ABSTRACT

Two mononuclear and one dinuclear copper(II) complexes, containing neutral tetradentate NSSN type ligands, of formulation $[Cu^{II}(L^1)Cl]ClO_4$ (**1**), $[Cu^{II}(L^2)Cl]ClO_4$ (**2**) and $[Cu^{II}_2(L^3)_2Cl_2](ClO_4)_2$ (**3**) were synthesized and isolated in pure form [where L^1 = 1,2-bis(2-pyridylmethylthio)ethane, L^2 = 1,3-bis(2-pyridylmethylthio)propane and L^3 = 1,4-bis(2-pyridylmethylthio)butane]. All these green colored copper(II) complexes were characterized by physicochemical and spectroscopic methods. The dinuclear copper(II) complex **3** changed to a colorless dinuclear copper(I) species of formula $[Cu^{I}_2(L^3)_2](ClO_4)_2{,}0.5H_2O$ (**4**) in dimethylformamide even in the presence of air at ambient temperature, while complexes **1** and **2** showed no change under similar conditions. The solid-state structures of complexes **1, 2** and **4** were established by X-ray crystallography. The geometry about the copper in complexes **1** and **2** is trigonal bipyramidal whereas the coordination environment about the copper(I) in dinuclear complex **4** is distorted tetrahedral.

1. Introduction

The potential role played by copper ions in the active sites of a large number of metalloproteins has stimulated efforts to design and characterize copper complexes as models for providing better understanding of biological systems and for assisting in the development of new homogeneous catalysts for selective oxidation. Particularly, the coordination chemistry and reactivity of copper complexes involving nitrogen–sulfur donor ligands has received considerable attention as models [1]. In particular the CuN_2S_2 chromophore is present in blue copper proteins such as plastocyanine [2] and copper(II) chelates of SNNS ligands have been found to have antineoplastic activities and to interact with biological systems [3].

Pursuing our continuous interest on nitrogen–sulphur polydentate chelators [4] and in addition of the importance of nitrogen–sulphur donor sets in the coordination chemistry of copper complexes, herein we report an account on the coordination properties of three neutral tetradentate ligands containing two pyridyl-N and two thioether-S donors. The mononuclear complexes **1** and **2** show penta-coordinated copper(II) ion with distorted trigonal bipyramid coordination geometry and the trigonality index (τ) of the solid-state structure increases (from 0.619 to 0.716) with the number of carbon atoms in the backbone of the ligands. The penta-coordinated copper(II) in the dinuclear green colored complex (**3**) is reduced to tetra-coordinated copper(I) species with concomitant change of color (colorless (**4**)) in dimethylformamide (DMF) even in the presence of air at ambient temperature within few days, while other complexes **1** and **2** show no change after several days. The single crystal X-ray structural analysis of **1, 2** and **4** are discussed and compared.

2. Experimental

2.1. Materials and physical measurements

All chemicals and reagents were obtained from commercial sources and used as received, unless otherwise stated. Tetra-*n*-butylammoniumperchlorate was prepared by addition of sodium perchlorate to a hot solution of tetra-*n*-butylammoniumbromide (Aldrich). The product was recrystallized from aqueous ethanol and tested for the absence of bromide. Solvents were distilled from an appropriate drying agent [5].

The C, H, N elemental analyses were performed on a Perkin Elmer model 2400 elemental analyzer. Copper analysis was carried out by Varian atomic absorption spectrophotometer (AAS) model-AA55B, GTA using graphite furnace. Electronic absorption spectra were recorded on a JASCO UV-Vis/NIR spectrophotometer model V-570 in the range of 1100–200 nm. IR spectra were obtained by JASCO FT-IR spectrometer model 460 *plus* using KBr disk. ^{1}HNMR spectra were recorded on a Bruker AC300 spectrometer

using TMS as an internal standard in $CDCl_3$. The room temperature magnetic susceptibility measurements were performed by using a vibrating sample magnetometer PAR 155 model. Molar conductance (Λ_M) were measured in a systronics conductivity meter 304 model using $\sim 10^{-3}$ mol L^{-1} solutions in acetonitrile. The measurement of pH of the reaction mixture was done with a systronics digital pH meter (Model 335). The separation and detection of the species in the reaction mixture were carried out using the hyphenated GC–MS system (Schimadzu, model GCMS-QP5050A). Electrochemical measurements were recorded on a computer controlled EG & G PAR model 270 VERSTAT electrochemical instruments using Ag/AgCl electrodes with TBAP as supporting electrolyte. All the measurements were made at 298 K with acetonitrile as solvent for complexes **1** and **2** and dimethylformamide for 3, using a concentration ca. 10^{-3}–10^{-4} M purged with dry nitrogen for 3–4 min in order to remove dissolved oxygen.

2.2. Preparation of the ligands

The syntheses of the ligands were carried out following the reported procedure [6] with slight modification. A common procedure has been performed to obtain the ligands. The procedure for the preparation of 1,2-bis(2-pyridylmethylthio)ethane, (L^1) is here described. An ethanolic solution of 2-picolyl chloride, hydrochloride (1.64 g, 10.0 mmol) was added to 1,2-ethandithiol (0.47 g, 5.0 mmol) in dry ethanol containing sodium ethoxide (0.46 g 20.0 mmol) at low temperature (0–5 °C). Then this mixture was allowed to stir at room temperature for 0.5 h and then it was refluxed for 2 h. The mixture was cooled to room temperature, water was added and finally the ethanol was off by rotary evaporator. The product was extracted into dichloromethane and dried by using $NaHSO_3$. The product, 1,2-bis(2-pyridylmethylthio)ethane (L^1) was obtained as a yellow oil by removing the dichloromethane by rotary evaporator. The other products were also obtained as liquids. Finally the products were verified by ^1H NMR spectroscopy.

2.3. Preparation of the copper(II) complexes

The copper(II) complexes were synthesized following a common procedure as described below, using copper(II) perchlorate hexahydrate and the respective organic compounds in equimolar ratio. For complex **1**, L^1 (276.0 mg, 1.0 mmol), for complex **2**, L^2 (292.0 mg, 1.0 mmol) and for complex **3**, L^3 (306.0 mg, 1.0 mmol) were mixed with 1.0 mmol of copper(II) perchlorate hexahydrate, and the mixture was stirred for 4 h in methanol. Then sodium chloride (1.0 mmol) was added to the resulting mixture and stirred for another 1 h at room temperature. The green coloured complexes were precipitated out and the solid complexes were filtered, washed with water, cold methanol and dried in vacuo. Yield: 84–85%.

2.4. Preparation of the copper(I) complex of 1,4-bis(2-pyridylmethylthio)butane (**4**)

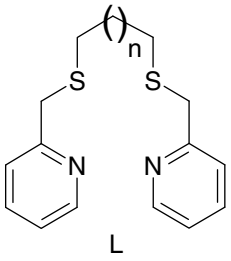
The solution of complex **3** in DMF was stirred for 1 h at room temperature in presence of air. After few days, the colorless single crystals of complex **4** were collected by slow evaporation of this solution

$[Cu_2(L^3)_2](ClO_4)_2,0.5H_2O$ (**4**): *Anal.* Calc. for $C_{32}H_{41}Cl_2Cu_2N_4O_{8.5}S_4$: C, 40.68; H, 4.34; N, 5.93, Cu, 13.45. Found: C, 40.01; H, 4.21; N, 5.88; Cu, 13.34%. IR (cm^{-1}): $\nu_{C=N}$, 1479; ν_{C-S}, 758; ν_{ClO4}, 1092 and 623.

2.5. X-ray crystal structure analysis

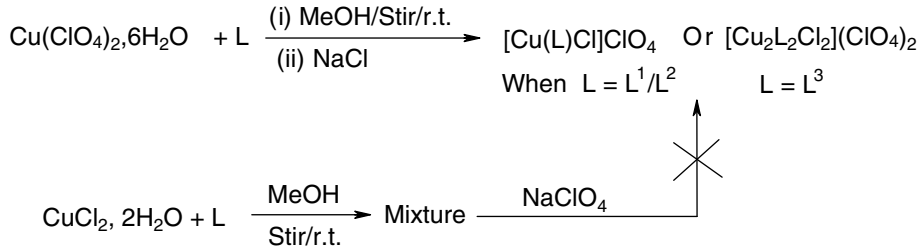
Single crystals suitable for X-ray diffraction analysis were grown by slow evaporation of acetonitrile solutions of complex **1** and **2** at ambient temperature, while crystals of complex **4** were obtained from dimethylformamide solution of copper(II) complex **3** by slow evaporation at room temperature in presence of air.

Crystal data and details of data collections and refinements for the structures reported are summarized in Table 1. Diffraction data of **1** and **2** were collected at 150(2) K on Oxford Diffraction X-Calibur CCD System, data collection of **4** were carried out, at room temperature, on a Nonius DIP-1030H system, by using Mo Kα radiation, $\lambda = 0.71073$ Å in both cases. Cell refinement, indexing and scaling of all the data sets were performed using programs Crys Alis [7], Denzo and Scalepack [8]. All the structures were solved by direct methods and subsequent Fourier analyses and refined by the full-matrix least-squares method based on F^2 with all observed reflections [9]. A residual in the difference Fourier map of **4**, located on a two-fold axis, was assigned to a water oxygen with occupancy 0.25. The contribution of hydrogen atoms at calculated positions were included in final cycles of refinement. All the calculations were performed using the WinGX System, Ver 1.70.01 [10].



3. Result and discussion

3.1. Synthesis and characterization



The organic compounds (L) were synthesized by the reaction of the respective alkyl dithiol compound with 2-picolyl chloride in

Scheme 1. Ligands and the reaction procedure.

presence of sodium ethoxide. These organic moieties have been confirmed by ^{1}H NMR spectral analyses. The five coordinated Cu(II) complexes with NSSN donor centers of these ligands and one chloride ion (**1, 2** and **3**) were obtained in good yield from the reaction of copper(II) perchlorate with equimolar amounts of the respective organic moieties in the methanol medium followed by the addition of aqueous sodium chloride solution at ambient temperature according to Scheme 1. Here, the sequence of the addition of anions along with Cu(II) ions to the ligand solutions is crucial. In the preparation of the complexes, it was found that the identity of the anion used was important. Thus the present complexes were obtained only when copper(II) perchlorate was used. A different series of copper(II) complexes were formed containing the decomposed product of these organic moieties and precipitated out from the reaction mixture when the organic moieties were allowed to react with copper(II) chloride in the first step. Characterization of these copper(II) complexes is in progress.

Here both monomeric **1** and **2** complexes are soluble in acetonitrile and DMF but sparingly soluble in methanol, ethanol and dichloromethane, while **3** is dimeric and soluble in DMF. At room temperature the magnetic moment (μ) of **1** and **2** is 1.81 and 1.79 B.M., respectively, while for **3** it is 1.40 B.M. per copper atom. The conductivity measurement of complexes **1** and **2** in acetonitrile shows the conductance values of 145 and 140 Λ_o mol^{-1} cm^{-1} respectively and while that of **3** in DMF is 150 Λ_o mol^{-1} cm^{-1} at 300 K. These values suggest that complexes **1** and **2** exist as 1:1 electrolytes and **3** as a 1:2 electrolyte in solution.

3.2. Structures of the Cu(II) complexes *1* and *2*

The ORTEP views of **1** and **2** with the atom numbering schemes are illustrated in Figs. 1 and 2, respectively, and a selection of bond distances and angles are listed in Table 2. In both mononuclear complexes, the copper center is coordinated by the tetradentate donor organic moiety and by a monodentate chloride ligand, but with a different geometrical disposition of the NSSN ligand in **1** and **2**. In fact, the highly distorted trigonal bipyramidal geometry about copper (II) shows axial positions occupied by the pyridyl-N donors in **1**, with chlorine and both thioether sulphur in the equatorial plane. On the other hand, in **2**, a pyridyl-N and a thioether-S reside at the axial positions, the equatorial plane consisting of the chlorine, the other pyridyl-N and thioether-S atoms. The almost

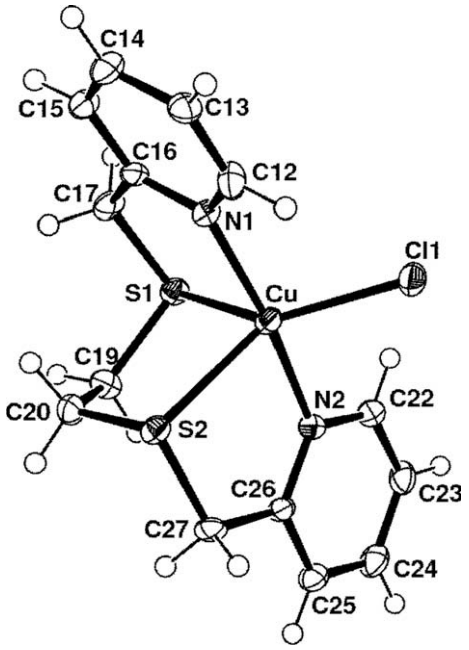

Fig. 1. ORTEP view of the cation in [Cu(L^1)Cl]ClO$_4$ (**1**) with labeling scheme.

trigonal bipyramid geometry present in complexes **1** and **2** is demonstrated by the trigonality index [11] τ of 0.619 and 0.716, respectively.

Coordination bond angles listed in Table 2 indicate large variation from the ideal geometry, especially for the atoms in the equatorial plane, indicating the strained suffered by the ligand coordinating the metal ion. In **1**, both axial bond distances Cu–N1 and Cu–N2 are comparable with their s.u. (2.006(3) and 1.994(3) Å, respectively), but in **2**, the axial Cu–N2 bond length (1.992(3) Å) is significantly shorter than the equatorial one (Cu–N1 of 2.076(3) Å) as the two pyridyl-N donors occupy different positions in the copper coordination sphere. It is worth noting that the Cl atom, located in equatorial position both in **1** and **2**, shows Cu–Cl bond length of 2.270(1) Å in **1**, and significantly longer in **2** (2.441(1) Å). The trend in Cu–Cl bond lengths follows

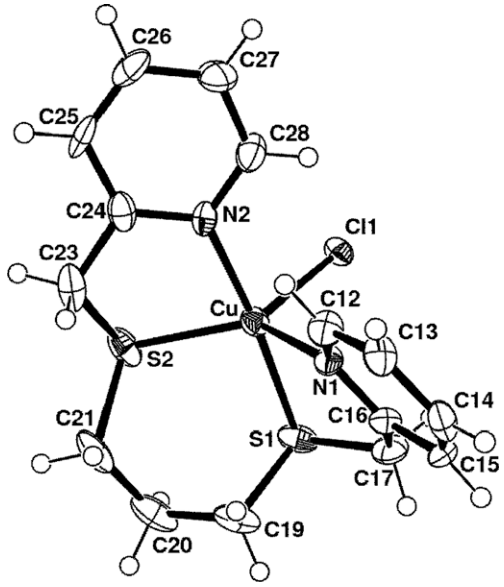

Fig. 2. ORTEP view of the molecular cation in $[Cu(L^2)Cl]ClO_4$ (**2**) with labeling scheme.

a reverse order with respect to the Cu–S bond distances (Table 2), which average to 2.436 Å in **1** and 2.280 Å in **2**. The Cu–Cl distance in **1** is within the range found in complexes $[Cu(L)Cl]^+$ [12], where L ligand is close comparable to L^1 by replacing pyridine by imidazolyl rings. Thus the addition of a methylene group inside the ligand leads to different donor atom arrays in **1** and **2** with a significant change in the structural geometry, likely attributable to steric constraint. This feature has been already observed by Reedijk for analogous NSSN ligands containing imidazolyl rings [11,12].

3.3. Reactivity of *3* and structure of the Cu(I) complex *4*

A colourless dinuclear copper(I) complex of formula $[Cu^I_2(L^3)_2](ClO_4)_2$, $0.5H_2O$ (**4**) was obtained from the solution of copper(II) complex (**3**) in DMF at ambient temperature in presence of air or in nitrogen atmosphere. On the other hand, the monomeric copper(II) complexes **1** and **2** in DMF showed no change *via* this type of reduction in nitrogen atmosphere even at elevated temperature. Here, 1,4-bis(2-pyridylmethylthio)butane (L^3) plays key role in DMF as no change has been observed in case of **1** and **2** under the same condition. This behavior is quite different from the observations where the ligand itself behaved as reducing agent [13,14].

Here, at the first step, DMF was hydrolysed in presence of the dimeric copper(II) complex (**3**) and in this reaction, formic acid and dimethylamine are formed as the hydrolytic products of DMF. Then formic acid as reducing agent, reacts with $[Cu_2^{II}(L^3)_2Cl_2](ClO_4)_2$ (**3**) to produce $[Cu_2^{I}(L^3)_2](ClO_4)_2$ (**4**), CO_2 and HCl. The other hydrolytic product dimethylamine reacts with HCl to form $[Me_2NH_2]Cl$. The proposed path was established following the pH decreasing of the reaction mixture associated with a colour change from blue to colourless. This observation indicates that the production of H^+ takes place in the reaction mixture and after 24 h, the pH of the solution remained unaltered. The steps of the reactions are as follows:

$$2Me_2NCHO + 2H_2O \rightarrow 2HCOOH + 2Me_2NH$$
$$2HCOOH + [Cu_2^{II}(L^3)_2Cl_2]^{2+} \rightarrow 2CO_2 + [Cu_2^{I}(L^3)_2]^{2+} + 2HCl$$
$$2Me_2NH + 2HCl \rightarrow 2\,[Me_2NH_2]Cl$$
$$2Me_2NCHO + [Cu_2^{II}(L^3)_2Cl_2]^{2+} + 2H_2O \rightarrow 2CO_2 + [Cu_2^{I}(L^3)_2]^{2+} + 2\,[Me_2NH_2]Cl$$

The presence of the HCOOH and $[Me_2NH_2]Cl$ was confirmed through GC–MS by injecting the reaction mixture into GC and detecting by mass spectrometry. Again the presence of chloride ion in the reaction mixture was confirmed as we got the precipitation of AgCl by adding a silver nitrate solution and the production of CO_2 was detected using saturated $Ca(OH)_2$ solution. The complex **4** was characterized by physicochemical tools and the molecular structure was established by single-crystal X-ray crystallography.

The reduction of the other copper(II) complexes (**1** and **2**) was observed when these species were allowed to react with formic acid but the first step of hydrolysis in DMF was not observed.

An ORTEP view of the cation of **4** with the atom numbering scheme is illustrated in Fig. 3, while a selection of bond distances and angles is listed in Table 2. The crystal structure consists of dinuclear complexes, located about a crystallographic two fold axis, and perchlorate anions. Thus the flexible NSSN ligand acts as a bis chelating agent towards the symmetry related metal ions which are separated by 8.089(2) Å. The copper exhibits a highly distorted tetrahedral coordination geometry, as evident from the coordination bond angles reported in Table 2. The Cu–S bond lengths are 2.344(2) and 2.402(3) Å, within the range measured in **1** and **2**, while the Cu–N distances are 2.032(6) and 2.008(6) Å. The chelating angles N–Cu–S (85.88(6) and 84.88(7)°) are comparable to those observed in **1** (84.58(9), 83.44(9)°), but larger than the values of **2** (81.98(8), 81.66(8)°), likely induced by the different coordination geometry in the latter species. The torsion angle of 162.6(9)° along the alkyl C atoms (anti conformation) indicates no strain in ligand L^3.

3.4. Spectral properties

Infrared spectra of all the complexes **1–4** exhibit an intense band at approximately 1090 cm^{-1} along with a weak band at 624 cm^{-1}, which have been assigned to $\nu_{s(ClO4)}$ and $\nu_{as(ClO4)}$ respectively. The $\nu_{C=N}$ band is observed at 1465–1478 cm^{-1} for all the complexes, in addition to the ν_{C-S} at 760 cm^{-1}.

The electronic absorption spectra of the complexes **1, 2** and **3** were recorded at room temperature using acetonitrile (for **1** and **2**) and dimethylformamide (for **3**) as solvent and the data has been

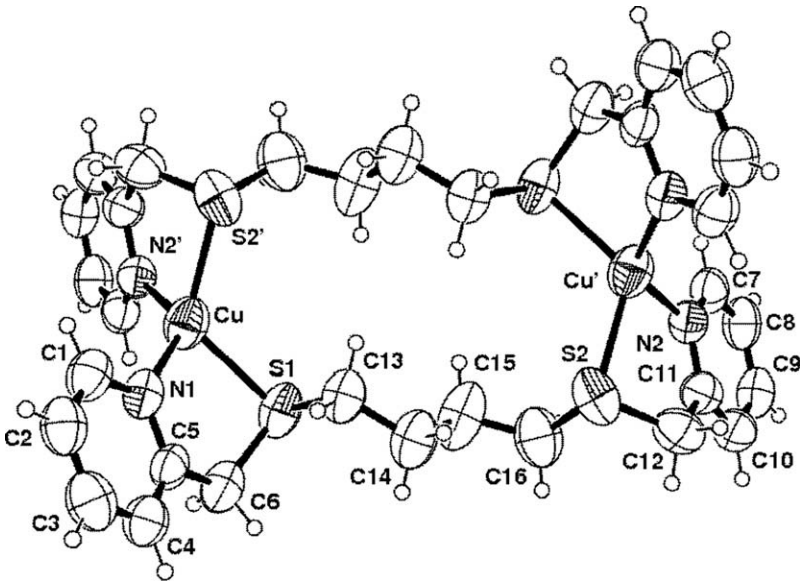

Fig. 3. ORTEP drawing of the molecular cation in $[Cu_2(L^3)_2](ClO_4)_2 \cdot 0.5H_2O$ (**4**) with labeling scheme of the crystallographic independent atoms.

tabulated in Table 3. All the spectra exhibit a band around 360 nm assignable to the $S(\sigma) \rightarrow Cu(II)$ charge transfer (LMCT) transition [15] along with the transition at high energy region corresponding to intramolecular $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions [16]. A characteristic d-d absorption band (above 640 nm) has been also observed in the electronic spectra of these complexes. In the electronic spectra of complex **2,** a high-energy shoulder at 626 nm along with the characteristic d–d band at 667 nm is present and this result emphasizes that the stereochemistry of the complex **2** in the solution state shows a typical trigonal bypyramidal geometry, as in many cases it has been shown that the presence of a single d–d band with high energy (low wave length) shoulder is typical of this stereochemistry for copper [17].

3.5. Electrochemistry

Redox properties of complexes **1**, **2** and **3** were examined by cyclic voltammetry using a Pt-disk working electrode and a Pt-wire auxiliary electrode in dry MeOH and in presence of $[n\text{-}Bu_4N]ClO_4$ as supporting electrolyte. The potentials (Table 3) are expressed with reference to Ag/AgCl electrodes. In solution all compounds displayed a quasi-reversible voltammogram having $i_{pc}/i_{pa} \approx 1$ in the range of −340 mV to −387 mV with ΔE = 132–294 mV. Only one quasi-reversible Cu(II)/Cu(I) redox couple at negative potential was observed and it indicates that the similar chemical environment of the two copper ions in dinuclear complex **3** towards the electrochemical properties.

4. Conclusion

Here, three tetradentate N_2S_2 neutral ligands (where L^3 is hitherto new) have been used to synthesize copper(II) complex having CuN_2S_2 chromophore. The addition of methylene group inside the ligand backbone leads to a significant change in the structural geometry and the chemistry of the organic moieties with copper. When the four methylene groups are present between the thioether-S donor atoms (in case of L^3), the chemistry of L^3 with copper is different from that of L^1 and L^2. The reduction of copper(II) in **3** resulted a new colorless dinuclear copper(I) complex of formula $[Cu^I_2(L^3)_2](ClO_4)_2$, $0.5H_2O$ (**4**) in DMF at ambient temperature in presence of air, where the complex **3** plays a key role in DMF as the complex is dimeric complex of L^3. On the other hand, the monomeric copper(II) complexes **1** and **2** in DMF showed no change *via* this type of reduction in nitrogen atmosphere even at elevated temperature.

ABSTRACT

Several copper(I) and zinc(II) complexes with 8-(diphenylphosphino)quinoline (PPh_2qn) or 8-diphenylphosphinoquinaldine (PPh_2qna) have been prepared. These ligands contain both imine and phosphine moieties, which can act as coordinating groups. X-ray analysis of the Cu(I) complexes reveals that $[Cu(PPh_2qn)_2]PF_6$ (**Cu-1**) and $[Cu(PPh_2qn)_2]PF_6$ (**Cu-2**), coordinated by two PPh_2qn and PPh_2qna ligands respectively, are obtained. In the Zn(II) complexes, a structural study shows that $[ZnCl_2(PPh_2qn)]$ (**Zn-1**), $[ZnBr_2(PPh_2qn)]$ (**Zn-2**) and $[ZnI_2(PPh_2qn)]$ (**Zn-3**) are coordinated by one PPh_2qn ligand and two of the corresponding halogeno ligands (Cl^-, Br^- and I^-). In the solid state **Cu-1** and **Cu-2** show luminescence which is assigned to a ^{3}MLCT transition involving π^* of the quinoline group, as shown in the $[Cu(dmp)(diphosphine)]^+$ complexes; due to the reduced bulkiness of the coordination sphere around the copper atom, no emission is observed in solution. **Zn-1** shows a similar emission band to that of free PPh_2qn at both room temperature and 77 K. It suggests the emission bands should be assigned to a ligand-centered (LC) transition. In the solid state, it is found that the emissive energy of the complexes shift to lower energy and the energy depends on the halogeno ligands in the zinc complexes.

1. Introduction

Much attention has been paid to emissive copper(I) complexes containing polypyridine and/or phenanthroline ligands as candidates for practical components for chemical sensors, display devices and solar-energy conversion schemes [1]. In contrast to the hitherto reported heavy metal complexes, the copper-based system is promising due to the comparative cost advantage. Recently, extensive studies of some mixed-ligand copper(I) complexes involving both imines and phosphines have been reported [2–6]. $[Cu(dmp)(DPEphos)]^+$ (DPEphos = bis[2-(diphenylphosphino)-phenyl]ether) exhibits an unprecedented high quantum yield and a long lifetime in CH_2Cl_2 at room temperature [3,4]. Armaroli et al. and our group have also studied the emissive properties of the mixed-ligand $[Cu(dimine)(diphosphine)]^+$ type complexes coordinated by a diimine ligand such as dmp and several types of diphosphine ligand [5,6]. As other alternatives to heavy metal complexes, several zinc(II) complexes with quinoline groups are potentially promising as luminescent probes and as emissive compounds in electroluminescent devices [7,8].

8-Quinolylphosphine derivatives, which have both imine and phosphine moieties, can act as bidentate ligands. Structural studies of several transition metal complexes with 8-diphenylphosphinoquinoline(PPh_2qn) (Chart 1, left) have been reported [9–11]. Photochemical and photophysical properties of several mixed-ligand ruthenium(II) polypyridine complexes with 8-quinolylphosphines have been investigated [12]. It is expected that copper(I) complexes containing this type of ligand can also behave as good emitters, because the ligands have both diimine and phosphine character. As a similar system, dinuclear copper(I) complexes bridged by 2-(diphenylphosphino)pyridine (PPh_2py) ligands have been reported [13]. However, the dinuclear complexes do not keep a rigid structure in solution due to coordination of donor solvent as well as a PPh_2py exchange process. In contrast, PPh_2qn, which can coordinate to a metal center in a chelate fashion, appears to provide discrete compounds even in solution.

We found that the $[Cu(PPh_2qn)_2]^+$ complex is readily prepared and shows emission in the solid state. In this study, the luminescence of such copper(I) complexes with phosphinoquinoline derivatives has been examined. In addition, treatment of zinc

halogenide with PPh_2qn readily gave the corresponding [ZnX_2-(PPh_2qn)] complexes (X = Cl, Br and I). Zinc complexes coordinated by phosphorus atoms are rare. The luminescence of these complexes are observed in both CH_2Cl_2 solution and in the solid state. In this work, the photophysical properties of the complexes are described in detail.

2. Experimental

2.1. General

8-(Diphenylphosphino)quinoline (PPh_2qn) [14] and [$Cu(CH_3CN)_4$]PF_6 [15] were prepared by the literature methods. 8-(Diphenylphosphino)quinaldine (PPh_2qna) (Chart 1, right) was synthesized by a similar method to that of PPh_2qn, with the use of 8-chloroquinaldine [16]. Each zinc halogenide was purchased from WAKO Chemical Co. Ltd. All reactions were carried under an argon atmosphere using Schlenk techniques until air-stable solid complexes were obtained. Elemental analyses of the complexes were performed on a Perkin Elmer model 2400 CHN analyzer. NMR spectra were obtained using a JEOL Λ-400 spectrometer, in which the chemical shifts are referenced to tetramethylsilane (^1H; as internal) or 85% H_3PO_4 ($^{31}P\{^1H\}$; as external). Absorption and emission spectra were measured with an Agilent 8453 spectrometer and a Shimadzu RF-5000 fluorometer, respectively.

2.2. General procedure to prepare the Cu complexes

PPh_2qn (58 mg, 0.184 mmol) or PPh_2qna (60 mg, 0.183 mmol) was added to a solution of [$Cu(CH_3CN)_4$]PF_6 (34 mg, 0.092 mmol) in $CHCl_3$ (10 ml). The mixture was continuously stirred for 1 h, then the solution was evaporated to a small volume. Addition of diethyl ether to the solution afforded a pale orange precipitate.

[Cu(PPh_2qn)$_2$]PF_6 (Cu-1): Yield: 51 mg (66%). *Anal.* Calc. for [$Cu(C_{21}H_{16}NP)_2$]PF_6 C, 60.40; H, 3.86; N, 3.25. Found: C, 60.22; H, 3.70; N, 3.22%. ^1H NMR ($CDCl_3$) δ 8.49 (d, 1H), 8.18 (d, 2H), 7.96 (d, 1H), 7.79 (t, 1H), 7.31–7.48 (m, 11H). ^{31}P NMR ($CDCl_3$): δ −16.1 (br).

[Cu(PPh_2qna)$_2$]PF_6 (Cu-2): Yield: 48 mg (56%). *Anal.* Calc. for [$Cu(C_{22}H_{18}NP)_2$]PF_6: C, 61.22; H, 4.20; N, 3.25. Found: C, 59.77; H, 4.04; N, 3.07%. ^1H NMR ($CDCl_3$) δ 8.42 (d, 1H), 8.16 (d, 1H), 7.83–7.87 (m, 1H), 7.72 (t, 1H), 7.47 (d, 1H), 7.14–7.20 (m, 10H), 2.0 (s, 3H). ^{31}P NMR ($CDCl_3$): δ −19.2 (br).

2.3. General procedure to prepare the Zn complexes

A solution of $ZnCl_2$, $ZnBr_2$ or ZnI_2 (1.0 mmol) in ethanol (5 ml) was dropped into a solution of PPh_2qn (0.157 g, 0.5 mmol) dissolved in 5 ml $CHCl_3$. The precipitated white powder was filtered and washed with a small amount of ethanol.

[$ZnCl_2$(PPh_2qn)] (Zn-1): Yield 0.15 g (67%). *Anal.* Calc. for [$ZnCl_2(C_{21}H_{16}NP)$]: C, 56.10; H, 3.59; N, 3.12. Found: C, 55.30; H, 3.34; N, 2.96%. ^1H NMR ($CDCl_3$) δ 9.21 (d, 1H), 8.54 (d, 1H), 8.16 (d, 1H), 7.99 (t, 1H), 7.80 (br, 2H), 7.66–7.70 (m, 4H), 7.47–7.53 (m, 6H). ^{31}P NMR ($CDCl_3$): δ −34.3

[$ZnBr_2$(PPh_2qn)] (Zn-2): Yield 0.18 g (67%). *Anal.* Calc. for [$ZnBr_2(C_{21}H_{16}NP)$]: C, 46.84; H, 2.99; N, 2.60. Found: C, 55.30; H, 3.34; N, 2.96%. ^1H NMR ($CDCl_3$) δ 9.23 (d, 1H), 8.54 (d, 1H), 8.17 (d, 1H), 7.99 (t, 1H), 7.79–7.83 (m, 2H), 7.66–7.70 (m, 4H), 7.46–7.53 (m, 6H). ^{31}P NMR ($CDCl_3$): δ −36.0.

[ZnI_2(PPh_2qn)] (Zn-3): Yield 0.12 g (38%). *Anal.* Calc. for [$ZnI_2(C_{21}H_{16}NP)$]: C, 39.88; H, 2.55; N, 2.21. Found: C, 55.30; H, 3.34; N, 2.96%. ^1H NMR ($CDCl_3$): δ 9.29 (d, 1H), 8.55 (d, 1H), 8.18 (d, 1H), 7.98 (t, 1H), 7.81–7.84 (m, 2H), 7.65–7.70 (m, 4H), 7.45–7.53 (m, 6H). ^{31}P NMR ($CDCl_3$): δ −37.3.

2.4. X-ray measurements

X-ray crystallographic measurements were made on a Rigaku AFC-5S (for **Cu-1**, **Cu-2** and **Zn-1** at 296 K) or a Rigaku Saturn 70 CCD area detector (for **Zn-2** and **Zn-3** at 123 K) with graphite-monochromated Mo Kα radiation. Absorption corrections were made by the numerical method. Each structure was solved by direct methods (SIR92 [17]) and refined by full matrix least square procedures (SHELXL-97 [18]). The non-hydrogen atoms were refined anisotropically and the hydrogen atoms were fixed at calculated positions. All calculations were carried out by CRYSTAL STRUCTURE software.[1]

3. Results and discussion

3.1. Preparation and characterization of the Cu(I) complexes

Since PPh_2qn has both phosphine-P and imine-N donor atoms, the coordination of two PPh_2qn ligands to the copper(I) ion leads to a similar structure to that of mixed-ligand complexes with diphosphine and diimine ligands. The reaction of [$Cu(CH_3CN)_4$]PF_6 with a two equivalent molar amount of PPh_2qn in $CHCl_3$ readily gave a pale yellow powder of the bis-PPh_2qn copper(I) complex **Cu-1**. The product was identified by elemental analysis and ^1H and $^{31}P\{^1H\}$ NMR spectra. The ^1H NMR spectrum of **Cu-1** shows a symmetric signal set; *e.g.* only one doublet assigned to the proton in the 2-position on a quinoline ring at δ 8.5 appeared The ^{31}P NMR spectrum of **Cu-1** shows a relatively broad signal at δ −16.1, whereas the signal of free PPh_2qn is sharp at δ −17.0. If the signal broadening results from a rapid exchange between the coordination and dissociation of a PPh_2qn ligand in solution, lowering the temperature may cause further broadening based on the splitting of signals assigned to the coordinated and the free ligand. However, the measurement of the ^{31}P NMR spectrum at −40 °C shows a slight sharpening of the signal. So the signal broadening could result from quadrapolar relaxation arising from the copper nucleus, which has been observed for $[Cu(dmpe)]^+$ (dmpe = 1,2-bis(dimethylphosphino)ethane) [19].

