_2)C_6H_4]BiCl[(XPPh_2)_2N]$ (X = S, Se) [23]. As result of the coordination patterns of the phosphorus ligands different metalocycles are formed. The six-membered Ni(1)S(2)P(4)N(2)P(3)O(4) and Ni(1)S(3)P(6)N(3)P(5)O(7) chelate rings have twisted boat or chair conformations, with Ni(1)/N(2) and Ni(1)/N(3) atoms, respectively, in apices. The K_2O_2 ring is planar, while the $NiKO_2$ ring is folded [dihedral angle O(4)Ni(1)O(7)/O(4)K(1)O(7) 22.1°]. The dihedral angle between the K_2O_2 ring and the KO_2 fragment of the $NiKO_2$ is 88.6°.

The Ni–chalcogen distances are similar for the three ligand units. The Ni–S bond lengths [Ni(1)–S(1) 2.464(2), Ni(1)–S(2) 2.477(2), Ni(1)–S(3) 2.422(2) Å] are longer than in other Ni(II) thioato derivatives, *i.e.* the tetrahedral $Ni[(OPPh_2)(SPR_2)N]_2$ [2.306(4)/2.305(4) Å, R = Me; 2.306(4)/2.286(4) Å, R = Ph] [8] or $Ni[(SPPh_2)_2N]_2$ [2.281(2)–2.316(2) Å] [5] and the square-planar $Ni[(SPMe_2)(SPPh_2)N]_2$ [2.231(1)/2.247(1) Å] [5], $Ni_3S_2(S_2COR)_2(dppe)$ [2.170(1)–2.235(1) Å, R = Me; 2.151(4)–2.247(6) Å, R = Et] or $Ni(S_2CO)(dppe)$ [2.1853(8)–2.1970(8) Å] [24] complexes. The Ni–O distances [Ni(1)–O(4) 2.094(5), Ni(1)–O(7) 2.086(5) Å] are similar to those found in compounds **3** · CH_2Cl_2 and **4** · $2H_2O$, but slightly longer in comparison with the values found in $Ni[(OPPh_2)(SPR_2)N]_2$ [1.950(7)/1.959(7) Å, R = Me; 1.950(8)/1.956(7) Å, R = Ph] [8]. Significant differences were observed in case of the K–O distances [range 2.346(6)–2.540(6) Å]. The shortest bonds correspond to the K–O–K bridge [K(1)–O(1) 2.362(6), K(1)–O(1a) 2.346(6) Å], while the longest one corresponds to the K–O_{Et} interaction [K(1)–O(8) 2.540(6) Å]. It can be mentioned that only one OEt group is involved in interaction to each potassium center.

The phosphorus–nitrogen and phosphorus–chalcogen distances suggest that the monothioimidodiphosphinato ligands are primarily coordinated to nickel through sulfur. The phosphorus–sulfur [P(2)–S(1) 1.984(3), P(4)–S(2) 1.999(3) and P(6)–S(3) 1.984(3) Å] and terminal phosphorus–oxygen [P(1)–O(1) 1.480(6), P(3)–O(4) 1.489(6) and P(5)–O(7) 1.485(5) Å] bond lengths are equivalent in all three ligand units. Their magnitude is intermediate between single P–S and the double P=S bonds [cf. $Ph_2P(=S)\text{–}N=P(\text{–}SMe)Ph_2$ [19]: P–S 2.071(1) and P=S 1.954(1) Å] and consistent with double P=O bonds, respectively [cf. $Ph_2P(O)OH$ [20]: P=O 1.486(6) Å, P–O 1.526(6) Å].

Oxidation of tris(1,10-phenanthroline)iron(II)

ABSTRACT

The oxidation of tris(1,10-phenanthroline)Fe(II) with peroxomonosulphate (oxone) ion is first order with respect to both the substrate and the oxidant. The rate is accelerated by the alkali metal ion and the plot of k_0 against $[M^+]$ indicates that a part of the rate is independent of [alkali metal ion] where k_0 is the true rate constant for the reaction and is equal to $k_{obs} - k_h$. The rate constant k_h refers to the hydrolysis of $[Fe(phen)_3]^{2+}$ ion. It is explained by assuming the formation of an ion pair between M^+ and SO_5^{2-} ions whereas a similar ion pair between M^+ and HSO_5^- ions is not favoured in view of the slope value of the Davies plot for the effect of ionic strength which has a slope of −2.02. There is spectral evidence for the formation of an intermediate and accordingly the intermediates $[Fe(phen)_3\cdots HSO_5]^+$ and $[Fe(phen)_3\cdots M\cdots SO_5]^+$ are assumed to be formed in the proposed mechanism where M^+ ion acts as a bridge. The disproportionation of the intermediates is considered to be rate determining. The H^+ ions retard the rate and the plot of $k_0[H^+]$ against $[H^+]$ has an intercept on the rate ordinate.

1. Introduction

The salts of two peroxoacids of sulphur, peroxomono and peroxodisulphuric acid, are strong oxidants. The peroxodisulphate ($S_2O_8^{2-}$) ion is one of the most powerful and useful oxidant with E° = 2.01 V [1]. Despite the high oxidation potential, several oxidation reactions do not proceed at a convenient rate at ambient temperature because the activation energy of the rate limiting homolysis of $S_2O_8^{2-}$ to $SO_4^{-\cdot}$ is approximately 125 kJ mol^{-1} [2] and such reactions were catalysed either by Ag^+ or Cu^{2+} ions. Ag^{2+} ion is usually considered as the active oxidant in Ag^+ catalysed reactions though in certain cases Ag^{3+} is the reactive entity. A large number of oxidations of both inorganic and organic substrates by $S_2O_8^{2-}$ ion have been extensively studied in the past and the subject was of such great interest that a number of reviews were published [3–7].

Peroxodisulphate salts, $K_2S_2O_8$, $(NH_4)_2S_2O_8$ or $Na_2S_2O_8$, are available in pure state whereas potassium salt of peroxomonosulphuric acid is obtained as a mixture of $KHSO_5 \cdot K_2SO_4 \cdot KHSO_4$. The triple salt, $2KHSO_5–KHSO_4–K_2SO_4$, is commercially known as oxone which is a monosubstituted derivative of H_2O_2. Thus it is thermodynamically more powerful as an oxidant than H_2O_2 and kinetically more reactive. These properties make HSO_5^- a potentially important strong oxidant which was first described in the oxidation reactions [8,9] and some of the later studies include the oxidations of aldehydes [10], $[(NH_3)_5CoS_2O_3]^+$ [11], amino acids [12], sulphide ion [13], tris (2,2′-bipyridyl) Ru(II) [14], Ti(III), Fe(II) and α-oxygen substituted radicals [15], NO_2^- ion [16], *para*-substituted anilines [17], aminobenzoic acids [18], Co^{2+} ion in presence of molybdate ion [19] and that of $[Co(II)W_{12}O_{40}]^{6-}$ [20].

Therefore it was considered timely to study the oxidation of tris(1,10-phenanthroline)Fe(II), hereafter referred to as $[Fe(phen)_3]^{2+}$ ion because its oxidation by 6-molybedocobaltate(III) ion had been investigated earlier in this laboratory [21]. It was noted that the optical density of the $[Fe(phen)_3]^{2+}$ solution in sulphuric acid decreased with time. Therefore, the rates of hydrolysis (k_h) were also studied. The true rate constant (k_0) for different reaction mixtures was calculated by subtracting the rate of hydrolysis (k_h) from the k_{obs} values or $k_0 = k_{obs} - k_h$.

2. Experimental

2.1. Materials

The peroxomonosulphate (oxone) solutions were freshly prepared by weighing of the sample (Dupont). The solution was standardised as described below.

An accurately weighed sample of oxone (0.3–0.4 g) is dissolved in 50 ml of decinormal oxalic acid solution in a glass stoppered conical flask. To this solution was added a Ag_2SO_4 solution prepared by dissolving 0.2 g of the sample in 20 ml of 10% sulphuric acid. The mixture was heated on a water bath until no more CO_2 was evolved. The mixture was diluted to about 100 ml with water

doi:10.1016/j.poly.2008.04.011

at 40 °C. The excess oxalic acid left in the mixture was titrated with a standard decinormal permanganate solution. The exact molecular weight of the sample was thus determined.

The few crystals of potassium permanganate (E. Merck, GR) are dissolved in hot distilled water that had been previously degassed with pure nitrogen gas. The solution, left overnight, is filtered and the concentration is checked by measuring its absorbance at 525 nm (ε_{525} = 2400) [22].

A standard solution of oxalic acid (E. Merck, GR) is prepared by accurate weighing of the sample.

The preparation of tris(phenanthroline)iron(II) complex is carried out in aqueous solution by mixing ferrous ammonium sulphate (Qualigens, AR) and 1,10-phenanthroline (phen) (E. Merck). The concentration of 1,10-phenanthroline is slightly more than three times the concentration of ferrous ammonium sulphate so that the ligand completely complexes the Fe(II). The purity of the prepared complex is verified by spectrophotometry. The complex shows a maximum absorbance at 510 nm with ε_{510} = 10990 ± 10 against a literature value = 11 000 $dm^3\ mol^{-1}\ cm^{-1}$ [23]. Solutions older than 48 h are discarded.

The tris(phenanthroline)iron(III) complex is prepared by oxidising tris(phenanthroline)iron(II) complex in sulphuric acid by lead oxide [24,25] and the blue solution so obtained is filtered through a sintered G4 crucible.

Sodium hydrogen sulphate solution is prepared by half neutralisation of a standard solution of sulphuric acid (Basynth, AR) with a calculated volume of a solution of sodium hydroxide (E. Merck, GR). The solution so prepared is checked again with titrating it against a standard solution of sodium hydroxide.

The solutions of LiCl (Sigma, LR), NaCl (Sarabhai M, GR), KCl (Ranbaxy, AR) and CsCl (Sigma, LR) are prepared by the direct weighing of the samples.

2.2. Spectral measurements

A HP 8452 UV–Vis spectrophotometer with a 2 nm band width and an integration time of 1 s is used to measure the spectra of the non-reacting solutions at room temperature.[1] The method adopted for recording the spectra of the reaction mixtures is described below.

The solutions of desired concentrations of oxone and $[Fe(phen)_3]^{2+}$ at appropriate $[H^+]$ are taken in test tubes, which are immersed in melting ice taken in a beaker and allowed to stand for sufficient time to attain the thermal equilibrium. The melted water is drained out from time to time. The idea is to slow down the rate of the reaction to an extent that would permit the recording of the meaningful spectra for qualitative analysis only because the temperature and the time taken in mixing and recording the spectra are not precisely and uniformly maintained. These solutions are quickly mixed to give reaction mixtures which are immediately transferred to silica cell which is returned to its compartment and the spectra are recorded immediately.

2.3. Spectral studies at different $[HSO_5^-]$ ion

The optical densities of the reaction mixtures, $10^5[Fe(phen)_3^{2+}]$ = 3.0, $[H^+]$ = 0.005 and $1.0 \leqslant 10^4[HSO_5^-] \leqslant 10.0$ mol dm^{-3} are measured under the experimental conditions described above (these spectra are available as Supplemental data). It is noted that the optical density of the reaction mixtures increased with the increase in $[HSO_5^-]$ though the wavelength of maximum absorbance of $[Fe(phen)_3]^{2+}$ ion is not changed.

2.4. Spectral studies at different $[H^+]$ ion

In another series of experiments the optical density of the reaction mixtures, $10^5[Fe(phen)_3^{2+}]$ = 3.0 and $10^4[HSO_5^-]$ = 5.0 mol dm^{-3} at $0.001 \leqslant [H^+] \leqslant 0.1$ mol dm^{-3} are measured. It is noted that the optical density did not show any change with the increase in $[H^+]$ suggesting that H^+ ion has no effect on the species formed by mixing of $[Fe(phen)_3]^{2+}$ and HSO_5^- ions.

2.5. Rate measurement

The oxidation of $[Fe(phen)_3]^{2+}$ is studied in sulphuric acid (0.05 mol dm^{-3}) at constant ionic strength (μ = 1 mol dm^{-3}, $NaHSO_4$) under pseudo first-order conditions. i.e., [oxone] ≫ $[Fe(phen)_3^{2+}]$ ion. The progress of the reaction is followed at 510 nm using a Spectrochem MKII colorimeter [26]. The pseudo first-order rate k_{obs} is calculated by plotting the log (optical density) against time, Fig. 1, which are drawn using EXCEL program which provides the least square values of the slopes and intercepts of the plots. The pseudo first-order rate constant k_{obs} is calculated from the slopes of the plots in Fig. 1. The plots were linear for 60–70% of the reaction. The reproducibility of the pseudo first-order rate was within 3–5%.

In addition to the above the rate of hydrolysis (k_h) of $[Fe(phen)_3]^{2+}$ ion is also estimated for a given condition of concentrations of H^+ ion, ionic strengths and temperatures used in the kinetics runs of the main reaction. The same set up was used except that HSO_5^- ion was not added to the kinetic run. The k_h is obtained from the slope of the linear plots such as shown in Fig. 1. The estimated k_h is subtracted from k_{obs} to have the true value of the pseudo first-order rate constant k_0 which are reported in the tables.

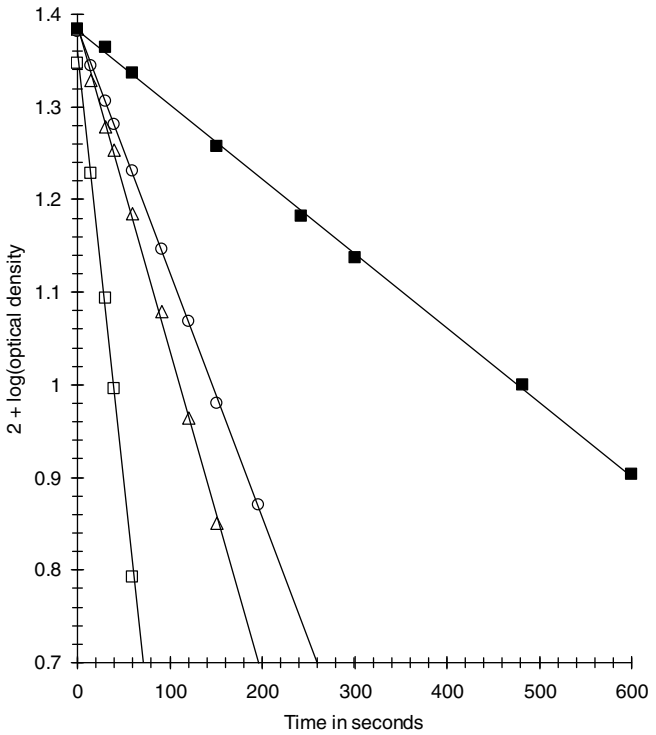

Fig. 1. The usual first-order plots of the log (optical density) against time with the initial $10^5[Fe(phen)_3^{2+}]$ = 2.0, and $[HSO_5^-]$ = 0.1, $[H^+]$ = 0.05, μ = 1.0 and 40 °C (□); $[HSO_5^-]$ = 0.05, $[H^+]$ = 0.05, μ = 0.9 and 40 °C (△); $[HSO_5^-]$ = 0.07, $[H^+]$ = 0.05, μ = 1.0 and 35 °C (○); $[HSO_5^-]$ = 0.01, $[H^+]$ = 0.15, μ = 3.1 mol dm^{-3} and 40 °C (■).

[1] The instrument could not be used for the kinetics study since it had no facility for thermostating the solutions at the desired temperature.

Table 1
Study of the stoichiometry of the reaction between HSO_5^- and $[Fe(phen)_3]^{2+}$ ions

S. no.	$10^4[Fe(phen)_3^{2+}]$ initial mol dm^{-3}	$10^4[HSO_5^-]$ initial mol dm^{-3}	$10^4[Fe(phen)_3^{2+}]$ final mol dm^{-3}	$\frac{\Delta[Fe(phen)_3^{2+}]}{\Delta[HSO_5^-]}$
1	3.13	1.16	0.84	1.97
2	5.07	2.22	0.61	2.01
3	11.1	5.08	0.88	2.01
4	17.4	7.58	2.54	1.96
5	34.3	15.0	4.47	1.99
6	31.5	15.0	1.62	1.99

Average $\Delta[Fe(phen)_3^{2+}]/\Delta[HSO_5^-] = 1.99 \pm 0.02$.

2.6. Stoichiometry

The stoichiometry of the reaction between $[HSO_5^-]$ and $[Fe(phen)_3]^{2+}$ is studied using reaction mixtures having different concentration ratios of the reagents but $[Fe(phen)_3^{2+}]$ ion is always present in excess. The unreacted $[Fe(phen)_3^{2+}]$ is estimated at 510 nm at the completion of the reaction. The oxidation products, $[Fe(phen)_3]^{3+}$ and SO_4^{2-} do not interfere in the study. The experimental results are given in Table 1. Thus the stoichiometry of the reaction is expressed by Eq. (1).

$$2[Fe(phen)_3]^{2+} + HSO_5^- + H^+ \rightarrow 2[Fe(phen)_3]^{3+} + SO_4^{2-} + H_2O \quad (1)$$

2.7. Characterisation of the oxidation product

That $[Fe(phen)_3]^{3+}$ is the oxidation product of $[Fe(phen)_3]^{2+}$, Eq. (1), is confirmed by comparing the spectra of an authentically prepared solution of $[Fe(phen)_3]^{3+}$ and that obtained from the spent reaction mixture each of which has a λ_{max} at 603 nm confirming that $[Fe(phen)_3]^{3+}$ is the oxidation product of $[Fe(phen)_3]^{2+}$.

2.8. Test for free radical

The solution of oxone and $[Fe(phen)_3]^{2+}$ are degassed by N_2 and 5 ml of distilled acrylonitrile is added to each solution, which remained clear over few minutes before these are mixed to initiate the reaction. The reaction mixture remained clear over a period of time. However, a negative test does not necessarily negates the formation of a free radical in the reaction; this is likely to be the case if the lower valent metal ion is oxidised at a rate much faster than the rate of initiation of the polymerisation of the monomer.

3. Results

The first-order dependence of the reaction on $[Fe(phen)_3]^{2+}$ is confirmed by the invariance of k_0 values, $10^3 k_0 = 3.42 \pm .02$ (s^{-1}), for several reactions with initial $0.025 \leqslant 10^4[Fe(phen)_3]^{2+} \leqslant 4.0$ mol dm^{-3} at the constant concentrations of the other reagents. The effect of the initial $[HSO_5^-]$ on the k_0, Table 2, resulted in the linear plots, Fig. 2, of k_0 against $[HSO_5^-]$ that passed through the origin indicating that the reaction is first order with respect to the $[HSO_5^-]$. The dependence of rate constants, k_0, on $0.005 \leqslant [H^+] \leqslant 0.50$ mol dm^{-3} at ionic strength = 3.1 mol dm^{-3}, Table 3, indicated that the k_0 decreased with the increase in $[H^+]$. The linear plot between $k_0[H^+]$ and $[H^+]$ with an intercept on the rate ordinate is shown in Fig. 3 Therefore the empirical rate law of the reaction is given by the Eq. (2).

$$\frac{-d[Fe(phen)_3^{2+}]}{dt} = \frac{(a[H^+] + b)[HSO_5^-][Fe(phen)_3^{2+}]}{[H^+]} \quad (2)$$

Table 2
Dependence of k_0 ($=k_{obs} - k_h$) on $[HSO_5^-]$ at different temperatures $10_5[Fe(phen_3)^{2+}] = 2.0$, $[H^+] = 0.05$ and $[\mu] = 1.0$ mol dm^{-3}

Table 3
Dependence of k_0 on $[H^+]$ at 40 °C $10^5[Fe(phen)_3^{2+}] = 2.0$, $[HSO_5^-] = 0.010$ and $[I] = 3.10$ mol dm^{-3}

$[H^+]$ (mol dm^{-3})	0.005	0.02	0.035	0.05	0.10	0.15	0.20	0.25	0.35	0.45	0.50
$10^3 k_0$ (s^{-1})	2.36	1.35	1.31	1.29	1.18	1.05	1.03	1.01	0.98	0.94	0.93

The effect of the alkali chlorides (MCl) ($M^+ = Li^+$, Na^+, K^+ and Cs^+) on the reaction rate is studied to find out if the rates in presence of M^+ ions follow the same pattern as reported in the oxidations of Cl^- and Br^- ions [27], and I^- ion [28] by HSO_5^- ion. The rate increased in the order $I^- > Br^- > Cl^-$ indicating that the rate increases in the direction of increasing polarisability of these halide ions [28]. A perusal of the results, Table 4 indicates that the k_0 for the same $[Cl^-]$ ion increases in the order $Cs^+ > K^+ > Na^+ > Li^+$ that paralleled their polarisability. The almost same intercept on the rate ordinate of the linear plots between k_0 (s^{-1}) and $[M^+]$, Fig. 4, indicate that the rate of the reaction is almost the same in the absence of the alkali metal ions. The linear plot between (k_0 – intercept)/$[M^+]$ (=slope of the plots) and respective polarisability, Fig. 5, values of which are taken from the literature [29] indicates that the rate accelerated by the alkali metal ions is linearly correlated with the polarisability of the alkali metal ion.

The effect of the ionic strength on the rate of the reaction is investigated with $NaHSO_4$, which does not chemically participate in the reaction. The results, Table 5, indicated that the k_0 value decreased with the increase in $[NaHSO_4]$. The linear plot of log k_0 against $\{\sqrt{\mu}/(1 + \sqrt{\mu}) - 0.01\mu\}$, Fig. 6, is consistent with the Davies

equation [30] with the slope equal to −2.02 indicating that the reacting ions have opposite charges and one of these ions has a charge of two.

4. Mechanism and discussion

The oxidation of $[Fe(phen)_3]^{2+}$ by $[HSO_5]^-$ is a first-order reaction both in $[HSO_5^-]$ and $[Fe(phen)_3^{2+}]$. The first indication that

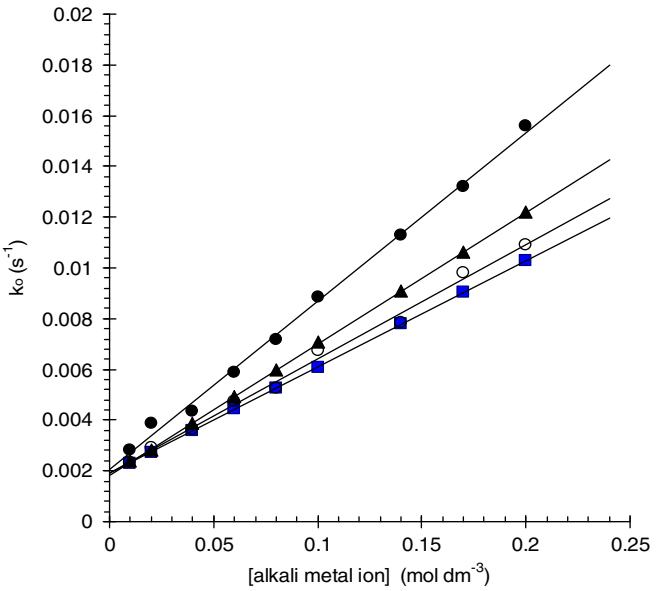

Fig. 4. The linear plot, that has an intercept on the rate ordinate, of k_0 (s^{-1}) against $[M^+]$ at 40 °C where $M^+ = Li^+$ (■), Na^+ (○), K^+ (▲) and Cs^+ (●).

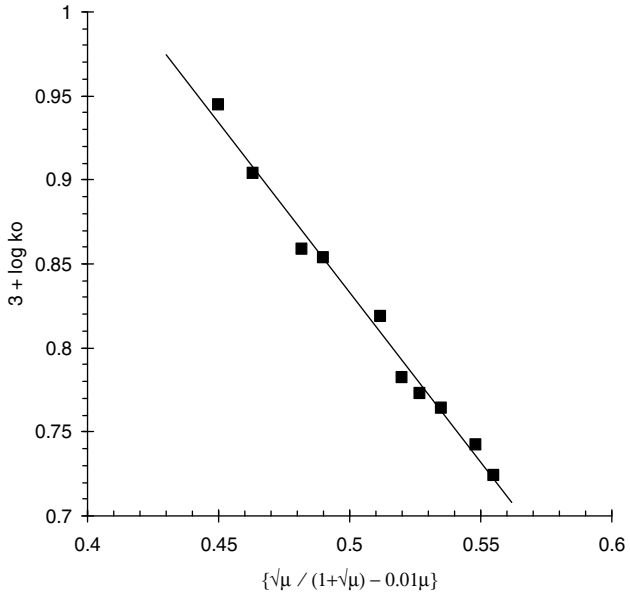

Fig. 6. The linear plot of log k_0 against $\{\sqrt{\mu}/(1+\sqrt{\mu}) - 0.01\sqrt{\mu}\}$. The slope of the plot is −2.02.

the pseudo first-order rate k_{obs}, calculated from the slopes of the linear plots of log(optical densities of the unreacted $[Fe(phen)_3]^{2+}$ solutions) against time, is not the true rate constant for the reaction is provided by the linear plot of k_{obs} against $[HSO_5^-]$ having intercepts on the rate ordinate and the fact that the k_{obs} is almost independent of $[H^+]$. The hydrolysis of $[Fe(phen)_3]^{2+}$ ion is indicated by the decrease in the optical density of sulphuric acid solution of $[Fe(phen)_3]^{2+}$ with time. Therefore, the rate constants (k_h) for the hydrolysis of $[Fe(phen)_3]^{2+}$ were measured under the identical conditions. The true rate constant, k_0, for the reaction is thus equal to ($k_{obs} - k_h$). The k_0 thus obtained is found to be dependent on $[H^+]$.

The electronic structure of peroxomonosulphuric acid is such that one of its proton is similar to that present in sulphuric acid and the other proton resembles that present in H_2O_2. Hence, peroxomonosulphuric acid is considered a strong acid which is fully ionized and its Lewis base $[HSO_5^-]$ is a weak acid with a K_a value = 4×10^{-10} mol dm^{-3} [31].

The formation of a weak intermediate, $[Fe(phen)_3 \cdots HSO_5]^+$ is indicated by the spectral study of the reaction mixtures, which has been discussed in the earlier part of the paper. It may be noted that a similar intermediate is proposed in the oxidation of SCN^- by $[Fe(phen)_3]^{3+}$ ion [32]. Since $[Fe(phen)_3]^{2+}$ is substitution inert, therefore an outer-sphere intermediate is most likely.

The role of alkali metal ions M^+ (=Li^+, Na^+, K^+ and Cs^+) has been discussed previously [33] and therefore a detailed discussion is avoided. The order of the retardation of the rate parallels the ionic size of the strongly hydrated alkali metal ions $Li^+ > Na^+ > K^+ > Cs^+$ [34] therefore the hydrated alkali metal ions are involved in the reaction. The linear plot of $k_{obs}/[M^+]$ against $\propto_{M+}$, Fig. 5, is suggestive of the role of alkali metal ions as a bridge between $[Fe(phen)_3]^{2+}$ and the reactive SO_5^{2-} ion species. A large sized alkali metal ion associated with high value of polarisability is likely to be more effective as a bridge. The greater polarisability of the larger cations [35], and the polarisability of the organic ligand acting as a bridge in the electron transfer between metal ions are reported [36]. The nature of the bridge is most likely to be $[Fe(phen)_3]^{2+} \cdots M^+ \cdots SO_5^{2-}$ where M^+ ion is part of the ion pair with SO_5^{2-} ion. The k_0, which is accelerated by M^+, has two components one of which is independent of $[M^+]$. It indicated that there are two reaction paths one of which involves M^+ ions.

In view of the stoichiometry of the reaction and the above discussion the following reactions are considered to constitute the most probable mechanism of the reaction:

$$HSO_5^- \overset{K_a}{\rightleftharpoons} H^+ + SO_5^{2-} \quad (3)$$

$$SO_5^{2-} + M^+ \overset{K_m}{\rightleftharpoons} MSO_5^- \quad (4)$$

$$[Fe(phen)_3]^{2+} + HSO_5^- \overset{K_1}{\rightleftharpoons} [Fe(phen)_3 \cdots HSO_5]^+ \quad (5)$$

$$[Fe(phen)_3]^{2+} + MSO_5^- \overset{K_2}{\rightleftharpoons} [Fe(phen)_3 \cdots M \cdots SO_5]^+ \quad (6)$$

$$[Fe(phen)_3 \cdots HSO_5]^+ \overset{k_1}{\rightarrow} [Fe(phen)_3]^{3+} + HSO_5^{2-} \quad (7)$$

$$[Fe(phen)_3 \cdots M \cdots SO_5]^+ \overset{k_2}{\rightarrow} [Fe(phen)_3]^{3+} + MSO_5^{2-} \quad (8)$$

$$H^+ + HSO_5^{2-} + [Fe(phen)_3]^{2+} \overset{fast}{\rightarrow} SO_4^{2-} + H_2O + [Fe(phen)_3]^{3+} \quad (9)$$

$$2H^+ + MSO_5^{2-} + [Fe(phen)_3]^{2+} \overset{fast}{\rightarrow} MSO_4^- + H_2O + [Fe(phen)_3]^{3+} \quad (10)$$

Since HSO_5^- is a derivative of H_2O_2, therefore HSO_5^- may act both as one and two electron accepting oxidant. In view of the stoichiometry and the fact that $[Fe(phen)_3]^{2+}$ is one electron donor the behaviour of HSO_5^- behaving as a one electron accepting oxidant in rate limiting steps (7) and (8) and the following fast reactions (9) and (10) is justified. In view of a single electron transfer the formation of the free radical is expected but the same was not detected probably for the reason that the rates of the reactions (9) and (10) far exceed the rate of initiation of the polymerisation of the monomer and there are several examples in the literature where free radical could not be detected for a single electron transfer.

The rate of disappearance of $[Fe(phen)_3]^{2+}$ in terms of the reactions (3)–(8) is deduced as given below:

$$\frac{-d[Fe(phen)_3{}^{2+}]}{dt} = 2(k_1K_1 + \frac{k_2K_2K_mK_a[M^+]}{[H^+]})[Fe(phen)_3{}^{2+}][HSO_5^-] \quad (11)$$

From the consideration of the equilibrium (3) and (4), and that of (5) and (6) it can be shown that $K_a + K_mK_a[M^+]$, and $K_1[HSO_5^-][H^+] + K_2K_a[HSO_5^-]$ are negligible in comparison to $[H^+]$. Therefore it is assumed that $[HSO_5^-] = [S^{VIII}]_0$ and $[Fe(phen)_3{}^{2+}] = [Fe^{II}(phen)_3]_0$ where $[X]_0$ denote the analytical concentrations of the related species. The Eq. (10) is therefore replaced by the Eq. (12) where k_0 as defined above is equal to $k_{obs} - k_h$.

$$\frac{-d[Fe^{II}(phen)_3]}{dt[Fe^{II}(phen)_3]_0} = k_0 = \frac{2(k_1K_1[H^+] + k_2K_2K_mK_a[M^+])[S^{VIII}]_0}{[H^+]} \quad (12)$$

Eq. (12) is consistent with the linear plots of k_0 against $[HSO_5^-]$ passing through the origin, Fig. 2, and is also consistent with the linear plots of $k_0[H^+]$ against $[H^+]$, Fig. 3, and the linear plots k_0 against $[M^+]$, Fig. 4, having an intercept on the rate ordinate.

An explanation is needed for not considering the equilibrium $HSO_5^- + M^+$ $HMSO_5$ in the mechanism. Such an equilibrium is not considered because the formation the intermediate complex of MSO_5 with $[Fe(phen)_3]^{2+}$, if considered, would have been inconsistent with the slope value −2.02 of the Davies plot in Fig. 6 which suggests that the reactants are oppositely charged and that one of the reactants has two charges which is consistent with the equilibrium (4).

ABSTRACT

Six new diorganotin(IV) complexes of the type $(R_2Sn)_2L$ (L = L1 R = Me **1**, *n*Bu **2**; L = L2 R = Me **3**, *n*Bu **4**; L = L3 R = Me **5**, *n*Bu **6**) have been obtained by the reaction of new hexadentate diacylhydrazone ligands H_4L1 [bis(2-hydroxybenzaldehyde)terephthalohydrazone], H_4L2 [bis(2-hydroxy-3-methoxybenzaldehyde)terephthalohydrazone] or H_4L3 [bis(2-hydroxy-1-naphthaldehyde)terephthalohydrazone] with diorganotin(IV) dichloride in the presence of sodium ethoxide. All the diacylhydrazones and the complexes were characterized by elemental analysis, IR and NMR spectra. Complexes **2**, **4**, **5** and **6** were also characterized by X-ray crystallography diffraction analysis which revealed that the complexes have similar structures containing binuclear diorganotin(IV) skeletons. Furthermore weak but significant intermolecular Sn···O bonds, hydrogen bonds, C–H···π stacking or π···π stacking lead to aggregation and assembly of these complexes into 1D, 2D or 3D supramolecular frameworks.

1. Introduction

Organotin complexes have been the subject of interest for some time because of their biological and commercial applications [1–6]. In recent years, organotin(IV) complexes with Schiff bases have received increasing attention owing to their antitumor activities and potential applications in biotechnology [7–13]. Acylhydrazones, as one kind of Schiff base, and their metal complexes have been widely studied due to their versatile applications in the fields of analytical, medicinal chemistry and biotechnology [14–21]. These ligands, owing to their facile keto–enol tautomerization and the availability of several potential donor sites, can coordinate with metals. So acylhydrazone organotin(IV) complexes were of interest for structural reasons. The crystal structures of some diorganotin(IV) complexes with the ONO tridentate ligands salicylaldehyde arylhydrazones have been studied [22,23], and we have recently reported some organotin(IV) complexes with *o*-hydroxyarylaldehyde arylhydrazones and pyruvic acid arylhydrazones [24–29]. Usually, tin atoms in complexes derived from ONO tridentate ligands are penta-coordinate with a trigonal bipyramidal (TBP) geometry [23,28,29]. In tin derivatives with a TBP geometry, the metal center can act as a Lewis acid, whose coordination number can be increased by addition of molecules having electron donating atoms [24–26,28], changing the geometry to distorted octahedral or pentagonal bipyramidal. The supramolecular structures of the Schiff base complexes [30] and organotin(IV) complexes [31,32] have been discussed.

However, organotin(IV) complexes with diacylhydrazone have been less widely studied [33,34]. As part of our investigation dealing with the study of diorganotin(IV) species derived from Schiff base ligands, we report herein the synthesis and structural analysis of six new derivatives containing hexadentate diacylhydrazones ligands. The ligands are derived from terephthalohydrazide and three different *o*-hydroxyarylaldehydes, and contain a double set of ONO donor atoms (Scheme 1), thus allowing for the preparation of dinuclear metal complexes. Similar ligands have been reported [35] with a double set of NNO donor atoms.

2. Experimental

2.1. Materials and measurements

All reagents were commercially available, and were used without further purification. Terephthalohydrazide was prepared by the reaction of dimethyl terephthalate with hydrazine hydrate in ethanol and recrystallized from a large amount of water as colourless needles according to the published methods [36]. IR spectra were recorded with a Nicolet-460 spectrophotometer, as KBr discs. ^1H, ^{13}C and ^{119}Sn NMR spectra were recorded with a Varian Mercury Plus 400 spectrometer. The chemical shifts are reported in ppm with respect to the references and are stated relative to the inner reference tetramethylsilane for ^1H and ^{13}C NMR spectroscopy, and to the external reference tetramethyltin for ^{119}Sn NMR

spectroscopy. Elemental analyses were performed with a PE-2400II elemental analyzer.

2.2. Synthesis of diacylhydrazones H_4L1, H_4L2 and H_4L3

2.2.1. Bis(2-hydroxybenzaldehyde)terephthalohydrazone (H_4L1)

A mixture of terephthalohydrazide (0.970 g, 5.0 mmol) and 2-hydroxybenzaldehyde (1.830 g, 15.0 mmol) was refluxed in acetic acid for 2 h. The yellow solid formed was filtered off, washed with water and ethanol in turn and dried in vacuum. Yield 1.569 g (78%). *Anal.* Calc. for $C_{22}H_{18}N_4O_4$ (402.40): C, 65.66; H, 4.51; N, 13.92. Found: C, 65.59; H, 4.54; N 14.01%. IR (KBr, cm^{-1}): 3415 (s, N–H), 3252 (s, O–H), 1675 (s, C=O), 1620 (m, C=N). ^1H NMR (400 MHz, DMSO-d_6, 25 °C): 12.22 (s, 2H, OH), 11.22 (s, 2H, NH), 8.69 (s, 2H, CH), 8.10 (s, 4H, ArH), 7.59 (d, J = 7.6 Hz, 2H, ArH), 7.33 (t, J = 7.2 Hz, 2H, ArH), 6.91–7.00 (m, 4H, ArH).

2.2.2. Bis(2-hydroxy-3-methoxybenzaldehyde)terephthalohydrazone (H_4L2)

A similar procedure to the synthesis of H_4L1 was carried out using 2-hydroxy-3-methoxybenzaldehyde in place of 2-hydroxybenzaldehyde. Yield 1.829 g (79%). *Anal.* Calc. for $C_{24}H_{22}N_4O_6$ (462.45): C, 62.33; H, 4.79; N, 12.12. Found: C, 62.43; H 4.70; N, 12.23%. IR (KBr, cm^{-1}): 3421 (s, N–H), 3260 (m, O–H), 1678 (s, C=O), 1626 (m, C=N). ^1H NMR (400 MHz, DMSO-d_6, 25 °C): 12.17 (s, 2H, OH), 11.79 (s, 2H, NH), 8.65 (s, 2H, CH), 8.11 (s, 4H, ArH), 6.85–7.10 (m, 6H, ArH), 3.89 (s, 6H, CH_3).

2.2.3. Bis(2-hydroxy-1-naphthaldehyde)terephthalohydrazone (H_4L3)

A similar procedure to the synthesis of H_4L1 was carried out using 2-hydroxy-1-naphthaldehyde in place of 2-hydroxybenzaldehyde. Yield 2.034 g (81%). *Anal.* Calc. for $C_{30}H_{22}N_4O_4$ (502.52): C, 71.70; H, 4.41; N, 11.15. Found: C, 71.58; H, 4.47; N, 11.23%. IR (KBr, cm^{-1}): 3426 (s, N–H), 3259 (s, O–H), 1675 (s, C=O), 1622 (m, C=N). ^1H NMR (400 MHz, DMSO-d_6, 25 °C): 12.84 (s, 2H, OH), 12.29 (s, 2H, NH), 9.57 (s, 2H, CH), 8.20 (d, J = 8.0 Hz, 2H, Np), 8.15 (s, 4H, ArH), 8.01 (d, J = 8.8 Hz, 2H, Np), 7.88 (d, J = 8.0 Hz, 2H, Np), 7.59 (t, J = 7.6 Hz, 2H, Np), 7.40 (t, J = 7.6 Hz, 2H, Np), 7.21 (d, J = 8.8 Hz, 2H, Np).

2.3. Synthesis of complexes **1**–**6**

2.3.1. $[(CH_3)_2Sn]_2L1$ (**1**)

The ligand H_4L1 (0.201 g, 0.5 mmol) was added in a mixture of ethanol and benzene (V/V: 1/1) (30 ml) to sodium ethoxide

Table 1
Crystal data and structure refinement details for complexes **2**, **4**, **5** and **6**

2.4. X-ray crystallography

Crystals were mounted in Lindemann capillaries under nitrogen. All X-ray crystallographic data were collected on a Bruker SMART CCD 1000 diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 298(2) K. A semi-empirical absorption correction was applied to the data. The structures were solved by direct methods using SHELXS-97 and refined against F^2 by full-matrix least squares using SHELXL-97. Hydrogen atoms were placed in calculated positions. Crystal data and experimental details of the structure determinations are list in Table 1.

3. Results and discussion

3.1. Synthesis of the diorganotin(IV) complexes

The hexadentate ligands H_4L1, H_4L2 and, H_4L3 were obtained from the reaction of terephthalohydrazide with 2-hydroxybenzaldehyde, 2-hydroxy-3-methoxybenzaldehyde and 2-hydroxy-1-naphthaldehyde, respectively. The dinuclear tin complexes **1**–**6**

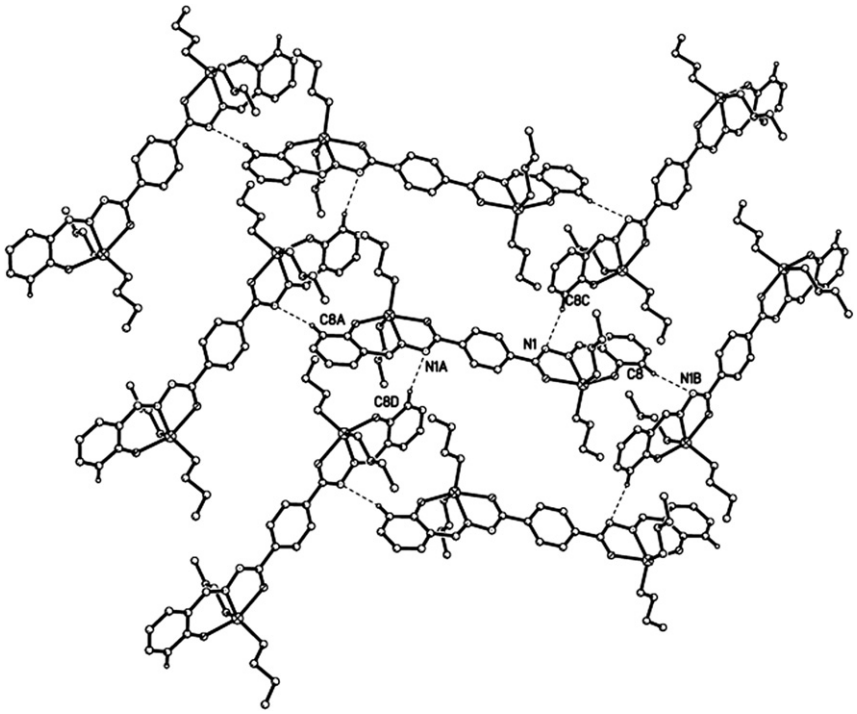

Fig. 5. Supramolecular structure of complex **2** showing the 2D framework *via* intermolecular C–H···N hydrogen bonds.

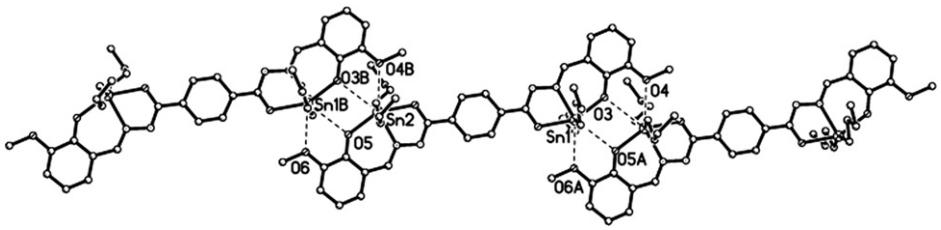

Fig. 6. The 1D chain linkage from intermolecular Sn···O interactions of complex **4**.

were prepared by reaction of one equivalent of the ligands with two equivalents of the corresponding diorganotin(IV) dichloride. Sodium ethoxide was used as a base for the deprotonation of the ligand as described in the preparative part (Scheme 2). Complexes **1**–**6** are solid, with an intense orange colour, and are soluble in polar organic solvents and stable under atmospheric conditions. The solids were recrystallized from dichloromethane–ethanol and orange single crystals were formed by slow evaporation at room temperature for **2**, **4**, **5** and **6**.

3.2. IR spectra

In the IR spectra of the ligands, the stretching vibration bands of N–H, O–H and C=O appear at 3415–3426, 3250–3260 and 1670–1678 cm^{-1}, respectively, and these bands disappear from the spectra of complexes **1**–**6**. The disappearance of ν_{O-H} shows the deprotonation of the –OH group and its subsequent coordination to the central tin atom. The disappearance of $\nu_{C=O}$ unambiguously confirms that the ligand coordinates with the tin in the enol form. The $\nu_{C=N}$ band of the ligands at 1620–1626 cm^{-1} shifts to 1611–1603 cm^{-1} in the spectra of the complexes **1**–**6**, suggesting coordination of the imine nitrogen to the tin moiety [24,25,27]. The characteristic absorptions at 1599–1585 cm^{-1} in the spectra of these complexes indicate the presence of a C=N–N=C group [23,25–27]. Two new bands at 578–564 and 470–481 cm^{-1} are characteristic of Sn–O and Sn–N absorptions, respectively [27].

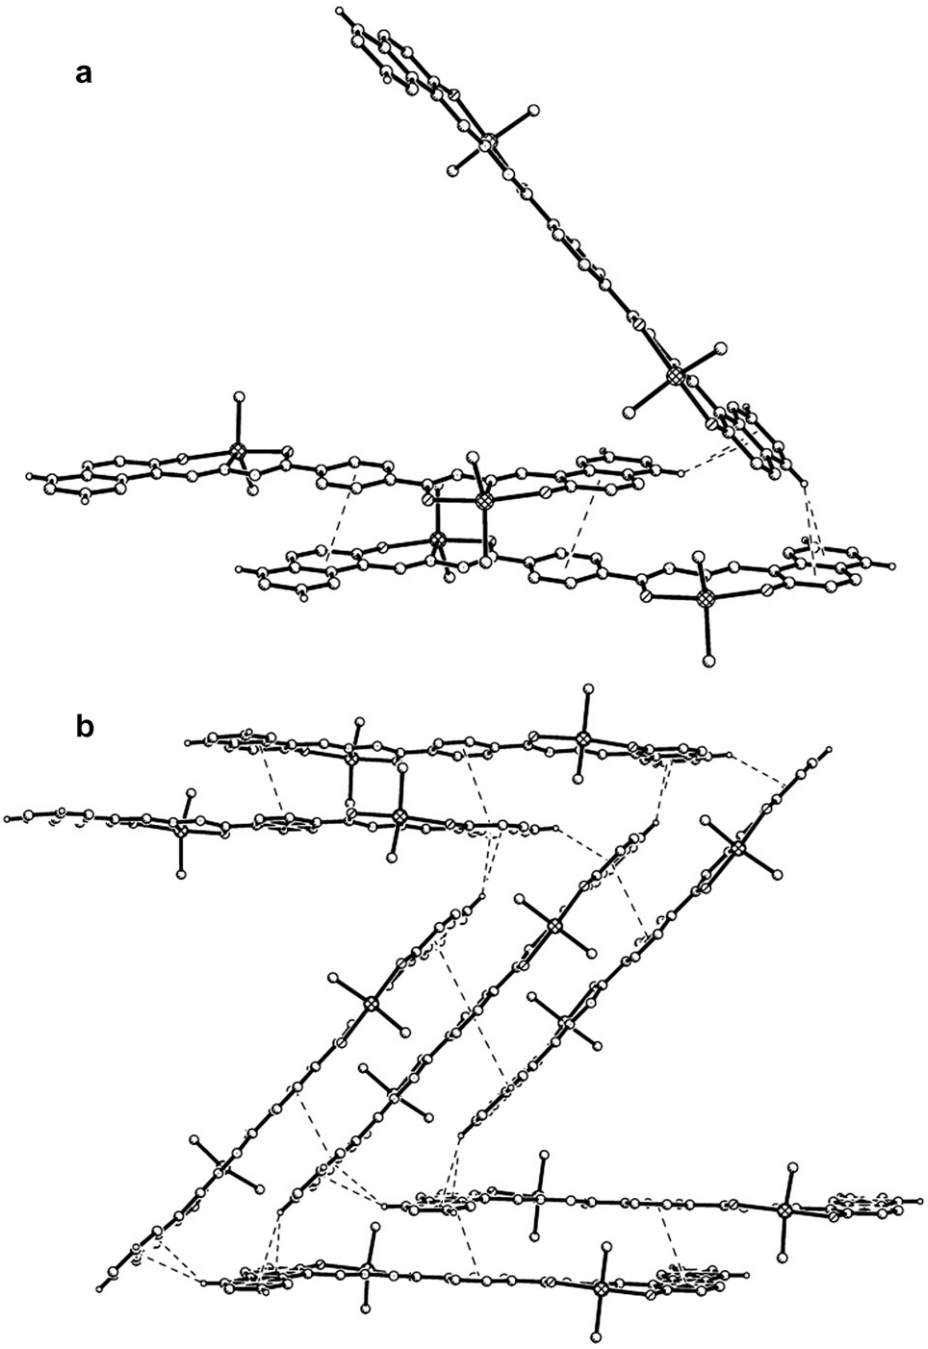

Fig. 7. Supramolecular structure of complex **5**, (a) showing C–H···π stacking and π···π stacking interactions and (b) showing the 2D framework via intermolecular C–H···π stacking and π···π stacking interactions.

3.3. NMR spectra

In the ^{1}H NMR spectra of the free ligands, the single resonance of the proton (–NHN=) is observed at 11.22, 11.79 and 12.29 ppm, respectively, and it is absent in the spectra of the complexes, thus indicating deprotonation of the –NHN= group and confirming that the ligand coordinates to the tin in the enol form. In the ^{1}H NMR spectra of complexes **1**–**6** there is no signal resonance for Ar–OH, which strongly suggests that the phenolic oxygen atoms participate in coordination to the tin atom. The ^{119}Sn NMR spectra of complexes **1**–**6** show only one signal at −149.82, −187.41, −148.76, −186.36, −154.20 and −188.78 ppm, respectively. According to the literature reported [37–39], the coordinated number of the tin atoms are all five-coordinate. The conclusions are supported by the results of the X-ray diffraction studies of complexes **2**, **4**, **5** and **6**, which suggests that the intermolecular Sn···O interaction of **4** probably does not survive in solution.

3.4. Description of structures *2*, *4*, *5* and *6*

The molecular structures of **2**, **4**, **5** and **6** are given in Figs. 1–4, respectively, and selected bond lengths and bond angles are given in Table 2. From the structures we can see that the complexes show similar structures, containing binuclear diorganotin(IV) skeletons showing a trans conformation (centrosymmetry). The alkyl side chains of complex **6**, however, are disordered. In all the complexes, each of the two tin atoms has a coordination number of five, resulting from the bonding to phenolate-O, imine-N and deprotonated amide-O atoms of the moieties of H_4L1, H_4L2 or H_4L3, which are hexadentate ligands that function as tetrabasic in the enol form, and two carbon atoms from the organic tin substituents. The distortion from the perfect trigonal bipyramidal geometry is mainly due to the rigidity of the chelate rings and the large covalent radius of the tin(IV) atoms. As observed in similar complexes, the oxygen atoms are in axial positions; the

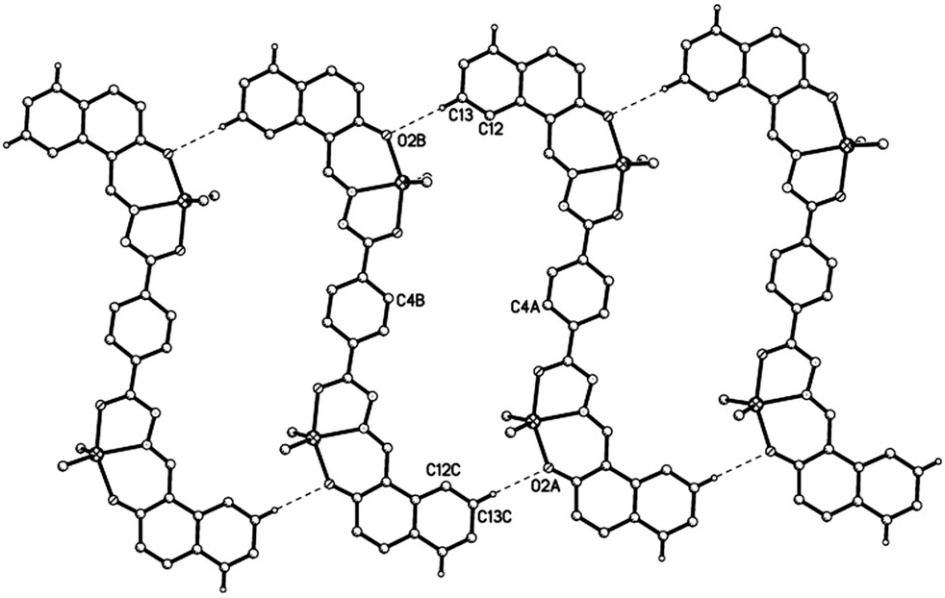

Fig. 8. Supramolecular structure of complex **5**, showing the 1D chain *via* intermolecular C–H···O hydrogen bonds.

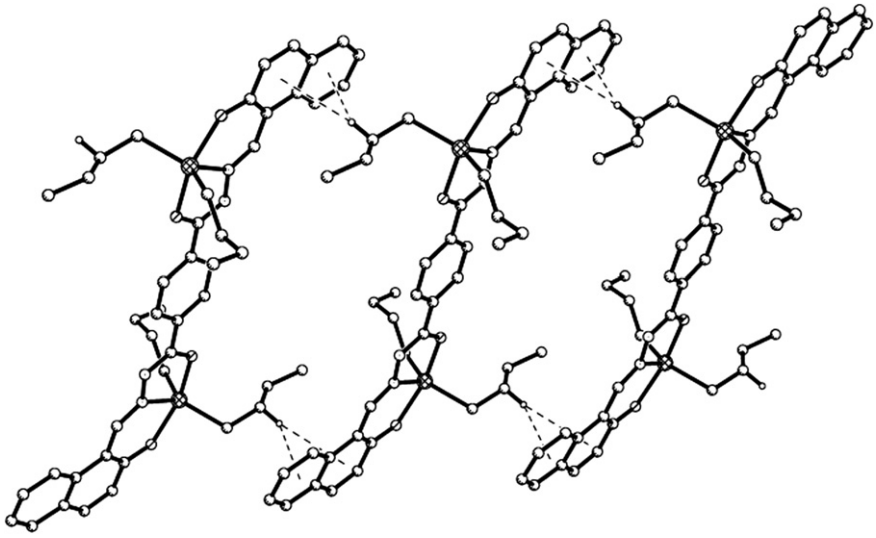

Fig. 9. The 1D chain linked by intermolecular C–H···π interactions of complex **6**.

nitrogen atom forms a coordination bond with the tin atom and it is found in an equatorial position, as well as the two organic substituents. There are five and six membered Sn–N–N–C–O and Sn–N–C–C–C–O rings imposing the constraints.

The C–O and C–N bond lengths in the amide functionality of the complexes are within 1.263(12)–1.297(7) and 1.277(13)–1.313(7) Å, respectively. These values are consistent with the enolate form of the amide functionality [27,40]. The Sn–N distances 2.174(5) Å for **2**, 2.198(9) and 2.219(9) Å for **4**, 2.154(4) Å for **5**, 2.152(5) Å for **6**] are greater than the sum of the non-polar covalent radii, 2.15 Å, but are considerably shorter than the sum of the Van der Waals radii (3.75 Å) and should be considered as bonding interactions, indicating strong tin–nitrogen interactions, and they lie in the range 2.140(6)–2.327(2) Å which has been reported for Sn–N bond lengths [25–29,33,34]. The Sn–O(amide) bond lengths [between 2.117(4) and 2.206(7) Å] and the Sn–O(phenolate) bond lengths [between 2.079(4) and 2.169(5) Å] are in excellent agreement with other previously known acylhydrazone diorganotin(IV) complexes in the literatures [25–29,33,34]. The Sn–O(amide) bond length is longer than the Sn–O(phenolate) in the same complex. The O–Sn–O bond angles [154.9(2)° for **2**, 153.1(3)° and 153.9(3)° for **4**, 155.4(2)° for **5**, 155. 3(2)° for **6**] are deviate from the linear angle 180°. The Sn–C bond lengths fall in a narrow range from 2.082(12) to 2.130(8) Å for complexes **2**, **4**, **5** and **6**, typical for organotin(IV) derivatives. The related C–Sn–C angles [131.8(3)° for **2**, 151.6(5)° and 152.5(5)° for **4**, 121.5(3)° for **5**, 126.8(3)° for **6**] are deviated from 120°.

Further analysis of the supramolecular structures of complexes **2**, **4**, **5** and **6** shows that they are different from each other. The supramolecular structure of complex **2** is shown in Fig. 5, showing a 2D framework with C–H···N hydrogen bonding interactions. It can be seen that each discrete molecule links with another four monomers through the same four intermolecular C(8)–H(8)···N(1) hydrogen bonds, and a 42-membered macrocycle is formed by the four such hydrogen bonds. The H(8)···N(1), C(8)···N(1) distances and the C(8)–H(8)···N(1) angle are 2.569 Å, 3.476 Å and 164.87°, respectively, which is similar to that reported in the literature [41].

The salient feature of the supramolecular structure of complex **4** is a 1D polymer linkage made up from weak interactions of Sn···O bonds. As shown in Fig. 6, there are four Sn···O bonds forming a head-to-tail arrangement. The distances of the Sn···O bonds (Sn(1)···O(5A) = 2.971 Å, Sn(1)···O(6A) = 2.824 Å, Sn(2)···O(3B) = 2.984 Å, Sn(2)···O(4B) = 2.829 Å) are considerably longer than the normal Sn–O covalent bond, but they are much shorter than the van der Waals radii of Sn and O (3.68 Å), which is reasonable as an intermolecular interaction according to literature reports [42]. Due to the Sn···O intermolecular interactions, the tin atoms adopt a distorted pentagonal bipyramidal geometry in the solid state, which is not observed in solution. The C–Sn–C bond angles have values of 151.6(5)° and 152.5(5)°, larger than 131.8(3)° for **2**, 121.5(3)° for **5** and 126.8(3)° for **6**, allowing for the Sn···O intermolecular interactions.

The supramolecular structure of complex **5** is dominated by intermolecular C–H···π, π···π stacking interactions and C–H···O hydrogen bonds. An intermolecular edge-to-face C–H···π stacking interaction has been identified between the C(15) atom and the naphthalene nucleus [H(15)···Cg(2) = 3.084 Å], as shown in Fig. 7a. This can be considered as a pair of bifurcated intermolecular C–H···π interactions (Table S1), which is similar to another organotin complex that has been reported [43], forming a head-to-tail zigzag 2D network (Fig. 7b). There is also π···π stacking interactions between the ring (C2–C4, C2A–C4A) and the ring (C6–C10) found in the structure (Fig. 7a), the distance between the ring centroids is 3.634 Å and the dihedral angle of the two rings is 20.61°. As shown in Fig. 8, a 34-membered macrocycle is formed by two intermolecular C–H···O [C(13)···O(2B) = 3.517 Å, H(13)···O(2B) = 2.588 Å, C(13)–H(13)···O(2B) = 177.67°] hydrogen bonds between two discrete molecules, and the size of the macrocycle channel is 15.633 × 6.690 Å (transannular C12···C12C and C4A···C4B). A one-dimensional polymeric chain structure along the a axis is linked by the C–H···O hydrogen bonds with a head-to-tail arrangement. Furthermore this zigzag 2D network is associated with adjacent layers by intermolecular C–H···O hydrogen bonds, forming a 3D framework.

In Fig. 9 the supramolecular structure of complex **6** exhibits a 1D chain structure *via* intermolecular point-to-face C–H···π stacking interactions. The C–H···π interaction is identified between C17 and the naphthalene nucleus. This can be considered as a pair of bifurcated intermolecular C–H···π interactions too (Table S1), the closest contact of 2.849 Å is H(17A)···C(11). The C–H···π interaction is similar to that in **5**, but the difference is that the C–H of **6** comes from the aryl group of the ligand and the C–H of **5** is the butyl group of the diorganotin moiety. These weak but significant stacking interactions stabilize the crystal structures.

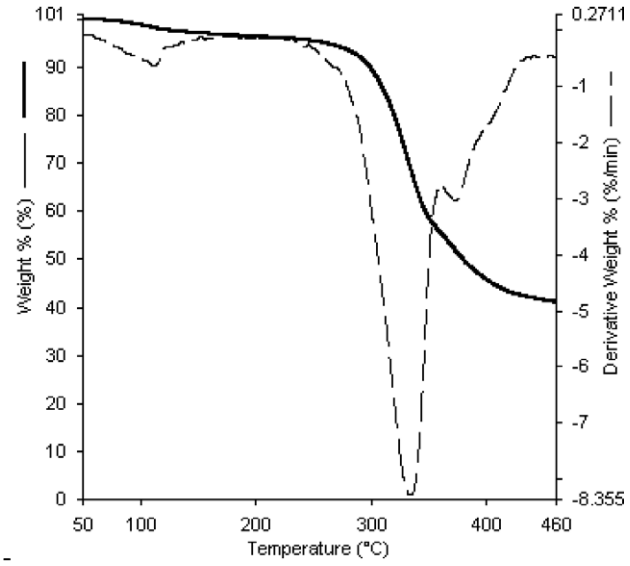

Fig. 10. TGA curve of complex **2**.

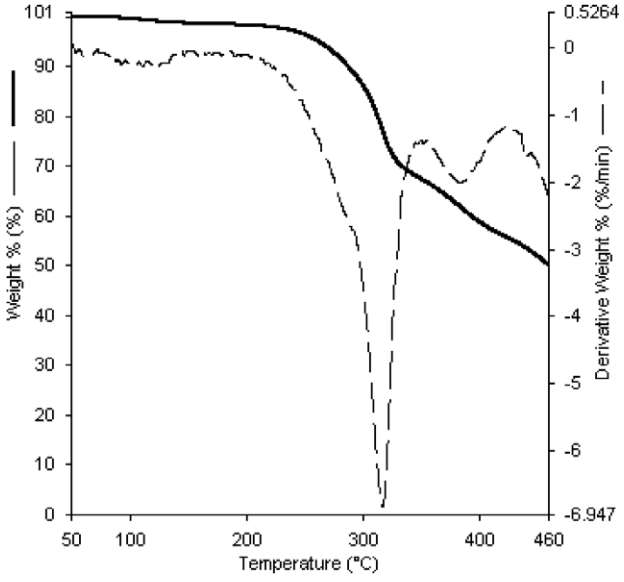

Fig. 11. TGA curve of complex **4**.

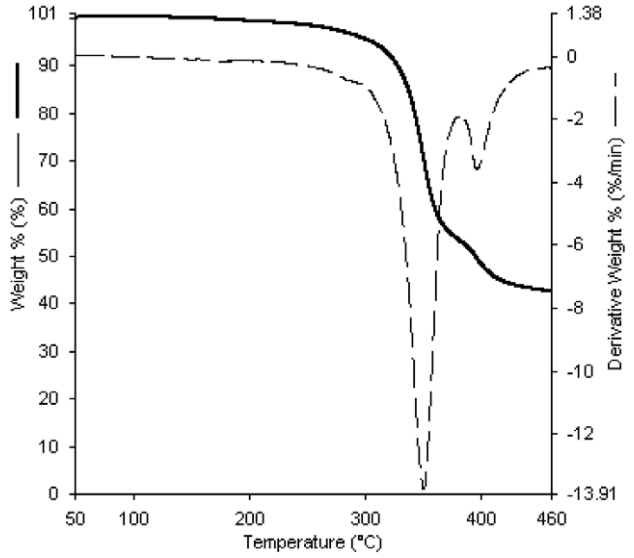

Fig. 12. TGA curve of complex **5**.

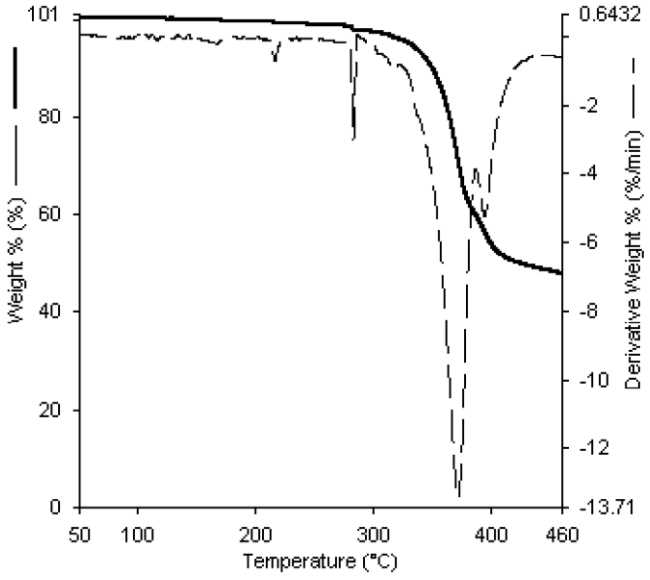

Fig. 13. TGA curve of complex **6**.

3.5. Thermogravimetric analysis

To study the stability of complexes **2**, **4**, **5** and **6**, thermogravimetric analysis (TGA) was performed in the temperature range 50–500 °C under a N_2 atmosphere. The TGA curves of complexes **2**, **4**, **5** and **6** exhibit one continuous weight loss stage in the range 250–400 °C (Figs. 10–13). In general, complexes **2**, **4**, **5** and **6** exhibit good thermal stability [44,45].

4. Conclusions

The molecular structures of four new diorganotin(IV) complexes have been reported. Although the *o*-hydroxyarylaldehyde terephthalohydrazone ligands have the same coordination capacity function as a rigid bridging tetrabasic hexadentate moiety binding two tin atoms through ONO donor atoms, and both tin atoms are in a trigonal bipyramidal environment, different intermolecular interactions which lead to aggregation and assembly of these complexes into 1D, 2D or 3D supramolecular frameworks are observed in the solid state. This can be attributed to different aryl groups of the hydrazones and alkyl groups of the diorganotin units.

ABSTRACT

$[Ag_2L^2(NO_3)_2]_n$ (**1**), $[HgL_{0.5}{}^2OAc_2]_n$ (**2**), $[HgL^2I_2]_n$ (**3**), $[Ag_3L_2{}^3(NO_3)_3]^n$ (**4**) and $[HgL^3I_2]_n$ (**5**) were assembled by the reactions of L^2 and L^3 (L^2 = 1,2-bis[4-(3-pyridyl)pyrimidinylthiomethyl]benzene, L^3 = 1,3-bis[4-(3-pyridyl)pyrimidinylthiomethyl]benzene) with $AgNO_3$, $Hg(OAc)_2$ and HgI_2. The structural motifs of these complexes are multiform, from 3D interpenetrating networks and corrugated 2D networks to a 1D single stranded helix.It is found that conformation changes of the ligands after interaction with the metal salts occur due to positional isomerism of the xylyl groups and the effect of the metal ions.

1. Introduction

Remarkable attention has been paid to the rational design and assembly of new coordination polymers and metal–organic frameworks with heterocyclic thiolates or thioethers in recent years for their fascinating structural topologies and potential uses as functional materials [1–6]. Within these molecules, not only N atoms from heterocyclic donors, but S atoms of thioether spacers are capable of binding metal ions, with a preference for d^{10} metal ions such as Cu(I) and Ag(I) ions, to form discrete and polymeric structures with 1D, 2D and 3D motifs. The generation of coordination architectures depends on the combination of factors including the geometric sphere of the inorganic metal ions and the geometry of the organic spacers, as well as counteranions and solvent effects.

In our previous work, we reported a flexible dithioether ligand, L^1 (shown in Scheme 1), which was treated with mercurous salts to yield discrete macrocyclic complexes or 1D polymers [7]. Since the ligand contains multiple metal binding sites, including pyridyl and pyrimidinyl donor sets, it is compatible with the coordination geometric requirement of specific metal centers to form multi-stranded arrays. The ligand also contains an alkyl chain that is liable to generate flexibility and to produce unpredictable structures, and so it is very difficult for us to modulate the frameworks to get the physical and chemical properties as desired. In our continuing study, we rectified the ligand by substituting xylyl groups for alkyl moieties to offer sufficient rigidity to impose a given stereochemistry at the metal centers. Herein reported are metallosupramolecular silver and mercury complexes produced by two new ligands L^2 and L^3, as shown in Scheme 1.

2. Experimental

2.1. Materials and physical measurements

All the commercially available chemicals were of reagent grade and were used as received without further purification. Analyses for carbon, hydrogen and nitrogen were performed on a Perkin–Elmer 1400C analyzer. Infrared spectra (4000–400 cm^{-1}) were measured with a Bruker Vector 22 FT-IR spectrophotometer on KBr disks. Electrospray ionization (ESI) mass spectra were recorded on a Finnigan MAT SSQ 710 mass spectrometer in a scan range of 100–1200 amu. ^1H NMR spectroscopic measurements were performed on a Bruker AM-500 NMR spectrometer, using TMS ($SiMe_4$) as an internal reference at room temperature. Thermogravimetric analysis (TGA) measurements were performed on a TGA Q500 thermal analyzer in flowing N_2 with a heating rate of 20 °C min^{-1}.

2.2. Syntheses of L^2 and L^3

Both L^2 and L^3 were made by a similar method as follows. To a solution of 4-(pyridin-3-yl) pyrimidine-2-thiol (1.89 g, 10 mmol)

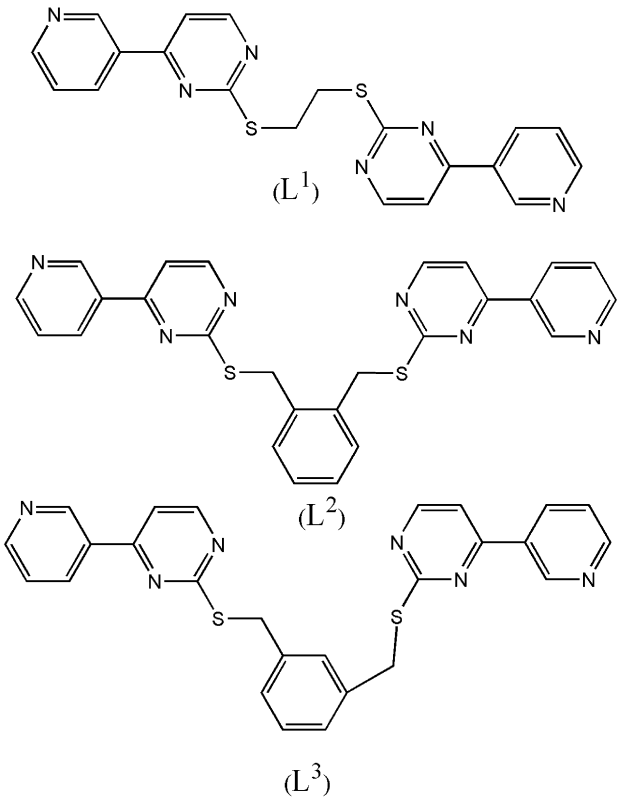

Scheme 1.

and sodium hydroxide (0.40 g, 10 mmol) in dry ethanol (150 mL), 1,2-bis(bromomethyl)benzene or 1,3-bis(bromomethyl)benzene (1.32 g, 5 mmol) in $CHCl_3$ (10 mL) was added. The mixture was stirred and refluxed for 6 h. After cooling, yellow precipitates were filtered, washed with water and ethanol, and dried in vacuum. For L^2: yield 74.6%, M.p.: 167–168 °C. *Anal.* Calc. for $C_{26}H_{20}N_6S_2$: C, 64.98; H, 4.19; N, 17.49. Found: C, 64.94; H, 4.17; N, 17.53%. IR (KBr, cm^{-1}): 1586 (w), 1578 (s), 1559 (vs), 1537 (s), 1478 (w), 1428 (m), 1399 (s), 1346 (s), 1328 (m), 1200 (m), 1180 (m), 1103 (w), 1023 (w), 828 (w), 810 (m), 703 (m). ESI-MS: 982.7 ($[2L^2+Na]^+$, 100%); 503.2 ($[L^2+Na]^+$, 20%); 481.3 ($[L^2+H]^+$, 10%). ^1H NMR (δ, 500 MHz, $CDCl_3$): 9.18 (s, 2H, pyridyl-H), 8.71 (d, 2H, pyrimidinyl-H), 8.54 (d, 2H, pyridyl-H), 8.35 (d, 2H, pyridyl-H), 7.53 (t, 2H, pyridyl-H), 7.42 (t, 2H, aryl-H), 7.33 (d, 2H, pyrimidinyl-H), 7.26 (d, 2H, aryl-H), 4.73 (s, 4H, methylene-H). Single crystals of L^2 suitable for X-ray diffraction were grown from a methanol solution by slow evaporation in air at room temperature.

For L^3: M.p.: 109–110 °C. *Anal.* Calc. for $C_{26}H_{20}N_6S_2$: C, 64.98; H, 4.19; N, 17.49. Found: C, 64.97; H, 4.23; N, 17.46%. IR (KBr, cm^{-1}): 1590 (w), 1556 (s), 1537 (s), 1479 (w), 1423 (m), 1398 (s), 1347 (s), 1322 (m), 1200 (s), 1178 (m), 1021 (w), 828 (w), 804 (m), 701 (m). Single crystals of L^3 suitable for X-ray diffraction were obtained in a similar way to that of L^2.

2.3. Preparation of the metal complexes

2.3.1. $[Ag_2L^2(NO_3)_2]_n$ (**1**)

To a suspension of L^2 (24.0 mg, 0.05 mmol) in chloroform (5 mL) in a tube, a solution of $AgNO_3$ (8.5 mg, 0.05 mmol) in acetonitrile (5 mL) was very slowly added dropwise. Crystal products formed after ten days in the dark (yield: 40%). *Anal.* Calc. for $C_{26}H_{20}N_8O_6S_2Ag_2$: C, 38.07; H, 2.46; N, 13.66. Found: C, 38.11; H, 2.43; N, 13.63%. IR (KBr, cm^{-1}): 1597 (w), 1569 (s), 1542 (m), 1480 (w), 1404 (m), 1384 (vs), 1348 (s), 1326 (s), 1292 (m), 1206 (m), 1181 (w), 1027 (w), 817 (w), 723 (w), 698 (w).

2.3.2. $[HgL_{0.5}{}^2OAc_2]_n$ (**2**)

Compound **2** was prepared by adding a methanol (50 mL) solution of the ligand (0.48 g, 1.0 mmol) to a methanol (30 mL) solution of $Hg(OAc)_2$ (0.32 g, 1.0 mmol). The resulting colorless solution was stirred and refluxed for 3 hours, then it was filtered after cooling. Colorless diamond-shaped crystals of **2** were obtained (yield: 63%). *Anal.* Calc. for $C_{17}H_{16}N_3O_4SHg$: C, 36.53; H, 2.88; N, 7.52. Found: C, 36.57; H, 2.84; N, 7.50%. IR (KBr, cm^{-1}): 1561 (s), 1542 (s), 1480 (w), 1432 (m), 1412 (m), 1341 (m), 1325 (m), 1202 (w), 1191 (w), 1048 (w), 1024 (w), 817(w), 723 (w), 699 (w).

2.3.3. $[HgL^2I_2]_n$ (**3**)

A solution of HgI_2 (0.45 g, 1.0 mmol) in methanol (40 mL) was added to a stirred solution of L^2 (0.48 g, 1.0 mmol) in 20 mL of

2.4. Crystallographic analyses

Diffraction data for L^2, L^3 and complexes **1**–**5** were measured on a Bruker SMART 1K CCD diffractometer [8] at 291 K using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Lorentz polarization and absorption corrections were applied. The structures were solved by direct methods and refined with the full-matrix least-squares technique using SHELXTL version 5.1 [9]. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. The hydrogen atoms were geometrically fixed and allowed to ride on the attached atoms. The Flack parameters of complexes **3** and **4** are 0.023(8) and 0.01(5). A summary of the crystal data and refinement results are listed in Table 1.

3. Results and discussion

3.1. Description of the crystal structures of L^2 and L^3

The molecular structures of L^2 and L^3 with the atom-numbering scheme are shown in Fig. 1. The two ligands crystallize in different space groups, *Pbca* (L^2) and $P\bar{1}$ (L^3), with different crystallographic symmetry. Due to the $-SCH_2-$ spacer, L^2 adopts a *cis* conformation with two arms on the same side of the central phenyl ring. It is noted that the pyridyl ring and the pyrimidinyl ring in each arm are not coplanar, their dihedral angles in the two arms are 8.4° and 15.9°, respectively. Similar to L^2, the arms of L^3 are also close and the dihedral angles between the heterocyclic rings are 2.2° and 16.8°, respectively.

3.2. $[Ag_2L^2(NO_3)_2]_n$ (**1**)

X-ray crystallographic analysis reveals that **1** crystallizes in the monoclinic system, $P2_1/n$ space group. As shown in Fig. 2a, there are two types of silver ions (named Ag1 and Ag2) in the crystal structure. Ag1 is coordinated by two N atoms and two O atoms in a distorted square planar geometry, in which the two N atoms (N3, N5#) are from different heterocycles of distinct ligands, and the two O donors (O1, O2) are from one nitrate anion. Ag2 adopts a distorted square pyramid configuration composed of two N donors and three O donors. The two nitrogen atoms (N1, N6#), from different ligands, and two oxygen atoms (O4, O5), from one nitrate anion, are placed in the equatorial plane, while the O5#2 atom from another nitrate anion is located in the axial position. Two neighboring Ag2 centers (Ag2 and Ag2#2), linked by O–O bridges of two nitrate anions, form a four-membered centrosymmetric dinuclear cyclic unit with an Ag–Ag distance of 4.149 Å. This distance is a little longer than the van der Waals contact distance for Ag–Ag (3.40 Å) [10]. In **1**, the Ag–O bond lengths are between 2.490(5) and 2.868 Å, while the Ag–N bond lengths vary from 2.197(6) to 2.248(5) Å, which are all in the range for normal values [3].

Similar to the structure of the free ligand, each L^2 ligand adopts a close *cis* conformation with two heterocyclic arms on the same side. L^2 presents a tetradentate-bridging mode. Due to the spacial

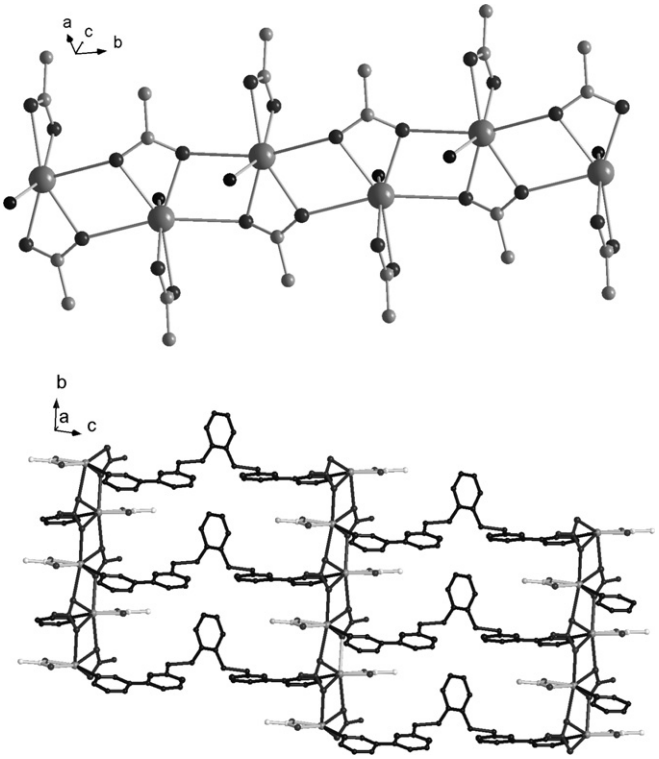

Fig. 3b. Top: view of the Hg–O tape; bottom: 2D network in **2**, tapes are linked by ligands in the *bc* plane.

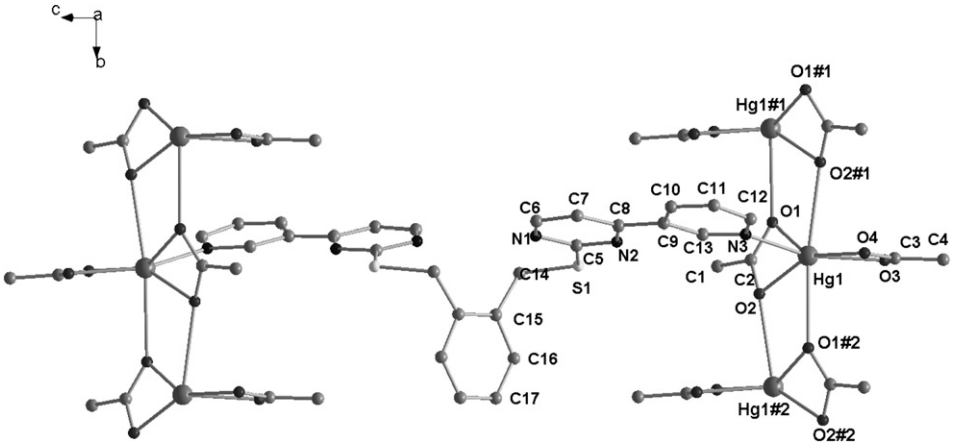

Fig. 3a. Molecular structure of complex **2**, hydrogen atoms are omitted for clarity. Selected bonds length (Å) and angles (°): Hg1–O1, 2.507(6); Hg1–O2, 2.329(6); Hg1–O3, 2.237(5); Hg1–O4, 2.495(6); Hg1–N3, 2.256(8); Hg1–O2#1, 2.738(5); Hg1–O1#2, 2.780(6); O3–Hg1–N3, 149.8(3); O1#2–Hg1–N3, 97.2(2); O2#1–Hg1–N3, 80.0(2); O4–Hg1–N3, 96.8(3); O2–Hg1–N3, 88.9(2); O1–Hg1–N3, 90.2(2); O2#1–Hg1–O3, 86.04(19); O1#2–Hg1–O3, 88.13(19); O1–Hg1–O3, 110.6(2); O2–Hg1–O3, 120.9(2); Hg1–O1–Hg1#1, 102.8(2); Hg1–O2–Hg1#2, 109.1(2). Symmetry code: #1, 0.5 − *x*, −0.5 + *y*, 0.5 − *z*; #2, 0.5 − *x*, 0.5 + *y*, 0.5 − *z*; #3, 1 − *x*, *y*, 1.5 − *z*; #4, 0.5 + *x*, −0.5 + *y*, 1 + *z*; #5, 0.5 + *x*, 0.5 + *y*, 1 + *z*.

hindrance with silver ions induced by the two arms in the *cis* position, only four N atoms of the heterocycles link four metal atoms to generate infinite 1D tapes, in which two pyrimidinyl planes of one ligand are almost parallel to each other, with a small dihedral angle of 1.7°, as are two pyridyl rings, with a dihedral angle of 2.9°. It is observed that some NO_3^- anions preferentially bridge the 1D tape structures via Ag2–O5 contacts to generate a 2D network (Fig. 2b).

3.3. $[HgL_{0.5}{}^2OAc_2]_n$ (**2**)

A single crystal XRD study has revealed that $[HgL_{0.5}{}^2OAc_2]_n$ (**2**) crystallizes in the *C*2/*c* space group. One symmetric unit of **2** contains one ligand, two metal atoms and four-coordinated acetate anions. As depicted in Fig. 3a, the metal ion lies in a seven-coordinated environment with a HgN_2O_5 unit. Each metal ion is chelated by two bidentate acetates through their O atoms, forming two four-membered metallocycles. Furthermore the chelating O atoms of one acetato ligand also link the neighboring Hg ions to yield 1D infinite ladders with a Hg–Hg distance of 4.134 Å (Fig. 3b, top), which run parallel to the *b* axis. These isolated ladders are interlaced into a corrugated plane through N atoms of pyridyl rings from L^2 (shown in Fig. 3b, bottom).

Different from **1**, L^2 in **2** adopts a *trans* conformation, opening its two heterocyclic arms which are on the opposite side of the central phenyl ring, and the ligand acts as a terminal pyridine group to weave the ladders. The pyrimidinyl and pyridyl rings are almost parallel each other with a dihedral angle of 2.1°, and the dihedral angle between the heterocyclic plane and the phenyl plane is 80.1° (see Figs. 4a and 4b).

3.4. $[HgL^2I_2]_n$ (**3**)

By replacing $Hg(OAc)_2$ with HgI_2 in the reaction with L^2, $[HgL^2I_2]_n$ (**3**) was obtained, which crystallizes in the monoclinic system, $P2_1$ space group. The structure of **3** consists of one-dimensional neutral chains where the Hg(II) ion is coordinated by two iodide anions and two pyridine nitrogen atoms of different ligands. In this case, the geometric sphere around each metal atom is tetrahedral, but slightly distorted.

Both Hg–N and Hg–I distances in **3** are in the range of those found in the other complexes [11]. It is noted that the pyrimidinyl ring and the pyridyl ring of L^2 are obviously not coplanar, the dihedral angle between the two heterocyclic rings is ca. 24.4°. In the solid state, the adjacent zigzag chains are stacked through C7–H···N5 hydrogen bonding (d_{C7-N5} = 3.436(19) Å; ∠C7–H···N5 = 147.00°, symmetry code: $1-x$, $-1/2+y$, $1-z$) to form corrugated 2D planes.

In the crystal packing of **3**, L^2 takes a *N*,*N*′-bidentate bridging pattern. Meanwhile, the ligand adopts a *trans* conformation with its arms on opposite sides of the central phenyl ring and outspreading to link two metal ions by using the N atoms of the pyridyl rings.

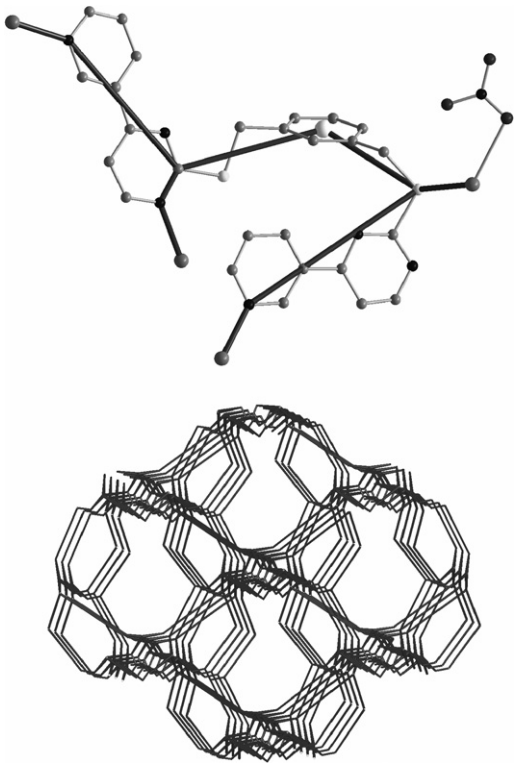

Fig. 5c. Top: the ligand can be abstracted as a kangaroo-shaped motif in black color; bottom: 3D network of **4**.

3.5. $[Ag_3L_2^3(NO_3)_3]^n$ (**4**)

Compound **4** crystallizes in the orthorhombic system of a non-centrosymmetric space group, *Pnn*2. The asymmetric unit is composed of three Ag ions, two independent L^3 ligands, two-coordinated nitrate anions and a free nitrate counteranion.

There are also two types of coordination modes for the metal atoms. Ag1 is coordinated by two pyridyl N atoms from different ligands in a slightly distorted linear geometry with a N–Ag–N bond angle of 163.9° and a Ag–N bond distance of 2.122(9) Å, similar to those found in the other two-coordinated Ag complexes [2,3]. Ag2 is tetra-coordinated in a distorted tetrahedral fashion (AgN_2OS) and bound by one S atom, two different N atoms from two ligands and one O donor from a nitrate anion.

Owing to the spacial hindrance induced by two arms in *meta* positions, each L^3 in **4** acts as a tetradentate ligand, in which a sulfur atom and three nitrogen atoms from different heterocycle groups are bound to four Ag atoms in four different directions (Fig. 5a). It is noteworthy that the S atom and the pyrimidinyl N atom from one arm are not coordinated to silver ions at the same time. Two kinds of modes of the nitrate anions are present, in which one is free and the other is moored to the four-coordinated Ag(I) center. Additionally, two arms attached to the central benzene ring adopt an ajar conformation, and the dihedral angles between each of the pyrimidinyl rings and the central benzene ring are 73.1° and 69.6°, while the angles between the pyrimidinyl rings and the pyridine rings are 7.5° and 6.2°, respectively. Furthermore, silver atoms with tetradentate patterns are bridged by L^3 to form a single chiral helical chain with a separation of 18.164(2) Å, then two adjacent single stranded helical chains with opposite chirality are connected by silver atoms with a bidentate pattern (shown in Fig. 5b).

As far as we know, such a structure is unprecedented for Ag(I) complexes with thioether ligands, although the silver–thioether system has been well investigated [2–5]. Interestingly, the ligand acts as a μ_4-bridge to link four silver ions, forming a kangaroo-shaped motif, and the framework can be assigned as an interpenetrating network (Fig. 5c).

3.6. $[HgL^3I_2]_n$ (**5**)

By replacing L^2 with L^3 in the reaction with HgI_2, $[HgL^3I_2]_n$ (**5**) was obtained. Differently from **3**, **5** crystallizes in the triclinic system, $P\bar{1}$ space group. The crystallographic analysis of **5** revealed that its structure is a one-dimensional polymeric helix consisting of $[HgL^3I_2]$ units (Fig. 6a). Each mercury atom, coordinated by two iodide anions and two pyridine nitrogen atoms of different ligands, is located in a slightly distorted tetrahedral geometric sphere.

Hg–N and Hg–I distances in **5** are almost equivalent and also in the range of those found in other complexes [11]. It is observed that the two dihedral angles between the pyrimidinyl ring and the pyridyl ring in L^3 are distinct, one is nearly coplanar with a small dihedral angle of 6.2°, and the other is ca. 26.4°. In comparison, the dihedral angle between two pyridyl rings coordinated to the mercury atom is 61.7° in **3**, while it is 81.4° in **5**.

Each L^3 in **5** takes an ajar configuration and acts as a *N,N′*-bidentate ligand to link mercury atoms to form a single stranded helix with a period of 8.504 Å. Furthermore, as shown in Fig. 6b, effective $\pi\cdots\pi$ stacking is observed between the adjacent helical chains with opposite chirality, and the centroid–centroid distance is 3.699 Å.

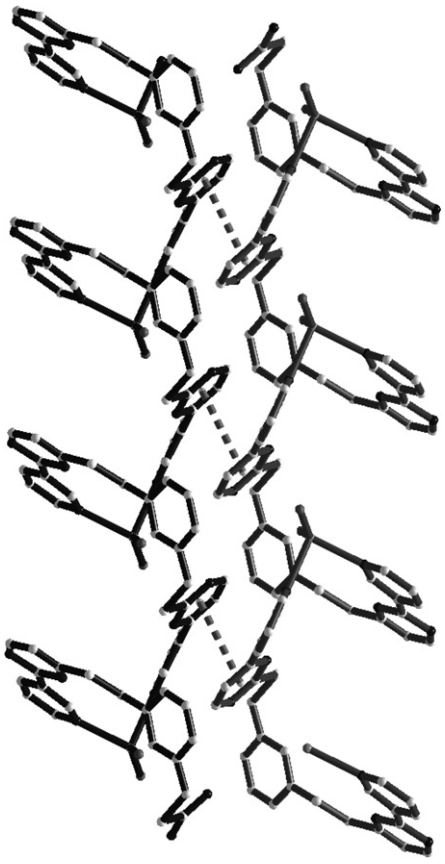

Fig. 6b. Perspective view of the helixes held by $\pi\cdots\pi$ stacking interactions.

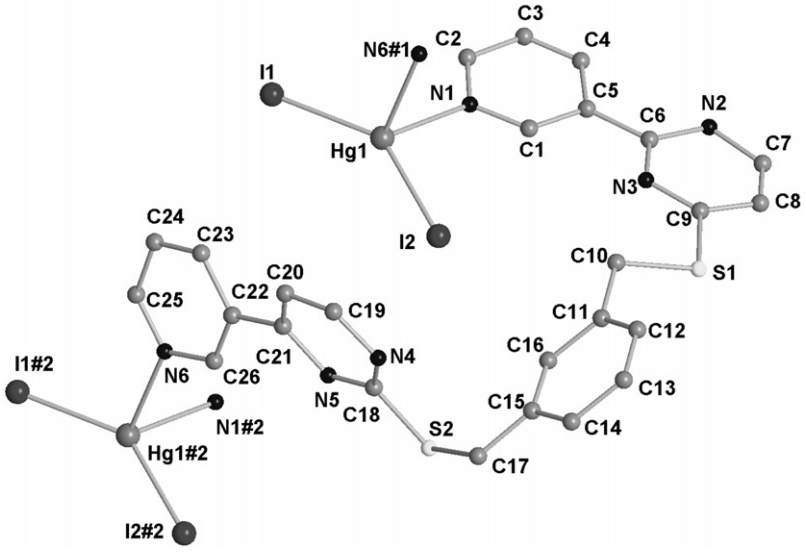

Fig. 6a. Molecular structure of **5** showing the numbering scheme, hydrogen atoms are omitted for clarity. Selected bonds length (Å) and angles (°): Hg1–I1, 2.492(2); Hg1–I2, 2.469(2); Hg1–N1, 2.435(14); Hg1–N6#1, 2.409(12); I1–Hg1–I2, 142.71(7); I1–Hg1–N1, 113.4(4); I1–Hg1–N6#1, 100.7(3); I2–Hg1–N1, 96.5(4); I2–Hg1–N6#1, 102.2(3); N1–Hg1–N6#1, 88.1(5). Symmetry codes: #1, $-1+x, y, z$; #2, $1+x, y, z$.

Additionally, there also are C–H···I hydrogen bonding interactions (d_{C19-I2} = 3.731(15) Å; ∠C19–H···I 2 = 155.0°; d_{C25-I1} = 3.562(17) Å; ∠C25–H···I1 = 129.00°, symmetry code: $-x$, $2-y$, $-z$; $1-x$, $3-y$, $1-z$) that form a 3D network.

In complex **1**, L^2 takes a tetradentate-bridging pattern through the nitrogen atoms from heterocycles to connect four silver ions and adopts a close *cis* configuration with respect to the xylyl group. While in **4**, L^3 adopts an ajar conformation with respect to the xylyl group and a tetradentate-bridging mode through the nitrogen atoms and sulfur atom to connect four silver ions. Owing to the positional isomerism of the two arms in L^2 and L^3, complex **1** packs into a centrosymmetric space group $P2_1/n$, while complex **4** packs into a noncentrosymmetric space group *Pnn*2, which includes single stranded helical chains. In **3**, L^2 adopts an open *trans* conformation with respect to the xylyl group and takes a *N*,*N*′-bidentate bridging pattern to connect the mercury atoms and form zig-zag chains. While in **5**, L^3 adopts an ajar conformation and the *N*,*N*′-bidentate bridging pattern to connect the mercury atoms, forming helixes with a similar reason as above. All these reveal that the positional isomerism of two arms in both L^2 and L^3 play an important role in the formation of the above compounds. As for **4** and **5**, both of them contain stranded helical chains, but the chirality was not present in complexes due to the interactions between opposite chiral chains.

Additionally, in complexes **1** and **2** counteranions also act as bridging ligands to chelate metal ions to form corrugated 2D planes.

4. Conclusion

In this study, five novel complexes with different architectures, $[Ag_2L^2(NO_3)_2]_n$ (**1**), $[Hg_2L^2(OAc)_4]_n$ (**2**), $[HgL^2I_2]_n$ (**3**), $[Ag_3L_2{}^3(NO_3)_3]^n$ (**4**) and $[HgL^3I_2]_n$ (**5**) were constructed from L^2 and L^3. In **1**–**3**, L^2 adopts different coordination modes and forms quite different coordination architectures. However, in the structures of **4** and **5**, L^3 takes an ajar configuration to construct more complicated networks than the other examples. Compared with those complexes [7] resulting from L^1, the present study demonstrates that the nature of positional isomerism and sufficient rigidity of the ligand in addition to the geometric needs of the metal atoms and the effect of the anions play an important role in the crystal packing of MOFs.

5. Supplementary data

CCDC 676723, 676724, 676725, 676726 676727, 676728 and 676729 contain the supplementary crystallographic data for two ligands and **1**, **2**, **3** , **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

Controlled radical polymerization

ABSTRACT

The reaction of various alkyl halides (1-bromoethylbenzene, BEB; 1-chloroethylbenzene, CEB; methyl iodide; 1-bromoethylacetate, BEA; and ethyl-2-bromopropionate, EBP) with CuBr/L (L = bipy, Me_6TREN) has been investigated in the presence of $[Co(acac)_2]$ or $[Co(acac)_2]$/py, with the goal of generating radicals by halogen atom transfer to Cu^I for subsequence trapping by Co^{II} and generation of an alkylcobalt(III) product. No evidence for the formation of the target product has been obtained. The various reactions, carried out under different conditions, have led to the crystallization of the following compounds: $\{[Cu(bipy)_2Br]^+\}_2\{[Cu_2Br_4]^{2-}\}$ (**1**); $[Cu(Me_6TREN)Br]Br$; $[Cu(Me_6TREN)Br_{0.37}Cl_{0.63}]Br$ (**2**); *trans*-$[Co(acac)_2(THF)_2]$ (**3**); $[Co(Me_6TREN)Br]Br$ (**4**); $[Cu(Me_7TREN)I]\{[Cu_2I_2(Br_{0.628}I_{0.372})_2]_{0.9}[I]_{0.2}\}$ (**5**); $[C_6H_8N]_2[CoI_4]$ (**6**); $[Co(acac)_3]$; and $[Co(acac)_2(THF)_2CoBr_2]$ (**7**). The structures of **1**–**7** have been determined by single-crystal X-ray diffraction.

1. Introduction

Controlled radical polymerization (CRP) is the fastest developing field in modern polymer chemistry [1]. The scope and flexibility of this technique to access polymers with well-defined structure, chain length, and composition is unmatched by any other polymerization method. Although non-metal-based methods are also known, the coordination and organometallic chemistry of the transition metals involving one-electron processes (homolytic bond cleavage, atom transfer reactions) has been shown to be of fundamental importance in CRP [2].

There are three ways in which a transition metal complex can mediate CRP, all based on one-electron processes: (i) reversible halogen atom transfer to a reduced metal catalyst, termed atom transfer radical polymerization (ATRP) [3,4]; (ii) homolytic cleavage of metal–carbon bonds, termed organometallic radical polymerization (OMRP) [5,6]; and (iii) degenerative transfer (DT), involving a rapid associative exchange between the active and dormant chains on a transition metal complex [7,8]. Our group investigates the intimate details of coordination chemistry related to transition metal mediated CRP. We have developed a family of compounds capable of simultaneous control by ATRP and OMRP [9–11], rationalized the effect of certain Lewis acid promoters [12,13] and explained the reason for the observation of low initiator efficiencies under certain conditions [14]. The possible interplay of various one-electron processes in CRP has been recently outlined in a review [2].

Of current interest is the unique ability of compound $Co(acac)_2$ to mediate the CRP of vinyl acetate (VAc), a challenging monomer for which previous attempts by ATRP and OMRP methods had failed. This compound was recently reported to provide excellent control by a proposed OMRP mechanism for a bulk polymerization (*i.e.* without solvent or additives) [15,16], but our studies have in fact demonstrated its action through a DT mechanism under these conditions, though the mechanism switches to OMRP in the presence of neutral donors [17]. The reasons for this behavior are summarized in Scheme 1. Whereas the Co–C bond in the organometallic dormant chain is not weak enough to afford a significant free radical concentration in the absence of ligand, stabilization of the Co^{II} radical trap by further coordination of L to give 6-coordinate $[Co(acac)_2L_2]$ shifts the radical formation equilibrium and allows the CRP to be sustained by the OMRP mechanism. The 6-coordinate, L-bonded Co^{III} dormant chain cannot undergo DT because it is coordinatively saturated, whereas the 5-coordinate ligand-free chain, $[(acac)_2Co\text{-}(m)_xR]$, is able to promote DT. In a more recent contribution, we have carried out computational investigations on the nature of the Co^{III} chain-end [18]. However, no simple alkylcobalt(III) compound that could represent a model of the OMRP dormant chain or DT transfer agent has so far been isolated and characterized with the acetylacetonate ligand environment, $[RCo(acac)_2]$ or $[RCo(acac)_2L]$. This is in contrast with other alkylcobalt(III) species, containing for instance a porphyrin ligand environment [19–21].

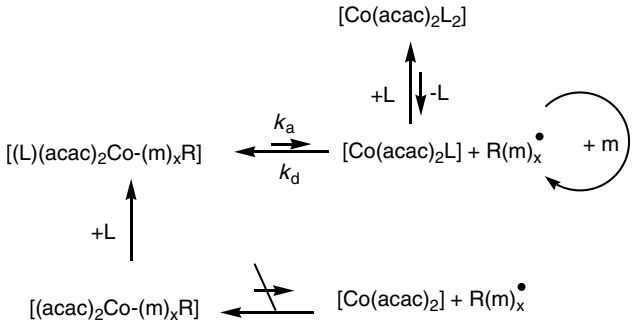
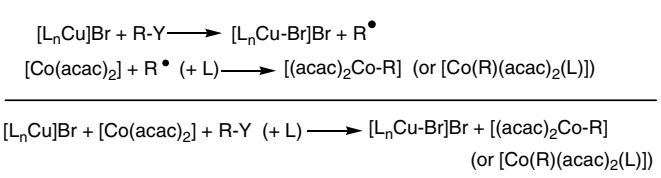


Scheme 1. Influence of ligand coordination to the mechanism of $[Co(acac)_2]$-mediated CPR of VAc.

We have therefore set out to prepare one such compound. This particular synthetic target does not appear straightforward. With supporting ligands such as porphyrin of Schiff bases, organylcobalt(III) products are easily accessed by first reducing $Co^{II}L$ to $[Co^{I}L]^-$, followed by reaction with an alkyl halide [19,20,22]. The hard acac ligand, however, does not provide sufficient stability to the putative $[Co(acac)_2]^-$ anion. A few derivatives have also been prepared by alkylation of halocobalt(III) reagents [23]. However, $[Co^{III}(acac)_2Y]$ (Y = halogen) are non-existing compounds. A final method leading to organylcobalt(III) compounds is one-electron oxidative addition of alkyl halides to Co^{II} reagents [23], see Scheme 2, a drawback being that half of the Co^{II} reagent is sacrificed for making the Co^{III}–Y by-product.

However, we find that no reaction takes place between $[Co(acac)_2]$ and BEB, which is a quite active alkyl halide (weak C–Y bonds). The reason for this lack of reactivity may be thermodynamic: cobalt prefers to remain in the +II oxidation state with hard ligands such as acac, and the co-product $[Co(acac)_2Y]$ (which is non-existent as already mentioned) does not provide sufficient thermodynamic help to achieve the oxidative addition process. A possible key to alleviate this problem is therefore to use a stronger halogen acceptor. We have considered the use of the Cu^{I} system CuBr/L (L = N-based ligand such as hexamethyl-tris(aminoethyl)amine (Me_6TREN) or 2,2′-bipyridine (bipy)). It has already been reported that CuBr/L systems abstract efficiency halide radicals from alkyl halides, forming the related Cu^{II} products [24–27], while Cu^{I} does not have sufficient affinity for carbon-based radicals [28]. Indeed, this is the basis for the high efficiency of this family of Cu^{I} systems as ATRP catalysts [3]. Some of these complexes, especially the *in situ* made [(Me_6TREN)CuBr], are very rapid under very mild conditions (room temperature or below) [29]. In this manner, we were hoping that alkyl radicals could be efficiently trapped by $[Co(acac)_2]$. Scheme 3 shows the reaction pathway envisaged for this transformation, which might be carried out in the presence of an additional monodentate ligand L, such as pyridine. Indeed, the organylcobalt(III) product should be stabilized by addition of a neutral ligand, with formation of a 6-coordinate $[Co(R)(acac)_2(L)]$ complex, because low-spin Co^{III} is known to strongly prefer an octahedral coordination environment.

Scheme 2. Generation of R–Co^{III} products by one-electron oxidative addition or R–Y to Co^{II} precursors.



Scheme 3. Possible reaction pathway for alkyl halides in the presence of [{Me_6-TREN}Cu]Br and $[Co(acac)_2]$.

In this contribution, we present the results of synthetic efforts along these lines. Unfortunately, we have not attained our desired goal, because many side reactions take place as will be discussed in detail in the next section. However, the isolated and characterized compounds present some novelty in $Cu^{I/II}$ and Co^{II} coordination chemistry and may therefore represent useful reference for future work in CRP by the use of these metal systems.

2. Results and discussion

2.1. Reaction of $[Cu(bipy)_2]Br$ and 1-bromoethylbenzene

We started our studies with the CuBr/bipy system, since the ligand is easily available. This is known to form the salt-like compound $[Cu(bipy)_2]^+Br^-$ in solution [30]. However, this compound is not one of the fastest activators for ATRP (*i.e.* capable of generating free radicals from an alkyl halide at a high rate under mild conditions) [29]. The rate of radical generation depends on the C–Y bond strength of the halide compound used [31], therefore we restricted our studies with this copper complex to the relatively active initiator 1-bromoethylbenzene (BEB). The reaction was carried out in MeOH at room temperature, leading to the immediate formation of a red precipitate after the addition of CuBr, signaling the formation of a Cu(II) product. This compound was crystallized and characterized by X-ray diffraction.

The X-ray determination revealed the formation of the mixed valence Cu(I)/Cu(II) salt $\{[Cu(bipy)_2Br]^+\}_2\{[Cu_2Br_4]^{2-}\}$ (**1**) (Fig. 1). Selected bond lengths and distances are shown in Table 1. The structure of **1** features a centrosymmetric $[Cu_2Br_6]^{2-}$ ion, which sits on two-fold axis, and two symmetry-related $[Cu(bipy)_2Br]^+$ cations. The Cu(II) cation is in a distorted trigonal bipyramidal coordination, with axial Cu–N bonds of 1.981(2) and 1.987(2) Å while longer Cu–N bonds of 2.070(2) and 2.083(3) Å occur in the equatorial positions as well as the Cu–Br bond with 2.4936(9) Å. The monovalent Cu2 site adopts a trigonal planar $CuBr_3$ coordination, with Cu2–Br2 (bridging) bonds of 2.4689(10) Å and Cu2–Br3 (terminal) bonds of 2.3215(12) Å. The structure of the cation has already been reported in the simpler $[Cu(bipy)_2Br]Br$ salt [32], as well as with other anions [33–36] and the $[Cu_2Br_6]^{2-}$ dianion has also been crystallographically characterized in other compounds [37–45]. All bond distances are in good agreement with those reported in the above cited structures.

The formation of this compound can be understood on the basis of bromine atom transfer from BEB to $[Cu(bipy)_2]^+$ to generate the Cu^{II} cation $[Cu(bipy)_2Br]^+$, while the Br^- ion is trapped by additional CuBr to yield the Cu^{I} dianion $[Cu_2Br_4]^{2-}$. Thus, not all CuBr has reacted with bipy, or perhaps bipy coordination is reversible and these particular crystallization conditions favor the precipitation of this ion combination. Other mixed-valence Cu^{I}/Cu^{II} salts have previously been obtained, for instance $[Cu^{II}(dNpby)_2Br]^+$-$[Cu^{I}Br_2]^-$ where dNpby = 4,4′-di(5-nonyl)-2,2′-bipyridine [46], but the anion is a linear mononuclear [Br–Cu–Br]$^-$ complex in this compound. It seems that small subtleties tip the choice of the Cu^{I} anion for a mononuclear ($[CuBr_2]^-$) or dinuclear ($[Cu_2Br_4]^{2-}$) form.

The formation of compound **1** suggests that $CH_3(Ph)CH$ radicals are being produced, therefore this reaction was repeated in the presence of $[Co(acac)_2]$. However, the course of the reaction did not change and there was no spectroscopic evidence for the formation of an alkylcobalt(III) derivative. It is possible that the Co–$CH(CH_3)Ph$ bond is too weak to be formed in an irreversible fashion

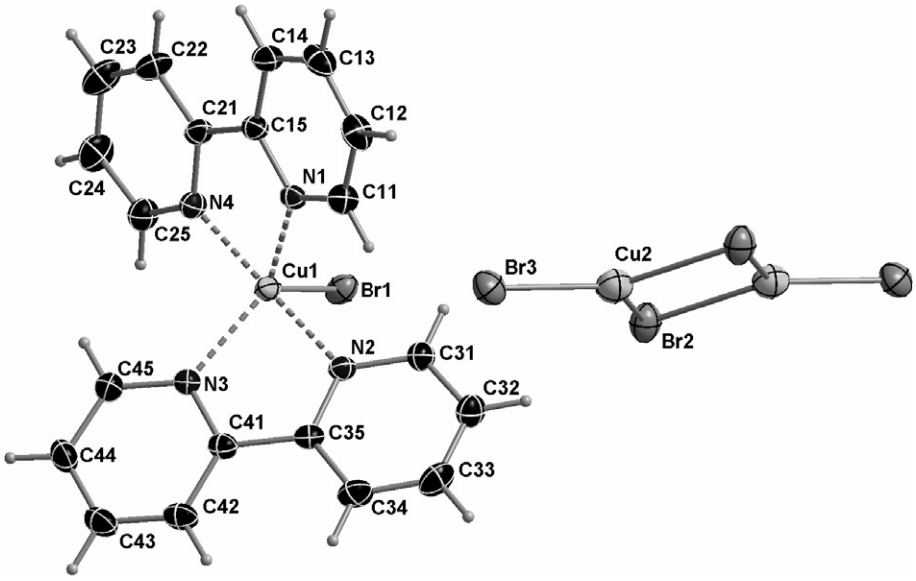


Fig. 1. Molecular structure of **1** at 180 K (50% probability ellipsoids).

[a] (i): $3-x, -y, 2-z$.

at room temperature. Therefore, we have tried to generate these radicals at lower temperatures with a more active Cu complex.

2.2. Reaction of CuBr(Me_6TREN) and 1-bromoethylbenzene or 1-chloroethylbenzene

Me_6TREN, in combination with CuBr, provides one of the fastest initiating systems in copper mediated CRP. In order to insure sufficient solubility of all materials at low temperature, we switched solvent to THF. As already described [47], complexes $[Cu(Me_6TREN)X]$ (X = Cl, Br, I) that form by combination of CuX and Me_6TREN are not stable at room temperature, yielding fast disproportionation into Cu^0 and $[Cu^{II}(Me_6TREN)X]X$ and are also quite sensitive to aerial oxidation. This has been confirmed in our study: the disproportionation can be easily observed by the development of a green color, characteristic of the Cu^{II} system, from the colorless solution of the Cu^I complex. At lower temperatures and under strict exclusion of air and moisture the solution remains colorless.

Addition of BEB (1 equiv.) and $[Co(acac)_2]$ led to the isolation of light green single-crystals, which were identified as the already reported [48] $[Cu(Me_6TREN)Br]Br$. The same reaction was worked out using 1-chloroethylbenzene (CEB) instead of BEB, with similar results. Single-crystal structure determination of the green crystals revealed the formation of $[Cu(Me_6TREN)Br_{0.37}Cl_{0.63}]Br$ (**2**). Selected bond lengths and angles for compound **2** are shown in Table 2 and the molecular structure is shown in Fig. 2. This structure is isomorphous with that of the all-Br analogue. The only difference is a compositional Cl/Br disorder in the Cu-bonded position, but not in the free anion. This selectivity is probably related to the lower solubility of the bromide salt, joint with the lower activation barrier for nucleation and crystal growth relative to the barrier for Cl/Br exchange between the coordinated and free position. The Cu atom adopts a trigonal bipyramidal coordination geometry, with the axial Cu–N1 and Cu–Cl/Br bonds coinciding with the crystallographic three-fold axis. The axial Cu–N bond is significantly shorter than the equatorial one. Because of the mixed Cl/Br position, the Cu–Cl/Br distance does not carry any chemical meaning. As expected, it is shorter compared to the Cu–Br bond in the all-Br analogue (2.393(3) Å) [48] while it is longer than the Cu–Cl distance in $[Cu(Me_6TREN)Cl]^+$ (2.234(2) Å) [47]. The trigonal bipyramidal environment is only slightly distorted with N1–Cu–N2 angles of 84.19(9)° and N2–Cu–$N2^i$ angles of 118.99(3)°.

The formation of these Cu^{II} complexes confirms the fast and effective oxidation of Cu^I by halogen atom transfer from the organic halide molecule, therefore implying the formation of $CH_3(Ph)CH$ radicals in solution. The above reactions yielded a pink/red THF solution as the mother solution of the isolated crystals. There was no indications from spectroscopic analyses that the formation of an alkylcobalt(III) compound had taken place, while attempts to crystallize the pink/red component soluble in THF were not successful. We conclude that, even at lower temperatures, the Co^{III}–$CH(CH_3)Ph$ bond is probably too weak to withstand reversible

Table 2

homolytic rupture and ultimately leads to decomposition with formation of the typical radical decomposition products (coupling to $PhCH(CH_3)CH(CH_3)Ph$ and disproportionation to ethylbenzene and styrene).

2.3. Reaction of CuBr(Me$_6$TREN) and ethyl-2-bromopropionate

Using this organic halide, no apparent reaction occurred at low temperature, indicating that the C–Br bond is less susceptible to atom transfer than that of BEB. Warming the solution to room temperature led to the development of a green color, which yielded crystals of $Co(acac)_3$. When the same reaction was repeated and maintained at low temperature for an extended period, red crystals were isolated, corresponding to the THF solvate complex $[Co(acac)_2(THF)_2]$ (**3**).

Compound **3** is only stable at low temperature and decomposes by solvent loss upon standing for longer than 5 min under mineral oil at ambient temperature. The Co^{II} ion has an octahedral coordination with the two acac ligands in equatorial positions and THF in the axial positions. A two-fold axis is situated in the metal center of the molecule (Fig. 3). Many X-ray structures of *trans*-$[Co(acac)_2(L)_2]$ derivatives have been previously published (L = py, H_2O, CH_3OH, imidazole, etc.) [49–54], but that with THF had not yet been reported. The THF molecules show disorder with half of the molecules oriented into two different envelope conformations. Selected bond distances and angles are shown in Table 3. The Co–O(acac) bond lengths are in good agreement with those reported for the above mentioned other solvent adducts, as well as with those of solvent-free $[Co(acac)_2]$ [51,55], where in fact the coordination environment is pseudo-octahedral due to skewed stacking with neighboring molecules. The Co–O(THF) distances are significantly longer than the Co–O(acac) bonds. This result is quite logical considering that a neutral solvent molecule should be more weakly bonded to the metal center compared to the anionic acac ligand.

Table 3
Selected bond distances (Å) and angles (°) of $[Co(acac)_2THF_2]$ (**3**)[a]

Co1–O1	2.163(2)	O2–Co1–O2^{i}	180.00(14)	O2–Co1–O1^{i}	89.4(1)

		O3–Co1–O1	90.16(9)	C1–O3–Co1	125.58(19)

[a] (i): −*i*, −*y*, 1 − *z*.

The isolation of compound **3** is not to be considered surprising, since the solution contains $[Co(acac)_2]$ in THF, thus the bis-adduct is certainly present, at least in equilibrium amounts, especially at low temperatures. The recovery of **3** gives no indication as to whether or not the Cu^{I} reagent has abstracted a halogen atom.

2.4. Reaction of CuBr(Me$_6$TREN) and methyl iodide

We have next turned our attention to an alkyl halide that would yield a stronger Co–C bond. The homolytic bond dissociation energy of R–X bonds for a variety of R groups and for X = Cl, Br, I has been the subject of a computational study [18]. Methyl is the alkyl group at the top of the list. Although not yet supported by

an extensive computational investigation on an homologous series of organometallic compounds, it may be anticipated that the strength of M–R bonds should roughly parallel that of R–X bonds, thus the $(acac)_2Co–CH_3$ bond is expected to have a reasonable strength. Indeed, recent calculations have shown that $(acac)_2Co–R$ bonds with $R = CH_3(X)CH$ ($X = CH_3O$, CH_3COO and CH_3OOC) are weaker than with $R = CH_3$ [18]. On the other hand, the strength of CH_3-X increases in the order X = I < Br < Cl. Thus, MeCl should be difficult to activate. We have chosen to work with CH_3I, also in consideration of the fact that this compound is a volatile liquid and therefore easier to handle. Several reactions were carried out at different temperatures and with different order of reagent addition, but no alkylcobalt(III) compound was crystallized under any circumstances. The products that were crystallized are summarized in Scheme 4.

2.5. Structure of [{Me_6TREN}CoBr]Br (**4**)

The violet crystals of **4** reveal a trigonal bipyramidal coordination geometry around the Co^{II} center with axial Co–N and Co–Br bonds and three equatorial Co–N bonds. The most important distances and angles are listed in Table 4, whereas the molecular structure is shown in Fig. 4. This structure is already reported in the literature, but based on data collected at room temperature and much less precisely determined [56]. The structure is also isomorphours with those of **2** and the all-Br analogue, [Cu(Me_6-TREN)Br]Br, discussed above. As expected, all distances are slightly longer in **3** than in the Cu analogue, because of the slightly larger ionic radius of Co^{II}.

Table 4
Selected bond distances (Å) and angles (°) of [Co(Me_6TREN)Br]Br (**4**)[a]

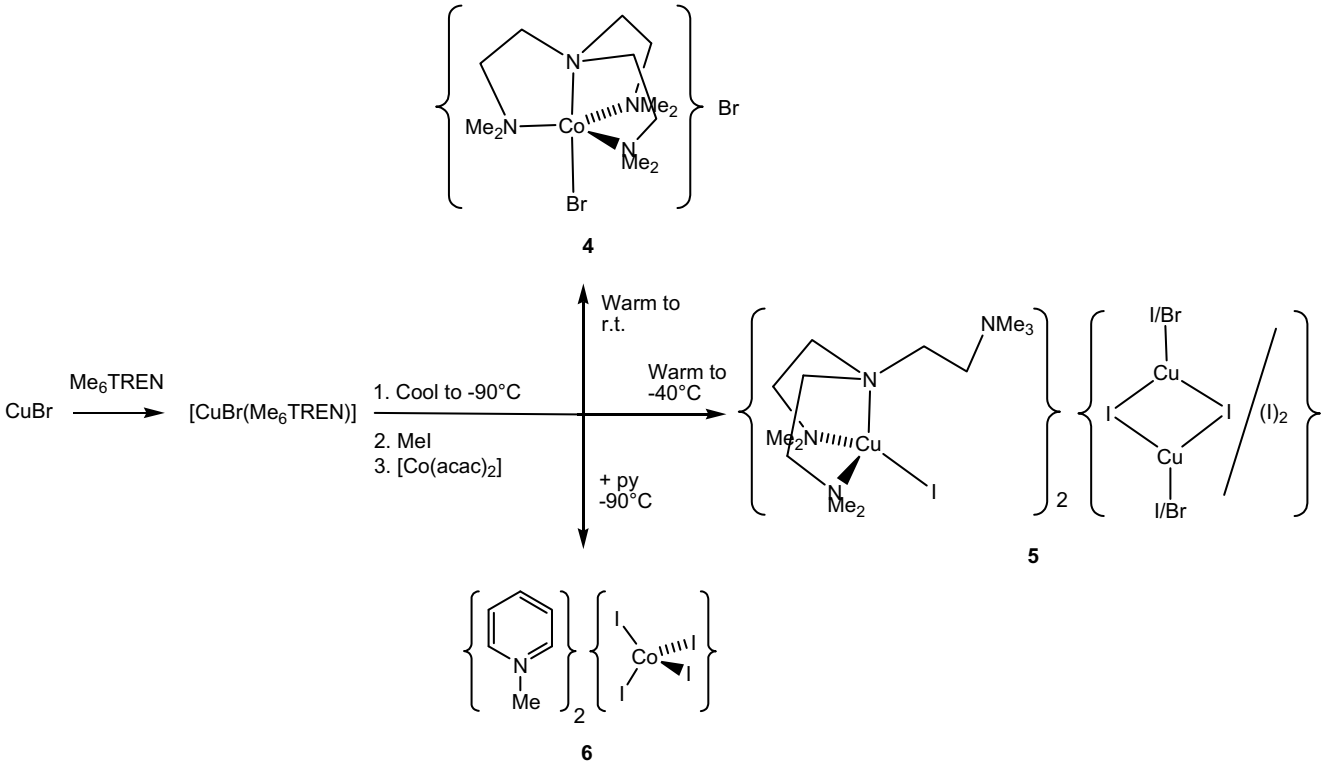
2.6. [{Me_7TREN}CuI]$_2$[$Cu_{1.80}Br_{1.13}I_{2.67}$] (**5**)

This structure features ordered $[Cu(Me_7TREN)I]^+$ ions in the cationic sites, whereas the anionic sites are occupied by a compositional disorder of $[Cu_2I_2(I/Br)_2]^{2-}$ and free I^- ions. There are two cations per each anionic site, with one full cation and half the dianion in the asymmetric unit around an inversion center. Overall, all Cu species are in the oxidation state I, explaining the almost



Scheme 4. Products generated by the reaction of $[Co(acac)_2]$ with MeI in the presence of [Cu(Me_6TREN)Br].

colorless aspect of the crystals. Fig. 5 shows a representation of the molecule with the dinuclear Cu^{I} dianion. Whereas the I3 site is fully occupied, the Cu2 and Br2/I2 sites refine with 90% occupancy. Moreover, the terminal halide position is a compositional disorder of atoms Br2 and I2 in a 62.8:37.2 ratio. Thus, the structure may be described as $[Cu(Me_7TREN)I]\{[Cu_2I_2(Br_{0.628}I_{0.372})_2]_{0.9}\ [I]_{0.2}\}$, with 90% of the molecules having the disordered $[Cu_2I_2(Br_{0.628}I_{0.372})_2]^{2-}$ ion and 10% having two I^- ions. This kind of crystallographic defect is well known for its ability to change the color of a correct structure significantly [57]. Selected distances and angles for this compound are listed in Table 5.

The Cu(I) cation is better described as a distorted trigonal pyramid than as a tetrahedron, with the Cu1–N3, Cu1–N2 and Cu1–I1 bonds being close to a trigonal planar arrangement with angles close to 120° (sum of the three angles = 353.8°), while a longer Cu1–N1 bond is located on the apex of the pyramid. This distortion is caused by the tridentate nature of the N_3 ligand, forcing the *cis*–N–Cu–N angles to be significantly smaller than the ideal tetrahedral value (N2–Cu1–N1: 84.3(4)°; N1–Cu1–N3: 83.7(4)°). Other cations with the same CuN_3I coordination environment around 4-coordinate Cu^{I} and with similar open tridentate N_3 ligands show the same distortion [58–62], while complexes with three monodentate N-donors or with symmetric *cyclo*-N_3 ligands adopt a more regular tetrahedral geometry [39,63–69]. The Cu2 site is in a trigonal planar coordination, like the $[Cu_2Br_4]^{2-}$ ion of compound **1**. A number of structures containing the $[Cu_2I_4]^{2-}$ ion have been previously reported [63–66], but no related structure with a compositional Br/I disorder has been described so far, to the best of our knowledge. The localization of the disorder in the terminal position suggests that the softer iodide anion has a stronger preference for the bridging site.

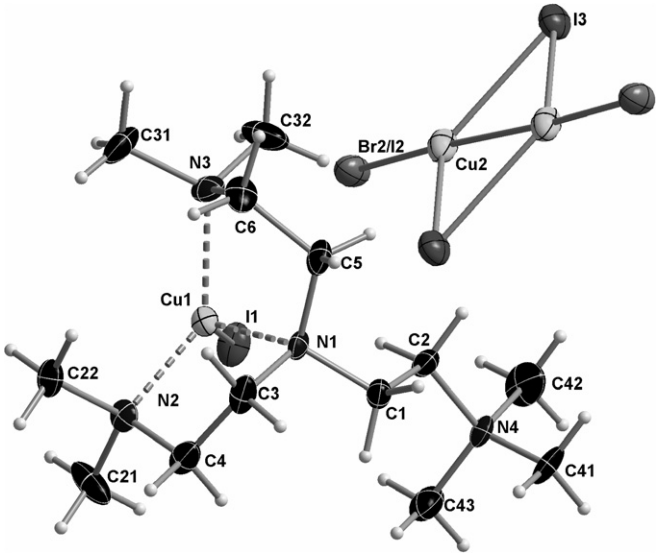


Fig. 5. Molecular structure of **5** at 160 K (50% probability ellipsoids).

2.7. $[C_5H_5NMe]_2[CoI_4]$ (**6**)

When the reaction was carried out as outlined above at −90 °C, except that pyridine was added in the hope of stabilizing an alkylcobalt(III) product in the form of a 6-coordinate complex, methylation of pyridine took place, as shown by the X-ray structure of a new compound with the composition $[C_6H_8N]_2[CoI_4]$ (**6**). A view of the molecule is shown in Fig. 6. The entire molecule, which is composed by two *N*-methylpyridinium cations and by a tetrahedral $[CoI_4]^{2-}$ dianion, is contained in the asymmetric unit. Selected bond lengths and distances are listed in Table 6. The geometry around Co^{II} is very close to ideal tetrahedral, with all I–Co–I angles laying between 107.3° and 112.8°. The Co–I bond distances of 2.583–2.608 Å coincide very well with those found in other compounds containing the same dianion [70–73].

The nature of the identified compounds resulting from this reaction (Scheme 4) brings us to the following conclusions. First, it is quite surprising to see how readily the acac ligand is displaced from Co^{II}, in spite of the chelate effect associated with this ligand. Two of the characterized compounds feature the Co^{II} ion surrounded by other ligands, in the 5-coordinate $[Co(Me_6TREN)Br]^+$ cation and in the 4-coordinate $[CoI_4]^{2-}$ dianion. Second, the electrophilic reactivity of MeI prevails on the homolytic rupture of the C–I bond and yields methylation of the Me_6TREN and py ligands, affording products that contain the $(Me_7TREN)^+$ and $(C_5H_5NMe)^+$ ions. One curious observation is that compound **4** contains only bromide and no iodide, including as free anion, even though it is obtained under very similar conditions as compound **5** where plenty of iodide enters the coordination sphere of the metal in both cation and anion.

2.8. Reaction of $CuBr(Me_6TREN)$ and 1-bromoethylacetate

Until now, we have found that the $CH_3(Ph)CH$ radicals are too stabilized to afford sufficiently strong R–Co^{III} bonds, whereas MeI, which should lead in principle to a stable Me–Co^{III} derivative, prefers to yield complex products of nucleophilic substitution at carbon and subsequent halide and neutral ligand exchange processes between copper and cobalt. In light of these results, our last attempt involved a halide molecule that is precursor of a radical of intermediate strength: $CH_3(CH_3COO)CH$. Indeed, the $[Co(acac)_2]$ complex controls the VAc polymerization by reversibly trapping the PVAc growing chain, $R_0\{CH_2CH(OOCCH_3)\}_nCH_2(CH_3COO)CH$, forming a Co^{III}-capped dormant chain as represented in Scheme 5 (R_0 = radical derived from the initiator) [15,17]. Another indication that the above-mentioned radical should lead to a stable adduct is

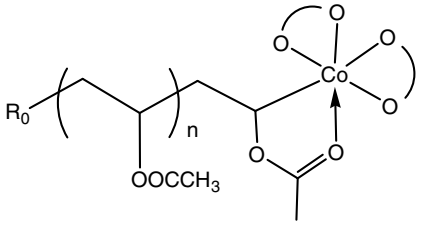
Ref. [18].



Scheme 5. Proposed structure of the dormant chain for the $[Co(acac)_2]$-controlled polymerization of VAc.

the recent isolation of a mixture of cobalt-capped short oligomers by thermally decomposing the mild radical initiator V-70 in the presence of VAc and a large excess of $[Co(acac)_2]$. The product was assigned the structure shown in Scheme 5, where $R_0 = (CH_3)_2(CH_3O)CCH_2C(CN)(CH_3)$, with an average n value of ca. 3 [18], on the basis of NMR and IR spectroscopy and derivatizations. The chelating mode indicated in Scheme 5 for the Co-bonded monomer unit is suggested by a DFT calculation on the model $[Co(acac)_2\{CH(OOCCH_3)CH_3\}]$ system and by the known preference of Co^{III} for an octahedral coordination. Thus, we have chosen compound $CH_3(CH_3COO)CHBr$ (1-bromoethylacetate, BEA) as halide precursor. Bromine rather than iodine was selected as halogen atom in order to disfavor the reactivity towards nucleophilic attack. Also, in order to minimize nucleophilic substitution problems, pyridine was not used in these reactions.

Using this organic halide, no apparent reaction occurred at low temperature, whereas only compound $Co(acac)_3$ was identified amongst the product obtained after warming the solution to room temperature, as already observed for the reaction with BEP. If the reaction solution was not allowed to warm up but rather kept at −80 °C, the formation of blue crystals was observed over a period of 10 days. This product was identified as a new binuclear Co(II) complex $[Co(acac)_2(THF)_2CoBr_2]$ (**7**). The molecular structure of this compound is depicted in Fig. 7 and selected bond lengths and distances are listed in Table 7. The corresponding dichloride compound, $[Co(acac)_2(THF)_2CoCl_2]$, displaying the same coordination geometry, has previously been described [74]. The molecule is composed of two bivalent Co atoms, connected to each other by two bridging oxygen atoms O11 and O22. Atom Co1 adopts an octahedral coordination mode, with two chelating acetylacetonate ligands and two *trans* THF molecules, whereas Co2 has a tetrahedral coordination environment, defined by the bridging atoms O11 and O22 of two different acetylacetonate ligands and two Br atoms. Due to the bridging oxygen atoms O11 an O22 which impose a small O11–Co2–O22 angle, the angle Br–Co–Br is widened relative to the tetrahedral value. The Co1–O bonds to the non-bridging atoms O12 and O21 are shorter than those to the bridging ones. The Co2–O bonds are even shorter, as expected from the lower coordination. All bond distances and angles involving the O atoms correspond very closely to those reported for the chloride analogue [74]. The Co–Br bonds agree well with values reported in the literature for other tetrahedrally coordinated Co^{II} bromides.

Compound **7** forms under similar operating conditions that led to the isolation of **3** by using the reagent BEP. Both products are coordination compounds of Co^{II}. However, whereas compound **3** may be obtained by direct interaction of $[Co(acac)_2]$ and the solvent, without the intervention of the halide reagent, the incorporation of bromine atoms in compound **7** requires the intervention of

Refs. [17,18].

the BEA reagent, therefore giving indirect evidence of the production of $CH_3(CH_3COO)CH$ radicals. Recall that no disproportionation occurs for [Cu(Me$_6$TREN)Br] when this is kept at low temperatures. The formation of compound **7** may be envisaged as follows. Bromine atom transfer to [CuBr(Me$_6$TREN)] affords $[Cu(Me_6TREN)Br]^+Br^-$ and $CH_3(CH_3COO)CH$. Ligand exchange between $[Co(acac)_2]$ and the bromide ion generates "Co(acac)Br", which may dimerize and undergo ligand redistribution, to yield **7** with the help of further coordination of two THF molecules. According to our previous findings [17,18], the $CH_3(CH_3COO)CH$ radicals should be efficiently trapped by $[Co(acac)_2]$. However, our best efforts to identify an organometallic species by ^{1}H NMR in the mother solution of the crystals have not met with success. We cannot exclude that such a species is formed, but we do not have any evidence to support this possibility at the moment.

3. Conclusion

$[Co(acac)_2]$ has so far resisted the synthesis of a simple alkyl derivative, $[RCo^{III}(acac)_2]$ or $[RCo^{III}(acac)_2(L)]$. All attempts made in our laboratory and reported herein have resulted in side reactions that reveal the limitations of this synthetic strategy and the challenge of this synthetic target: the R–Co^{III} is weak for the unreactive radicals, namely those that can be generated most easily; R–X precursors with reactive radicals engage more readily in other reaction pathways (nucleophilic halide displacement by neutral ligands) whereas the simple one-electron oxidative addition is thermodynamically unfavorable. However, we still believe that it may be possible, given an appropriate method of rapidly generating a large amount of reactive radicals under very mild conditions, to synthesize a sufficiently stable organylcobalt(III) complex supported by two acetylacetonate groups, which would represent a model for the chain end in the dormant form of PVAc grown by $[Co(acac)_2]$-mediated CRP.

4. Experimental

4.1. General

All manipulations were carried out under strict oxygen-free and dry argon atmosphere. Reaction vessels were flame-dried under vacuum before use and standard Schlenk techniques were used to carry out all reactions. Toluene and THF were purified by distillation under argon after drying over sodium/benzophenone ketyl. *n*-Pentane and CH_2Cl_2 were dried respectively over $LiAlH_4$ and P_4O_{10} and then freshly distilled under argon prior to use. MeI, ethyl-2-bromoproprionate (EBP), 1-bromoethylbenzene (BEB), and 1-chloroethylbenzene (CEB) were dried over molecular sieve and distilled under reduced pressure before use. Me$_6$TREN [75] and 1-bromoethylacetate (BEA) [76,77] were synthesized according to the literature methods. $[Co(acac)_2]$ was purchased from Alfa Aesar and sublimed under reduced pressure and filled into glass ampoules under argon atmosphere. CuBr (99.9%) was purchased from Alfa Aesar. All other reagents used were of commercially available reagent-grade quality and were used without further purification.

4.2. Syntheses

4.2.1. Formation of compound $\{[Cu(bipy)_2Br]^+\}_2\{[Cu_2Br_4]^{2-}\}$ (**1**)

A Schlenk tube equipped with a magnetic stirrer was charged with 2 mL of freshly distilled methanol, 0.043 g 2,2′-bipyridine (0.272 mmol), and 35 μL BEB (0.262 mmol). CuBr (0.019 g; 0.13 mmol) was added subsequently at room temperature, leading to an immediate color change to intense brown–red. Stirring overnight yielded a red precipitate, which was isolated and dissolved in acetone. Single-crystals of **1** were produced upon storing the solution at 4 °C for 2 days.

4.2.2. Formation of [Cu(Me$_6$TREN)Br]Br

CuBr (0.05 g, 0.35 mmol) was placed into a Schlenk tube equipped with a magnetic stirrer and 3 mL of freshly distilled toluene was added. Three freeze–pump–thaw cycles guaranteed an oxygen-free atmosphere. One hundred and twenty-four microliters Me$_6$TREN (0.52 mmol) were added at room temperature and the mixture was stirred until a colorless solution was obtained. The solution was then cooled to −90 °C using acetone and liquid nitrogen. Subsequently, BEB (71 μL, 0.052 mmol) was added and the solution was stirred for another 30 min. In a separate Schlenk tube $[Co(acac)_2]$ (0.09 g, 0.35 mmol) was dissolved in 2 mL of THF and the solution was cooled to −90 °C. Three freeze–pump–thaw procedures guaranteed an oxygen-free atmosphere. While cooling down, the violet $[Co(acac)_2]$ solution became red. Then, the $[Co(acac)_2]$ solution was added to the other solution at −90 °C using a cannula and the reaction was stirred for another 2 h and then placed in a −20 °C freezer. Crystallization took place in 3 days. The crystalline green solid was redissolved in CH_2Cl_2 and crystallized placing the solution again into the freezer (−20 °C). Suitable light green single-crystals were obtained, which were identified as the already reported [48] [Cu(Me$_6$TREN)Br]Br by comparison of the unit cell parameters.

4.2.3. Formation of compound [Cu(Me$_6$TREN) $Br_{0.37}Cl_{0.63}$]Br (**2**)

CuBr (0.134 g, 0.93 mmol) was placed into a Schlenk tube equipped with a magnetic stirrer and 3 mL of freshly distilled

THF was added. Three freeze–pump–thaw cycles guaranteed an oxygen-free atmosphere. Me_6TREN (220 μL, 0.93 mmol) was added at room temperature and the mixture was stirred until a colorless solution was obtained. The solution was then cooled down to −90 °C using acetone and liquid nitrogen. Subsequently, CEB (97 μL, 0.93 mmol) was added and the solution was stirred for another 30 min. In a separate Schlenk tube $[Co(acac)_2]$ (0.09 g, 0.35 mmol) was dissolved in 2 mL of THF and the solution was cooled to −90 °C. Three freeze–pump–thaw procedures guaranteed an oxygen-free atmosphere. While cooling down, the violet $[Co(acac)_2]$ solution became red. Then, the $[Co(acac)_2]$ solution was slowly added to the other solution at −90 °C using a cannula and the reaction was stirred for another 7 h. Crystallization took place after addition of 0.5 mL *n*-pentane and yielded tetrahedral shaped dark green single-crystals of **2**.

4.2.4. Reaction of CuBr, Me_6TREN, $[Co(acac)_2]$ and EBP. Formation of compound $[Co(acac)_3]$

$[\{Me_6TREN\}CuBr]$ was prepared freshly at −90 °C in THF by addition of Me_6TREN (139 μL, 0.6 mmol) to a mixture of CuBr (0.086 g, 0.6 mmol) in 3 mL THF. Addition of equimolar amounts of $[Co(acac)_2]$ (0.152 g), EBP (0.072 mL) and acetonitrile (0.060 mL) took place subsequently. After addition of $[Co(acac)_2]$ the solution turned red and after addition of EBP no change of color was observed. The solution was warmed up slowly to room temperature, leading to a green solution. This was evaporated to dryness and the residue was redissolved in acetone. The solution was placed into the fridge at 4 °C and dark green crystals were obtained after 2 weeks. X-ray diffraction experiments identified this compound as $[Co(acac)_3]$ by comparison of the unit cell parameters with those already available in the literature [78,79].

*4.2.5. Formation of compound $[Co(acac)_2(THF)_2]$ (**3**)*

$[\{Me_6TREN\}CuBr]$ was prepared freshly at −90 °C in THF by addition of Me_6TREN (90 μL, 0.35 mmol) to a mixture of CuBr (0.050 g, 0.35 mmol) in 3 mL THF. In a separate Schlenk tube $[Co(acac)_2]$ (0.100 g, 0.39 mmol) was dissolved in 3 mL of THF and EBP (0.038 mL, 0.35 mmol) was added dropwise to the pink solution. The two solutions were combined at −80 °C using a cannula. The resulting intense red solution was kept stirring for 3 h and than stored at −80 °C. After 1 week a blue solution had formed and red crystals of **3** had formed at the bottom of the Schlenk tube.

*4.2.6. Formation of compound $[\{Me_6TREN\}CoBr]Br$ (**4**)*

CuBr (0.066 g, 0.46 mmol) was placed in a Schlenk tube equipped with a magnetic stirrer and 2 mL of freshly distilled THF was added. Three freeze–pump–thaw cycles guaranteed an oxygen-free atmosphere. Me_6TREN (107 μL, 0.46 mmol) was added at room temperature and the mixture was stirred until a colorless solution was obtained. The solution was then cooled down to −90 °C. Subsequently, methyl iodide (62 μL, 0.46 mmol) and immediately afterwards $[Co(acac)_2]$ (0.118 g, 0.46 mmol) were added to the solution. Warming up the reaction mixture to room temperature led to a brown solution over a large amount of amorphous white precipitate. The solid was separated and washed with a mixture of toluene/acetone. All toluene/acetone fractions were united and left standing on a vibration-free place. After 1 week both a white precipitate and violet crystals had formed at the bottom of the Schlenk tube. The crystals were separated and redissolved in CH_2Cl_2. Cooling the solution to 4 °C yielded tetrahedral shaped violet crystals of compound **4**.

*4.2.7. Formation of compound $[\{Me_7TREN\}CuI]_2[Cu_{1.80}Br_{1.13}I_{2.67}]$ (**5**)*

CuBr (0.1 g, 0.70 mmol) was placed into a Schlenk tube equipped with a magnetic stirrer and 3 mL of freshly distilled THF was added. Three freeze–pump–thaw cycles guaranteed an oxygen-free atmosphere. Me_6TREN (165 μL, 0.70 mmol) was added at room temperature and the mixture was stirred until a colorless solution was obtained. The solution was then cooled to −90 °C. Subsequently, methyl iodide (100 μL, 1.2 mmol) and immediately afterwards $[Co(acac)_2]$ (0.02 g, 0.08 mmol) were added to the solution. Warming up the reaction mixture to −40 °C led to a green solution over a colorless precipitate. The solution was separated from the solid and evaporated to dryness under reduced pressure. The solid was dissolved in dry acetone, yielding a green solution. Addition of *n*-pentane and crystallization at −80 °C with pentane layered on top of the CH_2Cl_2 solution yielded almost colorless (slightly greenish) air and moisture sensitive crystals of compound **5** at the bottom of the Schlenk tube.

*4.2.8. Formation of compound $[C_5H_5NMe]_2[CoI_4]$ (**6**)*

CuBr (0.021 g, 0.15 mmol) was placed in a Schlenk tube equipped with a magnetic stirrer and 3 mL of freshly distilled THF was added. Three freeze–pump–thaw cycles guaranteed an oxygen-free atmosphere. Me_6TREN (35 μL, 0.15 mmol) was added at room temperature and the mixture was stirred until a colorless solution was obtained. The solution was then cooled to -90 °C. $[Co(acac)_2]$ (0.080 g, 0.31 mmol) was added and dissolved, followed by methyl iodide (39 μL, 0.62 mmol) and pyridine (25 μL, 0.31 mmol). Storing the resulting red solution at −80 °C for 1 week yielded green plate-like crystals of compound **6**.

*4.2.9. Formation of compound $[Co(acac)_2(THF)_2CoBr_2]$ (**7**)*

$[\{Me_6TREN\}CuBr]$ was prepared freshly at −90 °C in THF by addition of Me_6TREN (135 μL, 0.58 mmol) to a mixture of CuBr (0.080 g, 0.56 mmol) in 3 mL THF. In a separate Schlenk tube $[Co(acac)_2]$ (0.150 g, 0.58 mmol) was dissolved in 2 mL of THF. Equimolar amounts of BEA (0.072 mL) and acetonitrile (0.060 mL) were subsequently added. The two solutions were combined at −80 °C using a cannula. The resulting brown–red solution was stirred for 3 h and than stored at −80 °C. After 5 weeks, blue crystals of compound **7** had formed on the bottom of the Schlenk tube.

4.2.10. X-ray structural studies

A single-crystal of each compound was mounted under inert perfluoropolyether on the tip of a cactus spike and cooled immediately in the cryostream of an Oxford-Diffraction XCALIBUR CCD diffractometer. The structures were solved by direct methods (SHELXS-97 [80]) and refined by least-square procedures on F^2 using SHELXL-97 [81]. All H atoms attached to carbon atoms were introduced in ideal positions and treated as riding models. Absolute structures were confirmed by the refinement of Flack's enantiopole parameter [82] and by careful examination of the sensitive reflections. Crystal data and refinement parameters are shown in Table 8.

5. Supplementary data

CCDC 674118, 674119, 674120, 674121, 674122, 674123 and 674124 contain the supplementary crystallographic data for **1**, **2**, **3**, **4**, **5**, **6** and **7**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Extraction

ABSTRACT

A soluble metal-free phthalocyanine **5** and its metal complexes (Zn, Ni, Co and Cu) **6**, **7**, **8** and **9** containing eight 16-membered tetrathiamonoaza macrocycles on peripheral substituent positions have been synthesized. The metal-free phthalocyanine **5** was synthesized from 4,5-*bis*{[2-(1,4,10,13-tetrathia-7-azacyclohexadecan-7-yl)ethyl]oxy}phthalonitrile **4**. The metal complexes **6**, **7** and **8** were prepared by a tetramerization reaction of the phthalonitrile derivative **4** with appropriate materials. Copper(II) phthalocyanine **9** was prepared by the reaction of 4,5-*bis*{[2-(1,4,10,13-tetrathia-7-azacyclohexadecan-7-yl)ethyl]oxy}-1,2-dibromobenzene **3** with excess CuCN and dry quinoline. Liquid–liquid extraction of several heavy metal ions such as Ag^+, Hg^{2+}, Pb^{2+}, Cd^{2+}, Cu^{2+} and Zn^{2+} with compound **5** was also tested using picrate as the anion of the ion pair. The extraction avidity of **5** for Ag^+ was found to be highest in the liquid–liquid phase extraction experiments. The new compounds were characterized by a combination of elemental analysis, UV–Vis, FT-IR, NMR and mass spectral data.

1. Introduction

Supramolecular materials can be designed and created from simple molecular building blocks by self-assembly and self-organization using non-covalent interactions [1]. Phthalocyanines [2] have been employed extensively as subunits for the construction of functional materials since they exhibit special optical and electronic properties and self-organizing abilities to form columnar mesophases, Langmuir–Blodgett (LB) multilayers and aggregates in solution, or in the solid state [3]. The main forces that drive these self-assembly processes are the π–π stacking interactions between the aromatic rings. The introduction of either or both long aliphatic hydrocarbon chains or/and macrocyclic substituents at the periphery of the rigid phthalocyanine core can improve the organization properties of these molecules by exploiting either their mesogenic behavior [4] or the ability of their macrocyclic subunits to form complexes with different ions [5,6]. By contrast, hydrogen-bonding interactions have hardly been employed at all to self-assemble phthalocyanine molecules [7].

The solubility and ion-binding ability of phthalocyanines containing homo- and hetero-crowns are receiving considerable attention in view of their effect on the aggregation of the molecules [5,6]. It has been demonstrated that phthalocyanines substituted with four 15-crown–5 analogs are capable forming ion channels that allow the migration of alkali or alkaline earth ions [8]. Phthalocyanines with long alkyl or alkoxy groups as well as with crown ethers are also reported to form a new type of liquid crystals, namely the discotic mesophase [9].

Alkyl substitution increases the solubility of phthalocyanines, and the effect of bulky substituents is shown to be higher than that of smaller ones, e.g. methyl [10]. Substitution of a phthalocyanine with eight ethoxy hetero-crown moieties, therefore, is expected to enhance the solubility and improve the intermolecular stacking. In this work we report the synthesis and properties of new heterocrowns and their phthalocyanines with eight ethoxy-tetrathiamonoaza macrocycles. In addition, the extraction capability of assorted heavy metal ions with the metal-free phthalocyanine **5** is tested.

2. Experimental

2.1. Materials

Starting reagents were either purchased from Aldrich or, unless noted otherwise, prepared in the manner described in previous papers. We prepared 1,7,10,14-tetrathia-4-azacyclohexadecane (**2**) [11] and 1,2-bis(2-iodoethoxy)-4,5-dibromobenzene (**1**) [12] using literature procedures. All reactions were performed under an argon atmosphere using standard Schlenk techniques. Pentan-1-ol was distilled from sodium. All other reagents and solvents were of

doi:10.1016/j.poly.2008.03.017

reagent grade quality from commercial suppliers and were dried before use as described in the literature [13]. Silica gel (70–230 mesh) and Merck 90 active neutral alumina were used in the separation and purification of compounds by column chromatography with the indicated eluents.

2.2. Measurements

Melting points were determined with an electrothermal apparatus and were uncorrected. Routine ^{1}H, ^{13}C NMR and IR spectra were recorded on a Varian XL-200 spectrometer and a Perkin–Elmer Spectrum One spectrometer with the samples in KBr pellets, respectively. UV–Vis spectra were recorded on a model Shimadzu 1601 UV–Vis spectrometer using cells of 10 mm pathlength at room temperature. Mass spectra were measured on Micromass Quatro LC/ULTIMA LC–MS/MS spectrometers. The elemental analyses of the compounds were determined on a CHNS-932 LECO instrument. The metal contents of the metallophthalocyanine were determined with a Unicam 929 AA spectrophotometer in solutions prepared by decomposition of the metallophthalocyanines in conc. sulfuric acid and conc. nitric acid solution followed by digestion in conc. hydrochloric acid solution and deionized water.

2.3. Synthesis

2.3.1. Synthesis of 4,5-bis{[2-(1,4,10,13-tetrathia-7-azacyclohexadecan-7-yl)ethyl]oxy}-1,2-dibromobenzene (**3**)

Compound **2** (5.96 g, 20 mmol) was dissolved in 300 mL of dry acetonitrile containing anhydrous Cs_2CO_3 (9.78 g, 30 mmol) and anhydrous NaI (0.45 g, 3 mmol), and purged under an argon atmosphere in a 1000 mL three necked round-bottomed flask. Initially the mixture was stirred at 50 °C for 1 h and afterwards a solution of **1** (7.2 g, 12.5 mmol, 25% excess) in 100 mL of dry acetonitrile was added dropwise over a period of 3 h, at the same temperature. The reaction mixture was refluxed at 100 °C under argon for 6 days and monitored by TLC using [chloroform:petroleum ether:methanol (6:3:1)]. The reaction mixture was cooled to room temperature, filtered and the solvent was removed by evaporation. The residue was dissolved in 150 mL of dichloromethane and extracted with (2×10 mL) water. The combined organic extract was dried over $MgSO_4$ and then filtered and evaporated to dryness. The crude product was purified by column chromatography on silica gel [chloroform:petroleum ether:methanol (6:3:1)] to give the dibromo derivative **3**. Yield: 6.3 g (69%), m.p. = 238–240 °C. *Anal.* Calc. for $C_{32}H_{54}Br_2N_2O_2S_8$ (915.08): C, 42.00; H, 5.95; N, 3.06; S, 28.03. Found: C, 41.68; H, 6.61; N, 2.81; S, 28.26%. IR (KBr): υ_{max} (cm^{-1}) = 3056 (C–H aromatic), 2977–2870 (CH_2), 1592–1581 (aromatic C=C), 1498 (C–H), 1234 (Ar–O–C), 645 (C–Br). ^{1}H NMR (ppm, $CDCl_3$): δ = 6.84 (s, 2H, ArH), 4.14 (t, 4H, $ArOCH_2$), 3.06–2.92 (m, 12H, NCH_2), 2.85–2.74 (m, 32H, CH_2SCH_2), 2.07–1.93 (m, 4H, CH_2–C*H*$_2$–CH_2). ^{13}C NMR (ppm, $CDCl_3$): δ = 148.3 (ArCO), 120.1 (ArCH), 114.2 (ArC–Br), 71.2 ($ArOCH_2$), 54.3 (CH_2NCH_2), 50.2 (NCH_2CH_2O–Ar), 33.1–32.9 (–N–CH_2–*C*H$_2$–S–*C*H$_2$–), 31.5–31.1 (–S–CH_2–*C*H$_2$–S–*C*H$_2$–), 29.4 (CH_2–*C*H$_2$–CH_2). MS (ES positive) *m*/*z*: 915.1 $[M]^+$.

2.3.2. Synthesis of 4,5-bis{[2-(1,4,10,13-tetrathia-7-azacyclohexadecan-7-yl)ethyl]oxy}phthalonitrile (**4**)

Compound **3** (7.00 g, 7.65 mmol), CuCN (2.05 g, 23 mmol), 30 mL of dry DMF and three drops of pyridine were placed in a Schlenk tube under argon and gently heated, then subsequently heated to 165 °C. The reaction was monitored by TLC using chloroform: petroleum ether (7:3). The reaction mixture was kept at this temperature for 24 h, after which the solution was cooled to room temperature. After adding 200 mL of NH_3 (25%) into the reaction mixture, oxygen gas was passed through the solution for 48 h. Then it was washed with water until the filtrate was neutral, and dried *in vacuo*. The crude product was placed in a Soxhlet extractor and extracted with chloroform for 3 days. The extract was evaporated to dryness under reduced pressure and dissolved in 25 mL of dry methanol and then placed inside the refrigerator at −18 °C for several hours. Light brown crystals were filtered off and dried *in vacuo*. Yield: 2.72 g (44%), m.p. = 226–227 °C. *Anal.* Calc. $C_{34}H_{54}N_4O_2S_8$ (807.31): C, 50.58; H, 6.74; N, 6.94; S, 31.77; Found: C, 50.93; H, 6.41; N, 7.23; S, 31.60%. IR (KBr): υ_{max} (cm^{-1}) = 3049 (C–H aromatic), 2920–2849 (CH_2), 2234 (C≡N), 1596–1506 (aromatic C=C), 1255 (Ar–O–C), 1100, 960, 750, 685. ^{1}H NMR (ppm, $CDCl_3$): δ = 7.78 (s, 2H, ArH), 4.25 (t, 4H, $ArOCH_2$), 3.14–2.87 (m, 12H, NCH_2), 2.82–2.78 (m, 32H, CH_2SCH_2), 2.10–1.96 (m, 4H, CH_2–C*H*$_2$–CH_2). ^{13}C NMR (ppm, $CDCl_3$): δ = 151.8 (ArCO), 118.4 (ArCH), 114.9 (C≡N), 109.6 (ArC), 71.9 ($ArOCH_2$), 53.6 (CH_2NCH_2), 51.4 (NCH_2CH_2O–Ar), 32.7–32.4 (–N–CH_2–*C*H$_2$–S–*C*H$_2$–), 31.3–30.9 (–S–CH_2–*C*H$_2$–S–*C*H$_2$–), 28.7 (CH_2–*C*H$_2$–CH_2). MS (ES positive) *m*/*z*: 807.4 $[M]^+$.

