4-fba = 4-fluorobenzoate; benz = benzoate; 1,4-bdc = 1,4-benzenedicarboxylate; 1,3-bdc = 1,3-benzenedicarboxylate; L = 4-(2-nitrophenyl)-3,6-dioxaoctane dioate; $(NH_2–NH–CO_2)$ = hydrazine carboxylate; gly = glycinate; dnSa = 3,5-dinitrosalicylato; 4-aba = 4-amino benzoate; DMF = *N*,*N*-dimethylformamide; OAc = acetate; 3-aba = 3-aminobenzoate; L^1 = 2,2′,2″-nitrilotribenzoate; leu = rac-leucinate; 4-CNbenz = 4-cyanobenzoate; $(O_2C)_2C_6H_3CO_2H$ = 1,2,4-benzenetricarboxylate; Nic = nicotinate; $C_8H_5O_3$ = 2-formylbenzoate; 2-OPA = 2-oxo-1,2-dihydropyridine-1-acetate; 2-aba = 2-aminobenzoate; Hpdc = 3,5-pyrazoledicarboxylate; Sa = salicylato; Phen = 1,10-phenanthroline; val = rac-valinate; PY = *N*-(6-amino-3,4-dihydro-3-methyl-5-nitroso-4-oxopyrimidin-2-yl); $C_9H_8NO_4$ = 2-(pyridinium-1-yl)butanedioate $C_9H_{11}N_6O_5$ = bis[*N*-(6-amino-3,4-dihydro-3-methyl-5-nitroso-4-oxopyrimidine-2-yl) glycylglycinate; AIP = 5-aminoisopthalate.

mentary data, Figs. 5 and 6). Both **1** and **1a** decompose at higher temperatures forming CaO as the final product as evidenced by the observed mass loss and also the featureless infrared spectra of the residues indicating the loss of organics. The DSC thermogram of **2** (Fig. 4) exhibits an endothermic peak at 188 °C, which can be

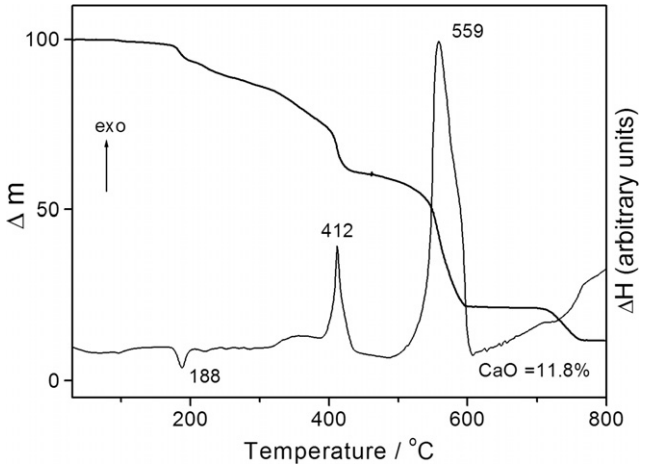

Fig. 4. TG-DSC thermogram of compound **2**.

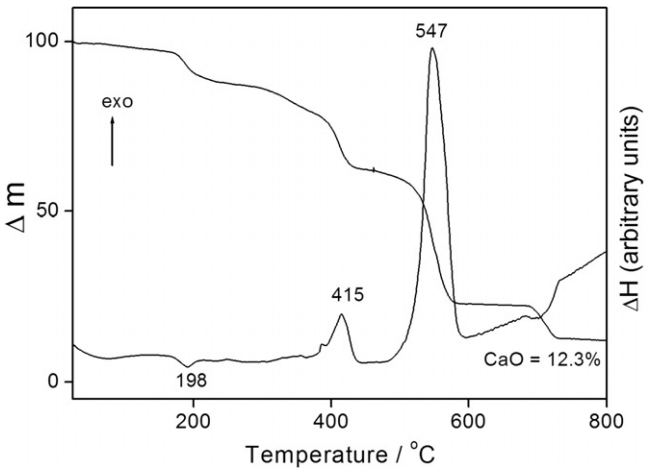

Fig. 5. TG-DSC thermogram of compound **3**.

attributed to the removal of *N*-methylimidazole and exothermic events above 400 °C assignable to the decomposition of the carboxylate ligand resulting in the formation of CaO. This assignment gains more credence as all the compounds **1**, **1a**, **2** and **3** exhibit the first exothermic event at around 410 °C. The removal of *N*-MeIm leads to further decomposition of **2** as evidenced by a steep drop in the TG curve of **2**. A scrutiny of **2** by isothermal weight loss studies at 185 °C, revealed a weight loss of 21.67% corresponding to the loss of one mole of *N*-MeIm, while further heating to 800 °C resulted in a total mass loss of 88% with 12% residue corresponding to the formation of CaO. However, our efforts to prepare the anhydrous compound $[Ca(4\text{-nba})_2]$ by heating **2** were not successful. The TG-DSC thermogram of **3** exhibits three thermal events at 198, 415 and 547 °C, respectively (Fig. 5). The endothermic signal at 198 °C can be assigned for the loss of the neutral Im ligand. This process appears to be complex and is not well resolved as evidenced by further drop in the TG curve. The exothermic signals at 415 and 547 °C can be attributed to the degradation of the carboxylate moieties leading to the decomposition of **3** to CaO with a residual mass of 12.3%, which is in good agreement with the calculated value. In the absence of associated mass spectral data of the emitted fragments the exact nature of the thermal decomposition taking place above 400 °C cannot be commented upon for both **2** and **3**. The formation of CaO as the final residue can be unambiguously confirmed by weight loss studies of compounds **2** and **3** in a temperature controlled furnace, as well as their characteristic X-ray powder pattern (see Supplementary data, Figs. 7 and 8). The diffractograms of the residues are in very good agreement with that of the reported CaO phase in the JCPDS file No. 37-1497.

4. Conclusions

In summary, we have shown that the zero dimensional mononuclear tetraaqua Ca(II) compound **1** can be transformed into the Ca(II) coordination polymer $[Ca(N\text{-MeIm})(4\text{-nba})_2]_n$ **2** by heating it in the presence of *N*-MeIm. The key step in this transformation is the formation of an intermediate monohydrate compound, which undergoes ligand substitution and incorporation of N-donor ligand into the coordination sphere of Ca(II). The use of imidazole instead of *N*-MeIm in the thermal reaction resulted in the formation of the anhydrous mixed ligand compound $[Ca(Im)(4\text{-nba})_2]_n$ **3**.

25,26,27,28-tetrakis-(dimethylphosphinoylmethoxy)calix[4]arene, S) on the solvent extraction of five selected lanthanoid ions (La^{3+}, Nd^{3+}, Eu^{3+}, Ho^{3+} and Lu^{3+}) with 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione (HL) in $CHCl_3$ and to determine the stoichiometry and the structure of solid complexes of Eu with the extractants by elemental analysis, IR, NMR and X-ray investigations.

2. Experimental

2.1. Reagents

The commercial product 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione, (purity > 99%, Fluka) was used as received. IR(KBr): ν(C=O), 1655(s) cm^{-1}; ν(Ar), 1606(m), 1522(m) cm^{-1}; ν(C–H in –H_2C–C(O)–), 1409(m) cm^{-1}; γ(C–H in thienyl), 1521(m) cm^{-1}; $\nu(CF_3)$, 1312(m) cm^{-1}. ^{1}H NMR (250MHz, CD_3OD, 25 °C): δ = 7.209 (dd, J = 3.9, 5.0 Hz, 1H, 4-Ar), 7.894 (dd, J = 1.1, 5.0 Hz, 1H, 3-Ar), 7.908 (dd, J = 1.1, 3.9 Hz, 1H, 5-Ar); ^{19}F{^{1}H} NMR (235 MHz, CD_3OD, 25 °C): δ = −82.07 ppm.

The lower rim substituted calix[4]arene, S, was synthesized according to the method described in [21]. The structural formula of S is shown in Fig. 1. Its quality has been checked by ^{1}H NMR in $CDCl_3$ (250 MHz, 25 °C): δ = 1.074 (s, 36H, $(CH_3)_3C$), 1.532 (d, $^2J_{HP}$ = 12.9 Hz, 24H, $(CH_3)_2P{=}O$), 3.268 (d, $^2J_{HH}$ = 13.0 Hz, 4H, Ar–CH_2–Ar), 4.688 (d, $^2J_{HP}$ = 1.3 Hz, 8H, $CH_2P{=}O$), 4.836 (d, $^2J_{HH}$ = 13.0 Hz, 4H, Ar–CH_2–Ar), 6.800 (s, 8H, Ar–H) and in CD_3OD (250 MHz, 25 °C): δ = 1.001 (s, 36H, $(CH_3)_3C$), 1.527 (d, $^2J_{HP}$ = 13.1 Hz, 24H, $(CH_3)_2P{=}O$), 3.292 (d, $^2J_{HH}$ = 13.2 Hz, 4H, Ar–CH_2–Ar), 4.668 (d, $^2J_{HP}$ = 1.3 Hz, 8H, $CH_2P{=}O$), 4.780 (d, $^2J_{HH}$ = 13.2 Hz, 4H, Ar–CH_2–Ar), 6.891 (s, 8H, Ar–H).

Stock solutions of La(III), Nd(III), Eu(III), Ho(III) and Lu(III) were prepared by dissolving of appropriate amounts of their oxides (Fluka, puriss.) in concentrated hydrochloric acid and diluting to required volume. The diluent was $CHCl_3$ (Merck, p.a.). Arsenazo III (Fluka) was of analytical grade purity as were the other reagents used.

2.2. Apparatus

S-20 Spectrophotometer Boeco (Germany) was used for measuring absorbances and pH 211 HANNA digital pH meter was used for pH measurements in the solvent extraction studies.

The melting points (uncorrected) of the solid complexes were measured on a Boetzius microheating plate PHMK05 (Germany).

Infrared spectra (400–4000 cm^{-1}) were recorded on a FTIR Bruker IFS113v IR spectrometer in KBr pellets.

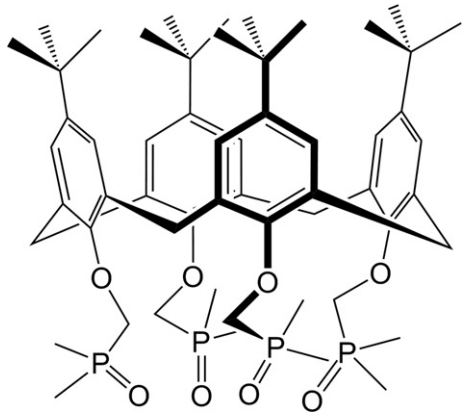

Fig. 1. Structural formula of 5,11,17,23-tetra-*tert*-butyl-25,26,27,28-tetrakis-(dimethylphosphinoylmethoxy)calix[4]arene.

The ^{1}H and ^{19}F NMR spectra were recorded on Bruker Avance DRX 250 MHz, while the ^{31}P NMR spectra were measured on Bruker Avance II+ 600 MHz high performance digital FT-NMR spectrometers. The ^{1}H NMR chemical shifts are given relative to TMS, the ^{19}F NMR chemical shifts are referenced to $CFCl_3$, while the ^{31}P NMR chemical shifts are calibrated relative to external 85% H_3PO_4.

X-ray data collection was carried out at 290 K on an Enraf-Nonius CAD-4 diffractometer with graphite monochromatized Mo Kα radiation (α = 0.71073 Å).

2.3. Solvent extraction procedure

The experiments were carried out using 10 cm^3 volumes of aqueous and organic phases. The samples were shaken mechanically for 45 min at room temperature which was sufficient to reach equilibrium. After the separation of the phases, the metal concentration in the aqueous phase was determined photometrically using Arsenazo III [22, p. 172]. The concentration of the metal ion in the organic phase was obtained by material balance. The acidity of the aqueous phase was measured by a pH-meter with an accuracy of 0.01 pH unit. The ionic strength was maintained at 0.1 mol dm^{-3} with (Na, H)Cl. The initial concentration of the metal ions was 2.5×10^{-4} mol dm^3 in all experiments.

The distribution coefficients of the lanthanoid ions were determined in three series of experiments, viz.:

- with fixed HL and S concentrations and varied pH;
- with fixed pH and S concentration and varied HL concentration;
- with fixed pH and HL concentration and varied S concentration.

2.4. Preparation of metal complexes

2.4.1. Complex of Eu(III) with 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione (HL)

The solution of 148 mg (0.5 mmol) $EuCl_3 \cdot 2H_2O$ in 30 cm^3 absolute ethanol was added at room temperature to a transparent solution of 334 mg (1.5 mmol) 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione in 2 cm^3 absolute ethanol and stirred for 5 h. The reaction mixture was light yellow transparent solution. It was concentrated under reduced pressure to 10 cm^3 and cooled. The crystal product was filtered, washed twice with absolute ethanol and dried in high vacuum over P_2O_5. It melts at 74–76 °C. Yield 320 mg (88.0%).

Anal. Calc. for $C_{16}H_8ClEuF_6O_4S_2 \cdot 3H_2O$ (M 683.81): C, 28.10; H, 2.06; S, 9.38. Found: C, 28.19; H, 2.28; S, 9.60%. IR(KBr): ν(C=O), 1605(vs) cm^{-1}; ν(Ar), 1605(vs), 1542–1510(s) cm^{-1}; ν(C–H in –H_2C–C(O)–), 1412(s) cm^{-1}; $\nu(-CF_3)$, 1029(m) cm^{-1}. ^{1}H NMR (250 MHz, CD_3OD, 25 °C): δ = 3.89 (bs, 1H, 3-Ar), 5.68 (bs, 1H, 4-Ar), 6.52 (bs, 1H, 5-Ar); ^{19}F{^{1}H} NMR (235 MHz, CD_3OD, 25 °C): δ = −83.69 ppm.

2.4.2. Complex of Eu(III) with 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione (HL) and 5,11,17,23-tetra-tert-butyl-25,26,27,28-tetrakis-(dimethylphosphinoylmethoxy)calix[4]arene (S)

A colorless solution of 30 mg (0.1 mmol) $EuCl_3 \cdot 2H_2O$ in 2 cm^3 absolute ethanol was added at room temperature to a solution containing 101 mg (0.1 mmol) S and 67 mg (0.3 mmol) HL in 3 cm^3 absolute ethanol. The reaction mixture was limpid solution and after 40 min it became a white gel. After stirring for 5 h the product was isolated by centrifugation, washed three times with absolute ethanol and dried in high vacuum over P_2O_5. The solid product does not melt up to 370 °C. Yield 160 mg (96%).

Anal. Calc. for $C_{72}H_{92}ClEuF_6O_{12}P_4S_2 \cdot 2H_2O$ (M 1674.96): C, 51.63; H, 5.78; S, 3.83. Found: C, 51.73; H, 5.52; S, 4.07%. IR(KBr): ν(C=O), 1617(vs) cm^{-1}; ν(P=O), 1144 (vs) cm^{-1}; ν(P–C–H in H_3C–P), 1300(vs) cm^{-1}; ν(1,2,3,5-tetrasubst Ar), 1478(m), 940(s) cm^{-1}; ν(Ar), 1617–1600 cm^{-1} (overlap with ν(C=O)), 1502(s) cm^{-1}; ν(C–H in –H_2C–C(O)–), 1414(m) cm^{-1}; γ(C–H in thienyl), 1537(m) cm^{-1}; ν(ArC–H), 1186(s) cm^{-1}; ν(Ar–O–C), 1029(m) cm^{-1}; ν(C–H in *t*-Bu), 3075–2870(m) cm^{-1}; ν(CF_3), 1360(m) cm^{-1}. ^{1}H NMR (250 MHz, CD_3OD, 25 °C) δ = 1.010 (s, 36H, (CH_3)$_3$C), 1.387 (d, $^2J_{HP}$ = 13.3 Hz, 24H, (CH_3)$_2$P=O), 3.63 (bs, 8H, CH_2P=O), 3.80 (bs, 4H, Ar–CH_2–Ar), 5.20 (bs, 4H, Ar–CH_2–Ar), 5.48 (bs, 2H, 3-Ar), 6.17 (bs, 2H, 4-Ar), 6.894 (d, *J* = 4.6 Hz, 2H, 5-Ar), 6.978 (s, 8H, Ar–*H*); ^{19}F{^{1}H} NMR (235 MHz, CD_3OD, 25 °C): δ = −80.00 ppm.

2.5. X-ray crystallography of the complex of Eu(III) with 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione (HL)

The crystals of the complex were prepared by slow crystallization from a diluted ethanol solution at room temperature with the possibility of partial evaporation of the solvent. A single crystal suitable for X-ray diffraction was used. The unit cell parameters were determined by least square refinement of 22 reflections, 18° < θ < 20°. The $\omega/2\theta$ technique was used for data collection using Nonius Diffractometer Control Software [23]. Lorentz and polarization corrections were applied to intensity data using the WINGX [24]. The structure was solved by direct methods using SHELXS-97 [25] and refined by full-matrix least-squares procedure on F^2 with SHELXL-97 [25]. The H atoms were placed in idealized positions ($CH_{aromartic}$ = 0.93 Å, CH_{methyl} = 0.96 Å, $CH_{methylen}$ = 0.97 Å) and were constrained to ride on their parent atoms, with $U_{iso}(H) = 1.2U_{eq}$.

3. Results and discussion

3.1. Synergistic solvent extraction of Ln(III) with mixtures of HL–S

The solvent extraction of the lanthanoid(III) ions with 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione (HL) in $CHCl_3$ has been studied previously [2]. It has been found that the metal extraction can be represented by the following equation:

$$Ln^{3+}_{(aq)} + 3HL_{(o)} \rightleftharpoons [LnL_3]_{(o)} + 3H^+_{(aq)} \quad (1)$$

The synergistic solvent extraction of the lanthanoids was studied using a traditional method called "slope analysis". It is based on an examination of the variation of $D_{L,S}$ (the distribution coefficient due to the synergistic effect) as a function of the relevant experimental variables. As the lanthanoid extraction with the calix[4]arene alone is negligible under the experimental conditions of the present study, the values of the distribution coefficient *D* obtained experimentally are the sum of $D_{L,S}$ and D_L (D_L is the distribution coefficients due to the lanthanoid extraction with HL alone under the same experimental conditions). So, the values of $D_{L,S}$ were calculated as $D - D_L$. A log–log plots of $D_{L,S}$ versus one of the variables [H^+], [HL] and [S] keeping the other two constant, indicate the stoichiometry of the extractable complex. This leads to the derivation of a suitable equilibrium expression and then to the calculation of the equilibrium constant. If the concentration of the extractants is constant and the hydrolysis in the aqueous phase as well as the polymerization in the organic phase occur to a negligible extent only, then the plots will be straight lines and their slopes will give the number of the ligands in the adducts.

The experimental data for the extraction of the lanthanoid(III) ions with mixture of HL and S are given in Figs. 2–4. The plots of log$D_{L,S}$ versus pH and log[HL] are linear with slope close to three and the plots of log$D_{L,S}$ versus log[S] – with slope close to two.

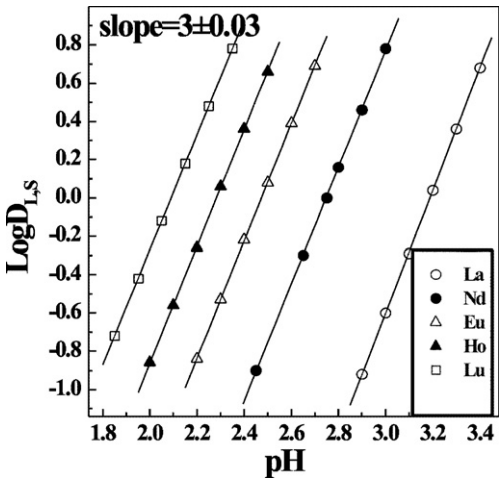

Fig. 2. Log$D_{L,S}$ vs. pH for the extraction of lanthanoid ions with mixtures of HL–S at [HL] = 6 × 10^{-2} mol dm^{-3} and [S] = 1 × 10^{-3} mol dm^{-3}.

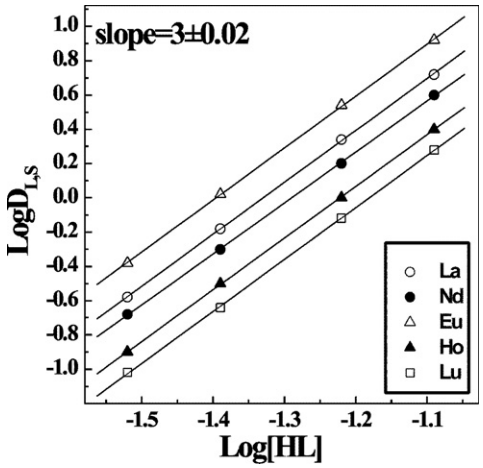

Fig. 3. Log$D_{L,S}$ vs. [HL] for the extraction of lanthanoid ions with mixtures of HL–S at [S] = 1 × 10^{-3} mol dm^{-3}; La, pH = 3.30; Nd, pH = 2.75; Eu, pH = 2.65; Ho, pH = 2.35; Lu, pH = 2.05.

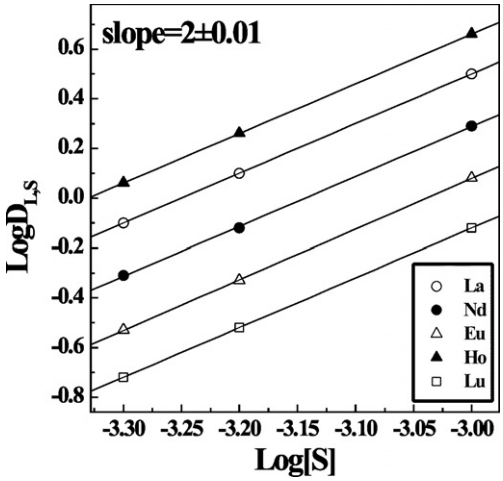

Fig. 4. Log$D_{L,S}$ vs. [S] for the extraction of lanthanoid ions with mixtures of HL–S at [HL] = 6 × 10^{-2} mol dm^{-3}; La, pH = 3.35; Nd, pH = 2.85; Eu, pH = 2.50; Ho, pH = 2.50; Lu, pH = 2.05.

Table 1
Values of the equilibrium constants K_L, $K_{L,S}$, $\beta_{L,S}$, synergistic coefficients ([HL] = 6×10^{-2} mol dm^{-3}, [S] = 1×10^{-3} mol dm^{-3}, pH = 2.50) and separation factors for the Ln(III) extraction with HL–S mixtures in $CHCl_3$

Ln^{3+}	log K_L[2]	log $K_{L,S}$	log $\beta_{L,S}$	S.C.	S.F.		
						HL	HL–S
La^{3+}	−11.06	−3.22	7.84	1.84	Nd/La	8.70	21.37
Nd^{3+}	−10.12	−1.89	8.23	2.23	Eu/Nd	27.54	6.60
Eu^{3+}	−8.68	−1.07	7.61	1.61	Ho/Eu	1.32	3.72
Ho^{3+}	−8.56	−0.50	8.06	2.06	Lu/Ho	2.57	3.80
Lu^{3+}	−8.15	0.08	8.23	2.23			

Note: The values of the equilibrium constants are calculated on the basis of the 38 experimental points, statistical confidence 95%, confidence interval ⩽±0.06.

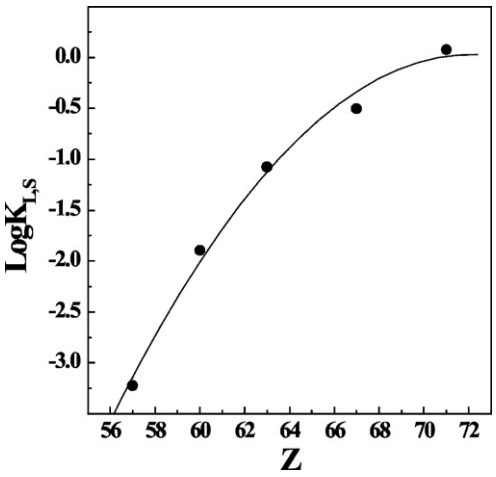

Fig. 5. Log $K_{L,S}$ vs. atomic number Z of La, Nd, Eu, Ho and Lu.

Therefore, in the presence of HL–S combination the lanthanoid extraction can be expressed by the following equation:

$$Ln^{3+}_{(aq)} + 3HL_{(o)} + 2S_{(o)} \rightleftharpoons [LnL_3S_2]_{(o)} + 3H^+_{(aq)} \quad (2)$$

where Ln^{3+} denotes a lanthanoid ion and the subscripts "aq" and "o" denote aqueous and organic phases, respectively.

Taking into account that the partition of HL [26] and S [21] toward the aqueous phase is very low, the overall equilibrium constant values $K_{L,S}$ can be determined by the equation

$$\log K_{L,S} = \log D_{L,S} - 3\log[HL] - 2\log[S] - 3pH \quad (3)$$

The formation of mixed complexes in the organic phase can be described by the following equation:

$$[LnL_3]_{(o)} + 2S_{(o)} \rightleftharpoons [LnL_3S_2]_{(o)} \quad (4)$$

The equilibrium constant $\beta_{L,S}$ for the organic phase synergistic reaction can be determined as

$$\log \beta_{L,S} = \log K_{L,S} - \log K_L \quad (5)$$

The values of the equilibrium constants $K_{L,S}$ and $\beta_{L,S}$ calculated from the experimental data are given in Table 1. The equilibrium constants are based on the assumption that the activity coefficients of the species do not change significantly under the experimental conditions i.e. they are concentration constants. The data presented in Table 1 show that the addition of the calix[4]arene to the system Ln(III)–HL leads to a very large increase of the values of $K_{L,S}$ in comparison with those of K_L (8 orders of magnitude approximately) as well as that the values of this constant increase from La(III) to Lu(III) as expected from their decreasing ionic radii. The values of log $K_{L,S}$ are smaller (up to 2 log units) than those obtained for the extraction of the same lanthanoids with mixtures 4-benzoyl-3-methyl-1-phenyl-5-pyrazolone (HP) and the same calix[4]arene [20]. This fact can be explained taking into account that HL is more weak acid than HP (pK_a = 6.2 [26], and pK_a = 3.95

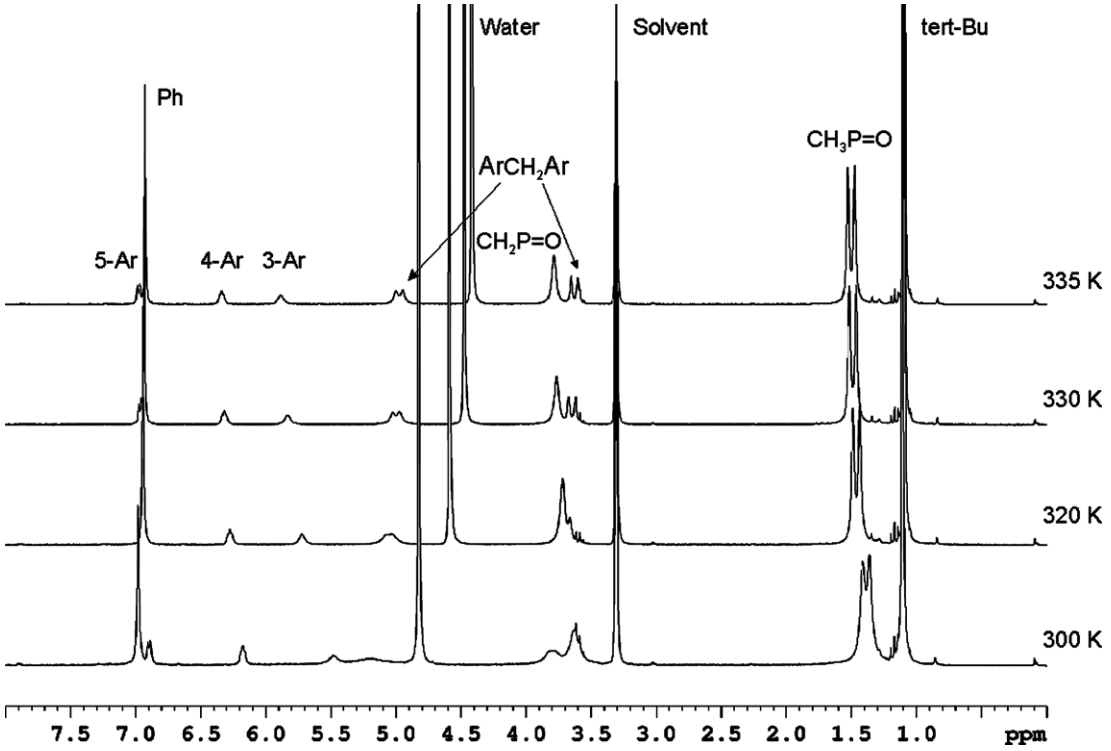

Fig. 6. The ^{1}H NMR spectra of the [EuL_2S]Cl complex in CD_3OD at 300, 320, 330 and 335 K. The assignment of signals in spectrum at 335 K is done by running 2D COSY spectrum at the same temperature.

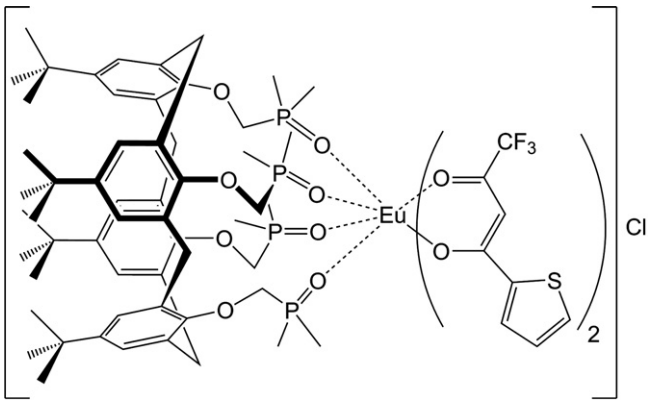

Fig. 7. Structure of the solid complex $[EuL_2S]Cl$ proposed on the basis of IR and NMR data.

[2], respectively). On the other hand, the lanthanoid(III) ions are more effectively extracted using the present mixture of extractants in comparison with the cases when 1-(2-pyridylazo)-naphthol [27], dibenzo-18-crown-6 or dibenzo-24-crown-8 [28], tri-(n-butyl)phosphate [2] or 2,2′-dipyridil [2] were used as synergistic agents in combination with HL. Similar value of the overall equilibrium constant ($\log K_{L,S} = 1.08$) has been obtained for Eu(III) extraction with mixtures of HL and tri(*n*-octyl)phosphine oxide in $CHCl_3$ and complexes of the same type, $[EuL_3S_2]$, has been found [2].

The variation of the equilibrium constant $K_{L,S}$ values versus the atomic number Z of the investigated lanthanoids is given in Fig. 5. It is seen that the values of $\log K_{L,S}$ do not increase monotonically with Z.

The synergistic enhancement produced by HL–S mixtures can be determined using the synergistic coefficients (S.C.). They were calculated according to [1] viz. $S.C. = \log(D_{1,2}/D_1 + D_2)$ where $D_{1,2}$ is the distribution coefficient of a metal obtained using mixture of the two extractants and D_1 and D_2 – the distribution coefficient values of the same metal using the extractants separately. The values of the synergistic coefficients are listed in Table 1. It is seen that the lanthanoids are extracted synergistically (S.C. > 0). So, the addition of S to the chelating extractant improves the extraction efficiency of the lanthanoid ions and produces rather large synergistic effects.

The separation of the lanthanoids using HL–S mixtures can be assessed by the separation factors (S.F.) calculated as a ratio of the distribution coefficients of two lanthanoids (the heavier and the lighter one). When the metal ions form complexes of the same type (as in the present case), the separation factors can be determined as a ratio of the equilibrium constants $K_{L,S}$. Their values are also given in Table 1. It is seen that the separation factors obtained for the extraction of the investigated lanthanoid ions with HL alone are smaller than those with HL–S combination with exception of the Eu/Nd pair. So, the synergistic mixture used in the present study combines (in the most cases) higher extraction efficiency with improved selectivity as compared with HL.

The comparison of the data for synergistic coefficients and separation factors found for the present synergistic system with those for 4-benzoyl-3-methyl-1-phenyl-5-pyrazolone and the same synergistic agent [20] shows that in the present case the synergistic enhancement is lower but the separation factors for the heavier lanthanoids are higher.

3.2. IR, ^1H, ^{19}F and ^{31}P NMR spectra and X-ray structure determination of the complexes

The elemental analysis, IR, NMR and X-ray studies of the isolated solid complexes give a possibility to make conclusions about the composition and the structure of the complexes.

In the IR spectrum of 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione the characteristic band observed at 1655 cm^{-1} for enol group in β-diketones is shifted to 1605 cm^{-1} in the complex of HL with

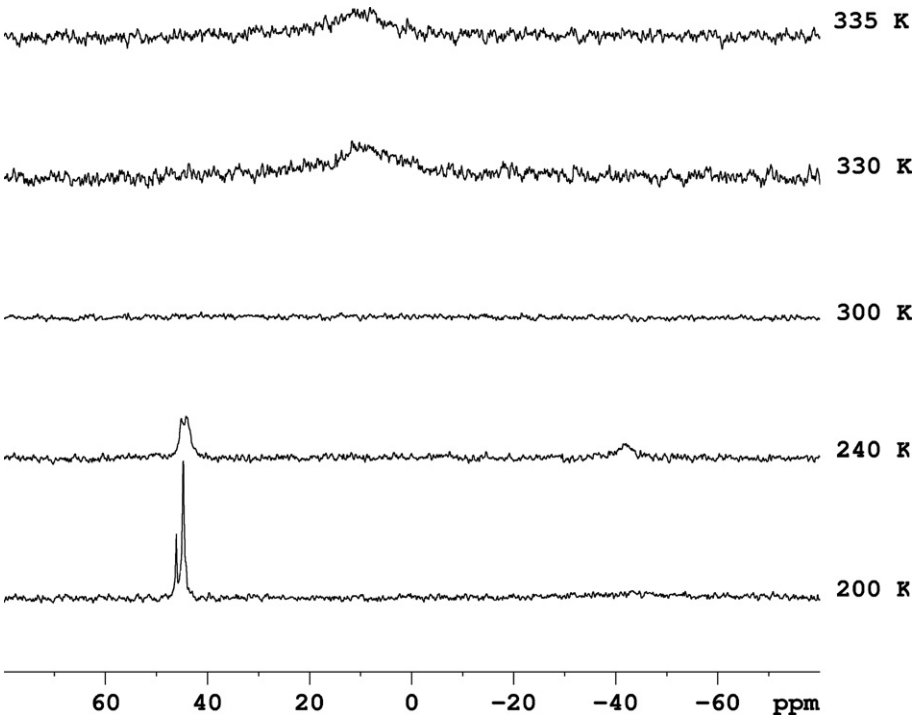

Fig. 8. The $^{31}P\{^1H\}$ NMR spectra of the $[EuL_2S]Cl$ complex in CD_3OD at 200, 240, 300, 330 and 335 K. The signals at about 45 ppm are assigned for noncoordinated P=O moieties, while the broad signal at about −40 ppm is assigned for coordinated P=O moieties. This assignment is based on the $^{31}P\{^1H\}$ NMR spectra of S (49.71 ppm) and EuS (6.13 ppm) at 300 K (Búnzli and Varbanov – unpublished results). The similar low chemical shifts of Eu(III) complexes with bisphosphonates (−50.6, −65.4 and −81 ppm) have been already reported by Platt et al. [29,30].

Eu(III) and at 1617 cm^{-1} in the complex of Eu(III), HL and calix[4]-arene. They are overlaped with the bands for aromatic rings.

The position of the bands typical for aromatic rings are around 1600 cm^{-1} and around 1500 cm^{-1} in the HL and its complexes with calix[4]arene and Eu(III).

The IR spectra show shift of the band for P=O group from 1160 cm^{-1} in the free calix[4]arene to 1144 cm^{-1} in the crystal complex of Eu with HL and S.

The expected ^1H NMR resonances of HL are significantly shifted to higher field upon coordination ($\Delta\delta$ is from −1.4 to −4.0 ppm in $[EuL_2]Cl$, while in $[EuL_2S]Cl$ it is from −1.0 to −2.4 ppm), while the signals of S are relatively less influenced ($\Delta\delta$ is less than 1.0 ppm). On the other hand, the signal of 3-Ar(HL) proton is the most shifted to higher field signal indicating proximity to the metal ion (Fig. 6).

There is no change in the symmetry of ligand S upon coordination and all resonances of S remain in the same form as for free S ligand, which indicates uniform interaction of all P=O with Ln(III) ion within the ^1H NMR time scale. The ^1H NMR spectra of Eu–HL–S complex at 300, 320, 330 and 335 K are presented in Fig. 6. At the highest temperature the signals are sufficiently resolved and on the basis of their integral intensity the ratio of the ligands in the synthesized complex was calculated as HL:S = 2:1. Therefore the composition of the complex can be represented by the formula $[EuL_2S]Cl$. The proposed structure of the complex is presented in Fig. 7.

The variable temperature $^{31}P\{^1H\}$ NMR measurements showed dynamic processes of exchanging phosphine oxides moieties. At 335 K intermediate exchange is observed, while at 240 K slow exchange between bounded and non bounded P=O groups is seen (Fig. 8). Most probably the all possible coordinations are realized at low temperature and the ratio between them is changed with the temperature (spectra at 200 K and 240 K). Although the existence of different S coordinations at low temperature, the structure given on Fig. 7 represents the picture at 335 K, which we state to be the most probable according to the coordination number of Eu.

The crystal structure of the complex of Eu(III) with HL is illustrated in Fig. 9. The X-ray data showed that the composition of this

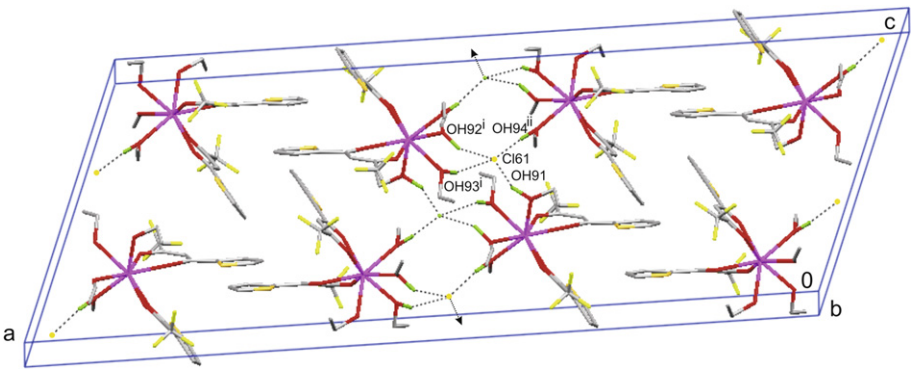

Fig. 10. A view of the molecular packing in $[Eu(L)_2(C_2H_5OH)_4]Cl$. Hydrogen bonds are represented by dotted lines. [Symmetry codes: (i) −1 − *x*, 1 − *y*, 1 − *z*; (ii) *x*, 1 − *y*, ½ + *z*].

complex is $[Eu(L)_2(C_2H_5OH)_4]Cl$. Basic crystallographic data for the complex, data collection and structural refinement are listed in Table 2. The complex shows a typical for Eu eight coordination sphere incorporating two bidentate 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione ligands while ethanol molecules complete the distorted square antiprism geometry. The thiophene ring is nearly planar (r.m.s. deviation of 0.01(6) Å) and forms an angle of 8.45(7)° with the extended trifluoro-3-oxobutanal plane (r.m.s. deviation of 0.03(5) Å).

The three-dimensional crystal packing is stabilized trough $O_{ethanol}$–H···Cl interactions producing chains propagating along *c* axis (Fig. 10). The head-to-head interaction of the ethanol molecules is in the inner side of the chains while on the outer side the thiophene ring blocks the formation of strong non-covalent interactions.

4. Conclusion

Selected lanthanoid(III) ions (La, Nd, Eu, Ho, Lu) are synergistically extracted by HL–S combination as $[LnL_3S_2]$ species. The addition of the phosphorus-containing *p-tert*-butylcalix[4]arene (S) produces a large synergistic effect and, in the most cases, improves the selectivity among the lanthanoid ions in comparison with HL alone.

On the basis of elemental analysis, IR and NMR spectra the stoichiometry of the complexes in solid state is found and the structure is proposed. The crystallographic data for the complex of Eu with HL have shown that Eu(III) is eight coordinated and its composition can be represented with the formula $[Eu(L)_2(C_2H_5OH)_4]Cl$. The coordination polyhedron of the complex is distorted square antiprism.

5. Supplementary data

CCDC 670123 contains the supplementary crystallographic data for $[Eu(L)_2(C_2H_5OH)_4]Cl$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

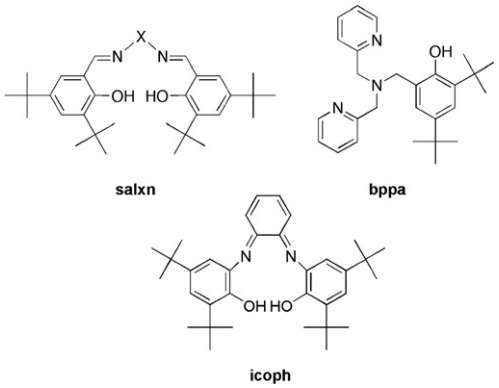

Chart 1. Ligand structures of bppa, icoph, and salxn, where X = $-CH_2CH_2-$ (salen), $-CH_2CH_2CH_2-$ (salpen), or $-CH_2CH_2CH_2CH_2-$ (salben).

aminium cations [20,21], which is significantly smaller than the apparent λ for the related tyrosine oxidation [19]. While the above suggests that the $PhO^{\cdot/-}$ ET reaction is subject to a smaller kinetic barrier than that of protonated phenols, it is unclear how this translates to the redox reactivity of metal-coordinated phenolates.

As the cofactors found in GalOx and CAO are proposed to form via oxidation of a copper–tyrosine precursor [27–32], our work was motivated by a desire to understand the ET reactivity of metal coordinated phenolates [33]. For these studies, the roughly square–planar complexes Cu(salxn) (H_2salxn, bis-salicylidinediamine) were synthesized to vary the planarity of the Cu(O_2N_2) center, as well as the more easily oxidized complexes Cu(bppa) (Hbppa, bis-pyridyl phenolamine) and Cu(icoph) (H_2icoph, bis-iminocatechol *o*-phenylenediamine) (Chart 1). Cu(salxn) complexes were observed to be efficient energy-transfer quenchers of $Ru(bpy)_3^{2+*}$, likely due to spectral overlap with a copper ligand-field state. In contrast, Cu(bppa) and Cu(icoph) quenched $Ru(bpy)_3^{2+*}$ by electron transfer, with observed reorganization energy $\lambda = 22$ kcal/mol. While this reactivity difference likely arises from the more favorable driving force for electron transfer in the case of Cu(bppa) and Cu(icoph), the large self-exchange reorganization energy calculated for the Cu-coordinated phenolate suggests that the CAO and GalOx cofactors may be poor $1e^-$ redox centers.

2. Materials and methods

Chemicals were obtained from commercial sources and used without further purification. For the electrochemical and time-resolved studies, CH_2Cl_2 and CH_3CN were dried over calcium hydride and distilled. ^1H NMR spectra were collected using a Bruker Avance 400 MHz NMR spectrometer. Electronic spectra were recorded using a Hewlett Packard 8453 UV–Vis spectrometer. Elemental analyses were performed at the University of Massachusetts Microanalysis Laboratory.

$Ru(bpy)_3(PF_6)_2$, $Ru(dMebpy)_3(PF_6)_2$, and $Ru(dOMebpy)_3(PF_6)_3$ were prepared according to literature procedures and recrystallized using CH_3CN/ether; $Ru(bpy)_3(PF_6)_3$ was prepared by oxidizing $Ru(bpy)_3^{2+}$ in 7 M H_2SO_4 using MnO_2. [34] The complexes Cu(bppa) [17] and Cu(icoph) [35] were produced and purified following literature methods. H_2salen, H_2salpen, H_2salben, and H_2saloph were synthesized through the condensation reaction of 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde and the appropriate diamine. Copper(II) complexes were produced by adding $Cu(OAc)_2$ to the ligands in ethanol. The resulting compounds were recrystallized in CH_2Cl_2/ether and characterized using elemental analysis.

Electrochemical measurements were performed using a Bioanalytical Systems BAS CV-50 W potentiostat with a standard three electrode cell. Glassy carbon (working), Pt wire (auxiliary), and Ag/AgCl (reference) electrodes were used. 1 mM solutions of each complex were prepared using CH_3CN or CH_2Cl_2 with 0.1 M of tetra-*n*-butylammonium hexafluorophosphate (TBA) as the supporting electrolyte and ferrocene as an internal standard. Samples were sparged with Ar before collection.

Lifetime experiments were performed using a Photon Technology International PL-2300 nitrogen laser at 23 °C. The emission was filtered using a 695 nm filter and detected using a photomultiplier. Decay traces were acquired using a digital oscilloscope triggered by a photodiode. The $Ru(R_2bpy)_3^{2+}$ concentration was approximately 5 μM while the quencher solutions contained $Ru(R_2bpy)_3^{2+}$ with an additional 0.3–4 mM metal phenolate. Since Cu(bppa) is a positively charged species in solution, 0.1 M TBA was added to attenuate any electrostatic interactions for that sample.

The lifetime of $Ru(R_2bpy)_3^{2+}$ alone, τ_0, was determined for each individual experiment, then aliquots of the quencher solution were transferred via a Hamilton gas-tight syringe to the cuvette, and lifetime measurements taken after each sequential addition. The lifetime values were determined from the slope of semilog plots [36]. The quenching efficiency (K_{SV}) for each quencher was determined from Stern–Volmer plots of τ_0/τ vs. quencher concentration. The observed quenching rate constants (k_{obs}) were determined from the relationship $k_{obs} = K_{SV} \times \tau_0$ and corrected for the rate of diffusion (k_{diff}) to obtain the diffusion-corrected quenching rate constant, k_q according to the equation $1/k_{obs} = 1/k_{diff} + 1/k_q$.

X-band (9.764 GHz) EPR experiments were performed on a Bruker ESP-300 spectrometer, with a liquid nitrogen finger-dewar used to control the sample temperature to 77 K. The modulation amplitude was 10 gauss and the frequency 100 kHz. Spectra were collected using 20 mW power. 0.9 mM solutions of Cu(salophen) and Zn(salophen) were prepared separately in CH_2Cl_2, then combined with an equal volume of 0.9 mM $Ru(bpy)_3^{3+}$ in CH_3CN. The mixtures were immediately transferred to EPR tubes and frozen in liquid nitrogen manually. Simulations were run using XSophe [37,38].

3. Results and discussion

3.1. $Ru(bpy)_3^{3+}$ oxidizes Cu-phenolates

$Ru(R_2bpy)_3^{3+}$ oxidized metal-coordinated phenolates, as expected from literature reports of non-coordinated phenolate oxidation. [19–21,39] Cu(salophen) (0.9 mM, CH_2Cl_2) and Zn(salophen) (0.9 mM, CH_2Cl_2) were separately mixed with $Ru(bpy)_3^{3+}$ (0.9 mM, CH_3CN), then added to an EPR tube and quickly frozen in liquid nitrogen. Zn(salophen) exhibited no EPR signal, as expected for this S = 0 ground state (Fig. 1A); upon reaction with ~1 equiv. of $Ru(bpy)_3^{3+}$, a narrow isotropic signal at $g_{eff} \sim 2.01$ appeared (Fig. 1C). This narrow signal is assigned to the phenoxyl radical (S = ½) of Zn(salophen)$^+$. Similarly, Cu(salophen) exhibited an axial signal with fine structure, as expected for a an S = 1/2 Cu^{2+} (Fig. 1D). This spectrum was simulated with $g_\perp = 2.034$, $g_{||} = 2.196$, and Cu-hyperfine coupling of $A_\perp = 3.0$ mT, $A_{||} = 19.2$ mT (Fig. 1E). These electronic parameters are similar to those reported for other square–pyramidal Cu(II) complexes with a predominantly $d_{(x^2-y^2)}$ ground state [40,41]. Oxidation of Cu(salophen) by ~1 equiv. of $Ru(bpy)_3^{3+}$ attenuated this Cu^{2+} signal, while a broad

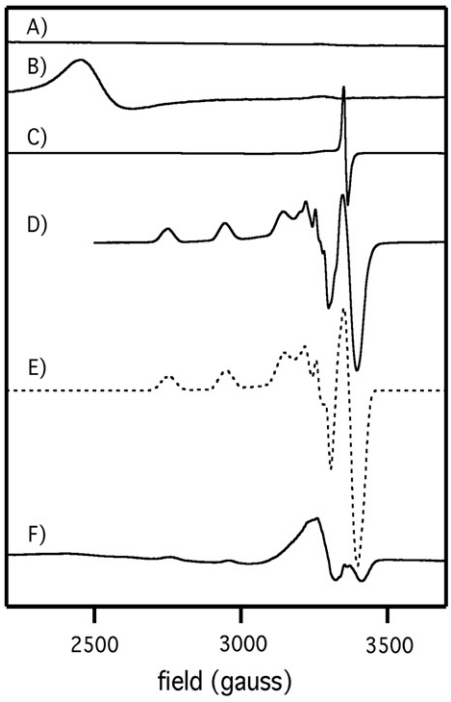

Fig. 1. 9.764 GHz EPR spectra at 77 K: (A) Zn(salophen); (B) $Ru(bpy)_3^{3+}$; (C) Zn(salophen) mixed with $Ru(bpy)_3^{3+}$ (×0.25); (D) Cu(salophen) (×0.75); (E) simulation for Cu(salophen) (×0.75, see text for details); (F) Cu(salophen) mixed with $Ru(R_2bpy)_3^{3+}$ (×2).

$g_{eff} \sim 2.1$ signal appeared, which we attribute to weak magnetic coupling between Cu^{2+} ($S = 1/2$) and a phenoxyl radical ($S = 1/2$) on $Cu(salophen)^+$.

The EPR spectra clearly indicated that $Ru(bpy)_3^{3+}$ oxidized the salophen ligand for both Cu(salophen) and Zn(salophen) to form the metal-coordinated phenoxyl radical. Cyclic voltammetry confirmed that such reactions were exothermic (Table 1). As we were interested in the electron-transfer reactivity of metal-phenolates, we attempted to measure the rate constants for metal-phenolate oxidation by stopped-flow methods. These experiments were unsuccessful, largely due to solvent incompatibilities. Rapid mixing of CH_2Cl_2 solutions of Cu-phenolate with CH_3CN solutions of $Ru(R_2bpy)_3^{3+}$ led to extensive turbidity, due to mixing, leading us to abandon this approach in favor of photo-induced experiments.

3.2. Quenching of $Ru(bpy)_3^{2+*}$ by Cu(salxn) through energy transfer

As $Ru(bpy)_3^{2+}$ is sufficiently soluble in CH_2Cl_2, and the photo-excited state has a long lifetime, transient fluorescence of Ru $(bpy)_3^{2+*}$ was monitored to determine the mechanism for quenching by Cu(salxn). The lowest-lying excited state, $Ru(bpy)_3^{2+*}$, is a charge-separated state conveniently represented as $[Ru(III)(bpy)_2(bpy^-)]^{2+}$ which may be deactivated either by oxidizing Cu(salxn) to form $Ru(bpy)_3^{1+}$, or else by energy transfer. As the electron transfer between $Ru(bpy)_3^{2+*}$ and Cu(salxn) would be exothermic, it was expected to form a phenoxyl radical as seen in the oxidation of Cu(salophen) by $Ru(bpy)_3^{3+}$ (Fig. 1)

$$Cu(II)(salxn) + Ru(bpy)_3^{2+*} \rightarrow Cu(II)(salxn)^{+\cdot} + Ru(bpy)_3^{1+} \quad (2)$$

The fluorescence lifetime of $Ru(bpy)_3^{2+*}$ was efficiently quenched by Cu(salxn), yielding concentration-dependent quenching data (Fig. 2). The normalized fluorescence quenching (τ_0/τ) was proportional to the Cu(salxn) concentration, as predicted by the Stern–Volmer equation (Eq. (3)) in which K_{SV} is the quenching efficiency. The linear Stern–Volmer plots indicate that a dynamic quenching mechanism is operative, in which a bimolecular collision between Cu(salxn) and $Ru(bpy)_3^{2+*}$ deactivates the excited state

$$\tau_0/\tau = 1 + K_{SV}[Cu(salxn)] \quad (3)$$

Table 2 lists the quenching data for Cu(salxn) complexes, indicating that the observed rate constants approach the rate of diffusion. Furthermore, the observed quenching rates for Cu(salxn) displayed no discernable dependence on driving force over the modest range of 4 kcal/mol spanned by this series, suggesting that Cu(salxn) quenched $Ru(bpy)_3^{2+*}$ either by diffusion-limited electron transfer, or by energy transfer. Treating k_{obs} with Marcus theory (Eq. (1)) indicated that the reorganization energy would need to be very small, $\lambda \sim 10$ kcal/mol, for diffusion limited kinetics. Thus, while thermodynamic arguments indicated that fluorescence quenching could occur by electron transfer, the rates were much faster than anticipated for quenching to occur by bimolecular electron transfer.

Energy transfer is the more likely mechanism for dynamic quenching of $Ru(bpy)_3^{2+*}$ by Cu(salxn), due to their spectral overlap. Förster and Dexter energy transfer are the two energy-transfer

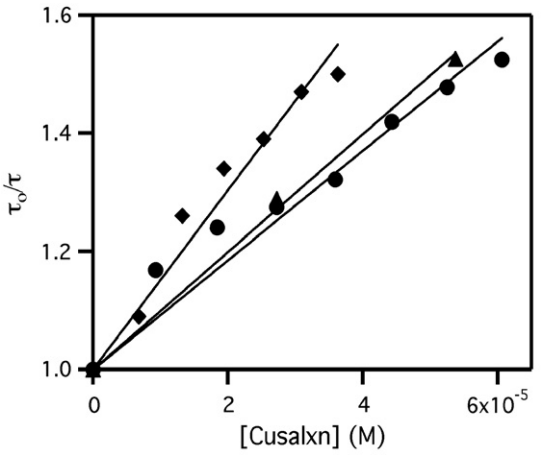

Fig. 2. Time-resolved Stern–Volmer data of $Ru(bpy)_3^{2+*}$ quenching by Cu(salen) (▲); Cu(salpen) (♦); Cu(salben) (●); see text for details.

mechanisms, with Förster energy transfer requiring spectral overlap between the emission of $Ru(bpy)_3^{2+*}$ and an absorption band of Cu(salxn) [42], The visible absorption spectra for Cu(salxn) was overlayed with the $Ru(bpy)_3^{2+*}$ emission spectrum (Fig. 3). A low energy electronic transition in the 570–670 nm range which is weakly allowed ($\varepsilon \sim 500\ M^{-1}\ cm^{-1}$) is observed for each Cu(salxn), which is appropriate for the ligand-field transition of Cu(II). As the overlap of this absorption with the $Ru(bpy)_3^{2+*}$ emission is considerable, it is likely that this would allow for quenching of $Ru(bpy)_3^{2+*}$ through energy transfer with Cu(salxn).

The excited-state lifetime of $Ru(bpy)_3^{2+}$ could have also changed due to complexation with Cu(salxn), as intermolecular aggregation would alter the local solvent environment. Such an effect was observed with phenols, which form a weak adduct with $Ru(bpy)_3^{2+}$ through face-to-face π–π stacking in weakly acidic aqueous solution; binding was enhanced for electron-withdrawing chlorophenols [43]. Complexation with phenol decreased the observed decay rates of $Ru(bpy)_3^{2+*}$, however, chlorophenols did not affect the excited-state properties of $Ru(bpy)_3^{2+*}$ [44]. We attempted to test for intermolecular complexation by observing the emission spectrum of $Ru(bpy)_3^{2+*}$ in the presence of increasing Cu(salxn) concentrations, and observed no changes in the peak emission wavelength. However, significant inner filter effects due to the absorption of Cu(salxn) would have precluded us from observing small wavelength shifts. As the bulky *tert*-butyl groups on the Cu(salxn) phenolic rings would strongly disfavor π–π stacking, we consider energy transfer as the more likely mechanism for $Ru(bpy)_3^{2+*}$ quenching by Cu(salxn).

3.3. Quenching of $Ru(bpy)_3^{2+*}$ by Cu(bppa), Cu(icoph) through electron transfer

As Cu(bppa) and Cu(icoph) are more easily reduced than Cu(salxn), their oxidations by $Ru(bpy)_3^{2+*}$ were calculated to be much more favorable (Table 3). The reactions of $Ru(bpy)_3^{2+*}$ by Cu(bppa) and Cu(icoph) were monitored by transient fluorescence quenching, with each yielding linear Stern–Volmer plots indicating a dynamic quenching reaction. The observed quenching rate constants for Cu(bppa) or Cu(icoph) ($k_{obs} \sim 10^9\ M^{-1}\ s^{-1}$) were noticeably slower than those observed for Cu(salxn), indicating that diffusion was not rate-limiting in these cases.

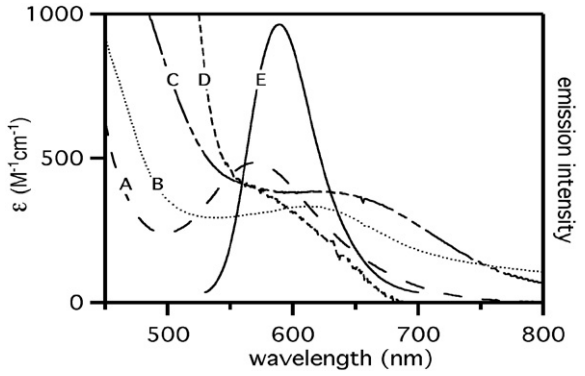

Fig. 3. Absorption spectrum of Cu(salxn) complexes: (A) Cusalen; (B) Cusalpen; (C) Cusalben; (D) Cusalophen; (E) Fluorescence of $Ru(bpy)_3^{2+}$.

Table 3
Time-resolved quenching of $Ru(R_2bpy)_3^{2+*}$ by Cu(bppa), Cu(icoph)

Quencher	Sensitizer	k_{obs} ($\times 10^9\ M^{-1}\ s^{-1}$)	k_q ($\times 10^9\ M^{-1}\ s^{-1}$)	ΔG° (kcal/mol)
Cu(icoph)	$Ru(bpy)_3^{2+}$	8.1	18	−14.9
Cu(bppa)	$Ru(bpy)_3^{2+}$	1.1	1.2	−12.6
Cu(icoph)	$Ru(dmbpy)_3^{2+}$	5.8	9.5	−11.1
Cu(bppa)	$Ru(dmbpy)_3^{2+}$	0.95	0.99	−8.8
Cu(bppa)	$Ru(dombpy)_3^{2+}$	1.9	2.1	−5.9

Lifetimes (μs): $Ru(bpy)_3^{2+}$ (0.6, CH_2Cl_2; 1.2; CH_3CN); $Ru(dmbpy)_3^{2+}$ (1.4, CH_2Cl_2; 1.6; CH_3CN); $Ru(dombpy)_3^{2+}$ (0.4; CH_3CN).

The observed rates (k_{obs}) were corrected for the rate of diffusion (k_{diff}) to obtain diffusion-corrected quenching rates (k_q), $k_q^{-1} = k_{obs}^{-1} - k_{diff}^{-1}$. The diffusion rate was estimated as $k_{diff} = 1.6 \times 10^{10}\ M^{-1}\ s^{-1}$ using the Smoluchowski equation (Eq. (4)), in which k_{diff} is a function of the solution viscosity ($\eta = 0.41$ cP for CH_2Cl_2, $\eta = 0.341$ cP for CH_3CN) [45], the radius of $Ru(bpy)_3^{2+}$ ($r_R = 7.1$ Å) [46], and the radius of Cu(bppa) and Cu(icoph) ($r_Q = 5.3$ Å) [47]

$$k_{diff} = \frac{2RT}{3\eta}\left\{2 + \frac{r_R}{r_Q} + \frac{r_Q}{r_R}\right\} \quad (4)$$

The diffusion corrected quenching rates (k_q) of $Ru(bpy)_3^{2+*}$ by Cu(bppa) or Cu(icoph) were correlated with driving force (Table 3), as predicted for an electron transfer quenching mechanism. Marcus theory predicts that intermolecular electron transfers will exhibit a parabolic $\ln k_q$ vs. ΔG° curve, cresting at $-\Delta G^\circ = \lambda$ [24]. Our quenching data (Fig. 4) was fitted to Eq. (1), yielding $\lambda = 20$ (±2) kcal/mol by fixing the collisional rate at $Z = 1.6 \times 10^{10}\ M^{-1}\ s^{-1}$. The good fit for the quenching data for Cu(bppa) and Cu(icoph) to the electron transfer model is in direct contrast to the driving force independent quenching data for Cu(salxn), suggesting that the more favorable driving force for Cu(bppa) and Cu(icoph) makes oxidation much faster than any energy-transfer quenching.

The reorganization energy for the Cu(bppa) and Cu(icoph) oxidations were very similar to those reported for comparable reactions. The oxidation of an appended tyrosine by $Ru(bpy)_3^{3+}$ apparently exhibited $\lambda = 46$ kcal/mol [19], however that reaction required the release of a proton to the bulk, leading to a significant additional kinetic barrier [19,25]. At elevated pH, when the tyrosine was deprotonated, the reorganization energy for oxidation by $Ru(bpy)_3^{3+}$ was 22 kcal/mol [19,25]. The oxidation of a substituted phenol with internal hydrogen-bonding by aminium radicals exhibited $\lambda = 34$ kcal/mol; while the proton was not released to bulk solvent, the proton-transfer within the internal hydrogen bond would likely impart some additional kinetic barrier [20,21]. The oxidization of substituted phenolates by photo-excited $Ru(NN)_3^{2+*}$ (NN indicates an aromatic diimine) in basic H_2O and H_2O/CH_3CN solution exhibited $\lambda = 25$ kcal/mol [22,23]. It is apparent that the reorganization energy for the $Ru(bpy)_3^{n+}$ oxidations of deprotonated phenolates by ET are all very similar, with values ranging from $\lambda = 20$–25 kcal/mol, and much smaller than those for phenol oxidation which require proton transfer in a PCET.

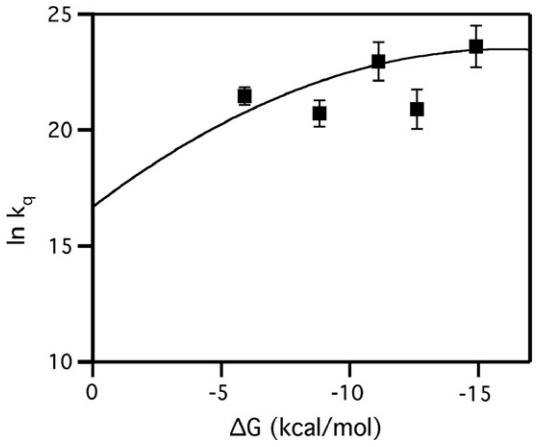

Fig. 4. Marcus plot for the reaction of Cu(bppa) and Cu(icoph) with $Ru(R_2bpy)_3^{2+*}$; see text for fitting details.

The Marcus cross-relation predicts that the reorganization energy for Cu(bppa) and Cu(icoph) oxidation by $Ru(bpy)_3^{2+*}$ should be the average of the self-exchange reorganization energies: $\lambda = \frac{1}{2}(\lambda_{Ru} + \lambda_{PhO})$ [24]. As the reorganization energy for the $Ru(bpy)_3^{2+*/1+}$ couple is dominantly due to outer-sphere reorganization [34], it is rather small. Marcus described the outer-sphere reorganization energy in terms of a dielectric continuum mode (Eq. (5)) [24,48], in which e is the charge of the electron, r_R is the radius of $Ru(bpy)_3^{2+*}$, and D_{op} and D_S are the optical and static dielectric constants of the solvent. Inserting tabulated values for the dielectric constants into Eq. (5) [45], we calculated that $\lambda_{Ru} = 9$ and 12 kcal/mol in CH_2Cl_2 and CH_3CN, respectively

$$\lambda_{Ru} \approx \lambda_o = e^2 \left[\frac{1}{2r_R}\right]\left[\frac{1}{D_{op}} + \frac{1}{D_s}\right] \quad (5)$$

These relationships allow us to estimate the self-exchange reorganization energy for $Cu(bppa)^{+/2+\cdot}$ and $Cu(icoph)^{0+/+\cdot}$ as $\lambda_{PhO.} \approx 30$ kcal/mol, assuming that both complexes have similar values for λ. This implies that, to the extent that these complexes are reasonable models for the Cu-associated tyrosine-derived cofactors found in CAO and GalOx, those proteins may undergo sluggish ET reactions. Typical biological redox proteins, such as those found in cytochromes *c* or azurin, exhibit $\lambda \sim 20$ kcal/mol [49], however the specific function of such proteins is to catalyze ET in energy-transformation pathways. As CAO and GalOx catalyze the $2e^-$ oxidation of small molecules, one-electron redox reactivity may suppressed to minimize inactivation pathways.

Acknowledgements

The authors thank Meaghan Germain for providing samples of Cu(bppa); and Professors S. Thayumanavan (fluorimeter), H. Stidham (PTI instrument), and the UMass-Amherst EPR facility (NSF CHE-0443180) for access to instrumentation. This research was supported by the ACS-PRF #40033-G4.

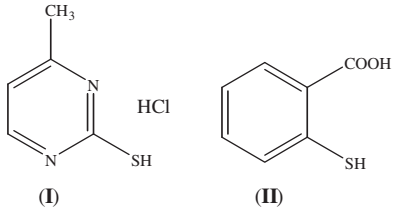

Scheme 1. Formulae of the ligands used; 2-mercapto-4-methyl-pyrimidine hydrochloride (I) and 2-mercapto-benzoic acid (II).

structures, it would be of interest to know the difference for obtaining either structure, if possible. The complexes {[Ph_3Sn(MPMT)]} (**1**) and {[Me_2Sn(MPMT)]$_2$} (**2**) were also prepared by Ma et al [16] by reacting 2-mercapto-4-methyl-pyrimidine hydrochloride with organtoin(IV) chlorides in benzene solution in the presence of EtONa. Crystals of complexes **1** and **2** were grown from ether and ether–dichloromethane solutions, respectively. All four complexes reported here were prepared again, with a slightly modified method, using a mixture of MeOH/H_2O of 1:2 in order to investigate the possible solvent effect in their preparation. Different solvents were also used for their crystallization (see below).

In addition, the inhibitory activity of these four organotin(IV) complexes [14,16] **1–4**, on the catalytic oxidation of linoleic acid to hydroperoxylinoleic acid by the enzyme lipoxygenase LOX is also reported. Such an inhibition may be the cause of the antitumor action of tin complexes [12,13] (Scheme 1).

Table 1
^{119}Sn Mössbauer spectroscopic data for complexes **1**, **3**, and **4**

Complex	Temperature (K)	IS (mm s^{-1})	ΔE_q (mm s^{-1})	Area (%)	IS (mm s^{-1})	ΔE_q (mm s^{-1})	Area (%)
1	80	1.28	1.48	75	1.40	2.53	25
3	80	1.39	3.23	50	1.52	3.32	50
4	80	1.27	2.95	50	1.32	3.26	50

2. Results and discussion

2.1. General aspects

The synthesis of complexes **1–4** were achieved with an alternative method to the one used previously for the synthesis of these complexes [14,16]. Instead of using EtONa, a methanolic/water (1:2) solution of the reactants and KOH were used. Crystallizations were achieved by slow evaporation of methanol/acetonitrile (1:1) solutions for **1** and **2**, and in the case of complexes **3** and **4** dichloromethane/methanol/toluene (3:1:1) solutions were used.

$$R_nSnCl_{4-n} + (4\text{-}n)\ HMPMT \xrightarrow{KOH} \{R_nSn(MPMT)_{4-n}\} + (4\text{-}n)\ KCl$$

n=3; R= Ph- (**1**) and n= 2; R= Me- (**2**);

$$2n\ R_2SnCl_2 + 2n\ H_2MBA \xrightarrow{KOH} \{[R_2Sn(MBA)]_2\}_n + 2n\ KCl$$

n= infinite; R= *n*-Bu- (**3**) and Me- (**4**)

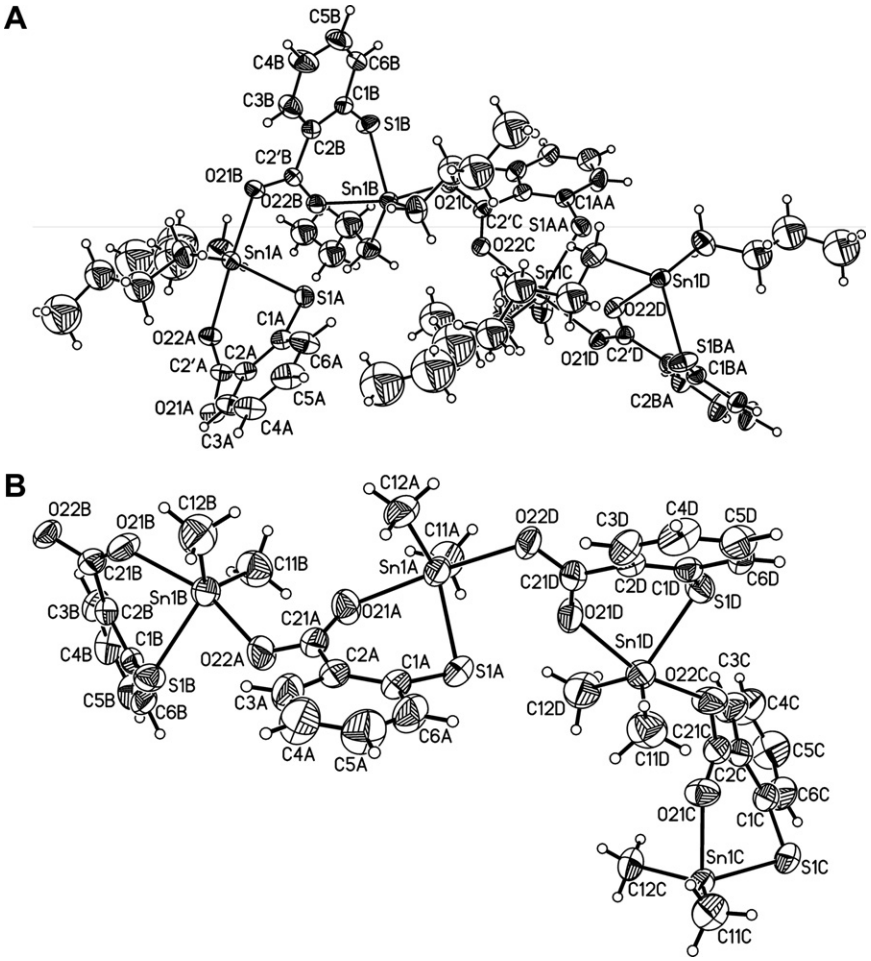

Fig. 1. ORTEP diagrams together with the atomic numbering schemes of the complexes {[(*n*-Bu)$_2$Sn(MBA)]$_2$}$_n$ (**3**) (**A**) and {[Me_2Sn(MBA)]$_2$}$_n$ **(4)** (**B**) measured at 293(2) K.

Both complexes **3** and **4** have a polymeric helical supramolecular structure. The structure of **3** was refined to $R = 6.1\%$, compared to the previous R value of 9.9%. The crystal structure of complex **2** has a monoclinic $P2_1$ space group in contrast to the structure already published with an orthorhombic $Cmc2_1$ space group [16]. The crystal structure of **1** was found to be identical with the previous one [16].

2.2. ^{119m}Sn Mössbauer spectroscopy

The solid state ^{119m}Sn Mossbauer spectroscopic data of complexes **1**, **3** and **4** are given in Table 1. The two symmetric Lorentzian doublets (50:50) observed for **3** and **4**, confirmed the presence of two tin atoms in different chemical environments in the dimers [8,10], which was also confirmed by the X-ray analysis (vide infra). The ΔE_q values of complexes **3** and **4** lie between 2.95 and 3.32 mm s^{-1} in both complexes, indicating distorted trigonal bipyramidal to octahedral geometries. The two symmetric Lorentzian doublets (75:25) observed for **1** indicate the presence of two structural isomers. The ΔE_q value of 1.48 mm s^{-1} corresponds to a complex with a tetrahedral arrangement (75%) while the ΔE_q value of 2.53 mm s^{-1} to a complex with a trigonal bipyramidal geometry around tin (25%) [2].

2.3. Crystal and molecular structure of complexes *1–4*

The structures of **3** and **4** (Fig. 1 and Table 2) consist of dimeric $\{[R_2Sn(MBA)]_2\}$ building blocks (R = Me– or *n*-Bu-group), infinitely repeated in space.

The polymeric structure of **4** consists of dimeric building blocks with a distorted trigonal bi-pyramidal arrangement around Sn(IV). The ligand undergoes double deprotonation upon coordination. In the case of the $[Me_2Sn(MBA)]_2$ dimer, selected distances are Sn1A–S1A 2.4050(11), Sn1A–O21A 2.235(3) and Sn1A–O22D 2.203(3) Å in the first moiety and Sn1B–S1B 2.4197(10), Sn1B–O21B 2.267(3) and Sn1B–O22A 2.174(3) Å for the second moiety (Fig. 1). The corresponding bond distances in the $[(n\text{-Bu})_2Sn(MBA)]_2$ dimer are Sn1A–S1A 2.4141(19), Sn1A–O22A 2.312(4) and Sn1A–O21B 2.191(5) Å for the first moiety and Sn1B–S1B 2.4155(18), Sn1B–O22B 2.1282(6) and Sn1B–O21C 2.216(4) Å for the second. These two units in both complexes are infinitely repeated to form the polymers **3** and **4**. The Sn–O and Sn–S bond distances found in **3** and **4** are similar with the corresponding bond distances measured in the complexes **5** and **6** [15].

Selected angles around the Sn1A atom of the first moiety of the dimer $[Me_2Sn(MBA)]_2$ are O21A–Sn1A–O22D 171.59(9)° and C11A–Sn1A–C12A 129.89(16)°, while those around the Sn1B atom of the second moiety are O21B–Sn1B–O22A 158.02(10)° and S1B–Sn1B–C12B 125.45(13)°. The corresponding angles around the Sn1A atom of $[(n\text{-Bu})_2Sn(MBA)]_2$ are O21B–Sn1A–O22A 177.22(17)° and C11A–Sn1A–C21A 130.35(3)° and those around Sn1B are O21C–Sn1B–O22B 164.35(16)° and C11B–Sn1B–C21B 129.93(3)°. According to Reedijk's criteria [17] the geometry around a metal center is octahedral when the parameter $\tau = (\beta - \alpha)/60$ equals zero and when τ is one it is trigonal bipyramidal. In the case of the $[Me_2Sn(MBA)]_2$ dimer, the τ values are 0.70 and 0.54 for Sn1A and Sn1B, respectively, while in the case of $[(n\text{-Bu})_2Sn(MBA)]_2$ the τ values are 0.78 and 0.57, thus justifying their description as distorted trigonal bipyramidal. The weak Sn···O contacts (Sn1A···O21D = 3.235 and Sn1B···O21A = 3.328 Å in **4** and Sn1A···O22B = 3.076 and Sn1B···O22C = 3.140 Å in **3**) confirm the distortions of the geometry (Fig. 1). The intra-molecular hydrogen bonding interactions observed, C3A[H3A]···O22A = 2.719(5) Å in **4** and C13C[H13C]···O22A = 3.471(4) Å in **3**, stabilize the structures in our case. π–π interactions were observed only in **4**, stabilizing the supramolecular assembly (3.647 Å), (Fig. 2). It is noteworthy that no X–H···O hydrogen bonding interactions were found in the case of complexes **5** and **6**, which have macrocyclic structures [15].

Table 2
Selected bond lengths (Å) and angles (deg) for the tri-organotin(IV) complexes **3** and **4** measured at room temperature (293(2)), e.s.d.'s in parentheses

Complex **3**		Complex **4**

Symmetry codes: [a]: $(-x + 3/2, y + 1/2, -z + 1/2)$, [b]: $(-x + 1/2, y + 1/2, -z + 1/2)$.

The torsional angles Sn–O···O′–Sn′ (namely Sn1B–O22A···O21A–Sn1A, Fig. 1) are −166.18° and 141.98° for **4** and −144.61° and 156.8° in the case of **3** (Sn1A–O22B···O22B–Sn1B). Thus, there is a difference of −24.2° in **4** and −12.2° in **3**, resulting in the formation of helical structures. In contrast, the six such torsional angles in the case of **6** are −151.38°, −164.40°, −160.90° followed by 151.38°, 164.40° and 160.90°, compensating the differences and resulting in the formation of hexanuclear macrocycles [15]. Similarly for **5**, the six torsional angles are 153.50°, −151.13°, 177.59° and −153.50°, 151.13°, −177.59°.

To study the influence of temperature and solvents in the preparation of complex **4** on its structure (helical polymeric or macrocyclic), XRPD spectra were recorded and compared (Fig. 3). The XRPD spectra of the product with the reaction carried out at 40 °C (Fig. 3A), 20 °C (Fig. 3B) and using EtOH as a recrystallization solvent (Fig. 3C) were extremely similar to the simulated spectrum (Fig. 3D) with the helical-polymer structure and were different from the simulated spectrum (Fig. 3E) of the macrocyclic product reported by Ma et al. [15].

The supramolecular assembly of compound **4** exhibits a helical pattern where in every two asymmetric units appreciable π–π stacking interactions between neighboring phenyl groups exist. The interplanar distance is 3.67 Å and the interplanar angle is 0°, implying completely parallel phenyl groups. The angle formed by the plane of the phenyl ring and the stack column axis is 19.89 °, characterizing this interaction as a parallel displaced non-covalent interaction [18]. It is likely that these π–π interactions play an important role in the stabilization of the molecular units. However

this is not the case in the butyl analog **3** where the interaction between the neighboring phenyl groups is considered as point-to-face C–H···π, with the distance between the centroid of the ring and the nearest carbon atom being 3.99 Å and the H···centroid distance being 3.37 Å. On the other hand, the weak intermolecular C–H···S hydrogen bonds together with stronger C–H···O ones, may also play an important role in the supramolecular arrangements.

2.4. DFT calculations

In an attempt to better understand the formation of two structurally different complexes of the formulae $\{[Me_2Sn(MBA)]_2\}_n$ (**4**) and $\{[Me_2Sn(MBA)]_6\ H_2O\}$ (**6**) we have also used computational DFT methods. Due to the requirement of lesser computational resources, only the methyl derivative has been examined here. Ignoring solid-state effects, symmetry plays a significant role to the computed outcome, since non-symmetric structures tend to converge to symmetric ones [19]. This fact led us to follow two different procedures: (i) to fully optimize all the geometrical parameters (ii) to impose symmetry constrains with the intention of improving the approximation of the solid state motif obtained from X-ray diffraction techniques. These constrains concern the dihedral angles of the six-membered rings formed by Sn, S, O, and two C atoms of each of the phenyl rings. As it is evident from the calculated data, although the standard LANL2DZ basis set is known to provide reliable results [20], the 3-21G** type basis set takes account of polarization functions on all atoms and consequently gives a more precise description of the tin-ligand interactions. The model with no constrains applied gave marginally better results than the one with the preset dihedral angles. The results showed that the energy difference between the two different structures, macrocycle [15] and helical [14], differ only slightly with ΔE = 1.65 Kcal/mol.

Fig. 4 shows the molecular diagrams of complexes **1** and **2**.

The crystal structure of complex **2** has now been refined in the monoclinic $P2_1$ space group, with no significant differences in the bond distances and angles from those found previously [16]. Thus

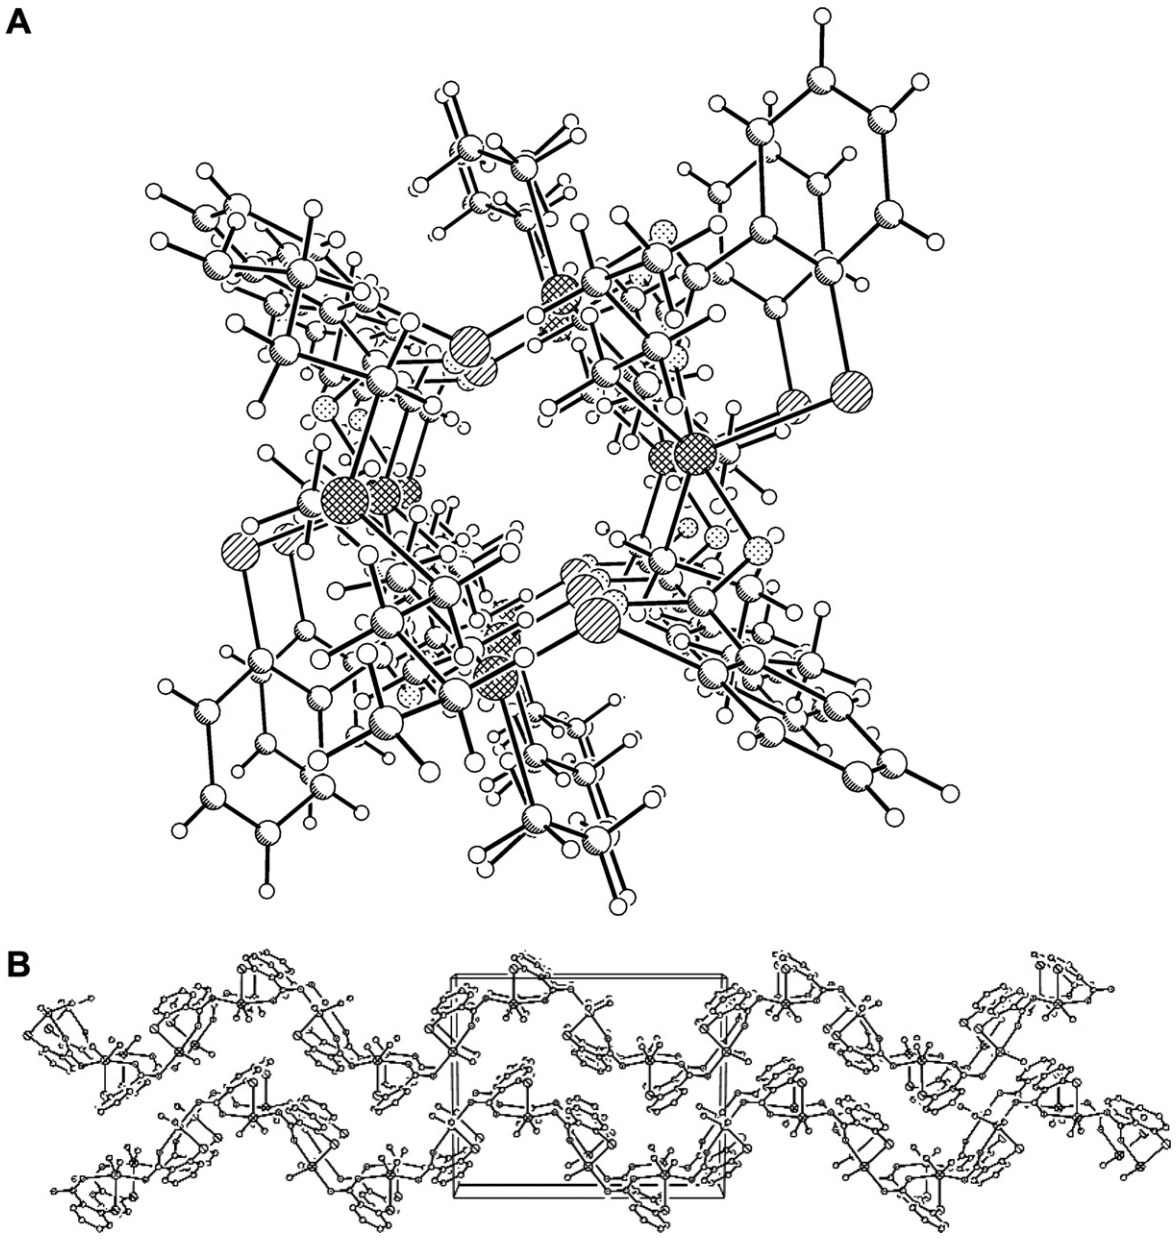

Fig. 2. The unit cell of the complexes **3** (**A**) and **4** (**B**). There are two independent helixes in the cell of **4**.

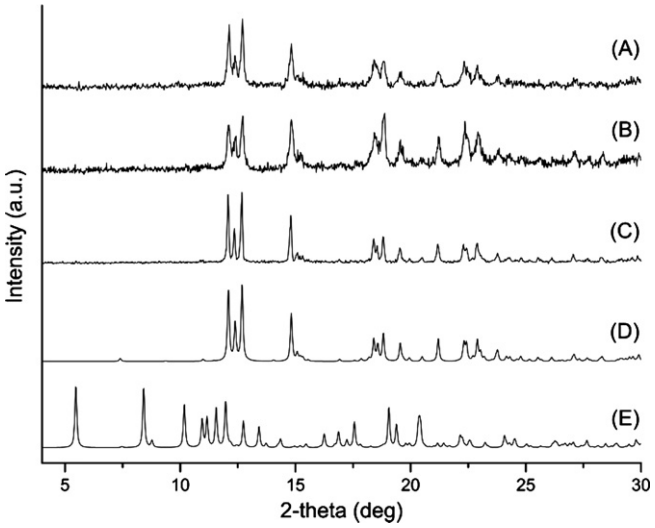

Fig. 3. XRPD diagrams of the reaction products (**A**) at 40 °C, (**B**) at 20 °C, (**C**) after recrystallization in EtOH and the simulated XRPD diagrams from the pattern of the single crystal X-ray diffraction of **4** (**D**) and **5** (**E**).

two sulfur and two nitrogen atoms from thiol ligands are coordinated to Sn(IV) forming a distorted octahedral arrangement around the metal center in case of **2**. This coordination mode through N, S donor atoms of the ligand is similar to that observed previously in $[Me_2Sn(PMT)_2]$ (HPMT = 2mercapto-pyrimidine) [21]. The presence of the methyl substituent, however, at the 5-position in the pyrimidine ring in the case of the 2-mercapto-5-methyl-pyrimidine ligand generates isomerism upon coordination to the tin atom. Thus in the case of **2** the ligand is coordinated through its adjacent and remote forms (Fig. 4B). The Sn–S bond distances are 2.490(3) and 2.496(2) Å, respectively in contrast to the 2.480(2) and 2.484(3) Å reported previously [16]. Table 3 summarizes the selected bond distances and angles found for complex **2** within this work in comparison to those previously reported [16]. The structure of **1** is found to be identical with that previously reported [16].

#1 is the geometrical equivalent C atom of C(11), bonded to Sn (See Ref. [16]).

*2.5. Study of the peroxidation of linoleic acid by the enzyme of lipoxygenase (LOX) in the presence of complexes **1–4***

The influence of the complexes **1–4** on the oxidation of linoleic acid by the enzyme LOX were studied over a wide concentration range. The degree of LOX activity (**A**, %) in the presence of each complex was calculated according to the method described previously [5–11]. The IC_{50} values determined are 23 (**1**), 30 (**2**), 30 (**3**) and 30 (**4**) μM, respectively, while no such activity was shown for cisplatin [5–11]. These values lie at the higher range to those found for other similar Sn(IV) complexes. For example, the IC_{50} values found for the organotin compounds tested towards LOX, were 26 and 14 μM for $[(C_6H_5)_2SnCl(HMNA)]$ and $[(C_6H_5)_3Sn(MNA)\text{-}Sn(C_6H_5)_3$ (acetone)] (H_2MNA = 2-thiobarbituric acid), respectively [9], 19, 16 and 21 μM for $[(C_6H_5)_3Sn(MBZT)]$, $[(C_6H_5)_3Sn(MBZO)]$, and $[(C_6H_5)_3Sn(CMBZT)]$ (MBZT = 2-mercapto-benzothiazole, MBZO = 2-mercapto-benzoxazole and CMBZT = 5-chloro-2-mercapto-benzothiazole), respectively [6], 10, 13 and 14 μM for $[(C_6H_5)_2Sn(CMBZT)_2]$, $[(n\text{-}C_4H_9)_2Sn(CMBZT)_2]$, and $[(CH_3)_2Sn\text{-}(CMBZT)_2]$, respectively [6], 61.3, 26.2, 20.5 and 16.9 μM for $[(CH_3)_2Sn(PMT)_2]$, $[(n\text{-}C_4H_9)_2Sn(PMT)_2]$, $[(C_6H_5)_2Sn(PMT)_2]$, and $[(C_6H_5)_3Sn(PMT)]$ (PMT = 2mercapto-pyrimidine), respectively, [7] and 25 μM for $[(n\text{-}Bu)_3Sn(TBA)\cdot H_2O]$ (HTBA = 2-thiobarbituric acid) [5].

3. Conclusions

The antiproliferative activity of organotin(IV)-thioamide complexes were found to correspond to the regularity of inhibition of the lipoxygenase (LOX) activity [5–11]. This inhibition activity was also found to be independent of the geometry or the number and type of the aryl and alkyl substituents at the tin(IV) ion, but it is determined to a great extent by the ligand nature [5–11]. Therefore the IC_{50} values towards LOX activity found for complexes 1–4 (20–30 μM), which lie at the higher range of the corresponding ones for similar complexes, suggest mild or low antitumor activity [5–11].

On the other hand, slight modifications in the synthetic and crystallization conditions in the case of complexes **3** and **4** results in different conformations of the products, independent of the hydrogen bonding and π–π interactions [15]. The small ΔE = 1.65 Kcal/mol between the two conformations (helical or macrocycle) observed in the dialkyltin derivatives with 2-mercapto-benzoic acid may easily be overcome subject to slight solvent or temperature modifications, leading to macrocycles or polymers. Thus, there are inherent physicochemical reasons which lead to the particular packing characteristics of each structure. The self-assembly process of these type of complexes, seems to be fortuity dependent and not based on intermolecular C–H···S weak

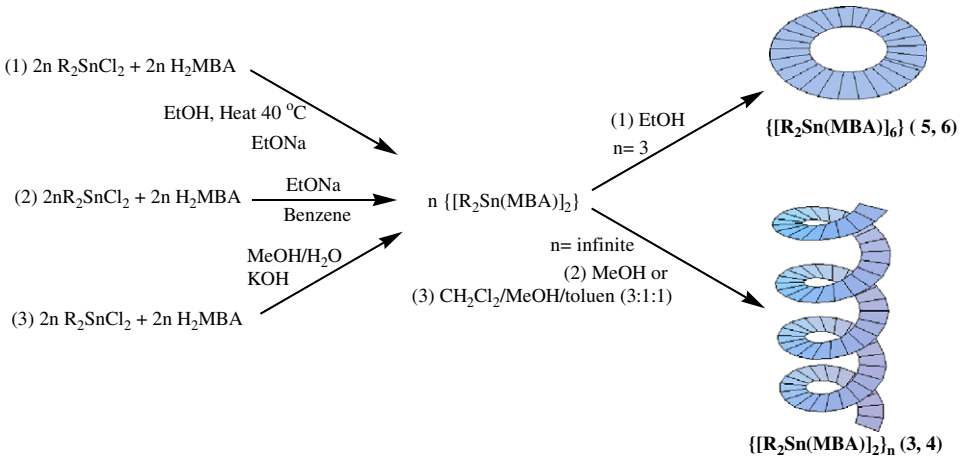

Fig. 5. Reaction conditions and structures obtained.

hydrogen bonds and π–π interactions. The results are summarized in Fig. 5.

4. Experimental

4.1. Materials and instruments

All solvents used were of reagent grade. 2-Mercapto-benzoic acid and the diorganotin dichlorides (Aldrich) were used with no further purification. Elemental analyses for C, H, N, and S were carried out with a Carlo Erba EA model 1108 elemental analyzer. The ^{119}Sn Mössbauer spectra were collected at various sample temperatures (85–150 K), with a constant acceleration spectrometer equipped with $CaSnO_3$ source kept RT. The calibration of the spectrometer was carried out with a ^{57}Co source and Fe absorber at room temperature. The line widths were very close to the natural width (0.28 mm/s). The content of the tin samples was calculated to be approximately 4 mg Sn in a 2 cm^2 area of sample holder. X-ray powder diffraction patterns, from powder derived from the crystals, were obtained using a Bruker AXS D8 Advance diffractometer in Bragg–Brentano geometry equipped with a Cu sealed-tube radiation source (λ = 1.54178 Å) and a secondary beam graphite monochromator.

4.2. Synthesis and crystallization of 1–4

A methanolic (3 cm^{-3}) solution of $(C_6H_5)_3SnCl$ (0.385 g, 1 mmol, (**1**)) and $(CH_3)_2SnCl_2$ (0.219 g, 1 mmol (**2**)) was added to a clear solution of 2-mercapto-4-methyl-pyrimidine (0.162 g, 1 mmol (**1**) and 0.326 g, 2 mmol (**2**)) in distilled water (8 cm^{-3}) which was treated with KOH 1 N (2 cm^{-3}, 2 mmol (**1**) and 4 cm^{-3}, 4 mmol (**2**)). A white precipitate formed immediately, which was filtered off after stirring for 3 h, washed with 5 ml of cold distilled water and dried *in vacuo* over silica gel. Complexes **3** and **4** were prepared by a similar method. A suspension of 2-mercapto-benzoic acid (0.308 g, 2 mmol) in distilled water (8 cm^{-3}) was treated with a solution of KOH 1 N (4 cm^{-3}, 4 mmol), giving a clear solution. A methanolic (3 cm^{-3}) solution of the diorganotin(IV) dichloride ($(n\text{-}C_4H_9)_2SnCl_2$ 0.304 g, 1 mmol, (**3**) and $(CH_3)_2SnCl_2$ 0.219 g, 1 mmol (**4**)) was subsequently added. A white precipitate formed immediately, which was filtered off after stirring for 3 h, washed with 5 ml of cold distilled water and dried *in vacuo* over silica gel. The yields of the preparations are 60% for **1**, **2,** and **4** and 50% for **3**. Crystals of complexes **1** and **2** suitable for X-ray analysis were formed by slow evaporation of methanol/acetonitrile (1:1) solutions while crystals of **1** and **2** suitable for X-ray analysis were formed by slow evaporation of dichloromethane/methanol/toluene (3:1:1) solutions.

4.3. Computational details

Using the crystallographic data reported above as a starting point, we performed geometry optimization at the gradient-corrected density functional theory (DFT) level by utilizing Becke's three-parameter fit of the exact exchange correlation potential [22] in combination with the gradient-corrected functional of Lee et al. [23], (B3LYP), within the GAUSSIAN 03 software package [24]. For this study, the all-electron, split-valence 3-21G** basis set and the LANL2DZ double-zeta effective core potential basis set were utilized. Attempts to use a mixed basis set (LANL2DZ/6-31G**) for increased accuracy were not successful as the optimization did not meet the convergence criterion. To characterize the nature of the stationary points, a harmonic vibrational calculation was carried out. No imaginary frequencies were computed.

4.4. X-ray structure determination

Data were collected by the ω scan technique in the range 2.6° < 2θ < 28.8° (**1**), 2.3° < 2θ < 29.0° (**2**), 2.8° < 2θ < 25.0° (**3**) and 2.6° < 2θ < 25.0° (**4**) on a KUMA KM4CCD four-circle diffractometer [25] with a CCD detector, using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. Cell parameters were determined by a least-squares fit [25]. All data were corrected for Lorentz-polarization effects and absorption [26].

The structure was solved with direct methods with SIR-92 [27] and refined by full-matrix least-squares procedures on F^2 with SHELXL97 [28]. In **4** all non-hydrogen atoms were refined anisotropically, hydrogen atoms were located at calculated positions and refined as a 'riding model' with isotropic thermal parameters fixed at 1.2 times (1.3 for methyl groups) the U_{eq}'s of the appropriate carrier atom. In **3** the *n*-butyl chains were disordered over two positions. Weak constraints for the molecular geometry were applied; the disordered atoms were refined isotropically, all other non-hydrogen atoms were refined anisotropically. Hydrogen atoms were treated as in **1**. Significant crystal data are given below:

Compound **1**: $C_{23}H_{20}N_2SSn$, orthorhombic, *Pbca*, a = 9.4530(19) Å, b = 15.525(3) Å, c = 28.170(6) Å, V = 4134.2(15) Å^3, Z = 8, T = 293(2) K, $\rho_{(calc)}$ = 1.527 g cm^{-3}, μ(Mo Kα) = 1.3 mm^{-1}, reflections collected: 17766, unique: 4984 (R_{int} = 0.019), 3969 observed data [$I > 2\sigma(I)$], final R: 0.0231, wR_2 [$I > 2\sigma(I)$] 0.0498, S = 1.04, min/max $\Delta\rho$: −0.73/1.01 e Å^{-3}.

Compound **2**: $C_{12}H_{16}N_4S_2Sn$, monoclinic, $P2_1$, $a = 7.5720(10)$ Å, $b = 17.704(2)$ Å, $c = 12.062(2)$ Å, $V = 1617.0(4)$ Å^3, $Z = 4$, $T = 293(2)$ K, $\rho_{(calc)} = 1.640$ g cm^{-3}, μ(Mo Kα) = 1.8 mm^{-1}, reflections collected: 2328, unique: 1191 ($R_{int} = 0.039$), 1029 observed data [$I > 2\sigma(I)$], final R: 0.0341, wR_2 [$I > 2\sigma(I)$] 0.0789, $S = 1.11$, min/max $\Delta\rho$: −1.09/0.99 e Å^{-3}.

Compound **3**: $C_{30}H_{44}O_4S_2Sn_2$, monoclinic, $P2_1/n$, $a = 10.9297(6)$ Å, $b = 14.8199(8)$ Å, $c = 22.3115(9)$ Å, $\beta = 97.739(4)°$, $V = 3581.0(3)$ Å^3, $Z = 4$, $T = 293(2)$ K, $\rho_{(calc)} = 1.429$ g cm^{-3}, μ(Mo Kα) = 1.5 mm^{-1}, reflections collected: 16256, unique: 6229 ($R_{int} = 0.036$), 4439 observed data [$I > 2\sigma(I)$], final R: 0.0612, wR_2 [$I > 2\sigma(I)$] 0.1950, $S = 1.08$, min/max $\Delta\rho$: −0.79/2.02 e Å^{-3}.

2.4. Physical measurements

Melting points were determined using an Electrothermal digital m.p. apparatus. Magnetic susceptibility was measured with a Sherwood Auto MSB at 298 K. All susceptibilities were corrected for the diamagnetic contribution using Pascal's constant. Carbon, hydrogen, nitrogen and sulfur analyses were carried out using a Leco CHNS-932 analyzer. The IR spectra were recorded in the range of 400–4000 cm^{-1} with KBr pellets on either a Perkin Elmer 1650X or 1750X infrared spectrophotometer. The molar conductance of a 10^{-3} M solution of each metal complex in DMSO was measured at 29 °C using a Jenway 4310 conductivity meter and a dip-type cell with platinized electrode. The UV–Vis spectra were recorded on a Shimadzu UV-2501 PC spectrophotometer (800–200 nm). ^1H NMR spectra were recorded on a NMR JNM ECA400 spectrometer. Metal determinations were carried out using a Perkin Elmer Plasma 1000 emission spectrometer.

2.5. X-ray structure determination

Crystals of SBNBODTC formed when an ethanol solution was allowed to slowly evaporate over a couple of weeks. A single crystal was selected and mounted on a glass fibre using perfluoropolyether oil and cooled rapidly to 150 K in a stream of cold N_2 using an Oxford Cryosystems CRYOSTREAM unit. Diffraction data were measured using an Enraf-Nonius Kappa CCD diffractometer (graphite-monochromated Mo Kα radiation, $\lambda = 0.71073$ Å). Intensity data were processed using the DENZO-SMN package [9]. The crystal was found to be triclinic with $a = 9.7080(2)$ Å, $b = 11.2247(3)$ Å, $c = 14.1051(4)$ Å and $\alpha = 85.6063(11)°$, $\beta = 75.8090(11)°$, $\gamma = 74.1825(12)°$. The structure was solved in the space group $P\{\bar{1}\}$ using the direct-methods program [10] to locate all non-hydrogen atoms. Subsequent full-matrix least-squares refinement on F^2 was carried out using CRYSTALS Program Suite [11]. Coordinates and anisotropic thermal parameters of all non-hydrogen atoms were refined. Hydrogen atoms were located through a difference Fourier map. Hydrogens on the N and C were refined positionally and isotropically. Further crystallographic and refinement details are shown in Table 5.

2.6. Bioactivity

Antimicrobial and cytotoxic activities were evaluated at the Animal Cell and Tissue Culture Laboratory, Department of Biotechnology, Universiti Putra Malaysia.

2.7. Target microorganisms

Eight pathogens were used to test the biological potential of the ligands and metal complexes. They were methicillin-resistant *Staphylococcus* (MRSA); *Pseudomonas aeruginosa* (60690); *Bacillus subtilis* mutant defective DNA repair (B28) *Saccharomyces typhimurium* (S-T), *Candida albicans* (C.A), *Aspergillus ochraceous* (398), *Saccharomyces cereviceae* (20341), *Candida lypolytica* (2075). The sources of microbes and culture maintenance were as previously described [12,13].

2.8. Qualitative antimicrobial assay

Antimicrobial activity of each compound was qualitatively determined by a modified disk diffusion method [12]. A lawn of microorganisms was prepared by pipetting and evenly spreading inoculum (10^{-4} cm^3, adjusted turbidometrically to 10^5–10^6 cfu cm^3 (cfu: colony forming units) on to agar set in Petri dishes, using nutrient agar (NA) for the bacteria and potato dextrose agar (PDA) for fungi. Whatman no. 1 filter paper disks of 6 mm diameter were impregnated with stock solution of the compound (100 mg cm^{-3}) and dried under sterile conditions. The dried disks were then placed on the previously inoculated agar surface. The plates were inverted and incubated for 24 h at 30 °C for bacteria and 37 °C for fungi. Antimicrobial activity is indicated by the presence of clear inhibition zones around the disks. Commercially available streptomycin was used as antibacterial control and nystatin as antifungal control.

2.9. Cytotoxic assay

HL-60 (human myeloid leukemia) cell line was obtained from the American Type Culture Collection, USA HL-60 was cultured in RPMI-1640 (Sigma) medium supplemented with 10% fetal calf serum, Cytotoxicity was determined using the microtitration of 3-(4, 5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) (Sigma, USA) following Mosmann's method [14]. Controls that contained only cells were included for each sample. Cytotoxicity was expressed as IC_{50}, i.e. the concentration that reduced the absorbance of treated cells by 50% with reference to the control (untreated cells). Doxorubicin and Tamoxifen were used as cytotoxic standards.

3. Results and discussion

3.1. Infrared and nuclear magnetic resonance spectra

The physical and analytical data for the SBNBODTC and its metal complexes are shown in Table 1. All analytical data obtained are in agreement with proposed structures. Important absorption bands in the IR spectra of these compounds are shown in Table 2.

S-Benzyl-β-*N*-(benzoyl) dithiocarbazate was formed from reaction of SBDTC with benzoyl chloride in the presence of potassium hydroxide. In solution, the thione tautomer of SBDTC is unstable and converted to the more stable thiolo forms by enethiolization [8]. Through the loss of a proton, SBDTC behaves as a uninegatively charged weak base due to resonance involving the nonbonding pair of electrons on the nitrogen atom thus the benzoyl group is directed to the α-nitrogen on SBDTC forming *S*-benzyl-β-*N*-(benzoyl) dithiocarbazate [15]. Steric hindrance due to the benzyl group in SBDTC also contributes to the formation of *S*-benzyl-β-*N*-(benzoyl) dithiocarbazate. Four tautomeric forms are possible for SBNBODTC (Fig. 1).

The spectrum of SBNBODTC shows sharp and strong υ(C=O) in addition to absorption bands in common with SBDTC. The υ_{asym}(N–H) and υ_{sym}(N–H) bands associated with the free amine group in SBDTC were replaced with a medium intensity band at 3062 cm^{-1} in the spectrum of SBNBODTC which is assigned to secondary υ(N–H). The absence of υ(S–H) and υ(O–H) from its IR spectrum, shows that SBNBODTC exists primarily as the thione tautomer (Fig. 1a) in the solid state (Table 2). The presence of the peak at 3.38 ppm attributed to the S–H proton and the absence of O–H in ^1H NMR spectrum confirmed that SBNBODTC exists as the thiol in DMSO-*d*6 solution. The signal at δ10.99 ppm is attributed to the N–H group on the aliphatic nitrogen atom, and resonance peaks associated with the aromatic groups are observed in the range δ 7.23–7.91 ppm. Combination of IR and NMR spectra verify that SBNBODTC exists in the thione form in solid state but undergoes enethiolization to form more stable thiolo tautomer in solution [8].

Both SBDTC and SBNBODTC display strong bands indicating the presence of C=S at 1048 cm^{-1} and 1052 cm^{-1}, respectively. However, this band is absent in the spectra of all the complexes indicating that ligation occurred through the thiolo sulfur. This is further supported by the splitting of υ(CSS) in these IR spectra. The υ(C=O) band exhibited a negative shift for all complexes clearly showing participation of carbonyl oxygen in the coordination to the metal

Table 1
Physical and analytical data of SBNBODTC and its complexes

Compound	Color	M.p. (°C)	Found (Calculated %)				Metal (%)	Yield (%)
			C	H	N	S		
$C_{16}H_{16}N_2OS_2$ (SBNBODTC)	white	143–144	60.43 (60.73)	5.62 (5.10)	8.35 (8.85)	20.99 (20.27)		75

$Cu(OS)_2$	3058		966, 850	1584	1292
$Ni(OS)_2$	3058		972, 930	1600	1294
$Pb(OS)_2$	3058		946, 908	1600	1294

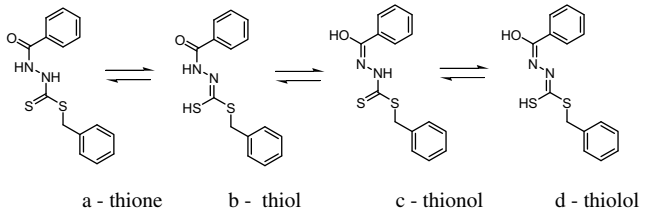

Fig. 1. Thione–thiol–thionol–thiolol tautomerism.

[16,17]. That there was no significant shift in either υ(N–N) or υ(N–H) corresponding to the *sec* NH group of SBNBODTC upon complexation shows that coordination did not occur through nitrogen.

3.2. Magnetic and conductivity data

The molar conductance data (Table 3) showed that all the metal complexes are essentially non-electrolytes in DMSO, indicating that they do not dissociate in solution. At room temperature, the cobalt, copper and nickel complexes are paramagnetic (Table 3). These paramagnetic Ni^{2+} and Co^{2+} complexes are expected to be tetrahedral while the Cu^{2+} complex should be square planar [18].

3.3. Electronic spectra

The spectrum of the SBNBODTC exhibits bands at ~281 and 260 nm attributed to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions respectively. These do not shift significantly upon complexation. $Cd(OS)_2$ showed absorption bands at 280–322 nm which may be attributed to intra-ligand transitions. $Co(OS)_2$ displayed absorption bands at 361 nm corresponding to the $^1T_{2g} \leftarrow {}^1A_{1g}$ d–d transition and at 281 nm, caused by intra ligand charge transfer, $n \rightarrow \pi^*$. $Cu(OS)_2$ exhibited absorption at 504 nm corresponding to the $^2E_{1g} \leftarrow {}^2B_{1g}$ transition [6]. The band at 276 nm is presumably due to charge transfer. This low spin complex thus has a square planar stereochemistry.

$Ni(OS)_2$ exhibits d–d transition bands at 729 and 537 nm attributable to $^3T_1(P) \leftarrow {}^3T_1(F)$, which may be observed as doublet due to the spin–orbital coupling compatible with the $Ni(OS)_2$ in an distorted tetrahedral environment [18]. The remaining bands at 387 and 280 nm were caused by charge transfer. The electronic spectra for $Pb(OS)_2$ exhibit charge transfer bands at 326 and 273 nm. (see Table 4).

3.4. X-ray crystal structure of S-benzyl-β-N-(benzoyl) dithiocarbazate(SBNBODTC)

A perspective view of SBNBODTC with its numbering scheme is shown in Fig. 2. A summary of crystal data and structure refinement parameters is given in Table 5. The relevant bond distances and bond angles are given in Table 6. The asymmetric unit consists of two independent *S*-benzyl-β-*N*-(benzoyl) dithiocarbazate molecules. Both asymmetric unit SBNBODTC crystallized as the thione in *cis–cis* conformation with the N–N bond adopting a *cis* geometry with respect to C=S, while the *S*-benzyl group adopts a *cis* geometry with respect to the thione sulfur atom across the C–S bond. Both molecules are related with a 179.21° rotation across [−1.0, −0.7, 0.6]. The asymmetric units deviates to each other in 25.76(5)°. The differences of the bond lengths of both independent molecules are below 3σ except for C2–N4 and S3–C2 (3.1σ and 3.2σ).

The C=S bond distances for SBNBODTC are shorter than that in SBDTC (1.678(3) Å) [19] but are comparable with Schiff bases derived from SBDTC [20,21]. These lengths are intermediate between the C–S and C=S bonds [22] showing there are conjugation effect along the –C–N–N–C(=S) bond. The C=O bond distances are comparable with previous literature as double bond character [22]. These two bonds are essential to confirm that SBNBODTC exist as thione tautomer.

The N4–N5 [1.384(2) Å] and N24–N25 [1.389(2) Å] are slightly longer than in Schiff bases of SBDTC, e.g. 1.3765(19) Å [20],

Table 3
UV–Vis, conductivity and magnetic susceptibility measurements data of SBNBODTC and its metal complexes

Compound	Λ ($\Omega\ cm^{-2}\ mol^{-1}$)	λ_{max}, nm (log ε, $cm^{-1}\ mol^{-1}\ L$)	μ_{eff} (B.M.)
SBNBODTC (OS)	0.1	281 (4.208), 260 (4.195)	
$Cd(OS)_2$	2.705	322 (3.942), 308 (3.921), 280.0 (4.217)	diamagnetic
$Co(OS)_2$	2.275	361 (3.607), 281 (4.140)	4.538
$Cu(OS)_2$	0.07	509 (3.207), 322 (4.330), 271 (4.374)	1.868
$Ni(OS)_2$	0.1	729 (2.068), 537 (2.068), 387 (3.868), 280 (3.993)	3.241
$Pb(OS)_2$	0.725	326 (4.266), 273 (4.391)	diamagnetic

Table 4
Cytotoxic activity of SBNBODTC ligand and its metal complexes

Compound	HL-60 (IC_{50}, μg cm^{-3})[a]
SBNBODTC (OS)	1.00
$Cd(OS)_2$	5.23
$Co(OS)_2$	5.62
$Cu(OS)_2$	2.15
$Ni(OS)_2$	3.62
$Pb(OS)_2$	1.54
Doxorubicin	0.1
Tamoxifen	36

[a] IC_{50} = inhibition concentration at 50%, i.e., the concentration to reduce growth of cancer cells by 50%. IC_{50} <5.0 μg cm^{-3} – strongly active; 5.0 ⩽ 10.0 μg cm^{-3} – moderately active; 10.0–25.0 μg cm^{-3} – weakly active; >25.0 μg cm^{-3} – not active.

1.3747(13) Å [21], which may due to delocalization along –C–N–N–C– involving C6–O7 and C26–O27 double bonds (1.240(2) Å and 1.233(2) Å).

The intramolecular hydrogen bonds, N4–H41···O7 [2.903(4) Å] and N24–H241···O27 [2.816(4) Å] stabilize the *cis–cis* conformation (Fig. 3) by imposing angle strain, N25–C26–O27 [122.61 (18)°], N24–N25–C26 [120.18(17)°], N4–N5–C6 [118.98(16)°] and N5–C6–O7 [120.88(17)°]. The N5–H51···O27 and N25—H251···O7 contacts are intermolecular hydrogen bonds that connects the molecules in its 3D packing [Fig. 3].

3.5. Biological activity

3.5.1. Antimicrobial assay

Clear inhibition zones less than 15 mm indicated that the all compounds synthesized are inactive against the pathogens tested. SBNBODTC was moderately active against Methicillin resistant *Staphyloccus* (MRSA) (9 mm diameter inhibition zone). $Cu(OS)_2$ is moderately active towards both *Pseudomonas aeruginosa* (60690) and *Saccharomyces typhimurium* (S–T). This result contrasts with

the marked activity of SBDTC and its metal complexes against bacteria and fungi [6,7]. The addition of the benzoyl functionality has rendered it moderately active.

3.5.2. Cytotoxic activity

SBNBODTC, $Cu(OS)_2$, $Ni(OS)_2$ and $Pb(OS)_2$ displayed marked cytotoxicity ($IC_{50} < 5.0\ \mu g\ cm^{-3}$) against HL-60 (human myeloid leukemia). $Cd(OS)_2$ and $Co(OS)_2$ are moderately active against HL-60 with IC_{50} of 5.23 and 5.62, respectively. The rank order of potency as a function of chelated metal ion follows the order Co < Cd < Ni < Cu < Pb. That there was no enhancement in cytotoxicity upon complexation of SBNBODTC with metal ions was unexpected considering that such enhancement has often been observed for related complexes containing NS donor ligands.

The similar reaction of ferrocenoylacetone (2.485 g, 9 mmol) and *N*-(2-hydroxyethyl)-1,2-diaminoethane (0.959 g, 9 mmol) in 25 ml of THF for 24 h afforded 2.70 g (84%) of enaminone $H_3\mathbf{L}^2$ as a dark red solid. M.p. 113 °C. *Anal.* Calc. for $C_{18}H_{24}FeN_2O_2$: C, 60.69; H, 6.79; N, 7.86. Found: C, 60.60; H, 6.75; N, 7.84%. IR (KBr disk, cm^{-1}): ν(OH) and ν(secondary amine NH), 3334 (br, m), ν(enamine NH) 3098 (w), ν(C=O) and ν(C=C) 1596 (vs) and 1527 (s). UV (nm, in DMF): λ_{max} ($\varepsilon \times 10^4$, in $dm^3\ mol^{-1}\ cm^{-1}$) 271.00 (B-band) (0.45), 342.50 (K-band) (1.27), 452.50 (CT-band) (0.08). ^1H NMR ($CDCl_3$, ppm): δ 1.93 (s, 1H, NH), 2.01 (s, 1H, OH), 2.02 (s, 3H, CH_3), 2.80–2.85 (t, 2H), 2.90–2.92 (t, 2H), 3.40–3.43 (q, 2H), 3.66–3.68 (t, 2H, OCH_2), 4.15 (s, 5H, C_5H_5), 4.34 (s, 2H, (H^3, H^4) of C_5H_4 ring), 4.71 (s, 2H, (H^2, H^5) of C_5H_4 ring), 5.29 (s, 1H, CH), 11.10 (s, 1H, enamino NH).

2.2. Syntheses of mixed-ligand complexes **I** and **II**

A solution of $Cu(OAc)_2 \cdot H_2O$ (0.1997 g, 1 mmol) and $H\mathbf{L}^1$ (0.360 g, 1 mmol) in 20 ml of absolute ethanol was stirred for 6 h at room temperature. The mixture was filtered to afford the brown crude product. The resulting solid was recrystallized from dichloromethane and petroleum ether to give 0.395 g (82%) of **I** as brown crystals. M.p. 176.2–176.8 °C. *Anal.* Calc. for $C_{22}CuH_{22}FeN_2O_3$: C, 54.84; H, 4.60; N, 5.81. Found: C, 54.92; H, 4.72; N, 5.73%. IR (KBr disk, cm^{-1}): ν(C=O) 1601 (vs), ν(C=C) 1509 (vs). UV (nm, in DMF): λ_{max} ($\varepsilon \times 10^4$, in $dm^3\ mol^{-1}\ cm^{-1}$) 270.00 (B-band) (1.08), 354.80 (2.43) (K-band), 454.20 (0.46) (CT-band).

A solution of $Cu(OAc)_2 \cdot H_2O$ (0.057 g, 28 mmol) and $H_3\mathbf{L}^2$ (0.102 g, 0.28 mmol) in 20 ml of absolute ethanol was stirred for 10 h at room temperature. The solvent was removed under vacuum, and the residue was recrystallized from dichloromethane and petroleum ether (60–90 °C) to afford 0.122 g (91%) of **II** as black crystals. M.p. 101.5–101.9 °C. *Anal.* Calc. for $C_{20}CuH_{26}FeN_2O_4$: C, 50.27; H, 5.48; N, 5.86. Found: C, 50.55; H, 5.64; N, 5.65%. IR (KBr disk, cm^{-1}): ν(OH) and ν(secondary amine NH), 3243 (s), ν(C=O) 1582 (s), ν(C=C) 1507 (vs). UV (nm, in DMF): λ_{max} ($\varepsilon \times 10^4$, in $dm^3\ mol^{-1}\ cm^{-1}$) 290.00 (B-band) (6.19), 340.00 (2.06) (K-band), 450.00 (0.12) (CT-band).

2.3. Crystal structure determinations

X-ray data were collected on an Enraf-Nonius CAD4 diffractometer for $H\mathbf{L}^1$, **I** and **II** at 295 K using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The structures were solved by direct methods and subsequently refined on F^2 by using full-matrix least-squares methods, all non-hydrogen atoms were anisotropically refined, and hydrogen atoms were located at calculated positions [12]. A summary of the data collection and structure refinement parameters of $H\mathbf{L}^1$, **I** and **II** is given in Table 1. Published plots of $H\mathbf{L}^1$, **I** and **II** are drawn using the PLATON software [13]. In complex **I**, the unsubstituted cyclopentadienyl ring is disordered over two positions.

3. Results and discussion

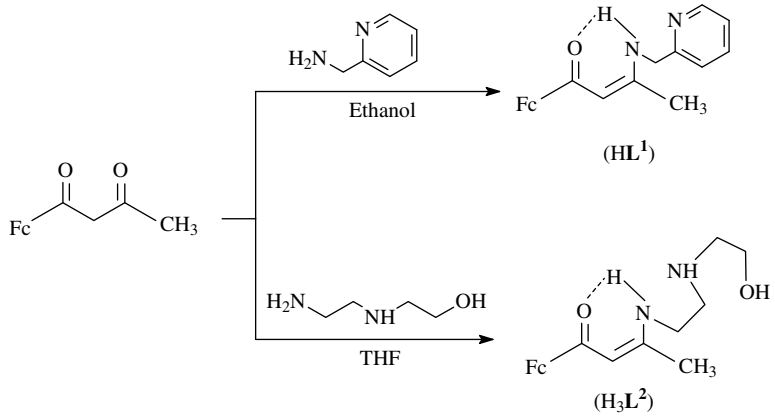
3.1. Syntheses of multidentate enaminones and mixed-ligand complexes

The reactions of ferrocenoylacetone with 2-(aminomethyl)pyridine and *N*-(2-hydroxyethyl)-1,2-diaminoethane afford the multidentate enaminones $H\mathbf{L}^1$ and $H_3\mathbf{L}^2$, as shown in Scheme 1. For $H\mathbf{L}^1$, its chromatography should be carried out with neutral Al_2O_3, because it decomposes on silica gel. For $H_3\mathbf{L}^2$, using THF as a solvent leads to a higher yield, because ethanol results in a complex mixture that is hard to separate. Reactions of copper acetate with $H\mathbf{L}^1$ and $H_3\mathbf{L}^2$ give the corresponding mixed-ligand complexes **I** and **II**, formulated as [Cu$\mathbf{L}^1$(OAc)] and [Cu($H_2\mathbf{L}^2$)(OAc)], respectively (Scheme 2). All the new compounds have been characterized by elemental analyses and IR, NMR and UV spectra. The structures of $H\mathbf{L}^1$, **I** and **II** have been unambiguously determined by single-crystal X-ray crystallography.

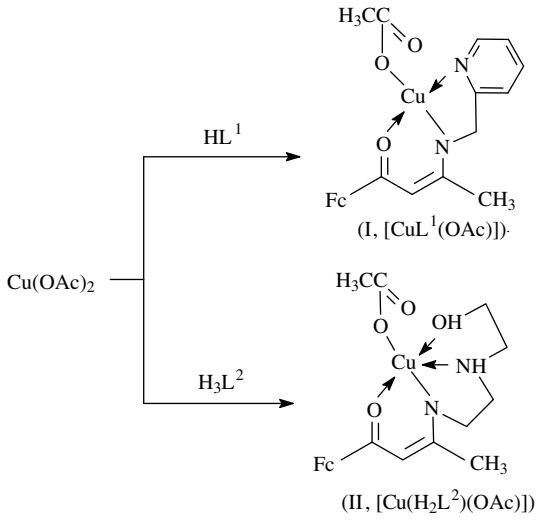
3.2. Crystal structures

3.2.1. Crystal structure of $H\mathbf{L}^1$

The molecular structure of $H\mathbf{L}^1$ is shown in Fig. 1. Selected geometric parameters for $H\mathbf{L}^1$ are listed in Table 2. $H\mathbf{L}^1$ crystallizes with Z = 4 in the space group $P2_1/c$. As noted in enaminones previously reported, the O=C–C=C–N moiety is planar and the bond lengths indicate electron delocalization [5,14]. The O=C–C=C–N plane is twisted with respect to the substituted cyclopentadienyl ring by 17.66(17)°. Moreover, the dihedral angle between the substituted cyclopentadienyl ring and the cyclopentadienyl ring is 2.4(2)°. Consistent with the large dihedral angle between the O=C–C=C–N plane and substituted cyclopentadienyl ring, the C10–C11 bond of 1.482(4) Å linking the O=C–C=C–N moiety and the substituted cyclopentadienyl ring is typical of a single bond (Csp^2–Csp^2), suggesting that the substituted cyclopentadienyl ring is not involved in the conjugation of the O=C–C=C–N moiety. As



Scheme 1. Syntheses of multidentate enaminones.



Scheme 2. Syntheses of mixed-ligand complexes

found in other enaminones, H**L**^{1} has a strong [N–H···O=C] intramolecular hydrogen bond. Furthermore, a [C–H···O=C] intermolecular hydrogen bond in which atom C19 in the molecule at (x, y, z) acts as a hydrogen-bond donor to the carbonyl atom O1 in the molecule at ($2 - x$, $2 - y$, $1 - z$) is also observed. By the intermolecular hydrogen bond, molecules of H**L**^{1} form centrosymmetric dimers.

3.2.2. Crystal structure of *I*

The molecular structure of complex **I** is shown in Fig. 2. Selected geometric parameters for complex **I** are listed in Table 3. Complex **I** crystallizes with $Z = 4$ in the space group $P2_1/n$. In **I**, H**L**^{1} acts as a tridentate monoanionic ligand after deprotonation of the enamine nitrogen atom, namely it is an N2O donor. The Cu1–O2 and Cu1–O3 distances are 1.930(5) and 2.823(5) Å, respectively. Since the Cu1–O3 distance is in excess of 2.8 Å, the O3 atom cannot be included in the first coordination sphere. Hence the acetate anion is monodentate. However, the distance of 2.823(5) Å indicates there is a short intramolecular contact between the Cu1 and O3 atoms [13]. The copper(II) ion is coplanar with four donor atoms O1, O2, N1 and N2; hence the coordination geometry of the copper(II) ion is square-planar. The Cu1–O1 bond length of 1.907(5) Å is close to the corresponding ones of copper complexes with enaminones previously reported, whereas the Cu1–N1 bond length of 1.918(5) Å is shorter than the reported values. Similar to a planar copper complex of Hacpa derived from acetylacetone and 2-aminomethylpyridine, the Cu–N(pyridyl) bond (Cu1–N2 = 2.001(5) Å) is longer than the Cu–N(enamine) bond [15,16].

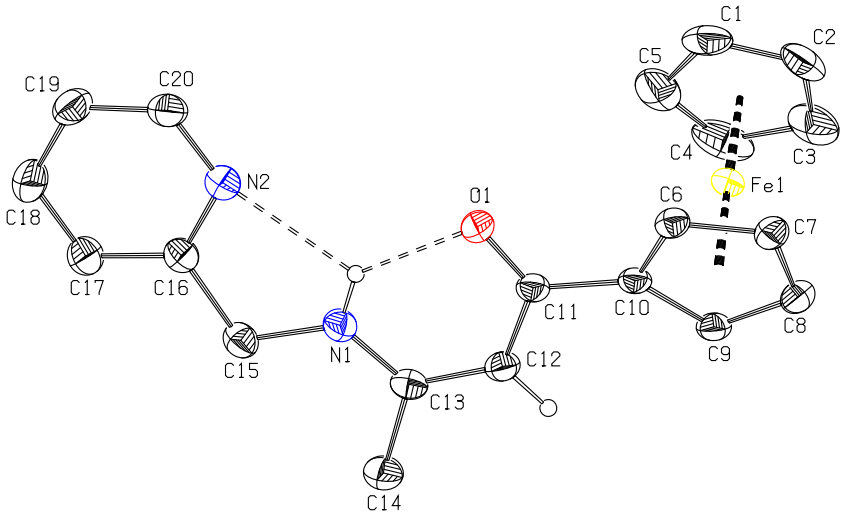


Fig. 1. ORTEP plot of H**L**^{1} showing the atom labelling, thermal ellipsoids are drawn as 30% probability ellipsoids. The intramolecular hydrogen bond is shown as a dashed line.

O1–C11–C10	115.0 (6)	C14–H14A···O2^{i}	136
C17–H17···O3^{ii}	141	C20–H20···O2	114

Symmetry codes: (i) $-x, 1-y, 1-z$; (ii) $1-x, 1-y, 1-z$.

The bond lengths and angles of the O=C–C=C–N moiety in **I** are analogous with those of H**L**[1], the related bond lengths in the O=C–C=C–N moiety are indicative of electron delocalization [5–11,14]. As expected, the dihedral angle between the two cyclopentadienyl rings is 1.4(10)° and shows that they are parallel to each other. The dihedral angle between the O=C–C=C–N moiety and the substituted cyclopentadienyl ring is 17.3(5)°. The C(10)–C(11) bond length of 1.479(10) Å is a typical single bond, thus suggesting that the substituted cyclopentadienyl ring is not involved in the conjugation of the O=C–C=C–N moiety. In addition to the [C–H···O=C] intramolecular hydrogen bond involving atom C20 as a hydrogen-bond donor to atom O2 of an acetate anion, for **I**, atom C17 in the molecule at (x, y, z) acts as a hydrogen-bond donor to the carbonyl atom O3 of an acetate in the molecule at $(1-x, 1-y, 1-z)$, resulting in the formation of centrosymmetric dimers. These dimers, linked by a C–H···O=C hydrogen bond, viz. atom C14 in the molecule at (x, y, z) as a donor via atom H14A to atom O2 of an acetate anion at $(-x, 1-y, 1-z)$, form an infinite double-chain in the [100] direction.

3.2.3. Crystal structure of *II*

The molecular structure of complex **II** is shown in Fig. 3. Selected geometric parameters for complex **II** are listed in Table 4. Complex **II**, solvated by CH_2Cl_2, crystallizes with $Z = 2$ in the space group $P\bar{1}$. In **II**, H_3**L**[2] acts as a tetradentate monoanionic ligand upon deprotonation of the enamine nitrogen atom, namely an N2O2 donor. Similarly, the acetate anion in **II** is a monodentate ligand. The O2, O3 and N1 atoms lie on the equatorial plane and the O1 and N2 atoms occupy the axial sites. The O1–Cu1–N2 bond angle of 173.45(14)° shows that the five-coordinate copper(II) ion adopts a distorted trigonal bipyramidal configuration. In **II**, the Cu1–O1 and Cu1–N1 bonds of 1.919(3) and 1.942(3) Å are stronger than the Cu1–O2 and Cu1–N2 bonds of 2.377(3) and 2.020(3) Å. The Cu1–O3 bond length of 1.994(3) Å is longer than the Cu1–O2 bond of 1.930(4) Å in **I**. The bond lengths and angles of the O=C–C=C–N system in **II** are similar to the corresponding values of **I**. Just like **I**, the bond lengths in the O=C–C=C–N skeleton indicate electron delocalization [5–11,14]. As expected, the dihedral angle between the cyclopentadienyl rings is 1.9(4)° and this shows that they are parallel to each other. However, the small dihedral angle of 8.1(3)° between the O=C–C=C–N skeleton and the substituted cyclopentadienyl ring and the short C(10)–C(11) bond length of 1.468(6) Å suggest that the substituted cyclopentadienyl ring is to some extent engaged in the conjugation of the O=C–C=C–N skeleton.

For **II**, atom O2 in the molecule at (x, y, z) acts as a hydrogen-bond donor to the carbonyl atom O3 of an acetate in the molecule at $(1-x, 1-y, 2-z)$, thus leading to the formation of centrosymmetric dimers. These dimers, linked by an N–H···O=C hydrogen

bond, viz. atom N2 in the molecule at (x, y, z) as a donor via atom H2N to atom O4 of an acetate anion at $(-x, 1-y, 2-z)$, generate an infinite double-chain in the [100] direction. In addition, an N–H···O=C intramolecular hydrogen bond is found. It is noted that a C–H···O intermolecular hydrogen bond [C21···O1 = 3.312(8) Å; C21–H21A···O1 = 172°] between CH_2Cl_2 and **II** in the same asymmetric unit is also observed.

3.3. ^1H NMR spectra

The spectrum of H**L**^{1} displays two singlets at δ 4.30 and 4.68 ppm, which are attributed to protons at the 3, 4- and 2, 5-positions of the substituted cyclopentadienyl ring. Another singlet signal at δ 4.10 ppm is assignable to the unsubstituted cyclopentadienyl ring protons. The CH_2 group exhibits one doublet at δ 4.57–4.58 ppm. The pyridyl group display two doublets at δ 5.51–5.52 and 7.26–7.28 ppm and two triplets at 7.13–7.15 and 7.61–7.64 ppm. The NH group appears at δ 11.30 ppm [5–11,14]. In addition, protons of the C(O)CH=CCH$_3$ moiety also show two singlets at δ 5.32 and 1.96 ppm, respectively. In the spectrum of H_3**L**^{2}, the methyl protons as one singlet appear at δ 2.02 ppm. Just like H**L**^{1}, the ferrocenyl group displays three singlets at δ 4.15, 4.34 and 4.71 ppm. The olefinic proton of the C(O)CHC moiety also shows a singlet at δ 5.29 ppm. Protons of the $NCH_2CH_2NCH_2CH_2O$ group appear as four triplets at δ 3.40–3.43, 2.80–2.85 (NCH_2CH_2N) and 2.90–2.92, 3.66–3.68 (NCH_2CH_2O) ppm. The secondary amine NH and OH groups exhibit two singlets at δ 1.93 and 2.01 ppm while the enamine NH group displays a signal at δ 11.10 ppm [5,7,9]. These singlets, generated from active hydrogens, disappear in the presence of D_2O.

3.4. IR spectra

In the IR spectra, complex **I** displays significant changes compared with H**L**^{1}. The band at 3086 cm^{-1} in the spectrum of H**L**^{1} due to ν(NH) does not appear in that of **I**, being indicative of deprotonated bonding of the enamine N atom. Furthermore, upon coordination, the strong bands assignable to stretching vibrations of the skeleton C=C and O=C groups, which are observed at 1539 and 1595 cm^{-1} in H**L**^{1}, respectively, are shifted to 1509 and 1601 cm^{-1} [5–10]. As usual, coordination of the enaminone O=C group leads to a red-shift of the O=C stretching vibration. Therefore, the blue-shift suggests that an acetate anion is involved in coordination. In other words, the band for the coordinated acetate anion obscures that of the coordinated O=C group of the enaminone. In fact, the IR spectrum of **I** displays only one O=C band. Although the IR spectrum does not afford unambiguous information on coordination of the pyridyl group and the acetate anion because of bands being overlapped, fortunately, the N2O bonding mode of H**L**^{1} and the monodentate bonding mode of the acetate anion are confirmed by the crystal structure of **I**, described above.

Compared with H_3**L**^{2}, the IR spectrum of complex **II** shows that a very broad band at 3334 cm^{-1} which is attributed to the ν(OH) and secondary amine ν(NH) is red-shift, suggesting that the hydroxy O and secondary amine N atoms participate in coordination. The

absence of the band at *ca.* 3098 cm^{-1}, which is due to the enaminone ν(NH), indicates that $H_3\mathbf{L}^2$ is coordinated to the copper(II) ion as the monoanionic ligand. Moreover, strong bands assignable to stretching vibrations of the skeleton C=C and O=C groups, which are observed at 1527 and 1596 cm^{-1} in $H_3\mathbf{L}^2$, are all red-shifted to 1507 and 1582 cm^{-1} in **II**, so revealing coordination of the enaminone O=C group. Although the IR spectrum does not give the clear information on coordination of the acetate anion because of bands being overlapped, fortunately, the N2O2 bonding mode of $H_3\mathbf{L}^2$ and the monodentate bonding mode of the acetate anion are confirmed by the crystal structure of **II**, described above.

3.5. UV spectra

In the UV spectra, the four compounds show three maxima at *ca.* 257.00–290.00, 340.00–354.80 and 424.20–454.20 nm which are attributed to the B-band, K-band and CT-band [5–9]. For each of complexes **I** and **II**, three absorption bands display red-shifts compared with the corresponding enaminones $H\mathbf{L}^1$ and $H_3\mathbf{L}^2$. Notably, the expected d–d absorption band of the copper(II) ion for each of **I** and **II**is not observed [5,15].

4. Conclusion

The reactions of ferrocenoylacetone with 2-(aminomethyl)pyridine and *N*-(2-hydroxyethyl)-1,2-diaminoethane afford the multidentate enaminones $H\mathbf{L}^1$ and $H_3\mathbf{L}^2$, respectively. Reactions of copper acetate with the two enaminones give the corresponding mixed-ligand complexes **I** and **II**, which are formulated as [Cu-$\mathbf{L}^1$(OAc)] and [Cu($H_2\mathbf{L}^2$)(OAc)], respectively. The structures of $H\mathbf{L}^1$, **I** and **II** have been determined by single-crystal X-ray crystallography. In complex **I**, the coordination geometry of the central metal is square planar in which the ligand acts as a monoanionic N2O donor via the carbonyl oxygen, deprotonated enamine nitrogen and pyridyl nitrogen atoms and the acetate anion is a unidentate donor. In complex **II**, the coordination geometry of the central metal is a distorted trigonal bipyramid in which the ligand is a monoanionic N2O2 donor via the carbonyl oxygen, deprotonated enamine nitrogen, secondary amine nitrogen and hydroxy oxygen atoms and the acetate anion is a monodentate donor.

neither soluble nor volatile, which limits their application as precursors. We were interested to develop soluble as well as volatile Cu/Zn metallo-organic SSPs for the preparation of nanostructured Cu/ZnO catalyst systems and other technological applications in powder or even thin film form.

Herein we report the synthesis and structure of a heterobimetallic precursor of copper and zinc, which is a potential SSP for the deposition of Cu–ZnO thin films.

2. Experimental

All manipulations were carried out under an atmosphere of dry argon using schlenk and glovebox techniques. Solvents were rigorously dried on sodium benzophenoate. 1,3-Bis(dimethylamino)-2-propanol (bdmapH) was purchased from Aldrich and used without further purification, while $[Cu(OCH_3)Cl]_4$ was prepared by literature procedure [24]. All other reagents were also purchased from Aldrich.

Elemental analysis was performed by the University of Manchester micro-analytical laboratory. Melting point was determined in a capillary tube using an electrothermal melting point apparatus, model MP.D Mitamura Riken Kogyo (Japan) and was uncorrected. FT-IR spectrum was recorded on a specie single reflectance ATR instrument (4000–400 cm^{-1}, resolution 4 cm^{-1}). TGA measurements were carried out by using a Seiko SSC/S200 thermal analyzer at a heating rate of 10 °C/min under N_2 flow. Mass spectrum was recorded on a Kratos concept IS instrument. PXRD studies were carried out by means of a Bruker AXS D8 diffractometer using monochromatic Cu Kα radiation. The morphology of films was determined by a FEG-SEM Philips XL30. Samples were carbon coated before observation and EDAX-DX_4 was used to calculate the composition (metallic ratio) of films. The thickness of films was measured with a Dektak 8 Stylus profilometer. The voltage–current characteristics of thin films were measured with Jandel Voltmeter, Model RM3, by the four-probe method.

2.1. Synthesis of $[Zn_2(OAc)_6(\mu\text{-}O)_2Cu_4(bdmap)_2Cl_2]$ (**1**)

0.32 g (2.2 mmol) of 1,3-bis(dimethylamino)-2-propanol (bdmapH) was added to a suspension of 0.50 g (4.4 mmol) $[Cu(OCH_3)Cl]_4$ and 0.72 g (3.3 mmol) $Zn(OAc)_2 \cdot 2H_2O$ in 25 ml toluene at room temperature. Reaction mixture was stirred for 3 h and filtered through cannula to remove the insoluble by-products. The blue solution was vacuum evaporated to dryness and the solid was redissolved in dichloromethane to recrystallize. Blue cubic crystals suitable for single crystal analysis were obtained. Yield 70%, m.p. 175 °C. *Anal.* Calc. for $C_{26}H_{46}Cl_2Cu_4N_4O_{16}Zn_2$: C, 27.72; H, 4.12; N, 4.97. Found: C, 27.14; H, 3.96; N, 4.53%. FT-IR (KBr, cm^{-1}): 2982w, 2927m, 2841w, 1612vs, 1442s, 1335m, 1204w, 1098m, 1021m, 993m, 890m, 860w, 826w, 672m, 663m, 616w, 534m, 507m, 456w. MALDI-MS (positive mode): *m*/*z* calc. (found) 896.5 (896) $[M-Cu_2Cl_2(O)_2]^+$, 783 $[M-Cu_2Cl_2(bdmap)]^+$, 719.7 (721) $[M-Cu_3Cl_2(bdmap)]^+$, 522.1 (523) $[M-Cu_4Cl_2(bdmap)(OAc)_2(O)]^+$, 479 (478) $[M-Cu_4Cl_2(bdmap)(OAc)_3]^+$, 388 (389) $[M-Cu_4Cl_2(bdmap)(OAc)_4(O)_2]^+$, 333.8 (333) $[M-Cu_4Cl_2(bdmap)_2(OAc)_3]^+$, 305 $[Zn(OAc)(bdmap)Cl]^+$, 285.6 (285) $[Zn(OAc)(bdmap)(O)]^+$. TGA: 160–189 °C (7.41 wt% loss), 189–226 °C (11.11 wt% loss), 226–340 °C (residue 37.2%).

2.2. X-ray crystallography

Single crystal X-ray data were collected on a Bruker Smart Apex CCD diffractometer using Mo radiation. Crystallographic and structure refinement data for complex (**1**): Empirical formula; $C_{26}H_{46}Cl_2Cu_4N_4O_{16}Zn_2$, F.wt. 1126.47, Temp. = 100(2) K, λ = 0.71073 Å, monoclinic, space group $P2(1)/n$, a = 12.076(2), b = 10.1958(18), c = 17.624(3) Å, α = 90°, β = 99.997(3)°, γ = 90°, V = 2137.1(6) $Å^3$, Z = 2, ρ_{calc} = 1.751 mg m^{-3}, μ = 3.250 mm^{-1}, 14468 reflections collected, 4369 unique (R_{int} = 0.1093), Refinement was by full-matrix least-squares on F^2; goodness-of-fit on F^2 was 1.021. Final R indices where $I > 2\sigma(I)$ are R_1 = 0.0611 and wR_2 = 0.1370. The R indices with all data are R_1 = 0.1114 and wR_2 = 0.1561. The largest difference peak and hole are 1.264 and 0.595 e $Å^{-3}$, respectively.

2.3. Deposition of thin films

Thin film deposition was performed via aerosol assisted chemical vapour deposition (AACVD) by dissolving 0.1 g of precursor in 13 ml THF + 2 ml dichloromethane in a two neck round bottomed flask. On one side, the flask was connected via tubing to a quartz reactor loaded with 2.5 × 1 cm glass substrates inside a carbolite tube furnace and a flow of argon gas was regulated using a platon flow gauge on the other. The flask was set in an ultrasonic humidifier equipped with a piezoelectric transducer, that generated droplets of the precursor solution, which were then transferred by the carrier gas into reactor chamber. Glass substrates were washed in concentrated nitric acid, subsequently washed with deionized water several times, and then oven dried. Deposition was done at four different temperatures i.e., 250, 325, 400 and 475 °C at a constant nitrogen flow rate of 130 ml/min on glass substrates for 2.5 h.

3. Results and discussion

3.1. Synthesis and characterization

Heterometallic hexanuclear complex (**1**), was prepared by mixing stoichiometric amounts of $Zn(OAc)_2 \cdot 2H_2O$, $[Cu(OCH_3)Cl]_4$ and 1,3-bis(dimethylamino)-2-propanol (bdmapH) in toluene for three hours as shown in chemical Eq. (1). The complex is readily soluble in common organic solvents such as toluene, dichloromethane and alcohols and is stable in air under normal conditions.

$$4[Cu(OCH_3)Cl]_4 + 3Zn(OAc)_2 \cdot 2H_2O + 2bdmapH \xrightarrow{Toluene} Zn_2(OAc)_6(\mu\text{-}O)_2Cu_4(bdmap)_2Cl_2 + ZnCl_2 + 4CH_3OH + 4H_2O \quad (1)$$

The composition of the complex (**1**) was ascertained by CHN analysis. IR absorption frequency of carboxylate appear at 1612 cm^{-1} for $\nu_{as}(CO_2)$ and 1442 cm^{-1} for $\nu_s(CO_2)$. The difference $\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)$ suggests a dominant chelating or chelating-bridging behaviour for the acetate ligands [25,26].

MALDI mass spectrum of complex (**1**) did not show the molecular ion peak while molecular ion fragments of different *m*/*z* ratios indicating the formation of complex were found. The largest fragment was of *m*/*z* (896) $[M-Cu_2Cl_2(O)_2]^+$ and the base peak at *m*/*z* (783) corresponding to $[M-Cu_2Cl_2(bdmap)]^+$ were present.

3.2. Structural analysis

Selected interatomic distances and angles for (**1**) are listed in Table 2. The molecule of (**1**) (Fig. 1) possesses an inversion center and two asymmetric units, each having two copper and one zinc atoms, connected by μ_2-oxygen of bdmap and bridging acetate ligands. In this heterohexanuclear complex, six metal atoms are linked by four μ_2-acetate, two μ_3-acetate, two μ_3-O and two μ_2-bdmap groups in a cyclic fashion whereas the remaining two chloride atoms behave as termini without any contribution in connecting the metals. Considering only copper atoms, a twelve membered ring comprised of four copper atoms, two CO_2 units

Table 1

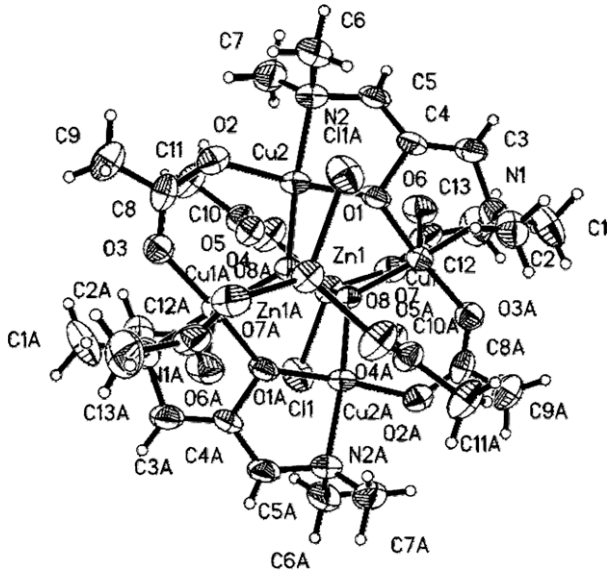

Fig. 1. ORTEP drawing showing the molecular structure of complex (**1**).

and two oxygen atoms is formed which is almost planar. The four copper atoms represent an approximate rectangular arrangement, Cu(1)–Cu(2) = 3.622 Å, Cu(2)–Cu(1)A = 3.282 Å, Cu(1)A–Cu(2)A = 3.622 Å, Cu(2)ACu(1) = 3.282 Å. Such type of arrangement and similar bonding pattern has been observed in the literature [27]. The bdmap ligand acts as a tridentate group and bridges two copper atoms through oxygen and two nitrogen atoms. The acetate ligands are bridging either two metals [Cu(1), Cu(2); Cu(1), Zn(1)] or three metal atoms, connecting Cu(1), Cu(2) of one asymmetric unit with Zn(1) of the other (Fig. 1).

The core unit of complex (1) (Fig. 2) indicates that the asymmetric unit consisting of three metal atoms, has three different geometric environments, with Cu(1) octahedral, Cu(2) square pyramidal and Zn(1) tetrahedral coordination spheres (Fig. 3). In each asymmetric unit, a triply bridged oxygen atom links three metal centers [Cu(1), Cu(2) and Zn(1)], in addition to two acetate ligands bridging two metal atoms [acetate group with C(8) bridges Cu(1), Cu(2), while that of C(12) links Cu(1), Zn(1)]. Oxygen atom O(5) of one acetate group [based on C(10)] again bridges Cu(1) and Cu(2).

The environment of the Cu(1) atom is tetragonally elongated octahedral with the ligation set CuO_5N, comprised of oxygen atoms [O(3), O(6)] of two doubly bridged acetate groups, a bridging oxygen [O(5)] of one triply bridged acetate ligand [based on C(10)], a triply bridged oxygen [O(8)], an oxygen [O(1)] and nitrogen atom [N(1)] of a chelating-bridging bdmap group. The Cu–O/N bond lengths in the basal planes range from 1.930(3) to 2.044(4) Å {normal values}, while the weaker apical bonds to oxygen atoms of acetate groups are 2.420(3) and 2.725(3) Å. The distorsion is further evident from the deviation of the O(5)–Cu(1)–O(6) angle (162.62°) from 180°, while the O(5)–Cu(1)–O(8) (74.62°) and O(5)–Cu(1)–N(1) (104.47°) angles from 90°. Distortion in octahedral geometry around $Cu^{II}(1)$, expected from the Jahn-Teller theorem [28], is due to the unequally occupied e_g (d_{z^2} and $d_{x^2-y^2}$) orbitals, the two axial acetate ligands based on O(5) and O(6) are repelled more strongly than the other four coordinating ligands. The overall geometry around Cu(2) is a square pyramidal, with a CuO_4N core, generated by a chelating-bridging bdmap ligand [O(1), N(2)], [the oxygen of which connects Cu(2) of one asymmetric unit to Cu(1) of the other], an oxygen atom of bridged acetate [O(2)], a triply bridged oxygen atom [O(8)], [connecting Cu(2) with Cu(1) and Zn(1)], and an oxygen atom of triply bridged acetate group [O(5)], [which links Cu(2) with Cu(1)]. Slight distortion in square pyramidal geometry is due to the doubly bridged oxygen [O(9)], being displaced towards O(8) and away from N(2), resulting in an O(5)–Cu(2)–N(2) angle being enlarged from the ideal 90 to 106.93° and O(5)–Cu(2)–O(8) being reduced to 78.54°. Again also the copper–oxygen bond distance of Cu(2) to apical oxygen atom [O(5)] is greater (2.563 Å) than the other Cu–O bond lengths, which are compatible to the sum of the ionic radii, 1.92 Å. Considering the chloride ion at 3.090(15) Å, the coordination environment of Cu(2)

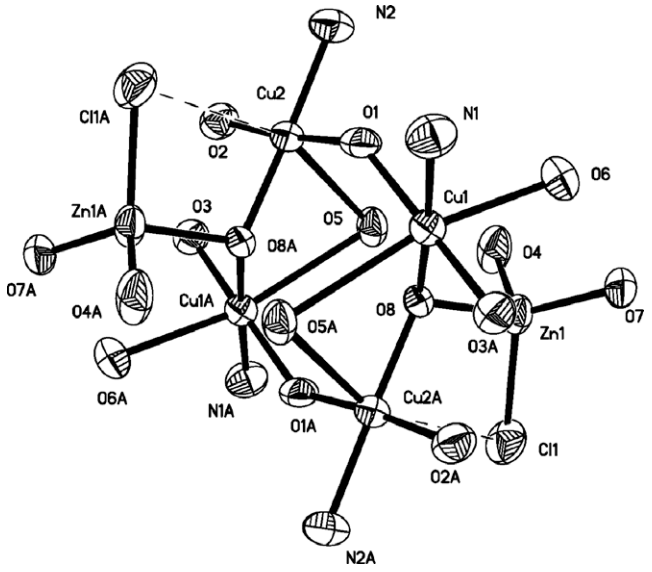

Fig. 2. The core unit of complex (**1**). Dashed lines show weak interactions. All carbon and hydrogen atoms are omitted for clarity (symmetry transformations used to generate equivalent atoms $-x+2$, $-y+2$, $-z+2$).

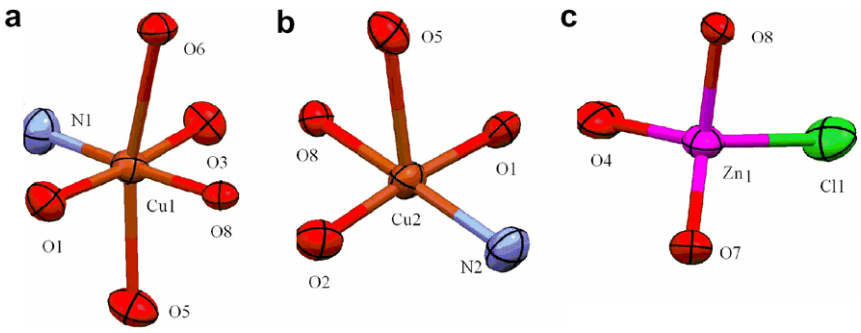

Fig. 3. Geometric spheres of (**1**), (a) distorted octahedral Cu(1), (b) square pyramidal Cu(2) and (c) tetrahedral Zn(1).

can also be described as tetragonally elongated octahedral with Cu–O/N bond distances in the basal plane ranging from 1.923(3) to 2.015(4) Å and weak apical bonds to oxygen and chloride atoms of 2.563(3) and 3.090(15) Å (Table 2). Zn(1) has a coordination number of four having a coordination environment almost tetrahedral, with ZnO_3Cl set of ligating atoms, composed of an oxygen of bridged acetate group [O(7)], an oxygen of triply bridged acetate ligand [O(4)], [that links Zn(1) with Cu(1) and Cu(2) of two asymmetric units], the μ_3-oxygen atom [O(8)], [which bridges three metal centers of asymmetric units] and a terminal chloride atom. The Zn–O bond distances around Zn(1), which range from 1.933(3) to 2.039(2) Å are in good agreement with the literature [29].

3.3. Thermal decomposition studies and characterization of thin films

TGA traces of complex (**1**) (Fig. 4) shows three step weight loss beginning at 160 °C and completed at 340 °C, leaving a residue of 37.2% of the initial weight, which is close to the expected composition of $Cu_4Zn_2O_2$ (37.01%). The residual mass also indicates the removal of most of the carboneous matter from the organic groups, leaving negligibly small carbon impurity in the composite and the complex (**1**) decomposes according to Eq. (2).

$$Zn_2(OAc)_6(\mu\text{-}O)_2Cu_4(bdmap)_2Cl_2 \xrightarrow{AACVD} 4Cu + 2ZnO + Volatiles \quad (2)$$

Deposition of the films was studied at four different temperatures i.e., 250, 325, 400 and 475 °C. The films deposited at 250 °C were amorphous, brown in colour with poor film coverage and adhesion to the substrate. The films deposited at 325 and 400 °C were crystalline, dark in colour and reflecting in nature. Diffractogram of the films (Fig. 5) obtained at 400 °C shows formation of cubic Cu and hexagonal ZnO phases which match very well with the JCPDS standard data 01-085-1326 and 01-079-0207, respectively. The PXRD of the films deposited at 475 °C (Fig. 6) shows high degree of crystallinity and appearance of new phase of Cu_2O at 2θ values of 42.4° and 61.4°.

Scanning electron microscopic images (Fig. 7) show that film deposition experiments performed at different temperatures result in different surface morphologies. In all the four cases, the particles are homogenously dispersed with well defined grain boundaries, especially at temperatures 325 and 400 °C. The image of films deposited at 250 °C shows less compact morphology having rela-

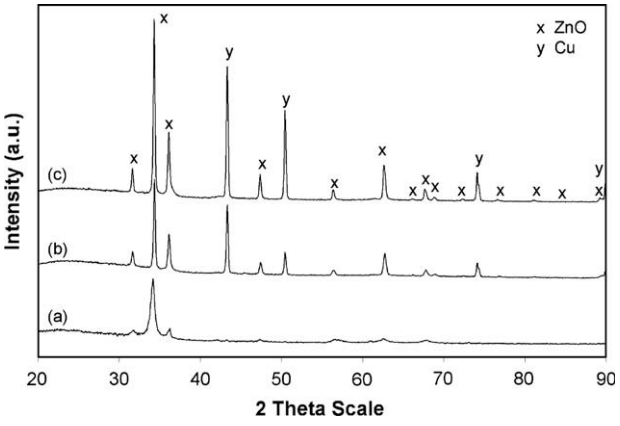

Fig. 5. Powder X-ray diffractograms of Cu–ZnO films obtained from precursor (**1**) at (a) 250 °C, (b) 325 °C and (c) 400 °C.

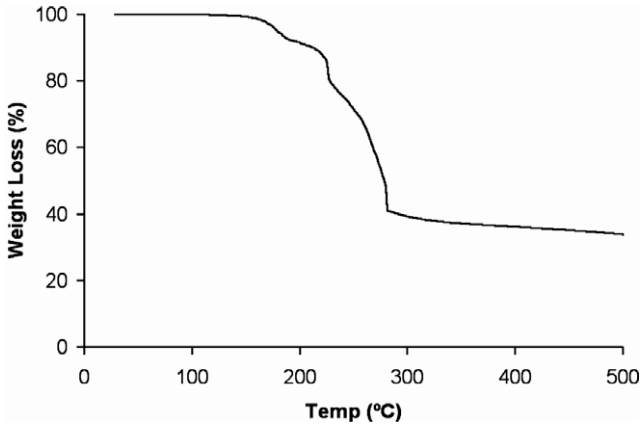

Fig. 4. Thermogram of the complex (**1**), showing loss in weight with rise in temperature.

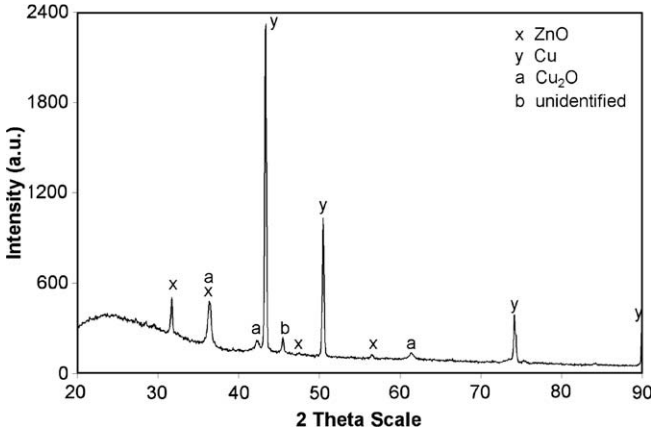

Fig. 6. Powder X-ray diffractograms of the films obtained from precursor (**1**) at 475 °C.

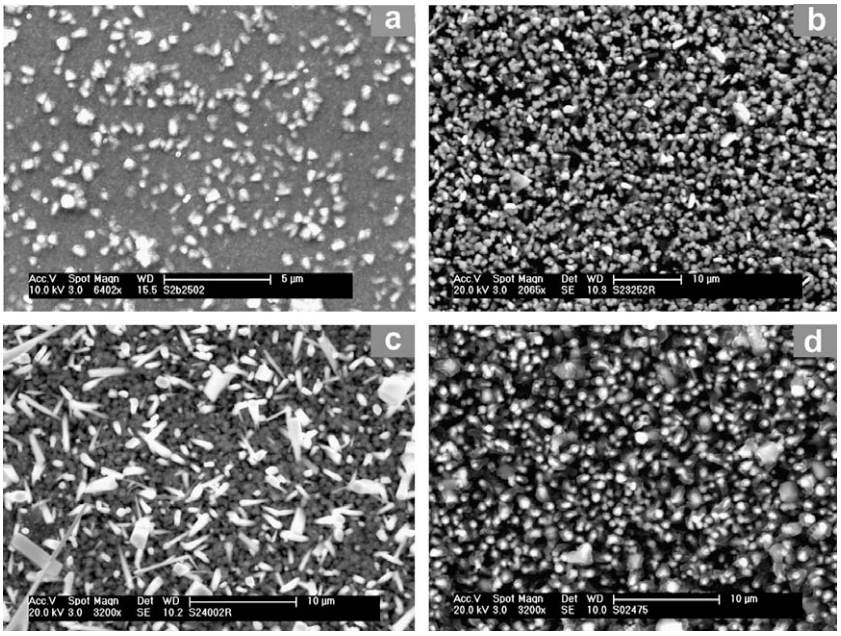

Fig. 7. SEM micrographs of films deposited from precursor (**1**) at (a) 250 °C, (b) 325 °C, (c) 400 °C and (d) 475 °C.

tively small individual rectangular crystallites ranging from 0.2 to 0.5 μm, while relatively large individual oval shaped grains, 0.4 to 0.9 μm, were obtained from the films deposited at 475 °C. At 325 and 400 °C, spherical with elongated strands like grains were obtained indicating dependence of grain shape and size on deposition temperature. The energy dispersive X-ray analysis (EDAX) was performed for the metallic Cu/Zn ratio in films deposited at 325 and 400 °C. The analysis indicates that the ratio of Cu/Zn is 1:1.1 and 1:1.2 for the films deposited at 325 and 400 °C, respectively. The deviation of Cu/Zn ratio from 2:1 indicates evaporation of copper with the rise in temperature from the surface of the film under CVD conditions [30].

The variation of the Cu–ZnO film's thickness as a function of deposition temperature is shown in Fig. 8. At 250 °C, the thickness of the film is monitored by surface decomposition reaction of the precursors. In the intermediate region i.e., 325–400 °C, the film growth rate is diffusion or mass transport limited, where all the reactants that reach the substrate essentially decompose. Finally, above 420 °C, the film thickness decreases with rise in temperature because of an increased desorption rate of the film components in addition to depletion of reactants by the reaction at the reactor walls. This observation is supported by EDAX analysis as stated earlier. The *V–I* curve (Fig. 9) is linear, indicating ohmic conduction.

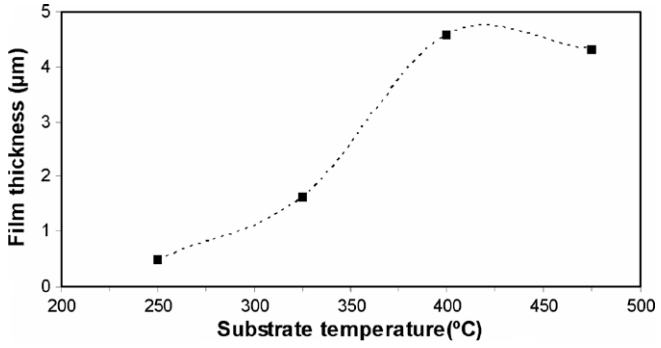

Fig. 8. Variation of Cu–ZnO thin film thickness as a function of substrate temperature with a dynamic nitrogen flow rate of 130 ml/min.

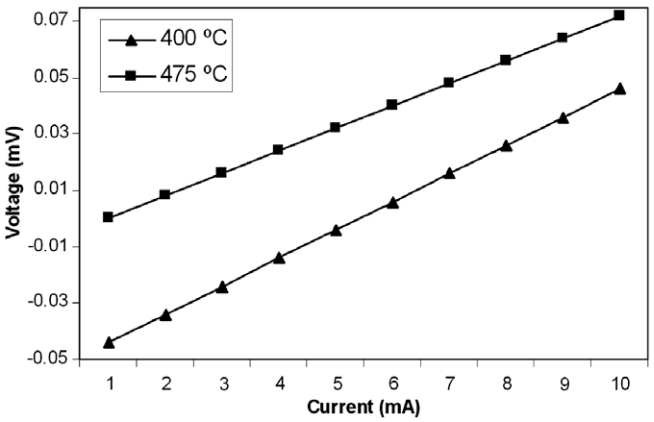

Fig. 9. *V–I* curves of Cu–ZnO films deposited at 400 and 475 °C.

The resistances determined from the slope of the curve are 10×10^{-3} and 8×10^{-3} Ω for the films deposited at 400 and 475 °C, respectively. The resistivity of the films at 400 and 475 °C were found to be 2×10^{-5} Ω cm and 1.6×10^{-5} Ω cm, respectively, using $\rho = 4.532(V/I) \times d$, where ρ is the resistivity in Ω cm, 4.532 is the instrument constant, V/I is the slope of curve in Ω and d is the film's thickness (Table 1), showing conducting nature of the films.

4. Conclusion

Heterobimetallic precursor $[Zn_2(OAc)_6(\mu\text{-}O)_2Cu_4(bdmap)_2Cl_2]$ (**1**) was prepared following a simple method by the reaction of $Cu(OCH_3)Cl$, $Zn(OAc)_2 \cdot 2H_2O$ and bdmapH in toluene at room temperature. Spectroscopic and single crystal X-ray analysis confirmed the identity of complex (**1**). The complex is stable for periods of several months at room temperature and is soluble in most organic solvents, which made it potentially useful precursor for the deposition of copper–zinc oxide thin films. The films deposited from (**1**) were characterized by PXRD, SEM, EDAX and thickness measurements. It was found that the morphology and the thickness of the films including the shape and size of the crystallites changed

with the change in the deposition temperature. The *V–I* measurements indicate that films are ohmic conductors.

but also for alkali-metal ions. These "ligand complexes" may act as a host molecule and include a guest metal ion by coordinating through cis-oxygen atoms such that new bi- or trinuclear metal complexes are produced [10]. Hence this adduct formation method may also be considered as host–guest chemistry. On this basis, Lindoy and Truter reported the X-ray structures of the sodium perchlorate adducts of [Ni(acacen)] [11] and [Cu(salen)] [12] [acacen = *N*,*N*′-ethylenebis(acetylacetoneiminate) and salen = *N*,*N*′-ethylenebis(salicylideneiminate)]. The structures of some other adducts of copper(II) chelates with alkali-metal salts have been reported since then [12–15]. From these results, it is observed that the structure of one sodium adduct of Cu-acacen [14], one potassium adduct each of Cu-acacen [14] and Cu-acactn [13] (acactn = *N*,*N*′-propylenebis(acetylacetoneiminate) are known with the acetylacetone derived Schiff bases. Interestingly, variable temperature magnetic properties of any such simple adducts have not been studied yet although it is well known that magnetic exchange between the paramagnetic centers can be mediated through the alkali-metal or other diamagnetic metal ions [16–20].

In this circumstances, we have systematically explored the formation of the 1:2 adduct of sodium perchlorate and square planar [CuL] complexes, where L stands for tetradentate di-Schiff-base ligands containing an acetylacetone moiety and one of the following diamines: 1,2-diaminoethane, 1,2-diaminopropane and 1,3-diaminopropane (Scheme 1). This effort has resulted in the formation of three new trinuclear Cu(II)–Na(I)–Cu(II) complexes, which have been characterized by X-ray single crystal structure analyses. The temperature-dependent magnetic properties of the complexes have been investigated.

2. Experimental

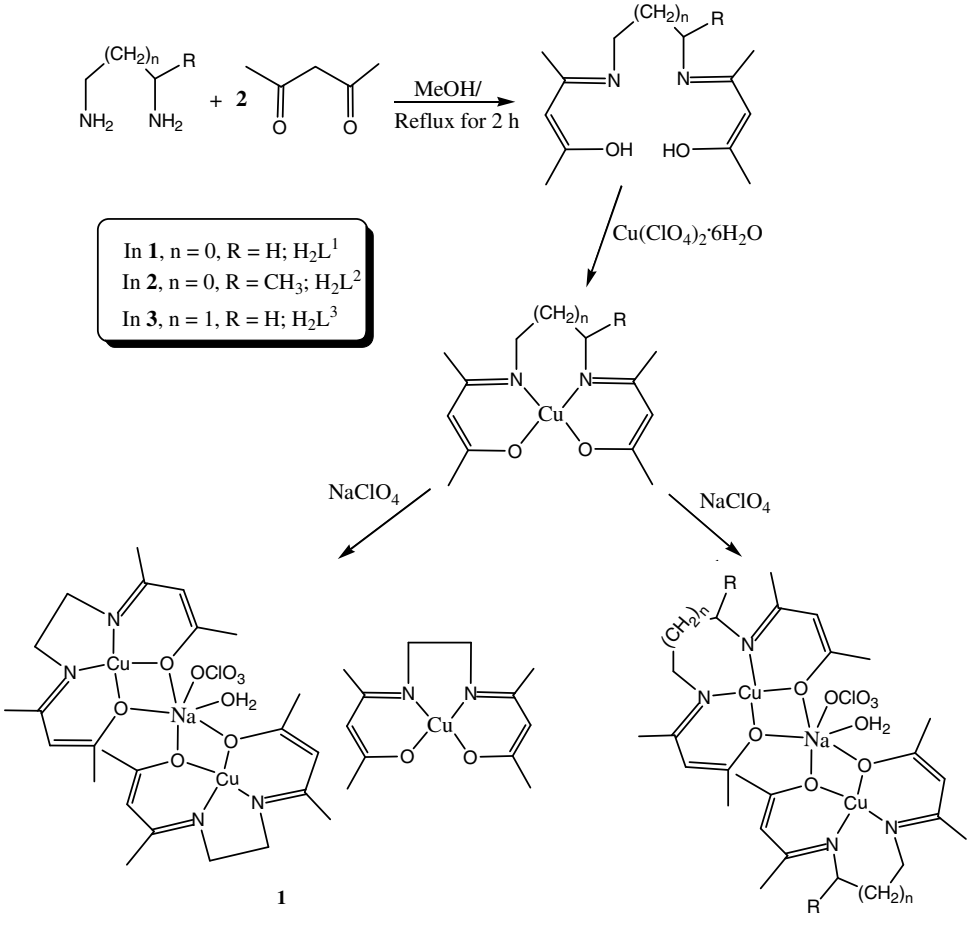
The diamines (1,2-diaminoethane, 1,2-diaminopropane and 1,3-diaminopropane) and triethylamine were dried over potassium hydroxide and distilled prior to use. Pentane-2,4-dione was dried over anhydrous sodium sulfate and distilled; the fraction boiling at 138–139 °C was collected. All the other chemicals were of reagent grade and used without further purification.

2.1. Preparation of the ligands H_2L^1, H_2L^2 and H_2L^3

The three di-Schiff-base ligands, H_2L^1, H_2L^2 and H_2L^3 were prepared by standard methods. Briefly, 10 mmol of pentane-2,4-dione (1.10 cm^3) were mixed with 5 mmol of the required amine [1,2-diaminoethane (0.31 cm^3), 1,2-diaminopropane (0.38 cm^3) and 1,3-diaminopropane (0.38 cm^3), respectively] in methanol (10 cm^3). The resulting solutions were refluxed for ca. 2 h, and allowed to cool. The Schiff-base ligands were not isolated and the yellow colored methanolic solutions were used directly for complex formation.

2.2. Synthesis of $[Cu(L^1)] \cdot H_2O$ (**A**), $[Cu(L^2)] \cdot H_2O$ (**B**) and $[CuL^3] \cdot H_2O$ (**C**)

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (1.85 g, 5 mmol) in methanol (10 cm^3) was added to a solution of H_2L^1 (5 mmol), H_2L^2 (5 mmol) or H_2L^3 (5 mmol), separately, in methanol (10 cm^3) with constant stirring. Triethylamine (1.40 cm^3, 10 mmol) in methanol (5 cm^3) was added drop wise to each of these solutions with constant stir-



Scheme 1.

ring. The mixture was stirred for 1 h at room temperature and then filtered. The filtrate was left to stand overnight in air, when purple crystalline compound of **A** and **B** and green compound of **C** appeared at the bottom of the vessel on slow evaporation of the solvent.

Complex **A**: (yield: 1.06 g; 70%). *Anal.* Calc. for $C_{12}H_{20}CuN_2O_3$ (303.84) C, 47.33; H, 6.63; N, 9.22. Found: C, 47.32; H, 6.77; N, 9.19%. λ_{max}/nm (ε_{max}/dm^3 mol^{-1} cm^{-1}) (methanol), 540 (420); IR: ν(O–H), 3474 cm^{-1}, ν(C=N), 1593 cm^{-1}.

Complex **B**: (yield: 1.20 g; 75%). *Anal.* Calc. for $C_{13}H_{24}CuN_2O_3$ (319.89) C, 48.81; H, 7.56; N, 8.76. Found: C, 48.52; H, 7.87; N, 8.62%. λ_{max}/nm (ε_{max}/dm^3 mol^{-1} cm^{-1}) (methanol), 541 (405); IR: ν(O–H), 3470 cm^{-1}, ν(C=N), 1598 cm^{-1}.

Complex **C**: (yield: 1.04 g; 65%). *Anal.* Calc. for. $C_{13}H_{24}CuN_2O_3$ (319.89) C, 48.81; H, 7.56; N, 8.76. Found: C, 48.52; H, 7.87; N, 8.62%. λ_{max}/nm (ε_{max}/dm^3 mol^{-1} cm^{-1}) (methanol), 540 (298); IR: ν(O–H), 3485 cm^{-1}, ν(C=N), 1603 cm^{-1}.

2.3. Synthesis of $[(CuL^1)_2Na(ClO_4)(H_2O)]$ $[CuL^1]$ (**1**), $[(CuL^2)_2Na(ClO_4)(H_2O)]$ (**2**) and $[(CuL^3)_2Na(ClO_4)(H_2O)]$ (**3**)

To methanolic solutions (10 cm^3) of **A** (5 mmol, 1.43 g), **B** (5 mmol, 1.49 g) or **C** (5 mmol, 1.49 g), solution of $NaClO_4$ (2.5 mmol, 0.305 g) in methanol (10 cm^3) was added with constant stirring. The resultant purple solutions of **A** and **B** and dark green solution of **C**, on keeping overnight at room temperature yielded purple (both for **1** and **2**) and green (**3**) single crystals suitable for X-ray analysis.

2.4. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra in KBr (4500–500 cm^{-1}) were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer. Electronic spectra in methanol (1200–350 nm) were recorded in a Hitachi U-3501 spectrophotometer. Cyclic voltammetry was carried out using Sycopel model AEW2 1820 F/S instrument. The measurements were performed at 300 K using 0.2 M TEAP as supporting electrolyte and 10^{-3} M Cu(II) complexes deoxygenated by bubbling with nitrogen. The working, counter, and reference electrodes used were a platinum wire, a platinum coil, and an SCE. The magnetic measurements were carried out on polycrystalline samples using a Quantum Design SQUID MPMS-XL7 magnetometer in the temperature range of 1.9–300 K at an applied magnetic field of 1 or 0.05 T above and below 30 K, respectively, to avoid any saturation effects. The field-dependent magnetization was measured in the applied magnetic field range 0–5 T at 2 K. The diamagnetic corrections were evaluated from Pascal's constants. The X-band EPR spectra were recorded on powder samples with a Bruker E300 automatic spectrometer, varying the temperature between 4 and 300 K.

2.5. Crystallographic studies

Crystal data are given in Table 1. Intensity data were measured at 150 K using the Oxford Xcalibur CCD System using Mo Kα radiation. The crystals were positioned at 50 mm from the CCD. 321 frames were measured with a counting time of 3 s. Data analyses were carried out with the CRYSALIS program [21]. The structures were solved using direct methods with the SHELXS 97 program [22]. The non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. Hydrogen atoms on water molecules were not located. Absorption corrections were carried out using the ABSPACK program [23]. The structures were refined on F^2 using SHELXL 97 [22]. Selected bond lengths and bond angles are presented in Table 2.

3. Results and discussion

3.1. General characterization

All three Schiff-base ligands (H_2L^1–H_2L^3) and their Cu(II) complexes, were synthesized in the usual way. The three tetradentate Schiff-base ligands are very similar but the general formula of complex **1** is different from that of complexes **2** and **3**. In complex **1,** an additional $[CuL^1]$ unit is present along with the main trinuclear part. Interestingly, even on decreasing the $[CuL^1]$: $NaClO_4$ ratio to 1:1 during incorporation of sodium ion guest from methanol

* The numbering system in **1** is different for these starred atoms due to the imposed symmetry around Cu(2) in [CuL1].

solution, the stoichiometric ratio of host: guest remains the same in complex **1**. Thus the numbers of guest molecules, which are incorporated in the hosts, seem to be determined by the requirement of the crystal lattice.

Besides elemental analysis all three complexes were initially characterized by IR spectra. The 'ligand complexes' [CuL] are neutral complexes and do not have any anion, whereas all three compounds, **1**, **2** and **3**, contain perchlorate as counter anion. Therefore, the appearance of characteristic intense peak for perchlorate (ν_3) in the IR spectra of **1**, **2** and **3** at 1091, 1093 and 1105 cm^{-1}, respectively, clearly indicate the formation of the adducts. The rest of the spectral pattern and band positions of respective adducts and the 'ligand complexes' are very similar. In all three complexes, a strong and broad band, centering at 3427, 3510 and 3487 cm^{-1} for **1**, **2** and **3**, respectively, is due to the presence of water molecule as is also found in the corresponding 'ligand complexes'. The other characteristic bands e.g. azomethine ν(C=N) appear at 1598, 1603 and 1584 cm^{-1} for **1**, **2** and **3**, respectively.

The electronic spectra of the complexes were recorded in methanol solution. A single absorption band at 541, 540 and 591 nm in the visible region and 293, 305 and 307 nm in the UV region are observed for **1**, **2** and **3**, respectively. In the visible region the bands indicate typical d–d transition in the square-planar environment around Cu(II) and the bands in UV region are due to charge transfer transitions. Electronic spectra are also measured for the starting "ligand complexes", **A**, **B** and **C** (**A** = [CuL^1], **B** = [CuL^2] and **C** = [CuL^3]). The positions and intensities of the bands in both UV and Vis regions for **A**, **B** and **C** are almost the same as that of complexes **1**, **2** and **3**, respectively.

The cyclic voltammograms of three sets of complexes, the "ligand complexes" and their corresponding sodium perchlorate adducts (A and **1**, B and **2** and C and **3**) are recorded in methanol (Pt electrode) under nitrogen at the potential range +1.0 to −1.0 V. All the complexes display an irreversible reductive response attributed to the Cu(II)/Cu(I) couple at −0.75 V (Ep_c) and −0.72 V (Ep_c) versus SCE for A and **1**, respectively, −0.78 V (Ep_c) and −0.76 V (Ep_c) versus SCE for B and **2**, respectively, and −0.72 V (Ep_c) and −0.78 V (Ep_c) versus SCE for C and **3**, respectively, during the cathodic potential scan. The appearance of nearly identical UV spectra and electrochemical responses of the adducts and their corresponding mononuclear 'ligand complexes' indicates that the trinuclear adducts probably dissociate in solution.

3.2. Description of structures of complexes *1*–*3*

The structures of complexes **1**–**3** have been solved by single crystal XRD and crystal data for the three compounds are given in Table 1. The trinuclear structures in the three complexes are similar and have a general formula $[(CuL)_2Na(ClO_4)(H_2O)]$ as shown in Fig. 1 (for complex **1**), Fig. 2 (for complex **2**) and *Fig.* S1 (for complex **3**), together with the atom-numbering scheme. The selected bond lengths and angles are summarized in Table 2. In all the three complexes, two neutral [CuL] units (where L represents the deprotonated, tetradentate, di-Schiff-base ligand) are bonded to a sodium cation Na(1) forming the trinuclear entity. The copper atoms are four coordinate with a square planar environment being bonded to two oxygen atoms and two nitrogen atoms of the Schiff-base ligand. The bond lengths in the trinuclear unit of **1** and **2** are very similar with average Cu–O 1.923(21) and 1.916(9) Å and average Cu–N 1.926(23) and 1.932(11) Å in **1** and **2**, respectively. In **3**, however, the ligand contains one more carbon atom in a central position giving rise to a six-membered chelate ring. As a consequence, the bond lengths are significantly greater with average Cu–O 1.947(6) Å and Cu–N 1.980(7) Å. In the previously reported [CuL^1] and [CuL^3] chelates [13,24] the average Cu–O distances (1.920 and 1.932 Å, respectively) are slightly lower than in **1** and **3**, indicating that upon adduct formation Cu–O bond lengths increase. The average O–Cu–N trans angles in the trinuclear units are 176.0(18)°, 178.9(7)°, 170.5(19)° for **1**, **2** and **3**, respectively, indicating that there is slight tetrahedral distortion from the ideal square planar geometry particularly in the later structure. The tetrahedral distortion is also apparent since one pair of diagonal donor atoms clearly lies below the plane while the other pair is above the plane with the metal ion in the mean plane. The dihedral angles between the two N–Cu–O planes in the trinuclear units are 5.79°, 1.28° and 8.99° for complexes **1**, **2** and **3**, respectively, considering 0° for a perfectly square-planar arrangement, and 90° for a perfect tetrahedral arrangement. The r.m.s. deviations of the five fitted atoms in the Cu–N_2O_2 plane are 0.10, 0.08 Å in **3** compared to 0.06 Å in **1** and 0.02, 0.01 Å in **2.** The increase in ring size in **3** compared to **1** and **2** results in higher tetrahedral distortion.

In **1**, the sodium cation has a six-coordinate distorted octahedral environment: four oxygen atoms from the two different "ligand complexes" are bonded to Na(1) ion and two terminal oxygen atoms complete its coordination sphere. The sodium ion is positioned on a twofold axis and it is assumed that the two terminal sites are occupied by a water molecule and a perchlorate anion both of which had 50% occupancy. O(94) was refined with 100% occupancy describing both the water molecule and a perchlorate oxygen atom in equivalent positions but the remainder of the perchlorate was refined with 50% occupancy.[1] On the other side, the perchlorate anion and water molecule can be observed separately occupying adjacent sites in the sodium coordination sphere for

[1] A referee has suggested that the structure should be refined in triclinic space group *P*1 to check on the disorder. In this space group there are two $[(CuL^1)_2Na(ClO_4)(H_2O)]$ dimers and two [CuL^1] monomers. However the disorder between perchlorate and water molecules persisted and no ordered dimers could be found which confirms that the structure solution in orthorhombic *Fd2d* is the optimum for this structure.

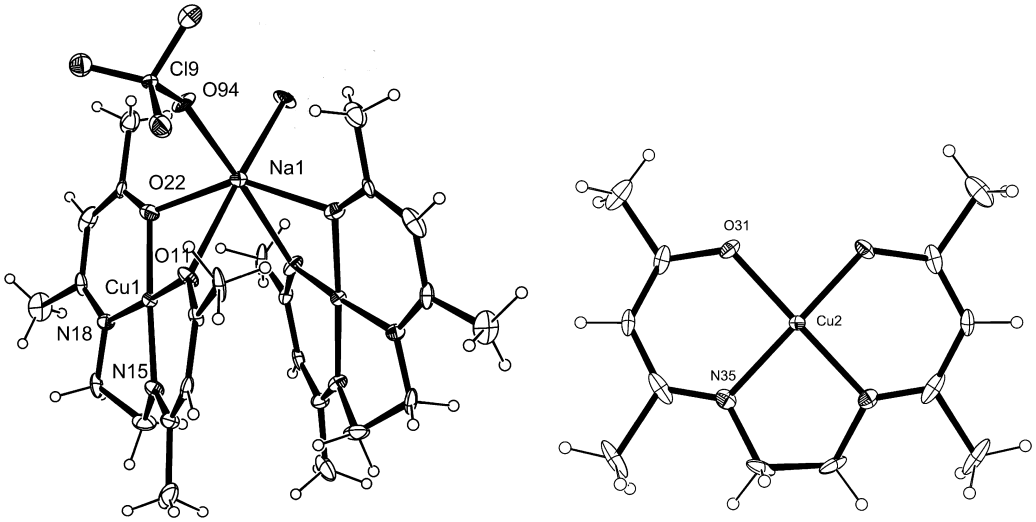

Fig. 1. Ortep-3 view of complex **1** with atom-numbering scheme (50% thermal ellipsoids).

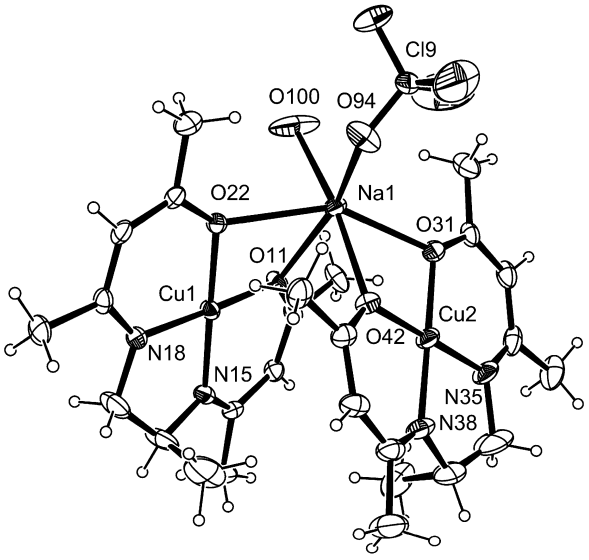

Fig. 2. Ortep-3 view of complex **2** with atom-numbering scheme (50% thermal ellipsoids).

complexes **2** and **3**. The four oxygen atoms of the Schiff-base ligands coordinate in facial manner to the central Na(1) resulting in a bent structure. The small bite of [CuL] on coordinating to Na(1) (66.9(2)°* for the trinuclear unit of **1**, 63.5(1)°, 67.3(1)° for **2** and 64.4(1)°, 63.8(1)° for **3**) is the main cause of distortion from the ideal octahedron of Na(1). In all the three complexes, the six-membered chelate rings incorporating the acetylacetone fragments are essentially planar with no atoms deviating more than 0.09 Å in **1** and **2** and 0.15 Å in **3** from their respective mean planes. In the trinuclear units of **1** and **2**, the five-membered rings comprising the diamine fragment adopt an envelope conformation, while the six-membered ring in **3** adopts a boat conformation.

In **1**, in addition to the trimer, there is a discrete [CuL^1] molecule which has crystallographic *C*2 symmetry (Fig. 1). The Cu(2) atom is four coordinate with a square planar environment being bonded to two oxygen atoms and two nitrogen atoms of the Schiff-base ligand. The *trans* angle is 177.4(2)° indicating that there is a slight tetrahedral distortion from the ideal square planar geometry. The dihedral angles between the two N(35)–Cu(2)–O(31) planes in the monomeric unit of complex **1** are 3.48°. The bond lengths in the discrete monomer [CuL^1] in **1** are somewhat different, with Cu(2)–O(31) 1.897(5) Å and Cu(2)–N(35) 1.989(7) Å, to that of trinuclear unit of **1** where average distances are 1.923(21) for Cu–O and 1.926(23) Å for Cu–N. Hence, the increase of Cu–O bond distances upon Na perchlorate adduct formation is confirmed, although there does seem to be a concomitant decrease in Cu–N distance.

In compound **1**, the trinuclear [$(CuL^1)_2Na(ClO_4)(H_2O)$] and the mononuclear [CuL^1] units are connected through H-bonding interactions (*Fig.* S2; Supplementary data) involving the water molecule O200 and the oxygen atoms O31 and O94. In compound **2**, the water molecule O100 and the oxygen atom O91 being involved in hydrogen bonding, forms dimeric entity as shown in *Fig.* S3.

3.3. Magnetic properties

The magnetic behavior for compounds **1**–**3** has been studied. The variable temperature susceptibilities for complexes **1**, **2** and **3** were measured over the range 2–300 K.

3.3.1. Complex *1*

Complex **1** shows a structure composed of alternated [Cu_2Na] and Cu(II) mononuclear discrete units. Accordingly, both of them have been considered in the magnetic study. The magnetic behavior of **1** is shown in Fig. 3 as the $\chi_M T$ *versus T* plot, χ_M being the molar susceptibility per three Cu(II) ions and *T* the temperature. At room temperature, the $\chi_M T$ value is 1.20 $cm^3\ mol^{-1}$ K which is slightly higher than the spin-only value, 1.13 $cm^3\ mol^{-1}$ K, expected for three Cu(II) ions with $S = 1/2$ and assuming a $g = 2$, suggesting higher values of *g* as is usual for Cu(II) ions. As the temperature is lowered, the $\chi_M T$ value is kept approximately constant until 40 K. Below that temperature the $\chi_M T$ *versus T* curve abruptly decreases until a final value of $\chi_M T = 1.02$ $cm^3\ mol^{-1}$ K is reached at 2 K. The low-temperature magnetic behavior confirms the presence of a weak antiferromagnetic exchange that could have its origin on either intra or intermolecular interactions. On the one hand, intramolecular exchange would undoubtedly take place through the different O–Na–O′ bridges present on the [Cu_2Na] unit, each oxygen atom corresponding to one different "ligand complex" of the unit. Such bridges are the only covalently bonded pathways by which unpaired electrons of the two Cu(II) atoms of the molecular unit could interact. The Cu···Cu intramolec-

ular distances are 4.134(2), 4.524(2), 3.966(1) Å, respectively, in the three structures.

Some examples have been previously published in the literature in which magnetic exchange coupling has been observed between paramagnetic species through diamagnetic metallic ions [16–20]. On the other hand, a detailed structural analysis of the intermolecular hydrogen bonds between one [Cu_2Na] and one discrete Cu(II) unit in complex **1** confirms that the possible intermolecular magnetic exchange pathway between Cu(II) ions would only be possible through the Na^+ ion, and would definitely contain two more atoms and therefore longer Cu(II)–Cu(II) distances compared to the intramolecular pathway.

Hence, it seems reasonable to assume that intermolecular interactions will be significantly weaker than intramolecular ones and so, only the intramolecular Cu(II)–Cu(II) coupling-type will be considered in our study. In order to quantify the magnitude of the intramolecular exchange interaction between Na^+ bridged-Cu(II) ions (J_{12}), an isotropic Heisenberg–Dirac–van Vleck Hamiltonian formalism for a dinuclear molecule plus a mononuclear discrete unit was used in the analysis [Eq. (1)]

$$\widehat{H}| = g_1\beta HS_1 + g_2\beta HS_2 + J_{12}S_1S_2 + g_3\beta HS_3 \quad (1)$$

where H is the value of the magnetic field and g_i, β and S_i have their usual meanings. Since intermolecular interactions in complex **1** are believed to be even weaker than intramolecular ones, no terms concerning this long-distance coupling have been introduced in the equation. Experimental data for **1**, corrected from diamagnetic contributions and TIP (180×10^{-6} cm^3 mol^{-1}/Cu atom) were analyzed by Eq. (1) on $\chi_M T$. In the fit procedure, $g_1 = g_2 \neq g_3$ was considered since the two Cu(II) ions in the [Cu_2Na] unit are structurally equivalent and different with respect to the Cu(II) ion located at the mononuclear entity. The g_3 value was fixed at 2.07 based on the value extracted from the epr spectrum at room temperature (see text below) which is considered as an average value of the parallel and perpendicular components of the anisotropic **g** tensor. The best fit parameters obtained are: $g_1 = g_2 = 2.07(0)$, $J = -1.09(1)$ cm^{-1} and $R = 2 \times 10^{-5}$ where R is the agreement factor defined as $R = \sum[(\chi_M T)_{calc} - (\chi_M T)_{obs}]^2 / \sum(\chi_M T)^2_{obs}$. These results confirm the weak antiferromagnetic exchange interaction between Cu(II) ions. The curve derived from the fit is plotted in Fig. 3 along with the experimental data. The value of the molar magnetization at 2 K and 5 T for complex **1** tends to 3 Nβ and it almost reaches saturation as seen in Fig. 4. Such low-temperature value of the magnetization confirms the weakness of the magnetic coupling in accordance with the temperature-dependent magnetic behavior.

3.3.2. Complexes *2* and *3*

The magnetic behavior of complexes **2** and **3** is shown in Fig. 3 as the $\chi_M T$ *versus* T *plot, being* χ_M the molar susceptibility per two Cu(II) ions and T the temperature. At room temperature, for both complexes, the $\chi_M T$ value is 0.80 cm^3 mol^{-1} K which is slightly higher than the spin-only value, 0.75 cm^3 mol^{-1} K, expected for two Cu(II) ions with $S = 1/2$ and assuming $g = 2$, suggesting higher values of g as usual for Cu(II) ions. As the temperature is lowered, the $\chi_M T$ value is kept approximately constant until 40 K. Below that temperature the $\chi_M T$ *versus* T curves abruptly decrease until a final value of $\chi_M T = 0.71$ and 0.68 cm^3 mol^{-1} K is reached at 2 K for complex **2** and **3**, respectively. The low-temperature magnetic behavior indicates the presence of a weak antiferromagnetic ex-

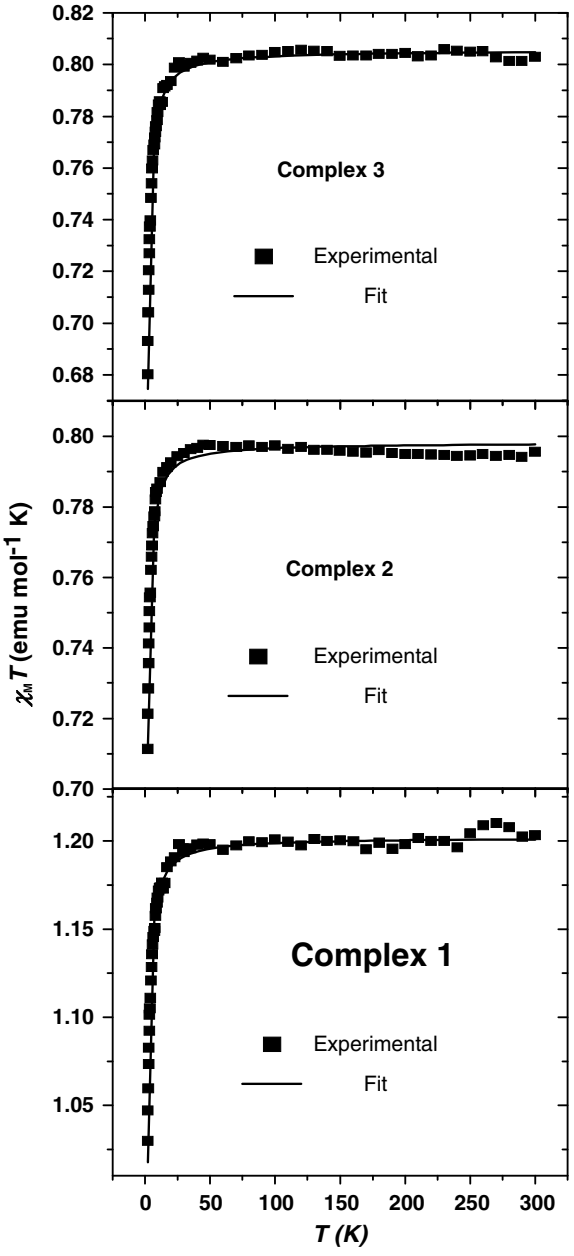

Fig. 3. Temperature dependence of the susceptibilities in the form of $\chi_M T$ vs T for complexes **1** (bottom), **2** (middle) and **3** (top). The solid lines are the fittings in the range between 300 to 1.9 K.

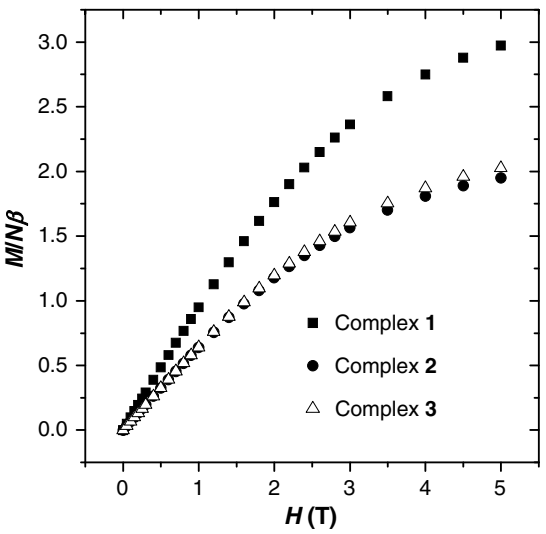

Fig. 4. Field dependence of the magnetization for complexes **1** (■), **2** (●) and **3** (△).

change. For the same reasons that stated for complex **1**, magnetic exchange mediated by intermolecular interactions will be much weaker than the intramolecular exchange coupling and hence they will not be considered in the magnetic analysis.

Complexes **2** and **3** are structurally similar and both show only [Cu_2Na] units in the crystal lattice with just one type of Cu(II) ion per structure. The different O–Na–O′ bridges present on each [Cu_2Na] unit, involving one Na^+ ion and four oxygen atoms of two different "ligand complexes", are responsible for the magnetic exchange coupling between Cu(II) ions. Taking in consideration all this information, an isotropic Heisenberg–Dirac–van Vleck Hamiltonian formalism for a dinuclear molecule was used in the fit of the experimental temperature-dependent $\chi_M T$ data [Eq.(2)],

$$\widehat{H} = g_1 \beta H S_1 + g_2 \beta H S_2 + J_{12} S_1 S_2 \quad (2)$$

where g_1 was considered equal to g_2 due to the symmetry equivalence of the two Cu(II) ions in the dimer. Experimental data for complexes **2** and **3**, corrected from diamagnetic contributions and TIP (120×10^{-6} cm^3 mol^{-1}/Cu atom) were analyzed by Eq. (2). The best fit parameters obtained are: $g_1 = g_2 = 2.06(0)$, $J = -0.55(1)$ cm^{-1} and $R = 0.5 \times 10^{-5}$ for complex **2** and $g_1 = g_2 = 2.07(0)$, $J = -0.80(1)$ cm^{-1} and $R = 0.4 \times 10^{-5}$ for complex **3** where R is the agreement factor defined as $R = \sum[(\chi_M T)_{calc} - (\chi_M T)_{obs}]^2 / \sum(\chi_M T)^2_{obs}$. These results confirm the weak antiferromagnetic exchange interaction between Cu(II) ions. The curves derived from the fits are plotted in Fig. 3 along with the experimental data. The value of the molar magnetization at 2 K and 5 T for complex **2** and **3** tends to 2 Nβ in both cases and they almost reach saturation as seen in Fig. 4. Such low-temperature values of the magnetization confirm that even at 2 K the unpaired electrons still populate the $S = 1$ excited state due to the weakness of the magnetic coupling. These data are in accordance with the fit of the temperature-dependent magnetic behavior of both complexes from which a very low value of the magnetic exchange constant was obtained.

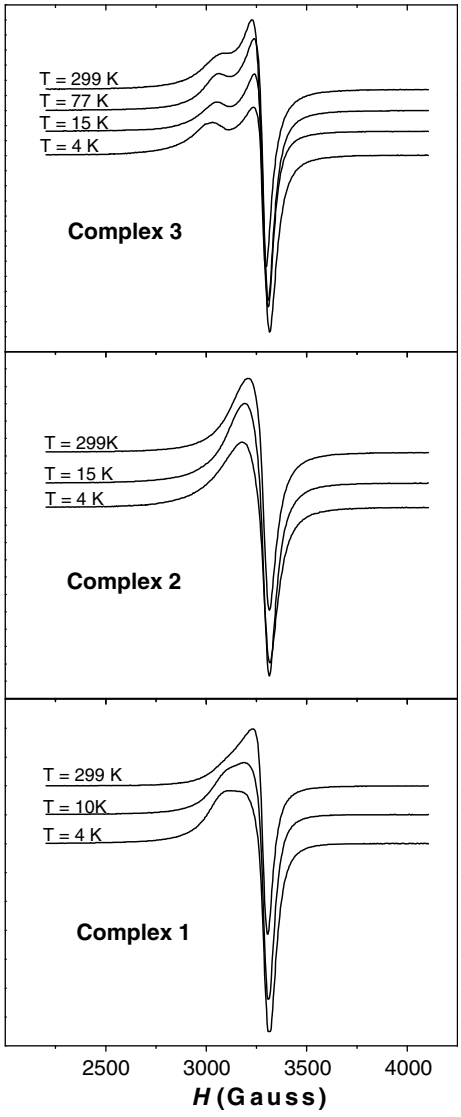

Fig. 5. Temperature-dependent EPR spectra for complexes **1** (bottom), **2** (middle) and **3** (top).

3.4. EPR spectra

The X-band epr spectra for complexes **1**–**3** were recorded on powder samples varying the temperature between 4 and 295 K (Fig. 5). The bands observed in the EPR spectra of the complexes have been analyzed as those corresponding to the transitions between $m_s = -1/2$ and $m_s = 1/2$ of non-interacting Cu(II) ions due to the extremely weak magnetic coupling that takes place in the dimeric unit. The profile of the spectra seems to be in agreement with the structural characterization of the complexes.

3.4.1. Complex *1*

At room temperature, complex **1** shows a broad absorption peak centered at $g_{eff} = 2.07$. With the temperature decrease, the same peak is observed but the slower relaxation dynamics of the complex allow to differentiate two different transitions with maxima at $g_{eff} = 2.13$ and 2.17, respectively. Due to their similar intensities the transitions can not be assigned to the $g_{\|}$ and $g_{\perp}$ components of the same **g**-tensor. The structure of complex **1** unambiguously shows the presence of two non-equivalent Cu(II) ions in the structure, both of them with a square planar environment. We attribute the observed peaks to the $g_{\perp}$ components of the two different Cu(II) ions. The peaks of the parallel transitions of both ions are probably overlapped with their perpendicular counterparts and only wide bands are observed even at low temperature. This fact does not allow to resolve the axial anisotropy of the metallic ions in the complex under these conditions.

3.4.2. Complexes *2* and *3*

The EPR spectra for complexes **2** and **3** show almost no evolution with temperature, confirming that only one transition coming from non-coupled metallic ions is observed. However, while for complex **2** only one broad absorption peak is observed, for complex **3** two different peaks are solved. Complexes **2** and **3** show just one type of Cu(II) ion in the crystal. In both cases Cu(II) ions are four coordinated with a square planar environment. Hence we expect to observe two different EPR transitions in each complex due to the axial anisotropy of the paramagnetic ions. Only in the spectra of complex **3** both $g_{\|}$ and $g_{\perp}$ components of the **g**-tensor can be observed while, for complex **2**, the low intensity parallel transition ($g_{\|}$) peak seems to be overlapped by the more intense perpendicular component ($g_{\perp}$). The reason for the more evidenced anisotropy of complex **3** could have a structural origin. Actually, the organic ligand L^3 used in the synthesis of complex **3** differs in length, from that used for complex **2**, containing one more carbon atom. This seems to have two main consequences in the bond lengths of the coordination sphere of the Cu(II) ions: (i) complex **3** shows much longer bond lengths with respect to complex **2** and ii) while in complex **2** Cu–O and Cu–N bond lengths show values in the same range (1.90–1.94 Å), in complex **3** their values belong to different ranges, such being 1.94–1.95 and 1.97–1.99 Å, respectively. These

structural differences could accentuate the magnetic anisotropy of the central ion.

3.5. Discussion

Several examples are available in the literature in which magnetic exchange between paramagnetic species takes place through bridges that contain diamagnetic metallic ions. The antiferromagnetic coupling has been reported between two Cu(II) ions with bridges containing a Zn(II) ion [16], a diamagnetic Ni(II) or Pd(II) ion [17], and a Na(I) ion [18]. On the other hand, ferromagnetic coupling has been also observed between two Cu(II) ions with bridges containing either a Zn(II) [19] or a CrO_4^{2-} moiety [20]. The values of the magnetic exchange constants (J) are generally very low, $-5 < J < 5\ cm^{-1}$, in agreement with what we observe in our [Cu_2Na] adducts. The ferromagnetic character of the coupling in the previously mentioned compounds has been usually rationalized in terms of strict orthogonality of the two magnetic orbitals that cancels their own overlapping [19,20]. The symmetry of the bridging ligand and the magnetic orbitals is responsible for that and probably the d-orbitals of the diamagnetic ion of the bridging ligand are somehow involved in the superexchange pathway. When either the symmetry of the bridging moiety or alternatively steric and electronic characteristics of the complex favor the overlapping of the magnetic orbitals, losing the previous orthogonality, the coupling between the two Cu(II) ions becomes clearly antiferromagnetic [16,17]. Neither in the case of complexes **1**–**3**, the $d_{x^2-y^2}$ magnetic orbitals of the paramagnetic ions show strict orthogonality nor hence an antiferromagnetic superexchange is expected and further confirmed by the corresponding magnetic analysis. However, due to the bent structure of the adducts (see Section 3.2), the magnetic orbitals of the two Cu(II) ions in the [Cu_2Na] units are tilted one from the other in contrast with the planar geometry of the molecule observed by Journaux et al. [16] and Chaudhuri et al. [17] for other molecular systems, and hence their overlapping could be substantially diminished leading to a very weak coupling.

The [Cu_2Na] units in complexes **1**–**3** are magnetically diluted in the crystal due to the absence of significant intermolecular interactions. This characteristic allows clearly identifying and studying the magnetic coupling through diamagnetic metallic ions without the interference of other long-distance couplings that could compete in strength with such particular kind of intramolecular interaction.

4. Conclusion

In the present study, it has been shown that sodium ion can be incorporated by the building block like [Cu(II)L] unit, simply on crystallization from methanol solution containing dissolved sodium perchlorate to result in trinuclear Cu_2Na adducts. Spectral and electrochemical analyses of both ligand complexes and sodium adducts indicate that the later exists in the solid state but breaks in solution. The temperature-dependent magnetic susceptibility measurements indicate that, in complexes **1–3** the two terminal paramagnetic Cu(II) centers are weakly antiferromagnetically coupled through Na(I) ion.

*2.1.2. Synthesis of [ZnL1(biim-6)] · H_2O (**2**)*

After a mixture of $ZnCO_3$ (0.125 g, 1 mmol), oxalic acid dihydrate (0.126 g, 1 mmol) in water was stirring for 10 min at room temperature, biim-6 (0.436 g, 2 mmol) in 1 mL ethanol was added to the solution with stirring and still precipitate was obtained. A minimum amount of ammonia (14 M) was added to give a colorless solution. Suitable colorless crystals were obtained from the filtrate after standing at room temperature in a 45% yield based on $ZnCO_3$. Elemental *Anal.* Calc. for $C_{14}H_{20}ZnN_4O_5$: C, 43.15; H, 5.26; N, 14.37. Found: C, 43.27; H, 5.31; N, 14.48%. *2.1.3. Synthesis of [MnL1(biim-6)] · H_2O (**3**)*

A mixture of $MnCO_3$ (0.115 g, 1 mmol), oxalic acid dihydrate (0.126 g, 1 mmol) in water (8 mL), and biim-6 (0.436 g, 2 mmol) in ethanol (1 mL) was sealed in a Teflon-lined stainless steel autoclave and heated at 140 °C for 4 days, and then it was cooled to room temperature at 10 °C h^{-1}. Colorless crystals were obtained in a 56% yield based on $MnCO_3$. Elemental *Anal.* Calc. for $C_{14}H_{20}MnN_4O_5$: C, 44.33; H, 5.32; N, 14.77. Found: C, 44.44; H, 5.39; N, 14.70%. IR (KBr, cm^{-1}): 3550 (w), 3413 (m), 3112 (m), 2932 (w), 2858 (w), 1668 (vs), 1615 (vs), 1516 (vs), 1362 (s), 1230 (m), 1227 (m), 1110 (s), 827 (m), 734 (w), 662 (s), 627 (m), 489 (m).

*2.1.4. Synthesis of [MnL1(biim-4)] (**4**)*

A mixture of $MnCO_3$ (0.115 g, 1 mmol), oxalic acid dihydrate (0.126 g, 1 mmol) in water (8 mL), and biim-4 (0.380 g, 1 mmol) in ethanol (1 mL) was sealed in a Teflon-lined stainless steel autoclave and heated at 140 °C for 4 days prior to being cool to room temperature at 10 °C h^{-1}. Colorless crystals were obtained in a 69% yield based on $MnCO_3$. Elemental *Anal.* Calc. for $C_{12}H_{14}MnN_4O_4$: C, 43.26; H, 4.24; N, 16.81. Found: C, 43.14; H, 4.27; N, 16.75%. IR (KBr, cm^{-1}): 3742 (s), 3116 (w), 2928 (w), 1679 (vs), 1652 (vs), 1618 (m), 1515 (vs), 1389 (m), 1229 (w), 1111 (w), 789 (w), 667 (s), 475 (m).

*2.1.5. Synthesis of [Co_2(L2)$_2$(biim-5)$_3$ · 6H_2O] · 8H_2O (**5**)*

A mixture of $CoCO_3$ (0.119 g, 1 mmol), fumaric acid (0.116 g, 1 mmol) in water was stirring for 10 min at room temperature. Then biim-5 (0.408 g, 2 mmol) was added to the mixture with stirring for 1 h and pink solution was obtained. Pink crystals were obtained from the filtrate after standing at room temperature for several days in a 75% yield based on $CoCO_3$. Elemental *Anal.* Calc. for $C_{41}H_{80}Co_2N_{12}O_{22}$: C, 40.66; H, 6.66; N, 13.88. Found: C, 40.74; H, 6.70; N, 13.95%. IR (KBr, cm^{-1}): 3670 (w), 3136 (m), 2945 (w), 2858 (w), 1568 (vs), 1455 (m), 1240 (vs), 1108 (vs), 991 (m), 843 (s), 763 (s), 663 (vs).

*2.1.6. Synthesis of [ZnL3(biim-6)] (**6**)*

A mixture of $ZnCO_3$ (0.125 g, 1 mmol), phthalic anhydride (0.148 g, 1 mmol) in water (8 mL), and biim-6 (0.437 g, 2 mmol) in ethanol (1 mL) was sealed in a Teflon-lined stainless steel autoclave and heated at 180 °C for 4 days, and then it was cooled to room temperature at 10 °C h^{-1}. Colorless crystals were obtained in a 60% yield based on $ZnCO_3$. Elemental *Anal.* Calc. for $C_{20}H_{22}ZnN_4O_4$: C, 53.65; H, 4.95; N, 12.51. Found: C, 53.77; H, 4.97; N, 12.65%. IR (KBr, cm^{-1}): 3123 (w), 3090 (w), 2865 (w), 1619 (vs), 1560 (vs), 1524 (s), 1475 (m), 1377 (vs), 1249 (m), 1144 (m), 950 (m), 768 (s), 655 (vs), 454 (w).

*2.1.7. Synthesis of [ZnL3(biim-5)] (**7**)*

A mixture of $ZnCO_3$ (0.125 g, 1 mmol), phthalic anhydride (0.148 g, 1 mmol) in water (8 mL), and biim-5 (0.408 g, 2 mmol) in ethanol (1 mL) was sealed in a Teflon-lined stainless steel autoclave and heated at 170 °C for 4 days, and then it was cooled to room temperature at 10 °C h^{-1}. Colorless crystals were obtained in a 66% yield based on $ZnCO_3$. Elemental *Anal.* Calc. for $C_{19}H_{20}ZnN_4O_4$: C, 52.61; H, 4.65; N, 12.92. Found: C, 52.77; H, 4.61; N, 12.81%. IR (KBr, cm^{-1}): 3421 (m), 3111 (m), 2938 (w), 1617 (vs), 1565 (vs), 1516 (s), 1457 (s), 1365 (vs), 1246 (m), 1147 (m), 953 (m), 833 (m), 756 (m), 659 (m), 478 (w).

*2.1.8. Synthesis of [CdL3(biim-5) · 1.5H_2O] · 0.5H_2O (**8**)*

A mixture of $Cd(OH)_2$ (0.146 g, 1 mmol), phthalic anhydride (0.148 g, 1 mmol) in water (8 mL), and biim-5 (0.408 g, 2 mmol) in ethanol (1 mL) was sealed in a Teflon-lined stainless steel autoclave and heated at 170 °C for 4 days, and then it was cooled to room temperature at 10 °C h^{-1}. Colorless crystals were obtained in a 56% yield based on $Cd(OH)_2$. Elemental *Anal.* Calc. for $C_{19}H_{24}CdN_4O_6$: C, 44.16; H, 4.68; N, 10.84. Found: C, 44.27; H, 4.60; N, 10.95%. IR (KBr, cm^{-1}): 3742 (w), 3118 (w), 2933 (w), 2862 (w), 1646 (m), 1560 (vs), 1516 (s), 1481 (m), 1397 (vs), 1235 (m), 1112 (m), 937 (m), 841 (m), 751 (s), 652 (vs), 438 (s).

*2.1.9. Synthesis of [CdL4(biim-6) · 2H_2O] (**9**)*

A mixture of $Cd(OH)_2$ (0.146 g, 1 mmol), *p*-phthalic acid (0.166 g, 1 mmol) in water (8 mL), and biim-6 (0.436 g, 2 mmol) in ethanol (1 mL) was sealed in a Teflon-lined stainless steel autoclave and heated at 180 °C for 4 days, and then it was cooled to room temperature at 10 °C h^{-1}. Colorless crystals were obtained

in a 67% yield based on $Cd(OH)_2$. Elemental *Anal.* Calc. for $C_{20}H_{26}CdN_4O_6$: C, 45.25; H, 4.94; N, 10.55. Found: C, 45.17; H, 4.86; N, 10.42%. IR (KBr, cm^{-1}): 3743 (w), 3414 (vs), 2935 (w), 2862 (w), 1643 (s), 1616 (s), 1560 (vs), 1515 (s), 1465 (s), 1383 (vs), 1235 (w), 1116 (m), 745 (m), 651 (m), 452 (m).

2.2. X-ray crystallography

Single-crystal X-ray diffraction data for compounds **1, 2** and **4** were recorded on a Bruker Apex CCD diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at 293 K. Crystallographic data for compounds **3** and **5–9** were collected on a Rigaku RAXIS-RAPID single-crystal diffractometer with Mo Kα radiation (λ = 0.71073 Å) at 293 K. Absorption corrections were applied using multi-scan technique. All the structures were solved by Direct Method of SHELXS-97 [25] and refined by full-matrix least-squares techniques using the SHELXL-97 program [26] within WINGX [27]. Non-hydrogen atoms were refined with anisotropic temperature parameters. The hydrogen atoms attached to carbons were generated geometrically; the aqua hydrogen atoms were located from difference Fourier maps and refined with isotropic displacement parameters. Analytical expressions of neutral-atom scattering factors were employed, and anomalous dispersion corrections were incorporated [28]. The disordered C atoms in compounds **4** and **5** and disordered O atoms in compound **8** were refined using C or O atoms split over two sites, with a total occupancy of 1. The water H atoms in compounds **1–3** and **8** could not be positioned reliably and were omitted from the final model. The bond distance restraints were used in the refinement for the water molecules in compound **5**.

Detailed crystallographic data and structure refinement parameters for **1–9** are summarized in Table 1. Selected bond distances and angles for compounds **1–9** are listed in Table S1 (see the Supplementary data).

3. Results and discussion

3.1. Descriptions of crystal structures

3.1.1. Structure of $[CuL1(biim\text{-}6)] \cdot H_2O$ (**1**)

Compounds **1–3** are isostructural and crystallize in the monoclinic *C2/c* space groups; therefore the structure descriptions of compounds **2** and **3** will be neglected.

As shown in Fig. 1a, each Cu(II) atom lies on an inversion center and six-coordinated by four O atoms from two oxalate anions (Cu–O 2.006(1)–2.321(1) Å) and two N atoms from biim-6 ligands (Cu–N 2.011(2) Å). Due to the Jahn–Teller effect, the Cu–O distance of axial site is much longer than those in the equatorial plane. Each oxalate anion coordinates to two Cu atoms to form a 1D chain with a Cu···Cu distance of 5.58 Å. The neutral ligand biim-6 connects two Cu atoms and a 2D network is obtained (Fig. 1b).

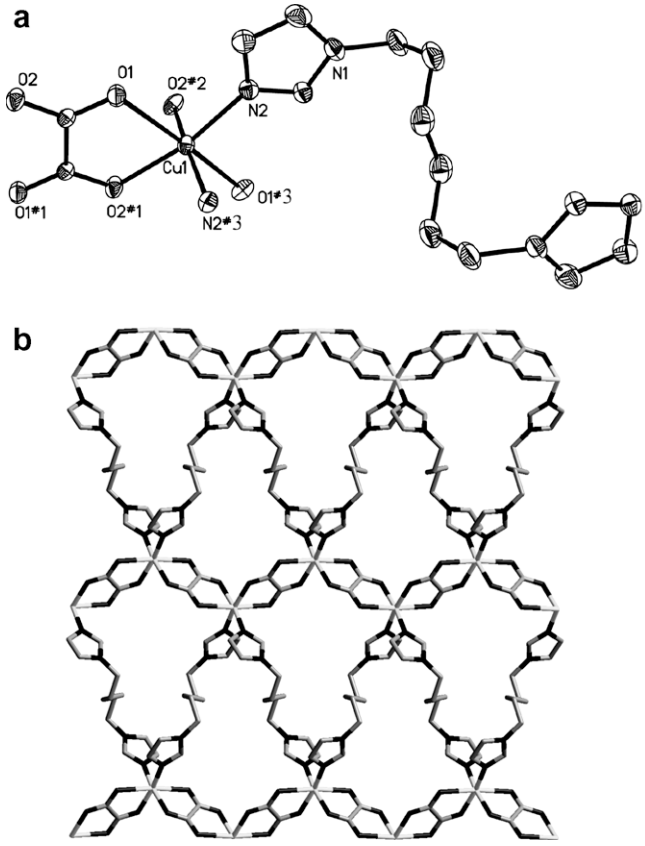

Fig. 1. (a) Coordination environment of the copper cation in **1**. (b) View of a single layer of **1**.

3.1.2. Structure of [MnL1(biim-4)] (**4**)

As illustrated in Fig. 2a, each central Mn(II) atom in **4** is coordinated by four O atoms (Mn–O 2.199(3)–2.211(3) Å) of two oxalate anions and two N atoms (Mn–N 2.198(4)–2.231(4) Å) from biim-4

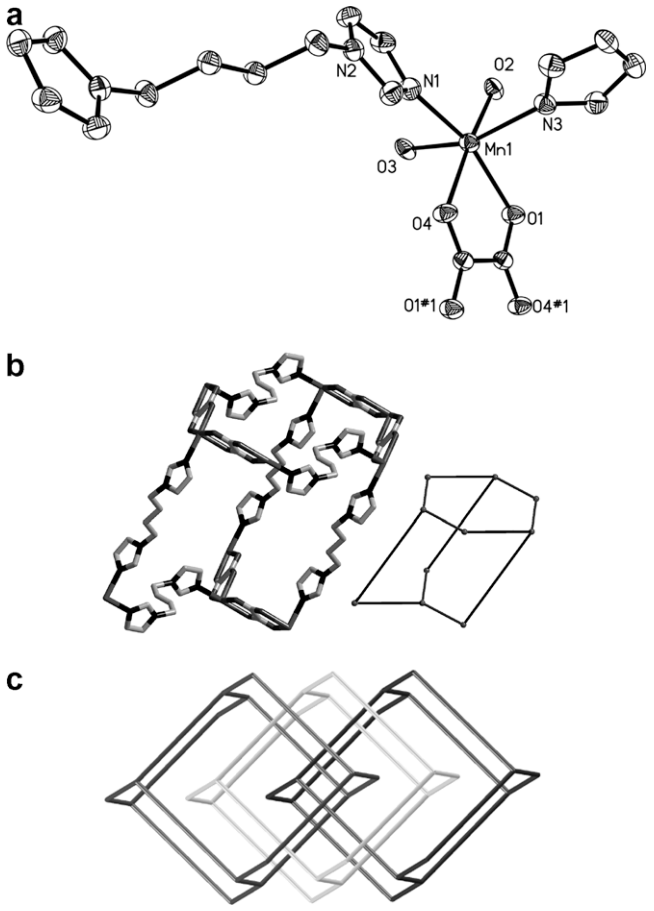

Fig. 2. (a) Coordination environment of the manganese cation in **4**. (b) Single adamantanoid cage. (c) Three interpenetrating diamondoid cages.

ligands to furnish a disordered octahedron geometry. Two crystallographically biim-4 ligands adopt "*S*" shaped and "zigzag" shaped conformations, respectively. The topology of the whole structure can be described as a typically diamondoid framework (Fig. 2b). As can be seen, the diamondoid cage are elongated significantly in one direction, and exhibit maximum dimensions (corresponding to the longest intracage Mn···Mn distances) of 21.37 Å × 20.18 Å × 18.90 Å. Because of the spacious nature of the single network, it allows two identical diamondoid networks to interpenetrate it in a normal mode giving rise to a threefold interpenetrating structure (Fig. 2c). According to topology classification, compound **4** belongs to Class Ia (all the independent nets are related by a single vector and the whole interpenetrating arrays are generated by translating a single net 2 times) [29], with the translating vector of [1 0 0] (8.06 Å).

3.1.3. Structure of $[Co_2(L2)_2(biim\text{-}5)_3 \cdot 6H_2O] \cdot 8H_2O$ (**5**)

As shown in Fig. 3a, there are three kinds of crystallographically unique Co centers in the structure of **5**. Co1 is coordinated by two N atoms (Co–N 2.111(2)–2.112(2) Å) from two neutral ligands and four water molecules (Co–O 2.095(2)–2.153(2) Å), showing a slightly disordered octahedral geometry. Co2 lies at an inversion center and is six-coordinated by four N atoms (Co–N 2.128(2)–2.137(2) Å) from biim-5 ligands and two water molecules (Co–O 2.154(2) Å). Co3 has the same coordination environment to that of Co2. The fumariate anions act as counterions. There exist two kinds of chains. For Co1, each biim-5 ligand connects two Co1 atoms to a 1D polymeric chain (Fig. 3b). For Co2 and Co3, the Co(II) atoms are joined by biim-5 ligands to form a double-stranded

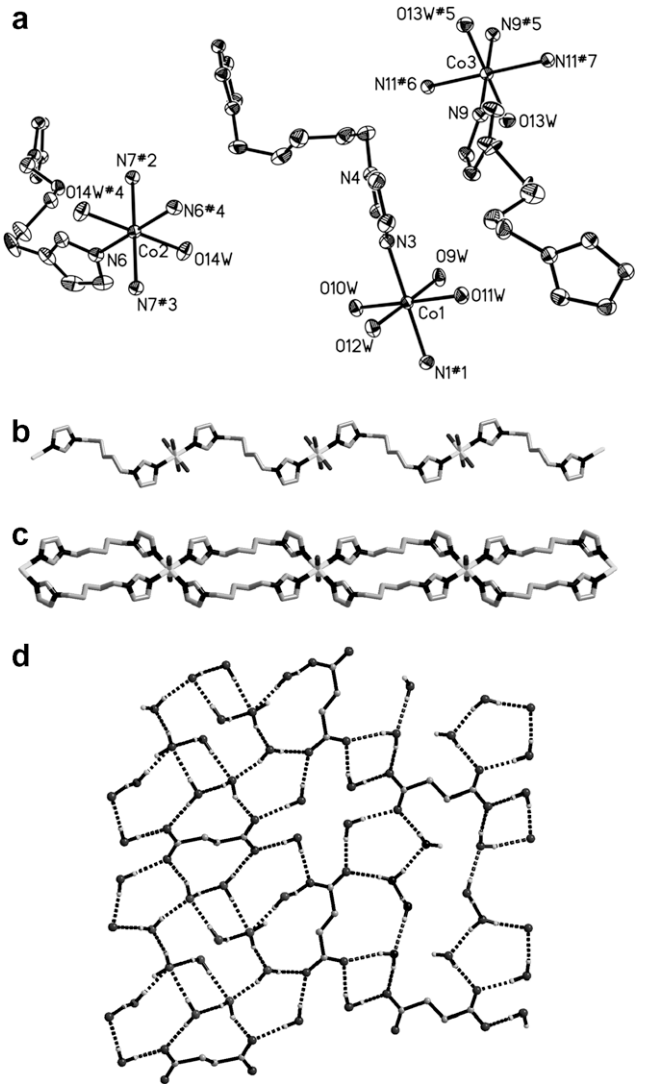

Fig. 3. (a) Coordination environment of the cobalt cations in **5**. (b) View of single chain composed of Co1 and biim-5 ligands. (c) View of double-stranded chain composed of Co2, Co3 and biim-5 ligands. (d) The hydrogen-bonded layer of L2 and water molecules.

chain (Fig. 3c). These two kinds of chains are connected by hydrogen bonds to construct a 3D supramolecular structure (Fig. S1a). As shown in Fig. 3d, the hydrogen bonds lead the water molecules and L2 anions to a 2D supramolecular network. In addition, a notable feature of **6** is the presence of two types of water clusters, namely $(H_2O)_{12}$ and $(H_2O)_8$. Within the $(H_2O)_{12}$ cluster, four water molecules (O8W, $O8W^{\#13}$, $O13W^{\#5}$ and $O13W^{\#12}$, symmetry code: $^{\#5}-x+1, -y+1, -z$; $^{\#12}1+x, y, z$; $^{\#13}2-x, 1-y, -z$) act as hydrogen bonds donors and others act as both donors and acceptors (Fig. S1b). In this water cluster, $O1W^{\#2}$, O2W, $O6W^{\#5}$, $O13W^{\#5}$ and $O1W^{\#3}$, $O2W^{\#13}$, $O6W^{\#12}$, $O13W^{\#12}$ (symmetry code: $^{\#2}-x, -y+2, -z$; $^{\#3}1+x, -1+y, z$) form two types 4-membered $(H_2O)_4$ rings, respectively and these rings are connected by $O7W^{\#2}$ and $O7W^{\#3}$ to form a much lager $(H_2O)_{10}$ ring. The $(H_2O)_{10}$ ring are joined by O8W and $O8W^{\#13}$ to form a $(H_2O)_{12}$ cluster. Moreover, the oxygen atoms O2, O3, O19 and O9 from L2 anions are involved in hydrogen bonds with water molecules, which helped to stabilize the $(H_2O)_{12}$ cluster. In $(H_2O)_{12}$ cluster, the average hydrogen bond is 2.78 Å, while these distances in regular ice, liquid water, and water vapor are 2.74, 2.85, and 2.98 Å, respectively [30]. In $(H_2O)_8$ cluster, four crystallographically unique lattice water molecules ($O3W^{\#8}$, O4W and $O5W^{\#9}$ act as both hydrogen-bond donors

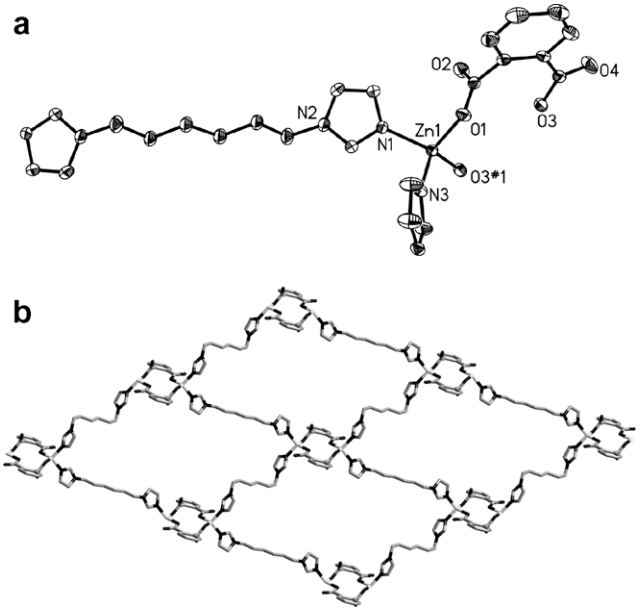

Fig. 4. (a) Coordination environment of the zinc cation in **6**. (b) View of a single layer.

and acceptors, while O14W$^{\#4}$ only acts as a hydrogen-bond donor) and their symmetry-related molecules link to each other to form a $(H_2O)_8$ cluster through hydrogen bonds (Fig. S1c). Furthermore, the oxygen atoms O1, O6$^{\#14}$, O21 and O22$^{\#8}$ from L2 anions (symmetry code: $^{\#14}2-x, 1-y, 1-z$) are involved in hydrogen bonds with water molecules to stabilize the $(H_2O)_8$ cluster.