Single crystals suitable for X-ray analysis were obtained by slow diffusion of diethylether into an acetone solution of the complex. The molecular structure of [$Cu(PPh_2qn)_2$]PF_6 is illustrated in Fig. 1, and detailed crystallographic data are shown in Table S1. In this complex, the copper atom is coordinated by two bidentate PPh_2qn ligands and has a four-coordinate structure with tetrahedral geometry. Selected bond lengths and angles are summarized in Table 1. The bond lengths of Cu–P are 2.220(1) and 2.229(1) Å. The bite angles for the chelate ring formed by the two PPh_2qn ligands are 87.4(1)° and 86.4(1)°, which are comparable to the other complexes containing PPh_2qn [12b]. The chelate rings are almost planar, as is evident from the torsion angles of Cu–P(1)–C(7)–C(8) (2.4(3)°) and Cu–N(1)–C(8)–C(7) (0.3(5)°). The P–Cu–P bond angle is 131.12(5)°, which is similar to that of [Cu(dmp)(DPEphos)]BF_4. One quinoline ring is arranged parallel to the quinoline ring on an adjacent molecule, and the interplanar distance between the quinoline rings is 3.6 Å.

The reaction of PPh_2qna instead of PPh_2qn with [$Cu(CH_3CN)_4$]PF_6 gave **Cu-2**. This product was also identified by elemental analysis and ^1H and $^{31}P\{^1H\}$ NMR spectra. Just as the case of **Cu-1**, a symmetrical signal set for **Cu-2** in the ^1H NMR spectrum was obtained. A methyl singlet of **Cu-2** was observed at δ 2.00, which is shifted to higher field compared to that of free PPh_2qna (δ 2.57)

[1] CrystalStructure, ver.3.60: Single Crystal Structure Analysis Software, Molecular Structure Corporation.

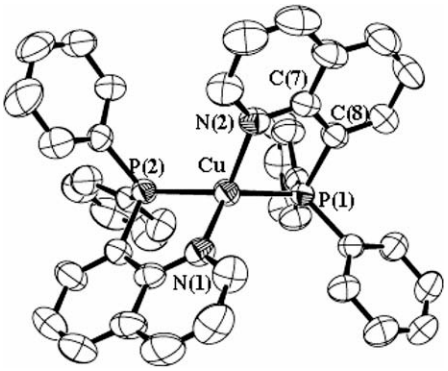

Fig. 1. ORTEP structure of **Cu-1**.

Table 1
Selected bond lengths (Å) and angles (°) for **Cu-1** and **Cu-2**.

Cu-1		**Cu-2**	
Cu–P(1)	2.220 (1)	Cu–P(1)	2.227 (2)
Cu–P(2)	2.229 (1)		
Cu–N(1)	2.071 (4)	Cu–N(1)	2.081 (3)
Cu–N(2)	2.073 (4)		
P(1)–Cu–P(2)	131.12 (5)	P(1)–Cu–P(1)*	118.27 (8)

P(2)–Cu–N(1)	86.4 (1)		

on coordination. The ^{31}P NMR spectrum of **Cu-2** shows a relatively broad signal at δ −19.23.

The crystals of **Cu-2** for X-ray analysis were obtained by slow diffusion of diethylether into a chloroform solution of the complex. The structure of $[Cu(PPh_2qna)_2]PF_6$ is illustrated in Fig. 2. Just as in the case of **Cu-1**, the copper atom coordinated by two PPh_2qna ligands has a four-coordinate structure with a tetrahedral geometry, however the crystal of **Cu-2** has different space group, *C*2/*c*, compared to $P2_1/c$ for **Cu-1**, as shown in Table 1. A twofold axis goes through the copper atom. Selected bond lengths and angles are summarized in Table 2. The Cu–P and Cu–N bond lengths are 2.227(2) and 2.081(3) Å, respectively, which are similar to those of **Cu-1**. The P–Cu–P bond angle is 118.27(8)°.

3.2. Preparation and characterization of the Zn(II) complexes

The treatment of $ZnCl_2$, $ZnBr_2$ and ZnI_2 with PPh_2qn readily afforded **Zn-1**, **Zn-2** and **Zn-3**, respectively. Unlike $[Cu(PPh_2qn)_2]^+$,

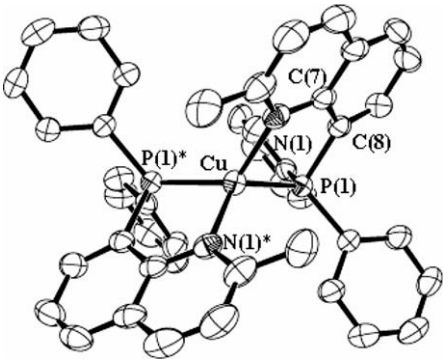

Fig. 2. ORTEP structure of **Cu-2**.

only one PPh_2qn ligand is coordinated to the zinc(II) ion in these complexes. Attempts to prepare $[Zn(PPh_2qn)_2]$ by treatment of $Zn(PF_6)_2$ without halides failed. Preparation of the $[ZnF_2(PPh_2qn)]$ complex by treatment with ZnF_2 was also unsuccessful. The products were identified by elemental analysis and ^{1}H and ^{31}P{^{1}H} NMR spectra. In the ^{31}P NMR spectra of the complexes, a sharp singlet signal was observed between δ −34 and −39, which shifted to higher field on coordination. Such higher field shifts are hardly ever observed in other Zn(II) complexes containing phosphines [20]. It suggests that the electron density around the phosphorus atom is considerably increased by either the zinc atom or the coordinated halides.

Recrystallization of the zinc complexes did not give single crystals available for X-ray analysis, whereas they were directly obtained by slowly mixing both solutions of PPh_2qn in $CHCl_3$ and ZnX_2 in CH_3OH. The molecular structures of **Zn-1**, **Zn-2** and **Zn-3** are illustrated in Fig. 3. It was found that the PPh_2qn ligand coordinates to the zinc center with two halide ions. Selected bond lengths and angles are summarized in Table 2. and crystallographic data are described in Table S2. The Zn–P bond lengths in these complexes range from 2.390(1) to 2.395(1) Å. Especially, **Zn-3** has the shortest bond length of the reported zinc complexes containing aryl phosphine derivatives [21–23]. The Zn–X bond lengths increase in the order of the following halide ions, Cl, Br and I, however there are no notable differences in the other bond lengths (*e.g.* Zn–N bonds) and bond angles in the three complexes. So the three complexes have a similar coordination environment with regard to PPh_2qn.

3.3. Photophysical properties of the complexes containing phosphinoquinoline ligands

The absorption spectra of **Cu-1** and **Cu-2** in CH_2Cl_2 are shown in Fig. 4. Each complex shows an absorption ranging from 380 to 450 nm, which is not observed for the corresponding free phosphinoquinoline ligand. The Cu–diimine MLCT bands are known to be observed in the region 400–360 nm, with an absorption coefficient of the order of 1.0×10^3 mol^{-1} dm^3 cm^{-1} for mononuclear Cu–P_2N_2 complexes [3–6]. It suggests that the absorption bands of **Cu-1** and **Cu-2** are assigned to the MLCT transition from the Cu(I) center to the quinoline moiety. The enhancement of the absorption intensity in the region from 300 to 340 nm for each complex stems from the coordination of the two ligands in one complex molecule. The bands are assigned to the quinoline-based intraligand π–π^* transition, as reported for the ruthenium(II) complexes containing PPh_2qn [12].

Cu-1 and **Cu-2** show emission in the solid state as shown in Fig. 5. The emission maximum of **Cu-1** is located at *ca.* 640 nm. The emission lifetime is estimated at 0.33 μs from the emission decay curve fitted with a single exponential function. The luminescent properties, which are comparable to that of $[Cu(dmp)(diphosphine)]^+$, suggests that the emission band is assigned to

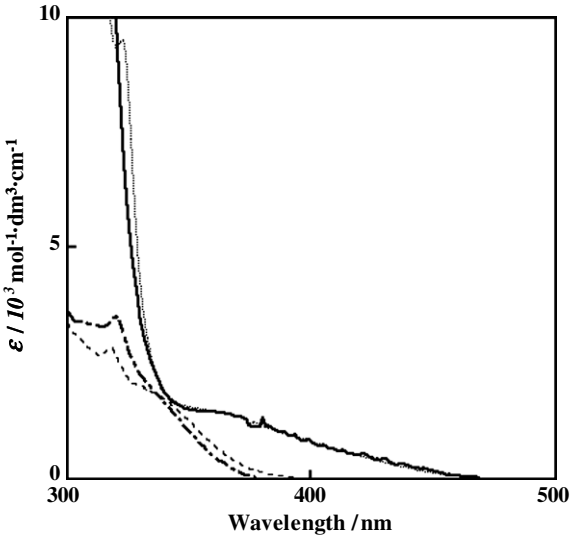

Fig. 4. Absorption spectra of **Cu-1** (solid line), **Cu-2** (dotted line), PPh_2qn (dashed line) and PPh_2qna (dashed-dotted line) in CH_2Cl_2.

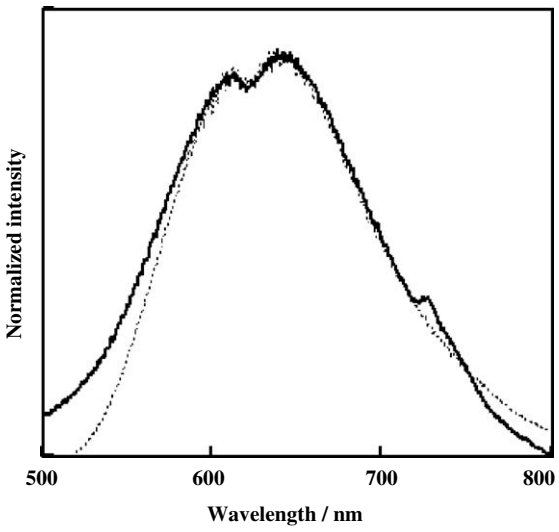

Fig. 5. Emission spectra (uncorrected) of **Cu-1** (solid line) and **Cu-2** (dotted line) in the solid state.

^{3}MLCT transition involving π^* of the quinoline group. The assignment is consistent with the suggestion that no emission is observed in solution because of the lower bulkiness of the coordination sphere around the copper atom in the complex structure, facilitating a tetragonal flattening distortion of the excited luminophore and/or attack of solvent molecules to the excited one in solution. The emission maximum of **Cu-2** is similar to that of **Cu-1**. However, the emission lifetime of **Cu-2** is ca. 1.0 μs, which is three times longer than that of **Cu-1**. In the case of copper(I) complexes containing dmp, it has already been shown that the steric effect of methyl-substituted groups usually results in a higher quantum yield and a longer emission lifetime [2–5]. However, as described in the X-ray structure, the coordination sphere around copper in **Cu-2** is not bulky enough to inhibit quenching of the excited states to emit in solution, even in the presence of the methyl-substituted group in PPh_2qna.

The absorption spectra of the zinc complexes are shown in Fig. 6. All the zinc complexes show similar absorption spectra. Although the free PPh_2qn ligand has an absorption band ranging from 330 to 370 nm, the zinc complexes show smaller intensity in this region. It suggests that the band is assigned to the n–π^* charge transfer transition from the lone pair on the phosphorus atom to the quinoline ring. This type of transition for some metal complexes was reported to have character similar to a protonated aryl phosphine, involving a shift to higher energies compared to the free phosphine [24].

Among the three Zn complexes, only **Zn-1** shows luminescence in CH_2Cl_2 solution at room temperature. As shown in Fig. 7, the emission spectrum of **Zn-1** is similar to that of free PPh_2qn. Therefore, the emission bands are assigned to the ligand-centered (LC) transition. Dissociation of PPh_2qn from **Zn-1** is not suggested because the ^{31}P NMR spectrum of **Zn-1** shows a sharp singlet, as described above. The emission lifetime of **Zn-1** is too short to be measured (<20 ns). It suggests that the emission is fluorescent.

The emission spectra in frozen CH_2Cl_2 at 77 K of **Zn-1** and free PPh_2qn show emission maxima at 535 and 530 nm, respectively (Fig. 7). The spectra were independent of the excitation wave-

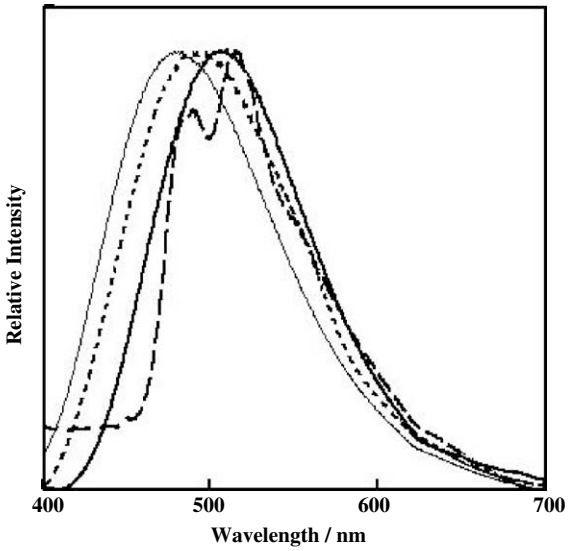

Fig. 8. Emission spectra of PPh_2qn (bold solid line) **Zn-1** (solid line), **Zn-2** (dotted line), **Zn-3** (dashed line) in the solid state at room temperature.

length, over the range 330–350 nm. Fife et al. have reported that the emission spectrum of $[ZnCl_2(PPh_2Me)]$ in diethylether–isopentane–ethanol glass at 77 K show a slightly higher energy emission maximum, at *ca.* 420 nm, than that of free PPh_2Me [24]. The emission band of **Zn-1** is also similar to that of $[Ru(bpy)_2(PPh_2qn)]$ observed in EtOH/MeOH glass at 77 K, which is assigned to a quinoline based $^3(\pi-\pi^*)$ transition [12]. In the case of zinc(II) complexes, a high promotion energy does not result in low-energy MLCT excited states [24]. Thus unlike the Cu(I) complexes, the emission band is assigned to not a metal-to-ligand but to a ligand-centered transition, maybe typically the $(\pi-\pi^*)$ transition in the quinoline ring. One more possibility is a $(n-\pi^*)$-like charge transfer from the Zn–P σ-bond orbital to the π^* orbital on the quinoline ring. However, such a CT emission should be observed at higher energy than that of the corresponding free phosphine [24]. The slight low-energy shift of the emission on coordination to the Zn center suggests that the emission is originates from $\pi-\pi^*$ states.

The emission spectra of the zinc complexes and the free ligand have been obtained in the solid state and are shown in Fig. 8. The emission band of **Zn-1** at *ca.* 500 nm is shifted to lower energy than that in solution, whereas the lifetime is very short (<20 ns). The emission maxima of **Zn-1** and **Zn-2** are slightly shifted to higher energy compared to that of the free PPh_2qn, whereas that of **Zn-3** is observed in the lower energy region and involves vibrational structure; thus the heavier the halogen in the zinc complex, the lower the energy of the emission. The emission energy dependence on the coordinated halogenide ions and structural similarity involving the Zn-PPh_2qn moiety between the complexes suggest that the halogen-to-ligand charge transfer (XLCT) from halogenide to quinoline ring may contribute to the emissive excited states. However, it should be noted that the absorption bands ranging from 300 to 330 nm hardly show any dependence on the halogenide ion, so the character of the excited states associated with the absorption, which may be $\pi-\pi^*$ of the quinoline ring, may differ from that of the emissive excited states.

4. Conclusion

The utilization of PPh_2qn or PPh_2qna, containing both imine and phosphine moieties, successfully gives the new copper complexes **Cu-1** and **Cu-2**, respectively. Both complexes have similar structures to those of mixed-ligand complexes with a P_2N_2 donor set. In the solid state, both Cu(I) complexes show an emission assigned to ^{3}MLCT. However, no emission is observed in solution, even for **Cu-2** coordinated by PPh_2qna which has a bulkier group than PPh_2qn. The bulkiness in the coordination sphere around the copper atom should be smaller than that of the reported mixed-ligand [Cu(dmp)(diphosphine)]-type complexes.

Meanwhile, a series of Zn(II) complexes coordinated by only one PPh_2qn ligand and two halogenide ions was also prepared. All the complexes are stable in solution, and each sharp singlet signal was shifted to amazingly higher field on coordination. Structural characterization shows the similarity of the coordination environment around the PPh_2qn ligand for the three complexes. **Zn-1** shows a similar emission band to that of free PPh_2qn at both room temperature and 77 K. It suggests the emission bands are assigned to a ligand-centered (LC) transition. In the solid state, it is found that the emissive energy of the complex is shifted to lower energy for the series, $Cl^- > Br^- > I^-$. A contribution of the halogenide orbitals in the emissive states is suggested Chart 1.

Appendix A. Supplementary data

CCDC 683537, 683538, 683539, 683540 and 683541 contain the supplementary crystallographic data for **Cu-1**, **Cu-2**, **Zn-1**, **Zn-2** and **Zn-3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. X-ray crystallographic data of the Cu(I) and Zn(II) complexes are shown in Figs. S1 and S2, respectively. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.08.028.

ABSTRACT

The energetic nitrogen-rich compounds 1,3-bis(1-methyltetrazol-5-yl)triaz-1-ene (**4**) and 1,3-bis(2-methyltetrazol-5-yl)triaz-1-ene (**5**) were synthesized by diazotation of 1-methyl-5-aminotetrazole (**2**) and 2-methyl-5-aminotetrazole (**3**), respectively, by using half an equivalent of sodium nitrite. The reaction of **4** and **5** with diluted ammonia solution yields ammonium bis(1-methyltetrazol-5-yl)triazenate (**6**) and ammonium bis(2-methyl-tetrazol-5-yl)triazenate (**7**). Treating of **4** and **5** with aqueous sodium hydroxide solution yields sodium bis(1-methyltetrazol-5-yl)triazenate (**8**) and sodium bis(2-methyltetrazol-5-yl)triazenate (**9**) almost quantitative. Compounds **8** and **9** were methylated using methyl iodide and dimethyl sulfate, respectively, originating bis(1-methyltetrazol-5-yl)-3-methyltriaz-1-ene (**10**) and bis(2-methyltetrazol-5-yl)-3-methyltriaz-1-ene (**11**). The products **4**–**11** were characterized by Raman, IR, multinuclear NMR and UV–Vis spectroscopy, mass spectrometry, elemental analysis and differential scanning calorimetry. The structures of the crystalline state of **4** · H_2O, **5**, **8** · MeOH, **10** and magnesium bis(2-methyltetrazol-5-yl)triazenate (**12**) were determined by low temperature single crystal X-ray diffraction. The heats of formation $\Delta_f H^\circ$ of **4**–**7**, **10** and **11** were calculated using energies of combustion $\Delta_c U^\circ$ determined by bomb calorimetry, resulting in strongly endothermic values. With these data and by using calculated (**4**, **5**, **10**) as well as measured (**6**, **7**, **11**) crystal densities, several detonation parameter (heats of explosion, detonation pressure, detonation velocity, explosion temperature) were calculated by the EXPLO5 software. In addition, the specific impulse of different propellant mixtures of the most promising compound **6** with ammonium dinitramide (ADN) were computed. Furthermore the *n*-octanol/water partition coefficients of **4**, **5**, **6** and **7** were determined and the long-term stability of **6** was tested by thermal safety calorimetry. Lastly the sensitivities toward impact and friction as well as electrical discharge were determined by the BAM drophammer, friction tester and a small scale electrical discharge tester.

1. Introduction

In contrast to high explosives, propellants need to release their energy in form of deflagration. In this way they produce high pressure without fracturing the containment chamber. Black powder [1] was one of the first propellants used in guns and motors. Today it is still used in pyrotechnic goods, especially small rockets. However the use of black powder as propellant for larger objects like missiles and space rockets contain too much disadvantages. There is a certain unpredictability of the behavior and development of extremely dirty gases [2]. Rocket propellants need to fulfill a couple of requirements: (i) The explosives must have a high energy content and slow burning rate to sustain impulse over a period of time. (ii) The substance additionally needs to be stable over a long time period and in a wide as possible temperature range. To compare different propellants in their performance the specific impulse I_{sp} is used. It is defined as the thrust divided by the mass flow rate of the explosive (Eq. (1)):

$$I_{sp} = \frac{\text{thrust of motor}}{\text{mass flow rate through nozzle}} \quad (1)$$

The specific impulse is also a function of the temperature in the combustion chamber and the average molar mass of the gases:

$$I_{sp} \approx \sqrt{\frac{\text{temperature of combustion chamber}}{\text{average molar mass of gaseous products}}} \quad (2)$$

Therefore I_{sp} depends on the properties of the propellant, on the design of the combustion chamber and the rocket motor, respectively [3]. The two main types of solid rocket propellant are double-base propellants and composite propellants. Double-base propellants are homogenous and composed of nitrocellulose with nitroglycerine or other nitroglycols as energetic plasticizers. Because the dimension of propellant grains based on this type of mixture is

doi:10.1016/j.poly.2008.09.015

limited, composite propellants were developed during the second world war. The most important composite propellant today is a mixture of aluminum as fuel and ammonium perchlorate as oxidizer. As binding agent serves a polymer, e.g. hydroxy- or carboxy-terminated polybutadiene. This type of mixture is used for example as solid rocket boosters at the US Space Shuttle (and also in Ariane rockets ESA). Depending on the kind of binder and other additives used the specific impulse reaches about 2400–2600 Ns/kg (engl. (I_{sp}/g): 245–265 s) and the flame temperature is about 2850–3500 K [3].

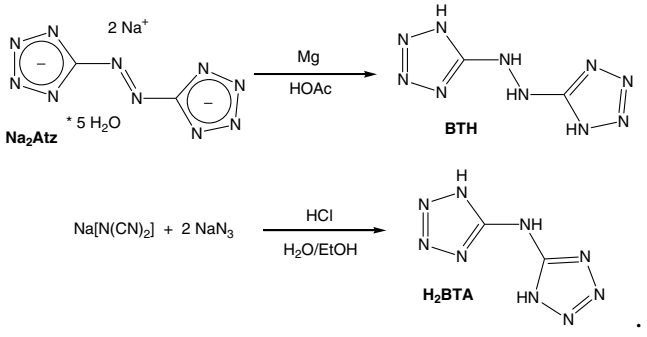
Although the performance of ammonium perchlorate is highly suitable as rocket propellant, it has one big disadvantage. As it can be seen from the decomposition Eq. (3) a high amount of HCl is produced.

$$2NH_4ClO_4 \rightarrow N_2 + 3H_2O + 2HCl + 2.5O_2 \quad (3)$$

With the fact of 500 kg propellant per booster for the Space Shuttle there is a total output of 217 tons of HCl per launch. With the humidity in the air a huge quantity of acid mist is released, which leads to acid rain. In addition the resulting Al_2O_3 is harmful for living creatures and plants. Some endeavors were made to reduce the environmental pollution, especially, concerning the HCl impact. One possibility is to add $NaNO_3$ to build up NaCl [4]:

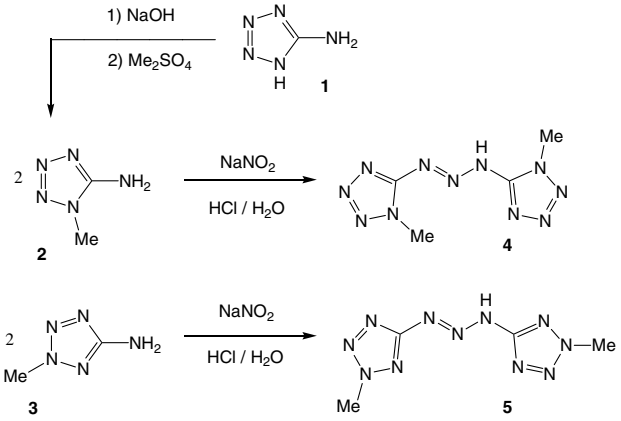
$$NH_4ClO_4 + NaNO_3 \rightarrow NH_4NO_3 + NaClO_4$$
$$\rightarrow \text{production of NaCl} \quad (4)$$

The simplest way to reduce the environmental pollution would be using propellants which contain no chloride and do not produce any other harmful residues. Many scientists today are searching for new energetic materials with good performance and at the same time having environmental friendly properties. Examples for this new class of energetic materials are 5,5′-bis(1*H*-tetrazolyl)amine (H_2BTA) [5] and salts of 5,5′-bis(1*H*-tetrazolyl)hydrazine (BTH) [6] as well as 5,5′-azotetrazolates (ATZ), which syntheses are illustrated in Scheme 1.



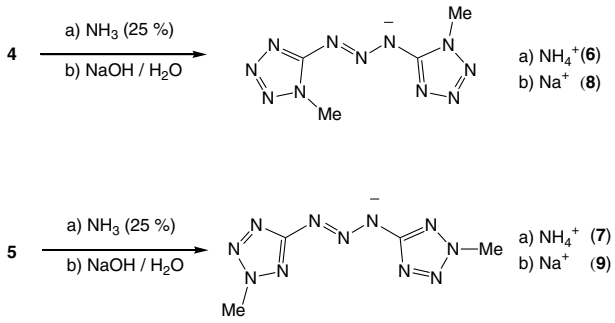
Compounds containing the 5,5′-azotetrazolate anion are particularly suitable target molecules, since these salts have a considerable nitrogen content and are expected to have appropriate stabilities toward friction, impact and heat. Metal salts of 5,5′-azotetrazolates have been extensively studied [7] and also N-rich guanidinium derivatives of 5,5′-azotetrazolate are described in literature as possible additives in solid propellants [8]. The main disadvantage is the incompatibility toward acids. Suitable alternatives for 5,5′-azotetrazolates are derivatives of bis-tetrazolyl-triazenes, which are also stable toward acid conditions. Derivates of bis-tetrazolyl-triazenes have also high-nitrogen contents and a very high positive heat of formation. Due to their high-nitrogen content the main decomposition product is also dinitrogen. In 1910, Hofmann and Hock synthesized bis(1*H*-tetrazol-5-yl)triaz-1-ene for the first time [9], which decomposes slowly by simple exposure to air but can be used as precursor producing 5-tetrazolylhydrazones. A great deal better are the methylated derivatives of bis(1*H*-tetrazol-5-yl)triaz-1-ene since they are thermally stable and show lower sensitivities. toward outer stimuli. These properties can be still improved by deprotonation of the triazene group forming triazenates. Bis(1-methyl-tetrazol-5-yl)-triazene is unknown in literature. Bis(2-methyltetrazol-5-yl)triaz-1-ene was synthesized accidentally by Hattori et al. during the attempt producing methylated 5-hydroxytetrazole, but was not further described [10]. It has been also mentioned in literature as intermediate in synthesis of arylidene-2-methyl-2*H*-tetrazol-5-yl-hydrazones [11] and 1,3,4,6-tetrakis(2-methyltetrazol-5-yl)hexaaza-1,5-diene [12]. In the work of A. Lyakhov deprotonated bis(2-methyltetrazol-5-yl)triaz-1-ene was used as a chelate ligand for Ni(II) [13]. In this work we present facile synthetic routes to several bis(methyltetrazolyl)-triazenes, bis(methyltetrazolyl)-triazenates and bis(methyltetrazolyl)-methyltriazenes, which were fully characterized and also tested with regard to their energetic properties.

2. Results and discussion



2.1. Synthesis

1-Methyl-5-aminotetrazole (**2**) and 2-methyl-5-aminotetrazole (**3**) were synthesized by methylation of 5-aminotetrazole (**1**) using dimethyl sulfate according to the literature [14]. The diazotation of **2** was carried out in water, according to Scheme 2. A matter of particular interest is the sequence of addition. In this case a solution of 1-methyl-5-aminotetrazole in diluted hydrochloric acid is slowly dropped to an ice cold solution of half an equivalent of sodium nitrite. Bis(1-methyltetrazolyl)triazene (**4**) starts to precipitate after a few minutes (from this solution) and was isolated by filtration. Recrystallization from hot water yielded single crystals of the monohydrate suitable for XRD. Bis(2-methyltetrazolyl)triazene (**5**) can also be synthesized via this route, but also, due to its solubility in organic solvents, by the reaction in THF as solvent and *i*-pentylnitrite as the diazotation agent. Recrystallization from hot water yielded also light yellow single crystals. A small amount of single crystals of magnesium bis(2-methyl-tetrazolyl)triazenate dodecahydrate (**12**) was accidentally obtained on working up one of the reactions originally carried out to establish the reaction conditions toward **5** using $MgSO_4$ as drying agent.



Deprotonation (Scheme 3) of **4** and **5** can be performed in water by adding common bases e.g metal hydroxides or carbonates. The reactions with conc. ammonia solution yielded the water free salts

ammonium bis(1-methyltetrazolyl)triazenate (**6**) and ammonium bis(2-methyl-tetrazolyl)triazenate (**7**). Both compounds are low soluble in water below ca. 50 °C and crystallize as microcrystalline materials. Many attempts to obtain single crystals for X-ray determination failed. To obtain other crystals containing the bis(methyltetrazolyl)triazenate anions the salts sodium bis(1-methyltetrazolyl)triazenate (**8**) and sodium bis(2-methyl-tetrazolyl)triazenate (**9**) were synthesized by the reaction of **4** and **5** with aqueous sodium hydroxide solutions. Suitable single crystals could be obtained of **8** by recrystallization from water or a H_2O/MeOH mixture, whereby only the methanol adduct could be determined by X-ray diffraction.

The triazenate unit can be alkylated by common alkylation reagents at one of the marginal nitrogen atoms. This was proofed by the reactions of **8** and **9** with methyl iodide and dimethyl sulfate, respectively, yielding bis(1-methyltetrazol-5-yl)-3-methyl-1-triazene (**10**) and bis(2-methyltetrazol-5-yl)-3-methyl-1-triazene (**11**) depicted in Scheme 4. The products are insoluble in water, slightly soluble in solvents like MeCN, THF, acetone and good soluble in DMF or DMSO. Compounds **10** and **11** could be recrystallized from hot EtOH.

2.2. Structures

2.2.1. X-ray diffraction studies

Suitable single crystal of **5** and **12** were picked from the crystallization mixture, mounted in Kel-F oil and transferred to the N_2 stream of Oxford Xcalibur3 diffractometer with a Spellman generator (voltage 50 kV, current 40 mA) and a KappaCCD detector. The data collection was performed using the CRYSALIS CCD software [15], the data reduction with the CRYSALIS RED software [16]. The data for compounds **4** · H_2O, **8** · MeOH and **10** were collected on a Nonius Kappa CCD diffractometer under a N_2 stream as well. Data collections and reductions were done by the Bruker "COLLECT" and the "HKL DENZO and SCALEPACK" software [17]. The structures were solved

Scheme 4. Methylation of **8** and **9** yielding bis(1-methyltetrazolyl)-3-methyl-1-triazene (**10**) and bis(2-methyltetrazolyl)-3-methyl-1-triazene (**11**).

with SIR-92 (**4** · H_2O, **5** and **10**) [18], and SHELXS-97 (**8** · MeOH, **12**) [19], refined with SHELXL-97 [20] and finally checked using the PLATON software [21], integrated in the WINGX software suite [22]. The non-hydrogen atoms were refined anisotropically. The hydrogen atoms of the methyl groups were partly fixed while the hydrogen atoms bonded ate nitrogen or oxygen atoms were located and freely refined. The absorption of **5** and **12** was corrected by a SCALE3 ABSPACK multi-scan method [23]. All relevant data and parameters of the X-ray measurements and refinements are given in Table 1. Further information on the crystal-structure determinations have been deposited with the Cambridge Crystallographic Data Centre[1].

The monohydrate of **4** crystallizes in the orthorhombic space group *Pnma* with four molecules in the unit cell. The density was calculated to be 1.529 g cm^{-3} which is low in comparison to other 5-*N* substituted tetrazoles in the literature, such as 5-amino-1*H*-tetrazole [24], 5-nitro-2*H*-tetrazole [25], 5-azido-1*H*-tetrazole [26–28] and 5-nitriminotetrazole [29–31]. The molecular moiety, which is shown in Fig. 1 is affected by a planar setup. All non-hydrogen atoms lie on the mirror plane in the a–c layer. The water molecule is coordinated via a strong hydrogen bond to the nitrogen atom N5. The geometry of the triazene unit follows that expected by the "Lewis structure". The distance between the atoms N6–N7 of 1.264(2) Å corresponds with the bond length of a N=N double bond (1.20 Å), while the N6–N5 distance of 1.331(2) is significantly longer, but also shorter than a N–N single bond (1.48 Å) [32]. The geometries of the two tetrazole rings differ considerably. In 5-*N* substituted tetrazoles, usually the shortest N–N distances are observed between the atoms N2 and N3 (1.297(2) Å) as well as N9 and N10 1.294(3) which is also the case in the structure of **4**. The other ring shows an opposed trend. In this the N9–N10 distance is found to be the longest (1.354(3) Å). The bond lengths to the external methyl groups have typical values (1.46 Å) found for C–N single bonds.

The packing of **4** is characterized by a layer structure along the c–a plane (Fig. 2a). The layers have distances of 3.15 Å. Within the layers, strong hydrogen bonds involving the NH group and water molecules, are observed (Fig. 2b). On this account columns along the *c* axes are formed.

Compound **5** crystallizes in the monoclinic space group *I*2/*a* with eight molecules in the unit cell and a slightly higher density of 1.532 g cm^{-3} in comparison to **4**. The molecular geometry in terms of the bond lengths is similar to that observed for **4**. Exact bond distances can be found in Table 2. However, **5** is not completely planar. While the triazene unit is planar (torsion angle C1–N5–N6–N11 = 179.7(2)°), the tetrazole rings are slightly out of phase, which can be seen on the N10–C3–C1–N4 torsion angle of 12.3(4)° (Fig. 3).

On inspection along the *a axes* wave like pattern can be detected (Fig. 4a). The discrete layers are connected by two kinds of interactions. On the one hand dimers are formed by the O1–H1···N7^{i} hydrogen bond (0.79(3) Å, 2.05(3) Å, 2.838(2) Å, 178(3)°; (i) $-1-x, y, 0.5-z$), on the other hand hydrophobic areas are build by the interaction of the methyl groups (marked in Fig. 4b).

8 · MeOH crystallizes in the monoclinic space group $P2_1/c$ with four molecules in the unit cell and a calculated density of 1.327 g cm^{-3}. The sodium cations are coordinated sixfold by a distorted pentagonal-pyramidal coordination sphere. The bis(1-methyl-tetrazolyl)triazenate anions act as tridentate ligands by the coordination of its atoms N4, N6, and N11. The fourth coordination position is filled by the methanol oxygen atom O1, while the fifth and sixth positions are filled by the nitrogen atoms N2 and N11 of two neighbored bis(1-methyl-tetrazolyl)triazenate molecules. Here dimers (Fig. 5) can be detected as a structural motive.

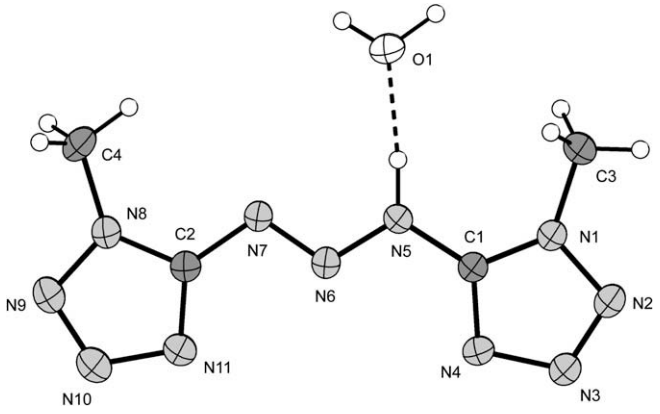

Fig. 1. Molecular moiety of **4** · H_2O. Ellipsoids of non-hydrogen atoms are drawn at the 50% probability level.