2.3.3. Synthesis of the metal-free phthalocyanine (**5**)

Compound **4** (1.91 g, 2.37 mmol), 2.5 mL of dry pentan-1-ol and 3–5 drops of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) were placed in a Schlenk tube under an argon atmosphere. The reaction mixture was heated gently to 90 °C for 1 h and then it was heated and stirred at 150 °C for 24 h. After cooling to room temperature, 10 mL of methanol/diethyl ether (1:1, v/v) was added and stirred for 45 min. The dark green metal-free phthalocyanine derivative was filtered off, washed with diethyl ether and dried *in vacuo*. Yield: 0.936 g (49%), m.p. > 300 °C. *Anal.* Calc. $C_{136}H_{218}N_{16}O_8S_{32}$ (3231.25): C, 50.55; H, 6.80; N, 6.94; S, 31.75. Found: C, 50.87; H, 6.47; N, 6.65; S, 31.98%. IR (KBr): υ_{max} (cm^{-1}) = 3394 (N–H), 3066 (Ar–H), 2917–2849 (CH_2), 1634 (C=N), 1595–1569 (C=C), 1268, 1250 (Ar–O), 1030 (N–H), 960, 853, 757, 687. ^{1}H NMR (ppm, DMSO-d_6): δ = 8.17 (s, 8H, ArH), 4.10 (t, 16H, $ArOCH_2$), 3.02–2.93 (m, 48H, NCH_2), 2.90–2.69 (m, 128H, CH_2SCH_2), 1.98–1.67 (m, 16H, CH_2–C*H*$_2$–CH_2), −3.96 (br, 2H, N–H). ^{13}C NMR (ppm, DMSO-d_6): δ = 152.4 (C=N), 150.3 (ArCO), 119.1 (ArCH), 106.8 (ArC), 70.3 ($ArOCH_2$), 52.3 (CH_2NCH_2), 50.8 (NCH_2CH_2O–Ar), 32.3–31.9 (–N–CH_2–*C*H$_2$–S–*C*H$_2$–), 30.7–30.4 (–S–CH_2–*C*H$_2$–S–*C*H$_2$–), 28.2 (CH_2–*C*H$_2$–CH_2). UV/Vis ($CHCl_3$) λ_{max} ($\log\varepsilon$) = 712 (4.82), 672 (4.70), 649 (4.45), 611 (3.78), 369 (4.63), 332 (4.75). MS (ES positive) *m*/*z*: 3231.4 $[M]^+$.

2.3.4. Synthesis of phthalocyaninato zinc(II) (**6**)

Compound **4** (0.81 g, 1 mmol), $Zn(OAc)_2 \cdot 2H_2O$ (55 mg, 0.25 mmol) and 1.5 mL of dry quinoline were placed into a well-stoppered Schlenk tube under an argon atmosphere. The reaction mixture was heated at 210 °C for 8 h. After cooling to room temperature, the dark green reaction mixture was diluted and the product was precipitated by adding 10 mL of ethanol. The resulting green precipitate was filtered off, washed with EtOH, H_2O and diethyl ether separately and dried *in vacuo*. Yield: 0.512 g (62%), m.p. > 300 °C. *Anal.* Calc. $C_{136}H_{216}N_{16}O_8S_{32}Zn$ (3294.61): C, 49.58; H, 6.61; N, 6.80; S, 31.15; Zn, 1.98. Found C, 49.89; H, 6.33; N, 6.51; S, 31.77; Zn, 1.72%. IR (KBr): υ_{max} (cm^{-1}) = 3032 (Ar–H), 2925–2857 (CH_2), 1618 (C=N), 1596–1555 (C=C), 1445 (C–H), 1380, 1224–1201 (Ar–O–C), 1121, 1048–1017 (CH_2–O), 946, 658. ^{1}H NMR (ppm, DMSO-d_6): δ = 7.97 (s, 8H, ArH), 4.16 (t, 16H, Ar-OCH_2), 3.15–2.89 (m, 48H, NCH_2), 2.86–2.68 (m, 128H, CH_2SCH_2), 2.06–1.73 (m, 16H, $CH_2CH_2CH_2$). UV/Vis (pyridine) λ_{max} ($\log\varepsilon$) = 694 (4.66), 652 (4.28), 624 (4.03), 366 (4.57), 325 (4.67), 292 (4.75). MS (ES positive) *m*/*z*: 3295.8 $[M+1]^+$.

2.3.5. Synthesis of phthalocyaninato nickel(II) (**7**)

A mixture of compound **4** (0.81 g, 1 mmol), $Ni(OAc)_2 \cdot 4H_2O$ (75 mg, 0.30 mmol) and DBU (152 mg, 1 mmol) was refluxed under

an argon atmosphere in pentan-1-ol (20 mL) for 24 h. The cooled suspension was poured into MeOH (60 mL) and the precipitate was centrifuged, washed with EtOAc, EtOH, H_2O and diethyl ether, and dried *in vacuo*. Further purification was carried out using column chromatography, silica gel, $CHCl_3$/MeOH, (9:1 v/v). Yield: 0.60 g (73%), m.p. > 300 °C. *Anal.* Calc. for $C_{136}H_{216}N_{16}O_8S_{32}Ni$ (3282.74): C, 49.68; H, 6.62; N, 6.82; S, 31.20; Ni, 1.79. Found: C, 49.87; H, 6.45; N, 6.58; S, 31.49; Ni, 1.93%. IR (KBr): υ_{max} (cm^{-1}) = 3045 (Ar–H), 2960–2870 (CH_2), 1624 (C=N), 1598–1560 (C=C), 1450 (C–H), 1374, 1220–1205 (Ar–O–C), 1100–1030 (CH_2–O), 958, 662. ^1H NMR (ppm, DMSO-d_6): δ = 7.93 (s, 8H, ArH), 4.10 (t, 16H, $ArOCH_2$), 3.20–2.93 (m, 48H, NCH_2), 2.82–2.64 (m, 128H, CH_2SCH_2), 2.03–1.78 (m, 16 H, $CH_2CH_2CH_2$). UV/Vis (pyridine) λ_{max} ($\log\varepsilon$)=695 (4.77), 640 (4.02), 606 (3.88), 369 (4.41), 322 (4.84). MS (ES positive) *m*/*z*: 3284.1 $[M+1]^+$.

2.3.6. Synthesis of phthalocyaninato cobalt(II) (**8**)

A mixture of compound **4** (0.81 g, 1 mmol), urea (105.6 mg, 1.76 mmol), $Co(OAc)_2 \cdot 4H_2O$ (75 mg, 0.30 mmol), a catalytic amount of $(NH_4)_2MoO_4$ (40 mg) and quinoline (2 mL) was kept at 200–210 °C under an argon atmosphere for 6 h. The cooled mixture was poured into CH_3CN (40 mL) and the precipitate was filtered off after 1 h of stirring. The crude product was washed sequentially with EtOAc, EtOH, H_2O and acetone, and dried *in vacuo*. The cobalt(II) phthalocyanine was purified by column chromatography, neutral alumina, $CHCl_3$/MeOH, (100:1 v/v). Yield: 0.39 g (47%), m.p. > 300 °C. *Anal.* Calc. for $C_{136}H_{216}N_{16}O_8S_{32}Co$ (3288.17): C, 49.68; H, 6.62; N, 6.82; S, 31.20; Co, 1.79. Found: C, 49.46; H, 6.79; N, 7.07; S, 31.46; Co, 1.58%. IR (KBr): υ_{max} (cm^{-1}) = 3050 (Ar–H), 2975–2889 (CH_2), 1625 (C=N), 1600–1575 (C=C), 1440 (C–H), 1365, 1234–1228 (Ar–O–C), 1120–1025 (CH_2–O), 950, 656. ^1H NMR (ppm, DMSO-d_6): δ = 7.96 (s, 8H, ArH), 4.12 (t, 16H, $ArOCH_2$), 3.15–2.90 (m, 48H, NCH_2), 2.87–2.69 (m, 128H, CH_2SCH_2), 2.09–1.82 (m, 16 H, $CH_2CH_2CH_2$). UV/Vis (pyridine) λ_{max} ($\log\varepsilon$) = 692 (4.66), 645 (3.93), 607 (3.86), 372 (4.62), 313 (4.80). MS (ES positive) *m*/*z*: 3289.1 $[M+1]^+$, 3288.2 $[M]^+$.

2.3.7. Synthesis of phthalocyaninato copper(II) (**9**)

A mixture of **3** (0.915 g, 1 mmol), CuCN (0.269 g, 3 mmol) and dry quinoline (2.5 mL) was heated under argon at 215 °C for 24 h. At the end of this period, the mixture was cooled to room temperature and 30 mL of ethanol was added to this mixture, and filtered, washed with ethanol and diethyl ether to remove any unreacted organic residue. The crude product was heated and stirred with a solution of 0.5 M NaCN in a mixture of 75 mL of water:ethanol (1:3) for 3 h and filtered off, then washed with hot water, ethanol and diethyl ether. The dark green solid was chromatographed on neutral alumina using chloroform:methanol (100:1) as the eluent. The extract was evaporated to dryness and dried *in vacuo*. Yield: 0.272 g (33%), m.p. > 300 °C. *Anal.* Calc. $C_{136}H_{216}N_{16}O_8S_{32}Cu$ (3292.78): C, 49.61; H, 6.61; N, 6.81; S, 31.16; Cu, 1.93. Found: C, 49.28; H, 6.35; N, 7.08; S, 31.70; Cu, 1.69%. IR (KBr): υ_{max} (cm^{-1}) = 3043 (Ar–H), 2923–2850 (CH_2), 1620 (C=N), 1590–1502 (C=C), 1425 (C–H), 1357, 1293 (Ar–O–C), 1122 (C–O–C), 960, 645. UV/Vis (pyridine) λ_{max} ($\log\varepsilon$) = 687 (4.73), 642 (4.06), 611 (3.93), 364 (4.59), 315 (4.75). MS (ES positive) *m*/*z*: 3293.9 $[M+1]^+$.

2.3.8. Measurement of the heavy metal-binding properties of (5)

The extraction properties of **5** were investigated under liquid–liquid phase and neutral conditions using heavy metal picrates (Ag^+, Hg^{2+}, Pb^{2+}, Cd^{2+}, Cu^{2+}, Zn^{2+}) as substrates and measuring by UV–Vis spectra the amounts of metal picrate in the aqueous phase before and after treatment with compound **5**. The heavy metal picrates were prepared from a mixture of the metal nitrates and picric acid in deionized water. We also prepared 2×10^{-3} M solutions of compound **5** in chloroform. Then equal volumes of both the metal picrate solutions and compound solution were added into plastic bottles, closed and then mechanically shaken for 5 h by a shaker at 25 ± 1 °C. Finally we took the aqueous phase and measured the absorbance at the maximum wavelength of each metal picrate solution. For each combination of host and metal picrate, the picrate extraction was conducted on three different samples and the average value of percent picrate extracted, with a standard deviation, was calculated. The picrate extraction results are presented in Table 1. In the absence of host, a blank experiment, no metal ion picrate extraction was detected. The extractability was determined based on the absorbance of the picrate ion in the aqueous solutions. The extractability was calculated by using the equation below:

$$E(\%) = [(A_{before} - A_{after})/A_{before}] \times 100$$

where A_{before} is the absorbance in the absence of ligand and A_{after} denotes the absorbance in the aqueous solution phase after extraction.

Table 1
Heavy metal picrate extractions from aqueous solutions into chloroform by using **5**[a]

Metal ion	Extractability of the metal-free phthalocyanine **5** (%)[b]	λ_{max} (nm) of metal picrate
Ag^+	93.2 ± 0.1	354
Hg^{2+}	64.7 ± 0.1	358
Pb^{2+}	48.4 ± 0.1	360
Cd^{2+}	70.5 ± 0.1	362
Cu^{2+}	43.6 ± 0.1	352
Zn^{2+}	37.3 ± 0.1	347

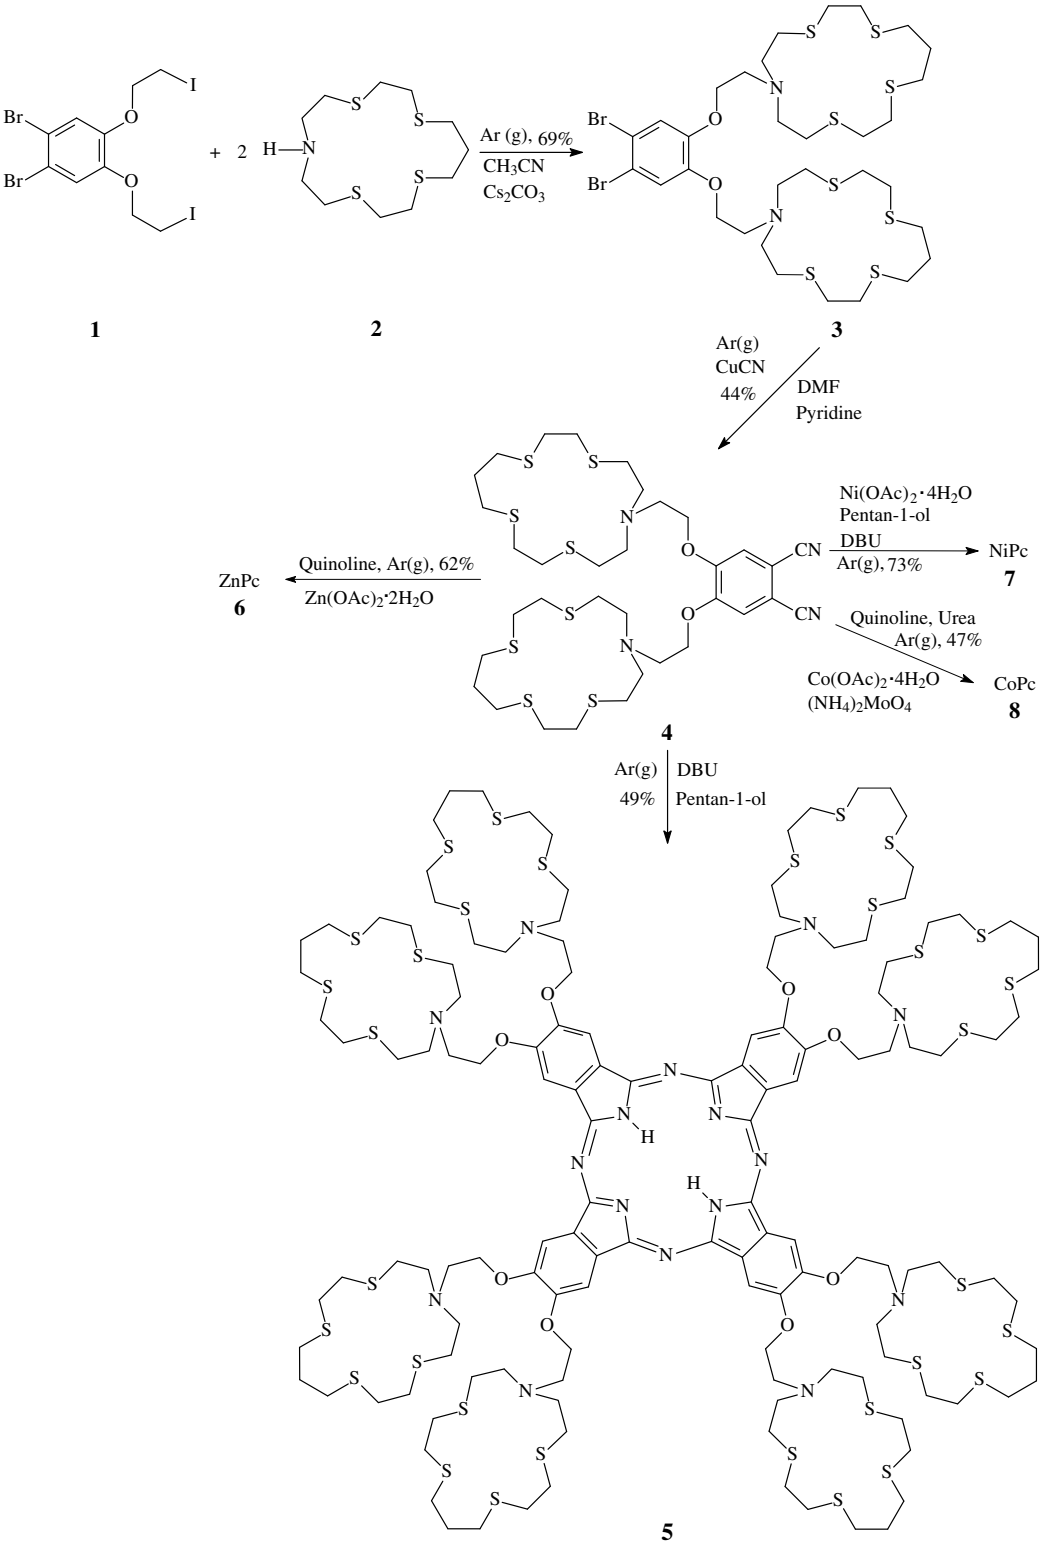
[a] Temperature 25 ± 1 °C; aqueous phase (10 mL), [picrate] = 2.0×10^{-3} M; organic phase (chloroform, 10 mL), [extractant] = 2.0×10^{-3} M.
[b] Average and standard deviation for three independent measurements.

3. Result and discussion

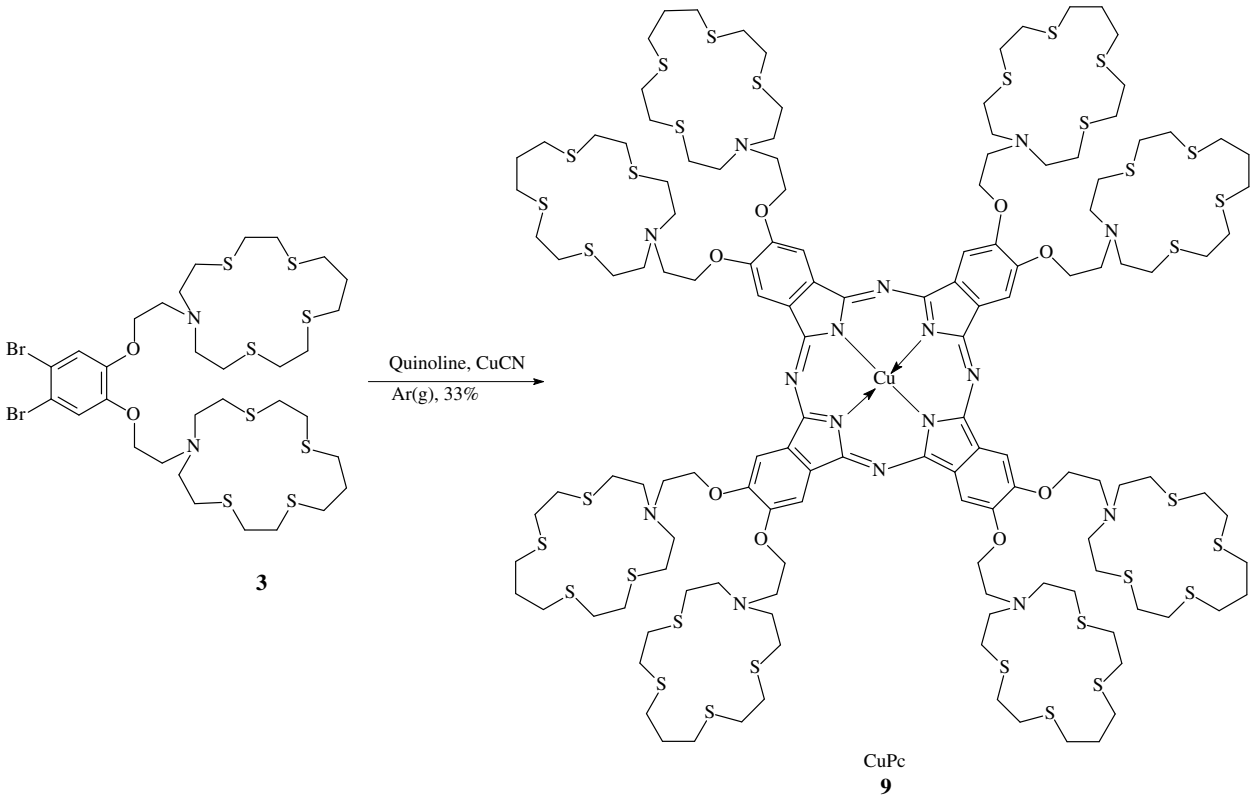
The synthetic routes to **3**–**9** are exhibited in Schemes 1 and 2. We report here the synthesis and structural properties of a series of novel metal-free and metallophthalocyanines. The dibromo derivative **3** was obtained by a substitution reaction of compound **2** and 1,2-bis(2-iodoethoxy)-4,5-dibromobenzene **1** in the presence of anhydrous Cs_2CO_3 and anhydrous NaI in dry acetonitrile at reflux temperature for 6 days under argon. The crude product was purified by column chromatography on silica gel, chloroform:petroleum ether:methanol (6:3:1) to give **3** in 69% yield. In the ^1H NMR spectrum of **3**, the signals corresponding to the N–H protons in the precursor compound **2** disappeared after the macrocyclization reaction. The resonance peaks are in good agreement with the proposed structure in the ^1H NMR spectrum of **3**, being at δ = 4.14, 3.06–2.92 and 2.85–2.74 ppm corresponding to Ar–O–CH_2, N–CH_2 and CH_2–S–CH_2 groups respectively. In the ^{13}C NMR spectrum, the existence of new carbon resonances at δ = 148.3, 120.1 and 114.2 ppm are also in good accord with the proposed structure. Further, the infrared data of **3** give sufficient support for the desired product formation. In the IR spectrum of compound **3**, the presence of characteristic vibrations belonging to (=CH aromatic ring), (aliphatic CH_2) and (C–Br) were observed at 3056, 2977–2870 and 645 cm^{-1}, respectively. The LC/ES mass spectrum of **3**, which shows a molecular ion peak at *m*/*z* = 915.1 $[M]^+$, confirms the proposed formula.

Substitution of the bromo groups in **3** by cyanide in a Rosenmund-von Braun reaction using three equivalents of CuCN [14], affords the corresponding phthalonitrile **4** in 44% yield after purification by column chromatography on silica gel with chloroform:petroleum ether: (7:3) solvent mixture. The critical point in this route is to isolate the dicyano derivative, which was

accomplished by keeping the concentration of the reactants sufficiently low and by making use of a moderately high boiling point solvent to avoid the formation of copper phthalocyanine [15]. In the IR spectrum of **3**, the signal at 645 cm^{-1} that was for the C–Br bond vanished and a new peak arose in the IR spectrum of **4** at 2234 cm^{-1}, which was attributed to the dicyano groups. The rest of the spectrum is closely similar to that of the precursor dibromo derivative, including the characteristic vibrations of **3**. The ^1H NMR spectrum of **4** was recorded after dissolution in $CDCl_3$ at room temperature, and exhibited the expected signals indicating the integrity of **4** in that solvent. The spectrum was almost identical with that of **3**, as expected. In the proton-decoupled ^{13}C NMR spectrum of compound **4**, the presence



Scheme 1. Synthesis of metal-free and metallo (Zn, Ni, Co) phthalocyanines.



Scheme 2. Synthesis of copper phthalocyanine.

of a signal at δ = 114.9 ppm, attributable to C≡N groups, indicates that the conversion has occurred. Compound **4** displayed the expected molecular ion peak in its mass spectrum at m/z = 807.4 $[M]^+$.

The self-condensation of the dicyano compound **4** in a high-boiling solvent, such as dry pentan-1-ol, in the presence of a few drops of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) as a strong base at reflux temperature under a dry argon atmosphere afforded the metal-free phthalocyanine **5** in 49% yield as a dark green solid. A diagnostic feature of the formation of **5** from **4** is the disappearance of the sharp vibration of the dicyano groups at 2234 cm^{-1} of the reactant. The stretching vibrations at 3394 cm^{-1} for **5** can be attributed to the N–H bond of the inner core of the metal-free phthalocyanine. A ^1H NMR investigation of compound **5** provided the characteristic chemical shifts for the expected structure. The inner core protons of compound **5** could also be observed at δ = - 3.96 ppm as a broad signal. In the ^{13}C NMR spectrum of this compound, all the signals are identical to those of the precursor dicyano derivative **4** except for the dicyano carbon atoms. The peak related to C≡N groups in the ^{13}C NMR spectrum of **4** vanished in the case of the metal-free phthalocyanine **5**. Other peaks in the ^{13}C NMR spectrum resembled those of the precursor compound **4**. The molecular ion of **5** was observed at m/z = 3231.4 $[M]^+$ and was in accord with the suggested structure.

Metallophthalocyanines **6**, **7** and **8** have been prepared from the dicyano derivative **4** and the appropriate metal salts in the required solvents and catalysts under an argon atmosphere in yields of 62%, 73% and 47%, respectively. A comparison of the IR spectra obtained for **4** and **6**, **7** and **8** confirmed the conversion of the C≡N groups into the characteristic skeleton of phthalocyanine. In this case, the C≡N band at 2234 cm^{-1} of compound **4** disappeared and C=N stretching vibrations of the inner core of the metallophthalocyanines **6**, **7** and **8** appeared at 1618, 1624, 1625 cm^{-1}, respectively. In the ^{13}C NMR spectrum of compound **4**, the presence of a signal at δ = 114.9 ppm, attributable to the C≡N groups, vanished in the case of complexes **6**, **7** and **8**. The ^{13}C NMR and ^1H NMR spectra of **6**, **7** and **8** were almost identical with that of the metal-free phthalocyanine **5**. The elemental analyses and LC/ES mass spectral data of all the metallophthalocyanines (**6**–**8**) were consistent with the proposed structures. The molecular ion clusters $[M+1]^+$ for metallophthalocyanines **6**, **7** and **8**, at 3295.8, 3284.1, and 3289.1, respectively, were found by the ES/MS technique, together with some reasonable fragment ions.

Copper(II) phthalocyanine **9** has been synthesized directly from the dibromo derivative **3** and CuCN in a high boiling solvent such as quinoline. The crude product was washed several times with ethanol to remove the unreacted starting material and was subsequently treated with a solution of NaCN to separate the excess CuCN. The yield of the crude product was only moderate (33%), and the purification steps were tedious and required a final chromatography on neutral alumina using chloroform:methanol (100:1) as the eluent. A comparison of the IR spectra obtained on **3** and **9** confirmed the conversion of the bromo groups into the characteristic skeleton of phthalocyanine. In this case, the C–Br band at 645 cm^{-1} disappeared and C=N stretching vibrations at 1620 cm^{-1} appeared. The mass spectrum of **9** was measured by the LC/ES MS technique and the complex displayed a peak corresponding to $[M+1]^+$ at m/z = 3293.9. Elemental analysis data were also in good accord with the proposed formula.

The electronic absorption spectrum of the metal-free phthalocyanine **5** in chloroform at room temperature is shown in Fig. 1. It displayed a split Q-band as expected and there are two strong bands in the Soret region [16]. The split Q-band, characteristic of metal-free phthalocyanines, is observed for **5** at λ_{max} = 712 and 672 nm with a shoulder at 649 nm, indicating monomeric species; monomeric species with D_{2h} symmetry shows two intense absorptions at around 700 nm [17]. Such split Q-band absorptions in

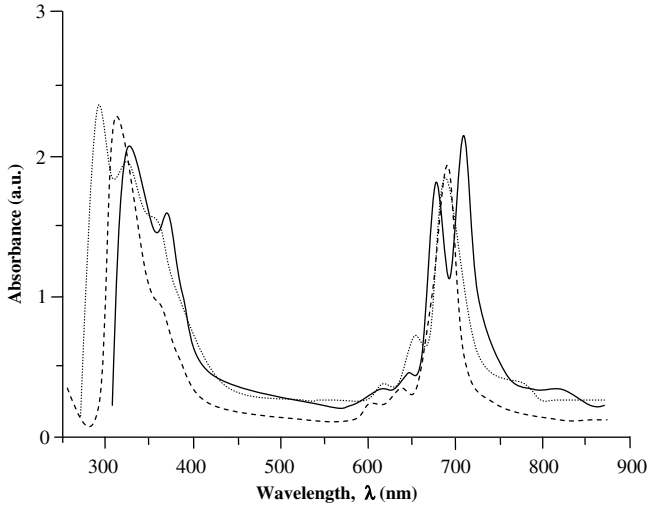


Fig. 1. Electronic absorption spectra of **5** (—) (3.50×10^{-5} M) in $CHCl_3$, **6** (···) (3.50×10^{-5} M) and **7** (---) (3.50×10^{-5} M) in pyridine.

chloroform are due to the $\pi \rightarrow \pi^*$ transition of this fully conjugated 18 π electron system [17d,18]. The zinc(II) **6**, nickel(II) **7**, cobalt(II) **8** and copper(II) **9** phthalocyanine complexes showed the expected absorptions (Figs. 1 and 2), with the main peaks of the Q- and B-bands appearing at λ_{max} = 694, 695, 692, 687 nm and 292, 322, 313, 315 nm, respectively. This result is typical of metal complexes of substituted and unsubstituted metallophthalocyanines with D_{4h} symmetry [5b,10], where a single band of high intensity in the visible region is observed. Upon dilution (*ca.* 3.5×10^{-5} M) the absorption spectra of these compounds displayed significant changes in band positions and molar absorptivities [19]. Increasing the concentration (1×10^{-4} M to 3.5×10^{-5} M) led to aggregation, which is easily monitored by the position of the Q-band, which shifted to shorter wavelengths and showed a decrease in the molar absorption coefficient.

3.1. Solvent extraction of heavy metal cations

Polythioether crowns are well-known to bind soft cations [20] while oxygen-containing crowns are ideally suited for the ligation of hard cations [21]. The heavy metal ion-binding property of compound **5**, having tetrathia-monoaza-16-crown-5 units, was estimated by solvent extraction of heavy metal picrates from the aqueous to an organic phase (Table 1). As can be seen in Table 1, the highest extraction avidity of **5** was determined as 93.2% for Ag^+. As expected, the obtained extraction values for Ag^+, Cd^{2+}, Hg^{2+} and Pb^{2+} were high. This is because sulfur containing ligands are especially appropriate for complexation with heavy metal cations such as Ag^+, Cd^{2+} and Hg^{2+} due to the softness of sulfur [20] and the size match between the cation and host cavity [22]. On the other hand, the metal-free phthalocyanine core has to be taken into consideration for the extraction process. There are many articles on the metal extraction properties of metal-free phthalocyanines [23] and the highest extraction affinity was determined for Ag^+. Although the extraction studies were not conducted under the same conditions, the extraction avidity of **5** in the case of Ag^+, Cd^{2+} and Hg^{2+} cations are somewhat higher than those of previously studied polymeric phthalocyanines which have acyclic polythio ether moieties [24]. The higher extraction avidity might be due to the macrocyclic effect. In the case of Cu(II) and Zn(II), the size of the 16-membered macrocyclic cavity of **5** is too large to accommodate the metal ion, which leads to the poorer extraction of these metals with this reagent.

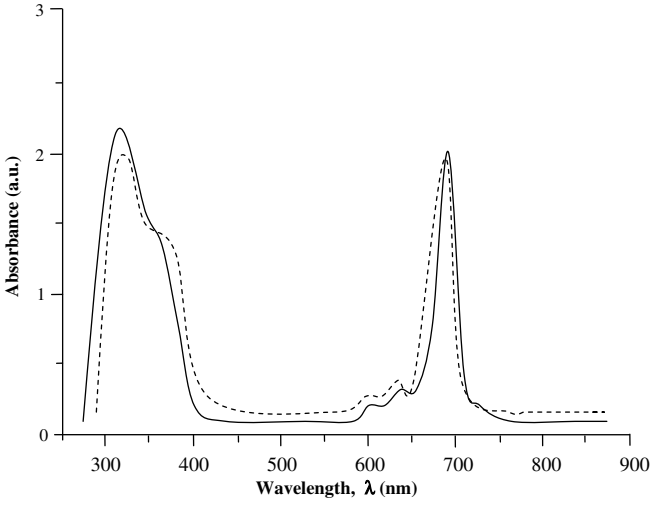

Fig. 2. Electronic absorption spectra of **8** (—) (3.50×10^{-5} M) and **9** (---) (3.50×10^{-5} M) in pyridine.

4. Conclusion

In this work, we describe the synthetic procedure and characterization of new soluble phthalocyanines substituted with eight tetrathiamonoaza macrocycles through ethoxy bridges. In addition, the heavy metal cation-binding property of **5** was evaluated using a solvent extraction technique and compared to our earlier works. The extractants from our earlier works in the case of Ag^+, Cd^{2+} and Hg^{2+} cations have lower cation-binding capacities than that in this work. Picrate was used as the counter anion. The cation-binding avidity of **5** for Ag^+, amongst the heavy metals, was found to be the highest.

ABSTRACT

Dinuclear trioxidic $[\{VOL\}_2\mu\text{-}O]$ (**1**–**4**) complexes were synthesized from the reaction of $[V^{IV}O(acac)_2]$ with an equimolar amount of H_2L [H_2L is the general abbreviation of hydrazone ligands (H_2L^{1-4}) derived from the condensation of benzoyl hydrazine with either 2-hydroxyacetophenone or its *para* substituted derivatives] in acetone or CH_2Cl_2 or acetonitrile. These $V_2O_3L_2$ complexes were also obtained from the reaction of $VOSO_4$ with H_2L in the presence of two equivalents sodium acetate in aqueous-methanolic (50% V/V) medium and also from the decomposition of $[V^{IV}O(L)(bipy/phen)]$ complexes in CH_2Cl_2 solution. Black monoclinic crystals of **2** and **4** with *C*2/*c* space group were obtained from the reaction of $[V^{IV}O(acac)_2]$, respectively, with H_2L^2 and H_2L^4 in acetone in which the respective ligands are bonded meridionally to vanadium in their fully deprotonated enol forms. The V–O bond lengths follow the order: V–O(oxo) < V–O(oxo-bridged) < V–O(phenolate) < V–O(enolate). Complexes (**1**–**4**) are diamagnetic exhibiting LMCT transition band near 380 nm in CH_2Cl_2 solution and they are electroactive displaying a quasi-reversible reduction peak in the 0.14–0.30 V *versus* SCE region. The λ_{max} and the reduction peak potential (E_p^c) values show linear relationships with the Hammett constant (σ) of the substituents in the hydrazone ligands.

These dinuclear complexes are converted to the corresponding mononuclear *cis* dioxo complexes $K(H_2O)^+[V^VO_2(L)]^-$ (**5**–**8**) and mixed-ligand $[V^VO(L)(hq)]$ complexes on reaction, respectively, with two equivalents KOH in methanol and two equivalents 8-hydroxyquinoline (Hhq) in $CHCl_3$. Ascorbic acid reduces the dioxovanadium(V) complexes reversibly under aerobic condition.

1. Introduction

Vanadium is an interesting transition metal which has the ability to exist in a wide range of oxidation states starting from −III to +V, of which the states III, IV and V are biologically important [1]. Vanadium easily switches between the oxidation states IV and V and the stabilization of either of these two states under aerobic condition depends upon the basicity of the coordinated ligand and also on the pH of the reaction medium. Of these three, the +V state has received considerable attention probably due to its two important properties: (i) it can exist in three motifs viz., mononuclear VO^{3+} and VO_2^+ motifs and dinuclear $V_2O_3^{4+}$ motif and (ii) it has the ability to exist in either five or six coordinated environment. These motifs are stable in solution around the physiological pH (~7) only when the metal is coordinated with sufficiently strong ligand for preventing the precipitation of hydroxides. A systematic study regarding the exclusive formation of any one of these three motifs with O,N-donor ligands [as V(V) due to its hard acidic nature, has strong affinity towards hard basic O,N-donor ligands] and their interconversion is an important area of contemporary research. Hydrazone ligands derived from the condensation of benzoyl hydrazine with aromatic 2-hydroxycarbonyl compounds are important tridentate O,N-donor ligands containing two intermediate basic phenolic and amide groups and one neutral imine moiety. This work was motivated by four objectives: (i) to synthesize the complexes containing $V_2O_3^{4+}$ core with a family of abovementioned hydrazone ligands, (ii) to rationalize the various synthetic routes for the formation of such type of complexes with these hydrazone ligands, (iii) to examine the feasibility of conversion of these dinuclear complexes into the mononuclear complexes with VO^{3+} and VO_2^+ motifs and (iv) to study the effect of *para* substituents in the hydrazone ligands on the electronic property of vanadium in these dinuclear complexes. With this background,

Scheme 1.

herein we have used four tridentate dibasic hydrazone ligands (H_2L^{1-4}, general abbreviation H_2L; the two H's representing the dissociable phenolic and amide protons) derived from the condensation of benzoyl hydrazine with 2-hydroxyacetophenone and its *para* substituted derivatives (Scheme 1). Stable structurally characterized oxo-bridge divanadium(V) complexes are not numerous [2–12] and particularly with hydrazone ligands are very rare [10–12]. The study of the chemistry of such type of dinuclear vanadium(V) complexes is important in connection with its catalytic [13–17] and medicinal [18–21] activities.

2. Experimental

2.1. Materials

$VOSO_4 \cdot 5H_2O$, acetyl acetone (Hacac) (CDH, India), benzoyl hydrazine, 2-hydroxyacetophenone and its *para* substituted derivatives (Aldrich, USA) were used as obtained. Hydrazone ligands (H_2L^{1-4}) [22] (Scheme 1) and $[V^{IV}O(acac)_2]$ [23] were prepared following the methods reported in the literature. Other chemicals and solvents were of analytical reagent grade and used without further purification.

2.2. Synthesis of the complexes $[V_2O_3(L)_2]$ (**1**–**4**)

All the four dinuclear complexes **1**–**4** were synthesized by a simple general method using either $[VO(acac)_2]$ or $VOSO_4 \cdot 5H_2O$ or $[V^{IV}O(L)(bipy/phen)]$ [24] as the starting material.

2.2.1. $[V_2O_3(L^1)_2]$ (**1**)

2.2.1.1. Method 1. To a filtered solution of H_2L^1 (0.254 g, 1 mmol) in acetone (20 cm^3) was added with stirring an acetone (15 cm^3) solution of $[VO(acac)_2]$ (0.265 g, 1 mmol) and the resulting reaction mixture was heated under reflux for 2 h. The reaction mixture was then kept for slow evaporation at room temperature. Black crystals of **1**, obtained after 3 days were collected by filtration after washing with acetone and dried over silica gel. Yield: 0.29 g (88.7%). *Anal.* Calc. for $C_{30}H_{24}N_4O_7V_2$ (654.43): C, 55.01; H, 3.67; N, 8.56. Found: C, 54.85; H, 3.95; N, 8.42%. Selected IR data (cm^{-1}): ν = 1592 (s, C=$N_{azomethine}$); 1302 (s, C–$O_{enolate}$); 1073 (m, N–N); 998 (s, V=O); 874 [s, V–(μ-O)–V]. ^1H NMR (300 MHz; $CDCl_3$): δ = 2.26 (s, 3H, 3 × 8-H); 7.04 (t, J = 7.3 Hz, 2H, 12-H and 14-H); 7.15–7.20 (m, 1H, 5-H); 7.30 (dd, J = 7.1 and 0.7 Hz, 1H, 3-H); 7.32–7.35 (m, 1H, 13-H); 7.37 (ddd, J = 7.1, 7.0 and 0.6 Hz, 1H, 4-H); 7.65 (dd, J = 7.4 and 0.7 Hz, 2H, 11-H and 15-H); 7.69 (dd, J = 7.3 and 0.6 Hz, 1H, 6-H) ppm.

Dark brown compound of **1** in the powder form was obtained on replacing acetone by acetonitrile or CH_2Cl_2 as the reaction medium.

2.2.1.2. Method 2. To a warm aqueous-methanolic solution (20 cm^3, 1:4 V/V) of H_2L^1 (0.254 g, 1 mmol) and sodium acetate trihydrate (0.272 g, 2 mmol) was added aqueous solution (10 cm^3) of $VOSO_4 \cdot 5H_2O$ (0.253 g, 1 mmol). The reaction mixture was stirred for 3 h at ~ 60 °C. A dark brown compound (0.25 g, 76.45%) (which was found to be identical in all respect with **1**, characterized by elemental analysis and also by various spectroscopic methods) thus obtained was filtered, washed with water, aqueous-methanol and then dried over silica gel (fused).

2.2.1.3. Method 3. Orange-red $[V^{IV}O(L^1)(bipy)]$ (0.10 g, 0. 21 mmol) complex was dissolved in wet dichloromethane (30 cm^3) and kept at room temperature. After 5 days black microcrystalline compound of **1** (0.061 g, 88.40%) were obtained. The compound was characterized by elemental analysis and also by various spectroscopic methods.

2.2.2. $[V_2O_3(L^2)_2]$ (**2**)

Complex **2** was prepared analogously to **1**, replacing H_2L^1 by H_2L^2 as black crystals (suitable for X-ray diffraction study). Yield: 0.29 g (85.04%). *Anal.* Calc. for $C_{32}H_{28}N_4O_7V_2$ (682.46): C, 56.27; H, 4.10; N 8.21. Found: C, 55.95; H, 4.21; N, 8.12%. Selected IR data (cm^{-1}): ν = 1590 (s, C=$N_{azomethine}$); 1294 (s, C–$O_{enolate}$); 1076 (m, N–N); 992 (s, V=O); 884 [s, V–(μ-O)–V]. ^1H NMR (300 MHz; $CDCl_3$): δ = 2.26 (s, 3H, 3 × 8-H); 2.45 (s, 3H, 3 × 16-H); 7.05 (t, J = 7.3 Hz, 2H, 12-H and 14-H); 7.24 (d, J = 8.0 Hz, 1H, 3-H); 7.31 (dt, J = 7.3 and 0.8 Hz, 1H, 13-H); 7.49 (dd, J = 8.0 and 1.0 Hz, 1H, 4-H); 7.51 (d, J = 1.0, 1H, 6-H), 7.64 (dd, J = 7.3 and 0.8 Hz, 2H, 11-H and 15-H) ppm.

2.2.3. $[V_2O_3(L^3)_2]$ (**3**)

Complex **3** was also prepared analogously to **1**, replacing H_2L^1 by H_2L^3. Yield: 0.31 g (86.83%). *Anal.* Calc. for $C_{32}H_{28}N_4O_9V_2$ (714.48): C, 53.75; H, 3.92; N, 7.84. Found: C, 53.54; H, 4.08; N, 7.77%. Selected IR data (cm^{-1}): ν = 1588 (s, C=$N_{azomethine}$); 1286 (s, C–$O_{enolate}$); 1068 (m, N–N); 993 (s, V=O); 877 [s, V–(μ-O)–V]. ^1H NMR (300 MHz; $CDCl_3$): δ = 2.26 (s, 3H, 3 × 8-H); 3.90 (s, 3H, 5-OCH_3); 7.07 (t, J = 7.3 Hz, 2H, 12-H and 14-H); 7.18 (d, J = 0.8 Hz, 1H, 6-H); 7.26 (dd, J = 7.6 and 0.8 Hz, 1H, 4-H); 7.29 (d, J = 7.6 Hz, 1H, 3-H); 7.33 (dt, J = 7.3 and 0.8 Hz, 1H, 13-H); 7.65 (dd, J = 7.6 and 0.8 Hz, 2H, 11-H and 15-H) ppm.

2.2.4. $[V_2O_3(L^4)_2]$ (**4**)

Complex **4** was also prepared similarly to **1**, replacing H_2L^1 by H_2L^4. Yield: 0.30 g (91.29%). *Anal.* Calc. for $C_{30}H_{22}Cl_2N_4O_7V_2$ (723.29): C, 49.77; H, 3.04; N, 7.74. Found: C, 49.56; H, 3.16; N, 7.70%. Selected IR data (cm^{-1}): ν = 1589 (s, C=$N_{azomethine}$); 1278 (s, C–$O_{enolate}$); 1094 (m, N–N); 1003 (s, V=O); 878 [s, V–(μ-O)–V]. ^1H NMR (300 MHz; $CDCl_3$): δ = 2.24 (s, 3H, 3 × 8-H); 7.10 (t, J = 7.3 Hz, 2H, 12-H and 14-H); 7.31 (d, J = 8.8 Hz, 1H, 3-H); 7.33 (dt, J = 7.3 and 0.7 Hz, 1H, 13-H); 7.62 (dd, J = 8.8 and 2.0 Hz, 1H, 4-H); 7.64 (dd, J = 7.3 and 0.7 Hz, 2H, 11-H and 15-H); 7.70 (d, J = 2.0 Hz, 1H, 6-H) ppm.

2.3. Conversion of $[V_2O_3(L)_2]$ complexes to $K(H_2O)^+[VO_2(L)]^-$ complexes

2.3.1. Conversion of $[V_2O_3(L^1)_2]$ (**1**) to $K(H_2O)^+[VO_2(L^1)]^-$ (**5**)

To a methanolic solution (25 cm^3) of KOH (0.02 g, ~0.3 mmol) was added $[V_2O_3(L^1)_2]$ (0.10 g, 0.15 mmol) and the reaction mixture was stirred for 4 h at ~60 °C. An intense yellow solution was obtained which was kept for slow evaporation at room temperature. A yellow microcrystalline product of **5**, obtained after 5 days, was filtered, washed with methanol and dried over silica gel. Yield: 0.10 g (83.33%). *Anal.* Calc. for $C_{15}H_{14}N_2O_5KV$ (392.33): C, 45.88; H,

3.57; N, 7.14. Found: C, 45.52; H, 3.78; N, 7.06%. Selected IR data (cm^{-1}): ν = 1594 (s, C=$N_{azomethine}$); 1240 (s, C–$O_{enolate}$); 1030 (m, N–N); 876, 945 (s, sym and antisym VO_2^+); 3435 (m, H_2O). Λ_M (DMF) = 65 Ω^{-1} cm^2 mol^{-1}. ^1H NMR (300 MHz; DMSO-d_6): δ = 2.81 (s, 3H, 3 × 8-H); 6.77 (t, J = 7.7, 2H, 12-H and 14-H); 7.26 (dt, J = 7.7 and 1.7, 1H, 13-H); 7.38–7.41 (m, 1H, 5-H); 7.42–7.44 (m, 1H, 3-H); 7.69 (dd, J = 7.4 and 1.3, 1H, 6-H); 7.70–7.72 (m, 1H, 4-H); 8.00 (dd, J = 7.7 and 1.7, 2H, 11-H and 15-H) ppm. UV/Vis (CH_3OH): λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 376 nm (7056), 309 nm (12 190).

*2.3.2. Conversion of $[V_2O_3(L^2)_2]$ (**2**) complex to $K(H_2O)^+[VO_2(L^2)]^-$ (**6**)*

Complex **6** was prepared analogously to **5**, replacing $[V_2O_3(L^1)_2]$ by $[V_2O_3(L^2)_2]$. Yield: 0.090 g (75.0%). *Anal.* Calc. for $C_{16}H_{16}N_2O_5KV$ (406.35): C, 47.25; H, 3.94; N, 6.89. Found: C, 46.95; H, 4.12; N, 6.78%. Selected IR data (cm^{-1}): ν = 1592 (s, C=$N_{azomethine}$); 1245 (s, C–$O_{enolate}$); 1030 (m, N–N); 905, 933 (s, sym and antisym VO_2^+); 3431 (m, H_2O). Λ_M (DMF) = 64 Ω^{-1} cm^2 mol^{-1}. ^1H NMR (300 MHz; DMSO-d_6): δ = 2.25 (s, 3H, 3 × 16-H); 2.80 (s, 3H, 3 × 8-H); 6.66 (d, J = 8.4 Hz, 1H, 3-H); 7.08 (dd, J = 8.4 and 1.0 Hz, 1H, 4-H); 7.36-7.39 (m, 2H, 12-H and 14-H); 7.40–7.43 (m, 1H, 13-H); 7.50 (d, J = 1.0 Hz, 1H, 6-H); 8.00 (dd, J = 7.9 and 2.2 Hz, 2H, 11-H and 15-H) ppm. UV/Vis (CH_3OH): λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 385 nm (6705), 310 nm (13 490).

*2.3.3. Conversion of $[V_2O_3(L^3)_2]$ (**3**) complex to $K(H_2O)^+[VO_2(L^3)]^-$ (**7**)*

Complex **7** was also prepared analogously to **5**, replacing $[V_2O_3(L^1)_2]$ by $[V_2O_3(L^3)_2]$. Yield: 0.10 g (84.75%). *Anal.* Calc. for $C_{16}H_{16}N_2O_6KV$ (422.35): C, 45.46; H, 3.79; N, 6.63. Found: C, 45.14; H, 3.98; N, 6.52%. Λ_M (DMF) = 63 Ω^{-1} cm^2 mol^{-1}. ^1H NMR (300 MHz; DMSO-d_6): δ = 2.81 (s, 3H, 3 × 8-H); 3.73 (s, 3H, 3 × 5-OCH_3); 6.70 (d, J = 8.9 Hz, 1H, 3-H); 6.94 (dd, J = 8.9 and 1.9 Hz, 1H, 4-H); 7.16-7.20 (m, 1H, 13-H); 7.33–7.41 (m, 2H, 12-H and 14-H); 7.43 (d, J = 1.9 Hz, 1H, 6-H); 8.02 (dd, J = 7.8 and 1.8 Hz, 2H, 11-H and 15-H) ppm. UV/Vis (CH_3OH): λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 400 nm (1046), 311 nm (2405).

*2.3.4. Conversion of $[V_2O_3(L^4)_2]$ (**4**) complex to $K(H_2O)^+[VO_2(L^4)]^-$ (**8**)*

Complex **8** was also prepared analogously to **5**, replacing $[V_2O_3(L^1)_2]$ by $[V_2O_3(L^4)_2]$. Yield: 0.11 g (93.22%). *Anal.* Calc. for $C_{15}H_{13}N_2O_5ClKV$ (426.77): C, 42.18; H, 3.05; N, 6.56. Found: C, 41.92; H, 3.17; N, 6.47%. Selected IR data (cm^{-1}): ν = 1595 (s, C=$N_{azomethine}$); 1240 (s, C–$O_{enolate}$); 1029 (m, N–N); 904, 945 (s, sym and antisym VO_2^+); 3450 (m, H_2O). Λ_M (DMF) = 57 Ω^{-1} cm^2 mol^{-1}. ^1H NMR (300 MHz; DMSO-d_6): δ = 2.81 (s, 3H, 3 × 8-H); 6.78 (d, J = 8.8 Hz, 1H, 3-H); 7.26 (dd, J = 8.8 and 2.6 Hz, 1H, 4-H); 7.39–7.42 (m, 2H, 12-H and 14-H); 7.44–7.48 (m, 1H, 13-H); 7.70 (d, J = 2.6, 1H, 6-H); 8.02 (dd, J = 7.8 and 1.8 Hz, 2H, 11-H and 15-H) ppm. UV/Vis (CH_3OH): λ_{max} (ε, dm^3 mol^{-1} cm^{-1}) = 386 nm (8620), 308 nm (14 630).

2.4. Conversion of $[V_2O_3(L)_2]$ complexes to [VO(L)(hq)] complexes

2.4.1. Conversion of $[V_2O_3(L^1)_2]$ complex to $[VO(L^1)(hq)]$ complex

$CHCl_3$ solution (10 cm^3) of 8-hydroxyquinoline (Hhq) (0.025 g, 0.17 mmol) was added to a solution of $[V_2O_3(L^1)_2]$ (0.05 g, 0.075 mmol) in $CHCl_3$ (20 cm^3). The yellow colour of the solution was changed gradually to violet. The mixture was stirred for 8 h and the intense violet solution was filtered and the filtrate was left to evaporate slowly in the air. Shiny black crystalline product (0.065 g, 91.55%) obtained after 6 days was collected by filtration after washing with $CHCl_3$ and then dried over silica gel, which was found to be identical in all respects with the compound $[VO(L^1)(hq)]$, which we have already prepared by different method and published very recently [22].

Other mixed-ligand complexes of this type with the H_2L^{2-4} ligands were also obtained similarly by the reaction of Hhq with the respective $[V_2O_3(L)_2]$ complex.

2.5. Physical measurements

Elemental analyses were performed on a Perkin–Elmer 2400 CHNS/O analyzer. Electronic spectra (in CH_2Cl_2 of $[\{VO(L)\}_2\mu$-O] and [VO(L)(hq)] complexes and in CH_3OH of dioxovanadium(V) complexes) were recorded on a Hitachi U-3501 spectrophotometer and IR spectra (as KBr pellets) were taken on a Perkin–Elmer 782 spectrophotometer. The ^1H NMR spectra were recorded either in $CDCl_3$ [of **1**–**4** complexes] or in DMSO-d_6 [of **5**–**8** complexes] on a Bruker AM 300L (300 MHz) superconducting FT NMR spectrophotometer. Conductivity measurements of complexes **5**–**8** were performed at 298 K in DMF solution with the Systronics 304 digital conductivity meter. Electrochemical measurements were performed at 298 K in CH_2Cl_2 solution of complexes **1**–**4** and in DMSO solution of complexes **5**–**8** for *ca.* 10^{-3} M using Et_4NClO_4 as supporting electrolyte under a dry N_2 atmosphere on a PC controlled PAR model 273 A electrochemistry system. A Pt disk, a Pt wire auxiliary electrode and an aqueous saturated calomel electrode (SCE) were used in a three-electrode configuration. All the potential values reported here are uncorrected for junction contribution. The ferrocene/ferrocinium (Fc/Fc^+) couple was used as the internal standard.

2.6. Crystallographic data collection and refinement

For **2**, data were measured with Mo Kα radiation at 298 K using the MAR research Image Plate System. Suitable single crystals were positioned at 70 mm from the Image Plate. A total of 95 frames were measured at 2° intervals with a counting time of 2 min. Data analyses were carried out with the XDS program [25]. The structures were solved using direct methods with the SHELXS-97 program [26]. Absorption corrections were carried out using the DIFABS program [27]. For complex **4**, data were measured with Mo Kα radiation at 150 K using the Oxford Diffraction X-calibur system. The crystal was mounted at 50 mm from the CCD. A total of 321 frames were measured with a counting time of 10 s. Data analysis was carried out with CRYSALIS [28] and absorption correction was carried out with the ABSPACK program [29]. For the two structures, the non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in

geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. The structures were refined on F^2 using SHELXL-97 program [26] and molecular graphics were computed using PLATON [30]. All crystallographic data are summarized in Table 1.

3. Results and discussion

3.1. Synthesis of dinuclear $[V_2O_3(L)_2]$ complexes and their conversion into their mononuclear analogues

$[V_2O_3(L)_2]$ (**1–4**) complexes were prepared by various synthetic routes starting from different VO^{2+} precursor, viz., $VOSO_4$, $[V^{IV}O(acac)_2]$ and $[V^{IV}O(L)(bipy/phen)]$ complexes. Reaction of equimolar amounts of $VOSO_4$ with the respective H_2L (where H_2L is the general abbreviation of H_2L^{1-4}) in presence of two equivalents sodium acetate in aqueous-methanolic (50% V/V) medium in air afforded the $[V_2O_3(L)_2]$ complex in good yield as dark brown powdered material, while, the black crystalline $[V_2O_3(L)_2]$ complexes were obtained by the reaction of $[VO(acac)_2]$ with equimolar amount of H_2L in refluxing acetone. Such complexes were further obtained on replacing acetone by acetonitrile or CH_2Cl_2 and also from the decomposition of the mixed-ligand $[V^{IV}O(L)(bipy/phen)]$ complexes (which were prepared by the reported method [24]) in CH_2Cl_2 solution. The oxidizing agent is most likely the aerial dioxygen and all the stated reactions can be represented by the following equations:

$$2V^{IV}OSO_4 + 2H_2L + 4CH_3COONa + 1/2O_2 \rightarrow [\{V^{V}O(L)\}_2\mu\text{-}O] + 2Na_2SO_4 + 4CH_3COOH \quad (1)$$

$$2[V^{IV}O(acac)_2] + 2H_2L + 1/2O_2 \rightarrow [\{V^{V}O(L)\}_2\mu\text{-}O] + 4Hacac \quad (2)$$

$$2[V^{IV}O(L)(bipy/phen)] + 1/2O_2 \rightarrow [\{V^{V}O(L)\}_2\mu\text{-}O] + 2bipy/phen \quad (3)$$

where Hacac, bipy and phen are, respectively, acetyl acetone, 2,2′-bipyridine and 1,10-phenanthroline.

These dinuclear oxovanadium(V) complexes can easily be converted to either dioxovanadium(V) complexes **5–8** or mixed-ligand complexes of the type $[V^{V}O(L)(hq)]$ (which we have already synthesized by different method and reported very recently [22]) on reaction, respectively, with two equivalents KOH in methanol and two equivalents 8-hydroxyquinoline (Hhq) in $CHCl_3$. Eqs (4) and (5) represent the above-mentioned reactions.

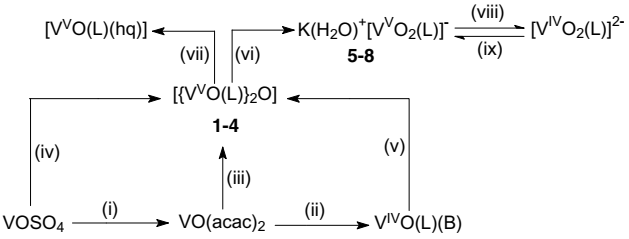
$$[\{V^{V}O(L)\}_2\mu\text{-}O] + 2KOH + H_2O \rightarrow 2K(H_2O)^{+}[VO_2(L)]^{-} \quad (4)$$

$$[\{V^{V}O(L)\}_2\mu\text{-}O] + 2Hhq \rightarrow 2[V^{V}O(L)(hq)] + H_2O \quad (5)$$

Complexes **1–4** are freely soluble in CH_2Cl_2, $CHCl_3$ but sparingly soluble in CH_3OH, C_2H_5OH etc. while complexes **5–8** are freely soluble in CH_3OH, DMSO, DMF but sparingly soluble in CH_3CN and insoluble in CH_2Cl_2. In spite of our best efforts, none of the dioxovanadium(V) complexes **5–8**, afforded single crystals suitable for structure determination by X-ray crystallography. Among the four $[V^{IV}O(L)(bipy)]$ and four $[V^{IV}O(L)(phen)]$ complexes, only the $[V^{IV}O(L^4)(bipy)]$ complex on decomposition in CH_2Cl_2–C_6H_6 solution yielded the crystals [31] of $[V_2O_3(L^4)_2]$ containing benzene molecules as solvent of crystallization. The analytical and spectroscopic data of the present $[V^{V}O(L)(hq)]$ complexes are identical in all respects to our earlier report [22]. Scheme 2 represents all the above-mentioned reactions.

3.2. IR spectra of the complexes

The IR spectral data of all the complexes are given in Section 2. Disappearance of two ligand bands in the regions 1646–1651 cm^{-1} and 2924-2989 cm^{-1} due to (C=O) and (NH) stretches [22],



Scheme 2. (i) Acetyl acetone (Hacac) + two equivalents CH_3COONa in water; (ii) H_2L + bipy or phen (B) in 1:1 molar ratio in methanol; (iii) one equivalent H_2L in acetone or dichloromethane or acetonitrile; (iv) H_2L + two equivalents CH_3COONa in methanol–water (50% V/V); (v) CH_2Cl_2; (vi) two equivalents KOH in methanol; (vii) two equivalents 8-hydroxyquinoline (Hhq) in $CHCl_3$; (viii) ascorbic acid (in excess) in methanol; (ix) air.

respectively, indicates the enolisation of the amide functionality and subsequent metal coordination through deprotonation. The enolisation is further supported by the appearance of a new band near 1278–1302 cm^{-1} region in complexes **1–4** and near 1213–1245 cm^{-1} region in complexes **5–8**, attributed to (C–O) (enolate) stretching. The characteristic (N–N) stretching band for the dimeric complexes appears in the 1068–1094 cm^{-1} region while that for dioxo complexes is observed in the 1027–1030 cm^{-1} region. These bands are appreciably in the higher energy region compared to the corresponding free ligands due to diminished repulsion between the lone pairs of adjacent nitrogen atoms, indicating the coordination of one of the two nitrogen lone pairs [32–34]. The coordination of the phenolic oxygen to the vanadium with deprotonation is confirmed from the disappearance of the ligand band in the region 3215–3240 cm^{-1} due to (O–H) (phenolic) stretching and the appearance of a new strong band in the 1349–1363 cm^{-1} attributed to (C–O) (phenoate) stretching [22,35,36]. Thus, all the four hydrazone ligands acting as tridentate dibasic ONO donors in all these complexes. In the IR spectra of complexes **5–8**, the strong sharp band appeared in the region 3421–3450 cm^{-1} may be assigned to H_2O molecule.

Two sharp bands, one near 1000 cm^{-1} and other near 880 cm^{-1} exhibited by the dinuclear complexes **1–4**, have been attributed to (V=O) and [V–(μ-O)–V] stretches, respectively [6,10,11]. The *cis* dioxo nature of complexes **5–8**, was confirmed from the appearance of two sharp bands in the 876–905 cm^{-1} and 915–945 cm^{-1} regions which are assigned to symmetric and antisymmetric stretching of the VO_2^{+} motifs [6,33,34,36–38]. Such (V=O) stretching values are in favour of the pentacoordinated environment [6,10,11,33,34,36–38] around the metal center in all the **1–8** complexes.

3.3. Structure of **2** and **4**

The structure of **4** is isomorphous with **2** with the chlorine atoms replacing the methyl groups in the *para* position with respect to phenolic OH in the aryloxy ring of the ligands and they belong to the monoclinic crystal system with *C*2/*c* space group. Molecular view of **2** and **4** are given in Figs. 1 and 2, respectively. The selected bond parameters are given in Table 2. Two structurally very similar but crystallographically distinct respective $[V_2O_3(L)_2]$ molecules are present in both the crystal lattices of **2** and **4** with the bridging oxygen lying on a crystallographic 2-fold axis such that the two halves of each of the two molecules are crystallographically equivalent. The coordination sphere of the vanadium is of the VO_4N type and the coordination geometry at the metal center can best be fitted to a distorted square pyramid with oxo oxygen O(1) at the apex. The phenolate O(2), the enolate O(3), the imine nitrogen N(1) atoms of the fully deprotonated $(L^2)^{2-}$ and $(L^4)^{2-}$ ligands in their enol forms and the bridging oxygen O(4)

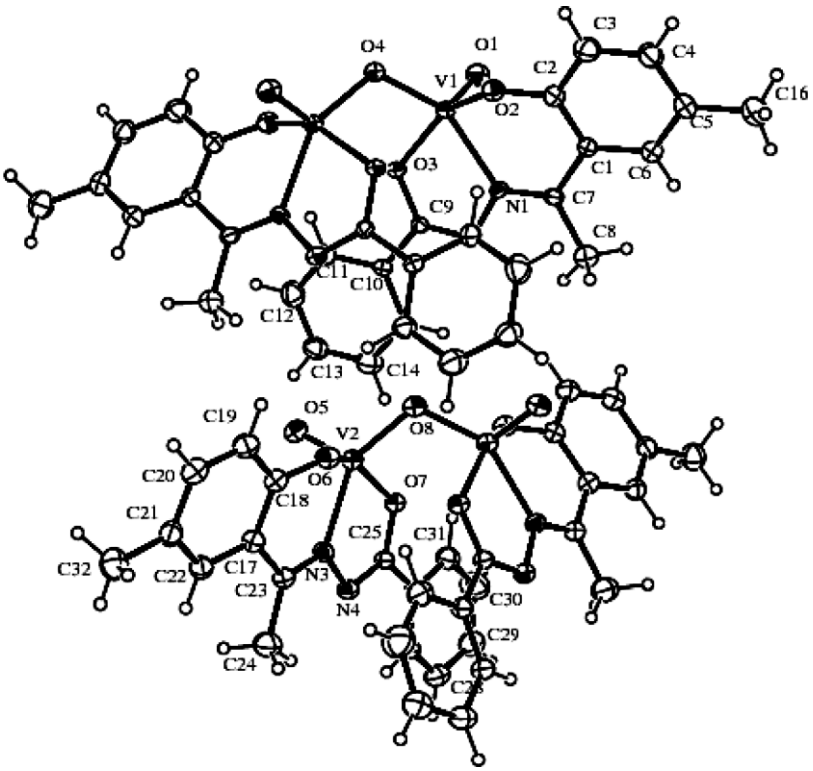


Fig. 1. Molecular structure of complex **2** with thermal ellipsoids drawn at 50% probability level.

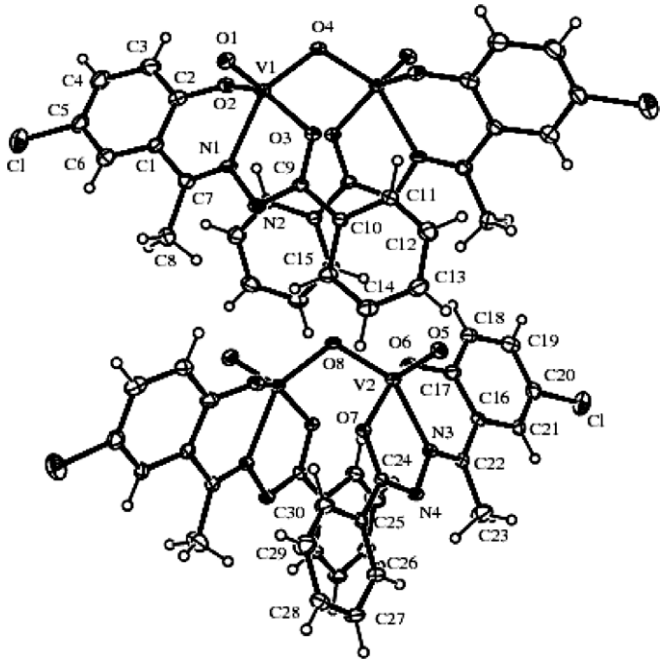

Fig. 2. Molecular structure of complex **4** with thermal ellipsoids drawn at 50% probability level.

atoms constitute the tetragonal plane from which the vanadium atom is displaced by 0.527 Å in one molecule and by 0.539 Å in the other molecule of **2** (these values are 0.534 and 0.525 Å for **4**) towards the terminal O(1) and O(5) atoms respectively. The average O(axial)–V–O/N(basal) angle is ~104°, which is only slightly different from the average angle of 102° for a square pyramidal complex (C_{4v}) as explained by Muetterties and Guggenberger [39]. The τ parameter [40] (equal to $\Delta/60°$, where Δ is the difference between the largest and next-to-largest ligand–metal–ligand angles) is also another useful geometrical discriminator ($\Delta = 0$, $\tau = 0$ for idealized square pyramid). The τ value is 0.039 and 0.004, respectively, for V(1) and V(2) centers for **2** while for **4** it is, respectively, 0.074 and 0.018, indicating very slight distortion from the perfect square pyramidal structure. These also indicate that the extent of distortion is different for each of the vanadium centers even within the same structure.

The dihedral angles between the two symmetry related pyramid bases V(1) and V(1)$1, V(2) and V(2)$1 ($1 = symmetry element $1 - x$, y, $0.5 - z$) in **2** are 62.19° and 59.25°, respectively (which are, respectively, 61.36° and 58.7° in **4**). The two terminal oxygen atoms O(1) and O(1) are mutually *trans* lying on opposite sides of the V–O–V plane and the distance of each oxygen atom from the plane is 0.875 Å and 0.889 Å in **2** while it is 0.860 Å and 0.874 Å in **4**. The O(1)–V(1)–V(1)$1–O(1)$1 and O(5)–V(2)–V(2)$1–O(5)$1 torsion angles are 134.99° and 133.95° in **2** while this angles are, respectively, 133.92° and 134.21° in **4**. The V=O^t (t = terminal) [1.584(4)–1.589(3) Å], V–O^b (b = bridging) [1.784(3)–1.801(2) Å] distances, the other bond lengths and bond angles are very similar to the reported analogous hydrazone complexes [10–12]. The O–C, N–C and N–N distances are consistent with the enolate forms of the corresponding ligands. An examination of the bond length parameters reveals a general order: V–O^t < V–O^b < V–O^p (p = phenolic) < V–O^e (e = enolic), which can be explained on the basis of basicity of donor atoms and their π-bonding ability. The V–O–V angles are very similar and are close to 113°, which is consistent with the reported values of analogous hydrazone complexes [10–12]. The non-bonded V–V distances are 2.988(4) Å and 2.976(3) Å in **2** [2.989(2) Å and 2.967(2) Å in **4**], which are also very similar to those of other reported hydrazone complexes [10–12].

3.4. Proton NMR spectra of the complexes

We are considering the ^{1}H NMR spectra of complexes **1**–**4** and **5**–**8** taken, respectively, in $CDCl_3$ and DMSO-d_6 solution and their spectral data are presented in the experimental section. The coordination modes of the ligands in the complexes were confirmed by comparing the ^{1}H NMR spectra of the complexes with the respective ligands. The DMSO-d_6 solution of the ligands exhibits signals at $\delta \sim 11.00$ ppm and $\delta \sim 13.00$ ppm which are attributed respectively to NH and OH protons [22]. These signals are absent in all these complexes suggesting their tautomerisation of the keto form into enol form and subsequent coordination of the enolic and phenolic oxygens through deprotonation.

In the ^{1}H NMR spectra of **1**–**4**, the methyl protons H(8) appear as a singlet at δ2.24–δ2.26 ppm region. The methyl protons H(16) in **2** also appear as a singlet at δ2.45 ppm and the singlet at δ3.90 ppm in **3** is attributed to methoxy H(5-OCH_3) protons. The aromatic protons appear in the δ7.04–δ7.70 ppm region. The significant downfield shift (~0.3 ppm) of the methyl protons H(8) (appearing at δ2.81 ppm in complexes **5**–**8**) indicating the coordination of azomethine (C═N) nitrogen to the metal. Singlets at δ2.25 ppm and δ3.73 ppm in **6** and **7** are attributed, respectively, to methyl H(16) and methoxy H(5-OCH_3) protons. In these dioxovanadium(V) complexes, the aromatic protons appear in the δ6.66–δ8.02 ppm region. The disappearance of signal corresponding to H_2O protons in these complexes is probably due to exchange with the solvent. The ^{1}H NMR spectral data of the mixed-ligand [VO(L)(hq)] complexes are identical with the reported values which are described in our earlier paper [22].

3.5. Conductivity of the dioxovanadium(V) complexes

The conductivity of the dioxovanadium(V) complexes **5**–**8** were measured in *N*,*N*-dimethylformamide (DMF) solution at 298 K with a view to examine their electrolytic nature and their molar conductance values have been found to be in the 57–65 Ω^{-1} cm^2 mol^{-1} region, indicating their 1:1 electrolytic [41] nature thus, supporting their molecular formulae.

Based on the results of above studies, it is reasonable to assume the gross structures **III** and **IV**, respectively, for the complexes **1**–**4** and **5**–**8** (Scheme 3).

3.6. Electronic spectra of the complexes

All the complexes are diamagnetic indicating the +V oxidation state of the metal with a 3d^0 configuration and consequently no d–d transition band is expected in their electronic spectra. The electronic spectra of **1**–**4** complexes and [VO(L)(hq)] complexes were recorded in CH_2Cl_2 solution while that of **5**–**8** complexes were recorded in CH_3OH in the 300–800 nm regions. The electronic spectral data of **1**-**4** are listed in Table 3 while those of **5**–**8** are described in Section 2. All these complexes exhibit very intense transitions; the lowest energy band near 380 nm is assigned to ligand-to-metal charge transfer (LMCT) transition. The ligand char-

[c] $E_{1/2}$ is calculated as the average of anodic (E_p^a) and cathodic (E_p^c) peak potential values.

acteristic $\pi \rightarrow \pi^*$ transition band of the azomethine group appeared near 320 nm for **1–4** complexes and near 310 nm for **5–8** complexes. An examination of the λ_{max} (for LMCT transition) values of **1–4** complexes indicates that an electron donating group (viz., CH_3 and OCH_3) at the *para* position with respect to phenolic OH group in the aryloxy ring, decreases the λ_{max} value, while, an electron withdrawing group (e.g., Cl) increases it, which is expected from the ligands' basicity point of view. But such a trend is not observed for the dioxo complexes **5–8**, probably due to the accumulation of negative charge on the vanadium, which eliminates the relatively small substituent effect inhibiting us to examine the substituent effect on the electronic property of vanadium in these dioxovanadium(V) complexes.

3.7. Electrochemistry of the complexes

Complexes **1–4** exhibit a quasi-reversible reduction peak ($E_{1/2}$) in CH_2Cl_2 solution (Fig. 3) near +0.25 V *versus* SCE due to VO^{3+}/VO^{2+} couple. The appearance of the single reduction peak suggests the identical electronic environment at both the two vanadium centers. However, the electrochemical study of complexes **5–8** in DMSO solution indicated that they are not electro-active in the voltage range −1.0 to 1.0 V. A scrutiny of the redox potential data (Table 3) indicates a similar trend in the reduction peak potential ($E^c{}_p$) values for complex **1–4** like their electronic spectra, it decreases with the increase of electron donating property of the substituent at the *para* position as in the case of **2** and **3** in comparison to the unsubstituted species (viz., **1**) and the opposite is true for the presence of an electron withdrawing group (viz., **4**).

3.8. Influence of ligand substituents on the electronic aspects of the complexes

Four hydrazone ligands H_2L^{1-4} with three substituents of different Hammett parameter (σ) values [H (σ = 0.00), CH_3 (σ = −0.17), OCH_3 (σ = −0.27) and Cl (σ = +0.23)] [42] in the aryloxy ring of the hydrazone ligands have been used in this work with a view to study their effect on the electronic property of the vanadium in these dinuclear complexes. We have already stated that in the complexes **2** and **3** with electron donating substituents, a decrease in λ_{max} value (for the LMCT transition) and reduction peak potential (E_p^c) value was observed compared to complex **1** and for complex **4** with an electron withdrawing substituent, the opposite is true. To find out the quantitative relation of λ_{max} and E_p^c values with σ, the respective values are plotted which give the following linear relations, equations (6) and (7) (Figs. 4 and 5).

$$\text{UV—Vis}: \ \lambda_{max}\ (\text{nm}) = 381.51 + 28.82 \times \sigma \quad (6)$$

$$\text{CV}: \ E_p^c\ (\text{V}) = 0.20 + 0.19 \times \sigma \quad (7)$$

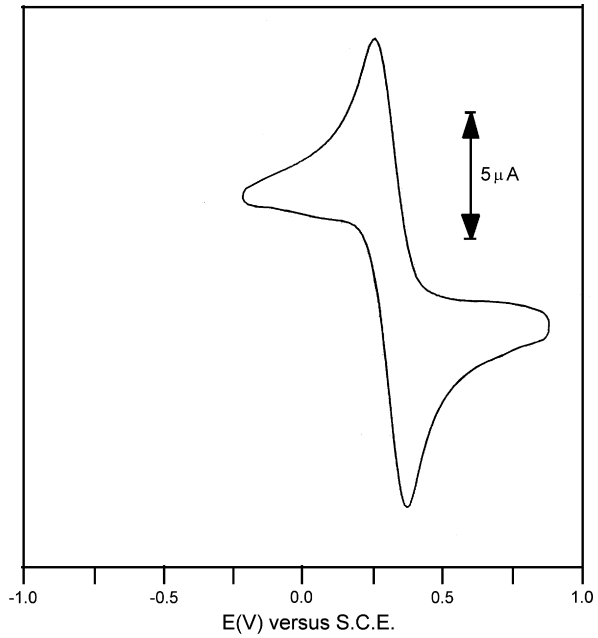

Fig. 3. Cyclic voltammogram of complex **4** in CH_2Cl_2 solution.

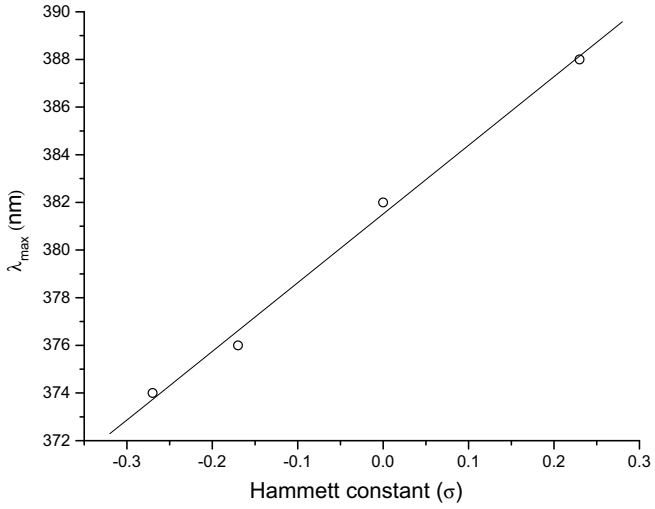

Fig. 4. Plot of λ_{max} *vs.* Hammett constant (σ) of complexes **1–4**.

These correlations have *r* values of ∼1.0 and 0.98, respectively and the estimated error in $d\lambda_{max}/d\sigma$ and $dE_p^c/d\sigma$ value is, respectively, 1.57 and 0.025. The estimated error in the intercept of Figs. 4 and 5 is, respectively, 0.31 and 0.005. These two relations indicate that the dependence of the λ_{max} value on the substituent (i.e., $d\lambda_{max}/d\sigma$) is 28.82 nm and that of E_p^c value (i.e., $dE_p{}^c/d\sigma$) is 0.19 V.

By the elimination of σ from the above two linear equations (6) and (7), one can obtain the following Eq. (8), a relation between λ_{max} and E_p^c parameters:

$$\lambda_{max}\ (\text{nm}) = 351.25 + 151.68 \times E_p^c \quad (8)$$

Almost identical relation, equation (9) is obtained with *r* value ∼0.99 when λ_{max} values are plotted against the respective E_p^c values (Fig. 6).

$$\lambda_{max} = 351.85 + 148.15 \times E_p^c \quad (9)$$

All these relations demonstrate the sensitivity of the vanadium electron density on σ of the R substituent in these dinuclear complexes.

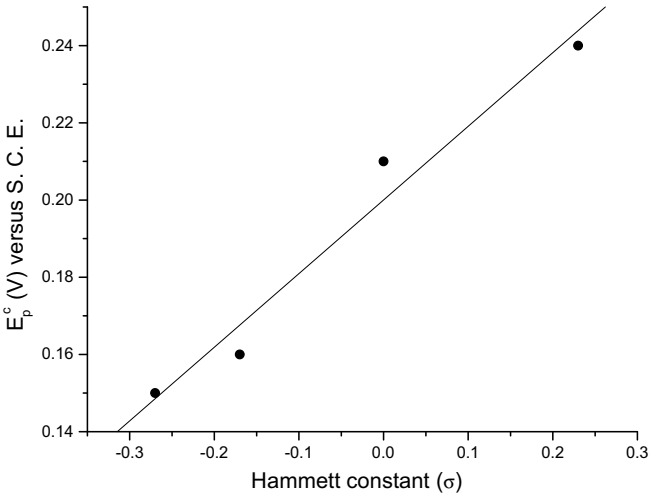

Fig. 5. Plot of E_p^c *vs.* Hammett constant (σ) of complexes **1**–**4**.

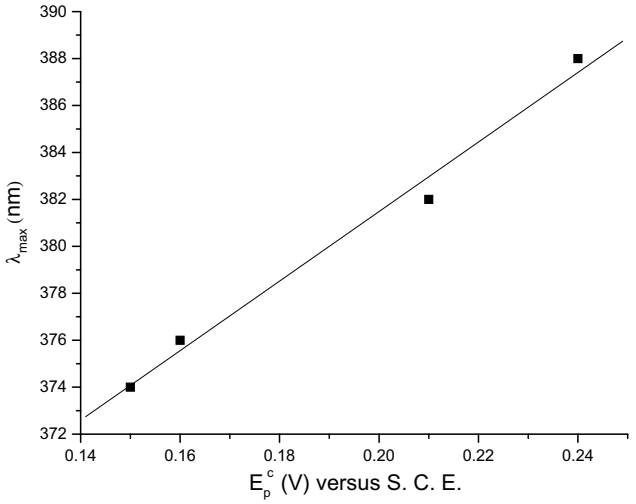

Fig. 6. Plot of λ_{max} *vs.* E_p^c of complexes **1**–**4**.

3.9. Reaction of $K(H_2O)^+[VO_2(L)]^-$ (**5**–**8**) complexes with ascorbic acid

The reaction of $K(H_2O)^+[VO_2(L)]^-$ complexes with ascorbic acid was monitored spectrophotometrically. In each case after the addition of reducing agent (*ca.* 10 times than of the complex) a new band in the visible region near 675 nm ($\varepsilon \sim 250\ dm^3\ mol^{-1}\ cm^{-1}$) (Table 4, Fig. 7) was detected which is assigned to a d–d transition of the resulting V^{IV} species [43,44]. After keeping the solution for sometime, the intensity of the new band decreases gradually and finally the initial spectrum was obtained in a time interval ~12 h. These observations strongly suggest that during the reaction with ascorbic acid, the $K(H_2O)^+[VO_2(L)]^-$ complexes are reduced by it to form the corresponding V^{IV} complex presumably of the type $[V^{IV}O_2(L)]^{2-}$. The reappearance of an almost identical original spectrum (before reduction) after ~12 h indicates that the ligand remained coordinated to the vanadium in the reduced V^{IV} species and these reduced species are not stable under this environment.

Table 4
Electronic spectral (400-800 nm) data of the complexes **5**–**8** in presence of excess (~10 times) ascorbic acid in methanol at 298 K

Compound	λ_{max}, nm (ε, $dm^3\ mol^{-1}\ cm^{-1}$)
$K(H_2O)^+[VO_2(L^1)]^-$ (**5**)	674 (226)
$K(H_2O)^+[VO_2(L^2)]^-$ (**6**)	677 (258)
$K(H_2O)^+[VO_2(L^3)]^-$ (**7**)	678 (262)
$K(H_2O)^+[VO_2(L^1)]^-$ (**8**)	674 (244)

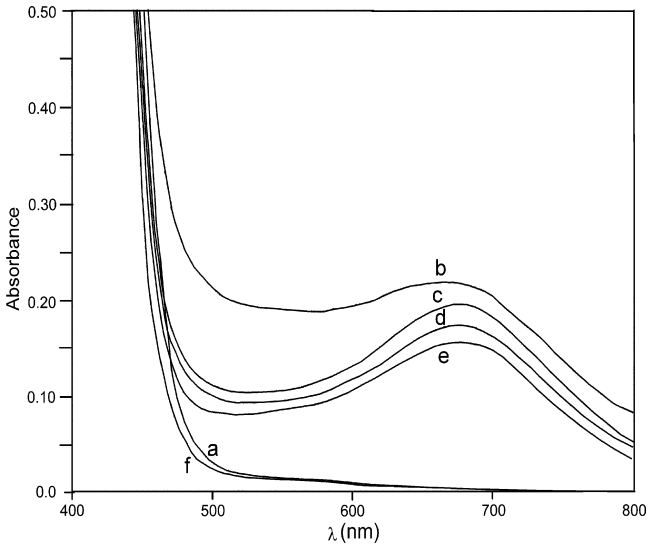

Fig. 7. Electronic spectra (400–800 nm) of a 7.973×10^{-4} mol dm^{-3} methanol solution of complex **2**: (a) before the addition of ascorbic acid, (b) immediately after the addition of ascorbic acid, (c) 10 min after the addition of ascorbic acid, (d) 30 min after the addition of ascorbic acid, (e) 60 min after the addition of ascorbic acid and (f) 720 min after the addition of ascorbic acid. The amount of ascorbic acid was about 10 times than that of the concentration of the complex.

4. Conclusion

Hydrazone complexes **1**–**4** containing $V_2O_3^{4+}$ motif can be synthesized following various synthetic routes starting from different VO^{2+} precursors and these hydrazone ligands are very suitable for the stabilization of this motif. The formation of these dinuclear complexes from the decomposition of mixed-ligand $[V^{IV}O(L)(bipy/phen)]$ complexes in CH_2Cl_2 solution indicates that these ligands have strong tendency for the stabilization of vanadium in its highest (+V) oxidation state. These dinuclear complexes can be converted to the complexes with VO_2^+ motif simply by increasing the pH (~11) of the solution (with the addition of KOH) and to the complexes with VO^{3+} motif by adding a monobasic bidentate strong chelating ligand (viz., Hhq). This study also indicates that the substituents(R) have significant effect on controlling the spectroscopic and electro-chemical properties of vanadium in these oxo-bridged dinuclear complexes. The dioxovanadium(V) complexes are reduced reversibly by the ascorbic acid under aerobic condition which is biologically important particularly in relation to insulin enhancing activity.

ABSTRACT

The highly luminescent polynuclear Cu^{I} iodide complexes, $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_2 \cdot 4H_2O$ (**1**), $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_\infty$ (**2**), $[(Cu_2I_2)(4,4'\text{-bipy})(dcpm)]_\infty$ (**3**) and $[(Cu_2I_2)(4,4'\text{-bipy})(dppm)]_\infty$ (**4**), were prepared by reacting CuI with tricyclohexylphosphine (PCy_3), bis(dicyclohexylphosphino)methane (dcpm) or bis(diphenylphosphino)methane (dppm) and 4,4′-bipyridine (4,4′-bipy), and their structures were determined by X-ray crystal analysis. The reported complexes $[CuClPCy_3]_2$ (**5**) and $[CuIPCy_3]_2$ (**6**) were also prepared for comparison. In solid state, complexes **1**–**6** display intense long-lived phosphorescence with λ_{max} at 605, 565, 640, 570, 430 and 450 nm at room temperature, and the solid-state emission quantum yields are 0.11, 0.20, 0.29, 0.35, 0.67 and 0.83, respectively. The relatively high-energy emissions of **5** and **6** are attributed to arising from metal-centered MC ($3d \rightarrow 4s, 4p$) excited state, while the low-energy emissions of **1**–**4** are assigned to a metal-to-ligand charge transfer ($d \rightarrow \pi^*$ MLCT) excited state.

1. Introduction

Copper(I) complexes of polypyridyl ligands, such as $[Cu(diimine)_2]^+$, have been extensively studied for their potential applications in photocatalysis, molecular electronics and materials science [1–4]. The structures of polynuclear Cu^{I} complexes formed by the reaction of CuX and phosphine or bulky nitrogen organic base have been described previously [5–11]. All these complexes contain μ_2 or μ_3-bridging X atoms, and their structures are dependent upon the phosphine or nitrogen donor auxiliary ligands. The complexes $[CuXPCy_3]_2$ (X = Cl, I) are neutral dimeric species, they have been structurally characterized but no photophysical properties have been reported [12]. Recent studies showed that polynuclear Cu^{I} complexes containing halide and phosphine ligands have intriguing structures and rich photoluminescent properties [13–15]. Examples of these copper(I) complexes having Cu centers arranged in a tetrahedron with the tetrahedral faces capped by halides are known [16]. There are also examples of polymeric copper(I) complexes having a "stairstep" configuration [17]. In the case of $[(CuI)_4(dcpm)_2]$, the peripheral dcpm and iodide ligands bridge each edge of the Cu_4 plane to form a $Cu_4P_4I_2$ core [18]. In general, polynuclear Cu^{I} complexes with phosphine and halide ligands have multiple emissive excited states, which were assigned to the excited state with either metal-to-ligand charge-transfer MLCT or ligand-to-metal charge-transfer XMCT, or a mixture of halide-to-copper and metal-centered MC charge-transfer parentage [19]. Ford and Vogler had reported detailed studies on the photophysical properties of the tetranuclear cubane CuX clusters with dpmp (dpmp = 2-(diphenylmethyl)pyridine) and Py (Py = pyridine) ligands [20]. The relatively higher energy emissions for the complexes $Cu_4X_4L_4$ at 440–500 nm were attributed to coming from halide-to-ligand charge-transfer XLCT excited states, whereas the longer wavelength emissions at 570–630 nm were assigned to originate from excited states with mixed XMCT and MC orbital parentages [21]. In this work, we report the structures and spectroscopic properties of the polynuclear Cu^{I} complexes, $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_2 \cdot 4H_2O$ (**1**), $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_\infty$ (**2**), $[(Cu_2I_2)(4,4'\text{-bipy})(dcpm)]_\infty$ (**3**) and $[(Cu_2I_2)(4,4'\text{-bipy})(dppm)]_\infty$ (**4**). The photophysical properties of the reported complexes $[CuClPCy_3]_2$ (**5**) and $[CuIPCy_3]_2$ (**6**) were also examined for comparison purpose, but their syntheses and crystal structures would not be described in this paper [12].

2. Experimental

The CuX (Aldrich), 4,4′-bipyridine (Aldrich), PCy_3 (Strem), dcpm (Strem) and dppm (Aldrich) were used as received. Solvents (HPLC grade) used in the spectroscopic procedure were dried over suitable reagents and distilled under an argon atmosphere immediately prior to use.

2.1. Preparation of $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_2$ (**1**) and $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_\infty$ (**2**)

To a suspending solution of CuI (0.095 g, 0.5 mmol) in dichloromethane (15 mL) was added solid 4,4′-bipyridine (0.039 g, 0.25 mmol). The mixture was stirred for 4 h, and then PCy_3 (0.14 g, 0.5 mmol) in dichloromethane (5 mL) was added to the yellow suspending solution. The mixture became red immediately and the yellow suspension dissolved gradually. The resulting solution was stirred for another 2 h and then filtered. The reaction mixture was concentrated in vacuum and the crude product was recrystallized from CH_2Cl_2/diethyl ether to give the orange crystals of complex **1**. 0.173 g (63%). ^{31}P NMR ($CDCl_3$): δ 51.5. *Anal.* Calc. $C_{92}H_{148}N_4P_4Cu_4I_4$ (powders): C, 50.33; H, 6.80; N, 2.55. Found: C, 50.28; H, 6.91; N, 2.59%. If the preparation of complex **1** was processed by refluxing in dichloromethane, complex **2** were obtained. 0.195 g (71%). ^{31}P NMR ($CDCl_3$): δ 51.7. *Anal.* Calc. $(C_{46}H_{74}N_2P_2Cu_2I_2)_\infty$: C, 50.33; H, 6.80; N, 2.55. Found: C, 50.42; H, 6.71; N, 2.61%.

2.2. Preparation of $[(Cu_2I_2)(4,4'\text{-bipy})(dcpm)]_\infty$ (**3**) and $[(Cu_2I_2)(4,4'\text{-bipy})(dppm)]_\infty$ (**4**)

Complex **3** was synthesized by adding excess 4,4′-bipyridine (0.078 g, 0.5 mmol) to a suspending solution of CuI (0.095 g, 0.5 mmol) in dichloromethane (20 mL). The mixture was stirred for 2 h, and dcpm (0.102 g, 0.25 mmol) in dichloromethane (5 mL) was then added to the yellow suspending solution. The mixture became red gradually. The product was separated by filtration, and the crude product was recrystallized from CH_2Cl_2/$CHCl_3$/diethyl ether to give the red crystals. 0.137 g (58%). ^{31}P NMR ($CDCl_3$): δ −2.8. *Anal.* Calc. $(C_{35}H_{54}N_2P_2Cu_2I_2)_\infty$: C, 44.45; H, 5.76; N, 2.96. Found: C, 44.51; H, 5.73; N, 3.05%. The orange crystals of complex **4** were prepared following the same procedure as **3** except that dppm was used. 0.154 g (67%). ^{31}P NMR ($CDCl_3$): δ −20.8. *Anal.* Calc. $(C_{35}H_{30}N_2P_2Cu_2I_2)_\infty$: C, 45.62; H, 3.28; N, 3.04. Found: C, 45.54; H, 3.36; N, 3.14%.

2.3. Calculation details

All calculations were carried out at the GAUSSIAN 03 package in Virtual Laboratory for Computational Chemistry, CNIC, CAS at the B3LYP level [22,23]. The basis sets which contained in G03 library used for C, P, N and H atoms was 6-31G(d) while effective core potentials with a LanL2DZ basis set of G03 were employed for transition metals. The 6-311G (d) basis set for I, Cl was downloaded from the EMSL basis set library [24]. The contour plots of MOs were obtained with the Gauss View 3.07 program.

2.4. Instrumentation and physical measurements

Electronic absorption spectra were recorded at ambient temperature with a HP8453 UV–Vis spectrophotometer. Crystals of suitable size were mounted either on glass fibres or in capillary tubes. X-ray data were collected either on an MAR PSD for **1**, a Rigaku Saturn for **2**, or a Bruker SMART diffractometer for **3** and **4**. Intensity data were collected by ω-2θ scans technique. The images were interpreted and integrated using program of DENZO [25]. The structures were solved by Direct method (SIR92) or Patterson method (PATTY) and expanded by Fourier method [26]. Structural refinement on F or F^2 by full-matrix least square analysis was performed using the SHELXL 97 program [27]. The ORTEP drawings of the structures were displayed with hydrogen atoms omitted for clarity. The unweighted and weighted agreement factors (R_f, R_w) and the goodness of fit are calculated. Crystal data and details on data collection and refinement are summarized in Table 1.

Corrected emission spectra were obtained on a Spex Fluorolog-2 Model F III A1 fluorescence spectrofluorometer adapted to a right-angle configuration. Filters of suitable bandpass were used to cut off the second harmonic of the monochromatic excitation light source and stray light. Solutions for emission measurements were degassed by at least four freeze–pump–thaw cycles. Low-temperature (77 K) emission spectra for glass- and solid-state samples were recorded for 5-mm diameter quartz tubes which were

placed inside a liquid nitrogen bath contained in a quartz optical Dewa flask.

Measurement of emission quantum yields of powdered samples involves determining the diffuse reflectance of complexes **1**–**6** relative to KBr at the excitation wavelength [28]. The measured results were corrected according to the relative response of the detector as a function of wavelength. Emission lifetimes of solid or solution samples were performed with a Quanta Ray DCR-3 Nd-YAG laser with pulse-width of 8 ns and excitation wavelength of 266 nm (fourth harmonic). Emission signals were collected at right angles to the excitation pulse by a Hamamatsu R928 photomultiplier tube and recorded on a Tektronix model 2430 digital oscilloscope.

3. Results and discussion

3.1. Description of the structures

The photophysical properties of CuX complexes with phosphine and/or bulky nitrogen organic base ligands have received considerable interest over the past decades. The complexes $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_2 \cdot 4H_2O$ (**1**) and $[(Cu_2I_2)(4,4'\text{-bipy})(PCy_3)_2]_\infty$ (**2**) were both obtained by reacting CuI with tricyclohexylphosphine and 4,4′-bipyridine in stoichiometric ratio of 1:1:0.5 in dichloromethane solutions. When the reaction was conducted at room temperature, **1** was isolated with two water molecules of crystallization. In contrast, the 1-D complex **2** was obtained from the reaction in refluxing dichloromethane solution. Their structures have been determined by X-ray crystal analysis. Perspective views of the molecules are depicted in Figs. 1 and 2, and their bond lengths and angles are given in Table 2. The asymmetric unit of complex **1** consists of half the molecule and the whole molecule is generated by inversion, as shown in Fig. 1. Complex **1** contains a 22-membered ring, and can be viewed as two $[CuIPCy_3]_2$ fragments connected by two bridging 4,4′-bipyridine ligands. In contrast, **2** consists of $[(Cu_2I_2)(PCy_3)_2]$ subunits bridged by 4,4′-bipyridine ligands into an infinite chain, being similar to that of $[(Cu_2I_2)(4,4'\text{-bipy})(PPh_3)_2]_\infty$ [29]. The Cu atoms of **1** and **2** have a distorted tetrahedral configuration. The distortion from tetrahedral geometry is evidenced by the wider P–Cu–N angle (123.2(2)°) and the narrower I–Cu–N (101.6(2)°), I–Cu–I (103.17(4)°) ones for **1**, and P–Cu–N (119.40(7)°), I–Cu–N (102.03(7)°) and I–Cu–I (105.14 (2)°) ones for **2**. Both complexes exhibit symmetric CuI_2Cu core. The average Cu–I bond lengths of 2.727 Å for **1**, and 2.680 Å for **2** are slightly longer than those of 2.573 Å in **6**. The average Cu–I–Cu angles in both **1** (72.48°) and **2** (77.00°) are slightly larger than that of **6** (70.97°). Complex **1** has a Cu···Cu distance of 3.224(2) Å, whereas different Cu···Cu distances of 3.267(0) and 3.404(1) Å are found in **2**. We note that the two pyridyl rings of 4,4′-bipyridine in **2** are twisted with a dihedral angle of 27.6°, while the 4,4′-bipyridine in **1** is almost coplanar.

The preparation of $[(Cu_2I_2)(4,4'\text{-bipy})(dcpm)]_\infty$ (**3**) and $[(Cu_2I_2)(4,4'\text{-bipy})(dppm)]_\infty$ (**4**) are similar to that of **1** except that the PCy_3 ligand is replaced by bridging dcpm or dppm ligand. Perspective views of **3** and **4** are depicted in Figs. 3 and 4, respectively. Selected bond lengths and angles of the complexes are listed in Table 2. The structures of **3** and **4** consist of 1-D [–Cu(P^P) $(\mu_2\text{-I})_2$Cu(4,4′-bipy–)] zig-zag chains. The [–Cu(P^P)$(\mu_2\text{-I})_2$Cu(4,4′-bipy–)] unit as the building block contains two 6-membered rings with bridging biphosphine and iodide lignds, and a distorted square –Cu$(\mu_2\text{-I})_2$Cu– unit with torsion angles being 36.25(2)° and 41.75(2)° in **3** and **4**, respectively (Fig. 4). In contrast, for **4** there are two crystallographically non-equivalent chains. The Cu···Cu distances in **3** (2.7110 Å) and **4** (2.7706 Å) are slightly shorter than that in **6** (2.8925 Å), while the Cu–I–Cu bond angles are 59.91(2)° for **3** and 61.41(2)° for **4**. The coordination geometry of the Cu^I center in **4** is much close to tetrahedron with bond angles varying from 104.91(7)° to 114.16(8)°, whereas those angles of **3** vary from 100.99(7)° to 123.37(8)°. The two pyridyl rings of bridging 4,4′-bipy ligand are twisted with dihedral angles being 29.3(4)° and 26.3(4)° for **3** and **4**, respectively.

3.2. Electronic absorption spectra

The UV–Vis absorption spectral data for **1**–**6** in acetonitrile or dichloromethane solutions are summarized in Table 3 and the absorption spectra are depicted in Fig. 5. For **5** and **6**, the electronic absorption spectra in dichloromethane show high-energy absorption peaks at 233 nm with tails extending to ca. 320 nm. A definitive assignment of the UV absorption is difficult due to the strong absorption of the ligands. However, density functional theory (DFT) calculation showed HOMO–LUMO gaps are 223.5 and 235.7 nm for **5** and **6**, respectively. This is consistent with the experimental results described as MC (metal-centered) transition (Fig. 6). The DFT investigations of complexes **2**–**4** containing bipy ligand show that the character of the HOMO is dominated by metal orbitals with iodide contribution, whereas the LUMO is mainly localized on the pyridyl rings and displays π^* character (Fig. 6). The energy gaps were calculated for **2**–**4**, being 337, 392 and 397 nm, respectively. The calculated wavelength nicely correlates with the presence of the broad absorption bands measured at 350–390 nm in dichloromethane solutions of **1**–**4**. Thereby, the low-energy absorptions are assigned to a MLCT ($Cu^I \rightarrow$ 4,4′-bipyridine) transition.

Complexes **5** and **6** have vacant coordination site at Cu^I, allowing for substrate-binding reactions. As depicted in Fig. 5, the absorption bands of **5** and **6** in acetonitrile solutions are red-shifted from 260 and 270 nm in dichloromethane to 275 and 286 nm, respectively, indicating the coordination of CH_3CN to Cu^I centers. Furthermore, this absorption band around 360 nm of **1** and **2** in dichloromethane is not present in acetonitrile solutions (**3** and **4** being sparely soluble). Indeed, the similarity of the absorption spectra for complexes **1**, **2**, **5** and **6** in acetonitrile solutions suggests that the substitution of 4,4′-bipyridine by CH_3CN solvent molecule occurs in the case of **1** and **2**.

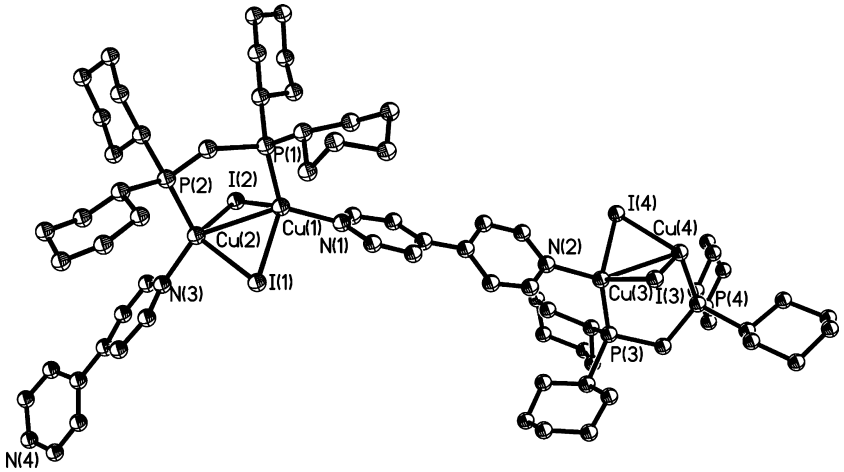

Fig. 3. Perspective view of $[(Cu_2I_2)(4,4'\text{-bipy})(dcpm)]_\infty$ (30% probability ellipsoids).

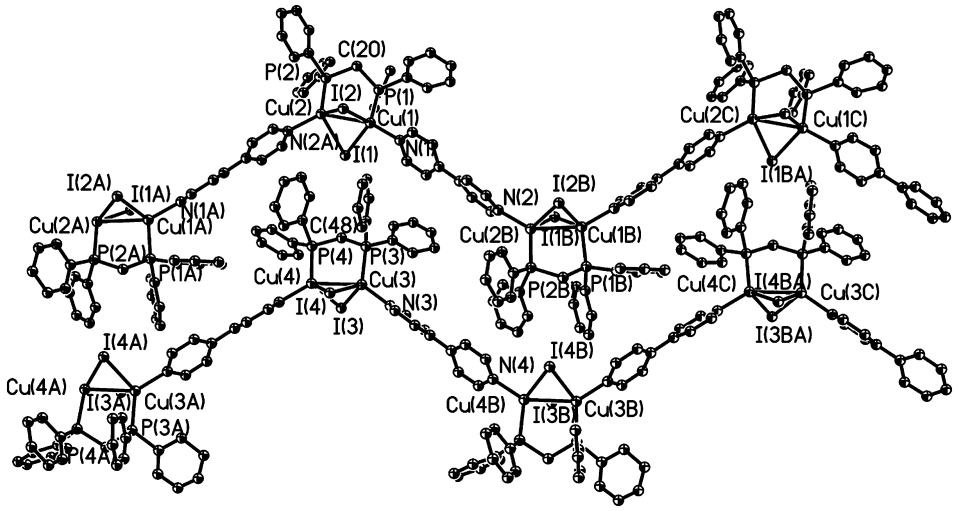

Fig. 4. Perspective view of $[(Cu_2I_2)(4,4'\text{-bipy})(dppm)]_\infty$ (30% probability ellipsoids).

3.3. Emission spectra

Upon excitation at 330 nm, **1**–**6** exhibit intense photoluminescence with λ_{max} at 605, 565, 640, 570, 430 and 450 nm and the measured emission quantum yields are 0.11, 0.20, 0.29, 0.35, 0.67 and 0.83 in the solid state at room temperature, respectively (Figs. 7 and 8). The high solid-state emission quantum yields of **5** and **6** suggest that the $[CuXPCy_3]_2$ solids can be useful as blue light emitting materials. The spectral data are summarized in Table 3. The emissions have lifetimes on the microsecond timescale, implying that these emissions originate from triplet excited state. We propose that the relative high-energy emissions for **5** and **6** originate from metal-centered 3d → (4s, 4p) triple excited state, and the low-energy emissions for **1**, **2**, **3** and **4** are from the triplet-parentage MLCT excited state, assignment of the latter is based on the results of DFT calculations and the fact that the emission maxima for **1**–**4** are red-shifted from that of **6** [30].

The solid state of complexes **1** and **2** at 77 K exhibits intense luminescences at 640 and 580 nm which are ascribed to phosphorescence derived from the ^{3}MLCT state. Whereas complex **6** displays two intense emission bands centered at 455 and 395 nm in solid state at 77 K, which are similar to the solid emissions of the reported $[(CuI)_4(pyridine)_4]$, $[(CuI)_3(dcpm)_2]$, and $[(CuI)_4(dcpm)_2]$ complexes at 77 K [18,31]. In butyronitrile glassy solution at 77 K, both of **5** and **6** exhibit two emission bands at 400, 480 nm and 390, 480 nm, respectively. The low-energy emission centered at 480 nm is tentatively attributed to solvent exciplex formation. All complexes are non-emissive in dichoromethane or acetonitrile solutions.

4. Conclusion

In this work, we obtained four new polynuclear Cu^I complexes by reacting CuI with 4,4′-bipyridine and tricyclohexylphosphine, bis(dicyclohexylphosphino)methane or bis(diphenylphosphino)-methane. Their crystal structures and photophysical properties have been examined. Also, we have examined the spectroscopic properties of the related $[CuClPCy_3]_2$ and $[CuIPCy_3]_2$ complexes. All of the complexes exhibit intense phosphorescent emissions with λ_{em} varying 430–640 nm in solid state at room temperature. These emissions were attributed to arising from metal-centered MC (3d → 4s, 4p) excited state for **5** and **6**, and a triplet-parentage MLCT (Cu^I → 4,4′-bipyridine) excited state for **1**–**4**. The successful preparation of these Cu^I complexes with relatively high emission quantum yields in solid state provides great potential for light emitting materials.

Azosalophen complex

ABSTRACT

The ligands 2-(arylazo)-1-*N*-salicylidene phenylamine, H_2L_{sal}, (where H represents the dissociable protons upon complexation) afford stable orthopalladated complexes, $[(L_{sal})Pd]$, upon treatment with $Na_2[PdCl_4]$. The dinegative anionic $(L_{sal})^{2-}$ ligands bind Pd(II) in a tetradentate (C, N, N, O) fashion with a distorted square planar geometry. The newly synthesized palladium complexes underwent oxygen insertion into the Pd–C bond with *m*CPBA (*m*-chloroperbenzoic acid) or TBHP (terbutylhydroperoxide)/$[VO(acac)_2]$ leading to the formation of stable *azosalophen* complexes of Pd(II) with the (O, N, N, O) coordination mode of the oxygenated ligand.

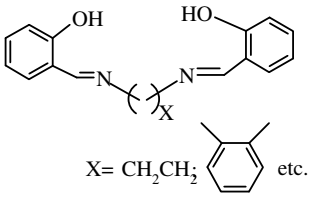
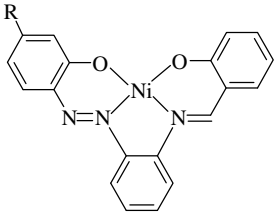
1. Introduction

The synthesis of target molecules via metal assisted routes is an important area of current chemical research [1]. Interest in the chemistry of transition metal complexes incorporating the *salen* type of ligands, **1**, has accelerated research in this area during the last few years due to the discovery of their catalytic properties – towards alkene epoxidation in particular [2].



1



2

Studies on tuning the catalytic activity of such complexes by modifying the ligand backbone are under progress. As a consequence, developments in the area of asymmetric epoxidation of unfunctionalised alkenes are remarkable [3]. Recently, we have reported the synthesis and properties of Ni(II) complexes incorporating new *azosalophen* ligands, **2** [4]. Although the *azosalophen* ligands are analogous to *salen*-like ligand systems in terms of coordination mode, there are significant differences in the characteristics of the donor atoms. The Ni(II)-*azosalophen* complexes could be prepared via orthonickelation followed by O-insertion into the Ni-C(aryl) bond with peroxo oxygen donors [4]. As described earlier, issues relating to O-insertion with peroxo reagents needed to be studied more extensively [4]. The inquisitiveness to such issues and our desire to prepare *azosalophen* complexes of a heavier congener of the group 10 elements (*i.e.* Pd(II)) prompted us to carry out this work.

Herein we report the synthesis and structure of new orthopalladated complexes of tetradentate (C, N, N, O) azo-aldimine ligands and the reactions of the newly synthesized Pd-C (aryl) bonded compounds with peroxo reagents, *viz.* *m*CPBA and TBHP, to obtain Pd(II) analogues of **2**.

2. Results and discussion

2.1. Syntheses and characterization of cyclopalladated $[(L_{sal})Pd]$ complexes

The reaction of H_2L_{sal}, **3**, with sodium tetrachloropalladate, $Na_2[PdCl_4]$, in warm methanol afforded the orthopalladated complexes $[(L_{sal})Pd]$, **4** (Eq. (1)). The analytical and spectroscopic data matched well with the formulation. The structure was confirmed by X-ray studies on $[(L^3{}_{sal})\ Pd]$ (see below) as a representative example.

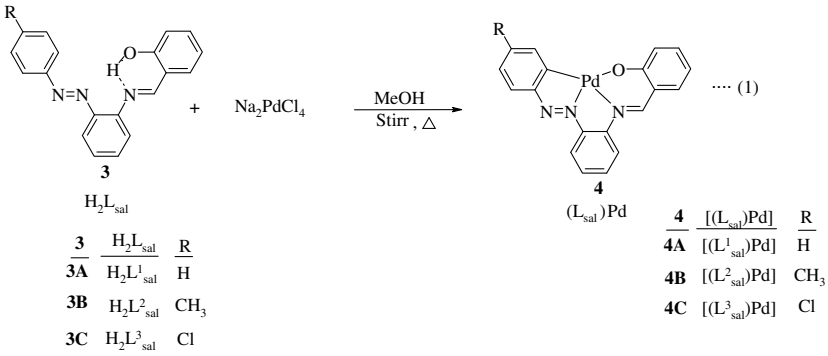
eqn (1)



H_2L_{sal}

3	H_2L_{sal}	R
3A	$H_2L^1_{sal}$	H
3B	$H_2L^2_{sal}$	CH_3
3C	$H_2L^3_{sal}$	Cl

4	[(L_{sal})Pd]	R
4A	[(L^1_{sal})Pd]	H
4B	[(L^2_{sal})Pd]	CH_3
4C	[(L^3_{sal})Pd]	Cl

The *bi*- and *tri*-dentate azo and imine ligands [5–7] have been demonstrated to form orthopalladated complexes, as given in Chart 1 (**5**–**9**). The complexes of type **9** are good examples where orthopalladation occurs in tridentate azo–imine ligand systems [5d]. It is worthwhile to mention, in this context, that [(L_{sal})Pd], **4**, are a type of orthopalladated complex incorporating tetradentate azo–imine ligands and the coordination mode (C, N, N, O) is also new.

The orange–brown solutions of the [(L_{sal})Pd] complexes in dichloromethane (CH_2Cl_2) display characteristic UV–Vis spectra with several structured absorption bands within the region 300–500 nm for MLCT transitions. A representative UV–Vis spectrum of [(L^2_{sal})Pd], **4B**, is shown in Fig. 1. The spectral data are collected in Section 3 and the spectra of the other complexes are given in Figs. S1–S3 (supplementary).

The $\nu_{C=N}$ and $\nu_{N=N}$ bands of the [(L_{sal})Pd] complexes are shifted to lower wavenumbers (~1605 and ~1430 cm^{-1}, respectively) than those of the ligands (~1615 and ~1452 cm^{-1}, respectively), consistent with the coordination of the aldimine (N=CH) and azo (N=N) nitrogens [4]. The IR spectral data of all the [(L_{sal})Pd] complexes are collected in Section 3 and the spectra are given in Figs. S4–S6.

The atom numbering scheme for the ^1H NMR spectral analysis is given in Fig. 3 (see below). The ^1H NMR spectra show that the aldimino proton (N=CH) of the [(L_{sal})Pd] complexes shifts marginally upfield (δ 8.43–8.57) relative to the ligands (~δ8.62) [4]. The –OH signal of the free ligands (~δ13.60) [4] is absent in the palladium complexes indicating deprotonation of the phenolic groups and their coordination to the metal as phenoxide. Twelve aromatic protons of [(L^1_{sal})Pd] (**4A**) appear within the δ 6.57–7.85 range. The ^1H NMR spectrum of [(L^2_{sal})Pd] (**4B**), and [(L^3_{sal})Pd] (**4C**), are less complicated in the aromatic region. The disappearance of two doublet resonances for 3, 5-H and 2, 6-H of the $H_2L^2_{sal}$ and $H_2L^3_{sal}$ ligands in **4B** and **4C** were

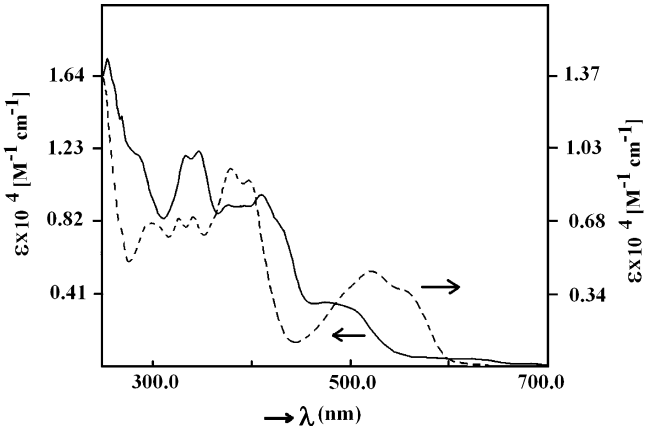


Fig. 1. UV–Vis spectra of **4B** (—) and **10B** (- - -). The arrows indicate the scales of the corresponding spectra.

attributed to the metallation at the ortho carbon of the pendant aryl ring. Unfortunately the singlet for 3H did not separate from the other aromatic proton resonances in the spectra of **4B** and **4C**. The ^1H NMR spectra of [(L_{sal})Pd] are given in Figs. S7–S9 and data are collected in Section 3.

The electrospray mass spectrum (HRMS-QTOF) in CH_2Cl_2 solution (positive mode) was recorded for [(L^3_{sal})Pd], **4C**, as a representative example (Fig. 2). The mass spectrum is consistent with the composition and molecular mass. The major envelope could be simulated satisfactorily (Fig. 2b) on the basis of the formula $C_{19}H_{12}N_3PdOCl$.

Unequivocal characterization of the orthometallated complexes, [(L_{sal})Pd], was performed by X-ray analysis of [(L^3_{sal})Pd]

N(2)–Pd(1)–N(3)	82.74(14)	Pd(1)–N(3)–C(8)	111.4(3)

(**4C**). Fig. 3 shows the perspective view of the molecular structure. Table 1 contains selected bond distances and angles. The dinegative anion $(L^3_{sal})^{2-}$ binds the Pd(II) centre in a distorted square planar geometry.

The Pd(C, N, N, O) coordination sphere of the [(L^3_{sal})Pd] molecule is planar with a maximum deviation of 0.08 Å from the least square plane. The planar molecules in the asymmetric unit are held as weak staggered dimers with Pd–Pd distances of 3.197 Å, as shown in Fig. 4.

The dimers are arranged in a stair-like manner where the inter dimer Pd–Pd distance is 6.296 Å. Pd–C 2.002(4) Å and Pd–O 1.995(3) Å distances are within the normal range [5a,7]. Between the Pd–N(azo) and Pd–N(imine) distances, the former is shorter due to either stronger π-backbonding or a stronger *trans* influence of carbon [8,9c] compared to the phenoxide oxygen.

2.2. Syntheses and characterization of [(OL_{sal})Pd] from [(L_{sal})Pd]

The new oxygenated complexes, [(OL_{sal})Pd] (**10**), were prepared by the highly selective metaloxylation [10] of [(L_{sal})Pd] with

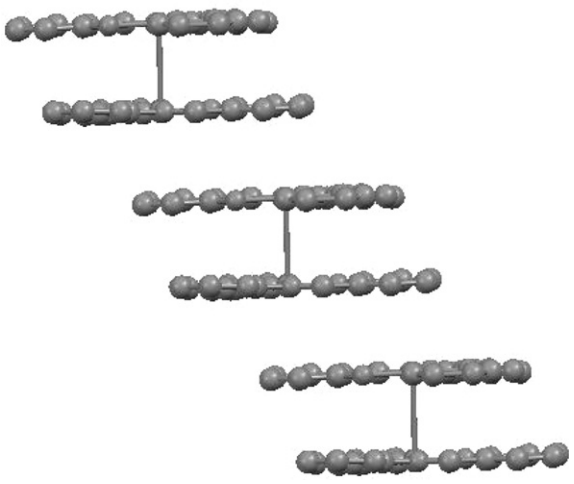

Fig. 4. Packing of [(L^3_{sal})Pd] showing the stair-like arrangement of planar molecules. The line between a pair indicates the weak Pd···Pd interaction at a distance of 3.206 Å

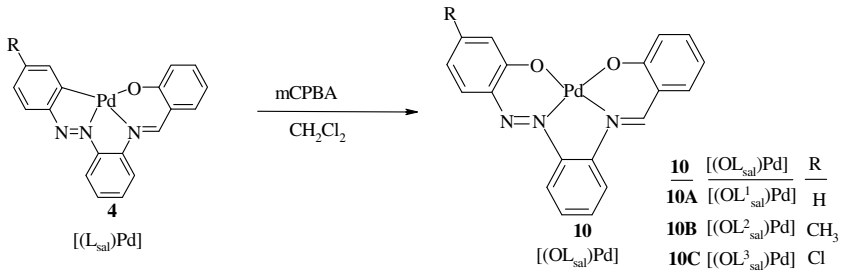

Scheme 1.

*m*CPBA. The oxygen insertion into the Pd–C bond of [(L$_{sal}$)Pd] occurred upon treatment with *m*CPBA in dichloromethane solvent at room temperature to afford diamagnetic and electro neutral Pd(II) complexes, [(OL$_{sal}$)Pd] (Scheme 1). The formation of the [(OL$_{sal}$)Pd] complexes from [(L$_{sal}$)Pd], was monitored spectrophotometrically up to the extent of ~75% conversion. Nevertheless, after every reaction, the pure [(OL$_{sal}$)Pd] complex was isolated in ~50% yield on employing a conventional purification procedure on a silica gel preparative TLC plate. Although the large difference between the spectrophotometric and isolated yields could not be accounted for, it was believed that a transformation on the silica gel TLC plate may be one of the reasons, since the pure products separated well leaving unidentified materials at the bottom of the plate.

The metaloxylated complexes, [(OL$_{sal}$)Pd], displayed two characteristic low energy overlapping absorptions near 560 and 520 nm in contrast to the parent orthopalladated complexes. Representative spectra of [(OL$^2_{sal}$)Pd] and [(L$^2_{sal}$)Pd] are given in Fig. 1 for comparison. There are six MLCT absorptions for [(OL$_{sal}$)Pd] in the 300–560 nm range. UV–Vis spectral data are collected in Section 3 and the spectra are given in Figs. S10 – S12.

The $\nu_{C=N}$ and $\nu_{N=N}$ stretches for the [(OL$_{sal}$)Pd] complexes appear in the ranges 1605–1607 cm^{-1} and 1430–1445 cm^{-1}, indicating the coordination of the azo (N=N) and aldimine (N=CH) nitrogen donors [4]. The IR spectra are given in Figs. S13–S15 and the spectral data are collected in Section 3.

The ^{1}H NMR spectra of the [(OL$_{sal}$)Pd] complexes feature the aldimine (N=CH) proton resonance near δ 8.60, indicating the intactness of the azo-methine function upon treatment with *m*CPBA. The spectral patterns for the aromatic protons of [(OL$_{sal}$)Pd] are similar to the parent [(L$_{sal}$)Pd] complexes, but there are expected mismatches in the chemical shifts. The singlet for 3-H separated well in the case of [(OL$^2_{sal}$)Pd] indicating substitution at C3. The ^{1}H NMR spectral features for the aromatic protons of all the complexes are consistent with their formulation and structures. Data are collected in Section 3 and the ^{1}H NMR spectra are given in Figs. S16–S18.

The electrospray mass spectrum in CH_2Cl_2 solution (positive mode) has been recorded for [(OL$^3_{sal}$)Pd] as a representative example. The mass spectrum is consistent with the composition and molecular mass. The major envelope could be simulated satisfactorily on the basis of the formula $C_{19}H_{13}N_3PdO_2Cl$ (Fig. 5).

The difference of 16 units between the masses of [(L$^3_{sal}$)Pd] and [(OL$^3_{sal}$Pd)] justified the O-insertion into the Pd–C bond.

Reaction of (L$_{sal}$)Pd (**4**) with *t*-butylhydroperoxide (TBHP) in protic (^{t}BuOH) or aprotic (CH_2Cl_2) solvents did not afford the metaloxylated complexes, [(OL$_{sal}$)Pd] (**10**), whereas in the presence of a catalytic amount of [VO(acac)$_2$] the metaloxylation reaction occurred in both CH_2Cl_2 or ^{t}BuOH solvents. Thus the oxygen transfer process has been assumed to take place via an *in situ* formation of a vanadium-peroxo species. The oxygen insertions into the Pd–C bond with *m*CPBA for orthopalladated complexes incorporating

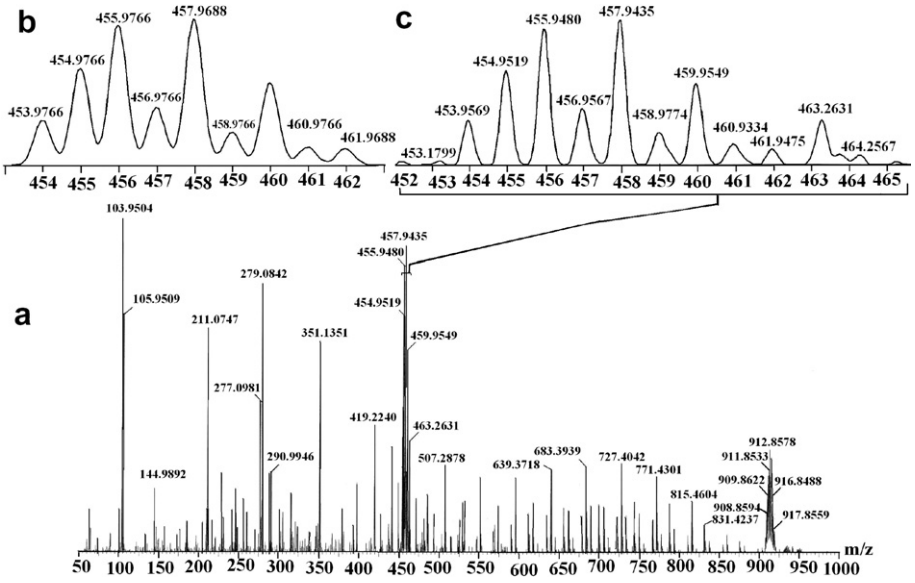

Fig. 5. (a) Electrospray mass spectrum (positive mode) of [(OL$^3_{sal}$)Pd] in CH_3CN. (b) Simulated spectrum of [(OL$^3_{sal}$)Pd]. (c) Enlarged view of the major envelope of the original spectrum.

azobenzene and related ligands were reported earlier [10]. TBHP induced oxygen insertion is hitherto unknown for such complexes.

3. Experimental

3.1. Materials

The solvents used in the reactions were of reagent grade obtained from E. Merck, Kolkata, India and were purified and dried by reported procedures [11]. Palladium chloride was purchased from Arora Matthey (India). H_2O_2 (6%, 50% in aqueous solution) was purchased from E. Merck, Kolkata, India. *m*CPBA (~70%) (the activity of *m*CPBA was determined iodometrically before use and it was 47.5%) and TBHP (~70%) were obtained from Aldrich, USA and used as received. Disodium tetrachloropalladate was prepared by a reported procedure [12]. 2-(Arylazo) aniline was prepared according to the procedure described earlier [12].

3.2. Syntheses of the complexes [(L_{sal})Pd] (**4**)

The complexes [(L^1_{sal})Pd], [(L^2_{sal})Pd] and [(L^3_{sal})Pd] (**4A**, **4B** and **4C**) were prepared by a similar procedure. The details for the preparation of **4A** are given below.

3.2.1. [(L^1_{sal})Pd] (**4A**)

A solution of $H_2L^1_{sal}$ (104 mg, 0.346 mmol) in 10 mL ethanol was added to a solution of Na_2PdCl_4 (100 mg, 0.346 mmol) in 20 mL ethanol. The mixture was stirred for 12 h. The brown solid precipitate was separated by filtration and purified by preparative silica gel G TLC with binder. The eluent was benzene. Upon evaporation of the solvent, the brown solid of pure **4A** was obtained (83 mg, 60% yield). IR (KBr, cm^{-1}): ν(C=N) 1605, ν(N=N) 1375. ^{1}H NMR ($CDCl_3$, 500 MHz): δ 6.56 (t, 1H), 7.03 (t, 1H), 7.14 (t, 1H), 7.22 (d, 2H), 7.32 (t, 2H), 7.47–7.42 (m, 2H), 7.62 (d, 1H), 7.77 (d, 1H), 7.85 (d, 1H), 8.55 (s, 1H). Electronic spectrum (λ_{max}/nm (ε/dm^2 mol^{-1}) in CH_2Cl_2 solution): 500^{sh}, 496 (1910), 475 (2090), 427 (4990), 407 (6260), 372 (6530), 341 (8510), 332 (8690), 255 (12980). *Anal.* Calc. for $C_{19}H_{13}N_3OPd$: C, 56.29; H, 3.20; N, 10.37. Found: C, 56.33; H, 3.18; N, 10.40%.

3.2.2. [(L^2_{sal})Pd] (**4B**)

This complex was prepared following a similar procedure as described for **4A** using the ligand $H_2L^2_{sal}$ in place of $H_2L^1_{sal}$ (59 mg, 57% yield). IR (KBr, cm^{-1}): ν(C=N) 1606, ν(N=N) 1378. ^{1}H NMR ($CDCl_3$, 500 MHz): δ = 2.37 (s, 3H), 6.57 (t, 1H), 6.95 (d, 1H), 7.04 (d, 1H), 7.20–7.23 (m, 3H), 7.31 (t, 1H), 7.44 (t, 1H), 7.61 (d, 1H), 7.65 (d, 1H), 7.83 (d, 1H), 8.50 (s, 1H). Electronic spectrum (λ_{max}/nm (ε/dm^2 mol^{-1}) in CH_2Cl_2 solution): 500^{sh}, 490 (4150), 475 (4400), 430 (9640), 410 (11930), 377 (11200), 347 (15050), 334 (14712), 255 (17000). *Anal.* Calc. for $C_{20}H_{15}N_3OPd$: C, 57.23; H, 3.57; N, 10.02. Found: C, 57.30; H, 3.60; N, 10.08%.

3.2.3. [(L^3_{sal})Pd] (**4C**)

This complex was prepared following a similar procedure as described for **4A** using the ligand $H_2L^3_{sal}$ in place of $H_2L^1_{sal}$ (75 mg, 50% yield). IR (KBr, cm^{-1}): $\nu_{C=N}$ 1605, $\nu_{N=N}$ 1376. ^{1}H NMR ($CDCl_3$, 500 MHz): δ = 6.58 (t, 1H), 7.00 (d, 1H), 7.11(d, 1H), 7.12 (d, 1H), 7.18- 7.23 (m, 2H), 7.30–7.36 (m, 1H), 7.47 (t, 1H), 7.59 (d, 1H), 7.65 (d, 1H), 7.80 (d, 1H), 8.48 (s, 1H). Electronic spectrum (λ_{max}/nm (ε/dm^2 mol^{-1}) in CH_2Cl_2 solution): 500^{sh}, 496 (5100), 471 (5813), 429 (10610), 402 (12750), 379 (16060), 344 (19120), 331 (19460), 255 (28880). ESI-MS: *m*/*z* 440. *Anal.* Calc. for $C_{19}H_{12}N_3PdOCl$: C, 51.81; H, 2.72; N, 9.54. Found: C, 51.90; H, 2.78; N, 9.50%.

3.3. Syntheses of the complexes [(OL_{sal})Pd] (**10**)

All the [(OL_{sal})Pd] complexes (**10**) were prepared by a similar procedure. The details for the preparation of **10A** are given below.

3.3.1. [(OL^1_{sal})Pd] (**10A**)

A solution of (72 mg, 0.412 mmol) *m*CPBA was added dropwise to a stirred solution of **4A** (50 mg, 0.123 mmol) in 25 mL dichloromethane. Immediately, the color of the solution began to change from brown to pink. The stirring was continued for 30 min. Evaporation of the solvent under vaccuo afforded a pink solid mass. The solid mass thus obtained was washed thrice with diethyl ether, taking 5 mL for each wash. The product was then purified by preparative TLC using benzene as the eluent. The pink band was collected (57 mg, 55% yield). IR (KBr, cm^{-1}): ν(C=N) 1605, ν(N=N) 1377. ^{1}H NMR ($CDCl_3$, 500 MHz): δ = 6.67 (t, 1H), 6.83 (t, 1H), 7.32 (t, 1H), 7.36–7.43 (m, 4H), 7.46–7.49 (m, 1H), 7.84–7.86 (m, 2H), 8.31 (d, 1H), 8.57 (s, 1H). Electronic spectrum (λ_{max}/nm (ε/dm^2 mol^{-1}) in CH_2Cl_2 solution): 560 (6250), 526 (7800), 390^{sh}, 374 (16470), 343 (13600), 326 (13790), 300 (14260). *Anal.* Calc. for $C_{19}H_{13}N_3PdO_2$: C, 54.15; H, 3.08; N, 9.97. Found: C, 54.19; H, 3.10; N, 10.00%.

3.3.2. [(OL^2_{sal})Pd] (**10B**)

Complex **10B** was prepared using **4B** in place of **4A** by a similar procedure as described for **10A** (49 mg, 60% yield). IR (KBr, cm^{-1}): ν(C=N) 1606, ν(N=N) 1378. ^{1}H NMR ($CDCl_3$, 500 MHz): δ = 2.46 (s, 3H), 6.68 (t, 2H), 7.18 (s, 1H); 7.24 (d, 1H), 7.32 (t, 1H), 7.38-7.43 (m, 3H), 7.72 (d, 1H), 7.84 (d, 1H), 8.30 (d, 1H), 8.59 (s, 1H). Electronic spectrum (λ_{max}/nm (ε/dm^2 mol^{-1}) in CH_2Cl_2 solution): 554 (3400), 522 (13300), 398 (26500), 379 (28150), 341 (21030), 327 (20570), 298 (20460). *Anal.* Calc. for $C_{20}H_{15}N_3PdO_2$: C, 55.17; H, 3.44; N, 9.65. Found: C, 55.20; H, 3.40; N, 9.68%.

3.3.3. [(OL^3_{sal})Pd] (**10C**)

This complex was prepared following a similar procedure as described for **10A** using **4C** in place of **4A** (52 mg, 50% yield). IR (KBr, cm^{-1}): ν(C=N) 1605, ν(N=N) 1376. ^{1}H NMR ($CDCl_3$, 500 MHz): δ = 6.70 (t, 1H), 6.83 (d, 1H), 7.36 (t, 1H), 7.41–7.43 (m, 2H), 7.44–7.48 (m, 2H), 7.80 (d, 1H), 7.85 (d, 1H), 8.30 (d, 1H), 8.57 (s, 1H). Electronic spectrum (λ_{max}/nm (ε/dm^2 mol^{-1}) in CH_2Cl_2 solution): 562 (6150), 518 (10120), 398^{sh}, 341 (19340), 326 (17100), 300 (17510). ESI-MS: *m*/*z*, 456. *Anal.* Calc. for $C_{19}H_{12}N_3PdO_2Cl$: C, 50.00; H, 2.63; N, 9.21. Found: C, 50.12; H, 2.60; N, 9.16%.

3.4. Physical measurements

Electronic spectra were recorded on a Shimadzu UV-2401 PC spectrophotometer. IR spectra were taken on a Perkin–Elmer L120-00A FT IR spectrophotometer (4000–225 cm^{-1}) in KBr pellets. C, H, N analyses were performed on a Perkin–Elmer 240C elemental analyzer. NMR spectra were drawn on a Brucker Avance RPX 500 MHz spectrometer in $CDCl_3$ using TMS as the internal standard. ESI mass spectra were recorded on a micro mass Q-TOF mass spectrometer (Serial No. YA 263).

3.5. Crystallography

Crystals of [(L^3_{sal})Pd] were grown by slow evaporation of dicholoromethane solution at 298 K. Data were collected on a Brucker smart CCD diffractometer using Mo-Kα monochromator (λ = 0.71043 Å). Structure solutions were performed using the SHELX-97 PC version program. The full-matrix least square and anisotropic refinements were performed on all the atoms. Hydrogen atoms were included at calculated positions. The data collection parameters and relevant crystal data are collected in Table 2.

Table 2
Crystallographic data for complex **4C**

Chemical formula	$C_{19}H_{12}ClN_3OPd$
Formula weight	440.19
Crystal system	triclinic
Space group	$P\bar{1}$
a (Å)	7.5450(16)
b (Å)	12.390(3)
c (Å)	18.383(4)
α (°)	79.352(3)
β (°)	81.081(3)
γ (°)	74.006(3)
λ (Å)	0.71073
V (Å^3)	1613.6(6)
Z	4
Temperature (K)	293
ρ (Mg/m^3)	1.812
μ (mm^{-1})	1.328
R (all data)	0.0465
wR_2 [$I > 2\sigma(I)$]	0.1144
Goodness-of-fit	1.16

4. Conclusion

Synthesis of *metalloazosalophen* of Pd(II) could be carried out via orthopalladation followed by O-insertion. TBHP or *m*CPBA have been used for O-insertion. Although TBHP alone was unsuitable, in the presence of $[VO(acac)_2]$ the O-insertion occurred. Nevertheless, the oxygenated complex $[(OL_{sal})Pd]$ could not be demetallated using conventional techniques to obtain the free azosalophen, H_2OL_{sal}, ligand.

ABSTRACT

Reaction of PhHgOAc with *N*-NHCOC$_6$H$_5$–Htpp gave a bismercury(II) complex [((benzamido-κ*N*)phenylmercury-κ*Hg*–N^{21},N^{22})-*meso*-tetraphenylporphyrinato-N^{23},N^{24}]phenylmercury(II) toluene solvate [Hg(Ph)(N^{21},N^{22}–(Ph)–Hg–N(COPh)tpp · C$_6$H$_5$CH$_3$; **3** · C$_6$H$_5$CH$_3$] with Hg(1)–N(5) as N^{21},N^{22}-bridged atoms. The crystal structure of **3** · C$_6$H$_5$CH$_3$ was determined. The Hg(1)···Hg(2) distance is 3.611(7) Å. Hence, no metallophilic Hg(II)···Hg(II) interaction is present. **3** in CDCl$_3$ was characterized by ^{1}H, ^{13}C, and ^{199}Hg NMR. The ^{199}Hg NMR spectrum for **3** in CDCl$_3$ solution 20 °C clearly reveals that there are two different Hg nuclei, i.e. Hg(1) and Hg(2) and this NMR data provides an evidence that **3** remains as a bismercury species in CDCl$_3$ solution. The ^{199}Hg NMR spectrum for a 0.2 M solution of **3** in CDCl$_3$ at 20 °C is observed at −1088 ppm for Hg(2) nucleus with ^3J(Hg–H) = 188 Hz and an effective coordination number of five and at −1119 ppm for Hg(1) nucleus with ^3J(Hg–H) = 177 Hz and an effective coordination number of four. The proton and ^{199}Hg NMR spectra clearly show ^3J(Hg–H) coupling and these NMR data indicate no ligand exchange for **3** in CDCl$_3$.

1. Introduction

Pd complexes of N^{21},N^{22}-bridged porphyrins with a one-carbon (methano) bridge were isolated by Callot and co-workers [1]. Setsune et al. have shown that N^{21},N^{22}-etheno bridged porphyrin serves as a bidentate nitrogen base ligand for stable coordination to palladium for complexes [(1,2-diphenyletheno-N^{21},N^{22})-*meso*-tetraphenylporphyrinato-N^{23},N^{24}](η^3-allyl)palladium(II) chloride (**1a**) [2] and Pd^{II}(C(O)Me)(Cl)(N^{21},N^{22}-(PhC═CPh)(TPP)) (**1b**) [3], and to rhodium for complexes [N^{21},N^{22}-(PhC═CPh)(TPP)]Rh^I(COD)-ClO$_4$ (**2a**) (where COD = η^4-1,5-cyclooctadienyl) and [N^{21},N^{22}-(PhC═CPh)(TPP)]Rh^I(CO)$_2$ClO$_4$ (**2b**) (Chart 1) [4].

Organopalladium complexes **1a** and **1b** with bidentate nitrogen base ligands have recently been recognized as useful in enantioselective organic transformations and polymerization reactions [2]. Organomercury(II) compounds of the type PhHg$^+$ has received growing attention mainly related to the search for toxicological compounds and versatile reagents in controlled transmetallation reactions [5]. In view of the rich photochemistry and electrochemistry of porphyrins, it is of great interest to generate organomercury complex of porphyrin. A thorough review of the literature shows that there is no prior report on phenylmercury(II) with free base *N*-NHCOC$_6$H$_5$–Htpp [6]. The coordination chemistry of phenylmercury(II) explored with anions derived from base *N*-NHCOC$_6$H$_5$–Htpp reveal the formation of the phenylmercury(II) complex of [((benzamido-κ*N*)phenylmercury-κ*Hg*–N^{21},N^{22})-*meso*-tetraphenylporphyrinato-N^{23},N^{24}]phenylmercury(II) toluene solvate [Hg(Ph)(N^{21},N^{22}–(Ph)–Hg–N(COPh)tpp · C$_6$H$_5$CH$_3$; **3** · C$_6$H$_5$-CH$_3$]. Compound **3** · C$_6$H$_5$CH$_3$ is a new class of bismercury porphyrin complex with Hg(1)–N(5) ligand bidentately coordinated to N^{21},N^{22}-porphyrin and with Hg(2) as metal bridge (Fig. 1). We report here on the synthesis, ^{1}H, ^{13}C and ^{199}Hg NMR spectroscopic characterization of this novel bidentate porphyrin **3** as well as the crystal structure of it.

2. Experimental

2.1. [Hg(Ph)(N^{21},N^{22}–(Ph)–Hg–N(COPh)tpp · C$_6$H$_5$CH$_3$; **3** · C$_6$H$_5$CH$_3$]

A mixture of PhHgOAc (0.07 g, 2.1 × 10^{-4} mol, 98% from Acros) and *N*-NHCOC$_6$H$_5$–Htpp (0.073 g, 1.0 × 10^{-4} mol) in pyridine (10 cm^3) was stirred at 100 °C for 3 h [6]. After concentrating, the residue was dissolved in a suitable amount of toluene, dried over anhydrous Na$_2$SO$_4$ and filtered. The filtrate was concentrated and recrystallized from toluene–hexane [1:3 (v/v)] yielding blue solid

of **3** (0.08 g, 7×10^{-5} mol, 70%) which was again dissolved in toluene and layered with hexane to get blue crystals for single crystal X-ray analysis. ^{1}H NMR (299.95 MHz, $CDCl_3$, 20 °C): δ 8.95 [d, $H_β$ (2, 13), ^3J(H–H) = 4.2 Hz]; 8.77 [d, $H_β$ (3, 12), ^3J(H–H) = 4.2 Hz]; 8.47 [s, $H_β$ (7, 8)]; 7.07 [s, $H_β$ (17, 18)]; 8.49 [s, *o*′-H(38, 40) and *o*′-H(34, 44)]; 8.17 [s, *o*-H(26, 32)]; 8.02 [s, *o*-H(22, 28)]; 7.89-7.73 (m, *m*, *p*-H); 6.61 [t, Hg(1)–Ph–H_4 or H(55), ^3J(H–H) = 7.5 Hz]; 6.49 [t, Hg(1)–Ph–$H_{3,5}$ or H(54, 56), ^3J(H–H) = 7.5 Hz]; 6.39 [t, BA–Ph–H_4 or H(49), ^3J(H–H) = 7.5 Hz], where BA = benzamido group; 6.18 [t, BA–Ph–$H_{3,5}$ or H(48, 50), ^3J(H–H) = 8.1 Hz]; 6.07 [t, Hg(2)–Ph–H_4 or H(61), ^3J(H–H) = 7.5 Hz]; 5.84 [t, Hg(2)–Ph–$H_{3,5}$ or H(60, 62), ^3J(H–H) = 7.8 Hz and ^4J(Hg–H) = 54 Hz]; 5.03 [d, BA–Ph–$H_{2,6}$ or H(47, 51), ^3J(H–H) = 8.4 Hz]; 4.23 [d, Hg(1)–Ph–$H_{2,6}$ or H(53, 57), ^3J(H–H) = 7.8 Hz and ^3J(Hg–H) = 186 Hz]; 3.18 [d, Hg(2)–Ph–$H_{2,6}$ or H(59, 63), ^3J(H–H) = 7.8 Hz and ^3J(Hg–H) = 198 Hz]. ^{199}Hg NMR (107.24 MHz, $CDCl_3$, 20 °C): δ −1088 [t, Hg(2), ^3J(Hg–H) = 188 Hz]; −1119 [t, Hg(1), ^3J(Hg–H) = 177 Hz]. MS (FAB): M^+ 1287 (calcd for $C_{63}H_{43}Hg_2N_5O$: 1287). UV–Vis spectrum, λ(nm) [$\varepsilon \times 10^{-3}$ (M^{-1} cm^{-1})] in CH_2Cl_2: 448 (213), 462 (48.1), 620 (25.3).

2.2. Spectroscopy

Proton and ^{13}C NMR spectra in $CDCl_3$ (99.8% from Aldrich) were recorded at 299.95 (or 599.94) and 150.87 MHz, respectively, on Varian VXR-300 (or Varian Unity Inova-600) spectrometers locked on deuterated solvent, and referenced to the solvent peak. Proton NMR spectrum is relative to $CDCl_3$ at 7.24. ^{199}Hg NMR spectrum in $CDCl_3$ was obtained at 107.24 MHz at 20 °C on a Bruker DMX-600 spectrometer locked on deuterated solvent. Chemical shifts of ^{199}Hg NMR spectrum were measured relative to an external reference of 0.5 M phenylmercury(II) acetate in DMSO-d_6 (−1439.5 ppm) but reported relative to dimethylmercury (0.0 ppm). HMQC (heteronuclear multiple quantum coherence) was used to correlate protons and carbon through one-bond coupling and HMBC (heteronuclear multiple bond coherence) for two- and three-bond proton–carbon coupling. Nuclear Overhauser effect (NOE) difference and ^{1}H–^{1}H COSY spectra were employed to determine the ^{1}H–^{1}H proximity through space over a distance of up to about 4 Å.

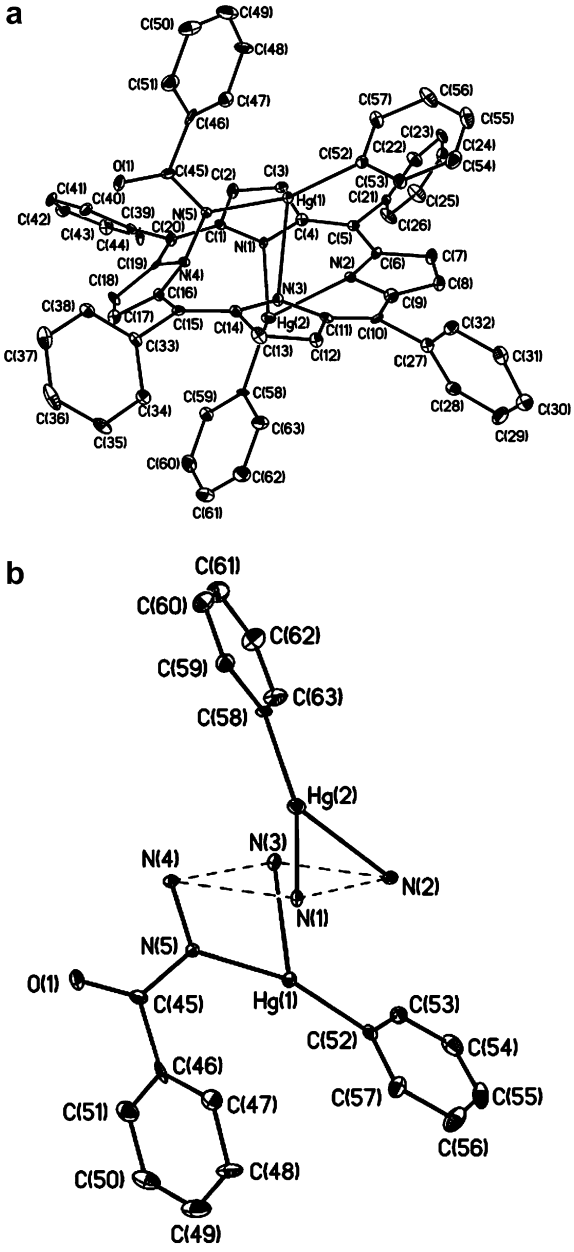

Fig. 1. (a) Molecular configuration and atom-labeling scheme for **3** · $C_6H_5CH_3$, with ellipsoids drawn at 30% probability. Hydrogen atoms and solvent $C_6H_5CH_3$ are omitted for clarity. (b) Diagram of two planes of Hg coordination [i.e., plane of Hg(2), N(1), N(2) and plane of Hg(1), N(3), N(4), N(5)] and the porphyrin 4N mean plane of **3**.

The positive ion fast atom bombardment mass spectrum (FAB MS) was obtained in a nitrobenzyl alcohol (NBA) matrix using a JEOL JMS–SX/SX 102A mass spectrometer. UV–Vis spectra were recorded at 20 °C on a HITACHI U–3210 spectrophotometer.

2.3. Crystallography

Table 1 presents the crystal data for **3** · $C_6H_5CH_3$. Measurements were taken on a BRUKER SMART APEXCCD area detector diffractometer using monochromatized Mo Kα radiation (λ = 0.71073 Å). Multi-scan absorption corrections were made for **3** · $C_6H_5CH_3$. The structure was solved by direct methods (SHELXTL-97) [7] and re-

fined by the full-matrix least-squares method. The three atoms [i.e., C(9), C(30), and C(42)] were refined with isotropic displacement parameters. All non-hydrogen atoms, except the three atoms [i.e., C(9), C(30), and C(42)] atoms, were refined with anisotropic thermal parameters, whereas all hydrogen atoms were placed in calculated positions and refined with a riding model. Table 2 lists selected bond distances and angles for **3** · $C_6H_5CH_3$.

3. Results and discussion

3.1. Molecular structure of **3** · $C_6H_5CH_3$

The molecular framework is depicted in Fig. 1a for **3** · $C_6H_5CH_3$. The covalent bond of Hg(2)–C(58) = 2.061(8) Å and Hg(1)–C(52) = 2.056(9) Å in **3** are smaller than the sum of the covalent radii of Hg and C (2.26 Å) [8,9]. The mercury nitrogen bond distances [Hg(2)–N(1) = 2.226(7), Hg(2)–N(2) = 2.425(7) and Hg(1)–N(3) = 2.693(7), Hg(1)–N(5) = 2.096(7) Å] in **3**, are well below the upper limit of a typical Hg–N covalent bond [2.75(2) Å] [8,9]. Hence, C(58), N(1) and N(2) are bonded covalently to Hg(2) atom in **3**. In a similar way, the Hg(1) is tri-coordinated with two nitrogen atoms [i.e., N(3) and N(5)] of the porphyrin and one carbon atom [i.e. C(52)] of phenyl group in **3**. We adopt the plane of four pyrrole nitrogen atoms [i.e., N(1), N(2), N(3), and N(4)] as a reference plane 4N for **3** · $C_6H_5CH_3$. Because of the larger size of Hg^{2+} [$\gamma(Hg^{2+})$ = 0.83 Å with coordination number (CN) = 3] [10], Hg(2) lies 1.47 Å above the 4N plane in **3** · $C_6H_5CH_3$, compared to Hg(1) which lies 2.07 Å below the plane in the same complex (Fig. S1 in Supplementary material). The separation between atoms Hg(1) and Hg(2) is 3.611 Å, which is larger than the sum of van der Waals radii of two Hg(II), 3.50(7) Å [9]. Hence, no metallophilic Hg(II)···Hg(II) interaction in **3** · $C_6H_5CH_3$ may be anticipated.

The mercury coordination sphere can be categorized in terms of their primary (or characteristic) and effective coordination [11,12]. The Hg(2)···N(3) = 2.831 Å, and Hg(2)···N(4) = 2.826 Å around the Hg(2) atom and Hg(1)···N(2) = 2.852 Å around the Hg(1) atom in **3** are longer than 2.75(2) Å but are significantly smaller than the sum of the van der Waals radii of Hg and N(3.28 Å). These three longer Hg···N contacts are described as weak (secondary) bonds. The effective coordination around Hg(2) in **3** may be construed as an expansion of the secondary valency of mercury from three to five {3 +2[N(3), N(4)]}. In a similar fashion, the effective coordination around Hg(1) in **3** is expanded from three to four {3 +1[N(2)]}.

In the X-ray structure of **3** · $C_6H_5CH_3$ shown in Fig. 1a and b, the N(1) N(2) Hg(2) is canted by 54.2° (or 46.1°) from the mean 4N porphyrin plane [or from the porphyrin plane defined by four *meso* carbons, C(5), C(10), C(15), and C(20)]. The angle (46.1°) is smaller than those of the corresponding canted angles of 53–63° in compounds **1a**, **1b** and **2a**, **2b** [13]. The Hg(1) N(3) N(4) N(5) plane is tilted from the 4N plane by 59.7°. The porphyrin macrocycle is indeed distorted because of the presence of the $NCOC_6H_5$ group in **3** · $C_6H_5CH_3$. Thus, N(4) pyrrole rings bearing the $NCOC_6H_5$ group in **3** · $C_6H_5CH_3$ deviate most from the 4N plane and are oriented separately with a dihedral angle of 40.9°, whereas small angles of 25.2°, 14.4° and 1.5° occur with N(1), N(2), and N(3) pyrroles for **3** · $C_6H_5CH_3$. Such a large deviation from planarity for the N(4) pyrrole is also reflected by observing a 15-16 ppm upfield shift in the ^{13}C NMR spectrum of C_β (17, 18) at 117.6 ppm compared to 133.6 ppm for C_β (7, 8), 132.9 ppm for C_β (3, 12), and 132.5 ppm for C_β (2, 13) (Table S1 in the Supplementary material). The dihedral angles between the mean plane of the skeleton (4N) and the plane of the phenyl groups are 68.6° [C(24)], 59.2° [C(30)], 50.8° [C(36)], and 28.8° [C(42)] for **3** · $C_6H_5CH_3$. Likewise, the dihedral angles between the mean plane of the 4N and the plane of the phenyl group coordinated to the Hg atom are 139.3° [C(55)], and 118.2° [C(61)] for **3** · $C_6H_5CH_3$. The Hg(1) atom may be described as transoid relative to carbonyl oxygen [i.e. O(1)] of the benzamido (BA) group.

3.2. ^1H, ^{13}C NMR spectra for **3** in $CDCl_3$

Complex **3** was characterized by ^1H and ^{13}C NMR spectra. Compound **3** remains the same as bismerury complex, but became more symmetrical than that of its solid state, due to some conformational changes in the solution state, with a mirror plane running through the N(2)–Hg(1)–Hg(2)–N(4) unit. There are four distinct β-pyrrole protons H_β, four β-pyrrole carbons C_β, four α-pyrrole carbons C_α, two different *meso* carbons C_{meso} and two phenyl-C_1 carbons for **3** (Table S1 in Supplementary material). The ^1H NMR spectra for a 0.02 M solution of **3** in $CDCl_3$ showed these four different types of H_β at 20 °C (Fig. S2 in Supplementary material). The doublet at 8.95 ppm is assigned to H_β (2, 13) with ^3J(H–H) = 4.8 Hz and the other doublet at 8.77 ppm is due to H_β (3, 12) with ^3J(H–H) = 4.2 Hz. The singlet at 8.47 ppm is due to H_β (7, 8) and the other singlet at 7.07 ppm is due to H_β (17, 18). The rotation of the phenyl group along C_1–C_{meso} [C(10)–C(27) or C(5)–C(21)] bond is slow at 20 °C. This slow rotation is evidenced by the two broad singlets at 8.17 and 8.02 ppm due to *ortho*-protons *o*-H(26,32) and *o*-H (22,28), respectively (Fig. S2 in Supplementary material). However, the rotation of the phenyl group along C(15)–C(33) [or C(20)–C(39)] bond for **3** at 20 °C is situated at the fast exchange region. In this fast exchange region, the ^1H NMR of phenyl group *ortho*-protons *o*-H (38,40) and *o*-H (34,44)

of **3** in $CDCl_3$ (or CD_2Cl_2) observed as broad singlet at 8.49 ppm at 20 °C. (Fig. S2 in Supplementary material). From our previous work we knew that the rate of intramolecular exchange of the *ortho*-protons for **3** should be slow at −50 °C in $CDCl_3$ (or at −90 °C in CD_2Cl_2) and should appear as two sets of doublets at −50 °C (or −90 °C): one doublet is assigned to *ortho*-protons *o*-H (38,40) and the other doublet is due to *ortho*-protons *o*-H (34,44) as for compounds Tl(tpp-*N*-O)(OAc) [14] and Cd(N–NHCO-2-C_4H_3O-tpp)(OAc) [15]. However, the solubility of **3** in $CDCl_3$ (or CD_2Cl_2) became worse as the temperature was decreased (at −50 °C in $CDCl_3$ or at −90 °C in CD_2Cl_2). Hence, the ^{1}H resonance for the *ortho*-protons *o*-H (38,40) and *o*-H (34,44) observed as broad singlet at 8.49 ppm at 20 °C. The benzamido group (BA), Hg(2)–Ph, Hg(1)–Ph protons in **3** are sitting at the region where a strong ring current effect of the bidentate porphyrin would be induced. Hence, all BA, Hg(2)–Ph, Hg(1)–Ph protons are shifted upfield compared to their counterparts on free BA–Ph, Hg(2)–Ph, and Hg(1)–Ph. On the basis of the ring model [16], as the distance between the geometrical center (C_t) of the 4N plane and axial protons gets smaller, the shielding effect becomes larger. The average distance between $C_t\cdots$Hg(2)–Ph–$H_{2,6}$, $C_t\cdots$Hg(2)–Ph–$H_{3,5}$ and $C_t\cdots$Hg(2)–Ph–H_4 increases from 4.026, 6.056 to 6.868 Å. Likewise, the average distance between $C_t\cdots$Hg(1)–Ph–$H_{2,6}$, $C_t\cdots$Hg(1)–Ph–$H_{3,5}$ and $C_t\cdots$Hg(1)–Ph–H_4 increases from 4.480, 6.492 to 7.250 Å. The fact that all three distances between $C_t\cdots$Hg(2)–Ph are shorter than those of $C_t\cdots$Hg(1)–Ph indicates that ring current effect in Hg(2)–Ph protons would be larger and in turn the ^{1}H upfield shifts for Hg(2)–Ph protons would be still higher. This observation is corroborated by the doublet at 3.18 ppm with satellites of ^3J(Hg–H) = 198 Hz for Hg(2)–Ph–$H_{2,6}$ and the doublet at 4.23 ppm with ^3J(Hg–H) = 186 Hz for the Hg(1)–Ph–$H_{2,6}$, the triplet at 5.84 ppm with well-resolved ^4J(Hg–H) of 54 Hz for the Hg(2)–Ph–$H_{3,5}$ and the triplet at 6.49 ppm with ^4J(Hg–H) = 48 Hz [1] for Hg(1)–Ph–$H_{3,5}$, the triplet at 6.07 ppm for Hg(2)–Ph–H_4 and the triplet at 6.61 ppm for Hg(1)–Ph–H_4 (Fig. 2a). Coupling of ^{199}Hg to both the *ortho* phenyl protons and *meta* phenyl protons of $HgPh^+$ in **3** was apparent. These coupling satellites had the same multiplicity as the parent resonance and appeared to be approximately one-fifth the size of the main resonance consistent with the 16.8% natural abundance of ^{199}Hg. The ^{1}H NMR also revealed that the aromatic protons of the BA–Ph group in **3** appear as two triplet at 6.39 ppm (BA–Ph–H_4) with ^3J(H–H) = 7.5 Hz and at 6.18 ppm (BA–Ph–$H_{3,5}$) with ^3J(H–H) = 8.1 Hz and a doublet at 5.03 ppm (BA–Ph–$H_{2,6}$) with ^3J(H–H) = 8.4 Hz (Fig. 2a). This observation is consistent with the fact that the average distance between $C_t\cdots$BA–Ph–$H_{2,6}$, and $C_t\cdots$BA–Ph–$H_{3,5}$, and $C_t\cdots$BA–Ph–H_4 increases from 4.906, 6.706 to 7.425 Å. X-ray diffraction analysis unambiguously confirms that **3** is a bismercury complex. In addition, FAB MS indicates that molecular ion (M^+) of **3** is 1287. This further supports that **3** is a bismercury species in the solid phase. The strong diamagnetic shielding observed for all six resonances of the Hg(2)–Ph and the Hg(1)–Ph protons within **3** in the ^{1}H NMR spectrum suggests that **3** remains in a dinuclear mercury(II) complex in the solution phase.