3.1.4. Structure of [ZnL3(biim-6)] (*6*)

In compound **6**, L3 was introduced to replace L1 ligand of compound **2**. As illustrated in Fig. 4a, each Zn(II) atom is four-coordinated by two O atoms (Zn–O 1.951(2)–1.957(2) Å) from two L3 anions and two N atoms (Zn–N 2.003(2)–2.035(2) Å) from biim-6 ligands to furnish a distorted tetrahedron geometry. The phthalate anions adopt bis(monodentate) coordination mode to connect two central Zn(II) atoms. Every two L3 anions coordinate with the same two Zn(II) atoms and form a dimer. Biim-6 ligands display two kinds of conformations, which link the dimers to a 2D layer network (Fig. 4b).

3.1.5. Structure of [ZnL3(biim-5)] (*7*)

As shown in Fig. 5a, every Zn(II) atom in **7** is four-coordinated by two O atoms from two L3 anions and two N atoms from two biim-5 ligands. The L3 anion adopts bis(monodentate) coordination mode and connects two Zn(II) atoms. As bridged ligand, each biim-5 connects two Zn(II) atoms to form a dimer (Fig. 5b). These dimers are connected by L3 anions to a 2D network with (6,3) topology (Fig. 5c).

3.1.6. Structure of [CdL3(biim-5) · 1.5H_2O] · 0.5H_2O (*8*)

In compound **8**, cadmium ion was introduced to replace zinc ion in compound **7**. As illustrated in Fig. 6a, each Cd(II) atom is eight-coordinated by four O atoms (Cd–O 2.359(5)–2.626(7) Å) [31,32] from two L3 anions, two N atoms (Cd–N 2.264(5)–2.278(5) Å) from two biim-5 ligands and two water molecules (Cd–O 2.487(6)–2.56(2) Å). Two L3 anions connect to the same two Cd(II) atoms in the chelating modes to form a dimer (Fig. 6b). These dimers are joined by biim-5 ligands to a 2D layer network (Fig. 6b).

3.1.7. Structure of [CdL4(biim-6) · 2H_2O] (*9*)

As illustrated in Fig. 7a, each Cd(II) atom in **9** lies on an inversion center and is six-coordinated by two O atoms from two L4 anions, two N atoms from two biim-6 ligands and two water molecules. Each L4 adopts bis(monodentate) coordination mode and connects with two Cd(II) atoms to a 1D chain. These chains are joined by biim-6 ligands to propagate a 2D layer network (Fig. 7b). In addition, hydrogen bonds between L4 and water molecules exist in **9**. These hydrogen bonds link L4 anions and water molecules resulting a 1D infinite chain. These chains stabilize the structure and connect the adjacent layers to form a 3D supramolecular structure (Fig. 7c).

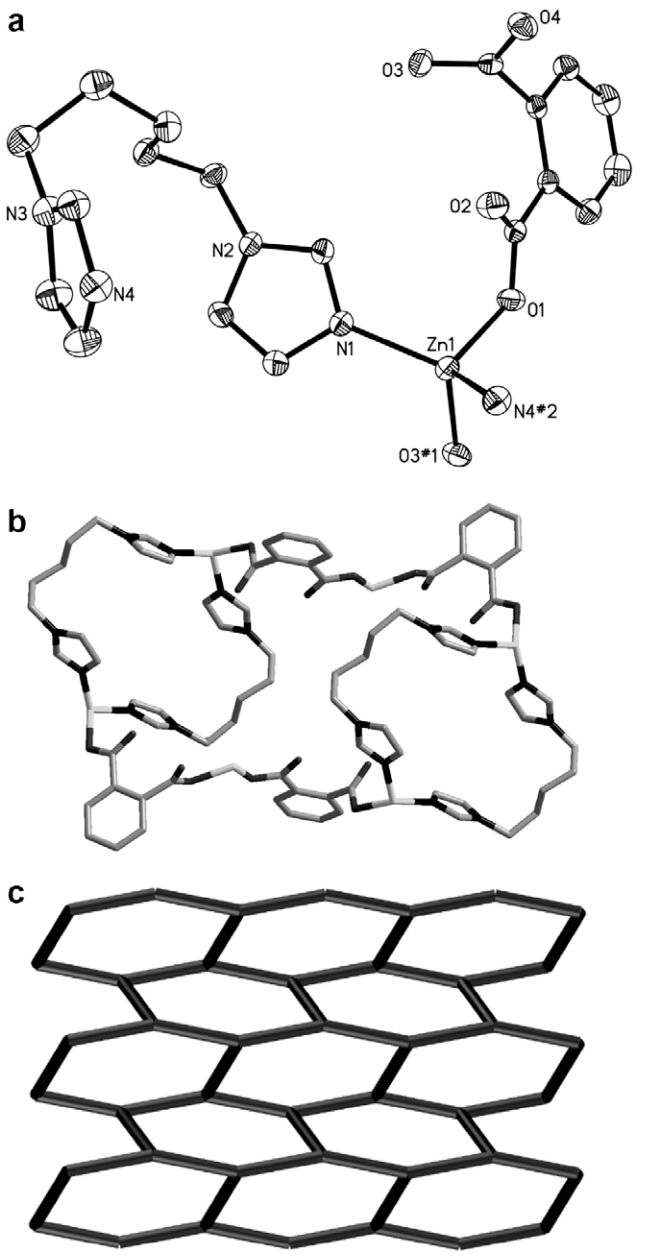

Fig. 5. (a) Coordination environment of the zinc cation in **7**. (b) View of the large ring of (6, 3) network. (c) View of a layer of (6, 3) topology.

3.2. Discussion

3.2.1. Effect of carboxylate anions

As expected, carboxylate anion plays an important role in determining the final structures. All of the L1 anions in **1**-**4** adopt bis(chelating) coordination modes, and M(II) centers are bridged

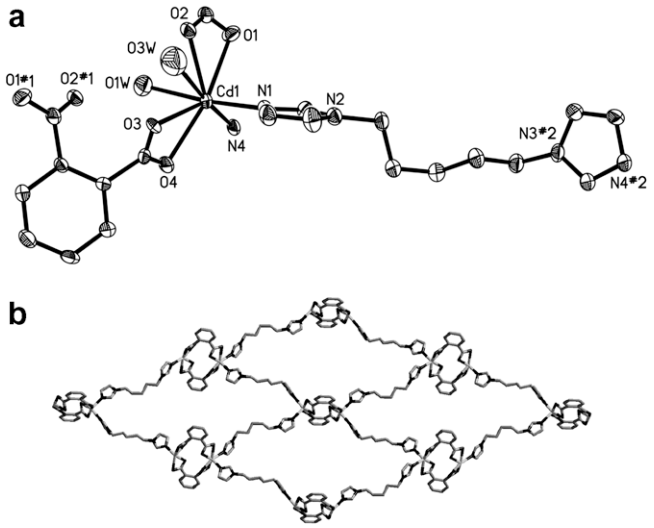

Fig. 6. (a) Coordination environment of the cadmium cation in **8**. (b) View of a single layer of compound **8**.

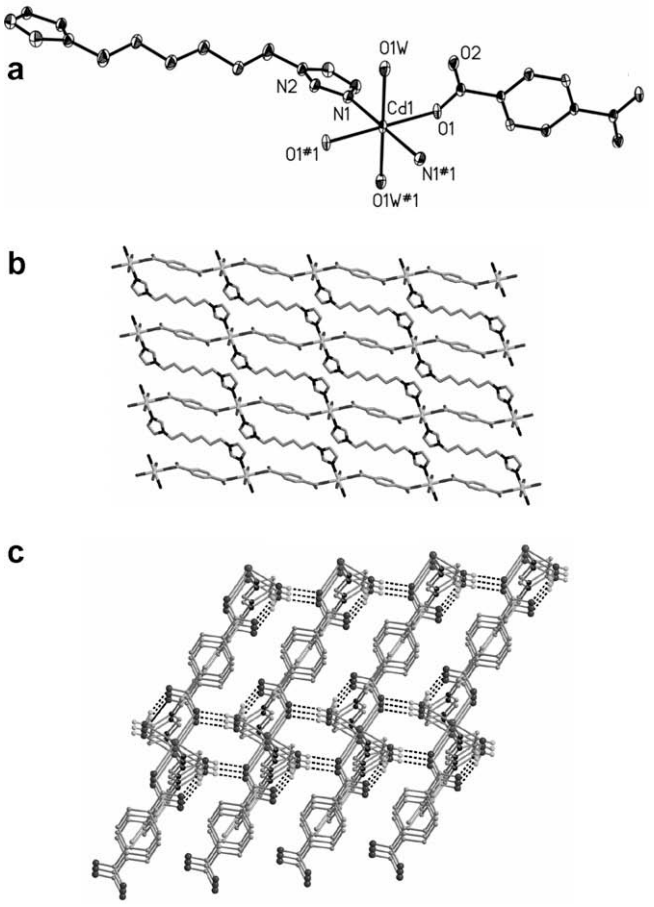

Fig. 7. (a) Coordination environment of the cadmium cation in **9**. (b) View of a single layer. (c) View of the 3D supramolecular structure formed by hydrogen bonds.

by L1 anions to form 1D chain skeletons. L2 anions in **5** act as counterions. Although the L2 anions in **5** are not coordinated with Co(II) ions, they joined by hydrogen bonds with water molecules, which also modulate the whole structure of **5**. L3 anions in **6** and **7** adopt bis(monodentate) coordination modes; and L3 anion in **8** adopts bis(chelating) coordination mode. The M(II) centers in **6** and **8** are linked by L3 anions to dimers, respectively, and the M(II) centers in **7** are linked by L3 anions to a chain. L4 anion in **9** adopts bis(monodentate) mode, and the L4 anions link M(II) center to form a chain.

3.2.2. Effect of bis(imidazole) ligands

In the structures of biim-6, biim-5 and biim-4, the imidazole groups are bridged by different spacers: 1,6-hexyl, 1,5-pentyl and 1,4-butyl. By comparing of the structures of compounds **1**–**9**, it was found that the flexibilities of the bis(imidazole) methylene groups have a great influence to the frameworks, because adjustments in the framework occur to accommodate the bend of the molecules. In compounds **1**–**3**, **6** and **9**, the neutral ligands are biim-6. The methylene groups of **1**–**3** display "*S*" conformations, with the distance between neighboring M(II) centers linked by biim-6 ligands being 11.77–12.34 Å. The methylene groups of **6** and **9** display zigzag conformations, with the distance between neighboring M(II) centers linked by biim-6 ligands being 14.19–16.49 Å. In compounds **5**, **7** and **8**, the neutral ligands are biim-5, and the methylene groups display "*S*" and "3" formed conformations, the distance between neighboring M(II) centers linked by biim-5 ligands are 8.39–15.12 Å. In compounds **4**, the neutral ligand is biim-4, and the methylene groups display "*S*" and zigzag conformations, with the distance between neighboring Mn(II) centers linked by the biim-4 ligands being 13.74 and 14.06 Å.

Comparing compounds **6** with **7**, it can be seen that the neutral ligands biim-6 of **6** display two kinds of conformations. The $[Zn(L3)_2Zn]$ dimers are linked by biim-6 to a 2D network (Fig. 4b). In **7**, biim-5 adopt only one kind of conformation to connect the central Zn(II) atoms to $[Zn(biim\text{-}5)_2Zn]$ dimers (Fig. 5b). By comparing **3** with **4**, the changes are more noticeable. Compound **3** has a 2D layer network, while compound **4** displays a 3D network with diamondoid topology.

3.3. Thermal analysis

In order to characterize the compounds more fully in terms of thermal stability, some of their thermal behaviors were studied by TGA (Fig. S2). The experiments were performed on samples consisting of numerous single crystals of **3**, **5** and **8**–**9** under N_2 atmosphere with a heating rate of 10 °C/min.

For compound **3**, the weight loss corresponding to the release of water molecules are observed from room temperature to 135 °C (obsd 3.9%, calcd 4.75%). The anhydrous compound begins to decompose at 253 °C. For compound **5**, the weight loss corresponding to the release of water molecules are observed from room temperature to 105 °C (obsd 19.1%, calcd 20.83%). The anhydrous compound begins to decompose at 253 °C. For compound **8**, the weight loss corresponding to the release of water molecules are observed from room temperature to 175 °C (obsd 4.7%, calcd 3.57%). The anhydrous compound begins to decompose at 240 °C. For compound **9**, the weight loss corresponding to the release of water molecules are observed from 120 to 236 °C (a weight loss of 5.1% is smaller than the calculated value 6.78% probably resulting from a slow losing of the guest molecules in the air at room temperature). The anhydrous compound begins to decompose at 305 °C.

3.4. Luminescent properties

The luminescence spectra of neutral ligands biim-5 and biim-6 were examined in an ethanol solution, because the solid samples cannot be isolated at room temperature (Table 2, Fig. S3). The solid state luminescence spectra of free carboxylate ligands, compounds

Table 2
The wavelengths of the emission maximums and excitation (nm)

Compound	2	6	7	8	9
λ_{em}	403	427	406	441	429
λ_{ex}	348	315	346	366	352
Ligand	Biim-5	Biim-6	Phthalic anhydride		H_2L4
λ_{em}	400	363, 379	389		390
λ_{ex}	342	343	352		347

2 and **6–9** were examined at room temperature (Table 2, Figs. S4 and S5).

Biim-5 shows an emission at 400 nm; and biim-6 shows a maximum at 379 nm and a shoulder at 363 nm. The peaks of the ligands biim-5 and biim-6 are probably due to $\pi^* \rightarrow \pi$ transitions [33].

The emissions of free ligands of phthalic anhydride (389, λ_{ex} = 352 nm) and H_2L4 (390 nm, λ_{ex} = 347 nm) [34] can also exhibit fluorescence at room temperature. The emission bands of the dicarboxylate ligands can be assigned to the $\pi^* \rightarrow n$ transitions [35]. The Zn(II) compounds (**2**, **6** and **7**) exhibit emissions at about 403 nm for **2**, at 427 nm for **6**, and at 406 nm for **7**. The emission peaks for these compounds may be attributed to the ligand-to-metal charge-transfer (LMCT) transitions [36,37]. The luminescent spectra of Cd(II) compounds **8** (441 nm) and **9** (429 nm) may also be assigned as LMCT [37].

3.5. Magnetic properties

The temperature-dependent magnetic susceptibility data of compounds **1**, **3** and **4** have been measured from polycrystalline samples at an applied magnetic field of 1000 Oe in the temperature range of 2–300 K (Fig. 8). Although compounds **1** and **3** are two-dimensional, and **4** is three-dimensional, from a magnetic point of view, the systems can be considered as one-dimensional owing to the long M···M distances (11.77 Å for **1**, 12.34 Å for **3** and 12.46 Å for **4**) along the bis(imidazole) ligands, for which we can assume a negligible magnetic exchange through the biim-6 and biim-4 ligands [38].

For **1**, the $\chi_m T$ value at 300 K is 0.451 $cm^3\ mol^{-1}$ K (1.900 μ_B), which is as expected (1.732 μ_B, considering g = 2.00) for a magnetically isolated spin doublet. Upon cooling, $\chi_m T$ gradually increase, reaching a value of 0.551 $cm^3\ mol^{-1}$ K at 2 K. This feature is indicative of the occurrence of an overall weak ferromagnetic coupling between the Cu(II) ions [39–43]. The magnetic susceptibility in the range of 300–100 K obeys the Curie–Weiss law with the Curie constant, C = 0.451 $cm^3\ mol^{-1}$ K, and the Weiss constant, Θ = 0.329 K.

For **3**, the $\chi_m T$ value at 300 K is 5.077 $cm^3\ mol^{-1}$ K (6.372 μ_B), which is slightly higher than the spin-only value (5.916 μ_B, considering g = 2.00) expected for a high-spin d^5 Mn(II) ion. Upon cooling, the values of $\chi_m T$ keep smoothly decreasing in 300–34 K range, and then exhibit a maximum value of 2.899 $cm^3\ mol^{-1}$ K at 32 K before goes down quickly to a minimum value of 0.186 $cm^3\ mol^{-1}$ K at 2 K. This behavior is indicative of antiferromagnetic coupling between the Mn(II) centers through the oxalate-bridging ligands. The inflexion at 32 K may be due to a small canting of the sub-lattice or a small amount of impurity [34]. The magnetic susceptibility above 34 K can be well fit to Curie–Weiss law with C = 5.66 $cm^3\ mol^{-1}$ K, Θ = –35.62 K. The negative Θ value further confirms the presence of antiferromagnetic interaction in **3**.

The magnetic behavior of compounds **3** and **4** is quite similar. For **4**, the $\chi_m T$ value at 300 K is 4.841 $cm^3\ mol^{-1}$ K (6.223 μ_B). Upon cooling, the values of $\chi_m T$ keep smoothly decreasing in 300–34 K range, and then go down quickly to a minimum value of 0.183 $cm^3\ mol^{-1}$ K at 2 K, indicating an overall antiferromagnetic coupling in compound **4**. There also exists an inflexion at 32 K [44]. The magnetic susceptibility above 34 K can be well fit to Curie–Weiss law with C = 5.38 $cm^3\ mol^{-1}$ K, Θ = –35.06 K.

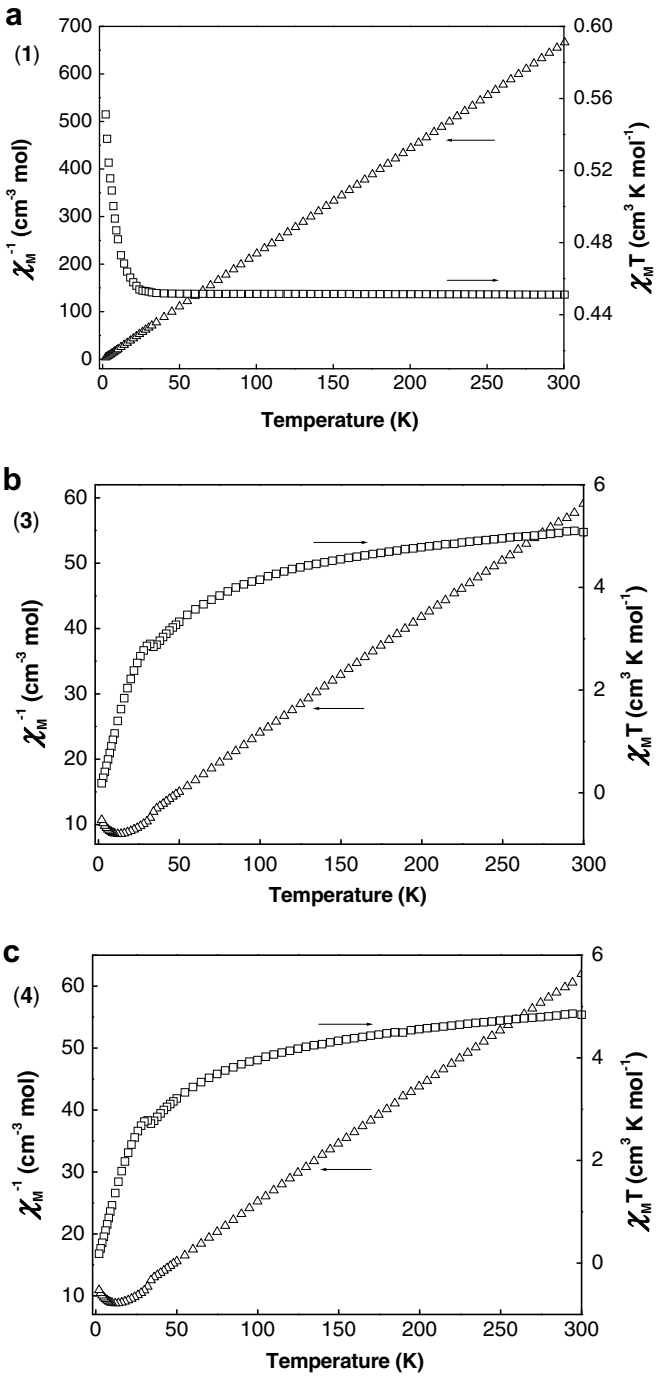

Fig. 8. Plots of the temperature dependence of $\chi_m T$ (squares) and χ_m^{-1} (triangles) for compounds **1**, **3** and **4**.

of the metal ions. Schrauzer and Windgassen [10] found that inorganic metal complexes might exhibit conducting properties, which are nowadays the subject of an active research area both in the field of solid state physics and inorganic chemistry; especially in nano-chemistry [11]. Conducting and semiconducting compounds have attracted considerable focus because of their useful function in molecular electronics and vital biological life processes [12]. Such semiconducting metal complexes stand on the threshold of a bright and exciting future. One of the most important aspects of the studies of electronic characteristics of such compounds is the relationship to their chemical structures, which is yet to be explored in detail. It is also considered that different applications might be found for supramolecular inorganic semiconductors, which do not necessarily parallel to the present uses for organic and discrete inorganic semiconducting materials. Much attention has also been paid to the optical properties of such compounds because of their application in material chemistry, particularly in optoelectronics. There are very rare reports on Schiff base [13] complexes that have such properties. Their preparation is still extremely challenging.

Keeping in view the aspects stated above, which open up new vistas for synthesizing unique metal complexes of both fundamental and technological importance, our aim is to prepare new Schiff base metal complexes and to tune their properties. We report here the synthesis and characterization of a new hexadentate N_4O_2 donor symmetrical Schiff base ligand having two carboxylic acid groups and its metal complexes, paying special attention to their X-ray crystal structures, electrical conductivity and optical properties. In all the three complexes prepared, both carboxylic acid groups remain non-coordinated to the metal ions, but surely exert their influence on the formation of mono- and bifurcated hydrogen bondings, which help to build up the supramolecular architecture and its persuasion in conductivity. This is in contrast to similar disalicylidene type complexes [14] that have no carboxylic acid moiety.

Density functional theory (DFT) calculations have also been carried out to optimize the structures and comparisons have been made with the experimental geometries. Moreover, the theoretical outcome of the DFT approach gives insight into the electronic structure and spectral properties of the complexes.

2. Experimental

2.1. Materials and general methods

Triethylenetetramine was purchased from Aldrich and used as such. 3-Formylsalicylic acid was synthesized according to Duff and Bills [15]. Spectrograde solvents were used for physical measurements. All the other reagents and solvents were purchased from commercial sources, purified and dried by standard procedures [16].

2.2. Physical measurements

The elemental analyses were carried out on Elementar Vario EL III, Carlo Erba 1108 elemental analyzers at the Sophisticated Analytical Instrument Facility (SAIF), Central Drug Research Institute, Lucknow. The electronic spectra (in DMSO and other media as indicated in the text) were recorded on a Shimadzu UV-2401PC spectrophotometer and infrared spectra (KBr) on a Perkin–Elmer L120-000A spectrophotometer. The ESR spectrum was measured in an ESR spectrometer at SAIF, IIT Madras. The molar conductance (10^{-3} M in DMSO) was measured using an Elico conductivity bridge and the magnetic data were measured on a Guoy Balance.

The samples for electrical conductivity measurements were prepared from the complexes in the form of tablets; their thickness was 0.1 cm at a pressure of approximately 1×10^8 Pa. These tablets were placed between two copper electrodes with silver paste and contacts were tested to be ohmic. The electrical conductivities of the prepared complexes were measured with a Keithley 6514 system electrometer, by applying a dc voltage using a Keithely 230 programmable voltage source. The conductivities were calculated by using the general equation $\sigma = (I/V_c)(d/a)$, where (I) is the current in amperes, V_c the potential drop across the sample of cross-sectional area (a) and thickness (d). Optical absorption spectra (in the solid state) were taken using a Perkin–Elmer Lambda 2S Double Beam spectrophotometer.

2.3. Computational details

The calculations were carried out using the Amsterdam density functional (ADF) program package [17]. Triple-ζ STO (Slater-type orbital) basis sets with one additional polarization function were used throughout. [Ar3d], [Ne] and [He] core definitions were used for Cd, Ni/Mn and C/N/O, respectively. Hence the valence set on the metals includes the $(n-1)$s and $(n-1)$p shells. The density functional chosen for the calculations was BP (Becke's gradient correction for exchange [18] plus Perdew's gradient correction for correlation [19]), which has been shown to yield satisfactory numerical results in previous computations. Electron excitation energies related to the electronic absorption spectra were calculated using the time-dependent density functional response theory (TDDFT) [20] as implemented in the ADF program. The recent implementation of TDDFT in the updated ADF program allows calculations of excitation energies for open-shell systems. Calculations of open-shell systems were spin-unrestricted. The spin multiplicities (2S + 1) for the Ni-, Cd- and Mn-complexes are 3, 1 and 6, respectively.

2.4. Preparation of the ligand. 1,8-N-Bis(3-carboxy)disalicylidene-3,6-diazaoctane1,8-diamine, (H_4fsatrien)

3-Formylsalicylic acid (3-fsa) (1.66 g, 10 mmol) was dissolved in methanol (25 ml), to which triethylenetetramine (trien) (0.73 g, 5 mmol) taken in methanol (20 ml) was added dropwise with stirring. Immediately, a yellow solution was obtained. Glacial acetic acid (3–4 drops) were then added to it with stirring to facilitate completion of the condensation reaction; stirring was continued for 6 h at −10 °C until the separation of a yellow powdery compound at room temperature. It was filtered off, washed with methanol and ether, and dried in vacuo over fused $CaCl_2$. Yield 25%. *Anal.* Calc. for $C_{22}H_{26}N_4O_6$ (H_4fsatrien): C, 59.72; H, 5.92; N, 12.66. Found: C, 59.63; H, 5.89; N, 12.71%. IR (KBr, cm^{-1}): 3412, 3290 (ν_{OH}, ν_{NH}), 1657 ($\nu_{C=N}$). UV–Vis (DMSO, λ_{max}, nm (ε, $L\,M^{-1}\,cm^{-1}$)): 265, 360, 495 (1128), 895 (23). ^{1}H NMR (DMSO-d_6, 300 MHz, ppm, 298 K): δ 12.28 (2H, s, COO*H*), 10.8(2H, s, O*H*), 8.94 (2H, s, C*H*=N), 7.91 (2H, d, Ar-*H*), 7.33 (2H, d, Ar-*H*), 6.67 (2H, t, Ar-*H*), 6.2 (2H, br, N*H*), 3.00–3.83 (8H, m, C*H*2), 2.50–2.79 (4H, m, C*H*2). ^{13}C NMR (DMSO-d_6, 300 MHz, ppm, 298 K): δ 172 (*C*OOH), 161.5 (*C*=N), 167.1, 139.1, 136.6, 130.3, 116.93, 114.09 (Ar-*C*), 51.2, 50.2, 49.15 (*C*H2).

Due to the poor yield of the ligand, we used the *in situ* reaction procedure for the synthesis of the metal complexes.

2.5. Syntheses of the metal complexes. [M(H_2fsatrien)] (M = Ni (**1**), Cd (**2**) and Mn (**3**))

A solution of the ligand H_4fsatrien was prepared by the method described above, by reacting 3-formylsalicylic acid (1.66 g, 10 mmol) and trien (0.73 g, 5 mmol) in methanol (45 ml). The metal(II) acetate (5 mmol), dissolved in minimum volume of methanol (15 ml), was then added dropwise to the Schiff base solution with stirring, and the mixture was kept under reflux for 1 h.

Precipitation occurred for all of the above complexes during the refluxing, and the precipitates were collected by filtration under the hot conditions. The precipitates were washed thoroughly with methanol and diethyl ether, and dried in vacuum over fused $CaCl_2$. The concentration, cooling and slow evaporation of the mother liquor produced crystalline compounds, suitable for single X-ray crystal study, for the nickel(II) and cadmium(II) complexes. The X-ray quality crystal of the manganese(II) complex was obtained by slow evaporation of a solution of the complex in methanol–dichloromethane–acetonitrile. Yield 70–85%. *Anal.* Calc. for $C_{22}H_{24}N_4O_6Ni$ (**1**): C, 52.94; H, 4.85; N, 11.22. Found: C, 52.89; H, 4.93; N, 11.16%. IR (KBr, cm^{-1}): 3425, 3266 (ν_{OH}, ν_{NH}), 1644 ($\nu_{C=N}$). 2.6. Crystallographic data collection and structure determination

The crystal data and refinement details are summarized in Table 1. In each case, a single crystal was mounted using Paratone(g) oil onto a glass fiber and cooled to the data collection temperature. Data were collected on a Brüker-AXS APEX CCD diffractometer with monochromatized Mo Kα radiation (λ = 0.71073 Å). Unit cell parameters were obtained from 60 data frames, 0.3° ω, from three different sections of the Ewald sphere. The systematic absences in the diffraction data and the unit cell parameters were uniquely consistent with the reported space groups. An inspection of the packing diagram of complex (**1**) displays no overlooked symmetry and the cell analysis routines in PLATON suggested no other unit cell or space group [21]. The data-set was treated with SADABS absorption corrections based on redundant multiscan data [22]. The structures were refined by full matrix least squares, based on F^2. Refinement of the absolute structure parameter in complex (**1**) yielded the Flack parameter 0.497(16), suggesting a twinned data set. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms on the hydroxyl groups, H(1) and H(2), were located from the electron density difference map and refined with a riding model. All other hydrogen atoms were treated as idealized contributions. Structure factors were contained in the SHELXTL 6.12 program library [23].

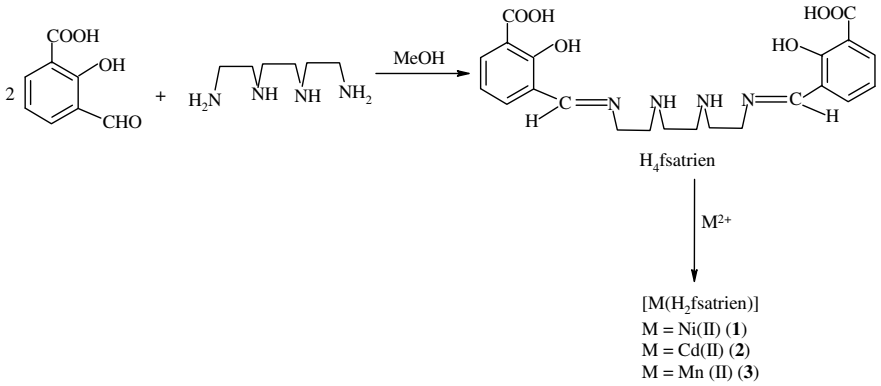
3. Results and discussion

The new dibasic hexadentate ligand 1,8-*N*-bis(3-carboxy)disalicylalidene-3,6-diazaoctane-1,8-diamine, H_4fsatrien, was prepared by the condensation reaction of 3-formylsalicylic acid with triethylenetetramine (2:1 molar ratio) in methanol, as described later and shown in Scheme 1. The *in situ* reaction of the ligand components and $Ni(CH_3COO)_2 \cdot 4H_2O$, $Cd(CH_3COO)_2 \cdot 2H_2O$ and $Mn(CH_3COO)_2 \cdot 2H_2O$ in methanol (Scheme 1) yielded the complexes (**1**)–(**3**) in good yield and purity. The ligand and all the complexes gave correct the elemental analyses and were further characterized by IR, UV–Vis, NMR, ESR, molar conductivity, magnetic measurements and X-ray crystallography.

3.1. Crystal and DFT-optimized structures

All the three complexes (**1**)–(**3**) were derived from the same polydentate ligand utilizing N_4O_2 donor sites. Complexes (**1**) and (**2**) crystallize in different crystallographic systems, orthorhombic (space group *P*2(1)2(1)2(1)) and monoclinic (space group *P*2(1)/*c*), respectively, while complex (**3**) crystallizes in the same crystal system as (**1**), with the space group *Pbca*. The crystallographic and refinement data are summarized in Table 1. Selected bond lengths and angles, from both the experiment and the DFT optimization, are given in Table 2. All cartesian coordinates are provided in the Supporting information (S1 and S2).

In general, there is good agreement between the calculated and X-ray crystal structural parameters, especially for the Ni-complex, where the largest deviation is 0.1 Å for the bond lengths and 5° for the bond angles. Relatively large discrepancies with the X-ray crystal measurements are found for the Mn-complex, where the largest deviation is 0.19 Å for the bond lengths and 8° for the bond angles. While the optimized Mn–N(2) and Mn–N(3) bond lengths are somewhat larger than the experimental ones, the Mn–N(1) and Mn–N(4) bond lengths optimized are notably (up to 0.2 Å) smaller than those in the crystal structure. Nevertheless, both experiment and theoretical calculations show an octahedral environment for the central metal ions. In the case of the Cd-complex, the calculated structural parameters compared in most cases favorably with the experimental ones.



Scheme 1.

The molecular structures of these complexes consist of pseudo-octahedrally coordinated metal ions with a hexadentate ligand. The ORTEP drawings of these molecular structures are depicted in Fig. 1 (**1**), Fig. 2 (**2**) and Fig. 3 (**3**). The metal ions are surrounded by two oxygen atoms in *cis* positions, two imino nitrogen atoms and two amine nitrogen atoms to complete the distorted octahedron. This arrangement is consistent with that of Ni(sal)$_2$trien · 3H$_2$O [24].

[a] O···H bond distance is in parentheses.

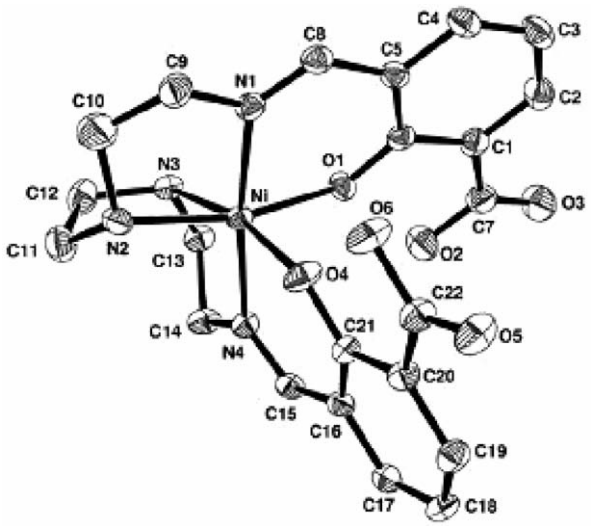

Fig. 1. ORTEP view of the Ni-complex with ellipsoids drawn at the 50% probability level.

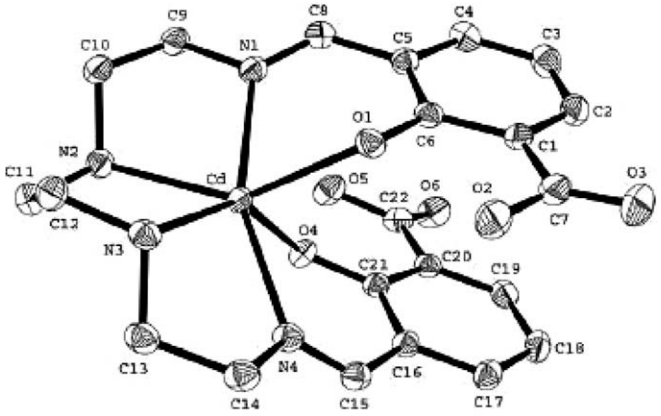

Fig. 2. ORTEP view of the Cd-complex with ellipsoids drawn at the 50% probability level.

The two imino nitrogen atoms [*d*(Mn–N) = 2.2387(13) and 2.2334(13) Å; *d*(Cd–N) = 2.3041(17) and 2.3060(16) Å; *d*(Ni–N) = 2.034(3) and 2.041(3) Å] are coordinated to the metal ions more strongly than the other two amine nitrogen atoms [*d*(Mn–N) = 2.3047(13) and 2.3116(13) Å; *d*(Cd–N) = 2.3544(16) and 2.3566(16) Å; *d*(Ni–N) = 2.110(3) and 2.145(3) Å]. This unequiva-

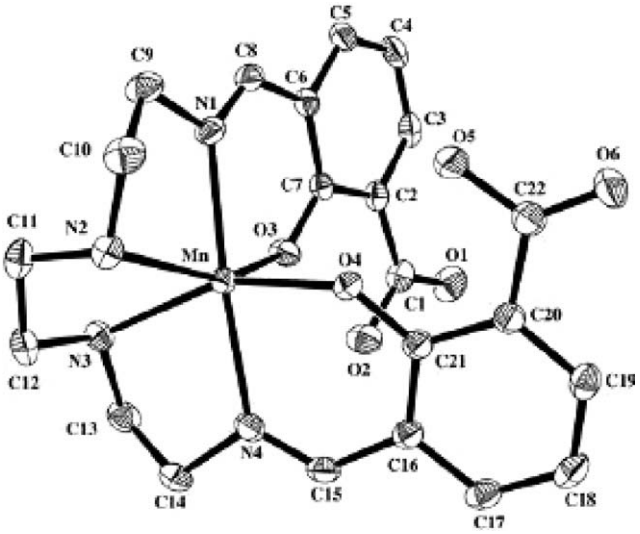

Fig. 3. ORTEP view of the Mn-complex with ellipsoids drawn at the 50% probability level.

lency in coordination of the metal-nitrogen bonds can be explained by the fact that imino nitrogens are better donors than amine nitrogens; the latter are somewhat influenced by the stereo-chemical arrangement of the trien and carboxylic acid groups. The axial bond angles of N_1–M–N_4 vary from 155.7(6)° to 175.0° and agree well with distorted octahedral structures. In most cases the metal–oxygen bond distances [2.039(2) and 2.053(2) Å for **1**; 2.3024(13) and 2.3070(14) Å for **2**; 2.1130(11) and 2.1267(11) Å for **3**] are shown to be shorter than the metal–nitrogen distances as a consequence of the negative charge borne by the phenolic oxygen atoms. The steric effect of the carboxyl group on the aromatic ring compels the *o*-phenolato plane to bend away from the central atom, which is helped by the presence of the highly flexible trien group [24]. The binding of the N_4O_2 hexadentate ligand by the metal ions results in the formation of three five-membered and two six-membered chelate rings, fused together creating large geometrical constraints. These steric strains, caused mainly by the formation of five-membered chelate rings, give rise to larger distortions from the octahedral angles, as reflected by numerous bond angles smaller or larger than 90°.

In the complex [Ni(H_2fsatrien)] (**1**), the adjacent mononuclear units are locked by face-to-face π–π interactions (distance between the centroids of the interacting rings, 3.968 Å; dihedral angle, 11.65°) exerted by terminal phenyl moieties and by hydrogen bonding interactions (Table 3). The molecules are arranged in an offset manner to maximize such interactions and generate a 1-D chain along the *c*-direction (Fig. 4). The adjacent zigzag chains are interwoven through C–H···π interactions with a ∠C–H···π angle of 161° and a C···π distance of 3.548 Å (Table 3), and are responsible for the formation of the 2-D supramolecular architecture in the *bc*-plane (Fig. 5).

The solid-state structure of [Mn(H_2fsatrien)] (**3**) is very similar to that of complex (**1**), but the π–π and C–H···π weak interactions in the former are stronger. Here the adjacent discrete molecular units are arranged into a 1-D chain along the *b*-direction (Fig. 6) *via* strong face-to-face π–π stacking interactions between the phenyl groups of the ligand with a centroid–centroid distance of 3.626 Å and dihedral angle of 6.50°. Furthermore, the adjacent zigzag 1-D chains are linked together to generate a supramolecular 2-D sheet in the *bc*-plane (Fig. 7) through C–H···π interactions, having a ∠C–H···π angle of 162° and a C···π distance of 3.428 Å (Table 4). The disposition of the adjacent sheets is shown in Fig. 8.

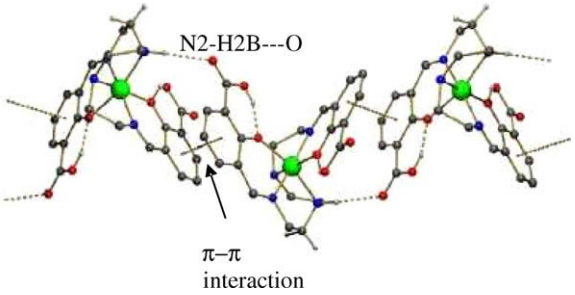

Fig. 4. The 1-D coordination structure of the Ni-complex.

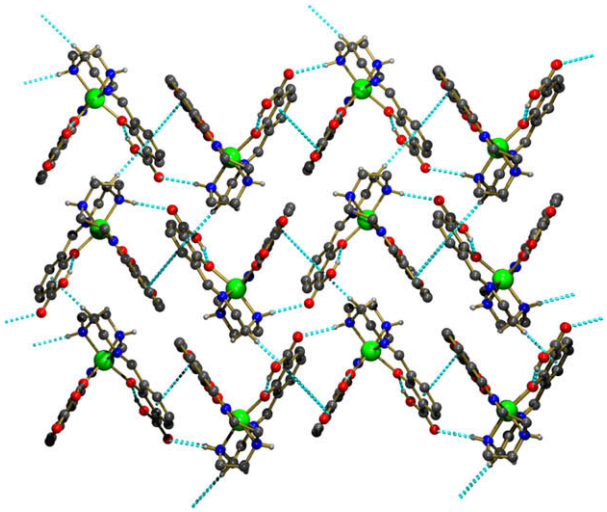

Fig. 5. The 2-D coordination structure of the Ni-complex showing intramolecular C–H···π and π–π interactions.

Unlike the complexes of Mn(II) and Ni(II), the supramolecular structure of the Cd(II) complex exhibits a 3-D architecture. Two terminal phenyl rings of the two closest mononuclear complexes of (**2**) are linked through face-to-face π interactions (distance between the barycentres of the interacting rings, 3.912 Å; dihedral angle, 10.05°) and through C–H···π interactions (∠C– H···π angle, 158° and C···π distance, 3.604 Å), and are responsible for the formation of the 1-D chain along the *a*-direction (Fig. 9). The 1-D chains pack alongside one another, and the 1-D columns are held

R(*i*)/R(*j*) denotes the centroids of the *i*th/*j*th ring; R(1)→C1–C2–C3–C4–C5–C6; R(2)→C16–C17–C18–C19–C20–C21.

together through O–H···O and N–H···O hydrogen bonding interactions (Table 5) to form a grid-like structure when viewed along the *a*-direction (Fig. 10), which also involves bifurcated H-bonding [25]. In this structure the sheets are arranged parallel to the *ab*-plane to generate a 3-D supramolecular architecture (Fig. 11), where another C–H...π interaction (∠C–H···π angle, 158° and C···π distance, 3.656 Å) (Table 5) is mainly responsible for the formation of the solid-state structure.

3.2. Electronic structures

The valence molecular orbital (MO) energy level diagrams of the ligands and their M^{II}-complexes (M = Ni, Cd, Mn) are illustrated in

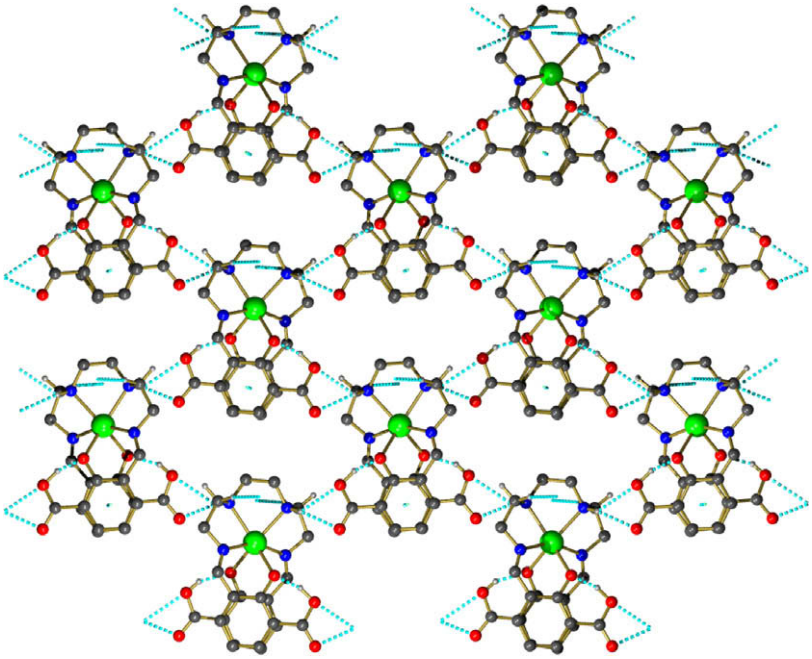

Fig. 10. The perspective view of the 2-D structure of the Cd-complex with bifurcated H-bonding.

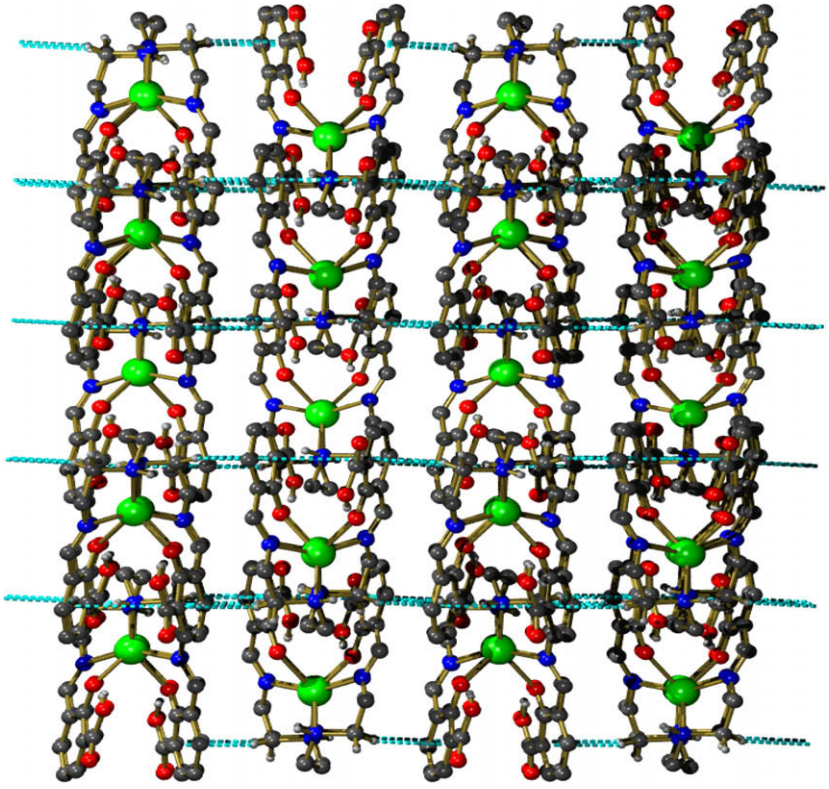

Fig. 11. A 3-D supramolecular assembly of the Cd-complex.

Fig. 12, from which we can see the change of the electronic structure on going from the ligand to the M^{II}–ligand complex. According to the calculations, the neutral ligand (H_2fsatrien) itself has an open-shell. This result is expected by examining the orbital energy level diagram of H_2fsatrien, where the HOMO (highest occupied molecular orbital) and second HOMO (i.e. HOMO − 1) are close to each other and therefore two unpaired electrons will enter the two orbitals, respectively. To confirm the open-shell ground state for the ligand, other density functionals (such as PW91, mPW, BLYP, PBE) were also tested and they gave the same results. We may note that the orbital energy level diagrams of H_2fsatrien are slightly different for different [M(H_2fsatrien)]. This is because

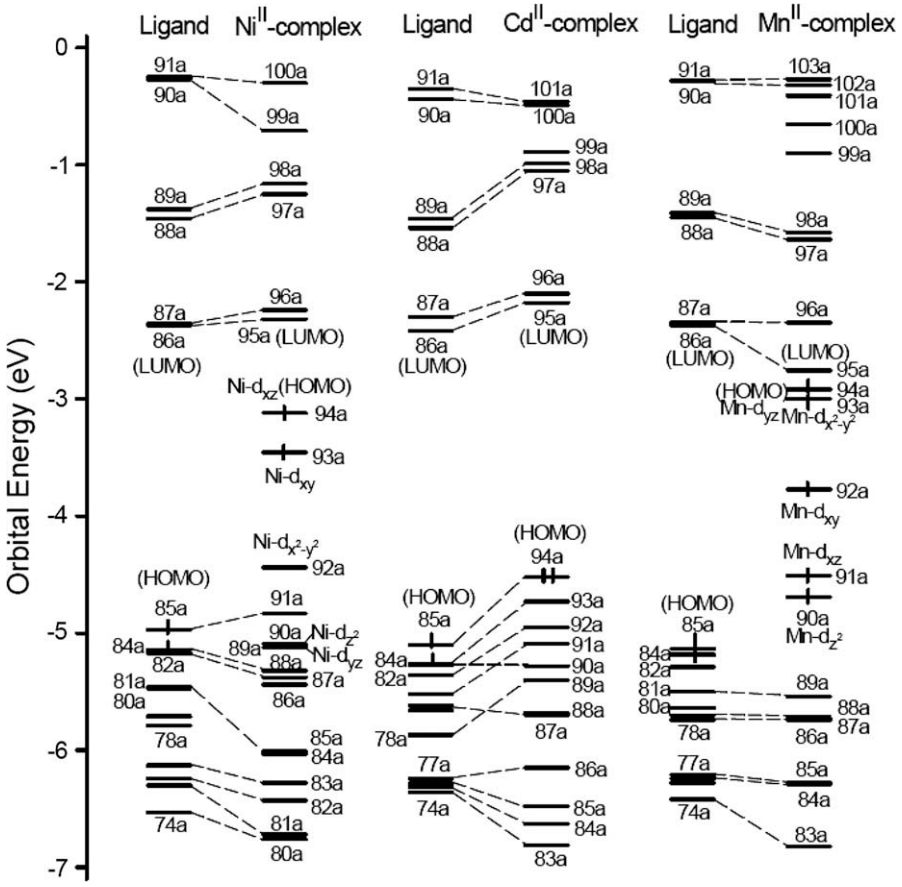

Fig. 12. Valence molecular orbital energy level diagrams of the ligands and their M^{II}-complexes (M = Ni, Cd, Mn)).

when we calculated the orbital energies of H_2fsatrien, the structure of H_2fsatrien in the respective [M(H_2fsatrien)] was adopted and this structure is somewhat different for different M. This also reflects slight perturbations of the ligand energy states by the different metals. The Ni- and Mn-complexes are open-shell as well, where some unpaired electrons are on the metal d-orbitals. Upon complexation, the singly occupied orbitals of the ligand become doubly occupied by obtaining electrons from the metal ns-orbitals. The Cd-complex has a closed-shell ground state because the Cd d-orbitals are fully occupied.

With M = Ni or Mn, the HOMO and LUMO (lowest unoccupied molecular orbital) are associated with the metal and ligand components, respectively. A very large splitting is found between the metal d-derived orbitals. The Mn-complex is calculated to be high-spin (2S + 1 = 6); that is, it has five unpaired electrons on the metal–d orbitals, in agreement with the magnetic susceptibility measurements. The low-spin state (2S + 1 = 2) is about 0.3 eV higher in energy than the high-spin state according to our calculations. The energies of the Mn–d orbitals are higher than those of the Ni–d ones so that the energy gap between the HOMO and LUMO is small in the Mn-complex. In the case of M = Cd, the d-orbitals are especially low in energy, so they do not appear in the valence set of the orbitals.

3.3. Electronic spectrum and TDDFT calculations

The UV–Vis (in DMSO) spectra were recorded both for the ligand and its metal complexes. The measured UV–Vis spectral data for the Ni(II), Cd(II) and Mn(II) complexes are presented in Table 6. To have a better insight into the electronic spectra, TDDFT calculations were performed for the allowed transitions from the ground state to the excited states. The theoretical results, obtained for both the crystal and optimized structures, are provided in the same table to compare the experimental data. The characters of the absorption bands are indicated by the contributions listed in the

Table 6
UV–Vis data for the complexes

Complex	Experimental		Calculated		
	λ_{max}[a]	E_{max}[b]	E[c]	f[d]	Contribution[e] (%)

[e] See Fig. 12 for the orbitals.

last column of the table. More calculated excitation energies (E^{exc}) for other, various (allowed) transitions are given in the Supporting information (S3–S5). Also, the calculated E^{exc} values for the complexes agree quite well with the experimental data.

The present TDDFT method is not able to calculate optical spectra of bulk materials. From Figs. 4–11, we see that the molecular units in all the crystal structures are rather discrete and are assembled through different weak force interactions. Therefore, the UV–Vis spectra (in the solution state) of the bulk materials can largely be represented by the spectra of the discrete molecules; although the optical spectra (in the solid state) show some features of band structure (see Section 3.6).

3.4. Magnetic moments, ESR and molar conductance values

The magnetic susceptibilities of the three complexes under investigation were measured in the solid state at room temperature. The complexes [Ni(H_2fsatrien)] (**1**) and [Mn(H_2fsatrien)] (**3**) are paramagnetic, while the complex [Cd(H_2fsatrien)] (**2**) is diamagnetic. Magnetic moments of octahedral nickel(II) complexes are usually found in the range 2.9–3.3 BM [26]. The observed magnetic moment of 3.10 BM for the nickel(II) complex, [Ni(H_2fsatrien)] (**1**) falls in the range for octahedral nickel(II) [27]. This eliminates the possibility of attaining other geometries by nickel(II) in the complex. The manganese(II) complex exhibits a magnetic mo-

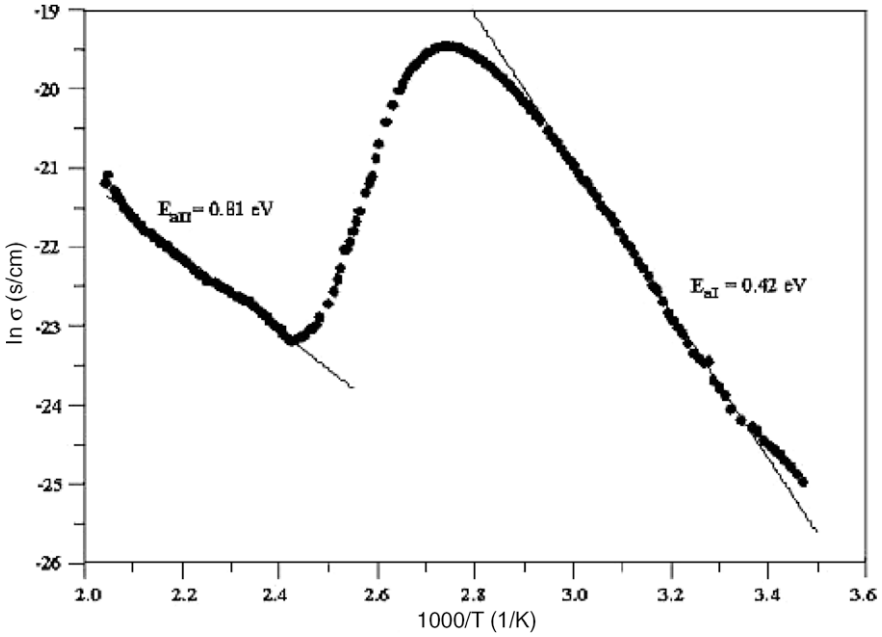

Fig. 13. Temperature dependence of the electrical conductivity of complex (**1**).

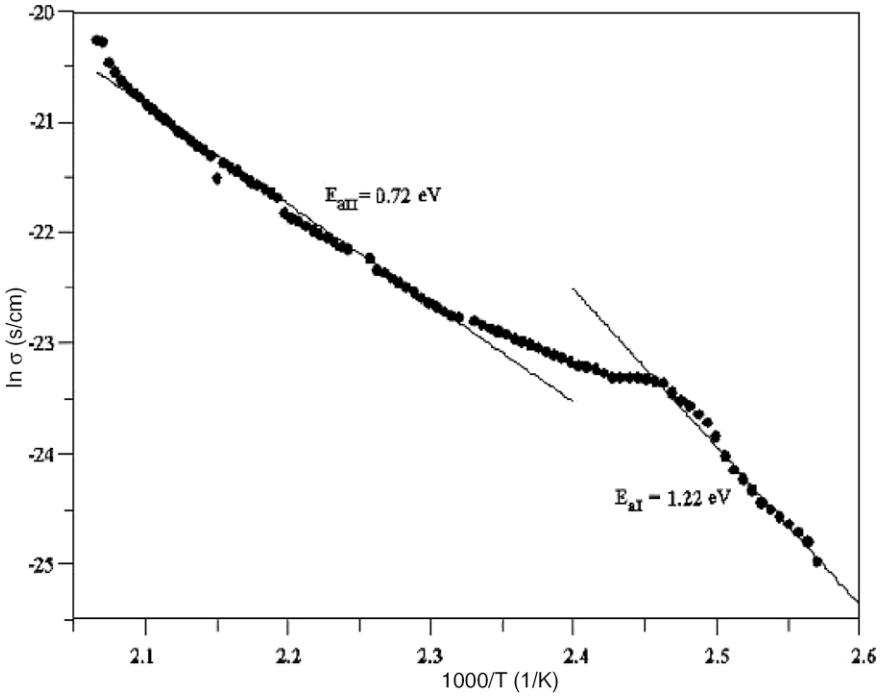

Fig. 14. Temperature dependence of the electrical conductivity of complex (**3**).

ment of 5.82 BM at room temperature and is indicative of a high-spin manganese(II) centre. The complex also exhibits a strong but broad ESR signal centered at $g = 2$, consistent with manganese(II) [28].

The molar conductance values of the complexes (**1**) to (**3**) in DMSO solution are found in the range $\Lambda_M = 15.3–16.4$ Ω^{-1} cm^2 mol^{-1}, indicating the non-electrolytic nature of the complexes in the DMSO solution [29].

3.5. Electrical conductivity

The electrical conductivity variations with temperature for the complexes (**1**) and (**3**) (shaped as a pellet) were measured and the $\ln\sigma - 1000/T$ graphs are given in Figs. 13 and 14. It can be observed that complex (**1**) shows three distinct regions, depending on the temperature (Fig. 13). At low temperatures (290–360 K) (large $1/T$) extrinsic behaviour dominates [22,30]. It can be seen from the figures that the conductivity is virtually temperature-independent at the beginning of the extrinsic region, where the increase in the number of electrons donated from the donor levels in its effect on the conductivity and is balanced by the decrease in the mean free path, being fully ionized, i.e., completely emptied. The conductivity starts dropping as a result of phonon scattering in the temperature range 360–410 K, until the onset of intrinsic conduction (at a temperature of 410 K), when the conductivity increases again with temperature [31]. Intrinsic conductivity occurs at high temperatures (410–480 K), as shown in the intrinsic region for the complex (**1**). The extrinsic and intrinsic regions have a positive temperature coefficient of electrical conductivity.

In spite of showing insulating properties at low temperatures, complex (**3**) showed conduction properties at about 390 K (Fig. 14). Complex (**3**) has a positive temperature coefficient between 390–405 K and 410–480 K. The conductivity is constant in the region between 405 and 410 K. We can say that the behaviour is similar to the behaviour in the exhausting region.

The increasing of conduction with temperature is semiconductor behaviour. The Arrhenius equation for the extrinsic region of n-type semiconductors is

$$\sigma = \sigma_0 \exp(-E_a/kT) \quad (1)$$

where σ_0 is the pre-exponential factor, E_a is the activation energy and k is the Boltzmann's constant. By using this equation, the activation energy can be calculated [22,26]. The slope in the extrinsic region for an n-type semiconductor is given by $(E_g - E_d)/k$ and $E_g/2k$ in the intrinsic region [22]. The calculated activation energies for complex (**1**) were found to be low (0.42 eV) in the lower temperature range (290–360 K), but considerably higher (0.81 eV) in the high-temperature range (410–480 K). The activation energies of complex (**3**) in the extrinsic region (390–405 K) and the intrinsic region (410–480 K) are 1.22 eV and 0.72 eV, respectively. Thus the conductivity of the compound shows the typical Arrhenius-type dependence on temperature. Such an n-type electrical semiconductivity mechanism of the present Schiff base complexes may be explained in terms of transfer of electrons in two possible ways. Firstly [32] the conduction process may be assumed to start with the delocalization of the π-electrons and then the excitation of electrons from the HOMO to the LUMO of π-MOs, which actually switch over the metal complexes to the semiconducting state. In a second [33] way, the electrons hop from one localized metal site to the next, i.e. in this case the holes have little effect on the mobility of negative charges. When the electron lands on a new site, it causes the surroundings to adjust their localization and the electron is trapped temporarily in the potential well and it resides until activated to migrate to another nearby site. Thus the electrons are supposed to tunnel from one molecular unit to the comparable unfilled level of the adjacent molecular unit. In this case the tunneling of electrons is observed through the intermolecular potential barrier to occupy the corresponding orbital in the adjacent unit *via* π–π stacking, C–H···π interactions and extensive H-bonding.

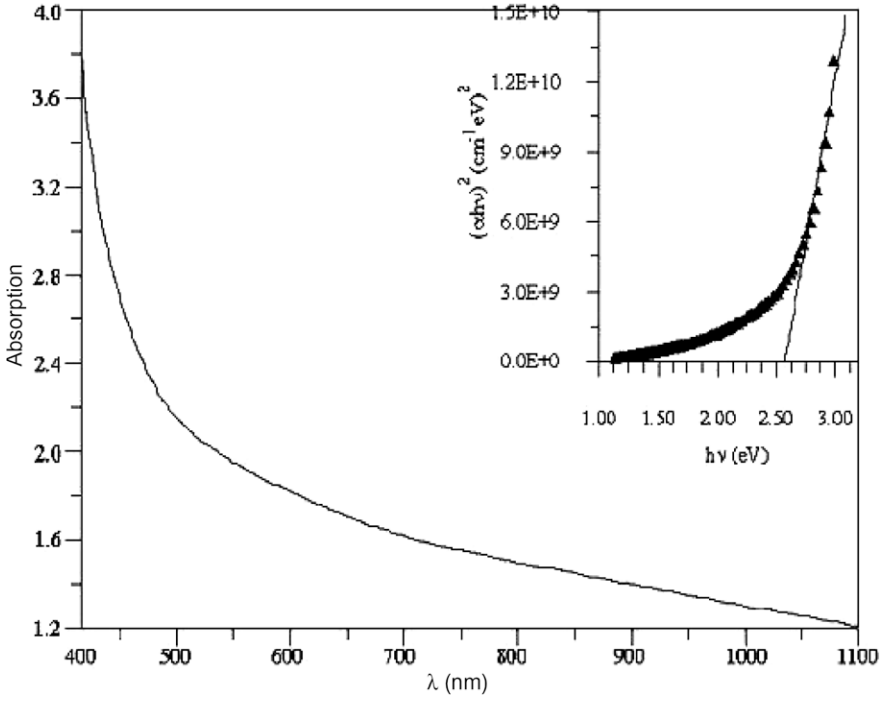

Fig. 15. The optical absorption spectra for complex (**1**).

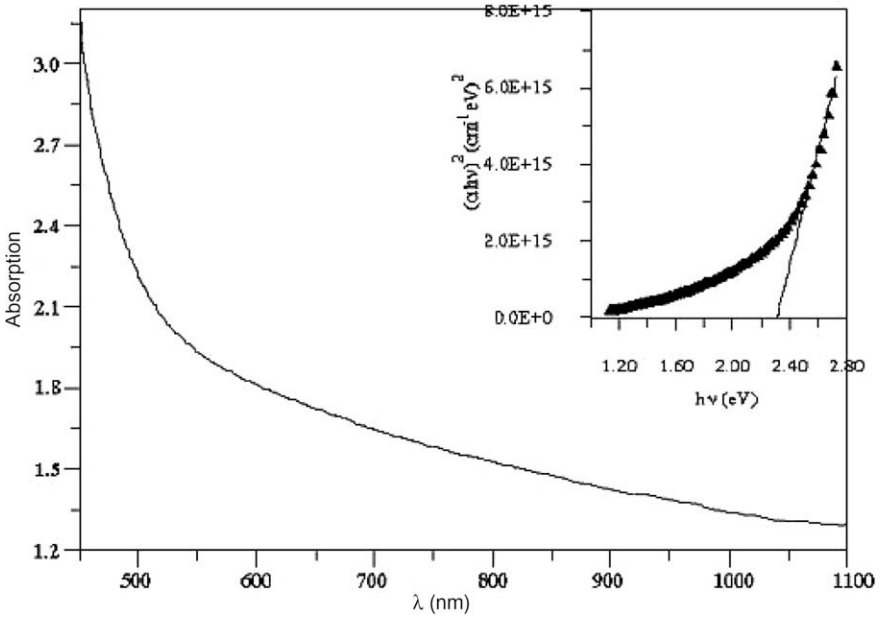

Fig. 16. The optical absorption spectra for complex (**3**).

3.6. Optical properties

To obtain the energy-band gaps and the nature of the optical transition involved in the complexes, the optical spectra were recorded at room temperature and the fundamental absorption edge is analyzed within the framework of the theory of Mott and Davis [30]. The optical band gaps of the samples were determined by applying the relation [31,34],

$$\alpha h\nu = A(h\nu - E_g)^n \quad (2)$$

where α is the linear absorption coefficient, $h\nu$ is the photon energy, E_g is the energy gap between the top of the valence band and bottom of the conduction band at the same value of wave number and n depends on the kind of optical transitions. Specifically, n is 1/2, 3/2, 2 and 3 for transitions which are directly allowed, directly forbidden, indirectly allowed and indirectly forbidden, respectively. A is a constant involving the properties of the bands.

The energy gap for allowed direct (E_{gd}) and indirect (E_{gi}) transitions can be determined by relating

$$\alpha h\nu = A_a(h\nu - E_{gd})^{1/2} \quad (3)$$

and

$$\alpha h\nu = A_i(h\nu - E_{gi})^2 \quad (4)$$

where A_a and A_i are the characteristic parameters for the respective transitions, independent of ν. From Eqs. (3) and (4), E_g can be determined from the extrapolation to zero of the linear parts of the $(\alpha h\nu)^2 = f(h\nu)$ and $(\alpha h\nu)^{1/2} = f(h\nu)$ curves.

The optical absorption spectra, i.e. the plots of $(\alpha h\nu)^2$ versus $h\nu$, are given in Figs. 15 and 16 for complexes (**1**) and (**3**) and analysis of the absorption data was carried out to determine the predominant optical transition. A satisfactory fit was obtained for $(\alpha h\nu)^2$ as a function of $h\nu$, showing the existence of a direct gap. The extrapolation of the graphs to $(\alpha h\nu)^2 = 0$ yields the optical band gap E_{gd}. The values of the optical band gap E_{gd} were determined from Figs. 15 and 16 by least squares fitting of the data. In this study, the optical band gaps, E_{gd}, of complexes (**1**) and (**3**) were found to be 2.57 and 2.30 eV, respectively.

4. Conclusions

The synthesis, characterization and crystal structures of three complexes [M(H_2fsatrien)] (M = Ni (**1**), Cd (**2**) and Mn (**3**)) with a new symmetrical hexadentate Schiff base (N_4O_2 donor) as a ligand have been described. Both the X-ray crystal structure determinations and theoretical calculations demonstrate that the complexes are all pseudo-octahedral with some variations in their configurations. Some intermolecular weak forces, such as π–π stacking, C–H···π interactions, unusual H-bonding interactions also play important roles by linking the discrete subunits and low-dimensional entities into high-dimensional (1-D, 2-D, 3-D) supramolecular coordination networks. The electrical semiconducting character of the metal complexes has been nicely correlated with these structural patterns. On the other hand, optical studies indicate that complexes (**1**) and (**3**) have direct band gaps. DFT/TDDFT calculations agree well with the experimentally observed structures and absorption spectra of the molecules.

Acknowledgments

One of the authors (K.D.) is thankful to the UGC, New Delhi for awarding Emeritus Fellowship and Financial grants to carry out this work. We are grateful to the Sophisticated Analytical Instrument Facility, Central Drug Research Institute, Lucknow and IIT Madras for elemental analyses and some spectroscopic measurements and IICB, Kolkata for NMR analysis. We are also grateful to the reviewers for their valuable comments.

Appendix A. Supplementary data

CCDC 677239, 677240 and 677238 contain the supplementary crystallographic data for complexes **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.07.034.

12-diphenyl-1,4,8,11-tetraazacyclo-tetradeca-7,12-diene) with oxamido bridge has been successfully synthesized. Based on this precursor, two trinuclear complexes $[Cu(VOL)_2(H_2O)_2](ClO_4)_2 \cdot 1.5H_2O$ (**2**) and $[Mn(VOL)_2(CH_3OH)_2](ClO_4)_2 \cdot 5CH_3OH$ (**3**) have been prepared and structurally characterized. Their spectroscopic properties and magnetic properties have also been investigated.

2. Experimental

2.1. General

All reagents were of analytical grade and were used as received from commercial sources without further purification. The complex H_2L' (H_2L' = 2,2′-(oxalyldiimino)bis(benzophenone)) was prepared as described elsewhere [27]. Elemental analyses were performed on a Perkin–Elmer 240 element analyzer. FT-IR spectra were recorded using KBr discs on a Bruker Tensor 27 spectrophotometer in the 4000–600 cm^{-1} region. Electronic spectra were measured on a JASCO V-570 spectrophotometer using DMF as the solvent. Magnetic susceptibility data were collected over the temperature range 2–300 K on a Quantum Design MPMS-7 SQUID magnetometer.

2.2. Synthesis of the complexes

2.2.1. Synthesis of VOL (*1*)

The precursor complex ligand VOL (**1**) was prepared by a solvent-thermal reaction. The reaction mixture of $VOSO_4 \cdot H_2O$ (0.178 g, 1 mmol), H_2L' (0.448 g, 1 mmol), ethylenediamine (1.2 mL, 2 mmol) and methanol (15 mL) was sealed in a 25 mL Teflon-lined stainless steel autoclave vessel at 140 °C under autogenous pressure for 72 h. After slow cooling, the resulting major phase of dark red crystals was filtered, washed with distilled water, methanol and dried in air at ambient temperature. Yield: 0.339 g (63%). Elemental *Anal.* Calc. for $C_{30}H_{22}N_4O_3V$: C, 67.04; H, 4.13; N, 10.42. Found: C, 67.1; H, 4.07; N, 10.4%. FT-IR (KBr, cm^{-1}): 3417 (m) 1671 (s), 1587 (s), 1547 (m), 1472 (w), 1442 (m), 1357 (m), 1326 (m), 1301 (w), 992 (s), 948 (s), 751 (m), 702 (m).

2.2.2. Synthesis of $[Cu(VOL)_2(H_2O)_2](ClO_4)_2 \cdot 1.5H_2O$ (*2*)

A methanol solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.038 g, 0.1 mmol) was added dropwise to a methanol solution (25 mL) of VOL (0.11 g, 0.2 mmol). The mixture was refluxed with stirring for 5 h, and the resulting red solution was cooled and filtered. Light red single crystals suitable for X-ray analysis were obtained by slow evaporation of the filtrate in the open air at room temperature two weeks later. The sample is stable in air and soluble in most common organic solvents. Yield: 0.12 g (85%). Elemental *Anal.* Calc. for $C_{60}H_{51}Cl_2CuN_8O_{17.5}V_2$: C, 51.42; H, 3.64; N, 8.0. Found: C, 51.35; H, 3.51; N, 8.05%. FT-IR (KBr, cm^{-1}): 3422 (m), 1601 (s), 1588 (s), 1476 (w), 1443 (m), 1322 (m), 1105 (s), 994 (s), 951 (s), 756 (m), 704 (m), 625 (m).

2.2.3. Synthesis of $[Mn(VOL)_2(CH_3OH)_2](ClO_4)_2 \cdot 5CH_3OH$ (*3*)

Complex **3** was obtained as pale red crystals by using the analogous procedure used to prepare complex **2** except that $Cu(ClO_4)_2 \cdot 6H_2O$ was substituted with $Mn(ClO_4)_2 \cdot 6H_2O$. However, the red microcrystalline product is not air-stable and quickly turns to into an amorphous phase, due to the loss of CH_3OH molecules, when it is removed from the mother liquid, so the compound should be stored under low temperature and crystallographic data were also collected under a liquid nitrogen atmosphere. Yield: 0.125 g (80%). Elemental *Anal.* Calc. for $C_{67}H_{72}Cl_2MnN_8O_{21}V_2$: C, 51.76; H, 4.63; N, 7.21. Found: C, 51.66; H, 4.55; N, 7.24%. FT-IR (KBr, cm^{-1}): 3418 (m), 1600 (s), 1586 (s), 1477 (w), 1445 (m), 1326 (m), 1109 (s), 1009 (s), 953 (s), 755 (m), 705 (m), 625 (m).

2.3. Crystal structure determination and refinement

Crystals of **1**–**3** suitable for single-crystal X-ray diffraction were mounted on a BRUKER SMART 1000 diffractometer with graphite-monochromatized Mo Kα radiation (λ = 0.71073 Å), using the ω scan technique at 294(2) K for **1** and **2** and 113(2) K for **3**. Empirical absorption corrections were applied using the SADABS program. The structures were solved by direct methods and refined by the full-matrix least-squares on F^2 with anisotropic thermal parameters for all non-hydrogen atoms [28]. All hydrogen atoms were added in idealized positions and refined isotropically. For **2**, the phenyl ring of the macrocyclic ligand experiences a serious disorder over two positions and the site occupancy factors of the disordered atoms were initially refined and later fixed at 0.5/0.5. Moreover, three oxygen atoms of the ClO_4^- anion were also disordered in two positions with a 0.4/0.6 site occupancy distribution, these effects probably give rise to the relatively higher final *R* index. For **3**, the oxygen atoms of the ClO_4^- anion and one of the CH_3OH molecules were also found to be disordered. 944 parameters and 72 restraints have been used in the final least-squares refinement. Further details of the structure analyses are summarized in Table 1.

3. Result and discussion

3.1. Synthesis and spectroscopy

The synthesis route for the precursor mononuclear complex **1** comprises the solvent-thermal in situ reaction of ethylenediamine, H_2L' and a VO(IV) source, which is different from the traditional reflux routes for other CuL and NiL complexes [29]. This route not only tends to afford large single crystals suitable for X-ray crystallography, due to slow crystallization, directly but also prevents the oxidation of V^{IV} to V^{V} in a sealed and pressurized environment. The synthesis of trinuclear complexes are both performed in a basic methanol solution of VOL under refluxing conditions. Some experimental parameters, including the reactant molar ratio, are varied, but the resulting products remain the same. Finally, a VO/Cu (or Mn) ratio of 2:1 was used. Although the two trinuclear complexes are made in a similar way and have similar structures, complex **2** is more stable in air than complex **3**.

The IR spectra of complexes **2** and **3** show the characteristic bands of the bridging oxamide moiety around 1600 cm^{-1} ($\nu_{C=O}$), which are significantly lower than that for the mononuclear entity (1670 cm^{-1}), suggesting a strong coordination of the oxamido carbonyl oxygens. In addition, the particular absorptions at ca. 1105 cm^{-1} are consistent with the presence of perchlorate ions. For complexes **1–3**, the stretching vibrations of vanadyl V=O are indicated by strong bands at around 951 and 993 cm^{-1}, and the ν(C=N) mode of the macrocyclic complexes are seen at 1587 cm^{-1}. Absorptions at 3418 cm^{-1} may be assigned to O–H stretching in H_2O or CH_3OH.

The electronic absorption spectra of the two trinuclear complexes in DMF at ca. 278 and 355 nm are dominated by intense bands due to intraligand π–π^* transitions and the charge-transfer transitions of the VO^{2+} chromophore. In the visible region, they both exhibit broad weak bands centered at ca. 495 and 605 nm, which are most likely due to $^2B_2 \rightarrow {}^2A_1$ and $^2B_2 \rightarrow {}^2B_1$ d–d electron transitions of VO^{2+} with an idealized C_{4V} symmetry [30]. The spin-allowed transition $^2B_{1g} \rightarrow {}^2E_g$ and $^2B_{1g} \rightarrow {}^2B_{2g}$ for the octahedral Cu(II) ion of complex **2** is probably obscured by this absorption [31]. For complex **3**, the coordination environment of Mn(II) is distorted octahedral. Thus, according to ligand-field theory and assuming O_h symmetry, the ground-state of Mn(II) is $^6A_{1g.}$ Because d–d transitions of Mn(II) ($^6A_{1g} \rightarrow {}^4T_{1g}$ (G), $^4T_{2g}$ (G), $^4A_{1g}\ldots$) are spin-forbidden, no characteristic band of Mn(II) is found in the electronic spectrum [32].

3.2. Description of the crystal structures

3.2.1. Mononuclear complex VOL (*1*)

The asymmetric unit of the mononuclear complex **1** is shown in Fig. 1. Selected bond lengths and angles are presented in Table 2. The central vanadium atom is in a square pyramidal environment: two nitrogen atoms (N1 and N2) from the deprotonated oxamide and another two (N3 and N4) from ethylenediamine form the basal plane, and the apical position is occupied by the terminal oxo ligand (O3). The deviations of the four N atoms from their least-squares plane are −0.022(8) (N1), +0.022(8) (N2), −0.021(8) (N3) and +0.021(8) (N4) Å, and the central vanadium(IV) atom is 0.667(4) Å out of the plane. Of the four V–N bonds, the bonds to the deprotonated oxamide nitrogens, N1 [1.977(2) Å] and N2 [1.993(2) Å], are somewhat shorter than V–N3 [2.063(2) Å] and V–N4 [2.066(2) Å]. This is in agreement with the fact that the deprotonated oxamide nitrogen is a very strong σ-donor. The short V=O bond length (1.590(2) Å) indicates considerable π-bond character, as in other monomeric V(IV) complexes with similar coordination geometries [30c,33]. The C=O distances of the oxamido bridge are 1.212(4) Å for C1–O1 and 1.219(4) Å for C2–O2, analogous to the situation of other oxamido bridges [29a].

3.2.2. $[Cu(VOL)_2(H_2O)_2](ClO_4)_2 \cdot 1.5H_2O$ (*2*)

The single-crystal X-ray analysis reveals that complex **2** consists of a trinuclear cation $[Cu(VOL)_2(H_2O)_2]^{2+}$, with ClO_4^- counter anions and 1.5 molecules of lattice water. The perspective view of the cation is given in Fig. 2 (the ClO_4^- and H_2O and hydrogen atoms have been omitted for clarity). Selected bond distances and angles are given in Table 3. The trinuclear unit is centrosymmetric, in which V1 and V1A also adopt a square pyramidal geometry and reside in the N4 cavity of macrocyclic complex ligand, with the four donor atoms deviating from their mean plane by −0.053(6) (N1), 0.053(0) (N2), −0.051(3) (N3) and 0.051(9) (N4) Å, and the vanadium atom is −0.6385 Å out of the plane. There are some differences in the V–N bond lengths when compared to the mononuclear complex **1**: both V–N1 and V–N2 have distances of 2.012(5) Å, which is somewhat longer than that of **1**, while V–N3 [2.057(5) Å] and V–N4 [2.054(6) Å] are shorter than the corresponding bond lengths as a result of the interaction of the copper ion and the oxygen atoms of the oxamido bridge. On the other hand, the V=O (terminal) distance (1.588(5) Å) compares well with that observed in the mononuclear complex. The central Cu(II) is located on a centrosymmetric center and is set in a distorted octahedral coordination sphere. The equatorial plane is defined by the four donor oxygen atoms from the oxamido macrocyclic ligand with bond lengths of Cu1–O1 2.105(5) Å and Cu1–O2 1.992(4) Å. The other oxygen atoms of the two coordinated water molecules are positioned in the remaining axial sites above and below the

copper ion at Cu1–O4 distances of 2.125(7) Å. The Cu···V separation across the oxamido bridge is 5.393 Å.

3.2.3. $[Mn(VOL)_2(CH_3OH)_2](ClO_4)_2 \cdot 5CH_3OH$ (**3**)

The crystal structure of complex **3** is built up of the heterotrinuclear cation $[Mn(VOL)_2(CH_3OH)_2]^{2+}$, two perchlorate ions and five uncoordinated methanol molecules. The main skeleton unit (Fig. 3) is asymmetric, which is appreciably different from the X-ray structure of complex **2** discussed above. The two VOL fragments are nearly perpendicular to each other with a dihedral angle of 87.91\. The central manganese also possesses a distorted octahedral geometry, surrounded by six oxygen atoms, four from the oxamido macrocyclic ligand and the other two from the coordinated methanol molecules. All the Mn–O bond lengths are different from each other, and are in the range 2.136(3) to 2.203(3) Å (detailed bond lengths and angles are available in Table 4). In the two VOL fragments, the vanadium atoms V1 and V2 are crystallographically distinct, though they both have square pyramidal geometries. However, N1–N4 substantially deviate from their mean plane by 0.104(8), −0.104(4), 0.101(3) and −0.100(6) Å, respectively, and the V1 atom is −0.669(6) out of the plane, while N5–N8 are nearly in the same plane with the largest deviations of 0.014(1) and −0.014(1) Å for N5 and N6, respectively, whilst the V2 atom is 0.564(9) Å above the mean plane. The V1···Mn1 separation (5.552 Å) is also slightly longer than that of V2···Mn1 (5.526 Å). The V=O (terminal) distance are very similar and they are both longer than the relative bond observed in the mononuclear complex **1**. In the $C_2O_2N_2$ bridge plane, the average C–O and C–N bond lengths in **3** are 1.248 and 1.333 Å, respectively, while the corresponding distances for the mononuclear precursor are 1.215 and 1.359 Å, respectively. The increase in the C–O and the decrease in the C–N distance in the trinuclear complex reflect the delocalization of the electron density from the N-atoms towards the O-atoms upon the coordination of the O-atoms to the Mn(II) ion [34].

3.3. Magnetic properties

Variable temperature (2–300 K) magnetic susceptibility measurements were collected for polycrystalline samples of complexes **2** and **3** in an applied magnetic field of 2 kOe. Diamagnetic corrections were made with Pascal's constants for all the constituent atoms [35]. As a predigesting approach to simulate the experimental magnetic behavior, the single *g* factor was treated as the sum of the contributions of the central atom, Cu(II) or Mn(II), and its neighbouring VO(IV) ions from the macrocyclic oxamido ligands.

The plot of χ_M and μ_{eff} versus *T* for compound **2** is shown in Fig. 4. At room temperature, the effective magnetic moment μ_{eff} is 3.11 μ_B, which is a little higher than the spin-only value (3.00 μ_B) expected for an isolated $V^{IV}_2Cu^{II}$ paramagnetic system. As the temperature decreases, the μ_{eff} value increases continuously over the whole range. These features are typical of a ferromagnetic exchange propagated between the VO(IV) and Cu(II) ions.

O(7)–Mn(1)–O(6)	94.8(1)	O(7)–Mn(1)–O(8)	87.1(1)

A magnetic analysis has been made using the magnetic susceptibility expression (1) based on the isotropic Heisenberg model. A molecular field approximation has also been introduced to take into account the small intermolecular interactions between the trinuclear entities using Eq. (2).

$$\hat{H} = -2J(\hat{S}_{V1}\hat{S}_{Cu} + \hat{S}_{V2}\hat{S}_{Cu})$$

$$\chi = \frac{Ng^2\beta^2}{4KT}\left[\frac{5+\exp(-3J/KT)}{1+\exp(-3J/KT)}\right] + N_\alpha \quad (1)$$

$$\chi_M = \frac{\chi}{1-(2zj'/Ng^2\beta^2)\chi} \quad (2)$$

where J is the exchange interaction parameter between the VO(IV) and Cu(II) ions, N_α is the temperature-independent paramagnetic term, and is set as 120×10^{-6} m^3 mol^{-1}, zJ' stands for the intermolecular interactions and the other symbols have their usual meanings. On this basis, the least squares fitting of the experimental data led to $J = 9.09$ cm^{-1}, $g = 2.00$ and $zJ' = 5.0 \times 10^{-3}$ cm^{-1}. The agreement factor defined as $R = \sum((\chi_M T)_{obs} - (\chi_M T)_{calc})^2 / \sum(\chi_M T)^2_{obs}$ is equal to 3.59×10^{-4}.

The magnetic behavior of complex **2** can be rationalized by the orthogonality of the magnetic orbitals. As already noted from the crystal structure of **2**, the symmetries of the metallic sites and the bridge in the Cu–VO region are very close to *Cs*. The magnetic orbital on the Cu(II) center, $d_{x^2-y^2}$ is roughly parallel to the copper-donor directions in the basal plane and is engaged in σ overlap with the bridging oxamido oxygens, and transforms as an α′ irreducible representation of the *Cs* group. On the other hand, the magnetic orbital on VO(IV), d_{xy}, which approximately bisects the equatorial donor-vanadium-donor angles, is delocalized toward the oxamido nitrogens by a π-type overlap and transforms as a α″ irreducible representation of the *Cs* group. Thus, for the magnetic orbitals (Φ_{Cu}, Φ_{VO}) being symmetry-related orthogonal, there is essentially zero overlap ($\langle\Phi_{Cu}|\Phi_{VO}\rangle \approx 0$), and no chemical bonding. This implies that in the expression for the singlet–triplet energy gap, $2J = J_{AF} + J_F$, the negative antiferromagnetic contribution J_{AF} is insignificant [36]. So the coupling is purely ferromagnetic.

The magnetic behavior of complex **3** is shown in Fig. 5. The effective magnetic moment μ_{eff} at 300 K (6.03 μ_B) is slightly lower than the spin-only value (6.40 μ_B) for the non-interaction of two vanadium(IV)-oxo and one manganese(II) ion. With the decreasing temperature, μ_{eff} decreases smoothly over the entire temperature region, and reaches a minimum value of 5.37 μ_B at 2 K. These behaviors are indicative of an overall weak antiferromagnetic coupling. The experimental data are fitted by using Eq. (3) derived from the spin-exchange Hamiltonian.

$$\hat{H} = -2J(\hat{S}_{V1}\hat{S}_{Mn} + \hat{S}_{V2}\hat{S}_{Mn})$$

$$\chi_M = \frac{Ng^2\beta^2}{4K(T-\theta)}\left[\frac{35+10\exp(-7J/KT)+35\exp(-2J/KT)+84\exp(5J/KT)}{3+2\exp(-7J/KT)+3\exp(-2J/KT)+4\exp(5J/KT)}\right] \quad (3)$$

The symbols in the expression have the same meaning as in expression (1) and θ is the correction term for the intermolecular interactions. For a satisfactory fit, the following parameters: $J = -0.27$ cm^{-1}, $g = 1.97$, $\theta = -0.03$ K are used with the agreement factor $R = 4.76 \times 10^{-4}$.

It is not difficult to rationalize the occurrence of weak antiferromagnetic coupling between the Mn(II) ion and VO(IV) ions. In a trinuclear system, with many electrons on metal centers, the exchange coupling parameter J is given by Eq. (4) [37].

$$J = \frac{1}{n_A n_B}\sum\nolimits_{\mu,\nu} J_{\mu,\nu} = \frac{1}{n_A n_B}[J_{AF} + J_F] \quad (4)$$

Where n_A and n_B are the number of unpaired electrons associated with the transition metal ions A and B, respectively. $J_{\mu,\nu}$ is the exchange between two singly occupied orbitals of symmetry μ and ν. When two orbitals have the same symmetry, they overlap and an antiferromagnetic contribution (J_{AF}, negative) arises. On the other hand, when two orbitals have different symmetries, the orthogonality leads to a ferromagnetic contribution (J_F, positive), the resulting sign of J is determined by a competition between them.

In the case of **3**, the Mn(II) site has five d_{xy}, d_{yz}, d_{xz}, $d_{x^2-y^2}$, d_{z^2} magnetic orbitals, and the VO(IV) site has only one d_{xy} orbital. By simple symmetry considerations, the J_{xy-xy} pathway involves an interaction between two magnetic orbitals of the same symmetry which contributes antiferromagnetically (J_{AF}) to the exchange, and it is expected to give the most important contribution in absolute value, while the other four routes (J_{xy-yz}, J_{xy-xz}, $J_{xy-x^2-y^2}$, J_{xy-z^2}) involve two orthogonal orbitals which lead to a ferromagnetic contribution (J_F). Consequently, the weak interaction will be overwhelmed by the opposite effects. The existence of the net antiferromagnetic interaction in **3** is indicative that the J_{xy-xy} pathway dominates the overall interaction.

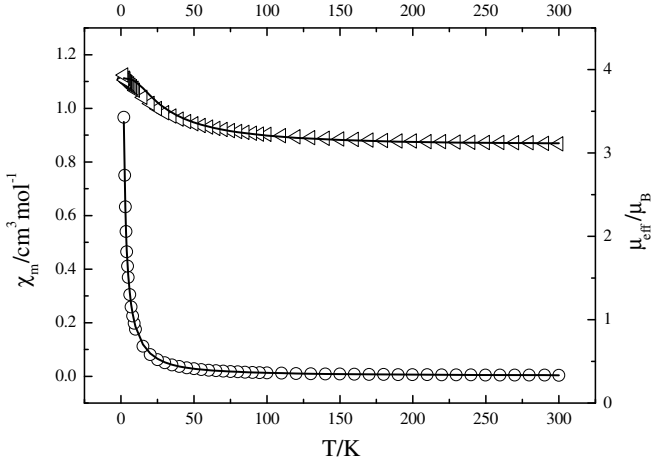

Fig. 4. Plots of χ_M vs. T (open circles) and μ_{eff} vs. T (open triangles) for **2**. The solid line shows the fitting values.

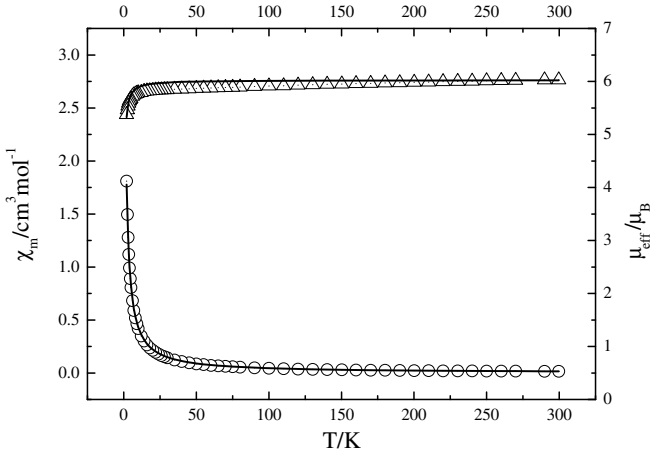

Fig. 5. Plots of χ_M vs. T (open circles) and μ_{eff} vs. T (open triangles) for **3**. The solid line shows the fitting values.

4. Conclusion

In summary, a new vanadium-oxo macrocyclic ligand with an oxamido bridge has been solvent-thermally synthesized, and based on the precursor ligand, two trinuclear complexes have been constructed and structurally as well as magnetically characterized. Both compounds **2** and **3** tend to adopt a trinuclear configuration as a result of the larger bulk of the rigid co-ligand VOL and the geometry around the central Cu(II) and Mn(II) ions is a distorted octahedron. Compound **2** exhibits ferromagnetic behavior, which is in accord with other Cu(II)–VO(IV) systems [36,38], while compound **3** shows a very weak antiferromagnetic coupling. The temperature dependence of the magnetic susceptibility for the complexes were analyzed by means of the Heisenberg Hamiltonian $\hat{H} = -2J\hat{S}_1\hat{S}_2$, leading to $J = 9.09\ \mathrm{cm}^{-1}$, $zJ' = 5.0 \times 10^{-3}\ \mathrm{cm}^{-1}$ for complex **2** and $J = -0.27\ \mathrm{cm}^{-1}$, $\theta = -0.03$ K for complex **3**. The present study reports, for the first time, a substitute VO(IV) ion for copper or nickel acting as the template metal ion of the macrocyclic ligand. It is clear from the above discussion that in this system the magnetic interactions may be tunable by changing the metal ions in the complex ligand or the central ions, and further investigations on this and similar systems are in progress in our laboratory.

tetraphenylporphyrin, T(*p*-ClP)P = tetra(4-chlorophenyl)porphyrin, T(*p*-MeP)P = tetra(4-methylphenyl)porphyrin, T(*m*-ClP)P = tetra(3-chlorophenyl)porphyrin, T(*m*-MeP)P = tetra(3-methylphenyl)porphyrin). The Ce^{IV}(porphyrin)$_2$ complexes were prepared by the method described by Buchler et al. [41]. The crude products were chromatographed on alumina by using *n*-hexane/toluene as eluent. The purification of the complexes was confirmed via UV–Vis and nuclear magnetic resonance spectroscopy. UV–Vis absorption spectra were obtained with a 1 cm quart cell using a Hewlett-Packard 8450 A diode array spectrophotometer. NMR experiments were performed on a 300 MHz Bruker instrument. Infrared spectra of the samples in KBr pellets were recorded on a Nicolet 550 spectrometer. The spectral slit width was 1 cm^{-1}.

3. Results

The infrared spectra of Ce(OEP)$_2$ and Ce(OEP)(TPP) are shown in Fig. 1. It is interesting to note that the features of the IR spectrum of the porphyrin dimer, Ce(OEP)$_2$, are closely related to those of the metalloporphyrin monomers [30–32,34]. To the best of our knowledge, the similarity of the IR spectra of the OEP monomer and dimer systems has not been fully discussed yet. In order to facilitate a comparison of the IR spectra, tentative assignments of the IR signals were carried out on the basis of the similar features of the IR spectra between the porphyrin dimers and metalloporphyrin monomers. However, it should be noted that the mode labelling is formally inappropriate for the porphyrin dimers as their symmetry is at most D_{4d} [14].

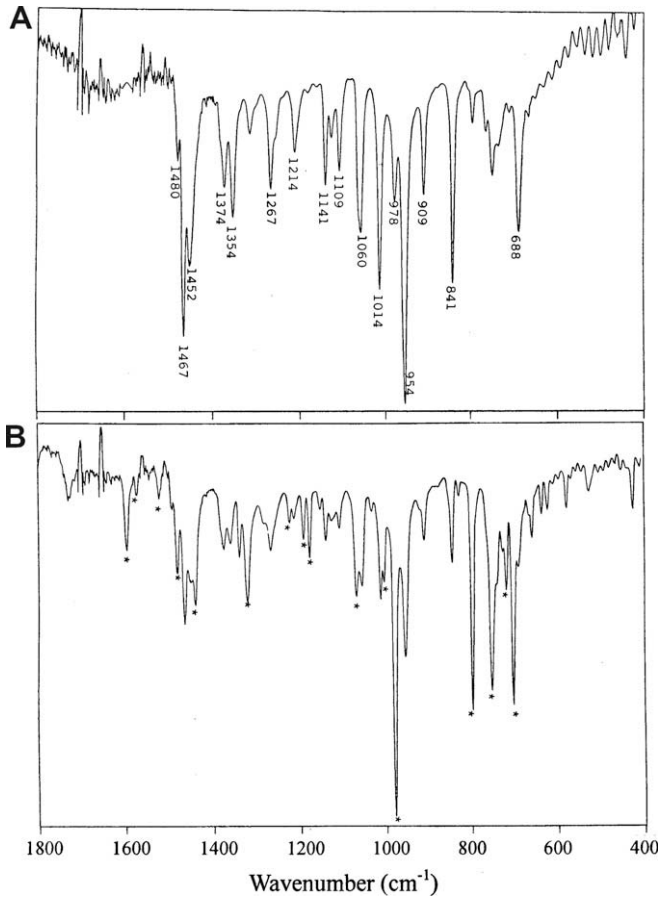

Fig. 1. IR spectra of (A) Ce(OEP)$_2$ and (B) Ce(OEP)(TPP) in KBr pellets. The IR signals from the TPP moiety are labelled with an asterisk.

The infrared spectrum of Ce(OEP)$_2$ displays three bands in the region between 1500 and 1450 cm^{-1}. Since they are similar to those of the metalloporphyrin monomers, the band observed at 1480 cm^{-1} is readily assigned to the core vibration, and the bands at 1467 and 1452 cm^{-1} are assigned to alkyl group vibrations. The region between 1400 and 1100 cm^{-1} contains several medium-intensity bands. Except for the band at 1354 cm^{-1}, its corresponding band in the metalloporphyrin monomers is too weak to be assigned, all the other signals can be readily assigned to their corresponding bands in the monomers. Additionally, an intensity change is also observed in this region especially for those of the skeletal modes at 1267, 1214 and 1141 cm^{-1}. After normalization, the relative intensities of these bands are shrunk to about one half of those of the corresponding bands in the metalloporphyrin monomers. The remaining absorptions in the region from 1100 to 600 cm^{-1} contain several strong bands. Except for the medium-strong bands at 841 and 688 cm^{-1}, the intensities of the other core vibrations at 978 and 909 cm^{-1} are much weaker than those of the alkyl group vibrations at 1060, 1014 and 954 cm^{-1}. Collectively, the overall feature of the IR spectrum Ce(OEP)$_2$ is highly correlated to that of the metalloporphyrin monomer. The major differences between these two systems are confined to the frequency shifts and the subtle changes in the relative intensities between the core vibrations and the group vibrations. It is worthwhile to note that the intensities of these two types of vibrations in the metalloporphyrin monomers are about the same generally, whereas in the Ce(OEP)$_2$ system, the intensities of the typical core vibrations, observed at 1267, 1214, 1141 and 978 cm^{-1}, are much weaker than those of the group vibrations at 1467, 1014 and 954 cm^{-1}.

In order to make the data comparison consistent, we have re-taken the IR spectrum of Ce(TPP)$_2$. As we have seen in the OEP system, most of the prominent IR bands in Ce(TPP)$_2$ can still find their corresponding signals in M(TPP) [33,38] (where M = Cu, and Zn). As shown in Fig. 2, the medium-intensity band observed at 1599 cm^{-1} in Ce(TPP)$_2$ can be easily assigned to the phenyl mode. The position and the relative intensity of this characteristic band are about the same in both monomer and dimer systems. It is interesting to note that this particular mode of the phenyl group is almost inert to the π–π interactions whereas the frequencies of the ethyl modes in the OEP dimers are all downshifted from their corresponding monomer signals. The following bands at 1575, 1525, 1483 and 1441 cm^{-1} are essentially unshifted from those of Zn(TPP). The location of the band at 1327 cm^{-1} corresponds to the electron-density-sensitive ν_4(Cα–N) mode of the

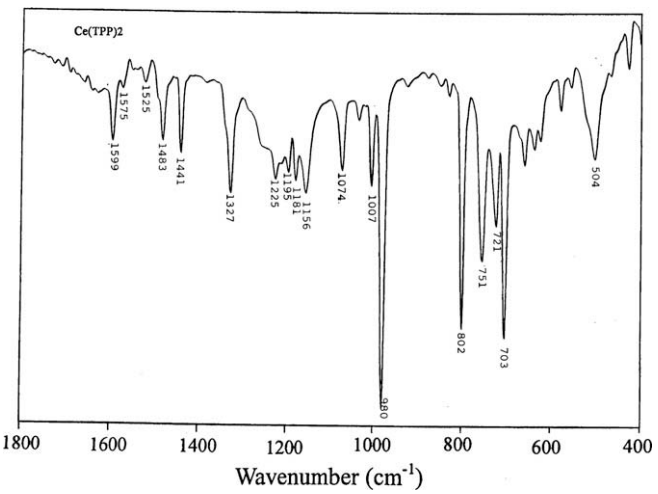

Fig. 2. IR spectrum of Ce(TPP)$_2$ in a KBr pellet.

metalloporphyrins [38]. This band, as well as the other two bands at 1599 cm^{-1} and 1007 cm^{-1}, has also been shown to have phenyl mode contributions, but only the band at 1327 cm^{-1} is downshifted by 12 cm^{-1} from the counterparts of Zn(TPP). There are four relatively weak signals observed around 1200 cm^{-1}. Except for the band at 1195 cm^{-1}, being downshifted, the remaining three bands at 1225, 1181 and 1156 cm^{-1} are all upshifted by 5–11 cm^{-1} from their corresponding signals of Zn(TPP). The medium-intensity band at 1074 cm^{-1} was assigned as a pyrrole-hydrogen bending mode [33] and was observed to be upshifted by 5 cm^{-1}. There are several strong and medium-strong bands that appear in the low frequency region. The band at 980 cm^{-1} is observed to be downshifted by 12 cm^{-1} whereas the bands at 802 and 721 cm^{-1} are upshifted by 7 and 5 cm^{-1}, respectively. The remaining two bands at 751 and 703 cm^{-1} are essentially unchanged from the monomer to dimer systems. Collectively, the π–π interactions do not cause all the IR frequencies of $Ce(TPP)_2$ to downshift from their corresponding monomer signals. These observations are in contrast to the monotonic change of the band frequencies in OEP systems. In addition, the relative intensity of the IR signals of $Ce(TPP)_2$ are essentially the same as those of Zn(TPP).

The methyl and chloro substituents represent typical electron donor and acceptor groups, respectively. Any change of the electronic configuration or geometrical conformation will in turn perturb the π–π interactions. Consequently, systematic studies of the IR spectra of the dimer complexes with suitable substituents should be able to reveal the perturbations of the inductive as well as the steric effects on the π–π interactions of the macrocycles.

The IR spectra of four different derivatives of $Ce(TPP)_2$ are shown in Figs. 3 and 4. In general, the features of these spectra are different to that of $Ce(TPP)_2$ with regard to the relative intensity and the number of signals. In order to explore the origin of these differences, we have also synthesized and compared the IR spectrum (not shown here) of Cu[T(*m*-clP)P] with those of the Ce[T(*m*-clP)P]$_2$ dimer. The results indicate that most of the prominent IR bands in Ce[T(*m*-clP)P]$_2$ can still find the corresponding signals in Cu[T(*m*-clP)P]. The typical bands at 1326 and 985 cm^{-1} are downshifted by 18 and 20 cm^{-1}, respectively, whereas the bands at 804, 782, 745, 724 and 697 cm^{-1} are all upshifted by 2–9 cm^{-1}. All these results indicate that both the nature and the position of the substituent groups perturb the IR spectra of the TPP monomer and dimer systems to a different extent. These substituent effects complicate the comparisons of the IR spectra of $Ce(TPP)_2$ with its dimer derivatives. However, the prominent signals at around 1327, 980, 802 and 724 cm^{-1} are relatively unaffected by the substituent groups.

Regarding heterodimers, the IR spectrum of Ce(OEP)(TPP) (as shown in Fig. 1) displays more complex features than those of either $Ce(OEP)_2$ or $Ce(TPP)_2$. A detailed analysis indicated that this spectrum can be de-convoluted to a simple combination of the IR spectra of $Ce(OEP)_2$ and $Ce(TPP)_2$. This result is similar to those obtained from a resonance Raman study on this complex [40]. Clearly, the effect of the symmetry decreasing does not play a major role in the heterodimers either. The similar properties of the linear combination of the IR spectra were also observed in other heterodimer derivatives (as shown in Figs. 5 and 6). Although most of the frequencies of the prominent signals are essentially unaffected on going from the homoleptic dimers to heteroleptic dimer, minor changes are still observed in both components. For example, the band at 845 cm^{-1} originating from the OEP moiety is upshifted by 4 cm^{-1} from its corresponding signal of $Ce(OEP)_2$. For those signals originating from the TPP moiety, the band at 1323 cm^{-1} is downshifted by 4 cm^{-1}, whereas the bands at 1069 and 798 cm^{-1} are downshifted by 5 and 4 cm^{-1}, respectively from their corresponding signals of $Ce(TPP)_2$.

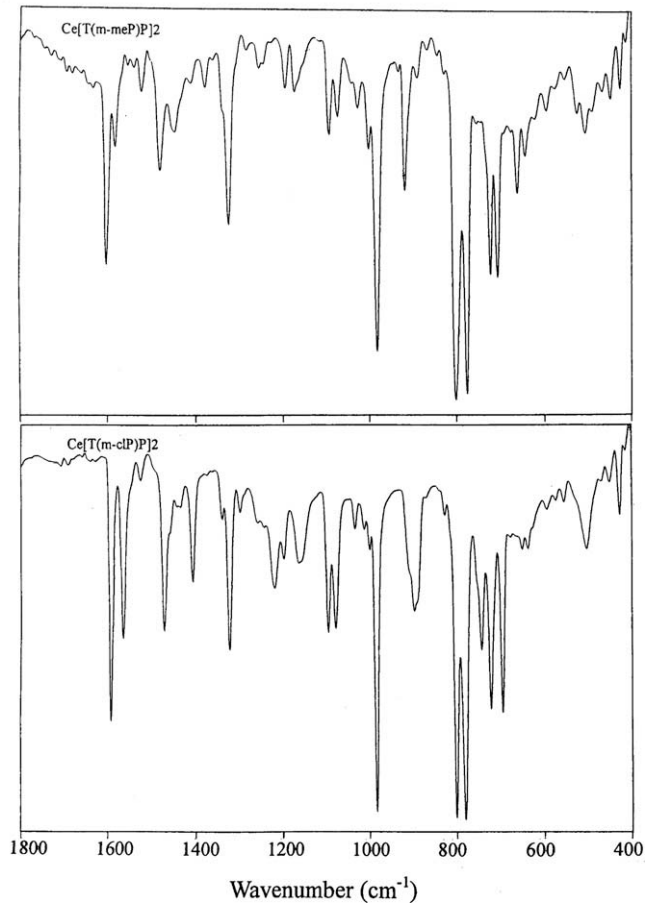

Fig. 3. IR spectra of Ce[T(*m*-MeP)P]$_2$ and Ce[T(*m*-ClP)P]$_2$ in KBr pellets.

Figs. 7 and 8 display the high frequency region of the IR spectra of $Ce(OEP)_2$, Ce(OEP)(TPP) and the heterodimer derivatives Ce(OEP)(TPP*) (where TPP* represents the derivatives of TPP). Coincidentally, they all display four signals at 2963, 2930, 2868 and 2850 cm^{-1}. These signals have previously been assigned to the vibrations of the ethyl group on the OEP macrocycle [30]. Similar to the other ethyl vibrations in the low frequency region, the frequencies of these bands are observed to be downshifted by about 4 cm^{-1} from their corresponding monomer signals. The distinction of these complexes can be characterized by the relative intensities of these four signals. Basically, the relative intensities of these four bands decline from 2963 to 2850 cm^{-1} in $Ce(OEP)_2$. However, in Ce[OEP][TPP], the relative intensities of the bands at 2963 and 2930 cm^{-1}, as well as the other two bands at 2868 and 2850 cm^{-1}, are inversed relative to those of the bands in $Ce(OEP)_2$. The relative intensities of these bands are also sensitive to the substituent groups on the TPP moiety. The IR spectra of the *para*-substituted heteroleptic dimers, Ce[OEP][T(*p*-ClP)P] and Ce[OEP][T(*p*-MeP)P], have similar contours to those of Ce[OEP][TPP] in this high frequency region, except for a minor difference between the signals at 2868 and 2850 cm^{-1}. However, both the *meta*-substituted heteroleptic dimers, Ce[OEP][T(*m*-MeP)P] and Ce[OEP][T(*m*-ClP)P], exhibit different IR figures to that of Ce[OEP][TPP]. The relative intensities of these four bands in Ce[OEP][T(*m*-MeP)P] are essentially similar to those in $Ce(OEP)_2$. Whereas in the case of Ce[OEP][T(*m*-ClP)P], the relative intensities of the bands at 2868 and 2850 cm^{-1} are similar to those in $Ce(OEP)_2$, the other two bands at 2963 and 2930 cm^{-1} display as the intermediate between $Ce(OEP)_2$ and Ce[OEP][TPP].

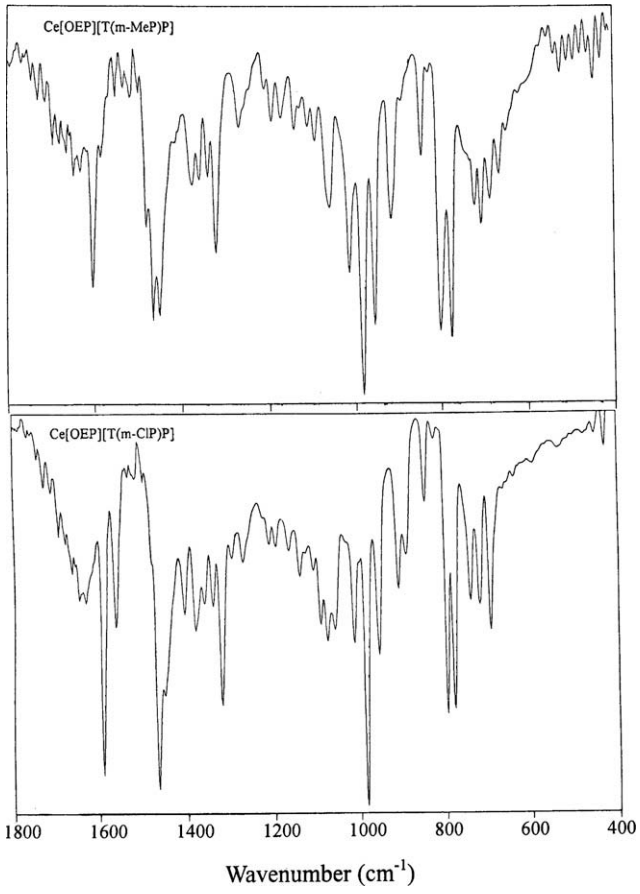

Fig. 5. IR spectra of Ce[OEP][T(*m*-MeP)P] and Ce[OEP][T(*m*-ClP)P] in KBr pellets.

4. Discussion

Although the IR spectrum is characterized by the geometry of the whole molecule, it turns out that certain groups of atoms give rise to bands at or near the same frequency regardless of the structure of the rest of the molecule. The intrinsic properties of these characteristic bands usually provide key information about the subtle change of the geometric and the electronic structure of the molecule. As has been shown in some typical metalloporphyrin monomers, the prominent IR spectra can be divided into two classes: the core vibrations, which are sensitive to the central metal ions, and the group vibrations, which are nearly unaffected by the central metal ions [31]. Since a change of the central metal ions also causes a structural change, the persistence of these characteristic group vibrations indicate that these bands are essentially inert to the structure perturbation of the macrocycle. Due to the similar features of the IR spectra between the porphyrin dimers and monomers, the dimer molecules can be treated as simple derivatives of metalloporphyrin monomers. Each macrocycle is acting as a special substituent group to each other. Following the same categorization of the IR signals in the monomer systems, we should be able to correlate the frequency and the relative intensity changes of the IR signals in the dimer systems to the effects of the induced π–π interactions between these two macrocycles.

In the case of Ce(OEP)$_2$, the IR bands of the core vibrations at 1480, 1267, 1214, 1141, 978, 909, 841, 749 and 688 cm^{-1} are observed to be downshifted by 5–21 cm^{-1} whereas the bands of the group vibrations at 1467, 1452, 1374, 1316, 1109, 1060, 1014 and 954 cm^{-1} are observed to be downshifted by 1–10 cm^{-1} from the corresponding signals of Ni(OEP). Since the group vibrations are nearly unaffected by the central metal ions in the metalloporphyrin monomers, the frequency shifts of these group vibrations observed in the Ce(OEP)$_2$ complex are then totally attributed to the effects of the π–π interaction between the macrocycles. In contrast to the relative simple effects of the π–π interaction on the group vibrations, the extent of the π–π interaction on the core vibrations is much harder to be resolved quantitatively, since the frequencies of the core vibrations are sensitive to the ionic radii of the central metal ions as well as the molecule conformations. These results imply that the dimerization of the macrocycles could lead to the adjustment of the mode composition and contributions of the core vibrations through the conformational change of the macrocycles. Unlike the other core vibrations, the strong band near 846 cm^{-1}, which has been assigned to a C_m–H out-of-plane bending vibration, is observed to be insensitive to the types of the central metal ions [30]. Any change of this particular mode reflects the extent of the π–π interactions on the core vibrations. The 5 cm^{-1} downshift of this band in the Ce(OEP)$_2$ dimer is consistent with the trend of the frequency changes in other group vibrations. The general trend of the frequency downshifts indicates that the π–π interaction causes bond weakness for the entire molecule.

In addition to the frequency changes caused by the π–π interactions, the change in the relative intensities of the core vibrations and the group vibrations is attributed to the symmetry change from the monomer to the dimer systems. Since the descending symmetry of the molecular structure could cause a significant signal split as well as intensity change, the minor change of the relative intensities of the core vibrations and the group vibrations accompanying the non-splitting of the signals implies that the π–π interactions rather than the symmetry change dominate the physical properties of the Ce(OEP)$_2$ complex.

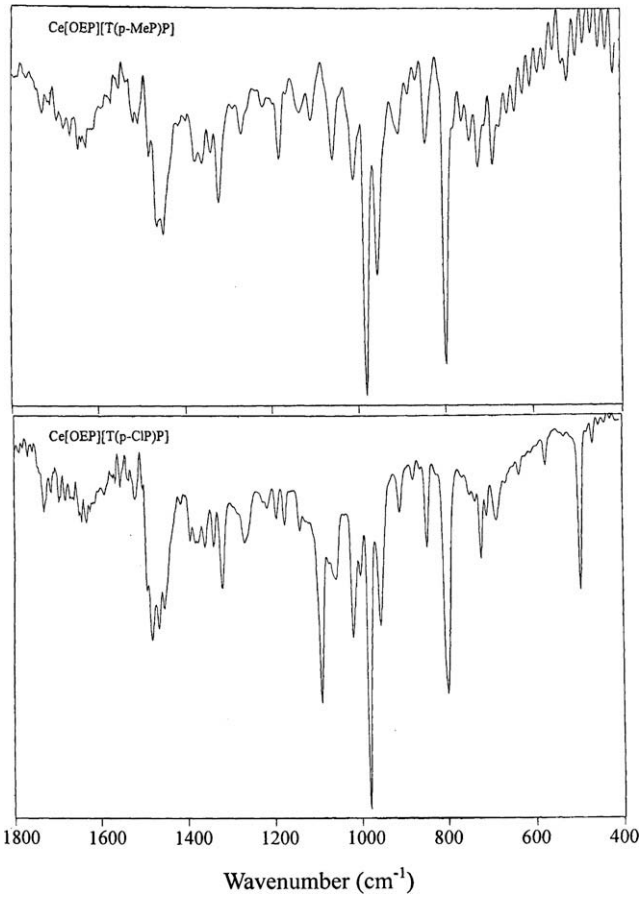

Fig. 6. IR spectra of Ce[OEP][T(*p*-MeP)P] and Ce[OEP][T(*p*-ClP)P] in KBr pellets.

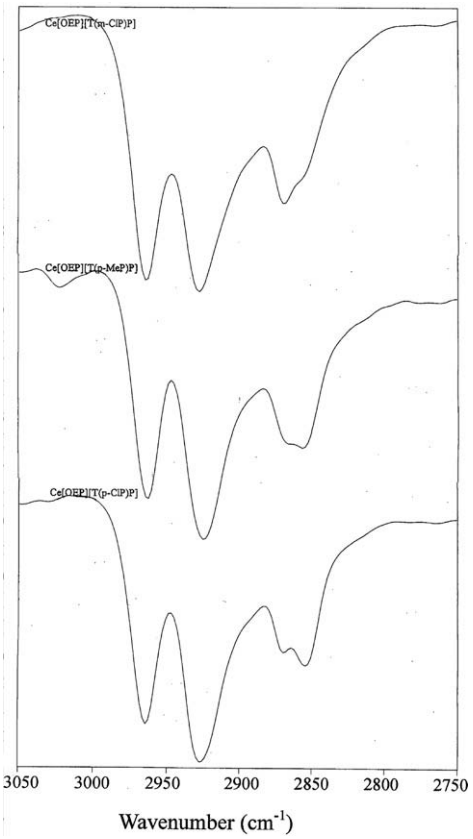

Fig. 8. The high frequency region of the IR spectra of Ce[OEP][T(*m*-ClP)P], Ce[OEP][T(*p*-MeP)P] and Ce[OEP][T(*p*-ClP)P] in KBr pellets.

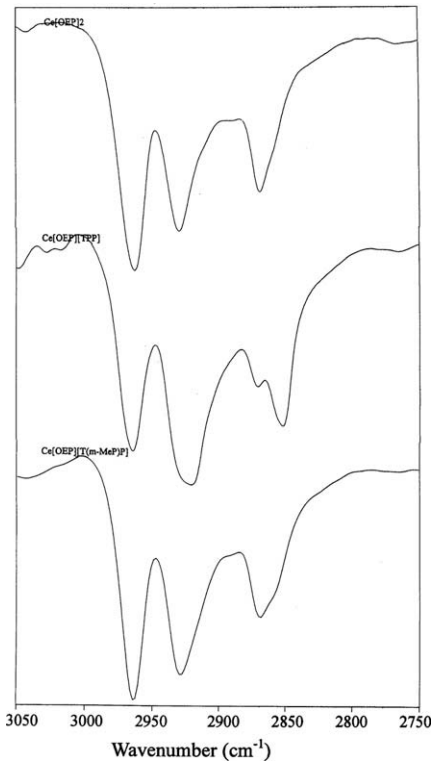

Fig. 7. The high frequency region of the IR spectra of $Ce[OEP]_2$, Ce[OEP][TPP] and Ce[OEP][T(*m*-MeP)P] in KBr pellets.

Significant effects of the π–π interactions are also observed in the IR spectra of the TPP system. The intimate correlation properties between the TPP monomer and dimer systems indicate again that the symmetry change caused by the dimerization does not induce a severe change on the vibrational modes of the porphyrin macrocycles. However, differences between the TPP and OEP systems are observed. In contrast to the regular change of the frequencies in the OEP systems, the π–π interactions in the TPP systems do not cause all the dimer vibrations to be downshifted from their corresponding monomer signals. Since the *meso*-substitution can affect the mode composition and contributions in the TPP system [36], the interactions of the vibrational modes might have been further perturbed in the TPP dimer. Consequently, the irregular alternations of the IR frequencies in the TPP dimer systems are attributed to the readjustment of the mode composition and contributions accompanying the π–π interactions between the macrocycles.

Symmetry insensitive properties also exist in the IR spectra of the heteroleptic dimer system. As we mentioned before, the IR spectrum of Ce(OEP)(TPP) is the simple composition of the IR spectra of $Ce(OEP)_2$ and $Ce(TPP)_2$ instead of the OEP and TPP monomers. These results indicate that the vibrational modes of each macrocycle are not mixed with each other, and the IR signals of each component are mainly affected by the π–π interactions of these two macrocycles. The substituent groups on the macrocycles exhibit very little perturbations on the vibrational modes of the opposite components. These deductions are further supported by the similar trends of the prominent IR signals of the OEP component in other heteroleptic $Ce(OEP)(TPP^*)$ complexes. Since the peripheral substituent groups were attached on the phenyl group rather than the tetrapyrrole macrocycle, the inductive effects of

these groups on the π–π interactions of the porphyrin dimers are believed to be weak. The frequency changes of the bands at 1323, 1069 and 798 cm^{-1}, originating from the TPP moiety, as well as the C_m–H out-of-plane bending vibration [31,34] at 845 cm^{-1}, originating from the OEP moiety, are then attributed to the mutual steric effects of the macrocycles.

In the region 2800–3000 cm^{-1}, $Ce(OEP)_2$ and its derivatives $Ce(OEP)(TPP^*)$ all display the same set of ethyl vibrations at 2963, 2930, 2868 and 2850 cm^{-1}. These results indicate again that the OEP moiety experiences the same magnitude of π–π interactions, no matter what the opposite component is – the OEP or TPP system. The similar contours of the IR spectra of Ce[OEP][T(*p*-ClP)P], Ce[OEP][T(*p*-MeP)P] and Ce[OEP][TPP] imply that both the inductive and the steric effects of the *para*-substituted groups are too small to be detected. However, for those of the *meta*-substituted heteroleptic dimers, significant changes of the band intensities are observed. These results indicate that the steric effects of the *meta*-substituted groups are not strong enough to cause changes of the frequencies by perturbing the electronic structure of the macrocycle π-electrons, the local perturbations on the molecular structure do affect the IR signals through the subtle changes of the band intensities. Referring to the crystallography study of porphyrin dimers, it has been shown that the porphyrin macrocycles are not perfectly flattened [11]. Both of the porphyrin rings are domed and the cerium metal ion protrudes from the porphyrinato plane. The whole molecule is arranged into five layers. The metal ion sits in the center of the molecule, the next pair of layers are formed by 4 nitrogens of each macrocycle, and the outer layers are formed by carbons of each macrocycle. It was also pointed out that the OEP ring is more deformed than the TPP ring [3]. The different deformations in the saucer-like geometries are believed to be responsible for the intensity changes of these four bands in $Ce(OEP)_2$ and Ce[OEP][TPP]. Since the substituent groups on the *para*-positions are not big enough to display effective steric effects, the IR spectra of these four bands in Ce[OEP][T(*p*-ClP)P], Ce[OEP][T(*p*-MeP)P] and Ce[OEP][TPP] are then similar to each others. However, the *meta*-substituted derivatives exhibit a different extent of steric effects on the porphyrin dimers. These effects lead to the perturbations of the porphyrin rings. Intrinsically, the methyl group has a larger steric effect than the chloride group. The essentially similar IR features of these four bands in Ce[OEP][T(*m*-MeP)P] and $Ce(OEP)_2$ imply that the deformations of the porphyrin rings are also similar in these two complexes. Finally, the intermediate IR features of these four bands in Ce[OEP][T(*m*-ClP)P] relative to those of $Ce(OEP)_2$ and Ce[OEP][TPP] are consistent with the weaker deformations of the porphyrin rings caused by the smaller chloride groups. Collectively, these four bands could be used as characteristic bands to monitor the deformations of the porphyrin rings.

5. Conclusions

The similar features of the IR spectra between porphyrin dimers and monomers indicate that the vibrational properties of the dimer molecules can be systematically compared to those of the metalloporphyrin monomers. The symmetry changes induced by the dimerization of the porphyrin rings only lead to a minor perturbation of the vibrational modes of the macrocycles. For the $Ce(OEP)_2$ complex, the frequency downshifts of the group vibrations, which are nearly unaffected by the central metal ions in the metalloporphyrin monomers, indicate that the π–π interactions of the porphyrin rings result in a weakness of the bonds in the dimer molecule. Additionally, the similar IR spectra of the OEP moiety in these different porphyrin dimers reveal that the effects the π–π interactions depend only on the π electrons of the macrocyclic rings instead of the electron configurations of the whole molecule. Finally, the systematic alterations of the IR intensities in the region of 2800–3000 cm^{-1} suggest that these group vibrational modes of the OEP moiety can be used as characteristic bands to monitor the subtle deformations of the porphyrin rings caused by the steric hindrance of the substituents in the dimer complexes.

In this work, the synthesis of new octa alkylthio and triethyleneoxysulfonyl substituted oxotitanium phthalocyanines (**1a** and **2a**) is described. The mesogenic properties of these new materials are studied by differential scanning calorimetry and optical microscopy. The electrical dark conductivities (σ_d) and photoconductivities (σ_{ph}) of deposited films of the oxotitanium Pcs on interdigitated electrodes were investigated. Also the photoconductivity mechanism and formation of Pc^+ which is positive charge carrier under the light irradiation of the phthalocyanine molecules are demonstrated using the theoretical calculations.

The first goal is to explore the effect of oxygen concentration on the dark and photoconductivity of differently substituted oxotitanium(IV) phthalocyanines under the same conditions, from the conductivity measurements. The second is to demonstrate the photoconductivity mechanism and formation of Pc^+ which is positive charge carrier under the light irradiation of phthalocyanine molecule, using the theoretical calculations.

To the best of our knowledge, it is the first time to report the theoretical investigation of oxygen doped photoconductivity of substituted oxotitanium phthalocyanine molecules. The theoretical data about oxygen effect on the photoconductivity of oxotitanium phthalocyanine molecules in question are not exist in the literature, although semi-empirical and density functional theory (DFT) calculations of oxotitanium phthalocyanine concerning the electronic spectra have been reported [16–20]. For this purposes, we have carried out semi-empirical calculations to elucidate the oxygen doped photoconductivity mechanism of substituted oxotitanium phthalocyanine molecules.

2. Experimental

2.1. Materials and equipment

1,2-Di(13,17-dioxa nonacosane-15-sulfanyl)phthalonitrile **(1)** [9] and 4,5-bis(4,7,10-trioxaundecan-1-sulfonyl)phthalonitrile **(2)** [10] were synthesized according to the reported procedures. All other reagents and solvents were reagent-grade quality, obtained from commercial suppliers and were dried as described in Perrin and Armarego [21] before use. Elemental analyses were obtained from Thermo Finnigan Flash 1112. Infrared spectra in KBr pellets were recorded on a Bio-Rad FTS 175C FT-IR spectrophotometer. Optical spectra in UV–Vis region were recorded with a Shimadzu 2001 UV PC spectrophotometer using 1 cm pathlength cuvette at room temperature. The mass spectra were recorded on a LCQ-ion trap (Thermofinnigan, San Jose, CA,USA), equipped with an ES (Electrospray) source. ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ solutions on a Varian 500 MHz spectrometer. Thermogravimetric analyses were carried out on Mettler Toledo Star^e Thermal Analysis System at a rate of 10 °C min^{-1} in a nitrogen flow (50 ml min^{-1}). The phase transition behavior of these compounds was observed by means of polarizing microscope (Leitz Wetzler Orthoplan-pol.) equipped with the hot stage (Linkam TMS 93) and temperature-controller (Linkam LNP). Transition temperatures were determined with the scan rate of 5 °C min^{-1} using a Mettler Toledo Star^e Thermal Analysis System/DSC 822^e. Differential scanning calorimeter system was calibrated with indium from 3 to 4 mg samples under nitrogen atmosphere.

2.2. Synthesis

2.2.1. 2,3;9,10;16,17;23,24-Octakis (13,17-dioxa nonacosane-15-sulfanyl)phthalocyaninato titanium(IV) oxides (**1a**)

Under argon atmosphere, 1,2-Di(13,17-dioxa nonacosane-15-sulfanyl)phthalonitrile (**1**) (0.800 g, 0.788 mmol), urea (30 mg, 0.30 mmol) and three drops of DBU was heated in 3 ml of 1-pentanol to 120 °C, then 100 mg (0.29 mmol) titanium(IV) butoxide was added. The mixture was refluxed for 6 h. After cooling to room temperature, the crude product was poured into MeOH and precipitated. The oxotitanium phthalocyanine was purified with column chromatography [silica gel, eluent CH_2Cl_2/*n*-hexane, 1:1 (v/v)]. Yield: 85 mg (11%). *Anal.* Calc. for $C_{248}H_{448}N_8TiO_{17}S_8$ (4115): C, 72.00; H, 11.35; N, 2.71. Found: C, 72.10; H, 10.95; N, 2.63%. IR (KBr) ν_{max} (cm^{-1}) 3040, 2950–2855 (CH_2, CH_3), 1600 (C_{ar}=N), 1460, 1370, 1330, 1120, 1105, 964 (Ti=O). MS (ES-MS), *m*/*z* (%): 2058 $[M]^{2+}$. ^1H NMR (500 MHz, $CDCl_3$): δ 1.10 (t, 48H, CH_3), 1.8 (m, 32H, CH_2), 3.25 (m, 64H, CH_2), 3.52–3.80 (m, 256H, CH_2), 3.90 (d, 32H, CH_2O), 4.05 (m, 8H, CH), 9.12 (s, 8H, CH_{ar}). ^{13}C NMR (500 MHz, $CDCl_3$): δ 13.56 (CH_3), 22.00 (CH_2), 26.50 (CH_2), 29.58–32.05 (CH_2), 32.16 (CH_2), 40.00 (CH_2), 59.50 (CH), 69.10–72.90 (CH_2), 122.05 ($C_{ar}H$), 134.12 (C_{ar}), 141.60 (C_{ar}–S), 151.10 (C_{ar} C=N).

2.2.2. 2,3;9,10;16,17;23,24-Octakis (4,7,10-trioxaundecan-1-sulfonyl)phthalocyaninato titanium(IV) oxides (**2a**)

A round-bottomed flask fitted with a condenser was degassed and flame-dried under dry argon. The flask was charged under argon with 4,5-bis(4,7,10-trioxaundecan-1-sulfonyl) (**2**) (0.75 g, 1.55 mmol), 4 ml of 1-pentanol, urea (40 mg, 0.66 mmol) and four drops of DBU (1,8-diazabicyclo[5.4.0.]undec-7-ene) and the reaction mixture were heated to 120 °C. At that temperature, 174 mg (0.51 mmol) titanium(IV) butoxide was added. The mixture was refluxed for 6 h. After cooling the mixture and the crude brownish green product was precipitated by addition of hexane and then the product was purified with column chromatography [silica gel, eluent CH_2Cl_2/MeOH, 15:1 (v/v)]. Yield: 95 mg (12%). *Anal.* Calc. for $C_{88}H_{128}N_8O_{25}S_8Ti$ (2001): C, 52.78; H, 6.44; N, 5.60. Found: C, 52.90; H, 6.48; N, 5.30%. IR (KBr): ν_{max} (cm^{-1}) 2925–2858 (CH_2, CH_3), 1592 (C_{ar}=N), 1530, 1352 (C–N), 1290, 1250, 1200, 1120 (C–O–C), 1140–1070, 949 (Ti=O). MS (ES-MS), *m*/*z* (%): 2002 (100) $[M+H]^+$, 1824 (25) $[M-6(OCH_3)]$. ^1H NMR (500 MHz, $CDCl_3$): δ 3.43 (s, 24H, CH_3), 3.53 (t, 16H, CH_2), 3.65 (t, 16H, SCH_2), 3.73 (t, 16H, CH_2), 3.76 (t, 16H, CH_2), 3.85 (t, 16H, CH_2), 4.11 (t, 16H, CH_2), 9.12 (s, 8H, CH_{ar}). ^{13}C NMR (500 MHz, $CDCl_3$): δ 34.35 (SCH_2), 57.45 (CH_3), 69.50 (CH_2), 70.18 (CH_2), 70.30 (CH_2), 70.50 (CH_2), 71.80 (CH_2), 122.05 ($C_{ar}H$), 138.12 (C_{ar}), 139.60 (C_{ar}–S), 158.10 (C_{ar} C=N).

2.3. Dark conductivity and photoconductivity measurements

The conductivity measurements were carried out on the Pc thin films deposited on a photolithographically patterned microelectrode array on a glass substrate. This array consisted of 10 interdigital pairs of gold fingers, evaporated in a Leybold Univex 450 coater system equipped with an Inficon Deposition Monitor (XTM/2), with a thickness of 120 nm, 100 μm wide and spaced 100 μm from the next finger, called interdigital electrodes (IDE). The overlapping length of the IDEs was 5 mm. The coating solutions containing oxotitanium(IV) phthalocyanines (**1a** and **2a)** were prepared as 5 mg of Pc per 2 ml chloroform which were deposited on the interdigital electrodes with the jet-spray method in a glove box in nitrogen atmosphere at room temperature. Compounds **1a** and **2a** form liquid crystals layers at room temperature. After coating the samples slowly adopt a mesophase without annealing and form homogenous layers. Generally, liquid crystals are so flexible that they can be spread uniformly on a plate and between two electrodes.

Dark current and photocurrent measurements of **1a** and **2a** under different conditions (such as in vacuum, atmosphere, 0–35% oxygen in nitrogen) at room temperature (the room is air conditioned and hold at temperature of 20 °C and relative humidity 35% RH) were carried out in a stainless steel chamber with electrical feedthrough, a quartz optic window for photoconductivity investigations and valves for adjusting partial pressure of oxygen. The *I*–*V*

characteristics were recorded with a sweep rate of 50 mV/s starting from 0 V to +1 V, from +1 V to −1 V and from −1 V to 0 V as a cycle with a Keithley 6517A Electrometer/High Resistance Meter.

The conductivity can be calculated from the *I–V* curves using the equation

$$\sigma = \frac{1}{V}\frac{d}{(2n-1)l\cdot h} \quad (1)$$

where d is spacing between fingers, n is the number of fingers, h is thickness of fingers and l is the overlapping length of the fingers [22].

For photoconductivity measurements the samples in the measurement chamber were irradiated by a 100 W halogen tungsten lamp through a monochromator. The light coming through the monochromator was focused onto the sample making sure that the region between the two electrodes is fully illuminated. Light intensities for different wavelengths were measured by a Lumacare Fiber Optic Probe. The photoconductivity data were calculated from photocurrent measurements and normalized dividing by normalized intensities. The photocurrent of the samples biased at +1.0 V were obtained by directing monochromatic light from a halogen lamp onto the sample under different conditions (in vacuum, atmosphere, 0–35% oxygen in nitrogen) at room temperature. During the measurement, the data were recorded to a computer using a home made program. For oxygen measurements, the desired oxygen concentration in nitrogen flowed through the measurement chamber until the oxygen diffusion reaches a steady state (ca. 1 h) [20].

2.4. Computational method

In the present study, the structures of the oxotitanium compounds **1a** and **2a** were subjected to geometry optimization using PM3 type semi-empirical quantum chemical method. All calculations were carried out at Hartree–Fock level with no configuration interaction [21]. The geometry optimizations were achieved using the steepest descent technique followed by the Polak Ribiere algorithm which is one of the conjugate gradient method until the root mean square (RMS) gradient was permanently staying less than 0.01 [22] .

Using the optimized structures, UV–Vis spectra have been calculated using ZINDO/S method [23–27]. ZINDO/S singly excited configuration interaction (CI) calculations involving 10 of each the uppermost occupied and the lower most unoccupied molecular orbital with the overlap weighting factors 1.267 and 0.585 for s–s and p–p types, respectively [28].

3. Results and discussion

3.1. Synthesis and characterization

The alkylthia substituted phthalocyaninatotitanium(IV) oxides (**1a** and **2a**) are obtained from the dinitrilles **1** [9] and **2** [10], urea and titanium(IV) butoxide in 1-pentanol, under the conditions given in Scheme 1.

The ^{1}H and ^{13}C NMR spectra of the phthalocyanine compounds **1a** and **2a** in $CDCl_3$ confirmed the proposed structure. The ^{1}H NMR spectra of **1a** and **2a** have broad absorptions relative to those of the phthalonitrile derivatives. It is likely that broadness is due to both chemical exchange caused by aggregation–disaggregation equilibrium. The phthalocyanines were found to be pure by ^{1}H NMR spectroscopy with all the substituents and ring protons observed in their respective regions. In the IR spectra the disappearance of the dinitrile stretches at ca. 2230 cm^{-1} and the presence of Ti=O stretching at ca. 960 cm^{-1} confirmed the formation of MPc.

In the electronic spectrum of the phthalocyanine derivatives (**1a** and **2a**) show intense Q absorption bands about 730 nm (Table 1). The effect of the central metal ion appears as a shift of these intense Q bands to higher wavelengths in comparison with their nickel and metal free derivatives [9,10].

3.2. The mesogenic properties of the oxotitanium complexes (*1a* and *2a*)

The phase transition temperatures were determined by differential scanning calorimetry (DSC). The DSC measurements were performed on the virgin materials with scanning rate of 10 °C min^{-1}. The DSC-measurements of **2a** show no significant sharp peaks representing melting or any other phase transition from −30 °C to 200 °C. Ni derivatives of **2a** were shown similar behavior in the DSC measurement [10]. This investigation indicates that compound **2a** exhibits a thermotropic liquid crystalline phase in the measured temperature range. The heating cycle was interrupted before reaching any clearing point to avoid decomposition However, the thermogram of compound **1a** recorded with increasing temperature showed clearly two endothermic peaks. We assume that the first peaks are related to the transitions from the crystal phases to discotic mesophases, and the second ones to the transitions from discotic mesophases to isotropic liquid phases. Phase transition temperatures and the corresponding enthalpy changes of the Pc complexes (**1a** and **2a**) are summarized in Table 2.

Also, the phase transition temperatures of the complexes (**1a** and **2a**) have been surveyed by polarization microscopy. Fig. 1 shows the photomicrograph of the mesophase of **2a** at 120 °C. For this typical fan-shaped texture often observed for Col_h, these mesophases could be thus confirmed as the Col_h phases [9–11,29].

A decrease in the melting point and an increase in the clearing temperatures was observed for the coordination of Ti^{4+} for **1a** in comparison with their Ni(II) and free derivatives [9]. It could be seen that coordination of Ti^{4+} to the phthalocyanine core extend the temperature range between mesophase and isotropic phase.

3.3. Dark conductivity

The dark conductivities of the compounds under different conditions (in vacuum, atmosphere, 0–35% oxygen in nitrogen were calculated from *I–V* curves using Eq. (1). The devices measured were operating in the ohmic region of the *I–V* characteristics in vacuum and in nitrogen ambient. With increasing oxygen concentration, space charge limited behavior and hysteretic effect were observed. This effect may be caused by ion migration and/or polarization in sample after oxygen exposure. As a typical example, the *I–V* characteristics of **1a** in the various ambient are shown in Fig. 2. Hysteresis widths are 0.03 V, 0.03 V, 0.05 V, 0.17 V, 0.26 V, 0.28 V and 0.39 V for vacuum, nitrogen, 5% oxygen, 15% oxygen, atmosphere, 25% oxygen and 35% oxygen ambient, respectively. The dark conductivities of samples are calculated using a linear fit of the *I–V* curves as σ_d = 8.68E−12 S/cm for **1a** and σ_d = 6.56E−11 S/cm for **2a** in vacuum and σ_d = 1.51E−11 S/cm for **1a** and σ_d = 2.95E−10 S/cm for **2a** in 35% oxygen in nitrogen. The dark current increases with increasing oxygen concentration slowly for both compounds (Fig. 6). The increase of dark conductivity with oxygen concentration is reversible; if we remove the oxygen in the ambient the dark current goes the vacuum level.

3.4. Photoconductivity

Figs. 3 and 4 show the photoconductivity curves of **1a** and **2a** versus wavelength for the different measurement conditions, respectively. Compounds **1a** and **2a** demonstrate a pronounced

photoconductivity response under visible light illumination. The photoconductivities of both compounds **1a** and **2a** calculated as $\sigma_{Ph} = 1.33 \times 10^{-11}$ S/cm and $\sigma_{Ph} = 9.1 \times 10^{-11}$ S/cm in vacuum and $\sigma_{Ph} = 7.24 \times 10^{-11}$ S/cm at 35% oxygen in nitrogen media at 680 nm and $\sigma_{Ph} = 1.09 \times 10^{-9}$ S/cm at 35% oxygen in nitrogen media at 740 nm using Eq. (1), respectively. In the ambient with 35% oxygen in nitrogen, the photoconductivity values of the compounds are greater than the dark conductivity values with a factor of 4 for **1a** and with a factor of 10 for **2a**. Compared each other σ_{Ph} of **2a** is greater 2–3 times than σ_{Ph} of **1a**. The oxygen induced increase of σ_{Ph} is also completely reversible; the current goes the value of photocurrent in vacuum.

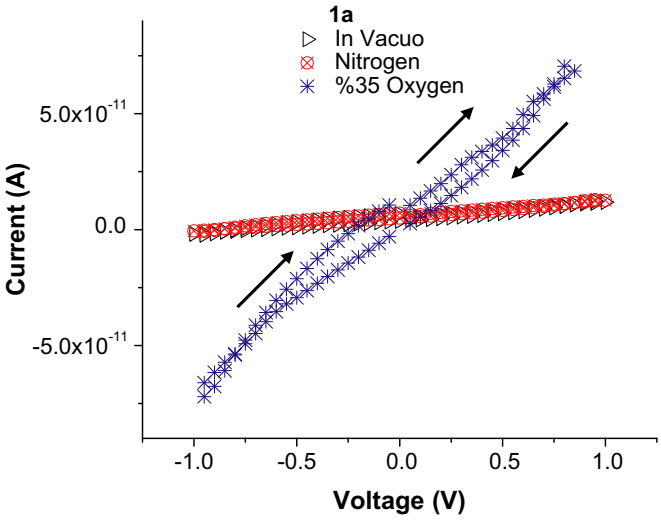

Fig. 2. *I–V* characteristics of **1a** in the various ambient.

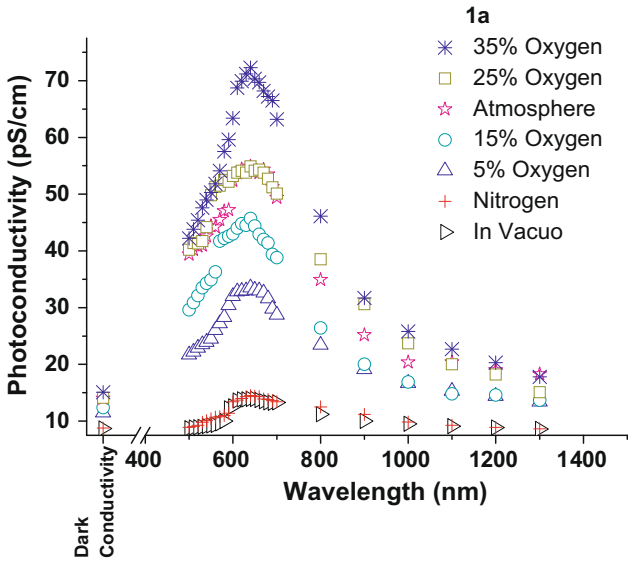

Fig. 3. Photoconductivity curves of **1a** function of wavelength.

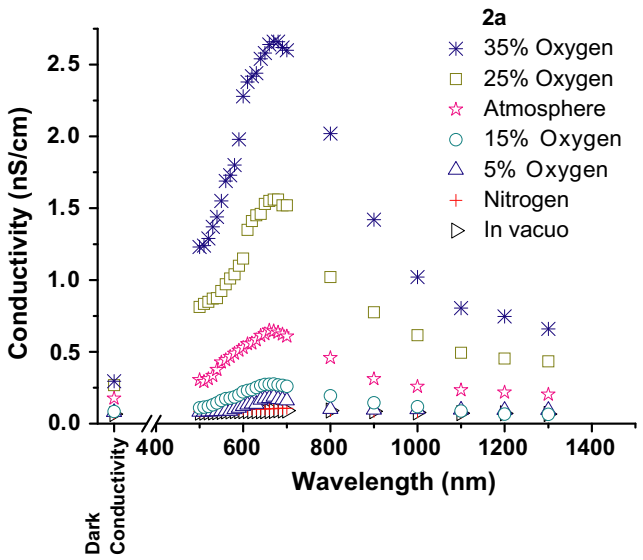

Fig. 4. Photoconductivity curves of **2a** function of wavelength.

Fig. 5 presents optical absorption spectra for the solution of TiOPc derivatives in dichloromethane and as-deposited films on quartz substrates. TiOPc derivatives in dichloromethane show Q bands as intense peaks at 727 and 733 nm with shoulders around 633, 659 and 699 nm for the derivatives **1a** and **2a**, respectively. The Q band in the films became broadened and the maxima were blue shifted to 705 and 689 nm for compounds **1a** and **2a**, respectively. The spectra of thin films are broader and they are shifted to longer wavelengths. The spectra of **1a** and **2a** suggest that they would be sensitive to visible sources. Because of low molecular weight, phthalocyanines are in the visible region of light absorbing semiconductors; photoconducting behavior is observed under irradiation [7]. Corresponding peaks observed in both UV–Vis and photoconductivity spectra of the TiOPc film in the range of 300–800 nm confirm that photoconductivity is generated via the excitation of TiOPc molecules.

Fig. 6 shows dark conductivity and photoconductivity curves of **1a** (a) and **2a** (b) exposed to different oxygen concentration at ambient atmosphere. The dark conductivities undergo a nearly 2-fold increase for **1a** and 4-fold increase for **2a** with increasing oxygen content whereas the values of photoconductivity undergo a nearly 5-fold increase for **1a** and 20-fold increase for **2a** with increasing oxygen content. The increase in σ_{Ph} is clearly correlated to the oxygen concentration. Compound **2a** offers rather intense photoconductivity as probe for the interaction with oxygen. When compared to the influence of substitution with alkoxy and polyoxo group upon the electrical properties of the Pc derivatives **1a** and **2a** the photoconductivity of **2a** substituted with polyoxo was higher than that of the alkoxy derivatives. The high photoconductivity of **2a** is thought to be caused by electronegative effects of oxygen atoms in the substitute group on phthalocyanine ring.

3.5. Computational works

PM3 Hamiltonian optimized structures of TiOPc molecules used in ZINDO/S calculations can regenerate excellent results. Excited-state energies of two TiOPc molecules have been calculated using ZINDO/S method as summarized in Table 3. Compound **2a** has the longest wavelength transition at 738 nm which corresponds to $\pi \rightarrow \pi^*$ transition (HOMO → LUMO). The introduction of polyoxo chains in **2a** can lead to extent the conjugation of Pc core. The strong electronegativity of oxygen atoms in polyoxo chains are

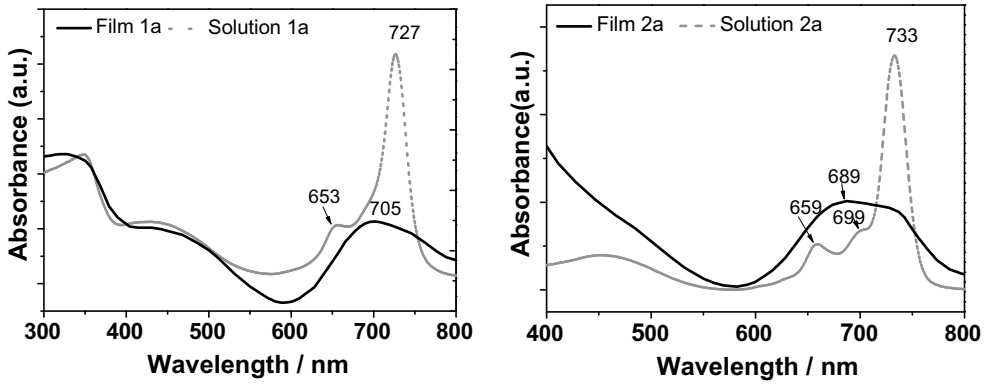

Fig. 5. Absorption spectra of **1a** and **2a** in dichloromethane and the films.

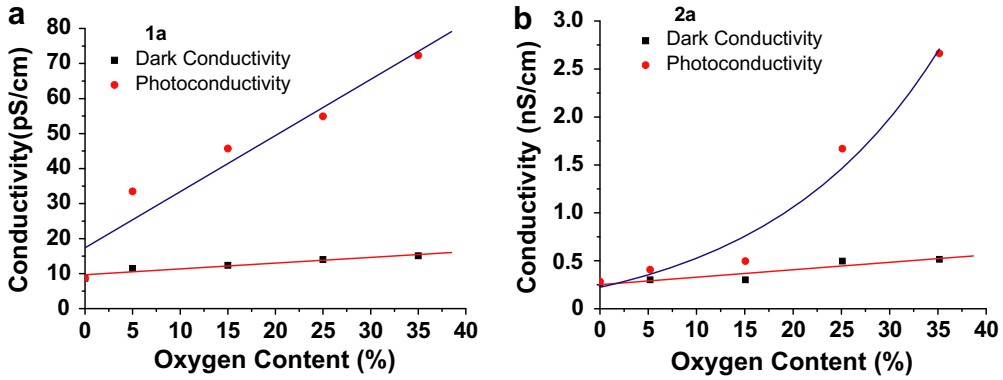

Fig. 6. Dark conductivity and photoconductivity curves of **1a** (a) and **2a** (b) exposed to different oxygen concentration at ambient atmosphere.

responsible from that effect. The extension of the conjugation can also cause the interfrontier molecular orbital energy gap (HOMO–LUMO energy difference) to narrow as compared to **1a** which is equivalent to a bathochromic shift in **2a** (Table 4). The HOMO–LUMO gap differences between **1a** and **2a** is about 3.41 kJ/mol (0.0354 eV). The charges on Ti and O (bonded to Ti) atoms are an evident to the extension of the conjugation. The dipole moments at the ground and first excited states were calculated using PM3 method (Table 5). The large dipole moment difference between the ground and first excited state results in increase in photoconductivity [30].

Another reason to higher photoconductivity of **2a** can be attributed to the larger difference dipole moment, $\Delta\mu$, value of compound **2a**. The quantum chemical calculations have been carried out to shed light on the oxygen induced increase of photoconductivity in substituted TiOPc's, **1a** and **2a** (Table 6). The predominant mechanism for charge-carrier formation is based on an oxygen-induced charge separation enhanced by illumination. Holes are charge carriers whilst electrons are trapped on a phthalocyanine oxygen complex. The positive charge carrier Pc^+ display very different behavior as seen Table 6. The oxygen-induced increase of photoconductivity in TiOPc's is due to the enhanced formation of charge carriers, Pc^+, by TiOPc–oxygen exciplexes, $(Pc^{\delta+}O_2^{\delta-})^*$, which are formed by the trapping of singlet excitons, Pc^*, at weakly bound charge-transfer adducts between TiOPc and oxygen (PcO_2) [31] (see Eq. (2)).

$$Pc, O_2 \xrightarrow{h\nu} Pc^*, O_2 \rightarrow \underset{(\text{hole})}{Pc^{\delta+}} \cdot O_2^{\delta-} \quad (2)$$

The effect of oxygen doping on the photoconductivity of differently substituted TiOPc compounds can clearly be seen in this study. The molecule, such as **1a**, is substituted with bulky group

or contains highly branching substituent may not allow the hopping electron between the two TiOPc molecules. More bulky structure (**1a**) has larger distances between the TiOPc molecules comparing to structure which is much less branching (**2a**). It increases the activation barrier of electron hopping which is strongly distance dependent parameter and can be elucidated on the basis of Marcus theory [32]. Furthermore, it weakens intermolecular π-π interactions resulting in to reduced propensity of crystallization and increased distance between the conjugated phthalocyanine cores. As a result, charge and energy transfer are rigorously diminished. Oxygen diffusion should be taken into account when the oxygen doping photoconductivity is elaborately discussed. Oxygen diffusion into the TiOPc molecules can also be severely effected by highly branched structures due to possible longer diffusion channel in those structures [33].

3.6. Comparision of conductivity measurements and computational results

We explored the effect of oxygen concentration on the dark and photoconductivity of differently substituted oxotitanium(IV) phthalocyanines under the same conditions. The present experimental results have shown that the electrical dark conductivities and photoconductivities of oxotitanium(IV) phthalocyanine derivatives increase with increasing oxygen concentrations. Theoretical calculation's results agree well with the observed results. Electrical dark and photoconductivities of vapor deposited films of unsubstituted oxotitanium phthalocyanine were investigated as a function of oxygen of variable pressure by Lüer et al. [23]. The dark conductivity value was obtained as 1×10^{-13} S/cm for unsubstituted TiOPc. Dark conductivity values of **1a** and **2a** obtained by us are nearly 100 times higher than obtained by Lüer at al. Fig. 7 shows calculated orbital energies of unsubstituted TiOPc [34] and neutral and positively charged **1a** and **2a** at their ground states. The HOMO–LUMO energy differences are −3.853 eV, −3.2798 eV and −3.7149 eV for unsubstituted TiOPc, **1a** (neutral) and **2a** (neutral), respectively. The narrower HOMO–LUMO gap of **1a** and **2a** stem from oxygen atoms in polyoxo chains. It results in higher dark conductivity. In the another work, alkyl substituted TiOPc films were studied by following the increase of electric photoconductivity of the films under fine vacuum during oxygen sorption and the photoconductivity was obtained as 4.27×10^{-11} S/cm by Lüer et al. [35]. We obtained photoconductivity curves of **1a** and **2a** exposed to different oxygen concentrations in nitrogen at atmospheric pressure. Photoconductivity values of **2a** were calculated as $\sigma_{Ph} = 9.1 \times 10^{-11}$ S/cm in vacuum and $\sigma_{Ph} = 1.09 \times 10^{-9}$ S/cm at 35% oxygen in nitrogen. Photoconductivity values obtained by us are slightly higher than the values obtained by Lüer.

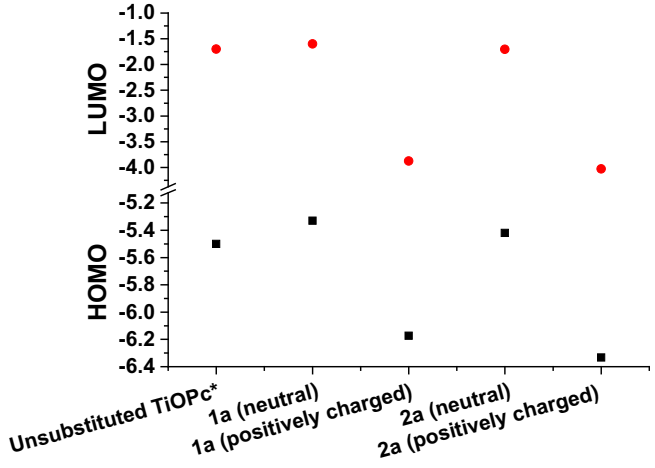

Fig. 7. Calculated orbital energies of TiOPc derivatives (* from [34]).

4. Conclusion

In the present work, the synthesis of the alkylthia and triethyleneoxysulfonyl substituted oxotitanium(IV) phthalocyanines was described. The oxotitanium(IV) phthalocyanine derivatives exhibit a hexagonal columnar (Col_h) structure. The electrical dark conductivities and photoconductivities of oxotitanium(IV) phthalocyanine derivatives were investigated as a function of the atmosphere containing different oxygen concentrations. The interaction of oxygen results from a reversible interaction with Pc, which is photo assisted. This interaction enhances rates of exciton dissociation, enhances photoconductivity. These comparative findings have been rationalized by computational methods. Electronic spectra, dipole moment, HOMO, LUMO energies and atomic charges of two susbstituted oxotitanium(IV) phthalocyanine molecules have been studied for clarification of the oxygen effect on the photoconductivity using PM3 and ZINDO/S methods. In general, our results are in good agreement with the spectroscopic experimental data and conductivity measurements. Our theoretical study of excited states and electronic spectra of substituted oxotitanium(IV) phthalocyanine molecules has shown that the electronic absorption spectra and HOMO–LUMO gap, dipole moments of the corresponding neutral and positively charged molecules clearly describe the distinctions between the oxygen-doped photoconductivity and dark conductivity. The effects of different substitution on photoconductivity of oxotitanium(IV) phthalocyanine molecules can be demonstrated by theoretical calculations as good as in experimental data. When compared to alkyl chain (**1a**) and polyoxo ethylene chain (**2a**) substitution, increasing of the number of oxygen atoms in substitute group increases the photoconductivity.

Acknowledgements

This work was supported by Research Fund of Gebze Institute of Technology (Project No.: 2006-A-07) and the authors wish to thank Colette Lebrun (CEA-Grenoble) for the mass spectra.

EI-MS (*m*/*z*): 304 (39.0%) [HL], 183 (33.6%) [O=C–$C_6H_6 \cdot SO_2NH_2$, 120 (100%) [py–C=N–NH]. ^1H NMR (DMSO-d_6, ppm): δ 12.33 [s, 1H, NH(I)]; 12.11 [s, 1H, OH(II)]; 8.61 [d, 1H(α), H(αpy(I)], 8.49 [d, 1H, H(αpy(II)]; 8.30 [s, 1H, CH=N(I)], 8.06 [s, 1H, CH=N(II)]; 8.01–7.30 [m, 8H, aromatic]; 7.23 [s, 2H, SO_2NH_2(II)]; 7.15 [s, 2H, SO_2NH_2(I)]. ^{13}C NMR (DMSO-d_6, ppm): δ 170 and 164 (C–O), 152.6 and 152.3 [C=N], 149.3 and 149.1 [C(2)-py], 148.4 [C(6-py)]; signals at δ = 143.8–119.8 ppm were assigned to the phenyl or pyridine group.

2.3. Synthesis of the complexes

All of the complexes were prepared by an electrochemical procedure [11]. The cell consisted of a metal anode suspended from a platinum wire and the cathode was also a platinum wire. The ligand was dissolved in acetonitrile and a small amount of tetraethylammonium perchlorate was added to the solution as a supporting electrolyte (*Caution*: perchlorate compounds are potentially explosive and should be handled in small quantities and with great care). Applied voltages of 10–15 V allowed sufficient current flow for smooth dissolution of the metal. During electrolysis, nitrogen was bubbled through the solution to provide an inert atmosphere and also to stir the reaction mixture. Under these conditions, the electrochemical cell can be summarized as

$$M_{(+)}/CH_3CN + HL/Pt_{(-)}; M = Co, Ni, Cu, Zn, Cd.$$

2.3.1. $[CoL_2]$

Electrochemical oxidation of a cobalt anode in a solution of HL (0.202 g, 0.661 mmol) and Et_4NClO_4 (*ca.* 20 mg) in acetonitrile (40 mL) at 12 V and 10 mA for 1.75 h caused 18.8 mg of cobalt to be dissolved; E_f = 0.49 mol F^{-1}. During the electrolysis hydrogen was evolved at the cathode and at the end of the reaction a brown crystalline solid appeared at the bottom of the vessel. The solid was filtered off, washed with acetonitrile and ether, dried under vacuum and characterized as $[CoL_2]$. *Anal.* Calc. for $C_{26}H_{22}N_8O_6S_2Co$ (mol. wt. 665.56): C, 46.9; H, 3.3; N, 16.8; S, 9.6. Found: C, 46.6; H, 3.6; N, 16.6; S, 9.6%. IR (cm^{-1}): 1606(s), 1570(s), 1560(s), 1491(s), 1458(s), 1430(s), 1343(s), 1163(s). FAB MS: *m*/*z*: 666.0 (79.0%) (CoL_2). Crystals of $[CoL_2]$ (**1**) suitable for X-ray analysis were obtained by crystallization of the initial product from 1:1 isopropanol/dichloromethane.

2.3.2. $[NiL_2] \cdot 2.5(CH_3CN)$

Following a similar procedure to that described above, starting from a nickel anode, HL (0.200 g, 0.660 mmol) and Et_4NClO_4 (*ca.* 25 mg) in acetonitrile (40 mL), at 15 V and 10 mA for 1.75 h, 18.0 mg of nickel were dissolved from the anode, E_f = 0.48 mol F^{-1}. At the end of the electrolysis the resulting solution was filtered to remove insoluble impurities and concentrated to give a brown crystalline solid. The solid was filtered off, washed with acetonitrile and ether, dried under vacuum and characterized as $[NiL_2] \cdot 2.5(CH_3CN)$. *Anal.* Calc. for $C_{31}H_{24.5}N_{10.5}O_6S_4Ni$ (mol. wt. 767.95): C, 48.9; H, 3.9; N, 19.1; S, 8.3. Found: C, 48.4; H, 3.8; N, 19.2; S, 8.2%. IR (cm^{-1}): 1562(s), 1608(s), 1493(s), 1460(s), 1433(s), 1346(s), 1163(s). FAB MS: *m*/*z*: 665.0 (6.12%) (NiL_2). Crystals of $[NiL_2] \cdot 2.5(CH_3CN)$ **(2)** suitable for X-ray analysis were obtained from the mother liquor.

2.3.3. $[CuL_2]$

Electrolysis of a solution of the ligand (0.207 g, 0.67 mmol) and a small amount of Et_4NClO_4 in acetonitrile (40 mL) at 10 V, 10 mA for 1.75 h dissolved 41.7 mg of Cu, E_f = 1.0 mol F^{-1}. The solution changed from colourless to green and at the end of the electrolysis the green solid was filtered off, washed with acetonitrile and ether, dried under vacuum and characterized as $[CuL_2]$. *Anal.* Calc. for $C_{26}H_{22}N_8O_6S_2Cu$ (mol. wt. 670.18): C, 46.7; H, 3.3; N, 16.8; S, 9.6. Found: C, 46.0; H, 3.5; N, 16.2; S, 9.2%. IR (cm^{-1}): 1606(s), 1571(s), 1565(s), 1491(m), 1459(s), 1433(s), 1343(s), 1161(s). FAB MS: *m*/*z*: 670.0 (11.87%) (CuL_2). Crystals of $[CuL_2] \cdot 2(CH_2Cl_2)$ **(3)** suitable for X-ray studies were obtained by crystallization of the initial product from 1:1 hexane/dichloromethane.

2.3.4. $[ZnL_2]$

HL (0.201 g, 0.66 mmol), acetonitrile (50 mL), Et_4NClO_4 (*ca.* 20 mg), 15 V, 10 mA, 1.75 h, 22.0 mg of Zn dissolved, E_f = 0.51 mol F^{-1}. At the end of the reaction the crystalline solid was filtered off, washed with acetonitrile and ether, dried under vacuum and characterized as $[ZnL_2]$. *Anal.* Calc. for $C_{26}H_{22}N_8O_6S_2Zn$ (mol. wt. 672.01): C, 46.5; H, 3.3; N, 16.7; S, 9.5. Found: C, 46.9; H, 3.4; N, 16.9; S, 9.5%. IR (cm^{-1}): 1598(s), 1565(s), 1498(s), 1462(s), 1434(s), 1345(s), 1163(s). ^1H NMR (DMSO-d_6, ppm): δ 8.80 [s, 1H, CH=N]; 8.14 [d, 1H, H(α-Npy]; 8.05–7.46 [m, 8H, aromatic], 7.51 [s, 2H, SO_2NH_2]. FAB MS: *m*/*z*: 670.9 (11.45%) (ZnL_2). Crystals of $[ZnL_2]$ **(4)** suitable for X-ray studies were obtained by crystallization of the initial product from 1:1 methanol/dichloromethane.

2.3.5. $[CdL_2] \cdot CH_3CN$

HL (0.201 g, 0.66 mmol), acetonitrile (50 mL), Et_4NClO_4 (*ca.* 25 mg), 12 V, 10 mA, 1.75 h, 38.6 mg of cadmium dissolved, E_f = 0.52 mol F^{-1}. At the end of the reaction the solution was filtered and concentrated in air to give crystals of $[CdL_2] \cdot CH_3CN$. *Anal.* Calc. for $C_{28}H_{25}N_9O_6S_2Cd$ (mol. wt. 760.09): C, 44.2; H, 3.3; N, 16.6; S, 8.4. Found: C, 44.2; H, 3.0; N, 16.7; S, 8.8%. IR (cm^{-1}): 1594(s), 1563(s), 1497(s), 1461(s), 1437(s), 1344(s), 1161(s). ^1H NMR (DMSO-d_6, ppm): δ 8.67 [s, 1H, $^3J(^{113}Cd–^1H)$ = 42.4 Hz, CH=N]; 8.32 [d, 1H, H(α-Npy]; 7.98–7.44 [m, 8H, aromatic], 7.63 [s, 2H, SO_2NH_2]. FAB MS: *m*/*z*: 720.0 (2.42%) (CdL_2). Crystals of $[CdL_2] \cdot CH_3CN$ **(5)** suitable for X-ray analysis were obtained from the mother liquor.

2.4. X-ray crystallographic studies

Intensity data sets for all compounds were collected using a Siemens Smart-CCD-1000 Bruker diffractometer (Mo Kα radiation, λ = 0.71073 Å) equipped with a graphite monochromator. Crystals of **1**, **3** and **5** were measured at 293 K while **2** and **4** were measured at 120 K. Compounds **2** and **4** are isostructural and the unit cell parameters are practically identical. The asymmetric unit of **2** contains two complex molecules and five acetonitrile molecules of crystallization. The asymmetric unit of **4** also contains two complex molecules and five acetonitrile molecules, although in this case the poor quality of the diffraction data did not allow the posi-

tions of these molecules to be resolved clearly. As a result, in this case the solvent was removed from the structure using the SQUEEZE program [12] implemented in PLATON [13]. In an analogous way, the crystal structure of the cobalt complex **1** has two complex molecules per asymmetric unit and disordered solvent molecules in the voids in the crystal lattice, although once again the poor quality of the diffraction data made refinement of these solvent units impossible and these were removed from the structure using the aforementioned program. In any case, analysis of the holes in the structure seems to indicate that the network contains 1.5 molecules of isopropanol, half a molecule of dichloromethane and one molecule of water per asymmetric unit. Each of the two complex molecules in the asymmetric unit in the crystal structures of compounds **1**, **2** and **4** have very similar structural parameters to each other.

The ω scan technique was employed to measure intensities in all crystals. Decomposition of the crystals did not occur during data collection. The intensities of all data sets were corrected for Lorentz and polarization effects. Absorption effects in all compounds were corrected using the program SADABS [14]. The crystal structures of all compounds were solved by direct methods. Crystallographic programs used for structure solution and refinement were those of SHELX97 [15]. Scattering factors were those provided with the SHELX program system. Missing atoms were located in the difference Fourier map and included in subsequent refinement cycles. The structures were refined by full-matrix least-squares refinement on F^2. Hydrogen atoms were placed geometrically and refined using a riding model with U_{iso} constrained at 1.2 (for non-methyl groups) and 1.5 (for methyl groups) times U_{eq} of the carrier C atom. For all structures non-hydrogen atoms were anisotropically refined. In the last cycles of refinement of all structures a weighting scheme was used, with weights calculated using the following formula $w = 1/[\sigma^2(F_o^2) + (aP)^2 + bP]$, where $P = (F_o^2 + 2F_c^2)/3$.

Pertinent details of the data collections and structure refinements are collected in Table 1. Further details regarding the data collections, structure solutions and refinements are included in the Supplementary data. ORTEP3 drawings [16] with the numbering schemes used are shown in Figs. 1–5.

3. Results and discussion

3.1. Synthesis

Metal complexes were easily prepared in good yield by oxidation of the metal anode in a cell containing a solution of the ligand (HL) in acetonitrile and a small amount of tetraethylammonium perchlorate as an electrolytic carrier. The compounds were obtained as crystalline solids at the bottom of the cell.

The *electrochemical efficiency*, E_f, defined as the number of moles of metal dissolved per Faraday of charge, was close to 0.5 mol F^{-1} for the Co, Ni, Zn and Cd complexes. These values, along with the evolution of hydrogen at the cathode, are compatible with the following mechanism:

$$\text{Cathode}: 2HL + 2e^- \rightarrow 2L^- + H_2$$

$$\text{Anode}: M \rightarrow M^{2+} + 2e^-$$

$$\text{Solution}: M^{2+} + 2L^- \rightarrow [ML_2]$$

M = Co, Ni, Zn, Cd

In the synthesis of the copper complex the electrochemical efficiency was close to 1.0 mol F^{-1}. This is compatible with an anodic oxidation to Cu(I) and deprotonation of the ligand at the cathode:

$$\text{Cathode}: HL + e^- \rightarrow L^- + 1/2H_2$$

$$\text{Anode}: Cu + L^- \rightarrow [CuL] + e^-$$

followed by oxidation to Cu(II) in solution:

$$[CuL] + HL \rightarrow [CuL_2] + 1/2H_2$$

Similar behaviour has already been observed in other copper systems in which low oxidation state species are the initial products [17].

The complexes are stable to air and moderately soluble in common organic solvents. They were characterized by microanalysis, IR spectroscopy, mass spectrometry and X-ray diffraction. The zinc and cadmium complexes were also studied in solution by ^1H NMR spectroscopy and the cobalt, nickel and copper complexes were analysed by UV–Vis spectroscopy.

3.2. Description of the structures

All metal compounds were studied by X-ray diffraction. The crystal parameters and experimental details for data collection are given in Table 1. Bond distances and angles for all these compounds are provided as Supplementary data. Figs. 1–5 show the molecular structure of the complexes along with the numbering schemes employed. In order to make direct comparison easier, the numbering schemes are the same for each compound. Given the great similarities between the complexes they will be discussed together in a comparative manner. A selection of bond distances and angles, with the estimated standard deviations, are given in Tables 2–6.

N(6)–Zn(1)–N(7)	75.75(15)	N(14)–Zn(2)–N(15)	76.54(18)

The structures of compounds consist of monomer units with the metal atoms bonded to two monoanionic tridentate ligands that are coordinated to the metal through two nitrogen atoms and the oxygen atoms. In all cases the environment around the metal is distorted octahedral. Coordination of the ligand to the metal gives rise to the formation of two five-membered rings with O–M–N chelate angles in the range 68.5(5)–77.89(12)° and N–M–N chelate angles in the range 65.6(6)–79.91(14)°, in both cases these values are low and outside the theoretical value expected for a regular geometry. These angles are the main cause of distortion from a regular octahedral geometry. The disposition of the two ligands in each of the complexes is such that the meridional isomer is obtained, probably due to the rigidity of the tridentate ligands. In this way each complex has two *trans* O–M–N bond angles in the range 131.7(5)–157.77(13)°, where donor atoms from the same ligand are involved, and a *trans* N–M–N bond angle in the range 163.6(5)–178.52(15)°, which involves donor atoms from two different ligands. All of the values are significantly different to the theoretical value of 180° expected for a regular geometry.

Table 6
Selected bond distances and angles for $[CdL_2] \cdot CH_3CN$ **(5)**

Cd(1)–O(1)	2.321(9)	Cd(1)–N(3)	2.410(11)
Cd(1)–O(4)	2.358(10)	Cd(1)–N(6)	2.285(18)
Cd(1)–N(2)	2.252(11)	Cd(1)–N(7)	2.360(12)
N(2)–Cd(1)–N(6)	163.6(5)	N(6)–Cd(1)–N(7)	65.6(6)
O(1)–Cd(1)–N(2)	69.0(4)	O(1)–Cd(1)–N(7)	95.1(4)
O(1)–Cd(1)–N(6)	123.2(5)	O(4)–Cd(1)–N(7)	131.7(5)
O(4)–Cd(1)–N(2)	100.5(4)	N(2)–Cd(1)–N(3)	70.4(4)
O(4)–Cd(1)–N(6)	68.5(5)	N(3)–Cd(1)–N(6)	98.1(5)
O(1)–Cd(1)–O(4)	97.3(4)	O(1)–Cd(1)–N(3)	138.7(4)
N(2)–Cd(1)–N(7)	127.4(5)	O(4)–Cd(1)–N(3)	96.8(4)

Three different types of bond distance can be found in the complexes and these correspond to the three types of donor atom that exist in the ligand (Table 7). With the exception of the cadmium complex, the similar covalent radii for the different metals mean that these bond distances in the different complexes are very similar, regardless of the metal in question. It is worth pointing out the existence of two bond distances in the copper complex, Cu(1)–O(1) 2.322(3) Å and Cu(1)–N(3) 2.309(4) Å (Table 4), clearly longer than the other four, in the range 1.926(3)–2.082(4) Å, as the result of the tetragonal distortion experienced by the complex due to the Jahn–Teller effect, which is typical copper(II) complex with an octahedral environment.

In general, all of the bond distances between metals and the donor atoms in question can be considered normal and are similar to those found in other compounds that contain similar monoanionic tridentate hydrazine ligands (HL′) with the metal in an octahedral environment. For example, $[NiL'_2]$ complexes with these types of ligand have Ni–O, Ni–N(iminic) and Ni–N(pyridinic) bond distances in the ranges 2.134–2.086 Å, 1.992–1.974 Å and 2.132–2.078 Å, respectively [18], and these are very similar to those in complex **2**. Analogous zinc complexes $[ZnL'_2]$ with this type of ligand show values for these three distances in the ranges 2.138–1.947 Å, 2.077–2.038 Å and 2.268–2.044 Å, respectively [19,18d], which are also very close to those found in the complex reported here. In copper complexes $[CuL'_2]$, the existence of two significantly longer bond lengths is a characteristic feature of these complexes [20]. Structural data for cobalt and cadmium complexes with this stoichiometry are not available in the literature, but values are

Table 7
Summary of selected bond lengths (Å) for the complexes (average values)

	[1]	[2]	[3]	[4]	[5]
M–O	2.105(3)	2.090(7)	2.187(3)	2.144(8)	2.340(9)
M–N(imine)	2.022(3)	1.971(9)	1.949(3)	2.055(8)	2.269(11)
M–N(pyridine)	2.134(4)	2.081(9)	2.196(4)	2.174(5)	2.385(12)
C=N(imine)	1.276(5)	1.278(12)	1.277(6)	1.282(6)	1.286(16)
C–N(amide)	1.320(5)	1.338(13)	1.320(6)	1.333(7)	1.329(16)
N–N	1.380(4)	1.395(12)	1.388(5)	1.380(6)	1.375(15)
C–O	1.276(5)	1.294(12)	1.272(5)	1.275(6)	1.271(16)

Scheme 2.

available for the corresponding distances in pentacoordinated complexes with the general formulae [CoL″] [21] and [CdL″] [22], in which L″ represents a pentadentate dianionic Schiff base derived from 2,6-diacetylpyridine. In all of these cases the values reported for these distances are very similar to those found in the complexes described here.

As far as the structural parameters of the ligand are concerned, it is worth highlighting the variation observed in some of the bond distances in comparison to those found in the free ligand. Although the crystal structure of the free ligand HL is not available, structural data for related ligands (HL′) are known [23]. In these compounds the C–O bond lengths are in the range 1.230–1.219 Å and the C–N(amide) bond lengths are in the range 1.373–1.347 Å. Comparison of these values with those found in the complexes reported here shows that the corresponding C–O distances, in the range 1.292(12)–1.258(15) Å, are in all cases slightly longer whereas the C–N(amide) distances, in the range 1.351(13)–1.317(6) Å, are always shorter. These data are consistent with the increased conjugation experienced by the ligand in its deprotonated form.

3.3. Spectroscopy studies

In the IR spectra of the complexes the ν(N–H) (at 3204 cm^{-1}) and ν(C=O) (at 1668 cm^{-1}) stretching vibrations corresponding to the free ligand are not observed. This fact, along with the presence of a medium intensity band at *ca.* 1260 cm^{-1} assignable to ν(C–O), indicates that the hydrogen atoms of the amide group are lost during the electrochemical synthesis and the deprotonated ligand is predominantly in the enolate resonance form (II) in the complexes (Scheme 2).

The IR spectra of the complexes also show a sharp band in the range 1560–1570 cm^{-1}, attributed to ν(C=N), which is shifted to higher frequency on going from the free ligand (at 1545 cm^{-1}) to the complexes. This is indicative of the coordination of the imine nitrogen to the metal [24] and is consistent with by X-ray diffraction results. Bands at 1161–1164 cm^{-1} and 1343–1346 cm^{-1} can be assigned, respectively, to the symmetric and asymmetric $\nu(SO_2)$ vibrations and these are slightly shifted with respect to those in the free ligand.

The ^1H and ^{13}C NMR spectra of the free ligand (Section 2) indicate that, in solution, this compound exists in an equilibrium between two forms, with the amide as the predominant one. The ^1H spectra of the complexes confirm the loss of the amide proton in the synthetic procedure and that the anionic ligand is in the enolate form in the complexes. The signal for the imine proton in the zinc and cadmium complexes appears at 8.80 and 8.67 ppm, respectively, and these are shifted downfield with respect to the corresponding signal in the free ligand, indicating that the metal–nitrogen bond is retained in solution. In the case of the cadmium complex this signal shows satellite peaks due to the coupling of the proton to ^{113}Cd, with a ^3J(113Cd–1H) value of 42.4 Hz. Finally, the doublet assigned to H(6) of the pyridine ring (8.14 and 8.32 ppm, respectively, for the two complexes) is shifted to lower field in the complexes consistent with coordination through the pyridine nitrogen.

The compounds were also characterized by mass spectrometry using the FAB (m/z) technique with *m*-nitrobenzyl alcohol as matrix. In all cases the mass spectra show the peaks associated with [ML_2] species (see Section 2) and they have the appropriate isotopic distribution. Peaks corresponding to fragments of the parent ion are not observed.

The diffuse spectrum in the near IR–visible region of the cobalt complex shows the presence of three bands at ν_1 = 8810 cm^{-1} $^4T_{2g}(P) \leftarrow {}^4T_{1g}(F)$, ν_2 = 12 050 cm^{-1} $^4A_{2g} \leftarrow {}^4T_{1g}(P)$ and ν_3 = 20 400 cm^{-1} $^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$, and these are characteristic of a six-coordinate high spin Co(II) complex in a distorted octahedral geometry [25]. The spectrum of the nickel complex shows three bands in the near IR–visible region at ν_1 = 9025 cm^{-1} $^3T_{2g} \leftarrow {}^3A_{2g}$, ν_2 = 11 550 cm^{-1} $^3T_{1g}(F) \leftarrow {}^3A_{2g}$ and ν_3 = 21 460 cm^{-1} $^3T_{1g}(P) \leftarrow {}^3A_{2g}$. These frequencies are well within the range expected for octahedral Ni(II) complexes. Finally, the spectrum of the copper complex shows two bands at 13 400 cm^{-1} $^2E_g \leftarrow {}^2B_{1g}$ and 7590 cm^{-1} $^2B_{2g} \leftarrow {}^2B_{1g}$ and these are characteristic of hexacoordinated copper complexes with a tetragonal distortion.

4. Conclusions

The work described in this paper involved the synthesis and structural characterization of a series of cobalt, nickel, copper, zinc and cadmium complexes with a Schiff base ligands derived from hydrazone. The complexes were prepared using an electrochemical procedure that involved anodic oxidation of the metal and deprotonation of the ligand at the cathode. All of the complexes were studied by spectroscopic techniques and their structures in solid state were determined by X-ray diffraction. In all cases the metal is in an octahedral environment with the three donor atoms of each ligand in a meridional position.

antibacterial, antiviral, cytotoxic, antifungal and anti-inflammatory properties [26]. The guanidinium counterions also favour the stabilization of the crystal network by extensive hydrogen bonding. No complexes of any of the peroxo metal compounds with quinaldic acid have been synthesized or structurally characterized.

Therefore, we report on the synthesis, the spectroscopic data and the X-ray structure of $(gu)_2[Nb(O_2)_3(quin\text{-}2\text{-}c)]\cdot H_2O$ with the distinctive feature of having the metal atom in a five-membered N-/O-chelation ring and the Nb–N(quin) bond significantly long. In addition the present work introduces the first DFT study for the triperoxo complex containing the quinaldate ligand in order to explain the spectroscopic, bonding and reactivity properties of the complex. A comparison of the NMR, electronic, vibrational and thermogravimetric data of the triperoxo and tetraperoxo complexes is expected to reveal the relationship of their properties.

2. Experimental

2.1. Materials and methods

Potassium niobate, quinoline-2-carboxylate acid and guanidinium carbonate obtained from Aldrich were used without further purification. Hydrogen peroxide (35%) obtained from Merck was used as received and de-ionized and distilled water was used throughout this study. Deuterated solvents for use in the NMR, D_2O and DMSO-d_6 were purchased from Merck. Elemental analyses were performed using a Perkin–Elmer 240B elemental analyzer. IR spectra were recorded using a KBr pellet on a Perkin–Elmer 880 IR spectrophotometer. High-frequency Raman spectra were recorded with a Perkin–Elmer GX Fourier transform spectrometer with a diode pumped Nd:YAG laser at 1064 nm as the excitation source. The UV–Vis absorption spectra in the range 900–200 nm were recorded using a Cary 3E spectrophotometer. ^1H and ^{13}C NMR spectra were recorded on a Varian UNITY plus operating at 300 MHz spectrometer using TSP (2,2,3,3-tetradeutero-3-trimethylsilylpropionic acid) or the solvent peak as an internal reference. Thermogravimetric (TG) and differential thermal analysis (DTA) were carried out on a Mettler Toledo S R apparatus in N_2 atmosphere (temperature range: 40–1000 °C; heating rate: 10 °C/min).

2.2. Preparation of $(gu)_3[Nb(O_2)_4]$ (**2**)

The starting reactant was synthesized according the following procedure that differs from the reported one [27]. A solution of potassium niobate (0.9 g, 5 mmol) in 35% H_2O_2 (20 mL) was treated with $(gu)_2CO_3$ (1.36 g, 7.5 mmol) in 40 mL distilled water. The cloudy solution is agitated for a few hours. Then the solid is filtered off in order to avoid the presence of any niobium oxide. Addition of acetone in the filtered solution yields a white precipitate, which was filtered off, washed with acetone and air dried. Yield: 80%. *Anal.* Calc. for $C_3H_{18}NbN_9O_8$: C, 8.98; H, 4.52; N, 31.43. Found: C, 9.09; H, 4.44; N, 31.81%.

2.3. Preparation of $(gu)_2[Nb(O_2)_3(quin\text{-}2\text{-}c)]\cdot H_2O$ (**1**)

Quinoline-2-carboxylate acid (0.108 g, 0.625 mmol) was dissolved in water (2.5 mL) and added to a solution of the tetraperoxo niobate (0.25 g, 0.625 mmol) in 35% H_2O_2 (2.5 mL) while stirring. The pH value of the solution was recorded as approximately 4.5. Yellow crystals were obtained upon storage at 4 °C, filtered off and dried in the air. Yield: 70%. The X-ray diffraction analysis was carried out on the crystals and they correspond to the above stoichiometry. *Anal.* Calc. for $C_{12}H_{20}NbN_7O_9$: C, 28.36; H, 4.16; N, 19.29. Found: C, 28.66; H, 4.17; N, 19.32%.

2.4. X-ray diffraction

Diffraction measurements were made on a Crystal Logic dual goniometer diffractometer using graphite monochromated Cu Kα radiation (λ = 1.54187 Å) at a temperature of 220(2) K. Unit cell dimensions were determined by the angular settings of reflections in the range $6.88° < 2\theta < 72.52°$. Lorentz, polarization corrections were applied using Crystal Logic software. The structure was solved by direct methods using SHELX-86 and refined in full-matrix least-squares procedure on F^2 with SHELX-97 [28]. All non-hydrogen atoms in the structure were refined anisotropically. All hydrogen atoms were located by difference maps and were refined isotropically. Structure presentations were prepared by ORTEP for Windows and the calculation of the dihedral angles was calculated with MERCURY [29].

3. Computational details

Ground-state electronic structure calculations of the niobium complex (**1**) have been performed using density functional theory (DFT) [30] methods employing the GAUSSIAN 98 [31] and 03 [32] software packages. The functional used throughout this study was the B3LYP, consisting of a hybrid exchange functional as defined by Becke's three-parameter equation [33] and the Lee–Yang–Parr correlation functional [34]. The ground state geometry was obtained in the gas phase by full geometry optimization, starting from structural data and the optimum structure located as stationary point on the potential energy surface was verified by the absence of imaginary frequencies. The final wavefunction was found free from internal instabilities.

The basis set used throughout this study is the full double-ζ LANL2DZ basis functions together with the corresponding effective core potential for niobium [35]. Percentage compositions of molecular orbitals from the contributing molecular fragments were calculated and analyzed using the AOMIX and AOMIX-S programs [36].

The first 36 singlet excited states of the closed shell complexes were calculated within the TDDFT formalism [37–41]. The percentage of different transitions contributing to a state and the simulations of calculated UV–Vis spectra, when needed, were calculated with the aid of SWIZARD [42].

The graphics presented in the report have been prepared with the aid of MOLEKEL [43] and CHEMCRAFT [44].

4. Results and discussion

4.1. Crystal structure

The complex (**1**) crystallizes in the triclinic space group P1. Details concerning crystal data and refinement are given in Table 1. The structural unit consists of two anions (**1a** and **1b**), four guanidinium cations and of three molecules of water and is stabilized by identical hydrogen-bonding patterns involving several ring motifs. The hydrogen-bonding parameters for the complex are listed in Table 2. The structure and numbering scheme of the atoms of the complex anion are presented in Fig. 1 and the selected atomic distances and bond angles are collected in Table 3. The formation of hydrogen bonds to peroxo oxygen atoms and nitrogen atoms from the guanidinium ion has the major role in controlling the crystal packing (Fig. 2).

The niobium atom is surrounded by seven oxygen atoms belonging to three n^2-peroxo groups and a carboxylato group and a nitrogen atom from the deprotonated quinaldate ligand. The quinaldate ligand allows the formation of the five-membered chelation ring, while the picolinate ligand of the corresponding triperoxo niobate complex gave a six-membered ring coordinated

via the oxidized nitrogen atom of the heteroligand [19]. The environment of the metal atom in both complexes is identical. The coordination polyhedron around the niobium atom is a dodecahedron. The two bidentate peroxide groups are in *cis* configuration and the third one is in *trans* position to the quinaldate ligand. The coordination distances fall in the range, which is typical of heteroleptic peroxo complexes of niobium(V) [19,27,45,46]. If one assumes that the peroxo ligand occupies one vertex of the polyhedron, then the coordination polyhedron of niobium may be described as a strongly distorted pseudotrigonal bipyramid with the N,O (quin) atoms in the equatorial positions and the peroxo ligands, O (3, 4) and O (7, 8) in the axial positions. The dihedral angle between the pseudoequatorial and pseudoaxial planes of the pseudotrigonal bipyramid (O5, O6, O1, N1/O3, O4, O7, O8) equals 89.1° and 87.5° in each anionic entity of the structure, respectively.

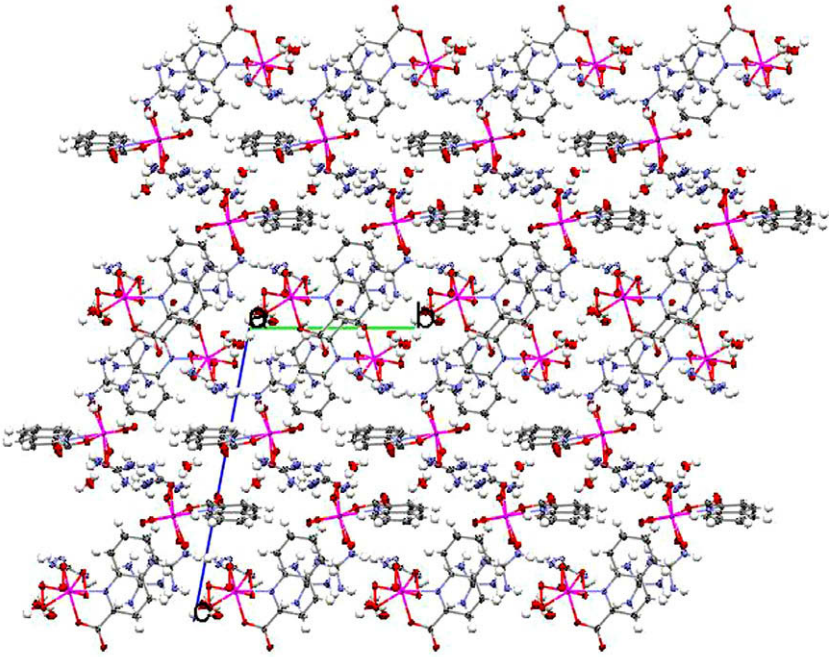

Fig. 2. A packing diagram of the title peroxo complex viewed down the α axis.

The angles between the corresponding planes in the peroxo niobate analogue with picolinate N-oxide reach 89.8° and 89.9° for each anionic entity, respectively [19].

It is interesting to point out that the quinoline ring and the five-membered ring formed via the N,O coordination with niobium atom are almost in the same plane due to the small folding of the coordination ring. This is shown by the following angles of the planes: Nb1, O1, N1/O1, C1, C2, N1 equals to 3.33° and Nb2, O11, N11/O11, C11, C12, N11 equals to 13.34° in each entity of the quinaldate peroxo complex, which has not been referenced before for the complexes of this class. It should be noted that the folding of the ring of the peroxo analogue with the picolinate N-oxide ligand is maximized as the angle between the planes containing Nb1, O7, O9/O7, O9, C2, C8, N1 equals to 24.88° and Nb2, O27, O29/O27, C28, C22, N21, O29 equals to 20.35° (Fig. 3). This difference can be attributable to the hydrogen-bonding between the guanidinium counterion and the carboxylate group. The value of the dihedral angle between the plane of COOH group and quinoline rings in the neutral molecule of the free quinoline-2-carboxylic acid equals 23.7° [47]. The main difference between the quinaldate peroxo complex (**1**) and the picolinato N-oxide one is that the metal atom in the complex **1** is in a five-membered chelate ring and coordinates directly to the nitrogen atom of the heteroligand which implies in that case the oxidation of the quinaldate ligand is not favoured. The folding angle observed in the case of the picO complex may also be enhanced by the coordination through the oxygen atoms, which provides a six-membered chelation ring.

It is worth noting that the coordination bond lengths between the quinoline N atom and the metal ion and between the carboxylate oxygen atom and the metal ion differs from the corresponding bond lengths in other metal quinaldate complexes [20–23,25,48,49]. The Nb–O(carboxylate) distance is 2.113(2) Å and 2.123(2) and the Nb–N bond distance reach 2.414(2) and 2.412(2) Å which are longer than that found for Ga^{III}, Fe^{II}, Co^{II}, Ni^{II} and Re^{V} quinaldate complexes and slightly shorter than that found for the quinaldate complex with Sn^{IV}, indicating a weaker coordination of the quinaldate ligand to the niobium atom due to the strong Nb-peroxo σ-bonding. The Nb–O(peroxo) bond lengths

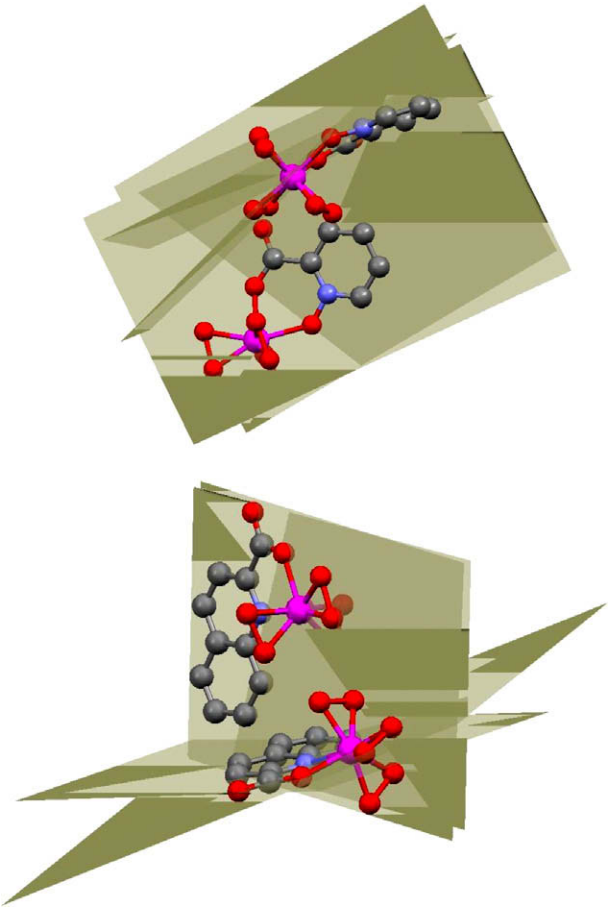

Fig. 3. The folding for the crystal structure reported in the literature [19] (up) and for the crystal structure of $[Nb(O_2)_3(quin\text{-}2\text{-}c)]^{2-}$ (down). The counterions and the water molecules are omitted for clarity.

range from 1.961 to 2.000 Å and the (O–O) distances range from 1.468 to 1.506 Å which are in good correlation with the corresponding ones in other triperoxo niobate complexes [50]. On the axial plane, the bonds $O–O_{ax}$ are longer than the bond $O–O_{eq}$ on the equatorial plane, as a result of the slightly higher contribution of the O_{eq} in HOMO (vide infra). Three water molecules are cocrystallized in the structure and all of the species are hydrogen bonded with the guanidinium cations, the oxygen atom of the ligand and between themselves.

4.2. Ground state structure

In order to study more thoroughly the electronic properties of **1**, we have used a standard DFT approach to optimize its ground state geometry and hence extract its frontier orbitals. In Table 3, calculated bond lengths and angles are depicted along with the experimental data as received from its crystal structure (vide supra).

From a comparison of the data of Table 3, we observe that all the calculated bonds are systematically overestimated. As this is anticipated [51] we can judge that the agreement between the theoretical and experimental data is satisfactory. We should also note that the ground state geometries were obtained in the gas phase by full geometry optimization, as free from intermolecular hydrogen bonds.

HOMO and LUMO orbitals are shown in bold.
[a] Oxygen atoms that lie opposite the quinoline-carboxylate ligand
[b] Oxygen atoms that lie in the axial positions of the pseudo-octahedral arrangement.

4.3. Molecular orbitals

The orbital energies, the contributions of the different fragments and the contour plots of the frontier orbitals are depicted in Table 4 and Fig. 4.

As we can notice, the three highest occupied orbitals are localized on the three peroxo units and are strongly π-antibonding in character with respect to the O–O bonds. HOMO − 6 to HOMO − 9 contain metal d_z^2 sigma and d_{yz} π-bonding contributions to the carboxylate moiety and the peroxo ligands. On the contrary, HOMO − 3 to HOMO − 5 are strongly Nb-peroxo σ-bonding, while smaller bonding and antibonding contributions from Nb quinoline-carboxylate ligand are also present.

LUMO, LUMO + 1 and LUMO + 2 are formed mainly by p_z bonding and antibonding contributions of the ring atoms of the quinoline-carboxylate ligand. LUMO + 3/+5 are formed by metal's d_{xy}/oxygen p_π antibonding contributions, while the LUMO + 4 is a peroxo sigma antibonding orbital.

Special attention should be drawn on the HOMO − 3 and HOMO − 5 orbitals. Both of them are indicative of the electron transfer from the main ligand to the $Nb(O_2)_3$ moiety. Our analysis according to the Frenking's decomposition analysis [36,51,52] showed that the former contains a contribution of 3.4% from the LUFO + 1 of $Nb(O_2)_3$, while the latter contains a contribution of 3.2% from the LUFO of the same fragment. The aforementioned scheme is supported by the total 10.6% of contributions of occupied

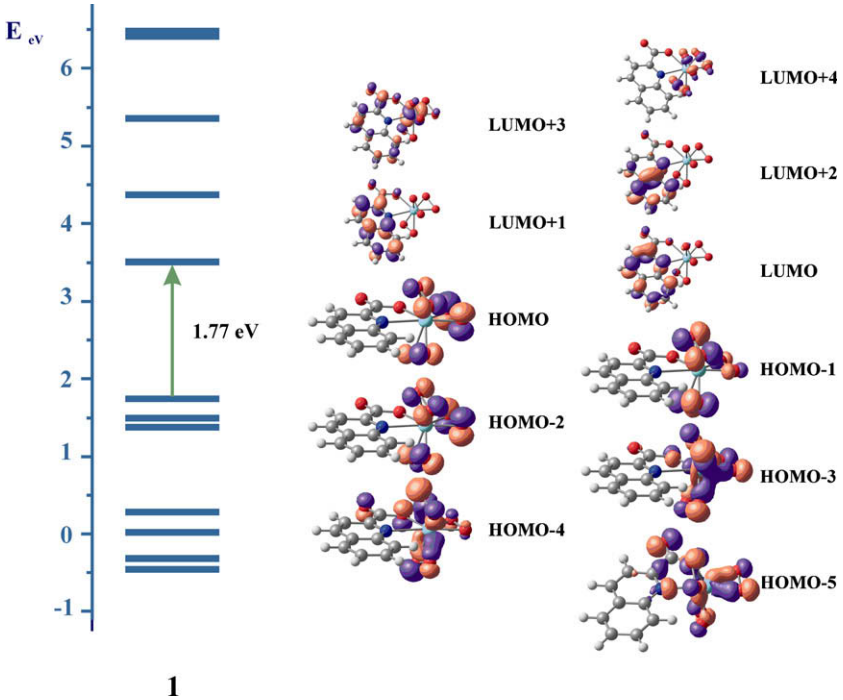

Fig. 4. Energy level diagram and graphic representation of frontier orbitals of **1**, given through isodensity surfaces of 0.05 a.u.

ligand orbitals to compound's unoccupied molecular orbitals. Thus, the net charge transfer from the quinoline-2-carboxylate to the Nb-peroxo core is calculated to be 0.19 electrons.

Besides, an unoccupied orbital with a predominant d(σ^*) character was not found among the spectroscopically important orbitals. Thus, low lying LF states, contradictory to the arguments of the traditional ligand field theory, are not expected.

4.4. Infrared and Raman data

The IR and Raman spectra of the triperoxo niobate complex displayed a sufficiently well resolved spectral pattern (Fig. 5). The theoretical results reported in the literature for the tetraperoxo complex and obtained in the present work for the complex **1** and some representative vibrational modes of the coordinated heteroligand are summarized in Table 5.

In the IR spectrum of the tetraperoxo niobate complex the prominent band at 814 cm^{-1} assigned to the O–O stretching vibration and another two broad bands with the same intensity appearing at 594 and 552 cm^{-1} attributable to ν_{as}(Nb–O_2) and ν_s(Nb–O_2) modes, respectively, gave the indication of the presence side-on bound peroxo ligands in the complex. In the Raman spectrum the stretching vibration of the peroxo group is observed at 850 cm^{-1}, which is active due to the symmetric vibration. As far as the metal–peroxo stretching Nb–O_2 vibrations are concerned two bands are observed at 535 and 525 cm^{-1}. These results are consistent with the results obtained by Bayot et al. for the same

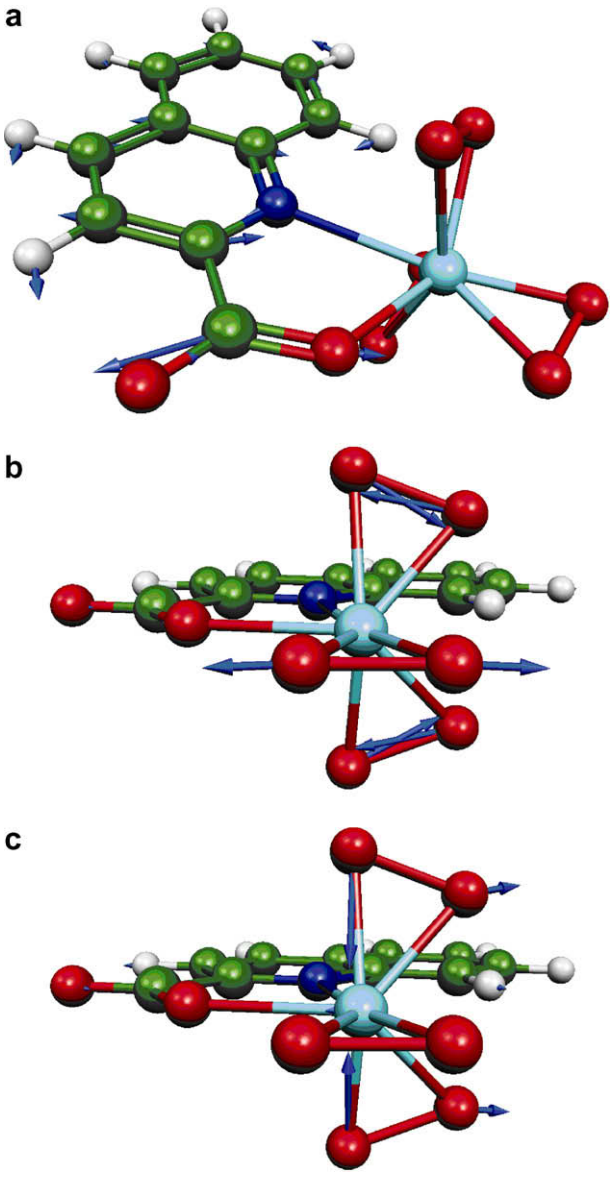

Fig. 6. Graphic representations of the compound's normal modes observed at 1622 cm^{-1} (a), 853 cm^{-1} (b) and 511 cm^{-1} (c).

tetraperoxo compound [27,45]. The additional bands occurring in the IR spectrum in the range 1390–1700 cm^{-1} are due to the bending vibration of the NH_2 and CN_3 groups presented in the guanidinium ion [53].

In the case of the triperoxo complex, the theoretical results confirmed the empirical rule which states that the presence of three ν(O–O) bands in the IR spectrum indicates the formation of the triperoxo complex. There are three calculated frequencies corresponding to the O–O vibration modes are 881, 865 and 861 cm^{-1} which are in agreement with the experimental spectra. In the Raman spectrum of the complex **1** the vibration modes which involve the O–O stretching are observed at 852, 824 and 804 cm^{-1}. The triperoxo complex also shows two characteristic Nb–peroxo modes calculated around 560 cm^{-1} in the IR spectrum as confirmed by the experimental observations as well as the Raman spectrum provides the corresponding vibrations at 539 and 523 cm^{-1}. Moreover, the triperoxo complex displays two bands calculated at 1606 cm^{-1} and 1332 cm^{-1} for the asymmetric and symmetric modes of the carboxylate moiety complexed to niobium, respectively. The coordination of the niobium atom by the carboxylato groups in the monodentate mode is evidenced by the broadening of this ν_{as}(COO) band, by the value of $\nu_{as} - \nu_s = 274$ cm^{-1} [54] and by its shift from a value of ca. 1694 cm^{-1} in the free carboxylic acid to ca. 1622 cm^{-1} in the complex. In any case the calculation fits well with the experimental results and some of the aforementioned modes are depicted in Fig. 6.

4.5. Thermal analyses

Thermogravimetric (TG) and differential thermal analysis (DTA) data of the peroxo niobate complexes provide crucial information regarding composition of the compounds and their thermal stability. They indicated that the existence of the heteroligand in the coordination sphere of the niobium atom gives different thermal

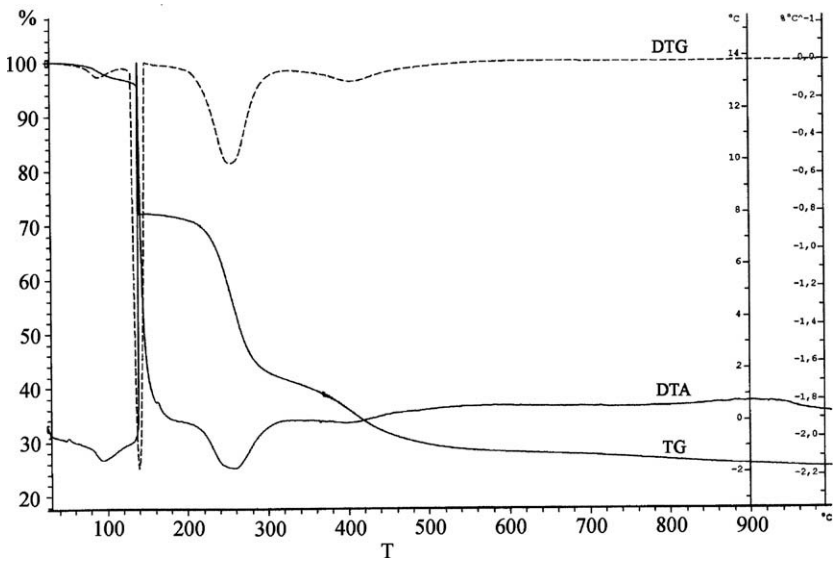

Fig. 7. TG, DTG and DTA of the triperoxo compound $(gu)_2[Nb(O_2)_3(quin\text{-}2\text{-}c)] \cdot H_2O$ in air (10 °C/min).

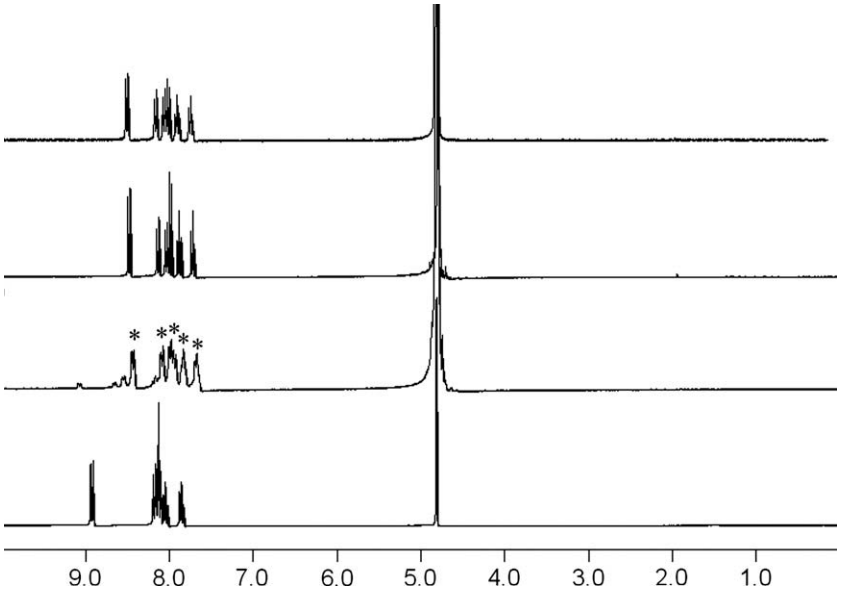

Fig. 8. ^1H NMR spectra of the quinaldate ligand, the triperoxo $(gu)_2[Nb(O_2)_3(quin\text{-}2\text{-}c)] \cdot H_2O$ 5 min and 90 min after dissolution and the quinaldate salt with the guanidinium ion in D_2O solution (from bottom to top). The peaks marked with an asterisk are from the quinaldate salt.

stability. The thermogram of the peroxo compound **1** is illustrated in Fig. 7. The first stage of decomposition occurs at 51–119 °C is believed to be associated with the liberation of the outer sphere H_2O molecule with a weight loss of 3.1% which is in agreement with the calculated value (3.5%). Another decomposition stage follows in the temperature region 123–157 °C. It has been shown that the guanidinium ion's decomposition starts at these temperatures [55]. This process seems to be exothermic and quite violent with considerable dispersion of the residue and a drastic weight loss of 24.5%. This value corresponds to the loss of the two guanidinium counterions (calc. value 23.6%). The decomposition gases released during the thermal degradation of the guanidinium moiety have been reported in the literature [55]. The next two steps of decomposition (temperature region 182–328 °C and 331–544 °C) continued with an experimental loss 43% are characterized by rather complex degradation mechanism of the peroxo groups and the quinaldic acid. The calculated loss of the coordinated peroxo groups and the quinoline moiety from the quinaldic acid is 44.3% [56]. According to the literature the loss of the peroxo groups in the tetraperoxo niobate complex occurs at lower temperature (187 °C) suggesting that the quinaldate ligand stabilize the peroxo complex [3].

The final decomposition temperature appears at 544 °C where the complex undergoes a complete degradation into Nb_2O_5. The weight of the residue was recorded to be 29.4% and the content per niobium is 19.1% which is in agreement with the theoretically calculated value of 18.3%.

4.6. NMR spectroscopy

The peroxo complexes of niobium were investigated with ^1H NMR spectroscopy in D_2O and DMSO solutions. Despite the difficulties in the measurements due to the rapid degradation in water of the complexes, the NMR analyses revealed information on their relative stability in aqueous solution and their relative catalytic activity in DMSO solution. The NMR spectra of all the solution of the complexes measured immediately on adding the complexes in water and DMSO. From the NMR solution spectra it is evident that no information is provided regarding the nature of the original solid compounds **1** and **2**. The relative stability and catalytic activity have been studied by obtaining spectra at different time for over a period of 48 h.

Fig. 8 illustrates the ^1H NMR spectrum of the triperoxo complex 5 min after the dissolution in D_2O showing broad signals around $\delta = 7.7$ and $\delta = 9.2$ ppm. The peaks of low intensity appear at lower fields compared to the free ligand suggesting that the decomposition of the complex has occurred. Several additional major peaks are observed at higher fields compared to the free ligand indicating the formation of a different 'compound' of the ligand. In order to confirm the main peaks observed in the spectrum, we prepared the quinaldate salt with the guanidinium counterion. Mixing equimolar amounts of the quinaldic acid and guanidinium carbonate in ethanol:water 1:1 results a white solid characterized by elemental analysis and IR spectroscopy (our work with all the experimental results and the crystal structure of this compound will be published elsewhere). The ^1H NMR spectrum of the salt in D_2O is identical with that of the triperoxo complex after dissolution in D_2O (Fig. 8, top). Remarkable at the spectrum is the decrease in the chemical shifts for the salt in comparison to the appropriate chemical shifts in the spectrum of the free ligand. A similar influence on the value of the chemical shifts of protons is mentioned for the alkali metal picolinates versus picolinic acid [57]. The assignment of the peaks that correspond to the protons of the free quinaldic acid is based on the ^1H–^1H COSY spectrum (Fig. 9). The corresponding proton shifts from the free ligand show that H_4 (0.5 ppm upfield)

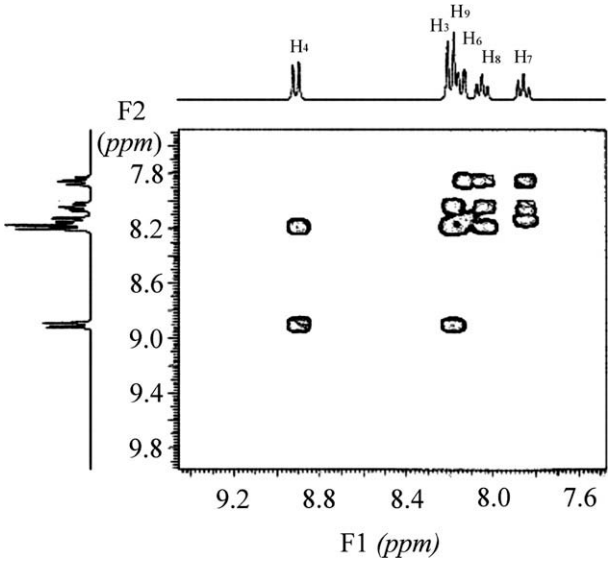

Fig. 9. COSY-NMR spectrum of quinaldic acid in D_2O.

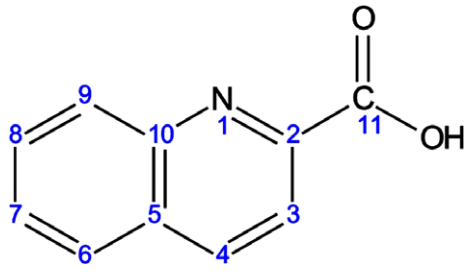

Scheme 1. Quinoline-2-carboxylate acid with atom numbering.

is more affected followed by the separation of H_3 and H_9 signals (Scheme 1).

The ^1H NMR spectrum of the triperoxo complex in DMSO (Fig. 10) 5 min after the dissolution displays a set of peaks with low intensity occurring in the region of the aromatic protons and assigned to the coordinated quinaldate ligand. The protons of the

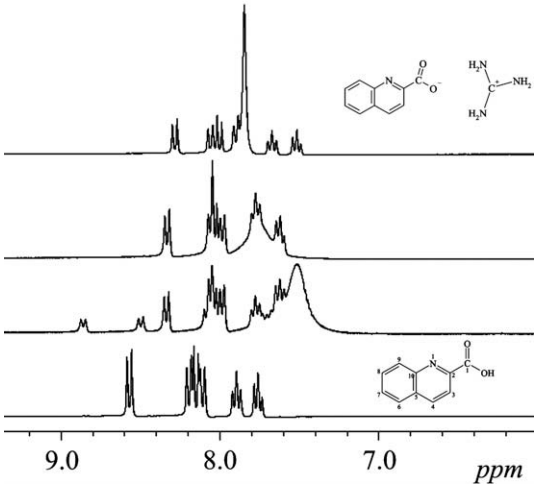

Fig. 10. ^1H NMR spectra of the quinaldate ligand and the triperoxo $(gu)_2[Nb(O_2)_3(quin\text{-}2\text{-}c)] \cdot H_2O$ (5 min and 90 min after dissolution) and the quinaldate salt in DMSO solution (from bottom to top).

ligand are shifted downfield in comparison to those of the free ligand, which results from the asymmetrical charge distribution in the valence orbital of the metal. The resulting paramagnetic moment deshields the ligand's protons. It is reported that in the tin quinaldate complex the protons are shifted slightly to the low field compared with the free ligand while a reverse tendency was reported for the aluminum and gallium complexes with the quinaldic acid [25,49]. The spectrum also displays additional more intense peaks attributed to the resulting liberated ligand salt with the guanidinium counterion. After 48 h of the dissolution the peaks attributed to the coordinated ligand disappear, the characteristic set of peaks due to the ligand salt remains and a peak at 3.012 ppm appears due to the protons of the dimethylsulfone. The latter peak is indicative of the oxidation of DMSO.

Fig. 11 illustrates the ^{1}H NMR spectra of the tetraperoxo and triperoxo complexes in the region of the dimethylsulfoxide protons in order to reveal the difference in the rate of the oxidation reaction catalyzed by the complexes mentioned. Oxidation of DMSO with a variety of oxidants has been studied [58] but no examples of peroxo metal complexes have been described as catalysts in the mentioned oxidation reaction. As it is observed in the spectrum of the tetraperoxo complex, the peak at 3.012 ppm is much more intense compared to this in the spectrum of the triperoxo complex indicating that the triperoxo complex in this period had lower catalytic activity on the oxidation in DMSO in comparison with the tetraperoxo complex. The reaction of dimethylsulfoxide with hydrogen peroxide was compared to that of the more reactive tetraperoxo complex. The oxidation of DMSO with hydrogen peroxide yields dimethylsulfone which is the main product [59] at low conversion and dimethylether as by-product. The increase in the intensity of the peak at 3.012 ppm is significant in the case of the tetraperoxo complex which means that the reaction is much faster than that of the reaction with hydrogen peroxide. A proposed mechanism of the oxygen transfer reaction in the oxidation of DMSO is represented in Scheme 2.

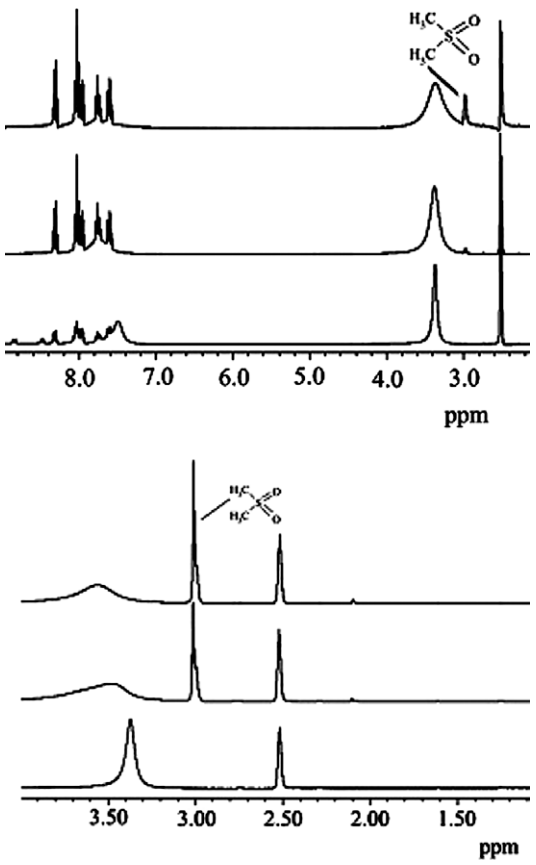

Fig. 11. ^{1}H NMR spectra of the triperoxo (up) and the tetraperoxo (down) complexes in DMSO solution

4.7. Absorption spectroscopy

The peroxo-niobate complexes **1** and **2** are soluble but not very stable in water. An amorphous precipitate forms after 1 h in both solutions and using IR spectroscopy the precipitate is identified as peroxoniobium hydrate (ESI). At low pH a condensation reaction probably occur to form polymeric niobium complexes. However, the freshly prepared aqueous solutions of **1** and **2** have the UV absorption peaks attributed to the peroxo metal charge transfer. The UV–Vis spectra of the peroxo niobate complexes are shown in Fig. 12. A UV absorption band around 280 nm is observed for the tetraperoxo complex and two bands around 280 and 330 nm for the triperoxo complex. According to the literature the complexes with peroxo:Nb mole ratios 1:1 show the characteristic absorption band in the range 255–260 nm while these with 2:1 and 3:1 mole ratios in the range 330–380 nm [9]. Therefore, the peroxo-complex containing the quinaldic ligand seems to be more stable than the homoleptic one since the latter loses easily the peroxide groups coordinated to the metal.

In order to investigate the lowest lying singlet states of **1**, TDDFT calculations have been performed. The most important calculated states along with their vertical excitation energies and oscillator strengths are gathered in Table 6. The lowest in energy

[c] Oscillator strength.

electronic transition can be ascribed as a HOMO–LUMO transition. As it can be seen from Fig. 4, the HOMO and LUMO orbitals are delocalized amongst the peroxo and quinoline-carboxylate ligand so a LLCT (ligand-to-ligand charge transfer) description can be used. The aforementioned band is not observed in the experimental spectrum due to the decomposition of the complex in water as we have indicated with the NMR experiments and have been discussed before. The experimental spectrum of the complex **1** exhibits the absorption band at 280 nm assigned to the transition of π^* orbital of the peroxo unit into the d ($\pi^* \rightarrow$ d LMCT) and the band at 330 nm resulting mainly from the $\pi_{quin} \rightarrow \pi^*_{quin}$ transition of the ligand. The intraligand transitions of the free quinaldate acid are assigned to the absorption bands below 320 nm (S2).

5. Conclusions

The synthesis, characterization and crystallographic analysis of a novel complex $(gu)_2[Nb(O_2)_3(quin\text{-}2\text{-}c)] \cdot H_2O$ are presented. The crystal data shows that the niobium atom displays eightfold coordination with the quinaldate ligand bound in a bidentate mode via the nitrogen atom and the carboxylato group. The structure is characterized by the presence of the unusual five-membered N-/O-chelation ring and is stabilized by the extended hydrogen bonds. First DFT calculations performed on this triperoxo niobate complex provide an insight on the nature of the chemical bonds in the peroxide group with Nb and new information on spectral properties. The triperoxo complex is also investigated for the relative stability and catalytic reactivity in comparison with the tetraperoxo niobate complex.

Acknowledgments

The present work was supported by the Special Research Account of Athens University (E.L.K.E. 70/4/6495). We are grateful to As. Prof. A. Moutsatsou (Chemical Engineering Department, National Technical University of Athens) for collecting the thermogravimetric data.

Appendix A. Supplementary data

CCDC 680571 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.08.006.

2.3. Preparation of [Zn(pchlorben)$_2$(py)$_2$] (**3**)

Complex **3** was prepared by using 4-chlorobenzoic acid (pchlorbenH) in similar way to that of (**1**), but was crystallised from a mixed solvent comprising of DMSO and pyridine. Yield: 46% (based on Zn). Elemental *Anal.* Calc. for $C_{24}H_{18}Cl_2N_2O_4Zn$: C, 53.87; H, 3.37. Found C, 53.90; H, 3.38%. FT-IR (KBr, cm^{-1}): 3223 (br s), 1925 (w), 1649 (m), 1611 (s), 1593 (s), 1550 (s), 1508 (m), 1383 (s), 1291 (w), 1172 (s), 1139 (w), 1115 (w), 868 (s), 849 (s), 791 (s), 763 (s), 633 (s); ^{1}H NMR (DMSO-d_6, 400 MHz): 8.62 (2H, br s), 7.93 (2H, d, J = 8.4 Hz), 7.83 (1H, t, J = 7.6 Hz), 7.46 (4H, m).