Single crystals of **8** recrystallized from hot water could also be obtained, measured at our diffractometer but only insufficiently refined. This may be a reason that the methyl groups are partly disordered and also huge amounts of partly strong disordered crystal water are included in the packing. Therefore a discussion of this structure with a sum formula $C_{12}H_{48}N_{33}Na_3O_{15}$ is abdicated. However the wR_2 value could be lowered to ca. 14% and the coordination of two of the sodium atoms representing a distorted octahedron is depicted in Fig. 6.

Single crystals of **9** could not have been measured since the crystal size was too small for reaching an adequate dataset. However, suitable crystals of magnesium bis(2-methyl-tetrazolyl)triazenate dodecahydrate (**12**) were accidentally obtained on a different work up procedure of **5** using $MgSO_4$ as drying agent. Compound **12** crystallizes with one molecular moiety in the unit cell in the triclinic space group $P\bar{1}$. The bis(2-methyl-tetrazolyl)triazenate anions do not participate in the coordination of the magnesium cations. These are surrounded by six water molecules building a regular octahedral coordination sphere with distances between 2.05 and 2.10 Å (Fig. 7).

Compound **10** crystallizes in the orthorhombic space group $Pca2_1$ with eight molecules in the unit cell. For better clearness only one molecule of the asymmetric unit is shown in Fig. 8. Although no hydrogen bonds can be formed the highest density of 1.559 g cm^{-3} is be observed. The methyl group bonded at the nitrogen atom N5 does not influence the geometry of the triazene unit. The distances N5–N6 (1.324(5) Å) and N6–N7 (1.269(5) Å) are similar to the other structures discussed in this work. Also the C–N bonds of the triazene group to the tetrazole rings are not affected. While the atoms C1, N5, N6 N7 and C2 lie in one plane, the tetrazole rings are twisted 16.1° (torsion angle N5–C2–C1–N4 molecule a) as well as 33.9° (b) to each other.

A view on the unit cell along the *b* axes is shown in Fig. 9. Thereby alternating columns can be found, which are mainly connected by "Van der Waals" forces.

2.3. Spectroscopy

2.3.1. Multinuclear NMR spectroscopy

NMR spectroscopy is a valuable method to identify bis(methyl-tetrazolyl)triazenes. All Shifts are given with respect to TMS (^{1}H, ^{13}C) and CH_3NO_2 (^{14}N, ^{15}N) as external standards. DMSO-d_6 (**4**, **5**, **6**, **7** and **9**), D_2O (**8**) and $CDCl_3$ (**10**, **11**) were used as solvents. The ^{1}H NMR spectra of **4** and **5** measured in DMSO-d_6 show sing-

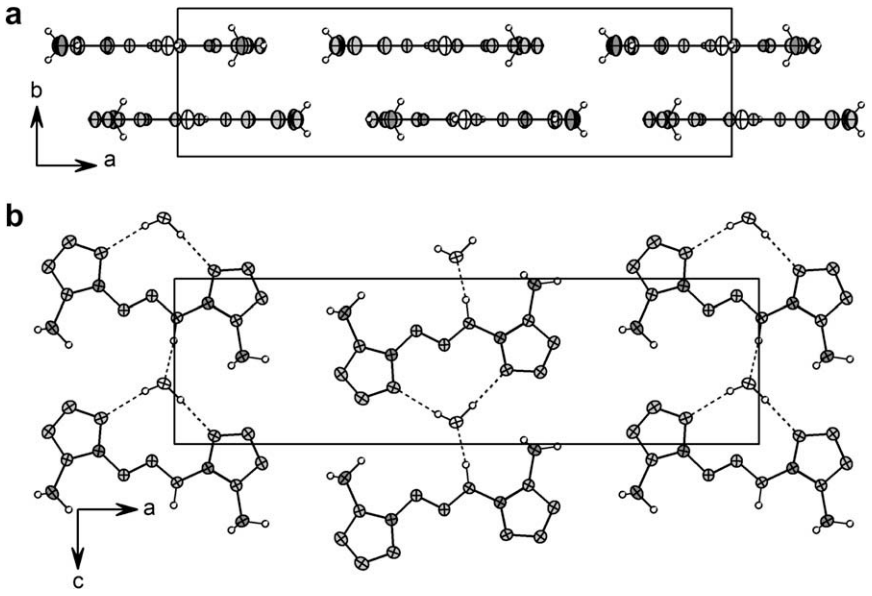

Fig. 2. View on the unit cell of **4** · H_2O along (a) the *c* axes showing the layers, (b) the *b* axes showing the connections within the layers. Hydrogen bonds: O1–H1a···N11 = 0.81(3) Å, 2.10(3) Å, 2.902(3) Å, 172(3)°; N5–H5···O1 = 0.94(3), 1.76(3), 2.703(2), 175(3); O1–H1b···N1 = 0.94(4), 1.99(4), 2.934(3), 178(4).

lets at 4.04 ppm and 4.32 ppm, respectively. The hydrogen atom at the triazene unit in **4** provides no visible signal, because of fast proton exchange in polar solvents like DMSO [33]. In **5** it is found weakly at 14.10 ppm. Deprotonation of the triazene unit decrease the hydrogen resonances to higher fields (**6**: 3.86, **7**: 4.20 ppm).

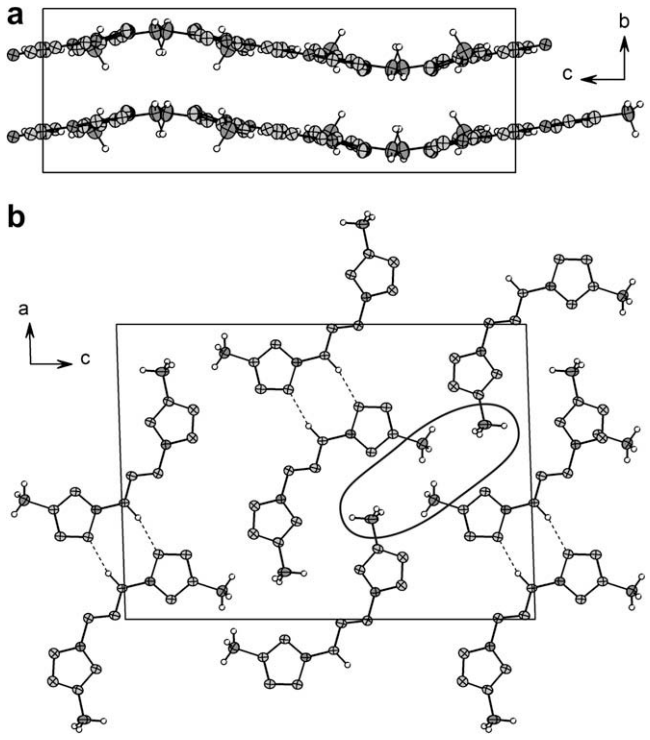

Fig. 4. View on the unit cell of **5** along (a) the *a* axes; (b) the *b* axes illustrating the formation of dimers.

Methylation affords a down field shift and also a split into two resonances (**6**: 4.12, 4.11 ppm, **7**: 4.38, 4.39 ppm). The ^{13}C NMR resonances of the methyl carbon atoms and the tetrazole carbon in **4** and **5** are found at 34.9 ppm and 155.2 ppm (**4**) as well as 40.5 and 162.9 ppm (**5**). In the ammonia salts the methyl resonances are found at higher fields (**6**: 33.1, **7**: 39.7 ppm) while the tetrazole carbon shifts significantly increase to 161.9 (**6**) and 173.7 ppm (**7**). In the case of the methylated compounds **10** and **11**, two signals are observed for the tetrazole carbon atoms (**10**: 157.9, 154.2; **11**: 169.5 and 165.0 ppm) whereby the higher ones can be assigned

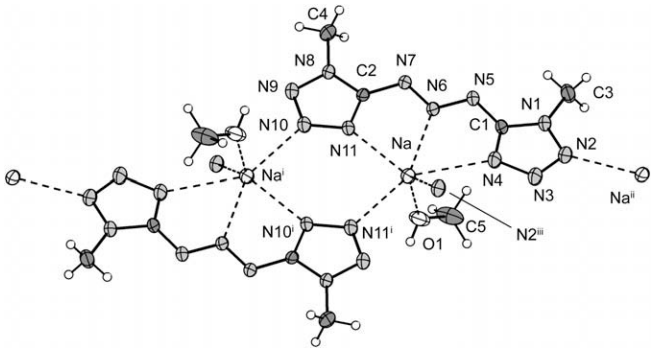

Fig. 5. View on the dimers in **8** · MeOH. Selected distances (Å): Na–O1 = 2.475(2), Na– N11 = 2.498(2), Na–N6 = 2.640(2), Na–N4 = 2.766(2), Na–N2^{iii} = 2.668(2), O1–C5 = 1.561(3); (i) $2-x$, $-y$, $1-z$; (ii) $2-x$, $0.5+y$, $1.5-z$; (iii) $2-x$, $-0.5+y$, $1.5-z$.

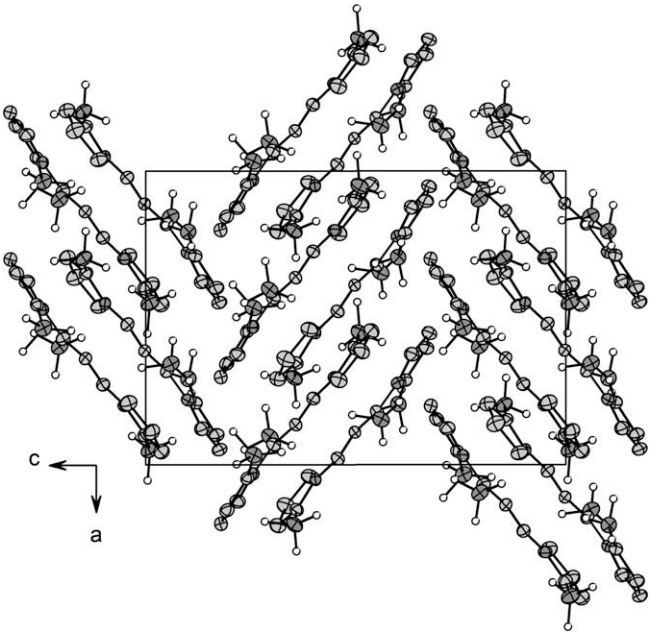

Fig. 9. View on the unit cell of in **10** along the *b* axes.

to the carbon atoms closer to the introduced methyl group. ^{14}N NMR spectroscopy of bis(methyltetrazolyl)triazenes yields uninterpretable spectra due to the quadrupole moment of the ^{14}N core. Solely in the ^{14}N spectra of **6** and **7** the ammonia nitrogen atoms could be detected at −358 ppm (**6**) and −359 ppm (**7**). ^{15}N NMR spectroscopy yields sharp signals, however, it is hard to measure due to the low frequency of the ^{15}N core (0.3%). Therefore high concentrations are required, which is hard to fulfill for the investigated compounds due to their low solubility. To exemplify, the proton coupled ^{15}N NMR spectra of compound **5** and **11** are shown in Fig. 10. The assignments are based on the analysis of the ^{15}N, ^{1}H coupling constants and on comparison with literature [32].

2.3.2. Vibrational spectroscopy

The investigated compounds **4–11** can be easily identified using IR and Raman spectroscopy. The Raman spectra of **4** and **5** are dominated by the asymmetric stretching mode $\nu_{asym}(N{=}N_{triazene})$ providing signals in the range of 1430–1460 cm^{-1}. This vibration is lower in energy in the spectra of the deprotonated triazenes **6–9**. The IR spectra contain more vibrations with high intensities.

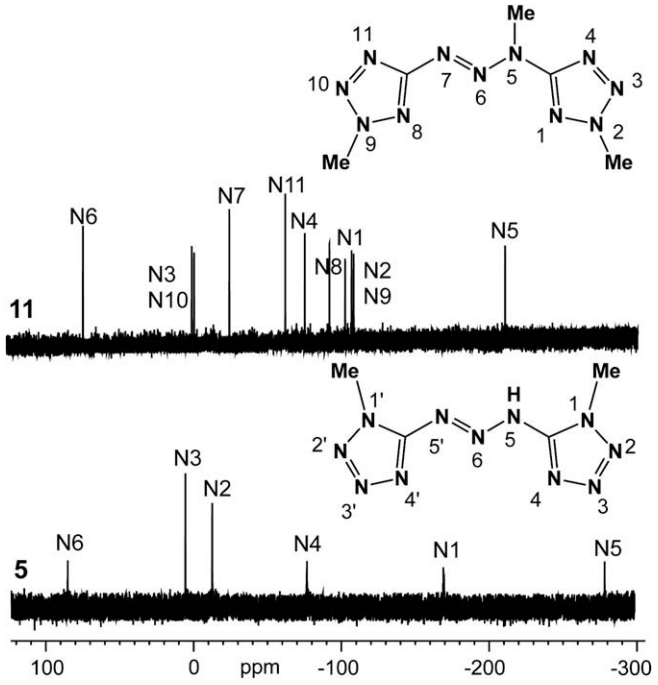

Fig. 10. ^{15}N NMR spectra of **5** and **11**. (δ, ppm): (**5**): 85.2 (N6), 5.54 (N3/N3′), − 76.6 (N4), −12.7 (N2/N2′, q, $^{3}J_{NH}$ = 1.8 Hz), −168.7 (N1, q, $^{2}J_{NH}$ = 2.1 Hz), −265.0 (N5/N5′); δ (**11**): 72.6 (N6), −0.6 (N3, q, $^{3}J_{NH}$ = 1.8 Hz), −2.2 (N10, q, $^{3}J_{NH}$ = 1.8 Hz), −25.8 (N7), −63.5 (N11), −76.6 (N4), −93.2 (N8, q, $^{3}J_{NH}$ = 1.8 Hz), −103.7 (N1, q, $^{3}J_{NH}$ = 1.8 Hz), −108.1 (N9, q, $^{2}J_{NH}$ = 2.2 Hz), −109.5 (N2, q, $^{2}J_{NH}$ = 2.3 Hz), −211.3 (N5, q, $^{2}J_{NH}$ = 2.4 Hz).

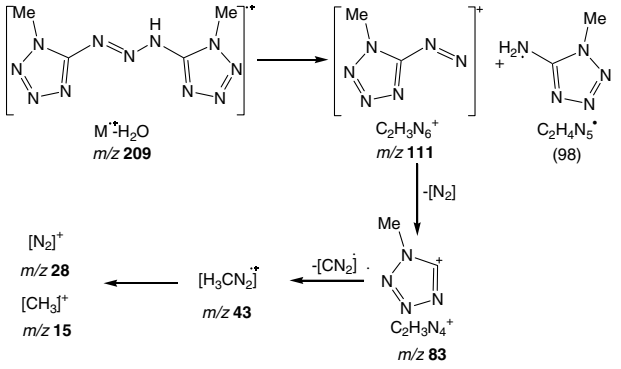

Of course the O–H vibration caused by the crystal water in **4**, **8** and **9** and the symmetric bending mode of the ammonia cations in **6** and **7** can be observed as broad signals above 3150 cm^{-1}. The vibrational spectra contain further vibrations: 3080–2980 cm^{-1} [$\nu_{sym}(CH_3)$], 3430–3140 cm^{-1} [$\nu_{sym/asym}$ (NH_4^+)], 1680–1550 [ν(N–H)], 1550–1350 [ν, tetrazole ring, $\nu_{as}(CH_3)$], ~1380 [$\nu(CH_3)$], 1350–700 [ν(N1–C1–N4), ν(N–N), ν(N–H), ν, tetrazole ring], <700 [ν, δ_{oop}(N–H)].

2.3.3. UV–Vis spectroscopy

The UV–Vis spectra of compounds (**4**–**11**) were measured in diluted methanol solutions. In general the observed resonances are n → π^* transitions. All substances show absorptions below the visible wavelength region. These results are consistent with the visible impressions since all substances are colorless or slightly yellow colored. The UV–Vis spectrum of **4** contains one absorbtion at 315 nm. The two corresponding salts **6** and **8** show both a maximum peak red shifted about 15 nm. In addition, the spectra of **6** and **8** include a shoulder at 240 nm. The resonance of the methylated compound **10** is blue shifted toward 299 nm. Compound **5** shows a maximum value for the absorption at 291 nm, whereby a shoulder can be found at 244 nm. The spectrum of salts **7** and **9** is nearly equal to this observed for **5**. The resonance of **11** is blue shifted to 281 nm.

2.3.4. Mass spectrometry

In all DEI$^+$ mass spectra of the neutral compounds (**4**, **5**, **10** and **11**) the mass peaks at *m*/*z* 209 and 223, respectively, could have been detected. In the spectra of the 1-methyl-tetrazolylderivatives the 1-methyl-5-azotetrazolyl radical was observed with a peak at *m*/*z* 111 as a main fragmentation product. In Scheme 5, one possible fragmentation pathway is shown, which is comparable to that of azotetrazoles [34].

Scheme 5. Possible fragmentation pathway of **4**.

Compound **5** shows analogue fragmentation than that of **4** (Scheme 5). An additional peak at 181 *m*/*z* was detected, which is generated by the loss of dinitrogen (M^+-N_2). Again ($NH_2^{\cdot+}$) (28 *m*/*z*) and CH_3^+ (15 *m*/*z*) arise as further intensive fragmentation products. The ammonium salts were measured in the FAB$^-$ mode, where the mass *m*/*z* 208 of the anion was detected.

2.4. Energetic properties

2.4.1. Differential scanning calorimetry

DSC measurements to determine the melt- and decomposition temperatures of **4**–**11** were performed in covered Al-containers containing a hole in the lid with a nitrogen flow of 20 mL/min on a Linseis PT10 DSC [35], calibrated by standard pure indium and zinc at a heating rate of 5 °C min^{-1}. The DSC plots in Fig. 11 show the thermal behavior of ca. 1.5 mg energetic material in the 50–400 °C temperature range. Temperatures are given as onset temperatures. In general it can be seen that the position of the methyl group does not influence the thermal behavior a lot. The neutral compounds **4** and **5** melt under exothermic decomposition at

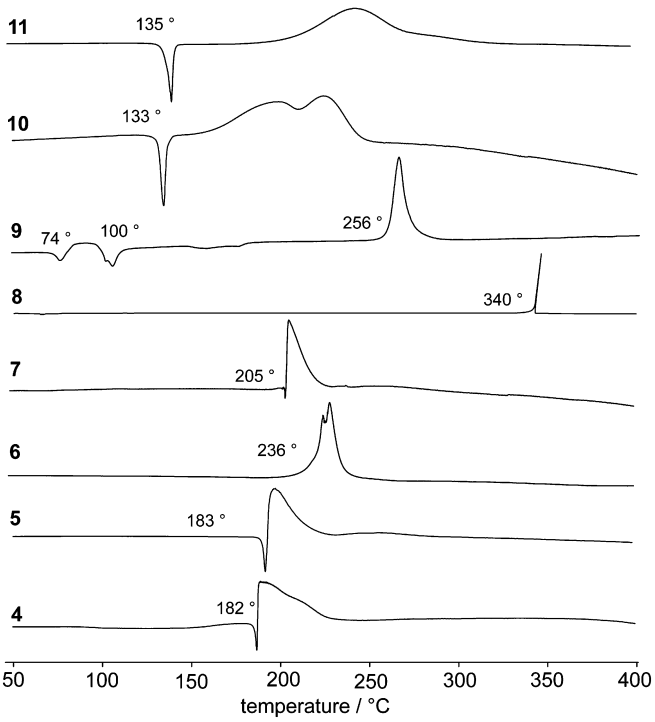

Fig. 11. DSC thermograms of compounds **4**–**11** (heating rate of 5 deg min^{-1}).

temperatures of 182 °C and 183 °C, respectively. Deprotonation increase the decomposition temperatures, which can be seen on the curves of **6**–**9**. Compound **6** decomposes without melting above a temperature of 236 °C. On the other hand ammonium salt **7** decomposes at lower temperatures of 205 °C. However, both nitrogen-rich salts decomposes above 200 °C, which is one of the most important criteria of new energetic materials for use in technical applications. The sodium salt **8** even decomposes not until 340 °C, which is more than 100 °C higher comparing with the corresponding ammonium salt. However, sodium salt **9** looses its five crystal water molecules in two steps at 74 and 100 °C followed by the decomposition above 256 °C. The methylation products **10** and **11** show discrete melting points at 133 °C and 135 °C, respectively, followed by a broad decomposition area starting at 160 °C (**10**) as well as 200 °C (**11**). These thermal behaviors are caused by that no classical hydrogen bonds could be formed in the structures of **10** and **11**.

2.4.2. Bomb calorimetry

The heats of combustion of compounds **4**–**7**, **10** and **11** were determined experimentally using a Parr 1356 bomb calorimeter (static jacket) equipped with a Parr 1108CL oxygen bomb [36]. To achieve better combustion, the samples (ca. 200 mg) were pressed with a defined amount of benzoic acid (ca. 800 mg) forming a tablet, and a Parr 45C10 alloy fuse wire was used for ignition. In all measurements, a correction of 2.3 cal cm^{-1} wire burned has been applied and the bomb was examined for evidence of non-combusted carbon after each run. A Parr 1755 printer was furnished with the Parr 1356 calorimeter to produce a permanent record of all activities within the calorimeter. The reported values are the average of three separate measurements. The calorimeter was calibrated by combustion of certified benzoic acid (SRM, 39i, NIST) in an oxygen atmosphere at a pressure of 3.05 MPa. The experimental results of the constant volume combustion energy ($\Delta_c U$) of the salts are summarized in Table 3. The standard molar enthalpy of combustion ($\Delta_c H^\circ$) was derived from $\Delta_c H^\circ = \Delta_c U + \Delta nRT$ ($\Delta n = \Delta n_i$ (products, g) $- \Delta n_i$ (reactants, g); Δn_i is the total molar amount of gases in the products or reactants). The enthalpy of formation, $\Delta_f H^\circ$, for each of the compounds was calculated at 298.15 K using Hess' law and the following combustion reactions.

$$\mathbf{4}: C_4H_9N_{11}O\ (s) + 5.75O_2\ (g) \rightarrow 4CO_2\ (g) + 4.5H_2O\ (l) + 5.5N_2\ (g)$$

$$\mathbf{5}: C_4H_7N_{11}\ (s) + 5.75O_2\ (g) \rightarrow 4CO_2\ (g) + 3.5H_2O\ (l) + 5.5N_2\ (g)$$

$$\mathbf{6},\mathbf{7}: C_4H_{10}N_{12}\ (s) + 6.5O_2\ (g) \rightarrow 4CO_2\ (g) + 5H_2O\ (l) + 6N_2\ (g)$$

$$\mathbf{10},\mathbf{11}: C_5H_9N_{11}\ (s) + 7.25O_2\ (g) \rightarrow 5CO_2\ (g) + 4.5H_2O\ (l) + 5.5N_2\ (g)$$

All investigated tetrazoles are strongly endothermic, which was expected by comparison with the literature ($\Delta_f H^\circ$ **4** · H_2O: +514, **5**: +792, **6**: +650, **7**: +647, **10**: +686, **11**: +586 kJ mol^{-1}). The influence of crystal water can be seen at the lower $\Delta_f H^\circ$ of **4** · H_2O, in comparison with **5**.

The enthalpies of energetic materials are governed by the molecular structure of the compounds and, therefore, heterocycles with a higher nitrogen content (e.g. imidazole ($\Delta_f H^\circ_{cryst}$ = 14.0 kcal/mol) [37]; 1,2,4-triazole ($\Delta_f H^\circ_{cryst}$ = 26.1 kcal/mol); ($\Delta_f H^\circ_{cryst}$ = 56.7 kcal/mol)) [38] show higher heats of formation. From the experimentally determined heats of formation and densities obtained from single crystal structure X-ray diffraction, various thermochemical properties have been calculated using the EXPLO5 software (see below) and are summarized in Table 4.

2.4.3. Sensitivities

Since the investigated bis(methyltetrazolyl)triazenes **4**–**7**, **10** and **11** are energetic compounds with high-nitrogen contents, the sensitivities toward friction and impact were tested [39]. The impact sensitivity (IS) tests were carried out according to STANAG 4489 [40] and were modified according to instruction [41] using a BAM (Bundesanstalt für Materialforschung, [42]) drophammer [43]. The friction sensitivity (FS) tests were carried out according to STANAG 4487 [44] and were modified according to instruction [45] using the BAM friction tester. Powdered **4** and **5** are sensitive toward impact (**4**: 3 J, **5**: 2.5 J). However, monohydrate **4** is only very weak sensitive toward friction (360 N), while **5** is very friction sensitive (70 N). The ammonium salts **6** (IS: 7.5 J, FS: 360 N) and **7** (IS: 4 J, FS: >360 N) are lower sensitive than their corresponding neutral derivatives. Interestingly also the methyl derivatives **10** and **11** containing a higher carbon and hydrogen content are very sensitive toward impact (**10**: 3 J, **11**: 3 J). Again only the 2-methyltetrazolyl derivative **11** is very sensitive toward friction (20 N) while **10** is nearly insensitive (360 N). According to the UN Recommendations on the Transport of Dangerous Goods,[2] compounds **4** · H_2O, **5**, **10** and **11** are classified as "very sensitive" regarding the impact sensitivity, while **6** and **7** are classified "only" as sensitive. Regarding the friction sensitivities **7** is classified as insensitive, **4**, **6** and **10** are less sensitive and **5** and **11** are classified as "very sensitive". Therefore all derivatives should only be handled with care and appropriate precaution. Thus compound **6** is not only most promising in terms of the thermal stability but also in terms of the sensitivities.

Electrostatic sensitivity tests of **6** were carried out using an electric spark tester ESD 2010EN (OZM Research) operating with the "WINSPARK 1.15 software package" [46]. The electrical spark sensitivity of microcrystalline (1–50 μm particle size) **6** was determined to be 1.2 (±0.1) J.

2.4.4. Detonation parameter

Some detonation parameters such as pressure, temperature, velocity, the heat of explosion, and the amount of gaseous decomposition products were calculated with the EXPLO5 V5.02 software [47,48]. This program is based on the steady-state model of equilibrium detonation and uses BKW E.O.S for gaseous detonation products and Cowan-Fickett E.O.S. for solid carbon [49]. The calculations were performed using the BKWN set of constants, the maximum densities, the molecular masses and the experimentally determined heats of formations. The results are given in Table 4. The most useful values for classifying new explosives are the detonation pressure and detonation velocity. In comparison with common explosives such as TNT (trinitrotoluene, p = 202 kbar, D = 7150 m s^{-1}), compounds **4**–**7**, **10** and **11** show higher detonation pressures (**4** · H_2O: 209, **5**: 221, **6**: 248, **7**: 248, **10**: 220, **11**: 215 kbar). Due to the correlation of the detonation pressure and velocity, the same trend can be found in the detonation velocities. (**4** · H_2O: 7825, **5**: 7982, **6**: 8484, **7**: 8484, **10**: 8014, **11**: 7961 m s^{-1}). Unfortunately all compounds show lower values than those of commonly used RDX (hexogen, p = 340 kbar, D = 8882 m s^{-1}). This may be a reason of the lower densities and that the compounds contain no oxygen resulting in a strongly negative oxygen balance. Therefore their use as solid propellants was investigated by calculating the specific impulse.

2.4.5. Specific impulse

Whereas the performance of HEs can be related to heat of explosion (Q), detonation pressure (p) and detonation velocity (D), the performance of rocket/missile propellants is best characterized by their specific impulse (I_{sp}), as mentioned in Section 1

[2] Impact: Insensitive > 40 J, less sensitive ⩾ 35 J, sensitive ⩾ 4, very sensitive ⩽ 3 J; friction: Insensitive > 360 N, less sensitive = 360 N, sensitive < 360 N, a > 80 N, very sensitive ⩽ 80 N, extreme sensitive ⩽ 10 N; According to the UN Recommendations on the Transport of Dangerous Goods (+) indicates: not safe for transport.

[50]. Moreover, for gun-propellants, erosivity is an additional concern. Also lower reaction temperatures and a high N_2/CO ratio of the reaction gases are desirable [51]. Equally important, an increase of the I_{sp} of only 20 s would be expected to increase the payload or range by ca. 100%. Moreover, smokeless combustion, which is an inherent feature of high-nitrogen compounds, is not only of environmental but particularly of strategic interest since localization of the gun, missile or rocket is much more difficult.

In order to evaluate the properties of the most suitable compound **6** as potential energetic component in gun or missile propellants we calculated the specific impulses and combustion temperatures under isobaric conditions at 45 and 70 bar, representative for rocket and gun-propellants, using the EXPLO5 code [48,49]. Table 4 summarizes the computed isobaric combustion temperatures (T_c, the lower the better for gun-propellants), the specific impulses (I_{sp}) and the molar N_2/CO ratios for mixtures of **6** with ADN and three typical conventional gun-propellants (single-, double-, triple-base) at 70 bar.

Whereas single-base propellants are used in all guns from pistols to artillery weapons, the more powerful (see I_{sp}) double-base propellants are commonly used in pistols and mortars [52]. The disadvantage of double-base propellants is the excessive erosion of the gun barrel (see N_2/CO ratio) by the much higher flame temperatures, and the presence of a muzzle flash (fuel–air explosion of the combustion products). In order to reduce erosion and muzzle flash, triple-base propellants with up to 50% nitroguanidine are used in tank guns, large calibre guns and naval guns. However, the performance of triple-base propellants is lower than that of double-base propellants. A formulation of **6** with ADN (**6**: ADN = 30:70) shows a suitable combustion temperature (3037 K, between single and double-based propellants), with an excellent molar N_2/CO ratio of 5.82 (which are usually 0.5 for conventional propellants). The computed specific impulse of 251 s for such a mixture make a possible application of **6** as promising energetic component in erosion-reduced gun-propellants very interesting. Table 5 summarized the propulsion parameters for formulations of **6** with ADN at 45 bar pressure and for a stoichiometric formulation of AP/Al which is presently used in large booster motors (e.g. ARIANE5, Space Shuttle).

2.4.6. Decomposition experiments

A specially equipped IR cell was loaded each with 50 mg of **4**, **5** and their corresponding ammonia salts **6** and **7**. After heating the cell to 300 °C, the resulting combustion products were analyzed via IR spectroscopy.

Table 5

[b] Ammonium perchlorate.
[c] Aluminum.

As it can be seen in Fig. 12 the IR active gaseous decomposition products are hydrogen cyanide (HCN), methane (CH_4) and ammonia (NH_3). The IR spectrum of **4** shows intensive resonances of HCN at 3300–3400 cm^{-1} and 1300–1500 cm^{-1}. In the region of 750 cm^{-1}, the signals are broadened due to a superposition with vibrational bands of methane.

This effect is even more obvious in the spectrum of **5**. Furthermore, signals at 1300 cm^{-1} and in the range of 3100–2900 cm^{-1} confirm the existence of methane in the explosion products.

In the spectrum of **6**, the vibrational resonances of methane in the low frequency area (750 cm^{-1}) appear almost without interference. In this spectrum only traces of HCN could be detected. The main products seem to be NH_3 and methane.

Interestingly, in the spectrum of the ammonia salt **7** only vibrational signals originating from NH_3 are visible. This contradicts with the expectation of seeing additional methane and HCN as explosion products. One possible reason could be an incomplete combustion because of insufficient heating. From the mass spectroscopic analysis of **4** and **5** of course N_2 arises as the main decomposition product.

2.4.7. Long-term stabilities

The long-term stability test of **6** was performed using a Systag FlexyTSC [53] (Thermal Safety Calorimetry) in combination with a RADEX V5 oven and the SYSGRAPH software. The test was undertaken as long-term isoperibolic evaluation in a glass test vessel at atmospheric pressure with 400 mg of **6**. It was previously shown that tempering a substance for 48 h at 40° under the decomposition point results in storage periods about over 50 years at room temperature. Initially for **6** a temperature of 190 °C was chosen and possible occurrences of exo- or endothermic behavior were investigated over period of 48 h. Compound **6** was completely stable during this period. It can therefore be reasoned, that **6** is long-term stable even at higher temperatures, which is a basic requirement for possible applications.

2.4.8. n-Octanol/water partition coefficient

With regard to environmental compatibility of new energetic materials the *n*-octanol/water partition coefficient [54] of **4–7** were tested. The partition coefficient of a substance between water and a lipophilic solvent (*n*-octanol) is one model variable which may be used to describe the transfer of a substance from the aquatic environment into an organism and the potential bioaccumulation of the substance. Studies show a highly significant relationship between the partition coefficient of different substances in the system water/*n*-octanol and their bioaccumulation in fish described in the literature [55]. It has also been shown to be a useful parameter in other forms of biological activity. The partition coefficient (P) is defined as the ratio of the equilibrium concentrations (C_i) of a dissolved substance in a two-phase system consisting of two largely immiscible solvents. In the case *n*-octanol and water: $P_{ow} = C_{n\text{-octanol}}/C_{water}$. The partition coefficient (P) therefore is the quotient of two concentrations and is usually given in the form of its logarithm to base ten ($\log P$). The tests were carried out with a mixture of analytical grade *n*-octanol and distilled water at 22 °C (±1 °C). The partition coefficients of **4** and **5** could not be determined, since the compounds are not soluble either in *n*-octanol or water. This represents the ideal case of new compounds. The partition coefficients (P) of **6** and **7** were determined to be 0.081 ($\log P = -1.09$, **6**) and 0.078 ($\log P = -1.11$, **7**). This is a appropriate value (comparable to that of urea (0.062, $\log P = -1.21$)) for a new compound, which could be upscaled in future times.

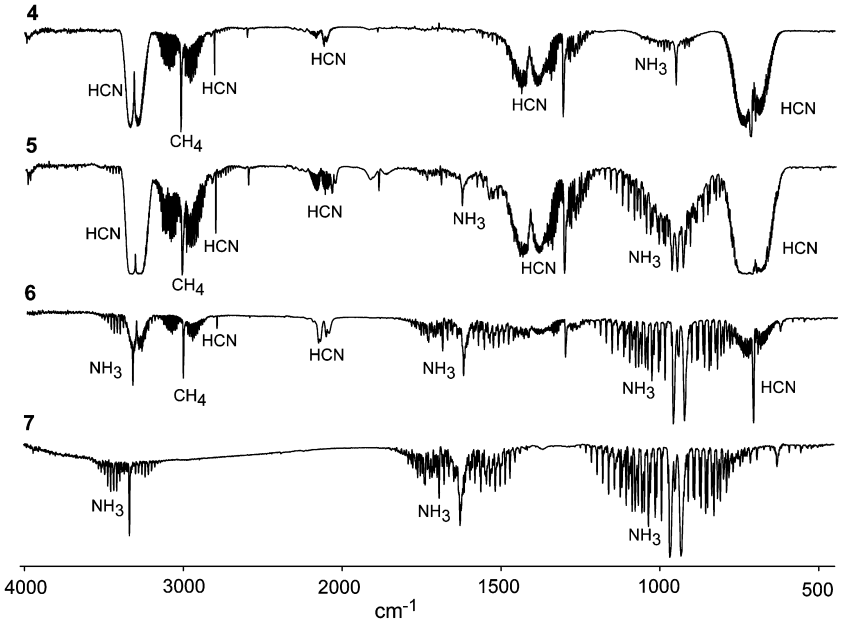

Fig. 12. Gas IR spectra of thermal decomposition products.