3.3. ^{199}Hg NMR spectrum for **3** in $CDCl_3$

We have obtained ^{199}Hg NMR data on **3** in $CDCl_3$ at 20 °C to minimize solvent, solvolysis, and temperature effects [17]. The ^{199}Hg NMR spectrum for a 0.2 M solution of **3** in $CDCl_3$ shows two different types of Hg at 20 °C (Fig. 2b). The triplet at −1088 ppm is assigned as Hg(2) with ^3J(Hg–H) = 188 Hz and the other triplet at −1119 ppm is due to Hg(1) with ^3J(Hg–H) = 177 Hz. The ratio of Hg(2)/Hg(1) species obtained via integration of the two ^{199}Hg NMR peaks is nearly 1:1. This ^{199}Hg NMR data provides a second evidence that **3** remains as a bismercury species in $CDCl_3$ solution. The ^3J(Hg–H) of 198 Hz (or 186 Hz) for the Hg(2)–Ph–$H_{2,6}$ [or Hg(1)–Ph–$H_{2,6}$] protons was observed by ^{1}H NMR and was ~10 Hz larger than that of 188 Hz (or 177 Hz) for the same Hg(2)–Ph–$H_{2,6}$ [or Hg(1)–Ph–$H_{2,6}$] with mercury nucleus being measured by ^{199}Hg NMR (Table 3). Similar results with Δ^3J(Hg–H) = 14.7 Hz were obtained for the Hg(1)–Ph–$H_{2,6}$ protons of HgPh(4-NCH_3NCTPP) (Table 3) [18]. The chemical shift anisotropy (CSA) relaxation mechanism is a dominant contribution to ^{199}Hg spin–lattice relaxation in **3** [19]. The high field NMR spectroscopy, at 14.1 T [ν_0(Hg) = 107.24 MHz], may lead to very rapid relaxation. In the case of spin–spin coupling this can cause line broadening for neighboring nuclei or even ^{199}Hg–H decoupling [20–22]. This rapid relaxation explained that ^3J(Hg–H) coupling constants for **3** obtained from proton spectra are larger than those from mercury spectra. The difference is about 10 Hz (or 5%) shown in Table 3. The proton and ^{199}Hg NMR spectra clearly show

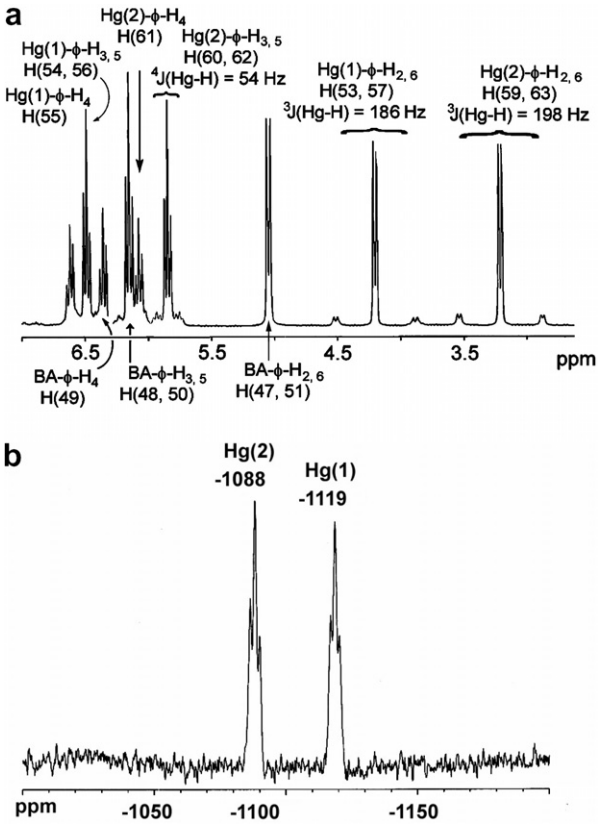

Fig. 2. (a) ^{1}H NMR spectrum at 299.95 MHz for a 0.02 M solution of **3** in $CDCl_3$ at 20 °C, showing Hg(1)–Ph, Hg(2)–Ph and BA protons, where BA = benzamido group, ϕ = Ph. (b) The ^{199}Hg NMR spectra at 107.24 MHz for a 0.2 M solution of **3** in $CDCl_3$ at 20 °C.

Table 3
Comparison of ^3J(Hg–H) (Hz) coupling constants for the Hg-Ph–$H_{2,6}$ protons via ^{1}H and ^{199}Hg NMR spectra for **3** in $CDCl_3$ and HgPh(4-NCH_3NCTPP) in CD_2Cl_2 at 20 °C

Compounds	^3J(Hg–H) [^{1}H]	^3J(Hg–H) [^{199}Hg]	Δ^3J(Hg–H)[a]
Complex **3**			
Hg(1)–Ph–$H_{2,6}$	186	177	9
Hg(2)–Ph–$H_{2,6}$	198	188	10
HgPh(4-NCH_3NCTPP) [16]:Hg(1)–Ph–$H_{2,6}$	186.7	172	14.7

[a] Δ^3J(Hg–H) = ^3J(Hg–H) [^{1}H] − ^3J(Hg–H) [^{199}Hg].

[1] ^4J(Hg–H) = 48 Hz for Hg(1)–Ph–$H_{3,5}$ of **3** was observed at 599.94 MHz in $CDCl_3$ at 20 °C.

^3J(Hg–H) coupling. The presence of the mercury–proton coupling is an important indicator of no ligand exchange in **3** [17].

Heteronuclear coupling constants for ^{199}Hg in alkyl mecurials have been determined to decrease in the order $^1J \gg {}^3J > {}^2J > {}^4J$ [21,22]. This order explains that the coupling constant of ^3J(Hg–H) = 193 ± 5 Hz (or 182 ± 5) for the Hg(2)–Ph–$H_{2,6}$ protons [or Hg(1)–Ph–$H_{2,6}$] of **3** is larger than that of ^4J(Hg–H) = 54 Hz (or 48 Hz) for Hg(2)–Ph–$H_{3,5}$ [or Hg(1)–Ph–$H_{3,5}$] protons. Changes in the coupling could possibly come from a Karplus-type relationship [24,25], but the variations in the number of bonds to the $HgPh^+$ unit could also be a critical factor. It is known in the case of ^{199}Hg NMR spectroscopy that an increasing coordination number generally lowers the chemical shift [23]. This fact explained that the ^{199}Hg signal of the Hg(2) nucleus with an effective coordination number of five lies downfield by 31 ppm from that of the Hg(1) nucleus with a smaller effective coordination number of four. Additionally, this also results in an increased effective nuclear charge for the mercury nucleus Hg(2), i.e., Z_{eff} [Hg(2)], and an increased s character of the hybrid orbital for Hg(2) in the three and four-bond couplings to the protons [26]. Therefore coupling constants of ^3J(Hg–H) and ^4J(Hg–H) from Hg(2) are larger than those couplings from Hg(1), respectively.

4. Conclusions

This paper describes synthesis, X-ray, multinuclear NMR and MS characterization of a single bis(mercury(II)) complex of *N*-substituted tetraphenylporphyrin, namely, **3**. The two Hg atoms are in different environments. The two different Hg environments are clearly seen in the ^{199}Hg NMR spectrum as well as some interesting Hg–H couplings.

ABSTRACT

The mono- and bis-Ni(II) chelates of 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine (**L**) having the molecular formula $[[Ni(\mathbf{L})(H_2O)_3](NO_3)_2]_3[Ni(\mathbf{L})(NO_3)(H_2O)_2](NO_3)\cdot 5H_2O$ (**1**) and $[Ni(\mathbf{L})_2](PF_6)_2\cdot 2H_2O$ (**2**), respectively, are synthesized. The structural, optical and magnetic characteristics are determined. The asymmetric unit of (**1**) contains three $[Ni(\mathbf{L})(H_2O)_3]^{2+}$ (**1a**) and one $[Ni(\mathbf{L})(NO_3)(H_2O)_2]^{+}$ (**1b**) species along with five water molecules and seven nitrate ions. In both **1a** and **1b**, the bivalent nickel has pseudo-octahedral *mer*-N_3O_3 and in **2**, *mer*-N_3N_3 environments. The molecular packing reveals the presence of water–nitrate ion network, $(NO_3^-)\cdots\pi$ interaction in **1** and F···π interaction in **2** and water dimer in both. Both **1** and **2** exhibits d–d transitions in visible and intra-ligand charge transfer (ILCT) in UV regions. The emission spectra are of $\pi \rightarrow \pi^*$ character for $\lambda_{ex} = 345$ nm.

1. Introduction

Polydentate ligands containing N-donor heterocyclic rings have covered extra dimension in the realms of coordination chemistry. The transition metal complexes of polypyridines have wide range of utilities as in the field of photochemistry [1], biological activities [2], enantioselective synthesis [3] and supramolecular chemistry [4]. The immobilization of terpyridine ligands onto poly(ethylene glycol)–polystyrene beads results in flexible and highly accessible metal grafting resins [5]. Bivalent nickel complexes of terpyridine and its 4′-(phenyl) derivatives containing mono- and bis-chelates are reported over the years [6,7].

Water plays a crucial role in many biological and chemical processes. Solid-state structural studies that describe water clusters, chains, and sheets in various crystalline solids are another important area of intensive research [8]. The formation and structure of co-crystals are of interest to the pharmaceutical industry as well [9].

This work stems from our interest in the coordination chemistry of 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine (**L**) [10] and is studied by other groups as well [11]. Herein, we report the synthesis, characterization and structure of mono- and bis-Ni(II) chelates of **L** that contain water–nitrate ion network, anion···π interaction and water dimer.

doi:10.1016/j.poly.2008.04.008

effects and empirical absorption corrections was applied using SAINT program [12,13]. All the structures were solved by direct methods using SHELXS-97 [14]. The Friedel opposites were merged (*R*(int) and *R*(sigma) values, respectively, for **1** are 0.0000 and 0.0017; for **2** are 0.0000 and 0.0024) and the data were used for further refinements. Non-hydrogen atoms located from the difference Fourier maps were refined anisotropically by full-matrix least-squares on F^2, using SHELXL-97 [14]. All hydrogen atoms were included in the calculated positions (except H2C, H5C, H14C, H36C, H37B and H37C, which were generated from FMAP for **1**) and refined isotropically using a riding model.

2-Acetylpyridine, 2-picolylamine, KPF_6 (Aldrich, USA), $Ni(NO_3)_2 \cdot 6H_2O$ (Merck India Ltd.), and solvents were used as received without further purification. 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine, **L**, was prepared using the reported procedure [10b].

2.2. Synthesis of the complexes

2.2.1. $[[Ni(\mathbf{L})(H_2O)_3][(NO_3)_2]_3[Ni(\mathbf{L})(NO_3)(H_2O)_2](NO_3) \cdot 5H_2O$ (**1**)

To 41 mg (0.13 mmol) of 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine (**L**) dissolved in 20 mL of methanol, a methanolic solution (10 mL) of 115 mg (0.395 mmol) $Ni(NO_3)_2 \cdot 6H_2O$ was added and stirred for 1 h. After a week, pale green crystals deposited were collected after washing with ice-cold methanol. Yield: 37 mg (50% based on **L**). IR (KBr), cm^{-1}: 1614 (C=N_{py}), 1558, 1384 (NO_3). *Anal.* Calc. for $C_{80}H_{88}N_{24}O_{40}Ni_4$: C, 42.46; H, 3.89; N, 14.86. Found: C, 42.62; H, 3.96; N, 14.71%. During the crystallization, small amounts of reddish-brown crystals of composition $[Ni(\mathbf{L})_2](NO_3)_2$ were also isolated.

2.2.2. $[Ni(\mathbf{L})_2](PF_6)_2 \cdot 2H_2O$ (**2**)

To 30 mg (0.10 mmol) of $Ni(NO_3)_2 \cdot 6H_2O$ dissolved in 50 mL of methanol, 63 mg (0.21 mmol) of 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine and then an aqueous solution of 50 mg (0.27 mmol) of KPF_6 were added with stirring. The reaction mixture was stirred for another 4 h and left undisturbed. Block like reddish-brown crystals of **2** were obtained after a week. Yield: 62 mg (60%). IR (KBr), cm^{-1}: 1614 (C=N_{py}), 1603 (C=N_{py}), 1573, 1557, 842 (P–F). *Anal.* Calc. for $C_{40}H_{32}F_{12}N_8O_2P_2Ni$: C, 47.74; H, 3.18; N, 11.14. Found: C, 47.81; H, 3.23; N, 11.05%.

3. Results and discussion

3.1. Optical spectra and magnetism

The UV–Vis spectrum of **1** and **2** in methanol (Fig. S1), exhibits d–d transitions in visible and intra-ligand charge transfer (ILCT) in UV regions [15]. The λ_{max} and their molar extinction coefficient values obtained after fitting to Gaussian are listed in Table 1. Both the complexes display the typical transitions, $^3A_{2g} \rightarrow {}^3T_{2g}$ at a lower and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ at the higher energies. The energy of the $^3A_{2g} \rightarrow {}^3T_{2g}$ transition, follow the trend **2** > **1** in accordance with strong field nature of **L** compared to H_2O/NO_3^-, while that of the $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ remain invariant. But the transition $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ was not observed which may be obscured by the intra-ligand bands. In case of **1** and **2** a sharp spin forbidden transition observed having their maxima at 770 and 750 nm, respectively. The intra-ligand charge transfer transitions are of $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ (from 4′-(2-pyridyl)) in origin.

Table 1
UV–Vis data[a]

Complex	λ_{max}, nm (ε, M^{-1} cm^{-1})	
	d–d transition	ILCT
1	890 (14), 770 (1.5), 570 (15)	344 (8770), 330 (10065), 296 (15665), 288 (28665), 265 (37045)
2	800 (18), 750 (1), 570 (13)	347 (12010), 330 (14630), 358 (15250), 300 (19170), 288 (36880)

[a] In methanol.

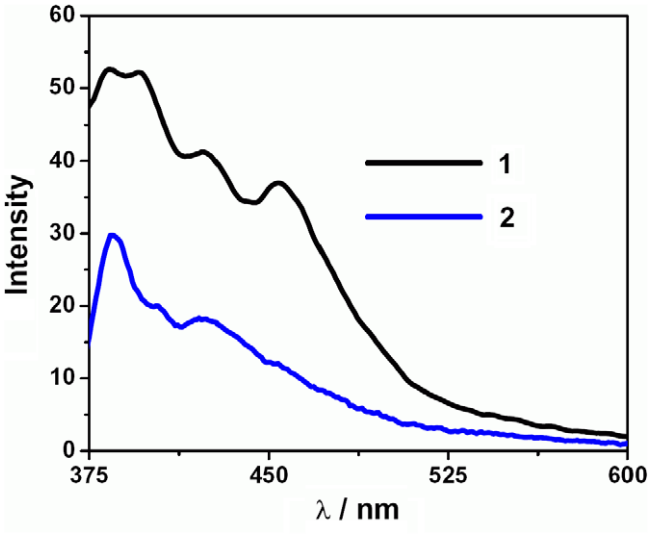

Fig. 1. Emission spectra of **1** and **2**.

The emission spectra of **1** and **2** in acetonitrile, exhibit $\pi \rightarrow \pi^*$ character (Fig. 1) and indicates that the emission is from a significantly intra-ligand $\pi \rightarrow \pi^*$ state [16]. The envelope of the vibronic structure has a 'domed' shape and the energy spacing within the transition is of the order 8.5×10^4 cm^{-1}. This is a typical signature of Frank–Condon envelope type $\pi \rightarrow \pi^*$ emission in polypyridine complexes [16]. The structured bands with vibronic components at 384, 397, 423 and 454 nm (for **1**) and at 385, 403, 423 and 455 nm (for **2**) are observed for λ_{ex} = 345 nm.

The μ_{eff} values calculated from the least square fitting of the initial magnetization curve ($\chi = M/H$) for **1** and **2** are, respectively, 2.97 and 3.66 BM. The value is slightly higher than the $\mu_{s.o.}$ value for **1**, and is largely higher for **2**. Complex **2** exhibits a distinct hysteresis loop having the coercivity loss is 186 G [17].

3.2. Molecular structures

The molecular structures of $[[Ni(\mathbf{L})(H_2O)_3](NO_3)_2]_3[Ni(\mathbf{L})(NO_3)(H_2O)_2]NO_3 \cdot 5H_2O$ (**1**) and $[Ni(\mathbf{L})_2](PF_6)_2 \cdot 2H_2O$ (**2**) were determined by X-ray crystallography. The crystallographic data and refinement parameters are summarized in Table 2 and selected bond parameters are listed in Table 3, Table S1.

The asymmetric unit of **1** contains three dicationic $[Ni(\mathbf{L})(H_2O)_3]^{2+}$ (**1a**) species and a monocationic $[Ni(\mathbf{L})(NO_3)(H_2O)_2]^+$ (**1b**) unit along with five water molecules. Overall, seven nitrate ions are present in the outer sphere to balance the cationic charge. The bond parameters in the three identical **1a** are comparable with each other. A perspective view of one of the **1a** and the **1b** are shown in Fig. 2.

In both **1a** and **1b**, the bivalent nickel is hexa-coordinated and has a distorted octahedral geometry having a *mer*-N_3O_3 environment. The three nitrogen atoms of **L** occupy sites in the equatorial plane and the fourth equatorial site is occupied by the oxygen atom of a water molecule in **1a** and a monodentate nitrate ion in **1b**. The two axial sites are occupied by two water molecules in both the species. In general, the Ni–$N_{(Y)}$ distances are shorter by 0.124(1) Å than Ni–$N_{(X)}$ and a similar trend is reported in the monochelates of terpyridine and its 4′-(phenyl) derivatives [6]. This is

R indices (all data)	$R_1 = 0.0293$[b], $wR_2 = 0.0713$[c]	$R_1 = 0.0762$[b], $wR_2 = 0.2053$[c]

[a] GOF = $[\sum[w(F_o^2 - F_c^2)^2]/M - N]^{1/2}$ (M = number of reflections, N = number of parameters refined).
[b] $R_1 = \sum||F_o| - |F_c||/\sum|F_o|$.
[c] $wR_2 = [\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]]$.

observed in transition metal complexes of terpyridine and substituted terpyridines is due to a more efficient overlap of metal t_{2g} orbitals with the π^* orbitals of the central pyridyl ring. Within the **1b** units, the Ni–$O_{(ax)}$ distances are longer by 0.049(1) Å than that of the Ni–$O_{(eq)}$ distances. In **1a** and **1b**, the intersection of the planes of NiN_3 and NiO_3 deviate from a right angle by 0–4°. The bond angles subtended at the metal center is suggestive of a distorted octahedral geometry. The distortion around the chelating ligand **L** is more severe as is evident from the *cis*-angles lying in the range 77–79°, while the *trans*-angles are in the range 155–158°. The **Z** rings of **L** deviate from planarity with respect to **Y** ring by about 5–12(1)°.

Table 3
Selected bond distances (Å)

1a		1b		2	
Ni1–N1	2.115(1)	Ni4–N13	2.144(1)	Ni1–N1	2.118(3)
Ni1–N2	1.988(1)	Ni4–N14	1.993(1)	Ni1–N2	2.005(3)
Ni1–N3	2.093(1)	Ni4–N15	2.114(1)	Ni1–N3	2.117(3)

Ni1–O2	2.067(1)	Ni4–O11	2.107(1)	Ni1–N6	1.989(3)
Ni1–O3	2.024(1)	Ni4–O12	2.069(1)	Ni1–N7	2.121(3)

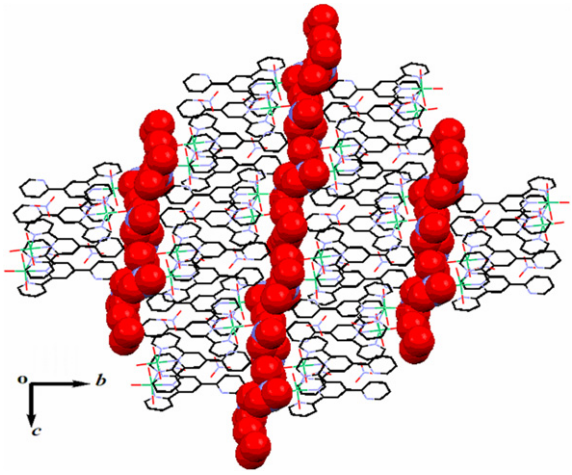

Fig. 3. Molecular packing of **1**.

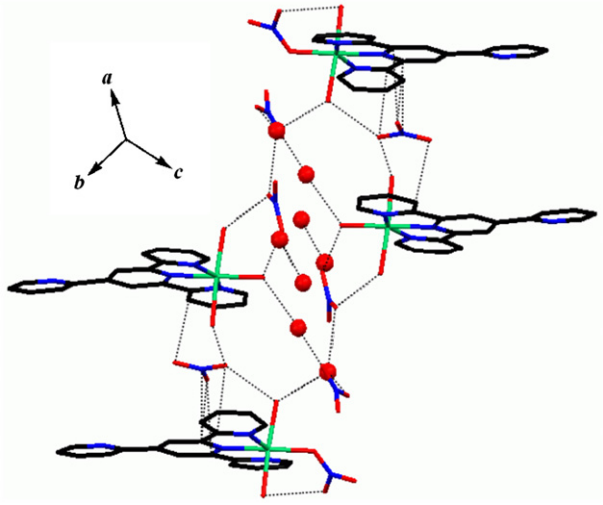

Fig. 4. Water–nitrate ions network and nitrate ion in π–π interaction.

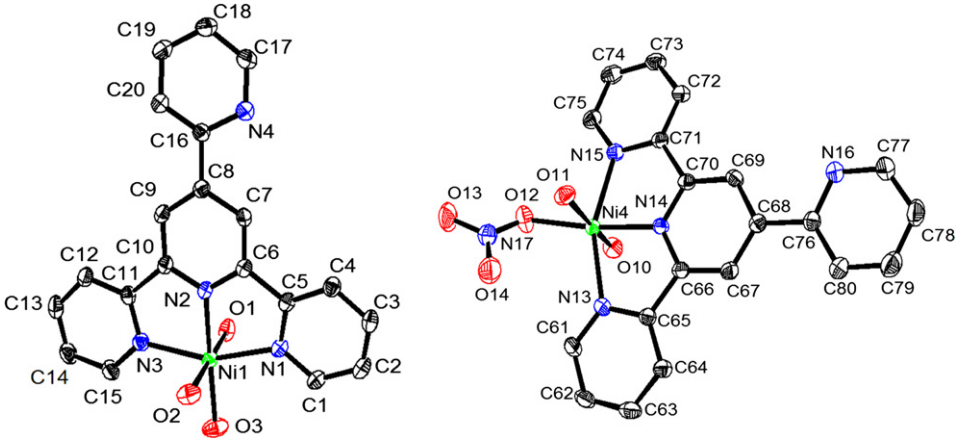

Fig. 2. ORTEP (30% probability and hydrogen atoms are omitted for clarity) of **1a** and **1b**.

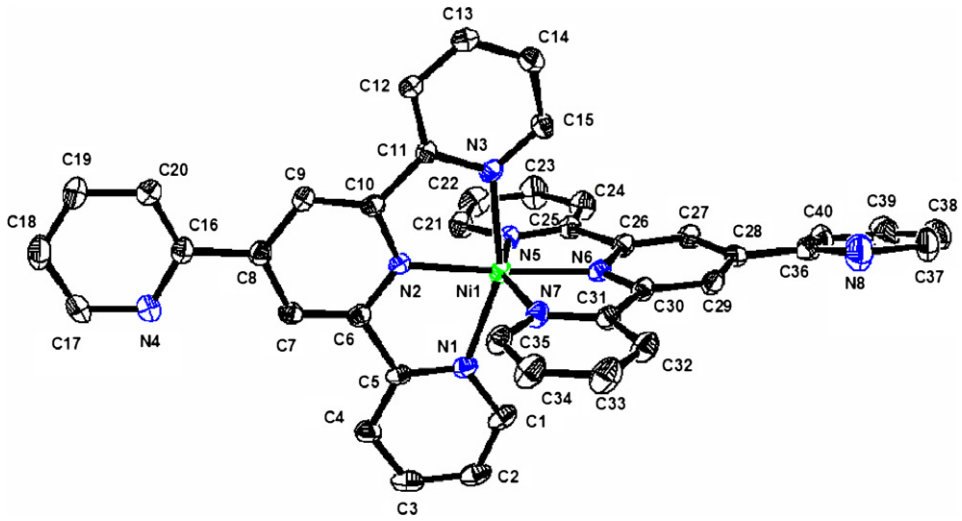

Fig. 5. ORTEP (30% probability and hydrogen atoms are omitted for clarity) of $[Ni(\mathbf{L})_2]^{2+}$ ion in **2**.

The molecular packing of **1** on viewing down the *a*-axis is shown in Fig. 3 and contains bands of **1a** and **1b**, juxtaposed with each other exposing the coordinated water and the nitrate for interlinking. The bands also incorporate four of nitrate ions and among them two are held by π–π stacking (with aromatic rings) [18] as well as hydrogen bonding interactions and the other two are by hydrogen bonding interactions only. These bands are interlinked by layers of five water molecules and the three nitrate ions through hydrogen bonds, leading the network structure. The network consists of centrosymmetric half-units containing crown-shaped $H_2O\cdots H_2O\cdots NO_3\cdots H_2O$–Ni1– $H_2O\cdots NO_3\cdots H_2O$ and chair form of $H_2O\cdots NO_3\cdots H_2O\cdots H_2O\cdots NO_3\cdots H_2O\cdots NO_3\cdots H_2O$ links (Fig. 4). Other notable feature is the presence of a water dimer O36···O40 (2.795(1) Å). The relevant non-bonded interactions are listed in Table S2.

Complex **2** crystallized in a triclinic space group $P\bar{1}$ and the asymmetric unit contains two $[Ni(\mathbf{L})_2]^{2+}$ species and four PF_6^- anions along with four water molecules. The bond parameters in both of the $[Ni(\mathbf{L})_2]^{2+}$ units are within comparable limits. A perspective view of one of the $[Ni(\mathbf{L})_2]^{2+}$ ion is shown in Fig. 5. The bivalent nickel atom is coordinated by six nitrogen atoms of two **L** ligands in a distorted octahedral fashion. The distortion around the nickel atom is evident from the *cis*- and *trans*-angles ranges of 77–78° and about 155°, respectively, within the **L**. The two NiN_3 planes intersect by 88°. As noted in **1**, the Ni–$N_{(Y)}$ distances in **2** are shorter than those of Ni–$N_{(X)}$ by about 0.121(1) Å and a similar trend is observed in the Ni(II) bischelates of terpyridine and its 4′-(phenyl) analog [7]. The **Z** rings of **L** deviate widely from planarity with respect to **Y** ring as inferred from the torsional angle range 2–31°.

The packing diagram of **2** depicting the presence of F···π interactions [19] with the aromatic ring is shown in Fig. 6. These non-bonded contacts lie in the narrow range 3.08(1)–3.12(1) Å. The PF_6^- anions also form C–H···F hydrogen bonds and the H···F non-bonded distances are included in Table S2. In addition, C–H···O and C–H···N interactions and the presence of a water dimer, O1···O2 having a distance of 2.622(1) Å are significant to note.

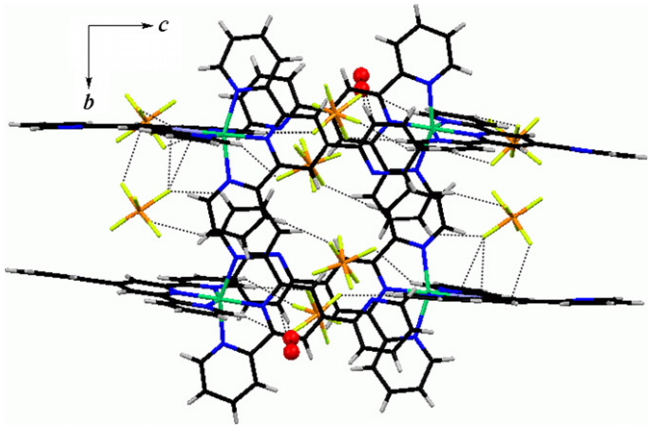

Fig. 6. Packing diagram of **2**.

4. Conclusion

The mono- and bis-nickel(II) chelates of 4′-(2-pyridyl)-2,2′:6′,2″-terpyridine were synthesized. Their electronic spectra reveal that the energy of the $^3A_{2g} \rightarrow {}^3T_{2g}$ transition, follow the trend **2** > **1** and that of the $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ remain invariant. The complexes exhibit $\pi \rightarrow \pi^*$ type emission and behave as two-electron paramagnets. Structural studies shows the presence of a water dimer (in both) as well as $(NO_3^-)\cdots\pi$ and F···π interactions, in **1** and **2**, respectively. In **1**, water–nitrate ion network having crown and chair forms are present.

ABSTRACT

The interaction of $B(OH)_3$ with $[R_3N\{CH_2CH(OH)CH_2OH\}]$ [OH] (R_3 = Me_3, Me_2Et, $MeEt_2$, Me_2Bz, $Me_2\{CH_2CH_2OH\}$) in a 1:2, 1:1, and 5:1 ratio in aqueous solution has been studied by ^{11}B NMR spectroscopy and the equilibrium species present have been identified. The cationic bischelate $[R_3N\{CH_2CH(O)CH_2O\}_2B]^+$ dominates the 2:1 ratio solutions, zwitterionic monochelate species, $[R_3N\{CH_2CH(O)CH_2O\}B(OH)_2]$, dominate the 1:1 solutions and the pentaborate anion, $[B_5O_6(OH)_4]^-$, dominates the 1:5 solutions. Borate solutions derived from $[NMe_4][OH]$ and $[Me_3NCH_2CH_2OH][OH]$ have also been studied by ^{11}B NMR. Spectra of these borate solutions are essentially the same as those observed for borate solutions with alkali metal cations, and structure directing effects (towards the anion) are not observed in borate systems.

1. Introduction

Boric acid is well known to form anionic four-coordinate tetrahedral complexes with bidentate chelating ligands (Eqs. (1) and (2)) [1]. Ligands studied include those derived from polyols, 1,2-diols, 1,3-diols, benzene-1,2-diols, and α-hydroxycarboxylic acids [2–6]. Borate complexes of this type have found use in the synthesis, separation and identification of both synthetic and naturally occurring polyol derivatives [1,7]. These reactions also form the basis of a volumetric analytical method for $B(OH)_3$ where the H_3O^+ ions that are liberated by the presence of excess polyol (usually mannitol or sorbitol) may be titrated with NaOH(aq) [8].

$$B(OH)_3 + HOCR_2CR_2OH \rightarrow [(HO)_2B(OCR_2CR_2O)]^- + H_3O^+ \quad (1)$$

$$B(OH)_3 + 2HOCR_2CR_2OH \rightarrow [B(OCR_2CR_2O)_2]^- + 2H_2O + H_3O^+ \quad (2)$$

^{11}B NMR is a convenient method for studying borate speciation in aqueous solution in the presence of diols since characteristic chemical shifts are observed for the different species present [9–14]. We have recently become interested in cationic 1,2-diols, derived from substituted ammonium cations, as potentially chelating ligands and report here their interactions with $B(OH)_3$ which result in the formation of new zwitterionic and cationic monoborate complexes.

2. Experimental

2.1. General

Reagents were purchased from Aldrich Chemical Co. and Lancaster Synthesis Ltd. and were used without further purification. Solvents were standard reagent grade and were used as supplied unless otherwise stated. Multi-element solution NMR spectra were recorded at room temperature (298 K) on a Bruker Avance 500 (11.7 T) spectrometer operating at 500 MHz for ^{1}H, 125 MHz for ^{13}C–{^{1}H}, and 160 MHz for ^{11}B–{^{1}H} and referenced to $(CH_3)_4Si$ or $BF_3 \cdot OEt_2$. Chemical shifts (δ) are reported in ppm, and J coupling in Hz. Mass spectrometry data were obtained by direct infusion (DI) of the samples using a Bruker microTOF spectrometer in electrospray ionisation (ESI) mode. MS samples were dissolved in H_2O or MeOH prior to analysis. Elemental analyses (C, H, N) were performed on a Carlo Erba EA-110E analyser, using helium as the carrier gas.

2.2. Preparation of tetraorganoammonium hydroxides

The general method is given for **1**[OH] which is a slightly modified version of a literature method [15]. Spectroscopic and analytical data are given for all compounds **1**–**7**[OH].

2.2.1. $[Me]_3NCH_2CH(OH)CH_2OH]OH$ (*1*[OH])

Ethanolic trimethylamine solution (23.80 ml, 100 mmol, *ca.* 4.2 M) was cooled on an ice bath. 2,3-Epoxy-1-propanol (8.00 ml, 120 mmol) was added slowly via syringe to the amine over 10 min, while maintaining the solution temperature between 15

doi:10.1016/j.poly.2008.04.007

and 25 °C. After 30 min, H_2O (10 ml) was added, causing an exothermic reaction. After reducing the temperature to 25 °C, H_2O (10 ml) was added and the reaction mixture was stirred overnight. The unreacted glycidol was extracted using $CHCl_3$ (4 × 40 ml), and the aqueous phase was reduced in volume on the rotary evaporator to a yellow solution (28.13 g). An aliquot of the solution (1.00 ml) was titrated against HCl (2.00 M) in order to determine the hydroxide concentration, using universal indicator solution to identify the neutral end point. [OH^-] = 3.50 M. Yield = 89%. NMR: (500 MHz, D_2O) δ_H = 2.98 s (9H), 3.04 dd (1H), 3.21 dd (1H), 3.35 dd (2H), 3.94 m (1H); (125 MHz, D_2O) δ_C = 54.0, 64.9, 67.3, 70.3. MS (DI/ESI): $^{12}C_6{}^1H_{16}{}^{14}N^{16}O_2$ calc. 134.1176 *m*/*z*; obs. 134.1159 *m*/*z*.

2.2.7. Attempted preparation of [$Et_3NCH_2CH(OH)CH_2OH$]OH (**7**[OH])

NMR: (500 MHz, D_2O) δ_H = 1.05 d (9H), 2.81 s (18H) 2.91 q (3H), 3.06–3.28 m (23H), 3.52 s (2H), 3.82 t (2H), 3.98 s (1H); (125 MHz, D_2O) δ_C = 7.5, 50.6, 50.8, 61.0, 62.7, 64.8, 66.9, 67.4, 67.8, 70.4, 72.3, 74.3. MS (DI/ESI): $^{12}C_9{}^1H_{22}{}^{14}N^{16}O_2$ calc. 176.1645 *m*/*z*; obs. 176.1649, 250.1984, 324.2331, 398.2680, 472.3009 *m*/*z*.

2.3. Preparation of tetraorganoammonium borate solutions

The tetraorganoammonium borate solutions were prepared in three sets with cation:boron ratios of 2:1, 1:1 and 1:5. In general, the required molar ratio of $B(OH)_3$ was dissolved in the tetraalkylammonium hydroxide solution (molarity as determined above) although in some cases this process was facilitated by additional H_2O solvent and gentle heating. This is described in detail for the 2:1 **1**[OH]:$B(OH)_3$ solution: an aqueous solution of **1**[OH] (3.1651 g, 3.50 M, 10.0 mmol) was placed in a narrow high-sided vial. $B(OH)_3$ (0.3051 g, 5.00 mmol) was added and the mixture stirred overnight to yield a transparent yellow solution. The resulting solution was ~1.8 M in [B]. ^{11}B NMR data for this and the other solutions arising from **1**–**6**[OH] and $B(OH)_3$ are given in Table 1. 1:1 and 1:5 [NMe_4][OH]:$B(OH)_3$ solutions and 1:1 and 1:5 [$Me_3NCH_2CH_2OH$][OH]:$B(OH)_3$ solutions were prepared in a similar manner to yield 2.0, 5.6, 2.0, and 6.8 M total [B], respectively. ^{11}B NMR (160 MHz, D_2O) data for these 4 solutions (in the same order) are δ_B = 2.4 (100%) $[B(OH)_4]^-$; δ_B = 1.1 (18%) $[B_5O_6(OH)_4]^-$, 13.0 $[B_3O_3(OH)_4]^-$ (33%), 18.6 (49%) $B(OH)_3$; δ_B = 2.0 (100%) $[B(OH)_4]^-$; and δ_B = 1.1 (15%) $[B_5O_6(OH)_4]^-$, 13.7 $[B_3O_3(OH)_4]^-$ (53%), 18.7 (32%) $B(OH)_3$.

[a] Neutral zwitterionic monochelate complex, [$R_3N\{CH_2CH(O)CH_2O\}B(OH)_2$], with δ ^{11}B ~ 6.0 ppm.
[b] Cationic bischelate complex, [$R_3N\{CH_2CH(O)CH_2O\}_2B$]$^+$, with $\delta^{11}B$ ~ 10.0 ppm.
[c] More correctly, $[B(OH)_3/[B(OH)_4]^-$ equilibrium fast exchange, $\delta^{11}B$ ~ 2.0 ppm.
[d] More correctly, $[B(OH)_3/[B(OH)_4]^-$ equilibrium fast exchange, $\delta^{11}B$ ~ 19.0 ppm.
[e] $\delta^{11}B$ ~ 1.0 ppm. This signal is attributed to the four-coordinate *spiro* B centre of the pentaborate anion. The four three-coordinate B centres of the pentaborate anion are very broad and difficult to detect above background noise by ^{11}B NMR [18].

2.4. Preparation of tetraorganoammonium chlorides, **1**,**2**,**4**–**7**[Cl]

The general method is described below for **1**[Cl]. Yields, analytical data and spectroscopic data are reported for compounds **2**,**4**–**7**[Cl].

2.4.1. [$Me_3NCH_2CH(OH)CH_2OH$]Cl (**1**[Cl])

Ethanolic trimethylamine solution (23.80 g, 100 mmol, *ca.* 4.2 M) was cooled on an ice bath. 3-Chloro-1,2-propanediol (8.40 ml, 100 mmol) was added slowly via syringe to the amine, followed by methanol (60 ml). The mixture was heated to reflux (*ca.* 60 °C) overnight, and the solvent was removed by rotary evaporation to give a crude yellow oil. Small portions of the oil were washed with a large excess of acetone to afford a fine white hygroscopic powder (9.42 g, 56%). NMR: (500 MHz, D_2O) δ_H = 3.19 s (9H), 3.39 dd (1H), 3.43 dd (1H), 3.56 d (2H), 4.25 m (1H); (125 MHz, D_2O) δ_C = 54.2, 63.6, 66.4, 68.2. EA: Calc. for $C_6H_{16}ClNO_2$: C, 42.5; H, 9.5; N, 8.3. Found: C, 42.0; H, 9.7; N, 8.2%. MS (DI/ESI): $^{12}C_6{}^1H_{16}{}^{14}N^{16}O_2$ calc. 134.1176 *m*/*z*; obs. 134.1138 *m*/*z*.

2.4.2. [$Me_2EtNCH_2CH(OH)CH_2OH$]Cl (**2**[Cl])

Colourless oil (87%). NMR: (500 MHz, D_2O) δ_H = 1.41 t (3H), 3.18 s (6H), 3.42–3.61 m (6H), 4.23 m (1H); (63 MHz, D_2O) δ_C = 9.5, 52.7,

52.9, 63.0, 66.0, 67.8, 68.4. EA: Calc. for $C_7H_{18}ClNO_2$: C, 45.8; H, 9.9; N, 7.6. Found: C, 44.3; H, 10.0; N, 7.1%. MS (DI/ESI): $^{12}C_7{}^1H_{18}{}^{14}N^{16}O_2$ calc. 148.1332 *m/z*; obs. 148.1313 *m/z*.

*2.4.3. [$Et_2MeNCH_2CH(OH)CH_2OH$]Cl (**4**[Cl])*

White hygroscopic powder (52%). NMR: (500 MHz, D_2O) δ_H = 1.43 t (6H), 2.99 s (3H), 3.29 d (2H), 3.38 m (4H), 3.47 dd (1H), 3.49 dd (1H), 4.16 p (1H); (63 MHz, D_2O) δ_C = 9.9, 50.6, 60.1, 60.5, 65.1, 66.4, 68.6. EA: Calc. for $C_8H_{20}ClNO_2$: C, 48.6; H, 10.2; N, 7.1. Found: C, 47.1; H, 10.1; N, 6.7%. MS (DI/ESI): $^{12}C_8{}^1H_{20}{}^{14}N^{16}O_2$ calc. 162.1489 *m/z*; obs. 162.1473 *m/z*.

*2.4.4. [$Me_2BzNCH_2CH(OH)CH_2OH$]Cl (**5**[Cl])*

White hygroscopic powder (16.53 g, 67%). NMR: (500 MHz, D_2O) δ_H = 3.05 s (3H), 3.08 s (3H), 3.38 m (2H), 3.51 d (2H), 4.31 m (1H), 4.54 s (2H), 7.50 m (5H); (63 MHz, D_2O) δ_C = 53.0, 53.5, 66.4, 68.7, 68.8, 72.3, 129.7, 131.8, 133.5, 135.8. EA: Calc. for $C_{12}H_{20}ClNO_2$: C, 58.6; H, 8.2; N, 5.7. Found: C, 58.8; H, 8.6; N, 5.9%. MS (DI/ESI): $^{12}C_{12}{}^1H_{20}{}^{14}N^{16}O_2$ calc. 210.1489 *m/z*; obs. 210.1496 *m/z*.

*2.4.5. [$Me_2N(CH_2CH(OH)CH_2OH)_2$]Cl (**6**[OH])*

Colourless oil (99%). NMR: (500 MHz, D_2O) δ_H = 3.20 d (3H), 3.22 s (3H), 3.44–3.49 m (4H), 3.52 d (2H), 3.53 d (2H), 4.24 m (2H); (125 MHz, D_2O) δ_C = 52.7, 53.0, 63.7, 66.2, 67.2, 67.5. EA: Calc. for $C_8H_{20}ClNO_4$: C, 41.8; H, 8.8; N, 6.1. Found: C, 38.7; H, 8.9; N, 5.9%. MS (DI/ESI): $^{12}C_8{}^1H_{20}{}^{14}N^{16}O_4$ calc. 194.1387 *m/z*; obs. 194.1389 *m/z*.

*2.4.6. [$Et_3NCH_2CH(OH)CH_2OH$]Cl (**7**[Cl])*

White hygroscopic powder (61%). NMR: (500 MHz, D_2O) δ_H = 1.23 t (9H) CH_3 ^3J 7.3, 3.24 dd (1H) CH_2 ^2J 14.8 ^3J 1.3, 3.28 dd (1H) CH_2 ^2J 14.8 ^3J 1.6, 3.32 dq (3H) CH_3CH_2 ^2J 14.5 ^3J 7.3, 3.39 dq (3H) CH_3CH_2 ^2J 14.5 ^3J 7.3, 3.49 dd (1H) CH_2OH ^2J 11.7 ^3J 6.0, 3.54 dd (1H) CH_2OH ^2J 11.7 ^3J 5.7,4.14 dt (1H) $CHOH$ ^3J 5.7 ^3J 6.0 ^3J 1.3 ^3J 1.6; (125 MHz, D_2O) δ_C = 6.8 CH_3, 53.7 CH_3CH_2N, 58.8 CH_2N, 63.7 $CHOH$, 65.7 CH_2OH. EA: Calc. for $C_9H_{22}ClNO_2$: C, 51.0; H, 10.5; N, 6.6. Found: C, 48.3; H, 9.8; N, 6.3%. MS (DI/ESI): $^{12}Cg138_9{}^1H_{22}{}^{14}$ $N^{16}O_2$ Calc. 176.1645 *m/z*; obs. 176.1629 *m/z*.

2.5. Reaction of tetraorganoammonium chlorides with sodium borate in MeOH/H_2O

The general method is given for **2**[Cl]. Spectroscopic and analytical data are given for all reactions involving **2**,**4**–**7**[OH] with $Na[B(OH)_4]$. **2**[Cl] (1.25 g, 6.8 mmol), dissolved in MeOH (15 ml), was added to H_2O (5 ml) containing NaOH (0.28 g, 6.8 mmol) and $B(OH)_3$ (0.42 g, 6.8 mmol). This resulted in an exothermic reaction, and the mixture was left to stir overnight. The solvent was removed (rotary evaporator) to yield a sticky white solid. NMR: (160 MHz, D_2O) δ_B = 10.4 (8%), 6.2 (51%), 4.7 (41%). This solid was extracted into MeOH, and the soluble fraction afforded a white solid, upon solvent evaporation. NMR: (160MHz, D_2O) δ_B = 10.4 (91%), 6.1, (9%). **4**[Cl] gave δ_B = 10.5 (11%), 6.1 (55%), 4.4 (34%); and then 10.4 (9%), 6.2 (91%). **5**[Cl] gave δ_B = 10.5 (7%), 6.2 (52%), 4.4 (41%); and then 10.4 (8%), 6.2 (56%), 3.2 (36%). **6**[Cl] gave δ_B = 10.5 (39%), 6.2 (61%); and then 10.5 (23%), 6.2 (77%). **7**[Cl] gave δ_B = 10.4 (3%), 6.2 (38%), 3.4 (59%); and then 10.4 (17%), 6.2 (49%), 3.3 (34%).

3. Results and discussion

In order to investigate the reactions of diol-functionalised tetraorganoammmonium cations with $B(OH)_3$ it was first necessary to prepare the cations in aqueous solutions with hydroxide counterions. The following cations, which contain increasing chain length and steric bulk about the N centre, were selected as suitable target compounds: $[R_3N\{CH_2CH(OH)CH_2OH\}][OH]$, where R_3 = Me_3 (**1**), Me_2Et (**2**), $Me_2\{CH_2CH_2OH\}$ (**3**), $MeEt_2$ (**4**), Me_2Bz (**5**), $Me_2\{CH_2CH(OH)CH_2OH\}$ (**6**), Et_3 (**7**). Compounds **3**[OH] and **6**[OH] also had additional OH functionalities. Lovett has published a method for the preparation of **3**[OH] [15] involving quarternisation of a tertiary amine by ring opening of 2,3-epoxy-1-propanol in the presence of H_2O and this method was attempted for the syntheses of **1**–**7**[OH] (Eq. (3)). All reactions, with the exception of that intended to produce **7**[OH], gave the desired products in relatively good yields (61–89%). ^1H and ^{13}C spectra of the resulting solutions (except **7**[OH]), although complicated by the chiral and prochiral centres on the cations, were consistent with the expected structures. The ^{13}C spectrum for "**7**[OH]" indicated that oligomerisation of the glycidol had occurred (δ_C 66.9–74.2 and δ_H 3.0–3.3 ppm) and signals attributable to unreacted Et_3N were also detected. This suggests that steric hindrance about the nitrogen atom prevented rapid quarternisation by the epoxide. Accurate mass spectrometry data (DI/ESI) confirmed that the desired cations had been formed in all reactions. Aqueous solutions of **2**[OH], **3**[OH], **4**[OH] and **6**[OH] also showed weak signals at *m/z* values corresponding to ions with masses that were multiples of 74 *m/z* greater than those of the target cations. 74 *m/z* corresponds to a 'ring-opened glycidol' unit and therefore suggests that oligomerisaton of the epoxide did occur to a small extent, as a competing reaction, under these experimental conditions. In contrast, and consistent with NMR data, the accurate mass spectrometry data for solution "**7**[OH]" demonstrated that the extent of oligomerisation was so great that this was the dominant reaction process. Solution **7**[OH] was therefore not used for further studies. With the exception of **3**[OH] [15] all other compounds are previously unreported.

$$R_3N + CH_2(O)CHCH_2OH + H_2O \rightarrow [R_3N\{CH_2CH(OH)CH_2OH\}][OH] \quad (3)$$

$$R_3N + ClCH_2CH(OH)CH_2OH \rightarrow [R_3N\{CH_2CH(OH)CH_2OH\}][Cl] \quad (4)$$

Chloride salts of the same series of diol-functionalised tetraorganoammonium cations were also prepared, **1**,**2**,**4**–**7**[Cl]. These chlorides, obtained as white hygroscopic solids or colourless oils, were isolated in good yields (56–99%) by the quaternisation reaction (Eq. (4)). The hygroscopic nature of these materials made it difficult to obtain reliable elemental analysis data, although 'close fits' are reported in Section 2. Surprisingly, only compounds **1**[Cl] and **4**[Cl] have had characterisation data previously reported [16,17]. ^1H and ^{13}C spectra were consistent with the structures. The ^1H spectrum of **7**[Cl] was particularly well resolved and a complete assignment of the observed coupling patterns is given in the experimental characterisation data. Accurate mass spectrometry data (DI/ESI) confirmed that the desired cations had been obtained in all cases.

The interaction of **1**–**6**[OH] with $B(OH)_3$ in aqueous solution in molar ratios 2:1, 1:1, and 1:5 were examined by ^{11}B NMR spectroscopy, and results are presented in Table 1. A representative ^{11}B spectrum for the solution obtained from **1**[OH] and $B(OH)_3$ in a 2:1 ratio is shown in Fig. 1, where the presence of 2 major high frequency signals and 2 very minor low frequency signals can clearly be seen. Formation of the neutral zwitterionic monoborate and cationic monoborate complexes are shown in Eqs. (5) and (6). The resonance signals at 10.0, 6.1, 1.8, and 0.96 may be assigned [11,14] to the (α,β)(α,β)-bischelate complex cation, $[R_3N\{CH_2CH(O)CH_2O\}_2B]^+$, Fig. 2(ii), the neutral (α,β)-monochelate zwitterionic complex, $[R_3N\{CH_2CH(O)CH_2O\}B(OH)_2]$, Fig. 2(i), the orthoborate ion, $[B(OH)_4]^-$, and the four-coordinate B atom of the pentaborate anion, $[B_5O_6(OH)_4]^-$, respectively.

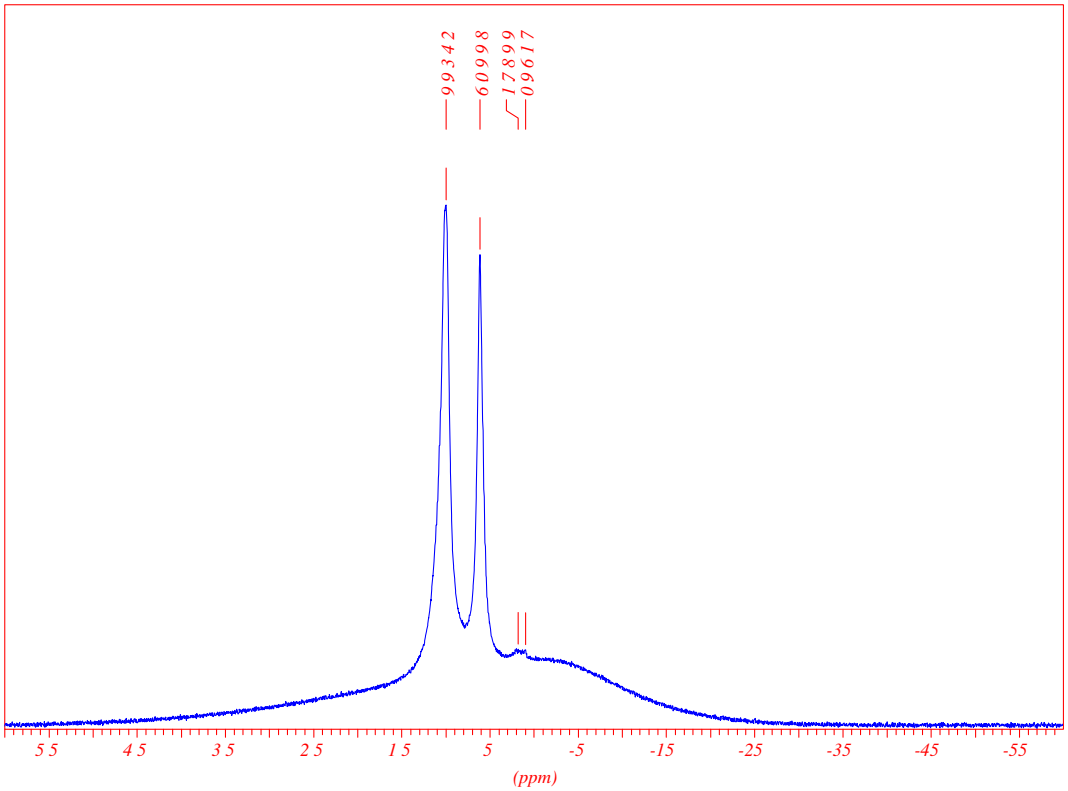

Fig. 1. Representative ^{11}B spectrum of a solution obtained from **1**[OH]:$B(OH)_3$ 2:1 in aqueous solution ([B] ~ 1.8 M).

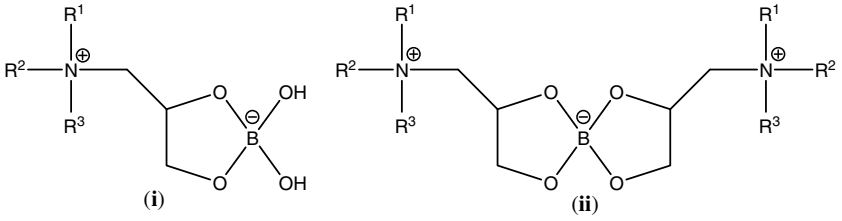

Fig. 2. Structural formula of the tetrahedral (i) zwitterionic and (ii) cationic monoborates.

The data reported for compounds **1**–**5**[OH] with $B(OH)_3$ in a 2:1 ratio in Table 1 demonstrate that bischelate cationic monoborate species are the major species present in solution, accounting for ~67% of the total B present. This result is not unsurprising considering the molar ratios, but that ~33% of the total B is present as the neutral zwitterionic monochelate species is perhaps unexpected. Presumably the neutral zwitterionic species are stabilised by Coulombic interactions, and such effects destabilise the bischelate cationic complex. The identity of the substituent groups at N^+ has very little influence on the equilibrium concentrations of the species observed. In particular, **3**[OH], with the 2-hydroxyethyl substituent on N^+, did not show any differing behaviour, indicating that this 'isolated' hydroxy group was not interacting with the B centre. The reaction of **6**[OH] with $B(OH)_3$ in a 2:1 ratio led to the formation of a cationic complex borate complex in a far higher proportion compared with that observed for **1**–**5**[OH]. Although **6**[OH] has two potential bidendate sites per N^+, the cation was still not observed exclusively.

$$[R_3N\{CH_2CH(OH)CH_2OH\}][OH] + B(OH)_3 \rightarrow [R_3N\{CH_2CH(O)CH_2O\}B(OH)_2] + 2H_2O \quad (5)$$

$$[R_3N\{CH_2CH(OH)CH_2OH\}][OH] + [R_3N\{CH_2CH(O)CH_2O\}B(OH)_2] \rightarrow [R_3N\{CH_2CH(O)CH_2O\}_2B][OH] + 2H_2O \quad (6)$$

The interaction of **1**–**5**[OH] with $B(OH)_3$ in a 1:1 ratio (Table 1) showed identical species present to those observed in the 2:1 ratio but their relative amounts were different. The neutral zwitterionic monoborate was now the dominant species (~65% of total B), but the cationic bischelate was still observed in significant quantities (~30%). **6**[OH], with the 2 diol substituents on N^+, gave a cationic complex in preference to the zwitterionic complex.

The spectra obtained for **1**–**5**[OH] with $B(OH)_3$ in a 1:5 ratio were fundamentally different from those with lower $B(OH)_3$ ratios (Table 1). Now the major species present were the pentaborate anion $[B_5O_6(OH)_4]^-$ and unreacted $B(OH)_3$, and the B atoms are approximately equally divided between these two species. At first sight this appears contrary to the integration values of ~18% and ~70%, respectively. However, the four three-coordinate centres of the pentaborate anion have never been observed and are believed to be so broad that they are effectively lost in the baseline and therefore may be considered as NMR silent [18]. Since there must be four such three-coordinate centres associated with each four-coordinate B atom, their presence, although not seen, must be taken into account when noting the location of the B atoms. The zwitterionic and cationic monoborate species are also present in theses samples, in small and approximately equal amounts, and comprise ~5–10% of total B. The reaction of **6**[OH] with $B(OH)_3$

at 1:5 again gave a solution with a higher proportion of zwitterionic and cationic species (~30% of total B) with the remaining total B split almost equally between the $B(OH)_3$ and $[B_5O_6(OH)_4]^-$.

In order to further extend the above study we investigated the reactions of $[Me_4N][OH]$ with $B(OH)_3$ and $[Me_3NCH_2OH][OH]$ with $B(OH)_3$ in 1:1 and 1:5 ratios. These cations have a strong structure directing effect in related silicate systems [19] where the octameric cubic $[Si_8O_{20}]^{8-}$ type structures are observed in preference to the normal equilibrium mixtures of Q^n species, which are favoured when alkali metal cations are present. The resulting solutions gave ^{11}B spectra which were similar to those described by Salentine [20] for aqueous solutions containing metal borates and 'synthetic' alkali metal borates prepared from corresponding ratios of alkali metal hydroxides and $B(OH)_3$, and contain $[B_5O_6(OH)_4]^-$, $[B_3O_3(OH)_4]^-$ and $B(OH)_3$. Our TMA and choline borate solutions were more concentrated than those described by Salentine and accordingly have more of the boron present as triborate anions rather than boric acid. Therefore there is very little or no structure directing effect, in relation to borate anion speciation, associated with these cations in aqueous solution. A comparison of sodium, TMA and choline borate solutions with the borate solutions prepared using **1**–**5**[OH] (Table 1) can also be made: the $[B_3O_3(OH)_4]^-$ anion does not occur in the presence of **1**–**5**[OH], and chelated monoborates are formed in preference to this anion.

Having shown by ^{11}B NMR the existence in aqueous solution of the neutral zwitterionic and cationic monoborate species, our attention was subsequently drawn to trying to isolate and then purify these species. Attempts to isolate the zwitterionic species by extraction into polar non-aqueous solvents were unsuccessful and our focus shifted to trying to obtain these neutral species in non-aqueous solvents. The reaction of the tetraorganoamomonium chlorides, **1**,**2**,**4**–**7**[Cl] with $B(OH)_3$ in a 1:1 molar ratio in MeOH solution was attempted but the three-coordinate B centres were unreactive towards ester formation [9,10]. A variation of this procedure involved the interaction of methanolic solutions of **2**,**4**–**7**[Cl] with 1 equiv. of $Na[B(OH)_4]$ (dissolved in the minimum amount of H_2O); the aim here was to eliminate NaCl and form the neutral zwitterionic monoborate (Eq. (7)).

$$[R_3N\{CH_2CH(OH)CH_2OH\}][Cl] + Na[B(OH)_4] \rightarrow NaCl + [R_3N\{CH_2CH(O)CH_2O\}B(OH)_2] + 2H_2O \quad (7)$$

NMR analysis of these solutions confirmed that they contained the desired zwitterionic monoborate as the major component (41–61%) in all cases, but that there were still significant amounts of the cationic (8–39%) and uncomplexed $B(OH)_3/B(OH)_4$ species present. Removal of solvent and extraction of the residues with MeOH yielded soluble fractions which contained predominantly zwitterionic monoborates; thus the proportion of B contained in the zwitterionic complexes derived from **2**[Cl] and **4**[Cl] was increased to 91%. Extraction with other polar solvents was attempted but were not as effective in 'purifying' the zwitterionic monoborates. However, it was never possible to isolate pure samples of the zwitterionic monoborates as the cationic monoborates were slightly soluble in MeOH. This was evidenced by their characteristic ^{11}B chemical shift and qualitative tests for $Cl^-(AgNO_3)$.

4. Conclusion

The interaction of $B(OH)_3$ with a number of cationic 1,2-diol moieties derived from substituted tetraorganoammonium cations $[R_3N\{CH_2CH(OH)CH_2OH\}]^+$ (with $[OH]^-$ or $[Cl]^-$ counterions) at B:N ratios of 2:1, 1:1 and 1:5 have been investigated by ^{11}B NMR spectroscopy. Complex equilibria appear to operate in all cases but cationic bischelate species, $[R_3N\{CH_2CH(O)CH_2O\}_2B]^+$, dominate in the 2:1 ratio solutions, zwitterionic monochelate species, $[R_3N\{CH_2CH(O)CH_2O\}B(OH)_2]$, dominate in the 1:1 solutions, and the pentaborate anion, $[B_5O_6(OH)_4]^-$, dominates in the 1:5 solutions. The ^{11}B NMR spectra of borate solutions derived from $[NMe_4][OH]$ and $[Me_3NCH_2CH_2OH][OH]$ are essentially the same as those observed for borate solutions with alkali metal cations, and structure directing effects (towards the anion) are not observed in these borate systems.

ABSTRACT

Two oxovanadium(V) salicylhydroximate complexes, $[VO(SHA)(H_2O)]\cdot 1.58H_2O$ (**1**) and $[V_3O_3(CSHA)_3(H_2O)_3]\cdot 3CH_3COCH_3$ (**2**) have been synthesized by reaction of VO_4^{3-} with *N*-salicyl hydroxamic acid ($SHAH_3$) and *N*-(5-chlorosalicyl) hydroxamic acid ($CSHAH_3$), respectively, in methanol medium. Compound **1** on reaction with pyridine 2,6-dicarboxylic acid ($PyDCH_2$) yields mononuclear complex $[VO(SHAH_2)(PyDC)]$ (**3**). Treatment of compound **3** with hydrogen peroxide at low pH (2-3) and low temperature (0–5 °C) yields a stable oxoperoxovanadium(V) complex $H[VO(O_2)(PyDC)(H_2O)]\cdot 2.5H_2O$ (**4**). All four complexes (**1**–**4**) have been characterized by spectroscopic (IR, UV–Vis, ^{51}V NMR) and single crystal X-ray analyses. Intermolecular hydrogen bonds link complex **1** into hexanuclear clusters consisting of six $\{VNO_5\}$ octahedra surrounded by twelve $\{VNO_5\}$ octahedra to form an annular ring. While the molecular packing in **2** generates a two-dimensional framework hydrogen bonds involving the solvent acetone molecules, the mononuclear complexes **3** and **4** exhibit three-dimensional supramolecular architecture. The compounds **1** and **2** behave as good catalysts for oxygenation of benzylic, aromatic, carbocyclic and aliphatic hydrocarbons to their corresponding hydroxylated and oxygenated products using H_2O_2 as terminal oxidant; the process affords very good yield and turnover number. The catalysis work shows that cyclohexane is a very easily oxidizable substrate giving the highest turnover number (TON) while *n*-hexane and *n*-heptane show limited yield, longer time involvement and lesser TON than other hydrocarbons.

1. Introduction

Activation of C–H bond is one of the challenging problems in homogeneous catalysis research since it involves conversion of crude oil and natural gas constituents into oxygenated derivatives such as alcohols or carbonyl compounds. In this respect dioxygen and hydrogen peroxide are two most useful oxidants from economic and environmental standpoints [1–3]. Interest in oxovanadium(V) chemistry has recently been accelerated due to high potentiality of dioxygen activation along with the ability of oxo-peroxo vanadium(V) species to function as important intermediates in the in vivo enzymatic processes [4–7]. Also synthetic oxoperxovanadium(V) complexes are known to exhibit stoichiometric and in some cases catalytic oxidation of various organic substrates to their oxidized products [8–10]. Mimoun et al. [11] reported oxovanadium(V) peroxo complexes of the types $[VO(O_2)(O–N)(L)]$ and $[VO(O_2)(O–N)_2]^-$, where L = solvent molecule; O–NH = pyridine 2-carboxylic acid and pyrazine 2-carboxylic acid and the complexes were shown to be good oxidizing agents for the stoichiometric hydroxylation of aromatic hydrocarbons. The first catalytic hydrocarbon oxidation using oxovanadium(V) compounds was furnished by Shul'pin et al. [12] using the Mimoun type compounds [11]. Using those catalysts Shul'pin et al. [13] also succeeded in the oxidation of methane to methanol, formaldehyde or formic acid with tertiary butyl hydroperoxides (TBHP) as oxidant [14]. Remias et al. [8] reported oxidation of benzene and cyclohexane using $[V(acac)_3]$, $[VO(acac)_2]$ and $[VO(O_2)(2\text{-picolinate})(H_2O)_2]$ as catalysts and H_2O_2 as oxidant. We described [15] the synthesis and crystal structure of a hydroxamato[1] complex, namely $[VO(BPHA)_2(Cl)]$; (BPHAH = *N*-benzoyl *N*-phenyl hydroxamic acid [16]) which was shown to act as catalyst for the oxidation of wide variety of hydrocarbons. Besides, being good analytical reagents [17,18] and having siderophoric role, the hydroxamic acids are also important for numerous biological functions [19]. In this paper, we report the

doi:10.1016/j.poly.2008.03.031

synthesis, spectroscopic and structural characterization of salicylhydroximato-oxovanadium(V) complexes, $[VO(SHA)(H_2O)] \cdot 1.58H_2O$ (**1**) and $[V_3O_3(CSHA)_3(H_2O)_3] \cdot 3CH_3COCH_3$ (**2**) ($SHAH_3$ = *N*-salicyl hydroxamic acid and $CSHAH_3$ = *N*-(5-chlorosalicyl) hydroxamic acid along with their catalytic properties in functionalization of hydrocarbons. This work also reports the synthesis and structural characterization of two mononuclear oxovanadium(V) complexes, $[VO(SHAH_2)(PyDC)]$ (**3**) and the other is a peroxovanadium(V) complex $H[VO(O_2)(PyDC)(H_2O)] \cdot 2.5H_2O$ (**4**), [20]. Complex **3** is obtained by reaction of complex **1** with $PyDCH_2$ and is the second example of an oxovanadium(V) complex containing uninegetive bidentate (O,O donor) salicylhydroximate ligands [21,22] whereas complex **4** is obtained by the reaction of **3** with hydrogen peroxide. Notably, oxoperoxovanadium(V) complexes with $PyDC^{2-}$ ligand [23] exhibits poor catalytic properties in the oxidation of hydrocarbons due to their unusual stability.

2. Experimental

2.1. Physical measurements

The IR spectra were recorded as KBr pallets on a Nicolet 520 FTIR spectrometer and Electronic spectra on a Hitachi U-3410 UV–Vis–NIR spectrophotometer. ^1H NMR spectra was measured in $CDCl_3$ on a Bruker AM 360 (300 MHz) FT NMR spectrometer using TMS as an internal standard. The 51 V NMR was recorded in CD_3CN on a GEOL 400 MHz NMR spectrometer and a systronics (India) model 335 digital conductivity bridges where a bottle type cell was used to determine the molar conductance values of the isolated complexes at 25 °C using a thermostatic arrangement. The magnetic susceptibilities at 298 K were obtained by the Gouy method using $Hg[Co(NCS)_4]$ as a standard. Elemental analyses were performed with the help of a Perkin–Elmer 240C elemental analyzer. GLC measurements were done in an Agilent model 6890N gas chromatograph using HP-1 and INNOWAX capillary column in FID mode with dinitrogen as carrier gas.

2.2. Materials

Ammonium metavanadate and hydroxylamine hydrochloride were of extrapure variety and obtained from Sisco Research Laboratory (India). Methyl Salicylate was obtained from S.D. Fine-Chem. Ltd (India). 5-Chloro salicylic acid and 2,6-pyridine dicarboxylic acid ($PyDCH_2$) were obtained from Aldrich Chemicals. Potassium hydroxide pellets and methanol (G.R.) were the products of E. Merck (India) and were directly used. Ethanol (95%) was obtained from Bengal Chemical and Pharmaceutical Works (Calcutta), and was lime distilled before use. All other chemicals needed were obtained from E. Merck (India). *N*-Salicyl hydroxamic acid ($SHAH_3$) and *N*-(5-chloro salicyl) hydroxamic acid ($CSHAH_3$) were synthesized following the literature method [16]. Acetonitrile, dichloromethane and acetone were further purified by the literature method [24] for physico-chemical studies. Iolar II grade dioxygen, dihydrogen, zero air, and dinitrogen gas used for chromatographic analysis were obtained from Indian Refrigeration Stores, Calcutta. Cyclohexane and ethylbenzene were obtained from S.D. Fine-Chem. Ltd (India) while cyclohexanol, cyclohexanone, tetralin and tetralone were obtained from Sisco Research Laboratory, India (extrapure AR grade). Toluene, benzene, *n*-hexane, *n*-heptane and *n*-pentane, diphenylmethane, *n*-heptanol, *n*-hexanol, *n*-pentanol, benzaldehyde and phenol were obtained from E. Merck (India) (G.R grade). Triply distilled (all glass) water was used whenever necessary. All the solvents used for chromatographic analysis were either of HPLC, spectroscopic, or GR grade and in all cases their purity was confirmed by GC analysis before use.

2.3. Preparation of the complexes

2.3.1. $[VO(H_2O)(SHA)] \cdot 1.58H_2O$ (**1**) and $[V_3O_3(H_2O)_3(CSHA)_3] \cdot 3CH_3COCH_3$ (**2**)

NH_4VO_3 (0.586 g, 5 mmol) was dissolved in 15 mL of distilled water by stirring at 40–55 °C. The pH of the solution was adjusted at 3–4 by adding 4(M) HCl. $SHAH_3$ (0.76 g, 5 mM; 0.94 g $CSHAH_3$ for compound **2**) was dissolved in minimum volume of methanol (ca.15 mL) and the resulting solution was added to vanadate solution, with stirring (15 min) when the solution becomes deep blue which was kept at room temperature. After 2–3 days, deep blue cubes separated. The crystals were collected (for **1**), washed off with distilled water and dried in vacuo. Yield: 1.05 g (77.5%). *Anal.* Calc. for $C_7H_6NO_{6.58}V$: C, 32.25; H, 2.32; N, 5.41; V, 19.60. Found: C, 32.03; H, 2.43; N, 5.10; V, 19.15%. IR (KBr disc, cm^{-1}): 3441(broad), 1626(w), 1598(s): ν(C=O), 1566(w), 1468(s), 1365(s), 1240(m), 1157(w), 1108(w), 1044(w), 971(s): ν(V=O), 757(m), 678(m), 644(m), 582(w), 508(w), 451(w). ^{51}V NMR (105.03 MHz, CD_3CN, 296 K): δ ppm, −236.58. UV–Vis, λ_{max} nm (ε $M^{-1}cm^{-1}$): 625(18380), 493(sh), 294(34690), 247(sh). The crude compound (**2**) was recrystallized by slow diffusion of acetone solution of the compound in light petroleum (40–60 °C). Yield: 1.2 g (73%). *Anal.* Calc. for $C_{30}H_{33}Cl_3N_3O_{18}V_3$: C, 36.6; H, 3.38; N, 4.27; Cl, 10.83; V, 15.56. Found: C, 36.47; H, 3.40; N, 4.16; Cl, 11.42; V, 15.13%. IR (KBr disc, cm^{-1}): 3367(broad), 1627(w), 1596(s): ν(C=O), 1556(w), 1500(s), 1458(s), 1429(m), 1334(s), 1294(m), 1230(m), 1161(w), 1122(w), 1051(w), 977(s) and 962(s): ν(V=O), 894(w), 862(w), 825(m), 763(w), 739(s), 669(w), 626(m), 601(w), 541(w), 499(w), 455(w), 375(w). UV–Vis λ_{max} nm (ε M^{-1} cm^{-1}): 629(14360), 488(sh), 292(27300), 239(35700).

2.3.2. $[VO(SHAH_2)(PyDC)]$ (**3**)

Complex **1**, 0.403 g (0.5 mmol) was dissolved in methanol (25 mL) and 10 mL aqueous solution of $PyDCH_2$ (0.250 g, 1.5 mmol) was mixed with stirring. After 30 min a deep purple solid was separated. The crude solid was filtered off, washed with water and dried in vacuo. Yield: 0.362 g (62%). Good crystals were obtained by slow diffusion of acetone solution of the complex in light petroleum (40–60 °C). *Anal.* Calc. for $C_{14}H_9N_2O_8V$: C, 43.75; H, 2.34; N, 7.29; V, 13.28. Found: C, 43.15; H, 2.35; N, 6.99; V, 12.92%. IR (KBr disc, cm^{-1}) 3103(m), 2879(w), 1684(s): ν(C=O), 1606(m), 1527(m), 1469(w), 1425(w), 1332(s), 1290(w), 1240(m), 1176(w), 1147(w), 1140(w), 1085(w), 979(s): ν(V=O), 919(m), 842(w), 755(m), 682(w), 669(w), 605(w), 449(w), 387(w). ^{51}V NMR (105.03 MHz, CD_3CN, 296 K): δ ppm, −423.80. UV–Vis λ_{max} nm (ε M^{-1} cm^{-1}): 478(8000); 289(6100); 243(18000).

2.3.3. $H[VO(O_2)(PyDC)(H_2O)] \cdot 2.5H_2O$ (**4**)

Compound **3** (0.401 g, 1.05 mmol) was treated with 30% aqueous H_2O_2 (1 ml, 12.5 mmol) by maintaining the pH of the solution at 2–3 with 4(M) HCl at 0–5 °C. The solution became orange red and was allowed stand in the deep freeze. After 15 days, orange red crystals separated. *Anal.* Calc. for $C_7H_{11}NO_{10.5}V$: C, 25.60; H, 3.34; N, 4.26; V, 15.54. Found: C, 25.27; H, 3.27; N, 4.13; V, 14.98 IR (KBr disc, cm^{-1}): 3209(broad), 3089(w), 2846(w), 1645(s): ν(C=O), 1437(m), 1380(s), 1273(w), 1188(m), 1151(w), 1081(m), 1037(w), 974(s): ν(V=O), 925(s): ν[O–O], 858(w), 837(w), 777(m), 750(m), 682(m), 605(w), 569(m), 451(w). UV–Vis λ_{max} nm (ε M^{-1} cm^{-1}): 427(2700), 270(26500).

2.4. X-ray structure analyses for complexes **1**, **2**, **3** and **4**

Intensity data of complexes were recorded on a Bruker SMART CCD area detector (for **1** and **3**) and an Oxford diffraction X-Calibur CCD system (for **2** and **4**) using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Data analyses were carried out with the

SMART [25] and CRYSALIS [26] programs. The data were corrected for absorption effects using the programs SADABS [27] for **1** and **3** and ABSPACK [28] for **2** and **4**. The structures were solved using direct methods with the SHELX-97 program [29]. In **1**, O8 atom of solvent water molecule was disordered over two positions with occupancy 0.5 and O6 atom of another solvent water molecule was partially occupied (occupancy 0.25). The hydrogen atoms on water molecule, bonded to V atom in **1**, **2** and **4**, were located from difference Fourier maps. The hydrogen atoms (excluding that on the disordered O atom) were included in geometrical positions and assigned fixed isotropic thermal parameters. The non-hydrogen atoms were refined with anisotropic thermal parameters. Relevant crystal data and refinement results for complexes **1**–**4** are given in Table 1.

2.5. Experimental procedure of catalytic hydrocarbons oxidation

The experimental procedure for the catalytic hydrocarbon oxidation reaction involving a wide variety of substrates is described as follows: an acetonitrile solution (10 cm^3) containing a given substrate (5 mmol), oxovadium(V) catalyst (0.05–0.005 mmol) and 30% H_2O_2 (25 mmol) in a high-pressure reactor (100 mL capacity Parr type hydrogenation apparatus) at 60–80 °C was stirred for definite period as shown in Table 7. When required, an aliquot (0.1 mL) of the reaction solution was withdrawn with the help of long needle syringe and was subjected to multiple ether extractions and 1 μL concentrated ether extract was injected to the GC port with the help of 10 μL syringe. The retention times of the peaks were compared with those of commercial standards and the unknown peaks were characterized by GC–MS analysis. In some cases nitrobenzene was used as the internal standard for the calculation of GC yield. The isolated yield in some cases is obtained by multiple ether extractions of the reaction solution after the reaction is over followed by evaporation of ether and acetonitrile by distillation at a mildly reduced pressure (using water aspirator). Isolated yields are however not included in the Table 8. Parr type apparatus was used for the convenience of the physico-chemical studies but it is not absolutely necessary for laboratory as well as industry.

3. Results and discussions

3.1. General characterization, IR and electronic spectroscopy

The compound **1**–**3** are non electrolytes in acetonitrile but **4** (which is freely soluble in water but not in acetonitrile) in aqueous solution exhibits a molar conductance value of 120 Ω^{-1} cm^2 mol^{-1}. This value is much lower for a free H_3O^+ as anticipated for an anionic complex with the structure $H[VO(O_2)(PyDC)(H_2O)] \cdot 2.5H_2O$ confirmed by analytical, spectroscopic and X-ray crystallographic methods. However a $\sqrt{c}$ versus Λ_M plot (Λ_M = molar conductance) of the said aqueous solution shows an asymptotic nature of curve (Fig. S.1) which indicates the existence of protons in undissociated form in one of the carboxylic acid group of coordinated $PyDC^{2-}$ ligand in aqueous solution [30]. All the compounds are diamagnetic at 298 K. As recorded in Section 2, the ν(V=O) vibration in **1**–**4** appears at 971, 977, 979 and 974 cm^{-1}, respectively, indicating that the ligand effect on ν(V=O) varies in the order **3** > **2** > **4** > **1**. The ν(C=O) bands for $SHAH_3$ and $CSHAH_3$ ligands are observed at 1620 and 1625 cm^{-1}, respectively. On complexation these ν(C=O) are shifted to lower wave numbers and appear almost in the same region for both the cases (see experimental section). In $PyDCH_2$, the ν(C=O) vibration occurs at 1705 cm^{-1} but in case of **3** which contains two types of C=O groups, one for the coordinated $SHAH_2^-$ and the other for $PyDC^{2-}$, respectively, appear at 1606 and 1684 cm^{-1}. In compound **4** the ν(C=O) of coordinated $PyDC^{2-}$ appears at 1647 cm^{-1}. In the case of coordinated $PyDC^{2-}$ ligand, the ν(C=O) appearing at ca. 40 cm^{-1} lower wave number region due to lower dative O → C π overlap. The ν(O–O) absorption band in **4** appears at 925 cm^{-1}.

In the complex **1** a new electronic spectral band appears at λ_{max} = 625 nm (ε = 18 375 M^{-1} cm^{-1}) along with a shoulder at 493 nm. These bands can be ascribed to the LMCT transitions in

the trinuclear deep blue compound (acidified VO_4^{3-} is light yellow and the $SHAH_3$ ligand is colourless). Two other low wave length bands are due to intra-ligand transitions and a drastic change in values is due to the fact that in one mole of complex there occurs three moles of ligand. The spectrum of trinuclear deep blue complex **2** ($CSHAH_3$ ligand is also colorless) exhibits similar band sequences as **1** (see Section 2). The slight difference of the actual position of bands between **1** and **2** is due to the presence of chlorine substituent in $CSHAH_3$ ligand. The electronic spectrum of compound **3** which contains both the $SHAH_2^-$ and $PyDC^{2-}$ ligands shows one new (which does not occur in ligand spectra) band at λ_{max} = 478 nm (ε = 8000 M^{-1} cm^{-1}) assignable to the LMCT transition in the reddish mononuclear compound **3** where $PyDC^{2-}$ (($PyDCH_2$ is colourless) coordinates via two oxygen atoms and one nitrogen atom and $SHAH_2^-$ ligand coordinates via two oxygen atoms (see Fig. 6) In orange red **4** the band at λ_{max} = 427 nm; (ε = 2700 M^{-1} cm^{-1}) is due to LMCT transition of $O_2^{2-} \rightarrow$ Vanadium(V).

3.2. Molecular structures

The asymmetric unit of **1** consists of one-third of the trinuclear vanadium salicylhydroximate cluster (Fig. 1), one aqua ligand coordinating to the metal center and solvent water molecules (one lying on the threefold axis, one disordered over two sites with occupancy 0.5 each, and the remaining one with occupancy value 0.25), while that in **2** comprises of a trinuclear vanadium chlorosalicylhydroximate (Fig. 2) with three solvent acetone molecules. The vanadium ions in **1** and **2** are in +5 oxidation state as VO^{3+} unit and related by a threefold axis. The three oxygen and one nitrogen atoms of triply deprotonated ligands, SHA^{3-} (in **1**) and $CSHA^{3-}$ (in **2**) are bound to vanadium, an individual ligand, however donates two hetero-atoms (O,N) to one vanadium atom while the remaining two oxygen atoms of the ligand bind to the adjacent vanadium atom. One oxo and one aqua ligands complete the hexa-coordination of each metal center. The bonding sequence repeats within the cluster forming a nine-membered $V_3N_3O_3$ ring with the vanadium atoms exhibiting distorted octahedral geometries. The phenolate O, aqua O and two hydroximate O, N atoms define the equatorial plane around each vanadium atom while the carboxyl and the oxo O atoms occupy the axial sites; the displacements of metal ions from the corresponding equatorial planes are 0.230(1) Å in **1** and 0.019(1)–0.235(1) Å in **2**. The vanadium-oxo bond lengths in **1** [1.597(3) Å] and **2** [1.580(3)–1.601(3) Å] (Tables 2 and 3) are similar to that reported for analogous structures [31,32]. The V–N [2.030(3) Å in **1** and 2.019(3)–2.037(3) Å in **2**] and V–O [1.851(3) Å in **1** and 1.852(3)–1.861(3) Å in **2**] bond lengths to the hydroximate ligands correspond to the bond distances in oxovanadium(V) hydroximate compounds that have been structurally characterized [33,34]. The V–O(aqua) bond distances in **1** [2.080(3) Å] and **2** [2.049(3)–2.070(3) Å] lie within the range 2.008(2) Å reported for $V–OH_2$(*cis*) and $V–OH_2$(*trans*) distances in aqua oxovanadium(V) complexes [35,36]. The lengthening of V–O (carbonyl) distances [2.136(3) Å in **1** and 2.129(3)–2.150(3) Å in **2**] compared to V–O (phenolic) bond lengths [1.868(3) Å in **1** and 1.862(2)–1.898(3) Å in **2**] in the complexes is due to *trans* influence of the oxo-ligand [37]. The V–V distances in **1** and **2** lie in the range 4.636–4.665 Å.

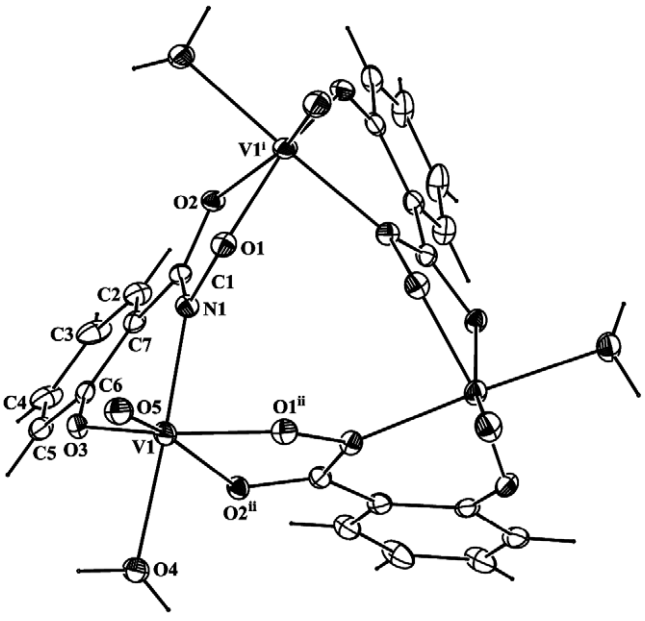

Fig. 1. A view of molecule **1** with atom numbering scheme (lattice held H_2O molecules are omitted for the sake of clarity) (symmetry codes: (i) $-y+1, x-y+1, z$; (ii) $-x+y, -x+1, z$).

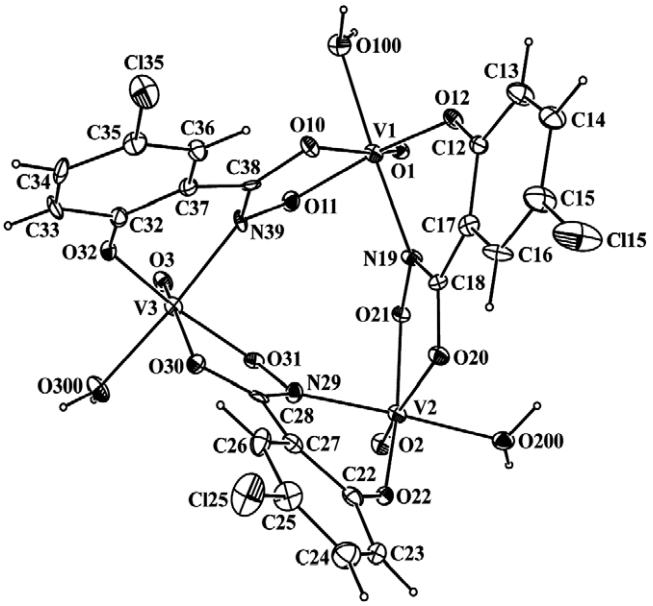

Fig. 2. A view of molecule **2** with atom numbering scheme (lattice held CH_3COCH_3 molecules are omitted for the sake of clarity).

The coordination geometry around the metal center in mononuclear complex **3** (Fig. 3) can be described as distorted octahedral, while that in **4** (Fig. 4) is distorted pentagonal bipyramidal with the oxo O [O(5) in **3** and O(300) in **4**] and carboxyl O [O(2) in **3** or aqua O(400) in **4**] atoms occupying the apical sites. In **3** and **4**, the V–O bond distances *trans* to the oxo ligand are elongated [V(1)–O(2) 2.126(3) in **3**, V(1)–O(400) 2.237(2) in **4**] compared to V–O (equatorial) bond lengths (Tables 4 and 5). Other V–O and V–N bond distances in **3** and **4** (Tables 4 and 5) are comparable to the corresponding values reported for monomeric oxovanadium(V) complexes [38,39]. The two essentially planar

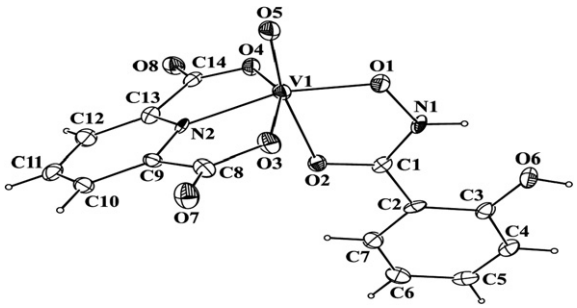

Fig. 3. A molecular view of **3** with atom numbering scheme.

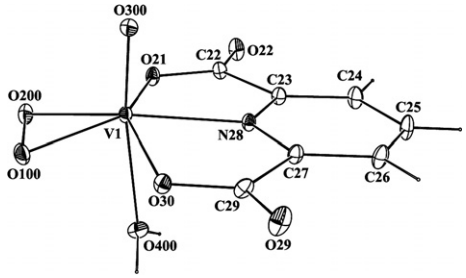

Fig. 4. A view of molecule **4** with atom numbering scheme (lattice held H_2O molecules are omitted for the sake of clarity).

2,6-pyridine dicarboxylate and *N*-salicylhydroximate ligands in **3** are nearly orthogonal to each other; the dihedral angle between the least-squares planes through the ligand atoms is 83.6°(1).

The trinuclear complex molecules in **1** are linked by intermolecular O–H···O hydrogen bonds (Table 6) forming a hexamolecular cluster (Fig. 5). Each hexamolecular cluster consists of six VNO_5 octahedra surrounded by twelve VNO_5 octahedra forming an annular ring with the inner and outer diameters 11.4 and 19.7 Å, respectively. The solvent H_2O molecules lie within the inner core of the ring. The hexamolecular clusters in **1** are interpenetrated forming a novel three-dimensional framework structure (Fig. 6).

In complex **2**, a pair of intermolecular O(300)–H(6)···O(2) hydrogen bonds (Table 6) connects two complex molecules forming a centrosymmetric $R_2^2(14)$ dimeric ring centered at (1/2,1/2,0). The linking of dimeric rings via intermolecular O(300)–H(5)···O(12) hydrogen bonds in **2** produces an infinite one-dimensional chain propagating along the [100] direction. Additional reinforcement within the polymeric chain is provided by the solvent

Symmetry codes: (i) $y-2/3, x-1/3, -z+1/6$; (ii) $-x, 1-y, 2-z$; (iii) $1+x, y, z$; (iv) $1-x, 1-y, 2-z$; (v) $x, -1+y, z$; (vi) $-x+1, y+1/2, -z+1/2$; (vii) $x-1, -y+1/2, z-1/2$; (viii) $-x+2, -y, -z+1/2$; (ix) $1-x, -y, -z$. $C_g(5)$ is the centriod of the ring C(2)–C(7).

acetone molecules through O(200)–H(4)···O(84) and O(100)–H(2)···O(84) intermolecular hydrogen bonds. The remaining C–H···N hydrogen bonds involving solvent acetone molecules join the parallel [100] chains along the [010] direction to generate a two-dimensional network in **2** (Fig. 7).

The intermolecular aggregation in **3** is determined by a combination of O–H···O, N–H···O, C–H···O hydrogen bonds and π–π stacking interactions (Table 6). Intermolecular O(6)–H(6A)···O(7) and N(1)–H(1)···O(8) hydrogen bonds link the molecules into two-dimensional net of $R_4^4(34)$ ring. Finally, the interlinking of two-dimensional nets by C(10)–H(10)···O(5) hydrogen bond forms a three-dimensional supramolecular framework in **3**. The molecular packing in **3** is such that the π–π stacking interactions between the phenyl rings (C2–C7) of adjacent molecules are optimized. The phenyl rings (C2–C7) of molecule at (x,y,z) and $(1-x,-y,-z)$ are strictly parallel, with an interplanar spacing of 3.34 Å, ring centriod separation of 3.778 Å, corresponding to a ring offset of 1.76 Å.

The crystal packing in **4** exhibits several intermolecular O–H···O and C–H···O hydrogen bonds (Table 7). The pairs of C–H···O hydrogen bonds, C(24)–H(24)···O(29) and C(26)–H(26)···O(22), connect molecules of **4** into infinite one-dimensional chain

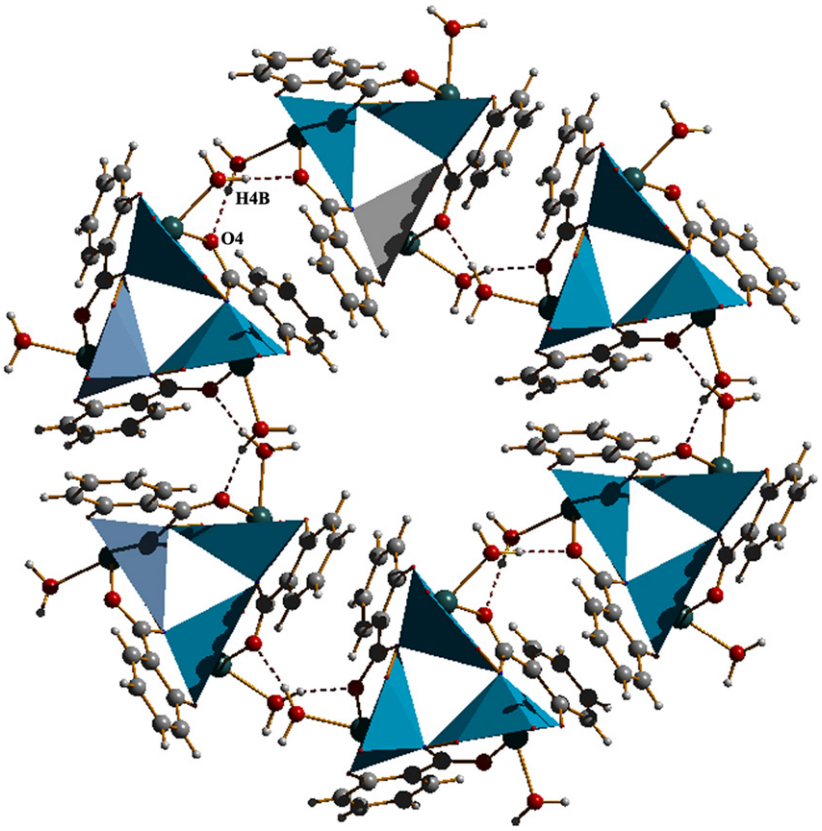

Fig. 5. The molecular packing of **1** showing the formation of hexamolecular cluster.

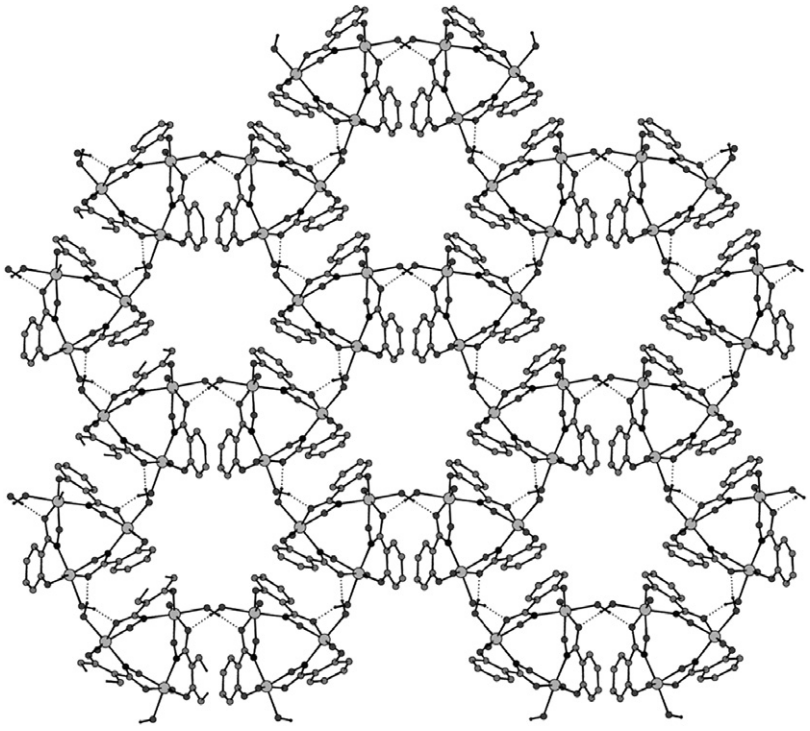

Fig. 6. Three-dimensional supramolecular network formed by interpenetrating hexamolecular rings in **1**.

propagating along the [101] direction through the formation of $R_2^2(10)$ rings. Inter-linking of parallel chains via O(400)–H(401)···O(22) hydrogen bonds generates two-dimensional molecular sheets, which are further connected by intermolecular O–H···O hydrogen bonds involving the lattice water molecules to form a three-dimensional supramolecular framework in **4**.

3.3. ^{51}V NMR spectroscopy

The ^{51}V NMR spectra for the complexes **1** and **3** at temperature 296 K in CD_3CN solvent exhibited a single peak namely, at −236.58 ppm for **1** and −423.80 ppm for **2** signifying a single species in solution in both the cases. The upfield shifting on going from **1** to **3** indicates that the nucleus of **3** is more shielded than that of **1** (by 187.2 ppm). This is due to the transformation of trinuclear complex **1** containing only bridging SHA^{3-} ligands to a mononuclear mixed ligand ($PyDC^{2-}$ and $SHAH_2^{-}$) complex **2**, in which one of the ligands, namely SHA^{3-} captures two protons [40] and also a new ONO ligand is incorporated which shields the vanadium nucleus more effectively.

3.4. Catalytic properties of the complexes

Complexes **1** and **2** posses efficient catalytic properties in the oxidation/functionalization of aromatic, carbocyclic and aliphatic hydrocarbons to their phenolic, alcoholic and carbonyl functions as shown in the Table 8, where **1** is shown as a representative catalyst. The catalytic efficiency of the two oxovanadium(V) complexes **1** and **2** for hydrocarbon oxidation are very much comparable (shown in Table 9) indicating that the electron withdrawing chlorine substituent in **2** has little resultant effect in the catalytic oxidation reaction. Compound **3** is not a good catalyst. The Table 8 exhibits that the catalytic potentiality of **1** is quite satisfactory without the uses of any additives or co-catalysts compared to other oxovanadium(V) catalysts reported earlier [8–10]. However product selectivity obtained are not very good excepting in a few cases, namely, benzene, diphenylmethane and toluene (up to 10 h). After 10 h toluene starts affording other products (see Table 8) but in benzene and diphenylmethane the selectivity is maintained until the completion of the reaction when almost quantitative conversion of substrate to products occurs (for details see S1). It has been observed that some products are selectively obtained at a short reaction time but if the reaction is allowed to proceed for a longer period other products appear. Interesting examples are shown by tetralin and cyclohexane substrates (for explanation see S2). Another interesting example is provided by the conversion of ethyl benzene to 1-phenyl ethanol vis-a-vis acetophenone. It is observed that the 1-phenyl ethanol (24%) is obtained at a higher proportion than acetophenone (19.5%) upto a reaction period of 12 h and then acetophenone production started increasing at the cost of 1-phenyl ethanol (Fig S2; see also Table 8). 2-pentanone (39.4%) and 2-pentanol (24.6%) and 2-pentanoic acid (9.2%) are obtained as the main products from n-pentane functionalization. 2-Hexanone (33.4%), 1-hexanol (18.46%), 2-hexanol (12%) and hexanoic acid (5%) are obtained as the principal products from *n*-hexane. The substrate *n*-heptane affords mainly 2-heptanone (31.8%), 1-heptanol (22.6%) and 2-heptanol (11.8%).

3.5. Probable mechanism of catalytic oxidation of hydrocarbons

The catalytic reaction mixture contains the hydrocarbon substrate, H_2O_2 and the trinuclear complex **1** as catalyst which is converted to a new intermediate peroxo species $[V^{V}O(O_2)(SHAH_2)(H_2O)]$ (**A**) by reacting with H_2O_2 (see Scheme 1). This in situ generated peroxo species **A** oxidizes the C–H bond of the substrate (hydrocarbons) leading to the oxygenated products via the forma-

[b] %Selectivity is a spectacular in the given time frame.
[c] T.O.N = ratio of moles of products obtained to the moles of catalyst used. The mole ratios of the catalyst to the substrate are as follows: 1:400 (for entries 1, 3, 4 and 5), 200 (for entries 2, 2a and 7), 1000 (for entry 6) and 100 (for entries 8 and 9).

Table 9
Comparative catalytic efficiency of compound **1** and **2** in the case of some representative hydrocarbons oxidation

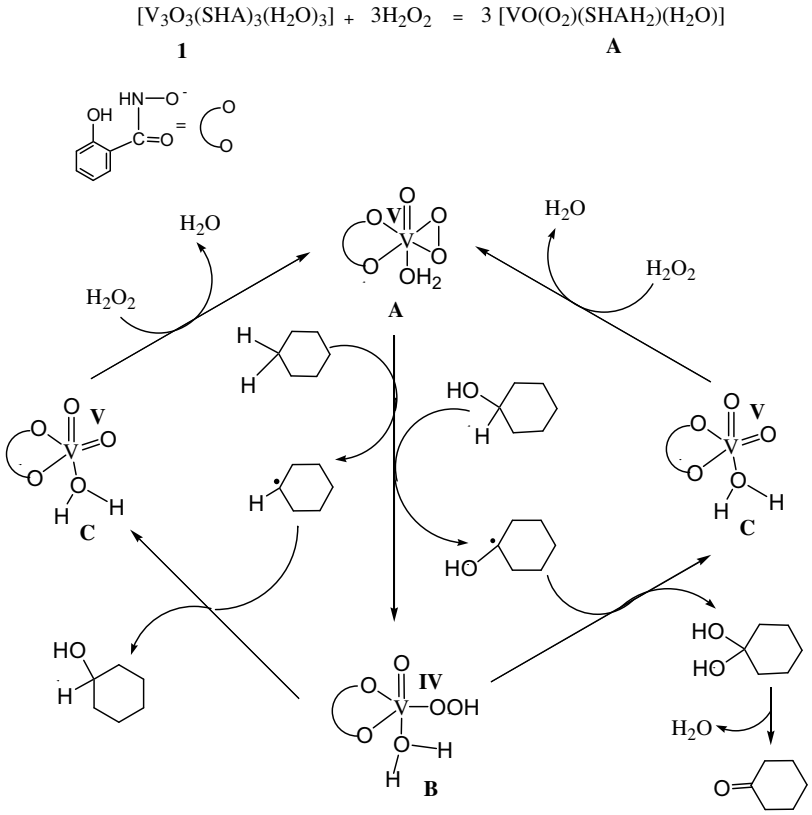
Entry	Catalyst	Oxidation of benzene (t = 15 h)		Oxidation of cyclohexanol (t = 10)	
		GC yield (%)	TON	GC yield (%)	TON
1	$[V_3O_3(SHA)_3(H_2O)_3]$ (**1**)	55	550	98	980
2	$[V_3O_3(CSHA)_3(H_2O)_3]$ (**2**)	48	480	84	840

In both the cases, the substrate: catalyst ratio is 1000:1 and concentration of H_2O_2 is 25 mmol.

tion of two intermediates $[V^{IV}O(OOH)(SHAH_2)(H_2O)]$ (**B**) and $[V^{V}O_2(SHAH_2)(H_2O)]$ (**C**). The intermediate **C** then reacts with H_2O_2 to form **A**. All the above observations suggest a sequence of reaction steps as is shown in the Scheme 1 using cyclohexane as representative substrate. That the invocation of radical mechanism is necessary, is confirmed by the acceleration of the rate of reaction when the experiment is conducted by the irradiation of a tungsten lamp as well as by adding traces of azoisobutyronitrile (AIBN) and decelaration of the same by using benzoquinone during the course of reaction. Surprisingly, in an earlier report [15] we failed to notice the effect of AIBN and benzoquinone.

4. Conclusions

V_2O_5 and the allied vanadium compounds were long known to have industrial uses as substrate oxidation catalyst operating via heterogeneous mode. But solid vanadium compounds acts as irritants to the conjunctive and respiratory tract. Consequently the



Scheme 1. Probable mechanism of the catalytic oxidation of hydrocarbons (cyclohexane as representative substrate) using compound **1** as catalysts in presence of H_2O_2.

inhalation of catalyst dust is extremely unpleasant and should be avoided. The homogeneous oxidation of organic compounds by vanadium complexes as catalyst becomes very much effective in presence of H_2O_2 or dioxygen as terminal oxidant instead of *tert*-butyl hydroperoxide (TBHP). We have observed that TBHP as terminal oxidant behaves as far less selective in hydrocarbon oxidation using **1** and **2** as catalyst. Moreover, TBHP is not at all an environment friendly oxidant specially at temperature above 50–60 °C and even if operated at a lower temperature waste disposal problem arises. If the experiment is conducted at higher temperature, CO and CO_2 are evolved via the decomposition of TBHP.

ABSTRACT

Treatment of $Ag_6(tsac)_6$ (tsac = thiosaccharinate anion) with pyridine (py) and 1,10-phenanthroline (*o*-phen) each affords two novel silver(I)-thiosaccharinate complexes: dinuclear $[Ag_2(tsac)_2py]$ (**1**) and polynuclear $[Ag(tsac)(o\text{-phen})]_n$ (**2**). Both crystal structures have been determined by X-ray diffraction and spectroscopic structural analysis (IR and Raman, UV–Vis, ^1H and ^{13}C NMR) have also been made for both compounds. Thermal stability analysis (TGA and DTA) of complex **1** are used to confirm the strength of the pyridine coordination to the silver ion. The molecular structure of complex **1** shows some astonishing characteristics. The two silver atoms are in different environments: one of them is surrounded by two S atoms, while the other completes its coordination sphere by three N atoms, two from the thiosaccharinate anions and the third from a pyridine molecule. The short Ag(1)–Ag(2) contact distance, 2.9681(8) Å, indicates an interaction between the two silver metal atoms exists. Complex **2** shows a thiosaccharinate molecule bridging two silver atoms through the exocyclic S atom while the *o*-phenanthroline ligand is coordinated as a bidentate *N,N* chelate, forming a polynuclear chain. Quantum chemical calculations confirm the argentophilic character of the Ag–Ag interaction in complex **1**, and its structure and vibrational assignments were correlated and confirmed theoretically.

1. Introduction

The use of silver(I) coordination compounds as building blocks for the construction of dimeric, polymeric or supramolecular structures is a continuous growing research field [1–4]. Interesting applications in photographic industry [5,6], medicine [7,8], luminescent [9] and magnetic [10] devices, have been investigated for such new substances. The flexibility of silver(I) ions to adopt different coordination geometries, such as linear, bent, T-shaped, trigonal planar, or tetrahedral, contributes to the existence of a great variety of coordination architectures [4]. Also, the tendency of silver(I) ions to aggregate themselves, reported as "argentophilicity", can control the shape of their coordination spheres in the solid state structures [11–14]. The argentophilic interaction has been calculated as weaker than the closed shell interactions of the other coinage metals [15–18], but the results are still controversial [14,19,20]. The argentophilicity of silver(I) ions has been demonstrated in a number of substances with ligand unsupported Ag(I)–Ag(I) short interactions [11–14] and more examples exist of ligand supported arrangements [8,21–23].

In the chemistry of silver carboxylates many examples of polymeric structures based on dimeric "$Ag_2(RCOO)_2$" building blocks have been reported (see Scheme 1I) [21,23]. In many of those complexes the intra-annular Ag–Ag distances fall in the range between 2.8 and 3.0 Å, very close to the 2.88 Å interatomic distance in metallic silver [24]. Also, very short distances have been reported for bis(3-hydroxy-4-phenyl-2,2,3-trimethylcyclohexane-carboxilato)disilver(I) (2.778(5) Å) [25] and silver-1,2-benzenedicarboxylate-monomethyl ester (2.7529(16) Å) [5]. The thioamidate functional group from deprotonated cyclic thioamides can also form similar dimeric silver complexes with short Ag–Ag distances [6,26]. Two different coordination arrangements are possible, one with a trans; *head-to-tail*, and another with a trans; *head-to-head* orientation of the bridges (Scheme 1-IIa and IIb, respectively) [24].

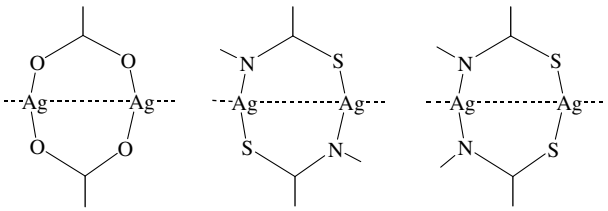

Scheme 1. Disilver(I) arrangements with bridging carboxylates (I) or thionates (II).

As far as we know, there are a few examples of silver(I) thionates (cyclic thioamidates) with the anions acting as μ_2-S,N bridges [6,26]. These complexes preferentially adopt the μ_2-S and μ_3-S,N coordination forms [28–30]. Recently we reported a new Ag(tsac) complex (tsac: thiosaccharinate anion) with a very uncommon polymeric structure built by dinuclear units, $[Ag_2(tsac)_2]_n$, with a short Ag–Ag distance of 2.9194(4) Å [26]. The dimers shown a trans; *head-to-tail* disposition.

Despite the great number of metal-thionate complexes reported in the last decades, which have been the subject of several reviews [27,31–34], the silver-thionate chemistry has been developed very recently. Most of the compounds reported have been binary silver thionates, with a dominance of tetra- or hexanuclear molecular structures [30], or silver-thionate-phosphane ternary complexes, ranging from mononuclear to very complex polynuclear structures [35–38]. There are almost no reports of ternary complexes of Ag(I)-thionates with nitrogenated bases as secondary ligands, in contrast to the broad field developed about the silver salts of less coordinating anions [39,40]. The number of atoms bonded to the silver cations is strongly dependent on the nature of the ligands and on the stoichiometry of the forming reaction. In the coordination chemistry of coinage (I) metals, metal–nitrogen containing ligand complexes are often used as building blocks [2,13,41], Recently we prepared the dinuclear $[Ag_2(tsac)_2(2,2'\text{-bipy})_2]$ complex, which shows a very short Ag–Ag bond distance of 2.7884(12) Å, one of the shortest distances reported for a dinuclear silver(I) complex [37].

Knowing the versatility of the thiosaccharinate ligand to coordinate metals in different forms, such as monocoordination through the exocyclic S atom (S_{exo}), S,N-chelating, S^2-bridging, S,N-bridging, or S^2,N-bridging [26,30,37,38,42–44], we decided to further explore the chemistry of silver thiosaccharinate with pyridine based nitrogenated compounds, with the aim to modulate the Ag(I)–tsac interaction. Silver(I)–pyridine complexes have been know for a long time, and they can show different metal to ligand molar relations [39,40,45]. In this work we report the structural and spectroscopic characterization of two new ternary silver thiosaccharinate complexes with pyridine and 1,10-phenanthroline. The results at DFT and MP2 (DFT: density functional theory; MP2: second order Moller–Plesset theory) levels of the new pyridine complex is also reported.

2. Experimental

2.1. General remarks

All chemicals were of analytical reagent grade and used as purchased. The solvents used were of analytical reagent grade and dried by commonly used techniques [46]. Solid thiosaccharin (Htsac) in its α-form was prepared following the technique published by Schibye et al. [47] and characterized by melting point and IR spectroscopy [48]. The elemental analysis of C, N, H and S were performed with a Carlo Erba EA1108 instrument at INQUIMAE (FCEyN, UBA, Argentina) and were found to be in good agreement with the calculated values. The IR spectra of the substances were recorded as KBr pellets in the 4000–400 cm^{-1} range on a Nicolet Nexus FTIR spectrometer. The Raman dispersion spectra of the solid substances in the region between 3500 and 100 cm^{-1} were obtained with a FRA 106 accessory mounted on a Bruker IFS 66 FTIR instrument, employing the 1064 nm line from a Nd-YAG laser. The UV–Vis spectra of the solids (dispersed in KBr) were registered using a Cecil 2021 spectrophotometer. The ^1H and ^{13}C NMR spectra of the compounds in DMSO-d_6 solutions, at 300 K, were recorded using a multi-nuclear Bruker ARX-300 instrument. The chemical shift data were measured employing the replacement methods and are reported relative to TMS. The use of PPh_3 for increasing the solubility of Ag complexes has been well established, and used before by ourselves and by other authors [30,49]. Thermal decomposition of the $[Ag_2(tsac)_2py]$ sample was evaluated simultaneously by thermogravimetric and differential thermal analyses (TGA/DTA) carried out in a Rigaku TAS 1000 equipment, under nitrogen flow, with Al_2O_3 powder as a reference sample. The heating rate was kept constant at 5 K min^{-1}. The sample was heated from room temperature (294 K) to 723 K.

2.2. Synthesis of [pyridine-bis{μ_2-S:N-(1,1-dioxide-1,2-benzoisothiazol-3-thionato-κ^2S:N^3)-silver(I)}] $[Ag_2(tsac)_2(py)]$ (**1**)

The complex was obtained by adding a solution of Htsac (0.010 g/0.050 mmol) in 3 mL of MeCN to a solution of $AgNO_3$ (0.0085 g/0.050 mmol) in 2 mL of pyridine. In the resulting clear solution, a pale yellow precipitate slowly appeared. The precipitate was filtered and washed with diethyl ether. Yield: 42%. *Anal.* Calc. for $C_{19}H_{13}Ag_2N_3O_4S_4$: C, 33.0; H, 1.9; N, 6.1; S, 18.6. Found: C, 32.9; H, 2.2; N, 6.1; S, 18.5%. ^1H NMR (DMSO-d_6, δ in ppm): 8.09–8.02 (m,2 H), 7.97–7.88 (m, 2H), 7.88–7.77 (m, 5H), 7.77–7.65 (m, 4H); ^{13}C NMR (DMSO-d_6, δ in ppm): δ 187.9, 150.0, 138.51, 136.52, 133.79, 132.85, 131.86, 125.58, 124.29, 120.60.

The same compound was also obtained by adding solid Ag(tsac) (0.012 g/0.039 mmol) to 2 mL of pyridine. The yellow solution formed produced crystals by slow diffusion of diethyl ether. Pale, yellow rods, both air and light stable and suitable for X-ray diffraction analysis were obtained.

It is important to point out the large excess of pyridine used in both synthesis.

2.3. Synthesis of poly[(1,10-phenanthroline-κ^2N:N)-μ_2-S-(1,1-dioxide-1,2-benzoisothiazol-3-thionato)silver(I)] $[Ag(tsac)(o\text{-phen})]_n$ (**2**)

A yellow solution of Ag(tsac) (0.012 g, 0.040 mmol) was obtained by dissolution in a PPh_3 solution (0.010 g, 0.040 mmol) in acetonitrile (MeCN) (5 mL) under mechanical stirring, at room temperature. Slow addition of an 1,10-phenanthroline (*o*-phen) solution (5 mL) in MeCN (0.007 g, 0.04 mmol) gave a pale yellow microcrystalline solid (Ag/tsac/*o*-phenanthroline molar ratio: 1:1:1). The solid was collected by filtration and washed with small amounts of diethyl ether. The compound was air and light-stable. Yield: 60%. *Anal.* Calc. for $C_{19}H_{12}AgN_3O_2S_2$: C, 46.9; N, 8.6; H, 2.5; S, 13.2. Found: C, 46.8; N, 8.6; H, 2.6; S, 13.2%. ^1H NMR ($CDCl_3$, δ in ppm): 9.44–9.22 (m, 2H), 8.48–8.27 (m, 2H), 8.14–7.79 (m, 1H), 7.84–7.77 (m, 2H), 7.75–7.68 (m, 1H), 7.65–7.38 (m, 4H).

Despite the low solubility of the complex in all common organic solvents, saturated solutions of the complex in MeCN were allowed to slowly evaporate at room temperature, and 24 h later yellow single crystals suitable for X-ray diffraction were formed.

The same compound was prepared by addition of $AgNO_3$ (0.0080 g, 0.050 mmol), to a MeCN solution (8 mL) of *o*-phen (0.0090 g, 0.050 mmol). A white solid then appeared. The addition

of Htsac (0.010 g, 0.050 mmol) with mechanical stirring turned the precipitate to a pale yellow microcrystalline solid in less than 10 min.

By reaction of *o*-phen (0.0090 g, 0.050 mmol) with Ag(tsac) (0.012 g, 0.040 mmol) in dimethylsulfoxide (DMSO) (2.0 mL), the same microcrystalline precipitate was obtained.

2.4. Crystal structures

For both complexes, data was collected on a Nonius Kappa-CCD area detector diffractometer with COLLECT (Nonius B.V., 1997–2002). The unit cell parameters were calculated and refined from the full data set. Crystal cell refinement and data reduction were carried out using HKL2000 DENZO-SMN (Otwinowski & Minor, 1997). The absorption correction was applied using HKL2000 DENZO-SMN (SCALEPACK). The SHELXTL/PC V6.14 for Windows NT (Sheldrick, G.M., 2001) [50] suite of programs was used to solve the structure by Patterson methods for **1** and direct methods for **2**. Subsequent difference Fourier syntheses allowed the remaining atoms to be located. Data for complex **1** were collected at 298 K and at 150 K for complex **2**. The crystal data and refinement parameters for the two structures are listed in Table 1. Interatomic distances and angles are listed in Tables 2 and 3. Complex **1** was located on a symmetry element so only half of the molecule was resolved and refined. Complex **2** was refined as a single species but the extended structure was a linear polymer. All of the non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atom positions were calculated geometrically and were included as riding on their respective carbon atoms.

2.5. Theoretical calculations

In order to save computational costs, density functional theory (DFT) quantum-mechanical calculations were done to optimize the geometry of complex **1**. The gradient corrected Becke's three parameters hybrid exchange function in combination with the correlation function of Lee, Yang and Parr (B3LYP) as implemented in the software package GAUSSIAN 03 [51] were used. Geometry optimization procedures were started from the experimental crystallographic data of $[Ag_2(tsac)_2py]$ employing the 6-31G** basis sets for C, H, S, N and O atoms. For silver atoms, the LANL2DZ effective core potentials and valence basis set were used. For complex **1**, the nature of Ag–Ag interaction was studied by analyzing their MO's within the Moller–Plesset perturbation (MP2) formalism. When using MP2 method, both LANL2DZ and LANL2DZ with f functions were used. Besides, a vibrational analysis was performed at B3LYP level of calculations.

The atomic charges were computed according to the NBO (natural bond orbital) population analysis which is based on quantum perturbation theory [52].

3. Results and discussion

3.1. Crystal structures

3.1.1. $[Ag_2(tsac)_2(py)]$ (**1**)

The solid state structure of complex **1** consists of dinuclear units of $[Ag_2(tsac)_2(py)]$. Fig. 1 shows a plot of its structure. The symmetric structure is fairly uncommon showing Ag atoms in two different environments and thiosaccharinate anions in a trans; *head-to-head* disposition. One Ag atom is in a planar arrangement bound to three atoms in a T-shaped structure, two exocyclic sulfur atoms

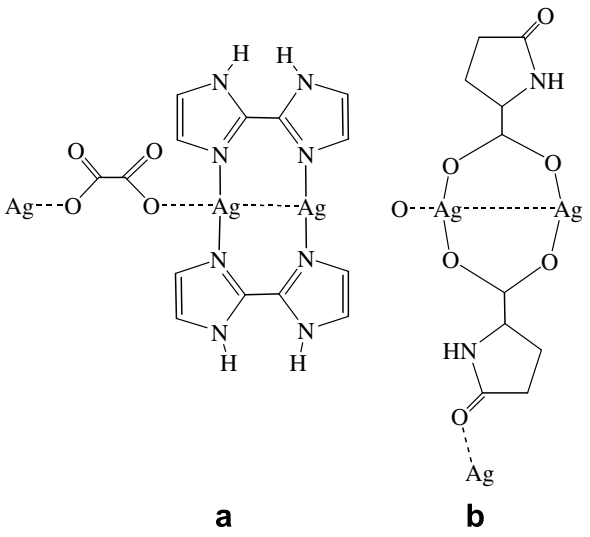
of thiosaccharinate anions (S_{exo}) and the other Ag atom. The second Ag atom is in a square-planar arrangement bound to the silver atom and three nitrogen atoms, two of them belonging to the endocyclic N atoms (N_{endo}) of thiosaccharinate anions and the other to the pyridine molecule. The Ag–Ag distance in this complex is 2.9681(8) Å, between the 2.88 Å assigned for metal–metal distance [24] and the sum of van-der-Waals radii of 3.44 Å [53], revealing a real metal–metal interaction. This intermetallic interaction is forced by the bridges of the tsac anions, as was confirmed from the theoretical calculations. As was already mentioned there are many examples of silver dimeric complexes in the literature, but as far as we know, none of them show this arrangement, which has three identical atoms surrounding one silver center and two different atoms around the second metal center. As examples of similar structures shown in the literature, Xu and Sang have reported the synthesis of [catena-(bis(μ_2-2,2′-bi-imidazole)-(μ_2-oxalato)-di-silver)] a complex which has two silver atoms, one of which is bonded to one O and two N atoms, and the other one is bonded to two nitrogen from the imidazol molecule (Scheme 2a) [54]. In this compound the silver–silver distance is 2.9331(17) Å. Nomiya et al. have synthesized catena-[(μ_3-(*R*)-2-pyrrolidone-5-carboxylato)-(μ_2-(*R*)-2-pyrrolidone-5-carboxylato)-di-silver(I)], where the two silver atoms are bonded to two and three oxygen atoms, respectively (Scheme 2b). The silver–silver distance in this compound is 2.899(2) Å, close to that of metallic silver [55].

The Ag–S distance (2.3875(11) Å) in complex **1** is the shortest that we have found in the different Ag-thiosaccharinates crystallized to date (between 2.4875 and 2.748 Å) [30,36,37]. The Ag–N_{endo} distance is 2.302(3) Å and the Ag–N_{py} distance is 2.352(5) Å, both in the order expected for such bonds [37,39]. The donor capacity of the thiosaccharinates coordinated through both the S_{exo} and the N_{endo}, are enough to fill the requirements of the coordination



Scheme 2. Disilver(I) complexes with asymmetric four/three coordination spheres from [54,55].

sphere of both silver centers. Some reported polynuclear Ag(I)–pyridine complexes with different counter anions also show Ag–Ag bond lengths of 2.96–3.00 Å [13]. The alignment of the pyridine with the two silver atoms (N(21)–Ag–Ag angle of 180°) introduces symmetry on complex **1**. The thiosaccharinate anions are almost planar and they are twisted from each other by only 6.6°, making them almost coplanar.

So far, we have crystallized only one other silver-thiosaccharinate coordinated to the metal center through a S,N-bridging coordination mode, the complex $[Ag_2(tsac)_2]_n$ [26]. As was already pointed out in this case each silver center is coordinated to the *exo*-sulfur and the *endo*-nitrogen of two different thiosaccharinates, in a dinuclear *head-to-tail* arrangement.

3.1.2. $[Ag(tsac)(o\text{-}phen)]_n$ (**2**)

Complex **2** was very well defined and was bound to adjacent molecules to ultimately form a linear chain of alternating Ag and

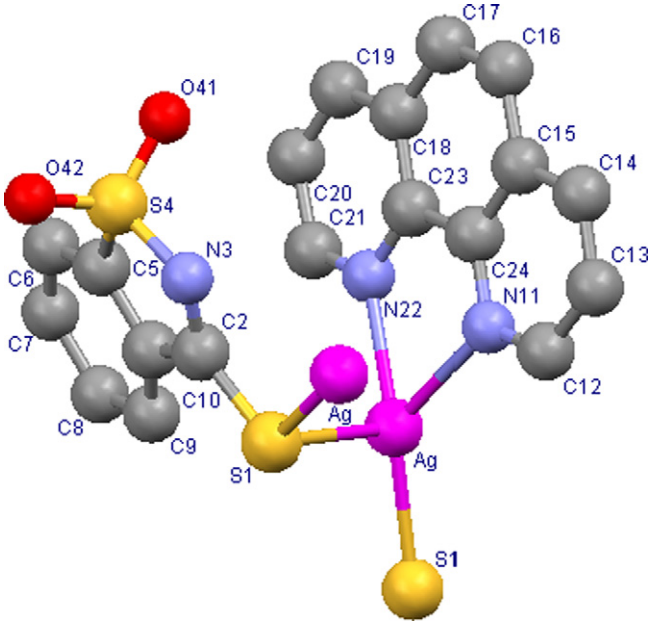


Fig. 2. Molecular structure of $[Ag(tsac)(phen)]_n$ (**2**) with 50% probability ellipsoids. H atoms have been omitted for clarity.

S atoms. Fig. 2 shows a plot of the structure. The silver atom is coordinated to the two N atoms of a 1,10-phenanthroline ligand and two S_{exo} atoms in a trigonal bipyramidal environment with one of the apical atoms missing. The structure strongly resembles that of the dimer $[Ag_2(tsac)_2(2,2'\text{-bipy})_2]$ in the way it is coordinated to the thiosaccharinate anion and to the second ligand [37]. However, in complex **2** there is an open chain perhaps because of the steric demands of the bulky 1,10-phenanthroline. The thiosaccharinate anion is coordinated in a μ_2-S bridging mode via the S_{exo} atom. The Ag–S bond distances (2.4312(8) and 2.7488(8) Å) and the Ag–N_{phen} bond lengths (2.324(3) and 2.364(3) Å) are in the order expected from other silver(I) complexes [33,39,56]. These latter distances are quite similar to the bond distances of Ag—$N_{2-2'bipy}$ in $[Ag_2(tsac)_2(2,2'\text{-bipy})_2]$ (2.327(5) and 2.356(5) Å). The C–S_{exo} bond distance is 1.701(3) Å, longer than the thiocarbonylic bond in complex **1** (1.694(4) Å). The Ag···Ag distance of 4.248 Å is greater than the sum of the van-der-Waals radii of two silver(I) atoms and no metal–metal interaction exist in complex **2** [53].

3.2. FTIR, Raman and UV–Vis spectra

The vibrational spectra of **1** and **2**, both compounds dispersed in KBr discs, are consistent with the X-ray structures. They show all the bands required by the presence of the thiosaccharinate anion and those bands due to the coligands. A selection of the characteristic bands and their assignments are listed in Table 4.

The most interesting bands to be observed in these complexes are those related to the five membered ring of the thiosaccharinate anions, located between 1500 and 400 cm^{-1}, and the low energy metal–ligands vibrations. The thione benzenic ring vibrational bands show no significant differences after coordination. The bands attributable to the N–H bond vibrations, ν(NH) and δ(NH), which in the free ligand appear at 3341 and 1376 cm^{-1}, respectively [30], are absent in the spectra of both complexes. Since there are also no bands between 3000 and 2550 cm^{-1} (the ν-(SH) absorption region) we conclude that the ligand is in the deprotonated form in both complexes. In complexes **1** and **2** the bands corresponding to the stretching motion of the reinforced C–N bonds appear at higher wavenumbers compared to the values found for the "free" thiosaccharinate in bis(triphenylphosphine) iminium thiosaccharinate, while those due to the stretching of the weakened C–S bonds move to lower frequencies (for PNP(tsac) ν(CN): 1365, and $\nu(CS_{exo})$: 1010 cm^{-1}) [57]. These observations confirm the presence of tightly bonded thiosaccharinate ligands. Complex **2** shows the same thiosaccharinate coordination mode (μ_2-S) as $[Ag_2(tsac)_2(2,2'\text{-bipy})_2]$, but the asymmetry of the bridge in complex **2** shifts the ν(CN) and $\nu(CS_{exo})$ vibrations of $[Ag_2(tsac)_2(2,2'\text{-bipy})_2]$ (1411 and 997 cm^{-1}, respectively) [37], to slightly higher frequencies. In the $[Ag_2(tsac)_2(py)]$ complex the thiosaccharinate anions are coordinated to the silver centers through a different coordination mode: μ-S,N, and the positions of the bands due to the thiosaccharinate movements discussed above are shifted (1409 and 1008 cm^{-1}), showing changes in the bond orders of the thioamidate functional groups upon relocalization of the negative charge.

For complex **1**, some characteristic vibrational bands (1594, 1441, 1217, 1071, 702 and 440 cm^{-1}) corresponding to stretching motions of the pyridine ring have been observed [58]. The vibrational bands of the 1,10-phenanthroline ligand in complex **2** remain virtually unaffected after complexation [59]. The metal–ligand stretching vibrations were assigned to the Raman bands appearing at 303 (sym-S_{exo}–Ag–S_{exo}), 180 (sym-N_{endo}–Ag–N_{endo}), and 132 cm^{-1} (Ag–N_{py}), taking into account the DFT theoretical structural calculations performed over the complex (see below).

The UV–Vis spectra of **1** and **2** as solid complexes dispersed in KBr disks yield results similar to each other. They show a weak broad band at 330 and 348 nm, respectively, due to the $\pi \rightarrow \pi^*$ transition of the C–S_{exo} bond expected for thiosaccharin and other thiones [60]. Other intense bands in the range 200–230 and 270 nm were assigned to the $\pi \rightarrow \pi^*$ transitions of the benzene rings [61].

3.3. ^{1}H and ^{13}C NMR spectra

The room temperature ^{1}H and ^{13}C NMR spectra of saturated solutions of complex **1** and **2** in DMSO-d_6, were obtained and the chemical displacements compared with the "free" thiosaccharinate ligand data [54] and also to the "free" pyridine and 1,10-phenanthroline molecules [62].

In accord with the vibrational spectra discussed above, the ^{1}H NMR spectra of the complexes contain neither the signal of the SH proton, appearing at 6.42 ppm in the spectrum of the free thiosaccharin, nor the signal due to the possible NH proton at around 9 ppm, indicating the presence of only deprotonated thiosaccharinate ligands in both compounds. The ^{1}H NMR signals of the tsac anions and the pyridine ligand lie superimposed in the same spectral region and cannot be assigned clearly. The ^{13}C NMR spectrum of complex **1** shows the signals of a coordinated pyridine moiety (150.01 (*o*-C), 139.51 (*p*-C) and 125.58 (*m*-C) ppm) (for free pyridine: 149.9, 135. 9, and 123.8 ppm, respectively [62]). One signal, appearing at 187.09 ppm (C2 atom) belongs to an anion coordinated through the exocyclic sulfur atom [38]. The other six signals of the tsac anions have been observed and assigned. Some other weak signals in the region between 138 and 120 ppm suggest that the structure of complex **1** partially breaks down in the DMSO-d_6 solution.

The ^{1}H NMR spectrum of complex **2** shows the signals of a coordinated 1,10-phenanthroline molecule, 9.44–9.22 (α-H), and 8.48–8.27 (β-H) ppm (for free *o*-phen: 9.11 and 7.79, respectively [62]) and the rest of the multiplets are due to the thiosaccharinate and to the other two phenanthroline hydrogens. The ^{13}C NMR spectra obtained for complex **2** were of poor quality due to the low solubility of the substance preventing any assignment of the observed signals.

3.4. Thermogravimetric analysis (TGA) and differential thermal analysis (DTA) of complex *1*

The thermogravimetric analysis of $[Ag_2(tsac)_2py]$ show a first step of weight loss of 10.85% of the initial mass, from 203 to 231 °C, with a corresponding endothermic peak in the DTA curve with a minimum at 222 °C. The calculated weight loss for one pyridine molecule was of 11.43%. These results indicate that the pyridine molecule is tightly bonded to one of the silver(I) centers of the molecule [63]. The end of the pyridine mass loss was partially superimposed with a second complex and continuous exothermic mass loss, not completed within the temperature range of the study, corresponding to the first part of the degradation of the thiosaccharinate ligands [44].

3.5. Quantum chemical calculations

In order to understand the curious structure of complex **1** and the metal–metal interaction from a theoretical point of view, quantum chemical investigations have been carried out, in a first stage, using the DFT formalism [64]. The geometric structure was optimized and the vibrational spectrum was predicted. The results obtained are a good reproduction of the experimentally observed structural parameters (see Table 2). It has been demonstrated for this type of substances that the B3LYP method (with the selected basis sets) yields good agreements with the experimental geometries, overestimating sometimes the bond distances in metal dimers [14,20,45,65]. As can be seen from Table 2, the calculated Ag–Ag distance is slightly larger than the experimental one. In calculations of neutral metal–metal interactions, it is generally accepted that the DFT formalism can reproduce reasonably well several experimental properties [20,66].

A complete MO analysis of complex **1** was performed at both DFT and MP2 approaches. The existence of MO's with high Ag–Ag bond character was similarly observed for both methods. Following the conclusions of other authors that MP2 formalism can be a better method to analyze metal–metal interactions [14,17,20], we will discuss the results obtained with the MP2 perturbation approach. For time computing convenience, the geometry obtained at B3LYP level was taken and a single point MP2 calculation was carried out. Those results showed that complex **1** has 141 occupied MOs. The use of two different basis sets (LANL2DZ and LANL2DZ with f diffuse functions) gave no significant differences in the shape and composition of the MOs. Here, only the results obtained using the LANL2DZ basis set have been presented. The HOMO (−9.09 eV) and LUMO (+0.95 eV) orbitals are both of π character. The first is localized basically over pyridine atoms and the second is primarily over the tsac anions. The Ag–Ag interaction was studied by analyzing the nature of all the MOs. It was observed that MOs HOMO-29, HOMO-30 and HOMO-34 show Ag–Ag bonding character. They are located at −14.56, −14.56 and −14.77 eV, respectively (Figs. 3–5). Along the Ag–Ag contact, the HOMO-30 is a σ-bond with 21% of Ag contribution. The HOMO-34 is also a σ-bond with 22% of Ag contribution and 9% of S(1) and S(1′). The HOMO-29 has a π-type character with a similar contribution of Ag atoms (23%).

As can be expected, several MOs have bonding character over the bridges Ag(1)–S–C–N–Ag(2), expressing the existence of tight bonds between the tsac anions and the Ag(I) centers.

According to the NBO analysis at MP2 level (calculations from B3LYP and MP2 methods yielded similar results, showing the same trend), the atomic positive net charge of Ag(2) is greater than that of Ag(1) (+0.89 and +0.69 e, respectively). On the other hand, the calculated net charges for N(3), S(1) and N(21) are −1.00, −0.36 and −0.65 e, respectively. When the NBO analysis was done on free pyridine and on the same dinuclear structure optimized without the pyridine molecule (*head-to-head* orientation), only the net charges for Ag(2) and N(21) decrease (+0.84 e) and increase (−0.51 e), respectively, showing that the Ag(2) center is harder when it has the pyridine ligand. The total energy of complex **1** is 0.55 eV more stable than the free pyridine plus the dinuclear structure optimized without the pyridine molecule, in agreement with the experimental observations of the existence of a tightly bonded pyridine molecule. The total energy of the dimeric unit was calculated also for the *head-to-tail* orientation observed for the

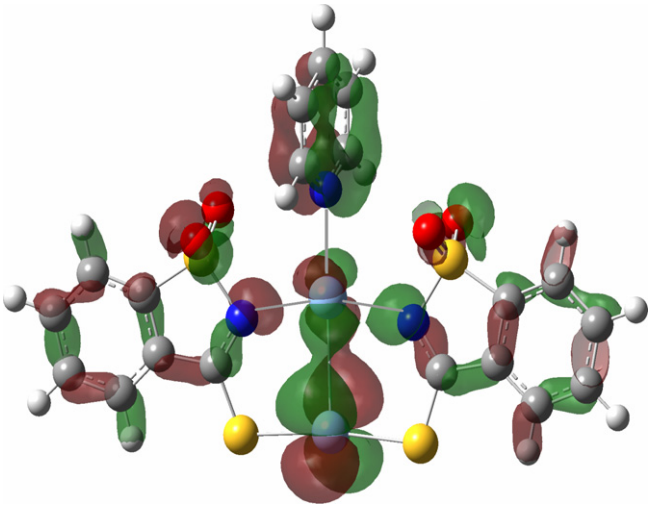

Fig. 3. Plot of HOMO-29 of complex **1** showing Ag–Ag interaction.

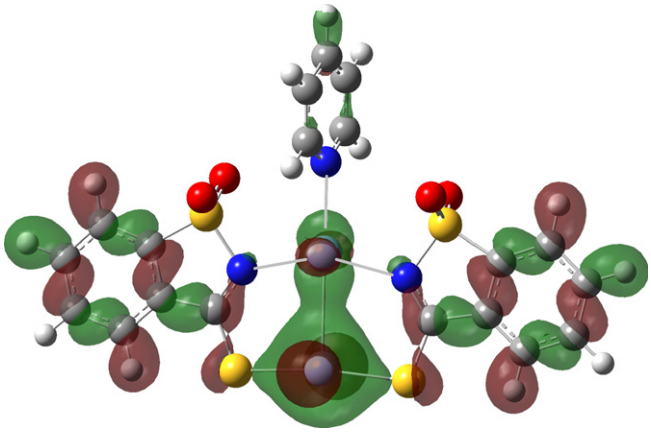

Fig. 4. Plot of HOMO-30 of complex **1** showing Ag–Ag interaction.

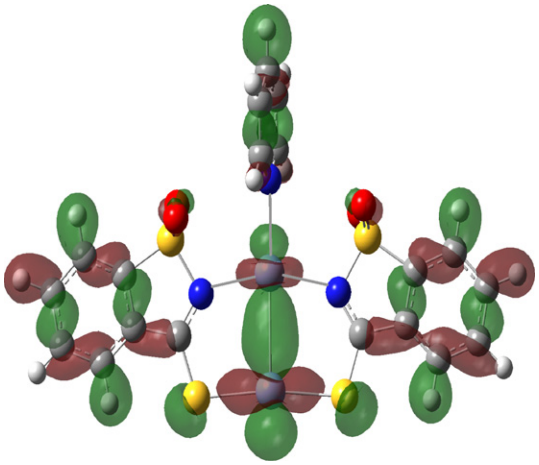

Fig. 5. Plot of HOMO-34 of complex **1** showing Ag–Ag and Ag–S interaction.

$[Ag_2(tsac)_2]_n$ complex, resulting in 0.11 eV more stable than for the *head-to-head* orientation [67].

The theoretical vibrational analysis performed with the optimized geometry of complex **1** at the DFT level yields vibrational spectra in good agreement with the experimental spectra. Considering an ideal C_{2v} symmetry point group for the complex $[Ag_2(tsac)_2py]$, the calculated 129 normal modes of vibration transform as 43 A1 + 20 A2 + 28 B1 + 38 B2. Some of the symmetric A1 vibrations are expected and observed with medium to high intensity in the Raman spectra of the substance as well as some of the B1 and B2 vibrational modes in the IR spectra. A selection of those molecular movements and their tentative assignments are shown in Table 4. The calculated wavenumbers for the stretching of the $Ag–N_{py}$ bond is between that predicted by Wu et al. for a py-Ag^+ fragment (184.6 cm^{-1}) and a py-Ag_2 fragment (106.8 cm^{-1}) in accord with the calculated positive net charges for the Ag centers [58]. Wu et al. also predicted the stretching of the Ag–Ag bond for a py-Ag_2 fragment (192.1 cm^{-1}), with an optimized Ag–Ag bond length of 2.616 Å. Our calculated stretching energy of the metal dimer in complex **1**, with a longer Ag–Ag optimized distance (3.0525 Å) and, thus, a lower calculated frequency, could not be confirmed experimentally, because it was outside of the range of confidence for our Raman spectra.

We tried to simulate the structure of complex **2** using the same type of calculation used for complex **1**, building short oligomeric structures with different kind of terminal molecules. However, owing to the polymeric nature of this structure, all the attempts to obtain reasonably good optimized geometries were unsuccessful.

4. Conclusions

Two new ternary silver(I) complexes are described, in which the metal atoms are coordinated by thiosaccharinate anions and by two other ligands: pyridine and 1,10-phenanthroline. One of the complexes, $[Ag_2(tsac)_2py]$, is particularly curious because of the two different environments that surround the metal centers. The other complex $[Ag(tsac)(o\text{-phen})]_n$, containing a bulky ligand, yields a polymeric chain, with the thiosaccharinates anions acting as bridging ligands between two metallic centers in a μ_2-S mode. The 1,10-phenanthroline chelates as expected in a η^2-N–N manner. The theoretical calculations performed corroborate that even if it is "ligand assisted", an argentophilic interaction is present in complex **1**.

Acknowledgements

We gratefully acknowledge the support of this project (Project M24/Q025) by SGCyT-UNS. We also want to thank Dr. J.A. Güida for recording the Raman spectra and Dra. M.R. Prat for helping us to record the TGA/DTA curves of one of the complexes studied in this work.

Appendix A. Supplementary data

CCDC 667712 and 667713 contain the supplementary crystallographic data for $Ag_2(tsac)_2py$ (**1**) and $[Ag(tsac)(o\text{-phen})]_n$ (**2**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Complete tables of experimental (**1** and **2**) and calculated (**1**) vibrational data, and of calculated structural parameters (**1**) can be obtained from authors upon request. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.04.012.

Thiosemicarbazones
Sulfur-bridged dinuclear complexes

ABSTRACT

Several thiosemicarbazones of the type ($R^1R^2C^2{=}N^3{-}N^2H{-}C(=S)N^1H_2$) were reacted with silver salts, yielding a variety of complexes with different ligand coordination modes, nuclearities and stoichiometries. Reaction of silver(I) chloride with 2-benzoylpyridine thiosemicarbazone, HL^1, has formed a sulfur-bridged dimer, $[Ag_2Cl_2(\mu\text{-}S\text{–}HL^1)_2(PPh_3)_2]$ **2**, while a similar reaction with 2-acetylpyridine thiosemicarbazone, HL^2, has formed a mononuclear complex $\{AgCl(\eta^1\text{-}S\text{–}HL^2)_2(PPh_3)\}$ **1**, with an unusual Ag:ligand:PPh_3 stoichiometry of 1:2:1. Reaction of silver(I) nitrate/acetate with benzophenone thiosemicarbazone, HL^3, and acetone thiosemicarbazone, HL^4, have yielded mononuclear complexes, $[Ag(ONO_2)(\eta^1\text{-}S\text{–}HL^3)(PPh_3)_2]$ **3**, and $[Ag(N^3,S\text{–}HL^4)(PPh_3)_2]X$ (X=NO_3 **4**, CH_3COO **5**). In complexes **1** and **3** and in dimeric complex **2**, the ligands exhibit the usual η^1-S-bonding and μ-S-bridging coordination commonly observed for thiosemicarbazone ligands with tetrahedral coinage metal ions. In complexes **4** and **5**, however, weak binding properties of nitrate or acetate anions to silver favored N^3,S-chelation with the methyl substituents at the C^2 carbon of the thiosemicarbazones.

1. Introduction

Thiosemicarbazones, an important class of N–S donor ligands, have displayed variable bonding properties in their complexes and have shown use in a variety of different applications [1–7]. Among coinage metals, copper in its divalent state has been intensively investigated [8,9c], while reports on the chemistry of Cu^I, Ag^I, Au^I are limited [9]. Recently, from our lab, several Cu^I halide complexes of thiosemicarbazones with triphenylphosphine coligands have been reported [10]. In a recent study of Ag^I–thiosemicarbazone complexes, it was observed that thiosemicarbazone ligands with alkyl or aryl rings at the C^2 carbon have formed halogen bridged dimers, $[Ag_2(\mu\text{-}X)_2(Htsc)_2(PPh_3)_2]$ {R^1 = Ph, R^2 = H, X = Br; R^1 = R^2 = Me, X = Br; R^1 = Ph, R^2 = Me, X = Cl, Br, see Chart 1 for substitution patterns of the thiosemicarbazones}, but with five membered rings such as pyrrole or thiophene, only sulfur-bridged dimers $[Ag_2X_2(\mu\text{-}S\text{–}Htsc)_2(PPh_3)_2]$ {R^1 = pyrrole, R^2 = H, X = Br; R^1 = thiophene, R^2 = H, X = Cl} were isolated [11]. For R^1 = pyridine, R^2 = H, only monomer complexes $[AgX(\eta^1\text{-}S\text{–}Htsc)(PPh_3)_2]$ (X = Cl, Br, I) were isolated [11].

The interest into the chemistry of thiosemicarbazone also pertains to their utility in the biosciences as anticancer, antibacterial and antifungal agents and in the analytical field as ion sensors [5–7]. For example, thiosemicarbazone derivatives of copper(II) – especially with pyridyl substituents at the C^2 carbon have proved to be more effective as anticancer or antimicrobial agents than the ligand by itself, probably due to the increased lipophilicity of the complexes as compared to the free ligand alone [8], and the complexes have also shown promising results in vivo. In view of the still limited investigations into the chemistry of silver(I) thiosemicarbazones as described above, we thus intended to investigate the coordination chemistry of particularly pyridyl based thiosemicarbazones with silver(I). In the present paper, we investigate the influence of different combinations of pyridyl, phenyl and methyl substituents at the C^2 carbon of thiosemicarbazones on the bonding patterns and the nuclearity of complexes with silver(I) halides and psuedohalides (Chart 1).

2. Experimental

2.1. Materials and techniques

Silver(I) nitrate, silver(I) acetate, sodium chloride, sodium bromide and triphenylphosphine were procured from Aldrich Chemicals Ltd. and used as received. Silver(I) halides (X = Cl, Br) were freshly prepared by reacting silver(I) nitrate with sodium chloride or bromide in methanol. 2-Benzoylpyridine thiosemicarbazone (HL^1), 2-acetylpyridine thiosemicarbazone (HL^2), benzophenone thiosemicarbazone (HL^3) and acetone thiosemicarbazone (HL^4)

HL[1] = 2-benzoylpyridine thiosemicarbazone
HL[2] = 2-acetylpyridine thiosemicarbazone
HL[3] = benzophenone thiosemicarbazone
HL[4] = acetone thiosemicarbazone

Chart 1.

were prepared using the literature methods [10a,12]. C, H and N analyses were obtained with a Thermoelectron FLASHEA1112 CHNS analyzer. Infrared spectra were recorded from KBr pellets in the range 4000–200 cm^{-1} on a Pye–Unicam SP-3-300 spectrophotometer. Melting points were determined with a electrically heated Gallenkamp apparatus. ^1H NMR were recorded on a JEOL AL-300 FT spectrometer operating at a frequency of 300 MHz using $CDCl_3$ as the solvent with TMS as the internal standard. ^{31}P NMR spectra were recorded on a Bruker ACP-300 spectrometer operating at a frequency of 121.5 MHz with H_3PO_4 as the external standard with $\delta = 0$.

2.2. Synthesis of the complexes

2.2.1. $[AgCl(\eta^1\text{-}S\text{–}HL^2)_2(PPh_3)]$ (**1**)

To AgCl (0.025 g, 0.17 mmol) suspended in acetonitrile (15 mL) was added ligand HL^2 (0.034 g, 0.17 mmol), and stirring was continued for 24 h. To the white solid formed was added solid PPh_3 (0.046 g, 0.17 mmol), which partially cleared the solution. Addition of another mole of PPh_3(0.046 g, 0.17 mmol) resulted in the formation of a clear solution, which was filtered and kept for crystallization. Slow evaporation yielded crystals of $[AgCl(HL^2)_2(PPh_3)]$ (**1**) along with that of the known $[AgCl(PPh_3)]_4$ cubane (50%) which were manually separated (**1** white, 37 %, m.p. 190–192 °C). *Anal.* Calc. for $C_{34}H_{35}AgClN_8PS$: C, 51.38; H, 4.41; N, 14.10. Found: C, 51.66; H, 4.89; N, 14.25%. Main IR peaks (KBr, cm^{-1}): ν(N–H) 3542s, 3427s, 3412m, 3280b (–NH_2–), 3153m (–NH–); ν(C=N) + δNH_2 + ν(C=C) 1585s, 1550s, 1521s; ν(C=S) 770s, 836s; ν(C–N) 1050s; ν(P–C_{Ph}) 1095s. The complex is soluble in $CHCl_3$ and partially in CH_3CN.

2.2.2. $[Ag_2Cl_2(\mu\text{-}S\text{–}HL^1)_2(PPh_3)_2]$ (**2**)

Compound **2** was prepared in a similar fashion as compound **1**. (Yellow, 57 %, m.p. 183–185 °C). *Anal.* Calc. for $C_{62}H_{54}Ag_2Cl_2N_8P_2S_2$: C, 56.20; H, 4.08; N, 8.46. Found: C, 56.60; H, 4.29; N, 8.93%. Main IR peaks (KBr, cm^{-1}): ν(N–H) 3417s, 3217s (–NH_2–); ν(N–H) 3170 cm^{-1}; ν(C=N) + δNH_2 + ν(C=C) 1604s, 1602s, 1477s; ν(C=S) 816s, 895s; ν(C–N) 995s; ν(P–C_{Ph}) 1096s. The complex is soluble in $CHCl_3$ and partially in CH_3CN.

2.2.3. $[Ag(ONO_2)(\eta^1\text{-}S\text{–}HL^3)(PPh_3)_2]$ (**3**)

To $AgNO_3$ (0.025 g, 15 mmol) in CH_3CN (15 mL) was added PPh_3 (0.076 g, 30 mmol) and stirring was continued at a temperature of 50–60 °C for 2 h. The solid ligand HL^3 was added (0.037 g, 15 mmol) to the clear hot solution, and stirring was continued for another 30 min after switching off heating. The resulting clear solution was filtered and kept for crystallization to form light yellow colored crystals. The complex is highly soluble in $CHCl_3$. (Yellow, 69%, m.p. 185–187 °C). *Anal.* Calc. for $C_{50}H_{43}AgN_4O_3P_2S$: C, 63.17; H, 4.53; N, 5.90. Found: C, 63.03; H, 4.64; N, 6.23%. Main IR peaks (KBr, cm^{-1}): ν(N–H) 3458s, 3321s (–NH_2–), 3141m (–NH–); ν(NO) 1434s, 1471s, 1369b; ν(C=N) + δNH_2 + ν(C=C) 1608s, 1565s, 1500s; ν(C=S) 823s (thioamide moiety); ν(C–N) 1184m, 1064s; ν(P–C_{Ph}) 1094s. The complex is soluble in $CHCl_3$ and partially in CH_3CN.

2.2.4. $[Ag(N^3,S\text{–}HL^4)(PPh_3)_2](NO_3)$ (**4**)

To $AgNO_3$ (0.025 g, 0.15 mmol) in CH_3CN (15 mL) was added HL^4 (0.020 g, 15 mmol) and stirring was continued for 2 h. To the white solid formed was added PPh_3 (0.039 g, 0.15 mmol), which partially cleared the solution. Addition of another mole of PPh_3 (0.039 g, 0.15 mmol) resulted in the formation of a clear solution, which was filtered and kept for crystallization. The complex is soluble in $CHCl_3$. (White, 65%, m.p. 154–156 °C). *Anal.* Calc. for $C_{40}H_{39}AgN_4O_3P_2S$: C, 58.14; H, 4.72; N, 6.78. Found: C, 58.42; H, 3.98; N, 6.81% Main IR peaks (KBr, cm^{-1}): ν(N–H) 3375s, 3325m (–NH_2–), 3186m (–NH–); ν(NO) 1359s, 1301b; ν(C=N) + δNH_2 + ν(C=C) 1645b, 1562s; ν(C=S) 823s (thioamide moiety); ν(C–N) 1041s, 1068s; ν(P–C_{Ph}) 1095s. The complex is soluble in $CHCl_3$ and partially in CH_3CN.

2.2.5. $[Ag(N^3,S\text{–}HL^4)(PPh_3)_2](CH_3COO)$ (**5**)

To $Ag(OOCCH_3)$ (0.025 g, 0.15 mmol) in acetone (15 mL) was added HL^4 (0.020 g, 0.15 mmol) and stirring was continued for 2 h. To the white solid formed, was added PPh_3 (0.039 g, 0.15 mmol), which partially cleared the solution. Addition of another mole of PPh_3 (0.039 g, 0.15 mmol) resulted in the formation of a clear solution, which was filtered and kept for crystallization. The complex is soluble in $CHCl_3$. Crystals were grown from an acetone solution at room temperature. (White, 69%, m.p. 150–152 °C). *Anal.* Calc. for $C_{42}H_{42}AgN_3O_2P_2S$: C, 61.26; H, 5.11; N, 5.43. Found: C, 61.62; H, 5.55; N, 5.43%. Main IR bands (KBr, cm^{-1}): ν(N–H) 3285b (–NH_2–), 3130m (–NH–); $\nu(C\text{–}O)_{as}$ 1670b, 1585s; $\nu(C\text{–}O)_{sym}$ 1404b; ν(C=N) + δNH_2 + ν(C=C) 1564s, 1477m; ν(C=S) 837s (thioamide moiety); ν(C–N) 1152s, 997s; ν(P–C_{Ph}) 1093s. The complex is soluble in $CHCl_3$ and CH_3CN.

3. X-ray crystallography

A suitable crystal of complex **1** was mounted on Bruker AXS SMART APEX CCD diffractometer and likewise crystals of **4** and **5** were mounted on a Bruker APEX II diffractometer with graphite monochromatised Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell dimensions and intensity data were measured at 100(2) K for **1** and at 273(2) K for **4** and **5**. Data were reduced and corrected for absorption using SMART and SAINT (**1**) [13a] or XCAD-49 (**4** and **5**). The structures were solved by direct methods and refined by full matrix least squares based on F^2 with anisotropic thermal parameters for non-hydrogen atoms using SHELXTL (structure solution, refinement and some molecular graphics). All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were placed in calculated positions and were refined with an isotropic displacement parameter 1.5 (methyl) or 1.2 times (all others) that of the adjacent carbon or oxygen atom.