2.4. Preparation of [Zn$_2$(μ^2-mtol)$_4$(py)$_2$] (**4**)

3-Methylbenzoic acid (0.272 g, 2 mmol) and zinc sulfate heptahydrate (0.287 g, 1 mmol) and sodium hydroxide (0.08 g, 2 mmol) were finely ground in a mortar and heated at 100 °C for 20 min. The mixture was cooled to room temperature and methanol (10 ml) was added to it and the heterogeneous mixture was transferred to a round bottom flask. To this solution pyridine (0.079 g, 1 mmol) was added and stirred at room temperature for 5 min. Colorless crystals were obtained after 5 days and dried in air. Yield: 48% (based on Zn). Elemental *Anal.* Calc. for $C_{42}H_{38}N_2O_8Zn_2$: C, 60.76; H, 4.58. Found: C, 60.79; H, 5.01%. FT-IR (KBr, cm^{-1}): 3431 (br s), 3064 (w), 3030 (w), 2912 (w), 1823 (w), 1644 (s), 1602 (s), 1583 (s), 1403 (br s), 1214 (m), 1082 (m), 1069 (m), 1046 (m), 788 (s), 755 (s), 747 (s), 693 (m), 674 (w), 642 (w), 493 (m), 458 (m). ^{1}H NMR (DMSO-d_6, 400 MHz): 8.84 (2H, br s), 8.07 (1H, t, J = 6.8 Hz), 7.95 (2H, s), 7.92 (2H, t, J = 4 Hz), 7.67 (2H, t, J = 6.8 Hz), 7.46 (4H, d, J = 5.2 Hz), 2.50 (12H, s).

2.5. Preparation of [Zn$_5$(μ^2-mtol)$_6$(mtol)$_2$(μ^3-OH)$_2$(py)$_2$] (**5**)

3-Methylbenzoic acid (0.272 g, 2 mmol), zinc sulfate heptahydrate (0.287 g, 1 mmol) and sodium hydroxide (0.08 g, 2 mmol) were finely ground in a mortar and heated at 100 °C for 15 min. The solid mixture was cooled to room temperature, transferred into a round bottom flask and dimethylsulfoxide: water (4:1) was added to it. The heterogeneous mixture was stirred at room temp for 5 min followed by addition of pyridine (0.079 g, 1 mmol). The colourless liquid was filtered and was left undisturbed. Colourless crystals were collected after 15 days and dried in air. Yield: 34% (based on Zn). Elemental *Anal.* Calc. for $C_{74}H_{68}N_2O_{18}Zn_5$: C, 55.49; H, 4.25. Found C, 55.52; H, 4.28%. FT-IR (KBr, cm^{-1}): 3432 (br s), 2919 (m), 1623 (s), 1601 (s), 1578 (s), 1531 (s), 1428 (s), 1404 (s), 1289 (w), 1229 (w), 1088 (m), 787 (s), 764 (s), 673 (m), 589 (m), 492 (s). ^{1}H NMR (DMSO-d_6, 400 MHz): 7.76 (4H, s), 7.73 (5H, m), 7.30 (6H, m) 2.38 (12H, s).

2.6. Preparation of [Zn$_2$(μ^2-otol)$_4$(py)$_2$] (**6**)

2-Methylbenzoic acid (0.272 g, 2 mmol), zinc sulfate heptahydrate (0.287 g, 1 mmol) and sodium hydroxide (0.08 g, 2 mmol) were finely ground in a mortar and heated at 100 °C for 20 min. The mixture was transferred to a round bottom flask and methanol (10 ml) was added, followed by pyridine (0.079 g, 1 mmol). The resultant mixture was stirred at room temperature for half an hour and then was filtered. The colourless filtrate was left undisturbed. Colourless crystals were obtained after 8 days and dried in air. Yield: 41% (based on Zn). Elemental *Anal.* Calc. for $C_{42}H_{38}N_2O_8Zn_2$: C, 60.76; H, 4.58. Found C, 60.81; H, 5.01%. FT-IR (KBr, cm^{-1}): 3420 (br s), 3064 (w), 3021 (w), 2929 (w), 1634 (s), 1609 (s), 1568 (s), 1435 (s), 1403 (br s), 1219 (m), 1157 (m), 1103 (m), 1071(m), 1048 (m), 852 (m), 741 (s), 700 (s), 665 (s), 550 (m). ^{1}H NMR (DMSO-d_6, 400 MHz): 8.62 (2 H, br s), 7.87 (1H, t, J = 6.8 Hz), 7.75 (2H, d, J = 7.2 Hz), 7.47 (2H, t, J = 6.8 Hz), 7.27 (2H, t, J = 8.0 Hz), 7.18 (4H, d, J = 7.6 Hz), 2.50 (12H, s).

2.7. Preparation of [Zn$_4$(μ^2-otol)$_6$(μ^4-O)(DMSO)$_2$] (**7**)

2-Methylbenzoic acid (0.272 g, 2 mmol), zinc sulfate heptahydrate (0.287 g, 1 mmol) and sodium hydroxide (0.08 g, 2 mmol) were finely ground in a mortar and heated at 100 °C for 15 min. The heated mixture was cooled to room temperature, transferred

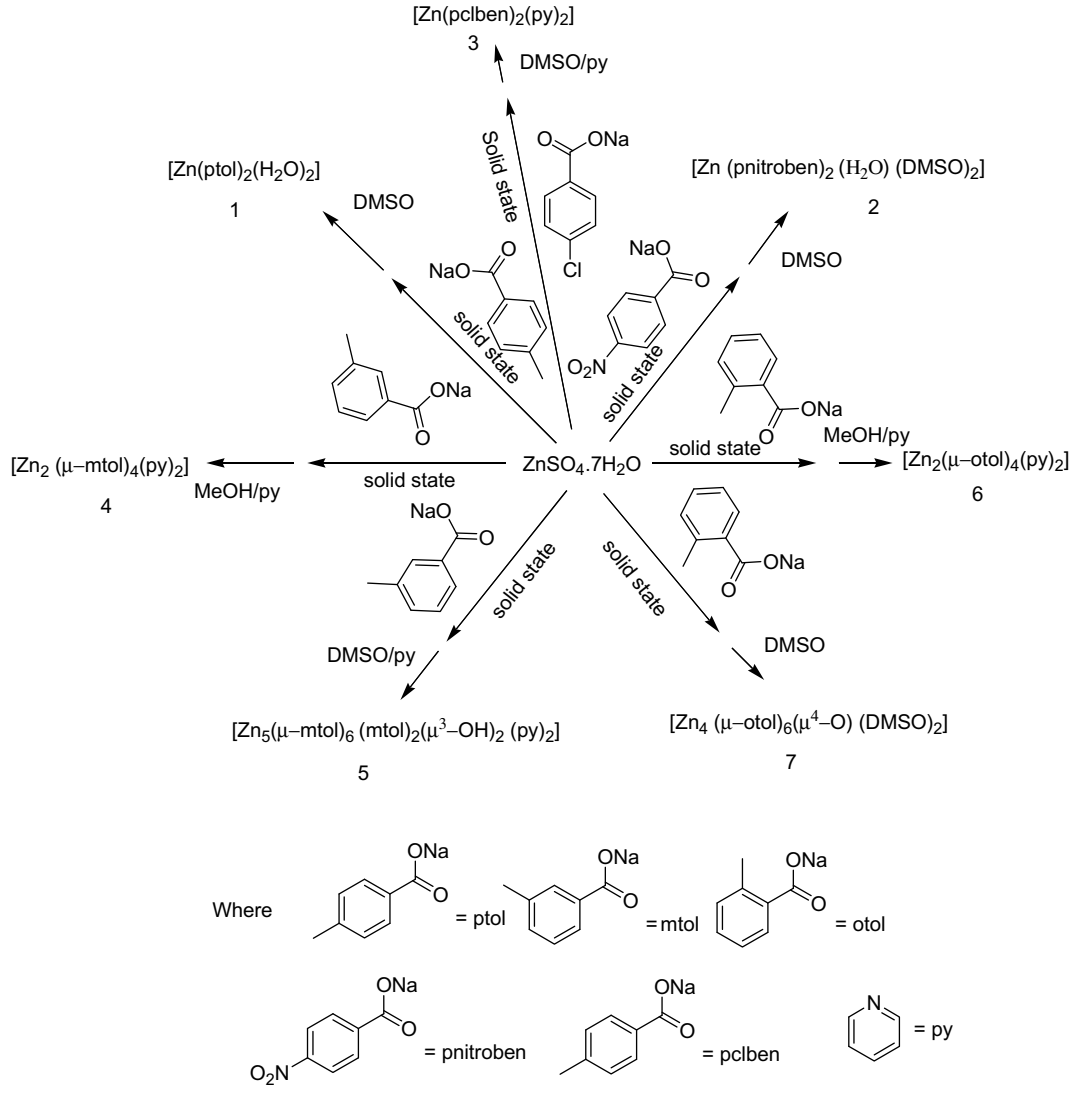
3. Structure determination

The X-ray data were collected at 296 K with Mo Kα radiation (λ = 0.71073 Å) using a Bruker Nonius SMART CCD diffractometer equipped with a graphite monochromator. SMART software was used for data collection and also for indexing the reflections and determining the unit cell parameters; the collected data were integrated using SAINT software. The structures were solved by direct methods and refined by full-matrix least-squares calculations using SHELXTL software. All the non-H atoms were refined in the anisotropic approximation against F^2 of all reflections. The H-atoms, except those attached to N and O, were placed at their calculated positions and refined in the isotropic approximation; those attached to the heteroatoms (N, O) were located in the difference Fourier maps, and refined with isotropic displacement coefficients. The crystal data for the complexes are listed in Table 1.

4. Results and discussion

A series of combined solid and solution phase reactions of the sodium salt of substituted benzoic acids with zinc sulfate heptahydrate, followed by dissolution of the reactant in methanol or dimethylsulfoxide in the presence or absence of pyridine were carried out (Scheme 1). A variety of complexes, as listed in Scheme 1, was obtained and each of the complexes was characterized by X-ray crystallography. This combined phase reaction methodology is in accordance with our earlier observation on the variation of product formation as compared to solution chemistry [5]. From the para-substituted benzoic acids, 4-methylbenzoic acid, 4-nitrobenzoic acid and 4-chlorobenzoic acid, on reaction with zinc sulfate and pyridine we could prepare mononuclear zinc complexes. However, the compositions and coordination geometries of the products were different in each case and depend on the solvent



Scheme 1.

of crystallization. For example, complex **1** has the composition $[Zn(ptol)_2(H_2O)_2]$, having two water ligands, complex **2** has dimethylsulfoxide ligands with the composition $[Zn(pnitroben)_2(H_2O)(DMSO)_2]$ and **3** has pyridine ligands [5a] with the composition $[Zn(pchlorben)_2(py)_2]$. These complexes were characterized by various spectroscopic techniques and also by X-ray crystallography. The structures of the three complexes are shown in Fig. 1. Complex **2** has a penta-coordinated structure close to a square pyramidal geometry with two DMSO and two carboxylate groups opposite to each other in the basal plane, and with a water molecule occupying an axial position. The complex shows sharp IR signals at 3368 cm^{-1} for the aqua ligand and 1010 cm^{-1} for DMSO. The monodentate carboxylate stretching appears at 1617 cm^{-1} and 1578 cm^{-1} (sym) and the anti-symmetric stretching appears at 1345 cm^{-1}. The monodentate nature of the carboxylate group is reflected in the Zn–O distances in the crystal structure; the distances between the two carbonyl oxygen atoms that are not participating in the metal ligand bond and zinc, namely Zn1–O6 and Zn–O1, are 3.166 Å and 2.584, whereas the other metal ligand bond distances, Zn–O2, Zn1–O5, Zn1–O9,

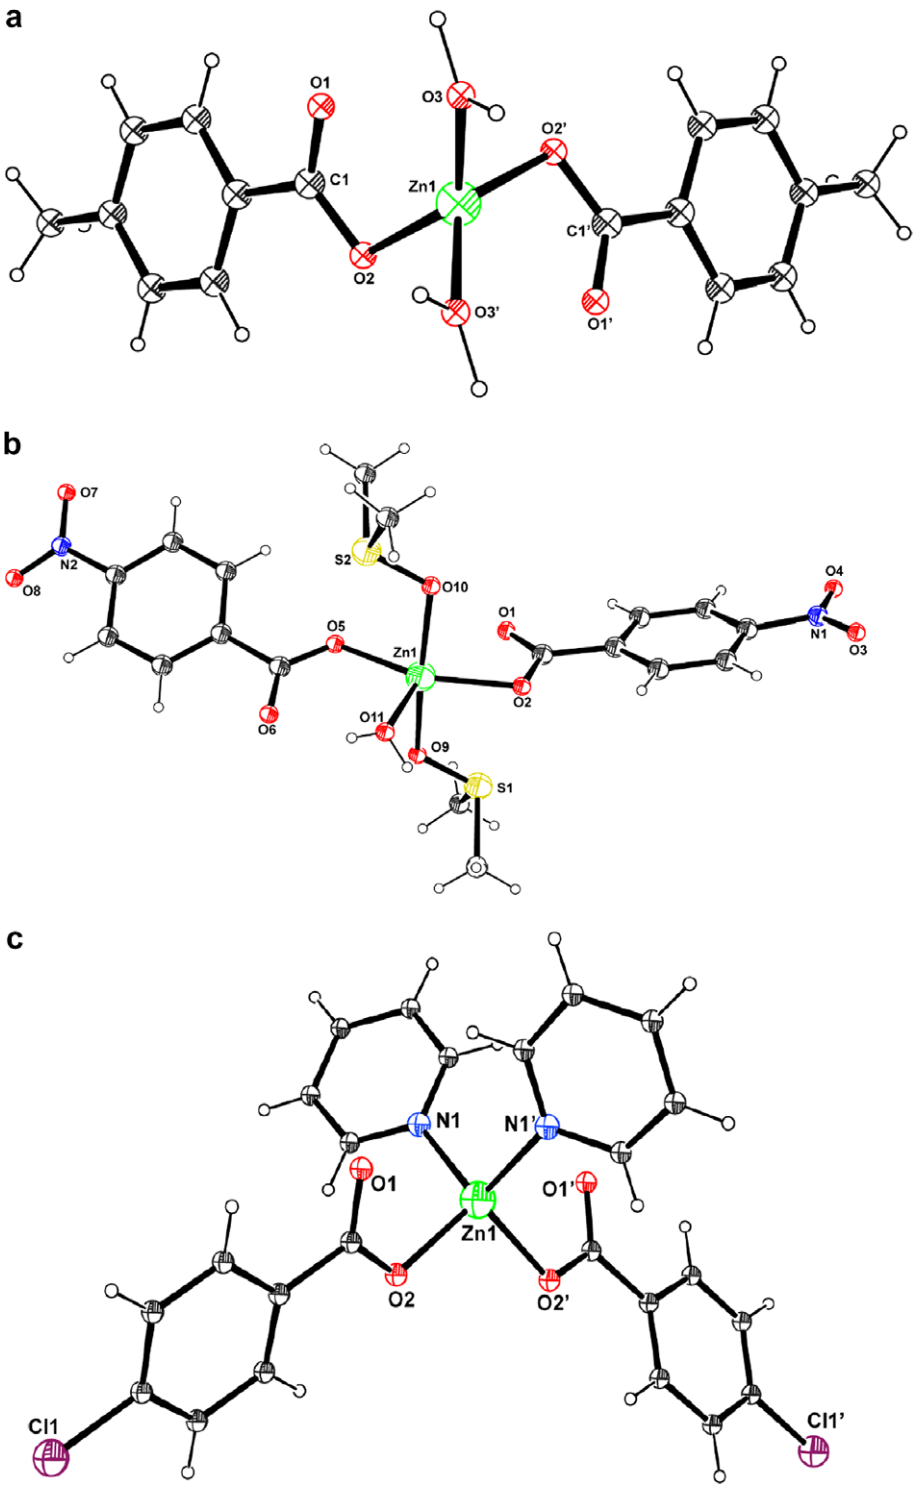


Fig. 1. The solid state structures of (a) $[Zn(ptol)_2(H_2O)_2]$ (**1**), (b) $[Zn\ (pnitroben)_2(H_2O)\ (DMSO)_2]$ (**2**) and (c) $[Zn(pchlorben)_2(py)_2]$ (**3**).

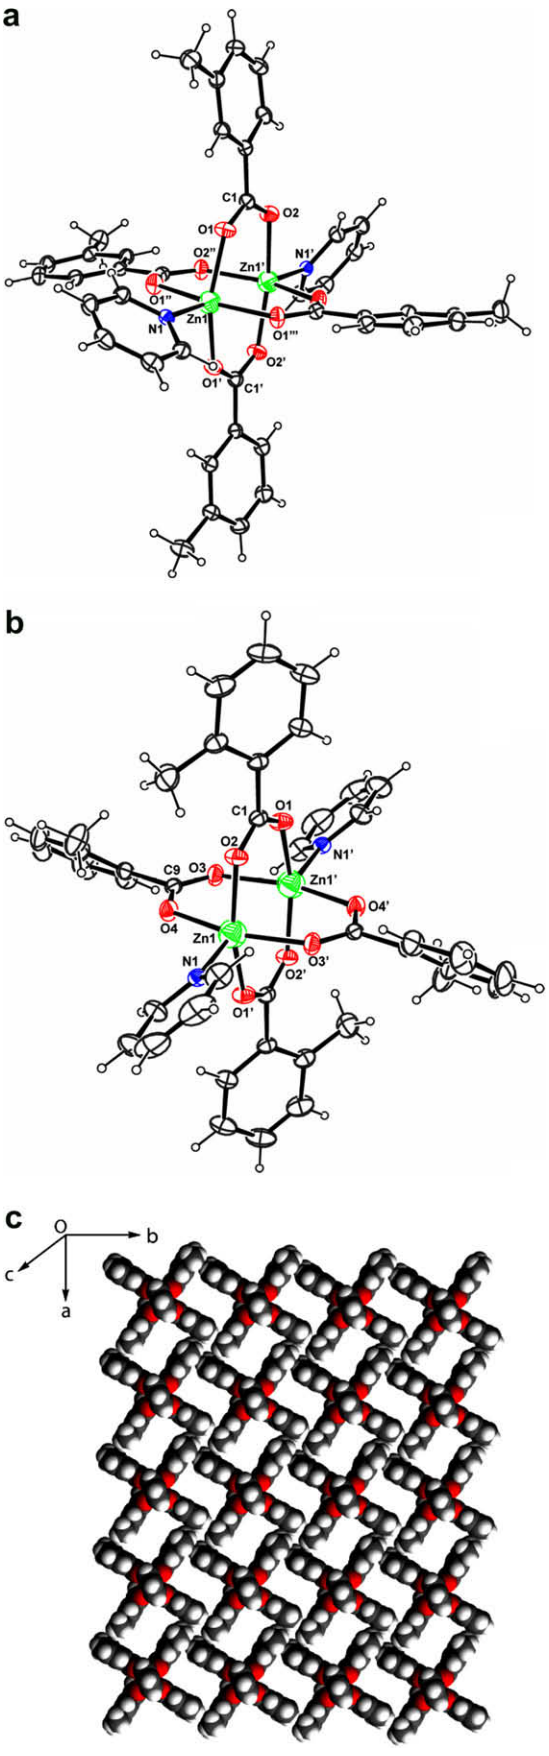

Fig. 2. The solid state structure of (a) $[Zn_2(\mu\text{-mtol})_4(py)_2]$ (**4**), (b) $[Zn_2(\mu\text{-otol})_4(py)_2]$ (**6**) and (c) the packing pattern in (**4**).

Zn1–O10 and Zn1–O11, are 2.045, 2.011, 2.120, 2.109 and 2.004 Å, respectively. The lone pairs of electrons on the two sulfur atoms of the dimethylsulfoxide ligands in the complex project in opposite directions and it becomes one of the factors for the five coordination geometry around the zinc centre. However, there are other very weak interactions such as C–H···O and S···N(pi) interactions [9] that also contribute to this geometry. These lone pairs in this complex also push the two carbonyl oxygens of the carboxylate away from each other and thereby making space for a water ligand to approach the metal center. In the case of complexes **1** and **3** such effects are not present; complex **1** can be considered to have a distorted square planar structure with two symmetric halves, having two types of Zn–O bonds (Zn1–O2, 2.009 Å and Zn1–O3, 1.990 Å). Complex **1** has an IR absorption at 3430 cm^{-1} and has two closely spaced carboxylate stretching frequencies at 1621 and 1608 cm^{-1}. Whereas complex **3** has the coordination number four with a distorted tetrahedral geometry in which the two carboxylate groups are monodentate. The molecule has a mirror plane and the Zn1–N1 and Zn1–O2 bond distances are 2.043 and 1.961 Å, respectively. The distance of separation between Zn1 and O1 is 2.787 Å, suggesting no bond formation between them and making the carboxylate group bind in a monodentate fashion. Mononuclear complexes of 2,6-dichlorobenzoate and 2,6-difluorobenzoate are characterized in the literature and have six and five coordination geometries, respectively [3a]. However our reactions are done under thermodynamically favorable conditions and the product composition varies from substituent, as observed in earlier studies. In our earlier study we have shown that the number of ancillary ligands in a carboxylate complex is decided by the substituent attached to the aromatic ring [6].

The reaction of zinc(II) sulfate heptahydrate with sodium salts of 3-methylbenzoic acid or 2-methylbenzoic acids in a methanolic solution containing pyridine gave dinuclear zinc complexes having a paddlewheel type structure with two pyridine ligands at axial positions (Fig. 2a and 2b). The metal ligand bond distances and angles are listed in Tables 2 and 3. In each case there are four carboxylate ligands bridging the two zinc centers. On a careful look at the geometry of the complexes it is observed that in the case of complex **4** the orientation of the two planes of the pyridine rings are perpendicular to each other, whereas in the case of **6** the two rings

C(9)–O(4)	1.252(2)		

lies in one plane. The orientation of the rings is attributed to the steric effect of the methyl groups on the crystal packing. The packing pattern of **4** is shown in Fig. 2c, which has a grid-like structure. Dinuclear paddlewheel structure benzoate complexes have been reported [7], but these have not been studied in detail. It has also been observed that non-symmetric carboxylato bridged complexes of zinc can be prepared with pyridine as an ancillary ligand [3a]. We have also recently shown that binuclear or co-crystals of bi and trinclear zinc benzoate complexes can be prepared by varying the reaction conditions [4].

The reaction of zinc sulfate with sodium salts of 3-methylbenzoic acid and 2-methylbenzoic acid in dimethylsulfoxide gave the tetranuclear and pentanuclear zinc complexes **5** and **7,** respectively. From the observation of the formation of two paddle wheel type structures in the case of **4** and **6**, it is clear that methanol has no role in the formation of these dinuclear structures, whereas DMSO, being a more coordinating solvent, leads to an expansion of the nuclearity. The IR spectrum of the dinuclear complex **4**, prepared in methanol solution, shows clear distinctions as compared to the tetranuclear complex **6**, as shown in Fig. 3. Distinctions between the dinuclear complex **5** and the pentanuclear complex **7** are also observed, again shown in Fig. 3. In the case of **5** all the carboxylate groups are bridging, whereas in complex **7** there are bridging as well as monodentate carboxylate ligands. The monodentate carboxylate of **5** shows an IR absorption at 1623 cm^{-1}, whereas for the bridging carboxylate absorptions of the complex, ν_a are at 1601 cm^{-1} and 1578 cm^{-1} and ν_{sCOO} stretchings appear at 1428 cm^{-1} and 1404 cm^{-1}. Complex **4** has ν_a at 1602 cm^{-1} and 1583 cm^{-1} along with a ν_{sCOO} stretching at 1403 cm^{-1}. It has an absorption at 1644 cm^{-1} due to a C=C absorption of the pyridine ring. In a similar manner, complex **6** has a C=C absorption from pyridine at 1634 cm^{-1}, ν_{aCOO-} at 1602 cm^{-1} and 1583 cm^{-1} and ν_{sCOO} stretching at 1403 cm^{-1}. However, complex **7** has all bridging carboxylate ligands and IR absorptions at 1611, 1591 (ν_{sCOO}) and 1399 cm^{-1} (ν_{aCOO}) are observed. The S=O stretching of coordinated DMSO appears at 1004 cm^{-1}.

Complex **7** is a tetranuclear complex having one oxy-ligand shared by four zinc centers. The oxy anion acts as a central point in a tetrahedral geometry formed by four zinc ions and one oxide anion. Among the four zinc centers, three zinc centers are equivalent, are anchored by three carboxylate bridges and are attached to the central oxygen, whilst the other zinc center is bridged by three carboxylate, one oxy ligand and two dimethylsulfoxide ligands. Complex **5** has two symmetry non-equivalent molecules per unit cell. This is a rare example of a polynuclear complex having symmetry non- equivalent molecules in the unit cell. The bond distances and bond angles of zinc with the different ligands, as illustrated in Fig. 4c and d, are listed in Tables 4 and 5. Both the complexes have a combination of six and four coordination geometry around zinc. Complex **7** is symmetric and has a mirror plane that bisects two halves containing the two tetrahedral units anchored by a six coordinated zinc. The complex has two hydroxyl ligands bridging Zn1, Zn2 and Zn3 centers, in which the OH are intramolecularly hydrogen bonded with two free carbonyl groups of the monodentate carboxylate hydrogen. The donor acceptor bond distances in this intramolecular hydrogen bonding O9–

H9···O2 are d_{D-H} 0.77 Å, $d_{D-A,intra}$ 2.73 Å; ⟨D–H···A 170.93°. On the six coordinated zinc center the two bulky groups occupy *cis* positions, which also comply with the strong intramolecular hydrogen bonding. The presence of two uncoordinated carbonyl oxygens at this position could be responsible for further abstraction of protons from the hydroxyl groups. Complex **5**, however, has a central oxy ligand which coordinates to four independent zinc centers to complete three tetrahedral and an octahedral geometry. Complex **5** is similar to the tetranuclear symmetric zinc core reported by Straughan et al. [8], but with the difference that one of the zinc centers gets coordinated to solvent making the complex less symmetric. Additionally such a change of coordination environment by a ligand with the retention of four uniformly coordinated geometries in tetranuclear zinc clusters is known in the literature [3a]. The presence of hexa and tetra coordinated zinc makes our clusters structurally unique. Thus, our clusters possess a new motif containing four coordinated zinc centers along with six coordinated zinc centers. Recently a tetranuclear oxo-cluster of zinc has been reported and it was observed that molecular oxygen is responsible for the formation of such clusters from organo-zinc reactions [2d]. In organo-zinc complexes there is a Zn–C bond, leaving scope for reactions with molecular oxygen, whilst in our reactions the oxo or hydroxo species are generated from water molecules in the sol-

vent and hydrated salts, as these reactions proceed under nitrogen atmosphere and the use of dry solvents led to poor yields of the clusters. DMSO, being an aprotic coordinating solvent, allows the deprotonation of water in basic medium whereas in methanol the labile hydrogen is in a large excess; this thus facilitates the formation of neutral dinuclear species. The formation of the mononuclear aqua complex in the case of **1** suggests that not only the reaction conditions but also the substituent controls the formation of different zinc complexes.

5. Supplementary data

Crystallographic details of the compounds in the form of CIF files are available and they have the CCDC numbers 668242, 668243, 676945–676948 and 612955. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

system. In this work, we present the synthesis, characterization and photophysical studies of monometallic and bimetallic complexes of rhenium(I) and osmium(II) complexes.

2. Experimental

2.1. Materials

$Re_2(CO)_{10}$ (Alfa), $(NH_4)_2OsCl_6$ (Aldrich), 2,2′-bipyridine (Merck), 4,4′-bipyridine (Fluka), $AgCF_3SO_3$ (Alfa) and NH_4PF_6(Alfa) were used as received. All solvents used for the synthesis were of reagent grade and for spectral measurements spectral grade solvents were used.

2.2. Physical Measurements

UV–Vis spectra were recorded on an Analtikjena Specord S100 spectrophotometer and emission spectra were measured in a JASCO FP6300 spectrofluorimeter. All the samples used for emission were purged with dry nitrogen gas for about 20 min. The emission quantum yield was calculated using $[Ru(bpy)_3]^{2+}$ as a standard, which has a quantum yield of 0.062 in degassed CH_3CN. IR spectra were measured using a JASCO FT-IR spectrophotometer. The samples were recorded in the form of KBr pellets. ^1H NMR spectra were recorded on a Bruker 300 MHz NMR spectrometer using $(CD_3)_2SO$ as the solvent. All the mass spectra were recorded using a Quattro LC triple-quadrupole mass spectrometer (Micromass, Manchester, UK) interfaced to an (Electro Spray ionization) ESI source; data acquisition was done under the control of MASSLYNX software (version 3.2). The ESI capillary voltage was maintained between 4.0 and 4.2 kV and the cone voltage kept at 25 V. Nitrogen was used as the desolvation and nebulization gas. The source and desolvation temperatures were 100 °C.

2.3. Electrochemistry

The redox potentials of the complexes were determined by cyclic voltammetric and differential pulse voltammetric techniques using an EG & G Princeton Applied Research Potentiostat/Galvanostat Model 273 A. Measurements were performed by purging the solution in acetonitrile (spectroscopic grade) by dry nitrogen gas for 30 min. The supporting electrolyte was 0.1 M TBAP, Pt was the working electrode, and the Ag/AgCl was the reference electrode.

2.4. Lifetime and transient measurements

The excited state lifetime measurements for all the complexes were made, after degassing the solutions with argon for 30 min, using the time correlated single photon counting (TCSPC) technique and the details are given in previous reports [49]. Transient absorption measurements were made with the laser flash photolysis technique as described elsewhere [49a].

2.5. Synthesis

The complexes $Re^I(CO)_5Br$ [50], $(bpy)(CO)_3ReBr$ [51], $[(bpy)(CO)_3Re(4,4'\text{-bpy})](PF_6)$ [52], $[\{(bpy)(CO)_3Re\}_2(4,4'\text{-bpy})](PF_6)_2$ [52], $[Cl(bpy)_2Os(4,4'\text{-bpy})](PF_6)$ [53] and $[Cl(bpy)_2Os(4,4'\text{-bpy})Os(bpy)_2Cl](PF_6)_2$ [53] were synthesized according to literature procedures.

2.6. $[(CO)_3(bpy)Re(4,4'\text{-bpy})Os(bpy)_2Cl](PF_6)_2$

$Re(CO)_3(bpy)Br$ (0.05 g, 0.099 mmol) and $AgCF_3SO_3$ (0.025 g, 0.099 mmol) were dissolved in MeOH (20 mL) and reluxed for 1 h under a nitrogen blanket. A white precipitate of AgBr was formed. The solution was cooled and filtered to remove the AgBr. To the filtrate was added $[Os(bpy)_2Cl(4,4'\text{-bpy})](PF_6)$ (0.041 g, 0.049 mmol) and the resulting mixture was refluxed for 8 h under an inert atmosphere. After completion of the reaction, the solvent was evaporated under reduced pressure and the residue was dried. The product was separated by column chromatography using alumina as the solid support and a mixture of CH_3CN/toluene as the eluent. A yellow band of unreacted rhenium(I) eluted first, and then increasing the composition of CH_3CN leads to the elution of unreacted $[Os(bpy)_2Cl(4,4'\text{-bpy})](PF_6)$. Finally a brownish band of the product $[(CO)_3(bpy)Re(4,4'\text{-bpy})Os(bpy)_2Cl](PF_6)_2$ got eluted. Yield 64%, ^1H NMR (CD_3COCD_3, δ in ppm): 9.4 (d, 6H), 8.7 (d, 4H), 8.6 (d, 6H), 8.4 (t), 8.0 (t, 6H), 7.7 (m, 6H). ES-MS: m/z = 1265 ($M-PF_6$). IR and electronic spectral data and redox potentials are given in Tables 1 and 2.

3. Results and Discussion

3.1. Preparation

The schematic structures of the complexes that are the focus of the present investigation are illustrated in Chart 1. The rhenium(I) complexes [52], **I**, **II** and osmium(II) complexes [53] **III**, **IV** were prepared by reported procedures. The rhenium(I)–osmium(II) heterobimetallic complex **V** was prepared by the complex as metal/complex as ligand approach [54]. The heterobinuclear complex was synthesized by reacting the monometallic osmium complex carrying the bridging ligand 4,4′-bipyridine with the rhenium precursor complex $[(CO)_3(bpy)Re(CH_3CN)](CF_3SO_3)$. These complexes were characterized by NMR, ESIMS, FT-IR, cyclic voltammetry, UV–Vis and luminescence spectroscopy.

3.2. Infra red spectra

The IR spectral data of the monometallic and bimetallic complexes are gathered in Table 1. The infra red spectra of the rhenium(I) complexes are characterized by intense carbonyl stretching frequencies, ν(CO). Three ν(CO) stretching frequencies are in general observed between 1900 cm^{-1} and 2040 cm^{-1}, corresponding to the facial orientation. The highest energy CO stretching band appears as a very sharp band around 2030 cm^{-1} and the other two bands are relatively broad and overlap considerably. When we compare the ν(CO) stretching frequencies of rhenium complexes **I** and **II** with the heterobimetallic complex **V**, little change is observed. This indicates that the interaction between the Re(I) unit and Os(II) unit is weak.

3.3. ESIMS

The monometallic and bimetallic complexes are characterized by the ESIMS spectral technique. The m/z values for complexes **I**, **III** and **V** are 582, 693 and 1264, respectively, corresponding to the loss of a PF_6^- ion. Other peaks are assigned to the loss of 4,4′-bipyridine and CO moieties. The ESIMS spectra of complexes **III** and **V** are shown in Figs. S1 and S2.

3.4. Electrochemistry

The electrochemical behavior of the monometallic and bimetallic complexes is studied in acetonitrile solution, and the relevant redox potentials are listed in Table 1. For the rhenium(I) complexes the oxidation occurs at 1.73 V. The oxidation/reduction potentials are not observed for the Re(I) complexes at a scan rate higher than 50 mV s^{-1}. In the cathodic region of the cyclic voltammogram, the

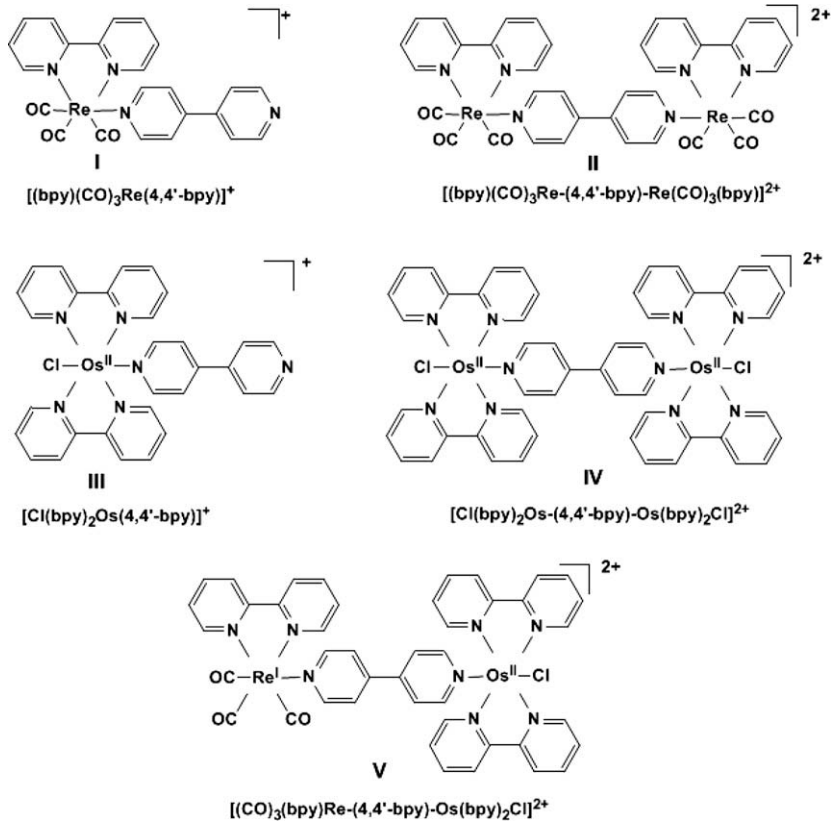

Chart 1. Structure of the complexes.

reduction at a less negative potential can be assigned to that of the bridging ligand. An irreversible wave at −1.20 V can be assigned to the $Re^{I/0}$ reduction. The osmium complexes **III** and **IV** show reversible waves with $E_{1/2}$ values of 0.30 and 0.31 V, respectively, with the anodic and cathodic peak separation (ΔE_p) of 72 mV. The cyclic voltammogram of complex **III** is shown in Fig. 1. In the case of homobimetallic complexes the oxidation potential of the two metal centers is hardly distinguishable. In the cathodic region reduction of the ligands occurs, and the first reduction occurs at a considerably lower potential (−0.84 V), which can be assigned to the reduction of bridging ligand, and the other two reductions at large negative potentials can be assigned to the reduction of the 2,2′-bipyridine ligands.

In the case of the rhenium(I)–osmium(II) heterobimetallic complex **V**, the $E_{1/2}$ value of the $Os^{II/III}$ couple is slightly shifted to a more positive region, which indicates the attachment of the electron withdrawing Re(I) unit to the osmium(II) unit (Fig. 1). The osmium unit shows a nice reversible wave having an $E_{1/2}$ value of 0.35 V. The rhenium(I) oxidation occurs at 1.71 V. In the negative part of the cyclic voltammogram, the bridging ligand reduction

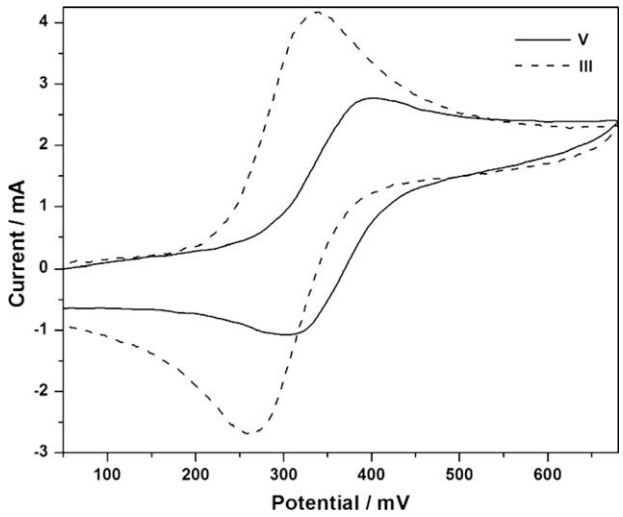

Fig. 1. Cyclic voltammogram of **III** (---) and **V** (—) recorded in CH_3CN at RT with 0.1 M TBAP.

gets merged with the rhenium(I) reduction, which occurs at −1.10 V. As seen in complex **I**, the 2,2′-bipyridine ligand reductions occur at higher negative potentials.

3.5. Absorption spectra

The absorption spectra for all the complexes are recorded in CH_3CN at room temperature and the data are summarized in Table 2. The absorption spectrum of **II** is shown in Fig. 2. For the rhenium(I) monometallic **I** and homobimetallic **II** complexes, the peak in the high energy region is assigned to a ligand centered $\pi \rightarrow \pi^*$ transition and a ^{1}MLCT transition is observed in the region 340–350 nm. For the osmium(II) complexes **III** and **IV**, the intense peak observed in the UV region can be assigned to a ligand centered $\pi \rightarrow \pi^*$ transition occurring in the bipyridine ligand. The bands seen in the visible region between 400 and 560 nm are assigned to spin-allowed ^{1}MLCT transitions and relatively less intense bands seen at wavelengths longer than 560 nm are attributed to a spin-forbidden ^{3}MLCT transition (Fig. 2). Since osmium is a heavy metal, enhanced spin–orbit coupling occurs, which leads to the spin-forbidden ^{3}MLCT transition occurring in the longer wavelength region. In the case of the Re–Os heterobimetallic complex **V**, a peak at *ca.* 348 nm is seen due to the Re(d π) $\rightarrow \pi^*$ MLCT transition and bands in the region 400–550 nm correspond to a Os(d π) $\rightarrow \pi^*$ ^{1}MLCT transition. A relatively less intense peak seen at *ca.* 656 nm is assigned to a ^{3}MLCT transition, arising out of the direct transition from the ground state to the triplet state, owing to spin–orbit coupling seen in osmium complexes. On comparing the absorption spectrum of the Re–Os heterobimetallic complex **V** with that of the rhenium(I) and osmium(II) homobimetallic complexes **II** and **IV**, the bands seen are similar to the latter complexes, except the band around 420 nm is shifted (Fig. 2). This indicates that in the heterobimetallic complex **V** there is only less interaction between the two metal centers.

3.6. Emission

The emission spectra of all the complexes were recorded in CH_3CN at room temperature. The rhenium(I) monometallic complex **I** and bimetallic complex **II** show an emission at *ca.* 580 nm and the emission occurs from a low lying ^{3}MLCT state upon excitation at 348 nm (Fig. 3). When the osmium(II) complexes **III** and **IV** are excited at the wavelength corresponding to the ^{1}MLCT absorption, they display an emission maximum at 690 nm from the ^{3}MLCT state. The Re–Os heterobimetallic complex **V** also shows emission at *ca.* 690 nm, indicating emission from the ^{3}MLCT state of osmium (Fig. 3). When complex **V** is excited at 290 nm, where the ligand centered absorption is predominant, it still shows an emission at 690 nm (Fig. 4). This indicates that irrespective of the excitation wavelength, complex **V** displays an emission at 690 nm from the osmium unit. Since in complex **V**, the lowest energy level may be the ^{3}MLCT state of osmium(II), the emission takes place from osmium. The quenching of emission from the rhenium(I) chromophore at 580 nm on excitation at 290 and 348 nm indicates that an energy transfer process takes place from the rhenium(I) chromophore to osmium(II). The uncorrected excitation spectrum of **V** is shown in Fig. 5, which closely matches the absorption spectrum. This indicates that no photochemical reaction takes place upon irradiation.

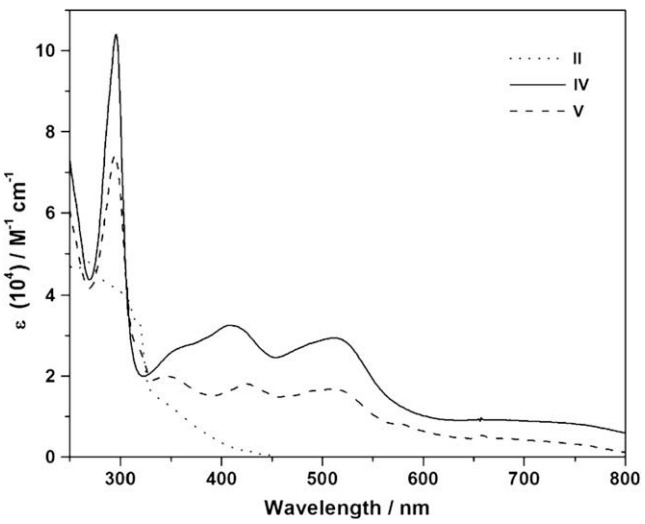

Fig. 2. Absorption spectra of complexes **II** (···), **IV**(—) and **V**(---) in CH_3CN at room temperature.

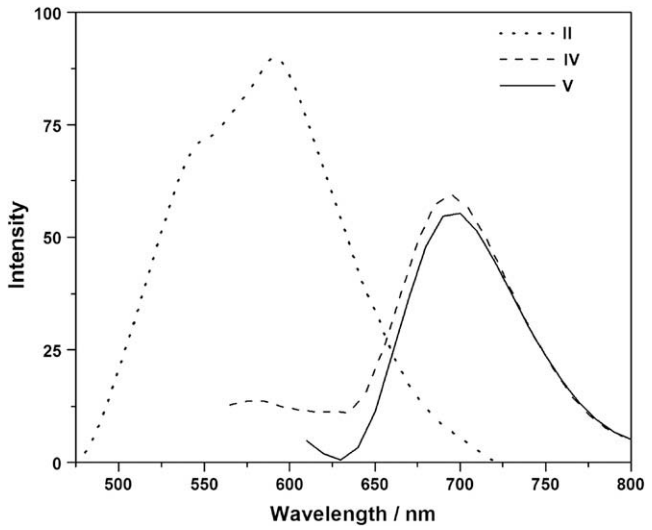

Fig. 3. Emission spectra of complexes **II** (···), **IV**(---) and **V**(—) in CH_3CN at room temperature.

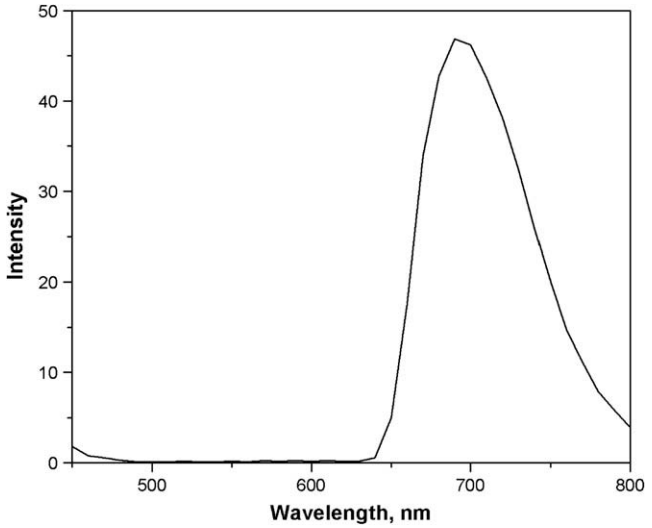

Fig. 4. Emission spectrum of complex **V** in CH_3CN at room temperature, (λ_{ex} = 290 nm).

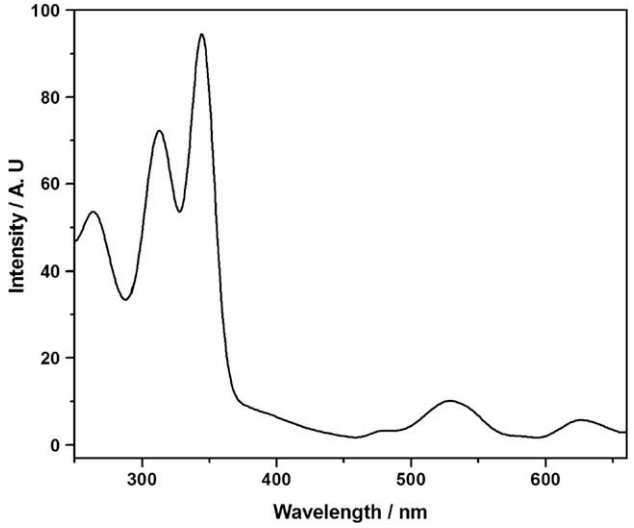

Fig. 5. Excitation spectrum (uncorrected) of **V**.

3.7. Excited state lifetime

The excited state lifetime of all the complexes were recorded in acetonitrile at 298 K and the results are given in Table 2. The excited state lifetime data show that the lifetimes of the rhenium(I) complexes are higher than the osmium(II) complexes. This is because in the osmium(II) complexes, the energy difference between the ground and excited ^{3}MLCT state is less. According to the energy gap law, the non-radiative rate increases exponentially with a decreasing energy gap between the ground state and excited state. So this leads to enhanced non-radiative decay and a decreased lifetime for the osmium(II) complexes. The rhenium(I) complexes **I** and **II** have excited state lifetimes of 240 and 270 ns, respectively. The excited state lifetimes observed here are in accordance with the reported values [52]. The osmium(II) complexes **III** and **IV** have excited state lifetimes of 56 ns each. The lifetimes of the osmium(II) complexes **III** and **IV** are comparable to that of $[Os(bpy)_3]^{2+}$, which has an excited state lifetime of 49 ns in CH_3CN [55]. The rhenium(I)–osmium(II) heterobimetallic complex **V** has an excited state lifetime of 80 ns. The lifetime data indicates that the Re–Os heterobimetallic complex behaves more like the osmium(II) complex.

When we look into the luminescence quantum yield values of the complexes (Table 2), the values are very much higher for the rhenium(I) complexes **I** and **II**. The rhenium(I)–osmium(II) heterobimetallic complex also has a quantum yield similar to that of the osmium(II) complexes. From the excited state lifetime (τ) and quantum yield (Φ_{em}), the radiative and non-radiative rate constants can be calculated using Eqs. (1) and (2):

$$k_r = \Phi_{em}/\tau \quad (1)$$

$$k_{nr} = 1/\tau - k_r \quad (2)$$

The radiative (k_r) and non-radiative (k_{nr}) rate constants for all the complexes are given in Table 2.

The experimental energy transfer rate constant can be calculated using the following equation:

$$k_{et} = (1/\tau) - (1/\tau^0) \quad (3)$$

where τ^0 and τ are the phosphorescence lifetime of **I** and quenched lifetime of the Re(I) component in **V**, respectively. The energy transfer rate constant is found to be 8.7×10^7 s^{-1}.

3.8. Transient spectra

The transient spectra of the complexes were recorded in acetonitrile at room temperature. The transient spectra of the rhenium(I) complexes **I** and **II** show a broad absorption from the near UV to mid-visible region, with higher intensity in the region 370–390 nm (Fig. 6). This corresponds to the formation of the Re^{II}(bpy$^{\cdot}$) excited state [52a]. The bleach, with a maximum occurring at 580 nm, corresponds to the emission of light from the ^{3}MLCT state. The transient spectrum of the osmium(II) complex **III** is shown in Fig. 7. A bleach is observed in the region 450–550 nm with the maximum occurring at 510 nm. This corresponds to the loss of the ground state MLCT absorption of osmium(II). When we compare the transient spectrum of the rhenium(I)–osmium(II) heterobimetallic complex **V** (Fig. 8) with the osmium(II) monometallic complex **III** (Fig. 7), a similar ground state bleach in the region 480–560 nm is observed for the heterobimetallic complex **V**. On the contrary, a broad absorption is seen in this region in the transient spectra of the rhenium(I) complexes **I** and **II** (Figs. 6 and 8). These spectral features indicate the occurrence of an energy

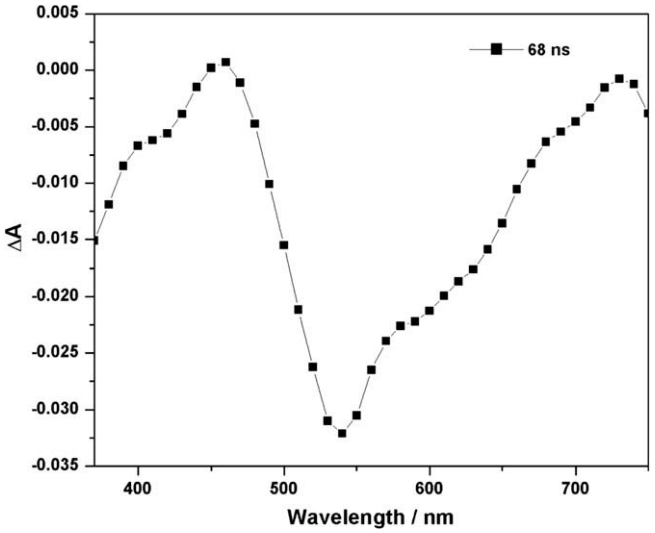

Fig. 7. Transient absorption spectrum of **III** recorded in argon degassed CH_3CN upon excitation at 355 nm at RT. Recorded at 68 ns after excitation.

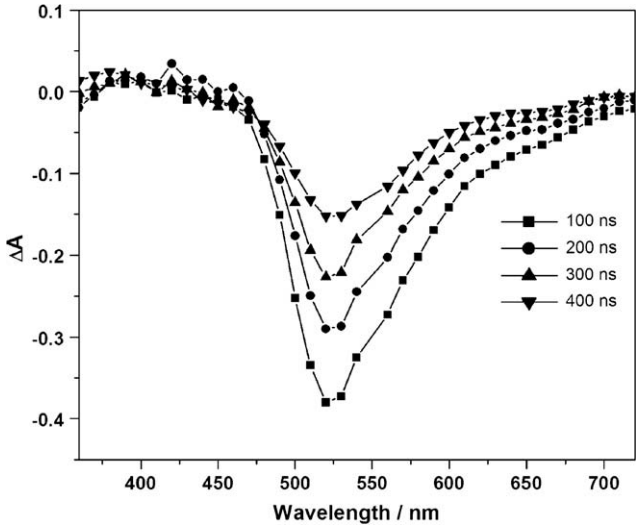

Fig. 9. Transient absorption spectra of **V** recorded at various time intervals in CH_3CN at room temperature.

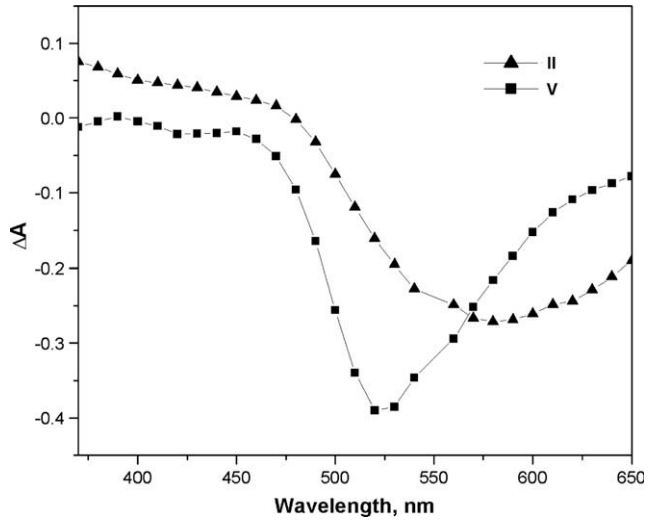

Fig. 8. Transient absorption spectra of **II** (-▲-) and **V** (-■-) recorded in argon degassed CH_3CN upon excitation at 355 nm at RT.

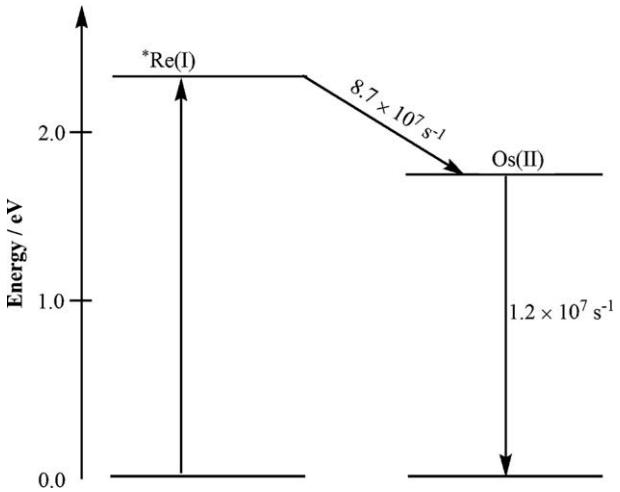

Fig. 10. Energy level diagram depicting the energy transfer from *Re(I) to Os(II) in **V**.

transfer process from the ^{3}MLCT state of *Re(I) to that of the osmium(II) chromophore in **V**. The transient absorption spectra of **V** recorded at various time intervals is shown in Fig. 9. Iha et al. [47b] have studied a series of bimetallic Re(I)–Os(II) complexes, $[(CO)_3(phen)ReLOs(trpy)(bpy)]^{3+}$ (phen = 1,10-phenanthroline, trpy = 2,2′:6′,2″-terpyridine and L = 4,4′-bipyridine (4,4′-bpy), *trans*-1,2-bis(4-pyridyl)ethylene (*t*-bpe) or 1,2-bis(4-pyridyl)ethane (bpa)) and found that an intramolecular energy transfer takes place from *Re(I) to Os(II) with an energy transfer rate constant $k_{en} > 4 \times 10^7\ s^{-1}$. Thus the value of k_{en} calculated in this work is close to the value reported by Iha et al. Also in Ru–Os heterobimetallic complexes, the bleach seen in the transient spectra is due to the decay of the ground state MLCT of osmium(II) because of energy transfer from *Ru(II) [23d,56]. Even in the case of Re(I)–Ru(II) heterobimetallic complexes, an intramolecular energy transfer occurs from *Re(I) to Ru(II) [57] and it is in the range $1.7 \times 10^8\ s^{-1}$–$1.2 \times 10^9\ s^{-1}$ for the complexes studied by Furue et al. [58] Based on the spectral features, a possible energy level diagram depicting the energy transfer process is shown in Fig. 10.

4. Conclusions

A series of monometallic and bimetallic complexes of rhenium(I) and osmium(II) **I**–**V** have been synthesized and characterized by various spectral techniques. The electrochemical and photophysical properties of all the complexes have been studied. From the emission and transient spectral studies it is found that an intramolecular energy transfer occurs from *Re(I) to Os(II). The energy transfer rate constant is found to be $8.7 \times 10^7\ s^{-1}$. The occurrence of energy transfer from Re(I) to Os(II) implies that this heterobinuclear complex has the potential to act as a light harvesting antenna.

Acknowledgements

M.V. and S.R. thank the Department of Science and Technology (DST), New Delhi, India for sanctioning a Project (No. SR/S1/IC-30/2002 dated 08-05-2003 and 15-07-2003) to carry out this research work.

'inactive' form 'active' form (I)

The species in the alkaline solutions are $RHPO_2^-$ (**A**) and $R:P(O)_2^{2-}$ (**B**). The conductivity data of sodium salt of phosphinic acid supports the species HPO_2^{2-} [18], which is intermediate in the base catalysed exchange of hydrogen on phosphinic anion [19] besides being the reactive entity in the oxidations by $Fe(CN)_6^{3-}$ [9], $[Ag(OH)_4]^-$ [20] and Ru(VII) [21] in alkaline solution.

2. Experimental

2.1. Material

The solution of hexacyanoferrate(III) (Fluka, Puriss), prepared from an accurately weighed sample, is stored in the dark. The purity of the sample is ensured by measuring its absorptivity coefficient, 990, that compares well with the value 1000 $dm^3\ mol^{-1}\ cm^{-1}$ at 420 nm [22,23]. The ε value is independent of pH [23] and ionic strength [24]. Subsequent solutions are standardised using ε_{420} = 1000 $dm^3\ mol^{-1}\ cm^{-1}$.

The 50% phosphinic acid solution (Fisher) is iodometrically analysed for H_2PO_3 and H_3PO_3 [25]. The sample had 9.21 and 0.1 mol dm^{-3} of H_2PO_3 and H_3PO_3, respectively. The $C_6H_5H_2PO_2$ sample (Fluka, Technical) is twice recrystallised from hot water. The m.p. of the recrystallised sample is 70–71 °C (lit. 71 °C [26]). The suitably prepared aqueous solutions of RH_2PO_2 are neutralised with a known solution of sodium hydroxide (Sarabhai-M, GR) and are standardised by cerimetry at room temperature [27]. Although the atmospheric oxidation of the $RHPO_2^-$ solutions is not detected over a week yet fresh solutions are prepared every 2–3 days.

The OsO_4 solution is prepared by the dissolution of a known weight of the sample (Johnson Matthey) in 0.1 mol dm^{-3} NaOH solution and stored in a refrigerator from which suitable dilutions are made and standardised by iodometry [9] and spectrophotometrically (ε_{316} = 500 $dm^3\ mol^{-1}\ cm^{-1}$) [28].

Sodium perchlorate solution is prepared by the neutralisation of a known weight of sodium carbonate (BDH, AnalaR) with a known perchloric acid (E. Merck, GR) solution and standardised as described [20]. Solutions of sodium chloride (Sarabhai-M, GR) and potassium chloride (Sarabhai-M, GR) are prepared by direct weighing of the respective samples.

The water is first distilled under mild alkaline conditions using a pinch of potassium permanganate. The first distillate is once again distilled and the second distillate is used through out for the preparation of the solutions. These solutions, if needed, are purged with nitrogen gas before use.

2.2. Rate measurements

The rates are measured at constant ionic strength (μ = 1 mol dm^{-3}, $NaClO_4$), ($[RHPO_2^-] \gg [Fe(CN)_6^{3-}]$), by measuring the disappearance of $Fe(CN)_6^{3-}$ at 420 nm using a Spectrochem Mk (II) colorimeter [29]. The linear plots of $(A_t - A_\infty)$ against time for more than three half-lives of the reaction rules out the biphasic nature of the reaction where A_t and A_∞ are the optical density at a given time and infinite time, respectively. Any contribution to the measured optical density from OsO_4 is negligible because of its very low concentration in the reaction mixture. A_∞ is measured few hours after completion of the reaction. The pseudo zero-order rate constant k_o is calculated by dividing the slope of the plots of $(A_t - A_\infty)$ against time by ε (=1000 $dm^3\ mol^{-1}\ cm^{-1}$). The Beers–Lambert law holds good over the concentrations used. The reproducibility of the pseudo zero-order rate constant k_o is with in ± 5%.

The EXCEL program is used to draw the plots and to obtain the least-square values of the slopes and intercepts. The program ACTE by H. Strahlow is used to calculate the activation parameters. The thermodynamic parameters are calculated with a computer program EQLBPARA written in basic in our laboratory.

2.3. Stoichiometry

The stoichiometry of the reaction is studied from several reaction mixtures with $Fe(CN)_6^{3-}$ in excess over the substrate. The disappearance of $Fe(CN)_6^{3-}$ is measured at 420 nm till the optical density has a constant value using a Hewlett Packard 8452A UV–Vis diode spectrophotometer with a bandwidth of 2 nm and integration time of 0.1 s. The calculated concentration of reacted $Fe(CN)_6^{3-}$ in each mixture indicated that $\Delta[Fe(CN)_6^{3-}]/\Delta[RHP(O)O^-] = 2 \pm 0.05$, which is consistent with the stoichiometry equation (1) and the stoichiometry reported previously [5,9].

$$2Fe(CN)_6^{3-} + RHPO_2^- + 2OH^- \xrightarrow{OsO_4} 2Fe(CN)_6^{4-} + RHPO_3^- + H_2O \quad (1)$$

2.4. Test for free radicals

The nitrogen purged solutions of $Fe(CN)_6^{3-}$ and $RHPO_2^-$ having appropriate concentrations of OsO_4 are taken separately and 2 ml of distilled acrylonitrile is added to each solution. The solutions do not show cloudiness over several minutes. These solutions are then mixed to initiate the reaction and no cloudiness or precipitate is observed over several minutes confirming that free radicals are not generated in the reaction.

3. Results

The zero-order dependence in hexacyanoferrate(III) ion is confirmed by proportionate increase in the $t_{1/2}$ and almost constant value of k_o over a 10-fold variation in the initial $Fe(CN)_6^{3-}$ (Table 1).

The k_o values measured over a 10-fold variation in the initial $[H_2PO_2^-]$ and $[C_6H_5HPO_2^-]$, at different $[OH^-]$ and temperatures, Tables 2 and 3, respectively, indicate that for the same concentrations the rate of $C_6H_5HPO_2^-$ oxidation is slower than that of $H_2PO_2^-$. The results provided linear plots of k_o^{-1} against $[RHPO_2^-]^{-1}$, Fig. 1, with intercepts on the rate ordinate indicating the formation of the intermediate osmium(VIII)–$RHPO_2^-$ complex. The formation of a similar complex is reported in the oxidation of $H_2PO_2^-$ ion [5] but the oxidation of $H_2PO_3^-$ ion does not report the formation of a similar complex [11]. The intercept and slope values of the plots in Fig. 1, Table 4, indicate that these decrease with the increase in the initial $[OH^-]$.

The k_o values increased proportionately with the increase in $[OsO_4]$ (Table 5). The linear plot of k_o against $[OsO_4]$, Fig. 2, almost passes through the origin confirming first-order dependence in OsO_4 and that the reaction between $Fe(CN)_6^{3-}$ and $RHPO_2^-$ is negligibly slow.

The increasing $[OH^-]$, Table 6, increases the k_o and the correlation between k_o and $[OH^-]$ is discussed in the mechanism section. A similar increase in the rate with OH^- is reported in the oxidation of phosphite ion [11] though the nature of dependence is different.

The effect of added NaCl and KCl, Table 7, indicated that the rates are almost the same in the presence of Na^+ and K^+ ions indicating the absence of specific cation effects in the reaction. The plot of k_o against [alkali metal ions] are linear with intercept on the rate ordinate.

Table 1
Dependence of k_o (mol dm^{-3} s^{-1}) on the initial $[Fe(CN)_6^{3-}]$ $10^6[OsO_4] = 1.25$, $[OH^-] = 0.1$, $[RHPO_2^-] = 0.01$ and $\mu = 1.0$ mol dm^{-3}

$10^4[Fe(CN)_6^{3-}] = 4.0$, $10^6[OSO_4] = 1.25$ and $\mu = 1.0$ mol dm^{-3}.

4. Mechanism and discussion

It would be instructive to consider the mechanisms of the OsO_4-catalysed [5] and uncatalysed [9] oxidation of $H_2PO_2^-$ with alkaline hexacyanoferrate (III) ion.

$$H_2PO_2^- + OsO_4(OH)^- \underset{k_{-4}}{\overset{k_4}{\rightleftharpoons}} [complex]^{2-} \quad (i)$$

$$complex^{2-} + OH^- \overset{k'}{\rightarrow} HP^+O_2^- + OsO_3(OH)_3^{3-} \quad (ii)$$

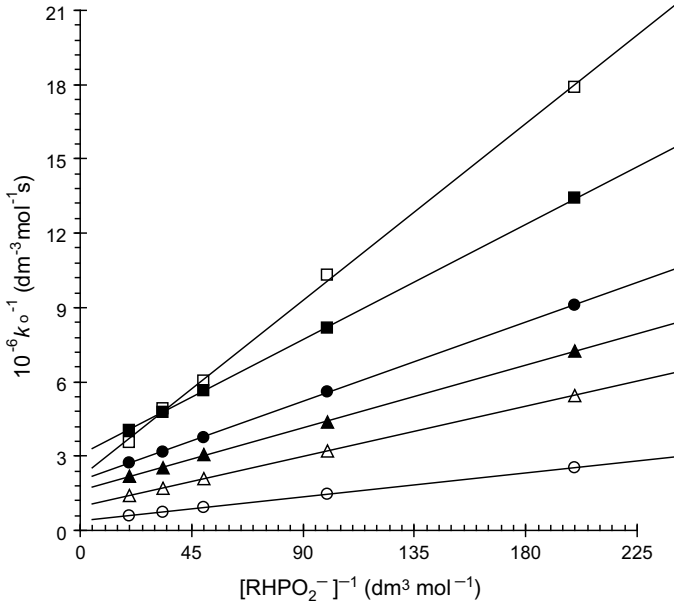

Fig. 1. Some of the linear plots of k_o^{-1} against $[RHPO_2^-]^{-1}$ with intercepts on the rate ordinate are consistent with Eq. (21). For R = H: (□) 30 °C and $[OH^-] = 0.1$; (○) 40 °C and $[OH^-] = 1.0$; (△) 45 °C and $[OH^-] = 0.2$ and for R = C_6H_5: (●) 35 °C and $[OH^-] = 0.5$; (▲) 35 °C and $[OH^-] = 0.7$ and (■) 40 °C and $[OH^-] = 0.1$ mol dm^{-3}. $10^4[Fe(CN)_6^{3-}] = 4.0$, $[OsO_4] = 1.25$ and $\mu = 1$ mol dm^{-3}.

$10^4[Fe(CN)_6^{3-}] = 4.0$, 10^6[OsO_4] = 1.25, [OH^-] = 0.1, [$RHPO_2^-$] = 0.01.

and for the uncatalysed reaction,

$$H_2PO_2^- + OH^- \rightleftharpoons H_3PO_3^{2-} \quad (a)$$

$$H_3PO_3^{2-} + Fe(CN)_6^{3-} \xrightarrow{k''} H_3PO_3^- + Fe(CN)_6^{4-} \quad (b)$$

$$H_3PO_3^- + Fe(CN)_6^{3-} \xrightarrow{fast} H_3PO_3 + Fe(CN)_6^{4-} \quad (c)$$

The empirical rate equation (2) based on the present results is different from the rate equation (v) [5] in respect of dependence on OH^- and $H_2PO_2^-$ ions. The present results indicate an additional path which is independent of OH^- ion. It is therefore imperative that the reaction has a different mechanism.

$$\frac{-d[Fe(CN)_6^{3-}]}{dt} = k_o = \frac{(a + b[OH^-])[RHPO_2^-][OsO_4]_o}{m + n[RHPO_2^-]} \quad (2)$$

Eq. (2) is similar to the rate equation in the oxidation of $H_2PO_2^-$ by square-planar $Ag(OH)_4^-$ ion [20]. However, $m \gg n[H_2PO_2]$ in the $Ag(OH)_4^-$ oxidation is not observed in the present reaction. The reason for the difference is attributable to the relative stability of the complex $H_2PO_2^-$ forms with $Ag(OH)_4^-$ and $OsO_4(OH)^-$/$OsO_4(OH)_2^{2-}$ ions. The osmium species form a stable complex whereas a transition complex is formed by $Ag(OH)_4^-$ ion.

In view of the zero-order dependence in $Fe(CN)_6^{3-}$ ion, an interaction between OH^- and $Fe(CN)_6^{3-}$ is unlikely and is not reported in the literature. It is for this reason that the OH^- dependence in the oxidation of $H_2PO_2^-$ is explained by invoking the equilibrium (a) [9]. A similar equilibrium is also considered in the mechanism of $H_2PO_2^-$ ion oxidation with $Ag(OH)_4^-$ ion [20]. It might be noted that OH^- ion does not react either with $Fe(CN)_6^{3-}$ or $Ag(OH)_4^-$ ions.

However, the equilibrium (a) is not considered in the present reaction for the reason that the equilibrium amount of HPO_2^{2-} is small under basic conditions used and that the (composite) second pK of H_3PO_2 is above 14. On the other hand OsO_4 forms various species with OH^- ions, which are in equilibrium with each other.

In the aqueous solution of OsO_4 the species OsO_4 and H_2OsO_5 are in equilibrium which is shifted more towards OsO_4. The apparent primary ionization constant K_{a1} (1×10^{-12} mol dm^{-3}, μ = 1 mol dm^{-3}, 25 °C) of OsO_4 in weakly KOH solution and the second ionization constant K_{a2} (3×10^{-15} mol dm^{-3}) in the more strong KOH solution are determined spectrophotometrically [30] and are defined by Eqs. (3) and (4), respectively, where $[OsO_4]_o$ is the analytical concentration.

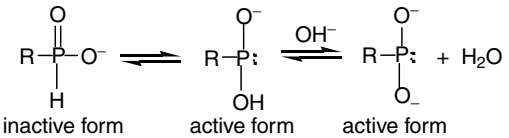
$$K_{a1} = \frac{[H^+][OsO_4OH^-]}{[OsO_4]_o[H_2O]} \quad (3)$$

$$K_{a2} = \frac{[H^+][OsO_4(OH)_2^-]}{[OsO_4(OH)^-][H_2O]} \quad (4)$$

trans-$[OsO_4(OH)_2]^{2-}$ is formed in NaOH and KOH [31,32] in two steps as shown in Eqs. (5) and (6) whereas $[OsO_4OH]^-$, $[O_4Os(\mu\text{-}OH)OsO_4]^-$ and *trans*-$[OsO_4(OH)_2]^{2-}$ ions are formed with RbOH and CsOH [33]. The equilibrium constants K_1 and K_2, estimated from the known K_{a1} and K_{a2} [30] using the relation $K_n = K_{an}/K_w$, have the values 5.55×10^{13} and 16.6 dm^3 mol^{-1}, respectively [32], the later is in fair agreement with the value 24 ± 4 dm^3 mol^{-1} estimated spectrophotometrically [11]. However, K_1 = 302 dm^3 mol^{-1} is reported in another estimate [34], and the use of it indicated that about 95% of OsO_4 existed as $[OsO_4(OH)]^-$. Hence, it is assumed that equilibrium (5) is almost shifted to the right so that OsO_4 is entirely present as $[OsO_4OH]^-$ even in very dilute alkali solution.

trans-$[OsO_4(OH)_2]^{2-}$ is obviously more likely to be the additional reactive species in addition to $[OsO_4(OH)]^-$ in view of the acceleration of the rate with OH^- and the equilibrium (6). The most likely mechanism of the reaction in view of the kinetics results is presented in Scheme 1. The formation of the $OsO_4(OH)RHPO_2^{2-}$ complex is consistent with the observed Michaelis-Menten kinetics [35] with respect to $RHPO_2^-$ ion. However, the formation of a similar complex by $OsO_4(OH)_2^{2-}$ and $RHPO_2^-$ ions is considered unlikely because of the relatively strong repulsion between these ions which react through a bimolecular collision.

The $Fe(CN)_6^{3-}$ ions may form $MFe(CN)_6^{2-}$ with M^+ ions (M = Li, Na, K, Rb). The specific catalytic effect of M^+ ion has been observed



(II)

$$OsO_4 + OH^- \underset{}{\overset{K_1}{\rightleftharpoons}} OsO_4OH^- \quad (5)$$

$$OsO_4(OH)^- + OH^- \underset{}{\overset{K_2}{\rightleftharpoons}} OsO_4(OH)_2^{2-} \quad (6)$$

$$OsO_4(OH)^- + RHPO_2^- \underset{}{\overset{\beta}{\rightleftharpoons}} OsO_4(OH)RHPO_2^{2-} \quad (7)$$

$$OsO_4(OH)RHPO_2^{2-} \xrightarrow{k} OsO_3(H_2O) + RP(O)O_2^{2-} \quad (8)$$

$$OsO_4(OH)_2^{2-} + RHPO_2^- \xrightarrow{k_2} RPO_3^{2-} + OsO_3(H_2O)(OH)^- \quad (9)$$

$$OsO_3(H_2O) + 2Fe(CN)_6^{3-} + 2OH^- \xrightarrow{fast} OsO_4(H_2O)_2 + 2Fe(CN)_6^{4-} \quad (10)$$

$$OsO_3(H_2O)(OH)^- + 2Fe(CN)_6^{3-} + OH^- \xrightarrow{fast} OsO_4(H_2O)_2 + 2Fe(CN)_6^{4-} \quad (11)$$

Scheme 1.

in the $Fe(CN)_6^{3-}$ oxidation of SO_3^{2-} [36], L-ascorbic acid [37], and substituted anilines [38]. $NaClO_4$ and KCl increased the rate in the alkaline $Fe(CN)_6^{3-}$ oxidation of $H_2PO_2^-$ but spectrophotometric measurements did not substantiate the ion pair formation even in presence of high [NaC1O$_4$] or [KCl] [9].

The zero order dependence in $Fe(CN)_6^{3-}$ ion precludes ion pair formation between $Fe(CN)_6^{3-}$ and M^+ ions. However, the ion pairs Na^+—$OsO_4(OH)^-$/Na^+—$OsO_4(OH)_2^{2-}$ can be speculated which are not reported even in the concentrated alkali solutions. M^+ ions are therefore unlikely to act as a bridge between $OsO_4(OH)^-$/$OsO_4(OH)_2^{2-}$ ions and $RHPO_2^-$ ions. The electrostatic repulsion between the negative species is, probably, reduced by the strong hydration of the negatively charged ions. Thus the solvent H_2O molecule is the likely bridge between the two anionic species.

Therefore, the rate acceleration by Na^+ and K^+ ions is attributed to the change in the ionic strength of the medium and the assertion is supported by the application of the Davies' equation (12) [39] since the plot of $\log k_o$ against $(\sqrt{\mu}/1+\sqrt{\mu}-0.01\mu)$ is linear with slopes 1.93 in $C_6H_5HPO_2^-$ and 1.98 in $H_2PO_2^-$. The slope values are consistent with the reaction between $OsO_4(OH)_2^{2-}$ and $RHPO_2^-$ ions.

$$\log k_o = \log k + z_a z_b \left(\frac{\sqrt{\mu}}{1+\sqrt{\mu}} - 0.01\mu\right) \quad (12)$$

The apparent rates of the reaction between $OsO_4(OH)_2^{2-}$ and $RHPO_2^-$ ions is more than four times the rate between OsO_4OH^- and $H_2PO_2^-$ ions and more than three times the rate between OsO_4OH^- and $C_6H_5HPO_2^-$ ions. Hence the major contribution to the effect of the ionic strength is from the reaction (9).

The rate equation derived from the reactions in Scheme 1 is given by Eq. (13).

$$\frac{-d[Fe(CN)_6^{3-}]}{dt} = (k\beta + k_2K_2[OH^-])[OsO_4OH^-][RHPO_2^-] \quad (13)$$

The mass balance of the osmium species considered in Eqs. (6) and (7) is given by Eq. (14).

$$[OsO_4OH^-] = \frac{[OsO_4]_o}{1 + K_2[OH^-] + \beta[RHPO_2^-]} \quad (14)$$

The relation expressed in Eq. (15) can be established in view of the reaction (10) or (11).

$$\frac{d[OsO_4]}{dt} = \frac{d[Fe(CN)_6^{3-}]}{2dt} \quad (15)$$

The substitution of the value of $[OsO_4OH^-]$ from Eq. (14) into Eq. (13) and the application of the relation expressed in Eq. (15), changes Eq. (13) to (24), which modifies to Eq. (25) on the assumption that $(1+\beta[RHP(O)O^-]) \gg K_2[OH^-]$ because K_2 is likely to have less value than the estimated values[1] in the present context because the concentrations of OsO_4OH^- and $OsO_4(OH)_2^{2-}$ are being constantly depleted by the reaction with $RHPO_2^-$ ion.

$$\frac{-d[Fe(CN)_6^{3-}]}{dt} = k_o = \frac{2(k\beta + k_2K_2[OH^-])[OsO_4]_o[RHPO_2^-]}{1 + K_2[OH^-] + \beta[RHPO_2^-]} \quad (16)$$

$$k_o = \frac{2(k\beta + k_2K_2[OH^-])[OsO_4]_o[RHPO_2^-]}{1 + \beta[RHPO_2^-]} \quad (17)$$

Eq. (25) is consistent with the linear plot of k_o against $[OsO_4]$, Fig. 2, that passes through the origin and the linear plots of k_o against $[OH^-]$, Fig. 3, with intercepts on the rate ordinate. The inverted Eq. (25) is given in Eq. (18).

$$\frac{1}{k_o} = \frac{1}{2(k\beta + k_2K_2[OH^-])[OsO_4]_o[RHPO_2^-]} + \frac{\beta}{2(k\beta + k_2K_2[OH^-])[OsO_4]_o} \quad (18)$$

Eq. (18) is consistent with the double reciprocal plots such as shown in Fig. 1. The estimated intercept and slope values of such plots, Table 4, are used to estimate the values of β (=intercept/slope) given in Table 8. It is noted that the β value is independent of the initial $[OH^-]$, which is in agreement with the Eq. (18) which further suggests that the correlation of the slope and intercept values, Table 4, with the $[OH^-]$ are given by Eqs. (19) and (20).

$$\text{Slope}^{-1} = 2(k\beta + k_2K_2[OH^-])[OsO_4]_o \quad (19)$$

$$\text{Intercept}^{-1} = 2(k + k_2K_2\beta^{-1}[OH^-])[OsO_4]_o \quad (20)$$

[1] Calculated values of K_2 from the data in [17] are 27, 30, 36 and 42.5 dm^3 mol^{-1} at 30, 35, 40 and 45 °C, respectively.

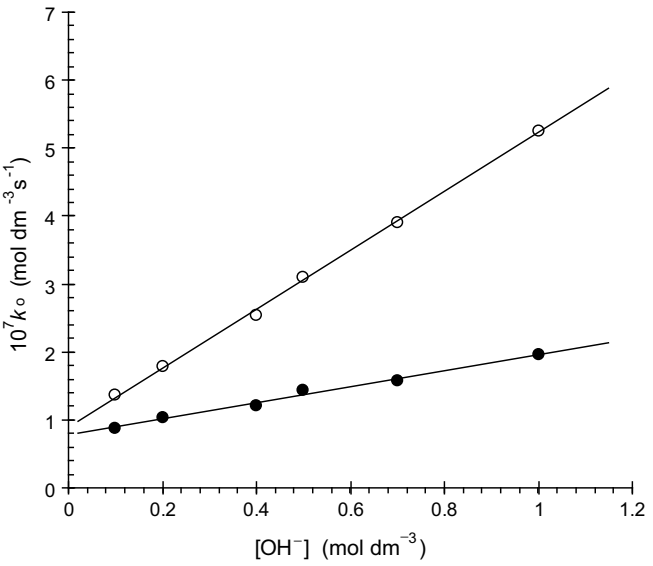


Fig. 3. Some representative plots of the dependence of k_o on the initial [OH$^-$] for the oxidation of $C_6H_5HPO_2^-$ at 30 °C (●) and (○) for $H_2PO_2^-$ at 35 °C. 10^4[Fe(CN)$_6^{3-}$] = 8.0, 10^6[OsO$_4$] = 1.25, [$RHPO_2^-$] = 0.01 and μ = 1 mol dm^{-3}.

The values of β, k and k_2K_2, Table 9, are calculated from the slope and intercept values of the plots in Figs. 4 and 5. The k and k_2K_2 values, calculated from the two plots, are in fair agreement and thus the proposed mechanism is supported. Although the K_2 values (footnote 2) are known yet the k_2 values are not separated from the estimated k_2K_2 values because the equilibria 6 and 7, from which the K_2 values were estimated, are disturbed by the depletion of the concentrations of the species OsO_4OH^- and $OsO_4(OH)_2^{2-}$ because of their reaction with the $RHPO_2^-$ ions as shown in reactions (8)–(10). Thus, K_2 is unlikely to retain the reported values during the course of the redox reaction. The Arrhenius plots for k, k_2K_2 and β are shown in Fig. 6.

The higher β value in the oxidation of $C_6H_5HPO_2^-$ is ascribed to the presence of nucleophilic C_6H_5 group which stabilises the Os(VIII)–$C_6H_5HPO_2^-$ complex. This is consistent with the significantly lower ΔH° and ΔS° values for $C_6H_5HPO_2^-$ than those for $H_2PO_2^-$ ion. It is further noted that the ΔG° value for $H_2PO_2^-$ and $C_6H_5HPO_2^-$ is almost identical indicating the compensatory effect of ΔH° and ΔS°. The plot of ΔH° against ΔS° to establish the isokinetic effect is not attempted because there are only two points.

The k and k_2K_2 values in $H_2PO_2^-$ are about two times the values in $C_6H_5HPO_2^-$ because the chances of C–H fission in $C_6H_5HPO_2^-$ are statistically reduced by half of those possible in $H_2PO_2^-$ ion. Another reason for the low values of k_2K_2 in $C_6H_5HPO_2^-$ is the steric effect of the bulky phenyl group. The $\Delta H_k^\ddagger$, $\Delta S_k^\ddagger$ and $\Delta G_k^\ddagger$ values for $H_2PO_2^-$ and $C_6H_5HPO_2^-$ are almost similar and so are the values of $\Delta H_{k_2K_2}^\ddagger$, $\Delta S_{k_2K_2}^\ddagger$ and $\Delta G_{k_2K_2}^\ddagger$ supporting the common mechanism. The negative entropies in both the cases are supportive of the bond making in the formation of the intermediate or the transition state. However, the $\Delta S_k^\ddagger$ corresponding to the intermediate $OsO_4(OH)RHPO_2^{2-}$ complex is significantly more negative than $\Delta S_{k_2K_2}^\ddagger$ which corresponds to the transition state is consistent with the expectation for the intermediate is more tightly held than the transition state. And another reason is that the large number of water molecules form the hydration sphere around the intermediate because of the increased charge on it so that the degree of freedom of water molecules is greatly curtailed.

Table 8
The values of β, which are independent of [OH$^-$], at different temperatures and related thermodynamic parameters

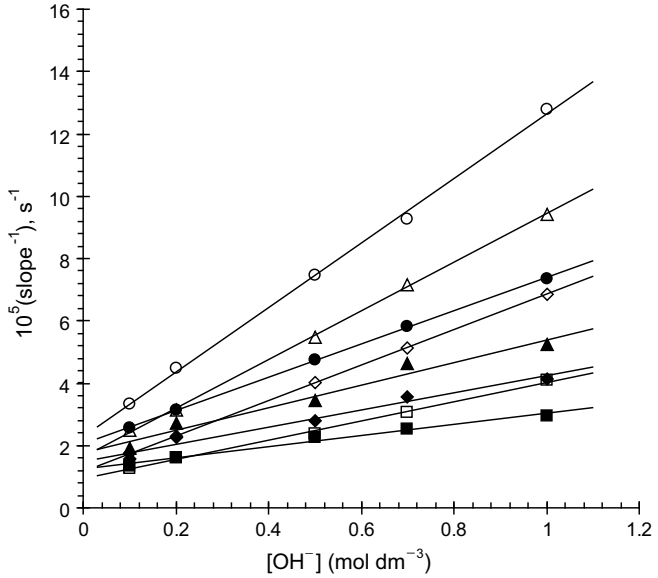

Fig. 4. The linear plots of slope^{-1} against [OH$^-$] with intercepts are consistent with Eq. (22) at temperatures 30 °C (□), 35 °C (◇), 40 °C (△) and 45 °C (○) for $H_2PO_2^-$, and for $C_6H_5HPO_2^-$ at 30 °C (■), 35 °C (♦), 40 °C (▲) and 45 °C (●). The slope values are from the plots such as shown in Fig. 1.

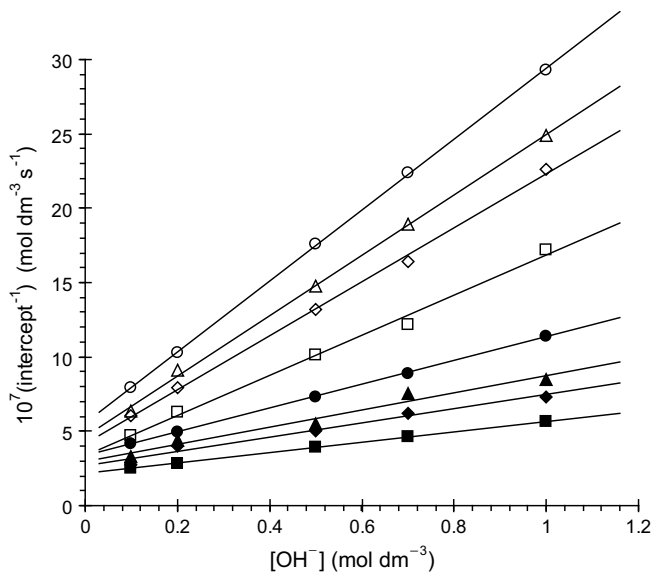

Fig. 5. The linear plots of intercept^{-1} against [OH$^-$] with intercepts are consistent with Eq. (23) at temperatures 30 °C (□), 35 °C (◇), 40 °C (△) and 45 °C (○) for $H_2PO_2^-$, and for $C_6H_5HPO_2^-$ at 30 °C (■), 35 °C (♦), 40 °C (▲) and 45 °C (●). The intercept values are from the plots such as shown in Fig. 1.

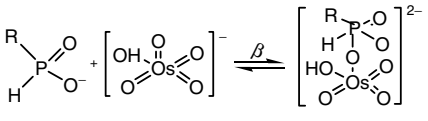
The considerably higher value of $\Delta H^{\ddagger}_{k_2K_2}$ than $\Delta H^{\ddagger}_{k}$ is obvious considering that a bimolecular reaction between $OsO_4(OH)_2^{2-}$ and $RHPO_2^-$ ions will have a high value of activation enthalpy than the activation enthalpy corresponding to the decomposition of the complex.

The structure of the complex $[OsO_4RP(O)O]^{2-}$ and the nature of electron transfer with in the complex and the bimolecular reaction between $[OsO_4(OH)_2]^{2-}$ and $RHP(O)O^-$ is shown in Eqs. Eqs. (21)–(23).



(21)

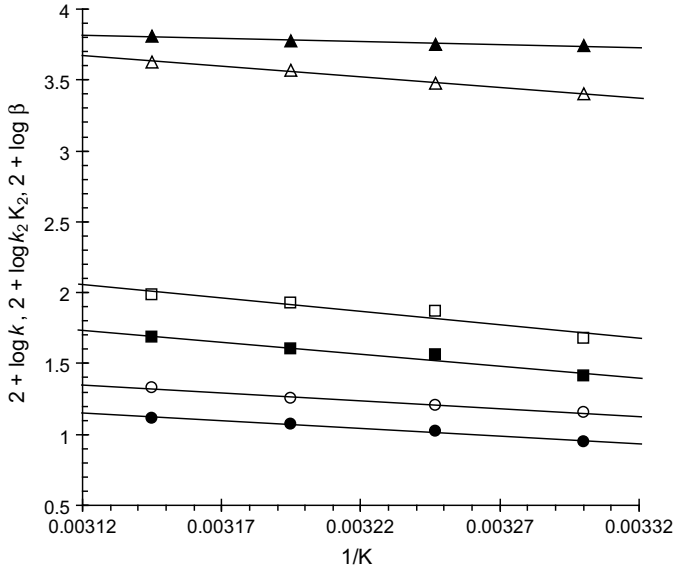


Fig. 6. The plots of log$k$ (□), logk_1 (○) and logβ (△) for $H_2PO_2^-$ and, that of log$k$ (■), logk_1 (●) and logβ (▲) for $C_6H_5HPO_2^-$ against 1/K.

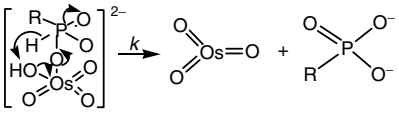
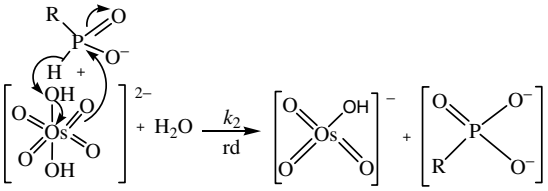


(22)



(23)

It is interesting to note that the Arrhenius energy of activation (83 kJ mol^{-1}, [19]) for the formation of the active tautomer from the inactive tautomer of $H_2PO_2^-$ ion is higher than those corresponding to the rate constants k and k_2K_2 for the rate determining steps considered in the mechanism. It is therefore considered appropriate to assume that the inactive tautomer is the reactant species and the active tautomer does not participate in the mechanism. Since the behaviour of $C_6H_5PO_2^-$ ion is similar to that of $H_2PO_2^-$ ion, therefore a similar conclusion can be made in respect of the reactive tautomeric form of $C_6H_5PO_2^-$ ion.

5. Conclusion

In conclusion it is surmised that the zero order in $Fe(CN)_6^{3-}$ preclude the ion pair formation between $Fe(CN)_6^{3-}$ and the alkali metal M^+ ions. Since the size of M^+ does not affect the rate, the M^+ ions are considered to contribute to the observed ionic strength. The major part of the slope of the Davies' plot, ~2, is probably contributed by the reaction between $OsO_4(OH)_2^{2-}$ and $H_2PO_2^-$ ($z_az_b = 2$) and the minor part by the reaction between OsO_4OH^- and $H_2PO_2^-$ ions ($z_az_b = 1$). it may be the resultant value of the two rate determining steps. The two osmium(VIII) species, which are in equilibrium with each other in the alkali solution, differ from each other by one hydroxyl ion and both of these are reactive. Thus the component of the rate independent of OH^- is ascribed to the reaction of $RHPO_2^-$ with the OsO_4OH^- ion. The reaction between $OsO_4(OH)_2^{2-}$ and $RHPO_2^-$ ions is probably through a bimolecular collision. The Michaelis-Menten plot is ascribed to the formation of the intermediate complex $OsO_4(OH)RHPO_2^{2-}$ by $OsO_4(OH)^-$

and $RHPO_2^-$ ions. This conclusion is based on the comparison of the rate limiting constants involving OsO_4OH^- and $OsO_4(OH)_2^{2-}$ ions. Therefore, the reaction does not have a resemblance with the mechanism of the oxidation of phosphinic acid by tetrahydroxoargentate(III) ion in which the OH^- ion attacks the transition state [20].

2.1.2. Preparation of the ligands

The ligands SMDTC and SBDTC have been synthesized according to the known methods of Audrieth et al. [23] and Ali and Tarafdar [24], respectively. Briefly, 11.4 g of (0.2 mol) KOH in 70 ml of absolute ethanol with 10 g (0.2 mol) of hydrazine hydrate was kept in an ice bath (temperature below 5 °C) and chilled CS_2 (0.2 mol, 15.2 g) was added dropwise over a period of 1 h with constant stirring (caution! CS_2 should not be added at a faster rate). A yellow mass was obtained after the complete addition of CS_2 and the reaction mixture was stirred for another half an hour. The yellow mass was separated and dissolved in cold 40% aqueous ethanol (60 ml). The mixture was again kept in an ice bath and CH_3I (0.2 mol, 20.8 g) for SMDTC or benzyl chloride (0.2 mol, 25.2 g) for SBDTC was added dropwise such that the temperature of the solution was maintained between 0 and 5 °C. After the complete addition of CH_3I or $PhCH_2Cl$, a white product formed which was filtered off and finally washed with water. Recrystallisation from CH_2Cl_2 gave the pure white crystalline ligand. The yield is 65–70% in each case. ^{1}H NMR of SMDTC (ppm, DMSO-d_6): δ 10.79 (1H, s, N*H*, thiol form), 5.06 (2H, s, NH_2), 3.48 (3H, s, SCH_3), 2.70 (1H, s, N*H* thione form). ^{1}H NMR of SBDTC (ppm, DMSO-d_6): δ 10.86 (1H, s, N*H*), 7.42–7.20 (5H, m, C_6H_5), 4.38 (2H, s, CH_2, thione form), 4.37 (2H, s, CH_2, thiol form).

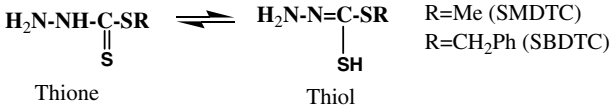
2.1.3. General method of preparation of the complexes

To 1 mmol (0.331 g) of cadmium nitrate tetrahydrate dissolved in ethanol (10 ml) (ACS grade, ≥99.5%) was added the appropriate *S*-alkyl/aryl dithiocarbazate (2 mmol) in the same solvent (20 ml). The resulting solution was heated at 60 °C while being stirred for 20 min, whereupon a white flocculent precipitate formed. The solid thus obtained was filtered off and washed with hot aqueous ethanol and dried over silica gel. The crude products were recrystallized from water. During recrystallization good quality colorless single crystals of **1** were obtained for X-ray data collection. Yield: 55–60% in each case. For **1**: m.p. (decomposition) 120–122 °C, $\Lambda_m = 180\ \Omega^{-1}\ cm^{-2}\ mole^{-1}$, *Anal.* Calc. for $C_6H_{18}N_8S_6O_6Cd$: C, 11.95; H, 2.98; N, 18.59; S, 31.87. Found: C, 11.78; H, 2.93; N, 18.81; S, 31.79%. ^{1}H NMR (ppm, DMSO-d_6): δ 10.93 [1H, br s, N*H*], 3.73 [1H, m, CN*H*]. For **2**: m.p. (decomposition): 152–154 °C, $\Lambda_m = 175\ \Omega^{-1}\ cm^{-2}\ mole^{-1}$, *Anal.* Calc. for $C_{16}H_{20}N_6S_4O_6Cd$: C, 30.36; H, 3.16; N, 13.28; S, 20.24. Found: C, 30.45; H, 3.17; N, 13.15; S, 20.38%. ^{1}H NMR (ppm, DMSO-d_6): δ 10.97 [1H, br s, N*H*], 7.35 [5H, m, C_6H_5], 4.46 [2H, s, CH_2].

2.2. Characterization

2.2.1. Instrumentations

Elemental analyses were carried out with a FISONS EA-1108 CHN analyzer. The molar conductances of 10^{-3} (M) solutions of the metal complexes in DMSO were measure at 30 °C using a Thermo Orion model 550A conductivity meter and a dip-type cell with a platinised electrode. IR spectra (4000–500 cm^{-1}) were recorded on a Bruker EQUINOX 55 FT-IR spectrophotometer with samples prepared in KBr pellets. The electronic spectra of the complexes were recorded with a Varian Cary 5000 spectrophotometer. The TG analyses were recorded in a TGA Q500 V6.7 Build 203 TG instrument at a heating rate of 10 °C/min under nitrogen. The ^{1}H NMR spectra were recorded on a Bruker AMX-500 FTNMR spectrophotometer at room temperature using DMSO-d_6 as the solvent.



Scheme 1. Thione–thiol tautomerism of the ligands.

2.2.2. Crystal structure determination by X-ray Crystallography

The epoxy-coated crystal was mounted on a Bruker SMART APEX II X-ray diffractometer equipped with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) and a CCD area detector. The intensity data were collected in the phi and omega scan mode, operating at 50 kV, 30 mA at 296 K [25]. The data reduction was performed using the SAINT and SADABS programs [26].

All calculations in the structural solution and refinement were performed using the Bruker SHELXTL program [27]. The structure was solved by the heavy atom method and refined by full-matrix least-squares methods. All the non-hydrogen atoms were refined anisotropically; the hydrogen atoms were geometrically positioned and fixed with isotropic thermal parameters. The final difference of electron density maps contained no significant features.

3. Results and discussion

The ligand molecules have a proton adjacent to the thiocarbonyl group and consequently can exhibit thione–thiol tautormerism (Scheme 1). The IR spectra do not display any ν_{S-H} band at *ca.* 2600 cm^{-1}, but exhibit ν_{NH} bands in the range 3100–3200 cm^{-1}, indicating that the ligands remain in the thio-keto tautomer in the solid state. The ^{1}H NMR spectra of the ligands in DMSO-d_6 show that the ligands exist in solution with a second isomer. A sharp singlet, which integrates as one hydrogen at δ = *ca.* 10.80 ppm, is assigned by the reduced intensity of the α-NH of the ligand molecule. Another singlet at δ = 5.06 ppm in the spectrum of SMDTC corresponds to NH_2 protons but the corresponding signal does not appear in the spectrum of SBDTC. Furthermore the existence of the thiol form is indicated by the presence of two overlapping signals for CH_2 at 4.37 and 4.38 ppm in the ^{1}H NMR spectrum of SBDTC [28].

3.1. Characterization of the complexes

Solid state isolation and the satisfactory results of elemental analysis, conductance values and spectral studies including thermogravimetric analysis revealed that the reported cadmium(II) complexes derived from SMDTC and SBDTC were of good purity. The complexes are stable at room temperature and may stored in a desiccator over silica gel for a long time without any sign of decomposition and they are soluble in polar coordinating solvents like water, pyridine, DMF and DMSO. The molar conductivity

Table 1
Characteristic IR data of the ligands and their cadmium(II) complexes

Compound	ν_{NH/NH_2}	ν_{C-N}	$\nu_{C=S}$	ν_{N-N-C}	Mixed ν_{C-N} and ν_{N-N}
SMDTC	3178	1495	941	1360	1615
$[Cd(SMDTC)_3]\cdot 2NO_3$ (**1**)	3154	1523	954	1382	1626s
SBDTC	3177	1468	950	1344	1608
$[Cd(SBDTC)_2]\cdot 2NO_3$ (**2**)	3159	1496	963	1383	1601

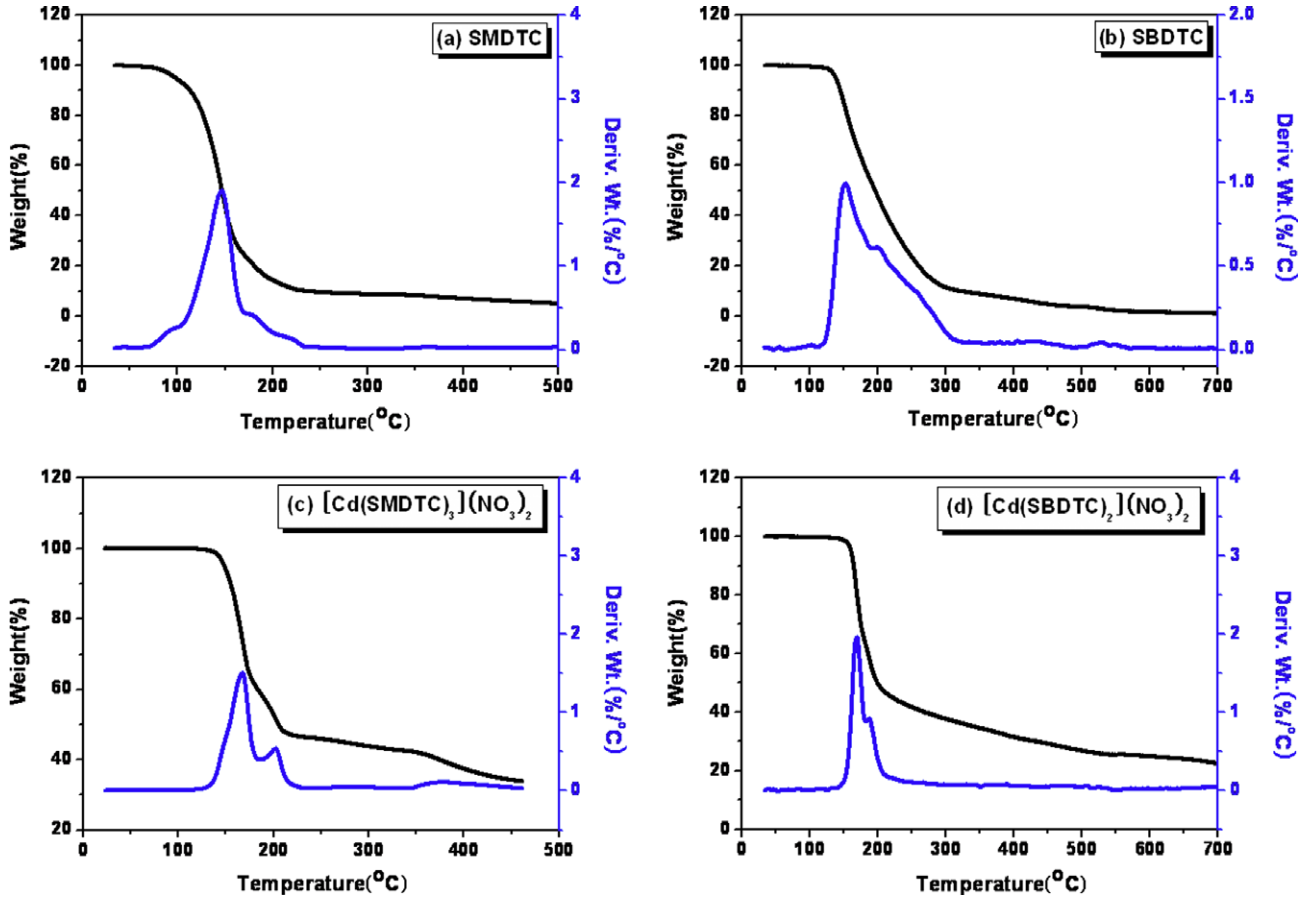


Fig. 1. TGA and DrTGA of the ligands and their cadmium(II) complexes.

values of the complexes in DMSO are quite close to those expected for 1:2 electrolytes and also confirm that the ligands coordinate to the cadmium atom in their neutral thione forms.

Infrared spectral studies (4000–500 cm^{-1}) for the uncomplexed ligands show two significant broad bands in the range 3300–3175 cm^{-1} which are attributed to the asymmetric and symmetric stretching modes of the NH_2 group and the absence of a band in the region 2600–2500 cm^{-1} indicates the absence of a free –SH group, at least in the solid state of the ligands [2]. The bands in the range 1468–1495 cm^{-1} and 1608–1615 cm^{-1} in the free ligand have been assigned to ν_{C-N} and mixed vibration ν_{C-N} and ν_{N-N}, respectively whereas the band in the region 1345–1360 cm^{-1} is due to the ν_{C-N-N} vibration. The other band in the range 950–941 cm^{-1} is ascribed to the C=S stretching vibration of the free ligands [10,22]. A comparative study of the IR spectral data of the reported complexes with those of the uncomplexed ligand (Table 1) provide meaningful information regarding the bonding sites of the ligand molecule. The strong IR band appearing in the range 3300–3175 cm^{-1} in the free ligand spectra has been found to shift to the lower frequency region in the spectra of the complexes, due to probable involvement of the nitrogen of the NH_2 group in bonding. The positive shift of the ν_{C-N} frequencies in the range 1468–1495 cm^{-1} (in the free ligands spectra) to 1496–1523 cm^{-1} on complexation with a cadmium ion indicates involvement of the nitrogen atom in bonding, indicating shorter C–N bond lengths. The vibration bands in the range 954–963 cm^{-1}, due to the C=S stretching vibration, shift to the high energy side by *ca.*15 cm^{-1} in comparison with the free ligands pointing to the participation

Table 2
Characteristic TGA data of the ligands and their cadmium(II) complexes

Complex	Loss in weight % found (calcd)	Assignment	Temperature range (°C)
SMDTC	70.17(72.13)	Loss of CH_3SH and H_2NNH_2 Loss of sulfur	80–160
	26.22(24.92)		160–240
$[Cd(SMDTC)_3] \cdot 2NO_3$ (**1**)	39.64(40.50)	Loss of two ligand	120–182
	13.71(14.94)	Loss unit $H_2NHNCSCH_3$	182–224
	12.91(12.61)	Loss of N_2O_3	230–400
	33.74(34.59)	Residue CdS and "2S"	400–461
SBDTC	46.07(45.95)	Loss of $PhCH_2$- unit	110–191
	52.16(54.05)	Loss of remaining part	191–700
$[Cd(SBDTC)_2] \cdot 2NO_3$ (**2**)	36.35(38.92)	Loss of two unit $PhCH_2S$	137–182
	21.96(19.60)	Loss of two NO_3 group	183–256
	18.76(18.65)	Loss of $SCNHNH_2$ and $CNHNH_2$ simultaneously	256–700
	22.33(22.83)	Residue CdS	>700

Table 3
Crystal data and structure refinement details for $[Cd(SMDTC)_3] \cdot 2NO_3$ (**1**)

Chemical formula	$C_6H_{18}N_8O_6S_6Cd$
Formula weight	603.04
Temperature (K)	296(2)
Wavelength (Å)	0.71073
Crystal system	monoclinic
Space group	$P21/n$
Unit cell dimensions	
a (Å)	14.9513(2)
b (Å)	7.9769(1)
c (Å)	19.4887(3)
α (°)	90
β (°)	111.418(1)
γ (°)	90
V (Å^3)	2163.80(5)
Z	4
D_{calc} (g cm^{-3})	1.851
μ(Mo Kα) (mm^{-1})	1.628
F(000)	1208
Crystal size (mm)	0.39 × 0.30 × 0.15
θ range for data collection (°)	1.48–28.38
Index range	$-19 \le h \le 14$, $-10 \le k \le 10$, $-26 \le l \le 26$
Reflections measured	22434
Independent reflections	5373 (R_{int} = 0.0218)
Completeness to θ = 28.38° (%)	99.1
Absorption correction	multi-scan
Maximum and minimum transmission	0.7923, 0.5694
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	5373/0/244
Goodness of fit on F^2	1.009
Final R indices [$I > 2\sigma(I)$]	0.0283, 0.0625
R indices (all data)	0.0421, 0.0685
Largest difference in peak and hole (e Å^{-3})	0.528, −0.555

of the sulfur atom of the C=S group as a possible coordination site [29,30].

The complexes were prepared using a metal:ligand molar ratio of 1:2. For complex **2** the elemental analysis is consistent with the proposition having a 1:2 molar ratio, whereas the elemental analysis result of complex **1** indicates that the complex has a metal–ligand ratio of 1:3. The reaction was repeated using a 1:3 metal:ligand ratio and the product had the same decomposition temperature and IR spectrum as that prepared using a 1:2 stoichiometry, this is also further substantiated by the crystal structure analysis of **1**. The electronic spectra of the ligands exhibit two distinct absorption bands with very high intensity above 25000 cm^{-1} because of the presence of the chromophore. The UV–Vis spectra of the complexes are similar in this region. The presence of very high intensity bands in the ligands results in the overlapping of the ligand bands and the charge-transfer bands electronic spectra, and are therefore not useful in deducing the structure of the complexes. However the spectra of most of the reported four coordinated complexes have tetrahedral structures [31,32], so the structure of complex **2** is also expected to be tetrahedral.

The ^{1}H NMR spectra of the cadmium(II) complexes, when compared to that of the free ligands, show slightly downfield shifts of the positions of the NH_2 protons, NH proton and SCH_2 protons (with different chemical environments), ascribed to the fact that the coordination of the ligands to the cadmium(II) center through the β-nitrogen and thione sulfur reduces the electron density at these atoms to different extents. The appearance of a peak at a δ value of *ca.* 10.95 ppm in the spectra of the complexes for an exchangeable proton of the ligands indicates that the coordination occurs with the thione form, which is also in accordance with the findings of the IR spectra. The presence of all the characteristic peaks slightly downfield in the spectra of the complexes with respect to their ligand spectra, along with the solvent peaks, which appears nearly at the same position both in the spectra of the ligands and complexes, indicates that the ligand molecules still remain coordinated with the cadmium ion in the presence of the strongly coordinating DMSO solvent. The ^{1}H NMR spectra thus provide support for the bonding characteristic of the primary ligand in forming complexes with cadmium(II) ion as a neutral 'NS' donor [28].

The thermogravimetric analyses (TGA) are conducted to evaluate the physical behavior of the complexes. The TGA and DrTGA curves of the ligands and complexes are presented in Fig. 1 and the results are tabulated in Table 2. From the TGA/DrTGA curve of SMDTC, it can be concluded that the decomposition of the ligand is initiated at 80 °C and loses almost 90.26% by 240 °C. The 4.88% residue may be due to some trace amount of elemental sulfur or

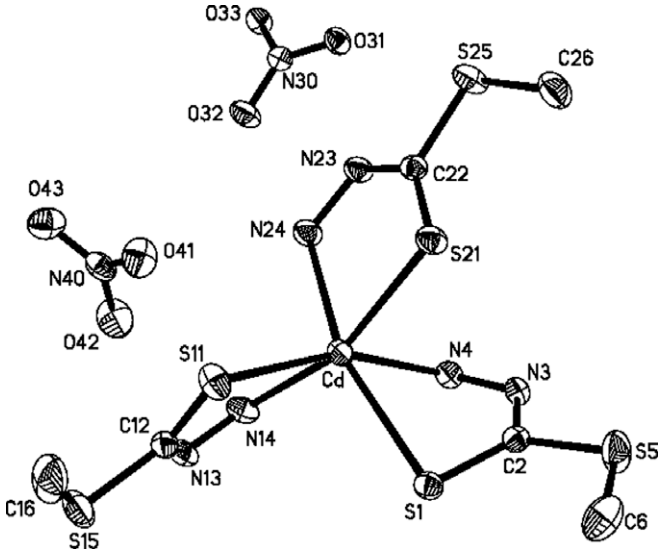

Fig. 2. ORTEP drawing of $[Cd(SMDTC)_3] \cdot 2NO_3$ (**1**) with the atomic numbering. Thermal ellipsoids are drawn at the 25% probability level.

impurities. SBDTC shows two significant mass losses in the temperature ranges 110–191 °C (46.07%) and 191–700 °C (52.16%) due to loss of the benzyl unit and the other residual part of the ligand, respectively. The TGA curve of complex **1** (Fig. 1c) shows three weight losses in the temperature ranges 120–182, 182–224 and 230–461 °C. The first mass loss can be attributed to the loss of two moles of SMDTC ligand, while the second represents loss of the $H_2NHNCSCH_3$ unit from the remaining ligand and N_2O_3 from nitrate groups is lost in the third stage. CdS formation starts from this stage and is complete at 461 °C. The TGA curve of complex **2** shows three stages (Fig. 1d). The first with a loss of 36.35% of the total weight of the complex is due to the loss of two units of $PhCH_2S$ at 137–182 °C. The second stage corresponds to the loss of 21.96% weight and is assigned to the loss of two NO_3 groups at 183–256 °C. The last stage can be assigned to the loss of 18.76% at 256–700 °C due to decomposition of the complex into CdS residue, which is very close to the 22.33% of the total weight of the complex. TGA analysis shows that the complexes are relatively volatile with respective to the other reported complexes derived from Schiff bases of *S*-alkyl dithiocarbazates [6,33] and thus these complexes will be very susceptible to give CdS nanoparticles in solvothermal processes.

3.2. Crystal structure of $[Cd(SMDTC)_3] \cdot 2NO_3$ (**1**)

The crystallographic data and detailed information on the structure solution and refinement for $[Cd(SMDTC)_3] \cdot 2NO_3$ (**1**) are listed in Table 3. The molecular structure with the atomic numbering is shown in Fig. 2. The molecular structure of complex **1** consists of a cadmium cation chelated by neutral SMDTC molecules and free nitrate anions in a 1:2 ratio. The cadmium(II) cation and nitrate anions are mainly constructed through ionic bonds. The central cadmium(II) atom is six-coordinated by three SMTDC ligands and

Symmetry transformations used to generate equivalent atoms: #1; $-x+1$, $-y+1$, $-z$, #2; x, $y+1$, z, #3; $-x+3/2$, $y+1/2$, $-z+1/2$.

forms three five-membered chelate rings with N and S donor atoms of each ligand molecule. The coordination environment around the cadmium(II) atom is octahedral. The N donor groups of the SMDTC ligand are directed towards a nitrate anion while the S donor groups are directed to the opposite faces of a nitrate anion. This conformation of ligands is very significance for the crystal packing structure and hydrogen bond networks. Selected bond lengths and angles for complex **1** are listed in Table 4. The bond lengths of Cd–N and Cd–S are within the range 2.368(2)–2.386(2) and 2.6090(7)–2.7234(7) Å, respectively, and are slightly longer than that of the previously reported structure [1]. The bond angles of N–Cd–N and S–Cd–S are in the range 87.04(7)–103.37(2)° while the bond angles of N–Cd–S are in the range 70.58(5)–75.45(6)° and 160.41(5)–162.28(6)°. The bond lengths and angles of the *S*-methyldithiocarbazate ligand and nitrate anion are within the normal ranges and are very similar to those of previously reported structures [1,34].

The crystal-packing diagram (see the Supplementary data) of this complex reveals a discrete structure and the conformation of each complex is arranged parallel to the *ac*-plane. The crystal structure consists of parallel layers of cations and anions. The SMDTC molecules in the cations are arranged with their N donor groups directed towards the anionic layer in an alternating fashion and form hydrogen bonds with the O atoms of the anion. There are inter-molecular weak hydrogen bonds between the N–H moieties of the SMDTC ligands and the O atoms of the nitrate ions. As listed in Table 5, the hydrogen bonds of N_{SMDTC}–H···$O_{nitrate}$ vary greatly in their lengths and linearity and are in the range H···$O_{nitrate}$ 2.07–2.64 Å, N_{SMDTC}···$O_{nitrate}$ 2.872(2)-3.207(3) Å, N_{SMDTC}–H···$O_{nitrate}$ 117.3–175.2°. The hydrogen bond lengths and angles of N(4)–H(4a)···O(43) (2.20 Å, 167.7°), N(13)–H(13a)···O(33) (2.07 Å, 169.6°), N(23)–H(23a)···O(31) (2.08 Å, 175.2°) and N(24)–H(24a)···O(43) (2.20 Å, 153.9°) are shorter and more linear than other hydrogen bonds. The N–H···O hydrogen bonds are linked together into two-dimensional hydrogen bond layers. These hydrogen-bonding interactions lead to a self-assembled molecular conformation and contribute to the stabilization of the crystal structure.

Attempts to grow crystals of complex **2** suitable for X-ray diffraction have been unsuccessful. Further work on the crystallization of complex **2** is in progress.

4. Conclusion

SMDTC and SBDTC behave as neutral bidentate ligands with a cadmium(II) center, as envisaged by the spectroscopic studies.

The IR spectra of the free ligands indicate that in the solid state the ligand remains in the thione form, where the existence of both tautomeric forms may be expected in solution. On the basis of the available physicochemical data and TG analysis, along with a representative crystal structure determination, it can be reasonably concluded that the ligand, SMDTC, coordinates through the nitrogen atom of the NH_2 group and the sulfur atom of the thiocarbonyl group in its neutral thione form in an approximately octahedral environment in complex **1**, whereas complex **2** is expected to be a tetrahedral complex with same set of donor atoms with a larger phenyl substituent of SBDTC in its neutral thione form. The presence of the phenyl group makes the ligand SBDTC bulkier than SMDTC and consequently only two SBDTC ligands are expected to be sufficient to meet the coordination saturation of the central cadmium atom in $[Cd(SBDTC)_2] \cdot 2NO_3$. The TG analysis of the complexes also reveals that both complexes are volatile above 100 °C and finally give a CdS residue, thus these complexes may be used as single source molecular precursors for CdS nanoparticle syntheses at moderately low temperatures. A primary investigation to synthesis CdS nanoparticles using these complexes gave positive results and further work on this is in progress. To the best of our knowledge, these cadmium(II) complexes of *S*-alkyl/aryl dithiocarbazates have been reported for the first time along with the determination of the crystal structure of one of the reported compounds.

2.2. Syntheses of $[La_2(PDP)_3(H_2O)_2]$ (**1**) and $[Eu_2(PDP)_3(H_2O)_2]$ (**2**)

A mixture of $La(NO_3)_3 \cdot 6H_2O$ (0.117 g, 0.27 mmol) and H_2PDP (0.060 g, 0.27 mmol) was placed in a Teflon-lined Parr bomb containing 5 mL of deionized water. The bomb was sealed, heated at 170 °C for 3 days, and allowed to cool to room temperature. Yellow crystals of **1** were isolated by decanting the supernatant; washed with deionized water, *N*,*N*-dimethylformamide (DMF), and ethanol; and air-dried to give 0.0195 g of product (44%). Main IR absorption bands (cm^{-1}): 1541 (s), 1410 (s), 1337 (m), 1318 (m), 1291 (m), 1237 (m), 875 (m), 845 (m), 826 (m).

Compound **2** was prepared analogously in 72% yield using $Eu(NO_3)_3 \cdot 6H_2O$. Main IR absorption bands (cm^{-1}): 1545 (s), 1425 (s), 1340 (m), 1320 (m), 1292 (m), 1234 (m), 877 (m), 847 (m), 823 (m).

2.3. X-ray crystallography

Several crystals of each compound were indexed on a Bruker SMART CCD diffractometer using 40 frames with an exposure time of 20 s per frame. One crystal of each compound with good reflection quality was chosen for data collection. The exposure time was 20 s for each frame. The reflections were collected in the hemisphere of the reciprocal lattice of the triclinic cell to ensure enough redundancy. An empirical absorption correction using the program SADABS [16] was applied to all observed reflections. The structure was solved with direct methods using the SHELXTL program [16,17]. Full matrix least-squares refinement on F^2 was carried out using the SHELXTL program [16]. The unit cell information and refinement details are summarized in Table 1.

3. Results and discussion

Compounds **1** and **2** have been synthesized from the hydrothermal reactions of lanthanide(III) nitrates with H_2PDP. They occur as crystalline solids that are insoluble in water or common organic solvents such as acetone and ethanol. The IR spectra of **1** and **2** are similar, both showing intense absorption bands around 1541 and 1410 cm^{-1} that are diagnostic of metal-coordinated carboxylate groups [18]. The absence of the strong carboxyl absorption band at 1703 cm^{-1} indicates complete deprotonation of H_2PDP.

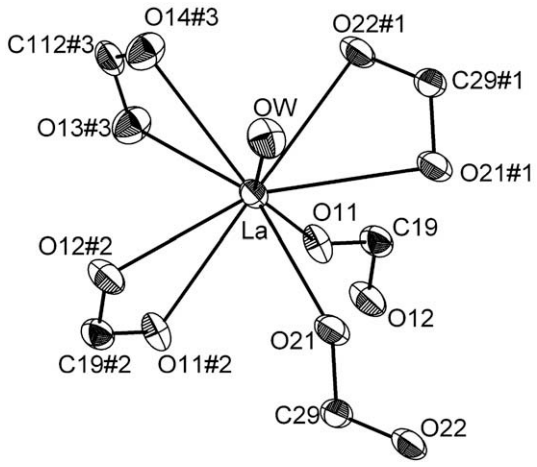

Fig. 1. An ORTEP diagram showing the lanthanum coordination environment in **1**. Thermal ellipsoids are at 30% probability. Symmetry labels #1–#3 are specified in Table 2.

Compounds **1** and **2** are isostructural, as shown by single-crystal X-ray diffraction analysis, and the structure of **1** is described here representatively. There exist one crystallographically independent La(III) ion and one and a half PDP moieties in the asymmetric unit. The La(III) ion is, apparently due to its large size, coordinated by nine oxygen atoms, eight of them from five carboxylate groups of different PDP units and one from a water molecule (Fig. 1). This coordination geometry can be regarded as a distorted tricapped trigonal prism, with O14#3, O22#1, OW, O11, O21, and O11#2 filling the vertices and O12#2, O13#3, and O21#1 capping the rectangular faces. We have previously observed a similar coordination environment for the nine-coordinate La(III) ion in $[La_2(PDA)_3(H_2O)] \cdot 2H_2O$ [12]. The La–O (carboxylate) bond distances in **1** range from 2.485(9) to 2.665(9) Å, and that of the La–O (aqua) bond is 2.534(9) Å, all of which are consistent with those observed for $[La_2(PDA)_3(H_2O)] \cdot 2H_2O$ [12]. Selected bond distances and angles are presented in Table 2.

In the network structure of **1**, each La(III) ion is interconnected through two COO groups with two other La(III) ions, forming an

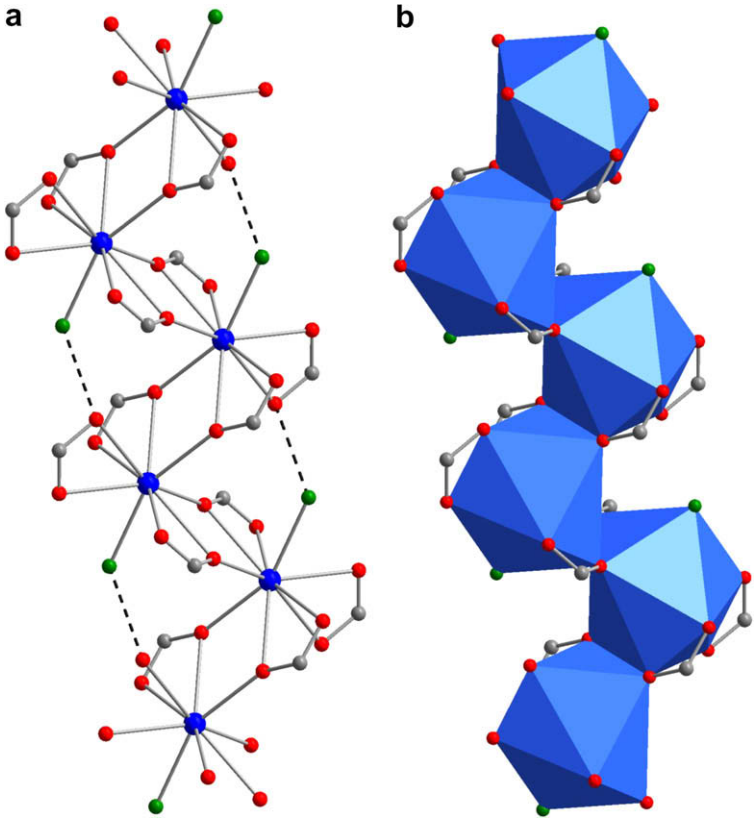

Fig. 2. (a) A ball-and-stick representation of the 1D La(H_2O)–OOC chain showing the interconnections between lanthanum ions, as well as the OW–O (carboxylate) hydrogen bonds (dashed lines). (b) A representation highlighting lanthanum coordination polyhedra. Color scheme: La, blue; O, red; C, dark gray. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

infinite La(H_2O)–OOC zigzag chain that extends along the crystallographic *a* axis (Fig. 2a). The La(III) ions act as nodes in the chain, and the two symmetry-equivalent COO moieties bridge two adjacent La(III) ions in tridentate bonding mode, affording two La–O–C–O–La strands. Although no hydrogen atoms were located for the coordinated water molecule, the OW–O (carboxylate) distances suggest that there is one class of hydrogen bonding interaction for O13···OW at 2.755(9) Å, as indicated by the dashed lines in Fig. 2a. A better view of the 1D zigzag chain is provided by a representation that highlights lanthanum coordination polyhedra (Fig. 2b). These infinite 1D chains constitute supramolecular SBUs that are cross-linked via $-CH_2CH_2C_6H_4CH_2CH_2-$ tethers of the PDP anions,

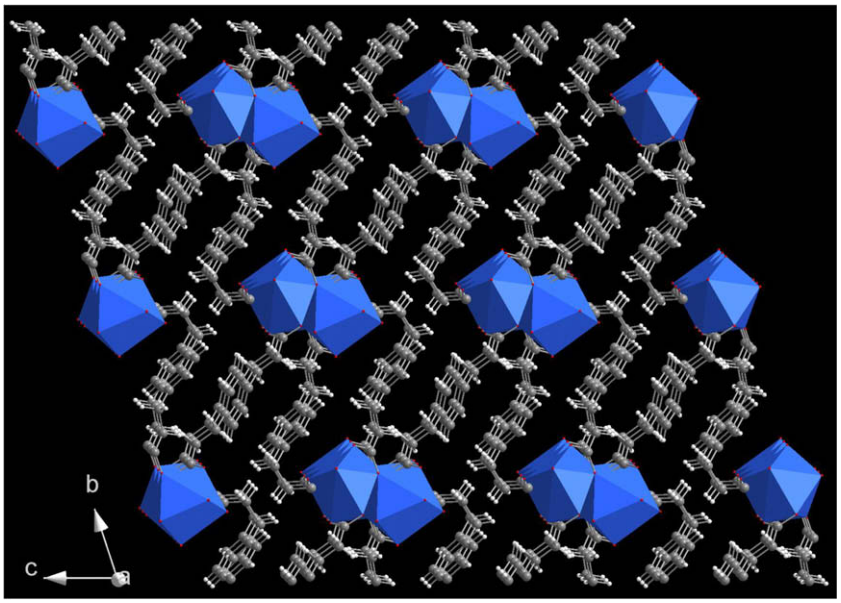

Fig. 3. The 3D network structure of [$La_2(PDP)_3(H_2O)_2$] viewed along the *a* axis. Color scheme: La coordination polyhedron, blue; C, gray; H, white. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

affording a 3D coordination polymer (Fig. 3). A space-filling model analysis of the network structure of **1** indicates that the void in the structure is not large enough to include guest water molecules. This explains why compound **1**, $[La_2(PDP)_3(H_2O)_2]$, contains only coordinated water and no guest water. Compared with $[Ln_2(PDA)_3(H_2O)] \cdot 2H_2O$ [12], compound **1** has a more condensed structure. Apparently, the more flexible $-CH_2CH_2C_6H_4CH_2CH_2-$ tether renders the atoms closer to one another, leaving little empty space in the channels.

In conclusion, we have synthesized $[Ln_2(PDP)_3(H_2O)_2]$ (Ln = La, Eu), two novel isostructural lanthanide–carboxylate coordination polymers. The 3D network structure of $[Ln_2(PDP)_3(H_2O)_2]$ consists of infinite 1D $La(H_2O)$–OOC chains that are cross-linked by organic spacer groups. These structures lend support to the notion of infinite supramolecular SBUs. We have also offered an insight into the condensedness of the structure of $[Ln_2(PDP)_3(H_2O)_2]$. Currently, we are investigating other ditopic carboxylates, hoping to correlate their structures with the frameworks of the resulting lanthanide–carboxylate coordination polymers.

Supplementary data

CCDC 658050 and 658051 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

used in tumor therapeutics [25]. Cobalt(III) nitrogen mustard complex has also been shown to be potential hypoxia-activated prodrug [26,27]. Some of the cobalt(II) complexes, such as $[Co(tfa)_2(happ)]$, are known to function as specific probe for DNA bulges due to its ability to cleave DNA specifically [28].

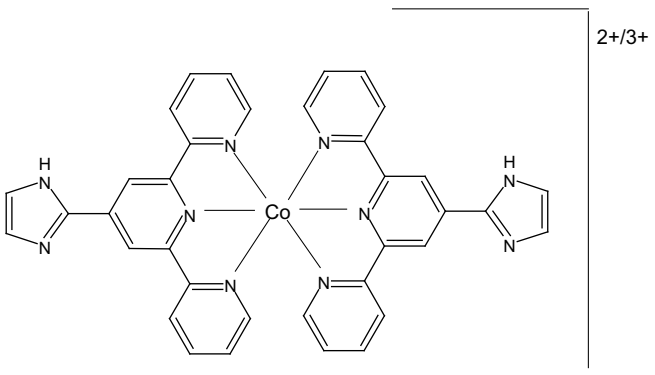
Our research group currently focuses on metallo-intercalators of various metals incorporating terpyridine ligands [29–31]. Terpyridine ligands are known for intercalation and due to the presence of conjugated aromatic core, exhibit several interesting luminescence properties. Like the excited state of the ruthenium(II) complex, excited state of cobalt(II) and cobalt(III) complexes too can bring about cleavage of macromolecules like protein and DNA. Schiff base ligand in the presence of cobaltous chloride has been shown to induce site-specific photocleavage of protein [32]. However, cobalt(II) and cobalt(III) complexes have not been exploited for photodynamic therapy. We have shown that some of the cobalt complexes with tridentate ligands like bzimpy and ptpy are good candidates for photoactivated DNA strand cleavage [33,34]. Towards achieving our goal of developing cobalt complexes of tridentate ligands, which may find therapeutic applications due to their oxidative cleavage or photocleavage of DNA, we report here the syntheses, characterization, DNA binding and cleavage studies of two new cobalt complexes, namely $[Co(Itpy)]^{2+}$ **1** and $[Co(Itpy)]^{3+}$ **2** derived from tridentate imidazole terpyridine ligand (Scheme 1).

A host of physical methods like absorption, fluorescence, cyclic voltammetry and viscosity measurements have been used to probe the interactions of the cobalt complexes with CT-DNA.

2. Experimental

2.1. Materials

Chemicals such as 2-acetyl pyridine and imidazole-2-carboxaldehyde used for ligand synthesis were purchased from Aldrich Chemicals and used as received. All other chemicals used in this study like ammonium acetate, potassium permanganate, sodium perchlorate and solvents like acetonitrile, dimethyl sulfoxide, diethyl ether, methanol, perchloric acid and hydrochloric acid, purchased from Rankem, were of analytical grade and used as received without further purification. The ligand imidazole terpyridine (Itpy) was prepared using published procedures [35]. Calf thymus DNA was purchased from SRL (India). Agarose (molecular biology grade) and Ethidium bromide were procured from Sigma chemicals. Buffers were prepared using deionised and sonicated triple distilled water. Tris (hydroxymethyl) aminomethane–HCl (Tris–HCl) buffer (pH, 7.2) was used for all DNA binding and cleavage studies. Concentrated stock solutions of CT-DNA (7 mM) were prepared in Tris buffer. A solution of CT-DNA in the buffer gave the UV absorbance ratio of ~1.8–1.9:1, at 260 and 280 nm indicating that the DNA was sufficiently free of protein [36]. DNA concentration, more precisely nucleotide phosphate (NP) concentration, was determined by UV absorbance at 260 nm. The extinction coefficient was taken to be 6600 mol^{-1} cm^{-1} [37]. Stock solutions of DNA were stored at 4 °C and used within 4 days.



Scheme 1. Complex **1** is dipositive and **2** is tripositive complex.

2.2. Physical measurements

UV–Vis spectra of the complexes and absorption titration studies were conducted using Perkin–Elmer Lambda 35 double beam spectrophotometer at 25 °C. Elemental Analyses were done using Heraeus CHN–O– Rapid Analyser. The infrared spectra of the complexes were recorded on Perkin–Elmer FT-IR spectrometer. Positive ion electrospray ionization mass spectra of the complexes were obtained by using Thermo Finnigan LCQ 6000 advantage max ion trap mass spectrometer. The emission spectra were recorded in varian spectrofluorimeter. Cyclic Voltammetric experiments were performed on CH instrument (USA) model CH-620 B, electrochemical analyzer. The three electrode configuration, a glassy carbon as working electrode, saturated calomel electrode as reference electrode and platinum electrode as auxillary electrode was used. Deoxygenated, anhydrous acetonitrile solutions containing tetrabutyl ammonium perchlorate (TBAP) as supporting electrolyte were used for the electrochemical measurements. All measurements were carried out in 10 mM Tris buffer, 50 mM NaCl (pH 7.2). ^1H NMR was recorded in DMSO-d_6 solvent using JEOL-500 MHz spectrometer. Chemical shifts (δ) are given in ppm.

Caution! Perchlorate salts are potentially explosives and should be handled only in small quantities with care.

2.3. Synthesis of bis(imidazole-terpyridine) cobalt(II) perchlorate, $[Co(Itpy)_2](ClO_4)_2$, (**1**)

The ligand imidazole terpyridine (Itpy) was prepared by slight modification of the reported procedure and the authenticity confirmed from ESI-MS, m/z = 300 [Itpy+H^+]. The cobalt(II) complex **1** was prepared directly by the addition of cobaltous chloride and the ligand imidazole terpyridine (Itpy) in 1:2 mole ratio, using methanol as reaction medium. The ligand Itpy (0.60 g, 2 mmol) in methanolic solution was added to the boiling methanolic solution of cobaltous chloride (0.23 g, 1 mmol). The solution immediately turned dark red. An aqueous solution of sodium perchlorate was added. Upon slow cooling, the dark red precipitate settled down. The crude precipitate was recrystallised from acetonitrile/methanol mixture (1:1 v/v) and the recrystallised product was filtered, washed with diethyl ether and then dried under vacuum. Yield: 85%. Elemental *Anal.* Calc. for $[Co(C_{18}H_{13}N_5)_2](ClO_4)_2$: C, 50.5; H, 3.04; N, 16.37; Co, 6.90. Found: C, 50.43; H, 3.7; N, 16.81; Co, 6.80%. ESI-MS m/z, 328.8, $[Co(Itpy)_2]^{2+}$. IR (KBr phase, cm^{-1}): 3461 br, 1629 m, 1473 w, 1114 m, 629 w (s, strong; w, weak; m, medium; br, broad). Single crystals of the complex were grown by ether diffusion method and the dark red crystals obtained were used for XRD studies.

2.4. Synthesis of bis(imidazole-terpyridine) cobalt(III) perchlorate, $[Co(Itpy)_2](ClO_4)_3$, (**2**)

Complex **2** was prepared from complex **1**. Cobalt(II) complex **1** prepared above was dissolved in methanol and few drops of dilute perchloric acid was added. To this solution 2.5 ml of hydrogen peroxide (30% w/v) was added and slightly warmed. Slowly, the colour of the solution turned deep yellow indicating the oxidation of cobalt(II) to cobalt(III). On standing, the solution yielded a yellow microcrystalline solid of the complex which was filtered, washed

with diethyl ether and then dried under vacuum. Yield: 80%. Elemental *Anal.* Calc. for $[Co(C_{18}H_{13}N_5)_2](ClO_4)_3$: C, 45.28; H, 2.73; N, 14.68; Co, 6.18. Found: C, 45.98; H, 3.1; N, 14.23; Co, 6.45%. ESI-MS *m/z*, 219.3, $[Co(Itpy)_2]^{3+}$. IR (KBr phase, cm^{-1}): 3401 m, 1610 m, 1482 m, 1420 w, 1087 br, 788 w, 629 m (s, strong; w, weak; m, medium; br, broad). ^1H NMR (DMSO-d_6) δ 9.67 (s, 2H); δ 8.8 (d, 2H); δ 8.35 (t, 2H); δ 7.48 (t, 2H); δ 7.63 (d, 2H); δ 7.8 (s, 2H); δ 4.7 (s, 1H) (s, singlet; d,doublet; t,triplet). The yellow solid was dissolved in a mixture of acetonitrile–water (1:1 v/v) in the presence of two drops of 0.5 N perchloric acid and kept for slow evaporation. After a few days, complex **2** crystallized as yellow needles, which were found suitable for single crystal X-ray analysis.

2.5. X-ray crystallographic data collection and refinement of the structures

Both dark red crystal of complex **1** and yellow coloured single crystal of complex **2** were coated with perfluoropolyether, picked up with a nylon fibre and mounted in the nitrogen cold stream (100 K) of a Bruker-Nonius KappaCCD diffractometer equipped with a Mo-target rotating-anode X-ray source and a graphite monochromator (Mo Kα, λ = 0.71073 Å). Final cell constants were obtained from a least squares fit of all integrated reflections. The Siemens SHELXTL [38] software package was used for solution and artwork of the structure, SHELXL97 [39] was used for the refinement. The structure was readily solved by Patterson method and subsequent difference Fourier techniques. All the non-hydrogen atoms were refined using anisotropic thermal parameter. Hydrogen atoms attached to carbon atoms were placed at calculated positions and refined as riding atoms with isotropic displacement parameters. The structural diagram was drawn using ORTEP-3 for Windows [40]. Crystallographic data for both complexes **1** and **2** are given in Table 1. For complex **2**, the perchlorate anion containing Cl(60) was found to be disordered and was split on two positions. The occupation factor refined to about 0.5 for both sets. In order to obtain a reasonable model, Cl–O and O–O distances were refined to be equal within errors and equal thermal displacement parameters were refined for corresponding atoms of the split model using SADI and EADP restraints of SHELXL.

[b] Goodness-of-fit = $[\sum[w(F_o^2 - F_c^2)^2]/(n-p)]^{1/2}$.
[c] $wR_2 = [\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]]^{1/2}$ where $w = 1/\sigma^2(F_o^2)+(aP)^2 + bP$, $P = (F_o^2 + 2F_c^2)/3$.

2.6. DNA binding and cleavage experiments

Concentrated stock solutions of metal complexes were prepared by dissolving the complex in acetonitrile and diluted suitably with 10 mM Tris buffer (1:10 as acetonitrile:buffer) to required concentrations for all the experiments. Absorption spectral titration experiments were carried out with both the complexes by maintaining a constant concentration of the complex (20 μM) and varying the CT-DNA concentration (20–500 μM). Equal concentrations of DNA in the sample and reference cells were maintained in order to eliminate the absorbance of DNA itself. The intrinsic binding constant was estimated using the following equation [41]:

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_b - \varepsilon_f) + 1/K_b(\varepsilon_b - \varepsilon_f),$$

where ε_a, ε_f and ε_b correspond to A_{obsd}/[Co], the extinction coefficient for the free cobalt complex, and the extinction coefficient for the cobalt complex in the fully bound form, respectively. A plot of [DNA]/($\varepsilon_a - \varepsilon_f$) versus [DNA], gives K_b, the intrinsic binding constant as the ratio of the slope to the intercept. For emission spectral titration measurements, Tris buffer was used as a blank to make preliminary adjustments. DNA was pretreated with ethidium bromide in the ratio [DNA]/[EB] = 2.5 for 30 min at room temperature. The excitation wavelength was fixed at 500 nm and the emission intensity was measured at 603 nm. The effect on emission intensity was measured by varying the concentration of complexes from 0 to 50 μM.

For viscosity measurements, the Ubberhold viscometer (3 mL capacity) was thermostated in water-bath maintained at 28 °C. The flow time for each sample was measured three times using digital stopwatch and an average flow time was calculated. The rate of flow of the buffer (10 mM Tris), DNA (100 μM) and DNA with the cobalt complexes at various concentrations were measured. The relative specific viscosity was calculated using the equation $\eta = (t - t_o)/t_o$, where t_o is the flow time for the buffer and t is the observed flow time for DNA in the absence and presence of the complex. Data are presented as $(\eta/\eta_o)^{1/3}$ versus $1/R$ (R = [complex]/[DNA]) where η is the viscosity of DNA in the presence of complex and η_o is the viscosity of DNA alone [42,43].

The cleavage of DNA was monitored using agarose gel electrophoresis. The experiments were performed using supercoiled pBR322 DNA. The DNA (0.5 μg) in Tris buffer, was treated with 100 μM and 140 μM of complex **2** and varying amounts of ascorbic acid and hydrogen peroxide. The samples were incubated at 28 °C for 1 h. The reactions were quenched using the loading buffer (0.25% bromophenol blue, EDTA and 40% sucrose). The reaction samples were then loaded on 0.8% agarose gel containing ethidium bromide and were run at 60 V for 2 h in Tris (boric acid) ethylenediaminetetraacetic acid (TBE) buffer, pH 7.2. The bands were viewed by placing the gel on UV illuminator and were photographed using gel documentation system.

3. Results and discussion

3.1. Synthesis and characterization of the complexes

Complex **1** was prepared by the direct addition of cobaltous chloride and the ligand in 1:2 molar ratio using methanol as reaction medium. Complex **2** was prepared by the oxidation of complex **1** using hydrogen peroxide. Both the complexes were obtained in good yield and showed well defined m/z = $[Co(Itpy)_2]^{2+/3+}$, peaks in acetonitrile as obtained from ESI mass spectrometry. Complexes **1** and **2** were isolated as perchlorate salts as evident from the presence of band at 1114–1089 cm^{-1} in the IR spectrum. Fig. 1 shows the electronic spectra of complexes **1** (1) and **2** (2) in the spectral range of 200–400 nm. The spectra

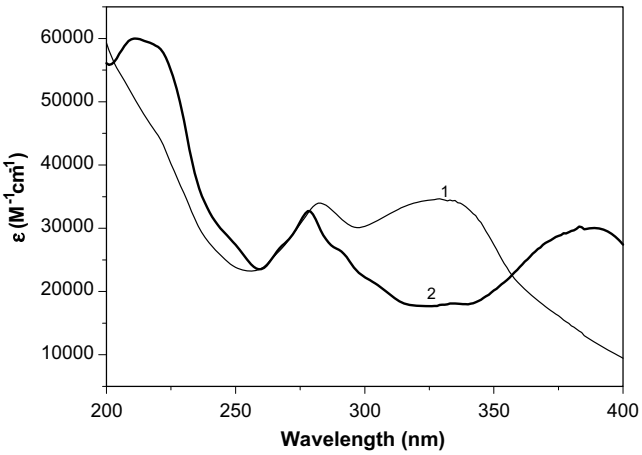

Fig. 1. Electronic absorption spectra (1) of complex **1** and (2) **2** in acetonitrile in the spectral range of 200–400 nm.

for ligand and both the complexes were taken in acetonitrile. The free ligand shows bands at 250, 283, 316 nm. These bands are due to the aromatic nature of the imidazole terpyridine ligand. Complex **1** shows bands at 284 and 330 nm. Complex **2** on the other hand shows absorption bands at 267, 279, 292 and 387 nm. These bands are due to the ligand centered transitions. Complex **2** showed NMR spectrum due to low spin, diamagnetic nature of the cobalt(III) complex. Cyclic voltammogram of complexes **1** and **2** show reversible redox wave in acetonitrile due to the Co(II)/Co(III) couple with cathodic (E_{pc}) and anodic peak potential (E_{pa}) 0.102 and 0.168 V, respectively, versus SCE. The peak separation (ΔE_p) was found to be 66mv at the scan rate of 0.1 V s^{-1} which is expected for a one electron reversible redox process.

3.2. Description of the structures

Complexes **1** and **2** were characterized structurally by X-ray crystallography. In both the complexes, cobalt ion is coordinated to two tridentate ligand to form CoN_6 octahedral complex. The perspective view of complex **1** is shown in Fig. 2. The structure shows that the cobalt(II) forms distorted octahedron with two Itpy ligands. Complex **1** crystallized with the molecular formula $[Co(L)_2](Cl)_2 \cdot 7H_2O$ and space group *C*2/*c*. Single crystal analysis of cobalt(III) complex **2** revealed that the compound crystallized with the molecular formula $[Co(LH)_2](ClO_4)_5 \cdot 5H_2O$ and space group *P*2(1)/*c*. The ORTEP diagram of complex **2** is shown in Fig. 3. The free nitrogen atom of the imidazole ring in the ligand is protonated in complex **2** (since single crystals were obtained in

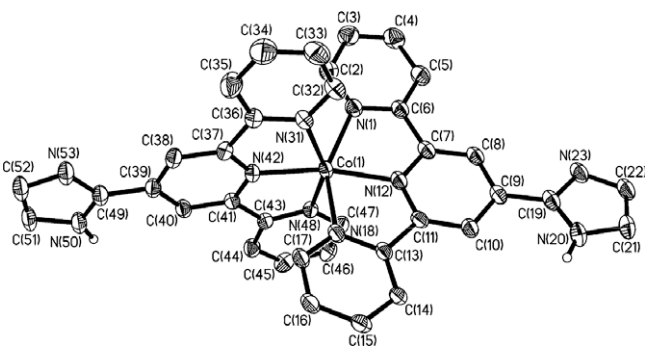

Fig. 2. ORTEP view of complex **1** and hydrogen atoms are being omitted for clarity.

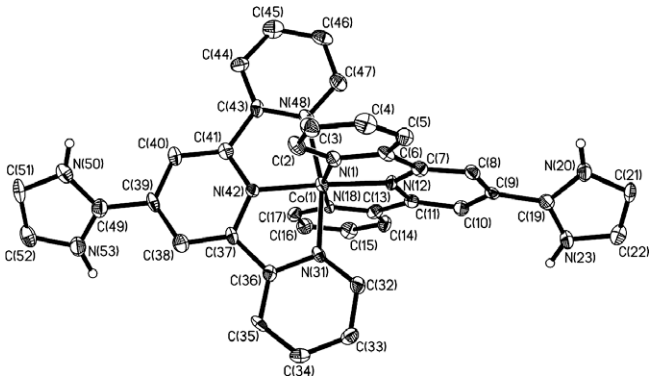

Fig. 3. ORTEP drawing of complex **2.** Hydrogen atoms are omitted for clarity.

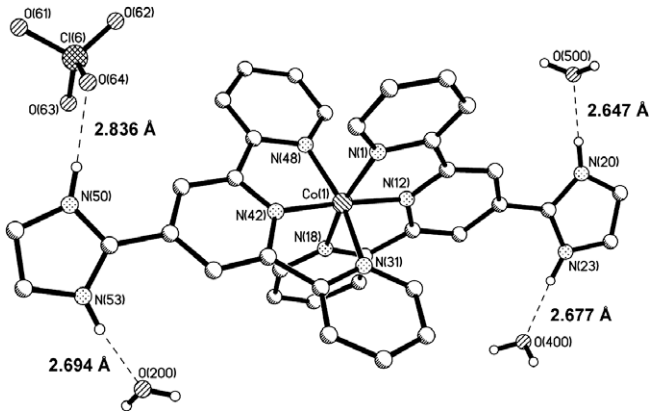

Fig. 3a. Represents ORTEP diagram of complex **2** with hydrogen bonding.

the presence of dilute perchloric acid), thereby leading to an overall increase in the positive charge of the complex. So, complex **2** contains five perchlorate counter anions in their crystal structure. The crystal structure of cobalt(III) imidazole terpyridine complex shows five water molecules, three of which are hydrogen bonded to three –NH moieties and their bond lengths vary from 2.647 Å to 2.697 Å. One of the –NH is seen hydrogen bonded to one perchlorate anion with a bond length of 2.836 Å (Fig. 3a). The crystal structure of complex **1** shows that the free imidazole nitrogen atom is not protonated and crystallizes as dication with two chloride counter ions. It is evident from the ORTEP diagrams, that both the complexes form distorted octahedron with meridional configuration and belong to monoclinic crystal system. Important bond lengths and bond angles for complexes **1** and **2** are given in Tables 2 and 3, respectively. Co(1)–N(1) and Co(1)–N(48) bond lengths in complex **1** were almost equidistant when compared to other Co–N bonds. The N–Co–N (76–169°) bond angles deviate largely from 180°. For complex **2**, Co–N bond lengths are similar to those reported for low spin cobalt(III) complexes and their bond lengths are much smaller than the cobalt(II) complex. The nitrogen atom of central pyridine ring of the two tridentate ligands is found to be closer to the central metal ion, than the other two terminal nitrogen atoms of each ligand by 0.08 Å. Interestingly, one of the remaining four Co–N bonds, namely Co(1)–N(1), has an unusually smaller bond length of 1.927 Å as against 1.942, 1.948 and 1.950 Å for Co(1)–N(18), Co(1)–N(31) and Co(1)–N(48) bonds, respectively. The N(42)–Co(1)–N(12) bond angle is found to be 176.7° while the remaining bond angles show deviations and vary from 82° to 165°.

4. DNA binding experiments

4.1. Electronic absorption spectra

Interaction of metal complexes with DNA can be monitored by absorption spectral titration [44]. In general, metal complex binding to DNA through intercalation, results in hypochromism and red shift (bathochromism), due to the strong stacking interaction between aromatic chromophore of the complex and the base pairs of DNA. The intercalative binding strength is determined by the extent of hypochromism exhibited by the complex. The absorption spectra of complex **2** in the absence and presence of calf thymus DNA is shown in Fig. 4. The cobalt(III) complex exhibits intense absorption bands in the UV–Vis region which is attributed to intraligand π–π^* transition of the coordinated groups. The absorption spectra of both complexes **1** and **2** showed hypochromism upon addition of CT-DNA which is suggestive of an intercalative mode of binding for both the complexes. This is due to the imidazole terpyridine ligand which possesses greater planar area and extended system, thereby leading to deeper penetration and stronger binding within the DNA base pairs.

In order to compare the DNA binding strengths of complexes **1** and **2** quantitatively, the intrinsic binding constant, K_b for both the complexes were obtained by monitoring the changes in the intraligand band. K_b for both the complexes were determined from the plot of $[DNA]/(\varepsilon_a - \varepsilon_f)$ versus [DNA] and found to be $(5.07 \pm 0.12) \times 10^3\ M^{-1}$ and $(7.46 \pm 0.16) \times 10^3\ M^{-1}$ for complexes **1** and **2**, respectively. The intrinsic binding constant values for both the complexes were found to be much smaller than that reported for the classical intercalators and our previous work on pytpy [45,34]. This is probably due to the absence of planarity of the imidazole ring with the terpyridine unit. From the crystal structure, it is seen that the imidazole moiety is twisted by about 33° away from the plane of the adjacent pyridine ring of the terpyri-

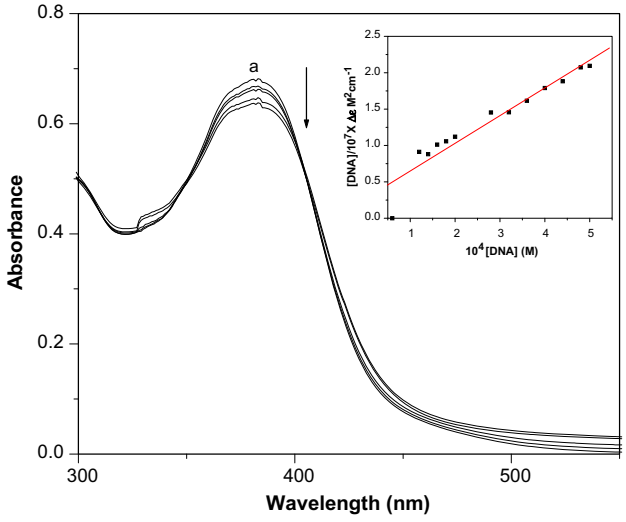

Fig. 4. Absorption spectra of complex **2** in the absence (a) and in the presence of increasing amounts of DNA. [Co] = 20 μM; [DNA] = 0–500 μM. The arrow shows the spectral changes on increasing DNA concentration. Inset: plot of $[DNA]/(\varepsilon_a - \varepsilon_f)$ vs. [DNA].

dine ligand. This deviation from planarity affects the magnitude of binding of these complexes although the mode of binding remains unaffected.

4.2. Competitive binding studies

Excitation of complexes **1** and **2**, either in aqueous solution or in the presence of CT-DNA did not result in any fluorescence emission at the room temperature. Competitive ethidium bromide binding studies were undertaken to gain support for the extent of binding of the metal complexes with DNA. The extent of quenching of emission of EB bound to DNA by competitive displacement is a measure of strength of intercalation between the second molecule and DNA [46]. EB emits intense fluorescence in the presence of DNA, due to its strong intercalation between the adjacent DNA base pairs. Increasing the concentration of both complexes **1** and **2** with respect to DNA pretreated with EB, causes an appreciable quenching in the emission intensity, indicating the displacement of EB fluorophore by these complexes. The fluorescence quenching curve of EB bound to DNA by complex **2** is shown in Fig. 5. The quenching behavior is then analyzed by Stern–Volmer equation [47], $I_0/I = 1+K_{sv}r$, where I_0 and I are fluorescence intensities in the absence and presence of the complex. K_{sv} is the linear Stern–Volmer quenching constant and r is the ratio of the total concentration of the complex to that of DNA. From the plot of I_0/I versus [complex]/[DNA], K_{sv} is given by the ratio of slope to the intercept. The K_{sv} value calculated for complex **2** is 4.25 which is in good agreement with the reported intercalators such as $[Co(phen)_2(pdta)]^{3+}$ and $[Co(phen)_2(pdtp)]^{3+}$ [48]. These results further confirm that both the complexes show an intercalative binding mode to CT-DNA.

4.3. Viscosity measurements

Though photophysical experiments, give necessary information about the binding modes of the metal complexes with DNA, they do not provide conclusive evidences for the exact mode of binding. Hydrodynamic measurements such as viscosity which is sensitive to length changes are regarded as the least ambiguous and the most critical tests of binding modes in solution [49]. It is considered as the convincing test for intercalative mode of binding. Viscosity of DNA is increased in the case of classical intercalators due to increase in the length of the DNA helix, as base pairs are separated to accommodate the intercalator. In contrast, decrease in DNA viscosity is noted in the partial or non-classical intercalator, because it may bend (or kink) DNA helix, thereby decreasing its effective length and therefore the viscosity. The effect of cobalt complexes **1** and **2** on the viscosity of rod-like DNA are shown in Fig. 6. Upon addition of complexes **1** and **2** (10–160 μM), the viscosity of rod-like calf thymus DNA increases steadily till the ratio of the complex to DNA reaches 0.8, which confirms that both the complexes bind to DNA through intercalation. This result parallels the observation found in the absorption spectral and emission studies. The more pronounced changes in relative viscosity of DNA observed in the case of complex **2** as compared to **1** is indicative of the fact that this complex is relatively better intercalator than complex **1**. This is also reflected in the DNA binding constant of the two complexes.

4.4. Differential pulse voltammetry

Binding of metal complexes to DNA is better understood by monitoring the DNA-induced changes in the electrochemical properties of small molecules. Both cyclic voltammetry (CV) and differential pulse voltammetry (DPV) techniques were employed to study metallointercalation. Both these techniques differ on their time scales τ. Under the same experimental conditions, the τ for CV is 250 ms and DPV is 17 ms. Therefore, the reversibility of heterogeneous electron transfer kinetics will be different for these two techniques [50]. Quantitative information about the interaction of metal complexes with DNA can be obtained from DPV. Fig. 7 shows DPV curve of 0.25 mM complex **2** in the absence and presence of 0.5 mM DNA. It is noted from the figure that there is a shift in the potential of cobalt(III) complex on the addition of CT-DNA. The observed shift in the potential is possibly because of the fact that the metal complex bound to the large macromolecule diffuses slowly to the electrode compared to the free metal complex [51]. Bard and co-workers have shown that the electrochemical potential of small molecules shift positively when it is intercalated into the base pairs of DNA and negatively when it is bound to DNA by electrostatically [52]. In the present case, the observed positive shift implies that the complex could bind to DNA by intercalation.

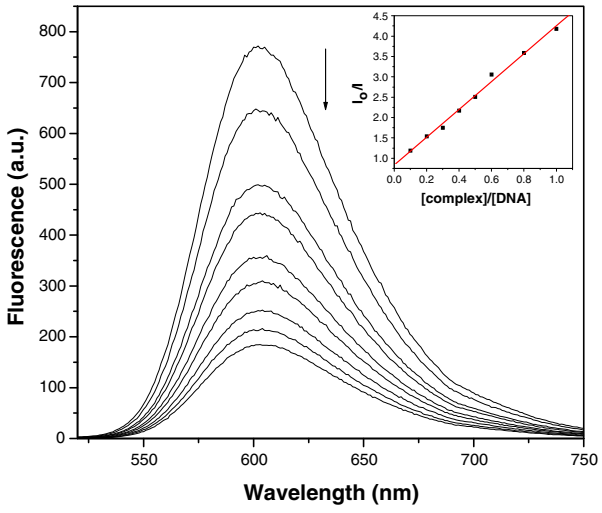

Fig. 5. Emission spectra of EB bound to DNA in the presence of complex **2** ([DNA]/[EB] = 2.5, [Co] = 0–50 μM, λ_{ex} = 500 nm. The arrow shows the intensity changes upon increasing the complex concentration. Inset: Fluorescence quenching curve of EB-DNA by complex **2**.

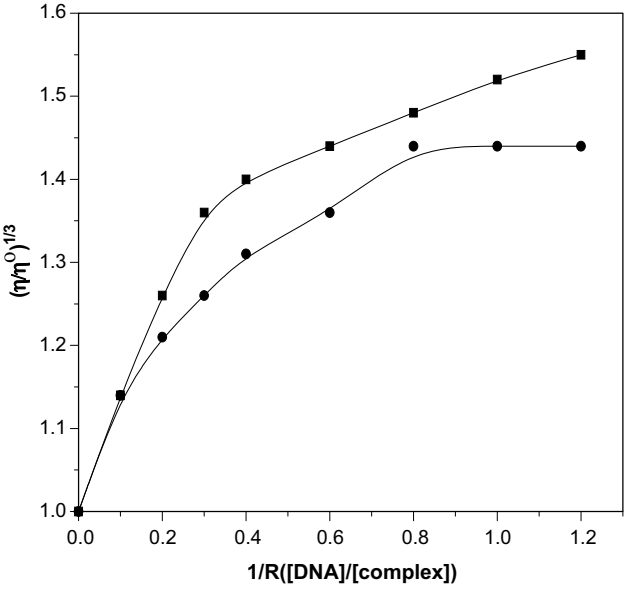

Fig. 6. Effect of increasing amounts of cobalt complexes **1** (●) and **2** (■) on the relative viscosity of CT-DNA at 28.0(±0.1) °C.

Differential pulse voltammetry can be used to calculate the corresponding equilibrium constant for one electron redox process, provided both the oxidized and reduced forms are associated with a third species (DNA) in the solution using the following equation [52]:

$$E_b^0 - E_f^0 = 0.059 \log(K_{II}/K_{III})$$

where E_b^0 and E_f^0 are the formal potentials of Co(III)/Co(II) couple in the bound and free forms, respectively. K_{II} and K_{III} are the binding constants for the binding of the oxidized and reduced forms to DNA. The addition of 0.5 mM CT-DNA to complex **2** results in a potential shift of 8 mV and the ratio of the binding constant (K_{II}/K_{III}) was calculated to be 0.73. This indicates the stronger DNA binding aptitude of the cobalt(III) complex as compared to cobalt(II) due to its higher nuclear charge.

4.5. Cleavage of plasmid PBR 322 DNA

In order to explore the metallonuclease activity of the newly synthesized cobalt(III) complexes, agarose gel electrophoresis experiments were carried out with plasmid pBR322 DNA. The DNA cleaving ability of complex **2** was analyzed by monitoring the conversion of supercoiled DNA (Form I) to nicked circular (Form II) and linear (Form III) forms and the gel electrophoretogram is given in Fig. 8. Complexes **1** and **2** does not bring about any hydrolytic or photocleavage of DNA. In order to explore the possibility of oxidative cleavage of DNA by the synthesised complexes, plasmid DNA was treated with complex **2** in the presence of hydrogen peroxide. No significant cleavage of DNA was observed even under high concentrations of peroxide (Lanes 1–3). However, on treatment of DNA with the complex in the presence of both hydrogen peroxide and ascorbic acid, significant cleavage was observed (Lanes 4–6). On varying the concentration of ascorbic acid and hydrogen peroxide, it is seen that the cleavage efficiency of complex **2** remarkably increases with increase in the concentration of ascorbic acid (200–600 μM). It was found that the cleavage remained almost unaffected beyond a certain minimum concentration of hydrogen peroxide (500 μM). Complex **1** (100 μM) on the other hand brought about DNA cleavage in the presence of hydrogen peroxide alone as seen from Lane 7.

The mechanism of cleavage in the present case involves the well-known Fenton type chemistry. The cobalt(III) complex bound to DNA through outer sphere gets reduced to cobalt(II) complex by ascorbic acid, which in turn reacts with hydrogen peroxide to generate the highly reactive hydroxyl radicals. The freely diffusible hydroxyl radical brings about the cleavage of DNA. This mechanism is supported by the fact that complex **1,** which is a Co(II) complex

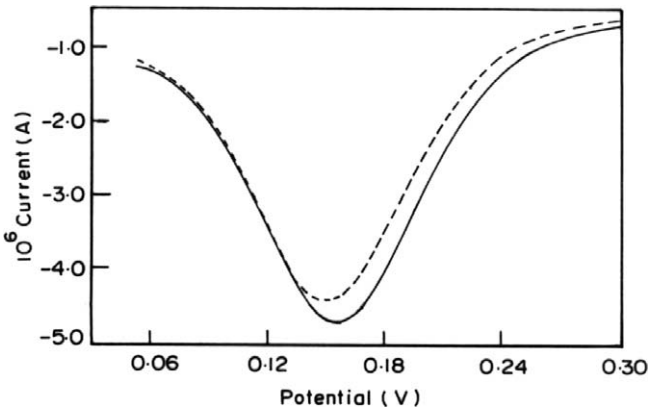

Fig. 7. DPV curves of 0.25 mM of complex **2** in the absence (—) and presence (- - -) of 0.5 mM of CT-DNA in 10 mM Tris buffer pH 7.2.

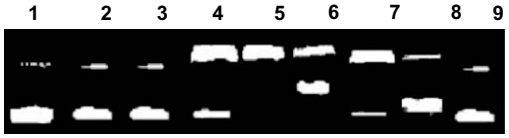

Fig. 8. Cleavage of pBR 322 DNA by cobalt complex **2** in the presence of hydrogen peroxide and ascorbic acid and complex **1** in the presence of hydrogen peroxide. [DNA] = 200 ng was incubated with complex **2** for 75 min in Tris buffer pH 7.2. Lane 1, DNA control; Lane 2, DNA + 100 μM of complex **2**; Lane 3, DNA + 100 μM of **2** + H_2O_2; Lane 4, DNA + 100 μM of **2** + 200 μM of ascorbic acid + 500 μM of H_2O_2; Lane 5, DNA + 100 μM of **2** + 400 μM of ascorbic acid + 500 μM of H_2O_2; Lane 6, DNA + 100 μM of **2** + 600 μM of ascorbic acid + 500 μM of H_2O_2; Lane 7, DNA + 100 μM of **1** + 500 μM of H_2O_2; Lane 8, DNA + 100 μM of **2** + 600 μM of ascorbic acid + 500 μM of H_2O_2 + 0.05 M of DMSO; Lane 9, DNA + 100 μM of **1** + 500 μM of H_2O_2 + 0.05 M of DMSO.

brings about DNA cleavage even in the absence of ascorbic acid as a co-reagent. Further, addition of hydroxyl radical scavenger DMSO, results in the inhibition of cleavage activity, as shown in Lanes 8 and 9, indicating that the hydroxyl radical is responsible for the nuclease activity exhibited by the complexes. Our previous reports on a similar cobalt(III) ptpy complex shows that the complex brings about photocleavage of DNA [34]. In the present case, however photocleavage was clearly ruled out. Normally, photocleavage mechanism in cobalt(III) complexes involves electron transfer from the excited state of the metal leading to guanine base oxidation [53]. The excited state properties of the metal ion are greatly influenced by the ligands coordinated to it [54]. In the present case, it is possible that, the presence of imidazole ring in the ligand lowers the excited state redox potential of the metal and thereby, makes guanine base oxidation impossible. Further studies on excited state properties of these complexes are underway.

5. Conclusion

Cobalt(II) and cobalt(III) complexes of tridentate ligand, imidazole terpyridine, were synthesized and characterized spectroscopically. Both the complexes were structurally characterized by X-ray crystallography and belong to monoclinic crystal system. The imidazole ring of the terpyridine ligand of complex **2** was protonated and hydrogen bonded to either water or perchlorate anion as evident from its crystal structure. The DNA binding capabilities of both complexes **1** and **2** were studied by spectroscopic, hydrodynamic and electrochemical techniques. The complexes exhibit intercalative mode of binding and the binding constant values from absorption spectral studies were found to be $(5.07 \pm 0.12) \times 10^3$ and $(7.46 \pm 0.16) \times 10^3\ M^{-1}$ for complexes **1** and **2**, respectively. The stronger DNA binding aptitude of cobalt(III) complex as compared to that of cobalt(II) complex was due to its higher nuclear charge. Further, viscosity and electrochemical studies offer further support for the intercalative mode of binding of these complexes. The cobalt(III) imidazole terpyridine complex exhibits efficient nuclease activity in the presence of ascorbic acid and hydrogen peroxide, whereas the corresponding cobalt (II) complex brings about DNA cleavage in the presence of hydrogen peroxide as a co-reagent.

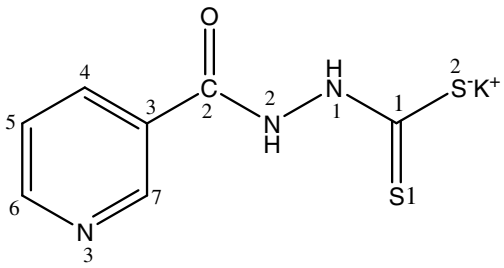

Fig. 1. [*N*′-(Pyridine-3-carbonyl)-hydrazine]-carbodithioate [$K^+(H_2L)^-$].

prepared potassium[*N*′-(pyridine-3-carbonyl)-hydrazine]-carbodithioate [$K^+(H_2L)^-$] (2 g, 8 mmol) in methanol (15 ml) and the reaction mixture was stirred continuously for 2 h at room temperature. On evaporation of the solvent and acidification of the product with dilute CH_3COOH (20% v/v), a yellow precipitate was obtained. This was suction filtered, washed with water, dried in vacuo and crystallized from hot methanol.

*2.3.1.1. Compound (**1a**).* Yellow single crystals of **(1a)** suitable for X-ray analyses were obtained by slow evaporation of its methanolic solution over a period of 10 days. Yield (68%); mp 172 °C. *Anal.* Calc. for $C_9H_{11}N_3OS_2$: C, 44.79; H, 4.59; N, 17.41; S, 26.67. Found: (241.33): C, 44.85; H, 4.55; N, 17.46; S, 26.62%. IR data (ν cm^{-1}, KBr): ν(NH) 3241 m; ν(C=O) 1672s; [β(NH)+ν(CN)] (Thioamide I) 1450s; [β(CN)+ν(NH)] (Thioamide II) 1348s; ν(N-N) 905m; ν(C=S) 1119; pyridine ring 649; (CH_3) 2979; (CH_2) 2930.

^{1}H NMR (DMSO-d_6; δ ppm): 11.57, 11.30 (m, 2H, –NH), 2.51 (m, 2H, >CH_2), 1.30 (m, 3H, –CH_3), 9.04, 8.81, 7.61, 8.24 (4H, pyridine ring). ^{13}C NMR (DMSO-d_6, δ ppm): 127.52 (C1), 152.96 (C2), 148.36 (C3), 123.87 (C4), 135.31 (C5), 163.92 (>C6=O), 203.11 (>C7=S), 27.88 (>C8H_2), 13.75 (–C9H_3). The structure was confirmed by XRD (Fig. 1a).

2.3.2. Synthesis of 1b (Method B)

The compound (**1b**) was synthesized by the reaction of CS_2 (1.5 ml, 22 mmol) with a methanol solution (20 ml) of nicotinic acid hydrazide (3 g, 22 mmol) in the presence of triethylamine (1.5 ml). Ethyl iodide (1.8 ml, 22 mmol) was added drop wise to the above clear solution and stirred continuously for 2 h at room temperature. On evaporation of the excess solvent and acidification of the residual mass with dilute CH_3COOH (20% v/v) a yellow precipitate was obtained which was suction filtered, washed with water, dried and crystallized from hot methanol.

*2.3.2.1. Compound (**1b**).* Dark yellow single crystals of **(1b)** suitable for X-ray analyses were obtained by slow evaporation of its methanolic solution over a period of 25 days. Yield 75%; mp 170 °C. *Anal.* Calc. for $C_9H_{11}N_3OS_2$: C, 44.79; H, 4.59; N, 17.41; S, 26.67. Found: (241.33): C, 44.64; H, 4.54; N, 17.39; S, 26.72%. IR (ν cm^{-1}, KBr): ν(NH) 3223m; ν(>C=O) 1646s; [β(NH)+ν(CN)] (Thioamide I)1429s; [β(CN)+ν(NH)] (Thioamide II) 1350s; ν(N-N) 901m; ν(>C=S) 1115m; pyridine ring 661; (CH_3) 2963; (CH_2) 2917. ^{1}H NMR (DMSO-d_6; δ ppm): 11.58, 11.31 (m, 2H, –NH), 2.50 (m, 2H, >CH_2), 1.31(m, 3H, –CH_3), 9.04, 8.79, 7.59, 8.24 (4H, pyridine ring).

^{13}C NMR (DMSO-d_6, δ ppm): 127.61 (C1), 152.98 (C2), 148.41 (C3), 123.94 (C4), 135.39 (C5), 164.02(>C6=O), 203.19(>C7=S), 27.97(>C8H_2), 13.81 (—C9H_3). The structure was confirmed by XRD. (Fig. 1b)

2.3.3. Preparation of complex (2)

A solution of H_2pchc (**1a**) (0.482 g, 2 mmol) in MeOH (10 ml) was added to a MeOH solution (10 ml) of $Mn(OAc)_2{\cdot}4H_2O$ (0.249 g, 1 mmol). This mixture was magnetically stirred for 3 h at room temperature. The resulting precipitate was filtered off, washed thoroughly with EtOH and air dried. This was suspended in MeOH to which *o*-phen (0.200 g, 1 mmol) was added and magnetically stirred for 2 h at room temperature. The clear yellow solution was filtered off and kept for crystallization.

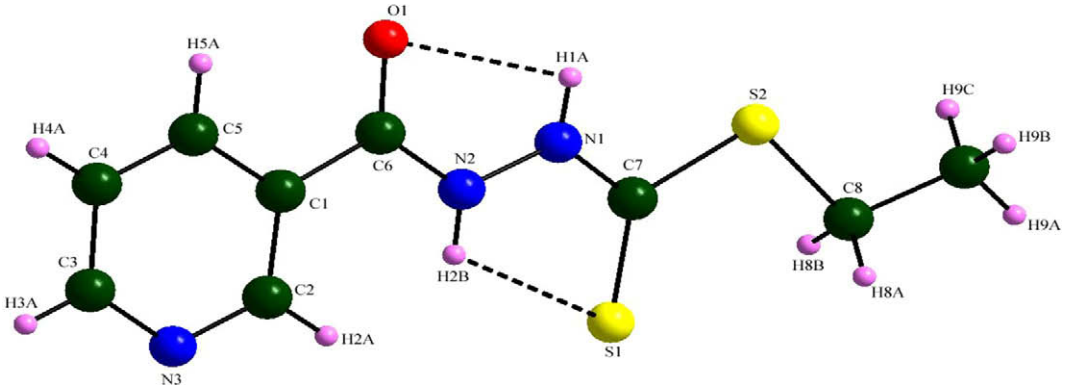

Fig. 1a. Crystal structure of H_2pchc (**1a**), showing the atom numbering scheme and intramolecular hydrogen bonding.

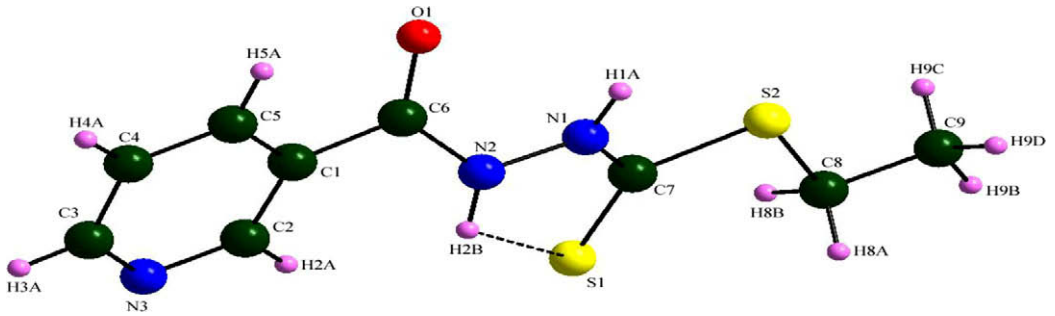

Fig. 1b. Crystal structure of H_2pchc (**1b**), showing the atom numbering scheme and intramolecular hydrogen bonding.

*2.3.3.1. Complex (**2**).* Light yellow single crystals of **(2)** suitable for X-ray analyses were obtained by slow evaporation of the above methanolic solution over a period of 7 days. Yield 58%; mp 176 °C, μ_{eff} = 6.10 BM. *Anal.* Calc. for $C_{30}H_{28}MnN_8O_2S_4$: C, 50.34; H, 3.94; N, 15.65; S, 17.92; Mn, 7.68. Found: (715.78): C, 50.34; H, 3.96; N, 15.62; S, 17.90; Mn, 7.72%. IR(ν cm^{-1}, KBr): ν(NH) 3224 m; ν(>C=O) 1646s; Thioamide(I) ν[β(NH)+ν(CN)] 1473s; Thioamide(II) [β(CN)+ν(NH)] 1353s; ν(N–N) 972m; ν(>C=S) 1117; (pyridine ring) 663; (CH_3) 2962; (CH_2) 2919. The structure was further confirmed by XRD (Fig. 4).

3. Analyses and physical measurements

Carbon, hydrogen, nitrogen and sulfur contents were estimated on a CHN Model CE-440 Analyser and on an Elementar Vario EL III Carlo Erbo 1108. By following standard procedure, the complex was analyzed for its metal content, after decomposition with a mixture of conc. HNO_3 and HCl, followed by conc. H_2SO_4 [18]. Magnetic susceptibility measurement was performed at room temperature on a Cahn Faraday balance using Hg[Co(NCS)$_4$] as the calibrant and electronic spectra were recorded on an UV-1700 Pharmaspec spectrophotometer. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a Varian Excalibur 3100 FT-IR spectrophotometer. ^{1}H and ^{13}C NMR spectra were recorded in DMSO-d_6 on a JEOL AL300 FT NMR spectrometer using TMS as an internal reference.

4. Crystal Structure determination

Single crystal X-ray diffraction measurements of **1a, 1b** and **2** were carried out with a Bruker SMART CCD area detector diffractometer equipped with a graphite crystal monochromator situated in the incident beam for data collection at 293(2) K and 173(2) K. Data collections were performed with Mo Kα radiation (λ = 0.71073 Å) by the phi and omega scan mode and the radiation source was a fine focus sealed tube. The structure was solved by direct methods (SHELX-97) and refined against all data by full-matrix least-squares on F^2 using anisotropic displacement parameters for all non-hydrogen atoms. All hydrogen atoms were included in the refinement at geometrically ideal positions and refined with a riding model [19,20]. MERCURY and DIAMOND packages were used for molecular graphics [21,22]. Crystal structure diagrams were generated by use of the ORTEP-3 for windows program [23].

5. Results and discussion

With an aim to obtaining N′-acylhydrazine carbodithioic acid ester ligand, H_2pchc was synthesized by the reaction of freshly prepared K$^+$[(H$_2$L)$^-$] and C_2H_5I in equivalent molar ratio in methanolic solution. Owing to the presence of amide and thioamide functional groups, it can exhibit keto–enol and thione–thiol forms [3]. The high polarizability, relatively weak C=S bond and the greater ability of sulfur with respect to oxygen to accommodate a negative charge makes NH–C=S more acidic [24]. But the IR (KBr) and ^{1}H NMR (DMSO-d_6) spectra are devoid of any peak to be attributed to SH for thiol form indicating that H_2pchc exists in thione form in solid (also by XRD) as well as in solution. Due to the more acidic character of NHC=S, this proton undergoes deprotonation during complexation. After deprotonation of NH(C=S), the extensive delocalization of π electron in (Hpchc)$^-$ on NHC=O moiety may be responsible for the retention of this proton. H_2pchc loses a proton directly from the HNC=S group to compensate the positive charge of the metal ion. The ligand H_2pchc reacts with $Mn(OAc)_2 \cdot 4H_2O$ to give a yellow solid product. The resulting solid was suspended in MeOH and reacted with *o*-phen which resulted in a clear solution of complex **2**. Complex **2** has been obtained as single crystals and analyzed, which shows that the carbonyl-oxygen and NH(C=S) nitrogen (after loss of proton) participate in bonding. The ligand and the complex are air-stable and can be kept in desiccators over a prolonged period without sign of decomposition.

5.1. IR spectra

The ligand H_2pchc **(1a and 1b)** contain the thioamide group (NHCS), which should give rise to characteristic bands namely, thioamide I, thioamide II and thioamide IV having contributions from [β(NH)+ν(CN)], [β(CN)+ν(NH)], ν(C=S) modes of vibrations, respectively. The IR spectra of H_2pchc (**1a** and **1b)** show only one band at 3241, 3223 cm^{-1}, respectively for –NH groups. The others bands at 1672–1646, 1450–1429, 1348–1350, 905–901, 1119–1115 cm^{-1} correspond to ν(>C=O), [β(NH)+ν(CN)] (thioamide I), [β(CN)+ν(NH)] (thioamide II), ν(N-N) and ν(>C=S), respectively. The pyridine ring, –CH_2 and –CH_3 bands occur at 649–661, 2930–2917, 2979–2963 cm^{-1}, respectively.

Comparison of the main vibrational bands of H_2pchc (**1a**) is used to establish its ligating behavior in its complex **2**. The bands at 3224 and 1646 cm^{-1} in **2** are assigned to ν(NH) and ν(C=O), respectively. A negative shift of 26 cm^{-1} in ν(C=O) indicates the involvement of carbonyl oxygen in bonding. The bonding through the sulfur of C=S is not indicated because ν(C=S) remains unchanged in the complex **2** in comparison to the free ligand H_2pchc **(1a)**. The involvement of the hydrazinic nitrogen in bonding is supported by a positive shift of 67 cm^{-1} in ν(N–N). The ν(NH) peak in complex **2** shows a negative shift as compared to the ligand **1a** due to disappearance of hydrogen bonding N–H···O during complexation. The pyridine ring vibrations at 649 cm^{-1} in the complex remains unchanged, as compared to the ligand H_2pchc (**1a)** indicating that the ring nitrogen is not involved in bonding.

5.2. ^{1}H and ^{13}C NMR spectra

The ^{1}H NMR spectra of H_2pchc (**1a** and **1b**) show peaks due to –NH, –CH_2, –CH_3 and multiplets for pyridine ring in aromatic region. The ^{1}H NMR spectra of H_2pchc (**1a** and **1b**) exhibit two signals at δ 11.57–11.58 and 11.30–11.31 ppm for the amide and thioamide protons, respectively. The protons due to the pyridine ring appear as multiplets between δ 7.61–9.04 ppm for **1a** and 7.59–9.03 ppm for **1b**. In solution downfield chemical shifts for hydrazinic protons as compared to K$^+$(H$_2$L)$^-$ (δ_H = 11.57 [NH(CS)], 11.30 [(NH(CO)] ppm for (**1a**) and (δ_H = 11.58 [NH(CS)], 11.31 [(NH(CO)] ppm for (**1b**) indicate the involvement of N–H group in intramolecular hydrogen bonding N2–H2···S1 and N1–H1···O1 in **1a** and N2–H2···S1 in **1b**, respectively (Figs. 1a and 1b). The ^{13}C NMR spectra exhibit signals due to >(C=S), >(C=O), –CH_2, –CH_3 and pyridine ring carbons as expected for the structures shown in Figs. 1a and 1b. The ^{13}C NMR spectra of both **1a** and **1b** show 9 signals for nine carbon atoms, of which the signals at δ 203.11–203.19 and 163.92–164.02 ppm are due to the >C=S and >C=O, carbons, respectively. The signals for >CH_2 and >CH_3 carbons are observed at 27.88–27.97 and 13.75–13.81 ppm, respectively. The pyridine ring carbons appear at C1:127.52–127.61, C2:152.96–152.98, C3:148.36–148.41, C4:123.87–123.94 and C5:135.31–135.39 ppm.

6. Electronic spectra and magnetic moment

The electronic spectra of **1a** and **1b** in MeOH show two bands at 288 and 214 nm which can be assigned to the $\pi \rightarrow \pi^*$ transition in the ligand. The magnetic moment of 6.10 B.M. for [Mn(Hpchc)$_2$(*o*-phen)] suggests a high spin Mn(II) with five unpaired electrons. The electronic spectrum of the complex shows d–d bands at 631,

548, 454 and 431 nm which are assigned to the $^6A_{1g} \rightarrow {}^4T_{1g}(G)$, $^6A_{1g} \rightarrow {}^4T_{2g}(G)$ and $^6A_{1g} \rightarrow {}^4E_g(G)$ and $^4A_{1g}(G)$ transitions, respectively for six coordinated high spin Mn(II) centre possessing distorted octahedral geometry [25].

7. Crystal structure description

7.1. Crystal structure of H_2pchc (**1a**)

The crystal structure of **1a** and **1b** are shown in Figs. 1a and 1b, respectively, with atomic numbering scheme. Crystallographic data and structural refinement details are given in Table 1 for compounds **1a** and **1b**. The hydrogen bonding parameters and intermolecular interactions are listed in Table 3. The main bond distances, bond angles and torsional angles of both ligands (**1a** and **1b**) are listed in Table 2. In the compound **1a,** the crystal packing is dominated by weaker C(4)–H(4A)···O(1) (2.561 Å) and stronger hydrogen bonding N(1)–H(1)···N(3) (1.963 Å). Views of the molecular packing in **1a** are shown in Fig. 2. Due to the presence of the intermolecular hydrogen bonding N–H···N and weak interaction C(8)–(S2)···N(3) (3.343 Å), the two adjacent molecules of the ligand are orthogonally arranged with respect to each other. The adjacent orthogonal arrangement of the molecules gives a twisted molecular conformation leading to a ladder type of arrangement where each step of the ladder happens due to the presence of hydrogen bonding between pyridine ring nitrogen and hydrazinic hydrogen (Fig. 2b). A similar arrangement has been reported by Gulyani et al. [26] and Suresh et al. [27]. This crystal is twined. i.e., forms a regular aggregates consisting of crystals of the same species joined together in some definite mutual orientation [28]. The pyridine ring carbon C3 shows a weak interaction with the O1 and hydrazinic hydrogen of N3. In the crystal lattice, the molecules are connected via intermolecular N–H···N hydrogen bond and form a twisted chain along *a*-axis (Fig. 2c). The distances and angle are: N(1)–H(1) = 0.860 Å, H(1)···N(1) = 1.963 Å, ∠N(1)–H(1)···N(3) = 171.44°. One hydrogen of methylene group [C(sp^3)-H(s)] of one molecule shows weak van der Waals interaction with a methylene hydrogen of another molecule (view along *b*-axis) with H···H distance of 2.363 Å. The H···H interaction between the **1a** molecules moves the chain in upward direction along *b*-axis. The packing of **1a** in the crystal lattice is stabilized by hydrogen bonding which is responsible for producing β-sheet pattern (Fig. 2a). The C–H···O hydrogen bond [d(H···A) = 2.5614 Å with an angle of ∠C–H···O = 132.71°] is formed between the hydrogen atom of sp^2 carbon of pyridine ring at position 4 and the amide oxygen. The sheet further grows in *b* direction by C4–H4A···O(1)═C(6). The values found for, H···A, ∠C–H···O is close to the bond distance and

bond angle reported by Suresh et al [25]. These weak interactions link the layers into 3D network. There is no π···π interactions operating in the structure of **1a.**

7.2. Crystal structure of H_2pchc (**1b**)

The hydrogen bonding parameters and intermolecular interactions are listed in Table 4. In the crystal structure of **1b**, the intermolecular N(1)–H(1A)···N(3) and N(2)–H(2B)···O(1) hydrogen bonding are present with the distances of 2.020 Å and 2.105 Å, respectively. However, **1b** lacks the N–H···O intramolecular hydrogen bonding which is present in **1a.** The structure is in turn stabilized by intramolecular N–H···S hydrogen bonding as also reported by Srinivasan and Chacko [29].

The intermolecular N–H···N and N–H···O hydrogen bonding give layers of the molecules stacked upon each other, along *a*-axis (Fig. 3a). This stacking results in face to face interaction between pyridine ring with centroid–centroid (Cp–Cp)* separation of 4.881 Å (Fig. 3b). However distance of centroid separation indicates that there is no co-facial interaction between successive pyridine rings. The molecules are linked together to form chain along *a*-axis via linear H···H weak interaction. One hydrogen atom of methyl group (Csp^3) shows van der Waals interaction with the hydrogen atom of pyridine ring at position 3 (Fig. 3c). There is edge to face interaction between the centroid of a pyridine ring (Cp) and methylene hydrogen atom (H8B) with a distance of 2.939 Å (C8–H8B···Cp, Cp = centroid of pyridine ring) and an angle ⩾C–H···Cp of 147.53°. The molecules of **1a** and **1b** also show extensive electron delocalization on the amide and thioamide due to intermediate bond distances found for –C(O)NHNHC(S)S– moiety [13]. Both **1a** and **1b** are stabilized by the presence of weak interactions, intermolecular and intramolecular hydrogen bonding.

7.3. Comparison of **1a** and **1b**

The ligands **1a** and **1b** crystallized in different crystal systems, monoclinic and triclinic, respectively, and show different molecular packing. The basic difference between **1a** and **1b** is that **1a** crystallized as twinned crystal in a regular orthogonal arrangement of molecules [28]. The bond lengths and bond angles in **1a** and **1b** are almost similar but the torsional angles of both are completely different [[N(1)–N(2)–C(6)–C(1) = −179.2(3), C(5)–C(1)–C(6)–O(1) = −0.3(6), C(2)–C(1)–C(6)–N(2) = −1.1(6) for **1a** and N(1)–N(2)–C(6)–C(1) = 178.76(16), C(2)–C(1)–C(6)–O(1) = 150.49(18), C(5)–C(1)–C

(6)–O(1) = −26.2(2), C(2)–C(1)–C(6)–N(2) = −30.8(2) for **1b**]. The ligand **1a** shows two types of intramolecular hydrogen bonding (NH···S and NH···O) while **1b** has only NH···S hydrogen bonding. Compound **1a** contains only one type of inter molecular hydrogen bonding N–H···$N_{(py)}$ while **1b** forms two types of hydrogen bonding i.e. N–H···$O_{(carbonyl)}$ and N–H···$N_{(py)}$.

7.4. Crystal structure of complex (*2*)

Fig. 4 shows an ORTEP diagram of the Mn(II) complex together with the atom numbering scheme. The structural refinement data related to complex **2** are listed in Table 1 and the selected bond distances, bond angles and torsion angles are listed in Table 5. The hydrogen bonding and weak interactions are listed in Table 6.

The metal center in complex **2** is coordinated in an N4O2 core by two uninegative bidentate ligands using hydrazine nitrogen (N1, after loss of proton) and carbonyl oxygen. The N2H2 nitrogen does not take part in bonding because of the presence of hydrogen bonding between N2–H2B···S1 atoms, both in the ligand and the complex. Various distances found within the chelate rings are intermediate between single and double bond lengths and also shorter or longer than the corresponding bond lengths in H_2pchc (**1a**). The average bond lengths in complex **2** are: O1–C6 = 1.247(19)(L), N2–C6 = 1.331(2)(S), N1–N2 = 1.392(18)(L), N1–C7 = 1.322(2)(S) Å (L = longer, S = shorter) which suggest considerable

Symmetry transformations used to generate equivalent atoms: #1 $-x, y, -z + 1/2$.

delocalization of charge [30]. The metal ligand bond lengths in **2** are found to be shorter than typical single bond which may be due to the π – donating or π – back bonding interactions between the metal and the ligand. Thus, the charge is transferred from the metal and the ligand into an orbital that is bonding with respect to the metal-ligand bond. Masui suggested that if an active electron delocalization within a metal–*N*-heterocyclic chelate ring is present it would exhibit some degree of metalloaromaticity [31]. The transition metal complexes in which bonding of the ligand takes place through carbonyl oxygen and nitrogen and also bonded with *N*-heterocyclic bases such as *o*-phen, 2,2′-bpy are prone to exhibit metalloaromaticity [32–34]. The above criteria of metalloaromaticity are fulfilled in complex **2**. The most noteworthy structural feature of complex **2** is that two *ortho*-H atoms from *o*-phen ring point towards the centre of the corresponding $MnOCN_2$ chelate rings [35]. This delocalized charge in the chelate ring forms an unusual intramolecular C–H···π interaction with ortho hydrogen of the adjacent phenyl ring of *o*-phen [31,32] (Fig. 5). The H···Cg, C···Cg and H···chelate ring plane distances are 3.375, 3.613 and 2.858 Å and C–H···Cg angle is 96.84° (below the optimal value of 180°) for the strongest C–H···π interactions, which may be due to the steric constraints in the molecule. Both chelate rings around Mn(II) formed by the $(Hpchc)^-$ are almost orthogonal to each other forming a dihedral angle of 86.44°. In the complex the chelate rings and the pyridine rings lie nearly in the same plane forming a dihedral angle of 20.75°. The pyridine rings thus make an extended coplanar system with both chelate rings forming a bite angle of 73.82° and with coligand, the bite angle is 73.94°. However, it has been observed that both the ligands coordinated to Mn(II) are antioriented with respect to each other, to minimize the steric hindrance by similar groups. The O(1)#1–Mn–O(1) angle involving the carbonyl oxygen of the two ligands is 179.35(6)°, showing less distortion from an octahedral geometry in complex **2**. The bond distances Mn–O, Mn–N and Mn–N_{phen} are 2.183, 2.249 Å and 2.259 Å which are comparable to the bond lengths reported for $[Mn_3(O_2CCH_3)_6(N–N)_2]$ (where N–N = *o*-phen) [36] and $[Mn_2(phen)(Hdcbi)]_n$ (Hdcbi = 4,5-dicarboxyimidazole) [37]. Due to deprotonation of hydrazinic hydrogen, the intermolecular hydrogen bonding present between the N(3) pyridine nitrogen and H1A–N1 of hydrazinic hydrogen in **1a** disappears in **2**. The intramolecular hydrogen bonding C=O···H1A–N1 is also absent due to involvement of carbonyl oxygen in coordination with Mn(II).

7.5. Crystal packing

There is notable intermolecular hydrogen bonding C3–H3AA···S1 (*o*-phen ring) in the complex **2** which gives stacking due to which the molecules are exactly superimposed on each other (Fig. S1). The shortest centroid to centroid separation found between parallel pyridine rings is 5.813(2) Å which rules out the possibility of face to face (π···π) interaction between pyridine rings in the crystal structure of **2** (Fig. 6). The C–H···π (edge to

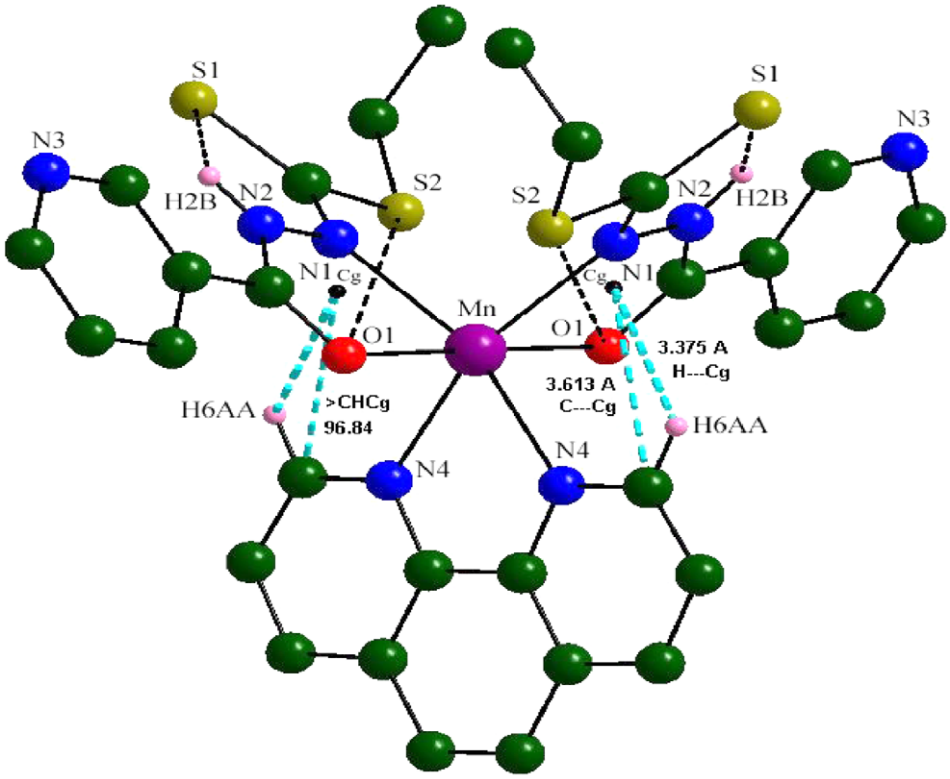

Fig. 5. Crystal structure of [Mn(Hpchc)$_2$(*o*-phen)], showing unusual intramolecular C–H···π interaction with Mn(II) chelate ring and intramolecular hydrogen bonding. For clarity other hydrogen atoms are omitted.

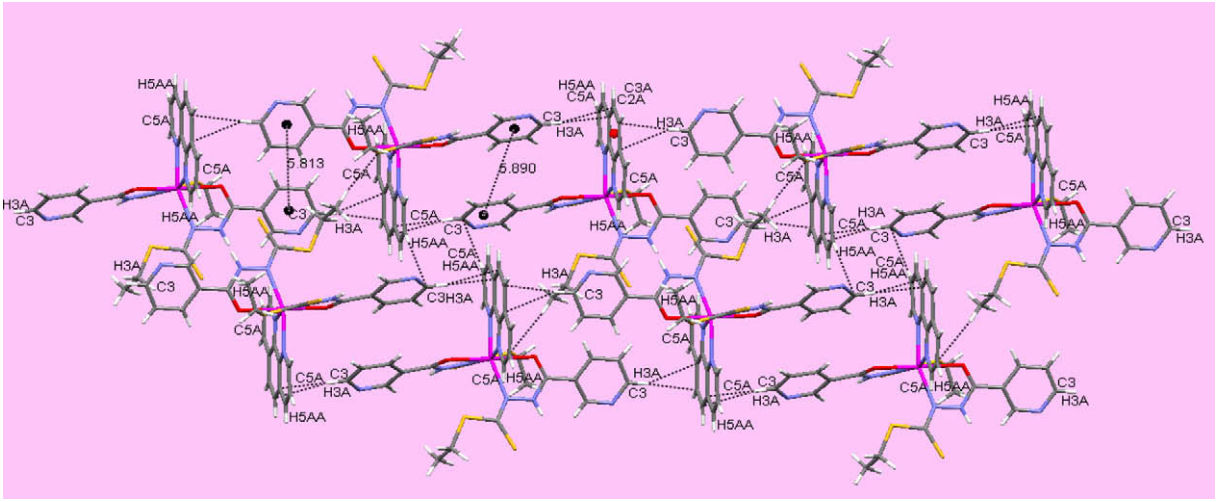

Fig. 6. Crystal packing of complex 2, showing centroid–centroid (Cp–Cp)* separation and edge to face interactions.

face) contacts follows a network of interconnected pattern giving rise to three dimensional supramolecular arrangement (Fig. 6, Fig. S2). The strong N(1)–H(1)···S(1) interaction serves as structure directing factor. The geometric parameters describing the intermolecular interactions in **2** are collected in Table 6. The extended supramolecular system is obtained due to the presence of three types of weak interactions C(3)–H(3A)···C(2A) (*o*-phen) = 2.839 Å, C(3)–H(3A)···C3A (*o*-phen) = 2.724 Å and C(5)–H(5AA)···C(3)(pyridine ring) = 2.927 Å. The crystal structure is in turn stabilized by intramolecular and intermolecular hydrogen bonding. The additional stabilization in the complex is due to intramolecular C–H···π interaction (Fig. 5).

8. Conclusion

Two different forms of a new *N′*-(pyridine-3-carbonyl) hydrazinecarbodithioic acid ethyl ester (**1a** and **1b**) and the Mn(II) complex (2) of **1a** have been synthesized. The crystals of **1a** are twined and show ladder like regular arrangement. The molecular packing of **1b** and **2** show layering and stacking upon each other. The

complex **2** shows an unusual intramolecular C–H···π (chelate ring) interaction which gives structural support for metalloaromaticity.

and after slow evaporation yellow crystals separated out, which were collected, washed with ether and dried over P_4O_{10} *in vacuo*.

Zn(HL)Br_2 (**1**): Yield ~0.35 g; found (calc): C, 40.16 (40.76); H, 2.79 (2.78); N, 12.91 (13.25); IR data (cm^{-1}): 3239, 1597, 1661, 1147, 407.

Zn(HL)Cl_2 (**2**): Yield ~0.28 g; found (calc): C, 47.66 (47.72); H, 3.33 (3.41); N, 15.44 (15.57); IR data (cm^{-1}): 3369, 1597, 1667, 1153, 404.

ZnL(OAc) (**3**): Yield ~0.32 g; found (calc): C, 54.25 (53.73); H, 4.33 (4.30); N, 15.82 (15.71); IR data (cm^{-1}): 1597, 1521, 1156, 414, 516.

2.3.2. Synthesis of $ZnLN_3$ (**4**)

A solution of the ligand HL (0.317 g, 1 mmol) in methanol was treated with a methanolic solution of $Zn(OAc)_2 \cdot 2H_2O$ (0.219 g,1 mmol). The solution was heated under reflux and sodium azide (0.130 g, 2 mmol) was added in portions to the solution and further refluxed for 4 h. The resulting solution was allowed to stand at room temperature and upon slow evaporation gave yellow crystals. The crystals that separated out were collected, washed with ether and dried over P_4O_{10} *in vacuo*. Yield ~0.25 g; found (calc): C, 54.25 (53.73); H, 3.33 (3.27); N, 26.44 (26.56); IR data (cm^{-1}): 1595, 1518, 1148, 404, 502.

2.3.3. Synthesis of ZnL_2 (**5**)

A solution of the ligand HL (0.317 g, 1 mmol) in 20 ml of methanol was treated with a methanolic solution of $Zn(OAc)_2 \cdot 2H_2O$ (0.109 g, 0.5 mmol). The solution was heated under reflux for 2 h. The resulting solution was allowed to stand at room temperature and after slow evaporation yellow crystals were separated out, which were collected, washed with ether and dried over P_4O_{10} *in vacuo*. Yield ~0.20 g; found (calc): C, 61.53 (61.94); H, 3.96 (4.04); N, 20.01 (20.07); IR data (cm^{-1}): 1597, 1515, 1223, 420, 518.

2.3.4. Synthesis of $ZnL_2 \cdot H_2O$ (**6**)

A solution of the ligand HL (0.317 g, 1 mmol) in methanol was treated with a methanolic solution of $Zn(OAc)_2 \cdot 2H_2O$ (0.219 g, 1 mmol). The solution was heated under reflux and sodium azide (0.065 g, 1 mmol) was added in portions to the solution and further refluxed for 4 h. The resulting solution was allowed to stand at room temperature and upon slow evaporation gave yellow crystals. The crystals that separated out were collected, washed with ether and dried over P_4O_{10} *in vacuo*. Yield ~0.16 g; found (calc): C, 59.87 (60.38); H, 4.01 (4.22); N, 19.25 (19.56); IR data (cm^{-1}): 1597, 1515, 1229, 416, 520.

2.4. X-ray crystallography

Single crystals of compound **1** suitable for X- ray diffraction were obtained by slow evaporation of its solution in a 1:1:1 mixture of CH_3OH, $CHCl_3$ and CH_2Cl_2. Single crystals of compound **5** were obtained by slow evaporation of its solution in a 1:1 mixture of CH_3OH and CH_3CN, and of compound **6** by slow evaporation of its solution in a 1:1:1:1 mixture of DMF, $CHCl_3$, CH_3CN and CH_3OH. X-ray diffraction measurements were carried out on a CRYSALIS CCD diffractometer with graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation. The program CRYSALIS RED was used for data reduction and cell refinement [8]. The structure was solved by direct methods using SHELXS [9] and refined by full-matrix least-squares refinement on F^2 using SHELXL [10]. The N–H hydrogen atoms were located from difference Fourier maps and refined isotropically. The remainder of the H-atoms were included in calculated positions and refined as riding atoms using default SHELXL parameters. Compound **6** is non-centrosymmetric and its Flack *x* parameter is 0.001(12). As this value is near 0, with small standard uncertainty, the absolute structure given by the structure refinement is likely correct [11]. The structures of the compounds were

plotted using the program ORTEP [12]. The crystallographic data along with the structural refinements are given in Table 1.

3. Results and discussion

3.1. Synthesis of complexes

Di-2-pyridyl ketone N^4-phenyl-3-semicarbazone (HL) reacts with zinc(II) halides in a 1:1 molar ratio to form **1** and **2**, complexes of the type $Zn(HL)X_2$ where X = Br and Cl. Complexes **3** and **4** were consistent with the general formula ZnLY where Y = OAc and N_3 and for complexes **5** and **6**, the composition ZnL_2 was obtained. For the preparation of complexes **3** and **5**, $Zn(OAc)_2 \cdot 2H_2O$ and HL were taken in 1:1 and 1:2 ratios, respectively, and for complexes **4** and **6**, $Zn(OAc)_2 \cdot 2H_2O$, HL and NaN_3 were taken in 1:1:2 and 1:1:1 ratios, respectively. In complex **6**, however, the azide added was not coordinated and $ZnL_2 \cdot H_2O$ was obtained accidentally, though the yield was much lower. Although the molecular formulae of **5** and **6** are same, the crystallographic parameters are different.

3.2. Description of the crystal structures of $Zn(HL)Br_2$ (**1**), ZnL_2 (**5**) and $ZnL_2 \cdot 0.3H_2O$ (**6**)

The molecular structure of complex **1**, along with the atom numbering scheme, is presented in Fig. 2. The compound crystallizes in the monoclinic crystal system with the space group $P2_1/n$. In this compound, the Zn atom is coordinated by an azomethine nitrogen (N2), pyridyl nitrogen (N1), ketoxy oxygen (O1) and two bromide ions (Br1 and Br2). The bond distances to Zn are in the order $Zn–N_{(azo)} < Zn–N_{(py)} < Zn–O_{(ketoxy)} < Zn–Br1 < Zn–Br2$. The bond lengths, $Zn–N_{(py)}$, 2.154(3) Å and $Zn–N_{(azo)}$, 2.130(3) Å are very similar compared to other Zn complexes of thiosemicarbazones [13–15]. The Zn–Br bond distances are 2.3561(5) and 2.4026(6) Å, but there is a difference of 0.0465 Å between the Zn–Br bonds of $[Zn(HL)Br_2]$. The basal plane could involve either Br1 or Br2 with the semicarbazone moiety, but because Zn–Br1 is marginally shorter and it can be designated as the apical position. The Zn atom is displaced by a distance of 0.8335 Å above the basal plane and elongated towards Br1. Selected bond lengths and bond angles are given in Table 2.

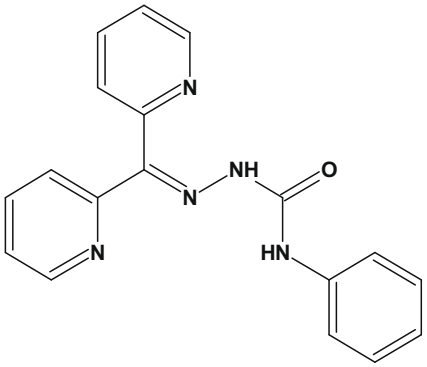

Fig. 1. Structure of HL.

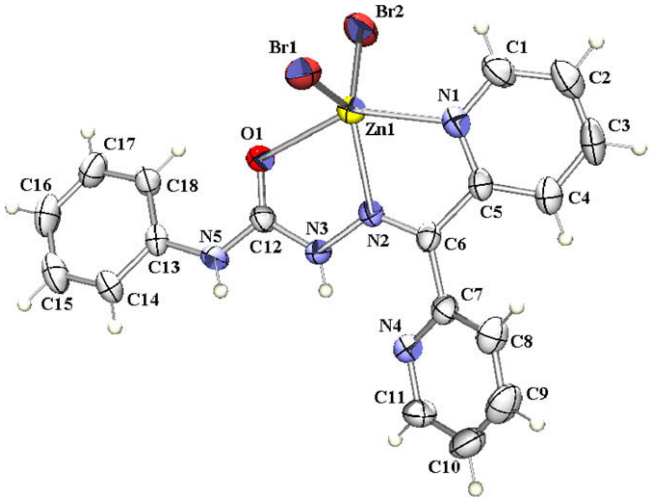

Fig. 2. Molecular structure of $Zn(HL)Br_2$.

According to Addison et al., for five coordinated complexes, the angular structural parameter (τ) is used to propose an index of trigonality. The value of τ is defined by an equation represented by $\tau = (\beta - \alpha)/60$, where β is the greatest basal angle and α is the second greatest angle; τ is 0 for rectangular pyramidal forms and 1 for trigonal bipyramidal forms [16,17]. However, in the case of five-coordinate systems, the structures vary from near regular trigonal bipyramidal (RTB) to near square based pyramidal (SBP). The τ value for the compound **1** of 0.27 indicates that the coordination geometry around Zn(II) is best described as a distorted square based pyramidal geometry [18].

The deviations from the least-square plane through the O1, N1, N2 and Br2 atoms comprising the square plane are 0.3697, 0.5336, −0.6794 and −0.0054 Å, respectively, and the Zn1 atom is deviated by 0.8335 Å in the direction of the Br1 atom. Ring puckering analysis and least square plane calculations show that the rings Cg(1) comprising of atoms Zn1, O1, C12, N3 and N2 and Cg(2) comprising of atoms Zn1, N1, C5, C6 and N2 adopt a twisted conformation [Cg(1) on N2–Zn1 and Cg(2) on C5–C6] [19]. In the crystal packing four molecules are present and two of them are complementary to each other (Fig. 3). In the unit cell π–π, C–H···π and hydrogen

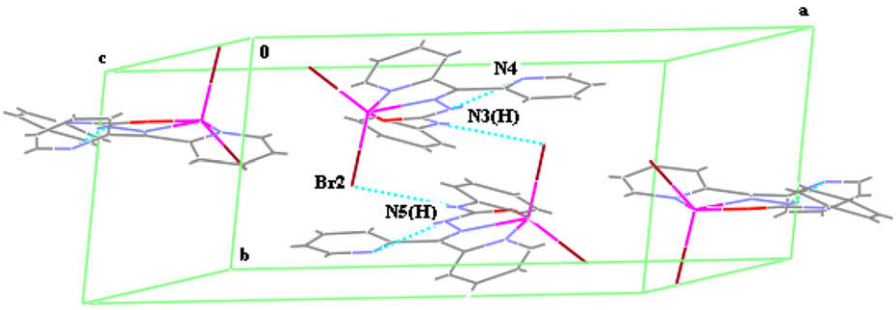

Fig. 3. Partial unit cell packing diagram for compound **1** with intra- and intermolecular hydrogen bonding interactions shown as dotted lines.

bonding interactions were observed. The π–π interaction is perceived at 4.0873 Å for Cg(1)–Cg(1)[a] [Cg(1) = Zn1–O1–C12–N3–N2; *a* = 1 − *x*, 1 − *y*, 1 − *z*]. Only one C–H···π interaction is shown in the unit cell and that is between C(8)–H(8)···Cg(5)[b] [Cg(5) = C(13)–C(14)–(15)–C(16)–C(17)–C(18); d_{H-Cg} = 2.95 Å; *b* = 1 − *x*, 1 − *y*, 1 − *z*]. One intra- and one intermolecular hydrogen bonding interaction were observed, *ie*, N3(H) and N4 of the same molecule and N5(H) of one molecule with Br2 of the other molecule [N(3)–H(3 N)···N(4), D–H = 0.80(3) Å, H···A = 2.04(3) Å, D···A = 2.669(4) Å, D–H···A = 135(3)°; N(5)–(H5N)···Br(2)[c], D–H = 0.70(3) Å, H···A = 2.68(3) Å, D···A = 3.374(3) Å, D–H···A = 170(3)°, *c* = 1 − *x*, 1 − *y*, 1 − *z*].

Figs. 4 and 5 show the molecular structures of compounds **5** and **6** along with the atom numbering schemes. Compound **5** crystallizes in the monoclinic crystal system with the space group $P2_1/n$, while compound **6** in the orthorhombic crystal system with the space group $P2_12_12_1$. In both the compounds [ZnL_2], the Zn atom is six coordinate in which both ligands are coordinated in their deprotonated enolate forms *via* the pyridine nitrogen, azomethine nitrogen and enolate oxygen atoms. The ligands with their donor atoms are arranged around the zinc ion in a meridional fashion and both compounds are polymorphic. In compound **5**, atoms O1, O2, N1 and N6 lie in the equatorial plane, and N2 and N7 occupy the axial positions, while in compound **6**, atoms O1, O2, N1 and N6 lie in the equatorial plane, and N2 and N7 occupy the axial positions of the distorted octahedron. In both compounds **5** and **6**, the atoms Zn1, O1, O2, N1, N6 do not deviate significantly from the least square plane [0.0034 Å for **5** and 0.0015 Å for **6**]. Each of the semicarbazone fragments {(O1 and N1, O2 and N6 for **5**); (O1 and N1, O2 and N6 for **6**)} are coordinated to the Zn centre with an angle of 150.95(6)°, 151.03(6)° and 151.17(11)°, 151.42(11)°, respectively, for **5** and **6**, having a large distortion from an ideal octahedron (180°). The planes containing Zn1, O1, N1, N2, N7 (plane 1) and Zn1, O2, N2, N6, N7 (plane 2) are deviated from the central metal atom (Zn1) by 0.0837 and 0.0248 Å, respectively, in compound **5**, similarly in compound **6**, the planes containing Zn1, O2, N7, N6, N2 (plane 3) and Zn1, O1, N2, N1, N7 (plane 4) are deviated from the central metal atom (Zn1) by 0.0314 and 0.0610 Å, respectively. The dihedral angle formed by the planes 1 and 2 is 85.81(0.04)° for compound **5** and by the planes 3 and 4 in compound **6** is 85.69 (0.08)°, consistent with a nearly 90° octahedral angle. Selected bond lengths and bond angles are given in Table 2.

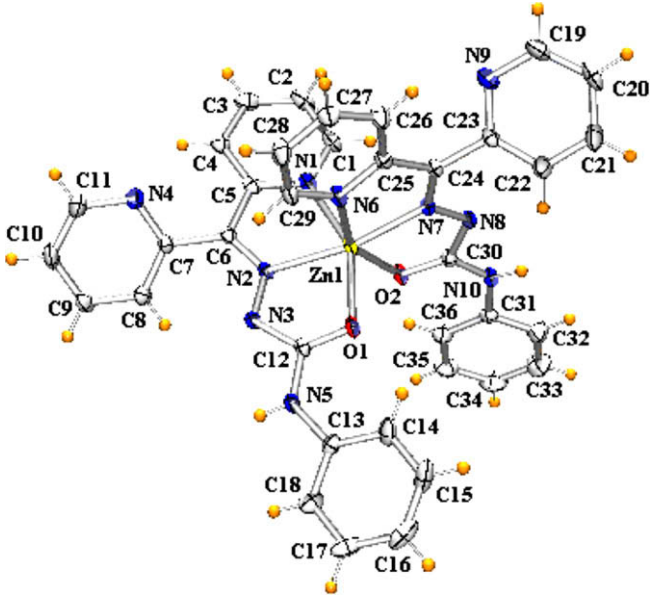

Fig. 4. Molecular structure of ZnL_2.

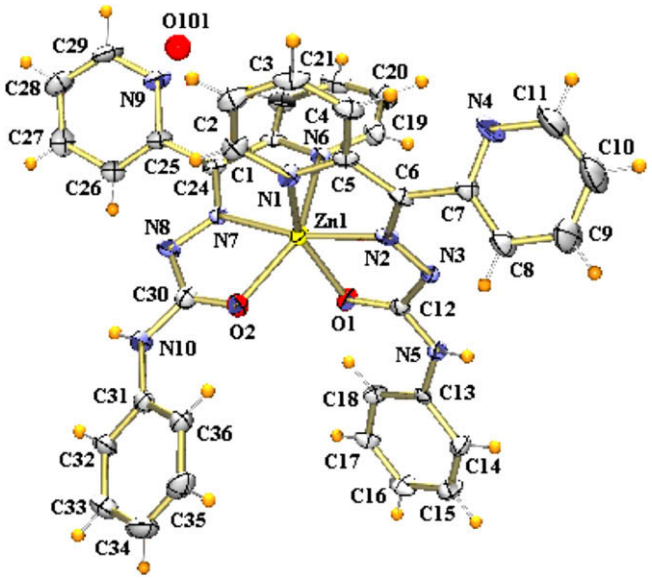

Fig. 5. Molecular structure of $ZnL_2 \cdot 0.3H_2O$.

In compound **5**, when viewed along *a* axis, the molecules are arranged in an opposite manner and are interconnected through N5(H) and N3 of the same molecule with N8 and N10(H) of the nearby molecule, respectively (Fig. 6) [D–H···A, N(5)–H(5)···N(8)[d]; D–H = 0.84(3) Å; H···A = 2.13(3) Å; D···A = 2.961(2) Å; D–H···A = 170.(2)°; Symmetry code, *d* = 1/2 − *x*, 1/2 + *y*, 3/2 − *z*; D–H···A, N(10)–H(10)···N(3)[e]; D–H = 0.83(2) Å; H···A = 2.21(2) Å; D···A = 3.023(2) Å; D–H···A = 170.(2)°; Symmetry code, *e* = 1/2 − *x*, −1/2 + *y*, 3/2 − *z*]. Intramolecular hydrogen bonding interactions were also observed i.e., C4(H) with N4 and C8(H) with N3 and C14(H) with O1 [D–H···A, C(4)–H(4)···N(4); D–H = 0.93 Å; H···A = 2.42 Å; D···A = 2.984(3) Å; D–H···A = 119°;

3.3. Infrared and electronic spectral studies

The infrared spectral data of the zinc(II) complexes are given in Table 4. The ν_a(NH) vibrations of the imino group are observed at *ca.* 3369 cm^{-1} in the IR spectrum of HL. The lack of an N–H stretching vibration in the spectra of the complexes ZnL(OAc) and $ZnLN_3$ endorses the ligand coordination to zinc(II) ion in the deprotonated enolate form. However in the complexes $Zn(HL)Br_2$ and $Zn(HL)Cl_2$ the presence of bands at 3239 and 3369 cm^{-1}, corresponding to ν(NH) vibrations, indicates that the semicarbazone is coordinated in the neutral form. A strong band at 1591 cm^{-1} in the IR spectrum of HL corresponds to the ν(N3–C6) stretching, which suffers a positive shift on complexation. Coordination of the azomethine nitrogen atom is also consistent with the presence of a band in the 404–420 cm^{-1} region, assignable to ν(Zn–N) for these complexes

Table 4
IR spectral assignments for the ligand and the zinc(II) complexes

Compound	ν(NH)	ν(C=N)	ν(CO)	ν(N=C)	ν(N–N)	ν(Zn–N)	ν(Zn–O)
HL	3369	1591	1718		1129		
$Zn(HL)Br_2$ (**1**)	3239	1597	1661		1147	407	
$Zn(HL)Cl_2$(**2**)	3369	1597	1667		1153	404	
ZnL(OAc) (**3**)		1597		1521	1156	414	516
$ZnLN_3$(**4**)		1595		1518	1148	404	502
ZnL_2(**5**)		1597		1515	1223	420	518
$ZnL_2 \cdot H_2O$ (**6**)		1597		1515	1229	416	520

Table 5
Electronic spectral assignments for the ligand and the zinc(II) complexes

compound	π–π^*	n–π^*	MLCT
HL	40000	30770	
$Zn(HL)Br_2$ (**1**)	37630	31840	24220
$Zn(HL)Cl_2$ (**2**)	37460	31450	24280
ZnL(OAc) (**3**)	37410	31350	24280
$ZnLN_3$ (**4**)	37200	32250	24210
ZnL_2 (**5**)	37280	32230	24230
$ZnL_2 \cdot H_2O$ (**6**)	37270	32240	24210

[20–22]. A band at 1718 cm^{-1} in the ligand has significant contribution from the C=O stretching vibration and it is shifted to 1667 cm^{-1} in $Zn(HL)Cl_2$ and 1661 cm^{-1} in $Zn(HL)Br_2$ confirming the keto form of HL in these complexes. In complexes **3**–**6**, the bands at 502–520 cm^{-1} are assignable to ν(Zn–O), consistent with oxygen coordination. The spectra of the complexes exhibit a systematic shift in the position of the ν(N–N) bands in the region 1129–1229 cm^{-1}. A medium band around 601 cm^{-1}, indicating an out-of-plane pyridyl ring vibration in the uncomplexed ligand, shifts to higher frequencies on complexation which confirms the coordination of the ligand to the metal via the pyridine nitrogen [23–26]. Compound $ZnLN_3$ exhibits strong bands at 2076 and 1302 cm^{-1} corresponding to the asymmetric and symmetric stretching of the coordinating azido group. For the complex ZnL(OAc) the asymmetric and symmetric stretching vibrations of the acetate group appear at 1562 and 1433 cm^{-1} respectively. The presence of a band at 3440 cm^{-1} for $ZnL_2 \cdot H_2O$ indicates the presence of the H_2O molecule.

The electronic spectral data of the zinc(II) complexes are given in Table 5. The ligand HL has an absorption at 40000 cm^{-1} due to the intra-ligand π–π^* transitions of the pyridyl ring and imine function of the semicarbazone moiety. Another band at 30770 cm^{-1} for HL corresponding to a n–π^* transition of the amide function, which undergoes a small blue shift on complexation, indicating coordination via the pyridyl nitrogen with a reduction in intensity [27]. The shift of the π–π^* bands to the longer wavelength region is the result of the C=O bond being weakened and the conjugated system being enhanced after the formation of the complexes. The metal–ligand CT bands are found around 24200 cm^{-1}.

2. Experimental

2.1. Materials and physical measurements

All the chemicals were of analytical grade and were used as received without further purification. The precursor complex, [bis(salicylaldiminato)manganese(II)], was prepared according to the procedure described previously [21]. XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Elemental analyses were obtained from a Carlo ERBA Model EA 1108 analyzer. Scanning electron microscopy (SEM) images were obtained on a Philips XL-30ESEM equipped with an energy dispersive X-ray spectroscopy. Transmission electron microscopy (TEM) images were obtained on a Hitachi H-800 transmission electron microscope with an accelerating voltage of 200 kV. The surface of the manganese compound was characterized by X-ray photoelectron spectroscopy (XPS). An ESCA-3000 electron spectrometer with non-monochromatic Mg Kα radiation was used to excite the photoelectrons. The metallic impurities were identified using an inductively coupled plasma-optical emission spectrometer (ICP-OES) Model Perkin–Elmer PLASMA-1000. FT-IR spectra were recorded on a Shimadzu Varian 4300 spectrophotometer in KBr pellets.

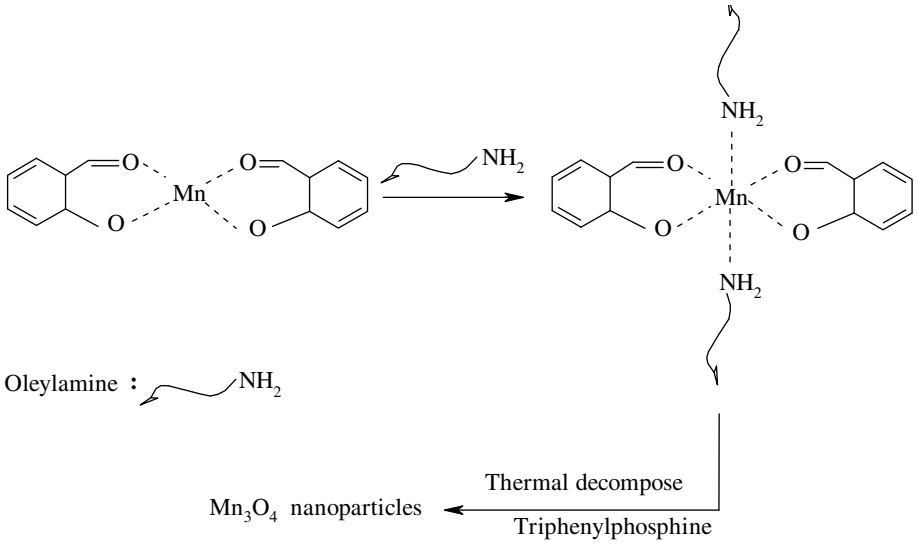
2.2. Preparation of Mn_3O_4 nanoparticles

The fabrication method of Mn_3O_4 nanoparticles was identical to that reported earlier [22], which was based on a thermal decomposition process of [bis(salicylaldiminato)manganese(II)], $[Mn(Sal)_2]$, without the presence of a catalyst. The current synthetic procedure is a modified version of the method developed by Hyeon and coworkers for the synthesis of nanocrystals for metals that employs the thermal decomposition of transition metal complexes [23]. Unless otherwise noted, all reactions were carried out in a dry-argon atmosphere. The overall synthetic procedure is shown in Scheme 1. In this synthesis Mn_3O_4 nanoparticles were prepared by the thermal decomposition of a $[Mn(sal)_2]$-oleyl amine complex. First, the $[Mn(sal)_2]$-oleyl amine complex was prepared by the reaction of 0.6 g of $[Mn(sal)_2]$ and 2 ml of oleyl amine. The mixed solution was placed in a 50 ml three-neck distillation flask and heated up to 100 °C for 90 min. During all the experimental processes, the flask was flushed with high-purity Ar gas to avoid oxidation. The resulting metal-complex solution was injected into 5 g of triphenylphosphine at 210 °C. The color of the solution changed from orange to black, indicating that colloidal nanoparticles were generated. The black solution was aged at 210 °C for 45 min, and was then cooled to room temperature. The nanoparticles were precipitated by adding excess ethanol to the solution. The precipitated nanoparticles were retrieved by centrifugation. The yield of the overall synthesis was 60% based on the amount of $[Mn(sal)_2]$. The final products were dispersed into *n*-hexane or toluene (Scheme 1).