3. Experimental

All reagents and solvents were used as received (Sigma–Aldrich, Fluka, Acros Organics) if not stated otherwise. 5-Aminotetrazole (97%) was purchased from Aldrich. Melting points were measured with a Perkin–Elmer Pyris6 DSC, using heating rates of 5°/min. Otherwise melting points were determined with a Büchi Melting Point B-450 apparatus and are not corrected. ^{1}H and ^{13}C spectra were recorded with a Jeol Eclipse 270, Jeol EX 400 or a Jeol Eclipse 400 instrument. All chemical shifts are quoted in ppm relative to TMS (^{1}H, ^{13}C). Infrared (IR) spectra were recorded using a Perkin–Elmer Spektrum One FT-IR instrument. Raman spectra were measured using a Perkin–Elmer Spektrum 2000R NIR FT-Raman instrument equipped with a Nd:YAG laser (1064 nm). Mass spectrometric analyses were obtained with a JOEL JMS 700. Elemental Analyses were performed with a Netsch STA 429 simultaneous thermal analyzer. Bomb Calorimetry was done, using a Parr 1356 Bomb calorimeter with a Parr 1108CL oxygen bomb. The sensitivity data were performed using a BAM drophammer and a BAM friction tester. The ESD test was performed using a OZM small scale electrostatic discharge tester.

Caution! The prepared compounds **4**–**11** are energetic compounds with increased sensitivities against heat, impact and friction. Although we had no problems in synthesis, proper protective measures (safety glasses, face shield, leather coat, earthened equipment and shoes, Kevlar® gloves and ear plugs) should be used during work on **4**–**11**.

3.1. Bis(1-methyl-tetrazol-5-yl)-triazene monohydrate (*4*)

1-Methyl-5-aminotetrazole (19.82 g, 200 mmol) was elutriated in 100 mL water and cooled to 0 °C. After adding concentrated HCl (21.24 g, 200 mmol), 1-methyl-5-aminotetrazole was solved completely. A solution of $NaNO_2$ (6.90 g, 10 mmol) in 40 mL water was added drop wise within 20 min. Thereafter the solution was stirred for 24 h, the resulting colorless solid was isolated by filtration and washed with water. Single crystals were obtained from a wet methanol solution (11.0 g, yield 52.6%). M.p.: 160 °C, 182 °C (dec.); IR (KBr, cm^{-1}): $\overline{\nu}$ = 3375 (m), 3270 (m), 3081 (w), 3031 (w), 2662 (m), 2554 (m), 1664 (m), 1631 (s), 1530 (m), 1502 (m), 1458 (m), 1437 (s), 1396 (m), 1308 (m), 1268 (s), 1247 (m), 1226 (m), 1194 (s), 1102 (w), 1036 (m), 1003 (w), 983 (w), 936 (m), 806 (m), 747 (m), 729 (m), 699 (s), 666 (m), 641 (m), 605 (m), 482 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{\nu}$ = 2987 (59), 1619 (17), 1531 (54), 1453 (43), 1429 (100), 1306 (8), 1284 (28), 1246 (12), 1250 (8), 1221 (11), 1113 (24), 938 (9), 697 (15), 485 (10), 421 (11), 393 (9), 220 (28), 184 (10); ^{1}H NMR (DMSO-d_6, 25 °C, ppm) δ: 4.04 (s, 6*H*, CH_3); ^{13}C NMR (DMSO-d_6, 25 °C, ppm) δ: 34.9 (s, CH_3), 155.2 (tetrazole); ^{15}N NMR (DMSO-d_6, 25 °C, ppm) δ: −265.0 (s, N5, N7), −168.7 (d, $^{2}J_{NH}$ = 2.1 Hz, N1), −76.59 (s, N4), −12.72 (d, $^{3}J_{NH}$ = 1.8 Hz, N2), 5.54 (s, N3), 85.20 (s, N6); EA ($C_4H_9N_{11}O$, 227.19): calc.: C, 21.15; H, 3.99; N, 67.82; O, 7.04. Found: C, 21.18; H, 3.89; N, 67.48%; *m/z* (DEI^+): 209 [M^+-H_2O] (11), 111 [$(C_2H_3N_6^+)$] (100), 83 [$(C_2H_3N_4^+)$] (12), 53 (19), 43 [$(CH_3N_2^+)$] (45), 28 [(N_2^+)] (64); UV–Vis (MeOH): λ_{max} = 315 nm; ΔU_c: −3556 cal g^{-1}; BAM drophammer: 3 J; friction tester: 360 N.

3.2. Bis(2-methyl-tetrazol-5-yl)-triazene (*5*)

2-Methyl-5-aminotetrazole (8.72 g, 88 mmol) was solved in 80 mL THF and cooled to 0 °C. After adding concentrated HCl (4.58 g, 44 mmol), the formation of a colorless solid could be observed. Within 30 min 5.9 mL *i*-pentylnitrite (5.15 g, 44 mmol) were added drop wise, the suspension turned into light yellow and was stirred for 24 h at room temperature afterwards. The resulting solid was recrystallized from methanol to obtain the colorless product (15.1 g, 82%). M.p.: 183 °C (dec.); IR (KBr, cm^{-1}) $\overline{\nu}$ = 3445 (m), 3190 (m), 3136 (m), 3060 (m), 2995 (m), 2920 (m), 2857 (m), 2686 (w), 2384 (w), 1598 (s), 1521 (m), 1468 (s), 1409 (m), 1389 (m), 1349 (m), 1285 (m), 1205 (s), 1100 (w), 1063 (w), 1040 (m), 1018 (m), 949 (m), 808 (m), 758 (m), 744 (m), 705 (m), 686 (m), 672 (m), 661 (m), 590 (w), 491 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{\nu}$ = 2980 (4), 2963 (8), 1601 (12), 1528 (24), 1455 (100), 1413 (8), 1361 (5), 1291 (7), 1193 (4), 1100 (7), 1079 (6), 1049 (9), 942 (6), 703 (4), 489 (3), 434 (2), 376 (3), 174 (5); ^{1}H NMR (DMSO-d_6, *25 °C, ppm)* δ: 4.32 (s, 6*H*, CH_3), 14.10 (s, 1*H*, NH); ^{13}C NMR (DMSO-d_6, 25 °C, ppm) δ: 40.5 (CH_3), 162.9 (tetrazole); EA ($C_4H_7N_{11}$, 209.17): calc.: C, 22.97; H, 3.37; N, 73.66. 3.3. Ammonium bis(1-methyl-tetrazol-5-yl)-triazenate (*6*)

Bis(1-methyl-tetrazol-5-yl)-triazene monohydrate (2.27 g, 10.0 mmol) was elutriated in 20 mL water. The suspension was heated to 80 °C and an excess of concentrated ammonia (25%, 25 mL) was added until the reactant was completely dissolved. The ammonium salt crystallized after cooling down to room temperature, was washed with ethanol and diethyl ether and finally dried using high vacuum (1.58 g, 70% yield). M.p.: 236 °C (dec.); IR (KBr, cm^{-1}) $\overline{\nu}$ = 3425 (m), 3158 (m), 3062 (m), 2956 (m), 2857 (m), 2760 (m), 2197 (w), 2125 (w), 1971 (w), 1720 (w), 1612 (w), 1519 (s), 1478 (s), 1451 (s), 1313 (s), 1229 (m), 1209 (m), 1119 (w), 1105 (w), 1047 (w), 1009 (w), 807 (w), 749 (m), 705 (m), 666 (m), 613 (m), 498 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{\nu}$ = 2987 (5), 2962 (6), 1529 (100), 1478 (14), 1467 (16), 1415 (7), 1327 (35), 1290 (14), 1204 (18), 1127 (14), 1007 (3), 948 (6), 707 (12), 498 (15), 422 (5), 405 (4), 221 (22); ^{1}H NMR (DMSO-d_6, 25 °C, ppm) δ: 3.86 (s, 6H, 2 × CH_3), 7.42 (s, 4H, NH_4^+); ^{13}C NMR (DMSO-d_6, 25 °C, ppm) δ: 33.1 (CH_3), 161.9 (tetrazole); ^{14}N NMR (DMSO-d_6, 25 °C, ppm) δ: −358 NH_4^+; EA ($C_4H_{10}N_{12}$, 226.2): calc.: C, 21.24; H, 4.46; N, 74.31. 3.4. Ammonium bis(2-methyl-tetrazol-5-yl)-triazenate (*7*)

Bis(2-methyl-tetrazol-5-yl)-triazene (2.09 g, 10 mmol) was elutriated in 20 mL water. The suspension was heated to 80 °C and concentrated ammonia (25%, 27.3 g, 0.4 mol) was added until the reactant was completely dissolved. The ammonium salt crystallized after cooling down to room temperature, was washed with ethanol and diethyl ether and afterwards dried in vacuum (1.63 g, 72% yield). M.p.: 205 °C (dec.); IR (KBr, cm^{-1}) $\overline{\nu}$ = 3434 (w), 3137 (m), 3063 (m), 2910 (m), 2756 (m), 2554 (m), 2115 (w), 1183 (w), 1701 (w), 1599 (w), 1563 (w), 1511 (m), 1461 (s), 1423 (m), 1408 (m), 1382 (m), 1322 (s), 1272 (s), 1205 (m), 1052 (m), 1030 (m), 812 (m), 767 (m), 710 (m), 671 (w), 519 (w), 432 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{\nu}$ = 2961 (4), 1509 (100), 1469 (5), 1410 (5), 1259 (12), 1259 (6), 1106 (7), 1050 (3), 1037 (3), 964 (11), 520 (5), 185 (4); ^{1}H NMR (DMSO-d_6, 25 °C, ppm) δ: 4.20 (s, 6*H*, CH_3), 6.10 (s br, 4H, NH_4^+); ^{13}C NMR (DMSO-d_6, 25 °C, ppm) δ: 39.7 (CH_3), 173.7 (tetrazole); ^{14}N NMR (DMSO-d_6, 25 °C, ppm) δ: −359 (NH_4^+); EA ($C_4H_{10}N_{12}$, 226.2): calc.: C, 21.24; H, 4.46; N, 74.31. Found: C, 21.27; H, 4.48; N, 74.31%; *m/z* (FAB^-): 208 [anion]; UV–Vis (MeOH):

λ_{max} = 292 nm; ΔU_c: −3864 cal g^{-1}; BAM drophammer: 4 J; friction tester: >360 N.

3.5. Sodium bis(1-methyltetrazol-5-yl)-triazenate (**8**)

Bis(1-methyltetrazol-5-yl)-triazene monohydrate (2.27 g, 10 mmol) was deprotonated using 100 mL of an aqueous NaOH (0.40 g, 10 mmol) solution. After stirring for 5 min at 80 °C, the solution was cooled while the product started to precipitate. The light yellow micro crystals were filtered off and washed with ethanol and diethyl ether. The elemental analysis fits to the monohydrate (2.39 g, 96% yield). The raw product could be recrystallized either from a small amount of water including five water molecules or from a water/methanol mixture co crystallizing with one molecule methanol. M.p.: 135 °C, 195 °C (dec.); IR (KBr, cm^{-1}) $\overline{v}$ = 3445 (m), 3203 (w), 1622 (w), 1519 (s), 1474 (m), 1456 (w) 1323 (vs), 1284 (m), 1218 (m), 1205 (w), 707 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{v}$ = 2987 (7), 2965 (7), 1546 (100), 1473 (11), 1402 (6), 1338 (22), 1288 (15), 1206 (24), 1129 (15), 1012 (5), 711 (10), 500 (22), 412 (9), 222 (22); ^{1}H NMR (D_2O-*d*, 25 °C, ppm) δ: 3.94 (s, 6*H*, tetrazole-C*H*$_3$); ^{13}C NMR (D_2O, 25 °C, ppm) δ: 161.0 (tetrazole-C), 33.0 (*C*H$_3$); EA ($C_4H_8N_{11}NaO$, 249.2): calc.: C, 19.28; H, 3.24; N, 61.84. Found: C, 19.27; H, 3.27; N, 61.32%; UV–Vis (MeOH): λ_{max} = 330 nm.

3.6. Sodium bis(2-methyl-tetrazol-5-yl)-triazenate pentahydrate (**9**)

To bis(2-methyltetrazol-5-yl)-triazene (2.09 g, 10 mmol) 20 mL of an 0.5 M NaOH (10 mmol) solution was added. After stirring for 10 min at 80 °C, the solution was evaporated. The raw product was recrystallized from hot ethanol, isolated by filtration and washed with small amounts of diethyl ether (3.08 g, 96% yield). M.p.: 74 °C (–H_2O), 100 °C (–H_2O), 256 °C (dec.); **IR** (KBr, cm^{-1}) $\overline{v}$ = 3588 (m), 3479 (s), 3422 (s), 3180 (s), 2163 (w), 1735 (w), 1682 (m), 1630 (m), 1517 (m), 1469 (vs), 1441 (m), 1419 (m), 1388 (m), 1340 (vs), 1274 (s), 1252 (s), 1212 (m), 1056 (m), 1031 (w), 820 (w), 767 (m), 710 (m), 669 (m), 594 (w), 505 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{v}$ = 3025 (1), 2961 (3), 1512 (100), 1463 (10), 1415 (7), 1372 (2), 1334 (2), 1250 (8), 1200 (1), 1107 (7), 962 (10), 712 (1), 503 (3), 420 (2), 316 (2), 211 (2); ^{1}H NMR (DMSO-d_6, 25 °C, ppm) δ: 4.18 (s, 6*H*, CH_3), 3.46 (s, 10*H*, H_2O); ^{13}C NMR (DMSO-d_6, 25 °C, ppm) δ: 174.8 (tetrazole), 39.7 (*C*H$_3$); EA ($C_4H1_6N_{11}NaO_5$, 321.23): calc.: C, 14.96; H, 5.02; N, 47.96. Found: C, 14.91; H, 5.36; N, 46.53%; UV–Vis (MeOH): λ_{max} = 295 nm.

3.7. Bis(1-methyl-tetrazol-5-yl)-3-methyltriaz-1-ene (**10**)

Bis(1-methyltetrazol-5-yl)-triazene monohydrate (4.54 g, 20 mmol) was stirred in 200 mL of an aqueous NaOH (800 mg, 20 mmol) solution for 5 min at 60 °C. Then 1.1 equivalent of methyl iodide (1.4 mL) was added drop wise and the solution was stirred for 2 h at 80 °C. The light yellow precipitate was filtered off and washed with water and a small amount of ethanol (3.04 g, 68% yield). Single crystals were obtained by recrystallization from hot ethanol. M.p.: 140 °C, 200 °C (dec.); IR (KBr, cm^{-1}) $\overline{v}$ = 3431 (w, br), 1574 (s), 1519 (m), 1491 (m), 1473 (m), 1454 (s), 1423 (vs), 1393 (m), 1322 (w), 1281 (s), 1263 (w), 1231 (m), 1194 (m), 1155 (s), 1098 (w), 991 (m), 914 (w), 742 (w), 731 (m), 723 (m), 701 (w), 688 (w), 649 (m), 570 (m), 499 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{v}$ = 2950 (11), 1573 (100), 1518 (44), 1490 (20), 1449 (54), 1422 (38), 1396 (42), 1322 (5), 1265 (25), 1230 (6), 1100 (18), 1033 (4), 991 (7), 916 (6), 724 (11), 708 (12), 568 (7), 501 (7), 421 (10); ^{1}H NMR ($CDCl_3$, 25 °C, ppm) δ: 4.12 (s, 3*H*, CH_3), 4.11 (s, 3*H*, CH_3), 3.83 (s, 3*H*, CH_3); ^{13}C NMR ($CDCl_3$, 25 °C, ppm) δ: 157.9 (tetrazole), 154.2 (tetrazole), 37.6 (CH_3), 35.9 (CH_3), 34.0 (CH_3); EA ($C_5H_9N_{11}$, 223.2): calc.: C, 26.91; H, 4.06; N, 69.03. Found: C, 26.90; H, 3.97; N, 68.54%; *m/z* (DEI$^+$): 43 [$CH_3N_2^+$] (100), 83 [$C_2H_3N_4^+$] (20), 111 [$C_2H_3N_6^+$] (17), 223 [M]$^+$ (38); UV–Vis (MeOH): λ_{max} = 299 nm; ΔU_c: −4225 cal g^{-1}; BAM drophammer: 3 J; friction tester: 360 N.

3.8. Bis(2-methyltetrazol-5-yl)-3-methyltriaz-1-ene (**11**)

Bis(2-methyl-tetrazol-5-yl)-triazene (2.09 g, 10 mmol) was stirred in 100 mL of an aqueous NaOH (400 mg, 10 mmol) solution for 5 min at 60 °C. Then 0.65 equiv. of Me_2SO_4 (0.62 mL) were added drop wise and the solution was stirred for 2 h at 80 °C. The light yellow precipitate was filtered off and washed with water and a small amount of ethanol (1.29 g, 58% yield). M.p.: 135 °C, 195 °C (dec.); IR (KBr, cm^{-1}) $\overline{v}$ = 3446 (w), 3038 (w), 1613 (w), 1569 (vs), 1476 (vs), 1422 (m), 1398 (vs), 1292 (w), 1234 (s), 1218 (s), 1175 (m), 1071 (m), 1032 (m), 980 (m), 916 (w), 801 (w), 761 (w), 745 (m), 713 (m), 631 (w), 590 (w), 99 (w); Raman (1064 nm, 200 mW, 25 °C, cm^{-1}) $\overline{v}$ = 3041 (3), 1964 (10), 1563 (85), 1478 (100), 1399 (20), 1360 (6), 1293 (10), 1207 (4), 1179 (3) 1083 (3), 1034 (15), 982 (10), 915 (4), 762 (2), 746 (2), 717 (7), 638 (2), 501 (7), 444 (6), 345 (3), 183 (5); ^{1}H NMR ($CDCl_3$, 25 °C, ppm) δ: 3.74 (s, 3*H*, triazene-CH_3), 4.38 (s, 3*H*, C*H*$_3$), 4.39 (s, 3*H*, tetrazole-CH_3); ^{13}C NMR ($CDCl_3$, 25 °C, ppm) δ: 169.5 (tetrazole), 165.0 (tetrazole), 40.2 (CH_3), 40.1 (CH_3), 33.7 (triazene-CH_3); ^{15}N NMR ($CDCl_3$, 25 °C, ppm) δ: 72.6 (s, N7), −0.57 (s, N3), −2.20 (s, N3′), −25.8 (s, N6), −63.5 (s, N4), −76.6 (s, N4′), −93.2 (s, N1), −103.7 (s, N1′), −108.1 (s, N2), −109.5 (d, $^2J_{NH}$ = 2.3 Hz, N2′), −211.3 (s, N8); EA ($C_5H_9N_{11}$, 223.1): calc.: C, 26.91; H, 4.06; N, 69.03. Found: C, 26.90; H, 3.97; N, 68.54%; *m/z* (DEI$^+$): 43 [$CH_3N_2^+$] (100), 55 (17), 83 [$C_2H_3N_4^+$] (8), 111 [$C_2H_3N_6^+$] (86), 223 [M]$^+$ (7); UV–Vis (MeOH): λ_{max} = 281 nm; ΔU_c: −4491 cal g^{-1}; BAM drophammer: 3 J; friction tester: 20 N.

4. Conclusion

From this experimental study the following conclusions can be drawn:

- Bis(1-methyltetrazolyl)triazene (**4**) and bis(2-methyltetrazolyl)triazene (**5**) were synthesized by diazotation of 1-methyl-5-aminotetrazole (**2**) and 2-methyl-5-aminotetrazole (**3**), respectively, by using half an equivalent of sodium nitrite. The sodium and ammonium salts of **4** and **5** were synthesized by aqueous ammonia as well as sodium hydroxide solution. These triazenate salts can be methylated yielding bis(1-methyltetrazolyl)-3-methyltriaz-1-ene (**10**) and bis(2-methyltetrazolyl)-3-methyltriaz-1-ene (**11**). All syntheses could be performed via facile routes in good yields using cheap available precursors.
- The molecular structures of **4** · H_2O, **5**, sodium bis(1-methyl-tetrazolyl)triazenate (**8**), magnesium bis(2-methyl-tetrazolyl)triazenate (**12**) and **10** were determined using low temperature single crystal X-ray diffraction and a detailed description is given in this work.
- All compounds were characterized by Raman, IR, multinuclear NMR and UV–Vis spectroscopy, mass spectrometry, elemental analysis and differential scanning calorimetry. The decomposition temperature of the investigated compounds range from 182 to 340 °C.
- All substances show desirable high positive heat of formation (514–792 kJ mol^{-1}) determined in bomb calorimetric measurements. With these values and densities either obtained by X-ray or pycnometry several detonation parameter were computed by the EXPLO5 program, resulting in values much higher than those of TNT but lower than those of RDX. In addition promising specific impulses of mixtures of ammonium

dinitramide (AND) and ammonium bis(1-methyl-tetrazolyl)triazenate (**6**) with good N_2/CO ratios were calculated.
- The sensitivities toward impact and friction were determined by the BAM drophammer and friction tester varying from very sensitive comparable to those of primary explosives to completely insensitive.
- The most promising new energetic material is ammonium bis(1-methyl-tetrazolyl)triazenate (**6**), which combine a high decomposition temperature and high heat of formation with low sensitivities and a long-term stability.

ABSTRACT

Solvent and reaction stoichiometry dictate the products isolated from reactions of the dinuclear precursor complex $[ZnNdL(H_2O)(NO_3)_3]$ (H_2L = *N*,*N*′-bis(3-methoxy-salicylidene)ethylene-1,2-diamine) with the anionic multidentate linker 1,4-benzenedicarboxylate (1,4-BDC). With a 2:1 molar ratio of ZnNd:$Na_2$1,4-BDC in CH_3CN–EtOH the tetranuclear complex $[Zn_2Nd_2L_2(1,4\text{-BDC})(NO_3)_4(EtOH)_2] \cdot 2MeCN$ (**1**) is produced while hexanuclear $[Zn_4Nd_2L_4(1,4\text{-BDC})_2] \cdot (NO_3)_2 \cdot 2Et_2O \cdot 4H_2O$ (**2**) can be isolated from a DMF–EtOH mixture. A 4:1 mole ratio in DMF–EtOH gave the unusual polynuclear complex $[Zn_4Nd_2L_4(1,4\text{-BDC})_2] \cdot [ZnNdL(NO_3)_3(OAc)]_2$ (**3**). The NIR photophysical properties of the new compounds are reported.

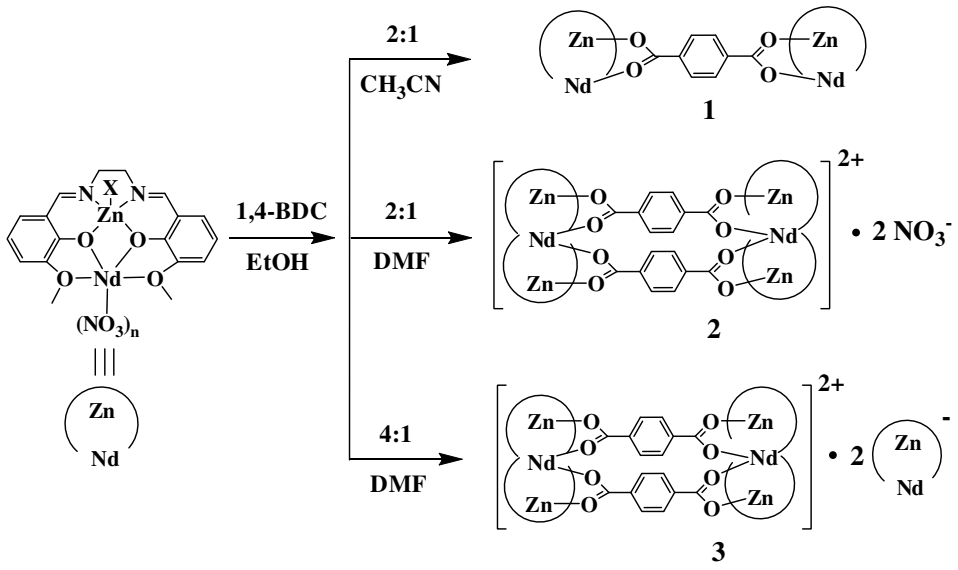
1. Introduction

Much recent attention has been focused on the near-infrared (NIR) emission properties of complexes of Nd(III), Yb(III) and Er(III), because of their potential applications in bioassays and laser systems [1]. However, this is limited by the low absorption coefficients of the lanthanide ions due to parity forbidden f–f transitions for these lanthanide ions [2]. This has led to considerable interest in the exploration of suitable chromophores [3] to sensitize the NIR emission of lanthanide ions in complex systems. One feasible way to solve this problem is to use organic dyes [4] or d-block metal complexes (Cr(III) [5], Ru(II) [6], Pt(II) [7], Re(I) or Os(II) [8]), with intense and tunable absorption maximum in the visible region, to act as sensitizers for NIR luminescence from lanthanides.

Our research has focused on the use of Zn(II) complexes of a variety of different Schiff-base ligands as possible chromophores and antennae for the sensitization of lanthanide ions [9]. We recently showed that by changing the electronic properties of the Schiff-base ligands (spacers or substituents on the phenyl rings), it is possible to influence the emissive properties of the lanthanide ions [9e]. Of relevance to the work described in this communication is our recent report of a luminescent Zn_4Nd_2 complex, in which the multidentate dianion, 1,4-benzenedicarboxylate (1,4-BDC) linked two 3d–4f moieties via axial sites to form a hexanuclear complex [10]. The compound appeared to have enhanced NIR luminescent properties over those of simple dinuclear 3d–4f complexes [9,11]. In this paper, we further demonstrate that by varying the solvent system used for crystallization and the stoichiometry of the self-assembly components, it is possible to control the nuclearity of the resultant isolated supramolecules (Scheme 1). Photophysical studies of the new compounds show that the structural variations cause modifications in the NIR luminescence of the Nd(III) ions.



2. Results and discussion

2.1. Synthesis of metal complexes

Reaction of the dinuclear precursor complex $[ZnNdL(H_2O)(NO_3)_3]$, generated in situ from the reaction of equimolar amounts of $Zn(OAc)_2 \cdot 2H_2O$, H_2L (H_2L = *N*,*N*′-bis(3-methoxy-salicylidene)ethylene-1,2-diamine) and $Nd(NO_3)_3 \cdot 6H_2O$ in ethanol, with sodium 1,4-benzenedicarboxylate ($Na_2$1,4-BDC) in a 2:1 molar ratio followed by the addition of MeCN gave the tetranuclear complex $[Zn_2Nd_2L_2(1,4\text{-BDC})(NO_3)_4(EtOH)_2] \cdot 2MeCN$ (**1**) (Scheme 1). In contrast the hexanuclear complex $[Zn_4Nd_2L_4(1,4\text{-BDC})_2] \cdot (NO_3)_2 \cdot 2Et_2O \cdot 4H_2O$ (**2**) was obtained when the reaction mixture was treated with DMF. The solid state structures of **1** and **2** were determined by single crystal X-ray crystallography. Fig. 1 shows the molecular structure of **1**. Two crystallographically equivalent

Scheme 1. Routes to polynuclear heterometallic 3d–4f complexes.

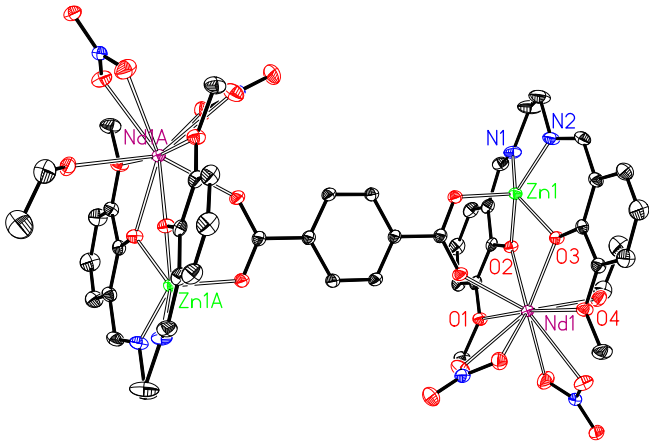

Fig. 1. A view of the molecular structure of **1**. H atoms and solvates have been omitted for clarity. Atoms are shown at the 25% probability level. Atoms whose labels are appended by an A are related by $2 - x, -y, 1 - z$.

Zn–Nd moieties lie about the inversion center, and are linked by one 1,4-BDC group. The Zn(II) ions have a distorted square pyramidal geometry, coordinated to the inner N_2O_2 cores of each Schiff-base ligand and one O atom of 1,4-BDC in the axial position. Each Nd(III) ion is 10-coordinate and surrounded by 10 O atoms, four from the outer O_2O_2 set of the Schiff-base ligand, four from the two bidentate nitrate ligands, one from the 1,4-BDC and one from an EtOH solvate. A view of the hexanuclear complex **2** is shown in Fig. 2. Two trimetallic Zn_2NdL_2 fragments are linked by two 1,4-BDC dianions to give the dicationic unit $[Zn_4Nd_2L_4(1,4\text{-BDC})_2]^{2+}$, in which the Nd(III) ions are also ten-coordinate, with eight O atoms from two outer O_2O_2 sets of two Schiff-base ligands and two O atoms from two 1,4-BDC linkers. The central core structure of **2** is similar to that found in $[Zn_4Nd_2L'_4(1,4\text{-BDC})_2] \cdot [Nd(NO_3)_5(H_2O)] \cdot 2EtOH \cdot 3H_2O$ (H_2L' = *N*,*N*′-bis(5-bromo-3-methoxysalicylidene)propylene-1,3-diamine), where the +2 charge is balanced by the dianion $[Nd(NO_3)_5(H_2O)]^{2-}$, not by the two NO_3^- ions as in **2**. [10] A somewhat related hexanuclear complex $[Cu_4Sm_2L''_4(fum)_2](OH)_2$ (H_2fum = fumaric acid; H_2L'' = *N*,*N*′-bis(3-methoxy-salicylidene)ethylene-1,3-diamine) has also been reported recently [12]. When the dinuclear precursor complex $[ZnNdL(H_2O)(NO_3)_3]$ and $Na_2$1,4-BDC were allowed to react in a 4:1 molar ratio in EtOH followed by treatment with DMF, the unusual polynuclear species $[Zn_4Nd_2L_4(1,4\text{-BDC})_2] \cdot [ZnNdL(NO_3)_3(OAc)]_2$ (**3**) was obtained in 30% yield. The solid state structure of **3**, determined by X-ray crystallography revealed the presence of one $[Zn_4Nd_2L_4(1,4\text{-BDC})_2]^{2+}$ dicationic unit (Fig. 3). The +2 charge is now balanced by the presence of two anionic $[ZnNdL(NO_3)_3(OAc)]^-$ groups instead of two NO_3^-. The anionic ZnNd moieties have structures typical of dinuclear Zn–Nd salen-type Schiff-base complexes. The Zn(II) ion adopts a distorted square-based pyramidal geometry and is five-coordinate being bound to the inner N_2O_2 cavity of the Schiff-base and to one O atom from the OAc^- group. The Nd(III) ion is 10-coordinate and bound by the outer O_2O_2 donor set of the Schiff-base ligand and six O atoms from the three bidentate NO_3^- anions. A detailed examination of the crystal stacking of complexes **1**–**3** (see Supplementary data) reveals that supramolecular interactions involving complimentary C–H···O hydrogen bonds (**1** and **2**), and electrostatic interactions (**3**) generate closely packed 3D frameworks for these compounds. Both solvent and nitrate anions in **1** and **2** were located inside the cavities of the 3D frameworks and appear to exhibit no strong interactions with the host structure.

2.2. Spectroscopy

The ^{1}H NMR spectra of all three compounds in CD_3OD solution are complex and span the range from δ *−8.38* to 14.66 ppm (see Supplementary data). There are no changes in the spectra for up to one month at room temperature.

At room temperature, complexes **1**–**3** and the precursor complex exhibit similar ligand-centered solution absorption spectra (Fig. S4) in the UV–Vis region (λ_{max} = 203, 230, 267 and 348 nm), which are red-shifted compared to the free Schiff-base (λ_{max} = 248, 337 nm) at the same concentration in degassed absolute MeOH. Complex **2** shows higher molar absorption coefficients than the other three compounds. The NIR emission spectra of all four compounds at room temperature in MeOH solution are shown in Fig. 4, and are typical for the NIR emission bands of Nd^{3+} ($^4F_{3/2} \rightarrow {}^4I_{j/2}$, j = 9, 11, 13). The emissions centered at 863, 1060 and 1328 nm can be assigned to the $^4F_{3/2} \rightarrow {}^4I_{9/2}$, $^4F_{3/2} \rightarrow {}^4I_{11/2}$ and $^4F_{3/2} \rightarrow {}^4I_{13/2}$ transitions of Nd^{3+}, respectively; while the free H_2L ligand and 1,4-BDC do not exhibit any NIR luminescence under similar conditions. At a con-

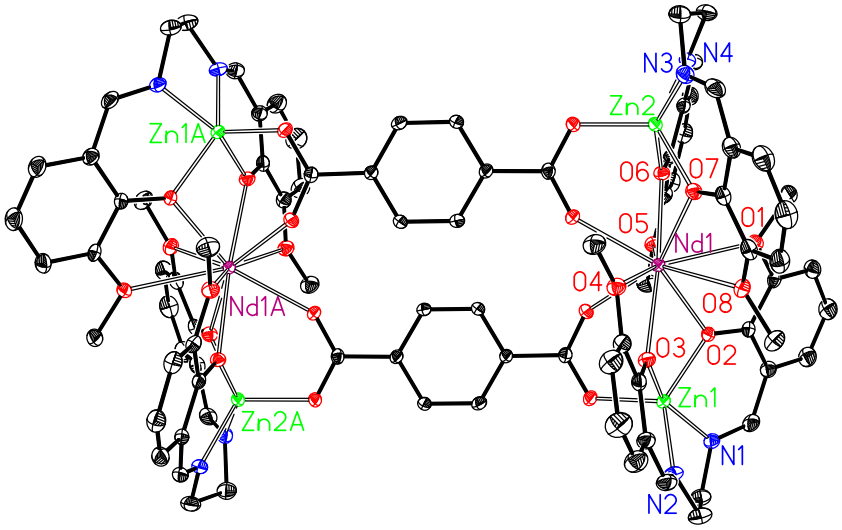

Fig. 2. A view of the cationic hexanuclear moeity of **2**. H atoms, nitrate anions and solvates have been omitted for clarity. Atoms are shown at the 30% probability level. Atoms whose labels are appended by an A are related by $2 - x, -y, 1 - z$.

centration of 4×10^{-5} M NIR Nd(III) emission was not observed for $Nd(NO_3)_3$ under the same experimental conditions.