Suitable light yellow crystals of complexes **2** and **3** were mounted on a Siemens P4 diffractometer and data were collected using a scanning mode with graphite monochromatised Mo Kα radiation ($\lambda = 0.71069$ Å). Unit cell dimensions and data were collected at 295(2) K. Cell parameters were refined using 25 reflections in the θ range of 1.70–29.96° using XSCANS [13b]. The data were corrected for Lorentz and polarization effects and a psi-scan absorption correction was also applied. The structures were solved

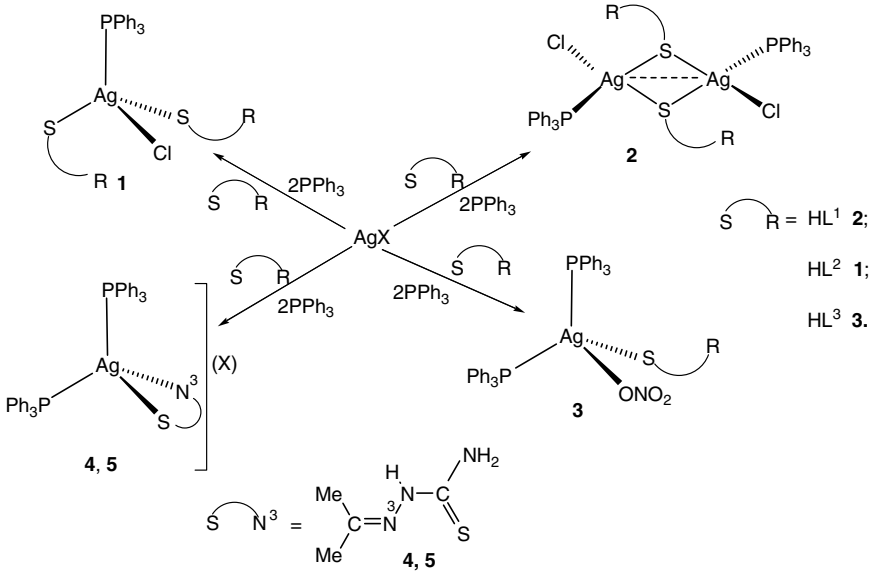
by direct methods and refined by Full-matrix least-squares refinement techniques on F^2 using SIR-92 and SHELXL-97 [13c]. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were attached geometrically riding on their respective carrier atoms with Uiso being 1.5, 1.2 and 1.2 times the Uiso of their carrier methyl, methylene and aromatic carbon atoms, respectively. Scattering factors from the International Tables for X-ray crystallography were used [13d]. Data reduction, structure solution, refinement and drawing of molecular graphics were performed using SHELXTL-PC [13e] and WINGX [13f]. Table 1 gives crystal data for complexes.

4. Results and discussion

4.1. Synthesis

Several thiosemicarbazones of the type ($R^1R^2C^2$=N–NH–C(=S)N^1H_2) were reacted with a selection of silver salts (see Chart 1 for the substitution patterns of the ligands). Addition of triphenylphosphine to the reaction mixtures yielded a variety of complexes with different ligand coordination modes, nuclearities and stoichiometries. An overview of reaction conditions and products formed is given in Scheme 1.

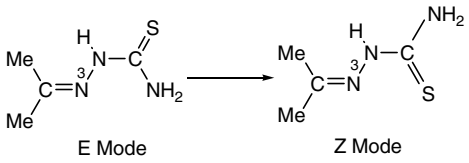
Silver(I) chloride suspended in acetonitrile slowly reacted with HL^2 (R^1 = py and R^2 = Me) over a period of 24 h and formed white insoluble solid and the addition of two moles of triphenylphosphine completely dissolved the solid. The clear solution on slow evaporation at room temperature yielded crystals of tetrahedral complex [AgCl(HL^2)$_2$(PPh_3)] **1**, with an unusual stoichiometry (Ag:Htsc:PPh_3: 1:2:1) along with crystals of the known cubane complex, [AgCl(PPh_3)]$_4$ [14]. Complex **1** differs from the known tetrahedral monomers such as [AgCl(η^1-S–Hpytsc)(PPh_3)$_2$] **6** (Hpytsc = pyridine-2-carbaldehyde thiosemicarbazone) [11]. Reaction of silver(I) chloride with HL^1ligand (R^1 = py and R^2 = Ph) did not form the similar complex, rather a sulfur-bridged dimer, [Ag_2Cl_2(μ-S–HL^1)$_2$(PPh_3)$_2$] **2** along with the known cubane complex [AgCl(PPh_3)]$_4$ were formed. Thus the formation of **2** is analogous to the more general trend of formation of the sulphur-bridged dimers, [Ag_2X_2(μ-S–Htsc)$_2$(PPh_3)$_2$], {R^1 = pyrrole, R^2 = H, X = Br; R^1 = thiophene, R^2 = H, X = Cl}, reported in the literature [11]. It is pointed



Scheme 1.

out here that only 1:1:2 (Ag:Htsc:PPh_3) molar ratio yielded the crystalline products **1** and **2**, and stoichiometry of these complexes is controlled by the nature of the substituents at C^2 carbon. Thus the substitution of the hydrogen atom at the C^2 carbon by a methyl group (sp3 carbon) was able to prevent the binding of a second PPh_3 ligand to the Ag^I center in case of **1.** Introduction of a similarly bulky phenyl substituent at C^2 also did prevent the addition of two phosphine ligands and no tetrahedral monomeric complex either similar to **1** or **6** was formed, and instead yielded a sulfur-bridged dimer, $[Ag_2Cl_2(\mu\text{-}S\text{–}HL^1)_2(PPh_3)_2]$ **2.** Reaction of HL^1 or HL^2 with silver(I) nitrate/acetate led to decomposition and no product could be identified.

Reaction of silver(I) nitrate or acetate with HL^4 ($R^1 = R^2 = Me$) yielded insoluble solids which were reacted with two moles of phosphine ligands and clear solutions formed on slow evaporation at room temperature yielded $[Ag(N^3,S\text{–}HL^4)(PPh_3)_2](NO_3)$ **4** and $[Ag(N^3,S\text{–}HL^4)(PPh_3)_2](CH_3COO)$ **5**, with an N^3, S-chelation mode (Scheme 1). Similar bonding was also observed in one mononuclear tetrahedral complex, $[Cu(HL^4)_2](Cl)$ [9a]. Thus with the methyl substituents at C^2 carbon and with the weak binding to silver by the nitrate or acetate anions vis-à-vis halide ions, HL^4ligand changes conformation from E-mode to Z-mode for chelation to the metal center.



This behaviour of HL^4 is different from that with silver(I) bromide which yielded bromo-bridged dimer $[Ag_2(\mu\text{-}Br)_2(HL^4)_2(PPh_3)_2]$ [11]. Silver(I) nitrate did not react with the ligand HL^3($R^1 = R^2 = Ph$). Thus silver(I) nitrate was first reacted with triphenylphosphine and to the clear solution was added the HL^3 ligand. Slow evaporation of the solution yielded crystals of $[Ag(ONO_2)(\eta^1\text{-}S\text{–}HL^3)(PPh_3)_2]$ **3**. Formation of **3** is analogous to the reaction of copper(I) halides with HL^3, wherein analogous tetrahedral $[CuX(\eta^1\text{-}S\text{–}HL^3)(PPh_3)_2]$ (X = Cl, Br) complexes were obtained [10a]. HL^3 did not react with silver(I) chloride neither directly or nor via reaction of $[AgCl(PPh_3)]_4$ with HL^3. Thus the behaviour of HL^3 and HL^4 is clearly different, and the nature of the substituents (Ph, Ph, **3** versus Me, Me, **4**, **5**) appears to control the final products.

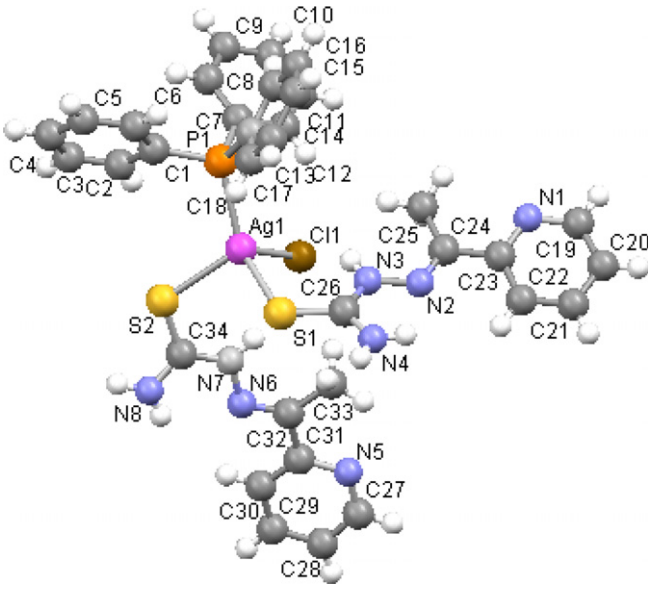


Fig. 1. Molecular structure of complex **1**.

4.2. Structures of complexes

The complexes were analyzed using single crystal X-ray diffraction. Complexes **1** and **2** crystallized in triclinic crystal system while complexes **3**–**5** crystallized in monoclinic system. Complex **2** is dinuclear while other complexes (**1**, **3**–**5**) are mononuclear. Table 2 shows important bond parameters and coordination modes of thiosemicarbazone ligands.

Silver(I) is coordinated by two sulfur atoms, one phosphorus and one chlorine atoms in mononuclear complex $[AgCl(\eta^1\text{-}S\text{–}HL^2)_2(PPh_3)]$ **1**(Fig. 1). The uncommon stoichiometry of this complex results in a slight deviation of both bond angles and distances relative to the commonly known tetrahedral Ag(I) complexes, such

Table 2

$[AgCl(\eta^1\text{-}S\text{–}Hpytsc)(PPh_3)_2]$ (**6**) (Hpytsc = pyridine-2-carbaldehyde thiosemicarbazone), $[Ag_2Br_2(\mu\text{-}S\text{–}Hptsc)_2(PPh_3)_2]$ (**7**) (Hptsc = pyrrole-2-carbaldehyde thiosemicarbazone), $[Ag_2Cl_2(\mu\text{-}S\text{–}Httsc)_2(PPh_3)_2]$ (**8**) (Httsc = thiophene-2-carbaldehyde thiosemicarbazone) [11].

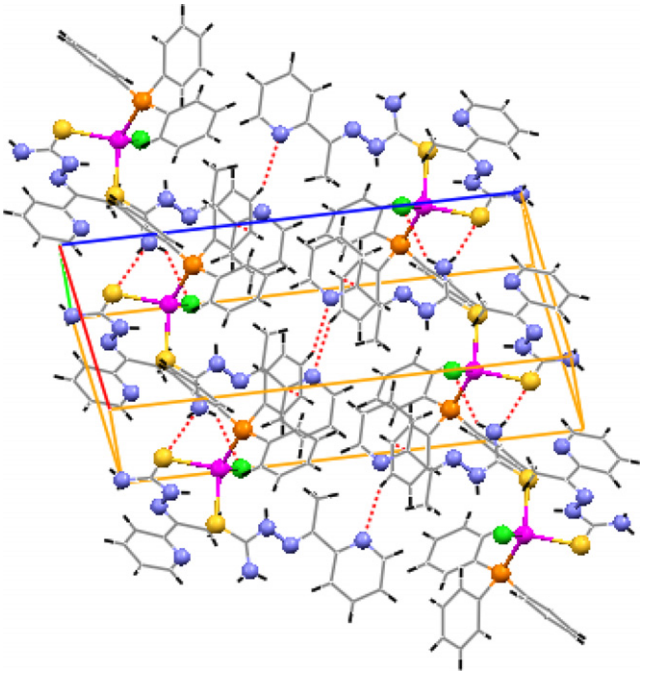

Fig. 2. Packing diagram of complex **1**.

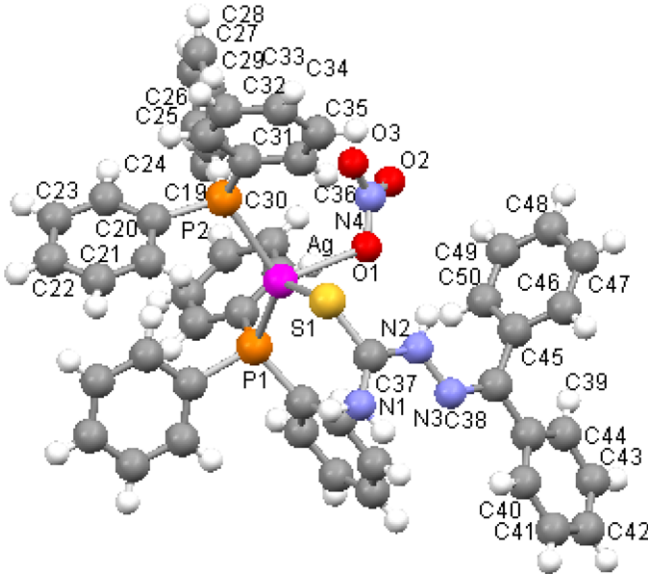

Fig. 3. Molecular structure of complex **3**. (Hydrogen atoms have been omitted for clarity.)

as [AgCl(η^1-S–Hpytsc)(PPh_3)$_2$] **6** (Hpytsc = pyridine-2-carbaldehyde thiosemicarbazone) [11]. The packing of complex **1** shows intermolecular $N^1H\cdots Cl$ and N^1–$H\cdots S$ hydrogen bonds forming 1D polymeric chains, which are further interlinked via intermolecular C–$H_{Ph-P}\cdots N^4_{(py)}$ hydrogen bonds to form a 2D structure (Fig. 2). Molecular structure of complex [Ag(ONO_2)(η^1-S–HL^3)(PPh_3)$_2$] **3** is similar to that of related tetrahedral complex **6**, except for the presence of the O-bonded nitrate group in lieu of the chlorine atom (Fig. 3). The presence of the weakly coordinating nitrate group significantly alter the bond angles and distances of **3** relative to those of **6** [11]. The packing diagram of **3** shows the presence of intermolecular $-HN^1H\cdots O$ type of hydrogen bonds between amino and nitrate groups resulting in a 1D linear chain parallel to the *a* axis. The linear chains are further extended into a 2D network by means of $CH_{Ph}\cdots S$ and $CH_{Ph}\cdots O_{NO3}$ interactions involving phenyl rings of PPh_3 (Figs. 4a and 4b).

The thiosemicarbazone ligand is N^3, S-chelated in complex [Ag(N^3,S–HL^4)(PPh_3)$_2$](NO_3) **4** (Fig. 5). The cation is linked to nitrate via its C–$H_{(methyl)}\cdots O$, N^2-$H\cdots O$ and N^1–$H\cdots O$ hydrogen bonds. Two units of **4** combine via second N^1–$H\cdots O$ hydrogen bonds forming a dimer (Fig. 6). The bonding and packing pattern of [Ag(N^3,S–HL^4)(PPh_3)$_2$](CH_3COO)] **5** is similar to **4**.

Finally the dinuclear complex [Ag_2Cl_2(μ-S–HL^1)$_2$(PPh_3)$_2$] **2** is sulfur bridged and its central $Ag_2(\mu\text{-}S)_2Ag$ core forms a parallelogram. Each silver atom is further coordinated to a terminal chlorine and one P atom of PPh_3 (Fig. 7). The bond parameters and core angles are comparable to other sulfur-bridged dimers reported in the literature (Table 2) [11]. Complex **2** shows the presence of intramolecular $-HN^1H\cdots Cl$ and $N^2H\cdots N^4$ hydrogen bonds and two dimeric molecules are further linked via short $CH\cdots Cl$ contacts involving phenyl rings of PPh_3 resulting in 1D polymeric chain. The chain is extended in 2D via intermolecular $CH\cdots\pi$ interactions (Fig. 8).

5. IR and NMR spectral studies

IR spectroscopy of all complexes confirmed the presence of the individual ligands and counterions via their ν(N–H), ν(C–N), ν(C=C), ν(C=N), and ν(N–O), ν(P–C) vibrational modes. The ν(C=S) thioamide bands are located at 770–837 cm^{-1}, which suggests (in agreement with the X-ray data) a significant weakening of the C=S double bond in all complexes. The ^{1}H NMR spectra of complexes **1**–**4** reveal the presence of -N^2H, -N^1H_2, methyl and ring proton signals generally at low field relative to their corresponding free ligands (Table 3). The ^{31}P NMR spectra of tetrahedral complexes**1**, **3**–**5** showed coordination shifts ($\delta_{complex} - \delta_{ligand}$) comparable to the literature reports on tetrahedral silver(I)–thiosemicarbazone complexes [11]. An additional band at δ 30.81 ppm in **3** reveals the formation of another species, probably a sulfur-bridged dimer in the solution state.

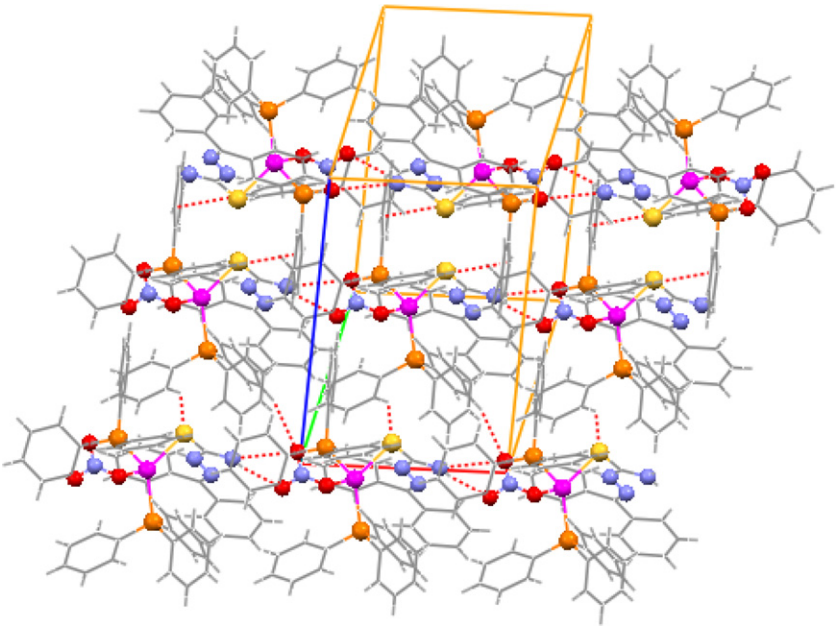

Fig. 4b. Formation of a 2D network in the *ab* plane of complex **3**.

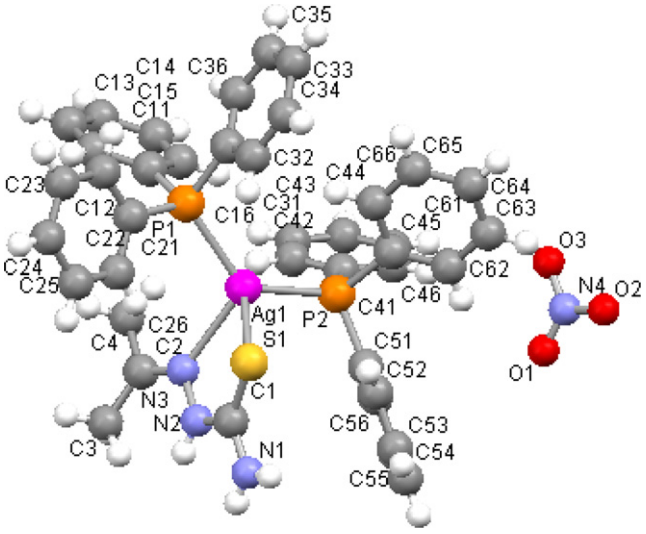

Fig. 5. Molecular structure of complex **4** (complex **5** has a similar structure).

6. Conclusion

The substituents at C^2 carbon appear to control the stoichiometry, nuclearity and dentacy of thiosemicarbazone complexes of silver(I) salts. For R^1 = pyridyl and R^2 = H, only tetrahedral monomers, $[AgCl(\eta^1\text{-S–Hpytsc})(PPh_3)_2]$ (X = Cl **6**) were formed [11]. The substitution of the hydrogen atom at the C^2 carbon by a methyl group (sp^3 carbon) (R^1 = pyridyl and R^2 = Me) was able to prevent the binding of a second PPh_3 ligand to the Ag^Icenter in case of **1** and formed complex $[AgCl(HL^2)_2(PPh_3)]$ **1**, with an unusual stoichiometry (1:2:1: Ag:Htsc:PPh_3). Introduction of a similarily bulky phenyl substituent at C^2 also did prevent the addition of two phosphine ligands, and presumably formed three coordinate species, $\{AgCl(HL^1)(PPh_3)\}$ which dimerised to yield a sulfur-bridged dinuclear complex, $[Ag_2Cl_2(\mu\text{-S–}HL^1)_2(PPh_3)_2]$ **2**, and no tetrahedral monomeric complex either similar to **1** or **6** was formed. The presence of both the methyl groups at C^2 carbon ($R^1 = R^2$ = Me, HL^4) favored N^3, S-chelation in **4** and **5**, and this property of HL^4 is supported by chelation in $[Cu(HL^4)_2]Cl$ reported in the literature [9a]. Also when the anion is more tightly bonded to the metal cen-

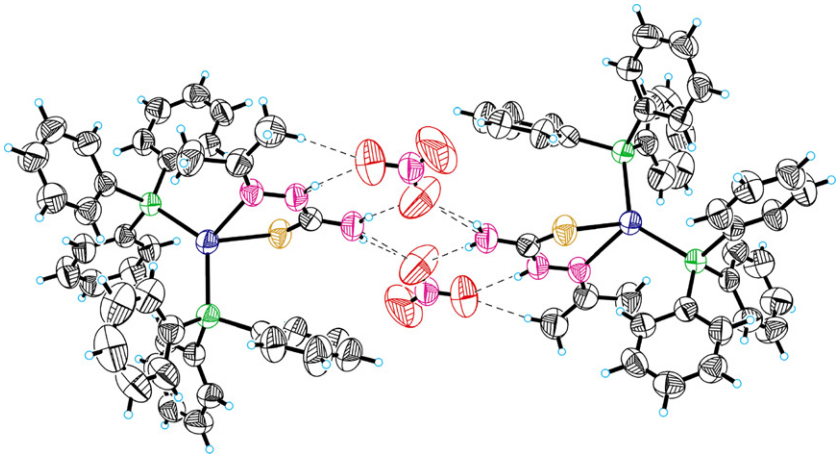

Fig. 6. Packing diagram of complex **4**.

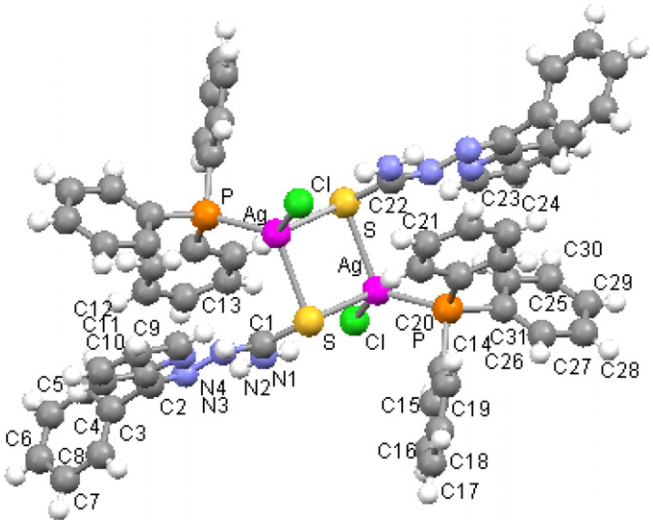

Fig. 7. Molecular structure of complex **2**.

ter as in silver(I) bromide, this ligand yielded a bromo-bridged dimer, $[Ag_2(\mu\text{-}Br)_2(\eta^1\text{-}S\text{–}HL^4)_2(PPh_3)_2]$ [11]. With both phenyl groups at C^2 carbon ($R^1 = R^2 =$ Ph, HL^3), only tetrahedral complexes of more common stoichiometry, $[Ag(ONO_2)(\eta^1\text{-}S\text{–}HL^3)(PPh_3)_2]$ **3** or $[CuCl(\eta^1\text{-}S\text{–}HL^3)(PPh_3)_2]$ [10a] are formed.

In short stoichiometry, dentacy and nuclearity of coinage metal complexes with thiosemicarbazones is influenced by the substituents at C^2 carbon, and also by the nature of the anion/metal. The chelation by neutral thiosemicarbazones is limited and apart from three examples discussed in this paper, there are only two more examples of chelation by neutral thiosemicarbazones [11,15].

ABSTRACT

The kinetics of the process $[Pt(SNS)(R\text{-}py)]^{2+} + Cl^- \rightarrow [Pt(SNS)Cl]^+ + R\text{-}py$ {SNS = 2,6-bis(methylsulfanylmethyl)pyridine; R-py = *meta*- or *para*-substituted pyridines covering a wide range of basicity} were studied in methanol at 25 °C. The reactions obey the usual two-term rate law observed in the substitution reactions of square-planar d^8 complexes. The plots of $\log k_2$ {k_2 = second-order rate constants} against the pK_a of the heterocycles conjugate acids highlighted a different sensitivity of the two groups of N-donors to changes in basicity, the*para*-substituted pyridines (4R-py) showing a weaker dependence on pK_a than the *meta*-substituted (3R-py). The results have been explained on the basis of a π-acidity difference between 3R-py and 4R-py which influences the reaction ground state.

1. Introduction

In several studies regarding the relationship between the basicity of N-donor heterocycles such as pyridines, thiazoles, imidazoles and oxazoles and their nucleophilic behavior towards planar tetra-coordinated Pt(II) complexes we reported kinetic and equilibrium data concerning the reversible displacement of chloride from some Pt(II) derivatives containing polydentate ligands, e.g., $[Pt(SS)Cl_2]$ [1], $[Pt(SNS)Cl]^+$ [2,3], $[Pt(NSN)Cl]^+$ [4], $[Pt(terpy)Cl]^+$ [5,6], $[Pt(NN)Cl_2]$ [7], $[Pt(bpma)Cl]^+$ [8] {SS = 1,2-bis(phenylsulfanyl)ethane; SNS = 2,6-bis(methylsulfanylmethyl)pyridine; NSN = bis(2-pyridylmethyl)sulfide; terpy = 2,2′:6′,2″-terpyridine; NN = biacethylbis(*N*-methyl-*N*-phenyl)oxazone, bpma = bis(2-pyridylmethyl)amine}. In all the cases, the substitution reactions take place with an associative mechanism, where the rate constants for the forward and reverse reactions obey the general relationship $k_{obs} = k_1 + k_2[\text{nucleophile}]$, which is usual for nucleophilic substitution on planar four-coordinate d^8 metal complexes [9]. The k_1 term is the first-order rate constant for the nucleophilic attack on the substrate by the solvent, whereas k_2 is the second-order rate constant for the nucleophilic attack on the substrate by the nucleophile.

The k_2 constants are remarkably influenced by the nature of the considered nitrogen donors and in both the forward and reverse reactions a linear free-energy relationship, $\log k_2 = \alpha pK_a + \text{constant}$, exists between the rate constant and the basicity of the ligands, represented by the pK_a values of their conjugate acids. Steric retardation is always observed for heterocycles containing one or two *ortho* groups (usually called hindered bases in these types of reactions) and these effects are in many cases about additive. Moreover, it was observed that the reactivity of the N-donors not only depends upon their basicity, but also upon the ligand nature in the order six-membered heterocycles > five-membered heterocycles and this different behavior was mainly attributed to different interactions of the two groups of ligands with the metal fragment in the ground state.

In some of the previously cited kinetic studies [5,8] *meta*-substituted pyridines (3R-py) were also considered and their reactivity appeared similar to that of *para*-substituted pyridines (4R-py), but during our last work on square-planar d^8 metal complexes, regarding the reaction $AuCl_3(R\text{-}py) + Cl^- \rightarrow AuCl_4^- + R\text{-}py$ {R-py = 3R-py and 4R-py}, we found kinetic data not completely comparable for the two groups of pyridines[10], the *meta*-substituted resulting slightly less reactive than the *para*-substituted of comparable pK_a. In order to determine if this difference in reactivity also exists in Pt(II) complexes, the kinetics of displacement of *meta*- and *para*-substituted pyridines by chloride from $[Pt(SNS)(R\text{-}py)]^{2+}$ substrates in methanol are here reported.

2. Results and discussion

2.1. Synthesis and characterization of the complexes

All the complexes $[Pt(SNS)(R\text{-}py)](ClO_4)_2$ {SNS = 2,6-bis(methylsulfanylmethyl)pyridine; R-py = 4-methoxypyridine (4-MeO-py), 4-chloropyridine (4-Cl-py), pyridine (py), 4-methylpyridine (4-Me-py), 4-aminopyridine (4-NH_2-py), 3-methoxypyridine (3-MeO-py), 3-methylpyridine (3-Me-py), 3-chloropyridine (3-Cl-py), 3-iodopyridine (3-I-py), 3-fluoropyridine (3-F-py), 3-phenylpyridine (3-Ph-py), 3-hydroxymethylpyridine (3-CH_2OH-py)} were obtained in pure form following the same reaction pathway, i.e., by reacting the chloro-precursor $[Pt(SNS)Cl](ClO_4)$ [11] with a stoichiometric amount of the appropriate N-donor heterocycle in hot water and subsequently adding an excess of lithium perchlorate as precipitating agent.

Elemental analyses (C, H, N) of the synthesized products are in good agreement with the proposed formulations. All the complexes are soluble in polar organic solvents such as dimethylformamide, where they behave as 2:1 electrolytes [12]. As already reported for $[Pt(SNS)(py)](ClO_4)_2$ [13], ^1H NMR spectra show that all the $[Pt(SNS)(R\text{-}py)](ClO_4)_2$ complexes exist in solution in two chemically non-equivalent isomeric forms depending on the relative position of the S-bonded methyl groups respect to the coordinating plane (see Section 3, Table 4 for NMR characterizations details). In particular, the two S–CH_3 can mutually be in *entgegen* (*E* form) or *zusammen* (*Z* form) position, as depicted in Fig. 1. The *E* isomer is a mixture of two chemically and magnetically equivalent enantiomers.

The Pt–S bonds are strongly enough to make the interconversion process slow on NMR timescale at room temperature, therefore the *E* and *Z* forms of $[Pt(SNS)(R\text{-}py)](ClO_4)_2$ can be easily observed in the ^1H NMR spectra. The *E*/*Z* ratio, determined from NMR signals integration, is about 2.5–3/1, corresponding to a Gibbs energy difference between the *Z* and the *E* forms in the range 2.3–2.7 kJ mol^{-1}. As example, in Fig. 2 are reported the sulfur-bonded methyl signals of the two chemically non-equivalent forms of $[Pt(SNS)(py)](ClO_4)_2$.

2.2. Substitution reactions

When a solution of the $[Pt(SNS)(R\text{-}py)](ClO_4)_2$ substrate was allowed to react with an appropriate excess of chloride in methanol, repetitive scanning of the spectrum in the region 220–380 nm showed that the reaction evolves with time in a first-order fashion leading to the substitution of the neutral base by a chloride ion. The presence of well maintained isosbestic points and the comparison of the final spectrum with that of original samples of the substitution products at the same concentration clearly indicate a single reaction stage. Even if, as described above, the $[Pt(SNS)(R\text{-}py)](ClO_4)_2$ derivatives exist in two isomeric forms, all kinetic runs are strictly monoexponential and subsequent changes have never been observed. This probably means that the equilibrium ratio of the *E* and *Z* forms is maintained throughout the substitution reactions and the interconversion is fast relative to the substitution rate, therefore what is measured is a weighted average of the reactivity of the two forms.

The kinetics were studied at constant ionic strength (I = 0.1 mol dm^{-3}, $[NBu^n_4]ClO_4$), primary salt effects being present in a reaction involving charged reagents. The reactions were studied in the presence of 0.01 mol dm^{-3} $HClO_4$. Preliminary experiments showed that, at constant chloride concentration, the rate of reaction was not dependent on the concentration of acid over the range 0.002–0.02 mol dm^{-3}. The acid serves to protonate the released N-donor ligand and force the reaction to completion.

For a better comparison of a possible reactivity difference between *meta*- and *para*-substituted pyridines we have again exam-

The indicated errors were obtained from the non linear least-squares fit of experimental data to $D_t = D_\infty + (D_0 - D_\infty)\exp(-k_{obs}t)$ {D_0 = absorbance after mixing the reactants, D_∞ = absorbance at completion of reaction}.

ined some of the reactions in Ref. [2], in the same experimental conditions, increasing the number of N-donors. The rate constants were determined in the usual way from the change in absorbance as a function of time at a convenient wavelength (260 nm) and the observed rate constants, k_{obs}, collected in Table 1, obey the general relationship $k_{obs} = k_1 + k_2[Cl^-]$ [9], which is usual for nucleophilic substitutions on square-planar platinum complexes. The k_1 terms, referring to the pathway in which the rate determining step is the nucleophilic attack of the solvent, followed by the rapid entry of chloride into the solvento complex [14], are usually quite small and give a negligible contribution to the whole process. The k_2 terms are the second-order rate constants for the direct attack of Cl^- at the substrate and are summarized in Table 2 together with the pK_a values of the heterocycles conjugated acids $[H(R\text{-}py)]^+$ taken from Refs. [15–17].

As depicted in Fig. 3, both for 4R-py (□ in Fig. 3) and 3R-py (■ in Fig. 3) a linear relationship between $\log k_2$ and the corresponding pK_a values exists, but the gradient values (α) for the two groups of ligands are meaningfully different, being $\alpha = -0.419 \pm 0.006$ for the *para*-substituted pyridines and $\alpha = -0.516 \pm 0.006$ for the *meta*-substituted. This means that a different sensitivity of the two groups of N-donors to changes in basicity exists, the 3R-pyridines showings a weaker dependence on the conjugate acid pK_a than the 4R-pyridines. As already observed in a previous work on Au(III) complexes [10], the chemical behavior of the non-substituted pyridine (py) in its displacement by chloride from the metal center is comparable to that of the *para*-substituted pyridines.

pK_a values were taken from Refs. [15–17].

This result can not be in any way ascribed to different steric effects in the ground or in the transition state between the two groups of heterocycles, this demonstrated by the behavior of ligands having very similar pK_a values but quite different bulks, such as 3-phenylpyridine and 3-methoxypyridine. Therefore, the differ-

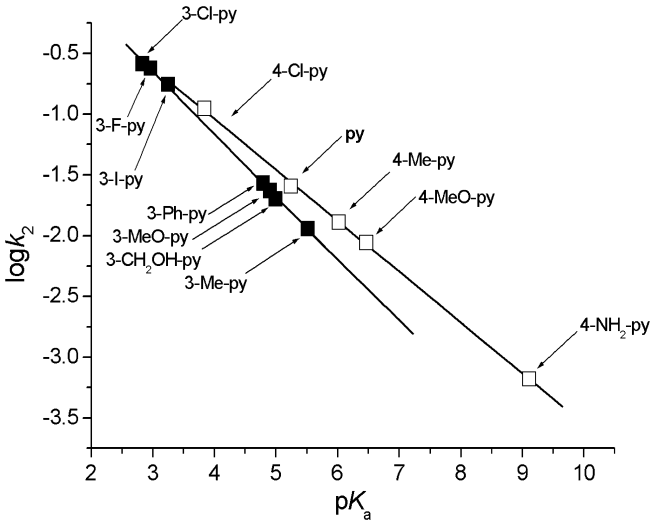

Fig. 3. Plots of $\log k_2$ for the reaction $[Pt(SNS)(R\text{-}py)]^{2+} + Cl^- \rightarrow [Pt(SNS)Cl]^{2+} + R\text{-}py$ against pK_a of $[H(R\text{-}py)]^+$. □ = pyridine and *para*-substituted pyridines, ■ = *meta*-substituted pyridines.

ent trends of *meta*- and *para*-substituted pyridines must have an electronic origin.

For the entry of pyridines on $[Pt(SNS)Cl](ClO_4)$, in the same experimental conditions, a free-energy relationship between $\log k_2$ and pK_a was found [2], with $\alpha = 0.15$. The parameter α is a measure of the ability of a substrate to discriminate among isosteric nitrogen donors and can be assumed to be a relative measure of its electrophilicity. The asynchronous substitution, characteristic of planar tetra-coordinate Pt(II) complexes, offers the opportunity to describe separately the energetic contributions of bond formation and bond rupture to the free energy of activation[14]. As already discussed [1,2] the relatively large dependence of reactivity upon the basicity of the nitrogen donors in the reverse as compared to the forward reactions allows us to postulate an associative asynchronous displacement mechanism with a transition state in which the nitrogen ligand is partially bonded to the metal, and the Pt–Cl bond is almost completely formed, as depicted in Fig. 4. Therefore, the different interaction with the Pt(II) fragment of *meta*- and *para*-substituted pyridines should not greatly affect the reaction transition state $[Pt(SNS)Cl(R\text{-}py)]^{\ddagger\oplus}$.

For these reasons it seems reasonable to conclude that the lower reactivity towards displacement of 3R-pyridines on growing the conjugate acid pK_a values could be mainly ascribed to an increasing stability of the corresponding $[Pt(SNS)(3R\text{-}py)]^{2+}$ ground state

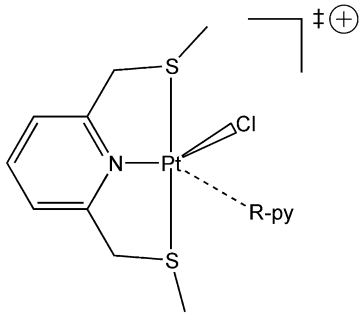

Fig. 4. Transition state geometry for the reaction $[Pt(SNS)(R\text{-}py)]^{2+} + Cl^- \rightarrow [Pt(SNS)Cl]^+ + R\text{-}py$.

complexes and a consequent growth of the ground state – transition state energy barrier, as illustrated in Fig. 5.

By admitting that the pK_a values could be used as a relative measure of pyridines σ-donor character, the enforcement of the Pt–N bond in the $[Pt(SNS)(3R\text{-}py)]^{2+}$ derivatives, compared to the corresponding 4R-py complexes, can be tentatively ascribed to a stronger π-acceptor character of *meta*-substituted pyridines respect to that of *para*-substituted, once bonded to the [Pt(SNS)] fragment. On growing the Pt ⇐ N σ-donor contribution by increasing the N-donor conjugated acid pK_a value, the Pt ⇒ N π-back-donation will be also enforced, the σ-donation increasing the electron density on the metal center. The synergy of the two bond contributions, if a more efficient metal-to-ligand back-donation in the case of $[Pt(SNS)(3R\text{-}py)]^{2+}$ complexes is admitted, is therefore able to explain the experimentally observed reactivity difference of the two groups of heterocycles towards their displacement from Pt(II) metal center and why this difference grows on increasing the conjugated acids pK_a.

When the same substitution reaction was studied for the gold(III) complexes $AuCl_3(R\text{-}py)$, the *meta*-substituted pyridines were found to be less reactive than the *para*-substituted independently from the pK_a [10]. This difference between $[Pt(SNS)(R\text{-}py)]^{2+}$ and $AuCl_3(R\text{-}py)$ complexes towards pyridine displacement can be due to the different electron density existing between the metal centers of the [Pt(SNS)] and $[AuCl_3]$ fragments. The [Pt(SNS)] fragment is positively doubly-charged and Pt is bonded to two π-acid sulfur atoms, while the $[AuCl_3]$ fragment is neutral and the chloro-ligands are σ- and π-donors. This means that in the described cases the platinum center is less electron rich than the gold one, therefore the more efficient metal-to-ligand back-donation of the *meta*-substituted pyridines is observable only when strongly σ-donor heterocycles, having high pK_a values, are coordinated to platinum.

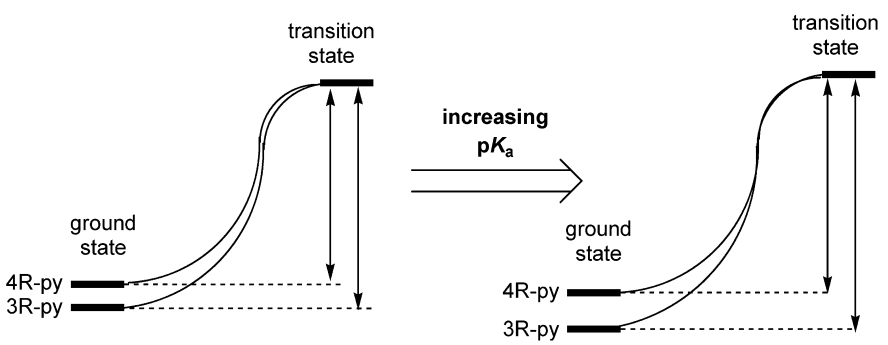

Fig. 5. $[Pt(SNS)(R\text{-}py)]^{2+} + Cl^- \rightarrow [Pt(SNS)Cl]^+ + R\text{-}py$ reaction energy barrier in the case of *meta*- and *para*-substituted pyridines considering different pK_a values.

3. Experimental

3.1. Materials

Pure reagent grade tetrabutylammonium perchlorate $[NBu^n_4]ClO_4$ and lithium chloride LiCl (Aldrich) were dried over P_2O_5 in a vacuum desiccator and used without further purifications. Pyridines were best-quality Aldrich products, distilled or re-crystallized before use if necessary. Anhydrous methanol was obtained by distillation over Mg wires, but traces of water did not appear to have any appreciable effect upon the reactions. Dimethylformamide (DMF) was distilled at reduced pressure before use. Deuterated nitromethane was purchased from Aldrich. 2,6-Bis(methylsulfanylmethyl)pyridine (SNS) was prepared by reacting 2,6-bis(chloromethyl)pyridine and

sodium methanthiolate following a published procedure [2,18]. The chloro-precursor [Pt(SNS)Cl](ClO_4) was obtained by reacting *cis*/*trans*-[$PtCl_2(SMe_2)_2$] and SNS according to a reported method [11] and its purity was confirmed by ^{1}H NMR spectroscopy and elemental analysis.

3.2. Kinetics

Electronic spectra and kinetic measurements were obtained on a Perkin–Elmer Lambda 15 spectrophotometer. The reactions were initiated by adding a 0.0151 mol dm^{-3} DMF solution (20 μl) of the substrate complex, [Pt(SNS)(R-py)]$^{2+}$, to a solution (3 cm^3) of the chloride ion in methanol, previously brought to the reaction temperature (25 °C) in a thermostatic cell in the spectrophotometer. The concentration of the entering group was always larger enough to provide pseudo-first-order conditions. After preliminary repetitive scan experiments in the range 240–360 nm to search for isosbestic points and spectral changes, the kinetics were studied by measuring the changing absorbance at suitable wavelength (260 nm) as a function of time. Pseudo-first-order rate constants (k_{obs}, s^{-1}) were obtained either from the gradients of plots of $\log(D_t - D_\infty)$ versus time or from a non-linear least-square fit of experimental data to $D_t = D_\infty + (D_0 - D_\infty)\exp(-k_{obs}t)$ with D_0, D_∞ and k_{obs} as the parameters to be optimized (D_0 = absorbance after mixing of reactants, D_∞ = absorbance at completion of reaction). Second order rate constants k_2 (dm^3 mol s^{-1}) were determined by linear regression of k_{obs} values versus chloride concentration. The k_{obs} and k_2 values are reported in Tables 1 and 2, respectively.

3.3. Preparation of the complexes

All the complexes [Pt(SNS)(R-py)](ClO_4)$_2$ {R-py = 4-methoxypyridine (4-MeO-py), 4-chloropyridine (4-Cl-py), pyridine (py), 4-methylpyridine (4-Me-py), 4-aminopyridine (4-NH_2-py), 3-methoxypyridine (3-MeO-py), 3-methylpyridine (3-Me-py), 3-chloropyridine (3-Cl-py), 3-iodopyridine (3-I-py), 3-fluoropyridine (3-F-py), 3-phenylpyridine (3-Ph-py), 3-hydroxymethylpyridine (3-CH_2OH-py)} were prepared by the following general method: [Pt(SNS)Cl](ClO_4) (0.264 g, 0.5 mmol) was dissolved in hot water (60–70 °C) (30 ml) and a stoichiometric amount of the nitrogen-donor base, dissolved in water (2–3 ml), was added drop by drop under stirring. After 10 min of reaction, addition of an excess of solid $LiClO_4$ (0.106 g, 1.0 mmol) and slow cooling of the solution at room temperature resulted in the formation of the crystalline product, which was filtered off, washed twice with methanol (2–4 ml) and dried *in vacuo* over P_2O_5.

3.4. Complexes characterization

^{1}H NMR spectra were taken in CD_3NO_2 at 25 °C on a Bruker Avance 300 or a Bruker AC 200 spectrometers. Chemical shifts were referenced internally to the non-deuterated solvent resonances and are quoted relative to tetramethylsilane (δ = 0 ppm). Very near resonances were sometimes resolved by applying a sine-bell apodization. COSY, NOESY and homonuclear decoupling experiments were performed to improve the characterizations of the complexes. The SWAN-MR and MESTRE-C software packages were used for NMR spectroscopic data treatment and spin systems simulation [19]. The conductivity of 1×10^{-3} mol dm^{-3} solutions of the complexes in DMF at 25 °C was measured with a Radiometer CDM 83 instrument. Elemental analyses were performed by the Microanalytical Laboratory of Faculty of Pharmaceutical Sciences of the University of Padua. Analytical and ^{1}H NMR spectra are collected in Tables 3 and 4, respectively. Hydrogen atoms are numerated following the common conventions for the considered heterocycles. *E* and *Z* suffixes are used to indicate the isomeric forms having the S-bonded methyl groups mutually in *entgegen* or *zusammen* position.

ABSTRACT

The properties of the iron(III) complexes of the ditopic macrocyclic ligand with three aminopropyl pendant arms, L^1 = 3,7,11-tris-(3-aminopropyl)-3,7,11,17-tetraazabicyclo[11.3.1]heptadeca-1(17),13,15-triene were investigated in aqueous solution. Potentiometric studies indicated the presence of mononuclear $[FeH_hL^1]^{h+3}$ (h = 0–3), and dinuclear $[Fe_2L^1]^{6+}$, $[Fe_2L^1(OH)]^{5+}$ and $[Fe_2L^1(OH)_2]^{4+}$ complexes, and their stability constants were determined at 298.2 K and ionic strength 0.10 mol dm^{-3} in KNO_3. The log$K$ values of mononuclear protonated species indicated the consecutive deprotonation of the aminopropyl arms, suggesting the nitrogen donor atoms from the macrocycle as the preferred coordination environment for the first metal centre, and the amines from the pendant arms for the second one. The dinuclear complex is formed at about 85% of the total amount of the metal ion for 2:1 Fe:L^1 ratio solutions at pH 4.0–4.5. The log$K$ values of the deprotonation of dinuclear hydrolysed species are consistent with the presence of two water molecules directly bound to the metal centres. Spectroscopic UV–Vis and IR data for 2:1 Fe^{3+}:L^1 ratio samples confirmed the existence of dinuclear and hydroxo dinuclear species. EPR spectra of these solutions were interpreted by an equilibrium of two high-spin d^5 state of iron(III) species with different rhombic E/D distortions. Electrochemical studies also established the formation of mono- and dinuclear complexes, showing irreversible redox behaviour. The two metal centres on the dinuclear complexes have only weak interactions.

1. Introduction

The iron(II/III) centres of nonheme-iron enzymes exhibit exceptional spectroscopic and electrochemical properties which give useful data for the comprehension of the catalytic and biological behaviour of these enzymes [1]. On the other hand, a significant number of synthetic models that replicate on some aspects of nonheme-iron enzyme active sites were produced based in macrocyclic polyamines [2] or tripodal multidentate ligands containing pyridine, amine and carboxamato units [3–5] or aliphatic and aromatic amines including nitrogen heterocyclic groups such as imidazol [6,7]. They form Fe(III) peroxo-species and some of them are able to duplicate the DNA cleavage action of bleomycin [8,9]. High-valent (Fe^{4+} or Fe^{5+})-oxo species, quoted as intermediate species in the reaction of nonheme iron enzymes with O_2, were created by photolysis of iron(III) complexes of an azide (N_3) derivative of macrocylic ligands such as tacn or cyclam [10,11] (see in Scheme 1 the structure of ligands). Reviews describing successes and challenges of models for nonheme iron dioxygen-activating enzymes were recently published [12,13]. The wide range of information on structural, spectroscopic and reaction mechanisms contributed to the better understanding of biological systems. This knowledge is also used to create new catalysts, in dioxygen green chemistry of varied organic reactions [1,4,9,12,13] and in medicine. For instance, the Fe^{2+}/Fe^{3+} complexes of *N*,*N*′,*N*″-tris(2-pyridylmethyl)-*cis*,*cis*-1,3,5-triaminocyclohexane display cytotoxicity toward cultured bladder cancer cells [14].

Functionalized derivatives of tetraazamacrocyclic ligands are able to coordinate ferric ion with strong binding ability and adopting various conformations of similar energy [15]. The dichloro iron(III) tetrafluoroborate complex of a 14-membered tetraazamacrocycle containing pyridine (L^2) was found to catalyse the decomposition of H_2O_2 in water up to pH 4.6, showing catalase-like or (and) peroxidise-like activities [16] and its X-ray crystal structure was determined [17]. The stability constants of Fe(III) complexes of acetate derivatives of 14- and 12-membered tetraazamacrocycles containing pyridine, L^3 and L^4, respectively, were determined and spectroscopic studies revealed that the metal centre is coordinated to the macrocyclic nitrogen atoms and one or two oxygen atoms from the pendant arms [18,19].

In the present work we decided to study the ferric complexes of a tetraazamacrocycle functionalized with aminopropyl pendant

arms, L^1 (3,7,11-tris-(3-aminopropyl)-3,7,11,17-tetraaza-bicyclo-[11.3.1]heptadeca-1(17),13,15-triene), taking into account that L^1 may exhibit specific and unpredicted coordination behaviour with some transition metal ions [20]. Mono- and dinuclear complexes are formed in water and they showed good solubility in this solvent. Potentiometric, spectroscopic and electrochemical studies in aqueous solution were carried out, revealing that the presence of soft nitrogen donor atoms in the ligand led to interesting and not expected behaviour.

2. Results and discussion

2.1. Stability constants

The complexation behaviour of L^1 with Fe^{3+} ion was studied by potentiometric method in aqueous solution, at 298.2 K and ionic strength 0.10 mol dm^{-3} in KNO_3. The stability constants determined are listed in Table 1, and the protonation constants also compiled were previously determined [20]. The final model obtained comprises titrations of different metal to ligand ratios, from 0.5:1 to 2:1. Precipitation limited the pH range studied, which was of about 7 for the 2:1 and 7.5 for the 0.5:1.

Mononuclear $[FeH_hL^1]^{h+3}$ ($h = 0$–3) and dinuclear $[Fe_2L^1]^{6+}$, $[Fe_2L^1(OH)]^{5+}$ and $[Fe_2L^1(OH)_2]^{4+}$ species were found at the studied pH range. The species distribution curves for the iron(III) complexes of L^1 at 1:1 and 2:1 ratios, obtained with the Hyss program [21], are shown in Fig. 1. The dinuclear complex exists even for the 1:1 stoichiometry while the $[FeL^1]^{3+}$ complex is only formed upon pH 6 and it is found in insignificant amounts at 2:1 ratio. Three mononuclear protonated species were formed at lower pH, simultaneously with the $[Fe_2L^1]^{6+}$, corresponding to the successive deprotonation of the ammonium groups of the arms. The $[Fe_2L^1]^{6+}$ species was formed at about 85% of the total amount of the metal ion at pH 4 for the 2:1 ratio (Fig. 1b). Upon this pH value two water molecules, directly bounded to the metal ion, start to deprotonate, forming the $[Fe_2L^1(OH)]^{5+}$ and $[Fe_2L^1(OH)_2]^{4+}$ species. At pH about 5 precipitation occurred probably resulting from dimerization of the dihydroxo species [22]. Indeed, the values of $\log K_{Fe_2L^1(OH)} = 5.95$ and $\log K_{Fe_2L^1(OH)_2} = 7.6$ suggest that the water molecules are strongly bound to the metal centres. Values of the same order were also found for the *N,N′*-bis(2-methylpyridyl) ethylenediamine ($\log K_{Fe_2L(OH)} = 5.7$ and $\log K_{Fe_2L(OH)_2} = 6.2$) [23] and the 24-membered of the hexaazadiphenol macrocyclic ligand (L^5) ($\log K_{Fe_2L^5(OH)} = 2.92$ and $\log K_{Fe_2L^5(OH)_2} = 7.34$) [24].

The $\log K_{FeL^1} = 25.95$ and $\log K_{Fe_2L^1} = 12.07$ are very high values for a ligand only containing amine donors, or when compared with the corresponding values of other derivatives of the parent tetraazamacrocycles with pyridine unit [18,19]. Then the first value was confirmed by a competition reaction using dtpa (diethylenetriamino-pentaethanoic acid) as the second ligand [18]. The second ligand need to be capable to compete with L^1 for iron(III) and to be a compound for which the protonation and the stability constants with Fe^{3+} are well known, as it is the case of dtpa [25]. The high stability constant values of L^1 with iron(III) can be partly explained by the large overall basicity of the aminopropyl arms of L^1 [26] and(or) special accommodation of the metal centre into the structure

Table 1
Protonation constants of L^1 and its stability constants with Fe^{3+}

Equilibrium reaction[a]	$\log \beta_{H_hL_1}$	Equilibrium reaction[a]	$\log K_{H_hL_1}$

$T = 298.2$ K and $I = 0.1$ mol dm^{-3} in KNO_3.

[a] Water molecules directly bound to the metal centres were omitted, because it is impossible by these studies to define the number of them.

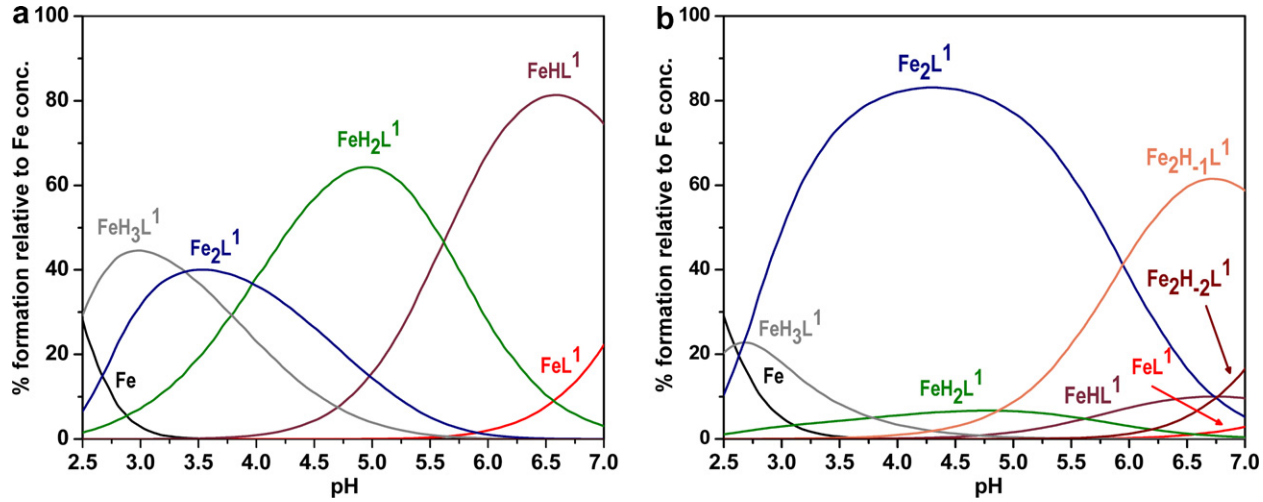

Fig. 1. Species distribution curves of iron(III) complexes of L^1: (a) $C_{Fe} = C_{L^1} = 0.001$ mol dm^{-3}; (b) $C_{Fe} = 2C_{L^1} = 0.001$ mol dm^{-3}. The charges of the species are omitted.

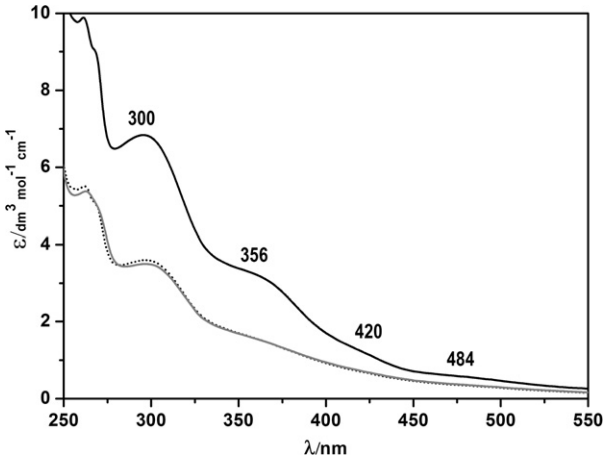

Fig. 2. UV–Vis spectra of 1:1 Fe^{3+}:L^1 ratio aqueous solutions ($C_{L^1} = 3.4 \times 10^{-4}$ mol dm^{-3}, pH 3.4, grey line and 7.4, short dot line) and 2:1 Fe^{3+}:L^1 ratio, ($C_{L^1} = 1.88 \times 10^{-4}$ mol dm^{-3}, pH 5.0, black solid line), at $T = 298$ K.

of L^1. The values of the three protonated species suggest the successive deprotonation of the aminopropyl arms. Upon coordination of the first metal ion by the donor atoms of the macrocycle, the second metal ion should coordinate to the arms. Both centres need additional water molecules to complete the corresponding coordination spheres.

The iron(III) ion usually bind strongly to "hard" donor atoms, such as oxygen atoms, and the amine ligands tend to prefer the iron(II) ion. However, the aminopropyl arms of predominantly donor character are likely to provide an electron-rich coordination environment for the metal centre imposing virtually no steric constraints. Additionally, the flexibility of the arms assists the metal centre to achieve the preferential octahedral geometry, and the relatively large distances between the two coordination sites also favours the dinuclear complex formation.

2.2. UV–Vis spectroscopic measurements

The UV–Vis spectral data of aqueous solutions of the iron(III) complexes of L^1 at 1:1 and 2:1 ratios and different pH values were recorded, see Fig. 2. All the spectra show very intense bands at 262–284 nm (with several shoulders), at 296–302 nm and shoulders at 420–422 nm. The former ones should be attributed to intra-ligand charge transfer bands, and the last ones were assigned to LMCT bands [6,27]. The electronic spectra as expected for a d^5 metal ion give no structural information because the strong charge-transfer absorptions overlap the weak forbidden d–d transitions.

The strong absorptions at 360–420 nm region have been tentatively ascribed to oxygen–iron(III) charge transfer bands [27] as found in natural proteins, such as oxohemerythrin [28,29], and synthetic oxo-bridged diiron complexes of ligands containing nitrogen donor atoms [6,30–32]. The bands at 440–510 nm have been assigned to mixed LMCT and near-UV oxygen to Fe charge transfer bands due to their unusual intensity [27,32].

Table 2
Rhombic distortions (E/D) and effective g-values expected from the high-spin species of the dinuclear iron(III) complex of L^1[a]

E/D	Doublet	g_1	g_2	g_3
$E/D \approx 0.173$	$\|\pm5/2\rangle$	9.93	0.18	0.22
	$\|\pm3/2\rangle$	<u>5.24</u>	3.08	3.43
	$\|\pm1/2\rangle$	1.31	<u>8.90</u>	2.35

[a] The values observed in the experimental spectra are underlined.

2.3. EPR spectroscopic studies

The spectrum of the 2:1 Fe(III)/L^1 ratio solution and pH about 5, for which the dinuclear ferric complex of L^1 was presented at about 85% in relation to total Fe(III) ion (Fig. 1b) at $T = 11.5$ and 98 K exhibits signals at $g \approx 8.90$, 5.24, 4.29 and large signal at $g \approx 2$. The resonances at lower field were ascribed to high-spin d^5 iron(III) species with different rhombic E/D distortions. The signal at $g \approx 2$ might be attributed to possible intermolecular interactions. No changes on resonances from the middle $|\pm3/2\rangle$ ($g \approx 5.24$) and the ground $|\pm1/2\rangle$ ($g \approx 8.90$) Kramer's doublets were observed from 11.5 to 98 K and very small differences were found on the relative intensity of the signals suggesting a low D value.

The well resolved signal at $g \approx 4.29$ is typical of the transition between the middle Kramer's doublet of other isomer of rhombic distorted iron(III) ion in high–spin state with $E/D = 1/3$. Using the spin-hamiltonian formalism for high-spin ferric iron [33], the low-field resonances at 8.90 and 5.24 can be assigned to another species with rhombic (E/D) distortion ≈0.173. The effective g-values expected for each Kramer's doublet are indicated in the Table 2.

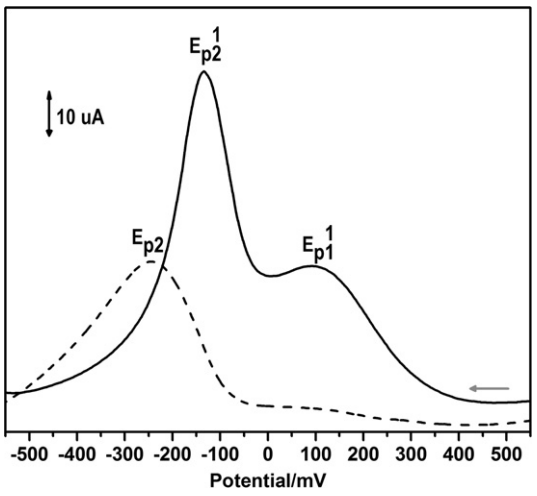

Fig. 3. Square-wave voltammetry profiles of Fe^{3+}/L^1 solutions at 1:1 ratio (dashed line), and 2:1 ratio (solid line) at pH 4.5. $C_{L^1} = 2.0 \times 10^{-3}$ mol dm^{-3} in 0.2 mol dm^{-3} KNO_3, potential vs. Ag/AgCl, glassy carbon working electrode, SW frequency 15 Hz, amplitude 25 mV and step height 4 mV.

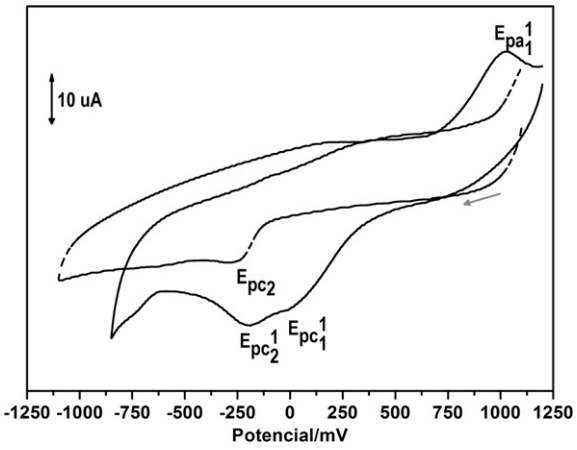

Fig. 4. Cyclic voltammetry profiles of Fe^{3+}/L^1 solutions at 1:1 (dashed line), and 2:1 ratios (solid line), at pH 4.5. $C_{L^1} = 2.0 \times 10^{-3}$ and 4.0×10^{-3} mol dm^{-3} in 0.2 and 0.4 mol dm^{-3} KNO_3, using glassy carbon working electrode at potential scan rate 0.1 V/s^{-1}, potential vs. Ag/AgCl.

2.4. IR spectroscopy

The IR spectrum of 2:1 Fe(III)/L^1 ratio solid sample in KBr showed bands at 3450 cm^{-1} (broad band) characteristic to the OH stretching modes of lattice water and intramolecular OH hydrogen bonds, 1380 cm^{-1} associated with tertiary aromatic amine vibrations and 1640 cm^{-1} due to the N–H bent vibrations characteristic for primary amines. The weak sharp asymmetric vibration band at 804 cm^{-1}, can be attributed to the metal–oxygen–metal asymmetric stretch vibrations [27,34], observed also for other hydroxo-bridged complexes of nitrogen donor ligands: linear [6,30] and macrocyclic ligands, such as 1,4,7-triazacyclononane [31] and L^6 [35]. The bands at 1030–1100 cm^{-1} region were only observed for the dinuclear ferric complex.

2.5. Electrochemical studies

The square wave voltammetry (SWV) profiles of iron(III)/L^1 solutions at 1:1 and 2:1 ratios, scanned at the potential window +1100/−1100 mV, were shown in Fig. 3, and the cyclic voltammograms (CV) of these solutions, recorded at the potential range of +1100 to −1100 and +1200 to −850 mV, respectively, are shown in Fig. 4. The 1:1 ratio solution showed one main peak, and a slightly amount of another species, suggesting that the main process corresponds to the reduction of the mononuclear complex, as indicated by the distribution diagram of Fig. 1a. The SWV profile of this species exhibits the reduction wave at $E_p = -240$ mV (peak E_{p2} in Fig. 3), and the oxidation wave was not observed. In the same experimental conditions, two peaks were observed (E_{p1}^1 and E_{p2}^1) for the 2:1 ratio solution at pH 4.5, at the value where 85% of dinuclear complex was formed relative to total metal concentration, see Fig. 1b. The process corresponding to the reaction $(Fe^{3+/3+})_2L^1 + e \rightleftarrows (Fe^{3+}/Fe^{2+})L^1$ was represented by the peak E_{p1}^1 and occurred at +95 mV (data from SWV). This peak is well defined at slow scan rate (25 mV/s^{-1}). To the peak at $E_{p2}^1 = -136$ mV corresponds the second redox process $(Fe^{3+}/Fe^{2+})L^{1+} + e \rightleftarrows (Fe^{2+}/Fe^{2+})L^1$. Only one anodic peak at $E_{pa1}^1 = +1010$ mV (Fig. 4) was observed at the sweep rate of 0.050–0.500 V/s. The reduction peak at about −750 mV can be attributed to a very small amount of $Fe(NO_3)_3$ in solution.

The electrochemical reactions in both cases are irreversible [36], the charge transfer is extremely slow and only one of the heterogeneous reactions on the electrode surface, the reduction, was measurable. Therefore, the concentrations of both redox species are controlled by the charge transfer reaction and are far from the thermodynamic equilibrium. The cathodic process occurred but the formed Fe^{2+} species was removed from the electrode surface due to reactions with oxygen (or other fast chemical transformation) in aqueous medium and thus no oxidation trace was observed.

The lack of solubility of the complexes in solvents other than water did not allow the study in a medium without presence of oxygen. Similar behaviour was found for the ferric mononuclear complexes of ligands with mixed nitrogen and oxygen donor atoms such as (2-hydroxybenzyl)(2-pyridylmethyl)-amine [11] and *N*,*N*′-bis(2-pyridylmethyl)-3-aminoacetate [37].

The E_{p2} value (see Fig. 3) may corresponded to the reduction of the iron(III) coordinated to the amines of the macrocyclic ring. In fact this value appears between the E_{pc} values for the Fe^{3+} complex of *N*,*N*′-bis(2-pyridylmethyl)-3-aminoacetate of −51 mV [37] and that for the Fe^{3+} complex of the N_6-macrocycle, diammac, of −350 mV [38] both values versus Ag/AgCl.

The value of E_{p2}^1 (data from SWV) is comparable to the value of the mononuclear complex, suggesting that the reduction processes occurs with the iron(III) in identical environments. The shift of this peak of 88 mV to more anodic potential in the dinuclear complex when compared to the equivalent reduction of the mononuclear complex was explained by the decrease of stabilization of the first centre imposed by the presence of the second iron(III) in the arms. As well known, the reduction potential is dependent not only of the type and number of donor atoms that can modify the Lewis acid–base character of the iron(III) core [39,40], but also of the strain of the ligand upon coordination. The different electrochemical data for both centres suggest that the two iron(III) centres have different coordination environments. The cathodic shift of the two individual reduction processes in the dinuclear complex of $\Delta E_p = E_{p2}^1 - E_{p1}^1 = 231$ mV is indicative of the weak interaction between both centres [41,42].

On the other hand, the irreversibility of the redox processes indicates that the species formed are not stable and suggests a mechanism involving other chemical steps, namely structural or conformational reorganization and/or disproportionation, as observed on other diiron complexes of nitrogen donor atoms ligands [43–45]. However, the differences on the electrochemical behaviour of the two studied complexes with the splitting and shifts of the redox potentials was explained by a weak electronic interference between the two metal centres on the dinuclear species.

3. Conclusions

The potentiometric studies of the complexation behaviour of L^1 with iron(III) ion have established the formation of mono- and dinuclear complexes in solution. Dinuclear hydroxo-complexes are formed upon pH 4. The dinuclear complex was formed even for the 1:1 stoichiometry simultaneously with mononuclear protonated species formed by the consecutive deprotonation of the ammonium groups of the arms. The ML^1 species is formed upon pH of about 6, and appears in insignificant amounts at 2:1 ratio. The thermodynamic stability constants of the mono- and dinuclear complexes were determined in the 2–7 pH range. The constant values for the deprotonation equilibria of the protonated mononuclear species are consistent with the consecutive deprotonation of the ammonium groups of the pendant arms, suggesting the macrocyclic nitrogen donor atoms as the preferred coordination sites of the first metal centre, and the aminopropyl arms for the second one. The low pH values at which the two dinuclear hydroxo-species are formed suggest that the water molecules are strongly bound to the metal centres.

The spectroscopic UV–Vis and IR data confirmed the existence of mono-, dinuclear and hydroxo-dinuclear complexes. The EPR spectral data of 2:1 ratio solution pointed to the presence of two high-spin d^5 state iron(III) species in different rhombic E/D distortion. The electrochemical studies were also consistent with the formation of mono- and dinuclear complexes with similar irreversible redox behaviour. The electrochemical properties of the two types of complexes are different, as expected, due to the different environment of both metal centres in the dinuclear complex, and the weak interaction between them.

In conclusion, our results support the formation of the dinuclear complex having the two metal centres coordinated in the two different sites of the ditopic macrocyclic ligand. Water molecules and counterions complete the metal coordination spheres. The formed dihydrolysed species precipitate below neutral pH, probably due to dimerization or polymerization, which precluded their characterization in solution at pH values higher than 5.5.

4. Experimental

4.1. Ligands and reagents

The parent macrocycle, 3,7,11,17-tetraazabicyclo[11.3.1]heptadeca-1(17),13,15-triene and its 3,7,11-tris(3-aminopropyl) derivative L^1 were synthesized by previously published methods [20]. All the chemicals were of reagent grade and used as supplied without further purification. The organic solvents were purified by standard methods [46]. The reference used for the ^1H NMR measurements in D_2O was 3-(trimethylsilyl)-propanoic acid-d_4-sodium salt and in $CDCl_3$ the solvent itself.

4.2. Potentiometric measurements

4.2.1. Preparation of solutions

The $Fe(NO_3)_3$ solutions were prepared at about 0.02 mol dm^{-3} from the analytical grade salt with demineralised water (from a Millipore/Milli-Q system). The solutions were standardized by titration with Na_2H_2edta [47] and were kept in excess of nitric acid to prevent the hydrolysis. The carbonate free solutions of the titrant, KOH, were prepared as described [20]. For the back titrations a 0.100 mol dm^{-3} solution of HNO_3 was used.

4.2.2. Equipment and work conditions

The equipment used was described previously [20]. The temperature was kept at 298.2 ± 0.1 K and atmospheric CO_2 was excluded from the cell during the titration by passing purified nitrogen across the top of the experimental solution in the reaction cell. The ionic strength of the solutions was kept at 0.10 mol dm^{-3} with KNO_3.

4.2.3. Measurements

The $[H^+]$ of the solutions was determined by the measurement of the electromotive force of the cell, $E = E^{'\circ} + Q\log[H^+] + E_j$. $E^{'\circ}$, Q, E_j, $K_w = ([H^+][OH])$ were obtained as described previously [20]. The value of K_w was found equal to $10^{-13.80}$ mol^2 dm^{-6}.

The potentiometric equilibrium measurements were carried out using 20.00 cm^3 of $\cong 2.50 \times 10^{-3}$ mol dm^{-3} ligand solution diluted to a final volume of 30.00 cm^3 in the presence of iron ion for the following C_{Fe}:C_{L1} ratios: 0.5:1, 0.7:1, 0.9:1, 1:1 at 2–7.5 pH range, and 1.5:1 and 2:1 at 2–6.5 pH range. Minimum of two replicate measurements were taken. The pH range taken for the studies was limited due to precipitation. Back-titration curves with standard HNO_3 were also performed when the equilibrium of the formed species was slow to attain.

4.2.4. Calculation of equilibrium constants

Stability constants of the various species formed in solution were obtained from the experimental data (potentiometric titrations) using the HYPERQUAD program [48]. The initial computations were obtained in the form of overall stability constants, $\beta_{M_mH_hL_1} = [M_mH_hL_1]/\{[M]^m[H]^h[L]^1\}$. Mononuclear ML, MH_hL (h = 1–3) and dinuclear $[M_2L]$, $[M_2H_{-1}L]$, $[M_2(H_{-1})_2L]$ species were found for iron(III) metal complexes of the studied ligand, being $\beta_{M_2H_{-1}L} = \beta_{M_2L(OH)} \times K_w$ and $\beta_{M_2(H_{-1})_2L} = \beta_{M_2L(OH)_2} \times (K_w)^2$.

The species proposed in a particular model were those that can be justified by the principles of co-ordination chemistry. The errors quoted are the standard deviations of the overall stability constants given directly by the program for the input data, which include all the experimental points of all titration curves used. The stability constants were obtained from about 220 experimental points and five titration curves.

4.3. Spectroscopic studies

Electronic spectra of the complexes in water were recorded with a UNICAM model UV-4 (in the UV–Vis range) or with a Shimadzu model UV-3100 (in the NIR range) spectrophotometers with solutions of 5×10^{-5} to 3.4×10^{-4} mol dm^{-3} at pH 3.4 and 7.4 for the iron(III) to ligand 1:1 ratio and 6×10^{-5}–1.9×10^{-4} mol dm^{-3} for the iron(III) to ligand 2:1 ratio at pH 4.9. EPR spectroscopic measurements of the dinuclear iron(III) complex was recorded with a Bruker ESP 380 spectrometer equipped with continuous-flow cryostats for liquid helium or liquid nitrogen, operating at X-band at 11.4 and 95 K. The complex was prepared at 2×10^{-3} mol dm^{-3} DMSO/H_2O (1:1, v/v) solutions with the metal to ligand ratio 2:1 at pH 5. IR spectra were recorded from KBr pellets of solid sample of iron(III) to ligand 2:1 ratio complex on a UNICAM Mattson 7000 spectrometer and from 2×10^{-3} mol dm^{-3} solution of iron(III) to ligand 2:1 ratio on a Bruker IFS 66/S spectrometer, using the OPUS program, version 5.5.

4.4. Electrochemical measurement

A BAS CV-50 W Voltammetric Analyzer connected to BAS/Windows data acquisition software was used for the electrochemical measurements. The cyclic voltammetry experiments were performed in a glass cell MF-1082 from BAS in a C-2 cell roofed in a Faraday cage, at 298.2 ± 0.1 K under a purified nitrogen atmosphere. The glassy carbon electrode was employed together with a reference Ag/AgCl (MF-2079 from BAS) electrode and 7.5 cm platinum coil ware (MW-2079 from BAS) with a gold plated connector

as a auxiliary electrode. The working electrode was electro-cleaned by multi cycle scanning in the electrode supporting solution, after polishing with alumina 0.3 μm, cleaned with water and sonicated before using, according with standard procedures [49]. The electrochemical reversibility of the glassy carbon electrode was tested by the simple one electron redox couple of 0.4 mol dm^{-3} aqueous solution of potassium ferricyanide $[Fe(CN)_6]^{3-}$, performed at various scan rate between 2 and 100 mV/s [50]. The applied aqueous solutions of the studied complexes were prepared in concentration 2.0–4.0 $\times 10^{-3}$ mol dm^{-3} in KNO_3 0.4 mol dm^{-3} as a supporting electrolyte, at the metal to ligand 1:1 and 2:1 ratios, which were purged by N_2 for 15 min before applying the voltage. The indicated species are predominant at the quoted pH range, based on the corresponding Hyss speciation curves [21].

Acknowledgements

The authors acknowledge Helena Carapuça, from Universidade de Aveiro, the help on the electrochemical measurements and the fruitful discussions of the results. The authors also thank Manuela Pereira for the acquisition of EPR spectra. K.P. Guerra acknowledges FCT for a grant (SFRH/BD/6492/2001).

ABSTRACT

The reaction of the potassium salts of *N*-(thio)phosphorylated thioureas of the common formula AdN(H)C(S)N(H)P(X)(O*i*Pr)$_2$ (X = O, **HL^{I}**; X = S, **HL^{II}**) with the Ni(II) cation in aqueous EtOH leads to [**Ni(L^{I,II})$_2$**] chelate complexes. The molecular structures of the thioureas **HL^{I,II}** and the complexes [**Ni(L^{I}-*N*,*S*)$_2$**] and [**Ni(L^{II}-*S*,*S*′)$_2$**] were elucidated by single crystal X-ray diffraction analysis, IR, ^{1}H and ^{31}P NMR spectroscopy and microanalysis. In the complex [**Ni(L^{I})$_2$**], the metal center is found to be in a square-planar N_2S_2 environment formed by the C=S sulfur atoms and the P–N nitrogen atoms of two deprotonated **L^{I}** ligands. The ligands are in a *trans* configuration. The Ni(II) atom in complex [**Ni(L^{II})$_2$**], with the deprotonated thiourea **L^{II}**, is coordinated in a square-planar fashion by the C=S and P=S sulfur atoms of two anionic ligands. The ligands are in a *cis* configuration.

1. Introduction

Competitive coordination of polydentate ligands has been of interest over the last four decades [1]. The Hard Soft Acid Base (HSAB) principle has been used to explain the coordination versatility of metal cations with donor centers of polyfunctional ligands [1a]. However, the HSAB principle is not enough if the ligand contains several hard or soft coordination atoms contesting for a place in the coordination environment of a metal cation. The influence of different steric factors, additional intra- and intermolecular bonding (e.g. hydrogen bonds), the electron effects of substituents and many other factors must be taken into account.

We recently published data illustrating the influence of intramolecular hydrogen bonds on the 1,3-*N*,*S*- and 1,5-*O*,*S*-coordination of *N*-phosphoryl-*N*′-(R)-thioureas RNHC(S)NHP(O)(O*i*Pr)$_2$ (**HL**) (R = Ph [2]; R = *p*-MeOC$_6$H$_4$, *p*-BrC$_6$H$_4$, *t*-Bu, *c*-Hex [3]) with Ni(II). It was established that intramolecular hydrogen bonds N–H···O=P are a necessary condition for the 1,3-*N*,*S*-isomer stabilization in square-planar complexes of Ni(II). The destabilization of Ni(II) complexes and a change of the coordination mode from the 1,3-*N*,*S*- to the 1,5-*O*,*S*-isomer chelates takes place when H-bonding in the coordinated anionic ligands **L** is not possible (R = Et$_2$N, morpholine-*N*-yl). Thus, intramolecular hydrogen bonding realized outside the coordination sphere of the metal cation is the reason for the dramatic changes of such important parameters as bite angle and the ligand's field strength.

Herein we present the structure of two new thioureas of the common formula AdNHC(S)NHP(X)(O*i*Pr)$_2$ and their complexing properties towards the nickel(II) cation. Comparative analysis on the coordination mode of the phosphorylated (X = O) and thiophosphorylated (X = S) derivatives have been performed.

2. Experimental

2.1. Synthesis of HL^{I} and HL^{II}

A solution of 1.510 g (10 mmol) 1-adamantylamine in anhydrous CH_2Cl_2 (15 mL) was treated, whilst vigorously stirring, with a solution of 2.676 g (12 mmol) of (*i*PrO)$_2$P(O)NCS or 2.868 g (12 mmol) of (*i*PrO)$_2$P(S)NCS in anhydrous CH_2Cl_2 (10 mL). The mixture was stirred for an additional 30 min to complete the reaction. The solvent was removed in a vacuum, and the product was purified by crystallization from dichloromethane by *n*-hexane.

2.2. Synthesis of [*Ni*(*L*^{I})$_2$] and [*Ni*(*L*^{II})$_2$]

A suspension of 1.112 g **HL^{I}** or 1.170 g **HL^{II}** (3 mmol) in aqueous EtOH (10 mL) was mixed with an aqueous EtOH solution of potassium hydroxide (0.185 g, 3.3 mmol). An aqueous EtOH (10 mL) solution of 0.245 g $NiCl_2$ (1.9 mmol) was added dropwise under vigorous stirring to the resulting potassium salt. The mixture was stirred at room temperature for a further 3 h and left overnight. The resulting complex was extracted with dichloromethane, washed with water and dried with anhydrous $MgSO_4$. The solvent was then removed in vacuo. Violet [**Ni**(**L^{I}**)$_2$] and dark blue [**Ni**(**L^{II}**)$_2$] crystals were isolated from dichloromethane by *n*-hexane. All yields are given with respect to the ligand.

2.3. Physical measurements

NMR spectra of **HL^{I}** and [**Ni**(**L^{I}**)$_2$] were recorded on a Bruker AC 200 spectrometer using Me_4Si as an internal standard. IR spectra were recorded using a Bruker Vektor 22. Elemental analyses were performed on a Vario EL III CHNS elemental analyzer at the IAAC, University Münster, Germany. NMR spectra of **HL^{II}** and [**Ni**(**L^{II}**)$_2$] were recorded on a Varian Unity-300 NMR spectrometer using Me_4Si as an internal standard. IR spectra were recorded using a Specord M-80. Elemental analyses were performed on a Perkin–Elmer CHN elemental analyzer.

2.4. Crystal structure determination and refinement

The X-ray data for **HL^{I}** and [**Ni**(**L^{I}**)$_2$] were collected at −173 °C using a KM4CCD diffractometer and graphite-monochromated Mo Kα radiation. The images were indexed, integrated and scaled using the KUMA data reduction package [4]. The structures were solved by a direct method using SHELX97 [5] and refined by the full-matrix least-squares method on all F^2 data [6]. Non-hydrogen atoms were included in the refinement, with anisotropic displacement parameters. The hydrogen atoms were positioned geometrically and refined isotropically. The hydrogen atoms of the NH groups were included from $\Delta\rho$ maps and refined isotropically. All calculations were preformed using the WINGX program [7]. The X-ray diffraction data for **HL^{II}** and [**Ni**(**L^{II}**)$_2$] were collected at 20 °C using Bruker Kappa Apex2 (graphite-monochromator Cu Kα radiation for **HL^{II}**) and Bruker Smart Apex2 (graphite-monochromator Mo Kα radiation for [**Ni**(**L^{II}**)$_2$]) diffractometers. The images were indexed, integrated and scaled using the APEX2 data reduction package [8]. All raw data were corrected for absorption using the SADABS program [9]. The structures were solved by a direct method using the SIR [10] program and the refinement was carried out with SHELXL [11] using anisotropic thermal parameters for all non-hydrogen atoms. Hydrogen atoms were added to the structural models in calculated positions and were refined as rigid atoms. Hydrogen atoms of the NH groups for **HL^{II}** were included from $\Delta\rho$ maps and refined isotropically. All figures were made using the program PLATON [12].

3. Results and discussion

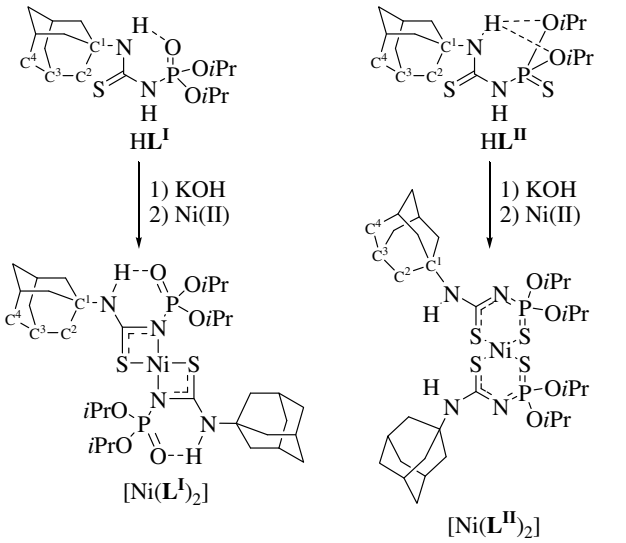
3.1. Synthesis

The thioureas **HL^{I}** and **HL^{II}** were prepared by the addition reaction of 1-adamantylamine to isothiocyanates of diisopropylphosphoric (iPrO)$_2$P(O)NCS and diisopropylthiophosphoric (iPrO)$_2$P(S)NCS acids, respectively. The complexes [**Ni**(**L^{I}**)$_2$] and [**Ni**(**L^{II}**)$_2$] were prepared by the following procedure: the ligand was converted to the potassium salt and followed by interaction with nickel(II) chloride (Scheme 1). The obtained compounds are crystalline solids and are soluble in most polar solvents. According to the elemental analysis, they have a ratio Ni:**L^{I,II}** of 1:2.

According to the X-ray diffraction analysis, IR, ^{1}H and ^{31}P NMR spectroscopy data, the metal center in complex [**Ni**(**L^{I}**)$_2$] is found in a square-planar N_2S_2 environment formed by the C═S sulfur atoms and the P–N nitrogen atoms. On the contrary, 1,5-*S*,*S*′-coordination of the Ni^{II} atom was found in the crystal of the [**Ni**(**L^{II}**)$_2$] complex.

3.2. IR and NMR spectroscopy

The IR spectra of **HL^{I}** and **HL^{II}** contain two absorption bands for the NH groups in the given areas: 3291–3382 (the narrow band)



Scheme 1. Preparation of the complexes $[Ni(L^{I,II})_2]$.

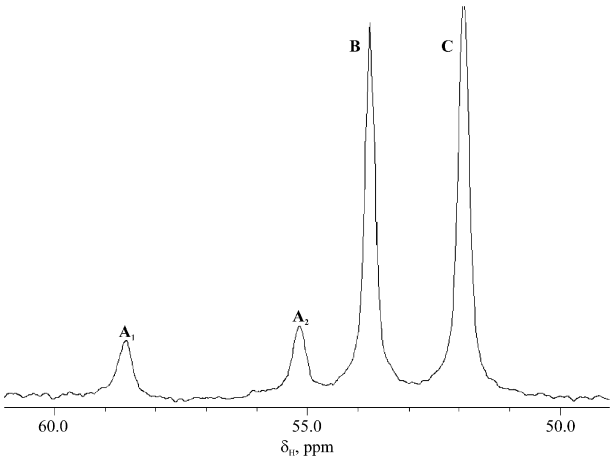


Fig. 1. ^{31}P NMR spectrum of the complex $[Ni(L^{II})_2]$.

and 3103–3123 (the wide intensive band) cm^{-1}. The bands in the low frequency region show the formation of hydrogen bonds in the solid state. The bands for the S═C–N group are at 1525–1557 cm^{-1} in the IR spectra of the obtained thioureas [13]. The absorption band of the P═S group of HL^{II} is observed in the characteristic area at 643 cm^{-1}. The IR spectrum of HL^{I} contains a strong band at 1241 cm^{-1} because of the P═O group. Presence of a wide absorption band of the POC fragments in HL^{I} and HL^{II} in the area 1000–1006 cm^{-1} also unequivocally confirms the presence of the substituted phosphoric fragment [13].

There is only a triplet signal at −0.8 and 53.4 ppm in the ^{31}P NMR spectra of HL^{I} and HL^{II}, respectively. The signal at −0.8 ppm is in the region that is characteristic for neutral *N*-phosphorylated thioureas, whereas the signal at 53.4 ppm corresponds to *N*-thiophosphorylated thioureas [14,15].

In the ^{1}H NMR spectra of HL^{I} and HL^{II} the adamantyl proton signals are at 1.63–2.27 ppm. The spectra of both ligands contain a set of signals for the *i*PrO protons: a doublet for the CH_3 protons at 1.33–1.34 ppm and a doublet of septets for the CH proton in the area 4.67–4.77 ppm. The signals at 7.85 and 6.51 ppm correspond to the P(O)NH and P(S)NH protons, respectively, in HL^{I} and HL^{II}. The main difference involves the signals at 9.05 ppm in the spectrum of the ligand HL^{I} and at 7.73 ppm for HL^{II}, corresponding to the AdNH hydrogen.

The IR and NMR spectra of the thiourea HL^{I} clearly show the presence of the strong intramolecular N–H···O═P hydrogen bonds both in the solid state and in solution [2,3,13]. The AdNH proton signal in the ^{1}H NMR spectrum of HL^{I} is low-field shifted because of the strong intramolecular N–H···O═P hydrogen bond which remains in the d_6-acetone solution.

The IR spectrum of the complex $[Ni(L^{II})_2]$ in Nujol contains an absorption band for the P═S group of the anionic form of L^{II}, which is shifted by 37 cm^{-1} to a lower frequency relative to the band of the parent ligand HL^{II}. This confirms its participation in chelate formation. The absorption band of the P═O group of L^{I} in complex $[Ni(L^{I})_2]$ is also shifted to a lower frequency relative to the band of the ligand HL^{I}, and the shift is 43 cm^{-1}. This value is the biggest among the obtained 1,3-*N*,*S*-chelates [2,3], but it is definitely smaller than those for the corresponding 1,5-*O*,*S*-isomers. The low frequency shift of the P═O group band reaches 80–100 cm^{-1} for the 1,5-*O*,*S*-chelates of similar ligands [2,3,16].

There is only the NH group absorption band in the IR spectra of complexes $[Ni(L^{I})_2]$ and $[Ni(L^{II})_2]$, at 3147 and 3409 cm^{-1}, respectively. The NH absorption band in the IR spectrum of the complex $[Ni(L^{I})_2]$ is practically in the same region as it was for the parent ligand. This, together with the small shift of the P═O group absorption band relative to the band of the ligand HL^{I}, indicates the preservation of the intramolecular N–H···O═P hydrogen bond on complex formation. A similar outcome was observed for the Ni(II) complexes with the common formula $Ni[RNHC(S)NP(O)(OiPr)_2]_2$ (R = Ph [2]; R = *p*-$MeOC_6H_4$, *p*-BrC_6H_4, *t*-Bu, *c*-Hex [3]). On the other hand, for $[Ni(L^{II})_2]$ the frequency of the NH group band is characteristic for 1,5-*O*,*S*- and 1,5-*S*,*S*′-chelates, showing the absence of intramolecular H-bonding [2,3,16,17].

In the IR spectra of the complexes $[Ni(L^{I})_2]$ and $[Ni(L^{II})_2]$ there is an intense absorption band at 1508–1549 cm^{-1} corresponding to the conjugated SCN fragment. This fact also confirms the complexes formation. In addition there is a wide intensive band for the POC group at 989–997 cm^{-1}. It confirms the preservation of the structure of the ligands in the obtained complexes.

The ^{31}P NMR spectrum of complex $[Ni(L^{I})_2]$ in $CDCl_3$ contains a single triplet signal at 0.9 ppm. which differs by a negligible margin from the signal of the parent ligand (−0.8 ppm). This confirms the non-participation of the oxygen atom of the P═O group in complex formation [2,3].

The ^{31}P NMR spectrum of $[Ni(L^{II})_2]$ is more complicated. There are four broadened singlet signals at 51.9, 53.8, 55.1 and 58.6 ppm which were denoted by A_1, A_2, **B** and **C** (Fig. 1). However, only a signal at 50.8 ppm is observed in the MAS NMR $^{31}P–\{^{1}H\}$ spectrum of the polycrystals of $[Ni(L^{II})_2]$.[1] According to the X-Ray data this signal corresponds to the *cis*-isomer.

Quite a similar pattern was found in the ^{31}P NMR spectra of the 1,5-*S*,*S*′-chelates of the formulas $Ni[PhNHC(S)NP(S)(OiPr)_2]_2$ and $Ni[tBuNHC(S)NP(S)(OiPr)_2]_2$ [17]. On the basis of this comparision, the three signal groups (A_1 + A_2, **B** and **C**) can be related respectively to the three following diamagnetic square-planar isomers, with different dispositions and conformations of two ligands. The further investigation of the structure and properties of the obtained compounds in solution is in progress.

The ^{1}H NMR spectrum of the complex $[Ni(L^{I})_2]$ contains a single set of signals for the $(iPrO)_2P(O)$ and Ad protons. The adamantyl proton signals are at 1.64–2.07 ppm. The isopropyl group is shown as a doublet for the CH_3 protons at 1.34 ppm and a doublet of septets for the CH proton at 4.62 ppm. The signal for the NHP(O) group proton is absent in the ^{1}H NMR spectrum. This confirms the presence of the anionic form of HL^{I} in the structure of the complex

[1] The detailed research of the MAS NMR $^{31}P–\{^{1}H\}$ spectra of the obtained chelates is in progress. The results will be published separately.

[**Ni(L^{I})$_2$**]. The broadened singlet signal at 8.51 ppm corresponds to the AdNH proton and is in the low-field region that is characteristic for Ni(II) complexes containing an intramolecular N–H···O=P hydrogen bond with [RNHC(S)NP(O)(O*i*Pr)$_2$]$^-$ anions [3,17].

The ^{1}H NMR spectrum of the complex [**Ni(L^{II})$_2$**] contains a double set of signals for the (*i*PrO)$_2$P(S) and Ad protons. The ratio of integrated intensities is practically equal to 1:1 and they correspond to the dominant forms **B** and **C** in solution. The signals in the area 1.12–2.36 ppm correspond to the protons of the Ad and CH_3 groups. There are two broadened singlet signals of the OCH protons at 4.66 and 4.96 ppm, and two signals of the protons of the NH group at 5.70 and 9.10 ppm.

The high-field resonance of the NH proton clearly shows a splitting due to the $^4J_{PNCNH}$ (5.5 Hz) spin–spin interaction. This was previously reported for the other 1,5-*O*,*S*- and 1,5-*S*,*S*′-chelates of *N*-(thio)phosphorylthioureas [16] and was attributed to the fact that the P–N–C–N–H chain matches the so-called *W*-criterion.

It should be noted that no such splitting is observed for the free ligands **HL^{I,II}**, other *N*-(thio)phosphorylthioureas or for the 1,3-*N*,*S*-chelates.

3.3. Crystal structures

The crystal structures of **HL^{I}** and **HL^{II}** are shown in Figs. 2 and 3, and selected values of bond lengths, bond angles are listed in Tables 1 and 2, respectively. In both ligands the NC(S)N fragment is almost planar, due to the conjugation between the nitrogen lone pairs and the double C=S bond. The phosphorus atoms are in a typical tetrahedral O_2XN environment (X = O, **HL^{I}**, X = S, **HL^{II}**). The P–N–C–N fragments are in the *syn*-conformation, and the torsion angles are as follows: −10.3(2)° **HL^{I}** and −4.6(3)° for **HL^{II}**. In the ligand **HL^{I}**, the oxygen atom of the P=O group and the sulfur atom of the C=S group are in an *anti* conformation, whereas in the ligand **HL^{II}** both sulfur atoms are located in a *syn* disposition.

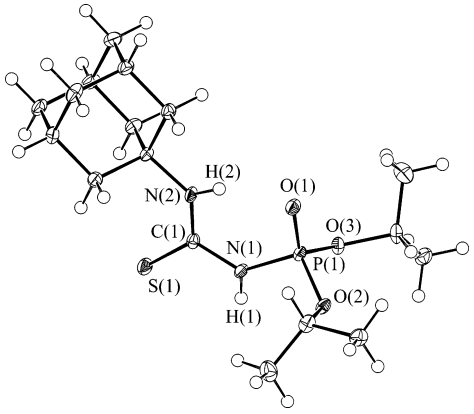

Fig. 2. Molecular structure of **HL^{I}**. Thermal ellipsoids are drawn at 50% probability.

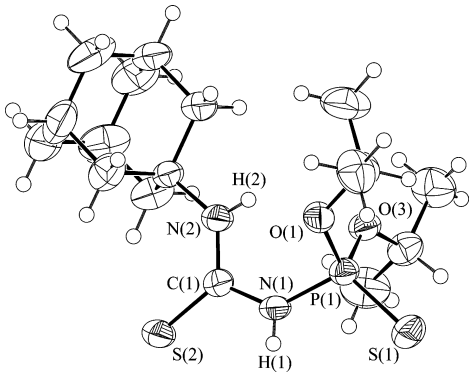

Fig. 3. Molecular structure of **HL^{II}**. Thermal ellipsoids are drawn at 50% probability.

The *W*-criterion in the structure of complex [**Ni(L^{II})$_2$**] is realized with an *anti*-orientation of the N–C–N–H moiety (Scheme 1), because of the sterically demanding adamantyl substituents. The contribution of the observed splitting to the presence of $^4J_{PNCNH}$ spin-spin coupling was unambiguously confirmed by recording ^{1}H NMR spectra with ^{31}P decoupling.

In the crystals of the thioureas **HL^{I}** and **HL^{II}** intramolecular hydrogen bonds were found. Their parameters are presented in Table 3. In the ligand **HL^{I}** the hydrogen bond is of the N–H···O=P(intra) type, between the hydrogen atom of the AdNH group and the oxygen atom of the P=O group, whereas the thiophosphorylated analogue **HL^{II}** contains intramolecular bifurcated H-bonds between the AdNH proton and the oxygen atoms of both O*i*Pr groups. The ligand **HL^{II}** is the first example among thiophosphorylthioureas of the common formula RNHC(S)NHP(S)(O*i*Pr)$_2$ that contains an intramolecular bifurcated hydrogen bond.

In the crystal structures of the ligands **HL^{I}** and **HL^{II}** there are also intermolecular hydrogen bonds (Table 3). In the thiourea **HL^{I}** the H-bond is of the N–H···O=P(inter) type between the hydrogen atom of the PNH group of one molecule and the oxygen atom of the P=O

Table 3
Parameters of hydrogen bonds for **HL^{I}**, **HL^{II}** and [**Ni(L^{I})$_2$**] [bond lengths (Å) and bond angles (°)]

	N–H···O	*d*(H···O)	*D*(N···O)	∠(NHO)

[a] (1 − *x*; −1/2 + *y*; 1/2 − *z*).
[b] (1/2 − *x*; 5/2 − *y*; 1 − *z*).

group of another one. As a result of the intermolecular hydrogen bonds, polymeric chains are formed along the 0*b* axis. The ligand **HL^{II}** contains intermolecular H-bonds of the N–H···S=C(inter) type, with the formation of a centrosymmetric dimer.

Figs. 4 and 5 show the structures of the complexes [**Ni**(**L^{I}**)$_2$] and [**Ni**(**L^{II}**)$_2$], respectively, and selected values of bond lengths, bond angles are given in Tables 4 and 5. According to the single crystal X-ray data these complexes are of a [**Ni**(**L**)$_2$] structure.

Complex [**Ni**(**L^{I}**)$_2$] (Fig. 4) is built in a centrosymmetric manner. The Ni(II) cation is coordinated in a square-planar fashion with the ligands arranged in a *trans* configuration. The four-membered Ni–S–C–N metallocycles are flat. The values of the two intracyclic S–Ni–N angles in the four-membered rings fall in the range 74–75°. The values of the intercyclic S–Ni–N angles are in the region 104–107° (Table 4). The C–S and C–N bonds of the chelate cycles in complex [**Ni**(**L^{I}**)$_2$] are lengthening whereas the P–N ones are shorten relative to those in the parent ligand. The length of the P=O bonds are practically the same as was found for **HL^{I}**. Thus, the C–S and P–N bond lengths indicate that these bonds are best described as single bonds, while the P=O group represents the double bond [18].

In the investigated compound [**Ni**(**L^{I}**)$_2$], the AdNH hydrogen atoms are engaged in intramolecular hydrogen bonds of the AdN–H···O=P type (Table 3). Due to their formation, a flat *syn, syn* conformation of the N–C–N–P–O moieties is observed.

X-Ray structural analysis of complex [**Ni**(**L^{II}**)$_2$] shows that the nickel atom is positioned in the symmetry center of a distorted square-planar arrangement, with a *cis*-configuration of the deprotonated ligands **L^{II}** (Fig. 5). Complex [**Ni**(**L^{II}**)$_2$] is the first example of a Ni(II) cationic complex with RC(S)NHP(S)(O*i*Pr)$_2$ ligands in a *cis* configuration investigated by X-ray analysis.

The six-membered metallocycle Ni(1)–S(2)–C(1)–N(1)–P(1)–S(1) has the form of an asymmetric boat; the P(1)–N(1)–C(1)–S(2) fragment is essentially planar. The exocyclic N(2) atom is located practically in the base plane of the heterocycle. The values of the two intracyclic S–Ni–S angles in the six-membered rings are 99.73(4)°. The values of the intercyclic S–Ni–S angles are in the region 79–81° (Table 5). There are no inter- or intramolecular hydrogen bonds in the crystal structure of the complex [**Ni**(**L^{II}**)$_2$].

The Ni(1)–S(1) and Ni(1)–S(2) distances of 2.2172(13) and 2.2043(14) Å, respectively, are close, suggesting electron density delocalization between the S(1) and S(2) atoms of the ligand. The C(1)–S(2) bond length [1.758(4) Å] also indicates such a delocalization; this distance differs significantly from the C=S double bond length in thioureas and the C–S single bond length in sulfides [18].

4. Conclusions

The data presented show that in the ligands **HL^{I,II}** the structure in the solid state and the type of coordination with a Ni(II) cation are determined by the nature of the atom X.

The ligand **HL^{I}** (X = O) contains an intramolecular hydrogen bond between the AdNH proton and the oxygen atom of the P=O group, whereas in the thiourea **HL^{II}** (X = S) bifurcated H-bonding takes place between the AdNH proton and two oxygen atoms of the *i*PrO groups.

The central cation in the complex [**Ni**(**L^{II}**)$_2$] is coordinated in the 1,5-*S*,*S*′-fashion. The square-planar $NiS_2S'_2$ core is stabilized by a π-dative interaction with the sulfur atoms. According to the X-ray data, the two anionic **L^{II}** ligands in the crystal are in a *cis* configuration in spite of the presence of the bulk adamantyl substituents.

There is competition between the two coordination modes, 1,5-*O*,*S*′- versus 1,3-*N*,*S*-, in the complex [**Ni**($\mathbf{L^I}$)$_2$]. The 1,5-*O*,*S*′-mode is obviously the most favorable for steric reasons, due to the formation of the unstrained six-membered cycle. However, we have established that the Ni(II) cation is in a N_2S_2 environment. There are three reasons for its stabilization: (1) the strong (~20–25 kJ/mol) [2,3] intramolecular hydrogen bond which blocks the phosphoryl group; (2) the stronger p-π conjugation in the thioamide moiety in comparison with the SCNPO backbone; and (3) the stronger ligand field provided by the 1,3-*N*,*S*-coordinated thiourea.

ABSTRACT

The reaction between cadmium nitrate dihydrate and benzil bis(4-methyl-3-thiosemicarbazone), LMe_2H_4, depends on the working conditions. In methanol the reaction gives the novel complex $[Cd(LMe_2H_4)(NO_3)_2][Cd(LMe_2H_4)(NO_3)(H_2O)]NO_3 \cdot H_2O$ (**1**). Its crystal structure shows the presence of two cadmium atoms with different coordination numbers, seven and eight, and the ligands acting as N_2S_2 neutral molecules. One cadmium has the coordination sphere completed by a bidentate nitrato group and a water molecule, whereas the other one is bonded to two bidentate nitrato groups. Both molecules are joined to one nitrate ion and to an additional water molecule by hydrogen bonds. In the presence of lithium hydroxide, the reaction leads to a binuclear complex with the ligand doubly deprotonated $[Cd(LMe_2H_2)]_2$ (**2**). The complexes were characterized by elemental analysis, mass spectrometry, ^{13}C and ^{113}Cd CP/MAS NMR and, in the case of complex **1**, by X-ray diffraction.

1. Introduction

In recent years, the heavy element cadmium has received increased attention due to its impact on plants and toxicity to humans, as well as for the luminescent properties of its complexes [1–6]. Cadmium is an extremely toxic element that is naturally present in the environment and also as a result of human activities. Its toxicity derives from the fact that it is rapidly localized intracellularly, mainly in the liver, and then is bound to metallothionein forming a complex that is slowly transferred to the bloodstream to be deposited in the kidneys. Therefore, it is an interesting area of research to get compounds which are able to form stable complexes with cadmium, because they could be employed as detoxificating agents. For this purpose thiosemicarbazone ligands could be very appropriate as both the ligands and their complexes have shown a wide range of pharmacological properties [7–9]. In particular, cadmium and mercury complexes of the related ligand benzil bis(thiosemicarbazone) have antimicrobial and antifungal activity [10], so it could be expected that these cadmium derivatives also possess some activity and studies are underway.

The coordination number of six for Cd(II) ions is well documented [11–13], but seven-coordinate complexes are scarce [14–17], and they are rarely found together in one compound [18]. An eight-coordinate structure is usually formed with species having larger ion radius, such as lanthanides and third row transition metals, and it is relatively unusual for the Cd(II) ion [19]. As far as we know, there are only two complexes containing simultaneously both seven- and eight-coordinate cadmium(II), a cluster and a complex with the ligand acting as bridge [20,21]. On the other hand, there are only two seven-coordinate cadmium(II) complexes of thiosemicarbazones that have been structurally characterized, one with a tridentate ligand and another containing 2,6-diacetylpyridine bis(^2N-methylthiosemicarbazone) [17,21]. Benzil bis(4-methyl-3-thiosemicarbazone) LMe_2H_4 (see Scheme 1) has four donor atoms that can lead to a tetradentate coordination mode, so there are at least two sites available on the Cd(II) ion for the NO_3^- coordination. This ligand has shown versatile behaviour with $PbPh_2Cl_2$, depending on the pH it acts as a monodeprotonated or dideprotonated ligand, it also acts as a bridge through a sulfur atom [22].

Following our systematic study on the coordination chemistry of thiosemicarbazone ligands with toxic metals [22], here we report the synthesis and structural characterization of two new cadmium coordination compounds derived from benzil bis(4-methyl-3-thiosemicarbazone). Complex **1** is obtained in methanol and it contains two different types of Cd(II) ions. The Cd(1) atom is seven-coordinate by two nitrogen and two sulfur atoms from the ligand and three oxygen from a bidentate nitrato ligand and one water molecule, but in the Cd(2) coordination sphere the water molecule is replaced by an additional bidentate nitrato group. Both units are linked to a nitrate ion and a water molecule by hydrogen bonds. Complex **2** is synthesised in the presence of lithium hydroxide, so the ligand is doubly deprotonated and the cadmium(II) atom could be penta-coordinate in a binuclear structure. To the best of our knowledge, here we report the first thiosemicarbazone

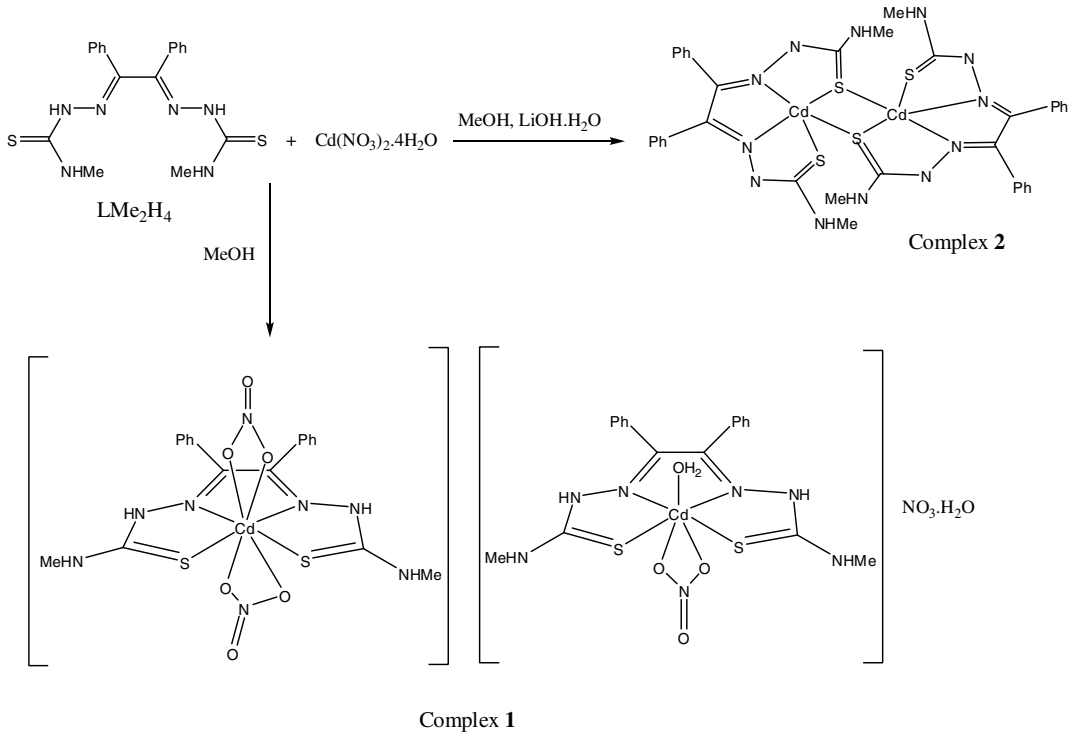

Scheme 1. A drawing showing the working conditions and the complexes obtained.

complex with eight-coordinate Cd(II). Moreover, it also is the first compound in which two cadmium ions are present with seven and eight coordination spheres in two independent units.

2. Experimental

2.1. Materials and methods

4-Methyl-3-thiosemicarbazide, 1,2-diphenylethanedione and cadmium nitrate tetrahydrate were used as received. Microanalyses were carried out using a Perkin–Elmer 2400 II CHNS/O Elemental Analyser. IR spectra in the 4000–400 cm^{-1} range were recorded as KBr pellets on a Jasco FT/IR-410 spectrophotometer. Fast atom bombardment mass spectra were recorded on a VG Auto Spec instrument using Cs as the fast atom and *m*-nitrobenzylalcohol (*m*NBA) as the matrix. ^{13}C NMR spectra were recorded on a Bruker AMX-300 spectrometer using methanol-d_4 and DMSO-d_6 as solvents and TMS as an internal reference. ^{113}Cd NMR spectra were recorded in the same spectrometer using methanol-d_4 or DMSO-d_6 as solvents and using absolutes as references, the chemical shifts are reported relative to $Cd(ClO_4)_2$ 0.1 M. ^{13}C CP/MAS NMR spectra were recorded at 298 K in a Bruker AV400WB spectrometer equipped with a 4 mm MAS-NMR probe (magic-angle spinning) and obtained using a cross-polarization pulse sequence. For the recorded spectra a contact time of 4 ms was used and recycle delays of 4 s were used. Chemical shifts are reported relative to TMS, using the CH group of adamantano as a secondary reference (29.5 ppm). ^{113}Cd CP/MAS NMR spectra were also recorded in the same spectrometer and the chemical shifts are reported relative to $Cd(ClO_4)_2$ 0.1 M, using $Cd(NO_3)_2 \cdot 4H_2O$ as secondary reference (−100 ppm).

2.2. Synthesis of benzil bis(4-methyl-3-thiosemicarbazone), LMe_2H_4

This molecule was synthesised as reported earlier [23]. Selected spectroscopic data: ^{13}C NMR (DMSO-d_6, 300 MHz, 25 °C): δ/ppm 178.6 (CS), 140.4 (CN), 133.2, 130.3, 129.1, 126.8 (Ph), 31.5 (CH_3). ^{13}C CP/MAS NMR (300 MHz, 25 °C): δ/ppm 177.2 (CS), 139.8 (CN), 130.6, 128.1, 124.7 (Ph), 32.1 (CH_3). FTIR (KBr, cm^{-1}): 3420, 3386, 3342, 3330, 3210, 3151 (s) [ν(NH)], 1608 (w) [ν(CN)], 1581 (s) [$\delta(NH_2)$] and 848 (w) [ν(CS)].

2.3. Synthesis of $[Cd(LMe_2H_4)(NO_3)_2][Cd(LMe_2H_4)(NO_3)(H_2O)]NO_3 \cdot H_2O$ (**1**)

Cadmium nitrate tetrahydrate (0.12 g, 0.39 mmol) dissolved in methanol (15 mL) was added to a LMe_2H_4 (0.15, 0.39 mmol) solution in methanol (15 mL). The mixture was stirred under reflux for 6 h. The solution was concentrated whereby a solid precipitated, which was filtered off, washed with methanol and dried in vacuo. M.p.: 187 °C. The compound was isolated as a yellow solid (0.16 g, 64%). Suitable crystals for X-ray analysis were obtained by slow evaporation of the mother liquor. M.p.: 187 °C. *Anal.* Calc. for $C_{36}H_{42}N_{16}O_{14}S_4Cd_2$ (1275.9): C, 33.88; H, 3.32; N, 17.57; S, 10.03. Found: C, 33.75; H, 3.44; N, 17.16; S, 10.19%. ^{13}C NMR (300 MHz, methanol-d_4): δ/ppm 181.0 (CS), 148.8 (CN), 131.9, 130.9, 130.7, 130.3, 130.1, 129.8, 129.5, 129.2, 128.1, 128.0 (Ph), 32.1 (CH_3). ^{113}Cd NMR (300 MHz, methanol-d_4): δ/ppm 167.3 ^{13}C CP/MAS NMR (300 MHz): δ/ppm 180.2 (CS), 148.1, 147.0 (CN), 134.1, 131.9, 130.8, 129.0, 128.1, 127.1 125.8 (Ph), 35.3, 31.4 (CH_3). ^{113}Cd CP/MAS NMR (300 MHz): δ/ppm 186.3, 144.3. MS (FAB^+): *m/z* 496.8 ($[Cd(LMe_2H_3)]^+$, 100%). FTIR (KBr, cm^{-1}) 3446, 3344, 3222 (m) [ν(NH)], 1617 (w) [ν(CN)], 1574 (s) [δ(NCS)], 1384 (s) [ν(NO)], 819 (w) [ν(CS)].

2.4. Synthesis of $[Cd(LMe_2H_4)]_2$ (**2**)

The reaction was carried out as described previously, but in the presence of $LiOH \cdot H_2O$ (0.04 g, 0.79 mmol). Complex **2** was isolated as an orange solid (0.17 g, 88%), washed with methanol and dried in vacuo. M.p.: 247 °C. *Anal.* Calc. for $C_{36}H_{36}N_{12}S_4Cd_2$ (988.8): C, 43.68; H, 3.67; N, 16.98; S, 12.96. Found: C, 43.52; H, 3.65; N, 16.84; S, 12.87%. ^{113}Cd NMR (300 MHz, DCM + $CDCl_3$): δ/ppm 410.4. ^{13}C CP/MAS NMR (300 MHz): δ/ppm 178.7, 162.5, 158.7

2.5. X-ray crystallography

Data for **1** (see Table 1) were collected at 100 K with a Bruker SMART 6K CCD area-detector three-circle diffractometer with a MAC Science Co., Ltd. Rotating Anode (Cu Kα radiation, λ = 1.54178 Å) generator. The unit cell parameters were obtained by full-matrix least-squares refinements of 8342 independent reflections. The structures were solved by direct methods (SHELXS-97), completed with difference Fourier syntheses, and refined with full-matrix least squares using SHELXL-97 minimizing $\omega(F_o^2 - F_c^2)^2$. Weighted R factors (R_w) and all goodness-of-fit S are based on F^2; conventional R factors (R) are based on F, giving $R_1 = 0.0371$, $wR_2 = 0.0960$ using 19983 reflections with $I > 2\sigma(I)$ [24,25]. All non-hydrogen atoms were refined with anisotropic displacement parameters. All scattering factors and anomalous dispersions factors are contained in the SHELXTL 6.10 program library. All the hydrogen atoms were included in geometric positions except those of the water molecule, which were located by difference maps and refined isotropically.

3. Results and discussion

3.1. Synthesis

The reaction between LMe_2H_4 and cadmium nitrate depends on the presence of a basic medium (Scheme 1). The reaction carried out in methanol gives a crystalline solid (**1**), which analytical data agree with a 1:1 cadmium:ligand ratio, confirmed by its FAB mass spectrum (Fig. 1a), and the presence of two nitrate groups and one water molecule. However, the reaction in the presence of lithium hydroxide yields complex (**2**), which analytical data are in agreement with a 1:1 ratio and the absence of nitrate groups. The FAB mass spectrum (Fig. 1b) shows a peak at 494.9 corresponding to $[Cd(LMe_2H_3)]^+$ and another one at 990.8, relatively intense, corresponding to $[Cd_2(LMe_2H_2)_2+1]^+$, suggesting a binuclear structure for this complex.

3.2. Spectroscopic studies

The shifts observed in the ν(CN) and ν(CS) bands in the IR spectra of both complexes are in accordance with the ligand being bonded to the cadmium through the imine nitrogen and the sulfur atoms, acting as a tetradentate chelate in both complexes. Moreover, the IR spectrum of **1** shows a sharp and strong band at 1385 cm^{-1} corresponding to ν(N–O) of the NO_3^- group. Several bands in the ν(N–H) and δ(N–H) regions are observed, which agrees with the ligand being in the neutral form. By contrast, the spectrum of **2** only shows two bands in the amine tension region and the absence of any band assignable to the nitrate group.

Complex **2** is sparingly soluble in all common solvents and its ^{1}H and ^{13}C NMR spectra are useless, indicating the decomposition. Therefore ^{13}C and ^{113}Cd CP/MAS of both complexes were measured for comparison. The ^{13}C CP/MAS NMR spectrum of **1** shows one signal corresponding to the thioamide carbon atom, two to the imine, three to the methine carbon and seven corresponding to the aromatic carbon atoms. By contrast, the spectrum of complex **2** shows three signals corresponding to the thioamide group, one to the imine and the methine carbons and six to the aromatic carbon atoms. These differences can be explained due to the presence of ligands with a different behaviour in each complexes: in complex **1** the two ligands act in the same way, but there are a slight differences in the bonds lengths and angles; in complex **2** at least one sulfur atom is bonded to two cadmiums, acting as a bridge as observed in the organolead(IV) derivative and in the binuclear cadmium complex obtained from benzil bis(thiosemicarbazone) [22,26].

It is well known that the ^{113}Cd chemical shift is very sensitive to changes in the coordination number of cadmium as well as to the nature of the bonding, so it is a useful tool to determine the environment of this metal in a complex. Replacement of sulfur by nitrogen and oxygen atoms tends to give greater shielding [27–30] and a decrease in the coordination number tends to give greater deshielding [31,32]. ^{113}Cd CP/MAS NMR spectrum of complex **1** shows two signals at 186.3 and 144.3 ppm, whereas complex **2** only shows a signal at 425.4 ppm. These data are consistent with two cadmium atoms with different environments in complex **1** and only one kind of geometry around the metal ion in complex **2**. The values of the chemical shifts agree with the presence of seven and eight-coordinate cadmium atoms, with several oxygen atoms in the coordination sphere of both Cd(II) centres in complex **1**, while a lower coordination number and the absence of oxygen atoms is suggested for complex **2** [11,13]. The ^{113}Cd NMR spectrum of **1** in methanol only exhibits one signal at 167.3 ppm, which is almost the average between the solid state signals, indicating partial substitution of the nitrato ligands and/or the water molecule by solvent molecules, giving the same coordination sphere. The ^{113}Cd NMR spectrum of complex **2** in DCM shows the signal has been slightly displaced to 410 ppm, which indicates that the coordination sphere remains in this solvent and it is in the range expected for S_3N_2 coordination.

3.3. Crystal structure of $[Cd(LMe_2H_4)(NO_3)_2][Cd(LMe_2H_4)(NO_3)(H_2O)]NO_3 \cdot H_2O$ (**1**)

The X-ray structural analysis of complex **1** revealed the presence of two units, each containing one cadmium atom and one li-

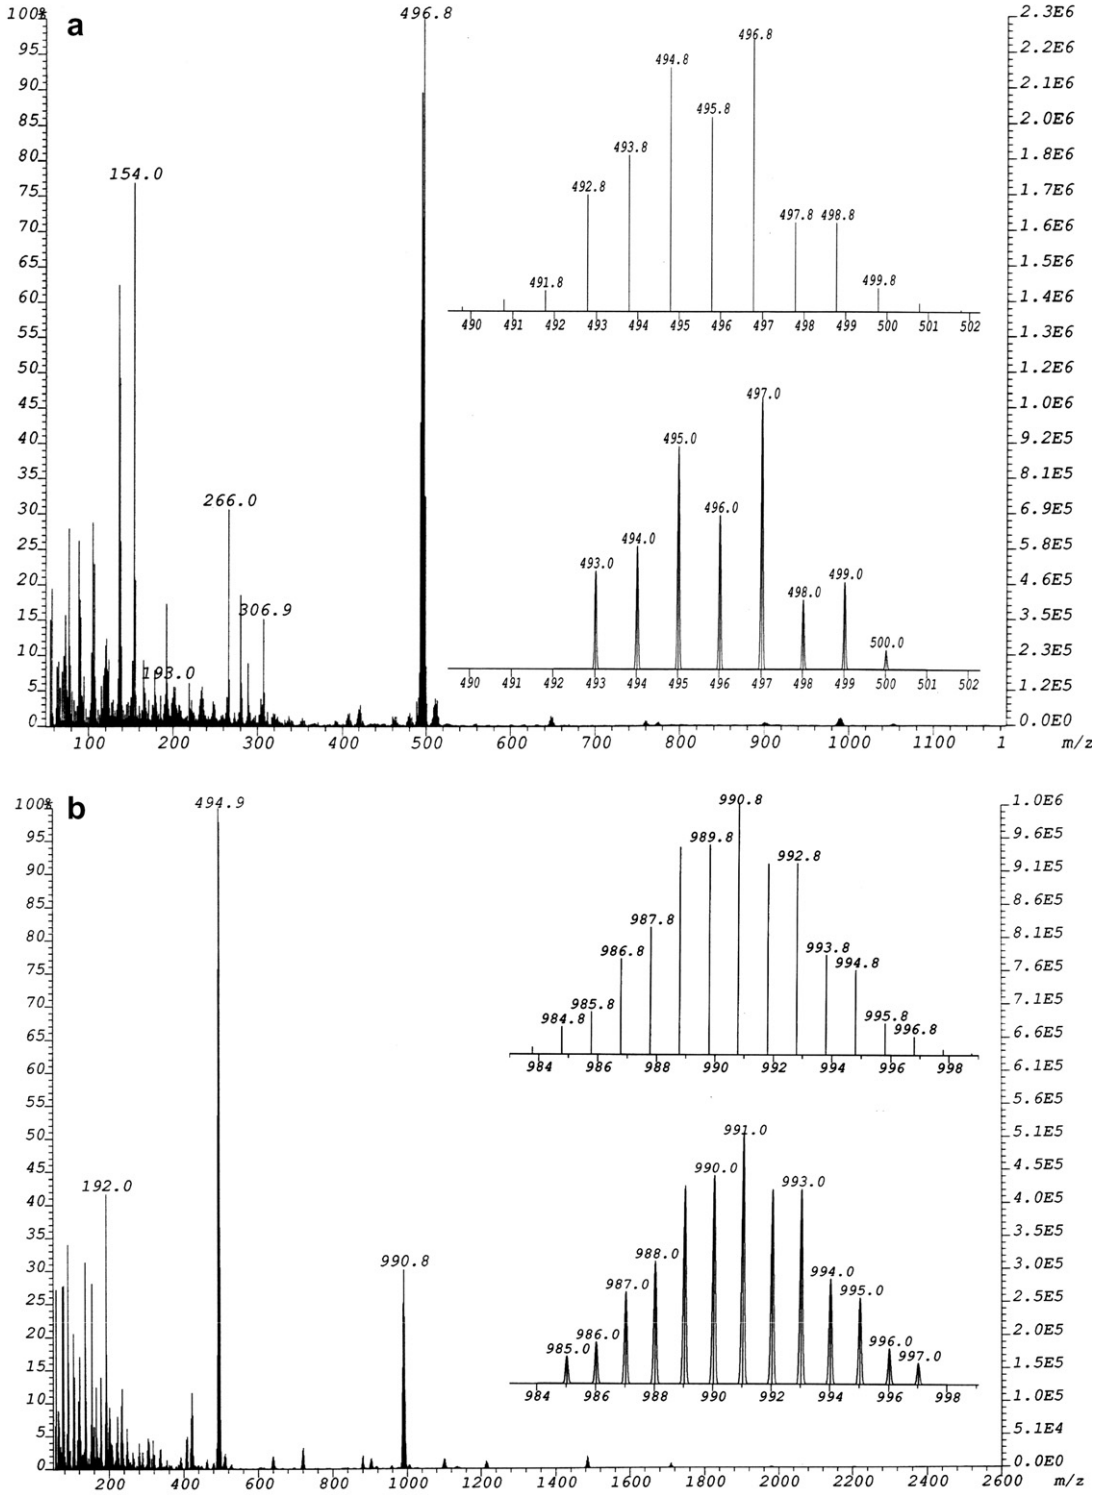

Fig. 1. (a) FAB mass spectrum of complex **1** (theoretical and experimental isotope distribution in the inset); (b) FAB mass spectrum of complex **2** (theoretical and experimental isotope distribution in the inset).

gand, with one nitrate group and a water molecule linking them (Fig. 2). The two Cd(II) ions have different coordination environments with the ligand acting, as it could be expected for this compound, as a N_2S_2 chelate and where the coordination spheres are completed by oxygen atoms. The $N_2S_2O_3$ coordination environment of the seven-coordinate Cd(1) (Fig. 3) is made up of the imine nitrogen and the sulfur atoms of the two arms of LMe_2H_4, one oxygen from a water molecule and two oxygens from a bidentate nitrato anion. The environment of the eight-coordinate Cd(2) is similar (Fig. 4), the difference being that the water molecule has been substituted by another nitrato ligand coordinated in a bidentate fashion.

The hepta-coordinate cadmium has a geometry based on a capped distorted octahedron, with the water molecule and the nit-

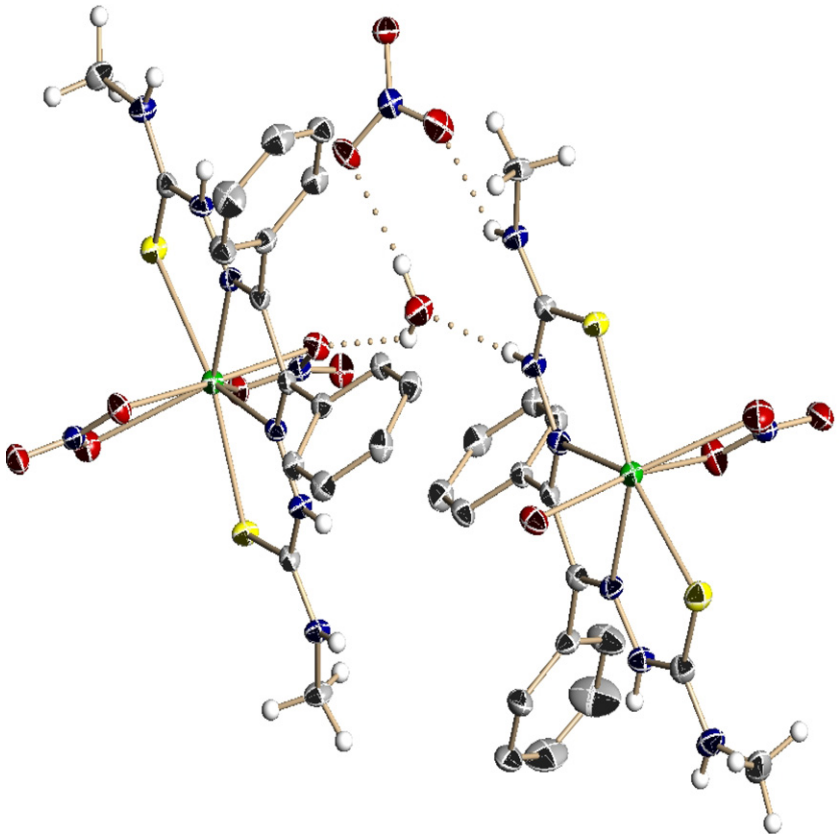

Fig. 2. The crystal structure of **1** at 50% probability including the intermolecular hydrogen bonds.

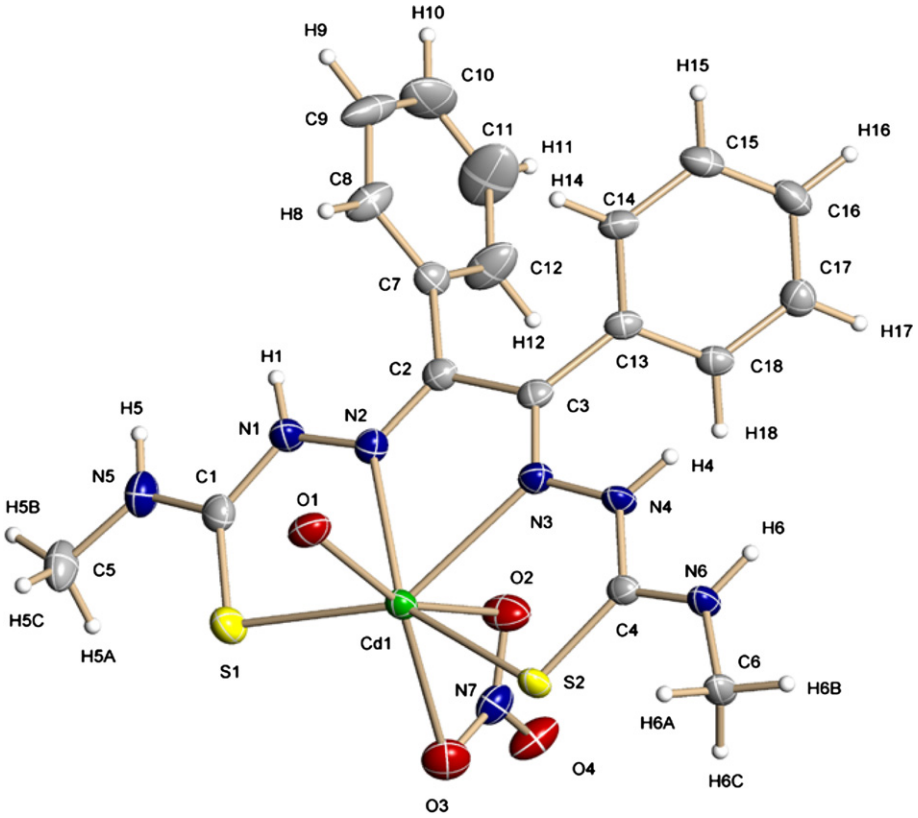

Fig. 3. The molecular structure of the complex cation in **1** with ellipsoids at 50%.

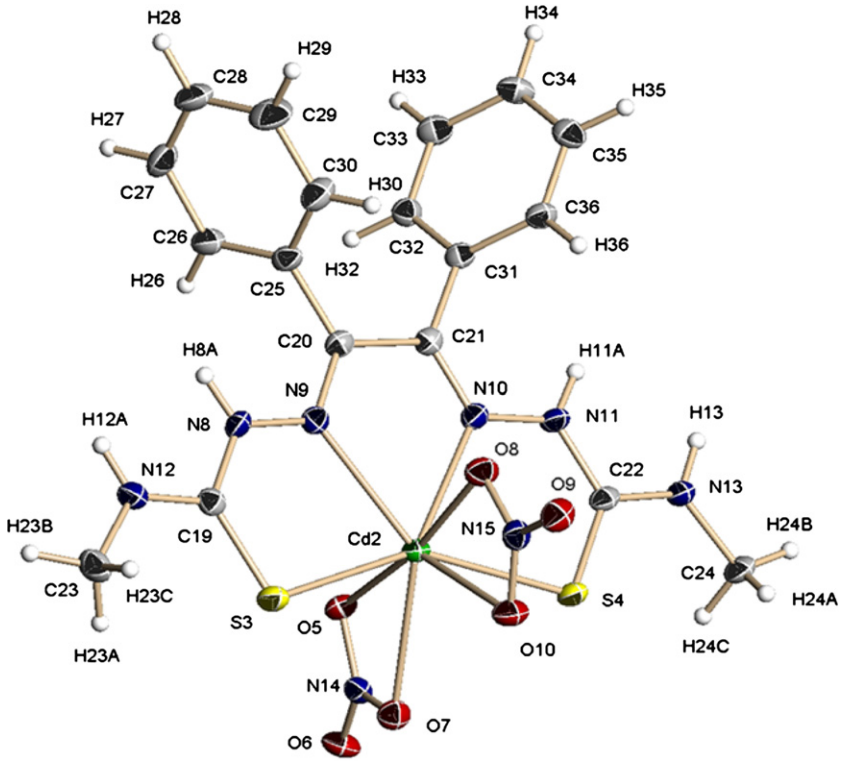

Fig. 4. The molecular structure of the neutral unit in **1** with ellipsoids at 50%.

rato group located above and under the tetradentate ligand, which is virtually planar (Fig. 3). The angle of 173.35° formed by the N atom of the bidentate nitrato group, the Cd atom and the water molecule is very close to that expected for a *trans* disposition. The Cd(1)–OH_2 bond length [2.320(3) Å] (see Table 2) is in the range observed in other Cd(II) complexes that contain nitrato ions and water molecules in their coordination sphere [20]. The Cd–O distances from the bidentate nitrato group, at 2.484(3) and 2.647(3) Å, fall within the range observed for Cd(II) compounds containing bidentate nitrato ligands and show a significant asymmetry $\delta = 0.16$ Å, which is of the same order as those observed in other cadmium complexes [14].

Cd(2) is eight-coordinate, with two nitrogen and two sulfur atoms from the benzil bis(thiosemicarbazone) ligand and four oxygen atoms from two bidentate nitrato ions (Fig. 4), which is not a common coordination number for Cd(II). The arrangement of the eight atoms around the Cd(II) centre corresponds to a distorted dodecahedron, with the angle between the N_2S_2Cd and O_4Cd planes very close to 90°. The Cd–O distances show two asymmetrically bidentate nitrato ligands with short Cd–O distances of 2.425(3) and 2.393(3) Å, and longer ones of 2.598(3) and 2.698(3) Å [33,34].

The presence of two distances for Cd–N and Cd–S bonds in each unit agrees with the distorted geometry. The Cd–N distances are not identical in both units, but they are in the range expected for a cadmium imine bond. The average bond lengths of Cd–S bonds in the seven and eight-coordinate structures are 2.583 and 2.609 Å, respectively, the difference of which arises from the increase in coordination number of the cadmium(II) ion in this complex. Similar variations are observed for the Cd–N distances.

The pseudomacrocyclic coordination mode of the ligand affords three five-member chelate rings. The bis(thiosemicarbazone) cores can be considered planar with a maximum deviation from the

main plane of 0.0760 Å for C(3) in the seven-coordinate unit and a 0.0616 Å deviation for the N(9) atom in the eight-coordinate one. In accordance with the symmetry of the ligand, the bond distances and angles in both thiosemicarbazone moieties in both units are very similar. The bond lengths agree well with an imine–thione form of the ligand, but with considerable electronic delocalisation through the thiosemicarbazone backbone. Thus, the thione bond distances of ca. 1.69 Å are intermediate between a theoretical C–S single and double bond (1.82 and 1.56 Å, respectively) as occurs with the N–N– bonds (ca. 1.35 vs. 1.44 Å calculated for a single N–N) and the three C–N bonds of each 4-methyl-3-thiosemicarbazone branch.

The two units are connected through hydrogen bonds involving the amino groups, the non-coordinated nitrate ion and the crystallization water molecule (Fig. 2). Finally, the molecules are held together in the crystal packing through an extended network of intermolecular hydrogen bonds involving the same groups (see Table 3).

4. Conclusions

The importance of the working conditions in the structure of coordination complexes from a bis(thiosemicarbazone) is reflected in the complexes obtained by the reaction of cadmium nitrate and benzil bis(4-methyl-3-thiosemicarbazone). Complex **1** is obtained in methanol and it contains two different types of Cd(II) ions. The Cd(1) atom is seven-coordinate by two nitrogen and two sulfur atoms from the ligand and three oxygens from a bidentate nitrato ligand and one water molecule, but the Cd(2) coordination sphere expands to eight by the exchange of the water molecule by an additional bidentate nitrato group. Both units are linked to a nitrate ion and a water molecule by hydrogen bonds. Complex **2** is synthesised in the presence of lithium hydroxide, so the ligand is doubly deprotonated and the cadmium(II) atom could be pentacoordinate in a binuclear structure. To the best of our knowledge, complex **1** is the first thiosemicarbazone complex containing eight-coordinate Cd(II). Moreover, it also is the first example in which two cadmium ions show seven and eight coordination in two independent units within the same crystal.

ABSTRACT

X-ray crystallographic studies have shown that the free base β-tetra-brominated *meso*-tetraphenylporphyrin (H_2TPPBr_4) has a slightly ruffled structure with the dihedral angles of 70.1–79.2° between the phenyl groups and the porphyrin mean plane. The N(pyrrole)–N(pyrrolenine) distance is very similar to that of the standard planar porphyrins. The decreased N–H bond length of H_2TPPBr_4 with respect to that of *meso*-tetraphenylporphyrin (H_2TPP) seems to be due to the weaker intramolecular hydrogen bond of the former relative to the latter caused by the electron-withdrawing effects of the β-bromine substituents. The large red shifts of the Soret and Q(0,0) bands of H_2TPPBr_4 in comparison with those of H_2TPP, in spite of the nearly planar porphyrin core of the compound, also may be explained on the basis of the electron-withdrawing effects of the bromine atoms. Oxidation of styrene, the *para*-substituted derivatives and cyclooctene with tetrabutylammonium oxone in the presence of catalytic amounts of β-tetra-brominated *meso*-tetraphenylporphyrinatomanganese(III) acetate immediately gives the epoxide as the sole product. Terminal double bonds and unconjugated ones are less reactive than the conjugated double bonds and show lower selectivities. Catalytic activity of the electron-deficient Mn(H_2TPPBr_4)OAc dramatically depends on the Co-catalytic activity of the nitrogen donors as the axial base. The best axial bases are the nitrogenous donors with mixed σ- and π-donor ability to the metal centre.

1. Introduction

Synthetic metalloporphyrins of Fe(III), Mn(III), Cr(III), and Ru(II), (III), (VI), especially with porphyrins bearing aryl-groups at *meso*-positions, have been used in a variety of oxidation reactions, with the intention of developing biomimetic catalysts which show regio-, stereo-, shape-, and enantioselectivity with a high efficiency under mild conditions. Iron and manganese porphyrins are the most often used metalloporphyrins in the oxidation reactions, and the catalytic activity of chromium porphyrins is much inferior to those of iron-, manganese-, and ruthenium porphyrins. Metalloporphyrins are effective catalysts for the selective oxidation of hydrocarbons and other organic compounds under mild conditions. As a consequence considerable effort has been devoted to investigating the effects of variables, such as the composition of the porphyrin, the oxidant, the solvent, and the substrate [1–7].

Metalloporphyrin halogenated on the periphery of the porphyrin ring or containing halogenated substituents attached to the porphyrin ring have been shown to be particularly efficient for both epoxidation and hydroxylation reactions [6–14]. Such porphyrins are also more resistant to degradation via free-radical attack than those containing electron-donating substituents [1].

The origin of the red shifts seen in the optical spectra of non-planar porphyrins has recently generated considerable debate in the literature [15]. The introduction of four bromine atoms at the β-positions of *meso*-tetraphenylporphyrin (H_2TPP) is accompanied by electronic and structural changes in the porphyrin core.

In the present work, the conformational changes of porphyrin core upon the substitution of four bromine atoms at β-positions of H_2TPP and the shift of the Soret and Q-bands of the porphyrin have been studied. The efficacy of β-tetra-brominated *meso*-tetraphenylporphyrinatomanganese(III) acetate, Mn($TPPBr_4$)OAc in the epoxidation of olefins with tetrabutylammonium oxone (TBAO) is reported.

2. Experimental

2.1. Instruments and reagents

^{1}H and ^{13}C NMR spectra were obtained in $CDCl_3$ solutions with a Bruker FT-NMR 250 (250 MHz) spectrophotometer. The residual $CHCl_3$ in conventional 99.8 at.% $CDCl_3$ gives a signal at $\delta = 7.26$ ppm, which was used for calibration of the chemical shift scale. A double beam spectrophotometer (Shimadzu, UV-240) was used for the UV–Vis absorption determination. The reaction products of oxidation were determined and analyzed by HP Agilent 6890 gas chromatograph equipped with a HP-5 capillary column (phenyl methyl siloxane 30 m × 320 μm × 0.25 μm) and flame-ionization detector.

The free base tetraphenylporphyrin was prepared and purified as reported previously [16]. Nitrogenous bases were purchased from Merck or Fluka. BzImH was recrystallized before use. n-Bu_4NHSO_5 was prepared as reported previously [17].

2.2. Bromination of H_2TPP

H_2TPPBr_4 (Fig. 1) was prepared according to the literature [18]. H_2TPP[1] (300 mg, 0.49 mmol) was dissolved in $CHCl_3$ (80 ml). To this solution, freshly recrystallised NBS (360 mg, 1.96 mmol) was added (recrystallised from hot water and dried at 80 °C under vacuum). The reaction mixture was stirred for 24 h and then $CHCl_3$ was evaporated to dryness. The residue was washed with methanol (2 × 20 ml) to remove any soluble succinimide impurities. The product, H_2TPPBr_4 was recrystallised from $CHCl_3$/n-hexane (3:1, v/v) and dried under vacuum. UV–Vis (CH_2Cl_2): λ_{max} (nm): 434.5, 533, 683. ^{1}H NMR ($CDCl_3$, 250 MHz): δ (ppm) 8.69 (s, 4H, β pyrrole), 8.16–8.19 (m, 8, o-phenyl), 7.7–7.9 (m, 12, m- and p- phenyl).

2.3. Metalation of H_2TPPBr_4

$Mn(TPPBr_4)OAc$ was prepared and purified according to the previously reported method [19]. H_2TPPBr_4 (110 mg, 0.13 mmol) was dissolved in minimum amount of methanol and then 30 ml chloroform was added. $Mn(OAc)_2 \cdot 4H_2O$ (250 mg, 1.04 mmol) was added to the reaction mixture and refluxed for a period of 2 h. UV–Vis (CH_2Cl_2): λ_{max} (nm): 379.5, 483.5, 590.

2.4. General oxidation procedure

Stock solution of the catalyst (0.003 M) and nitrogenous bases (0.5 M) (except BzImH (0.0625 M)) were prepared in CH_2Cl_2. In a 10 ml round-bottom flask the reagents were added in the following order: alkene (0.25 mmol), catalyst (0.003 mmol, 1.0 ml), nitrogenous bases (0.03 mmol, 60 μl). Tetrabutylammonium oxone (0.5 mmol, 0.206 g) was then added to the reaction solutions at 25 °C. The mixture was stirred thoroughly for 2 min at ambient temperature. Formation of epoxide was detected by GC analysis.

2.5. X-ray crystallography

The dark brown 0.26 × 0.16 × 0.05 mm single crystal was used in the diffraction experiment. The structural analysis revealed multiple bromination sites of the porphyrin system. Two of these sites occur in the same pyrrole ring at C7 and C8. They were refined as fully occupied (Br2 and Br3) although their relatively high atomic displacement parameters suggest the occupancy slightly lower than 100%. The third site at C2 (Br1) appeared in the second pyrrole ring on the final electron density maps. The occupancy of 10% was assumed, based on the observed height of the electron density peak. That reflects the statistical disorder accounting for bromination of one out of ten molecules at Br1 position. Consequently, the statistical level of the ring bromination is 4.2 per a porphyrin ring. For the Br1 bromination site, the presence of hydrogen atom with 90% occupancy was assumed to complete the model of the structure.

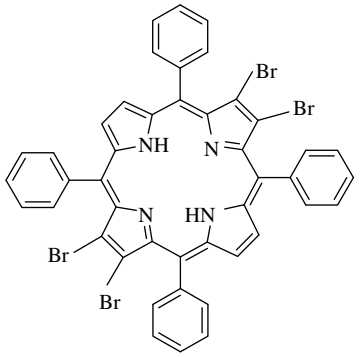

Fig. 1. H_2TPPBr_4.

The X-ray data were collected with an Oxford Sapphire CCD diffractometer using Mo Kα radiation $\lambda = 0.71073$ Å, at 293(2) K, by ω–2θ method. The space group $P2(1)/n$ was determined based on the systematic absences. The numerical absorption correction was applied [20] with the maximum and minimum transmissions of 0.8167 and 0.3711. The structure was solved by direct methods and refined with the full-matrix least-squares method on F^2 with the use of SHELX-97 program package [21]. Positions of hydrogen atoms bound to carbon were calculated from geometry, while the position of hydrogen atom bound to nitrogen was determined from the electron density map.

The data collection and refinement processes are summarized in Table 1.

3. Results and discussion

The similar crystal structure of H_2TPPBr_4 has been reported by Zou et al. [22], but revealed different cell parameters, although the same space group symmetry was reported. The differences might be attributed to the different crystallization conditions. Crystals of H_2TPPBr_4 reported here have been obtained from the $CHCl_3$/n-hexane (3:1, v/v) solution, while Zou et al. [22] obtained crystals by layering a solution of H_2TPPBr_4 in $CHC1_3$ with petroleum/piperidine (333–363 K). Also, the structure of H_2tppBr_4 reported here has an additional bromination site with 10% occupancy at C2 position.

3.1. Conformational studies

X-ray crystallographic studies show that the porphyrin ring system is slightly folded (Fig. 2), with the dihedral angles between the N1–N2–N1 [$-x+1$, $-y+1$, $-z$]–N2[$-x+1$, $-y+1$, $-z$] best plane and the pyrrole ring planes being 10.0(8)° and 3.4(8)° for N1–C1–C2–C3–C4 and N2–C6–C7–C9–C9 rings, respectively. The porphyrin system is slightly more ruffled than that reported previously [22], with the dihedral angle between two pyrrole rings of 7.5(9)°, larger than the corresponding angle of 4.8(5)° in the other structure. That might be caused by the partially occupied bromination site at Cβ (C2 position). Small change in the porphyrin geometry results in the similar N1···N1[$-x+1$, $-y+1$, $-z$] and N2···N2[$-x$;+1, $-y+1$, $-z$] distances across the ring system 4.142 (18) and 4.157

[1] According to the comment, the sentence "H_2TPPBr_4 (Fig. 1) was prepared according to the method reported by Bhyrappa et al. [18]" has been changed to "H_2TPPBr_4 (Fig. 1) was prepared according to the literature [18]". If you mean that the procedure following the above sentence should be omitted, please feel free to do that.

Table 1
Crystal data and structure refinement for H_2TPPBr_4

Compound	H_2TPPBr_4
Formula	$C_{44}H_{25.90}Br_{4.10}N_4$
Formula weight	938.22

[a] $R_1 = \sum||F_0| - |F_c||/\sum|F_0|$.
[b] $wR_2 = [\sum w(F_0^2 - F_c^2)^2/\sum(w|F_0|^2)^2]^{1/2}$.

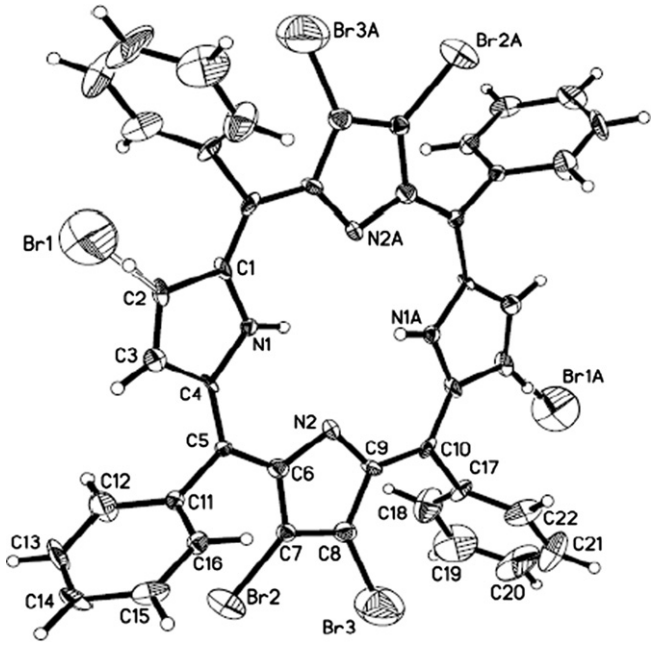

Fig. 2. View of the molecular structure of H_2TPPBr_4 in the crystal.

(18) Å, respectively. The corresponding distances in the more flat structure [22] are 4.21(2) and 4.10(2) Å. The phenyl rings are tilted relative to the pyrrole rings. The dihedral angles between C11–C16 phenyl and N1–C4 and N2–C9 pyrroles being 79.2(4)° and 76.5(4)°, respectively, while for C17–C22 phenyl the corresponding values are 76.4(5)° and 70.1(5)°. In a ruffled conformation the *meso* carbons are alternately above and below the porphyrin mean plane while the core nitrogens are in the plane. Furthermore, all of the atoms along a given edge of the porphyrin macrocycle (C_β–C_α–C_{meso}–C_α–C_β) will be on the same side of the porphyrin mean plane. The transition from edge to edge is accompanied with a transition of the atom positions from one side of the porphyrin mean plane to the other. A point of comparison to be made here is that in the ruffled conformation β carbons of the same pyrrolic subunit will be on opposite sides of the porphyrin mean plane while in the saddled conformation β carbons of the same pyrrolic subunit will be on the same side of the porphyrin mean plane. When the porphyrin is substituted with bulky substitutents on adjacent β and *meso* carbons there is an additional steric strain between those substituents. It has been shown that the bulkier the nature of the substituents, the more non-planar the porphyrin macrocycle will be. It seems that in the case of H_2TPPBr_4, partial ruffling of porphyrin core as well as the decreased co-planarity of phenyl substituents with the porphyrin mean plane would provide relief of steric strain. Angles of 60–85° between the phenyl and porphyrin mean planes were found in solids, and angles of about 40° has been calculated by Wolberg for H_2TPP in solution [23]. The dihedral angle between the phenyl substituents and porphyrin mean plane in H_2TPP and $H_2TPPBr_4$are 60–85° and 70.1–79.2°, respectively.

The N–H bond of H_2TPPBr_4 is shorter than that of H_2TPP [24,25] (Table 2) which may be explained on the basis of the weaker N–H–N hydrogen bond of former relative to that of the latter. The length of NH bond of free base porphyrins is very sensitive to the N–H–N hydrogen bond strength [26]. It has been shown that intramolecular hydrogen bonding in porphyrins can be strongly enhanced by a specific type of non-planar distortion (ruffling) of porphyrin core. Although, the bromination of porphyrin core leads to an increase in the polarity of N–H bond, but it decreases the electron densities at the pyrrolenine nitrogen atoms. Therefore, the N–H–N intramolecular hydrogen bond of electron-deficient porphyrins is expected to be weaker than that of electron rich ones [27]. However, the slight ruffling of porphyrin core of H_2TPPBr_4 seems to have little or no effect on the strength of hydrogen bond; the average N(pyrrole)–N(pyrrolenine) distance (Table 2) of H_2TPPBr_4 is 2.93 Å which is very similar to that of standard planar porphyrins and H_2TPP [26].

3.2. UV–Vis spectra of H_2TPPBr_4

UV–Vis spectra of H_2TPPBr_4 is given in Table 3. The Soret and Q-bands of H_2TPPBr_4 are red shifted with respect to that of H_2TPP (Table 2). Large shifts of the Soret and Q(0,0) bands of porphyrin

Table 2
Average bond lengths (in Å) and bond angles for H_2TPPBr_4 and H_2TPP determined by the X-ray crystallographic analysis

Table 3
The Soret and Q(0,0) bands of H_2TPPBr_4 in comparison with the bands of H_2TPP

Porphyrin	Soret band λ (nm)	Q(0,0) band λ (nm)
H_2TPP	416	649
H_2TPPBr_4	438	685
$\Delta\nu$ (cm^{-1})[a]	1207.4	809.8

[a] $\Delta\nu = 10^7(1/\lambda_1 - 1/\lambda_2)$.

have been usually attributed to the out-of-plane deformations of the macrocycle and/or the enhanced co-planarity of phenyl groups with the porphyrin mean plane and/or the inductive effects of substituents at *meso* and β-positions [15,28–30]. Due to the slight folding of porphyrin core of H_2TPPBr_4 and the dihedral angles of 70-79 degrees between the phenyl substituents and the mean plane, the large red shifts of the bands of H_2TPPBr_4 relative to those of H_2TPP seems to be due to the electron-withdrawing effects of four bromine atoms. The a_{2u} to the e_g transition is responsible for the Q(0,0) band. The a_{2u} electron densities are largest on the methane carbons and pyrrole nitrogens [31,32]. Accordingly, the substitution of for bromine atoms at β-positions seems to have little or no effect on the energy level of this orbital. But the e_g electron densities are largest on the β, *meso* and α positions. Thus, the energy level of the e_g orbitals may be influenced by the electron-withdrawing effects of the bromine atoms. It is proposed that the observed red shift of the Q(0,0) band of H_2TPPBr_4 relative to the band of H_2TPP is due to the stabilization of the eg orbitals, resulted in by the inductive effects of the bromine substituents, rather than the destabilization of the a_{2u} one. the Soret band is due to the a_{1u} to e_g transition. For the a_{1u} orbitals the electron densities are largest on the pyrrole carbon atoms and the methane bridges lie on nodal planes [31,32]. Therefore, the energy level of the a_{1u} orbital may also be influenced by the electronic effects of the bromine atoms. However, the red shift of the Soret band which is larger than that of the Q(0,0) band (Table 3), may be attributed to the decreased a_{1u}–e_g gaps, resulted in by the stabilization of the e_g orbitals and the destabilization of the a_{1u} orbital.