3. Results and discussion

The presence of triphenylphosphine led the particles to be well dispersed with no agglomeration; while much larger particles flocculating together were synthesized in the absence of triphenylphosphine (TPP) [24]. Triphenylphosphine is a high-boiling point surfactant with a patulous long chain structure providing greater steric hindrance. So, this agent might slow the addition rate of materials to the nanoparticles during their growth, resulting in much smaller nanoparticles. Furthermore, the surfactants in the solution coordinated onto the metal of the nanoparticles, providing a dynamic organic structure that stabilizes the nanoparticles in solution. The addition of TPP into the mixture of oleyl amine and complex as an additional surfactant reduced the particle size much further and resulted in very uniform size distribution (Scheme 1). Oleyl amine is known as a ligand that binds tightly to the metal nanoparticle surface. The combined effects of TPP and oleyl amine were much more profound than those of the individual components.

Fig. 1 shows the XRD of Mn_3O_4 nanoparticles using thermal decomposition. The powders showed a crystalline pattern and the observed d-lines matched the reported values for the tetragonal Mn_3O_4 phase (JCPDS; 1–1127). The calculated lattice parameters, by a least square fit, are $a = 5.752$ Å and $c = 9.421$ Å. The additional lines that are not indexed may arise from intermediate phases that are formed during the reaction. The surface area of these powders was found to be 130 m^2/g. The crystallite size measurements were also carried out using the Scherrer equation, $D = k\lambda/\beta\cos\theta$, where D is the crystallite size, k is a constant (=0.9 assuming that the particles are spherical), λ is the wavelength of the X-ray radiation, β is the line width (obtained after correction for the instrumental broadening) and θ is the angle of diffraction. The average particle size obtained from the XRD data is 25 nm.



Scheme 1. Synthesis of Mn_3O_4 nanoparticles by the thermal decomposition of Mn-oleyl amine complexes.

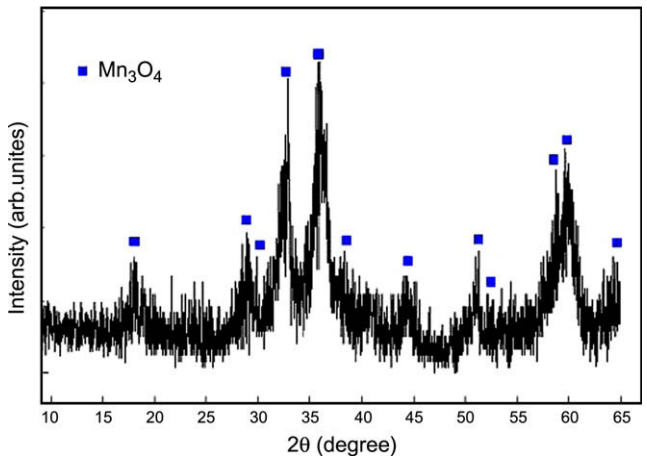


Fig. 1. X-ray diffraction (XRD) pattern of the as-synthesized Mn_3O_4 nanoparticles.

No diffraction peaks for metallic Mn were seen in Fig. 1. The absence of the Mn phase in our sample was ascribed to the high reactivity of Mn at high temperatures, resulting in complete oxidation of Mn in air.

Fig. 2 depicts the SEM pictures of sample Mn_3O_4 nanoparticles. From the micrograph, it was observed that the nanoparticles were agglomerated but were almost uniform in size. The particle morphology observed was either spherical or cubic like with uneven shapes.

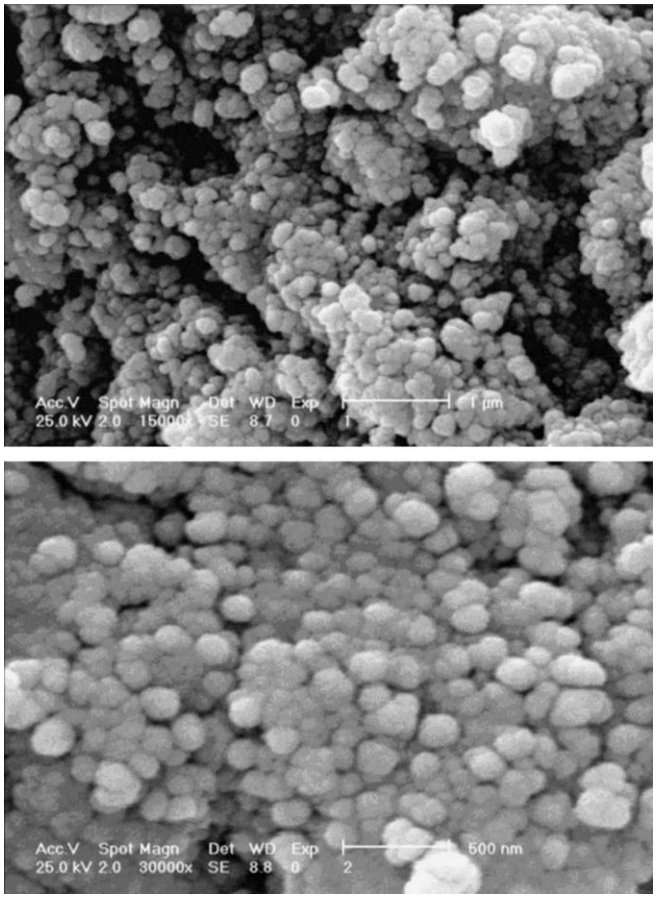

Fig. 2. SEM images of Mn_3O_4 nanoparticles.

As-synthesized samples were subjected to ICP-OES analysis for the identification of the metallic impurity level, wherein it was observed that impurities such as Na, Ca and Cu were at a considerably low level (<0.01%). It implies that better quality Mn_3O_4 can be obtained by thermal decomposition.

The morphology, size distribution and microstructure of the products were further studied by TEM. Fig. 3 shows a representative TEM image of the sample at low magnification. It is interesting to note that most of the particles appear to have a spherical morphology. Statistical analysis of the diameter distribution of the nanoparticles indicates that the mean diameter is about 20–30 nm.

Fig. 4 shows the FT–IR spectra of the obtained Mn_3O_4 powders by thermal decomposition of $[Mn(sal)_2]$. It can be seen from Fig. 4 that there are no characteristic IR absorption bands of salicyclaldehyde, oleyl amine and triphenylphosphine, indicating that the Mn_3O_4 product was free of solvent. The FT-IR spectra of the product demonstrated a notable resemblance to those of Mn_3O_4 in the previous studies [25–27]. In the region from 650 to 400 cm^{-1}, three absorption peaks were observed at 642, 521 and 423 cm^{-1} due to Mn–O vibrations.

The surface of the Mn_3O_4 nanoparticles was characterized by X-ray photoelectron spectroscopy (Fig. 5). A hemispherical sector analyzer with a multi-channel detector was used to detect the ejected electrons energy wise. All the measurements were carried out with reference to the C 1s binding energy (285 eV) as an internal standard. All the spectra were recorded in an optimized high vacuum, 10^{-9} Torr. The details about the electron spectrometer were given in an earlier publication [28]. The XPS spectra of Mn $2p_{3/2}$, Mn $2p_{1/2}$ Mn 3s and O 1s energy levels were recorded. The Mn 2p peak is broad due to multiple splitting. The binding energy value of Mn $2p_{3/2}$ is 641.7 eV. The spin–orbit splitting is the difference between BE values of Mn $2p_{3/2}$ and Mn $2p_{1/2}$ levels. The observed spin–orbit splitting is 11.6 eV, the same as manganese oxides [29]. There is no change in the spin–orbit splitting as compared with the various manganese oxides. The BE value of Mn $2p_{3/2}$ (641.7 eV) and spin–orbit splitting (11.6 eV) are well matching with the reported values of manganese oxide. The BE of the 3s level is 86.1 eV and the multiple splitting is 5.2 eV. The magnitude of the splitting is proportional to the number of unpaired electrons in the d-orbital. The observed BE values and the splitting of the 3s levels exactly match with the reported values of the Mn_3O_4 compound [30]. The O 1s spectra is broad and shows a symmetry towards higher BE sides. It is resolved into two components. The BE values are 529.7 and 532.5 eV for the first and the second peak, respectively. The first peak is assigned to the lattice oxygen of manganese

oxide and second can be assigned to either carbonate species or OH species present on the surface. In the present case, it is due to hydroxyl species of the surface.

Recently, amine compounds have been used due to their moderate reducibility [31–34]. At certain pressures, 1,2-diaminoethane mainly performs the role of an electron transfer agent, displaying moderate intensity reductive characteristics [30,31]. In view of this, in our case we feel that the formation of Mn_3O_4 by thermal decomposition at high temperature in oleyl amine may also be a form of typical mild reduction process. In the present case, after coordination of oleyl amine to the manganese precursor solution there may be formation of MnO(OH). These amines are also acting as the solvent. Being a polarizing solvent, oleyl amine can greatly enhance the solubility, diffusion and reactivity of the reactant species. Especially, when oleyl amine is coordinated with manganese, the short distance between the manganese and nitrogen or oxygen atom in the compound is favorable for electron transfer from N or O to manganese [31–34], resulting in the formation of Mn_3O_4. The synthesis of phase pure Mn_3O_4 using the hydrothermal method has rarely been reported in the literature. However, good quality Mn_3O_4 formation by thermal decomposition is attributed to the instant reaction due to localized superheating. In the hydrothermal method, the formation of Mn_3O_4 takes a very long time (24 h). MnO(OH) is always present as one of the phases in the Mn_3O_4 prepared by the hydrothermal method. Surprisingly, MnO(OH) is not present in the Mn_3O_4 prepared by the thermal decomposition method.

In addition Mn_3O_4 nanoparticles have been prepared under different conditions. By controlling the quality of the nanoparticles, Mn_3O_4 with various sizes and morphologies can be formed. For example, mixing and heating 0.6 g $[Mn(sal)_2]$ and 2 ml of oleyl amine led to 10–15 nm Mn_3O_4 nanoparticles, but the obtained nanoparticles were irregular and not monodispersed. To prepare monodispersed Mn_3O_4 nanoparticles, the same procedure was executed with a temperature of 100 °C for 90 min. The resulting metal-complex solution was injected into 5 g of triphenylphosphine at 210 °C. Uniform-shaped Mn_3O_4 nanoparticles with an average size of 20–30 nm were obtained. In this experimental TPP was used as a stabilizing agent.

4. Conclusion

Pure phase Mn_3O_4 nanoparticle powder was synthesized successfully by the thermal decomposition method from [bis(salicylidiminato)manganese(II)] in the presence of oleyl amine and triphenylphosphine. The particles were mostly tetragonal Mn_3O_4 phase and had a size in the range 20–30 nm. The BE values of the Mn $2p_{3/2}$ (641.7 eV) and spin–orbit splitting (11.6 eV) is well matching with the reported value of the manganese oxide. Significantly, the metallic impurities were below 0.01%, and so high quality products were prepared.

$[Et_3NH]_4[V_{10}O_{26}(OH)_2]$ (**1**) ($V_{10}C_{24}H_{66}N_4O_{28}$): C, 21.07; H, 4.86; N, 4.09. Found: C, 20.92; H, 4.73; N, 3.97%.

2.4. Synthesis of $[Me_2HN(CH_2)_2NHMe_2]_3[V_{10}O_{28}] \cdot 4H_2O$ (**2**)

Compound **2** was synthesized from aqueous medium in 47% yield by following a very similar procedure as described for **1** using *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (3.3 mmol) instead of triethylamine. *Anal.* Calc. for $[Me_2HN(CH_2)_2NHMe_2]_3[V_{10}O_{28}] \cdot 4H_2O$ (**2**) ($V_{10}C_{18}H_{62}N_6O_{32}$): C, 15.62; H, 4.51; N, 6.07. Found: C, 15.45; H, 4.42; N, 5.89%.

2.5. X-ray crystallography

X-ray quality single crystals of **1** and **2** were collected directly from the products obtained during synthesis. Unit cell parameters and the intensity data were obtained on a Bruker-Nonius SMART APEX CCD single crystal diffractometer, equipped with a graphite monochromator and a Mo Kα fine-focus sealed tube (λ = 0.71073 Å). Data were collected at 298 K with a scan width of 0.3° in ω and an exposure time of 10 s/frame. The SMART and the SAINT-PLUS packages [22] were used for data acquisition and extraction, respectively. In each case, the SADABS program [23] was used for absorption correction. The SHELX-97 programs [24] available in the WINGX package [25] were used for structure solution by direct method and refinement on F^2 by full-matrix least-squares procedures. All non-hydrogen atoms were refined anisotropically. In the case of **1**, the hydrogen atoms of the ammonium N–H groups and the hydrogen atoms of the dihydrogendecavanadate were located on a difference map and refined isotropically. In the case of **2**, the hydrogen atoms of the ammonium groups and the water molecules were also located on a difference map. The N–H hydrogens were refined with $U_{iso}(H) = 1.2U_{eq}(N)$ and the water hydrogen atoms were refined with geometric restraints and $U_{iso}(H) = 1.5U_{eq}(O)$. All other hydrogen atoms in both structures were included at idealized positions by using a riding model. The ORTEX6a [26] and PLATON [27] packages were used for molecular graphics. Selected crystallographic data are listed in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

Both **1** and **2** have been prepared by treating an aqueous suspension of V_2O_5 with the corresponding amine under boiling condition. The elemental analysis data are consistent with the empirical formula obtained from the X-ray structures. Each of the two compounds is diamagnetic and EPR silent in the solid state indicating the +5 oxidation state of all the vanadium centres.

The infrared spectral features of both compounds are very similar to that reported for polyvanadates [10–14,16,17,19]. The spectra of **1** and **2** display the terminal V=O stretching bands within 1000–930 cm^{-1}. The asymmetric and symmetric vibrations of the bridging V–O–V fragments appear in the ranges 850–730 and 600–450 cm^{-1}, respectively. Compound **1** shows several weak bands within 3370–2485 cm^{-1}. These are possibly due to the O–H, N–H and C–H stretches. Two moderately strong bands are observed at 3486 and 3044 cm^{-1} in the spectrum of **2**. The former is most likely associated with the water of crystallization and the latter is attributed to the N–H stretching.

^{51}V NMR spectra were recorded using aqueous solutions of **1** and **2**. The spectra of both compounds are very similar and typical of decavanadate containing species. Three resonances observed at −426, −507 and −525 ppm for **1** and at −424, −501 and −516 ppm for **2** are within the range reported previously [10,12].

3.2. Thermal studies

Thermogravimetric measurements with both compounds have been performed in the temperature range 50–800 °C with a scan rate of 10°/min in the presence of a nitrogen flow. The profiles of the thermal decomposition curves obtained for **1** and **2** are comparable with that reported for decavanadates containing organic cations [11,14,19]. The anhydrous compound **1** is stable up to 160 °C. After this temperature the decomposition starts in two successive steps due to the loss of the organic cations. In the relatively sharp first step up to 200 °C the weight loss is about 12%. A further 18% weight loss occurs in the following step which continues up to 310 °C. Above this temperature up to 800 °C there is a small progressive weight loss without any clear peak. The hydrated compound **2** shows the loss of water (obsd. 5.6%, calcd. 5.2%) in the temperature range 60–115 °C. After the water loss there is a stable form up to 160 °C. The loss of the organic cations occurs in two steps. In the sharp first step between 160 and 175 °C the weight loss is about 7%. In the broad second step between 175 and 380 °C the weight loss is about 19%. As observed for **1**, there is a small but progressive weight loss without any peak in the temperature range 380–800 °C.

3.3. Description of structures

Compound **1** crystallizes in the space group $P2_1/n$. The asymmetric unit contains four triethylammonium cations and the dihydrogendecavanadate anion $[V_{10}O_{26}(OH)_2]^{4-}$. The crystal structure of **1** synthesized by a different procedure has been reported earlier in the space group $P2_1/c$ [18]. Compound **2** crystallizes in the space group $C2/m$. The asymmetric unit contains half of one disordered diammonium cation, one fourth of a second diammonium cation, one fourth of the decavanadate anion $[V_{10}O_{28}]^{6-}$ and two water molecules each having half occupancy. The methylene groups of the disordered diammonium are found in four places. The intracation bond parameters are unexceptional for both **1** and **2**. The structures of $[V_{10}O_{26}(OH)_2]^{4-}$ and $[V_{10}O_{28}]^{6-}$ are shown in Fig. 1. Two hydrogen atoms of $[V_{10}O_{26}(OH)_2]^{4-}$ are bonded to a μ_2-oxo

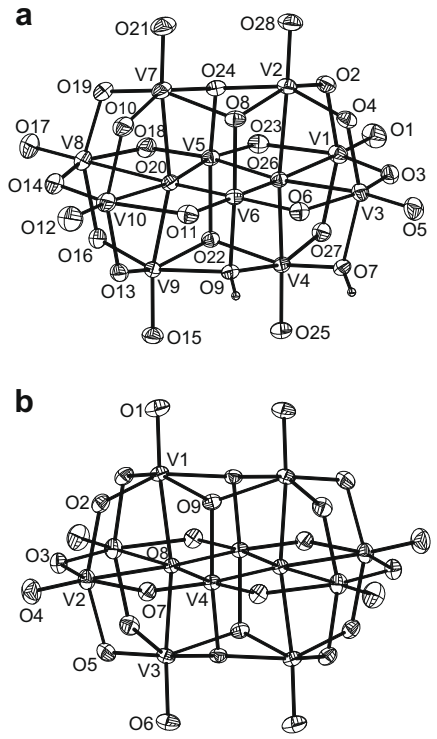

Fig. 1. The structures of (a) $[V_{10}O_{26}(OH)_2]^{4-}$ and (b) $[V_{10}O_{28}]^{6-}$ with the atom-labeling schemes. All non-hydrogen atoms are represented by their 40% probability thermal ellipsoids.

atom (O7) and a μ_3-oxo atom (O9). All the metal centres in both decavanadates are in distorted O_6 octahedra. The bond parameters associated with the metal centres in both compounds are comparable with that reported for structurally characterized decavanadates [10–21]. The *cis* and *trans* O–V–O bond angles are in the ranges 72.53(10)–107.78(12)° and 150.88(10)–177.26(11)°, respectively. All the V–O bond lengths for **1** and **2** are listed in Tables 2 and 3, respectively. Eight terminal V=O bond lengths are within 1.598(2)–1.622(2) Å. Each metal centre of these terminal V=O groups has a very long V–O bond length (2.217(2)–2.427(2) Å) involving the hexacoordinated O-atoms (O20 and O26 for **1** and O8 for **2**). Other V–O bond lengths for these eight metal centres are in the range 1.731(2)–2.129(2) Å. Remaining two central metal centres (V5 and V6 for **1** and V4 for **2**) without terminal oxo group have two short (1.667(2)–1.700(2) Å), two medium (1.865(2)–2.049(2) Å) and two long (2.050(2)–2.160(2) Å) V–O bond lengths.

3.4. Hydrogen bonding and self-assembly

Both **1** and **2** contain several classical hydrogen bond donor and acceptor centres. We have investigated the self-assembly patterns of both **1** and **2** via intermolecular hydrogen bonding. Dihydrogendecavanadates are known to form hydrogen bonded dimeric aggregates in the crystal lattice [16–18]. Compound **1** also forms discrete dimeric units (Fig. 2). The $[V_{10}O_{26}(OH)_2]^{4-}$ anion dimerises via two pairs of complementary O–H···O hydrogen bonds involving the two hydroxy groups (O7–H and O9–H) and two terminal V=O group O-atoms (O15 and O25). The O7···O15 and the O9···O25 distances are

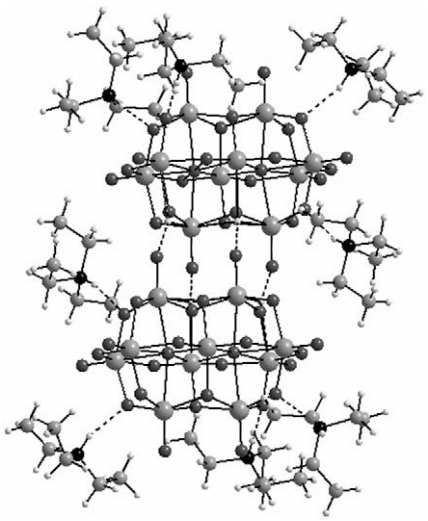

Fig. 2. The dimeric aggregate of $[Et_3NH]_4[V_{10}O_{26}(OH)_2]$ (**1**).

2.734(3) and 2.708(3) Å, respectively. The O7–H···O15 and the O9–H···O25 angles are 167(4)° and 166(4)°, respectively. The triethylammonium moieties are connected to the corresponding anions through N–H···O hydrogen bonds. Four μ_2-oxo atoms (O2, O4, O10 and O13) of the dihydrogendecavanadate act as donors in these N–H···O hydrogen bonds. The N···O distances and the N–H···O angles are in the ranges 2.713(4)–2.833(4) Å and 160(4)–176(5)°, respectively. Due to the presence of the diammonium cations and water of crystallization the self-assembly of **2** is more intricate in comparison to that of **1**. The disordered diammonium cations, water molecules and the $[V_{10}O_{28}]^{6-}$ anion form a two-dimensional sheet structure via N–H···O and O–H···O hydrogen bonds (Fig. 3a). In the N–H···O hydrogen bonds, μ_2-oxo atom (O3) of the decavanadate unit is involved. The N2···O3 distance and the N2–H···O3 angle are 2.634(5) Å and 178(6)°, respectively. The μ_2-oxo atom O2 and the terminal V=O group O-atom O6 of $[V_{10}O_{28}]^{6-}$ are involved in the O–H···O hydrogen bonds with the water molecules. The O10···O2 and the O11···O6 distances are 2.850(3) and 2.853(4) Å, respectively. The O10–H···O2 and O11–H···O6 angles are 147(2) and 166(5)°, respectively. The third diammonium cation connects the parallel sheets through N–H···O hydrogen bonds and a three-dimensional network of **2** is formed (Fig. 3b). The acceptor in this N–H···O hydrogen bond is the μ_3-oxo atom O9 of the anion. The N1···O9 distance and the N1–H···O9 angle are 3.010(4) Å and 161(5)°, respectively.

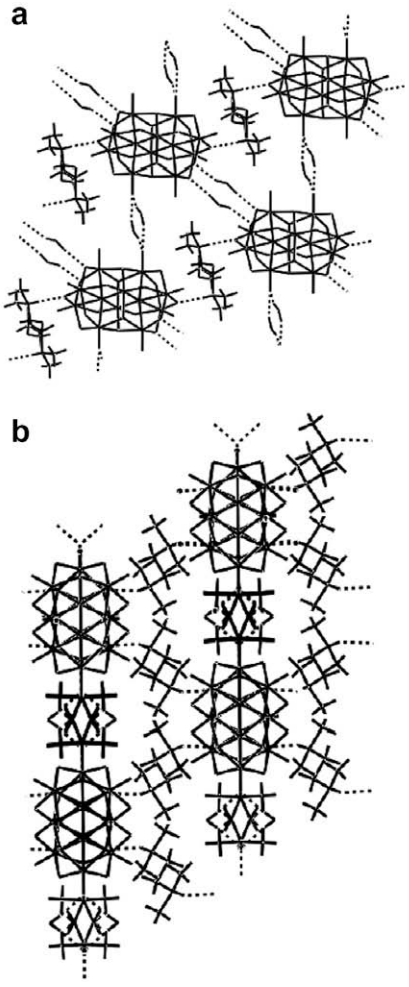

Fig. 3. Packing of $[Me_2HN(CH_2)_2NHMe_2]_3[V_{10}O_{28}] \cdot 4H_2O$ (**2**): (a) two-dimensional ordering of the two diammonium cations, the anion and the water molecules and (b) bridging of the parallel two-dimensional sheets by the remaining diammonium cation to form a three-dimensional network.

4. Conclusion

In conclusion, triethylammonium and *N*,*N*,*N*′,*N*′-tetramethylethylenediammonium decavanadates have been synthesized and characterized by elemental analysis, magnetic, thermal, IR and NMR measurements. The X-ray structures of both compounds have been determined. The $[V_{10}O_{26}(OH)_2]^{4-}$ is isolated with $[Et_3NH]^+$ in anhydrous form, while the $[Me_2HN(CH_2)_2NHMe_2]^{2+}$ salt of $[V_{10}O_{28}]^{6-}$ is obtained in tetrahydrated form. The self-assembly patterns via intermolecular hydrogen bonding have been scrutinized. The structure of $[Et_3NH]_4[V_{10}O_{26}(OH)_2]$ reveals that the four cations are simply connected to the anion via N–H···O hydrogen bonds but due to complementary interanionic O–H···O hydrogen bonds the compound forms discrete dimeric aggregates. On the other hand, the diammonium cations and the water molecules help to form a complex three-dimensional network of $[Me_2HN(CH_2)_2NHMe_2]_3[V_{10}O_{28}] \cdot 4H_2O$ through N–H···O and O–H···O hydrogen bonds.

5. Supplementary data

CCDC 678220 and 678221 contain the supplementary crystallographic data for **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.ac.uk.

Acknowledgments

This work was supported in part by the Department of Science and Technology (DST) (Grant No. SR/S1/IC-10/2007). Ms. A. Sarkar thanks the Council of Scientific and Industrial Research for a fellowship. X-ray structures were determined at the National Single Crystal Diffractometer Facility, School of Chemistry, University of Hyderabad (established by DST). We thank the University Grants Commission for the facilities provided under the UPE and CAS programs.

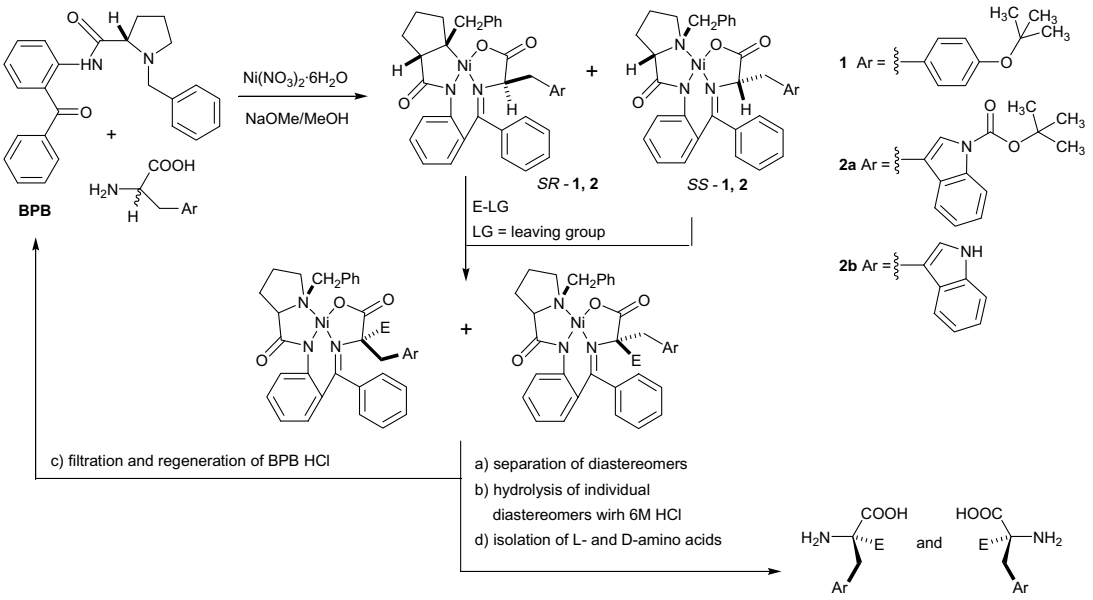


Scheme 1.

complexes was assessed using a model complex derived from tyrosine protected by a methyl group in the side chain.

2. Results and discussion

Ratios of starting compounds for the preparation of complexes were chosen from a previous optimisation protocol of the ratio of starting compounds for the preparation of the glycine-derived complex [5]. Twenty percent excess of nickel nitrate(II) to BPB was predicted to be optimal for both maximisation of the yield of complexes and minimisation of the amount of nickel in waste water. Five and fifty percent excess were also tested (Table 1). Unlike glycine used in the previous work, both side-chain protected amino acids are relatively expensive. Thus, the previously applied two-fold excess of amino acid was considered to be uneconomical. Ten, twenty and forty percent excess of amino acid to BPB were tested (Table 1). Experiments demonstrated that in this particular case the Boc-protective group of the indole residue nitrogen is unstable during chromatographic purification on silica gel. A significant amount of the complex derived from the protected tryptophan lost the protective group during quick preparative TLC purification of an analytical sample. Clean deprotection was observed in all the four preparative syntheses followed by time-consuming purification of the product by column chromatography on silica gel. No observations of low stability of indole nitrogen Boc-protected derivatives of tryptophan [9] were found in the literature. Deprotection was confirmed by NMR, MS/MS and X-ray data. In order to demonstrate the necessity of including the protective group for the preparation of quaternary α-amino acids via C-methylation of carbanion generated from tertiary precursor [7b], a sample of deprotected complex was methylated with an excess of CH_3I/KOH in 1,3-dimethylimidazolidin-2-one (DMI). This resulted in pure N-methylated product without any traces of the C-methylated product as confirmed by both MS^n and X-ray data (Scheme 2, Figs. 1C, D, 2 and 3).

Table 1
Yields of complexes (both *SS* and *SR* diastereomers) depending on the ratios of the starting compounds used

$Ni(NO_3)_2 \cdot 6H_2O$ excess	Amino acid excess	BPB	Yield of complex **1** (sum of diastereomers)	Yield of complex **2b** (sum of diastereomers)
1.05	1.1	1	57	55
1.2	1.2	1	79	61
1.2	1.4	1	83	86
1.5	1.4	1	87	79

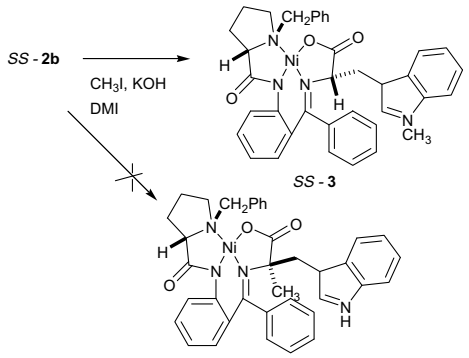
Development of an alternative purification method was successful, but the methylation of the *N*-Boc protected complex with an excess of CH_3I/KOH in DMI resulted in complete deprotection followed by complete N-methylation [10]. Similar *N*-Si(*i*-Pr)$_3$ protected tryptophan complex is stable during chromatographic purification on silica gel, but its methylation with an excess of CH_3I/KOH in DMI also resulted in almost complete deprotection followed by predominant N-methylation and less than 1% of C-methylation (Scheme 3). *tert*-Butyl protection of the phenolic group of tyrosine is perfectly compatible with the reaction conditions used and with column chromatography on silica gel (Fig. 1A, B).

Typical ions in the first-order positive-ion ESI mass spectra are protonated molecules and adducts with alkali metal ions, such as $[M+Na]^+$ and $[M+K]^+$ (Fig. 1A). The presence of these ions was used for the determination of molecular weights of all analysed compounds (see Section 3 for more details). Based on the determination of the molecular weights, the presence or the absence of a protective group or another substituent on the aromatic nitrogen (for tryptophan) or oxygen atom (for tyrosine side-chains) can be recognised [10]. Furthermore, the presence of a protective group can be confirmed using tandem mass spectrometry by the typical neutral losses associated with a particular group. In the case of complex 1, the typical neutral losses are $\Delta m/z$ 56 (butene) and 106 (see Fig. 1B). For deprotected complex 2b, the characteristic neutral loss is $\Delta m/z$ 129 (see Fig. 1C). However, the difference neutral loss $\Delta m/z$ 145 is observed in the spectra of N-methylated complex 3 (see Fig. 1D).

Both complexes *SS*-**2b** and *SS*-**3** crystallize with solvent molecules in the crystalline lattice. The crystals loose some solvent molecules during drying in air at ambient temperature. For such crystallosolvates, X-ray crystallography of shock-frozen single crystals is an informative method of structure characterisation.

2.1. SS-2b

There are 2 crystallographically different complexes co-crystallized with 3 benzene molecules in the asymmetric unit. Both complexes suffer from disorder at C2 atoms and one of them even has



Scheme 2.

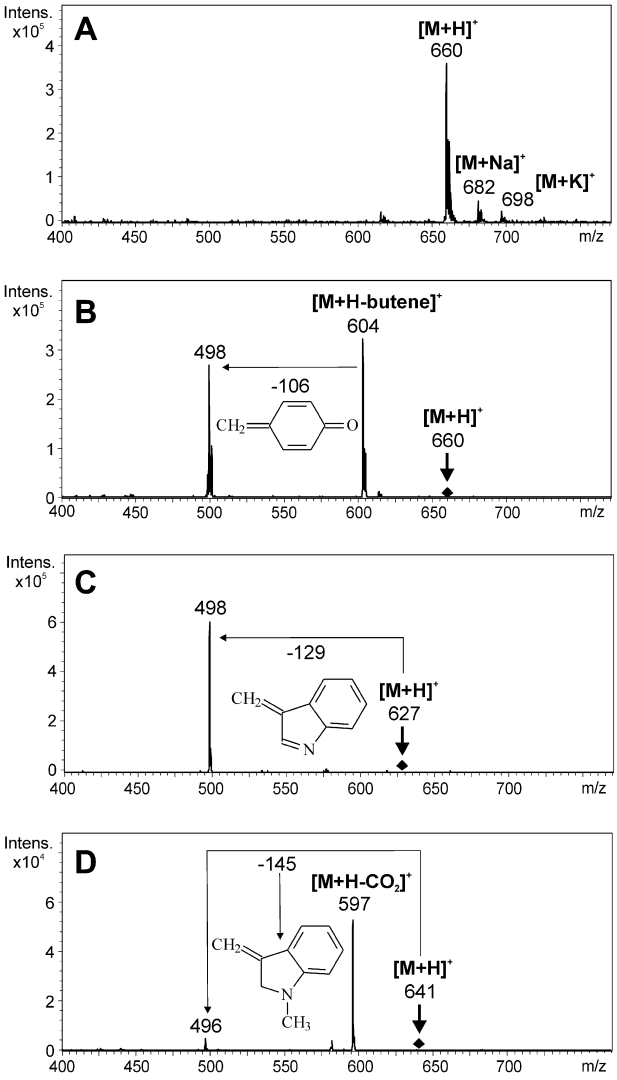


Fig. 1. Positive-ion electrospray ionization mass spectra: (A) First-order spectrum of **1**, (B) MS/MS spectrum of ion *m*/*z* 660 $[M+H]^+$ for **1**, (C) MS/MS spectrum of ion *m*/*z* 627 $[M+H]^+$ for **2b**, (D) MS/MS spectrum of ion *m*/*z* 641 $[M+H]^+$ for **3**.

the disorder of the phenyl group, see Figs. 2 and 5 (in Supplementary material). There are hydrogen bonds in the structure producing an helical arrangement of the complexes, see Figs. 6 and 7 (in Supplementary material). Packing in the unit cell along the monoclinic *b*-axis is shown in Fig. 8 (in Supplementary material).

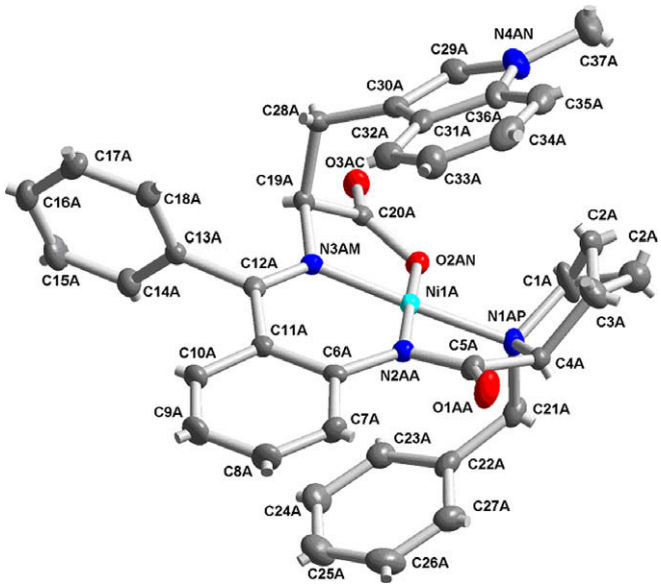

Fig. 3. The numbering scheme for *SS*-**3**, the first complex, with atomic displacement ellipsoids at 30% probability level. Note disorder of C2A. Hydrogens are omitted for clarity.

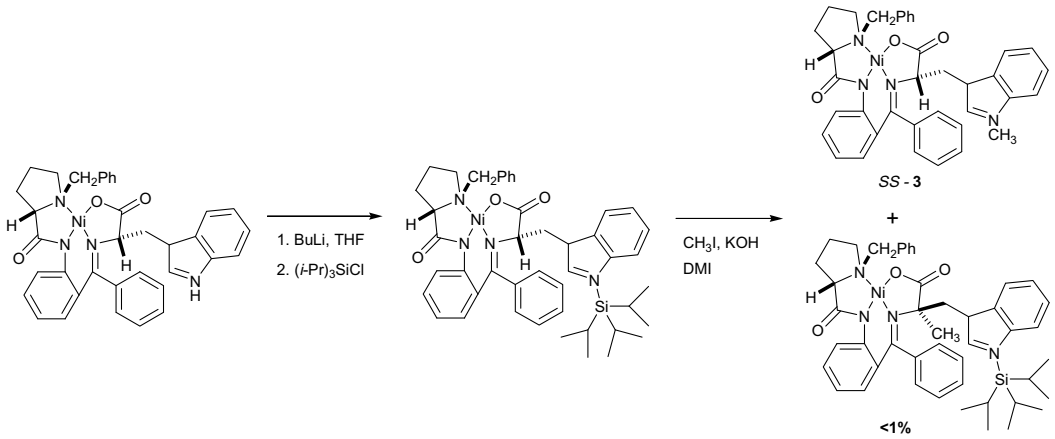
2.2. *SS*-**3**

There are 2 crystallographically different complexes co-crystallized with 2 benzene and 2 water molecules in the asymmetric unit. Again, both complexes suffer from disorder at C2 atoms see Figs. 3 and 9 (in Supplementary material). There are hydrogen bonds in the structure producing an helical arrangement of the complexes, see Figs. 10 and 11 (in Supplementary material). Packing in the unit cell along the orthorhombic *a*-axis is shown in Fig. 12 (in Supplementary material).



Scheme 3.

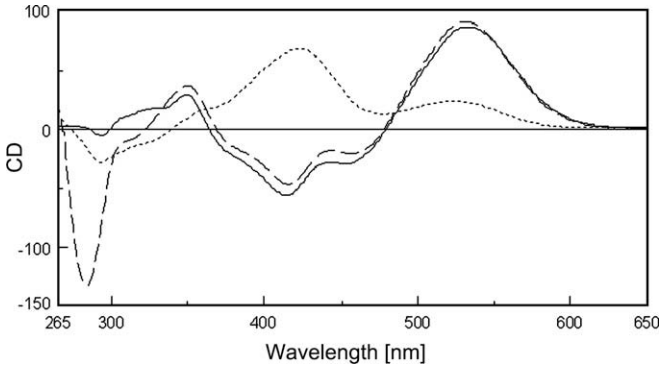


Fig. 4. CD spectra of *SS*-**4** (—), the first fraction, *SS*-**5** (— — —) and the second fraction *SR*-**5** (. . . . . .).

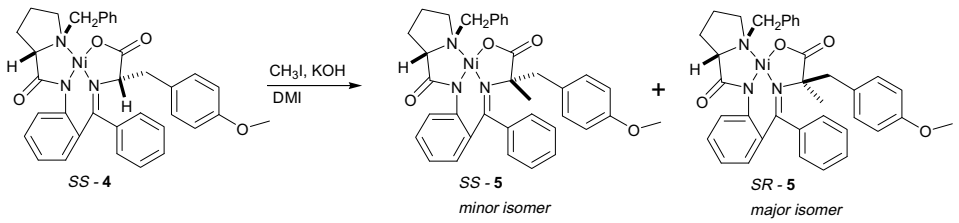
For both structures, the absolute structures were unambiguously determined. All nickel complexes show square-planar coordination geometry with small pyramidal distortions.

Five and ten percent excess of nickel nitrate and amino acid, respectively, led to poor yields of both complexes (Table 1). This result corresponds with the low yield of glycine-derived complex obtained with five percent excess of nickel nitrate [5]. As expected, twenty percent excess of nickel nitrate led to the high yield of both complexes. With such an excess of nickel salt, a higher excess of amino acid gave a slightly higher excess of complex **1** derived from tyrosine, and led to significantly higher yield of the complex derived from tryptophan (**2a** → **2b**) (Table 1). Lower yield of this complex, in the case when fifty percent excess of nickel nitrate was used, is consistent with the previously observed relationship between an excess of nickel nitrate used and yields of the complexes derived from glycine. Diastereomeric excess of (*SS*)-diastereomers in all cases was >95%. Minor (*SR*)-diastereomers were collected and partially characterised. Due to retroracemisation of the amino acid chiral centre in basic conditions, in further alkylation reaction mixtures of both diastereomers could be used without separation [8].

Due to poor preparative TLC separation of diastereomeric products of α-methylation of complex *SS*-**1**, its analogue complex *SS*-**4** (carrying methyl protective group of the side chain instead of *tert*-Bu) was used to assess the stereochemistry of products of α-methylation of such complexes (Scheme 4). These diastereomeric products of methylation *SS*-**5** and *SR*-**5** are separable by preparative TLC on silicagel while for the separation of many other similar diastereomers expensive preparative HPLC is necessary.

Stereochemistry of the diastereomers of 5 was assessed by circular dichroism (CD) and ^{13}C NMR spectroscopy:

- Two intense peaks were observed in the ^{13}C NMR spectrum of the reaction mixture after alkylation of *SS*-**4** with $^{13}CH_3I$/KOH in DMI (Scheme 4): minor at δ 29.3 ppm and major at δ 28.5 ppm. According to the integral intensities of peaks in ^{13}C NMR spectra, the diastereomeric excess of methylation was 6.9%;
- Two fractions were obtained after the preparative TLC separation of the reaction mixture. The first fraction giving a main ^{13}C NMR peak at δ 29.3 ppm was associated with the minor diastereomer. The second fraction where the main peak was at δ 28.5 ppm, was associated with the major diastereomer;
- CD spectra of starting *SS*-**4** and both diastereomers of **5** were recorded. Cotton effects in the spectra of both *SS*-**4** and the first TLC fraction (minor diastereomer) of **5** were similar in two areas (650–480 nm and 480–360 nm). Cotton effect in the spectrum of the second TLC fraction (major diastereomer) of **5** in the range 480–360 nm had an opposite sign (Fig. 4). Based on these CD data, the *SS* configuration was assigned to the first fraction (minor diastereomer) and the *SR* configuration was assigned to the second fraction (major diastereomer). This assignment is consistent with the proposed predominance of *Si*-alkylation leading to the major formation of *SR*-**5** (Scheme 4)[8].



Scheme 4.

3. Experimental

The ^1H and ^{13}C NMR spectra were obtained in $CDCl_3$ solutions using a Bruker AMX-360 or Bruker 500 spectrometer equipped with a multinuclear 5 mm tunable probe. ^1H NMR chemical shifts δ are expressed in parts per million (ppm) downfield from tetramethylsilane as an internal standard. Coupling constants J are given in Hz. ^{13}C NMR chemical shifts are given with respect to the solvent signal (δ = 77 ppm). Data are given in the following order: δ value (number of protons, multiplicity (s, singlet; d, doublet; dd doublet of doublet; m, multiplet; t, triplet; br s, broad singlet).

Positive-ion electrospray ionization (ESI) mass spectra were measured on an Esquire 3000 ion trap analyzer (Bruker Daltonics, Bremen, Germany) in the range m/z 50–1000. The samples were dissolved in 100% acetonitrile and analyzed by direct infusion at the flow rate 5 μl/min. The selected precursor ions were further analyzed by MS/MS analyses under the following conditions: the isolation width m/z = 8, the collision amplitude (in the range 0.8–1.0 V depending on the precursor ion stability), the ion source temperature (300 °C), the tuning parameter compound stability (100%), the flow rate and the pressure of nitrogen (4 l/min and 10 psi), respectively. The elemental composition of the complexes *SS*-**1** and *SS*-**2b** was confirmed on an orthogonal hybrid quadrupole time-of-flight (QTOF) mass spectrometer fitted with electrospray ionization source (Bruker Daltonics). The instrument was externally calibrated using ESI tunning mix before the measurement. The samples were dissolved in acetonitrile and analyzed by direct infusion at the flow rate of 3 μl/min. Interface parameters were set as follows: capillary voltage −4.5 kV, drying temperature 200 °C, the flow rate and pressure of nitrogen were 4 l/min and 0.4 bar, respectively. For the recording of exact masses, QTOF data were acquired by the summation of 50 000 scans with 10 rolling averages. The typical ions observed in the first-order positive-ion mass spectra were $[M+H]^+$, $[M+Na]^+$ and $[M+K]^+$, and the elemental composition was confirmed by the comparison of experimental and theoretical values for all studied compounds. Table 2 shows mass accuracies for monoisotopic masses, mean mass accuracies correspond to the mean value for all isotopic peaks, and the sigma is a combined value for the standard deviation of masses and intensities for all peaks.

The elemental composition of the complexes *SS*-**5** and *SR*-**5** was confirmed on a sector mass spectrometer fitted with electron-impact ionization source (VG Analytical) by a commercial analytical laboratory.

Diffraction data were collected using a Siemens SMART CCD diffractometer with Mo Kα radiation (λ = 0.71073 Å, graphite monochromator). The crystals were cooled to 173(2) K by a flow of nitrogen gas using the LT-2A device. A full sphere of reciprocal space was scanned by 0.3 steps in ω with a crystal-to-detector distance of 3.97 cm. Preliminary orientation matrices were obtained from the first frames using SMART program. The collected frames were integrated using the preliminary orientation matrices which were updated every 100 frames. Final cell parameters were obtained by refinement of the positions of reflections with $I > 10\sigma(I)$ after the integration of all the frames using SAINT software [11]. The data were empirically corrected for absorption and other effects using the SADABS program [12]. The structures were solved by direct methods and refined by full-matrix least-squares analysis on all $|F^2|$ data using SHELXTL software [13]. The crystallographic and refinement data are summarized in Tables 3 and 4. The hydrogen bonding geometrical parameters are summarized in Tables 5 and 6 (in Supplementary material). Selected bond lengths, selected bond angles and their estimated standard deviations are listed in Tables 7 and 8 (in Supplementary material). The molecular graphics (Figs. 2,3,5–12) were prepared using the program DIAMOND [14]. Circular dichroism spectra were recorded using a Jasco J-715 spectropolarimeter.

3.1. General procedure for the synthesis of complexes

2.47 M MeONa/MeOH (7.9 ml, 19.5 mmol) was added to a stirred suspension of BPB (500 mg, 1.3 mmol) and the corresponding amount of nickel nitrate and protected amino acid (Table 1) in dry MeOH (4 ml) under argon at 50 °C. The volume of the reaction mixture was then adjusted to 20 ml with dry MeOH. After stirring at 55 °C for 30 min, the mixture was poured into 0.7% aqueous citric acid (300 ml), stirred and the resulting precipitate was filtered off, washed with water on a filter and dried on air. The dry precipitate was purified by column chromatography using silica gel (Merck 40/63) and eluted with chloroform.[1] The first red fractions containing minor (*SR*)-diastereomers and the second red fractions containing major (*SS*)-diastereomers were collected. Yields of complex formation are given in Table 1. Complexes *SS*-**2b** and *SS*-**3** were purified by preparative TLC followed by crystallisation from a (wet) acetone-benzene mixture which gave a crystallosolvate. Resulting red single crystals are unstable in air at ambient temperature; they loose benzene (and water in the case of *SS*-**3**) and decompose within tens of minutes.

Positive-ion mass spectra: m/z 698 $[M+K]^+$, m/z 682 $[M+Na]^+$, m/z 660 ($[M+H]^+$, 100%). MS/MS of m/z 660: m/z 604 $[M+H-butene]^+$, m/z 498 $[M+H-butene-106]^+$.

(*SS*)-diastereomer of complex **4** was prepared according to the published procedure [15].

3.1.6. α-(^{13}C)Methylation of SS-4

Under an atmosphere of Ar at 20 °C to a solution of *SS*-**4** (62 mg, 0.1 mmol) in DMI (3 ml), excess of KOH and $^{13}CH_3I$ (63 μl, 1 mmol) was added and the reaction mixture was stirred for 30 min. The reaction mixture was poured into 10% aqueous citric acid (50 ml), stirred and the resulting red oil was filtered off. The filter was dried and extracted with chloroform. The extract was evaporated in vacuo. The diastereomeric excess was calculated based on the ratio of the integral intensities of the $^{13}CH_3$-signals in the ^{13}C NMR spectra of the mixtures of the diastereomers. *SS*-**5** and *SR*-**5** were separated by preparative TLC using silica gel (Merck 60H) eluted with CH_2Cl_2. Yield of *SS*-**5** and *SR*-**5** varies (40–70%) depending on the dryness of KOH used for the synthesis.

*3.1.7. (SS)-Diastereomer of complex **5***

The first fraction, red solidified oil, *SS*-**5**. The obtained complex was then purified by chromatography on Sephadex LH-20 with toluene: MeOH = 2:1. δ_H (500.13 MHz, $CDCl_3$; Me_4Si) 8.10 (1H, d), 7.99 (2H, m), 7.47 (1H, m), 7.37 (1H, m), 7.30 (5H, m) 7.25 (1H, s), 7.20 (1H, m), 7.10 (2H, m), 6.98 (3H, m), 6.59 (2H, s), 4.29 (1H, d, A part of AB system of CH_2Ar, $^2J_{AB}$ 12.6 Hz) and 3.54 (1H, d, B part of AB system of CH_2Ar, $^2J_{AB}$ 12.6 Hz), 3.81 (3H, s), 3.27 (1H, m), 3.10 (2H, m), 2.34 (1H, m), 2.24 (2H, m), 2.10 (1H, m), 1.91 (1H, m), 1.70 (1H, m), 1.13 (3H, $^{13}CH_3$, d, ^1J(H, C) = 130 Hz). δ_C (125.77 MHz, $CDCl_3$) 29.32 ($^{13}CH_3$). Calculated mass for $C_{35}{}^{13}CH_{35}N_3O_4Ni$ $[M]^+$ = 632.2015. High resolution EI-MS found $[M]^+$ = 632.2015.

*3.1.8. (SR)-Diastereomer of complex **5***

The second fraction, red crystals, *SR*-**5**. The obtained complex was then purified by chromatography on Sephadex LH-20 with toluene: MeOH = 2:1. Mp 274–276 °C (from acetone). δ_H (500.13 MHz, $CDCl_3$; Me_4Si) 7.86 (1H, d), 7.75 (2H, m), 7.51 (1H, m), 7.41 (2H, m), 7.33 (2H, m), 7.25–7.01 (6H, m), 6.94 (2H, m), 6.70 (1H, m), 6.62 (1H, t), 4.13 (1H, d, A part of AB system of CH_2Ph, $^2J_{AB}$ 14.3 Hz) and 3.39 (1H, d, B part of AB system of CH_2Ph, $^2J_{AB}$ 14.3 Hz), 3.72 (3H, s), 3.32 (1H, m), 3.06 (1H, m), 2.99 (1H, d, A part of AB system of CH_2Ar, $^2J_{AB}$ 14.7 Hz) and 2.86 (1H, d, B part of AB system of CH_2Ar, $^2J_{AB}$ 14.7 Hz), 2.32 (1H, m), 2.13 (2H, m), 1.91 (1H, m), 1.42 (3H, $^{13}CH_3$, d, ^1J(H, C) = 130 Hz).). δ_C (125.77 MHz, $CDCl_3$) 28.58 ($^{13}CH_3$). Calculated mass for $C_{35}{}^{13}CH_{35}N_3O_4Ni$ $[M]^+$ = 632.2015. High resolution EI-MS found $[M]^+$ = 632.2018.

NMR data are consistent with published data for similar complexes derived from α-methylphenylalanine or α-methyltyrosine-(OBn) [8a]. Half-minute intervals between pulses were applied for the recording of integral intensities of signals in ^{13}C NMR spectra.

4. Conclusions

A preparative procedure for the synthesis of a practically important chiral synthon of side-chain protected tyrosine was developed and optimised for the maximum reduction of nickel salts waste. While preparing a similar side-chain protected tryptophan synthon, unexpected low stability of Boc-protective group of tryptophan aromatic nitrogen was found during purification on silica gel. Stereochemistry of diastereomers of α-methylated complexes was disclosed using model compounds.

of ligands, as well as other factors, is still important and necessary to be studied.

In order to prepare functional supramolecular complexes with intriguing structures and potential applications especially in catalysis and to systematically investigate the substituent effect of an organic ligand on the structure of zinc-carboxylate containing coordination polymers, in this work, we have reacted Zn-benzoate with pyrazine (pyz) and its derivatives, 2,3-dimethylpyrazine (2,3-Me_2pyz), 2,5-dimethylpyrazine (2,5-Me_2pyz), 2,6-dimethylpyrazine (2,6-Me_2pyz), and quinoxaline, and report herein five new Zn(II)-benzoate coordination architectures, **1** ($Zn_2(O_2CPh)_4$(quinoxaline)$_2$), **2** ($Zn_3(O_2CPh)_6$(2,3-Me_2pyz)$_2$), **3** ($Zn_5(\mu_3\text{-}OH)_2(O_2CPh)_8$(2,6-$Me_2$pyz)$_2$), **4** (1-D, $[Zn_2(O_2CPh)_4(2,5\text{-}Me_2pyz)]_n$), **5** (2-D, $[Zn(O_2CPh)(\mu_2\text{-}O_2CPh)(\mu_2\text{-}pyz)_{0.5}]_n$). Assembly of zinc(II)-benzoate with different types of pyrazine shows different structures, from dinuclear, trinuclear and pentanuclear complexes to one-dimensional and two-dimensional coordination polymers. Moreover, compounds **1**–**5** catalyzed efficiently the transesterification of a variety of esters.

2. Experimental

2.1. Materials

Acetone, methanol, ethanol, propanol, 2-propanol, *para*-substituted phenyl acetate, *para*-substituted phenyl benzoate, methylacetate, methylbenzoate, quinoxaline, 2,3-dimethylpyrazine, 2,6-dimethylpyrazine, 2,5-dimethylpyrazine, pyrazine, ammonium benzoate, and zinc nitrate were purchased from Aldrich and were used as received. 4-Fluorophenyl acetate and 4-nitrophenyl benzoate were obtained from Lancaster.

2.2. Instrumentation

Elemental analysis for carbon, nitrogen, and hydrogen was carried out by using an EA1108 (Carlo Erba Instrument, Italy) in the Organic Chemistry Research Center of Sogang University, Korea. IR spectra were measured on a BIO RAD FTS 135 spectrometer as KBr pellets. Product analysis for the transesterification reaction was performed on either a Hewlett–Packard 5890 II Plus gas chromatograph interfaced with Hewlett–Packard Model 5989B mass spectrometer or a Donam Systems 6200 gas chromatograph equipped with a FID detector using 30-m capillary column (Hewlett–Packard, HP-1, HP-5, and Ultra 2).

2.3. Synthesis of dinuclear zinc-benzoate with quinoxaline ligand ($Zn_2(O_2CPh)_4$(quinoxaline)$_2$) (**1**)

Thirty-eight milligrams (0.125 mmol) of $Zn(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL water and carefully layered by 4 mL methanol solution of quinoxaline ligand (29.0 μL, 0.25 mmol). The yield was 55.0 mg (50.5%) for compound **1**. Suitable crystals of compound **1** for X-ray analysis were obtained in a month. *Anal.* Calc. for $C_{44}H_{32}N_4O_8Zn_2$ (875.48), **1**: C, 60.36; H, 3.69; N, 6.40. Found: C, 60.01; H, 3.62; N, 6.70%. IR (KBr): $\nu(cm^{-1})$ = 3434(br), 3068(w), 2369(m), 1641(s), 1574(w), 1505(w), 1402(s), 1068(w), 1039(w), 967(w), 866(w), 840(w), 764(m), 717(s), 680(m), 464(m).

2.4. Synthesis of trinuclear zinc-benzoate with 2,3-dimethylpyrazine ligand ($Zn_3(O_2CPh)_6$(2,3-Me_2pyz)$_2$) (**2**)

Thirty-eight milligrams (0.125 mmol) of $Zn(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL water and carefully layered by 4 mL acetone solution of 2,3-dimethylpyrazine ligand (27.0 μL, 0.25 mmol). The yield was 60.0 mg (42.2%) for compound **2**. Slow evaporation of the diffused mixture provided suitable crystals of **2** for X-ray crystallography in a month. *Anal.* Calc. for $C_{54}H_{46}N_4O_{12}Zn_3$ (1139.06), **2**: C, 56.94; H, 4.08; N, 4.92. Found: C, 56.54; H, 4.10; N, 4.73%. IR (KBr): $\nu(cm^{-1})$ = 3061(s), 3030(w), 1973(w), 1919(w), 1829(w), 1638(br s), 1572(br s), 1421(br s), 1258(w), 1178(s), 1071(s), 1024(s), 978(m), 942(m), 884(w), 862(s), 841(s), 819(m), 723(s), 680(s), 596(w), 466(s), 438(m).

2.5. Synthesis of pentanuclear zinc-benzoate with 2,6-dimethylpyrazine ligand ($Zn_5(\mu_3\text{-}OH)_2(O_2CPh)_8$(2,6-$Me_2$pyz)$_2$) (**3**)

Thirty-eight milligrams (0.125 mmol) of $Zn(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL methanol and carefully layered by 4 mL acetone solution of 2,6-dimethylpyrazine ligand (28.0 mg, 0.25 mmol). The yield was 32.0 mg (16.6%) for compound **3**. Slow evaporation of the diffused mixture provided suitable crystals of **3** for X-ray crystallography in a month. *Anal.* Calc. for $C_{68}H_{58}N_4O_{18}Zn_5$ (1546.03), **3**: C, 52.82; H, 3.79; N, 3.62. Found: C, 52.55; H, 4.00; N, 3.88%. IR (KBr): $\nu(cm^{-1})$ = 3440(br), 3066(m), 1603(s), 1565(s), 1416(br s), 1309(w), 1259(w), 1174(m), 1070(m), 1025(m), 942(w), 842(m), 719(s), 685(s), 576(w), 472(s).

2.6. Synthesis of one-dimensional polymeric compound containing zinc-benzoate with 2,5-dimethylpyrazine ligand (1-D, $[Zn_2(O_2CPh)_4(2,5\text{-}Me_2pyz)]_n$) (**4**)

Thirty-eight milligrams (0.125 mmol) of $Zn(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL methanol and carefully layered by 4 mL acetone solution of 2,5-dimethylpyrazine ligand (27.0 μL, 0.25 mmol). The yield was 75.0 mg (72.8%) for compound **4**. Slow evaporation of the diffused mixture provided suitable crystals of **4** for X-ray crystallography in a month. *Anal.* Calc. for $C_{40}H_{36}N_4O_8Zn_2$ (831.47), **4**: C, 57.78; H, 4.37; N, 6.74. Found: C, 58.02; H, 4.11; N, 6.35%. IR (KBr): $\nu(cm^{-1})$ = 3741(w), 3431(br w), 3064(w), 2360(w), 1637(s), 1573(w), 1499(w), 1406(s), 1171(w), 1082(w), 1049(w), 1027(w), 840(w), 727(s), 715(s), 680(m), 464(w), 429(w).

2.7. Synthesis of two-dimensional polymeric compound containing zinc-benzoate with simple pyrazine ligand (2-D, $[Zn(O_2CPh)(\mu_2\text{-}O_2CPh)(\mu_2\text{-}pyz)_{0.5}]_n$) (**5**)

Thirty-eight milligrams (0.125 mmol) of $Zn(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL water and carefully layered by 4 mL methanol solution of pyrazine ligand (20.0 mg, 0.25 mmol). The yield was 43.0 mg (24.7%) for compound **5**. Slow evaporation of the diffused mixture provided suitable crystals of **5** for X-ray crystallography in a month. *Anal.* Calc. for $C_{64}H_{48}N_4O_{16}Zn_4$ (1390.54), **5**: C, 55.28; H, 3.49; N, 4.03. Found: C, 54.96; H, 3.40; N, 3.98%. IR (KBr): $\nu(cm^{-1})$ = 3127(w), 3070(w), 1598(s), 1555(s), 1428(s), 1398(m), 1157(w), 1121(m), 1067(s), 1024(w), 859(w), 828(m), 715(s), 688(s), 558(w), 461(s), 424(m).

2.8. Catalytic activity of compounds **1**–**5**

Catalytic homogeneous reaction conditions: Ester (0.05 mmol) was dissolved in an appropriate solvent (1 mL), methanol or propanol, and the catalyst (1.0 mg, 1.14×10^{-3} mmol for **1**, 1.0 mg, 0.88×10^{-3} mmol for **2**, 1.0 mg, 0.65×10^{-3} mmol for **3**, 1.0 mg, 1.20×10^{-3} mmol for **4**, and 1.0 mg, 0.72×10^{-3} mmol for **5**, respectively) was added and shaken in an incubator at 50 °C (450 rpm). Reaction conversion was monitored by GC/Mass analy-

sis of 20 μL aliquots withdrawn periodically from the reaction mixture. All reactions were run at least three times and the average conversion yields are presented. We had the same results under N_2 instead of air, suggesting that air does not effect the transesterification reaction.

2.9. X-ray crystallography

The X-ray diffraction data for all five compounds were collected on a Bruker SMART APX diffractometer equipped with a monochromator in the Mo Kα (λ = 0.71073 Å) incident beam. Each crystal was mounted on a glass fiber. The CCD data were integrated and scaled using the Bruker-SAINT software package, and the structure was solved and refined using SHEXTL V6.12 [24]. All hydrogen atoms were placed in the calculated positions. The crystallographic data for compounds **1**–**5** are listed in Table 1.

3. Results and discussion

3.1. Synthesis and spectral characterization

To investigate the effect of structure and substituent of organic ligands on the structure of their metal complexes, four pyrazine derivative ligands, quinoxaline, 2,3-dimethylpyrazine, 2,6-dimethylpyrazine, 2,5-dimethylpyrazine and simple pyrazine, were used to react with Zn(II)-benzoate. The coordination complexes **1**–**5** were prepared cleanly as single phase crystalline products and shows dinuclear **1**, trinuclear **2**, pentanuclear complexes **3**, one-**4** and two-dimensional **5** polymeric compounds, respectively. All five compounds are shown in Scheme 1. The infrared spectra of **1**–**5** were fully consistent with their formulations [25]. Sharp medium intensity bands in the range of ~1300 cm^{-1} to ~700 cm^{-1} were ascribed to stretching modes of the pyrazine ring moiety. Asymmetric and symmetric C=O stretching modes of the ligated benzoate moieties were evidenced by very strong, slightly broadened bands at ~1600 cm^{-1} and ~1400 cm^{-1}. The absence of any bands in the area of ~1710 cm^{-1} indicates full deprotonation of all carboxylate groups in **1**–**5**.

3.2. Dinuclear zinc-benzoate with quinoxaline ligand ($Zn_2(O_2CPh)_4(quinoxaline)_2$) (**1**)

Asymmetric unit contains half of whole molecule, and there is an inversion center in the middle of Zn–Zn bond. Symmetric operation ($-x+2$, $-y+1$, $-z+1$) produces a paddle-wheel type dinuclear zinc-benzoate complex **1** (Fig. 1). The paddle-wheel type dinuclear complex is constructed by four bridging benzoate groups and two terminal quinoxaline ligands. Thus each Zn atom is NO4 donor penta-coordinated to form square pyramidal geometry. The similar paddle-wheel type of structures from zinc-benzoate or zinc-acetate have been reported in literature [19,26]. Zn–O bond distances range from 2.0191(15) to 2.0537(17) Å, Zn–N bond distance is 2.0792(18) Å which is typical in Zn(II) complexes, and Zn–Zn distance is 2.9900(7) Å (Table 2).

3.3. Trinuclear zinc-benzoate with 2,3-dimethylpyrazine ligand ($Zn_3(O_2CPh)_6(2,3\text{-}Me_2pyz)_2$) (**2**)

Asymmetric unit contains half of whole molecule, and there is a crystallographic inversion center on the central Zn atom. Symmetric operation ($-x+2$, $-y+2$, $-z+1$) produces a trinuclear zinc-benzoate complex **2** constructed by six bridging benzoate ligands and two axial 2,3-dimethylpyrazine ligands (Fig. 2) which is similar to the previously described trinuclear zinc-benzoate with axial pyridine ligands [19b]. Out of three Zn centers the central Zn is all O-donor hexa-coordinated from six benzoate groups to form a distorted octahedral geometry. The other two Zn centers are symmetric to each other, and each has a terminal 2,3-dimethylpyrazine ligand and four oxygen atoms from benzoate ligands. Thus each Zn2 center has NO4 coordination environment with a distorted trigonal bipyramid geometry. The coordination modes of benzoate ligands show two kinds of bridging modes [15]: one mode is a typical bridging mode, and the other is the unusual coordination mode that chelates to one Zn2 atom and, at the same time, bridges the other Zn1 atom as shown in Fig. 2. This unusual coordination mode of carboxylate group provides a big distortion around Zn2. In the typical bridging carboxylate coordination mode, Zn1–$O_{bridging}$ distances are 2.0362(15) and 2.0894(16) Å, and Zn2–$O_{bridging}$

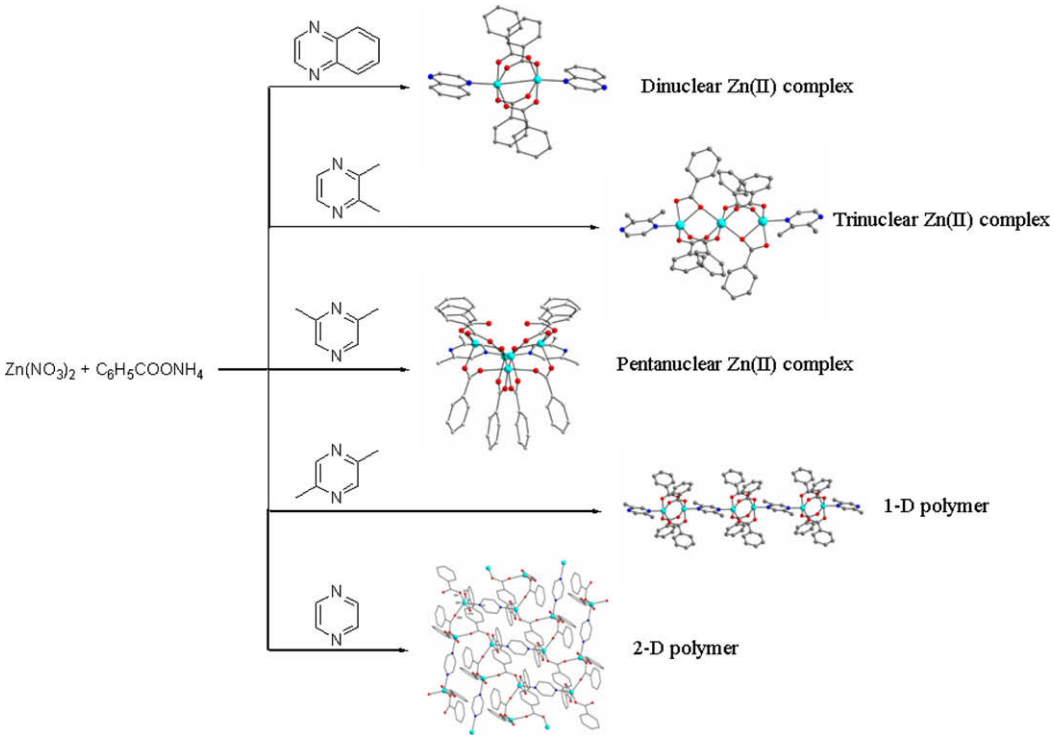

Scheme 1.

distances are 1.9532(16) and 1.9453(16) Å. In the unusual coordination mode, Zn1–$O_{bridging}$ distance is 2.1744(16) Å which is a little longer than typical one, and Zn2–$O_{chelating}$ distances are 2.1804(17) and 2.1798(18) Å. Zn–N bond distance is 2.075(2) Å which is typical in Zn complexes. The Zn–Zn distance is 3.362(4) Å which is much longer than that of dinuclear one (Table 2).

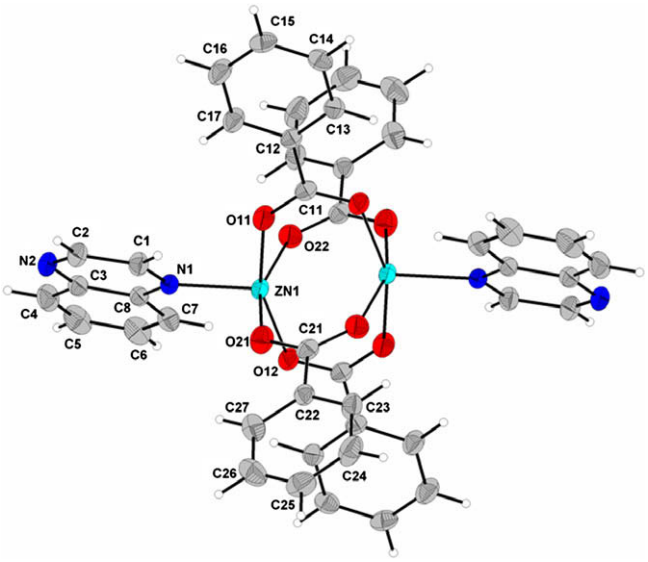

Fig. 1. Structure of dinuclear Zn complex **1**. Displacement ellipsoids are shown at the 30% probability level.

3.4. Pentanuclear zinc-benzoate with 2,6-dimethylpyrazine ligand ($Zn_5(\mu_3\text{-}OH)_2(O_2CPh)_8(2,6\text{-}Me_2pyz)_2$) (**3**)

Asymmetric unit contains half of whole molecule, and there is a C_2 axis through the middle Zn atom. Symmetric operation ($-x+1$, y, $-z+1/2$) produces a pentanuclear zinc-benzoate complex **3** constructed by six bridging benzoate ligands, two μ_3-hydoxyl ligands, two terminal 2,6-dimethylpyrazine ligands, and two terminal monodentate dangling benzoate ligands (Fig. 3). The central Zn1 ion is all O-donor hexa-coordinated from four benzoate ligands and two hydroxyl ligands to form a distorted octahedral geometry, and another two Zn2 ions are all O-donor tetra-coordinated from two bridging benzoate ligands, a dangling (monodentate)-benzoate ligand and a hydroxyl ligand to form a distorted tetrahedral geometry, and another two Zn3 ions are NO3-donor tetra-coordinated from two bridging benzoate ligands, a hydroxyl ligand and a 2,6-dimethylpyrazine ligand to form a distorted tetrahedral geometry. Importantly, this Zn-containing pentanuclear complex is unprecedented, to our best knowledge. The coordination modes of benzoate ligands are two types, bridging and monodentate (dangling) modes as shown in Fig. 3. A hydroxyl ligand bridges three Zn atoms. Zn–$O_{benzoate}$ bond distances range from 1.933(3) to

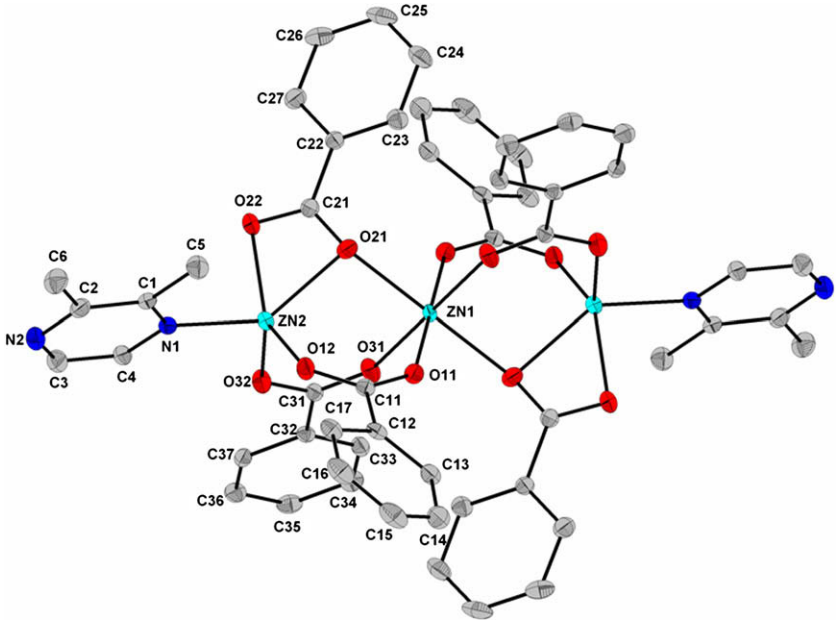

Fig. 2. Structure of trinuclear Zn complex **2**. Displacement ellipsoids are shown at the 30% probability level.

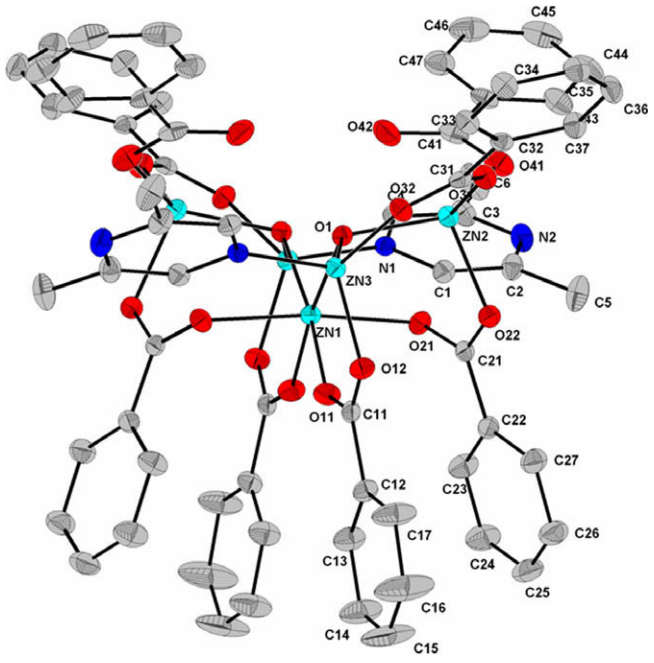

Fig. 3. Structure of pentanuclear Zn complex **3**. Displacement ellipsoids are shown at the 30% probability level. All hydrogen atoms were omitted for clarity.

2.083(3) Å, Zn–$O_{hydroxyl}$ bond distances range from 1.941(3) to 2.111(3) Å, and Zn–N bond distance is 2.013(3) Å which is typical in Zn complexes. The Zn1–Zn2, Zn1–Zn3, and Zn2–Zn3 distances are 3.295(21), 3.397(4), 3.143(2) Å, respectively (Table 2).

3.5. One-dimensional polymeric compound containing zinc-benzoate with 2,5-dimethylpyrazine ligand (1-D, $[Zn_2(O_2CPh)_4(2,5\text{-}Me_2pyz)]_n$) (**4**)

The crystal structure of **4** is shown in Fig. 4. The paddle-wheel type units are bridged by 2,5-dimethylpyrazine to form a one-dimensional polymeric compound. The paddle-wheel type units are similar to those of compound **1**. Zn–O bond distances range from 2.017(2) to 2.063(2) Å, which are almost close to those in **1**, and Zn–N bond distance is 2.083(2) Å which is typical in Zn(II) complexes. Zn–Zn distance is 2.9525(10) Å (Table 2), that is shorter than that of the discrete dinuclear complex **1**. The Zn′–Zn–N bond angle (175.25(1)°) shows a nearly linear chain structure. Interestingly, this compound shows an one-dimensional structure unlike **1**, **2**, and **3**. The coordination mode of benzoate shows only bridging type as shown in Fig. 4. In case of similar one-dimensional compound $[Zn_2(bpy)(OAc)_4]_n$, acetate bridged dinuclear Zn_2 unit is not a paddle-wheel type, and each Zn(II) ion has different coordination geometry: Zn1 has an octahedral geometry and Zn2 has a trigonal bipyramid geometry [27].

3.6. Two-dimensional polymeric compound containing zinc-benzoate with simple pyrazine ligand (2-D, $[Zn(O_2CPh)(\mu_2\text{-}O_2CPh)(\mu_2\text{-}pyz)_{0.5}]_n$) (**5**)

Asymmetric unit contains a Zn atom, two benzoate ligands, and half pyrazine, and symmetry operations $(-x+2, -y+3, -z+2)$, $(-x+2, y+1/2, -z+3/2)$, and $(-x+2, y-1/2, -z+3/2)$ produce a two-dimensional polymeric compound (Fig. 5). Mononuclear $Zn(O_2CPh)$ units are bridged by bridging benzoate and pyrazine ligands to form a two-dimensional sheet. Thus, the Zn atom has NO4-donor penta-coordinated environment. The coordination modes of benzoate ligands show two types, bridging and chelating modes as shown in Fig. 5. Zn–$O_{bridging}$ bond distances are 1.9627(17) and 1.9924(17) Å, and Zn–$O_{chelating}$ bond distances are 2.0068(18) and 2.3407(18) Å. Zn–N bond distance is 2.085(2) Å which is typical in Zn complexes (Table 2). Pyrazine does not have any substituents on its own ring, indicating no steric effect. Therefore, pyrazine may produce 2-D structure. However, in case of using acetate ligands instead of benzoate ligands, an unusual heptanuclear complex $Zn_7(\mu_4\text{-}O)_2(OAc)_{10}(pyz)_2$ has been made by reaction of $Zn(OAc)_2 \cdot 2H_2O$ with pyrazine (pyz) in refluxing ethanol [21]. The structure of the heptanuclear complex revealed a central Zn core in which two pseudo-tetrahedral Zn_4 units are joined at a common vertex, and two pyrazine molecules are bound as terminal ligands. Furthermore, $Cu_2(O_2CPh)_4$-pyz system showed a linear one-dimensional [28]. The structure of $Cu_2(O_2CPh)_4$-pyz showed the linear geometry with the chain skeleton bridged by pyrazine in axial direction of the paddle-wheel type Cu_2 core which is similar to our one-dimensional compound **4** containing

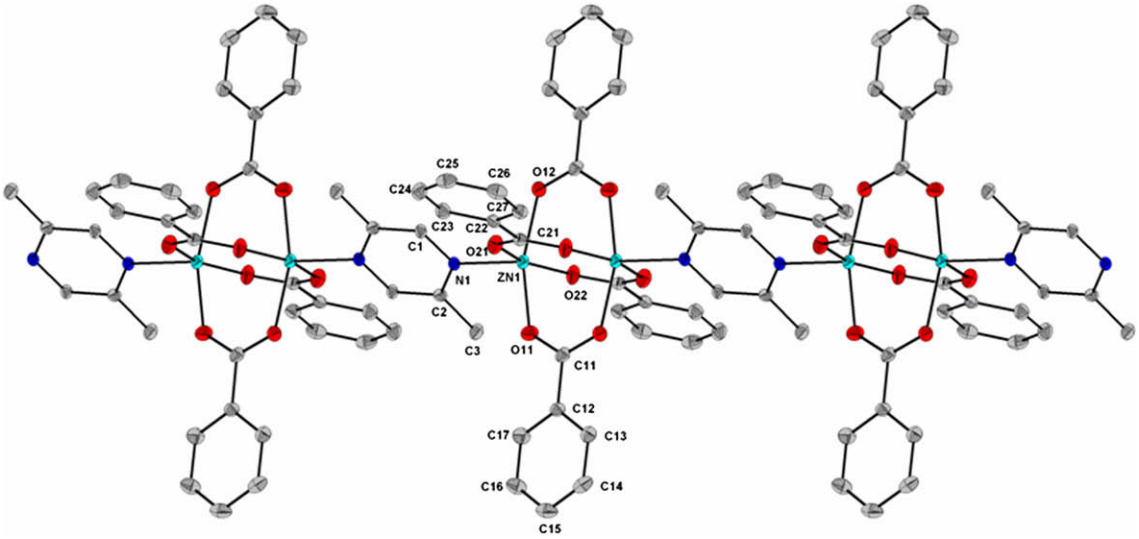

Fig. 4. Structure of one-dimensional Zn complex **4** containing paddle-type dinuclear Zn units. Displacement ellipsoids are shown at the 30% probability level. All hydrogen atoms were omitted for clarity.

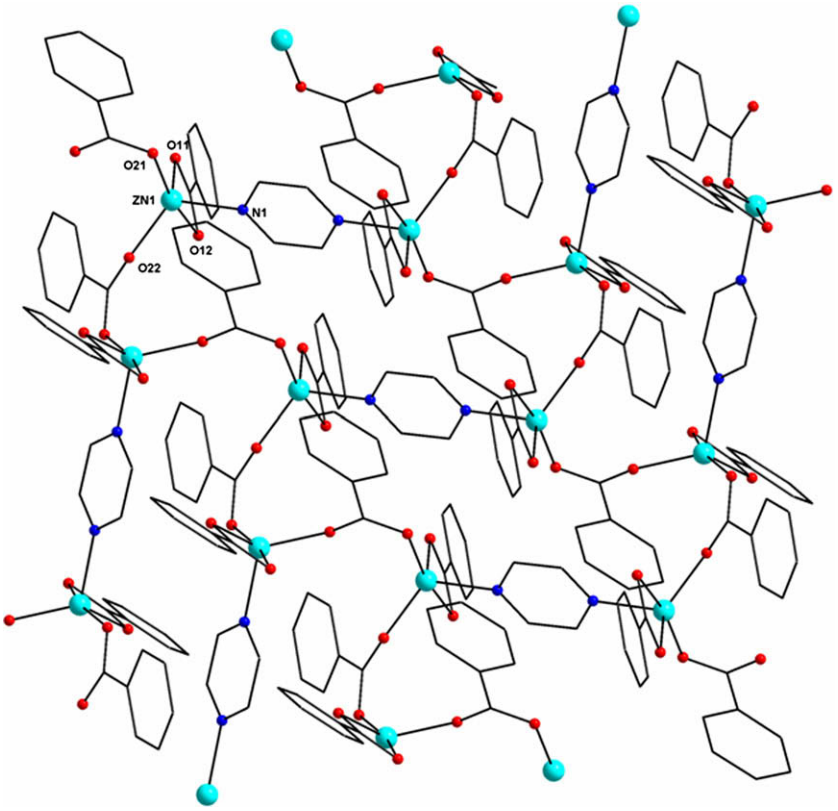

Fig. 5. Structure of two-dimensional Zn complex **5** containing $Zn(O_2CC_6H_5)$ units. All hydrogen atoms were omitted for clarity.

2,5-dimethylpyrazine. These different results might be because of (1) using different metal ions (Cu(II) versus Zn(II)), (2) using different ligands (acetate versus benzoate) and (3) using different reaction conditions from our self-assembly system.

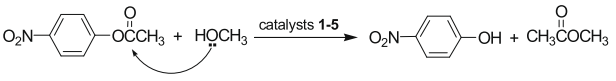
3.7. Influence of the substituents of the organic ligand on the structure of the coordination compounds

To investigate how the change of the substituents of the bridging pyrazine ligand influences on construction of Zn-benzoate complexes, substituted pyrazine ligands (2,3-dimethylpyrazine, 2,6-dimethylpyrazine, 2,5-dimethylpyrazine, and quinoxaline) as well as simple pyrazine have been employed. Simple pyrazine and 2,5-dimethlpyrazine are used as bridging ligands to form two-dimensional and one-dimensional polymeric compounds, respectively. The other quinoxaline and two dimethyl-substituted pyrazine ligands are used only as terminal ligands to form dinuclear, trinuclear, and pentanuclear complexes. The structures of complexes **1**–**5** clearly show that the change of the substituents on the pyrazine ring are critical in the construction of molecular architecture of Zn-benzoate complexes. The coordination modes of benzoate ligand are also different according to the change of the

substituents of pyrazine. Complexes **1** and **4** have only a bridging coordination mode, and **2** shows two different coordination modes, unusual chelating and bridging. **3** and **5** have two different coordination modes (bridging and monodentate (dangling) modes for **3** and bridging and chelating modes for **5**). These results suggest that selection of appropriate substituted groups would be an ideal way to construct novel metal-pyz coordination polymers.

3.8. Catalytic transesterification reactions by the compounds *1–5*

Transesterifications are important transformations in organic synthesis in industrial as well as in academic laboratories [29]. Although there are many catalysts available for transesterification, they require harsh reaction conditions such as high reaction temperatures and acidic conditions [30]. Such drawback experienced with these catalysts derives us to develop new catalysts that operate under milder conditions. Therefore, as part of our efforts to design transesterification catalysts based on metal ions that are not redox active, we have recently reported that Zn-containing coordination polymers could carry out the catalytic transesterification of a range of esters with methanol at room temperature under the mild conditions [31]. While these catalyst systems constitute a promising class of catalysts that appears to be an efficient, mild, and easily recyclable method for the alcoholysis of esters, there is still more demand to develop new type of catalysts that show a high efficiency. Based on the previous results, therefore, compounds **1–5** have been also employed as a homogeneous catalyst for transesterification reaction in methanol. The ester, *p*-nitrophenyl acetate, was initially used as a substrate (Eq. (1)).



(1)

We observed that compounds **1–5** catalyzed the reaction of methanol with phenyl acetate, with quantitative conversion to methyl acetate in 0.04–0.5 day (1–12 h; see the entry 1 of Table 3) at 50 °C under the homogeneous neutral conditions. Among them, pentanuclear complex **3** shows the most efficient reactivity. Importantly, this result is best among the catalytic systems reported previously in Zn-containing coordination and polymeric compounds, to our best knowledge [31,32]. Once having established that **1–5** represent excellent catalysts for the transesterification reaction of *p*-nitrophenyl acetate with methanol, we have investigated the transesterification of various *p*-substituted phenyl acetates and benzoates. The substrates with the electron-withdrawing substituents have undergone faster transesterification (entries 1 and 5), while those with the electron-donating ones have shown slow reaction (entries 4 and 8). In addition, *p*-nitrophenyl acetate and *p*-nitrophenyl benzoate, known to be problematic substrates for the transesterification reaction due to undesirable side reactions such as isomerization or polymerization [33], were also converted quantitatively to the corresponding products.

Transesterification of esters with alcohol cannot, sometimes, achieve high conversions since the reaction is reversible. To solve this problem, therefore, enol esters are usually used as acylating agents, since the resultant enolate is converted to an aldehyde or ketone that is unable to participate in the reverse reaction [34]. In this work, vinyl acetate was used as an acylating agent and, expectedly, converted efficiently to the product methyl acetate within 0.06–0.5 day by **1–5** (entry 9), suggesting that this catalytic system can be useful for preparing various esters by transesterification.

Moreover, this promising result led us to test the transesterification with more challenging nucleophiles such as ethanol, 2-propanol, and propanol, in the presence of the most efficient catalyst **3**. Phenyl acetate reacted very slowly with either ethanol (70 days) or 2-propanol (75 days), respectively, whereas propanol drove the reaction to completion within 4 days (the sixth column in Table 3). Various esters were also examined with propanol as a nucleophile in the presence of **3**. The substrates with the electron-withdrawing substituents have undergone faster conversion to the corresponding products (entries 1 and 5 of the sixth column), while those with the electron-donating ones have shown slow transesterification reaction (entries 4 and 8 of the sixth column).

Table 3
Transesterification of esters by methanol and propanol in the presence of compounds **1**, **2**, **3**, **4**, and **5** at 50 °C[a]

Entry	Substrate	**1** (time/days)[b]	**2** (time/days)[b]	**3** (time/days)[b]		**4** (time/days)[b]	**5** (time/days)[b]
		MeOH[c]	MeOH[c]	MeOH[c]	PrOH[d]	MeOH[c]	MeOH[c]
1	4-Nitrophenyl acetate	0.21	0.5	0.04	1	0.25	0.13
2	4-Fluorophenyl acetate	4	1.5	1	4	3	2
3	Phenyl acetate	2	1.5	0.37	4	2	2
4	4-Methylphenyl acetate	9	4	1	8	6	6
5	4-Nitrophenyl benzoate[e]	3	0.5	0.21	13	3	3
6	4-Chlorophenyl benzoate	3	2	1	11	3	4
7	Phenyl benzoate	7	4	0.83	26	7	7
8	4-Methylphenyl benzoate	6	3	1	25	6	6
9	Vinyl acetate	0.46	0.5	0.06	3	0.35	0.42

[a] All esters were completely converted to the corresponding products, methyl acetate and methyl benzoate. Reaction conditions: esters; 0.05 mmol, catalyst; 1.14×10^{-3} mmol for **1**, 0.88×10^{-3} mmol for **2**, 0.65×10^{-3} mmol for **3**, 1.20×10^{-3} mmol for **4**, 0.72×10^{-3} mmol for **5**, solvent; methanol or propanol (1 mL). See Section 2 for the detailed reaction conditions.
[b] Time necessary for the complete conversion of substrate to product.
[c] Transesterification of esters was carried out in methanol (MeOH).
[d] Transesterification of esters was carried out in propanol (PrOH).
[e] The solvent was a mixture of MeOH/CH_2Cl_2 or PrOH/CH_2Cl_2 (1/1) because of low solubility of substrate in MeOH or PrOH.

Protection of a primary alcohol in the presence of a secondary alcohol is useful in natural product synthesis [34,35]. Therefore, selectivity of primary over secondary alcohol protection has been tested with the catalyst **3**. In a mixture of propanol and 2-propanol in the presence of **3** and phenyl acetate, only the propanol reacted, providing propyl acetate in 99.7% yield while the secondary acetate formed in <0.3% yield. This reaction clearly demonstrates the potential utility of our catalyst in selecting for primary alcohols.

Though we do not know, at this moment, about the exact reactive species and the reaction mechanism for the transesterification reaction by the catalysts, it has been proposed that the mechanism of metal ion catalyzed transesterification probably involves electrophilic activation of the carbon center of the carbonyl moiety by binding of the metal to the carbonyl oxygen [16]. Therefore, Lewis acidity of the metal center may be important in catalytic transesterification. Based on this idea, a possible transesterification mechanism in this catalyst system can be proposed. The substrate phenyl acetate substitutes a labile ligand, maybe benzoate, to give the adduct –Zn–O=$CR_1(OR_2)$R. Then, the nucleophile methanol would attack the carbon atom of carbonyl moiety of the adduct to produce the product methyl acetate. Detailed mechanistic studies are currently under investigation.

4. Conclusions

To investigate the influence of the substituent change of ligands on the crystal structure, five new coordination polymers constructed by self-assembly of the pyrazine and its derivatives and

zinc(II)-benzoate have been structurally characterized. Simple pyrazine and 2,5-dimethlpyrazine are used as bridging ligands to form two-dimensional and one-dimensional polymeric compounds, respectively. The other quinoxaline and two dimethyl-substituted pyrazine ligands are used only as terminal ligands to form dinuclear, trinuclear, and pentanuclear complexes. The structural differences between such complexes reveal that the change of the substituents of the ligands has a great influence on the complex structures. This approach may be useful for synthesizing other complexes with high-dimensional structures. We have also shown that the compounds **1**–**5** catalyzed efficiently the transesterification of a variety of esters. Among them, pentanuclear complex **3** shows the most efficient reactivity. In addition, the scope of the application of **3** as a transesterification catalyst has been expanded to now include ethanol and propanol. Moreover, selectivity test of primary over secondary alcohol protection in the presence of **3** and phenyl acetate has provided, exclusively, the primary acetate propyl acetate, demonstrating the potential utility of our catalyst in selecting for primary alcohols. Furthermore, this observation is very significant since it encourages us to construct new polymeric compounds that might be efficiently used as heterogeneous catalysts friendly to the environment.

and H_2O (10 mL) was heated to 150 °C for 50 h in a 23 mL Teflon-lined stainless-steel autoclave and then it was cooled to room temperature at 10 °C h^{-1} to obtain colorless plate-like single crystals of **1** (yield: 52% based on Eu). *Anal.* Calc. for $Ag_2EuC_{24}H_{26}N_4O_{17}Cl$: C, 27.57; H, 2.51; N, 5.36. Found: C, 27.53; H, 2.53; N, 5.38%. IR frequencies (KBr, cm^{-1}): 3431, 1612, 1560, 1411, 1203, 1099, 840, 756, 692, 538, 420.

2.2.2. $[Ag_2Gd(nic)_4(H_2O)_4 \cdot (ClO_4) \cdot H_2O]$ (**2**)

An identical procedure as for **1** was used to prepare **2** except that Eu_2O_3 was replaced by Gd_2O_3. Colorless plate-like single crystals of (**2**) were obtained (yield: 57% based on Gd) *Anal. Calc.* for $Ag_2GdC_{24}H_{26}N_4O_{17}Cl$: C, 27.43; H, 2.49; N, 5.33. Found: C, 27.40; H, 2.50; N, 5.35%. IR frequencies (KBr, cm^{-1}): 3437, 1614, 1560, 1411, 1203, 1097, 840, 756, 696, 534, 420.

2.2.3. $[AgTb(nic)_2(ox)_{0.5}(H_2O)_2 \cdot (ClO_4) \cdot H_2O]$ (**3**)

A mixture of nicotinic acid (0.123 g; 1 mmol), $Na_2C_2O_4$ (0.0335 g; 0.25 mmol); $AgNO_3$ (0.100 g; 0.59 mmol), Tb_4O_7 (0.100 g, 0.284 mmol), $HClO_4$ (0.385 mmol) and H_2O (10 mL) was heated to 150 °C for 50 h in a 23 mL Teflon-lined stainless-steel autoclave. Colorless plate-like single crystals (**3**) were obtained (yield: 48% based on Tb) on cooling the solution to room temperature at 10 °C h^{-1}. *Anal. Calc.* for $AgTbC_{13}H_{12}N_2O_{12}Cl$: C, 22.61; H, 1.75; N, 4.06. Found: C, 22.62; H, 1.73; N, 4.07%. IR frequencies (KBr, cm^{-1}): 3423, 1612, 1568, 1421, 1201, 1072, 864, 756, 692, 623, 551, 424.

2.2.4. $[AgYb(nic)_2(ox)_{0.5}(H_2O)_2 \cdot (ClO_4) \cdot H_2O]$ (**4**)

An identical procedure as for **3** was used to prepare **4** except that Tb_4O_7 was replaced by Yb_2O_3. Colorless plate-like single crystals (**4**) were obtained (yield: 41% based on Yb) *Anal. Calc.* for $AgYbC_{13}H_{12}N_2O_{12}Cl$: C, 22.16; H, 1.72; N, 3.98. Found: C, 22.12; H, 1.75; N, 3.94%. IR frequencies (KBr, cm^{-1}): 3423, 1612, 1568, 1421, 1201, 1064, 864, 759, 696, 623, 557, 418.

2.3. Crystal structure determination

Single-crystal X-ray diffraction data collections of **1–4** were performed on a Bruker Apex II CCD diffractometer operating at 50 kV and 30 mA using Mo Kα radiation (λ = 0.71073 Å). Data collection and reduction were performed using the APEX II software [9]. Multi-scan absorption corrections were applied for all data sets using the algorithms implemented in APEX II [9]. All four structures were solved by direct methods and refined by full-matrix least squares on F^2 using the SHELXTL program package [9]. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms attached to carbon were placed in geometrically idealized positions and refined using a riding model. Hydrogen atoms on water molecules were located from difference Fourier maps and were also refined using a riding model. Crystallographic data for **1–4** are listed in Table 1 and selected bond lengths and angles for all compounds are given in Table 2. Hydrogen bonding parameters for **1** and **3** are given in Table 3.

3. Results and discussion

3.1. Synthesis and characterization

We initially tried to isolate single crystals of the target compounds by the reactions of lanthanide salts with a mixture of $AgNO_3$, nicotinic acid and/or oxalate salt using conventional solution methods; however, only white precipitates were obtained. Hydrothermal synthesis has been proven to be a powerful method for the construction of organic–inorganic hybrid compounds [10]. By introducing hydrothermal techniques, we obtained a small quantity of microlite unsuitable for single-crystal X-ray diffraction when lanthanide salts were used as the lanthanide source. In our previous work, lanthanide oxides and perchloric acid have been proven to play an important role in the formation of unusual Ln–M coordination polymers [11]. Therefore, we tried lanthanide oxides as the lanthanide source and perchloric acid to synthesize new Ln–M coordination frameworks under hydrothermal conditions.

3.1.1. Structures of $[Ag_2Ln(nic)_4(H_2O)_4 \cdot (ClO_4) \cdot H_2O]$ (Ln = Eu **1**; Gd **2**)

Single-crystal X-ray diffraction studies revealed that compounds **1** and **2** are isostructural, and only the structure of **1** is representatively described here in detail. It exhibits novel 2D wave-like heterometallic coordination frameworks constructed from 1D zigzag chains and perchlorate anions, and crystallizes in the orthorhombic space group *Cmca*. The asymmetric unit of **1** exhibits half a europium ion, one silver ion, half a perchlorate anion, two crystallographically unique nicotinate ligands, and two coordinated and half a non-coordinated water molecule (Fig. 1). Each Eu(III) center lies on an inversion center and is bonded to four oxygen atoms from monodentate nicotinate ligands, and to four

water oxygen atoms. The 8-fold coordination polyhedron of the europium center can be described as a slightly distorted square antiprism. The Eu–O bond lengths and O–Eu–O bond angles are all within the range of those observed for other eight-coordinate Eu(III) complexes with oxygen donor ligands [12] and range from 2.328(7) to 2.468(7) Å and 69.6(3)° to 146.6(3)°, respectively. The Ag(I) ion is coordinated in a linear fashion by each of the two pyridyl nitrogen atoms of the nicotinate ligands. This coordination is augmented by a weaker interaction with one oxygen atom from the ClO_4^- anion, and the silver cations also exhibit argentophilic interactions with an Ag···Ag bond length of 3.333(2) Å, which is smaller than the sum of the van der Waals radii for two silver atoms (3.44 Å) [13]. The two Ag–N distances are 2.176(10) and 2.187(9) Å and the N–Ag–N angle is 173.7(4)°; the pyridyl rings of the nicotinate ligands coordinating to this Ag ion are almost coplanar and have a dihedral angle of only 1.74(3)°. The two unique nicotinate ligands in compound **1** exhibit only one type of coordination mode as shown in Chart 1a. The nitrogen atom connects to one Ag center and the carboxylate group bonds to one Eu center via monodentate coordination.

In the polymeric structure of **1**, the cationic $Ag(nic)_2^+$ units interconnect europium centers to form an infinite zigzag chain (Fig. 2a). These chains are further extended into a 2D layer in the *a*-axis direction through bridging perchlorate ions by the weak Ag–O interactions (Fig. 2b). It should be noted that the layer is

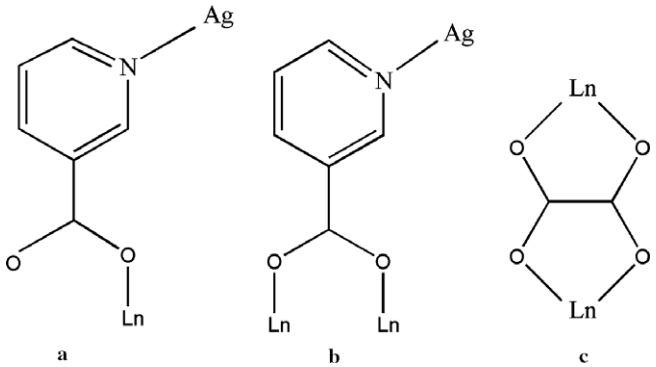

Chart 1. Coordination modes of nicotinate and oxalate ligands in compounds **1**–**4**.

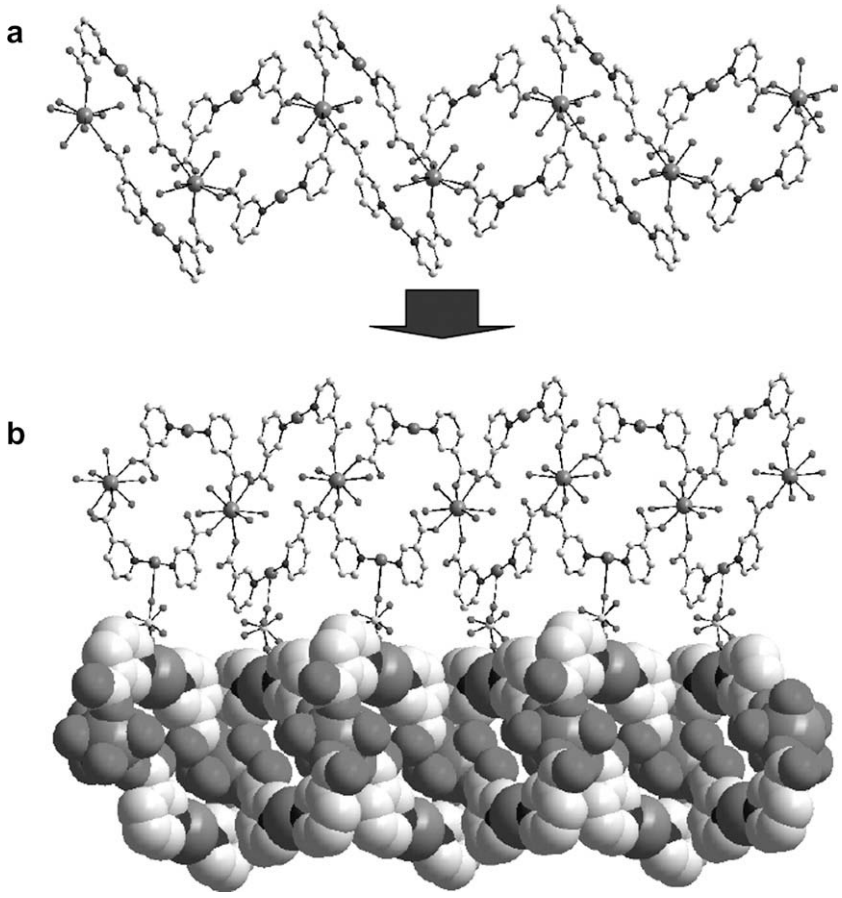

Fig. 2. View of a zigzag chain of **1** (a), view of 2D wave-like layer assembled by weak Ag–O contacts (b).

not smooth but is wave-like. The water molecules act as both H-bond donors and acceptors (Table 3), and play an important part in the structural packing, thus linking neighboring layers to form a three-dimensional network structure. Moreover, the above-mentioned Ag···Ag bonds and π···π stacking interactions enhance the structure's stability. The adjacent pyridyl rings within these connecting layer have centroid to centroid distances of 3.661(2) Å, and the offset value between them is less than 1.5 Å, indicating a normal π···π stacking interaction [14].

*3.1.2. Structures of $[AgLn(nic)_2(ox)_{0.5}(H_2O)_2 \cdot (ClO_4) \cdot H_2O]$ (Ln = Tb **3**; Yb **4**)*

Single-crystal X-ray diffraction studies revealed that compounds **3** and **4** are also novel 3D heterometallic coordination framework constructed from the linkage of lanthanide–oxalate layers and cationic $[Ag(nic)_2]^+$ units, crystallizing in the monoclinic space group $P2_1/c$. Because **3** and **4** are also isostructural, only the structure of **3** is described here in detail. In the asymmetric unit of **3**, there are one Tb(III) ion, one Ag(I) ion, half an oxalate ligand, one ClO_4^- anion, two crystallographically unique nic ligands and two coordinated water molecules (Fig. 3). The Tb(III) ion is surrounded by eight oxygen atoms and exhibits a slightly distorted square antiprismatic coordination geometry: four oxygen atoms from four bis(monodentate) bridging nicotinate ligands, two oxygen atoms from one oxalate ligand and two oxygen atoms from two water molecules. The Tb–O bond lengths range from 2.302(6) to 2.463(7) Å, all of which are within the range of those observed for other eight-coordinate Tb(III)-carboxylate complexes [15]. The O–Tb–O bond angles fall in the range 67.0(2)–146.5(2)°. The Ag(I) ion is coordinated in a linear fashion by each of the two pyridyl nitrogen atoms of the nic ligands. The Ag–N distances are 2.144(7) and 2.157(7) Å and the N–Ag–N angle is 174.4(4)°. The dihedral angle between the pyridyl rings of the nicotinate ligands coordinated to the Ag ion is 16.3(4)°. In compound **3**, the two nicotinate ligands adopt a bridging coordination mode different from that in **1** and **2**, as depicted in Chart 1b. The nitrogen atom coordinates to one Ag center and the carboxylate group connects two Tb centers through a bis-monodentate coordination. The oxalate ligand bonds to two Tb centers through a bridging and chelating coordination (Chart 1c).

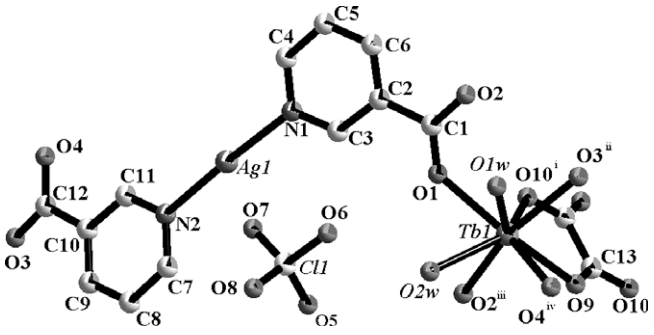

Fig. 3. Perspective view of the asymmetric unit of **3**.

In the polymeric structure of **3**, the carboxylate groups of the nicotinate ligands link the oxalate-connected dimeric terbium subunits to form a smooth layered network perpendicular to the *a*-axis (Fig. 4a). These layers are in turn connected through the pyridyl coordinated silver ions to form a three-dimensional network

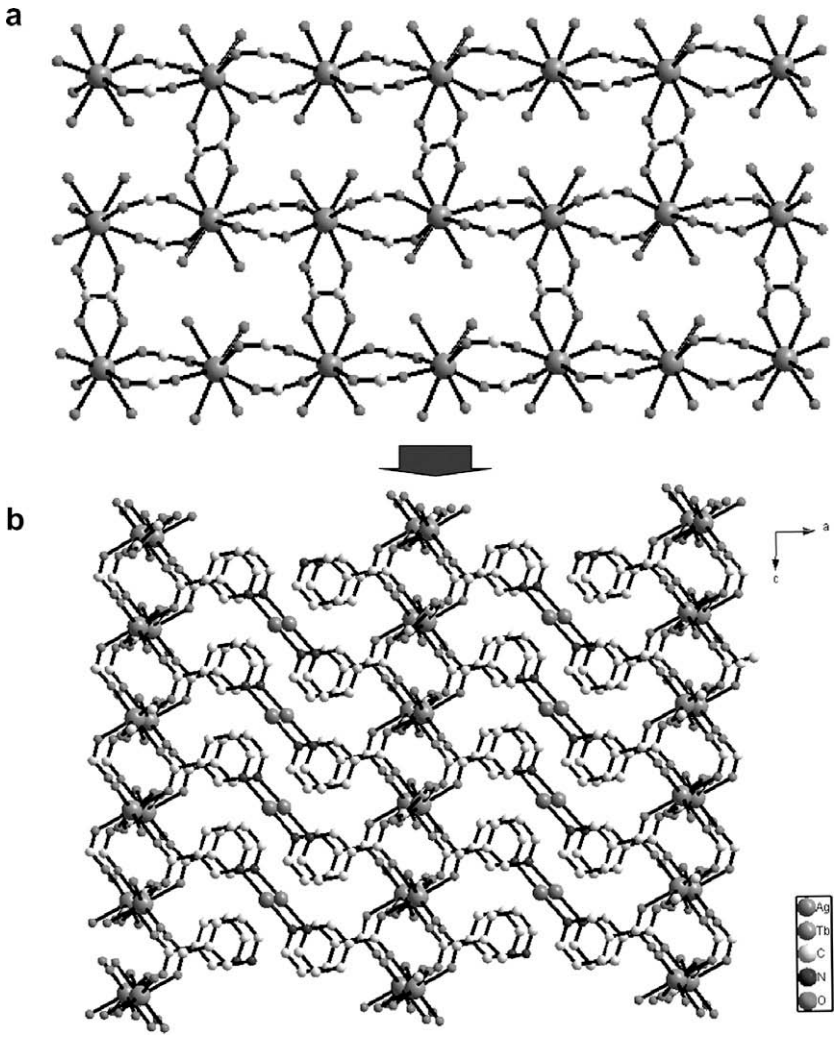

Fig. 4. View of lanthanide–oxalate layer of **3** (a), view of 3D network of **3** constructed by lanthanide–oxalate layers and $Ag(nic)_2$ units (b).

(Fig. 4b). Hydrogen bonds (Table 3) between the coordinated water molecules and the carboxylate groups of the nicotinate ligands also stabilize the structure. The shortest Ag···Ag distance is 3.602(2) Å, which is larger than the sum of the van der Waals radii for two silver atoms (3.44 Å) [13]. This complex thus shows no significant Ag···Ag interactions. The charge balancing perchlorate ions are well separated from both the Tb and Ag ions with separations between adjacent Ag and O atoms being between 2.723 and 2.748 Å.

3.2. IR spectroscopy

The IR spectra of compounds **1–4** shows the characteristic bands of the asymmetric stretching vibrations of carboxylate groups in the range 1560–1614 cm^{-1}, those for symmetric stretching vibrations are at 1411 cm^{-1}. The broad band at around 3430 cm^{-1} is assigned to the vibration of the water molecules in these compounds. Another broad band in the region 1099–1064 cm^{-1} can be ascribed to the ClO_4^- stretching vibrations [16].

3.3. Luminescent properties

Owing to the excellent luminescent properties of Eu(III) and Tb(III) ions, the room temperature photoluminescence in the solid state of nicotinate as well as of **1** and **3** were investigated. The emission peak of the nicotinate ligand is observed at about 378 nm (λ_{ex} = 329 nm) with a relatively intense broad band (Fig. S1).

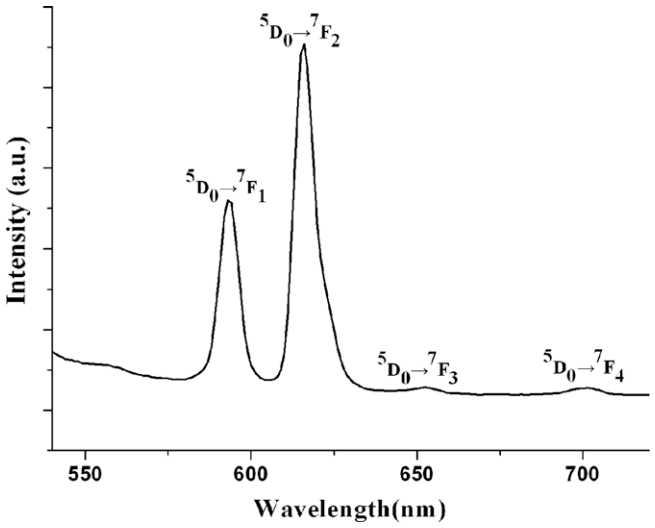

Fig. 5. Solid-state emission spectrum of **1** at room temperature.

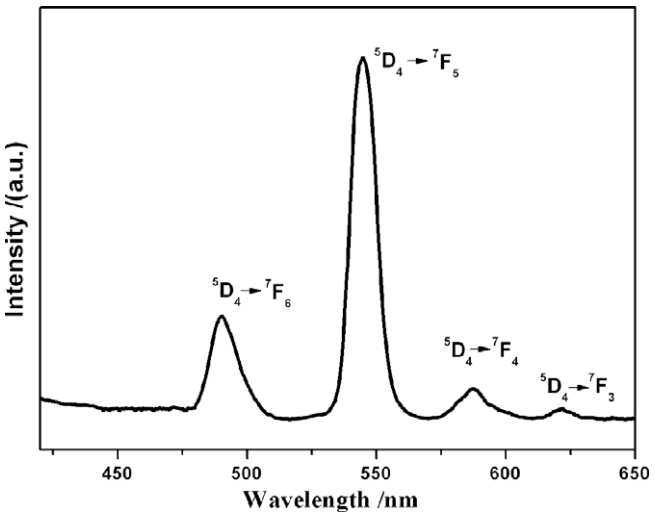

Fig. 6. Solid-state emission spectrum of **3** at room temperature.

As shown in Fig. 5, the emission spectrum of **1** at room temperature upon excitation at 394 nm displays intense red luminescence and exhibits the characteristic transitions of $^5D_0 \rightarrow {}^7F_n$ (n = 1–4) of Eu(III) ions at 593, 615, 652 and 701 nm, respectively, which indicate a moderately efficient of ligand-to-metal (europium) energy transfer (LMCT) [17,7b]. The band at 615 nm can be attributed to an electric-dipolar $^5D_0 \rightarrow {}^7F_2$ transition, the band at 593 nm can be assigned to $^5D_0 \rightarrow {}^7F_1$ and the band at 701 nm to a $^5D_0 \rightarrow {}^7F_4$ transition. The $^5D_0 \rightarrow {}^7F_1$ emission peak at 593 nm is a magnetic dipole transition and its intensity should vary with the crystal field strength acting on the Eu(III) ion. The strongest $^5D_0 \rightarrow {}^7F_2$ transition is an electric dipole transition and the intensity of this transition increases as the site symmetry of the Eu(III) ions decreases. The intensity of the $^5D_0 \rightarrow {}^7F_2$ transition is stronger than that of the $^5D_0 \rightarrow {}^7F_1$ transition, the intensity ratio $I(^5D_0 \rightarrow {}^7F_2)/I(^5D_0 \rightarrow {}^7F_1)$ is ca. 1.7, which indicates that the Eu(III) ions have a low symmetric coordination environment [18]. The luminescent spectrum of **3** is shown in Fig. 6. The bands at 489, 545, 588 and 623 nm can be attributed to the $^5D_4 \rightarrow {}^7F_6$, $^5D_4 \rightarrow {}^7F_5$, $^5D_4 \rightarrow {}^7F_4$ and $^5D_4 \rightarrow {}^7F_3$ transitions, respectively [19]. The peak at 545 nm is the strongest. The quantum yield of luminescence of **1** and **3**, determined as described by Bünzli and coworkers [20], are 3.2% and 7.6%, respectively. As powders, the complexes feature long luminescence lifetimes of 2.01(2) ms for **1** and 2.50(1) ms for **3** [21]. Thus, **1** and **3** may be candidates for use in luminescent materials.

4. Conclusion

In conclusion, we have successfully synthesized four new 4d–4f coordination frameworks based on oxalate and nicotinate ligands. They all represent unusual structural examples of heterometallic coordination frameworks by spontaneous assembly of N-/O-donor ligands. This successful synthetic idea can be used to prepare other novel high-dimensional lanthanide–transition metal heterometallic coordination polymers materials with particular functions.

antitumor properties (such as cytostasan [16]). With regard to the aim to achieve reduced cytotoxicity and increasing the bioavailability of the benzimidazole-platinum complexes different modifications of this heterocycle have been reported [17,18]. Here we report on the synthesis, crystal structure, UV–Vis, IR, Raman, EPR and NMR spectroscopic properties of new Cd(II) and Cu(II) complexes with chelating ligand. Their coordination chromophores and shape of polyhedra have also been compared.

2. Experimental

2.1. Physical measurements and instrumentation

Elemental analyses were run on a Model 240 Perkin–Elmer CHN Analyzer. Infrared spectra (Perkin–Elmer 180 spectrophotometer; 4000–400 cm^{-1}) were recorded in KBr and FIR spectra (400–30 cm^{-1}) in Nujol with specimens applied as suspension of the complexes in Nujol onto a polyethylene window. Raman spectra were performed at room temperature with a Bio-Rad spectrometer, resolution 4 cm^{-1}. The incident radiation (λ = 1064 nm) was provided by a Neodymium laser YAG (Spectra-Physics). The electronic spectra (Cary 5 UV–Vis–NIR spectrophotometer; 5000–30 000 cm^{-1}) were recorded in Nujol mulls. The visible-range absorption spectra of Cu(II) complexes in aqueous solution were recorded on a Specord M-500 (Carl Zeiss, Jena) spectrophotometer.

Magnetic measurements were carried out on a magnetic susceptibility balance (Sherwood Scientific) at room temperature by Guoy's method using $Hg[Co(NCS)_4]$ as the calibrant.

Electron paramagnetic resonance (EPR) spectra were performed on a Bruker ESP 300 E spectrometer at the X-band frequency (about 9.45 GHz) and equipped with the Bruker NMR gaussmeter ER 035 M and the Hewlett–Pacard microwave frequency counter HP 5350B [19]. The spectra were analyzed by a computer simulation program written by dr Andrew Ozarowski, National High Magnetic Field Laboratory, Florida University, as well as applying BRUKER program WIN EPR SimFonia version 1.25.

^1H and ^{13}C NMR spectra were run on Mercury-400BB spectrometer. ^1H NMR spectra were recorded at 400.09 MHz. Chemical shifts were referenced to the residual proton signals of CD_3OD (3.30 ppm). ^{13}C NMR were run at 100.60 Hz (standard methanol $^{13}CD_3OD$, 50.28 ppm). $Cd(NO_3)_2 \cdot 4H_2O$ and $Cu(NO_3)_2 \cdot 3H_2O$ were purchased from Merck Chemical Company and 2-hydroxymethylbenzimidazole (Aldrich 97%) were used as received.

2.2. Synthesis

2.2.1. Preparation of $[CdL_2(NO_3)_2]$ (1)

2-CH_2OHBIm (L; 0.5 mmol) dissolved in 25 ml of pure EtOH was stirred with $Cd(NO_3)_2 \cdot 4H_2O$ dissolved in 25 ml of redistilled water. The molar ratio *M*/*L* was 1:2. The solution was left to crystallize at room temperature. After six weeks, colourless crystals, suitable for X-ray, were obtained. The precipitate was separated by filtration and washed with isopropanol, before drying under vacuum. The product was collected in 75% yield.

Anal. Calc. for $C_{16}H_{16}N_6O_8Cd$: C, 36.34; H, 3.03; N, 15.77. Found: C, 36.34; H, 2.95; N, 15.73%. ^1H NMR: (400.09 MHz, 295 K, CD_3OD) δ: 4.85 (1H, O*H*), 4.90 (s, 2H, CH_2), C–$H_{\text{benzimidazole ring}}$: 7.28 H(5), 7.31 H(6), 7.62 H(7), 7.64 H(4); ^{13}C NMR: (100.60 MHz, 295 K, CD_3OD) δ: 58.39 (CH_2OH), 138.87 (*C*=N), $C_{\text{benzimidazole ring}}$: 116.67 C(4,7), 125.47 C(5,6), 157.17 C(8,9);

IR (KBr, Nujol): ν (cm^{-1}) 3206 (vb), 1775 (m), 1735 (m), 1628 (s), 1596 (s), 1555 (s), 1457 (vs), 1412 (vs), 1385 (vs), 1334 (vs), 1278 (vs), 1080 (vs), 1032 (vs), 750 (vs), 644 (m), 486 (s), 426 (s), 398 (m), 278 (s), 198 (vb), 152 (vb), 121 (vb);

2.2.2. Preparation of $[CuL_2(NO_3)](NO_3)(H_2O)$ (2) and mer-$[CuL_3](NO_3)_2(H_2O)$(*i*-PrOH) (**4**)

The coordination compounds **2** and **4** were prepared according to the following general procedure: 1 mmol (0.2416 g) of the $Cu(NO_3)_2 \cdot 3H_2O$ and 2 mmol (0.2964 g) of the ligand were each dissolved in ca. 10 mL of ethanol/water (2:1) solution. Under vigorous stirring the ligand solution was then added slowly to the Cu(II)-salt solution. After the addition was complete, the coloured solution was stirred for 1 h and filtered off to remove any undissolved material. Usually, after a few days green crystals of $[CuL_2(NO_3)](NO_3)(H_2O)$ **2** were separated as the first fraction. These were isolated by filtration and dried under high vacuum.

Anal. Calc. for $C_{16}H_{18}N_6O_9Cu$: C, 38.29; H, 3.62; N, 16.75. Found: C, 38.41; H, 3.50; N, 16.42%. IR (KBr,): ν (cm^{-1}) 3369 (vb), 3229 (vb), 3210 (vb), 1627 (m), 1593 (s), 1549 (s), 1476(s), 1459 (s), 1436 (vb), 1383 (vs), 1317 (vs), 1283 (vs), 1066 (vs), 1038 (vs), 763 (s), 750 (vs), 430 (vs), 397 (s), 330 (vs), 309 (vs), 290 (vs), 241 (m), 211 (s), 175 (s), 142 (vb); Raman: ν (cm^{-1}) 3203 (m), 3076 (vs), 2946 (vs), 2875 (s), 1625 (s), 1549 (vs), 1447 (s), 1344 (m), 1282 (vs), 1241 (m), 1096 (vs), 1048 (vs), 811 (s), 706 (s), 576 (s), 532 (m), 420 (s), 320 (s), 293 (s), 220 (s), 184 (vs).

After ca. one week turquoise blue crystals of $[CuL_3](NO_3)_2(H_2O)$ were separated from the remaining solution (second fraction). The complex was filtered off and re-crystallized from isopropanol (note: the solvent participates in the structure of the compounds: $[CuL_3](NO_3)_2(H_2O)$(*i*-PrOH) **4**) and dried under high vacuum.

Anal. Calc. for $C_{27}H_{34}N_8O_{11}Cu$: C, 45.66; H, 4.83; N, 15.78. Found: C, 45.86; H, 4.60; N, 15.77%. IR (KBr,): ν (cm^{-1}) 3490 (vb), 3216 (vb), 2915 (vb), 2843 (vs), 1624 (m), 1593 (s), 1455 (s), 1436 (vb), 1378 (vs), 1343 (vs), 1072 (vs), 1038 (vs), 743 (s), 487 (m), 437 (m), 432 (m), 385 (s), 333(s), 329 (s), 300 (s), 286 (m), 247 (m), 208 (m), 167 (vb), 142 (vb). Raman: ν (cm^{-1}) 3077 (s), 2915 (vs), 2881 (vs), 2849 (vs), 1598 (vs), 1542 (s), 1458 (s), 1280 (vs), 1240 (m), 1096 (m), 1046 (vs), 1008 (s), 706 (s), 639 (s), 540 (s), 501 (s), 430 (s), 350 (m), 307 (m), 276 (s), 193 (s).

2.2.3. Preparation of $[CdL_3](NO_3)_2$ L(EtOH)$_{0.25}$ (**3**)

The ligand (0.5 mmol) dissolved in 20 mL of pure EtOH was added to cadmium salts ($Cd(NO_3)_2 \cdot 4H_2O$, 2 mmol) dissolved in redistilled water (20 mL). The molar ratio *M*/*L* was 1:4. The mixture was stirred for about 2 h and left to crystallize at lower temperature (2–5 °C). After four weeks, colourless crystals suitable for X-ray were obtained. The product was collected by filtration and washed with the same solvent as used in the first complex of cadmium. The crystals were dried in vacuum box. The precipitate was collected in 70% yield.

Anal. Calc. for $C_{32.5}H_{33.5}N_{10}O_{10.5}Cd$: C, 46.43; H, 4.03; N, 16.66. Found: C, 46.17; H, 3.74; N, 16.73%. ^1H NMR: (400.09 MHz, 295 K, CD_3OD) δ_{complex}: 4.90 (1H, O*H*), 4.95 (s, 2H, CH_2), C–$H_{\text{benzimidazole ring}}$: 7.23 H(5), 7.25 H(6), 7.56 H(7), 7.58 H(4); δ_{EtOH}: 1.17 (s, 3H, CH_3), 3.61 (s, 2H, CH_2), 3.13 (1H, O*H*); ^{13}C NMR: (100.60 MHz, 295 K, CD_3OD) δ: 58.70 (CH_2OH), 139.31 (*C*=N), $C_{\text{benzimidazole ring}}$: 116.50 C(4,7), 125.21 C(5,6), 157.32 C(8,9); δ_{EtOH}: 58.70 (CH_2), 19.21 (CH_3); IR (KBr, Nujol): ν (cm^{-1}) 3198 (vb), 1625 (s), 1597 (s), 1545 (s), 1457(vs), 1385 (vs), 1334 (vs), 1279 (vs), 1073 (vs), 1035 (vs), 914 (s), 825 (s), 750 (vs), 734 (vs), 648 (m), 483 (s), 428 (s), 387 (vs), 319 (vb), 277(s), 252 (m), 190 (vb), 118 (vb).

2.3. Crystal structure determination

Diffraction intensity data for single crystal of the Cd(II) and Cu(II) complexes were collected at room temperature on a KappaCCD (Nonius) diffractometer with graphite-monochromated MoK_α radiation (λ = 0.71073 Å). Corrections for Lorentz, polarization and absorption effects [20,21] were applied. The structures

were solved by direct methods using the program package SIR-92 [22] and refined using a full-matrix least square procedure on F^2 using SHELXL-97 [23]. Anisotropic displacement parameters for all non-hydrogen atoms and isotropic temperature factors for hydrogen atoms were introduced. Further details of the structures analysis are given in Table 1 and in the Supplementary data.

3. Results and discussion

3.1. Crystal structure

3.1.1. The molecular structure of $[CdL_2(NO_3)_2]$ (**1**)

The cadmium complex crystallizes in the tetragonal system (space group $P4_32_12$) (Fig. 1.).

Two molecules of 2-CH_2OHBIm **(L)** and two nitrate ions are bounded directly to the metal ion, as bidentate ligands, to give a CdN_2O_6 chromophore. Thus, the Cd atom is eight-coordinated with two pyridinic N-atoms of the benzimidazole rings [N(3) and N(3a)] and six oxygen atoms, two of hydroxymethyl groups O(10) and O(10a), and four of the nitrate ions [O(21), O(23), O(21a), O(23a)]. Cadmium-nitrogen bond distances of 2.268(2) Å are relatively short and cadmium-oxygen distances of 2.377(2)–2.827(2) Å are, in general, in agreement with those found in the literature [25–31]. Selected geometrical data for **1** are given in Table 2. The most interesting feature of the cadmium complex is the shape of coordination polyhedron which can be described as a transition form between the dodecahedron and the tetragonal antiprism. It consists of an equatorial plane [O(23), O(21), O(23a), O(21a)] – typical for the antiprism, and a part of the dodecahedron, in which the oxygen atoms occupy the vertices with the five neighbours and the nitrogen atoms are in the vertices with four neighbours (compare Fig. 1).

The crystal packing is stabilized by the moderate intermolecular hydrogen bonds of N–H···O and O–H···O types (Table 6). Additionally, weak interactions of C–H···π type exist between C(5)-H and C(10)-H and π electron systems of the neighbouring benzimidazole rings (Fig. 2.).

3.1.2. The molecular structure of $[CuL_2(NO_3)](NO_3)(H_2O)$ (**2**)

The copper ion is five-coordinated with ligation of N, O-donor atoms of two 2-CH_2OHBIm residues and one oxygen atom of the nitrate ion (Fig. 3). Cu(II) polyhedron could be described as a distorted tetragonal pyramid with a structural index parameter (τ) value of 0.105 (the trigonality index τ is calculated using the equation $\tau = (\beta - \alpha)/60$ [32]; for perfect square pyramidal and trigonal bipyramidal geometries the values of τ are zero and unity, respectively). The form of distortion in the $[CuL_2(NO_3)]^+$ cation involves not only bond-length but also apparent bond-angles distortion (Table 3). In the case of coordination cation, both N(imidazole)- and O(hydroxymethyl)-donors of each of two 2-CH_2OHBIm ligands are involved in a five-membered chelate rings, from which one is rather symmetric with Cu–N(23) = 1.9525(2) Å and Cu–O(2) = 2.0385(2) Å, and the second – clearly asymmetric (Cu–N(3) = 1.9467(2) Å; Cu–O(1) = 2.2812(2) Å). The basal plane of the distorted pyramid is formed by N(3), N(23), O(2) and O(41) and the apex of the pyramid is occupied by the oxygen atom, O(1), of the hydroxymethyl group. Selected bond distances and valence angles are listed in Table 3.

The H_2O molecule and NO_3^- ion present in the complex molecule are engaged in very strong hydrogen bonding interactions. There are two kinds of hydrogen bonds between N–H imidazole molecules and nitrate oxygen atoms: typical N–H···O bonds. The water molecule participates in hydrogen bonding to the oxygen atom of the hydroxymethyl group of the ligand, to oxygen atom of NO_3^- ion and to oxygen atoms of coordinated and non-coordinated nitrate group. The details of the hydrogen bond geometry are given in Table 6.

3.1.3. The molecular structure of $[CdL_3](NO_3)_2L(EtOH)_{0.25}$ (**3**)

The molecular structure of cadmium(II) complex **3**, which crystallizes in the monoclinic space group *C*2/c, is shown in Fig. 4.

The central ion is surrounded by three molecules of 2-CH_2OH-BIm, which act as bidentate ligands. 2-CH_2OHBIm is bound to the metal through the pyridine-like nitrogen atoms of the benzimidazole ring and oxygen atoms of the hydroxymethyl groups. Structural data indicated that coordination geometry around the Cd(II) ion can be considered as distorted pseudo-octahedron (chromophore type CdN_3O_3). The equatorial plane is formed by N(3), N(23), N(33) and O(3) atoms with Cd-N bond lengths ranging from 2.207(2) to 2.247(2) Å and Cd–O = 2.497(2) Å. Two coordination axial sites are occupied by O(1) and O(2) oxygen atoms of $-CH_2OH$ groups with Cd–O distances of 2.427(3) and 2.450(2) Å. Selected bond distances and valence angles are given in Table 4. The most interesting features of the crystal packing is existence of channels running along [1 0 1] direction, filled with the free ligand and ethanol molecules (Fig. 5).

The channels comprise 26.5% of the unit cell volume (6.625% per each of four symmetry-related voids). Complex molecules are held together by hydrogen bonds of the O–H···O and N–H···O types, the geometry of which is given in Table 6.

3.1.4. The molecular structure of mer-$[CuL_3](NO_3)_2(H_2O)$(*i*-PrOH) (**4**)

The crystal of *mer*-$[CuL_3] \cdot (NO_3)_2 \cdot H_2O \cdot i$PzOH consist of CuL_3^{2+} cation, nitrate anions, and water and propan-2-ol molecules as co-crystallizing solvents. The copper atom has a distorted tetragonal bipyramid coordination geometry with the equatorial plane formed by three nitrogen atoms, N(23), N(3), N(33), from the imid-

azole rings of 1-CH_2OHBIm molecules and one oxygen atom O(1), of the hydroxymethyl group of the ligand. Therefore, the structure of the complex (Fig. 6) is assigned as *mer*-$[CuL_3] \cdot (NO_3)_2 \cdot H_2O \cdot$ *i*P-zOH isomer.

The Cu–N distances vary from 1.967(2) to 1.987(2) Å, while Cu–O distance is a little bit longer, 2.057(2) Å (Table 5). The axial positions are occupied by the oxygen atoms of the hydroxymethyl groups of two remaining 2-CH_2OHBIm molecules. The Cu–O apex distances, 2.370(2) and 2.465(2) Å, are longer due to the Jahn–Teller effect. The three ligands act as bidentate, forming a five-membered chelate rings with central ion, however, two of them are asymmetric because of the longer *z*-axis distances. The crystal structure of the complex is stabilized by complicated network of typical and bifurcated hydrogen bonds with the geometric details given in Table 6.

3.2. UV–Vis, EPR spectra and magnetic studies

The UV/Visible spectra of copper(II) complexes suggest that water solution structure of the **2** and **4** complexes are very similar. Within the visible region of **2** and **4** of the Cu(II)-complexes manifest absorption with the λ_{max} of 330 ($\varepsilon = 614\ M^{-1}\ cm^{-1}$) and 726 nm ($\varepsilon = 59\ M^{-1}\ cm^{-1}$) and 330 ($\varepsilon = 760\ M^{-1}\ cm^{-1}$) and 715 nm ($\varepsilon = 61\ M^{-1}\ cm^{-1}$), respectively. This suggests that the Cu centre of **2** can accommodate the H_2O molecule as a sixth ligand and both complexes exist as six coordinated species. In each case, the higher energy transition is assigned to a ligand-based π-π^* transition [33–35] the lower energy of the feature is assigned to d-d transition of hexacoordinated Cu(II) complexes with distorted octahedral geometry. The UV–Vis spectra of **2** in the solid state differ from those found in the solution. The reflectance spectra exhibit a very broad intense absorption between 550 and 900 nm. By means of the Gaussian distribution the following peaks position are established: 625, 875 nm which are typical of pentacoordinated Cu(II) complexes [33] with distorted square pyramidal geometry ($d_{xz},d_{yz}) \leftarrow d_{x^2-y^2}$ and $d_{z^2} \leftarrow d_{x^2-y^2}$, respectively). In addition, the electronic spectra of all the Cu(II) complexes feature a characteristic absorption in the 200–400 nm range. The position of individual bands for **2** and **4** obtained from Gaussian analysis were 228, 263, 321 and 248, 313, 387 nm, respectively which are typical of π–π^* transition of benzimidazole moiety. Furthermore, both of

the complexes show bands at 399 (**2**) and 387 nm (**4**) which are assigned to LMCT transition from the benzimidazole to the Cu(II) metal centre [33,36,37].

3.3. EPR spectra and magnetic studies

3.3.1. $[CuL_2(NO_3)](NO_3)(H_2O)$ (**2**), mer-$[CuL_3](NO_3)_2(H_2O)(i\text{-}PrOH)$ (**4**)

The powder EPR spectrum of **2** exhibits rhombic character of *g* parameters ($g_z = 2.32$, $g_x = 2.11$, $g_y = 2.04$) in agreement with the apparent distortion of the square-pyramidal geometry of the complex [38] towards trigonal pyramid. On other hand, the EPR spectrum of **4** corresponds to the axial g parameters typical for tetragonal Cu(II) complexes ($g_{II} = 2.255$, $g\perp$ and $A_{II} = 190 \times 10^{-4}\ cm^{-1}$) [39] and shows the copper hyperfine splitting of parallel orientation, a very rare case for solid state Cu(II) complexes (Fig. 7).

This effect is usually observed for Cu(II) centres at relatively long distance and was previously observed by us for the Cu(II) complex coordinated by four 1-benzyl-2-hydroxymethylimidazoles, with a Cu-Cu distance of 9.6 Å [39]. This parameter is in the 8.56–8.98 Å range (except for Cu1–Cu1$_{(-x+1,\ -y,\ -z+1)}$ = 6.83 Å) in **2** and in the 8.96–9.36 Å range in **4**. The EPR parameters of **4** in the solid state are strongly suggestive of O(1)N(3)N(23)N(33) coordination in Cu(II) plane realized by three ligands, in agreement with the crystal structure data. It is noteworthy that the EPR parameters for **4** in methanol solution show a significant increase of g_{II} and decrease of A_{II} ($g_{II} = 2.303$, $g_\perp = 2.062$ and $A_{II} = 155 \times 10^{-4}\ cm^{-1}$, $A_\perp 14 \times 10^{-4}\ cm^{-1}$) as compared to the solid state spectrum. The frozen solution spectrum exhibits seven lines nitrogen hyperfine splitting ($A(^{14}N) = 13 \times 10^{-4}\ cm^{-1}$) in the region of Cu(II) perpendicular orientation (Fig. 8), strongly indicating that three nitrogen donors are still involved in Cu(II) coordination. In view of the spectral parameters the fourth position in Cu(II) plane is most likely substituted by the solvent. The EPR spectrum of the compound **2** in methanol solution exhibits slight rhombic distortion according to $g_z = 2.325$, $g_x = 2.058$, $g_z = 2.073$ and $A_z = 142 \times 10^{-4}\ cm^{-1}$, $A_x = A_y = 14 \times 10^{-4}\ cm^{-1}$ and five line splitting of the perpendicular orientation line due to hyperfine interactions with two nitrogen nuclei $A(^{14}N) = 13 \times 10^{-4}\ cm^{-1}$ (Fig. 8). It supports (X-ray data) that two nitrogen donors are coordinated in the Cu(II) plane. A relatively greater g_{II} and smaller A_{II} as compared to those observed for complexes with two *bis* chelating ON ligands implies [39] mono-

dentate binding of the ligands; the remaining coordination positions are occupied by solvent molecules.

The magnetic susceptibility was measured for powder samples of the complexes **2** and **4** at room temperature. The calculated magnetic moment values for copper(II) complexes are 1.82 MB and 1.93 MB, respectively, which are very close to that of the spin only value (1.73 MB) expected for complexes having one Cu(II) ion with single unpaired electron sited in an essentially $d_{x^2-y^2}$ orbital.

3.4. IR(R) spectra

Selected vibration bands of the free ligand and their Cu(II), Cd(II) complexes, which are useful for determining the ligand's mode of coordination, are given in Table 7. In the IR spectra the $\nu_{(O\text{-}H)}$ bands of 2-hydroxymethylbenzimidazole complexes are shifted by 27–58 cm^{-1} to lower wavenumbers and the intense heteroatomic ring vibrations (C=N) are shifted by 17–21 cm^{-1} to higher wavenumbers in comparison to the absorption of the free ligand. Such shifts in the mentioned bands upon coordination are consistent with bidentate coordination of the ligand through the hydroxymethyl oxygen and pyridine-like nitrogen atom of 2-hydroxymethylbenzimidazole. In addition, the electron accepting capabilities of the central ion can be estimated by comparing the O–H and C=N stretching vibration bonds of the ligand. For this reason Table 7 shows a comparison of IR stretching vibrations between the free ligand and **1**, **2**, **3** and **4** compounds. The Δ values calculated from IR data indicate that Cd(II) ions are evidently better acceptors compared to Cu(II). Furthermore, the IR spectra have presented evidence for the different coordination mode of the NO_3^- ions (in agreement with X-ray data). The frequency difference of the vibrations $\Delta\nu = 40$ ($\Delta\nu = 1774–1735$ cm^{-1}) [40,41] indicate the bidentate coordination of nitrate in the **1**. Two kinds of bands 1432 and 1383 cm^{-1} in **2** confirm the existence of monocoordinated and non-coordinated NO_3^- ion, respectively. For other **3** and **4** compounds the absorption bands at 1385 and 1378 cm^{-1} reveal that the charge of the cationic complex is balanced by two non-coordinated nitrate anions. Moreover, in the far-IR spectra new bands, not detected in the spectrum of 2-hydroxymethylbenzimidazole, are observed, which arise from ν(M–O) and ν(M–N) stretches, respectively (Table 7).

3.5. NMR spectra

The NMR spectra confirmed X-ray data of the chelating mode of coordination of 2-hydroxymethylbenzimidazole. Metal coordina-

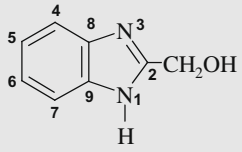
Table 8
^1H and ^{13}C NMR data for the **1** and **3**

	(1H, O*H*)	(s, 2H, CH_2)	H(5)	H(6)	H(7)	H(4)
Ligand	4.82	4.83	7.17	7.19	7.50	7.53
1 $\Delta\delta$	4.85 (+0.03)	4.90 (+0.07)	7.28 (+0.11)	7.31 (+0.12)	7.62 (+0.12)	7.64 (+0.11)
3 $\Delta\delta$	4.90(+0.08)	4.95 (+0.12)	7.23 (+0.06)	7.25 (+0.06)	7.56 (+0.06)	7.58 (+0.05)
Ligand			C(4,7)	C(5,6)		C(8,9)
1 $\Delta\delta$			116.67 (+0.20)	125.47 (+1.23)		157.17 (+0.16)
3 $\Delta\delta$			116.50 (+0.03)	125.21 (+0.97)		157.32 (+0.31)



tion of the oxygen atom should lead to deshielding the H and C of the –CH_2OH group of the ligand (Table 8). Such a dieshielding is actually observed with $\Delta\delta$ values of 1.09–1.4 ppm for the ^{13}C resonances while the ^1H resonances (0.03–0.08 ppm) are so close to those of the free alcohol that they cannot be discussed. Likewise the ^{13}C NMR spectra confirm coordination of pyridine-like nitrogen atom of 2-CH_2OHBIm with Cd(II) ion of **1** and **3** (chemical shifts for (*C*=N) are 0.28 and 0.84 ppm, respectively (Table 8). Moreover, the data from Table 8 indicate that the ^{13}C NMR method can be a powerful tool to study weak C–H···π type interactions which were extracted from X-ray data of **1** (see Fig. 2.)

4. Conclusions

The new complexes of Cd(II) (**1**,**3**) and Cu(II) (**2**,**4**) with 2-hydroxymethylbenzimidazole have been prepared and their crystal structures solved using single-crystal X-ray diffraction data. It is noteworthy that the NMR, IR, R and X-ray studies have confirmed a bidentate fashion of coordination of the 2-CH_2OHBIm to the Cd(II) as well to the Cu(II) ions. This results in the formulation of a five-membered chelate ring in which both the N(imidazole) and O(hydroxymethyl) donors of the ligand are involved. Formation of the chelates is not accompanied by loss of a proton from the hydroxyalkyl substituent. The X-ray data extracted from a comparison of Cu(II) ($[CuL_3](NO_3)_2(H_2O)(i\text{-}PrOH)$) **4** and Cd(II) ($[CdL_3](NO_3)_2L(EtOH)_{0.25}$) **3** model complexes with N, O-donor ligand show that both metals may form complexes which exhibit identical structures (distorted octahedral) forming chromophores of the MN_3O_3 type. The most interesting feature of the crystal packing of **3** is the existence of channels running along the [101] direction, filled with the free ligand and ethanol molecules. The channels comprise 26.5% of the unit cell volume (6.625% for each of the four symmetry-related voids). Complex molecules are held together by hydrogen bonds of the O–H···O and N–H···O type. On the other hand, when the central ions are associated with two molecules of 2-CH_2OHBIm, the metals exhibit different structures because of the different role of NO_3^- ions which are employed as additional ligands. Copper complex **2** is five-coordinated with a tetragonal pyramid as coordination polyhedron (CuN_2O_3) however, cadmium forms an eight-coordinated (CdN_2O_6) complex **1**. The interesting feature of the eight-coordinated cadmium complex is the shape of the coordination polyhedron which can be described as a transition form between the dodecahedron and the tetragonal antiprism. The IR data (ν_{O-H} and $\nu_{C=N}$ stretching vibration bonds) indicated that Cd(II) is considerably better acceptor (Lewis acid) than Cu(II) ion for the N, O-donor ligand. But the lower acceptor strength of Cu(II) does not result in longer Cu–N and Cu–O bonds. The similarities and differences revealed in the coordination behaviour of Cu(II) and Cd(II) towards the N, O-donor ligand should be treated as a test of the possibility that copper(II) ions might be displaced by cadmium(II), for example, in intracellular sites. The effective substitution may result in increased ionic copper concentration but is also expected to be one of the possible pathways for heavy-metal intoxication of the redox process in biological systems.

Appendix A. Supplementary data

CCDC 645635, 645636, 645637 and 645638 contains the supplementary crystallographic data for **1**, **2**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.ukSupplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.07.038.

2.3. Physical measurements

Elemental analyses were performed in a Carlo-Erba EA microanalyser. Infra-red spectra were recorded as KBr discs on a Bruker IFS-66 V spectrophotometer. LSI mass spectra were recorded using a Kratos-MS-50T spectrometer connected to a DS90 data system using 3-nitrobenzyl alcohol as the matrix. Conductivity measurements were carried out in 10^{-3} mol dm^{-3} acetonitrile solutions at 20 °C using a WTW LF3 conductivimeter. ^{1}H and ^{13}C, COSY, DEPT, and HMQC NMR spectra were recorded on a Varian 400 MHz, and CD_3CN was used as solvent.

2.4. Crystal structure determination

By slow recrystallisation from acetonitrile, crystals of $[CdL^1](NO_3)_2$, $[CdL^1](ClO_4)_2 \cdot CH_3CN$ and $[CdL^2](ClO_4)_2 \cdot H_2O$ suitable for X-ray diffraction were obtained. The details of the X-ray crystal data, and the structure solution and refinement for all them are given in Table 1. Measurements were made on a Nonius CAD4 for L and on a Bruker SMART CCD 1000 area diffractometer for the metal complexes. All data were corrected for Lorentz and polarization effects. Empirical absorption corrections were also applied for all the crystal structures obtained [19]. Complex scattering factors were taken from the program package SHELXTL [20]. The structures were solved by direct methods which revealed the position of all non-hydrogen atoms. All the structures were refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters for all non hydrogen atoms. The hydrogen atoms were located in their calculated positions and refined using a riding model. Molecular graphics were generated using ORTEP-3 [21].

3. Results and discussion

3.1. Crystal structure of $[CdL^1](NO_3)_2$ and $[CdL^1](ClO_4)_2 \cdot CH_3CN$

Colourless prisms of $[CdL^1](NO_3)_2$ and $[CdL^1](ClO_4)_2 \cdot CH_3CN$ were obtained by slow recrystallization of the obtained compounds in acetonitrile. The asymmetric unit of $[CdL^1](NO_3)_2$ is comprised by two $[CdL^1]^{2+}$ cations and four well resolved nitrate ions, while in $[CdL^1](ClO_4)_2 \cdot CH_3CN$ the asymmetric unit shows the presence of the $[CdL^1]^{2+}$ cation, two independent perchlorate counterions and an interstitial acetonitrile molecule. Only the ORTEP diagram of one $[CdL^1]^{2+}$ cation of $[CdL^1](NO_3)_2$, is shown in Fig. 1 together with selected bond lengths and angles. Fig. 2 shows the ORTEP diagram of the $[CdL^1]^{2+}$ cation of $[CdL^1](ClO_4)_2 \cdot CH_3CN$. Both $[CdL^1]^{2+}$ cations in $[CdL^1](NO_3)_2$ are similar, and only present small bond lengths and angles deviations between them. Also, these cations are similar to that present in $[CdL^1](ClO_4)_2 \cdot CH_3CN$.

In all cases, the $[CdL^1]^{2+}$ cation contains the Cd(II) ion sited in the middle of the macrocyclic cavity in a distorted octahedral geometry arising from coordination by the six donor nitrogen atoms of the macrocyclic backbone.

The six Cd–N bond lengths are in the range 2.237–2.440 Å, affording an average Cd–N bond distance of 2.356 Å. The distances found are shorter than other found in previously reported Cd(II) complexes with the metal ion in octahedral environments with similar N donor ligands [22,23]. The shortest bond distances correspond to the pyridinic nitrogen atoms according with bond distances found in similar complexes.

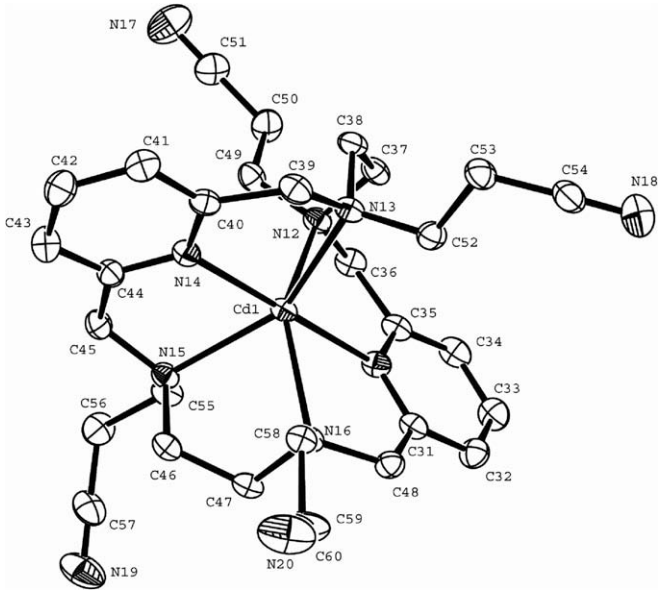

Fig. 1. ORTEP drawing of the molecular structure of one of the $[CdL^1]^+$ cations in $[CdL^1](NO_3)_2$ with displacement ellipsoids drawn at 50% probability level with selected bond lengths (Å) and angles (°). Hydrogen atoms are omitted for clarity. N(1)–Cd(2) 2.250(2), N(2)–Cd(2) 2.397(2), N(3)–Cd(2) 2.422(2), N(4)–Cd(2) 2.237(2), N(5)–Cd(2) 2.411(2), N(6)–Cd(2) 2.406(2), N(11)–Cd(1) 2.254(2), N(12)–Cd(1) 2.393(2), N(13)–Cd(1) 2.414(2), N(14)–Cd(1) 2.240(2), N(15)–Cd(1) 2.419(2), N(16)–Cd(1) 2.405(2), N(14)–Cd(1)–N(11) 179.88(10), N(14)–Cd(1)–N(12) 106.33(8), N(11)–Cd(1)–N(12) 73.77(9), N(14)–Cd(1)–N(16) 107.37(8), N(11)–Cd(1)–N(16) 72.53(8), N(12)–Cd(1)–N(16) 146.28(8), N(14)–Cd(1)–N(13) 74.01(8), N(11)–Cd(1)–N(13) 106.08(9), N(12)–Cd(1)–N(13) 79.86(8), N(16)–Cd(1)–N(13) 108.41(8), N(14)–Cd(1)–N(15) 73.46(8), N(11)–Cd(1)–N(15) 106.45(9), N(12)–Cd(1)–N(15) 111.02(9), N(16)–Cd(1)–N(15) 79.99(8), N(13)–Cd(1)–N(15) 147.43(8), N(4)–Cd(2)–N(1) 179.89(10), N(4)–Cd(2)–N(2) 106.37(8), N(1)–Cd(2)–N(2) 73.65(9), N(4)–Cd(2)–N(6) 107.32(8), N(1)–Cd(2)–N(6) 72.66(8), N(2)–Cd(2)–N(6) 146.28(8), N(4)–Cd(2)–N(5) 73.95(8), N(1)–Cd(2)–N(5) 106.16(9), N(2)–Cd(2)–N(5) 79.73(8), N(6)–Cd(2)–N(5) 108.39(8), N(4)–Cd(2)–N(3) 73.52(9), N(1)–Cd(2)–N(3) 106.36(9), N(2)–Cd(2)–N(3) 111.01(8), N(6)–Cd(2)–N(3) 80.14(8), N(5)–Cd(2)–N(3) 147.44(8).

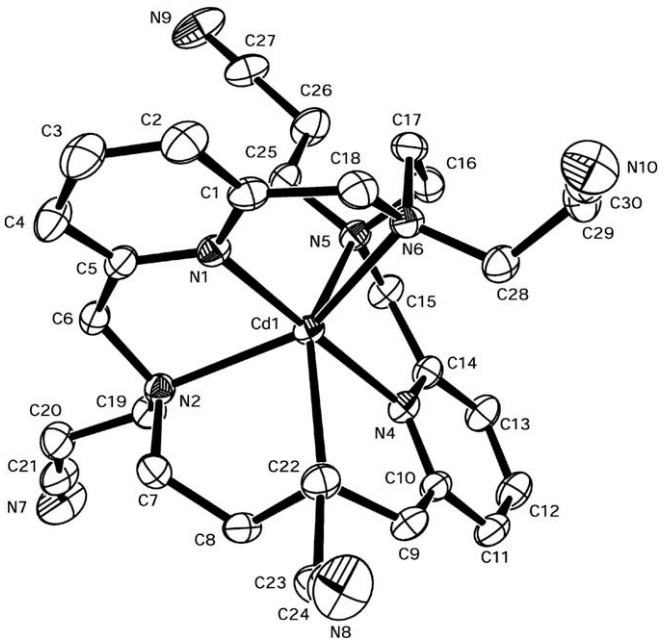

Fig. 2. ORTEP drawing of the molecular structure of the $[CdL^1]^+$ cation in $[CdL^1](ClO_4)_2 \cdot CH_3CN$ drawn as for Fig. 1 with selected bond lengths (Å) and angles (°). N(1)–Cd(1) 2.237(3); N(2)–Cd(1) 2.419(3); N(3)–Cd(1) 2.440(3); N(4)–Cd(1) 2.231(3); N(5)–Cd(1) 2.394(3); N(6)–Cd(1) 2.443(3); N(4)–Cd(1)–N(1) 174.89(10); N(4)–Cd(1)–N(5) 74.26(10); N(1)–Cd(1)–N(5) 108.96(9); N(4)–Cd(1)–N(2) 108.82(10); N(1)–Cd(1)–N(2) 73.87(9); N(5)–Cd(1)–N(2) 112.91(9); N(4)–Cd(1)–N(3) 73.11(10); N(1)–Cd(1)–N(3) 103.49(10); N(5)–Cd(1)–N(3) 147.34(9); N(2)–Cd(1)–N(3) 79.38(9); N(4)–Cd(1)–N(6) 104.39(10); N(1)–Cd(1)–N(6) 72.70(10); N(5)–Cd(1)–N(6) 80.05(9); N(2)–Cd(1)–N(6) 146.51(9); N(3)–Cd(1)–N(6) 106.74(9).

The ligand adopts a typical 'twist-wrap' conformation with the two pyridine rings oriented at 86.73 (0.10)° and 86.55 (0.10)° for each one of the cationic complexes of $[CdL^1](NO_3)_2$ and 87.43 (0.11)° for $[CdL^1](ClO_4)_2 \cdot CH_3CN$.

The angle between the pyridinic nitrogen atoms and the metal ion, N(4)–Cd(2)–N(1) 179.89(10) and N(14)–Cd(1)–N(11) 179.88(10) for $[CdL^1](NO_3)_2$ and N(4)–Cd(1)–N(1) 174.89(10) for $[CdL^1](ClO_4)_2 \cdot CH_3CN$, shows that the macrocycle is slightly folded in the perchlorate complex.

The nitrile groups are not interacting with the metal ion due to their linear nature as has been found in previously related crystal structures [14–17].

The nitrate and perchlorate ions were refined with no disorder giving bond distances and angles typical for these ions.

Inter- or intramolecular π,π-stacking interactions between the pyridine rings are not observed, however, as has been previously described in other reported nitrate complexes with this type of nitrile derivates ligands [14–17], interactions between nitrate anions, nitrile groups and pyridine rings from the macrocycle have been observed in the crystal structure of $[CdL^1](NO_3)_2$ (Fig. 3a). One nitrate ion is situated between a pyridine ring and a pendant nitrile group interacting with the π-systems of these groups.

If we consider the distance between the centroid of the pyridine and the N atom of the nitrate group as analogous to the centroid–centroid distance, this distance (d_{C-N}) is 3.4 Å. Table 2 contains some atom–atom distances between this nitrate ion and the pyridine ring and nitrile group of one pendant-arm, suggesting an interaction between the nitrate ion and the π-shell of the nitrile pendant group.

In the case of $[CdL^1](ClO_4)_2 \cdot CH_3CN$ the acetonitrile molecule is occupying the position of the nitrate ion in the previously described compound and it is this solvent molecule which interacts with the π-shell of the pyridine ring and the nitrile pendant group (Fig. 3b). Table 2 shows also atom–atom distances for $[CdL^1](ClO_4)_2 \cdot CH_3CN$.

3.2. Crystal structure of $[CdL^2](ClO_4)_2 \cdot H_2O$

By recrystallization of the Cd(II) perchlorate complex with L^2 in acetonitrile, crystals suitable for X-ray diffraction were obtained. The details of the X-ray crystal structure and refinement of $[CdL^2](ClO_4)_2 \cdot H_2O$ are given in Table 1. The molecular structure of the $[CdL^2]^+$ cation with selected bond lengths and angles are given in Fig. 4.

The complex is mononuclear and contains the Cd(II) ion endomacrocyclically coordinated in a distorted N6 octahedral geometry by coordination of the six donor nitrogen atoms from the macrocyclic framework. The cyanomethyl pendant arms remain not coordinated as happened with the complexes described for L^1.

Table 2
Intermolecular atom–atom distances (Å) shorter than 3.5 Å for $[CdL^1](NO_3)_2$ and $[CdL^1](ClO_4)_2 \cdot CH_3CN$

$[CdL^1](NO_3)_2$	$[CdL^1](ClO_4)_2 \cdot CH_3CN$
O1N–C60 3.385 Å	N1S–C1 3.432 Å
O2N–C40 3.153 Å	N1S–C2 3.309 Å
O3N–C42 3.363 Å	N1S–N8 3.443 Å
O2N–N20 3.453 Å	N1S–C24 3.449 Å
O2N–C60 3.368 Å	C1S–C2 3.304 Å
	C1S–C3 3.348 Å

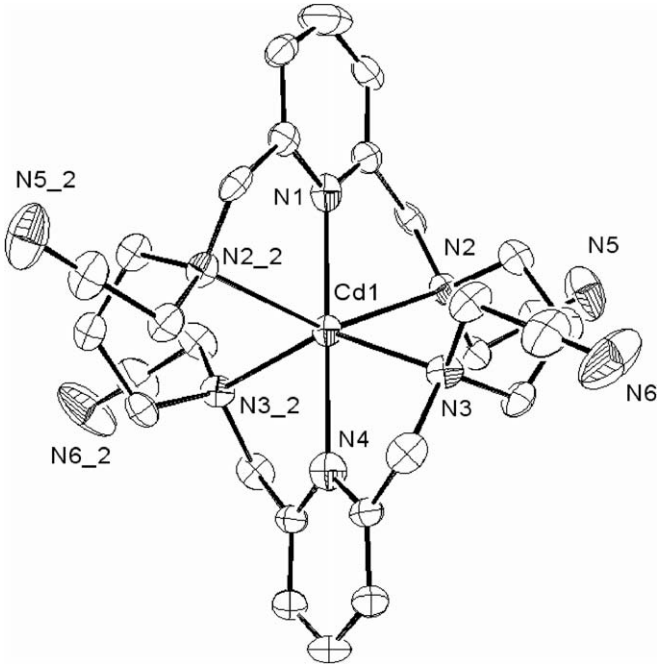

Fig. 4. ORTEP drawing of the molecular structure of the $[CdL^2]^+$ cation in $[CdL^2](ClO_4)_2 \cdot H_2O$ drawn as for Fig. 1 with selected bond lengths (Å) and angles (°). N(1)–Cd(1) 2.185(11); N(2)–Cd(1) 2.503(7); N(3)–Cd(1) 2.520(7); N(4)–Cd(1) 2.207(11); N(1)–Cd(1)–N(4) 180.000(2); N(1)–Cd(1)–N(2) 71.25(17); N(4)–Cd(1)–N(2) 108.75(17); N(2)–Cd(1)–N(2)#1 142.5(3); N(1)–Cd(1)–N(3) 108.51(16); N(4)–Cd(1)–N(3) 71.49(16); N(2)–Cd(1)–N(3) 85.7(2); N(2)–Cd(1)–N(3)#1 106.2(2); N(3)–Cd(1)–N(3)#1 143.0(3).

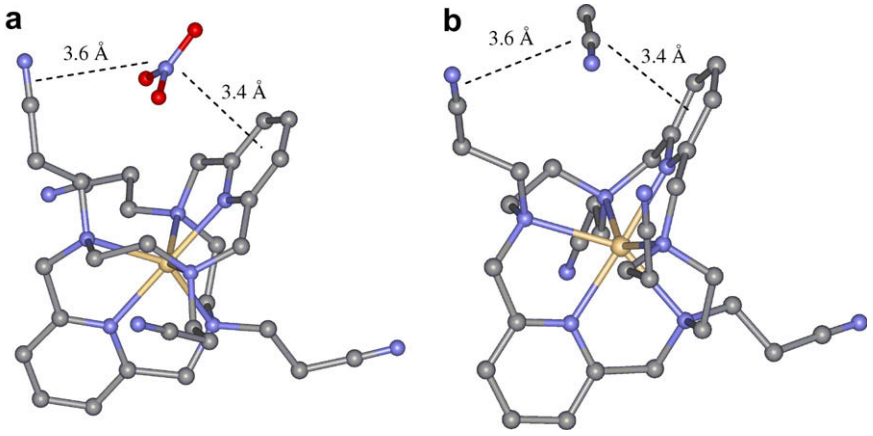

Fig. 3. Triple π-stacking interaction between (a) the pyridine ring, the nitrile group and the nitrate ion in $[CdL^1](NO_3)_2$, and (b) the pyridine ring, the nitrile group and the acetonitrile molecule in $[CdL^1](ClO_4)_2 \cdot CH_3CN$.

The structure shows also a 'twist-wrap' typical conformation where the macrocycle adopts a helical shape with the two pyridine rings oriented at 65.34° relative to each other. The angle between the pyridinic nitrogen atoms and the metal ion [N(1)–Cd(1)–N(4), 180.000(2)], shows that the macrocycle is not folded.

The pyridine groups provides again the shortest bond distance to the Cd(II) atom [Cd(1)–N(1) 2.185(11) and Cd(1)–N(4) 2.207(11) Å], while the bond lengths of the tertiary amine groups [N(2)–Cd(1) 2.503(7) and N(3)–Cd(1) 2.520(7)] are similar than those found in similar complexes that have been reported previously [22,23]. The perchlorate ions are not coordinated to the metal; they were refined with no disorder, giving bond distances and angles typical for these ions.

Inter- or intramolecular π,π-stacking interactions between the pyridine rings are not observed.

3.3. Spectroscopic studies

The IR spectra of the complexes (KBr discs) show in all cases that the ν(C=N) vibration band of the pyridine groups are shifted to higher wavenumber than in the free ligands suggesting coordination to the metal atom [24]. The IR spectra of the Cd(II) complexes of L^1 show two bands at *ca.* 2250 and 2425 cm^{-1}, assigned to the ν(C≡N) band that can be related with the interaction of the nitrile pendant groups with different π systems present in the structures (pyridine rings, nitrate ions or acetonitrile molecules), accordingly with the crystal structures found for these complexes [15,17]. However, in the case of the Cd(II) complexes of L^2, the spectra show only one band at *ca.* 2250 cm^{-1}, similar than in the free ligand.

The IR spectra of the perchlorate complexes feature absorptions attributable to ionic perchlorate at 1100 and 626 cm^{-1}, indicating that these groups are not coordinated to the metal centers in any case [25,26]. The IR spectra of the nitrate complexes present the band at 1384 cm^{-1} associated with the ionic nitrate groups [27].

The LSI mass spectra of the complexes confirm in all cases the mononuclear nature of the complexes.

Molar conductivity data, measured at room temperature using acetonitrile as solvent, showed the presence of ionic counterions, since they are in the range reported in that solvent for 2:1 electrolytes [28]. This is in agreeing with the results obtained from the IR and X-ray studies.

The ^{1}H NMR spectra of the complexes were recorded in CD_3CN. The spectra are in general more complicated than expected showing that fast interconversion of isomer in solution does not occur. All the spectra show in general that the signals are shifted downfield compared with the free ligands.

The ^{1}H NMR spectra of $[CdL^1](NO_3)_2$ and $[CdL^1](ClO_4)_2 \cdot CH_3CN$ are similar. They show that pyridyl protons appear at δ 8.3 and 7.8 ppm as a triplet and a doublet, respectively. However, the aliphatic signals appear as different multiplets: the adjacent to pyridine protons appear at δ 4.4–4.2 ppm while the remaining aliphatic protons collapse in a multiplet at δ 3.3–2.3 ppm.

The ^{1}H NMR spectra of $[CdL^2](ClO_4)_2 \cdot H_2O$ and $[CdL^2](NO_3)_2$ are also similar. In this case, the pyridyl protons appear again as a triplet and a doublet at δ 8.3 and 7.8 ppm, respectively, the adjacent to pyridine and the pendant arms proton signals collapse in a multiplet between δ 3.9 and 4.4 ppm, and the remaining aliphatic protons appears as a multiplet at δ 2.5–3.0 ppm.

4. Conclusion

In summary, we described the synthesis of different nitrate and perchlorate cadmium(II) complexes with two cyano pendant arm azamacrocyclic ligands (L^1 and L^2). The structure of the complexes $[CdL^1](NO_3)_2$, $[CdL^1](ClO_4)_2 \cdot CH_3CN$ and $[CdL^2](ClO_4)_2 \cdot H_2O$ have been determined by X-ray analysis, showing that they are mononuclear complexes with the metal atom endomacrocyclicly coordinated in all cases to the six nitrogen donor atoms from the macrocyclic framework being the pendant groups not coordinated. In all cases, the geometry around the Cd(II) ion can be described as N6 distorted octahedral. Also, different interactions between nitrate ions, nitrile groups and pyridine rings from the macrocycle were found in the $[CdL^1](NO_3)_2$ and $[CdL^1](ClO_4)_2 \cdot CH_3CN$ structures.

purification. Copper oxalate precursor was synthesized according to this procedure: the $Cu(OOCCH_3)_2 \cdot H_2O$ (2 mmol) was dissolved into 10 mL of distilled water to form a homogeneous solution. A stoichiometric amount of potassium oxalate dissolved in an equal volume of distilled water was dropwise added into the above solution under magnetic stirring. The solution was stirred for about 15 min and a blue precipitate was centrifuged and washed with ethanol several times. The product was dried at 50 °C. The copper oxalate, $Cu(O_4C_2)$, was characterized by elemental analyses, powder X-ray diffraction (XRD) and thermo gravimetric analysis (TGA) [31,34]. *Anal.* Calc. for $[Cu(O_4C_2)]$: C, 15.84; Cu, 41.93. Found: C, 15.75; Cu, 41.84%.

2.2. Characterization

XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Elemental analyses were obtained from Carlo ERBA Model EA 1108 analyzer. Scanning electron microscopy (SEM) images were obtained on Philips XL-30ESEM equipped with an energy dispersive X-ray spectroscopy. Transmission electron microscopy (TEM) images were obtained on a Philips EM208 transmission electron microscope with an accelerating voltage of 200 kV. Fourier transform infrared (FT-IR) spectra were recorded on Shimadzu Varian 4300 spectrophotometer in KBr pellets. Thermogravimetric-differential thermal analysis (TG-DTA) were carried out using a thermal gravimetric analysis instrument (Shimadzu TGA-50H) with a flow rate of 20.0 mL min^{-1} and a heating rate of 10 °C min^{-1}. The electronic spectra of the complexes were taken on a Shimadzu UV–Vis scanning spectrometer (Model 2101 PC).

2.3. Synthesis of Cu nanoparticles

The current synthetic procedure is a modified version of the method developed by Hyeon and others for the synthesis of metal nanoparticles which employs the thermal decomposition of transition metal complexes [32,33,35]. The synthetic pathway is shown in Scheme 1. In this synthesis Cu nanoparticles were prepared by the thermal decomposition of copper oxalate, $[Cu(O_4C_2)]$–oleylamine complex as precursor. First, the $[Cu(O_4C_2)]$–oleylamine complex was prepared by reaction 0.6 g of $Cu(O_4C_2)$ and 5 mL of oleylamine. The mixed solution was placed in a 50 mL three-neck distillation flask and heated up to 140 °C for 60 min under an argon atmosphere. The resulting metal-complex solution was injected into 5 g of triphenylphosphine (TPP) at 240 °C. As the thermal decomposition proceeded, the azury solution turned to red, indicating the formation of metallic copper. The reddish solution was aged at 240 °C for 45 min, and was then cooled to room temperature. The reddish nanoparticles were precipitated by adding excess ethanol to the solution. The final product was washed with ethanol several times to remove excessive surfactant. This product could easily be re-dispersed in nonpolar organic solvents, such as hexane or toluene (Scheme 1).

3. Results and discussion

The TGA curve of the as-prepared precursor is shown in Fig. 1. There is only one weight loss step in the temperature range 250–310 °C. The weight loss at 250–315 °C may be ascribed to the decomposition of the oxalate. The weight loss is about 43.23%, which is close to the theoretical value.

X-ray powder diffraction (XRD) patterns of Cu nanoparticles at room temperature shows in Fig. 2. The XRD pattern is consistent with the spectrum of copper, and no peak attributable to possible impurities is observed. The peak positions are consistent with metallic copper. All possible peaks of copper are observed, which indicates the polycrystalline nature of the product. Bragg's reflections for Cu nanoparticles are observed in XRD pattern at 2θ value of 43.6°, 50.7° and 74.45° representing [111], [200] and [220] planes of fcc structure of copper with the space group of *Fm3m*

(JCPDS No. 4–0836). The size of the crystallites was estimated from Debye–Scherrer equation is about 40 nm.

FT-IR spectroscopy is a useful tool to understand the functional group of any organic molecule. The infrared spectra of free TPP, oleylamine and copper nanoparticles coated with oleylamine and TPP are shown in Fig. 3. By comparing the infrared spectra of the nanoparticles with free surfactants in Fig. 3 we can see that the organic molecules have indeed become a part of the nanoparticles. As shown in Fig. 3a and b, peaks corresponding to P–ph stretching at 1710 cm^{-1}, rocking and bending mode of the methylene group $\omega(CH_2)$ at 1270 cm^{-1}, bending mode of the phenyl group $\gamma(=CH)$ at 742 cm^{-1} and υ (benzene ring) at 697 cm^{-1} can be seen clearly. The only difference among these characteristic peaks is either the peak intensity or a slight shift in the peak position. For example, the peak position of the longitudinal modes of oleylamine and TPP shifts to lower wavenumbers after TPP and oleylamine are adsorbed on the surface of the copper nanoparticles. The FT-IR of the copper nanoparticles shows the intense adsorption peaks at 2920 and 2850 cm^{-1} attributed to the alkyl chains of oleylamine. The bands attributed to the antisymmetric and symmetric vibration modes of –N–H are observed at 3437 and 3232 cm^{-1}, respectively (Fig. 3c). Due to the coordination of the unpaired electron couple of the nitrogen atom, the vibration bands are observed in lower values than those expected for the free amine group, i.e., 3500 and 3300 cm^{-1}, respectively. This indicates that oleylamine is bound on the surface through the unpaired electron couple of the amine group [36]. From these results, a chemical bond can be formed between N and Cu atoms and a coordinate bond between P and Cu atoms on the surface of the nanoparticles. Thus, the phenyl stretching mode ν(P–ph) at 1430 cm^{-1} is still visible in Fig. 3c. So the oleylamine and TPP serves as the capping ligand that controls growth. Triphenylphosphine (TPP) was widely used in the synthesis of phosphine-stabilized cobalt or other metal nanoparticles

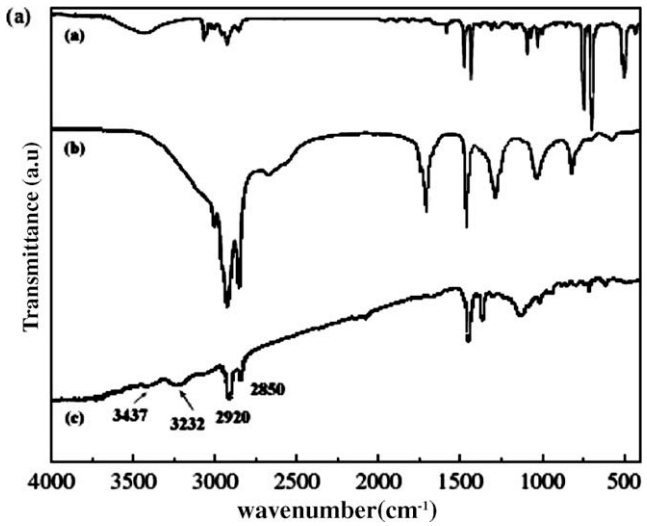

Fig. 3. FT-IR spectra of (a) free TPP absorption, (b) free oleylamine and (c) Cu nanoparticles coated by oleylamine and TPP.

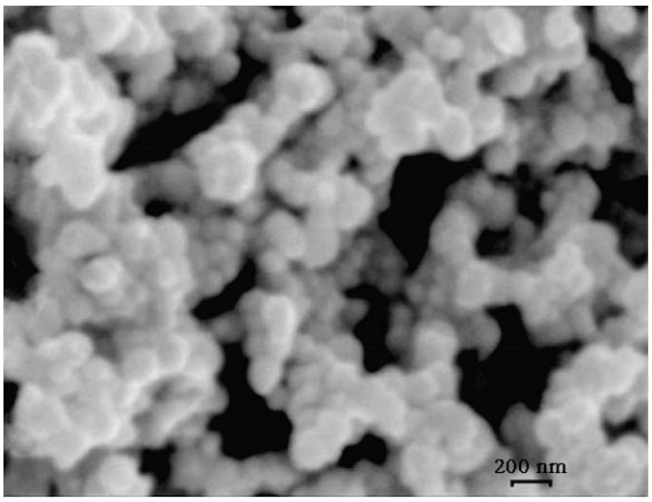

Fig. 4. SEM image of Cu nanoparticles.

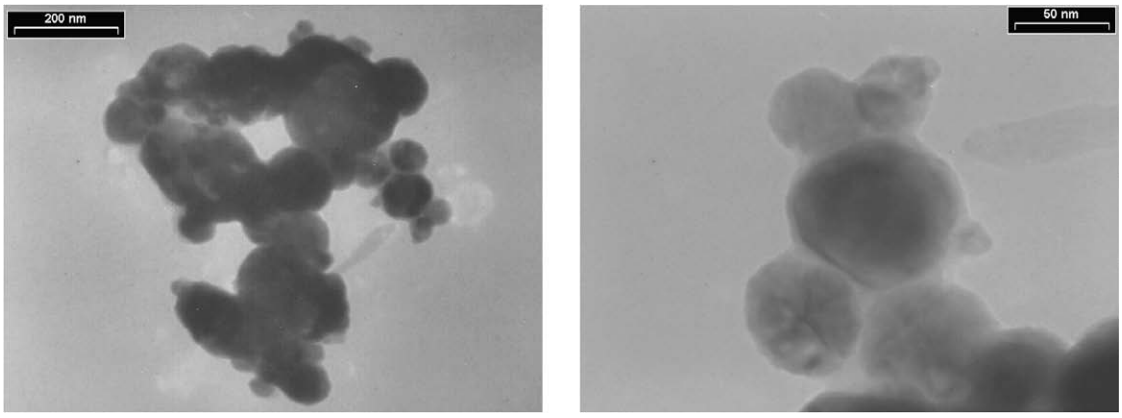

Fig. 5. TEM images of Cu nanoparticles.

[37]. The phenyl groups in TPP can provide greater steric hindrance than straight-chained alkyl groups such as tributyl and trioctyl to control the size of nonmagnetic metal nanoparticles and to stabilize efficiently the magnetic nanoparticles.

The morphology of the Cu nanoparticles is examined by SEM (Fig. 4). From the micrograph, it was observed that the nanoparticles were agglomerated. The TEM image (Fig. 5) shows the presence of dense agglomerates. The particles have an irregular shape, and their distribution, likewise, is not uniform (30–80 nm).

The growth mechanism could be well understood on the basis of the following reactions and the crystal habits of Cu. In the presence of oleylamine as solvent [$Cu(O_4C_2)$]–oleylamine were synthesized. After addition of TPP to these solutions at high temperature the complexes were decomposed. TPP is a high-boiling point surfactant with a patulous long-chain structure providing great steric hindrance. The addition of TPP into the mixture of oleylamine and complex as an additional surfactant reduced the particle size much further and resulted in nanoparticles with very thin arrays. Oleylamine is known as a ligand that binds tightly to the metal nanoparticles surface. The combined effects of TPP and oleylamine were much more profound than those of individual contributions. On the other hand these complexes transform to Cu under an argon atmosphere. When the triphenylphopsphine (TPP) was used as the complexing agent, the spherical nanoparticles capped by this surfactant were obtained. The growth of the Cu nanoparticles can be explained on the basis of the schematic view presented in Scheme 1. The Cu nanoparticles agglomerated together to form a spherical structure. In this synthetic rout oleylamine acts not only as the reaction solution but also as the stabilizer, which prevents the nanoparticles from oxidizing. Recently, copper oxalate was used as precursor for synthesizing CuO. In that method copper oxalate was calcined at 400 °C for 4 h [31] or 350 °C for 10 h [34] without any capping agent and argon atmosphere. So, metal oxide nanoparticles obtained. But here with use of capping agent, metallic nanoparticles obtained. We believe that capping agents used here help to the formation of metal rather than metal oxide.

Nanosized particles exhibit unique optical properties with an exponential-decay Mie scattering profile with decreasing photon energy. Some transition metal nanoparticles show a distinct surface-plasmon resonance (SPR). The SPR is very sensitive to metal size, dielectric constant of metal and embedding medium (here is oleylamine) [20,29]. For instance, Cu nanoparticles typically exhibit SPR at around 600 nm [38]. However, for the fresh Cu nanoparticles synthesized here show an absorption peak at around 572 nm (Fig. 6). This peak can be assigned to the absorption of nanoparticles of copper [38]. A modest blue shift (about 28 nm) of the absorption edge relative to that of the bulk copper powder is

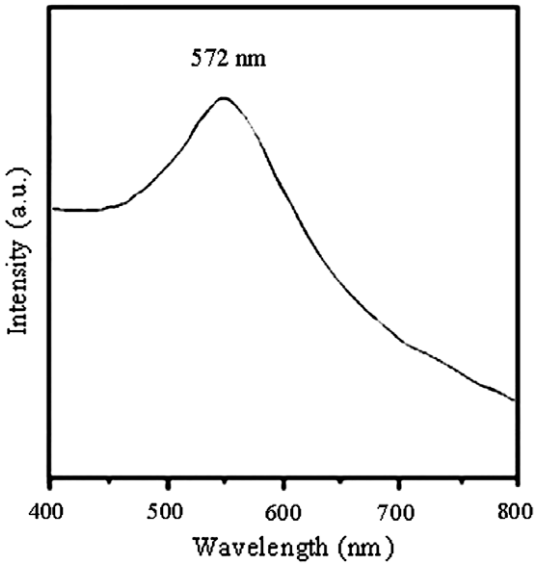

Fig. 6. UV–Vis absorption of the Cu nanoparticles.

observed. This observation alludes to the size effect to the Cu nanoparticles. The synthesized particles were stable for ~6 days. This kind of stabilization of Cu nanoparticles was due to the capping of particles by oleylamine in thermal treatment. The arrangement of capping agent, oleylamine surrounding the nanoparticles is size dependent. After a few days, slow oxidation of copper particles sets in with the disappearance of absorption peaks [39] and finally the as-synthesized product becomes black. This indicated that the sample was oxidized.

4. Conclusion

In summary, Cu nanoparticles with diameters from 30 to 80 nm have been successfully synthesized via thermal decomposition of [$Cu(O_4C_2)$]-oleylamine complex. This method employed an inexpensive, reproducible process for the large-scale synthesis of copper nanoparticles.

Acknowledgment

Authors are grateful to council of University of Kashan for providing financial support to undertake this work.

graphical user interface. Least square refinements were performed by the full-matrix method with SHELXL [29]. The hydrogen atom positions were geometrically fixed.

2.2. Preparation of chiral p-tert-butyl-calix[4]arene bisphosphites (L^1 and L^2)

Triethylamine (2.33 g, 23×10^3 mol) was added to a stirred suspension of *p-tert*-butyl-calix[4]arene (3.11 g, 4.8×10^3 mol) in 60 cm^3 THF, and the reaction mixture was stirred at room temperature for 15 min. The solution was cooled in an ice bath and (1*S*,2*R*,5*R*)-(+)-*iso*-menthyl phosphorodichloridite (2.47 g, 9.6×10^3 mol) was slowly added through a dropping funnel at 0 °C. The reaction mixture was allowed to attain ambient temperature and stirred for 4 h. During this time, a white precipitate was formed. The ^{31}P NMR spectrum of the reaction mixture showed the formation of the expected product. The precipitate was filtered off and the filtrate was evaporated under reduced pressure to obtain a yellowish-white foamy solid. The mixture was subjected to column chromatographic separation over silica gel using petrol/EtOAc (200:1 v/v) as the eluant. The initial fraction contained *p-tert*-butyl-calix[4]arene *iso*-menthyl bisphosphite ($\mathbf{L}^1$). Yield: 1.36 g (28%); m.p. = 136–142 °C; $[\alpha]_D^{25} = 77.7$ (*c* 1.0, $CHCl_3$); *Anal.* Calc. for $C_{64}H_{90}O_6P_2$ (mol. wt.: 1017.5): C, 75.5; H, 8.9. Found: C, 75.9; H, 8.4%; ^1H NMR $\delta = 0.72$ (d, 6H, $J = 2.8$ Hz), 0.84 (d, 6H, $J = 4.2$ Hz), 0.94 (d, 6H, $J = 3.8$ Hz), 1.01 (s, 18H, Bu^t), 1.08–1.58 (m, 18H, *iso*-menthyl group + 18H, Bu^t), 3.25 (d, 2H, Hb_2, $J = 5.2$ Hz), 3.28 (d, 2H, Hb_1, $J = 6.0$ Hz), 4.55 (br s, 2H-methyne protons of the *iso*-menthyl group), 4.56 (d, 2H, Ha_2, $J = 13.2$ Hz), 4.81 (d, 2H, Ha_1, $J = 14.4$ Hz), 6.74 (s), 6.82 (s) (8H, aromatic protons of the calixarene); ^{13}C NMR (100 MHz, $CDCl_3$) $\delta = 15.54$, 22.26, 22.88, 24.91, 27.02, 31.27, 31.29, 31.32, 31.36, 31.38, 31.64, 31.68, 31.82, [33.83 and 34.08 (bridged methylene carbons)], 34.32, 38.54, 44.61, 48.66 (aliphatic carbons), 76.42 (*iso*-menthyl carbon), 124.13, 124.24, 125.81, 126.06, 131.87, 133.52 (aromatic carbons) 145.11, 146.23, 147.59, 148.84 (aromatic carbons directly attached to the oxygen atoms).

p-tert-Butyl-calix[4]arene menthyl bisphosphite ($\mathbf{L}^2$) was synthesized as described above for ligand ($\mathbf{L}^1$): Yield: 1.41 g (29%); m.p. = 132–138 °C; $[\alpha]_D^{25} = 93.7$ (*c* 1.0, $CHCl_3$); *Anal.* Calc. for $C_{64}H_{90}O_6P_2$: (mol. wt.: 1017.5): C, 75.5; H, 8.9. 2.3. Preparation of achiral p-tert-butyl-calix[4]arene bisphosphite (L^3)

The title compound ($\mathbf{L}^3$) was prepared as described above for ligand ($\mathbf{L}^1$) by the reaction of *p-tert*-butyl-calix[4]arene (3.11 g, 4.8×10^3 mol) with 2.98 g (9.6×10^3 mol) of $ROPCl_2$ (R = C_6H_4-Bu^t-4) in toluene in the presence of triethylamine for 8 h. Yield: 1.83 g (38%); m.p. = 166–172 °C; *Anal.* Calc. for $C_{64}H_{78}O_6P_2$ (mol. wt.: 1004.4): C, 76.5; H, 7.8. Found C, 77.1; H, 7.4%; ^1H NMR (400 MHz,$CDCl_3$) $\delta = 1.12$ (s, 36H, Bu^t), 1.27 (s, 18H, Bu^t), 3.34 (d, 2H, Hb_2, $J = 8.4$ Hz), 3.44 (d, 2H, Hb_1, $J = 12.6$ Hz), 4.64 (d, 2H, Ha_2, $J = 14.4$ Hz), 4.88 (d, 2H, Ha_1, $J = 14.8$ Hz), 6.80 (s), 6.90 (s), (8H, aromatic protons of calixarene), 7.17 (d, 4H, $J = 7.4$ Hz, aromatic protons), 7.24 (d, 4H, $J = 7.8$ Hz, aromatic protons); ^{13}C NMR (100 MHz, $CDCl_3$) $\delta = 31.43$, 31.89, 33.55, [33.77 and 34.18 (bridged methylene carbons)], 34.76, 38.56, 38.72 (aliphatic carbons), 120.44, 124.68, 126.23, 126.54, 131.60, 132.22, 144.36, 146.57, 148.06 (aromatic carbons).

2.4. Preparation of chiral p-tert-butyl-calix[4]arene iso-menthyl bisphosphite–$PdCl_2$ complex (**1**) and menthyl bisphosphite–$PdCl_2$ complex (**4**)

Chiral *p-tert*-butyl-calix[4]arene *iso*-menthyl bisphosphite ($\mathbf{L}^1$) (107 mg, 10.5×10^5 mol) was treated with [$PdCl_2$(COD)] (30 mg, 10.5×10^5 mol) or $PdCl_2(PhCN)_2$ (40 mg, 10.5×10^5 mol) in THF (20 ml) and the reaction mixture was stirred for 1 h. The solvent was evaporated and the residue was washed several times with petrol to obtain complex (**1**) as a light yellow powder. The product was crystallized from THF:petrol (1:3) to obtain pale yellow crystals. Yield: 120 mg (96%); m.p. = 289–294 °C; *Anal.* Calc. for $C_{64}H_{90}O_6P_2PdCl_2$ (mol. wt.: 1194.6): C, 64.3; H, 7.5. Found C, 64.8; H, 7.8%; ^1H NMR $\delta = 0.80$ (d, 6H, $J = 3.4$ Hz), 0.85 (d, 6H, $J = 3.8$ Hz), 0.94 (d, 6H, $J = 3.6$ Hz), 1.06–1.69 (m, 18H, *iso*-menthyl group + 18H, Bu^t +18H, Bu^t), 3.44 (d, 2H, Hb_2, $J = 6.4$ Hz), 3.48 (d, 2H, Hb_1, $J = 7.6$ Hz), 4.56 (d, 2H, Ha_2, $J = 16.4$ Hz), 4.60 (d, 2H, Ha_1, $J = 13.6$ Hz), 5.77 (br s, 2H-methyne protons of the *iso*-menthyl group), 6.90 (s), 6.96 (s) (8H, aromatic protons of calixarene); ^{13}C NMR (100 MHz, $CDCl_3$) $\delta = 18.66$, 19.99, 20.35, 21.53, 26.44, 28.26, 31.24, 31.28, 32.18, [34.06 and 34.18 bridged methylene carbons], 34.22, 37.18, 38.36, 47.29 (aliphatic carbons); 85.69 (*iso*-menthyl carbon), 125.48, 125.69, 126.65, 126.79, 129.38, 129.76, 132.49, 132.88 (aromatic carbons), 147.14, 147.24 148.22, 148.31 (aromatic carbons directly attached to the oxygen atom).

The palladium dichloride complex (**4**) of chiral *p-tert*-butyl-calix[4]arene menthyl bisphosphite ($\mathbf{L}^2$) was prepared as described above for complex (**1**): pale yellow crystals, yield: 118 mg (94%); m.p. = 284–292 °C; *Anal.* Calc. for $C_{64}H_{90}O_6P_2PdCl_2$ (mol. wt.: 1194.6): C, 64.3; H, 7.5. Found C, 64.7; H, 7.8%; ^1H NMR $\delta = 0.80$ (d, 6H, $J = 2.6$ Hz), 0.86 (d, 6H, $J = 3.4$ Hz), 0.94 (d, 6H, $J = 3.8$ Hz), 1.03 (s, 18H, Bu^t), 1.06–1.72 (m, 18H, menthyl group + 18H, Bu^t), 3.42 (d, 2H, Hb_2, $J = 6.2$ Hz), 3.49 (d, 2H, Hb_1, $J = 7.4$ Hz), 4.54 (d, 2H, Ha_2, $J = 12.2$ Hz), 4.66 (d, 2H, Ha_1, $J = 12.4$ Hz), 5.74 (bs, 2H-methyne protons of the menthyl group), 6.73 (s), 6.83 (s), (8H, aromatic protons of calixarene); ^{13}C NMR (100 MHz, $CDCl_3$) $\delta = 18.61$, 19.97, 20.30, 21.52, 26.41, 28.20, 31.19, 31.26, 32.09 [33.94 and 34.15 (bridged methylene carbons)], 34.21, 37.16, 38.33, 47.27 (aliphatic carbons), 85.68 (menthyl carbon), 125.47, 125.67, 126.63, 126.76, 129.36, 129.74, 132.47, 132.86 (aromatic carbons), 147.11, 147.28, 148.21, 148.29 (aromatic carbons directly attached to the oxygen atoms).

2.5. Preparation of chiral p-tert-butyl-calix[4]arene iso-menthyl bisphosphite–$PtCl_2$ complex (**2**) and menthyl bisphosphite–$PtCl_2$ complex (**5**)

The platinum dichloride complex (**2**) was prepared by the reaction of chiral *p-tert*-butyl-calix[4]arene *iso*-menthyl bisphosphite ($\mathbf{L}^1$) (107 mg, 10.5×10^5 mol) with [$PtCl_2$(COD)] (39 mg, 10.5×10^5 mol) in 20 ml of toluene and the reaction mixture was stirred for 1 h. The solvent was evaporated and the residue was washed several times with petrol to obtain complex (**2**). The product was crystallized from chloroform:petrol (1:3) to obtain colorless crystals: Yield 113 mg (84%); m.p. = 291–298 °C; *Anal.* Calc. for $C_{64}H_{90}O_6P_2PtCl_2$ (mol. wt.: 1283.5): C, 59.9; H, 7.1; Found C, 60.2; H, 6.9%; ^1H NMR $\delta = 0.79$ (d, 6H, $J = 2.8$ Hz), 0.84 (d, 6H, $J = 3.6$ Hz), 0.92 (d, 6H, $J = 3.2$ Hz), 1.04–1.67 (m, 18H, *iso*-menthyl group + 18H, Bu^t + 18H, Bu^t), 3.42 (d, 2H, Hb_2, $J = 6.2$ Hz), 3.46 (d,

2H, Hb_1, J = 7.4 Hz), 4.54 (d, 2H, Ha_2, J = 16.0 Hz), 4.59 (d, 2H, Ha_1, J = 13.4 Hz), 5.76 (br s, 2H-methyne protons of the *iso*-menthyl group), 6.90 (s), 6.95 (s) (8H, aromatic protons of calixarene); ^{13}C NMR (100 MHz, $CDCl_3$) δ = 18.66, 19.99, 20.35, 21.53, 26.44, 28.26, 31.24, 31.28, 32.18, [34.06 and 34.18, bridged methylene carbons] 34.22, 37.18, 38.36, 47.29 (aliphatic carbons), 85.69 (*iso*-menthyl carbon), 125.48, 125.69, 126.65, 126.79, 129.38, 129.76, 132.49, 132.88 (aromatic carbons), 147.14, 147.29, 148.22, 148.31 (aromatic carbons directly attached to the oxygen atoms).

The menthyl bisphosphite-platinum dichloride complex (**5**) was synthesized as described above for complex (**2**). Yield: 115 mg (85%); m.p. = 287–294 °C; *Anal.* Calc. for $C_{64}H_{78}O_6P_2PtCl_2$: (mol. wt.: 1283.5): C, 59.9; H, 7.1; Found C, 60.4; H 7.4%; ^{1}H NMR δ = 0.79 (d, 6H, J = 3.4 Hz), 0.87 (d, 6H, J = 3.8 Hz), 0.96 (d, 6H, J = 3.6 Hz), 1.06–1.54 (m, 18H, menthyl group + 18H, Bu^t + 18H, Bu^t), 3.24 (d, 2H, Hb_2, J = 3.9 Hz), 3.29 (d, 2H, Hb_1, J = 4.8 Hz), 4.12 (br s, 2H-methyne protons of the menthyl group), 4.56 (d, 2H, Ha_2, J = 14.2 Hz), 4.81 (d, 2H, Ha_1, J = 14.4 Hz), 6.73 (s), 6.83 (s) (8H, aromatic protons of calixarene); ^{13}C NMR (100 MHz, $CDCl_3$) δ = 16.45, 21.11, 21.95, 22.54, 30.89, 30.93, 31.13, 31.62, 32.20 [33.85 and 33.93, bridged methylene carbons), 34.49, 37.23, 47.22, 48.62 (aliphatic carbons), 87.22 (menthyl carbon), 125.14, 125.68, 127.30, 127.80, 130.77, 131.38, 135.32 (aromatic carbons), 146.84, 146.91, 147.50, 148.77 (aromatic carbons directly attached to the oxygen atom).

2.6. Preparation of chiral p-tert-butyl-calix[4]arene iso-menthyl bisphosphite PdMeCl complex (3) and menthyl bisphosphite PdMeCl complex (6)

Chiral *p-tert*-butyl-calix[4]arene *iso*-menthyl bisphosphite (**L**^{1}) (107 mg, 10.5×10^5 mol) was treated with PdMeCl(COD) (28 mg, 10.5×10^5 mol) in 20 ml of toluene. The reaction mixture was stirred for 30 min. The solvent was evaporated and the residue was washed several times with petrol to obtain complex (**3**) as a colorless powder. Yield: 110 mg (82%); m.p. = 279–284 °C; *Anal.* Calc. for $C_{65}H_{93}O_6P_2PdCl$ (mol. wt.: 1174.4): C, 66.4; H, 7.9; Found C, 66.9; H 8.2%; ^{1}H NMR δ = 0.68 (d, 3H, J = 2.4 Hz), 0.72 (d, 3H, J = 2.6 Hz), 0.76 (dd, 3H, Pd–Me), 0.81 (d, 3H, J = 3.8 Hz) 0.84 (d, 3H, J = 3.2 Hz) 0.86 (d, 3H, J = 2.6 Hz), 0.92 (d, 3H, J = 4.2 Hz), 1.04–1.60 (m, 18H, *iso*-menthyl group + 18H, Bu^t + 18H, Bu^t), 3.38 (d, 2H, Hb_2, $Hb_{2'}$, J = 14.2 Hz), 3.44 (d, 2H, Hb_1, $Hb_{1'}$, J = 9.4 Hz), 4.57 (d, 2H, Ha_2, $Ha_{2'}$, J = 12.6 Hz), 4.70 (d, 2H, Ha_1, $Ha_{1'}$, J = 14.0 Hz), 4.98 (br s, H-methyne protons of the *iso*-menthyl group, *cis* to the methyl group), 6.04 (br s, H-methyne protons of the *iso*-menthyl group, *trans* to the methyl group), 6.80 (s), 6.86 (s), 6.88 (s), 7.19 (s) (aromatic protons of calixarene); ^{13}C NMR (100 MHz, $CDCl_3$) δ = 16.62, 16.74, 21.15, 21.42, 21.95, 22.17, 22.51, 22.82, 25.69, 26.23, 30.90, 30.99, 31.04, 31.25, 31.42, 31.60, 31.66, 31.84, 32.05, 33.80 (Pd–Me), 34.10, 34.11, 34.35, 37.49, 37.96, 42.87, 43.97, 48.64, 48.87 (aliphatic carbons), 82.15, 82.48 (*iso*-menthyl carbons), 124.63, 124.76, 124.97, 125.18, 125.58, 125.88, 126.66, 127.15, 127.71, 128.62, 128.94, 131.23, 131.68, 134.51, 135.11, 146.49, 146.68, 146.88, 147.11, 147.13, 147.51, 147.84 (aromatic carbons).

Complex (**6**) was synthesized by the same procedure as that described above for complex (**3**). Yield: 106 mg (79%); m.p. = 278–281 °C; *Anal.* Calc. for $C_{65}H_{93}O_6P_2PdCl$ (mol. wt.: 1174.4): C, 66.4; H, 7.9; Found C, 66.8; H 7.5%; ^{1}H NMR δ = 0.79 (d, 3H, J = 2.4 Hz), 0.80 (d, 3H, J = 3.2 Hz), 0.83 (d, 3H, J = 3.6 Hz), 0.84 (d, 3H, J = 2.8 Hz), 0.86 (d, 3H, J = 3.2 Hz), 0.87 (d, 3H, J = 3.4 Hz), 0.89 (dd, 3H, Pd–Me), 0.90 (s, 9H, Bu^t), 0.92 (s, 9H, Bu^t), 1.06–1.54 (m, 18H, menthyl group + 18H, Bu^t), 3.34 (d, 2H, Hb_2, $Hb_{2'}$, J = 8.2 Hz), 3.40 (d, 2H, Hb_1, $Hb_{1'}$, J = 12.0 Hz), 4.32 (br s, H-methyne protons of the menthyl group, *cis* to the methyl group), 4.57 (d, 2H, Ha_2, $Ha_{2'}$, J = 16.2 Hz), 4.60 (d, 2H, Ha_1, $Ha_{1'}$, J = 18.2 Hz), 5.75 (br s, H-methyne protons of the menthyl group, *trans* to the methyl group), 6.63 (s), 6.65 (s), 7.03 (s), 7.22 (s) (8H, aromatic protons of calixarene); ^{13}C NMR (100 MHz, $CDCl_3$) δ = 16.59, 16.68, 21.12, 21.40, 21.93, 22.16, 22.50, 22.80, 25.67, 26.20, 30.89, 30.98, 31.03, 31.23, 31.43, 31.58, 31.65, 31.82, 32.03, 33.84 (Pd–Me), 34.09, 34.09, 34.33, 37.48, 37.95, 42.85, 43.78, 48.63, 48.85 (aliphatic carbons), 82.14, 82.46 (menthyl carbons), 124.64, 124.75, 124.95, 125.18, 125.56, 125.87, 126.62, 127.12, 127.70, 128.59, 128.92, 131.21, 131.67, 134.50, 135.10, 146.47, 146.67, 146.86, 147.02, 147.14, 147.49, 147.81 (aromatic carbons).

2.7. Preparation of achiral p-tert-butyl-calix[4]arene bisphosphite–$PdCl_2$ complex (7) and $PtCl_2$ Complex (8)

The $PdCl_2$ complex (**7**) was prepared by the reaction of achiral *p-tert*-butyl-calix[4]arene bisphosphite (**L**^{3}) (105 mg, 10.5×10^5 mol) with [$PdCl_2$(COD)] (30 mg, 10.5×10^5) or $PdCl_2(PhCN)_2$ (40 mg, 10.5×10^5) in 20 ml of toluene and the reaction mixture was stirred for 2 h. The reaction mixture was worked up as described above for the synthesis of complex (**1**). The product was crystallized from dichloromethane:petrol (1:3) and few drops of acetone to obtain yellow crystals. Yield: 108 mg (87%); m.p. = 295–298 °C; *Anal.* Calc. for $C_{64}H_{78}O_6P_2PdCl_2(CH_3COCH_3)$ (mol. wt.: 1240.6): C, 64.9; H, 6.8; Found C, 65.3; H 7.2%; ^{1}H NMR δ = 1.08 (s, 36H, Bu^t), 1.21 (s, 18H, Bu^t), 3.45 (d, 2H, Hb_2, J = 3.2 Hz), 3.49 (d, 2H, Hb_1, J = 5.2 Hz), 4.57 (d, 2H, Ha_2, J = 15.2 Hz), 4.69 (d, 2H, Ha_1, J = 13.6 Hz), 6.82 (s), 6.90 (s) (8 H, aromatic protons of calixarene), 7.14 (d, J = 8.4 Hz), 7.18 (d, J = 7.8 Hz) (8H, aromatic protons); ^{13}C NMR (100 MHz, $CDCl_3$) δ = 31.13, 31.36, 34.18, 37.11 (aliphatic carbons), 118.27, 125.86, 126.25, 129.01, 132.45, 146.96, 147.59, 148.36, 148.71 (aromatic carbons).

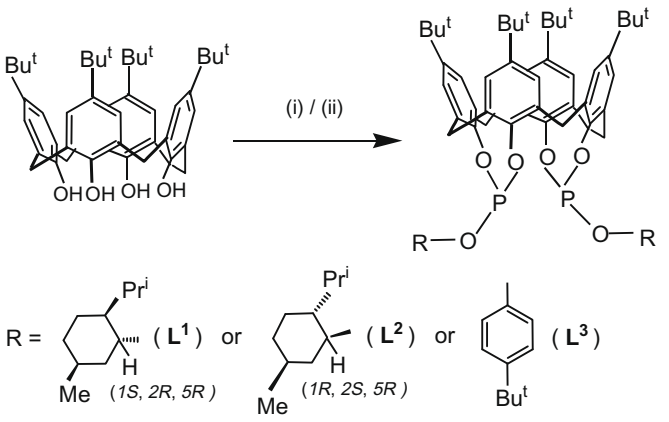
The analogous $PtCl_2$ complex (**8**) was prepared by the reaction of ligand (**L**^{3}) (105 mg, 10.5×10^5 mol) with [$PtCl_2$(COD)] (39 mg, 10.5×10^5 mol) in 20 ml of toluene and the reaction mixture was stirred for 2 h. The reaction mixture was worked up as described above for the synthesis of complex (**2**). The product was crystallized from chloroform:petrol (1:3) to obtain colorless crystals. Yield: 112 mg (84%); m.p. = 292–295 °C; *Anal.* Calc. for $C_{64}H_{78}O_6P_2PtCl_2(CHCl_3, H_2O)$ (mol. wt.: 1408.6): C, 55.4; H, 5.8; Found C, 56.1; H, 5.3%; ^{1}H NMR δ = 1.07 (s, 36H, Bu^t), 1.22 (s, 18H, Bu^t), 3.44 (d, 2H, Hb_2, J = 3.4 Hz), 3.51 (d, 2H, Hb_1, J = 5.4 Hz), 4.62 (d, 2H, Ha_2, J = 15.4 Hz), 4.75 (d, 2H, Ha_1, J = 14.2 Hz), 6.82 (s), 6.90 (s) (8H, aromatic protons of calixarene), 7.16 (d, J = 8.2 Hz), 7.19 (d, J = 8.4 Hz) (8H, aromatic protons); ^{13}C NMR (100 MHz, $CDCl_3$) δ = 31.14, 31.37, 34.15, 37.09 (aliphatic carbons), 117.98, 125.80, 126.06, 126.70, 128.96, 132.48, 146.86, 147.25, 148.48, 148.81 (aromatic carbons).

3. Results and discussion

3.1. Synthesis of calix[4]arene bisphosphites and their NMR spectra

Chiral *p-tert*-butyl-calix[4]arene *iso*-menthyl bisphosphite (**L**^{1}) and menthyl bisphosphite (**L**^{2}) have been synthesized in moderate yields (~30%) by the reaction of *p-tert*-butyl-calix[4]arene with (1S,2*R*,5*R*)-(+)-*iso*-menthyl or (1*R*,2*S*,5*R*)-(−)-menthyl phosphorodichloridites, respectively, in the presence of Et_3N. Similarly, the achiral *p-tert*-butyl-calix[4]arene bisphosphite (**L**^{3}) has been isolated from the reaction of *p-tert*-butyl-calix[4]arene with *p-tert*-butyl-phenyl-phosphorodichloridite (Scheme 1). Bisphosphites of the type **L**^{1}–**L**^{3}, in which a single phosphorus atom is bonded to two phenolic oxygen atoms of the calixarene framework, were first reported by Paceillo et al. [14] and Mahalakshmi et al. [19a,30].

The ^{31}P NMR chemical shift values for ligands (**L**^{1}–**L**^{3}) and their palladium and platinum complexes (**1**–**8**) are listed in Table 1. The



Scheme 1. (i) $ROPCl_2$, THF, Et_3N, 25 °C, 4 h ($\mathbf{L}^1$ or $\mathbf{L}^2$); (ii) $ROPCl_2$, toluene, Et_3N, 25 °C, 8 h ($\mathbf{L}^3$).

^{31}P NMR spectra of ligands ($\mathbf{L}^1$), ($\mathbf{L}^2$) and ($\mathbf{L}^3$) display singlets indicating the magnetic equivalence of the two phosphorus centres. The ^1H NMR spectra show two AB patterns for the methylene protons as would be anticipated for a cone conformation of the calix[4]arene framework [1a,19a] (see Section 3.3). The ^1H NMR spectrum of ligand ($\mathbf{L}^1$) shows a broad singlet at 4.55 ppm for the proton attached to the *iso*-menthyl carbon atom carrying the oxygen atom. This signal merges with the resonances arising from the methylene protons which exist outside the phosphite cage and away from the calixarene cavity. However, the ^1H NMR spectrum of ligand ($\mathbf{L}^2$) shows a broad singlet at 4.06 ppm for the proton attached to the menthyl carbon bearing the oxygen atom. This resonance is flanked by the resonances arising from the two sets of methylene protons which point towards and away from the calix[4]arene cavity. It is also noteworthy that two distinct signals are observed for the *tert*-butyl (CMe_3) protons of the calix[4]arene framework in both ($\mathbf{L}^1$) and ($\mathbf{L}^2$) because of the presence of the chiral *iso*-menthyl or menthyl group.

3.2. Palladium and platinum complexes of chiral and achiral p-tert-butyl-calix[4]arene bisphosphite ligands

The reaction of bisphosphite ligands ($\mathbf{L}^1$), ($\mathbf{L}^2$) and ($\mathbf{L}^3$) with one molar equivalent of $PdCl_2(COD)$ or $PdCl_2(PhCN)_2$ in THF or toluene gives, respectively, the complexes [$PdCl_2(\mathbf{L}^1)$] (**1**), $PdCl_2(\mathbf{L}^2)$ (**4**) and $PdCl_2(\mathbf{L}^3)$ (**7**) which are isolated as pale yellow solids. The analogous Pt complexes [$PtCl_2(\mathbf{L}^1)$] (**2**), [$PtCl_2(\mathbf{L}^2)$] (**5**) and [$PtCl_2(\mathbf{L}^3)$] (**8**) are prepared by the reaction of $PtCl_2(COD)$ with the ligands ($\mathbf{L}^1$), ($\mathbf{L}^2$) and ($\mathbf{L}^3$), respectively. The methyl palladium complexes [PdMeCl($\mathbf{L}^1$)] (**3**) and [PdMeCl($\mathbf{L}^2$)] (**6**) are obtained by the reaction of [PdMeCl(COD)] with the chiral bisphosphite ligands ($\mathbf{L}^1$) and ($\mathbf{L}^2$), respectively. These reactions are shown in Scheme 2.

The ^{31}P NMR chemical shifts for the palladium and platinum dichloride complexes (**1**), (**4**), (**7**) and (**8**) lie very much upfield to those of the free ligands (see Table 1). The ^1H NMR spectra of the complexes display four doublets for the methylene protons of the calix[4]arene framework. The *cis* stereochemistry around the palladium metal centre can be inferred from the far IR spectra which show two ν(Pd–Cl) bands for each of the complexes. The ^{31}P NMR spectra of the platinum complexes (**2**), (**5**) and (**8**) show large $^1J_{Pt-P}$ couplings (see Table 1), confirming the *cis* stereochemistry [18a,31]. The structures of the $PdCl_2$ complexes (**1**), (**4**) and (**7**) and the $PtCl_2$ complex (**8**) have been confirmed by single crystal X-ray diffraction analysis. The exclusive formation of *cis*-chelate complexes and the absence of oligomeric products (as shown by the ^{31}P NMR spectra of the reaction mixtures) is presumably due to the strong "*cis*-preference" exhibited by phosphite ligands in their palladium and platinum complexes, as pointed out by Pringle and coworkers [31].

The ^{31}P NMR spectra of the PdMeCl complexes (**3**) and (**6**) show an AB pattern because of the chemical non-equivalence of the two phosphorus nuclei. The ^{31}P chemical shifts lie in a region, which is in between those for the free ligands and the dichloride complexes (see Table 1). The $^2J_{P-P}$ coupling constants are 113.2 and 106.4 Hz, respectively, for the two complexes. The proton-coupled ^{31}P NMR spectrum of complex (**6**) shows a doublet of quartets for the downfield phosphorus resonance (centered at 113.5 ppm) because of further splitting by coupling with the protons of the methyl group attached to palladium. Hence the downfield resonance can be assigned to the phosphorus which is *trans* to the methyl group. The ^1H NMR spectra of these complexes (**3**) and (**6**) show two broad singlets {6.04 and 4.98 ppm for complex (**3**); 5.75 and 4.32 ppm for complex (**6**)} for the two different methyne protons of the *iso*-menthyl/menthyl carbon atoms directly attached to the oxygen atoms. Although the eight methylene protons of the calix[4]arene framework in the complexes (**3**) and (**6**) are magnetically non-equivalent, only four doublets are observed at room temperature.

3.3. X-ray crystallographic studies

The solid-state structures of complexes (**1**), (**4**), (**7**) and (**8**) have been determined by single crystal X-ray diffraction analysis. Details pertinent to data collection, structure solution and refinement are summarized in Table 2. Selected bond lengths and angles are given in Tables 3 and 4. The data are comparable to those observed for calix[4]arene bisphosphite–$PdCl_2$ complexes reported by Matt and coworkers [17]. There is a slight deviation from a square planar geometry around the metal in all these complexes, presumably because of the involvement of chlorine atom(s) in hydrogen bonding (see below).

The ORTEP plots of the molecular structures of the palladium dichloride complexes (**1**) and (**4**) are presented in Figs. 1 and 2, respectively. The crystal packing diagrams are shown in Fig. S1 (see Supplementary information). When viewed down the *c*-axis, one can clearly see a hexagonal shaped self-assembly of molecules of complexes (**1**) or (**4**) resulting in a hydrophobic channel surrounded by alkyl groups of the *iso*-menthyl and menthyl unit,

Table 1
The ^{31}P {^1H} NMR data for ligands ($\mathbf{L}^1$–$\mathbf{L}^3$) and their palladium and platinum complexes (**1**)–(**8**)[a]

Ligand	δ	Pd complex	δ	$\Delta\delta$	Pt complex[c]	δ	$\Delta\delta$

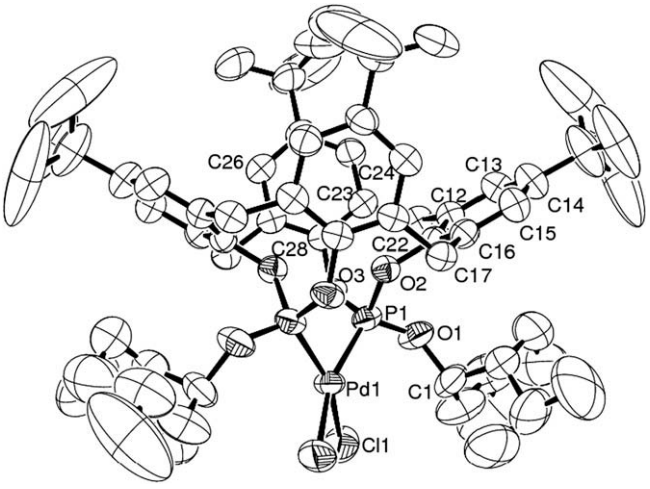

Fig. 1. ORTEP plot of calix[4]arene *iso*-menthyl bisphosphite–palladium dichloride complex (**1**). Only selected atoms are labelled and hydrogen atoms are omitted for clarity.

respectively. A significant difference in the hydrophobic channels of these two complexes is that in complex (**1**), the alkyl groups of the *iso*-menthyl unit surround the channel without any gaps but in complex (**4**), the alkyl groups of the menthyl unit surround the channel with discrete gaps. This difference may be due to the orientation of the *iso*-menthyl and menthyl subunits in the two complexes.

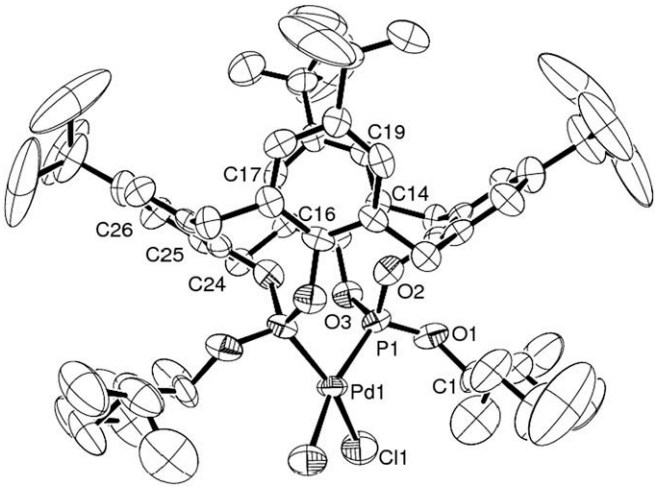

Fig. 2. ORTEP plot of calix[4]arene menthyl bisphosphite–palladium dichloride complex (**4**). Only selected atoms are labelled and hydrogen atoms are omitted for clarity.

The near perfect hexagonal shaped packing of molecules of complexes (**1**) and (**4**) in their crystal lattices arises because of hydrogen bonding interactions as shown in Fig. S2 (see Supplementary information) and Fig. 3, respectively. The crystal lattice of complex (**1**) features a bifurcated hydrogen bond involving Cl(1) and the *ortho*-aryl protons of the calix[4]arene back bone [Cl(1)–aryl proton H(24) distance = 2.936 Å, Cl(1)–aryl proton H(13) distance = 2.954 Å]. We also observed an intramolecular hydrogen bond between an oxygen and a methylene proton [O(1)···H(22B) methylene proton distance = 2.343 Å] (Fig. S2). In the structure of complex **4**, there is an intermolecular hydrogen bond between the chlorine atom and an *ortho*-proton of the calix[4]arene back bone [Cl(1)···H(1) aromatic proton distance = 2.576 Å]. In addition, two intramolecular hydrogen bonds, one between Cl(1) and a methyne proton (H19) of the menthyl unit and another between O(1) and the methylene proton H(13B) of the

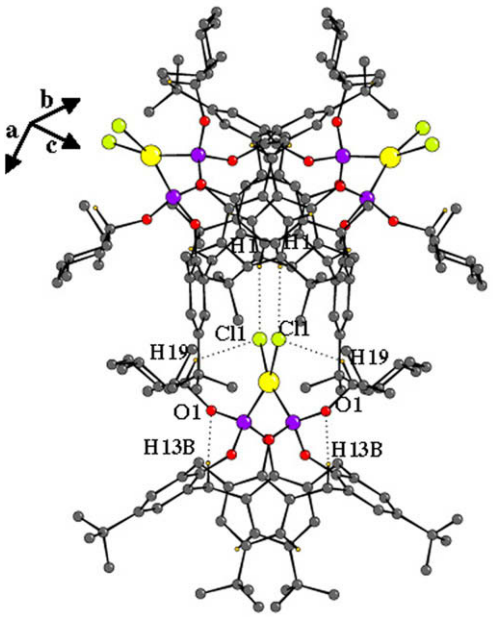

Fig. 3. A view of a crystal segment of palladium dichloride complex (**4**) showing the bifurcated intermolecular and intramolecular hydrogen bonding interactions.

calix[4]arene framework [Cl(1)···H(19) menthyl proton distance = 2.833 Å, O(1)···H(13B) distance = 2.322 Å] are observed (Fig. 3).

The $PdCl_2$ and $PtCl_2$ complexes (**7**) and (**8**) crystallize in the monoclinic C2/c space group and are isostructural. The ORTEP plots of the molecular structures of complexes (**7**) and (**8**) are shown in Figs. 4 and 5, respectively. The structural features are similar to those of the chiral *p*-*tert*-butyl-calix[4]arene *iso*-menthyl and menthyl palladium dichloride complexes (**1**) and (**4**) described above.

The packing of molecules of complex (**7**) in the crystal lattice shows a layer-like arrangement along the *b*-axis; the orientations of the two adjacent molecules are different from each other. Each molecule is surrounded by two other molecules connected by intermolecular hydrogen bonds formed between the chlorine atom and a methylene proton [Cl(1)···H(2A) distance = 2.867 Å], and also between the oxygen atom and alkyl proton of the *tert*-butyl group [O(3)···H(51A) distance = 2.694 Å]. There is also an intramolecular hydrogen bond formed between the oxygen atom and a methylene proton [O(6)···H(14B) distance = 2.311 Å] (see Fig. 6). In the crystal lattice of complex (**8**), each discrete molecule is surrounded by two other molecules and one solvent molecule. The observed intra- and intermolecular hydrogen bonds are shown in Fig. S3 (see Supplementary information). The relevant data are given in Table 5.

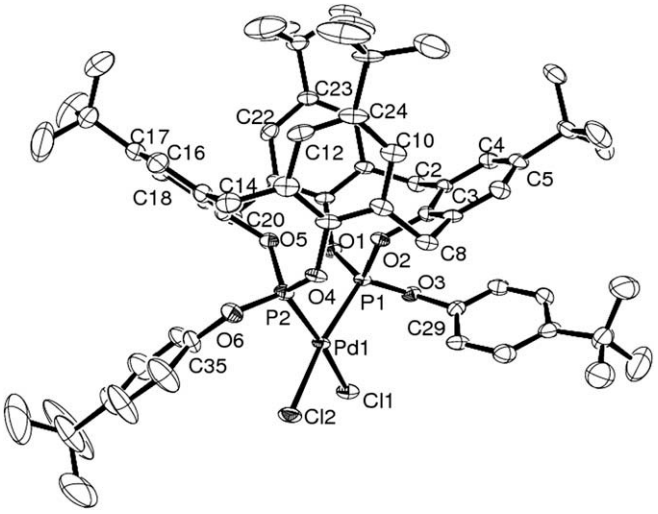

Fig. 4. ORTEP plot of calix[4]arene 4-*tert*-butyl-phenyl bisphosphite-palladium dichloride complex (**7**). Selected atoms are labelled and hydrogen atoms and solvent molecules are omitted for clarity.

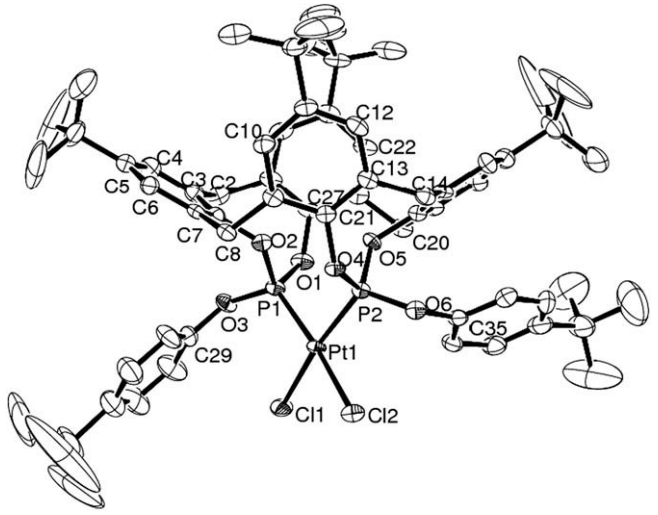

Fig. 5. ORTEP plot of calix[4]arene 4-*tert*-butyl-phenyl bisphosphite–platinum dichloride complex (**8**). Selected atoms are labelled and hydrogen atoms and solvent molecules are omitted for clarity.

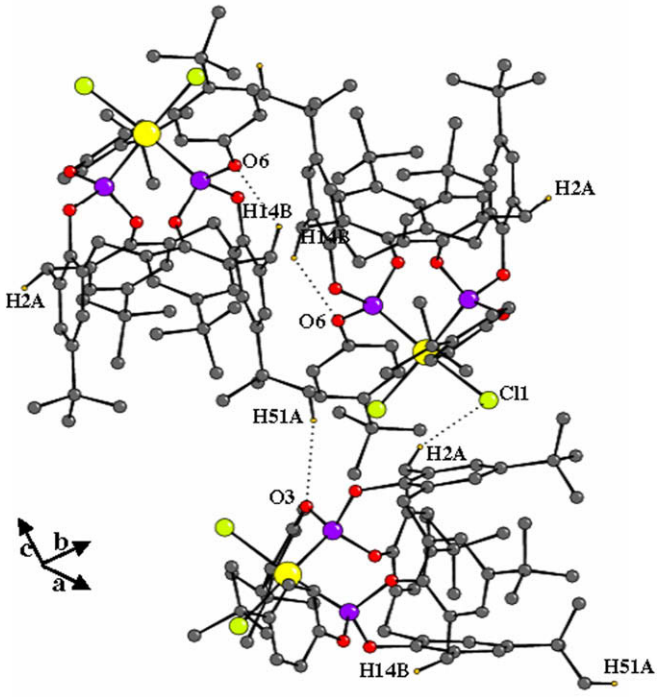

Fig. 6. A view of a crystal segment of palladium dichloride complex (**7**) showing the intra and intermolecular hydrogen bonding interactions.

The calix[4]arene framework in all these compounds (**1**), (**4**), (**7**) and (**8**) adopts a cone conformation. The conformation of the calix[4]arene backbone can be discussed in terms of either torsion angles or dihedral angles. The dihedral angles of the calix[4]arene aryl rings (A = A′ and B = B′) with the plane X of the four methylene carbon atoms{C17, C22, C17′ and C22′ for the complex (**1**) and C13, C24, C13′ and C24′ for complex (**4**)} are listed in Table S-1 (see Supplementary information). These data show that there is a distortion of the cone conformation in the two complexes. The torsion angles involving the bridging methylene carbon atoms and aryl ring carbon atoms for the complexes (**1**) and (**4**) are listed in Table S-2 (see Supplementary information). The sequence of signs for the two torsion angles ϕ and χ is found to be +−, +−, +−, +− and confirms the cone conformation for both the complexes. A comparison of the observed torsion angles ϕ and χ for the two palladium complexes (**1**) and (**4**) with those expected for an ideal cone conformation [90° and 90°, respectively] shows that there is a larger deviation for two aryl rings (larger torsion angles) and a smaller deviation for the other two aryl rings (smaller torsion angles). The two aryl rings with larger torsion angles are parallel with respect to each other; the other two aryl rings with smaller torsion angles are tilted from the mean plane X of the methylene carbon atoms. This type of conformation is known as a "flattened cone conformation" [32]. Similar results are observed for the palladium and platinum dichloride complexes, (**7**) and (**8**). The relevant dihedral angles and torsion angles are listed in Tables S-3 and S-4, respectively (see Supplementary information). These values indicate that the cone conformation is more flattened in complexes (**1**), (**4**), (**7**) and (**8**) than in the free calix[4]arene bisphosphites [19a,33].