In solution the relative emission intensities of the tetranuclear complex **1** (Zn_2Nd_2) and the hexanuclear complex **2** (Zn_4Nd_2) at 1060 nm were estimated to be *ca.* 1.13 and 2.74 times that of the dinuclear Zn–Nd precursor, respectively. Complex **3** has a relative emission intensity which is greater than that of the precursor (*ca.* 1.45 times), but significantly weaker than that of complex **2.** In solution complex **3** no doubt exists as a mixture of $Zn_4Nd_2^{2+}$ cations plus two $[ZnNd]^-$ anions, so that direct comparison of the relative emission intensities of **3** versus **2** is less reliable [11]. In the solid state structure of **1** there is one coordinated EtOH molecule, which can assist in the quenching of the luminescence of Nd^{3+} ions. In contrast there are no coordinated solvent molecules in **2** which also exhibits a higher molar absorption coefficient than **1**. This may partly explain the emission enhancement of **2** versus that of **1**. [13] The solution NIR emission spectra of the four complexes are almost identical to their solid state spectra (Fig. S5) with similar relative intensities.

In conclusion, luminescent compounds of varying stoichiometries can be isolated by controlling the mole ratios and solvent systems used in the preparation and isolation of Schiff-base stabilized 3d–4f units linked with 1,4-BDC groups.

3. Experimental

All operations were performed under a dry oxygen-free dinitrogen atmosphere using standard Schlenk techniques. Solvents and starting materials were all purchased commercially and used without further purification unless otherwise stated. Elemental analyses were performed on a Perkin–Elmer 240C elemental analyzer. Infrared spectra were recorded on a Nicolet Nagna-IR 550 spectrophotometer in the region 4000–400 cm^{-1} using KBr pellets. ^1H NMR spectra were recorded on a JEOL EX270 spectrometer with $SiMe_4$ as internal standard in CD_3OD at room temperature. Electronic absorption spectra in the UV/Vis region were recorded with a Hewlett Packard 8453 UV/Vis spectrophotometer, and NIR emission was detected by a liquid nitrogen cooled INSb IR detector (EG & G) with a preamplifier and recorded by a lock-in amplifier system. The third harmonics, 337-nm line of a Nd-YAG laser (Quantel Brilliant B), was used as the excited light source. Melting points

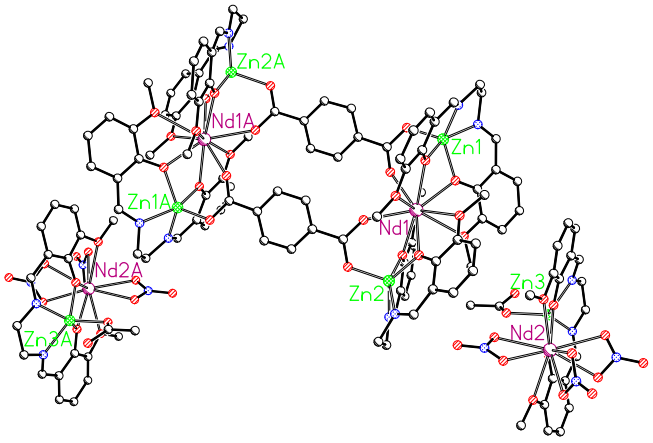

Fig. 3. A view of the structure of **3** showing both anions and cations. H atoms have been omitted for clarity. Atoms whose labels are appended by an A are related by $-x, 1 - y, -z$.

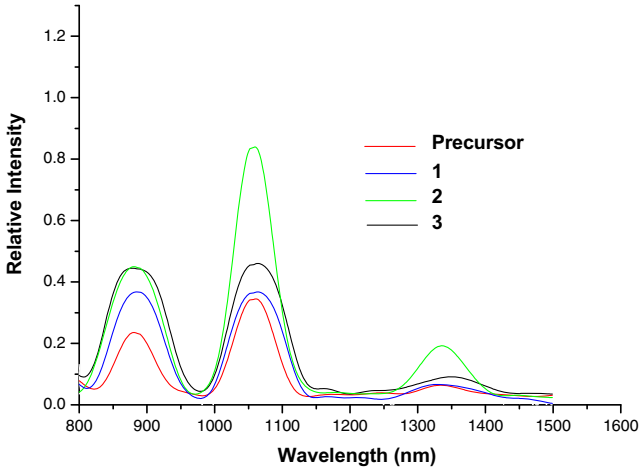

Fig. 4. NIR emission spectra of the four compounds in MeOH solution at 2×10^{-5} M at room temperature. λ_{ex} = 337 nm.

were obtained in sealed glass capillaries under dinitrogen and are uncorrected.

3.1. Synthesis

3.1.1. In situ generation of [ZnNdL(H$_2$O)(NO$_3$)$_3$] (precursor)

To a stirred suspension of H_2L (0.033 g, 0.10 mmol) in absolute ethanol (5 ml), $Zn(OAc)_2 \cdot 2H_2O$ (0.022 g, 0.10 mmol) was added and the mixture was refluxed for 5 h. Upon cooling to room temperature, a solution of $Nd(NO_3)_3 \cdot 6H_2O$ (0.044 g, 0.10 mmol) in absolute ethanol (2 ml) was added to the reaction solution, and then further refluxed for another 3 h. The yellow clear solution was then cooled to room temperature and used as the starting material for further reactions.

3.1.2. [Zn$_2$Nd$_2$L$_2$(1,4-BDC)(NO$_3$)$_4$(EtOH)$_2$] · 2MeCN (**1**)

To an ethanol solution (7 ml) of [ZnNdL(H$_2$O)(NO$_3$)$_3$] (0.10 mmol), generated in situ as above, was added half an equivalent of sodium 1,4-benzenedicarboxylate ($Na_2$1,4-BDC, 0.011 g, 0.05 mmol) and the mixture was refluxed for 2 h. The reaction solution was cooled down to room temperature and then 2 ml of anhydrous CH_3CN was added to give a clear yellow solution. Diethyl ether was allowed to diffuse slowly into this solution at room temperature and pale yellow single crystals were obtained in two weeks. Yield: 34 mg (41%). *Anal.* Calc. for $C_{52}H_{58}N_{10}O_{26}Zn_2Nd_2$: C, 37.66; H, 3.53; N, 8.45. 3.1.3. [Zn$_4$Nd$_2$L$_4$(1,4-BDC)$_2$](NO$_3$)$_2$ · 2Et$_2$O · 4H$_2$O (**2**)

To an ethanol solution (7 ml) of [ZnNdL(H$_2$O)(NO$_3$)$_3$] (0.10 mmol), generated in situ as above, was added half an equivalent of $Na_2$1,4-BDC (0.011 g, 0.05 mmol) and the mixture was refluxed for 2 h. The resultant solution was cooled down to room temperature and then 2 ml of anhydrous DMF was added to give a clear yellow solution. Diethyl ether was allowed to diffuse slowly into this solution at room temperature and pale yellow single crystals were obtained in two weeks. Yield: 21 mg (31%). *Anal.* Calc. for $C_{96}H_{108}N_{10}O_{36}Zn_4Nd_2$: C, 45.61; H, 4.31; N, 5.54. Found: C, 45.08; H, 3.82; N, 5.65%. ^{1}H NMR (270 MHz, CD_3OD): δ (ppm) 14.64 (2H), 13.98 (2H), 13.76 (2H), 11.57 (2H), 11.45 (2H), 10.62 (2H), 8.52 (2H), 8.03 (2H), 3.71 (2H), 3.57 (2H), 1.29 (3H), −1.06 (6H), −2.47 (2H), −3.69 (2H), −8.38 (6H). 3.2. X-ray crystallographic studies

Details of crystallographic parameters, data collection and refinements are listed in Table 1. Selected bond lengths (Å) and angles (°) for **1–3** are listed in Tables 2–4, respectively. Reflection intensity data single crystals of **1–3** with suitable dimensions were mounted onto thin glass fibers. All the intensity data were collected at on a Bruker SMART 1K CCD diffractometer (Mo Kα radiation, λ = 0.71073 Å) in φ and ω scan modes. Structures were solved by the direct method followed by difference Fourier syntheses, and then refined by full-matrix least squares refinement on F^2 using SHELXL. [14]. All the non-hydrogen atoms were refined with anisotropic parameters while H atoms were placed in calculated positions and refined using a riding model. The OAc^- groups in **3** were found to exhibit disorder and refined with fractional occupancies. Neutral atom scattering factors were taken from Cromer and Waber [15].

ABSTRACT

Novel water soluble free-base, Zn(II) and Co(II) metallo phthalocyanines with four cinnamic acid moieties were prepared from the corresponding tetrakis(7-coumarinthio-4-methyl)-phthalocyanine by the lactone ring opening reaction. The new compounds were purified and characterized by elemental analysis, ^{1}H NMR, Maldi-TOF, FT-IR and UV–Vis spectral data. Cyclic and differential pulse voltammetry and *in situ* spectroelectrochemistry of the 2,9,16,23-tetrakis(7-coumarinthio-4-methyl) substituted free-base **1a**, Zn(II) **1b** and Co(II) **1c** phthalocyanines, employed as the starting compounds have been studied. This allowed us not only to identify metal- and phthalocyanine ring-based redox processes of the complexes, but also the effect of aggregation on these processes.

1. Introduction

Since their accidental synthesis in 1928, phthalocyanines (Pcs) have enjoyed considerable industrial importance for use in dyes, paints, color for metal surfaces, fabrics and plastics. Accordingly, in recent years, various Pc complexes have been synthesized, characterized and investigated in terms of their properties. Various investigations have concerned the potential utility of metallo phthalocyanines (MPcs) as solar cell functional materials [1], sensing elements in chemical sensors [1,2], optical storage vehicles and nonlinear optical limiting devices [1–3], photoconducting agents in photocopying machines [1–4], electrocatalysts [1–5], and photodynamic reagents for cancer therapy and for other medical applications [1–10]. Water-soluble Pcs are the most promising materials as photosensitizers in photodynamic therapy (PDT), due to their intense absorption in the red region of the optical spectrum (ca. 700 nm) and superior photophysical properties [11]. Therefore, the synthesis of water-soluble MPcs is of great theoretical and practical significance. The solubility of Pcs in water provides additional advantage despite the fact that the aggregation tendency in such polar medium, in particular, is very high [6]. It is well known that due to their extended π-systems, macrocyclic Pc compounds exhibit an high aggregation tendency forming dimeric and oligomeric species, and thus cause a decrease in light absorptions. On the other hand, the formation of Pc aggregates is useful in materials applications where the self-assembly of Pc cores in close proximity is beneficial. The aggregation process of Pcs can be monitored using electronic spectroscopy since the coupling between the electronic states of individual monomeric Pc units causes significant spectral perturbations upon formation of higher order complexes.

Cinnamic acid (3-phenyl-2-propenoic acid) a derivative of phenylalanine, composed of relatively large family of organic acid isomers and possesses antibacterial, antifungal and parasite fighting abilities. In nature, cinnamic acid derivatives are important metabolic building blocks in the production of lignins for higher plants. Carboxyl groups in cinnamic acid molecules are separated from aromatic rings by a C=C double bond, linked with styryl substituents, and thus conjugated with the extended delocalized π-electronic systems. These compounds possess antitumor activity and behave as an important class of pharmaceuticals for high blood pressure and stroke prevention [12]. On the other hand, it is well known that coumarin (2*H*-1-benzopyran-2-one) and its derivatives are biologically active substances with numerous metabolites, and widespread in nature [13]. Some coumarin derivatives were used as anticoagulants, additives in food and cosmetics, reagents in the preparation of insecticides, optical brighteners, dispersed fluorescent, and laser dyes [14–19]. Coumarin and its derivatives are one kind of significant organic fluorescent chromophores and widely used in synthesizing laser dyes, fluorescent whiteners, the organic nonlinear optical materials and so on [20].

We report herein the synthesis and characterization of new highly water soluble free-base and MPcs (Zn and Co) bearing 2-alkoxycinnamic acid and their sodium salts. Pcs coupled with the cinnamic acid moiety may exhibit biological activities. The introduction of carboxy or amino groups enhances their solubility in water. Moreover, soluble Pcs synthesized in this study may provide new optical, electronic, redox and magnetic properties, and thus increase possible applications. The functions of metal Pcs and their derivatives are based mainly on their redox or electron transfer reactions. The understanding of the redox properties of the Pc complexes is important in terms of their applications in many areas. These processes occur at either the Pc ring or the metal center. However, it is not possible to distinguish such processes by voltammetry alone. Spectroelectrochemistry provide additional support for the assignment of the redox processes. Moreover, spectroelectrochemical studies of Pcs are also important in identifying the aggregation–deaggregation equilibrium of Pcs which is known to affect their redox behavior. Taking into consideration these purposes in this study, we also report voltammetry and *in situ* spectroelectrochemistry of **1a**, **1b** and **1c**.

2. Experimental

Routine IR spectra were recorded on a Shimadzu Fourier Transform FTIR-8300 Infrared Spectrometer using KBr pellets, electronic spectra on a Shimadzu UV-1601 UV–Vis Spectrometer, ^{1}H NMR spectra on a Varian Unity Inova 500 MHz NMR Spectrometer using TMS as internal reference at Erzurum University Laboratory. Mass spectra were performed on a Bruker Daltonic Autoflex MALDI-TOF spectrometer at Marmara University.

2,9,16,23-Tetrakis(7-coumarinthio-4-methyl)-phthalocyanine (**1a**), 2,9,16,23-tetrakis(7-coumarinthio-4-methyl)-phthalocyaninatozinc (**1b**) and 2,9,16,23-tetrakis(7-coumarinthio-4-methyl)-phthalocyaninatocobalt (**1c**) were synthesized according to reported procedure [21]. All reagents and solvents were of reagent-grade quality obtained from commercial suppliers. All solvents were purified and stored over molecular sieves (4 Å). The homogeneity of the products was checked at each stage in their synthesis by TLC (SiO_2).

The cyclic voltammetry, differential pulse voltammetry, and controlled potential chronocoulometry (CPC) measurements were carried out with a Princeton Applied Research Model Versostat II potentiostat/galvanostat controlled by an external PC and utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt plate with a surface area of 0.10 cm^2. The surface of the working electrode was polished with H_2O suspension of Al_2O_3 before each run. The last polishing was done with a particle size of 50 nm. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a double bridge. Electrochemical grade tetrabutylammonium perchlorate (TBAP) in extra pure DMSO was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}. High purity N_2 was used for deoxygenating the solution at least 20 min prior to each run and to maintain a nitrogen blanket during the measurements. For CPC studies, a Pt gauze working electrode (10.5 cm^2 surface area), a Pt wire counter electrode separated by a glass bridge, and a SCE as reference electrode were used. Spectroelectrochemical measurements were carried out by an Agilent Model 8453 diode array spectrophotometer equipped with the potentiostat/galvanostat and utilizing an optically transparent thin layer (OTTLE) cell with three-electrode configuration at 25 °C. The working electrode was transparent Pt gauze. A Pt wire counter electrode and a SCE reference electrode separated from the bulk of the solution by a double bridge were used.

*2.1. General procedure for the synthesis of 2,9,16,23-tetrakis[(E)-3-(2-(hexyloxy)-4-mercaptophenyl)but-2-enoic acid] phthalocyanine (**2a**), 2,9,16,23-tetrakis[(E)-3-(2-(hexyloxy)-4-mercaptophenyl)but-2-enoic acid] phthalocyaninatozinc (**2b**), their sodium salts and 2,9,16,23-tetrakis[(E)-3-(2-(hexyloxy)-4-mercaptophenyl)but-2-enoic acid] phthalocyaninatocobalt (**2c**)*

To a solution of each 2,9,16,23-tetrakis(7-coumarinthio-4-methyl) substituted Pc [(0.075 g, 0.06 mmol H_2Pc, **1a**) (0.050 g, 0.03 mmol ZnPc, **1b**) (0.050 g, 0.03 mmol CoPc, **1c**)] in dry DMSO (10 ml) was added NaOH pallets (0.024 g, 0.60 mmol for **1a**; 0.015 g, 0.37 mmol for **1b** and 0.015 g, 0.37 mmol for **1c**). Each mixture was held at 50 °C for two days and then cooled to room temperature. 1-Bromohexane (0.05 ml) was added to each mixture and it was stirred at room temperature in a sealed tube for two days. Each product poured into 2 M HCl ice-water. Each precipitate was collected by filtration, washed with water and finally dried. The products were purified by extraction with ethylacetate, ethanol, methanol, acetone, THF and $CHCl_3$. The compounds **2a** and **2b** were soluble in DMF, DMSO and 5% NaOH. Compound **2c** was soluble in DMF and DMSO, but insoluble in 5% NaOH.

Sodium salts of **2a** and **2b** were obtained by dissolving these compounds in 5% NaOH, and then precipitating with MeOH.

*2.1.1. Compound **2a***

Yield: 0.060 g (60%). M.p.: > 300 °C. IR γ_{max} (cm^{-1}): 3053 (aryl CH), 2858–2925 (alkyl CH), 3276 (NH), 2950–3400 (OH), 1718 (C=O acid), 1595 (C=C), 1242 (Ar–O–C). ^{1}H NMR δ_H (DMSO): 7.22–8.09 (m, 24H, Ar–H), 6.24 (s, 4H, C=C*H*), 4.30–4.40 (t, 8H, OCH_2Ar), 3.65–3.70 (t, 8H, OCH_2), 2.40 (s, 12H, CH_3), 1.74–2.10 (t, 8H, C$H_2$$CH_2$OAr), 0.85–1.43 (m, 72H, alkyl CH), 11.0 (b, OH). Found: C, 67.98; H, 5.45; N, 6.28; S, 7.24%. MS (MALDI-TOF) *m/z*: 1745 $[M]^+$.

*2.1.4. Compound **2b** sodium salt*

IR γ_{max} (cm^{-1}): 3043 (aryl CH), 2852–2902 (alkyl CH), 1650 (C=O acid), 1465 (C=C), 1249 (Ar–O–C), 3425 (moisture peak). UV–Vis (5% NaOH) λ_{max} (nm) ($\log\varepsilon$): 701 (4.41), 657 (4.63.), 357 (4.60). *Anal.* Calc. for $C_{96}H_{92}N_8O_{12}S_4ZnNa_4$ (1833): C, 62.84; H, 5.01; N, 6.11; S, 6.98. Found: C, 62.04; H, 4.98; N, 6.01; S, 6.78%. MS (MALDI-TOF) *m/z*: 1833 $[M]^+$.

*2.1.5. Compound **2c***

Yield: 0.027 g (41%). M.p.: > 300 °C. IR γ_{max} (cm^{-1}): 3058 (aryl CH), 2858–2933 (alkyl CH), 2950–3400 (OH), 1718 (C=O acid), 1595 (C=C), 1242 (Ar–O–C). UV–Vis (DMF) λ_{max} (nm) ($\log\varepsilon$): 691 (4.84), 627 (4.37), 305 (4.94). *Anal.* Calc. for $C_{96}H_{96}N_8O_{12}S_4Co$ (1739): C, 66.24; H, 5.52; N, 6.44; S, 7.36. Found: C, 65.17; H, 5.50; N, 6.36; S, 7.01%. MS (MALDI-TOF) *m/z*: 1739 $[M]^+$.

*2.2. General procedure for the 2,9,16,23-tetrakis[(E)-3-(2-(2-(dimethylamino)ethoxy)-4-mercaptophenyl)but-2-enoic acid] phthalocyanine (**3a**) and 2,9,16,23-tetrakis[(E)-3-(2-(2-(dimethylamino)ethoxy)-4-mercaptophenyl)but-2-enoic acid] phthalocyaninatozinc (**3b**) and their sodium salts*

To a solution of each 2,9,16,23-tetrakis(7-coumarinthio-4-methyl) substituted Pc [(0.050 g, 0.04 mmol H_2Pc, **1a**) (0.050 g, 0.04 mmol ZnPc, **1b**) in dry DMSO (10 ml) was added NaOH pallets (0.015 g, 0.40 mmol for **1a** and 0.015 g, 0.40 mmol for **1b**). Each mixture was stirred at room temperature in vacuo for two days, and then 2-(dimethylamino)chloroethanhydrochloride salt (0.058 g, 0.40 mmol for **1a** and 0.058 g, 0.40 mmol for **1b**) was added. Each mixture was stirred at room temperature in a sealed tube for two days in vacuo and each product was poured into acetone (10 ml). Each precipitate was collected by filtration, washed with 2 M HCl for removing excess NaOH and water, and finally dried. The green products **3a** and **3b** were purified by extraction with ethylacetate, ethanol, methanol, acetone, THF and $CHCl_3$. The compounds were soluble in DMF, DMSO and 8% NaOH.

Sodium salts of **3a** and **3b** were obtained by dissolving these compounds in 8% NaOH, and then precipitating with MeOH.

*2.2.1. Compound **3a***

Yield: 0.040 g (63%). M.p.: > 300 °C. IR γ_{max} (cm^{-1}): 3053 (aryl CH), 2819–2931 (alkyl CH), 3278 (NH), 2950–3400 (OH), 1639 (C=O acid), 1596 (C=C), 1242 (Ar–O–C). ^1H NMR δ_H (DMSO): 7.36–8.14 (m, 24H, Ar–H), 6.32 (s, 4H, C=C*H*), 4.36–4.45 (t, 8H, OCH_2Ar), 3.66–3.74 (t, 8H, OCH_2), 2.46 (s, 12H, CH_3), 1.78–2.15 (t, 8H, CH_2CH_2OAr), 0.90–1.46 (m, 72H, alkyl CH); 11,96 (b, OH), UV–Vis (DMF) λ_{max} (nm) ($\log\varepsilon$): 691 (4.33), 651 (4.07), 343 (4.39). *Anal.* Calc. for $C_{88}H_{86}N_{12}O_{12}S_4$ (1630): C, 64.78; H, 5.27; N, 10.30; S, 7.85. Found: C, 63.26; H, 4.93; N, 9.97; S, 7.82%. MS (MALDI-TOF) *m/z*: 1630 $[M]^+$, 1628 $[M-2]^+$.

*2.2.2. Compound **3a** sodium salt*

IR γ_{max} (cm^{-1}): 3042 (aryl CH), 2914–2950 (alkyl CH), 3275 (NH), 1642 (C=O acid), 1597 (C=C), 1245 (Ar–O–C), 3390 (moisture peak). UV–Vis (8% NaOH) λ_{max} (nm) ($\log\varepsilon$): 702 (3.58), 661 (4.08), 327 (4.40). *Anal.* Calc. for $C_{88}H_{82}N_{12}O_{12}S_4Na_4$ (1718): C, 61.46; H, 4.77; N, 9.77; S, 7.45. Found: C, 61.26; H, 4.93; N, 9.97; S, 7.42%. MS (MALDI-TOF) *m/z*: 1693 $[M]^+$, 1691 $[M-2]^+$.

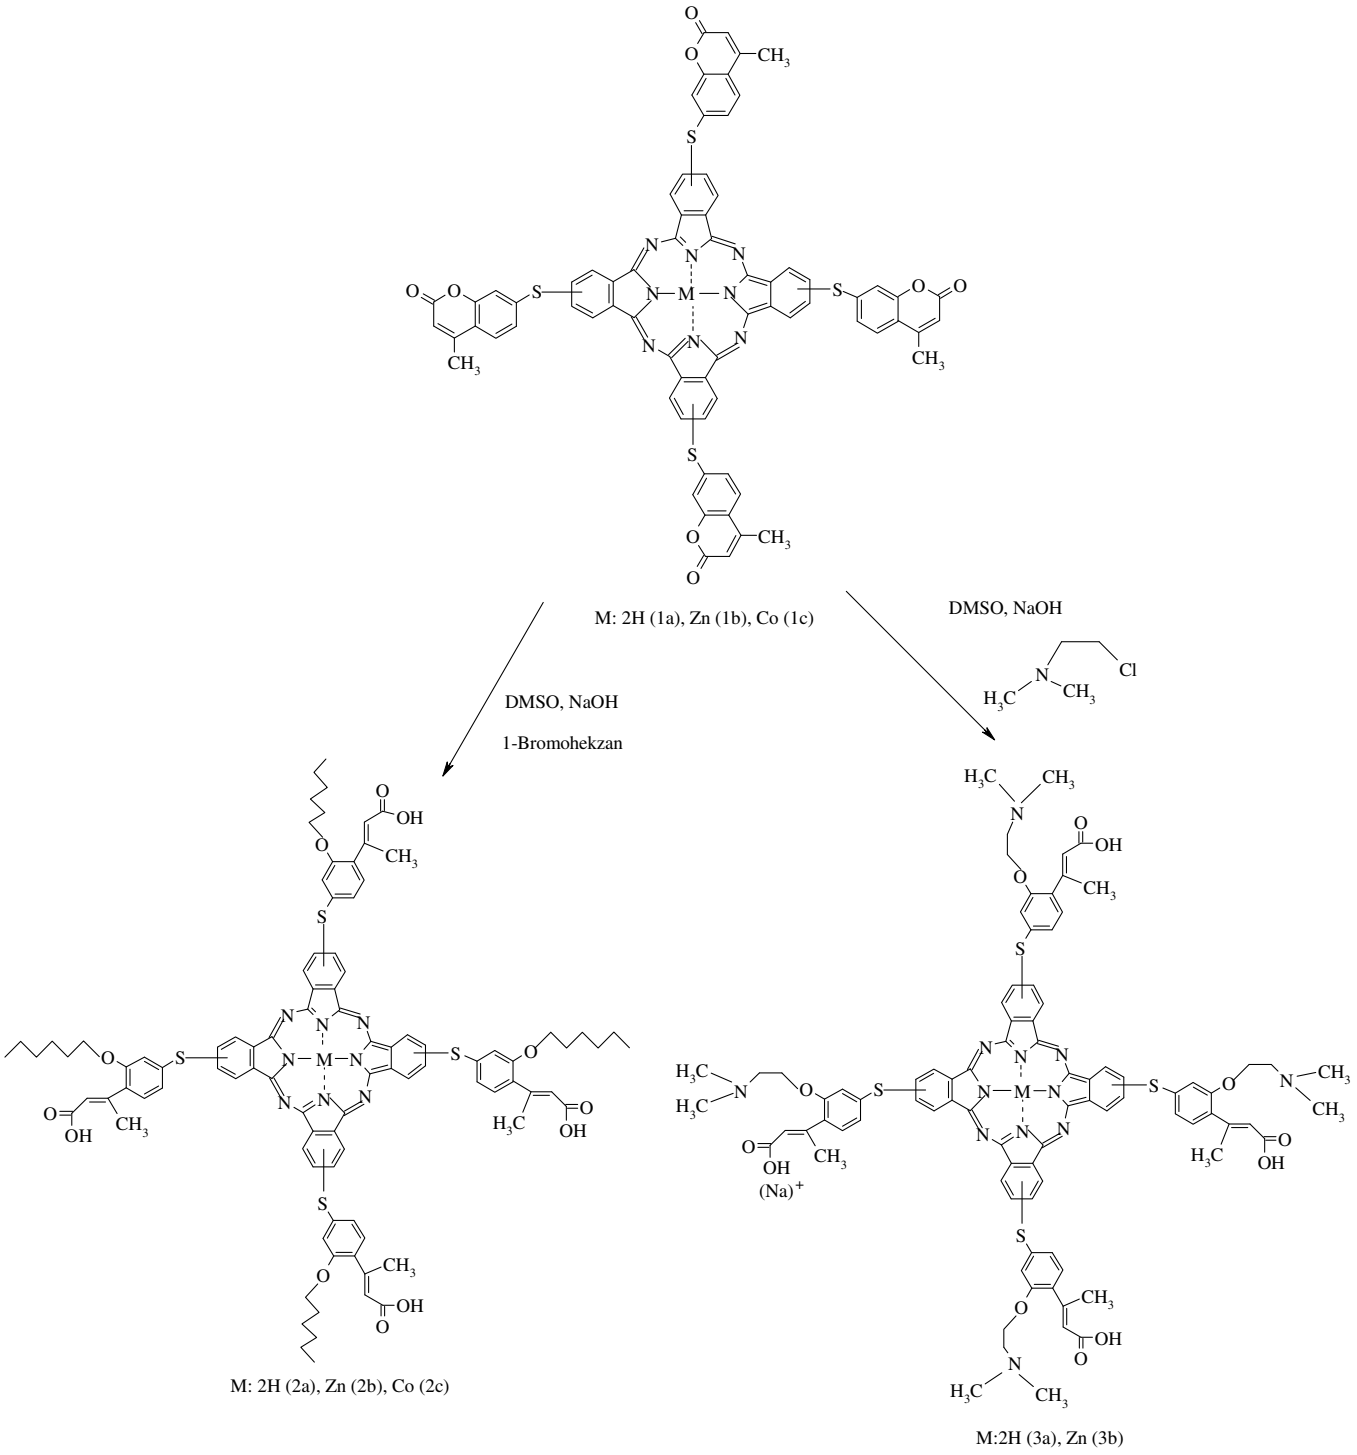
*2.2.4. Compound **3b** sodium salt*

IR γ_{max} (cm^{-1}): 3040 (aryl CH), 2859–2916 (alkyl CH), 1654 (C=O acid), 1469 (C=C), 1245 (Ar–O–C), 3430 (moisture peak). UV–Vis (8% NaOH) λ_{max} (nm) ($\log\varepsilon$): 703 (4.64), 658 (4.48), 319 (4.72). *Anal.* Calc. for $C_{88}H_{80}N_{12}O_{12}S_4ZnNa_4$ (1781): C, 59.29; H, 4.49; N, 9.43; S, 7.18. Found: C, 58.16; H, 4.45; N, 9.26; S, 7.08%. MS (MALDI-TOF) *m/z*: 1781 $[M]^+$, 1779 $[M-2]^+$.

3. Result and discussion

3.1. Synthesis and characterization



Novel free-base and metallo Pcs containing four 7-phenylthio-4-methylcoumarin moieties were synthesized according to the reported procedure [21]. The coumarin substituents on the periphery of the Pc bring out a vast number of possibilities for binding with different nucleophiles. Opening all of the four lactone rings in **1a**, **1b** and **1c** with NaOH in DMSO, then concomitant reaction of formed hydroxy group with 1-bromohexane or 2-(dimethylamino)chloroethane gave Pcs **2a**, **2b** and **2c** or **3a** and **3b**. These compounds were purified by extraction with ethylacetate, ethanol, methanol, acetone, THF and $CHCl_3$. The products **2a** and **2b** show good solubility in organic solvents such as DMF, DMSO and 5% $NaOH_{(aq)}$. Compound **2c** was soluble in DMF and DMSO, but insoluble in 5% $NaOH_{(aq)}$. For this reason, sodium salt of **2c** could not be prepared. Compounds **3a** and **3b** were soluble in DMF, DMSO and 8% NaOH.

Starting from 2,9,16,23-tetrakis(7-coumarinthio-4-methyl)-phthalocyanine (**1a**), 2,9,16,23-tetrakis(7-coumarinthio-4-methyl)-phthalocyaninatozinc (**1b**) and 2,9,16,23-tetrakis(7-coumarinthio-4-methyl)-phthalocyaninatocobalt (**1c**), the derived novel cinnamic acid substituted Pcs **2a**, **2b**, **2c**, **3a** and **3b** were prepared according to the route shown in Scheme 1. The characterization of the products involved a combination of methods including, ^1H NMR, FT-IR, UV–Vis, elemental analysis and MALDI-TOF spectrometer.

In the IR spectra, N–H stretching peaks in the core of free-base Pcs (**2a**, and **3a**) were monitored at around 3280 cm^{-1}. The increase in the intensity of alkyl CH peaks and the appearance of C–OH stretching bands in the range of 2940–3400 cm^{-1} for **2a**, **2b** and **2c**, as compared with that of starting compounds (**1a**, **1b** and **1c**) [21], confirmed the formation of cinnamic acid substituted Pcs with long alkyl chains. C–OH stretching bands for **3a** and **3b** were observed in a similar range. Additionally, C–N stretching for **3a** and **3b** were also recorded around 1020–1420 cm^{-1}. All these IR data clearly proved the opening of the lactone ring of coumarin substituted starting compounds.

^1H NMR spectra of the compounds synthesized were almost identical except for small shifts. These spectra exhibited vinilic protons at 6.24 ppm for **2a**, 6.12 ppm for **2b**, 6.32 ppm for **3a** and 6.30 ppm for **3b**. The aromatic protons of all compounds appeared at 7.22–8.09 ppm for **2a**, 7.48–8.14 ppm for **2b**, 7.36–8.14 ppm for **3a** and 7.34–8.13 ppm for **3b**. The acid protons were observed at 11.0 ppm for **2a**, 11.27 ppm for **2b**, 11.96 ppm for **3a** and 11.90 ppm for **3b**. A common feature of these spectra is the broad signals probably caused by the aggregation of Pcs.

A closer investigation of the mass spectra of the Pcs confirmed the proposed structures. In the mass spectra of the compounds, the $[M^+]$ peaks were identified easily, as shown as an example in Fig. 1 for **3a**. The MALDI-TOF-MS spectra provided definitive characterization of the structures of all complexes. Linear mode positive ion MALDI mass spectra could be obtained in 7-hydroxycoumarin (umbelliferone) MALDI matrix. The protonated molecular ion peak of the complexes were observed at 1682 Da for **2a**, at 1745 Da for **2b**, at 1339 Da for **2c**, at 1630 Da for **3a** and at 1693 Da for **3b**. These mass values corresponded to the theoretical calculated mass values for the molecular ion of all the complexes.

Scheme 1. Synthesis of the free-base and metallo phthalocyanines with four cinnamic acid moieties.