3.3. Catalytic alkene epoxidation by $MnTPPBr_4(OAC)/Im/n\text{-}Bu_4HSO_5$ system

Oxidation of cyclooctene with TBAO in the presence of catalytic amounts of $MnTPPBr_4(OAc)$ leads to cyclooctene oxide as the sole product (Table 4). Styrene, α-methylstyrene and *para*-substituted styrenes are 100% converted within 2 min with 100% selectivity for epoxide products except for α-methylstyrene which gives 25% acetophenone as the by-product. Electron-donating (entries 3 and 4) as well as electron-deficient substituents (entry 2) on the *para* position of the aryl ring of styrene were compatible with the reaction conditions, and gave the corresponding epoxide. With the exception of cyclooctene, terminal double bonds and unconjugated ones (Table 4, entries 7, 9 and 10) are less reactive than the conjugated double bonds and show lower selectivities. Much reactivity and high selectivity observed in the case of conjugated double bonds in comparison with terminal double bonds and unconjugated ones seems to be due to the π-electron donation effects of aryl-groups to the double bond. The double bond may be cosidered as a nucleophile in the oxidation reaction.

Epoxidation of terminal alkene (oct-1-ene) and norbornene proceedes in moderate yield (51% and 24%, respectively). Alkenes with potential π-donor aryl substituents (entries 1–5), were generally more reactive than cyclohexene, cyclooctene, and 1-octene (entyies 6–8).

It has been observed that $MnTPPBr_4(OAc)$ (95% yield of epoxide) is more efficient than MnTPP(OAc) (80% yield of epoxide) in the epoxidation of cyclooctene with TBAO. This observation may be due to the enhanced electrophilic character of the possible high valent manganese oxo [33] of [$MnTPPBr_4$] with respect to that of [MnTPP] and the stability of $MnTPPBr_4$ relative to MnTPP against the degradation with oxidant.

Table 4
Epoxidation of alkenes with $n\text{-}Bu_4HSO_5$ catalyzed by $MntppBr_4(OAC)$ in the presence of Im[a]

Entry	Alkene	Conversion %	Epoxide	Selectivity %
1		100		100
2		100		100
3		100		100
4		100		100
5		100		75[b]
6		95		100
7		92		83
8		97		100
9		51		35
10		24		100

[a] The molar ratio for alkene:oxidant:Im:catalyst is 167:83:10:1.
[b] Acetophenone is the by-product.

3.4. Axial base effects

The results of epoxidation of cyclooctene by $n\text{-}Bu_4NHSO_5$ in the presence of different nitrogen donors as co-catalysts, under similar conditions, are given in Table 5. Although, the co-catalytic activity of the stronger donor bases is greater than that of others, but there is no correlation between the co-catalytic activity of the nitrogenous donors and the pK_a of the corresponding BH^+. The basicity of nitrogenous donors is defined relative to a bare or solvated pure σ-acceptor, i.e. proton, while the co-catalytic activity is defined on the basis of σ- or/and π- donation to a metal centre. Consequently, factors such as the steric hindrance around the metal centre and the extent of π-interaction between the axial base and the metal centre should also be considered.

Table 5
Co-catalytic activity for different nitrogen donors[a]

Entry	Nitrogen donor	pK_a (BH^+)	$MnTPPBr_4$
1	piperidine	11.123	57
2	Et_2NH	11.02	55
3	Et_3N	10.75	53
4	ImH	6.953	95
5	1-MeImH	7.86	87
6	BzImH	5.532	93
7	Py	5.25	81
8	2-MePy	5.97	43
9	3-MePy	5.52	86
10	4-MePy	6.02	90
11	3-CNPy	1.78	26
12	4-CNPy	1.86	17
13	none		9

[a] The molar ratio for alkene:oxidant:nitrogen donor:catalyst is 167:83:10:1.

The best co-catalytic activity has been observed in the case of imidazole that is the smallest axial base among the nitrogenous donors of the Table 5. While, the introduction of π-electron-withdrawing substituents at different positions of pyridine (entries 11 and 12) dramatically decreases the activity of pyridine as a nitrogen donor, substitution of methyl at 4-position of pyridine leads to only a 10 percents increase in the yield of the epoxidation of cyclooctene. It seems that the activity of nitrogen donors is strongly depends on the π-donor ability of axial base. In accordance with the explanation, co-activity of benzimidazole (entry 6) is almost equal to that of imidazole (entry 4), although the size of the former is much larger than that of the latter. It is also observed that simple amines (entries 1, 2, 3) which may be considered as pure σ-donors, are less effective than those with both σ- and π-donor abilities.

3.5. The effect of co-catalyst/catalyst ratio

The interaction of catalyst with nitrogen donors (D) can lead to the formation of both catalytically active 1:1 $DMnTPPBr_4$ and catalytically inactive 2:1 $D_2MnTPPBr_4$. Co-catalytic activity of imidazole as a function of different co-catalyst/catalyst ratio are presented in Fig. 3. An increase in Im/Mn-porphyrin molar ratio up to 10 remarkably improved the rate of conversion of cyclooctene epoxidation. However, its co-catalytic activity decreased at co-catalyst/catalyst ratio $\lesssim 50$.

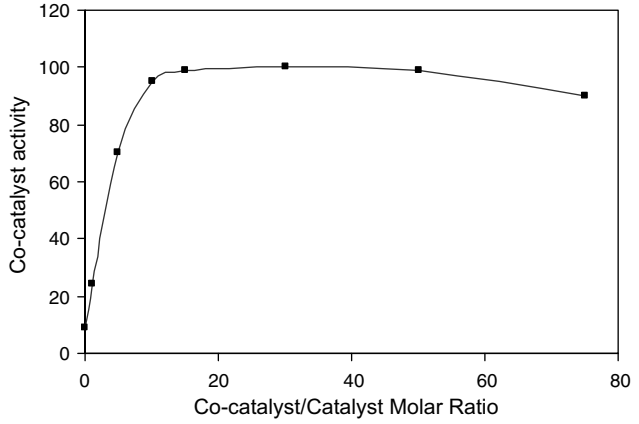

Fig. 3. Co-catalyst activity of imidazole as a function of different co-catalyst/catalyst ratio.

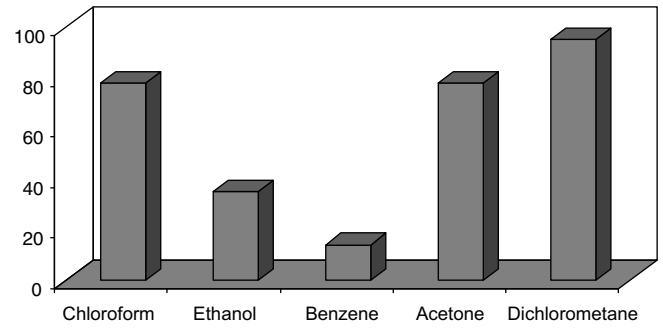

Fig. 4. Effect of the type of solvent on the conversion of cyclooctene to cyclooctene oxide at room temperature.

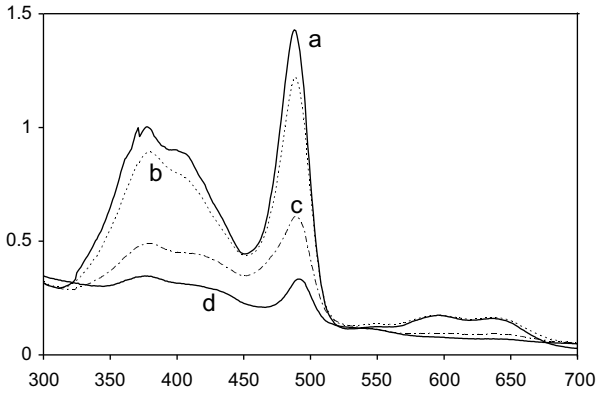

Fig. 5. UV–Vis spectra of a solution of $Mn(TPPBr_4)OAc$ in CH_2Cl_2 (a), in the presence of imidazole (b), in the presence of imidazole/TBAO and cyclooctene (c) and in the presence of imidazole/TBAO (d), at room temperature after 1 min.

3.6. Solvent effect in the epoxidation reactions with n-Bu_4HSO_5

The influence of the solvent nature in the catalytic epoxidation of cyclooctene by $MnTPPBr_4$/Im/n-Bu_4HSO_5 system, were examined. Inspection of results in Fig. 4 shows that CH_2Cl_2 is the best solvent because of high solubility of all starting materials.

3.7. Stability of the catalyst against the degradation with oxidant

It has been shown that catalyst stability is a major factor contributing to apparent catalyst ability [34]. It is observed that destruction of metalloporphyrin in the absence of olefin is faster than the time that cyclooctene was used (Fig. 5).

4. Conclusions

In spite of the nearly planar structure of H_2TPPBr_4, the Soret and Q(0,0) bands of the β-brominated porphyrin are red shifted with respect to those of H_2TPP which is probably due to the electron-withdrawing effects of four bromine atoms. $Mn(TPPBr_4)OAc$/TBAO/Imidazole is an efficient catalytic system for the selective epoxidation of conjugated double bonds. The enhanced stability of $Mn(TPPBr_4)OAc$ relative to Mn(TPP)OAc against degradation with the oxidant and higher yields of epoxide make this electron-deficient Mn-porphyrin more efficient than Mn(TPP)OAc in the epoxidation of olefins.

ABSTRACT

Hydrothermal synthesis has afforded three nickel coordination polymers incorporating both aromatic dicarboxylates and the kinked and hydrogen bonding capable organodiimine 4,4′-dipyridylamine (dpa). These were characterized by single-crystal X-ray diffraction, infrared spectroscopy, and thermogravimetric analysis. $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ (1,2-phda = 1,2-phenylenediacetate, **1**) displays (4,4) rhomboid grid-like 2D layers that aggregate into 3D through O–H···O hydrogen bonding. Shortening one of the pendant arms of the dicarboxylate ligand resulted in a shift to (6,3) herringbone style 2D coordination layer motifs in $\{[Ni(hmph)(dpa)] \cdot 1.33H_2O\}_n$ (hmph = homophthalate, **2**), which stack in an AA′B pattern. $[Ni(1,3\text{-phda})(dpa)(\mu\text{-}H_2O)_{0.5}]_n$ (1,3-phda = 1,3-phenylenediacetate, **3**) manifests a canted primitive cubic type coordination polymer lattice constructed from dinuclear $\{Ni_2(\mu\text{-}H_2O)\}$ kernels linked into 3D through tethering 1,3-phda and dpa ligands. Analysis of the variable temperature magnetic susceptibility of **3** indicated the presence of antiferromagnetic superexchange within its dinuclear units ($g = 2.290(2)$, $J = -4.21(2)\ cm^{-1}$).

1. Introduction

Coordination polymer solids generated from divalent metal ions and dicarboxylate tethering ligands have attracted significant interest not only for their aesthetically appealing structures, but also for their promise in diverse technological applications such as gas storage [1], small molecule shape-selectivity [2], ion-exchange [3], catalysis [4], and optical devices [5]. A wide range of structural patterns occurs in these systems, based on the disposition of the donor groups within the dicarboxylate moieties, coordination geometry preferences of the specific metal ions used, and an array of available binding and bridging modes achievable with these ligands. While the predominant synthetic effort has focused on aromatic dicarboxylate tethers such as isophthalate and terephthalate, aliphatic α,ω-dicarboxylate ligands have also proven useful in the construction of new coordination polymer topologies due to their ability to adopt energetically similar but different conformations [6]. However, coordination polymers constructed from dicarboxylate tethers containing both aromatic rigidity and aliphatic pendant arm flexibility, for example phenylenediacetate isomers, are less common [7].

More recently, several researchers have augmented the structural complexity and functional utility of dicarboxylate-containing inorganic/organic hybrid materials by employing neutral organodiimine co-ligands such as the rigid-rod 4,4′-bipyridine (4,4′-bpy). These dipodal nitrogen bases can link metal cations through their distal pyridyl nitrogen donor atoms, supplementing the covalent connectivity provided by the metal/dicarboxylate backbone to produce structurally interesting solids with promising properties [8–11]. Several members of this dual-ligand class of coordination polymers with d^{10} ions exhibit luminescent properties [9]; one especially intriguing solid, the interpenetrated 3D material $[Zn(terephthalate)(4,4'\text{-bpy})_{0.5}]$, can serve as a stationary phase for the chromatographic separation of linear and branched alkanes [11]. The conformational flexibility of α,ω-dicarboxylate ligands can also facilitate reversible crystal-to-crystal structural reorganizations upon removal/re-addition of guest species within dual-ligand coordination polymers [12].

Recently our group has been investigating the synthesis and characterization of metal/dicarboxylate coordination polymers containing the organodiimine 4,4′-dipyridylamine (dpa) as a neutral co-ligand. Unlike the more commonly employed 4,4′-bpy, dpa has a kinked disposition of its terminal nitrogen donor atoms in addition to hydrogen bonding donating capability at its central amine. We have shown that both covalent and supramolecular interactions provided by the dpa ligand can synergistically act in

doi:10.1016/j.poly.2008.04.038

structure-direction during self-assembly, to produce structural patterns different from those within similar coordination polymers based on 4,4′-bpy [12–15]. For example, $[Ni(adipate)(dpa)(H_2O)]_n$ exhibited the first-ever example of 3-fold interpenetration within the PtS structure type [12], and $\{[Ni(dpa)_2(succinate)_{0.5}]Cl\}_n$ manifested an unprecedented 5-connected self-penetrated network with a "regular" 6^{10} topology [13]. The combination of zinc salts with phenylenediacetate isomers and dpa resulted in luminescent coordination polymers with differing two-dimensional (2D) and three-dimensional (3D) structural morphologies, depending on the position of the pendant acetate arms within the dicarboxylate moieties [14].

Herein we report the successful extension of this previous work into a nickel-based system, with the synthesis and structural characterization of three new coordination polymers with differing morphologies, constructed from both dpa and aromatic dicarboxylates with one or more flexible pendant arms: $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ (**1**; 1,2-phda = 1,2-phenylenediacetate), $\{[Ni(hmph)(dpa)] \cdot 1.33H_2O\}_n$ (**2**; hmph = homophthalate), and $[Ni(1,3\text{-phda})(dpa)(\mu\text{-}H_2O)_{0.5}]_n$ (**3**; 1,3-phda = 1,3-phenylenediacetate). Thermal properties of these new coordination polymers are also reported herein, along with a variable temperature magnetic susceptibility study for **3**.

2. Experimental

2.1. General considerations

$NiCl_2 \cdot 6H_2O$ (Fisher) and all dicarboxylic acids (Aldrich) were obtained commercially. The organodiimine 4,4′-dipyridylamine (dpa) was prepared via a published procedure [15]. Water was deionized above 3 MΩ in-house. Thermogravimetric analysis was performed on a TA Instruments TGA 2050 Thermogravimetric Analyzer with a heating rate of 10 °C/min up to 900 °C. Elemental Analysis was carried out using a Perkin Elmer 2400 Series II CHNS/O Analyzer. IR spectra were recorded on powdered samples on a Perkin Elmer Spectrum One instrument. Powder X-ray diffraction patterns were obtained via θ–2θ scans performed on a Rigaku Rotaflex instrument. Variable temperature magnetic susceptibility data (2–300 K) were collected on a Quantum Design MPMS SQUID magnetometer at an applied field of 0.1 T. After each temperature change the sample was kept at the new temperature for 5 min before magnetization measurement to ensure thermal equilibrium. The susceptibility data were corrected for diamagnetism using Pascal's constants.

2.2. Preparation of $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ (**1**)

$NiCl_2 \cdot 6H_2O$ (0.088 g, 0.37 mmol), dpa (0.127 g, 0.74 mmol) and 1,2-phenylenediacetic acid (0.072 g, 0.37 mmol) were added to 10 mL of distilled H_2O in a 23 mL Teflon-lined Parr acid digestion bomb. The bomb was sealed, heated to 120 °C for 48 h, and then gradually cooled to ambient temperature. Green blocks of **1** (0.050 g, 31% yield based on Ni) were obtained after filtration, washing with distilled water and acetone, and drying in air. Crystals of **1** were stable indefinitely in air. *Anal.* Calc. for $C_{20}H_{19}N_3NiO_5$**1**: C, 54.59; H, 4.35; N, 9.55. Found: C, 53.99; H, 4.46; N, 9.54%. 2.3. Preparation of $\{[Ni(hmph)(dpa)] \cdot 1.33H_2O\}_n$ (**2**)

$NiCl_2 \cdot 2H_2O$ (0.088 g, 0.37 mmol), homophthalic acid (0.067 g, 0.37 mmol), dpa (0.127 g, 0.74 mmol), and 0.25 mL 1.0 M NaOH solution were placed into 10 g (555 mmol) distilled H_2O in a 23 mL Teflon-lined Parr acid digestion bomb (1:1:2: 1500 mol ratio). The bomb was sealed and heated at 120 °C for 48 h, whereupon

3. X-ray crystallography

Single crystals of all materials were subjected to single-crystal X-ray diffraction using a Bruker-AXS SMART 1k (**1**, **3**) or APEX II CCD (**2**) instrument. Reflection data were acquired using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). The data were integrated via SAINT [16]. Lorentz and polarization effect and empirical absorption corrections were applied with SADABS [17]. The structures were solved using direct methods and refined on F^2 using SHELXTL [18]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms bound to carbon atoms were placed in calculated positions and refined isotropically with a riding model. The hydrogen atoms bound to the central nitrogen of the dpa moieties and all aqua ligands were found via Fourier difference maps, restrained at fixed positions, and then refined isotropically with thermal parameters 1.2 times the average U_{ij} values of the atoms to which they are bound. Hydrogen atoms could not be located for the disordered water molecule of crystallization within the structure of **2**. The aromatic rings within the 1,3-phda ligands in **3** exhibited disorder over three sets of positions, which were modeled as a 50:25:25 ratio. Relevant crystallographic data for **1**–**3** are listed in Table 1.

4. Results and discussion

4.1. Synthesis and spectral characterization

The coordination polymers **1**–**3** were prepared cleanly under hydrothermal conditions via combination of nickel chloride, dpa, and the requisite dicarboxylic acid. The infrared spectra of **1**–**3** were consistent with their structures as determined by X-ray diffraction (*vide infra*). Sharp, medium intensity bands in the range of ~1600 cm^{-1} to ~1200 cm^{-1} were ascribed to stretching modes of the pyridyl rings of the dpa moieties [19]. Features corresponding to pyridyl ring puckering mechanisms were evident in the region between 820 cm^{-1} and 600 cm^{-1}. Asymmetric and symmetric C–O stretching modes of the carboxylate moieties were evidenced by very strong, slightly broadened bands at ~1590 cm^{-1} and ~1370 cm^{-1}. Broad bands in the region of ~3400 cm^{-1} to ~3000 cm^{-1} in all cases represent N–H stretching modes within the dpa ligands and O–H stretching modes within ligated or unligated water molecules. The broadness of these latter spectral features is caused by significant hydrogen bonding pathways within **1**–**3**. Phase purity was verified with powder XRD by comparison with powder patterns predicted from the single-crystal structures.

4.2. Structural description of $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ (*1*)

As revealed by single-crystal X-ray diffraction, the asymmetric unit (Fig. 1) of compound **1** contains two crystallographically distinct nickel atoms (Ni1, Ni2), two 1,2-phda dianions (*phda-A*, C21–C30/O1–O4; *phda-B*, C31–C40/O5–O8), two dpa ligands (*dpa-A*, C1–C10/N1–N3; *dpa-B*, C11–C20/N4–N6), and two ligated water molecules (O9, O10). Both crystallographically distinct Ni atoms display a distorted octahedral $[NiO_4N_2]$ coordination geometry, where the two *trans*-disposed nitrogen donor atoms belong to *dpa-A* and *dpa-B* ligands, respectively. The equatorial plane of each coordination octahedron is occupied by two oxygen atoms from a chelating carboxylate terminus of a 1,2-phda ligand, one oxygen atom from a monodentate carboxylate group of a crystallographically distinct 1,2-phda ligand, and an aqua ligand. Bond lengths and angles about the nickel atoms are consistent with the chelation-imposed distorted octahedral coordination geometry (Table 2).

Extension of the structure through the exobidentate chelating/monodentate 1,2-phda ligands results in a one-dimensional (1D) $[Ni(1,2\text{-phda})(H_2O)]_n$ chain motif that propagates along the *a* crystal direction. Within the $[Ni(1,2\text{-phda})(H_2O)]_n$ chain Ni1 and Ni2

Hydrogen atoms and water molecules of crystallization have been omitted for clarity. Atoms labelled with an "A" designation are generated by crystallographic symmetry.

centers are linked through *phda-A* and *phda-B* ligands in an alternating pattern, with Ni···Ni distances toggling between 8.112 Å and 8.976 Å, respectively. The varying Ni···Ni distances are promoted by the conformational flexibility of the pendant arms of the 1,2-phda ligands, despite the identical carboxylate binding modes. The carboxylate termini of *phda-A* are twisted by ~60° and ~70° relative to the ligand's aromatic ring plane, while the related carboxylate torsions for *phda-B* are ~40° and ~57°, thus allowing a greater distance span across the ligated pendant arms of *phda-B*. Covalent bonding within the $[Ni(1,2\text{-phda})(H_2O)]_n$ chains is supplemented by hydrogen bonding donation by the aqua ligands to unligated oxygen atoms from the monodentate carboxylate groups of the 1,2-phda ligands.

Adjacent $[Ni(1,2\text{-phda})(H_2O)]_n$ chain subunits are subsequently conjoined into a two-dimensional (2D) $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ (4,4) rhomboid grid coordination polymer layer (Fig. 2) by exobidentate dpa ligands; the layer motif runs parallel to the *ac* crystal plane. Ni1 centers are linked by *dpa-B* ligands, fostering a Ni1···Ni1 contact distance of 11.525 Å; the pyridyl rings within *dpa-B* are twisted by 28.1° with respect to each other. Similarly, Ni2 atoms are strutted by *dpa-A* ligands with a Ni2···Ni2 contact distance of 11.548 Å. The inter-ring torsion within *dpa-A* is slightly larger, at 32.7°.

Due to the conformation-imposed varying tether lengths, two different grid sizes are observed within the $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ layers. The grid spaces bracketed by the shorter *phda-A* tethers measure 11.067 × 16.595 Å, as determined by through-space Ni···Ni distances, with Ni···Ni···Ni angles of 66.0° and 114.2°. The more pinched grid spaces, delineated by the longer *phda-B* tethers, measure 10.766 × 17.646 Å, with Ni···Ni···Ni angles of 61.8° and 118.0°. Neighboring $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ layers stack in an ABA pattern along the *b* crystal direction, primarily through interlayer hydrogen bonding between the central amine units of the dpa ligands and oxygen atoms belonging to chelating carboxylate moieties within 1,2-phda ligands (Fig. 3). Hydrogen bonding parameters for **1** are given in Table 3. The 2D non-interpenetrated layered structure of **1** is dramatically different from its related zinc congener, $\{[Zn(1,2\text{-phda})(dpa)] \cdot H_2O\}_n$, which

Symmetry transformations to generate equivalent atoms: #1 x, $-y+1/2$, $z+1/2$; #2 x, $-y+3/2$, $z+1/2$; #3 $-x$, $-y+1$, $-z+1$.

possesses a 4-fold interpenetrated $SrAl_2$(sra) lattice [14]. The octahedral coordination preference of the nickel ions in **1**, at the expense of tetrahedral coordination in the zinc analogue, is a plausible rationalization for this significant structural change.

4.3. Structural description of $\{[Ni(hmph)(dpa)] \cdot 1.33H_2O\}_n$ (**2**)

The large asymmetric unit of compound **2** (Fig. 4a and b) consists of three crystallographically unique nickel atoms (Ni1–Ni3), hmph dianions (*hmph-A*, O1–O4; *hmph-B*, O5–O8; *hmph-C*, O9–O12) and dpa ligands (*dpa-A*, N1–N3; *dpa-B*, N4–N6; *dpa-C*, N7–N9), along with four water molecules of crystallization. All nickel atoms adopt a $[NiO_4N_2]$ distorted octahedral geometry, with *cis*-disposed nitrogen donors from two different, yet crystallographically identical, dpa ligands. The remaining four coordination sites are taken up by oxygen atoms from chelating carboxylate groups from crystallographically distinct *hmph-A* and *hmph-B* ligands for Ni1 and Ni2, and from a pair of crystallographically identical *hmph-C* ligands for Ni3. Bond lengths and angles about Ni1, Ni2, and Ni3 are similar, and are stated in Table 4.

By means of two bisbridging bischelating hmph ligands (*hmph-A* and *hmph-B*), Ni1 and Ni2 are joined into a binuclear kernel with a Ni···Ni distance of 5.590 Å. In turn, Ni1 atoms are linked through tethering *dpa-B* ligands (with an inter-ring torsion of 23.5°), providing a Ni···Ni distance equal to 11.633 Å. Ni2 atoms conjoin to other Ni2 atoms through *dpa-C* (inter-ring torsion = 18.1°) with a slightly shorter Ni···Ni through-ligand distance of 11.591 Å. Therefore each Ni1 is connected to two other Ni1 atoms and one Ni2 atom, while Ni2 is connected to two other Ni2 atoms and one Ni atom, constructing a 3-connected 2D $[Ni(hmph)(dpa)]_n$ coordination polymer layer motif (Layer A, Fig. 5a). Considering the

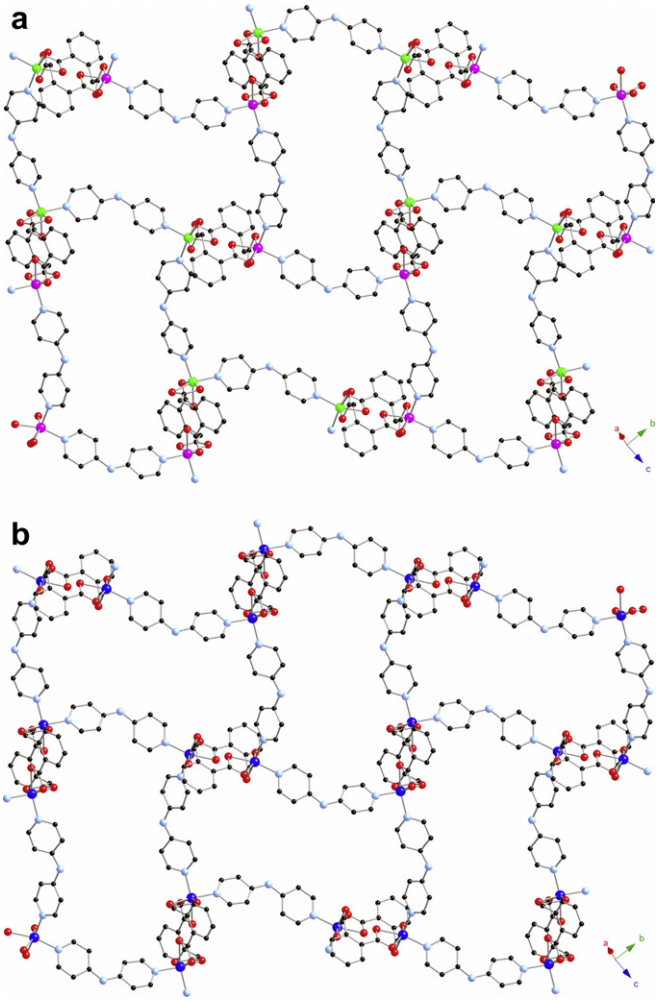

Fig. 5. Layers A (top) and B (bottom) in **2**, viewed individually slightly offset from the *a* crystal direction.

hmph-A and *hmph-B* linkages as a single connector between Ni1 and Ni2 atoms allows the visualization of the coordination polymer layer as a (6,3) herringbone pattern.

A very similar 2D $[Ni(hmph)(dpa)]_n$ (6,3) herringbone pattern is formed by linkage of Ni3 atoms to three other Ni3 atoms, through two *dpa-A* ligands (inter-ring torsion = 27.2°) and two *hmph-C* ligands (Layer B, Fig. 5b). The through-dpa Ni3···Ni3 distances within the layer are all identical, at 11.578 Å; while the through-space Ni3···Ni3 distances bracketed by the crystallographically identical *hmph-C* tethers are 5.584 Å. Both layer A and layer B motifs are situated parallel to the *bc* crystal plane.

It is likely that the subtle conformational variances between the dpa and hmph ligands result in the presence of two crystallographically distinct layers within the structure of **2**; the layers should be considered conformers as opposed to true supramolecular isomers. The different Ni···Ni through-space distances across the six-membered circuits within each layer type may also reflect these variances. Ni···Ni through-space distances within layer *A* measure 15.85, 18.31, and 22.14 Å, allowing accommodation of water molecule dimers (O1W···O3W) and isolated water molecules of crystallization (O4W). On the other hand, only isolated water molecules of crystallization (O2W) are present within layer B, where the Ni···Ni through-space distances measure 16.57, 18.25, and 21.61 Å.

The $[Ni(hmph)(dpa)]_n$ (6,3) layer motifs stack along the *a* crystal direction in a repeating AA′B pattern (Fig. 6), where layers A and A′

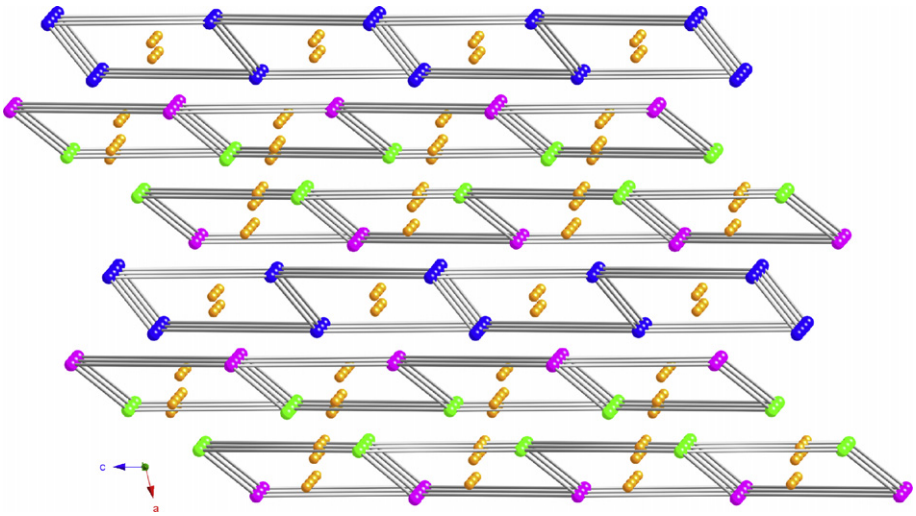

Fig. 6. AA′B layer stacking pattern within **2**. Water molecules of crystallization can be seen as spheres within the layers.

are related by crystallographic inversion. The pattern repeat distance of 14.950 Å defines the *a* lattice parameter. Interlayer supramolecular connectivity is fostered by the central amine units of the dpa ligands, which engage in hydrogen bonding to chelating carboxylate oxygen atoms at the longer pendant arm of the hmph ligands that project into the incipient voids within the (6,3) layers. Metrical parameters for the hydrogen bonding patterns in **2** are given above in Table 3.

4.4. Structural description of $[Ni(1,3\text{-phda})(dpa)(\mu\text{-}H_2O)_{0.5}]_n$ (**3**)

The asymmetric unit of compound **3** (Fig. 7) contains a single divalent nickel atom, one 1,3-phda dianion, one entire dpa molecule, and a ligated water molecule located on a crystallographic 2-fold axis. As is the case for **2**, the nickel atom possesses a distorted $[NiO_4N_2]$ octahedral coordination environment with a *cis* orientation of its nitrogen donors, which belong to two different dpa ligands. Bond lengths and angles about the nickel atom are standard for octahedral coordination (Table 5). Three of the oxygen donors belong to three different 1,3-phda ligands, while the remaining coordination site is occupied by an aqua ligand. Each 1,3-phda ligand serves as an exotridentate linker, connecting two nickel atoms at one carboxylate terminus in a bisbridging binding mode with a third nickel atom via the other carboxylate locus in a monodentate binding mode.

The aqua ligand serves to bridge two Ni atoms in a μ_2-fashion; both Ni atoms are in turn also bridged by two carboxylate termini from two different 1,3-phda ligands to a triply bridged binuclear unit (Fig. 8). These have a Ni···Ni distance of 3.603 Å, with the two bridging carboxylate groups situated 88.13° apart. Individual binuclear units are connected into a 1D $[Ni_2(1,3\text{-phda})_2(\mu\text{-}H_2O)]_n$ chain motif, coursing along the *a* crystal direction, by means of the monodentate carboxylate termini of the 1,3-phda ligands (Fig. 9). The Ni···Ni contact distance through the full extent of the 1,3-phda dianionic tethers is 8.881 Å.

Adjacent $[Ni_2(1,3\text{-phda})_2(\mu\text{-}H_2O)]_n$ chains are conjoined in the *b* and *c* crystal directions by dpa ligands to construct the 3D coordination polymer network of **3**. The dpa ligands contain an inter-ring

Symmetry transformations to generate equivalent atoms: #1 $-x+1/2, y, -z+1$; #2 $-x, y+1/2, -z+1/2$.

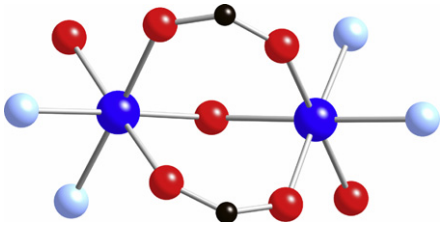

Fig. 8. Triply bridged {$Ni_2(\mu\text{-}H_2O)$} binuclear unit in **3**, with complete coordination spheres shown.

torsion of 41.3°, which fosters a Ni···Ni distance of 11.337 Å. Alternatively, the structure of **3** may be visualized as $[Ni_2(\mu\text{-}H_2O)(dpa)_2]_n^{4n+}$ cationic layers buttressed via 1,3-phda ligands. Treating the centroids of the {$Ni_2(\mu\text{-}H_2O)$} kernels as the connecting nodes allows the coordination polymer connectivity of **3** to be considered as a 6-connected canted primitive cubic (pcu) lattice with $4^{12}6^3$ topology (Fig. 10). The 3D covalent connectivity of **3** is supplemented by hydrogen bonding patterns mediated by the bridging water molecules and the central amine groups of the dpa ligands (see Table 3 for more detail).

4.5. Variable temperature magnetism of 3

To probe possible spin communication across its binuclear subunits, a sample of **3** was subjected to variable temperature magnetic study. The $\chi_m T$ product at 300 K was 1.09 cm^3 K mol^{-1} Ni, slightly higher than expected for an uncoupled Ni^{2+} $S=1$ ion (1.00 cm^3 K mol^{-1}), perhaps indicative of some crystal field anisotropy. The value of $\chi_m T$ decreased slowly below 50 K, reaching 1.00 cm^3 K mol^{-1}; the decrease was significantly more rapid below this temperature, reaching 0.00796 cm^3 K mol^{-1} at 2 K. Decreasing $\chi_m T$ product values in systems with dimeric {Ni_2} kernels can be ascribed either to antiferromagnetic superexchange through bridging ligands, or zero field splitting due to anisotropy.

The magnetic data was fit to Eq. (1), derived for a Heisenberg dimer of $S=1$ spins [20], and a temperature independent magnetism term was included (Fig. 11). The variables have their usual magnetochemical meanings. Best fit parameters were $g=2.290(2)$, $J=-4.21(2)\ cm^{-1}$, $\chi_{TI}=-6.2\times10^{-4}\ cm^3\ mol^{-1}$ with $R=1.48\times10^{-3}=\{\sum[(\chi_m T)_{obs}-(\chi_m T)_{calc}]^2\}^{1/2}$. The negative value of J corroborates the presence of antiferromagnetic coupling through the bridging carboxylate and aqua ligands in **3**. However, this value should be construed as an upper limit due to the likely presence of cooperative effects due to zero-field splitting (D parameter).

$$\chi_m T=\left(\frac{Ng^2\beta^2}{k}\right)\left[\frac{e^x+5e^{3x}}{1+3e^x+5e^{3x}}\right]+\chi_{TI}T \qquad (1)$$

where $x=J/kT$.

Given the substantially longer Ni···Ni distances in **1** and **2**, the magnetic behavior of these materials is expected to be dominated by zero-field splitting. As such, they were not subjected to variable temperature magnetic study.

4.6. Thermal analysis of 1–3

Thermogravimetric analysis was performed on samples of compounds **1**–**3** to investigate their robustness and decomposition pathways. Compound **1** manifested minimal mass loss until ~150 °C, whereupon dehydration commenced. This process was complete by ~240 °C, with the mass loss of 5.1% roughly consistent with elimination of one equivalent of water per nickel atom (4.1% calc.). The thermogram then exhibited a plateau until ~300 °C, at which temperature the organic components of the coordination polymer were ejected. The final mass remnant of 14.3% at 900 °C roughly matches with the deposition of Ni metal (13.3% calc.). Compound **2** underwent dehydration between 25 °C and 330 °C, with an observed mass loss of 5.2% (5.5% calc. for complete loss of water molecules of crystallization). At this latter temperature combustion of the organic ligands occurred. The final mass remnant of 17.6% represents the production of NiO (17.2% predicted). Compound **3** released its bridging water molecules between 25 °C and ~250 °C (3.0% mass loss, 2.1% predicted). Removal of the organic components took place between ~275 °C and ~600 °C, likely depositing NiO (17.2% mass loss observed, 17.7% calc.). TGA traces for **1**–**3** are depicted in Figs. S1–S3.

5. Conclusions

Variance of pendant arm length and position within aromatic dicarboxylate ligands has allowed access to a diversity of two-

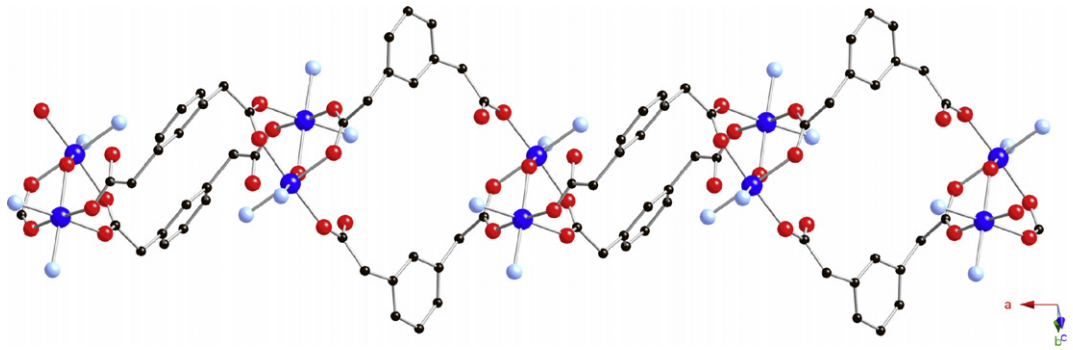

Fig. 9. $[Ni_2(1,3\text{-phda})_2(\mu\text{-}H_2O)]_n$ 1D chain motif in **3**.

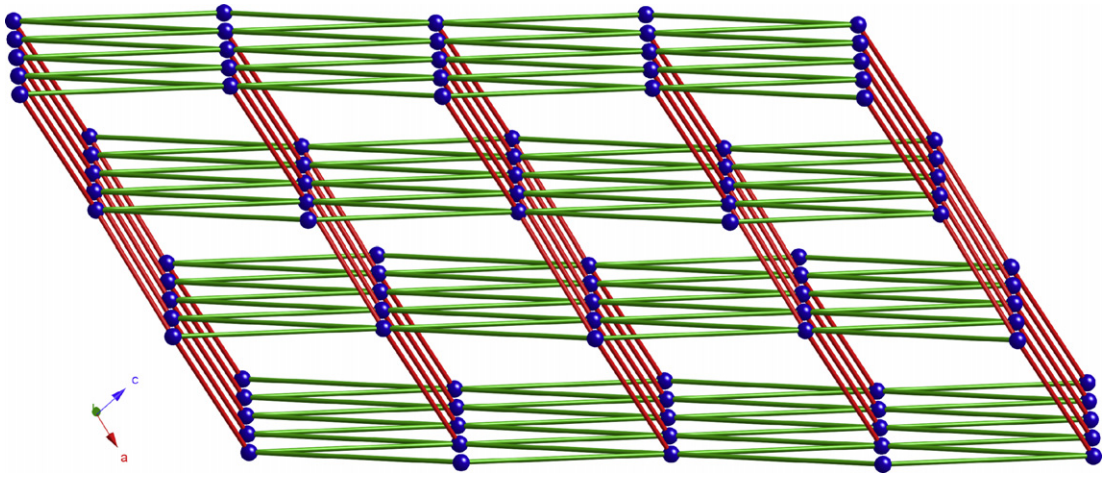

Fig. 10. Framework view of the canted primitive cubic 3D structure pattern in **3**. The $\{Ni_2(\mu\text{-}H_2O)\}$ binuclear units are represented as spheres, with organic ligands shown as solid rods. The 1,3-phda ligands connect the binuclear units along the *a* crystal direction.

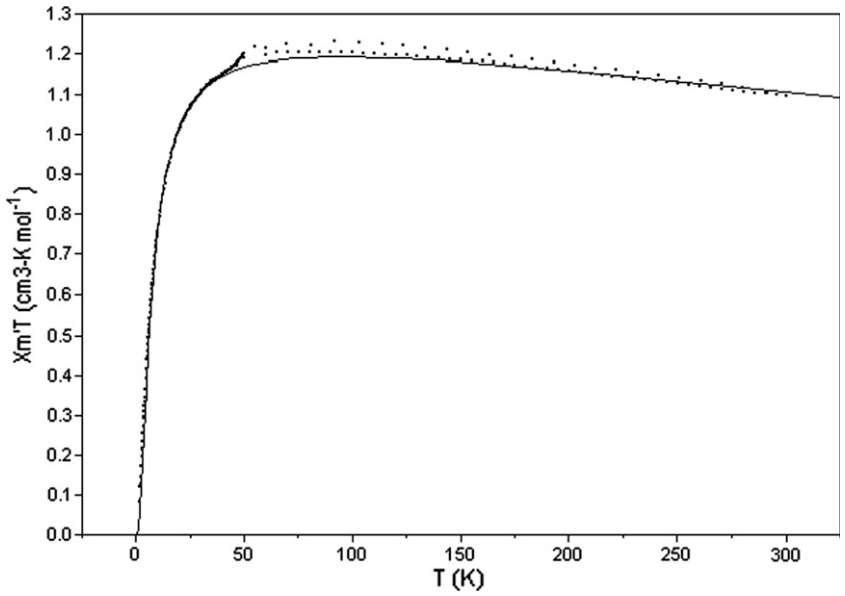

Fig. 11. $\chi_m T$ vs. T plot for **3**. The solid line indicates the best fit to Eq. (1) in the text.

and three-dimensional nickel coordination polymer structure types in a co-ligand system with the kinked and hydrogen bonding donating organodiimine dpa. The *ortho* disposition of acetate groups within 1,2-phda results in a "standard" rhomboid grid 2D coordination polymer morphology in **1**, albeit with slightly different grid apertures imparted by the conformational flexibility of the dpa ligands and the pendant arms of the dicarboxylate ligands. Shortening one of the pendant arms by one methylene unit did not change the overall coordination polymer dimensionality, but did adjust the layer morphology into a herringbone pattern and also altered the stacking pattern of the layered motifs. Use of the 1,3-phda ligand, which possesses a *meta* disposition of acetate pendant arms and a wider separation between its carboxylate termini, appeared to promote the formation of antiferromagnetically coupled triply bridged dinuclear units which conjoined into a 3D coordination polymer with a canted primitive cubic structure type. In all cases, the supramolecular hydrogen bonding pathways provided by the dpa ligand serve an important ancillary structure-directing role. Additional coordination polymers incorporating the dpa ligand have been recently prepared in our laboratory; reports concerning their structures and physicochemical properties will ensue in due course.

ABSTRACT

Two new macrocyclic ligands, L^1 (14-membered N_2O_2) and L^2 (28-membered N_4O_4) from [1+1] and [2+2] condensation, respectively, have been obtained in a one-pot synthesis starting from 1,4-bis(2′-formylphenyl)-1,4-dioxabutane and *cis*-1,2-diaminocyclohexane.

Both ligands were synthesized in the same pot reaction in satisfactory yield and purity. The use of a washing and recrystallization processes allowed the separation of each macrocyclic ligand.

No metal complexes were isolated with the small L^1 macrocycle. However, metal complexes with the 28-membered macrocycle L^2, using hydrated nitrate and perchlorate salts of transition Co(II), Ni(II) and Cu(II) metal ions, have been synthesized and characterized by microanalysis, LSI mass spectrometry, IR, UV–Vis spectroscopy, magnetic studies and conductivity measurements.Crystal structures of L^1, as well as $[Co(HL^2)(NO_3)_2(CH_3CN)]$ $(NO_3)\cdot 2CH_3CN$, $[NiL^2(NO_3)](NO_3)\cdot 2H_2O\cdot CH_3CN$ and $[Cu_2L^2(NO_3)_4]\cdot 4CH_3CN$ complexes, have been determined. The X-ray studies show the presence of a hexacoordinated mononuclear exomacrocyclic complex for Co(II), whilst in the dinuclear Cu(II) complex both copper atoms are exocyclically coordinated by the nitrogen atoms from the ligand in a square planar environment. The crystal structure of $[NiL^2(NO_3)](NO_3)\cdot 2H_2O\cdot CH_3CN$ shows a mononuclear endomacrocyclic complex with the metal ion in a distorted octahedral environment.

1. Introduction

The complexation properties of oxaazamacrocycles have been extensively studied in the last decades [1–8]. The cavity size, the rigidity and the donor type of the macrocycle is important in governing the host–guest interactions and the selectivity of metal ions [9,10].

The formation of multimetallic transition metal complexes offers an important route for the construction of new types of magnetic materials [11–14], development of catalytic reagents [15–18] models of metalloenzymes [19–21] and the construction of metallosupramolecular architectures [22,23].

One strategy for the synthesis of multimetallic complexes includes the use of large macrocycles, which allow accommodation of two or more metal ions. They can be used to hold the metal centers at a fixed distance, and the fact that metal ions can be precisely positioned within the macrocyclic entity provides then interesting properties [24,25].

During the last years our research group has been investigating structure–function relationships in the complexation behavior of transitional and post-transitional metal ions with mixed donor atoms macrocyclic ligands [26–29].

In previously works Lindoy and co-workers reported that with the oxaazamacrocycle ligand L^A (Fig. 1), the 1:1 metal:ligand complexes in solution and in solid state were observed [30–34], but they have no evidence for the formation of 2:1 metal:ligand species with L^B in solution or in the solid state, and only mononuclear complexes were obtained [35].

In this paper, we report the synthesis and characterization of two macrocyclic systems: the [1+1] 14-membered N_2O_2 macrocycle, L^1, and the analogue [2+2] 28-membered N_4O_4 macrocycle, L^2 (Fig. 1), which present cyclohexyl rings between amine groups instead of ethylenic chains in the case of the L^A and L^B mentioned above. We also report a study of the complexation capability towards Co(II), Ni(II) and Cu(II) transition metal ions. We have seen that no metal complexes were able to be isolate with L^1 but the formation of dinuclear species was confirmed with L^2.

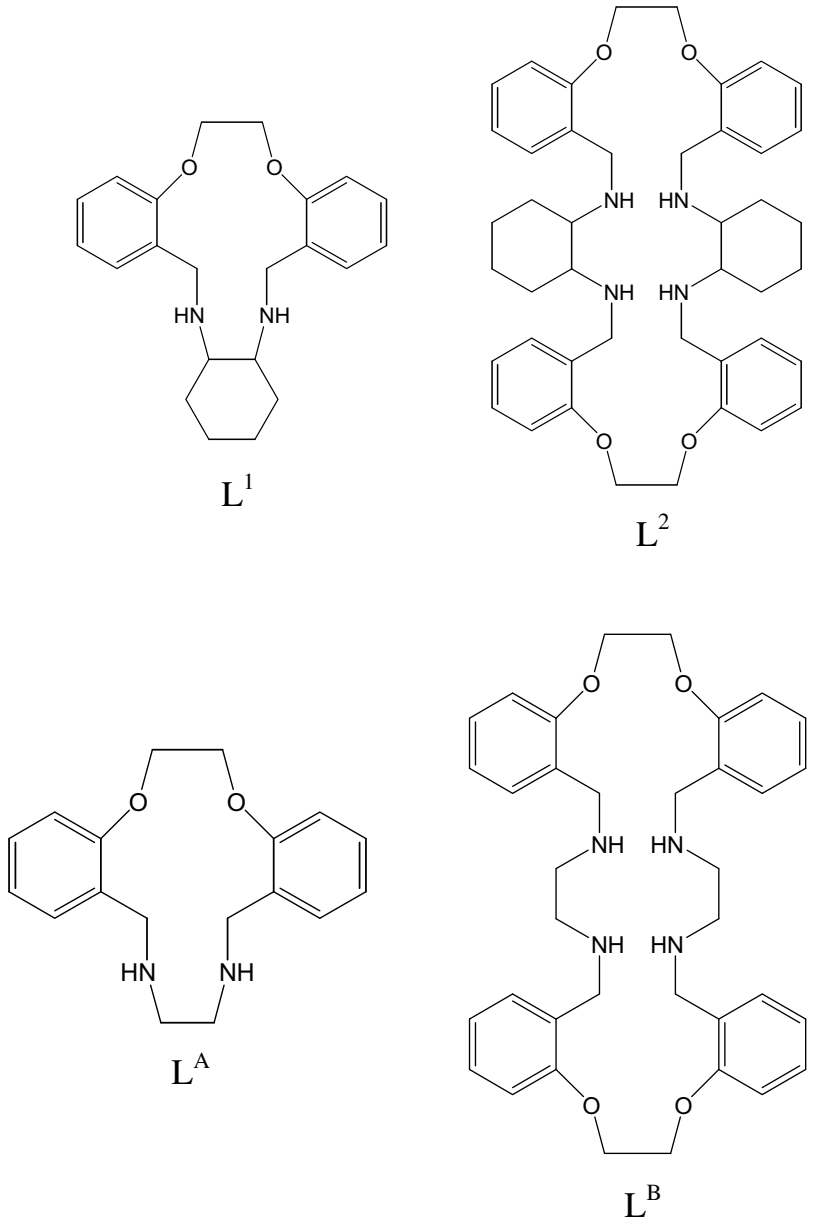

Fig. 1. L^1 and L^2 macrocyclic ligands.

The X-ray crystal structure of the ligand L^1 and the crystal structures of the Co(II), Ni(II) and Cu(II) nitrate complexes with L^2 are reported.

2. Experimental

2.1. Chemicals and starting materials

1,4-bis(2′-formylphenyl)-1,4-dioxabutane was synthesized as described [36], *cis*-1,2-diaminocyclohexane and metal salts were commercial products (from Alfa and Aldrich) and were used without further purifications. Solvents were of reagent grade and were purified by the usual methods. *Caution*: Although no problems were encountered during the course of this work, perchlorate salts must be handled with care due to their potentially explosive nature.

2.2. Synthesis of the ligands

1,4-Bis(2-formylphenyl)-1,4-dioxabutane (2 mmol, 0.54 g) was dissolved in methanol (75 mL) under reflux and a solution of *cis*-1,2-diaminocyclohexane (2 mmol, 0.4 g) in methanol (30 mL) was added. The solution was refluxed for 4 h and stands to cool. $NaBH_4$ (20 mmol, 0.76 g) were added slowly. The solution was evaporated to dryness. The residue was then extracted with water–chloroform. The organic layer was dried over $MgSO_4$ filtered off and evaporated to dryness to yield a yellow oil. Ethyl ether was added and the resultant white solid was filtered off and recrystallized in acetonitrile giving the ligand L^1 as a white crystalline solid. The solution was concentrated to dryness and the white solid taken up in acetone, filtered off and the filtrate was concentrated to dryness and the resultant solid was dissolved in acetonitrile. After three days, the solution was filtered off and the filtrate reduced to dryness and characterized as L^2.

L^1: *Anal. Calc. for $C_{22}H_{28}N_2O_2$: C, 74.9; H, 8.0; N, 7.9. Found: C, 74.8; H, 8.0; N, 7.9%. Yield: 30%. IR (KBr, cm^{-1}): 1600, 1490, 1452 [ν(C=C)],* 1058 [ν(C–O–C)]. LSI-MS (*m/z*): 353 $[L^1+H]^+$. Colour: white.

L^2: *Anal. Calc. for $C_{44}H_{56}N_4O_4$: C, 74.9; H, 8.0; N, 7.9. Found: C, 74.8; H, 8.0; N, 7.8%. Yield: 42%. IR (KBr, cm^{-1}): 1600, 1490, 1452 [ν(C=C)],* 1058 [ν(C–O–C)]. LSI-MS (*m/z*): 705 $[L^2+H]^+$. Colour: white.

2.3. Synthesis of metal complexes

To a methanolic solution (10 mL) of L^2 (0.1 mmol, 0.0704 g) was added a solution of the appropriate metal salt (0.15 mmol) in methanol (10 mL) and the solution was heated at reflux for 3 h and stand to cool. The solution was concentrated until *ca.* 10 mL. The product obtained was filtered off and dried under vacuum. The complexes were found to be air-stable and soluble in acetonitrile, dimethyl sulfoxide and dimethyl formamide and are, in general, insoluble in water, absolute ethanol, methanol, diethyl ether, chloroform, dichloromethane and acetone.

2.3.3. $[Ni_2L^2](ClO_4)_4 \cdot 3CH_3CN$

Anal. Calc.: C, 44.8; H, 4.7; N, 7.3. Found: C, 44.2; H, 5.1; N, 7.6%. Yield: 65%. IR (KBr, cm^{-1}): 1454, 1490, 1602 [ν(C=C)$_{ar}$], 624, 1103 [$\nu(ClO_4^-)$]. LSI-MS (*m/z*): 861 $[NiL^2(ClO_4)]^+$, 762 $[NiL^2]^+$. Λ_M/Ω^{-1} cm^2 mol^{-1} (in CH_3CN): 420 (4:1). Colour: green.

2.3.4. $[NiL^2](NO_3)_2$

Anal. Calc.: C, 59.5; H, 6.4; N, 9.5. Found: C, 59.9; H, 6.1; N, 9.6%. Yield: 32% IR (KBr, cm^{-1}): 1452, 1490, 1601 [ν(C=C)$_{ar}$], 756, 1086, 1239, 1384 [$\nu(NO_3^-)$]. LSI-MS (*m/z*): 824 $[NiL^2(NO_3)]^+$, 761 $[NiL^2]^+$. Λ_M/Ω^{-1} cm^2 mol^{-1} (in CH_3CN): 127 (1:1). Colour: blue.

2.3.5. $[Cu_2L^2](NO_3)_4$

Anal. Calc.: C, 49.0; H, 5.0; N, 10.4. Found: C, 48.8; H, 5.3; N, 10.5%. Yield: 42%. IR (KBr, cm^{-1}): 1453, 1492, 1602 [ν(C=C)$_{ar}$], 753, 1058, 1238, 1384 [$\nu(NO_3^-)$]. LSI-MS (*m/z*): 766 $[CuL^2]^+$, 705 $[L^2+H]^+$. Λ_M/Ω^{-1} cm^2 mol^{-1} (in CH_3CN): 308 (2:1). Colour: blue.

2.4. Physical measurements

Elemental analyses were performed in a Carlo-Erba EA microanalyser. Infra-red spectra were recorded as KBr discs on a Bruker IFS-66V spectrophotometer. LSI-MS were recorded using a Micromass Autospec spectrometer with 3-nitrobenzyl alcohol as the matrix. Conductivity measurements were carried out in 10^{-3} mol dm^{-3} acetonitrile solutions at 20 °C using a WTW LF3 conductivimeter. ^{1}H, ^{13}C, DEPT 135 and HMQC ^{1}H-^{13}C NMR spectra were recorded on a Bruker 500 MHz, and $CDCl_3$ was used as solvent. Solid state electronic spectra were recorded on a Hitachi 4-3200 spectrophotometer using $MgCO_3$ as reference. Magnetic studies were determined at r.t. on a vibration sample

2.5. X-ray data collection, structure determination, and refinement

The crystals were obtained by slow recrystallization of the compounds from acetonitrile. The details of the X-ray crystal data, and the structure solution and refinement are given in Table 1. Measurements were made on a Bruker SMART CCD 1000 area diffractometer. All data were corrected for Lorentz and polarization effects. Empirical absorption corrections were also applied for all the crystal structures obtained [37]. Complex scattering factors were taken from the program package SHELXTL [38]. The structures were solved by direct methods which revealed the position of all non-hydrogen atoms. All the structures were refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters for all non-hydrogen atoms. The hydrogen atoms were located in their calculated positions and refined using a riding model.

3. Results and discussion

L^1 and L^2 ligands were each readily obtained in a one-pot synthesis from commercial reagents in satisfactory yield and purity without the need for column chromatography. The direct reaction of 1,4-bis(2′-formylphenyl)-1,4-dioxabutane and *cis*-1,2-diaminocyclohexane in methanol under reflux followed by an *in situ* reduction with $NaBH_4$ gave an air-stable pale yellow solid characterized as a mixture of the ligands L^1 and L^2, as was evidenced by mass spectrometry. Through studies employing the pure L^1 product, the pure L^2 product and known mixtures of both, we have shown that mass spectrometry can be employed to give an indication of purity. The use of a washing and recrystallization processes allowed the separate isolation of each macrocycle. By slow crystallization of the mixture in acetonitrile, a white crystalline compound was obtained after two days. The crystalline precipitate was filtered off and characterized as pure L^1 ligand. The solution was concentrated by rotary evaporation and a white powder was obtained, which was characterized as the L^2 ligand with a little impurity of L^1. The solid was taken up in acetone, filtered off, and the filtrate was reduced to dryness. The solid was again dissolved in acetonitrile and after three days the solution was filtered off, reduced to dryness, and the white powder obtained was characterized as pure L^2 ligand.

Crystals suitable for X-ray diffraction of L^1 were obtained from the acetonitrile solution. Crystal data and structure refinement are given in Table 1. Molecular structure and bond lengths (Å) are given in Fig. 2. The structure belongs to $P21/n$ monoclinic space group. Bond distances and angles are all within the normal ranges. The structure shows that the molecule is slightly folded with a dihedral angle between the plane containing the aromatic rings of 79.65°; the cyclohexane ring shows a chair conformation. The presence of the cyclohexane and the two aromatic rings introduce a high rigidity in the small [1+1] macrocycle L^1, but beforehand the arrangement of the donor atoms seems to be adequate for complexation. The rms value of the four donor atoms in the molecule is 0.23.

No inter- or intramolecular π,π-stacking interactions are present in the structure.

L^1 and L^2 ligands were also characterized by elemental analysis, LSI-MS, IR, ^1H and ^{13}C NMR spectroscopy. LSI mass spectrometry provided evidence for the sole presence of L^1 (*m/z* 353, assignable to $[L^1+H]^+$), or L^2 (*m/z* 705, assignable to $[L^2+H]^+$).

The IR spectra (KBr disc) of both ligands show no bands corresponding to carbonyl or primary amine groups, further confirming that cyclization took place. Also no imine bands appear in the spectra. A broad band centered at 3423 cm^{-1} present in the spectra, attributable to the presence of solvent molecules, hides the secondary amine bands of the ligands. Two intense bands at 1600, 1490 and 1452 cm^{-1} attributable to the ν(C=C) of the aromatic rings of the molecules are also observed.

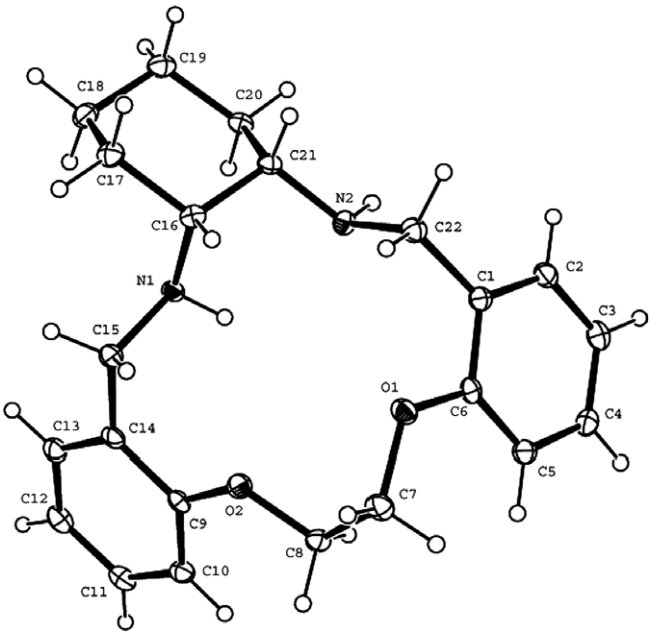

Fig. 2. Crystal structure of **L**[1] and bond lengths (Å): C(1)–C(2) 1.386(2); C(1)–C(6) 1.405(2); C(1)–C(22) 1.505(2); C(2)–C(3) 1.383(2); C(3)–C(4) 1.379(2); C(4)–C(5) 1.387(2); C(5)–C(6) 1.384(2); C(6)–O(1) 1.3721(18); C(7)–O(1) 1.4310(18); C(7)–C(8) 1.498(2); C(8)–O(2) 1.4258(18); C(9)–O(2) 1.3628(18); C(9)–C(10) 1.390(2); C(9)–C(14) 1.400(2); C(10)–C(11) 1.389(2); C(11)–C(12) 1.379(2); C(12)–C(13) 1.386(2); C(13)–C(14) 1.381(2); C(14)–C(15) 1.506(2); C(15)–N(1) 1.4583(19); C(16)–N(1) 1.4671(19); C(16)–C(17) 1.528(2); C(16)–C(21) 1.536(2); C(17)–C(18) 1.518(2); C(18)–C(19) 1.521(2); C(19)–C(20) 1.520(2); C(20)–C(21) 1.520(2); C(21)–N(2) 1.4716(19); C(22)–N(2) 1.4665(19).

The ^1H and ^{13}C NMR spectra of the ligands L^1 and L^2 (Table 2) have been recorded using deuterated chloroform as solvent, and confirm the integrity of the ligands and their stability in solution. The NMR spectra of the ligands are completely similar, and assignment of the proton signals was based upon standard 2D homonuclear (COSY) and $^1H/^{13}C$ heteronuclear spectra (HMQC). The aromatic region of the ^1H NMR spectrum shows two multiplets belonging to the phenyl groups; the ethylenic protons signal appears as a singlet at δ 4.2 ppm. The benzyl protons appear as a multiplet at δ 3.6 ppm, probably due to the rigidity incorporated to the macrocyclic framework by the cyclohexane groups. The peaks belonging to the cyclohexane protons appear between δ 2.5 and 1.15 ppm.

Attempts to isolate metal complexes with L^1 were unsuccessful and the free ligand was always recovered from the reaction.

Transitional Co(II), Ni(II) and Cu(II) metal complexes of L^2 were synthesized by reaction of the ligand and the appropriate metal salt in refluxing acetonitrile. The complexes were synthesized as described in Section 2 and, in general, the reactions gave in general good yields of analytically pure products. Complexes were characterized by elemental analysis, LSI mass spectrometry, IR and UV–Vis spectroscopy, magnetic and conductivity measurements.

3.1. Crystal structures

By slow recrystallization of the dinuclear compound $[Co_2L^2](NO_3)_4 \cdot 2CH_3CN$ in acetonitrile, crystals of $[Co(HL^2)(NO_3)_2(CH_3CN)](NO_3) \cdot 2CH_3CN$ were obtained. The crystal structure was

studied by X-ray diffraction and the molecular structure of the complex is shown in Fig. 3 together with the atomic numbering scheme adopted and selected bond distances (Å) and angles (°). Crystal data and structure refinement are given in Table 1.

The crystal structure is consistent with the cation complex $[Co(HL^2)(NO_3)_2(CH_3CN)]^+$, and a well separated nitrate ion and two acetonitrile molecules.

The structure of $Co(HL^2)(NO_3)_2(CH_3CN)]^+$ shows the presence of a Co(II) mononuclear complex, where the metal ion is exomacrocyclicly coordinated by two nitrogen atoms from one diaminocyclohexane fragment, one oxygen atom from a monodentate nitrate ion, two oxygen atoms from a bidentate nitrate ion and the nitrogen atom from an acetonitrile molecule. The Co(II) ion presents a six coordination number in a $\{N_3O_3\}$ core with a distorted octahedral environment. The equatorial plane can be described by one nitrogen donor atom from the ligand, N(3), and the three oxygen atoms from the nitrate groups [N(3)–O(4N)–O(3N)–O(1N), rms 0.0825]. The axial axis is determined by the nitrogen donor atom from the ligand N(4), and the nitrogen atom from the acetonitrile molecule N(3S). All the bond lengths between the metal ions and the donor atoms are quite similar. The monodentate nitrate group provides the shortest bond distance to the ion [Co(1)–O(4N), 2.026(10) Å], whilst the main distortion from a regular octahedral geometry is attributable to the small bite of the bidentate nitrate ligand [O(1N)–Co(1)–O(3N), 58.97(4)°]. The average value of the Co–N bond length is 2.15 Å, which is similar to that found in other macrocyclic nitrate complexes of octahedral Co(II) [39]. The ether oxygen atoms are not coordinated to the metal ion.

The hydrogen atoms belonging to the amine groups of the ligand have been encountered, and the structure shows that the ligand molecule is protonated in one of the free secondary amine groups. An extra nitrate ion is present in the structure to ensure the electric neutrality of the lattice. Thus, starting from the dinuclear compound $[Co_2L^2](NO_3)_4 \cdot 2CH_3CN$, the protonation of the

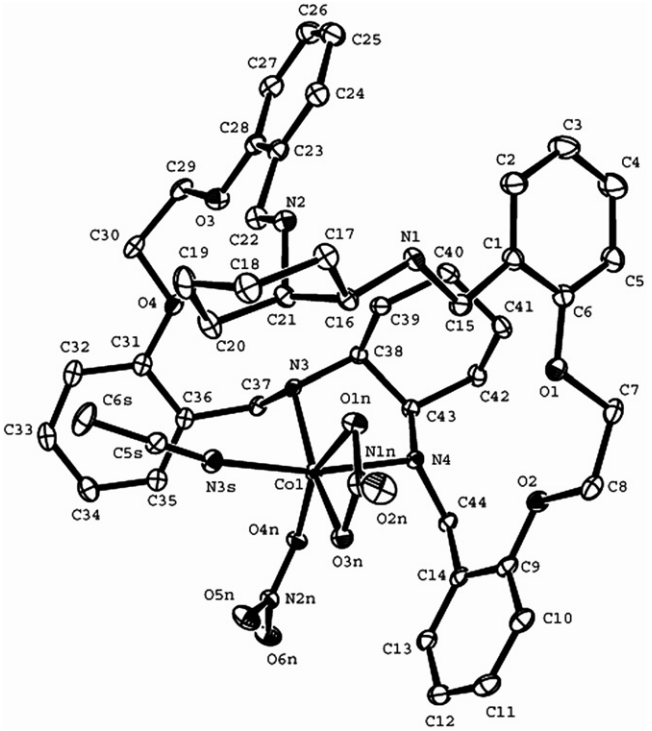

Fig. 3. Crystal structure of $[Co(HL^2)(NO_3)_2\ (CH_3CN)](NO_3) \cdot 2CH_3CN$; Selected bond lengths (Å) and angles (°): N(3)–Co(1) 2.1490(12); N(3S)–Co(1) 2.1148(13); N(4)–Co(1) 2.1574(12); O(1N)–Co(1) 2.1811(11); O(3N)–Co(1) 2.1907(11); O(4N)–Co(1) 2.0269(10); O(4N)–Co(1)–N(3S) 101.14(5); O(4N)–Co(1)–N(3) 93.06(4); N(3S)–Co(1)–N(3) 89.06(5); O(4N)–Co(1)–N(4) 87.48(4); N(3S)–Co(1)–N(4) 168.00(5); N(3)–Co(1)–N(4) 82.10(4); O(4N)–Co(1)–O(1N) 160.74(4); N(3S)–Co(1)–O(1N) 87.57(5); N(3)–Co(1)–O(1N) 104.33(4); N(4)–Co(1)–O(1N) 86.78(4); O(4N)–Co(1)–O(3N) 103.76(4); N(3S)–Co(1)–O(3N) 88.20(4); N(3)–Co(1)–O(3N) 163.18(4); N(4)–Co(1)–O(3N) 97.92(4); O(1N)–Co(1)–O(3N) 58.97(4).

ligand and a demetalation reaction of one of the Co(II) metal ions took place (a precipitate, probably due to hydroxyl species was also observed). The configuration of the coordinated amine groups N(3) and N(4) is R,S (or S,R), as both isomers are present in the structure.

The dihedral angle between the plane containing the aromatic rings C1–C6 and C9–C14 is 87.70°, and 80.17° between C23–C28 and C31–C36.

Some intra and intermolecular interactions through hydrogen bonds are present in the crystal lattice: [N1–H1N···N2 = 2.614 Å, 127.61°], [N3–H4N···O4 = 2.963Å, 126.94°], [N4–H5N···O2 = 2.948 Å, 124.20°], [N1–H2N···O9N_$1 = 2.804 Å, 155.46°], [N1–H2N···O7N_$1 = 3.085 Å, 143.04°], [N2–H3N···O8N_$2 = 3.568 Å, 155.20°], [N2–H3N···O9N_$2 = 3.064 Å, 152.31°]. $1 = x, $+y$, $+z + 1$, $2 = $-x + 1$, $-y + 1$, $-z + 1$.

The complex $[NiL^2(NO_3)](NO_3) \cdot 2H_2O.CH_3CN$ was obtained by recrystallization of the complex $[NiL^2](NO_3)_2$ from acetonitrile. The molecular structure together with selected bond lengths (Å) and angles (°) are given in Fig. 4. The crystal data and structure refinement are given in Table 1.

The X-ray crystal structure shows a mononuclear endomacrocyclic cation complex of type $[NiL^2(NO_3)]^+$. A free nitrate ion, two water and one acetonitrile molecules are also present in the crystal lattice. The metal center presents a six-coordinate $\{N_4O_2\}$ core in a distorted octahedral geometry. The Ni^{2+} ion is situated in the cavity of the macrocycle and it is bonded to the four nitrogen atoms from the macrocyclic backbone and two oxygen atoms from a bidentate nitrate group. The ether oxygen atoms from the ligand are not coordinated to the metal. The main distortion from a regular octahedral geometry can be attributed again to the small bite of the bidentate nitrate group [O(2N)–Ni(1)–O(1N), 60.70(11)°]. The

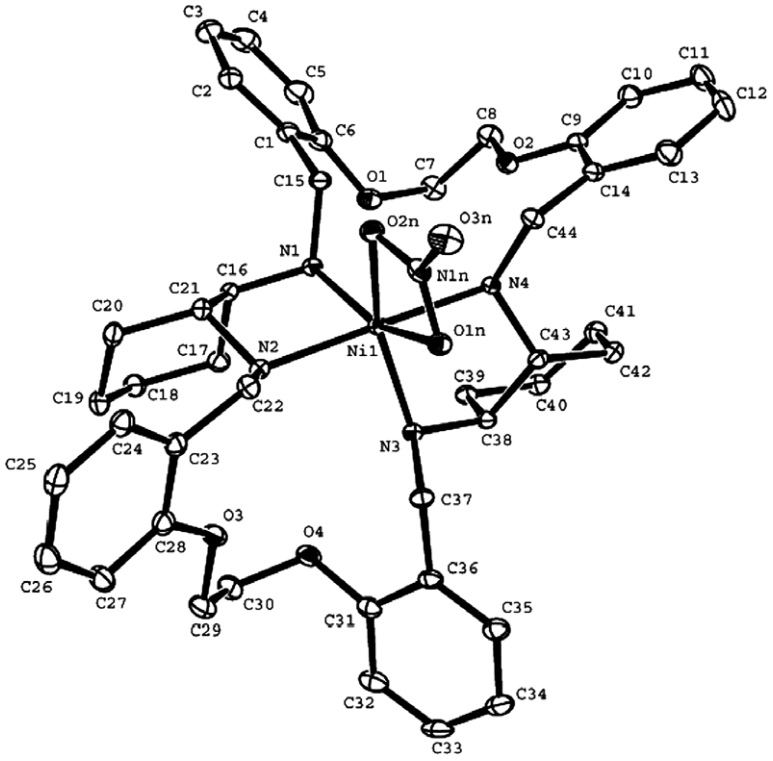

Fig. 4. Crystal structure of $[NiL^2(NO_3)](NO_3) \cdot 2H_2O \cdot CH_3CN$; Selected bond lengths (Å) and angles (°): Ni(1)–N(3) 2.075(3); Ni(1)–N(1) 2.079(3); Ni(1)–O(2N) 2.124(3); Ni(1)–O(1N) 2.150(3); Ni(1)–N(2) 2.153(3); Ni(1)–N(4) 2.184(3); N(3)–Ni(1)–N(1) 107.89(14); N(3)–Ni(1)–O(2N) 155.86(13); N(1)–Ni(1)–O(2N) 96.15(12); N(3)–Ni(1)–O(1N) 95.23(12); N(1)–Ni(1)–O(1N) 156.83(13); O(2N)–Ni(1)–O(1N) 60.70(11); N(3)–Ni(1)–N(2) 94.58(13); N(1)–Ni(1)–N(2) 82.75(13); O(2N)–Ni(1)–N(2) 90.49(12); O(1N)–Ni(1)–N(2) 97.21(12); N(3)–Ni(1)–N(4) 82.94(12); N(1)–Ni(1)–N(4) 94.32(13); O(2N)–Ni(1)–N(4) 93.32(12); O(1N)–Ni(1)–N(4) 86.87(12); N(2)–Ni(1)–N(4) 175.43(13).

structure is similar to that obtained by Lindoy and co-workers with L^B $[NiL^B(NCS)_2]$ [35], which presents two *cis* thiocyanate ions instead of a nitrate group, with the metal also in an octahedral geometry.

The Ni–N distances are lightly shorter in $[NiL^2(NO_3)]^+$ (the average value being 2.128 Å) than in $[NiL^B(NCS)_2]$ (average value of 2.149 Å). The longer distance corresponds to Ni(1)–N(4), 2.184(3) Å. The average value of the Ni–O bond length is 2.138 Å, which is similar to that found in other macrocyclic nitrate complexes of octahedral Ni(II) [40,41].

The equatorial plane can be described by the nitrogen donor atoms N(1) and N(3) from the ligand and both oxygen atoms from the nitrate group O(1N) and O(2N). [N(1)–N(3)–O(1N)–O(2N), rms 0.0071]. The axial axis is occupied by the nitrogen donor atom N(2) and N(4) from the ligand [N(2)–Ni(1)–N(4), 175.43(13)°].

The configuration of the coordinated amine groups N(1), N(2), N(3) and N(4) is *S*,*R*,*S*, R (or *R*,*S*,*R*,*S*), as both isomers are present in the structure.

The dihedral angles between the planes containing the aromatic rings are 70.67° between C1–C6 and C9–C14 and 72.83° between C23–C28 and C31–C36.

Some intramolecular interactions through hydrogen bonds have been found: [N1–H1C···O1 = 2.837 Å, 125.25°], [N2–H2C···O3 = 2.825 Å, 126.58°], [N3–H3C···O4 = 2.845 Å, 128.76°], [N4–H4C···O2 = 2.873 Å, 134.82°]. Also hydrogen bond interactions occur between the water molecules and the nitrate ions and acetonitrile molecules.

The crystal structure shows that the free nitrate group is disordered with an occupancy of ca. 50% in each site.

Crystals suitable for X-ray diffraction belonging to the compound $[Cu_2L^2(NO_3)_4] \cdot 4CH_3CN$ were obtained by slow recrystallization of the complex $[Cu_2L^2](NO_3)_4$ in acetonitrile. The molecular structure of the complex together with selected bond lengths (Å) and angles (°) are given in Fig. 5. Crystal data and structure refinement are given in Table 1.

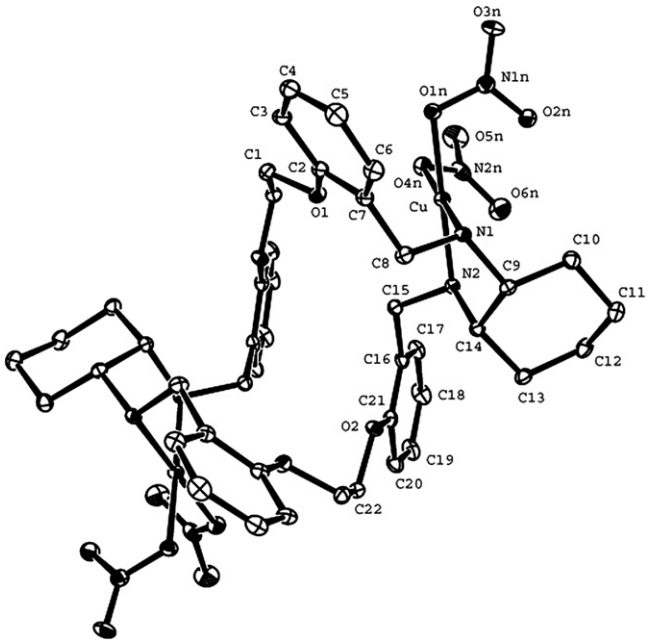

Fig. 5. Crystal structure of $[Cu_2L^2(NO_3)_4] \cdot 4CH_3CN$; Selected bond lengths (Å) and angles (°): Cu–O(4N) 1.9692(15); Cu–N(1) 1.9757(18); Cu–O(1N) 1.9905(15); Cu–N(2) 2.0135(18); O(4N)–Cu–N(1) 179.78(8); O(4N)–Cu–O(1N) 86.73(6); N(1)–Cu–O(1N) 93.40(7); O(4N)–Cu–N(2) 95.45(7); N(1)–Cu–N(2) 84.43(7), O(1N)–Cu–N(2) 177.82(6).

As has been shown previously in the coordination behavior of other oxaaza macrocyclic ligands towards Cu(II) ions, the metal

ion is coordinated mainly with the N donor atoms. [7,31] In this case, the structural analysis shows a dinuclear exomacrocyclic complex where each Cu(II) ion is in a $\{N_2O_2\}$ coordination environment. Both Cu(II) ions are out of the macrocyclic cavity, coordinated by two contiguous amine nitrogen atoms from one aminocyclohexane fragment, and the coordination environment is completed by two monodentate nitrate groups. The geometry around each Cu(II) ion can be described as quite regular square planar. The four donor atoms are practically in a plane (rms 0.0023) and the distance between the Cu(II) and the plane is 0.0008 Å. The bond distances from the donor atoms to the Cu(II) ion are similar, and the shortest one belongs to one monodentate nitrate group [Cu–O(4N), 1.9692 Å]. The configuration of the amine groups N(1) and N(2) is *R*,*S* (or *S*,*R*).

Again, the ether oxygen atoms from the ligand do not participate in coordination. The Cu^{2+} ions are displaced out of the macrocyclic cavity and there is no interaction between them [Cu···Cu_$1, 8.36 Å].

The macrocycle is folded and the aromatic rings are stacked in pairs. Analysis of the intramolecular ring–ring interactions reveals a slipped π,π-interaction between the aromatic rings C16–C21 and C16_$1-C21_$1 of the molecule (Symmetry operation $-x, y, z + 1/2$) [42]. The distance between centroids (D_{c-c}) has a value of 4.05 Å and the dihedral angle between the planes containing these aromatic rings is 11.98°. The dihedral angle between the planes containing the aromatic rings C2–C7 and C2_$1–C7_$1 is 33.6°, and the average distance between the planes is 3.6 Å.

Two intramolecular interactions through hydrogen bonds were found in the crystal structure: [N1–H1N···N2S = 3.107 Å, 175.1°], [N2–H2N···O6N = 2.879 Å, 136.4°].

3.2. Spectroscopic and magnetic studies

The IR spectra of the L^2 complexes show similar features. The ν(C=C) bands of the aromatic rings are generally shifted to higher wavenumbers than in the free ligand, suggesting the coordination to the metal ions [43,44].

An intensive broad band centered about 3440 cm^{-1} in the IR spectra of the complexes due to the presence of solvent molecules is present in all spectra.

In the IR spectra of the nitrate complexes, the region associated with the NO stretches show bands that clearly identify these species as containing coordinate nitrate groups. A band at 1380 cm^{-1}, associated with the presence of ionic nitrate, is also present.

The IR spectra of the perchlorate complexes feature absorptions attributable to ionic perchlorate at 1100 and 626 cm^{-1}, indicating that these groups are not coordinated to the metal centers [45,46].

The results of LSI-MS of the complexes provide important evidence of the formation of the complexes as they feature peaks attributable in all cases to the species $[ML^2X]^+$ and $[ML^2]^+$ (M = Co, Ni, Cu; X = NO_3^-, ClO_4^-).

Molar conductivity data were measured at room temperature using acetonitrile as solvent (10^{-3} M solutions of the complexes). The molar conductivity values obtained lie in the range previously observed for 4:1 electrolytes for the dinuclear perchlorate complexes, indicating the low coordination capability of the perchlorate groups. For the nitrate complexes, the values lie within the range of 2:1 electrolytes for the dinuclear complexes, and 1:1 for the mononuclear $[NiL^2](NO_3)_2$ complex, showing the coordination of some of these groups to the metal in solution [47].

The reflectance spectrum of $[Co_2L^2](ClO_4)_4 \cdot 2CH_3$[CN and $Co_2L^2](NO_3)_4 \cdot 2CH_3CN$ complexes shows three d–d transition bands at *ca.* 8976 (ν_1), 18248 (ν_2) and 22831 cm^{-1} (ν_3) which are probably due to the $^4T_{2g} \leftarrow {}^4T_{1g}$, $^4A_{2g} \leftarrow {}^4T_{1g}$ and $^4T_{1g}(P) \leftarrow {}^4T_{1g}$ transitions, respectively, according to a distorted octahedral high-spin Co(II) complexes [48].

The reflectance spectra of the nickel complexes $[Ni_2L^2](ClO_4)_4 \cdot 3CH_3CN$ and $[NiL^2](NO_3)_2$ show three bands at *ca.* 9980 (ν_1), 16502 (ν_2) and 28571 cm^{-1} (ν_3). These bands are attributable to the $^3T_{2g} \leftarrow {}^3A_{2g}$, $^3T_{1g}(F) \leftarrow {}^3A_{2g}$ and $^3T_{1g}(P) \leftarrow {}^3A_{2g}$ transitions, respectively, and are indicative of octahedral Ni(II) compounds. One absorption band at *ca.* 12658 cm^{-1} present also in the spectra, is probably due to the spin forbidden transition $^1Eg \leftarrow {}^3A_{2g}$, usually observed for Ni(II) complexes [49,50].

The UV–Vis spectrum of $[Cu_2L^2](NO_3)_4$ show a broad band between 14837 and 18248 cm^{-1}, typical of square planar Cu(II) complexes [51].

The value of the room temperature magnetic moments (by metal atom) of the compounds $[Co_2L^2](ClO_4)_4 \cdot 2CH_3CN$ (3.6 BM), $[Co_2L^2](NO_3)_4 \cdot 2CH_3CN$ (3.9 BM), $[Ni_2L^2](ClO_4)_4 \cdot 3CH_3CN$ (2.8 BM) and $[NiL^2](NO_3)_2$ (2.9 BM) lies in the range usually observed for high-spin octahedral Co(II), and octahedral Ni(II) complexes, respectively [52]. The magnetic moment of $[Cu_2L^2](NO_3)_4$ (1.9 BM) lie in the range observed for Cu(II) complexes.

4. Conclusion

Two new macrocyclic ligands, the14-membered N_2O_2 macrocycle L^1, and the analogue [2+2] 28-membered N_4O_4 macrocycle L^2, have been obtained in a one-pot synthesis in satisfactory yield and purity, and we also report the study of the complexation capability towards to nitrate and perchlorate salts of Co(II), Ni(II) and Cu(II) transitional metal ions. We have seen that no metal complexes were possible to isolate with L^1 but the formation of dinuclear species were confirmed with L^2.

The crystal structure of L^1 as well as of the $[Co(HL^2)(NO_3)_2(CH_3CN)](NO_3)$. $2CH_3CN$, $[NiL^2(NO_3)](NO_3) \cdot 2H_2O \cdot CH_3CN$ and $[Cu_2L^2(NO_3)_4].4CH_3CN$ complexes have been determined. In all cases the ligand is bounded to the metal ions by the nitrogen donor set of the ligand, remaining the ether oxygen atoms without participating in the coordination sphere in accordance with Pearson's *hard–soft* acid base principle. The Co(II) and the Ni(II) nitrate complexes present a mononuclear exomacrocyclic and endomacrocyclic structure, respectively, with the metal ion in an octahedral environment. The Cu(II) complex is dinuclear and the two copper atoms are exocyclically coordinated in a square planar environment.

^{1}H relaxation

ABSTRACT

The reaction of PhHgOAc with 2-NCH$_3$NCTPPH (**2**) gave a mercury(II) complex of (phenylato)(2-*N*-methyl-5,10,15,20-tetraphenyl-21-carbaporphyrinato-*N*,*N*′,*N*″)-mercury(II), [HgPh(2-NCH$_3$NCTPP); **7**]; the coordination sphere around Hg(1) in **7** was a four-coordinate derivative with a seesaw geometry and dipole–dipole (DD) interaction governed the longitudinal relaxation rate for Hg(1)–Ph–H$_{2,6}$ protons of **7** in CDCl$_3$ (0.01 M) at 599.95 MHz.

1. Introduction

Latos-Grazynski and coworkers first reported the synthesis of 2-*N*-methyl-5,10,15,20-tetraphenyl-21-carbaporphyrin, 2-NCH$_3$NCTPPH (**2**) [or 2-NCH$_3$CTPPH] [1]. Recently, Ziegler et al. reported an improved methodology for the *N*-alkylation of the porphyrin isomer *N*-confused porphyrin [2]. The combination of polar solvent and the use of Cs_2CO_3 base affords externally modified products in high yield without separation difficulties eliminating the use of large excess of alkylating reagent. In this paper, we focus on *N*-methylated N-confused porphyrin. Hence the choice of the references is restricted to *N*-methylated *N*-confused porphyrin. Compound **2** in this work was prepared in the way as described by Ziegler group using CH_3I and *p*-xylene in 48.6% yield [2] (Scheme 1). Unlike the NH tautomerism exists in NCTPPH$_2$ (**1**), the free base **2** has only one stable form. Thus, a placement of a metal ion of interest with a diamagnetic property and with I = 1/2 in a core of *N*-methylated carbaporphyrin provides a promising route to reveal the coordination modes of 2-NCH$_3$NCTPP$^-$. Hitherto, 2-NRNCTPPH (R = CH_2COOEt, CH_2CH_2Br) has been shown to coordinate metals in the core forming metal square-planar complexes possessing a carbon–metal bond (Chart 1a) for Co(II) (I = 7/2) in Co(NCTPP-CH_2COOEt)py (**3**) [2], Ni(II) (I = 3/2) in [2-(2′-CH_2CH_2Br)NCTPP]Ni^{II} (**4**) [3] and κ^3-fashion coordination type complex with Re(I) (I = 5/2) in Re (NMeNCTPP)(CO)$_3$ (**5**) [4] and with Fe(II) (I = 1/2) in (MeCTPPH)Fe^{II}Br (**6**) [5] (Chart 1b). The phenylmercury(II) cation which binds to a variety of ligand sites ranging from N, O and C atoms, serves as a good probe ion as it is unifunctional, affording complexes with a well-defined stereochemistry [6]. The coordination chemistry of phenylmercury(II) explored with anions derived from base **2** reveals the formation of the phenylmercury(II) complex of (phenylato)(2-*N*-methyl-5,10,15,20-tetraphenyl-21-carbaporphyrinato-*N*,*N*′,*N*″)-mercury(II), [HgPh(2-NCH$_3$NCTPP); **7**]. Here we described the synthesis, X-ray structure determination and spectroscopic characterization of **7**. Our understanding is that such structure-spectroscopic correlations will provide valuable info for further development of the coordination modes in inverted *N*-methylated metal porphyrin complex for metal with I = 1/2. To the best of our knowledge, compound **7** represents the first stable, diamagnetic and monomeric mercury(II) complex in *N*-confused porphyrin derivative with the HgPh$^+$ moiety and I = 1/2. In order to explain the discrepancy of Hg–H coupling constant between the proton spectra and the mercury spectra (the difference is about 8%), we discuss the relaxation effects (T_1) for the Hg(1)–Ph–H$_{2,6}$ protons of **7** in CDCl$_3$. We report herein the measurements of T_1 (^{1}H) as a function of temperature for Hg(1)–Ph–H$_{2,6}$ protons of **7** by considering the relaxation pathways with the relative roles of dipolar coupling and chemical shift anisotropy, respectively.

2. Experimental

2.1. NCH$_3$NCTPP (**2**)

Heating a solution of NCTPPH$_2$ (0.5 g, 0.81 mmol) and CH_3I (0.3 mL, 2.1 mmol) in dry *p*-xylene (10 mL) in the presence of dry Cs_2CO_3 (0.5 g, 1.5 mmol) for 2 h followed by filtration, afforded the crude product. Elution with EtOAc–CH_2Cl_2 [1:4 (v/v)] as green band on silica gel (70–230 mesh, 60 g) and removal of the solvent

and recrystallization from CH_2Cl_2–MeOH [1:2 (v/v)] gave the blue solids of **2** (0.3 g, 0.47 mmol, 48.6%).

2.2. HgPh(NCH$_3$NCTPP) [or HgPh(NCTPP-CH$_3$)] (7)

A mixture of PhHgOAc (40 mg, 0.12 mmol) and 2-NCH_3 NCTPPH (63 mg, 0.1 mmol) in pyridine (5 cm^3) was stirred at 60 °C for 2 h. After concentrating, the residue was dissolved in a suitable amount of toluene, dried over anhydrous Na_2SO_4 and filtered. The filtrate was concentrated and recrystallized from CH_2Cl_2–hexane [1:1 (v/v)] yielding blue solids of **7** (53 mg, 0.058 mmol, 58%) which was again dissolved in $CHCl_3$ and layered with hexane to get blue crystals for single crystal X-ray analysis. ^{1}HNMR (599.95 MHz, CD_2Cl_2, 20 °C): δ 8.16 [d, H_β(7), ^3J(H–H) = 4.8 Hz]; 8.06 [d, H_β(18), ^3J(H–H) = 4.8 Hz]; 7.84 [d, ^3J(H–H) = 5.1 Hz] and 7.83 [d, ^3J(H–H) = 5.1 Hz] for H_β(12) and H_β(13); 7.75 [d, H_β(8), ^3J(H–H) = 4.2 Hz]; 7.72 [d, H_β(17), ^3J(H–H) = 4.8 Hz]; Inverted *N*-methylate pyrrole ring: 2.79 [s, N-CH_3], −0.08 [d, C(2)-H, ^4J(H–H) = 1.5 Hz], 6.09 [d, C(3)–H, ^4J(H–H) = 1.5 Hz]. Hg–Ph (where Hg–Ph = the phenyl group (Ph) coordinated to Hg atom): 4.58 [d, Hg(1)–Ph–$H_{2,6}$, ^3J(H–H) = 7.8 Hz and ^3J(Hg–H) = 186.7 Hz], 6.25 [t, Hg(1)–Ph–$H_{3,5}$, ^3J(H–H) = 7.5 Hz and ^4J(Hg–H) = 48 Hz], 6.36 [t, Hg(1)–Ph–H_4, ^3J(H–H) = 7.2 Hz]. Ph: 7.99 [d, Ph–$H_{2,6}$(28, 38), ^3J(H–H) = 6.6 Hz], 7.96 [s, Ph–$H_{2,6}$(22)], 7.95 [s, Ph–$H_{2,6}$(26)], 7.89 [bs, Ph–$H_{2,6}$(32, 34)], 7.69-7.59 [m, Ph–$H_{3,5}$ and Ph–H_4]. ^{13}CNMR(150.87 MHz, $CDCl_3$, 20 °C): δ 162.0 (s) and 153.8 (s) for C_α(16, 19); 161.8 (s) and 152.0 (s) for C_α(6, 9); 157.1 (s) and 156.4 (s) for C_α(11, 14); 137.0 [s, C_{meso}(5, 20)]; 126.8 [s, C_{meso}(10, 15)]; 134.2 [s, C_β(7)]; 133.8 [s, C_β(18)], 132.6(s) and 132.2 (s) for C_β(12, 13); 131.8 [s, C_β(17)]; 131.1 [s, C_β(8)]; 148.4 [s, Hg(1)–Ph–C_1 or C(46)]; 135.3 [s, Hg(1)–Ph–$C_{2,6}$ or C(47, 51)]; 126.2 [s, Hg(1)–Ph–$C_{3,5}$ or C(48, 50)]; 125.3 [s, Hg(1)–Ph–C_4 or C(49)]; 38.3 [s, N-CH_3 or C(45)]; 131.1 [s, C(1)]; 96.6 [s, C(2)]; 129.8 [s, C(3)]; 125.1 [s, C(4)]; 136.1 [s, Ph–$C_{2,6}$ or C(22, 26)]; 134.4 [s, Ph–$C_{2,6}$ or C(28, 38)]; 133.8 [s, Ph–$C_{2,6}$ or C(32, 34)]; 128.4(s), 128.35(s), 128.1(s), 127.4(s), 127.17(s), and 127.16(s) for Ph–$C_{3,5}$ and Ph–C_4; 142.94(s), 142.87(s), 141.3(s) and 140.7(s) for Ph–C_1 [or C(21), C(27), C(33), C(39)]. ^{199}Hg NMR (107.24 MHz, $CDCl_3$, 20 °C): δ −1037 [t, Hg(1), ^3J(Hg–H) = 172 Hz]. Fig. 1. Molecular configuration and atom-labeling scheme for **7** · 0.5 C_6H_{14} · $CHCl_3$ · CH_2Cl_2 · H_2O, with ellipsoids drawn at 30% probability. Hydrogen atoms and solvents (0.5 C_6H_{14}, $CHCl_3$, CH_2Cl_2 and H_2O) are omitted for clarity.

0.5 M phenylmercury(II) acetate in DMSO-d_6 (−1439.5 ppm) but reported relative to dimethylmercury (0.0 ppm). HMQC (heteronuclear multiple quantum coherence) was used to correlate protons and carbon through one-bond coupling and HMBC (heteronuclear multiple bond coherence) for two- and three-bond proton–carbon coupling. Nuclear Overhauser effect (NOE) difference spectroscopy was employed to determine the ^1H–^1H proximity through space over a distance of up to about 4 Å.

The positive ion fast atom bombardment mass spectrum (FAB MS) was obtained in a nitrobenzyl alcohol (NBA) matrix using a JEOL JMS-SX/SX 102 A mass spectrometer. UV–Vis spectra were recorded at 20 °C on a HITACHI U-3210 spectrophotometer.

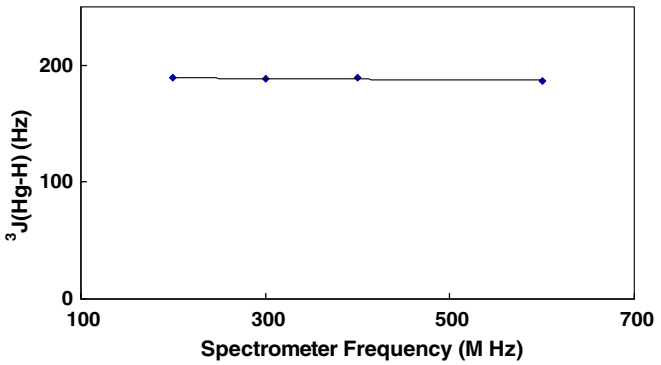

Fig. 3. Frequency (or field) dependence of ^3J(Hg–H) coupling constants for Hg(1)–Ph–$H_{2,6}$ of **7** in $CDCl_3$ (0.01 M) at 20 °C.

2.4. Crystallography

Table 1 presents the crystal data as well as other information for **7** · $0.5C_6H_{14}$ · $CHCl_3$ · CH_2Cl_2 · H_2O. Measurement was taken on a Bruker AXS SMART-1000 diffractometer using monochromatized Mo Kα radiation (λ = 0.71073 Å). Empirical absorption correction was made for **7** · 0.5 C_6H_{14} · $CHCl_3$ · CH_2Cl_2 · H_2O. The structure was solved by direct methods (SHELXTL-97) [7] and refined by the full-matrix least-squares method. One equivalent of CH_2Cl_2 solvent in **7** · $0.5C_6H_{14}$ · $CHCl_3$ · CH_2Cl_2 · H_2O is disordered with an occupancy factor of 0.57 [or 0.6] for Cl(4′) [or Cl(5)] and 0.43 [or 0.4] for Cl(4) [or Cl(5′)], respectively. All non-hydrogen atoms were refined with anisotropic thermal parameters, whereas all hydrogen atoms were placed in calculated positions and refined with a riding model. Table 2 lists selected bond distances and angles for **7** · $0.5C_6H_{14}$ · $CHCl_3$ · CH_2Cl_2 · H_2O.

3. Results and discussion

3.1. Molecular structure of 7

Using the d^{10} metal mercury(II), new mononuclear mercury **7** complex was synthesized. The synthetic strategy is outlined in Scheme 1.

During the metallation of free base **2** with PhHg(OAc) (Scheme 1), the soft acid Hg^{2+} prefers to retain one phenyl ligand (soft base)

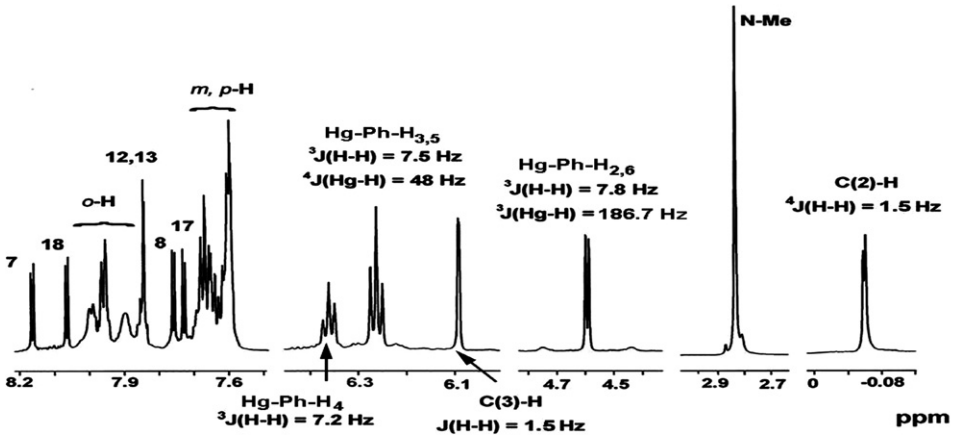

Fig. 2. ^1H NMR spectra at 599.94 MHz for a 0.01 M solution of **7** in CD_2Cl_2 at 20 °C.

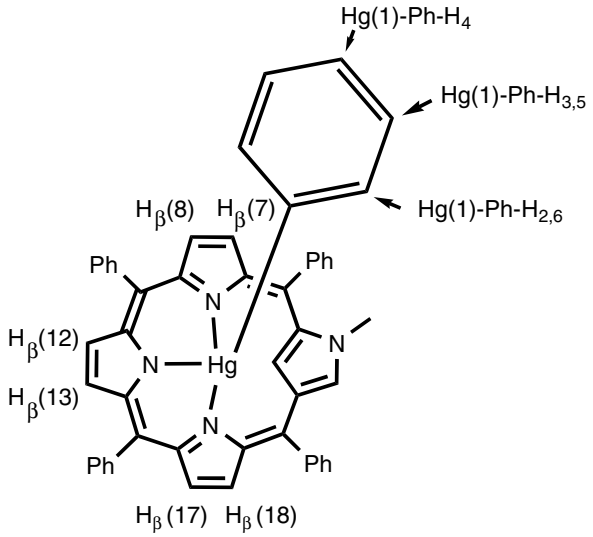

(7)

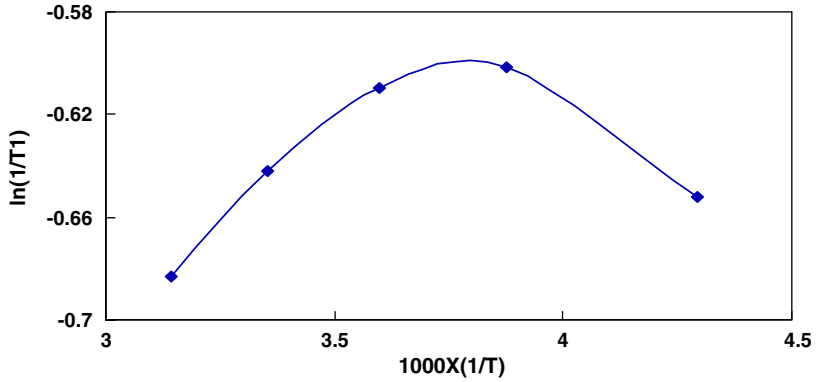

Fig. 4. Temperature dependence of ^{1}H spin-lattice relaxation rate for Hg(1)–Ph–$H_{2,6}$ of **7** in $CDCl_3$ (0.01 M) at 599.95 MHz.

and coordinates to the N [i.e., N(2)] of **2** to form a four-coordinate complex **7** with a seesaw geometry and the angle of N(2)–Hg(1)–C(46) in **7** is 171.3(3)° (Table 2).

The molecular structural information of **7** was elucidated by X-ray crystallographic analysis (Fig. 1 and Tables 1 and 2). In **7**, tripyrran (or tri-pyrrole) moiety coordinated to the metal center in κ^3-fashion and the mercury metal further has one phenyl ligand. The rest pyrrole ring was tilted from the porphyrin mean plane, consisting of $C_{20}N_4$ atoms, at 26.5° for **7**, so as to avoid steric repulsion. The metal–ligand bond distances and the angles are summarized in Table 2. The covalent bond of Hg(1)–C(46) = 2.058 (9) Å in **7** is smaller than the sum of the covalent radii of Hg and C (2.26 Å). The mercury nitrogen bond distances [Hg(1)–N(1) = 2.581(8), Hg(1)–N(2) = 2.130(7), and Hg(1)–N(3) = 2.607(8) Å] in **7** are well below the upper limit of a typical Hg–N covalent bond [2.75(2) Å] [8]. The C(2) is no longer bonded to Hg(1) in **7** as indicated by their longer internuclear distances, 3.057(7) Å for Hg(1)···C(2) in **7**. Hence, C(46), N(1), N(2), and N(3) are bonded covalently to the Hg(1) atom in **7** and the Hg(1)···C(2) and Hg(1)···H(2A) distances are 3.057(7) and 2.821(7) Å. These values are in the similar magnitude as compared to the van der Waals contact (3.15–3.20 Å for Hg···C and 2.70–2.95 Å for Hg ···H) [9]. Thus, these two distances do not support the formation of a weak agostic bond for Hg(1)···H(2A). The value of 95.7(3)° for Hg(1)–H(2A)–C(2) angle is well outside the reported range for a "truly agostic" type of bond. Furthermore, the satellite doublet signals with J(Hg–H) coupling for the resonance of C(2)–H was not observed. Thus the overall Hg(II) complex of **7** is not a side-on η^1-coordination type complex [10]. Since the three remaining nitrogen atoms and the Ph group are linked to the Hg(II) cation, the structure of **7** in inverted *N*-methylated porphyrin is similar to that

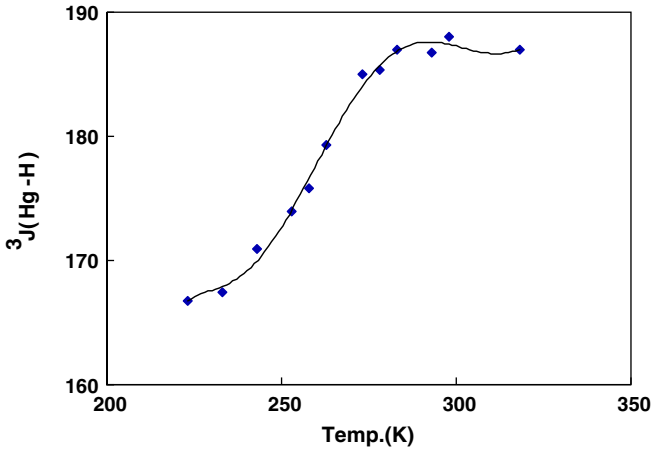

Fig. 5. Temperature dependence of observed ^{3}J(Hg–H) coupling constant for Hg(1)–Ph–$H_{2,6}$ of **7** in $CDCl_3$ (0.01 M) at 599.95 MHz.

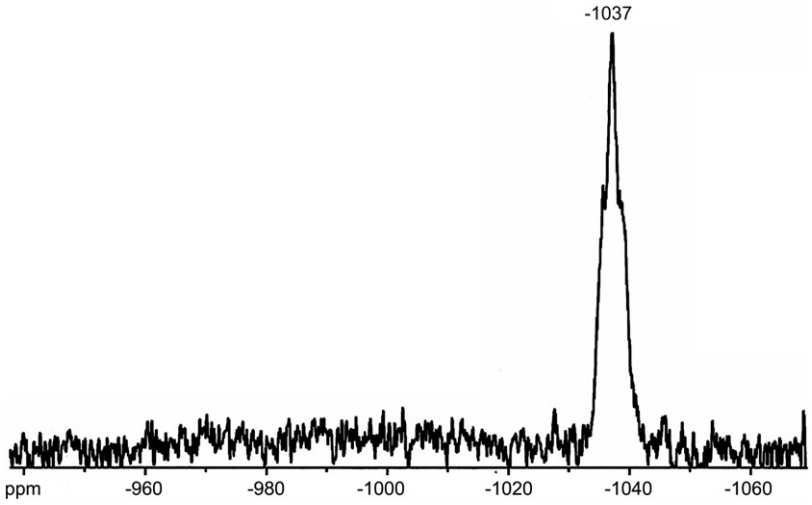

Fig. 6. ^{199}Hg NMR spectra at 107.24 MHz for a 0.2 M solution of **7** in $CDCl_3$ at 20 °C.

of HgPh(*N*-NHCO-2-C_4H_3S-TPP) (**8**) in the normal porphyrin derivatives with one inner nitrogen atom of the porphyrin being functionalized [6].

3.2. ^{1}H NMR for 7 in CD_2Cl_2

Complex **7** was characterized by ^{1}H, ^{13}C and ^{199}Hg NMR spectra. In solution, the molecule has effective C_s symmetry with a mirror plane running through the Hg(1)–C(22)–N(2)–C(2) unit for **7**. As a result, the ^{1}H NMR spectrum will exhibit six pyrrole resonances [H_β(7), H_β(18), H_β(12), H_β(13), H_β(8), H_β(17)] for **7** (Fig. 2). The ^{1}H NMR indicates that the aromatic protons of Hg(1)–Ph in **7** appears as a doublet at 4.58 ppm with a coupled satellites ^3J(Hg–H) of 186.7 Hz for Hg(1)–Ph–$H_{2,6}$, a triplet at 6.25 ppm with ^4J(Hg–H) of 48 Hz for the Hg(1)–Ph–$H_{3,5}$, and a triplet at 6.36 ppm for Hg(1)–Ph–H_4 of **7** in CD_2Cl_2 at 20 °C (Fig. 2). The methyl of **7** gives the resonance at 2.79 ppm (CD_2Cl_2, 293 K) strongly upfield of the signal that free base 2-NCH_3NCTPPH exhibits (3.31 ppm). The outer C(3)–H proton (δ = 6.09 ppm) is scalar coupled [^4J(H–H) = 1.5 Hz] to inner C(2)–H proton (δ = −0.08 ppm) (Fig. 2). Non-equivalence of the two sides of the macrocycle will cause each phenyl ring to have two distinct *ortho* resonances with one set of *ortho* protons *o*-H(28, 38), *o*-H(32, 34), for phenyl C(30) and C(36) and the other set of *ortho* protons *o*′-H(22,44), *o*′-H(26,40), for phenyl C(24) and C(42), unless the rotation around the C_{meso}–C_1 [C(10)–C(27), C(15)–C(33) or C(5)–C(21), C(20)–C(39)] bond is sufficiently fast in **7** (Fig. 2).

$(T_1)^{-1} = R_1$ is in general a sum of four contributions;

$(T_1)_{obs}^{-1} = (T_1)_{SR}^{-1} + (T_1)_{DD}^{-1} + (T_1)_{CSA}^{-1} + (T_1)_{SC}^{-1}$ corresponding to relaxation arising from the spin–rotation interaction, nuclear dipole–dipole coupling, chemical shift anisotropy, and scalar coupling [11]. $(T_1)_{CSA}^{-1}$ and $(T_1)_{SC}^{-1}$ are field dependent contributions which vary, respectively, as H_0^2 and H_0^{-2}(H_0 is the external field strength) [11]. The apparent coupling constant ^3J(Hg–H) for Hg(1)–Ph–$H_{2,6}$ of **7** in $CDCl_3$ at 20 °C is independent of the magnetic field strength implicating that chemical shift anisotropy (CSA) and scalar coupling (SC) are not the sources of the ^{1}H relaxation in the extreme narrowing conditions (Fig. 3). The temperature dependence of $(T_1)^{-1}$ for Hg(1)–Ph–$H_{2,6}$ in $CDCl_3$ at 599.95 MHz (Fig. 4) indicates the substantial contribution from dipole–dipole (DD) interaction in the −40 °C to +45 °C temperature range. This DD interaction is due to the coupling between [Hg(1)–Ph–$H_{2,6}$] protons and [Hg(1)] metal. In addition to the above magnetic field independence of the coupling constants, strong temperature dependence is observed. Specifically, the ^3J(Hg–H) coupling constants are maximum close at room temperature as illustrated in Fig. 5. Since the dipole–dipole interactions (DD) are the major contributors to the ^{1}H T_1 relaxation, these interactions indicate that the increase of temperature [12] leads to reduced T_1^{-1} (^{1}H) for Hg(1)–Ph–$H_{2,6}$ through a decrease of rotational correlation time (τ_c) during the fast motion regime. This decrease in T_1 relaxation rate explains that ^3J(Hg–H) increases from 166.7 to 186.7 Hz when temperature is increased from −50 °C to 20 °C (Fig. 5).

3.3. ^{199}Hg NMR for 7 in $CDCl_3$

The ^{199}Hg spectra at 20 °C shows a triplet signal at −1037 ppm with ^3J(Hg–H) = 172 Hz for a 0.2 M solution of **7** in $CDCl_3$, which is near to −1074 ppm, the position of the Hg(2) signal observed for a 0.05 M solution of [$(HgPh)_2$(*N*-*p*-$NSO_2C_6H_4{}^t$Bu-TPP); **9**] in $CDCl_3$, (Fig. 6) [6]. Hence the signal at δ −1037 ppm of **7** is due to Hg(1) nucleus with a coordination number of four. The chemical shift anisotropy (CSA) relaxation mechanism is a dominant contribution to ^{199}Hg spin-lattice relaxation in **7** [13]. The high field NMR spectroscopy, at 14.1 T [ν_o(Hg) = 107.24 MHz], may lead to very rapid relaxation. In the case of spin–spin coupling this can cause line broadening for neighboring nuclei or even ^{199}Hg–H decoupling [12,14,15]. This rapid relaxation of **7** obtained from its proton spectra in $CDCl_3$ at 20 °C (^3J(Hg–H) of 186.7 Hz for the Hg(1)–Ph–$H_{2,6}$ protons) is larger than that of mercury spectra (172 Hz), which gives the difference of about 15 Hz (8%).

4. Conclusions

The metal complex **7** bearing κ^3-porphyrin ligand with coordination environment [*N*,*N*, *N*, *C*(axial)] was synthesized. Compound **7** has been characterized by X-ray crystallography and NMR. Longitudinal relaxation rate composed of dipolar contribution for the Hg(1)–Ph–$H_{2,6}$ of **7** in 0.01 M solution was discussed.

Appendix A. Supplementary data

CCDC 674872 contains the supplementary crystallographic data for **7**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033 or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

The systematic investigation of the parameter space of the $CuCl_2/H_2mal/phen$ reaction system in MeOH resulted in the isolation of seven different complexes either as mixtures or in pure form, six of which have been structurally characterized. The molar ratios of the reactants and the crystallization methods have been systematically varied, leading to the isolation of compounds $[Cu(H_2O)(phen)(mal)]$ (**1**), $[Cu(MeOH)(phen)(mal)]$ (**2**), $[Cu_2Li_2Cl_2(phen)_2(mal)_2(MeOH)_4]$ (**3**), $[Cu_2(phen)_4(mal)][CuCl(phen)(mal)](OH)$ (**4**), $[CuCl(phen)_2]Cl$ (**5**), and $[CuCl(phen)(mal)][CuCl(phen)_2][Cu(phen)_2(Hmal)]Cl$ (**6**). The coordination versatility of the malonato ligand has been confirmed by the presence of three different coordination modes and its two deprotonation states in compounds **1**–**6**. Solution studies on methanolic solutions of **2**–**4** and **6** by mass spectrometry revealed the absence of parent ion peak and the presence of fragment ions of low relative abundance not previously found in their crystal structure, thus indicating decomposition and rearrangement/reorganization of the complexes in solution and confirming the dynamic character of their solutions. Compounds **3** and **4** have been also studied in the solid state by EPR spectroscopy and magnetic measurements.

1. Introduction

The coordination chemistry of the aliphatic α-ω dicarboxylates of the general formula $^-OOC–(CH_2)_n–COO^-$ has been widely investigated because it has found to exhibit a high coordination versatility. This is mainly due to (i) the presence of two carboxylato groups, (ii) the conformational freedom of the carbon skeleton (for $n \geqslant 1$), giving rise to various relative orientation of the two carboxylato moieties, (iii) the possibility to obtain mono- or di-anionic forms, (iv) the probability of triply coordinated oxygen atoms, and (v) the possibility to form secondary building blocks [1]. Thus, while oxalates ($n = 0$, H_2ox), act as rigid bridging ligands, giving rise to structures with dimensionalities ranging from zero to three [2], with the 2D honeycomb structure being the predominant one [3], the malonato ion ($n = 1$, H_2mal), offers the additional advantage of the relative location of the two carboxylato groups in the 1,3 positions supporting simultaneous chelating bidentate and various carboxylato-bridging coordination modes, thus leading to structures with variable architectures [4]. When combined with other bridging and/or chelating ligands, the malonato ion has afforded mononuclear, dinuclear, trinuclear, tetranuclear as well as 1D, 2D and 3D structures [5–11].

One of our areas of interest lies in the field of structure/properties relationship. For that purpose we have been embarked on the systematic exploration of the parameter space of reaction systems involving first-row transition-metal ions and various ligands, by varying several "degrees of freedom", like ligand substituents [12], solvent [13], crystallization method [14], as well as reactivity of metal clusters [15]. The isolation of one – or more – products from these systems in a pure form is also of prime importance, since a parallel area of interest is the physical study of these products in the solid state. The coordination versatility of the malonato ligand and its substituted derivatives, which can lead to novel metal ion topologies and cluster nuclearities bearing interesting physical properties, has prompted us to investigate their coordination chemistry. We have previously reported our results concerning the copper(II) coordination chemistry of methyl-malonic acid ($HOOC–CH(CH_3)–COOH$) in the presence of 1,10-phen and 2,2′-bpy [16]. Herein we present a systematic investigation of the parameter space of the $CuCl_2/H_2mal/phen$ reaction system in MeOH, and we examine the products that result from variations of two "degrees of freedom", i.e. the reaction mixture stoichiometry and the crystallization method (Table 1). Apart from crystallographic studies of products that result as single-crystals, we

Table 1
The crystallographically characterized products from the $CuCl_2/H_2mal/phen$ reaction system in MeOH

Complex	Formula
1	$[Cu(H_2O)(phen)(mal)] \cdot H_2O$
2	$[Cu(MeOH)(phen)(mal)]$
3	$[Cu_2Li_2Cl_2(phen)_2(mal)_2(MeOH)_4]$
4	$[Cu_2(phen)_4(mal)][CuCl(phen)(mal)](OH) \cdot 4.4(MeOH) \cdot 0.4(H_2O)$
5	$[CuCl(phen)_2]Cl \cdot MeOH$
6	$[CuCl(phen)(mal)][CuCl(phen)_2][Cu(phen)_2(Hmal)]Cl \cdot 2MeOH \cdot 2H_2O$

conduct solution studies of some of the isolated products by means of mass spectrometry.

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials as received (Aldrich Co.). All chemicals and solvents were of reagent grade. Elemental analysis for C, H, and N was performed on a Perkin Elmer 2400/II automatic analyzer. IR spectra were recorded from KBr pellets in the range 4000–400 cm^{-1} on a Bruker Equinox 55/S FT-IR spectrophotometer. Electron-spray ionization mass spectra of **2**–**4** and **6** were recorded on an AQA Navigator, Finnigan mass spectrometer. Test solutions in 50% aqueous methanol were infused into the electrospray interface at a flow rate of 0.1 mL min^{-1}, using a Harvant Syringe pump. Negative or positive ion ESI spectra were acquired by adjusting the needle and cone voltages accordingly. Hot nitrogen gas (Dominic-Hunter UHPLCMS-10) was used for desolvation at 170 °C. Variable-temperature magnetic susceptibility measurements were carried out on polycrystalline samples of **3** and **4** in the 5.0–300 K temperature range using a Quantum Design MPMS SQUID magnetometer under a magnetic field of 1 T. Diamagnetic corrections for the complexes were estimated from Pascal's constants. The magnetic susceptibility has been computed by exact calculation of the energy levels associated with the spin Hamiltonian, through diagonalization of the full matrix with a general-symmetry program [17]. Least-squares fittings were accomplished with an adapted version of the function-minimization program MINUIT [18]. The error factor R is defined as $R = \sum \frac{(\chi_{exp} - \chi_{calc})^2}{N\chi^2_{exp}}$, where N is the number of experimental points. X-band EPR spectra were recorded on a Bruker ER 200D EPR spectrometer equipped with an Oxford Instruments ESR900 cryostat, a Bruker NMR Gaussmeter and an Anritsu microwave frequency counter.

2.2. Compound preparation

2.2.1. $[Cu(H_2O)(phen)(mal)] \cdot H_2O$ (**1** $\cdot H_2O$)

Solid phen $\cdot H_2O$ (0.099 g, 0.50 mmol) and $CuCl_2 \cdot 6H_2O$ (0.085 g, 0.50 mmol) were added to a refluxing solution of H_2mal (0.052 g, 0.50 mmol) and LiOH $\cdot H_2O$ (0.042 g, 1.0 mmol) in methanol (20 mL). The colour of the solution immediately turned to sky-blue and the reflux continued for 15 min, during which time no noticeable colour change or solid precipitation was observed. Slow evaporation of the sky-blue solution afforded large X-ray quality blue prismatic crystals of **1** after 4 days (yield: 0.013 g, 7.14%). The crystals were collected by filtration and dried *in vacuo*. The resulting powder was analyzed as solvent-free. *Anal.* Calc. for $C_{15}H_{12}CuN_2O_5$: C, 49.52; H, 3.32; N, 7.70. Found: C, 49.37; H, 3.34; N, 7.66%. FT-IR (KBr discs, cm^{-1}): 3480(m), 3050(s), 2980(sh), 2910(sh), 1590(vs), 1520(vs), 1495(sh), 1428(s), 1380(vs), 1340(s), 1282(s), 1224(m), 1209(m), 1143(m), 1110(m), 1050(m), 1033(m), 980(m), 955(m), 855(vs), 792(w), 778(m), 725(vs), 645(m), 430(m).

2.2.2. [Cu(MeOH)(phen)(mal)] (**2**)

2.2.2.1. Method A. A procedure same as for the synthesis of **1** was followed and X-ray quality blue prismatic crystals of **2** were obtained by layering of Et_2O (2:1 v/v) to the sky-blue reaction solution (yield: 0.015 g, 7.94%). The crystals were collected by filtration and dried *in vacuo*. *Anal.* Calc. for $C_{16}H_{14}CuN_2O_5$: C, 50.86; H, 3.73; N, 7.41. Found: C, 50.70; H, 3.71; N, 7.38%. FT-IR (KBr discs, cm^{-1}): 3490(s), 3407(vs), 3279(s), 3050(s), 2980(sh), 2910(sh), 1592(vs), 1520(vs), 1494(sh), 1428(s), 1381(vs), 1364(sh), 1343(s), 1282(s), 1224(m), 1209(m), 1144(m), 1108(m), 1049(m), 1033(m), 981(m), 955(m), 855(vs), 792(w), 779(m), 725(vs), 647(m), 430(m).

2.2.2.2. Method B. Solid phen $\cdot H_2O$ (0.049 g, 0.25 mmol) and $CuCl_2 \cdot 6H_2O$ (0.043 g, 0.25 mmol) were added to a refluxing solution of H_2mal (0.052 g, 0.50 mmol) and LiOH $\cdot H_2O$ (0.042 g, 1.0 mmol) in methanol (20 mL). The colour of the solution immediately turned to sky-blue and the reflux continued for 15 min, during which time no noticeable colour change or solid precipitation was observed. X-ray quality blue prismatic crystals of **2** were obtained either by layering or by vapour diffusion of Et_2O (2:1 v/v) to the reaction mixture. The identity of the products in each case was established by unit cell determination [a = 7.074(9), b = 11.84(2), c = 18.38(2) Å, β = 95.35(4)°, V = 1533(6) $Å^3$ (crystals from vapour diffusion) and a = 7.09(2), b = 11.86(3), c = 18.40(4) Å, β = 95.51 (3)°, V = 1540(10) $Å^3$ (crystals from layering), see Table 2].

2.2.3. $[Cu_2Li_2Cl_2(phen)_2(mal)_2(MeOH)_4]$ (**3**)

2.2.3.1. Method A. A procedure same as for the synthesis of **1** was followed, and X-ray quality light-blue crystals of **3** (yield: 0.015 g, 3.32%), along with large blue prismatic crystals of **2**, were obtained by vapour diffusion of Et_2O (2:1 v/v) to the sky-blue reaction solution. The crystals were separated manually and dried *in vacuo*. *Anal.* Calc. for $C_{34}H_{36}Cl_2Cu_2Li_2N_4O_{12}$: C, 45.15; H, 4.01; N, 6.19. Found: C, 45.01; H, 3.99; N, 6.17%. FT-IR (KBr discs, cm^{-1}): 3426(vs), 3066(sh), 1618(vs), 1518(s), 1489(m), 1421(vs), 1342(sh), 1331(s), 1312(sh), 1272(sh), 1252(sh), 1217(m), 1198(w), 1165(m), 1140(s), 1105(m), 1050(w), 1035(w), 1002(w), 970(s), 947(m), 874(m), 852(vs), 837(m), 785(m), 725(vs), 649(w), 577(s), 493(w), 472(w), 430(w).

2.2.3.2. Method B. Solid phen $\cdot H_2O$ (0.099 g, 0.50 mmol) and $CuCl_2 \cdot 6H_2O$ (0.128 g, 0.75 mmol) were added to a refluxing solution of H_2mal (0.052 g, 0.50 mmol) and LiOH $\cdot H_2O$ (0.042 g, 1.0 mmol) in methanol (20 mL). The colour of the solution immediately turned to sky-blue and the reflux continued for 15 min, during which time no noticeable colour change or solid precipitation was observed. X-ray quality light-blue prismatic crystals of **3**, along with small portions of a green powder, were obtained either by layering or by vapour diffusion of Et_2O (2:1 v/v) to the reaction mixture. The identity of the product was established by unit cell determination (a = 8.40(1), b = 8.75(2), c = 14.32(2) Å, α = 84.10 (4)°, β = 76.65(4)°, γ = 69.93(4)°, V = 962(6) $Å^3$, see Table 2).

2.2.4. $[Cu_2(phen)_4(mal)][CuCl(phen)(mal)](OH) \cdot 4.4(MeOH) \cdot 0.4(H_2O)$ (**4** $\cdot 4.4MeOH \cdot 0.4H_2O$)

2.2.4.1. Method A. Solid phen $\cdot H_2O$ (0.099 g, 0.50 mmol) and $CuCl_2 \cdot 6H_2O$ (0.043 g, 0.25 mmol) were added to a refluxing solution of H_2mal (0.052 g, 0.50 mmol) and LiOH $\cdot H_2O$ (0.042 g, 1.0 mmol) in methanol (20 mL). The colour of the solution immediately turned to sky-blue and the reflux continued for 15 min, during which time a white precipitate was formed and removed by filtration. X-ray quality blue-turquoise crystals of **4** were obtained by slow vapour diffusion of Et_2O (2:1 v/v) to the sky-blue reaction solution (yield: 0.049 g, 14.47%). The same reaction mixture when layered with Et_2O (2:1 v/v) leads to the formation of a mixture of **2**

and **3**. The crystals of **4** were collected by filtration and dried *in vacuo*. The resulting powder was analyzed as solvent-free. *Anal.* Calc. for $C_{66}H_{51}ClCu_3N_{10}O_9$: C, 58.54; H, 3.80; N, 10.34. Found: C, 58.36; H, 3.81; N, 10.31%. FT-IR (KBr discs, cm^{-1}): 3406(vs), 3053 (m), 1582(vs), 1518(vs), 1494(w), 1427(vs), 1355(m), 1341(m), 1247(w), 1224(w), 1144(w), 1105(w), 959(w), 938(w), 851(vs), 779(w), 723(vs), 648(m), 428(w).

2.2.4.2. Method B. Solid phen · H_2O (0.099 g, 0.50 mmol) and $CuCl_2 \cdot 6H_2O$ (0.043 g, 0.25 mmol) were added to a refluxing solution of H_2mal (0.026 g, 0.25 mmol) and LiOH · H_2O (0.021 g, 0.50 mmol) in methanol (20 mL). The colour of the solution immediately turned to sky-blue and the reflux continued for 15 min, during which time no noticeable colour change or solid precipitation was observed. X-ray quality blue-turquoise crystals of **4** were obtained by layering of Et_2O (2:1 v/v) to the reaction mixture. The identity of the crystals was established by FT-IR spectroscopy.

2.2.4.3. Method C. Solid phen · H_2O (0.165 g, 0.83 mmol) and $CuCl_2 \cdot 6H_2O$ (0.085 g, 0.50 mmol) were added to a refluxing solution of H_2mal (0.034 g, 0.33 mmol) and LiOH · H_2O (0.028 g, 0.66 mmol) in methanol (20 mL). The colour of the solution immediately turned to sky-blue and the reflux continued for 15 min, during which time no noticeable colour change or solid precipitation was observed. X-ray quality blue-turquoise crystals of **4**, along with blue prismatic crystals of **2**, light-blue prismatic crystals of **3**, green prismatic crystals of **5** and green needle-like crystals of **7**, were obtained by vapour diffusion of Et_2O (2:1 v/v) to the sky-blue reaction mixture. The crystals were separated manually and they were identified by FT-IR spectroscopy.

*2.2.5. [CuCl(phen)$_2$]Cl · MeOH (**5** · MeOH)*

A procedure as for the synthesis of **4** was followed (Method A), the only difference being the rapid rate of vapour diffusion of Et_2O to the sky-blue reaction mixture. As a result a mixture of large X-ray quality green prismatic crystals of **5**, blue-turquoise crystals and light-green needle-like crystals was formed which were separated manually. The blue-turquoise crystals and the light-green needles were identified by FT-IR spectroscopy as **4** and as a copper phenanthrolinato complex (**7**), respectively. Compounds **5** and **7** present similar infrared spectra (see below) and presumably they have analogous molecular structures with different unit cell parameters and/or solvate molecules. The crystals of **5** were separated manually and were dried *in vacuo*. The resulting powder was analyzed as solvent-free. *Anal.* Calc. for $C_{24}H_{16}Cl_2Cu_2N_4$: C, 51.62; H, 2.89; N, 10.03. Found: C, 51.46; H, 2.88; N, 9.99%. FT-IR (KBr discs, cm^{-1}) for **5**: 3521(m), 3364(m), 2987(m), 1625(m), 1605(m), 1583(m), 1518(vs), 1494(m), 1427(vs), 1339(m), 1309(w), 1227 (m), 1209(w), 1144(m), 1105(m), 1034(w), 956(vw), 911(vw), 869(sh), 856(vs), 782(m), 723(vs), 649(m), 614(m), 588(m), 428 (m). FT-IR (KBr discs, cm^{-1}) for **7**: 3416(vs), 3051(w), 2921(w), 1626(m), 1605(w), 1584(m), 1518(s), 1494(w), 1427(vs), 1339(w), 1308(w), 1225(w), 1144(m), 1105(m), 869(sh), 852(vs), 780(m), 723(vs), 648(w), 429(w).

*2.2.6.[CuCl(phen)(mal)][CuCl(phen)$_2$][Cu(phen)$_2$(Hmal)]Cl · 2MeOH · 2H$_2$O (**6** · 2MeOH · 2H$_2$O)*

2.2.6.1. Method A. Solid phen · H_2O (0.099 g, 0.50 mmol) and $CuCl_2 \cdot 6H_2O$ (0.043 g, 0.25 mmol) were added to a refluxing solution of H_2mal (0.026 g, 0.25 mmol) and LiOH · H_2O (0.021 g, 0.50 mmol) in methanol (20 mL). The colour of the solution immediately turned to sky-blue and the reflux continued for 15 min, during which time no noticeable colour change or solid precipitation was observed. X-ray quality blue-turquoise crystals of **6** were obtained by slow vapour diffusion of Et_2O (2:1 v/v) to the sky-blue reaction solution (yield: 0.020 g, 5.70%), along with large green crystals and light green needle-like crystals which were identified as **5** and **7**, respectively, by FT-IR spectroscopy. The crystals of **6** were separated manually and dried *in vacuo*. The resulting powder was analyzed as solvent-free. *Anal.* Calc. for $C_{66}H_{45}Cl_3Cu_3N_{10}O_8$: C, 56.50; H, 3.23; N, 9.98. Found: C, 56.33; H, 3.24; N, 9.95%. FT-IR (KBr discs, cm^{-1}): 3347(s), 3058(m), 2930(sh), 2817(w), 1714(s), 1605(vs), 1583(sh), 1518(vs), 1493(m), 1428(vs), 1372(m), 1340 (m), 1274(m), 1255(w), 1225(w), 1208(w), 1152(m), 1106(m), 1030(m), 999(vw), 970(w), 938(w), 912(w), 869(sh), 851(vs), 779 (w), 724(vs), 672(w), 648(m), 582(w), 507(w), 474(w), 429(m).

2.2.6.2. Method B. The procedure was the same as above but 0.25 mmol of LiOH · H_2O were used instead. Layer or slow vapour diffusion of Et_2O (2:1 v/v) to the sky-blue solution afforded blue-turquoise crystals of **6** whose identity was confirmed by unit cell determination. (a = 14.05(1), b = 15.18(2), c = 17.22(2) Å, α = 68.28(3)°, β = 74.44(3)°, γ = 72.89(3)°, V = 3209(9) Å^3, see below, X-ray crystallography).

2.3. Single-crystal X-ray crystallography

Blue prismatic crystals of **1** (0.10 × 0.30 × 0.70 mm) and **2** (0.30 × 0.40 × 0.70 mm) were mounted in air. A light-blue prismatic crystal of **3** (0.30 × 0.40 × 0.70 mm), a blue-turquoise crystal of **4** (0.15 × 0.50 × 0.70 mm), a green crystal of **5** (0.15 × 0.30 × 0.55 mm) and a blue-turquoise crystal of **6** (0.15 × 0.30 × 0.60 mm) were mounted in capillaries. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo radiation (for **1**–**3**, **5** and **6**) and on a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic using graphite monochromated Cu radiation (for **4**). Important crystal data and parameters for data collection for **2**–**4** are reported in Table 2. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$ (for **1**–**3**, **5** and **6**) and in the range $22° < 2\theta < 54°$ (for **4**). Three standard reflections monitored every 97 reflections showed less than 3% intensity fluctuation and no decay. Lorentz, polarization and psi-scan absorption corrections (for **4** only) were applied using Crystal Logic software. The structures were solved by direct methods using SHELXS-97 [19] and refined by full matrix least-squares techniques on F^2 with SHELXL-97 [20]. For compounds **1**, **5** and **6** only preliminary crystallographic determination was performed. The molecular structures of **1** and **5** are known, although in different space groups, but their characterization was crucial from the chemical point of view in terms of the species isolated from the reaction mixture examined. Thus we felt that the complete structural characterization of **1** and **5** would not add any further potential to our investigation. On the other hand, the crystals of the new compound **6** were of poor quality showing large ω-widths with shoulders on one side, a fact that is also reflected to the quality of the crystallographic data (see below), while our repeating efforts to improve the quality of the crystals of **6** were unsuccessful. Even so, the structural characterization of **6** was valuable, since complex **6** constitutes the only isolated species containing the $Hmal^-$ anion; an observation very helpful for the interpretation of the Mass Spectra (see below). Further experimental crystallographic details for **1** · H_2O: $C_{15}H_{15}CuN_2O_6$; f_w = 382.83; space group triclinic $P\bar{1}$; a = 8.093(6) Å, b = 11.017(8) Å, c = 17.66 (1) Å, α = 88.39(3)°, β = 79.82(3)°, γ = 74.94(2)°, V = 1503.18 Å^3, Z = 4; ρ_{calc} = 1.692 g cm^{-3}; μ(Mo Kα) = 1.49 mm^{-1}; T = 25 °C; $2\theta_{max}$ = 34°; scan speed 4.0°/min; scan range 1.6 + $\alpha_1\alpha_2$ separation; reflections collected/unique/used, 1949/1754 [R_{int} = 0.0091]/1754; 273 parameters refined; $(\Delta/\sigma)_{max}$ = 0.004; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.506/−0.294 e/Å^3; R_1/wR_2 for 1670 reflections with $I > 2\sigma(I)$, (for all data), 0.0497/0.1306, (0.0522/0.1363). All non-H atoms were refined anisotropically, except of the solvate molecules and those of the [Cu(phen)$_2$(Hmal)]$^+$ cation which were refined isotropically (only the copper ion was refined anisotropically). No H-atoms were included in the refinement.

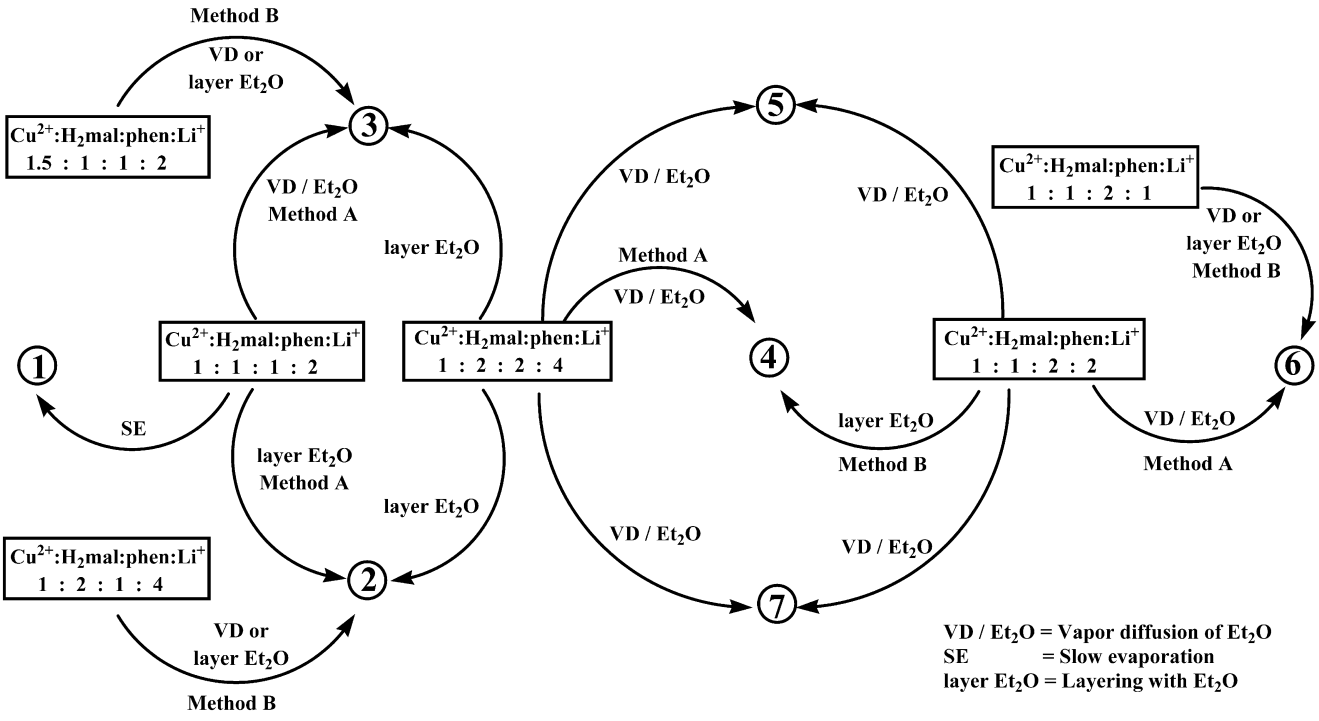
3. Results and discussion

3.1. Syntheses

In order to explore the parameter space of the $CuCl_2$/H_2mal/phen reaction system in methanol, we first employed the 1:1:1 molar ratio reaction in the presence of stoichiometric amounts of LiOH · H_2O to ensure deprotonation of the malonic acid. Three species have been isolated from the same sky-blue reaction mixture depending on the crystallization method employed: (i) slow evaporation afforded the mononuclear complex [Cu(H_2O)(phen)(mal)] (**1**), (ii) layering of Et_2O afforded the analogous mononuclear complex [Cu(MeOH)(phen)(mal)] (**2**) (see Section 2, Method A), and (iii) vapour diffusion of Et_2O led to the heterometallic tetranuclear complex [$Cu_2Li_2Cl_2$(phen)$_2$(mal)$_2$(MeOH)$_4$] (**3**) (see Section 2, Method A). The 1:1:1 stoichiometry initially employed in the Cu^{II}/H_2mal/phen reaction system is reflected to the stoichiometry of the three products. A summary of the reactions employed and the complexes isolated is depicted in Scheme 1.

To further explore the parameter space of the above reaction system we varied the molar ratios of the reactants, first by systematically increasing each one's molar ratio, leaving at the same time all other parameters unchanged. Thus, the 1.5:1:1 respective molar ratio led to the isolation of complex **3** regardless of the crystallization method (see Section 2, Method B) along with small portions of green powder which is probably a copper(II) phenanthrolinato complex (based on its colour). The excess of the Cu^{II} ions in the reaction mixture is not reflected to the Cu^{II}/H_2mal/phen stoichiometry in **3**, but it promoted the isolation of a non-malonato complex (green powder). The 1:2:1 respective molar ratio led to **2** regardless of the crystallization method (see Section 2, Method B). Thus, excess of H_2mal in the reaction mixture afforded exclusively **2** without 'pushing' the equilibrium to the isolation of other complexes from the reaction mixture. On the contrary, the 1:1:2 Cu^{II}/H_2mal/phen molar ratio reaction afforded several products depending on the crystallization method: (i) layering of Et_2O to the sky-blue solution afforded compound [Cu_2(phen)$_4$(mal)]-[CuCl(phen)(mal)](OH) (**4**) (see Section 2, Method B), and (ii) vapour diffusion of Et_2O to the same reaction mixture afforded a mixture of [CuCl(phen)$_2$]Cl (**5**), [CuCl(phen)(mal)][CuCl(phen)$_2$][Cu(phen)$_2$-(Hmal)]Cl (**6**) (see Section 2, Method A), and light-green microcrystalline needles (**7**) showing superimposable IR spectra with **5**. Thus,



Scheme 1. Diagram of the reaction pathways, showing the various combinations of stoichiometries and crystallization methods, and the products obtained by each. The 1.5:1:2.5:2 system leads to **2**–**5** and **7**, and is not shown for simplicity.

from a chemical point of view, we conclude that complexes **5** and **7** are identical, although they present different crystal structure parameters. The excess of phen in the reaction mixture seems as the most determinant factor since it 'pushes' the equilibrium to the isolation of phen-rich complexes (see molecular structures of **4**, **5** and **6**).

In a next step, we varied the molar ratios of the reactants by simultaneously increasing the H_2mal and phen, leaving at the same time all other parameters unchanged. Thus, the 1:2:2 respective molar ratio led to the isolation of different mixtures of products depending on the crystallization method: (i) layering of Et_2O afforded a mixture of **2** and **3**, (ii) slow vapour diffusion of Et_2O afforded exclusively compound **4**, and (iii) rapid vapour diffusion of Et_2O afforded a mixture of **4**, **5** and **7**. As in the previous case, the excess of phen, rather than the excess of H_2mal, plays the predominant role since it facilitates the isolation of phen-rich complexes (see molecular structures of **4**, and **5).**

Similarly, we increased the molar ratios of Cu^{II} and phen with respect to H_2mal using the 1.5:1:2.5 Cu^{II}/H_2mal/phen molar ratio (not shown in Scheme 1), based on the stoichiometry of **4** (see synthesis of **4**, method C). By keeping the same reaction conditions (i.e. respective H_2mal/LiOH · H_2O molar ratio, solvent, crystallization method) that led to the isolation of **4**, we have simultaneously isolated compounds **2**–**5** and **7**. The simultaneous excess of Cu^{II} (previously leading to the isolation of **3** and probably **7**) and phen (previously leading to the isolation of **4**, **5**, **7**) in the reaction mixture is in agreement with the isolation of a mixture of complexes.

In all cases above, the 1:2 H_2mal/LiOH · H_2O molar ratio was used to ensure the full deprotonation of H_2mal. This is in agreement with the presence of the mal^{2-} anion in the crystal structures of compounds **1**–**4**, whereas the presence of $Hmal^-$ in the $[Cu(phen)_2(Hmal)]^+$ species found in **6** was not anticipated. We have thus wondered whether the isolation of a compound containing exclusively the $Hmal^-$ anion would be possible, and we have employed the 1:1 H_2mal/LiOH · H_2O molar ratio while keeping the overall Cu^{II}/H_2mal/phen molar ratio to 1:1:2 (see Section 2, Method B). However, regardless of the crystallization method, the only product isolated was compound **6**, leading us to conclude that both mal^{2-} and $Hmal^-$ anions coexist in the reaction mixtures and their subsequent coordination is impeded by complicated and yet unknown reaction mechanisms and conditions.

Conclusively, our results from the investigation of the parameter space of the $CuCl_2/H_2$mal/phen reaction system in MeOH can be summarized as follows: (i) the reaction mixtures examined have afforded seven different products either in pure form or as mixtures; (ii) the complexes have been isolated based on their different solubilities; (iii) the excess of Cu^{II} in the reaction mixture leads to the isolation of **3** and probably **5** or **7** as green powder; (iv) the excess of H_2mal in the reaction mixture leads to the isolation of pure **2** despite the 1:1:1 stoichiometry found in its molecular structure; (v) the excess of phen seems to play the predominant role leading to the isolation of the phen-rich complexes **4**, **5**, **6** and **7** along with the equimolar complexes **2** and **3**; (vi) each of the 1:1:1, 1:1:2, 1:2:2 and 1.5:1:2.5 Cu^{II}/H_2mal/phen reaction mixtures has afforded several products, some of which resulted from two different mixtures, and some of which were afforded by only one (Scheme 1); and (vii) other species coexisting in the reaction mixture cannot be excluded. Thus, we may conclude that each of these mixtures behaves like a Dynamic Combinatorial Library (DCL), containing many different species in equilibrium. These species can be selectively isolated, by means of crystallization in different solvent systems. It is also of interest, that these DCLs exhibit overlaps, as many isolated species are common to more than one of those DCLs.

The fact that solutions of transition-metal ions and one or more ligands form complicated mixtures of products in equilibrium, due to the labile nature of the metal–ligand and other non-covalent bonds that may eventually form (H-bonds, π–π stacking, etc.) is not new, and this is one of the attributes that make this chemistry so difficult to control. From this multitude of products in equilibrium it is often possible to isolate one or more products by their selective precipitation and subsequent crystallization, although it

still remains a challenge to isolate different species from a DCL, and more so to structurally characterize them [21]. In other cases, structures were not available [22], or of marginal quality [23], but the products were identified spectroscopically. In most cases, the molecular recognition of the DCL member with small molecules or ions has been served as the selection process. Very elegant examples of this work include metallosupramolecular tetrahedral [24], cubes and open books [25], tetra-, hexa- and octanuclear ferric wheels [26], linear and circular helicates [27], tetra- and hexanuclear helicates [28], bowls and capsules [29], porphyrin cages [30], tetrahedra and helicates [31], various metallacryptates [32] and Borromean Rings and Solomon Knots [33] which have been identified as members of DCLs, and in some cases isolated.

The particularity of the present system is that the isolation of specific species is not based on supramolecular recognition, but on their solubility in a given solvent system. What is also noteworthy is that a large number of such species has been structurally characterized.

3.2. Description of structures

The crystallographic characterization of **1** and **2** revealed the presence of mononuclear species [Cu(L)(phen)(mal)] (L = H_2O (**1**), MeOH (**2**)). The structure of **1** has been reported previously [5a]. An ORTEP plot of **2** is given in Fig. 1, selected bond distances and angles for both structures are given as Supplementary data (Table S1). The coordination geometry around the Cu^{II} ion in both **1** and **2** is square-pyramidal; the basal positions are occupied by the nitrogen atoms of the phen and the oxygen atoms (O(1) and O(3)) of the bidentate chelating mal^{2-} ligand, whereas the apical position is occupied by the monodentate ligand. In the structure of **2**, two centrosymmetrically related mononuclear species are hydrogen bonded and form dimers [Om(1)···O(4) ($-x$, $-y$, $1-z$) = 2.813 Å, HOm(1)···O(4) = 2.221 Å, Om(1)–HOm(1)···O(4) = 166.6°] (Fig. S1).

An ORTEP plot of the structure of **3** is given in Fig. 2, selected bond distances and angles are listed in Table S2. The structure of **3** consists of neutral heterometallic tetranuclear $Cu^{II}_2Li^{I}_2$ units held together by two bidentate [chelating] + bis(unidentate) mal^{2-} ligands (Scheme 2). The coordination geometry around the two Cu^{II} ions is square-pyramidal, (τ = 0.19). The basal positions of the square pyramid are occupied by the nitrogen atoms of the phen and the oxygen atoms O(1) and O(3) of the mal^{2-} ligand. The apical position is occupied by a chloride atom at 2.502(2) Å. The Cu–N and Cu–O bond lengths are *ca.* 2.02 and 1.95 Å, respectively. The coordination

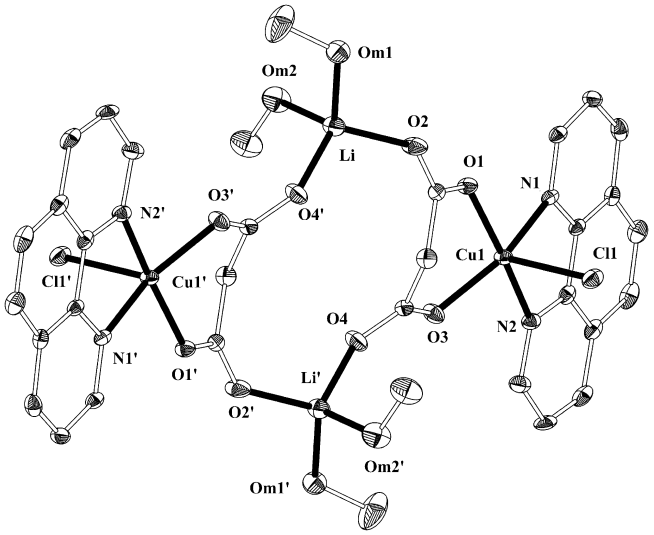

Fig. 2. Partially labeled ORTEP plot of **3** with ellipsoids drawn at the 30% probability level (Hydrogen atoms have been omitted for clarity). Primed atoms are generated by symmetry ($' = -x, -y, 1-z$).

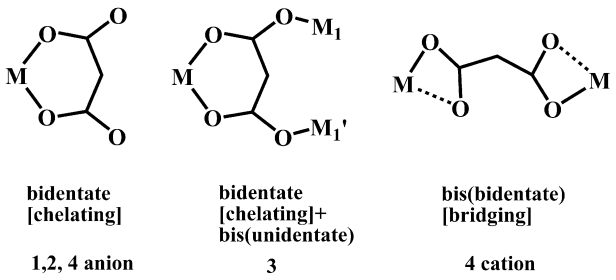

Scheme 2. The coordination modes of the malonato ligand in **1**–**4**.

geometry around the two Li^{I} ions is tetrahedral comprised by two oxygen atoms O(2) and O(4′) belonging to two centrosymmetrically related mal^{2-} ligands and two coordinated methanol molecules. The bond distances around Li^{I} range from 1.901(5) to 1.956(5) Å. The neutral heterometallic tetranuclear molecules of **3** are hydrogen bonded [Om(1)···O(4) ($-1+x$, y, z) = 2.831 Å, HOm(1)···O(4) = 2.240 Å, Om(1)–HOm(1)···O(4) = 156.7°; Om(2)···Cl(1) (x, $-1+y$, z) = 3.058 Å, HOm(2)···Cl(1) = 2.327 Å, Om(2)–HOm(2)···Cl(1) = 163.1°] and form layers that extend parallel to the *ab* plane (Fig. S2).

The molecular structure of **4** consists of the complex cation $[Cu_2(phen)_4(mal)]^{2+}$, the complex anion $[CuCl(phen)(mal)]^{-}$, one hydroxide anion, as well as methanol and water solvate molecules. An ORTEP plot of the complex cation and anion is given in Fig. 3, and selected bond distances and angles are listed in Table S3. Each Cu^{II} ion in the cation of **4** presents an O_2N_4 distorted octahedral coordination geometry comprised by the nitrogen atoms of two phen molecules and two carboxylato oxygen atoms of the mal^{2-} ligand. Each carboxylato group of the mal^{2-} ligand is asymmetrically coordinated to the Cu^{II} ions (Cu(1)–O(1) = 1.955(5), Cu(1)–O(2) = 2.884(5), Cu(2)–O(3) = 1.970(6), Cu(2)–O(4) = 2.770(6) Å), presenting the novel bis(bidentate) [bridging] coordination mode (Scheme 2). The Cu–N bond distances fall in the range 1.990(7)–2.207(10) Å. The coordination geometry around the Cu^{II} ion in the anion of **4** is square-pyramidal (τ = 0.16) comprised of the nitrogen atoms of the phen and the oxygen atoms of the bidentate chelating mal^{2-} ligand (Scheme 2) in the basal positions and a chloride atom at the apex at 2.567(6) Å. The Cu–N and Cu–O bond distances are *ca.* 2.02 and 1.92 Å, respectively. The overall coordination environment around

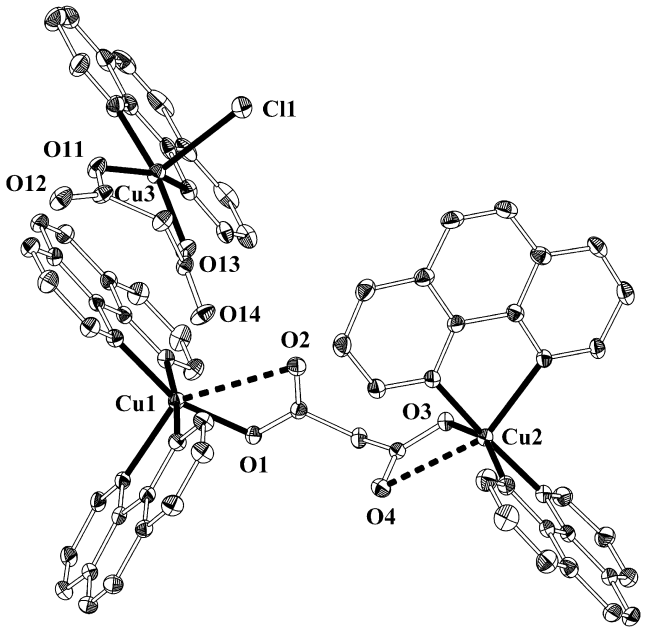

Fig. 3. Partially labeled ORTEP plot of the cation and anion of **4** with ellipsoids drawn at the 30% probability level (hydrogen atoms have been omitted for clarity).