Table 5
Hydrogen bonding parameters for complexes (**1**), (**4**), (**7**) and (**8**)

D–H···A	r(H···A) (Å)	r(D···A) (Å)	Angle (D–H···A) (°)

4. Conclusions

We have described the synthesis of new chiral and achiral bisphosphites anchored to a *p-tert*-butyl-calix[4]arene framework. These bisphosphites behave as chelating ligands in palladium(II) and platinum(II) complexes. These complexes provide examples of the presence of non-covalent interactions such as intermolecular C–H···Cl and C–H···O hydrogen bonds which lead to novel structural motifs in the solid state. These rigid chiral and achiral bisphosphites with hydrophobic cavities may have significant applications in homogeneous catalysis.

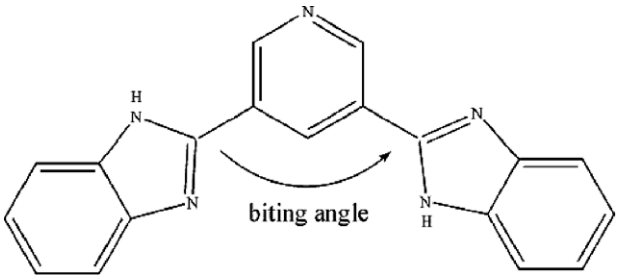


Scheme 1. Schematic view of pyridine-3,5-bis(benzimidazole-2-yl).

2. Experimental

2.1. Materials and analyses

All reagents and solvents were used directly as supplied commercially without further purification, except that the ligand (pbb) was prepared. Elemental analyses (C, H, and N) were determined with a Perkin–Elmer model 240 °C automatic instrument. Infrared spectra on KBr pellets were performed in a BRUKER EQUINOX–55 spectrometer in the range of 4000–400 cm^{-1}. ^1H NMR spectra were recorded using an INOVA–400 MHZ (Varian, America). Mass spectra were obtained with a JEOL HX–110 HF double focusing spectrometer operating in the positive ion detection mode. A Micro DSC III Thermal Activity Monitor (Setaram, France) was used to determine the power-time curves of *Escherichia coli* growth.

2.2. Syntheses

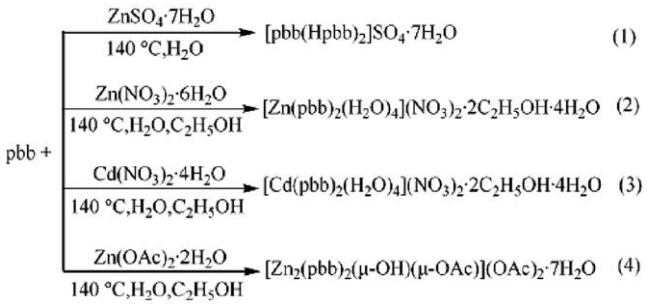
The formation of **1**, **2**, **3,** and **4** with the experimental conditions are shown in Scheme 2. Their syntheses are given in the sequel.

2.2.1. Preparation of the ligand

The ligand (pbb) was prepared from o-phenylenediamine and 3,5-pyridinedicarboxylic acid monohydrate by a modified literature method [11]. The product was a pale-yellow powder in 60% yield, mp > 280 °C. *Anal.* Calc. for $C_{19}H_{13}N_5$: C, 73.29; H, 4.21; N, 22.49. Found: C, 73.28; H, 4.18; N, 22.50%. IR (cm^{-1}, KBr): 3386 (s), 3185 (s), 2930 (s), 1602 (w), 1514 (w), 1437 (m), 1322 (w), 1279 (m), 1224 (w), 1118 (w), 1016 (w), 959 (w), 898 (w), 734 (s), 699 (m). MS (FAB): *m/z* (%) = 312.3 (pbb). ^1H NMR (ppm, DMSO): δ = 9.319 (s, 1H, 1-H), 9.426 (s,2H,2-H), 13.347 (s, 2H, 3-H), 7.682 (dd, 4H, 4-H), 7.281 (m, 4H, 5-H).

2.2.2. $[pbb(Hpbb)_2]SO_4 \cdot 7H_2O$ (**1**)

A mixture of pbb (31 mg, 0.1 mmol), $ZnSO_4 \cdot 7H_2O$ (29 mg, 0.1 mmol) and 10 mL H_2O was sealed in a 25 mL Telfon-lined stainless steel container, which was heated to 140 °C for 72 h. After cooling to room temperature at a rate of 2 °C per hour, well-shaped yellow block crystals of **1**, suitable for X-ray diffraction, were obtained. The final pH value of the mixture was about 5. Notably, **1** was obtained under the emergence of $ZnSO_4$. It has been confirmed that the existence of $ZnSO_4$ is required in this process, although the mechanism is not clear. *Anal.* Calc. for $C_{57}H_{57}N_{15}O_{12}S$ (1176.24): C, 58.20; H, 4.88; N, 17.86. Found: C, 58.20; H, 4.89; N, 17.88%. IR (cm^{-1}, KBr): 3745 (m), 3381 (s), 1596 (m), 1490 (w), 1429 (s), 1342 (m), 1312 (m), 1275 (m), 1254 (m), 1137 (w), 1015 (w), 955 (w), 896 (w), 857 (w), 742 (s), 616 (m).



Scheme 2. The formation of **1**–**4** together with the experimental conditions.

2.2.3. $[Zn(pbb)_2(H_2O)_4](NO_3)_2 \cdot 2C_2H_5OH \cdot 4H_2O$ (**2**)

A mixture of pbb (31 mg, 0.1 mmol), $Zn(NO_3)_2 \cdot 6H_2O$ (30 mg, 0.1 mmol) and 10 mL water–ethanol (1:1) was sealed in a 25 mL Telfon-lined stainless steel container, which was heated to 140 °C for 72 h. Slow cooling of the reaction mixture to room temperature gave light-yellow block crystals in ca. 60% yield. *Anal.* Calc. for $C_{42}H_{54}N_{12}O_{16}Zn$ (1048.34): C, 48.12; H, 5.19; N, 16.03. Found: C, 48.11; H, 5.14; N, 16.02%. IR (cm^{-1}, KBr): 3443 (s), 1764 (w), 1628 (m), 1481 (m), 1385 (s), 1224 (m), 1025 (w), 904 (w), 826 (w), 743 (m), 693 (w).

2.2.4. $[Cd(pbb)_2(H_2O)_4](NO_3)_2 \cdot 2C_2H_5OH \cdot 4H_2O$ (**3**)

The preparation of **3** was similar to that of **2** except that $Cd(NO_3)_2 \cdot 4H_2O$ (0.1 mmol) was used instead of $Zn(NO_3)_2 \cdot 6H_2O$. Pale-yellow block crystals were obtained in ca. 66% yield. *Anal.* Calc. for $C_{42}H_{54}N_{12}O_{16}Cd$ (1095.37): C, 46.05; H, 4.97; N, 15.34. Found: C, 46.04; H, 4.96; N, 15.36%. IR (cm^{-1}, KBr): 3467 (s), 1763 (w), 1623 (m), 1478 (m), 1423 (m), 1383 (s), 1225 (w), 1123 (w), 1045 (w), 961 (w), 901 (w), 826 (w), 735 (m), 690 (m).

2.2.5. $[Zn_2(pbb)_2(\mu\text{-}OH)(\mu\text{-}OAc)](OAc)_2 \cdot 7H_2O$ (**4**)

The preparation of **4** was similar to that of **2** except that $Zn(OAc)_2 \cdot 2H_2O$ (0.1 mmol) was used instead of $Zn(NO_3)_2 \cdot 6H_2O$. Pale-yellow block crystals were obtained in ca. 48% yield. *Anal.* Calc. for $C_{44}H_{50}N_{10}O_{14}Zn_2$ (1073.68): C, 49.22; H, 4.69; N, 13.04. Found: C, 49.24; H, 4.69; N, 13.10%. IR (cm^{-1}, KBr): 3121 (s), 1591 (s), 1482 (m), 1430 (m), 1332 (m), 1277 (m), 1227 (w), 1184 (w), 1132 (w), 1051 (w), 1021 (w), 960 (w), 932 (w), 903 (w), 847 (w), 744 (s), 699 (s), 614 (w).

2.3. X-ray crystallography

Diffraction experiments for **1**, **2**, **3,** and **4** were carried out with Mo Kα radiation using a BRUKER SMART APEX CCD diffractometer at 293 (2) or 296 (2) K. The structures were solved by direct methods and refined with the full-matrix least-squares technique on F^2 using the SHELXS–97 and SHELXL–97 [12] programs. All non-hydrogen atoms were refined anisotropically. A summary of the crystallographic data and structure refinement is shown in Table 1, selected bond lengths and angles of the complexes are listed in Table 2, and possible hydrogen bond geometries are given in Table 3.

2.4. Biological activity tests

Bacteria (*E. coli*, *Staphylococcus aureus,* and *Bacillus subtilis)* and mould (*Glomerella cingulata*, *Alternaria solani,* and *Monilinia fructicola)* strains were provided by the College of Life Sciences at Northwest University (China). The antimicrobial activities of pbb and its complexes were examined by the bacteriostatic ring test method. The antibacterial activity was measured as the diameter of the inhibitory zones in the soft agar layer stained after 24 h incubation at 37 °C, while inhibition again mould after 72 h at 28 °C. An inhibitory zone with a diameter less than 6 mm corresponds to lack of activity (6 mm is the diameter of the spot). Control experiments with solvents show that the solvents have no activity. Selected duplicates were run to ensure reproducibility.

Microcalorimetry is an important tool for measuring metabolic activities of cells and biological tissues [13]. Here, the power-time curves for growth of *E.* coli at 37 °C were determined in the presence of pbb and its complexes by using a microcalorimetric method. In the exponential growth phase of *E. coli*, the thermal power given out by the microbe and time are related with the following equation [14]:

$$\ln P_t = \ln P_o + kt$$

where P_t and P_0 are the thermal power at time t and t_0, respectively, k is the growth rate constant. Using the experimental data, P_t and t obtained from the thermal power-time curves under various concentrations of the samples, the corresponding growth rate constant k can be calculated from linear regression analysis. Under the same cultivation conditions, the experimental results (the thermal power-time curves) display high repeats.

3. Results and discussion

The pale-yellow powder pbb is obtained in good yield. In order to confirm the identity of the product, the MS and ^{1}H NMR spectra of pbb were measured, and the spectra are given in Fig. S1.

3.1. Description of structures

3.1.1. Crystal Structure of **1**

The single-crystal X-ray structural analysis of complex **1** reveals a H_2SO_4 solvate of pbb, in which three pbb molecules, eight water molecules and one SO_4^{2-} ion are observed. As shown in Fig. 1a, two of the three pbb molecules are protonated, and intramolecular dihedral angels between the benzimidazolic rings are 9.04, 12.31, and 3.92 °. The bite angles of the three rings are 125.97, 133.69, and 124.56 °, respectively. The above data suggest that the middle pbb molecule may be potentially affected by the other two via π–π stacking interactions. Notably, there are O–H···O hydrogen bonds and weak O···O interactions in the unit of **1**, forming 1D chains in which three six-membered rings and one four-membered ring units are alternately arranged (Fig. S2).

The most striking feature of these chains is that the six-membered rings formed by free water molecules adopt a chair conformation (Fig. 1b), of which four oxygen atoms are located in the same geometry plane (O···O···O angles: 71.372° and 108.628°) and the remaining two oxygen atoms are symmetrically arranged on the bilateral sides of the plane (the dihedral angel between the plane O1A, O2, O3 and the plane O1A, O2, O1 is 49.39°). Here, the hexameric water cluster is unlike the previously published hexamer clusters [1b,15]. In the inter-$(H_2O)_6$ rings, water–water connections have an average O···O distance of 2.853 Å, which is very close to the corresponding value observed in liquid water (2.85 Å) [16] and longer than corresponding value of 2.759 Å in hexagonal ice (I_h) [17]. The emergence of a chair conformation, to some extent, may have a significant effect on the construction of a stable supramolecular network. Further, each $(H_2O)_6$ subunit and two $(H_2O)_3$ subunits are associated to form a centrosymmetric $(H_2O)_{12}$ cluster by hydrogen-bonds. Two dangling trimeric water molecules at the periphery are situated alternately right and left of the $(H_2O)_6$ subunit, so as to associate with the SO_4^{2-} ion. A closer view of the $(H_2O)_{12}$ cluster illustrates that each water monomer, except for O8, acts as both a hydrogen-bonding donor and acceptor. In the supramolecular $(H_2O)_{12}$ morphology, the O···O distances range from 2.592 to 3.079 Å, resulting in an average O···O distance of 2.800 Å, which is very close to those observed in liquid water (2.80 Å) [18] and comparable to the corresponding value in the ice phase (2.77–2.84 Å) [19]. However, the O···O···O angles vary widely (ca. 71.439–131.023°) with an average of 102.447°, considerably deviating from the preferred ideal tetrahedral geometry of water. Compared with other water morphologies reported recently [20], our observation of $(H_2O)_{12}$ clusters in such a water framework may be due to its different interactions with surrounding water molecules and the SO_4^{2-} ions. The present association mode of the $(H_2O)_{12}$ cluster, comprising of a chair conformation $(H_2O)_6$ ring core and the additional two dangling trimeric water clusters, in **1** is rather unusual.

Moreover, 1D supramolecular chains are linked with pbb molecules through N···O hydrogen-bonding to give rise to 2D layers (Fig. S3). The adjacent layers are connected further to afford a 3D supramolecular structure, in which face-to-face π–π stacking interactions between the aromatic rings (centroid-to-centroid distances: 3.531, 3.598, 3.616, and 3.658 Å) are dominant.

3.1.2. Crystal structures of ***2*** and ***3***

Complexes **2** and **3** are isomorphous, and thus only the structure of **2** is described here in detail. Complex **2** crystallizes in the triclinic space group $P\bar{1}$ and is composed of a mononuclear unit. The coordination geometry around each Zn^{II} atom can be attributed to a slightly distorted octahedron with four water molecules in the equatorial sites and two nitrogen atoms from pyridine rings of two pbb molecules in the axial positions (Fig. 2a). The Zn–N (2.158 Å) and Zn–O (2.112 and 2.098 Å) bond lengths are in the normal range and are similar to those of mononuclear Zn^{II} complexes reported in literature [21]. The biting angle of pbb in **2** is 123.27°, and the intramolecular dihedral angel between the benzimidazole groups is 4.87°, which are different from the corresponding values in **1**. As expected, hydrogen-bonding and π–π stacking interactions are also present, arranging and stabilizing of the

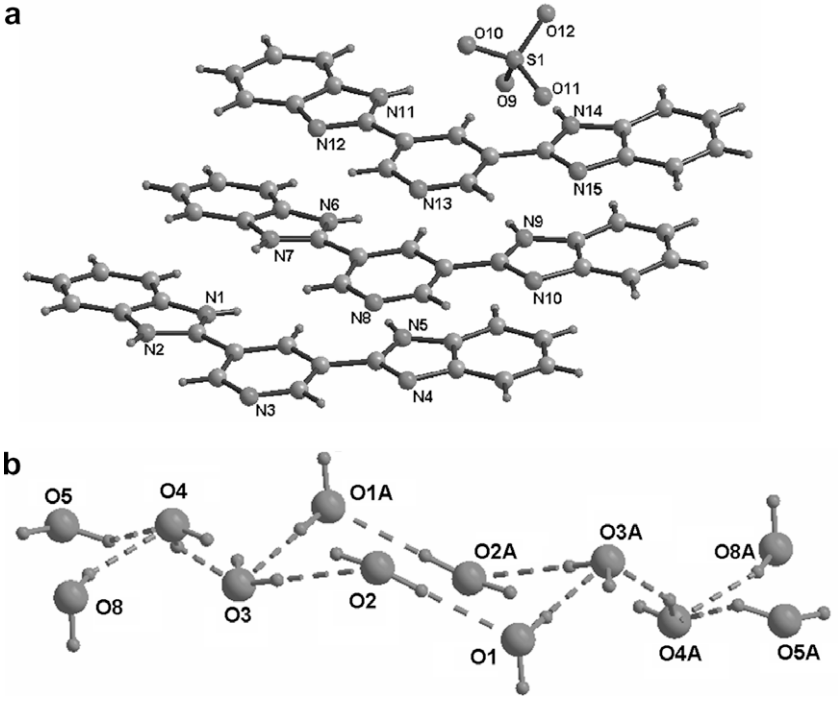

Fig. 1. (a) Molecular structure of **1** (the water molecule is omitted for clarity); (b) Perspective view of the discrete $(H_2O)_{12}$ cluster containing a chair conformation. Dash lines show the hydrogen bonding between water molecules.

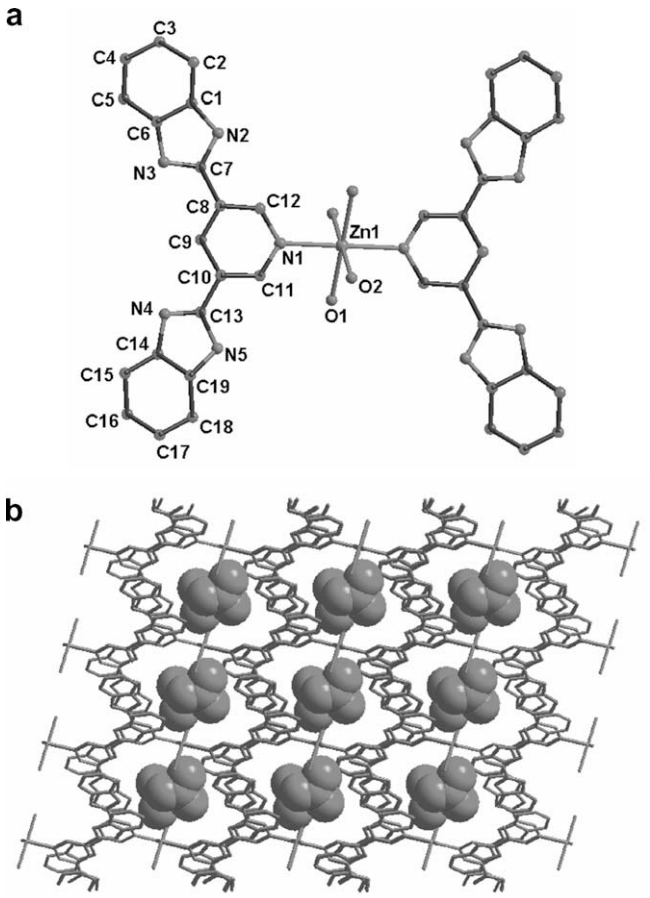

Fig. 2. (a) View of the coordination environment of Zn(II) in **2**; (b) 3D network of **2** containing 1D open channels encapsulating NO_3^- ions.

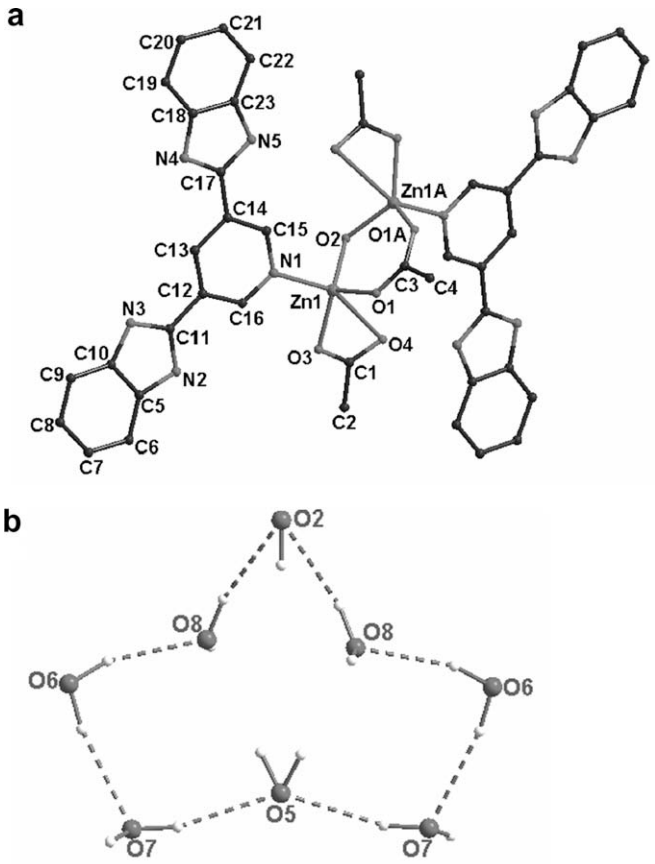

Fig. 3. (a) Coordination environment of Zn(II) in **4**; (b) Perspective view of the crown-like ring formed by hydrogen bonding.

supramolecular framework of **2**. There exist intense O–H···O interactions between the coordinated water and the free water, forming 1D chair chains (Fig. S4). The range of the O···O distances is approximately from 2.690 to 2.791 Å. It is interesting that four oxygen atoms (O2, O2A, O7, and O7A) are arranged in one plane, whilst O8 and O8A are symmetrically arranged on both sides of the plane. That is, similar to **1**, a chair conformation is built by these six oxygen atoms in **2**. The dihedral angel between the plane O1A, O2, O3 and the plane O1A, O2, O1 is 52.43°. Further, the 1D chair chains are connected into a 2D layered structure via weak N···O interactions (2.748 and 2.786 Å) and strong π–π stacking interactions between the two imidazole rings (minimum centroid-to-centroid distance: 3.512 Å) (Fig. S5). Adjacent 2D layers are further linked by hydrogen bonds (N2–H2···O3 2.999 Å) to give a 3D structure with 1D open channels encapsulating NO_3^- ions (Fig. 2b).

3.1.3. Crystal structure of *4*

Unlike **2** and **3**, the basic structure of **4** consists of a binuclear unit (Fig. 3a). The Zn^{II} center in **4** is four-coordinate with a distorted tetrahedral geometry, and is coordinated by one nitrogen atom in the pyridine ring of pbb and one oxygen atom in an acetate group. Zn1 and Zn1A are linked by one μ_2-OH (O2) and one μ_2-OAc (O1, O1A) with a Zn1···Zn1A distance of 3.215 Å. The bite angle of pbb in **4** is 123.55° and this is similar to that found in **2**. However, the intramolecular dihedral angels between the benzimidazole groups in **4** are 2.60°, which is very different to those of **1** and **2**. The bond distances of Zn–N and Zn–O in **4** are shorter than those in **2**, which may be as a result of the different coordination environment of Zn^{II}. Similar to **2**, there also exist rich hydrogen-bonding and strong π–π stacking interactions in **4**. A 1D chain (Fig. S6) is obtained due to hydrogen bonding interactions (O7–H7···O3 2.862, O7–H7···O5 2.751 Å) between three lattice water molecules and the oxygen atoms of the acetate groups. Interestingly, free water and the bridge oxygen (O2) are associated by hydrogen bonding to form a crown-like ring, as shown in Fig. 3b. In the eight-membered ring, the O···O distances fall in the range 2.696–2.868 Å, with an average of 2.768 Å, which is very close to the corresponding value of 2.759 Å in ice I_h [17], but is shorter than those observed in containing-water rings [16a,22]. This might be attributed to its different modes of connectivity with the surrounding water molecules. Furthermore, these rings link adjacent 1D chains to give rise to a 2D layered supramolecular structure (Fig. S7). Strong face-to-face π–π stacking interactions (minimum centroid-to-centroid distance 3.517 Å) contribute to the stabilization of the 3D supramolecular network of **4**. Additional hydrogen bonds involve the coordinated/uncoordinated carboxylate oxygen atoms, uncoordinated nitrogen atoms and free water molecules.

3.2. Biological results and discussion

3.2.1. Inhibitory zone test method

The antimicrobial activities of pbb and its complexes (**2**, **3**, and **4**) against bacteria (*E. coli*, *S. aureus*, and *B. subtilis*) and mould (*G. cingulata*, *M. fructicola*, *A. solani*) were examined by the inhibitory zone test method. The selected results obtained by this method are shown in Fig. 4. In this model, it could turn out that the samples have some antibacterial activity against the selected strains, the diameter of the inhibitory zone ranges from 7 to 25 mm. Inhibition

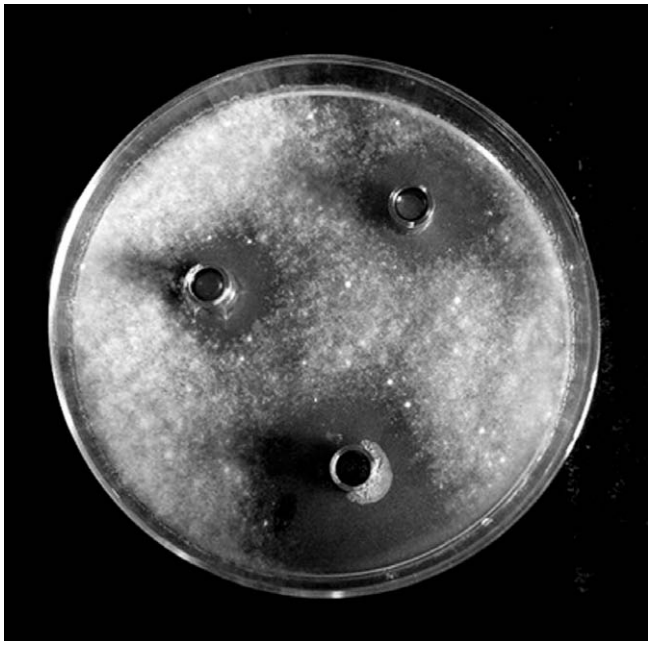

Fig. 4. Effect of concentrations of **2** on the growth of *Alternaria solani*: top left—2.5 μg mL^{-1}; top right—5 μg mL^{-1}; bottom—7.5 μg mL^{-1}.

again mould was observed clearly, whilst when the moulds were replaced by bacteria, there was a general decrease in activity. The ability of the samples to inhibit growth of the tested strains is listed in Table 4. From the viewpoint of the test, four samples exhibit only poor activity against *E. coli* and *S. aureus*, but an inhibition ring with a diameter of 7–8 mm against *B. subtilis* was found. Comparatively, it seems that the germproof ability of the samples against mould is superior to that against bacteria. However, different strains result in a different antibacterial effect of the samples. The average inhibitive ring diameters are, respectively, 21 mm (*G. cingulata*), 13 mm (*M. fructicola*) and 24 mm (*A. solani*). In addition, the antibacterial activity of pbb and its complexes against the same strain give distinctness. The ligand pbb presents optimal antibacterial activity versus *G. cingulata* and *A. solani* whereas **2–4** have good antibacterial activity against *M.* fructicola and are slightly active against *B. subtilis*.

These results indicate that pbb and its complexes possess selective antimicrobial properties for the tested objects. That is, they maybe possess higher antimicrobial activities against mould than bacteria. Consequently, pbb and its complexes are expected to have higher special bio-activity through further survey.

3.2.2. Microcalorimetric method

On the other hand, the antimicrobial activities of pbb and **2–4** were also investigated by the microcalorimetric method. Take *E. coli* as an example. Their partly thermal power-time (p–t) curves at 37 °C are shown in Fig. 5. All the curves are similar in shape,

Table 4
Biological results[a]

Sample	pbb	2	3	4
Escherichia coli	–	–	–	–
Bacillus subtilis	+	+	+	+
Staphylococcus aureus	–	–	–	–
Glomerella Cingulata	++	+	+	+
Alternaria Solani	++	+	+	+
Monilinia fructicola	+	++	++	++

[a] –, weak or no inhibition; +, inhibition; ++, strong inhibition.

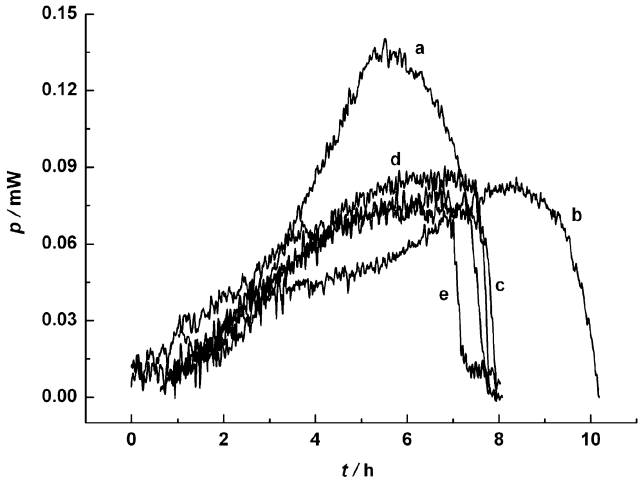

Fig. 5. Power–time curves of *E. coli* at 37 °C under different conditions in: (a) blank; (b) pbb, c = 2 μg mL^{-1}; (c) **2**, c = 2 μg mL^{-1}; (d) **3**, c = 5 μg mL^{-1}; (e) **4**, c = 3 μg mL^{-1}.

which testifies the good reappearance using this method. However, the thermal powers in the growth phase for *E. coli* are reduced evidently in the presence of pbb or its complexes. This result shows that the samples (pbb, **2**, **3**, and **4**) can inhibit the growth of *E. coli*.

According to the p–t curves, the corresponding growth rate constant k can be calculated from linear regression analysis. The k versus c curves of pbb and **2–4** were obtained, as illustrated in Fig. 6. The k value is ca. 0.83 h^{-1} when the concentration of the samples is 0 μg mL^{-1}. It can be seen that the k values clearly decrease due to the addition of the samples. The results can be described that pbb and its complexes exhibit good activities against *E. coli*. In the concentration range 2–100 μg mL^{-1}, the k values increase, then decrease. Therefore it may be predicted that the concentration of the samples is important to the antibacterial action [23]. What is more, one concentration peak value c_p can be observed in every k–c curve. It is clear that the c_p values of **2–4** are less than that of pbb. It could be deduced that, under the same conditions, the antibacterial actions of the complexes against *E. coli* are superior to that of the ligand. That means the presence of metal ions has improved the antibacterial activity of ligand. Accordingly, we believe that this work may contribute basic information to the further

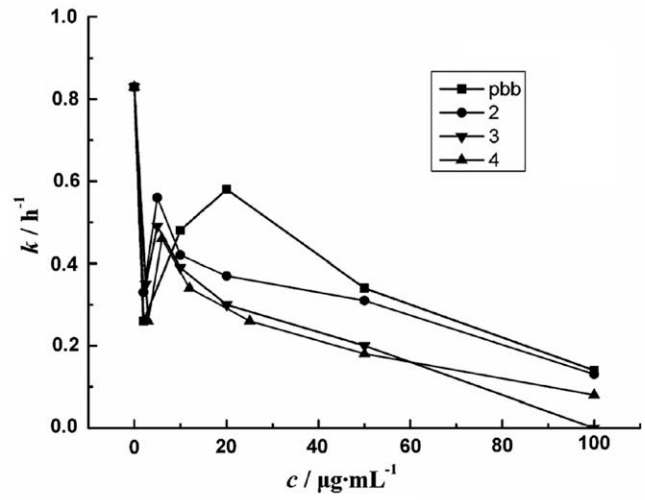

Fig. 6. The k–c curves of *E. coli* at 37 °C with different concentrations of pbb, **2**, **3**, and **4**.

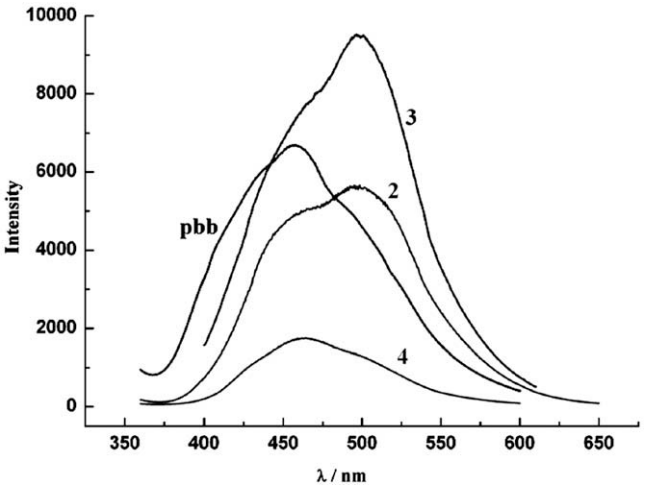

Fig. 7. Solid-state fluorescence emission spectra of pbb, **2**, **3**, and **4** at room temperature.

application of pbb and its complexes in the field of biological chemistry.

3.3. Fluorescent properties

The solid-state fluorescent properties of pbb and complexes **2–4** were investigated at room temperature (Fig. 7). Free pbb exhibits an intense emission peak at 458 nm upon excitation at 320 nm. The emission should be assigned to the intraligand π–π^* transitions. Excitation at 300 nm leads to a fluorescent emission band at about 465 nm for **4**. The emission spectra of **2** and **3** show a main peak at 498 nm (λ_{ex} = 305 nm) and 497 nm (λ_{ex} = 340 nm), respectively. It can be seen that complexes **2–4** clearly exhibit a red-shift with respect to free pbb. We tentatively assign it to a ligand-to-metal charge transfer (LMCT) [1g]. The differences of the peak positions may be considered to be a result of the dissimilar coordination of the metal centers because the emission behavior is closely associated to the metal ions and ligands around them [1d]. These complexes may be good candidates for stable fluorescent materials.

4. Conclusion and perspectives

In this paper, we have successfully synthesized a new ligand, pbb, and four of its complexes with different architectures and properties. It is worth mentioning that a rarely known discrete $(H_2O)_{12}$ cluster, with a chair conformation, and a crown-like eight-membered ring have been observed in **1**–**4**. These results indicate that these complexes enrich the supramolecular chemistry of organic aromatic derivatives. Our studies also show that hydrogen-bonding, π–π stacking interactions and weak interaction between atoms play a crucial role in connecting the low-dimensional units into high-dimensional supramolecular structures. Importantly, the strong fluorescent properties and the selective bioactivity of pbb and **2**–**4** make them excellent candidates for potential photoactive materials and bio-inhibitors. Further studies will focus on the construction of new metal-organic coordination polymers from pbb, and their bioactivities.

Scheme 1. Synthesis of the new complexes and the *N*-benzoyl thiourea derivatives used in this study.

The new mononuclear complexes were obtained in moderate to good yields as yellow microcrystalline solid products, which are stable under atmospheric conditions. Their structures were confirmed by elemental analysis, IR spectroscopy as well as ^{1}H and ^{13}C NMR spectroscopy and X-ray diffraction.

The coordination of the *N*-benzoyl thiourea derivatives in the deprotonated form was confirmed by the disappearance of the ν_{NH} frequency in the IR spectra of the Pd(II) complexes, which suggests the absence of the NH hydrogen located between the carbonyl and the thiocarbonyl groups of the benzoyl thioureic moiety, information that is further supported by ^{1}H NMR spectroscopy. The formation of the *ortho*-metallated mononuclear complexes can be confirmed readily by ^{1}H NMR spectroscopy where a pattern specific to 1,3,4-substitution of an aromatic ring can be seen as two doublets (H-2, H-3, $^3J_{H2,H3} = 8.4$ Hz) and a doublet of doublets (H-6, $^4J_{H2,H6} = 2.4$ Hz).

Also, the ^{1}H NMR spectra indicate the presence of only one isomer in solution (one set of signals) for all the prepared complexes, though it is possible for the complexes to exist as a mixture of two isomers with the sulfur atom of the *N*-benzoyl thiourea ligand in a *trans* or *cis* position to the nitrogen atom of the imine group of the Schiff base ligand. This information is supported by X-ray diffraction studies that showed only one isomer in the solid state for the complexes isolated as single crystals.

The ^{13}C NMR spectra show all the expected signals. The shift of the signals ($\Delta\delta \sim 13$ ppm) due to the imine and C-5 carbon atoms are consistent with the existence of a Pd–N and a Pd–C-5 bond. This deshielding effect caused by Pd bonding ($\Delta\delta = 4$–9 ppm) is also visible for the *ortho* positions with respect with the metallated position (C-4, C-6). In the case of the benzoyl moiety of the *N*-benzoyl thiourea derivative, coordination to the metal center leads to a deshielding of C-1′ ($\Delta\delta = 5$ ppm) and *para* C-4′ ($\Delta\delta = 2$ ppm), as compared with the free ligand. The signals corresponding to C=O and C=S undergo relatively large downfield and upfield chemical shifts of $\Delta\delta = 7$ and 6 ppm, respectively. This behaviour is similar to that observed for simple Pd(II) complexes with other *N*,*N*-dialkyl-*N*′-aroyl or acyl thiourea derivatives [13].

It is interesting to note that for the complexes **2–6a** the signals corresponding to the alkyl groups from the $N(Alk)_2$ moiety are not magnetically equivalent, both in the ^{1}H and ^{13}C NMR spectra. This is due to a hindered rotation about the C–$N(Alk)_2$ bond, which in turn can be explained through the conjugation between the amine and the Pd containing ring.

2.2. Structures

Single crystals of **2a**, **10a** and **13a** suitable for analysis by X-ray diffraction were obtained from a mixture of dichloromethane and ethanol (ca. 1/1 v/v) at −25 °C. Complex **13a** crystallised with two independent molecules in the structural unit. The crystallographic data are collected in Table 1, while selected bond lengths and angles for all three complexes are presented in Table 2.

The molecular structure of **2a** is shown in Fig. 1. The palladium atom is surrounded by one sulfur atom and one oxygen atom of the *N*-benzoyl thiourea ligand, one aromatic carbon atom (metallated phenyl ring) and one nitrogen atom (imine group) in an approximatively square-planar arrangement, with the sulfur atom located *cis* to the nitrogen atom of the imine group. The corresponding chelate ring around the Pd centre is essentially planar with a maximum deviation from the mean plane of 0.040 Å. However, while the metallated phenyl ring is almost coplanar with respect to the mean plane, the unmetallated ring of the imine ligand is twisted by 37.7° with respect to the core plane. The phenyl ring of the benzoyl group from the *N*,*N*-diethyl-*N*′-benzoyl thiourea ligand is also twisted by 32.9° with respect to the mean plane.

The Pd–Pd distance between two neighbouring molecules is 8.2 Å, precluding any Pd–Pd interactions. The Pd–C and Pd–N bond lengths are comparable with the values reported for similar *ortho*-palladated complexes with Schiff bases, while the Pd–O and Pd–S bond lengths are very well situated between the two values found for the simple *cis* complex of Pd(II) with *N*,*N*-diethyl-*N*′-benzoyl thiourea, which are 2.10 and 1.99 Å for the Pd–O bonds and 2.215 and 2.31 Å for the Pd–S bonds [14].

Complex **10a** (Fig. 2) crystallised with the same square-planar arrangement around the palladium atom; indeed the bond lengths and angles for the central core are all very similar to those found in

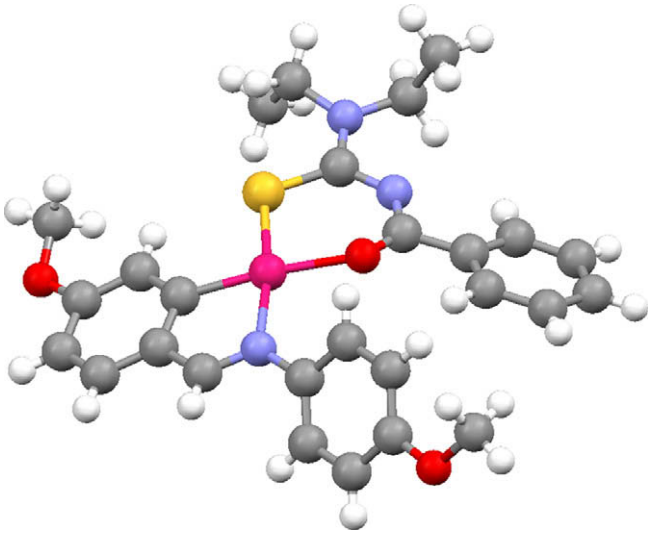

Fig. 1. The molecular structure of **2a**.

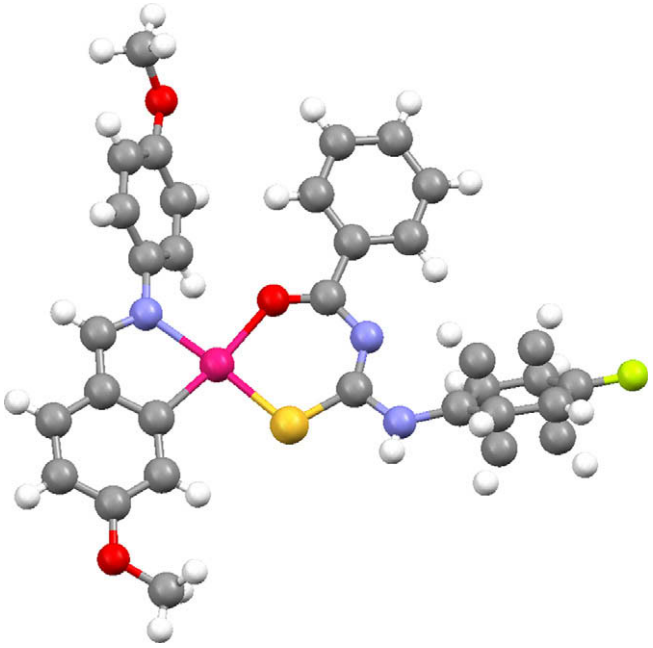

Fig. 2. The molecular structure of **10a**.

2a. The same orientation with respect to the core plane was found for the unmetallated ring of the imine ligand, which is twisted by 54.2°, a larger value when compared to **2a**. The phenyl ring of the benzoyl group from the *N*-benzoyl thiourea ligand is also twisted in respect to the core plane by 14.2°, a smaller value compare to that found for **2a**. An interesting feature of this complex is the two possible configurations adopted by the *p*-F-phenyl ring of the *N*-benzoyl thiourea ligand, with a twist of 73.6°, each with 50% probability as revealed by the site occupancy factors. In both cases there is a twist of this ring by 49.4° and 57.2° with respect to the core plane. Another factor that contributes to the crystal packing of **10a** are intermolecular –C–H···F–C– interactions, found between the fluorine atom of the *N*-benzoyl thiourea ligand and the methoxy group of the metallated ring of the imine ligand. The measured H···F distance is 2.50 Å, which is smaller than the sum of the van der Waals' radii of fluorine and hydrogen of 2.67 Å (the van der Waals' radius of fluorine is 1.47 Å)[15].

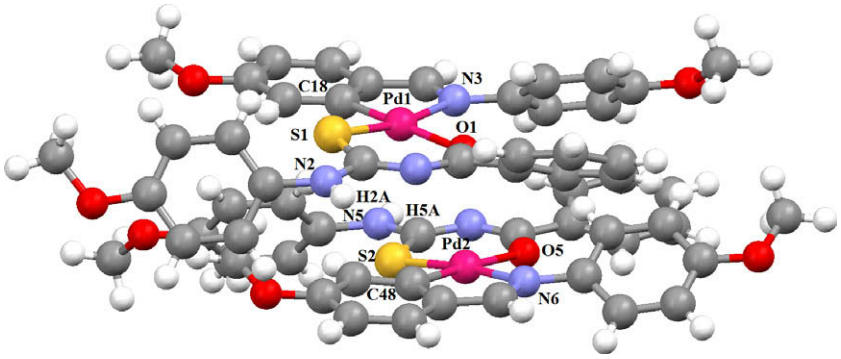

Fig. 3. The molecular structure of **13a**.

Complex **13a** crystallises in the monoclinic crystal system, group *P2*(1)/*c*, as a dimer (Fig. 3). The crystal structure of this compound shows Pd(II) in a square-planar environment bound to the imine ligand in an *ortho*-metallated fashion and chelated to the *N*-benzoyl thiourea derivative with the same coordinated atoms (one aromatic C atom (metallated ring), one N atom (imine group), one O atom (carbonyl group) and one S atom (thiocarbonyl group)) as found for **2a** and **10a**. The two five- and six-membered chelate rings are almost co-planar with the metallated ring of the imine ligand while the unmetallated ring is twisted in respect to the core plane by 34.9° for one molecule, and by 36.3° for the second.

For this compound the maximum deviation from the mean plane is 0.063 and 0.047 Å for Pd_1 and Pd_2, respectively. In this case, the complexes are arranged so that one sits over another with a short Pd–Pd distance of 3.92 Å. This distance is greater than twice the van der Waals' radius of Pd. Additionally, within the dimer the Pd···Pd vector deviates from orthogonality to the coordination plane (25° angle with the plane normal) and so the relative disposition of the complexes is not felt to be due to any intermolecular metal–metal interaction. The C–O and C–S bond lengths of the *N*-benzoyl thiourea ligand in **13a** are longer than those found in the free ligand (1.231 and 1.659 Å, respectively) while the N–C(S) and N–C(O) bond lengths are shorter in **13a** than in the free ligand (1.392 and 1.376 Å, respectively) as a consequence of the coordination of the ligand to the palladium centre in the deprotonated form which leads to the partial double-bond character of the C–N bonds [16]. An important factor that contributes to the crystal packing of **13a** is intermolecular N–H···S hydrogen bonds, found between the S atom of the thiocarbonyl group and the hydrogen atom of the amino –NHR group from the *N*-benzoyl thiourea ligand.[1] This type of interaction is usually found in the uncomplexed *N*-benzoyl thiourea ligands and is typically shorter than the interactions found for **13a** [17,18].

2.3. Thermal behaviour

The palladium complexes, bearing alkoxy groups with six carbon atoms chains (**2**–**13b**), were investigated for their potential liquid crystal properties by hot stage polarising optical microscopy and differential scanning calorimetry (DSC). DSC data were recorded only for those compounds showing mesomorphic behaviour. The thermal data are summarised in Table 3. Mesophases were assigned by their optical texture and two examples are shown in Fig. 4.

[1] Hydrogen bonds for **13a**: N(5)–H(5A)···S(2)#1, 3.772(2) Å and N(2)–H(2A)···S(1)#2, 3.6967(19) Å. Symmetry transformations used to generate equivalent atoms: (1) $-x+1, y-1/2, -z+1/2$; (2) $-x, y+1/2, -z+1/2$.

Table 3
Thermal data for the palladium(II) complexes

Compound	Transition	T (°C)	ΔH (kJ mol^{-1})
2b	Cr–I (N–I)[b]	110 (61)	23.8 (0.3[d])
3b	Cr–I (I–N) (N–Cr)	104 (64[a])	30.8 (20.4[c])
5b	Cr–Cr′ Cr′–I (I–N) (N–Cr)	102 108 (78[a])	18.2 21.5 (29.8[c])
6b	Cr–Cr′ Cr′–I (I–N) (N–Cr)	53 95 (58[a])	3.4 29.9 (22.2[c])

[a] These values represent the temperatures taken from microscopy.
[b] In this case $T_{(N-I)}$ is quoted as the sample was cooled from isotropic to nematic and then re-heated back to the isotropic phase.
[c] The two transitions could not be separated and the values represent the combined enthalpies.
[d] Compound **2b** was the only compound for which it was possible to extract the enthalpy parameter associated with the isotropic to nematic phase transition. The nematic phase of **2b** is stable up to room temperature for several hours after which a slow crystallization process occurs.

This family of complexes offers a broad and systematic picture of the possibility to use *N*-benzoyl thiourea derivatives in designing liquid crystalline materials as well as the effects of changing the substituents on this type of ligand on the mesogenic behaviour. The nature of the *N*-benzoyl thiourea derivative, more specific the R_1 and R_2 substituents, has a major influence on the mesogenic properties of these complexes (Table 3), though it is very clear that their mesogenic behaviour is driven by the *ortho*-metallated imine fragment. Thus, complexes **7**–**13b** show no mesomorphic properties and this behaviour could be assigned to the more flexible structures adopted by the *N*-benzoyl thiourea derivatives bearing aromatic fragments, in particular due to the aromatic groups linked to the nitrogen atom, which imposes a less favourable molecular shape in connection with the intermolecular hydrogen bonds N–H···S that can be formed between the S atom of the thiocarbonyl group and the hydrogen atom of the amino –NHR group. This type of intermolecular interaction (hydrogen bonding between the NH_2 and the carboxyl groups within the amino acids groups) within the crystal lattice was supposed to be responsible for increasing the melting points of the liquid crystals based on *ortho*-metallated Pd imine complexes with amino acids [5b]. On the other hand, the Pd(II) complexes with *N*,*N*-dialkyl-*N*′-benzoyl thiourea derivatives (**2**–**6b**) show a monotropic nematic phase on cooling, except for **4b** ($R_1 = R_2 = Bu$) for which no mesophase was seen either on heating or cooling. This behaviour could be dis-

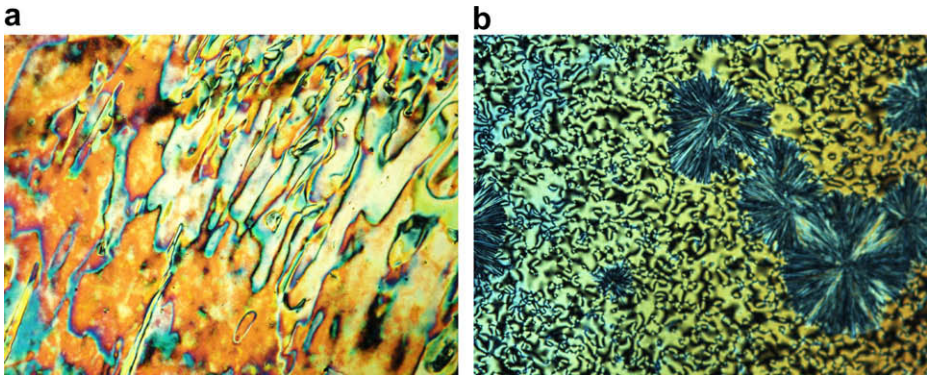

Fig. 4. Polarised optical micrograph of the nematic phase of **2b** at 60 °C (a) and of **6b** at 58 °C (b). In the later case the transition to the nematic phase occurs just before the crystallisation process.

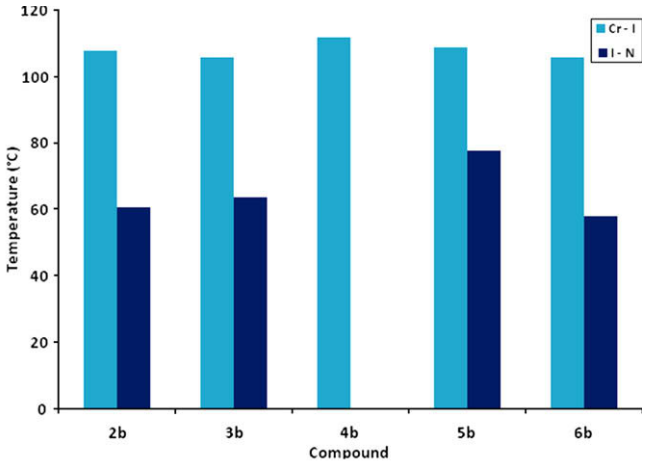

Fig. 5. Thermotropic behaviour of Pd(II) complexes **2–6b.**

cussed in terms of molecular anisotropy of these complexes, e.g. the length-to-breadth ratio [19]. As the terminal alkoxy chains of the imine are not changed, increasing the length of the alkyl chain of the *N*-benzoyl thiourea derivative leads to an increase of the breadth of the molecule with immediate consequences on the mesogenic behaviour. One can assume that the maximum breadth of the molecule is reached for $R_1 = R_2 =$ butyl, when the mesogenic behaviour is being totally suppressed.

Fig. 5 shows the influence of the chain length on the mesogenic properties of Pd(II) complexes with *N*,*N*-dialkyl-*N*′-benzoyl thiourea derivatives. Though the melting points and the temperature of the transition from isotropic to nematic phase do not follow the same trend, there is a clear tendency of increase of T_{I-N} with the increasing chain length up to hexyl groups, followed by a significant drop, 20 °C, on going from hexyl to octyl groups. The same effect of decreasing the transition temperatures with increasing the alkyl chain length from ethyl to octyl has been seen for *ortho*-metallated imine Pd(II) complexes with dialkyldithiocarbamates as chelating ligands [7].

It is very clear that compared with the other types of co-ligands, such as β-diketones or β-aminoenonates, the use of *N*-benzoyl thiourea derivatives as co-ligands destabilise the mesogenic behaviour to such an extent that only monotropic behaviour is seen, with the transitions to the nematic mesophase occurring at approximately 30–50 °C below the clearing point. While changing β-diketones to β-aminoenonate co-ligands leads to more accessible nematic phase but over slightly narrower temperature [3a], the effect of introducing the *N*-benzoyl thiourea derivatives is to further decrease the melting points and the mesophase range together with a change of transition type.

3. Conclusions

A series of organometallic palladium(II) complexes bearing imine ligands and different types of *N*-benzoyl thiourea derivatives as co-ligands were prepared and investigated for their liquid crystal properties. The structures of three of the complexes have been solved by X-ray diffraction.

The first liquid crystals based on metal complexes containing the *N*-benzoyl thiourea moiety are reported here and their mesogenic properties are compared to those of palladium complexes with other types of co-ligands. The use of *N*-benzoyl thiourea derivatives as co-ligands in company of the *ortho*-palladated imine fragment destabilise the mesogenic behaviour of these complexes. Thus, in the case of complexes bearing *N*,*N*-dialkyl-*N*′-benzoyl thiourea derivatives only monotropic behaviour is seen, with the transitions to nematic mesophase occurring approximately 30–50 °C below the clearing point, while in the case where *N*-aryl-*N*′-benzoyl thiourea derivatives were employed, the mesomorphic behaviour was totally suppressed.

These results suggest the possibility of using these simple *N*-benzoyl thiourea derivatives in designing liquid crystals together with the *ortho*-metallated imine fragment but, probably, the mesogenic behaviour of such compounds can be considerably improved by changing the type of imine ligand employed.

4. Experimental

Dichloromethane was distilled from phosphorus pentaoxide, while acetone was distilled from calcium chloride; other chemicals were used as supplied. Proton and carbon NMR spectra were recorded on a Varian Gemini 300 BB spectrometer operating at 300 MHz, using $CDCl_3$ as solvent. ^1H chemical shifts were referenced to the solvent peak position, δ 7.26 ppm. Analysis by DSC was carried out using a Perkin–Elmer DSC7 instrument using a 10 °C/min heating rate. Mesomorphism was studied by hot stage polarising microscopy using a Nikon 50i Pol microscope equipped with a Linkam THMS600 hot stage and a TMS94 temperature controller. Mesophases were assigned by their optical texture [20].

Diffraction data were collected at 110 K on a Bruker Smart Apex diffractometer with Mo Kα radiation (λ = 0.71073 Å) using a SMART CCD camera. Diffractometer control, data collection and initial unit cell determination was performed using "SMART" (v5.625 Bruker-AXS). Frame integration and unit-cell refinement was carried out with the "SAINT+" (v6.22, Bruker AXS) sofware. Absorption correc-

tions were applied by SADABS (v2.03, Sheldrick). Structures were solved by "direct methods" using SHELXS-97 [21] and refined by full-matrix least squares using SHELXL-97 [21]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms (except for NH hydrogens) were placed using a "riding model" and were included in the refinement at calculated positions. NH hydrogens were found by a difference map after all other atoms were found.

The synthesis of the μ-acetato bridged Pd(II) complexes (**1a**,**b**) was carried out as described elsewhere [22]. The *N*-benzoyl thiourea derivatives used in this work were prepared according to the methods published in literature [8].

4.1. Preparation of the sodium salts of N-benzoyl thiourea derivatives

The sodium salts of *N*-benzoyl thiourea derivatives were prepared by reacting the corresponding *N*-benzoyl thiourea with sodium ethoxide (1:1 molar ratio) in petroleum ether for 2 h under reflux. A white or off-white precipitate developed for all *N*-benzoyl thiourea derivatives, which was filtered off and washed with petroleum ether several times. The sodium salts were used in the next step without further purification. Their formation was checked by IR spectroscopy. Their IR spectra confirmed the loss of the proton by the disappearance of ν_{NH} (~3300 cm^{-1}) and $\nu_{C=O}$ (~1670 cm^{-1}) frequencies (compare to the IR spectra of the free ligands) together with a shift of ν_{C-N} frequency towards lower wavenumbers.

4.2. Synthesis of **2a**

The solid sodium salt of *N*,*N*-diethyl-*N*'-benzoyl thiourea (0.0715 g, 0.27 mmol) was added to a solution of the binuclear palladium complex (0.075 g, 0.09 mmol) in CH_2Cl_2 (15 cm^3) and the mixture was stirred at room temperature for 24 h. Evaporation of the solvent gave a yellow solid, which was purified by chromatography on silica using CH_2Cl_2 as the eluant to give a yellow solid. This was recrystallised from a mixture of CH_2Cl_2/C_2H_5OH (1/1) at −25 °C.

4.2.1. Compound **2a**

Yield: 52%, m.p. 144 °C. *Anal.* Calc. for $C_{27}H_{29}N_3O_3PdS$: C, 55.7; H, 4.6; N, 7.2. Found: C, 55.3; H, 4.1; N, 7.5%.

by the full-matrix least-squares method on all F^2 data using the program SHELXL-97 [5]. Geometrical analysis was performed using SHELXL-97. The structures were drawn by ORTEP-3 for Windows. The single crystal suite WINGX was used as an integrated system for all crystallographic programs and software for preparing the material for publication [6]. Crystal data and conditions of data collection and refinement are reported in Table 1.

2.3. Preparation of the complexes

2.3.1. Cu(meclof)$_2$H$_2$O

To an aqueous solution of copper(II) sulfate (5 mmol), an aqueous solution of meclofenamate and an equimolar quantity of sodium hydroxide (10 mmol) were added, and the reaction mixture was refluxed for 30 min. The blue green precipitate that formed was filtered off and dried at ambient temperature.

Elemental *Anal.* Calc. for $C_{28}H_{22}N_2O_5Cl_4Cu$: C, 50.06; H, 3.30; N, 4.17; Cu, 9.46. Found: C, 49.84; H, 3.32; N, 4.68; Cu, 9.48%. UV–Vis spectrum: 675 nm (band I) and 375 nm (band II).

Cu(meclof)$_2$L$_2$ (L = 2-pyridylcarbinol (2-pyca), 3-pyridylcarbinol (3-pyca), nicotinamide (na) and *N*,*N*-diethylnicotinamide (dena)).

A solution of L (10 mmol) in methanol (20 ml) was added to a solution of Cu(meclof)$_2$H$_2$O (5 mmol) in methanol (50 ml). The resulting solution was heated and left to stand at ambient temperature. The blue precipitate that formed was collected by filtration, washed with cold methanol and finally dried at ambient temperature (the yield of the complexes was ~70%).

Elemental *Anal.* Cu(meclof)$_2$(2-pyca)$_2$: Calc. for $C_{40}H_{34}N_4O_6Cl_4$-Cu(%): C, 55.09; H, 3.93; N, 6.42; Cu, 7.29. Found: C, 54.32; H, 4.11; N, 6.67; Cu, 7.31%. UV–Vis spectrum: 615 nm (band I) and 330 nm (band II).

3. Results and discussion

An ORTEP plot of Cu(meclof)$_2$(2-pyca)$_2$ is shown in Fig. 1, and selected bond distances and angles are given in Table 2. In the structure of the complex, the Cu(II) atom is six-coordinated and the coordination polyhedron can be described as a tetragonally distorted octahedron. Two equatorial positions are occupied by two oxygen atoms [Cu1–O1 1.968(3) Å] from the carboxyl groups of two meclofenamate anions, which are coordinated to the central atom in an unidentate manner. Two heterobidentate (O, N) 2-pyridylcarbinol ligands, which span the equatorial plane [Cu1–N1 2.021(5) Å] and the axial positions [Cu1–O3 2.387(4) Å], complete the distorted tetragonal bipyramidal arrangement. The value of the angle which is part of the five-membered metallocycles (N1$_{(eq)}$–Cu1–O3$_{(ax)}$) of 76.8(2)°) is about 7.87° smaller than those of (O1$_{(eq)}$–Cu1–O3$_{(ax)}$) 84.67(14)°. However, the (N1$_{(eq)}$–Cu1–O3$_{(ax)}$) angle from the cis-angles is the most open, with a value of 103.2(2)°. All the trans L–Cu–L angles are linear (180.0°).

The structural chemistry for over 600 coordinated monomeric copper(II) compounds has been reviewed by us [7]. From the three principal forms of distortion of the octahedron, all of which occur in the chemistry of Cu(II) to varying degrees, the tetragonal distor-

tion most commonly involves an elongation of one C_4 axis. There are some examples of the general formula $CuX_2(2\text{-pyca})_2$ (X = mefanamate, clofibriate, salicylate, 2-bromopropionate and meclofenamate) and selected data of these complexes are given in Table 3. The value of the T ($T = R_S/R_L$) parameter for $CuX_2(2\text{-pyca})_2$, indicating the degree of the tetragonal distortion about the Cu(II) centers, decreases in the order: X = salicylate 0.850 > meclofenamate 0.835 > clofibriate 0.832 > 2-bromopropionate 0.829 > mefanamate 0.819.

The IR spectrum of Cu(meclof)$_2$H$_2$O shows two absorption bands at 3308 and 3248 cm^{-1}. These bands correspond to the antisymmetric and symmetric OH stretch and confirm the presence of water in the complex. Moreover, the IR spectrum exhibits characteristic bands at approximately 850 and 550 cm^{-1} assigned to the rocking and wagging mode of the coordinated water molecule [12]. Each complex showed carboxylate stretching frequencies, $V_{as}(COO^-)$ and $V_s(COO^-)$, which are in the expected region (Table 4). The broad bands at about 1610 cm^{-1} (assigned to the asymmetric stretch $V_{as}(COO^-)$) are overlapped with the stretching vibration of C=N of the pyridine ring. The difference between the asymmetric and symmetric stretching vibration ($\Delta\nu = V_{as}(COO^-) - V_s(COO^-)$) (Table 4), which gives information on the carboxylate bonding mode, especially for Cu(meclof)$_2 \cdot$ H$_2$O, could not be determined accurately. However, splitting of the bands assigned to $V_s(COO^-)$ indicates that the meclofenamate anion as a ligand in Cu(meclof)$_2 \cdot$ H$_2$O is coordinated as a bidentate bridging carboxyl group (see electronic and EPR spectra). The difference $\Delta\nu = 245$ cm^{-1} for Cu(meclof)$_2 \cdot$ (2-pyca)$_2$ is typical for a unidentately bonded carboxylic group of meclofenamate (see the crystal structure). The smaller Δ values from 164 to 188 cm^{-1} for the complexes Cu(meclof)$_2 \cdot$ L$_2$ (L = 3-pyca, na, dena) indicate that the meclofenamate anions are coordinated as asymmetrically bidentate chelating carboxylic groups.

The electronic spectrum of Cu(meclof)$_2 \cdot$ H$_2$O shows a broad absorption band (band I) in the visible region at 675 nm, which could be assigned to the $d_{xz,yz} \rightarrow d_{x^2y^2}$ transition [13]. Moreover, the spectrum displays a shoulder at 375 nm (band II). Band II has been assigned to a charge transfer LMCT absorption [14] and is believed to be indicative of a dimeric structure [15]. The electronic spectra of all the remaining Cu(meclof)$_2 \cdot$ L$_2$ complexes exhibit a broad asymmetrical ligand field band with a maximum in the range 605–610 nm (Table 5). For complexes Cu(meclof)$_2 \cdot$ L$_2$ (L = 3-pyca, na and dena) there is also a charge transfer band at about 330 nm.

3-pyca	615	
2-pyca	615	330
na	640	330

The EPR spectrum of a powdered sample of Cu(meclof)$_2 \cdot$ H$_2$O was made at room temperature. The spectrum exhibit feature typical of those for dimeric carboxylate copper(II) complexes [16], absorption at low and high field ($H_{Z1} \sim 300$ G and $H_{Z2} \sim 6000$ G, respectively) and line $H_{\perp 2} \sim$ about 4700 G. Absorption at about 3200 G ($g = 2100$) confirms monomeric impurities in measured powered sample of ~2.6%. The EPR spectrum was interpreted by using the effective spin Hamiltonian [17] for a randomly oriented triplet state, $S = 1$:

$$H = g\beta H\acute{S} + D\acute{S}_z^2 + E(\acute{S}_x^2 - \acute{S}_y^2) - 2/3 \cdot D$$

where D and E are the axial and rhombic zero-field splitting parameters, and x, y, z are the principal axes of a coordinated system fixed with respect to the Cu–Cu bond. The obtained parameters are $g_\perp = 2.090$, $g_{||} = 2.397$, $g_{av} = 2.192$, $|D| = 0.331$ cm^{-1} and $E = 0.003$ cm^{-1}.

The EPR spectra of all the remainding complexes exhibit a monomeric type of signal and have either axial (complexes Cu(meclof)$_2 \cdot$ L$_2$, L = 2-pyca, 3-pyca and na) or rhombic symmetry (Cu(meclof)$_2$dena$_2$) with $g_\perp < g_{||}$. This indicates that the unpaired electron is located mostly on the $d_{x^2-y^2}$ orbital of the copper(II) atom. The values of the g factors are summarized in Table 6. Complexes Cu(meclof)$_2 \cdot$ L$_2$ (L = 3-pyca and dena) also exhibit well-resolved parallel hyperfine splitting with $A_{||}$ values of 166 and 157 G, respectively.

On the basis of the spectral data observed, a dimeric structure for Cu(meclof)$_2 \cdot$ H$_2$O can be proposed, in which two copper(II) atoms are held together by four bidentate meclofenamate anions in a *syn–syn* arrangement. Each Cu(II) atom is penta-coordinated with four oxygen atoms of four different meclofenamate anions assuming the basal positions in a tetragonal pyramidal arrangement and molecule water occupying an apical position.

For Cu(meclof)$_2 \cdot$ L$_2$ (L = 3-pyca, na and dena) we proposed, on the basis of the spectroscopic data observed, a monomeric structure with a tetragonal bipyramidal geometry around the Cu(II) atom. We propose that meclofenamate use both carboxylate

Table 3

2.3. Computational method

The geometry of the resulting complexes $[Mn(L_{22pyfp})Cl]^+$ and $[Cd(L_{22pyfp})NO_3]^+$ in the gas phase were fully optimized at both the Hartree–Fock and DFT (B3LYP) [18] levels of theory using the GAUSSIAN 98 set of program (Figs. 1 and 2) [19]. The atomic coordinates of the complexes in their crystal structures were used for ab initio calculations. Both complexes were optimized using the standard LanL2MB [20] for all atoms, or 3-21G* and/or 6-31G* basis sets [21,22] for ligand atoms, and LanL2DZ for the metal ions [23]. The optimized structures of the ligands of both complexes were used for molecular orbital analysis and time-dependent DFT (TD-DFT) calculations at the B3LYP/LanL2MB level of theory. Calculations were performed on a Pentium-PC computer with a 4400 MHz processor.

2.4. Synthesis

2.4.1. Synthesis of $[Cd(L_{22pyfp})NO_3](ClO_4)\cdot H_2O$ (**1**)

This complex was prepared by the template condensation method [5]. L_{22py}.3HCl (0.1 g, 0.33 mmol) and NaOH (0.039 g, 0.99 mmol) were mixed and heated under reflux for 30 min in EtOH (15 ml). The NaCl which formed upon cooling was filtered off. The filtrate was added to 2-pyridinecarboxaldehyde (0.07 g, 0.66 mmol) in dry EtOH (40 ml) and the solution was stirred. $Cd(NO_3)_2\cdot 4H_2O$ (0.1 g, 0.33 mmol) dissolved in MeOH (5 ml) was subsequently added. The mixture was stirred at 50–60 °C for 24 h, then $NaClO_4$ (0.92 g, 0.66 mmol) was added. The solution was filtered and the filtrate was reduced to ca. 10 cm^3. A crystalline compound was obtained by slow diffusion of Et_2O vapor into this solution. Yield of the complex $[Cd(L_{22pyfp})NO_3](ClO_4)\cdot H_2O$ (**1**), 0.15 g, 75%. *Anal.* Calc. for ($C_{22}H_{26}CdClN_7O_8$): C, 39.77; H, 3.92; N, 14.75. Found: C, 39.21; H, 3.65; N, 14.17%. IR (KBr, cm^{-1}): 1667 (νC=N schiff base), 1591 (νC=N pyridine), 1568 (νC=C), 1081. ^{1}H NMR (DMSO, ppm, 300 MHz, py = pyridine): δ 2.76 (m, 2H, 1-Hα), 3.12 (m, 2H, 1-H$_\beta$), 3.95 (4H, t, 2-H), 4.24 (s, 2H, CH_2-Py), 7.37 (t, 1H), 7.57 (d, 1H), 7.84 (t, 2H) 7.96 (t, 1H), 8.01 (d, 2H), 8.26 (m, 5H) 8.82 (s, 2H, with two satellite peaks in the ratio 1:6:1 relative to the main signal $^3J(^{111/113}Cd\text{-}^1H) = 44.53$ Hz). ^{1}H COSY (DMSO, 300 MHz) δ: 2.76/312 (1-Hα/1-H$_\beta$), 2.76/3.95 (1-Hα/2-Hα), 2.76/3.95 (1-Hα/2-H$_\beta$), 312/3.95 (1-H$_\beta$/2-H$_\alpha$), 312/3.95 (1-H$_\beta$/2-H$_\beta$), ^{13}C NMR (DMSO, ppm, 300 MHz): δ 53.83 (C-1), 54.69 (C-2), 57.66 (C-3), 124.53 (C-8), 125.50 (C-6), 129.28 (C-9 and C-5), 140.17 (C-7), 141.06 (C-13), 147.43 (C-11), 149.39 (C-12), 150.04 (C-10), 156.95 (C-14), 162.47 (C-4).

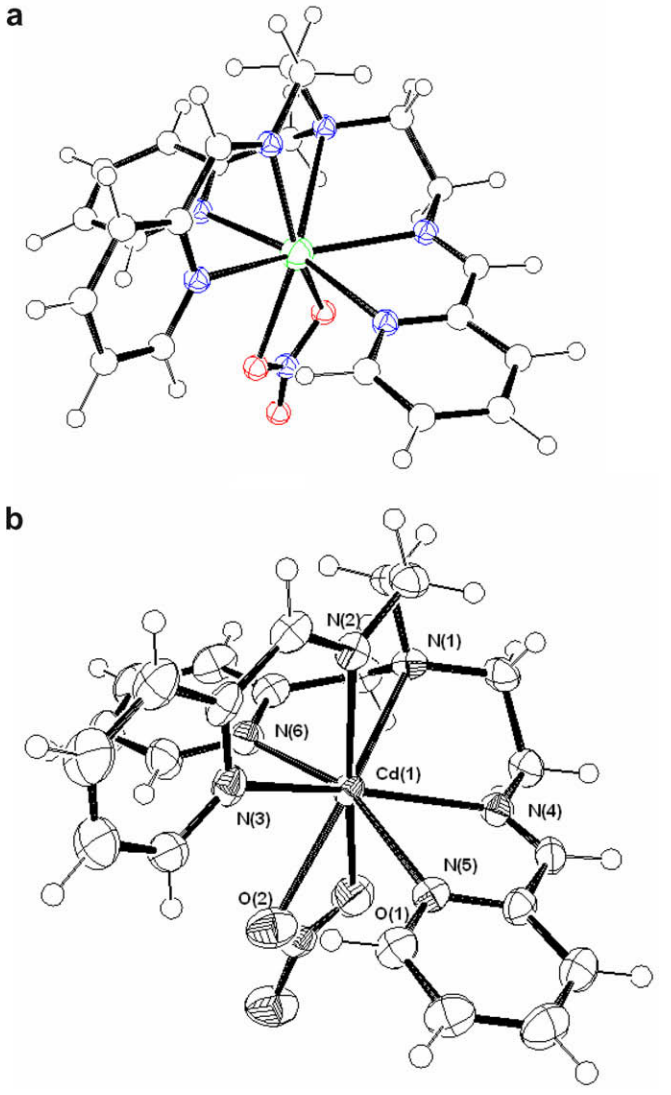

Fig. 1. DFT optimized (a) and crystal structure (b) of compound **1**. The perchlorate anion and solvated H_2O are omitted for clarity.

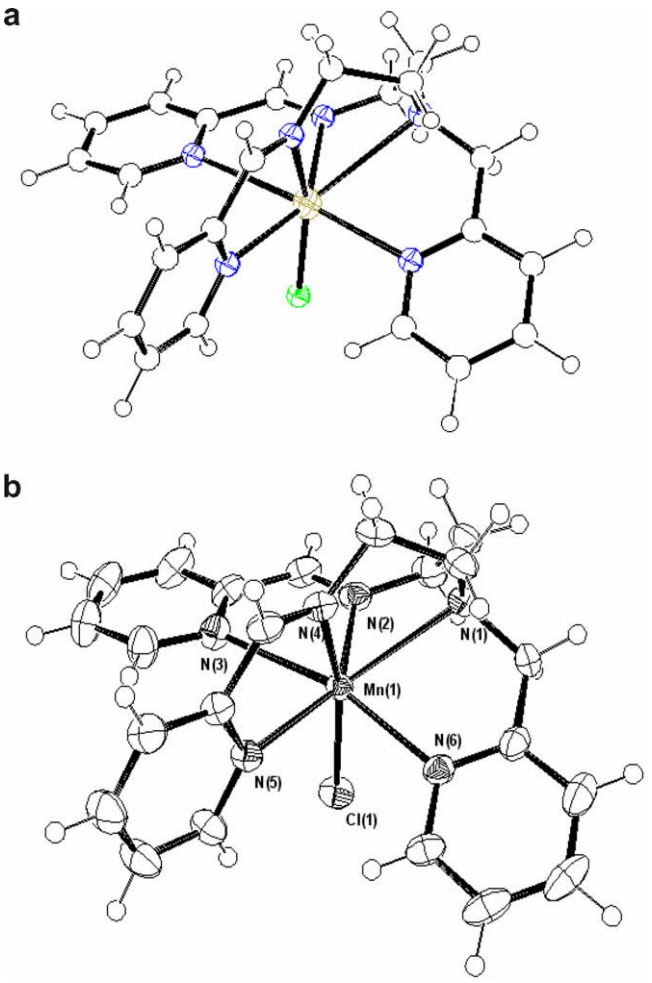

Fig. 2. RHF optimized (a) and crystal structure (b) of compound **2**. The perchlorate anion and solvated MeOH are omitted for clarity.

2.4.2. Synthesis of $[Mn(L_{22pyfp})Cl](ClO_4)\cdot MeOH$ (**2**)

Compound **2** was prepared in an analogous method to **1**. $L_{22py}\cdot 3HCl$ (0.1 g, 0.33 mmol) and NaOH (0.039 g, 0.99 mmol)

were mixed and heated under reflux for 30 min in EtOH (15 ml). The resulting solution was worked up as previously stated, however $MnCl_2{\cdot}6H_2O$ (0.65 g, 0.33 mmol) was added in place of $Cd(NO_3)_2 \cdot 4H_2O$. Yield of the complex $[Mn(L_{22pyfp})Cl](ClO_4) \cdot MeOH$ (**2**), (0.08 g, 40%). *Anal.* Calc. for ($C_{23}H_{28}Cl_2MnN_6O_5$): C, 46.47; H, 4.71; N, 14.13. Found: C, 46.15; H, 4.31; N, 13.86%. IR (KBr, cm^{-1}): 1660 (νC=N Schiff base), 1596 (νC=N pyridine), 1569 (νC=C), 1094.

3. Results and discussion

3.1. Synthesis and characterization

Both complexes **1** and **2** were readily synthesized by the templated condensation of the neutralized L_{22py} tripodal ligand [5] with 2-pyridinecarboxaldehyde in the presence of either Mn(II) or Cd(II) metal ions, respectively. These compounds are quite stable in air and can be stored in a desiccator for long periods of time without decomposition. The resulting compounds were characterized by, IR, elemental analysis and X-ray diffraction, and by ^1H NMR in the case of Cd(II). Condensation of all the primary amino group is confirmed by the lack of N–H stretching bands in the IR reign (3150–3450 cm^{-1}) and the presence of strong C=N (Schiff base) stretching bands at 1668 and 1660 cm^{-1} for **1** and **2**, respectively. The band observed at 1387 cm^{-1}, for complex **1**, can be assigned to the bidentate nitrate group. A broad intense band at ca. 1100 cm^{-1} due to ClO_4^- shows no splitting, indicating the absence of coordination of ClO_4^- for both complexes. The NMR studies of **1** are completely consistent with its formulation. The electronic spectra of both complexes in acetonitrile (10^{-4} M) show two intense bands in the UV region, at 200–300 nm as expected for imino-substituted pyridines [24].

3.2. X-ray crystal structure analysis

Suitable crystals of **1** and **2** were obtained by slow diffusion of diethyl ether vapor into a methanol-ethanol solution of the corresponding complexes. ORTEP diagrams of the molecular structures of **1** and **2** are shown in Figs. 1 and 2, respectively, with the atomic numbering. Selected bond lengths and bond angles are listed in Tables 2 and 3. The Cd–N and Mn–N bond lengths are within the normal range. The crystal structure of **1** consists of a cadmium metal center coordinated to six nitrogen and two oxygen donor atoms from the nitrate counter ion and the crystal structure of **2** consist of a manganese metal center coordinated to six nitrogen atoms and a chloride ion. Eight-coordinate systems are found to adopt a cube, a square antiprism or a triangulated dodecahedron (TD) arrangement [25]. On the basis of the observed angles, (N–Cd–N, N–Cd–O and O–Cd–O), complex **1** adopts a slightly distorted TD geometry [26] with N(2) as the lone capping atom, whereas O(1) and O(2) are the shared capping atoms (see Fig. 3). The two Cd–O distances [2.643(3) and 2.436(3) Å] in the cadmium complex differ substantially, one being short and the other long. The Cd–O distance for the bidentate nitrate group (*av*. 2.539 Å) is comparable with the calculated mean value [2.482(144) Å] observed in 28 eight-coordinate Cd(II) complexes obtained from the Cambridge Structural Database [27], navigated using CONQUEST [28], thus both oxygen atoms are coordinated to the central cadmium ion. The Cd–N distances are in the normal range [from 2.344(3) to 2.659(2) Å)]. The bond distance between the atom Cd(1) and the tertiary nitrogen atom N(1) of complex **1** is 2.659(2) Å, which is much longer that the nor-

[a] The parameters obtained at the HF level are given as plain text, those for the B3LYP level are in bold.

mal bond distance. This phenomenon is probably attributed to the steric requirements of the tripodal ligand. The Cd–N_{imine} bond lengths are shorter than the Cd–$N_{pyridine}$ bond lengths due to the fact that the imine nitrogens are involved in two chelate rings. The X-ray crystallography of **2** reveals a seven-coordinate Mn atom best described as a distorted pentagonal bipyramid, with five nitrogen atoms lying in an approximately pentagonal ring (forming a distorted equatorial plane). The axial positions are occupied by one of the two imine nitrogen atoms and the chloride ion with an axial *trans* angle N(4)–Mn–Cl(1) = 164.47(7)°. The longest bond is found between Mn and N(3) [2.562(3) Å] and the shortest bond is between Mn and N(4) [2.242(2) Å]. All of the three equatorial five-membered chelate bond angles subtended by the ligand at the manganese atom are close to the ideal value of the pentagonal bipyramidal geometry (72°), [N(1)–Mn–N(2) = 69.75(9)°, N(2)–Mn–N(3) = 67.76(9) and N(1)–Mn–N(6) = 68.36(8)°]. The Mn–N_{imine} bond lengths, similar to those in **1**, are shorter than the Mn–$N_{pyridine}$ bond lengths.

3.3. NMR spectra

The NMR spectra of the cadmium complex confirm the formation of a fully condensed Schiff base complex. The ^{13}C NMR and DEPT 135° of this complex shows three distinct methylene carbons in the aliphatic region. It is interesting that the ^{1}H NMR spectrum (Fig. 4) of this complex shows two kinds of protons for the methylene group adjacent to the tertiary nitrogen atom. The COSY spectrum confirms the geminal coupling between the latter protons, indicating that the protons are diastereotopic in the rigid five-membered rings. We have reported similar observations for all methylene groups involved in the six-membered rings of seven-coordinate tripodal cadmium complexes [8,10]. It is clear from the COSY spectrum that both diastereotopic protons of C(1) (Scheme 1a) display coupling to protons of C(2) in addition to the above observations the ^{1}H NMR spectrum of the cadmium complex synthesized here, which shows that the signal corresponding to the imine proton displays two satellite peaks (^{3}J = 44.4 Hz) with intensities in the ratio 1:6:1 (Fig. 4) due to coupling with the neighboring $^{111/113}$Cd nucleus (^{111}Cd, 12.81; ^{113}Cd, 12.22%). The very similar magnetogyric ratio of ^{113}Cd and ^{111}Cd, −5.93303 and −5.6720 × 10^{-7} rad/Ts, respectively, lead to satellite overlap at the collection frequency. It should be noted that there are several reports of $^{111/113}$Cd–^{1}H heteronuclear coupling, [29–33] and we very recently published clear illustrations of such satellites very similar to that shown in Fig. 4 [5,10,11]. The coupling constant observed here is in the range expected for tripodal Schiff base cadmium complexes [5,10,11]. Obviously the observation of such coupling suggests that the Cd–N_{im} bond remains intact in

solution. It should be noted that the value of the $^{111/113}$Cd–^{1}H heteronuclear coupling in coordinated Schiff base compounds can be considerably dependent on the value of the torsion angle of the H–C=N–Cd bond. The mean value for the latter torsion angle in compound **1** is 173.76° and is very close to calculated values (172–178°) for seven-coordinate tripodal Schiff base cadmium complexes [5,10,11]. Thus this is a clear reason for the fact that the coupling constant observed here is in the range expected for the latter tripodal Schiff base cadmium complexes.

3.4. Ab initio and DFT studies

The geometry of both complexes was fully optimized at both the Hartree–Fock (HF) and density functional B3LYP levels of theory. As can be seen, the degree of agreement between the theoretical and experimental data depends on both the method and the basis sets. The results show that the gas-phase structures of both complexes are similar to their solid state structures. It should be note that we could not optimize the Mn complex at the DFT level of theory using the 6-31G* basis set in a reasonable time. We also carried out a LanL2MB basis set for the calculation of the highest occupied molecular orbital (HOMO) and the lowest-unoccupied molecular orbital (LUMO) and the energy gap of complexes **1** and **2**. The calculated energies for the HOMO and LUMO of these compounds are given in Table 4. The HOMO and LUMO for compounds **1** and **2** are illustrated in Fig. 5. As can be seen, in the Cd(II) complex the HOMO is a bonding π orbital that is essentially distributed on the metal atom and the coordinated nitrate ion and the LUMO is an anti-bonding π orbital that is distributed on one of the pyridine Schiff base rings. In the Mn (II) complex the HOMO is a bonding σ orbital that is essentially distributed on the metal and chloride ions and the LUMO is an anti-bonding π orbital that, similar to the Cd(II) complex, is distributed on one of the pyridine Schiff base rings. The results of the TD-DFT calculations at the B3LYP/lanl2mb level of theory for compounds **1** and **2** and the corresponding free Schiff

base tripodal ligand (optimized at the same level of theory) are given in Table 5. It is clear that the results of the latter calculations for complexes **1** and **2** agree with the relative size of the HOMO-LUMO energy gap in these complexes. On the other hand, the result does not agree with the observed spectra for the latter complexes. Note that both complexes do not have any spin-allowed electronic transitions. Thus the experimental spectra must be related to intra-ligand (LL) transitions. Fortunately there is a good agreement between the results of the TD-DFT calculations on the ligand itself with the experimental data.

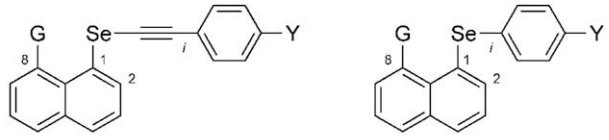
We intended to employ the ethynyl group in the construction of supramolecular compounds such as **A**,[1] which are built by the ethynyl group cooperating with the extended hypervalent bonds of Z_4 4c–6e (Z = S [25j,26] and Se [25b,e,26]). As a first step to study such compounds, the factors that control the structures of 1-(arylethynylselanyl)naphthalenes [**1**: 1-(*p*-$YC_6H_4C{\equiv}CSe)C_{10}H_7$, 1-(ArC-CSe)Nap] have been investigated very recently, together with the structures [27]. One factor is called the ethynyl effect. The ethynyl group operates to determine the fine structures of **1**, which are completely different from those in 1-(arylselanyl)naphthalenes [**I**: 1-(*p*-$YC_6H_4Se)C_{10}H_7$] [28b]. The effect of G substituted at the 8-position of **1** also operates to control the fine structures. 8-G-1-(*p*-$YC_6H_4C{\equiv}CSe)C_{10}H_6$ [**2** (G = Cl) and **3** (G = Br): Y = H (**a**), OMe (**b**), Me (**c**), F (**d**), Cl (**e**), CN (**f**) and NO_2 (**g**)] have been prepared and the NMR spectra were measured, in addition to **1** (G = H). The fine structures were determined by X-ray crystallographic analysis exemplified by **2b**, **2e** and **2g**, to clarify the factor which controls the fine structures. The factor is called the G-dependence in **2**.



1 (G = H), **2** (G = Cl), **3** (G = Br) **I** (G = H)

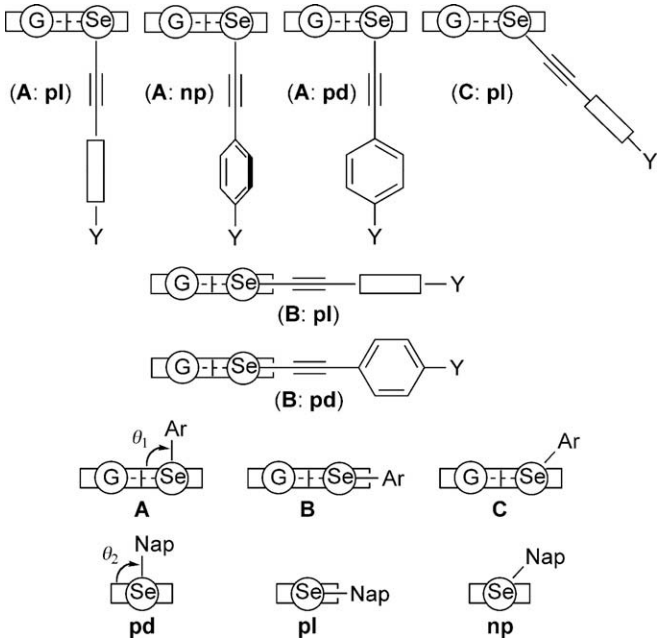
The structures of the naphthalene system are well explained by three types, defined as **A**, **B** and **C**, where the Se–C_{sp} bond is perpendicular to the naphthyl plane in **A**, it is placed on the plane in **B** and **C** is intermediate between **A** and **B** [25c,d,f–i,28b]. The **A**, **B** and **C** notations are employed to specify the structures around the Se–C_{Nap} bonds in **1**–**3**. The planar (**pl**), perpendicular (**pd**) and non-planar and non-perpendicular (**np**) notations are also used to specify the structures around the linear Se–C_{sp}–C_{sp}–C_{Ar} alignment in **1**–**3**. Scheme 1 illustrates plausible structures of **1**–**3**. Combined notations such as (**A**: **pl**) and (**B**: **pd**) are employed for the structures.

We often worry about the structures of compounds in solution when investigations are carried out in solution and the compounds have plural dominant conformers. NMR spectroscopy plays an important role in determining the structures in solutions through the careful examination of the chemical shift values. The structures of **2** and **3** in solution are examined based on the NMR data, employing standard values of ^{1}H and ^{77}Se NMR parameters which are useful to determine structures in solutions, as proposed recently.

Here, we report the fine structure of **2**, determined by X-ray crystallographic analysis, together with the factors that controls the fine structure. Quantum chemical (QC) calculations are employed to understand the origin of the factors, which reveals that the G-dependence arises from the non-bonded $n_p(G)\cdots\sigma^*(Se–C_{sp})$ 3c–4e interaction or the $G\cdots Se–C_{sp}–C_{sp}–C_{sp2}$ 5c–6e type interaction. The behaviors of **2** and **3**, together with **1**, in solution are also examined to estimate the efficiency of the factors based on NMR parameters.

[1] **A** with *n* = 0 and 1 were prepared and the structure of **A** (*n* = 0) was determined by X-ray analysis. The results will be reported elsewhere.



Scheme 1. Plausible structures of **1**–**3** together with the **A**, **B** and **C** notations.

2. Experimental

2.1. General experimental considerations

Manipulations were performed under an argon atmosphere with standard vacuum-line techniques. Glassware was dried at 130 °C overnight. Solvents and reagents were purified by standard procedures as necessary. Melting points were determined on a Yanaco MP-S3 melting point apparatus and are uncorrected. NMR spectra were recorded at room temperature on a JEOL AL-300 spectrometer (^{1}H, 300 MHz; ^{13}C, 75 MHz; ^{77}Se, 57 MHz) and on a JEOL Lambda-400 spectrometer (^{1}H, 400 MHz; ^{13}C, 100 MHz; ^{77}Se, 76 MHz). The ^{1}H, ^{13}C and ^{77}Se NMR spectra were recorded in $CDCl_3$ solution. Chemical shifts are given in ppm relative to Me_4Si for the ^{1}H and ^{13}C NMR spectra, and relative to the reference compound Me_2Se for the ^{77}Se NMR spectra. Column chromatography was performed using silica gel (Fujishilysia PSQ-100B) and basic alumina (E. Merck).

2.2. Preparation of the 8-G-1-(arylethynylselanyl)naphthalenes

2.2.1. 8-Chloro-1-(phenylethynylselanyl)naphthalene (*2a*)

Under an argon atmosphere, ethynylbenzene (0.13 g, 1.25 mmol) was dissolved in anhydrous THF (10 mL), and LDA (diisopropylamine (0.13 g, 1.31 mmol) and *n*-BuLi (0.8 mL, 1.31 mmol, 1.62 M)) were added to the solution at 0 °C. After the mixture was stirred for 1 h at 0 °C, 8-chloro-1-naphthylselanyl bromide in anhydrous THF (10 mL) was added to the above solution at 0 °C. The reaction mixture was stirred for 2 h at 0 °C, and allowed to warm up to room temperature. Then, acetone (5 mL) was added, evaporated and the mixture dried in vacuo. The crude product was purified by column chromatography (flash column, SiO_2, acidic alumina, hexane). **2a** was isolated in 65% yield as colorless prisms, m.p. 59.5–60.5 °C; $C_{18}H_{11}ClSe$ requires C, 63.27; H, 3.24. Found: C, 63.18; H, 3.12%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.30–7.40 (m, 4H), 7.43 (t, *J* 7.9 Hz, 1H), 7.52–7.63 (m, 3H), 7.73 (dd, *J* 0.8, 8.3 Hz, 1H), 7.76 (dd, *J* 1.2, 8.4 Hz, 1H), 8.38 (dd, *J* 1.1, 7.6 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 73.1, 105.3, 123.2, 125.9, 127.0, 127.6, 127.9, 128.4, 128.6, 128.7, 128.7, 129.5, 129.5, 130.6, 131.9, 137.0; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 327.9.

*2.2.2. 8-Chloro-1-(p-anisylethynylselanyl)naphthalene (**2b**)*

A similar method to that described for the preparation of **2a** was used. Compound **2b** was isolated in 82% yield as colorless prisms, m.p. 157.5–158.5 °C; $C_{19}H_{13}ClOSe$ requires C, 61.39; H, 3.53. Found: C, 61.35; H, 3.54%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 3.84 (s, 3H), 6.89 (d, *J* 9.0 Hz, 2H), 7.35 (t, *J* 7.9 Hz, 1H), 7.41 (t, *J* 7.9 Hz, 1H), 7.52 (d, *J* 9.0 Hz, 2H), 7.54 (dd, *J* 1.3, 7.4 Hz, 1H), 7.71 (dd, *J* 0.9, 8.2 Hz, 1H), 7.76 (dd, *J* 1.1, 8.2 Hz, 1H), 8.37 (dd, *J* 1.2, 7.7 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 55.4, 71.2, 105.4, 114.0, 115.3, 125.9, 127.0, 127.8, 128.0, 128.6, 128.7, 129.4, 129.8, 130.7, 133.8, 137.0, 160.1; δ_{Se}(57 MHz; $CDCl_3$; Me_2Se) 327.1.

*2.2.3. 8-Chloro-1-(p-tolylethynylselanyl)naphthalene (**2c**)*

A similar method to that described for the preparation of **2a** was used. Compound **2c** was isolated in 70% yield as light yellow prisms, m.p. 103.5–104.5 °C; $C_{19}H_{13}ClSe$ requires C, 64.15; H, 3.68. Found: C, 63.89; H, 3.64%; δ_H (400 MHz; $CDCl_3$; Me_4Si) 2.38 (s, 3H), 7.18 (d, *J* 8.2 Hz, 2H), 7.35 (t, *J* 7.8 Hz, 1H), 7.42 (t, *J* 7.8 Hz, 1H), 7.47 (d, *J* 7.8 Hz, 2H), 7.54 (dd, *J* 0.9 and 7.8 Hz, 1H), 7.72 (dd, *J* 0.9 and 7.8 Hz, 1H), 7.76 (dd, *J* 0.9 and 8.2 Hz, 1H), 8.37 (dd, *J* 0.9 and 7.8 Hz, 1H); δ_C (100 MHz; $CDCl_3$; Me_4Si) 21.6, 72.1, 105.5, 120.1, 125.9, 127.0, 127.8, 127.9, 128.6, 128.7, 129.2, 129.4, 129.8, 130.7, 131.9, 137.0, 139.1; δ_{Se} (76 MHz; $CDCl_3$; Me_2Se) 329.2.

*2.2.4. 8-Chloro-1-(p-fluorophenylethynylselanyl)naphthalene (**2d**)*

A similar method to that described for the preparation of **2a** was used. Compound **2d** was isolated in 64% yield as colorless prisms, m.p. 116.5–117.5 °C; $C_{18}H_{10}ClFSe$ requires C, 60.11; H, 2.80. Found: C, 59.88; H, 3.01%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.06 (t, *J* 8.7 Hz, 2H), 7.36 (t, *J* 7.9 Hz, 1H), 7.42 (t, *J* 7.9 Hz, 1H), 7.51–7.59 (m, 3H), 7.73 (dd, *J* 1.1, 8.5 Hz, 1H), 7.77 (dd, *J* 1.2, 8.2 Hz, 1H), 8.34 (dd, *J* 1.1, 7.6 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 68.9 ($^5J_{C,F}$ 1.9 Hz), 101.6, 115.7 ($^2J_{C,F}$ 22.4 Hz), 119.3 ($^4J_{C,F}$ 3.7 Hz), 125.5, 126.3, 126.5, 126.9, 127.2, 128.4, 128.8, 129.1, 132.2, 133.8 ($^3J_{C,F}$ 8.7 Hz), 134.1, 162.7 ($^1J_{C,F}$ 250.0 Hz); δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 327.7.

*2.2.5. 8-Chloro-1-(p-chlorophenylethynylselanyl)naphthalene (**2e**)*

Under an argon atmosphere, *p*-chloroethynylbenzene (0.17 g, 1.25 mmol) was dissolved in anhydrous THF (10 mL), and LDA (diisopropylamine (0.13 g, 1.31 mmol) and *n*-BuLi (0.8 mL, 1.31 mmol, 1.62 M)) were added to the solution at −78 °C. After the mixture was stirred for 1 h at 0 °C, 8-chloro-1-naphthylselanylbromide in anhydrous THF (10 mL) was added to the above solution at −78 °C. The reaction mixture was stirred for 2 h at −78 °C, and allowed to warm up to 0 °C. Then, acetone (5 mL) was added, evaporated, and the mixture dried in vacuo. The crude product was purified by column chromatography (flash column, SiO_2, acidic alumina, hexane). Compound **2e** was isolated in 40% yield as colorless prisms, m.p. 142.5–143.5 °C; $C_{18}H_{10}Cl_2Se$ requires C, 57.48; H, 2.68. Found: C, 57.46; H, 2.84%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.34 (d, *J* 7.3 Hz, 2H), 7.36 (t, *J* 7.8 Hz, 1H), 7.43 (t, *J* 7.9 Hz, 1H), 7.49 (d, *J* 8.7 Hz, 2H), 7.55 (dd, *J* 1.0, 7.5 Hz, 1H), 7.73 (dd, *J* 1.0, 8.2 Hz, 1H), 7.77 (dd, *J* 1.0, 8.2 Hz, 1H), 8.33 (dd, *J* 1.1, 7.7 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 74.5, 104.1, 121.7, 126.0, 126.9, 127.3, 128.0, 128.7, 128.7, 128.8, 129.4, 129.7, 130.6, 133.1, 134.8, 137.0; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 329.0.

*2.2.6. 8-Chloro-1-(p-cyanophenylethynylselanyl)naphthalene (**2f**) [33]*

α-(*p*-Cyanophenylcarbonyl)-α-(8-chloronaphthylselanyl)phosphorane (**4**) (0.40 g, 0.62 mmol) was heated under vacuum (0.1 mmHg) at 230 °C for 5 min. The crude product was purified by column chromatography (flash column, SiO_2, hexane:benzene = 9:1). Compound **2f** was isolated in 27% yield as colorless prisms, m.p. 164.5–165.0 °C; $C_{19}H_{10}ClNSe$ requires C, 62.23; H, 2.75; N, 3.82. Found: C, 62.01; H, 2.74; N, 3.98%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.38 (t, *J* 7.8 Hz, 1H), 7.45 (t, *J* 7.9 Hz, 1H), 7.57 (dd, *J* 1.3, 7.4 Hz, 1H), 7.59–7.67 (m, 4H), 7.76 (dd, *J* 0.9, 6.4 Hz, 1H), 7.79 (dd, *J* 1.1, 6.4 Hz, 1H), 8.30 (dd, *J* 1.1, 7.7 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 79.4, 103.7, 111.6, 118.5, 126.1, 126.7, 126.9, 127.9, 128.3, 128.8, 129.5, 129.7, 130.5, 131.9, 131.9, 132.1, 137.0; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 332.7.

*2.2.7. α-(p-Cyanophenylcarbonyl)-α-(8-chloronaphthylselanyl)phosphorane (**4**) [33]*

Under an argon atmosphere, (*p*-cyanophenylcarbonylmethylidene)triphenylphosphorane [34] (1.20 g, 2.96 mmol) was dissolved in benzene (26 mL), and added to a benzene solution (6 mL) of 1-naphthylselanylbromide at the room temperature, and stirred for 2 h at room temperature. A white suspension was formed, and the solid was filtered out from the reaction mixture. The filtrate was evaporated and dried in vacuo. The crude product was purified by column chromatography (flash column, SiO_2, CH_2Cl_2). Compound **4** was isolated in 21% yield as yellow prisms, m.p. 228.0–229.5 °C; $C_{37}H_{25}ClNOPSe$ requires C, 68.90; H, 3.91; N, 2.17. Found: C, 68.58; H, 3.94; N, 2.19%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.19–7.39 (m, 9H), 7.39–7.48 (m, 3H), 7.48–7.68 (m, 10H), 7.80 (d, *J* 8.4 Hz, 2H), 8.31 (dd, *J* 1.1, 7.5 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 57.2 ($^1J_{C,P}$ 88.2 Hz), 112.1, 119.1, 125.5, 126.0 ($^1J_{C,P}$ 101.6 Hz), 125.9, 126.5 ($^3J_{C,P}$ 10.5 Hz), 127.6, 128.1 ($^4J_{C,P}$ 1.9 Hz), 128.3, 128.4 ($^3J_{C,P}$ 12.5 Hz), 130.4, 131.3, 131.7, 132.0, 132.0 ($^4J_{C,P}$ 1.9 Hz), 133.6 ($^2J_{C,P}$ 9.6 Hz), 136.6, 137.4 ($^4J_{C,P}$ 1.9 Hz), 146.3 ($^3J_{C,P}$ 12.5 Hz), 190.5 ($^2J_{C,P}$ 10.5 Hz); δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 406.8 ($J_{Se,P}$ 6.0 Hz).

*2.2.8. 8-Chloro-1-(p-nitorophenylethynylselanyl)naphthalene (**2g**) [33]*

α-(*p*-Nitrophenylcarbonyl)-α-(8-chloronaphthylselanyl)phosphorane (**5**) (0.30 g, 0.79 mmol) was heated under vacuum (0.1 mmHg) at 250 °C for 5 min. The crude product was purified by column chromatography (flash column, SiO_2, hexane:benzene = 4:1). Compound **2g** was isolated in 7% yield as yellow prisms, m.p. 173.0–174.0 °C; $C_{18}H_{10}ClNO_2Se$ requires C, 55.91; H, 2.61; N, 3.62. Found: C, 55.59; H, 2.62; N, 3.69%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.39 (t, *J* 7.8 Hz, 1H), 7.46 (t, *J* 7.8 Hz, 1H), 7.57 (dd, *J* 1.2, 7.5 Hz, 1H), 7.66 (d, *J* 9.0 Hz, 2H), 7.77 (dd, *J* 1.0, 8.2 Hz, 1H), 7.79 (dd, *J* 1.0, 8.2 Hz, 1H), 8.23 (d, *J* 9.0 Hz, 2H), 8.31 (dd, *J* 1.1, 7.7 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 80.7, 103.6, 123.7, 126.1, 126.6, 126.9, 128.4, 128.8, 128.8, 129.6, 129.7, 129.9, 130.4, 132.0, 137.0, 147.0; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 334.2.

*2.2.9. α-(p-Nitrophenylcarbonyl)-α-(8-chloronaphthylselanyl)-phosphorane (**5**) [33]*

A similar method to that described for the preparation of **4** was used. Compound **5** was isolated in 33% yield as yellow prisms, m.p. 138.0–139.0 °C; $C_{36}H_{25}ClNO_3PSe \cdot 2H_2O$ requires C, 61.68; H, 4.17; N, 2.00. Found: C, 61.49; H, 3.90; N, 2.01%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.21–7.29 (m, 5H), 7.30–7.39 (m, 6H), 7.42–7.49 (m, 2H), 7.53–7.68 (m, 7H), 7.82 (d, *J* 8.9 Hz, 2H), 8.07 (d, *J* 9.0 Hz, 2 H), 8.31 (dd, *J* 1.1, 7.5 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 57.7 ($^1J_{C,P}$ 88.3 Hz), 122.7, 125.2, 125.5, 125.9, 126.4, 126.6, 127.6, 128.1 ($^4J_{C,P}$ 1.3 Hz), 128.4 ($^3J_{C,P}$ 12.5 Hz), 128.5 ($^3J_{C,P}$ 11.8 Hz), 129.4 ($^1J_{C,P}$ 100.9 Hz), 131.6, 132.1 ($^4J_{C,P}$ 3.1 Hz), 133.7 ($^2J_{C,P}$ 9.3 Hz), 136.6, 137.2 ($^4J_{C,P}$ 2.5 Hz), 147.8, 148.3 ($^3J_{C,P}$ = 11.8 Hz), 190.4 ($^2J_{C,P}$ 11.2 Hz); δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 406.4 ($J_{Se,P}$ 6.0 Hz).

*2.2.10. 8-Bromo-1-(phenylethynylselanyl)naphthalene (**3a**)*

A similar method to that described for the preparation of **2a** was used. Compound **3a** was isolated in 65% yield as colorless prisms,

m.p. 90.5–91.5 °C; $C_{18}H_{11}BrSe$ requires C, 55.99; H, 2.87. Found: C, 55.93; H, 2.86%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.28 (t, *J* 7.8 Hz, 1H), 7.33–7.38 (m, 3H), 7.41 (t, *J* 7.8 Hz, 1H), 7.53–7.59 (m, 2H), 7.74 (dd, *J* 1.1, 8.1 Hz, 1H), 7.77–7.84 (m, 2H), 8.44 (dd, *J* 1.1, 7.7 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 73.7, 104.7, 119.5 123.2, 126.3, 126.9, 128.3, 128.4, 128.4, 128.7, 129.4, 130.3, 131.3, 131.9, 132.9, 137.3; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 323.7.

2.2.11. 8-Bromo-1-(p-anisylethynylselanyl)naphthalene (**3b**)

A similar method to that described for the preparation of **2a** was used. Compound **3b** was isolated in 33% yield as colorless prisms, m.p. 161.5–162.5 °C; $C_{19}H_{13}BrOSe$ requires C, 54.83; H, 3.15. Found: C, 54.69; H, 3.33%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 3.84 (s, 3 H), 6.89 (d, *J* 8.9 Hz, 2H), 7.27 (t, *J* 7.8 Hz, 1H), 7.40 (t, *J* 7.9 Hz, 1H), 7.51 (d, *J* 8.9 Hz, 2H), 7.72 (dd, *J* 1.1, 8.1 Hz, 1H), 7.77–7.83 (m, 2H), 8.43 (dd, *J* 1.1, 7.7 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 55.4, 71.8, 104.7, 114.0, 115.3, 119.6, 126.3, 126.9, 128.2, 128.7, 129.4, 130.2, 131.3, 132.9, 133.7, 137.2, 160.1; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 323.2.

2.2.12. 8-Bromo-1-(p-tolylethynylselanyl)naphthalene (**3c**)

A similar method to that described for the preparation of **2a** was used. Compound **3c** was isolated in 70% yield as light yellow prisms, m.p. 115.0–116.0 °C; $C_{19}H_{13}BrSe$ requires C, 57.03; H, 3.27. Found: C, 57.05; H, 3.52%; δ_H (400 MHz; $CDCl_3$; Me_4Si) 2.38 (s, 3H), 7.17 (d, *J* 7.8 Hz, 2H), 7.27 (t, *J* 7.8 Hz, 1H), 7.41 (t, *J* 7.8 Hz, 1H), 7.46 (d, *J* 8.2 Hz, 2H), 7.73 (dd, *J* 0.9, 8.2 Hz, 1H), 7.77–7.83 (m, 2H), 8.44 (dd, *J* 1.4, 7.3 Hz, 1H); δ_C (100 MHz; $CDCl_3$; Me_4Si) 21.6, 72.7, 104.9, 119.6, 120.1, 126.3, 126.9, 128.3, 128.5, 129.2, 129.4, 130.2, 131.3, 131.9, 132.9, 137.2, 139.0; δ_{Se} (76 MHz; $CDCl_3$; Me_2Se) 325.2.

2.2.13. 8-Bromo-1-(p-fluorophenylethynylselanyl)naphthalene (**3d**)

A similar method to that described for the preparation of **2a** was used. Compound **3d** was isolated in 48% yield as colorless prisms, m.p. 105.0–106.0 °C; $C_{18}H_{10}BrFSe$ requires C, 53.50; H, 2.49. Found: C, 53.31; H, 2.64%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.05(t, *J* 8.8 Hz, 2H), 7.27 (t, *J* 7.8 Hz, 1H), 7.41 (t, *J* 7.8 Hz, 1H), 7.49–7.59 (m, 2 H), 7.73 (dd, *J* 0.9, 8.2 Hz, 1H), 7.77–7.84 (m, 2H), 8.40 (dd, *J* 1.1, 7.7 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 73.5 ($^5J_{C,F}$ 1.9 Hz), 103.5, 115.7 ($^2J_{C,F}$ 22.4 Hz), 119.3 ($^4J_{C,F}$ 3.7 Hz), 119.5, 126.3, 126.9, 128.2, 128.4, 129.4, 130.2, 131.3, 133.0, 134.0 ($^3J_{C,F}$ 8.1 Hz), 137.3, 162.8 ($^1J_{C,F}$ = 250.0 Hz); δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 323.71.

2.2.14. 8-Bromo-1-(p-chlorophenylethynylselanyl)naphthalene (**3e**)

A similar method to that described for the preparation of **2e** was used. Compound **3e** was isolated in 15% yield as colorless prisms, m.p. 147.0–148.0 °C; $C_{18}H_{10}BrClSe$ requires C, 51.40; H, 2.40. Found: C, 51.36; H, 2.33%; δ_H (300 MHz; $CDCl_3$; Me_4Si) 7.28 (t, *J* 7.8 Hz, 1H), 7.33 (d, *J* 8.8 Hz, 2H), 7.41 (t, *J* 7.8 Hz, 1H), 7.48 (d, *J* 8.8 Hz, 2H), 7.75 (dd, *J* 1.0, 8.1 Hz, 1H), 7.78–7.83 (m, 2H), 8.39 (dd, *J* 1.1, 7.6 Hz, 1H); δ_C (75 MHz; $CDCl_3$; Me_4Si) 75.0, 103.4, 119.5, 121.7, 126.4, 126.9, 128.1, 128.5, 128.8, 129.4, 130.3, 131.3, 133.0, 133.1, 134.8, 137.3; δ_{Se} (57 MHz; $CDCl_3$; Me_2Se) 324.8.

While the 8-chloro derivatives **2f** and **2g** were obtained by the Wittig reaction via triphenylphosphine ylides, similarly to the case of **1f** and **1g** [27,33], the 8-bromo derivatives **3f** and **3g** were not obtained due to facile C_8–Br bond cleavage.

2.3. X-ray structure determination

Single crystals of **2b**, **2e** and **2g** were obtained by slow evaporation of dichloromethane–hexane at room temperature. X-ray diffraction data were collected on a Rigaku/MSC Mercury CCD diffractometer equipped with a graphite-monochromated Mo Kα radiation source (λ = 0.71070 Å) at 103(2) K. The structures were solved by direct methods (SHELXS-97 [35], SIR97 [36] and SIR-2004 [37], respectively) [38] and refined by the full-matrix least squares method on F^2 for all reflections (SHELXL-97) [39].

2.4. Quantum chemical calculations

Quantum chemical (QC) calculations were performed on **1a**–**3a** and their related species. The 6-311+G(d,p) basis set of the GAUSSIAN 03 program [40] was employed for geometry optimizations at the density functional theory (DFT) level of the Becke three-parameter hybrid functionals combined with the Lee–Yang–Parr correlation functional (B3LYP) [41].[2,3] QC calculations were also performed at the Møller–Plesset second order energy correlation (MP2) level [42–44], employing the 6-311+G(d) basis set for Se, Cl and Br and the 4-31G(d) basis set for C and H of the GAUSSIAN 03 program [40].[2,3] The natural bond orbital analysis (NBO) [45–47] and atoms-in-molecules (AIM) analysis [48,49] were also carried out to evaluate the magnitudes of the $n_p(G)\cdots\sigma^*(Se–C_{sp})$ interactions (G-dependence).

3. Results and discussion

3.1. Structures of *2* in crystals

Single crystals were obtained for **2a**–**g**, via slow evaporation of dichloromethane–hexane solutions. X-ray crystallographic analysis was carried out for suitable crystals of **2b**, **2e** and **2g**. Figs. 1–3 show the structures of **2b**, **2e** and **2g**, respectively. The crystallographic data are collected in Table 1. Table 2 collects the selected interatomic distances, angles and torsional angles necessary for the discussion. Scheme 2 shows the structural changes from **1** to **2**, which is called G-dependence.

As shown in Figs. 1–3 and Table 2, the structures are (**B**: **pd**) for **2b** and **2e** and (**B**: **pl**) for **2g**. The results exhibit that the structure of **1b** (**A**: **pl**) changes dramatically to **2b** (**B**: **pd**) by substitution of H with Cl at the 8-position in **2**. We call the effect the G-dependence in **2**. The effect fixes the structure of **2** to **B**. While a variety of structures, such as (**A**: **pl**), (**B**: **pd**) or (**B**: **pl**), are observed in **1**, the observed structure is only **B** in **2**. The observation is quite different from that in **1**. The Y-dependence in **2** must be very similar to that in **1**.

The G-dependence in **2** (**B**: **pd**) should arise from the energy lowering effect of the $n_p(Cl)\cdots\sigma^*(Se–C_{sp})$ 3c–4e interaction, together with the $n_p(Cl)$–π(Nap)–$n_p(Se)$–π(C≡C) interaction of the through bond type. Scheme 3 illustrates the plausible interactions in **2** (**B**: **pd**) and **2** (**B**: **pl**). Y at the *p*-position in **2** (**B**: **pd**) seems not to stabilize the electrons in $n_p(Se)$ due to the orthogonal orientations between $n_p(Y)$ and $n_p(Se)$. The G-dependence must also operate in **3**, which fixes the structures of **3** to be (**B**: **pd**) or (**B**: **pl**) more strongly, since the energy lowering effect of the $n_p(Br)\cdots\sigma^*(Se–C)$ 3c–4e interaction is expected to be larger than the case of G = Cl.

How does the G-dependence stabilize (**B**: **pd**) and (**B**: **pl**)? Factors that control the fine structures of **2** and **3**, together with **1**, are examined based on the QC calculations.

[2] Our procedure for the optimization is explained and exemplified by **2a**: Three structures of types **A**, **B** and **C** are plausible around the Se–C_{Nap} bond in **2a**, with three conformers of **pl**, **pd** and **np** around the linear Se–C≡C–C_{Ar} alignment for each. Consequently, nine structures are expected to exist for **1a** in all. The nine structures are pre-optimized with the B3LYP/3-21G* method. Some structures will fuse to others. Then a few conformers are identified, which are optimized with the B3LYP/6-311+G(d,p) method. The optimized structures with the B3LYP/6-311+G(d,p) method are further optimized at the MP2 level employing suitable basis sets. The results are shown in Table 3, although higher energy species could exist.

[3] The optimized structures are available in the Supplementary data.

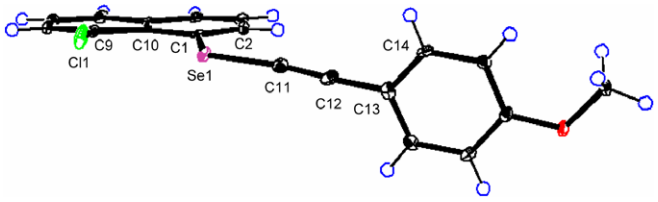


Fig. 1. Structure of **2b** (thermal ellipsoids are shown at the 50% probability level).

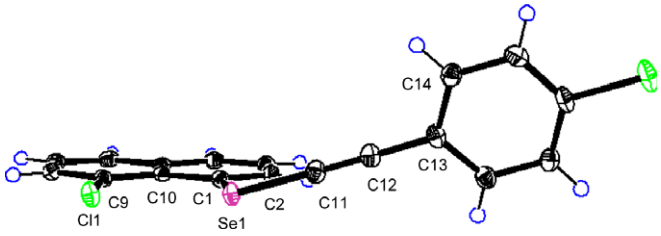

Fig. 2. Structure of **2e** (thermal ellipsoids are shown at the 50% probability level).

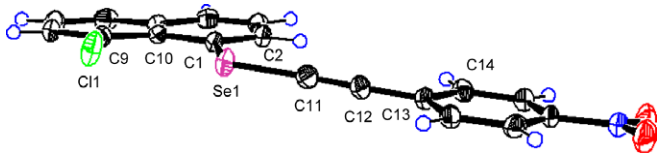

Fig. 3. Structure of **2g** (thermal ellipsoids are shown at the 50% probability level).

3.2. QC calculations

3.2.1. QC calculations on *1a–3a*

QC calculations were performed on (**A**: **pl**), (**B**: **pd**) and (**B**: **pl**) of **1a–3a**[2,3,4] with the B3LYP/6-311+G(d,p) method [41] of the GAUSSIAN 03 program [40]. QC calculations were also performed at the MP2 level [42–44] by employing the 6-311+G(d) basis set for Se, Cl and Br, and the 4-31G(d) basis set for C and H of the GAUSSIAN 03 program [40]. The results are collected in Table 3.

The relative stability of (**A**: **pl**) is predicted to be almost equal to that of (**B**: **pd**) and (**B**: **pl**) at the B3LYP level or the former is more stable than the latter at the MP2 level in **1a**. However, (**A**: **pl**) becomes much less stable relative to (**B**: **pd**) and (**B**: **pl**) in **2a** and **3a**. The $n_p(G)\cdots\sigma^*(Se–C_{sp})$ 3c–4e interaction in (**B**: **pd**) and (**B**: **pl**) must play an important role to lower the energy of the structures. The energy differences between (**B**: **pd**) and (**B**: **pl**) are very small in **2** and **3**, and therefore, the two conformers would be in equilibrium in solution.

How does the $n_p(G)\cdots\sigma^*(Se–C_{sp})$ 3c–4e interaction operate to stabilize (**B**: **pd**) and (**B**: **pl**) in **2** and **3**? Natural bond orbital analysis (NBO) and atoms-in-molecules analysis (AIM) were carried out on the models of **2** and **3**, as well as **2a** and **3a**.

[4] The (**B**: **pd**) and (**B**: **pl**) structures are optimized assuming C_s symmetry. Then they are calculated assuming C_1 symmetry, starting from those very close to the optimized C_s structures. The optimized structures of C_1 symmetry are very close to those of the C_s symmetry for **1a** (**B**: **pd**), **2a** (**B**: **pd**) and **3a** (**B**: **pd**): The frequency analysis of **1a** (**B**: **pd**) showed that it is the global minimum. The calculations are converged to (**B**: **pd**) for **1a–3a**, when started from the structures of C_1 symmetry very close to the optimized (**B**: **pl**) structures of C_s symmetry for **1a–3a**, respectively: The frequency analysis of **1a** (**B**: **pd**) showed that it is a transition state. Table 4 shows the results of the calculations for (**B**: **pd**) and (**B**: **pl**), although **2b** and **2e** are observed as C_1. See also footnote 2 and the Supplementary data (Table S2) of Ref. [27].

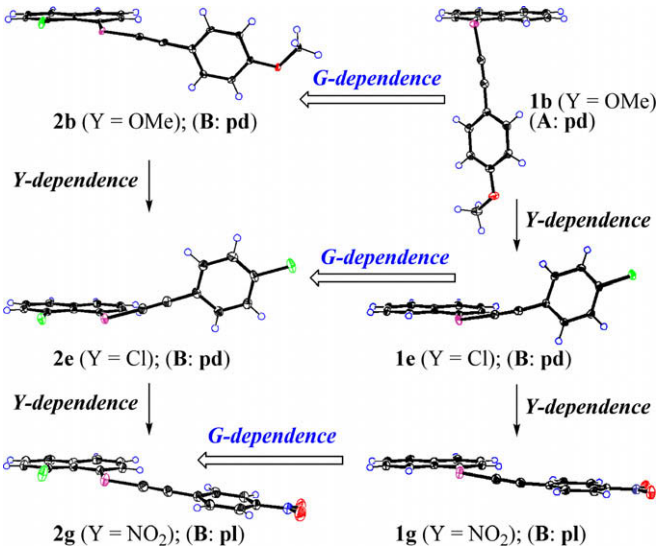
3.2.2. NBO and AIM analyses of the G-dependence

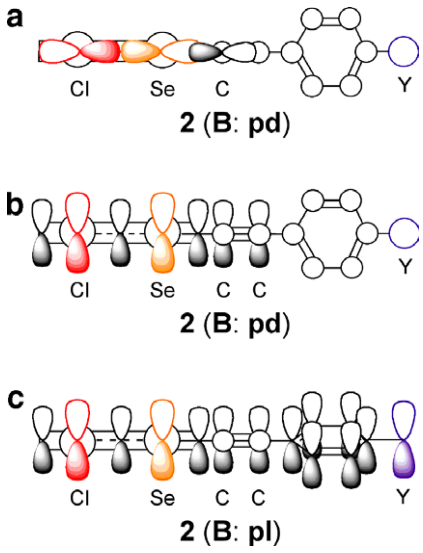
NBO [45–47] and AIM [48,49] analyses were performed on 8-G-1-(HC≡CSe)Nap (**6** (**B**): G = Cl and Br), 8-G-1-(H_2C=CHSe)Nap (**7** (**B**): G = Cl and Br) and 8-G-1-(CH_3CH_2Se)Nap (**8** (**B**): G = Cl and Br), together with **2a** (**B**: **pd**) and **3a** (**B**: **pd**). The B3LYP/6-311+(d,p) method [41] was employed at the B3LYP level and the 6-311+G(d) basis set for Se, Cl and Br and the 4-31G(d) basis set for C and H are at the MP2 level [42–44]. The structures were optimized to be C_s symmetry for **6** (**B**) and **8** (**B**). **7** (**B**) was optimized by placing the S–C_{sp2} bond in the naphthyl plane.

$$E(2) = \Delta E_{ij} = q_i F(i,j)^2/(\varepsilon_j - \varepsilon_i) \quad (1)$$

The CT interactions can be evaluated as the second order perturbation of the Fock matrix in NBO, which is defined by Eq. (1). For each donor NBO (i) and acceptor NBO (j), the stabilization energy $E(2)$ associated with delocalization is estimated as in Eq. (1), where q_i is the donor orbital occupancy, ε_j and ε_i are diagonal ele-



Scheme 2. The G-dependence in **2**: The Y-dependence in **2** must be very similar to that in **1**.



Scheme 3. Orbital interactions: (a) $n_p(Cl)\cdots\sigma^*(Se–C_{sp})$ 3c–4e interaction in **2** (**B**: **pd**), (b) $n_p(Cl)–\pi(Nap)–n_p(Se)–\pi(C{\equiv}C)$ interaction in **2** (**B**: **pd**) and (c) $n_p(Cl)–\pi(Nap)–n_p(Se)–\pi(C{\equiv}C)–\pi(C_6H_4)–n_p(Y)$ interaction in **2** (**B**: **pl**).

ments (orbital energies) and $F(i,j)$ is the off-diagonal NBO Fock matrix element. The results of NBO analysis at the B3PLY level are very similar to those at the MP2 level. The results of the MP2 calculations are collected in Table 4.[5]

The magnitudes of the $n_p(G)\cdots\sigma^*(Se–C)$ interactions are larger than those of the corresponding $n_s(G)\cdots\sigma^*(Se–C)$ interactions and the latter seem not to affect the conclusions. Those of the $n_p(Br)\cdots\sigma^*(Se–C)$ interactions are predicted to be larger than those of the corresponding $n_p(Cl)\cdots\sigma^*(Se–C)$ interactions. The magnitudes of the $n_p(G)\cdots\sigma^*(Se–C)$ interactions of **6** (**B**)–**8** (**B**), shown in Table 4, are summarized as shown in Relation (2). The order shown in Relation (2) show that the contributions stabilize the system through the $n(G)\cdots\sigma^*(Se–C)$ interactions. The optimized non-bonded G···Se distances become longer in the inverse order shown in Relation (2). The results show that the magnitudes of the energy

[5] Those at the B3LYP level are shown in the Supplementary data (Table S1).

Table 3

[i] Supplementary data (Table S2) of Ref. [27].

lowering effect by the $n(G)\cdots\sigma^*(Se–C)$ interactions are closely related to the optimized non-bonded G···Se distances.

$$Se–C_{sp3} \leqslant Se–C_{sp2} < Se–C_{CCAr}\ (\mathbf{2a}(\mathbf{B}\text{: }\mathbf{pd})\text{ and }\mathbf{3a}\ (\mathbf{B}\text{: }\mathbf{pd})) < Se–C_{sp} \quad (2)$$

The results of AIM analysis at the B3PLY level are very close to those at the MP2 level. Table 5 shows the results of the MP2 calculations on the optimized structures of **6** (**B**)–**8** (**B**), **2a** (**B**: **pd**) and **3a** (**B**: **pd**) at the bond critical points (BCPs) for the non-bonded $n(G)\cdots\sigma^*(Se–C)$ (G = Br and Cl) interactions.

The total electron energy density at the BCP ($H_b(r_c)$) is recognized to be a better parameter to discuss weak interactions, as well as the electron density at BCP ($\rho_b(r_c)$) and the Laplacian ($\nabla^2\rho_b(r_c)$). The interactions are ionic and covalent in nature when the values of $H_b(r_c)$ and $\nabla^2\rho_b(r_c)$ are positive and negative, respectively. The nature of the interactions must be close to that of hydrogen bonds

[a] With the 6-311+G(d) basis sets for Se, Cl and Br and the 4-31G(d) basis sets for C and H.

(or the CT interactions in molecular complexes), since the values are all positive with small magnitudes. The $H_b(r_c)$ values for the n(Br)···σ*(Se–C) interactions are smaller than those for the n(Cl)···σ*(Se–C) interactions, which shows that the former are substantially stronger than the latter. The n(Br)···σ*(Se–C_{sp}) interaction seems slightly stronger than other n(Br)···σ*(Se–C) interactions, judging from the $H_b(r_c)$ values.

Fig. 4 draws the results of AIM analysis of **3a** (**B**: **pd**). Fig. 4a shows the BCPs, ring critical points (RCPs) and bond paths of **3a** (**B**: **pd**). Fig. 4b shows contour map of $\rho_b(r_c)$ for **3a** (**B**: **pd**), together with BCPs, RCPs and bond paths. The BCP between Br and Se clearly shows the n(Br)···σ*(Se–C_{sp}) interaction in **3a** (**B**: **pd**). While a bond path is detected between H_2 and C_{sp}, the interaction must be very small.

The nature of the G-dependence of the n(G)···σ*(Se–C) interactions as factors to control the fine structures of **2** and **3** is well clarified by the NBO and AIM analyses. The next extension is to examine the structures in solution.

3.3. Behavior of *1–3* in solution based on NMR spectroscopy

^{1}H and ^{77}Se NMR spectra of **1**–**3** are measured in chloroform-*d* solution (0.050 M) at 297 K.[6] Table 6 collects the $\delta(H_2)$, $\delta(H_8)$ and δ(Se) values for **1**–**3**. The values change depending on Y, although not by much. How are the values correlated with the structures in solution? The δ(H) and δ(Se) values of 9-(arylselanyl)anthracenes [9-(*p*-YC_6H_4Se)$C_{14}H_9$: **9**] and 1-(arylselanyl)anthraquinones [9-(*p*-YC_6H_4Se)$C_{14}H_7O_2$: **10**] are demonstrated to serve as standards to determine the structures of (**A**: **pl**) and (**B**: **pd**) in solution, respectively [50,51]. Scheme 4 illustrates the structures of **9** (**A**: **pl**) and **10** (**B**: **pd**). The values for **9** and **10** are also given in Table 6.

The $\delta(H_2)$ values of **1**–**3** are plotted versus $\delta(H_1)$ of **9** (δ (H_1: **9**)) and $\delta(H_2$: **10**). Fig. 5 shows the plots. The correlations are collected in Table 7 (entries 1–6). The $\delta(H_2)$ values appear more downfield in the order $\delta(H_2$: **1**) ≪ $\delta(H_2$: **2**) < $\delta(H_2$: **3**) (Table 6 and Fig. 5). The results are in accordance with the expectation that each H_2 in **2** and **3**

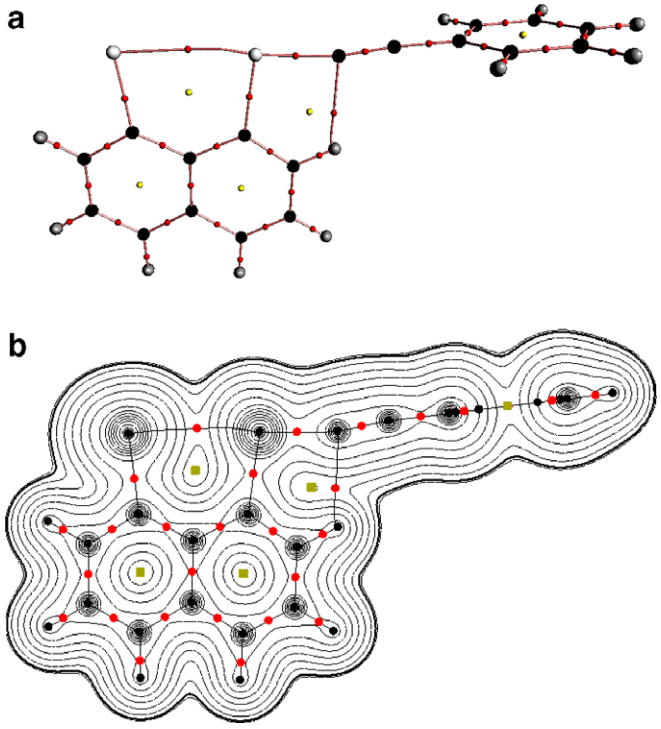

Fig. 4. AIM analysis of **3a** (**B**: **pd**): (a) BCPs (●), RCPs (●) and bond paths and (b) BCPs (●), RCPs (■) and bond paths on the contour map of $\rho_b(r_c)$.

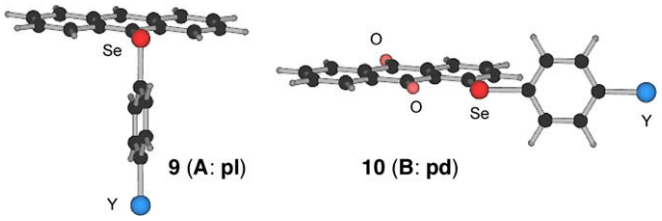
[a] In $CDCl_3$.
[b] From TMS for δ(H) and from Me_2Se for δ(Se).

[6] The concentration dependence of δ(H) is carefully examined for **1**–**3**. No dependence on the concentrations was detected in the measurements, which shows that the contribution from dimers is negligible in **1**–**3**, although dimers are detected for **1a**–**c** in the crystalline state. For the concentration dependence see also Ref. [49].



Scheme 4. Illustration of the **9** (**A**: **pl**) and **10** (**B**: **pd**) structures.

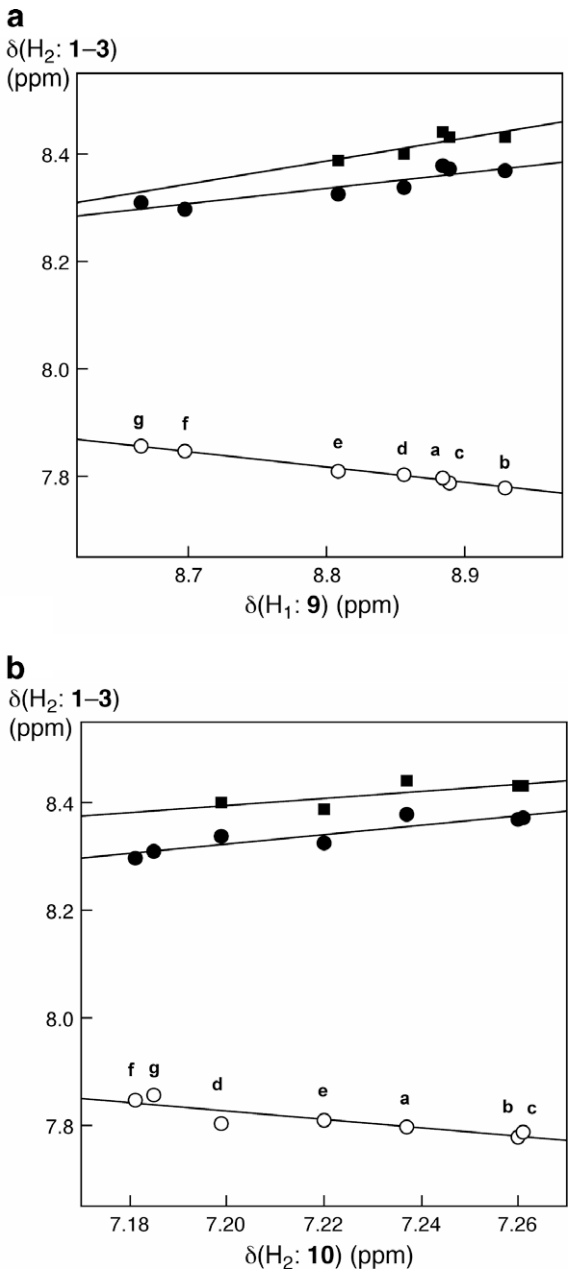


Fig. 5. Plots of $\delta(H_2$: **1**–**3**$)$ vs. $\delta(H_1$: **9**$)$ (a) and $\delta(H_2$: **10**$)$ (b): ○ stands for **1**, ● for **2** and ■ for **3**.

is more deshielded due to the location above the C≡C bond. Namely, the structures of **2** and **3** must be **B** in solution. The anisotropic effect of the C≡C bond in **3** seems to be stronger than that in **2**. The results imply the substantive contributions of (**A**: **pd**) and (**B**: **pl**) to **1** in solution.

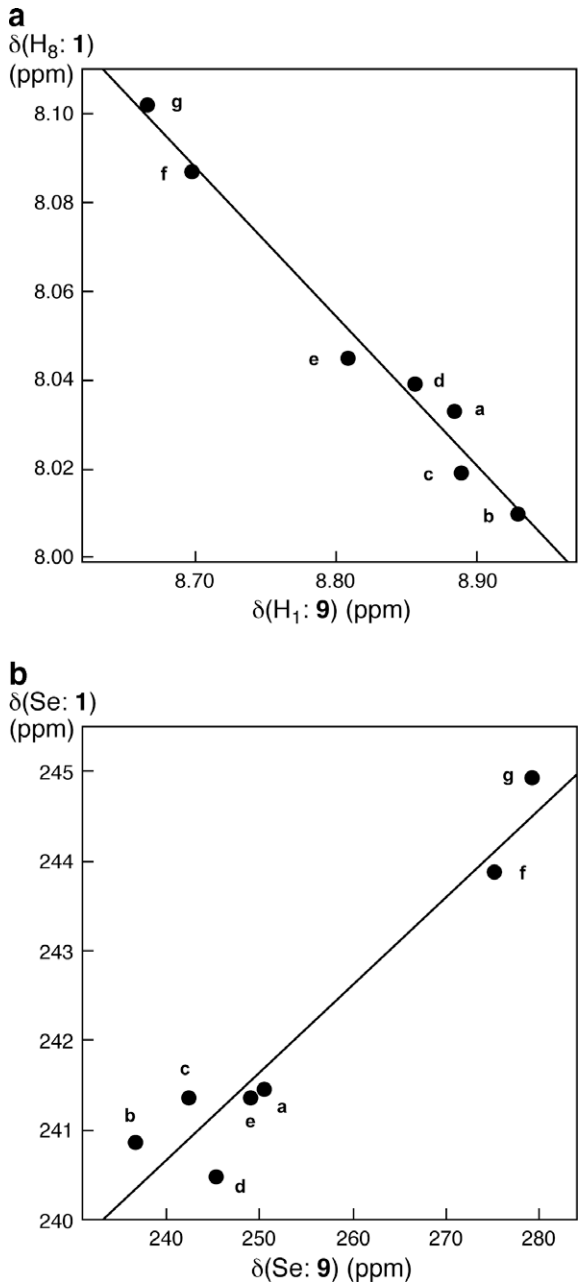

Fig. 6. Plots of $\delta(H_8$: **1**$)$ vs. $\delta(H_1$: **9**$)$ (a) and δ(Se: **1**) vs. δ(Se: **9**) (b).

$\delta(H_8$: **1**$)$ and δ(Se: **1**) are plotted versus $\delta(H_1$: **9**$)$ and δ(Se: **9**), respectively. Fig. 6 shows the results. The correlations are shown in Table 7 (entries 7 and 8, respectively). The correlation in Fig. 6a is good (entry 7), which means that the structures of **1** are closely related to those of **9** (**A**: **pl**). Namely, (**A**: **pl**) contributes predominantly to the structures of **1**, although the correlation constant is a negative value of −0.34. The negative value is a reflection of the inverse anisotropic effect between the phenyl π system and the ethynyl group. It is concluded that the structures of **1** in solution are substantially (**A**: **pl**) with some contributions of (**B**: **pd**) and/or (**B**: **pl**) through an equilibrium. The correlation of the plots of δ(Se: **1**) versus δ(Se: **9**) also supports the conclusion (entry 8).

The preferential contribution of **B** is predicted for **2** and **3** based on the $\delta(H_2)$ values. However, the plots of $\delta(H_2$: **2**$)$ versus $\delta(H_2$: **10**$)$ (entry 5) and those of δ(Se: **2**) versus δ(Se: **10**) (entry 9) do not give good correlations. The plots of δ(Se: **2**) versus δ(Se: **9**) give rather a

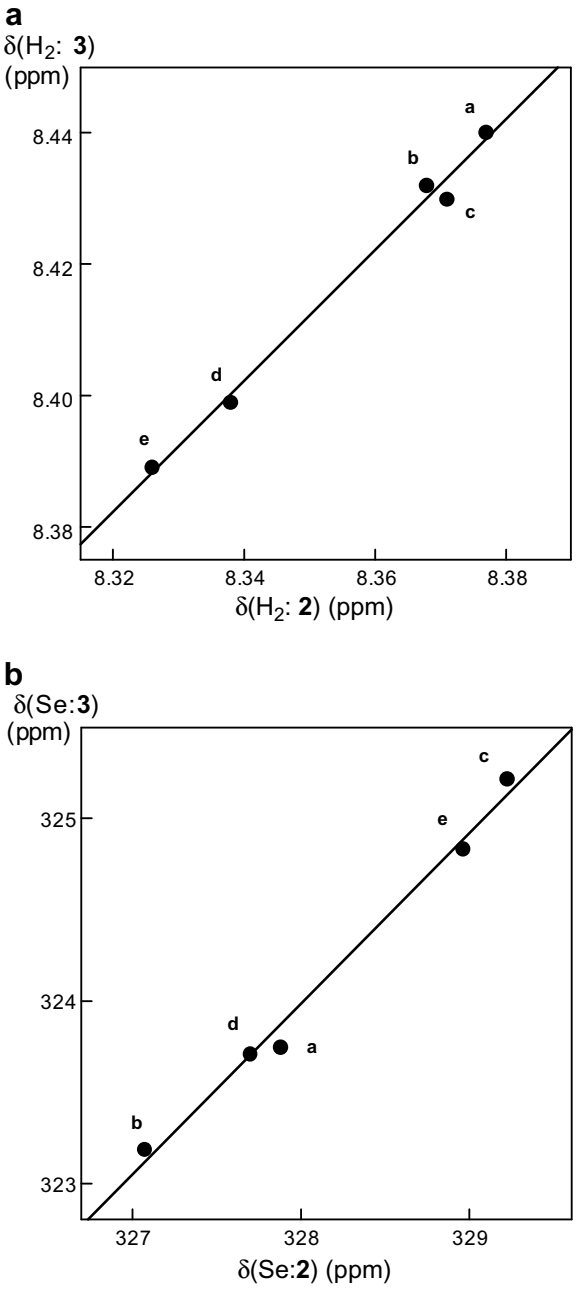

Fig. 7. Plots of $\delta(H_2$: **3**) vs. $\delta(H_2$: **2**) (a) and δ(Se: **3**) vs. δ(Se: **2**) (b).

Table 7
Correlations of δ(H) and δ(Se) in solution for **1**–**3**, **9** and **10**[a]

12	δ(Se: **3**)	δ(Se: **2**)	0.939	16.1	0.995

[a] Analyzed according to $y = ax + b$ (r: correlation coefficient).

good correlation (entry 10). The discrepancy must come mainly from the equilibrium between (**B**: **pd**) and (**B**: **pl**). The consideration is supported by the QC calculations displayed in Table 3. Compilation of these results led us to the conclusion that the structures of **2** are predominantly **B**, which are in equilibrium between (**B**: **pd**) and (**B**: **pl**). The equilibrium with **A** could exist but the contribution must be small for most of Y.

What are the structures of **3** in solution? Fig. 7 shows the plots of $\delta(H_2$: **3**) versus $\delta(H_2$: **2**) and δ(Se: **3**) versus δ(Se: **2**). The correlations are excellent as shown in Table 7 (entries 11 and 12, respectively). The results show that effects and behavior of G = Br in **3** on the structures are very similarly to the case of G = Cl in **2** in solution.

4. Conclusions

The ethynyl π and π^* orbitals play an important role in the appearance of specific properties, but the ethynyl σ and σ^* orbitals must also be of interest for the functionalities of the materials. 8-G-1-(*p*-$YC_6H_4C{\equiv}CSe)C_{10}H_6$ [**2** (G = Cl) and **3** (G = Cl): Y = H (**a**), OMe (**b**), Me (**c**), F (**d**), Cl (**e**), CN (**f**) and NO_2 (**g**)] have been prepared and the chemical shifts measured. Structures have been determined by X-ray crystallographic analysis for **2b**, **2e** and **2g**. The structures are all **B** around the Se–C_{Nap} bonds, in our definition. The structures around the linear Se–C_{sp}–C_{sp}–C_{Ar} alignment are **pd** for Y = OMe and Cl and **pl** for Y = NO_2. The **1b** (**A**: **pl**) structure with Y = OMe changes dramatically to **2b** (**B**: **pd**) with G = Cl at the 8-position in **2**. The effect is called G-dependence. The G-dependence must arise from the energy lowering effect of the $n_p(Cl)\cdots\sigma^*$(Se–C_{sp}) 3c–4e interaction. The $n_p(Cl)$–π(Nap)–n_p(Se)–π(CC) interaction may also contribute to the stabilization of the structure. The **B** structures must be greatly stabilized by the $n_p(Cl)\cdots\sigma^*$(Se–C_{sp}) 3c–4e interaction (G-dependence) even if the structures of **2** and **3** are not changed from those of **1**. The G-dependence can be analyzed as the G···Se–C_{sp}–C_{sp}–C_{sp2} 5c–6e type interaction. The structures of **2** and **3** were also examined in solution based on NMR parameters for (**A**: **pl**) of 1-(arylselanly)anthracene (**9**) and (**B**: **pd**) of 1-(arylselanly)anthracene (**10**). The results show that **2** and **3** behave very similarly in solution and the structures of **2** and **3** are predominantly **B** in solution, with some equilibrium between (**B**: **pd**) and (**B**: **pl**). The observed results and the origin of the G-dependence in **2** and 3 are well rationalized by QC calculations containing NBO and AIM analyses.

ent cytotoxic effects. Although differences between oxaliplatin and cisplatin in DNA binding, adduct formation, strand breaks, and apoptosis have been reported, the mechanisms behind the more potent cytotoxic activity of oxaliplatin compared with cisplatin against colon cancer cells have not yet been completely elucidated.

On the theoretical front, the interaction of cisplatin with water has been studied by various authors [19–35]. However, to our knowledge, no such studies have been reported for the third generation platinum drug, oxaliplatin (eloxatin). In view of the biological importance of this compound, we have carried out a systematic study of the structural properties of oxaliplatin and its various conformational forms. After comparing the relative energies of various conformers, we identified the most stable one. To check the accuracy of the methods used, the results of our density functional (DF) calculations were also compared with the experimental results, wherever possible. In addition, the experimental FT-IR spectrum was determined for the more potent isomer and compared with the theoretically predicted values.

2. Methods

2.1. Computational details

First-principles density functional (DF) calculations were performed on the various conformers of oxaliplatin using the DMol^3 code [36–39] available from Accelrys Inc. in the MATERIALS STUDIO 3.2 package. Our calculations employed numerical basis sets of double-ζ quality plus polarization functions (DNP) to describe the valence orbitals. This is the numerical equivalent of the Gaussian 6-31G** basis set. The core electrons were treated using DFT semilocal pseudopotentials (DSSP) [40]. These core potentials include some degree of relativistic effects and are thus very useful approximations for heavier elements, and, furthermore, the calculation is less computationally expensive since the core electrons are dropped. Details of the calculations are described elsewhere [41].

Geometry optimizations, without restrictions, were performed using delocalized internal coordinates. The exchange-correlation contribution to the total electronic energy was treated in a spin-polarized generalized-gradient corrected (GGA) form with the Perdew-Wang-91 correlation (PW91). Density functional calculations at the GGA level are expected to give good prediction for the bond lengths and bonding energies. We chose PW91 for our study because the Perdew-Wang density functional is superior to other DFT methods for the simultaneous prediction of both molecular geometries and vibrational frequencies of platinum(II) complexes [42]. The vibrational frequencies were calculated and these were used to calculate the zero-point corrections to the energies and to confirm that the structures are minima on the potential energy surface, i.e. all the vibrational frequencies are real. Free valences and bond orders were calculated using Mayer's procedure [43].

2.2. Experimental details

Oxaliplatin was purchased from the Sigma Chemical Company and used as such without further purification. The FT-IR spectrum (4000–400 cm^{-1}) was recorded on a Perkin Elmer FT-IR Spectrometer Spectrum 2000. High quality KBr was used as the dispersal medium.

3. Results and discussion

3.1. Conformers of DACH

The spectator ligand DACH plays an important role in determining the higher biological activity of oxaliplatin compared to cisplatin. Besides imparting lipophilic character to the complex, DACH is expected to display a wide range of possible conformers because of the presence of the cyclohexane ring. Investigations on this type of chiral complexes showed that the *trans* isomer *trans-l (trans-(−)-1R,2R)* is more efficacious than the corresponding *trans-d (trans-(+)-1S,2S)* and the *cis*-isomer (1*R*,2*S*) [17]. Thus, the activity might be explained by speculating on the stereochemical structures of the complexes.

The cyclohexane ring of DACH can have various conformations, such as chair, boat or twist boat. The chair form, expected to be the most stable one, is the obvious choice for the study, but the twist boat form has also been reported to exist [44], and is higher in energy than the other possible conformers in which the cyclohexane moiety is in the chair form.

The ligand DACH has two amino groups attached to two adjacent carbons. Each amino group may be attached at either the axial or equatorial position. The chair form of DACH may exist in three conformers:

(i). *cis*-Cyclohexyl-1,2-diamine [cis-(1*R*,2*S*)], in which one amine group is axial (a) and the other is equatorial (e).
(ii). *trans-d*-Cyclohexyl-1,2-diamine [*trans-d* (1*S*,2*S*)], in which both the amine groups are in equatorial position, and
(iii). *trans-l*-Cyclohexyl-1,2-diamine [*trans-l* (1*R*,2*R*)], in which both the amine groups are in equatorial position.

The (ii) and (iii) forms are optical isomers of each other.

In addition to these three isomers, we have also incorporated another form, in which the cyclohexane ring is in a twist boat conformation, in our studies.

3.2. Relative energies

In oxaliplatin, platinum is bound on one side to the two amine nitrogens of the large 1,2-diaminocyclohexane (DACH) ligand and to the other side by two oxalate oxygens in a chelating fashion (see Fig. 1). Taking the various conformers of the cyclohexane ring in turn, the energies of the complexes were determined, and the relative energies are listed in Table 1.

As expected, the diaxial conformation of DACH is not preferred in the complex (relative energy = 36.9 kcal/mol), and the equilibria between the diaxial and diequatorial conformations for the *trans* isomers favor the latter. This is due to the increased steric hindrance of axial locations. The relative energy of 6.6 kcal/mol obtained for the twist boat form proves theoretically the possibility of existence of the complex with DACH in the twist boat form at higher temperatures. No such complex has been experimentally reported as yet.

Both the *trans* forms are most stable. However, a close inspection of the relative energy values for *trans-(S,S), trans-(R,R)* and *cis-(R,S)* isomers reveals that they all co-exist at room temperature, as the energy difference between them is significantly less than 5 kcal/mol. Of these, *trans-d* (*S*,*S*) and *trans-l* (*R*,*R*) deserve special mention as they are optical isomers and the energy difference

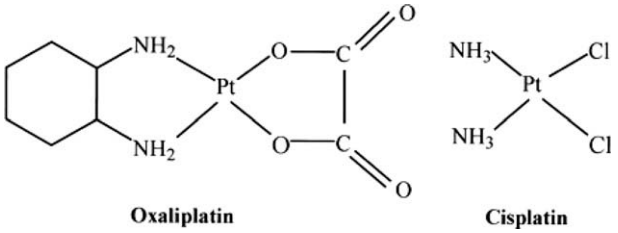

Fig. 1. Chemical structures of oxaliplatin and cisplatin.

Table 1
DFT relative energies (kcal/mol) of the various isomers of oxaliplatin

DACH conformation	Relative energy
trans ee (*S*,*S*)	0.0[a]
trans ee (*R*,*R*)	0.3
cis ae (*R*,*S*)	1.1
Twist boat form	6.6

[a] ZPVE corrected energy: −576828.2 kcal/mol.

between them is negligibly small. On the basis of these calculations, we expect both isomers to have almost an equal population at room temperature.

Our expectations are borne out by the experimental results. In an effort to solve the structure of the active species of oxaliplatin, an X-ray structural investigation was carried out on oxaliplatin [45]. The complex was prepared by reacting the enantiomerically pure isomer *trans-l* (*trans*-(−)-1*R*,2*R*-diaminocyclohexane (DACH)) and the platinum salt $K_2[PtCl_4]$ in H_2O. They found that the oxaliplatin which was isolated does not consist only of the desired isomer, but a mixture of both the *trans-l* and *trans-d* isomers. No retention of optical isomerism was observed despite the fact that the enantiomerically pure DACH ligand was utilized, although it had been earlier reported [46] that only the absolute configuration of the *trans-l*-DACH ligand exists in the platinum complex.

The Pt complexes of the three isomers [*cis-(R,S)*, *trans-l* (*R*,*R*) and *trans-d* (*S*,*S*)] interact differently with DNA. It has been shown that the *trans-l* (*R*,*R*) isomer of oxaliplatin is the most effective against cisplatin-sensitive and cisplatin-resistant cancer cell lines [17].

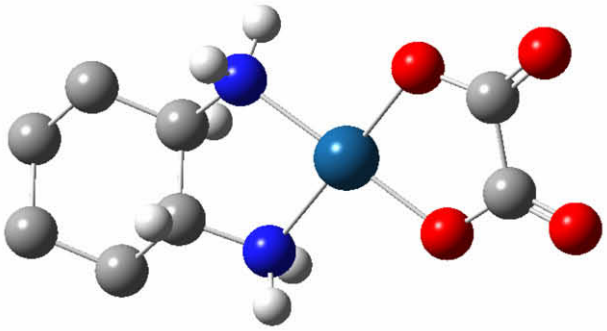
Proteins that discriminate between cisplatin–DNA adducts and oxaliplatin-DNA adducts are thought to be responsible for the differences in tumor range, toxicity, and mutagenicity of these two important chemotherapeutic agents. However, the structural basis for differential protein recognition of these adducts has not been determined and could be important for the design of more effective platinum anti-cancer agents. Recently, a lot of work has been devoted to understanding the differences between cisplatin and oxaliplatin binding to DNA [47–50]. Several significant conformational differences were observed between the cisplatin–GG adduct and the oxaliplatin–GG adduct [49,50]. It has also been demonstrated [51,52] that the chirality at the carrier ligand of oxaliplatin can affect its biological effects.

Thus, the stereochemistry of the carrier amine ligands of cisplatin analogues can modulate their anti-cancer and mutagenic properties. The significance of this finding is also reinforced by the fact that, in general, interstrand cross-links formed by various compounds of biological significance result in greater cytotoxicity than is expected for monofunctional adducts or other intrastrand DNA lesions [53]. Therefore, the unique properties of the interstrand cross-links of oxaliplatin are at least partly responsible for this drug's unique antitumor effects.

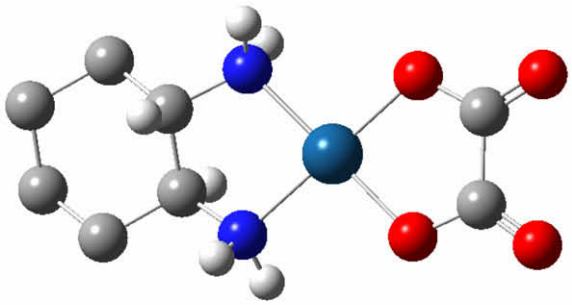
3.3. Optimized geometries

Geometry optimizations were performed on all possible conformers. The isomers differ in the orientations related to the cyclohexane ring of the DACH ligand. As far as the coordination sphere is concerned, all the isomers exist in the square planar geometry. This is expected, as Pt(II) compounds show stability in this form only [54]. The oxalate group is not only planar in itself but also in plane with the coordination sphere. All the optimized structures are shown in Fig. 2.

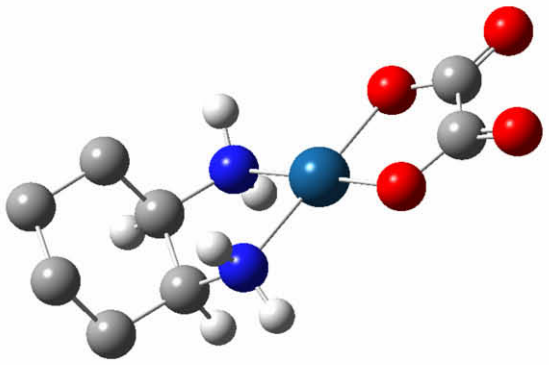
The calculated bond lengths and bond angles for the *trans-l* (*trans*-(−)-1*R*,2*R*) isomer are listed in Table 2 along with the corresponding experimental data [46] obtained from single crystal X-ray analysis of oxaliplatin. The numbering scheme used in these optimized structures is displayed below (Scheme 1):



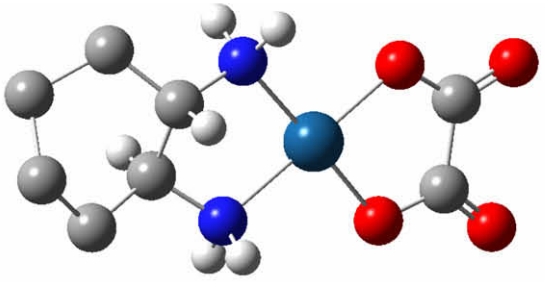
[Pt(1,2-*trans*-*R*,*R*-diaminocyclohexane)(O-O-oxalato)]



[Pt(1,2-*trans*-*S*,*S*-diaminocyclohexane)(O-O-oxalato)]



[Pt(1,2-*cis*-*R*,*S*-diaminocyclohexane)(O-O-oxalato)]



Twist boat form of oxaliplatin

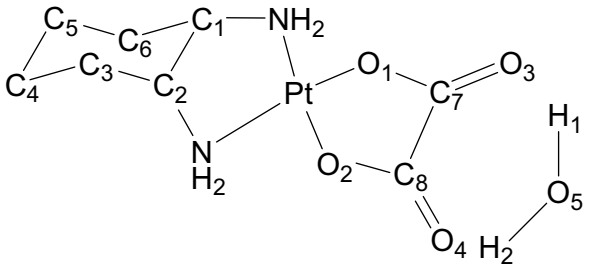
[b] From Ref. [46].



Scheme 1. Structure and numbering scheme of $[Pt(C_2O_4)(DACH)] \cdot H_2O$.

Although the computed gas phase free structure cannot be compared with the X-ray structure for the solid state, in the absence of any other available data we compared the structural parameters of the *trans-(R,R)* form with the X-ray crystallographic data. It is found that the DFT results are in good agreement with experiment (Table 2).

The optimized geometries of all the investigated isomers are compared in Table 3. Our earlier hypothesis that the difference between the isomers is limited to the DACH ligand area only has been proved by a comparison of the geometric parameters of the isomers (Table 3). All the isomers have very close values as far as the oxalate ligand parameters are concerned, since the calculated O_1–Pt, O_2–Pt, C_7–C_8, O_1–C_7 and O_2–C_8 bond lengths have very little difference among all the isomers. In a similar fashion, all the C–C bond lengths, except C_1–C_2, which is slightly higher for the *cis* isomer, have quite similar values.

The two amino groups are bound to platinum in a way to form a distorted square planar geometry of the coordinate sphere, and the Pt–N bond lengths are ~2.1 Å in all the complexes. Except in the *trans*-(+)-*S,S* isomer, there is considerable difference in the N_1-Pt and N_2-Pt bond lengths, but the O_1–Pt and O_2–Pt bond lengths are similar. The ∠NPtO bond angles are much larger than the ∠NPtN and ∠OPtO bond angles.

Hence we conclude that all the chair forms have almost equal thermal stability, and are much more stable than the twist boat conformer. Of the three stable chair forms, the *trans-(R,R)* conformer has been found to be the most potent [17]. Thus we consider only the two *trans*-forms for further studies.

3.4. Charge population analysis

Table 4 presents the calculated Hirshfeld [55,56] and Mulliken partial atomic charges on the various atoms in the free ligands, DACH and oxalate anion, and the two *trans* complexes of Pt(II). The Hirshfeld charges are considered to give a better description of the charge distribution than the Mulliken charges, which show a large dependence on the basis set.

The charge of the metal ion in the free state is +2.0. It is seen that the positive charge of the metal ion decreases in the complex to +0.18, which indicates that transfer of electrons from the ligands to the metal ion has occurred and the coordination bonds have formed. To see how the charge transfer occurs, we compared the values of partial atomic charges on the free ligand with that of the Pt(II) complex (oxaliplatin), in which the charge transfer takes place.

Although there is no change in the charge density on the carbon atoms of DACH on complexation, a decrease of 0.13 *e* in the charge density on each of the two nitrogens indicates that transfer of electron density to the metal ion occurs through these coordinated atoms.

The observation from the Mulliken charges is quite the opposite, i.e. an appreciable increase (~0.1) in the negative charge on each of the C_3, C_4, C_5 and C_6 carbon atoms of DACH, and practically no change on the nitrogen atoms.

A decrease (~0.3) in negative charge on each of the oxygens of oxalate shows that a considerable amount of charge is transferred from these four oxygens to the metal ion. Simultaneously, an increase of about ~0.1 in the positive charges of C_7 and C_8 is also noted. These observations indicate contribution of the whole of the ligand in the charge transfer from the oxalate ion to the metal ion.

A noteworthy point is the similarity in the charge distributions of all the isomers, signifying that electronic differences are not the reason for the differences in their reactivity.

According to Pearson's HSAB concept, Pt^{2+} is a soft acid and O^{2-} is a soft base, while NH_3 is a hard base. This indicates that there

* See Scheme 1 for the numbering of atoms.

should be stronger interaction between Pt^{2+} and O^{2-} than between Pt^{2+} and the NH_2 groups of DACH. Our calculations are in accord with this principle, as there is a transfer of only 0.6 *e* from DACH to Pt while 1.2 *e* is transferred by oxalate. This shows that a total charge of ~1.8 *e* is transferred to Pt(II) during the complexation, and the net charge on Pt(II) reduces to ~0.2 *e*. The electronic configuration of platinum in the complex is: [core] $5s^2 6s^{0.92} 5p^{5.99} 6p^{0.35} 5d^{8.53}$. This shows that, out of the total charge density donated by the ligands to Pt^{2+}, approximately one electron goes to the 6s orbital, and approximately one-half to 5d, and the rest of the electron density is gained by the 6p orbital.

3.5. Bond order analysis

We calculated the Mayer bond orders for all the bonds of the complex and the results are produced in Table 5.

Table 5 shows that there is practically no difference in the bonding pattern of the two complexes. The N–Pt and O–Pt bond orders are around 0.6 and 0.7, respectively, which indicates covalent character in the bonds. Reduction in the bond order of O_1–C_7 and O_2–C_8 from 1.6 to 1.15 shows that charge has been carried away from these bonds. The C_7–O_3 and C_8–O_4 bonds regain their double bond character which was lost in the free oxalate ion due to resonance. However, there is a slight increase in the C_7–C_8 bond order of the oxalate group. The N–C and C–C bond orders of the DACH ligand decrease due to electron density transfer from these bonds.

We also examined the ligand orbitals in free DACH, oxalate ion and complex. Fig. 3a gives a plot of the highest occupied molecular orbital (HOMO) of DACH. This orbital has an energy of −4.71 eV. It is clear that the HOMO is centered on the nitrogens, which being thus electron rich, can donate charge density to the vacant metal ion orbital.

Fig. 3b gives the plot of the HOMO of the oxalate ion. In oxalate, as expected, the HOMO comprises the four oxygen atoms equally. The energy of this orbital is 6.26 eV.

Fig. 3c shows the plot of the HOMO of oxaliplatin. It can be seen from the plot of the HOMO of the complex that not only are the oxalate ligand orbitals retained, but the metal *d* orbitals also

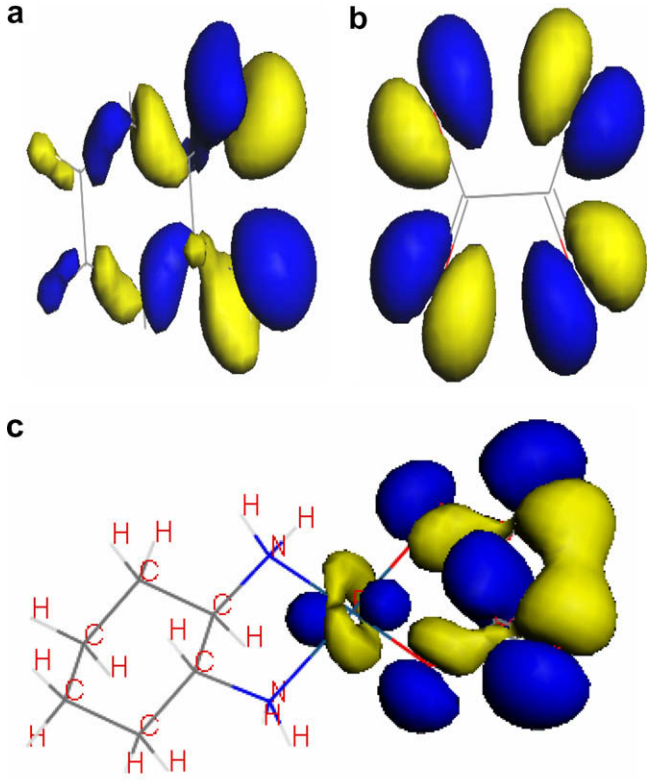

Fig. 3. Plot of HOMOs of (a) 1,2-diaminocyclohexane (DACH), (b) oxalate, (c) Pt(II) complex (oxaliplatin).

become part of the HOMO for the square planar Pt(II) complex, showing an interaction between oxalate and Pt(II) orbitals. The energy of the HOMO of the Pt(II) complex is −4.68 eV. It is interesting to note that the HOMO of the other ligand (DACH) is not a part of the HOMO of the complex. This can be explained quite conveniently by comparing the energies of the HOMOs of the two ligands. Oxalate ion, being negatively charged, has a high energy HOMO, which can contribute electron density to Pt^{2+}, forming the complex whose HOMO lies above the HOMO of DACH.

3.6. Vibrational analysis

The FT-IR spectrum of oxaliplatin was recorded in the range 400–4000 cm^{-1}. The detailed list of calculated frequencies and the corresponding intensities, as well as the experimental FT-IR and the corresponding computed infrared absorption spectrum are given as Supplementary data. The spectra have a very complicated pattern, as each band corresponds to mixed vibrations.

3.6.1. Pt–Ligand Vibrations

The platinum–ligand vibrations are expected to occur in a very low frequency range (below 600 cm^{-1}). In the process of assigning the frequencies obtained from the theoretical IR spectra, we found that the band at 551 cm^{-1} corresponds to the symmetric stretching vibration, ν_s(Pt–N). Calculations have also revealed that the frequency of the asymmetric Pt–N stretching vibration ν_a(Pt–N), which is at 559 cm^{-1}, is very close to ν_s(Pt–N). It is clear that both the symmetric and asymmetric Pt–N stretching vibrations in oxaliplatin contribute to a strong band observed in the experimental FT-IR spectrum at 573 cm^{-1}. The frequency of Pt–N stretching in oxaliplatin is higher in comparison to that in carboplatin and cisplatin. In the FT-Raman spectrum of cisplatin, the strongest band observed at 522 cm^{-1} and weaker band at 506 cm^{-1} were assigned to the symmetric and asymmetric Pt–N stretching vibrations [57], respectively. However in the FT-IR spectrum of carboplatin, the strong band at 545 cm^{-1} and a weak band at 548 cm^{-1} were assigned to the symmetric and asymmetric Pt–N stretching vibrations [58].

The theoretical results consistently indicate that the strong band at 780 cm^{-1} should be assigned to the asymmetric Pt–O stretching and the band at 854 cm^{-1} to the symmetric Pt–O stretching, coupled with the symmetric stretching of the C–C bond of the oxalate group. Similarly the very strong band at 808 cm^{-1} in the experimental FT-IR spectrum is assigned to the symmetric Pt–O stretching. The medium intensity band at 306 cm^{-1} in the calculated theoretical spectra is assigned to O–Pt–O bending. The band in the range of 50–173 cm^{-1} in the theoretically predicted IR spectrum is assigned to the N–Pt–O bending. Similarly the band at 195 cm^{-1} is assigned to the N–Pt–N bending. Comparison of the experimental and theoretical spectra has revealed that both the positions and intensities of the bands are well predicted by the PW-91 method.

3.6.2. Oxalate group vibrations

In the calculated theoretical spectrum, the very weak band at 339 cm^{-1} is assigned to the O–C=O in-plane bending. A strong band at 433 cm^{-1} is assigned to the O–C=O out-of-plane bending. The strong band at 1142 cm^{-1} in the calculated theoretical spectrum is assigned to the asymmetric C–O stretching. However, very strong bands at 1282 cm^{-1} and 1284 cm^{-1} are assigned to the Pt–O symmetric stretching, coupled with the C–C stretching. The band for C–O stretching in the experimental FT-IR occurs at 1226 cm^{-1}.

In the region 1550–1700 cm^{-1}, the ν(C=O) stretching vibrations and the NH_2 degenerate deformations, $\delta_d(NH_2)$ are expected to occur. In the FT-IR spectrum of oxaliplatin, two closely lying strong bands at 1662 and 1700 cm^{-1} are undoubtedly due to the C=O stretching vibrations; however, in the theoretical spectrum the bands at 1723 and 1741 cm^{-1} are assigned to the C=O stretching vibrations.

3.6.3. DACH group vibrations

The diaminocyclohexane ring vibrations are further discussed in two subsections:

3.6.3.1. Cyclohexane ring vibrations. In the calculated FT-IR spectrum of oxaliplatin, the strong band at 1039 cm^{-1} is assigned to the C–N stretching vibrations; similarly, in the theoretical spectrum the very strong band at 1012 cm^{-1} is assigned to the C–N stretching. In the theoretically calculated spectrum the bands at 1026–1062 cm^{-1} are assigned to the characteristic ν(C–C) stretching of the cyclohexane ring, similarly the strong band at 1106 cm^{-1} corresponds to the symmetric stretching of the C–C bond of the two carbons attached to nitrogens.

The scissoring vibrations of the methylene group in oxaliplatin are assigned to the bands observed at 1444 and 1456 cm^{-1} in the calculated theoretical spectrum. Similar results are recorded for the theoretical spectrum of carboplatin in which the scissoring vibrations of methylene group were observed at 1436 and 1463 cm^{-1} [58]. The band in the range of 2954–3058 cm^{-1} is assigned to the C–H stretching vibration in the calculated theoretical spectrum; similar bands at 2928 and 3085 cm^{-1} appear in the experimental FT-IR spectrum.

3.6.3.2. Amino group vibrations. The strong band at 3085, 3158 and 3212 cm^{-1} in the experimental FT-IR spectrum and the bands in the range of 3364–3460 cm^{-1} in the calculated theoretical spectrum are assigned to the N–H stretching vibrations of the amino groups of oxaliplatin.

The degenerate deformation vibration of ammonia gives a strong band at 1610 cm^{-1} in the FT-IR spectrum; similarly, we get two strong bands at 1609 and 1620 cm^{-1} which correspond to wagging of NH_2. The symmetric deformation vibrations of NH_2 are coupled with the degenerate deformation mode (twisting and wagging vibrations) of the methylene group and generate the medium intensity bands at 1444 and 1456 cm^{-1} in the calculated theoretical spectrum. However, in the experimental FT-IR spectrum, these vibrations give a very strong band at 1377 cm^{-1}. No peak corresponding to NH_2 rocking vibrations is found in the FT-IR spectrum since, as shown by theoretical calculations, NH_2 rocking vibrations give rise to the bands at 659 and 697 cm^{-1} of negligible intensity.

3.7. Oxaliplatin monohydrate

Al-Allaf et al. [59] synthesized crystals of oxaliplatin for X-ray determination. It was found that, although the complex was prepared starting from the enantiomerically pure isomer *trans-l* (1*R*,2*R*) as confirmed by X-ray analysis [45], it does not consist of the desired (1*R*,2*R*) isomer, but rather the (1*R*,2*S*) isomer. This encouraged them to prepare the platinum complex of the *cis* isomer of the DACH ligand in order to study its behavior from the X-ray point of view and to compare the results with those of the isomeric complex [Pt(C_2O_4){(1*R*,2*R*)-DACH}] reported previously [46]. It was seen that the [Pt(C_2O_4)(*cis*-DACH)] complex crystallizes with one molecule of water as [Pt(C_2O_4)(*cis*-DACH)] · H_2O in well-shaped colorless crystals.

The water molecule is reported to be placed at the oxalate end, in plane with the oxalate group and oriented to have two H-bonds with the two non-bound oxygens of the oxalate ligand [59]. We therefore restricted our studies to this position of the water molecule. The hydrated molecule thus has following structure:

3.7.1. Optimized geometries

The optimized geometry of *cis*-(*R*,*S*) was taken as calculated earlier. The water molecule is placed in such a way that the two hydrogen of the water molecule are in close contact with the two carbonyl oxygens of the oxalate ring, as has been previously reported [59], and geometry optimization was performed on the resulting structure. The numbering scheme and the optimized structure of [Pt(C_2O_4)(*cis*-DACH)] · H_2O are shown in Figs. 2 and 4.

The calculated bond lengths and bond angles for the [Pt(C_2O_4)(*cis*-DACH)] · H_2O isomer are listed in Table 3, together with the corresponding experimental data obtained from single crystal X-ray analysis of [Pt(C_2O_4)(*cis*-DACH)] · H_2O [59] to check the accuracy of our calculation.

It is found that the DFT results are in good agreement with the experimental data within the error range, considering that the former are obtained for the gas phase and the latter are for the solid state.

To gauge the effect of hydrogen bonding on the geometry and stabilization of the complex we compared the geometric parameters of the hydrated complex with the anhydrous complex. It is found that there is no major change in the geometric parameters of DACH in the hydrated and anhydrous [Pt(C_2O_4)(*cis*-DACH)] forms of the complex.

A slight change is noted in the geometric parameters of the coordination sphere. In the hydrated form, the equatorial N–Pt bond is shorter by 0.003 Å, while for the axial N–Pt bond this change is 0.008 Å. The O–Pt bond gets elongated by 0.003 Å. No change is noted in the equatorial N_1–C_1 bond, but the equatorial N_2–C_2 bond increases by 0.003 Å.

The effect on the bond lengths of the oxalate ring in the hydrated form is found to be larger, as expected. The O_1–C_7 and O_2–C_8 bond lengths decrease by 0.006 Å, while an increase in bond length by 0.004 Å is noted in case of the C_7–O_3 and C_8–O_4 bonds. The distance of 2.1 Å between the carbonyl oxygen of the oxalate group and the hydrogens of water, indicates hydrogen bonding between the two, as this is much smaller than the sum of the van der Waals radii of oxygen and hydrogen (2.72 Å).

3.7.2. Charge population analysis

Table 4 represents the calculated Hirshfeld partial atomic charges in [Pt(C_2O_4)(*cis*-DACH)] · H_2O and anhydrous [Pt(C_2O_4)(*cis*-DACH)]. No significant change is noted in the charge densities on the atoms of the DACH ring in the anhydrous and hydrated *cis* complex. A decrease of 0.03 in the negative charge on O_3 and O_4 is noted, showing the decrease in electron density at these two oxygens on hydration, as these two oxygens are directly involved in hydrogen bonding.

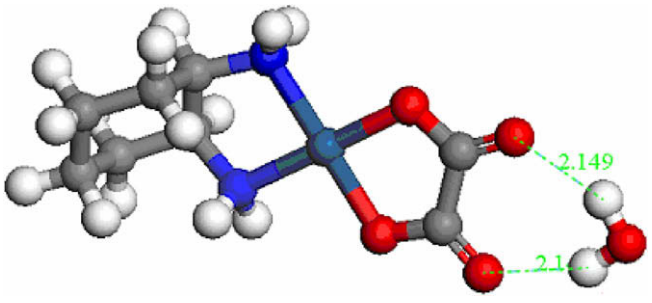

Fig. 4. Optimized structure for Pt(C_2O_4)(*cis*-DACH)] · H_2O.

3.7.3. Bond order analysis

We calculated the Mayer bond order for the bonds in [Pt(C_2O_4)(*cis*-DACH)] · H_2O, and the results are compared with those in the anhydrous [Pt(C_2O_4)(*cis*-DACH)] complex to find out the structural difference caused by the hydrogen bonding on the metal ligand binding. Table 5 shows the calculated bond orders for [Pt(C_2O_4)(*cis*-DACH)] · H_2O and the anhydrous complex.

Compared to the anhydrous complex, the Pt–N bond strengthens slightly, while the Pt–O bond becomes slightly weaker. Thus, coordination with a water molecule increases the capacity of oxalate as a leaving group. No significant change is noted in the bond orders of the bonds involved in the DACH ring for the hydrated and anhydrous forms.

The O_1–C_7 and O_2–C_8 bond orders increase by about 0.02. A major change is noted in case of the C_7–O_3 and C_8–O_4 bonds. The bond orders here decrease by about 0.05, which indicates the weakening of these bonds as a result of the transfer of electrons away from them, due to hydrogen bonding with water.

The O_3···H_1 and O_4···H_2 bond orders are expected to be zero, but a value of 0.04 is calculated, which indicates that hydrogen bonds have formed.

4. Conclusions

We have performed density functional calculations at the GGA-PW91 level in order to gain an understanding into the structure of the third generation anti-cancer drug, oxaliplatin. We have paid particular emphasis on the conformation of the DACH ligand and have found that the *trans* forms of the ligand are more stable than the *cis* form. However, of the two equally stable enantiomers, the *trans-l* (1*R*,2*R*) one is found to be more potent biologically. Since very minor differences are observed in the electronic structures of the two enantiomers, their difference in activity may be attributed to the chiral recognition of the ligand by DNA. The calculated vibrational frequencies are in good agreement with our experimental FT-IR spectrum. It has been observed that the *trans-d* (1*S*,2*S*) and the *cis*-(1*R*,2*S*) isomers are less active than the *trans-l* (1*R*,2*R*) isomer, but have similar activities. Calculations were also performed on the *cis* isomer and its monohydrate, experimental data on whose geometry is known. Comparison between the theoretically predicted geometries and the experimental ones yielded good correspondence, validating our methodology, although these calculations pertain to the gas phase, and the experimental data are for the solid state, in which crystal-field effects may affect the relative energies of the conformers and the geometries. In the biological environment, hydrogen bonding with the solvent is also expected to affect the relative energies of the conformers, but the good correspondence between our calculations and experimental data suggest that crystal packing and hydrogen bonding effects are negligible.

to the identity of the $Mn^{III}/H_2salox/RCO_2^-$ (R = Ph) reaction system, i.e. the synthesis, structural and physical properties studies of the hexanuclear complexes $[Mn^{III}_6(\mu_3\text{-}O)_2(O_2CPh)_2(salox)_6(L_1)_2(L_2)_2] \cdot x MeCN \cdot y MeOH \cdot z H_2O \cdot w Me_2CO$ (L_1 = py, $L_2 = H_2O$, $x = 6$, $y = 0$, $z = 0$, $w = 0$ (**1**); $L_1 = Me_2CO$, $L_2 = H_2O$, $x = 0$, $y = 0$, $z = 0$, $w = 2$ (**2**); $L_1 = L_2$ = MeOH, $x = 0$, $y = 1$, $z = 0.5$, $w = 0$ (**3**)) and the 1D complexes $[Mn^{III}_3Na(\mu_3\text{-}O)(O_2CPh)_2(salox)_3(S)]_n \cdot nS$ (S = MeCN (**4**); S = Me_2CO (**5**)).

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials as received (Aldrich Co). All chemicals and solvents were of reagent grade. $[Mn^{III}_2Mn^{II}(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ [15] and $(NBu^n_4)[Mn^{III}_4O_2(O_2CPh)_9(H_2O)]$ [16] were synthesized as previously described. Elemental analysis for carbon, hydrogen, and nitrogen was performed on a Perkin Elmer 2400/II automatic analyzer. Infrared spectra were recorded as KBr pellets in the range 4000–400 cm^{-1} on a Bruker Equinox 55/S FT-IR spectrophotometer. Variable-temperature magnetic susceptibility measurements were carried out on polycrystalline samples of **1** and **5** using a Quantum Design MPMS SQUID susceptometer. DC data were collected in the 2–300 K temperature range under magnetic fields of 0.1, 0.5, 1, 2.5 and 5 T for **1** and under a field of 0.5 T for **5**. AC data for **1** were collected between 2 and 7.5 K, with an oscillating field of 1 G amplitude oscillating at frequencies of 0.1, 1, 10, 33, 99.9, 332, 997, 1400 Hz. Diamagnetic corrections for the complexes were estimated from Pascal's constants. The magnetic susceptibility of **5** has been computed by exact calculation of the energy levels associated with the spin Hamiltonian through diagonalization of the full matrix with a general program for axial symmetry [17]. Least-squares fittings were accomplished with an adapted version of the function-minimization program MINUIT [18]. The error factor R is defined as $R = \sum \frac{(x_{exp} - x_{calc})^2}{N x^2_{exp}}$, where N is the number of experimental points. ^1H pulsed NMR experiments on polycrystalline sample of **1** were performed at 2.4 T using a coherent spectrometer operating at 2.4 T (100 MHz for ^1H NMR). An Oxford 1200 CF continuous flow cryostat was employed for measurements in the range 5–300 K. The T_1 spin-lattice relaxation time was obtained using the standard saturation technique [19].

2.2. Compound preparations

2.2.1. $[Mn^{III}_6(\mu_3\text{-}O)_2(O_2CPh)_2(salox)_6(py)_2(H_2O)_2] \cdot 6MeCN$ (**1** · 6MeCN)

2.2.1.1. Method A. Solid H_2salox (0.014 g, 0.10 mmol) was added to a red brown solution of $[Mn_3(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ (0.108 g, 0.10 mmol) in MeCN (30 mL) and the resulting brown solution was refluxed for 1 h. Small portions of an orange-brown precipitate were filtered off, and the brown filtrate was left for slow evaporation. After 5 days, a mixture of green-brown prismatic crystals of **1** and orange cubic crystals were formed. The latter identified as the mixed-valence hexanuclear complex $[Mn^{II}_4Mn^{III}_2(\mu_4\text{-}O)_2(O_2CPh)_{10}(py)_2(H_2O)(MeCN)] \cdot 2MeCN$ by unit cell determination [20].

2.2.1.2. Method B. Solid H_2salox (0.069 g, 0.50 mmol) was added to a red brown solution of $[Mn_3(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ (0.184 g, 0.17 mmol) in MeCN (50 mL) and the resulting brown solution was refluxed for 1 h. The brown solution was left for slow evaporation and after 20 days green-brown prismatic crystals of **1** were formed, which were filtered off, washed with cold MeCN and dried *in vacuo* (yield: 0.093 g, 67% based on the metal). The resulting powder was analyzed as solvent free. $C_{66}H_{54}Mn_6N_8O_{20}$ requires: C, 49.27; H, 3.38; N, 6.96. Found: C, 49.02; H, 3.36; N, 6.93%. FT-IR (KBr pellets, cm^{-1}): 3450(br), 3054(w), 3013(w), 2927(w), 1598(vs), 1529(vs), 1472(m), 1440(vs), 1394(vs), 1358(w), 1324(m), 1283(vs), 1200(m), 1154(m), 1126(m), 1068(w), 1043(s), 1027(vs), 1009(m), 961(w), 918(s), 851(w), 826(m), 754(s), 721(s), 678(vs), 652(m), 625(w), 530(w), 472(m).

2.2.2. $[Mn^{III}_6(\mu_3\text{-}O)_2(O_2CPh)_2(salox)_6(Me_2CO)_2(H_2O)_2] \cdot 2Me_2CO$ (**2** · $2Me_2CO$)

2.2.2.1. Method A. Solid H_2salox (0.034 g, 0.25 mmol) was added to a refluxed red brown solution of $[Mn_3(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ (0.092 g, 0.085 mmol) in Me_2CO (30 mL) and the resulting brown solution was further refluxed for 15 min. Vapor diffusion of Et_2O to the brown reaction mixture afforded X-ray quality brown needle-like crystals of **2**, which were filtered off, and dried *in vacuo* (yield: 0.040 g, 60% based on the metal). The resulting powder was analyzed as solvent free. $C_{62}H_{56}Mn_6N_6O_{22}$ requires: C, 47.53; H, 3.60; N, 5.36. Found: C, 47.29; H, 3.57; N, 5.33%. FT-IR (KBr pellets, cm^{-1}): 3410(br), 3056(w), 3015(w), 1701(m), 1634(sh), 1597(vs), 1536(vs), 1472(s), 1440(vs), 1396(vs), 1327(m), 1282(vs), 1202(s), 1152(m), 1125(m), 1044(vs), 1028(vs), 956(w), 917(vs), 856(w), 825(m), 755(s), 722(s), 676(vs), 648(s), 550(w), 531(m), 465(s).

2.2.2.2. Method B. Solid H_2salox (0.034 g, 0.25 mmol) and solid NaOMe (0.027 g, 0.50 mmol) were added to a refluxed red brown solution of $[Mn_3(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ (0.092 g, 0.085 mmol) in Me_2CO (30 mL) and the resulting brown solution was further refluxed for 20 min. Small portions of a white precipitate (probably insoluble NaOMe) were filtered off, and the brown filtrate was layered with Et_2O/*n*-hex to afford brown crystals, which were filtered off and dried *in vacuo* (yield: 0.043 g, 65% based on the metal). The brown crystals were identified as compound **2** · $2Me_2CO$ by unit cell determination (a = 32.948(1), b = 32.948(1), c = 14.381(1) Å, V = 15611.6(2) $Å^3$, see Table 1).

2.2.3. $[Mn^{III}_6(\mu_3\text{-}O)_2(O_2CPh)_2(salox)_6(MeOH)_4] \cdot MeOH \cdot 0.5H_2O$ (**3** · $MeOH \cdot 0.5H_2O$)

Solid H_2salox (0.034 g, 0.25 mmol) and solid MeONa (0.027 g, 0.50 mmol) were added to a red brown solution of $[Mn_3(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ (0.092 g, 0.085 mmol) in MeOH (30 mL) and the resulting green-brown solution was refluxed for half hour, upon which time the solution turned to brown. Small portions of a dark brown precipitate were filtered off, and the brown filtrate was left for slow evaporation. After a period of one month, brown prismatic crystals of **3** were formed, which were filtered off, washed with cold MeOH and dried *in vacuo* (yield: 0.039 g, 60% based on the metal). The resulting powder was analyzed as solvent free. $C_{60}H_{56}Mn_6N_6O_{22}$ requires: C, 46.71; H, 3.66; N, 5.45. Found: C, 46.47; H, 3.63; N, 5.42%. FT-IR (KBr pellets, cm^{-1}): 3420(br), 3052(w), 3011(w), 2926(w), 1597(vs), 1527(vs), 1471(m), 1440(vs), 1393(vs), 1358(w), 1322(m), 1282(vs), 1200(m), 1154(m), 1126(m), 1067(w), 1042(s), 1027(vs), 1009(m), 960(w), 918(s), 851(w), 826(m), 755(s), 722(s), 679(vs), 652(m), 625(w), 531(w), 474(m).

2.2.4. $[Mn^{III}_3Na(\mu_3\text{-}O)(O_2CPh)_2(salox)_3(MeCN)]_n \cdot nMeCN$ (**4** · $nMeCN$)

2.2.4.1. Method A. Solid H_2salox (0.034 g, 0.25 mmol) and solid NaOMe (0.027 g, 0.50 mmol) were added to a refluxed red-brown solution of $[Mn_3(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ (0.092 g, 0.085 mmol) in MeCN (30 mL), and the resulting brown solution was further refluxed for half hour. Small portions of a white precipitate (probably insoluble NaOMe) were filtered off, and the brown filtrate was left undisturbed in closed vials. After one week X-ray quality brown needle-like crystals were formed, which were filtered off and dried *in vacuo* (yield: 0.053 g, 70% based on the metal). The resulting

2.3. Single-crystal X-ray crystallography

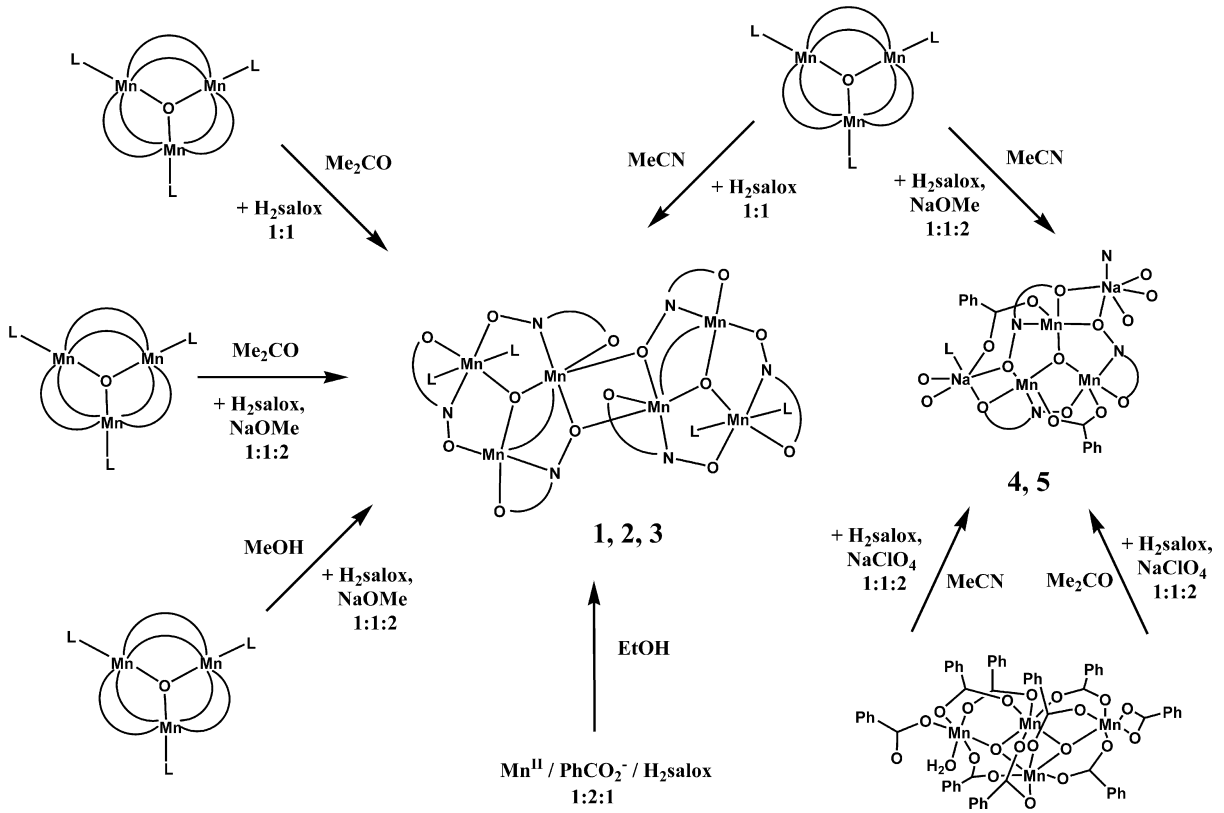
A green-brown prismatic crystal of **1** (0.18 × 0.36 × 0.70 mm) was mounted in capillary. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo Kα radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the range 11° < 2θ < 23°. Three standard reflections monitored every 97 reflections showed less than 3% intensity fluctuation and no decay. Lorentz, polarization corrections were applied using Crystal Logic software. Brown crystals of **2** (0.08 × 0.12 × 0.60 mm), **4** (0.08 × 0.25 × 0.25 mm), and **5** (0.08 × 0.55 × 0.65 mm) were mounted in capillaries with drops of mother liquor. A brown crystal of **3** (0.09 × 0.09 × 0.19 mm) was taken directly from the mother liquor and immediately cooled to −170 °C. Diffraction measurements for **2–5** were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Mo Kα (**3**, **5**) and Cu Kα radiation (**2**, **4**). Data collection (ω-scans) and processing (cell refinement, data reduction and empirical absorption correction) were performed using the CRYSTALCLEAR program package [21]. Important crystal data and parameters for data collection are reported in Table 1. The structures were solved by direct methods using SHELXS-97 [22] and refined by full matrix least-squares techniques on F^2 with SHELXL-97 [23]. Further experimental crystallographic details for **1**: $2\theta_{max}$ = 50°; reflections collected/unique/used, 7648/7276 [R_{int} = 0.0217]/7276; 611 parameters refined; $(\Delta/\sigma)_{max}$ = 0.004; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 1.192/−01.409 e/Å^3; R/R_w (for all data), 0.0830/0.1955. Hydrogen atoms were located by difference maps and were refined isotropically, except those of the coordinated pyridine and the solvate molecules which were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. The crystals of **2** were very thin needles. Repeating efforts to increase their size proved unsuccessful. Data were collected to $2\theta_{max}$ = 144° but only those to $2\theta_{max}$ = 125° were used for the refinement, since in greater θ values more than 50% of the collected data were unobserved. Further experimental crystallographic details for **2**: $2\theta_{max}$ = 125°; reflections collected/unique/used, 31770/5864 [R_{int} = 0.0491]/5864; 557 parameters refined; $(\Delta/\sigma)_{max}$ = 0.008; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.564/−0.341 e/Å^3; R/R_w (for all data), 0.0758/0.1423. Hydrogen atoms were located by difference maps and were refined isotropically, except those of the methyl groups which were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. The crystals of **3** were very small in size. Repeating efforts to increase their size proved unsuc-

cessful. Data were collected to $2\theta_{max} = 55°$ but only those to $2\theta_{max} = 46.5°$ were used for the refinement, since in greater θ values more than 50% of the collected data were unobserved. Further experimental crystallographic details for **3**: reflections collected/unique/used, 19418/9471 [$R_{int} = 0.0684$]/9471; 884 parameters refined; $(\Delta/\sigma)_{max} = 0.007$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.847/-0.673$ e/Å^3; R/R_w (for all data), 0.1034/0.2107. Hydrogen atoms were introduced at calculated positions as riding on bonded atoms; no H-atoms for the water solvate molecule were included in the refinement. All non-H atoms were refined anisotropically. The solvate water molecule was refined anisotropically with occupation factor fixed to 0.50. Further experimental crystallographic details for **4**: $2\theta_{max} = 144.1°$; reflections collected/unique/used, 27919/7418 [$R_{int} = 0.0662$]/7418; 634 parameters refined; $(\Delta/\sigma)_{max} = 0.005$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.418/-0.705$ e/Å^3; R/R_w (for all data), 0.0814/0.1110. Hydrogen atoms were located by difference maps and were refined isotropically, except those of the methyl groups which were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. The crystals of **5** showed poor diffraction ability (despite their sufficient size) and signs of twinning. Data were collected to $2\theta_{max} = 54°$ but only those to $2\theta_{max} = 45°$ were used for the refinement, since in greater θ values more than 50% of the collected data were unobserved. The twinning problem was handled by omitting reflections showing large F^2_o compared to the expected F^2_c values because an exact twin law could not be found. As it was proved after the solution of the structure, compound **5** is analogous to **4** thus we felt that the complete structural characterization would not add further significant information to our work. Therefore, we have not attempted to improve the quality of the crystals. Further experimental crystallographic details for **5**: $2\theta_{max} = 45°$; reflections collected/unique/used, 40444/5493 [$R_{int} = 0.1240$]/5493; 554 parameters refined; $(\Delta/\sigma)_{max} = 0.017$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 2.162/-0.608$ e/Å^3; R/R_w (for all data), 0.1204/0.2448. Hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically.

3. Results and discussion

3.1. Syntheses

Previous investigation of the use of H_2salox in manganese carboxylate chemistry by Perlepes and his co-workers has led to the hexanuclear compounds $[Mn^{III}_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(EtOH)_4]$ (R = Me, Ph) [14] isolated from the 1:1 $Mn(O_2CR)_2 \cdot 2H_2O/H_2$salox molar ratio reaction in EtOH. Both complexes exhibit single-molecule magnetism (SMM) behaviour [24], and have been isolated under identical reaction conditions suggesting that the nature of the carboxylate ligand does not affect the identity of the products. Recently Brechin and co-workers have expanded this family of clusters by changing the carboxylate groups and/or by introducing steric bulk at the oximate carbon atom [25]; these modifications led to dramatic improvement of the SMM properties [25b,c]. In order to further investigate the parameter space of this reaction system, we have decided to modify other key factors and in particular: (i) the Mn/H_2salox stoichiometry, (ii) the reaction media, (iii) the source of the manganese ions, (iv) the addition of base and/or counterions, and (v) the crystallization method, in order to study their influence on the metal ions' topology, oxidation state and nuclearity. Thus, reaction of one equivalent of $[Mn^{III}_2Mn^{II}(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ with one equivalent of H_2salox in MeCN and slow evaporation of the reaction mixture afforded green-brown prismatic crystals of $[Mn^{III}_6(\mu_3\text{-}O)_2(O_2CPh)_2(salox)_6(py)_2(H_2O)_2]$ (**1**) and orange cubic crystals of the known mixed-valence hexanuclear complex $[Mn^{II}_4Mn^{III}_2(\mu_4\text{-}O)_2(O_2CPh)_{10}(py)_2(H_2O)(MeCN)]$ [20] in mixture. With the identity of **1** established by X-ray crystallography the stoichiometric Mn:H_2salox reaction has been performed which afforded pure **1** for further physical measurements (Scheme 1). Further investigation of



Scheme 1. The synthetic routes employed for the preparation of **1**–**5** (see text for details).

the reaction media, by reaction of one equivalent of $[Mn^{III}_2Mn^{II}(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ with three equivalents of H_2salox in Me_2CO afforded compound $[Mn^{III}_6O_2(O_2CPh)_2(salox)_6(Me_2CO)_2(H_2O)_2]$ (**2**) either by slow evaporation or layering of Et_2O or vapour diffusion of Et_2O or Et_2O/*n*-hexane (Scheme 1).

Compounds **1** and **2** are quite similar to the previously reported hexanuclear complexes $[Mn_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(EtOH)_4]$ (R = Me, Ph), suggesting that these species are spontaneously formed, perhaps due to their thermal and/or thermodynamic stability, and/or their insolubility in the reaction solvent. Thus, changes in the source of the manganese ions and the reaction media have not affected the identity of the product isolated, whereas the change of the reactants stoichiometry (excess of manganese ions in the case of **1**) most likely promotes the simultaneous isolation of the known mixed-valence compound $[Mn^{II}_4Mn^{III}_2(\mu_4\text{-}O)_2(O_2CPh)_{10}(py)_2(H_2O)(MeCN)]$. Of course the presence of other more soluble species in the reaction mixture cannot be excluded.

In order to examine the influence of the base and/or counterions we have employed reactions analogous to those leading to **1** and **2** in the presence of NaOMe and/or $NaClO_4.H_2O$. Thus, reaction of one equivalent of $[Mn^{III}_2Mn^{II}(\mu_3\text{-}O)(O_2CPh)_6(py)_2(H_2O)]$ with three equivalents of H_2salox in the presence of six equivalents of NaOMe in MeOH yielded compound $[Mn^{III}_6O_2(O_2CPh)_2(salox)_6(MeOH)_4]$ (**3**), which is completely analogous to **1** and **2**. On the other hand, the analogous reaction in MeCN yielded only the 1D complex $[Mn^{III}_3Na(\mu_3\text{-}O)(O_2CPh)_2(salox)_3(MeCN)]_n$ (**4**) whose structure is completely different than **1**–**3**, whereas the same reaction mixture in Me_2CO afforded only **2** as confirmed by X-ray crystallography (Scheme 1). Finally the reaction of one equivalent of $(NBu^n_4)[Mn^{III}_4O_2(O_2CPh)_9(H_2O)]$ with four equivalents of H_2salox in the presence of eight equivalents of $NaClO_4 \cdot H_2O$ in MeCN also afforded compound **4**, whereas the analogous reaction in Me_2CO afforded the 1D complex $[Mn^{III}_3Na(\mu_3\text{-}O)(O_2CPh)_2(salox)_3(Me_2CO)]_n$ (**5**) which is analogous to **4** (Scheme 1).

In conclusion, the reaction media, the use of oligonuclear manganese complexes as starting materials and the crystallization methods have not affected the identity of the hexanuclear complexes **1**–**3**, whereas analogous modifications on the salicylaldoximato iron(III) carboxylate chemistry revealed that the reaction media is determinative for the identity of the product. Trinuclear $[Fe_3(\mu_3\text{-}O)(O_2CPh)_5(salox)(L_1)(L_2)]$ ($L_1 = L_2$ = MeOH, L_1 = EtOH and $L_2 = H_2O$ depending on the reaction solvent) [10] or hexanuclear $[Fe_6(\mu_3\text{-}O)_2(O_2CPh)_{10}(salox)_2(L)_2]$ ($L = H_2O$, $MeCONH_2$) [8a] complexes have been isolated from alcoholic or MeCN solutions, respectively; the former being transformed to the latter by simple recrystallization from MeCN solutions. Compounds **1**–**3** and $[Fe_6(\mu_3\text{-}O)_2(O_2CPh)_{10}(salox)_2(L)_2]$ contain the same $[M^{III}_6(\mu_3\text{-}O)_2(\mu_2\text{-}OR)_2]^{12+}$ core, although the rest of the ligation pattern is different. On the other hand, the presence of sodium ions in the reaction mixtures in MeCN and Me_2CO, either as NaOMe or $NaClO_4 \cdot H_2O$, revealed dramatic changes to the identity of the products isolated yielding the 1D complexes **4** and **5**.

3.2. Description of structures

Compound **1** crystallizes in the triclinic space group $P\bar{1}$ with one molecule per unit cell. The molecular structure of **1** is given in Fig. 1 and selected bond distances and angles are listed in Table 2. The structure contains the $[Mn_6(\mu_3\text{-}O)_2(\mu_2\text{-}OR)_2]^{12+}$ core, whose topology consists of six manganese(III) ions arranged as two centrosymmetrically related off-set stacked $[Mn_3(\mu_3\text{-}O)]^{7+}$ subunits bridged by two oximato oxygen atoms (O(12) and O(12′)). In each $[Mn_3(\mu_3\text{-}O)]^{7+}$ subunit, there are two Mn···Mn pairs [Mn(1)/Mn(3) and Mn(1)/Mn2)] bridged by a μ_2 oxide and a μ_2-κ*O*:κ*O*′:κ*N* salox^{2-} ligand, while the third pair [Mn(2)/Mn(3)] is further bridged by a μ_2 benzoato ligand. The coordination

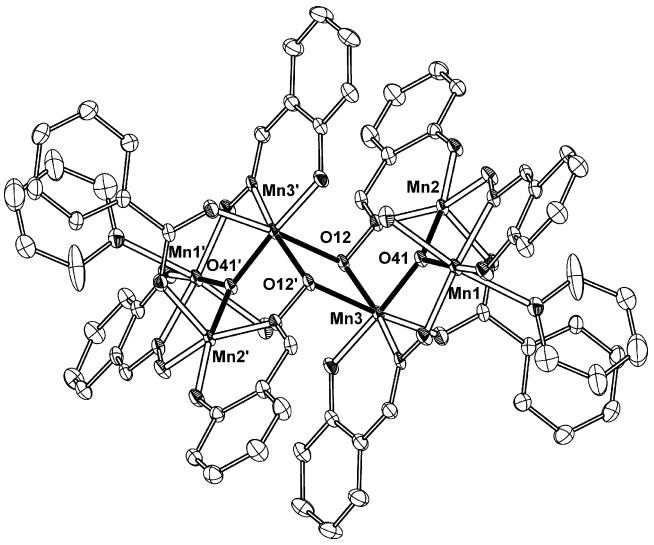


Fig. 1. Partially labelled ORTEP plot of **1** with ellipsoids drawn at the 30% probability level. For clarity hydrogen atoms have been omitted. Primed atoms are generated by symmetry (′ = −*x*, 2 − *y*, 1 − *z*).

geometry around Mn(1) is distorted octahedral where the equatorial positions are occupied by one salox^{2-} ligand (through $O_{phenolic}$ and $N_{oximato}$ atoms), the $O_{oximato}$ atom of a second salox^{2-} ligand and the oxide group, while the Jahn–Teller axis of the octahedron is completed by a pyridine and a coordinated water molecule. The coordination geometry around Mn(2) is square pyramidal comprised by one salox^{2-} ligand (through $O_{phenolic}$ and $N_{oximato}$ atoms), the $O_{oximato}$ atom of a second salox^{2-} ligand and the oxide group occupying the equatorial plane, while the apical position is occupied by an oxygen atom of the μ_2 benzoato ligand. Finally, the coordination geometry about Mn(3) is distorted octahedral comprised by one salox^{2-} ligand (through $O_{phenolic}$ and $N_{oximato}$ atoms), the oxide group and the $O_{oximato}$ atom of a second salox^{2-} directed in the equatorial plane of the octahedron, while the Jahn–Teller positions are completed by a benzoato oxygen and an $O_{oximato}$ atom of a third salox^{2-} ligand. Thus, in each $[Mn_3(\mu_3\text{-}O)]$ subunit two of the salox^{2-} ligands adopt the common μ_2-κ*O*:κ*O*′:κ*N* coordination mode, while the third one presents the rare μ_3-κ^2*O*:κ*O*′:κ*N* coordination mode (Scheme 2), that has been also observed in $[Mn_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(R'OH)_4]$ [14,25a], $[Fe_6(\mu_3\text{-}O)_2(O_2CPh)_{10}(salox)_2(H_2O)_2]$ [8a], and in $[M^{III}_6(\mu_3\text{-}O)_2(salox)_6(\mu_2\text{-}O_2CR)_2(OH_2)_2\ (RCN)_2]$ (M = V^{III}, Cr^{III}, Mn^{III}, Fe^{III}, $RCO_2^- = Ph_3CCO_2^-$, $Me_3CCO_2^-$, $Ph_2C(OH)CO_2^-$, $PhCO_2^-$, $C_2H_5CO_2^-$) [26], but also in trinuclear and tetranuclear complexes [27].

The three Mn^{III} ions in each $[Mn_3(\mu_3\text{-}O)]^{7+}$ subunit form an almost isosceles triangle (see Table 2). The Mn(2)···Mn(3) separation (3.158(2) Å) is shorter than the other two in the triangular subunit (3.248(5), 3.273(5) Å) due to the presence of the extra benzoate bridge. The Mn···Mn distance in the central $[Mn_2(\mu_2\text{-}O)_2]$ core is 3.335(5). The central μ_3-O^{2-} ion in each $[Mn_3(\mu_3\text{-}O)]$ subunit is displaced at 0.17 Å out of the $[Mn_3]$ mean plane, an observation that has been also seen in the analogous compound $[Mn_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(R'OH)_4]$ [14,25a] as well as in the trinuclear complexes $[Mn_3(\mu_3\text{-}O)(O_2CR)_3(mpko)_3](ClO_4)$ (R = Me, Et, Ph; mpkoH = methyl-2-pyridyl ketone oxime, 0.30 Å) [28]. The Mn–O_{oxo} bond distances are in the range 1.863–1.881 Å. The Mn–$O_{phenoxo}$ and the Mn–$N_{oximato}$ bond lengths are ~1.86 and ~2.0 Å, respectively. The Mn–$O_{oximato}$ chelating bond distances are ~1.94 Å while the corresponding bridging bond distances are significantly longer (2.420 Å). All the salox^{2-} ligands are planar and make an angle of 5.1°, 13.3° and 28.7° (for the salox^{2-} ligands defined by O(1), O(11), and O(21), respectively) with the $[Mn_3]$ mean

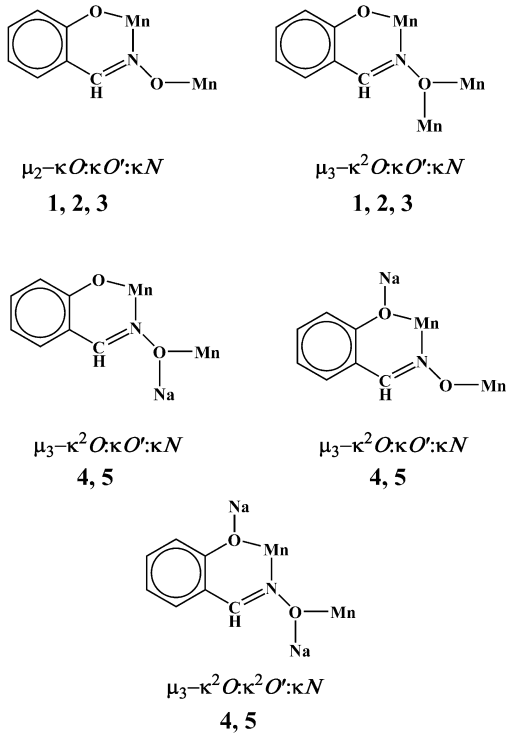
Symmetry transformations used to generate equivalent atoms: ′ = −*x*, 2 − *y*, 1 − *z*.



Scheme 2. The coordination modes of salox^{2-} ligands in the structures of **1**–**5** (see text for details).

plane. The benzoate ligands are coordinated through the common *syn*,*syn* μ$_2$-κ*O*:κ*O*′ mode. The Mn–O$_{carboxylate}$ bond distances are ~2.13 Å. There is a moderate twisting of the Mn–O–N–Mn moieties within each Mn$_3$ subunit; this is evidenced by the Mn–N–O–Mn torsion angles which are 5.9°, 22.3° and 19.8° for the Mn(1)/Mn(2), Mn(2)/Mn(3) and Mn(3)/Mn(1) pairs (and their symmetry-equivalents), respectively.

Compound **2** crystallizes in the tetragonal space group $I4_1/a$, with eight molecules per unit cell, and compound **3** crystallizes in the triclinic space group $P\bar{1}$ with two half molecules in the asymmetric unit. The molecular structures of **2** and **3** (Figs. 2 and 3, respectively) are completely analogous to **1** and they will not be discussed further. Selected bond distances and angles are given as Supplementary material (Tables S1 and S2, respectively); a comparison of their structural characteristics with those of **1** is given in Table 4.

Compound **4** crystallizes in the monoclinic space group $P2_1/c$ with one molecule per asymmetric unit. The molecular structure of **4** consists of anionic trinuclear oxo-centered units, [Mn$^{III}_3$(μ$_3$-O)(O$_2$CPh)$_2$(salox)$_3$]$^-$, sodium cations and MeCN molecules. An ORTEP plot of the structure of **4** is given in Fig. 4, selected bond distances and angles are listed in Table 3. The trinuclear anion contains a central [Mn$_3$(μ$_3$-O)]$^{7+}$ core, in which two Mn···Mn pairs [Mn(1)/Mn(2) and Mn(2)/Mn(3)] are bridged by a μ$_2$ oxide and a μ$_2$-κ*O*:κ*O*′:κ*N* salox^{2-} ligand, while the third pair [Mn(1)/Mn(3)] is further bridged by a μ$_2$ benzoato ligand. The coordination geometry

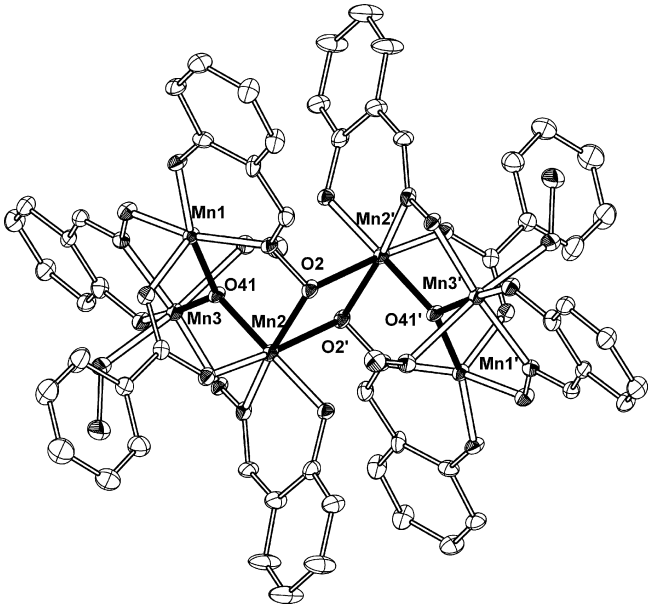

Fig. 3. Partially labelled ORTEP plot of one of the crystallographically independent hexanuclear molecules in the structure of **3** with ellipsoids drawn at the 30% probability level. For clarity hydrogen atoms have been omitted. Primed atoms are generated by symmetry (′ = 1 − *x*, −*y*, −*z*).

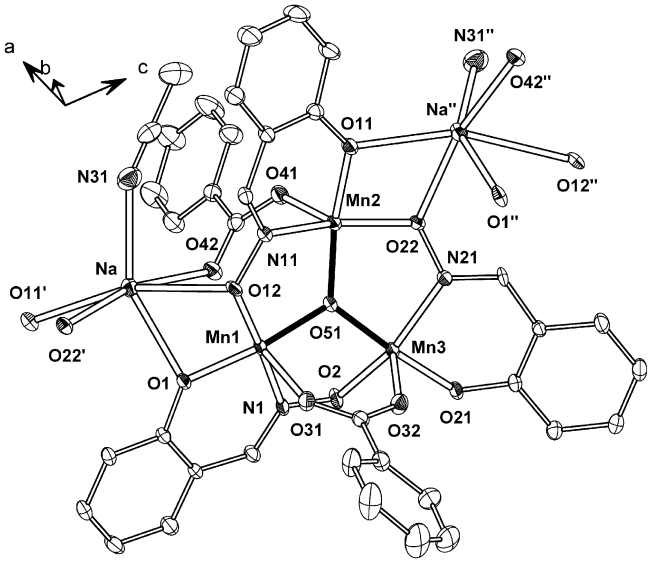

Fig. 4. Partially labelled ORTEP plot of a small fragment of the chains of **4** with ellipsoids drawn at the 30% probability level. For clarity hydrogen atoms have been omitted. Symmetry transformations used to generate equivalent atoms: ′ = *x*, 0.5 − *y*, −0.5 + *z*; ″ = *x*, 0.5 − *y*, 0.5 + *z*.

around each Mn^{III} ion is square pyramidal where the basal positions are occupied by one $salox^{2-}$ ligand (through $O_{phenolic}$ and $N_{oximato}$ atoms), the $O_{oximato}$ atom of a second $salox^{2-}$ ligand and the oxide group, and the apical position is occupied by a carboxylato oxygen atom [O(31), O(41) and O(32) for Mn(1), Mn(2) and Mn(3), respectively].

The three Mn^{III} ions in the $[Mn_3(\mu_3\text{-}O)]^{7+}$ subunit form a scalene triangle with edges 3.138(1)–3.305(1) Å (Table 3). The central $\mu_3\text{-}O^{2-}$ ion lies in the plane defined by the three Mn^{III} ions, as in the case of the 'basic carboxylates' of the general formula $[M^{III}_3(\mu_3\text{-}O)(O_2CR)_6(L)_3]^+$ (M = Mn, Fe, Cr; L = neutral monodentate ligands) [29], suggesting that the replacement of the carboxylato and monodentate ligands by the tridentate $salox^{2-}$ ligand has not affected the structural characteristics of the planar $[Mn_3(\mu_3\text{-}O)]^{7+}$ core. The Mn–O_{oxo} bond distances are in the range 1.845–1.867 Å. The average Mn–$O_{phenoxo}$, Mn–$O_{oximato}$ and Mn–$N_{oximato}$ bond lengths are 1.863, 1.914 and 2.008 Å, respectively.

All the $salox^{2-}$ ligands are planar and make an angle of 18.6°, 16.8° and 25.8° (for the $salox^{2-}$ ligands defined by O(1), O(11), and O(21), respectively) with the $[Mn_3]$ mean plane. The three $salox^{2-}$ ligands adopt different coordination modes, bridging pairs of Mn^{III} ions of the anionic complex with the sodium cations. Two of the $salox^{2-}$ ligands (defined by O(1) and O(21)) adopt the $\mu_3\text{-}\kappa^2O{:}\kappa O'{:}\kappa N$ coordination mode bridging Mn(3)/Mn(1) and Mn(3)/Mn(2) pairs to Na through the μ_2 phenoxo oxygen O(1) and through the μ_2 oximato oxygen O(22), respectively. The third $salox^{2-}$ ligand (defined by O(11)) adopts the $\mu_4\text{-}\kappa^2O{:}\kappa^2O'{:}\kappa N$ coordination mode bridging Mn(1)/Mn(2) pair to two adjacent Na atoms through the μ_2 phenoxo oxygen O(11) and through the μ_2 oximato oxygen O(12). The coordinational flexibility of the $salox^{2-}$ ligands is reflected in the Mn–N–O–Mn torsion angles in the Mn_3 subunit, suggesting a moderate twisting of the Mn–O–N–Mn moieties in the case of $\mu_3\text{-}\kappa^2O{:}\kappa O'{:}\kappa N$ ligands (22.1° and 16.7° for the Mn(1)/Mn(3) and Mn(3)/Mn(2) pairs, respectively), whereas the same moiety is planar (0.8° for the Mn(2)/Mn(1) pair) in the case of the $\mu_4\text{-}\kappa^2O{:}\kappa^2O'{:}\kappa N$ ligand.

The two benzoato ligands also adopt different coordination modes. One of them bridges Mn(1) and Mn(3) in the trinuclear anion through the common *syn,syn* $\mu_2\text{-}\kappa O{:}\kappa O'$ coordination mode, whereas the second one bridges the trinuclear anion to the sodium cation through the *syn,anti* $\mu_2\text{-}\kappa O{:}\kappa O'$ coordination mode. The Mn–$O_{carboxylate}$ bond distances range from 2.045 to 2.170 Å. The coordination geometry around the Na^+ ions is distorted octahedral comprised of two phenoxo and two oximato oxygen atoms belonging to four $salox^{2-}$ ligands, one carboxylato oxygen atom and one MeCN molecule. Each Na^+ ion is triply and doubly bridged to its adjacent trinuclear anions forming 1D polymeric arrays which extend parallel to the crystallographic *c*-axis. The Na–O bond interatomic distances range from 2.406 to 2.673 Å.

Compound **5** crystallizes in the monoclinic space group $P2_1/c$ with one molecule per asymmetric unit, and is completely analogous to **4**; the only difference being the solvate molecule coordinated to the Na^+ ions. An ORTEP plot of a small fragment of the chains of **5** is given in Fig. 5, selected bond distances and angles are given as Supplementary material (Table S3), and a comparison of its structural characteristics with those of **4** is given in Table 4.

Compounds **1**–**5** join a small family of structurally characterized Mn complexes with the mono-($Hsalox^-$) and/or the dianion ($salox^{2-}$) of salicylaldoxime as ligand. Other members are the "butterfly" complex $[Mn^{III}_4O_2(salox)_2L_3L'_2](ClO_4)$ [30], where L is the diphenylglycolate(−1) ligand and L′ is 1,4,7-trimethyl-1,4,7-triazacyclononane, and the structurally similar $[Mn^{III}_6O_2(O_2CR)_2(salox)_6(R'OH)_4]$ (R = H, Me, Ph; R′ = Me, Et) mentioned above [14,25a]. Compounds **1**–**3** are also members of a small family of Mn^{III}_6 complexes whose cores are based on two linked trinuclear $[Mn^{III}_3(\mu_3\text{-}O)]^{7+}$ subunits [14,25,31]. Compounds **4** and **5** represent the first trinuclear oxo-centered Mn^{III} anionic complexes with $salox^{2-}$. Recently, a neutral trinuclear oxo-centered Mn^{III} complex has been reported which contains Me-$salox^{2-}$, compound $[Mn_3O(O_2CMe)(Me\text{-}salox)_3(py)_4]$ [32].

3.3. Magnetic susceptibility studies

3.3.1. DC susceptibility

The $\chi_M T$ product of **1** (Fig. 6) at 300 K (1 T) is 15.62 $cm^3\ mol^{-1}$ K, lower than the theoretically expected value for six non-interacting $S = 2$ spins (18.01 $cm^3\ mol^{-1}$ K, $g = 2$), indicating the interplay of antiferromagnetic interactions. Upon cooling, this progressively decreases to a minimum of

Symmetry transformations used to generate equivalent atoms: ′ = *x*, 0.5 − *y*, −0.5 + *z*; ″ = *x*, 0.5 − *y*, 0.5 + *z*.

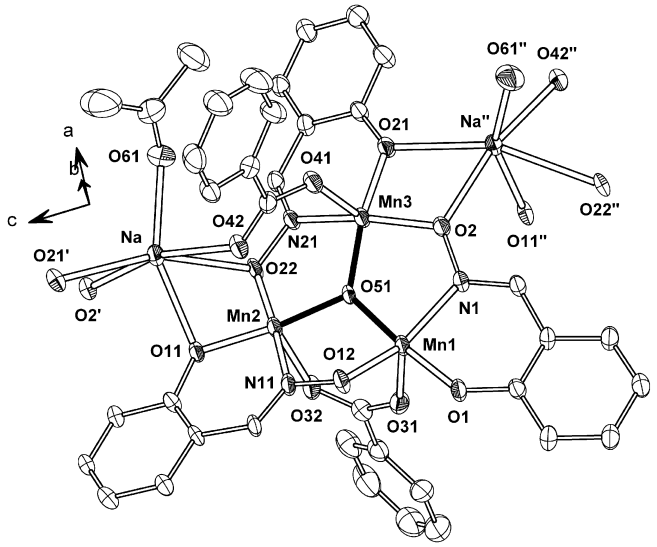

Fig. 5. Partially labelled ORTEP plot of a small fragment of the chains of **5** with ellipsoids drawn at the 30% probability level. For clarity hydrogen atoms have been omitted. Symmetry transformations used to generate equivalent atoms: ′ = *x*, 0.5 − *y*, 0.5 + *z*; ″ = *x*, 0.5 − *y*, −0.5 + *z*.

7.63 $cm^3\ mol^{-1}\ K$ at 30 K, and then increases to a maximum of 9.22 $cm^3\ mol^{-1}\ K$ at 10 K, before falling to 4.71 $cm^3\ mol^{-1}\ K$ at 2 K. This overall behaviour shows the interplay of both ferro- and antiferromagnetic interactions. The drop below 10 K is associated with zero-field splitting effects of the Mn^{III} ions. The maximum around 10 K is field-dependent, being suppressed and shifted to higher temperatures with increase of the applied magnetic field. This is attributed to the additional Zeeman splitting of the ground multiplet.

The overall behavior is very similar to that encountered in complexes $[Mn_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(EtOH)_4]$ (R = Me, Ph) [8], which is in accord with the structural similarities of the complexes. *M* versus HT^{-1} plots (Fig. 6) confirm that in **1** an $S = 4$ ground state is also stabilized. Fits of the low-temperature data, and assuming a well-isolated ground state, yield values of $|D| \sim 0.5\ cm^{-1}$ and $g = 2.00$ for the ground state. The magnitude of *D* for the ground state of complex **1**, is lower than the values previously reported ($|D| = 1.22$ [14] and 1.39 cm^{-1} [25a]) for the respective Mn_6 complexes with $S = 4$ ground states. Although these fits qualitatively confirm the ground state as an $S = 4$ one, they fail to accurately reproduce the data, probably due to the existence of low-lying excited states. This is to be expected, given the relatively weak exchange couplings between Mn^{III} ions, which lead to a closely

Table 4

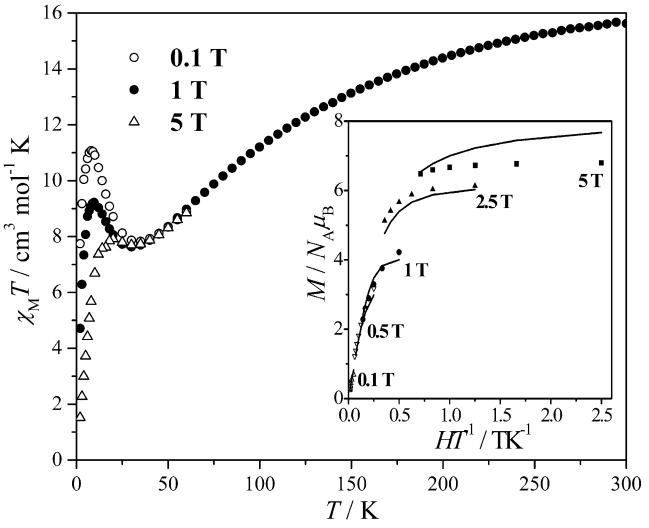

Fig. 6. $\chi_M T$ vs. T data for **1** under various magnetic fields. The M vs. HT^{-1} dependence along with a fit assuming an isolated $S = 4$ ground state are shown in the inset.

spaced energy spectrum. Thus, the values of the above fits should not be considered as quantitatively accurate.

The $S = 4$ ground state is in accord [25] with the moderate twisting of the Mn–N–O–Mn moieties within each Mn_3 subunit, the average torsion angle being $\alpha_v = 16°$. Brechin and co-workers recently showed [25b,c] that when this twisting in this family of Mn_6^{III} SMMs becomes severe (as a consequence of the use of bulky substituents on the oximate carbon), e.g. $\alpha_v = 36.5°$ or 39.1°, the resulting ground state is $S = 12$ and record U_{eff} values up to 86.4 K can be achieved.

The $\chi_M T$ product of **5** (Fig. 7) at 300 K (0.5 T) is 6.64 cm^3 mol^{-1} K, lower than the theoretically expected value for three non-interacting $S = 2$ spins (9.00 cm^3 mol^{-1} K, $g = 2$), indicating the interplay of antiferromagnetic interactions. Upon cooling, this rapidly decreases, attaining a value of 0.51 cm^3 mol^{-1} K at 2 K.