The Pcs synthesized in this study show typical electronic spectra with two absorption regions, one of them in the UV region at about 300–350 nm (B band) and the other in the visible part of the spectrum around 600–700 nm (Q band). Fig. 2A exemplifies the UV–Vis spectra of the Pcs involving cinnamic acid (**2a**, **2b** and **2c**) in DMF. The absorption bands around 700 nm correspond to characteristic $a_{1u}(\pi) \rightarrow e_g(\pi^*)$ transitions while the B bands are assigned to $a_{2u}(\pi) \rightarrow e_g(\pi^*)$ transitions of the complexes with fully conjugated 18π electron system. Free-base derivative, **2a** showed a splitted Q band absorption in the visible region, as expected, due to its D_{2h} symmetry. On the other hand, the weak bands around 641 nm, as satellite, at the blue side of the main Q band, observed for **2b** and **2c** are known as "vibrionic Q_m band". The absence of an additional absorption band around 630–640 nm at the blue side of the main Q band shows that complexes **2b** and **2c** are mainly in the form of monomers in DMF. The UV–Vis spectral behavior of tetra substituted coumarin Pcs (**1a**, **1b** and **1c**) and involving 2-(dimethylamino)ethyloxy tetra substituted cinnamic acid Pcs (**3a**, **3b**) were considerably similar to those of **2a**, **2b** and **2c**, except small shifts due to different substituent effects (Fig. 2B). However, the UV–

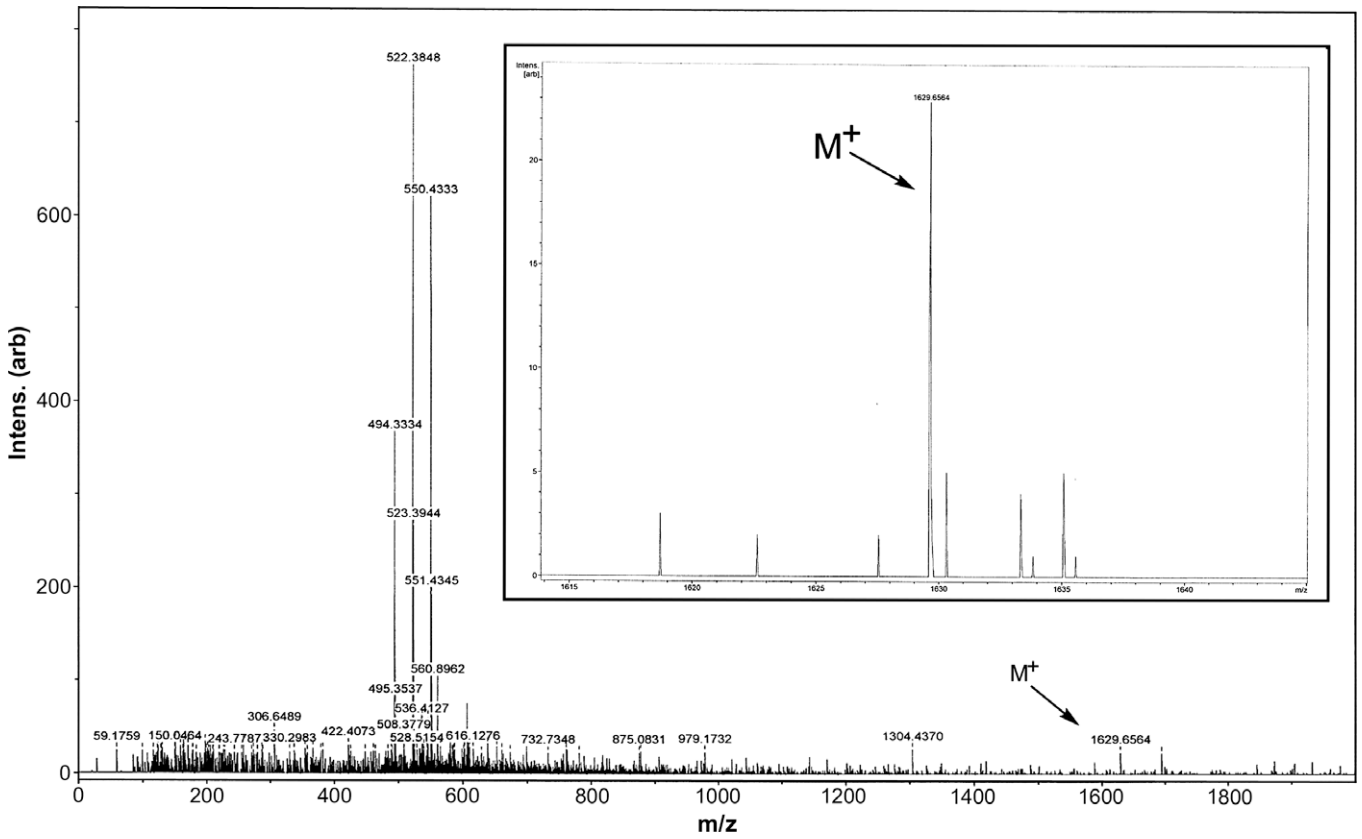


Fig. 1. The positive ion and linear mode MALDI-TOF MS spectrum of **3a** in 7-hydroxycoumarin (umbelliferone) MALDI matrix using nitrogen laser accumulating 50 laser shots. Inset spectrum shows expanded molecular mass region of the complex.

Vis spectra of the Pc compounds in DMSO and especially in water are remarkably different from those of in DMF. Typical spectra of some Pc compounds in various solvents are shown in Fig. 3. As shown in Fig. 3A for **2b**, the appearance of a new band around 656 nm, at the blue side of the main Q band absorption, in DMSO and water suggests clearly the presence of aggregated species. Aggregation is usually depicted as a coplanar association and strongly dependent on the concentration and nature of the solvent. Generally, it results in a decrease in intensity in the components of the Q band corresponding to the monomeric species, in the mean time a new broader and blue-shifted band is observed to increase in intensity. This shift to lower wavelengths corresponds to H-type aggregates. At the high concentrations or with solvents of high polarity, it is usually more pronounced. Fig. 3B indicates the effect of increasing concentration on the UV–Vis spectra of 1×10^{-6} mol dm^{-3} **3b** in DMSO, as an example. At the beginning (for 1×10^{-6} mol dm^{-3} **3b**), the intensities of two bands are approximately equal to each other. As the concentration of **3b** is increased, the band with the lower wavelength becomes higher in intensity as compared with the other band. This clearly suggests that the band with the higher energy corresponds to the aggregated species, and provides additional support for H-type aggregation. The other complexes also displayed a similar behavior in the same solvents.

3.2. Electrochemistry and spectroelectrochemistry

Voltammetry and spectroelectrochemistry of the complexes **1a**, **1b** and **1c** were performed in de-aerated DMSO containing TBAP. The half-wave potentials ($E_{1/2}$) are listed in Table 1. Controlled potential coulometry studies at the peak potentials suggested that the number of electrons transferred for all redox processes of the complexes are one with deviation from unity for some couples at the end of potential window. Anyway, in Pcs, multi-electron processes occurring in one step are not common. Thus, all the complexes displayed three reductions and one oxidation signal. The ratio of anodic to cathodic peak currents for the redox couples were near unity and anodic to cathodic peak separation, ΔE ranged 60–200 mV, thus suggesting reversible to quasi-reversible behavior, ΔE of 90 mV at 0.100 V s^{-1} was obtained for the ferrocene internal standard.

Fig. 4 shows the cyclic voltammogram (CV) in (A) and differential pulse voltammogram (DPV) in (B) of 5.00×10^{-4} mol dm^{-3} **1a** in DMSO/TBAP, with three reduction processes (labelled II–IV) and an oxidation process (labelled I). These processes are clearly ligand-based. The rounded shape of the reduction couples, II and III, are probably due to the aggregation of the complex which is known to occur usually at high concentrations employed for voltammetric studies. Fig. 5 shows the cyclic and differential pulse voltammograms (CV in A and DPV, in B) of 5.00×10^{-4} mol dm^{-3} **1b** in DMSO/TBAP. The redox potentials of **1a** and **1b** are similar to each other except half-wave potentials of **1b** are usually more negative as compared with those of **1a**. This can be attributed to the difference in the polarizing effects of Zn(II) and 2H. The similarity between the redox potentials of **1a** and **1b** suggests that the redox processes of **1b** are also ligand-based. Anyway, the central Zn metal in ZnPc complexes is electro-inactive [22]. Reduction of the Pc ligand is associated to the position of the lowest occupied molecular orbital (LUMO) whereas oxidation of the ligand is associated to the position of the highest occupied molecular orbital (HOMO). Thus, the difference between the potentials of the first oxidation and the first reduction processes ($\Delta E_{1/2}$) reflects the

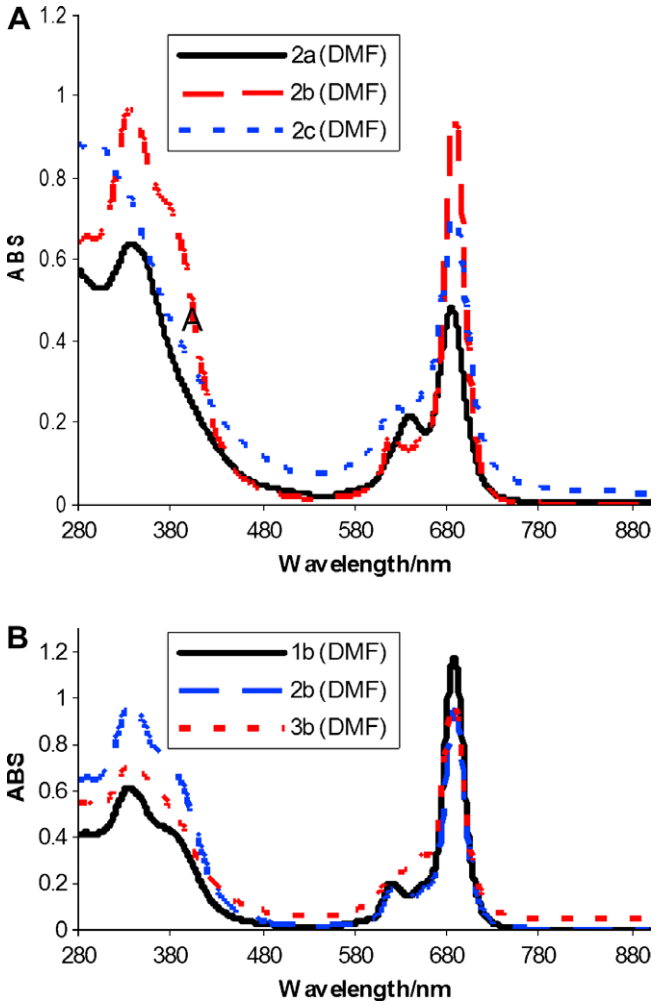

Fig. 2. UV–Vis spectra of 1×10^{-5} mol dm^{-3} **2a**, **2b** and **2c** (A) and **1b**, **2b** and **3b** (B) in DMF.

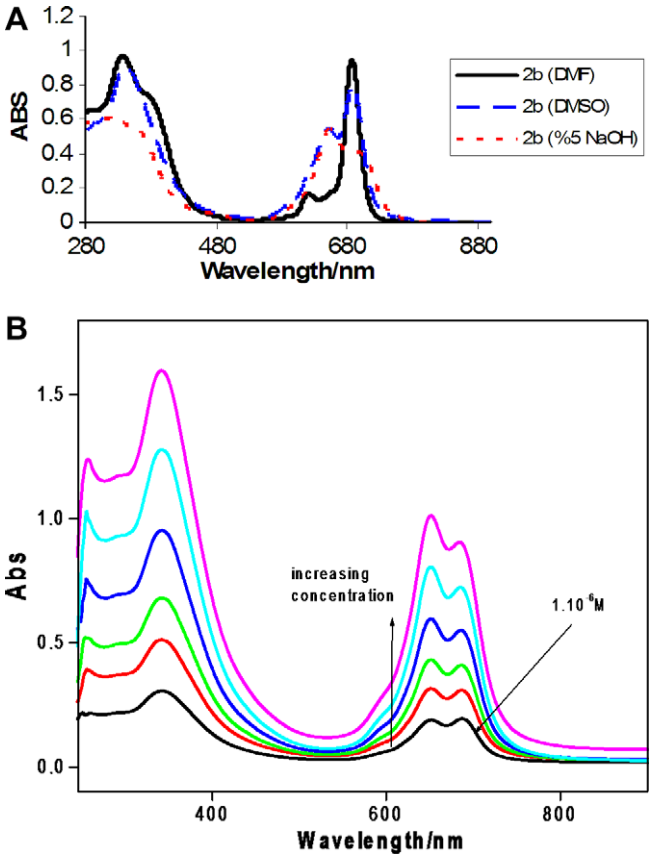

Fig. 3. UV–Vis spectra of 1×10^{-5} mol dm^{-3} **2b** in various solvents (DMF, DMSO and 5% NaOH) (A), and the effect of increasing concentration on the UV–Vis spectra of 1×10^{-6} mol dm^{-3} **3b** in DMSO (B).

homo–lumo gap for free-base Pcs and it is closely related with the homo–lumo gap in MPc species involving redox-inactive metal center. $\Delta E_{1/2}$ values recorded for **1a** (1.35 V) and **1b** (1.47 V) in this study are in agreement with the values reported previously for the relevant Pcs involving redox-inactive metal center [22–26].

Fig. 6 shows the cyclic and differential pulse voltammograms (CV in A and DPV in B) of 5.00×10^{-4} mol dm^{-3} 1 c in DMSO/TBAP. The redox potentials of **1c** are highly different in comparison with those of **1a** and **1b** (Table 1). As compared with **1a** and **1b**, the first reduction of Co(II) complex, **1c** occurs at a potential less negative (−0.40 V versus SCE), and the first oxidation at a potential less positive (0.43 V versus SCE) (Table 1). This difference in the voltammetric behavior is due to the fact that MPcs, such as MnPc, CoPc and FePc, having a metal that possesses energy levels lying between the HOMO and the LUMO of the Pc ligand, in general exhibit redox processes centered on the metal [22,25–28]. For CoPc complexes, the first oxidation and first reduction processes occur on the metal center in polar solvents such as DMF and DMSO, however the first oxidation process occurs on the Pc ring in nonpolar solvents such as DCM and THF. Therefore, the first reduction (couple II) and the first oxidation (couple I) processes of **1c** could be assigned to the $[Co(II)Pc(-2)]/[Co(I)Pc(-2)]^{-}$ and $[Co(II)Pc(-2)]/[Co(III)Pc(-2)]^{+}$ redox couples, respectively. The second and third reduction processes (couples III and IV) are probably ligand-based and can be assigned to $[Co(I)Pc(-2)]^{-}/[Co(I)Pc(-3)]^{2-}$ and $[Co(I)Pc(-3)]^{2-}/[Co(I)Pc(-4)]^{3-}$. The separation between the first oxidation and the first reduction potentials of the metal center for the Co(II) complex, **1c** (0.83 V) is comparable with the relevant values in the literature [22,25–28], and does not reflect the HOMO–LUMO gap.

Table 1
The electrochemical data for **1a**, **1b** and **1c**.

Complex	Redox processes		$E_{1/2}$[a] (V versus SCE)	ΔE_p[b] (V)	ΔE_{12}[c] (V)
1a	$[H_2Pc(-1)]^{-}/H_2Pc(-2)$	I	0.72	0.06	1.35
	$H;Pc(-2)/[H_2Pc(-3)]^{-}$	II	−0.63	0.10	
	$[H:Pc(-3)]^{-}/[H_2Pc(-4)]^{2-}$	III	−0.88	0.20	
	$[H:Pc(-4)]^{2-}/[H:Pc(-5)]^{3-}$	IV	−1.64	0.20	
1b	$[Zn(II)Pc(-1)^{-}/Zn(II)Pc(-2)$	I	0.67	0.06	1.47
	$Zn(II)Pc(-2)/[Zn(II)Pc(-3)]^{-}$	II	−0.80	0.10	
	$[Zn(H)Pc(-3)]^{-}/$ $[Zn(II)Pc(-4)]^{-}$	III	−1.19	0.06	
	$[Znai)Pc(-4)]^{2-}/$ $[Zn(II)Pc(-5)]^{3-}$	IV	−1.45	0.08	
1c	$[Co(III)Pc(2)]^{-}/Co(II)Pc(2)$	I	0.13	0.11	0.83
	$Co(II)Pc(-2)/[Co(I)Pc(-2)]^{-}$	II	−0.40	0.20	
	$[Coa)Pc(-2)]^{-}/$ $[Co(I)Pc(-3)]^{-}$	III	−1.30	0.08	
	$[Co(I)Pc(-3)]^{-}/$ $[Co(I)Pc(-4)]^{3-}$	IV	1.65	0.10	

[a] $E_{1/2} = (E_{pa} - E_{pc})/2$ at 0.100 V s^{-1}.
[b] $\Delta E_p = E_{pa} - E_{pc}$ at 0.100 V s^{-1}.
[c] $\Delta E_{1/2} = E_{1/2}$ (first oxidation) − $E_{1/2}$ (first reduction). This value reflects the HOMO–LUMO gap for **Ia** and **Ib** but does not for **Ic**.

Spectroelectrochemical measurements in solution have a vital importance in confirming the assignment of the redox processes. Thus, *in situ* spectroelectrochemistry of MPcs, **1b** and **1c**, during the controlled potential electrolysis of the complexes was employed to further provide information on the nature of the redox processes observed in Figs. 5 and 6, respectively. The spectral changes during the redox processes of **1b** are shown in Fig. 7. Aggregation in MPc complexes is typified by a broadened or split Q band, with the high energy band being due to the aggregate and the low energy band due to the monomer. Thus, the starting spectrum with the split Q band reflects clearly the presence of an equilibrium between the aggregated and monomer species (Fig. 7A). Upon first reduction at −1.00 V versus SCE, two different types of subsequent spectral changes are observed (Fig. 7A and B). These spectral changes are accompanied by a very slight increase in absorption at around 500 nm. It appears that monomer-aggregate equilibrium shifts toward monomer species just before the first reduction process, since the band at 650 nm decreases and the other at 680 nm increases with a red shift. Normally, the shift in the Q band absorption is not observed during the reduction of Pc ligand. The formation of deaggregated species is confirmed by well-defined isosbestic points appeared at 560, 676 and 724 nm during the former spectral changes. The slight increase in absorption at around 500 nm may be due to the reduction of some aggregated species. The former spectral changes in Fig. 7A are followed by a decrease in both the Q band absorptions at 650 and 690 nm without shift, and the appearance of a new band at 580 nm (Fig. 7B). Well-defined isosbestic points are observed at 472, 615 and 735 nm. These spectral changes probably correspond to the reduction of disaggregated species [29,30]. The new band at 580 nm and the decrease in the Q band absorption without shift are characteristic for Pc ring reduction, and thus the formation of Zn(II)Pc(−3) species, confirming the CV assignment of couple II to Pc(−2)/Pc(−3) redox process [31,32]. In the mean time, two new bands with low intensity at 828 and 974 nm form in the near IR region, during the latter changes. These bands are usually observed in dinuclear Pcs and attributed to the some conformational changes during the redox processes [33], but also observed for some mononuclear Pcs [34,35]. The well-defined UV–Vis spectral changes during the second reduction of **1b** with applied potential of −1.25 V in OTTLE cell are shown in Fig. 7C. A decrease in the absorption of the bands at 650, 680 and 690 nm without shift are observed while a new band (at 746 nm) at the red side of the Q band appears. In the mean time, the absorption of the band at 828 nm increases with disappearance of the one at 974 nm. The decrease in the Q band absorption without shift and the appearance of a new band in the Q band region are characteristic for ligand reduction. The first and second reduction processes were chemically reversible on the spectroelectrochemical time scale and the nearly original spectrum of compound **1b** was obtained upon reoxidation at a positive potential of the first reduction potential. Thus, the species produced during the first and second reduction processes remained stable throughout the measurement. The subsequent third reduction is also expected to be on the ring in comparison with literature [22]. The UV–Vis spectral

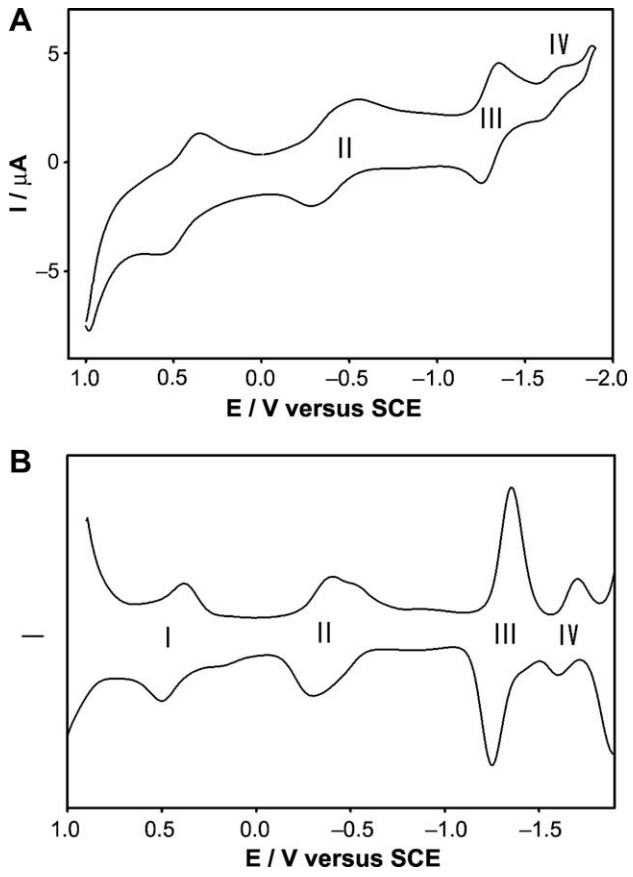

Fig. 6. Cyclic (A) and differential pulse (B) voltammograms of 2.5×10^{-4} mol dm^{-3} **1c** in DMSO/TBAP.

changes recorded during the first oxidation process of **1b** are shown in Fig. 7D. There is a continuous decrease in the absorption of all bands. In addition, re-reduction of oxidized species did not generate the compound **1b** with its original spectrum. This is probably due to the fact that the first oxidation process occurs at considerably positive potentials, and decomposition of the complex may occur when the potential is held constant at a potential considerably positive.

Fig. 8 shows the UV–Vis spectra of **1c** and its electrochemically generated species. The broad blue-shifted Q band at 670 nm in the starting spectrum of **1c** implies that the complex is mainly in aggregated form. Fig. 8A shows the UV–Vis spectral changes of **1c** during its first reduction at −0.90 V versus SCE. Upon the first reduction, the Q band absorption at 670 nm decreases considerably at first with a red shift and then increases slightly. This spectral change is accompanied by the formation of two newly formed absorption bands at 483 and 715 nm. The position of the isosbestic points is not clear during these spectral changes. when the spectral changes in Fig. 8A are divided in two parts accordingly, we obtained the spectral changes in Fig. 9A and B. In Fig. 9A, the first reduction process has well-defined isosbestic points at 412, 550 and 742 nm. The new band at 483 nm is typical for Co(I)Pc(−2) species, and thus clearly suggests that the first reduction of **1c** (couple II in Fig. 6) occurs at the metal center [36,37]. On the other hand, as shown in Fig. 9B, both Q and B band absorptions increase continuously without formation of isosbestic points after the changes at the beginning. These two different spectral changes during the first reduction imply that the former changes are due to the metal-based reduction of aggregated CoPc species while the latter changes result from deaggregation of reduced species. During the second reduction process, a new band appears at 677 nm (Fig. 8B). There is also a remarkable increase in the absorption within the range of 525–600 nm, while the spectral changes

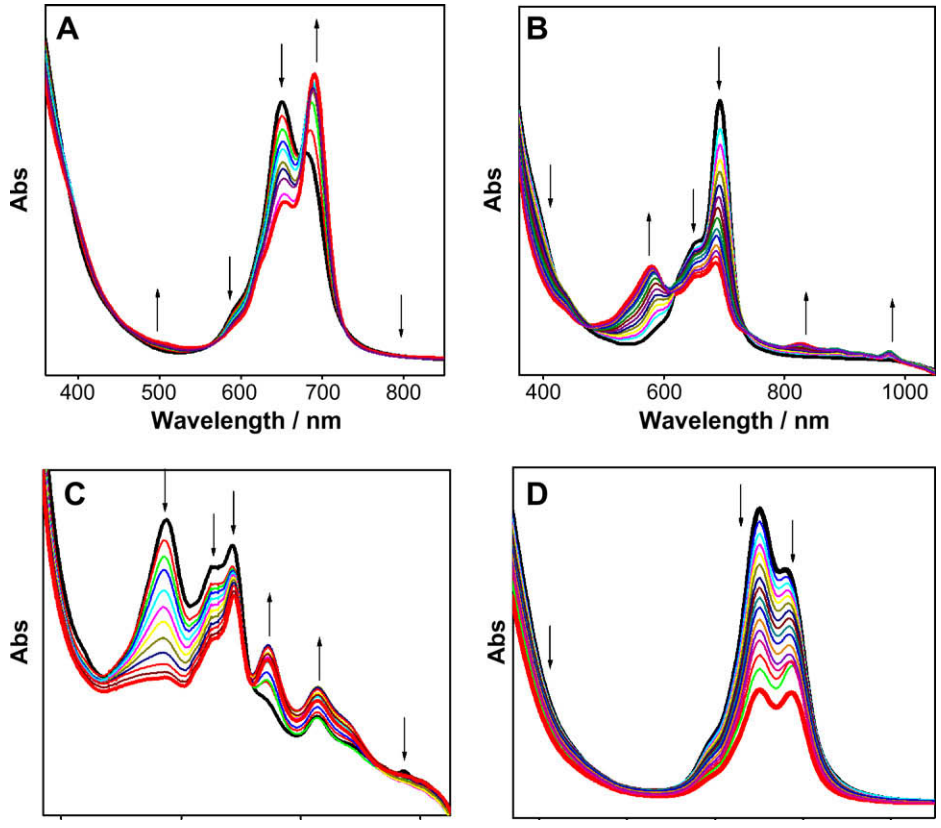

Fig. 7. *In situ* UV–Vis spectral changes during the first reduction (A) and (B), the second reduction (C) and the first oxidation (D) of **1b**.

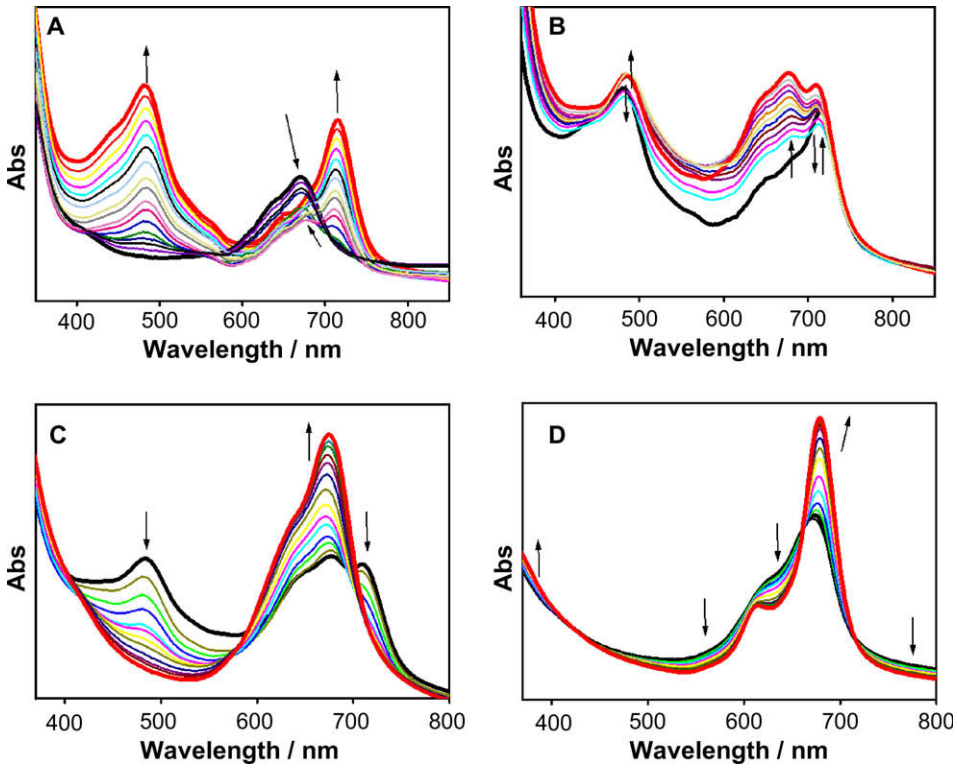

Fig. 8. *In situ* UV–Vis spectral changes during the first reduction (A), the second reduction (B), the third reduction (C) and the first oxidation (D) of **1c**.

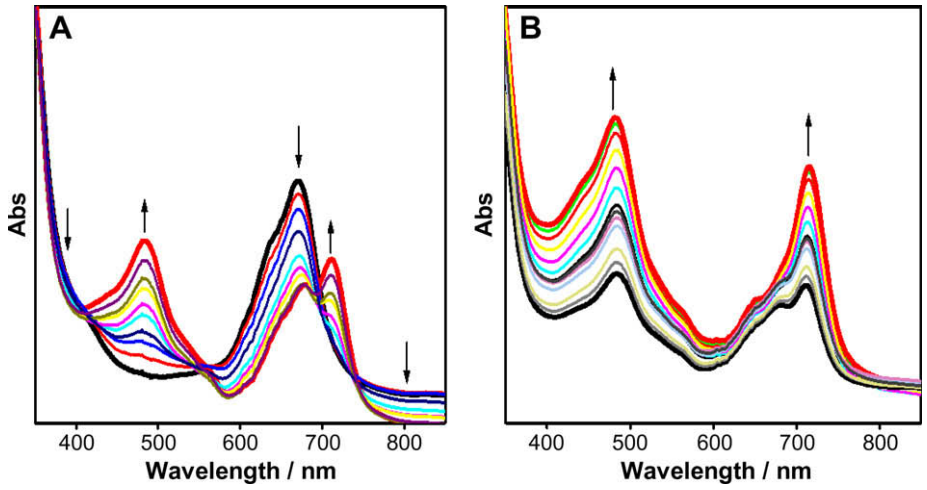

Fig. 9. *In situ* UV–Vis spectral changes during the first reduction processes of **1c** deaggregation process (A), reduction of deaggregated species (B).

are very limited at around the band at 483 nm. Thus, these changes are probably due to ring-based reduction in Pc complexes [30,36,37]. In most of the studies in literature [29,33,38,39], it was reported that a decrease in the Q band intensity and a decrease or increase in absorption at around 480 nm occurred during the ligand-based second reduction process of a Co(II)Pc. The broad split band observed in this study may suggest that aggregation still affects the electron transfer process during the second reduction process. On the other hand, nearly all studies in literature about the spectroelectrochemistry of MPcs do not report on the spectral changes during the third reduction process. The third reduction in this study results in disappearance of the band at around 715 nm and the narrowing of the Q band absorption due to completely deaggregated reduced species resulting from high negative charge on the Pc ring as shown in Fig. 8C. In the mean time, the band at around 483 nm disappears. Fig. 8D shows the spectral changes observed when potentials corresponding to first oxidation process were applied to solution of **1c**. There is a shift in wavelength of the Q band from 670 to 677 nm as the electrolysis progressed. This is typical of a metal-based oxidation in CoPc complexes [29,30,36]. The final spectrum in Fig. 8D is therefore belong to Co(III)Pc(−2), confirming CV assignment.

ABSTRACT

The substitution reaction of Keggin-type polyoxometalates, $[XM_{12}O_{40}]^{n-}$ (*X = Si,* Ge, P, or As; M = Mo or W), with vanadium(V) ion was investigated with cyclic voltammetry, Raman spectroscopy, and ^{31}P NMR. The effect of organic solvents, such as acetonitrile (ACN), tetrahydrofuran (THF), formamide (FA), N-methylformamide (NMF), and N-methylacetoamide (NMA) on their substitution reactions was examined. In aqueous and aqueous-FA, -NMF, and -NMA solutions, the molybdenum or tungsten unit in the Keggin-anions was substituted with vanadium(V) ion to form V(V)-substituted polyoxometalates, while no substitution reaction occurred in aqueous-ACN and -THF solutions. It is suggested that this results from the relationship between the total anion charge and the permittivity of organic solvents.

1. Introduction

Many kinds of polyoxometalates have been prepared and characterized since the first report on the formation of 12-molybdophosphate in 1826 [1]. Polyoxometalates with Keggin structure, whose formulas are denoted as $XM_{12}O_{40}^{n-}$ (X = Si, P, etc.; M = Mo and W), have been applied to various fields such as analytical chemistry, biochemistry, and catalysis [1,2]. It has been well known that one or three addenda units are generally removed from the Keggin-type polyoxometalate to form so-called lacunary anions as $XM_{11}O_{39}^{n-}$ and A-$XM_9O_{34}^{n-}$ and that the other metal ions are incorporated to the vacant sites of these lacunary anions to form metal-substituted polyoxometalates. The structures of these polyoxometalates are not only Keggin-type but also sandwich-type. Metal-substituted polyoxometalates are attracting interest because of their use in specific catalysis rather than non-substituted polyoxometalates. Though much attention has been directed toward the preparation and the application of polyoxometalates, their formation mechanisms still remain ambiguous.

In general, many polyoxometalates have been prepared in aqueous solution, while some new polyoxometalates with new types of structures have been also reported to be formed under specific conditions such as non-aqueous, mixed media, and hydrothermal condition [1–4]. Novel polyoxometalates containing diphosphate, phosphonate, arsenite, selenite, or tellurite as hetero ions were synthesized from aqueous organic solutions [5–9]. Even though in aqueous solution $[PMo_{12}O_{40}]^{3-}$ does not form as the main species and $[AsMo_{12}O_{40}]^{3-}$ does not form at any appreciable concentrations, the addition of water-miscible organic solvents, such as acetonitrile and acetone, makes the formation of these complexes more stable and their likelihood greater [10]. Recently, the vanadium(V)-substitution reactions of Keggin-type molybdophosphates, tungstophosphates, and arsenate analogues were examined in aqueous and aqueous-ACN solutions, and it was found that water-miscible organic solvents played important roles on their substitution reactions [11,12]. The Pettersson group also reported the detailed formation conditions of molybdovanadophosphates in aqueous solution obtained through ^{31}P and ^{51}V NMR and potentiometry [13].

The V(V)-substituted molybdosilicates and tungstosilicates, and the corresponding germanates, were prepared in aqueous solution and characterized with various methods, such as cyclic voltammetry, IR, UV–Vis, and NMR. There has been, however, no report on the formation of these complexes in aqueous solution and mixed media. Therefore, in the present study, to obtain a detailed examination of the effect of organic solvent on the formation of V(V)-substituted polyoxometalates, the V(V)-substitution reactions with Keggin-type molybdosilicate and tungstosilicate, and the corresponding germanates were investigated in aqueous solution and mixed media.

2. Experimental

2.1. Apparatus and materials

Voltammetric measurements were made with a microcomputer-controlled system. A glassy carbon electrode (BAS GC-30S) with a surface area of 0.071 cm^2 was used as a working electrode and a platinum wire served as a counter electrode. The reference electrode was an Ag/AgCl (saturated KCl) electrode. Prior to the measurement, the GC electrode was polished with 0.1 μm diamond slurry and washed with distilled water. The voltammograms were recorded at 25 ± 0.1 °C, and the voltage scan rate was set at 100 mV s^{-1}. Raman spectra were recorded with a Jobin Yvon Model HR-800 spectrophotometer. The argon line at 514.5 nm was used for excitation. The Raman measurements were made at 25 °C. The Raman intensity was normalized by the Raman band of each of the organic solvents used: 922 cm^{-1} for ACN, 914 cm^{-1} for THF, 1093 cm^{-1} for FA, 962 cm^{-1} for NMF, and 885 cm^{-1} for NMA, and the 1048 cm^{-1} band due to NO_3^- (50 mM $NaNO_3$) in aqueous solution. IR spectra were obtained on a Jasco FT/IR-460 plus spectrophotometer by the KBr pellet method.

A stock solution of V(V) was prepared by dissolving 22.735 g of V_2O_5 and 15.0 g of NaOH in 250 mL of water. Other reagents were of analytical grade and were used as received.

2.2. Preparation of heteropolymolybdates and -tungstates and vanadium(V) derivatives

Tetrabutylammonium (n-Bu_4N^+) salts of $SiW_{12}O_{40}^{4-}$ (SiW_{12}), $GeW_{12}O_{40}^{4-}$ (GeW_{12}), $SiMo_{12}O_{40}^{4-}$ ($SiMo_{12}$), and $GeMo_{12}O_{40}^{4-}$ ($GeMo_{12}$) were prepared according to the reported procedures and recrystallized from ACN [14]. The n-Bu_4N^+ salts of $SiVW_{11}O_{40}^{5-}$ ($SiVW_{11}$), $GeVW_{11}O_{40}^{5-}$ ($GeVW_{11}$), $SiVMo_{11}O_{40}^{5-}$ ($SiVMo_{11}$), and $GeVMo_{11}O_{40}^{5-}$ ($GeVMo_{11}$) were prepared according to both the formation conditions reported in the present study and described procedures with modifications [15–18]. They were recrystallized from acetonitrile and cross checked by FT-IR spectra and elemental analysis [19].