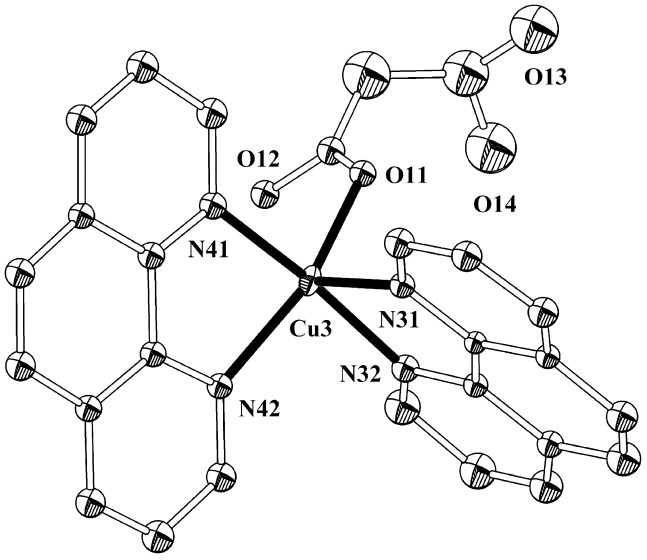

Fig. 4. Partially labelled ORTEP plot of the new cationic species $[Cu(phen)_2(Hmal)]^+$ found in the structure of **6** with ellipsoids drawn at the 30% probability level (hydrogen atoms have been omitted for clarity).

Cu(3) is quite similar to that found around Cu(1) and its centrosymmetric equivalent in the structure of **3**.

The structural characterization of **5** revealed the presence of $[CuCl(phen)_2]Cl$, whose structure has been previously reported [34]. The coordination geometry around the Cu^{II} ion is distorted trigonal bipyramidal ($\tau = 0.58$) comprised of two phen ligands and a chloride atom.

The structural characterization of **6** revealed the presence of three mononuclear species, the cation $[CuCl(phen)_2]^+$ also found in **5**, the anion $[CuCl(phen)(mal)]^-$ also found in **4**, and the new cationic species $[Cu(phen)_2(Hmal)]^+$ whose structure is shown in Fig. 4. Selected bond distances and angles are given as Supplementary data (Table S4). The coordination geometry around the Cu^{II} ion in $[Cu(phen)_2(Hmal)]^+$ resembles that of Cu(1) and Cu(2) in the cation of **4**. Two phen molecules and an oxygen atom from the $Hmal^-$ ligand are coordinated to the metal in a square-pyramidal geometry ($\tau = 0.17$). Three nitrogen atoms and the unidentate $Hmal^-$ ligand occupy the basal positions of the square pyramid, whereas the forth nitrogen atom is directed at the apex. The presence of the monoanion $Hmal^-$ has not been encountered in the other structurally characterized species isolated from this reaction system. The Cu–N bond lengths fall in the range 1.988(11)–2.177(11) Å, the Cu(3)–O(11) bond distance is 2.035(2) Å whereas O(12) is 2.980 Å away of the metal ion.

3.3. Mass spectrometry

For the elucidation of the solution chemistry of the system, the complexes that could be obtained in pure form were studied. Mass spectra of complexes **2**–**4** and **6** recorded in 50% aqueous methanolic solutions are given in Figs. 5–8, respectively. Characteristic peaks and their interpretation are listed in Table 3 and summarized in Scheme 3. The main characteristic of all spectra is the absence of the parent ion peak leading to the conclusion that all complexes spontaneously decompose in solution, thus the peaks observed correspond to various molecular fragments, some of which are common in all spectra. In the spectra of **2**–**4** and **6** the basic peak (with relative abundance 100%) appears at $M/z \sim 302$

Fragment (calc. *M*/*z*)	**2** Obs. *M*/*z*(%)	**3** Obs. *M*/*z* (%)	**4** Obs. *M*/*z* (%)	**6** Obs. *M*/*z* (%)
$[Cu(phen)_2(malH)]^+$ (526.5)	526.1 (3.5)	526.1 (3.5)	526.4 (3)	526.4 (3)
$[CuCl(phen)_2]^+$ (459)		458.3 (12)	458.3 (45)	458.3 (45)
$[CuCl(phen)(CH_3COOH)]^+$ (339)		338.3 (3)	338.3 (8)	338.3 (10)
$[Cu(OH)(phen)(CH_3COOH)]^+$ (319.5)	319.3 (3)	319.2 (5)	319.2 (25)	319.3 (25)
$[Cu(phen)(CH_3COOH)]^+$	302.2 (100)	302.2 (100)	302.3 (100)	302.3 (100)
Abstraction of OH^- from $[Cu(phen)(CH_3COO)]^+$ (284.5)	284.2 (25)	284.2 (20)	284.2 (10)	284.2 (10)
$[CuCl(MeOH)(malH)]^+$ (235)		232.3 (5)	232.3 (85)	232.3 (80)
$[phenH]^+$ (181)			181.3 (15)	181.3 (12)

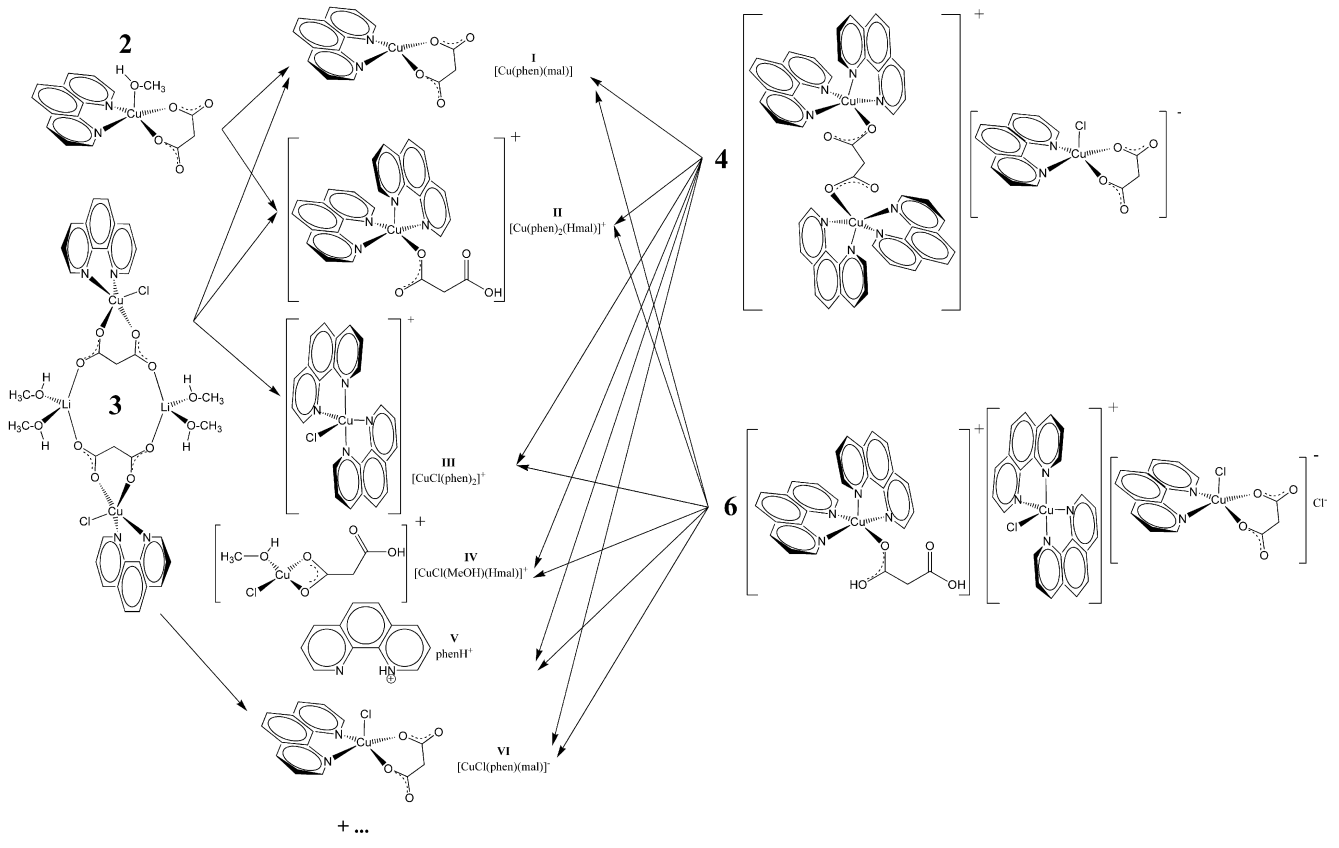
and it is attributed to the molecular fragment $[Cu(phen)(CH_3COO)]^+$ (theoretical $M/z = 302.5$) generated by decarboxylation of the malonato ligand. Further abstraction of OH^- from the above fragment, also common during the decomposition of organic acids, is recorded at 284.2 in the spectra of the four complexes. In the spectra of $[Cu_2Li_2Cl_2(phen)_2(mal)_2(MeOH)_4]$ (**3**) the peak at $M/z = 458.3$ is assigned to the fragment $[CuCl(phen)_2]^+$ (theoretical $M/z = 459$). In the spectra of $[Cu_2(phen)_4(mal)][CuCl(phen)(mal)](OH)$ (**4**) the two peaks at M/z 458.3 and 232.4 are assigned to the cationic fragments $[CuCl(phen)_2]^+$ (theoretical $M/z = 459$) and $[CuCl(MeOH)(Hmal)]^+$ (theoretical $M/z = 233$). A peak at $M/z = 181.3$ with relative abundance 15% corresponds to the cation $[phenH]^+$ (theoretical $M/z = 181$). Finally, in the spectra of $[CuCl(phen)(mal)][CuCl(phen)_2][Cu(phen)_2(malH)]Cl$ (**6**), a set of peaks at 232.3 and 319.3 with relative abundance 80% and 25%, respectively, are assigned to the cationic fragment $[CuCl(MeOH)(Hmal)]^+$ (theoretical $M/z = 233$) as in the case of **4**, and to $[Cu(OH)(phen)(CH_3COO)]^+$ (theoretical $M/z = 319.5$). The peak at $M/z = 458.3$ with relative abundance 45% is attributed to the presence of the cationic fragment $[CuCl(phen)_2]^+$, one of the cations found in the crystal structure of **6**, as well as in the structure of **5**. The molecular ion of $[phenH]^+$ also appears in the spectra of **6** at $M/z = 181.3$.

Another common feature in the mass spectra of the four complexes is the presence of peaks with relative abundance less than 15% at $M/z \sim 526$ and ~ 338. In particular, the peak at $M/z \sim 526$ corresponds well to the theoretical value of 526.5 calculated for the cationic species $[Cu(phen)_2(Hmal)]^+$, one of the cations found in the crystal structure of **6**. The peak at $M/z \sim 338$, may be attributed to the cation $[CuCl(phen)(CH_3COOH)]^+$ with theoretical M/z value 339.

Careful inspection of the mass spectra leads to the following conclusions: (i) the cationic fragment $[Cu(phen)_2(Hmal)]^+$ present in the methanolic solutions of the four compounds is present in the solid state only in **6**; (ii) the cationic fragment $[CuCl(phen)_2]^+$ present in the methanolic solutions of **3**, **4** and **6** is present in the solid state in **5** and **6**; (iii) the cationic fragment $[Cu(phen)(CH_3COO)]^+$ in the methanolic solutions of the four compounds originates from the species $[CuX(phen)(mal)]^z$, which in the solid state are present in **2** ($z = 0$, X = MeOH) and in **4** and **6** ($z = -1$, X = Cl); and (iv) the cationic fragment $[CuCl(phen)(CH_3COOH)]^+$ in the methanolic solutions of **3**, **4** and **6** originates from the anionic species $[CuCl(phen)(mal)]^-$ which in the solid state is present in **4** and **6**. Thus the methanolic solutions of **2**–**4** and **6** contain fragments of the complexes that have been previously isolated from the various $CuCl_2/H_2mal/phen$ reaction systems, and the most important is that these fragments are not present in the solid state structure of the complex under examination. It is thus evident that compounds **2**–**4** and **6** decompose in solution followed by rearrangement/reorganization to species isolated in complexes **1**–**6**, confirming the dynamic character of the system. Thus mass spectrometry supports indirectly our consideration that the various $CuCl_2/H_2mal/phen$ reaction mixtures examined constitute a set of overlapping Dynamic Combinatorial Libraries whose members are complexes of the various ligands to the metal ions in solution.

3.4. Magnetic susceptibility studies

Complexes **3** and **4** were chosen for a magnetic study since their structures suggested the possibility of magnetic exchange. The $\chi_M T$ products for **3** and **4** at 300 K are 0.77 and 1.41 $cm^3\,mol^{-1}\,K$ (Fig. 9). These are close to the values expected for two and three non-interacting $S = 1/2$ spins (0.83 and 1.24 $cm^3\,mol^{-1}\,K$, respectively, $g = 2.1$). For **3**, the slightly lower value than theoretically predicted indicates antiferromagnetic interactions. This is confirmed by the drop of $\chi_M T$ upon cooling, which is more abrupt below 50 K, falling to 0.75 $cm^3\,mol^{-1}\,K$ at 5 K. For **4**, on the other hand, $\chi_M T$ increases upon cooling to a broad maximum of



Scheme 3. Species that form upon dissolution of **2**–**4** and **6** in MeOH. Species **II**–**V** are directly observed by ESI-MS data, while the presence of **I** and **VI** is inferred by the presence of the decarboxylated fragments $[Cu(phen)(CH_3COO)]^+$ and $[CuCl(phen)(CH_3COOH)]^+$, respectively. Dissolved species, present in certain complexes (e.g. **II** in **6**) may have formed from transformation of complexes that did not initially contain them in the solid state (e.g. **II** from **2**), confirming the dynamic character of the reaction system.

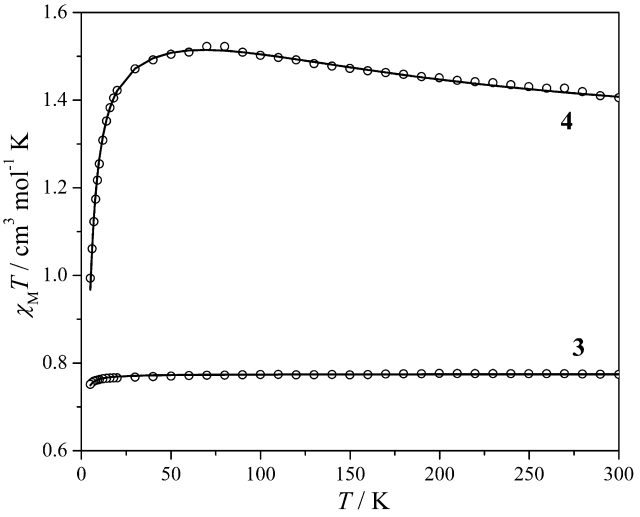


Fig. 9. χ_M vs. T and $\chi_M T$ vs. T experimental data for complexes **3** and **4**, and theoretical curves based on the Hamiltonians of Eqs. (1) and (2), respectively.

1.51 $cm^3\ mol^{-1}$ K at ~70 K, before falling abruptly to a value of 0.99 $cm^3\ mol^{-1}$ K at 5 K. This overall behaviour indicates the interplay of ferro- and antiferromagnetic interactions.

The close Cu···Cu distances between neighboring molecules (8.4–8.7 Å), which are comparable to the intramolecular intermetallic separation (9.818 Å), suggest the possible existence of both intra- and intermolecular magnetic interactions. However, in order not to overparametrize our problem, a simple dimer model was considered for the interpretation of the magnetic susceptibility data of **3**. The corresponding Hamiltonian was

$$\hat{H} = -2J\hat{\mathbf{S}}_1\hat{\mathbf{S}}_2 \quad (1)$$

Fitting of the data according to this model yielded best-fit parameters $J = -0.19\ cm^{-1}$, $g = 2.032$ with $R = 3.9 \times 10^{-6}$. This very weak coupling agrees with the structural parameters of **3**, in which Cu(1) and Cu(1′) are separated by a distance of ~9.82 Å, and magnetic exchange must be transmitted through a series of seven diamagnetic atoms.

For the interpretation of the magnetic susceptibility data of **4**, certain assumptions were made. Given its structure, a relatively strong interaction was expected between Cu(1) and Cu(2) via the malonato bridge. Initial attempts to fit the data considering only this interaction failed to reproduce the data. Thus, it was considered that Cu(3) might also be involved in magnetic exchange. Inspection of the molecular structure of **4**, led us to assume that Cu(3) should mainly interact with Cu(1) through a π–π stacking interaction. Thus, inclusion of a second exchange coupling brought about a remarkable improvement to the fits. The Hamiltonian used was

$$\hat{H} = -2(J_1\hat{\mathbf{S}}_1\hat{\mathbf{S}}_2 + J_2\hat{\mathbf{S}}_1\hat{\mathbf{S}}_3) \quad (2)$$

Fitting according to that model yielded best-fit parameters $J_1 = 80.0\ cm^{-1}$, $J_2 = -3.4\ cm^{-1}$, $g = 2.136$ with $R = 3.7 \times 10^{-5}$. J_1 corresponds to the magnetic exchange mediated through the malonato bridge, which is expected to be stronger than the one mediated through the π–π interaction and more ferromagnetic, given the propensity of malonates to promote ferromagnetic couplings in various coordination modes [35].

Another point of interest concerns the malonato-mediated exchange coupling, which is strongly ferromagnetic. Qualitatively we could rationalize this by the relatively large intermetallic separation, in combination with the fact that the malonato bridge is coordinated to the equatorial positions of the copper atoms. Due to the first situation, the direct orbital overlap of the copper atoms is expected to be negligible, thus suppressing the antiferromagnetic component of the magnetic exchange. Due to the second situation, the malonate occupies the magnetic orbitals of the copper atoms (mainly of $d_{x^2-y^2}$ character), thus strong interactions can be expected, which should be of ferromagnetic character. We should stress, however, that complex **4** is the first copper(II) complex to our knowledge to exhibit the *syn–syn* bridging mode of the malonate through two different carboxylate functions. Thus, it is not a simple task to propose a mechanism for the magnetic exchange, and theoretical studies should be pursued toward that direction. These, however, are beyond the scope of this work.

3.5. EPR spectroscopy

X-band EPR spectra from powdered samples of **3** and **4** were recorded in the 4.2–300 K temperature range. For both complexes no significant variation with temperature was observed. The 4.2 K spectra are shown in Fig. 10. Evident is the lack of hyperfine splitting features as is frequently observed in concentrated solid samples of Cu^{II} complexes where exchange interactions are present [36].

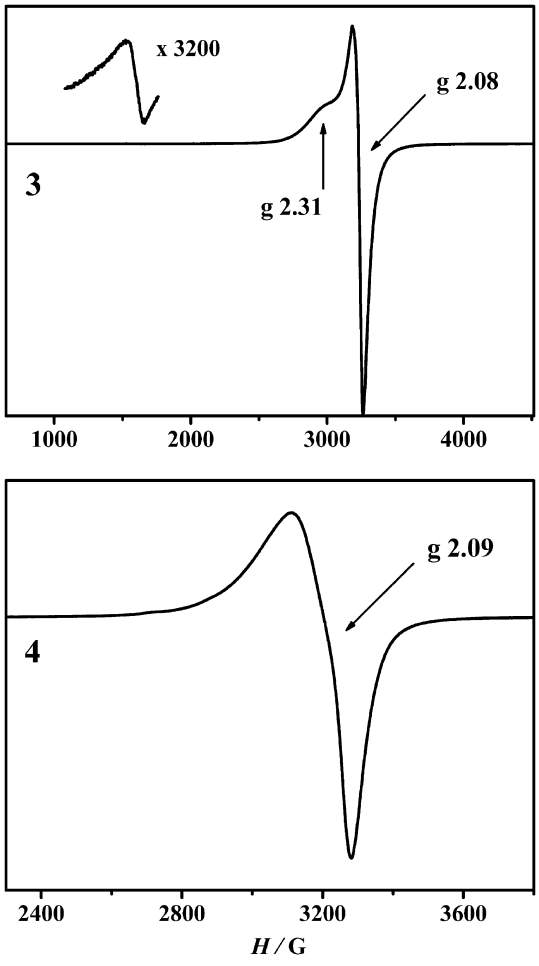

Fig. 10. X-band EPR spectra from powdered samples of **3** and **4** at 4.2 K. *EPR conditions*: **3**: microwave power, 0.13 mW; mod. ampl., 0.5 Gpp ($\Delta m_S = \pm 1$ transitions); microwave power, 2.2 mW; mod. ampl., 10 Gpp (half field transition). The half-field transition signal has been multiplied by the indicated factor; the different recording conditions have been considered. Compound **4**: microwave power 0.13 mW; mod. ampl., 1.0 Gpp. Microwave frequency (9.42 GHz).

For **3** the spectrum consists of a relatively broad absorption at $g \sim 2.31$ and a narrower derivative feature at $g \sim 2.08$. Present also is a much weaker signal at ~1600 G. From the crystal structure of **3**, the closest intramolecular Cu···Cu distance within the heterometallic tetranuclear unit is ~9.8 Å, whereas hydrogen bonding interactions lead to the formation of layers extending parallel to the *ab* plane (Fig. S2). The intermolecular Cu···Cu distances within these layers range from *ca.* 8.3 to 14.5 Å. The magnetic measurements discussed above indicate small intramolecular exchange interactions. Weak dipolar intra- or intermolecular interactions, may affect the EPR spectra. The weak feature at ~1600 G is consistent with the so-called half-field transition ($\Delta m_S = \pm 2$) arising from such dipolar interactions [37]. If we approximate the present situation with a dimeric model, the relative intensity between the weak feature at ~1600 G ($\Delta m_S = \pm 2$ transition) and the much stronger signal in the $g = 2.31$–2.07 region ($\Delta m_S = \pm 1$ transitions) may be used in order to estimate the Cu···Cu distances [37]. We find that this ratio is consistent with Cu···Cu distances of the order of 8–9 Å, in reasonable agreement with the crystallographic data.

The EPR spectrum from a powdered sample of **4** consists of a broad asymmetric signal in the 3000 G region, with a zero cross point at $g \sim 2.09$ (Fig. 10). No other signals are observed in spectra recorded in various temperatures. The magnetic susceptibility measurements for **4** were modeled with an exchange coupled trimer yielding an $S = 3/2$ ground state. The temperature behaviour of the spectra indicates that the individual spin states cannot be discriminated. The apparent anisotropy of the spectrum is lower than this anticipated for an isolated Cu^{II} ion in a square-pyramidal geometry. Such a behaviour is observed in concentrated solid state Cu^{II} complexes in the presence of misalignment of the local molecular axes of the copper ions [36]. Misalignment for the three copper ions is indicated from the crystal structure of **4** (Fig. 3).

4. Summary and conclusions

The investigation of the $CuCl_2/H_2mal$/phen reaction system (H_2mal = malonic acid) in MeOH led to the isolation of an unexpectedly large number of products. Indeed, seven complexes have been isolated, six of which have been structurally characterized, i.e. complexes $[Cu(H_2O)(phen)(mal)]$ (**1**), $[Cu(MeOH)(phen)(mal)]$ (**2**), $[Cu_2Li_2Cl_2(phen)_2(mal)_2(MeOH)_4]$ (**3**), $[Cu_2(phen)_4(mal)][CuCl(phen)(mal)](OH)$ (**4**), $[CuCl(phen)_2]Cl$ (**5**), and $[CuCl(phen)(mal)][CuCl(phen)_2][Cu(phen)_2(Hmal)]Cl$ (**6**). Complex **7** was identified as analogous to **5** based on their superimposable IR spectra. The large variety of accessible complexes initially obtained, prompted us to study this system in greater depth and in a systematic manner.

Thus, variation of the molar ratios and the crystallization methods employed, afforded compounds **1**–**7** either in pure form or as mixtures, indicating that all these species (and probably other, more soluble ones) exist in equilibrium in the reaction solution. Initial attempts to isolate those complexes by employing stoichiometric reactions, resulted in various mixtures of **1**–**7** rather than pure products. However, careful choice of stoichiometries and crystallization conditions allowed us to obtain pure products in most cases (**1**–**4**, **6**). The observation that several species are present in equilibrium in solution, in ratios depending on the starting materials stoichiometries, led us to conclude that, in effect, these reaction systems constitute a set of overlapping Dynamic Combinatorial Libraries. Indeed, due to the labile nature of the metal–ligand coordination bonds, complexes **1**–**7** should coexist in various ratios in the reaction mixtures, through a constant formation–decomposition process.

However, we wished to corroborate this conclusion through an independent experimental technique. Mass-spectrometric studies would be ideally suited to study the chemical equilibrium in this reaction system, and were therefore undertaken. Mass spectra recorded on solutions of pure **2**–**4** and **6** in 50% aqueous MeOH revealed the absence of the parent ion peaks along with the presence of fragments previously observed in the crystal structures of **1**–**6**. The most important feature observed in the mass spectra of pure **2**, **3**, **4** and **6** is the presence of fragments not present in the crystal structure of the corresponding complex. Thus, a conclusion that can be safely drawn is that each of the complexes decomposes upon dissolution to yield a dynamic mixture of species, although a full identification of the species present in solution does not seem a tractable task. The existence of such equilibria is a characteristic trait of a DCL.

Concluding, we may note that several examples of DCLs based on transition-metal complexes have been previously reported. However, what is unprecedented in this case is that the "selection" step employed to separate the DCL members, is based on their solubility and crystallization properties, and not on supramolecular recognition. Also noteworthy is the number of DCL members identified, characterized and isolated: *seven* DCL members were identified, *six* of them were structurally characterized and *five* of them were isolated in pure form. Following these synthetic and spectroscopic studies in solution, physical studies in the solid state, i.e. magnetic and EPR studies of **3** and **4**, were carried out in order to complete the investigation of the system.

Appendix A. Supplementary data

CCDC 644552, 644553, 644554, 644555, 644556 and 644557 contain the supplementary crystallographic data for **1**, **2**, **3**, **4**, **5** and **6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Tables S1–S4 contain selected bond distances and angles for compounds **1**–**4** and **6**, respectively. Figs. S1 and S2 show the lattice structures of **2** and **3**, respectively, due to hydrogen bonding interactions. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.04.044.

Photoluminescence property

ABSTRACT

Five cadmium(II) metal-organic frameworks, namely $[Cd(BIPA)(daf)(H_2O)_3]\cdot 2H_2O$ (**1**), $Cd_2(BDC)_2(pdon)_2(H_2O)_2$ (**2**), Cd(BIPA)(pdon) (**3**), Cd(BIPA)(daf) (**4**) and $[Cd_2(BIPA)_2(pdon)_2]\cdot H_2O$ (**5**) (H_2BIPA = 5-bromoisophthalic acid, H_2BDC = terephthalic acid, pdon = 1,10-phenanthroline-5,6-dione, daf = 4,5-diaza-fluoren-9-one), have been constructed from cadmium(II) salts with multi-carboxylate ligands and pdon ligands under different reaction pH. The framework structures of these polymeric complexes have been determined by the X-ray single crystal diffraction technique. The differences of the five metal-organic frameworks demonstrate that the reaction pH has an important effect on the structure of these complexes. The thermal analyses of these five complexes have been measured and discussed. Additionally, four complexes show strong fluorescence in the solid state at room temperature.

1. Introduction

The rational design and synthesis of metal-organic frameworks have been of increasing interest recently in materials science and chemical research since they may provide a new strategy for achieving solid functional materials with potential applications in the areas of catalysis, gas storage, magnetism and optics [1,2]. Consequently, a series of metal-organic frameworks with various structural motifs including honeycomb, brick wall, bilayer, ladder, herringbone, diamondoid and rectangular grid, have been deliberately designed and synthesized. Being an important subclass of metal-organic polymers, d^{10} metal complexes have been found to exhibit intriguing structures and photoluminescent properties [3]. A series of d^{10} metal-organic frameworks with bridging carboxyate ligands and phenanthroline-like terminal chelating ligands have been described recently [4]. So far, many efforts in this field have focused on the influence of ligand spacers of flexible bridging ligands on framework formation of their coordination polymers [5]. However, studies on the effects of the reaction pH on framework formation of complexes have rarely been reported [6].

Additionally, recent studies have revealed that crystal growth under hydrothermal conditions occasionally involves in situ ligand synthesis, which not only provides a powerful synthesis method for organic ligands that are difficult to synthesize but also represents a potential new direction for novel inorganic–organic hybrid network construction through crystal engineering [7,8]. Examples of in situ ligand syntheses under hydrothermal conditions include hydrolysis of –CN and –COOR groups [7], hydroxylation [8] and carbon–carbon bond formation by reductive coupling or oxidative coupling [9].

Taking into account the factors mentioned above, we have paid considerable interest to the reactions of various metal salts with multi-carboxylate ligands and the influence of the reaction pH on the structure of the resultant complexes, and we have found that the reaction pH is one of the key factors in the formation of the coordination architectures [10]. As an extension of our previous work, we are paying attention to 1,10-phenanthroline-5,6-dione (pdon) because of its peculiar reactivity (Scheme 1) in organic chemistry [11]. Two nucleophilic centers (nitrogen and oxygen lone pairs) are contained in the quinone-like pdon molecule, with all the non-hydrogen atoms being sp^2-hybridized. The presence of two electronegative heteroatoms not only creates basic properties in the Lewis sense but also, because of conjugation, makes it possible to alter the electron density in different parts of the molecule. As a result, a dramatic change in reactivity can occur, which is not observed in the case of the corresponding aromatic homocyclic analogue, phenanthrenequinone. Herein we report on five new coordination polymers, namely $[Cd(BIPA)(daf)(H_2O)_3]\cdot 2H_2O$ (**1**), $Cd_2(BDC)_2(pdon)_2(H_2O)_2$ (**2**), Cd(BIPA)(pdon) (**3**), Cd(BIPA)(daf) (**4**) and $[Cd_2(BIPA)_2(pdon)_2]\cdot H_2O$ (**5**), obtained by the reaction of cadmium(II) salts with multi-carboxylate ligands and pdon ligands under different reaction pH, which involve in situ synthesis of 4,5-diaza-fluoren-9-one (daf) from pdon.

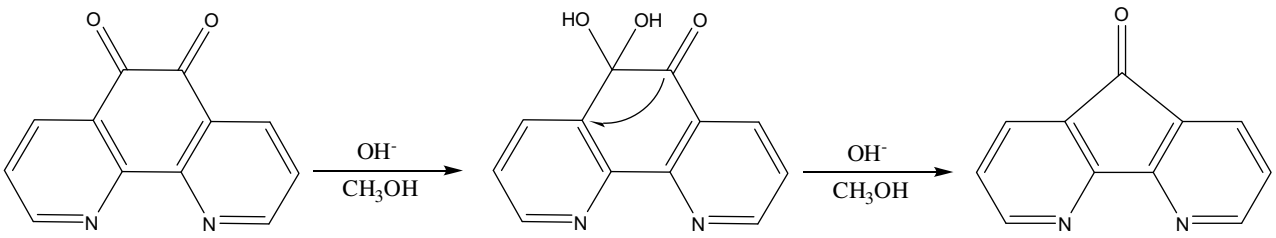

Scheme 1. Schematic representation of the possible transformation mechanism of pdon to daf.

2. Experimental

2.1. Materials and methods

All commercially available chemicals and solvents were of reagent grade and were used as received without further purification. 1,10-Phenanthroline-5,6-dione (pdon) was synthesized following the published procedure [12]. Elemental analyses for C, H and N were performed on a Perkin–Elmer 240C Elemental Analyzer at the Analysis Center of Nanjing University. FT-IR spectra were recorded in the range 400–4000 cm^{-1} on a Bruker Vector22 FT-IR spectrophotometer as KBr pellets. The luminescent spectra for the powdered solid samples were recorded at room temperature on an Aminco Bowman Series 2 spectrofluorometer with a Xenon arc lamp as the light source. In the measurements of emission and excitation spectra the pass width was 5.0 nm. All the measurements were carried out under the same experimental conditions. TG analyses were performed on a Perkin–Elmer TGA7 instrument in flowing N_2 with a heating rate of 20 °C min^{-1}.

2.2. Synthesis of the complexes

2.2.1. Synthesis of $[Cd(BIPA)(daf)(H_2O)_3] \cdot 2H_2O$ (**1**)

A mixture containing $Cd(NO_3)_2 \cdot 4H_2O$ (30.8 mg, 0.1 mmol), pdon (21.0 mg, 0.1 mmol), H_2BIPA (16.6 mg, 0.1 mmol), NaOH (16.0 mg, 0.4 mmol), 5 ml H_2O and 5 ml CH_3OH (the pH value was 9) was heated at 160 °C for 3 days in a 25 ml Teflon lined stainless steel vessel under autogenous pressure. After the reaction mixture was slowly cooled down to room temperature, yellow platelet crystals were produced in a yield of 54%. *Anal.* Calc. for $C_{19}H_{19}N_2BrO_{10}Cd$: C, 36.36; H, 3.05; N, 4.46. Found: C, 36.33; H, 3.04; N, 4.44%. 2.2.2. Synthesis of $Cd_2(BDC)_2(pdon)_2(H_2O)_2$ (**2**)

A mixture containing $Cd(NO_3)_2 \cdot 4H_2O$ (30.8 mg, 0.1 mmol), pdon (21.0 mg, 0.1 mmol), H_2BDC (16.6 mg, 0.1 mmol), NaOH (8.0 mg, 0.2 mmol) and 10 ml H_2O (the pH value was 7) was heated at 160 °C for 3 days in a 25 ml Teflon lined stainless steel vessel under autogenous pressure. After the reaction mixture was slowly cooled down to room temperature, yellow platelet crystals were produced in a yield of 58%. *Anal.* Calc. for $C_{40}H_{24}N_4O_{14}Cd_2$: C, 47.59; H, 2.40; N, 5.55. Found: C, 47.61; H, 2.43; N, 5.57%. Symmetry transformations used to generate equivalent atoms: #1 $x+1, y-1, z$; #2 $x-1, y+1, z$.

2.3. X-ray crystallography

The crystallographic data collections for complexes**1**–**5** were carried out on a Bruker Smart Apex II CCD with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) at 293(2) K using the ω-scan technique. The data were integrated using the SAINT program, which also corrected the intensities for Lorentz and polarization effects [13]. An empirical absorption correction was applied using the SADABS program [14]. The structures were solved by direct methods using the program SHELXS-97 and all non-hydrogen atoms were refined anisotropically on F^2 by the full-matrix least-squares technique using the SHELXL-97 crystallographic software package [15,16]. The hydrogen atoms of water molecules were located from difference Fourier maps and the other hydrogen atoms were generated geometrically. All calculations were performed on a personal computer with the SHELXL-97 crystallographic software package. The details of the crystal parameters, data collection and refinement for four complexes are summarized in Table 1. Selected bond lengths and angles with their estimated standard deviations for **1**, **2**, **4** and **5** are shown in Tables 2–5, respectively.

3. Results and discussion

Symmetry transformations used to generate equivalent atoms: #1 $x-1/2, y-1/2, -z+1/2$; #2 $-x+2, y, -z+1/2$.

was transformed in situ into daf during the hydrothermal process. The asymmetric unit in **1** consists of one Cd(II) atom, one BIPA ligand, three coordinated water molecules and two lattice water molecules. Each Cd(II) atom is seven-coordinated with a distorted pentagonal bipyramidal geometry, being coordinated by two nitrogen atoms of one daf in a chelate mode, two oxygen atoms of one carboxylate group and three aqua ligands. Two nitrogen atoms (N1, N2) and three oxygen atoms (O1, O2, O3W) lie in the equatorial plane, while the other two other aqua ligands occupy the apical positions, as shown in Fig. 1a. The coordination bond lengths and angles around the Cd(II) centre are in the range 2.294(4)–2.515(5) Å and 54.08(14)–175.65(13)°, respectively, as listed in Table 2.

The coordination modes of BIPA and BDC in this work are summarized in Scheme 2. As can be seen in Scheme 2a, one carboxylate group adopts a bidentate chelating mode and the other carboxylate group remains depronated and does not take part in the coordination. As a result complex **1** is a zero-dimensional complex and is further linked into a 1D chain structure through π···π interactions (Fig. 2b).

In the packing structure of **1**, as shown in Fig. 1c, the 1D chains are firstly linked into a 2D layer by O–H···O hydrogen bonds between the oxygen atoms of the coordinated water molecules (O2W and O3W) and the carboxylate group from adjacent chains, with O···O distances ranging from 2.744(6) to 2.874(6) Å (Table S1). Then the 2D layers are further connected through O–H···O hydrogen bonds between the oxygen atoms of the coordinated water molecules (O1W and O2W) and the oxygen atoms of the lattice water molecules (O4W and O5W) with O···O distances of 2.744(6) and 2.756(3) Å (Fig. 1c, Table S1).

Although pdon was used as the original organic reagent in the preparation of **1**, the daf ligand was unexpectedly found in the final

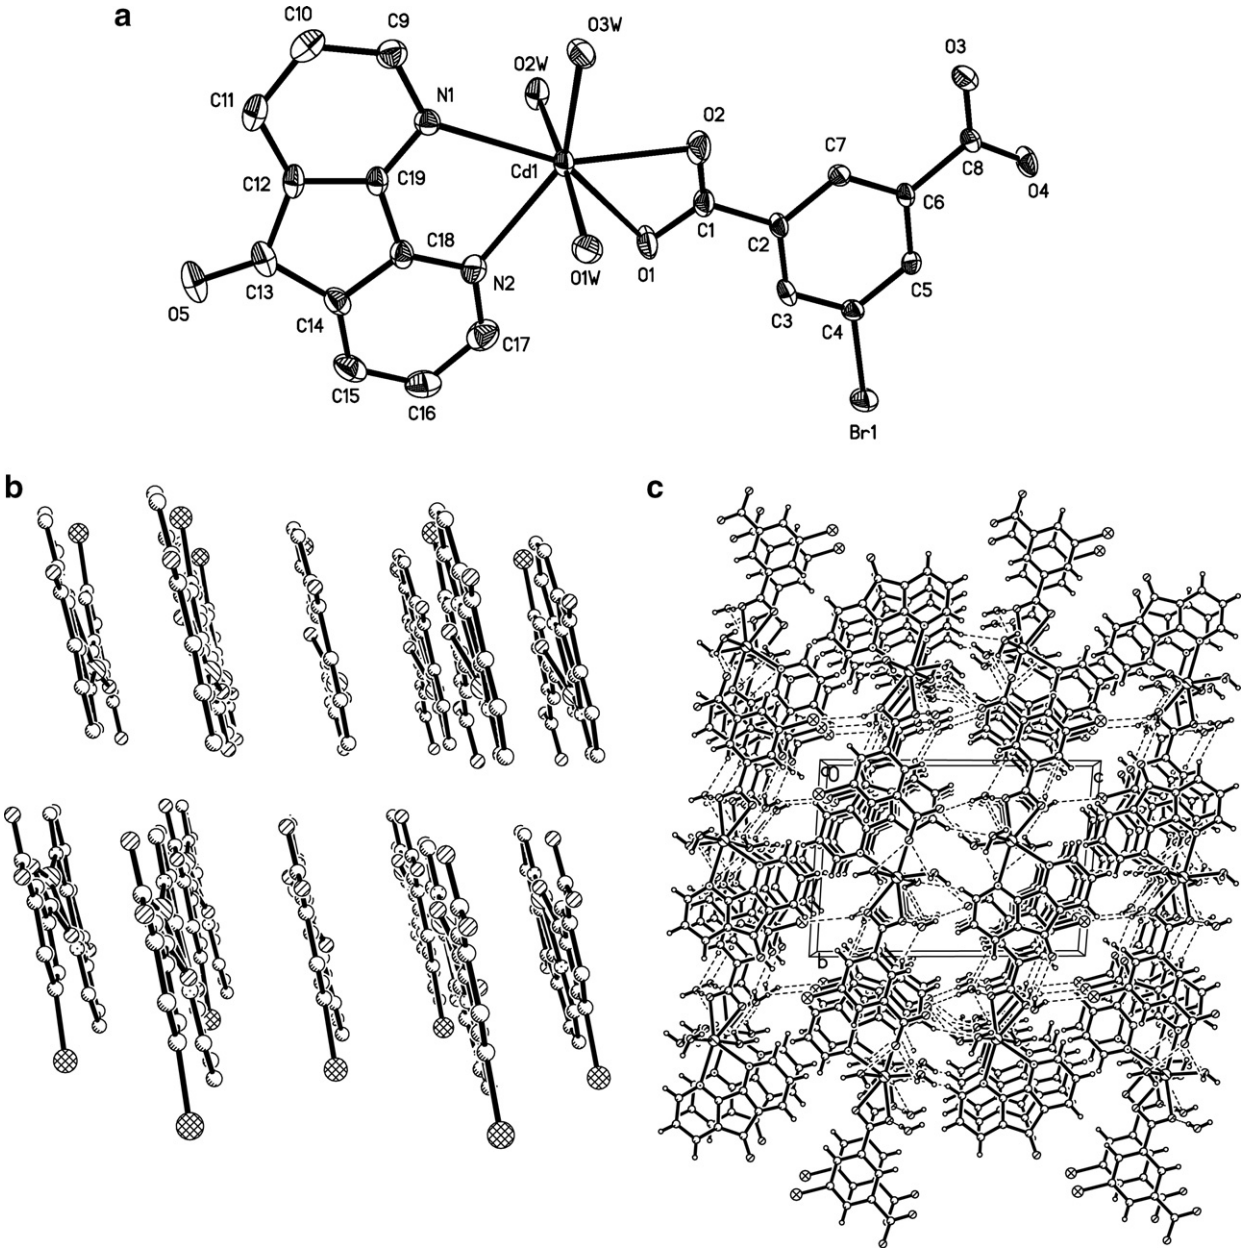

Fig. 1. (a) Coordination environment of the Cd(II) atom in complex **1** with the ellipsoids drawn at the 30% probability level, hydrogen atoms and water molecules are omitted for clarity. (c) Projection of the structure of **1** along *a*-axis (dotted lines represent hydrogen-bonding).

products, which indicates an in situ transformation of pdon into daf during the course of the hydrothermal treatment. As shown in the literature [8] on ligand reactions under hydrothermal conditions in the presence of metal ions, the ligation of the metal ion will cause some decrease of electron density on the aromatic ring of the organic ligand, and hence promote nucleophilic attack by water molecules or hydroxy groups. In this case, it seems most probable that the hydroxy groups act effectively as nucleophiles, attacking the carbonyl carbon atoms of pdon. As a result, the hydration of the carbonyl groups of pdon furnishes an intermediate diol or even a double diol. When the sp^2 carbonyl carbon atoms become sp^3-hybridized, the carbon–carbon bond is then cleaved, probably because of the crowding, resulting in the formation of daf. The formation mechanism of daf in **1** shows some similarity to that of dimethyl 2,2′-bipyridine-3,3′-dicarboxylate in a previously reported pure organic reaction [11b]. Although the exact mechanism of ligand transformation has not yet been proved, slow hydrolysis of the carbonyl groups ensures that an excess of NaOH remains in solution, thereby promoting the formation of less soluble polymeric networks. Equally important, the in situ slow daf formation also ensures the growth of large single crystals that are suitable for X-ray structure determination.

3.1.2. $Cd_2(BDC)_2(pdon)_2(H_2O)_2$ (**2**)

Single-crystal X-ray diffraction analysis revealed that complex **2** is a 1D zigzag coordination polymer. The asymmetric unit of **2** contains two cadmium atoms, two BDC ligands, two pdon ligands and two coordinated water molecules. As illustrated in Fig. 2a, the two Cd atoms are both six-coordinated by three oxygen atoms from two different BDC ligands, two nitrogen atoms from one pdon molecule and one oxygen atom from a coordination water molecule to give a distorted octahedral geometry. The Cd–O bond lengths fall in the range 2.163(6)–2.398(5) Å and the Cd–N bond lengths fall in the range 2.328(7)–2.397(6) Å (Table 3), which are in good agreement with those found in other Cd-containing coordination frameworks [17]. The BDC^{2-} ligands acts as a bidentate bridging ligand, but the coordination modes of the carboxyl groups are different, one adopt a bis(bidentate) chelating mode, while the other adopts a bis(monodentate) mode (Scheme 2d and e). Each BDC ligand bridges two cadmium atoms to form a 1D zigzag infinite chain (Fig. 2b) with Cd···Cd distances of 11.551 and 11.191 Å. The 1D zigzag chains form a 2D undulating network due to hydrogen-bonding interactions between the coordinated water molecule and the carboxylate group (Table S1). Adjacent 2D networks are ultimately extended into a 3D supramolecular structure through π–π stacking interactions with a centroid-to-centroid distance of 3.775(3) Å between pdon ligands (Fig. 2c).

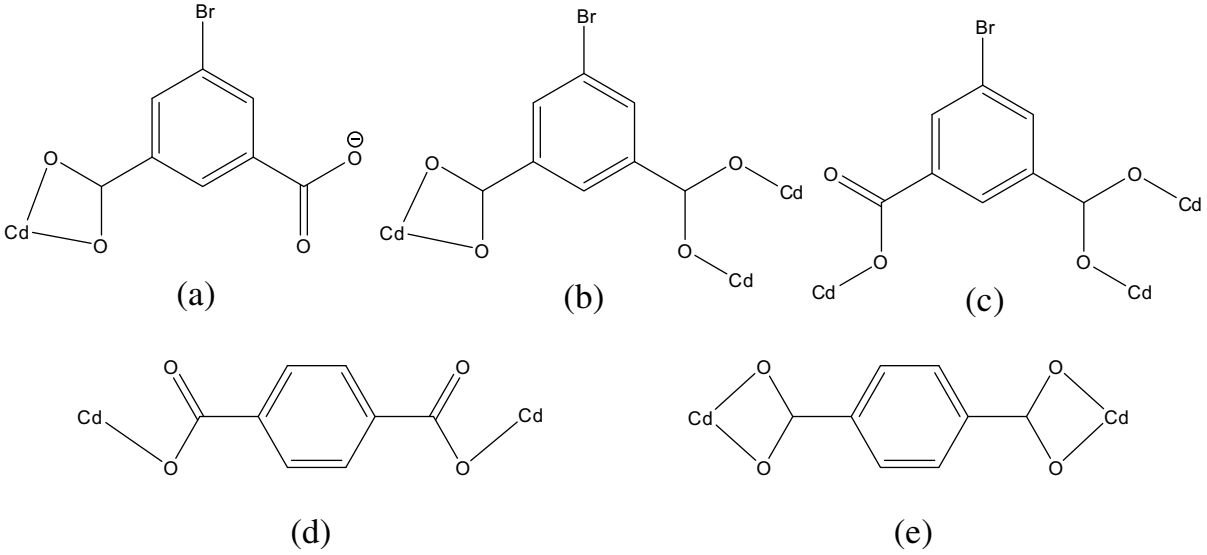
3.1.3. Cd(BIPA)(pdon) (**3**) and Cd(BIPA)(daf) (**4**)

The results of X-ray crystallographic analysis revealed that complexes **3** and **4** crystallize in the same monoclinic $P2_1/c$ space group with similar cell parameters (Table 1), which indicate that they are isomorphous and isostructural. Thus, as a typical example, only the structure of **4** is described here in detail. The asymmetric unit of **4** consists of one Cd(II) atom, one BIPA ligand and one daf ligand. The Cd(II) atom is in a square-pyramidal coordinated geometry with three oxygen atoms and two nitrogen atoms. Two oxygen atoms (Cd1–O1 = 2.222(2) Å, Cd1–O2 = 2.298(2) Å) from two carboxylate groups of the BIPA ligands and two nitrogen atoms (Cd1–N1 = 2.477(3) Å, Cd1–N2 = 2.378(3) Å) from one def ligands are ligated to the Cd(II) ion in the quasi-plane, with another oxygen atom belonging to the third BIPA ligand (Cd1–O3 = 2.228(2) Å) being located in the axial position (Table 4), as displayed in Fig. 3a.

Different from that of complex **1**, each BIPA ligand acts as a tri-connector linking three Cd(II) atoms in complex **4** (Scheme 2c), one of carboxylate groups is connected with one Cd(II) atom through a monodentate O atom, while the other bonds with two Cd(II) atoms, consequently resulting in the formation of a 2D layer (Fig. 3b). The 2D layer is developed in an undulated bilayer pattern parallel to the *bc*-plane. By treating the Cd(II) atom as a single node and connecting the nodes according to the connectivity defined by the geometrical centers of the benzene rings of the BIPA ligands, a distorted 2D (4.8^2) network (denoted the feb net) [18] sustained by 3-connected nodes is then yielded, as illustrated in Fig. 3c. The van de Waals interactions extend the 2D layer into a 3D supramolecular net.

3.1.4. $[Cd_2(BIPA)_2(pdon)_2] \cdot H_2O$ (**5**)

In order to further investigate the pH influence on the formation and structure of the complex, the pH value of the ligand solution was carefully adjusted to 6.0, while the other experimental conditions remained the same as those used for the preparation of **3**. As a result, complex **5** was obtained with an entirely different structure. The asymmetric unit of complex **5** contains one Cd ion, one



Scheme 2. Coordination modes of the BIPA and BDC ligands in complexes **1**–**5**.

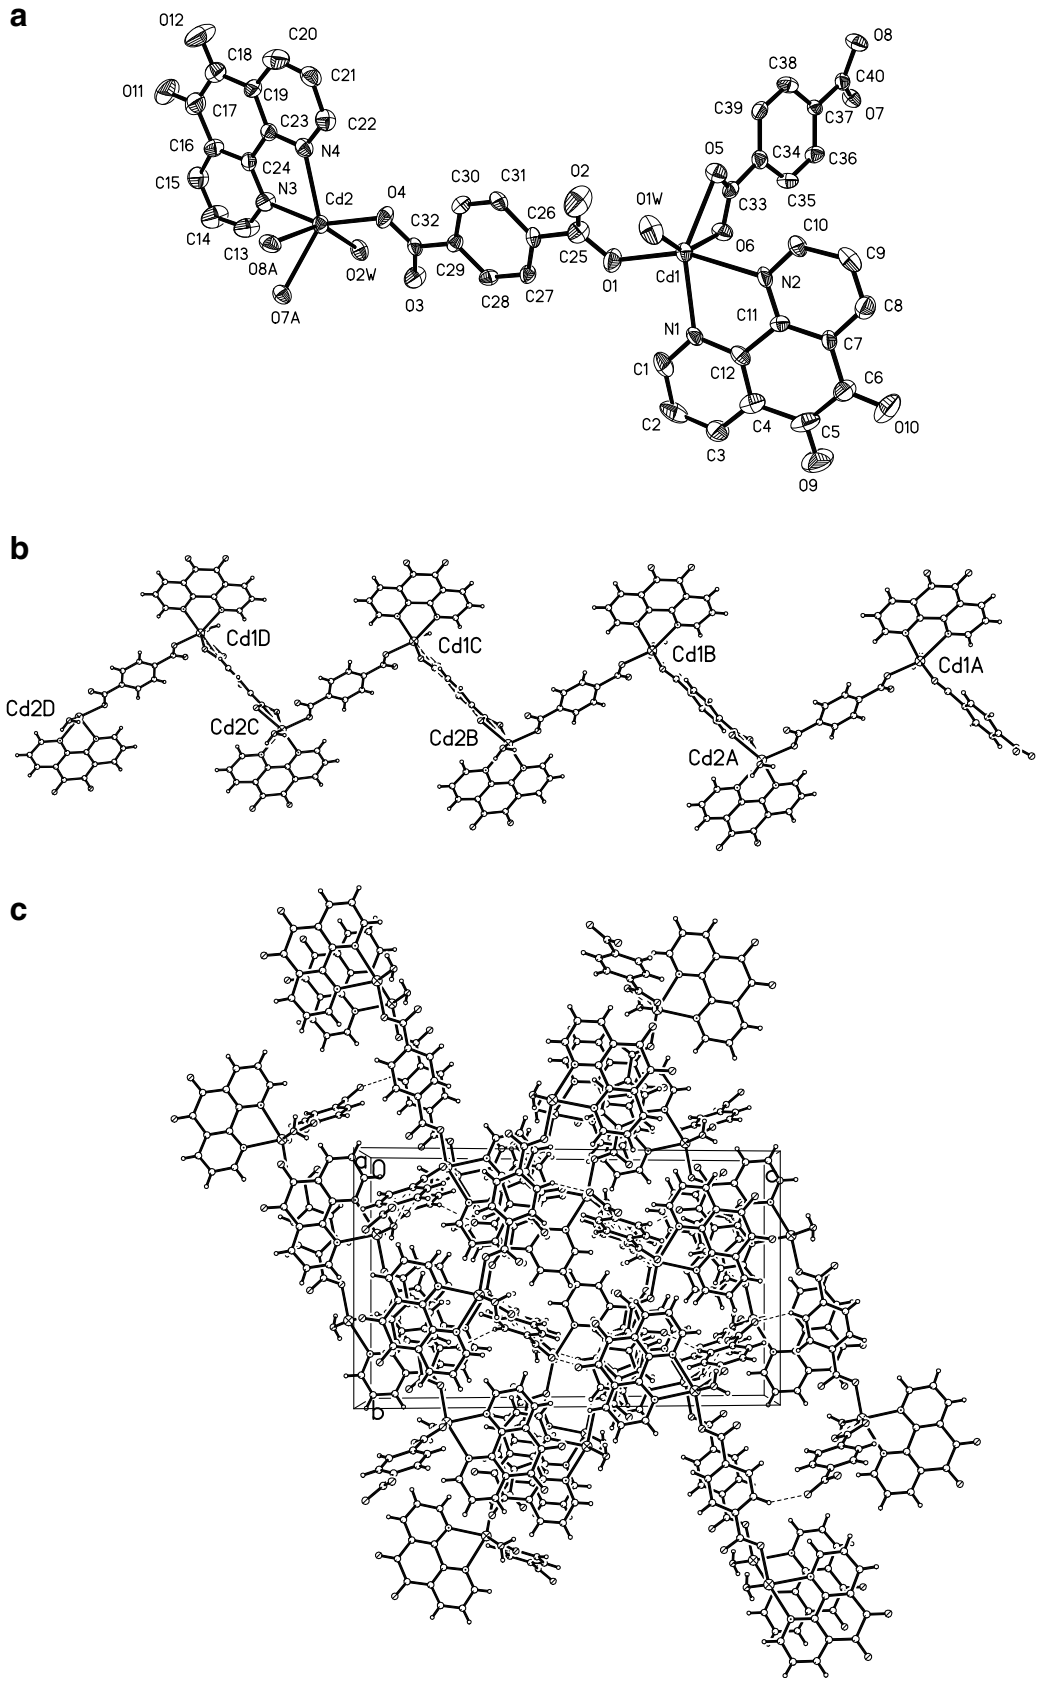


Fig. 2. (a) Coordination environment of the Cd(II) atom in complex **2** with the ellipsoids drawn at the 30% probability level, hydrogen atoms are omitted for clarity. (b) One-dimensional zigzag chain structure of complex **2**. (c) Projection of the structure of **2** along *a*-axis (dotted lines represent hydrogen-bonding).

pdon ligand, one BIPA ligand and half of the lattice water molecule. As shown in Fig. 4a, the Cd atom shows a distorted-octahedral geometry, being chelated by two N atoms from one pdon ligand. The remaining four coordination sites are occupied by four oxygen

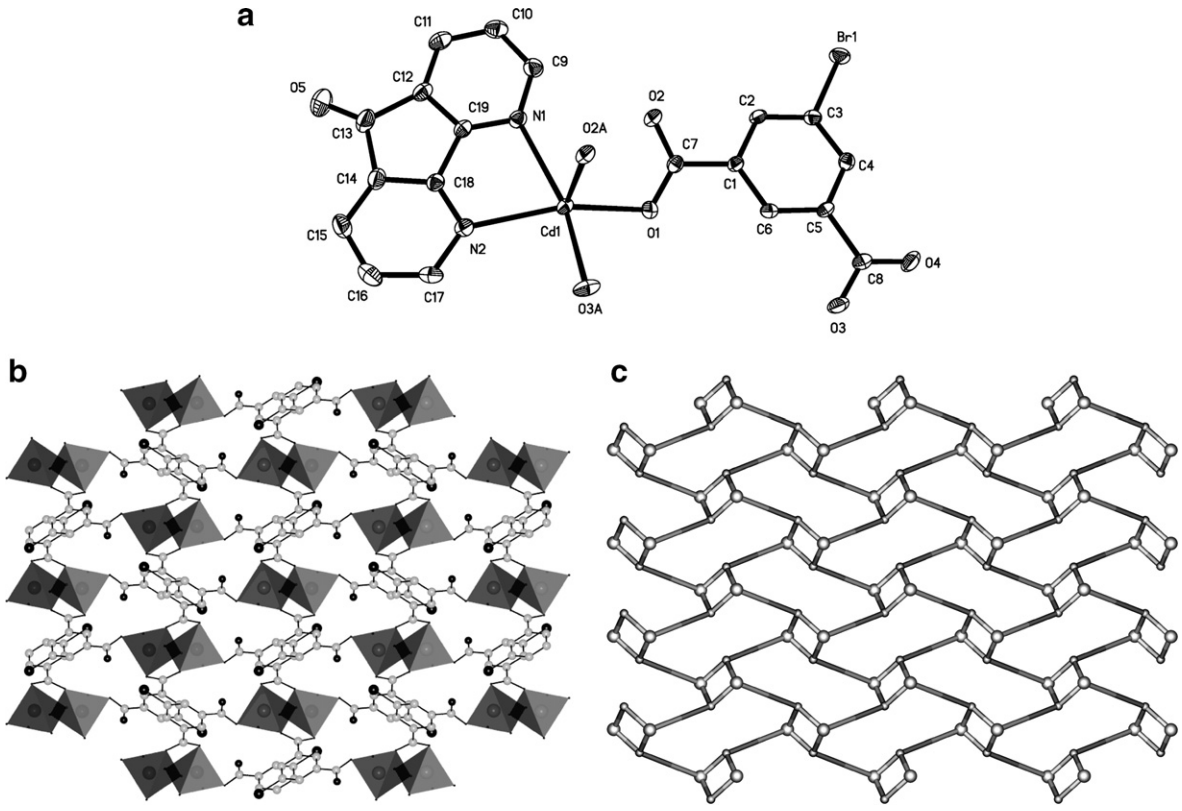

Fig. 3. (a) Coordination environment of the Cd(II) atom in complex **4** with the ellipsoids drawn at the 30% probability level, hydrogen atoms are omitted for clarity. (b) 2D layer structure of complex **4** along the *a*-axis. (c) Projection of the structure of **4** showing the (4.8^2) net based on Cd atoms and BIPA ligands.

atoms from three BIPA ligands. The Cd–O bond lengths are in the range 2.185(3)–2.561(2) Å and the Cd–N bond lengths are 2.322(3) and 2.352(2) Å (Table 5). In complex **5**, the BIPA ligands adopt a coordination mode different from those in complexes **1**, **3** and **4**: it acts as a tri-connector to link three Cd atoms through one bis-monodentate carboxylic O atom from one carboxylate group and a bidentate carboxylic O atom from the other carboxylate group, as depicted in Scheme 2b.

As shown in Fig. 4b, the bidentate carboxylic group links two Cd atoms in a *syn-anti* fashion to form a one-dimensional zigzag chain structure with a Cd···Cd separation of 5.135(3) Å, in which the distances are in the normal range compared with those reported (4.972–5.256 Å) in the literature [19]. The 1D Cd(CO_2) chains are further bridged into a two-dimensional undulating bilayer structure through the other carboxylate group. Interestingly, when viewed along the *b*-axis, the two-dimensional layer contains rectangular windows with dimensions of ca. 4.974×5.535 Å^2 that are occupied by pdon ligands and the lattice water molecules. By treating the Cd(II) atom as a single node and connecting the nodes according to the connectivity defined by the geometrical centers of the benzene rings of the BIPA ligands, a distorted 2D (4.10^2) network (denote the KIb net) [20] sustained by three-connected nodes is then yielded, as illustrated in Fig. 4c. The van de Waals interactions extend the 2D layer into a 3D supramolecular framework.

3.2. Effect of synthetic conditions on the structures of the complexes

It has been reported that synthetic conditions, such as pH value, reaction temperature, solvent, etc., are the key factors in assembling MOFs. As to the synthesis of **1**, **3** and **4**, all the reaction conditions are the same except for the difference of the reaction pH. As a result, complex **1**, obtained at a relatively high pH value, is a 0D structure with the Cd(II) center bonded by three water molecules, and it is accompanied by an in situ reaction. While in **4**, obtained at a slightly lower pH than **1**, a more complicated 2D network was generated, also accompanied by an in situ reaction. However for **3**, obtained at a pH close to 7, its framework is similar to that of **4**, but the in situ reaction did not happen in the absence of alkali. Therefore, a rough conclusion could be made that the pdon ligand can be converted into the daf ligand in the presence of alkali, which is in agreement with the previous reports [21].

In addition, it might be ascribed to the fact that the carboxylate ligands were deprotonated before the in situ reaction by a comparison of **3** and **4**. From the points discussed above, it is suggested that the increase of reaction pH may result in a different connectivity of the carboxylate ligand, controlling the in situ reaction and further fabricating a more complicated structure.

3.3. Properties

3.3.1. Luminescent properties

Inorganic–organic hybrid coordination complexes, especially with d^{10} metal centers, have been investigated for fluorescence properties owing to their potential applications as luminescent materials, such as light-emitting diodes (LEDs) [22]. Therefore, in the present study, the photoluminescence properties of **2**–**5** as well as free H_2BIPA and the H_2BDC ligand were investigated in the solid state at room temperature. As shown in Fig. 5, there are two intense emission peaks at 413 and 435 nm (λ_{ex} = 310 nm) for **2**, 421 and 442 nm (λ_{ex} = 330 nm) for **3**, 422 and 450 nm (λ_{ex} = 334 nm) for **5**. For excitation wavelengths between 280 and 480 nm, there is no obvious emission observed for free H_2BIPA and H_2BDC under the same experimental conditions, while it is reported that free pdon shows fluorescence emission in the solid state. The emission bands for phen are at 371 and 395 nm (λex = 290 nm) [23], and compared with the pdon ligand a clear

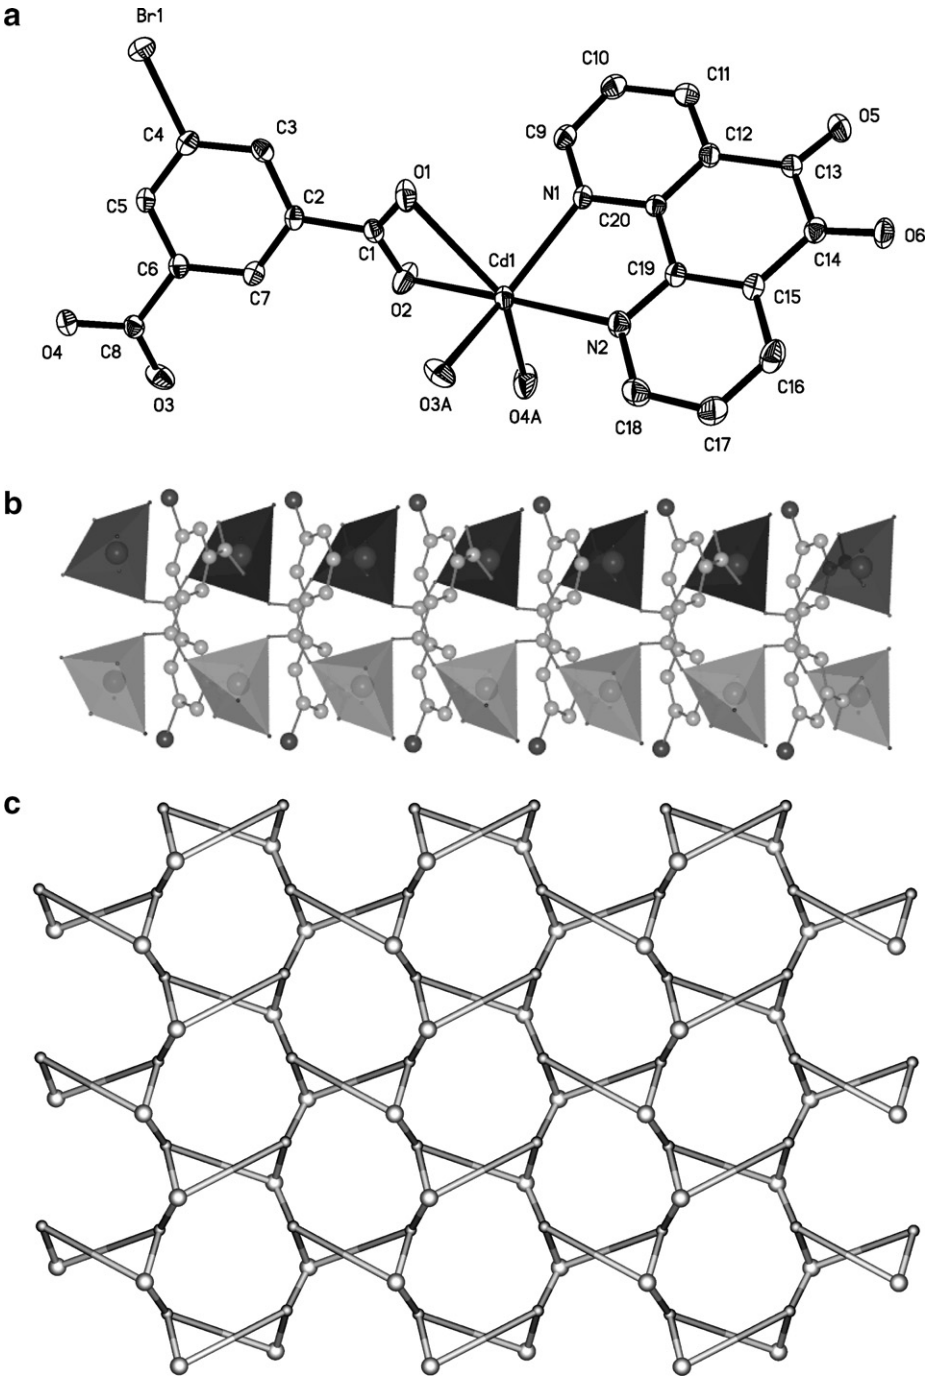

Fig. 4. (a) Coordination environment of the Cd(II) atom in complex **5** with the ellipsoids drawn at the 30% probability level, hydrogen atoms are omitted for clarity. (b) Bilayer structure of complex **5** along the *a*-axis. (c) Projection of the structure of **5** showing the (4×10^2) net based on Cd atoms and BIPA ligands.

red shift occurs in **2**, **3** and **5**, which might also be attributed to a ligand-to-metal charge transfer (LMCT) transition [24]. There is only a intense emission peak at 406 nm for **4**, which means a red shift of ca. 40 nm relative to that of the free daf (λ_{max} = 375 nm) [25]. We tentatively assign it to a LMCT transition [26].

3.3.2. Thermal properties

Thermal gravimetric analyses (TGA) were carried out to examine the thermal stabilities of **1**–**5**. The results show that complexes **1**–**5** are very stable in air at ambient temperature, which make them potential candidates for practical applications. The samples were heated up in air at 1 atm pressure with a heating rate of 20 °C min^{-1}, as shown in Fig. 6. The TGA curve shows that**1** is stable up to 96 °C. A weight loss of 5.6% occurred in the temperature range 96–128 °C, presumably due to the removal of two lattice water molecules (calcd. 5.7%). A total weight loss of 8.4% occurred in the temperature range 136–200 °C, mainly corresponding to the removal of the one coordinated water molecule per formula unit (calcd. 8.6%). Another weight loss of 65.7% occurred in the temperature range 300–465 °C, corresponding to the removal of one BIPA ligand and one pdon ligand per formula unit (calcd. 66.2%), no weight losses were observed up to 800 °C, indicating the complete deposition of the complex with the formation of CdO as the final product. The TGA curve of **2** shows that the first weight loss of 3.4% between 110 and 160 °C corresponds to the loss of the two coordinated water molecule per formula unit (calcd. 3.56%), then

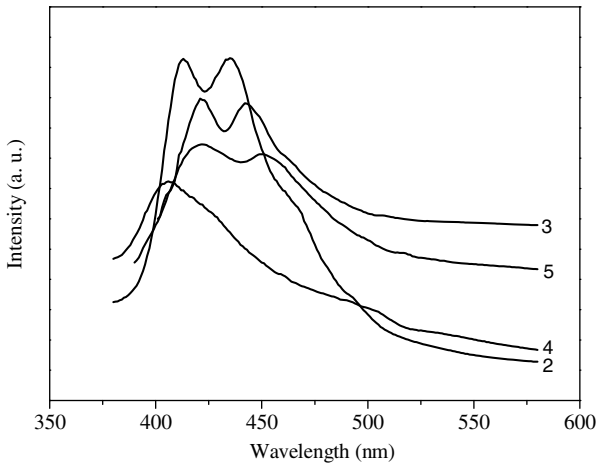

Fig. 5. The emission spectra of **2**–**5** in the solid state at room temperature.

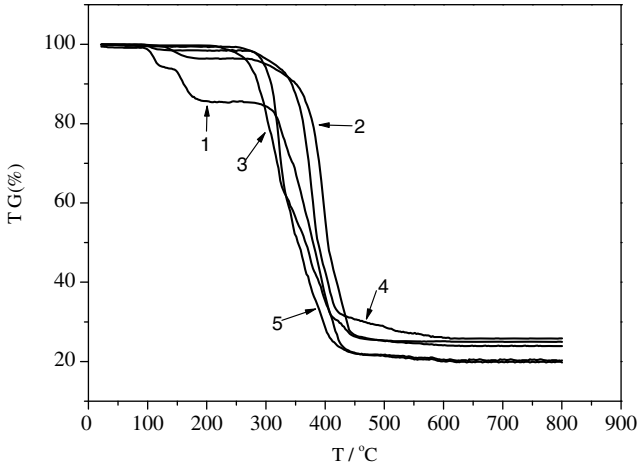

Fig. 6. TG curve of complexes **1**–**5**.

it was stable up to 290 °C. The framework collapsed in the temperature range 290–800 °C before the final formation of a metal oxide. The TGA curve shows that **3** and **4** are stable up to 300 °C. The framework collapsed in the temperature range 300–800 °C, suggesting that the organic ligands decompose slowly over a wide temperature range. The TGA curve of **5** shows that the first weight loss of 1.51% between 90 and 136 °C corresponds to the loss of the one lattice water molecules (calcd. 1.57%), and then it is stable up to 280 °C. The framework collapsed in the temperature range 280–800 °C, before the final formation of a metal oxide.

4. Conclusion

In summary, we have synthesized five novel metal-organic frameworks based on multi-carboxylate ligands and a chelate ligand by hydrothermal reactions. The successful syntheses of the five complexes indicate that it is promising to build up unusual architectures via a different reaction pH, thus opening up a new field in the preparation of metal coordination polymers with potential luminescent properties.

5. Supplementary data

CCDC 675859, 666353, 675860, 675861 and 675862 contain the supplementary crystallographic data for **1**, **2**, **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Terphenyl

ABSTRACT

The reaction of the bulky lithium terphenyl thiolate LiSAr′ (Ar′ = C_6H_3-2,6-(C_6H_3-2,6-Pr^i_2)$_2$) with $VI_2(THF)_2$ in THF resulted in the formation of two new V(II) and V(III) thiolate complexes. The addition of one equivalent of LiSAr′ to $VI_2(THF)_4$ led to the isolation of the dimeric V(II) species {V(μ-SAr′)I}$_2$ (**2**); a rare example of a structurally characterized V(II) thiolate. The thiolate ligands bridge the two vanadium centers, which are also bonded to a terminal iodide. In addition, there is an η^6-interaction between a flanking aryl ring from a terphenyl substituent with each metal. The attempted preparation of the vanadium dithiolate V(SAr′)$_2$ by reaction of $VI_2(THF)_2$ with two equivalents of LiSAr′ led to disproportionation which resulted in the isolation of the V(III) product V(SAr′)$_2$I (**3**) in which the vanadium center is coordinated by two sulfurs, an iodine, and a weaker interaction to a flanking aryl ring of the terphenyl group.

1. Introduction

Transition metal thiolate and related derivatives [1–4] have been extensively studied because of their relevance for biological systems [5,6]. In many instances, they can serve as structural models for active sites in numerous metal–sulfur proteins such as ferredoxins [7,8] or nitrogenases [9–11], which feature cysteine residues as ligands [6]. However, the preparation of the simplest neutral homoleptic transition metal thiolates has often been difficult because of extensive M-(μ-SR)-M thiolate bridging which results in the formation of intractable oligomers or polymers. The use of sufficiently bulky ligands [12,13] such as –SC_6H_2-2,4,6-Bu^t_3 (–SMes*) [14,15] and –SC_6H_2-2,4,6-Ph_3 [16] mitigates extensive bridging interactions so that low coordinate species, exemplified by the dimeric transition metal complexes [{M(SMes*)$_2$}$_2$] (M = Mn, Fe, Co) [15] and [{Fe(SC_6H_2-2,4,6-Ph_3)$_2$}$_2$] [16], can be obtained. In a more recent development, the use of the very hindered thiolate derivative, –SAr* (Ar* = C_6H_3-2,6-(C_6H_2-2,4,6-Pr^i_3)$_2$) has led to the isolation of a series of soluble, monomeric first row transition metal(II) dithiolates M(SAr*)$_2$ (M = Cr, Mn, Fe, Co, Ni and Zn) in which the metals are nominally two-coordinate [17]. These complexes exhibit linear (or nearly linear) S–M–S units with varying degrees of weak interaction between the metal center and the flanking aryl rings of the terphenyl ligands. We wished to extend these results to vanadium via the synthesis and characterization of low valent vanadium thiolates of formula V(SAr)$_2$ (Ar = bulky terphenyl). Vanadium thiolates have been studied because of their potential relevance to the function of vanadium nitrogenase enzymes [18–20]. Vanadium nitrogenases, although less well understood than their molybdenum analogues [6–10,21], are believed to have a similar coordination environment to Mo in Mo-based nitrogenases, with low oxidation state (II–IV) oxidation states [11,18–20] wherein the metal is coordinated to several sulfur atoms. We now report on our initial investigations which have resulted in the synthesis of two low coordinate V(II) and V(III) thiolate complexes.

2. Experimental

2.1. General procedures

All manipulations were carried out with use of modified Schlenk techniques under an argon atmosphere or in a Vacuum Atmospheres HE-43 drybox. All solvents were dried by the method of Grubbs and degassed three times (freeze–thaw) prior to use, $VI_2(THF)_4$ was synthesized according to the literature procedure [22]. ^{1}H NMR spectra were recorded on a Varian 300 MHz instrument and referenced to the residual protio benzene in the C_6D_6 solvent. Melting points were recorded in glass capillaries sealed under N_2 or Ar and are uncorrected. UV–Vis data were recorded on a Hitachi-1200 spectrometer. Solution magnetic moment measurements were carried out by the method of Evans as a solution in C_6D_6 [23].

2.2. Ar′SH (*1*)

The terphenyl thiol Ar′SH was synthesized in an analogous manner to that described for the related thiol HSC_6H_3-2,6(C_6H_2-2,4,6-Pr^i_3)$_2$ [24]. Yield: 72%, m.p. 165–168 °C. ^{1}H NMR (C_6D_6, 400 MHz, 25 °C): δ 1.11 (d, $^3J_{HH}$ = 6.8 Hz 12 H, *o*-CH(CH_3)$_2$), 1.32 (d, $^3J_{HH}$ = 6.8 Hz, 12H, *o*-CH(CH_3)$_2$), 2.83 (sept,

$^3J_{HH}$ = 6.9 Hz, 4H, *o*-C*H*(CH$_3$)$_2$), 3.08 (S, 1H, –SH), 6.96 (1H *p*-C$_6$H$_3$), 7.21 (d, $^3J_{HH}$ = 7.6 Hz, 2H, *m*-C$_6$H$_3$-2, 6-Pr$_2^i$), 7.31 (d, $^3J_{HH}$ = 7.6 Hz, 2H, *p*-C$_6$H$_3$-2, 6-Pr$_2^i$. ^{13}C{^{1}H} NMR (C$_6$D$_6$, 100.59 MHz): δ 24.00, δ 24.92 (*o*-CH(*C*H$_3$)$_2$), 31.14 (*o*-*C*H(CH$_3$)$_2$), 123.67 (*m*-C$_6$H$_3$-2, 6-Pr$_2^i$), 124.36 (*i*-C$_6$H$_3$), 129.20 (*p*-C$_6$H$_3$-2, 6-Pr$_2^i$, 129.9 (*m*-C$_6$H$_3$), 135.61 (*i*-C$_6$H$_3$-2, 6-Pr$_2^i$), 138.00 (*p*-C$_6$H$_3$) 138.68 (*o*-C$_6$H$_3$-2, 6-Pr$_2^i$), 147.26 (*o*-C$_6$H$_3$).

2.3. [V(μ-SAr′)I]$_2$ (**2**)

(LiSAr′)$_2$ (generated in solution from 0.872 g, 2.0 mmol and LiBu^n (1.6 M in hexanes, 1.25 mL)), in THF (25 mL), was added dropwise to a stirred suspension of VI$_2$(THF)$_4$ (1.186 g, 2.0 mmol) in THF (25 mL) cooled to *ca.* 0 °C. The resulting dark, brown-red solution was stirred overnight while it was allowed to warm to room temperature. The solvent was removed under reduced pressure and the resulting dark red solid was extracted with hexane (30 mL) and filtered. The volume of the filtrate was reduced to *ca.* 5 mL under reduced pressure to afford dark red, X-ray quality crystals of **2** after storage for 3 days at *ca.* −20 °C. Yield: 0.768 g (63%) m.p. = 230 °C (dec). ^{1}H NMR (400 MHz, C$_6$D$_6$, 25 °C): δ = 7.1 (br, s), 6.9 (br, s), 3.7 (br, s), 2.7 (br, m), 1.3 (br, d), 1.0 (br, d). UV/Vis (hexanes; λ_{max}, nm (ε, mol^{-1} L cm^{-1})): 282 (7300), 384 (2500), 466 (2000). μ_{eff} = 3.61 μ_B/vanadium.

2.4. [V(SAr′)$_2$I] (**3**)

A THF (40 mL) solution of (LiSAr′)$_2$ (1.744 g, 4.0 mmol) in THF (50 mL) was added dropwise to a stirred suspension of VI$_2$(THF)$_4$ (1.186 g, 2.0 mmol) in THF (25 mL) with cooling in an ice bath. The resulting dark green solution was allowed to warm to room temperature and stirred overnight. The solvent was removed under reduced pressure and resulting dark green solid was extracted with hexane (40 mL) and filtered. The volume of the solution was reduced to *ca.* 10 mL which afforded green, X-ray quality crystals of **3** after 7 days at *ca.* 7 °C. Yield 0.552 g (23%) m.p. = 174–178 °C (dec). ^{1}H NMR (300 MHz, C$_6$D$_6$, 25 °C): δ = 7.10 (br, d), 2.95 (br, s), 1.21 (br, s), 1.05 (br, s). UV/Vis (hexanes; λ_{max}, nm (ε, mol^{-1} L cm^{-1})): 328 (3050), 390 (2000), 440 (1400), 638 (1600). μ_{eff} = 2.64 μ_B/vanadium.

2.5. X-ray data collection

X-ray quality crystals of **2** or **3** were removed from the Schlenk tube and immediately covered with a layer of hydrocarbon oil. A suitable crystal was selected, attached to a glass fiber, and placed in the cold temperature stream as previously described [25]. The data were collected near 90 K using a Bruker APEX (**2**) or a SMART 1000 (**3**) diffractometer and Mo Kα (λ = 0.71073 Å) radiation. Absorption corrections were applied using SADABS [26]. The structures were solved by use of direct methods in SHELXS [27] and refined by the full-matrix least-squares procedure in SHELXL. All non hydrogen atoms were refined anisotropically, while hydrogens were placed at calculated positions and included in the refinement by using a riding model. Some details of the data collection and refinement are given in Table 1. Further details are in the supplementary material.

3. Results and discussion

The use of sterically encumbering ligands has played a key role in the stabilization of low coordinate (coordination number $\leqslant$3) compounds throughout the periodic table [28]. Early work focused on bulky ligands attached via a second row element C, N, or O in alkyl, aryl, amido, alkoxo on aryloxo ligands. The application of ligands based on elements from the third or later rows, involving for example, silyl, phosphido, or thiolate ligands, was a later development for a number of reasons that included synthetic and steric considerations as well as weaker metal–ligand bonding [28]. Although there is now a vast chemistry of transition metal thiolates, the fact that the sulfur can carry only one organic substituent has limited their application in the stabilization of low coordination numbers. We have recently used the very large terphenyl thiolate ligand −SC$_6$H$_3$-2, 6(C$_6$H$_2$-2, 4, 6-Pr$_3^i$)$_2$ (–SAr*) [24] to synthesize a series of divalent transition metal complexes (M(SAr*)$_2$ (M = Cr, Mn, Fe, Co)) [17] and their zinc analogue Zn(SAr*)$_2$. These feature linear or almost linear metal coordination for Cr, Mn, Co, Ni and Zn whereas Fe(SAr*)$_2$ displays a bent (S–Fe–S = 151.48(2)°) geometry and an apparent tendency to rearrange to a sandwich structure involving metal–aryl ring coordination [17]. A feature of the complexes is that, with the exception of the unique iron derivative, all the secondary metal–ligand interactions (mainly to *ipso*-carbons from a flanking aryl ring of the terphenyl ligand) are weak and exceed 2.5 Å, with the longest being observed for Mn(SAr*)$_2$ (Mn–S=2.951(2) Å). Such distances exceed those in the corresponding η^5 or η^6-bonded metal arene complexes by a significant margin. For example, the Cr–C interaction is 2.502(2) Å in Cr(SAr*)$_2$ whereas in Cr(η^5-C$_5$H$_5$)$_2$ the Cr–C distance is 2.142(3) Å and the Cr–centroid distance is 1.61 Å [29]. The above findings encouraged us to extend the approach to vanadium and it was hoped that the employment of a bulky terphenyl thiolate ligand would allow us to obtain the first example of a two-coordinate V(II) species.

The reaction of VI$_2$(THF)$_4$ with one or two equivalents of LiSAr* did not afford readily characterizable products. We turned instead to the related –SAr′ ligand which has similar steric properties to –SAr* and can be synthesized by a similar route. It differs from Ar* only in the absence of *para*-Pr^i substituents from the flanking aryl rings. The addition of one equivalent of LiSAr′ to a suspension of VI$_2$(THF)$_4$ in THF at 0 °C (Eq. (1)) afforded a dark red-brown solution from which deep red crystals of **2** could be isolated in

$$2VI_2(THF)_4 + 2LiSAr' \xrightarrow{0\ ^\circ C, THF} [V(\mu\text{-}SAr')I]_2 + 2LiI \quad (1)$$

63% yield. These were characterized by UV–Vis spectroscopy, magnetic studies and X-ray crystallography. The results of the diffraction study of **2** are illustrated in Fig. 1. It represents a very rare example of a structurally characterized vanadium (II) thiolate [4,30–33]. It is dimeric and the metals are linked by thiolate bridges to form a V$_2$S$_2$ core structure. Each vanadium is also coordinated to a terminal iodide. The V$_2$S$_2$ core is characterized by an inversion center with internal S–V–S and V–S–V angles of 100.86(4)° and

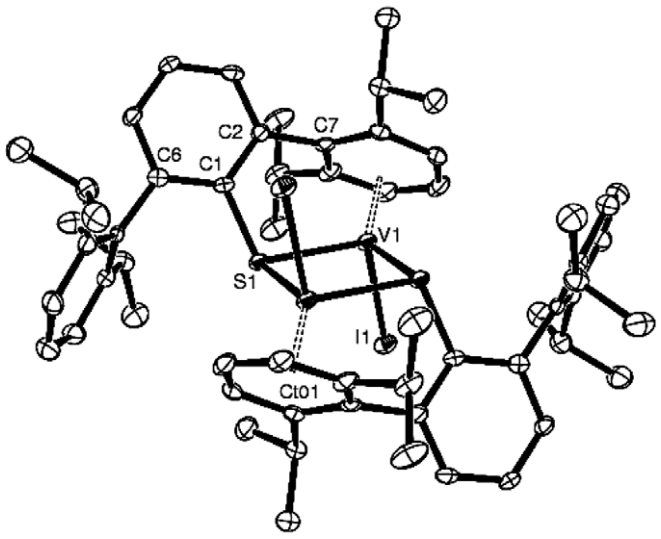

Fig. 1. Thermal ellipsoid (30%) plot of $[V(\mu\text{-}SAr')I]_2$ (**2**) ($Ar' = C_6H_3\text{-}2,6\text{-}(C_6H_3\text{-}2,6\text{-}Pr^i_2)_2$). Hydrogen atoms are not shown.

79.14(4)°, respectively. The V–I bonds subtend an angle of 100.37(3)° with respect to the V_2S_2 plane. In addition there is an η^6-interaction between a flanking aryl ring of the terphenyl ligand and each vanadium center. This interaction is relatively short (V(1)–Ct = 1.909(2) Å, Ct = centroid) and is comparable to that observed in vanadocene (1.917 (2) Å) [30] (1.962 Å), but marginally longer than that in $V(\eta^5\text{-}C_5Me_5)_2$ (1.873(2) Å) [31]. The data thus indicate the presence of a relatively strong vanadium–aryl ring interaction in **2**. This is also supported by the difference in the average C–C bond lengths in the interacting (1.415 Å avg.) and non interacting (1.401 Å avg.) aryl ring. The V–S bond lengths are 2.395(1) and 2.412(1) Å. These may be compared with the V(II)–S distances in $[V(Spy)_2(TMEDA)]$ (Spy = pyridine-2-thiolate, TMEDA = tetramethylethylenediamine; V–S = 2.252(2) and 2.547(2) Å) [33], $[V(Spy)_3]^-$ (V–S = 2.545 Å (avg.)) [31] and in $[V(SC_6H_3\text{-}2,6\text{-}Cl_2)_2(TMEDA)]$ (V–S = 2.464(2) and 2.468(2) Å) [34]. The metal centers in these complexes are six-coordinate or quasi six-coordinate, and, if the V–aryl interaction in **2** is viewed as occupying three coordination sites, the metal center in **2** may also be regarded as having six-coordination. In view of this, the V–S bond lengths in **2** may be regarded as being somewhat shorter than expected especially since the thiolate groups are bridging. It may be that the presence of a halogen ligand in **2**, which increases the positive charge on the metal, may cause the shorter V–S bond. The V–I bond length in **2** (2.7228(8) Å) is a little shorter than that in vanadium (II) complexes $[VI_2(depe)_2]$ (depe = bis(diethylphosphino)ethane) [22,30] (2.779(2) Å), $[VI_2(THF)([9]aneS_3)]$[35] ([9]aneS$_3$ = 1,4,7-trithiacyclononane) (2.787(2) and 2.798(3) Å) and *cis*-$VI_2(DME)_2$ [36] (2.811(2) and 2.805(2) Å) (see Tables 2 and 3)

The addition of freshly prepared Ar′SLi to $VI_2(THF)_4$ suspended in THF in a 2:1 ratio results in the formation of the monomeric vanadium (III) thiolate $[V(SAr')_2I]$ **3**, which presumably arises via a disproportionation process. Each vanadium center is coordinated to a terminal iodide and two thiolate ligands. However, the coordination geometry of the (see Fig. 2)

$$VI_2(THF)_4 + 2LiSAr' \xrightarrow{0\ ^\circ C,THF} [V(SAr')_2I] + 2LiI + V(I) \quad (2)$$

VS_2I array is pyramidal ($\sum$ °V = 295.72(5)) rather than planar and there is an η^6-interaction involving the flanking aryl ring of the terphenyl substituent and the vanadium center. The V–(Ct) distance (1.972(3) Å) is significantly longer than it is in **2**, however. This is especially noteworthy in view of the fact that effective ionic radius of six-coordinate V^{3+} (0.64 Å) is smaller that of V^{2+} (0.79 Å) [37] which may lead to an expectation for a shorter V^{3+}-centroid contact. On the other hand, the higher electron deficiency and reduced crowding of the metal center in **2** may account for the shorter V(II)–centroid distance. Nonetheless, inspection of the bond distances in the interacting and non interacting aryl rings of the S(I) ligand shows the average C–C distance in the former 1.405 Å are longer than those in the latter consistent with a weakening of the CC-bonding. The V–S–C angle for the interacting terphenyl V(I)–S(I)–C(1) = 106.8(2)° is ca. 12.5° narrower than the 119.3(2) observed for the thiolate ligand. The difference in the V^{n+} effective ionic radii is indeed reflected in the V–S bond lengths, 2.292(1) and 2.284(1) Å, which are over 0.1 Å shorter than those in **2**. The V–S distances are also shorter than those in $[V(tipt)_3(THF)_2]$ (tipt = 2,4,6-tri-isoproplbenzenethiolate) [38] (2.308(1), 2.334(1), 2.320(1) Å) or the 2.364 Å in $[V(SNC_9H_6)_3]$ [32]. The V–I distance 2.6659(8) Å is also shorter in **3**, but the shortening is not as great as it is for the V–S bonds. It may be compared with the V–I distance in $[VI(Ind)_2]$ (2.794(1) Å) [39].

The magnetic moments of the two compounds were measured in C_6D_6 by the Evans' method. These measurements afforded magnetic moments consistent with d^3 (**1**, μ_{eff} = 3.67μ_B per vanadium) and d^2 (**2**, μ_{eff} = 2.64μ_B) electron configurations. Both values indicate that there is little orbital contribution to the magnetic moment and that there is little coupling between the vanadiums in **2** (V–V = 3.063(1) Å). The presence of unpaired electrons gave rise to

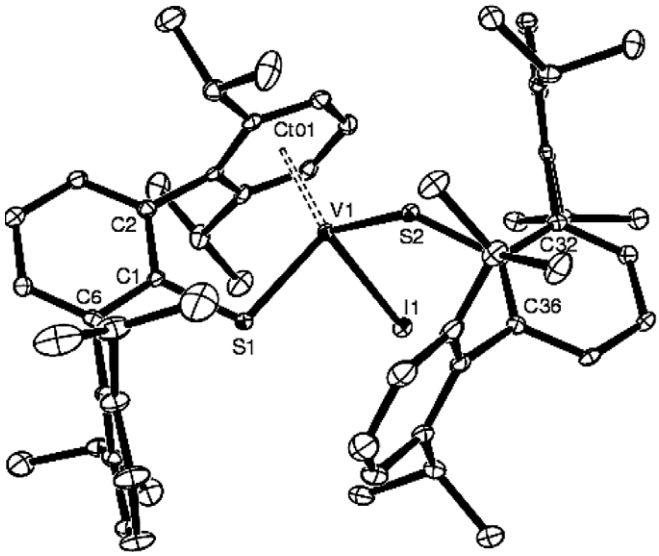

Fig. 2. Thermal ellipsoid (30%) plot of $V(SAr')_2I \cdot hexane \cdot THF$ (**2** · hexane · THF) ($Ar' = C_6H_3\text{-}2,6\text{-}(C_6H_3\text{-}2,6\text{-}Pr^i_2)_2$). Hydrogen atoms and solvent molecules are not shown.

broad and largely featureless paramagnetically shifted ^{1}H NMR spectra for both **2** and **3**.

4. Conclusions

The synthesis of **2** and **3** demonstrates the ability of bulky terphenyl thiolates to stabilize early transition metal complexes in low oxidation states. Nonetheless, a vanadium dithiolate V(SAr′), analogous to those reported for $M(SAr^{*})_2$ (M = Cr, Mn, Fe, Co, Ni, Zn), could not be isolated by a similar synthetic route due to a disproportionation reaction. However, the isolation of the iodide **2** in good yield may prove to be a useful reagent for further synthesis and the study of additional reactivity. For example, it may be useful as a precursor for the construction of V–V bonds via reductive coupling. In addition, two-coordinate V(II) may yet be obtainable from **2** with use of another less reducing coligand. Attempts to isolate such complexes are in hand.

ABSTRACT

Sterically bulky pyrazines have been successfully utilized for the preparation of discrete oligo-nuclear TBP (trigonal bipyramidal), SqP (square pyramidal), and Oh (octahedral) copper(II) complexes. We have synthesized a unique linear pentanuclear complex [{Cu(hfac)$_2$}$_5$(μ-2-butyl-3-methylpyrazine)$_4$]. The two terminal copper(II) ions have a SqP structure while the three inner ions have an Oh one. The solvent molecule was incorporated in the clearance of the lattice. From another reaction under harsh conditions, we separated [{Cu(hfac)$_2$}$_3$(μ-2-butyl-3-methylpyrazine)$_2$], which can be regarded as the central moiety of the pentanuclear one. We also prepared a dinuclear complex [{Cu(hfac)$_2$}$_2$(μ-tetramethylpyrazine)], in which the pyrazine nitrogen atoms were located at TBP equatorial positions. Single-crystal EPR measurements supported its compressed TBP structure. The exchange coupling was antiferromagnetic with $J_{TBP-TBP}/k_B = -3.6$ K. The linear trinuclear [{Cu(hfac)$_2$}$_3$(μ-2,3,5-trimethylpyrazine)$_2$], having two TBP Cu ions with an intervening Oh Cu ion, showed very weak antiferromagnetic coupling. DFT calculations on these compounds indicated that the σ-type orbital overlap between the Cu and N atoms is essential for superexchange interactions.

1. Introduction

A wide variety of complexes have been developed in which π-conjugated *N*-donor ligands are used for rigid building blocks and controllable superexchange couplers [1]. Pyrimidines and pyrazines have a highly directive nature of the nitrogen lone pairs and have attracted much attention in the construction of supramolecular structures such as porous materials [2] and molecular grids [3]. These diazaaromatic rings have characteristic σ/π-electron systems providing magnetic exchange pathways, and especially the pyrimidine skeleton has been utilized as a ferromagnetic coupler as expected from its spin-polarization mechanism [4]. However, the role of couplers has proved to depend on the coordination structures and the σ/π nature of the transition-metal spins [5,6]. On the other hand, pyrazines mostly work as an antiferromagnetic coupler [7–9]. For convenience of discussion, the bridging geometries of the pyrazine (pyz) systems are classified into three types (Chart 1) for copper(II) complexes ($3d^9$; $S_{Cu} = 1/2$). Only a few examples showing ferromagnetic coupling are known, which has been explained in terms of orbital orthogonality in the equatorial–axial (eq–ax) combination of the two nitrogen lone pairs [10,11].

The ax–ax type is less important for magnetochemistry, since these magnetic couplings are very small; for example, one-dimensional (1-D) [Cu(hfac)$_2$(μ-pyz)]$_n$ (Hhfac stands for 1,1,1,5,5,5-hexafluoropentane-2,4-dione) showed $J/k_B = -0.03$ K [12,13], where the spin Hamiltonian is defined as $-2J\Sigma S_i \cdot S_j$. We also systematically prepared 1-D [Cu(hfac)$_2$(μ-L)]$_n$ (L = substituted pyrazines) and revealed that they exhibited practically negligible antiferromagnetic interactions [14].

The magneto-structural relation has been discussed on the octahedral (Oh) Cu ion whose magnetic orbital is well defined as $3d_{x^2-y^2}$ located on a coordination basal (i.e., eq) plane. Studies on the magnetic coupling across diazaaromatic rings between trigonal bipyramidal (TBP) Cu ions are relatively rare [9,15], whilst those of oxo-, halo- and cyano-bridged TBP compounds are more often found in the literature [16]. In the present work, we have synthesized and characterized a simple dinuclear complex containing two TBP Cu ions with a pyz bridge, which can be regarded as a successful example of the application of steric hindrance from substituents on a pyz ring. Discrete oligo-nuclear complexes have

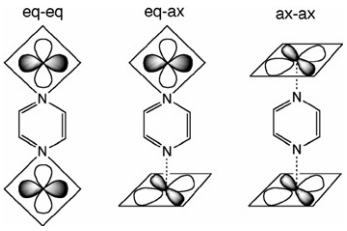

Chart 1. Coordination geometry of Cu-μ-pyz-Cu systems.

various coordination spheres at the terminal Cu ions, and accordingly they can provide us good examples for the study on the magneto-structural relationship.

In addition, we have characterized a very unique linear-arrayed pentanuclear copper(II) complex where the two terminal Cu ions possess a square pyramidal (SqP) coordination sphere. We can compare the magnetic couplings between the Oh–SqP and Oh–TBP interactions. The lobe direction of the magnetic orbital can be confirmed from theoretical calculations, and the magnetic coupling mechanism will be explained in connection with the above classification.

2. Results

2.1. Preparation and spectral characterization

Complexation of anhydrous $[Cu(hfac)_2]$ and 2-butyl-3-methylpyrazine (bmpyz) afforded a novel linear pentanuclear complex $[\{Cu(hfac)_2\}_5(\mu\text{-bmpyz})_4]$ (**1**). The preparation was highly reproducible as indicated by the same product being obtained from complexations in various solvents such as pentane, hexane, octane and cyclohexane. In spite of the ample reproducibility of the pentanuclearity, we also found that thermal degradation of the reaction mixture, after prolonged refluxing conditions for example, gave a trinuclear compound $[\{Cu(hfac)_2\}_3(\mu\text{-bmpyz})_2]$ (**2**). Compound **2** was usually contaminated with **1** and could not be obtained in a pure form, as indicated by the elemental analysis (see Section 5).

Complexation of $[Cu(hfac)_2]$ with tetramethylpyrazine (tmpyz) gave a 2:1 compound, $[\{Cu(hfac)_2\}_2(\mu\text{-tmpyz})]$ (**3**). For comparison, we investigated the known linear trinuclear complex $[\{Cu(hfac)_2\}_3(\mu\text{-trpyz})_2]$ (**4**; trpyz stands for 2,3,5-trimethylpyrazine), in which the central Cu ion has an Oh structure while two outer Cu ions have a TBP structure [17].

One of the authors (T.K.) has been reported that IR spectroscopy is a versatile tool for structural determination of various compounds obtained from $[Cu(hfac)_2]$ [14,17,18]. In the simple complex **3**, split ν(C–O) bands were observed at 1653 and 1645 cm^{-1}, which are assigned to the stretching vibrations of carbonyls in the chelated hfac ligands with short and long C–O distances, respectively. The splitting arises from non-equivalent C–O bonds in each hfac chelate ring (for the molecular structure, see Chart 2). Similarly, split ν(C–O) bands were observed for the hfac chelate rings around the five-coordinated Cu ion of **4**. The IR spectrum of **4** has three bands at 1658, 1644 and 1639 cm^{-1} in the C–O stretching region [17]. As compared with the spectrum of **3**, the split bands (1658 and 1644 cm^{-1}) may be assigned to the vibrations of the hfac ligands around the five-coordinated Cu ion with a TBP structure, the rest (1639 cm^{-1}) around the six-coordinated Cu ion with an Oh structure.

On the other hand, no split was observed for the hfac ring deformation band at 675 cm^{-1} for **3**, indicating that the two chelated hfac ligands are equivalent. *N*-Ax square-pyramidal (SqP) structures showed no split in the ν(C–O) and hfac ring deformation bands [12,18c], while the *N*-eq SqP structure shows both split bands. From the analysis of the ν(C–O) and hfac ring deformation bands, the *N*-eq TBP structures of **3** and **4** can be characterized as an *N*-ax or *N*-eq SqP type.

The IR spectrum of **1** was somewhat complicated, indicating the presence of various types of hfac chelate rings. Weak and strong ν(C–O) bands were observed at 1657 and 1641 cm^{-1}, respectively. Strong and weak hfac ring deformation bands were also observed at 679 and 670 cm^{-1}, respectively. We can point out that both weak bands arise from one of the non-equivalent hfac chelate rings around the five-coordinated Cu ion, namely an *N*-eq SqP structure. On the other hand, both strong bands are assigned to the stretching vibrations of carbonyls in the hfac chelated rings and hfac ones around the six-coordinated Cu ion having an elongated Oh geometry [12,14].

2.2. Molecular structures

Fig. 1 shows the molecular structure of **1** in the crystal of **1** · (octane). The terminal Cu ions (Cu1 and Cu1*) have an *N*-eq SqP structure. The ax Cu1–O4 bond length (2.150(4) Å) is longer than the eq ones (1.940(3)–2.029(4) Å). The angular structural index parameter τ [19] and its modified parameter χ [20] have been defined for the five-coordination geometry. The τ and χ values for Cu1 in **1** are 0.18 and 0.23, respectively. These values are close to zero, the value for an ideal SqP structure. The inner Cu ions (Cu2, Cu3 and Cu2*) have an elongated Oh geometry. Owing to steric reasons, all of the nitrogen atoms occupy the ax positions. The Cu–N distances are considerably long (2.442(5)–2.513(4) Å), and are comparable with those of the 1-D $[Cu(hfac)_2(\mu\text{-L})]_n$ (L = substituted pyrazines) [14]. The two bmpyz ligands around Cu3 are arranged in a head-to-head fashion, but those around Cu2 are in a head-to-tail fashion. The intramolecular Cu1···Cu2 and Cu2···Cu3 distances are 7.2473(10) and 7.5574(8) Å, respectively.

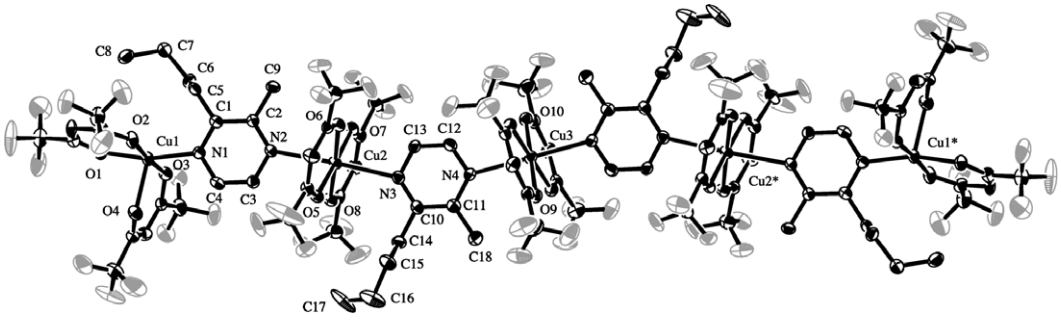

Fig. 1. Ortep drawing of $[\{Cu(hfac)_2\}_5(\mu\text{-bmpyz})_4]$ (**1**) in the crystal of **1** · (octane). Thermal ellipsoids are drawn at the 50% probability level. Hydrogen atoms are omitted. Symmetry operation code of * is $-x, -y+2, -z$. Selected bond lengths: Cu1–N1, 2.029(4); Cu2–N2, 2.513(4); Cu2–N3, 2.485(4); Cu3–N4, 2.442(5) Å. Only the major conformation is shown for the disordered terminal methyl group (C17).

The N4···N3–Cu2 angle (164.0(2)°) is considerably bent from an ideal axial array, which would relieve the steric congestion nearby and enable Cu2 to form an Oh structure. On the other hand, the environment around N1–Cu1 is still highly crowded, leading to a penta-coordination SqP structure at Cu1, and the chain growth is limited accordingly. Note that the N2–Cu2 distance is longer than the other ax N3–Cu2 and N4–Cu3 distances, being consistent with a possible mechanism of the formation of **2**; N2–Cu2 bond cleavage may easily occur in the thermal degradation reaction of **1**, leading to a decrease of the steric repulsion between the large butyl group (C14–C15–C16–C17) and the hfac ligands coordinated to Cu2.

The crystal of **1** has a large void volume where the solvent molecules are incorporated. We can find relatively large thermal ellipsoids at the butyl groups, such as C14–C15–C16–C17. The terminal methyl group (C17) is disordered into two conformational positions with an occupancy ratio of 0.668(17):0.332(17). The molecular packing seems to be still loose around in that area.

The crystal structure analysis as well as elemental analysis on **1** indicate that the solvent molecule is incorporated with a molar ratio of 1:1 when pentane, hexane and octane are used as solvents, and two solvent molecules are present when **1** is crystallized from cyclohexane (Fig. 2). Severe disorder of the solvent molecules was found for **1** · (pentane) and **1** · (hexane). The cell parameters are quite similar to each other in the triclinic $P\bar{1}$ space group and the molecular skeletons of **1** are practically identical among the various solvated crystals, regardless of the solvent used. The rigid rod-like structure of **1** seems to have a strong self-assembly character and constructs a tough host network.

The single-crystal X-ray diffraction study revealed that **2** approximately corresponds to the central Cu_3 portion of **1**. There are two crystallographically independent molecules in a unit cell, which are quite similar to each other. One molecule is shown in Fig. 3. Each molecule has an inversion center at the central Cu ion. The butyl groups exhibit some disorder with respect to the zig-zag conformation. All of the nitrogen atoms are located at ax positions. The outer $Cu(hfac)_2$ moieties are slightly pyramidalized. The Cu1 ion is located above the basal O1–O2–O3–O4 plane by 0.211(2) Å. This distance is close to the values of similar *N*-ax SqP copper(II) compounds (0.228(3) Å for $[\{Cu(hfac)_2\}_3(\mu\text{-}5\text{-}pym)_2]$ [17] and 0.24 Å for $[\{Cu(hfac)_2\}_2(\mu\text{-}pyz)]$ [12]), but is slightly longer than those of *N*-eq SqP copper(II) compounds (0.167(2) Å at the terminal copper ion in **1** and 0.157(2) Å in $[Cu(hfac)_2(5\text{-}Hmpz)]$ [18c] for example). However, the Cu1–N1 distance (2.333(3) Å) is considerably longer than the values for the corresponding bond in $[\{Cu(hfac)_2\}_2(\mu\text{-}pyz)]$ (2.250(17) Å) [12] and

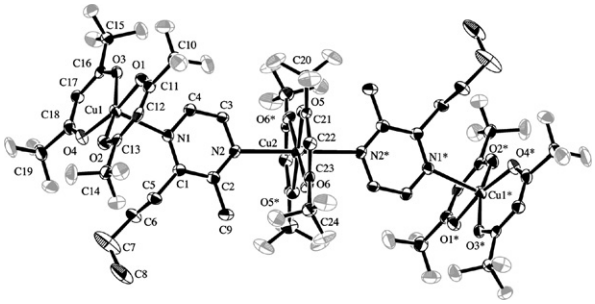

Fig. 3. Ortep drawing of $[\{Cu(hfac)_2\}_3(\mu\text{-}bmpyz)_2]$ (**2**). Thermal ellipsoids are drawn at the 50% probability level. Hydrogen atoms are omitted. Symmetry operation code of * is $-x+1, -y, -z+1$. Selected bond lengths: Cu1–N1, 2.333(3); Cu2–N2, 2.463(4), Cu1–O1, 1.943(3); Cu1–O2, 1.940(3); Cu1–O3, 1.950(3); Cu1–O4, 1.940(3); Cu2–O5, 1.955(3); Cu2–O6, 1.968(3) Å. Only the major conformation is shown for the disordered terminal methyl group (C8).

$[\{Cu(hfac)_2\}_3(\mu\text{-}5\text{-}pym)_2]$ (2.282(5) Å) [17], owing to the bulky butyl group.

The single-crystal X-ray diffraction study revealed that **3** crystallized in the orthorhombic *Fddd* space group. Fig. 4 shows the molecular structure of **3**. A quarter of the structure is a crystallographically independent unit. The Cu1–N1–O2–$O2^{\#}$ atoms of **3** form a strict plane because of the crystal symmetry. The ax Cu1–O1 (1.919(2) Å) distance is somewhat shorter than the eq Cu1–O2 and Cu1–N1 distances. The coordination geometry of the Cu ion belongs to a compressed *N*-eq TBP type. The τ and χ values are 0.67 and 0.71, respectively. Although these values are appreciably smaller than unity for an ideal TBP structure, they belong to the TBP category [19,20]. The O2–Cu1–N1 and $O2^{\#}$–Cu1–N1 bond angles (136.81(6)°) are considerably larger than the ideal trigonal angle of 120°. The resultant O2–Cu1–$O2^{\#}$ angle is only 86.37(9)°. The slightly small index values are attributed to such angular deviations, which arise from substantial steric interactions from the methyl groups in tmpyz. The two Cu ions are separated by 6.8542(8) Å in the molecule.

The crystal structure of **4** was determined at 90 K (not shown; Chart 2 for the molecular structure), though the determination at room temperature has already been reported [17]. The coordination geometry around the terminal Cu ions is similar to that of Cu1 in **3**. The Cu1–N1 distance in **3** (2.066(3) Å) is slightly longer than that of the corresponding bond in **4** (2.023(2) Å). The central Cu ion in **4** has an elongated Oh structure, the hfac oxygen atoms being coordinated at the eq positions. Owing to the partially relief of the steric hindrance, six-coordination is allowed, but the ax

bonds (2.443(2) Å) are elongated like the quinoxaline- and phenazine-bridged Oh copper(II) chain compounds [14]. The coordinating ability of the 1-nitrogen atom in tmpyz and trpyz seems to be stronger than the 1-nitrogen atom in 2,6-dimethylpyrazine, because the latter occupied an Oh–ax position with a quite long Cu–N bond (2.606(2) Å) [14]. The intramolecular Cu···Cu separation is 7.1845(3) Å.

The τ and χ values for the TBP Cu ion in **4** were found to be 0.71 and 0.73, respectively, at room temperature. However, they became somewhat smaller, 0.66 and 0.68, respectively, at 90 K. This finding means that the distortion proceeds from TBP to SqP at low temperature.

2.3. EPR spectra

We measured the EPR spectra of **3** to confirm the TBP structure of the copper(II) ion. Thanks to the orthorhombic lattice of the crystal of **3**, we could easily determined $g_{//}$ as a g factor when a magnetic field was applied along the crystallographic a axis, while $g_{\perp}$ was obtained when a field was applied on the bc plane. At room temperature we observed a single line in the $\Delta m_S = \pm 1$ region using a single crystal of **3** by means of X-band EPR spectroscopy. We determined anisotropic g factors as $g_a = 2.083$, $g_b = 2.245$ and $g_c = 2.138$ (Fig. 5). These values fell in the typical ranges of g factors found in room-temperature data of compressed TBP copper(II) complexes [21]. The finding of $2 \leqslant g_{//} < g_{\perp}$, known as the "inverse" trend, indicates the d_{z^2} magnetic state of the copper(II) ion [21,22]. In addition, a forbidden transition of $\Delta m_S = \pm 2$ was also observed almost isotropically at $g \approx 4.25$, which can be assigned to the triplet state in a thermal equilibrium.

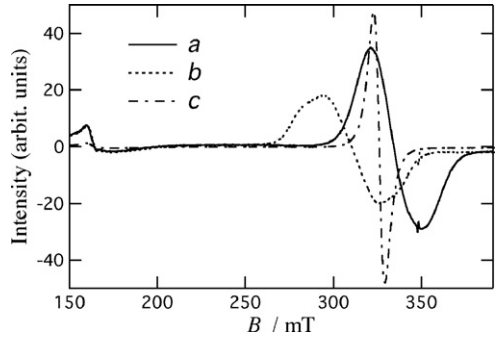

Fig. 5. X-Band EPR spectra of **3**. Symbols a, b and c denote the measurements with applied fields parallel to the crystallographic a, b and c axes, respectively.

The dominant TBP character in **3** could finally be confirmed by the fact that the magnetic orbital corresponds to $3d_{z^2}$ from a calculational study (see below).

2.4. Magnetic properties

We measured the magnetic susceptibilities of **1** · (octane), **3** and **4** on a SQUID magnetometer. Compound **4** is known, but its magnetic properties have not been reported to date [17]. Compound **2** could not be obtained as a pure form. All of the nitrogen atoms are located at ax positions in **2**, and accordingly we can expect that the magnetic couplings in **2** are negligible [12–14].

Fig. 6a shows the $\chi_m T$ product plotted against T for the three specimens below 100 K. The $\chi_m T$ value of **1** · (octane) was practically constant, with a value of 2.23 cm^3 K mol^{-1}. We estimated $|J|/k_B < 0.1$ K (antiferromagnetic) between any neighboring copper ions with $g_{avg} = 2.173(2)$ (the exchange parameter is defined as $-2J$). The small interaction in **1** is confirmed from the magnetization curve; that is the data measured at 1.8 and 4.5 K almost followed the theoretical Brillouin function (Fig. 6b). Similar magnetic measurements and analysis on other solvated specimens gave almost identical results.

On the other hand, **3** exhibited obvious magnetic coupling. The $\chi_m T$ value of **3** monotonically decreased upon cooling, indicating the presence of an antiferromagnetic interaction. The observed interaction is attributed to the through-bond Cu(TBP)-μ-tmpyz-Cu(TBP) superexchange. We applied the spin Hamiltonian, $H = -2J_{TBP-TBP} S_1 \cdot S_2$; i.e., the molar magnetic susceptibility can be written as the Bleaney–Bowers equation [23]. The optimized parameters are: $J_{TBP-TBP}/k_B = -3.583(6)$ K with $\chi_{TIP} = 0.001289(5)$ cm^3 mol^{-1} and $g = 2.2531(9)$, where χ_{TIP} stands for the temperature-independent paramagnetic susceptibility. The calculated curve is superposed in Fig. 6a, and the fit was satisfactory. The antiferromagnetic interaction in **3** was confirmed in the magnetization curve (Fig. 6b). The magnetization data measured at 1.8 K fell appreciably below the theoretical Brillouin function with $S = 1/2$. The S-shape curve is attributed to a spin reorientation from a singlet to a triplet state. The Zeeman energy ($g\mu_B H$) obtained from the magnitude of the field (ca. 3 T at 1.8 K) at which the magnetization starts to upsurge can be converted to the thermal energy ($k_B T$) at 4.5 K. The $|J_{TBP-TBP}|$ value agrees well with this estimation. At higher temperatures the S-shape became ambiguous, indicating the thermal population of the triplet state.

The $\chi_m T$ value of **4** only slightly decreased upon cooling, clearly indicating a structure-dependence of magnetic coupling; i.e., the superexchange interaction $|J_{TBP-Oh}|$ along the Cu(TPB)-μ-trpyz-Cu(Oh) skeleton in **4** is much smaller than $|J_{TBP-TBP}|$ across tmpyz in **3**. We determined the exchange parameter from the doublet–quartet model [24] based on the spin Hamiltonian $H = -2J_{TBP-Oh}(S_1 \cdot S_2 + S_2 \cdot S_3)$, to give $J_{TBP-Oh}/k_B = -0.121(4)$ K with $\chi_{TIP} = 0.000458(7)$ cm^3 mol^{-1} and $g_{avg} = 2.2272(8)$. The small interaction in **4** is also indicated from the magnetization curve (Fig. 6b).

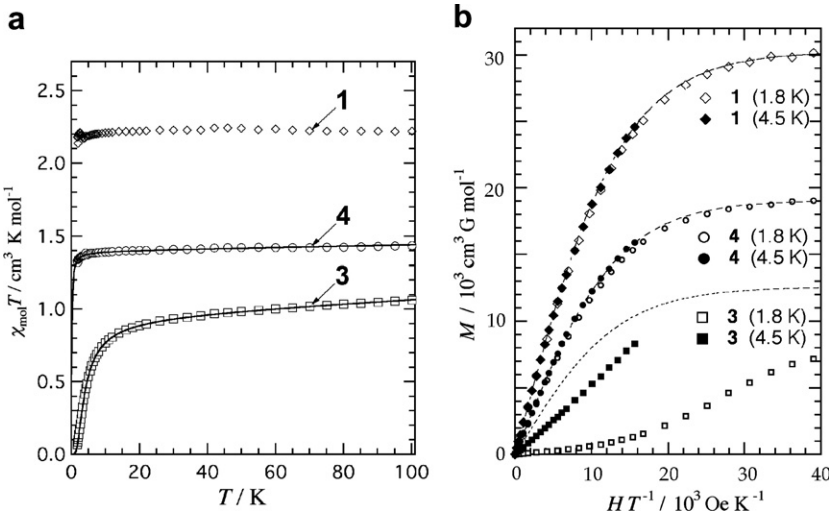

Fig. 6. (a) Temperature dependence of the product $\chi_{mol}T$ for **1** · (octane), **3** and **4** measured at 5000 Oe. The solid lines represent the best fit curves. See the text for the parameters. (b) Magnetization curves for **1** · (octane), **3** and **4** measured at 1.8 and 4.5 K. Dotted lines represent calculated curves for non-interacting Cu_5, Cu_3 and Cu_2 spins based on the $S = 1/2$ Brillouin function.

2.5. DFT calculation

A $3d_{z^2}$ or $3d_{x^2-y^2}$ character is crucial for the Cu-Cu magnetic coupling and may be predicted from the geometry and crystal-field theory. However, a theoretical calculation would be a more reliable way to determine the direction of the magnetic orbitals as well as the ground spin states. We performed a UB3LYP/6-31G(d,p) calculation using the structural parameters given from the crystallographic study.

A dinuclear model [{Cu(hfac)$_2$}$_2$(μ-bmpyz)$_2$] as a terminal dinuclear moiety of **1** was examined to explain part of the magnetic properties of **1**. We can reduce the calculation cost, assuming that the inner Cu-Cu interactions are disregarded. We found that the converged self-consistent-field (SCF) energies of [{Cu(hfac)$_2$}$_2$(μ-bmpyz)$_2$] were −7964.55583715 and −7964.55583691 a.u. for the singlet and triplet states, respectively, where the SCF convergence criterion was set to 10^{-9} a.u. The ground low-spin state was indicated. The exchange coupling parameter J was calculated to be −0.038 K from $\Delta E_{ST} = -2.4 \times 10^{-7}$ a.u. The spin density surface is drawn in Fig. 7a, clearly representing the singly-occupied molecular orbitals (SOMOs) carrying a $3d_{x^2-y^2}$ character both at the SqP and Oh Cu ions as usual. The present ΔE_{ST} seems close to the limit of the accuracy of such MO calculations. However the ground state prediction was reproducible when other basis sets were applied, such as Lanl2dz.

The converged SCF energies of **3** were −7464.54993268 and −7464.54992288 a.u. for the singlet and triplet states, respectively. A ground low-spin state was indicated. The exchange coupling parameter J was calculated to be −1.6 K from $\Delta E_{ST} = -9.8 \times 10^{-6}$ a.u. The spin density surface is drawn in Fig. 7b, clearly representing the SOMOs carrying a $3d_{z^2}$ character at the TBP Cu ions, being consistent with the EPR result. The N lone pair at the TBP eq position appreciably contributes to the SOMO.

We applied a dinuclear model in **4**, namely [{Cu(hfac)$_2$}$_2$(μ-trpyz)$_2$], to a similar calculation (Fig. 7c). We obtained the converged SCF energies of −7806.71550428 and −7806.71550348 a.u. for the singlet and triplet states, respectively. The low-spin state is favored, and therefore the whole molecule of **4** would also favor a low spin (doublet) state at the ground state owing to antiferromagnetic interaction on both sides. The exchange coupling parameter J was calculated to be −0.13 K from $\Delta E_{ST} = -8.0 \times 10^{-7}$ a.u. In sharp contrast to the TBP Cu ions, the Oh Cu ion has a magnetic orbital solely on the eq plane as clarified from the absence of the spin distribution onto the pyrazine bridge.

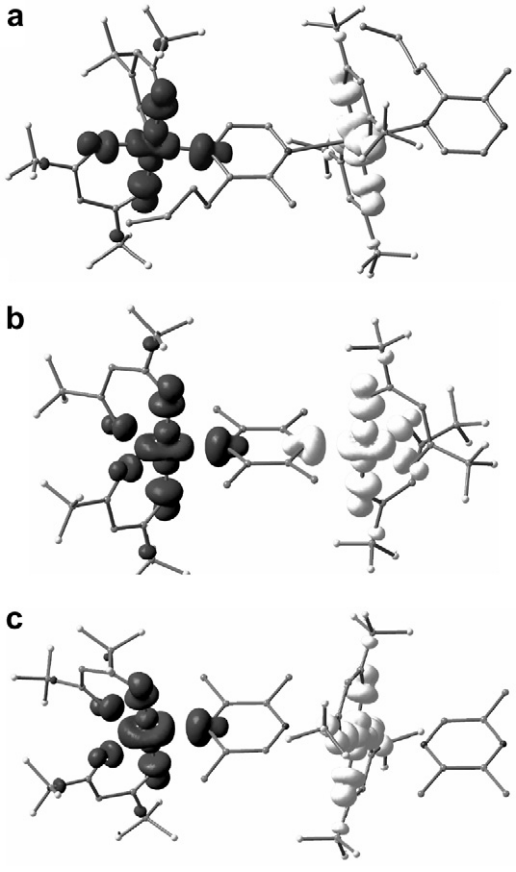

Fig. 7. Spin density surfaces of the singlet states of (a) the dinuclear model [{Cu(hfac)$_2$}$_2$(μ-bmpyz)$_2$] in **1**, (b) [{Cu(hfac)$_2$}$_2$(μ-tmpyz)$_2$] (**3**) and (c) the dinuclear moiety [{Cu(hfac)$_2$}$_2$(μ-trpyz)$_2$] in **4**. Dark grey: positive spin; light grey: negative spin. Hydrogen atoms are omitted.

The exchange interaction parameters were well reproduced as follows: $|J_{SqP-Oh}|/k_B < 0.1$ K versus −0.038 K (calc.) for **1**, $J_{TBP-TBP}/k_B = -3.6$ K versus −1.6 K (calc.) for **3** and $J_{TBP-Oh}/k_B =$

−0.12 K versus −0.13 K (calc.) for **4**. These satisfactory results support the reliability of the magnetic orbital pictures. The magnetic coupling depends on the presence or absence of the interaction between the Cu dσ and N lone pair orbitals, as Fig. 7 clearly illustrates.

3. Discussion

Somewhat large *J* values (−30.5 and −44 K) were observed for the dicopper complexes containing the sterically hindered tetra(2-pyridyl)pyrazine [25]. When the large displacement of the metal from the pyz plane causes the orbital overlap between the Cu $3d_{x^2-y^2}$ and N $2p_z$ orbitals, the pyz π-pathway would be operative and strengthens the antiferromagnetic interaction [26] as expected from the spin polarization scheme [4]. In the present study, **3** belongs to the eq–eq category, where the Cu ions have a TBP structure. The magneto-structure relation exploited on Oh Cu complexes basically holds for complexes containing TBP Cu ions, since the magnetic orbital is distributed at the eq positions as well as the ax positions of the TBP coordination sphere. The magnitude of the *J* value (−3.6 K) seems quite usual among the eq–eq pyz-bridged complexes [7,8]. The observed coupling can be attributed to the intrinsic σ-type exchange pathway, thanks to the strict orthogonal arrangement between the Cu e_g and N $2p_z$ orbitals.

Haddad et al. reported that the pyz nitrogen atom was located at a TBP ax position in $[\{Cu(tren)_2\}_2(\mu\text{-pyz})](ClO_4)_2$ (tren stands for tris(2-aminoethyl)amine) [9]. The exchange interaction was −4.6 K [9], which is slightly larger than that of **3**, despite of the longer ax Cu–N distance. The reason apparently resides in the character of the lobe direction of the magnetic $3d_{z^2}$ orbital.

To our knowledge, there have been two reports on ferromagnetic compounds belonging to the eq–ax category of pyz-bridged Oh Cu complexes [10,11]. The orthogonality between the Cu $3d_{x^2-y^2}$ and N $2p_z$ orbitals is essential, which is supported by an extended superexchange mechanism, originally proposed for M–X–M systems by Anderson [27], Goodenough [28] and Kanamori [29,30]. Fig. 8a shows a possible MO diagram explaining the role of the ferromagnetic couplers. When the energy gap Δ is sufficiently small, the electron configuration is regulated by Hund's rule. We can draw practically the same diagrams including two $3d_{x^2-y^2}$ orbitals for Oh(eq)-Oh(ax) and SqP(eq)-Oh(ax) dinuclear complexes as well as $3d_{z^2}$ and $3d_{x^2-y^2}$ orbitals for TBP(eq)-Oh(ax) dinuclear complexes.

In the present study, although the dinuclear portions of **1** and **4** belong to the eq–ax category, we could not observe ferromagnetic coupling. A reason for this may be attributed to the broken orthogonality, which is indicated by the N1···N2–Cu2 angles of 168.0(2)° for **1** and the corresponding angle (N2···N1–Cu1) of 168.76(12)° for **4**.

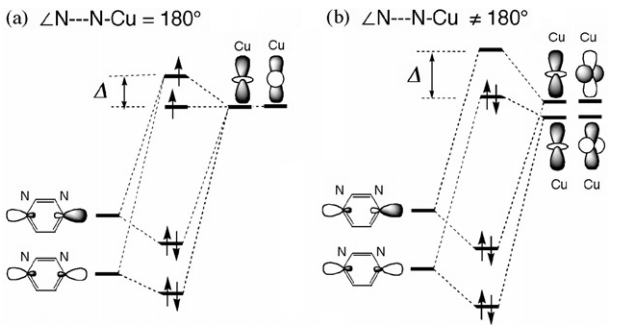

Fig. 8. Orbital interaction diagram between the pyz N lone pairs and two Cu magnetic orbitals (a) with a linear N···N–Cu geometry and (b) with a non-linear N···N–Cu geometry.

Fig. 8b depicts the antiferromagnetic couplings from the MO theory. The energy gap Δ becomes wide owing to the increase of the orbital overlaps, leading to the preference of the ground low-spin state.

4. Conclusions

Sterically bulky pyrazines are successfully utilized for the preparation of discrete oligo-nuclear TBP, SqP and Oh Cu complexes, in contrast to the previous report on the infinite Oh Cu chains involving less bulky pyrazine bridges [14]. We have characterized the unique linear pentanuclear complex (**1**). Although several branched pentanuclear copper(II) complexes are known [31], to the best of our knowledge, the present compound is the first self-assembled linear pentanuclear copper(II) complex without preorganization of bridging ligands. We synthesized a dinuclear copper(II) complex (**3**) in which the N atoms are located at an eq site at each TBP Cu ion. The magneto-structure relation exploited on Oh Cu complexes basically holds for complexes containing TBP Cu ions as well as SqP ions, since the magnetic orbital is confirmed to be present at the eq positions of the TBP and SqP coordination spheres. Appreciable magnetic coupling was found for **3**, which belongs to the eq–eq category. The σ-pathway is essential for the superexchange mechanism, and the magnitude of *J* was precisely evaluated.

5. Experimental

5.1. Materials

Bis(1,1,1,5,5,5-hexafluoropentane-2,4-dionato)copper(II) was purified by the reported method [32]. 2-Butyl-3-methylpyrazine (Tokyo Chemical Industry Co.), tetramethylpyrazine and 2,3,5-trimethylpyrazine (Aldrich Chemical Co.) were used without further purification.

5.1.1. Preparation of *1*

The complex $[Cu(hfac)_2]$ (273 mg, 0.57 mmol) was dissolved in octane (30 cm^3) with 2-butyl-3-methylpyrazine (68.8 mg, 0.46 mmol). The solution was refluxed for 1 h. After the solvent was evaporated at room temperature, green crystals were formed. They were filtered and then washed with a small amount of chilled octane. The yield was 35% as **1** · (octane). Mp. 85 - 87°C. The crystals were suitable for elemental analysis, X-ray diffraction study and magnetic measurements without further purification. The elemental analysis (C, H, N) of the products was carried out on a Fisons EA-1108 by the usual combustion method. *Anal.* Calc. for $C_{94}H_{84}Cu_5F_{60}N_8O_{20}$: C, 36.38; H, 2.73; N, 3.61. Found: C, 36.13; H, 2.65; N, 3.67%. IR spectra were recorded on a Horiba TF-720 Fourier transform infrared spectrophotometer. IR (KBr disk) *ν*(C–O) 1657 and 1641, ring def. 679 and 670, $\delta_s CF_3$ 596 and 580 cm^{-1}.

5.1.2. Preparation of *2*

The complex $[Cu(hfac)_2]$ (258 mg, 0.54 mmol) was dissolved in octane (8 cm^3) with 2-butyl-3-methylpyrazine (66 mg, 0.44 mmol). The solution was refluxed for 2.5 h. After the solvent was evaporated at room temperature, green crystals were formed. The yield was 34% as **2**. Mp. 79–83°C. The elemental analysis indicated the presence of a small amount of **1** · (octane) as an impurity. *Anal.* Calc. for $\{C_{48}H_{34}Cu_3F_{36}N_4O_{12}\}_{0.8}\{C_{94}H_{84}Cu_5F_{60}N_8O_{20}\}_{0.2}$ (i.e., $\mathbf{2}_{0.8}(\mathbf{1} \cdot (\text{octane}))_{0.2}$): C, 34.22; H, 2.21; N, 3.35. Found: C, 34.09; H, 2.51; N, 3.62%. IR (KBr disk) *ν*(C–O) 1641, ring def. 680, $\delta_s CF_3$ 597 cm^{-1}.

5.1.3. Preparation of *3*

The complex $[Cu(hfac)_2]$ (97 mg, 0.20 mmol) was dissolved in pentane (10 cm^3) with half a molar quantity of tetramethylpyr-

azine (14 mg, 0.10 mmol). The solution was refluxed for 1 h. After the solvent was evaporated at room temperature, green crystals were formed. They were filtered, washed with a small amount of chilled pentane and dried *in vacuo*. The yield was 62%. Mp. 116–118 °C. The crystals were suitable for elemental analysis, X-ray diffraction study and magnetic measurements without further purification. *Anal.* Calc. for $C_{28}H_{16}Cu_2F_{24}N_2O_8$: C, 30.81; H, 1.48; N, 2.57. Found: C, 31.03; H, 1.72; N, 2.56%. The formula of **3** was also confirmed by Electro-spray-ionization time-of-flight mass spectroscopy (ESI-MS), which was recorded on a JEOL JMS-T100LC mass spectrometer, using methanol as a solvent. Calc. for **3**: m/z 1089.9, found: m/z 1113.6 ($M + Na^+$). IR (KBr disk) ν(C–O) 1653 and 1645, ring def. 675, $\delta_s CF_3$ 596 and 586 cm^{-1}.

5.1.4. Preparation of 4

Compound **4** (mp. 105–107°C) was prepared by the reported method [17].

5.2. X-ray crystallographic analysis

X-ray diffraction data of **1**–**4** were collected on a Rigaku *R*-axis RAPID diffractometer with graphite monochromated Mo Kα radiation ($\lambda = 0.71069$ Å). The structures were directly solved by the heavy-atom method and expanded using Fourier techniques in the CRYSTALSTRUCTURE program package [33]. A numerical absorption correction was used. All of the hydrogen atoms were located at calculated positions and the parameters were refined as "riding". The thermal displacement parameters of the non-hydrogen atoms were refined anisotropically. Full-matrix least-squares methods were applied using all of the unique reflection data. The crystal structure of **4** was also determined, which is practically the same as that of the previous report [17] and the refinement was improved because of the lower temperature. Selected crystallographic data are listed in Table 1.

The cell parameters of the solvated complexes from **1** are listed below. **1** · (pentane): $a = 11.660(10)$, $b = 13.919(13)$, $c = 19.545(19)$ Å, $\alpha = 102.26(8)$, $\beta = 98.52(7)$, $\gamma = 101.50(7)°$, $V = 2977(5)$ Å^3. **1** · (hexane): $a = 11.678(5)$, $b = 13.821(5)$, $c = 19.601(10)$ Å, $\alpha = 101.42(4)$, $\beta = 98.62(4)$, $\gamma = 102.00(4)°$, $V = 2972(2)$ Å^3. The molecular skeletons of **1** were confirmed, though the solvent molecules were highly disordered.

5.3. Magnetic measurements

Magnetic properties of polycrystalline specimens of **1**, **3** and **4** were measured on a Quantum Design MPMS SQUID magnetometer equipped with a 7 T coil in a temperature range 1.8–300 K. The magnetic responses were corrected with diamagnetic blank data of the sample holder measured separately. The diamagnetic contribution of the sample itself was estimated from Pascal's constants.

5.4. EPR measurements

EPR spectra of **3** were recorded on a Bruker ESP300E X-band (9.7 GHz) spectrometer. A single crystal sample was mounted on a quartz sample tube with a slight amount of Apiezon H grease and the crystal axis was carefully oriented under a microscope. The crystal planes were defined with Miller indexes by means of X-ray diffraction, and the crystallographic axes could be assigned on a single crystal.

5.5. DFT calculation

Molecular orbital calculations were performed on the GAUSSIAN 03 program [34]. We applied unrestricted density functional (DFT) UB3LYP methods with the Becke exchange functional [35] and the Lee–Yang–Parr correlation functional [36]. The 6-31G(d,p) basis set was chosen. The convergence criterion for the energy was set at 10^{-9} a.u. The structural parameters of **1**, **3** and **4** were given from the crystallographic data. The energies of the triplet and broken-symmetry singlet states were calculated, and the exchange parameter J was derived by the expression $2J = E_{BS} - E_T$ [37].

6. Supplementary data

CCDC 662859, 662860, 662861, 631791 and 631792 contains the supplementary crystallographic data for **1** · (octane), **1** · (cyclohexane)$_2$, **2**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Reaction of copper(II) acetate, lanthanium(III) or gadolinium(III) nitrate (1/5 equiv.) with pyrazinohydroxamic acid (H_2Pyzha) in DMF led to a series of new heterobimetallic 15-metallacrown-5 complexes. In a MeOH/H_2O solution the complexes exist as molecular unassociated metallacrowns. In solid state their structures are more complicated as it has been confirmed by X-ray analysis: discrete molecular metallacrowns $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(NO_3)] \cdot 0.5C_6H_6 \cdot H_2O$ (**1**), $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5](NO_3) \cdot 1.5DMF \cdot 0.5H_2O$ (**2**), $[La(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]NO_3 \cdot 1.5DMF \cdot 2C_6H_6$ (**3**) are solvates, whereas compound $[\{La(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5\}_2(\mu^2\text{-}NO_3)](NO_3) \cdot 3DMF$ (**4**) is a dimer, where μ-bridged nitrate links two copper centres of the adjacent metallamacrocycles. Complex $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_2(H_2O)(NO_3)] \cdot CH_2Cl_2 \cdot DMF$ (**5**) self-associates into a polymer chain by means of one pyrazine moiety and the copper ring atom. Reaction of the molecular metallacrowns with excess of inorganic salts $CdBr_2$ or $Cu(OAc)_2$ proceeds as anion methathesis process affording heteroanionic metallacrowns: molecular $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]$ $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(H_2O)][CdBr_4] \cdot 1.5DMF$ (**6**), and 3D hydrogen bonded polymer $[La(\mu^2\text{-}OAc)(H_2O)_3\{Cu(pyzha)\}_5(H_2O)_4(NO_3)](NO_3) \cdot 4H_2O$ (**7**).

1. Introduction

Heterometallic lanthanide/metal multinuclear complexes containing multiple-binding sites represent attractive examples of acceptor (Lewis acid) systems for selective interaction with neutral guest molecules and anions. They are used as catalysts [1–3], chemical sensors [4], contrast reagents for magnetic resonance imaging (Gd(III) chelates [5,6]), and in preparation of unique magnetic materials [7–22]. Molecular design of such receptors with further controllable integration into frameworks is an interesting perspective. These frameworks may be used as sophisticated materials with many potential applications. In particular, the lanthanide encapsulated 15-metallacrown-5 complexes (15-MC-5), discovered by Pecoraro and co-workers [6,23–32], provide a sufficient number of coordination sites situated in close proximity to bind substrates and, thus, they could be regarded as a multiple Lewis acid moiety. These metallamacrocycles could be designed rationally from simple inorganic salts and available organic precursors, such as picoline or isoquinoline hydroxamic acids and related non-planar α-amino hydroxamic acids. Such organic ligands may form two fused five-membered metalochelate rings, therefore they yield planar pseudo-pentagonal core of 15-MC-5. Only few examples of extended structural motifs of the metallacrowns have been realized through either bridging anions [6,26,27] or ligand periphery functionality, e.g., carbonyl oxygen atoms [26,29,31,32]. In this context, the employing the pyrazine moieties, *via* introducing pyrazinohydroxamic acid into 15-MC-5 core, offers essential advantages versus, for instance, pyridine heterocycle because in this case five additional σ-donor groups are introduced into the metallacrown periphery (Scheme 1). Such a ligand modification opens a possibility towards controllable association of the metallamacrocycles into the framework exploiting its Lewis amphoteric nature: either donor activity of five exterior nitrogen/oxygen atoms to coordinate bridging metal ions or alternative acceptor properties of the metallacrown metal centres for binding bridging anions.

In this paper, we describe synthesis, solution behaviour, reactivity towards typical inorganic salts ($CdBr_2$ or $Cu(OAc)_2$) and solid

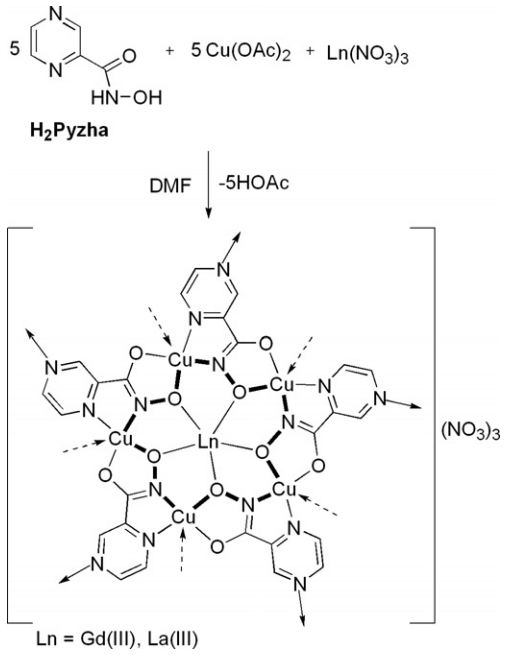


Scheme 1.

state structures of new Gd(III) and La(III) encapsulated 15-MC-5 complexes based on pyrazinohydroxamate ligand. The differentiation of ionic radii between the encapsulated La(III) and Gd(III) could be rationally utilized as an important tool to control bowl-shape distortion of the MC platform from the planar geometry.

2. Results and discussion

Pyrazinohydroxamic acid reacts readily with a mixture of Cu(II) and Ln(III) salts (Ln = Gd(III), La(III)), generating heterobimetallic metallamacrocyclic core, 15-metallacrown-5 complex. A one-step reaction is carried out in DMF solution and affords the desired product in expected high yield ranging from 50% to 70%. In contrast to previous studies describing the general method for preparation of the 15-MC-5 complexes [30], we have used a higher concentration of lanthanide(III) salt (16 mM), hydroxamic acid and copper(II) acetate (80 mM) in the reaction solution (see Section 4).

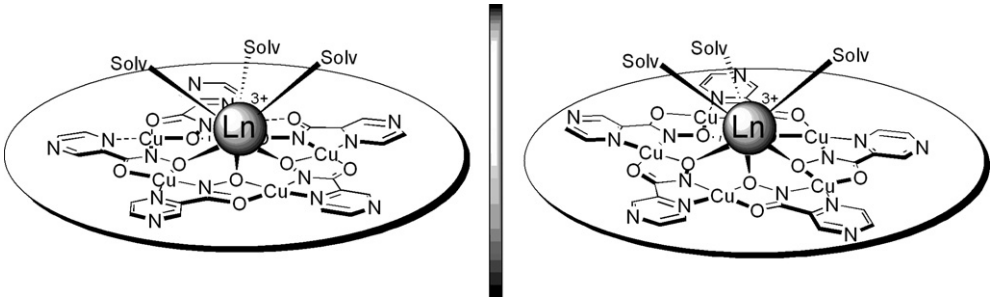
First, we examined the solution behaviour of the pyrazinohydroxamate metallacrowns by electrospray mass spectrometry (ESI-MS$^+$). These spectra demonstrated the following features: in water–methanol solution the corresponding peaks of molecular ions $Ln(NO_3)_2[15\text{-}MC_{Cu(II)N(pyzha)}\text{-}5]^+$, $Ln(NO_3)[15\text{-}MC_{Cu(II)N(pyzha)}\text{-}5]^{2+}$, $Ln[15\text{-}MC_{Cu(II)N(pyzha)}\text{-}5]^{3+}$ (Ln = Gd, La) remained intact and were found at 1288.9 *m*/*z*, 610.7 and 386.5 for Gd(III) complexes and at 1269.3, 601.2, 308.2 for the La(III)-encapsulated complexes, respectively. These data reflect the similarity in a solution behaviour between the prepared pyrazinometallacrowns and picolinato-metallacrowns described by Pecoraro and co-workers [6].

As previously shown [26], two faces of the 15-MC-5 pentagonal platform could be discriminated by distribution of axially bound molecules. This situation, in case of the 15-MC-5 pyrazinohydroxamates, induces chirality within the molecular macrocyclic structure generating a pair of enantiomers: anticlockwise (A) with the cyclic Cu–N–O orientation and clockwise (C) with the opposite Cu–N–O orientation (Scheme 2).

In the solid state these features have been confirmed by X-ray analysis. The crystal structures of molecular compounds $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(NO_3)] \cdot 0.5C_6H_6 \cdot H_2O$ (**1**), $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5](NO_3) \cdot 1.5DMF \cdot 0.5H_2O$ (**2**) and $[La(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]NO_3 \cdot 1.5DMF \cdot 2C_6H_6$ (**3**) reveal a racemic mixture of the both enantiomers consisting of a typical metallacrown core (Figs. 1, 2 and Tables 1, 2). Either of the five pyrazinohydroxamic ligands is twice deprotonated and forms two fused five-membered metalochelates with the two ring-forming Cu(II) atoms. For the closely related complexes **1** and **2**, the effective agreement between the cavity radius of the macrocycle (1.12 Å) and the ionic radius of nine-coordinate gadolinium ion (1.12 Å [21]) affords perfect location of the lanthanide in the center of the metallacrown with the negligible displacement from the least-square plane of five hydroxamate oxygen atoms (±0.02 Å). The coordination sphere of the Gd(III) ion is completed by five equatorial oxygen atoms of hydroxamates (Gd–O 2.39–2.46 Å) and two axial bidentate nitrate groups, which are symmetrically bound to the metal center above and below the MC plane (Gd–O 2.44–2.53 Å). The similar coordination was previously described for the Eu(III)/Cu(II) picolinehydroxamate 15-MC-5 complex [6]. The coordinated DMF molecules occupy the apical positions of the square-pyramidal Cu(II) atoms from one side of the metallacrowns, forming a complete coordination shell. Note that metallacrown-face discrimination phenomenon towards the bound solvent molecules results in a non-planar distortion of the 15-MC-5 core and, therefore, a cone-shaped geometry of the metallamacrocycle. The deviation from planarity is evidenced by displacements of the cavity centre of the metallacrown from the least-square plane of the five peripheral pyrazine nitrogens. Presumably, such a distortion effect is dependent upon the number of coordinated molecules, their molecular size and distribution on either metallacrown platform.

In neutral complex **1**, four DMF molecules and one nitrate, which are bound to the Cu(II) ring atoms from the convex side, fill up less space above the metallacrown plane than five coordinated DMF molecules in complex **2**. This affords notable difference in the deviation value of Gd(III) atom, centered in the cavity, from the best plane of the five exterior nitrogen atoms (0.80 and 1.00 Å for **1** and **2**, respectively).

Unlike the gadolinium complexes, the significantly smaller MC cavity size versus ionic radius of La(III) ion (1.22 Å for nine-coordinate



Scheme 2.

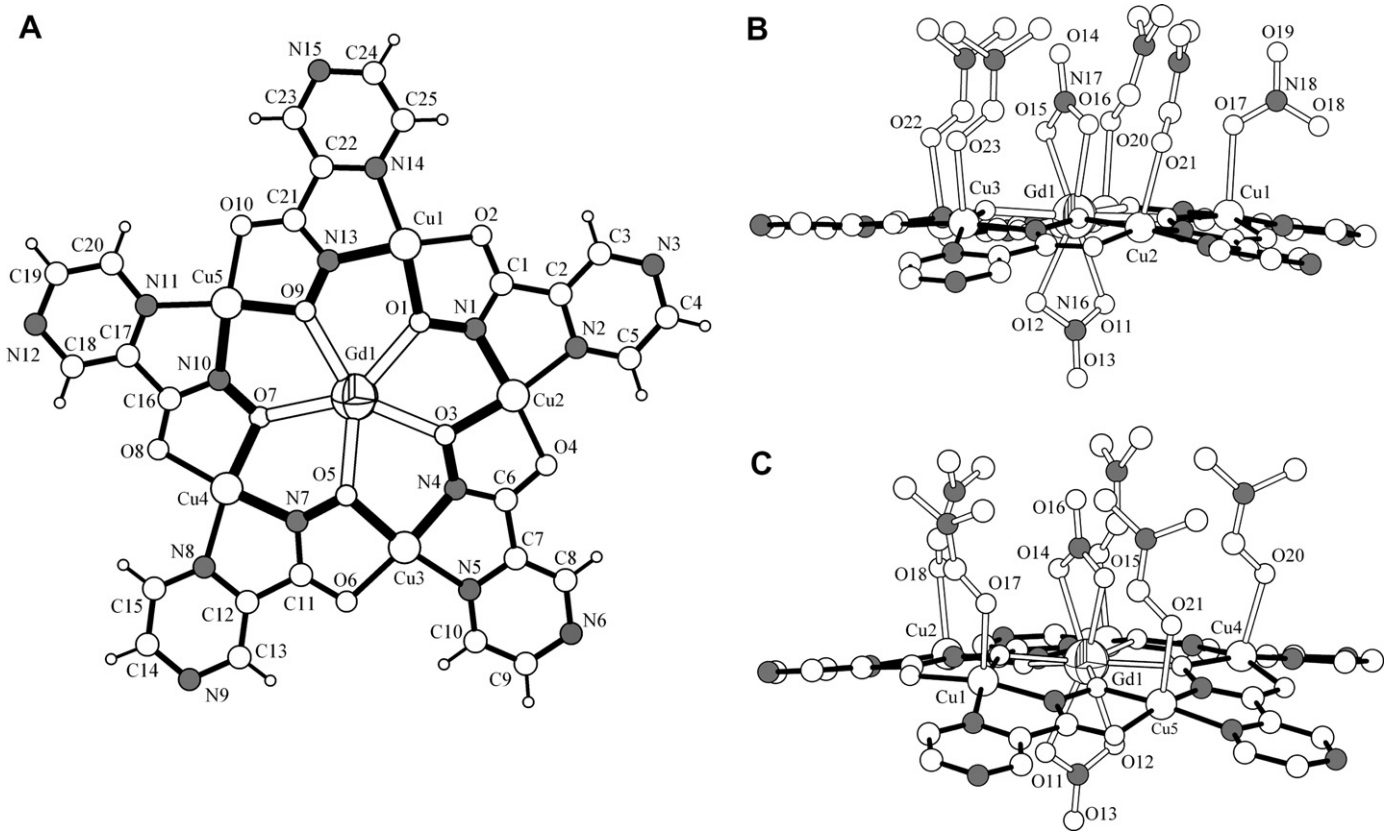


Fig. 1. Molecular structure of Gd(III) encapsulated 15-MC-5 complexes: (A) top view of $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(NO_3)] \cdot 0.5C_6H_6 \cdot H_2O$ **1** (a ring based on the –Cu–N–O– unit is outlined in bold); (B) side view of complex **1**; (C) side view of complex cation $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]^+$ of metallacrown **2**. (Unbound solvent molecules or/and nitrate anions located in the lattice are not shown.)

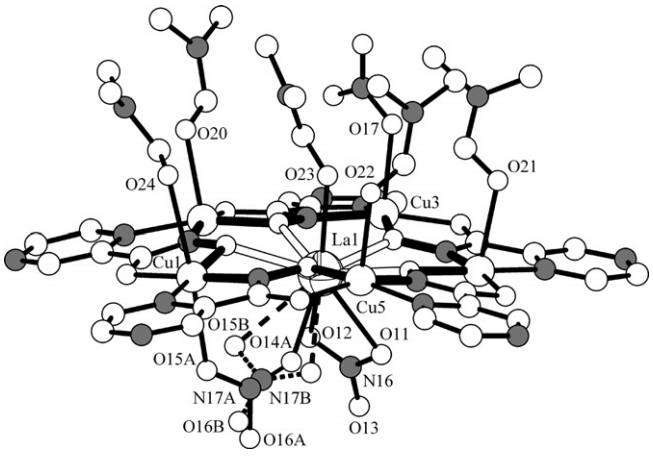

Fig. 2. Side view of the La(III) encapsulated cation $[La(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]^+$ of metallacrown **3** (one of disordered nitrate anion is shown as a dash line), (La(1)–O(23) 2.52 Å, La(1)–O(12) 2.62 Å, La(1)–O(11) 2.71 Å, Cu(3)–O(17) 2.31 Å); the third nitrate, unbound DMF and benzene molecules are present in the crystal lattice (not shown).

ion) in metallacrown **3** (Fig. 2) results, similarly to a lanthanide porphyrin, in a half-sandwich-type complex, where the encapsulated La(III) centre lies ~0.62 Å above the plane of the macrocycle. The cone-shape metallacrown platform binds five DMF molecules and monodentate nitrate from the convex side, whereas the opposite side is occupied by two nitrate anions coordinated to La(III). Such a distribution of the bound molecules and anions leads to less deviation from planarity (~0.73 Å) of the whole metallacrown platform unlike those observed for complexes **1** and **2**. The nitrate groups coordinated to La(III) demonstrate different binding modes: one NO_3-group is bound in a bidentate chelate fashion, while the other is crystallographically disordered between two positions displaying different chemical roles, such as chelating-bidentate (La(1)–O(14B) 2.72 and La(1)–O15(B) 2.85 Å) and a bridging-bidentate mode between the lanthanide atom and the Cu(1) atom.

The crystal packing behavior of the metallacrowns **1**–**3**, possessing a distinct bowl-shape geometry and large surface area (~215 $Å^2$), offers the opportunity to form intermolecular cavities, which are perfectly suitable to accommodate unbound solvent guests (e.g., DMF, H_2O, benzene) (Fig. 3). The tight packing of the metallamacrocycles also achieved through intermolecular π–π stacking interaction (~3.20 Å).

The La(III) encapsulated complex **4** has a molecular dimeric structure (Fig. 4A). An enantiomeric pair of metallacrowns are linked by a bidentate nitrate anion, which bridges two copper centres from the convex faces of adjacent metallacrowns. Additionally, the convex side is occupied by five DMF molecules, which complete the coordination environment of square pyramidal Cu(II) (Cu–I 2.27–2.34 Å) as well as the deca-coordinated La(III) ion (La(1)–O(17) 2.55 Å), while the concave side contains two bidentate nitrates which are symmetrically bound to the La(III) ion. The crystal packing of such a dimer affords formation of the cages which are filled by uncoordinated DMF molecules (Fig. 4B).

The Lewis amphoteric nature of the synthesized complexes may be the driver to its spontaneous assembly to form the extended network. In the crystal structure of metallacrown **5**, the adjacent enantiomers $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_2(H_2O)(NO_3)]$ are linked to each other through one of the five peripheral pyrazine nitrogens

(donor) and the Cu(II) ring atom (acceptor) (Cu(2)–N(12), x, 0.5 − y, 0.5 + z, 2.36 Å) giving the achiral polymer chain (Fig. 5). Two bidentate nitrate anions are symmetrically bound to the encapsulated nine-coordinated Gd(III) ion (Gd–O 2.47–2.54 Å) on either side of the metallacrown ring while the third nitrate anion is bound to a copper(II) ion (Cu(1)–O(17) 2.25 Å), maintaining the charge balance. The axial positions in coordination environment of the other Cu(II) ions are completed by DMF (Cu–O 2.23, 2.26 Å) and water molecule (Cu(4)–O(21) 2.48 Å). The cone-shape distortion of the macrocycle (~0.85 Å) is close to that for molecular complex **1**. There are CH_2Cl_2 and DMF molecules that are present in the crystal lattice. This structure demonstrates that bound molecules (anions) in the coordination shell of the metallamacrocycle could be effectively exchanged by even weak σ-donor ligands, e.g., pyrazine.

We assumed that integration of the molecular metallacrowns into frameworks could be a versatile process utilizing a step-by-

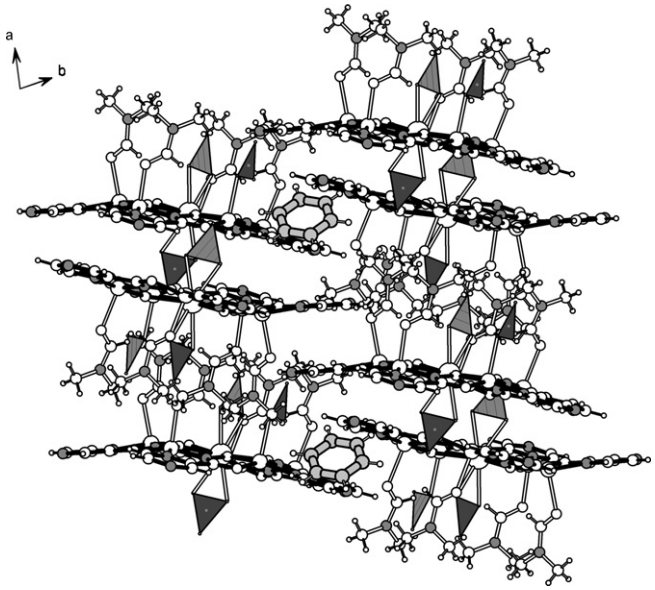

Fig. 3. Crystal packing view of molecular metallacrowns **1** illustrating the accommodation of benzene molecules (side view).

step approach, where the metallamacrocycle behaves as a ligand towards inorganic salts. However, the interaction between the Gd/Cu metallacrowns, generated *in situ*, and a five-fold molar equivalent excess of $CdBr_2$ followed by crystallization affords anion methathesis reaction prior to formation of coordination framework polymer. The crystal structure of molecular compound $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5][Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(H_2O)]\ [CdBr_4] \cdot 1.5DMF$ (**6**) consists of two kinds of discrete metallacrown cations, uncoordinated $CdBr_4^{2-}$ dianion and DMF molecules. The complex cations differ from each other by coordinated solvent shell. In the crystal lattice they both are stacked together in a concave/concave packing mode to form a pocket of 3×4 Å suitable for incorporating a DMF molecule (Fig. 6A and B). The packing motif is supported by shorted contacts between the negatively charged oxygen atom of the bidentate nitrate and the carbon atoms of pyrazine ($-x$, $1-y$, $-z$: O–C 2.99–3.14 Å). The remaining space within the lattice is occupied by additional uncoordinated DMF molecules, which are directed towards the metallacrown rings giving a short interaction of O22–C5B 3.10 Å ($-x$, $2-y$, $1-z$). Such features in the packing behaviour increase a bowl-shape geometry of the metallacrown cations (1.07 and 1.20 Å for $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]^+$ and $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(H_2O)]^+$, respectively).