In order to interpret the experimental data, an isosceles model of three interacting $S = 2$ spins was assumed, based on the repeating unit of the complex. Due to its polymeric structure, intra-unit interactions are expected, while significant single-ion zero-field splitting parameters D, are also common for Mn^{III} complexes. The former was accounted for by a mean-field correction term zj, while the latter by an axial zfs parameter D, common for all spins ($D = D_1 = D_2 = D_3$). Initial fitting attempts over 2–300 K yielded very poor results. It was then decided that the intramolecular interactions might be too complex to be successfully accounted for by a mean-field term, while the single-ion zfs parameters might be substantially different for the three sites. In addition, it was also acknowledged that since both parameters zj and D are mainly manifested in the low temperature range, inclusion of both in our model might lead to overparametrization of our problem. Thus, a simpler model was used, considering only the intra-unit exchange couplings, while the data over the 300–100 K range were fitted. The corresponding Hamiltonian is given in Eq. (1):

$$\hat{H} = -2[J_1(\hat{\mathbf{S}}_1\hat{\mathbf{S}}_2 + \hat{\mathbf{S}}_1\hat{\mathbf{S}}_3) + J_1\hat{\mathbf{S}}_2\hat{\mathbf{S}}_3] \quad (1)$$

Best-fit parameters for this model were $J_1 \sim J_2 = -11.8$ cm^{-1}, $g = 2.01$ with $R = 4.1 \times 10^{-5}$, corresponding to a $S = 2$ ground state.

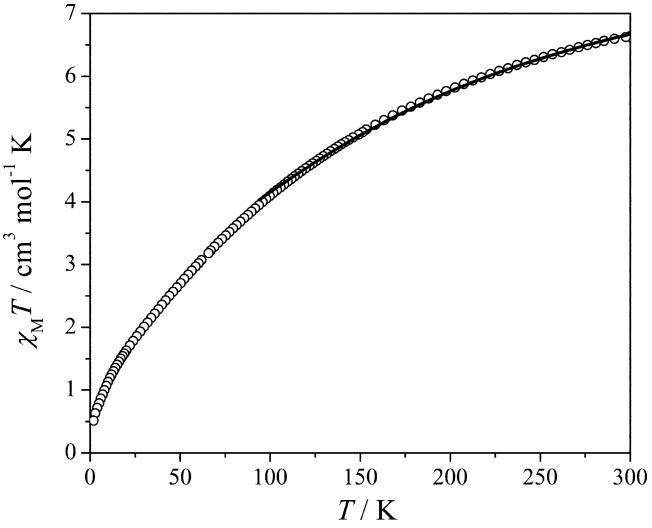

Fig. 7. $\chi_M T$ vs. T data for **5** and best fit according to the model described in the text.

3.3.2. AC susceptibility

Given the pronounced similarities of **1** with $[Mn_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(EtOH)_4]$ (R = Me, Ph), we decided to test whether it also behaves as an SMM. Thus, in order to probe its relaxation properties, AC susceptibility experiments were carried out at low temperatures (Fig. 8). These showed characteristic out-of-phase signals attributed to slow magnetic relaxation phenomena. The signals show clear maxima between 2.13 K (10 Hz) and 3.50 K (1400 Hz). For lower frequencies the maxima occur below 1.9 K, which is the lower limit of our instrument. Fits of these data to an Arrhenius law, $\tau = \tau_0 \cdot e^{U_{eff}/k_BT}$, yielded parameters

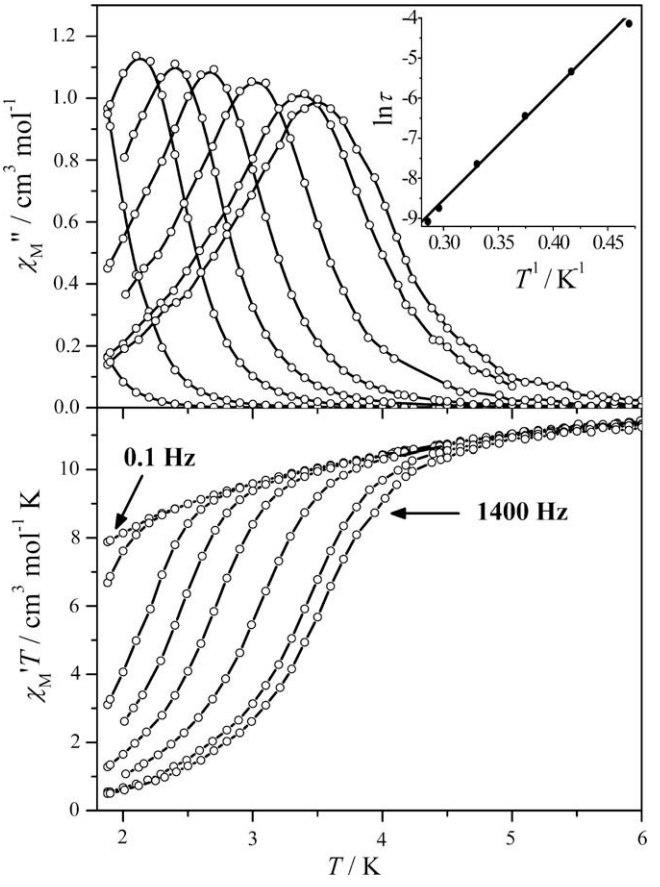

Fig. 8. χ'_M (top) and $\chi''_M T$ vs. T data for **1** between 1.9 and 6 K for oscillating magnetic fields of 0.1, 1, 10, 33, 100, 333, 1000 and 1400 Hz. A fit of the out-of-phase data to an Arrhenius law is shown in the inset.

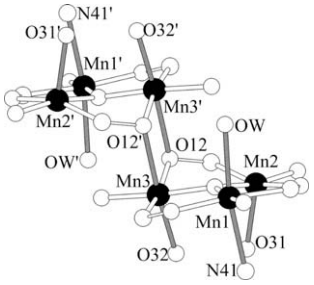

Fig. 9. Simplified view of **1**, showing the coordination spheres of the Mn^{III} ions. The Jahn–Teller elongated bonds (shown in gray) are roughly parallel to each other.

$\tau_0 = 5.5 \times 10^{-8}$ s and $U_{eff} = 27.4$ K = 19.0 cm^{-1}. For an $S = 4$ ground state and considering that $\Delta E = S^2|D| > U_{eff}$, it turns that the lowest limit for $|D|$ is 1.2 cm^{-1}, or in other words $D < -1.2$ cm^{-1}. These results are in close agreement with the results obtained for $[Mn_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(R'OH)_4]$ (R = H, Me, Ph; R′ = Me, Et) [14,25a].

The relatively high value of D predicted by the relaxation experiments deserves some comment. Generally speaking, the anisotropy of the ground state is related to the single-ion anisotropies of the coupled spins. The projection of each single-ion anisotropy on the molecular anisotropy axis (i.e. the z-axis) contributes to the total anisotropy. High-spin ($S = 2$) Mn^{III} ions, are highly anisotropic ions, with their easy axes coinciding with their Jahn–Teller axes. In the case of **1** we observe that the Jahn–Teller elongation axes are roughly parallel (Fig. 9). This should have an important effect on the total D value. We should note that for a D value of -1.2 cm^{-1}, a cluster like Mn_{12} ($S = 10$) should present a spin-reversal energy barrier of ca. 120 cm^{-1}. This relatively high D value should be responsible for the fact that clear out-of-phase signals are observed despite the relatively low spin ($S = 4$) of the ground state.

3.4. Solid state NMR studies

Nuclear magnetic resonance is a powerful tool in order to probe the internal fields that are present in paramagnetic and magnetic solids. In particular the nuclear T_1 spin-lattice relaxation is sensitive to the electron spin dynamics of the system since the nuclei under investigation probe the fluctuating local magnetic fields induced at the nuclear sites through the hyperfine interaction.

The ^1H T_1 spin-lattice relaxation time of complex **1** was measured at an applied magnetic field $H = 2.4$ T, between room and liquid-helium temperatures. The nuclear relaxation rate $1/T_1$ as a function of temperature is shown in Fig. 10.

At high temperatures $1/T_1$ is nearly temperature independent while below 70 K the rate increases exponentially with an appearance of a peak at around 15 K. This behaviour has been frequently encountered in previous ^1H NMR studies of molecular clusters, rings and single-molecule magnets and it is observed when the temperature is of the order of the magnetic exchange constant J/k_B between the magnetic ions [33].

In these molecular clusters, due to finite size of the spin system, the low-lying energy states are well separated among themselves and at low temperatures, the spin dynamics is governed by magnetic excitations between the ground state and the next excited state separated by an energy difference Δ. This energy difference Δ is largely determined by the exchange interaction J/k_B and the peak of the nuclear relaxation rate $1/T_1$ occurs when the temperature is of the order of the energy gap. Thus the appearance of the NMR peak provide us with a direct estimate of the energy difference between the ground state and the first excited state and can be compared with results of magnetic measurements.

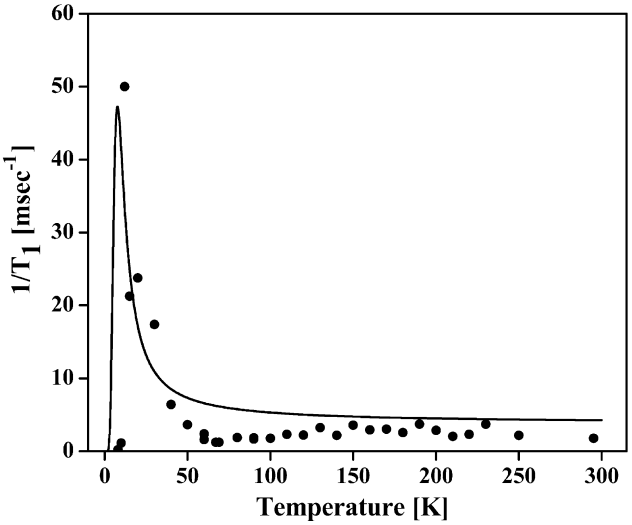

Fig. 10. ^1H NMR $1/T_1$ spin-lattice relaxation rate of complex **1** as a function of temperature (solid line represents the fitted data according to Eq. (2)).

For the analysis of the NMR data, we adopt a simple model, originally proposed by Hardeman et al. [34] based on a two level scheme for the fluctuations of the orientation of the magnetic moment.

In this model the NMR relaxation is caused by the local field fluctuations originating from the magnetic excitations from the ground state to the excited state, separated by the energy difference Δ. Assuming that the Mn spin system remains in the ground state for an average time τ_0 and in the excited state for a lifetime τ_1, during which an effective transverse local field $h_\perp$ appears at the nuclear site, the relaxation rate is expressed as [34]

$$\frac{1}{T_1} = (\gamma_N h_\perp)^2 \frac{\tau_1 \tau_0}{(\tau_1 + \tau_0)^2} \frac{\tau}{(\omega_N \tau)^2 + 1} \tag{2}$$

where

$$\frac{1}{\tau} = \frac{1}{\tau_0} + \frac{1}{\tau_1},$$

γ_N is the proton gyromagnetic ratio and ω_N is the Larmor angular frequency.

This model has been frequently employed for the nuclear magnetic relaxation in paramagnets [29d,33a,35].

Considering an activation-type process for the excitation, we set

$$\frac{1}{\tau_0} = B_0 \exp\left(-\frac{\Delta}{k_B T}\right) \tag{3}$$

where Δ represents the energy-level spacing between the ground state and the first excited state. For the lifetime τ_1 we consider a temperature independent term:

$$1/\tau_1 = C_1 \tag{4}$$

Setting $\nu_N = 100$ MHz ($H = 4.7$ T), and using Eqs. (3) and (4), the experimental NMR points are fitted to Eq. (2), shown as solid line in Fig. 10. The fitted parameters are $\Delta/k_B = 20$ K for the energy gap and $B_0 = 5\times10^9$ s^{-1} and $C = 5\times10^8$ s^{-1}, which are slow fluctuations of the order of the Larmor frequency. We observe that the line describes the overall experimental features rather well.

Therefore the NMR analysis of the low-frequency dynamics of the Mn electron spin system clearly demonstrates the existence of a sizeable energy gap between the ground state and the first excited multiple. Also we have given a measure of the magnitude

of the local-field fluctuations present in the electronic spin system.

4. Conclusions

Three hexanuclear compounds presenting the $[Mn_6(\mu_3\text{-}O)_2(\mu_2\text{-}OR)_2]^{12+}$ core, complexes $[Mn^{III}_6(\mu_3\text{-}O)_2(O_2CPh)_2(salox)_6(L_1)_2(L_2)_2]$ (L_1 = py, L_2 = H_2O (**1**); L_1 = Me_2CO, L_2 = H_2O (**2**); L_1 = L_2 = MeOH (**3**)) have been prepared. The influence of the reactants stoichiometry, the reaction media, the use of oligonuclear manganese clusters as starting materials and crystallization, on the isolation of the congener compounds **1**–**3** is negligible. On the other hand, the presence of Na^+ ions (either as NaOMe or $NaClO_4 \cdot H_2O$) in the corresponding MeCN and Me_2CO solutions, dramatically influenced the identity of the products, yielding the 1D complexes $[Mn^{III}_3Na(\mu_3\text{-}O)(O_2CPh)_2(salox)_3(S)]_n$ (S = MeCN (**4**), Me_2CO (**5**)). The magnetic properties of the representative compounds **1** (hexanuclear) and **5** (polymeric) have been studied. The magnetic susceptibility measurements from polycrystalline samples of **1** revealed the interplay of both ferro- and antiferromagnetic interactions stabilizing an $S = 4$ ground state as confirmed by M versus HT^{-1} plots. The AC susceptibility measurements at 1.9–6 K showed characteristic out-of-phase signals due to slow magnetic relaxation phenomena. Fits of the AC data to the Arrhenius law, yielded parameters $\tau_0 = 5.5 \times 10^{-8}$ s and $U_{eff} = 27.4$ K = 19.0 cm^{-1}. The magnetic behavior of **1** is analogous to the SMM behavior displayed by the prototype complexes of this series, compounds $[Mn_6(\mu_3\text{-}O)_2(O_2CR)_2(salox)_6(R'OH)_4]$ (R = Me, Ph; R′ = Et). Investigation of the electron spin dynamics of **1** carried out by solid state ^1H NMR measurements, clearly revealed an energy gap of $\Delta/k_B = 20$ K between the ground and the first excited state. Magnetic susceptibility measurements from polycrystalline samples of **5** revealed the presence of antiferromagnetic interactions in the $[Mn^{III}_3]$ unit. The data were fitted in the 100–300 K range by considering only intra-unit exchange couplings and yielded $J = -11.8$ cm^{-1}, corresponding to an $S = 2$ ground state.

Appendix A. Supplementary data

CCDC 694623, 694624, 694625, 694626 and 694627 contain the supplementary crystallographic data for **1** · 6MeCN, **2** · $2Me_2CO$, **3** · MeOH · $0.5H_2O$, **4** · *n*MeCN and **5** · nMe_2CO. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Tables of selected bond distances and angles for **2** · $2Me_2CO$, **3** · MeOH · $0.5H_2O$ and **5** · nMe_2CO are also available. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.08.021.

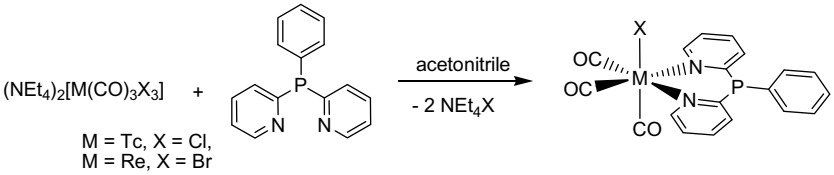
2. Results and discussion

$PPhpy_2$ and Ppy_3 react with tricarbonyl complexes of rhenium(I) or technetium(I) under coordination of two pyridyl rings. Complexes of the composition $[M(CO)_3X(PPhpy_2\text{-}N,N')]$ were obtained in moderate yields from reactions of $(NEt_4)_2[M(CO)_3X_3]$ (M = Tc, X = Cl; M = Re; X = Br) with 1 equiv. of $PPhpy_2$ in acetonitrile at room temperature Eq. (1). The respective yields can be increased by concentration of the mother liquors, the purity of the resulting second crops of products, however, is lower and the separation from oily side-products causes is difficult.



(1)

$[Re(CO)_3Br(PPhpy_2\text{-}N,N')]$ crystallizes from a xylene solution in form of yellow blocks, while $[Tc(CO)_3Cl(PPhpy_2\text{-}N,N')]$ was isolated as colorless needles from the mother liquor. The air and moisture stable compounds are readily soluble in organic solvents. Strong bands in the infrared spectrum of the rhenium complex at 2021 and 1909 cm^{-1} and in that of the technetium compound at 2033 and 1925 cm^{-1} can be assigned to the $\nu_{(C\equiv O)}$ stretches and confirm the retention of the *fac*-$[M(CO)_3]^+$ cores. The ^{99}Tc NMR spectrum of the technetium compound shows a signal at −990.06 ppm. This corresponds to a to high-field shift of about 120 ppm with regard to the resonance of the precursor, which appears at −868.16 ppm. The finding is in good agreement with the positions of the ^{99}Tc NMR signals of the tricarbonyl complexes *mer*-$[Tc(CO)_3Br(py)_2]$ (−946 ppm) and *fac*-$[Tc(CO)_3Br(bipy)]$ (−1078 ppm) [13]. The $^{31}P\{^1H\}$ NMR spectra of $[Re(CO)_3Br(PPhpy_2\text{-}N,N')]$ and $[Tc(CO)_3Cl(PPhpy_2\text{-}N,N')]$ show signals at 1.04 ppm and −2.24 ppm, respectively. They belong to non-coordinated phosphorus atoms, while signals of coordinated phosphines typically appear at lower field in such complexes [5d]. Moreover, the detection of H^6 signals in the ^1H NMR spectra at 9.52 ppm for the rhenium complex and at 9.36 ppm for the technetium analog confirm the coordination of two pyridyl rings. The signals of ^6H protons, adjacent to nitrogen in the pyridyl group, generally appear downfield from the other protons in the phenyl region. For non-coordinated pyridylphosphines, such signals appear as multiplets [14] in the range of 8.60–8.75 ppm ($CDCl_3$) [7b,14,15]. The coordination of the nitrogen atom, however, displaces the signal positions to 9–10 ppm [5d,7b,16].

$[Tc(CO)_3Cl(PPhpy_2\text{-}N,N')]$ as well as $[Re(CO)_3Br(PPhpy_2\text{-}N,N')]$ have been also characterized by X-ray structure analysis. Their structures are isotypic and the coordination environments of the metal atoms are slightly distorted octahedra with the carbonyl ligands in facial configuration. $PPhpy_2$ coordinates with the two nitrogen atoms forming six-membered chelate rings. Chlorine or bromine atoms occupy the remaining coordination sites. Fig. 1 shows an ellipsoid representation of the technetium complex. The structure of the rhenium analog is virtually identical and the same atomic labeling scheme has been applied. Therefore, it is not shown separately. Selected bond lengths and angles of both compounds are compared in Table 1. Main distortions from an ideal octahedron are mainly due to the restricting bite angle of the chelating ligand. The mean values of the M-N, M-C and M-X bond lengths are fully in agreement with the values of structurally related compounds [9,17].

The reaction of $(NEt_4)_2[Tc(CO)_3Cl_3]$ with 1 equiv. of Ppy_3 in THF at room temperature affords $[Tc(CO)_3Cl(Ppy_3\text{-}N,N')]$. The complex crystallizes directly from the mother liquor as colorless needles. The air and moisture stable complex is moderately soluble in THF, acetonitrile or CH_2Cl_2. Strong carbonyl bands at 2032, 1948 and 1882 cm^{-1} are observed in the IR spectrum of the compound.

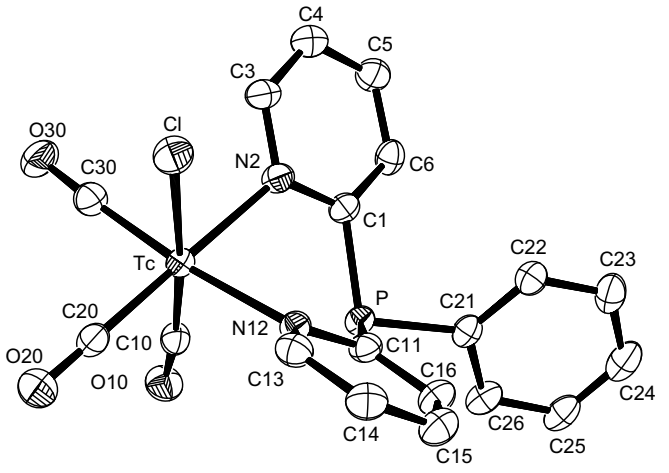


Fig. 1. Ellipsoid representation [26] of $[Tc(CO)_3Cl(PPhpy_2\text{-}N,N')]$. Thermal ellipsoids represent 50% probability. H atoms have been omitted for clarity.

C10–M–X	175.6(4)	175.0(1)

The atomic labeling scheme of the technetium complex in Fig. 1 has also been applied for the rhenium compound.

The latter two values refer to a broad, splitted $\nu_{(C\equiv O)}$ band. The ^{99}Tc NMR signal is observed at −988.42 ppm, which is almost perfectly the value, which was observed for [Tc(CO)$_3$Cl(PPhpy$_2$-*N*,*N*′)] and strongly suggests a bidentate *N*,*N*′ coordination mode also for Ppy$_3$ in the technetium complex under study. The ^{1}H NMR signals of the H^6 protons appear at 9.36 and 8.99 ppm with a 2:1 ratio and, thus, support this suggestion. [Tc(CO)$_3$Cl(Ppy$_3$-*N*,*N*′)] crystallizes as a racemic twin in the orthorhombic space group Pna2$_1$ with two molecules per asymmetric unit. The Flack parameter has a value of 0.56(5). All attempts to refine the structure in the corresponding centrosymmetric space group *Pnma* were not successful. A slightly distorted octahedron with facial configuration of the carbonyl ligands represents the coordination environment of the technetium atom as is shown in Fig. 2. Ppy$_3$ coordinates solely via two nitrogen atoms and the sixth coordination position is occupied by a chloro ligand. Thus, the structure is isotypic with the [M(CO)$_3$X(PPhpy$_2$-*N*,*N*′)] (M = Tc, Re; X = Cl, Br) complexes discussed above and in agreement with the bonding mode, which was proposed for analogous rhenium complex on the basis of spectroscopic data [12]. There are only marginal differences in the bond lengths and angles (Table 2). The position of the nitrogen atom of the non-coordinated pyridyl ring was derived on the basis of the thermal parameters.

In all our reactions of (NEt$_4$)$_2$[M(CO)$_3$X$_3$] complexes with PPhpy$_2$ and Ppy$_3$, we never observed the coordination of the phosphine (i) as monodentate phosphorus donor as previously observed in (NEt$_4$)[Re(CO)$_3$Br$_2$(PPh$_2$py-P)] [9], (ii) as P,N chelate, or (iii) in a tripodal *N*,*N*′,*N*″ arrangement. The first two facts can be explained by the preferred formation of the more stable six-membered chelate rings and the well-known high tendency of [M(CO)$_3$]$^+$ centers to bind to aromatic amines, which has been demonstrated previously and finds application in the labeling of histidine-rich protein sites [18,19]. A simple explanation for our observation, that the formation of species of the composition [M(CO)$_3$(Ppy$_3$-*N*,*N*′,*N*″)]$^+$ (M = Re, Tc) is less favored, however, cannot be given in the light that a number of transition metal complexes with N$_3$-tripodal Ppy$_3$ ligands are reported, and also the isotypic molybdenum(0) complex [Mo(CO)$_3$(Ppy$_3$-*N*,*N*′,*N*″)] has been isolated and characterized by X-ray crystallography [7]. In the case of the corresponding technetium and rhenium complexes, obviously charge compensation by the coordination of an anionic ligand is preferred. This assumption is supported by the results of our attempt to support tripodal coordination by the removal of all halide ligands from the metal atom.

In order to avoid the co-coordination of halide, we added 3 equiv. of the AgNO$_3$ to a solution of (NEt$_4$)$_2$[Re(CO)$_3$Br$_3$] in water/THF or water/MeOH mixtures. After removal of the precipitated AgBr, the remaining solution, which mainly contains the [Re(CO)$_3$(OH$_2$)$_3$]$^+$ cation, was brought to dryness. The resulting oil was redissolved in THF and 1 equiv. PPy$_3$ was added. The mixture was stirred for 1 h at room temperature Eq. (2). Colorless crystals of [Re(CO)$_3$(NO$_3$)(Ppy$_3$-*N*,*N*′)] deposited from the yellow mother liquor upon standing for 2 days. The compound is only sparingly soluble in water or organic solvents. Its IR spectrum shows two strong carbonyl bands at 2029 and 1913 cm^{-1}. The N–O frequency of the coordinated NO$_3^-$ ligand appears at 1281 cm^{-1} and is in agreement with values of the similar nitrato complexes (NEt$_4$)[ReBr$_2$(CO)$_2$(NO$_3$)NO] and (NMe$_4$)[Re(CO)$_2$(NO$_3$)$_3$NO] [20].

A single-crystal diffraction study on [Re(CO)$_3$(NO$_3$)(Ppy$_3$-*N*,*N*′)] confirms the coordination of a nitrato ligand and the role of Ppy$_3$ as an *N*,*N*′ chelating ligand. An ellipsoid representation of the neutral complex is shown in Fig. 3. Selected bond lengths and angles are summarized in Table 3. The position of the nitrogen atom in

the non-coordinated pyridyl ring was derived from a comparison of the thermal parameters of the corresponding atoms. Some distortions from an ideal octahedron are due to the small bite angle of the Ppy_3 and steric effects caused by the nitrato ligand, which is bent away from the two pyridine rings. The Re–O1 bond length of 2.175(7) Å is relatively long, but is in agreement with values found in analogous complexes and the weakness of such bonds [20,21]. This weakness is supported by a mass spectrometric study on the complex, which shows in addition to the molecular ion a peak at $m/z = 552$, which can be assigned to a deprotonation product of $[Re(CO)_3(OH_2)(Ppy_3)]$.

Concluding it must stated, that $PPhpy_2$ and Ppy_3 in all the isolated products coordinate to $\{M(CO)_3\}^+$ fragments (M = Re, Tc) exclusively as *N*,*N*′ bidentate ligands under formation of six-membered chelate rings. The unoccupied P or P,N donor positions recommend such compounds for the synthesis of bimetallic compounds.

3. Experimental

$(NEt_4)_2[Tc(CO)_3Cl_3]$ [22] and $(NEt_4)_2[Re(CO)_3Br_3]$ [23] were prepared by literature procedures. $PPhPy_2$ and PPy_3 were synthesized by a modification of a procedure previously reported by Kurtev et al. [5e]. ^{99}Tc is a weak β^--emitter. All manipulations with this isotope were performed in a laboratory approved for the handling of low-level radioactive materials. Normal glassware provides adequate protection against the low-energy beta emission of the technetium compounds. Secondary X-rays (bremsstrahlung) play an important role only when larger amounts of ^{99}Tc are used. IR spectra were measured as KBr pellets on a Shimadzu FTIR-spectrometer 8300. FAB^+ mass spectra were recorded with a TSQ (Finnigan) instrument using a nitrobenzyl alcohol matrix. Elemental analysis of carbon, hydrogen and nitrogen were determined using a Heraeus (vario EL) elemental analyzer. ^1H, ^{13}C, $^{31}P\{^1H\}$ and ^{99}Tc NMR spectra were taken with a JEOL 400 MHz multinuclear spectrometer.

3.1. $PPhpy_2$ and Ppy_3

n-Butyllithium (50 ml of a 1.6 m solution in *n*-hexane) was cooled to −70 °C under an atmosphere of dry argon. 2-Bromopyridine (7.7 ml, 80 mmol) in 50 ml of dry diethylether was added dropwise with stirring. The resulting red-brown solution was diluted with additional 20 ml of diethylether and stirred for 4 h. $PPhCl_2$ (40 mmol) or PCl_3 (27 mmol) were added dropwise in 10 ml diethylether, and an extra amount of 40 ml diethylether was added when the addition of the phosphine was completed. The resulting turpid, orange-brown suspension was vigorously stirred for 2 h at −70 °C and slowly warmed to room temperature. The mixture was extracted with 100 ml of degassed 2 m sulfuric acid. The pH was adjusted to 8–9 by the addition of concentrated NaOH. The resulting yellow solid was filtered off, washed with water and petrol ether, and recrystallized from acetone/petrol ether. Yield about 50%.

3.5. $[Re(CO)_3(NO_3)(Ppy_3\text{-}N,N')]$

$(NEt_4)_2[Re(CO)_3Br_3]$ (76.8 mg, 0.1 mmol) was dissolved in 10 ml THF and ca. 1 ml H_2O. $AgNO_3$ (51.0 mg, 0.3 mmol) was added. The mixture was stirred for 2 h at room temperature. AgBr was filtered off and the mother liquor was brought to dryness under vacuum. The resulting oil was redissolved in 1.5 ml THF and Ppy_3 (26.5 mg, 0.1 mmol) was added in 1.5 ml THF. The solution was stirred for 1 h at room temperature. A colorless solid of $[Re(CO)_3(NO_3)(Ppy_3\text{-}N,N')]$ deposited from the light yellow solution upon standing for 2 d. Single crystals were grown from MeOH. Yield: 25.4 mg (42.5%). *Anal.* Calc. for $C_{18}H_{12}N_4O_6PRe$: N, 9.37; C, 36.12; H, 2.02. Found: N, 9.13; C, 36.51; H, 1.95%. IR (ν_{max}, cm^{-1}): 2029 (vs, CO), 1913 (vs, CO), 1281 (m, NO_3). NMR spectra of sufficient quality could not be obtained due to the low solubility of the compound. FAB$^+$ MS: m/z 552 ($[Re(CO)_3O(Ppy_3)]^+$); 536 ($[Re(CO)_3(Ppy_3)]^+$).

3.6. X-ray structure determinations

The intensities for the X-ray determinations were collected on CAD4 (Enraf-Nonius) or STOE IPDS automated single crystal diffractometers with Mo Kα radiation. The structures were solved by direct methods using SIR 92 [24], SHELXS-86 [25] or SHELXS-97 [25]. Subsequent Fourier-difference map analyses yielded the position of the non-hydrogen atoms. Refinement was performed using SHELXL-97 [25]. Hydrogen atom positions were calculated for idealized positions and treated with the 'riding model' option of SHELXL. Crystal data and more details of the data collections and refinements are contained in Table 4.

Supplementary data

CCDC 698149, 698150, 698151 and 698152 contain the supplementary crystallographic data for $[Tc(CO)_3Cl(PPhpy_2\text{-}N,N')]$, $[Re(CO)_3Br(PPhpy_2\text{-}N,N')]$, $[Tc(CO)_3Cl(Ppy_3\text{-}N,N')]$ and $[Re(CO)_3(NO_3)(Ppy_3\text{-}N,N')]$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. General consideration

All starting materials were obtained commercially from Aldrich. IR spectra were recorded on a JASCO FTIR-410 spectrometer using KBr pellets. UV/Vis spectra were recorded on a Perkin–Elmer Lambda25 UV/Vis spectrophotometer. Thermogravimetric analysis was performed on a Mettler Toledo Star system from room temperature to 700 °C with a heating rate of 10 °C/min. Elemental analysis was carried out using a Perkin–Elmer 1400 C analyzer. Magnetic susceptibility measurements were performed on a George Associate Faraday Force Magnetometer.

2.2. Preparation of $[Co(tmb)_2(4,4'\text{-bpy})_2(H_2O)_2](Htmb)_2$ (**1**)

A mixture of cobalt acetate tetrahydrate (0.0311 g, 0.125 mmol), Htmb (0.041 g, 0.250 mmol), 4,4′-bpy (0.039 g, 0.250 mmol) and water (2.5 mL) was stirred for 30 min, sealed in a 23 mL polyfluoroethylene-lined stainless steel bomb, and kept at 100 °C under autogenous pressure for 72 h. After cooling at a ramp of 10 °C/h to room temperature, pink colored crystals of 1 were collected by filtration, washed with deionized water followed by diethyl ether, and then dried (0.0858 g, 65% yield).

For **1**: *Anal.* Calc. for $C_{60}H_{66}N_4O_{10}Co$: C, 67.85; H, 6.26; N, 5.28. Found: C, 68.25; H, 6.02; N, 5.60%.

2.3. Preparation of $\{[Ni(tmb)_2(\mu\text{-}4,4'\text{-bpy})_2(H_2O)_2]\ (4,4'\text{-bpy})\}_n$ (**2**)

A mixture of nickel acetate tetrahydrate (0.0311 g, 0.125 mmol), Htmb (0.041 g, 0.250 mmol), 4,4′-bpy (0.039 g, 0.250 mmol) and water (2.5 mL) was stirred for 30 min, sealed in a 23 mL polyfluoroethylene-lined stainless steel bomb, and kept at 75 °C under autogenous pressure for 72 h. After cooling at a ramp of 10 °C/h to room temperature, green colored crystals of **2** were collected by filtration, washed with de-ionized water followed by diethyl ether, and then dried (0.0641 g, 70% yield).

For **2**: *Anal.* Calc. for $C_{40}H_{42}N_4O_6Ni$: C, 65.50; H, 5.77; N, 7.64. Found: C, 66.23; H, 5.49; N, 7.51%.

2.4. X-ray data collection and structure refinement of **1** and **2**

X-ray single-crystal diffraction data for compound **1** was collected on a CAD-4 diffractometer equipped with graphite monochromated Mo Kα radiation at 293 K. The data was collected by the $\omega/2\theta$ scan mode. The standard direct method was used to position the heavy atoms. The remaining non-H atoms were located from the subsequent difference Fourier synthesis. All non-H atoms were refined anisotropically. All H atoms were calculated in ideal positions and were riding on their respective carbon atoms (Biso = 1.2 Beq and 1.5 Beq). The structure was refined in a full matrix least-squares calculation on F^2. Programs used to solve and refine the structure: SHELXS97 and SHELXL97 [15]. Molecular graphics: ORTEP-3 for windows [16].

X-ray single-crystal diffraction data for compound **2** was collected on a Bruker Apex II CCD diffractometer at 293(2) K. A semi-empirical absorption correction was applied using SADABS [17] and the SAINT program [18] was utilized for integration of the diffraction profiles. The structure was solved by direct methods using the SHELXS program of the SHELXTL package [19] and refined with SHELXL. The final refinement was implemented by full-matrix least-squares methods on F^2 with anisotropic thermal parameters for all the non-H atoms. In general, H atoms attached to the ligands were placed geometrically and allowed to ride during the subsequent refinement. The crystal data for both complexes are presented in Table 1, and selected bond distances and angles are in Tables 2 and 3.

3. Results and discussion

3.1. Structural description of $[Co(tmb)_2(4,4'\text{-bpy})_2(H_2O)_2](Htmb)_2$

Compound **1** crystallizes in the monoclinic space group $P2_1/n$. The cobalt center locates on the inversion center and coordinates to two nitrogen atoms from two 4,4′-bipyridyl, two oxygen atoms from two 2,4,6-trimethylbenzoate groups, and two oxygen atoms from a pair of water molecules to form an octahedral geometry. In this complex, there exist two unique 2,4,6-trimethylbenzoic acid moieties (see Fig. 1), one in anionic form to constitute the $[Co(tmb)_2(4,4'\text{-bpy})_2(H_2O)_2]$ monomer via coordination with car-

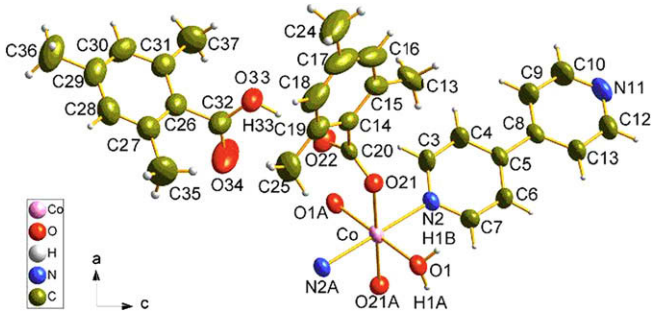

Fig. 1. A portion view of **1** with atom labeling of the asymmetry unit and metal coordination sphere. Symmetry code (A) $-x+1, -y, -z$.

boxylate and the other in the free acid form that is involved in hydrogen bonding linkage.

The bond lengths involving 4,4′-bipyridyl and 2,4,6-trimethyl benzoate ligands, Co(1)–N(2) [2.1787(16) Å], Co(1)–O(1) [2.0749(16) Å] and Co(1)–O(21) [2.1338(14) Å], are comparable to those found in similar cobalt complexes [20]. The *cis*-O–Co–O/N angles are in the range of 86.75(6)–91.81(6)° and the O–C–O angle is 123.6(2)°.

Due to the trans-disposition of the aqua molecules and both types of organic ligands at each metal center, a square grid layer network is propagated along the crystallographic bc plane with the adjacent Co–Co distance of 13.022 Å via intermolecular O–H···N interactions, as shown in Fig. 2 [21]. The bridging role of 4,4′-bipyridyl ligand via both coordination and H-bonded contacts leads to the formation of a (4,4) sheet, in which the ligated 2,4,6-trimethyl benzoate moieties lie along the shorter diagonals within each subunit and the unligated 2,4,6-trimethyl benzoic acid molecules recline the length of the longer diagonal by virtue of hydrogen bonds (Scheme 1).

In detail, the water ligands form strong intermolecular hydrogen bonds to the uncoordinating carboxylate oxygen atoms with $d_{O1-H1A\cdots O22\ (-x+1,\ -y,\ -z)} = 2.660(2)$ Å and ∠ = 158(3)°, and also to the uncoordinating N atoms of 4,4′-bipyridyl, with $d_{O1-H1B\cdots N11\ (-x+3/2,\ y+1/2,\ -z+1/2)} = 2.767(3)$ Å and ∠ = 179(4)°. In addition, there exist strong hydrogen bonds between the 2,4,6-trimethyl benzoic acid guests and the unligated O atoms of the 2,4,6-trimethyl benzoate ligands with $d_{O33-H33\cdots O22} = 2.586(3)$ Å and ∠ = 175(4)°.

Also, there are C–H···O interactions present in the structure [$d_{C36-H36B\cdots O21\ (x+1/2,\ -y+1/2,\ z-1/2)} = 3.594(4)$ Å and ∠ = 163.86(2)°], [$d_{C10-H10\cdots O34\ (x+1/2,\ -y-1/2,\ z+1/2)} = 3.333(4)$ Å and ∠ = 154.77(20)°], [$d_{C7-H7\cdots O34(-x+1,\ -y,\ -z)} = 3.630(4)$ Å and ∠ = 152.04(15)°], and [$d_{C3-H3\cdots O22} = 3.721(3)$ Å and ∠ = 143.81(16)°], which play a significant role in stabilizing the overall 3D structure (see Fig. 3). The parameters of hydrogen bonds are given in Table 4.

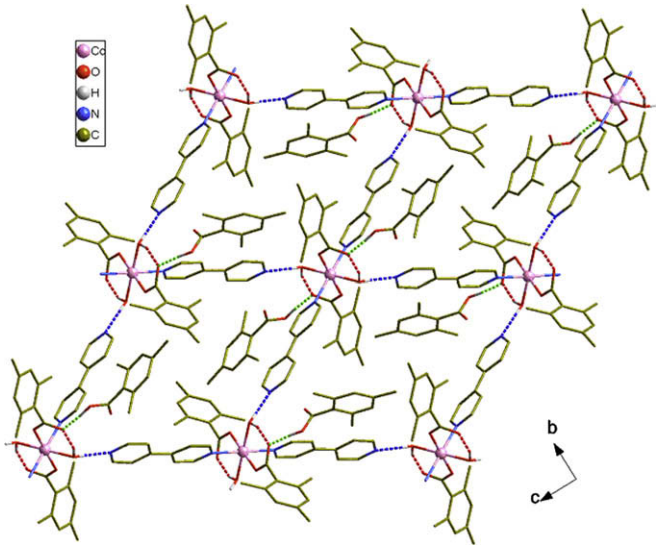

Fig. 2. A perspective view of the 2D H-bonding layer in **1** along the [100] direction. (H-bonds are shown in red, blue, and green broken lines). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

From the least square plane calculations, the phenyl rings of two 2,4,6-trimethylbenzoate anions and the two 4,4′-bipyridyl ligands are located in the parallel planes and separated by the distances of 1.914 and 0.264 Å, respectively.

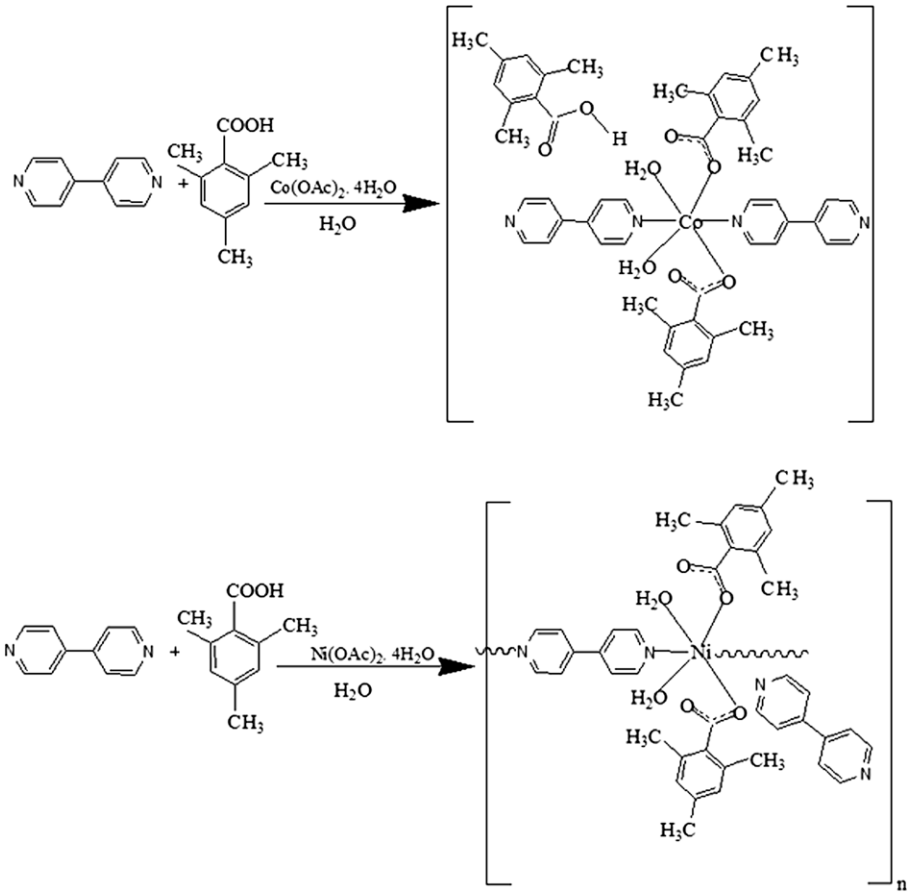
The dihedral angle between the 4,4′-bipyridyl ring and a phenyl ring of 2,4,6-trimethyl benzoate anion is 63.79° for the planes containing (C14, C15, C16, C17, C18, and C19) and (N2, C3-C10, N11, C12, and C13), and the dihedral angle between the phenyl rings of coordinated and uncoordinated acids is 63.20° for the planes containing (C14, C15, C16, C17, C18, and C19) and (C26, C27, C28, C29, C30, and C31) [22].

The group of atoms (N2, C3-C10, N11, C12, and C13) in the 4,4′-bipyridyl unit deviate significantly from planarity. Among all, C4 has the highest deviation of 0.0877 Å. The group of atoms (C14–C20 and C23–C25) of the trimethyl benzoate moiety also deviate significantly from planarity and C24 has the highest deviation of 0.1668 Å.

The group of atoms (C20, O21, and O22) in the carboxylate moiety are coplanar but, almost perpendicular (dihedral angle 88.84°) to its phenyl ring (C14–C19). The group of atoms (C26–C32 and C35–C37) deviates significantly from planarity, and C32 has the higher deviation of 0.0182 Å. From the puckering parameters (φ_2, θ_2, and Q) [23,24] the conformation for ring 1 (C14–C19) is boat conformation $^{1,4}B$, for ring 2 (C26–C31) is twist conformation $^{4}T_2$, for ring 3 (N2 and C3–C7) is twist conformation $^{3}T_1$, and for ring 4 (C8–C9, N11, C12, and C13) is sofa conformation $^{3}S_4$.

3.2. Structural description of *{[Ni(tmb)$_2$(μ-4,4′-bpy)(H$_2$O)$_2$](4,4′-bpy)}$_n$*

Compound **2** crystallizes in the orthorhombic space group *Ccca*. It is a 1:1:2 complex with Ni ion, 2,4,6-trimethylbenzoic acid (Htmb), and 4,4′-bipyridyl. The Ni atom lies on a diad axis and has a *trans*-N_2O_4 octahedral coordination through bonds to two 4,4′-bpy N atoms, two equivalent water O atoms and two equivalent carboxylate-O atoms. In the asymmetric unit, both COOH group of Htmb and 4,4′-bpy interact with Ni(II). Thus, each Ni(II) is connected to two 4,4′-bpy molecules that lie at the axial positions and two Htmb to complete the six coordination sites with the aid of two water molecules (Fig. 4). As a result, in this case, infinite linear polymeric chains of –Ni–bpy–Ni–bpy– are formed



Scheme 1.

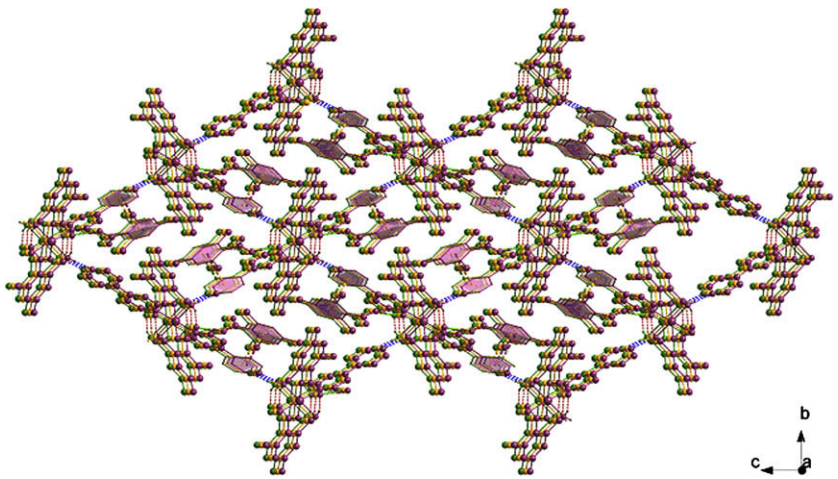


Fig. 3. 3D packing diagram of **1**, in which the interlayer aromatic interactions are indicated by pink. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

running parallel to the *c*-axis by repeated operations of *c*-glide (see Fig. 5), with the 4,4′-bpy connectors joining the adjacent Ni^{II} octahedrons using their typical bridging role. In each chain, the basal plane of carboxylate and water O atoms is stabilized by O3–H···O2 hydrogen bonding from water to the uncoordinated carboxylate O.

These polymeric chains are further held together by O3–H···N(bpy)N···H–O3 bridges. In short, there is much symmetry including glide planes and 2-fold rotation axes in all three directions, 2-fold screw axes in two directions, inversion centers, and lattice centering in this structure.

In the structure of 2, two unique 4,4′-bipyridyl molecules are found, one of which coordinates to the nickel center via its nitrogen atoms, whereas the other is involved only in hydrogen bonded linkage. Both types of 4,4′-bipyridyl units are nonplanar, having torsional twists about their central linking bonds of ca. 16.3° and 43.1°, respectively. Notably, the non-coordinated 4,4′-bipyridyl guest is positioned over a crystallographic inversion center, and

Table 4
Hydrogen bonds exhibited by **1** and **2**

D–H	d(D–H)	d(H···A)	∠D–H···A	d(D···A)	A [symmetry]

therefore, there is a statistical reversal of the N–N axis throughout the structure, which however does not change the crosslinking hydrogen bonding role of it.

The least square plane calculations show that the dihedral angle between the phenyl rings of two 2,4,6-trimethylbenzoate anions is 8.32° for the planes containing (C8, C9, C10, C11, C12, and C13) and (C8a, C9a, C10a, C11a, C12a, and C13a), and the dihedral angle between the two 4,4′-bipyridyl units is 73.51° for the planes containing (N1, C1–C6, N2, and C1′–C6′) and (N1a, C1a–C6a, N2a, and C1a′–C6a′), and the dihedral angle between the 4,4′-bipyridyl ring and a phenyl ring of 2,4,6-trimethyl benzoate anion is 48.41° for the planes containing (C8, C9, C10, C11, C12 and C13) and (N1, C1–C6, N2 and C1′–C6′).

The bond lengths involving 4,4′-bipyridyl and 2,4,6-trimethyl benzoate ligands are Ni–O(carboxyl) [2.042(1) Å], Ni–O(water) [2.0084(1) Å], and Ni–N [2.104(1) and 2.105(2) Å], being virtually similar to the mean database values for these bonds [2.061, 2.087, and 2.103 Å, respectively]. The O–Ni–O angles are in the range of 89.54(5)–177.55(7)° with the average value of 118.99° and the O–C–O angle is 125.32(18)°.

Each coordinated water molecule provides one H atom to the coordinating carboxylate O atom and the other to the N atom of uncoordinated 4,4′-bpy [$d_{O3-H3A\cdots N3\ (x-1/2,y,-z+1)}$ = 2.799(0) Å and ∠ = 167.30(1)°] and [$d_{O3-H3B\cdots O2\ (-x+1/2,\ -y,\ z)}$ = 2.650(0) Å and ∠ = 164.76(1)°]. The strong hydrogen bonds are apparently responsible for the supramolecular assembly of the 1D coordination chains to generate 3D networks. In fact, considering these H-bonds, each metal center behaves as a planar four-connected node to constitute 3D $CdSO_4$ topological frameworks [25], which are interestingly of 2-fold interpenetration in the crystalline lattice (see Figs. 6–8). Intermolecular C–H···O interactions [$d_{C5-H5\cdots O2\ (-x+1,-y,-z+1)}$ = 3.444 Å and ∠ = 178.34(1)°] and [$d_{C21-H21\cdots O1\ (x+1/2,\ y,\ -z+1)}$ = 3.201 Å and ∠ = 163.25(1)°] are also found, which play a significant role in stabilizing this structure. The vibrational frequencies [26] of **1** and **2** are given in Table 5.

3.3. Magnetic properties

Temperature-dependent magnetic susceptibility measurements for complexes **1** and **2** were performed on polycrystalline samples. The effective magnetic moments of **1** and **2** are 5.68 and 3.42 μ_B, being close to the expected values (5.2 and 3.9 μ_B) for the isolated high-spin Co(II) and Ni(II) ($S = 5/2$). A χ_M versus T plot for **1** over the temperature range of 23.7–291.8 K (Fig. 9), in which χ_M is the corrected magnetic susceptibility per Co(II) unit, could be fitted according to the Curie–Weiss law $\chi_M = C/(T-\theta)$, giving a Curie constant C = 4.03 $cm^3\ mol^{-1}$ K, and a Weiss constant $\theta = -22.51$ K. The negative value of θ indicates weak antiferromagnetic interactions between Co(II), since the adjacent Co(II) ions are separated with distance of 13.022 Å as revealed by X-ray crystal structure. The χ_M value of 1.2×10^{-2} $cm^3\ mol^{-1}$ at room temperature increases as the temperature decreases, attaining 9.8×10^{-2} $cm^3\ mol^{-1}$ at 23.7 K. A χ_M versus T plot for **2** over the temperature range of 8.4–296.7 K (Fig. 10), in which χ_M is the corrected magnetic susceptibility per Ni(II) unit, could be fitted according to the Curie–Weiss law $\chi_M = C/(T-\theta)$, giving a Curie constant C = 1.46 $cm^3\ mol^{-1}$ K, and a Weiss constant $\theta = -34.92$ K. Similarly, the negative value of θ indicates antiferromagnetic interactions between Ni(II), since the adjacent Ni(II) ions are separated by 4,4′-bpy ligands with distance of 11.3 Å. The χ_M value of 4.91×10^{-3} $cm^3\ mol^{-1}$ at room temperature increases as the temperature decreases, attaining 6.8×10^{-2} $cm^3\ mol^{-1}$ at 8.4 K.

3.4. Thermal properties

Thermal analysis (TGA) of complexes **1** and **2** were performed between room temperature and 700 °C under the nitrogen atmo-

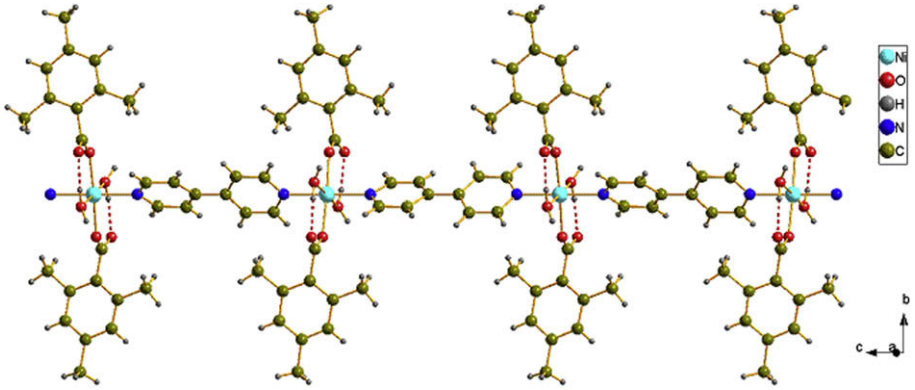

Fig. 5. The polymeric single chain in **2**.

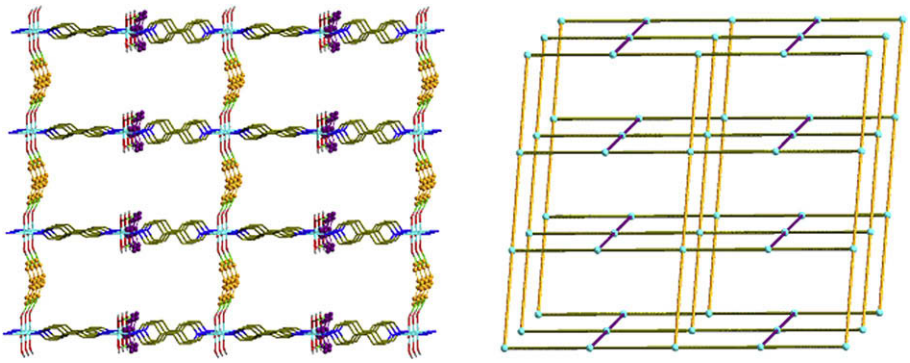

Fig. 6. A single 3D network in **2** (left). A schematic representation of the cds ($CdSO_4$) topology (right). The 4,4′-bipy molecules involving in H-bonds are shown in violet and orange, respectively, and the 2,4,6-trimethyl benzencarboxylic acid ligands are omitted for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

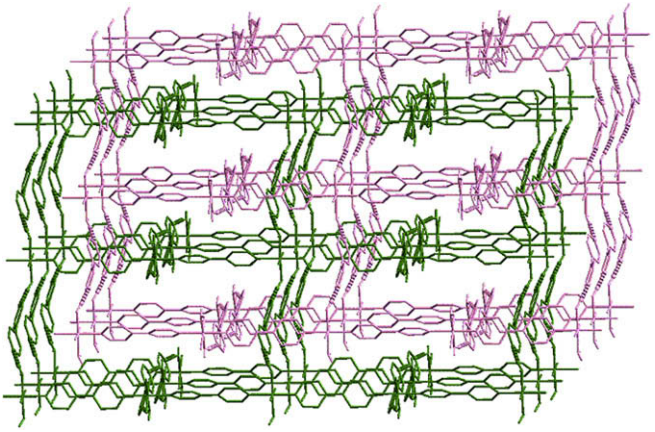

Fig. 7. 2-Fold interpenetrating structure of **2**. The two cds arrays are shown in green and rose, respectively. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

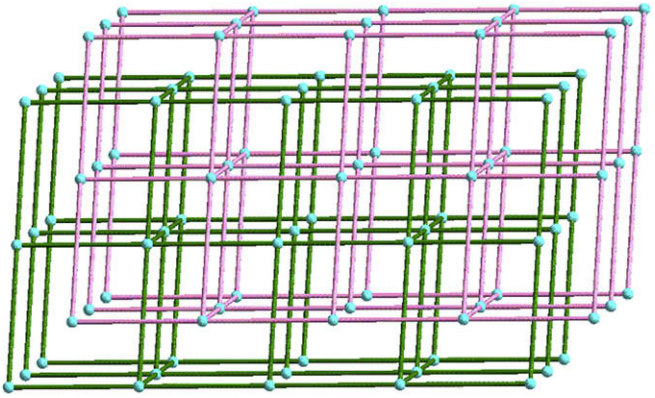

Fig. 8. A schematic view of two interpenetrating networks.

sphere. The TGA results indicate that **1** undergoes a weight loss of 3.7% (Calc. 3.3%) in the temperature range of 85–106 °C, corresponding to the removal of two coordinated water molecules. The second stage has the weight loss of 52.2% (Calc. 51.5%) in the temperature range of 146–274 °C, corresponding to removal of two 4,4′-bpy moieties and an unligated Htmb. The third stage occurs with the gradual decomposition of the remaining species, leading to the formation of cobalt oxide. The saturation temperature above which there is no obvious weight loss occurs at ~425 °C.

The TGA results indicate that complex **2** loses 5.1% (Calc. 4.9%) of its mass in the temperature range of 92–108 °C, corresponding

to the loss of coordinated water molecules. The second stage involves the loss of 85.7% (Calc. 87.0%) of its mass in the temperature range of 290–395 °C, corresponding to the loss of two 4,4′-bpy and two tmb components. The third stage occurs with the gradual decomposition of the remaining species, leading to the formation of nickel oxide. The saturation temperature above which there is no obvious weight loss occurs at ~530 °C.

3.5. Electronic absorption spectra

In the electronic spectrum for complex **1**, the ligand 4,4′-bipyridyl exhibits a low energy band at 320 nm region, which is gener-

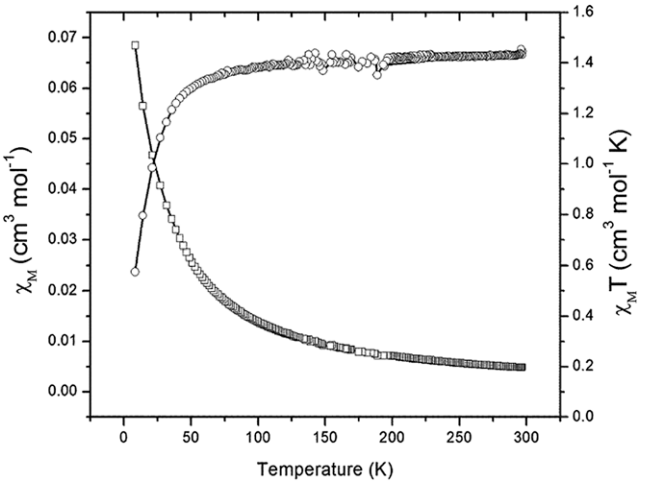

Fig. 10. χ_M and $\chi_M T$ vs. T plots for complex **2**. The solid lines represent the best fit of the experimental data.

ally assigned to π–π^* transition of the benzenoid and/or (C=N) chromophore of the ligand. As a rule, the longer wavelength bands in the spectra of metal complexes may be considered as evidence for the complex formation. The absorption band at 535 nm due to the $^4T_{1g} \rightarrow {}^4T_{1g}$ (P) transition, suggests a high-spin octahedral sphere. However, the presence of an additional absorption band as a shoulder in the 680 nm region, assigned to the $^4T_{1g} \rightarrow {}^4A_{2g}$ transition, suggests a distorted-octahedral configuration due to the Jahn–Teller effect.

The electronic spectrum of the Ni(II) complex **2** shows two absorption bands at 390 and 700 nm due to the MLCT transitions, as generally observed for octahedral Ni(II) complexes.

3.6. Antibacterial and antifungal activity

The *in vitro* biological screening effects of both complexes were tested against the bacteria: *Escherichia coli, Staphylococcus aureus, Pseudomonas aeruginosa,* and *Bacillus subtilis* by the well-diffusion method [27] using agar nutrient as the medium. The antifungal activities were also evaluated by the well-diffusion method against the fungi viz., *Aspergillus niger, Aspergillus flavus* and *Rhizoctonia bataicola* cultured on potato dextrose agar as medium. The compounds were tested at a concentration of 50 μg/0.01 mL in aqueous solution. In a typical procedure [28], a well was made on the agar medium inoculated with microorganisms. The well was filled with the test solution using a micropipette and the plate was incubated for 24 h for bacteria and 72 h for fungi at 35 °C. During this period, the test solution diffused and the growth of the inoculated microorganisms was affected. The inhibition zone was developed, at which the concentration was noted. The percentage inhibition was calculated as $100(C - T)/C$, where C is the average diameter of bacteria or fungal growth on the control plate (water) and T is the average diameter of bacteria or fungal growth on the test plate.

The susceptibility zones were measured in diameter (mm) and the results are shown in Tables 6 and 7. The susceptibility zones measured are the clear zones around the discs killing the bacteria. The complexes individually exhibit varying degrees of inhibitory effect on the growth of the tested bacterial species. On complexation, the polarity of the metal ion will be reduced to a greater extent due to the overlap of the ligand orbital and partial sharing of the positive charge of the metal ion with the donor groups. Further, it increases the delocalization of π-electrons over the whole ligand and enhances the penetration of complexes into lipid membranes and blocking of the metal binding sites in the enzymes of microorganisms. The complexes may also disturb the respiration process of the cell and thus block the synthesis of proteins, which restricts further growth of the organism [29].

Table 6
Antibacterial activity of the complexes **1** and **2**

Complex	Bacterial species				
	a	b	c	d	e
$[Co(tmb)_2(4,4'\text{-bpy})_2](Htmb)_2$	+++	++	++	+++	+++
$[Ni(tmb)_2(\mu\text{-}4,4'\text{-bpy})(H_2O)_2]_n(4,4'\text{-bpy})$	+++	++	++	+++	+++

a: *Escherichia coli*, b: *Staphylococcus aureus*, c: *Pseudomonas aeruginosa*, d: *Bacillus subtilis*; e: *Klebsiella pneumoniae*. Inhibition zone diameter mm (% inhibition): +, 6–10 (27–45%); ++, 10–14 (45–64%); +++, 14–18 (64–82%); ++++, 18–22 (82–100%). Percent inhibition values were relative to inhibition zone (22 mm) of standard antibacterials (sulfadiazine, sulfathiazole), considered as 100% inhibition, tested under the same conditions as the new compounds reported here.

Table 7
Antifungal activity of the complexes **1** and **2**

Complex	Fungal species		
	a	b	c
$[Co(tmb)_2(bpy)_2](Htmb)_2$	+++	++	++
$[Ni(tmb)_2(\mu\text{-}4,4'\text{-bpy})(H_2O)_2]_n(4,4'\text{-bpy})$	+++	++	++

a: *Aspergillus niger*, b: *Aspergillus flavus*, c: *Rhizoctonia bataicola*. Inhibition zone diameter mm (% inhibition): +, 6–10 (27–45%); ++, 10–14 (45–64%); +++, 14–18 (64–82%); ++++, 18–20 (82–100%), (–) = no inhibition zone. Percent inhibition values were relative to inhibition zone (20 mm) of standard antifungal (Bavistin), considered as 100% inhibition, tested under the same conditions as the new compounds reported here.

4. Conclusion

In summary, two new supramolecular complexes of Co^{II} and Ni^{II} using 2,4,6-trimethyl benzoic acid and 4,4′-bipyridyl as ligands have been synthesized by hydrothermal reaction and characterized by X-ray crystallography, IR, UV/Vis spectra, elemental analysis and magnetic susceptibility measurements. Both complexes display interesting 3D hydrogen-bonded assemblies from the fundamental discrete or 1D coordination arrays. Weak intermolecular antiferromagnetic interactions are found in **1** and **2**, which also show good antibacterial and antifungal activity.

2.3. 4′-(5-Bromo-2,2′-bithien-5′-yl)-2,2′:6′,2″-terpyridine (*1*)

4′-(2,2′-Bithien-5′-yl)-2,2′:6′,2″-terpyridine [39] (0.31 g, 0.81 mmol) was dissolved in a mixture of glacial acetic acid (5 cm^3) and *N*-bromosuccinimide (0.17 g, 0.97 mmol) and stirred at room temperature overnight in the absence of light. The reaction mixture was neutralised with aqueous $NaHCO_3$ and the solution was extracted into CH_2Cl_2 (3 × 25 cm^3). The CH_2Cl_2 extracts were dried over Na_2SO_4 and the solvent was removed. Compound **1** was isolated as a yellow solid (0.26 g, 0.55 mmol, 68%). m.p. = 185.6 °C. ^{1}H NMR (500 MHz, $CDCl_3$) δ/ppm 8.72 (ddd, *J* 4.8, 1.8, 0.9 Hz, 2H, H^{A6}), 8.64 (s, 2H, H^{3B}), 8.63 (dt, *J* 7.5, 1.0 Hz, 2H, H^{A3}), 7.86 (dt, *J* 7.7, 1.8 Hz, 2H, H^{A4}), 7.68 (d, *J* 3.9 Hz, 1H, H^{C4}), 7.35 (ddd, *J* 7.5, 4.8, 1.2 Hz, 2H, H^{A5}), 7.15 (d, *J* 3.9 Hz, 1H, H^{C3}), 7.00 (s, 2H, H^{D3+D4}). ^{13}C NMR (125 MHz, $CDCl_3$) δ/ppm 156.2 (C^{B2}), 156.0 (C^{A2}), 149.3 (C^{A6}), 143.0 (C^{B4}), 140.9 (C^{C5}), 138.7 (C^{D2}), 138.2 (C^{C2}), 137.2 (C^{A4}), 131.0 (C^{D4}), 126.9 (C^{C4}), 125.1 (C^{C3}), 124.5 (C^{D3}), 124.2 (C^{A5}), 121.6 (C^{A3}), 116.9 (C^{B3}), 111.9 (C^{C5}). EI MS *m/z* 476 $[M]^+$. $C_{23}H_{14}BrN_3S_2 \cdot 1.5H_2O$ requires C, 54.87; H, 3.40; N, 8.35. Found: C, 54.26; H, 2.83; N, 8.25%.

2.4. $[Ru(tpy)(\mathbf{1})][PF_6]_2$

$[Ru(tpy)Cl_3]$ (0.12 g, 0.27 mmol) was added to a stirring solution of compound **1** (0.13 g, 0.25 mmol) in EtOH (20 cm^3) with a few drops of *N*-ethylmorpholine. The mixture was stirred at room temperature for 15 min, and then heated at reflux for 5 h in the absence of light. The mixture was cooled to room temperature, and was added to aqueous NH_4PF_6 and the solution diluted with water (100 cm^3). The resulting precipitate was collected and dissolved in MeCN and purified by column chromatography (SiO_2, MeCN:H_2O:aqueous KNO_3 9:0.9:0.1). The second (red) band was collected, excess aqueous NH_4PF_6 was added and solvent was removed. The solid was dissolved in acetonitrile, and the product precipitated by addition to water. Recrystallization from MeCN/Et_2O gave $[Ru(tpy)(1)][PF_6]_2$ as a red solid (40 mg, 0.036 mmol, 13%). ^{1}H NMR (500 MHz, CD_3CN) δ/ppm 8.88 (s, 2H, H^{B3}), 8.75 (d, *J* 8.2 Hz, 2H, H^{F3}), 8.64 (d, *J* 8.1 Hz, 2H, H^{A3}), 8.49 (d, *J* 8.0 Hz, 2H, H^{E3}), 8.41 (t, *J* 8.2 Hz, 1H, H^{F4}), 8.11 (d, *J* 3.9 Hz, 1H, H^{C4}), 7.95 (dt, *J* 7.8, 1.3 Hz, 2H, H^{A4}), 7.92 (dt, *J* 7.9, 1.4 Hz, 2H, H^{E4}), 7.51 (d, *J* 3.9 Hz, 1H, H^{C3}), 7.43 (d, *J* 5.5 Hz, 2H, H^{A6}), 7.34 (d, *J* 5.6 Hz, 2H, H^{E6}), 7.29 (d, *J* 3.9 Hz, 1H, $H^{D3/D4}$), 7.22 (d, *J* 3.9 Hz, 1H, $H^{D3/D4}$), 7.17 (m, 4H, H^{A5+E5}). $^{13}C\{^1H\}$ NMR (125 MHz, CD_3CN) δ/ppm 159.1 ($C^{A2/E2}$), 158.9 ($C^{A2/E2}$), 156.5 ($C^{B2/F2}$), 156.4 ($C^{B2/F2}$), 153.6 ($C^{A6/E6}$), 153.5 ($C^{A6/E6}$), 141.7 (C^{B4}), 140.6 ($C^{C2/D2}$), 139.8 (C^{C5}), 139.2 ($C^{A4/E4}$), 139.1 ($C^{A4/E4}$), 138.8 ($C^{C2/D2}$), 136.9 (C^{F4}), 132.9 (C^{D4}), 130.4 (C^{C4}), 128.6 ($C^{A5/E5}$), 128.5 ($C^{A5/E5}$), 127.2 (C^{C3}), 126.8 (C^{D3}), 125.7 ($C^{A3/E3}$), 125.5 ($C^{A3/E3}$), 124.8 (C^{F3}), 120.3 (C^{B3}), 113.2 (C^{D5}). ESI MS *m/z* 957 $[M-PF_6]^+$, 405 $[M-2PF_6]^{2+}$. $C_{38}H_{25}Br_1F_{12}N_6P_2Ru_1S_2 \cdot H_2O$ requires C, 40.80; H, 2.43; N, 7.51. Found: C, 41.10; H, 2.77; N, 7.18%.

2.5. $[Ru(\mathbf{1})_2][PF_6]_2$

$RuCl_3 \cdot 3H_2O$ (31 mg, 0.12 mmol), **1** (110 mg, 0.23 mmol) and $AgNO_3$ (0.06 g, 0.35 mmol) were added to DMF (15 cm^3). The solution was stirred at room temperature for 15 min, after which time it was heated at reflux for 8 h in the absence of light. The reaction mixture was filtered to remove AgCl, and then saturated aqueous NH_4PF_6 (excess) was added to the filtrate to precipitate the product which was purified by column chromatography (SiO_2, MeCN:aqueous KNO_3, 15:1). The main red fraction was collected and saturated aqueous NH_4PF_6 was added to effect nitrate/hexafluorophosphate exchange. Solvent was removed, the solid residue dissolved in MeCN, and the product precipitated by addition of water. $[Ru(1)_2][PF_6]_2$ was recrystallized from MeCN/Et_2O and was isolated as an orange-red solid (80 mg, 0.060 mmol, 52%). ^{1}H NMR (400 MHz, CD_3CN) δ/ppm 8.89 (s, 4H, H^{B3}), 8.64 (d, *J* 8.0 Hz, 4H, H^{A3}), 8.11 (d, *J* 4.0 Hz, 2H, H^{C4}), 7.95 (dt, *J* 7.9, 1.5 Hz, 4H, H^{A4}), 7.51 (d, *J* 3.9 Hz, 2H, H^{C3}), 7.43 (d, *J* 4.8 Hz, 4H, H^{A6}), 7.29 (d, *J* 3.9 Hz, 2H, $H^{D3/D4}$), 7.23 (d, *J* 3.9 Hz, 2H, $H^{D3/D4}$), 7.18 (m, 4H, H^{A5}). ESI MS *m/z* 1198 $[M-PF_6]^+$.

2.6. Ligand *2*

4′-Ethynyl-2,2′:6′,2″-terpyridine (100 mg, 0.388 mmol), 5-bromo-2,2′-bithiophene (100 mg, 0.408 mmol), $[Pd(PPh_3)_2Cl_2]$ (14 mg, 0.020 mmol) and CuI (4 mg, 0.021 mmol) were dissolved in Et_3N (8 cm^3). The solution was heated under reflux for 48 h. The solvent was then evaporated under reduced pressure. The crude material was dissolved in hexane (200 cm^3). After filtration, solvent from the filtrate was removed under reduced pressure. The crude product was purified by several, sequential column chromatographic separations (see text) (Al_2O_3, hexane:ethyl acetate 1:1), and the third band was collected. Compound **2** was isolated as a yellow solid (45 mg, 0.11 mmol, 28%). M.p. = 152.4 °C. ^{1}H NMR (500 MHz, CD_3CN) δ/ppm 8.70 (d, *J* 4.6 Hz, 2H, H^{A6}), 8.60 (d, *J* 7.9 Hz, 2H, H^{A3}), 8.53 (s, 2H, H^{B3}), 7.85 (dt, *J* 7.8, 1.7 Hz, 2H, H^{A4}), 7.33 (dd, *J* 7.2, 4.8, 0.7 Hz, 2H, H^{A5}), 7.25 (dd, *J* 5.0, 1.0 Hz, 1H, H^{D3}), 7.24 (d, *J* 3.9 Hz, 1H, H^{C4}), 7.21 (d, *J* 3.7 Hz, 1H, H^{D5}), 7.08 (d, *J* 3.8 Hz, 1H, H^{C3}), 7.02 (dd, *J* 3.8, 5.0 Hz, 1H, H^{D4}). $^{13}C\{^1H\}$ NMR (125 MHz, CD_3CN) δ/ppm 155.8 ($C^{A2/B2}$), 155.7 ($C^{A2/}$

^{E2}), 149.4 (C^{A6}), 140.5 ($C^{D2/C5}$), 137.1 (C^{A4}), 136.7 (C^{C2}), 134.3 (C^{C4}), 133.3 (C^{B4}), 128.2 (C^{D4}), 125.5 ($C^{D3/D5}$), 124.3 ($C^{D3/D5}$), 124.1 (C^{A5}), 123.9 (C^{C3}), 122.5 (C^{B3}), 121.4 (C^{A3}), 121.1 ($C^{D2/C5}$), 92.6 ($C^{tpyC\equiv C}$), 87.4 ($C^{tpyC\equiv C}$). EI MS *m/z* 421.1 $[M]^+$. $C_{25}H_{15}N_3S_2 \cdot 1.5H_2O$ requires C, 66.94; H, 4.04; N, 9.37. Found: C, 67.35; H, 3.87; N, 8.68%.

2.7. [Ru(**2**)(tpy)][PF_6]$_2$

Ligand 2 (40 mg, 0.095 mmol) and [Ru(tpy)Cl_3] (41 mg, 0.094 mmol) were dissolved in EtOH (40 cm^3). A few drops of *N*-ethylmorpholine were added. The reaction mixture was heated under reflux for 48 h, then filtered through Celite, and washed through with EtOH. The filtrate was concentrated under reduced pressure and aqueous NH_4PF_6 was added to precipitate the product. The crude product was filtered through Celite, washed with Et_2O and dissolved in MeCN. It was purified by column chromatography (SiO_2, MeCN:H_2O:saturated aqueous KNO_3 7:2:2). The third band (orange-red) was collected, and was concentrated under reduced pressure. Aqueous NH_4PF_6 was added to precipitate the product, which was collected on Celite and was washed with Et_2O and dissolved in MeCN. Removal of solvent gave [Ru(2)(tpy)][PF_6]$_2$ as a dark red powder (23 mg, 0.030 mmol, 32%). ^{1}H NMR (500 MHz, CD_3CN) δ/ppm 8.84 (s, 2H, H^{B3}), 8.76 (d, *J* 8.2 Hz, 2H, H^{F3}), 8.49 (overlapping d, *J* 8.1 Hz, 4H, H^{A3+E3}), 8.43 (t, *J* 8.2 Hz, 1H, H^{F4}), 7.95 (dt, *J* 8.0, 1.3 Hz, 2H, H^{A4}), 7.91 (dt, *J* 8.0, 1.3 Hz, 2H, H^{E4}), 7.56 (d, *J* 3.8 Hz, 1H, H^{C4}), 7.51 (d, *J* 3.9 Hz, 1H, H^{D5}), 7.48 (dd, *J* 5.0, 0.9 Hz, 1H, H^{D3}), 7.44 (dd, *J* 3.6, 0.9 Hz, 1H, H^{D3}), 7.39 (d, *J* 5.5 Hz, 2H, H^{A6}), 7.36 (m, 3H, H^{E6+C3}), 7.18 (m, 4H, H^{A5+E5}), 7.15 (t, *J* 4.3 Hz, 1H, H^{D4}), ^{13}C{^{1}H} NMR (125 MHz, CD_3CN) δ/ppm 159.0 (C^{B2}), 158.6 (C^{E2}), 156.4 (C^{F2}), 156.2 (C^{A2}), 153.6 ($C^{A6/E6}$), 153.55 ($C^{A6/E6}$), 142.7 (C^{C5}), 139.3 ($C^{A4/E4}$), 139.2 ($C^{A4/E4}$), 137.2 (C^{F4}), 137.0 (C^{C4}), 136.7 (C^{D2}), 130.6 (C^{B4}), 129.6 (C^{D4}), 128.7 ($C^{A5/E5}$), 128.5 ($C^{A5/E5}$), 127.8 (C^{D5}), 126.6 (C^{D3}), 125.7 ($C^{A3/E3}$), 125.6 ($C^{A3/E3}$), 125.5 (C^{B3}), 124.8 (C^{F3}), 120.3 (C^{C2}), 92.2 ($C^{tpyC\equiv C}$), 91.0 ($C^{tpyC\equiv C}$). FAB MS *m/z* 900 $[M-PF_6]^+$, 755 $[M-2PF_6]^+$. $C_{40}H_{26}F_{12}N_6P_2RuS_2 \cdot 2H_2O$ requires C, 44.41; H, 2.80; N, 7.77. Found: C, 43.96; H, 2.87; N, 7.79%.

2.8. Crystal structure determination

Data were collected on a Bruker Nonius Kappa CCD instrument; data reduction, solution and refinement used the programs COLLECT [40], SIR92 [41], DENZO/SCALEPACK [42] and CRYSTALS [43]. Structures have been analysed using Mercury v. 1.4.2 [44].

2.9. 4′-(5-Bromo-2,2′-bithien-5′-yl)-2,2′:6′,2″-terpyridine (**1**)

$C_{23}H_{14}BrN_3S_2$, M = 476.42, colourless blocks, monoclinic, space group $P2_1/a$, a = 8.3099(1), b = 11.5704(1), c = 20.5872(3) Å, β = 99.9846(7)°, U = 1949.46(4) Å^3, Z = 4, D_{calc} = 1.623 Mg m^{-3}, μ(Mo K_α) = 2.338 mm^{-1}, T = 173 K, 5691 reflections collected. Refinement of 3901 reflections (262 parameters) with $I > 3\sigma(I)$ converged at final R_1 = 0.0257 (R_1 all data = 0.0394), wR_2 = 0.0294 (wR_2 all data = 0.0396), Goodness-of-fit = 1.072.

3. Results and discussion

We approached the assembly of a conjugated system connecting tpy, thienyl and alkynyl domains by two strategies: by starting with 4′-(2,2′-bithien-5′-yl)-2,2′:6′,2″-terpyridine [39], or by using 4′-ethynyl-2,2′:6′,2″-terpyridine [36] as the precursor. Bromination of 4′-(2,2′-bithien-5′-yl)-2,2′:6′,2″-terpyridine by NBS in acetic acid in the absence of light produced ligand **1** (Scheme 1) in 68% yield after workup. This reaction proved to be sensitive to the scale, and optimum yields of **1** were obtained under the conditions described in Section 2. The electron impact mass spectrum of **1** exhibited a parent ion at *m/z* 476 with the characteristic isotope pattern of a monobromo-derivative. The ^{1}H NMR spectrum was assigned using COSY and NOESY techniques, the doublet for thiophene proton H^{C4} (see Scheme 1) being assigned on the basis of a NOESY cross peak to the signal for tpy proton H^{B3}. The signals for thiophene protons H^{D3} and H^{D4} are coincident and give rise to a singlet at δ 7.00 ppm. The ^{13}C NMR spectrum was fully assigned using HMQC and HMBC experiments; the bromo-attached carbon atom C^{D5} appears at lowest frequency at δ 111.9 ppm. X-ray quality crystals of 1 were grown by slow diffusion of hexane into a chloroform solution of the compound. Fig. 1 shows the molecular structure of **1** and gives selected bond parameters. The ligand deviates somewhat from planarity, although not sufficiently that conjugation along the tpy-bithiophene backbone will be significantly perturbed (angles between the least squares planes of the rings containing atoms N1 and N2, N2 and N3, N2 and S1, and S1 and S2 are 17.65(8)°, 18.9(1)°, 12.52(8)° and 14.14(8)°). Molecules assemble in the crystal lattice so that there are segregated domains of bithiophene units and of tpy units (Fig. 2). Within the former, the closest S···S atom contacts are S2···S2i of 3.6447(6) Å (symmetry code i = $-x$, $1-y$, $1-z$) which is less than the sum of the van der Waals radii (3.70 Å).

Ligand **1** was incorporated into the homoleptic complex [Ru(**1**)$_2$]$^{2+}$ and heteroleptic complex [Ru(tpy)(**1**)]$^{2+}$ by treament of $RuCl_3 \cdot 3H_2O$ with two equivalents of **1** in the presence of $AgNO_3$, and by the reaction of [Ru(tpy)Cl_3] with **1** in the presence of *N*-ethylmorpholine, respectively. Both complexes were isolated as the hexafluorophosphate salts, although it was difficult to obtain pure samples of the homoleptic complex. The highest mass peak in the electrospray mass spectrum of [Ru(1)$_2$][PF_6]$_2$ appeared at *m/z* 1198 and exhibited the correct isotope pattern for the ion $[M-PF_6]^+$. For [Ru(tpy)(**1**)][PF_6]$_2$, the electrospray mass spectrum showed peaks both for $[M-PF_6]^+$ (*m/z* = 957) and $[M-2PF_6]^{2+}$ (*m/z* = 405), again with the correct isotopic distrubtions. The appearance of the ^{1}H NMR spectrum of [Ru(**1**)$_2$][PF_6]$_2$ confirmed the presence of a single ligand environment. The significant shift in the signal for proton H^{A6} from δ 8.72 ppm in free **1** to δ 7.43 ppm in [Ru(**1**)$_2$][PF_6]$_2$ is consistent with coordination of the tpy domain to the ruthenium(II) centre. Coordination also has the effect of separating the signals for thiophene protons H^{D3} and H^{D4} which appear as doublets (*J* 3.9 Hz) at δ 7.23 and 7.29 Hz, compared to δ 7.00 ppm in the uncoordinated ligand. The ^{1}H NMR spectrum of

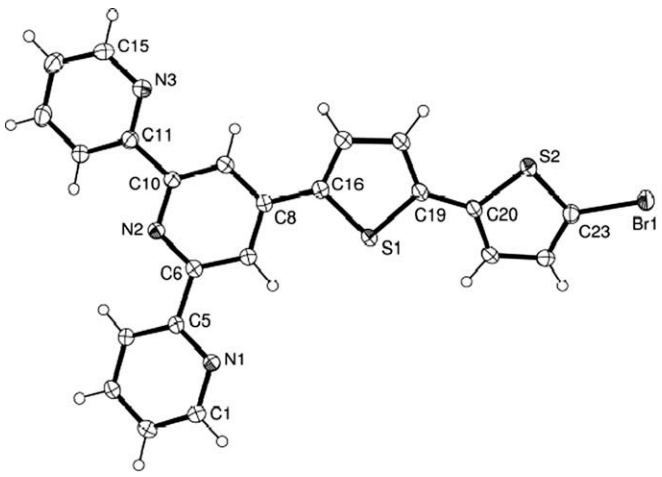

Fig. 1. The structure of ligand **1** with thermal ellipsoids plotted at 40% probability level. Selected bond distances and angles: C8–C16 = 1.465(2), Br1–C23 = 1.875(2), S1–C16 = 1.731(2) , S1–C19 = 1.726(2), S2–C20 = 1.730(2), S2–C23 = 1.720(2) Å; C16–S1–C19 = 92.22(8), C20–S2–C23 = 91.12(8), C8–C16–S1 = 120.6(1), S1–C19–C20 = 119.9(1), C19–C20–S2 = 120.6(1), Br1–C23–S2 = 120.9(1)°.

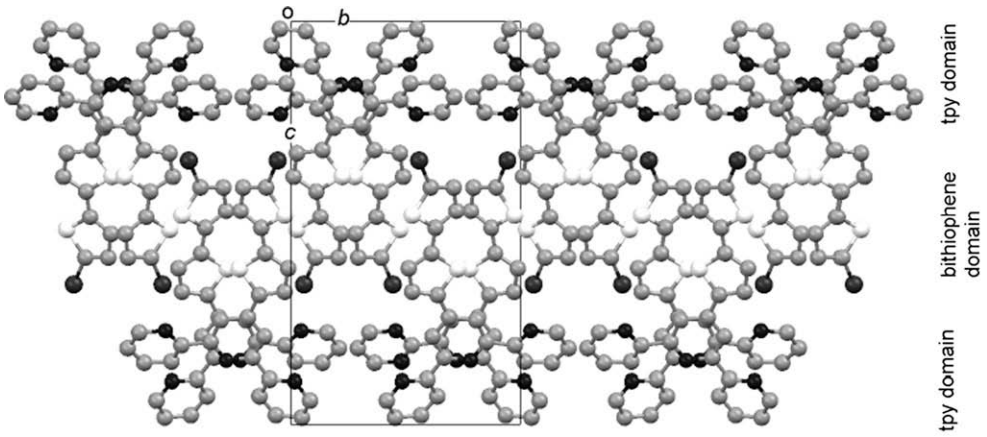

Fig. 2. Packing of molecules of **1** in the solid state, viewed down the crystallographic *a*-axis and showing separated bithiophene and tpy domains.

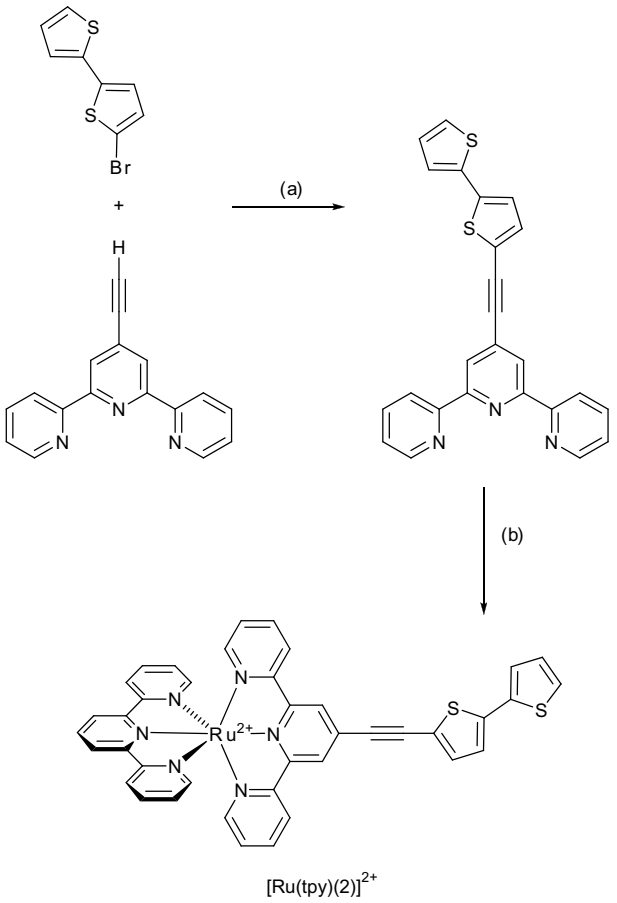
$[Ru(tpy)(\mathbf{1})][PF_6]_2$ was assigned by use of 2D-NMR spectroscopic techniques and by comparison with the spectra for $[Ru(\mathbf{1})_2][PF_6]_2$ and $[Ru(tpy)_2][PF_6]_2$ [45]. The spectrum of the heteroleptic complex is essentially a superimposition of the spectra of the two homoleptic complexes. Residual impurities in the sample of $[Ru(\mathbf{1})_2][PF_6]_2$ precluded us from obtaining a satisfactory elemental analysis, and the ^{13}C NMR spectrum was not well resolved. The ^{13}C NMR spectrum of $[Ru(tpy)(\mathbf{1})][PF_6]_2$ was assigned by use of HMQC and HMBC experiments, and as for the free ligand **1**, the lowest frequency signal (δ 113.2 ppm) was assigned to carbon atom C^{D5}. Attempts to carry out Suzuki coupling reactions between $[Ru(tpy)(\mathbf{1})]^{2+}$ and HC≡C(TIPS) did not yield the desired product within reasonable reaction times (for example, >2 h in a Biotage Initiator 8 microwave reactor at 120 °C). Hence, this strategy towards ruthenium(II)-centred building blocks terminated with conjugated bithienyl-alkynyl units was abandoned in favour of a second approach which yielded more promising results.

Our second strategy (Scheme 3) involved the attachment of a pendant bithiophene unit to directly coupled alkyne and tpy units. The reaction of 4′-ethynyl-2,2′:6′,2″-terpyridine with 5-bromo-2,2′-bithiophene under Sonogashira conditions [46,47] resulted in the formation of ligand **2**. Initial purification of the ligand using a single pass through a chromatography column (see Section 2) gave a product, the EI mass spectrum of which showed a base peak at *m/z* 421 corresponding to $[M]^+$ for **2**. However, in addition, a peak at *m/z* 501 exhibiting an isotope pattern consistent with a monobromo-derivative was also observed. This was assigned to compound **3** (Scheme 4). We had observed that the synthesis of 5-bromo-2,2′-bithiophene also produced 5,5′-dibromo-2,2′-bithiophene [38] as an impurity which was difficult to separate, and its presence was presumably responsible for the formation of **3**. In the ^1H NMR spectrum ($CDCl_3$ solution) of the mixture of **2** and **3**, most signals for the two derivatives overlapped. However, the presence of **3** was most easily seen by the appearance to two singlets for H^{B3}, δ 8.53 ppm for **2**, and δ 8.52 ppm for **3**, and by doublets ($J \approx 7.8$ Hz) for H^{A3} centred at δ 8.60 pm for **2** and δ 8.59 pm for **3**. The thienyl protons for **3** give rise to four doublets (δ 7.21, 7.00, 6.97 and 6.94 ppm, each with $J \approx 3.8$ Hz). Ligand **2** was eventually purified by sequential column chromatography. The ^1H and ^{13}C NMR spectra of **2** were assigned by a combination of COSY, NOESY, HMQC and HMBC techniques. In thiophene ring C, proton H^{C3} was distinguished from H^{C4} by the appearance of a cross peak in the NOESY spectrum between H^{C3} and H^{D3}. A cross peak in the HMBC



Scheme 3. Strategy for the formation of a ruthenium(II) centred building block containing conjugated tpy, bithienyl and alkynyl substituents: (a) $[Pd(PPh_3)_2Cl_2]$, CuI in Et_3N, reflux; (b) $[Ru(tpy)Cl_3]$, *N*-ethylmorpholine in EtOH.

Scheme 4. Structure of **3**; proton labelling is as for **2**.

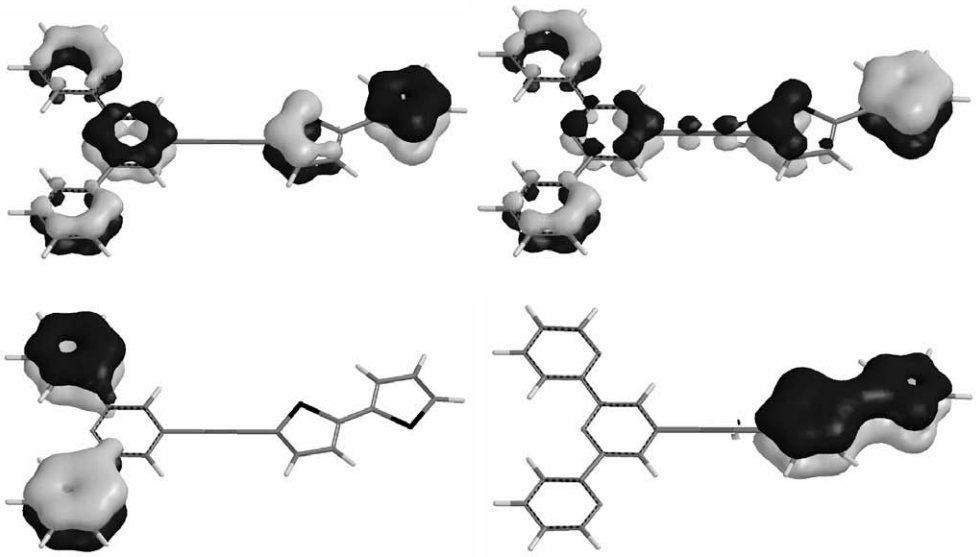

Fig. 3. Representations of the four lowest-lying, occupied π-MOs of ligand **2**.

spectrum to proton H^{B3} allowed the two alkyne carbon signals in the ^{13}C NMR spectrum to be distinguished ($C^{tpyC\equiv C}$at δ 92.6 ppm, and $C^{tpyC\equiv C}$ at δ 87.4 ppm).

In order to gain insight into the degree of conjugation across the tpy, alkynyl and thienyl units, we have run approximate molecular orbital calculations on ligand **2** at the HF 6-31G* level, the structure having been first optimised at the PM3 level [48]. The energy minimised structure indicates that all the heterocyclic rings lie approximately in plane. Fig. 3 illustrates the composition of the lowest-lying π-molecular orbitals, and the appearance of π-character delocalized across the tpy–C≡C–thiophene domains in one of the MOs is consistent with there being electronic communication along the molecule through the π-bonding electrons.

The heteroleptic complex $[Ru(tpy)(\mathbf{2})]^{2+}$ was prepared by treatment of $[Ru(tpy)Cl_3]$ with one equivalent of ligand **2** in the presence of *N*-ethylmorpholine as the reducing agent. The complex was isolated as the hexafluorophosphate salt, and the FAB mass spectrum exhibited peak envelopes at *m/z* 900 and 755, with isotope distributions that matched those predicted for $[M-PF_6]^+$ and $[M-2PF_6]^+$, respectively. The ^1H NMR spectrum of a CD_3CN solution of $[Ru(tpy)(\mathbf{2})][PF_6]_2$ confirmed the presence of two tpy environments. In addition to the use of 2D-techniques, one set of signals could be assigned to the unsubstituted tpy by comparison with spectra of $[Ru(tpy)_2][PF_6]_2$ [45] and $[Ru(tpy)(\mathbf{1})][PF_6]_2$. For ligand **2**, coordination to ruthenium(II) leads to the expected shift to lower frequency for the signal for H^{A6} (from δ 8.70 ppm in **2** in $CDCl_3$, to δ 7.39 ppm for $[Ru(tpy)(\mathbf{2})][PF_6]_2$ in CD_3CN). Sets of thiophene protons belonging to rings C and D were assigned through a COSY experiment, and protons H^{C3} and H^{D3} were distinguished by a cross peak in the NOESY spectrum. Each of the five thiophene proton signals shifts to higher frequency upon coordination of ligand **2**, and largest change being for the signal for H^{C4} ($\Delta\delta$ = +0.32 ppm). The ^{13}C NMR spectrum of the complex was fully assigned using HMQC and HMBC spectra; the signals for the alkyne carbon atoms (δ 92.2 and 91.0 ppm) were only slightly shifted from those of the free ligand (δ 92.6 and 87.4 ppm). Attempts to grow good quality crystals of the complex for X-ray diffraction analysis were unsuccessful.

4. Conclusions

In this exploratory investigation, we have demonstrated that a ligand incorporating π-conjugated tpy, alkynyl and bithienyl units is most conveniently assembled through the reaction of 4′-ethynyl-2,2′:6′,2″-terpyridine with 5-bromo-2,2′-bithiophene under Sonogashira conditions. Use of 5,5′-dibromo-2,2′-bithiophene leads to a bromo-functionalized analogue (**3**) of the first ligand (**2**). Protection–deprotection strategies need to be tailored to the individual alkyne derivatives. A representative ruthenium(II) complex, $[Ru(tpy)(\mathbf{2})][PF_6]_2$, has been prepared and characterized. In subsequent work, we plan to investigate the bromination of this and related complexes, and the synthesis of complexes incorporating ligand **3** in order to produce building blocks suitable for the assembly of larger systems using reactions of coordinated ligands rather than conventional linear ligand synthesis.

Supplementary data

CCDC 693514 contains the supplementary crystallographic data for ligand **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

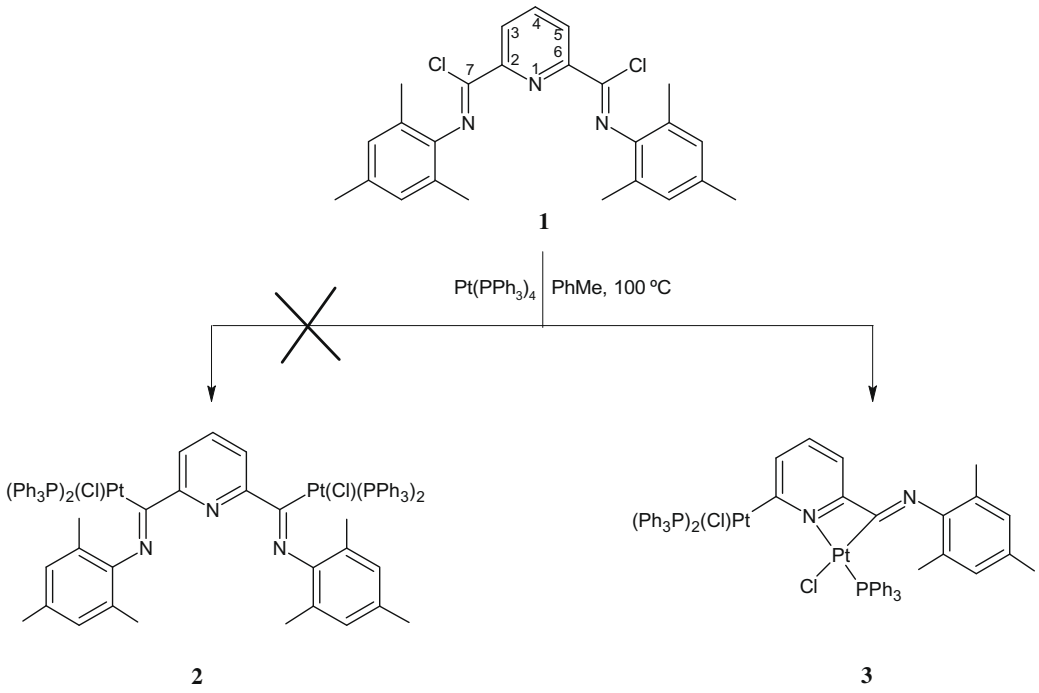

Fig. 1. Reaction of imidoyl chlorides with low valent transition metal complexes.

2.2. Synthesis of the title complex and analytical characterization

2.2.1. Synthesis of ***3***

A mixture of *N*,*N*′-bis(2,4,6-trimethylphenyl)pyridine-2,6-carboxyimidoyl dichloride (88 mg, 0.2 mmol) and [$Pt(PPh_3)_4$] (500 mg, 0.4 mmol) in toluene (20 mL) was stirred under argon for 2 h at 100 °C. After cooling, the solvent was removed *in vacuo* and the waxy residue was suspended in pentane and stirred for 1 h at ambient temperature to form a fine powder. The pentane was discarded and the residue was extracted with pentane to remove the remaining PPh_3. The crude product was then recrystallized from CH_2Cl_2 to precipitate impurities. After filtration, crystallization of the product was induced by slowly diffusing pentane into the CH_2Cl_2 solution to afford the complex as a light brown crystals.

Yield: 0.210 g (63%). *Anal.* Calc. for $C_{69}H_{59}Cl_2N_2P_3Pt_2$: C, 56.37; H, 4.04; N, 1.91. Found: C, 57.06; H, 3.57; N, 2.38%. ^{1}H NMR (δ in ppm, 400 MHz, *J* in Hz, $CDCl_3$): 1.58 (s, 6H, *o*-CH_3-Mes), 2.14 (s, 3H, *p*-CH_3-Mes), 6.6 (s, 2H, *CH*-Mes), 7.43 (m, 18H, *oH*-P*Ph*$_3$), 7.73 (m, *pH*-P*Ph*$_3$, 9H), 7.82 (m, *H*-Py and *mH*-P*Ph*$_3$, 21H) ^{13}C NMR (δ in ppm, 101 MHz, $CDCl_3$): 14.21, 18.74, 127.79, 127.85, 128.37, 128.42, 128.49, 128.54, 129.19, 129.83, 130.73, 131.17, 132.04, 134.12, 134.18, 134.23, 134.75, 134.81, 134.86.

Table 1
Crystal data and details of the structure refinement for the title complex.

Empirical formula	$C_{69}H_{59}N_2P_3Cl_2Pt_2$
Formula weight	1470.17
Crystal system, space group	triclinic, $P\bar{1}$
Unit cell dimensions	
a (Å)	11.9074(5)
b (Å)	12.1059(5)
c (Å)	25.7888(10)
α (°)	96.294(3)
β (°)	93.269(3)
γ (°)	117.350(3)
V (Å^3)	3257.6(3)
Z, D_{calc} (g/cm^3)	2, 1.499
μ (Mo Kα) (mm^{-1})	4.485
F(000)	1444
Crystal size (mm^3)	0.60 × 0.36 × 0.18
Absorption correction	integration
θ Range for data collection (°)	1.60–26.15
Reflections collected/unique (R_{int})	58735/12790 (0.045)
Data/restrain/parameters	10093/0/703
Final *R* indices [$I > 2\sigma(I)$]	$R = 0.0310/R_w = 0.0762$
R indices (all data)	$R = 0.0423/R_w = 0.0791$
Goodness-of-fit (GoF) on F^2	0.993
Highest peak/deepest hole (e Å^{-3})	2.210/−1.231

2.3. Crystal structure determination

Light brown single crystals suitable for data collection were mounted on a glass fibre and the diffraction intensity data were collected at room temperature on a STOE IPDS 2 diffractometer using graphite-monochromatized Mo Kα radiation (λ = 0.71073 Å). A summary of crystallographic data and details of the structure refinement are listed in Table 1. The cell parameters were determined by using X-AREA software [13] on the setting angles of 58735 reflections [1.60° < θ < 26.15°]. Absorption correction was achieved by the integration method via X-RED software [13]. A total of 58735 reflections were collected for $h_{min} = -14$, $h_{max} = 14$, $k_{min} = -14$, $k_{max} = 14$, $l_{min} = -31$, $l_{max} = 31$. The crystal structure was solved by SHELXS-97 [14]. The refinement (on F^2) was carried out by full-matrix least square techniques using the SHELXL-97 program [15]. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were treated as riding atoms, with C–H distances of 0.93 Å for aromatic H atoms and 0.96 Å for methyl H atoms.

Examination of the structure of the title compound with PLATON [16] showed that there was a solvent-accessible void (380 Å^3) in the region around (1/2, 1/2, 1). The reflection (*hkl*) data were modified using the SQUEEZE option of PLATON. Although the empty space seemed large enough to accommodate small solvent molecules, the spaces are too constricted to hold any molecule larger than water. Since no water was present during the synthesis or recrys-

tallization, and since little electron density in the area of the void was found, we conclude that the voids are empty.

3. Results and discussion

Pyridine-2,6-dicarboxyimidoyl dichloride (**1**) is an interesting diimidoyl chloride that has been reported recently. Keeping the above mentioned facts in mind and in continuation of our study with aminocarbene complexes [17], we treated **1** with tetrakis(triphenylphosphine)platinum(0) in toluene at 100 °C for 2 h with the hope of obtaining **2**. The easy cleavage of the C_2–C_7 bond implies that this bond is probably the weakest bond in **1**. However, ^{1}H NMR solution studies on the crystalline light brown solid revealed the presence of a pyridine skeleton with one mesityl substituent. In order to determine the atom connectivity we performed a crystallographic study which confirmed unequivocally the structure depicted as **3**. The mechanistic details of the cleavage reaction are not fully understood.

In summary, pyridine-2,6-dicarboxyimidoyl dichloride (**1**) experiences complex transformations when reacted with $[Pt(PPh_3)_4]$. The mechanistic aspect of this process remains to be elucidated.

An ORTEP3 [18] view of the title complex is shown in Fig. 2. The title compound crystallizes in the triclinic space group $P\bar{1}$.

The asymmetric unit contains one neutral binuclear complex. The coordination environments of the Pt centres are different. The coordination geometry around Pt1 atom is distorted square-planar, formed by the C and N atoms of the platinalactam ring, Cl atom and P atom from the triphenylphosphine group. The N1–Pt1–C1 angle is acute, with a value of 66.68(15)°, but is comparable to those found in similar metallalactam complexes [19–21]. The Cl1–Pt1–P1 angle is more obtuse [97.17(4)°] to accommodate the steric bulk of the PPh_3 ligand. The maximum deviation of the coordination plane formed by the Pt1/Cl1/C1/N1/P1 atoms is −0.050 Å for Pt1. The Pt2 atom has the expected square-planar geometry, involving one Cl atom, the coordinating C atom of the pyridine ring and two P atoms from the triphenylphosphine groups, with no atom deviating by more than 0.077 Å [for Pt2] from the coordination plane defined by Pt2/Cl2/P2/P3/C2. The coordination planes are almost perpendicular to each other [88.12(5)°].

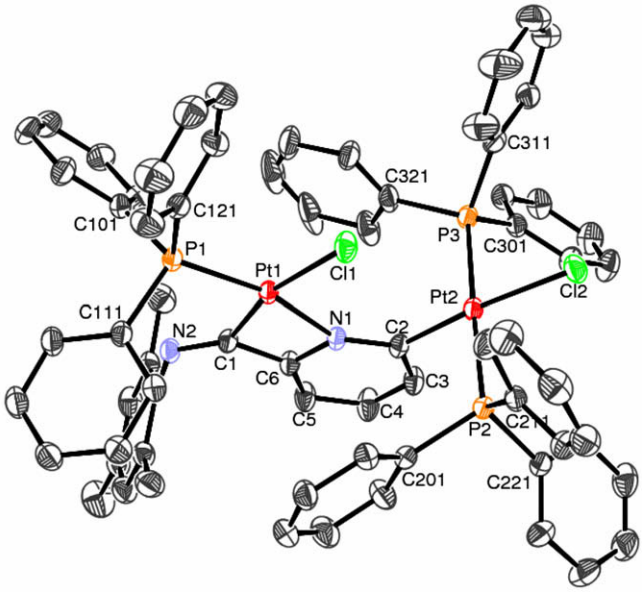

Fig. 2. An ORTEP3 view of the title compound. Displacement ellipsoids are shown at the 20% probability level and hydrogen atoms have been omitted for clarity.

Table 2
Selected geometrical parameters (Å, °) for the title complex.

Pt1–Cl1	2.374(1)	Pt2–Cl2	2.381(1)
Pt1–C1	1.984(5)	Pt2–C2	1.992(5)
Pt1–N1	2.105(3)	N2–C1	1.278(5)
N1–C6	1.367(6)	C1–C6	1.486(6)
N2–C7	1.423(6)	N1–C2	1.324(5)
N1–Pt1–Cl1	98.86(10)	C2–Pt2–P3	89.77(13)
P1–Pt1–Cl1	97.17(4)	C2–Pt2–P2	90.58(13)
N1–Pt1–P1	163.58(10)	P3–Pt2–Cl2	90.10(5)
C1–Pt1–Cl1	165.16(12)	P2–Pt2–Cl2	89.20(4)
C6–C1–Pt1	95.3(3)	P3–Pt2–P2	177.25(4)
C6–N1–Pt1	94.0(2)	C2–Pt2–Cl2	172.62(12)
N2–C1–Pt1	134.0(3)	N1–C2–Pt2	125.0(3)
C2–N1–Pt1	143.0(3)	C3–C2–Pt2	118.3(3)
C1–N2–C7	122.3(4)		

The Pt–P and Pt–N coordination distances are in the expected range and are in accordance with other reported Pt structures [19,22–24]. Selected interatomic distances, bond and torsion angles for the title complex are listed in Table 2.

The mesityl ring is rotated with respect to the platinalactam ring (Pt1/N1/C1/C6) plane by 89.5(3)°. The Pt2-P2 and Pt2-P3 bonds [2.298(1) and 2.297(1) Å] are significantly longer than the Pt1–P1 bond *trans* to the platinalactam N atom [2.216(1) Å]. This difference appears to be a result of a stronger *trans* influence of the P atom.

In the crystal structure, the molecules of the title compound are linked by C–H···N weak hydrogen bonds into centrosymmetric dimmers, as shown in Fig. 3. The C113 atom in the molecule at (x,y,z) acts as a weak hydrogen-bond donor, via atom H113, to the N2 atom at $(1-x,1-y,1-z)$, thus forming a dimer characterized by an $R_2^2(16)$ motif [25] with an inversion centre at (1/2,1/2,1/2) with

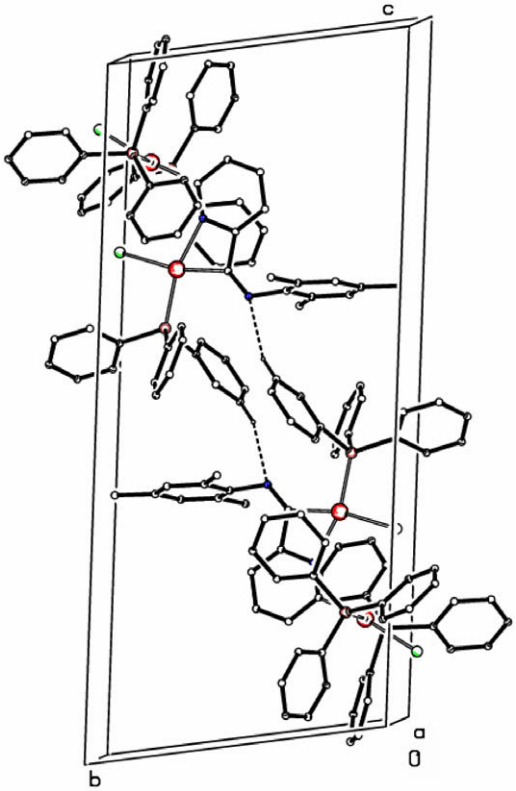

Fig. 3. Part of the crystal structure of the title compound showing the centrosymmetric dimer containing the $R_2^2(16)$ ring. For the sake of clarity, all H atoms except H113 have been omitted.

dimensions H113···N2^a = 2.62 Å, C113···N2^a = 3.505(7) Å and ∠C113–H113···N2^a = 160° (a: $1-x, 1-y, 1-z$).

4. Supplementary data

CCDC 666496 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

These two dipyridyl ligands can coordinate to the metal centers through their pyridyl nitrogen atoms and interact with each other through hydrogen bonds involving the amide groups, which are important for molecular recognition and constructing supramolecular arrays. The syntheses, structures, thermal and luminescent properties of the coordination polymer complexes $[Cu(\mathbf{L1})_2X_2]_\infty$ (X = Cl, **1** and X = Br, **2**), $\{[Cu(\mathbf{L1})_2(DMF)](NO_3)_2\}_\infty$, **3**, $\{[Ag_2(\mathbf{L1})_2](SO_4)\}_\infty$, **4** and $\{[Cu(\mathbf{L2})(DMSO)_2(NO_3)](NO_3)\}_\infty$, **5**, form the subject of this report.

2. Experimental

2.1. General procedures

All manipulations were carried out under dry, oxygen-free nitrogen by using Schlenk techniques, unless otherwise noted. Solvents were dried and deoxygenated by refluxing over the appropriate reagents before use. Diethyl ether was purified by distillation from sodium/benzophenone, methanol from Mg/I_2. The UV–Vis spectra were recorded on a Shimadzu UV-2450 spectrophotometer. ^1H NMR spectra in DMSO-d_6 were measured on a Bruker Avance 300 MHz spectrometer. IR spectra (KBr disk) were obtained from a Jasco FT/IR-460 plus spectrometer. Elemental analyses were obtained from a PE 2400 series II CHNS/O analyzer or a HERAEUS VaruoEL analyzer.

2.2. Materials

The reagents $CuBr_2$ and $Cu(NO_3)_2 \cdot 3H_2O$ were purchased from Strem Chemical Co. *N*,*N*-Dimethylformamidine (DMF), dimethyl sulfoxide (DMSO), 4,4′-diaminodiphenylmethane, triphenyl phosphite, and pyridine were purchased from Aldrich Chemical Co. $CuCl_2 \cdot H_2O$, Ag_2SO_4, nicotinic acid and isonicotinic acid were purchased from Merck Co. All the reagents were used as received.

2.3. Preparation of *N*,*N*′-(methylenedi-p-phenylene)bis(pyridine-4-carboxamide) (*L1*)

Isonicotinic acid (2.46 g, 20.00 mmol) was placed in a flask containing 20 mL of pyridine, followed by addition of 4,4′-diaminodiphenylmethane (1.98 g, 10.00 mmol) and triphenyl phosphite (6.83 g, 22.00 mmol) in 30 mL of pyridine. This mixture was refluxed for 6 h. After cooling to room temperature, the residue was added to deionized water (800 mL) with stirring. The light yellow solid was collected by filtration, washed with deionized water and then dried under vacuum. Yield: 3.37 g (83%). *Anal.* Calc. for $C_{25}H_{20}N_4O_2$ (MW = 408.46): C, 73.51; H, 4.94; N, 13.72. Found: C, 73.11; H, 5.18; N, 13.75%. IR (cm^{-1}): 3359(w), 3039(br), 1654(s), 1594(m), 1523(s), 1486(w), 1405(s), 1322(s), 1259(w), 1205(m), 1162(m), 1014(m), 944(br), 825(m), 759(w), 678(w). ^1H NMR (ppm): 10.44 (s, N*H*, 2H), 8.75 (d, aromatic, 4H), 7.82 (d, aromatic, 4H), 7.66 (d, aromatic, 4H), 7.20 (d, aromatic, 4H), 3.88 (s, CH_2, 2H).

2.4. Preparation of *N*,*N*′-(methylenedi-p-phenylene)bis(pyridine-3-carboxamide) (*L2*)

Prepared as described for **L1** except nicotinic acid (2.46 g, 20.00 mmol) was used. Yield: 3.45 g (84%). *Anal.* Calc. for $C_{25}H_{20}N_4O_2$ (MW = 408.46): C, 73.51; H, 4.94; N, 13.72. Found: C, 73.22; H, 4.97; N, 13.81%. IR (cm^{-1}): 3345(w), 3041(br), 1662(s), 1596(m), 1529(s), 1409(s), 1317(s), 1261(w), 1195(m), 1110(m), 1024(m), 823(s), 771(w), 700(w), 647(w). ^1H NMR (ppm): 10.38 (s, N*H*, 2H), 9.06 (d, aromatic, 2H), 8.72 (d, aromatic, 2H), 8.25 (t, aromatic, 2H), 7.66 (d, aromatic, 4H), 7.54 (t, aromatic, 2H), 7.20 (d, aromatic, 4H), 3.34 (s, CH_2, 2H).

2.5. Preparation of $[Cu(\mathbf{L1})_2Cl_2]_\infty$, *1*

To a solution of **L1** (0.80 g, 2.00 mmol) in 20 mL of DMF was added a solution of $CuCl_2 \cdot H_2O$ (0.17 g, 1.00 mmol) in 30 mL of water. The mixture was then stirred at room temperature for 20 h to give a light blue solution with some blue precipitate. The solid was filtered, washed with diethyl ether and then dried under vacuum. Yield: 0.29 g (30% based on Cu). *Anal.* Calc. for $C_{50}H_{40}Cl_2CuN_8O_4$ (MW = 951.34), C, 63.12; H, 4.24; N, 11.78. Found: C, 63.05; H, 4.01; N, 12.08%. IR (cm^{-1}): 3197(br), 3152(br), 1677(m), 1652(s), 1600(s), 1523(br), 1497(s), 1413(s), 1321(s), 1268(w), 1106(m), 1062(s), 1024(m), 904(w), 850(s), 808(w), 765(m), 684(s). Blue crystals suitable for X-ray diffraction were grown by layering H_2O solution of $CuCl_2 \cdot H_2O$ with **L1** in DMF for several weeks.

2.6. Preparation of $[Cu(\mathbf{L1})_2Br_2]_\infty$, *2*

Prepared as described for **1** except $CuBr_2$ (0.22 g, 1.00 mmol) was used. Yield: 0.35 g (34% based on Cu). *Anal.* Calc. for $C_{50}H_{40}Br_2CuN_8O_4$ (MW = 1040.26), C, 57.73; H, 3.88; N, 10.77. Found: C, 57.94; H, 4.07; N, 10.68%. IR (cm^{-1}): 3152(br), 1671(m), 1654(s), 1602(s), 1536(br), 1503(s), 1413(s), 1322(s), 1267(w), 1105(m), 1062(s), 1025(m), 906(w), 854(s), 767(m), 684(s). Crystals suitable for X-ray diffraction were grown by layering H_2O solution of $CuBr_2$ with **L1** in DMF for several weeks.

2.7. Preparation of $\{[Cu(\mathbf{L1})_2(DMF)](NO_3)_2\}_\infty$, *3*

Prepared as described for **1** except $Cu(NO_3)_2 \cdot 3H_2O$ (0.24 g, 1.00 mmol) was used. Yield: 0.42 g (39% based on Cu). *Anal.* Calc. for $C_{53}H_{47}CuN_{11}O_{11}$ (MW = 1077.56), C, 59.08; H, 4.40; N, 14.30. Found: C, 58.97; H, 4.07; N, 14.27. IR (cm^{-1}): 3188(br), 3152(br), 1654(m), 1604(s), 1542(br), 1503(s), 1411(s), 1384(s), 1324(m), 1265(w), 1114(m), 1058(s), 1018(m), 948(w), 825(s), 767(m), 684(s). Crystals suitable for X-ray diffraction were grown by layering H_2O solution of $Cu(NO_3)_2 \cdot 3H_2O$ with **L1** in DMF for several weeks.

2.8. Preparation of $\{[Ag_2(\mathbf{L1})_2](SO_4)\}_\infty$, *4*

Prepared as described for **1** except Ag_2SO_4 (0.31 g, 1.00 mmol) was used. Yield: 0.47 g (42% based on Ag). *Anal.* Calc. for $C_{50}H_{40}Ag_2N_8O_8S$ (MW = 1128.70), C, 53.21; H, 3.57; N, 9.93. Found: C, 53.14; H, 3.87; N, 9.63. IR (cm^{-1}): 3426(w), 3148(br), 1656(s), 1600(s), 1536(br), 1497(s), 1328(s), 1249(w), 1213(m), 1122(m), 931(s), 823(s), 759(m), 678(s), 613(w). Crystals suitable for X-ray diffraction were grown by layering H_2O solution of Ag_2SO_4 with **L1** in DMF for several weeks.

2.9. Preparation of $\{[Cu(\mathbf{L2})(DMSO)_2(NO_3)](NO_3)\}_\infty$, *5*

To a solution of **L2** (0.80 g, 2.00 mmol) in 20 mL of DMSO was added a solution of $Cu(NO_3)_2 \cdot 3H_2O$ (0.48 g, 2.00 mmol) in 30 mL of methanol. The mixture was then stirred at room temperature for 12 h, resulting in a blue solution with some blue precipitate. The solid was filtered off and layered with diethyl ether to give blue plate crystals. The crystal was collected, washed with diethyl ether and then dried under vacuum. Yield: 0.48 g (32% based on Cu). *Anal.* Calc. for $C_{29}H_{32}CuN_6O_{10}S_2$ (MW = 752.27), C, 46.30; H, 4.29; N, 11.17. Found: C, 45.97; H, 4.39; N, 11.04%. IR (cm^{-1}): 3372(w), 3152(br), 2395(w), 1913(w), 1762(s), 1656(s), 1604(s), 1532(m), 1485(s), 1383(s), 1324(s), 1199(w), 1117(m), 1059(m), 1019(s), 950(s), 921(m), 899(s), 860(w), 824(m), 777(m), 733(s), 654(w), 512(m), 446(s), 418(m).

3. X-ray crystallography

The diffraction data for complexes **1, 2** and **4** were collected on a Bruker AXS P4 diffractometer while those of **3** and **5** were collected on a Bruker AXS SMART-1000 diffractometer and a Bruker-Nonius APEXII CCD diffractometer at 22 °C, respectively, which were equipped with a graphite-monochromated Mo Kα (λ_α = 71073 Å) radiation. Data reduction was carried by standard methods with use of well-established computational procedures [9]. A blue crystal of **1** was mounted on the top of a glass fiber with epoxy cement. The hemisphere data collection method was used to scan the data points at $4.26° < \theta < 50.00°$. The structure factors were obtained after Lorentz and polarization correction. The positions of some of the heavier atoms, including the copper atom, were located by the direct methods. The remaining atoms were found in a series of alternating difference Fourier maps and least-square refinements [10].

For the structures of complexes **1–5,** all the hydrogen atoms were added by using the HADD program in SHELXTL 5.10 [10]. Disordered solvent molecules, presumably to be DMF and/or water molecules, were present in complexes **1–5**, and PLATON/SQUEEZE tool was applied [11]. Large solvent void volumes were observed for these structures. The relative percentages per unit cell are 40.5% for **1** (2662.1 out of 6579.6 Å^3), 45.4% for **2** (3085.5 out of 6800.0 Å^3), 21.7% for **3** (672.2 out of 3092.9 Å^3), 27.2% for **4** (805.2 out of 2960.7 Å^3) and 3.9% for **5** (134.5 out of 3430.5 Å^3), respectively. Where relevant, data cited in are given without disordered solvent contribution. The bonded DMSO molecule of **5** is disordered such that for each sulfur and methyl carbon atom, two positions each with occupancy of 0.5 were located. The crystallographic procedures for **2–5** were similar to those for **1**. Basic information pertaining to crystal parameters and structure refinement is summarized in Table 1. Selected bond distances and angles for complexes **1–5** are listed in Table S1 as Supplementary data.

4. Results and discussion

4.1. Syntheses and spectroscopic studies

The angular dipyridyl ligands *N,N′*-(methylenedi-*p*-phenylene)bis(pyridine-4-carboxamide), **L1**, and *N,N′*-(methylenedi-*p*-phenylene)bis(pyridine-3-carboxamide), **L2**, were prepared by the reactions of isonicotinic acid and nicotinic acid, respectively, with 4,4′-diaminodiphenylmethane and triphenyl phosphite in refluxing pyridine. The reactions of **L1** with $CuCl_2 \cdot H_2O$, $CuBr_2$, $Cu(NO_3)_2 \cdot 3H_2O$, and Ag_2SO_4 in DMF/H_2O afforded the complexes $[Cu(\mathbf{L1})_2X_2]_\infty$ (X = Cl, **1** and X = Br, **2**) and $\{[Cu(DMF)(\mathbf{L1})_2](NO_3)_2\}_\infty$, **3**, and $\{[Ag_2(\mathbf{L1})_2](SO_4)\}_\infty$, **4**. Complex $\{[Cu(\mathbf{L2})(DMSO)_2(NO_3)](NO_3)\}_\infty$, **5**, was prepared by reaction of $Cu(NO_3)_2 \cdot 3H_2O$ with **L2** in methanol/DMSO at room temperature. Complexes **1–5** are very stable in air at ambient temperature and almost insoluble in common solvents such as water, ethanol, methanol, THF, acetonitrile, chloroform and acetone. Table 2 lists the emission data for **L1**, **L2** and complexes **1–5**. There is no significant energy shift observed upon coordination of the ligands to the metal atoms and hence the emission bands may be tentatively assigned as intraligand (IL) $\pi \rightarrow \pi^*$ transitions.

4.2. Structures of *1* and *2*

The structures of $[Cu(\mathbf{L1})_2Cl_2]_\infty$, **1** and $[Cu(\mathbf{L1})_2Br_2]_\infty$, **2**, were solved in the space group *C*2/*c*. Fig. 1a shows a representative asymmetric unit for complexes **1** and **2**, which contains a half copper(II) atom, one complete **L1** ligand and one coordinated halide atom. Fig. 1b depicts the molecular structures for complexes **1** and **2**, showing the arrangements about the Cu(II) metal centers and Fig. 1c presents a space-filling model showing the rhombohedral molecular squares for **1** and **2**. The coordination environment of the copper(II) atoms are elongated tetragonal bipyramidal and the tetragonal planes are built up by four pyridyl nitrogen atoms [Cu–N = 2.036(3) and 2.036(4) Å for **1**; 2.022(5) and 2.042(5) Å for **2**]. The *cis* N–Cu–N bond angles show some deviations from perpendicularity [N–Cu–N = 88.0(2), 90.31(13) and 91.40(19)° for **1**; 87.7(3), 90.3(2) and 91.7(3)° for **2**]. The adjacent Cu atoms are linked to each other through the pyridyl nitrogen atoms to form double-stranded chains involving 44-membered rings with a dimension of 16.95 × 19.13 Å^2 for **1** and 17.03 × 19.06 Å^2 for **2**, respectively. The cavity sizes were defined by measuring the Cu–Cu distances and the distances between two methylene carbon atoms. The halogen atoms, occupying the axial positions of the square planes, interacts with the Cu metal atoms through weak Cu–X [Cu–Cl = 2.840(3) Å and Cl–Cu–Cl = 175.36(4)° for **1**; Cu–Br = 2.998(4) Å and Br–Cu–Br = 176.71(3)° for **2**] interactions. Hathaway and Hodgson have investigated the dependence of *T* ($T = R_S/R_L$, tetragonality) on the parameters R_S and R_L for some copper complexes, where R_S is the average value of the four interatomic distances in the equatorial plane and R_L is the average value of central atom–donar atom distance at the fifth and sixth

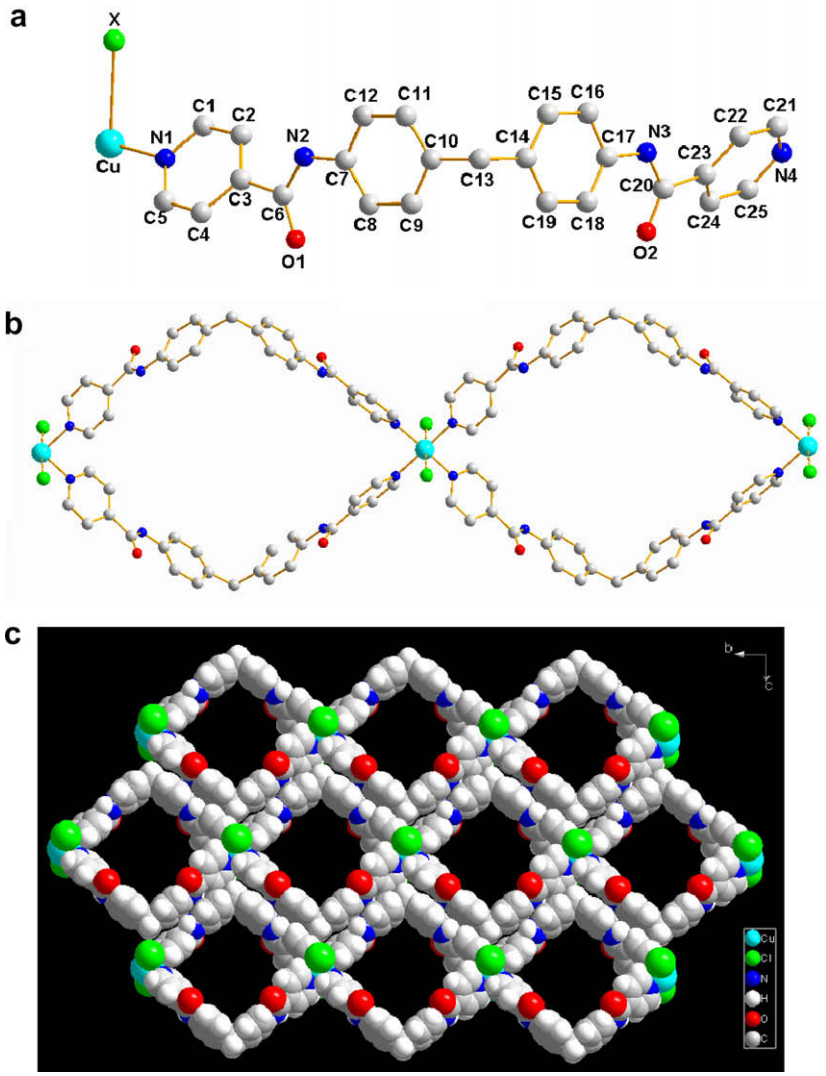

Fig. 1. (a) A representative molecular structure showing the asymmetric unit of complexes **1** (X = Cl) and **2** (X = Br). (b) A representative molecular structure showing the coordination environments of **1** (X = Cl) and **2** (X = Br). Hydrogen atoms are omitted for clarity. (c) The space-filling model showing the rhombohedral molecular squares for **1** and **2**, looking down the *a*-axis.

coordination sites for coordination number 4 + 2 (tetragonally distorted octahedron) [12]. The values of the *T* parameter show the degree of tetragonal distortion about the copper(II) centers. The calculated *T* values for **1** and **2** are 0.715 and 0.678, respectively, which indicate that the bromo complex **2** distorted more from octahedron.

4.3. Structure of **3**

The structure of $\{[Cu(\mathbf{L1})_2(DMF)](NO_3)_2\}_\infty$, **3** was solved in the space group $P\bar{1}$. Fig. 2a shows a representative asymmetric unit for complex **3**, which contains one copper(II) atom, two complete **L1** ligands, one bonded DMF ligand and two uncoordinated nitrate anions. The copper metal center adopts a slightly distorted square pyramidal coordination geometry with the bond angles only deviates slightly from 90° or 180°. The Cu atom is bonded to four pyridyl nitrogen atoms [Cu–N = 2.014(2)–2.042(2) Å] from four different **L1** ligands in the basal plane. The Cu atom is also bonded to one DMF ligand [Cu–O(5) = 2.277(2) Å] in the axial position to complete the distorted square pyramidal coordination geometry. The *cis* N–Cu–N bond angles show significant deviation from perpendicularity [N–Cu–N = 87.35(9), 90.27(9), 90.41(9) and 91.04(9)°]. The Cu atoms are linked to each other through the pyridyl nitrogen atoms to form 1-D double-stranded polymeric chains involving 44-membered rings with a dimension of 16.66×19.94 Å^2, Fig. 2b. The space-filling model is shown in Fig. 2c.

4.4. Structure of **4**

The structure of $\{[Ag(\mathbf{L1})_2](SO_4)\}_\infty$, **4**, was solved in the space group $P\bar{1}$. Fig. 3a shows the asymmetric unit of **4**, which contains two silver(I) atoms, two complete **L1** ligands and an uncoordinated sulfate anion. Fig. 3b shows its infinite one-dimensional chains. Both the silver(I) metal centers, Ag(1) and Ag(2), adopt the bent coordination geometry [N(1)–Ag(1)–N(8) = 161.45(16) and N(4)–Ag(2)–N(5A) = 161.75 (17)°]. The Ag(I) atoms are bonded to two pyridyl nitrogen atoms [Ag(1)–N(1) = 2.173(4) Å, Ag(1)–N(8) = 2.173(4) Å, Ag(2)–N(4) = 2.150(4) Å and Ag(2)–N(5A) = 2.142(4) Å] from two different **L1** ligands. The uncoordinated sulfate ions

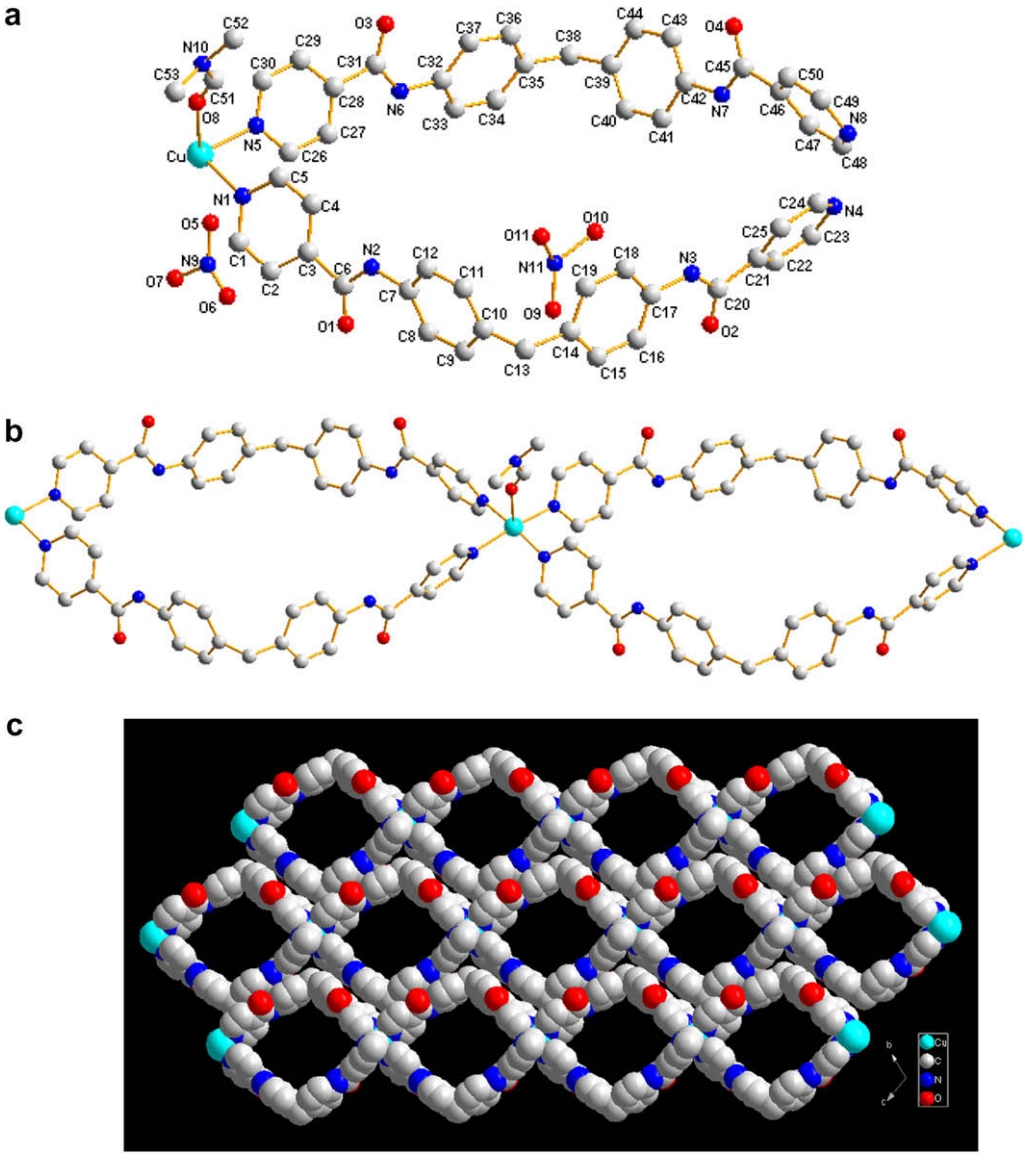

Fig. 2. (a) A molecular structure showing the asymmetric unit of complex **3**. (b) A molecular structure showing the coordination environment of **3**. Hydrogen atoms are omitted for clarity. (c) The space-filling model showing the rhombohedral molecular squares for **3**, looking down the *a*-axis.

interact with the Ag(I) centers in the zigzag chains through the Ag–O interactions [Ag(1)–O(5) = 2.658(4), Ag(1)–O(7) = 2.668(4), Ag(2)–O(6) = 2.757(5) and Ag(2)–O(8) = 2.724(4) Å] forming the 1-D ladder like chain structure, as shown in Fig. 3c. Fig. 3d shows a space-filling model. The Ag–O distances are significantly shorter than their van der Waals contact of 3.24 Å (van der Waals radius for Ag = 1.72 and O = 1.52 Å). It is noted that the typical range of Ag–O bonds is 2.3–2.6 Å [13]. The Ag–Ag distances in the zigzag polymeric chains separated by the bridging **L1** are 19.487(3) and 20.496(4) , while the distance between the zigzag chains separated by the bridging SO_4^{2-} anion is 6.535(2) . No significant hydrogen bond was observed.

4.5. Structure of *5*

The complex $\{[Cu(\mathbf{L2})(DMSO)_2(NO_3)](NO_3)\}_\infty$, **5**, was solved in the space group *Pbcm* and each asymmetric unit contains one copper(II) atom, one **L2** ligand, two DMSO molecules and two NO_3^- anions. Fig. 4a shows the coordination geometry about the Cu metal center. The copper metal center adopts slightly distorted square pyramidal coordination geometry with the bond angles only deviates slightly from 90 or 180°. The Cu atom is bonded to two *trans* pyridyl nitrogen atoms [Cu–N(1) = 2.018(4) Å] and two *trans* oxygen atoms, which are one of the monodentate nitrate groups [Cu–O(4) = 2.029(9) Å] and one of the DMSO ligands [Cu–O(3) = 1.810(5) Å] in the basal plane. The Cu atom is also bonded to one DMSO ligand [Cu–O(2) = 2.260(6) Å] in the axial position to complete the distorted square pyramidal coordination geometry. Along the *c*-axis, adjacent Cu atoms are bridging through the pyridyl nitrogen atoms of **L2** ligands to form a 1-D sinusoidal chain, as shown in Fig. 4b, where the sinusoidal waves propagate along the axis formed by linking the methylene carbon atoms. The Cu–Cu distance in the polymeric chain separated by the bridging **L2** ligand is 18.529(2).

4.6. Conformations of the ligands

The structures of **1–5** provide an opportunity to investigate the conformation of **L1** and **L2** ligands. Based on the relative orientation of the C=O (or N–H) groups, each conformation can adopt a *cis* or *trans* arrangement as shown in Fig. 5. Thus, the ligand **L1** can possibly show two different conformations in the solid state. In addition to the *cis* and *trans* conformations, the *syn* and *anti* designations, which indicate the relative positions of the pyridyl nitrogen atoms can also be applied to the **L2** ligands. Thus, the ligand **L2** can possibly show four different conformations in the solid state as shown in Fig. 5. Based on this descriptor, the conformations of the ligand **L1** in complexes **1, 2** and **3** are assigned as *cis* while that in complex **4** is *trans*, and the ligand **L2** in complex **5** is *trans-anti*.

4.7. Structural comparisons

Complexes **1**–**5** make interesting comparisons with the metal complexes of *N*,*N*′-bis(4-pyridylcarbonyl)-4,4′-diaminodiphenyl ether (**L**′) [14]. Table S2 inSupplementary data lists some important parameters of the rhomboidal area formed by two metal atoms and two methylene carbon atoms of **L1** ligands or two oxygen atoms of **L**′ ligands, where the X denotes the central carbon and oxygen atoms of **L1** and **L**′, respectively. The area of the rhomboidal area was calculated by using the long diagonal length (d_{M-M}) and the

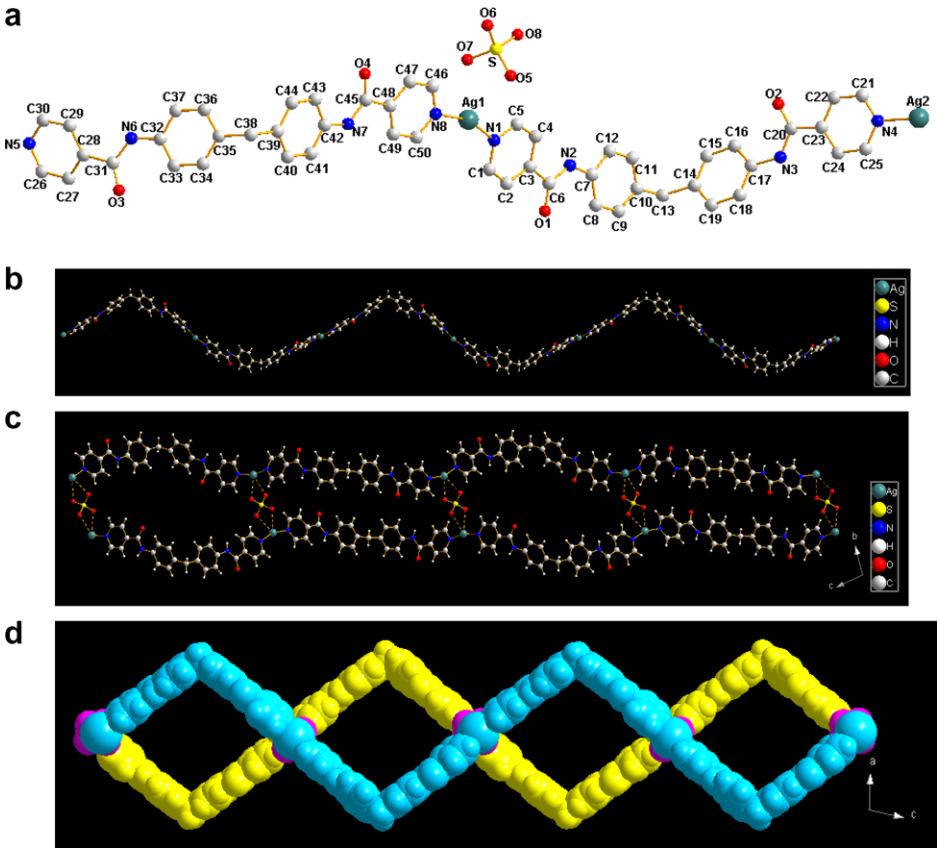

Fig. 3. (a) A molecular structure showing the asymmetric unit of complexes **4**. (b) A molecular structure showing the coordination environment of **4**. (c) The 1-D chains are linked by the SO_4^{2-} anions through Ag–O interactions to form 1-D ladder-like chain like structure. (d) The space-filling model showing the rhombohedral molecular squares for **4**, looking down the *a*-axis.

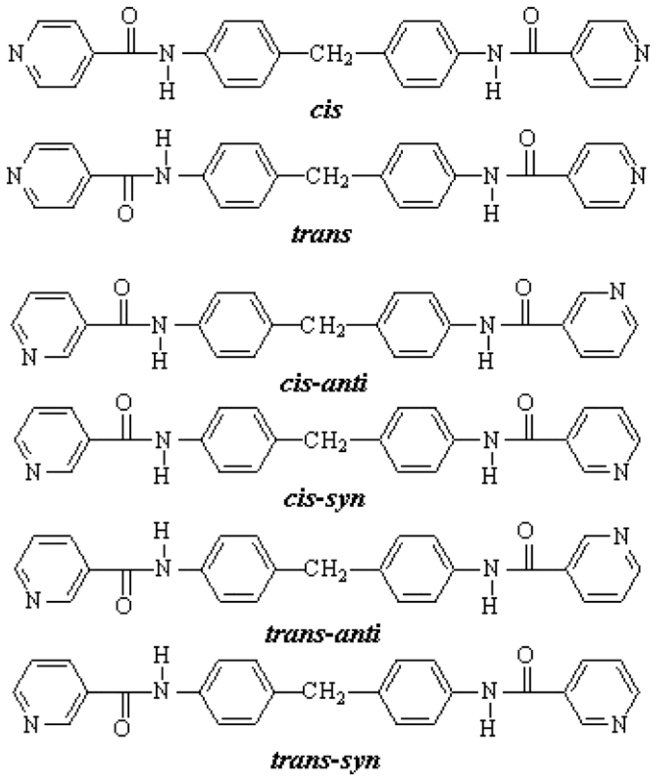

Fig. 5. Possible conformations for **L1** and **L2** ligands.

short diagonal length (d_{X-X}). The result shows that complexes **1**–**3** have the larger sizes than those of the complexes prepared from the **L′** ligands, which may be ascribed to the smaller C–X–C and larger N–Cu–N angles in complexes **1**–**3**.

4.8. Thermal properties

Thermal gravimetric analyses (TGA) were carried out to examine the thermal stability of **1**–**5**. The samples were heated up in air at 1 atm pressure with the heating rate of 10 °C min^{-1}. A weight loss of 42.8% and 39.3% occurred in the temperature range 245–425 °C for **1** and 250–420 °C for **2**, respectively, due to the removal of the first **L1** ligand per formula unit (calcd. 42.9% and 39.1%). Another weight loss occurred in the temperature range 425–590 °C for **1** and 420–587 °C for **2**, corresponding to the removal of the second **L1** ligand and decomposition of the structure. Finally, the residual product weights of 8.7% for **1** and 8.1% for **2** were found in the temperature range 590–700 and 587–700 °C, corresponding to the formation of CuO (calcd. 8.4% and 7.6%), respectively. TGA for **3** showed the loss of two NO_3^- anions and DMF groups in the range 120–232 °C (calcd. 18.4%, obs. 18.1%), followed by the loss of two **L1** ligands above 232–584 °C. The residual product weight of 7.6% was finally found in the temperature range 584–700 °C, corresponding to the formation of CuO (calcd. 7.4%). For complexes **1**–**3**, the results show that the nature of the anions has no significant effect on the decomposition of the double-stranded chains.

The TGA curve shows that **4** is stable up to 300 °C. A total weight loss of 8.7% occurred in the temperature range 300–330 °C, presumably due to the removal of the SO_4^{2-} anions per

formula unit (calcd. 8.5%). A weight loss of 71.9% occurred in the temperature range 330–550 °C, corresponding to the removal of **L1** ligands (calcd. 72.4%) and decomposition of the chain structure. TGA for **5** showed the first loss took place between 123 and 185 °C and was associated with the loss of the coordinated NO_3^- anions and DMSO molecules (calcd. 18.6%, obs. 18.8%). The second loss took place between 185 and 250 °C, corresponding to the loss of the bounded NO_3^- anions and another DMSO groups. A loss occurred in the temperature range 250–485 °C, corresponding to the removal of the **L2** ligands and decomposition of the chains. The residual product weight of 11.0% was found in the temperature range 485–700 °C, corresponding to the formation of CuO (calcd. 10.5%). The TGA results show that complexes **1–5**, which contain the ligands with multi-phenyl and pyridyl groups, are thermal stable and the **L1** or **L2** ligands decomposed at temperatures above 230 °C.

5. Conclusion

In this study, the coordination chemistry of two new angular dipyridyl ligands *N,N′*-(methylenedi-*p*-phenylene)bis(pyridine-4-carboxamide), **L1**, and *N,N′*-(methylenedi-*p*-phenylene)bis(pyridine-3-carboxamide), **L2**, with Cu(II) and Ag(I) salts was investigated. Complexes **1–3** show 1-D double-stranded polymeric chains involving M_2L_2 rhombic molecular squares with the dimensions of 16.95×19.13 for **1**, 17.03×19.06 for **2** and 16.66×19.94 Å^2 for **3**, which are larger than those of the complexes containing the *N,N′*-bis(4-pyridylcarbonyl)-4,4′-diaminodiphenyl ether (**L′**) ligand. Complex **4** forms infinite 1-D zigzag polymeric chains, which are interlinked through a series of Ag–O interactions to form wavy 1-D ladder like chains, while complex **5** shows 1-D bent sinusoidal chains. Table S3 in Supplementary data summarizes some important parameters of these complexes.

The conformations of the **L1** and **L2** ligands are susceptible to the change in the structural type. The **L1** ligands in complexes **1, 2** and **3** adopt the *cis* conformation to present 1-D double-stranded polymeric chains with rhombic molecular squares and those in **4** adopts the adopts *trans* conformation to show 1-D zigzag polymeric chains, while the **L2** ligands in complex **5** adopt the *trans-anti* conformation to give the 1-D sinusoidal chains. Although the **L1** ligands in complexes **1–3** adopt the same *cis* conformation, significant differences in the dihedral angles between the rings were observed, presumably due to the supramolecular interactions. Thus, the *cis* conformation is necessary for coordination polymers containing the angular dipyridyl ligand bearing amide spacer to form structures with rhombic molecular squares, while the *trans* conformation produces the open 1-D chains. Obviously, the **L1** and **L2** ligands are sufficiently flexible to adjust to the stereochemical requirements for the formation of the complexes **1–5**, which adopt the conformation that maximizes the intra- and intermolecular forces.

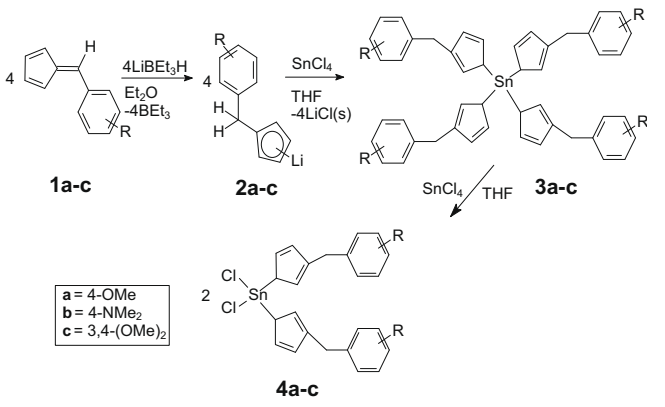
tetrakis cyclopentadienyl tin(IV) intermediate is produced, which undergoes additional transmetallation to isolate the desired organotin dichloride [19]. The reaction scheme can be viewed in Scheme 1.

Within this paper we present the synthesis, preliminary cytotoxicity and antibacterial studies of a series of three organotin dichloride derivatives, modelled on Titanocene **Y**.

2. Experimental

2.1. General conditions

Manipulations of air and moisture sensitive compounds were performed under an inert atmosphere of nitrogen or argon using standard Schlenk techniques. Tin tetrachloride ($SnCl_4$ 1.0 M solution in heptane) and Super Hydride ($LiBEt_3H$, 1.0 M solution in THF) were obtained commercially from Sigma–Aldrich. All solvents were dried and distilled according to standard methods. ^1H and ^{13}C NMR spectra were measured on a Varian 500 MHz spectrometer with C_6D_6 as solvent and TMS as internal standard. ^{119}Sn NMR spectra were measured on a Varian 500 MHz spectrometer with C_6D_6 as solvent and t-But_2SnCl_2 as internal standard. IR spectra were recorded on a Perkin Elmer Paragon 1000 FT-IR Spectrometer employing NaCl discs. UV/Vis spectra were recorded on a Unicam UV4 Spectrometer. Electron spray mass spectrometry (MS) was performed on a quadrupole tandem mass spectrometer (Quattro Micro, Micromass/Water's Corp., USA), using solutions made up in 50% dichloromethane and 50% methanol. MS spectra were obtained in the ES- (electron spray negative ionisation) mode for compounds **4a** and **4b**. Compound **4c** was obtained in ES+ (electron spray positive) mode. X-ray diffraction data for compound **5** was collected using a Bruker SMART APEX CCD area detector diffractometer. A full sphere of reciprocal space was scanned by phi–omega scans. Pseudo-empirical absorption correction based on redundant reflections was performed by the program SADABS [20]. The structures were solved by direct methods using SHELXS-97 [21] and refined by full matrix least-squares on F^2 for all data using SHELXL-97 [21]. In **5**, hydrogen atoms were added at calculated positions and refined using a riding model. Their isotropic temperature factors were fixed to 1.2 times (1.5 times for methyl groups) the equivalent isotropic displacement parameters of its parent atom. Anisotropic thermal displacement parameters were used for all non-hydrogen atoms. The chloroform molecule could not be located in the unit cell. Platon SQUEEZE [22] was used to compensate for the spread electron density. The solvent is included in the overall formula, $F(000)$, absorption coefficient and density. Further details about the data collection are listed in Table 2, as well as reliability factors. Suitable crystals of **5** were formed from the slow evaporation of a saturated trichloromethane solution.



Scheme 1. General reaction scheme for the synthesis of benzyl-substituted organotin dichloride derivatives.

2.2. Synthesis

6-(*p*-Methoxyphenyl) fulvene **1a**, 6-(*p*-*N*,*N*-dimethylaminophenyl) fulvene **1b** and 6-(3,4-dimethoxyphenyl) fulvene **1c** were synthesised according to already published procedures [23–24].

2.2.1. Synthesis of bis-[(p-methoxybenzyl)cyclopentadienyl] tin(IV) dichloride, $[\eta^1$-C_5H_4–CH_2–C_6H_4–O–$CH_3]_2SnCl_2$ (**4a**)

15.0 ml (15.0 mmol) of 1 M solution of Super Hydride ($LiBEt_3H$) in THF was concentrated by removal of the solvent by heating it to 60 °C under reduced pressure of 10^{-2} mbar for forty minutes and then to 90 °C for 20 min in a Schlenk flask. The concentrated Super Hydride was dissolved in 30 ml of dry diethyl ether to give a cloudy white suspension. 2.40 g (13.0 mmol) of the red solid **1a** was added to a Schlenk flask and was dissolved in 90 ml dry diethyl ether to give a red solution. The red fulvene solution was transferred to the Super Hydride solution *via cannula*. The solution was left to stir for 8 h to give a white precipitate of the lithium cyclopentadienide intermediate and the solution had changed colour from orange/red to colourless with a white precipitate formed. The precipitate was filtered on to a frit and was washed with 20 ml of diethyl ether. The white precipitate was dried briefly under reduced pressure and was transferred to a Schlenk flask under nitrogen. 2.06 g (10.7 mmol, 82.2% yield) of the lithiated cyclopentadienide intermediate **2a** was obtained. 2.68 ml (2.68 mmol) of a 1 M solution of tin tetrachloride in heptane was dissolved in 30 ml of dry toluene in a Schlenk flask. The lithium cyclopentadienide intermediate was dissolved in 60 ml of dry toluene to give a colourless solution. The solution of tin tetrachloride was added to the lithium cyclopentadienide intermediate solution slowly at 0 °C *via cannula* to give a yellow solution. The tin solution was allowed to stir for 16 h at room temperature followed by the removal of the solvent under reduced pressure which yielded a yellow solid, tetrakis-[η^1-*(p-methoxybenzyl)cyclopentadienyl] tin(IV)* intermediate **3a**. The yellow solid was dissolved in 30 ml of dry toluene and 2.68 ml (2.68 mmol) of a 1 M solution of tin tetrachloride in heptane was added slowly at 0 °C. The solution was stirred at room temperature for 2 h after which it was allowed to settle, followed by filtration in an inert atmosphere of nitrogen using a frit. The resulting clear yellow solution was reduced under vacuum to yield the title compound as a light yellow, waxy and air sensitive solid (0.960 g, 1.71 mmol, 31.9% yield) **4a**.

^1H NMR (δ ppm C_6D_6, 500 MHz): 3.28 [s, 6H, C_6H_4–OCH_3], 3.61 [s, 4H, C_5H_4–CH_2], 5.15 [s, 4H, C_5H_4–CH_2], 6.05 [s, 4H, C_5H_4–CH_2], 6.75 [d, 4H, J 7.82 Hz, C_6H_4–OCH_3], 7.04 [d, 4H, *J* 7.82 Hz, C_6H_4–OCH_3].

^{13}C NMR (δ ppm C_6D_6, 125 MHz, proton decoupled): 35.5 [C_5H_4–CH_2], 54.4 [C_6H_4–OCH_3], 97.1, 114.0, 123.3, 129.8, 132.3, 145.8, 158.4.

^{119}Sn NMR (δ ppm C_6D_6, 186 MHz, proton decoupled): −36.5.

MS (m/z, QMS-MS/MS): 559 $[M-H]^-$.

IR absorptions (NaCl, cm^{-1}): 2996, 2905, 2833, 1610, 1575, 1511, 1463, 1431, 1300, 1247, 1176, 1036, 919, 803.

UV–Vis (toluene, nm): λ 216 (ε 56000), λ 239 (ε 53000), λ 266 (ε 49000), λ 274 (ε 39000), λ 299 (ε 13000), λ 321 (ε 7800), λ 337 (ε 2000), λ 425 (ε 5900), λ_{max} 555 (ε 600).

2.2.2. Synthesis of bis-[(p-N,N-dimethylaminobenzyl)cyclopentadienyl] tin(IV) dichloride, $[\eta^1$-C_5H_4–CH_2–C_6H_4–N–$(CH_3)_2]_2SnCl_2$ (**4b**)

15.0 ml (15.0 mmol) of 1 M solution of Super Hydride ($LiBEt_3H$) in THF was concentrated by removal of the solvent by heating it to 60 °C under reduced pressure of 10^{-2} mbar for forty minutes and then to 90 °C for 20 min in a Schlenk flask. The concentrated Super

Hydride was dissolved in 30 ml of dry diethyl ether to give a cloudy white suspension. 2.38 g (12.1 mmol) of the red solid **1b** was added to a Schlenk flask and was dissolved in 90 ml dry diethyl ether to give a red solution. The red fulvene solution was transferred to the Super Hydride solution *via cannula*. The solution was left to stir for 8 h to give a white precipitate of the lithium cyclopentadienide intermediate and the solution had changed colour from orange/red to faint yellow. The precipitate was filtered on to a frit and was washed with 20 ml of diethyl ether. The white precipitate was dried briefly under reduced pressure and was transferred to a Schlenk flask under nitrogen. 1.94 g (9.45 mmol, 78.2% yield) of the lithiated cyclopentadienide intermediate **2b** was obtained. 2.36 ml (2.36 mmol) of a 1 M solution of tin tetrachloride in heptane was dissolved in 30 ml of dry toluene in a Schlenk flask. The lithium cyclopentadienide intermediate was dissolved in 60 ml of dry toluene to give a colourless solution. The solution of tin tetrachloride was added to the lithium cyclopentadienide intermediate solution slowly at 0 °C *via cannula* to give a yellow solution with a white precipitate. The tin solution was allowed to stir for 16 h at room temperature followed by the removal of the solvent under reduced pressure which yielded a dark yellow solid, tetrakis-[η^1-*(p-dimethylaminobenzyl)cyclopentadienyl] tin(IV)* intermediate **3b**. The dark yellow solid was dissolved in 30 ml of dry toluene and 2.36 ml (2.36 mmol) of a 1 M solution of tin tetrachloride in heptane was added slowly at 0 °C. The solution was stirred at room temperature for 2 h after which it was allowed to settle, followed by filtration in an inert atmosphere of nitrogen using a frit. The resulting clear yellow solution was reduced under vacuum to yield the title compound as a yellow, waxy and air sensitive solid (1.21 g 2.06 mmol, 43.7% yield) **4b**.

^{1}H NMR (δ ppm C_6D_6, 500 MHz): 2.23 [s, 12H, C_6H_4–N(CH_3)$_2$], 3.36 [s, 2H, C_5H_4–CH_2], 3.43 [s, 2H, C_5H_4–CH_2], 4.93 [s, 2H, C_5H_4–CH_2], 4.98 [s, 2H, C_5H_4–CH_2], 5.72 [s, 2H, C_5H_4–CH_2], 5.86 [s, 2H, C_5H_4–CH_2], 6.32 [d, 4H, J 8.31 Hz, C_6H_4–N(CH_3)$_2$], 6.82 [d, 4H, *J* 8.31 Hz, C_6H_4–N(CH_3)$_2$].

^{13}C NMR (δ ppm C_6D_6, 125 MHz, proton decoupled): 35.4 [C_5H_4–CH_2], 40.2 [C_6H_4–N-(CH_3)$_2$], 97.0, 100.3, 113.0, 121.6, 123.4, 129.5, 146.3, 148.1, 149.3.

^{119}Sn NMR (δ ppm C_6D_6, 186 MHz, proton decoupled): −26.8

MS (*m*/*z*, QMS-MS/MS): 585 $[M-H]^-$.

IR absorptions (near, NaCl windows, cm^{-1}): 3007, 2888, 2798, 1614, 1567, 1518, 1478, 1444, 1347, 1224, 1162, 1131, 947, 805.

UV–Vis (toluene, nm): λ 218 (ε 42 000), λ 227 (ε 36 000), λ 236 (ε 43 000), λ 246 (ε 41 000), λ 263 (ε 48 000), λ 299 (ε 20 000), λ 322 (ε 8400), λ 426 (ε 4500), λ 555 (weak).

*2.2.3. Synthesis of bis-[(3,4-dimethoxybenzyl)cyclopentadienyl] tin(IV) dichloride, [η^1-C_5H_4–CH_2–C_6H_3–$(OCH_3)_2$]$_2$$SnCl_2$ (**4c**)*

16.0 ml (16.0 mmol) of 1 molar solution of Super Hydride (Li-BEt_3H) in THF was concentrated by removal of the solvent by heating it to 60 °C under reduced pressure of 10^{-2} mbar for 40 min and then to 90 °C for 20 min in a Schlenk flask. The concentrated Super Hydride was dissolved in 30 ml of dry diethyl ether to give a cloudy white suspension. 2.40 g (11.2 mmol) of the red solid **1c** was added to a Schlenk flask and was dissolved in 90 ml dry diethyl ether to give a red solution. The red fulvene solution was transferred to the Super Hydride solution *via cannula*. The solution was left to stir for 8 h to give a white precipitate of the lithium cyclopentadienide intermediate and the solution had changed colour from orange/red to faint yellow with a white precipitate formed. The precipitate was filtered on to a frit and was washed with 20 ml of diethyl ether. The white precipitate was dried briefly under reduced pressure and was transferred to a Schlenk flask under nitrogen. 2.16 g (9.72 mmol, 86.8% yield) of the lithiated cyclopentadienide intermediate **2c** was obtained. 2.43 ml (2.43 mmol) of a 1 molar solution of tin tetrachloride in heptane was dissolved in 30 ml of dry toluene in a Schlenk flask. The lithium cyclopentadienide intermediate was dissolved in 60 ml of dry toluene to give a colourless solution. The solution of tin tetrachloride was added to the lithium cyclopentadienide intermediate solution slowly at 0 °C *via cannula* to give a yellow solution. The tin solution was allowed to stir for 16 h at room temperature followed by the removal of the solvent under reduced pressure which yielded a dark brown solid, tetrakis-[η^1-(*p-N,N*-dimethylaminobenzyl)cyclopentadienyl] *tin(IV)* intermediate **3c**. The dark yellow solid was dissolved in 30 ml of dry toluene and 2.43 ml (2.43 mmol) of a 1 M solution of tin tetrachloride in heptane was added slowly at 0 °C. The solution was stirred at room temperature for 2 h after which it was allowed to settle, followed by filtration in an inert atmosphere of nitrogen using a frit. The resulting clear brown solution was reduced under vacuum to yield the title compound as a brown, waxy and air sensitive solid (0.740 g 1.20 mmol, 24.6% yield) **4c**.

^{1}H NMR (δ ppm C_6D_6, 500 MHz): 3.14 [s, 6H, C_6H_3-(OCH_3)$_2$], 3.18 [s, 6H, C_6H_3–(OCH_3)$_2$], 3.46 [s, 4H, C_5H_4–CH_2], 4.77 [s, 4H, C_5H_4–CH_2], 5.95 [s, 4H, C_5H_4–CH_2], 6.37 [d, 2H, J 8.31 Hz, C_6H_3–(OCH_3)$_2$], 6.48 [s, 2H, C_6H_3–(OCH_3)$_2$], 6.52 [d, 2H, J 8.31 Hz, C_6H_3–(OCH_3)$_2$].

^{13}C NMR (δ ppm C_6D_6, 125 MHz, proton decoupled): 35.1 [C_5H_4–CH_2], 54.2 [C_6H_3–(OCH_3)$_2$], 99.2, 111.7, 112.1, 120.0, 120.9, 131.7, 146.3, 149.2.

^{119}Sn NMR (δ ppm C_6D_6, 186 MHz, proton decoupled): −48.9.

IR absorptions (neat, NaCl windows, cm^{-1}): 2998, 2934, 2833, 1609, 1590, 1510, 1463, 1417, 1235, 1139, 1028, 804, 733.

UV–Vis (toluene, nm): λ 213 (ε 63 000), λ 230 (ε 53 000), λ 240 (ε 55 000), λ 248 (ε 56 000), λ 266 (ε 58 000), λ 300 (ε 8600), λ 321 (ε 5600), λ 426 (ε 4300), λ_{max} 555 (ε 400) (see Fig. 1).

2.3. Antibacterial Studies

Two different strains of the Gram-positive bacteria *Staphylococcus aureus* (SA) were used; a clinical isolate of Methicillin-resistant SA (MRSA identified as isolate CC), and the commercially available Methicillin-sensitive SA (MSSA ATCC 6538). For comparison, a Gram-negative bacterium was also tested (*Escherichia coli,* lab strain BL21).

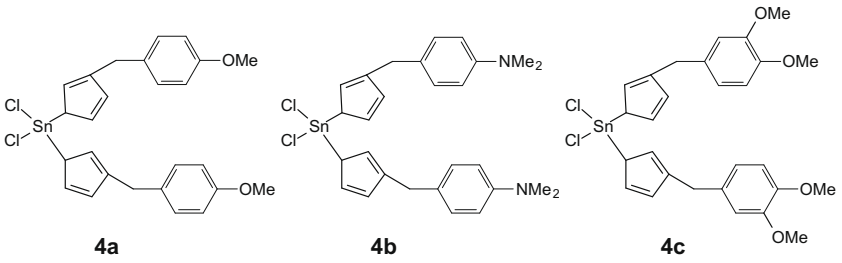

Fig. 1. Structures of η^1 organotin dichlorides **4a–c**.

Table 1
Zone of clearance for compounds **4a–c** in mm

Bacteria	DMSO	**4a** (mm)	**4b** (mm)	**4c** (mm)
Gram-positive				
MRSA	N/A	5	10	14
MSSA	N/A	8	8	14
Gram–negative				
E. coli	N/A	5	6	5

To assess the biological activity of compounds **4a–c**, the Kirby–Bauer disk-diffusion method was applied [25]. All bacteria were individually cultured from a single colony in sterile LB medium [26] overnight at 37 °C (orbital shaker incubator). All the work carried out was performed under sterile conditions.

For each strain, 50 μl of culture were spread evenly on agar-LB medium. Four 5 mm diameter paper discs were placed evenly separated on each plate. 50 mg of each sample (**4a** 0.089 M, **4b** 0.085 M and **4c** 0.081 M) were dissolved in 1 ml of DMSO to prepare the drug formulation. 5 μl of **4a–c** solution (250 μg) were placed on the paper discs and 5 μl of DMSO was placed on the fourth circle of filter paper as a control. The plates were covered and placed in an incubator at 30 °C for 24 h. The plates were then removed and the zone of clearance (defined as the diameter of inhibited bacterial growth around the filter paper) for each sample was measured in mm (see Table 1).

2.4. Cytotoxicity studies

Preliminary *in vitro* cell tests were performed on the cell line LLC-PK (long-lasting cells–pig kidney) in order to compare the cytotoxicity of the compounds presented in this paper. This cell line was chosen based on their regular and long-lasting growth behaviour, which is similar to the one shown in kidney carcinoma cells. It was obtained from the ATCC (American Tissue Cell Culture Collection) and maintained in Dulbecco's Modified Eagle Medium containing 10% (v/v) FCS (foetal calf serum), 1% (v/v) penicillin streptomycin and 1% (v/v) L-glutamine. Cells were seeded in 96-well plates containing 200 μl microtitre wells at a density of 5000-cells/200 μl of medium and were incubated at 37 °C for 24 h to allow for exponential growth. Then the compounds used for the testing were dissolved in the minimal amount of DMSO (dimethylsulfoxide) possible and diluted with medium to obtain stock solutions of 5×10^{-4} M in concentration and less than 0.7% of DMSO. The cells were then treated with varying concentrations of the compounds and incubated for 48 h at 37 °C. Then, the solutions were removed from the wells and the cells were washed with PBS (phosphate buffer solution) and fresh medium was added to the wells. Following a recovery period of 24 h incubation at 37 °C, individual wells were treated with a 200 μl of a solution of MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) [27] in medium. The solution consisted of 30 mg of MTT in 30 ml of medium. The cells were incubated for 3 h at 37 °C. The medium was then removed and the purple formazan crystals were dissolved in 200 μl DMSO per well. A Wallac Victor (Multilabel HTS Counter) Plate Reader was used to measure absorbance at 540 nm. Cell viability was expressed as a percentage of the absorbance recorded for control wells. The values used for the dose response curves represent the values obtained from four consistent MTT-based assays for each compound tested.

Largest difference in peak and hole (e Å^{-3})	0.907 and −0.536

3. Discussion

3.1. Synthesis

The lithium intermediates used in the synthesis of derivatives **4a–c** were synthesised by the hydridolithiation reaction of aryl-fulvenes with Super Hydride ($LiBEt_3H$). This form of nucleophilic addition to the exocyclic double bond of the fulvene is highly selective due to the increased polarity as a result of the inductive effect of the corresponding phenyl ring. There is no nucleophilic attack seen at the diene element of the aryl-fulvenes. The lithiated cyclopentadienide intermediate was isolated with good yields of 79–87%.

Four equivalents of the lithiated cyclopentadienide intermediate were then transmetallated with one equivalent of tin tetrachloride to form a tetrakis cyclopentadienyl tin(IV) intermediate and lithium chloride as a by-product. This tetrakis cyclopentadienyl tin(IV) intermediate was isolated but not characterised due to extreme air sensitivity. This was then further reacted with 1 equiv. of tin tetrachloride to yield the organotin dichlorides **4a**, **4b**, and **4c** in yields of 25–44%. Elemental analysis was not possible due to the level of air and moisture sensitivity of the compounds.

Derivatives **4a**, **4b**, and **4c** are soluble in organic non-chlorinated solvents, but decompose rapidly in chlorinated solvents such as dichloromethane. The synthesis of organotin dichlorides is dependent upon the solvent. The expected dichloride species were formed only when toluene or benzene was used as the solvent.

A notable feature of the organotin species **4a**, **4b**, and **4c** is the η^1-bonded Cp ligand in these molecules. This results in an interesting ^{1}H NMR spectrum, which appears to suggest a η^5-bonding due to the symmetry of two singlet peaks for the cyclopentadienyl hydrogens, approximately 1 ppm apart. This can be rationalised by fast sigma tropic shift in solution.

3.2. Structural discussion

Despite the effort to crystallise the organotin derivatives **4a-c**, no crystal structures were obtained. 2,2-Bipyridine was success-

fully used as a bidentate nitrogen base in an attempt to crystallise a six co-ordinated tin complex for the organotin dichloride species. This produced single crystals of the bipyridine adduct of η^1-(*p*-methoxybenzyl)cyclopentadienyl tin(IV) trichloride (**5**), where one of the Cp ligands is replaced with a Cl atom, which can be viewed in Fig. 2. This shows that the tin(IV) cyclopentadienyl chlorides undergo more than one exchange reaction: The above mentioned sigma tropic shift and a ligand exchange in a Schlenk-type equilibrium. The structure is monoclinic and contains $CHCl_3$ solvent molecules in the crystal (see Table 3).

The bond lengths for Sn–Cl(1) 2.420 Å, Sn–Cl(2) 2.442 Å, and Sn–Cl(3) 2.414 Å of the six co-ordinated Sn species are slightly longer when compared with other tin(IV) complexes [28], due to the increased electron density surrounding the central Sn atom. Also, the bond length of the Sn–C(3) 2.222 Å is comparable with other organotin complexes such as Me_2SnCl_2 where the Sn–C bond

Cl(1)–Sn–Cl(2)	89.53

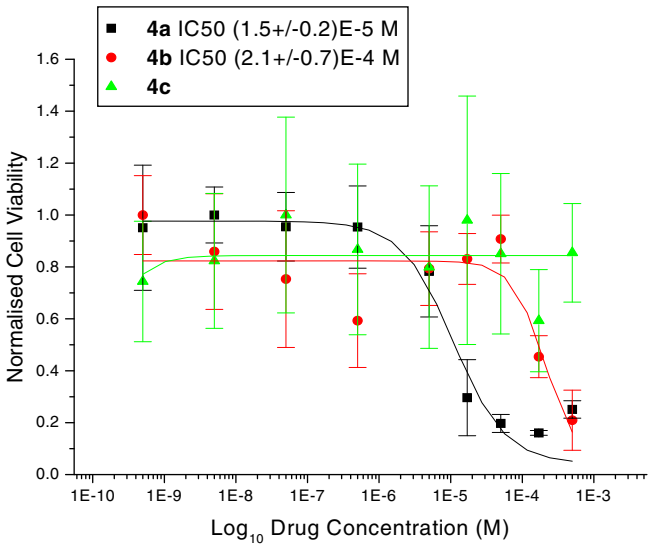

Fig. 3. Cytotoxicity curves from typical MTT assays showing the effect of compounds **4a–c** on the viability of LLC-PK cells.

lengths are in the region of 2.210 Å [29]. This structure also demonstrates the η^1-bonded conformation for the Sn–C bond, which is believed to be present in complexes **4a–c**. The two double bonds present in the cp ring are evident due to the shortening of the carbon-carbon bond lengths, C(1)–C(2) 1.349 Å and C(4)–C(5) 1.346 Å. The longer single CC bonds within the Cp ring were; C(2)–C(3) 1.482 Å, C(3)–C(4) 1.460 Å, and C(1)–C(5) 1.453 Å. The structure displays a distorted octahedral conformation, with the N(1)–Sn–N(2) angle of 72.51° being compressed due to the co-ordinated bipyridine ligand.

3.3. Biological evaluation

Almost no antibacterial effect was observed for complexes **4a–c** against the Gram-negative bacteria *E. coli* using the Kirby–Bauer disk diffusion method. Against the Gram-positive bacteria MRSA and MSSA however, a low to medium effect was observed with the compounds **4b** and **4c** having the greatest effect over 24 h. The solvent used to prepare the stock solutions (DMSO) played no role in growth inhibition. These results are in keeping with other organotin(IV) results found in the literature.

3.4. Cytotoxicity studies

As seen in Fig. 3, compounds **4a** and **4b** showed IC50 values 15 and 210 μM respectively. Complex **4c** displayed no antitumor activity. All three compounds suffered from very poor solubility along with decomposition due to certain air sensitivity of the compounds, which resulted in relatively large error margins for compounds **4b** and **4c**. Compound **4a** showed surprisingly good results of 15 μM with reduced error margins when compared with the titanium equivalent, Titanocene **Y**, which yielded an IC50 value of 21 μM. This result emphasises the importance of the *p*-methoxy phenyl moiety that is present in both **4a** and Titanocene **Y**. However the IC50 value for **4a** did not reach the level set by cisplatin with an IC50 value of 3.3 μM.

4. Conclusion and outlook

The hydridolithiation of 6-aryl substituted fulvenes followed by transmetallation has been found to be a very effective and reproducible way to medium to highly cytotoxic benzyl-substituted

organotin complexes. Although preliminary anti-bacterial results were lower than expected, **4a** yielded a promising anti-tumour IC50 value of 15 μM. While the possibility of **4a** becoming a viable anti-cancer drug are low due to high air sensitivity of **4a** and general toxicity of organotin compounds, these results are encouraging enough to warrant further work in this area.

Supplementary data

CCDC 699232 contains the supplementary crystallographic data for **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

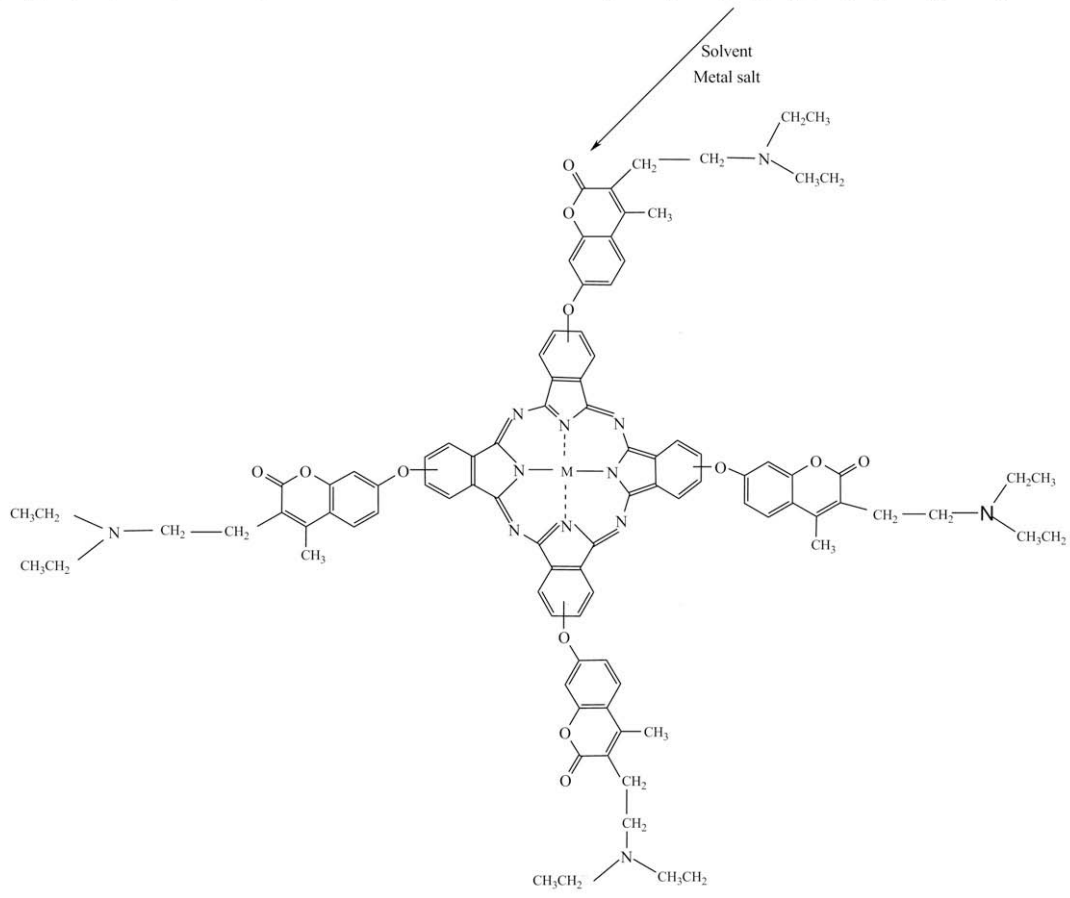
3-[(2-Diethylamino)ethyl]-7-hydroxy-4-methylcoumarin hydrochloride

3-[(2-Diethylamino)ethyl]-7-[(3,4-dicyanophenoxy)]-4-methylcoumarin



Scheme 1. Synthesis of the starting compounds, metal-free and metallo phthalocyanines.

Inova 500 MHz NMR spectrophotometer using TMS as an internal reference at the Bogazici University Laboratory. Elemental analysis was performed by the Instrumental Analysis Laboratory of TUBITAK Ankara Test and Analysis Laboratory. Mass spectra were performed on a Bruker Daltonic Autoflex MALDI-TOF spectrometer at Marmara University.

1,2-Dicyano-4-nitrobenzene was synthesized according to a reported procedure [16] and 3-[(2-diethylamino)ethyl]-7-hydroxy-4-methylcoumarin hydrochloride was purchased from the Aldrich Chemical Company.

2.1. Synthesis of 3-[(2-diethylamino)ethyl]-7-[(3,4-dicyanophenoxy)]-4-methylcoumarin (*1*)

3-[(2-Diethylamino)ethyl]-7-hydroxy-4-methylcoumarin hydrochloride (0.500 g, 1.60 mmol) and 1,2-dicyano-4-nitrobenzene (0.270 g, 1.60 mmol) were added successively with stirring to dry DMF (10 ml). After stirring for 15 min, finely ground anhydrous K_2CO_3 (0.330 g, 2.40 mmol) was added portionwise over 2 h and the mixture was stirred vigorously at room temperature for a further 48 h. Then the reaction mixture was poured into water (100 ml) and the precipitate that formed was filtered off, and washed with water until neutral. The yellow product (**1**) was obtained in the pure form. The compound is soluble in ethanol, methanol, tetrahydrofuran, chloroform, dichloromethane, dimethylformamide and dimethylsulfoxide.

Compound **1**: Yield: 0.500 g (86%); m.p.: 280–285 °C. IR (KBr) γ_{max} (cm^{-1}): 3074 (aryl CH), 2804–2957 (alkyl CH), 2229 (C≡N), 1704 (C=O lactone), 1589 and 1489 (C=C), 1245 (Ar–O–Ar). ^1H NMR ($CHCl_3$) δ_H (ppm): 7.75 (d, 1H, Ar–H), 7.66 (d, 1H, Ar–H), 7.33 (d, 1H, Ar–H), 7.31 (dd, 1H, Ar–H), 7.01 (d, 1H, Ar–H), 6.97 (dd, 1H, Ar–H), 3.41 (t, 2H, $ArCH_2CH_2$), 2.82 (q, 4H, NCH_2), 2.06 (t, 2H, $ArCH_2$), 2.45 (s, 3H, CH_3), 1.09 (t, 6H, CH_2CH_3). ^{13}C NMR (DMSO) δ_C (ppm): 161.1 (C=O), 153.7 (CH_3–C=C–CH_2), 118.1 (CH_3–C=C–CH_2), 115.3 (CN), 114.8 (CN), 160.7, 155.5, 146.0, 135.8, 126.9, 125.0, 122.4, 122.3, 118.9, 116.2, 110.2, 108.6, 51.0, 47.1, 47.1, 25.2, 15.3 ($ArCH_3$), 12.2, 12.2 ppm. UV–Vis ($CHCl_3$) λ_{max} (log ε) (nm): 320 (4.85). *Anal. Calc.* for $C_{24}H_{23}N_3O_3$: C, 71.82; H, 5.73; N, 10.47. Found: C, 70.64; H, 5.02; N, 10.41%. MS (MALDI-TOF) *m/z*: 401 $[M]^+$, 402 $[M+1]^+$.

2.2. Synthesis of the metal-free and zinc phthalocyanines (*2* and *3*)

2.2.1. Synthesis of 2,9,16,23-tetrakis[7-oxo-(3-[(2-diethylamino)ethyl)]-4-methylcoumarin] phthalocyanine (*2*)

3-[(2-Diethylamino)ethyl]-7-[(3,4-dicyanophenoxy)]-4-methylcoumarin (**1**) (0.050 g, 0.12 mmol) was heated with 2 ml dry 2-*N*,*N*-dimethylaminoethanol in a sealed tube. The mixture was held at 145 °C for 48 h. After cooling to room temperature, the reaction mixture was treated with dilute HCl, then filtered off and washed with water until the filtrate became neutral. The green product was purified by washing with tetrahydrofuran, chloroform, dichloromethane, acetonitrile, acetone, ethylacetate and ether, and the dried. The compound is soluble in acetic acid, dimethylformamide (slightly) and dimethylsulfoxide (slightly).

Compound **2**: Yield: 0.020 g (57%); m.p.: >300 °C. IR γ_{max} (cm^{-1}): 3269 (N–H), 3058 (aryl CH), 2850–2970 (alkyl CH), 1701 (C=O lactone), 1604 (C=C), 1242 (Ar–O–Ar). ^1H NMR (DMSO) δ_H (ppm): 7.0–8.04 (m, 24H, Ar–H), 2.88 (m, 32H, CH_2), 2.45 (s, 12H, CH_3), 1.12 (s, 24H, CH_2CH_3), −2.85 (s, 2H, NH). 2.2.2. Synthesis of 2,9,16,23-tetrakis[7-oxo-(3-[(2-diethylamino)ethyl)]-4- methylcoumarin] phthalocyaninatozinc (*3*)

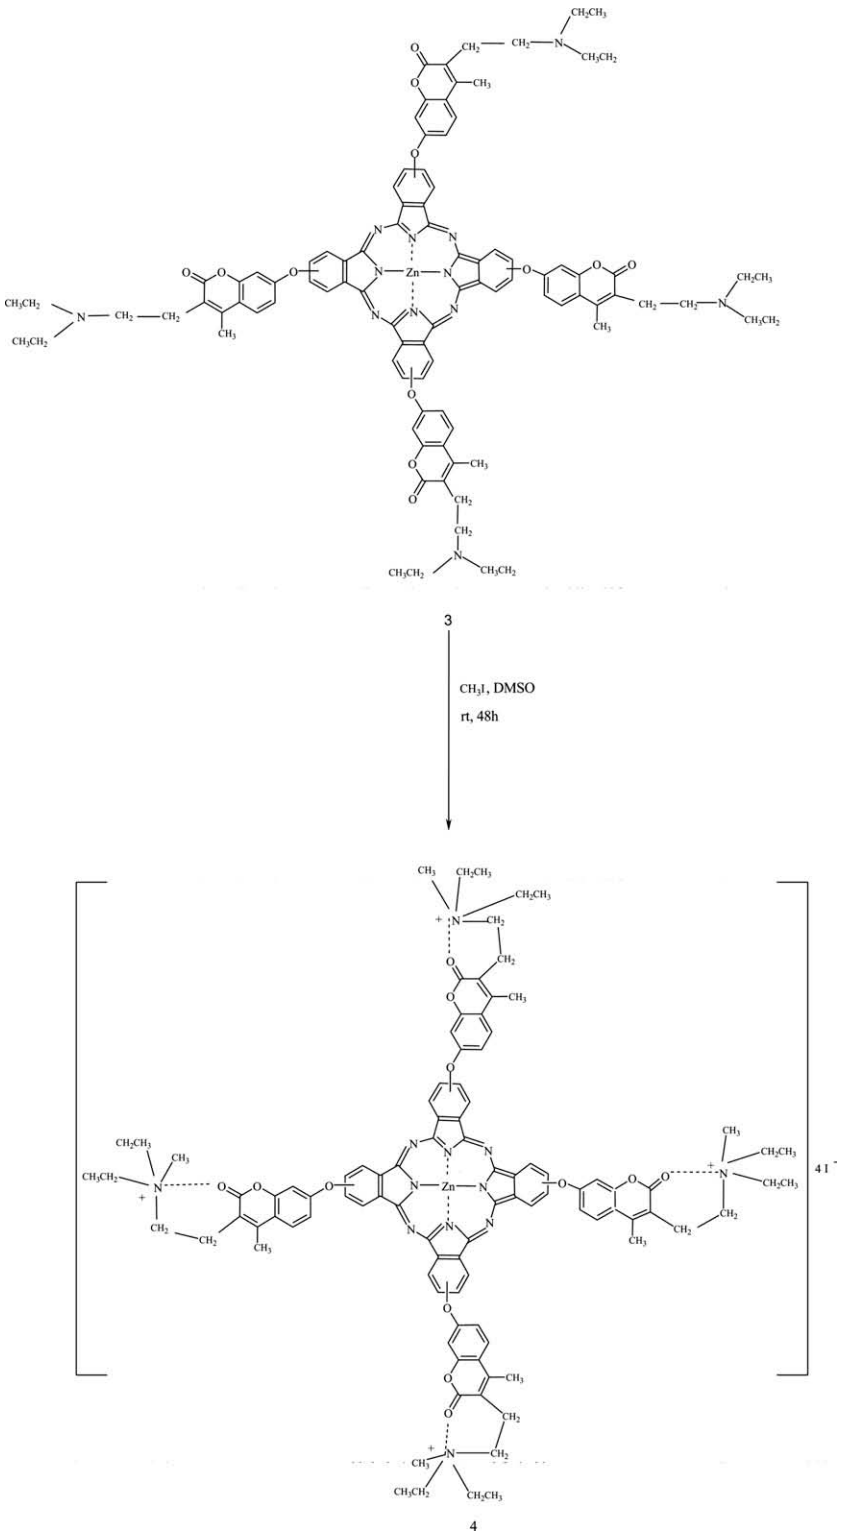
A mixture of compound **1** (0.050 g, 0.12 mmol) and $Zn(CH_3COO)_2 \cdot 2H_2O$ (0.007 g, 0.03 mmol) were heated at 160 °C with 2 ml dry 2-*N*,*N*-dimethylaminoethanol in a sealed tube, and stirred for 24 h. After cooling to room temperature, the reaction mixture was treated with ethyl acetate, and the precipitate that formed was filtered off and washed with water to remove unreacted $Zn(CH_3COO)_2 \cdot 2H_2O$. The green product was purified by washing with tetrahydrofuran, chloroform, dichloromethane, acetonitrile, acetone, ethylacetate, ether and then dried. The compound is soluble in dimethylformamide and dimethylsulfoxide.

Compound **3**: Yield: 0.040 g (77%); m.p.: >300 °C. IR γ_{max} (cm^{-1}): 3051 (aryl CH), 2916–2947 (alkyl CH), 1701 (C=O lactone), 1604, 1465 (C=C), 1238 (Ar–O–Ar). UV–Vis (DMF) λ_{max} (log ε) (nm): 679 (4.08), 617 (4.38), 337 (4.56). *Anal. Calc.* for $C_{96}H_{92}N_{12}O_{12}Zn$: C, 69.02; H, 5.51; N, 10.06. Found: C, 68.16; H, 5.59; N, 9.84%. MS (MALDI-TOF) *m/z*: 1669 $[M]^+$, 1670 $[M+1]^+$ (Fig. 1).

2.3. Synthesis of 2,9,16,23-tetrakis[7-oxo-(3-[(2-diethylaminomethyliodide)ethyl)]-4-methylcoumarin] phthalocyaninatozinc (*4*)

To a solution of 2,9,16,23-tetrakis[7-oxo-(3-[(2-diethylamino)-ethyl)]-methylcoumarin]-phthalocyaninatozinc (0.020 g, 0.012 mmol) **(3)** in dry DMSO (10 ml) was added CH_3I (0.017 g, 0.12 mmol). The mixture was stirred vigorously at room temperature for 48 h. Then the reaction mixture was poured into ethylacetate (20 ml) and the precipitate formed was filtered off. The green product was purified by washing with ethylacetate, ethanol, methanol, acetone and tetrahydrofuran. The compound is soluble in DMF, DMSO and water. Yield: 0.015 g (56%); m.p.: >300 °C. IR γ_{max} (cm^{-1}): 3054 (aryl CH), 2920–2964 (alkyl CH), 1704 (C=O lactone), 1603, 1459 (C=C), 1234 (Ar–O–Ar). UV–Vis (DMF) λ_{max} (log ε) (nm): 680 (5.38), 617 (4.64), 330 (5.15). *Anal. Calc.* for $C_{100}H_{104}N_{12}O_{12}ZnI_4$: C, 53.64; H, 4.64; N 7.51. Found: C, 50.26; H, 5.01; N, 6.64%. MS (MALDI-TOF) *m/z*: 2237 $[M]^+$ (Fig. 3).



Scheme 2. Synthesis of the phthalocyanine bearing quaternizable coumarin (**4**).

3. Result and discussion

The novel 3-[(2-diethylamino)ethyl]-7-[(3,4-dicyanophenoxy)]-4-methylcoumarin (**1**) was prepared by a base catalyzed nucleophilic aromatic nitro displacement of 1,2-dicyano-4-nitrobenzene with 3-[(2-diethylamino)ethyl]-7-hydroxy-4-methylcoumarin hydrochloride. The reaction was carried out in a single step synthesis by using K_2CO_3 as the nitro-displacing base at room temperature in dimethylformamide under a N_2 atmosphere, and the yield was 86%. Cyclotetramerization of the phthalonitrile derivative (**1**) to the metal-free Pc (**2**) was accomplished in 2-*N*,*N*-dimethylaminoethanol (DMAE) at 145 °C in sealed tube. The Zn Pc (**3**) was obtained from the dicyano derivative (**1**) and the $Zn(CH_3COO)_2 \cdot 2H_2O$ salt in the anhydrous solvent DMAE

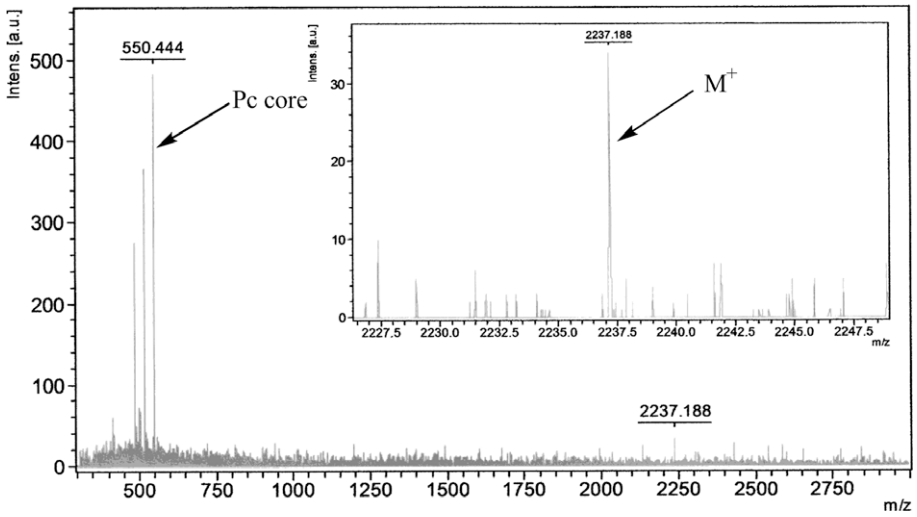


Fig. 3. The positive ion and linear mode MALDI-TOF-MS spectrum of **4** (2237 Da), obtained in 7-hydroxycoumarin (umbelliferone) MALDI matrix, using a nitrogen laser, accumulating 50 laser shots. Inset spectrum shows the expanded molecular mass region of the complex.

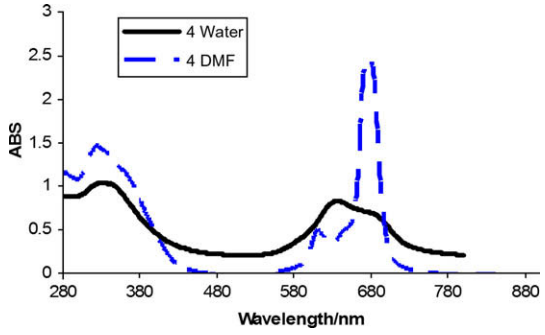

Fig. 4. UV–Vis spectra of **4** in water and DMF (1×10^{-5} M).

(Scheme 1). The tetraoxycoumarin substituted Pc products (**2**,**3**), purified by washing with tetrahydrofuran, acetone, acetonitrile, ethylacetate and ether, are soluble in DMF and DMSO. Characterization of the products involved a combination of methods including elemental analysis, ^{1}H and ^{13}C NMR, UV–Vis and MALDI-TOF spectroscopy.

Spectral data of the newly synthesized compounds are consistent with the proposed structures. The IR spectrum clearly indicates the formation of compound **1**, with the appearance of new absorption bands at 2229 cm^{-1} (C≡N) and 1245 cm^{-1} (Ar–O–Ar). After conversion of the dinitrile derivative (**1**) into the Pcs (**2**,**3**), the sharp peak for the C≡N vibration around 2229 cm^{-1} disappeared. The IR spectra of the metal-free Pc **2** and the zinc complex (**3**) are very similar, with the exception of **2** showing a NH stretching band

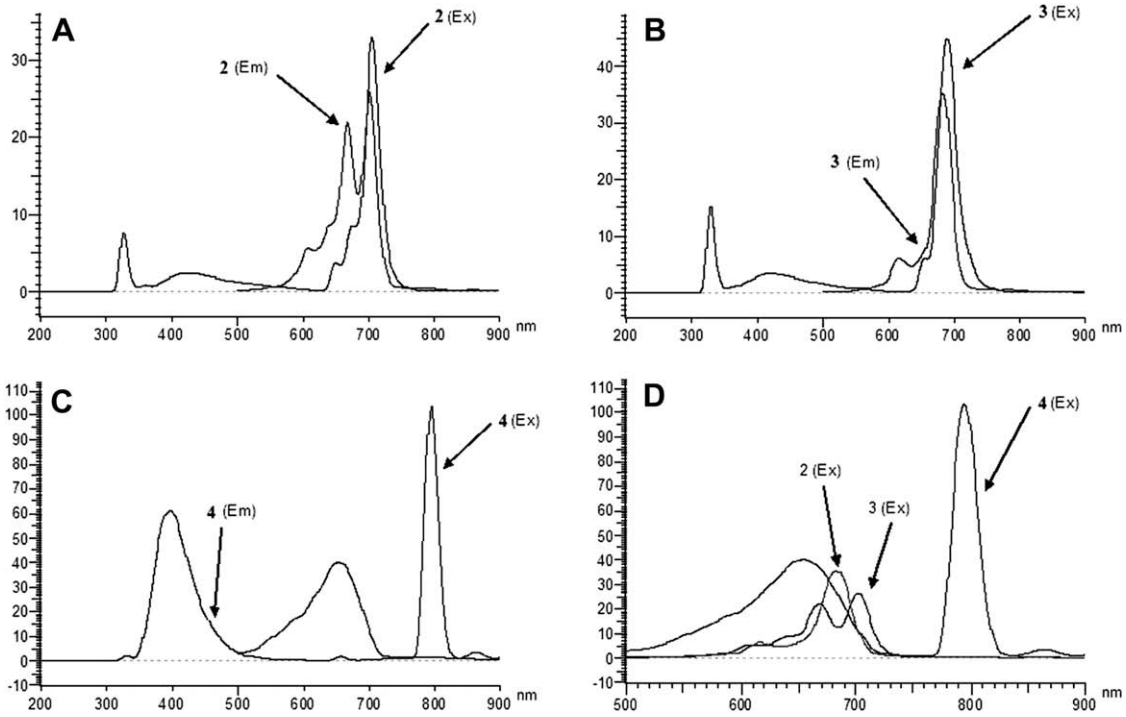

Fig. 5. Excitation and emission spectra of compound **2** (A), compound **3** (B) in DMF, compound **4** (C) in water and all the complexes overlapped (6×10^{-6} M).

due to the inner core. These bands were absent from the spectra of the complexes. The NH group of the metal-free Pc (**2**) in the inner core gave a weak absorption peak at 3269 cm^{-1}. The C=O and C=C bands for the Pcs in the IR spectra were broader and shorter than those of **1** because of H-type aggregation of the coumarin moiety.

The ^1H NMR spectrum of **1** was almost identical except for small shifts; The ^1H NMR spectrum exhibited aromatic protons at 7.75, 7.66, 7.33, 7.31, 7.01 and 6.97 ppm and methyl protons at 2.45 ppm. The ^{13}C NMR data are accord with the expected structure. The ^{13}C NMR spectrum of compound **1** indicate nitrile carbons at 115.3 and at 114.8 ppm, and the carbonyl carbon of the lactone ring appears at 161.1 ppm for **1**.

The ^1H NMR spectrum of Pc **2** was as expected . A common feature of this spectrum is the broad absorptions caused by the aggregation of the Pc. The NH protons of the metal-free Pc (**2**) were also identified in the ^1H NMR spectrum with a broad peak at $\delta = -2.85$ ppm, and the signals disappeared after the addition of D_2O.

A closed investigation of the mass spectra of the Pcs confirmed the proposed structures. In the mass spectra of the compounds, the [M^+] peaks were identified easily, as is shown as an example in Fig. 1 for **3**. The MALDI-TOF-MS spectra provided definitive characterization of the structures of all complexes. The linear mode positive ion MALDI mass spectra could be obtained in 7-hydroxycoumarin (umbelliferone) MALDI matrix. The protonated molecular ion peaks of the complexes were observed at 401 Da for **1**, 1606 Da for **2**, 1669 Da for **3** and 2237 Da for **4**. These mass values overlapped with the theoretical calculated mass values for the molecular ions of all the complexes.

The coumarins show maximum absorption with a single band at 310 nm. The UV–Vis spectrum of **1** in $CHCl_3$ showed a band at 320 nm (Fig. 2). Pcs **2** and **3** show typical electronic spectra with two strong absorption regions, a typical spectrum of the metal-free Pc (**2**) in acetic acid showed a doublet in the Q band region at 707 and 674 nm, and a B band region at 325 nm; while the ZnPc (**3**) each gave an intense Q band at 679 and 617 nm and a B band region at 337 nm. The UV–Vis spectrum of **3** in DMSO is remarkably different from that in DMF. The spectra of **3** in DMF and DMSO are shown in Fig. 2A and B. As shown in Fig. 2B for **3**, the appearance of a new band around 643 nm, at the blue side of the main Q band absorption, in DMSO suggests clearly the presence of aggregated species. Aggregation is usually depicted as a coplanar association and is strongly dependent on the concentration and nature of the solvent. Fig. 2B indicates the effect of increasing concentration on the UV–Vis spectra of 1×10^{-6} mol dm^{-3} **3** in DMSO, as an example. At the beginning (for 1×10^{-6} mol dm^{-3} **3**), the intensities of the two bands are approximately equal to each other. As the concentration of **3** is increased, the band with the lower wavelength becomes more intense than the other band.

2,9,16,23-Tetrakis[7-oxo-(3-[(2-diethylaminomethyliodide) ethyl)]-4-methylcoumarin]-phthalocyaninatozinc (**4**), bearing quaternizable coumarin, was synthesized from 2,9,16,23-tetrakis[7-oxo-(3-[(2-diethylamino)ethyl)]-methylcoumarin]-phthalocyaninatozinc (**3**) by methylation with CH_3I. The product (**4**) shows good solubility in solvents such as DMF, DMSO and water (Scheme 2). The mass spectra of **4** confirmed the proposed structure, with the molecular ion being easily identified at 2237 [M^+] (Fig. 3).

A typical UV-spectrum of 2,9,16,23-tetrakis[7-oxo-(3-[(2-diethylaminomethyliodide)ethyl)]-4-methylcoumarin]-phthalocyaninatozinc (**4**) in DMF showed a Q band at 680 nm and a B band at 330 nm (Fig. 4). The shoulder of **4** registered at 617 nm. The UV–Vis spectrum of **4** in water is different from that in DMF. Typical spectra of **4** in DMF and water are shown in Fig. 4. The appearance of a new band around 639 nm at the blue side of the main Q band absorption in water suggests clearly the presence of aggregated species.

Fig. 5 shows the fluorescence emission and excitation spectra for complexes **2**, **3** and **4** in DMF (for **2** and **3**) and in water (**4**). Fluorescence emission peaks were observed at: 709 nm for **2**, 700 nm for **3** and 693 nm for **4**. The excitation spectra were similar to the absorption spectra and both were mirror images of the fluorescent spectra in DMF for complexes **2** and **3**, and in water for **4**. For complex **4** in water, an excitation peak was indicated, which shifted to a more longer wavelength than the emission peak (red shifted), because of α,β-electron delocalization over the carbonyl oxygen of the lactone ring up to the nitrogen cation (Scheme 2).

2. Results and discussion

2.1. Preparation of complexes

Copper(II) complexes **1** and **3** were obtained by a reaction of copper(II) sulfate with 6-methylpicolinic or 6-bromopicolinic acid, respectively, in mildly alkaline aqueous solution. Both **1** and **3** can be prepared as well in highly acidic solutions (pH = 1) without the addition of the base, but with smaller yields and rates of formation due to the lower concentration of anionic form of ligands in the acidic solutions. The same thing was observed during the synthesis of copper(II) complex with 3-methylpicolinic acid, $[Cu(3\text{-}Mepic)_2] \cdot 2H_2O$ [31]. Thus, the pH value of the reaction solution does not influence on the type of the complexes formed, but it affects their formation rates, leading to the slower crystallization and, eventually, to smaller yields in the case of lower pH values. Slow evaporation of the pyridine solution of **1** leads to the formation of **2** by replacing the coordinated water molecule in **1** with the coordinated pyridine molecule.

All isolated complexes **1**–**3** are air-stable, blue crystalline substances, less soluble in water and alcohols, but well soluble in solvents with pronounced donor properties (such as DMF, DMSO, pyridine and 4-picoline).

2.2. Structural description of *1*

ORTEP-3 view of the molecular structure of **1** is depicted in Fig. 1a and its crystal structure in Fig. 2a. The selected molecular

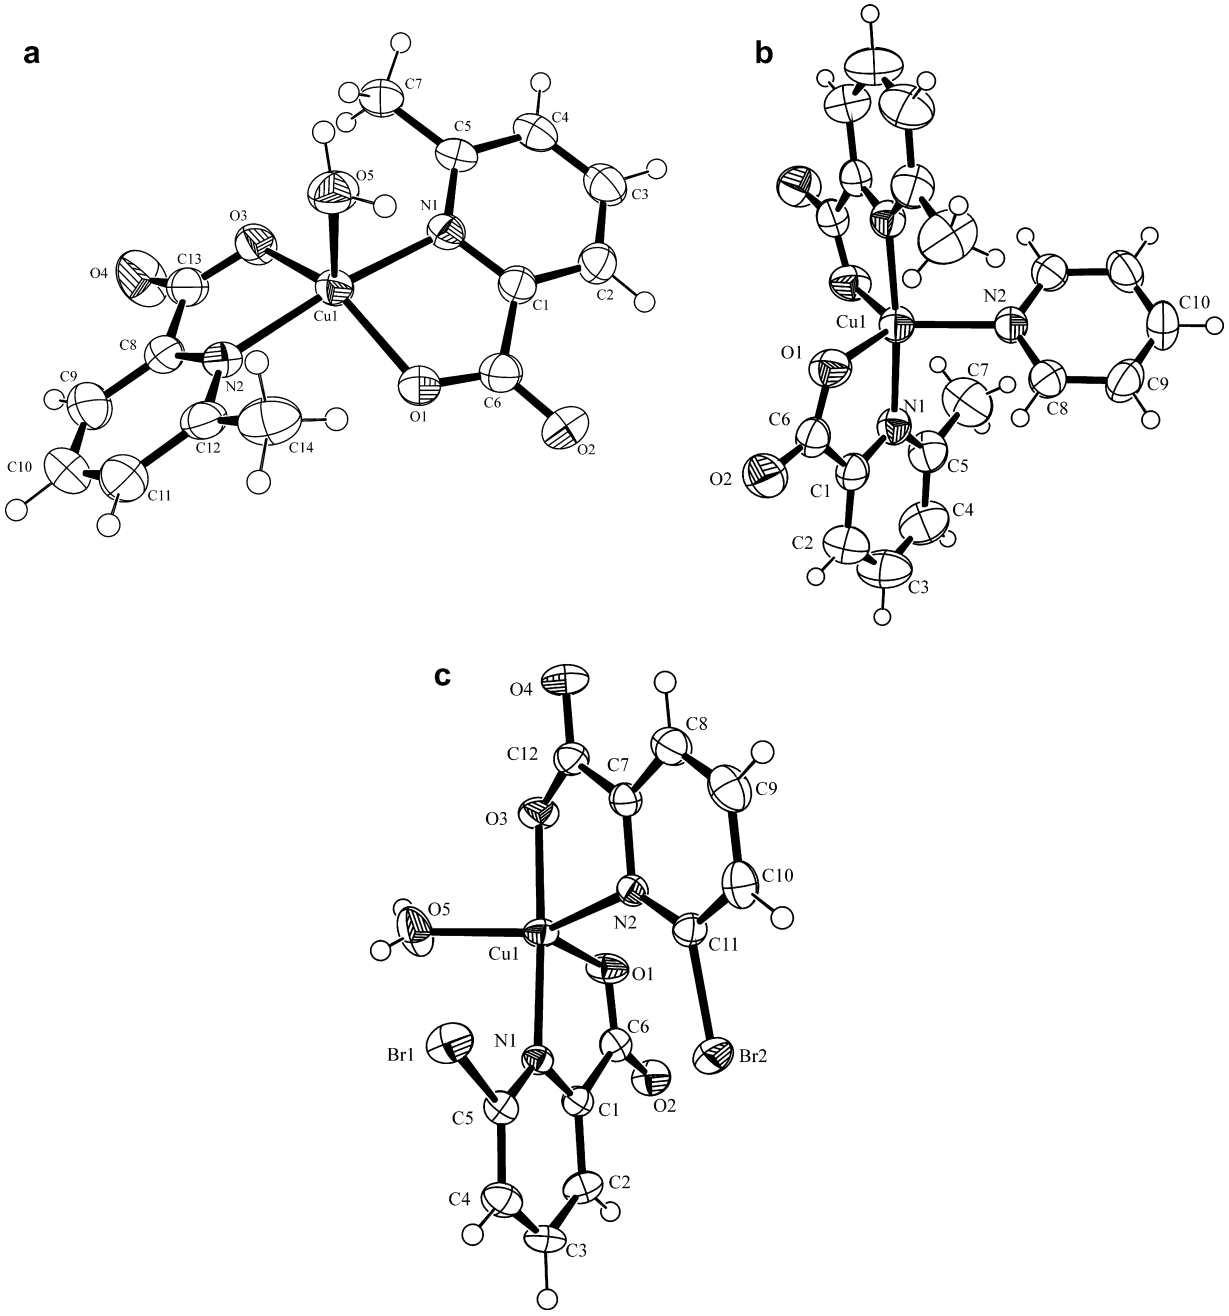

Fig. 1. ORTEP-3 drawing of (a) $[Cu(6\text{-}Mepic)_2(H_2O)]$ (**1**), (b) $[Cu(6\text{-}Mepic)_2(py)]$ (**2**) and (c) $[Cu(6\text{-}Brpic)_2(H_2O)]$ (**3**) with the atomic numbering scheme of the asymmetric unit. The thermal ellipsoids are drawn at the 50% probability level at 296 K.

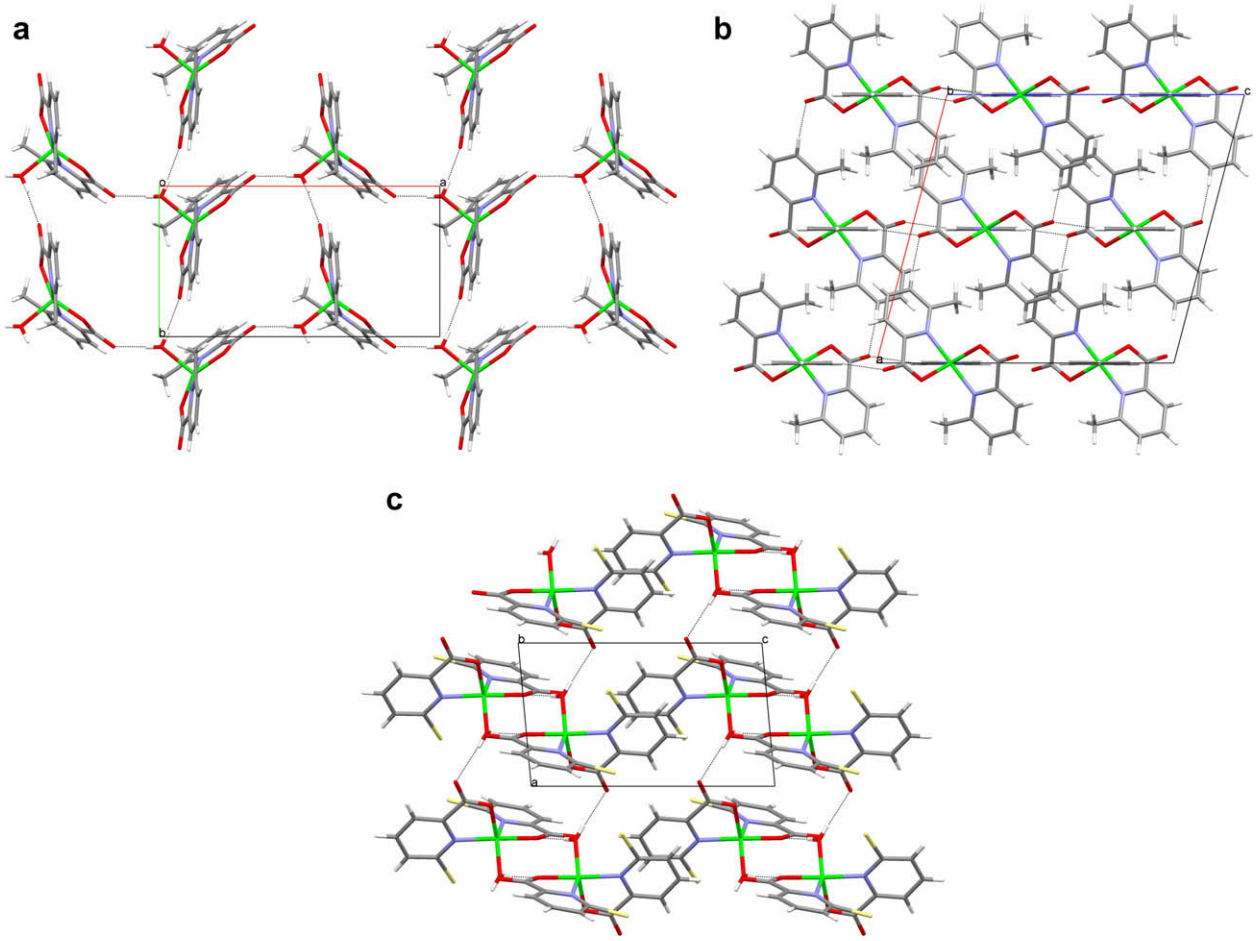

Fig. 2. (a) A view of the crystal packing of $[Cu(6\text{-Mepic})_2(H_2O)]$ (**1**) in *ab* plane, showing molecules linked into a two-dimensional network by hydrogen bonds of the O–H···O type, represented by dotted lines. (b) A view of the crystal packing of $[Cu(6\text{-Mepic})_2(py)]$ (**2**) in *ac* plane, showing a part of the three-dimensional structure. Intermolecular hydrogen bonds of C–H···O type are represented by dotted lines. (c) A view of the crystal packing of $[Cu(6\text{-Brpic})_2(H_2O)]$ (**3**) in *ac* plane, showing centrosymmetric dimers linked into chains in a [100] direction by hydrogen bonds of the O–H···O type (represented by dotted lines). Chains are mutually assembled in a [001] direction by π···π stacking interaction between pyridine rings defined by atoms N1/C1/C2/C3/C4/C5.

geometry parameters are listed in Table 1 and hydrogen bond geometry in Table 2.

The copper(II) ion in **1** is coordinated by two 6-methylpicolinato ligands which are both bound in a bidentate *N*,*O*-chelated mode, forming a five-membered chelate ring, and by one water molecule (Fig. 1a). The geometry around this pentacoordinated copper(II) ion can be best described as an intermediate between a square pyramid and a trigonal bipyramid since $\tau = 0.45[\tau = (\alpha - \beta)/60°$ (α and β are the largest angles), 0 for the ideal square pyramid, 1 for the ideal trigonal bipyramid] [32].

The dihedral angle between the least squares calculated planes through the atoms of pyridine ring (N1/C1/C2/C3/C4/C5) and the corresponding five-membered chelate ring (Cu1/N1/C1/C6/O1) is 2.0(1)°, while the analogous angle (between planes defined by atoms N2/C8/C9/C10/C11/C12 and Cu1/N2/C8/C13/O3) is 7.7(1)°.

The crystal packing of **1** is controlled by two intermolecular hydrogen bonds of the O–H···O type, while an additional weak intramolecular hydrogen bond of the C–H···O type [33–35] is also present (Fig. 2a and Table 2). Molecules of **1** are linked by the intermolecular O–H···O hydrogen bonds into a two-dimensional network in *ab* plane (Fig. 2a). These networks are mutually assembled in a [001] direction only by the π···π stacking interaction [36] between the pyridine rings defined by atoms N2/C8/C9/C10/C11/C12 (centroid–centroid distance 3.652(1) Å, dihedral angle 0°, slippage 0.959 Å, slip angle 15.2°, symmetry code $-x$, $1-y$, $-z$), forming a three-dimensional supramolecular architecture.

There is one more π···π stacking interaction [36] between the pyridine rings defined by atoms N1/C1/C2/C3/C4/C5 (centroid–centroid distance 3.625(1) Å, dihedral angle 0°, slippage 1.094 Å, slip angle 17.6°, symmetry code $1/2-x$, $1/2-y$, $1/2-z$) and an intermolecular interaction between five-membered chelate ring defined by atoms Cu1/N1/C1/C6/O1 and pyridine ring (N1/C1/C2/C3/C4/C5) (centroid–centroid distance 3.683(1) Å, dihedral angle 2.0(1)°, slip angle 20.3°, symmetry code $1/2-x$, $1/2-y$, $1/2-z$).

2.3. Structural description of **2**

ORTEP-3 view of the molecular structure of **2** is depicted in Fig. 1b and its crystal structure in Fig. 2b. The selected molecular geometry parameters are listed in Table 1 and hydrogen bond geometry in Table 2.

Copper(II) ion in **2** is situated on a twofold symmetry axis and its coordination environment can be described as a distorted trigonal bipyramid since $\tau = 0.87$. The equatorial plane of the pyramid is defined by two carboxylato O atoms from two 6-methylpicolinato ligands and one pyridine N atom from coordinated pyridine molecule. The axial positions are occupied by two pyridine N atoms from two 6-methylpicolinato ligands which are both bound to

C10–H10···O2	0.93	2.38	3.304(3)	170.0	$x, y - 1, z$

the copper(II) ion in a bidentate *N*,*O*-chelated mode forming a five-membered chelate ring (Fig. 1b).

The dihedral angle between the least squares calculated planes through the atoms of pyridine ring (N1/C1/C2/C3/C4/C5) and the corresponding five-membered chelate ring (Cu1/N1/C1/C6/O1) is 4.4(1)°.

There are three weak intermolecular hydrogen bonds of the C–H···O type [33–35] in the crystal packing of **2** (Fig 2b and Table 2) which assemble molecules of **2** into a three-dimensional supramolecular architecture.

2.4. Structural description of *3*

ORTEP-3 view of the molecular structure of **3** is depicted in Fig. 1c and its crystal structure in Fig. 2c. The selected molecular geometry parameters are listed in Table 1 and hydrogen bond geometry in Table 2.

The copper(II) ion in **3** is coordinated by two 6-bromopicolinato ligands which are both bound in a bidentate *N*,*O*-chelated mode, forming a five-membered chelate ring, and by one water molecule (Fig. 1c). The coordination environment around this pentacoordinated copper(II) ion can be described as an intermediate between a trigonal bipyramid and a square pyramid since $\tau = 0.62$.

The dihedral angle between the least squares calculated planes through the atoms of pyridine ring (N1/C1/C2/C3/C4/C5) and the corresponding five-membered chelate ring (Cu1/N1/C1/C6/O1) is 0.9(1)°, while the analogous angle (between planes defined by atoms N2/C7/C8/C9/C10/C11 and Cu1/N2/C7/C12/O3) is 7.8(1)°.

The crystal packing of **3** is dominated by two intermolecular hydrogen bonds of the O–H···O type, while three weak intermolecular hydrogen bonds of C–H···O type [33–35] are also present (Fig. 2c and Table 2). Molecules of **3** are linked into centrosymmetric dimers by two O5–H25O···O3 hydrogen bonds. These dimers are further connected into an infinite chain in [100] direction by O5–H15O···O2 hydrogen bond. The chains are mutually assembled in [010] direction only by weak interactions such as C10–H10···O2 hydrogen bond and π···π stacking interaction [36] between pyridine rings defined by atoms N2/C7/C8/C9/C10/C11 (centroid–centroid distance 3.677(2) Å, dihedral angle 0°, slippage 1.431 Å, slip angle 22.9°, symmetry code $2 - x, -y, -z$), forming a layer in *ab* plane (Fig. 2c). The layers are assembled together in a [001] direction by weak C2–H2A···O2 and C3–H3···O4 hydrogen bonds and by π···π stacking interaction [36] between pyridine rings defined by atoms N1/C1/C2/C3/C4/C5 (centroid–centroid distance 3.678(2) Å, dihedral angle 0°, slippage 1.281 Å, slip angle 20.4°, symmetry code $1 - x, 1 - y, 1 - z$), forming a three-dimensional supramolecular architecture.

2.5. Vibrational spectroscopy

Infrared spectroscopy data for **1**, **2** and **3** confirm the coordination of 6-methylpicolinato ligand to copper(II) ion in **1** and **2** and the coordination of 6-bromopicolinato ligand to copper(II) ion in **3** *via* the carboxylate group. Tentative assignments for the origin of the bands in the spectra are based on those found in the literature for cobalt complex with 6-methylpicolinic acid [25] and for complexes of 3-hydroxypicolinic acid [13,37], especially the ones with copper(II) [14]. In the spectra of **1**, **2** and **3**, the band associated to the asymmetric stretching vibrational mode, $\nu_{asym}(-COO^-)$, appears at 1651 cm^{-1} (**1**), 1641 cm^{-1} (**2**) and 1631 and 1683 cm^{-1} (**3**), together with the $\nu_{sym}(-COO^-)$ band at 1365 cm^{-1} (**1**), 1355 cm^{-1} (**2**) and 1335 and 1371 cm^{-1} (**3**). The measured value of $\Delta(\nu_{asym}(-COO^-) - \nu_{sym}(-COO^-))$ amounts 286 cm^{-1} for both **1** and **2**, and 304 cm^{-1} (average Δ value) for **3**, indicating the presence of carboxylato group coordinated to copper(II) ion in the unidentate mode [14,38,39], which is in agreement with the crystal structures of **1**, **2** and **3**. The typical stretching ν(C–N) vibrational mode of substituted pyridines appears for the uncoordinated 6-methylpicolinato ligand at 1612 cm^{-1} and shows shifts (9 cm^{-1} for **1** and 10 cm^{-1} for **2**) to lower wave numbers. These shifts are in a good agreement with *N*,*O*-chelation (involving the endocyclic nitrogen atom of 6-methylpicolinato ligand) proposed for both **1** and **2**. The broad absorption band at 3407 cm^{-1} (**1**) and 3217 cm^{-1} (**3**) indicates hydrogen bonds involving coordinated water molecule present in **1** and **3** [39].

2.6. EPR spectroscopy

The EPR spectrum of **1** shows one copper(II) spin $S = ½$ signal. The signal is weakly resolved and may be related to an elongated axial symmetry of the coordination sphere ($g_{\perp(x,y)} = 2.09$, $g_{\parallel(z)} = 2.21$, Fig. 3). This is in agreement with a distorted square-pyramidal environment around copper(II) (which is very close to the intermediate between trigonal bipyramid and square pyramid) in **1**, suggesting the $\{d_{x^2-y^2}\}^1$ ground state.

The spectrum of **2** reveals one almost isotropic symmetry signal with $g_{av} = 2.16$. This agrees with the same range of lengths for all five coordination bonds to the central copper(II) ion (Cu–O,N 2.005(1)–2.085(2) Å). The determination of the complex ground state is thus not clearcut.