3. Results and discussion

3.1. IR and Raman spectra and cyclic voltammograms of XM_{12} and XVM_{11} (X = Si, Ge; M = Mo, W)

Table 1 shows the vibrational frequencies of XM_{12} and XVM_{11} in their IR and Raman spectra. All spectra of XVM_{11} were very similar to those of the corresponding XM_{12}, though each of frequencies was slightly shifted. From these results, we can interpret that all of the XVM_{11} retained a Keggin structure. It has been reported that counter cations, especially small cations, affect the vibrational frequencies of polyoxometalates in the solid state [14]. In general, the Raman band of the Mo–O_d bond in non-substituted Keggin anions is at a higher wavenumber than that in vanadium-substituted ones in solutions under the same conditions [11,12]. The Raman bands of the n-Bu_4N salts of $GeMo_{12}$ and $SiMo_{12}$, however, are at a lower wavenumber than those of the n-Bu_4N salts of $GeVMo_{11}$ and $SiVMo_{11}$ in the solid state. This is because $GeVMo_{11}$ and $SiVMo_{11}$ contain a proton as a counter cation, which interacts with a proton to shift the Raman band to a higher wavenumber [14]. In fact, the Raman bands of $GeVMo_{11}$ and $SiVMo_{11}$ anions are at a lower wavenumber than those of $GeMo_{12}$ and $SiVMo_{12}$ anions in the reaction mixtures, as shown below. The Raman peaks observed in the reaction mixtures were assigned on the basis of the Raman bands of the complex in the solid state.

Fig. 1 shows the cyclic voltammograms of GeV_xMo_{12-x} and GeV_xW_{12-x} (x = 0, 1) in 95% (v/v) CH_3CN containing 0.1 M $HClO_4$, respectively. The $GeMo_{12}$ and $GeVMo_{11}$ complexes exhibit reversible step waves with E_{mid} of 505, 400, 155, and 15 mV, and 670, 480, 340, 150, and 5 mV, respectively, where $E_{mid} = (E_{pc} + E_{pa})/2$; E_{pc} and E_{pa} are the cathodic and the anodic peak potential, respectively. Each wave was diffusion controlled. Coulometric analysis and normal-pulse voltammetric measurements confirmed that the four-step reduction waves of the $GeVMo_{11}$ complex corresponded to one- and three two-electron transfers, and those of the $GeMo_{12}$ complex corresponded to four two-electron transfers, respectively. The first wave in curve (a) and (c) in Fig. 1 indicates the reduction (V → IV) of vanadium atom in each of complexes, as with $[XV_xW_{12-x}O_{40}]^{(3+x)-}$ and $[XV_xMo_{12-x}O_{40}]^{(3+x)-}$, while other waves are ascribed to the reduction (VI → V) of molybdenum or tungsten atoms. Unfortunately, the oxidation peak at ca. 300 mV in Fig. 1(a) could not be assigned, although no peak at ca. 300 mV appeared when switching potential was set at −150 mV. The oxidation peak at ca. 300 mV should be indicated to be an

adsorption wave. Cyclic voltammograms of the other XVM_{11} and XM_{12} anions were also measured in acidic aqueous-CH_3CN solution under the same conditions as in Fig. 1, and E_{mid} values obtained are listed in Table 2. Each of the E_{mid} values of the redox waves for $GeVMo_{11}$ and $GeVW_{11}$ is ca. 50 mV more positive than each of those for $SiVMo_{11}$ and $SiVW_{11}$, respectively. This behavior is similar to that seen for other complexes in that each of the E_{mid} potentials of AsV_xM_{12-x} (x = 0, 1; M = Mo, W) is more positive than each of those of the corresponding PV_xM_{12-x}. On the basis of these voltammetric manners, the occurrence of vanadium substitution reaction can be determined from the appearance of new peak at more positive potential than redox potentials of Mo or W parts in polyoxometalates after the addition of V(V) into the reaction mixtures.

3.2. V(V)-substitution reaction of heteropolysilicates and heteropolygermanates

Fig. 2A and B shows the cyclic voltammograms and Raman spectra for a 50 mM Mo(VI)–5 mM Ge(IV)–0.5 M HCl–40% (v/v) FA system. Three-step voltammetric waves at E_{pc} = 180, 15, and −115 mV corresponding to two-electron transfers, respectively, and Raman band at 980 cm^{-1} were observed (Fig. 2(a)). These reduction waves and Raman peak indicate the formation of the $GeMo_{12}$ anion. After the addition of 5 mM V(V), new reduction peaks at 335 and −70 mV and a new Raman band at 974 cm^{-1} appeared, while three reduction peaks and a Raman band at 980 cm^{-1} disappeared (Fig. 2(b)). Simultaneously, the color of the solution changed to yellow from colorless. These new reduction peaks and Raman bands were due to the formation of the $GeVMo_{11}$. The changes of voltammograms and Raman spectra indicate that the $GeMo_{12}$ anion was substituted with V(V) to form the $GeVMo_{11}$ anion in aqueous-FA solution. When the same experiments were carried out with 20% (v/v) NMF and NMA, instead of FA, in aqueous-NMF and -NMA, a new redox wave appeared at more positive potential than the redox waves of $GeMo_{12}$ as well as a new Raman band at around 974 cm^{-1} after the addition of 5 mM V(V) and heating at 80 °C for 1 day. These voltammetric and Raman spectroscopic changes are the same as those obtained in the aqueous-FA solution, indicating that the $GeMo_{12}$ anion was also substituted with V(V) ion to form the $GeVMo_{11}$ anion in respective aqueous-organic solution. If, after the addition of 5 mM V(V), the solution was not heated or >40% (v/v) NMF or NMA was added, there was no voltammetric and Raman spectroscopic change.

To investigate the V(V)-substitution reaction in aqueous solution, cyclic voltammograms and Raman spectra for a 50 mM Mo(VI)–5 mM Ge(IV)–pH 2.0 system were recorded (Fig. 3A and B). In the absence of V(V), two voltammetric waves at E_{pc} = 290 and 185 mV and a Raman band at 980 cm^{-1} were observed. After

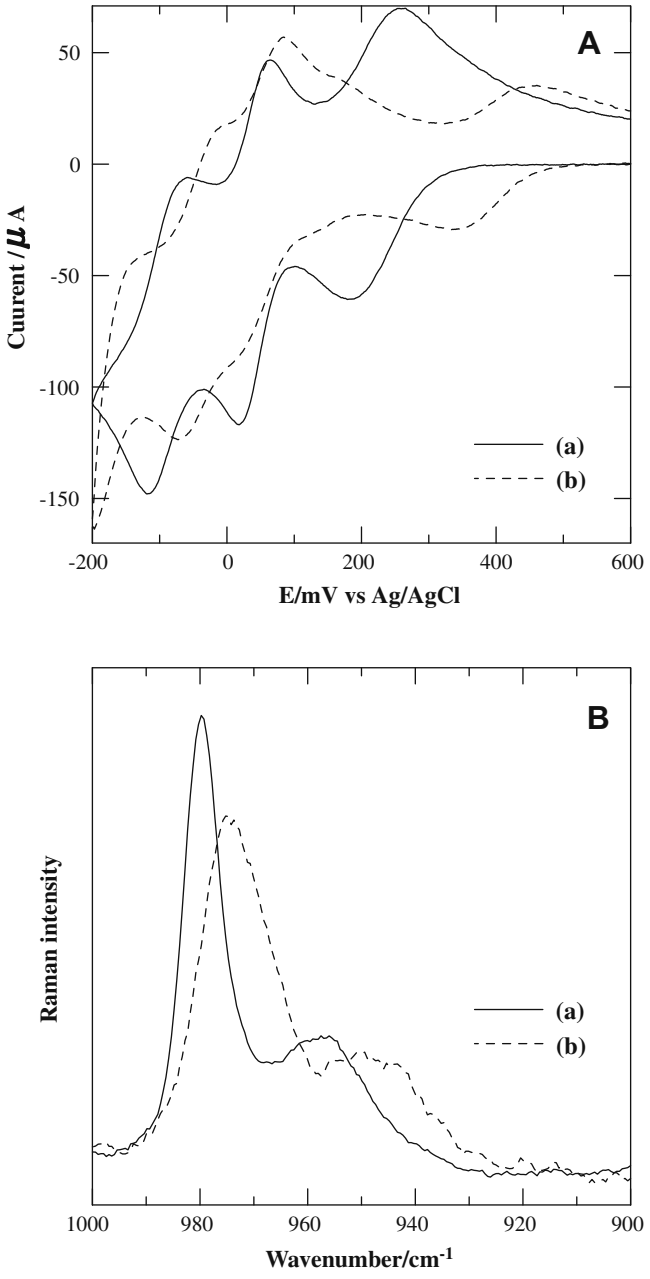

Fig. 2. Cyclic voltammograms (A) and Raman spectra (B) for a 50 mM Mo(VI)–5 mM Ge(IV)–0.5 M HCl–50% (v/v) FA system without (a) and with (b) 5 mM V(V).

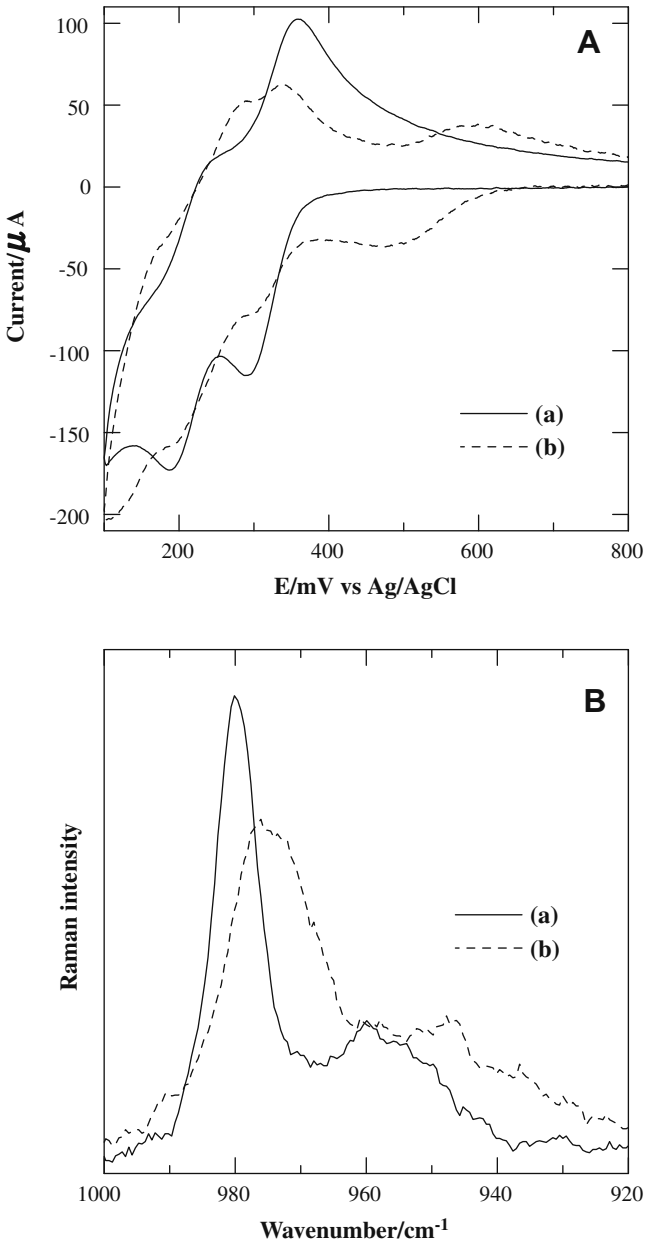

Fig. 3. Cyclic voltammograms (A) and Raman spectra (B) for a 50 mM Mo(VI)–5 mM Ge(IV)–pH 2.0 system without (a) and with (b) 5 mM V(V).

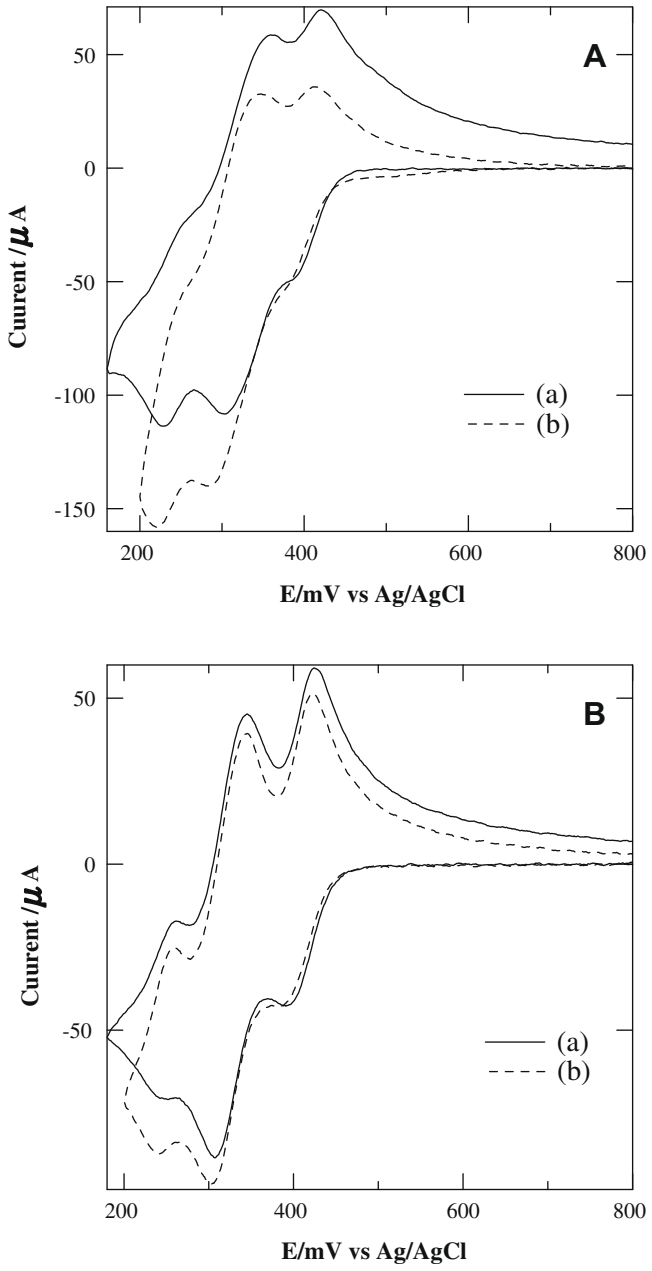

Fig. 4. Cyclic voltammograms for 50 mM Mo(VI)–5 mM Ge(IV)–0.5 M HCl–50% (v/v) ACN (A) and THF (B) systems without (a) and with (b) 5 mM V(V).

the addition of 5 mM V(V), the readjustment of pH at 2.0 by a small amount of HCl, and heating at 80 °C for 1 day, a new reduction peak at 475 mV and a new Raman band at 974 cm^{-1} appeared, though the reduction waves at 290 and 185 mV and the Raman peak at 980 cm^{-1} did not completely disappear. In aqueous solution, the $GeMo_{12}$ anion was substituted with V(V) to form the $GeVMo_{11}$ anion in systems similar to aqueous-FA, -NMF and -NMA, but not all of the $GeMo_{12}$ anion was transformed into the $GeVMo_{11}$ anion.

Furthermore, the vanadium-substitution reaction of the $GeMo_{12}$ anion was investigated in aqueous-CH_3CN and -THF solution. Fig. 4A and B shows cyclic voltammograms for 50 mM Mo(VI)–5 mM Ge(IV)–0.5 M HCl–40% (v/v) CH_3CN and THF systems. Before the addition of V(V), reduction waves were observed at 385, 305 and 230 mV in aqueous-CH_3CN solution and at 390, 305, and 240 mV in aqueous-THF solution. Cyclic voltammograms for a Mo(VI)–P(V)–HCl system in aqueous-CH_3CN solution gave three redox waves: the first and second reduction waves are due to the formation of β-PMo_{12}, and the second and third ones are due to the formation of α-PMo_{12}. It is thought that the first and second waves in Fig. 4 are ascribed to the formation of the β-$GeMo_{12}$ anion and that the second and third waves are ascribed to that of the α-$GeMo_{12}$ anion. After the addition of 5 mM V(V), no peak appeared at a more positive potential than the 1st reduction wave of β-$GeMo_{12}$, while the currents of the second and third waves increased without the shifts of peak potentials. This may indicate that the V(V) ion gives rise to catalytic waves, similar to Mo(VI)–P(V)–V(V), in aqueous-ACN solution [11]. Even though the 5 mM V(V) containing solution was heated at 80 °C for aqueous-ACN, or 50 °C for aqueous-THF for 1 day, no new reduction peak appeared as was seen for the aqueous-NMF and -NMA systems. In aqueous-ACN or -THF solution, no substitution reaction of $GeMo_{12}$ with V(V) occurred.

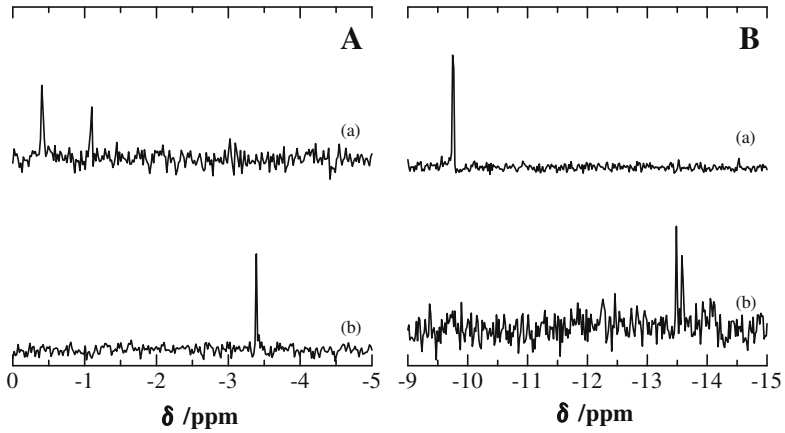

Fig. 5. ^{31}P NMR for 50 mM Mo(VI)–5 mM Ge(IV)–0.5 M HCl–50% (v/v) NMF (A) and 50 mM W(VI)–5 mM Ge(IV)–0.5 M HCl–50% (v/v) NMF (A) systems without (a) and with (b) 5 mM V(V).

Similarly to the Mo(VI)–Ge(IV) systems, the vanadium(V) substitution reaction in the W(VI)–Ge(IV) systems was also investigated. For a 50 mM W(VI)–5 mM Ge(IV)–0.2 M HCl–20% (v/v) NMF or NMA system, two reduction waves at $E_{pc} = -200$ and -440 mV for aqueous-NMF system, and -235 and -485 mV for the aqueous-NMF system, and a Raman band at 997 cm^{-1} were observed after the solution was heated at 80 °C for 3 days. After the addition of 5 mM V(V) and heating again at 80 °C for 1 day, new reduction peaks at $E_{pc} = 470$ mV for the aqueous-NMF system, 430 mV for the aqueous-NMF system, and a Raman band at 991 cm^{-1} appeared, while the original reduction peaks and Raman band disappeared. These results indicate that the GeW_{12} anion was substituted with V(V) to form the $GeVW_{11}$ anion. In aqueous-FA solution, however, no new reduction wave at a more positive potential than the redox of tungsten, and only a Raman peak at around 990 cm^{-1} were obtained before and after the addition of V(V), even though reaction mixtures containing various concentrations of HCl and FA were measured. This indicates that no Keggin anion exists and no vanadium substitution reactions occur.

The vanadium substitution reactions for Mo(VI)–Si(IV) and W(VI)–Si(IV) systems were also examined with CV and Raman at the same conditions as Mo(VI)–Ge(IV) and W(VI)–Ge(IV) systems, respectively. The results for Mo(VI)–Si(IV) and W(VI)–Si(IV) systems were very similar to the ones for Mo(VI)–Ge(IV) and W(VI)–Ge(IV) systems.

3.3. V(V)-substitution reaction of heteropolyphosphates and heteropolyarsenates in aqueous-FA, -NMF and -NMA solution

Recently, V(V)-substitution reactions were investigated in aqueous solution and aqueous-organic solutions for M(VI)–X(V) (M = Mo, W; X = P, As) systems [11,12]. In aqueous solution, the PMo_{12} and PW_{12} are substituted with V(V) to form PV_xMo_{12-x} and PV_xW_{12-x}, respectively, while no substitution reaction occurs for M(VI)–As(V) systems, though small amounts of AsV_xMo_{12-x} and AsV_xW_{12-x} form. In aqueous organic solution, such as ACN and THF, however, all types of Keggin anions are substituted with V(V) to form XV_xM_{12-x}, though PM_{12} is not perfectly substituted due to the stability of the anion. In the present study, the substitution reactions of XM_{12} (X = P, As; M = Mo, W) with V(V) were investigated in aqueous-FA, -NMF and -NMA solution. Fig. 5 shows the ^{31}P NMR spectra for 50 mM Mo(VI) or W(VI)–5 mM P(V)–0.5 M HCl–50 (v/v)% NMF systems with and without 5 mM V(V). In the absence of V(V), NMR peaks appeared at -0.40 and -1.10 ppm for the Mo(VI) system (Fig. 5A(a)) and -9.75 ppm for the W(VI) system (Fig. 5B(a)), but no peaks appeared at around -3.1 and -14.6 ppm corresponding to PMo_{12} and PW_{12}, respectively. The PMo_9 and PW_9 complexes form in each of the studied solutions. After the addition of 5 mM V(V), new peaks appeared at -3.39 ppm (Fig. 5A(b)), -13.49, and -13.58 ppm (Fig. 5B(b)). These peaks indicate the formation of $PVMo_{11}$ and PV_xW_{12-x} ($x = 2, 3$) [11,20], but these reactions are not substitution reactions but mere formation reactions of PM_9 and V(V). The vacant sites of PM_9 were fulfilled with V(V) and M(VI), which were decomposed from PM_9 or from an excess of M(VI), to form stable Keggin-type vanadium-substituted heteropolyphosphates. For M(VI)–P(V) systems in aqueous-FA solution and a W(VI)–P(V) system in aqueous-NMA, no PM_{12} anion was detected, though the PVM_{11} anion formed after the addition of V(V), as seen for M(VI)–P(V) systems in aqueous-NMF. For a 50 mM Mo(VI)–5 mM P(V)–0.5 M HCl–50% (v/v) NMA system, however, in the absence of V(V), a ^{31}P NMR peak at -3.11 ppm was obtained. After the addition of V(V), this peak diminished, and a new peak appeared at -3.45 ppm, indicating that PMo_{12} was substituted with V(V) to form $PVMo_{11}$.

The substitution reactions for As(V)–Mo(VI) and –W(VI) systems in aqueous-FA, -NMF, and -NMA solutions were investigated. No reversible redox waves, which were assigned to the formation of AsW_{12}, were observed for 50 mM Mo(VI) (or W(VI))–5 mM As(V)–0.5 M HCl systems in aqueous-NMF and -FA solutions, though redox waves due to the formation of $AsVMo_{11}$ and $AsVW_{11}$ were obtained after the addition of V(V). These results were ascribed to the formation of $AsVMo_{11}$ and $AsVW_{11}$ by incorporation of V(V) and M(VI) into the vacant sites of lacunary species similar to those seen in P(V) systems. Based on the results of voltammetric and Raman spectroscopic measurements, a large number of AsM_{12} anions do not form in aqueous-NMA solution, those that undergo substitution form the $AsVM_{11}$ anions, as seen for the Mo(VI)–P(V) system in aqueous-NMA solution.

4. Conclusion

The substitution reactions of Keggin-type heteropolysilicates and heteropolygermanates with V(V) were investigated in aqueous and mixed media and compared with those of heteropolyphosphates and heteropolyarsenates. For heteropolysilicates and heteropolygermanates, substitution reactions occurred when the media were water or aqueous-FA, -NMF, and -NMA, while they did not occur when the media were aqueous-ACN and -THF. In contrast, for heteropolyphosphates and heteropolyarsenates, the V(V)-substituted species formed in aqueous-FA, -NMF, and -NMA, while Keggin-type PMo_{12} and $AsMo_{12}$ did not form at any appreciable concentration. The corresponding lacunary species occurred in

Table 3
Physical properties of solvents [21–23].

Solvent	DN	AN	Permittivity
THF	20.0	8.0	7.6
ACN	14.1	18.9	35.9
Water	18(33)	54.8	78.4
FA	(24)	39.8	111
NMF	49	32.1	182.4
NMA			191.3

solution, and the V(V) ion incorporated into their vacant site to form the vanadium-substituted species. Table 3 shows the physical properties of the solvents used in the present study [21–23]. The relative permittivity of FA, NMF, and NMA is higher than that of water, while that of ACN and THF is lower. The size of all of the Keggin-type heteropolymolybdates and -tungstates, respectively, is nearly the same. Their radius has been reported as ca. 5.6 Å, independent of the kind of hetero atoms and the substitution of vanadium, while only the total charge of anions is different [1,24–27]. The change in the total charge by vanadium substitution reactions ranges from −4 (non-substituted species) to −5 (substituted species) for Keggin-type heteropolysilicates and -germanates, while it ranges from −3 to −4 for Keggin-type heteropolyphosphates and -arsenates. It is well known that Keggin-type heteropolysilicates and -germanates form stable complexes in aqueous solution, while Keggin-type heteropolyphosphates and -arsenates do so in aqueous-organic solution, such as ACN and THF. Therefore, it is certain that Keggin anions with a total charge of over −4 are favorable in media with a higher permittivity than water. Unfortunately, no reason has been elucidated for why PM_{12} and AsM_{12} form in aqueous-NMA, and substitution reactions did not occur for W(VI)–Ge(IV) and –Si(IV) systems in aqueous-FA solution. Though no direct dependence has been thought to exist between the vanadium-substitution reactions and AN or DN of organic solvents, it has been suggested that whether or not vanadium-substitution reactions occur should depend on the permittivity of the solvents used.

ABSTRACT

A new symmetrical polyaza macrocyclic binucleating ligand $\mathbf{L^1}$ and its permethylated derivative ligand $\mathbf{L^2}$ have been synthesized by using the precursor compound 2-[2-(2,6-diformyl-4-methylphenoxy)propoxy]-5-methylisophthalaldehyde and bis(aminoethyl) amine. The molecular structure of the precursor compound and the ligand $\mathbf{L^2}$ were determined by the single crystal XRD method. The ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ were treated with two equivalents of $Cu(ClO_4)_2 \cdot 6H_2O$ to afford the new binuclear complexes $[Cu_2L^1(\mu\text{-}OH)(ClO_4)_2](ClO_4)$ (**1**) and $[Cu_2L^2(\mu\text{-}OH)(ClO_4)_2](ClO_4)$ (**2**), respectively. Both the complexes were characterized by elemental and spectral methods. A cyclic voltammetric investigation of these Cu(II) complexes show a quasireversible followed by an irreversible one electron reduction processes around $E^1_{pc} = -0.59$ V, -0.55 V and $E^2_{pc} = -1.07$ V, -1.02 V. ESR spectra of the copper(II) complexes **1** and **2** show a broad signal at $g = 2.08$ and 2.10, and μ_{eff} values of 1.43 and 1.46 BM, respectively, which convey a spin–spin interaction between the two copper(II) ions. The initial rate (V_{in}) for the oxidation of 3,5-di-*tert*-butylcatechol to *o*-quinone by the binuclear Cu(II) complexes **1** and **2** are 1.15×10^{-4} and 1.66×10^{-4} Ms^{-1} respectively. Both the complexes remarkably promote the hydrolytic cleavage of supercoiled plasmid DNA under physiological conditions in the presence of H_2O_2 at pH 7.2 and 37 °C. The reaction profile for the complex **1** mediated reaction displayed approximately pseudo-first-order kinetic behavior, with $k_{obs} \sim 0.07$ min^{-1} and $R^2 = 0.984$.

1. Introduction

Polyaza macrocyclic Schiff bases have been studied as potential inorganic and organic cation receptors [1], electron transfer agents, homogeneous catalysts and DNA, RNA interacting agents [2]. Because of their unique and selective complexing properties [3], macrocyclic ligands are particularly suited for the synthesis of such complexes as they are more stable than their acyclic counterparts and the two metal ions are fixed in close proximity which has important implications for metal–metal interactions and binuclear metal reactivity [4]. They are smaller than enzymes, which allows them to attack macromolecular regions that are inaccessible to enzymes, and also their specificity and efficiency may be modulated. These properties have turned chemical nucleases into useful tools as adjuvants in PCR diagnostics [5], nucleic acid attacking and cleaving agents [6]. These polyaza copper(II) complexes are a beacon in modelling, and they serve as bioinorganic model compounds not only in enzymatic reactions, but also in catalytic synthetic oxidation reactions [7,9]. Hence, binuclear copper(II) complexes are of interest for availing magnetostructural correlations and as useful model systems for catalysis. Catechol oxidases are ubiquitous plant enzymes belonging to the oxidoreductase class that contain a dinuclear Cu center in their site, which catalyses the two-electron oxidation of a broad range of *o*-diphenols (catechol) to the corresponding quinones, coupled with the reduction of molecular oxygen to water [7]. Further, catechol oxidases exclusively catalyze the oxidation of catechols to quinones without tyrosine [10]. This reaction is of great importance in medical diagnosis for the determination of the hormonally active catecholamine adrenaline, noradrenalin and dopa [11]. The synthesis and investigation of functional model complexes for metalloenzymes with oxidize or oxygenase activity is therefore of great promise for the development of new and efficient catalysts for oxidation reactions [12]. Further, compounds showing the property of cleaving double stranded DNA under physiological conditions are of importance since these could be used as diagnostic agents in medicinal and genomic research [13]. Several efficient cleaving agents have been developed over the course of time, however, most of the studies deal with macrocyclic mononuclear Cu(II) complexes [14–16]. It has been noticed that macrocyclic binuclear copper(II) complexes show greater DNA cleaving efficiency than mononuclear complexes [17,18]. For these reasons, we aimed to design new polyaza macrocyclic binuclear Cu(II) complexes, which are suitable to

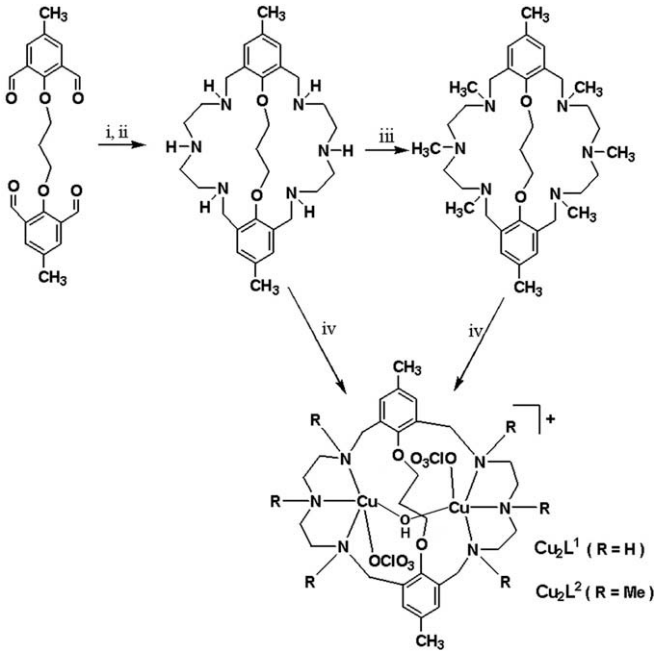
doi:10.1016/j.poly.2008.09.022

cleave DNA significantly. As a consequence, the design of the binucleating ligand has to satisfy a number of conditions: metal–metal distance, steric, electronic and bridging ligand features, etc. A new aromatic tetraldehyde is used to function as a precursor in the preparation of polydentate ligands which can form binuclear complexes. The above features can be altered by condensing the precursor compound with various amines. The tetraldehyde is readily condensed with aliphatic α,ω-diamines and subsequent reduction of the intermediate imine compounds provides many macrocyclic ligands [19]. In this paper, we report the synthesis and characterization of new symmetrical macrobicyclic ligands and their dicopper(II) complexes. We describe here two macrocyclic binucleating ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ (Scheme 1) by employing the new precursor compound, 2-[2-(2,6-diformyl-4-methylphenoxy)propoxy]-5-methylisophthalaldehyde and α,ω-diamines.



2. Experimental

2.1. Materials

2,6-Diformyl-4-methylphenol [20] and the binucleating macrobicyclic ligands $\mathbf{L^1}$ and $\mathbf{L^2}$ were prepared by a modified procedure of the literature methods [21]. Tetra(*n*-butyl)ammonium perchlorate (TBAP), used as the supporting electrolyte in electrochemical measurements, was purchased from Fluka and recrystallized from hot methanol (Caution! All perchlorate salts are potentially explosive; hence, care should be taken in handling TBAP and complexes containing the perchlorate anion). All the solvents were purified by reported procedures [22]. The supercoiled pBR322 DNA was purchased from Bangalore Genei (India). Superoxide dismutase (SOD), ethidium bromide (EB) and L-histidine were obtained from Sigma (USA). Tris(hydroxymethyl)aminomethane–HCl (Tris–HCl) buffer solution was prepared by using deionized, sonicated triple distilled water.

2.2. General methods

Elemental analysis was carried out on a Carlo Erba model 1106 elemental analyzer. FT-IR spectra were obtained on a Perkin Elmer FTIR spectrometer with the samples prepared as KBr pellets. UV–Visible spectra were recorded using a Perkin Elmer Lambda 35 spectrophotometer operating in the range 200–1400 nm with quartz cells and ε values are given in $M^{-1}\,cm^{-1}$. NMR spectra were recorded in $CDCl_3$, using TMS as an internal standard, on a BRUKER 300 instrument. EI mass spectra were recorded on a JEOL DX-303 EI mass spectrometer. Electrospray ionization mass spectral measurements were done using a Thermo Finnigan LCQ-6000 Advantage Max-ESI mass spectrometer. Cyclic voltammograms were obtained on a CH11008 Electrochemical analyzer using a three-electrode set-up comprising of a glassy carbon working, platinum wire auxiliary and a saturated Ag/AgCl reference electrode under oxygen free conditions. The concentration of the complexes was 10^{-3} M. TBAP (Tetra(butyl)ammonium perchlorate) (10^{-1} M) was used as the supporting electrolyte. The FAB mass spectra of the complexes were recorded on a JOEL SX 102/DA 6000 mass spectrometer using 3-nitrobenzyl alcohol as the matrix solvent. EPR spectra were recorded on powdered samples of **1** and **2** using a JEOL TES 100 ESR spectrometer. Low temperature measurements were made using a liquid nitrogen Dewar.