Another situation was observed in crystal structure of $[La(\mu^2\text{-}OAc)(H_2O)_3\{Cu(pyzha)\}_5(H_2O)_4(NO_3)](NO_3) \cdot 4H_2O$ (**7**) (Fig. 7). The acetate-anion, which is more nucleophilic than the nitrate, and water molecules effectively substitute the nitrates and DMF in the coordination sphere of encapsulated La(III) and ring-forming Cu(II) atoms. The nine-coordinated La(III) ion sits 0.71 Å above the convex side of the metallacrown plane towards the bound acetate. The latter, in a similar bridging coordination mode of nitrate in structure **3**, behaves an as intramolecular bridge between La(III) and one of the copper centres (La(1)–O(11) 2.45 and Cu(5)–O(12) 2.23 Å). The nine-coordinated environment of La(III) is completed in the axial positions by water molecules (La–O 2.64, 2.70 Å), two of which occupy the convex face of the metallacrown, while the other is located on the opposite side (La–O13 2.55 Å). The other, axial ligands (H_2O and NO_3) bound to the Cu(II) ring atoms, are distributed between both faces of the metallacrown. The coordinated anions and aqua molecules form complicated intra- and intermolecular hydrogen bonding interactions shown in Fig. 7A, affording the first formation of a hydrogen bonded centrosymmetrical metallacrown dimer (O(13)···O(8), $2-x$, $2-y$, $2-z$ 2.743(3), ∠O13–H2W···O8 159°). These two metallacrowns are tightly stacked together (~3.36 Å) leading to almost flat geometry of the macrocycle with minimal distortion from planarity ~0.23 Å. In the crystal lattice, the intermolecular hydrogen bonding interactions define the integration of the metallacrown dimers into the 3D network. Such bonding involves the uncoordinated periphery pyrazine moieties on one hand and coordinated to Cu(II) centres aqua ligands on the other (N6···O17, $2-x$, $1-y$, $1-z$, 2.900(4), ∠O17–H7W···N6 160°; O29···N3, $1-x$, $2-y$, $1-z$, 2.881(5), ∠O29–H19W···N3 163°) as well as interactions between two types of nitrate anions and water molecules.

3. Conclusion

We have introduced a series of Cu(II)–Ln(III) 15-metallacrown-5 based on pyrazinohydroxamic acid as a new multiple-binding platform bearing Lewis amphoteric properties. These complexes have discrete molecular 15-MC-5 core, which could be either dimerized in solid state by means of bridging nitrate anion or self-assembled into the extended framework through periphery pyrazine nitrogen atoms and copper centres. Reaction of molecular metallacrowns with excess of $CdBr_2$ or $Cu(OAc)_2$ proceeds as an anion methathesis process affording heteroanionic metallacrowns.

4. Experimental

4.1. Reagents and general procedures

Compound H_2Pyzha [33] was prepared according to the literature procedures. All chemicals were reagent grade and used without further purification. The hydrate stoicheometry of gadolinium nitrate used $Gd(NO_3)_3 \cdot xH_2O$ ($x = 5.44$) was established by complexonometry.

4.2. Spectroscopy and analytical characterizations

The solution speciation of the planar 15-MC-5 structures was investigated by mass spectrometry using Q-Tof Ultima ESI mass spectrometer (Macromass/Waters). Samples were injected at 5 μL/min rate using a syringe pump. Positive ions were detected. IR spectra were recorded with a UR-10 spectrometer (4000–400 cm^{-1}).

Elemental analyses (C, H and N) were performed with a Perkin–Elmer 2400 analyzer.

4.3. Preparation of metallacrowns

The synthesis of **1**–**5** was essentially the same. In a typical procedure, a 5.25 mL DMF solution of $Cu(OAc)_2 \cdot H_2O$ (99.8 mg, 0.500 mmol) and $La(NO_3)_3 \cdot 6H_2O$ or $Gd(NO_3)_3 \cdot xH_2O$ ($x = 5.44$) (0.100 mmol) was mixed with a 1 mL DMF solution of H_2Pyzha (69.6 mg, 0.500 mmol). It immediately caused change in color from blue to intensive dark green. The resultant solution was stirred at rt for 1 h followed by vapor diffusion technique: diffusion of ether–benzene solution (1:1) gave compounds $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(NO_3)] \cdot 0.5C_6H_6 \cdot H_2O$ (**1**), $[La(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]NO_3 \cdot 1.5DMF \cdot 2C_6H_6$ (**3**), diffusion of Et_2O resulted in $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5](NO_3) \cdot 1.5DMF \cdot 0.5H_2O$ (**2**), $[\{La(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5\}_2(\mu^2\text{-}NO_3)](NO_3) \cdot 3DMF$ (**4**); Et_2O/CH_2Cl_2 (1:1) yielded $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_2(H_2O)(NO_3)] \cdot CH_2Cl_2 \cdot DMF$ (**5**).

Synthesis of heteroanionic metallacrowns $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5][Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(H_2O)][CdBr_4] \cdot 1.5DMF$

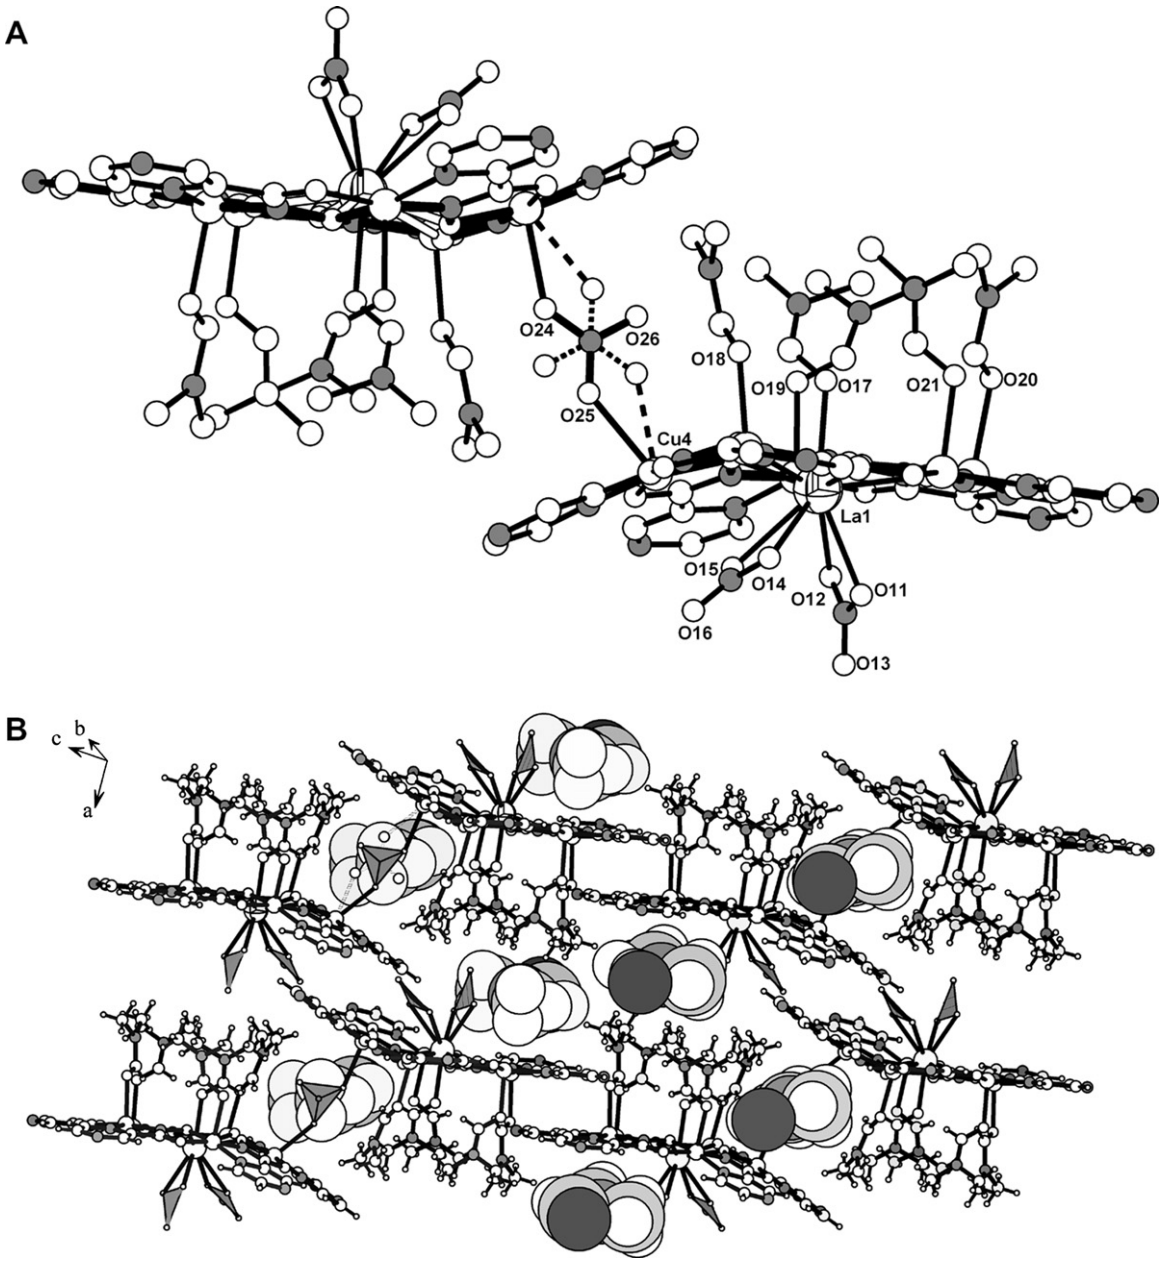

Fig. 4. (A) Side view of metallacrown $[\{La(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5\}_2(\mu^2\text{-}NO_3)](NO_3)\cdot 3DMF$ (**4**), (Cu(4)–O(25) (x, y, z) 2.45 Å, Cu(4)–O(24) ($1-x$, $1-y$, $2-z$) 2.40 Å, La(1)–O(11) 2.68 Å, La(1)–O(12) 2.67 Å, La(1)–O(14) 2.76 Å, La(1)–O(15) 2.71, Å) (one of the disordered bridging nitrate is shown as a dash line); (B) crystal packing side view of **4** illustrating the accommodation of the unbound DMF molecules.

(**6**), and $[La(\mu^2\text{-}OAc)(H_2O)_3\{Cu(pyzha)\}_5(H_2O)_4(NO_3)](NO_3)\cdot 4H_2O$ (**7**).

A 5.25 mL DMF solution of $Cu(OAc)_2\cdot H_2O$ (99.8 mg, 0.500 mmol), $Gd(NO_3)_3\cdot xH_2O$ ($x = 5.44$) (44.1 mg, 0.100 mmol) was mixed with a 1 mL DMF solution of H_2Pyzha (69.6 mg, 0.500 mmol). The resulted solution was stirred at rt for 1 h and then $CdBr_2\cdot 4H_2O$ (86.1 mg, 2.50 mmol) was added. The resultant solution was stirred for another hour and then filtered off. The desired dark green crystals of complex **6** were grown at rt for a few weeks.

A 5.25 mL DMF–H_2O solution of $Cu(OAc)_2\cdot H_2O$ (99.8 mg, 0.500 mmol), $La(NO_3)_3\cdot 6H_2O$ (43.3 mg, 0.100 mmol) was mixed with a 1 mL DMF solution of H_2Pyzha (69.6 mg, 0.500 mmol). The resulted solution was stirred at rt for 1 h and then Cu powder (15.9 mg, 0.250 mmol) was added. The mixture was stirred at 75 °C for ~8 h, then a vapor diffusion with ether yielded the desired complex $[La(\mu^2\text{-}OAc)(H_2O)_3\{Cu(pyzha)\}_5(H_2O)_4(NO_3)](NO_3)\cdot 4H_2O$ (**7**).

(A) A concave/concave packing of two metallacrown cations $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_5]^+$ and $[Gd(NO_3)_2\{Cu(pyzha)\}_5(DMF)_4(H_2O)]^+$ (**6**) affords encapsulation of DMF molecule ($-x$, $1-y$, $-z$: C15A–O16B 3.00, O13A–C19B 2.99, O13A–C20B 3.01, O16B–C14A 3.14 Å); (B) crystal packing side view of **6** demonstrating the accommodation of the unbound DMF molecules within the lattice.

The typical IR absorption bands (KBr, cm^{-1}) observed for the complexes: 3030 m, 1650 m, 1600 s, 1580 s, 1520 w, 1470 m, 1380 s, 1190 m, 1150 w, 1070 s, 960 s, 860 w, 750 m, 690 w, 570 m.

4.4. Crystal structure determinations

Crystallographic measurements were made using a Bruker SMART CCD area-detector diffractometer (graphite monochromated Mo Kα radiation, $\lambda = 0.71073$ Å; empirical absorption correction using SADABS). The structures were solved by direct methods using the program SHELXS-97 [34]. The refinement and all further calculations were carried out using SHELXL-97 [34]. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares of F^2 (Table 1). CH hydrogen atoms were placed in calculated positions with their isotropic U values set to be 1.2 (CH) or 1.5 (CH_3) times greater then U_{eq} of the corresponding carbon atom.

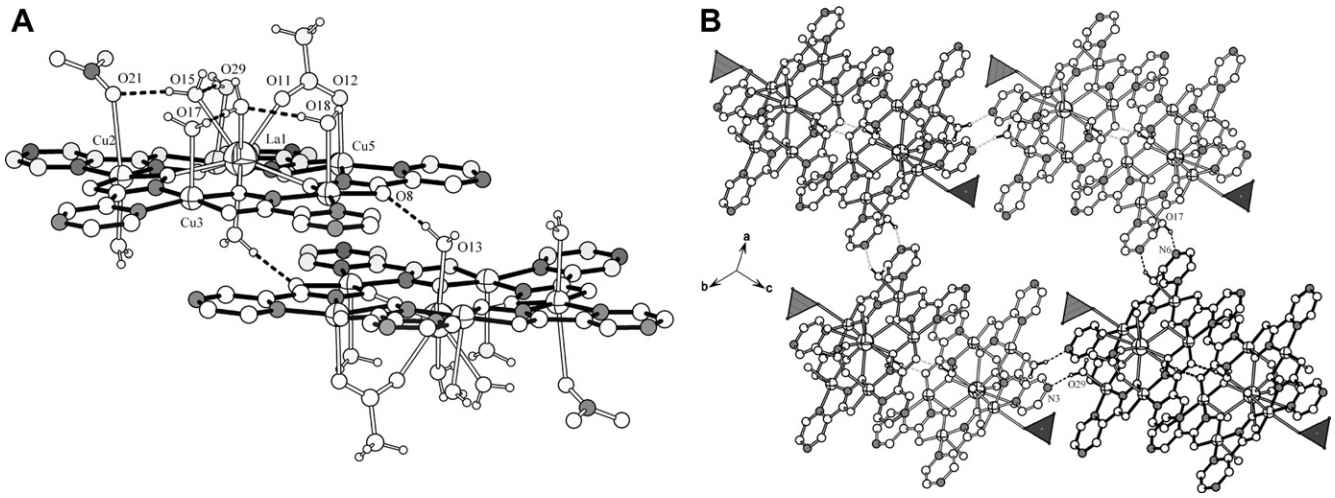

Fig. 7. (A) Side view of centrosymmetrical hydrogen bonded molecular dimer $[La(\mu^2\text{-}OAc)(H_2O)_3\{Cu(pyzha)\}_5(H_2O)_4(NO_3)](NO_3)\cdot 4H_2O$, **7**; (B) the hydrogen bonded metallacrown dimers are integrated in crystal lattice by means of a number of intermolecular hydrogen bondings involving uncoordinated nitrate anions and aqua ligands. The lattice water molecules and the third nitrate are not shown.

Some of the structures exhibit typical disorder for solvent of crystallization molecules as well as high thermal motion for outer methyl groups of coordinated DMF molecules. For structure **6**, the corresponding carbon atoms as well as the atoms of non-coordinated DMF were refinded with isotropic displacement parameters. These DMF solvent molecules were refined with fixed standard geometry parameters. In structure **5**, non-coordinated molecules of DMF and CH_2Cl_2 were badly disordered and the remaining electron density was modelled using squeeze [35], only the heavy Gd and Cu atoms were refined anisotropically for the sake of overall convergence and the hydrogen atoms of the water molecule were not included. The squeeze routine was also successfully used for modelling of electron density corresponding to a non-coordinated disordered NO_3^- anion in **4**. In this structure, the nitrogen atom of NO_3^- group resides on a centre of inversion and hence three oxygen atoms were equally disordered. It was possible to refine the atoms anisotropically without restraints in geometry. Very high anisotropy of thermal motion for Cu(1) atom in structure **3** was indicative of the disorder and two equal contributions (separated by 0.54 Å above and below the molecular plane) were refined anisotropically. Structure **7** shows equal disorder for one coordinated water molecule and non-coordinated NO_3^- anion. The hydrogen atoms of disordered water molecule were not added, while for the rest of water molecules the hydrogen atoms were located and then fixed with standard OH separations (0.85 Å). Graphical visualisation of the structures was made using program DIAMOND [36].

ABSTRACT

A series of new compounds containing rare earth cations (Eu to Yb) and paramagnetic cluster anion $[Re_6Te_8(CN)_6]^{3-}$ was prepared and investigated. The X-ray structural analyses have revealed that the compounds $[\{Ln(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$; Ln = Eu (**1**), Tb (**3**), Dy (**4**), Ho (**5**), Er (**6**), Tm (**7**), $[\{Gd(H_2O)_3\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**2**) and $[\{Yb(H_2O)_4\}\{Re_6Te_8(CN)_6\}]$ (**8**) are three-dimensional polymers based on Re–CN–Ln interactions. Measurements of magnetic susceptibility for **2** and **5** showed that effective magnetic moment (at 300 K) was 8.13 μ_B for compound **2** and 10.79 μ_B for compound **5** with weak antiferromagnetic ordering appeared at low temperatures.

1. Introduction

The chemistry of rhenium octahedral cluster cyanides $[Re_6Q_8(CN)_6]^{4-/3-}$, Q = S, Se, Te (Fig. 1) is in a stage of rapid investigation in past decade [1–19]. Ability of cyanogroups coordinated to rhenium to act as bridging ligands allowed to use these anions as building blocks for construction of coordination polymers based on strong covalent Re–C≡N–M bridges. To date, numerous polymeric coordination compounds were obtained with transition and post transition metals. With few exceptions [4,6,17] 3d transition metals in these polymers have octahedral environment. The type of structure depends mainly on a number of bridged cyanogroups of cluster anion as well as a number of cyanide ligands in coordination environment of cation.

The crystallochemistry of rare earth metals differs from that of 3d transition metals due to increased ionic radii, larger coordination numbers and stereochemical flexibility of ligand environment. Compounds $[Ln(H_2O)_3Re_6Te_8(CN)_6] \cdot nH_2O$ (Ln = La, Nd) obtained by reaction of $K_4Re_6Te_8(CN)_6$ with $LnCl_3 \cdot nH_2O$ in hydrothermal conditions [13] contained lanthanide atoms having tricapped trigonal prismatic environment. They are coordinated by six nitrogen atoms of CN groups of different cluster anions and three water molecules. In the recent work [20] it was shown that the interaction of heavy Ln^{3+} cations (Ln = Tb–Lu) with $[Re_6Se_8(CN)_6]^{3-}$ complex anion lead to formation of another family of polymer based on lanthanide cations and rhenium cluster complexes with general formula $Ln(H_2O)_3[Re_6Se_8(CN)_6] \cdot 3.5H_2O$. In these compounds each lanthanide is surrounded by five cyanogroups and three water molecules that resulted in formation of unusual framework with (5,5) connectivity according to notation given in [21]. It was shown that for heavy Ln^{3+} cations (Ln = Tb–Lu) structure of forming polymer is intact to nature of lanthanide.

In present work we report the synthesis and crystal structures of new compounds built from rare earth cations Ln^{3+} (Ln = Eu–Yb) and $[Re_6Te_8(CN)_6]^{3-}$ cluster anion obtained by reaction in aqueous solution. These compounds are described with general formula $[\{Ln(H_2O)_n\}\{Re_6Te_8(CN)_6\}] \cdot xH_2O$ (n = 3, 4; x = 0, 2.5) and characterized by extended three-dimensional framework based on strong covalent Re–CN–Ln interactions. The compounds **1**, **3**–**6** ($[\{Ln(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$) were isostructural while the compounds $[\{Gd(H_2O)_3\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**2**), $[\{Tm(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**7**) and $[\{Yb(H_2O)_4\}\{Re_6Te_8(CN)_6\}]$ (**8**) were crystallized in different structure types.

2. Experimental

2.1. General

$Cs_4Re_6Te_8(CN)_6 \cdot 2H_2O$ was prepared from polymeric Re_6Te_{15} as described elsewhere [12]. All other reagents were used as

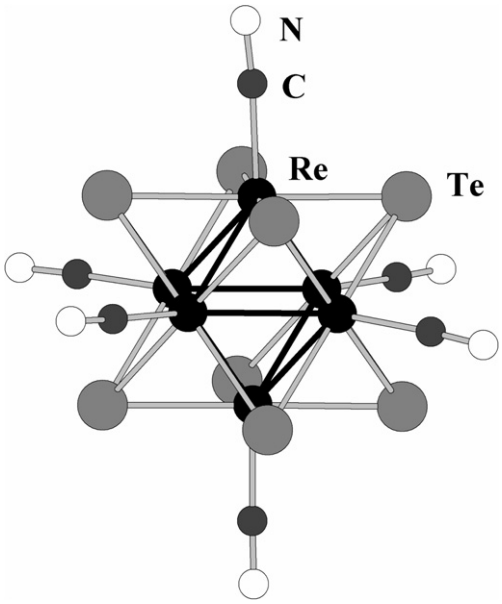

Fig. 1. Structure of cluster anion $[Re_6Te_8(CN)_6]^{3-}$.

purchased. Infrared spectra were measured in KBr disks with Scimitar FTS 2000 spectrometer in the range 4000–375 cm^{-1}. Individuality of crystalline powder samples was confirmed by X-ray powder diffractometry on Philips APD 1700 diffractometer. Magnetic measurements were performed in applied magnetic field of 5 kOe within the temperature range 4–300 K using a Quantum Design MPMS-5 SQUID magnetometer. Diamagnetic corrections were estimated from Pascal tables. Analyses were performed on a Thermo Jarrell Ash Atomscan 25 with the use of standards purchased from GFS Chemicals, Inc. (Re, Te) and Aldrich Chemical Company (Co, Ni, Zn). Energy Dispersive Spectrometry (EDS) analyses, using an Oxford LINK ISIS spectrometer implanted on a scanning electron microscope JEOL JSM 6400 (standards were taken from the apparatus standard library), were performed on several selected single-crystals from the preparation.

2.2. Syntheses

2.2.1. Preparation of $[\{Eu(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**1**)

$Cs_4Re_6Te_8(CN)_6 \cdot 2H_2O$ 57.2 mg (0.02 mmol) was dissolved in 6 mL of water, then $EuCl_3 \cdot 6H_2O$ 14.6 mg (0.04 mmol) in 2 mL of water and 0.1 mL of concentrated HCl were added. After three days dark brown crystals of **1** were filtered and washed with small amount of water. Yield: 32.5 mg (62.9%). *Anal.* Calc. for $C_6H_{13}EuN_6O_{6,5}Re_6Te_8$: C, 2.81; H, 0.51; N, 3.28. Found: C, 2.7; H, 0.45; N, 3.2%. Heavy atoms ratio by EDS (normalized to Re_6): Eu:Re:Te = 0.95:6.0:7.9. IR: ν_{OH} 3431–3417 cm^{-1} (band); δ_{HOH} 1625–1610 cm^{-1} (band); ν_{CN} 2092 cm^{-1}; ν_{ReC} 472 cm^{-1}; δ_{ReCN} 403 cm^{-1}.

2.2.2. Preparation of $[\{Gd(H_2O)_3\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**2**)

Compound was prepared using the same method. The $GdCl_3 \cdot 6H_2O$ (14.9 mg, 0.04 mmol) was used instead of $EuCl_3 \cdot 6H_2O$. Yield: 46.11 mg (90.4%). *Anal.* Calc. for $C_6H_{13}GdN_6O_{6,5}Re_6Te_8$: C, 2.81; H, 0.51; N, 3.27. Found: C, 2.9; H, 0.45; N, 3.4%. Heavy atoms ratio by EDS (normalized to Re_6): Gd:Re:Te = 1.0:6.0:8.1. IR: ν_{OH} 3589–3404 cm^{-1} (band); δ_{HOH} 1603 cm^{-1}; ν_{CN} 2104, 2117 cm^{-1}; ν_{ReC} 474 cm^{-1}; δ_{ReCN} 401 cm^{-1}.

2.2.3. Preparation of $[\{Tb(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**3**)

Compound was prepared using the same method. The $TbCl_3 \cdot 6H_2O$ (14.9 mg, 0.04 mmol) was used instead of $EuCl_3 \cdot 6H_2O$. Yield: 39.2 mg (76.3%). *Anal.* Calc. for $C_6H_{13}TbN_6O_{6,5}Re_6Te_8$: C, 2.80; H, 0.51; N, 3.27. Found: C, 2.7; H, 0.55; N, 3.1%. Heavy atoms ratio by EDS (normalized to Re_6): Tb:Re:Te = 1.1:6.0:8.0. IR: ν_{OH} 3433 cm^{-1}; δ_{HOH} 1610 cm^{-1}; ν_{CN} 2094 cm^{-1}; ν_{ReC} 470 cm^{-1}; δ_{ReCN} 403 cm^{-1}.

2.2.4. Preparation of $[\{Dy(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**4**)

Compound was prepared using the same method. The $DyCl_3 \cdot 6H_2O$ (15.1 mg, 0.04 mmol) was used instead of $EuCl_3 \cdot 6H_2O$. Yield: 37.7 mg (59.3%). *Anal.* Calc. for $C_6H_{13}DyN_6O_{6,5}Re_6Te_8$: C, 2.80; H, 0.51; N, 3.27%. Found: C, 2.8; H, 0.47; N, 3.3%. Heavy atoms ratio by EDS (normalized to Re_6): Dy:Re:Te = 1.09:6.0:8.0. IR: ν_{OH} 3433 cm^{-1}; δ_{HOH} 1626 cm^{-1}; ν_{CN} 2096, 2083 cm^{-1}; ν_{ReC} 487, 471 cm^{-1}; δ_{ReCN} 403 cm^{-1}.

2.2.5. Preparation of $[\{Ho(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**5**)

Compound was prepared using the same method. The $HoCl_3 \cdot 6H_2O$ (15.2 mg, 0.04 mmol) was used instead of $EuCl_3 \cdot 6H_2O$. Yield: 20 mg (31.3%). *Anal.* Calc. for $C_6H_{13}HoN_6O_{6,5}Re_6Te_8$: C, 2.80; H, 0.51; N, 3.26. Found: C, 2.8; H, 0.53; N, 3.1%. Heavy atoms ratio by EDS (normalized to Re_6): Ho:Re:Te = 1.1:6.0:8.1. IR: ν_{OH} 3593–3425 cm^{-1} (br.); δ_{HOH} 1603 cm^{-1}; ν_{CN} 2100, 2085 (w.) cm^{-1}; ν_{ReC} 474 cm^{-1}; δ_{ReCN} 403 cm^{-1}.

2.2.6. Preparation of $[\{Er(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**6**)

Compound was prepared using the same method. The $ErCl_3 \cdot 6H_2O$ (15.3 mg, 0.04 mmol) was used instead of $EuCl_3 \cdot 6H_2O$. Yield: 33.6 mg (53.3%). *Anal.* Calc. for $C_6H_{13}ErN_6O_{6,5}Re_6Te_8$: C, 2.79; H, 0.51; N, 3.26. Found: C, 2.7; H, 0.55; N, 3.2%. Heavy atoms ratio by EDS (normalized to Re_6): Er:Re:Te = 1.0:6.0:8.1. IR: ν_{OH} 3435 cm^{-1}; δ_{HOH} 1630 cm^{-1}; ν_{CN} 2100, 2085 cm^{-1}; ν_{ReC} 492, 476 cm^{-1}; δ_{ReCN} 403 cm^{-1}.

2.2.7. Preparation of $[\{Tm(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**7**)

Compound was prepared using the same method. The $TmCl_3 \cdot 6H_2O$ (15.3 mg, 0.04 mmol) was used instead of $EuCl_3 \cdot 6H_2O$. Yield: 48.8 mg (77.3%). *Anal.* Calc. for $C_6H_{13}TmN_6O_{6,5}Re_6Te_8$: C, 2.79; H, 0.51; N, 3.26. Found: C, 2.9; H, 0.45; N, 3.3%. Heavy atoms ratio by EDS (normalized to Re_6): Tm:Re:Te = 0.95:6.0:8.0. IR: ν_{OH} 3431 cm^{-1}; δ_{HOH} 1616 cm^{-1}; ν_{CN} 2102, 2088 (w.) cm^{-1}; ν_{ReC} 478 cm^{-1}; δ_{ReCN} 406 cm^{-1}.

2.2.8. Preparation of $[\{Yb(H_2O)_4\}\{Re_6Te_8(CN)_6\}]$ (**8**)

Compound was prepared using the same method. The $YbCl_3 \cdot 6H_2O$ (14.5 mg, 0.04 mmol) was used instead of $EuCl_3 \cdot 6H_2O$. Yield: 22.9 mg (45.1%). *Anal.* Calc. for $C_6H_8YbN_6O_4Re_6Te_8$: C, 2.84; H, 0.32; N, 3.31. Found: C, 2.8; H, 0.3; N, 3.2%. Heavy atoms ratio by EDS (normalized to Re_6): Gd:Re:Te = 1.0:6.0:7.9. IR: ν_{OH} 3439 cm^{-1}; δ_{HOH} 1626 cm^{-1}; ν_{CN} 2104, 2089 cm^{-1}; ν_{ReC} 497, 480 cm^{-1}; δ_{ReCN} 403 cm^{-1}.

2.2.9. X-ray structural studies

The structures of **1**–**8** were solved by single-crystal X-ray diffraction analysis. A suitable single-crystals were taken from bulk samples and were mounted on Bruker Nonius X8 Apex 4K CCD diffractometer fitted with graphite monochromated Mo Kα radiation (λ = 0.71073 Å). The data were collected at 150 K for all structures by standard technique [22]. Absorption corrections were made empirically using SADABS program [23]. Structures were solved by direct methods and refined by full-matrix least-squares method using SHELXTL program set [24]. Crystal data and details of the final refinement are given in Table 1.

Structures **2** and **7** were ordered while in structures **1**, **3**–**6** and **8** a disorder of Ln atoms and coordinated water molecules was found.

On the first stage of refinement of structure **1** europium atom located in general 4e Wickoff position had unusual atomic displacement parameters (principal mean square atomic displacements were about 0.1290 0.0100 0.0059). In addition coordination environment of lanthanide contained 11 ligands (nitrogen from clusters and oxygen atoms) with non-reliable distances to lanthanide cation (from 2.1 to 2.7 Å). Then Eu atom was split in two positions with s.o.f equal to 50% and refined anisotropically. On the last stage s.o.f. of Eu1 and Eu2 atoms were refined in assumption that the sum of occupancies was restricted to a fully occupied 4e position. Atoms of N1, N2, N4, N6 and O1 are common to two positions of europium atoms and are fully occupied. Occupancies for other oxygen atoms completing coordination environment of Eu1 (O11, O12 and O13) and Eu2 (O21, O22 and O23) were fixed to the value of corresponding lanthanide atom. The same procedure was applied for compounds **3–6**. Models of disorder for compound **6** are given in Fig. 2.

In the structure of **8** Yb atom occupies special 4h Wickoff positions located near inversion center with the distance between symmetry generated atoms 1.781 Å and its s.o.f. was set to 0.5. Occupancy factors of oxygen atoms O1 and O2 linked to Yb1 atom were assumed as 0.5 according to s.o.f. of Yb. Hydrogen atoms of the water molecules were not located.

3. Results and discussion

3.1. The crystal structures

All structures contain cluster anion complexes $[Re_6Te_8(CN)_6]^{3-}$. Structure of octahedral cyano-telluride rhenium cluster in oxidized state was described previously [25] and depicted in Fig. 1. Interatomic distances in anions for **1–8** are listed in Table 2. These distances are consistent with those found in other compounds with this anion [13,18,25]. Comparison of data for compounds **1–8** shows no dependence of nature of lanthanide cations on interatomic distances in $[Re_6Te_8(CN)_6]^{3-}$ cluster anion.

3.2. Structures of *1*, *3–6*

The compounds **1**, **3–6** crystallize in *P2/n* space group and are isostructural. Details of structure of Er (**6**) compound are shown in Figs. 2, 3 and Figs. S1a, S1b. In this structure Er atoms occupy two neighbor positions with close occupancies (0.46(2) for Er1 and 0.54(2) for Er2).

Four nitrogen atoms of cyanogroups of different cluster anions (N1, N2, N4, N6) and one oxygen atom of water molecule (O1) are common for two positions of erbium atoms (Fig. 2). Additionally each Er atom is coordinated by three half occupied oxygen

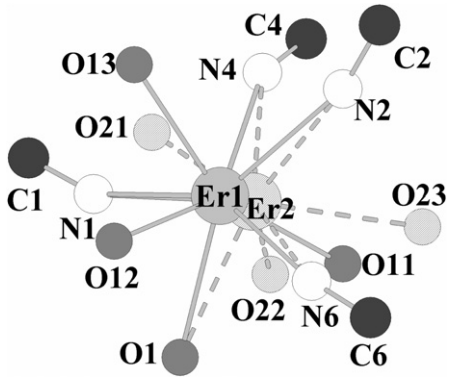

Fig. 2. Coordination environment of Er(III) in compound **6**.

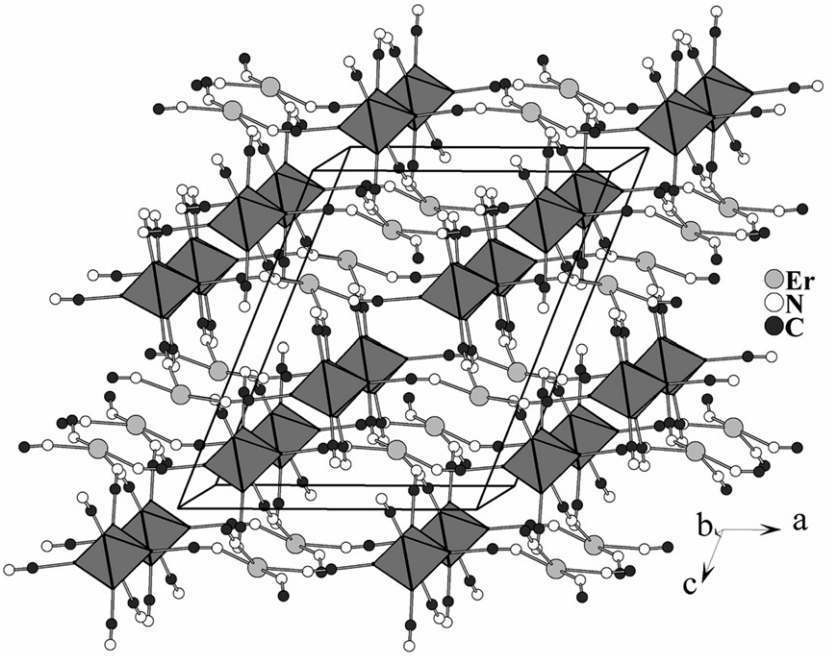

Fig. 3. View of framework in structure of $[\{Er(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**6**). Te, Er2 and O atoms are omitted for clarity. Clusters Re_6 are shown as polyhedral.

atoms (O11, O12 and O13 for Er1 and O21, O22 and O23 for Er2) that complete coordination sphere of Er to distorted tetragonal antiprism (Figs. S1a, S1b). Interatomic distances in coordination environment of Ln as well as Ln(1)–Ln(2) distances are listed in Table 3. Ln–O and Ln–N(CN) distances have typical values lying within 2.3–2.5 Å (see for example [26] – Eu, [27] – Tb, [28] – Dy, [29] – Ho, Er, Gd, [20] – Tb – Yb).

Each cluster anion is bridged with four cations of lanthanide by cyanogroups. Coordination environment of Ln(III) contains four nitrogen atoms that leads to formation of three-dimensional framework with (4,4) connectivity according to notation given in [21]. Two *trans*-cyanogroups of cluster complex remain uncoordinated. Coordination environment of Ln(III) contains four nitrogen atoms and therefore form 3D network (Fig. 3). Additionally structures contain four positions of solvate water molecules (O1w, O2w, O3w and O4w) forming six hydrogen bonds to coordinated water molecule (O–O distances are within 2.69–2.99 Å) and to nitrogen atoms (N–O distances are within 2.67–2.85 Å).

The distances in lanthanide environment (Ln–N(CN) and Ln–O(H_2O)) are gradually decreased in the series **1**, **3**–**6** with the increase of atomic number of Ln according to lanthanide contraction.

3.3. Structure of *2*

The compound **2** is crystallizing in $P\bar{1}$ space group. The coordination polyhedron of Gd(III) is distorted tetragonal antiprism (Fig. 4). Coordination environment consists of three water molecules (O1, O2, O3) and five nitrogen atoms (N1, N2, N3, N4, N5) of different cluster anions. Ln–O and Ln–N(CN) distances have typical values lying within 2.3–2.5 Å.

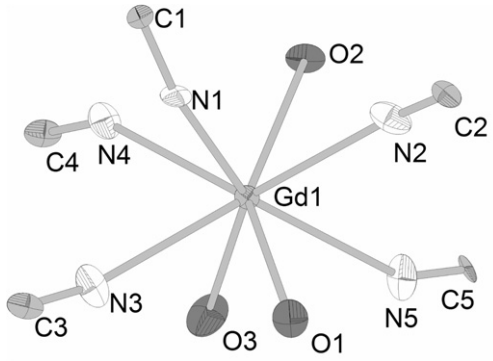

Fig. 4. Coordination environment of Gd(III) in compound **2**. Displacement ellipsoids are drawn at the 50% probability level.

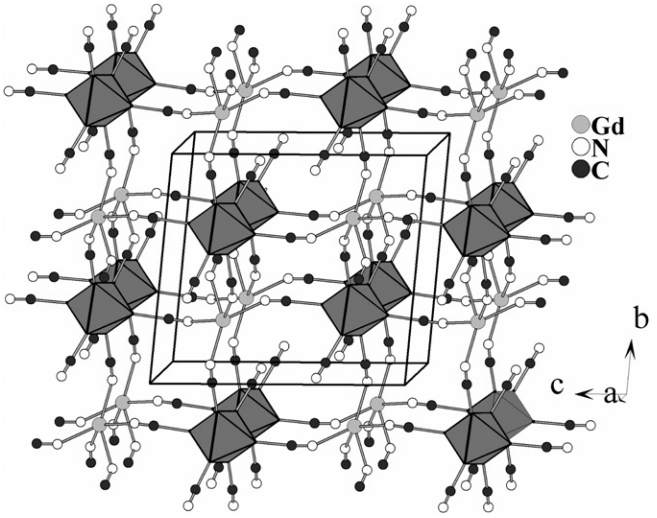

Fig. 5. View of framework in structure of $[\{Gd(H_2O)_3\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**2**). Te and O atoms are omitted for clarity. Clusters Re_6 are shown as polyhedral.

Each cluster anion connects with five cations of gadolinium and each cation of gadolinium is coordinated by five nitrogen atoms of cluster complexes, that leads to formation of three-dimensional network with (5,5) connectivity (Fig. 5). Additionally structure **2** contains three solvate water molecules (O1w–O3w) forming three hydrogen bonds to coordinated water molecules (O–O distances are 2.81, 2.85 Å) and to nitrogen atoms (N–O distance is 2.69 Å). Distance between uncoordinated atom of nitrogen and Gd(III) is 4.563(18) Å.

3.4. Structure of **7**

The compound **7** is crystallizing in *P*2/*c* space group. The structure of **7** contains two crystallographically independent cluster anions (Re11–Re16 and Re21–Re26) and two independent Tm atoms (Tm11 and Tm21). Coordination environment of each Tm atoms are formed by four nitrogen atoms from different cyanoclusters and four oxygen atoms (N11, N12, N23, N26, O11, O12, O13, O14 for Tm11 and N14, N16, N21, N25, O21, O22, O23, O24 for Tm21) and can be described as distorted tetragonal antiprism (Figs. S2a and S2b). Distances Tm–O and Tm–N are lying within 2.3–2.5 Å and are listed in Table 3. Each cluster anion is linked by cyanogroups to four Tm cations that leads to formation of three-dimensional framework with (4,4) connectivity (Fig. 6). Two *trans*-cyanogroups of each cluster complex remain uncoordinated. Additionally structure **7** contains five solvate water molecules (O1w–O5w) forming seven hydrogen bonds to coordinated water molecules (O–O distances are 2.65–2.87 Å) and to nitrogen atoms (N–O distances are 2.76–3.03 Å).

3.5. Structure of ***8***

The compound **8** is crystallizing in *C*2/*m* space group. Details of structure compound are shown in Fig. 7. In this compound ytterbium cation is located in two close positions generated by mirror plane. Two nitrogen atoms of cyanogroups of different cluster anions (N2, N2′) are common for these two positions of ytterbium atoms (Fig. 8). Additionally each Yb atom is coordinated by two nitrogen atoms (N1, N1′) of different cluster anions and four half occupied oxygen atoms (O1, O1′, O2, O2′) that

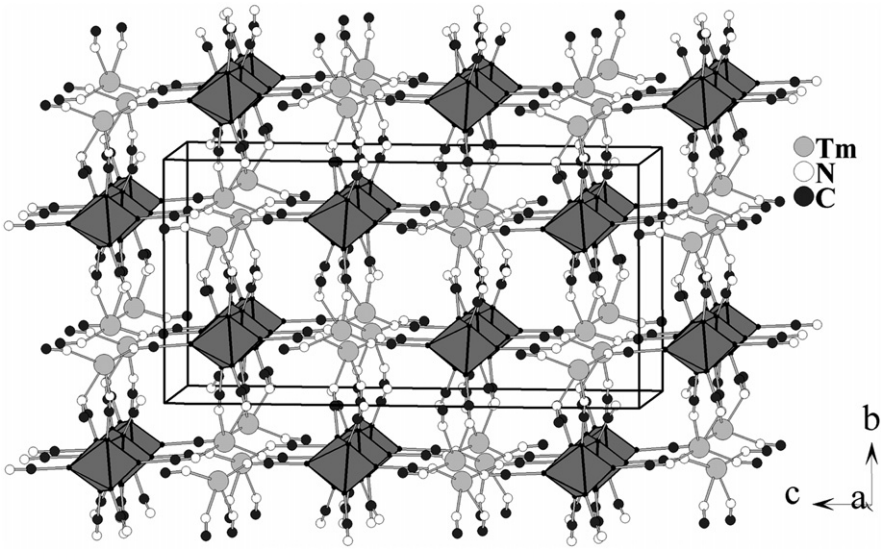

Fig. 6. View of framework in structure of $[\{Tm(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**7**). Te and O atoms are omitted for clarity. Clusters Re_6 are shown as polyhedral.

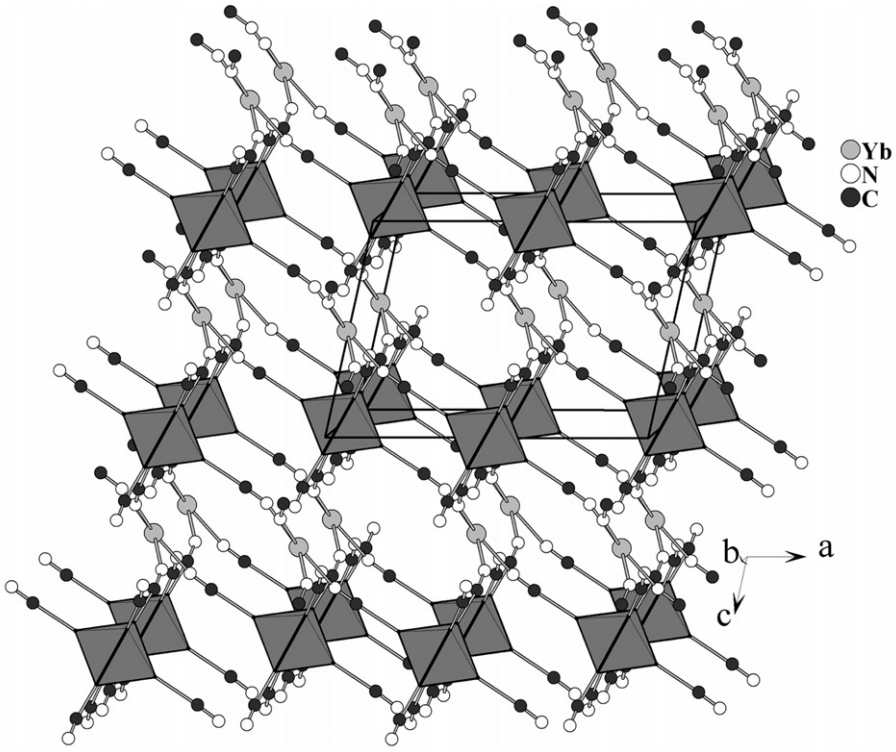

Fig. 7. View of framework in structure of $[\{Yb(H_2O)_4\}\{Re_6Te_8(CN)_6\}]$ (**8**). Te and O atoms are omitted for clarity. Clusters Re_6 are shown as polyhedral.

complete coordination sphere of Yb to distorted tetragonal antiprism (Fig. S3). Interatomic distances in coordination environment of Ln and Ln(1)–Ln′(1) distances are listed in Table 3. Ln–O(H_2O) and Ln–N(CN) distances have typical values lying within 2.3–2.6 Å [29].

4. Discussion

4.1. Synthesis

All compounds **1**–**8** were obtained by interaction of aqueous solutions of $Cs_4Re_6Te_8(CN)_6$ with $LnCl_3 \cdot nH_2O$ in acidic media. Mixture of these solutions were stable in oxygen-free atmosphere and no crystals were formed within a week. Exposure of reaction mixture on air resulted in slow one-electron oxidation of $[Re_6Te_8(CN)_6]^{4-}$ anion to paramagnetic $[Re_6Te_8(CN)_6]^{3-}$ by oxygen. It was found [3] that tellurium anion $[Re_6Te_8(CN)_6]^{4-}$ undergoes one-electron oxidation in electrochemical cell at 0.53 V. Chemical oxidation of $[Re_6Te_8(CN)_6]^{4-}$ by bromine [25] or iodine [30] was also reported. The process of oxidation of anion can be easily monitored by change of colour of solution from dark orange to dark brown and this process is followed by precipitation of black prism of compounds **1**–**8**. The precipitation of cluster polymers upon oxidation of tellurium cluster anion in solution was found also in

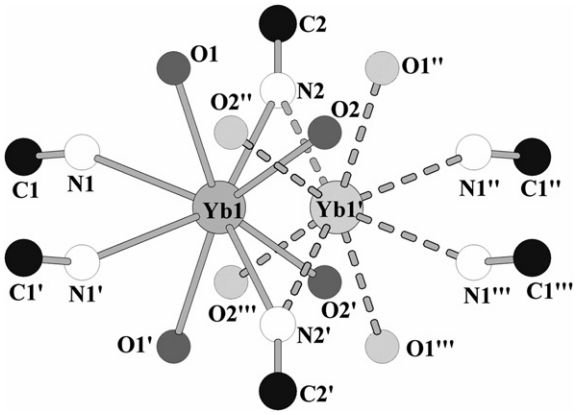

Fig. 8. Coordination environment of Yb(III) in compound **8**.

hydrothermal conditions [13] as well as for selenium cluster anion in acid solution [20].

The crystals **1**–**8** were rather stable under mother liquor while exposure on air resulted in partial dehydration of compounds and in loss of crystallinity of samples.

4.2. Structures

X-ray structural analysis revealed that all studied structures are coordination polymers with Re–CN–Ln bridges. Comparison of the structures**1**–**8** showed that despite of relatively small distinctions in atomic radii of lanthanides Eu–Yb in series of compounds **1**–**8** four types of structures are realized.

Structures **1**, **3**–**6** are isostructural and can be roughly described as primitive cubic packing of anions (Fig. S4). Distances between centers of cluster anions vary 9.1–9.54 Å (for Er structure). Cations of Ln occupy two close positions near center of cube formed by anions. The Ln1–Ln2 distance increases slightly from Eu compound (0.479 Å) to Er one (0.551 Å). The framework of these compounds has (4,4) connectivity.

Structure of compound **7** (Tm) has similar connectivity (4,4) of framework and is closely related to above structures. Unit cell volume is doubled and thulium atoms occupy two ordered positions in neighbor cubes. The application of cell vector transformation **a**′ = **2c**, **b**′ = **b**, **c**′ = **a** to compound **7** leads to structural model similar to that found in compound **1.** Structure of **8** has reduced unit cell compared to **1** with retention of packing motif. In the unit cell ytterbium atoms are disordered over two symmetry generated positions with Yb–Yb separation about 1.77 Å.

It should be noted that compounds $[\{Ln(H_2O)_3\}\{Re_6Te_8(CN)_6\}]\cdot 4H_2O$ (**9**) with large lanthanides, Ln = La, Nd [13] crystallized in another structure with six cyano-bridges Re–CN–Ln per cluster.

The diversity of structural types formed in systems Ln–$[Re_6Te_8(CN)_6]^{3-}$ is quite surprising, because inorganic lanthanides often adopt one or two structural types for all series of lanthanides [31]. Related compounds based on selenocyanide cluster anion $[Re_6Se_8(CN)_6]^{3-}$, namely $[\{Ln(H_2O)_3\}\{Re_6Se_8(CN)_6\}]\cdot 3.5H_2O$, were isostructural for heavy lanthanides Ln = Tb–Lu [20]. Such distinctions may be explained of different sizes of $[Re_6Te_8(CN)_6]^{3-}$ and $[Re_6Se_8(CN)_6]^{3-}$. Increased size of tellurium anion compared to selenium one leads to increased voids between anions and hence several possible positions for lanthanide cations. That also may stimulate structural disorder of cations between close positions.

To best our knowledge topology of reported compounds **1**, **3**–**7** with (4,4) connectivity framework have never occurred in cyanometallate polymers, while compound **2** with (5,5) framework has only one topologic equivalent to $(H_3O)\{Ce(H_2O)_4[W(CN)_8]\}\cdot 2H_2O$ [32].

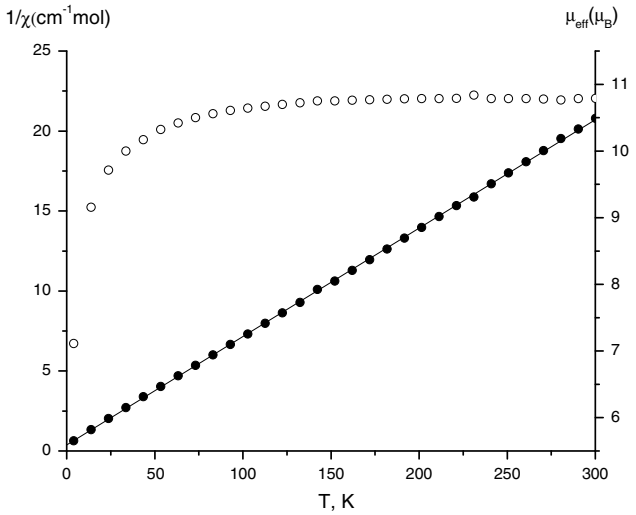

Fig. 9. The temperature dependence of effective magnetic moment (μ_{eff}) and reciprocal magnetic susceptibility ($1/\chi$) for **5**.

4.3. Magnetic properties

The measurement of the temperature dependence of the magnetic susceptibility for polycrystalline samples **2** and **5** showed that these compounds are paramagnetic over the temperature range (4–300 K). Effective magnetic moment for compound **2** at 300 K is 8.13 μ_B. This value is in a good agreement with μ_{eff} = 8.14 μ_B calculated for two non-interacting magnetic centers: Gd^{3+} ($\mu_{eff} = [g_J^2 J(J+1)]^{1/2}$ μ_B = 7.9 μ_B) and paramagnetic anion $[Re_6Te_8(CN)_6]^{3-}$ (μ_{eff} = 1.96 μ_B [33]). Temperature dependence for magnetic susceptibility for **2** follows to Curie–Weiss law $\chi = \frac{N\beta^2\mu_{eff}^2}{3k(T-\theta)} = 8.275/(T-1.95)$. Effective magnetic moment for compound **5** at 300 K is 10.79 μ_B. This value is in a good agreement with μ_{eff} = 10.78 μ_B, calculated for two weakly interacting magnetic centers: Ho^{3+} ($\mu_{eff} = [g_J^2 J(J+1)]^{1/2}$ μ_B = 10.61 μ_B) and paramagnetic anion $[Re_6Te_8(CN)_6]^{3-}$ (μ_{eff} = 1.96 μ_B [33]). Temperature dependence for magnetic susceptibility for **5** follows to Curie–Weiss law $\chi = \frac{N\beta^2\mu_{eff}^2}{3k(T-\theta)} = 14.76/(T+5.5)$ (Fig. 9).

pH response

ABSTRACT

The synthesis of a quinoxaline-appended aza-macrocyclic ligand together with corresponding Ln^{III} complexes are described. The luminescence properties of the complexes show that the quinoxaline unit sensitises both visible (Eu^{III}) and near-IR (Nd^{III} and Yb^{III}) emitting lanthanide ions. UV–Vis absorption and time-resolved photophysical studies together with X-ray structural data suggest that as well as contributing chromophorically, the quinoxaline moiety generally participates in the first coordination sphere of Ln^{III}. The luminescent pH response of the Eu^{III} complex is also reported. The form of the steady state spectrum changes profoundly in the pH range 2–12, implying a change in the coordination environment, which was confirmed with time-resolved lifetime measurements that suggest an increase in europium inner sphere hydration at acidic pH.

1. Introduction

The use and potential application of lanthanide ion complexes to a variety of bio-imaging modalities has driven significant progress and diversity in the design of such compounds [1]. This rapid development has advanced the discipline with respect to lanthanide-based responsive probes for, amongst others, Zn^{II} [2], Cu^{II} [3], alkali metals [4], pH [5], pO_2 [6], halide ions [7], and various anionic residues [8]. The nature of the response is clearly dependent on the lanthanide in question. Gd^{III}-based probes are attractive in MRI applications and rely upon control of the hydration sphere and therefore overall relaxivity of the Gd^{III} complex [9]. Notable examples include MRI probes for esterase activity [10] where the inner sphere hydration of the Gd^{III} centre is enhanced upon esterase exposure and Ca^{II} response [11]. However, the design of luminescent lanthanide-based probes requires an alternative set of criteria. Although high-denticity ligands are a prerequisite (stability in aqueous environments is clearly preferential for biological applications) the incorporation and photophysical compatibility of the photoactive components is essential. Lanthanide luminescence arises from f–f transitions and therefore requires the use of a sensitising chromophore. In turn, the choice of chromophore is determined, to a certain extent, by the lanthanide to be sensitised. The generally accepted and most common mechanism for lanthanide sensitisation proceeds *via* a chromophore-localised triplet state [12]. Therefore for the visibly emitting lanthanides such as Eu^{III} and Tb^{III} the choice of chromophore is far more limited than for near-IR emitting lanthanides such as Nd^{III}, Er^{III} and Yb^{III}. However, consideration of the optical properties of biological tissue and particularly autofluorescence in fluorescence microscopy, are also key in the choice of chromophore [13]. Consequently, luminescent lanthanide complexes which allow long wavelength sensitisation are extremely attractive. The successful choices of antennae for use with millisecond lifetime emitters like Eu^{III} and Tb^{III} are too numerous to cover here, but notable examples are heterocyclic species such as xanthone derivatives [14], and entities like acridone [15]. Such aromatic species absorb in the low energy portion of the UV region whilst maintaining sensitising capabilities for Eu^{III} and Tb^{III}. Although autofluorescence can be circumvented by utilising time-gating techniques, depth of tissue penetration can still be problematic and this has led to the exploitation of near-IR fluorophores for enhanced fluorescence imaging [13]. Lanthanides of relevance to this area are predominantly Yb^{III} and Nd^{III} whilst Er^{III} generally possesses poor or non-emissivity in protic media with only rare exceptions [16]. For such ions, with energetically lower lying excited states, the variety of sensitising chromophore can be greatly expanded. As well as heterocyclic species, d-metal chromophoric entities derived from Ru^{II} (diimine and tetracyano varieties) [17], Re^{I} and Os^{II} [18] moieties (which utilise

triplet MLCT donor states) to Ir^{III} [19], Cr^{III} [20], Pt^{II} [21], and even Tb^{III} ions [22] all of which have been shown to facilitate sensitised f–f emission.

In this paper we describe the use of quinoxaline as a sensitising chromophore for both visible and near-IR emitting lanthanide ions. The study reports synthetic routes to the ligand and its corresponding Ln^{III} complexes together with the spectroscopic and photophysical attributes of the complexes, concluding with a description of the luminescent pH response of the Eu^{III} complex.

2. Results and discussion

2.1. Synthesis of the ligand and complexes

Our synthetic methodology relied upon coupling 2-bromomethylquinoxaline with a 1,4,7-functionalised tetraaza macrocycle. Initially the macrocyclic precursor of choice was 1,4,7-tris(*tert*-butoxycarbonylmethyl)-1,4,7,10-tetraazacyclododecane, which has been successfully employed to access a large range of functionalised DO3A-derived macrocyclic ligands. However, in this case we found that the deprotection step (trifluoroacetic acid, dichloromethane) associated with the conversion of the ^{t}Bu-ester to the carboxylic acid induced cleavage of the methyl-quinoxaline from the cyclen framework as evidenced by mass spectrometry and ^{1}H NMR. Therefore our attention turned to amide-functionalised macrocyclic derivatives where there is no need for a deprotection step. In particular we selected the diethylamido version since we anticipate exploiting the inherent amphiphilicity of the resultant complexes in future applied work (Scheme 1).

IR vibrational spectra were obtained on solid samples utilising an ATR-equipped IR spectrometer. **2** displayed vibrational frequencies consistent with the presence of appropriate organic functional groups, in particular the amide stretch, ν(C=O), at 1703 cm^{-1}. For the complexes the amide stretch is diagnostic of coordination and was observed at *ca.* 1600 cm^{-1}, the low energy shift indicative of a weakening of the carbonyl bond due to lanthanide coordination. Additionally the spectra for the complexes also confirmed the presence of the relevant counter ions, for example a strong ν(S=O) stretch was noted at 1027 cm^{-1} corresponding to the triflate anion. Mass spectra of the complexes were recorded and for each sample showed a cluster of peaks associated with the loss of one counter anion, yielding the monocation, $\{M \cdot 2X\}^+$ with appropriate isotopic distributions in each case. Additional peaks at lower *m*/*z* were assigned according to the expected sequential loss of counter ions.

The absorption properties of the ligand were investigated. The spectrum of **2** in acetonitrile displayed a well-resolved transition at 294 nm with a weaker feature at 357 nm. These are assigned to π–π^* (with the possibility of some n–π^* contribution particularly in the lower energy band) transitions. The corresponding lanthanide complexes showed one dominant transition at approximately 320 nm (π–π^*) with a much weaker shoulder on the red-edge of this transition.

3. Single crystal X-ray structural determination of Na{1,4,7-tris[(*N*-diethyl)carbamoylmethyl]-1,4,7,10-tetraazacyclododecane-10-(2-methylquinoxaline)}I_3 C_7H_8

A highly concentrated toluene solution of the ligand was stored at −20 °C for 2 weeks after which time crystalline material started to form. A brown, block-like crystal with dimensions of 0.35 × 0.03 × 0.02 mm was subjected to single crystal X-ray diffraction analysis. The study confirmed the integrity of the proposed ligand framework as the sodium salt, with two unique whole molecules in the asymmetric cell together with two solvent (toluene) molecules and two counter ions (I_3^-). The chemical formula of the crystal is $C_{42}H_{67}N_9NaO_3$ I_3 C_7H_8. Diffraction data were collected on a Nonius Kappa CCD 4-circle diffractometer controlled using KAPPACCD Server Software [23] and collect [24] and using graphite-monochromated Mo Kα radiation (k = 0.71073 Å) at 150(3) K. Final cell refinement and data reduction were carried out using DENZO and SCALEPACK from the HLKF suite of programmes [25]. An absorption correction was applied by the multiscan method using the SORTVA program. The theta range for data collection was 1.15–27.08 ° with 20579 independent reflections and completeness to 27.08° of 94.4%. The structure was refined on F_0^2 using all data with final R indices [$I > 2\sigma(I)$] of R_1 = 0.0839 and wR_2 = 0.2065. The crystal system is triclinic with a $P\bar{1}$ space group and the unit cell itself possesses dimensions a = 12.562(3) Å, b = 18.648(4) Å and c = 22.955(5) with α = 99.34(3)°, β = 103.65(3)° and γ = 103.09(3)°. The unit cell has a volume of 4955.6(17) $Å^3$ and Z = 4 giving a density of 1.946 mm^{-1}. Selected bond lengths and bond angles reported in Table 1. As represented in Fig. 1 the structure reveals an encapsulated sodium ion coordinated by three amide oxygens, four macrocyclic nitrogens and the N(5) quinoxaline nitrogen. There are no other solvent molecules associated with the coordination sphere of the sodium ion. The charge is balanced by the I_3^- counterion, presumably liberated by the use of KI in the synthesis of **2**. Although solid state the structure solution of Na{1,4,7-tris[(*N*-diethyl)carbamoylmethyl]-1,4,7,10-tetraazacyclododecane-10-(2-methylquinoxaline)}I_3 is informative since it suggests that a lanthanide complex of the ligand would probably favour a coordination environment where the quinoxaline chromophore participates in the first coordination sphere, despite the relatively bulky ethyl groups of the amide arms. The ionic radius of an 8-coordinate sodium ion is 1.32 Å and therefore larger than that of the trivalent lanthanides Nd^{III}, Eu^{III} and Yb^{III} with 1.12, 1.09 and 1.01 Å, respectively [26]. Despite this we have found sodium complexes of these types of ligands to be useful predictors of the corresponding lanthanide coordination environment [2d]. This is of particular

use when interpreting the luminescence behaviour of the lanthanide complexes.

3.1. Photophysical studies

The lanthanide complexes **Ln · L** were synthesised to investigate the suitability of the quinoxaline chromophore to sensitise both visibly (Eu^{III}) and near-IR emissive (Nd^{III} and Yb^{III}) lanthanide ions. As discussed earlier the quinoxaline unit absorbs reasonably at *ca.* 355 nm, but due to its coordinative ability and thus proximate positioning, should promote efficient energy transfer upon sensitisation. Firstly the fluorescent properties of the non-lanthanide precursor were assessed. In aerated aqueous solution the precursor complex **2** is fluorescent upon irradiation at 300–360 nm. The broad, structureless emission is centred on 415 nm. Unfortunately, room temperature measurements conducted on a de-aerated solution did not allow the triplet state of the quinoxaline component to be obtained.

For the complexes **Ln · L** each gave emission spectra characteristic of the coordinated ion and are consistent with inclusion in the binding site. The use of chromophoric *'antennae'* to sensitise lanthanide ions is a well-established methodology for circumventing the inherently poor molar extinction coefficients associated with f–f transitions [1c]. However, for the visibly emitting ions such as Eu^{III} careful choice of the chromophore is required. Lowering the energy of excitation is an attractive proposition with regard not only to the energetic efficiency of the system, but also the avoidance of UV light which can cause autofluorescence in applied studies such as fluorescence microscopy [1]. In this study the coordinating quinoxaline chromophore can be sensitised at wavelengths of 320–390 nm (Fig. 2).

Time-resolved measurements were obtained on either H_2O/D_2O or $MeOH/CD_3OD$ solutions of the complexes (Table 2). The wavelengths of excitation for each system were indirect irradiation (λ_{ex} = 355 nm) for Nd^{III} and Yb^{III} and both direct and indirect irradiation for Eu^{III} (λ_{ex} = 396 and 355 nm, respectively). In each case the decay profile was analysed as a single exponential component indicative of a single coordinated lanthanide environment, except where discussed.

Fig. 2 shows the steady state fluorescence emission spectrum of **Eu · L** in methanol and highlights two key features: the tail of the residual emission of the quinoxaline chromophore and the well-resolved line-like emission bands from the emissive $^5D_0$ state of the Eu^{III} ion. The transitions associated with Eu^{III} appear at λ_{em} = 579, 592, 616, 651, 688 and 699 nm following excitation at 320–380 nm, thus confirming that the quinoxaline chromophoric unit sensitises Eu^{III}. The excitation spectrum (Fig. 2, left) confirms sensitisation *via* the quinoxaline chromophore with features at 325 nm and 355–390 nm attributed to the ligand. The luminescence lifetimes in H_2O and D_2O are reasonably typical of amide-derived ligands and overall nine-coordinate Eu^{III} complexes.

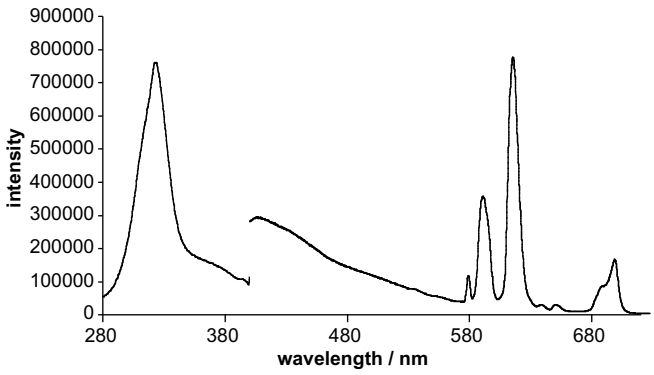

Fig. 2. Excitation (left, λ_{em} = 615 nm) and emission (right, λ_{ex} = 320 nm, not time-gated) spectra of **Eu · L** in methanol solution.

Table 2
Luminescence lifetimes of the complexes

Complex	τ_H (μs)	τ_D (μs)	q
Nd · L[a]	0.186	0.399	0.4
Eu · L[b]	551	1250	0.9
Yb · L[a]	0.904	1.370	0.7

[a] Measurements obtained in MeOH and CD_3OD using λ_{ex} = 355 nm.
[b] Measurements obtained in H_2O and D_2O using λ_{ex} = 355 or 396 nm. Lifetimes are associated with a ±10% error.

Application of the lifetimes to the determination of the inner sphere solvation of Eu^{III} was undertaken using the relation $q = 1.25[(k_{H_2O} - k_{D_2O}) - 0.25]$ [27]. In the case of **Eu · L** this yielded q = 0.9, corresponding to one inner sphere solvent molecule, which is consistent with an eight-coordinate binding mode of the ligand and therefore probably suggests that the quinoxaline unit participates in binding to Eu^{III} even in the presence of a coordinating polar solvent such as water.

For the near-IR emitting species **Nd · L** and **Yb · L** an excitation wavelength of 355 nm was employed. The Nd^{III}complex displayed near-IR emission dominated by a peak at 1058 nm ($^4F_{3/2} \rightarrow {}^4F_{11/2}$) (note: utilising a longpass filter prevented the observation of the higher energy $^4F_{3/2} \rightarrow {}^4F_{9/2}$ transition). The lifetimes of the transition were recorded as 186 and 399 ns in MeOH and CD_3OD (Fig. 3), respectively. These values were also obtained when using a detection wavelength of 1340 nm corresponding to the much weaker $^4I_{13/2}$ transition. Such lifetimes are reasonably consistent with the proposed coordination environment of Nd^{III}, but the abundance of proximate C–H oscillators may well quench the emission and lifetimes to some degree. Application of the equation for the inner sphere hydration of Nd^{III} $[q = 290(k_{MeOH} - k_{CD_3OD}) - 0.4]$ also adds credence to our assertion that the quinoxaline chromophore participates in the coordination sphere since using this relationship gives q = 0.4. However, the application of such an approach to Nd^{III} should be treated with care since the inherent errors associated with q in this case are much higher [27]. The steady state emission spectrum of **Yb · L** in CD_3OD (Fig. 4) revealed a spectral profile common for Yb^{III} with a peak at 972 nm ($^2F_{5/2} \rightarrow {}^4F_{7/2}$)together with a broadened shoulder to low energy beyond 1000 nm. The latter feature is frequently assigned to vibronic components within the transition although in this case no fine structure was observed. The time-resolved studies for **Yb · L** were less clear cut with the decay in methanol fitting well to a single exponential giving a lifetime of 904 ns, whereas in CD_3OD the decay was best fitted to two components of 1.37 (87%, and used in Table 2) and 2.59 μs (13%). Using the dominant component equates to q = 0.7 whilst the lesser results in q = 1.4. It is reasonable that the two forms of the complex exist in non-deuterated methanol as well, but possess very similar lifetimes that are difficult to differentiate statistically. However, given that the wavelength of absorption (λ_{max} = 319 nm) of the quinoxaline chromophore is not as red-shifted as for the other lanthanide complexes it may be that in coordinating solvent the quinoxaline is more weakly bound to Yb^{III} and resolved on the timescale of the lifetime measurements. What is clear however is that the quinoxaline unit sensitises ytterbium and in the case of a coordinated chromophore it is important to consider a Dexter mechanism for energy transfer. Consequently, in the case of **Yb · L**, it is also possible that energy transfer proceeds *via* electron exchange and the formation of an Yb^{II} intermediate (*i.e.* LMCT) [28].

We are also interested in designing responsive complexes for use as chemosensors. In particular utilising the emissive properties of Eu^{III} which possess structured emission in the visible region through deactivation of the $^5D_0$ excited state to the ground states of ^7F_J (J = 0,1,2,3,4). The relative intensity of the J = 2 state is known to be hypersensitive and can thus be exploited in the design of responsive complexes. We have been developing such an approach for use in the detection of metal ions in physiologically modelled aqueous environments whereby binding of the analyte modulates the degree of hydration of the Eu^{III} ion. Our interest in exploiting the coordinating quinoxaline for such applications is described below with respect to pH response in aqueous solution.

The pH dependent luminescence properties were investigated since the nitrogen heteroatoms in the quinoxaline chromophore should be liable to protonation in acidic media. As noted earlier the Eu^{III} complex should be a particularly interesting complex to study in this regard since the J = 2 state is known to be hypersensitive and the emission profile, in general, sensitive to changes in both the coordination geometry and nature of the donor atoms within the coordination sphere [1c,2d,5]. Thus, the pH dependence was assessed in H_2O. Our investigations show that **Eu · L** is very sensitive to changes in pH in the range 2–11. At pH/pD 2 the analysis of the decay profiles suggest that **Eu · L** possesses q = 2.2 obtained from lifetimes of 0.35 and 1.24 ms in H_2O and D_2O respectively. This change in innersphere hydration is ascribed to

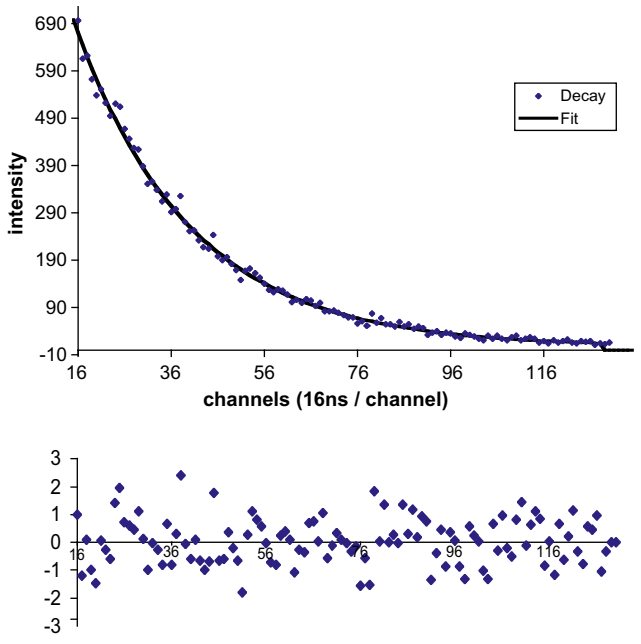

Fig. 3. Above: Fitted single-exponential decay for the complex **Nd · L** in CD_3OD obtained with λ_{ex} = 355 nm and λ_{em} = 1055 nm. Below: associated residuals.

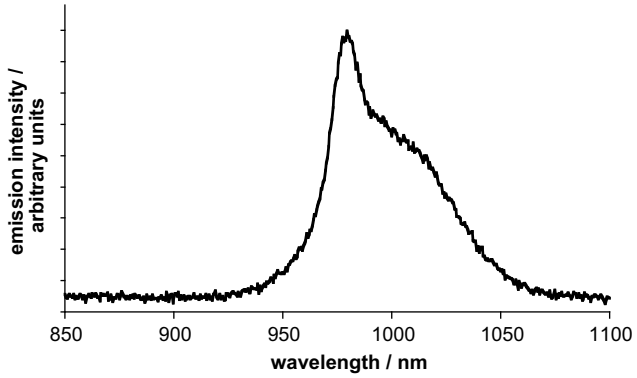

Fig. 4. Steady state emission spectrum for **Yb · L** in CD_3OD solution (λ_{ex} = 355 nm).

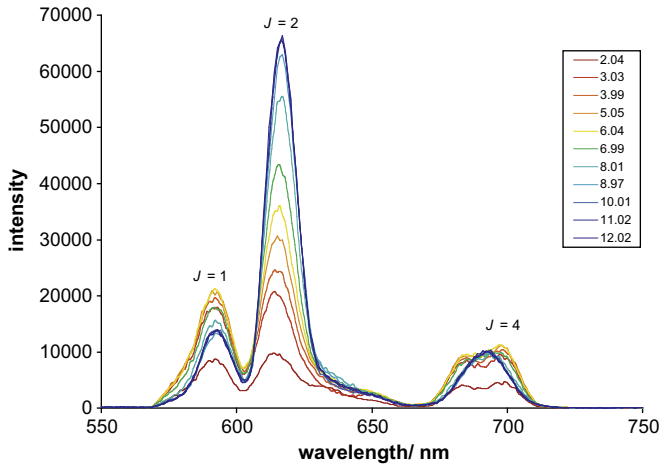

Fig. 5. Steady state spectra showing the changes in the Eu^{III} emission between pH 12.0 and 2.0.

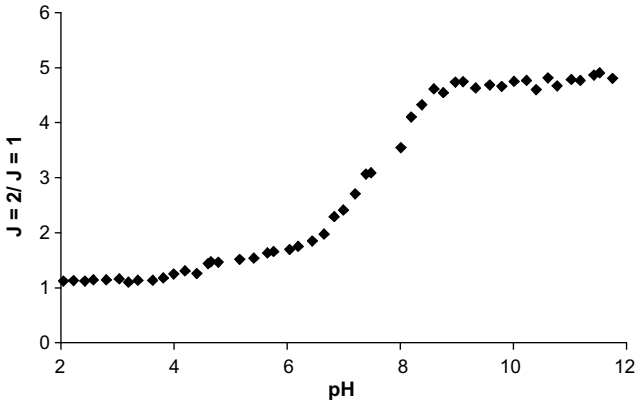

Fig. 6. Graph demonstrating the $J = 1$ and 2 ratiometric pH response of the Eu^{III} complex.

the quinoxaline becoming uncoordinated from the Eu^{III} centre, presumably as a consequence of protonation. Fig. 5 shows the changes in emissive spectral form associated with the various pH regimes. In basic conditions the $J = 4$ transition appears as a broad single peak at 692 nm, but as the pH decreases this is resolved into two separate peaks at 684 and 699 nm. As the pH decreases from pH 7 to pH 3 the intensity of the $J = 1$ transition increases to a broad maximum, before decreasing slightly, while the intensity of the $J = 2$ transition increases throughout the pH range. The result of these differing intensities is that the ratio of $J = 1$ to $J = 2$ changes significantly in the biorelevant region of pH 6–9 (Fig. 6). Such a ratiometric change is advantageous in responsive probes as it allows a modulation in emission to be attributed to a change in microenvironment rather than variable probe concentration, which fluorescence intensity alone cannot distinguish.

4. Conclusions

This study shows that the simple quinoxaline moiety is a useful chromophore for sensitising a range of visible and near-IR emitting lanthanide ions. It facilitates relatively longwave irradiation (300–350 nm) and is thus a useful consideration in the future design of lanthanide-based probes aimed at fluorescence applications. When combined with the unique luminescence properties of Eu^{III} this work demonstrates that the emission properties of the resultant complex, **Eu** · **L**, are highly sensitive to different pH regimes, in particular those of physiological relevance (pH 6–8.5). Towards acidic pH this appears to be a consequence of protonation of the quinoxaline unit and a consequential increase in the inner sphere hydration of Eu^{III}.

5. Experimental

5.1. Materials and procedures

Although all new compounds are air stable both in the solid state and solution, the complexes appear to be mildly hygroscopic. Luminescence pH titrations were carried out in a background of constant ionic strength ($I = 0.1$ NaCl, 295 K). Solutions were made basic by addition of 1 M NaOH and titrated to acidic pH using small aliquots of (1–30 μL) of 1 M, 0.1 M or 0.01 M HCl solution in accordance with related studies [5]. In order to avoid any errors due to dilution, HCl solutions contained the same concentration of {Eu · L}$(OTf)_3$ as the sample. Luminescence spectra were recorded every 0.25 pH with $\lambda_{ex} = 320$ nm.

5.2. General physical measurements

All photophysical data were obtained on a JobinYvon–Horiba Fluorolog spectrometer fitted with a JY TBX picosecond photodetection module and a Hamamatsu R5509-73 detector (cooled to −80 °C using a C9940 housing). The pulsed laser source was a Continuum Minilite Nd:YAG configured for 355 nm output. Lifetimes were obtained using the JY–Horiba FluorHub single photon counting module. IR spectra were recorded on a Varian 7000 FT-IR. Mass spectra were obtained using a Bruker MicroTOF LC.

5.3. Syntheses of ligands and complexes

5.3.1. 1,4,7-Tris[(N-diethyl)carbamoylmethyl]-1,4,7,10-tetraazacyclododecane [29]

A mixture of 1 equiv. cyclen (0.25 g, 1.45 mmol), 3 equiv. $NaHCO_3$ (0.37 g, 4.35 mmol) and a catalytic amount of KI were stirred in acetonitrile (50 ml) under nitrogen and cooled to 0 °C. A solution of 3 equiv. *N*-diethyl-2-chloroacetamide (0.65 g, 4.35 mmol) in acetonitrile (20 ml) was added dropwise over 30 min. The mixture was allowed to warm to room temperature and stirred for a further 72 h. The solvents were removed *in vacuo* and the crude reaction mix was purified by recrystallisation with diethyl ether followed by recrystallisation from hot toluene to give the pure product as a brown oil. Yield: 0.429, 52%. ^{1}H NMR (400 MHz, $CDCl_3$, 300 K): $\delta_H = 9.96$ (1H, br s, N*H*), 3.52 (2H, s, COCH_2), 3.45 (4H, s, COCH_2), 3.27 (8H, q, $^3J_{HH} = 7.2$ Hz, CH_2CH$_3$), 3.18 (4H, q, $^3J_{HH} = 7.1$ Hz, CH_2CH$_3$), 3.04 (4H, d, ring CH_2), 3.02 (4H, s, ring CH_2), 2.81 (8H, s, ring CH_2), 1.10 (6H, t, $^3J_{HH} = 7.1$ Hz, CH$_2$CH_3) and 1.02 (12H, t, $^3J_{HH} = 7.1$ Hz, CH$_2$CH_3). ES$^+$ MS (MeCN): found m/z 512. $\{M+H\}^+$ requires m/z 512.

5.3.2. {1,4,7-Tris[(N-diethyl)carbamoylmethyl]-1,4,7,10-tetraazacyclododecane-10-(2-methylquinoxaline)} · NaCl (**2**)

One equivalents of 2-bromomethyl quinoxaline (0.035 g, 0.157 mmol) was added to a stirred solution of 1 equiv. of the cyclen triamide (0.08 g, 0.157 mmol) in dry acetonitrile (20 ml) and heated to 60 °C under nitrogen. After 1 h 1.1 equiv. $NaHCO_3$ (0.0145 g, 0.168 mmol) and a catalytic amount of KI were added and the reaction was stirred for a further 18 h. The reaction mixture was filtered, the solvent was removed *in vacuo* and the crude reaction mixture was purified by recrystallisation from hot toluene to give the pure product as a yellow-brown solid, isolated as the

sodium chloride salt. Yield: 0.047 g, 42%. ^{1}H NMR (400 MHz, $CDCl_3$, 300 K): δ_H = 8.85 (1H, s, aromatic), 8.00 (2H, m, aromatic), 7.63 (1H, m, aromatic), 7.56 (1H, m, aromatic), 3.42 (8H, br m, CH_2CO and –CH_2–quin), 3.20 (8H, m, CH_2CH_3), 2.97 (8H, br s), 2.73 (4H, m, CH_2CH_3), 2.1–2.7 (8H, br m), 1.11 (12H, m, CH_2CH_3) and 0.83 (6H, t, $^3J_{HH}$ = 6.4 Hz, CH_2CH_3) ppm. $^{13}C\{^1H\}$ NMR ($CDCl_3$, 300K): δ_C 13.1, 14.5, 14.8, 40.9, 41.5, 41.6, 55.3, 56.1, 129.5, 129.8, 129.9, 130.0, 146.5, 169.3, 170.5 ppm. IR ν_{max}(ATR, solid): 1703, 1588, 1503, 1458, 1372, 1290, 1267, 1202, 1107, 1015, 881, 838, 791, 748 cm^{-1}. ES$^+$ MS: found m/z 654. {M+H−NaCl}$^+$ requires m/z 654.

5.4. General method for lanthanide complexation

The lanthanide complexes were prepared by stirring the ligand with 1 equiv. of $Ln(OTf)_3$or $Yb(NO_3)_3$ in MeOH (approx. 15 ml) for approximately 24 h at 50 °C. The reaction was followed by TLC (MeOH:DCM 1:9) and judged to be complete when free ligand was no longer observed on the TLC plate. The resulting mixture was concentrated and the desired product precipitated from solution upon addition of diethyl ether. The complexes were obtained as light brown solids in >90% yield.

5.4.1. {Eu · L}(OTf)$_3$

ES$^+$ MS (MeCN): found m/z 1104. {M−OTf}$^+$$C_{37}H_{59}EuF_6N_9O_9S_2$ requires m/z 1104. IR ν_{max}(ATR, solid): 1600, 1458, 1250, 1155, 1079, 1028, 954, 918, 636 cm^{-1}. UV–Vis λ_{max} (ε/mol^{-1} dm^3 cm^{-1}): 238 (14942), 324 (3718) nm.

5.4.2. {Nd · L}(OTf)$_3$

ES$^+$ MS (MeCN): found m/z 1095. {M−OTf}$^+$$C_{37}H_{59}F_6N_9NdO_9S_2$ requires m/z 1095. IR ν_{max}(ATR, solid): 1598, 1482, 1445, 1256, 1160, 1078, 1027, 954, 918, 793, 636 cm^{-1}. UV–Vis λ_{max} (ε/mol^{-1} dm^3 cm^{-1}): 241 (12377), 323 (4725) nm.

5.4.3. {Yb · L}(NO$_3$)$_3$

ES$^+$ MS (MeCN): found m/z 1013, 991 and 951. {M}$^+$ $C_{35}H_{59}N_{12}O_{12}Yb$ requires m/z 1013, {M−NO_3+MeCN}$^+$$C_{37}H_{62}$-$N_{12}O_9Yb$ requires m/z 992, {M−NO_3}$^+$$C_{35}H_{59}N_{11}O_9Yb$ requires m/z 951. IR (ν_{max})(ATR, solid): 1605, 1404, 1295, 1260, 1075, 1023, 952, 793, 636 cm^{-1}. UV–Vis λ_{max}(ε/mol^{-1} dm^3 cm^{-1}): 219 (18785), 319 (2503) nm.

5.5. Structure analysis and refinement

The structure was solved by direct methods using SHELXS-97 and was completed by iterative cycles of ΔF-syntheses and full-matrix least squares refinement. All non-H atoms were refined anisotropically and difference Fourier syntheses were employed in positioning idealised hydrogen atoms and were allowed to ride on their parent C-atoms. All refinements were against F^2 and used SHELX-97 [30].

Bridge cleavage

ABSTRACT

A new Ni_4 distorted cubane complex [$Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4$] (**1**) (where Q^- is the anion of 8-quinolinol) is obtained from the reaction of NaQ with $Ni(OAc)_2 \cdot 4H_2O$ in refluxing MeOH *via* solvent derived μ_3-OMe assisted self-assembly of four nickel(II) centres. The periphery of [$Ni_4(OMe)_4$] cubane is covered by four Q^- and four MeOH molecules. This methanol specific reaction is not supported in solvent glycinol (Hgl; $NH_2(CH_2)_2OH$), an amine substituted ethanol, producing monomeric [$NiQ_2(Hgl)_2$] $\cdot 2H_2O$ (**2** $\cdot 2H_2O$) instead and is able to cleave **1** to yield **2** $\cdot 2H_2O$. The cryomagnetic susceptibility data of powdered **1** can be modeled by a two *J* equation yielding $J_1 = -1.8(1)\ cm^{-1}$, $J_2 = 3.9(1)\ cm^{-1}$ and $g = 2.24$.

1. Introduction

Interest in synthesis and characterization of high-nuclearity transition metal complexes has grown considerably in recent years, particularly due to their relevance to multi-electron transfer centers in biology [1] and magnetostructural research [2]. Donor groups from both endo- and exogenous ligands can initiate the nucleation of self-assembly processes during the multinuclear complex formation [2,3]. Several single atom bridging groups (X) such as MeO^-, HO^-, RO^-, PhO^- or N_3^- in different bridging modes play key roles in [Ni_4] complex geometry, for example star-shaped A [4], defective dicubane B [5], or distorted cubane C [6,7] (Scheme 1). Within these structures, reports on exogenous μ_3-OMe [8] supported cubane complexes having peripheral bidentate ligands are scarce.

The ligand 8-quinolinol (HQ) and its derivatives have been known as a potent analytical reagents for more than a century and showed renewed interest in recent time for novel electron transport and emissive behavior when coordinated to Al^{3+} as novel organic light-emitting device (OLED) fabrication material [9]. Attachment of conjugated fluorophores to this family of ligands lead metal ion coordination dependent changes in fluorescence pattern for sensor development [10]. Recently Winpenny et al. have shown that reactions of HMQ (2-methyl 8-quinolinol) with [$M_2(H_2O)(Piv)_4(HPiv)_4$] (M = Ni, Co) [11] in acetone yield four O,O′ face-diagonal bridged [$M_4(Piv)_4(MQ)_4$] (Piv = $(CH_3)_3CCO_2$) (Scheme 2, left) [12].

Another closely related ligand Hhmp (2-hydroxymethylpyridine) has shown to provide [Ni(hmp)(MeOH)Cl]$_4$ (Scheme 2, right) from the μ_3 corner supports [2c]. In this paper we report the synthesis and characterization of [$Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4$] (**1**) on four solvent derived exogenous μ_3-methoxide cube corners showing different mode of binding of peripheral N,O donor ligands (Scheme 2, top). In **1** the key role of solvent derived methoxo bridges was identified following the same synthesis in glycinol (Hgl) as reaction solvent yielding [$NiQ_2(Hgl)_2$] $\cdot 2H_2O$ (**2** $\cdot 2H_2O$) quantitatively. This synthetic result may be considered novel since glycinol based Schiff bases are known to support tetranuclear Ni^{II} complexes by providing four μ_3-ethoxide imine supports [13]. Complex **2** $\cdot 2H_2O$ can also be obtained *via* the methoxo bridge cleavage reaction of **1** is refluxing glycinol for half an hour. The contrasting role of glycinol as a solvent and a component of Schiff base can be indicated (Scheme S1). The biology the resting state of acireductone dioxygenase [14] and *Escherichia coli* glyoxalase I (GlxI) [15] responsible for detoxification of cytotoxic pyruvaldehyde exhibit octahedral O/N coordination around mononuclear Ni(II) centres. We herein describe the synthesis, crystal structure and low temperature magnetic characterization of a new tetranuclear Ni^{II} complex and its solvent-triggered descend to an octahedral mononuclear Ni^{II} complex.

2. Experimental

2.1. Materials and instrumentation

All preparations and manipulations were performed under aerobic conditions using chemicals as received. The chemicals used were obtained from the following sources: 8-quinolinol from S.D. Fine Chem, India. Nickel acetate tetrahydrate was obtained from Fluka AG, Switzerland. All other chemicals and solvents were reagent grade materials and were used as received without further purification. Microanalyses (C, H and N) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra in 200–4000 cm^{-1} range were obtained on a Perkin–Elmer RX1 FT-IR spectrometer prepared as KBr pellets. Electronic spectra in 190–3200 nm range were recorded on a Shimadzu 1601 UV–Vis–NIR spectrophotometer using 1 cm quartz cells. Solution electrical conductivity was measured using a Unitech type UI31C digital conductivity meter with a solute concentration of 10^{-3} M. Powder X-ray diffraction in the powder sample have been measured using X pert pro, Philips, The Netherlands. The room temperature magnetic susceptibilities in the solid-state were measured using a home built Gouy balance fitted with a Polytronic d.c. power supply. The experimental magnetic susceptibilities were corrected for the diamagnetism using Pascal's constants. Variable temperature magnetic measurements were carried out on polycrystalline samples (ca. 30 mg) using a Quantum Design MPMS-7 SQUID magnetometer operating at a constant magnetic field of 1 T between 1.8 and 300 K. The experimental magnetic moment was corrected for the diamagnetic contribution from the sample holder and the diamagnetic response from the sample, which was evaluated from Pascal's constants.

CAUTION!! Perchlorate salts are potentially explosive and should be handled in very small quantities.

2.2. Synthesis

2.2.1. NaQ

Solutions of HQ (4.0 g, 27.5 mmol) in MeCN (80 ml) and NaOH (1.1022 g, 27.5 mmol) in MeOH (30 ml) were combined, and the mixture was heated to reflux for 15 min. The resultant yellow solution was then concentrated in vacuum until crystals began forming. Storage of the solution at 0 °C for 24 h afforded white needles, which were filtered off and washed with cold MeOH. Further concentration of the filtrate and washings and storage at 0 °C gave a second crop of crystals; total yield 80%. The white crystalline product becomes yellow on drying. IR (KBr, cm^{-1}): 3230 (br), 3043 (m), 1561 (s), 1493 (s), 1459 (s), 1421 (m), 1373 (m), 1361 (s), 1314 (s) 1277 (m), 1096 (s), 1064 (m), 894 (m), 822 (s), 792 (s), 752 (s), 714 (m), 650 (m).

2.2.2. $[Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4]$ (**1**)

A mixture of $Ni(O_2CCH_3)\cdot 4H_2O$ (0.3017 g, 1.2 mmol), NaOH (0.048 g, 1.2 mmol), and NaQ (0.2 g. 1.2 mmol) in MeOH (50 ml) was refluxed for 30 min, affording a yellow-green precipitate, which was filtered off and washed with MeOH. Single crystals of **1** were obtained by the slow evaporation of a dichloromethane solution of compound layered with methanol in 1:1 (v/v) ratio. The isolated crystals are of X-ray quality but lose solvent when removed from the mother liquor. The powdered sample was finally dried in vacuum over P_4O_{10}. Yield: 1.16 g (90%). *Anal.* Calc. for $C_{44}H_{52}N_4O_{12}Ni_4$ (1063.74): C, 49.67; H, 4.88; N, 5.26; Ni, 22.09. Found: C, 49.9; H, 4.84; N, 5.24; Ni, 22.03%. IR (KBr, cm^{-1}): 3195 (br), 3042 (m), 1601 (m), 1577 (s), 1498 (s), 1465 (s), 1323 (m), 1282 (m), 1034 (s), 820 (s), 786 (m), 735 (m), 643 (m), 504 (m). Scheme 2.

2.2.3. $[NiQ_2(Hgl)_2] \cdot 2H_2O$ ($\mathbf{2} \cdot 2H_2O$)

A mixture of $Ni(O_2CMe) \cdot 4H_2O$ (0.301 g, 1.2 mmol), NaOH (0.048 g, 1.2 mmol), and NaQ (0.2 g. 1.2 mmol) in glycinol (100 ml) was refluxed for 30 min, affording green block crystals by evaporation of solvent after 3 weeks. The powdered compound was finally dried in vacuum over P_4O_{10}. Yield: 0.31 g (45%). *Anal.* Calc. for $C_{22}H_{30}N_4O_6Ni$ (504.878): C, 52.33; H, 5.94; N, 11.09; Ni, 11.62. Found: C, 51.9; H, 5.23; N, 11.05; Ni, 11.18%. IR (KBr, cm^{-1}): 3313 (m), 2940 (m), 1598 (m), 1567 (s), 1495 (s), 1462 (s), 1369 (m), 1314 (s), 1217 (s), 1109 (s), 1028 (sb), 821(s), 780 (m), 748 (m), 498 (m). Molar conductance, Λ_M: (DMF solution) 35 Ω^{-1} cm^2 mol^{-1}. UV–vis spectra [Λ_{max}, nm (ε, 1 mol^{-1} cm^{-1})]: (DMF solution) 578 (268), 410 (27352), 335 (98818), 271 (16749).

2.2.4. Solvent driven transformation of **1** to $\mathbf{2} \cdot 2H_2O$

Complex **1** (0.5 g, 0.47 mmol) was refluxed in glycinol (10 ml) for half an hour and the resulting brownish green solution kept for solvent evaporation. After 30 days green colored block crystals was subsequently obtained from the reaction mixture in 43% yield (0.2 g). The formation of $\mathbf{2} \cdot 2H_2O$ was confirmed by elemental analysis and X-ray structure determination.

2.3. X-ray crystallography

The green block single crystals of complexes $[Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4]$ (**1**) and $[NiQ_2(Hgl)_2] \cdot 2H_2O$ ($\mathbf{2} \cdot 2H_2O$) are suitable for the X-ray analysis. Complex **1** was grown by the slow evaporation of dichloromethane with methanol in 1:1 (v/v) ratio afforded large green crystals of the complex and green crystal of $\mathbf{2} \cdot 2H_2O$ was grown by the slow evaporation of the reaction mixture. The intensity data for single crystal of compound **1** and $\mathbf{2} \cdot 2H_2O$ were collected on a Bruker APEX-II CCD diffractometer with Mo Kα radiation (λ = 0.71073 Å) and an Oxford Cyrosystem Cobra low-temperature attachment. The structures were solved by direct methods (SIR97 [16]) and refined using full-matrix least-squares with all non-hydrogen atoms anisotropically and hydrogens included on calculated positions, riding on their carrier atoms. All calculations were performed using SHELXL-97 [17] and PARST [18] implemented in WINGX [19] system of programme.

3. Results and discussion

3.1. Syntheses, reactivity and spectroscopic characterizations

Using bidentate N,O donor ligand quinonemonoximate we reported a family of distorted $[Ni_4]$ cubane complexes in 1998 [20]. This was the first example of use of oxime based N,O donor ligands for the isolation of tetranuclear nickel(II) complexes. In 2003 Winpenny et al. used another N,O donor ligand 8-hydroxy quinolidine (HMQ, Scheme 2) and showed its reactions with $[M_2(H_2O)(Piv)_4(HPiv)_4]$ (M = Co, Ni) in acetone to provide ligandμ_3-phenolate end supported novel M_4 cubanes [12]. 2-Hydroxymethylpyridine (Hhmp) in deprotonated form provides one more example of {N,O} donor ligand coordinated $[Ni_4]$ cubane $[Ni(hmp)(MeOH)(Cl)]_4$ having μ_3 supports from hmp^- ligands. In this background we explored the latest example of N,O donor ligand HQ (Scheme 2) in this sequel. The synthesis of $[Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4]$ (**1**) was achieved via the reaction of $Ni(OAc)_2 \cdot 4H_2O$, sodium 8-quinolinolate (NaQ) and NaOH in 1:1:1 molar ratio in MeOH medium at room temperature under reflux for 0.5 h. Green microcrystalline product was subsequently obtained from the reaction mixture in 90% yield.

The elemental analysis, solution electrical conductivity and room temperature magnetic susceptibility data are consistent with the molecular formula $[Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4]$ for **1**. If the same reaction is carried out in MeCN we get the reported mononuclear species $NiQ_2(HQ)$ [21]. In the above reaction replacement of MeOH solvent by $NH_2CH_2CH_2OH$ (Hgl; glycinol) produced $[NiQ_2(Hgl)_2] \cdot 2H_2O$ ($\mathbf{2} \cdot 2H_2O$) thus identifying the important role of the solvent (Scheme S1). Dark green micro crystals of $\mathbf{2} \cdot 2H_2O$ in 45% yield were subsequently obtained after solvent evaporation.

The crucial role of the MeOH solvent was further verified by observing a solvent driven bridge cleavage of **1**. Reaction of **1** with glycinol in refluxing condition for 0.5 h leads to a brownish green solution, which on keeping undisturbed for 30 days yields green block crystals of $\mathbf{2} \cdot 2H_2O$ in 43% yield. Elemental analysis, solution molar electrical conductivity, room temperature magnetic susceptibility and molecular structure determination by X-ray crystallography confirm the formation of $\mathbf{2} \cdot 2H_2O$.

3.2. Infrared spectroscopy

The FTIR spectral data for the complexes **1** and $\mathbf{2} \cdot 2H_2O$ are given in the experimental section. The complexes **1** and $\mathbf{2} \cdot 2H_2O$ show strong absorption bands at 1577 and 1567 cm^{-1} respectively due to C=C and C=N vibrations [22] of the ligand Q^- (the value for free NaQ is 1561 cm^{-1}). The peaks for ring vibrations are obtained at 786 and 780 cm^{-1}, respectively for complexes **1** and $\mathbf{2} \cdot 2H_2O$. Broad medium bands centred at 3195 and 3313 cm^{-1} are observed corresponding to ν(OH) stretching vibrations of the coordinated methanol and lattice water molecules in **1** and $\mathbf{2} \cdot 2H_2O$, respectively.

3.3. Description of structures

3.3.1. $[Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4]$ (**1**)

Compound is soluble in chlorinated solvents, and layering of a solution of **1** in dichloromethane with methanol in 1:1 (v/v) ratio afforded large yellow-green crystals suitable for X-ray structure determination. Compound **1** crystallizes in tetragonal $I4_1/a$ space group and its labeled ORTEP is shown in Fig. 1. Crystallographic data for **1** and $\mathbf{2} \cdot 2H_2O$ are given in Table 1. The bond distances and angles for the **1** and $\mathbf{2} \cdot 2H_2O$ are given in Table 2.

The structure of **1** incorporate a distorted $[Ni_4(\mu_3\text{-}O)_4]$ cubane core, where the μ_3-O bridges are derived from methanol molecules [23]. The peripheral coordinations around each distorted octahedral (inset of Fig. 1) Ni^{II} ion is completed by four terminal MeOH ligands, which participate in intramolecular hydrogen-bonding interactions (O···O distance: 2.74 Å) with the phenolate type O atoms of the Q^- ligands, across four of the six faces of the Ni_4 cubane. As a result, these four faces exhibit shorter Ni···Ni separation (3.07 Å), longer O···O distance of 2.74 Å, smaller Ni–O–Ni angles (95.9° (3) and 96.3° (3)), and smaller Ni–O–O–Ni dihedral angle (166°). The other two faces that are not engaged in hydrogen-bonding interactions show shorter O···O distance of 2.65 Å [6], longer Ni···Ni separations of 3.16 Å, greater Ni–O–Ni [11] angle (100.0° (3)), and greater Ni–O–O–Ni dihedral angle (176°). This has the effect of lowering the effective symmetry of the $[Ni_4(OMe)_4]^{4+}$ unit from T_d to D_{2d} [8]. The molecular flat surface of each Q^- ligand is coplanar with the Ni_2O_2 faces involved in hydrogen-bonding interactions (dihedral angle is 8.05°). In addition, **1** appears to possess a slight tetragonal compression within the octahedral NO_5 coordination environment along the O–Ni–O axis made from the O atoms of phenolate group of Q^- and bridging MeO^- ligand, with Ni–O bonds on this vector of 2.05–2.07 Å versus 2.07–2.09 Å for the in plane Ni–O and Ni–N bonds. These Ni–O bond lengths lie well within the range of reported values for the corresponding lengths in other Ni_4 clusters [8]. The individual Ni_4 molecules are well separated with neighboring intermolecular Ni···Ni separations of 6.39 and 7.29 Å. In addition, there are no obvious intercubane hydrogen bonds. Along crystallographic '*b*'

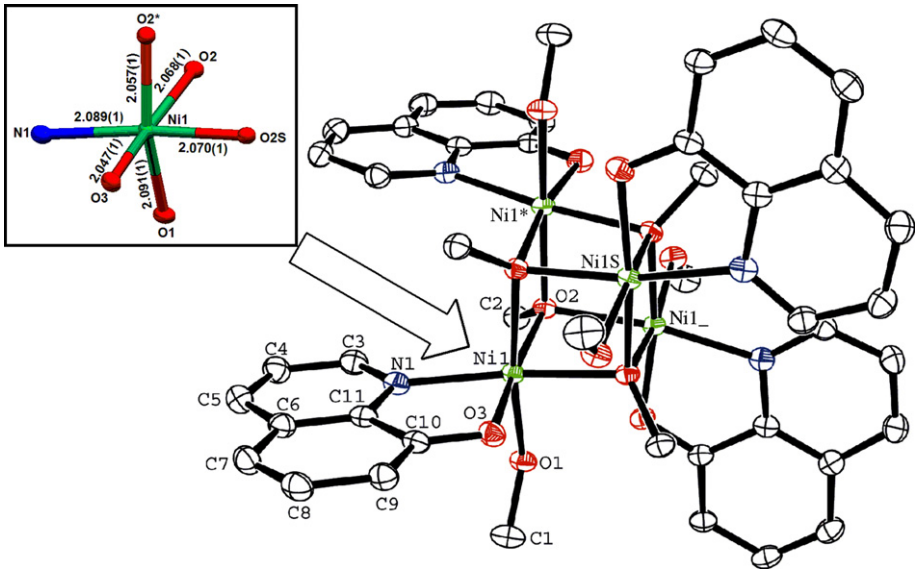

Fig. 1. ORTEP [19] representation of $[Ni_4(\mu_3\text{-}OMe)_4Q_4(MeOH)_4]$ (**1**) showing the thermal ellipsoids at 30% probability level. Hydrogen atoms are omitted for clarity. Symmetry code: (*) $-x+1, -y+3/2, z+0$ (S) $y-1/4, -x+5/4, -z+1/4$ (_) $-y+5/4, x+1/4, -z+1/4$.

$w = 0.75/(\sigma^2(F_o) + 0.0010F_o^2)$.

axis the complex **1** is packed nicely in a pair wise arrangement of well separated tetramers (Fig. S1a) and whereas an interpenetrating net-like arrangement is observed along '*c*' axis (Fig. S1b). Several other $[Ni_4]$ complexes are known with similar cubane structures engaged in intermolecular hydrogen-bonding interactions [6d,6e,6h]. In a space-fill model the D_{2d} symmetry of the complex **1** is shown with four different colors for each of the repeating unit (Fig. S2). The five-membered chelate rings from capping ligands exert a tetragonal compression around the Ni coordination sites of complex **1**.

3.3.2. $[NiQ_2(Hgl)_2] \cdot 2H_2O$ (**2**)

Complex **2** · $2H_2O$ crystallizes in triclinic $P\bar{1}$ space group. The solid-state structure of **2** · $2H_2O$ (Fig. 2) identifies the ctc (*cis–trans–cis*; N^{py}, O^{ph}, N^{am}) isomer and contains discrete mononuclear complex of Ni^{II} with amine end coordinated dangling glycinols in N_4O_2 environment and different from the NO_5 environment in **1**.

Such amine end coordinations are important and shown to be photolabile and useful for amino acid photodelivery [24]. The bis-chelated nickel(II) centre prefers to bind the neutral nitrogen ends of glycinol in comparison to the hydroxy ends as seen earlier in $[Ni(NH_3CH_2CH_2OH)_2(H_2O)_4](SO_4)_2$ [25]. We were unable to replace coordinated MeOH molecules in **1** by glycinol in OH coordination mode. The distorted octahedral N_4O_2 coordination environment around Ni^{II} shows (inset of Fig. 2) tetragonal compression originating from five-membered chelation of ligands along the O–Ni–O vector involving the phenolate O atoms of Q^- ligands, with Ni–O bonds on this vector of 2.05(1)–2.07(1) Å versus 2.09(1)–2.13(1) Å for the in plane Ni–N bonds. The average Ni–O and Ni–N distances are slightly longer than those in $[Ni_4]$ complex. A columnar packing of complex **2** is observed along crystallographic '*b*'-axis (Fig. S3). The most interesting feature of this structure is the formation of an intramolecularly hydrogen bonded tetrameric water cluster from lattice water molecules present in the crystals of **2** · $2H_2O$. The four water molecules of crystallization, two from each monomer, show intricate H-bonding network within the intermolecular space forming a dimer of Ni^{II} neutral monomers [26]. Out of these only O(1W) show full occupancy and O(2W) is disordered with partial occupancies 0.5, 0.3 and 0.2 on O(2aW), O(2bW) and O(2cW). The monomers are linked together through six self complementary H-bonds as established between phenolate oxygen O(1) with water O(1W), O(1W) and O(2aW*) and O(3) of pendant alcohol and O2aW, having O(1)···O(1W), O(1W)···O(2aW*)and O(3)···O(2aW) distances of 2.66, 2.84 and 2.82 Å, respectively (Fig. S4). The relevant hydrogen bonded O···O separations are given in Table 3.

Water hydrogen atoms could not be located in the crystal structure [27]. The involvement of the hydroxy ends of coordinated glycinol molecules in H-bonding interactions with lattice water molecules prevent deprotonation and made them unavailable for metal ion coordination. The individual mononuclear Ni complexes are well separated with intermolecular Ni···Ni separations of 7.80–9.80 Å.

3.4. Magnetic behavior

The magnetic data for **1** were measured at 1 T in the temperature range of 1.8–300 K and plotted in the form of $\chi_M T$ versus T

Table 2
Selected bond lengths (Å) and bond angles (°) of complex **1** and **2** · $2H_2O$

Bond lengths of **1**			
Ni(1)–O(3)	2.0476(8)	Ni(1)–O(2)	2.0687 (7)
Ni(1)–N(1)	2.089(1)	Ni(1)–O(1)	2.0913(8)

Symmetry code: (*) $-x+1, -y+3/2, z+0$; (S) $y-1/4, -x+5/4, -z+1/4$; (_) $-y+5/4, x+1/4, -z+1/4$.

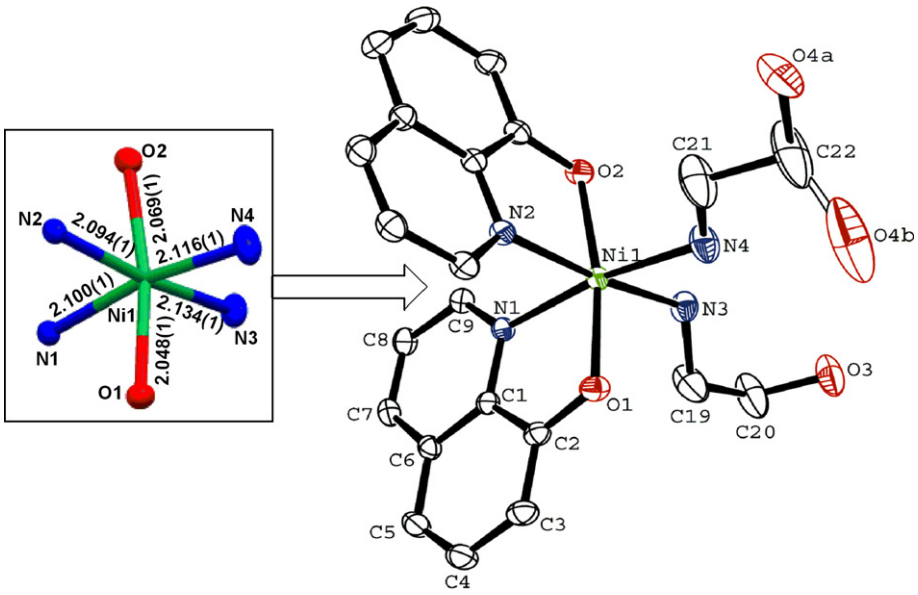

Fig. 2. ORTEP [19] representation of $[NiQ_2(Hgl)_2]$ showing the thermal ellipsoids at 30% probability level. Hydrogen atoms are omitted for clarity.

(Fig. 3). At 300 K, the $\chi_M T$ value of 5.22 $cm^3\ K\ mol^{-1}$ is larger than the spin-only one (5.02 $cm^3\ K\ mol^{-1}$) expected for non-interacting four Ni^{II} spins with $g = 2.24$, indicating that dominant ferromagnetic interactions are present. As temperature is lowered, $\chi_M T$ increases gradually, reaching a maximum of 9.15 $cm^3\ K\ mol^{-1}$ at 15 K and then decreases drastically. The magnetic pathways are shown in Scheme 3; the J_1 and J_2 stand for the longer Ni···Ni (3.163 Å) and the shorter routes (3.074 Å), respectively. From the structural data, the J_1 pathway involves the greater Ni–O–Ni angle (100.0°) and greater Ni–O–O–Ni dihedral angle (176°), whereas the J_2 route consists of the smaller Ni–O–Ni angles (95.9° and 96.3°) and smaller Ni–O–O–Ni dihedral angle (166°). It is known that the exchange interactions between Ni(II) centers in the Ni_4 cubane structures are governed by the Ni–O–Ni angle and Ni–O–O–Ni dihedral angle [28]. The ferromagnetic to antiferromagnetic transition takes place when the Ni–O–Ni angle and Ni–O–O–Ni dihedral

Table 3
O···O hydrogen bond lengths (Å) in hydrogen bonded nickel(II) dimer complex (**2** · $2H_2O$) (see Fig. 3)

O(1)···O(1W)	2.657	O(1W)···O(2aW*)	2.838
O(3)···O(2aW)	2.825	O(1W*)···O(2cW)	2.851
O(4B)···O(2cW)	3.033	O(2cW)···O(2cW*)	2.646
O(2cW)···O(2aW)	2.416	O(4B)···O(2aW*)	2.111

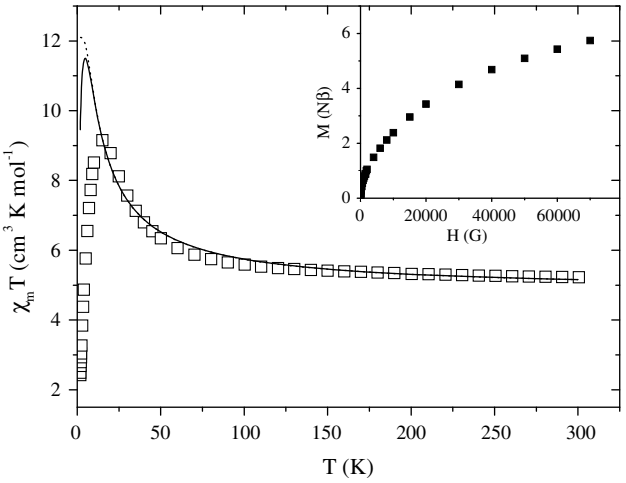

Fig. 3. Plot of $\chi_M T$ vs. T of **1** at 1 T. The dotted and solid lines are the simulated results from isotropic and anisotropic magnetic models, respectively. The inset shows the field dependence of the magnetization at 1.8 K.

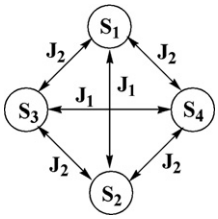

Scheme 3.

angle pass through about 98° and 170°, respectively [28]. Accordingly, it would be reasonably assigned that J_1 mediates an antiferromagnetic coupling and J_2 transmits a ferromagnetic coupling. The spin Hamiltonian used to fit the data is $H = -2J_1(S_1 \cdot S_2 + S_3 \cdot S_4) - 2J_2(S_1 \cdot S_3 + S_1 \cdot S_4 + S_2 \cdot S_3 + S_2 \cdot S_4)$. The data above 7 K was fitted employing the analytical expression of a tetranuclear Ni_4 cubane system under consideration of a molecular field approximation (zJ'). A best fit affords $g = 2.24(1)$, $J_1 = -1.8(1)\ cm^{-1}$, and $J_2 = 3.9(1)\ cm^{-1}$, and $zJ' = 0.39(1)\ cm^{-1}$. The obtained results are similar to those of other Ni_4 spin clusters [6d,6h,28]. The M(H) data at 1.8 K, shown in the inset of Fig. 3, are not saturated even at 7 T.

4. Conclusions

In summary, simultaneous bridging and five-membered chelation of solvent derived MeO^- in μ_3 mode and the bidentate ligand, Q^-, leads to the formation of a distorted $[Ni_4(MeO)_4]$ cubane exhibiting two different types of Ni_2O_2 faces having Ni···Ni separations of 3.07 and 3.16 Å, respectively. The coupling between adjacent Ni ions is moderately antiferromagnetic for longer separation and the shorter separation feature a weak ferromagnetic super-exchange. The role of solvent for tetranuclear assembly has been justified when the synthesis is repeated in solvent glycinol in place of MeOH and the studying the reactivity of glycinol toward **1** which culminates in bridge cleavage and generation of $[NiQ_2(Hgl)_2] \cdot 2H_2O$.

ABSTRACT

The cyclic structure of 2-phenyl-2-(2-pyridyl)imidazolidine (**1**) derived from the condensation of 1,2-diaminoethane and 2-benzoylpyridine has been confirmed by X-ray crystallography. Reaction of (**1**) with salts of nickel(II) and copper(II) leads to metal induced ring opening and the formation of complexes containing the tridentate ligand (L). The formulae of the complexes derived from NiX_2 and CuX_2 are $[NiL_2]X_2$ and $[CuLY]X_2$ (X=ClO_4^-, Y = H_2O, CH_3CN and N_3^-). Crystal structures were obtained for (**1**), $[NiL_2][ClO_4]_2$, $[CuL(CH_3CN)][ClO_4]_2$, $[CuL(H_2O)][NO_3]_2$ and $[CuLN_3][ClO_4]$.

1. Introduction

Schiff base ligands have played an important role in our understanding of the coordination chemistry of transition metal ions and Schiff base complexes have a broad range of applications including, enzyme inhibition [1], anti-microbial action [2] and catalytic activity when encapsulated in zeolite Y [3]. In this paper, the imidazoline (**1**), the result of a disfavoured 5-*Endo-Trig* cyclization [4], is reacted with nickel and copper salts to yield tridentate complexes. The structures of the complexes which could be crystallized and analysed by X-ray diffraction are discussed. Prompted by reports of the use of DFT calculations in modeling nickel and copper complexes, with similar and greater complexity than those described here [5,6], it has been found that while calculations for the nickel system reproduced the details of the crystallographic results the copper results were less satisfactory.

2. Experimental

2.1. Chemicals and materials

2-Benzoylpyridine and 1,2-diaminoethane (from Sigma–Aldrich and BDH) were used without further purification. Sodium azide (Sigma–Aldrich), $Ni(ClO_4)_2 6H_2O$ (Sigma–Aldrich), $Cu(ClO_4)_2 6H_2O$ (Aldrich), $Ni(NO_3)_2 6H_2O$ (Merck) and $Cu(NO_3)_2 4H_2O$ (Riedel de-Haen) were used as received. All other chemicals and solvents were AR grade and used as received. Ethanol was dried prior to use.

2.2. Instrumentation

Elemental analyses (carbon, hydrogen and nitrogen) were carried out on a Perkin–Elmer 240 CHN elemental analyzer. IR spectra were measured on a Perkin–Elmer Spectrum One Diamond-ATR-FT-IR instrument spectrometer, UV–Vis spectra were recorded using a Varian Cary 50 spectrometer using 1 cm quartz cuvettes. ^1H and ^{13}C NMR spectra were recorded on a JEOL ECX-400 NMR spectrometer at room temperature with tetramethylsilane as internal reference. Magnetic moments were measured on a Sherwood Scientific magnetic susceptibility balance at room temperature. The diamagnetic corrections were calculated by using Pascal's constants and $Hg[Co(SCN)_4]$ was used as a calibrant. Molar conductivities were measured using freshly prepared 10^{-3} M solutions in nitromethane, acetonitrile and dimethylformamide at

room temperature, using a Jenway 4310 conductivity meter and the cell constant was calibrated with 0.01 M KCl solution. Melting points were measured using a Gallenkamp melting point apparatus.

2.3. Synthesis of 2-phenyl-2-(2-pyridyl)imidazolidine (**1**)

The ligand 2-phenyl-2-(2-pyridyl) imidazolidine was prepared using a slight variation of the procedure reported in the literature [7]. An anhydrous ethanol solution (15 cm^3) of 2-benzoylpyridine (8.0 g, 0.04 mol), was treated dropwise with 1,2-diaminoethane (2.62 g, 0.05 mol) in the same solvent (5.0 cm^3) with constant stirring and the mixture was then heated under reflux for 16 h. The yellow solution was concentrated under reduced pressure, cooled and the formed faint yellow precipitate filtered. The product was re-crystallized from *n*-hexane giving almost colourless crystals, melting point is (83–85 °C). *Anal.* Calc. for $C_{14}H_{15}N_3L$: C, 74.63; H, 6.7; N, 18.67. Found: C, 74.81; H, 6.47; N, 18.46%. IR (Diamond ATR cm^{-1}): υ(N–H) 3320, 3247 (broad); υ(C=N) 1620, 1538, 1567, υ(C=C) 1490 1448, 1425. ^1H NMR data in $CDCl_3$ at 298 K: δ (ppm): 8.73 d(1) (H_6); 8.5 t(1) (H_4); 7.95 m(1) (H_5); 7.69 d(1) (H_3); 7.57–7.42 m(5) (H_{13}–H_{17}); 3.05 m(2) (H_{10}); 2.99 m(2) (H11); 2.82 br(2) (H 7, 9).^{13}C NMR in $CDCl_3$: δ (ppm): 163.3 (C-2); 150.2 (C6); 144.2 (C12); 136.7 (C4); 128.28 (C14, 16); 127.1 (C13, 17); 122.1 (C15); 85.9 (C8); 46.3(C10,11); UV–Vis (CH_3CN): λ_{max} 290, 275 and 252 nm.

2.4. Preparation of metal complexes, L= (**1**)

2.4.1. [Ni(L)$_2$][ClO$_4$]$_2$ (**2**)

To a stirred solution of (**1**) (1.0 g, 0.004 mol) in acetonitrile (7 cm^3), a solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (1.6 g, 0.004 mol) in the same solvent (7 cm^3) was added dropwise with constant stirring. The solution colour changed from yellow to a dark red. The reaction mixture was stirred at room temperature for 3 h and left to stand overnight. Evaporation of the solvent left a toffee like residue. This was dissolved in warm methanol from which red crystals were obtained. *Anal.* Calc. for $C_{28}H_{30}N_6Cl_{I2}NiO_8$ (**2**): C, 47.48; H, 4.23; N, 11.86. Found: C, 47.49; H, 4.07; N, 12.21%. Λ_M (Ω^{-1} cm^2 mol^{-1}) in CH_3CN and CH_3NO_2: 275 and 156. IR (Diamond ATR cm^{-1}): υ(N–H) 3342, 3293 (broad, m); 1646 υ(C=N); 1595, 1580 υ(C=C), υ(C=N)$_{py}$, δ(N–H), υ(ClO_4) 1070; UV–Vis (CH_3CN; λ_{max}):784, 531, 464 nm. μ_{eff} (BM): 3.34.

The red crystals were re-crystallized from a chloroform methanol mixture to give a second crop of red crystals of formula $C_{28}H_{30}N_6Cl_{I2}NiO_8 \cdot CHCl_3$ which were suitable for crystallography.

2.4.2. [Ni(L)(N$_3$)$_2$DMF] (**3**)

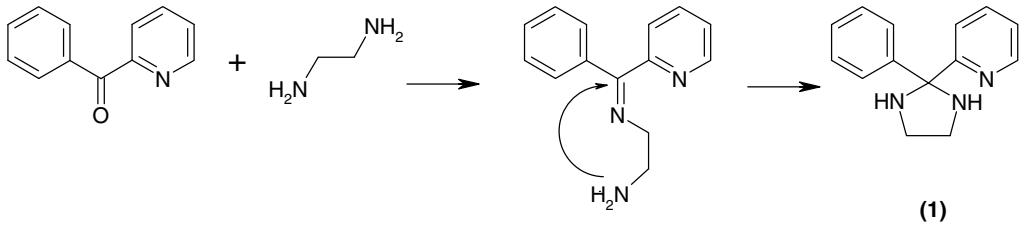
The ligand (**1**) (1.0 g, 0.004 mol) was dissolved in absolute ethanol (5 cm^3) and a solution of $Ni(ClO_4)_2 6H_2O$ (1.6 g, 0.004 mol) in ethanol (7 cm^3) was added drop-wise with constant stirring. The yellow colour of the solution changed to a dark red with the formation of a semi-solid mass. Rapid stirring for one hour led to the formation of a solid which was treated with a hot methanolic solution (15 cm^3) of NaN_3 (1.2 g, 0.016 mol). The reaction mixture was stirred for 4 h and a buff precipitate formed. This was left to stand for 24 h and then stirred for 2 h, filtered and the filtrate was dissolved in hot acetonitrile filtered concentrated and allowed to cool to room temperature yielding yellowish brown micro crystals. These crystals were dissolved in DMF and re-crystallized by vapour diffusion of diethyl ether from an adjacent container. This afforded dark brown crystals (melting point 195 °C) which were not suitable for crystallography. *Anal.* Calc. for $C_{17}H_{22}N_{10}ONi$: C, 46.28; H, 5.02; N, 31.75. Found: C, 45.35; H, 4.08; N, 33.91%. Λ_M (S cm^2 mol^{-1}) in DMF: 23.0. IR (cm^{-1}): υ(N–H) 3312, 3247, 3153; υ(N_3) 2020; υ(C=N) 1650; υ(C=C), υ(C=N)$_{py}$, δ(N–H), 1589, 1570. UV–Vis (DMF. λ_{max}): 690, 522, 463 nm. μ_{eff} (BM): 3.30.

2.4.3. [Cu(L)(CH$_3$CN)][ClO$_4$]$_2$ (**4**)

To a stirred solution of (**1**) (1.0 g, 0.004 mol) in absolute ethanol (6 cm^3), a solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (1.6 g, 0.004 mol) in acetonitrile (3 cm^3) was added dropwise with constant stirring. The colour changed from yellow to green and then to blue as the copper perchlorate solution was added. The reaction mixture was stirred for 5 h at room temperature and a blue precipitate formed. It was isolated by filtration, washed with a mixture of ethanol and acetonitrile and dried under vacuum. Crystals grown from acetone solution were of poor quality however crystallization from a mixture of acetonitrile and ethanol afforded a blue needles of suitable quality for X-ray crystallography. Melting point 200 °C. *Anal.* Calc. for $C_{16}H_{18}N_4O_8Cl_2Cu$: C, 36.34; H, 3.34; N, 10.59. Found: C,36.11; H, 3.19; N, 10.59%. Λ_M (S cm^2 mol^{-1} in CH_3CN) and CH_3NO_2: 270 and 133. IR (cm^{-1}): υ(N–H) 3300, 3255, 3158; υ(C=N) 1636; υ(C=C), υ(C=N)$_{py}$, δ(N–H) 1598, 1580; υ(ClO_4) 1053. UV–Vis (CH_3CN; λ_{max}): 606, 412 nm. μ_{eff} (BM): 1.75.

2.4.4. [CuL(N$_3$)][NO$_3$] (**5**)

An ethanolic solution (12 cm^3) of $Cu(NO_3)_2 6H_2O$ (2.2 g, 0.01 mol) was added dropwise to ethanolic solution (10 cm^3) of (**1**) (1.0 g, 0.0044 mol) with continuous stirring. The reaction mixture was stirred for one hour and the solution changed colour to a greenish-blue. To this NaN_3 (1.2 g, 0.02 mol) in hot methanol (15 cm^3) was added slowly with constant stirring. The colour changed immediately and a brown precipitate formed. The reaction mixture was stirred for 3 h. at room temperature, the precipitate was filtered, washed with few drops of ethanol and dried under vacuum. This precipitate was disgraded (as it proved to be a mixture). The green filtrate was concentrated using a rotary evaporator and kept at 4 °C in a fridge for several weeks. Unusual dark green spherical pseudo-crystals (unsuitable for crystallography) were isolated, washed with few drops of ethanol and dried under vacuum. Melting point 115 °C. *Anal.* Calc. for $C_{14}H_{15}N_7O_3Cu$: C, 42.8; H, 3.84; N, 24.96. Found: C, 42.32; H, 3.10; N, 25.09%. Λ_M (S cm^2 mol^{-1}) in CH_3CN and CH_3NO_2: 128 and 68. IR (cm^{-1}): υ(N–H) 3292, 3244, 151; υ(N_3) 2042; υ(C=N) 1660, 1636; υ(C=C), υ(C=N)$_{py}$, δ(N–H) 1594, υ(NO_3) 1411. UV–Vis (CH_3CN; λ_{max}): 614, 518 nm. μ_{eff} (BM): 1.74.



(1)

Scheme 1.

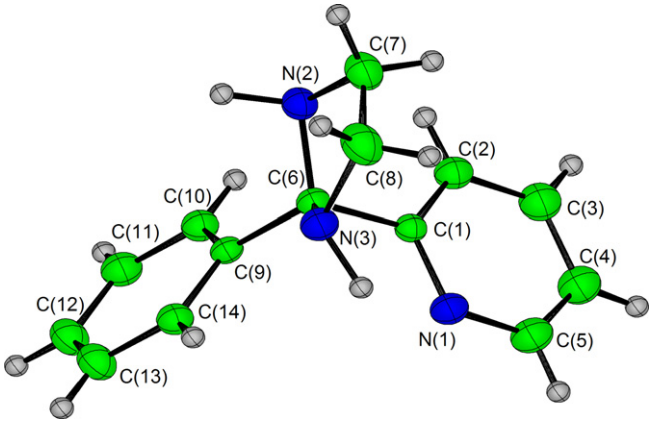


Fig. 1. ORTEX diagram of $C_{14}H_{15}N_3$, L (**1**) with 40% probability ellipsoids.

2.4.5. $[CuL(H_2O)][NO_3]_2$ (**6**)

The filtrate remaining after the filtration of (**5**) was left to stand at room temperature for several weeks and a precipitate formed. This was isolated by filtration, and washed with few drops of ethanol and crystallized from methanol solution and dark blue crystals were grown by slow vapour diffusion of diethyl ether from an adjacent container which were suitable for X-ray crystallography. Melting point 135 °C. *Anal.* Calc. for $C_{14}H_{17}N_5O_7Cu$ (**6**): C, 39.03; H, 3.97; N, 16.25. Found: C, 38.49; H, 4.01; N, 15.23%. Λ_M ($S\,cm^2\,mol^{-1}$) in CH_3CN and CH_3NO_2: 141 and 50. IR (cm^{-1}): υ(O–H) 3400–2327; υ(N–H) 3293, 3240,3135; υ(C=N) 1645; 1597, 1585; $\upsilon(NO_3)$ 1411. UV–Vis (CH_3CN; λ_{max}): 648, 516 nm. μ_{eff} (BM): 1.76.

2.4.6. $[CuL(N_3)][ClO_4]$ (**7**)

A blue methanolic solution (7 cm^3) of $Cu(ClO_4)_2 \cdot 6H_2O$ (1.6 g, 0.004 mol) was added dropwise to a methanolic solution (7 cm^3) of **L** (0.5 g, 0.002 mol) with continuous stirring. The mixture was stirred for 20 min and then NaN_3 (0.6 g, 0.01 mol) in aqueous methanol (10 cm^3, 1:1) was added slowly with a constant stirring. The blue colour of the reaction mixture changed to dark brown with the formation of green precipitate. This was filtered off washed with methanol and dried. It was re-crystallized from hot acetonitrile to give blue crystals which were suitable for crystallography. Its melting point is 175 °C. *Anal.* Calc. for $C_{14}H_{15}N_6O_4ClCu$ (**7**): C, 39.07; H, 3.51; N, 39.53. Found: C,39.27; H, 2.99; N, 19.45%. (Λ_M $S\,cm^2\,mol^{-1}$) in CH_3CN CH_3NO2: 153 and 104. IR (cm^{-1}): υ(N–H) 3317, 3264, 3148; υ(C=N) 1649; 1598, 1585; $\upsilon(ClO_4)$ 1096. UV–Vis (CH_3CN; λ_{max}): 611, 513 nm. μ_{eff} (BM): 1.80.

2.4.7. $[Cu_2(L)_2(Pyz)][ClO_4]_4\ CH_3CN \cdot (H_2O)_{0.5}$ (**8**)

To a solution of (**1**) (1.0 g, 0.004 mol) in C_2H_5OH (10 cm^3) was added solution of $Cu(ClO_4)_26H_2O$ (3.3 g, 0.004 mol) in water (5 cm^3). The solution colour changed from yellow to blue and the reaction mixture was then stirred for 30 min. at room temperature. To this pyrazine (1.4 g, 0.02 mol) in water (5 cm^3) was added slowly with constant stirring. After stirring at room temperature for 5 h the solution was allowed to stand and a precipitate was filtered, washed with ethanol and dried under vacuum over P_2O_5. It was crystallized from a mixture of CH_3CN and CH_3OH (1:3) by slow vapour diffusion of diethyl ether from an adjacent container giving dark violet crystals which were not suitable for X-ray crystallography. Melting point 140 °C. *Anal.* Calc. for $C_{34}H_{38}N_9O_{16.5}Cl_4Cu_2$ (**8**): C, 36.93; H, 3.46; N, 11.49. Found (>250 °C): C, 37.12; H, 3.36, N, 10.54%. Λ_M ($S\,cm^2\,mol^{-1}$) in CH_3CN: 507. IR (cm^{-1}): υ(O–H) 3567, 3407; υ(N–H) 3316, 3260, 3140; υ(C=N) 1649; υ(C=C), $\upsilon(C{=}N)_{py}$

2.5. Crystallography

Reflection data were collected either on a Marresearch image plate system or on a Nonius kappa CCD system. Data reduction were carried out using the XDS and DENZO/SCALEPACK packages. respectively [8] The structures was solved by direct methods, SHELXS-97, and refined by full matrix least squares using SHELXL-97 [9,10]. SHELX operations were automated using ORTEX which was also used to obtain the drawings [11]. Hydrogen atoms were included in calculated positions with thermal parameters 30% larger than the atom to which they were attached. The non-hydrogen atoms were refined anisotropically. All calculations were performed on a Pentium PC.

2.6. Calculations

DFT calculations were carried out using PC-GAMESS [12] which was driven by the molecular modeling software within the OSCAIL package [13].

3. Results and discussion

3.1. Structure of the ligand

The condensation of 2-benzoyl pyridine and 1,2-diaminoethane has been reported and the structure of the product assigned as 2-

phenyl-2-(2-pyridyl)imidazolidine, (**1**), using ^{1}H and ^{13}C NMR. It is reasonable to suggest that the reaction proceeds *via* initial formation of the imine and subsequent cyclization as shown in Scheme 1.

Since this is an example of an unfavorable 5-*Endo-Trig* cyclization [4], the crystal structure was determined to confirm the NMR assignment. The X-ray structure of (**1**) is shown in Fig. 1.

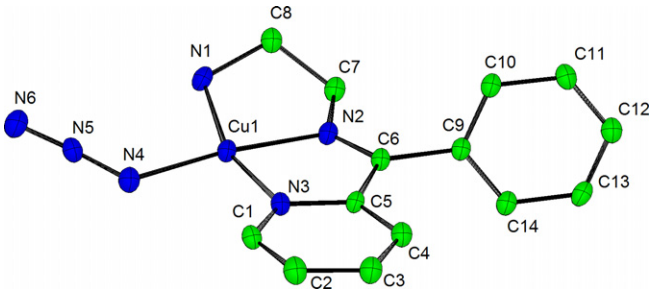

Fig. 6. ORTEX diagram of the cation of $[Cu(L)N_3][ClO_4]$ (**7**), with 40% probability ellipsoids and hydrogen atoms omitted for clarity.

Crystal data are given in Table 1 and selected bond lengths and angles are given in Table 2.

DFT calculations on (**1**) using B3LYP functionals at the 6-31G* level suggest that in the gas phase the cyclic structure is more stable than the open imine form by 13.1 kJ mol^{-1}. Thus the unfavourable 5-*Endo-Trig* cyclization may in part be possible in this case due to the higher stability of the cyclic form. If solvent effects are ignored, and if equilibrium was possible, this energy difference translates to an equilibrium concentration of the cyclic form that is approximately 5×10^3 times greater than the imine form. There is spectroscopic and kinetic evidence that the imine form may have appreciably higher concentrations in polar solvents [14]. There are many well established examples of 5-*Endo-Trig* cyclizations in the literature [15,16].

3.2. Ring opening complexation

When (**1**) was reacted with Cu(II) and Ni(II) salts no complexes containing the cyclic structure were observed. In every case where crystal structures were obtained only the open form was observed in the complexes. This reaction is probably an example of a cationic

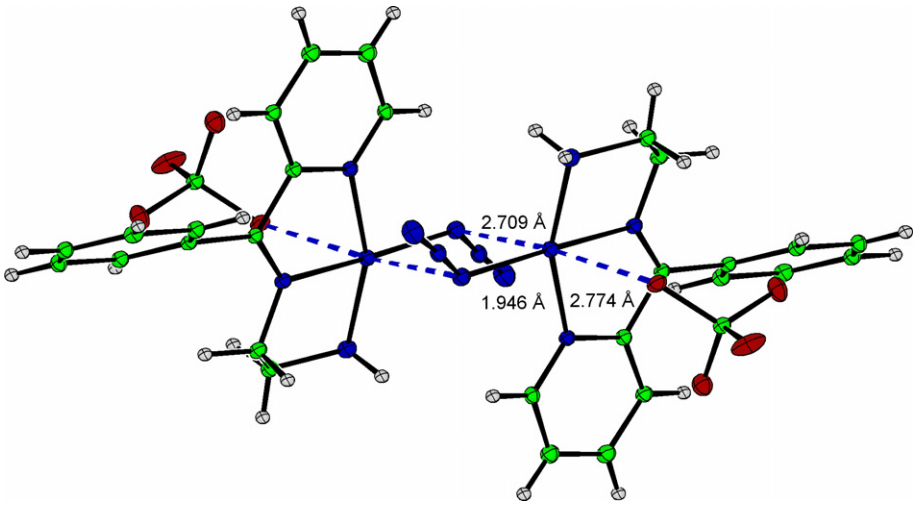

Fig. 7. ORTEX diagram of showing the weak interactions in the crystal structure of (**7**).

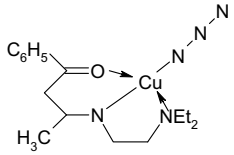

Fig. 8. Structure of (**8**).

metal induced ring opening reaction. A possible mechanism is illustrated in Fig. 2.

This mechanism is related to that proposed for the Fe(III) catalysed opening of an imidazolidine ring in the presence of alcohols [17].

3.3. Reaction of (*1*) with nickel perchlorate (*2*)

Reaction of (**1**) with nickel perchlorate led to the isolation of a red solid. It was characterized by elemental analysis, IR and ^{1}H and ^{13}C NMR. Crystals grown from a chloroform/methanol mixture were suitable for X-ray crystallography. The structure of a cation from the crystal structure of (**2**) is shown in Fig. 3. Crystal data are given in Table 1 and selected bond lengths and angles are given in Table 3. There are two almost identical formula units in the crystallographic asymmetric unit. Each of the ligands in the cation is tridentate with and the overall geometry is close to octahedral. Thus within each asymmetric unit there are four examples of nickel ligand binding moeties. The nickel–nitrogen distances in all cases are in order of increasing length; imine, pyridine and primary amine. For example in Fig. 3 the Ni(1)–N(2), Ni(1)–N(3) and Ni(1)–N(1) are 1.996(5), 2.103(5) and 2.121(5) Å.

To see if this order of bond lengths was due to crystal packing or a genuine property of the complex the structure of the cation was optimized using DFT calculations using B3LYP functionals at the 6-31G* level [12]. The results while giving slightly longer distances nevertheless gave the same order of bond lengths; N-i-N(2) 2.040, Ni–N(3) 2.115 and Ni–(N1) 2.183 Å. The bonding to nickel on the part of the unsaturated nitrogens is clearly stronger than that of the primary nitrogen. It is possible that a small amount of strain in the chelate rings is the cause of the shortest Ni–N bond being to the middle nitrogen. The observed magnetic moment of 3.34 μB is higher that the spin-only value for two unpaired electrons of 2.83 μB however it is within the observed range for octahedral nickel(II) complexes [18,19].

3.4. Reaction of (*2*) with sodium azide

When complex (**2**) was reacted with sodium azide a product of formula $[Ni(L)(N_3)_2(DMF)]$ (**3**) was isolated. Single crystals suitable for X-ray crystallography could not be obtained. This formula is assigned on the basis of elemental analysis, spectroscopic, magnetic and conductivity data. In the IR spectrum bands due to azide, DMF and the Schiff base were all observed. The observed conductivity is an order of magnitude lower than that observed for (**2**) in agreement with its covalent formulation.

3.5. Reaction of (*1*) with copper nitrate and acetonitrile in methanol

Treatment of a solution of (**1**) in methanol with copper perchlorate gave a blue solution from which after addition of acetonitrile blue crystals of formula $[CuL(CH_3CN)][ClO_4]_2$ (**4**) were obtained. The structure of a cation from (**4**) and its contacts to one of the perchlorate anions is shown in Fig. 4, crystal data are in Table 1 and selected bond distances and angles are given in Table 4. The geometry about copper is tetragonally distorted octahedral with metal nitrogen distances within the square plane close to 2.0 Å and longer contacts to the oxygen atoms of symmetry related perchlorate anions of 2.391(2) and 2.526(2) Å, respectively. The metal nitrogen bond lengths within the salicylaldimine ligand show the same order observed in the nickel complex (**2**) above.

3.6. Reaction of (*1*) with copper nitrate and sodium azide in ethanol

An ethanolic solution of copper nitrate was reacted with (**1**) and sodium azide. On standing for some time tiny green spheres grew from solution. These spheres did not diffract X-rays and they had the properties of a glass. The formula $[CuLN_3][NO_3]$ (**5**) was assigned to this solid on the basis of analytical and spectroscopic data. Attempts to grow crystals from the filtrate of this reaction led to the isolation of crystals of $[Cu(L)(H_2O)][(NO_3)_2]$ (**6**), in which water had replaced the azide anion. The structure of the cation from (**6**) is shown in Fig. 5, crystal data are given in Table 1 and selected bond lengths and angles are given in Table 5. The geometry about the copper is tetragonally distorted octahedral with longer contacts to nitrate oxygens. The coordinated water molecule is involved in strong hydrogen bond contacts to nitrate ions, O···O distances of 2.739(7) and 2.763(7) Å to O6 and O3, respectively, and there are contacts from nitrate O7 to N1 of 3.078(7) Å which extend the hydrogen bond network throughout the lattice.

When weak interactions are included the stereochemistry of the copper(II) ion is often difficult to describe due to the distortions resulting from the Jahn–Teller effect. In an extensive review of this area using structure correlation analysis Murphy and Hathaway have analysed the range of observed structures and the crystal structure of (**5**) lies well within that range [20]. Attempts were made to model the strongly bonded square planar portion of the structure using the DFT calculation methods that had been successfully applied to the nickel complex above. In the crystal structure of (**6**) the copper and the three nitrogen atoms are essentially planar, with a maximum deviation from least squares plane of 0.02 Å. The oxygen atom is just 0.10 Å above this plane. In the DFT optimised structure the maximum deviation from the plane defined by the copper and the three nitrogens is 0.18 Å and the oxygen is 1.12 Å out of that plane. Attempts to model the complete $[Cu(L)(H_2O)][(NO_3)_2]$ unit were even less successful. The B3LYP functional appears to be able to model Cu(II) when the relative geometry of the ligating atoms is restrained to some extent [5,6]. A recent review of DFT functionals has suggested that B3LYP has some serious shortcomings and perhaps more advanced functionals are required for the Cu(II) complexes described here [21].

3.7. Reaction of (*1*) with copper perchlorate and sodium azide in methanol

When the reaction above was repeated using copper perchlorate in methanol solution it was possible to isolate good quality crystals of the copper azide $[Cu(L)N_3][ClO_4]$ (**7**). Crystal data are given in Table 1 and selected bond lengths and angles are in Table 6. The crystal structure of the cation from this salt without the weaker interactions which complete the tetragonally distorted octahedral geometry is shown in Fig. 6.

The geometry about the copper is close to square-planar with N2 showing the greatest deviation from the best plane through the four nitrogens of 0.15 Å and the copper is 0.04 Å out of the plane. The tetragonally distorted octahedral geometry about copper is achieved by the addition of two weak interactions involving highly asymmetric bridging on the part of the azide ligands, 1.946(3) and 2.709(3) and a weak interaction involving a perchlorate anion, 2.774(3) Å (Fig. 7).

There are many reported structures of azide complexes in which the azide ligand is seen to span the range from mono-dentate through semi-bridging to symmetrical bridging. Structure (**7**) is close to mono-dentate. The energy difference between mono-dentate and bridging structures is however small and less than typical lattice energies. This point is clearly evident in the recently reported structure of complex (**8**), depicted in Fig. 8, which Sarker et al. have described [22,23]. In the reported crystal structure both symmetrically bridged μ-azido and mono-dentate square-planar geometries are present in the same asymmetric unit.

4. Conclusion

2-Phenyl-2-(2-pyridyl)imidazolidine reacts with Ni(II) and Cu(II) salts to give stable complexes containing the tridentate open form of the ligand. Combined structural and theoretical calculations show that DFT calculations using the B3LYP functionals at the 6-31G* level reproduce the geometry of the Ni(II) complexes but are less successful in modelling the Cu(II) complexes.

Appendix A. Supplementary data

CCDC 677183, 677184, 677185, 677186 and 677187 contain the supplementary crystallographic data for **1**, **2**, **4**, **6** and **7**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.04.028.

Glutamic acid
Deamination

ABSTRACT

A deamination process was observed after copper(II) complexation reaction with guanidinoacetic (Gaa) and glutamic acids (Glu), forming the binuclear copper(II) complex $K_2Cu_2C_{16}H_{23}N_7O_{12} \cdot 1/2H_2O$ (**1**), which was characterized by elemental analysis (CHN), spectroscopy methods (IR and EPR), powder X-ray diffraction, thermogravimetric analysis (TGA), and mass spectrometry. A new ligand, namely biguanide-1,5-diethanoate (Bge) ($C_6H_9N_5O_4$), was formed during complexation, probably due to the reaction between two Gaa species and the consequent release of a significant amount of ammonia, thus, characterizing the deamination process. In complex **1**, Bge behaved as a tetradentated ligand, using its oxygen and nitrogen atoms as coordinating sites to both Cu(II) ions. In addition, Glu has coordinated to Cu(II) through its α-N and O atoms. Theoretical calculations of the *cis–cis*, *cis–trans*, and *trans–trans* isomers of **1**, considering three prototropic forms of the Bge ligand, were carried out using semi-empirical quantum mechanics (PM3/*d*). DFT (B3LYP and B3P86) calculations of complex **1**, in which a hydrogen atom replaced the side chain of Glu, were also carried out using the 6-31G(d) basis set and the LanL2DZ effective core potential for the transition metal. Based on experimental and theoretical data, we concluded that the *trans–trans* isomer of the binuclear copper(II) complex **1** should be the most stable, although the occurrence of other isomers, even if in minor quantities, should not be disregarded.

1. Introduction

Deamination and deimination reactions play important biological roles due to the anti-cancer and anti-viral potential use of the enzymes that catalyze them. One example is the transcription-coupled mutagenesis that is induced by the activation-induced deaminase (AID), which deaminates C and U in DNA [1,2]. Another example is arginine deiminase (ADI), which is mainly found in prokaryotes, and which catalyzes the deimination of the guanidino group of L-arginine producing ammonia [1,2]. ADI has also been found in a primitive eukaryote, *Giardia intestinalis*, which is one of the most commonly transmitted intestinal pathogens [1,2]. ADI has been considered a potential anti-cancer agent due to its cell proliferation inhibitory activity, and its *in vivo* anti-tumor activity has been reported [3,4]. Another example is peptidylarginine-deiminase (PAD), which has been described primarily in mammalians, and is responsible for the guanidino group deimination of the carboxy-terminal arginine residues of various peptides to produce ammonia [5,6]. It is interesting to note that mammalian PAD's are metalloenzymes [7].

Due to fact that there are several examples of deamination reactions involving the guanidino group of arginine, we began to investigate these processes with the guanidino group of guanidinoacetic acid (Gaa) (Fig. 1). Although Gaa is a non-essential amino acid, it is the immediate precursor of creatine, formed, mainly in the kidneys, by the reaction between arginine and glycine [8]. The biological functions in which Gaa takes part in or is involved in are of great diversity. Besides being considered as an endogenous convulsant [9,10], it has already been used as a more sensitive marker for renal dysfunction [11]. Gaa is also involved in insulin regulation [11], cholesterol production [12] and hepatic encephalopathy [13]. The increase of Gaa concentration in the brain is responsible for epileptic seizures [14]. Recently, Gaa quantification in plasma and urine has turned out to be very important, since it can be used as a diagnosis tool for the guanidinomethlytransferase deficiency

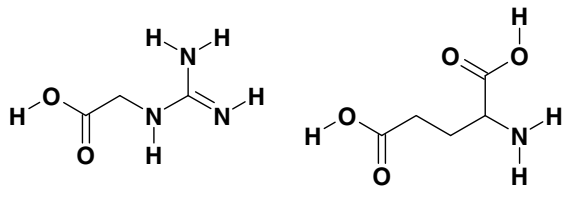

Fig. 1. Chemical structures of the neutral forms of guanidinoacetic acid (Gaa) and glutamic acid (Glu).

[15–19]. In addition, it has been observed that after cisplatin administration on the urinary tract of neoplasic patients, Gaa concentration decreased significantly [20].

Besides Gaa (Fig. 1), another amino acid, glutamic acid (Glu) (Fig. 1), is also present in the system that we are investigating. Glu was chosen because we were interested on the influence of the possible guanidino-carboxylate interactions in the deamination reactions. These guanidino-interactions are known to be highly specific due to the double hydrogen bonds formation pattern [21], and they are present in some important recognition sites, e.g. in Cu, Zn-superoxide dismutase [22], in carboxypeptidase [23], and between the human immunodeficiency virus and the host cell wall receptor [25].

Since several biological deamination reactions are metal dependent, we have chosen copper(II) ion not only due to its important role in a number of enzymatic reactions in the organism [26], specially those involving the guanidino group [22,23], but also to its well known template function in coordination reactions. Moreover, previous work has already been done in aqueous solution with Gaa, Glu and Cu(II), in the study of guanidino-carboxylate interactions in copper(II) ternary complexes with both of these amino acids [22]. The predominant complex species in specific pH ranges are already known, and so is the mechanism of competition between Gaa and Glu.

Several Gaa complexes have already been synthesized with different metal ions, such as Cr(III), Co(II), Ni(II), Cu(II) and Zn(II) [27]. In one of the copper complexes – $Cu_2(GAA)_4(NO_3)_2$ (tetrakis(μ-guanidinoacetic acid-κ2O:O′)bis[(nitrate-κO)copper(II)]), Gaa coordinates only through the two oxygen atoms of the carboxylate groups in a bridged way [28]. However, in another copper(II) complex, synthesized in different conditions, a new derivative of Gaa was formed, the Oag ligand, N^1-carboxylate-methylguanidinooxidoacetate, which formed the complex $[Cu_2(Oag)(Gaa)H_2O]NO_3 \cdot 2H_2O$ [29]. A mechanism of formation of Oag, based on EPR and potentiometric analyses, has been proposed [30].

In this work, we focused our attention in the synthesis and structural elucidation of **1** ($K_2Cu_2C_{16}H_{23}N_7O_{12} \cdot 1/2H_2O$), a binuclear copper(II) complex formed from Gaa, Glu, and Cu(II). The complexation reaction was accomplished with a deamination process, producing a new ligand, biguanide-1,5-diethanoate (Bge) ($C_6H_9N_5O_4$). The synthesized Cu(II) complex **1** , $K_2Cu_2(Bge)(Glu)_2 \cdot 1/2H_2O$, was characterized by elemental analysis (CHN), spectroscopy methods (IR and EPR), powder X-ray diffraction, thermogravimetric analysis (TGA), and mass spectrometry. In addition, the possible geometric isomers and prototropic forms of **1** have been investigated by theoretical methods. The new ligand Bge has been also isolated and analyzed by ^{1}H NMR and ^{13}C NMR.

2. Experimental

2.1. Materials and methods

All reagents were of pure grade and were used without further purification.

2.2. Synthesis of $K_2Cu_2(Bge)(Glu)_2 \cdot 1/2H_2O$ (**1**)

An aqueous solution of glutamic acid (1 mmol/L, 0.14714 g, Aldrich) was added to an aqueous solution of Gaa (1 mmol/L, 0.11712 g, Aldrich). $Cu(NO_3)_2 \cdot 3H_2O$ (0.2446 g, Merck) was slowly added to the resultant mixture, under permanent stirring at 60 °C, and the solution was refluxed at 60 °C for 2 h. After that, an aqueous solution of KOH (0.3 mol/L, Merck) was slowly added until the solution reached pH 6–7, the range value observed in previous potentiometric studies [22], in which the ternary complex among Cu(II), Gaa and Glu was predominant. After that, the mixture was refluxed at 60 °C for 24 h, and by reduction of the solvent volume, a blue precipitate was formed. The blue precipitate was thoroughly washed with water and acetone. The yield was 40% and its melting point was 219–220 °C. Elemental analysis (CHN) was conducted according to standard micro analytical procedures (CHN Perkin–Elmer Analyzer). *Anal.* Calc. for $K_2Cu_2C_{16}H_{23}N_7O_{12}.1/2H_2O$: C, 26.15%; H, 3.36%; N, 13.35%. Found: C, 25.92%; H, 3.17%; N, 13.64% (M.M. = 719 Da).

2.3. Spectroscopy methods

Infrared (IR) spectroscopy analyses were performed in a Nicolet 760-FT-IR spectrometer, using KBr pellets in the 4000–500 cm^{-1} range and polyethylene nujol films in the 600–100 cm^{-1} range, with gain 2, strong apodization, aperture 30, resolution 4.0 and number of scan superior to 100.

Electron paramagnetic resonance (EPR) spectra were recorded at room temperature and at 77 K on a Bruker ESP 380 FT-CW spectrometer, operating in X-band (9.5 GHz) and 100 kHz field modulation, using quartz tubes and a cylindrical resonant cavity. The modulation amplitude was 5.0 Gauss and microwave power was 2.21×10^2 mW. Measurements of *g*-factors were done against DPPH standard (g = 2.0037).

2.4. Powder X-ray diffraction

Powder X-ray diffraction data were obtained with an X-ray diffractometer using Cu Kα radiation. Samples were spread out on glass and scanned at 20 min^{-1}. The beam voltage and beam current were 35 kV and 14 mA, respectively.

2.5. Thermogravimetric analysis

Thermogravimetric analysis (TGA) was done in a Perkin–Elmer TGA 7 thermogravimetric balance in nitrogen atmosphere, in a 25–900 °C temperature range and a step range of 5–10 °C.

2.6. Mass spectrometric analysis

The mass spectrometric analysis was done in a $_{252}$Cf PDMS (Plasma Desorption Mass Spectrum) mass spectrometer. A suspension of complex **1** in ethanol has been prepared for this analysis.

2.7. Isolation and NMR analysis of the new ligand Bge from the complex $K_2Cu_2(Bge)(Glu)_2 \cdot 1/2H_2O$ (**1**)

The ligand Bge has been isolated from complex **1** in order to be analyzed separately. First, a 1:1 nitric acid:water solution was added to 0.478 g of complex **1** until total solubilization. Three mL of water were added to the resultant solution which pH was 1. This latter solution has been eluted in a 20 cm × 1.2 cm height × diameter column packed with a cationic Rhome and Haas resin. The time of the elution was 30 min.