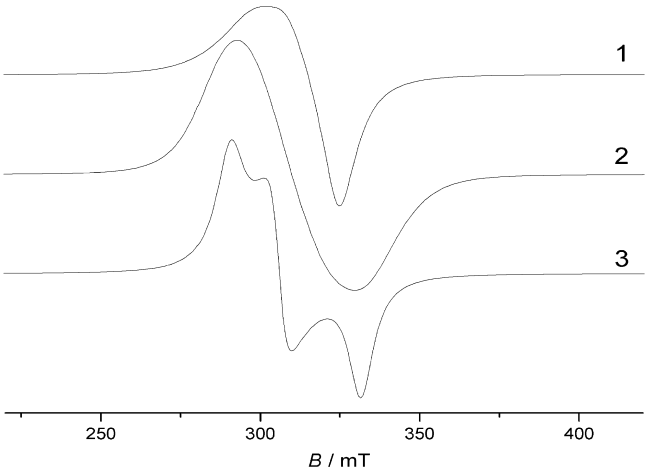

Fig. 3. The EPR spectra of $[Cu(6\text{-}Mepic)_2(H_2O)]$ (**1**), $[Cu(6\text{-}Mepic)_2(py)]$ (**2**) and $[Cu(6\text{-}Brpic)_2(H_2O)]$ (**3**), showing three different types of copper(II) $S = ½$ symmetry signals (**1** – elongated axial, **2** – isotropic, **3** – rhombic).

The spectrum of **3** shows three distinctive signals of the rhombic symmetry with $g_1 = 2.01$, $g_2 = 2.18$ and $g_3 = 2.29$ (Fig. 3). Due to the $g_1 \ll g_2 < g_3$ and $g_1 \sim g_e$, the possibility of the $\{d_{z^2}\}^1$ ground state may be assumed for this complex [40]. The distorted axially compressed trigonal-bipyramidal coordination sphere (which is very close to the intermediate between trigonal bipyramid and square pyramid) in **3** is also in favour of the $\{d_{z^2}\}^1$ ground state, instead of the $\{d_{x^2-y^2}\}^1$, more commonly observed for copper(II) $S = ½$.

2.7. Thermal analysis (TGA/DTA)

Compound **1** is thermally stable up to 150 °C. One water molecule was released in a step with an endothermic peak at 193.5 °C (observed weight loss 5.1%, calculated 5.1%). The thermal decomposition of **1** continues through step with an endothermic peak at 270.3 °C, corresponding to the release of both 6-methylpicolinato ligands (61.3%). The observed residue (33.6%) at 600 °C corresponds to CuO.

Compound **2** is thermally stable up to 130 °C. One pyridine molecule was evolved in a step with an endothermic peak at 155.3 °C (observed weight loss 18.8%, calculated 19.1%). The thermal decomposition of **2** finishes with a step with an endothermic peak at 279.1 °C, corresponding to the release of both 6-methylpicolinato ligands (53.5%). The observed residue (27.7%) at 600 °C corresponds to CuO.

Compound **3** is thermally stable up to 190 °C. One water molecule (observed weight loss 5.0%, calculated 3.7%) and one 6-bromopicolinato ligand (observed weight loss 41.2%, calculated 41.6%) were evolved in a cumulative step with an endothermic peak at 226.2 °C. The further step of the decomposition (22.2%) occurs in the wide temperature range of 310–600 °C and results with the complete decomposition of **3**. The observed residue (31.6%) at 600 °C corresponds to CuO.

2.8. Magnetic measurements

The susceptibility measurements for the complexes **1** and **2** reveal constant $\chi_M \cdot T$ values of 0.42 cm^3 K/mol in the temperature range of 2–300 K suggesting paramagnetic behaviour of both complexes. Differently for **3**, a significant decrease of $\chi_M \cdot T$ appears below 100 K, revealing an antiferromagnetic interaction. The structure of **3** shows a mononuclear molecule, as found also for **1** and **2**. Therefore, the magnetic interaction takes place *via* an alternative path, either through hydrogen bonding (Table 2) or π···π stacking interaction. The hydrogen bonds are connecting the mononuclear units into chains (O5–H15O···O2), as well as into binuclear units (O5–H25O···O3), while π···π stacking into binuclear units (*via* two N1 rings or two N2 rings). To estimate the magnitude of the antiferromagnetic coupling, the magnetic susceptibility data were fitted to the Bleaney-Bowers equation (Eq. (1)) for two interacting copper(II) ions with the Hamiltonian in the form $H = -2J\ S_1 \cdot S_2$ [41]. The least-squares fitting of the data with Eq. (1) leads to $2J = -7.2\ cm^{-1}$, $g = 2.19$, $\rho = 0.035$ (residual paramagnetic contribution) and the theoretical curve using the above parameters is shown as a solid line in Fig. 4. On the other hand, the fitting with the Bonner-Fisher model [41] for 1D chain showed significantly less successful fit with the experimental data. Therefore, the origin for the antiferromagnetic interaction is suggested to be an intradinuclear (e.g. $[Cu(6\text{-}Brpic)_2(H_2O)]_2$) and not within the chain (e.g. $[Cu(6\text{-}Brpic)_2(H_2O)]_n$). Due to the mononuclear coordination moieties in **3**, with no coordination bridges between the Cu(II) species, the alternative or pseudobinuclear units may be suggested. One option for the intradinuclear bridging is by two H-bonds (Cu–O3···H25O–O5–Cu′ and vice versa), but that path may not be appropriate due to the water O5 atom in the equatorial

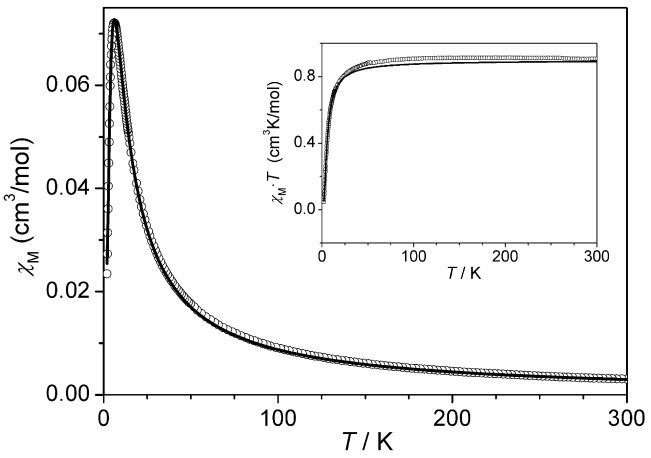

Fig. 4. χ_M and $\chi_M T$ (inset) vs. T experimental (○) and fitted (solid line) curves for $[Cu(6\text{-}Brpic)_2(H_2O)]$ (**3**). Parameters for the Bleaney-Bowers equation of the binuclear moiety are: $2J = -7.2\ cm^{-1}$, $g = 2.19$, $\rho = 0.035$.

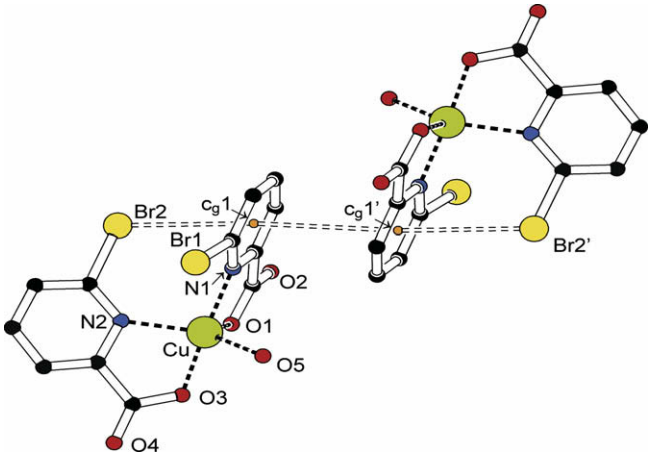

Fig. 5. An almost linear Br···c_g···c_g'···Br′ connection of the bromine atoms and the centroids of the N1 ring atoms into a pseudobinuclear units as found in the structure of $[Cu(6\text{-}Brpic)_2(H_2O)]$ (**3**). Hydrogen atoms are omitted for clarity.

Cu coordination plane (non-magnetic Cu orbital in that direction for the compressed axial geometry), although the oxygen O3 is axially coordinated to copper (magnetic Cu orbital in that direction for the compressed axial geometry). The structure is additionally stabilized by a π···π stacking *via* the ligand pyridine rings, where each ring is stacked by the same type of ring from the adjacent molecule. The N1 pyridine ring is coordinated axially to the copper(II) coordination sphere (the magnetic d_{z^2} orbital), while the N2 ring coordinated equatorially (the non-magnetic $d_{x^2-y^2}$ orbital). Therefore, the N1 rings path (Cu–N1(py)···N1′(py)–Cu′) seems to be the most suitable candidate to maintain the antiferromagnetic interaction in **3**. Interestingly, on almost the same line as both adjacent N1 ring centroids (c_g) are, also two Br atoms from the N2 ligands of the same mononuclear units are present at relatively short distance Br···c_g of 3.478(1) Å, showing a line Br···c_g···c_g'···Br′ within a symmetrical binuclear unit (Fig. 5). This may well be related to the anion (atom)···π interactions, a topic investigated intensively in the last years [42–44].

In the last section, the magnetic interaction within the binuclear units in **3** is discussed due to the presumed $\{d_{z^2}\}^1$ ground state, as at least at first glance could most easily be explained from the structural and the EPR data. Nevertheless, the intermediate geometry between trigonal bipyramid and square pyramid (e.g. $\tau = 0.62$) may clearly suggest a strong d-orbital mixing, so the unpaired electron density is probably in multiple d-orbitals. Therefore, the other *d*-orbitals may as well play an important role in the predominantly binuclear magnetic interaction found for **3**. If that would be the case, another intrabinuclear path should be decisive for the antiferromagnetism in **3**, either N2(py)···N2′(py) or O5–H25O···O3 double H-bond bridges. To verify these pathways, some theoretical calculations would be necessary.

3. Conclusion

We have prepared and fully characterized three copper(II) complexes, namely aquabis(6-methylpyridine-2-carboxylato-*N*,*O*)copper(II), [Cu(6-Mepic)$_2$(H$_2$O)] (**1**), bis(6-methylpyridine-2-carboxylato-*N*,*O*)(pyridine)copper(II), [Cu(6-Mepic)$_2$(py)] (**2**) and aquabis(6-bromopyridine-2-carboxylato-*N*,*O*)copper(II), [Cu(6-Brpic)$_2$(H$_2$O)] (**3**) which were characterized by elemental analysis, IR and EPR spectroscopy and by thermal methods (TGA/DTA), while their crystal structures were determined by X-ray single-crystal diffractometry method. The magnetic susceptibility of powdered polycrystalline samples of **1**–**3** were measured in order to obtain more information about their magnetic behaviour.

Synthesis of **1** and **3** were done in mildly alkaline solution, although **1** and **3** can be prepared in acidic solution as well, but with smaller yields. The X-ray structural analysis revealed the intermediate between square-pyramidal and trigonal-bipyramidal coordination around copper(II) ion in both **1** and **3**. It is evident that substituent in the ligands' pyridine ring (electron-donating methyl group in 6-methylpicolinic acid or electron-withdrawing bromine atom in 6-bromopicolinic acid) has influence on the crystal packing patterns of **1** and **3**. Molecules of **1** are assembled by intermolecular O–H···O hydrogen bonds into 2D network. These networks interact through π···π stacking in the third dimension. Molecules of **3** are linked into centrosymmetric dimers which are connected into infinite chains, both by intermolecular O–H···O hydrogen bonds. These chains are linked into 3D structure by π···π stacking. Complex **2** was prepared by a recrystallization of **1** from pyridine. Substitution of water molecule by pyridine molecule affects both coordination polyhedron and crystal packing pattern, leading to a trigonal-bipyramidal geometry of **2** in contrast to **1**. 3D supramolecular structure of **2** is supported only by weak interactions such as intermolecular hydrogen bonds of C–H···O type.

The methyl group or bromine atom, as a substituent in the ligands' pyridine ring, mostly affect the type of the coordination polyhedron around copper(II), leading to the pentacoordinated copper(II) ion in **1**, **2** and **3**. This is quite different from the copper(II) complexes with picolinic [45], 3-hydroxypicolinic [8] and 6-hydroxypicolinic acid [12] reported in the literature. The coordination environments in these complexes are usually square-planar or octahedral and square-pyramidal only in copper(II) complex with 3-methylpicolinic acid [31]. However, the Cu–N and Cu–O

bond distances in **1**, **2** and **3** are in agreement with the values reported in the literature for the abovementioned complexes [8,12,31,45].

EPR spectra show three different types of copper(II) $S = ½$ symmetry signals. Most probably they could be assigned to the elongated axial in **1**, the isotropic in **2** and the rhombic in **3**. The ground state is suggested to be $\{d_{x^2-y^2}\}^1$ for **1** and $\{d_{z^2}\}^1$ for **3**, while we were unable to determine it for **2**.

The measurements of magnetic susceptibility revealed paramagnetic behaviour of both **1** and **2**, as it was expected. On the other hand, **3** exhibits an antiferromagnetic interaction. This interaction is ascribed to the formation of pseudobinuclear units by $\pi\cdots\pi$ stacking between pyridine rings.

4. Experimental

4.1. Materials and physical measurements

All chemicals for the syntheses were used as received without further purification. Copper(II) sulfate pentahydrate was purchased from Merck, while 6-methylpicolinic and 6-bromopicolinic acids were purchased from Aldrich.

CHN analyses were performed on Perkin–Elmer 2400 Series II CHNS analyzer in the Analytical Services Laboratories of the Ruđer Bošković Institute, Zagreb, Croatia.

The IR spectra were obtained from KBr pellets in the range 4000–450 cm^{-1} with a Perkin–Elmer Spectrum RXI FTIR-spectrometer.

TGA/DTA measurements were performed at a heating rate of 5 °C/min for **1** and **3** and 10 °C/min for **2** in the temperature range of 25–600 °C, under nitrogen flow of 10 mL/min on instrument Mettler-Toledo TGA/SDTA 851[e]. Approximately 10 mg of sample were placed in standard aluminium crucible (40 μL).

X-band powder EPR spectra were recorded at room temperature on a Bruker ESP-300 electron spin resonance spectrometer. The g values were calculated by the equation $E = h\nu = g\beta_e B$.

The magnetic susceptibility data of powdered polycrystalline samples were measured with a Quantum Design SQUID MPMS-XL-5 magnetometer, equipped with a 5 T magnet. The molar magnetic susceptibility χ_M was investigated in the temperature interval between 300 and 2 K in a magnetic field strength $H = 1000$ Oe. The data were corrected for the experimentally determined contribution of the sample holder. Corrections for the diamagnetic response of the compounds, due to closed atomic shells as estimated from the Pascal's constants, were applied [41].

4.2. Synthesis of aquabis(6-methylpyridine-2-carboxylato-N,O)copper(II), [Cu(6-Mepic)$_2$(H_2O)] (**1**)

A solution of 6-methylpicolinic acid (0.40 g, 2.92 mmol) in water (15 mL) was added to a solution of copper(II) sulfate pentahydrate (0.36 g, 1.44 mmol) in water (5 mL). The pH value of the resulting deep blue solution was adjusted to 8 by adding a few drops of concentrated ammonia solution. The blue product was formed immediately and it was left to stand at room temperature until the next day to complete precipitation. The product was then filtered off, washed with water and dried in a desiccator over $CaCl_2$. Yield: 0.44 g (86.3%). *Anal.* Calc. for $C_{14}H_{14}CuN_2O_5$ (353.81): C, 47.52; H, 4.00; N, 7.92. Found: C, 47.27; H, 4.17; N, 8.57%. IR data (KBr pellet, cm^{-1}): 3407m, 1651s, 1603s, 1573m, 1468m, 1407m, 1365s, 1260m, 803m, 767s.

The crystals suitable for X-ray crystal structure analysis were obtained by slow evaporation of the mother liquor solution, remained after filtration of the product described above, at room temperature.

4.3. Synthesis of bis(6-methylpyridine-2-carboxylato-N,O)(pyridine)copper(II), [Cu(6-Mepic)$_2$(py)] (**2**)

A solution of **1** (0.20 g, 0.57 mmol) in pyridine (7 mL) was left to stand at room temperature for five days to give a blue product, which was filtered off and dried *in vacuo*. Yield: 0.14 g (59.7%). *Anal.* Calc. for $C_{19}H_{17}CuN_3O_4$ (414.91): C, 54.99; H, 4.14; N, 10.13. Found: C, 54.95; H, 4.29; N, 11.20%. IR data (KBr pellet, cm^{-1}): 1641s, 1602s, 1572m, 1448m, 1355s, 1255m, 795m, 769m, 712m.

The crystals suitable for X-ray crystal structure analysis were obtained by recrystallization from pyridine.

4.4. Synthesis of aquabis(6-bromopyridine-2-carboxylato-N,O)copper(II), [Cu(6-Brpic)$_2$(H_2O)] (**3**)

A solution of 6-bromopicolinic acid (0.20 g, 0.99 mmol) in water (15 mL) was added to a solution of copper(II) sulfate pentahydrate (0.12 g, 0.48 mmol) in water (5 mL). The pH value of the resulting light blue solution was adjusted to 7 by adding a few drops of concentrated ammonia solution. The blue product was formed slowly and it was left to stand at room temperature until the next day to complete precipitation. The product was then filtered off, washed with water and dried in a desiccator over $CaCl_2$. Yield: 0.18 g (78.3%). *Anal.* Calc. for $C_{12}H_8Br_2CuN_2O_5$ (483.56): C, 29.80; H, 1.67; N, 5.79. Found: C, 29.54; H, 1.70; N, 6.20%. IR data (KBr pellet, cm^{-1}): 3217m, 3078m, 1683s, 1653m, 1631s, 1588s, 1552s, 1437s, 1408m, 1371s, 1335s, 1247m, 1177m, 1161s, 1140m, 1124m, 1078m, 1004m, 784s, 775m, 750m, 668m.

The crystals suitable for X-ray crystal structure analysis were obtained by slow evaporation of the mother liquor solution, remained after filtration of the product described above, at room temperature.

4.5. X-ray single-crystal structure determination

Suitable single crystals of **1**, **2** and **3** were selected and mounted in air onto thin glass fibres. The data collection was carried out on Oxford Diffraction Xcalibur four-circle kappa geometry single-crystal diffractometer with Xcalibur Sapphire 3 CCD detector by applying the CRYSALIS Software system, Version 171.32.4 at room temperature (296 K) [46]. Data reduction has been applied by the same programme [46]. Eleven runs containing 1277 data collection frames for **1**, 11 runs containing 1425 data collection frames for **2** and 13 runs containing 1603 data collection frames for **3** were collected at the crystal–detector distance of 60 mm with the exposure time of 20, 20 and 15 s for **1**, **2** and **3**, respectively, and with ω scan type for all structures.

The X-ray diffraction data have been corrected for Lorentz-polarization factor and scaled for absorption effects by multi-scan. The structures were solved by direct methods. Refinement procedure by full-matrix least squares methods based on F^2 values against all reflections has been performed including anisotropic displacement parameters for all non-H atoms.

The positions of hydrogen atoms belonging to the carbon atoms Csp^2 and methyl Csp^3 atoms were geometrically optimized applying the riding model [Csp^2–H, Csp^3(methyl)–H, 0.93 Å and 0.96 Å, respectively; $U_{iso}(H) = 1.2U_{eq}(C)$ for Csp^2 and $1.5U_{eq}(C)$ for Csp^3(methyl)]. H atoms belonging to water molecules in **1** and **3** were found in difference Fourier maps and restrained with the average O–H value of 0.82(5) Å using SHELXL-97 DFIX instruction.

Calculations were performed with SHELXS-97 [47], SHELXL-97 [47] and PLATON [48]. The molecular graphics were done with ORTEP-3 [49] and MERCURY (Version 1.4.2) [50].

Crystal data and details of the structure determination for **1**, **2** and **3** are given in Table 3.

grade. The epoxides and used solvents were purified by standard procedures.

2.2. Apparatus

IR spectra were recorded as KBr pellets on a Perkin–Elmer 781 spectrophotometer and on an Impact 400 Nicolet FTIR spectrophotometer. ^{1}H NMR spectra were recorded with a 400 MHz spectrometer in dimethylsulfoxide (DMSO) using tetramethylsilane (TMS) as an internal reference. The melting points were determined by a Yanagimoto micro melting point apparatus. The purity determination of the substrates and reaction monitoring were accomplished by thin layer chromatography (TLC) on silica gel polygram SILG/UV 254 plates. The chromatography was carried out on Silica Gel 60 (70–230 mesh).

2.3. General procedure

2.3.1. General procedure for the preparation of the Schiff base ligands

To a mixture of salicylaldehyde (0.4 g, 3.27 mmol) in MeOH was added the diamine (1.65 mmol) with stirring in one portion. The stirring was continued to completion the reaction. The progress of the reaction was monitored by thin layer chromatography (TLC). After the completion of the reaction, a colored substance was obtained. The solid product was filtered off and washed with cold MeOH. The crude product was purified by recrystallization from ethanol and the pure Schiff base was obtained in high yield after leaving for the appropriate time. The Schiff base products were identified by physical and spectroscopic data and by a comparison with authentic samples prepared in accordance to the literature procedures [20].

2.3.2. General procedure for the preparation of the Schiff base complexes of metal(II)

To a solution of the Schiff base ligand (1 mmol) in MeOH (10 ml) was added $M(O_2CCH_3)_2$ (1 mmol) dropwise under reflux conditions. The reaction mixture was stirred to completion the reaction. The progress of the reaction was monitored by TLC. After the completion of complex formation, a colored substance was obtained. The solid product was filtered off and washed with MeOH. The crude product was purified by recrystallization from methanol and the pure Schiff base complex was obtained. The complex products were identified by comparison with authentic samples prepared in accordance to the literature procedures [20].

2.3.3. General procedure for the preparation of the catalysts

Alumina was activated by treatment at 500 °C for 8 h. Then 2 g of activated alumina was added to 0.02 mmols of each of the complexes and the obtained mixture was stirred for 0.5 h. The catalysts were analyzed by dissolving a known amount of catalyst in concentrated hydrochloric acid, then using an atomic absorption spectrophotometer.

2.3.4. General procedure for conversion of epoxides to β-halohydrins

A mixture of 1.0 g catalyst **2a**, 25 ml CH_2Cl_2 as solvent and 10 mmol substituted epoxide was stirred in a 50 ml round-bottom flask equipped with a condenser and a dropping funnel at room temperature. Then a solution of 10 mmol halogen (Br_2 or I_2) in 5 ml dichloromethane was added dropwise over 20 min to the above-mentioned mixture. The progress of the reaction was monitored by gas chromatography (GC) and TLC. After the complete disappearance of the starting material, the reaction mixture was filtered and the obtained solution was washed with 10% aqueous $Na_2S_2O_3$ (2×10 ml) and water (2×10 ml). The aqueous layer was further extracted with CH_2Cl_2 (2×10 ml). The combined organic layer was dried over $MgSO_4$. The solvent was evaporated, and the pure halo alcohol was obtained. The halo alcohol products were identified by a comparison with authentic samples prepared accordance to the literature procedures [20,23–29].

3. Results and discussion

Schiff base complexes of metal (II) have been recognized as being among the most promising catalysts for various reactions. These complexes show wide applicability and are now used as catalysts for a variety of enantioselective reactions, such as oxidation [30,31], aziridination [32], cyclopropanation [33], the Diels–Alder reaction [34,35], the addition of TMSCN to aldehydes [36,37], the Sterecker reaction [38], and the conversion of 1,2-epoxyethanes to 2-haloethanols with molecular halogen [20]. Metal(II)-salen complexes can be readily synthesized from metal(II) salts and salen ligands, which are prepared by simply mixing 1 mol of various diamines and 2 mol of salicylaldehyde.

Indeed the whole area of supported transition metal complex catalysts is rapidly expanding again as the advantages which arise from ease of handling, recovery, separation and recycling, coupled with the potential for automation which has become recognized by more and more rank-and-file industrial and academic synthetic chemists [39,40]. Nowadays, on the basis to immobilize the transition metal complex catalysts, key targets are highly active and selective asymmetric catalysts. Heterogeneous analogues [41] of these homogeneous catalysts would not only simplify their use and facilitate product separation and isolation, but would also offer considerable economic benefits if recycling and their reuse were possible.

The preparation of catalysts readily occurred via the immobilized complexes on activated alumina (alumina was activated at 500 °C for 8 h before use) [21] and were estimated by dissolving a known amount of the catalyst in concentrated HCl (Scheme 1). From this solution, transition metal contents were estimated on an atomic absorption spectrometer (AAS) [21]. The concentration of the metal ions was 0.01 mmol/gr.

In this study, the reaction of styrene oxide with iodine and bromine in the presence of some alumina-supported Mn(II) Schiff base-complexes as the catalyst were carried out (Scheme 2).

A mixture of 1.0 g catalyst, 25 ml solvent and 10 mmol styrene oxide was stirred in a 50 ml round-bottom flask equipped with a condenser and a dropping funnel at room temperature. Then 10 mmol of halogen (solution in 5 ml dichloromethane) was added dropwise. The resulting mixture was stirred at 25 °C and was checked by GC and TLC analysis up to the end of the reaction. After filtration and washing with solvent, workup of the filtrate with thiosulfate and concentration of the solution, was obtained the

Table 1
Reaction of styrene oxide with elemental iodine and bromine in the presence of various Al_2O_3–SB complexes as catalysts in CH_2Cl_2 at 25 °C

Entry	Catalyst	Iodination		Bromination

[a] Isolated product yields based on epoxide.

neat products (**3a–p**). The results of the reaction of 1,2-epoxy-3-phenylpropane with elemental iodine and bromine in the presence of the above-mentioned catalysts are summarized in Table 1.

In each case, cleavage of the epoxide ring occurs. The reaction product was 2-halo-1-phenylethanol, and the yields were determined by GC and TLC analysis. The catalysts were easily recovered and could be reused several times.

In comparison, the cleavage behavior of styrene oxide with elemental iodine and bromine in the absence of catalyst is given in Table 1, entry 7. Iodination of styrene oxide did not occur with excess elemental iodine in the absence of a catalyst even under refluxing conditions and an extension of the reaction time to several days [42]. In addition, the yield and regioselectivity of the bromination reaction were very low in the absence of catalyst. As shown in Table 1, the yields of both iodination and bromination with this new methodology are quite fair. The catalysts **2a**, **2b** and **2c** are the most effective ones in these reactions.

It seems that immobilizing of the complexes obtained from the Schiff base ligand obtained from ortho phenylene diamine on an alumina surface is stronger and more suitable than the other ones; as a result the utilized catalyst has a better effect in the reaction. As it is shown in the results, the yield of the products of β-halohydrin in the reactions with these Schiff base ligands is more significant.

Moreover, the effect of various first-row transition metals(II) in supported Schiff base complexes as catalysts on the reaction rate and the yield of bromination and iodination reactions are featured in Table 1 (entries 4–6). As can be seen by using the supported Mn(II)-salen complex as a catalyst, the iodo alcohol and bromo alcohol were formed in high yields and the reaction rate was much faster than other metal complexes. These results are comparable with the results of the usage of Schiff base complexes as catalysts presented previously [20].

To ascertain the scope and limitation of the ring-opening reactions promoted by the above mentioned supported complexes, the reactions on various epoxides were carried out (Scheme 2). The results of the reactions with some representative epoxides in the presence of complex **2a** as the catalyst are indicated in Table 2.

However, other factors can exert a controlling influence such as; (1) steric hindrance of the epoxides (for example, compare in Table 2, entry 7 with entry 8); (2) the nature of the solvent; (3) the rate of admixing the reagents; and (4) the order in which the reagents are combined. Each one can have a pronounced effect on the observed ratio of β-halohydrins isomers and the overall yield.

The order and rate in which the reagents are combined were found to exert a subtle influence on the yield and regioselectivity in both bromohydrin and iodohydrin formation. For example, if bromine is added to the epoxide before the catalyst is added, two bromohydrin isomers are produced, but if the epoxide is added to the catalyst and then bromine is added dropwise over a period of time, only one isomer is formed. Furthermore, it appears that fast addition of bromine can reduce the regioselectivity too.

The results of the ring opening of styrene oxide in the presence of catalyst **2a** in various solvents are summarized in Table 3. The iodination and bromination reactions can cleanly proceed in dichloro-methane, while those performed in THF, DMSO, chloroform, diethylether and acetonitrile lead to a lower yield of the β-halohydrins.

As shown in Table 2 (entry 5), where only the *trans* isomers were detected, the reactions are completely *anti*-stereoselective. A contra-Markovnikov-type [3,43] regioselectivity is generally observed in these reactions. In many cases, this type of regioselectivity appears to be the opposite of that observed in the ring opening of the same epoxides with aqueous hydrohalogenic acid, under classic conditions [44] (entries 14 and 15). However, this new method appears to be highly competitive with the other methods reported in the literature. The reaction occurs under neutral and

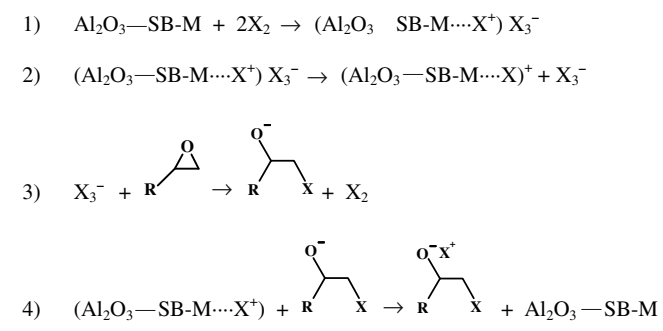
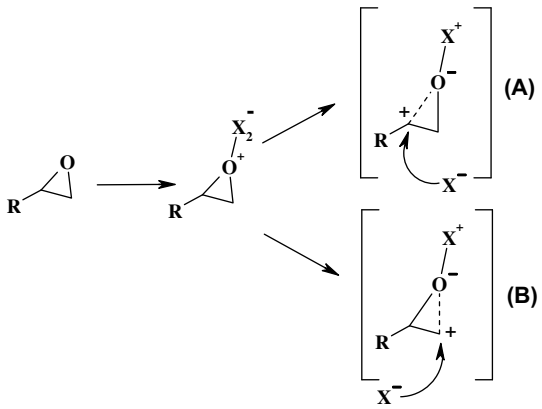
[a] GC yield.



Scheme 3. The mechanism of halogenative cleavage of epoxides with the Al_2O_3–SB-M catalyst.



Scheme 4. The cleavage of epoxides in the absence of a catalyst.

mild conditions on the acid sensitive substrates and vicinal halohydrins were obtained in high yields and with high regioselectivity.

The regiochemical mode of epoxide cleavage by elemental iodine or bromine in the presence of alumina supported Schiff base complexes as a catalyst can be viewed as occurring via nucleophilic attack by a halide ion on the less sterically hindered epoxide carbon. This mechanism closely resembles the S_N2 model for aliphatic nucleophilic displacement. On the basis of accomplished research on the complexation of Schiff base metals [20] and other works reported on different ligands [42,45–48] with elemental halogen, the mechanism of halogenative cleavage of epoxides with this new catalyst follows the given mechanism for the same reaction with Schiff base complexes as catalysts [20] and is done in the following four steps (Scheme 3):

The first step (Eq. (1), Scheme 3) involves the formation of a 1:2 or 1:1 molecular complex between the catalyst and elemental halogen, in which the halogen ion (X_3^-) exists as a contact ion pair [49]. In the second step (Equation 2) this complex is further decomposed to release the X_3^- ion into the solution. Therefore, in this way, molecular iodine or bromine is converted to a nucleophilic halogen species in the presence of Al_2O_3–SB-M and, in the third step (Eqs. (3) and (4)), this ion participates in the ring opening reaction of the epoxides, and the catalyst is reproduced and is used in the first step again. These steps occur continuously until all of the epoxides and halogen are consumed, and after filtrations, the catalyst can be recovered easily.

On the other hand, when the catalyst is not present, cleavage of epoxides can occur via two limiting mechanistic pathway, either electrophilic attack by molecular halogen, behaving as a Lewis acid, giving the more stable carbonium ion-like transition state **A** (Scheme 4), or via nucleophilic attack by the halide ion on the epoxide or epoxide-halogen complex, giving the more stable transition state **B**. Most Lewis acidic compounds, such as titanium halides, foster electrophilic opening of the epoxide ring to yield transition state **A**. When weaker Lewis acids are employed, namely bromine or iodine, nucleophilic attack, by the halide ions generated, should be fostered and transition state **B** may be expected to be lower in energy. In this case, the cleavage leads to a mixture of secondary and primary alcohol products [3].

In addition, the advantages such as high regio- and stereoselectivity of the reactions, stability, commercially availability, inexpensive catalysts, high yield and ease of workup make this method a useful addition to the present methodologies in organic synthesis. All the products are known compounds and yields refer to GC yields.

4. Conclusions

In conclusion, this new method for the preparation of vicinal haloalcohols have some advantages such as high regioselectivity, high yields of products, short reaction times relative to other procedures, and simplicity of workup. This reaction occurs under neutral and mild conditions on acid sensitive substrates and appears to be highly competitive with the other methods reported in the literature.

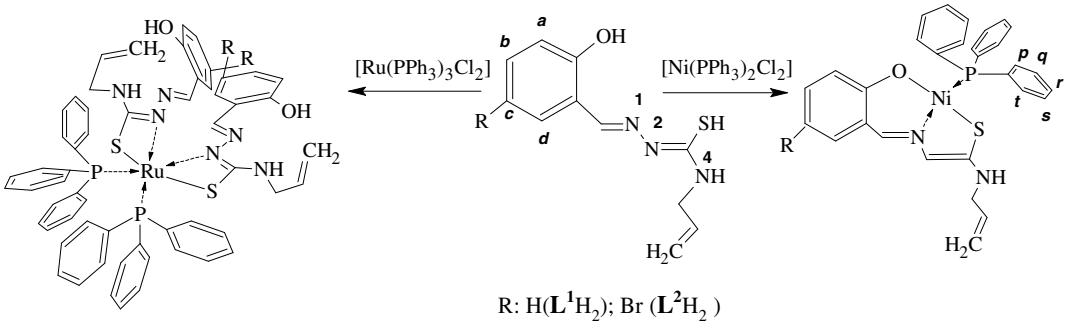

Fig. 1. The formation of the [Ni(L)(PPh$_3$)] and [Ru(HL)$_2$(PPh$_3$)$_2$] complexes.

complexes were recorded in 10^{-4} M $CHCl_3$ solution with an ATI-Unicam spectrometer in the 800–200 nm range. The ^{1}H and ^{31}P NMR spectra were recorded on a Bruker Avance-500 model spectrometer using DMSO-d_6 as solvent, relative to $SiMe_4$ and H_3PO_4, respectively. Magnetic measurements were carried out at room temperature with a Sherwood Scientific MK I apparatus by using $CuSO_4.5H_2O$ as the calibrant. The molar conductivities of the compounds were measured in 10^{-3} M DMSO solution at 25 ± 1 °C using a digital WPA CMD 750 conductivity meter.

The APCI MS analyses were carried out in the positive ion mode using a Thermo Finnigan LCQ Advantage MAX LC/MS/MS. The mobile phase consisted of MeOH. A hypersil Betabasic-8 (5 μ, 100 mm × 4.6 mm) column was used at a flowrate of 0.5 ml/min at 25 °C. APCI-MS inlet conditions in the positive ion mode: heated capillary temp. 200 °C; vaporizer temp. 450 °C.

2.2. Synthesis of the ligands and complexes

2.2.1. Ligands

The ligands, $\mathbf{L^1}H_2$ and $\mathbf{L^2}H_2$, were prepared by the literature method [34]. The colours, m.p. (°C), yields (%), R_f value (hexane–EtAc, 2:1), elemental analysis, UV–Vis. (λ_{max} (ε), nm (dm^3 cm^{-1} mol^{-1})), IR (cm^{-1}) and ^{1}H NMR (ppm, J in Hz) data of the ligands are as follows:

$\mathbf{L^1}H_2$: Cream, 155-157; 82; 0.50. *Anal.* Calc. for $C_{11}H_{13}N_3OS$ (235.3 g): C, 56.15; H, 5.57; N, 17.86; S, 13.63. Found: C, 56.19; H, 5.57; N, 17.95; S, 13.61%. 2.2.2. Complexes

2.2.2.1. Synthesis of [NiL^1(PPh$_3$)] (I). A solution of 2-hydroxy-benzaldehyde-4-allyl-thiosemicarbazone ($\mathbf{L^1}H_2$) (50 mg, 1 mmol) in dichloromethane (10 ml) was added dropwise to a solution of [Ni(PPh$_3$)$_2$Cl$_2$] (139 mg, 1 mmol) in 10 ml of absolute ethanol under a nitrogen atmosphere. The solution was stirred for 5 h at room temperature. The resulting dark red precipitate was collected by filtration, and dried over anhydrous $CaCl_2$.

The complex [Ni($\mathbf{L^2}$)(PPh$_3$)] was prepared in a similar manner. The colours, m.p. (°C), yields (%), R_f ($CHCl_3$), μ_{eff} value (BM), molar conductivity (ohm^{-1} cm^2 mol^{-1}), elemental analysis, electronic, IR (cm^{-1}) and NMR (ppm, J in Hz, *p–t* are the symbols for the PPh$_3$ protons) data of the nickel complexes are as follows:

*[Ni(L^1)(PPh$_3$)](**I**):* Red; 198-199; 85; 0.52; 0.12; 8.2. *Anal.* Calc. for $C_{29}H_{26}N_3OPSNi$ (554.27 g): C, 62.84; H, 4.73; N, 7.58; S, 5.79; Ni, 10.59. Found: C, 62.79; H, 4.79; N, 7.43; S, 5.99; Ni, 10.68%. UV–Vis (nm, dm^3 cm^{-1} mol^{-1}): 246 (76320), 299 (shoulder), 366 (12420), 412 (7110), 819 (80), 962 (30). 2.2.2.2. Synthesis of [Ru(L^{1}H)$_2$(PPh$_3$)$_2$](III). Triethylamine was used to pluck the acidic –SH proton in the synthesis of the Ru complexes because the ruthenium complexes were not obtained according to the syntheses procedure of the nickel complexes. To the solution of

the salicylaldehyde-4-allyl-thiosemicarbazone ligand (100 mg; 1 mmol) in absolute ethanol (15 ml) was added triethylamine (0.15 ml), and the mixture was stirred for 1 h under a nitrogen atmosphere at room temperature. The mixture was combined with a suspension of $[Ru(PPh_3)_3Cl_2]$ (408 mg, 1 mmol) in 10 ml of dichloromethane and refluxed for 5 hours. After several days, yellow plates were isolated and dried over anhydrous $CaCl_2$.

The complex $[Ru(\mathbf{L^2}H)_2(PPh_3)_2]$ (**IV**) was synthesized by means of the same procedure. The colours, m.p. (°C), yields (%), R_f (pet-ether:$CHCl_3$, 1:1), μ_{eff} value (BM), molar conductivity ($ohm^{-1}\,cm^2\,mol^{-1}$), elemental analysis electronic, IR (cm^{-1}) and NMR (ppm, *J* in Hz) data of the **III** and **IV** are as follows:

$[Ru(L^1H)_2(PPh_3)_2]$ (**III**)*:* Yellow; 174–175; 71; 0.38; 0.22; 9.9. *Anal.* Calc. for $C_{58}H_{54}N_6O_2P_2S_2Ru$ (1094.24 g): C, 63.66; H, 4.97; N, 7.68; S, 5.86. 2.3. X-ray crystallography

2.3.1. $[NiL^2(PPh_3)]$ (II)

A red prism crystal of $C_{29}H_{25}BrN_3NiOPS$ of dimensions 0.60 × 0.40 × 0.20 mm was mounted on a glass fiber. All measurements were made on a Rigaku RAXIS RAPID imaging plate area detector with graphite monochromated Mo Kα radiation. The absorption correction was applied using the multi-scan technique [35]. The structure was solved by direct methods [36] and the molecular structure is shown in Fig. 2. The non-hydrogen atoms were refined anisotropically. H atoms were positioned geometrically and treated using a riding model, fixing the bond lengths at

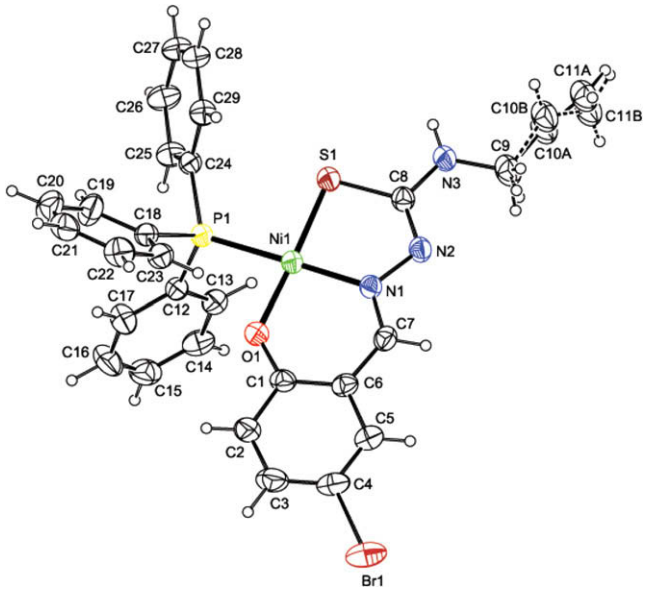

Fig. 2. Molecular structure of $[Ni(L^2)(PPh_3)]$, showing 30% probability displacement ellipsoids and the atom numbering scheme. The H atoms have been omitted for clarity.

0.97 Å for atom C9, 0.93 Å for the phenyl rings and atoms C7, C10 and C11, and 0.86 Å for the NH group. The displacement parameters of the H atoms were constrained as $U_{iso}(H) = 1.2U_{eq}$ of the parent atom. In the molecule, the (C10–C11) group shows positional disorder and the refined site-occupancy factors of the disordered parts, viz. C10A–C11A and C10B–C11B, are 70(1) and 30(1)%, respectively. The disordered atoms were refined using the following restraints: SIMU, DELU and SADI [37].

2.3.2. $[Ru(L^1H)_2(PPh_3)_2]$(III)

A brown prism crystal of $C_{58}H_{54}N_6O_2P_2RuS_2$ of dimensions 0.72 × 0.52 × 0.28 mm was mounted on a glass fiber. All measurements were made on a STOE IPDS 2 imaging plate area detector with graphite monochromated Mo Kα radiation. The absorption correction was applied using X-RED32 [39]. The structure was solved by direct methods [36] and refined by full-matrix least-squares refinement [37]. H atoms bounded to C atoms were positioned geometrically and treated using a riding model, fixing the bond lengths at distances in the range 0.93–0.97 Å, and with $U_{iso}(H) = 1.2U_{eq}(C)$. The H atoms bound to the N and O atoms were found from a Fourier map and refined freely.

3. Results and discussion

3.1. Some physical properties of the compounds

The thiosemicarbazone ligands are in the form of powder crystals, and they are soluble in methanol, ethanol and chlorinated hydrocarbons. The reactions of the ligands with $[NiCl_2(PPh_3)_2]$ and $[RuCl_2(PPh_3)_3]$ in a 1:1 molar ratio in ethanol-dichloromethane mixture yielded the 1:1 and 1:2 complexes of the formula $[Ni(L)(PPh_3)]$ and $[Ru(LH)_2(PPh_3)_2]$, respectively. The complexes (I–IV) form as very fine crystal materials, and they are very soluble in common organic solvents. The relative low molar conductances of **I**–**IV** between 5.9 and 10.9 $ohm^{-1}\,cm^2\,mol^{-1}$ indicate non-ionic structures. All the complexes are stabile in air, and the magnetic susceptibility values (0.12–0.22 BM) evince a square planar environment of the d^8 nickel ion and a low-spin structure (d^6) of the ruthenium ion in the 2+ oxidation state.

3.2. Spectral data

UV–Vis spectra of the ligands and complexes showed the expected $\pi \rightarrow \pi^*$ bands at 217–251 nm. The bands in the range 270–355 nm may be assignable to $n \rightarrow p^*$ transitions of the azomethine and thioamide region of the thiosemicarbazone moiety [39]. The spectra of the nickel complexes show broad bands in the visible region that are probably due to the expected MLCT transitions. The absorptions at 336 (for I) and 372 (for II) nm may be attributed to S → nickel(II) charge-transfer transitions, Although these bands did not separate, the triple band appearance of absorptions in the visible region indicate that **I** and **II** consist of a square planar geometry around the nickel(II) ion [40]. For the ruthenium complexes, the $(4d\pi) \rightarrow \pi^*$(thioamide) transitions appear at 382 and 393 nm, respectively for **III** and **IV**. The bands at 960 (for III) and 967 (for IV) nm can be designated as d–d transition bands of a spin-paired d^6 species with a distorted octahedral structure [41].

The chelation of the thiosemicarbazone ligands can be easily monitored by means of IR and ^{1}H NMR spectra. In the infrared spectra of the ligands, the bands of the NH and OH groups were clearly visible in the regions 3500–3150 and 1640–1550 cm^{-1}. After the complexation, ν(OH) and one of the N^2H and N^4H bands, probably N^2H, disappear in the IR spectra of the nickel complexes (**I** and **II**), while only the vibrations of N^2H were removed from the spectra of the ruthenium complexes **III** and **IV**. The $\nu(C{=}N^1)$ bands of **I**–**IV** were recorded with a shift of approx. 8 cm^{-1} to lower frequencies compared to the free ligands.

The NMR signals of the ligand protons showed the expected chemical shift values [38–40]. After chelation of the nickel(II) ion, the proton signals of OH and N^2H were absent in the spectra of **I** and **II**. Because $\mathbf{L^1}$ and $\mathbf{L^2}$ act as bidentate ligands through the N^2 and S atoms towards ruthenium(II), the signals of the phenolic proton can be still observed at *ca.* 10 ppm in the spectra of **III** and **IV**. In all the complex spectra, the chemical shifts of the N^4H protons were recorded at a higher field compared to the free ligands, but the CH=N protons were to a lower field region.

In the ^{31}P NMR spectra of the nickel and ruthenium complexes, the bands which were observed in the range 18.54–24.02 ppm are attributed to the P atom in the basal plane, while the bands at −75.28 ppm (**III**), −76.86 ppm (**IV**) in the spectra of the ruthenium complexes are assigned to an apical P atom.

The analytical and spectral results indicate that the nickel complexes give 1:1 complexes with an ONS coordination mode, and the

Single crystals of **I–IV** were grown by crystallization from ethanol by ether diffusion. Crystallographic analyses of **II** and **III** were carried out and are reported here.

3.3. X-ray structure determination

3.3.1. Crystal structure of $[NiL^2(PPh_3)]$ (II)

Additional information for the structure determinations are given in Table 1. Selected bond distances, angles and torsion angles are listed in Table 2.

In the $[Ni(\mathbf{L^2})(PPh_3)]$ complex (Fig. 2), the structure of the molecule adopts a square planar geometry with O1–Ni1–S1 and N1–Ni1–P1 bond angles of 177.23(12) and 175.13(13)°, respectively (Table 2). The Ni atom almost lies in the basal plane containing the P, N, S and O donor atoms. The geometric parameters are comparable to those observed in other similar complexes [42].

In the Ni complex, the molecular conformation is stabilized by C–H···O and C–H···Br intramolecular hydrogen bonding interactions (Table 3). The crystal packing interactions and the hydrogen bonds of the title complex are shown in Fig. 3.

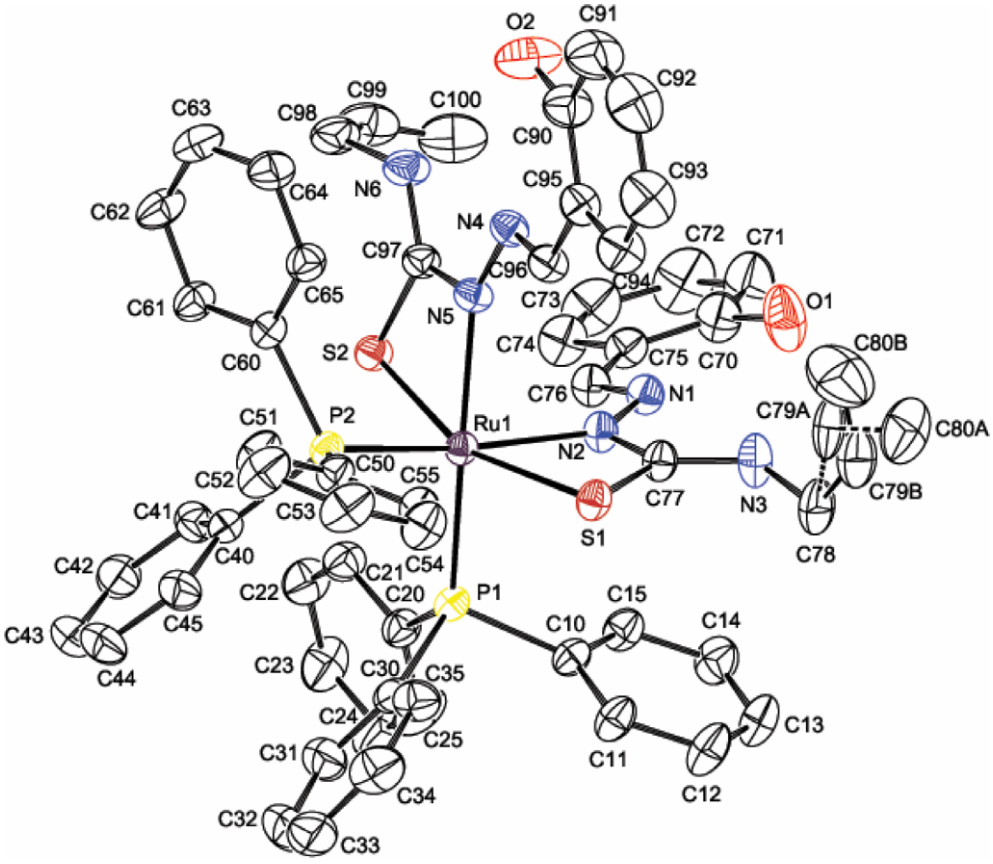

Fig. 4. Molecular structure of $[Ru(L^1H)_2(PPh_3)_2]$, showing 30% probability displacement ellipsoids and the atom numbering scheme. The H atoms have been omitted for clarity.

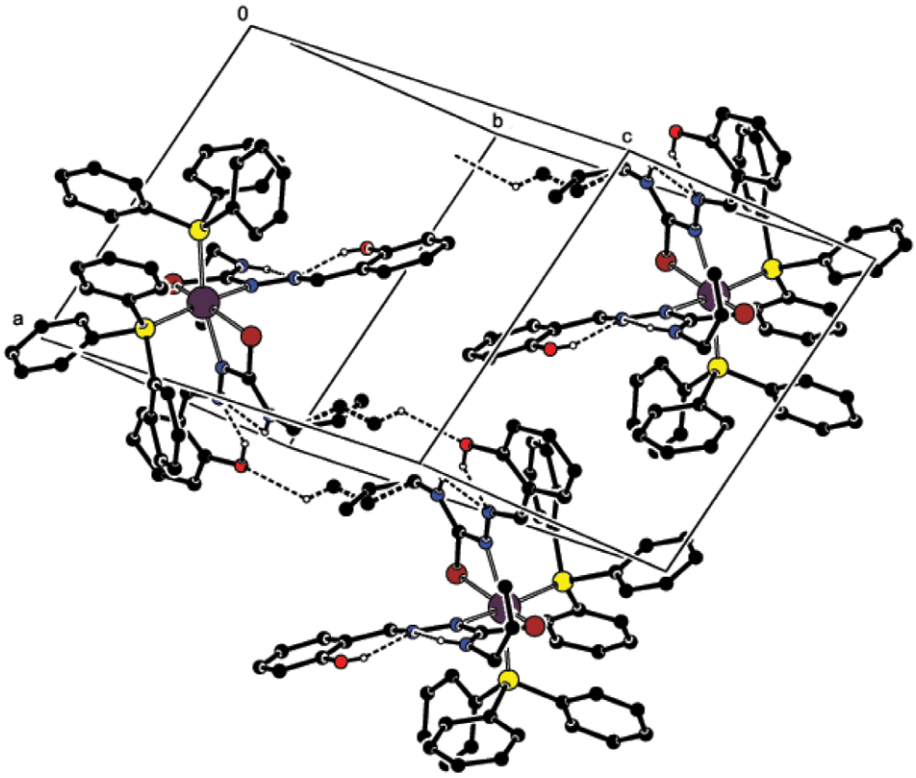

Fig. 5. A view the packing and hydrogen bonding of $[Ru(L^1H)_2(PPh_3)_2]$. H atoms not involved in hydrogen bonding have been omitted for clarity.

3.3.2. Crystal structure of $[Ru(L^1H)_2(PPh_3)_2]$(III)

In the molecule, the (C79–C80) group shows positional disorder and the refined site-occupancy factors of the disordered parts, viz. C79A–C80A and C79B–C80B, are 45(1)% and 55(1)%, respectively. Additional information on the structure determination is given in Table 1. Selected bond distances, angles and torsion angles are listed in Table 4.

In the $[Ru(\mathbf{L^1}H)_2(PPh_3)_2]$ complex (Fig. 4), the Ru atom is coordinated by two N atoms, two S atoms and two P atoms in a distorted octahedral geometry. The Ru–N distances are in the range 2.147 (2)–2.166 (2) Å, Ru–S distances 2.4229 (6)–2.4372 (6) Å and Ru–P distances 2.3176 (7)–2.3231 (7) Å. These distances are comparable to those found in other similar complexes [43–51]. Within the ligands, other geometric parameters all lie within the expected ranges.

In the Ru complex, the molecular conformation with the four-membered chelate ring formed by the ligand [52] and the distorted octahedral coordination geometry of the Ru atom are stabilized by C–H···S and O–H···N type-intramolecular hydrogen bonding interactions (Table 5). The crystal packing interactions and the hydrogen bonds of the title complex are shown in Fig. 5.

4. Conclusion

The interaction of $[NiCl_2(PPh_3)_2]$ with the dianionic ligands, $\mathbf{L^1}$ and $\mathbf{L^2}$, yielded the expected ON^1S chelates, **I** and **II** (Fig. 2). However, $[RuCl_2(PPh_3)_3]$ gave the 1:2 complexes (**III** and **IV**) through the N^2S donor set in the monoanionic forms of the ligands, even when a 1:1 mole ratio of the reactants was used (Figs. 4 and 5). Taking into consideration our data together previous studies [25–31] it is obvious that the substituents on the aryl and amide region of the tridendate thiosemicarbazones do not effect their chelating preferences. As for the reason of these interesting results, it can be said that ruthenium(II) prefers the higher symmetry of the octahedral geometry than of the bipyramidal geometry.

research opportunities and potential applications is chemical functionalization.

Functionalization of carbon nanotubes is an effective way to enhance the physical properties and improve the solubility. However, the aromatic character of nanotubes restricts the possible addition reactions. The functionalization of carbon nanotubes may extend the range of their potential applications. The electric properties of CNTs can be modified using chemical functionalization and the contact resistance between the interconnected tubes can be reduced by chemically binding functional groups. Suitable functionalization enables the linking of individual carbon nanotubes to form complex networks for nanoscale electronic circuits [17]. The functionalization solubilizes the nanotubes in a variety of solvents [18,19], allows chemical manipulations and improves the dispersion in composite applications. In nanocomposites, the functional groups attached to the walls of CNTs can form strong chemical bonds with the surrounding polymer matrix, increasing the binding force between the nanotube and the polymer [20,21].

Some of the functionalization approaches previously reported have involved the formation of covalent bonds [22–25], while others have employed non-covalent interactions [26–29]. Both non-covalent and covalent modifications of the surface have been developed to improve solubility. Non-covalent chemistry includes surfactant modification [30–32], polymer wrapping [33] and polymer absorption [34] in which the polymers were produced by an in situ ring-opening metathesis polymerization or emulsion polymerization. The initial attempts for covalent functionalization took advantage of the higher reactivity of carbon atoms at the ends of the nanotubes to carry out the series of reaction steps leading to the covalent attachment.

In this paper, we report the synthesis and characterization of manganese(II) complex of the Schiff-base ligand; *N*,*N*-bis(4-hydroxysalicylidene)-ethylene-1,2-diamine, $H_2[(OH)_2$-salen]; and this complex was covalently attached on MWNTs (Scheme 1), [Mn($(OH)_2$-salen)]@MWNTs, and used in the oxidation of cyclohexene with TBHP. As far as we know, our report constitutes the first example of MWNTs as a support for a manganese(II) salen complex in heterogeneous catalysis.

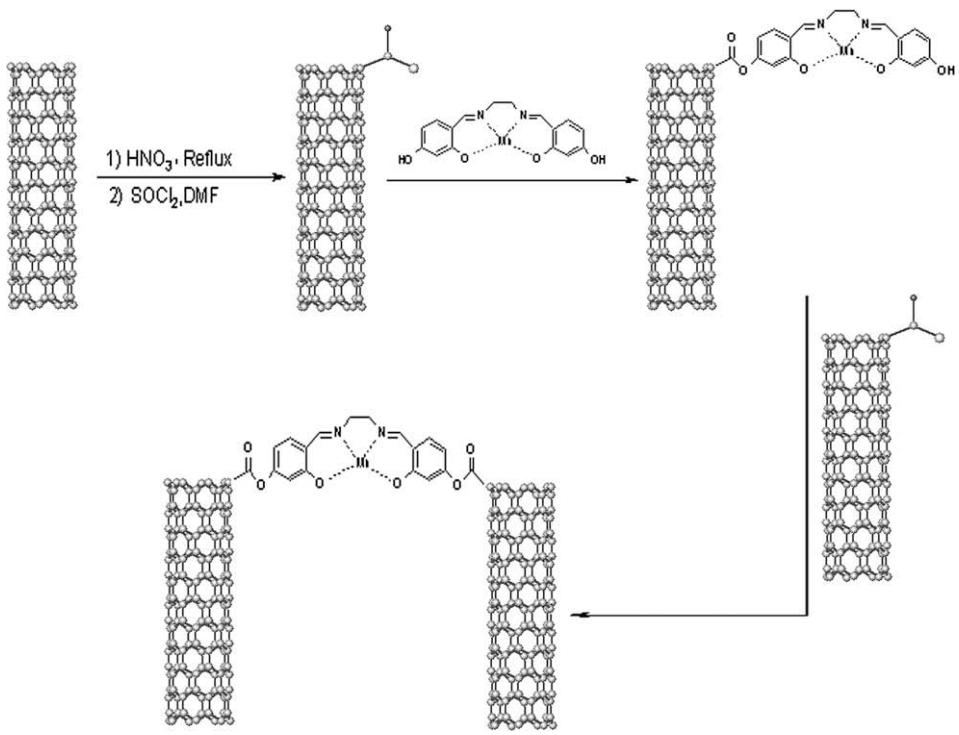
2. Experimental

2.1. Materials

All the solvents were purchased from Merck (pro analysi) and were distilled and dried using molecular sieves (Linde 4 Å). Manganese(ll) acetate, 4-hydroxysalicyclaldehyde and *tert*-butylhydroperoxide (solution 80% in di-*tert*-butylperoxide) were obtained from Merck Co. Cyclohexene was distilled under nitrogen and stored over molecular sieves (4 Å). Cyclohexanone was used as an internal standard for the quantitative analysis of the product using gas chromatography. Reference samples of 2-cyclohexene-1-ol and 2-cyclohexene-1-one (Aldrich) were distilled and stored in a refrigerator.

2.2. Physical measurements

^{1}H NMR (400 MHz) spectra were measured in DMSO solutions and referenced to the solvent signals. XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Transmission electron microscopy (TEM) images were obtained on a Hitachi H-800 transmission electron microscope with an accelerating voltage of 200 kV. FT-IR spectra were recorded on a Shimadzu Varian 4300 spectrophotometer in KBr pellets. The electronic spectra of the neat complexes were taken on a Shimadzu UV–Vis scanning spectrometer (Model 2101 PC). The stability of the complex covalently attached to the MWNTs was checked after the reaction by UV–Vis and possible leaching of the complex was investigated by UV–Vis in the reaction solution after filtration of the heterogeneous catalyst. The amounts of manganese complex grafted in the MWNTs matrix were determined by the elemental analysis and by subtracting the amount of manganese complex left in the solutions after the synthesis of the



Scheme 1.

catalysts, as determined by UV–Vis spectroscopy, from the amount taken for the synthesis. Atomic absorption spectra (AAS) were recorded on a Perkin–Elmer 4100–1319 spectrophotometer using a flame approach, after acid (HF) dissolution of known amounts of the nanotubes. Diffuse reflectance spectra (DRS) were registered on a Shimadzu UV/3101 PC spectrophotometer in the range 1500–200 nm, using MgO as a reference. The elemental analysis (carbon, hydrogen and nitrogen) of the materials was obtained from a Carlo ERBA Model EA 1108 analyzer. XPS (small area X-ray photoelectron spectroscopy) data were recorded with the PHI-5702 Multi-Technique System, Power Source by Mg Kα line and Ag $3d_{5/2}$ FWHM $\leqslant$ 0.48 eV. Thermogravimetric-differential thermal analysis (TG-DTA) were carried out using a thermal gravimetric analysis instrument (Shimadzu TGA-50H) with a flow rate of 20.0 mL min^{-1} and a heating rate of 10 °C min^{-1}. The products were analyzed by GC–MS, using a Philips Pu 4400 Chromatography (1.5 m, 3% OV-17 Column), Varian 3400 Chromatography (25 m, DB- 5 Column) coupled with a QP Finnegan MAT INCOF 50, 70 eV.

2.3. Preparation of N,N-bis(4-hydroxysalicylidene)ethylene-1,2-diamine; $H_2[(OH)_2$-salen]

A stoichiometric amount of 4-hydroxysalicylaldehyde (0.02 mol, 2.76 g) in dissolved methanol (25 ml) was added drop by drop to a 1,2-diaminoethane solution (0.01 mol, 0.60 g) in 25 ml methanol. The contents were refluxed for 4 h and a bright yellow precipitate of the symmetrical Schiff-base ligand, $H_2[(OH)_2$-salen], was obtained. The yellow precipitate was separated by filtration, washed and dried in vacuum. It was then recrystallized from methanol to yield $H_2[(OH)_2$-salen]. Yield 97% (3.26 g); orange solid; mp > 230 °C; IR (KBr, cm^{-1}) $\nu_{C=N}$ 1640. *Anal.* Calc. for the Schiff-base ligand: C, 63.99; H, 5.37; N, 9.33; C/N, 6.86. Found: C, 63.80; H, 5.20; N, 9.46; C/N, 6.74%. ^{1}H NMR (DMSO-d_6, ppm) δ 3.76 (s, 4H), 6.14 (d, 2H), 6.24 (dd, 2H), 7.15 (d, 2H), 8.35 (s, 2H), 12.6 (s, 4H).

2.4. Preparation of $[Mn((OH)_2$-salen)]

The Schiff-base ligand (3.30 g, 0.011 mol) was dissolved in 100 ml of refluxing ethanol and a stream of nitrogen was purged through the solution for 4 h to eliminate any oxygen. A solution containing 2.7 g (0.011 mol) of manganese(II) acetate tetrahydrate in water was added dropwise to the deoxygenated ligand solution. The resulting mixture was agitated and refluxed under nitrogen with 5 ml of ethanol followed by 5 ml of water. The mixture was then cooled and filtered under reduced pressure. The collected solid was washed with diethyl ether and dried in air to give yellow crystalline $[Mn((OH)_2$-salen)], which was purified by recrystallization from chloroform (Yield: 51%). *Anal.* Calc. for $[Mn((OH)_2$-salen)]: C, 54.40; H, 3.99; N, 7.93; C/N, 6.86; Mn, 15.55; Mn/N, 1.96. Found: C, 54.27; H, 3.82; N, 8.08; C/N, 6.72; Mn, 15.32; Mn/N, 1.90%; IR (KBr, cm^{-1}) $\nu_{C=N}$ 1633.

2.5. Multi-wall carbon nanotubes (MWNTs) preparation and purification

The multi-wall carbon nanotubes (MWNTs) used in this study were prepared by chemical vapor deposition (provided by Jiang Youg Trade Co. (China)) with diameters ranging from 20 nm to 40 nm, lengths varying from 1 mm to 10 mm and a purity of 85%. The raw product was first immersed in an aqueous solution of HF to remove SiO_2, then filtered, washed with distilled water, and refluxed in diluted HNO_3 for 4 h to remove the metals and amorphous carbon. The resulting solid was then thoroughly washed with deionized water and THF, and dried in vacuum. TEM analysis showed that the carbon nanotubes exhibited a multi-wall structure and their diameters were about 20–40 nm.

2.6. Chlorination of MWNTs

The purified MWNTs (100 mg) previously dried under vacuum were suspended in a solution of $SOCl_2$ (25 ml) and DMF (1 ml). The suspension was stirred at 65 °C for 24 h. The solid was then separated by filtration and washed with anhydrous THF and dried in vacuum.

2.7. Anchoring the manganese(II) salen complex to the MWNTs; $[Mn((OH)_2$-salen)]@MWNTs

The MWNs were added (50 mg) to a solution of $[Mn((OH)_2$-salen)] (100 mg) in degassed $CHCl_3$ (8 ml), and the suspension was stirred for 20 h under N_2 atmosphere at 70 °C. The solid was then separated by filtration and exhaustively washed with THF and CH_2Cl_2, and dried in a vacuum. The loading of the $[Mn((OH)_2$-salen)] complex in the MWNTs, determined by elemental (N) analysis, was 0.4 mg. The Mn content for the manganese(II) complexes on MWNTs was below the detection limit of quantitative absorption spectroscopy.

Anal. Calc. for $[Mn((OH)_2$-salen)]@MWNTs: Mn/N, 1.78%; IR (KBr, cm^{-1}) $\nu_{C=N}$ 1604. Elemental and spectroscopic analysis of $[Mn((OH)_2$-salen)] and $[Mn((OH)_2$-salen)]@MWNTs confirmed the molecular composition of ligand.

2.8. Oxidation of cyclohexene

The catalytic oxidation of cyclohexene was carried out using both the catalysts. In a typical reaction, an aqueous solution of TBHP (2.28 g, 20 mmol), cyclohexene (0.82 g, 10 mmol) and catalyst (9.2×10^{-5} mol) were mixed in 20 ml of CH_3CN and the reaction mixture was heated at 80 °C with continuous stirring in an oil bath. The progress of the reaction was monitored as mentioned above and the identity of the various products confirmed by GC–MS. The concentration of the products was determined using cyclohexanone as an internal standard.

3. Results and discussion

Synthesis of the manganese(II) complex involved heating and stirring of stoichiometric amounts of $H_2[(OH)_2$-salen] and manganese(II) acetate in methanol. The desired complex crystallized upon cooling and was recrystallized from chloroform. Elemental analysis indicates that the complex is a monomeric species formed by coordination of 1 mol of Mn(II) and 1 mol of $[(OH)_2$-salen]. The metal chelates in this study are insoluble in water but soluble in most organic solvents. Electrical conductivity measurements of the manganese(II) complex gave Λ_M values of 11 Ω^{-1} cm^{-1} mol^{-1} and confirmed that it is a non-electrolyte. The manganese content of the MWNTs catalysts were estimated by dissolving known amounts of the heterogeneous catalyst in concentrated HNO_3 and from these solutions, transition metal contents were estimated by atomic absorption spectrometry. The chemical composition confirmed the purity and stoichiometry of the neat and MWNTs-grafted complex. The chemical analysis of the samples revealed the presence of organic matter with a Mn/N ratio roughly similar to that of the neat complex. The loading of the complex was 82 μ mol g^{-1}. The chemical composition confirmed the purity and stoichiometry of the neat and multi-wall carbon nanotube complex.

MWNTs-Schiff-base complexes have enhanced chemical stability in most common solvents and enhanced thermal stability. The

homogeneous suspension of the MWNTs-Schiff-base complexes in methanol without any surfactant can be formed by stirring and remains very stable for at least 2 months at room temperature (no breakdown was detected even after high-speed centrifugation or high temperature treatment), while pristine MWNTs are easy to breakdown after high-speed centrifugation or high temperature treatment. The enhanced chemical and thermal stability of the MWNTs-Schiff-base complexes might result from the covalent interaction between the MWNTs and the Schiff-base complex. Because the Schiff-base complexes are covalently bonded to the MWNTs, the strong and super-stable covalent bond interactions between the Schiff-base complexes and MWNTs are responsible for the thermal stability of the MWNTs-Schiff-base complexes material.

Comparison of the spectra of this catalyst with the ligand provides evidence for the coordinating mode of the ligand in the catalyst. The ligand exhibits a broad band in the 2450–2750 cm^{-1} range due to extensive hydrogen bonding between the phenolic hydrogen and nitrogen of the azomethine group. Absence of this band in the spectra of the covalently anchored complex indicates the destruction of the hydrogen bond followed by the coordination of the phenolic oxygen after deprotonation. The sharp band appearing at 1640 cm^{-1} due to ν(C=N) (azomethine), shifts to a lower wavenumber, and appears at 1633 cm^{-1}. This indicates the involvement of the azomethine nitrogen in coordination. The presence of multiple bands in the 2850–2935 cm^{-1} region in the ligand and its complexes with slight shifts suggests the presence of the CH_2 group of ethylene in the ligand as well as its complexes. The neat complex [Mn($(OH)_2$-salen)] exhibits a sharp band at 1633 cm^{-1} due to the ν(C=N) stretch, while on the covalently anchored manganese(II) complex the location of the bands due to the ν(C=N) structure shifts to a lower wavenumber and appears at 1604 cm^{-1}. The intensity of the peaks on the covalently anchored complex is weak, due to their low concentration on the MWNTs, though the spectra of the covalently anchored as well as the neat complex show essentially similar bands. Meanwhile, the disappearance of the band at 3400 cm^{-1} due to ν(OH) may be due to the covalent anchoring of the [Mn($(OH)_2$-salen)] complex on the modified MWNTs.

The most informative spectroscopic data to support the covalent anchoring of the [Mn($(OH)_2$-salen)] complex on the modified MWNTs were obtained from a comparison of the set of IR data corresponding to the purified MWNTs, HOOC@MWNTs, ClCO@MWNTs and [Mn($(OH)_2$-salen)]@MWNTs (Fig. 1). The sharp peak at A (1519 cm^{-1}) in the IR spectrum (a in Fig. 1) is from the stretch mode of the aromatic carbon–carbon bond in raw MWNTs. After the reaction of the shortened MWNTs with $SOCl_2$, the IR spectrum (Fig. 1) showed well defined bands at about 1724, 1221 and 615 cm^{-1} which are clearly related to the formation of the –COCl group on the ends and side-wall of the MWNTs. The near-IR region of the purified MWNTs is preserved upon functionalization in ClCO@MWNTs and [Mn($(OH)_2$-salen)]@MWNTs, thus showing that the multi-walled structure of the nanotubes has been preserved unaltered during the treatment (Fig. 1).

In addition, a control experiment in which a mechanical mixture of MWNTs and 100 μmol g^{-1} of commercial [bis(salicylidene)ethylene-1,2-diiminemanganese(II)], [Mn(salen)], (no covalent linkage between the complex and MWNTs) was submitted for an extraction procedure with $CHCl_3$ and this revealed that essentially all the complex can be recovered by our workup procedure.

The X-ray diffraction patterns of MWNTs containing the manganese(II) complex are similar to the MWNTs alone. This indicates that the crystallinity and morphology of the MWNTs are preserved during the grafting. Fig. 2 shows the XRD pattern of the MWNTs, which is similar to that of highly oriented pyrolytic graphite (HOPG). The (002) peak emerges at around 26°, corresponding to an inter-planar spacing of 0.342 nm, which is little greater than that of HOPG of about 0.336 nm. Fig. 2 shows the XRD patterns of MWNTs with the modification grafted method. It can be seen that the XRD patterns are similar to the raw MWNTs. Modified MWNTs still have the same cylinder wall structure as raw MWNTs and the inter-planar spacing of all samples remains the same.

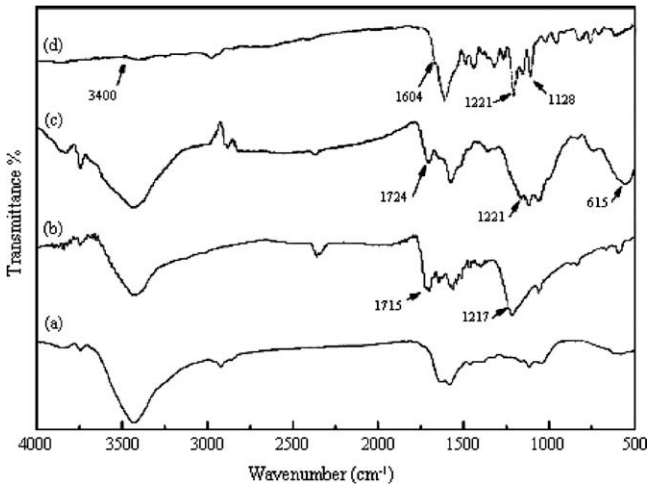


Fig. 1. FT-IR spectra of (a) raw MWNTs, (b) HOOC@MWNTs, (c) ClCO@MWNTs, (d) [Mn($(OH)_2$-salen)]@MWNTs.

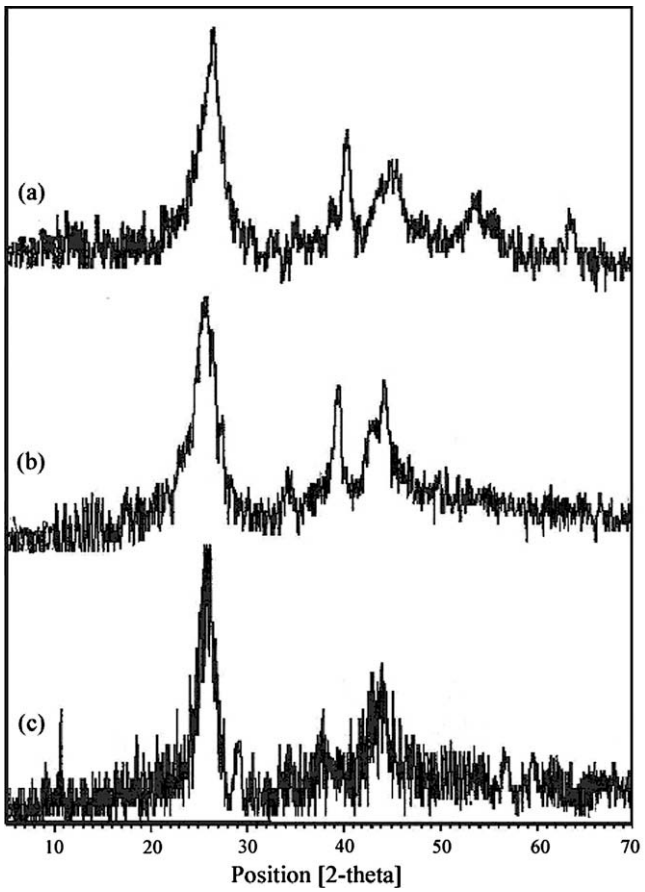

Fig. 2. XRD pattern for (a) MWNTs, (b) HOOC@MWNTs, (c) [Mn($(OH)_2$-salen)]@MWNTs.

Fig. 3 shows a TEM image of the MWNTs with high quality, uniform diameter and a high length/diameter ratio, which shows that the diameter is about 20–40 nm. From Fig. 3 it is found that each MWNTs before modification is mainly a long and folded pipe. The MWNTs-Schiff-base complexes exhibit a stretched or folded feature with the Schiff-base complex (black dots) mainly congregating in the convex surfaces of the MWNTs (Fig. 3). These images of the sample also confirm the junction formations through the Schiff-base complex. As expected most of the junctions occur at the tips of the MWNTs, as hydroxyl (OH) groups of the Schiff-base complex react with the carboxylic (COOH) groups at the open end of the MWNTs. Scheme 1 illustrates the synthetic step and the structure of the resulting [Mn((OH)$_2$-salen)] complex anchored to the MWNTs. According to Fig. 3 in which bundles of MWNTs rather than isolated tubes are seen, drawn in Scheme 1, multi-wall nanotubes represent a simplification of the functionalization process.

The electronic spectral data of the ligand and the complex are also given in the experimental section. The electronic spectral profiles of [Mn((OH)$_2$-salen)] and [Mn((OH)$_2$-salen)]@MWNTs are reproduced in Fig. 4. The electronic spectrum of the ligand H$_2$[(OH)$_2$-salen] exhibits three bands at 335, 265 and 208 nm and these are assigned due to $n \rightarrow \pi^*$, $\pi \rightarrow \pi^*$ and $\phi \rightarrow \phi^*$ transitions, respectively. All these bands shift to the higher wavelength side, indicating the restructuring of the ligand after coordination to the metal ion. The appearance of a weak band due to a ligand to metal transition underneath the $n \rightarrow \pi^*$ transition make this a band broad. No band could be located in the higher wavelength region due to the expected d–d transition in the covalently anchored complex. The neat complex exhibits at least one broad band at 340 nm for [Mn((OH)$_2$-salen)]. The magnetic measurement obtained at room temperature for the manganese complex in the powder state is 5.92 BM, *i.e.* close to the spin only value expected for high spin manganese(II) in a tetrahedral environment [35–37].

Further evidence for the modification of MWNTs comes from the XPS spectrum of the [Mn((OH)$_2$-salen)]-functionalized MWNTs, that reveals the surface chemical state as shown in Fig. 5a. The peaks at 294.8, 397.8 and 531.1 eV are attributed to C, N and O, respectively, [38]. By calculating the content of the elements on the surface of MWNTs by area for each element, we can show that the weight content of N is about 2%, indicating the presence of Schiff-base groups. It was found that O 1s can be fitted to three line shapes with binding energies at 532.7, 531.2 and 529.9 eV, which are assigned to –CO–, –C–O–C– and –C–O–Mn(II), respectively (Fig. 5b). The structure of the complexes could be confirmed as shown in Scheme 1. The XPS spectra relating to the core levels of Mn 2p are shown in Fig. 5c. The peaks at 640.0 and 651.4 eV are attributed to Mn 2p3/2 and Mn 2p1/2, respectively. These data confirm the loading of the [Mn((OH)$_2$-salen)] complex in the MWNTs.

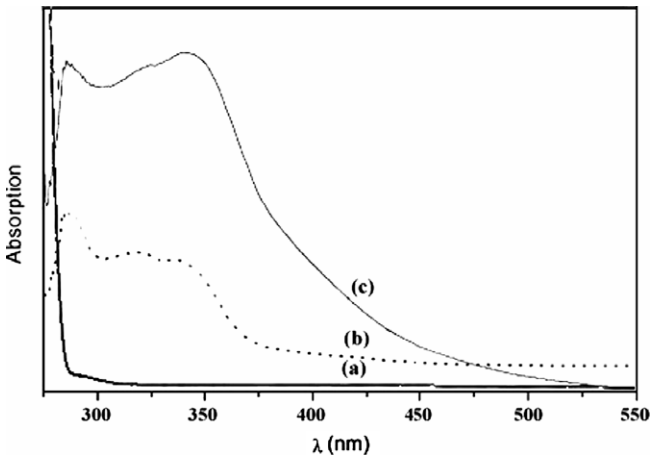

Fig. 4. UV–Vis spectra of the (a) raw MWNTs (b) [Mn((OH)$_2$-salen)]@MWNTs (c) Schiff-base complex.

TGA demonstrates that the composites of [Mn((OH)$_2$-salen)]@MWNTs have been prepared (Fig. 6). The mass loss in temperature range below 250 °C reflects the deprotonation of COOH, the loss of the acid group of HOOC@MWNTs and humidity. Also the mass loss in this temperature is related to the loss of COCl of the MWNTs. On the other hand, Fig. 6 is the TGA curve for the as-prepared MWNTs-Schiff-base complexes, [Mn((OH)$_2$-salen)]@MWNTs, presenting several weight losses in the temperature range 125–400 °C. According to Fig. 6, decomposition [Mn((OH)$_2$-salen)] starts above 250 °C. The significant weight loss of between 250 and 320 °C is due to the surface grown salen groups. Another weight loss below 200 °C corresponds to the loss of humidity. No further weight loss can be observed over 480 °C.

The complex [Mn((OH)$_2$-salen)]@MWNTs catalyzes the oxidation of cyclohexene by TBHP efficiently to give 2-cyclohexene-1-one, 2-cyclohexene-1-ol and 1-(*tert*-butylperoxy)-2-cyclohexene (Table 1). The reaction conditions have also been optimized for the maximum oxidation of cyclohexene by varying different parameters.

Three different TBHP:cyclohexene molar ratios, viz. 1:1, 2:1 and 3:1, were considered while keeping a fixed amount of cyclohexene (0.82 g, 10 mmol) and catalyst (9.2×10^{-5} mol) in 20 ml of CH_3CN, and the reaction was carried out at 75 °C. The percentage conversions noted at various times are presented in Fig. 7. A maximum of 52.1% conversion was noted for the TBHP to cyclohexene ratio of 1:1 after 2 h of reaction time. This conversion reached 63.4% at a TBHP to cyclohexene molar ratio of 2:1. On increasing the TBHP to cyclohexene ratio further to 3:1 results in only a 40.6%

conversion of cyclohexene. This is possibly due to the presence of excess water, as has been noted earlier. Thus, a large amount of oxidant is not an essential condition to maximize the oxidation.

The effect of the amount of catalyst on the oxidation of cyclohexene is shown in Fig. 8. Three different amounts of catalyst, viz. 3.9×10^{-5} mol, 6.6×10^{-5} mol and 9.2×10^{-5} mol, were considered while keeping other conditions as above. It is clear from the plot that 9.2×10^{-5} mol catalyst amount is the best one to obtain the highest cyclohexene conversion. Temperature also has an influence on the oxidation of cyclohexene. As shown in Fig. 9, amongst the three temperatures of 55, 65 and 75 °C, the maximum conversion of cyclohexene was obtained at 75 °C. Thus, the optimized conditions for the oxidation of 10 mmol of cyclohexene were fixed as follow: 9.2×10^{-5} mol catalyst, 20 mmol TBHP, 20 ml CH_3CN and 75 °C reaction temperature. Under these reaction conditions the catalyst [Mn((OH)$_2$-salen)]@MWNTs gave 82.1%

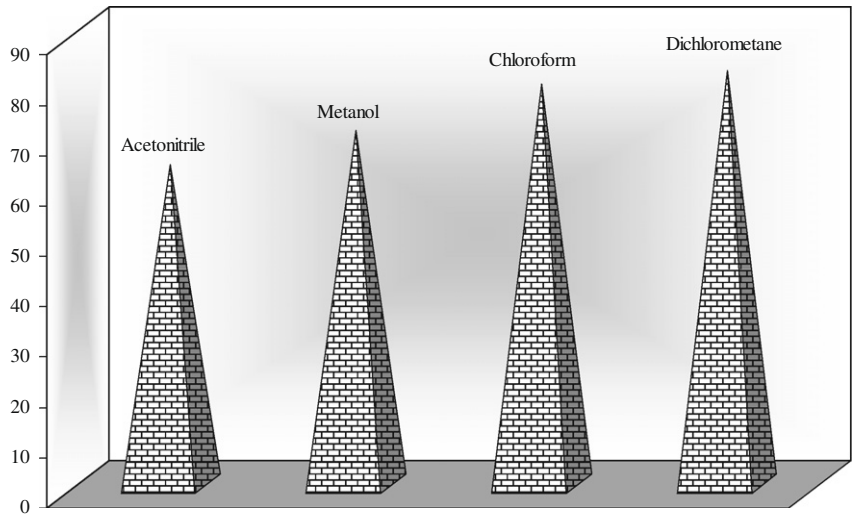

Fig. 10. Effect of solvent on the oxidation of cyclohexene (reaction conditions: 9.2×10^{-5} mol catalyst, 20 mmol TBHP, 20 ml solvent, 10 mmol of cyclohexene, catalyst [Mn($(OH)_2$-salen)]@MWNTs).

achieve equilibrium in these reactions. Amongst the various products formed, the selectivity of 2-cyclohexene-1-one was found to be highest while the selectivities of the other two products were much less. As a result 2-cyclohexene-1-one is the major product.

The solid was used as a heterogeneous catalyst for the oxidation of cyclohexene (Table 1). One of the major advantages of anchoring the [Mn($(OH)_2$-salen)] complex on the MWNTs as a support is the ease in which the catalyst can be suspended in the solvent due to the bundled agglomerates of MWNTs that aggregate slowly. Upon initial stirring of the suspension, the black solid remains suspended without setting down for long period of time.

The reusability of [Mn($(OH)_2$-salen)]@MWNTs was confirmed by performing a series of consecutive experiments in which the used catalyst was filtered, washed with fresh solvent, and re-employed without any further treatment in another run. The results shown in Table 1 clearly prove that no loss of activity occurs, giving a minimum productivity of 300 mol of product per mole of complex. Results of elemental (N) analysis exhibit that leaching of the Mn complex along with catalytic reaction does not occur.

The effect of various solvents for the oxidation of cyclohexene with the [Mn($(OH)_2$-salen)]@MWNTs catalyst was also studied (Fig. 10). The oxidation reactions were carried out in protic and aprotic solvents. The results are given in Fig. 10. In all the oxidation reactions, 2-cyclohexene-1-one was formed as the major product. When the reaction was carried out in a coordinating solvent like CH_3CN the conversion decreased by a factor of ~1.29 (Fig. 10). This might be attributed to the donor number of acetonitrile (14.1) and, therefore, to its higher ability to occupy the vacant spaces around the metal center and prevent the approach of oxidant molecules. In dichloromethane and chloroform the yields of 2-cyclohexene-1-o1 and 2-cyclohexene-1-one were higher and a lower yield of the peroxy species was obtained as compared to the other solvents. The efficiency of the catalysts for oxidation of cyclohexene in different solvents decreases in the order: dichloromethane > chloroform > methanol > acetonitrile.

The results clearly suggest that [Mn($(OH)_2$-salen)]@MWNTs efficiently catalyses the conversion of cyclohexene to 2-cyclohexene-1-one with 73.2% selectivity and a conversion of 82.1% in dichloromethane. The greater activity of the $(OH)_2$-salen system has clearly arisen from the existence of an electron donating ligand which facilitates the electron transfer rate, a process that has previously been observed by us in other oxidation reactions [39–44].

The trend observed in Table 1 can be explained by the donor ability of the ligand available in the complex catalysts. As Wang and co-workers have pointed out recently, the key point in the conversion of cyclohexene to the products is the reduction of ($(OH)_2$-salen)-Mn^{3+} to ($(OH)_2$-salen)-Mn^{2+}. This reduction to ($(OH)_2$-salen)-Mn^{2+} is facilitated by ligands available around the metal cation [45]. The formation of the allylic oxidation products 2-cyclohexene-1-one and 2-clohexene-1-ol shows the preferential attack of the activated C–H bond over the C=C bond. The formation of 1-(*tert*-butylperoxy)-2-cyclohexene shows the presence of radical reactions [46]. That TBHP as an oxidant promotes the allylic oxidation pathway and epoxidation is minimized, especially in presence of MWNTs with divalent and trivalent transition metal ions and complexes, has been observed by us and others [44–52].

4. Conclusion

MWNTs covalently bonded by a manganese(II) Schiff-base complex were successfully obtained via the method of chemical modification. The "neat" and MWNTs covalently anchored manganese(II) Schiff-base complex exhibit efficient catalytic activity in the oxidation of cyclohexene using TBHP. The reaction conditions have been optimized considering different parameters to get a maximum conversion of this substrate. A maximum of 82.1% conversion with three different oxidation products of cyclohexene has been obtained with [Mn($(OH)_2$-salen)]@MWNTs. The selectivity of these products follows the order: 2-cyclohexene-1-one (73.2%) > 2-cyclohexene-1-ol (18.1%) > 1-(*tret*-butylperoxy)-2-cyclohexene (8.7%). This complex is stable and does not leach during the catalytic reaction, as has been confirmed by testing the filtrate for the corresponding metal ion, thus suggest their heterogeneous nature. The high conversion of the complex makes this system a suitable catalyst for this catalytic oxidation. The extension of the method to different olefins is currently under investigation in our laboratory.

These are some examples of the importance of PCr and Cu(II) which explain why it is important to know how these two species interact to form a Cu–PCr complex.

At physiological pH, PCr is present as the anion PCr^{2-} and this species can coordinate to metal cations [3] (Fig. 1). The PCr molecule has three possible donor atoms: one oxygen atom of the phosphate group, the nitrogen atom of the guanidine group and the oxygen atom of the carboxylate group. Thus, there is the possibility of PCr acting as a tridentate ligand.

In previous studies performed by us in solution we could see that PCr acts as a bidentate ligand, the guanidine group being one of the donor atoms. However, it was not possible to conclude whether the second donor atom was the oxygen atom of the phosphate or of the carboxylate group [1,2]. For this reason we decided to synthesize a complex of Cu–PCr in solid state in order to understand better the coordination site therein. The present work reports the synthesis and characterization of a solid binary Cu–PCr compound, and the results suggest that PCr in solid state is acting as a tridentate ligand.

2. Experimental

2.1. Materials

Na_2PCr was purchased from Sigma–Aldrich and was used as received. $CuSO_4 \cdot 5H_2O$ (Merck) was used to prepare $Cu(OH)_2$ (synthesized according to reported method [16]). All other chemicals were reagent-grade and were used without further purification.

Table 1
TGA data for the CuPCr complex

Compound	Step	ΔT (°C)	Mass loss% Exp. (calc.)	Probable species
CuPCr	1	20–120	5.1 (5.8)	OH
	2	120–311	11.8 (11.3)	$CH_3 + H_2O$
	3	311–899	23.9 (23.4)	$CO–CH_2–N–C$
	4	Residue	59.0 (58.3)	PO_2 + CuONHC

2.2. Synthesis

Binary Cu–PCr compound was synthesized by suspending $Cu(OH)_2$ and PCr in 4 mL of distilled water using the stoichiometric ratio 1:1. The initially blue suspension obtained was stirred for 6 h at 30 °C and then the solvent was slowly filtered. After solvent filtration the suspension was mixed again for 4 h at 15 °C. The blue powder was precipitated by reducing the solution temperature to −10 °C and using H_2SO_4 as a desiccant agent. The blue powder was dried at 47 °C for 4 h. After compound purification with water and a 5:1 water/ether mixture, the solid was kept in a vessel containing $CaCl_2$.

2.3. Elemental analysis and melting point

Carbon, hydrogen and nitrogen determinations were performed in an elemental analyzer EA 1110 from CE Instruments. The copper content was determined by atomic absorption spectrometry in a Varian AA5 Instrument. The measurements were taken using a wavelength of 324.7 nm and a slit of 0.1 nm. Melting Points were obtained with a MQAPF-302 apparatus.

Yield: 47%; M.p. 210 °C (decomposition). Elemental *Anal.* Calc. for $C_4H_{10}N_3PO_6Cu$: C, 16.52; H, 3.44; N, 14.45; Cu, 21.85. Found: C, 17.12; H, 3.31; N, 15.03; Cu, 21.23%.

2.4. Thermogravimetric analysis

Thermogravimetric analyses were performed with a Perkin–Elmer TGA 7. The temperature range used was from 20 to 900 °C, with a scanning rate of 10.0 °C min^{-1} in a nitrogen atmosphere.

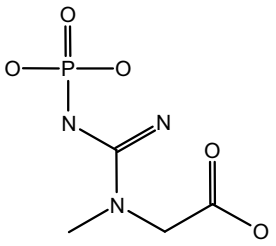

Fig. 1. Structure of phosphocreatine.

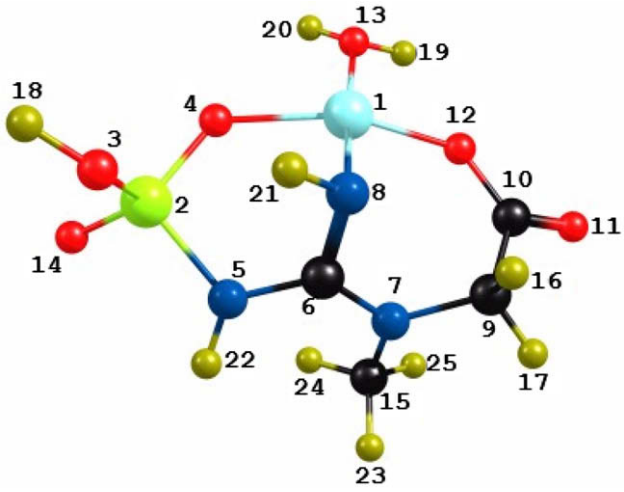

Fig. 2. DFT:B3LYP/6-311G calculated structure of the [Cu(PCr)(H_2O)] complex showing the atom numbering.

2.5. Spectroscopic measurements

The infrared spectra were carried out using a model FT-IR 2000 Perkin–Elmer spectrophotometer. Samples were prepared as KBr pellets for the range of 4000–370 cm^{-1} and polyethylene ones for the range of 710–30 cm^{-1}. Electron paramagnetic resonance (EPR) spectra were obtained at room temperature (300 K) on a Bruker ESP300E apparatus with modulation frequency of 100 kHz

operating at 9.5 GHz (X-band); solid samples for EPR analyses were firmly accommodated in quartz tubes; aqueous solutions spectra were obtained at room temperature (300 K) in a quartz flat cell. The EPR parameter values were obtained by treating and simulating the experimental spectra using the Windows software programs WIN-EPR and SIMFONIA, and the WEAK PITCH BRUKER sample pattern.

3. Results and discussion

3.1. General

The presence of three donor groups in phosphocreatine and, thus, the possibility of different types of coordination is a source of controversy, particularly in solution studies [2,3]. To obtain insight about the coordination properties of the system involving PCr and copper(II) ion, one solid complex was synthesized. The composition of the compound was confirmed by elemental analysis and is in agreement with a [Cu(PCr)(H_2O)] species and a molar ratio of 1:1. The coordination mode was determined based on the EPR, IR and thermogravimetric analyses and confirmed by theoretical calculations.

3.2. TG analysis

The decomposition CuPCr complex was observed by TG analysis. Thermal analysis results are in agreement with the assignments of the coordination sites.

Dry Na_2PCr salt decomposes in three steps with the inflexion points at 114 °C, 195 °C, and 308 °C. Above 900 °C there is a residue corresponding to 40.7% (calc. 40%) of the total mass. It is probably associated with the phosphate moiety, which is present in the residue of the complex as described below.

CuPCr undergoes a four-stage decomposition process. Calculations based on mass loss confirmed the stoichiometry of one PCr ligand and one H_2O molecule *per* metal. Between 20 and 120 °C a small part of the phosphate unit is probably lost. The experimental mass loss of 5.1% is in agreement with a mass of 5.8% calculated for the hydroxide molecule from phosphate. The next step occurs between 120 and 311 °C and the experimental mass loss is in agreement with a mass loss of a CH_3 species from phosphocreatine and a water molecule. This temperature is in agreement with a loss of a coordinated water molecule. The TG curve of the CuPCr interpretation is difficult to determine. The suggested species proposed for step 3 and the residue are shown in Table 1. Above 900 °C the curve attains a plateau with the formation of a stable residue corresponding to 59.1% of the total mass (calc. at 59.5%).

3.3. Electron paramagnetic resonance

The EPR parameters found for the CuPCr compound are: $g_{||}$ 2.3150; $A_{||}$ 170 $cm^{-1} \times 10^4$; $g_{\perp}$ 2.0860; $A_{\perp}$ 25 $cm^{-1} \times 10^4$. We can see that the perpendicular parameters, A and g, are in accordance with those found for copper(II) complexes with approximately axial symmetry [17]. The EPR parallel parameter values for the CuPCr complex $A_{||}$ $g_{||}$ are between those for Cu(II) bounded to four oxygen atoms and four nitrogen atoms [18,19], which is consistent with the hypothesis of complexation through three oxygen atoms and one nitrogen atom (two oxygen atoms of the PCr ligand, one oxygen atom of a molecule of water, and one nitrogen atom from PCr).

3.4. Optimization of the geometrical parameters

Ab initio optimization of the geometrical parameters, and hence a structural analysis of copper and phosphocreatine, [Cu(PCr)(H_2O)], was carried out employing DFT levels with B3LYP/6-311G basis set. The calculated stabilization energy was E(RB=HF-LYP) = −2755.91 a.u. The calculated bond lengths for the Cu–O bond were 1.958, 1.960 and 1.912 Å for the Cu–OH_2, Cu–O(carboxylate) and Cu–O(phosphate) bonds, respectively. For the phosphate group we found the following values: P–O 1.631 Å; P–O(H) 1.732 Å; P═O 1.569 Å. The calculated value for the Cu–N bond was 1.967 Å. Selected bond lengths and bond angles are given in Table 2. The full [Cu(PCr)(H_2O)] complex structure is shown in Fig. 2.

3.5. Vibrational assignments

The infrared spectra of the complex are shown in Fig. 3. Vibrational assignments were carried out with the aid of density functional theory (DFT) [20–22] calculations with B3LYP/6-311G basis set. To discuss the vibrational assignments, we took the functional density (DFT) calculated wave numbers corrected by a scale factor of 0.9613. For an accurate description of the normal modes in the metal–ligand spectral range, instead of the potential energy distribution (PED) we used the normalized percentage of deviation of the geometrical parameters (PDPG) [23] from the equilibrium position. This way we were able to obtain the percentage of participation of the bond stretching and bending internal vibrational coordinates in the normal modes.

3.5.1. N–H stretching

There are two NH groups in phosphocreatine. We observed two infrared bands at 3568 and at 3404 cm^{-1}, and calculated at 3483 and at 3329 cm^{-1}. These bands were assigned to the NH stretching.

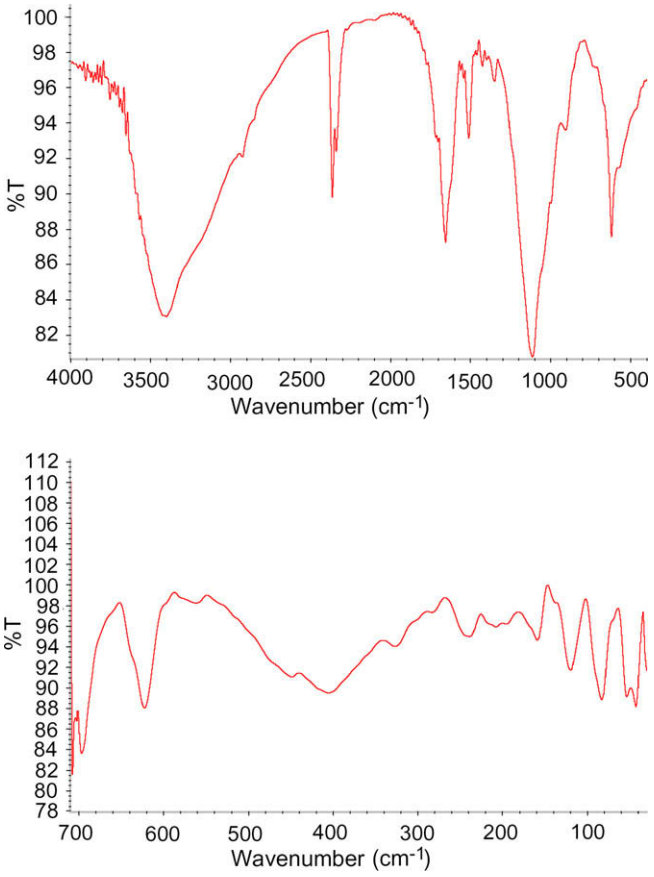

Fig. 3. FT-IR spectra of complex [Cu(PCr)(H_2O)] in the region of 4000–370 cm^{-1} and in the region of 700–30 cm^{-1}.

3.5.2. O–H stretching

One water molecule coordinates the Cu(II)–phosphocreatine complex, creating two O–H stretchings. In the phosphate group after deprotonation one P–O–H group remains, displaying one O–H stretching. In the infrared spectrum we observed a very broad band in the region of the O–H absorptions from which we can assign the peaks at 3630 and at 3591 cm^{-1} as the bands pertaining to the phosphate group and to the water molecule, the latter being the O–H symmetrical stretching. The DFT scaled calculated values were: 3719, 3570 and 3530 cm^{-1}, for O–H (H_2O), O–H (phosphate) and O–H (H_2O), respectively.

3.5.3. C–H stretching

We expected to observe five infrared bands pertaining to the phosphocreatine ligand in the [Cu(PCr)(H_2O)] complex. The calculated DFT values were: 3022, 3007, 2979, 2957 and 2907 cm^{-1}. These wave numbers can be correlated with the experimental ones found at 2958, 2922 and 2852 cm^{-1}. There were two very weak bands observed at 3270 and 3176 cm^{-1} which were assigned preferentially as combination bands.

3.5.4. C=O and C=N stretching

Recently we informed the synthesis, structural and vibrational analysis of the guanidinoaceticserinenickel (II) complex [Ni(GAA)-(Ser)] [24], in which the DFT calculation showed that the C=N stretching is at a higher energy position than the C=O stretching, and the experimental data were in good agreement. In the case of [Cu(PCr)(H_2O)], the $(NH)_2C{=}NH$ group binds to the Cu atom through the –C=NH group, and the C=N bond becomes weak and shifts the C=N stretching wave number to a lower region. As discussed by Bellamy [25], the position of the C=N absorption in conjugated cyclic systems is not very clear, and the C=N absorptions have been assigned as being within the range of 1660–1480 cm^{-1}. We observed the C=N stretching at 1478 cm^{-1}, according to the calculated value at 1454 cm^{-1}. The C=O stretching was assigned at 1720 cm^{-1}. The calculated value was 1657 cm^{-1}.

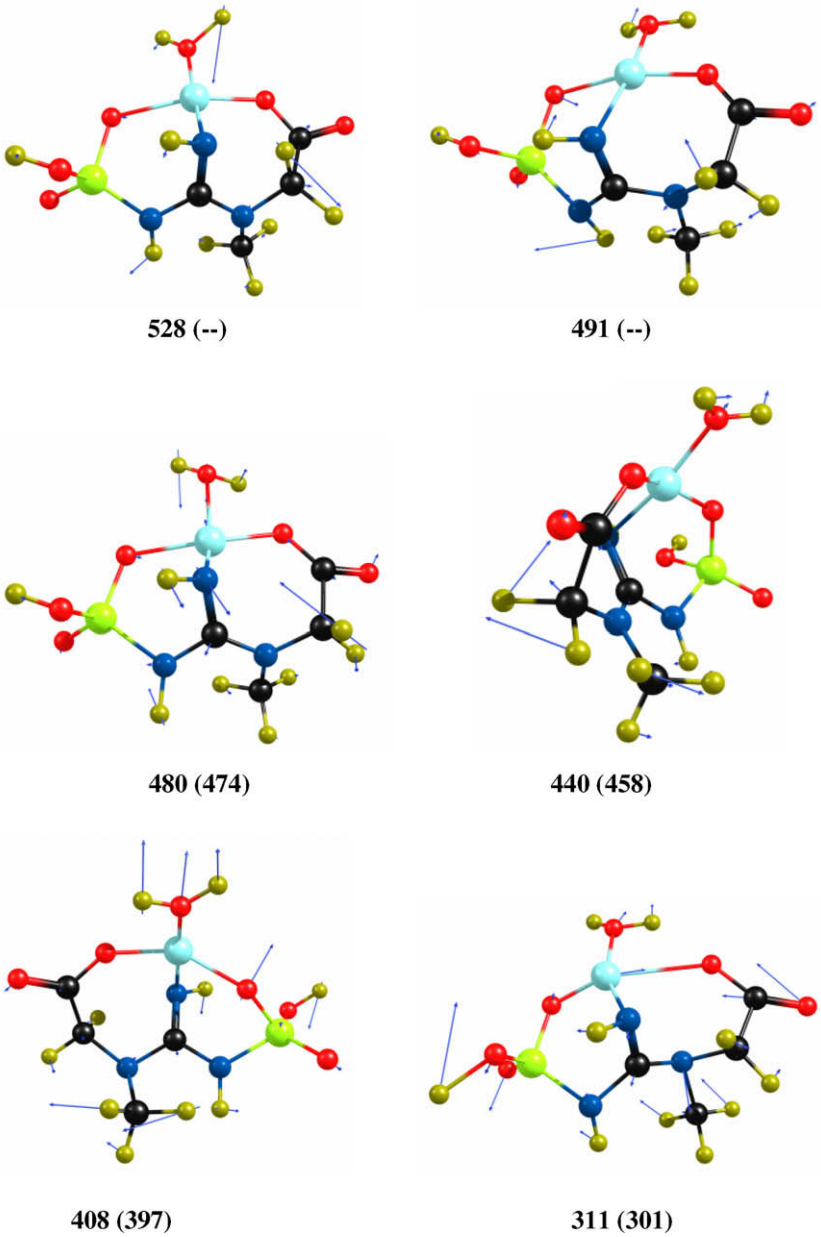

Fig. 4. Distorted geometries of some normal modes.

3.5.5. P=O and P–O stretching

The assignments for the phosphorous compounds present some difficulties due to structural effects caused by the surrounding atoms. The DFT calculated spectra indicate the following assignments for the P=O and P–O stretching: 1114 cm^{-1} (1067 cm^{-1} calculated), 850 cm^{-1} (845 cm^{-1} calculated) and (835 cm^{-1} calculated) for the ν(P=O), ν_s(P–O) and ν_{as}(P–O) vibrational modes, respectively. The experimental bands found at 1114 cm^{-1} agree well with earlier assignments for phosphorous compounds.

3.5.6. CNH and HCH bending vibrations

In general terms, the CNH and HCH bending vibrations are considered as characteristic wave numbers. As usual we can differentiate scissoring, wagging, twisting and rocking vibrations within the $-CH_2$ group. The two CNH structural fragments in the complex can form two δ(CNH)/or δ(CuNH) and δ(CNH)/or δ(PNH) bendings. In total we have expected to assign 13 bendings including the rocking vibrational modes. The DFT calculated spectra indicate the following assignments: the observed band at 1704 cm^{-1} (calculated value at 1620 cm^{-1}) can be assigned to the coupled mode as δ(C=NH) + δ(NCN). The infrared bands found at 1620 cm^{-1} (calculated at 1550 cm^{-1}), 1561 cm^{-1} (1541 cm^{-1} calculated) and 1544 cm^{-1} (1494 cm^{-1} calculated) were assigned to the δ(HCH) of the CH_3 group. The bands observed at 1512 cm^{-1} (1486 cm^{-1} calculated), 1428 cm^{-1} (1376 cm^{-1} calculated), 1173 cm^{-1} (1160 cm^{-1} calculated) and 1134 cm^{-1} (1146 cm^{-1} calculated) were assigned to the δ(HCH) of the CH_2 group. For the rocking vibrations of the $-CH_3$ and $-CH_2$ groups we found the following results: 1046 cm^{-1} (1049 cm^{-1} calculated) and 993 cm^{-1} (980 cm^{-1} calculated), respectively. The observed band at 740 cm^{-1} (727 cm^{-1} calculated) was assigned to one of the ρ(NH) vibrational modes. Descriptions of the assignments of these modes are given in Table 3.

3.5.7. CN, CO, and CC stretching vibrations

The C–O stretchings were assigned at 1342 cm^{-1} (1280 cm^{-1} calculated) and at 1252 cm^{-1} (1270 cm^{-1} calculated), both vibrations coupled with ν(CC). The band found by means of the second derivative at 1205 cm^{-1} (1225 cm^{-1} calculated) can be assigned as the coupled mode ν(CN) + ρ(CH)CH_3. The other bands that could be assigned to the C–N stretching present higher coupling degrees; they are 835 cm^{-1} calculated and 717 cm^{-1} calculated.

3.5.8. Skeletal framework vibrations

A clear identification of the metal–ligand vibrations is not straightforward due to the greater mixture of the different internal coordinates which form part of the description of the normal mode. With the purpose of better understanding this energy region and of achieving a better assignment of the low energy vibrational bands, we have studied the distorted geometry of some vibrational modes whose description is not clear under visual inspection. Our goal was to obtain a better description of the coupling degree between the different internal coordinates which compose the normal mode. Analysis of the low energy yielded the following approximate assignments in which the Cu–O and Cu–N stretching spread out in several vibrational modes with different participation degree: the calculated band at 528 cm^{-1} (no observed band) can be assigned as the coupled mode ν(Cu–O) + δ(HOH)wagging + $\rho(CH_2)$; the calculated band at 492 cm^{-1} (no observed band) corresponds to the coupled mode ν(Cu–O) + ν(Cu–N) with distortions of the order of 12% and 8%, respectively; the observed band at 474 cm^{-1} (second derivative) may be assigned as ν(Cu–N) + ν(Cu–O) with distortions of the order of 14% and 13%, respectively. The band found at 458 cm^{-1} may be assigned as $\rho(CH_2)$ + ν(Cu–O). The second derivative band found at 397 cm^{-1} corresponds approximately to the mode ν(Cu–O) + δ(OPN) + ν(Cu–N). The observed band at 301 cm^{-1} may be assigned to the mode ν(Cu–O) + angle ring distortion. The remaining assignments are given in Table 3. Fig. 4 shows the distorted geometry of some of the normal modes which were discussed above. The images were captured using the free CHEMKRAFT program [26].

4. Conclusions

The data reported here show that the reactions lead to a compound with a 1:1 metal/ligand ratio.

Solution studies involving PCr and copper(II) ions show that PCr acts as a bidentate ligand where one center of metallation is the nitrogen atom of the guanidine group, but are not conclusive about the second donor atom from PCr, as to whether it is the oxygen atom of the phosphate or the oxygen atom of the carboxylate groups from PCr [2,3]. The experimental and calculated data obtained for CuPCr has led us to propose that in solid state PCr acts as a tridentate ligand and coordinates to the metal ion through two oxygen atoms, one from the phosphate and one from the carboxylate group, as well as one nitrogen atom from the guanidine group. The fourth position is occupied by a water molecule. These results show that PCr has different behaviors in solution and in solid state. Calculations made from thermogravimetric curves suggest that the last remaining bond is that of Cu–phosphate. Phosphate is present in the residue of the thermal decomposition, and the coordination seems to increase its thermal stability.

Infrared spectral analysis combined with the quantum mechanical DFT:B3LYP/6-311G was useful to determine the geometrical structure of the [Cu(PCr)(H_2O)] complex, and to determine the description of the coupling degree of the Cu–O and Cu–N stretching internal coordinates and the associated framework bending coordinates in the composition of the normal modes belonging to the low energy region.

Mechanisms of many processes involving phosphocreatine and metal ions have not been explained yet. Thus, knowledge about the coordination modes of this system can be useful for a better understanding of its behavior in living organisms.

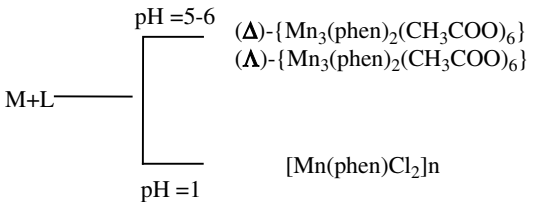

Scheme 1.

about 48% based on Mn). *Anal.* Calc. for **1**: C, 49.27; H, 3.90; N, 6.37. Found: C, 49.34; H, 3.94; N, 6.42%. IR (KBr): 1587 s, 1515 m, 1425 s, 1342 m, 1222 w, 1140 w, 1102 w, 1047 w, 1016 m, 942 w, 849 s, 776 w, 728 s, 657 m, 617w.

2.2.2. Synthesis of $[Mn(phen)Cl_2]_n$ (**2**)

The crystals of complex **2** were obtained in a similar method to complex **1**, just adjusting the pH to about **1** with hydrochloric acid. Yellow prism single crystals suitable for X-ray diffraction were obtained after three weeks (yield: about 32% based on Mn). *Anal.* Calc. for **1**: C, 47.09; H, 2.64; N, 9.15. Found: C, 47.15; H, 2.71; N, 9.22%. IR (KBr): 1621 m, 1586 m, 1515 m, 1423 s, 1349 w, 1284 w, 1224 w, 1144 m, 1104 m, 1046 w, 985 w, 950 w, 862 s, 748 m, 728 s, 638 w.

2.3. Crystallographic data collection and structure determination

A single-crystal X-ray diffraction study of complexes **1**–**2** was performed on a Bruker SMART diffractometer equipped with a CCD area detector with a graphite monochromator situated in the incident beam for data collection. The determination of unit cell parameters and data collections were performed with Mo Kα radiation ($\lambda = 0.71073$ Å) by the ω scan mode in the range $1.56 \leqslant \theta \leqslant 31.96$ (for **1**), and $2.33 \leqslant \theta \leqslant 35.59$ (for **2**) at 293(2) K. All data were corrected by the semi-empirical method using the SADABS program. The program SAINT [9] was used for integration of the diffraction profiles.

Both structures were solved by direct methods using the SHELXS program of the SHELXTL-97 package and refined with SHELXL [10]. The metal atom centers were located from the E-maps and other non-hydrogen atoms were located in successive difference Fourier syntheses. The final refinements were performed by full matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms on F^2. All the hydrogen atoms were first found in difference electron density maps, and then placed in the calculated sites and included in the final refinement in the riding model approximation with displacement parameters derived from the parent atoms to which they were bonded. Further crystallographic data and experimental details for the structural analyses of both complexes are summarized in Table 1, and selected bond lengths and angles with their estimated standard deviations for complexes **1** and **2** are in Tables 2 and 3, respectively.

3. Results and discussion

3.1. Description of the crystal structures of complexes *1* and *2*

3.1.1. (Δ, Λ)-$\{Mn_3(phen)_2(CH_3COO)_6\}$ (**1**)

Structural analysis revealed that **1** is a kind of neutral trinuclear cluster. In each trinuclear cluster there are two crystallographically distinct Mn atoms, and the three Mn^{II} atoms are in a linear form linked by six acetate groups with Mn···Mn distances of 3.266 Å, and with two 1,10-phenanthroline ligands as terminal ligands (Fig. 1a). All of the three Mn^{II} atoms have a distorted octahedral geometry and two adjacent manganese octahedra share a triangular face. The middle Mn^{II} atom of the linear trinuclear cluster is coordinated by six oxygen atoms (Mn–O = 2.123(6) – 2.163(5) Å) belonging to three crystallographically distinct acetate carboxylate groups, while each of the two terminal Mn^{II} atoms is coordinated by four oxygen atoms (Mn–O = 2.171(5) – 2.406(13) Å) belonging to three different acetate carboxylate groups and two nitrogen atoms (Mn–N = 2.256(4) – 2.282(4) Å) of one chelate 1,10-phenanthroline. Interestingly, the acetate carboxylate group O3–C13–O4 chelates the terminal Mn(2) atom to form an O(3)–Mn(2)–O(4) angle of 50.7(3)°, and the O(3) atom acts as a bridge to link Mn(1) and Mn(2) with a Mn(1)–O(3)–Mn(2) angle of 95.9(4)° and distances Mn(1)–O(3) = 2.117(11)° and Mn(2)–O(3) = 2.441(12)°.

The structural analysis revealed that the two terminal chelating 1,10-phenanthroline molecules of one neutral trinuclear cluster

are not in a plane, but have a torsion angle of 36.44(6)°, which means **1** exists as two kinds of chiral neutral trinuclear enantiomers. The absolute configurations of these are as shown in Fig. 1b. Compound **1a** adopts a Δ configuration, while **1b** adopts a Λ configuration.

Detailed structural analysis revealed that the distance between the two planes of two adjacent 1,10-phenanthroline molecules in two neighboring trinuclear clusters is about 3.480(8) Å, within the range of π···π packing interactions (3.3–3.7 Å). It is the π···π packing interactions that link these clusters to result in the crystal of **1** as depicted in Fig. 1c.

3.1.2. $[Mn(phen)Cl_2]_n$ (**2**)

X-ray single crystal structure determination reveals that complex **2** is a coordination polymer based on neutral one-dimensional infinite coordination chains. In each asymmetric unit of **2**, one Mn^{II} center coordinates to two N donors (Mn–N = 2.2608(10) Å) of 1,10-phenanthroline and four chlorine atoms (Mn–Cl = 2.4809(3)-2.6630(3) Å), forming a distorted octahedral geometry as shown in Fig. 2a.

Detailed structural analysis revealed that the neutral one-dimensional infinite chain of **2** is assembled by Δ-configuration and Λ-configuration Mn^{II} units, alternately. In each Mn^{II} unit, one Mn^{II} coordinates to (i) two N donors of a 1,10-phenanthroline ligand, forming a Mn1–N1–C1–C2–N2–Mn1 five-member ring and (ii) four chlorine atoms which are bridge coordinated with another two neighboring units, forming two Mn1–Cl1–Mn2–Cl2–Mn1 four-member rings. As a result, two kinds of configuration of Mn^{II} units are formed, one in a Δ configuration and the other in a Λ configuration [11], as shown in Fig. 2b. Then they assemble alternately to form the one-dimensional chains of **2** (Fig. 2c).

Analysis of the crystal packing of **2** indicates that the distance between two planes of two adjacent 1,10-phenanthroline molecules of two neighboring chains is about 3.251(6) Å, which indicates strong π···π packing interactions. The inter-chains π···π packing interactions link these one-dimensional infinite coordination chains to result in the coordination polymer of **2** as depicted in Fig. 2d.

(a) Perspective view of **1**, showing the linear trinuclear cluster, hydrogen atoms are omitted for clarity; (b) perspective view of the Δ configuration and Λ configuration of compound **1a** (left) and **1b** (right), respectively; (c) crystal packing diagram of **1** along the *c* axis, showing the π···π packing interactions between two adjacent trinuclear clusters.

3.2. Magnetic properties

The variations of the molar magnetic susceptibilities χ_M were investigated for compounds **1** and **2** in the temperature range 2–300 K at a field of 1000 Oe. The study of the temperature

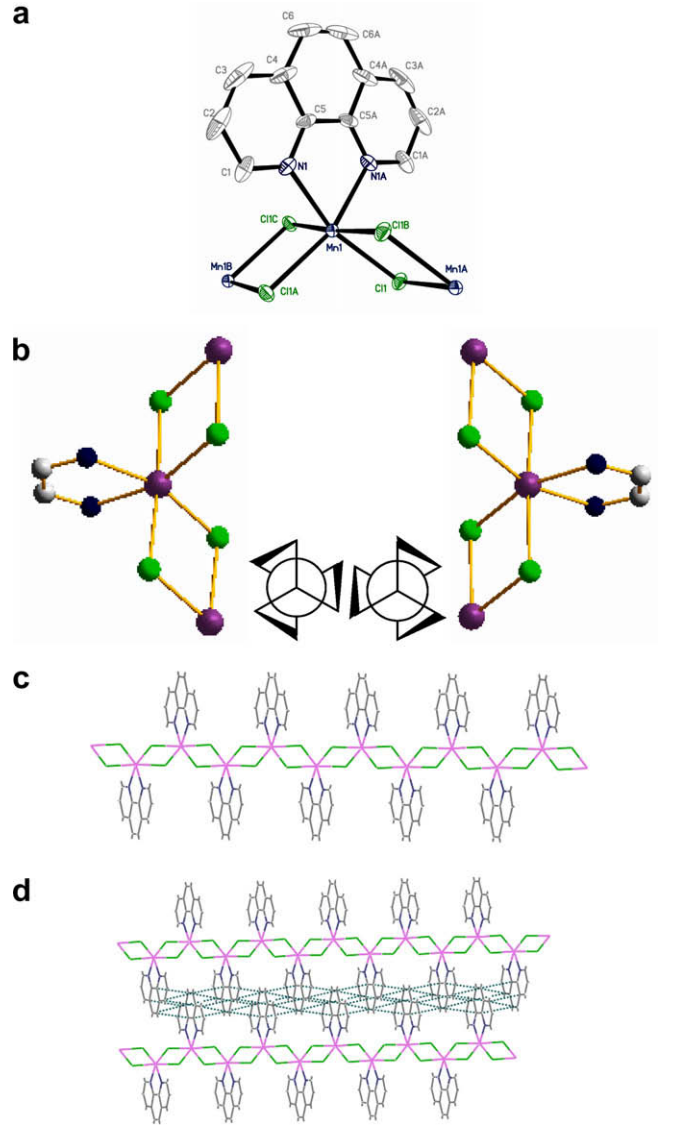

Fig. 2. (a) Perspective view of an asymmetric unit of **2**, hydrogen atoms are omitted for clarity; (b) perspective view of the Δ configuration (left) and Λ configuration (right) of Mn^{II} units of **2**; (c) the neutral hetero-assembled one-dimensional infinite coordination chains of **2**, (d) crystal packing diagram of **2**, showing the π···π packing interactions between two adjacent 1-D infinite coordination chains of **2**.

dependent magnetic susceptibilities revealed that **1** shows an antiferromagnetic coupling between the Mn^{II} ions while **2** displays a ferromagnetic interaction within the chain.

The χ_M^{-1} and $\chi_M T$ *versus* T plots of **1** are displayed in Fig. 3a. The inverse susceptibility plot as a function of temperature is linear (above 80 K), following the Curie–Weiss law $\chi_M = C/(T-\theta)$ for Mn^{II} centers with the Curie constant $C = 14.72\ cm^3\ K\ mol^{-1}$ and Weiss temperature $\theta = -24.6$ K. Below this temperature, a departure from the line may be caused by antiferromagnetic interactions. The $\chi_M T$ versus T plot exhibits a value of 13.63 cm^3 K mol^{-1} at 300 K, which is slightly above the expected value $\chi_M T = 13.12\ cm^3\ K\ mol^{-1}$ for three uncoupled Mn^{II} ions with $S = 5/2$ and $g = 2$ each [12]. It continuously decreases on cooling to a value of 1.167 $cm^3\ mol^{-1}$ K at 2 K. Such magnetic behavior is typical for antiferromagnetic coupling between Mn^{II} ions [13].

Taking into account the structure of the isolated and linear Mn(II) trimer units in **1** and assuming that the exchange coupling within the cluster is isotropic and that there is no interaction

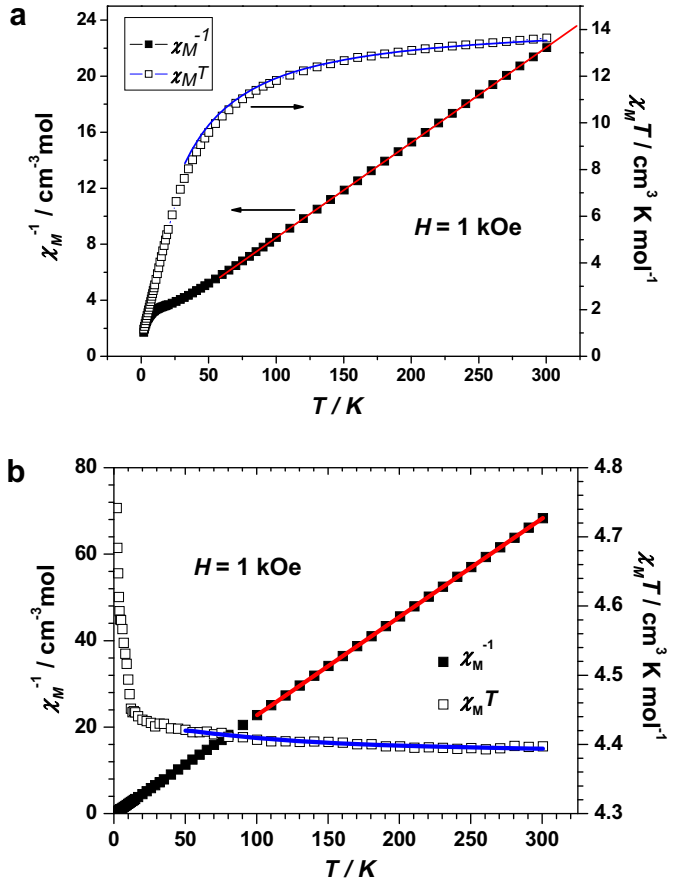

Fig. 3. The χ_M^{-1} and $\chi_M T$ vs. T plots, (a) for **1** and (b) for **2** at $H = 1000$ Oe. The red solid lines represent the best fit for the Curie–Weiss Law and the blue ones are the fitting lines with the models mentioned in the text.

between the two terminal Mn(II) ions, the Heisenberg Hamiltonian for the trimer system can be written as

$$H = -J(S_1S_2 + S_2S_3)$$

where J is the exchange coupling constant (negative for antiferromagnetic and positive for ferromagnetic interactions) and S_1, S_2, $S_3 = 5/2$ for the three Mn(II). By application of Van Vleck's equation, [14] a theoretical expression for the molar susceptibility may be derived as follows:

$$\chi_M = \frac{Ng^2\beta^2}{3kT}\left(\frac{3F_1}{4F_2}\right)$$

where $F_1 = 680\ e^{27.5x} + 455(e^{20x} + e^{25x}) + 286(e^{13.5x} + e^{18.5x} + e^{22.5x}) + 165(e^{8x} + e^{13x} + e^{17x} + e^{20x}) + 84(e^{3.5x} + e^{8.5x} + e^{12.5x} + e^{15.5x} + e^{17.5x}) + 35(e^{15x} + e^{5x} + e^{9x} + e^{12x} + e^{14x}) + 10(e^{2.5x} + e^{6.5x} + e^{9.5x} + e^{11.5x}) + (e^{5x} + e^{8x}) + 35,$

$F_2 = 8\ e^{27.5x} + 7(e^{20x} + e^{25x}) + 6(e^{13.5x} + e^{18.5x} + e^{22.5x}) + 5(e^{8x} + e^{13x} + e^{17x} + e^{20x}) + 4(e^{3.5x} + e^{8.5x} + e^{12.5x} + e^{15.5x} + e^{17.5x}) + 3(e^{15x} + e^{5x} + e^{9x} + e^{12x} + e^{14x}) + 2(e^{2.5x} + e^{6.5x} + e^{9.5x} + e^{11.5x}) + (e^{5x} + e^{8x}) + 3$

$$x = J/(kT)$$

The best fitting for the data from 32 to 300 K gives $J = -6.60\ cm^{-1}$ and $g = 2.10$. The negative J value indicates antiferromagnetic coupling between the Mn^{II} ions, which is consistent with similar compounds [14].

The magnetic properties of **2** are shown in Fig. 3b. The molar susceptibility also follows the Curie–Weiss law in the range 100–

300 K, with a value of the Curie constant $C = 4.39\ cm^3\ K\ mol^{-1}$ and Weiss temperature $\theta = +0.43$ K, as shown in Fig. 3b. At 300 K, the $\chi_M T$ value of **2** is $4.40\ cm^3\ K\ mol^{-1}$ per Mn^{II}, which is slightly above the expected value for $S = 5/2$ of a spin-only ground state for per couple of uncorrelated Mn^{II} centers ($4.35\ cm^3\ K\ mol^{-1}$). Then it continuously increased to a maximum of $4.74\ cm^3\ K\ mol^{-1}$ when the temperature was cooled to 2 K. This behavior of the $\chi_M T$ curve shows that **2** is a one-dimensional ferromagnetic coupled chain [15].

The value of the exchange interaction of **2** has been estimated according to the Fisher model of the isotropic Heisenberg antiferromagnet for a $S = 1/2$ system and later modified by Wagner and Friedberg [16] for the Mn(II) system of $S = 5/2$. The molar susceptibility of the Fisher chain can be expressed as

$$\chi = \frac{NS(S+1)}{3kT} g^2 \beta^2 \frac{1-u(K)}{1+u(K)}$$

where $u(K)$ is $1/K - \coth(K)$, $K = 2JS(S+1)/kT$, $g = 2$ and $S = 5/2$. The best fitting to the data from 50 to 300 K gives $J = +0.02\ cm^{-1}$, $g = 2.00$. The small positive J value shows a slightly ferromagnetic interaction within the Mn^{II} chain.

4. Conclusions

By the strategy of pH-directed assembly, we have synthesized two polynuclear manganese(II) complexes. In the pH range 5–6, chiral linear trinuclear manganese molecules were obtained, while on adjusting the pH to about 1 with hydrochloric acid, one-dimensional infinite manganese chains were gained. Further studies on the preparation of polynuclear manganese functional complexes are under way in our laboratory.

Supplementary data

CCDC 603481 and 603482 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. Chemicals and starting materials

All the solvents were purified by conventional procedures and distilled prior to use. Commercially available chemicals (Aldrich) were used as supplied without further purification.

2.2. Synthesis of the ligand dmpt

The ligand (*R*,*R*)-(+)-di-*N*,*N*′-methylpyridino-tartramide (dmpt) (Fig. 1) was prepared as previously described and was characterized by IR, ^1H–^{13}C NMR and elemental analysis [19].

2.3. Synthesis of the complexes

2.3.1. Synthesis of $Na[Cu_2(dmptH_{-3})(CO_3)] \cdot 8H_2O$ (**1**)

A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.74 g, 2 mmol) in 15 mL of ethanol was added dropwise to a solution of dmpt (0.33 g, 1 mmol) dissolved in 20 mL of absolute ethanol. Then, solid Na_2CO_3 (0.21 g, 2 mmol) was added in small portions and the mixture was stirred for 20 min and filtered. Slow evaporation of the solution at room temperature yielded blue crystals suitable for X-ray diffraction analysis. Yield: 0.45 g (67%). *Anal.* Calc. for $C_{17}H_{31}Cu_2N_4NaO_{15}$: C, 29.96; H, 4.54; N, 8.22; Cu, 18.6. Found: C, 30.11; H, 4.40; N, 8.24; Cu, 19%. IR (KBr) (cm^{-1}): 3424 (s, ν_{O-H}), 1614 (vs, $\nu_{C=O}$), 1585 (s, $\nu_{pyridine\ ring}$), 1420, (s, νCO_2), 1560 and 1319 (s, ν_{C-N} and δ_{N-H}). UV–Vis λ_{max} (nm) (ε, $mol^{-1}\,dm^3\,cm^{-1}$): (solid state) 640, broad; (H_2O) 640 (310); (DMF) 610 (280).

2.3.2. Synthesis of $[Ni_2(dmptH_{-2})_2] \cdot 2H_2O$ (**2**)

$Ni(OH)_2$ was freshly obtained by adding 2 equiv. of NaOH to an aqueous solution of nickel chloride. $Ni(OH)_2$ (0.09 g, 1 mmol) was added to a solution of dmpt (0.33 g, 1 mmol) in 10 mL of a mixture of CH_3OH and H_2O (v/v = 1/1), and stirred for 2 h. The blue-purple precipitate obtained was filtered, washed with ethanol and dried in vacuum. Yield: 0.3 g (75%). *Anal.* Calc. for $C_{32}H_{36}N_8Ni_2O_{10}$: C, 47.4; H, 4.4; N, 13.8; Ni, 14.5. Found: C, 47.7; H, 4.5; N, 14.1; Ni, 14.1%. IR (KBr) (cm^{-1}): 3386 (s, ν_{O-H}), 1608 (vs, $\nu_{C=O}$), 1563 and 1480 (s, $\nu_{pyridine\ ring}$), 1565 and 1399 (s, ν_{C-N} and δ_{N-H}). UV–Vis λ_{max} (nm) (ε, $mol^{-1}\,dm^3\,cm^{-1}$): (solid state) 365, 568, 987 (broad); (CH_3OH) 280 (68), 575 (9), 975 (33).

$[Ni_2(dmptH_{-2})_2] \cdot 9.75H_2O$ (**2**), was obtained as monocrystals by mixing a solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1 mmol) in 10 mL of ethanol and a solution of dmpt (0.33 g, 1 mmol) in 20 mL of ethanol. Then, potassium *tert*-butoxide (0.224 g, 2 mmol) dissolved in 5 mL of ethanol was added and the mixture was stirred for 2 h and filtered. The resulting purple solution concentrated at room temperature gave blue-purple crystals suitable for X-ray diffraction analysis.

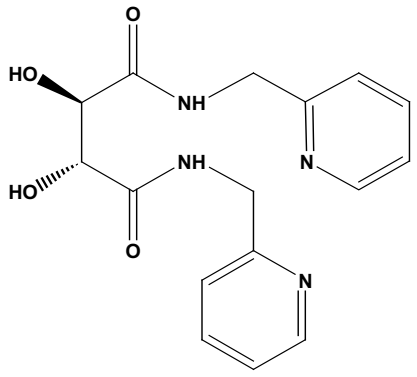

Fig. 1. Schematic structure of the ligand dmpt (neutral form).

2.3.3. Synthesis of $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$ (**3**)

To avoid cobalt oxidation the synthesis was monitored in a glovebox under N_2 atmosphere. A solution of $Co(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1 mmol) in 10 mL of ethanol was added dropwise to a solution of dmpt (0.165 g, 0.5 mmol) in 20 mL of ethanol. Then, sodium hydroxide (0.08 g, 2 mmol) dissolved in 5 mL of water was added. The mixture was heated at 60 °C, and stirred for 1 h. The red powder which precipitated was then filtered, washed with ethanol and dried in vacuum; yield 0.16 g (50%). *Anal.* Calc. for $C_{16}H_{24}Co_2N_4O_{13}NaCl$: C, 28.4; H, 3.8; N, 8.3; Co, 17.4; Na, 3.4. Found: C, 28.8; H, 3.9; N, 8.6; Co, 17.8, Na 3.3%. IR (KBr) (cm^{-1}): 3422 (s, ν_{O-H}), 2899 (vs, ν_{CH}), 1586 (vs, $\nu_{C=O}$), 1560 (s, ν_{C-N} and δ_{N-H}), 1085 (s, ν_{ClO_4}). UV–Vis λ_{max} (nm) (ε, $mol^{-1}\,dm^3\,cm^{-1}$): (CH_3OH) 503 (75), 560 (52), 582 (46).

2.4. Physical measurements

Elemental analyses (C, H and N) were carried out on a Perkin–Elmer 2400 C, H, N element analyzer in our university. The metal analysis was performed on an ICP AES Liberty Series II Varian apparatus.

ESI-MS experiments were monitored on a hybrid tandem quadrupole/time-of-flight (Q-TOF) instrument, equipped with a pneumatically assisted electrospray (Z-spray) ion source (Micromass, Manchester, UK) operated in the positive mode. The electrospray potential was set to 3 kV in the positive ion mode and the extraction cone voltage was usually varied between 30 and 90 V in order to obtain optimized mass spectra.

Magnetic measurements were performed at the Institut de Physique et Chimie des Matériaux de Strasbourg (UMR CNRS-ULP 7504) using a Quantum Design MPMS-XL SQUID magnetometer. The susceptibility measurement was performed in the 300–1.8 K temperature range with an applied magnetic field of 0.5 T. Magnetization measurements at different fields at a given temperature confirm the absence of ferromagnetic impurities. Data were corrected for the sample holder and diamagnetism was estimated from Pascal constants.

The UV–Vis spectra in solution were recorded on a Perkin–Elmer Lambda 6 spectrophotometer. In the solid state, the visible spectra were obtained on a Beckman 5240 spectrophotometer by depositing the compound on a Schleicher and Schul ash-free filter paper. The paper was used as the reference. IR spectra were obtained in KBr pellets with a Nicolet Avatar 320. Thermogravimetric analysis (TGA) studies were carried out in the 25–300 °C range using a 2950 TA-Analyser. Electrochemical measurements were performed at room temperature in DMF using an Autolab PGSTAT12 potentiostat equipped with a three-electrode assembly comprising a glassy carbon-working electrode, a Pt counter electrode and a Ag/AgCl reference electrode. The ferrocenium(1+)/ferrocene couple was used as an internal standard. All potentials were reported relative to the Ag/AgCl reference electrode. The $E_{½}$ value of the ferrocenium/ferrocene (Fc^+/Fc) system under the experimental conditions was 630 mV in DMF and ΔEp for Fc^+/Fc was 110 mV. Tetrabutylammonium hexafluorophosphate (10^{-1} mol L^{-1}) was used as the supporting electrolyte. The sample concentration was 10^{-3} mol L^{-1} and the solution was de-aerated with Argon gas for at least 20 min before measurement.

2.5. Crystal structure determination

The intensity data were collected in the phi scan mode at 293 K for compound **1** and at 100 K for compound **2** on a Bruker-Nonius

Kappa-CCD diffractometer, equipped with a graphite monochromator, using Mo Kα radiation (λ = 0.71073 Å). The structures were solved by direct methods using the SIR92 software package [20] and refined by full matrix least-squares on F^2 using SHELXL97 [21]. The intensities were corrected for Lorentz and polarization effects. In both crystal structure determinations, non-hydrogen atoms were located in the difference Fourier syntheses and were refined with anisotropic thermal parameters. Not all hydrogen atoms were observed in the difference Fourier syntheses, in particular those belonging to the alcohol groups and to 12 disordered water molecules in **2**. Observed hydrogen atoms were placed at calculated positions using a riding model, except those of water molecules which were either refined (**1**) or restrained to the mean Ow–H distances (0.97 Å) and H–Ow–H angles (~107°) observed from neutron diffraction data (**2**). In both crystal structure determinations, a global isotropic thermal parameter was refined for the H-atoms. Within each dimer of the asymmetric unit of **2**, one pyridylmethyl group of each ligand was found to be disordered. When compared to each other, the groups exhibited a very similar disorder, and the moieties show statistically equivalent site occupation factors (0.61(2)/0.39(2) and 0.63(2)/0.37(2)). In fact, the dimers of **2** are related by twofold axes pseudo-symmetry elements, which could eventually lead to the orthorhombic $C\,222_1$ space group. However, close inspection of the systematic absences clearly indicates the good choice of the monoclinic $P2_1$ space group, the pseudo-symmetry elements being non-crystallographic mainly due to the co-crystallized water molecules (many of them are disordered).

Crystal data and refinement details for $Na[Cu_2(dmptH_{-3})(CO_3)]\cdot 8H_2O$ (**1**) and $[Ni_2(dmptH_{-2})_2]\cdot 9.75H_2O$ (**2**) are shown in Table 1. Additional experimental information, including atomic positional parameters, is supplied in CIF format as described in the Supplementary data.

2.6. XAS data collection and analysis

The XANES (X-ray Absorption Near Edge Structure) and EXAFS (Extended X-ray Absorption Fine Structure) spectra were collected at the ELETTRA Synchrotrone (Trieste, Italy) on the Beamline 11.1 of the storage ring operating at 2/2.4 GeV with an optimal storage beam current of around 300/130 mA. The measurements were carried out at the cobalt *K*-edge (≈7709 eV) and the incident beam was mono-chromatized with a Si(1 1 1) double crystal. The energy was calibrated by measuring the absorption edge of a cobalt metallic foil (fixed at 7709 eV). The detectors were low-pressure (≈0.2 atm) air-filled ionization chambers and the measurements were performed at room temperature in the transmission mode. The XANES spectra were the sum of three recordings in the range 7660–7780 eV, and the EXAFS spectra were the sum of three recordings in the range 7660–8660 eV (including the cobalt *K*-edge (≈7709 eV)). The spectra were recorded using sampling steps of 0.2 eV (XANES) and 2 eV (EXAFS), and an integration time of 2.0 s per point was used in both cases. The spectrum of the 0.5 μm metallic foil was recorded just before the unknown XANES spectra to check the energy calibration. Spectra were measured on well-powdered samples mixed with boron nitride, to give a sample thickness of *ca.* 1 mm, placed in aluminium sample holders and held in place by Kapton tape.

The EXAFS data analysis was performed using the "EXAFS pour le Mac" and EXAFS98 programs [22,23]. The $\chi(k)$ functions were extracted from the data with a linear pre-edge background and a polynomial atomic-absorption background, and normalized using the Lengeler–Eisenberger method [24]. The extraction procedure was conducted as previously described [25]. In this work, all Fourier transforms were calculated and presented without phase correction. The major peak below 2 $Å^{-1}$ in the Fourier transformed curve was isolated and back-Fourier transformed. An *R* range of ≈0.80–2.15 $Å^{-1}$ was used for the first peak. This back-Fourier transformed peak was fit in *k* space. Structural parameters (R_i, distances between neighbours, N_i, number of neighbours and σ_i, Debye-Waller factor) were extracted with fits to the standard EXAFS formula, realized in the framework of a single scattering. The estimated errors for distances and coordination numbers are ±0.02 Å and ±20%, respectively. The backscattering phase, $\Phi_i(k,R_i)$, and amplitude, $A_i(k,R_i)$, functions were obtained using the ab initio FEFF 7 code [26]. The validity of the theoretical functions was ascertained using a reference compound of known crystallographic structure: Co^{III}[1,12-bis(2-pyridyl)-5,8-dioxa-2,11-diazadodecane] [27] for the Co–O and Co–N waves. Moreover, the FEFF 7 code was used to check if the multiple scattering of our reference compounds of known crystallographic structure was negligible in the 0–3 Å range. No constraints were placed on the fitting parameters of the first neighbour O shells, but the Debye-Waller factor (σ^2) of the oxygen atom from water molecules was fixed at 0.01 $Å^2$ to reduce the number of free parameters in the fitting procedure.

3. Results and discussion

3.1. Synthesis

The new complexes with deprotonated forms of the ligand, $Na[Cu_2(dmptH_{-3})(CO_3)]\cdot 8H_2O$ (**1**), $[Ni_2(dmptH_{-2})_2]\cdot 2H_2O$ and $[Ni_2(dmptH_{-2})_2]\cdot 9.75H_2O$ (**2**) and $[Co_2(dmptH_{-3})(\mu\text{-}OH)]\cdot NaClO_4\cdot 5H_2O$ (**3**) were synthesized in a mixture of water and ethanol under basic conditions (pH ≈ 8). NaOH, Na_2CO_3, $KtBuO^-$ and/or $Ni(OH)_2$ were used as bases to deprotonate the NH amido- and the OH alcohol groups of the ligand. When NaOH is used in the preparation of the copper complex (**1**), the absorption of atmospheric CO_2 during the recrystallization leads to the formation of a carbonato bridged complex.

3.2. Thermal decomposition

For the Cu(II), Ni(II) and Co(II) complexes, TGA experiments were monitored under a nitrogen atmosphere in the temperature

range 20–250 °C. For complexes (**2**) and (**3**), the analytical data show a weight loss, which occurs in one step in the temperature range 50–100 °C, corresponding to the loss of coordinated and uncoordinated water molecules. This weight loss corresponds to 13.6% in the case of complex (**3**), in agreement with the empirical formula $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$ (theoretical weight loss 13.7%). For the $[Ni_2(dmptH_{-2})_2] \cdot 2H_2O$ complex, the weight loss is equal to 4.6% (theoretical weight loss 4.4%), and is equal to 18.4% for the $[Ni_2(dmptH_{-2})_2] \cdot 9.75H_2O$ complex (**2**) (theoretical weight loss 18.5%). For complex (**1**), the thermal curve shows that the decomposition occurs in three steps, which correspond to the release of 3 (42 °C), 2 (47 °C) and 3 (120 °C) water molecules, giving a total weight loss of 20.9%, in accordance with the empirical formula $Na[Cu_2(dmptH_{-3})(CO_3)] \cdot 8H_2O$ (theoretical weight loss 21.1%).

3.3. X-ray diffraction studies

3.3.1. $Na[Cu_2(dmptH_{-3})(CO_3)] \cdot 8H_2O$ (**1**)

Complex (**1**) crystallizes as a water solvate in the space group $P2_12_12_1$ with four formula units present in the unit cell. The molecular structure consists of a dinuclear $[Cu_2(dmptH_{-3})(CO_3)]^-$ anion with one sodium cation and eight water molecules of crystallization. In the crystal lattice, the sodium cation is coordinated by six water molecules in an octahedral fashion with Na···OH_2 distances in the range 2.3–2.5 Å. Moreover, these octahedra are aligned into chains with μ-OH_2 bridges from the equatorial water ligand and OH···O hydrogen bonds from the axial water ligands. Selected bond lengths and angles are listed in Table 2. A Platon [28] drawing of the $[Cu_2(dmptH_{-3})(CO_3)]^-$ anion together with the labelling-scheme is shown in Fig. 2.

The dinuclear core is composed of two copper(II) ions bridged by one deprotonated endogenous alcohol group of the ligand and also by the carbonate anion. The Cu···Cu separation in the compound is 3.379 Å. Both copper(II) ions are tetracoordinated with an identical set of N_2O_2 donors atoms in a distorted square planar geometry. However, the coordination of the deprotonated alcohol O(2) has led to the existence of asymmetry in the compound: there are two five-membered chelate rings formed around Cu(1) with *cis* angles of 82.5° and 84.3°, whereas Cu(2) possesses one five-membered chelate ring and one six-membered chelate ring with *cis* angles of 82.9° and 95.6°, respectively. This implies a lengthening of the N_{amido}–Cu(2) bond of 0.041 Å compared to the N_{amido}–Cu(1) bond and a shortening of the $O_{carbonate}$–Cu(2) bond of 0.011 Å compared to the $O_{carbonate}$–Cu(1). The bond lengths involving the pyridylmethylamido nitrogen atoms are entirely consistent with those in other Cu(II) amido complexes [29,30]. The *trans* angles

in Cu(2) of 162.5° and 163.1°, smaller than their analogues of 166.7° and 175.8° in Cu(1), reflect the larger distortion around Cu(2).

3.3.2. $[Ni_2(dmptH_{-2})_2] \cdot 9.75H_2O$ (**2**)

Complex **2** crystallizes in the monoclinic system (space group $P2_1$) with four dimeric complexes and 39 co-crystallized water molecules per unit cell. Selected bond lengths and angles are summarized in Table 3, and a Platon drawing of the molecular structure of the dimer $[Ni_2(dmptH_{-2})_2]$ is shown in Fig. 3.

The molecular structure of each dimer is symmetric, with each half unit consisting of the first pyridylmethylamido group and the undeprotonated alcohol oxygen donor of the ligand coordinated to one nickel centre, with the same set of donor atoms of the same ligand being coordinated to the second nickel centre. In each dimer complex one pyridylmethyl group is disordered. It should be noted that, in spite of the hydrogen atoms of the alcohol groups not being found in the structure determination, the range and average of the C–$O_{alcohol}$ and $O_{alcohol}$–Ni^{2+} bond distances observed in **2** (1.429 < C–$O_{alcohol}$ < 1.445 Å, average 1.437 Å and 2.151 < $O_{alcohol}$–Ni^{2+} < 2.259 Å, average 2.165 Å) are significantly closer to those observed in Ni(II) complexes with undeprotonated alcohol groups, as found in the Cambridge Structural Database (corresponding to 25 hits, 1.399 < C–OH < 1.478 Å, average 1.444 Å; 1.901 < $O_{alcohol}$–Ni^{2+} < 2.182 Å, average 2.097 Å, respectively). In the same database, there was no hit corresponding to a nickel complex in which the ligand is coordinated through the deprotonated alcohol group, but 13 hits show a deprotonated alcohol group of the ligand in which the oxygen atom behaves as a bridge between two metallic ions, as observed in complex **1** (see above). In these metal ions (M^{2+} = Cu^{2+}, Zn^{2+}, Fe^{2+}), the C–$O^-_{alcohol}$ and M–$O^-_{alcohol}$ bond distances are: 1.363 < C–O^- < 1.453 Å, average 1.397 Å; 1.908 < O^-–M^{2+} < 2.021 Å, average 1.946 Å.

The intramolecular Ni···Ni separations within each dimer of the asymmetric unit are 5.268 and 5.269 Å. The geometry around the nickel atoms in both dimers is essentially identical and they are therefore discussed together, giving average values for the four coordinations. Both coordination geometries are distorted octahedral, with an N_4O_2 donor set of atoms coming from four nitrogen atoms from the two pyridylmethylamido moieties in the equatorial plane and two oxygen donor atoms from undeprotonated alcohol groups in the axial positions. Around each nickel centre, the two pyridyl nitrogen atoms and two alcohol oxygen atoms are each mutually trans. The average Ni–$N_{pyridyl}$ bond length of 2.086 Å is comparable to those observed in other six coordinate nickel(II) complexes with a pyridylcarboxamido moiety [31–34]. The average Ni–N_{amido} bond length of 1.977 Å, shorter than Ni–$N_{pyridyl}$, is

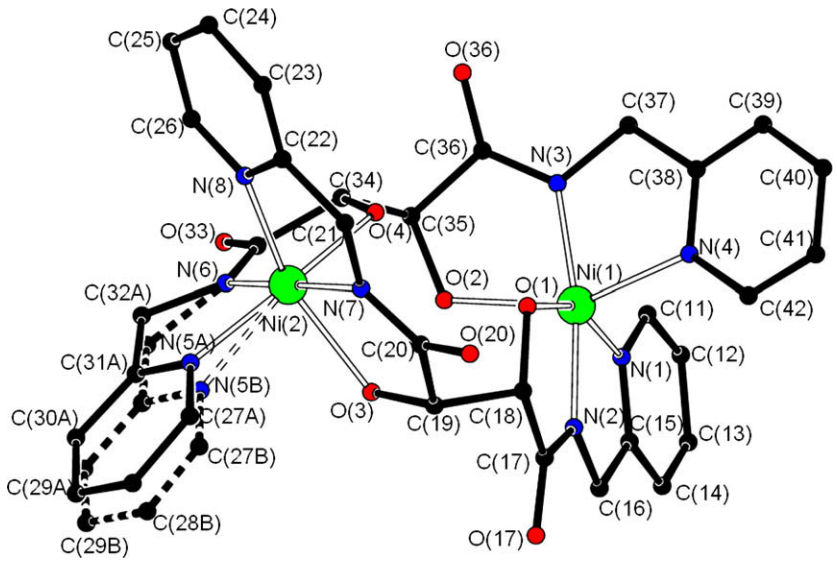

Fig. 3. Platon drawing of the dimer $[Ni_2(dmptH_{-2})_2]$ and the atom labelling-scheme. Water molecules and hydrogen atoms are omitted for clarity.

Table 3
Selected bond lengths (Å) and angles (°) for $[Ni_2(dmptH_{-2})_2] \cdot 9.75H_2O$ (**2**). The Ni–N bonds distance and N–Ni–N, or N–Ni–O bonds angles showing two values correspond to the disordered nitrogen atoms.

O(1)–Ni(1)–O(2)	87.47(14)	O(4)–Ni(2)–O(3)	85.11(15)

consistent with the stronger donor ability of the deprotonated amido nitrogen atoms. This amido bond length is well within the range of Ni–N_{amido} distances noted in similar complexes [31–35]. The average trans bond angles $N_{pyridyl}$–Ni–$O_{alcohol}$ and N_{amido}–Ni–N_{amido} (157.1° and 172.5°, respectively) deviate from the ideal octahedral trans angle of 180°. The range of the four five-membered chelate ring bond angles subtended by the ligands at the nickel atoms 75.8-81.2° (average, 78.5°) differ from 90°, indicating a large distortion around each nickel centre.

3.4. XAS investigations of $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$

XANES spectra were used to probe the oxidation state of the cobalt. There are a number of characteristic features in the XANES spectra of cobalt(II) and cobalt(III) complexes. Many cobalt compounds display a weak pre-edge feature at ~7709 eV that can be assigned to the 1s → 3d transition. Most cobalt(III) spectra show two main peaks, the absorption edge peak at ~7727 eV and a neighbouring peak at around ~7736 eV. Both peaks can be assigned to the 1s → 4p transitions [36]. In contrast, the XANES spectra of cobalt(II) complexes show a single main absorption peak at ~7723 eV. This is in accordance with several studies which have shown that the main absorption peak is shifted to lower values with a decreased effective charge of the nucleus [36,37]. Finally, the post-edge minima of the XANES spectra for cobalt(III) complexes are observed in the range 7757–7762 eV, whereas those of most cobalt(II) complexes occur in the range 7749–7750 eV. This post-edge minimum is a consequence of multiple-scattering phenomena which depend upon inter-atomic distances and angles [38–40].

Fig. 4 shows the Co *K*-edge XANES spectra of the $Co^{II}Cl_2$ reference compound and $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$ in the solid state and in solution. The three spectra exhibit a weak pre-edge feature at 7709 eV, which corresponds to a 1s → 3d transition. The relatively weak intensity of this pre-edge is consistent with an octahedral symmetry. Indeed, for this point group, a weak pre-edge feature is observed, despite being theoretically forbidden by the centre of symmetry. This is because the point group represents a static model derived by time-averaging the asymmetric vibrations within the molecule, whereas XAS reacts to the individual, and constantly changing, structures of the local environment as intramolecular vibrations which momentarily eliminate the

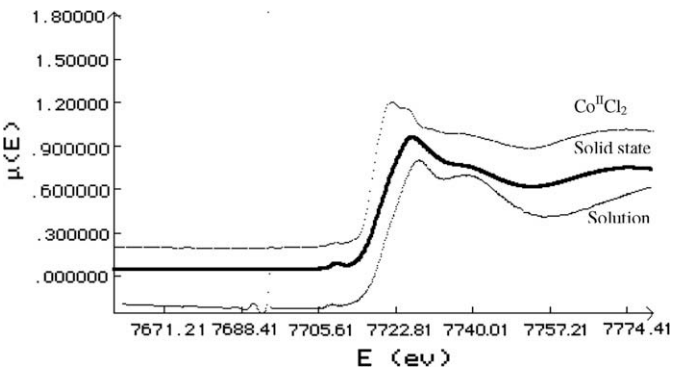

Fig. 4. Normalized XANES spectra of the $Co^{II}Cl_2$ reference compound and of $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$ in solid state and in solution.

centre of symmetry [41]. The absorption edge (1s → 4p transition) of the solid complex is at 7725.4 eV, whereas in solution the absorption edge is shifted to a higher value (7728.1 eV). The former value is in accordance with a +II oxidation state of the cobalt cation, which is oxidized in solution to cobalt(III). The presence of cobalt(II) is in agreement with the magnetic measurements. This oxidation state is also supported by the fact that the post-edge minimum in the XANES spectra differs between the solid state and solution. As a solid, cobalt(II) has its post-edge minimum at 7752.8 eV, while the complex in solution has its minimum at 7756.0 eV. Nevertheless, this difference may also be due to a strong effect of the coordination environment, which limits its usefulness in the determination of an oxidation state in complex systems [36]. However, this shift in the post-edge minimum combined with the one absorption edge confirms the +II oxidation state of the solid cobalt complex.

The experimental and least-squares fitting of the first shell filtered EXAFS spectra of the $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$ complex in solid state are shown in Fig. 5 with their corresponding Fourier transforms. A single shell fitting was performed to obtain the local structural parameters because the different atomic contributions to EXAFS oscillations do not interfere with one another, so each contribution to the EXAFS oscillation could be well resolved. The first shell was fitted with two Co–N/O contributions with a distance of 2.03 ± 0.02 Å and four Co–O/N contributions with a distance of 2.01 ± 0.02 Å. Even if the oxygen and nitrogen atoms have very similar phase and similar amplitude functions, the nature of the ligand allows us to propose a CoN_2O_4 chromophore: the two nitrogen atoms coming from pyridyl and amidic groups and the two bridged oxygen atoms from a deprotonated alcohol group and an hydroxyl group; the hexacoordination is achieved by two water molecules as depicted in Fig. 6. These results are in agreement with those obtained by UV–Vis spectroscopy and magnetism measurements, which underline a slightly distorted octahedral geometry around the cobalt(II) metallic cation.

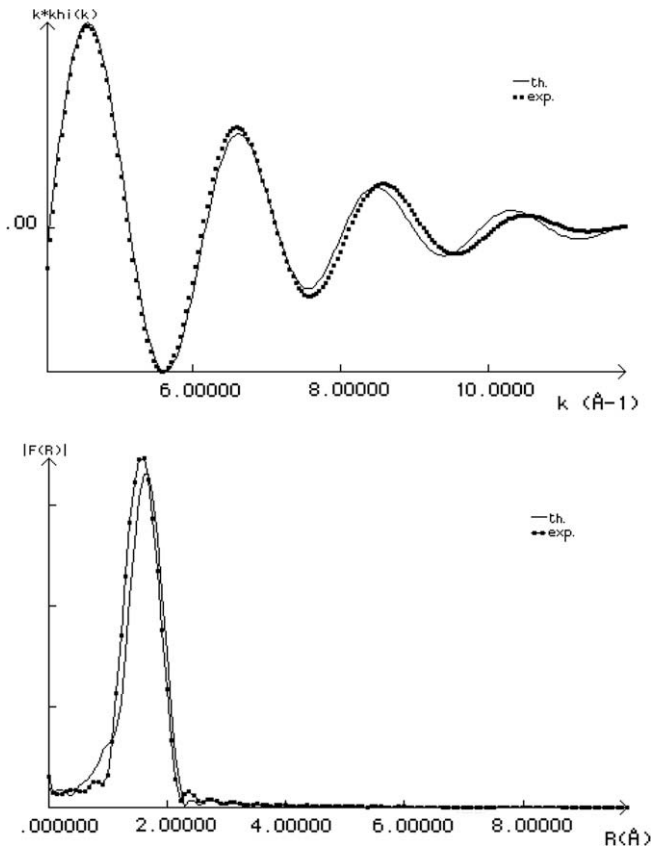

Fig. 5. First shell filtered Co *K*-edge EXAFS spectra (top) and the corresponding Fourier transforms (bottom) of the $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$ complex.

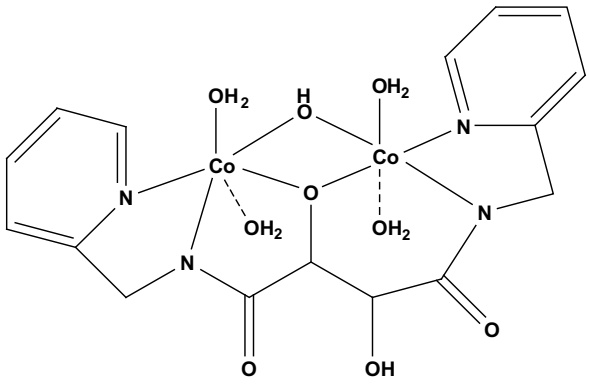

Fig. 6. Proposed structure for the complex $[Co_2(dmptH_{-3})(\mu\text{-}OH)]$.

Unfortunately, no significant peak on the Fourier transform at higher *R* values (>2.15 Å) could be interpreted. Indeed, fitting attempts which were performed at higher values on the very weak peaks lead to insignificant contributions. This is in accordance with a metal–metal distance higher than the one found for the copper complex (3.379 Å).

4. Spectral studies

4.1. IR spectroscopy

All the complexes exhibit broad bands around 3400 and 3500 cm^{-1}, which is caused by the OH vibration of coordinated and uncoordinated water molecules. The binding metal–ligand is indicated by a shift of the ν(CO) vibration from 1673 cm^{-1} in the free ligand to 1614, 1608 and 1586 cm^{-1} in the complexes (**1**), (**2**) and (**3**), respectively. The dinuclear copper complex (**1**), which is bridged by a carbonate ion, showed a strong $\nu(CO_2)$ band around 1420 cm^{-1} [42]. The presence of an uncoordinated perchlorate anion in complex (**3**) is inferred from the bands around 1085 and 630 cm^{-1} [42].

4.2. UV–Vis spectroscopy

4.2.1. Nickel complex

The UV–Vis spectra of the nickel complex in methanol and in DMF show three bands corresponding to the predicted $^3A_{2g} \rightarrow {}^3T_{2g}$ (950–800 nm), $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ (560–500 nm) and $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ (300–400 nm) transitions for a d^8 metallic cation held in an octahedral symmetry [43,44]. The overall pattern of the spectra for the solid state and solution are closely similar, which confirms that the complex structure is retained in the solution state. Moreover, ESI-MS analysis (in the positive mode) of the complex dissolved in CH_3OH solution is in agreement with the retention in solution of the dinuclear structure. The ESI-MS spectrum shows a major peak at *m*/*z* equal to 773.2 (*m*/*z* of the first peak of the isotopic clump), which corresponds to the formula $[Ni_2(dmptH_{-2})_2+H]^+$.

4.2.2. Copper complex

The electronic absorption spectra in water and in DMF exhibit a broad absorption band in the visible region with a maximum at 640 (ε = 310 mol^{-1} dm^3 cm^{-1}) and 610 nm (ε = 280 mol^{-1} dm^3 cm^{-1}), respectively. The symmetrical shape of the absorption band is typical of tetragonally distorted Cu(II) in a square

pyramidal geometry [34,45–47]. The small blue shift of the absorption maximum observed in DMF compared to the one in water is in accordance with the coordination of an additional solvent molecule to the copper centre compared to the coordination observed in the solid state. The electronic spectrum of the copper complex in the solid state exhibits two main transitions. The moderately intense peak close to 375 nm is probably due to a metal–ligand charge transfer, whereas the very broad band at λ_{max} equal to 640 nm is due to a d–d transition, which confirms the square planar geometry in the solid state.

4.2.3. Cobalt complex

The electronic absorption spectrum of $[Co_2(dmptH_{-3})(\mu\text{-}OH)] \cdot NaClO_4 \cdot 5H_2O$ dissolved in CH3OH is typical of a high spin Co(II) complex. The spectrum exhibits a broad band in the 450-650 nm region, which can be deconvoluted into three contributions: 503 ($\varepsilon = 75\ mol^{-1}\ dm^3\ cm^{-1}$), 560 ($\varepsilon = 52\ mol^{-1}\ dm^3\ cm^{-1}$) and 582 nm ($\varepsilon = 46\ mol^{-1}\ dm^3\ cm^{-1}$), which correspond respectively to the following forbidden transitions $4T_{1g}(F) \rightarrow 4B_{1g}(F)$, $4T_{1g}(F) \rightarrow 4E_g(P)$ and $4T_{1g}(F) \rightarrow 4A_{2g}(P)$ in D_4h symmetry [42,48].

5. EPR and magnetic susceptibility studies

The copper complexes are EPR-silent in the solid state and in a H_2O–CH_3OH solution at 150 K, suggesting an anti-ferromagnetic coupling between the copper ions. Such behaviour is confirmed by the temperature dependence of the molar magnetic susceptibility χ_M and of the product $\chi_M T$, depicted in Fig. 7a. The value of $\chi_M T$ at 300 K is 0.336 $cm^3\ K\ mol^{-1}$, well below the spin-only value for two Cu(II) ions (0.75 $cm^3\ K\ mol^{-1}$, considering $g = 2$). Upon cooling, χ_M and $\chi_M T$ decrease steadily, indicating a strong antiferromagnetic coupling between the Cu(II) ions. Below 10 K, a "Curie tail" appears in the χ_M versus T curve, which is attributed to the presence of a small quantity of a paramagnetic impurity. The experimental data were reproduced correctly using the following spin Hamiltonian where all parameters have their usual meaning [49] and where the spin operator $\mathbf{S}$ is defined as $\mathbf{S} = \mathbf{S_{Cu1}} + \mathbf{S_{Cu2}}$:

$$\mathscr{H} = -J\mathbf{S_{Cu1}}\mathbf{S_{Cu2}} + g\beta H\mathbf{S}$$

To satisfactorily reproduce the data, we had to consider a certain amount ρ of paramagnetic impurity, which was assumed to be a mononuclear copper(II) species ($\mathbf{S_{impur}} = ½$). The best-fit parameters are $J = -329.3(1)\ cm^{-1}$, $g = 1.92(1)$ and ρ = 0.18% with an excellent agreement factor $R = 3.2 \times 10^{-5}$ which is defined as: $R = \frac{\sum(\chi_{exp} - \chi_{calc})^2}{\sum \chi^2_{exp}}$.

These medium anti-ferromagnetic couplings should be correlated to a significant overlap between the two magnetic orbitals of the two copper(II) ions in the complexes through the oxo bridge. The coordination sphere around the two copper ions is square pyramidal and the unpaired electron of copper(II) occupies the $d(x^2–y^2)$ orbital, which points along the Cu–O bond. Short Cu–O bonds and large Cu–O–Cu angles in square-planar dinuclear copper complexes result in a strong overlap of the $d(x^2–y^2)$ orbitals and thus produce strong to very strong anti-ferromagnetic coupling. In the literature, much research has been undertaken to describe the relationship between the Cu–O–Cu angle and the magnetic interaction [50–55]. It has been clearly established [53] that large Cu–O–Cu angles (>110°) have a strongly anti-ferromagnetic contribution. The J value ($-329\ cm^{-1}$) follows the magneto-structural correlation between the Cu–O–Cu angle reported by Van Albada and co-workers [53]. The ferromagnetic interaction via the $Cu(\mu CO_3)Cu$ bridge observed in compounds in which the carbonate is monodentately bound to two copper ions by two oxygen atoms and the third oxygen, being uncoordinated [56–58], can be considered as negligible in our compound, taking into account the high J value.

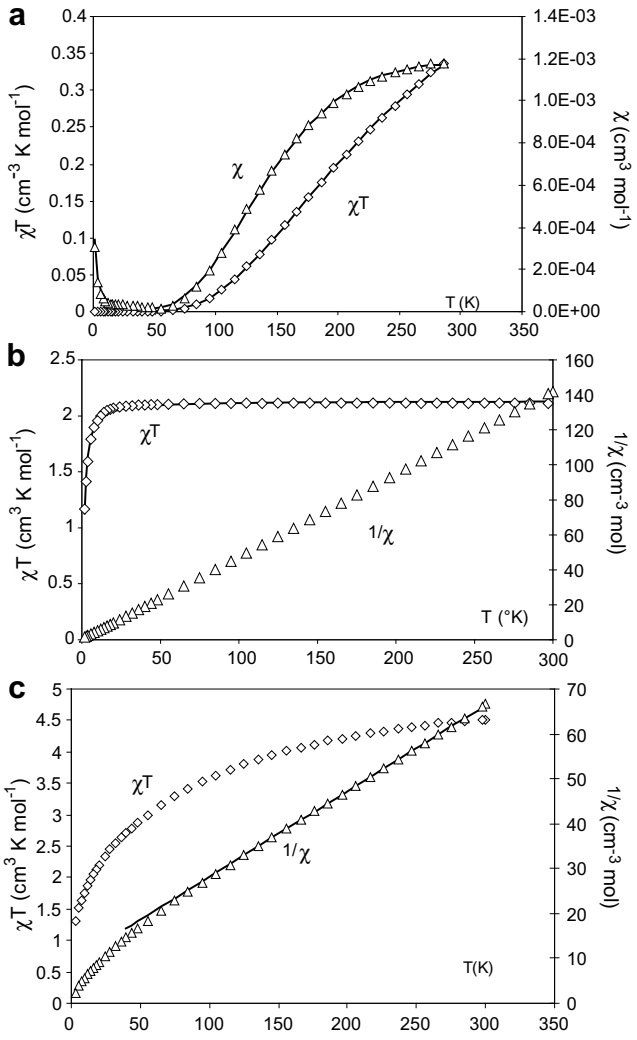

Fig. 7. Plots of $\chi_M T$ (◇) and χ_M (or $1/\chi_M$) (△) versus T for the copper (a), nickel (b) and cobalt (c) complexes. The solid lines are the fit of the data.

The magnetic behaviour of the nickel dimer is presented Fig. 7b. From room temperature to around 50 K, the χT product is almost constant (2.11 $cm^3\ K\ mol^{-1}$), indicating two almost non-coupled octahedral Ni(II) ions, with a g value of 2.05 [42,44,59–61]. The decrease of χT below 50 K (2.10 $cm^3\ K\ mol^{-1}$ at 50 K down to 1.17 $cm^3\ K\ mol^{-1}$ at 1.8 K) may be attributed to a zero-field splitting of the Ni(II) ions and/or to a very weak intramolecular antiferromagnetic coupling, in agreement with the long intramolecular Ni–Ni distance. Fitting the curve by considering zero-field splitting of Ni(II) ions and/or intramolecular anti-ferromagnetic coupling leads nearly to the same value of the agreement factor, which does not permit the two possibilities from being distinguished.

The plots of χ^{-1} and χT versus temperature for the Co(II) dinuclear complex are shown in Fig. 7c. The μ_{eff} value of this complex at 300 K, is 6.05 MB ($\chi_M T = 4.57\ cm^3\ K\ mol^{-1}$), which is consistent with the literature reports for high spin d^7 Co(II) [62–64]. The value of χT decreases regularly upon cooling from 4.57 $cm^3\ K\ mol^{-1}$ at room temperature to 1.26 $cm^3\ K\ mol^{-1}$ at 1.8 K. This decrease may be due to a spin-orbit coupling and/or to anti-ferromagnetic interactions. Above 50 K, the χ^{-1} versus T plot obeys the Curie-Weiss law, and the fitting provides a Curie constant C of 2.62 $cm^3\ K\ mol^{-1}$/Co and a Weiss temperature θ of −47.5 K. The

absence of crystallographic structure, as well as the existence of a spin–orbit coupling, prevented us from performing an accurate determination of the *g* and *J* parameters for this complex.

6. Electrochemistry

The range of potential recording is limited to −2.2 V to 0.9 V versus Fc^+/Fc taking into account the intrinsic redox processes of the ligand. The ligand voltammogram underlines an oxidation peak at 0.18 V versus Fc^+/Fc.

The cyclic voltammograms recorded in the negative potential range for the Ni(II) and Cu(II) complexes do not show any significant reduction process.

The cyclic voltammogram of the $Na[Cu_2(dmptH_{-3})CO_3]$ complex is shown in Fig. 8a. The cyclic voltammetry experiments underline two irreversible oxidation waves at 0.25 V (peak a) and 0.50 V (peak b) versus Fc/Fc^+. These two peaks corresponds to the successive oxidation of the two copper(II) centres into Cu(III), following two consecutive mono-electronic oxidation processes. Peak c corresponds to the ligand oxidation. The irreversible nature of the oxidation process suggests that the hypothetical Cu(III) species are highly reactive and might lead to ligand degradation. Within the functional groups present, the bridging alkoxide functions are most susceptible to be oxidized, which can produce aldehyde and carboxylic acid derivatives or C–C coupled products [65]. The dinuclear $[Ni_2(dmptH_{-2})_2]$ complex has two similar environments around the nickel atoms (see Section 3.3) and, consequently, these atoms present the same electrochemical behaviours. The cyclic voltammogram (Fig. 8b) in the positive potential range shows one single step of electron transfer processes at an $E_{1/2}$ value of 0.15 V versus (Fc^+/Fc). It corresponds to the simultaneous oxidation of the two Ni(II) centres, which indicates that the distance between the two metallic centres is sufficiently important so that the oxidation of one Ni(II) is not affected by the oxidation of the other centre. The second peak corresponds to the ligand oxidation. Cyclic voltammograms recorded between 0 and 1 V at three scan rates show that the oxidation process corresponding to the formation of the Ni(III)–Ni(III) complex is quasi reversible, taking into account the following criteria: (i) the $E_{1/2}$ values are independent of the scan rate, (ii) ΔEp increases with increasing scan rate and is always greater than 60 mV and (iii) the peak currents i_{pc} and i_{pa} are not equal [66].

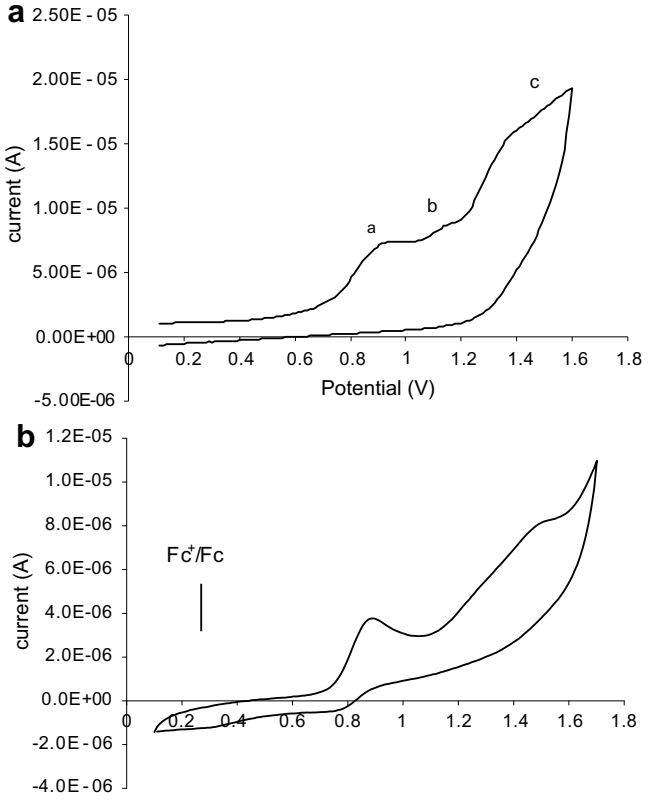

Fig. 8. Oxidation peaks for the copper (a) and nickel (b) complexes. Data were recorded in a 0.1 mol L^{-1} solution of Bu_4NPF_6 in DMF using Fc^+/Fc as a reference.

Under our experimental conditions, the cyclic voltammogram of the Co(II) dinuclear complex does not show any redox processes. This seems to indicate that the oxidation in solution of Co(II) into Co(III), which was revealed by the XANES experiments, is probably a process which requires the contribution of atmospheric oxygen.

7. Conclusion

We have described the synthesis and structure of new Cu(II), Ni(II) and Co(II) dinuclear complexes formed with a tartramide ligand. These complexes were characterized by X-ray diffraction study or XAS experiments, UV–Vis spectroscopy and cyclic voltammetry. The magnetic properties were also investigated using EPR spectroscopy and variable temperature magnetic measurements. In the dinuclear copper complex, the two metallic centres are in a square planar geometry and are linked together by alkoxo (Cu···O···Cu) and carbonato bridges. The short Cu···Cu distance and the large Cu–O–Cu angle favor strong antiferromagnetic interactions between the two copper centres. The octahedral geometry around the Ni(II) ions enhances the formation of the dimer species $[Ni_2(dmptH_{-2})_2]$ in which the metallic centres are coordinated by the nitrogen atoms of the pyridyl groups and the deprotonated amide functions, as well as the hydroxyl groups of the ligands. In this structure, the metal centres are weakly coupled. The cobalt(II) complex was obtained as a powder and the structural investigation was monitored by XAS, which leads us to consider an octahedral coordination around the metal centres. The study of the variable temperature magnetic behaviour of the complex shows that the two metallic cobalt(II) cations are also weakly coupled.

Acknowledgements

The authors are grateful to Dr S. Belin (Synchrotron Soleil) and Dr L. Olivi (Staff Beamline) for their help in XAS data recording. Assistance of Dr E. Wenger, Pr. P. Leconte and Pr. E. Espinosa for X-ray diffraction, and Dr F. Massicot, R. Plantier-Royon and C. Portella for ligand synthesis is greatly appreciated. We also thank Dr D. Harakat for ESI-MS spectra recording and helpful discussions.

The XAS experiments were financially supported by the European Community Research Infrastructure Action under the PF6 "Structuring the European Research Area" Program (RII3-CT-2004-506008).

We thank the Conseil Général de la Marne for a grant to N. Tounsi and for its financial support.

Appendix A. Supplementary data

CCDC 652895 and 652896 contain supplementary crystallographic data for $Na[Cu_2(dmptH_{-3})(CO_3)] \cdot 8H_2O$ and $[Ni_2(dmptH_{-2})_2] \cdot 9.75H_2O$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.09.020.

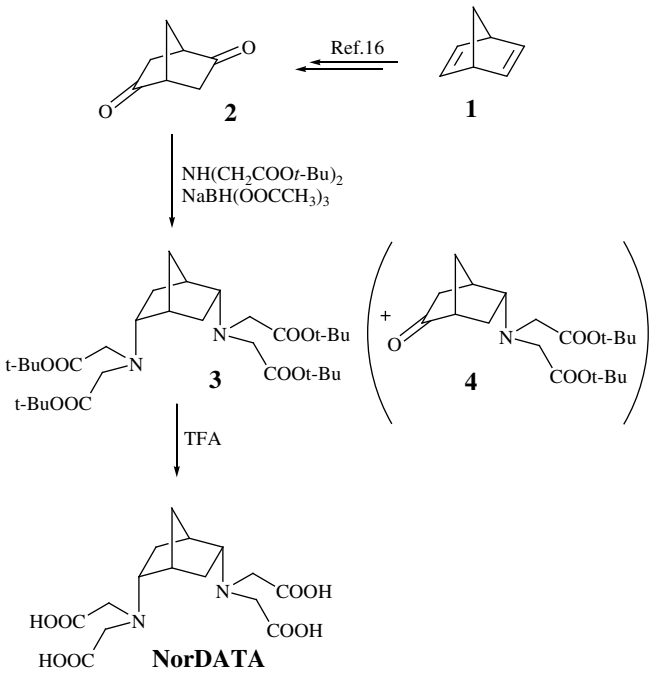

Scheme 1. Synthesis of **NorDATA**.

nitrogen atoms sticking out from a rigid bicyclic structure seemed promising for stable coordination of metal ions. Thus we decided to synthesize the aminocarboxylate ligand we christened **NorDATA** (Scheme 1) that is derived from the above diamine by adding four carboxymethyl arms to it, and subsequently to evaluate its potential as chelating agent.

Norbornadiene **1** was converted to 2,5-norbornanedione **2** by double addition of formic acid and subsequent Jones oxidation, according to a published procedure [16]. A direct reductive amination was then performed with di-*t*-butyl iminodiacetate and sodium triacetoxyborohydride [17], yielding tetraester **3**. A minor amount of a byproduct arising from a single reductive amination was also isolated. NMR analysis of **3** confirmed the *endo,endo* configuration of the amino groups. Removal of *t*-butyl ester groups in neat trifluoroacetic acid completed this short and efficient synthesis of **NorDATA**. The ligand was then characterized and studied for its complexing properties.

Table 1
Protonation constants of the ligands **NorDATA**, BDTA, DCTA and EDTA

Ionic strength	NorDATA 0.1 M KCl		BDTA[18] 0.1 M KNO_3		CDTA[19] 0.1 M KNO_3		EDTA[20a] 0.1 M KCl	
	$\log \beta$	$\log K_i^H$	$\log \beta$	$\log K_i^H$	$\log \beta$	$\log K_i^H$	$\log \beta$	$\log K_i^H$
$\log \beta_{011}$	10.54 (0.01)	10.54	10.45	10.45	12.3	12.3	10.18	10.18
$\log \beta_{021}$	18.17 (0.01)	7.63	19.43	8.98	18.42	6.12	16.33	6.15
$\log \beta_{031}$	20.80 (0.02)	2.63	22.11	2.68	22.01	3.59	19.03	2.7
$\log \beta_{041}$	22.71 (0.02)	1.91	24.11	2.0	24.43	2.42	21.11	2.08

2.2. Determination of complexing properties

In order to characterize the complexation properties of the ligand **NorDATA**, its protonation constants were first determined. The protonation constants ($\log \beta_i$) of **NorDATA** determined by pH-potentiometry are listed in Table 1 (standard deviations are shown in parentheses) and compared to those of archetypal EDTA (1,2-ethylenediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid), monocyclic CDTA (1,2-cyclohexanediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid) and structurally related BDTA (1,4-butanediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid), the latter sharing with **NorDATA** the number of carbon atoms lying between the coordinating nitrogen atoms.

On the basis of previously reported information, the protonation scheme of the BDTA, DCTA and EDTA is well defined [19,21]. We assume that the protonation sites and sequence of **NorDATA** are similar because all these ligands have similar structures and donor groups array. For all of them, starting from basic pH values, the first and second protonation take place at the nitrogen atoms of the ligand backbone. The third and fourth protonations involve two carboxylate groups. For **NorDATA**, all protonation constants are comparable to those of the flexible "parent" BDTA, but the second protonation constant of **NorDATA** $\log K_2^H = 7.63$ is appreciably lower than the corresponding one in parent BDTA $\log K_2^H = 8.98$, in which protonations occur practically independently. This difference may be ascribed to the larger electrostatic repulsion between the close protonated amino groups that reduces the basicity of the second one. This lower basicity and the rigid structure of the molecule result in slightly different complexation properties for **NorDATA** as compared to BDTA. The stability constants obtained by pH-potentiometric titration for some divalent metal and lanthanide ions are presented in Table 2 and Table 3, where the corresponding data for BDTA, DCTA and EDTA are also reported.

By comparing the stability constants of complexes formed by aminopolycarboxylate ligands with the same donor atoms we could shed some light on the complexation behavior of **NorDATA**. The inspection of data presented in Table 2 indicates that $\log \beta_{101}$ values of **NorDATA** complexes formed with metal ions of lower size (Mg^{2+}, Cu^{2+}, Zn^{2+}) do not differ much from those of EDTA complexes. This suggests that the distance between the two nitrogen atoms in the rigid **NorDATA** allows the coordination of the iminodiacetate ("imda") groups in the complexes. The $\log \beta_{101}$ values of the **NorDATA** complexes of Cu^{2+} and Zn^{2+} are somewhat higher than those of BDTA, which shows that in the "preorganized" **Nor-**

Table 2
Cumulative stability and protonation constants of **NorDATA**, BDTA, DCTA and EDTA complexes

Ionic strength	NorDATA 0.1 M KCl			BDTA[21] 0.5 M $NaClO_4$			CDTA[23] 1.0 M KCl	EDTA[20a] 0.1 M KCl

Er^{3+}	5.50	4.72	6.2	4.98
Lu^{3+}	5.56	4.62	5.94	4.76

DATA ligand the imda groups lies in a more favorable position. In the Cu^{2+} and Zn^{2+} **NorDATA** complexes the coordination of the two nitrogen atoms with the formation of a seven-membered ring leads to a chelate effect, as their $\log \beta_{101}$ values (Table 2) are higher than the $\log \beta_{102}$ values of the Cu(imda)$_2$ ($\log \beta_{102}$ = 16.68) [22] and Zn(imda)$_2$ ($\log \beta_{102}$ = 12.6) [22] complexes. However the stability constants of both Ln(**NorDATA**) and Ln(BDTA) complexes are low and significantly lower than the $\log\beta_{102}$ values of Ln(imda)$_2$ complexes (e.g., for Lu(imda)$_2$ $\log \beta_{102}$ = 13.73) [22], indicating the absence of a chelate effect. As it was found by Hancock and Martell, the hard metal ions of larger size, like Ln^{3+}, prefer to form the five-membered chelate rings in their complexes, while metal ions of lower size are able to form larger-size chelate rings [24].

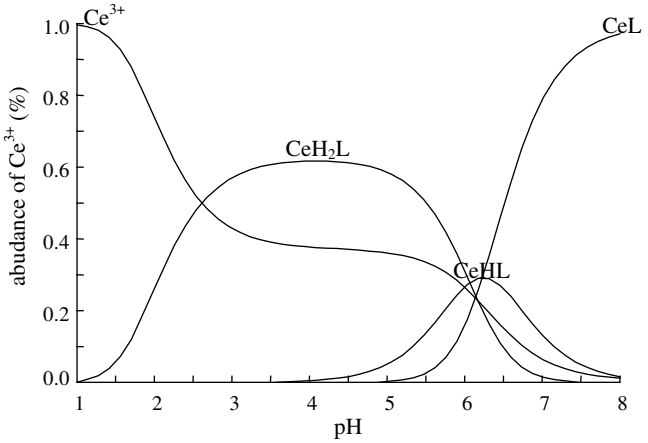

Fig. 1. Distribution diagram of the Ce^{3+}-**NorDATA** system ([Ce^{3+}] = [L] = 0.001 M).

In the protonated complexes formed with Cu^{2+}, as well as in Zn(**NorDATA**), protonation probably occurs at a carboxylate group of the ligand, because $\log K^{H}_{MNorDATA}$ values are relatively low (Table 3). However, the protonation constants of complexes formed with Mg^{2+}, Ca^{2+} and Ln^{3+} ions are large, suggesting that the nitrogen atoms of the coordinated ligand are protonated. The large $\log K^{H}_{MNorDATA}$ and $\log K^{H}_{MHNorDATA}$ values show that the interactions of Mg^{2+}, Ca^{2+} and Ln^{3+} ions with the nitrogen donor atoms are very weak.

The stability constants of Ln(**NorDATA**) complexes are relatively small; in fact the **NorDATA** ligand cannot prevent hydrolysis of Ln^{3+} ions at pH > 8.0. The stability constants of Ln(**NorDATA**) complexes increase from La^{3+} to Gd^{3+}, then remain practically constant for the heavier lanthanides. The stability constants of lanthanides complexes often increase with increasing atomic number because of the lanthanide contraction. For example, $\log \beta_{101}$ values of Ln(BDTA) complexes increase by 2.4 $\log \beta$ units from La^{3+} to Lu^{3+}. However, for Ln(**NorDATA**) complexes the increase in $\log \beta_{101}$ values is much lower, probably because of the more rigid structure of the **NorDATA** ligand.

The distribution diagram and UV-spectra of the Ce^{3+}-**NorDATA** system are reported in Figs. 1 and 2, respectively.

The UV-spectrum of the Ce^{3+}-**NorDATA** system was examined in order to ascertain the existence of each species. UV spectra show significant changes in the position of the absorption maxima as a result of complexation. In the pH range 1.8–4.5 a new absorption band appears at about 270 nm, which is related to the coordination of the carboxylates to the Ce^{3+}-ion and the formation of Ce(H_2**NorDATA**), a species in which N atoms are protonated. Above pH 4.5 the deprotonation and coordination of the N-atoms occur practically simultaneously, resulting in significant changes in absorption spectra. In general, the position of Ce^{3+} absorption bands depends on the number of the coordinated donor atoms [25]. For Ce(H_2**NorDATA**) the deprotonation and coordination of the N-atoms increase the number of the coordinated donor atoms and modify the coordination sphere of the Ce^{3+} ion, which is indicated by the 20 nm red shift in the maximum of the absorption bands. The absorption spectrum of Ce(**NorDATA**) at pH 6.7 is very similar to that of Ce(EDTA) [25]. This is not surprising, since in both complexes two N-atoms and four carboxylates are coordinated to the Ce^{3+} ion.

3. Experimental

3.1. General

All chemicals were purchased from Sigma-Aldrich or from Alfa-Aesar and were used without purification unless otherwise stated. NMR spectra were recorded on a JEOL ECP 300 (operating at

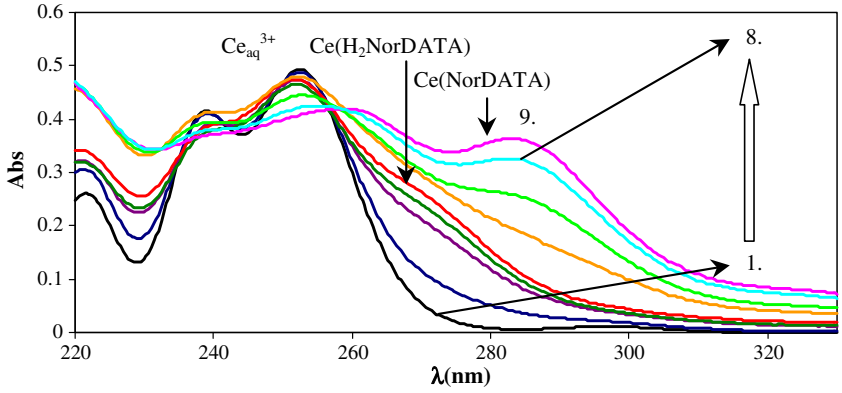

Fig. 2. Absorption spectra of the Ce^{3+}-NorDATA system. ([Ce^{3+}] = [NorDATA] = 7 × 10^{-4} M; (1) Ce^{3+}_{aq}; (2) pH 1.82; (3) pH 2.52; (4) pH 3.05; (5) pH 4.00; (6) pH 5.92; (7) pH 6.21; (8) pH 6.44; (9) pH 6.62, 25 °C, 0.1 M KCl).

7.05 T). ESI mass spectra were recorded on ThermoFinnigan LCQ-Deca XP-Plus and melting points (uncorrected) with a Stuart Scientific SMP3 apparatus.

3.2. Synthesis

3.2.1. ***NorDATA***, *tetra-t-butyl ester (**3**)*

In a 50-mL round-bottomed flask 2,5-norbornanedione[16] (**2**, 1.00 g, 8.06 mmol) and di-*t*-butyl iminodiacetate (3.96 g, 16.1 mmol) were dissolved in 1,2-dichloroethane (20 mL) at room temperature and under a dinitrogen atmosphere. Sodium triacetoxyborohydride (3.42 g, 16.1 mmol) was added in a single portion and the mixture stirred at room temperature. After 15 h a second portion of di-*t*-butyl iminodiacetate (0.79 g, 3.2 mmol) was added and stirring was maintained for another 70 h. The reaction mixture was poured in water and extracted with dichloromethane (3×20 mL). The combined extract were dried over Na_2SO_4, filtered and evaporated *in vacuo*. The viscous oily residue was subjected to column chromatography on silica gel (petroleum ether/ethyl acetate 9:1 as eluant), yielding pure **3** (3.140 g, 67% yield) and some compound **4** (0.69 g, 24%).

Compound **3**: white waxy solid. M.p. 66.9–67.8 °C. Mass spectrum (ESI) 583.1 (MH^+). *Anal.* Calc. for $C_{31}H_{54}N_2O_8$: 582.1. ^1H NMR ($CDCl_3$): 3.48 (d, 4H, J = 17.0 Hz), 3.37 (d, 4H, J = 17.0 Hz), 3.27 (m, 2H), 2.12 (m, 2H), 1.62 (m, 2H), 1.48–1.34 (m, 4H), 1.46 (s, 36H). ^{13}C NMR ($CDCl_3$): 171.1 (C), 80.6 (C), 64.2 (CH), 54.9 (CH_2), 40.4 (CH), 36.8 (CH_2), 28.2 (CH_3), 25.4 (CH_2).

Compound **4**: light yellow oil. Mass spectrum (ESI) 354.2 (MH^+). *Anal.* Calc. for $C_{19}H_{31}NO_5$: 353.2. ^1H NMR ($CDCl_3$): 3.63 (dt, 1H, J_1 = 9.6 Hz, J_2 = 4.1 Hz), 3.45 (d, 2H, J = 17.0 Hz), 3.36 (d, 2H, J = 17.0 Hz), 2.63 (m, 1H), 2.50 (m, 1H), 2.47 (d, 1H, J = 8.8 Hz), 1.99 (m, 1H), 1.89 (dd, 1H, J_1 = 17.8 Hz, J_2 = 4.4 Hz), 1.72 (m, 2H), 1.42 (s, 18H), 1.27 (m, 1H). ^{13}C NMR ($CDCl_3$): 216.6 (C), 170.5 (C), 81.2 (C), 61.0 (CH), 54.1 (CH_2), 50.3 (CH), 38.5 (CH), 37.5 (CH_2), 36.3 (CH_2), 30.3 (CH_2), 28.2 (CH_3).

3.2.2. NorDATA

Tetraester **3** (1.45 g, 2.49 mmol) was dissolved in trifluoroacetic acid (10 mL) and stirred at room temperature for 24 h. Volatiles were removed by vacuum evaporation, trifluoroacetic acid (10 mL) was added to the residue and the mixture stirred at room temperature for another 24 h. After evaporation, the oily crude product was redissolved in methanol (3 mL) and excess diethyl ether was added dropwise. **NorDATA** precipitated and was isolated by centrifugation, washed with diethyl ether and dried *in vacuo* to constant weight (0.65 g, 74%).

Amorphous off-white solid. M.p. 175.9-177.0 °C (dec.). Mass spectrum (ESI) 359.1 (MH^+), 381.1 (MNa^+). *Anal.* Calc. for $C_{15}H_{22}N_2O_8$: 358.1. ^1H NMR ($CDCl_3$): 4.21 (s, 8H), 3.98 (m, 2H), 2.72 (m, 2H), 2.15 (m, 2H), 1.95 (dd, 2H, J_1 = 14.7 Hz, J_2 = 5.6 Hz), 1.71 (s, 2H). ^{13}C NMR ($CDCl_3$): 169.2 (C), 69.4 (CH), 56.7 (CH_2), 38.3 (CH), 36.6 (CH_2), 23.7 (CH_2).

3.3. Equilibrium measurements

The chemicals used for the experiments were of the highest analytical grade. The $LnCl_3$ solutions were prepared from $LnCl_3 \cdot xH_2O$ (x = 5–7) (Aldrich; 99.9%). The concentration of $MgCl_2$, $CaCl_2$, $ZnCl_2$, $CuCl_2$ and $LnCl_3$ solutions were determined by complexometric titration with standardized Na_2H_2EDTA and xylenol orange ($ZnCl_2$, $LnCl_3$), murexide ($CuCl_2$), *Patton & Reeder* ($CaCl_2$) and eriochrome black T ($MgCl_2$) as indicators. The concentration of **NorDATA** was determined by pH-potentiometric titration either in the presence or the absence of a large (40-fold) excess of $CaCl_2$.

For the calculation of $[H^+]$ from the measured pH values, the method proposed by Irving et al. was used [26]. A 0.01 M HCl solution (0.1 M KCl) was titrated with a standardized KOH solution. The differences between measured and calculated pH values were used to obtain the H^+ concentration from the pH values, measured in the titration experiments. The ionic product of water was found to be 13.85 under these conditions. For pH measurements and titration, a Crison micro pH *2002* pH-meter, a Crison micro BU2030 autoburette and a Metrohm-6.0233.100 combined electrode were used. Equilibrium measurements were carried out at constant ionic strength (0.1 M KCl) on 10 mL sample at 25 ± 0.2 °C. The solutions were stirred while N_2 was being bubbled through. Titrations were performed in the pH range 1.7-11.7. For the calibration of the pH meter, buffer standard solutions, color-coded "pink" (pH 4.010) (Fluka) and "yellow" (pH 7.000) (Fluka) were used.

The protonation constants of **NorDATA** and the stability constants of the complexes it formed with Mg^{2+}, Ca^{2+}, Cu^{2+}, Zn^{2+} and Ln^{3+} ions were determined by pH-potentiometric titration. The equilibrium constants of ligands and complexes are defined by the following equations, where M, H and L are the metal ion, proton and ligand, respectively (i = 1, 2, ...).

$$pM^{n+} + qH^+ + rL \rightleftharpoons M_pH_qL_r$$

$$\beta_{pqr} = \frac{[M_pH_qL_r]}{[M^{n+}]^p[H^+]^q[L]^r}$$

$$H_{i-1}L + H^+ \rightleftharpoons H_iL$$

$$K_i^H = \frac{[H_iL]}{[H_{i-1}][H^+]}$$

$$MH_{i-1}L + H^+ \rightleftharpoons MH_iL$$

$$K^H_{MH_{i-1}L} = \frac{[MH_iL]}{[MH_{i-1}L][H^+]}$$

The protonation constants of **NorDATA** ($\log\beta$) were calculated from titration data (152 data points) obtained by the titration of 0.002 M solution samples. The metal/ligand concentration ratio was 1:1; for Cu^{2+} and Zn^{2+} complexes, titrations were also carried out at metal/ligand ratio of 2:1 in order to examine the possible formation of dinuclear complexes in the Zn^{2+}-**NorDATA** and Cu^{2+}-**NorDATA** systems (ligand concentration was 0.002 M). pH-potentiometric titration data obtained for the equilibrium study of metal ion – **NorDATA** systems could be described by the formation of ML, MHL and MH_2L species. The protonation and stability constants of Zn(**NorDATA**) and Cu(**NorDATA**) complexes were calculated separately from the titration curves obtained at 1:1 and 2:1 metal/ligand concentration ratios by using the model considering only the formation of the ML and MHL species. In both cases values of the protonation and stability constants of the ML complexes were identical, implying that dinuclear complexes were not involved. To calculate the stability and protonation constants of complexes formed in metal ion – **NorDATA** systems about 160 data points were normally used. Protonation and stability constants ($\log\beta$) were calculated with the PSEQUAD program [27].

The formation of Ce(**NorDATA**)$^-$ complex was studied at 25 °C in a thermostated cell holder with a Cary 1E spectrophotometer. The complexation equilibria were followed in the UV range 340–220 nm (the UV absorption band of Ce^{3+} resulting from the 4f–5d transition is very sensitive to complex formation). The concentration of **NorDATA** and $CeCl_3$ were 7×10^{-4} M in the presence of 0.1 M KCl.

4. Conclusion

In this paper we report the four-step synthesis of the novel polyaminopolycarboxylic ligand **NorDATA**, as well as its complexation behavior towards selected metal ions as assessed by potentiometry and UV–Vis spectrophotometry.

NorDATA complexes generally show higher stabilities than those formed by the acyclic congener BDTA, except for the smaller lanthanides. The stability constant of the Zn^{2+} chelate is close to that of the prototypal EDTA congener, while it is significantly smaller in the lanthanide series and in comparison with the monocyclic CDTA.

The result of using the rigid bicyclic skeleton with conformationally locked nitrogen atoms is manifest in the log K_2^H value and is probably responsible for the stability of alkaline earth and transition metal ion complexes. The lower affinity of lanthanides for **NorDATA** can possibly be ascribed to the less than optimal size match of the ligand cavity with the Ln^{3+} ion.

2. Experimental

2.1. Materials and physical measurements

Purchased chemicals and solvents were used as received. Elemental analysis of **1** was performed on a VARIO EL (Heraeus) CHNS analyzer. The IR spectrum was recorded on a Perkin–Elmer Spectrum 2000 FT-IR spectrometer by using the KBr pellet technique in the scan range 4000–400 cm^{-1}, the UV–Vis–NIR spectrum on a Perkin–Elmer Lambda 900 spectrophotometer, in acetonitrile solution, in the range 250.0–1200.0 nm ($c = 5.571 \times 10^{-5}$ mol/L), and the EPR spectrum on a Bruker Elexsys E500 CW EPR spectrometer in frozen solution (acetone/chloroform 1:1) at 110 K, MW-power: 0.615 mW, frequency: 9.4374 GHz. The magnetic measurement was carried out at 298 K using a Quantum Design SQUID-based MPMSXL-5-type magnetometer at the University of Wroclaw (Poland). ^{1}H, ^{13}C and ^{195}Pt NMR spectra were attempted for **1** in $CDCl_3$ at room temperature using a 600 MHz Varian Unity spectrometer, but to no avail, since the sample is paramagnetic.

2.2. Synthesis of *1*

Benzene-1,2-dithiol (1.5 g, ≈10 mmol, Fluka 97%) in 95% ethanol (20 mL) was mixed together with a solution of $[NBu_4]Cl$ (2.7 g, ≈10 mmol, Fluka 99% +) in water (10 mL). The green-yellow solution was stirred at room temperature and treated with K_2PtCl_4 (1.1 g, ≈5 mmol, Degussa p.a.) dissolved in water (10 mL). The color of the reaction mixture rapidly turned deep green, and a thick green solid finally formed. After stirring for 1.5 h, the solid was separated by filtration, washed twice with water (3 mL), and dried in air between filter papers. The combined filtrates were evaporated to near complete dryness to produce an additional crop that was washed and dried likewise. The total yield of 0.7 g (97.49%) of crude material was recrystallized from saturated solutions in $CHCl_3$ or CH_3CN to afford large dark green crystals. M.p.: 184.3–184.5 °C. *Anal.* Calc. for $C_{28}H_{44}NPtS_4$ (MW 717.97): C, 46.84; H, 6.18; N, 1.95; S, 17.86. Found: C, 46.85; H, 6.32; N, 2.10; S, 17.80%. UV–Vis–NIR: $\lambda_{max}1 = 270.2$ nm ($\varepsilon = 28\,715\ M^{-1}\ cm^{-1}$), $\lambda_{max}2 = 340.8$ nm ($\varepsilon = 2820\ M^{-1}\ cm^{-1}$), $\lambda_{max}3 = 365.0$ nm ($\varepsilon = 2326\ M^{-1}\ cm^{-1}$), $\lambda_{max}4 = 454.9$ nm ($\varepsilon = 444\ M^{-1}\ cm^{-1}$), $\lambda_{max}5 = 635.2$ nm ($\varepsilon = 1844\ M^{-1}\ cm^{-1}$), $\lambda_{max}6 = 707.3$ nm ($\varepsilon = 4058\ M^{-1}\ cm^{-1}$), and $\lambda_{max}7 = 867.1$ nm ($\varepsilon = 23\,345\ M^{-1}\ cm^{-1}$).

2.3. X-ray crystallography

Suitable single crystals of **1** were produced by slow evaporation of a saturated solution in $CHCl_3$ at room temperature. A dark green prismatic crystal of dimensions $0.2 \times 0.06 \times 0.06$ mm was used and data collection was carried out on a Siemens SMART [10a] CCD diffractometer using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å). Data reduction with SAINT [10b], ω-scan rotation mode, structure solved by direct methods (SHELXS) [10c] and refined with SHELXL [10d], non-hydrogen atoms refined anisotropically, H atoms calculated on idealized positions and refined isotropically, empirical absorption correction with SADABS [10d], refinement by full-matrix least-squares on F^2. Crystal data and structure refinement parameters for **1** are given in Table 1, selected bond lengths and bond angles in Table 2.

3. Results and discussion

3.1. Formulation of *1*

In accord with the conclusions of Sellmann et al. [2a], we assume that the benzene-1,2-dithiol (H_2bdt) system behaves like a normal dithiolate, bdt^{2-}, and we logically suspect compound **1** to result from the straightforward reaction of Eq. (1), whereby Pt(II) is oxidized to Pt(III), presumably by air, similar to the oxidation of Ni(II) to Ni(III) [3f]:

$$K_2[PtCl_4] + [NBu_4]Cl + 2H_2bdt + 1/2O_2 \rightarrow [NBu_4][Pt(bdt)_2]\ (\mathbf{1}) + 2KCl + 3HCl + 1/2H_2O \quad (1)$$

3.2. Vibrational and electronic absorption spectra of *1*

3.2.1. The IR spectrum

The IR spectrum of **1** exhibits typical absorption peaks at $\nu = 3033.6\ cm^{-1}$ (w, Ar-H), at 2870.7–2958.0 cm^{-1} (s, m, C–H) [4],

at 1378–1482 cm^{-1} (w, m) characteristic of the alkane C–H bending mode, and a very strong peak at 750.1 cm^{-1} attributable to the Ar-H out-of-plane absorption. Most interestingly, previous IR studies [9a] have revealed that the presence of one or two π radical anions in bis(benzene-1,2-dithiolato)metal complexes considerably enhances the intensity of the ν(CS) stretching mode at 1100–1115 cm^{-1}. The IR spectrum of **1**, however, exhibits only a very weak peak at 1106 cm^{-1}, thus suggesting that the bdt^{2-} ligands in this case behave like normal dithiolates. This observation, as a matter of fact, is in line with the X-ray structural and EPR spectroscopic results discussed below; moreover, it nicely corroborates the virtual absence of the ν(CS) stretching band noticed earlier in the IR spectrum of the structurally closely related, but diamagnetic Cu(III) (d^8) complex anion, $[Cu^{III}(L^{Bu})_2]^-$, where $(L^{Bu})^{2-}$ = 3,5-di-*tert*-butylbenzene-1,2-dithiolate [9a].

3.2.2. The electronic spectrum

The UV–Vis–NIR spectrum of **1** exhibits seven absorption bands ($\lambda_{max}1$–$\lambda_{max}7$) mentioned above. Obviously bands $\lambda_{max}1$ to $\lambda_{max}3$ result from π–π* and n–π* electronic transitions within the bdt^{2-} ligands; band $\lambda_{max}4$ may be attributed to ligand-to-metal charge transfer (LMCT), bands $\lambda_{max}5$ and $\lambda_{max}6$ to d–d transitions, and band $\lambda_{max}7$ to ligand-to-ligand charge transfer (LLCT), or else, to intervalent charge transfer (IVCT) [9a].

3.3. The magnetic behavior of *1*

It is necessary to take a closer look at the magnetic behavior of compound **1** for the purpose of reliable comparisons with previous results obtained on closely related materials. Alves et al. [4] have pointed out that the number of Pt(III) complexes studied sofar by EPR spectroscopy is small. One such complex is the anion $[Pt(dcbdt)_2]^-$ contained in the salt $[NBu_4][Pt(dcbdt)_2]$ [4], which may be considered as derived from the parent anion $[Pt(bdt)_2]^-$ contained in the present salt, $[NBu_4][Pt(bdt)_2]$ (**1**). The close relationship between these complex ions is quite obvious, indeed. In the solid, however, the former ions are dimerized, hampering, therefore, any straightforward assessment of the fundamental question surrounding spin density at and oxidation state of the central platinum. The latter ions in **1**, by contrast, are well isolated in the solid state (*vide infra*). Thus, compound **1** now appears to provide the most suitable template system for reliable magnetic studies that may enable unequivocal assignment of the effective oxidation state of the central Pt atom as well as the paramagnetic spin density surrounding this atom.

The experimental EPR spectrum of **1** and a simulation with the resulting parameters is displayed in Fig. 1. The spectrum was simulated with the Bruker SIMFONIA Program [11] individually for $I = 0$ and $I = ½$ and combined in the ratio of the natural abundance (66.2:33.8). It is, moreover, strikingly similar to the rhombic spectra reported previously for the closely related Pt(III) complexes, $[NEt_4][Pt(C_2H_2S_2)_2]$ [1a] and $[NBu_4][Pt(dcbdt)_2]$ [4]. The spectrum can be described as arising from a doublet state ($S = 1/2$), showing rhombic anisotropy with the experimental parameters $g_1 = 1.797 \pm 0.002$, $g_2 = 2.052 \pm 0.002$, $g_3 = 2.220 \pm 0.002$ confirmed by the simulated spectrum (Fig. 1). An attribution of the tensor parameters to the *x*, *y*, z directions and a comparison to the crystallographic orientation from a frozen solution spectrum without detailed calculations (and/or single crystal studies) is nearly impossible, and it is not the aim of this research project anyway (see Ref. [9] for more details on related systems). The central intense line of each signal is attributed to the platinum isotopes with $I = 0$ (sum of 66.2% natural abundance), and the satellites (not resolved for the low field signal) correspond to the ^{195}Pt isotope ($I = 1/2$, 33.8% natural abundance). The experimental anisotropic hyperfine structure tensor parameters for **1** are $A_1 < 15 \times 10^{-4}$ cm^{-1} (not resolved), $A_2 = 63 \pm 1 \times 10^{-4}$ cm^{-1}, $A_3 = 34 \pm 1 \times 10^{-4}$ cm^{-1}. The spectrum of the liquid solution at room temperature (295 K) consists of a single unresolved broad signal (~400 G) with a *g*-value of approximately 2.03. These parameters are in good correlation with those of other Pt(III) dithiolato complexes reported previously [1a,12]. The magnitude of the hyperfine structure parameter indicates a significant contribution of the metal center to the singly occupied molecular orbital (SOMO) of the unpaired electron. Hence, the observed paramagnetism of **1** (first revealed by the failure to record a ^1H, ^{13}C and ^{195}Pt NMR spectrum) is assumed to be confined mainly to the PtS_4 core, without any remarkable contribution of the ligand backbone. Indeed, the room temperature magnetic susceptibility measurement yields an effective moment $\mu_{eff} = 1.80$ BM (Bohr magneton) compatible with a d^7 SOMO [4].

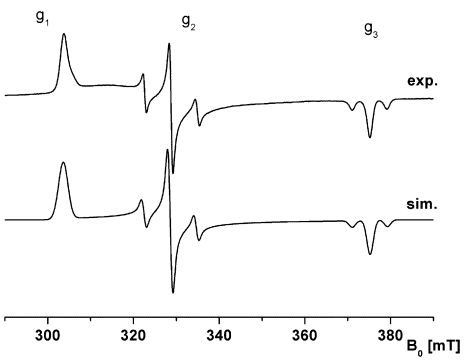

Fig. 1. Experimental (exp.) and simulated (sim.) X-band EPR spectrum of **1**, recorded at 110 K in acetone/$CHCl_3$ (1:1). The spectrum clearly displays rhombic symmetry and hyperfine structures of the transitions at g_2 and g_3, due to ^{195}Pt ($I = 1/2$, natural abundance 33.8%).

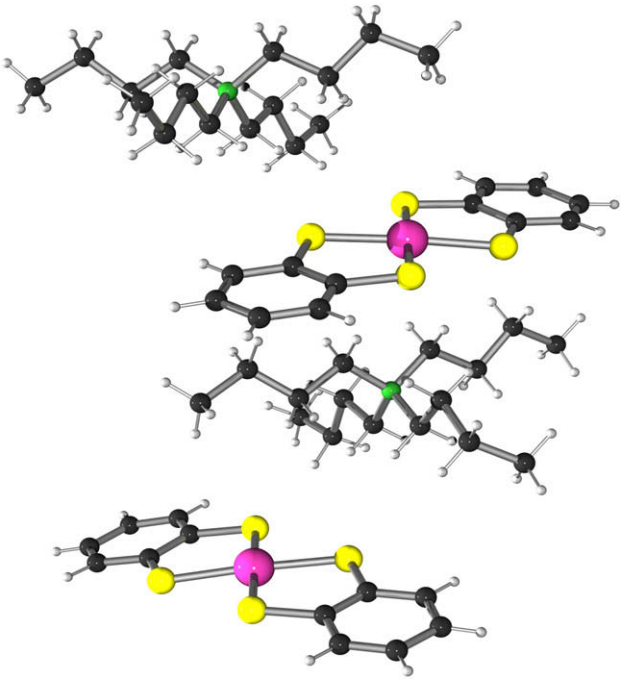

Fig. 2. Ball-and-stick picture of the crystallographically independent anions, $[Pt(bdt)_2]^-$, and cations $[NBu_4]^+$, in **1** (Pt = red, S = yellow). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

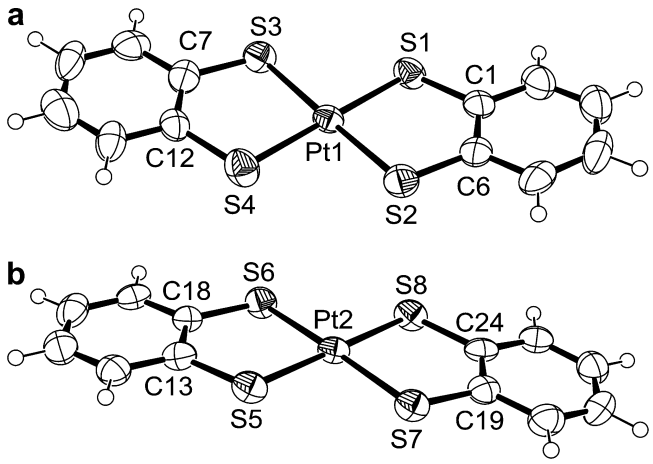

Fig. 3. ORTEP drawing [13] of the crystallographically independent complex anions, $[Pt1(bdt)_2]^-$ (a) and $[Pt2(bdt)_2]^-$ (b), in solid **1**, showing atoms labeling and numbering, and displacement ellipsoids at 50% probability. Note that these anions are rotated by an angle of nearly 90° relative to each other.

3.4. The crystal structure of *1*

Compound **1** represents the first well-resolved crystal structure of a complex based on benzene-1,2-dithiolato ligands coordinated to a Pt(III) central atom in a square-planar geometry. Compound **1** is isostructural to its Ni(III) counterpart, $[NBu_4][Ni(bdt)_2]$ [3a], crystallizing in the orthorhombic space group $Pna2_1$. The unit cell of **1** contains eight asymmetric units with two crystallographically independent $[Pt(bdt)_2]^-$ anions and two $[NBu_4]^+$ cations (Fig. 2). The ORTEP drawing [13] of the anions is displayed in Fig. 3. The spatial orientation of these anions is nearly a 90° rotation relative to each other, which would lead to the right angle stacking structure reported previously for the $Pt(bqd)_2$ system [7c] – bqd^- is benzene-1,2-dione dioximate(1−) – if they were allowed to pile up on top of one another. The [Pt1S1S2S3S4] and [Pt2S5S6S7S8] motifs occupy two distinct crystallographic positions, and the $[PtS_4]$ cores define quasi-perfect squares with Pt1 and Pt2, respectively, at the symmetry centers. Indeed, the Pt–S distances average 2.264 Å, and the angles within these cores are close to the values of 90° and 180° for a perfect S_4 square (Table 2). It should be noted that this particular structural feature differs quite noticeably from what was observed previously in a closely related Ni(III) salt, namely $[IB_zP_y][Ni(bdt)_2]$ (IB_zP_y = 1-(4-iodobenzyl)pyridinium) [3d], in which the corresponding bond angles depart markedly from square geometry. Within the benzene rings of **1**, C–C-bond lengths compare quite satisfactorily with classical aromatic values, with an average of 1.388 Å. The aliphatic C–C-bond lengths within the *n*-butyl groups of the cations average 1.513 Å, as expected.

The relative ordering of the complex anions within the unit cell of **1** is shown in Fig. 4. These anions are slightly bent and positioned in a fishbone manner parallel to the *a* axis. The Pt atoms are well separated from each other (Pt···Pt = 9.148 Å), so that there are no detectable contacts between them. Note that the $[NBu_4]^+$ countercations, omitted here for clarity, are embedded in this anionic framework. The packing of the bulk structure is insured by the mutual electrostatic attraction and the neat space filling of the cations and the anions.

4. Conclusion

We have prepared and characterized unambiguously compound **1** as the first well-resolved crystal structure of a complex based on benzene-1,2-dithiolate(2−) ligands coordinated to a central Pt(III) atom in a discrete square-planar PtS_4 geometry. It is obvious that the straightforward oxidation process (presumably by the oxygen of the air) of the starting Pt(II) to the final Pt(III) central atom in compound **1** is quite reminiscent of the well-documented oxidations of a whole range of central metal atoms such as Co(II), Fe(II), Ni(II), Pd(II), Pt(II), Cu(II), Au(II) [4]. The assignment of the Pt(III) oxidation state (d^7) in compound **1** is nicely confirmed by the value of μ_{eff} = 1.80 BM derived from the room temperature magnetic susceptibility measurement, quite in line with the effective moments of 1.90 and 1.74 BM obtained previously [12] for the related systems $[NBu_4][M(dmi\text{-}t)_2]$ (M = Ni^{III}, Pd^{III}, Pt^{III}; dmi-t = isotrithionedithiolate(2−)). Thus, as another seldom report on a well-characterized Pt(III) complex, this paper may be considered a significant empirical contribution that is expected to help shed more light on the sensitive theoretical discussion of effective oxidation states and magnetic spin density distributions within this important category of bis(dithiolene) or bis(dithiolato) transition metal complexes. It is noteworthy, finally, that the empirical conclusions arrived at in this work grossly parallel the detailed theoretical and experimental results reported recently by Grosshans et al. [14] and Cauchy et al. [15] on closely related materials such as the

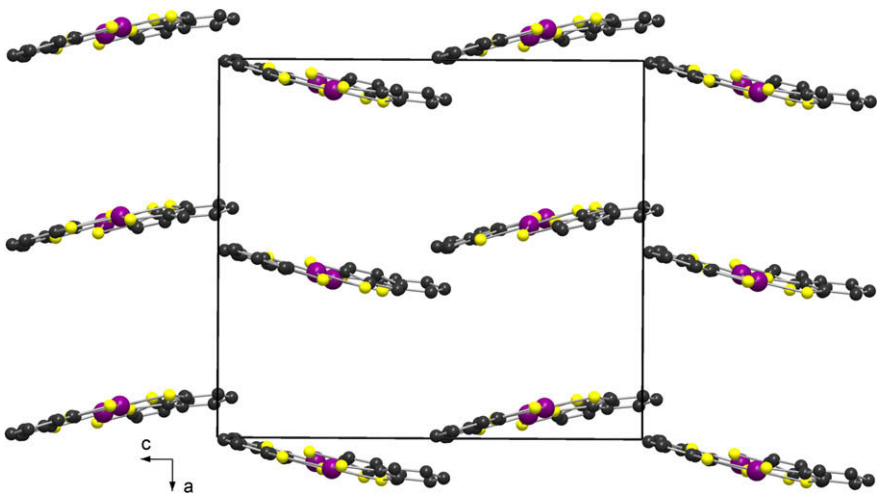

Fig. 4. Projection down the *b* axis of the unit cell of **1**, highlighting the relative ordering of the anionic complexes, $[Pt(bdt)_2]^-$. The counter cations, $[TBA]^+$ (left out for clarity) are actually embedded between these anions.

CpNi(bdt) neutral complexes. These workers have reliably demonstrated, indeed, that there is excellent agreement between DFT calculations and EPR measurements of spin density distributions within this class of complexes, with the SOMO at stake overwhelmingly confined to the inner sphere around the central metal site, and only faintly delocalized over the external benzene ring moieties.

5. Supplementary data

CCDC 682039 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgments

The authors thank Prof. Jerzy Mrozinski (Univ. Wroclaw) for the susceptibility measurement, and one reviewer for drawing their attention to the important Refs. [14] and [15]; MMB is grateful to Deutscher Akademischer Austausch-Dienst, (DAAD), Bad-Godesberg (Germany) for a grant-in-research-stay at the University of Heidelberg.

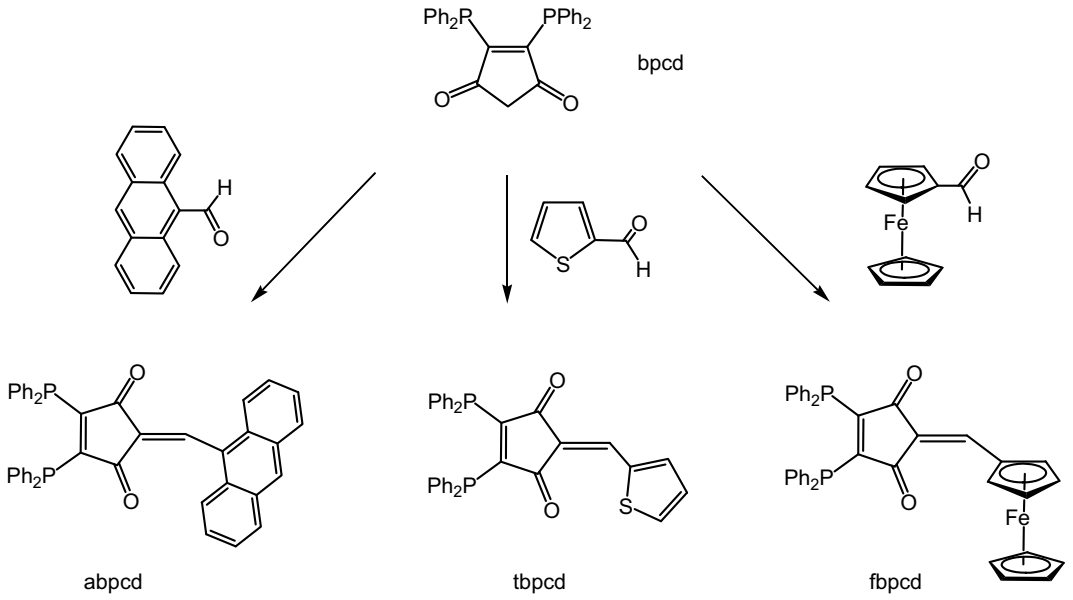

Scheme 1.

Given the dearth of Pt(diphosphine)(S–S) compounds that possess an energetically accessible phosphine-based LUMO, we have prepared and investigated the redox properties of Pt(fbpcd)(mnt) through the use of cyclic voltammetry and molecular orbital calculations at the extended Hückel level. The electrochemical and MO results are discussed with respect to related dithiolate-substituted platinum compounds.

2. Experimental

2.1. General

The $PtCl_2$(cod) starting material was prepared from $H_2PtCl_6 \cdot xH_2O$ and 1,5-cyclooctadiene (cod) according to the known procedure [12], and the fbpcd ligand synthesized via the condensation reaction of bpcd and ferrocenecarboxaldehyde [13]. The disodium maleonitriledithiolate (Na_2mnt) was prepared according the published literature procedure [14]. The chemicals cod and ferrocenecarboxaldehyde were purchased from Aldrich Chemical Co. All reaction and NMR solvents were distilled from an appropriate drying agent under argon using Schlenk techniques and stored under argon in storage vessels equipped with high-vacuum Teflon stopcocks [15].

All IR spectra were recorded on a Nicolet 20 SXB FT-IR spectrometer in amalgamated 0.1 mm NaCl cells, while the absorption spectra were recorded on a HP 8425A diode array spectrometer using 1.0 cm quartz UV–Vis cells that were equipped with a high-vacuum Teflon stopcock to facilitate handling on the vacuum line. The ^{1}H spectra were recorded at 200 MHz on a Varian Gemini-200 spectrometer, and the ^{31}P NMR spectra were collected in the proton-decoupled mode on a Varian 300-VXR spectrometer at 121 MHz, with the reported chemical shifts referenced to external H_3PO_4 (85%), taken to have $\delta = 0$. The ESI mass spectrum for **2** was recorded at the UNT mass spectrometry facility in the positive ion mode using a matrix composed of MeCN and 1% trifluoroacetic acid (UNT), while the mass spectral data for **3** were recorded at the University of the Pacific mass spectrometry facility in the negative ion mode.

2.2. Synthesis of the $PtCl_2$(fbpcd) (**2**)

To a small Schlenk flask under argon was added 0.10 g (0.27 mmol) of $PtCl_2$(cod) and 0.17 g (0.27 mmol) of the diphosphine ligand fbpcd, followed by 20 mL of CH_2Cl_2 via syringe. The reaction mixture was stirred at room temperature for ca. 0.5 h, and then solvent was removed under vacuum and the residue washed with 2×10 mL portions of hexane to remove the liberated cod ligand. The crude product was recrystallized from a 1:1 mixture of CH_2Cl_2/hexane to afford 0.22 g (90% yield) of **2**. IR (CH_2Cl_2): ν(CO) 1718 (w, sym dione), 1676 (vs, antisym dione) cm^{-1}. UV–Vis (CH_2Cl_2): λ_{max} 356 (ε = 12 149), 584 (ε = 2192). ^{1}H NMR ($CDCl_3$): δ 4.22 (s, 5H, Cp), 4.93 (s, br, 2H, Cp), 5.21 (s, br, 2H, Cp), 7.25–8.30 (m, 21H, aryls and alkenyl). ^{31}P NMR ($CDCl_3$): δ 26.51 (s, J_{Pt-P} = 1838 Hz), 27.44 (s, J_{Pt-P} = 1838 Hz). ESI-MS (m/z): 949.27 [**2** + Na]$^+$.