The resultant light brown solution has been analyzed by ^{1}H NMR and ^{13}CNMR. The ^{1}H and ^{13}C NMR experiments were carried

out on a Bruker DRX-400 (9.4T) spectrometer operating at Larmor frequencies of 400.13 and 100.61 MHz, respectively, using a 5.0 mm probe head in D_2O/H_2O solution. The ^1H NMR spectrum was recorded with water suppression using 3-9-19 pulse sequence with gradients [31–33]. The ^{13}C NMR spectra were recorded using a single pulse acquisition with small pulse angle ($\pi/2$) and a recycle delay of 0.3 s. The ^{13}C and ^1H NMR spectra were referenced relatively to TSS.

2.8. Theoretical methods

Graphical manipulations and semi-empirical quantum mechanics calculations were carried out using the Spartan'04 Windows (version 1.0.1) molecular modeling package (Wave function, Inc., Irvine, CA) [34]. Geometry optimizations and heats of formation were calculated using the Parametric Method 3 (PM3) Hamiltonian that is parameterized for copper atom among others transition-metal elements. All calculations were performed in vacuum without any kind of geometric restrictions.

We have performed energy minimizations on the three possible geometric isomers of complex **1**, namely, *cis–cis* (*cc*), *cis–trans* (*ct*), and *trans–trans* (*tt*) (Fig. 2A). In addition, it was also considered the tautomerism involving the biguanide group of the Bge ligand of **1**, since we cannot establish a definitive position of the hydrogen atom. Therefore, we have investigated the stability of the three possible prototropic forms of **1**, namely tautomers A, B, and C (see Fig. 2B), for each isomer. Fig. 2B shows the three prototropic forms (A, B, and C) of the *cis–cis* isomer. Moreover, each prototropic form B could also have two spatial isomers, since one nitrogen atom is a tetrahedral stereocenter, which means that the absolute configuration of this atom could be *R* or *S*.

Regarding the overall charge of complex **1**, we have calculated three species, namely the dianionic form ($Cu_2C_{16}H_{23}N_7O_{12}$, total charge = −2), and two neutral forms, in which in the former the negative charge of each carboxylate group was neutralized with a proton ($Cu_2C_{16}H_{25}N_7O_{12}$, total charge = 0) and in the latter, with a sodium cation ($Na_2Cu_2C_{16}H_{23}N_7O_{12}$, total charge = 0), since potassium is not parameterized in the PM3 method.

In addition, we have performed DFT calculations for complex **1**, replacing the side chain of Glu by a hydrogen atom in order to reduce computer time. We have carried out the DFT calculations using B3LYP and B3P86 functionals [35]. The 6-31G(d) basis set was applied for all atoms except for the copper atom, for which was chosen the LanL2DZ effective core potential [36]. All geometries were fully optimized using the GAUSSIAN 98 program [37].

3. Results and discussion

3.1. IR spectroscopic analysis

The relevant infrared data are presented in Table 1. The two bands at 3545 and 3438 cm^{-1} are due to the stretching modes of O–H of lattice water. The H_2O bending mode was observed at 1630 cm^{-1}. The rocking and wagging bands of water occurred in 708 and 572 cm^{-1}. The shift observed for water bands are due to extensive hydrogen bonding [38].

In addition, several other bands, related to stretching N–H modes of amines were observed in the same range. The spectrum shows a greater number of νN–H bands in **1** as compared to the original amino acids, Glu and Gaa. The bands at 3390 and 3309 cm^{-1}, as well as at 3335 and 3289 cm^{-1} can be attributed to the two pairs of asymmetric and symmetric stretching of N–H of primary amines [39,40]. Since the first pair of bands is shifted in relation to the correspondent Gaa ones (at 3384 and 3303 cm^{-1}) [27], they should be attributed to the biguanide-1,5-diethanoate (Bge) ligand. Another band at 3134 cm^{-1} can be also related to the primary νN–H, although, in this case, it is closer to the correspondent Glu band, which occurs at 3132 cm^{-1} [41]. The significant increase in the number of primary N–H stretching modes is in agreement with the proposed structure, considering that all of these bands except the last one (which is related to the Glu fragment) could be related to the primary amines in the intermediary chain formed by the new ligand, Bge. The bands at 3237 and 3250 cm^{-1} were neither present in the Gaa nor in the Glu spectra, and could be attributed to the νN–H of the secondary amine, present in the Bge spectrum.

The band at 1668 cm^{-1} is characteristic of the νC=N from the guanidino group [27], and indicates that this group is still present and is not directly involved in the coordination to Cu(II). This is in agreement with the Bge structure that includes a guanidino group in its central moiety. The non-participation of the terminal

[a] Ref. [27].
[b] Ref. [39].

nitrogen atoms of the guanidino group in the coordination was also observed in other copper(II) complexes of Gaa previously synthesized by our group [27,28].

The IR spectrum shows that the carboxylate asymmetric (1609, 1583 cm^{-1}) and symmetric stretching (1405, 1385 cm^{-1}) modes, both related to coordinated carboxylate groups, are shifted due to the metal coordination. On the other hand, the bands at 1560 and 1394 cm^{-1} should be related to the terminal ionic carboxylate groups since the difference between them ($\Delta\nu$ = 166 cm^{-1}) is similar to the one observed for the ionic acetate group [38]. The amino group deformation bands that are observed at 1624 cm^{-1} probably couple with the carboxylate stretching modes.

Therefore, the fact that significant shifts are observed in the normal amino and carboxylate group frequencies prompted us to assume that the nitrogen and oxygen atoms from these groups should be involved in coordination. Consequently, there are two possible geometric isomers for each copper coordination center, i.e., *cis* and *trans*, whereas for the whole complex involving two copper sites, there are three possibilities, the *cis–cis*, the *cis–trans*, and the *trans–trans* isomers. Since in the 500–100 cm^{-1} range the bands relative to two νCu–N and two νCu–O vibrations were observed at 444, 412, 352 and 336 cm^{-1} respectively, a C_2 symmetry could be proposed for the complex **1**. Considering the whole complex, the only isomer that presents geometry closer to a C_2 symmetry is the *trans–trans*, even though we cannot disregard the presence of the other isomers. In addition, some skeletal modes of Glu were observed in 419 and 400 cm^{-1}, but the characteristic skeletal modes of Gaa (436 and 319 cm^{-1}) were absent. This can be easily understood since the Glu chain was not changed in the complex **1**, while Gaa suffered severe modifications.

3.2. EPR spectroscopic analysis

The electron paramagnetic resonance spectrum of complex **1** indicated the presence of a square-planar copper(II) environment. Comparisons were done between EPR data from the complex **1** and the paddlewheel complex $Cu_2(Gaa)_4(NO_3)_2$ [28]. The solid powdered compounds were analyzed by EPR, but their spectra consist of unresolved broad lines, characteristic of large line widths with respect to the value of the hyperfine coupling constant *A*. The estimated isotropic $\langle g \rangle$ values of the mentioned complexes were the same and equal to 2.13, which corroborates the square-planar geometry for each site, typical of Cu(II) coordination to amino acids such as aspartic acid [42,43].

3.3. Powder X-ray analysis

The powder X-ray diffractogram of **1** as well as of $Cu(Glu)_2$ [44] are shown in Fig. 3. They are similar, with the exception of one special peak. This can be explained by the similarity of the coordination sites of both complexes (α-N and O atoms). However, the bridged ligand Bge can somehow affect the packing of the layers and account for this difference.

3.4. Thermogravimetric analysis

Complex **1** presents a-two-step weight loss process and it is stable up to 219 °C. From 30 to 120 °C, only the crystallization water was lost (1%). The first and most important step of mass loss (Fig. 4a) was between 219 and 260 °C that corresponds to the decarboxylation of the compound relative to the loss of five carboxylate groups (29%). The second step of weight loss (Fig. 4b), from 260 to 600 °C corresponds to the degradation of the decarboxylated fragment of **1**, forming a residue that may be relative to K_2O + 2 CuO.

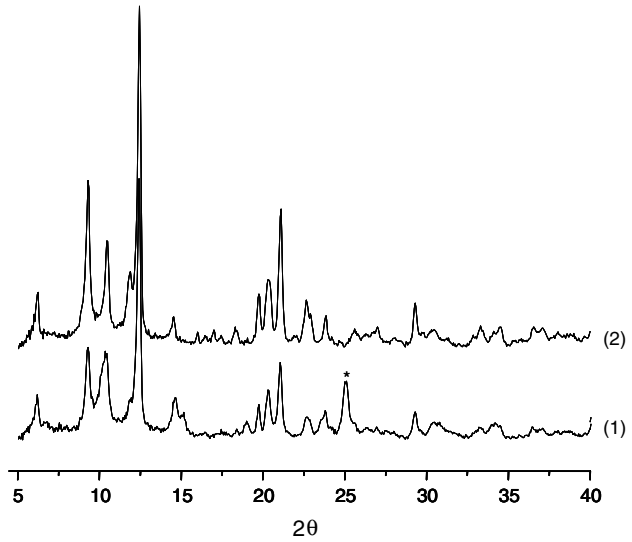

Fig. 3. Powder X-ray diffractograms of complexes $Cu_2Bge(Glu)_2$ (**1**) and $Cu(Glu)_2$ (**2**) (Kα Co and $5° \leqslant 2\theta \geqslant 40°$). The asterisk is related to Bge structural modification in the whole complex.

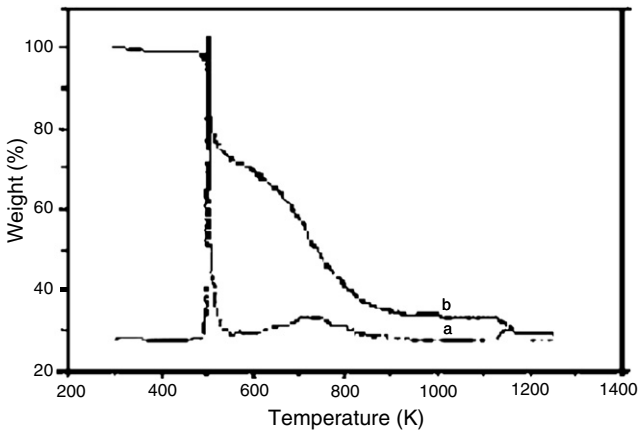

Fig. 4. Thermogravimetric analysis of complex $K_2[Cu_2(Bge)(Glu)_2]$.

3.5. Mass spectrometry analysis

The positive mass spectrum of **1** (Fig. 5) presents the fragmentation pattern analogous to other copper complexes with amino acids, such as Gly, Tyr, Glu and Arg [45]. The single and intense peak at 220 is related to H_3L (L = Bge), while the peak at 289 may be related to H_7LCu, with all the amino, imino and carboxylate groups protonated with the exception of one carboxylate group involved in the copper coordination. The peaks with higher mass are related to species involving both L (Bge) and Glu. The peak at 499 is attributed to Cu_2H_5LGlu, the one at 497 to $Cu_2H_3LH_2Glu$ and the one at 554 to $Cu_2H_3LH_2Glu_2$ with loss of the two most external carboxylate groups.

3.6. Analysis of the eluted solution from the isolated ligand Bge

The ^1H NMR spectrum of the eluted solution of complex **1**, $K_2Cu_2(Bge)(Glu)_2 \cdot 1/2H_2O$, is shown in Fig. 6. Although Cu(II) ion has been removed from the elution, in addition to Bge ligand, glutamic acid is also present in this solution. We did not attempt to remove it by derivatization due to possible interference in Bge characterization.

Table 2 shows the assignments of the chemical shifts in ppm related to Bge and Glu from the eluted solution, and also to Gaa from the literature [46]. Since the experiments were recorded in H_2O/D_2O, the exchange of the NH protons occurred as it is already expected. Ethanol hydrogen peaks are also present as a triplet at 1.16 ppm and a quartet at 3.64 ppm. Five peaks should be related to Glu: a triplet at 4.18 ppm for Hα, a multiplet at 2.26 ppm for Hβ, a triplet at 2.67 for Hγ and a broad peak at 8.22 ppm for the amino-H. Those assignments are in good agreement with the literature data considering the difference in pH value [47].

Bge presents three peaks (Table 2). The doublet at 4.13 ppm should be related to Ha from Bge (at pH 1) since the analogous hydrogen atom in Gaa, which is Ha, is at 3.73 ppm (at pH 3). The peak at 7.37 ppm (1H) should be relative to Hb, which corresponds to Hb signal (6.65 ppm) in Gaa structure. The peak at 8.22 ppm is very broad and should be attributed to both Hc and Hd from Bge and the amino group from Glu, which is in agreement with the calculated integration value of eight protons. The correspondent Hc in Gaa is at 7.12 ppm. Comparing the structures of Bge and Gaa, it can be easily observed that the hydrogen atoms are more deshielded in Bge, due to the presence of two carboxylic groups in addition to the resonance π bonds.

^{13}C NMR spectrum is shown in Fig. 7. In Table 3 the ^{13}C chemical shifts from Bge and Glu are shown. Analogous to ^1H NMR, in addition to the chemical shifts relative to carbon atoms from Bge, there are also other ones due to carbon atoms from Glu. Ethanol peaks are also present as a triplet at 57.79 ppm and a quartet at 18.13 ppm. As Glu is present in the eluted solution at pH 1, we can attribute the peaks comparing with its data at pH 3.34 in the literature, which was the closest pH value available [47]. Therefore, the peaks at 175.98 and 171.07 ppm should be related to C1 and C5, respectively (177.83 and 174.45 ppm [47]) , at 52.15 ppm to C2, 29.27 to C3 and 24.58 ppm to C4 (54.78, 30.94 and 26.39 ppm lit.).

Bge should present three peaks in the ^{13}C NMR spectrum (Fig. 7) due to its symmetric structure, which results in three equivalent carbon atoms. Actually, there are three peaks in its ^{13}C NMR spectrum (Table 3). The carboxylic carbon atoms C1 in Bge should be equivalent and assigned as 171.88 ppm, which is characteristic to carboxylic chemical shift. The peaks at 157.06 and at 42.56 ppm should be relative to C3 and C2, according to their positions.

3.7. Proposal of a mechanistic scheme for the new ligand formation (Bge)

Since a new ligand, i.e. biguanide-1,5-diethanoate (Bge), has been formed during the complexation reaction, probably due to the reaction between the guanidino groups of two Gaa moieties, we now propose a mechanism for its formation. This proposal is in line with the already proposed mechanism for transamidination on the copper(II) Gaa complex [30], and takes into account the quantification of ammonia in the final solution obtained during synthesis of **1** that characterizes the deamination process. We have found a significant amount of ammonia, which, however, could not be related to the total ammonia content due to possible losses during the synthetic process.

Fig. 8 shows the proposed mechanistic scheme for the new ligand formation (Bge) in the $K_2[Cu_2(Bge)(Glu)_2]$ complex, where R (Fig. 8) replaces the lateral chain of Glu (i.e. R = $CH_2CH_2CO_2^-$) for the sake of simplicity. Moreover, the copper ion was already considered complexed with Gaa and Glu, i.e. forming the Glu–Cu(II)–Gaa complex, and probably it may play a template effect in the catalytic process, because the direct reaction between the two amino acids (i.e. Gaa and Glu) without the metal participation does not take place. In the proposed mechanism, the first step describes a nucleophilic attack of a guanidino group of the first Glu–Cu(II)–Gaa specie on another guanidino group of the second Glu–Cu(II)–Gaa specie. The second step is an internal proton transfer (p.t.) probably mediated by a solvent water molecule involving two steps, and the third step corresponds to the ammonia elimination to form the new ligand (Bge), which makes a bridge between the two Glu moieties. The final complex, i.e. Glu–Cu(II)–Bge–Cu(II)–Glu, is shown as a zwitterion (Fig. 8). This kind of condensation, a transamination reaction in which ammonia is evolved, is known and it was observed in polycondensation reactions performed with hexamethylenediamine and dicyandiamide to give polyhexamethylene biguanidine [45].

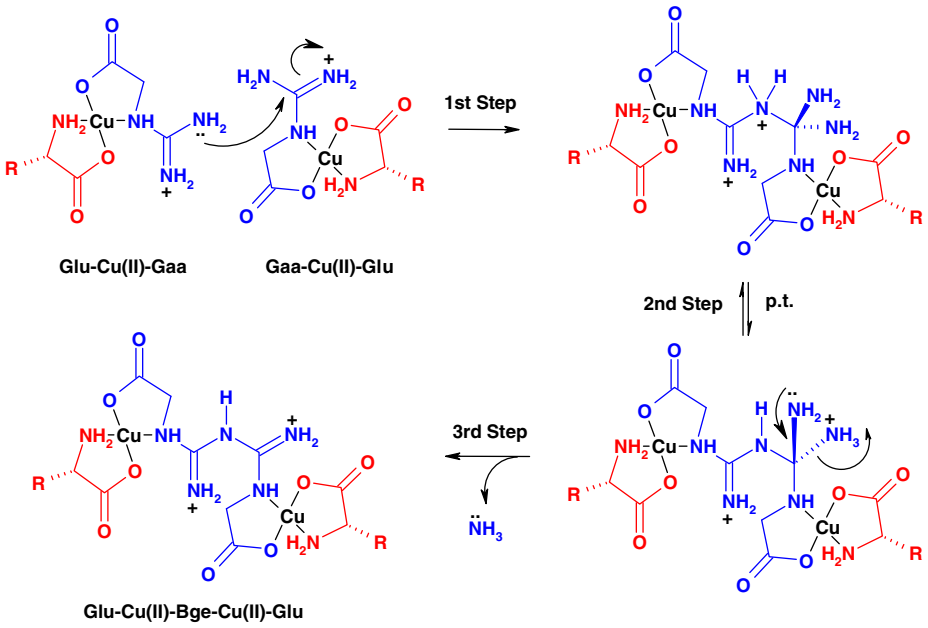

Fig. 8. Proposed mechanistic scheme of the new ligand (Bge) formation in the $K_2[Cu_2(Bge)(Glu)_2]$ complex from the reaction between two Glu–Cu(II)–Gaa species ($R = CH_2CH_2CO_2^-$).

3.8. Theoretical results

The prototropic form A (Fig. 2B) of complex **1** was not stable, regardless if we considered the dianion or the neutral forms and the *cis–cis*, *cis–trans* or *trans–trans* isomers. All tentative calculations of prototropic form A did not converge or resulted in a different final system in which one or more covalent bonds were broken, and hydrogen atom migrations were observed. Therefore, Table 4 shows only the PM3/*d* heats of formation (ΔH_f) values for the prototropic forms B and C of the dianionic and the neutral (X = H or Na) states of complex **1** considering *cis* and *trans* isomers.

Our calculations showed that the model complexes using the prototropic form B of the dianionic states of complex **1** in which at least one Cu(II) coordination center is *trans* are more stable than the *cis–cis* isomer by at least 100 kcal/mol (Table 4). However, when one considers the prototropic form C, this difference falls to about 10 kcal/mol. Overall, the *cis–trans* and *trans–trans* isomers of the prototropic form C of complex **1** are the most stable among the dianionic states. Fig. 9 shows the *trans–trans* isomer, the most stable anionic isomer of **1**. The same tendency described above for the stability of the *cis–cis* and *trans–trans* isomers was also observed in the prototropic forms B and C of the neutral states (X = H) of complex **1**.

Table 4

[a] PF means the prototropic form A, B and C of complex **1** (see Fig. 2).
[b] X means the element in the general formulae $X_2[Cu_2(BGE)(Glu)_2]$ of the modeled complex.
[c] TC means the total charge of the modeled complex.
[d] Possible geometric isomers of the modeled complex, where *c* and *t* means *cis* and *trans* geometric isomer, respectively, and ^{R} and ^{S} means *R* and *S* absolute configuration, respectively, of the tetrahedral nitrogen atom (stereocenter).
[e] ΔH_f means heat of formation in kcal/mol.
[f] None final stable structure was obtained starting from A prototropic form.

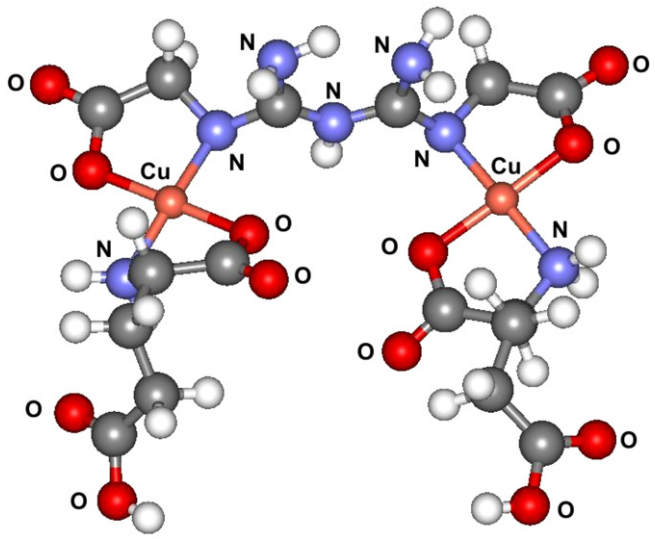

Fig. 9. The ball and stick representation of the prototropic form C of the neutral *trans–trans*, *tt*-1C (H) (Table 1), isomer of complex **1** calculated by PM3/*d* method.

Considering the prototropic form B of the neutral states (X = Na) of complex **1**, the optimized complexes *cis–trans*^{R} and *cis–trans*^{S} are more stable than the other isomers by about 30 kcal/mol (Table 4). However, for the prototropic form C, the complexes in which at least one Cu(II) coordination center is *trans* are more stable than the *cis–cis* isomer by at least 80 kcal/mol. Overall, the prototropic forms C *trans–trans* and*cis–trans* are more stable than the prototropic forms B by at least 40 kcal/mol (Table 4).

The results obtained by the PM3/*d* method (Table 2) for the dianionic and neutral prototropic forms (B and C) of complex **1** pointed to the *trans–trans* isomer as the most stable structure. This is consistent with our infrared data, since its geometry has a C_2 symmetry.

These results are in agreement with DFT theoretical calculations of the *cis–trans*-isomerization reaction of a bis(glycinato)copper(II) complex in which a reaction barrier (*cis–trans*) of about 7.9 kcal/mol was found for a ring-twisting mechanism [48]. They are also in accordance with experimental results in which the isomerization was only observed in the *cis–trans* direction [49].

Table 5 shows some selected geometric parameters of the metal coordination center of the *trans*-Cu(II)$(Gln)_2$ structure as determined by X-ray diffraction [50]. The calculated (PM3/*d*) gas phase geometric parameters of the most stable structure of **1** in the neutral form (X = H), the *trans–trans* prototropic form C. They are also in good agreement with the corresponding experimental values. The O–Cu–O and N–Cu–N angles are very close to 180°, according with the EPR data.

Although semi empirical calculations provided valuable information for the present systems at low computational cost, we decided to perform geometry optimizations using more accurate methods. We performed DFT calculations on simpler models of the geometrical isomers of complex **1**, making a substitution on the final carbon chain of Glu by hydrogen atoms. The *trans–trans* was the most stable structure, favored by more than 20 kcal/mol in comparison to the *cis–trans* and by around 50 kcal/mol in comparison to the *cis–cis* on both levels of theory used (B3LYP/6-31G* and B3P86/6-31G*). The *trans–trans* structure showed similar C_2

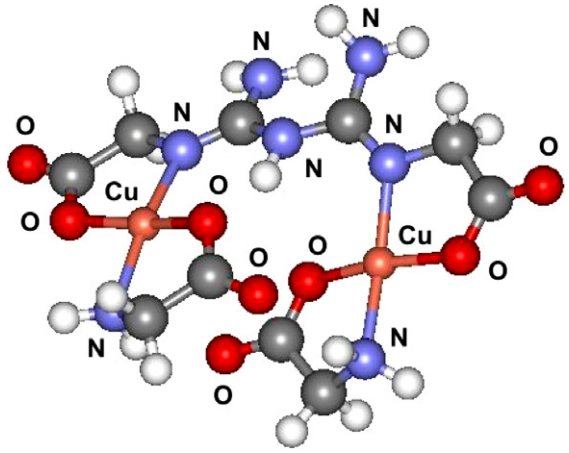

Fig. 10. The ball and stick representation of the prototropic form C of the *trans–trans* isomer of complex **1**, replacing the α-carbon substituent of Glu by a hydrogen atom, calculated by DFT method.

symmetry (Fig. 10), which is in agreement with the experimental results.

4. Conclusions

We have synthesized a complex involving the guanidinoacetic acid, glutamic acid and copper(II) ion via a deamination reaction between these two amino acids and a consequent formation of an adduct between them that is the new ligand, biguanide-1,5-diethanoate (Bge). The infrared spectroscopy, X-ray diffraction, electronic paramagnetic resonance, thermogravimetric analysis and mass spectrum data have characterized the formation of the complex $K_2[Cu_2(Bge)(Glu)_2]$ (**1**), where two copper sites are coordinated by a bridged Bge in addition of the α-*N*,*O*-glutamic acid coordination. The possibility of different isomers of **1** led us to perform semi-empirical and also *ab initio* calculations. Among the *cis–cis*, *cis–trans* and *trans–trans* isomers, the latter showed the greater stabilization from the modeling studies. This is in agreement with the spectroscopic data, especially from infrared data, since the symmetry of the *trans–trans* isomer is close to a C_2 point group, which presents four infrared active bands, two νCu–O and two νCu–N, all of them observed in the complex spectrum.

Considering the *trans–trans* isomer of **1**, it is interesting to notice that guanidino–carboxylate interactions, which play important biological role, are possible to occur between the non-carboxylate group of Glu and the guanidino group of the neighbor complex, making specific recognizing sites.

The isolation and ^{1}H NMR and ^{13}C NMR analysis of Bge showed a good agreement with the expected results comparing with the Gaa NMR analysis.

Finally, the formation of Bge *in vitro*, catalyzed by copper, an important metal site of several enzymes, may represent an alternative route of synthesis of biomolecules. Since the deamination and deimination processes are involved in anti-viral and anti-cancer diseases, this kind of reaction between two amino acids that are present in our organism may contribute to the understanding of the biological role of these two species.

ABSTRACT

The preparation of 4′-(3,5-dimethylpyrazol-1-yl)-2,2′:6′,2″-terpyridine (**2**) under acidic conditions results in the formation of the salts $[H_2\mathbf{2}][MeOSO_3]_2$ and $[H_2\mathbf{2}][EtOSO_3]_2$, treatment of which with base leads to neutral **2**. The structure of $[H_2\mathbf{2}][EtOSO_3]_2 \cdot H_2O$ has been established by single crystal X-ray diffraction. The complexes $[Fe(\mathbf{2})_2][PF_6]_2$ and $[Ru(\mathbf{2})_2][PF_6]_2$ have been prepared and characterized, and the single crystal structure determination of $[Ru(\mathbf{2})_2][PF_6]_2$ is reported; $[Fe(\mathbf{2})_2][PF_6]_2$ is isostructural with $[Ru(\mathbf{2})_2][PF_6]_2$. Treatment of $[Fe(\mathbf{2})_2]^{2+}$ with $PdCl_2$ produces $[Pd(\mathbf{2})Cl]^+$, isolated and structurally characterized as the hexafluoridophosphate salt, illustrating that metal exchange within the tpy-binding domain occurs in preference to palladium(II) coordination by the *N*-donor atom of the pendant 3,5-dimethylpyrazol-1-yl unit in **2**. $[Pd(\mathbf{2})Cl]^{2+}$ can also be prepared from $PdCl_2$ and $[H_2\mathbf{2}][MeOSO_3]_2$ in refluxing methanol.

1. Introduction

The coordination chemistries of ligands based upon 2,6-di(pyrazol-1-yl)pyridine, 6-(pyrazol-1y-l)-2,2′-bipyridine and 6,6′-di(pyrazol-1-yl)-2,2′-bipyridine are now well established, the coordination domain of 2,6-di(pyrazol-1-yl)pyridine being analogous to that of 2,2′:6′,2″-terpyridine [1,2]. In contrast, ligands in which one or more pyrazol-1-yl substituents are directly linked to 2,2′:6′,2″-terpyridine remain unexplored, although a report of a 2,2′:6′,2″-terpyridine bearing a pendant tris(pyrazol-1-yl) functionality has appeared [3]. We considered it worthwhile to explore synthetic routes to 4′-(pyrazol-1-yl)-2,2′:6′,2″-terpyridine ligands and to investigate their coordination chemistry. We are currently interested in using homoleptic metal complexes with pendant coordination domains (e.g. $[M(\mathbf{1})_2]^{2+}$ where **1** = 4′-(4-pyridyl)-2,2′:6′,2″-terpyridine) as building blocks in the formation of coordination polymers [4–7]. The replacement of the pendant 4-pyridyl units in $[M(\mathbf{1})_2]^{2+}$ by pyrazol-1-yl or substituted pyrazol-1-yl units should generate a complex which may be viewed as an expanded bis(pyrazolyl)methane ligand, in much the same way as we consider $[M(\mathbf{1})_2]^{2+}$ to be an expanded 4,4′-bipyridine [4–10]. Altering the position of the *N*-donor atom in the pendant pyridine rings [11,12] does not preclude the corresponding homoleptic complex from functioning as an expanded bipyridine ligand [13]. However, we appreciated that the basicity of the pyrazolyl *N*-donors may prove to be too low to facilitate coordination to metal ions. With the ligands 2,6-di(pyrazol-1-yl)pyridine, 6-(pyrazol-1yl)-2,2′-bipyridine and 6,6′-di(pyrazol-1-yl)-2,2′-bipyridine, the chelate effect provides critical additional stability. The pK_a value of pyrazolium (2.52) indicates that pyrazole is a weaker base than imidazole (pK_a of imidazolium, 7.1), but complexes of 1-phenylimidazole, which is sterically analogous to ligand **2**, are well-known.

We report here the synthesis of the 4′-(3,5-dimethylpyrazol-1-yl)-2,2′:6′,2″-terpyridine-1,1″-diium ion $[H_2\mathbf{2}]^{2+}$, its deprotonation to form **2**, and the formation of iron(II), ruthenium(II) and palladium(II) complexes containing ligand **2**.

2. Experimental

2.1. General

^1H and ^{13}C NMR spectra were recorded on a Bruker Avance DRX 500 or 400 spectrometer; the numbering scheme adopted for ligand **2** is shown in Scheme 1. Chemical shifts for ^1H and ^{13}C NMR spectra are referenced to residual solvent peaks with respect to TMS = δ 0 ppm. Electrospray (ES) mass spectra were recorded using a Finnigan MAT LCQ mass spectrometer. Electronic absorption spectra were recorded on a Varian-Cary 5000 spectrophotometer. Electrochemical measurements were performed with an Eco

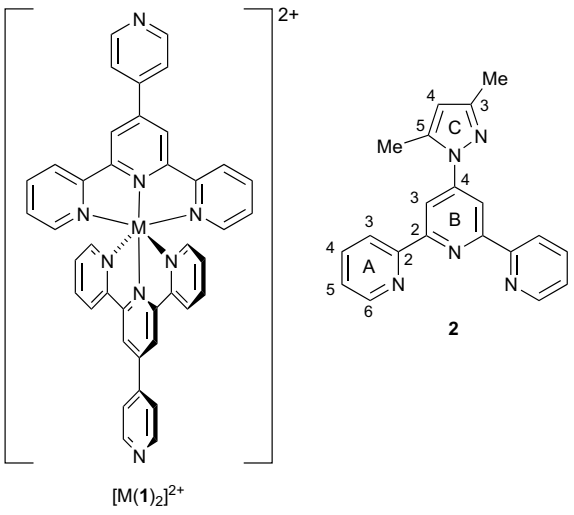


Scheme 1. Structures of $[M(\mathbf{1})_2]^{2+}$ (**1** = 4′-(4-pyridyl)-2,2′:6′,2″-terpyridine) and ligand **2** with the labelling scheme used for NMR spectroscopic assignments.

Chemie Autolab PGSTAT 20 system using glassy carbon working and platinum auxiliary electrodes with a silver wire as pseudo-reference electrode; purified MeCN was used as solvent and 0.1 M $[^nBu_4N][PF_6]$ as supporting electrolyte; ferrocene was added at the end of each experiment as an internal reference. Reactions were carried out under argon. All solvents were dried and distilled before use.

4′-Hydrazino-2,2′:6′,2″-terpyridine was prepared according to the literature procedure [14–16].

2.2. $[H_2\mathbf{2}][EtOSO_3]_2$

Pentane-2,4-dione (0.10 g, 1.0 mmol) was added to a solution of 4′-hydrazino-2,2′:6′-2″-terpyridine (0.11 g, 0.42 mmol) in EtOH (15 cm^3) and the mixture heated. Two drops of concentrated H_2SO_4 were added to the colourless solution causing the immediate formation of a milky, pale yellow suspension which dissolved on heating. The mixture was heated at reflux for 3 h and then cooled to room temperature. Et_2O was added carefully until the first sign of the formation of a precipitate was observed. The solution was then left to stand at −18°C. The fine white needles of $[H_2\mathbf{2}][EtOSO_3]_2$ which formed were collected by filtration and washed with chilled EtOH and Et_2O. $[H_2\mathbf{2}][EtOSO_3]_2$: 0.22 g, 0.38 mmol, 92%. ^{1}H NMR (500 MHz, DMSO-d_6) δ/ppm 8.88 (m, 4H, $H^{A6,A3}$), 8.71 (s, 2H, H^{B3}), 8.32 (t, J 7.3 Hz, 2H, H^{A4}), 7.78 (dd, J 6.0, 5.5 Hz, 2H, H^{A5}), 6.29 (s, 1H, H^{C4}), 3.74 (q, J 8.0 Hz, 4H, CH_2^{anion}), 2.62 (s, 3H, Me^{C5}), 2.27 (s, 3H, Me^{C3}), 1.11 (t, J 8.0 Hz, 6H, CH_3^{anion}). $^{13}C\{^1H\}$ NMR (125 MHz, DMSO-d_6) δ/ppm 154.0 (C^{B2}), 151.8 (C^{A2}), 150.5 (C^{C3}), 148.9 (C^{B4}), 147.5 (C^{A6}), 141.0 (C^{A4}), 140.8 (C^{C5}), 126.0 (C^{A5}), 122.7 (C^{A3}), 114.1 (C^{B3}), 110.2 (C^{C4}), 13.4 ($C^{Me(C5)}$), 13.3 ($C^{Me(C3)}$). ES MS m/z 328 $[H\mathbf{2}]^+$. *Anal.* Calc. for $[H_2\mathbf{2}][EtOSO_3]_2 \cdot 0.3H_2O$ requires: C, 49.23; H, 5.11; N, 11.96. Found: C, 48.94; H, 5.18; N, 12.27%.

2.3. $[H_2\mathbf{2}][MeOSO_3]_2$

Pentane-2,4-dione (0.090 g, 0.90 mmol) was added to a solution of 4′-hydrazino-2,2′:6′,2″-terpyridine (0.20 g, 0.76 mmol) in hot MeOH. Two drops of concentrated H_2SO_4 were added to the colourless solution causing the immediate formation of a milky, pale yellow suspension. The reaction mixture was heated at reflux for 2 h, after which time the precipitate had completely dissolved. After a further 3 h at reflux, the solution was cooled to room temperature and Et_2O was added carefully until the first sign of a precipitate was observed. The solution was left standing overnight at −18 °C. $[H_2\mathbf{2}][MeOSO_3]_2$ precipitated as an off-white microcrystalline solid which was collected by filtration and washed with cold EtOH. $[H_2\mathbf{2}][MeOSO_3]_2$ (0.20 g, 0.36 mmol, 47%): ^{1}H NMR (500 MHz, DMSO-d_6) δ/ppm 8.85 (d, 2H, J 5.0 Hz, H^{A6}), 8.83 (d, J 8.1 Hz, 2H, H^{A3}), 8.71 (s, 2H, H^{B3}), 8.25 (td, J 8.0, 1.3 Hz, 2H, H^{A4}), 7.72 (dd, J 6.7, 5.6 Hz, 2H, H^{A5}), 6.29 (s, 1H, H^{C4}), 3.37 (s, 3H, CH_3^{anion}), 2.62 (s, 3H, H^{C5}), 2.27 (s, 3H, H^{C3}). $^{13}C\{^1H\}$ NMR (125 MHz, DMSO-d_6) δ/ppm 154.6 (C^{B2}), 152.5 (C^{A2}), 150.4 (C^{C3}), 148.7 (C^{B4}), 148.0 (C^{A6}), 140.8 (C^{C5}), 139.9 (C^{A4}), 125.7 (C^{A5}), 122.2 (C^{A3}), 113.6 (C^{B3}), 110.2 (C^{C4}), 13.4 ($C^{Me(C5,C3)}$). ES MS m/z 328 $[H\mathbf{2}]^+$, 677 $[2(\mathbf{2}) + Na]^+$. *Anal.* Calc. for $[H_2\mathbf{2}][MeOSO_3]_2$ requires: C, 42.92; H, 4.09; N, 11.37. Found: C, 42.89; H, 4.02; N, 11.62%.

2.4. 4′-(3,5-Dimethylpyrazol-1-yl)-2,2′:6′,2″-terpyridine, **2**

$[H_2\mathbf{2}][EtOSO_3]_2$ (100 mg, 0.17 mmol) was dissolved in H_2O (10 cm^3) and an aqueous solution of NaOH (0.5 M) was added dropwise until a white precipitate resulted. Collection of the sticky solid was difficult. It was extracted into CH_2Cl_2 and the solvent removed to give neutral **2** (15 mg, 0.046 mmol, 27%). ^{1}H NMR (400 MHz, $CDCl_3$) δ/ppm 8.69 (ddd, J 4.8, 1.8, 1.0 Hz, 2H, H^{A6}), 8.66 (s, 2H, H^{B3}), 8.63 (dt, J 8.0, 1.0 Hz, 2H, H^{A3}), 7.84 (dt, J 7.6, 1.5 Hz, 2H, H^{A4}), 7.32 (ddd, J 7.6, 4.8, 1.6 Hz, 2H, H^{A5}), 6.06 (s, 1H, H^{C4}), 2.63 (s, 3H, Me^{C5}), 2.32 (s, 3H, Me^{C3}). $^{13}C\{^1H\}$ NMR (125 MHz, $CDCl_3$) δ/ppm 157.0 (C^{B2}), 155.7 (C^{A2}), 150.5 (C^{C3}), 149.3 (C^{A6}), 149.0 (C^{B4}), 140.2 (C^{C5}), 136.9 (C^{A4}), 124.1 (C^{A5}), 121.3 (C^{A3}), 114.5 (C^{B3}), 109.1 (C^{C4}), 13.7 ($C^{Me(C3)}$), 13.5 ($C^{Me(C5)}$). ^{1}H NMR (500 MHz, DMSO-d_6) δ/ppm 8.75 (ddd, J 4.6, 1.4, 0.8 Hz, 2H, H^{A6}), 8.67 (s, 2H, H^{B3}), 8.66 (d, J 7.1 Hz, 2H, H^{A3}), 8.03 (td, J 7.8, 1.8 Hz, 2H, H^{A4}), 7.53 (ddd, J 7.4, 4.8, 0.9 Hz, 2H, H^{A5}), 6.24 (s, 1H, H^{C4}), 2.59 (s, 3H, Me^{C5}), 2.26 (s, 3H, Me^{C3}). $^{13}C\{^1H\}$ NMR (125 MHz, DMSO-d_6) δ/ppm 156.4 (C^{B2}), 154.5 (C^{A2}), 150.0 (C^{C3}), 148.4 (C^{B4}), 149.4 (C^{A6}), 140.5 (C^{C5}), 137.5 (C^{A4}), 124.8 (C^{A5}), 121.0 (C^{A3}), 112.3 (C^{B3}), 110.0 (C^{C4}), 13.5 ($C^{Me(C5)}$), 13.4 ($C^{Me(C3)}$). ES-MS m/z 328 $[\mathbf{2}+H]^+$. *Anal.* Calc. for $C_{20}H_{17}N_5$ requires: C, 73.37; H, 5.23; N, 21.39. Found: C, 73.34; H, 5.29; N, 21.30%.

2.5. $[Fe(\mathbf{2})_2][PF_6]_2$

$[H_2\mathbf{2}][EtOSO_3]_2$ (19 mg, 0.033 mmol) and $FeCl_2 \cdot 4H_2O$ (4.0 mg, 0.020 mmol) were dissolved in MeOH (10 cm^3) and stirred at room temperature for 2 h. Excess aqueous NH_4PF_6 was added to precipitate the purple complex which was collected on Celite, washed with H_2O, EtOH and Et_2O, and redissolved in MeCN. Removal of the solvent gave $[Fe(\mathbf{2})_2][PF_6]_2$ as a purple solid (15 mg, 0.015 mmol, 78%). ^{1}H NMR (500 MHz, CD_3CN) δ/ppm 9.04 (s, 4H, H^{B3}), 8.53 (d, J 8.0 Hz, 4H, H^{A3}), 7.90 (td, J 7.9, 1.4 Hz, 4H, H^{A4}), 7.25 (d, J 5.5 Hz, 4H, H^{A6}), 7.10 (ddd, J 7.0, 5.7, 1.2 Hz, 4H, H^{A5}), 6.43 (s, 2H, H^{C4}), 2.90 (s, 6H, Me^{C5}), 2.44 (s, 6H, Me^{C3}). $^{13}C\{^1H\}$ NMR (125 MHz, CD_3CN) δ/ppm 161.7 (C^{B2}), 158.6 (C^{A2}), 154.4 (C^{A6}), 153.3 (C^{C3}), 149.6 (C^{B4}), 142.9 (C^{C5}), 139.7 (C^{A4}), 128.5 (C^{A5}), 125.1 (C^{A3}), 117.3 (C^{B3}), 112.0 (C^{C4}), 13.9 ($C^{Me(C3)}$), 13.8 ($C^{Me(C5)}$). ES-MS m/z 855 $[M-PF_6]^+$, 355 $[M-2PF_6]^{2+}$. UV–VIS (MeCN, 8.80×10^{-6} mol dm^{-3}) λ/nm 565 (ε/dm^3 mol^{-1} cm^{-1} 14600), 502 (sh, 5900), 317 (39000), 307 (38000), 284 (46200), 241 (23700). *Anal.* Calc. for $C_{40}H_{34}F_{12}FeN_{10}P_2 \cdot 1.5CH_3OH \cdot H_2O$ requires: C, 46.73; H, 3.97; N, 13.11. Found: C, 47.09; H, 3.61; N, 12.79%. $E°$/V versus Fc/Fc^+: +0.75, −1.44 and −1.66 V (all reversible).

2.6. $[Ru(\mathbf{2})_2][PF_6]_2$

$RuCl_3 \cdot 3H_2O$ (9.0 mg, 0.035 mmol), and $[H_2\mathbf{2}][EtOSO_3]_2$ (20 mg, 0.035 mmol) were suspended in ethane-1,2-diol (2 cm^3) and the

reaction mixture was heated in a microwave oven (800 W, 2 min). A second equivalent of $[H_2\mathbf{2}][EtOSO_3]_2$ (20 mg, 0.035 mmol) was added with one drop of *N*-ethylmorpholine and the solution was again heated in the microwave oven (800 W, 2 min) to give a deep red solution which was cooled to room temperature. It was then poured into water (50 cm^3) containing an excess of NH_4PF_6 to precipitate the hexafluoridophosphate salt of the product. The resulting red-orange precipitate was collected on Celite and washed well with H_2O, EtOH and Et_2O. The solid was dissolved in MeCN and the solvent removed to give the crude product (35 mg, 0.033 mmol, 96%, approximately 95% pure by ^1H NMR spectroscopy). This was purified by column chromatography (SiO_2, MeCN:H_2O:saturated aqueous KNO_3 7:2:2). The central portion of the main red fraction was collected, excess NH_4PF_6 was added and the volume reduced leading to the precipitation of the pure product as a dark red microcrystalline solid (26 mg, 0.025 mmol, 72%). ^1H NMR (500 MHz, CD_3CN) δ/ppm 8.86 (s, 4H, H^{B3}), 8.55 (dt, *J* 8.0, 1.0 Hz, 4H, H^{A3}), 7.94 (td, *J* 8.0, 1.3 Hz, 4H, H^{A4}), 7.49 (dt, *J* 5.6, 1.0 Hz, 4H, H^{A6}), 7.20 (ddd, *J* 7.0, 5.6, 1.3 Hz, 4H, H^{A5}), 6.37 (s, 2H, H^{C4}), 2.81 (s, 6H, Me^{C5}), 2.42 (s, 6H, Me^{C3}). $^{13}C\{^1H\}$ NMR (125 MHz, CD_3CN) δ/ppm 158.8 (C^{A2}), 156.7 (C^{B2}), 153.7 (C^{A6}), 153.0 (C^{C3}), 147.6 (C^{B4}), 142.5 (C^{C5}), 139.1 (C^{A4}), 128.7 (C^{A5}), 125.7 (C^{A3}), 117.7 (C^{B3}), 111.4 (C^{C4}), 13.8 ($C^{Me(C3)}$), 13.5 ($C^{Me(C5)}$). ES-MS *m*/*z* 901 $[M-PF_6]^+$, 378 $[M-2PF_6]^{2+}$. UV–Vis (MeCN, 1.51×10^{-5} mol dm^{-3}) λ/nm 489 (ε/ $dm^3\,mol^{-1}\,cm^{-1}$ 23 200), 307 (65 100), 284 (59 400), 241 (28 000). *Anal.* Calc. for $C_{40}H_{34}F_{12}N_{10}P_2Ru$ requires: C, 45.94; H, 3.28; N, 13.39. Found: C, 45.80; H, 3.26; N, 13.40%. E°/V versus Fc/Fc^+: +0.93, −1.52 and −1.73 V (all reversible).

2.7. [Pd(**2**)Cl][PF_6]: method 1

$[H_2\mathbf{2}][MeOSO_3]_2$ (0.035 g, 0.063 mmol) and $PdCl_2$ (0.012 g, 0.068 mmol) were dissolved in MeOH (10 cm^3) and the solution was heated at reflux for 18 h, during which time a cream precipitate formed. The reaction mixture was cooled to room temperature, filtered and the solid product washed with EtOH, $CHCl_3$ and Et_2O. The solid was dissolved in hot water and excess solid NH_4PF_6 was added to precipitate the hexafluoridophosphate salt which was collected and recrystallised from MeCN/H_2O. [Pd(**2**)Cl][PF_6] was isolated as a pale yellow solid (0.017 g, 0.027 mmol, 40%). ^1H NMR (500 MHz, DMSO-d_6) δ/ppm 8.82 (d, *J* 7.8 Hz, 2H, H^{A3}), 8.79 (dd, *J* 5.6, 1.0 Hz, 2H, H^{A6}), 8.69 (s, 2H, H^{B3}), 8.48 (td, *J* 7.9, 1.3 Hz, 2H, H^{A4}), 7.93 (ddd, *J* 6.9, 5.6, 0.9 Hz, 2H, H^{A5}), 6.41 (s, 1H, H^{C4}), 2.66 (s, 3H, Me^{C5}), 2.30 (s, 3H, Me^{C3}). Low solubility prevented ^{13}C NMR spectroscopic data from being recorded. ES MS *m*/*z* 469 $[M-PF_6]^+$. *Anal.* Calc. for $C_{20}H_{17}ClF_6N_5PPd\cdot0.5H_2O$ requires: C, 38.59; H, 2.92; N, 11.26. Found: C, 38.59; H, 3.11; N, 10.90%.

2.8. [Pd(**2**)Cl][PF_6]: method 2 (see text)

$[Fe(\mathbf{2})_2][PF_6]_2$ (0.070 g, 0.068 mmol), $PdCl_2$ (0.012 g, 0.068 mmol) and K_2CO_3 (0.10 g, 0.73 mmol) were dissolved in MeCN (30 cm^3). The solution was stirred overnight at room temperature and filtered to remove a small amount of pale yellow precipitate, assumed to be $PdCl_2$. Aqueous NH_4PF_6 was added and the resulting precipitate was collected and washed with H_2O, EtOH and Et_2O. The ^1H NMR spectrum of a CD_3CN solution of the precipitate indicated the presence of $[Fe(\mathbf{2})_2][PF_6]_2$ and [Pd(**2**)Cl][PF_6]. Slow evaporation of the CD_3CN solution gave X-ray quality crystals of [Pd(**2**)Cl][PF_6].

2.9. Crystal structure determinations

Data for $[H_2\mathbf{2}][EtOSO_3]_2\cdot H_2O$, $[Ru(\mathbf{2})_2][PF_6]_2$, [Pd(**2**)Cl][$PF_6$] and $[Fe(\mathbf{2})_2][PF_6]_2$ (see electronic supplementary data) were collected on an Enraf Nonius Kappa CCD instrument; data reduction, solution and refinement used the programs COLLECT [17], SIR92 [18], DENZO/SCALEPACK [19] and CRYSTALS [20]. Structures have been analysed using MERCURY v. 1.4.2 [21].

2.10. Crystal data for $[H_2\mathbf{2}][EtOSO_3]_2\cdot H_2O$

$C_{24}H_{31}N_5O_9S_2$, M = 597.67, triclinic, space group $P\bar{1}$, a = 7.7597(1), b = 12.6160(2), c = 15.1917(3) Å, α = 107.2079(9)°, β = 102.5902(9)°, γ = 102.9589(9)°, U = 1318.31(4) $Å^3$, Z = 2, D_{calc} = 1.506 Mg m^{-3}, μ(Mo Kα) = 0.265 mm^{-1}, T = 173 K, 6280 reflections collected. Refinement of 4355 reflections (361 parameters) with $I > 3\sigma(I)$ converged at final R_1 = 0.0386 (R_1 all data = 0.0577), wR_2 = 0.0448 (wR_2 all data = 0.0599), goodness-of-fit = 1.046.

2.11. $[Ru(\mathbf{2})_2][PF_6]_2$

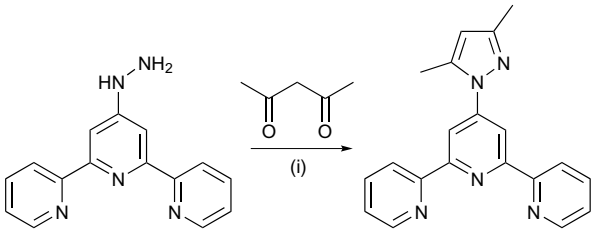
$C_{40}H_{34}F_{12}N_{10}P_2Ru$, M = 1045.77, monoclinic, space group $P2_1$, a = 9.3368(3), b = 13.0679(4), c = 17.5480(6) Å, β = 103.341(2)°, U = 2083.3(1) $Å^3$, Z = 2, D_{calc} = 1.667 Mg m^{-3}, μ(Mo Kα) = 0.553 mm^{-1}, T = 173 K, 9271 reflections collected. Refinement of 7592 reflections (587 parameters) with $I > 3\sigma(I)$ converged at final R_1 = 0.0440 (R_1 all data = 0.0576), wR_2 = 0.0402 (wR_2 all data = 0.0453), goodness-of-fit = 1.080.

2.12. [Pd(**2**)Cl][PF_6]

$C_{20}H_{17}ClF_6N_5PPd$, M = 614.20, triclinic, space group $P\bar{1}$, a = 8.3796(2), b = 10.8068(2), c = 13.2536(3) Å, α = 99.108(1)°, β = 103.461(1)°, γ = 110.1509(9)°, U = 1057.73(4) $Å^3$, Z = 2, D_{calc} = 1.928 Mg m^{-3}, μ(Mo Kα) = 1.153 mm^{-1}, T = 173 K, 6172 reflections collected. Refinement of 4716 reflections (361 parameters) with $I > 3\sigma(I)$ converged at final R_1 = 0.0308 (R_1 all data = 0.0441), wR_2 = 0.0337 (wR_2 all data = 0.0435), goodness-of-fit = 1.148.

3. Results and discussion

The strategy for the preparation of ligand **2** was the cyclization reaction of pentane-2,4-dione with 4′-hydrazino-2,2′:6′,2″-terpyridine [14–16]. Such cyclizations are well documented for the syntheses of a range of pyrazoles, both in solution and over heterogeneous catalysts [22–24]. The conditions shown in Scheme 2 are similar to those reported recently for the synthesis of 1,3,5-trisubstituted pyrazoles [25]. Treatment of 4′-hydrazino-2,2′:6′,2″-terpyridine with pentane-2,4-dione in methanol in the presence of concentrated H_2SO_4, followed by cooling, resulted in the formation of an off-white crystalline solid. An analogous reaction in ethanol proceeded in a similar manner also to give a white solid. Both products proved to be poorly soluble in common organic solvents, and their solution ^1H NMR spectra were not well resolved. Elemental analysis indicated that methyl or ethyl sulfate salts of the diprotonated ligand $[H_2\mathbf{2}]^{2+}$ had been formed, and this was confirmed by a single crystal X-ray diffraction study. X-ray



Scheme 2. Synthetic route to ligand **2**: (i) MeOH or EtOH at reflux, conc. H_2SO_4 catalyst.

quality crystals of $[H_2\mathbf{2}][EtOSO_3]_2 \cdot H_2O$ were grown by slow evaporation of an ethanol/water (1:1) solution of $[H_2\mathbf{2}][EtOSO_3]_2$. The H atoms bonded to the nitrogen atoms and the two protons of the water molecule were localized in the difference map, but were included in the refinement as fixed contributions riding on either N or O atoms. The diprotonated state of the ligand was consistent with the presence of two ethyl sulfate ions in the asymmetric unit, and is also consistent with the observation of a *cis*,*cis*-conformation for the tpy unit. Free tpy ligands typically adopt a *trans*,*trans*-conformation to minimize nitrogen lone pair–lone pair interactions. Monoprotonated ligands, $[Htpy]^+$, adopt a *cis*,*trans*-conformation as a result of a hydrogen-bonded N–H···N interaction [26–28]. Typically, in $[H_2tpy]^{2+}$, the two outer pyridine rings are protonated and hydrogen-bonded interactions involving the central pyridine *N*-atom, in addition to an acceptor atom in a solvent molecule or anion, result in a *cis*,*cis*-conformation [28–33]. In $[H_2\mathbf{2}][EtOSO_3]_2 \cdot H_2O$, the $[H_2\mathbf{2}]^{2+}$ ion is hydrogen-bonded to atom O4 of one ethyl sulfate ion as illustrated in Fig. 1 (N1···O1 = 2.757(2) Å, N1–H1···O1 = 159°, N1···N2 = 2.630(2) Å, N1–H1···N2 = 101°, N3···O1 = 2.752(2) Å, N3–H1···O1 = 156°, N3···N2 = 2.644(2) Å, N3–H1···N2 = 106°). The tpy unit deviates slightly from a planar conformation (angles between the least squares planes of the rings containing atoms N1 and N2, and N2 and N3 are 16.02(9)° and 10.37(9)°, respectively). The bond parameters within the tpy domain are unexceptional. The pyrazolyl ring is twisted out of the plane of the pyridine ring to which it is bonded, with an angle between the least squares planes of 24.2(1)°.

Hydrogen-bonded pairs of cations and anions stack with alternating pyrazolyl rings and pyridine rings contain N1; the inter-ring separation is 3.7 Å (Fig. 2). Each remaining $[EtOSO_3]^-$ anion is hydrogen bonded to a water molecule (O9···O7 = 2.864(2) Å, O9–H4···O7 = 175°). A weaker hydrogen bond links each water molecule to a cation-associated ethyl sulfate anion (O9···O2 = 3.089(2) Å, O9–H3···O2 = 156°).

Solutions of $[H_2\mathbf{2}][EtOSO_3]_2$ in DMSO-d_6 were monitored by ^{1}H NMR spectroscopy, and the appearance of a new set of ethyl signals corresponding to ethanol (quartet at δ 3.44 ppm and triplet at δ 1.06 ppm) grew in at the expense of those arising from the ethyl sulfate anions. This observation was consistent with the hydrolysis of the ethyl sulfate ion by residual water in the solvent [34], giving rise to the sulfate or hydrogen sulfate salt of $[H_2\mathbf{2}]^{2+}$. This salt was not isolated.

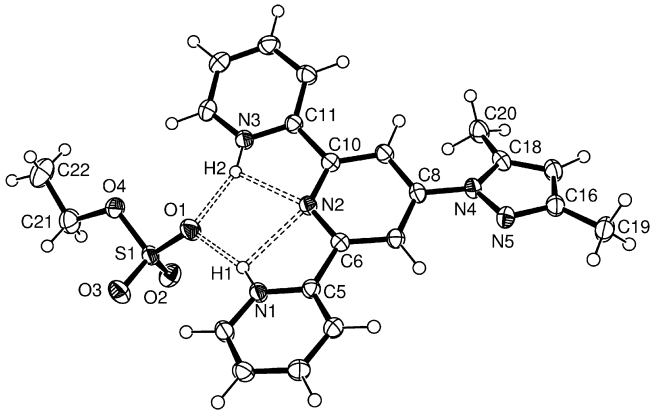


Fig. 1. The molecular structure of the $[H_2\mathbf{2}]^{2+}$ cation and the ethyl sulfate anion to which it is hydrogen-bonded in $[H_2\mathbf{2}][EtOSO_3]$textsubscript2 · H_2O; thermal ellipsoids are plotted at the 50% probability level. Selected bond parameters: N4–N5 = 1.382(2), N4–C8 = 1.404(2), N5–C16 = 1.326(2), N4–C18 = 1.379(2), C16–C17 = 1.417(3), C17–C18 = 1.361(3), S1–O1 = 1.461(1), S1–O2 = 1.442(2), S1–O3 = 1.437(1), S1–O4 = 1.588(1) Å; N4–C8–C7 = 119.5(2)°, N4–C8–C9 = 121.1(2)°, N5–N4–C18 = 111.7(1)°, N4–N5–C16 = 104.7(2)°.

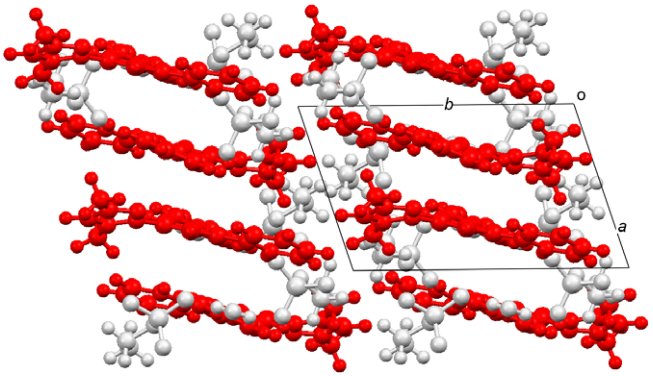

Fig. 2. Part of the packing in $[H_2\mathbf{2}][EtOSO_3]_2 \cdot H_2O$ (viewed down the *c* axis), showing stacking of cations. The $[EtOSO_3]^-$ anions and water molecules are shown in pale grey.

The methyl sulfate salt $[H_2\mathbf{2}][MeOSO_3]_2$ exhibited the same NMR spectroscopic signature to its ethyl analogue, with a singlet at δ 3.37 ppm for the methyl group replacing the triplet (δ 1.11 ppm) and quartet (δ3.74 ppm) assigned to the ethyl group in $[H_2\mathbf{2}][EtOSO_3]_2$. The isolation of ethyl or methyl sulfate salts of complexes from media in which esterification of sulfate or sulfuric acid [34] has precedent, although examples appear to be rare [35–37]. The fact that the ^{1}H and ^{13}C NMR spectroscopic signatures of $[H_2\mathbf{2}]^{2+}$ in both alkyl sulfate salts are virtually identical confirms a common protonation state of the tpy unit.

Addition of solid K_2CO_3 to an NMR sample of $[H_2\mathbf{2}][EtOSO_3]_2$ or $[H_2\mathbf{2}][MeOSO_3]_2$ resulted in a shift of the signals for the tpy protons and formation of neutral ligand **2**. Spectroscopic signals were assigned by COSY, NOESY, HMQC and HMBC techniques. The signals for protons H^{A3} and H^{A6} (see Scheme 1) overlap in the spectrum of $[H_2\mathbf{2}][EtOSO_3]_2$, appearing (in DMSO-$d_6$) as a poorly resolved multiplet centred at δ 8.88 ppm. The signals are slightly better separated in the spectrum of $[H_2\mathbf{2}][MeOSO_3]_2$. In the ^{1}H NMR spectrum of **2**, resonances for H^{A3} and H^{A6} are well separated (δ 8.63 and 8.69 ppm, respectively in $CDCl_3$ and δ 8.66 and 8.75 ppm in DMSO-d_6). The signals assigned to H^{A4} and H^{A5} shift to lower frequency on going from $[H_2\mathbf{2}]^{2+}$ to **2**, (for $[H_2\mathbf{2}][MeOSO_3]_2$ to **2** in DMSO-d_6, δ 8.25–8.03 ppm for H^{A4}, and δ 7.72–7.53 ppm for H^{A5}). In contrast, a comparison of the ^{1}H NMR spectra of $[H_2\mathbf{2}]^{2+}$ and **2** (DMSO-d_6 solutions) shows that the chemical shifts of signals assigned to protons which are remote from the site of ligand protonation vary little between the two species. There is, however, a significant solvent dependence, with signals shifting between 0.01 and 0.21 ppm on changing from a DMSO-d_6 to $CDCl_3$ solution of **2** (see Section 2). The signals for the pyrazolyl methyl groups were distinguished by the appearance in the NOESY spectrum of a cross peak between H^{B3} and H^{C5}.

On a preparative scale, the conversion of $[H_2\mathbf{2}][EtOSO_3]_2$ or $[H_2\mathbf{2}][MeOSO_3]_2$ to **2** was carried out by neutralization of an aqueous solution of $[H_2\mathbf{2}][EtOSO_3]_2$ or $[H_2\mathbf{2}][MeOSO_3]_2$ with aqueous NaOH. The resulting white precipitate was collected, dissolved in CH_2Cl_2 followed by the removal of solvent. Alternatively, solid K_2CO_3 was added to an aqueous solution of $[H_2\mathbf{2}][EtOSO_3]_2$ or $[H_2\mathbf{2}][MeOSO_3]_2$, and the resulting suspension was extracted into CH_2Cl_2. The yield of **2** (which is not particularly soluble in water) by either method is typically $\leqslant$30%. This low yield prompted us to investigate whether complex formation could be carried out using the alkyl sulfate salts instead of neutral **2**. As described below, this is indeed the case and avoids loss of material during deprotonation and ligand purification.

Ligand **2** has two potential coordination domains: the tpy and pyrazolyl *N*-donor sites. $[H_2\mathbf{2}][EtOSO_3]_2$ reacts with iron(II) at room

temperature to give a complex, the purple colour of which is characteristic of the $\{Fe(tpy)_2\}^{2+}$ chromophore. The product was isolated as the hexafluoridophosphate salt $[Fe(\mathbf{2})_2][PF_6]_2$, and its electrospray mass spectrum showed peak envelopes at m/z 855 and 355 (base peak) corresponding to $[M-PF_6]^+$ and $[M-2PF_6]^{2+}$, respectively, with isotope patterns that matched those simulated. The ^{1}H NMR spectrum of a CD_3CN solution of $[Fe(\mathbf{2})_2][PF_6]_2$ exhibited the characteristic pattern of signals for a coordinated tpy domain. In particular, the resonance for H^{A6} appears at δ 7.25 ppm, i.e. at significantly lower frequency than in the free ligand, while coordination to the metal centre causes the signal for H^{B3} to move to noticeably higher frequency (δ 9.04 ppm).

Treatment of $RuCl_3 \cdot 3H_2O$ with an equivalent of $[H_2\mathbf{2}][EtOSO_3]_2$ produces $[Ru(\mathbf{2})Cl_3]$ which reacts with a second equivalent of $[H_2\mathbf{2}][EtOSO_3]_2$ in the presence of *N*-ethylmorpholine to give $[Ru(\mathbf{2})_2]^{2+}$, isolated as the hexafluoridophosphate salt. The electrospray mass spectrum of the complex is in accord with a formulation of $[Ru(\mathbf{2})_2][PF_6]_2$, with the highest mass peak appearing at m/z 901 (assigned to $[M-PF_6]^+$) and the base peak at m/z 378 (assigned to $[M-2PF_6]^{2+}$). The isotope distributions agreed with those simulated for these ions. The ^{1}H NMR spectrum of a CD_3CN solution of $[Ru(\mathbf{2})_2][PF_6]_2$ confirmed that the tpy domain was coordinated to the ruthenium(II) centre.

The structure of the $[Ru(\mathbf{2})_2]^{2+}$ cation was confirmed by an X-ray diffraction study of $[Ru(\mathbf{2})_2][PF_6]_2$, suitable crystals being grown by slow evaporation of a CH_3CN/H_2O solution of $[Ru(\mathbf{2})_2][PF_6]_2$. The structure of the complex cation is shown in Fig. 3. The coordination environment around the ruthenium(II) centre is as expected, with the central Ru–N bond being shorter than the two outer bonds to each ligand (caption to Fig. 3). Each pyrazolyl ring is twisted with respect to the pyridine ring to which it is bonded (angles between the least squares planes for the rings containing N2 and N7, and N5 and N9 are 20.0(3)° and 36.2(3)°, respectively). The packing of cations in the solid state is supported by weak C–H(methyl)···π(pyridine) interactions. Each pyrazolyl methyl group containing atom C36 sits directly over a tpy pyridine ring containing atom N1 of the adjacent cation (Fig. 4); the distance from C36 to the centroid of the pyridine ring is 3.35 Å, which is relatively short for this type of intermolecular contact [40]. These interactions lead to the formation of loosely held chains which run parallel to the crystallographic *b* axis. Extensive interactions between aromatic C–H hydrogen atoms and the F atoms of the $[PF_6]^-$ ions also contribute towards the solid state packing. The $\{Ru(tpy)_2\}$ units are held significantly away from one another, preventing them from engaging in face-to-face or edge-to-face π-interactions [41,42]. Crystalline $[Fe(\mathbf{2})_2][PF_6]_2$ is isostructural with $[Ru(\mathbf{2})_2][PF_6]_2$ (see electronic supplementary material).

The electronic absorption spectra of acetonitrile solutions of $[Fe(\mathbf{2})_2][PF_6]_2$ and $[Ru(\mathbf{2})_2][PF_6]_2$ show MLCT bands at 565 and 489 nm, respectively. Both absorptions are shifted to lower energy compared to the MLCT absorptions for the parent $[Fe(tpy)_2]^{2+}$ (551 nm) and $[Ru(tpy)_2]^{2+}$ (475 nm) [38], but are similar to the corresponding absorptions for homoleptic complexes of iron(II) and ruthenium(II) containing 4′-(*n*-pyridyl)-2,2′:6′,2″-terpyridine (n = 2, 3 or 4) ligands [38,39]. This indicates that the introduction of the 4′-pyridyl or 4′-pyrazolyl substituents results in a lowering of the ligand π^* orbitals to a similar extent. The electronic spectra of $[Fe(\mathbf{2})_2][PF_6]_2$ and $[Ru(\mathbf{2})_2][PF_6]_2$ also exhibit a series of higher energy absorptions arising from ligand-centred $\pi^* \leftarrow \pi$ and $\pi^* \leftarrow$ n transitions. The MLCT bands of $[Fe(\mathbf{1})_2]^{2+}$ and $[Ru(\mathbf{1})_2]^{2+}$, and of the analogous complexes containing 2- and 3-pyridyl substituents, are sensitive to protonation at the pendant *N*-atom [12,38,39]. For example, red-orange $[Ru(\mathbf{1})_2]^{2+}$ (λ_{max} = 488 nm) turns pink when fully protonated (for $[Ru(H\mathbf{1})_2]^{4+}$, λ_{max} = 502 nm). The addition of an excess of trifluoroacetic acid to an acetonitrile solution of $[Ru(\mathbf{2})_2][PF_6]_2$ resulted in no shift in the position of the MLCT band, indicating that no protonation of the free nitrogen atoms on the pendant pyrazolyl substituents occurred. A similar experiment with $[Fe(\mathbf{2})_2][PF_6]_2$ also indicated that no protonation occurred; in the presence of a large excess of trifluoroacetic acid, the complex decomposed. Acetonitrile solutions of $[Ru(\mathbf{2})_2][PF_6]_2$, and solutions to which trifluoroacetic acid has been added, are non-luminescent.

Both the ruthenium and iron complexes $[M(\mathbf{2})_2]^{2+}$ are electrochemically active and each exhibits a number of reversible or quasi-reversible redox processes (Figs. S2 and S3). The M(II)/(MIII) redox processes are observed as fully reversible waves in the cyclic voltammogram (MeCN, $[Bu_4N][PF_6]$ supporting electrolyte, referenced to internal Fc/Fc^+) at +0.75 and +0.93 V for the iron and ruthenium species, respectively. These are very slightly shifted to more positive potential than the corresponding $[M(tpy)_2]^{2+}$ complexes (Ru, +0.88 V [43], Fe, +0.74 V) [38]. The iron complex also exhibits fully reversible one-electron reductions at −1.44 and

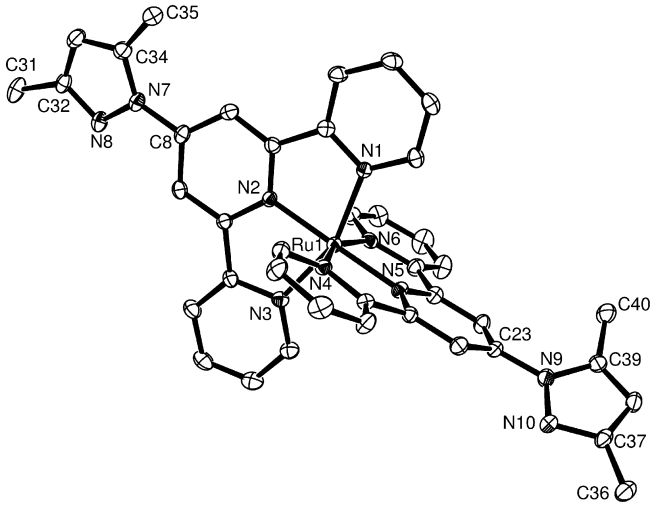

Fig. 3. Molecular structure of the $[Ru(2)_2]^{2+}$ cation in $[Ru(2)_2][PF_6]_2$ with thermal ellipsoids plotted at the 30% probability level; hydrogen atoms are omitted. Selected bond distances and angles: Ru1–N1 = 2.058(4), Ru1–N2 = 1.979(4), Ru1–N3 = 2.058(5), Ru1–N4 = 2.060(4), Ru1–N5 = 1.976(4), Ru1–N6 = 2.070(5), N7–N8 = 1.384(7), N9–N10 = 1.376(7), N7–C8 = 1.417(7), N9–C23 = 1.416(6), N7–C34 = 1.392(8), N9–C39 = 1.389(7) Å; N1–Ru1–N2 = 79.4(2)°, N2–Ru1–N3 = 78.8(2)°, N4–Ru1–N5 = 79.3(2)°, N5–Ru1–N6 = 78.7(2)°, N8–N7–C34 = 111.4(4)°, N10–N9–C39 = 111.9(4)°.

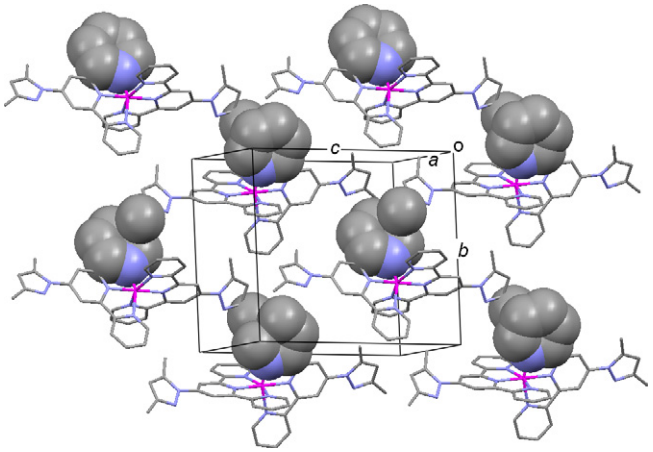

Fig. 4. Close contacts between pyridine π-systems and pyrazolyl Me substituents (shown in spacefilling representation) in the solid state structure of $[Ru(\mathbf{2})_2][PF_6]_2$. Anions and hydrogen atoms are omitted from the figure.

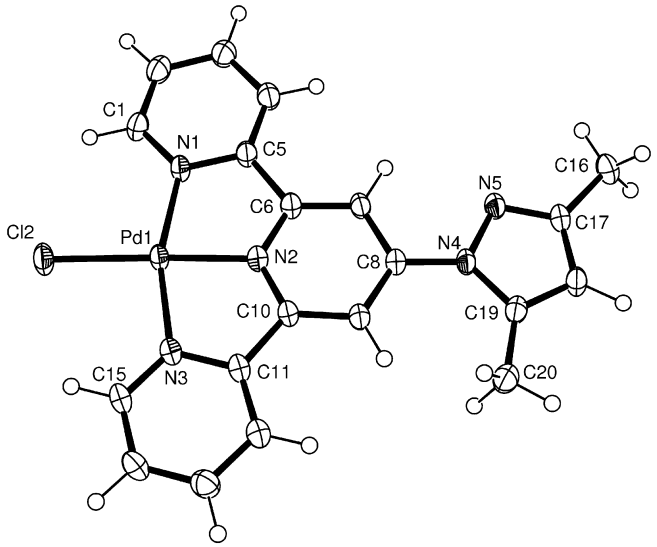

Fig. 5. Molecular structure of the $[Pd(\mathbf{2})Cl]^+$ cation in $[Pd(\mathbf{2})Cl][PF_6]$ with thermal ellipsoids plotted at the 50% probability level. Selected bond parameters: Pd1–Cl2 = 2.2932(6), Pd1–N1 = 2.030(2), Pd1–N2 = 1.941(2), Pd1–N3 = 2.021(2), N4–C8 = 1.388(3), N4–N5 = 1.381(3) Å; Cl2–Pd1–N1 = 100.13(6)°, Cl2–Pd1–N3 = 98.17(6)°, N1–Pd1–N2 = 80.73(8)°, N2–Pd1–N3 = 80.93(8)°.

−1.66 V, while the ruthenium compound shows reversible one electron-processes at −1.52 and −1.73 V. These correspond well to the ligand reduction in $[Fe(tpy)_2]^{2+}$ (−1.64 and −1.82 V) [38] and $[Ru(tpy)_2]^{2+}$ (−1.67 and −1.92 V) [38] with the shift to more positive potential of ~20 mV being attributed to the extended conjugation. In each case, there are additional quasi-reversible processes in the region of −2.3 V.

The homoleptic iron(II) and ruthenium(II) complexes each possess free *N*-donor coordination sites on the pendant pyrazolyl substituents. It is therefore of interest to investigate their use as building blocks in the formation of coordination polymers. As a preliminary experiment, we chose to investigate the reaction of $[Fe(\mathbf{2})_2][PF_6]_2$ with $PdCl_2$. An acetonitrile solution of these compounds with K_2CO_3 were stirred at room temperature overnight. The ^1H NMR spectrum of a CH_3CN solution of product precipitated as the hexafluoridophosphate salts showed the presence of $[Fe(\mathbf{2})_2][PF_6]_2$ and $[Pd(\mathbf{2})Cl][PF_6]$. X-ray quality crystals of $[Pd(\mathbf{2})Cl][PF_6]$ grew from the NMR solution (see below). No polymeric material was obtained from the reaction. $[Pd(\mathbf{2})Cl][PF_6]$ may also be prepared by treating $PdCl_2$ with $[H_2\mathbf{2}][MeOSO_3]_2$ in refluxing methanol. After the addition of NH_4PF_6, $[Pd(\mathbf{2})Cl][PF_6]$ was isolated in 40% yield. The base peak in the electrospray mass spectrum of the product appeared at *m*/*z* 469 with an isotopic distribution that was consistent with the $[Pd(\mathbf{2})Cl]^+$ ion. The palladium(II) complex is poorly soluble in most organic solvents. A ^1H

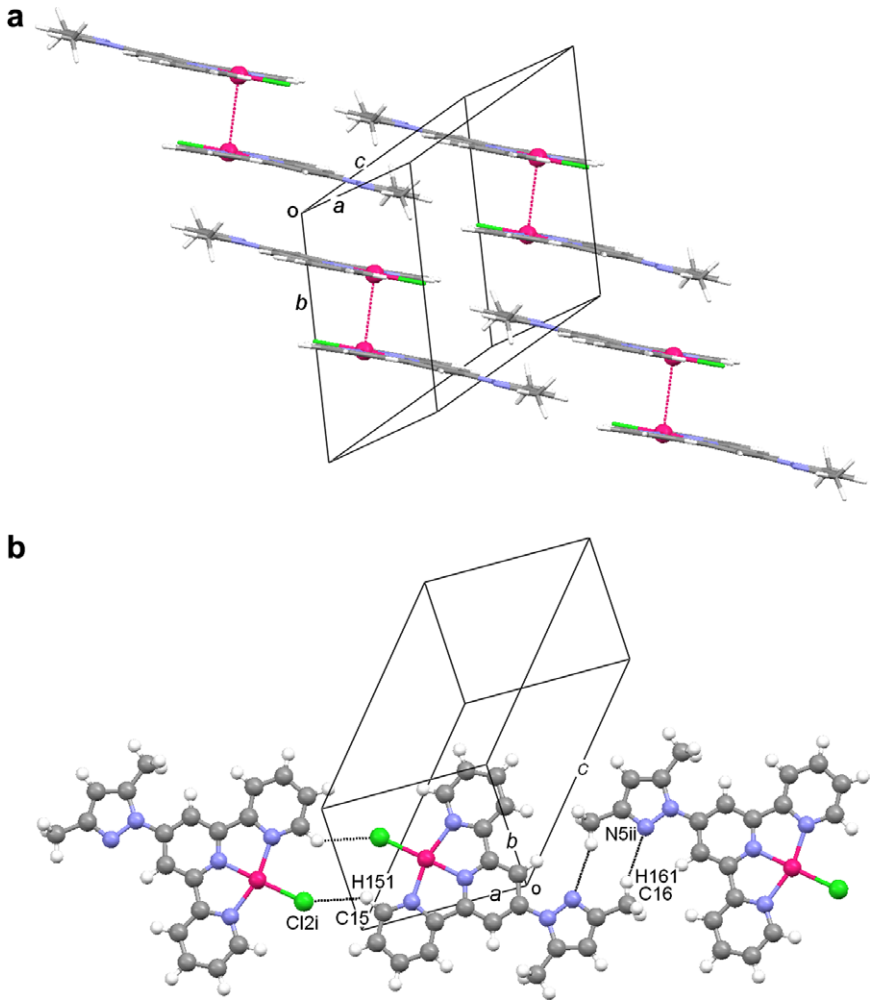

Fig. 6. (a) The assembly of step-like stacks of $[Pd(2)Cl]^+$ cations in $[Pd(2)Cl][PF_6]$. (b) Hydrogen-bonded interactions between stacks (symmetry codes: i = 2 − *x*, 1 − *y*, −*z*; ii = −1 − *x*, −*y*, −*z*).

NMR spectrum was obtained in DMSO-d_6 solution and was assigned by routine 1D and 2D-techniques. The signals for each of the tpy protons shifts to higher frequency, H^{A4} and H^{A5} being the most affected: $\Delta(\delta_{complex} - \delta_{free\ ligand}) = 0.45$ ppm for H^{A4} and 0.40 ppm for H^{A5} (both ligand and complex in DMSO-d_6). The resonances for the pyrazolyl ring proton, H^{C4}, and the methyl groups also show small shifts to higher frequency.

The structure of [Pd(**2**)Cl][PF_6] was confirmed by a single crystal X-ray diffraction study, and the molecular structure of the [Pd(**2**)Cl]$^+$ cation is depicted in Fig. 5. The palladium(II) centre is in a square planar environment, and bond parameters for the coordination sphere are as expected. Compared to the free protonated ligand [H_2**2**]$^{2+}$ in [H_2**2**][$EtOSO_3$]$_2 \cdot H_2O$, and the coordinated ligands in [Fe(**2**)$_2$]$^{2+}$ and [Ru(**2**)$_2$]$^{2+}$, the structure of the metal-bound ligand [Pd(**2**)Cl]$^+$ is noteworthy for the coplanarity of the central pyridine and the pendant pyrazolyl rings. The angle between the least squares planes of these rings is 1.0(2)°. The origin of this feature can be traced to the stacking of cations in the solid state. Fig. 6a illustrates that cations pair up by virtue of a short Pd···Pd contact of 3.3218(4) Å, and then these dimers assemble into step-like stacks, supported by aromatic π-interactions. The latter occur between sets of three heterocycles, viz. a pyridine ring containing N1 in sandwiched between a pyrazolyl ring and a pyridine ring containing N3, with inter-ring separations of ≈3.4 Å. Additional hydrogen-bond operate between the stacks, in the self-complementary pairs of interactions shown in Fig. 6b (C15H151···Cl2i = 2.78 Å, C15···Cl2i = 3.562(3) Å, C15H151···Cl2i = 135°; C16H161···N5ii = 2.61 Å, C16···N5ii = 3.566(3) Å, C16H161···N5ii = 160°). We recently reported the structure of [Pd(**1**)Cl]Cl · $3H_2O$ · DMF[44] in which the [Pd(**1**)Cl]$^+$ cations assemble into columns supported by ···Pd···Pd···Pd··· stacks. In this report, we discussed the structural classes of complexes containing {Pd(tpy)} or {Pt(tpy)} units, viz. those with ···M···M···M··· stacks and those with dimeric units.[1] The hexafluoridophosphate anions are disordered and have been modelled with each F atom disordered over two sites having fractional occupancies of 0.28 and 0.72.

4. Conclusions

In this paper, we have described the acid catalysed condensation of 4′-hydrazino-2,2′:6′,2″-terpyridine with pentane-2,4-dione to give alkyl sulfate salts of [H_2**2**]$^{2+}$. The conjugate base 4′-(3,5-dimethylpyrazol-1-yl)-2,2′:6′,2″-terpyridine, **2**, can be isolated by treatment of [H_2**2**][$ROSO_3$]$_2$ (R = Me or Et) with base, but for the synthesis of metal complexes containing ligand **2**, it is more convenient to use [H_2**2**][$ROSO_3$]$_2$ as the precursor. The complexes [Fe(**2**)$_2$]$^{2+}$, [Ru(**2**)$_2$]$^{2+}$ and [Pd(**2**)Cl]$^+$ have been prepared and characterized.

ABSTRACT

Three Mn^{II}-terephthalate coordination polymers, $\{Mn^{II}(tp)(bpy)(H_2O)\}_n$ (**1**), $\{Mn^{II}_3(tp)_{6/2}(bpy)_2\cdot(dmf)\}_n$ (**2**) and $\{Mn^{II}(tp)(phen)\}_n$ (**3**) (tp = terephthalic dianion, bpy = 2,2′-bipyridine, phen = 1,10-phenanthroline) have been synthesized and characterized by single crystal X-ray diffraction studies and low temperature (2–300 K) magnetic measurements. The structure analysis of **1**–**3** show that they all are coordination polymers composed of Mn atoms as nodes and terephthalate dianions as spacers. Interestingly, compound **1** consists of 1D infinite zigzag chains, while compound **2** consists of 2D sheets and compound **3** has a 3D framework structure. The study of the temperature dependent magnetic susceptibilities revealed that all of the polymers show antiferromagnetism.

1. Introduction

The design and construction of multi-dimensional functional metal-organic coordination polymers with metal ions as nodes and bridging ligands as spacers have attracted much attention from chemists in recent years [1–3]. This has arisen not only for their various intriguing topological structures, but also for their unexpected properties for potential practical applications in material chemistry, such as heterogeneous catalysis, gas sorption, storage and separations, molecular recognition, non-linear optics, luminescent and magnetic properties [4–6].

Selection of the appropriate multidentate ligand to link paramagnetic metal ions is a powerful way for the building of polyfunctional coordination polymers. As a multidentate ligand, terephthalic acid (H_2tp) and its dianion have been used in synthetic systems, not only because they can act as short bridges via one carboxylic group or long bridges via the benzene ring, leading to abundant varieties of multi-dimensional coordination polymers with various kinds of topology, but also terephthalic acid, as an example of a benzenedicarboxylic acid, has a rigid aromatic unit as a spacer which can make give rise to very special systems that can have interesting electronic and magnetic interactions between the metal ions in the network through possible conjugative interactions (shown in Scheme 1) [7,8]. On the other hand, the terminal ligands play an important role in the structures and properties of the coordination polymers [9].

Herein, we report the synthesis, crystal structure and magnetic properties of three manganese coordination polymers, $\{Mn^{II}(tp)(bpy)(H_2O)\}_n$ (**1**), $\{Mn^{II}_3(tp)_{6/2}(bpy)_2\cdot(dmf)\}_n$ (**2**) and $\{Mn^{II}(tp)(phen)\}_n$ (**3**) (tp = terephthalic dianion, bpy = 2,2′-bipyridine, phen = 1,10-phenanthroline, dmf = *N*,*N*-dimethylformamide), with the terephthalic dianion acting as a bridging ligand and 2,2′-bipyridine (in **1** and **2**) and 1,10-phenanthroline (in **3**) as terminal ligands.

2. Experimental

2.1. Materials and general methods

All reagents for the syntheses and analyses were obtained commercially, were of analytical grade and were used without further purification, and all manipulations were carried out in the laboratory atmosphere. Elemental analyses (C, H and N) were performed on a Perkin–Elmer 240C elemental analyzer. Infrared spectra were recorded as KBr pellets on a Bruker EQUIN0X 55 IR spectrometer. Magnetic measurements were carried out with polycrystalline samples on a Quantum Design MPMS XL-5 SQUID magnetometer. The diamagnetic corrections were evaluated from Pascal's constants.

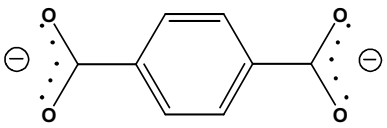

Scheme 1.

2.2. Syntheses of complexes *1* and *3*

2.2.1. $\{Mn^{II}(tp)(bpy)(H_2O)\}_n$ (*1*)

A mixture of $Mn(OAc)_2 \cdot 4H_2O$ (0.169 g, 1 mmol) in water (10 ml) and terephthalic acid (0.166 g, 1 mmol) in NaOH (80 mg, 2 mmol) aqueous solution (10 ml) were stirred at room temperature for about 12 h. Yellow crystals of compound **1** were obtained by diffusion of a 10 ml ethanol solution of 2,2′-bipyridine (0.156 g, 1 mmol) and the filtrate of the mixed solution after about 1 week (yield: about 32% based on Mn). *Anal.* Calc. for $\{Mn^{II}(tp)(bpy)(H_2O)\}_n$ (**1**): C, 54.98; H, 3.59; N, 7.12. Found: C, 55.01; H, 3.62; N, 7.16%. IR (KBr, cm^{-1}): 1576.53 s, 1475.14 m, 1438.82 s, 1378.05 s, 1151.97 m, 1058.54 w, 1018.48 m, 866.10 w, 805.18 m, 760.16 s, 736.45 m, 649.63 m, 524.31 m.

2.2.2. $\{Mn^{II}_3(tp)_{6/2}(bpy)_2 \cdot (dmf)\}_n$ (*2*)

A solution of $MnCl_2$ (0.136 g, 1 mmol) in 10 ml of water was added to a solution of terephthalic acid (0.249 g, 1.5 mmol) and 2,2′-bipyridine (0.156 g, 1 mmol) in DMF (10 ml), stirring for about 2 h at room temperature. Then the resulting solution was transferred into a Teflon-Steel autoclave inside a programmable electric furnace reactor. The mixed-solvo-thermal reaction lasted for about 3 days at about 423.15 K, and then the mixture was cooled to room temperature naturally. Yellow single crystals were obtained (yield = about 78% based on Mn). *Anal.* Calc. for $\{Mn^{II}_3(tp)_{6/2}(bpy)_2 \cdot (dmf)\}_n$ (**2**): C, 54.14; H, 3.38; N, 6.72. Found: C, 54.28; H, 3.51; N, 6.83%. IR (KBr, cm^{-1}): 1576.76 s, 1474.78 m, 1439.04 s, 1380.86 s, 1313.63 m, 1151.88 m, 1095.69 w, 1058.42 w, 1018.52 m, 971.55 w, 803.94 m, 760.23 s, 668.17 w, 649.94 m, 628.01 w, 524.9 m.

2.2.3. $\{Mn^{II}(tp)(phen)\}_n$ (**3**)

A solution of $MnCl_2$ (0.136 g, 1 mmol) in 10 ml of water was added to a solution of terephthalic acid (0.249 g, 1.5 mmol) and 1,10-phenanthroline (0.198 g, 1 mmol) in DMF (10 ml), stirring for about 2 h at room temperature. Then the resulting solution was transferred into a Teflon-Steel autoclave inside a programmable electric furnace reactor. The mixed-solvo-thermal reaction lasted for about 3 days at about 423.15 K, and then the mixture was cooled to room temperature naturally. Yellow single crystals were obtained (yield = about 82% based on Mn). *Anal.* Calc. for $\{Mn^{II}(tp)(phen)\}_n$ (**3**): C, 60.17; H, 3.01; N, 7.01. Found: C, 60.31; H, 3.19; N, 7.12%. IR (KBr, cm^{-1}): 1598.26 s, 1514.15 m, 1495.77 w, 1425.86 m, 1387.00 s, 1100.70 w, 1046.49 w, 1024.00 w, 890.79 w, 863.80 w, 846.12 m, 807.17 m, 770.50 w, 750.31 s, 729.00 m, 633.97 w, 505.50 m.

2.3. Crystallographic data collection and refinement

X-ray diffraction measurements were performed on a Bruker SMART diffractometer equipped with a CCD area detector with graphite-monochromated Mo Kα radiation (Kα = 0.71073 Å) at about 290(2) K. The reflections were successfully indexed by an automated indexing routine built in the SMART program [10]. The solutions were solved by direct methods and refined by full-matrix least-squares calculations on F^2 with SHELX-97 [11]. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were located in the calculated positions using the riding model. Crystallographic data and refinement details for the structural analyses of all the complexes are summarized in Table 1, and selected bond lengths and angles with their estimated standard deviations for complexes **1**–**3** in are in Tables 2–4, respectively.

3. Results and discussion

3.1. Description of the crystal structures of complexes **1**–**3**

3.1.1. $\{Mn^{II}(tp)(bpy)(H_2O)\}_n$ (**1**)

X-ray single crystal structure determination reveals that complex **1** is a neutral one-dimensional infinite zigzag coordination chain. Each Mn^{II} center coordinates to two N donors of one 2,2′-bipyridine, three oxygen atoms belonging to two different carboxyl groups of two different terephthalic acid molecules and one water molecule, forming a distorted octahedral geometry as shown in Fig. 1a. Then, two neighboring Mn^{II} centers are connected by a terephthalic dianion which acts as a long bridge through the benzene ring as shown in Scheme 1. The 2,2′-bipyridine molecule acts as a terminal ligand which prevents the chain from growing in a straight forward direction, and making it into a zigzag chain. (Fig. 1b). Selected bond lengths and angles are listed in Table 2.

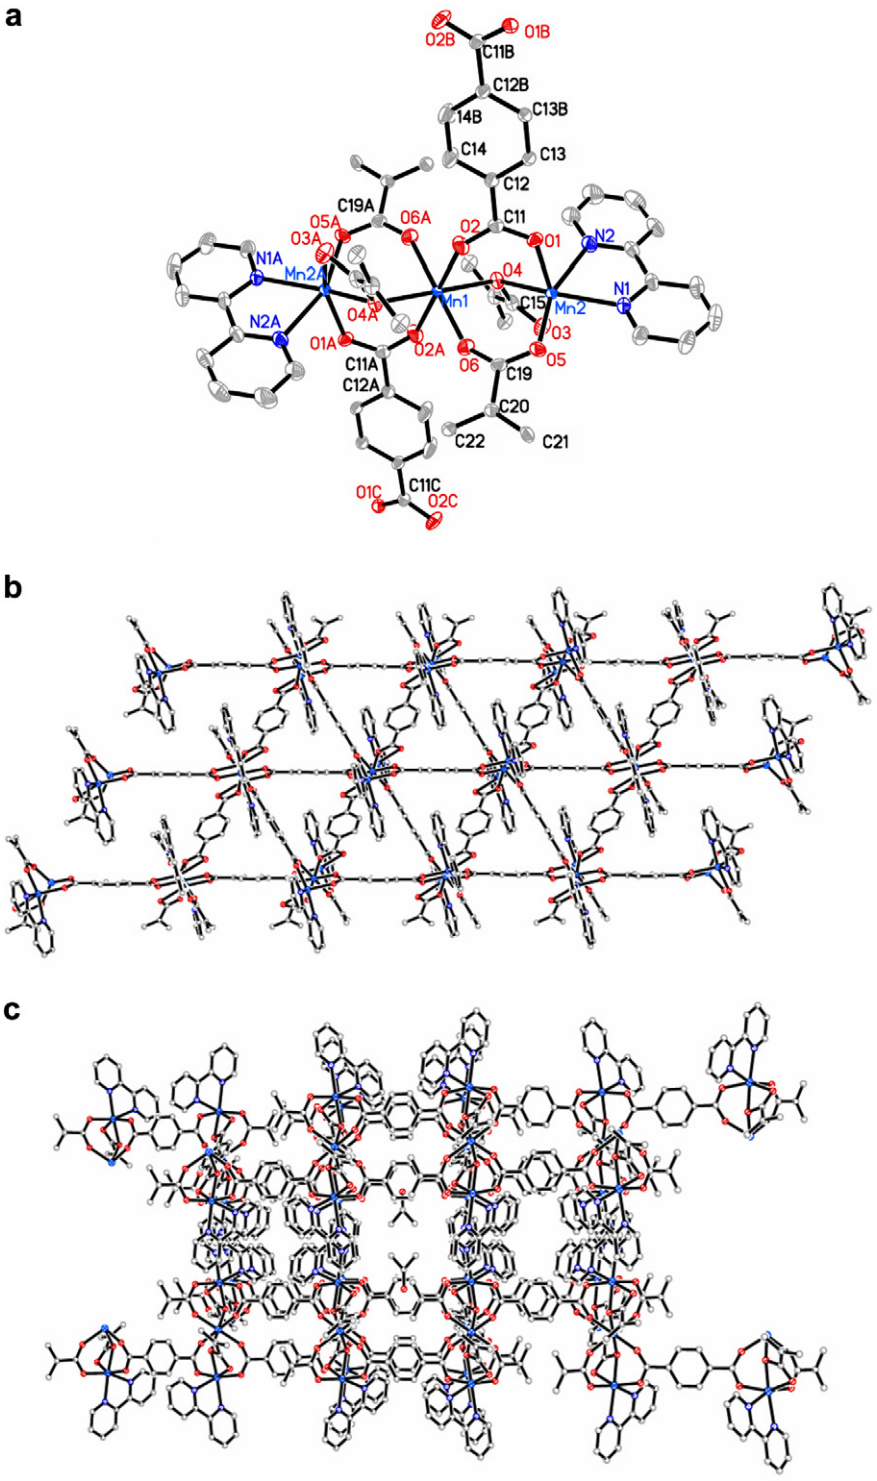

Fig. 2. (a) Perspective view of the trinuclear node of **2**; (b) perspective view of the two-dimensional sheet of **2**, viewing along the *b* axis; (c) crystal packing diagram of **2** along the *c* axis, showing the $\pi\cdots\pi$ stacking interaction between two sheets.

Analysis of the crystal packing of **1** in the unit cell indicates that there is one type of independent inner-chain O–H···O hydrogen bond and one kind of independent inter-chain O–H···O hydrogen bond (Table 3). The former is formed by the O–H group of the coordinated water molecule with the uncoordinated oxygen atom of the neighboring carboxyl groups of the terephthalic dianion in an asymmetric unit with a D···A distance of 2.6749(18) Å and an O–H–O angle of 147.1°. The inter-chain O–H···O hydrogen bonds are formed by the O–H group of the coordinated water molecule in one coordination chain with one of the coordinated oxygen atoms of the carboxyl groups of the terephthalic dianion in the adjacent coordination chain, with a D···A distance of 2.7111(17) Å and an O–H–O angle of 165(3)°.

3.1.2. $\{Mn^{II}_3(tp)_{6/2}(bpy)_2 \cdot (dmf)\}_n$ (**2**)

The crystal structure analysis shows that complex **2** adopts a 2D framework. The 2D skeleton is formed by Mn ions as nodes and tp dianions as spacers, through coordination bonds. At each node there are three Mn^{II} atoms that are in a linear arrangement with Mn···Mn distances of 3.266 Å (Fig. 2a), all of which have a distorted octahedral geometry and two adjacent octahedrons share a triangular face. The middle Mn^{II} atom is coordinated by six oxygen atoms (Mn–O = 2.038(3)–2.254(3) Å) belonging to six different tp carboxylate groups, while each of the two terminal Mn^{II} atoms is coordinated by four oxygen atoms (Mn–O = 2.038(3)–2.254(3) Å) belonging to four different tp carboxylate groups and two nitrogen atoms (Mn–N = 2.038(3)–2.254(3) Å) of one chelating 2,2′-bipyridine ligand.

Each three Mn^{II}-atoms-cluster node is bridged by six tp ligands in six directions in the 0 1 0 plane with two 2,2′-bipyridine ligands upon and down the plane, respectively, and the angles between the two directions are nearly 60° (Fig. 2b). Every three nodes are connected by three tp ligands along the 1 0 0, 1 0 1 and 2 0 1 planes to form an equilateral triangle. Then the remarkable two-dimensional

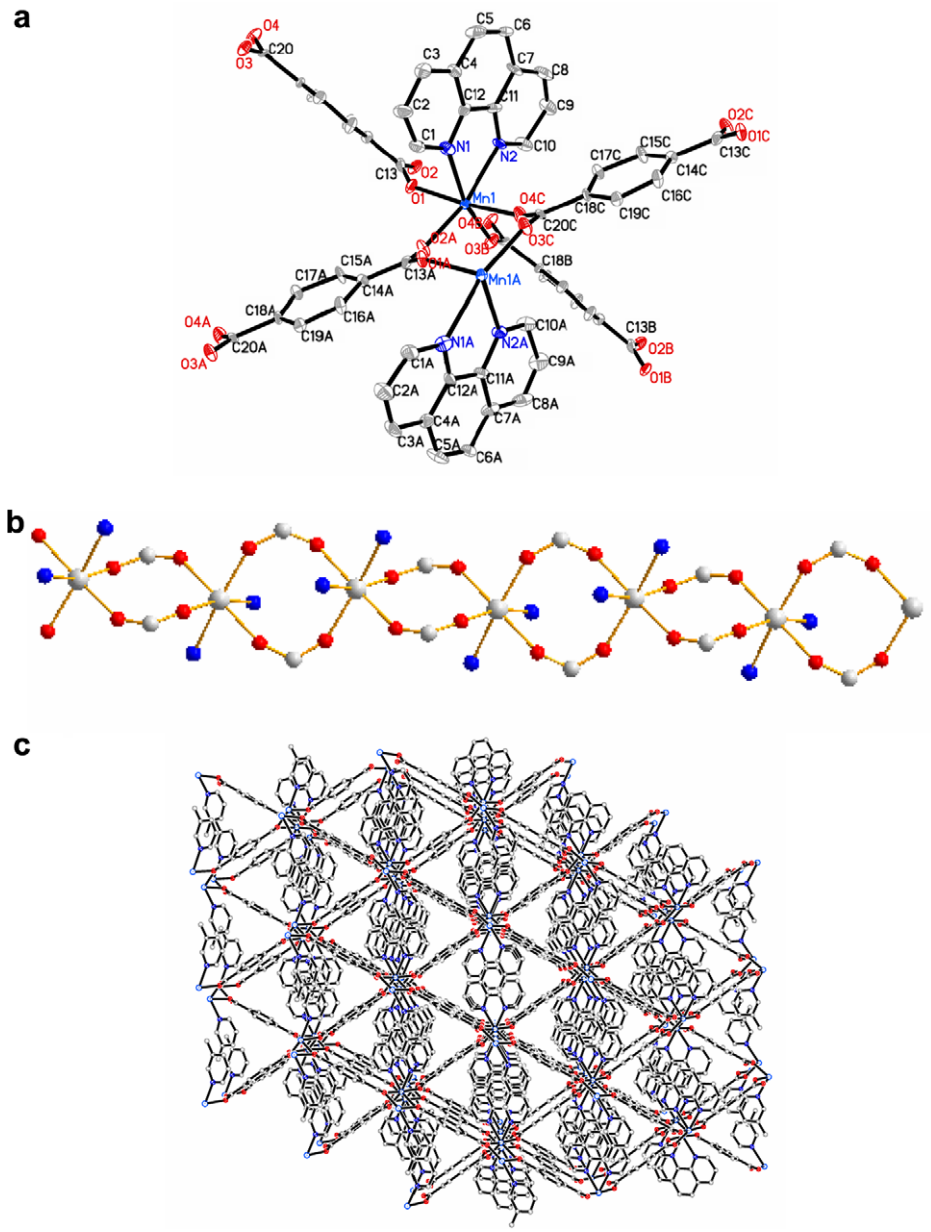

Fig. 3. (a) Perspective view of the asymmetry unit of **3**; (b) perspective view of the one-dimensional $\{Mn\}_n$ chain of **3**; (c) perspective view of the three-dimensional framework of **3** along the *c* axis.

sheets are formed by the equilateral triangle arrays (Fig. 2b). The distance between two adjacent 2,2′-bipyridine ligands of two neighboring sheets is 3.446 Å, which is within the range of $\pi\cdots\pi$ stacking interactions, 3.3–3.7 Å. The $\pi\cdots\pi$ stacking interactions between the two sheets connects the sheets into a 3D coordination polymer (Fig. 2c), the interspace of which is filled by isolated DMF molecules.

3.1.3. $\{Mn^{II}(tp)(phen)\}_n$ (3)

The crystal structure analysis shows that there is one terephthalic ligand, one 1,10-phenanthroline ligand and one Mn^{II} atom in each asymmetric unit of complex **3**, which build up a three-dimensional structural framework. Each Mn^{II} atom has a distorted octahedral geometry, being coordinated to four oxygen atoms (Mn–O = 2.106(2)–2.145(2) Å) belonging to four different carboxyl groups of four different terephthalic dianions, and two nitrogen atoms of one phen molecule (Mn–N = 2.323(2)–2.368(2) Å) (Fig. 3a).

The bidentate carboxylate groups, in pairs, belong to two different terephthalic dianions and, acting as short bridges, bridge two neighboring Mn atoms to form an eight-membered ring in a chair configuration. One of the two Mn atoms and another neighboring Mn atom are bridged by two other bidentate carboxylate groups in a pair to form another eight-membered ring plane. The two planes cross with angles of nearly 60°, and each two crossed eight-membered rings alternatively bridge the neighboring Mn atoms to form 1D $[Mn_2(CO_2)_2(phen)_2]_n$ chains with Mn···Mn distances of 4.7894 Å (Fig. 3b). Then the terephthalic dianions, acting as long bridges via the benzene ring in the directions of the two basal eight-membered ring planes, link $[Mn_2(CO_2)_2(phen)_2]_n$ chains to form the 3D structure of **3** and 1D channels along the 1D $[Mn_2(CO_2)_2(phen)_2]_n$ chains.

The 1D channels along the 1D $[Mn_2(CO_2)_2(phen)_2]_n$ chains in **3** are filled with coordinated 1,10-phenanthroline molecules. It should be pointed out that the mean distance of two neighboring face-to-face stacked 1,10-phenanthroline molecules is about 3.629 Å, which is within the range of $\pi\cdots\pi$ stacking interactions, 3.3–3.7 Å.

3.2. Magnetic properties

The variation of the molar magnetic susceptibilities χ_M was investigated for compounds **1**–**3** in the temperature range 2–300 K at a field of 1000 Oe. The study of the temperature dependent magnetic susceptibilities revealed that all the compounds show antiferromagnetic behaviour.

The thermal variation of χ_M^{-1} and $\chi_M T$ of **1** are displayed in Fig. 4a. According to the χ_M^{-1}–T curve, the magnetic behavior of **1** follows the Curie–Weiss law $\chi_M = C/(T-\theta)$ with a Curie constant C value of 4.14 $cm^3\,K\,mol^{-1}$ and a Weiss temperature θ of −0.70 K. The value of $\chi_M T$ at 300 K is 4.64 $cm^3\,K\,mol^{-1}$ per Mn^{II}, which is slightly above the expected value for the $S = 5/2$ spin-only ground state per couple of uncorrelated Mn^{II} centers (4.35 $cm^3\,K\,mol^{-1}$). This value decreases smoothly to close to 3.35 $cm^3\,K\,mol^{-1}$ at 2 K. Such magnetic behavior is typical for an antiferromagnetic coupling between the Mn^{II} ions in the chain. The magnetic susceptibility of **1** has been fitted to the Fisher model [12] of the isotropic Heisenberg antiferromagnet, and later modified by Wagner and Friedberg [13] for a Mn^{2+} system of spin 5/2, which is

$$\chi = \frac{NS(S+1)}{3kT}g^2\beta^2\frac{1-u(K)}{1+u(K)} \qquad (1)$$

where $u(K)$ is $1/K - \coth(K)$, $K = 2JS(S+1)/kT$, $g = 2$, $S = 5/2$ for Mn(II) and N, β, K, g and T have their usual meanings. Due to the interaction between adjacent chains, the fit function can be modified to include the inter-chain coupling [14]. The function, therefore, is

$$\chi_M = \frac{\chi}{1-(2zJ'/Ng^2\beta^2)\chi} \qquad (2)$$

where J' is the inter-chain exchange coupling constant and z is the number of the nearest neighbor chains. The best fitting for the data in the range of 2–300 K gives $J = -0.035$ cm^{-1}, $zJ' = +0.028$ cm^{-1} and $g = 2.00$, with $R = 4.2\times10^{-6}$, $\left[R = \left[\sum(\chi_{obs}-\chi_{calc})^2/\sum(\chi_{obs})^2\right]\right]$.

According to the χ_M^{-1}–T curve, the magnetic susceptibility data for **2** also fit well to the Curie–Weiss law in the range 2–300 K and give a Curie constant C value of 10.8 $cm^3\,K\,mol^{-1}$ and a Weiss temperature θ of −1.81 K. The value of $\chi_M T$ at 300 K is 10.85 $cm^3\,K\,mol^{-1}$ per tri-Mn^{II} unit. These value decreases smoothly to close to 7.83 $cm^3\,K\,mol^{-1}$ at 2 K. Such magnetic behavior shows antiferromagnetic couplings between the Mn^{II} ions.

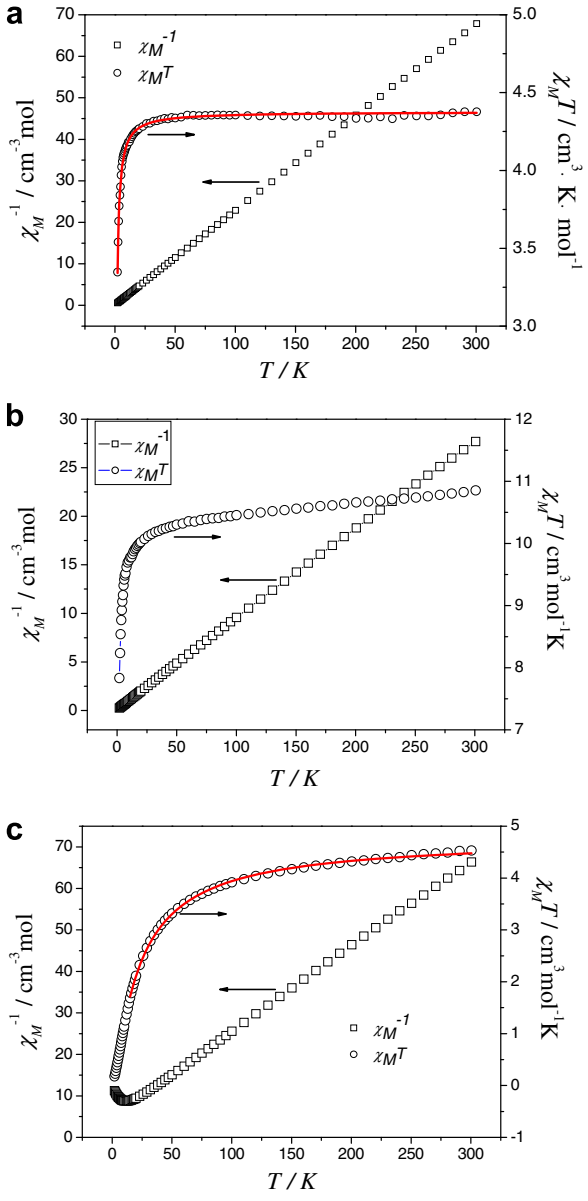

Fig. 4. (a) The thermal variation of χ_M^{-1} and $\chi_M T$ of **1**; (b) the thermal variation of χ_M^{-1} and $\chi_M T$ of **2**; (c) the thermal variation of χ_M^{-1} and $\chi_M T$ of **3**.

The magnetic susceptibility data for **3** also follows the Curie–Weiss law in the range 12–300 K ($C = 5.10\ cm^3\ K\ mol^{-1}$, $\theta = -34.4$ K). At 300 K, the $\chi_M T$ value of **3** is $4.53\ cm^3\ K\ mol^{-1}$, which is slightly above the expected value for $S = 5/2$ of a spin-only ground state per couple of uncorrelated Mn^{II} centers ($4.35\ cm^3\ K\ mol^{-1}$). This value decreases smoothly to close to $0.18\ cm^3\ K\ mol^{-1}$ at 2 K. The decrease of $\chi_M T$ is attributed to antiferromagnetic interactions between the Mn^{II} ions. As mentioned above, the 3D structure of **3** can be viewed as $[Mn_2(CO_2)_2(phen)_2]_n$ chains linked by a long bridge, the terephthalic dianions. So we can evaluate the value of the couplings via the Fisher model as in the case of **1**, where zJ' is the inter-chain interactions of the neighboring $[Mn_2(CO_2)_2(phen)_2]_n$ chains. The best fitting for the data in the range 15–300 K gives $J = -0.53\ cm^{-1}$, $zJ' = -0.69\ cm^{-1}$ and $g = 2.09$, with $R = 3.2 \times 10^{-5}$, $\left[R = \left[\sum(\chi_{obs} - \chi_{calc})^2 / \sum(\chi_{obs})^2\right]\right]$.

Comparing the magnetic properties of **1**–**3**, especially the Weiss constants (−0.70, −1.81 and −34.4 K, respectively), it is obvious that the antiferromagnetic coupling in **1** and**2** is much weaker than that in **3**, which mainly results from the difference between their structures. Compound **1** can be viewed as having isolated Mn^{II} nucleii and **2** can be viewed as isolated trinuclear Mn^{II} clusters separated by the terephthalate ligands, which act as long bridges via the benzene ring, while compound **3** can be regarded as infinite 1D Mn^{II} chains linked by short three-atom O–C–O bridges.

4. Conclusion

Three Mn^{II}-terephthalate coordination polymers have been synthesized with different terminal ligands, and the crystal structure analyses show that the compounds are in the form of 1D infinite chains or 2D sheets with 2,2′-bipyridine as a terminal ligand, while the compound with 1,10-phenanthroline as a terminal ligand has a 3D framework. Despite the different structures, a magnetic investigation indicates that all three coordination polymers show antiferromagnetism. Further works are focused on investigation of the influence of other multidentate ligands and terminal ligands to the structures and properties of the coordination polymers.

ABSTRACT

Metal complexes of Schiff bases derived from an aromatic hydrazide are well characterised and have been reported several times. Single crystal structures of metal hydrazone complexes derived from an aliphatic hydrazide are very rare and still remain unexplored. In this paper we report two new end-on azido bridged dinuclear copper(II) and cobalt(III) hydrazone complexes derived from an aliphatic hydrazide. The Schiff base [**LH** = $CH_3C(O)NHN{=}CHC_5H_4N$] has resulted from the condensation of acetic hydrazide and pyridine-2-carboxaldehyde. The ligand and the complexes $[Cu_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ (**1**) and $[Co_2(L)_2(\mu_{1,1}\text{-}N_3)_2(N_3)_2]$ (**2**) are characterised by elemental analysis, IR and UV–Vis spectral studies and in addition mass spectroscopy has been also carried out for **LH**. The structures of **1** and **2** have been established by X-ray crystallography. Variable temperature magnetic susceptibility measurement studies of **1** indicate the $\chi_M T$ values remain constant in the whole range of temperature 10 to 300 K at a value close of 0.75 $cm^3\,K\,mol^{-1}$, which is in good agreement with the one expected for two uncoupled copper(II) centers.

1. Introduction

Synthesising dinuclear complexes using tridentate Schiff bases and bridging ligands have been carried out by many authors [1]. Coordination sites of metal ions which prefer square pyramidal geometry are blocked by such tridentate Schiff base ligands and to saturate the coordination number of the metal ion a bridging ligand (e.g. N_3, NCO, NCS, NCSe) is used to synthesise such dinuclear complexes [2–5]. Aroylhydrazones of pyridine-2-carboxaldehyde act as a potentially tridentate blocking ligand and can coordinate a given metal ion via the pyridine-N, the imine–N and the amide–O centres. Moreover, these ligands exhibit keto–enol tautomerism and can coordinate metal ions in neutral and monoanionic forms [6]. Metal complexes of aromatic hydrazide and aroylhydrazones have been synthesised earlier by Mitra and his group [7] and recently pseudohalide bridged dinuclear and polynuclear metal complexes of (*E*)-*N*′-((pyridin-2-yl)methylene)benzohydrazide have been reported by his research group [8]. Although metal complexes of aromatic hydrazones have been thoroughly explored, metal complexes of aliphatic hydrazones are yet to be explored. In order to exploit the bridging abilities of the pseudohalides several pseudohalide bridged Schiff base metal complexes of different nuclearities have been synthesised [9–11]. Such complexes especially dinuclear and polynuclear have drawn attention of many authors as they show significant structural variations and can act as potent magnetic materials. Magnetic interactions between the metal centers of such complexes can be tuned by skillful control of the chain length and the byte angle of the bridging ligands and in this respect the azide ion plays a significant role. The different types of binding modes of azide ion are shown in Fig. 1. The end-to-end or 1,3-coordination mode of N_3^- results in antiferromagnetic coupling between the metal centres but if the bond angle in M-$\mu_{1,3}$-N_3–M is very large then the sign of the coupling may be reversed [12–15]. In contrast the end-on or 1,1-coordination mode produces ferromagnetic coupling but the ferromagnetic ordering between the metal centres is reduced if the bridging byte angle exceeds 108° [16]. Dinuclear copper(II) complexes with such azide bridges have been extensively studied as they show interesting structural, magnetic, catalytic, and electron transfer properties [17–20]. Even though azide ion acts as an inhibitor of metalloprotein activities [21–23] such dinuclear azido bridged copper(II) complexes have been studied extensively [23] as dinuclear and trinuclear metallo species can act as models for active sites of metallo proteins [21a,21b,24–27].

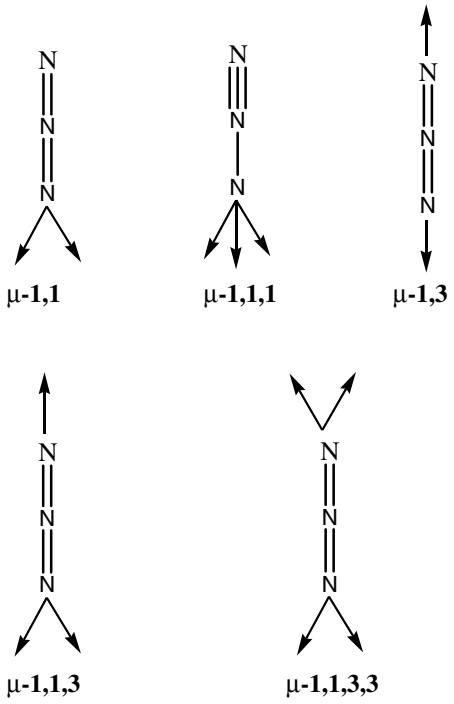

Fig. 1. Different types of binding modes of azide ion.

As an extension of the earlier work, we report two new end-on azido bridged hydrazone metal complexes $[Cu_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ (**1**) and $[Co_2(L)_2(\mu_{1,1}\text{-}N_3)_2(N_3)_2]$ (**2**) where [**LH** = $CH_3C(O)NHN{=}CHC_5H_4N$] obtained from condensation of acetic hydrazide and pyridine-2-carboxaldehyde. Aromatic hydrazides have been used so far for the preparation of Schiff bases but here we have especially chosen an aliphatic hydrazide and have condensed it with pyridine-2-carboxaldehyde to prepare the Schiff base ligand (**LH**) and have successfully synthesised two new complexes of copper(II) and cobalt(III) where N_3^- anion have bridged the respective metal centres in its end-on 1,1-coordination mode. To the best of our knowledge metal complexes of aliphatic hydrazones are rare in the literature and our group is the first to synthesise and characterise metal complexes of the (*E*)-*N*′-((pyridin-2-yl)methylene) acetohydrazide Schiff base ligand. Low temperature magnetic studies have been carried out on 1 in order to see the extent of variation caused by replacing the aromatic ring with a methyl group in the Schiff base ligand **LH**. Other routine studies have also been carried out on both the complexes and have been described.

2. Experimental

2.1. Materials

All chemicals and solvents used for the syntheses were of analytical grade. Acetichydrazide, pyridine-2-carboxaldehyde (Fluka), sodium azide (Aldrich) were used as received. Copper perchlorate hexahydrate and cobalt perchlorate hexahydrate were prepared by treatment of copper carbonate and cobalt carbonate (E. Merck, India), respectively, with 60% aqueous perchloric acid (E. Merck, India) followed by slow evaporation on a steam bath. It was then filtered through a fine glass frit and preserved in a desiccator.

2.2. Syntheses

Caution! Perchlorate salts are potentially explosive and should be used in small quantity and with much care.

2.2.1. Synthesis of the Schiff base ligand

*2.2.1.1. $[CH_3C(O)NHN{=}CHC_5H_4N]$ (**LH**).* The ligand **LH** was prepared by the condensation of acetichydrazide (0.74 g, 10 mmol) with pyridine-2-carboxaldehyde (0.95 ml, 10 mmol) in presence of glacial acetic acid (0.6 ml, 10 mmol) in methanol medium. On refluxing the methanolic solution for 5 h a pale yellow colouration was observed. The colour indicated the formation of the Schiff base ligand **LH**. The resulting light yellow liquid was used without further purification. The scheme of synthesis and the keto–enol tautomerisation of the ligand **LH** is shown in Fig. 2.

2.2.2. Syntheses of the complexes

*2.2.2.1. $[Cu_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ (**1**).* To a 20 ml methanolic solution of copper perchlorate hexahydrate (0.370 g, 1 mmol), methanolic solution of the hydrazone ligand (**LH**) (1 mmol) was added dropwise while the mixture was stirred. It was then followed by the addition of sodium azide (0.065 g, 1 mmol) in minimum volume of water–methanol mixture. The mixture was stirred for 2 h at room temperature and then filtered. The filtrate was kept at refrigerator temperature yielding bluish green, plate shaped crystals suitable for X-ray diffraction after a week. Bluish green crystals were isolated by filtration and air-dried. *Anal.* Calc. for $[C_8H_8N_6O\text{-}Cu]$: C, 35.85; H, 2.98; N, 31.37. Found: C, 35.95; H, 3.01; N, 31.41%.

2.2.3. $[Co_2(L)_2(\mu_{1,1}\text{-}N_3)_2(N_3)_2]$ (**2**)

To a 20 ml methanolic solution of cobalt perchlorate hexahydrate (0.365 g, 1 mmol), methanolic solution of the hydrazone ligand (**LH**) (1 mmol) was added dropwise and stirred. Sodium azide (0.130 g, 2 mmol) in minimum volume of water–methanol mixture was added to the mixture and was stirred for 3 h at 40 °C. While stirring the colour of the solution changed from red to dark brown. The brown solution was kept at refrigerator temperature yielding dark green, needle shaped crystals suitable for X-ray diffraction after a week. Crystals were isolated by filtration and were air-dried. *Anal.* Calc. for $[C_8H_8N_9OCo]$: C, 31.45; H, 2.62; N, 41.28. Found: C, 31.48; H, 2.69; N, 41.31%.

2.3. Physical measurements

Elemental analyses were carried out using a Perkin–Elmer 2400 II elemental analyser. The infrared spectra were recorded on a Perkin–Elmer RX 1 FT-IR spectrophotometer with a KBr disc. The electronic spectra were recorded, in acetonitrile, on a Perkin–Elmer Lambda 40 (UV–Vis) spectrophotometer. Electrochemical measurements were performed on a VersaStat–PotentioStat II cyclic voltammeter using HPLC grade acetonitrile solution as solvent and tetrabutylammonium perchlorate was used as supporting electrolyte at a scan rate 0.05 V/s. Platinum and saturated calomel electrode (SCE) were the working and the reference electrodes in the process, respectively. Mass spectra of the ligand (**LH**) was recorded by Qtof Micro YA mass spectrophotometer. Variable-temperature magnetic susceptibility measurements were carried out with a Quantum Design MPMS-5S SQUID magnetometer under an applied magnetic field of 5000 Oe. Diamagnetic corrections were estimated from Pascal tables and magnetic data were corrected for diamagnetic contributions of the sample holder. The temperature dependence of the molar magnetic susceptibility, χ_M, was measured on a polycrystalline sample in the temperature range 4–300 K.

2.4. X-ray crystallography

The X-ray diffraction experiments were carried out at 203 K on a bluish green plate shaped single crystal (0.42 mm × 0.38 mm × 0.05 mm) of **1** and a dark green needle shaped single crystal (0.42 mm × 0.18 mm × 0.16 mm) of **2**. The single crystals of **1**

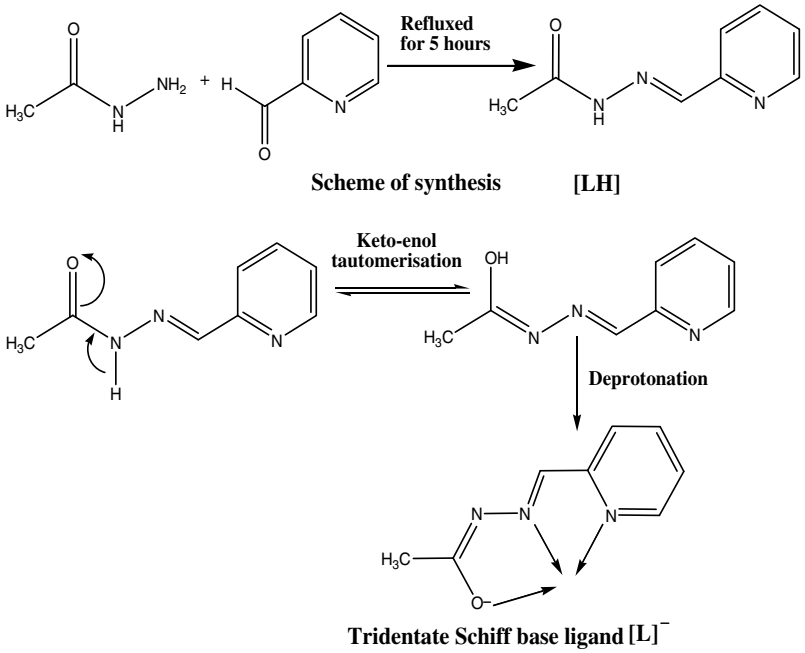

Fig. 2. Scheme of synthesis and keto–enol tautomerisation of [**LH**].

and **2** were mounted on the tip of a glass fibre and was exposed to a graphite monochromatised Mo $K\alpha$ radiation ($\lambda = 0.71073$ Å) emerging from a fine-focus sealed tube. The intensity data collection was performed with Oxford Diffraction Gemini R-Ruby diffractometer using multi scan technique. Data collection and cell refinement were performed using CRYSALISPRO software [28]. The structures of the two complexes were solved by direct method procedures in SHELXS and refined by full-matrix least-squares methods in SHELXL [29]. The calculations were carried out with the WINGX package program [30] running on a PC. Carbon-bonded hydrogen atoms were included in idealised positions and set to ride on the parent atoms. Selected crystallographic data, experimental conditions and some important features of the structural refinements of both the complexes are summarised in the Table 1.

Table 1
Crystallographic and refinement data for **1** and **2**

Complex	**1**	**2**
Chemical formula	$C_{16}H_{16}Cu_2N_{12}O_2$	$C_{16}H_{16}Co_2N_{18}O_2$

Largest difference in peak and hole (e Å^{-3})	0.505 and −0.335	0.762 and −0.434

3. Results and discussion

The formation of the new Schiff base ligand (*E*)-*N*′-((pyridin-2-yl)methylene) acetohydrazide (**LH**) has been supported by infrared and mass spectroscopy. IR bands obtained at 1666 cm^{-1} clearly indicate the presence of an imine functionality which must have resulted due to the condensation of acetic hydrazide with pyridine-2-carboxaldehyde. IR bands at 3339 and 3302 cm^{-1} for the asymmetric and symmetric –NH_2 stretching were not observed which indicate that the primary amine functionality of acetic hydrazide has successfully condensed with the carbonyl functionality of pyridine-2-carboxaldehyde.

The mass spectrum also ensures the formation of the Schiff base ligand (**LH**). The mass spectrum of the ligand (**LH**) shows peak at m/e 186 which is attributed to the molecular ion peak $[C_8H_9N_3O\text{-}Na]^+$. In the mass spectrum the highest intensity peak was obtained at m/e 186 (100%) may be assigned to the neural hydrazone ligand **LH** bound to one sodium ion to generate molecular ion. Hence it is assertive from the mass spectrum that the proper condensation of the acetic hydrazide and pyridine-2-carboxaldehyde has resulted the Schiff base ligand (**LH**).

The most conclusive evidence which supports the condensation of acetic hydrazide with pyridine-2-carboxaldehyde is the single crystal X-ray study of **1** and **2** which clearly indicate the coordination of the deprotonated tridentate hydrazone ligand ($\mathbf{L}^-$) to the respective metal centres.

3.1. Infrared spectra

The IR spectra of **1** and **2** were analysed in comparison with that of the free ligand (**LH**) in the region 4000–250 cm^{-1}. The IR spectrum of the hydrazone ligand contains a strong C–O absorption band at 1651 cm^{-1} and a N–H absorption band at 3186 cm^{-1}. Both of these bands disappear on complexation, and a new C–O absorp-

tion band appears at 1086 and 1084 cm^{-1} in the two complexes, indicating that the hydrazone ligands have undergone deprotonation on complexation. These data give evidences for the coordination of the deprotonated Schiff base ligand to the respective metal ions [Cu(II) and Co(III)] via two nitrogen atoms and one oxygen atom. The infrared spectra of **1** and **2** display IR absorption bands at 1617, and 1605 cm^{-1} which can be assigned to the C=N stretching frequencies of the deprotonated coordinated ligand, whereas for the free ligand (**LH**) the same bands are observed at 1666 cm^{-1}, respectively. The shift of these bands on complexation towards lower wave number indicates coordination of the imine nitrogen to the metal center [31]. In the spectra of complexes strong, well resolved sharp bands at 2053 cm^{-1} and a bifurcated peak at 2076 and 2014 cm^{-1} were obtained for **1** and **2**, respectively, which are assigned to $\upsilon_{N=N}$ of the azide (N_3) group coordinated to two different metal centers, respectively. The ligand coordination to the metal center is substantiated by two bands appearing for each complex, at 414, 318 (**1**) and 421, 310 (**2**) cm^{-1} attributable to υ_{M-N} and υ_{M-O}, respectively, where M = Cu(II) for **1** and M = Co(III) for **2**. The low energy pyridine ring in-plane and out-of-plane vibrations observed in the spectrum of **LH** at 611 and 412 cm^{-1} but for the complexes are shifted to higher frequencies at 632, 640 cm^{-1} and 420, 428 cm^{-1} for **1** and **2**, respectively, which is a good indication of the coordination of the heterocyclic nitrogen to the metal centers [32].

3.2. Electronic spectra

The electronic spectral data for the complexes in acetonitrile are in good agreement with their geometries. The UV absorption bands exhibit a charge transfer transition (CT) in the range 360–390 nm for **1** and may be assigned to the ligand-to-metal charge transfer transition. The spectrum of **1** displays a broad band at 650 nm which is consistent with the expected five-coordinate geometry for copper(II) complex. For **2**, containing distorted octahedral cobalt(III) centers, the band at 570 nm appeared due to $^1A_{1g} \rightarrow {}^1T_{1g}$ transition. The higher energy band $^1A_{1g} \rightarrow {}^1T_{2g}$ was obscured by ligand to metal charge transfer bands obtained in the broad range 410–375 nm.

3.3. Cyclic voltammetry

Electrochemical properties of **1** and **2** were studied in HPLC grade acetonitrile medium with tetrabutylammonium perchlorate as supporting electrolyte at a scan rate 50 mV s^{-1}. Peaks corresponding to the potentials +1.0 V and −0.41 V were obtained for **1**. Anodic response obtained near +1.0 V (versus SCE) is believed to be due to $Cu^{II} \rightarrow Cu^{III}$ oxidation; the oxidized complex is too reactive to survive for the cathodic scan. The complex displays an irreversible reduction at −0.41 V (versus SCE) corresponding to the $Cu^{II} \rightarrow Cu^{I}$ reduction couple. The voltammogram of **2** shows peak at −0.15 V (versus SCE) which can be attributed for the reduction of cobalt(III) to cobalt(II). Another peak obtained at 0.12 V (versus SCE) is assigned to the oxidation of cobalt(II) to cobalt(III). This process is completely irreversible, characterised by a peak to peak separation (ΔE_p) of 270 mV, which remains unchanged upon changing the scan rate. There is also an inequality in the anodic peak current (i_{pa}) and the cathodic peak current (i_{pc}) of **2**, as expected for an irreversible electron transfer process.

3.4. Description of the crystal structures

3.4.1. $[Cu_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ (**1**)

An ORTEP diagram of **1** with atom numbering scheme is shown in Fig. 3. The bond dimensions about the copper centers for **1** are listed in Table 2. Crystal structure of the di-$\mu_{1,1}$-azido bridged dinuclear copper(II) complex **1**, have been compared with respect to the earlier reported dichloro and diacetato bridged copper(II) complexes $[Cu_2(\mu\text{-}Cl)_2(pabh)_2]$ (**A**), $[Cu_2(\mu\text{-}O_2CCH_3)_2(pabh)_2]$ (**B**), $[Cu_2(\mu\text{-}O_2CCH_3)_2(pamh)_2]$ (**C**) derived from two different NNO donor aroylhydrazones of pyridine-2-carboxaldehyde (pabh and pamh) [1d]. The structural study reveals that like **A**, **B** and **C**; **1** is

2	C(4)–H(4A)···N(121)	0.94	2.57	3.447(5)	155.00

Symmetry transformations used to generate equivalent atoms for **1**: #2 $x+1$, y, $z+1$.

also a centrosymmetric dimer in which the copper centers are five-coordinate, bonded to three coordinating N_2O atoms from the planar ligand $\mathbf{L}^-$ and nitrogen atoms from two bridging azide anions. In **1** the chelate bite angles in the five-membered rings formed by the amide–O and the imine–N, and the pyridine-N and the imine–N are 79.78 and 80.31, respectively, and are very close to that of the earlier reported chloro and acetato species. The N–N (1.383 Å), C–N (1.276 Å) and C–O (1.964 Å) distances of the coordinated ligand $\mathbf{L}^-$ are consistent with the coordinated pabh and pamh in **A**, **B** and **C** which suggest that the hydrazone ligand have coordinated copper(II) ions in its deprotonated form. Each of the two azide anions in **1** bridges the copper(II) centers in an *end-on* fashion and this leads to a relatively smaller Cu—Cu (3.199 Å) separation in comparison to that of dichloro (3.3918 Å) and diacetato (3.273 Å) bridged copper(II) dinuclear species **A**, **B**, **C**. In **1** the azide ion bridges in an asymmetric (basal–apical) fashion so that the Cu–N bond lengths are significantly different ($\Delta d = 0.498$ Å) and the Cu–N(11)–Cu(A) bridge angle (92.87(6)°) is greater than that of Cu–Cl–Cu bridge angle in **A** (86.89(3)°) but smaller than the Cu–O–Cu bridge angle in **B** and **C** (101.4(2)°). The di-$\mu_{1,1}$-azido bridging nitrogen atoms are in a planar Cu_2N_2 ring about a crystallographic inversion centre. The azide ions are nearly linear with N–N–N angle of 175.9(2)°. The geometry of the copper(II) centers are very close to square pyramidal with $\tau = 0.291$, [$\tau = |\beta - \alpha|/60°$], where β and α are the two largest angles around the central atom; $\tau = 0$ and 1 for the perfect square pyramidal and trigonal bipyramidal geometries, respectively [33]. The square base of each of the copper(II) centers is formed by pyridyl and imine nitrogen atoms, an enolate oxygen of the Schiff base ligand ($\mathbf{L}^-$) and one bridging azide nitrogen atom. The copper(II) atoms in **1** suffer a relatively lesser displacement of 0.093 Å from the square base towards the apical bridging azide ions than that of **A**, **B** and **C**. There is only one type of N–H hydrogen bonding interaction present in **1** and is given in Table 3. In a dinuclear unit of **1** two H(6A) atoms of the two-coordinated Schiff base ligands and the two N(13) atoms of the two *end-on* coordinated azide ions participate in intermolecular H-bonding with N(13) and H(6A) atoms, respectively, of the two adjacently placed dinuclear units to form an infinite 1D polymeric chain. The 1D polymeric chain structure of **1** generated by intermolecular H-bonding interactions is shown in Fig. 4.

3.4.2. $[Co_2(L)_2(\mu_{1,1}\text{-}N_3)_2(N_3)_2]$ (**2**)

An ORTEP diagram of **2** with atom numbering scheme is given in Fig. 5 and the bond dimensions about the cobalt centers are listed in Table 2. The centrosymmetric dimer **2** differs in its coordination environment from that of **1**. Unlike the copper complex, the two cobalt(III) centers in **2** are six-coordinated. The structural study reveals that in **2** both the cobalt(III) centers are in a distorted octahedral environment which has resulted from the coordination of the polydentate N_2O donor ligand ($\mathbf{L}^-$) and three azide ions which make the chromophore a heteroatomic specie. The equatorial sites of each cobalt(III) centers in **2** are occupied by two nitrogen atoms, one enolate oxygen of the Schiff base ligand ($\mathbf{L}^-$) and one azide ion coordinated in an *end-on* fashion thereby connecting the two cobalt(III) centers. The two axial sites of the each distorted octahedral cobalt(III) centers are occupied by two other azide ions of which one shows an *end-on* bridging mode and connects the two adjacent cobalt(III) centers while the other one is in a terminal site. In the dinuclear complex two azide ions bridge in an asymmetric (basal–apical) fashion and the other two occupy terminal positions. The two $\mu_{1,1}$-bridging azide ions and the two terminally coordinated azide ions in **2** are almost linear with N–N–N angles of 177.0(4)° and 177.2(4)°, respectively. The two cobalt(III) centers are shifted from the equatorial base plane towards the axially coordinated terminal azide ions by 0.063 Å and the Co(III)···Co(III) separation in **2** is 3.041 Å. The oxidation state of the two cobalt centers in the complex is 3+ instead of 2+ which is mainly attributed to the coordination of the two terminal azide ions to the respective metal centers in the complex. Although there is only one type of N–H hydrogen bonding interaction present in **2** but weak interactions led an increase in dimensionality of **2** with respect to **1**. In the dinuclear unit of **2** two H(4A) atoms of the two coordinated Schiff base ligands and the two N(121) atoms of the two terminally coor-

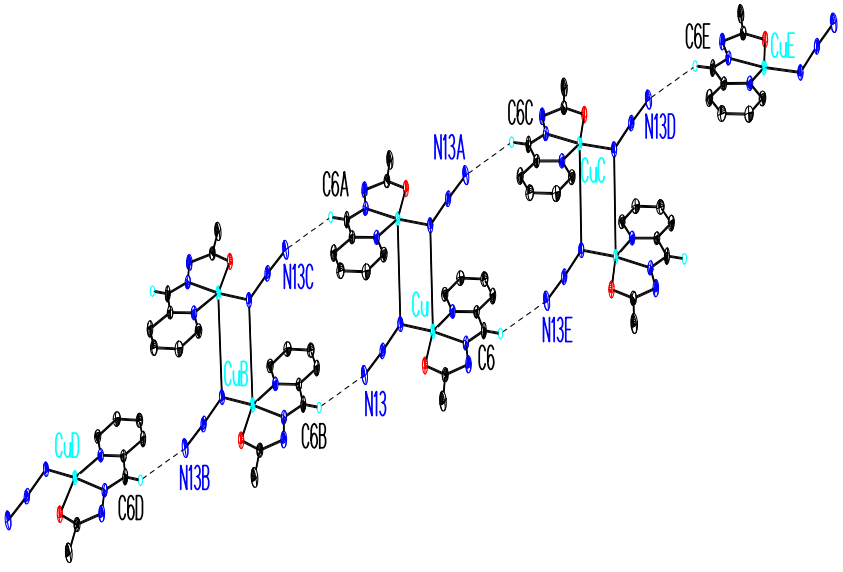

Fig. 4. Intermolecular H-bonding interactions generating 1D polymeric chain of **1**.

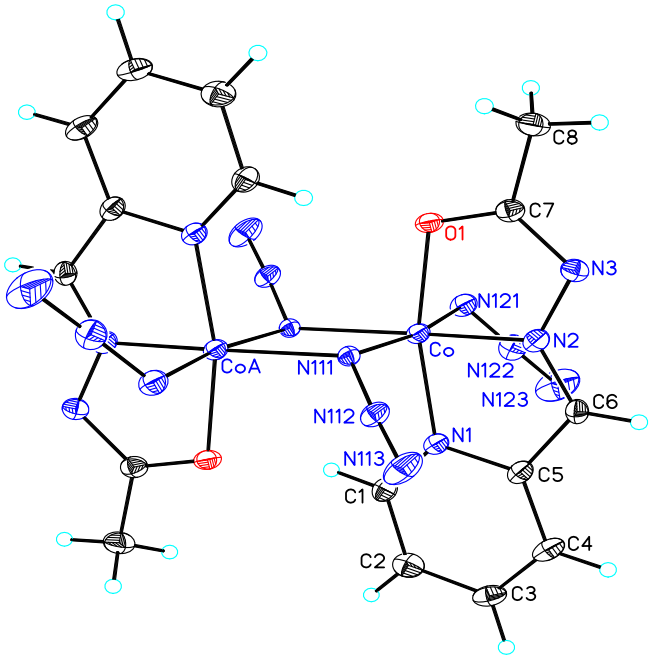

Fig. 5. ORTEP diagram of **2** with atom labeling scheme.

dinated azide ions participate in intermolecular H-bonding with H(4A) and N(121) atoms, respectively, of the other two dinuclear units to form 2D grid like structure. In the unit cell of the complex four such dinuclear units of **2** are interconnected to each other by intermolecular H-bonding to form a single grid. The intermolecular hydrogen bonding interactions is clearly indicated in the packing diagram of the complex shown in Fig. 6 and the H-bonding parameters is given in Table 3.

3.5. Magnetic study

For **1** low temperature magnetic study was performed to see the extent of interaction between two copper(II) centers through two *end-on* bridged azido ligands. In **1** the two azido ions coordinate two copper(II) centers in a basal–apical mode, i.e. each of the N atoms of the two azido-ligand connects the two copper(II) centers by binding first copper center at its apical site and the second copper center at its equatorial site, respectively. The two magnetic orbital on the copper atoms are $d_{x^2-y^2}$ (the *x* and *y* axes being defined by the short equatorial bonds). Thus the coupling is expected to be very weak. So it is well expected that there will be no direct overlap between the magnetic orbitals through the azido bridges. Thus it can be predicted that such overlap will result to a very weak coupling. The experimentally observed result of **1** is quite consistent with the theoretical explanation as the $\chi_M T$ values recorded by SQUID remains constant in the whole range of temperature 10–300 K at a value close of 0.75 $cm^3\,K\,mol^{-1}$ and is in good agreement with the one expected for two uncoupled spins 1/2. For **2** low temperature magnetic study was not performed as the complex is a dinuclear cobalt(III) species and all cobalt (III) compounds are low-spin and thus diamagnetic in nature.

4. Conclusion

This paper contributes a new class of hydrazone metal complexes which is derived from an aliphatic hydrazide. We have shown that the H-bonding interactions in both the complexes have increased the dimensionality of **1** and **2**. In **1** the dinuclear units are inter connected by H-bonding interactions to produce a 1D polymeric chain whereas in **2** it generated a 2D polymer where four such dinuclear units are inter connected to produce a grid like structure. The synthesis and characterisation of the hydrazone ligand (**LH**) and its complexes **1** and **2**, will help us and others to ex-

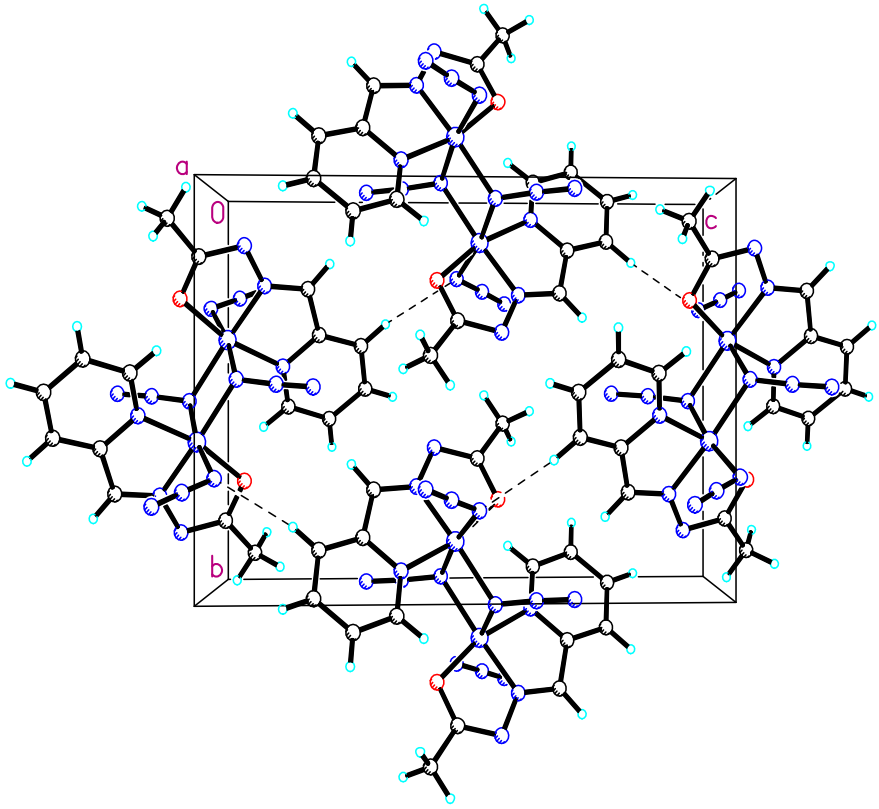

Fig. 6. Unit cell packing diagram showing intermolecular H-bonding of **2**.

plore the biological activities related to such aliphatic metal hydrazone complexes which still remain unexplored. The further extensions of this work lies in obtaining multinuclear complexes of other transition metals and to study the biological activities of such complexes.

Sitting-atop complex
Zirconium tetrachloride
SAT complex

ABSTRACT

We have succeeded in the preparation and spectroscopic characterization of sitting-atop (SAT) complexes of *meso*-tetraarylporphyrins (H_2t(X)pp) with zirconium(IV) chloride under mild conditions and at room temperature, where two pyrrolenine nitrogens in the SAT complexes, [(H_2t(X)pp)$ZrCl_4$], coordinate to a zirconium atom and two protons still remain on the pyrrole nitrogens. UV–Vis and NMR (^{1}H and ^{13}C) spectral data show that the porphyrin core of the SAT complexes is distorted and two pyrrolenine nitrogen atoms of the porphyrin act as electron donors to the zirconium atom of $ZrCl_4$.

1. Introduction

Porphyrin complexes are one of the most important class of compounds in biochemistry, due to their central role in photosynthesis, oxygen transport and biological redox processes [1–5]. Fleischer and Wang studied the reaction of protoporphyrin IX derivatives with several metal ions in chloroform and observed the formation of reaction intermediates, which were called sitting-atop (SAT) complexes [6]. Such structures are formed each time during the incorporation of the metal centers, when in the stable intermediates two pyrrolic protons still remain on the porphyrins. Several sitting-atop complexes of naturally occurring and synthesis porphyrins including platinum (II), copper (II), and rhodium (I) have been reported [7–9]. Recently, Ryde and Shen performed a quantum mechanical study of SAT complexes of Mg^{2+}, Fe^{2+} and Cu^{2+} with porphyrin in water and acetonitrile solutions [10]. It was suggested that there are a large number of possible structures for the SAT complex, with 1–5 solvent molecules, one or two metal ions, and *cis* or *trans* protonation of the porphyrin ring [11]. More clear evidence for the sitting-atop complex was spectrophotometrically observed during the reaction of *meso*-tetraphenylporphyrin (H_2tpp) with the copper (II) ion in acetonitrile [12]. The basicity of acetonitrile is very weak, and therefore the pyrrole protons of H_2tpp are not easily released, even after forming the intermediate with the copper (II) ion without additional proton acceptors. This acid–base property of the solvent is responsible for the stability of the sitting-atop intermediate. But, Tsai et al. [13] working on the same reaction, reported that in a less basic solvent (chloroform) and tetra-*p*-tolylporphyrin (H_2t(4-Me)pp), only the metallated porphyrin and diprotonated free base were observed (Eq. (1)).

$$2(H_2t(4\text{-Me})pp) + M^{2+} \rightarrow M(t(4\text{-Me})pp) + H_4t(4\text{-Me})pp^{2+} \qquad (1)$$

Newly, Reed et al. studied the treatment of a metalloporphyrin with a strong acid by the microscopic reverse reaction [14]. They observed no SAT complex as an intermediate, and suggested that Funahashi et al. might have misinterpreted a mixture of M(por) and H_4(por)$^{2+}$ as SAT complexes. The similarity of the spectral data for SAT complexes and the related diprotonated species cause their characterization to be difficult and lead to a challenge in the majority of cases.

We have recently reported that the reaction of *meso*-tetraarylporphyrins with $SbCl_3$ and $BiCl_3$ acceptors produced dimer molecular complexes, [(H_2t(X)pp)MCl_3]$_2$ (M = Sb, Bi). In these complexes, the porphyrin core was distorted and acted as an electron donor to the central atom of the acceptors by the pyrrolenine nitrogens, and so two pyrrolic protons still remained on the porphyrin. The structure of the dimer molecular complexes was similar to SAT complexes. This article presents the synthesis and characterization of SAT complexes of *meso*-tetraarylporphyrins (Fig. 1) with zirconium(IV). The selection of zirconium with a high oxidation number, suitable solvent and mild conditions are the reasons that we successfully prepared the stable SAT complexes as solids. The reaction did not progress to the metallation of the porphyin and remained in the intermediate step (SAT complex). Therefore, we

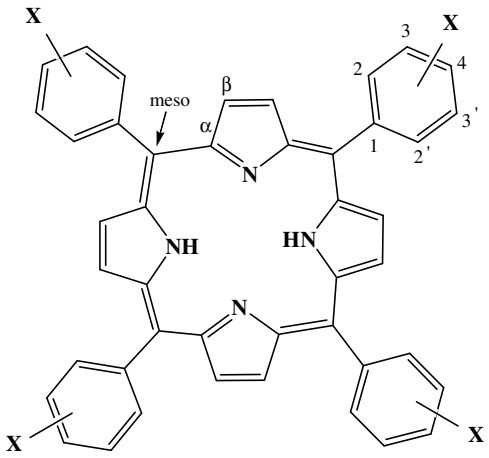

Fig. 1. *Meso*-tetraarylporphyrins, $H_2t(X)pp$.

synthesized SAT complexes containing zirconium ([$(H_2t(X)pp)$-$ZrCl_4$]) and no diprotonated or metalloporphyrin species in our reaction system.

2. Experimental

2.1. Materials

Benzaldehyde, the substituted benzaldehydes (2-Me, 3-Me, 4-Me, 2-OMe, 3-OMe, 4-OMe and 4-Cl) and $ZrCl_4$ were obtained from Merck and were used as received. All other solvents for the synthesis of the porphyrins and related SAT complexes were obtained from Merck and Fluka, and were used without further purification. Chloroform (Merck) was dried over anhydrous calcium chloride for 3 days. Pyrrole (Merck) was distilled before use. The substituted *meso*-tetraarylporphyrins and H_2tpp were prepared by the literature methods [17]. Alumina and hydrochloric acid were purchased from Merck and were used as received.

2.2. Physical measurements

The NMR spectra (^1H and ^{13}C) were recorded on a Bruker 500 Ultrashield spectrometer in $CDCl_3$. To obtain good integration results (in ^1H NMR), the concentration of the SAT complexes was 0.006 M. The residual $CHCl_3$ in the conventional 99.8% atom $CDCl_3$ gives a signal at $\delta = 7.26$ ppm, which was used for calibration of the chemical shift scale. The electronic absorption spectra were recorded in chloroform solutions on an ATI UNICAM-UV/Vis Vision SOFTWARE V-2011, spectrophotometer. The cell had an optical path length of 1 cm. FT-IR spectra were recorded on a Magna 550 Nicolet spectrometer using KBr pellets. The percentages of zirconium in the SAT complexes were obtained on a flame atomic absorption spectroscopy Model 2380 Perkin–Elmer spectrometer. The molar conductance of the SAT complexes and the diprotonated species of the porphyrins was measured on a METROHM 644 conductometer.

For the quantitative analysis of Zr and Cl in the [$(H_2t(X)pp)ZrCl_4$] SAT complexes, 0.05 mmol of each SAT complex was dissolved in 20 ml chloroform and then decomposed by adding 15 ml of double distilled water to the solution. $ZrCl_4$ hydrolyzed in water and the porphyrin remained in the organic solvent. The two phases were then separated by a decanter. The percentages of chloride and zirconium ions in the SAT complexes were determined by the mercury thiocyanato method [18] and flame atomic absorption technique, respectively.

2.3. Preparations

2.3.1. [$(H_2t(4\text{-}OMe)pp)ZrCl_4$]

Equimolar quantities (0.5 mmol) of $H_2t(4\text{-}OMe)pp$ and $ZrCl_4$ (in 2–3 ml of chloroform) were ground together in a mortar at ambient temperature for 20–30 min. The completion of the complexation was determined by UV–Vis spectroscopy. The porphyrin was completely converted to the related SAT complex and the mixture had no absorption band due to the free base porphyrin. The green related SAT complex was dried in a vacuum oven for 12 h at 50 °C. *Anal.* Calc. for $C_{48}H_{38}N_4O_4ZrCl_4$: C, 59.6; H, 4.0; N, 5.8; Cl, 14.6; Zr, 9.4. Found: C, 58.7; H, 3.9; N, 5.6; Cl, 14.2; Zr, 9.1%. ^1H NMR ($CDCl_3$): δ 0.55 (s, 2H, NH), δ 4.17 (s, 12H, OCH_3), δ 8.52–8.54 (d, 8H, 2, 2′), δ 7.52–7.55 (d, 8H, 3, 3′), δ 8.48 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.3.2. [$(H_2t(4\text{-}Me)pp)ZrCl_4$]

This SAT complex was synthesized by the method described above. *Anal.* Calc. for $C_{48}H_{38}N_4ZrCl_4$: C, 63.8; H, 4.2; N, 6.2; Cl, 15.7; Zr, 10.1. Found: C, 63.3; H, 4.0; N, 6.1; Cl, 15.2; Zr, 9.8%. ^1H NMR ($CDCl_3$): δ 0.25 (s, 2H, NH), δ 2.83 (s, 12H, CH_3), δ 8.48–8.50 (d, 8H, 2, 2′), δ 7.80–7.82 (d, 8H, 3, 3′), δ 8.54 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.3.3. [$(H_2tpp)ZrCl_4$]

This complex was synthesized by the method used for the [$(H_2t(4\text{-}OMe)pp)ZrCl_4$] complex. *Anal.* Calc. for $C_{44}H_{30}N_4ZrCl_4$: C, 62.3; H, 3.6; N, 6.6; Cl, 16.7; Zr, 10.7. Found: C, 61.8; H, 3.5; N, 6.5; Cl, 16.2; Zr, 10.5%. ^1H NMR ($CDCl_3$): δ 0.29 (s, 2H, NH), δ 8.59–8.62 (d, 8H, 2, 2′), δ 8.00–8.03 (t, 8H, 3, 3′), δ 7.96–7.97 (d, 4H, 4), δ 8.58 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.3.4. [$(H_2t(3\text{-}Me)pp)ZrCl_4$]

This complex was synthesized by the method used for the [$(H_2t(4\text{-}OMe)pp)ZrCl_4$] complex. *Anal.* Calc. for $C_{48}H_{38}N_4ZrCl_4$: C, 63.8; H, 4.2; N, 6.2; Cl, 15.7; Zr, 10.1. Found: C, 62.6; H, 4.1; N, 6.1; Cl, 15.5; Zr, 9.9%. ^1H NMR ($CDCl_3$): δ 0.25 (s, 2H, NH), δ 2.83 (s, 12H, CH_3), δ 8.40–8.42 (br., 8H, 2, 2′), δ 7.89–7.92 (t, 4H, 3), δ 7.76–7.78 (d, 4H, 4), δ 8.57 (s, 8H, β). IR (KBr): υ_{NH} ($\sim$3320 cm^{-1}).

2.3.5. [$(H_2t(3\text{-}OMe)pp)ZrCl_4$]