2.3. Synthesis of Pt(mnt)(fbpcd)

To 0.10 g (0.11 mmol) of $PtCl_2$(fbpcd) in a Schlenk tube was added 30 mL of acetone, after which 20 mg (0.11 mmol) of Na_2mnt was added in one portion. The solution was stirred for 3 h and then examined by TLC analysis, which revealed the desired product as a blue spot at R_f = 0.40 using CH_2Cl_2 as the eluent. The solvent was removed under vacuum and the crude product was purified by flash-column chromatography over silica gel. The isolated product was recrystallized from CH_2Cl_2 and hexane to afford compound **3** in 83% yield (90 mg). IR (CH_2Cl_2): ν(CN and CO) 2209 (m, nitrile), 1718 (w, sym dione), 1679 (s, antisym dione) cm^{-1}. UV–Vis (CH_2Cl_2): λ_{max} 360 (ε = 12 288), 582 (ε = 2750). ^{1}H NMR ($CDCl_3$): δ 4.20 (s, 5H, Cp), 4.93 (s, b, 2H, Cp), 5.20 (b, 2H, Cp), 7.45–7.95 (m, 21H, aryls and alkenyl). ^{31}P NMR ($CDCl_3$): δ 30.26 (s, J_{Pt-P} = 1420 Hz), 31.08 (s, J_{Pt-P} = 1420 Hz). ESI-MS (m/z): 874.04 [**3**-CpFe]$^-$.

2.4. X-ray diffraction data for clusters **2** and **3**

Tables 1 and 2 contain the X-ray data and processing parameters and selected bond distances and angles, respectively, for compounds **2** and **3**. Single crystals of **2** and **3** suitable for X-ray diffraction analysis were grown at 5 °C from CH_2Cl_2 solutions containing each compound that had been layered with hexane. The X-ray data for **2** · CH_2Cl_2 and **3** · CH_2Cl_2 were collected on an APEX II CCD-based diffractometer at 100 K. The frames were integrated with the available APEX2 [16] software package using a narrow-frame algorithm, and the structures were solved and refined using the SHELXTL program package [17]. The molecular structures were checked using PLATON [18], and all nonhydrogen atoms were refined

anisotropically. All hydrogen atoms were assigned calculated positions and allowed to ride on the attached carbon atom. The refinement for **2** · CH_2Cl_2 converged at $R_1 = 0.0286$ and $wR_2 = 0.0698$ for 7512 independent reflection with $I > 2\sigma(I)$, with **3** · CH_2Cl_2 yielding convergence values of $R_1 = 0.0211$ and $wR_2 = 0.0453$ for 8733 independent reflection with $I > 2\sigma(I)$.

2.5. Electrochemical studies

All cyclic voltammograms were recorded on a PAR Model 273 potentiostat/galvanostat, equipped with positive feedback circuitry to compensate for *i*R drop. The homemade three-electrode cell that was employed allowed the cyclic voltammograms to be recorded under oxygen- and moisture-free conditions. A platinum disk (area = 0.0079 cm^2) was utilized as the working and auxiliary electrode, and the reference electrode utilized a silver wire as a quasi-reference electrode, with the reported potential data standardized against the formal potential of the $Cp^*_2Fe/Cp^*_2Fe^+$ (internally added) redox couple, taken to have $E_{1/2} = -0.20$ V [19].

2.6. Extended Hückel MO calculations

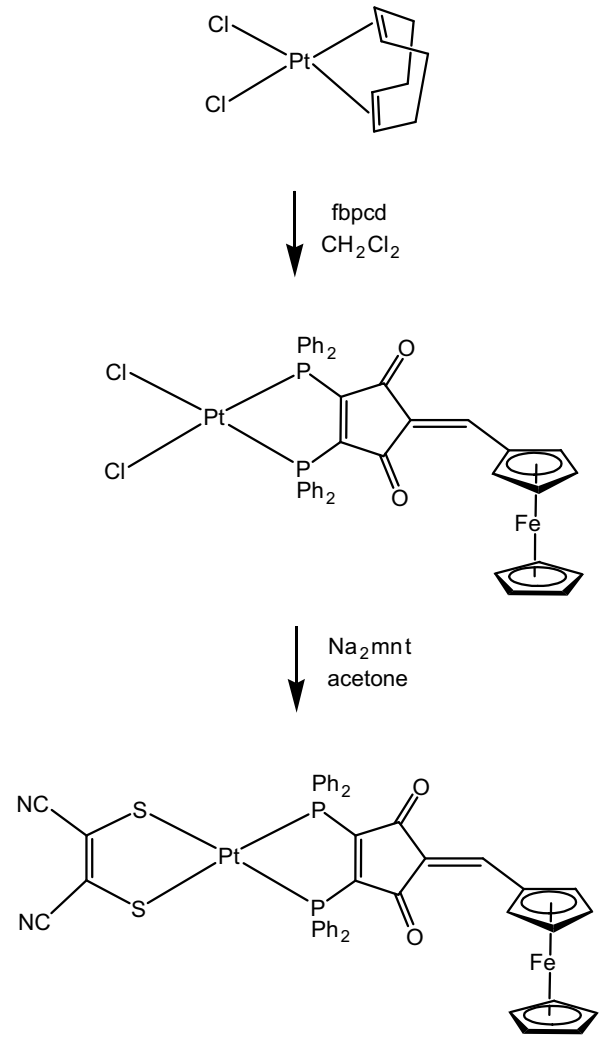
The extended Hückel calculations reported here were carried out using the original program developed by Hoffmann [20], as modified by Mealli and Proserpio [21]. The weighted H_{ij}'s contained in the program were used in the calculations, and the input *Z*-matrices for **2** and **3** were constructed from the available X-ray data. The *Z*-matrix for the free ligand fbpcd was constructed from the appropriate bpcd and ferrocene fragments.

3. Results and discussion

3.1. Synthesis and spectroscopic characterization of compounds *2* and *3*

Treatment of $PtCl_2$(cod) at room temperature in CH_2Cl_2 with an equimolar amount of the diphosphine ligand 2-(ferrocenylidene)-4,5-bis(diphenylphosphino)-4-cyclopenten-1,3-dione (fbpcd) furnishes the expected product of cod displacement, namely $PtCl_2$(fbpcd). The structure of **2** is depicted in Scheme 2. Compound **2** was isolated in greater than 90% yield after recrystallization and was characterized initially by traditional spectroscopic methods and mass spectrometry. The IR spectrum reveals the presence of two vibrationally coupled carbonyl bands associated with the dione ring at 1718 (w) and 1676 (vs) cm^{-1}, whose frequencies are in good agreement with the data reported by us for the isomeric $Os_3(CO)_{10}$(fbpcd) clusters containing chelating and bridging fbpcd ligands [10]. The electronic absorption spectrum of **2** recorded in CH_2Cl_2 exhibits a moderately intense near UV–Vis absorbance at 356 nm in excellent agreement with the optical data reported by Eisenberg and coworkers for sundry Pt(mnt)(diphosphine) complexes [4b], with the weak visible band at 584 nm ascribed to a d–d transition localized on the pendant ferrocene moiety [22]. The four sets of ^{1}H NMR resonances at δ 4.22 (s, 5H, Cp), 4.93 (s, br, 2H, Cp), 5.21 (s, br, 2H, Cp), 7.25–8.30 (m, 21H, aryls and alkenyl) and the two inequivalent ^{31}P singlets at δ 26.51 and 27.44 are in accord with the formulated structure. The ESI mass spectrum of $PtCl_2$(fbpcd) displayed a prominent *m*/*z* peak at 949.27 consistent with the sodiated species $[\mathbf{2} + Na]^+$. The solid-state structure of **2**, as the CH_2Cl_2 solvate, confirms the presence of a four-coordinate, square-planar platinum center possessing two ancillary chlorine groups and a chelating fbpcd ligand. Fig. 1 shows the thermal ellipsoid plot of **2**. The Pt–P and Pt–Cl bonds display a mean distance of 2.218 Å and 2.347 Å, respectively, and agree with those bond distances in the related platinum(II) compounds $PtCl_2$[1,2-bis(diphenylphosphino)ethane], $PtCl_2$[(*Z*)-1,2-bis(diphenylphosphino)ethene], and derivatives based on diphosphine ligands having an ethano backbone [23]. The remaining bond distances and angles are unremarkable and require no comment.

The reaction of **2** with disodium maleonitriledithiolate (Na_2mnt) in acetone at room temperature afforded the corresponding mnt-substituted complex Pt(mnt)(fbpcd) (**3**) in good yield after flash-column chromatographic separation and recrystallization.



Scheme 2.

The new dithiolate complex was isolated as a navy blue colored solid that is stable under argon in the solid state but solutions containing **3** that have been exposed to oxygen are less stable, with decomposition observed after several hours. **3** was fully characterized by IR, UV–Vis, and NMR spectroscopies, and by ESI mass spectrometry and X-ray diffraction analysis. The IR spectrum of **3** recorded in CH_2Cl_2 revealed a moderately intense ν(CN) stretch at 2209 cm^{-1} for the two nitrile groups and a pair of ν(CO) bands at 1718 and 1679 cm^{-1} for the kinematically coupled dione groups in the fbpcd residue [24]. The UV–Vis and ^{1}H NMR spectral data for **3** parallel those data found in the dichloride precursor **2**. The ^{31}P NMR spectrum of **3** exhibits two singlets at δ 30.26 and 31.08, both of which display a pair of satellites from geminal coupling with a ^{195}Pt center. Interesting, the $^1J_{P-Pt}$ coupling of 1420 Hz recorded in **3** is 418 Hz smaller than that found in **2**, and strongly supports the existence of longer Pt–P bond distances in compound **3** compared to **2**. This empirical trend was initially discovered by Pidcock and coworkers in a series of four- and six-coordinated phosphine-substituted platinum compounds and was corroborated by the X-ray diffraction structures of compounds **2** and **3** [25]. Finally, **3** was examined by ESI mass spectrometry in the negative ion mode, where a peak at *m*/*e* 874.04 corresponding to [**3**-CpFe]$^-$ was found. Attempts to observe the molecular ion derived from **3** were unsuccessful as a result of the facile loss of the "CpFe" fragment, a phenomenon with ample literature precedent [26]. The X-ray structure of **3**, as the CH_2Cl_2 solvate, that is shown in Fig. 1 con-

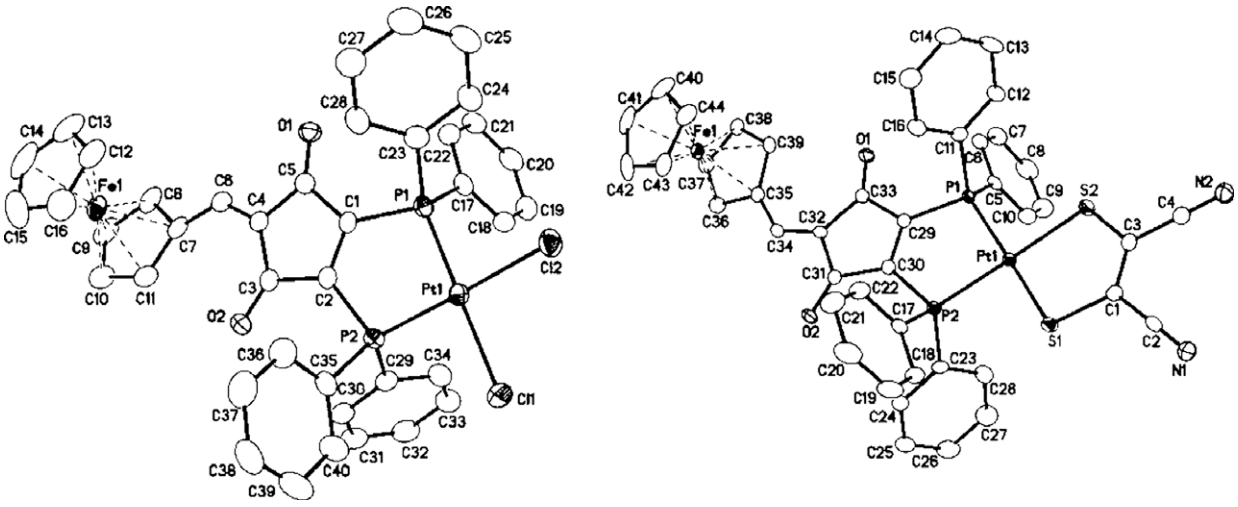


Fig. 1. Thermal ellipsoid plot of **2** · CH_2Cl_2 (left) and **3** · CH_2Cl_2 (right) showing the thermal ellipsoids at the 50% probability level. The CH_2Cl_2 solvent molecule in each plot has been omitted for clarity.

firms the formal replacement of the chlorine ligands by the mnt group. The two Pt–P bond lengths of 2.2589(6) Å [Pt(1)–P(1)] and 2.2572(7) Å [Pt(1)–P(2)] exhibit an average distance of 2.2581 Å and account for the aforementioned trend in the $^1J_{P-Pt}$ coupling constants in **2** and **3**. The mnt and fbpcd moieties in **3** exhibit bond distances and angles consistent with related derivatives containing these ligands.

3.2. Cyclic voltammetric and MO data on the ligand fbpcd and compounds *2* and *3*

Given the rich redox history of the organometallic compounds containing ferrocene, mnt, and bpcd ligands, we next investigated the cyclic voltammetric behavior of the fbpcd ligand and compounds **2** and **3**. The CV data were recorded at platinum electrodes in CH_2Cl_2 at room temperature using 0.2 M TBAP as the supporting electrolyte. The CV of the free ligand fbpcd when scanned at a rate of 250 mV/s over the potential range of −1.0 V to 1.5 V revealed two reversible, diffusion-controlled processes at $E_{1/2}$ = 0.63 and −1.08 V for the $0/1^+$ and $0/1^-$ redox couples [27]. The assignments for these redox couples are straightforward and ascribed to an oxidation and reduction of the ferrocene appendage [i.e., Fe(II) to Fe(III)] and dione moiety (i.e., e^- occupation of the ψ_4-based π^* MO) moiety, respectively, in good agreement with the reported redox potentials of related ferrocene derivatives and the parent ligand bpcd [7,10,28]. The assignments for the redox data were also corroborated by extended Hückel MO calculations, which yielded the expected ferrocene-based HOMO at −11.80 eV and a π^* LUMO at −10.40 eV at the dione platform of the fbpcd ligand.

Examination of **2** by CV in a manner identical to that of the free fbpcd ligand revealed the presence of two well-defined redox waves at $E_{1/2}$ = 0.62 and −0.63 V, as depicted in Fig. 2. While the oxidation potential of the ferrocene portion of the molecule remains unchanged relative to the free fbpcd ligand, an anodic shift of 0.45 V in the $0/1^-$ redox couple is observed upon coordination of the fbpcd ligand to the Pt(II) center. The electrochemical assignments in **2** were verified by carrying out extended Hückel MO calculations. The orbital composition and approximate energy of the HOMO and LUMO levels in **2**, which are shown below, are in keeping with the nature of the ancillary fbpcd ligand. The HOMO occurs at −11.82 eV and resembles the universally seen a_{1g} metal-based orbital for ferrocene and its derivatives [22a,29]. The LUMO in **2** occurs at −10.35 eV and traces its parentage to ψ_4 of the π system associated with the dione moiety [30]. The relatively low energy

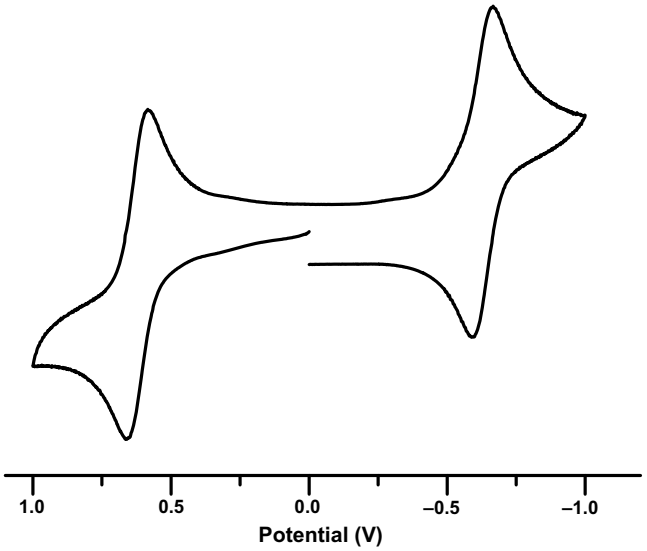

Fig. 2. Anodic scan cyclic voltammogram of **2** (ca. 10^{-3} M) in CH_2Cl_2 containing 0.2 M TBAP at 0.25 V/s at 298 K.

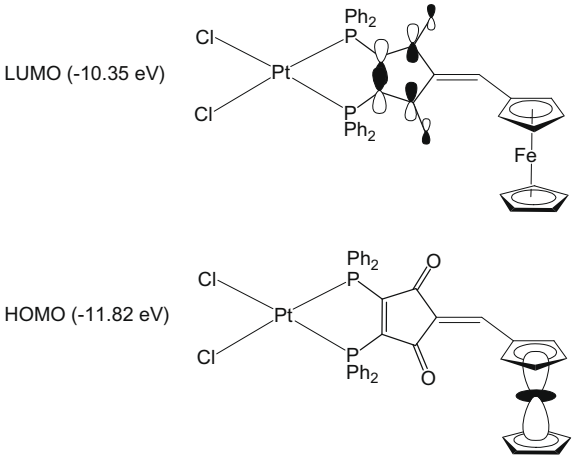
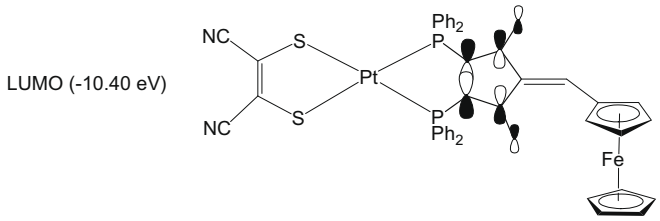
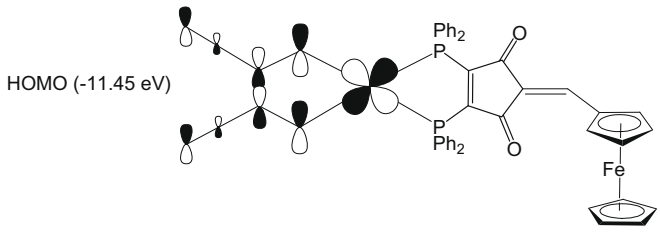
of this π^* orbital makes it a superb electron reservoir vis-á-vis common diphosphine ligands such as dppe and (*Z*)-$Ph_2PCH{=}CHPPh_2$ that do not possess an electrochemically accessible π^* counterpart.



The CV of **3** exhibited three redox waves when examined over the potential range of −1.0 V to 1.5 V at a scan rate of 250 mV/s, with the one-electron reduction wave at $E_{1/2} = -0.57$ V unambiguously assigned to an electron accession at the dione residue. Unlike the straightforward assignment of the oxidation in compound **2** that had single, well-defined oxidation center, the diffusion-controlled waves at $E_{1/2} = 0.65$ (fully reversible) and 1.27 (quasi-reversible) V in **3** could not be made with certainty because dithiolate ligands in other four-coordinate Pt(II) compounds have also been reported to undergo oxidation in the same vicinity as the $E_{1/2}$ value displayed by **3**. The reported oxidation values for Pt(N–N)(S–S) and Pt(P–P)(S–S) compounds (where N–N = bpy and phen derivatives; S–S = mnt, dmit, ecda, tdt; P–P = $2PR_3$, diphosphine) vary considerably, ranging from ca. 0.30 V to 1.0 V depending on the donor/acceptor properties of the dithiolate ligand. For example, the platinum compounds Pt(dppe)(dmit) and Pt(bpy)(tdt) reveal a $0/1^+$ redox response at ca. 0.5 V that mirrors the oxidation potential recorded for **3** [3f,4a]. Oxidation of the HOMO in this latter genre of compounds is controlled exclusively by dπ–pπ interactions between the ancillary dithiolate ligand and platinum metal [3c].

The nature and orbital energies of the important HOMO and LUMO levels in **3** were established by MO analysis, as illustrated below. The LUMO in **3** is concentrated on the dione moiety and is unremarkable in comparison to the energy level and orbital composition of the LUMO found in free fbpcd ligand and compound **2**. The HOMO is best viewed as arising from an out-of-phase union of the $2b_1$ and d_{zy} orbitals of the $[mnt]^{2-}$ and $[Pt(fbpcd)]^{2+}$ fragments, respectively [31]. This particular interaction accounts nicely for observed pπ–dπ bond that is exhibited by the HOMO in compound **3** and that has been similarly found by Eisenberg in the compounds Pt(mnt)(bpy), $Pt(SPh)_2$(bpy), and other Pt(II) derivatives [3c]. In fact, the filled-filled or $4e^-$ interaction in play between these π-based fragments allows one, in theory, to control or tune the energy level associated with the HOMO in this family of compounds [32]. Our calculations on **3** reveal a HOMO energy of −11.45 eV that is in excellent agreement with those HOMO energies reported for Pt(mnt)(bpy) and $Pt(SPh)_2$(bpy) [3c]. Accordingly, the observed $0/1^+$ redox process at $E_{1/2} = 0.65$ in **3** is assigned to the oxidation of the mnt π^*-based orbital. Finally, the Hückel calculations demonstrate that the subjacent highest occupied molecular orbital (SHOMO) at −11.81 eV corresponds to the anticipated ferrocence-based a_{1g} molecular orbital, whose oxidation potential has been shifted to more positive potential relative to compound **2** that is dithiolate free.





4. Conclusions

The synthesis and spectroscopic properties of the new platinum compounds $PtCl_2$(fbpcd) (**2**) and Pt(mnt)(fbpcd) (**3**) have been presented and discussed. The solid-state structures and the redox properties of $PtCl_2$(fbpcd) (**2**) and Pt(mnt)(fbpcd) (**3**) have been established through a combination of electrochemical and computational methods. Future studies will focus on the photophysical investigation of these and related compounds, and the luminescent properties will be reported in due course.

Acknowledgments

Financial support from the Robert A. Welch Foundation (B-1093-MGR) is much appreciated, and Prof. Guido F. Verbeck and graduate student Ms. Nicole Ledbetter (UNT) and Prof. Andreas H. Franz (University of the Pacific) are thanked for recording the mass spectra of compounds **2** and **3**, respectively.

Appendix A. Supplementary data

CCDC 683128 and 683129 contain the supplementary crystallographic data for $\mathbf{2} \cdot CH_2Cl_2$ and $\mathbf{3} \cdot CH_2Cl_2$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Cyclic voltammogram of **3** recorded in CH_2Cl_2 and 0.2 M TABP. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.09.005.

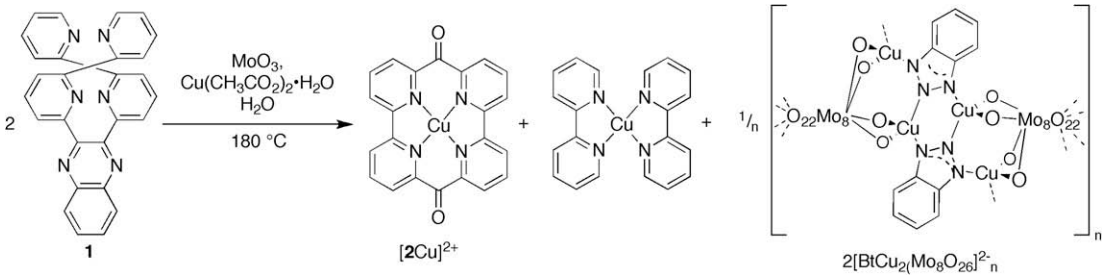
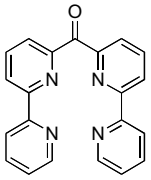


Scheme 1.



3

dication contains two planar 2-acyl-6,2′-bipyridyl (Bpy) fragments that are interrelated by the inversion center passing through the Cu center (Fig. 1). The constituent atoms of each plane are separated from its congener by 0.588–0.689 Å. In this conformation, the diameter of the macrocyclic cavity, as measured between pairs of opposing N atoms, is 3.95–4.00 Å. All bond lengths in **2**Cu^{2+} are within expected values, except for one of the two C–C lengths that are associated with the carbonyl groups (1.69(2) Å) and exhibit some disorder at the carbon sites [27,28].

The structure of **2**Cu^{2+} invites comparison to the Cu(II) complexes of **3**. This would be erroneous, since the latter do not simultaneously maintain molecular planarity and sp^2 hybridization of the carbonyl group. Arguably, this is a result of bond angle strain induced by the geometry about the carbonyl group, and would be relieved by a highly twisted global molecular geometry [29,30]. Alternatively, carbonyl hydration permits coplanarity of the heteroaromatic groups, but disrupts interannular conjugation. In contrast, **2**Cu^{2+} is largely coplanar and does not occur as a hydrate – in the crystal lattice *and* in spite of the reaction conditions. The observed widening of the angle around C=O, and of the opposite bite angle, would provide a means of strain relief.

To understand its anticipated electronic structure, we calculated the molecular orbitals and geometry of **2**Cu^{2+} using scalar relativistic ZORA DFT methods on ADF2005.01 [31]. Either full or D_{2h}-constrained optimization, followed by vibrational analysis, converged to a D_{2h} structure that was energetically preferred by 33.8 kcal mol^{-1} over C_i and C_{2h} symmetries. The resulting Cu–N distance, 1.989 Å, closely resembles commonly accepted values for d^9 square planar Cu(II) porphyrins and Bpy complexes [27,28], with ∠N4—Cu1—N5 being 96.4° (bite angle) and ∠C7—C17—C16 narrowing to 125.3°.

The HOMO is energetically disfavored by 1.02 eV, relative to the remaining filled orbitals, but stabilized by 1.29 eV relative to the B_{1u} symmetrical orbital that corresponds to the closest empty level with the same spin. We take this latter value to approximate the anticipated band gap in **2**Cu^{2+}. The corresponding LUMO is ligand centered and has overall anti-bonding character. See Figs. S2 and S3 in Supplementary data for diagrams of initial and final orbitals, plus energy levels.

In the lattice, **2**Cu^{2+} has closest through-space contacts to two symmetry-related Bt equivalents, which are parallel to, and within typical stacking distances from, inversion symmetry-related 2-acyl-6,2′-bipyridyl fragments (average separation of closest C_5H_3N to Bt mean plane: 3.425 Å; see Fig. 2). The Bt fragments occur in head-to-tail π-stacked pairs (average separation to plane: 3.522 Å) and dimerize by bridging of two symmetry-related Cu atoms to give N_4Cu_2-rings. Bt units that are related by either π-stacking or a dicopper bridge are associated with different **2**Cu^{2+} equivalents. Stacked and coordinating Bt pairs thus translate between the **2**Cu^{2+} equivalents.

The Cu atoms of the N_4Cu_2 rings and an additional Cu outside of the ring bond with tetrahedral ligand field to oxygen of Mo_8O_{24}. The Cu–N bond lengths, 1.898–1.960 Å, and the Cu–O distances, in the 1.916–2.263 Å range, are ~0.1–0.2 Å greater than in known Bt–Cu(II) complexes with oxygen-donor ligands (*loco cite* [32]) but do not allow distinguishing the Cu oxidation state.

Summarizing, we have uncovered a highly unusual synthesis of a electron-deficient, oligopyridyl-type macrocycle forming a planar Cu(II) complex. Future studies will focus on its mechanism of for-

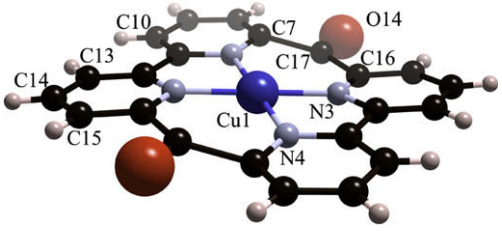


Fig. 1. Structure of **2**Cu^{2+} in the crystal. Selected bond angles: ∠C7–C17–C16: 130°; ∠N4–Cu1–N5: 97.9° (bite angle).

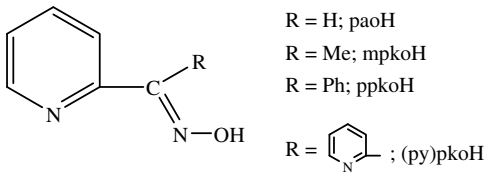

Fig. 1. General structural formula and abbreviations of the 2-pyridyl oximes that are used in our laboratories, including methyl 2-pyridyl ketone oxime (mpkoH) employed in this work.

[9–11]. As an extension to this work, we have now asked if other products might result from the $Mn/R'CO_2^-$/mpkoH reaction system. Four years ago, we described in detail the synthesis and structural, spectroscopic and magnetochemical characterization of the remarkable cluster $[Mn^{II}_4Mn^{III}_4O_2(OH)_2(O_2CPh)_{10}(ppko)_4]$ (**1**) and showed that it has a $S = 0$ ground state [7]. We have wondered if the $mpko^-$ analogue of **1** could be prepared and have thus pursued its synthesis. There are two reasons to prepare such a complex: (i) to determine if it would be isostructural with **1** and be isolated at the same oxidation level, and (ii) if it is isostructural, to assess any influence of the Me versus Ph difference on magnetochemical properties. We herein report the successful development of synthetic procedures to prepare the $mpko^-$ analogue of **1** and describe its characterization.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. $Mn(O_2CPh)_2 \cdot 2H_2O$ [15a], $NBu^n_4MnO_4$ [15b], $(NBu^n_4)[Mn^{III}_4O_2(O_2CPh)_9(H_2O)]$ [15a] and $[Mn_3O(O_2CPh)_6(py)_2(H_2O)]$ [16] were synthesized according to published methods. Elemental analyses (C, H, N) were performed by the in-house facilities of the University of Florida Chemistry Department. IR spectra (4000–400 cm^{-1}) were recorded on Perkin–Elmer 16 PC and Nicolet Nexus 670 FTIR spectrometers with samples prepared as KBr pellets. Variable-temperature dc and ac magnetic susceptibility data were collected at the University of Florida using a Quantum Design MPMS-XL SQUID susceptometer equipped with a 7 T magnet. The sample was embedded in eicosane to prevent torquing. Diamagnetic corrections were applied to the observed paramagnetic susceptibilities using Pascal's constants.

2.2. Compound preparation

2.2.1. $[Mn(O_2CPh)_2(mpkoH)_2]$ (**2**)

Solid mpkoH (0.082 g, 0.60 mmol) was added to a pale pink solution of $Mn(O_2CPh)_2 \cdot 2H_2O$ (0.100 g, 0.30 mmol) in CH_2Cl_2 (30 mL). The solid soon dissolved to give a yellow solution. The solution was stirred for 30 min and layered with Et_2O/*n*-hexane (1:1 v/v, 60 mL). After 1 d, X-ray quality, yellow prismatic crystals of the product were collected by filtration, washed with Et_2O (2×2 mL), and dried in air. Yield: 85%. *Anal.* Calc. for $C_{28}H_{26}MnN_4O_6$: C, 59.05; H, 4.61; N, 9.84. Found: C, 58.97; H, 4.32; N, 9.72%. IR (KBr, cm^{-1}): ~3488mb, 3065w, 1599s, 1543s, 1478m, 1437m, 1404s, 1327m, 1255w, 1170w, 1137w, 1098w, 1047s, 1024m, 964w, 834w, 786s, 720s, 684m, 674s, 636w, 563w, 452m, 406w.

2.2.2. $[Mn_8O_2(OH)_2(O_2CPh)_{10}(mpko)_4]$ (**3**)

2.2.2.1. Method A. To a deep red solution of $(NBu^n_4)[Mn^{III}_4O_2(O_2CPh)_9(H_2O)]$ (0.160 g, 0.10 mmol) in CH_2Cl_2 (30 mL) was added solid mpkoH (0.054 g, 0.40 mmol). The resulting dark brown solution was stirred for 30 min, during which time no further colour change occurred. The solution was filtered and the filtrate layered with Et_2O/*n*-hexane (1:1 v/v, 60 mL). After 2 d, dark red prismatic crystals of $\mathbf{3} \cdot 1.8CH_2Cl_2 \cdot 1.8Et_2O$ were collected by filtration, washed with cold Et_2O (2×2 mL), and dried in air. Yield: 60%. The air-dried sample analyzed as $\mathbf{3} \cdot 2H_2O$. *Anal.* Calc. for $C_{98}H_{84}Mn_8N_8O_{30}$: C, 51.32; H, 3.70; N, 4.88. Found: C, 51.51; H, 3.84; N, 4.83%. IR (KBr, cm^{-1}): 3435mb, 3063w, 2921w, 1597s, 1553s, 1491w, 1484w, 1447m, 1404s, 1317w, 1273w, 1175w, 1151w, 1098w, 1068m, 1046m, 1025m, 934w, 820w, 778m, 718s, 689w, 676m, 639w, 604m, 537w, 457w.

2.2.2.2. Method B. Treatment of a stirred, dark brown solution of $[Mn_3O(O_2CPh)_6(py)_2(H_2O)]$ (0.108 g, 0.10 mmol) in CH_2Cl_2 (30 mL) with solid mpkoH (0.027 g, 0.20 mmol) gave a solution of essentially the same colour. This was stirred for 30 min and layered with Et_2O (60 mL). Slow mixing gave dark red prismatic crystals which were collected by filtration, washed with Et_2O (2×3 mL) and dried in air. Yield: 40%. The IR spectrum of the product was identical with that of the authentic material prepared by Method A.

2.2.2.3. Method C. Treatment of a stirred, pale pink solution of $Mn(O_2CPh)_2 \cdot 2H_2O$ (0.100 g, 0.30 mmol) in MeOH/MeCN (15 mL, 1:2 v/v) with solid $NBu^n_4MnO_4$ (0.040 g, 0.12 mmol) resulted in a dark brown solution. Solid mpkoH (0.040 g, 0.29 mmol) was slowly added to the solution, and it soon dissolved to give a somewhat darker solution that was stirred for a further 20 min. The solvents were then evaporated under reduced pressure. The dark brown residue was dissolved in CH_2Cl_2 (30 mL), filtered and the essentially black filtrate layered with Et_2O (60 mL). Slow mixing gave dark red crystals of the product after 4 d, which were collected by filtration, washed with cold CH_2Cl_2 (2×2 mL) and Et_2O (5 mL), and dried in air. Yield: ~35%. The IR spectrum of the product was identical with the spectra of the material from Methods A and B. The purity of the sample prepared from this method was also confirmed by microanalytical data.

2.3. Single-crystal X-ray crystallography

The crystallographic data and structure refinement details for the two complexes are summarized in Table 1. A selected crystal of **2** ($0.07 \times 0.35 \times 0.66$ mm) was mounted in air. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$. Intensity data were recorded using a θ–2θ scan to a maximum 2θ value of 50°. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using CRYSTAL LOGIC software. The structure was solved by direct methods using SHELXS-97 [17a] and refined on F^2 by full-matrix least squares techniques with SHELXL-97 [17b]. All H atoms were located by Fourier difference maps and refined isotropically. All non-H atoms were refined anisotropically.

A selected crystal of $\mathbf{3} \cdot 1.8CH_2Cl_2 \cdot 1.8Et_2O$ ($0.28 \times 0.30 \times 0.55$ mm), prepared by Method A, was taken from the mother liquor, mounted, and immediately cooled to 103(2) K. Data were collected on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite-monochromated Mo radiation. Data collection (ω-scans) to a maximum 2θ value of 51° and processing (cell refinement, data reduction and empirical absorption correction) were performed using the CRYSTALCLEAR program package [17c]. The structure was solved by direct methods using SHELXS-97 [17a] and

refined by full-matrix least squares techniques on F^2 with SHELXL-97 [17b]. All H atoms were introduced at calculated positions and refined as riding on their bound atoms. All non-H atoms were refined anisotropically. Two of the benzoates as well as the solvate molecules were found disordered and refined in two orientations with occupancies adding up to 100%.

3. Results and discussion

3.1. Syntheses and IR spectroscopy

The preparation of pure **2** in excellent yield was achieved by the reaction of $Mn(O_2CPh)_2 \cdot 2H_2O$ with two equivalents of mpkoH in CH_2Cl_2, see Eq. (1):

$$Mn(O_2CPh)_2 \cdot 2H_2O + 2mpkoH \xrightarrow{CH_2Cl_2} [Mn(O_2CPh)_2(mpkoH)_2] + 2H_2O \quad (1)$$

Three procedures to $Mn^{II}_4Mn^{III}_4$ complex **3** were developed. The first (and best) involves the conversion of $[Mn^{III}_4O_2(O_2CPh)_9(H_2O)]^-$ into a higher nuclearity product. The anion, which contains only $PhCO_2^-$ and H_2O ligands [15a], is a very useful starting material for the synthesis of higher nuclearity clusters [15a,18]. Thus, treatment of the $NBu^n_4{}^+$ salt of $[Mn^{III}_4O_2(O_2CPh)_9(H_2O)]^-$ with an excess of mpkoH in CH_2Cl_2 led to pure crystalline **3** in good yields (~60%) upon layering of the reaction solution with precipitation solvents. The formation of **3** is summarized in Eq. (2). The $4Mn^{II}$, $4Mn^{III}$ description of **3** requires the reduction of four Mn^{III} ions to have occurred. The source of the reducing agent is probably an

$$2[Mn^{III}_4O_2(O_2CPh)_9(H_2O)]^- + 4mpkoH \xrightarrow{+4e^-} [Mn^{II}_4Mn^{III}_4O_2(OH)_2(O_2CPh)_{10}(mpko)_4] + 2PhCO_2H + 6PhCO_2^- + 2H_2O \quad (2)$$

impurity of the solvent or excess ligand groups, facilitated by the strongly oxidizing nature of Mn^{III} [15a]. An alternative means for the generation of the Mn^{II} ions in **3** might be disproportionation of Mn^{III}, in which case Mn^{IV}-containing species would be present in the coloured filtrate [15a]. We have not attempted to identify the exact origin of the Mn^{II} ions in the product, nor would it be a simple investigation.

The second procedure to **3** gave a lower yield and involved the reaction of $[Mn^{II}Mn^{III}_2O(O_2CPh)_6(py)_2(H_2O)]$ [16] with two equivalents of mpkoH in CH_2Cl_2. Many synthetic procedures to make polynuclear manganese carboxylate clusters rely on the reactions of triangular $[Mn_3O(O_2CR)_6L_xL'_y]^{0/+}$ species ($x + y = 3$) with a potentially chelating/bridging ligand [5b,11]. The formation of **3** by this method can be summarized in Eq. (3). As stated above, it is not uncommon to find Mn^{III} – a strong oxidizing agent – being reduced by ligand groups, solvent impurities, etc.:

$$8[Mn^{II}Mn^{III}_2O(O_2CPh)_6(py)_2(H_2O)] + 12mpkoH + 4H^+ \xrightarrow{+4e^-} 3[Mn^{II}_4Mn^{III}_4O_2(OH)_2(O_2CPh)_{10}(mpko)_4] + 18PhCO_2H + 16py + 4H_2O \quad (3)$$

Once the identity of **3** had been established, we also sought its synthesis from simpler starting materials, and we found that it can be prepared by the comproportionation between $Mn(O_2CPh)_2.2H_2O$ and $NBu^n_4MnO_4$ [15b] in a 2.5:1 ratio in the presence of mpkoH in MeOH/MeCN. Such comproportionation reactions between Mn^{II} and Mn^{VII} sources in the presence of appropriate ligand groups have found extensive prior use to produce clusters of several nuclearities at various Mn oxidation levels [11,15a,19]. The ratio employed in this work gives, on paper, an average Mn oxidation state in solution of $Mn^{+3.4}$, higher than that ($Mn^{+2.5}$) observed in solid **3**, but the MeOH can act as reducing agent. The yield was only ~35%, and it is possible there are other products in the coloured filtrates. We also explored higher Mn^{II}:Mn^{VII} ratios, but this led to **3** contaminated with $[Mn^{II}_4Mn^{III}_2O_2(O_2CPh)_{10}(MeCN)_4]$ [20] containing no bound $mpko^-$ groups.

Note that the $Mn(O_2CPh)_2 \cdot 2H_2O/MnO_4^-$/mpkoH and $[Mn_3O(O_2CPh)_6(py)_2(H_2O)]$/mpkoH reaction systems in EtOH or MeOH/MeCN/CH_2Cl_2 in the presence of appropriate counterions (e.g. ClO_4^-) have led to salts of the $[Mn_3O(O_2CPh)_3(mpko)_3]^+$ cation, which were amongst the first examples of SMMs with a triangular structure [9,11]. Thus, it is likely, as with many other reactions in higher oxidation state Mn chemistry, that the reaction solution contains a complicated mixture of several species in equilibrium, with factors such as relative solubilities, absence/presence of counterions, lattice energies, crystallization kinetics and others determining the identity of the isolated product [19].

The presence of neutral oxime groups in **2** is manifested by a broad IR band of medium intensity at 3488 cm^{-1}, assigned to $\nu(OH)_{oxime}$ [6,21]. The IR spectrum of **3** exhibits a medium band at 3435 cm^{-1} assignable [22] to $\nu(OH)_{OH^-}$. The broadness and relatively low wavenumber of these bands are both indicative of hydrogen-bonding. A medium-intensity band at 604 cm^{-1} is present in the spectrum of **3**; this band, which is absent from the spectrum of **2**, is tentatively assigned to a vibration involving a Mn^{III}–O^{2-} stretch [23]. The $\nu(CO_2)$ bands are difficult to assign in the spectra of **2** and **3** due to the appearance of overlapping carboxylate, phenyl, 2-pyridyl and oxime/oximate stretching vibrations in the 1600–1400 cm^{-1} region [24] and thus the application of the spectroscopic criterion of Deacon and Phillips [25] is very difficult.

3.2. Description of structures

The molecular structures of complexes **2** and **3** are depicted in Figs. 2 and 3, respectively. Selected interatomic distances and angles are listed in Tables 2 and 3.

Complex **2** crystallizes in the triclinic space group $P\bar{1}$. Its structure consists of well-separated $[Mn(O_2CPh)_2(mpkoH)_2]$ molecules. The Mn^{II} center is coordinated by two monodentate $PhCO_2^-$ groups and two *N*,*N*′-chelating (η^2) mpkoH ligands. The mpkoH donor atoms are the nitrogen atoms of the neutral oxime and the 2-pyridyl groups. The six-coordinate molecule is the *cis–cis–trans* isomer

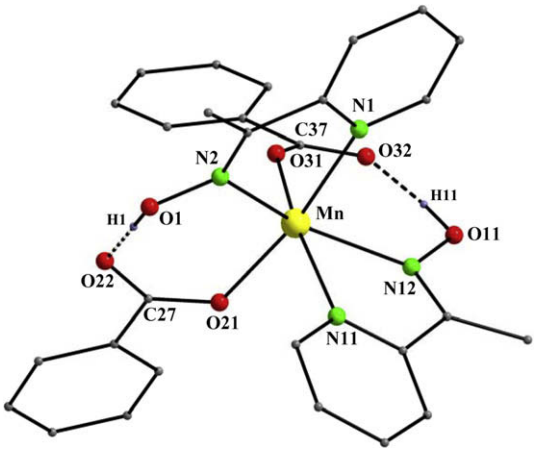

Fig. 2. Partially labelled plot of complex **2**. The dashed lines are H-bonds. Colour scheme: Mn^{II}, yellow; O, red; N, green; C, gray; H, purple. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

with respect to the disposition of the benzoate oxygen, pyridyl nitrogen and oxime nitrogen atoms, respectively. The *cis* arrangement of the oxime groups seems unfavorable, probably due to the steric hindrance arising from the Me groups upon oxime coordination. The molecule has no imposed symmetry, although it closely approximates C_2 symmetry, with the pseudo C_2 axis bisecting the O(21)–Mn–O(31) angle. The main distortion from octahedral geometry is due to the small bite angles of the mpkoH chelates (70.2°, 70.6°). There are very strong intramolecular H-bonds between unbound oxime –OH groups and the unbound benzoate O atoms (O(22), O(32)). The dimensions are: O(1)···O(21) 2.542(4) Å, HO(1)···O(22) 1.650(4) Å, O(1)–HO(1)···O(22) 178.9(1)° and O(11)···O(32) 2.535 Å, HO(11)···O(32) 1.672(5) Å, O(11)–HO(11)···O(32) 170.5(1)°. Complex **2** joins a very small family of $[Mn^{II}(O_2CR')_2(L–L)_2]$ complexes (L–L = neutral 2-pyridyl oximes) with an analogous *cis–cis–trans* arrangement of the donor atoms [6–8].

Complex $\mathbf{3}\cdot 1.8CH_2Cl_2\cdot 1.8Et_2O$ crystallizes in the monoclinic space group *C*2/*c*. Its structure consists of the $[Mn_8O_2(O\text{-}H)_2(O_2CPh)_{10}(mpko)_4]$ molecule and solvate CH_2Cl_2 and Et_2O molecules; the latter will not be further discussed. The molecule lies on a crystallographic twofold axis. The eight Mn ions are held together by two μ_4-O^{2-} (O(71), O(71′)) and two μ_3-OH^- (O(72), O(72′)) groups to give a $[Mn_8(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core (Fig. 4). Bond-valence sum (BVS) calculations [26] give values of 1.8 and 1.2 for O(71) and O(72), respectively, supporting their assignments as oxo and hydroxo oxygen atoms (Table 4). Peripheral ligation is provided by two monodentate (η^1) $PhCO_2^-$ (those containing the ligating atoms O(51) and O(51′)), four *syn,syn*-η^1:η^1:μ $PhCO_2^-$ (those containing O(41)/O(42), O(61)/O(62) and their symmetry-related partners), four η^1:η^2:μ_3 $PhCO_2^-$ groups (those containing O(21)/O(22), O(31)/O(32′) and their symmetry-related partners)

Mn(4)	*1.98*	1.85	1.88
	BVS	Assignment	
O(71)	1.79	O^{2-}	
O(72)	1.17	OH^-	

[a] The italic value is the one closest to the charge for which it was calculated. The oxidation state of a particular Mn center can be taken as the nearest whole number to the italic value.

[b] An O BVS in the ~1.8–2.0, ~1.0–1.2 and ~0.2–0.4 ranges is indicative of zero, single, and double protonation, respectively.

and four $\eta^1{:}\eta^1{:}\eta^1{:}\mu$ $mpko^-$ ligands. Each $mpko^-$ ligand chelates one metal ion through its nitrogen atoms forming a five-membered ring and bridges this metal ion with a second one through the terminally ligated, deprotonated oximate O atom (O(1), O(1′), O(11), O(11′)). If we consider the monoatomic carboxylate bridges and the bridging diatomic oximate groups as part of the core, then the latter becomes $[Mn_8(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2(\mu\text{-}OR'')_4(\mu\text{-}ONR''')_4]^{6+}$;

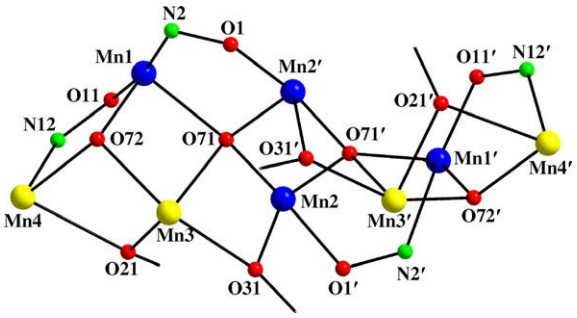

Fig. 5. The core of **3** emphasizing the oxime bridging modes. For the chemical nature of most atoms, see the caption of Fig. 4. O(21), O(31), O(21′) and O(31′) are the monoatomically bridging benzoate O atoms. N(2), O(1), N(12), and O(11) are the $mpko^-$ oximate groups. Colour scheme as in Fig. 3.

this view is emphasized in Fig. 5. The Mn_8 topology of **3** is shown in Fig. 6.

Mn(1) and Mn(4) are bound to an O_4N_2 set of donor atoms, while Mn(2) and Mn(3) to an O_6 set. Charge considerations require a $4Mn^{II}$, $4Mn^{III}$ mixed-valence description, and Mn(1) and Mn(2) are assigned as Mn^{III} on the basis of (i) their shorter average Mn-O bond lengths (2.015 Å) compared with those for Mn(3) and Mn(4) (average 2.194 Å, with no individual value shorter than 2.10 Å); (ii) a Jahn–Teller (JT) axial elongation at Mn(1) and Mn(2) (the JT elongation axes are O(71)–Mn(1)–N(1) and O(31)–Mn(2)–O(41′)), as expected for high-spin d^4 ions in near-octahedral geometry; and (iii) BVS calculations [26] (Table 4). Thus, the hydroxide group bridges one Mn^{III} and two Mn^{II} atoms, while the oxide group bridges one Mn^{II} and three Mn^{III} atoms.

The μ-O atom O(21) does not bridge the two Mn^{II} ions symmetrically, with Mn(3)–O(21) (2.238(4) Å) noticeably shorter than Mn(4)–O(21) (2.450(4) Å). The Mn(3,4)–O(72) bond distances (average (2.164(4) Å) are longer than the Mn(1)–O(72) distance (1.942(4) Å), consistent with a higher oxidation state for Mn1. It should also be noted that the O^{2-} groups (O(71), O(71′)) bridge the three Mn^{III} atoms in an asymmetric fashion. Thus, Mn(2,2′)–O(71) distances average 1.889(4) Å, whereas the Mn(1)–O(1) bond length is noticeably longer (2.180(4) Å). This is the result of O(71) lying on the JT elongation axis of Mn(1); Mn^{III}–O^{2-} distances at ~2.2 Å are extremely rare [27]. The Mn···Mn distances (Table 3) depend on the number and nature of the bridges between two given metal centers and on the oxidation state of each Mn atom. The central Mn(2)···Mn(2′) distance is the shortest (2.804(2) Å) and is typical for $\{Mn_2^{III,III}(\mu_4\text{-}O)_2\}^{2+}$ subunits in Mn^{III}-containing clusters [20,28]. The uncoordinated O atoms of the monodentate $PhCO_2^-$ ligands (O(52) and O(52′)) are H-bonded to the OH^- ligands, with the O(52)···O(72) distance being 2.777(2) Å.

The core of **3** can be described in various ways: (i) as two $\{Mn_2^{II}Mn_2^{III}(\mu_3\text{-}O)(\mu_3\text{-}OH)\}^{7+}$ subunits (atoms Mn(1)–Mn(4) and their symmetry equivalents) becoming linked through their μ_3-O

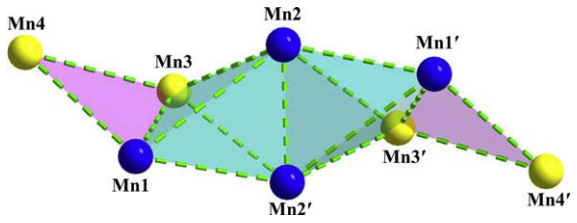

Fig. 6. The Mn_8 skeleton of **3** emphasizing the 'edge-sharing tetrahedra', 'butterfly-like' and various triangular subunits. Colour scheme: Mn^{II}, yellow; Mn^{III}, blue. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

$^{2-}$ converting to μ_4 and thus providing the two 'inter-fragment' Mn(2)–O(71′) and Mn(2′)–O(71) bonds. The four metal ions in each subunit are nearly coplanar with the Mn(1)–Mn(2)–Mn(3)–Mn(4) torsion angle being 7.18°. The $\{Mn^{II}_2Mn^{III}_2(\mu_3\text{-}O)(\mu_3\text{-}OH)\}^{7+}$ subunit has not been seen before in a discrete Mn_4 cluster or as a recognizable sub-fragment of a higher nuclearity cluster; (ii) as a central $\{Mn^{II}_2Mn^{III}_4(\mu_4\text{-}O)\}^{12+}$ subunit (the oxidized version of the familiar $[Mn^{II}_4Mn^{III}_2(\mu_4\text{-}O)_2]^{10+}$ core [29]) with an additional Mn^{II} atom at each end linked through the μ_3-OH^- ion. The central $\{Mn^{II}_2Mn^{III}_4(\mu_4\text{-}O)_2\}^{12+}$ subunit consists of six Mn ions arranged as two edge-sharing tetrahedra, each with a central μ_4-O^{2-}. The Mn–μ_4-O^{2-}–Mn angles range from 95.3° to 142.3°, deviating significantly from the 109.5° ideal values of a tetrahedron. The central $\{Mn^{II}_2Mn^{III}_4(\mu_4\text{-}O)_2\}^{12+}$ subunit can also be considered as two $\{Mn_3O\}^{6+}$ triangular units (Mn(1,2,3) and Mn(1′,2′,3′) or, alternatively, Mn(1,2′,3) and Mn(1′,2,3′)) joined together by each of their μ_3-O^{2-} ions (O71 and O71′) becoming μ_4 by ligating to the Mn^{III} center of the adjacent unit. Note that this central $\{Mn_6O_2\}^{12+}$ subunit of **3** is similar to the recently reported Mn_6 cation $[Mn^{II}_2Mn^{III}_4O_2(OMe)_2(dapdo)_2(dapdoH)_4]^{2+}$ (dapdoH$_2$ = 2,6-diacetylpyridine dioxime) [5b]; and (iii) as a central $\{Mn^{III}_4(\mu_3\text{-}O)_2\}^{8+}$ butterfly-like [15a,30] subunit (atoms Mn(1), Mn(2), Mn(2′), Mn(1′), O(71), O(71′)) to which are attached two $\{Mn^{II,II}_2(\mu\text{-}OH)\}^{3+}$ subunits via the interfragment bonds Mn(1)–O(72), Mn(3)–O(71) and their symmetry equivalents; as a result, each OH^- group becomes μ_3, forming a bond with a 'wing-tip' Mn^{III} atom (Mn(1), Mn(1′)), and each O^{2-} group is converted to μ_4 forming a bond with one of the Mn^{II} atoms (Mn(3), Mn(3′)).

Complex **3** joins only a small family of Mn clusters of nuclearity eight, which currently comprise the metal oxidation levels Mn^{II}_8 [31], $Mn^{II}_6Mn^{III}_2$ [32], $Mn^{II}_4Mn^{III}_4$ [7,33], $Mn^{II}_2Mn^{III}_6$ [5b,15a,34], Mn^{III}_8 [35] and $Mn^{III}_2Mn^{IV}_6$ [36], and thus it becomes the fourth member of the $Mn^{II}_4Mn^{III}_4$ subfamily.

3.3. Magnetochemistry

Variable-temperature dc magnetic susceptibility data in a 0.1 T field and in the 5.0–300 K range were collected on a powdered microcrystalline sample of **3** restrained in eicosane to prevent torquing. The obtained data are plotted as χ_MT versus T in Fig. 7. The χ_MT value at 300 K is 29.34 cm^3 K mol^{-1}. This value is slightly less than that expected for a cluster comprising four Mn^{II} and four Mn^{III} non-interacting ions (29.50 cm^3 K mol^{-1} with g = 2). The χ_MT product gradually decreases with decreasing temperature to 15.12 cm^3 K mol^{-1} at 50 K before dropping to 2.99 cm^3 K mol^{-1} at

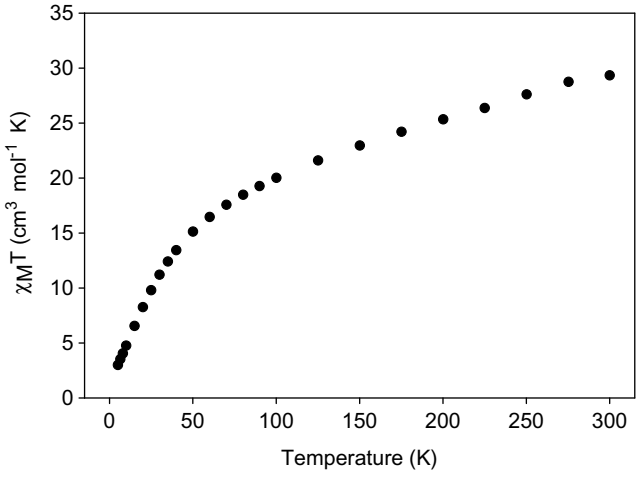

Fig. 7. Plot of χ_MT vs. T for cluster **3**.

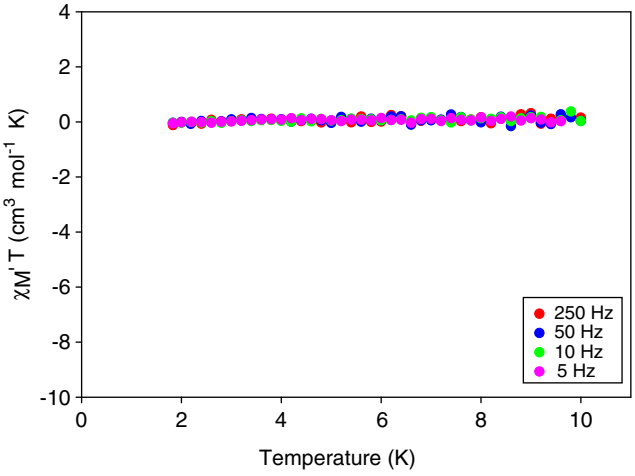

Fig. 8. Plot of the in-phase ac susceptibility signals as a χ'_MT vs. T plot for complex **3** in a 3.5 G field oscillating at the indicated frequencies.

5.0 K. The χ_MT versus T data appear to be heading for 0 cm^3 K mol^{-1} at 0 K. This behaviour is indicative of dominant antiferromagentic interactions between the metal centers with the low temperature value suggesting a small ground state spin of S = 0 or 1. To determine which one it is, and to avoid complications from an applied dc field, we employed the ac susceptibility technique [37] with a zero dc field and a 3.5 G ac field (Fig. 8). The χ'_MT signal below 10 K is zero, confirming an S = 0 ground state [29], and the essentially constant value in this temperature range indicates little population of excited states.

Similarly low or S = 0 ground states have been reported for the other $Mn^{II}_4Mn^{III}_4$ clusters in the literature [33], and we have provided elsewhere a detailed rationalization of the S = 0 ground state for the structurally similar cluster **1** [7] on the basis of the well-established magnetic behaviour of the central, butterfly-like $\{Mn^{III}_4(\mu_3\text{-}O)_2\}^{8+}$ subcore [30,38].

4. Conclusions

The present work extends the body of results that emphasize the ability of mpkoH to form interesting structural types in Mn carboxylate chemistry. In addition to the $[Mn^{III}_3O(O_2CR')_3(mpko)_3]^+$ cationic SMMs reported previously [9–11], the Mn/$PhCO_2^-$/mpkoH reaction system has provided access to the octanuclear $Mn^{II}_4Mn^{III}_4$ cluster **3** and the mononuclear Mn^{II} compound **2**. Complex **3** is a new addition to the Mn_8 family of clusters. Although this compound has been found to possess a S = 0 spin ground state, the potentially μ_3 mode of mpko$^-$ (which has not been realized in the present study) [13] would undoubtedly give Mn_x/RCO_2^-/mpko$^-$ products structurally different from **3** and which may have high-spin ground states. The bridging mode(s) of mpko$^-$ also suggests possibilities for other Mn_x non-carboxylate clusters to exist, e.g. clusters containing the strongly coordinating inorganic anions N_3^-, NCO^- and SO_4^{2-}.

As far as the specific goals of this work mentioned in the Introduction are concerned, it has been demonstrated that the attainment and stability of clusters containing the $[Mn^{II}_4Mn^{III}_4(\mu_4\text{-}O)_2(\mu_3\text{-}OH)_2]^{14+}$ core are not limited to the use of ppko$^-$ (Fig. 1), nor are they in some way a consequence of any specific property of this ligand, other than its chelating/bridging nature. The employment of mpko$^-$ leads to a product with the same formulation, superimposable cores and almost identical magnetic behaviour. In many ways, this was surprising given how often similarly small changes to a reaction, such as changing the carboxylate or solvent, can lead to a completely different product. There are examples in nickel chemistry

where mpkoH and ppkoH give different products in otherwise similar reactions [24,39]. The presence or absence of counteranions such as ClO_4^- does make a difference, however; its absence from the present reactions precludes formation of the trinuclear $[Mn_3O]^{7+}$-containing, mixed $R'CO_2^-/mpko^-$ complexes, another thermodynamically favorable arrangement and potential product of $Mn/R'CO_2^-/mpko^-$ components.

CCD diffractometer using graphite monochromated Mo Kα (λ = 0.7107 Å) radiation and the intensities were measured using the ω scan method. Preliminary lattice parameters and orientation matrices were obtained from four sets of frames. Unit cell dimensions were determined from the setting angles of 6903 reflections in the range 2.17° < θ < 25.79°. Integration and scaling of intensity data was accomplished using the SAINT program [20]. The structure was solved by direct methods using SHELXS97 [21] and refinement was carried out by full-matrix least-squares techniques using SHELXL97 [21]. Anisotropic displacement parameters were included for all non-hydrogen atoms. The side chain atoms were disordered and refined with site-occupation factors of 0.563(7) and 0.437(7). The geometries of the disordered atoms were refined with distance restraints. The displacement parameters of the disordered atoms were restrained with SIMU and DELU commands.

2.4. Synthesis and analyses

N,N′-Di-4-(4′-pentyloxybenzoate)salicylidene diaminoethane, **3** (Scheme 1), was synthesized from the precursor materials **1** and **2**, as reported earlier [15,16]. The [ML^5] (M = Mn, Co, Ni, Cu and Zn) complexes were prepared by refluxing solutions of the Schiff-base H_2L^5 and the corresponding metal acetate in a 1:1 molar ratio in dichloromethane/ethanol medium for ~2 h at 80 °C. The reaction mixture was left overnight in the flask, closed with a guard tube. The solid complex that separated out in each case was filtered under suction and washed repeatedly with cold ethanol and dried over fused $CaCl_2$ in a desiccator.

2.4.1. Synthesis of *N,N′*-di-4-(4′-pentyloxybenzoate)salicylidene diaminoethane, H_2L^5

N,N′-Di-4-(4′-pentyloxybenzoate)salicylidene diaminoethane, H_2L^5, was prepared by mixing together absolute ethanolic solutions of 4-pentyloxy-(4′-formyl-3′-hydroxy)benzoate (16.42 g, 50 mmol, in 100 mL) and 1,2-diaminoethane (1.9 mL, 25 mmol in 10 mL) and magnetically stirring for ~1 h in the presence of a few drops of acetic acid and leaving the resultant solution overnight in the reaction flask at room temperature. The micro-crystalline product was suction-filtered, thoroughly washed with cold ethanol, recrystallized from a solution of absolute ethanol/chloroform (v/v, 1/1) and dried at room temperature; yield: 12.76 g (75%) as a yellow solid; mp 230 °C. Calc. for $C_{40}H_{44}N_2O_8$ (680.31): C, 70.57; H, 6.51; N, 4.11. Found: C, 70.53; H, 6.53; N, 4.13%.

2.4.2. Synthesis of the Mn^{II} complex

Yield: 0.50 g (68%) as a brown coloured solid; mp 200 °C (decomposes). Calc. for $C_{40}H_{42}MnN_2O_8$ (733.71): C, 65.48; H, 5.77; N, 3.82; Mn, 7.49. Found: C, 65.50; H, 5.74; N, 3.80; Mn, 7.52%.

2.4.3. Co^{II} complex

Yield: 0.52 g (70%) as an olive green solid; mp 210 °C (decomposes). Calc. for $C_{40}H_{42}CoN_2O_8$ (737.70): C, 65.12; H, 5.74; N, 3.80; Co, 7.99. Found: C, 65.15; H, 5.72; N, 3.81; Co, 8.01%.

2.4.4. Ni^{II} complex

Yield: 0.58 g (79%) as a dark orange solid; mp 255 °C. Calc. for $C_{40}H_{42}N_2O_8Ni$ (737.46): C, 65.15; H, 5.74; N, 3.80; Ni, 7.96. Found: C, 65.27; H, 5.80; N, 3.85; Ni, 8.01%.

2.4.5. Cu^{II} complex

Yield 0.52 g (70%) as a violet solid; mp 260 °C. Calc. for $C_{40}H_{42}N_2O_8Cu$ (742.32): C, 64.72; H, 5.70; N, 3.77; Cu, 8.56. Found: C, 64.77; H, 5.72; N, 3.80; Cu, 8.53%.

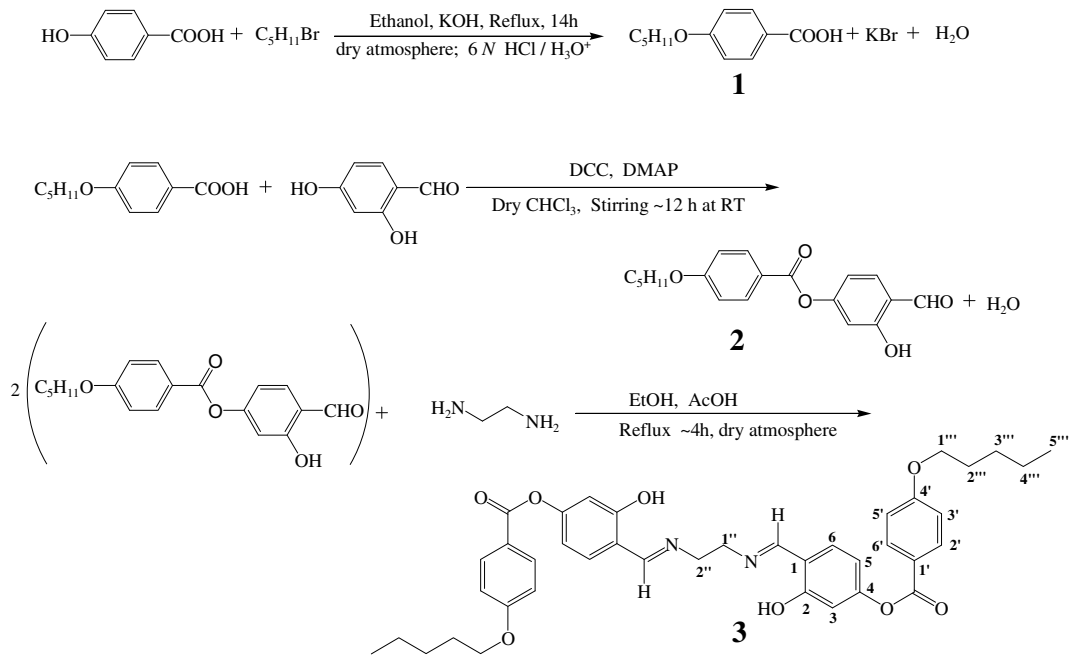
2.4.6. Zn^{II} complex

Yield 0.48 g (65%) as a white solid; mp 140 °C. Calc. for $C_{40}H_{42}N_2O_8Zn$ (744.16): C, 64.56; H, 5.69; N, 3.76; Zn, 8.79. Found: C, 64.57; H, 5.71; N, 3.77; Zn, 8.78%.

3. Results and discussion

3.1. Physical properties and spectral investigation

The Schiff-base ligand H_2L^5 as well as the metal complexes are soluble in chloroform, dichloromethane, DMF and DMSO, but are



Scheme 1. Synthetic steps involved in the synthesis of **1** (*p*-pentyloxybenzoic acid), **2** (4-pentyloxy-(4′-formyl-3′-hydroxy)benzoate) and **3** (*N,N′*-di-4-(4′-pentyloxy benzoate)salicylidene diaminoethane, H_2L^5.

insoluble in water, methanol, ethanol and acetonitrile. The structure and purity of the parent ligand and the complexes were checked and confirmed by elemental analyses, IR, ^{1}H and ^{13}C NMR and FAB mass spectra. The mass spectral features of H_2L^5 were characterized by the base peak (m/e = 191 corresponding to the fragment $C_5H_{11}O$–Ph–CO^+), and the molecular ion peak (m/e = 681) with ~72% intensity, and those of ML^5 (M = Mn^{II}, Co^{II}, Ni^{II} and Cu^{II}) by the base peak (m/e = 121 corresponding to the fragment, HO–Ph–CO^+) and the molecular ion peak (m/e = 734, 737, 737 and 742, respectively) with ~92–98% intensity. Further, additional peaks (corresponding to the formation of dimeric units) were observed in the FAB mass spectra of the Mn^{II}, Co^{II} and Ni^{II} complexes; based on the decomposition behaviour of the former two complexes, they may be presumed to be polymeric, which upon bond rupture under the experimental conditions might give rise to dimeric units. A comparison of the ^{1}H and ^{13}C{^{1}H} NMR spectral data of the ligand with those of the diamagnetic Ni^{II} and Zn^{II} complexes shows the absence of the phenolic-OH signal (13.537 ppm) and a significant shift (8.358 to 7.195 and 8.458 ppm, respectively) in the peak position for –N=C*H* in the spectra of the metal complexes, which implies bonding through the phenolate anion and azomethine nitrogen atom [22] of the ligand. Similar shifts observed in the ^{13}C{^{1}H} NMR spectra were of considerable magnitude in the case of the carbon atoms directly attached to the bonding atoms. Thus, the NMR spectral data imply a tetra-dentate bonding of $(L^5)^{2-}$ through the two >C=N groups and two phenolate oxygen atoms. In the IR spectrum of H_2L^5 the broad absorptions centred at 3443 cm^{-1} may be assigned to the ν(O–H)$_{phenolic}$ vibration, and further the strong bands occurring at 1740 and 1255 cm^{-1} may be assigned [23] to ν(>C=O) and ν(C–O) modes of the aromatic ester; the band occurring at 1628 cm^{-1} may be due to the ν(C=N) absorption of the azomethine moiety. These bands are shifted to lower frequencies in the complexes, indicating that the nitrogen atom of the azomethine group is coordinated to the metal ion [24]. Coordination through one of the nitrogen atoms of the ligand is also implied by the appearance of a new band (468–472 cm^{-1}) in the complexes, assignable to ν(M–N) [25,26]. Coordination through the phenolate oxygen to the metal ion is implied by the shifts of the ν(C–O) band in the complexes [27] and by the appearance of new bands, assignable to ν(M–O), in the 440–448 cm^{-1} region in the spectra of the complexes.

Table 2
Crystal structure data and structure refinement parameters

Details	Ligand, H_2L^5 [*jpl5*]	$[NiL^5]_2$ [*jpni1*]	$[CuL^5]$ [*ac27*]
Formula	$C_{40}H_{44}N_2O_8$	$C_{40}H_{42}N_2O_9Ni$	$C_{40}H_{43}N_2O_9Cu$

The room temperature magnetic moments and electronic spectral data of the present complexes are included in Table 1 while the spectra of the complexes of Co^{II}, Ni^{II} and Cu^{II} are shown in Fig. 1. The overall geometry assigned to the metal ion is based not only on the μ_{eff} values and the nature of the electronic spectra, but also

Table 1
Magnetic and electronic spectral data[a] of the complexes of H_2L5

Complex	Colour	μ_{eff} (B.M)	d–d transitions (nm)	Transition		Assignment
				Ground state(s)	Excited state(s)	
$[MnL^5]_n$	Brown	5.85	317, 260	$^6A_{1g}$	$^4A_{2g}$(F); ^4E_g(D)	Octahedral with M–M bonding
$[CoL^5]_n$	Olive green	3.52	974, 895, 860	^2E_g	$^2A_1$	Octahedral with M–M bonding (l.s.)
$[NiL^5]_2$	Dark orange	Diamag	530, 406	$^1A_1$	^1E; $^1A_2$	Square-pyramidal (M–M bonding[b] of 3.337 Å)
$[CuL^5]$	Violet	2.74	562	*xz*, *yz*	x^2–y^2	Sq. planar (M–M distance[b] of 3.457 Å)

[a] Spectra recorded in chloroform solutions.
[b] Vide single crystal structure data.

on the denticity of the ligand (*vide* IR and NMR) and the number of such ligands coordinated to the metal ion (vide elemental analyses). Although the μ_{eff} values imply ferromagnetic type interactions in the Mn^{II}, Co^{II} and Cu^{II} complexes, no concrete conclusion to this effect could be drawn in the absence of variable temperature magnetic moment data. The $[MnL^5]_n$ complex gives rise to extremely weak bands in the electronic spectrum, presumably with an octahedral environment (square-planar units polymerically

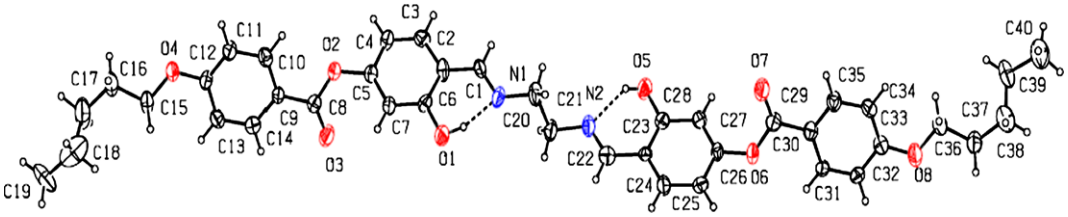

Fig. 2. The asymmetric unit of H_2L^5, with the atom numbering scheme. Displacement ellipsoids are drawn at the 30% probability level. H atoms are shown as small spheres of arbitrary radii. Hydrogen bonds are shown as dashed lines.

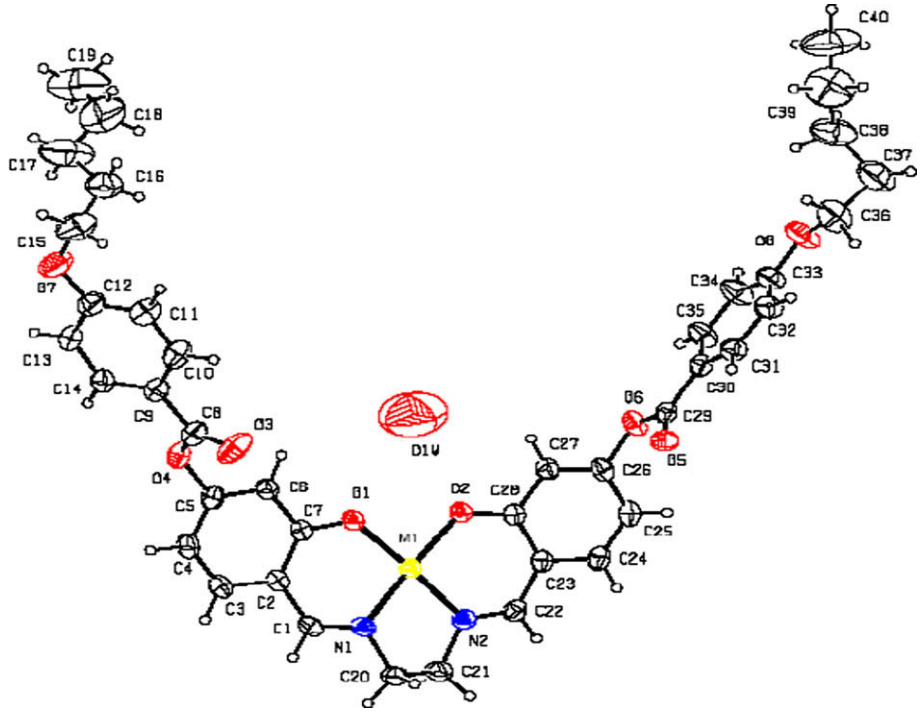

Fig. 3. The asymmetric unit of the isomorphous complexes $[ML^5]$ [M = Ni or Cu] with the atom numbering scheme. Displacement ellipsoids are drawn at the 30% probability level. The disordered atoms of the minor component (C161 and C361/C371/C381/C391/C401) have been omitted for clarity.

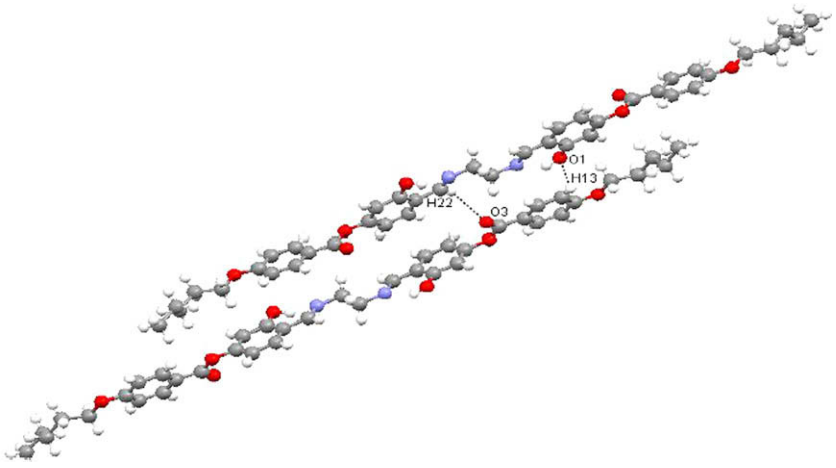

Fig. 4. A view of H_2L^5 molecules in the crystal lattice showing [C–H···O] intermolecular interactions along the *b* axis.

connected with M–M bonding) for the metal ion. The spectrum of the $[CoL^5]_n$ complex shows bands at 860, 895 and 974 nm which may be assigned to the transition(s) from the ^2E_g ground state to the $^2A_1$ excited state in an octahedral (low-spin) environment around the metal ion [28]. The electronic spectrum of the $[NiL^5]_2$ complex shows two absorptions at 406 and 530 nm which may be assigned to the ^1E and $^1A_2$ excited states from the $^1A_1$ ground state in a low-spin square-pyramidal environment of the diamagnetic metal ion [28]. The spectrum of $[CuL^5]$ shows a single band at 562 nm, assignable to the transition from the *xz, yz* ground state to the x^2–y^2 excited state in a square-planar environment [28].

3.2. Crystal structure and molecular association

The crystal data and structure refinement details for H_2L^5, $[NiL^5]_2$ and $[CuL^5]$ are given in Table 2. The molecular structure and atomic labelling scheme of the ligand and its nickel and copper complexes are as shown in Figs. 2 and 3, respectively, while their packing diagrams are shown in Figs. 5, 6 and 8.

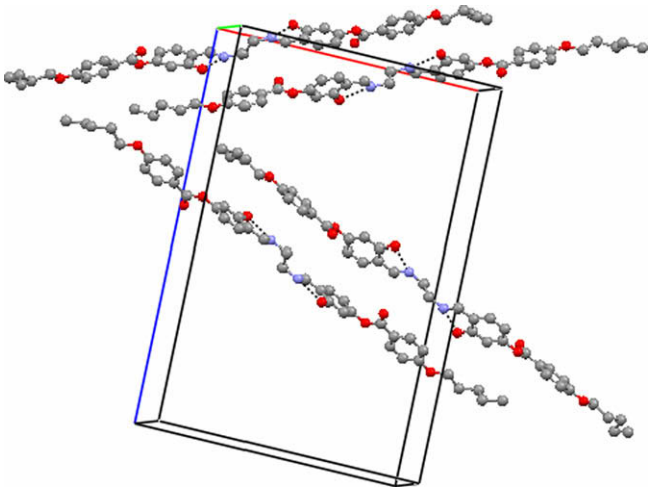

Fig. 5. Packing diagram of H_2L^5 showing intra molecular interactions along the *c* axis.

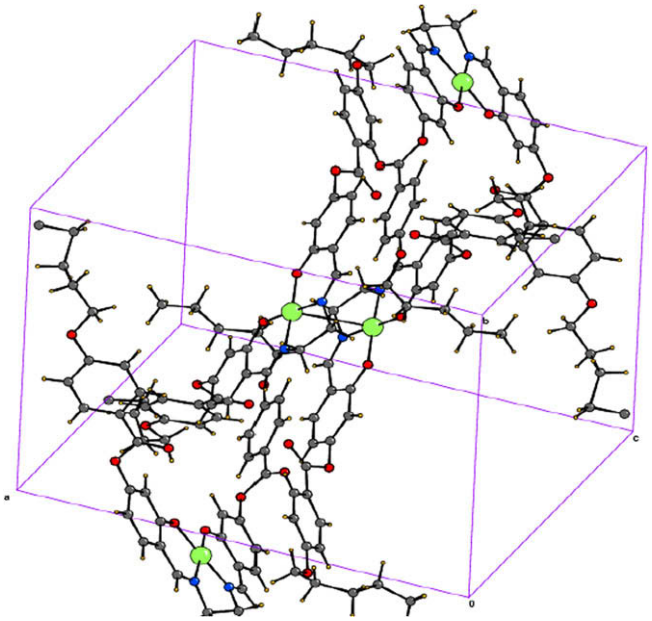

Fig. 6. Packing of molecules in the unit cell of $[NiL^5]_2$.

The Schiff-base crystallizes in the non-centrosymmetric space group $Pna2_1$ with $Z = 4$. The conformation of the ligand (Fig. 2) presents several interesting features: the molecule prefers to be as an extended linear conformation with all *trans* central linkages; the angle between the two six-membered rings adjacent to the central linkage is 0.39° (nearly planar); however, the angle between the adjacent rings in each flank is 52.50° (avg.); the extended arms of the aliphatic chains show large thermal vibrations compared to the central atoms, typical of any such molecule. Table 3 provides the details of the short intramolecular contacts while Fig. 4 represents a section of the intermolecular space, highlighting the C–H···O–H bond regions.

Both the isomorphic nickel and copper complexes $[NiL^5]_2$ and $[CuL^5]$ crystallize in the centrosymmetric space group $P2_1/c$ with

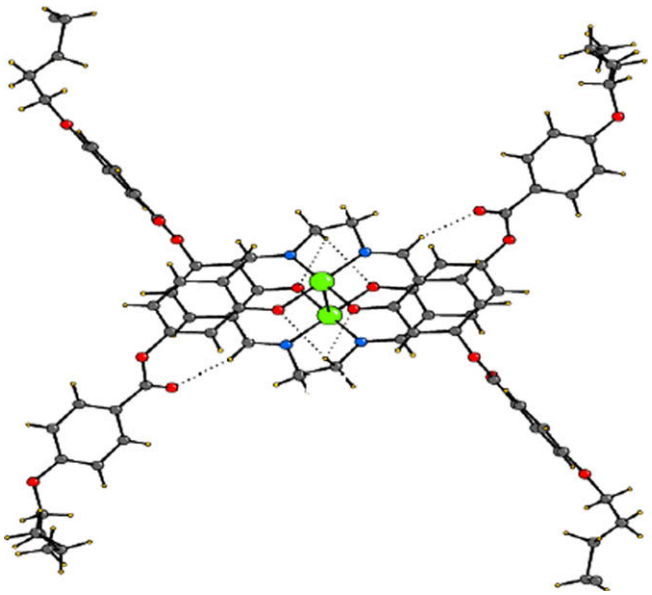

Fig. 7. A view of the $[NiL^5]_2$ molecule in the crystal lattice showing [C–H···O] inter molecular interactions.

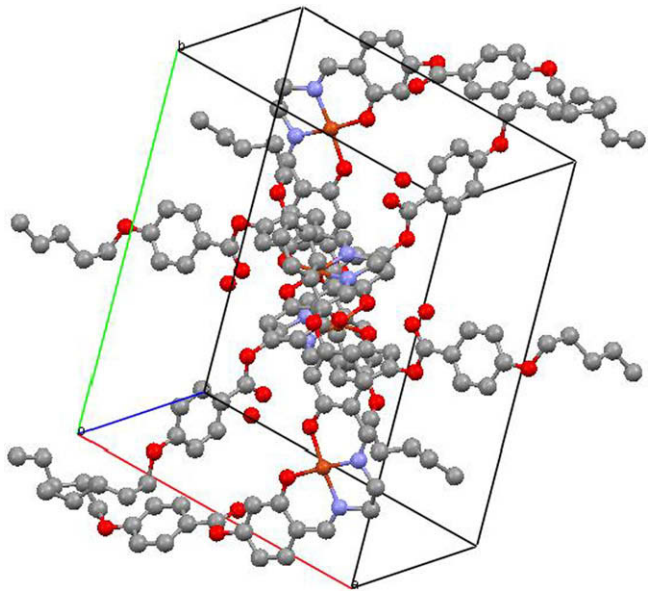

Fig. 8. Packing of molecules in the unit cell of $[CuL^5]$ along the *b* axis.

Table 3

[b] Data as obtained from the first DSC cycle.

$Z = 4$ and the ORTEP diagram is shown in Fig. 3. It appears that the ligand takes up an entirely different conformation, effectively generating a "V" shaped molecular unit. The coordination around Ni^{II} is believed to be a distorted square-pyramidal environment, generating a tricyclic moiety, while that around Cu^{II} is considered to be square-planar with a *cis*-conformation, which may be invoked on the basis of the four adjacent bond angles around the metal ion which are close to 90° (84.40(9), 88.95(8), 93.23(8), 93.73(8)) and the angles between the diagonal atoms of the square plane are close to 180° (175.19(9), 175.17(9)).

Table 4 describes the conformational features of the isomorphous Ni^{II} and Cu^{II} complexes. The angle between the two six-membered rings nearest to Ni is 2.92° while such an angle on the outside flanks is 73.81°. As expected, the thermal ellipsoids are once again large on the terminal chain atoms on either side. It is noteworthy that the conformations of the two flanks are different from each other, with one of the flanks displaying an intramolecular C–H···O interaction (C10–H10···O3). Also, the angle between the adjacent six-membered rings in one flank is 88.04° while in the other it is 56.82°. The angle between the planes containing the C24, O2, Ni1 and N2 atoms and C5, O1, Ni1 and N1 atoms is 2.74°. The Ni atom is penta-coordinated with a Ni–Ni metal bond of 3.336 Å; the distortion of the square base from planarity is quite negligible since the angles between the diagonal atoms of the square base are close to 180° (N2NiO1: 177.83 and N1NiO2: 177.17) in both the planes of the dimeric unit. Fig. 7 shows the packing features of $[NiL^5]_2$ along with the intermolecular interactions.

The mesogenic nature of the ligand (H_2L^5) as well as the $[NiL^5]_2$ and $[CuL^5]$ complexes has been studied by two methods, using polarized optical microscopy and differential scanning calorimetry (DSC); the introduction of the metal ion into the metal-coordination sphere, as expected, resulted in the elevation of the transition temperature, melting and clearing points. The assignment of the mesophase (*nematic*) in each case is on the basis of the optical textures (Fig. 9a–c) and the DSC thermograms (Fig. 10a–c). The details of the transition temperatures, enthalpy changes and the mesophases of H_2L^5, $[NiL^5]$ and $[CuL^5]$ are given in Table 5. However, no such mesogenic property was observed with the complexes of Mn^{II}, Co^{II} and Zn^{II}.

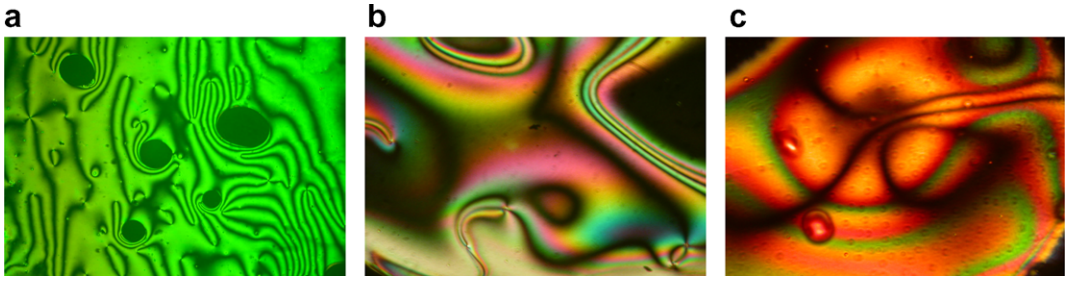

Fig. 9. Optical textures of: (a) H_2L^5 at 210 °C (b) $[NiL^5]_2$ at 252 °C and (c) $[CuL^5]$ at 245 °C.

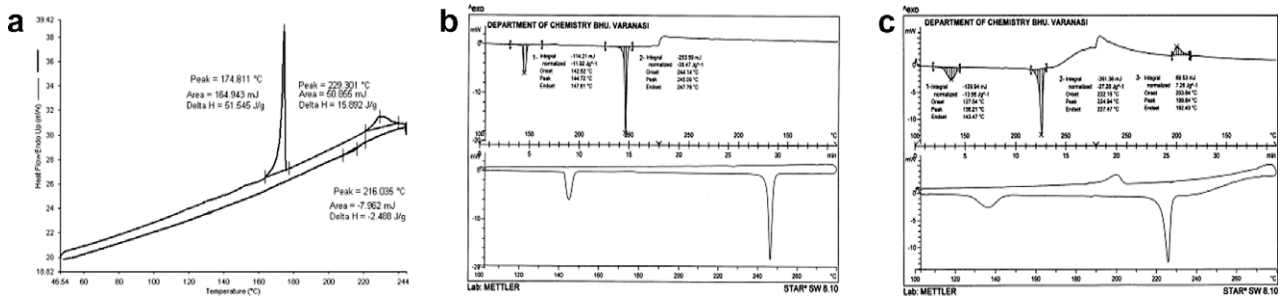

Fig. 10. DSC thermograms of: (**a**) H_2L^5 (**b**) $[NiL^5]_2$ and (**c**) $[CuL^5]$.

4. Conclusion

The mesogenic (*nematic)* Schiff-base *N,N′*-di-(4′-pentyloxybenzoate)salicylidene diaminoethane (H_2L^5) coordinates to Mn^{II}, Co^{II}, Ni^{II}, Cu^{II} and Zn^{II} to yield the isomorphous mesogenic (*nematic*) Ni^{II}, Cu^{II} complexes and the non-mesogenic Mn^{II}, Co^{II}, Zn^{II} complexes. The Schiff-base crystallizes in the non-centrosymmetric space group $Pna2_1$ with $Z = 4$ and the nickel and copper complexes, $[NiL^5]_2$ and $[CuL^5]$, in the centrosymmetric space group $P2_1/c$, with $Z = 4$. The coordination geometry around Ni^{II} is low-spin distorted square-pyramidal (*cis*-NiN_2O_2) while that of the Cu^{II} complex is square-planar with a *cis*-CuN_2O_2 configuration.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2008, volume 27 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2008, volume 27 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2008, volume 27 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2008, volume 27 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2008, volume 27 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

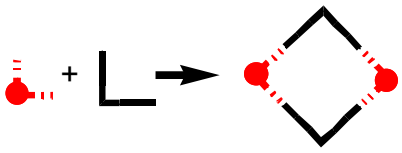
Polyhedron 27 (2008) 1329

^{31}P NMR spectroscopy and discrete metallocycles from non-rigid ligands

Discrete M_2L_2 cyclic containing metal centers are thermodynamically favored over larger species. Depending on the different conformations of the non-rigid ligand, can display varied shapes in solution. ^{31}P NMR spectroscopy has been used in the determination of the isomeric *syn* an *anti* molecular rhombus.

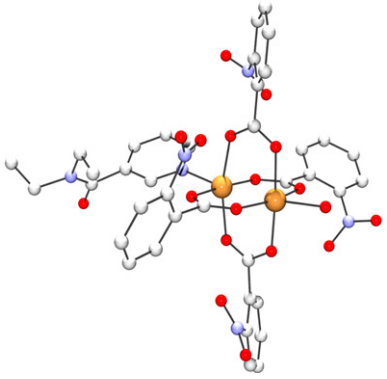


J. Kavalírová, M. Korabik, P. Stachová, J. Moncol, R. Sillanpää, T. Lis, D. Mikloš, M. Melník, J. Mroziński and D. Valigura

Polyhedron 27 (2008) 1333

Synthesis, spectral and magnetic properties of two different 2-nitrobenzoatocopper(II) complexes containing *N*,*N*-diethylnicotinamide

Two structurally different complexes $[Cu_2(2\text{-}NO_2Bz)_4(denia)_1]_n$ (**1**) $[Cu(2\text{-}NO_2Bz)_2(denia)_2(H_2O)_2]$ (**2**) were prepared from the same reaction (where 2-NO_2Bz = 2-nitrobenzoate, denia = *N*,*N*-diethylnicotinamide). In the polymeric chain of (**1**) the denia molecules serve as bridges between the dimeric $Cu_2(2\text{-}NO_2bz)_4$ units and in compound (**2**) the denia molecules serve as monodentate ligands with the pyridine nitrogen donor atom. The spectral and magnetic data of the complexes are analyzed in relation to their structures.

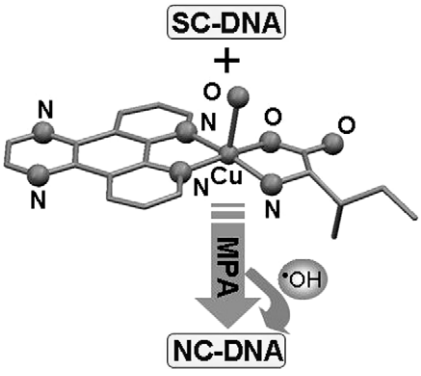


Ramakrishna Rao, Ashis K. Patra and P.R. Chetana

Polyhedron 27 (2008) 1343

Synthesis, structure, DNA binding and oxidative cleavage activity of ternary (L-leucine/isoleucine) copper(II) complexes of heterocyclic bases

The synthesis, characterization, DNA binding and "chemical nuclease" activity of ternary copper(II) complexes, $[Cu(AA)(B)(H_2O)](X)$ containing AA = L-leu/ile and planar phenanthroline bases (B), are described. The complexes are avid DNA binders and show oxidative DNA cleavage activity involving formation of a hydroxyl radical in the presence of a reducing agent.



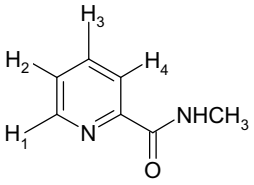
Elsevier Ltd.

L. Fuks, E. Gniazdowska, J. Mieczkowski and N. Sadlej-Sosnowska

Polyhedron 27 (2008) 1353

Structural features of tricarbonyl(*N*-methyl-2-pyridinecarboxyamide)chloro-rhenium(I)-potential precursor of radiopharmaceuticals

Structural characteristics of the novel complex, tricarbonyl(*N*-methyl-2-pyridinecarboxyamide)-chloro-rhenium(I), is presented. Molecular structure of the complex has been established by means of X-ray single crystal diffraction and compared with quantum mechanical calculations.

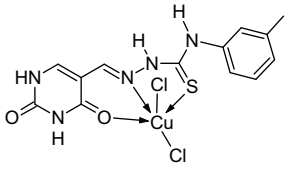


Marisa Belicchi-Ferrari, Franco Bisceglie, Giorgio Pelosi and Pieralberto Tarasconi

Polyhedron 27 (2008) 1361

Heterocyclic substituted thiosemicarbazones and their Cu(II) complexes: Synthesis, characterization and studies of substituent effects on coordination and DNA binding

New 5-formyluracilthiosemicarbazones (H_3ut) derivatives have been synthesised and characterized. In their complexes derived from copper chloride the metal atom is pentacoordinated, while in the nitrate derivatives the copper coordination is 4 + 2. The substituents on the thiosemicarbazidic moiety were varied. Interactions with DNA were studied and the nuclease activity was verified on plasmid DNA.

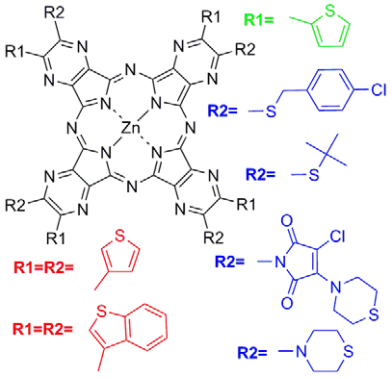


Petr Zimcik, Eva H. Mørkved, Trygve Andreassen, Juraj Lenco and Veronika Novakova

Polyhedron 27 (2008) 1368

Syntheses of octasubstituted zinc azaphthalocyanines with thiophene or thiophene combined with sulfanyl, amino or imido substituents: Influence of the substituents on photochemical and photophysical properties

New octasubstituted complexes of zinc azaphthalocyanines with thiophen-2-yl, thiophen-3-yl or benzo[*b*]thiophen-3-yl peripheral groups were synthesized and characterized. Unsymmetrically substituted ZnAzaPcs were also synthesized by cyclotetramerisations of pyrazine-2,3-dicarbonitriles attached to one thiophen-2-yl group and one alkylsulfanyl, thiomorpholinyl or imide group. Singlet oxygen and fluorescence quantum yields of these complexes were measured and the results were discussed.

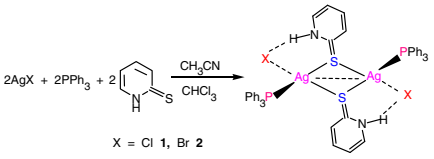


Tarlok S. Lobana, Rohit Sharma and Ray J. Butcher

Polyhedron 27 (2008) 1375

Pyridine-2-thione (pySH) derivatives of silver(I): Synthesis and crystal structures of dinuclear $[Ag_2Cl_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ and $[Ag_2Br_2(\mu\text{-S-pySH})_2(PPh_3)_2]$ complexes

Pyridine-2-thione has yielded dinuclear complexes with silver(I) chloride/bromide in presence of PPh_3 (**1** and **2**).

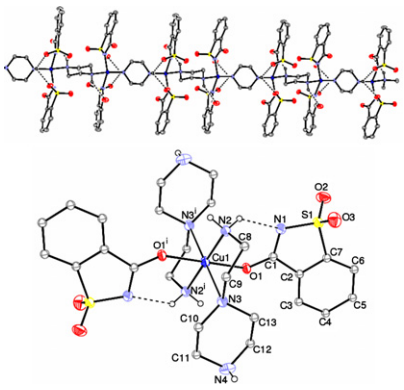


Veysel T. Yilmaz, Serkan Guney and Canan Kazak

Polyhedron 27 (2008) 1381

Copper(II)-saccharinato complexes with piperazine and *N*-(2-aminoethyl)piperazine ligands

Synthesis, characterization, crystal structure and thermal properties of two copper(II)-saccharinato complexes with piperazine (ppz) and *N*-(2-aminoethyl)piperazine, $[Cu(sac)_2(ppz)(H_2O)]_n$ (**1**) and *trans*-$[Cu(sac)_2(aeppz)_2]$ (**2**), have been reported. Complex **1** is a helical chain polymer assembled by bridging ppz ligands, while complex **2** is a centrosymmetric mononuclear compound.

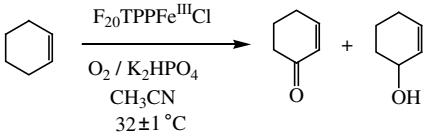


Vivek Bagchi and Debkumar Bandyopadhyay

Polyhedron 27 (2008) 1387

The porphyrin complex catalyzed dioxygen activation in presence of solid inorganic phosphates and small quantities of *t*-BuOOH.

The definitive role of several inorganic phosphates in the oxygenation of cyclohexene has been established where several iron(III) and manganese(III) porphyrins are used as a catalyst. Presence of *t*-BuOOH in the medium enhances the process further.

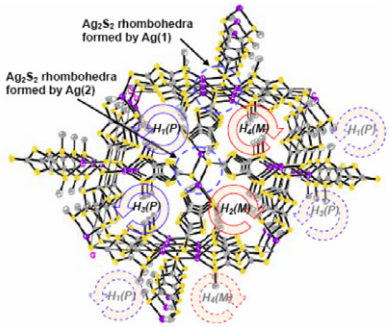


Yi Ding, Qing Chen, Jian-Chu Zhong, Megumu Munakata, Hisashi Konaka, Gui-Ling Ning and Hong-Zhi Wang

Polyhedron 27 (2008) 1393

Three-dimensional metal–organic frameworks: Two Ag(I) coordination polymers of TTF derivatives with axially chiral helical motifs

Two 3D TTF-silver(I) coordination polymeric networks with axially chiral helical motifs were obtained. Complex **1** has novel "8"-shaped channels and twisted double- helical structure. Polymer **2** exhibits an attractive "cds" network with a $6^5.8$ topology, and Ag_2S_2 rhombohedra subunits are formed which connect the ligands head to tail and result in fascinating helical structures.

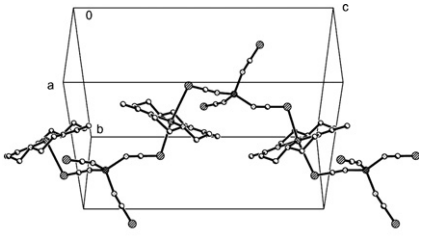


Jerzy Mroziński, Julia Kłak and Rafał Kruszyński

Polyhedron 27 (2008) 1401

Crystal structure and magnetic properties of the 1D bimetallic thiocyanate bridged compound: $\{(CuL_1)[Co(NCS)_4]\}$ (L_1 = *N-rac*- 5,12-Me_2-[14]-4,11-dieneN$_4$)

The synthesis, crystal structure and magnetic properties are reported for the new bimetallic compound $\{(CuL_1)[Co(NCS)_4]\}$ where L_1 = *N-rac*-5,12-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene. The complex forms a one-dimensional zig-zag coordination polymer along the crystallographic *c* axis, with Co(II) and Cu(II) ions connected via thiocyanate bridges. The Co(II) centre in the $[Co(NCS)_4]$ fragment approximates a distorted tetrahedral symmetry. The Cu(II) geometry is a distorted tetragonal bipyramid with the apical position occupied by the bridging thiocyanate ligand and the basal ones by the four nitrogen atoms from the macrocyclic ring. The polymer chain nearest Cu(1)···Co(1) distances are 6.4152(9) and 6.0988(9) Å and the nearest Cu(1)···Co(1) interchain distances are 6.8609(9), 6.9628(9) and 6.0336(10) Å. The magnetization measurements for the examined compound have been carried out over the range 1.8–300 K. This data suggest ferromagnetic interactions through the thiocyanate bridge.



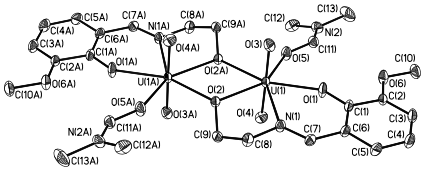
The coordination polymer of the $\{(CuL_1)[Co(NCS)_4]\}$ complex.

Susanta Hazra, Samit Majumder, Michel Fleck and Sasankasekhar Mohanta

Polyhedron 27 (2008) 1408

Synthesis, molecular and supramolecular structure, spectroscopy and electrochemistry of a dialkoxo-bridged diuranyl(VI) compound

The synthesis, molecular and supramolecular structure, spectroscopy and electrochemistry of a dialkoxo-bridged diuranyl (VI) compound $[(UO_2)_2(L)_2(\text{dimethylformamide})_2]$ (**1**) derived from the Schiff base ligand H_2L, obtained by condensation of 3-methoxysalicylaldehyde with 2-aminoethanol, have been described.

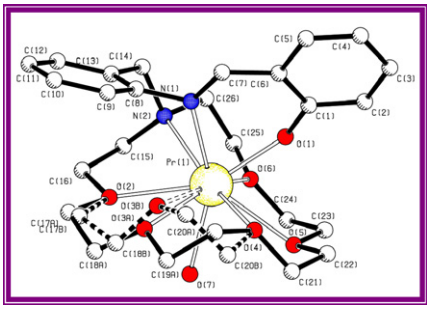


Marina González-Lorenzo, Carlos Platas-Iglesias, Marta Mato-Iglesias, David Esteban-Gómez, Andrés de Blas and Teresa Rodríguez-Blas

Polyhedron 27 (2008) 1415

Conformational study of lanthanide(III) complexes of *N*-(2-salicylaldiminatobenzyl)-1-aza-18-crown-6 by using X-ray and *ab initio* methods

An X-ray and computational (HF) structural study of nine-coordinate lanthanide complexes with an azacrown containing a 2-salicylaldiminato-benzyl pendant is presented.

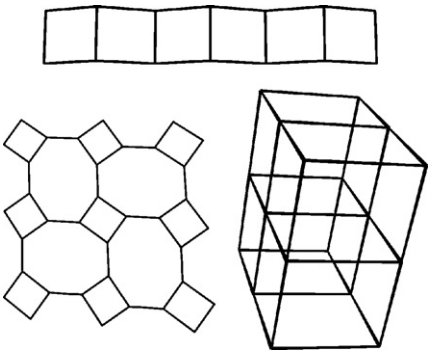


Mohamed A.S. Goher, Beate Sodin, Brigitte Bitschnau, Elmar C. Fuchs and Franz A. Mautner

Polyhedron 27 (2008) 1423

Ladders, rings and cubes as structural motifs in three new zinc(II) azide complexes: Synthesis, spectral and structural characterization

Ladders (1D), rings (2D) and cubes (3D) are the structural motifs of three new zinc(II) azide polymers, $\{[Zn_2(N_3)_4(\text{py-tetrazole})_2](\text{py-tetrazole})\}_n$, $\{[Zn_2(N_3)_4(3\text{-OHpy})] \cdot 2H_2O\}_n$, and $[Zn(N_3)_2(\text{pym})]_n$, with py-tetrazole = tetrazolo-[1,5-*a*]pyridine, 3-OHpy = 3-hydroxypyridine and pym = pyrimidine.

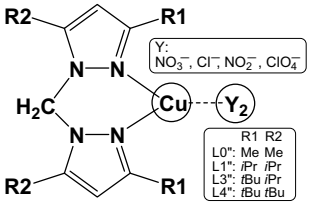


Kiyoshi Fujisawa, Ryosuke Kanda, Yoshitaro Miyashita and Ken-ichi Okamoto

Polyhedron 27 (2008) 1432

Copper(II) complexes with neutral bis(pyrazolyl)methane ligands: The influence of steric hindrance on their structures and properties

New mononuclear copper(II) complexes using the bidentate nitrogen-containing ligands bis(3,5-dimethyl-1-pyrazolyl)methane (L0″), bis(3,5-diisopropyl-1-pyrazolyl)methane (L1″), bis(3-tertiary-butyl-5-isopropyl-1-pyrazolyl)-methane (L3″), and bis(3,5-ditertiary-butyl-1-pyrazolyl)methane (L4″) were synthesized and structurally characterized. Structural and physicochemical studies of these complexes demonstrate the critical differences in the properties depending on the second coordination sphere of the coligands.

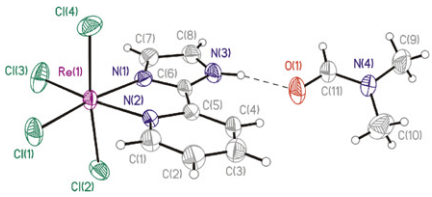


José Martínez-Lillo, Donatella Armentano, Giovanni De Munno and Juan Faus

Polyhedron 27 (2008) 1447

Magneto-structural study on a series of rhenium(IV) complexes containing $biimH_2$, pyim and bipy ligands

By reacting $(NH_4)_2[ReCl_6]$ and the chelating ligands $biimH_2$, pyim and bipy in *N*,*N*-dimethylformamide (DMF), three Re(IV) compounds namely $[ReCl_4(biimH_2)] \cdot 2DMF$ (**1**), $[ReCl_4(pyim)] \cdot DMF$ (**2**) and $[ReCl_4(bipy)]$ (**3**) are obtained, respectively. Magnetic susceptibility measurements show significant antiferromagnetic couplings in **1**–**3**, which are compared and discussed.

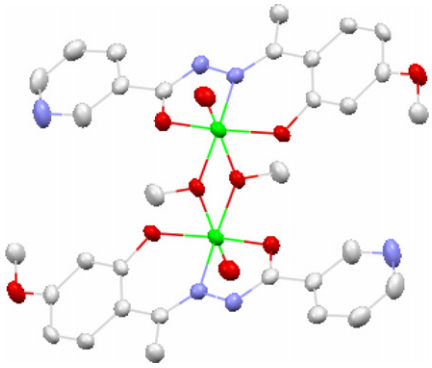


E.B. Seena, Nancy Mathew, Mini Kuriakose and M.R. Prathapachandra Kurup

Polyhedron 27 (2008) 1455

Synthesis, spectral and EPR studies of oxovanadium(IV) complexes incorporating tridentate ONO donor hydrazone ligands: Structural study of one oxovanadium(V) complex

Five oxovanadium(IV) complexes of 2-hydroxy-4-methoxybenzaldehyde nicotinic acid hydrazone (H_2L^1), 2-hydroxy-4-methoxyacetophenone nicotinic acid hydrazone (H_2L^2) and a binuclear oxovanadium(V) complex of H_2L^2 have been synthesized. These complexes are characterized by different physicochemical techniques like electronic, infrared and EPR spectral studies. The complexes $[VOL^1]_2 \cdot H_2O$ (**1**) and $[VOL^2]_2 \cdot H_2O$ (**4**) are binuclear and $[VOL^1bipy]$ (**2**), $[VOL^1phen] \cdot 1.5H_2O$ (**3**) and $[VOL^2phen] \cdot 2H_2O$ (**6**) are heterocyclic base adduct complexes and are EPR active. In frozen DMF at 77 K, all the oxovanadium(IV) complexes show axial anisotropy with two sets of eight line pattern. The complex $[VOL^2 \cdot OCH_3]_2$ (**5**) is an unusual product and having distorted octahedral geometry, as obtained by X-ray diffraction studies.

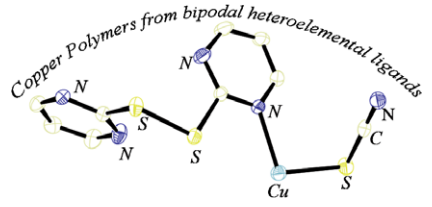


Christian R. Samanamú, Peter M. Lococo, William D. Woodul and Anne F. Richards

Polyhedron 27 (2008) 1463

Copper halide clusters and polymers supported by bipodal heteroelemental ligands

The flexible, multi dentate, heteroelemental, dipodal ligands; bis(2pyridylthio)methane, bis(2pyrimidylthio)methane and bipyrimidyldisulfide, afforded infinite polymeric chains when reacted with copper(II) chloride, copper(I) cyanide and copper(I) thiocyanate. Similar reactions with copper(I) iodide yielded tetranuclear clusters supported by two ligand molecules.

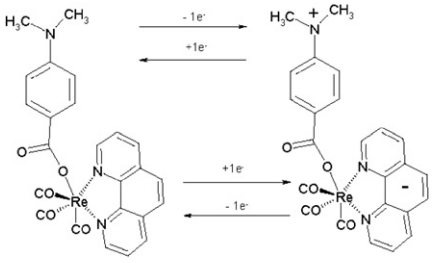


M.P. Juliarena, R.O. Lezna, G.T. Ruiz, M.R. Féliz, G.J. Ferraudi and E. Wolcan

Polyhedron 27 (2008) 1471

On the nature of the redox products of 4-$((CH_3)_2N)C_6H_4$–$CO_2^-$and 4-$((CH_3)_2N)C_6H_4$–CO_2–$Re(CO)_3$(1,10-phenanthroline): A spectroelectrochemical, pulse radiolysis and flash photochemical study

The UV–Vis absorption spectra of $DMAB^+$ and $phen^-$ were obtained by spectroelectrochemistry, flash photolysis and pulse radiolysis experiments on DMAB–CO_2–$Re^I(CO)_3$(phen) and DMAB–COOH.



Boris-Marko Kukovec, Zora Popović, Gordana Pavlović, Marijana Vinković and Dražen Vikić-Topić

Polyhedron 27 (2008) 1479

Synthesis and characterization of some novel cadmium(II) complexes with 3-hydroxypicolinic acid (3-OHpicH): Crystal and molecular structures of $[CdI(3\text{-}OHpic)(3\text{-}OHpicH)(H_2O)]_2$, $[Cd(3\text{-}OHpic)_2(H_2O)_2]$ and $[Cd(3\text{-}OHpic)_2]_n$

Three new cadmium(II) complexes of 3-hydroxypicolinic acid were prepared and characterized by spectroscopic methods (IR, NMR) and their molecular and crystal structures were determined by X-ray crystal structure analysis. Three different coordination modes of 3-hydroxypicolinic acid were established in the solid state, but only monodentate one in the DMF solution.

Spectral properties of Eu(III) compound with antibacterial agent ciprofloxacin (cfqH). Crystal structure of $[Eu(cfqH)(cfq)(H_2O)_4]\text{-}Cl_2 \cdot 4.55H_2O$

A novel europium(III) complex of antibacterial agent ciprofloxacin (cfqH) with formula $[Eu(cfqH)(cfq)(H_2O)_4]Cl_2 \cdot 4.55H_2O$ was synthesized and its crystal structure was determined by X-ray crystallography. The spectral properties (IR, Raman, luminescence, NMR) of the isolated compound were studied and analysis of the Stark structure of the luminescence spectra was carried out.

Polyhedron 27 (2008) 1497

A DFT study on the interactions between the $[Pt(H_2O)(terpy)]^{2+}$ cation and the triflate and perchlorate counter-anions

The results of DFT calculations on the $[Pt(OH_2\cdots X)(terpy)]^{+}$ and $[Pt(OH_2\cdots S)(terpy)]^{2+}$ {terpy = 2,2′:6′,2″-terpyridine; X = ClO_4, SO_3CF_3; S = CH_3NO_2} models are reported. The computational results likely fit the previously reported X-ray and NMR data on the $[Pt(H_2O)(terpy)]X_2$ {X = ClO_4, SO_3CF_3} species and allowed to estimate the energy difference between the $[(terpy)Pt\text{–}OH_2\cdots OSO_2CF_3]^{+}$ and the $[(terpy)Pt\text{–}OH_2\cdots OClO_3]^{+}$ hydrogen-bond adducts. Finally, it was highlighted that also nitromethane is able to strongly interact with the aqua ligand of the $[Pt(H_2O)(terpy)]^{2+}$ cation.

Polyhedron 27 (2008) 1511

Competition between the albumin and three histidine fragment of amyloid precursor protein sites to bind Cu(II)

The present paper reports the results of combined potentiometric and spectroscopic studies on the copper(II) complexes of two octadecapeptides (DAHQERMDVSETHLHWHT and Ac-DAHQERMDVSETHLHWHT-NH_2) having two distinct metal-binding-domains, the albumin-like N-terminal (DAH) and APP cysteine-rich three His. The -HXHYH- motif is very effective in binding metal ion although it is unable to compete with albumin-like coordination mode in unprotected peptide.

Polyhedron 27 (2008) 1517

An investigation of the positional isomeric effect of terpyridine derivatives: Self-assembly of novel cadmium coordination architectures driven by N-donor covalence and π···π noncovalent interactions

The reaction of two pyridyl substituted terpyridine isomers L1 and L2 with Cd^{II} atoms resulted in different dimensional architectures. L1 as a mono-tridentate bridging ligand links Cd_3 and Cd_4 clusters into 1D grid-like and 2D wave-like polymers, respectively. However, L2 as a chelating ligand forms binuclear structures.

Polyhedron 27 (2008) 1527

Synthesis and X-ray crystal structures of metal complexes of three isomeric bibenzodiazines: Discrete and polymeric assemblies

Thirteen complexes of three isomericbi benzodiazines were prepared and X-ray crystal structures were determined for seven of these. It is shown that 2,2′-biquinazoline prefers to form mononuclear complexes with chelation involving the less hindered nitrogen donors. 2,2′-Biquinoxaline is shown to offer two modes of coordination; in the first, it acts as a "stepped-linear" bridging ligand using the two less hindered nitrogens, while in the second mode it chelates to copper(I) centres using its more hindered nitrogens. The presence of the fused benzo rings leads to a higher propensity for π–π stacking of the heterocyclic ligands within such complexes.

Syntheses and crystal structures of copper mixed-ligand complexes of multidentate enaminones and acetate anions

Reactions of ferrocenoylacetone with 2-(aminomethyl)pyridine and *N*-(2-hydroxyethyl)-1,2-diaminoethane afford the multidentate enaminones H**L**^{1} and H_3**L**^{2}, respectively. Reactions of copper acetate with the two enaminones generate the corresponding mixed-ligand complexes **I** and **II**, which are formulated as [Cu**L**^{1}(OAc)] and [Cu(H_2**L**^{2})(OAc)], respectively. The structures of H**L**^{1}, **I** and **II** have been determined by single-crystal X-ray crystallography. In complex **I**, H**L**^{1} acts as a monoanionic tridentate donor via the carbonyl oxygen, deprotonated enamine nitrogen and pyridyl nitrogen atoms, the acetate anion is monodentate and the coordination geometry of the central metal is square planar. In complex **II**, H_3**L**^{2} is a monoanionic tetradentate ligand via the carbonyl oxygen, deprotonated enamine nitrogen, secondary amine nitrogen and hydroxy oxygen atoms, the acetate anion is monodentate and the coordination geometry of the central metal is a distorted trigonal bipyramid.

Bridged bis(amidinate) lanthanide complexes: Synthesis, molecular structure and reactivity

Four novel lanthanide complexes bearing bridged bisamidinate ligand $Me_3SiNC(Ph)N(CH_2)_3NC(Ph)NSiMe_3$, L were synthesized in high yields and fully characterized. Treatment of $LLnCl(sol)_x$ (Ln = Yb, sol = THF, x = 2 **1**; Ln = Y, sol = DME, x = 1 **2**) with the dilithium salt $Li_2L(THF)_{0.5}$ afforded lanthanide complexes supported by three ligands, $Ln_2(\mu_2\text{-}L)_3 \cdot DME$ (Ln = Yb **3**, Y **4**). Reaction of $LnCl_3$ (Ln = Yb, Y) with 2 equiv. of $Li_2L(THF)_{0.5}$ gave the anionic complexes $[Li(DME)_3][L_2Ln]$ (Ln = Yb **5**, Y **6**). The complexes **3** and **4** can also be synthesized by the reaction of $LnCl_3$ with 1.5 equiv. of $Li_2L(THF)_{0.5}$ or the reaction of **1** and **2** with the anionic complexes **5** and **6**. Complexes **3**, **4**, **5** and **6** were found to be high active catalysts for the ring-opening polymerization of ε-caprolactone (CL).

The oxidation of carbohydrazide by the 12-tungstocobaltate(III) ion in acidic medium: Kinetics and mechanism

The redox reaction between the 12-tungstocobaltate(III) ion and carbohydrazide is first order with respect to both the oxidant and the substrate. The observed pseudo first-order rate constant, k_{obs}, is retarded by increasing the concentrations of H^+ and alkali metal ion (Li^+, Na^+ and K^+). There is a linear correlation between the k_{obs} and the concentrations of carbohydrazide and H^+ ion, but the plots of k_{obs} against the concentrations of the alkali metal ions is non-linear. However, the same data is applicable to the Davies equation for the effect of the ionic strength on the k_{obs}. Complex formation between the 12-tungstocobaltate(III) ion and carbohydrazide is indicated by optical density measurements, which increased with increasing H^+ concentration in the reaction mixture. This indicated that $^+H_3NNHCONHNH_2$ probably formed a complex with the 12-tungstocobaltate(III) ion. A suitable mechanism involving deprotonation of the complex and subsequent decomposition of the deprotonated complex as the rate limiting step is suggested.

Polyhedron 27 (2008) 1995

Monodentate *S-vs*. bidentate 1,5-*O*,*S*-coordination of *N*-phosphoryl-*N*′-(R)-thioureas with Pd(II)

We reported three new complexes of the Pd(II) cation with *N*-phosphorylated thioureas RNHC(S)NHP(O)(O*i*Pr)$_2$ (R = *t*Bu, **HL^{I}**; R = Ph, **HL^{II}**; R = 4′-benzo-15-crown-5, **HL^{II}**). Reaction of *N*-phosphorylated thioureas of common formula RC(S)NHP(O)(O*i*Pr)$_2$ (R = Et$_2$N, **HL^{IV}**; R = morpholine-*N*-yl, **HL^{V}**) in the same conditions leads to complexes Pd(**L^{IV}**-*O*,*S*)$_2$ (**4**) and Pd(**L^{V}**-*O*,*S*)$_2$ (**5**), where the palladium(II) atoms are coordinated in a square-planar fashion by the C=S sulfur atoms and the P=O oxygen atoms of two anionic ligands. Structures of the obtained compounds were investigated by IR, ^{1}H and ^{31}P{^{1}H} NMR spectroscopy and elemental analysis. The crystal structure of complex *trans*-Pd(HL^{I}-*S*)$_2$Cl$_2$ has been investigated by X-ray crystallography. It was established that the thiourea ligands are in a *trans*-configuration and the palladium(II) cation is coordinated by the sulfur atoms of the C=S groups and the chlorine atoms. Complex *trans*-Pd(HL^{I}-*S*)$_2$Cl$_2$ is the first example of palladium(II) complex in which the potentially chelating *N*-phosphorylated thiourea ligand is bound through the sulfur atom only.

Synthesis, characterization, electrochemical and photophysical properties of bimetallic complexes of rhenium(I) and osmium(II)

Monometallic and bimetallic diimine complexes of rhenium(I) and osmium(II), $[(CO)_3(bpy)Re(4,4'\text{-}bpy)](PF_6)$ **I**, $[(CO)_3(bpy)Re(4,4'\text{-}bpy)Re(bpy)(CO)_3](PF_6)_2$ **II**, $[Cl(bpy)_2Os(4,4'\text{-}bpy)](PF_6)$ **III** and $[Cl(bpy)_2Os(4,4'\text{-}bpy)Os(bpy)_2Cl](PF_6)_2$ **IV**, and a new heterobimetallic complex of rhenium(I) and osmium(II) $[(CO)_3(bpy)Re(4,4'\text{-}bpy)Os(bpy)Cl](PF_6)_2$ **V** (bpy = 2,2′-bipyridine; 4,4′-bpy = 4,4′-bipyridine) have been synthesized and characterized by various spectral techniques. The photophysical properties of all the complexes have been studied and a comparison is made between the heterobimetallic and corresponding monometallic and homobimetallic complexes. Emission and transient absorption spectral studies reveal that an excited state energy transfer from the rhenium(I) chromophore (*Re) to osmium(II) takes place. The energy transfer rate constant is found to be $8.7 \times 10^7\ s^{-1}$.

Kinetics and mechanism of the Os(VIII)-catalysed oxidation of hypophosphite and phenylphosphinite ion by alkaline hexacyanoferrate(III) ion

The OsO_4-catalysed oxidation of $RHPO_2^-$ by alkaline $Fe(CN)_6^{3-}$ is zero order in $Fe(CN)_6^{3-}$, first order in OsO_4 and Michaelis-Menten kinetics is observed with respect to $RHPO_2^-$. Consistent with this the suggested mechanism is:

Polyhedron 27 (2008) 3433

Synthesis, spectroscopic characterization and thermal behavior of cadmium(II) complexes of *S*-methyldithiocarbazate (SMDTC) and *S*-benzyldithiocarbazate (SBDTC): X-ray crystal structure of $[Cd(SMDTC)_3] \cdot 2NO_3$

The reaction of *S*-methyl dithiocarbazate (SMDTC) and *S*-benzyl dithiocarbazate (SBDTC) with $Cd(NO_3)_2 . 4H_2O$ gave monomeric 1:2 complexes $[Cd(SMDTC)_3](NO_3)_2$ and $[Cd(SBDTC)_2](NO_3)_2$ respectively in which the ligands, in its neutral thione form, adopt bidentate chelating bonding mode to the metal center. The coordination geometry around cadmium(II) in $[Cd(SMDTC)_3](NO_3)_2$ is distorted octahedral, as obtained by X-ray diffraction study whereas $[Cd(SBDTC)_2](NO_3)_2$ is expected to be tetrahedral.

Polyhedron 27 (2008) 3451

Synthesis and X-ray structural studies of *N*′-(pyridine-3-carbonyl) hydrazinecarbodithioic acid ethyl ester (H_2pchc) and [Mn(Hpchc)$_2$(*o*-phen)]

Complex [Mn(Hpchc)$_2$(*o*-phen)] formed with N′-(pyridine-3-carbonyl)-hydrazine-carbodithioic acid ethyl ester (H_2pchc) has MnN_4O_2 coordination and the ligand behaves as uninegative bidenate donor and forms a five membered chelate ring. In complex, the ortho C–H bond from *o*-phen ring forms an unusual C–H$\cdots\pi$ intramolecular interaction with $MnOCN_2$ chelate ring which gives structural support for metalloaromaticity in the complex.

Synthesis of Mn_3O_4 nanoparticles by thermal decomposition of a [bis(salicylidiminato)manganese(II)] complex

The present investigation reports on the novel synthesis of Mn_3O_4 nanoparticles using thermal decomposition and their physicochemical characterization. The Mn_3O_4 nanoparticle powder has been prepared using [bis(salicylidiminato)manganese(II)] as a precursor. The effect of oleyl amine and triphenylphosphine on the particle morphology has been investigated. Transmission electron microscopy (TEM) analysis demonstrated Mn_3O_4 nanoparticles with an average diameter of about 25 nm.

Polyhedron 27 (2008) 3509

Synthesis and crystal structures of Cd(II) complexes with di-pyridyl hexa-azamacrocyclic ligands having cyano pendant-arms

The coordination capability of two pendant-armed azamacrocyclic ligands with cyanoethyl L^1 and cyanomethyl L^2 pendant groups towards cadmium nitrate and perchlorate salts was achieved. All metal complexes were characterized by elemental analysis, LSI-MS, IR, conductivity measurements and ^1H NMR spectroscopy. The X-ray crystal structure of the complexes $[CdL^1](NO_3)_2$, $[CdL^1](ClO_4)_2 \cdot CH_3CN$, and $[CdL^2](ClO_4)_2 \cdot H_2O$ were also determined. All the complexes are mononuclear with the metal ion in a distorted octahedral environment. The pendant groups are not coordinated to the metal due the linear nature of the cyano groups; however, different interactions between nitrate ions, nitrile groups and pyridine rings from the macrocycle have been observed in the Cd(II) complexes with L^1.

Polyhedron 27 (2008) 3061

Spectral and electrochemical studies of ruthenium(II) complexes with N^4-methyl-4-nitrobenzaldehyde and N^4-methyl-4-nitrobenzophenone thiosemicarbazone: Potential anti-trypanosomal agents

N^4-Methyl-4-nitrobenzaldehyde thiosemicarbazone ($H4NO_2Fo4M$), N^4-methyl-4-nitrobenzophenone thiosemicarbazone ($H4NO_2Bz4M$) and their ruthenium(II) complexes $[Ru(4NO_2Fo4M)_2(PPh_3)_2]$ (**1**), $[Ru(4NO_2Bz4M)_2(PPh_3)_2]$ (**2**), $[Ru(4NO_2Fo4M)_2(dppb)]$ (**3**) and $[Ru(4NO_2Bz4M)_2(dppb)]$ (**4**) were obtained. The nitro anion radical, one of the proposed intermediates in the mechanism of action of nitro-containing anti-trypanosomal drugs, is formed at approximately −1.00 V in the free thiosemicarbazones as well as in their corresponding ruthenium(II) complexes, suggesting their potential to act as antitrypanosomal drugs. The natural fluorescence of $H4NO_2Fo4M$, $H4NO_2Bz4M$ and complexes (**1**)–(**4**) provides a way to identify and to monitor their concentration in biological systems.

Polyhedron 27 (2008) 1860

Spectroelectrochemistry and investigation of charge transport mechanisms of iron poly(pyridyl) redox polymers

In this work, we describe the characterization of the complex $[Fe(tpy\text{-}NH_2)_2](PF_6)_2$ (tpy-NH_2 = bis[4′-(3-aminophenyl)-2,2′:6′,2″-terpyridine] and report the electropolymerization and charge transport parameters. The results showed that poly-$[[Fe(tpy\text{-}NH_2)_2]^{2+}]_n$ can exhibit three regimes of charge transport as a function of film thickness and polymerization time. Morphological characterization was provided by atomic force microscopy.

Polyhedron 27 (2008) 1867

Synthesis, electrochemical, catalytic and antimicrobial activities of novel unsymmetrical macrocyclic dicompartmental binuclear nickel(II) complexes

A series of novel unsymmetrical dicompartmental binuclear nickel(II) complexes have been prepared by simple Schiff base condensation of the compound 1,8-[bis(3-formyl-2-hydroxy-5-methyl)benzyl]-l,4,8,11-tetraazacyclotetradecane (PC-1) with appropriate aliphatic or aromatic diamine, nickel(II) perchlorate and triethylamine. The effect of chain length on spectral, magnetic, electrochemical and catalytic studies was carried out.

Polyhedron 27 (2008) 1875

Three new polynuclear tetracarboxylato-bridged copper(II) complexes: Syntheses, X-ray structure and magnetic properties

The synthesis, crystal structure and magnetic properties of a novel 1D complex $\{[Cu_4(phen)_2(\mu\text{-}O_2CC_2H_5)_8] \cdot (H_2O)\}_n$ (**1**) and two dinuclear paddle-wheel complexes $[Cu_2(\mu\text{-}O_2CC_6H_4OH)_4(C_7H_7NO)_2] \cdot 6H_2O$ (**2**) and $[Cu_2(\mu\text{-}O_2CCH_3)_4(C_7H_7NO)_2]$ (**3**) are reported. The magnetic interaction between Cu(II) ions inthe two classical paddle-wheel compounds are strongly antiferromagnetically coupled with $J = -278.5$ and $-287.0\ cm^{-1}$ for **2** and **3**, respectively. In compound **1** the magnetic susceptibility could be fitted with two different, independent Cu(II) units, one strongly coupled with a J value of $-299.5\ cm^{-1}$ and one weakly coupled with a J value of $-0.75\ cm^{-1}$. The magneto-structural correlations for complexes **1**, **2**, and **3** are discussed on the basis of the structural parameters and magnetic data.

Polyhedron 27 (2008) 1883

Synthesis, characterization, and electrochemical, and electrical measurements of novel 4,4′-isopropylidendioxydiphenyl bridged bis and cofacial bis-metallophthalocyanines (Zn, Co)

The new cofacial bis-phthalocyanines Zn(II) (**7**) and Co(II) (**8**) were synthesized. The electrochemical properties of the complexes were examined by cyclic voltammetry, differential pulse voltammetry and controlled potential coulometry in nonaqueous media. Measurements of capacitance showed a well defined decrease with increasing frequency and an increase with increasing temperature at lower frequencies.

Polyhedron 27 (2008) 1898

Synthesis, structure and nuclease activity of copper complexes of disubstituted 2,2′-bipyridine ligands bearing ammonium groups

A series of Cu(II) complexes of disubstituted 2,2′-bipyridine bearing ammonium groups at 5,5′- and 4,4′-positions were synthesized. All complexes, especially the two with 5,5′-ammonium groups, exhibit strong DNA cleavage abilities. The high nuclease activity may be attributed to the strong interaction of the metal moiety and two ammonium groups with three adjacent phosphate groups of DNA.

Polyhedron 27 (2008) 1917

New Ru(II)–dmso complexes with heterocyclic hydrazone ligands towards cancer chemotherapy

A series of new Cl–Ru(II)–dmso complexes containing heterocyclic hydrazone ligands have been synthesized and characterized. The hydrazone ligands behave as neutral bidentate ligands. The redox properties of the complexes were studied by cyclic voltammetry. The substituents present in the hydrazone ligands affect the redox behavior. The antibacterial activity of the ligands and the complexes were studied in terms of minimum inhibitory concentration (MIC). The complexes were found to bind Herring sperm ds DNA in mixed modes.

Polyhedron 27 (2008) 1925

Synthesis and characterization of nickel(II) and copper(II) complexes of hexaaza macrocycle, 4-methyl-1,3,5,8,11,14-hexaazatricyclooctadecane

Square-planar Ni(II) and Cu(II) complexes of macrotricyclic ligand 4-methyl-1,3,6, 8,11,14-hexaazatricyclooctadecane (PCHA) have been synthesized from the template condensation reactions of formaldehyde with triethylenetetraamine and 1,2-propanediamine in the presence of metal ion. The complexes have been characterized by spectroscopic, electrochemical and molar conductivity measurements. The crystal structure of $[Ni(PCHA)](ClO_4)_2$ determined by X-ray crystallography confirms a square-planar geometry around the metal centre.

Polyhedron 27 (2008) 1937

Ligational aspects of the hydrazide-based Schiff-base, *N*-(4″-pyridylcarboxamido)-4-(4′-hexyloxybenzoato)salicylaldimine towards some 3d metal ions and crystal structures of the Schiff-base and Zn(II) complex

A novel hydrazide-based mesogenic (nematic) Schiff-base, *N*-(4″-pyridylcarboxamido)-4-(4′-hexyloxyben-zoato)salicylaldimine, Hpychbsal (abbreviated as H_2L) was prepared and its structure studied by elemental analyses, mass, NMR and IR spectra and single crystal XRD (triclinic space group $P\bar{1}$ with $Z = 4$) techniques. The Schiff-base behaves as a uninegative bi/tridentate species in its non-mesogenic complexes of the general formula, $[M(HL)_2]$ [M = Mn, Co, Ni, Cu and Zn] and as a dinegative tridentate species with Zn(II) in the distorted square-pyramidal complex, [ZnL · 2py], for which the crystal structure was solved (triclinic space group $P\bar{1}$ with $Z = 2$). The IR and NMR spectral data imply bonding of HL^- and L^{2-} species through phenolate oxygen and/or amidic oxygen and azomethine nitrogen atoms.

Polyhedron 27 (2008) 3287

Evidence of change in the molecular organization of 1-*n*-butyl-3-methylimidazolium tetrafluoroborate ionic liquid solutions with the addition of water

Specific conductivity of the IL solutions increases in the water-rich region and decreases in the salt-rich region, exhibiting a maximum at IL mole fraction ca. 0.9. Increasing specific conductivity has been attributed to the weakness of the intermolecular interaction of the [BMIm][BF4] structure provoked by adding water, increasing the dissociation and, consequently, increasing the ionic mobility of the ionic species. The decrease in the intermolecular interaction between the anionic and cationic species of [BMIm][BF4] due to the addition of water has been shown by IR.

Polyhedron 27 (2008) 3325

Synthesis, characterization and biological studies of *S*-benzyl-β-*N*-(benzoyl) dithiocarbazate and its metal complexes

S-Benzyl-β-*N*-(benzoyl) dithiocarbazate (SBNBODTC) a new disubstituted dithio-carbazate oxygen–sulfur (OS) donor ligand derived from reaction of *S*-benzyl dithiocarbazate with benzoyl chloride, formed bis-chelated complexes of general formula $[M(OS)_2]$ where M is Cu^{2+}, Ni^{2+}, Cd^{2+}, Co^{2+} or Pb^{2+} and OS is a uninegative bidentate ligand. The ligand and its metal complexes have been characterized by a variety of physico-chemical techniques. *S*-benzyl-β-*N*-(benzoyl) dithiocarbazate crystallized with $Z' = 2$ in its thione form in *cis*–*cis* conformation, with the N–N bond adopting a *cis* geometry with respect to C=S, while the *S*-benzyl group adopts a *cis* geometry with respect to the thione sulfur atom across the C–S bond. SBNBODTC, $Cu(OS)_2$, $Ni(OS)_2$ and $Pb(OS)_2$ display marked cytotoxicity against HL-60 (human myeloid leukemia) while $Cd(OS)_2$ and $Co(OS)_2$ are moderately cytotoxic. The compounds showed moderate but selective activity towards targeted pathogens.

Mun-Hoe Eddy Chan, Karen A. Crouse, M. Ibrahim M. Tahir, Rozita Rosli, Nasir Umar-Tsafe and Andrew R. Cowley

Polyhedron 27 (2008) 1141

Synthesis and characterization of cobalt(II), nickel(II), copper(II), zinc(II) and cadmium(II) complexes of benzyl *N*-[1-(thiophen-2-yl)ethylidene] hydrazine carbodithioate and benzyl *N*-[1-(thiophen-3-yl)ethylidene] hydrazine carbodithioate and the X-ray crystal structure of bis{benzyl *N*-[1-(thiophen-2-yl)ethylidene] hydrazine carbodithioate}nickel(II)

Cobalt (II), nickel (II), copper (II), zinc (II) and cadmium (II) complexes of general formula ML_2 were prepared using bidentate Schiff bases (SB2ATP and SB3ATP) synthesized by reaction of S-benzyldithiocarbazate with 2-acetylthiophene and 3-acetylthiophene. Single crystal X-ray crystal structure analysis of $Ni(SB2ATP)_2$ showed it to be a distorted square planar complex. SB2ATP and $Cd(SB3ATP)_2$ showed significant bioactivity towards human myeloid leukemia (HL-60) while SB2ATP, SB3ATP, $Co(SB2ATP)_2$, $Cu(SB2ATP)_2$, $Cu(SB3ATP)_2$, $Zn(SB2ATP)_2$ and $Cd(SB2ATP)_2$ showed significant chemotherapeutic activity against human breast carcinoma with positive estrogen receptor (MCF-7). With the exception of $Cu(SB3ATP)_2$, the Schiff bases displayed higher cytotoxic activity than their metal complexes. None of the compounds were active against human cervical cancer (HeLa) or human breast carcinoma with negative estrogen receptors (MDA-MB-231). $Cu(SB2ATP)_2$ showed strong activity towards *Candida lypolytica*.

Polyhedron 27 (2008) 1150

Synthesis and biological activity of triorganogermanium substituted heteropolytungstates

Four new compounds, $[Me_4N]_4H_5[(RGe)_3(XW_9O_{34-n})_2]$ (R = $HOOCCH_2CH_2$, $HOOCCH_2(m\text{-}NO_2C_6H_4)CH$, X = P, $n = 0$; X = Sb, $n = 1$) have been prepared from trichlorogermanium precursors and lacunary polyoxometallates ($[PW_9O_{34}]^{9-}$ and $[SbW_9O_{33}]^{9-}$). The products were characterized by means of elemental analysis, IR spectroscopy, ^1H NMR and ^{183}W NMR spectroscopy. ^{183}W NMR spectra of the complexes support the stoichiometry of the new heteropolyanions and the probable retention of the XW_9 units in water. The organogermanium substituted complexes showed promising activity against two human tumor cell lines (leucocythemia Hela cells and S180 cells) in vitro and $[Me_4N]_4H_5[(HOOCCH_2CH_2Ge)_3(SbW_9O_{33})_2]$ exhibited some certain antitumoral activity in vivo and can increase the immune ability of the spleen.

Polyhedron 27 (2008) 1155

Synthesis and EPR studies of porphyrazines with bulky substituents

Magnesium porphyrazinate substituted with eight 4-tert-butylphenylthio-groups on the peripheral positions has been synthesized by cyclotetramerization of 1,2-bis(4-tert-butylphenylthio) maleonitrile. The novel metal porphyrazinates MPz (M=Cu(II), Zn(II), Co(II)) have been characterized by elemental analysis, together with FT- IR, ^1H NMR, UV–Vis spectral data. The EPR spectra of Cu(II) doped porphyrazine sample as powder and solution forms were measured at room temperature.

Polyhedron 27 (2008) 1161

Synthesis and study of the structure of new 3d-metal coordination compounds with substituted 2-amino-4(5H)-ketothiophens

A series of 3d-metal complexes based on 2-amino-4(5H)-ketothiophens (HL^1) and (HL^2) were prepared and studied by spectroscopic and X-ray methods (for $[CuL^1{}_2] \cdot H_2O$). The coordination polyhedron of the copper atom is formed by four nitrogen atoms from two ligand anions and the geometry of the coordination sphere is intermediate between tetrahedral and square planar (Fig. 1).

Polyhedron 27 (2008) 1201

Self-assembled [2 × 1 + 1 × 2] heterotetranuclear $Cu^{II}_3Mn^{II}$/$Cu^{II}_3Co^{II}$ and [2 × 2 + 1 × 3] heptanuclear Cu^{II}_7 compounds derived from *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine): Structures and magnetic properties

Syntheses, characterization, and magnetic properties of one mononuclear inclusion product $[Cu^{II}L^1 \subset (H_2O)]$, one interesting heptanuclear copper(II) compound $[\{Cu^{II}L^1Cu^{II}(H_2O)_3\}_2\{Cu^{II}L^1\}_3](ClO_4)_4 \cdot 2CH_3COCH_3$, and two heterotetranuclear $Cu^{II}_3M^{II}$ compounds $[\{Cu^{II}L^1M^{II}(H_2O)_3\}\{Cu^{II}L^1\}_2](ClO_4)_2 \cdot H_2O \cdot CH_3COCH_3$ (M = Co or Mn) derived from the hexadentate Schiff base compartmental ligand *N*,*N*′-*o*-phenylenebis(3-ethoxysalicylaldimine) (H_2L^1) have been described. Two monophenoxo-bridged dinuclear $[Cu^{II}L^1Cu^{II}(H_2O)_3]^{2+}$ cationic units are self-assembled and cocrystallized with three mononuclear $[Cu^{II}L^1]$ complex units in the Cu^{II}_7 compound, while the tetrametallic complexes consist of cocrystals of one diphenoxo-bridged heterodinuclear $[Cu^{II}L^1M^{II}(H_2O)_3]^{2+}$ cationic unit and two mononuclear $[Cu^{II}L^1]$ moieties. Formation of the mononuclear inclusion product and the dinuclear–mononuclear cocrystals are related to the tendency of a water molecule to be encapsulated in the O_4 compartment of the $[Cu^{II}L^1]$ moiety.

Complexes with carbonate as a tridentate ligand: Synthesis and characterization of sandwich-type polyoxometallates $[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(MOH_2)_3(CO_3)]^{11-}$ (M = $Y^{(III)}$, $Yb^{(III)}$ and $Sm^{(III)}$)

Three new sandwich-type polyoxometallates $[(A\text{-}\alpha\text{-}AsW_9O_{34})_2(MOH_2)_3(CO_3)]^{11-}$ M = $Y^{(III)}$ **1**, $Yb^{(III)}$ **2** and $Sm^{(III)}$ **3** have been synthesized by the reaction of the trilacunary $[A\text{-}\alpha\text{-}AsW_9O_{34}]^{9-}$ ligand with $M^{(III)}$ in a carbonate solution, and characterized by elemental analysis, IR, ^{13}C NMR, UV–Vis spectroscopy, TGA, DSC and single crystal structure analysis. The crystal structure of the complexes consist of two lacunary $A\text{-}\alpha\text{-}[AsW_9O_{34}]^{9-}$ Keggin moieties which are linked by a M_3CO_3 belt into an assembly of virtual C_{3v} symmetry. The CO_3^{2-} anion acts as a tridentate ligand and fixes three $M^{(III)}$ centres together by its oxygen atoms. The syntheses of the complexes require the presence of a carbonate anion and their decomposition take place with the loss of it. Each $M^{(III)}$ cation adopts a mono-capped trigonal-prismatic coordination, the local 3-fold axis of the MO_6 group lying in the M_3CO_3 plane. The trigonal prismatic geometry is achieved by two the terminal oxygen atoms of an edge shared paired of WO_6 octahedra to each $A\text{-}\alpha\text{-}[AsW_9O_{34}]^{9-}$ moiety and two oxygen atoms from the belt, and the cap by one external water ligand.

Polyhedron 27 (2008) 3529

Crystal structures, bioactivities and fluorescent properties of four diverse complexes with a new symmetric benzimidazolic ligand

Four new supramolecular complexes based on a new ligand have been constructed and characterized. Interestingly, six or eight-membered hydrogen bonding rings play a key role in the assembly of high-dimensional networks extended by lower dimensional coordination polymers. Among them, complex 2 presents a 3D supramolecular structure with 1D open channels encapsulating NO_3^- ions.

Structure and spectral characterisation of copper(II) meclofenamate complexes

Characterisation of $Cu(meclof)_2(2\text{-pyca})_2$ has been made based on elemental analyses, electronic, IR and EPR spectra. The crystal and molecular structures of $Cu(meclof)_2(2\text{-pyca})_2$ were measured. The carboxyl group of the meclofenamate anions coordinates to the Cu(II) atom as an unidentate or as a chelating ligand. On the basis of the spectroscopic parameters observed, a monomeric structure with a tetragonal bipyramidal geometry around the Cu(II) atom is deduced for $Cu(meclof)_2L_2$ and for $Cu(meclof)_2 \cdot H_2O$ a dimeric structure is predicted.

Novel organotin antibacterial and anticancer drugs

Three benzyl-substituted bis(cyclopentadienyl)tin dichloride derivatives were synthesised through the hydridolithiation reaction of appropriately substituted fulvenes with $LiBEt_3H$. Within the synthesis of the three organotin compounds are reported along with a structural discussion of an isolated six co-ordinated tin(IV) species. Additionally, the compounds were tested for their antibacterial and anticancer activity.

Synthesis and characterization of novel phthalocyanines bearing quaternizable coumarin

The synthesis of novel metal-free and zinc phthalocyanines with four 3-[(2-diethylamino)ethyl]-7-oxo-4-methylcoumarin dye groups on the periphery were prepared by cyclotetramerization of the novel 3-[(2-diethylamino)ethyl]-7-[(3,4-dicyanophenoxy)]-4-methylcoumarin. The novel chromogenic compounds were characterized by elementel analysis, ^1H NMR, ^{13}C NMR, MALDI-TOF, IR and UV–Vis spectral data. The electronic spectra exhibit bands of coumarin identity along with characteristic Q and B bands of the phthalocyanine (Pc) core. The IR spectra of all the Pcs showed three characteristic intense bands, at 1704 cm^{-1} for the lactone carbonyl and two bands at 1489–1604 cm^{-1} for the conjugated olefinic system.

3D supramolecular architectures of copper(II) complexes with 6-methylpicolinic and 6-bromopicolinic acid: Synthesis, spectroscopic, thermal and magnetic properties

Three copper(II) complexes with 6-methylpicolinic and 6-bromopicolinic acid were prepared and characterized by spectroscopic (IR, EPR), thermal methods (TGA/DTA) and by magnetic susceptibility measurements. Their crystal structures were determined by X-ray structural analysis and their magnetic properties discussed in correlation with the structure.

Alumina-supported metal(II) Schiff base complexes as heterogeneous catalysts in the high-regioselective cleavage of epoxides to halohydrins by using elemental halogen

A highly regioselective method for the synthesis of β-iodohydrins and β-bromohydrins by direct ring opening of epoxides with elemental halogen in the presence of alumina-supported Mn(II), Co(II), Ni(II) and Cu(II) Schiff-base complexes as new catalysts is described. This method occur regioselectively under mild conditions with high yields in various aprotic solvents, even when sensitive functional groups are present.

Chelate structures of 5-(H/Br)-2-hydroxybenzaldehyde-4-allyl-thiosemicarbazones (H_2L): Synthesis and structural characterizations of $[Ni(L)(PPh_3)]$ and $[Ru(HL)_2(PPh_3)_2]$

The reactions of 5-*R*-2-hydroxybenzaldehyde-4-allyl-thiosemicarbazone {R: H (**L**^{1}); Br (**L**^{2})} with $[M^{II}(PPh_3)nCl_2]$ (M, *n* = Ni, 2 and Ru, 3) in a 1:1 molar ratio have given the stable solid complexes $[Ni(L)(PPh_3)]$ and $[Ru(HL)_2(PPh_3)_2]$. While the 1:1 nickel complexes are formed from an ONS donor set of the thiosemicarbazone and the P atom of triphenylphosphine in a square planar structure, the 1:2 ruthenium complexes consist of a couple from each of N, S and P donor atoms in a distorted octahedral geometry.

Synthesis, characterization and catalytic oxyfunctionalization of cyclohexene with *tert*-butylhydroperoxide over a manganese(II) complex covalently anchored to multi-wall carbon nanotubes (MWNTs)

The chemical modification of multi-wall carbon nanotubes (MWNTs) is an emerging area in material science. In the present study, hydroxyl functionalized manganese(II) Schiff-base has been covalently anchored on modified MWNTs. The new modified MWNTs have been characterized by transmission electron microscopy (TEM), X-ray diffraction (XRD), X-ray photoelectron (XPS), thermal analysis, UV–Vis, diffuse reflectance (DRS), FT-IR spectroscopy and elemental analysis. Multi-wall carbon nanotubes covalently anchored manganese(II) complex ($[Mn((OH)_2$-salen)]@MWNTs) catalyze the oxidation of cyclohexene with TBHP.

pH-Directed assembly and magnetic properties of two polynuclear Mn^{II} complexes: (Δ, Λ)-$\{Mn_3(phen)_2(OOCCH_3)_6\}$ and 1-D $[Mn(phen)Cl_2]_n$

When the reaction conditions are deliberately controlled by the pH, two different polynuclear manganese complexes, (Δ, Λ)-$\{Mn_3(phen)_2(CH_3COO)_6\}$ (**1**) and $[Mn(phen)Cl_2]_n$ (**2**) (phen = 1,10-phenanthroline), have been synthesized from the same raw materials. The structural analyses show that **1** has a structure formed by neutral chiral linear trinuclear molecules, while **2** has a structure consisting of one-dimensional infinite chains. A study of the temperature dependent magnetic susceptibilities reveal that **1** is an antiferromagnetically coupled trimer molecule while **2** shows ferromagnetic interactions within the chain.

Synthesis of new Cu(II), Ni(II) and Co(II) complexes with a bis-amide ligand functionalized with pyridine moieties: Spectral, magnetic and electrochemical studies

The reaction of Cu^{2+}, Ni^{2+} and Co^{2+} ions with a bis-amide ligand functionalized with pyridine moieties gives square planar $Na[Cu_2(dmptH_{-3})(CO_3)]$ and octahedral $[Ni_2(dmptH_{-2})_2]$ and $[Co_2(dmptH_{-3})(\mu\text{-OH})]$ complexes. In all cases coordination occurs to the pyridyl and deprotonated amidic nitrogen atoms and to the oxygen atoms of an hydroxyl and a carbonato group for the copper complexes.

Synthesis, EPR spectrum and X-ray structure of tetra-*n*-butylammonium bis(benzene-1,2-dithiolato(2−)-κ^2S,S')platinate(III)

The reaction of tetra-*n*-butylammonium chloride (NBu_4Cl), dipotassium tetrachloroplatinate(II) ($K_2[PtCl_4]$) and benzene-1,2-dithiol (H_2bdt) in ethanol/water readily affords the 1:1 salt of general formula $[NBu_4][Pt(bdt)_2]$. Single crystal X-ray structure of this salt shows that the central platinum is in a square-planar coordination geometry of four S atoms, and the frozen solution EPR spectrum and the room temperature magnetic moment of μ_{eff} = 1.80 B.M. are in accord with the assignment of the Pt(III) oxidation state.

Polyhedron 27 (2008) 2507

Unexpected differences in the reactivity between MPh_2Cl_2 (M = Pb or Sn) and benzil bis(thiosemicarbazone). X-ray crystal structure of benzil bis(thiosemicarbazonate)lead(II)

The differences in the reactivity of diphenyllead and diphenyltin dichloride with benzil bis(thiosemicarbazone) LH_6 are explored. The reaction of $PbPh_2Cl_2$ afforded the complex $[Pb(LH_4)]$ **1**. The reaction with $SnPh_2Cl_2$ in the absence of solvent yielded the complex $[Sn(LH_4)Cl_2]$ **2**. The lead(II) complex, also obtained by the reaction with lead(II) nitrate, was formed by a redistribution of the organolead derivative followed by a reductive elimination reaction, while the tin one was formed by a dephenylation process. Reactions in solution of the organotin derivative are complicated and depending on the working conditions other compounds could be isolated: the organostannoxane $[Sn_2Ph_4ClO(OH)]_2$, or $[SnPh_2(C_{15}H_{10}N_3S)Cl]$, was formed by the loss of one thiosemicarbazone arm with a subsequent cyclisation.

Polyhedron 27 (2008) 2513

Synthesis, spectroscopic characterization, X-ray structure and DFT calculations of five-coordinated chlorocopper(II) complex with bis(3,5-dimethylpyrazol-1-yl)methane

The reaction of copper dichloride dihydrate and bis(3,5-dimethylpyrazol-1-yl)methane affords $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]Cl \cdot 3H_2O$. The compound has been studied by IR, UV–Vis spectroscopy and X-ray crystallography. The electronic structure of the $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ cation has been calculated with the density functional theory (DFT) method. The spin-allowed doublet–doublet electronic transitions of $[Cu\{H_2C(3,5\text{-}Me_2pz)_2\}_2Cl]^+$ have been calculated with the time-dependent DFT method, and the UV–Vis spectrum of the title compound has been discussed on this basis.

Polyhedron 27 (2008) 2519

Synthesis, characterization and magnetostructural correlation studies on three binuclear copper complexes of pyrimidine derived Schiff base ligands

Two Schiff base ligands (HL_1 and HL_2) which are closely related in their donor environment only differing at one donor center (O versus S) have been utilized to synthesize a bis(μ-thiolato) and a bis(μ-phenoxo) binuclear Cu(II,II) complex(**1** and **2**) respectively. These two complexes are found to vary appreciably in their magnetic properties despite their structural similarities. Ligand HL_2 has been found to adapt well enough to form the (μ-4,4′-bipyridyl) Cu(II,II) binuclear complex (**3**).

Polyhedron 27 (2008) 2539

The carbodiphosphorane–CS_2 adduct as a complex ligand: Crystallographic characterization of $[I_2Pt\{S_2CC(PPh_3)_2\}] \cdot CH_2Cl_2$, $[Pt\{S_2CC(PPh_3)_2\}_2][SiF_5]_2 \cdot 2CH_2Cl_2$ and $[(Me)_2PtFI\{S_2CC(PPh_3)_2\}] \cdot 2CH_2Cl_2$

Various Pt^{II} and Pt^{IV} complexes with the betain-like ligand $S_2CC(PPh_3)_2$ (**1**) were studied by X-ray analyses. **1** is composed of CS_2 and the double ylide $C(PPh_3)_2$ and acts as a chelating ligand. The structures of $[I_2Pt\{S_2CC(PPh_3)_2\}]$ (**2**), $[Pt(Me)_2FI\{S_2CC(PPh_3)_2\}] \cdot 2CH_2Cl_2$ (**4**) and $[Pt\{S_2CC(PPh_3)_2\}_2][SiF_5]_2 \cdot 2CH_2Cl_2$ (**5**) were presented. Upon complex formation the C–S bond lengths of **1** are elongated accompanied by a slight shortening of the S_2C–CP_2 bonds.

Polyhedron 27 (2008) 2672

pH-dependent self-assembly of copper(II) complexes with a new imidazole-containing polyamine ligand: Synthesis, structure and magnetic property

Four copper(II) complexes were synthesized by reactions of new imidazole-containing polyamine ligand with $Cu(ClO_4)_2 \cdot 6H_2O$ under different pH and their structures were found to be from protonated ligand, dinuclear, one-dimensional chain polynuclear to cyclic-tetranuclear coordination compounds by varying reaction pH from acidic to basic. The results indicate that the reaction pH has great impact on the formation and structure of the complexes. The magnetic property of the complexes was investigated.

Synthesis, crystal engineering, and magnetic properties of an anionic 4-terpyridone based copper(II) azide supramolecule containing dinuclear–mononuclear cocrystal

Synthesis, crystal engineering, and magnetic properties of an anionic 4-terpyridone (L) based three-dimensional supramolecule, $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2] \cdot 2[Cu^{II}(L)(N_3)(H_2O)] \cdot 6H_2O$, have been described. In this compound, one dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit is cocrystallized with two mononuclear $[Cu^{II}(L)(N_3)(H_2O)]$ units. Eight O–H···O type strong hydrogen bonds involving the oxygen centers of anionic 4-terpyridone ligand and water molecules link the components into a three-dimensional framework containing hydrogen bonded sheets interlinked by the dinuclear $[Cu^{II}_2(L)_2(\mu_{1,1}\text{-}N_3)_2]$ unit.

Polyhedron 27 (2008) 2698

Synthesis and characterization of ruthenium(II) azoimine-diphosphine mixed-ligand complexes

A novel family of the general type *cis*-$[Ru^{II}(dppe)LCl_2]$ {L = $C_6H_5N{=}NC(COCH_3){=}NAr$, and dppe = $Ph_2P(CH_2)_2PPh_2$] has been synthesized. These complexes have been characterized through analytical, spectroscopic (IR, UV–Vis and NMR) and electrochemical (cyclic voltammetry) techniques. In addition, a representative complex has been further characterized by X-ray diffraction analysis. Crystallographic, electrochemical and electronic spectral data are all consistent with the azomethine ligand possessing strong π-acceptor properties. These π-acceptor properties can be "tuned" by a judicious choice of substituent on the azomethine ligand.

Preparation and *cis*-to-*trans* transformation study of square-planar $[Pt(L_n)_2Cl_2]$ complexes bearing cytokinins derived from 6-benzylaminopurine (L_n) by view of NMR spectroscopy and X-ray crystallography

Mononuclear, square-planar platinum(II) complexes involving derivatives of aromatic cytokinins as the ligands, and having the general formula *cis*-$[Pt(L_n)_2Cl_2]$ (**1**–**3**) and *trans*-$[Pt(L_n)_2Cl_2]$ (**4**–**6**), where n = 1–3, L_1 = 2-chloro-6-(benzylamino)-9-isopropylpurine, L_2 = 2-chloro-6-[(4-methoxybenzyl)amino]-9-isopropylpurine and L_3 = 2-chloro-6-[(2-methoxybenzyl) amino]-9-isopropylpurine, have been synthesized and characterized. Dynamic *cis*-to-*trans* isomerization process of complex **1** in DMFA has been investigated by means of multinuclear NMR spectroscopy. The solid-state structures of **1**, **4** · 2DMF, and **5** have been determined by single crystal X-ray analysis. *In vitro* cytotoxicity of the prepared complexes against MCF7, G361, K562, and HOS has been evaluated.

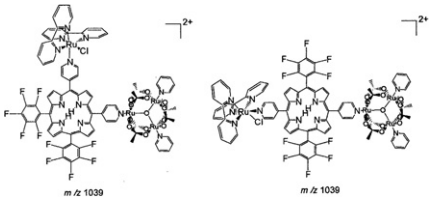
Polyhedron 27 (2008) 2721

The use of electrospray ionization tandem mass spectrometry on the structural characterization of novel asymmetric metallo-organic supermolecules, based on pentafluorophenylporphyrins and ruthenium complexes

This article focuses the development of a synthetic route to obtain the novel asymmetric triads *cis*- and *trans*-$[B(4\text{-py})BFPPH_2\{Ru_3O(Ac)_6(py)_2\}\{Ru(bpy)_2Cl\}](PF_6)_2$ and their structural characterization based on high resolution ESI mass spectrometry and ^1H and ^{19}F NMR spectroscopy. Preliminary photophysical essays showed that the porphyrinic core emission is being quenched by the modifying complexes, opening the possibility to use the triads as photophysical devices.



The Publisher encourages the submission of articles in electronic form thus saving time and avoiding rekeying errors. For detailed instructions on the preparation of manuscripts and of electronic artwork, consult the Author Gateway for Elsevier at http://authors.elsevier.com

Polyhedron 27 (2008) 905

The first hydroxo-bridged saccharinate complexes: Syntheses, spectral, thermal, structural characterization and antimicrobial activities of $[Cu(\mu\text{-OH})(sac\text{-}N)(deten)]_2 \cdot 2H_2O$ and $[Cu(\mu\text{-OH})(sac\text{-}O)(tmen)]_2$

Two novel saccharinate complexes, $[Cu(\mu\text{-OH})(sac\text{-}N)(deten)]_2{\cdot}2H_2O$ (**1**) and $[Cu(\mu\text{-OH})(sac\text{-}O)(tmen)]_2$ (**2**) (deten = *N*,*N*-diethylethylenediamine, tmen = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine and sac = saccharinate) have been synthesized and characterized. Although a lot of saccharinato complexes are well known, quite surprisingly, up to now hydroxo-bridged dimeric metal complexes of the saccharinate have not been reported. In the complexes, the sac ligands exhibit different coordination modes: in **1**, sac ligand is *N*-bonded, while the other complex is *O*-coordinated.

Polyhedron 27 (2008) 969

DFT and NBO theoretical study of protonation of tri-*tert*-butoxysilanethiol and its anion

Protonation on the sulfur atom gives elongation of the Si–S bond, while protonation on the oxygen atom causes shortening of the Si–S bond. Natural bond orbital (NBO) analysis was applied for justification of the changeability of the Si–S and Si–O bond lengths. Interaction of sulfur and oxygen lone pairs with anti-bonding Si–O orbitals may be a good explanation for the accounted trends.

Polyhedron 27 (2008) 977

Synthesis, spectroscopic and structural characterization of diphenyltin(IV) complexes of acetone Schiff bases of *S*-alkyldithiocarbazates

The structures of the acetone Schiff bases of *S*-methyldithiocarbazate (Hacsme) and (Hacsbz) and $[Sn(C_6H_5)_2(NS)Cl]$ have been determined by X-ray diffraction. In the solid state, both the Schiff bases exist in their thioketo tautomeric forms with the azomethine nitrogen atom *trans* to the thione sulfur atom but in the tin(IV) complexes they are present in their deprotonated ene-thiolate forms. The tin atom adopts a five-coordinate, approximately trigonal bipyramidal geometry, with the thiolate sulfur atom of the Schiff base and the two phenyl groups occupying the equatorial positions. The azomethine nitrogen atom and the chlorine ligand occupy axial positions.

Polyhedron 27 (2008) 992

On the role of anion templates for the self-assembly of octanuclear copper(I) dichalcogenophosph(in)ate clusters

The cubic octanuclear clusters $[Cu_8(S_2PPh_2)_6]^{2+}$ and $[Cu_8(\mu_8\text{-}Cl)(S_2PPh_2)_6]^{+}$ have been prepared from the reaction of $[Ph_2PS_2][HNEt_3]$ with $[Cu^{I}(CH_3CN)_4][PF_6]$ in hexane/CH_2Cl_2 or refluxing CH_2Cl_2, respectively. Both are rare examples of copper(I) dithiophosphinate clusters and $[Cu_8(S_2PPh_2)_6]^{2+}$ is the first example of a non-anion-centered dithiophosph(in)ate Cu^{I}_8 cluster. Theoretical calculations show that the stability of this 'empty' cluster can be attributed to the strong metal–ligand interactions.

Polyhedron 27 (2008) 1121

Reactivity of oxorhenium(V) complexes towards quinoline carboxylic acids. X-ray structure of $[ReOCl_2(hquin\text{-}7\text{-}COOH)(PPh_3)] \cdot OPPh_3$, $[ReOBr_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ and $[ReOX_2(hmquin\text{-}7\text{-}COOH)(PPh_3)]$. DFT and TD-DFT calculations for $[ReOCl_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$

The reactions of $[ReOX_3(PPh_3)_2]$ (X = Cl, Br) with 8-hydroxyquinoline-7-carboxylic acid (Hhquin-7-COOH) and 8-hydroxy-2-methylquinoline-7-carboxylic acid (Hhmquin-7-COOH) have been examined and $[ReOX_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ and $[ReOX_2(hmquin\text{-}7\text{-}COOH)(PPh_3)]$ complexes have been obtained. All the complexes were characterized by IR, UV–Vis spectroscopy and elemental analysis. The crystal and molecular structures have been determined for $[ReOCl_2(hquin\text{-}7\text{-}COOH)(PPh_3)] \cdot OPPh_3$, $[ReOBr_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ and $[ReOX_2(hmquin\text{-}7\text{-}COOH)(PPh_3)]$. The electronic structure of $[ReOCl_2(hquin\text{-}7\text{-}COOH)(PPh_3)]$ has been calculated with the density functional theory (DFT) method.

Diruthenium(II, III) complexes of ibuprofen, aspirin, naproxen and indomethacin non-steroidal anti-inflammatory drugs: Synthesis, characterization and their effects on tumor-cell proliferation

$[Ru_2(dNSAID)_4Cl]$ and novel $[Ru_2(dNSAID)_4(H_2O)_2]$ PF_6 complexes, where dNSAID = deprotonated carboxylate from the non-steroidal anti-inflammatory drugs (NSAIDs) have been prepared and characterized. Coordination of Ru_2(II, III) core led to synergistic effects that increased significantly the inhibition of C6 rat glioma proliferation in relation to the organic NSAIDs naproxen and ibuprofen.

Novel supramolecular network in tri- and mono-nuclear oxovanadium(V)-salicyl-hydroximate: Synthesis, structure and catalytic oxidation of hydrocarbons using H_2O_2 as terminal oxidant

Two oxovanadium(V)salicylhydroximate complexes, $[VO(SHA)(H_2O)] \cdot 1.58H_2O$ (**1**) and $[V_3O_3(CSHA)_3(H_2O)_3] \cdot 3CH_3COCH_3$ (**2**) and a mono nuclear oxovanadium(V) complex $[VO(SHAH_2)(PyDC)]$ (**3**) with salicylhydroxamic acid ($SHAH_3$) and 2,6-pyridine dicarboxylic acid ($PyDCH_2$), a mono nuclear oxoperoxo vanadium(V)complex $H[VO(O_2)(PyDC)(H_2O] \cdot 2.5H_2O$ (**4**) with $PyDC^{2-}$, have been synthesized and structurally characterized. All the complexes exhibit supramolecular networks. Compound **1** and **2** behave as a good catalyst for functionalization of hydrocarbons.

Polyhedron 27 (2008) 2243

Unusual coordination in a silver thionate complex. Synthesis, structural characterization and theoretical calculations of dinuclear and polynuclear silver(I) thiosaccharinates with pyridine and 1,10-phenanthroline

New ternary silver(I) thiosaccharinates with pyridine and 1,10-phenanthroline are prepared and structurally characterized. The pyridine derivative is a dinuclear silver complex, $[Ag_2(tsac)_2py]$, with argentophilic interaction and very unusual metal environments. One Ag(I) is coordinated by two S atoms and the other silver atom by three N atoms.

Polyhedron 27 (2008) 2251

The influence of substituents at the C^2 carbon of thiosemicarbazones on bonding and nuclearity of silver(I) complexes

The substitution at C^2 carbon has led to a change in stoichiometry, nuclearity and dentacy of thiosemicarbazone complexes of silver(I). For example, 2-acetylpyridine thiosemicarbazone (HL^2) has yielded complex **1**, while 2-benzoylpyridine thiosemicarbazone (HL^1) has yielded a sulfur-bridged dimer **2**.

Polyhedron 27 (2008) 2259

Displacement of neutral nitrogen donors by chloride in $[Pt(SNS)(R\text{-}py)](ClO_4)_2$ (SNS = 2,6-bis(methylthiomethyl)pyridine; R-py = pyridines): A reactivity comparison between *meta*- and *para*-substituted pyridines

The kinetics of displacement by chloride of *meta*- and *para*-substituted pyridines (R-py) from $[Pt(SNS)(R\text{-}py)]^{2+}$ complexes {SNS = 2,6-bis(methylsulfanylmethyl)pyridine} are reported. The reactivity of the two groups of N-donors is different, the *meta*-substituted pyridines resulting less reactive than the *para*-substituted on growing their basicity. These results have been explained on the basis of a different π-acidity between the two groups of ligands which influences the reaction ground state.

Nickel(II) complexes with *N*-(thio)phosphorylthioureas AdNHC(S)NHP(X)(O*i*Pr)$_2$: Versatile coordination of phosphoryl (X = O) and thiophosphoryl (X = S) derivatives

The reaction of the potassium salts of *N*-(thio)-phosphorylated thioureas of the common formula AdN(H)C(S)N(H)P(X)(O*i*Pr)$_2$ (X = O, $\mathbf{HL^I}$; X = S, $\mathbf{HL^{II}}$) with the Ni(II) cation in aqueous EtOH leads to $[\mathbf{Ni(L^{I,II})_2}]$ chelate complexes. The molecular structures of the thioureas $\mathbf{HL^{I,II}}$ and the complexes $[\mathbf{Ni(L^I}\text{-}\boldsymbol{N,S})_2]$ and $[\mathbf{Ni(L^{II}}\text{-}\boldsymbol{S,S'})_2]$ were elucidated by single crystal X-ray diffraction analysis, IR, ^{1}H and ^{31}P NMR spectroscopy and microanalysis. In the complex $[\mathbf{Ni(L^I)_2}]$, the metal center is found to be in a square-planar N_2S_2 environment formed by the C=S sulfur atoms and the P–N nitrogen atoms of two deprotonated $\mathbf{L^I}$ ligands. The ligands are in a *trans* configuration. The Ni(II) atom in complex $[\mathbf{Ni(L^{II})_2}]$, with the deprotonated thiourea $\mathbf{L^{II}}$, is coordinated in a square-planar fashion by the C=S and P=S sulfur atoms of two anionic ligands. The ligands are in a *cis* configuration.

Polyhedron 27 (2008) 2277

Reactivity of benzil bis(4-methyl-3-thiosemicarbazone) with cadmium nitrate. Crystal structure of $[Cd(LMe_2H_4)(NO_3)_2][Cd(LMe_2H_4)(NO_3)(H_2O)]NO_3 \cdot H_2O$

Benzil bis(4-methyl-3-thiosemicarbazone) and cadmium nitrate form, depending on the pH, two new complexes: $[Cd(LMe_2H_4)(NO_3)_2]$-$[Cd(LMe_2H_4)(NO_3)(H_2O)]NO_3 \cdot H_2O$ (**1**) and $[Cd(LMe_2H_4)]_2$ (**2**). Complex **1** contains two different types of Cd(II) ions. The Cd(1) atom is seven-coordinate with a $S_2N_2O_3$ coordination sphere, but the coordination number of the Cd(2) atom expands to eight by an additional oxygen atom. Both units are linked by hydrogen bonds.

β-Tetra-brominated *meso*-tetraphenylporphyrin: A conformational study and application to the Mn-porphyrin catalyzed epoxidation of olefins with tetrabutylammonium oxone

In spite of the nearly planar structure of H_2TPPBr_4, the Soret and Q(0,0) bands of β-tetrabrominated porphyrin are significantly red shifted with respect to those of H_2TPP which is probably due to the electron-withdrawing effects of the substituents. $Mn(TPPBr_4)OAc$ is an efficient catalyst for the selective epoxidation of conjugated double bonds with tetrabutylammonium oxone.

Polyhedron 27 (2008) 2291

Effect of pendant arm position and length on the structure and properties of nickel aromatic dicarboxylate coordination polymers incorporating a kinked organodiimine

Hydrothermal synthesis has afforded coordination polymers incorporating 4,4′-dipyridylamine (dpa) and flexible pendant arm aromatic dicarboxylate ligands. $[Ni(1,2\text{-phda})(dpa)(H_2O)]_n$ (1,2-phda = 1,2-phenylenediacetate) displays rhomboid grid 2D layers. $\{[Ni(hmph)(dpa)] \cdot 1.33H_2O\}_n$ (hmph = homophthalate) possesses (6,3) herringbone style 2D coordination layer motifs. $[Ni(1,3\text{-phda})(dpa)(\mu\text{-}H_2O)_{0.5}]_n$ (1,3-phda = 1,3-phenylenediacetate) manifests a 3D canted primitive cubic type coordination polymer lattice featuring antiferromagnetically coupled dinuclear kernels.

Polyhedron 27 (2008) 2301

Co(II), Ni(II) and Cu(II) complexes of new [1+1] and [2+2] macrocyclic ligands derived from 1,4-bis(2′-formylphenyl)-1,4-dioxabutane and *cis*-1,2-diaminocyclohexane

Two new macrocyclic ligands, L^1(14-membered, N_2O_2) and L^2(28-membered, N_4O_4) from [1+1] and [2+2] condensation, respectively, have been obtained in a one-pot synthesis starting from 1,4-bis(2′-formylphenyl)-1,4-dioxabutane and *cis*-1,2-diaminocyclohexane, in satisfactory yield and purity. Metal complexes of L^2 using hydrated nitrate and perchlorate salts of transitional Co(II), Ni(II) and Cu(II) metal ions have been synthesized and characterized by microanalysis, LSI-MS, IR and UV–Vis spectroscopy, magnetic measurements and conductivity measurements. Crystal structures of L^1 and the mononuclear $[Co(HL^2)(NO_3)_2(CH_3CN)](NO_3) \cdot 2CH_3CN$, $[NiL^2(NO_3)](NO_3) \cdot 2H_2O \cdot CH_3CN$ and the dinuclear $[Cu_2L^2(NO_3)_4] \cdot 4CH_3CN$ complexes have been determined by X-ray diffraction.

Polyhedron 27 (2008) 2341

A pyrazine-bridged linear pentanuclear copper(II) complex and related tri- and dinuclear complexes showing various coordination structures and magnetic couplings

Sterically bulky pyrazines are successfully utilized for the preparation of discrete oligo-nuclear TBP, SqP and Oh copper(II) complexes. A unique linear pentanuclear complex [{Cu-(hfac)$_2$}$_5$(μ-2-butyl-3-methylpyrazine)$_4$] is presented. Related tri- and dinuclear copper complexes were structurally and magnetically characterized. The σ-pathway is essential for the superexchange mechanism across the pyrazines.

Polyhedron 27 (2008) 2357

A series of three-dimensional coordination polymers with general formula $[\{Ln(H_2O)_n\}\{Re_6Te_8(CN)_6\}] \cdot xH_2O$ (Ln = Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb; n = 3, 4, x = 0, 2.5)

The eight three-dimensional coordination compounds $[\{Ln(H_2O)_4\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$; Ln = Eu (**1**), Tb (**3**), Dy (**4**), Ho (**5**), Er (**6**), Tm (**7**), $[\{Gd(H_2O)_3\}\{Re_6Te_8(CN)_6\}] \cdot 2.5H_2O$ (**2**) and $[\{Yb(H_2O)_4\}\{Re_6Te_8(CN)_6\}]$ (**8**) were synthesized and X-ray characterized. Comparison of the structures **1**–**8** showed that despite of relatively small distinctions in atomic radii of lanthanides Eu–Yb in series of compounds **1**–**8** four types of structures are realized.

Polyhedron 27 (2008) 2402

Syntheses, crystal structures and magnetic behaviors of three Mn^{II}-terephthalate coordination polymers containing terminal ligands

Three coordination polymers have been synthesized and the structure analyses show that they are all composed of Mn atoms as nodes and terephthalate dianions as spacers. Interestingly, compound **1** consists of 1D infinite zigzag chains, while compound **2** consists of 2D sheets and compound **3** has a 3D framework structure. The study of the temperature dependent magnetic susceptibilities revealed that all of the polymers show antiferromagnetism.

Polyhedron 27 (2008) 2459

Synthesis, structure and magnetic properties of unsymmetrical dodecanuclear Mn–Ln clusters

Reaction of manganese acetate and lanthanide nitrates in the presence of excess of PhCOOH affords highly asymmetric dodecanuclear mixed-metal $[Mn_{10}Ln_2(OH)(O)_8(PhCOOH)(PhCOO)_{19}]$ (Ln = Pr^{III} (**1**), Nd^{III} (**2**)) clusters. The similar reaction, but with only 2 equiv. of PhCOOH resulted in a compound with the higher nuclearity $[Mn_{11}Eu_4(O)_8(OH)_8(PhCOO)_{18}(NO_3)_2(H_2O)_6]\text{-}NO_3 \cdot 4CH_3CN$ (**3**). Variable-temperature solid-state magnetic susceptibility of **1** and **2** in the temperature range 1.8–300 K were carried out, and for both complexes predominantly antiferromagnetic exchange interactions between the metal centers were observed, giving an estimated $S = 17/2$ ground state. AC magnetic susceptibility data have revealed out-of-phase signals, which suggest that these complexes exhibit a slow relaxation of magnetization as observed in single-molecule magnets.

Polyhedron 27 (2008) 2464

Rhenium(IV)–copper(II) heterobimetallic complexes: Synthesis, crystal structure and magnetic properties

Two Re(IV)–Cu(II) heterometallic complexes $\{(CuL_\alpha)[ReCl_4(ox)]\}_n$ (where L_α = *N-meso*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$), **1**, and (CuL_β)-$[ReCl_4(ox)]$ (L_β = *N-rac*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$*N-rac*-5,12-Me_2-7,14-Et_2-[14]-4,11-dieneN$_4$), **2**, were synthesized. The $[CuL^{2+}]$ macrocyclic cation is coordinated from above and below by $[ReCl_4(ox)]^{2-}$ units through the chloro-ligands and creates a chloro-bridged hetero-metallic Re^{IV}–Cu^{II} one-dimensional zig-zag chain. Compound **2** can be viewed as a hetero-bimetallic dinuclear unit, in which the Re(IV)–Cu(II) centers are linked by an oxalato bridge. The magnetic behavior of **1** and **2** has been investigated over the temperature range 1.8–300 K. Compound **1** behaves like a ferrimagnetic {Re(IV)–Cu(II)} bimetallic, one-dimensional chain with intrachain antiferromagnetic coupling. Compound **2** shows a weak antiferromagnetic interaction within the [Re(IV)–Cu(II)] unit along with a strong single-ion anisotropy, $D(Re) = -63\ cm^{-1}$.

A new coordination mode of pyrazine-2,3-dicarboxylic acid and its first monodentate complexes: Syntheses, spectral, thermal and structural characterization of $[Cu(pzdca)(H_2O)(en)_2] \cdot H_2O$ and $[Cu(pzdca)(H_2O)(dmpen)_2]$

In the $[Cu(pzdca)(H_2O)(en)_2]\cdot H_2O$ and $[Cu(pzdc)(H_2O)(dmpen)_2]$ complexes, the pyrazine-2,3-dicarboxylate ligand exhibits new coordination mode and these complexes are the first example of the pzdca ligand exhibiting monodentate coordinated to the metal ions.

Fine structures of 1-(arylethynylselanyl)-naphthalenes: Characteristic features brought by the ethynylselanyl group

Fine structures of 1-(*p*-$YC_6H_4C{\equiv}CSe)C_{10}H_7$ (**1**) have been determined by X-ray analysis. The Y dependence of the fine structures are just the opposite to the case of 1-(*p*-$YC_6H_4Se)C_{10}H_7$ (**3**). The factor that controls the fine structures of **1** is called the "*ethynyl effect*". Structures in solution are also clarified.

The role of the histidine residue in the coordination abilities of peptides with a multi-histidine sequence towards copper(II) ions

The coordination of the group of protected and unprotected peptides containing three histidyl residues in the sequence were investigated towards Cu^{2+} ions. The investigations were performed by potentiometric, spectroscopic and computer calculations. Obtained results have determined a number of different binding modes strictly depending on position of histidyl residue.

Interaction of vanadium(III) with imidazole carboxylic acids

Complex formation between vanadium(III) and several imidazole carboxylic derivatives (urocanic acid, imidazole-4-carboxylic and imidazole-4,5-dicarboxylic acid) was studied using pH-potentiometric and spectroscopic (UV–Vis absorption and fluorescence) methods. The results show that urocanic acid is a weak ligand in aqueous solution and hydrolysis of vanadium(III) effectively competes with the complexation processes. Imidazole mono and di-carboxylate are relatively stronger donor (N,O) ligands and are able to prevent, to some degree, the hydrolysis processes. The main complex species in the vanadium(III)–imidazole-4,5-dicarboxylic acid system is the dinuclear μ-oxo bridged V_2OL_2 species.

Co(II)-promoted transformation of diethyl-(quinolin-2-ylmethyl)phosphonate to quinoline-2-carboxylate (2-qca): Synthetic, structural and magnetic studies of [$Co(2\text{-qca})_2$-$(EtOH)_2$]

The synthesis and single-crystal X-ray structural characterization of a novel compound of the formula [$Co(2\text{-qca})_2(EtOH)_2$] (2-qca = quinoline-2-carboxylate) is reported. This compound has been synthesized by the oxidative decomposition of the diethyl(quinolin-2-ylmethyl)phosphonate ligand. In this reaction the cobalt(II) ion promotes C–P bond cleavage. Detailed characterization of $Co(2\text{-qca})_2$-$(EtOH)_2$ includes structural, spectroscopic and magnetic studies.

Polyhedron 27 (2008) 1650

New long-chain-substituted polymeric metal-free and metallophthalocyanines by microwave irradiation: Synthesis and characterization

A tetranitrile monomer *N*,*N*-bis{2-[2-(3,4-dicyanophenoxy)ethoxy]ethyl}-4-methylbenzenesulfonamide (**3**) was synthesized by nucleophilic aromatic substitution of *N*,*N*-bis[2-(2-hydroxyethoxy)ethyl]-4-methylbenzenesulfonamide (**1**) onto 4-nitrophthalonitrile (**2**). The metal-free phthalocyanine polymer (**4**) was prepared by the reaction of a tetranitrile monomer **3** in 2-(dimethylamino)ethanol. Ni(II), Co(II) and Cu(II) phthalocyanine polymers were prepared by the reaction of the tetranitrile compound with the chlorides of Ni(II), Co(II) and Cu(II) in 2-(dimethylamino)ethanol (DMAE). The Zn(II)-phthalocyanine polymer was prepared by the reaction of the tetranitrile compound with the acetate of Zn(II) in DMAE. The new compounds were characterized by a combination of IR, ^{1}H NMR, ^{13}C NMR, UV–Vis, elemental analysis and MS spectral data.

Polyhedron 27 (2008) 1665

Synthesis and molecular structure of new heterometal alkoxide clusters $Ln_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (Ln = Sm, Y, Yb): Highly active catalysts for polymerization of ε-caprolactone and trimethylene carbonate

The novel polynuclear heterometal alkoxide clusters $Ln_2Na_8(OCH_2CF_3)_{14}(THF)_6$ (Ln = Sm **1**, Y **2**, Yb **3**) have been synthesized by the reaction of anhydrous $LnCl_3$ with 7 equiv of $NaOCH_2CF_3$ in good yields. Clusters **1-3** show extremely high activity for the polymerization of -caprolactone (-CL) and trimethylene carbonate (TMC), and the reactivity is much higher than those found for the monometallic alkoxides lanthanide complexes previously reported.

Novel oxorhenium complexes with 2-(2′-hydroxyphenyl)-2-benzothiazolinato ligand: X-ray studies, spectroscopic characterization and DFT calculations

The $[ReOX_2(hbt)(EPh_3)]$ (X=Cl, Br; E=As, P) chelates have been prepared in the reactions of $[ReOX_3(EPh_3)_2]$ complexes (X=Cl, Br; E=P, As) with 2-(2'-hydroxyphenyl)-2-benzothiazole (hbtH) in acetone. From the reactions of $[ReOX_3(PPh_3)_2]$ with hbtH two kind of crystals $[ReOX_2(hbt)(PPh_3)] \cdot MeCN$ and $[ReOX_2(hbt)(PPh_3)]$ with different arrangement of halide ions (*cis* and *trans*) were isolated, whereas the $[ReOX_3(AsPh_3)_2]$ oxocompounds react with hbtH to give only *cis*-halide isomers. The complexes were structurally and spectroscopically characterised. The electronic structures of both $[ReOBr_2(hbt)(PPh_3)]$ isomers have been calculated with the density functional theory (DFT) method. The TDDFT/PCM calculations have been employed to produce a hundred of singlet excited-states starting from the ground-state geometry optimized in the gas phase of *cis*- and *trans*-halide isomers of $[ReOBr_2(hbt)(PPh_3)]$ and the UV–Vis spectra of these complexes have been discussed on this basis.

Polyhedron 27 (2008) 1690

Intramolecular photoinduced electron transfer in a ruthenium polypyridyl functionalised β-cyclodextrin capped with a hydroxo bridged Cu(II) dimer

The photophysics of a novel supramolecular donor–acceptor system comprising a ruthenium polypyridyl unit covalently linked to a hydroxo bridged dinuclear copper(II) β-cyclodextrin (CD) moiety indicates efficient photoinduced electron transfer is occurring. The parent ruthenium linked CD complex is readily quenched by copper ions at high pH whereas zinc ion has no impact on the photophysics of the complex. Although more commonly studied in the context of inclusion, such luminescently labelled CDs may have value in metal sensing.

Polyhedron 27 (2008) 1721

Ferromagnetic exchange coupling in phosphonato-bridged dinuclear copper(II) compound with monoethyl (pyridyn-2-ylmethyl)phosphonate ligand (2-mpmpe): Cu_2(2-mpmpe)$_2$-$(H_2O)_2(NO_3)_2$

Synthesis, spectroscopic and magnetic properties, and X-ray crystal structure of dinuclear copper(II) compound of formula Cu_2(2-mpmpe)$_2(H_2O)_2(NO_3)_2$, where 2-mpmpe = monoethyl (pyridyn-2-ylmethyl)phosphonate is described. Its structure consists of copper(II) ions doubly bridged by phosphate –OPO– groups. The magnetic properties of the compound revealed the occurrence of a weak ferromagnetic coupling through phosphonate bridge (J = 1.86 cm^{-1}) and interdimer superexchange coupling through H-bond network (zJ' = −0.17 cm^{-1}).

Polyhedron 27 (2008) 1739

Synthesis, spectroscopic characterization, X-ray structure and DFT calculations of rhenium(III) complex with 1-isoquinolinyl phenyl ketone

The $[ReCl_3(MeCN)(PPh_3)]$ complex reacts with 1-isoquinolinyl phenyl ketone (N–O) to give $[ReCl_3(N–O)(PPh_3)]$. The compound has been studied by IR, UV–Vis spectroscopy, magnetic measurements and X-ray crystallography. The magnetic behavior is characteristic of mononuclear octahedral Re(III) complex with d^4 low-spin ($^3T_{1g}$ ground state) and arises because of the large spin-orbit coupling, which gives diamagnetic ground state. The molecular orbital diagram of $[ReCl_3(N–O)(PPh_3)]$ has been calculated with the density functional theory (DFT) method, and TDDFT calculations have been employed in order to discussion of its spectroscopic properties in more detail.

Polyhedron 27 (2008) 1747

The structure of mimetite, arsenian pyromorphite and hedyphane – A near-infrared spectroscopic study

A comparison of Raman spectra of pyromorphites with published infrared and Raman data of similar minerals has been made. Crystals of the pyromorphite- mimetite series are chemically zoned, resulting in changes in the crystal structure with the isomorphic replacement of phosphate by arsenate with the consequential change in crystal structure from monoclinic to hexagonal. Such dimorphic relationships are exemplified by the shift in the Raman spectral band positions of phosphate with increasing arsenate substitution.

Synthesis, characterization and bioactivity of a new Fe(III) 18-metallacrown-6 and a new trinuclear linear Ni(II) complexes

The chelating modes of these types of ligands to metal ions are the same. When we use bivalent nickel salt, we get a linear trinuclear complex; when we use trivalent iron salt, we get a new 18-metallacrown-6 compound.

Dinuclear copper complexes with cyanamide derivatives as bridging ligands

Three mixed-valence copper complexes [{Cu(phen)$_2$}$_2$ (μ-L)](PF$_6$)$_2$ (where phen = 1,10-phenanthroline, L = 1,4-dicyanamidobenzene (dicyd)), 1,4-dicyanamido-2,5-dimethylbenzene (Me$_2$ dicyd) and 1,4-dicyanamido-2,5-dichlorobenzene (Cl$_2$ dicyd), and one dinuclear Cu(II) complex [{Cu(phen)$_2$}$_2$ (μ-apc)](PF$_6$)$_3$ (where apc = monoanion of 4-azo(phenylcyanamido)benzene) have been prepared and characterized by elemental analysis, IR and electronic absorption spectroscopies and cyclic voltammetry. [{Cu(phen)$_2$}$_2$(μ-apc)](PF$_6$)$_3$ · 2CH$_3$COCH$_3$ crystallized in the triclinic system and both five-coordinate Cu(II) ions in the dinuclear unit are linked through a bridging 4-azo(phenylcyanamido)benzene (apc) ligand.

Synthesis and characterization of metal diselenophosphates: M[Se$_2$P(OR)$_2$]$_2$ (M = Pd, Pt; R = Et, ^{n}Pr, ^{i}Pr)

The first square-planar Pd(II) and Pt(II) complexes incorporating diselenophosphate ligands have been reported. Structural elucidations indicate that minute differences exist in the M–Se bond distances and these were observed from solution ^{31}P and ^{77}Se NMR studies. A packing diagram showed a chain-like motif which was composed of square-planar M[Se$_2$P(OR)$_2$]$_2$ units and occurred via noncovalent Se···Se secondary interactions.

Synthesis and spectral studies of cadmium(II) complexes derived from di-2-pyridyl ketone and N^4-phenylsemicarbazide: First structural report of a cadmium(II) complex of semicarbazone

A new semicarbazone based on di-2-pyridyl ketone and its three cadmium(II) complexes $[CdL(CH_3COO)]_2 \cdot 2CH_3OH$ (**1**), $Cd(HL)Br_2$ (**2**) and $[Cd_2L_2N_3]_2 \cdot H_2O$ (**3**) were synthesized and characterized by different physicochemical techniques. The complex, $[CdL(CH_3COO)]_2 \cdot 2CH_3OH$ (**1**) is having a dimeric structure. In complexes **1** and **3**, the ligand moieties are coordinated as monoanionic (L^-) forms and in complex **2**, the ligand coordinated as neutral (HL) one. The coordination geometry around cadmium(II) in **1** is distorted octahedral, as obtained by X-ray diffraction studies.

Thermal fragmentation of the guanidinato aluminum amide precursor $[Me_2NC(N^{i}Pr)_2]Al(NMe_2)_2$: An investigation of reactive species by matrix-isolation FTIR spectroscopy and time-of-flight mass spectrometry

The guanidinato aluminum amide precursor **1** cleanly produces the reactive intermediate $Al(NMe_2)_3$ in gas-phase thermolyses. This monomeric aluminum amide was characterized in argon matrices by matrix-isolation FTIR spectroscopy supported by DFT calculations.

Polyhedron 27 (2008) 2731

Synthesis, characterization, crystal structures, *in vitro* and *in vivo* antitumor activity of palladium(II) and zinc(II) complexes with 2-formyl and 2-acetyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone

The present paper includes synthesis and spectral characterization of the novel prepared palladium(II) and zinc(II) complexes with 2-formyl pyridine N(4)-1-(2-pyridyl)-piperazinyl Thiosemicarbazone, HFo4Npypipe, **1** and the 2-acetyl pyridine N(4)-1-(2-pyridyl)-piperazinyl thiosemicarbazone, HAc4Npypipe, **2**. The Pd(II) complexes [PdCl(Fo4Npypipe)], **3**, [PdCl(Ac4Npypipe)], **4** and the Zn(II) complexes [$ZnCl_2$(Fo4Npypipe)], **5** and [$ZnCl_2$(Ac4Npypipe)], **6** have been characterized by elemental analyses and spectroscopic studies. The crystal structure of the complexes [PdCl(Fo4Npippy)], **3** and [PdCl(Ac4Npippy)], **4**, have been solved by single-crystal X-ray diffraction. The results of the cytotoxic activity of **1**–**6** have been evaluated *in vitro* against the cells of three human cancer cell lines: MCF-7, T24, A-549 and a mouse L-929. For selected compounds **2** and **6** the acute toxicity and antitumor activity were evaluated on leukemia P388-bearing mice. The cytotoxic activity shown by these Zn(II) compounds **5** and **6** against MCF-7 and T24 cell lines indicate that coupling of **1** and **2** to Zn(II) metal center result in metallic complexes with important biological properties and remarkable cytotoxic activity, since they are display IC_{50} values in a μM range better to that of the antitumor drug *cis-platin*.

Dimethyl sulfoxide ruthenium(II) complexes of thiosemicarbazones and semicarbazone: Synthesis, characterization and biological studies

A family of new Cl–Ru(II)-dmso complexes of thiosemicarbazones along with benzaldehyde semicarbzone has been prepared and characterized. The benzaldehyde semicarbazone ligand has been obtained by the reaction of benzaldehyde and thiosemicarbazide in ethanol through water assisted conversion of C=S to C=O. The previously structurally uncharacterized [$RuCl_2$(dmso)$_2$(benzaldehyde semicarbazone)] complex has been characterized by single crystal XRD studies. The redox behavior of the complexes has been studied by cyclic voltammetry. The antibacterial activity and preliminary DNA-binding ability of the complexes has also been studied.

Polyhedron 27 (2008) 2751

Mononuclear and binuclear iron(III) complexes incorporating N_4O_3 coordinating heptadentate ligand: Synthesis, structure and magnetic properties

The N_4O_3 coordinating heptadentate ligand afforded the mononuclear $[Fe^{III}(HL)][BPh_4]$ (**1**) and binuclear $[Fe_2^{III}L(OAc)_2][BPh_4]$ (**2**) complexes. In complex **1**, the ligand binds in a trianionic N_2O_3 fashion whereas in the case of **2** the ligand binds in the trianionic N_4O_3 form in which the iron ions are held together by μ-phenoxo and bis μ-acetato bridges. Complex **2** shows an intramolecular weak antiferromagnetic interaction. Gas phase geometry optimizations have been performed using density functional theory without any symmetry constraints.

Platinum(IV) complexes with purine analogs. Studies of molecular structure and antiproliferative activity *in vitro*

Here, we described the platimum(IV) complexes containing 1,2,4-triazolo[1,5-*a*]pyrimidine as carrier ligands. Their structures are characterized by multinuclear NMR, IR spectroscopy and X-ray analysis. The platinum(IV) complexation results in a large shielding of ^{15}N NMR signals of coordinated nitrogen atom (ca. 87–115 ppm) and proves that coordination of investigated 1,2,4-triazolo[1,5-*a*]pyrimidines occurs via N(3). In addition, $PtCl_4(dbtp)_2$ exhibits high cytotoxic activity and may be recommended for further preclinical studies.

Polyhedron 27 (2008) 2771

Synthesis, structure, and electrochemistry of pyridinecarboxamide cobalt(III) complexes; the effect of bridge substituents on the redox properties

Co(III) complexes of two substituted pyridine carboxamide ligands, Mebpb and cbpb, with two axial amine ligands have been synthesized and structurally characterized. The effect of methyl and chloro substitution on the redox properties, and the sensitivity of the Co^{III}–Co^{II} redox potentials to the donor strength of the axial ligands have been investigated. The irreversible Co(III/II) redox process becomes quasi-reversible in the presence of excess amine. The two redox waves, resulting from the combination of Co^{II}–Co^{I} couple and the redox couple corresponding to one of the pyridyl rings, overlap in $[Co(Mebpb)(amine)_2]^+$, but are resolved in $[Co(cbpb)(amine)_2]^+$ complexes.

Theoretical modeling of electrochemical interactions in bimetallic molybdenum nitrosyl complexes incorporating saturated bridges

DFT modeling for {Mo(NO)(Tp$^{3\text{-Me}}$)} binuclear complexes with ethane-1,2-diolate ligands provides direct evidence for electron localization in reduced species. Electron trapping is confirmed by geometric asymmetry, spin density distribution and the splitting of ν_{NO} stretching frequencies. In the doubly bridged complex 10% partial delocalization of unpaired electron occurs, while in the singly bridged one it is negligible.

Coordination studies of 5,6-diphenyl-3-(2-pyridyl)-1,2,4-triazine towards Cu^{2+} cation. X-ray studies, spectroscopic characterization and DFT calculations

The reactions of 5,6-diphenyl-3-(2-pyridyl)-1,2,4-triazine with $CuCl_2 \cdot 2H_2O$, $Cu(NO_3)_2 \cdot 3H_2O$ and $CuSO_4 \cdot 5H_2O$ have been examined, and four $[CuCl_2(dppt)]$ (**1**), $[CuCl_2(dppt)_2] \cdot 2MeOH$ (**2**), $[Cu(dppt)_2(H_2O)_2](NO_3)_2$ (**3**) and $[Cu(SO_4)(dppt)(H_2O)]_n \cdot nH_2O$ (**4**) complexes have been obtained. All the complexes have been structurally and spectroscopically characterized, and compound **4** has been additionally studied by magnetic measurement. The electronic structure of **1** has been calculated with the density functional theory (DFT) method, and the time-dependent DFT calculations have been employed to calculate the electronic spectrum of **1**.

Nickel, copper and zinc complexes of (2-methoxycarbonylmethylimino-5-methyl-thiazol-3-yl)-acetic acid

A disodium salt of (2-methoxycarbonylmethylimino-5-methyl-thiazol-3-yl)-acetic acid has been prepared from a thiamine derivative. This salt forms mononuclear or polynuclear complexes with nickel(II), copper(II) and zinc(II). In the mononuclear complex the dicarboxylate acts as a tridentate ligand, whereas in the polynuclear complex it acts as a tetradentate ligand.

Theoretical study of hydrogen bonded clusters of water and cyanic acid: Hydrogen bonding in terms of the molecular structure

Ab initio and density functional calculations were used to analyze the interaction between a molecule of cyanic acid (HOCN) and up to 4 molecules of water at the B3LYP/6-311++G(d,p) and MP2/6-311++G(d,p) computational levels. The cooperative effect (CE) is increased with the increasing size of the studied clusters. Red shifts of the H–O stretching frequency for complexes involving HOCN as an H-donor were predicted. The strength of the hydrogen bonds in terms of molecular structures could be deduced from a comparison of HOCN–H_2O with HCNO–H_2O, HONC–H_2O and HNCO–H_2O HB clusters. The atom in molecules (AIM) method was used to analyze the cooperative effects on topological parameters.

Complexes of *N*-thiophosphorylthiourea $(EtO)_2P(O)CH_2C_6H_4$-4-[NHC(S)NHP(S)(O*i*Pr)$_2$] with Zn(II), Cd(II), Co(II) and $Cu(PPh_3)(I)$

Reaction of *O,O*'-diisopropylthiophosphoric acid isothiocyanate $(iPrO)_2P(S)NCS$ with diethyl 4-aminobenzylphosphonate $(EtO)_2P(O)CH_2C_6H_4$-4-NH_2 leads to the new *N*-thiophosphorylated thiourea $(EtO)_2P(O)CH_2C_6H_4$-4-[NHC(S)NHP(S)-(O*i*Pr)$_2$] (**HL**). Reaction of the potassium salt of **HL** with Zn(II), Cd(II) and Co(II) in aqueous EtOH leads to complexes of formula M(L-*S*,*S*')$_2$ (**ML$_2$**). Heteroligand copper(I) complex of **HL** and triphenylphosphine was prepared by the reaction of the potassium salt **KL** and $Cu(PPh_3)_3I$. Copper in complex **Cu(PPh$_3$)L** is bound by one PPh_3 and one SCNPS fragmnet of the chelating ligand. Compounds obtained were investigated by IR, UV–Vis, ^1H and $^{31}P\{^1H\}$ NMR spectroscopy, and microanalysis. The structures of **HL** and **Cu(PPh$_3$)L** were investigated by single crystal X-ray diffraction analysis.

Seven-coordinate rhenium(III) complexes of 1-(2-pyridylazo)-2-naphtholate: X-ray studies, spectroscopic characterization and DFT calculations

The reactions of $[ReX_3(MeCN)(PPh_3)_2]$ (X = Cl or Br) with 1-(2-pyridylazo)-2-naphthol (HPAN) have been examined and the $[ReBr(PAN)_2]\cdot 2CHCl_3$ (**1**) and $[ReCl(PAN)_2]$ (**2**) complexes have been obtained. The both complexes have been structurally and spectroscopically characterized, and compound **1** has been additionally studied by magnetic measurements. The magnetic behavior is characteristic of mononuclear seven-coordinated Re(III) complex with d^4 low-spin configuration, which gives diamagnetic ground state. The electronic structure of $[ReBr(PAN)_2]$ has been calculated with the density functional theory (DFT) method. The time-dependent DFT calculations have been employed to calculate the electronic spectrum of $[ReBr(PAN)_2]$, and the UV–Vis spectra of the $[ReX(PAN)_2]$ compounds have been discussed on this basis.

Ruthenium–carbonyl complexes of 1-alkyl-2-(arylazo)imidazoles: Synthesis, structure, spectra and redox properties

$[Ru(CO)_2Cl_2(PaiR/TaiR)]$ are described in this work where PaiR or TaiR are 1-alkyl-2-(arylazo)imidazoles, acting as imidazole-N, azo-N chelating agents. One of the structures, $[Ru(CO)_2Cl_2(PaiEt)]$, has been characterized by its X-ray structure determination, which shows a *trans*-(Cl,Cl) arrangement. Addition of excess Me_3NO has synthesized the mono-carbonyl complex, $[Ru(CO)Cl_2(PaiR/TaiR)(NCMe)]$. The electronic spectra and redox properties of the complexes have been supported by DFT and TD-DFT calculations.

Coordination properties of some nickel(II) monophosphono dipeptides species in aqueous solution: The role of phosphonic oxygen in complex stabilization and ligand-fields analysis

Equilibrium studies on the nickel(II) complexes of some monophosphono dipeptides were performed by potentiometric titration and NIR–Vis spectroscopy. The ligand-field parameters (CFM/AOM) were estimated and discussed. The lowest tetragonal distortion was observed in the case of the [NiHL] species, whereas the strongest in the $[NiL_2]$ species. In nickel(II) complexes with Gly-(Bz)Cys(P) additional interaction between sulfur and nickel(II) was suggested.

Selenated Schiff bases of 2-hydroxyacetophenone and their palladium(II) and platinum(II) complexes: Syntheses, crystal structures and applications in the Heck reaction

Selenated Schiff bases 2-HO-$C_6H_4C(CH_3)$=$N(CH_2)_nSePh$ (n = 2, $\mathbf{L}^1$; n = 3, $\mathbf{L}^2$) and their complexes, [Pd($\mathbf{L}^1$–H)Cl] (**1**), [Pt($\mathbf{L}^1$–H)Cl] (**2**), [Pd($\mathbf{L}^2$–H)Cl] (**3**) and [Pt($\mathbf{L}^2$)Cl_2] (**4**), have been synthesized and characterized with proton carbon-13 and selenium-77 NMR spectra. On coordination of $\mathbf{L}^1$ and $\mathbf{L}^2$ the signals in the $^{77}Se\{^1H\}$ spectra undergo deshielding (by up to ~158 ppm). The single-crystal structures of $\mathbf{L}^1$, $\mathbf{L}^2$, **1** and **2** were solved. In the square planar complexes **1** and **2**, Pd/Pt–Se bond distances are 2.3683(11)–2.3654(10)/2.3549(15)–2.3536(17) Å. Complexes **1** and **2** are the first examples of crystal structures of Pd and Pt complexes of a (Se, N, O^-) ligand. Complex **1** catalyzes the Heck type C–C coupling reaction.

A general route for the synthesis of hydridocarboxylate complexes of the type MH(CO)-(κ^3-OCOR)(PPh_3)$_2$ [M = Ru, Os; R = CH_3, CH_2Cl, C_6H_5, $CH(CH_3)_2$] and their use as precatalysts for hydrogenation and hydroformylation reactions

Complexes MH(CO)(κ^3-OCOR)(PPh_3)$_2$ were obtained by reaction of the respective cationic complex [MH(CO)($NCMe$)$_2$(PPh_3)$_2$]BF_4 with the sodium salt of the corresponding carboxylic acid in a CH_2Cl_2/MeOH solution at room temperature. These complexes showed to be efficient precatalysts for the quinoline hydrogenation and for the hydroformylation of 1-hexene. The osmium complexes showed low activities for the benzothiophene hydrogenation whereas the corresponding ruthenium ones were inactive.

Polyhedron 27 (2008) 583

Syntheses and characterizations of four metal coordination polymers constructed by the pyridine-3,5-dicarboxylate ligand

Four new complexes based on divalent metal, pyridine-3,5-dicarboxylate acid ligand and two chelate ligands have synthesized under hydrothermal condition. The framework structures of these neutral polymeric complexes have been determined by the X-ray single crystal diffraction technique. In four complexes, pyridine-3,5-dicarboxylate acid ligand exhibits diverse coordination modes, which plays an important role in the construction of metal-organic frameworks. The thermal analyses of these four complexes are measured and discussed. In addition, complex **2** shows strong phosphorescent emission at room temperature and the magnetic measurement of polymer of **4** reveals that typical antiferromagnetic exchange.

Polyhedron 27 (2008) 602

Crystal structure and spectral characterization of hexanuclear oxo titanium(IV) clusters: $[Ti_6O_6(OSi(CH_3)_3)_6(OOCR)_6]$ (R = Bu^t, CH_2Bu^t, $C(CH_3)_2Et$)

Hexanuclear oxo titanium(IV) siloxo carboxylate complexes with the general formula $[Ti_6O_6(OSi(CH_3)_3)_6(OOCR)_6]$ (R = Bu^t (**1**), CH_2Bu^t (**2**), $C(CH_3)_2Et$ (**3**)) were synthesized in quantitative yield, by the reaction of $Ti(OSiMe_3)_4$ with the appropriate organic acid. Crystal structure determination revealed that molecules of **1**–**3** are composed of $[Ti_6\text{-}(\mu_3\text{-}O)_6]$ cores stabilized by six *syn–syn* carboxylato bridges and six terminal siloxide ligands. Each metal atom is surrounded by six oxo atoms, capping the triangular faces of the distorted octahedron. Spectral characterization (IR, NMR) of **1**–**3** revealed a significant non-equivalence of the carboxylate group interactions, resulting from the asymmetry of the Ti-μ-OOC bonds of the *syn–syn* bridges. The thermal stability of the studied compounds was determined from TGA/DTA analysis.

Polyhedron 27 (2008) 609

Oxidation of S(IV) by the dodecatungstocobaltate(III) ion over an extended pH range using acetic acid–acetate buffer: Different kinetics, oxidation product and mechanism

The reinvestigation of the title reaction over the extended pH range, 3.25 pH 6.3, has shown that the reaction is first-order in [Co(III)W]$^{5-}$, [SIV] and [M^+] where M^+ is the alkali metal ion, with SO_4^{2-} as the exclusive product. The alkali metal ions form ion-pairs with SO_3^{2-} and [Co(III)W]$^{5-}$ (abbreviation for 12-tungstocobaltate(III)) ions and also act as a bridge between the ion-pairs in the formation of the activated complex, the decomposition of which is rate limiting. A mechanism based on the above fact explains the kinetics results. Because of the nature of the rate dependence on M^+ and H^+, the application of the extended Marcus theory involving work terms could not be applied, but the application in its simple form does support that the reaction is outer-sphere.

A unique chain of trinuclear Cu(II) units containing both neutral and anionic *N*-(pyrimidin-2-yl) acetamide (Haapm, resp. aapm) as a ligand and dicyanamide (dca): Synthesis, characterization, X-ray structure and magnetism of $[Cu_3(\mu\text{-aapm})_2(\mu\text{-dca})_2(Haapm)_2]\text{-}(CF_3SO_3)_2$

A new trinuclear Cu(II) compound $[Cu_3\text{-}(\mu\text{-aapm})_2(\mu\text{-dca})_2(Haapm)_2](CF_3SO_3)_2$, containing the ligands *N*-(pyridin-2yl)acetamide (Haapm) and dicyanamide (dca) is reported. The dca anions are connected in an end-to-end fashion to a neighboring Cu(II) ion, forming in this way a chain of trinuclear units bridged by two dca anions.

Study of protonation and Zn(II), Cd(II), Cu(II) and Mn(II) complexation with a glutamic acid *N*-pyrimidine derivative: Crystal structure of a neutral Cd(II) complex of the bianionic ligand

Aminoacids N-5-nitroso-pyrimidine derivatives behave as bifunctional ligands whose pyrimidine residue reveals bipolar nature that favours adsorption at the arene centres of graphitic activated carbon and their behaviour as versatile ligands. Water reaction of N-2-(4-amino-1,6-dihydro-1-methyl-5-nitroso-6-oxo-pyrimidinyl)-glutamic acid with Cd^{2+} yields a molecular layered compound with $\{[Cd(HL)H_2O] \cdot 3H_2O\}_n$ units containing three different coordination modes ($^1\eta$, $\mu\text{–}^2\eta$ and $\mu\text{–}^3\eta$).

Extended structures of copper(II) complexes with 2-di1*H*-2-imidazolylmethylmalonate (DIMMAL), a versatile bis(imidazole)–bis(carboxylate) ligand: Solution studies, crystal structures and spectroscopic characterization

Copper(II) complexes of 2-di1*H*-2-imidazolylmethylmalonate (DIMMAL) have been studied by potentiometric methods. Beside this, the synthesis, characterization and structure solution of two new complexes based on this novel bis(imidazole)–bis(carboxylate) ligand are reported. Non-covalent interactions (H-bonds and π–π) drive the build-up of infinite three-dimensional arrays in both compounds.

Synthesis and characterization of three Cd(II) Schiff-base macrocyclic N_3O_2 complexes

Three polyamine ligands of N1-(2-nitrobenzyl)-N1-(2-aminoethyl)ethane-1,2-diamine (L_1), N1-(2-nitrobenzyl)-N1-(2-aminoethyl)-propane-1,3-diamine (L_2) and N1-(2-nitrobenzyl)-N1-(3-aminopropyl)propane-1,3-diamine (L_3) were synthesized and their cyclo-condensation with 2-[2-(2-formyl phenoxy)ethoxy]benzaldehyde (L_4) in the presence of various metal(II) ions was examined. These reactions only in the presence of a stoichiometric amount of cadmium(II) nitrate gave the related cadmium(II) macrocyclic Schiff-base complexes. In all the other cases no cyclic complexes have been obtained and metal(II) polyamines were the only products. The complexes have been studied with IR, ^1H NMR, ^{13}C NMR, DEPT, COSY, HMQC and microanalysis. The crystal structures of $[Cd(NO_3)(L_5)(\mu\text{-}NO_3)Cd(NO_3)(L_5)]0.5Cd(NO_3)_4$ (**1**) and $[CdL_5(NO_3)(CH_3OH)]ClO_4$ (**2**) have been also determined.

Spectral and structural studies of nickel(II) complexes of salicylaldehyde 3-azacyclothiosemicarbazones

Four nickel(II) complexes of salicylaldehyde *N*(4)-hexamethyleneiminyl thiosemicarbazone (H_2L^1) and two nickel(II) complexes of salicylaldehyde *N*(4)-pyrrolidine thiosemicarbazone (H_2L^2) have been synthesized and characterized by different physicochemical techniques. The complexes were given the formulae $[Ni(HL^2)_2]$ (**1**), $[NiL^2py]$ (**2**), $[NiL^2\alpha\text{-pic}]$ (**3**), $[NiL^2\gamma\text{-pic}] \cdot H_2O$ (**4**), $[NiL^4py]$ (**5**) and $[NiL^4\gamma\text{-pic}]$ (**6**). In complex **1**, the ligand moieties are coordinated as monoanionic (HL^-). The other complexes posses the stoichiometry NiLB, where B represents different bases, *viz.* pyridine and α/β/γ-picoline. The coordination geometry around nickel(II) in **2** and **3** is found to be distorted square planar in geometry with coordination of azomethine nitrogen, thiolato sulfur, phenolato oxygen and pyridyl nitrogen atoms.

Novel manganese (III) porphyrin containing peripheral "$[RuCl(dppb)(X\text{-bipy})]^+$" cations [dppb = 1,4-bis(diphenylphosphino)butane and X = $-CH_3$, –OMe, –Cl]. X-ray structure of the *cis*-$[RuCl(dppb)(bipy)(4\text{-Mepy})]PF_6$ complex

New tetraruthenated manganese (III) porphyrins were synthesized and characterized (^{31}P NMR, cyclic voltammetry, UV–Vis). This new system presents four units of cationic "$[RuCl(dppb)(X\text{-bipy})]^+$". The electrochemical and catalytic properties of the central manganese (III) show dependence on the characteristics of the peripheral ruthenium complexes as evidenced by the $Mn^{(III)}/Mn^{(II)}$ reduction potential.

New ferromagnetic dinuclear triply-bridged copper(II) compounds containing carboxylato bridges: Synthesis, X-ray structure and magnetic properties

Six new triply-bridged dinuclear copper(II) complexes containing carboxylato bridges have been reported and their magnetic properties studied. A structural classification of this type of dimers has been performed, based on the local five-coordinate geometry with different degrees of distortion and the relative arrangement of the two basal planes, giving rise to different classes (A–F) of complexes. The most logical explanations have been made for each class describing different magnetic interactions. Practically, the correlations between structural data and *J* values are found for some classes of complexes. Extended Hückel calculations were preformed for class B complexes, the results are found to be useful for the proper interpretation and correlation of the magnetic data and dimer structure of the present complexes.

Synthesis of polylactide using a zinc complex containing (*S*)-*N*-ethyl-*N*-phenyl-2-pyrrolidinemethanamine

The reaction between $ZnCl_2$ and (*S*)-*N*-ethyl-*N*-phenyl-2-pyrrolidinemethanamine (***S*-EPP**) as a chiral ligand affords [**$ZnCl_2$(*S*-EPP)**], whose structure has been determined by X-ray crystallography. [**$ZnEt_2$(*S*-EPP)**] has demonstrated high activity towards the polymerization of *rac*-lactide with a maximum turnover frequency (TOF) of 121. The observed heterotacticity was limited to under 0.6.

New antimony-capped iron(II) and cobalt(III) clathrochelate precursors of the polytopic hybrid cage complexes: Synthesis, X-ray structures and electrochemistry

Template macrocyclization on the iron(II) ion and the capping of K_3CoDm_3 complex with triethylantimony(V) derivatives afforded the triethylantimony-capped iron(II) and cobalt(III) tris-dimethylglyoximates, characterized using elemental analysis, mass, IR, UV–Vis, ^{57}Fe Mössbauer, NMR spectroscopies, and X-ray crystallography. The cyclic voltammograms show oxidation and reduction waves assignable to $Fe^{2+/3+}$ and $Co^{2+/3+}$ couples.

Anion dependent formation of linear trinuclear mixed valance cobalt(III/II/III) complexes and mononuclear cobalt(III) complexes of a pyrazole derived ligand – Synthesis, characterization and X-ray structures

Co(II) mediated anion dependent Schiff base complex formation was studied. Depending upon the proportion of 5-methylpyrazole-3-carbaldehyde (MPA), 1,3-diamino-2-propanol (DAP) and metal salts with different anions, two trinuclear linear pyrazolate bridged mixed valence Co(III/II/III) complexes and a few mononuclear Co(III) complexes were characterized.

Reactivity of oxorhenium(V) complexes towards 8-hydroxyquinoline-2-carboxylic acid: X-ray structure of $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)] \cdot MeCN$ and $[ReOCl_2(hquin\text{-}2\text{-}COOH)(PPh_3)] \cdot MeCN$ complexes. DFT and TDDFT calculations for $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]$

The reactions of $[ReOX_3(EPh_3)_2]$ with 8-hydroxyquinoline-2-carboxylic acid (Hhquin-2-COOH) have been examined and $[ReOX_2(hquin\text{-}2\text{-}COOH)(EPh_3)] \cdot MeCN$ (X = Cl, Br; E = As, P) complexes have been obtained. All the complexes were characterised by IR, UV–Vis spectroscopy and elemental analysis. The crystal and molecular structures have been determined for $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)] \cdot MeCN$ and $[ReOCl_2(hquin\text{-}2\text{-}COOH)(PPh_3)] \cdot MeCN$. The electronic structure of $[ReOCl_2(hquin\text{-}2\text{-}COOH)(AsPh_3)]$ has been calculated with the density functional theory (DFT) method, and TDDFT calculations have been employed to produce a hundred of singlet excited-states starting from the ground-state geometry optimized in the gas phase.

Synthesis of a new *N*,*N*′-ethane-1,2-bis-(4-methoxyphenyl)carbothioamide ligand and its Cu(I) and Ag(I) complexes

Complexes $[M(H_2L)(PPh_3)_2]NO_3 \cdot 0.5H_2O$, (M = Cu, Ag) formed with *N*, *N*′-ethane-1,2-bis(4-methoxyphenyl)carbothioamide (H_2L) have MS_2P_2 coordination and the ligand is bonded through the sulfur atoms forming a nine-membered chelate ring. The molecular packing in the copper(I) complex is dominated by hydrogen bonding offered by the NO_3^- ion and the basal plane of the CuS_2 chelate ring. The specific arrangement of two nitrate ions and two complex cations results in a rectangular shaped anionic channel.

Antiferromagnetic spin-coupling between Mn^{II} and amminium radical cation ligands: Models for coordination polymer magnets

A one-electron oxidation converts the triarylamine ligand of the complex $L_2Mn(hfac)_2$ (L = 4″,4‴-di-*tert*-butyl-2′,2″,2‴ trimethoxy-{4-(4′-diphenylaminophenyl)pyridine}) to the radical cation and gives an $S = 2$ system: $J/k_b = -1.5$ K. A two-electron oxidation converts both triarylamine ligands to the radical cation; $S = 3/2$: $J/k_b = -0.3$ K.

Imidazole-based bifunctional chelates for the "*fac*-$[Re(CO)_3]^+$" core

This paper presents the syntheses of tridentate bis-imidazole type ligands, and the study of their coordination chemistry with $[Re(OH_2)_3(CO)_3]Br$ or $(NEt_4)_2[ReBr_3(CO)_3]$ as Re(I) precursor compounds. Crystal structure evidence for one of the analogues shows that the tridentate ligand adopts a facial arrangement around the Re(I) ion, imposed by the *fac*-$[Re(CO)_3]^+$ core.

Polyhedron 27 (2008) 411

Novel octahedral nickel(II) dithiocarbamates with bi- or tetradentate *N*-donor ligands: X-ray structures of $[Ni(Bzppzdtc)(phen)_2]ClO_4 \cdot CHCl_3$ and $[Ni(Bz_2dtc)_2(cyclam)]$

A series of novel octahedral nickel(II) dithiocarbamate complexes involving bidentate nitrogen-donor ligands (phen or bpy) or a tetradentate ligand (cyclam) of the composition $[Ni(BzMetdtc)(phen)_2]ClO_4$ (**1**), $[Ni(Pe_2dtc)(phen)_2]ClO_4$ (**2**), $[Ni(Bzppzdtc)(phen)_2]ClO_4 \cdot CHCl_3$ (**3**), $[Ni(Bzppzdtc)(phen)_2](SCN)$ (**4**), $[Ni(BzMetdtc)(bpy)_2]ClO_4 \cdot 2H_2O$ (**5**), $[Ni(Pe_2dtc)(cyclam)]ClO_4$ (**6**), $[Ni(BzMetdtc)_2(cyclam)]$ (**7**), $[Ni(Bz_2dtc)_2(cyclam)]$ (**8**) and $[Ni(Bz_2dtc)_2(phen)]$ (**9**) have been synthesized. Broad spectrum of physical techniques, including X-ray analysis of **3** and **8**, proved the octahedral geometry in the vicinity of the nickel atom in all cases. The catalytic influence of complexes **2**, **3**, **6**, and **7** on graphite oxidation was studied and discussed.

Polyhedron 27 (2008) 420

Syntheses, characterizations and crystal structures of monomeric or macrocyclic compounds of di- or triorganotin (IV) moieties with 4,4′-thiodibenzenethiol

Six organotin compounds with 4,4′-thiodibenzenethiol (LH_2) of type $R_nSnL_{4-n}SnR_n$ (n = 3: R = Me **1**, Ph **2**, $PhCH_2$ **3**, n = 2: R = Me **4**, Ph **5**, $PhCH_2$ **6**) have been synthesized. All compounds were characterized by elemental analysis, IR and NMR (^1H, ^{13}C, ^{119}Sn) spectra. The structures of compounds **1**, **2**, **4**, **5** and **6** were also determined by X-ray diffraction analysis, which revealed that compounds **1** and **2** were monomeric structures, compounds **4**, **5** and **6** were centrosymmetric dinuclear macrocyclic structures, all the tin(IV) atoms are four-coordinated. Furthermore, supramolecular structures were also found in compounds **1**, **2**, **4**, **5** and **6**, which exist one-dimensional chains, two-dimensional networks or three-dimensional structure through intermolecular C–H···S weak hydrogen bonds (WHBs), non-bonded Sn···S interactions or C–H···π interactions.

Synthesis, structure, dehydration transformations and ion exchange characteristics of iron-silicate with various Si and Fe contents as mixed oxides

Iron silicate was obtained from iron oxide impregnated with silica in different Fe/Si molar ratios. Kinetics of dehydration transformation indicated a 1st order process for different silicate ratios. Application of the materials as ion exchangers showed a high affinity for ions of different charges on increasing the solution pH as well as with the silica content increasing.

Polyhedron 27 (2008) 440

Synthesis, spectral characterization of the zinc(II) mixed-ligand complexes of *N*(4)-allyl thiosemicarbazones and *N*,*N*,*N*′,*N*′-tetramethylethylenediamine, and crystal structure of the novel [ZnL_2(*tmen*)] compound

Mixed-ligand zinc complexes with *N*,*N*,*N*,*N*′-tetramethylethylenediamine (*tmen*) and R-salicylaldehyde N(4)-allyl thiosemicarbazones (R: 3-OCH_3 (L_1), 5-Br(L_2)), [$ZnL_{1,2}$(*tmen*)], were synthesized and the complexes were characterized by elemental, spectral and single crystal analysis. Crystal of [ZnL_2(*tmen*)] have a slightly distorted square pyramid involving O, N, S atoms of thiosemicarbazone and one N atom of *tmen* in basal plane and the other N atom of *tmen* in apex of the pyramid. The non-coordinated allyl group is disordered.

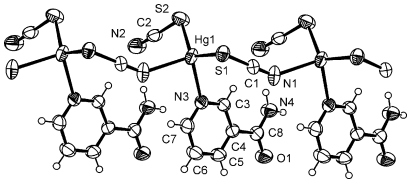
Synthesis, spectroscopic and structural investigation of $Zn(NCS)_2(nicotinamide)_2$ and $[Hg(SCN)_2(nicotinamide)]_n$

The nicotinamido (nia) complexes of the thiocyanates of zinc (**1**) and mercury(II) (**2**) were prepared and spectroscopically and thermally characterized, and their structures were determined by X-ray crystallography. The nia ligand acts as a monodentate ligand through the pyridine nitrogen. Compound **1** comprises of monomeric $[Zn(SCN)_2(nia)_2]$, while compound **2** of polymeric $[Hg(SCN)_2(nia)]_n$ units. Centrosymmetric H-bond dimers of $R_2^2(10)$ type in **1** and of $R_2^2(8)$ type in **2** are formed.



Corrigendum to "Three novel trinuclear zinc(II)/nickel(II) complexes with pentadentate ligands *N*-nitrobenzoylsalicylhydrazidate" [Polyhedron 26 (2007) 4793–4798]. 473