2.3. Synthesis

2.3.1. Synthesis of the precursor compound (2-[2-(2,6-diformyl-4-methylphenoxy)propoxy]-5-methylisophthalaldehyde)

A mixture of 2,6-diformyl-4-methylphenol (3 g, 18.2 mmol), 1,3-dibromopropane (1.73 g, 9.1 mmol) and K_2CO_3 (1.26 g, 9.1 mmol) was stirred in dry DMF at 90 °C for 2 h. The resulting solution was cooled to room temperature and poured onto crushed ice. A white solid separated by filtration and was dried. Colorless crystals suitable for XRD analysis were obtained by slow evaporation of a dichloromethane solution of this solid. Yield: 5.5 g (81%). Mp 210 °C. Elemental *Anal.* Calc. for $C_{21}H_{20}O_6$ (L^1) C, 68.5; H, 5.4. Found: C, 68.4; H, 5.5%. EI Mass: $[M^+ + 1] = 369$. ^1H NMR ($CDCl_3$, 300 MHz): 2.36 ($2CH_3$, s, 6H), 2.43 (CH_2, quintet, 2H), 4.28 ($2CH_2$, t, 4H, J = 6.3 Hz), 7. 84 (Ar H, s, 4H), 10.28 (CHO, s, 4H). ^{13}C NMR ($CDCl_3$, 75 MHz): 20.5 (CH_3), 29.6 (CH_2), 75.9 (CH_2), 129.8, 136.0 (ArH), 188.5 (CHO). IR (cm^{-1}, KBr pellet): 2925 (CH stretching), 1669 (CO stretching), 1435 (O–CH_2).

2.3.2. Synthesis of the macrobicyclic binucleating ligand ($\mathbf{L^1}$)

The precursor compound (3.68 g, 10 mmol) in chloroform (100 ml) and diethylenetriamine (2.06 g, 20 mmol) in ethanol were added simultaneously over a period of 8 h to a mixture of chloroform (300 ml) and ethanol (100 ml). After complete addition, the reaction mixture was stirred at room temperature for 24 h. The chloroform was then removed at reduced pressure and a solution of sodium borohydride (3.03 g, 80 mmol) in ethanol (100 ml) was added. After stirring at room temperature for 2 h, the reaction mixture was acidified to pH 1 with conc. hydrochloric acid and the resulting colorless suspension was evaporated to dryness. Water (100 ml) and chloroform (200 ml) were added to the residue, the pH of the aqueous phase was adjusted to 13 with 3 M aqueous potassium hydroxide, and the heterogeneous mixture was stirred vigorously for 1 h. The aqueous phase was extracted with chloroform and dried over sodium sulfate. Evaporation of the solvent gave $\mathbf{L^1}$ as a colorless foamy solid. Yield: 4.3 g (84%). M.p. 173 °C. Elemental *Anal.* Calc. for $C_{29}H_{46}N_6O_2$ ($\mathbf{L^1}$) C, 68.2; H, 9.0; N, 16.5. Found: C, 68.1; H, 9.2; N, 16.7%. ESI-MS in CH_3OH: *m*/*z* 511.47 $[M+H]^+$. ^1H NMR ($CDCl_3$, 75 MHz): 2.09 (CH_3, s, 6H), 2.29 (–CH_2–, t, 2H, J = 6.6 Hz), 2.69 (–CH_2–, s, 16H), 3.67 (–CH_2–, s, 8H), 4.18 (–CH_2–, t, 4H, J = 6.6 Hz), 4.54 (NH, s, 2H), 4.72 (NH, br s, 4H), 6.90 (ArH, s, 4H). ^{13}C NMR $CDCl_3$, 75 MHz): 19.6 ($2CH_3$), 30.6 (CH_2), 48.1 ($4CH_2$), 48.5 ($4CH_2$), 71.5 ($2CH_2$), 129.7, 132.0, 132.5, 153.4 (ArC). IR (cm^{-1}, KBr pellet): 3235 (NH stretching), 2916 (CH stretching), 1517 (NH bending), 1215 (O–C stretching).

2.3.3. Synthesis of the macrobicyclic binucleating ligand (L^2)

The binucleating macrobicyclic ligand L^1 (5.1 g, 10.0 mmol) was dissolved in formic acid (20 mL). To the above warm solution, aqueous formaldehyde (37%, 20 mL) was added. The reaction mixture was heated under reflux for 24 h, then concentrated in vacuo to about 10 mL. Water (50 mL) and dichloromethane (100 mL) were added to the sticky residue, the pH of the aqueous phase was adjusted to 13 by the addition of 3 M aqueous potassium hydroxide solution and the heterogeneous mixture was stirred vigorously for 30 min. The layers were separated and the aqueous phase was extracted with dichloromethane (3 × 100 mL). The combined organic fractions were dried over K_2CO_3 and filtered. Methanol (100 mL) was added to the clear solution. On evaporation of the dichloromethane, the permethylated macrocycle **L^2** was obtained as colorless crystals. Yield: 5.2 g (87%). M.p. 120 °C. Elemental *Anal.* Calc. for $C_{35}H_{58}N_6O_2$ (**L^2**) C, 70.7; H, 9.8; N, 14.1. Found: C, 70.8; H, 9.5; N, 14.3%. ESI-MS in CH_3OH: *m/z* 595.53 $[M+H]^+$. ^1H NMR ($CDCl_3$, 300 MHz): 2.24 (N–CH_3, s, 18H), 2.28 (Ar–CH_3, s, 6H), 2.76 (–CH_2–, quintet, 2H), 2.66 (8CH_2, s, 16H), 3.52 (–CH_2–, s, 8H), 4.32 (–CH_2–, t, 4H, J = 6.6 Hz), 6.99 (ArH, s, 4H). ^{13}C NMR ($CDCl_3$, 75 MHz): 20.7 (2CH_3), 31.7 (1CH_2), 42.0 (4N–CH_3), 54.8 (CH_2), 55.2 (8CH_2), 57.5 (8CH_2), 72.18 (2CH_2), 131.2, 132.2, 132.4, 155.11 (Ar-C). IR (cm^{-1}, KBr pellet): 2946 (CH stretching), 1224 (O–C stretching).

*2.3.4. Synthesis of the binuclear Cu(II) complex (**1**) [Cu_2L^1 (μ-OH)(ClO_4)$_2$] (ClO_4)*

The binuclear Cu(II) complex **1** was synthesized by refluxing a methanolic solution of the ligand **L^1** (1 g, 1.96 mmol) and a methanolic solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (1.45 g, 3.92 mmol). A blue colored solid was separated on evaporating the solution at room temperature and the resulting compound was washed with cold methanol and dried. Yield: (77%). Elemental *Anal.* Calc. for $C_{29}H_{47}Cl_3Cu_2N_6O_{15}$ (**1**) C, 36.5; H, 4.9; N, 8.8. Found: C, 36.2; H, 4.6; N, 8.3%. FAB-MS in NBA: *m/z* 837 $[L^1 + 2Cu + 2ClO_4 + H]^+$; 738 $[L^1 + 2Cu + ClO_4 + H]^+$. Λ_M, S $m^2\,M^{-1}$ in CH_3CN at 25 °C: 81. IR (cm^{-1}, KBr pellet): 3431, 3221w ν(N–H), 2926w, 2879 ν(C–H), 1635m, 1458w, 1209s (C–O), 1105vs, 1085vs $\nu(ClO_4)$, 624m, 420s. UV–Visible [λ/nm ($\epsilon/M^{-1}\,cm^{-1}$)] in CH_3CN: 633 (380), 272 (84,000). g = 2.081. μ_{eff}, μ_B at 298 K: 1.43.

*2.3.5. Synthesis of the binuclear Cu(II) complex (**2**) [Cu_2L^2 (μ-OH)(ClO_4)$_2$] (ClO_4)*

The complex **2** was prepared by following the above method using ligand **L^2** (1 g, 1.68 mmol) and $Cu(ClO_4)_2 \cdot 6H_2O$ (1.24 g, 3.36 mmol), which resulted in a bluish green colored solid. Yield: (56%). Elemental *Anal.* Calc. for $C_{35}H_{59}Cl_3Cu_2N_6O_{15}$ (**2**) C, 40.5; H, 5.7; N, 8.1. Found: C, 40.9; H, 5.4; N, 8.4%. FAB-MS in NBA: *m/z* 921 $[L^2 + 2Cu + 2ClO_4 + H]^+$; 822 $[L^2 + 2Cu + ClO_4 + H]^+$. Λ_M, S $m^2\,M^{-1}$ in CH_3CN at 25 °C: 85. IR (cm^{-1}, KBr pellet) 3462br, 2931m, 2860m ν(C–H), 1685, 1637, 1463, 1212s ν(C–O), 1105vs, 1088vs $\nu(ClO_4)$, 627m, 420s. UV–Visible [λ/nm ($\epsilon/M^{-1}\,cm^{-1}$)] in CH_3CN: 657 (260), 283 (3,90,000). g = 2.102. μ_{eff}, μ_B at 298 K: 1.46.

2.4. X-ray data collection and reduction

Crystals of the precursor compound and ligand **L^2** were colorless and could be sorted using a polarizing microscope (Leica DMLSP). Crystals were cut to a suitable size (less than the collimator cross section diameter) and mounted on a Kappa Apex 2 CCD diffractometer equipped with graphite monochromatic Mo(Kα) radiation (λ = 0.71073 Å). The unit cell parameters were obtained using 36ω-frames of 0.5° width and scanned from three different zones of the reciprocal lattice. The intensity data were collected using ω and φ scans with a frame width of 0.5°. The frame integration and data reduction were performed using Bruker SAINT-PLUS (Version 7.06a) software [23]. The multi-scan absorption corrections were applied to the data using the SADABS [24] program. Both samples were stable at room temperature. The structures were solved using SIR92 [25]. Full matrix least squares refinement was performed using SHELXL-97 [26] programs. All the non-hydrogen atoms were refined with anisotropic displacement parameters. All the hydrogen atoms could be located in the Difference Fourier map. However, they were relocated at chemically meaningful positions and were given riding model refinement with following restraints: tertiary CH_3 groups (C–H = 0.96 Å, U_{iso} = 1.5U_{eq} of parent carbon), secondary CH_2 group (C–H = 0.97 Å, U_{iso} = 1.2U_{eq} of the parent carbon), aromatic C–H group (C–H = 0.93 Å U_{iso} = 1.2U_{eq} of the parent carbon). Selected crystallographic data of the precursor compound and ligand **L^2** are depicted in Table 1.

2.5. Kinetic studies of oxidation of catechol (catecholase activity)

The catalytic oxidation of 4,5-ditertiarybutyl catechol (DTBC) to the corresponding *o*-quinone (DTBQ-ditertiary butyl quinone) was studied using 10^{-3} M of the copper(II) complexes as a biomimetic catalyst in acetonitrile solution. The reaction was followed spectrophotometrically by choosing the strongest absorbance of the product, DTBQ, around 395 nm and monitoring the increase in the absorbance at this wavelength over time intervals of 10 min. Initial rates (d*c*/d*t*) (<2% conversion of DTBC into DTBQ) were determined by a spectrophotometric method. The initial reaction rate values were obtained from the slope of the trace at 395 nm during the first 30 min of the reactions, when the absorption at 395 nm increases linearly.

2.6. DNA cleavage experiments

The cleavage of supercoiled pBR322DNA by the complexes was studied by agarose gel electrophoresis. The gel electrophoresis experiments were performed as follows: pBR322DNA (0.2 μg, 33 μM) was treated with the copper(II) complexes **1** and **2** in 50 mM Tris–HCl/NaCl buffer (pH 7.2) and H_2O_2 followed by dilution with Tris–HCl buffer to a total volume of 18 μL. All the samples were incubated for 30 min at 37 °C followed by their addition to

the loading buffer containing 25% bromophenol blue, 0.25% Xylene cyanol, 30% glycerol (3 μL). The solution was finally loaded on 0.8% agarose gel containing ethidium bromide (1 μg/mL^{-1}). Electrophoresis was done for 1 h at 50 V in TBE (45 mM Tris, 45 mM H_3BO_3, 1 mM-EDTA, pH 8.3) buffer. Bands were visualized by UV light and photographed. Quantification of closed circular and nicked DNA was made by densitometric analysis of ethidium bromide containing agarose gels. Quantification was performed by fluorescence imaging by the use of a Gel-Doc 1000 (BioRad) and data analysis with MULTIANALYSIS software (version 1.1) provided by the manufacturer, using the volume quantification method. In all cases, background fluorescence was subtracted by reference to a lane containing no DNA. A correction factor of 1.47 was used for supercoiled DNA since the ability of ethidium bromide to intercalate into supercoiled DNA (form I) decreased relative to the nicked circular (form II). The fraction of each form of DNA was calculated by dividing the intensity of each band by the total intensities of all the bands in the lane. All results were obtained from experiments that were performed at least in triplicate.

3. Result and discussion

The precursor compound and the ligand **L^1** were prepared by using a modified literature procedure of Clark et al. [27]. We synthesized two macrocyclic binucleating ligands by employing the new precursor compound, 2-[2-(2,6-diformyl-4-methylphenoxy)propoxy]-5-methylisophthalaldehyde and α,ω-diamines. The macrocycle **L^1** was obtained by a (2+1) condensation between the precursor compound and bis(aminoethyl)amine in ethanol-dichloromethane, followed by reduction with $NaBH_4$ (Scheme 1). Reductive methylation of **L^1** with formaldehyde and formic acid under Eschweiler–Clarke conditions gave the permethylated derivative **L^2**. The structure of **L^2** was derived from that of ligand **L^1** by replacing the six NH hydrogen atoms by methyl groups. Synthetic pathways for the complexes are shown in Scheme 1. The molar conductivity measurements of the copper(II) complexes **1** and **2** in CH_3CN resulted in Λ_M values of 81 and 85 S m^2 M^{-1} respectively, which indicate that the complexes are 1:1 electrolytes [28]. The FAB mass spectrum of complex 1, $[Cu_2L^1(\mu\text{-}OH)(ClO_4)_2]$ (ClO_4), showed a peak at $m/z = 837$, corresponding to the $[L^1 + 2Cu + 2\text{-}ClO_4 + H]^+$ ion, and the complex **2**, $[Cu_2L^2(\mu\text{-}OH)(ClO_4)_2]$ (ClO_4), showed a peak at $m/z = 920$, corresponding to the $[L^2 + 2Cu + 2\text{-}ClO_4 + H]^+$ ion. The FAB mass spectral data of the copper(II) complexes confirm the proposed formula of the complexes.

3.1. Crystal structures

The precursor compound crystallizes in the monoclinic system with the space group C2 and half of the molecule in the asymmetric unit. The molecule has twofold symmetry with a two fold axis passing through at C11. The tetraldehyde molecule and its twofold equivalents are linked through C10–H10B···O2 hydrogen bonds (2.58 Å, 143.25°, Symm: 1.5 − x, ½ + y, −z). The hydrogen bonding extends through a-translation to form a one dimensional chain. The packing is further stabilized through Van der Waals interactions. The ORTEP diagram of the precursor compound is given in Fig. 1. The permethylated macrocyclic ligand **L^2** crystallizes in the triclinic space group $P\bar{1}$ with one molecule in the asymmetric unit. The molecules are stabilized by Van der Waals interactions, weak intramolecular C–H···O, C–H···N bonds and intermolecular C–H (π) interactions. Fig. 2 represents the ORTEP diagram of the macrocyclic ligand **L^2**.

3.2. Spectral studies

The IR spectra of the two complexes showed a strong band in the region around 1000–1100 cm^{-1} and a sharp band in the region around 626 cm^{-1}, which could be due to the antisymmetric stretch and antisymmetric bend of perchlorate ions, respectively. The perchlorate peak around 1100 cm^{-1} splits in to two peaks around 1105 and 1085 cm^{-1}, indicating that the perchlorate ions present in the complexes are coordinated to the Cu(II) ions. Complex **1** has another prominent feature of a sharp but weak band at 3221 cm^{-1}, a frequency typical for the N–H stretching vibration of a coordinated secondary amine group. The disappearance of the band around 3220 cm^{-1} and the increasing intensity of the band at 2925 cm^{-1} for complex **2** confirms the N-methylation of the ligand **L^2**. The important strong band observed at around 3460 cm^{-1} for both of the macrocyclic Cu(II) complexes are assignable to OH vibrations. The electronic spectra of an acetonitrile solution of complexes **1** and **2** show three intense intraligand bands in the UV region. In the visible region the copper(II) complexes **1** and **2** exhibit absorption maxima at 633 and 657 nm (Fig. 3), respectively. This strongly suggests that the coordination geometry around the metal ion might be distorted square pyramidal [29]. An increase in λ_{max} (red shift) of complex **2** may be due to the weaker field strength of ligand **L^2** and larger distortion of the coordination geometry around the Cu(II) ion than for complex **1**. The EPR spectra of the solid com-

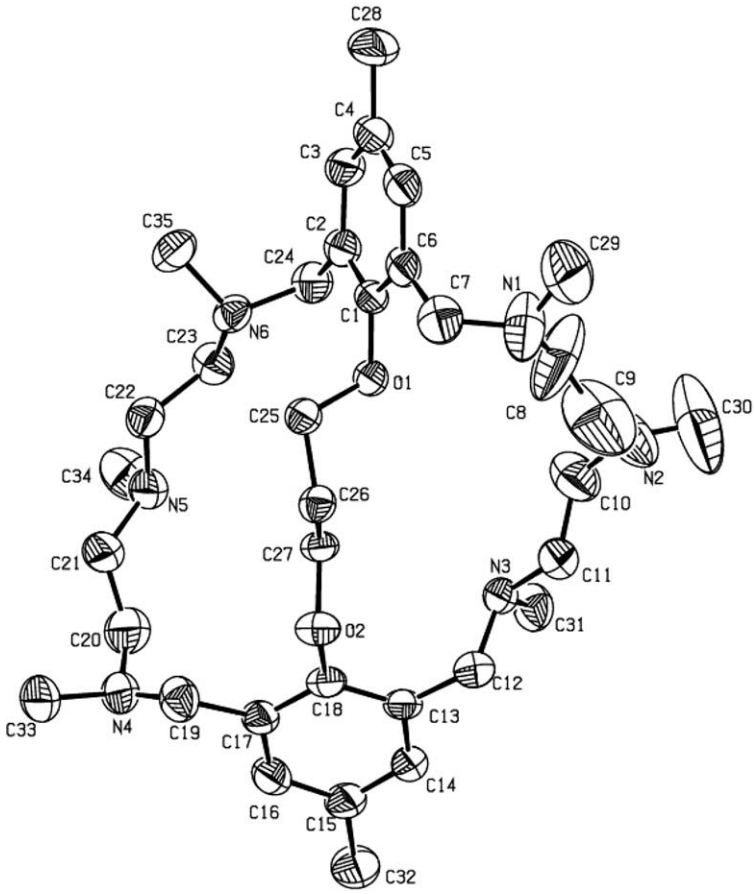

Fig. 2. ORTEP diagram of ligand L^2. Displacement ellipsoids are drawn at the 50% probability level.

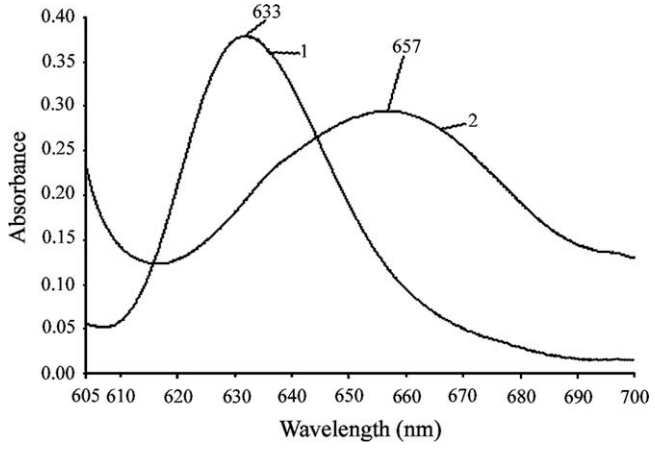

Fig. 3. Electronic spectra of complexes **1** and **2** in CH_3CN.

plexes **1** and **2** were recorded at liquid nitrogen temperature (LNT). Both the binuclear complexes showed a single broad-band resonance at ca. $g = 2.06–2.10$, with the half field signal at 1500G ($M = \pm 2$), which suggest magnetic interactions between the two copper ions through the hydroxyl bridge (Fig. 4). The probe room temperature magnetic studies of the binuclear copper(II) complexes **1** and **2** resulted in magnetic moment values of 1.43 and 1.46 BM, respectively, which suggest the presence of an antiferromagnetic interaction between the two Cu(II) ions.

3.3. Electrochemistry

The cyclic voltammograms of complexes **1** and **2** (Fig. 5) were recorded in CH_3CN solution. Both complexes display in the negative region of potentials a quasireversible redox wave followed by an irreversible cathodic peak at a lower potential. The first reduction potentials are observed at (E^1_{pc}) −0.59 V and −0.55 V for complexes **1** and **2**, respectively. Coulometric titrations by potentiostatic exhaustive electrolysis performed at 100 mV more negative to the first reduction wave consumed approximately one electron ($n \approx 0.96$). This indicates that each process corresponds to a single electron transfer process, and this can be assigned to the redox couple $Cu^{II}Cu^{II}/Cu^{II}Cu^{I}$. The second reduction potentials for complexes **1** and **2** are irreversible and are observed at $E^2_{pc} = -1.07$ and −1.02 V versus Ag/AgCl, respectively. These can be attributed to the transformation $Cu^{II}Cu^{I} \rightarrow Cu^{I}Cu^{I}$. The fact that this process is completely irreversible for both complexes suggests a fast decomposition of the $Cu^{I}Cu^{I}$ species, as evidenced by Neves et al. [7]. Complex **2** reduces at less negative potentials than the complex **1**. This suggests that the geometry around the copper ions with ligand $\mathbf{L^2}$ is more distorted than the copper ions with ligand $\mathbf{L^1}$. The ligands are structurally different in that the amine donor nitrogens of $\mathbf{L^2}$ contain bulky methyl groups, whereas the ligand $\mathbf{L^1}$ has hydrogen atoms. The deviation of the metal from its coordination plane should be larger for the $\mathbf{L^2}$ complex in order to destabilize the Cu(II) oxidation state. Thus, the electron density on the copper ions of complex **2** is less and the copper coordination geometry may also be more distorted due to the steric effect of the bulky methyl group substituents. It has been suggested [30,31] that reduction in electron density on the copper ions and distortion in

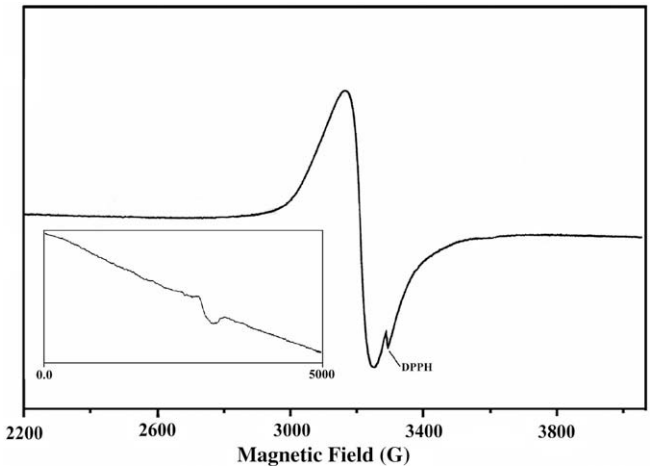

Fig. 4. X- band EPR spectrum of frozen solid (**1**) at 77 K. Inset gives the EPR showing the $\Delta M_s = \pm 2$ transition.

geometry favors the reduction process ($Cu^{II} \rightarrow Cu^{I}$) at less negative potentials, as observed in the complex of the ligand $\mathbf{L^2}$ relative to the ligand $\mathbf{L^1}$.

3.4. Catalytic studies

The catecholase activity of the polyaza binuclear copper(II) complexes **1** and **2** has been studied, with the help of electronic spectroscopy, by monitoring the appearance of the absorbance maximum of the substituted quinone [(DTBQ) ditertiary butyl quinone] (λ_{max} = 395 nm). The time dependent formation of DTBQ in the presence of **1** and **2** is shown in Fig. 6. The initial rate values for the binuclear copper(II) complexes **1** and **2** are 1.15×10^{-4} and $1.66 \times 10^{-4}\,Ms^{-1}$ respectively. The oxidation of catechol to *o*-quinone requires the presence of two metal ions in close proximity; hence, the initial rate values for binuclear complexes are comparatively high. The intrinsic flexibility of the ligand $\mathbf{L^2}$ makes the metal ion reduce easily and bind with the substrate; this facilitates the better catalytic activity of complex **2** compared to complex **1**. It has been assumed that the geometry around the copper ions and the intermetallic distance are the two key factors that determine the catalytic activity of the complexes. The Cu(II) ions may be in close proximity when coordinated by the ligand $\mathbf{L^2}$, and the bridging catechol coordination is compatible with the distance between

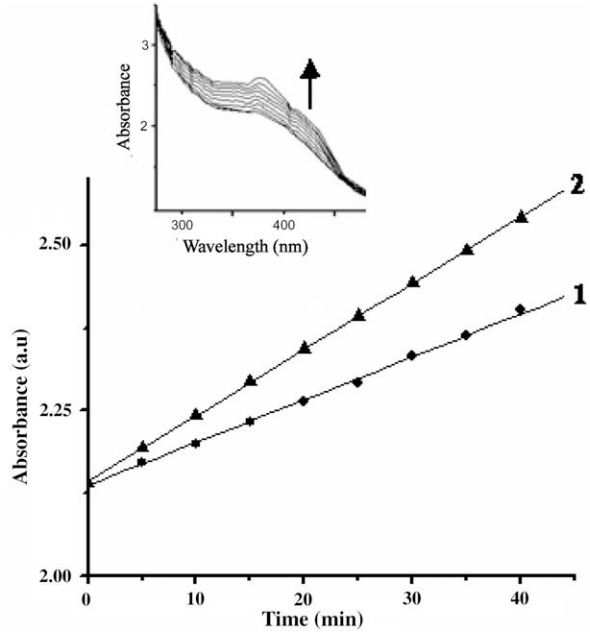

Fig. 6. Time-dependent formation of DTBQ in the presence of complexes **1** and **2**. Inset shows oxidation of 3,5-DTBC by the binuclear copper(II) complex **2**.

the two *o*-diphenol oxygen atoms [32]. The presence of the bulky *N*-methyl group of ligand $\mathbf{L^2}$ makes the coordination geometry around the copper(II) ions more distorted than with the macrocycle ligand $\mathbf{L^1}$. It is evident from the literature [33,34] that the initial rate values for more distorted complexes are higher than those of less distorted complexes.

3.5. DNA cleavage studies

As evident from the literature, complexes of polyamine ligands play an important role due their good nuclease activity [35,36]. In order to assess any cleavage of DNA as a result of the binding of complexes **1** and **2**, agarose gel electrophoresis has been performed with the supercoiled form of plasmid DNA. This method using supercoiled pBR322 DNA in the presence of the macrocyclic Cu(II) complexes **1** and **2** was carried out in a medium of 50 mM Tris–HCl/NaCl Buffer (pH 7.2). Both complexes showed remarkable cleavage in the presence of H_2O_2 (40 μM) as an oxidizing agent. Fig. 7a shows the gel electrophoretic results of the interaction of complexes **1** and **2** with plasmid pBR322 DNA. Under similar conditions, no cleavage of pBR322 DNA occurred for free H_2O_2 (Fig. 7b; lane 2) or free complex (lane 4). The control DNA (lane 1) itself shows two bands [Form I, SC $\geqslant$ 90%; Form II, NC $\leqslant$ 10%]. The Cu(II) complex/H_2O_2 treated DNA also results in two bands, which are exactly parallel to the bands of lane 1, and the band intensity corresponding to Form I (SC DNA) is diminished whilst the band

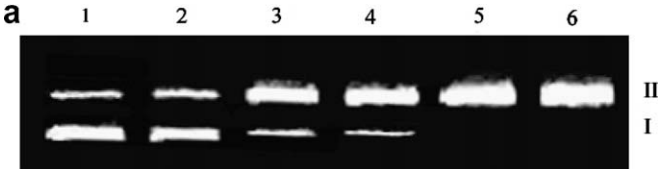

Fig. 7a. Cleavage of SC pBR322 DNA (0.2 μg, 33 μM) by the Cu(II) complexes **1** and **2** (30–50 μM) in the presence of reducing agent H_2O_2 (40 μM) in 50 mM Tris–HCl/NaCl buffer (pH 7.2). Lane 1, DNA control; Lane 2, DNA + 40 μM H_2O_2; Lanes 3–4, DNA + 40 μM H_2O_2 + **1** and **2** (30 μM), respectively; Lanes 5–6, DNA + 40 mM H_2O_2 + **1** and **2** (50 μM), respectively.

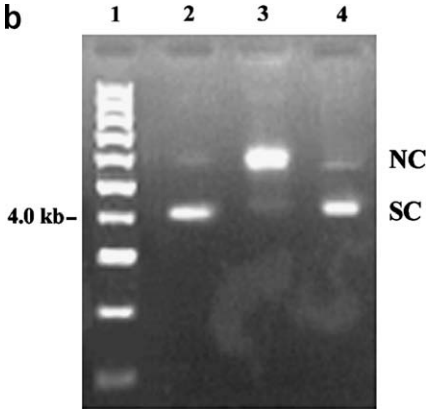

Fig. 7b. Lane 1, Molecular weight markers (1 kb); lane 2, DNA control, lane 3, DNA + 40 μM H_2O_2 + Complex **1** (50 μM); lane 4, DNA + Complex **1** (50 μM). SC – supercoiled, NC – Nicked circular.

intensity of Form II (NC DNA) is increased (lanes 3–4), confirming the formation nicked DNA. At a slightly higher concentration of the binuclear complexes (50 μM), the cleavage is found to be much more efficient in lane 5 and 6. The amount of Form I (supercoiled) decreases, whereas that of Form II (nicked circular) increases with the increase in complex concentration. It is clear that the cleavage of pBR322 DNA is highly dependent on the concentration of the complexes. The cleavage mechanism of pBR322 DNA induced by complexes **1** and **2** was investigated (Fig. 8) and clarified in the presence of a hydroxyl radical scavenger, 1 mM DMSO (lanes 1–2), superoxide scavenger (SOD) (lanes 3–4) and singlet oxygen quencher L-histidine (lanes 5–6) [37]. Only a slight inhibition of DNA cleavage was observed in the presence of the scavengers, which suggests that hydroxyl radical, superoxide and singlet oxygen might not occur in the reaction. The binuclear Cu(II) complexes were found to be highly active in cleaving DNA in the presence of hydrogen peroxide. The H_2O_2 is coordinated to the copper ions of the complexes, affording a peroxo-dicopper species [38]. This coordinated peroxide ion attacks the DNA phosphate bond via a nucleophilic mechanism and hydrolyzes the P–O bond [39–41]. The polyamine groups of the ligand also have the ability to promote the performance of the metal complex in the cleavage of DNA under physiological conditions [17]. The reactions of SC (Form I) plasmid DNA with complex **1** were carried out in the presence of H_2O_2. Typical results from this set of experiments are shown in Fig. 9a and 9b. The disappearance of SC versus time followed pseudo first-order kinetics. The reaction profile for the complex **1** mediated reaction displayed approximately pseudo-first-order kinetic behavior (Fig. 9b), with $k_{obs} \sim 0.07\ min^{-1}$ and $R^2 = 0.984$. On comparison of the cleavage property with some reported results [42,43] of Cu(II) complexes, we note that a lesser amount of oxidizing agents (here hydrogen peroxide) and complex are required in our case for maximum cleavage of DNA. This is well reflected from the cleavage data which show more than 80% of cleavage occurs with a very low

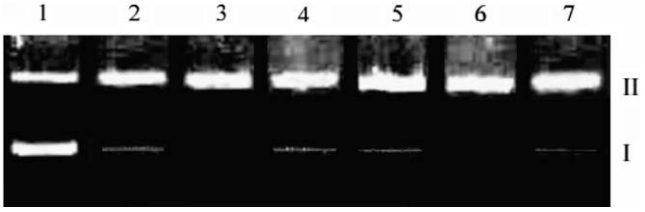

Fig. 8. Lane 1, DNA control; lanes 2–3, DNA + 40 μM H_2O_2 + DMSO (0.1 mM) + **1** and **2** (50 μM), respectively; lanes 4–5, DNA + 40 μM H_2O_2 + SOD (4 units) + **1** and **2** (50 μM) respectively; lanes 6–7, DNA + 40 μM H_2O_2 + L-histidine (0.21 mM) + 1 and 2 (50 μM), respectively.

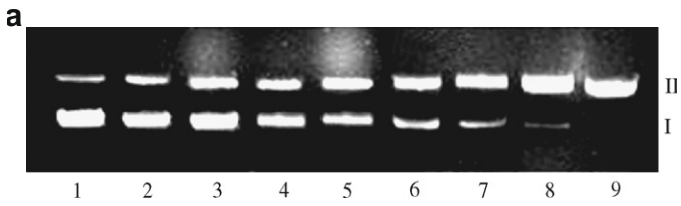

Fig. 9a. Cleavage activity of **1** monitored by 0.8% agarose gel electrophoresis, where [DNA] 0.2 μg, 33 μM (complex 1) 50 μM, and [H_2O_2] 40 μM. Time course measured in 10 mM Tris buffer, pH 7.4, 37 °C, showing the disappearance of supercoiled DNA (I) at (1) 0 min, (2) 2 min, (3) 4 min, (4) 6 min, (5) 10 min, (6) 15 min, (7) 20 min, (8) 25 min, (9) 30 min. (Gel image showing supercoiled (Form I) and circular relaxed (Form II) DNA).

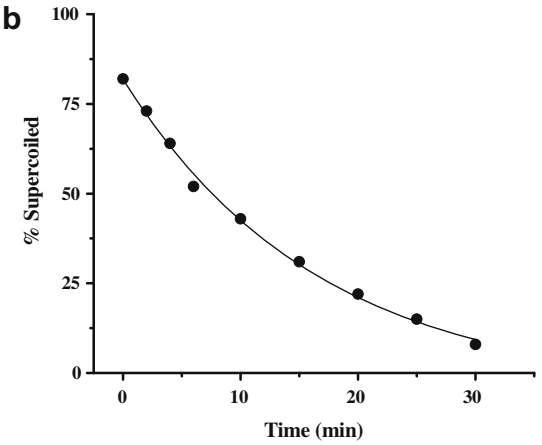

Fig. 9b. Reaction curve, showing a pseudo-first-order kinetic profile (R^2) 0.974, $k_{obs} \sim 0.04\ min^{-1}$.

amount of complex concentration (50 μM). Meanwhile, due to the cyclic nature of the ligands, the two Cu(II) ion centers display an appropriate distance and angle in the cleavage process, so a synergistic effect might exist in the system. Further studies on the macrocyclic ring size effect on DNA molecules as well as on the sequence selectivity of the copper(II) complexes are in progress.

4. Conclusions

Two symmetrical polyaza macrobicyclic binuclear Cu(II) complexes have been synthesized from the new macrocyclic ligand $\mathbf{L^1}$ and its permethylated derivative ligand $\mathbf{L^2}$ and subsequently characterized. Both ligands were prepared using a new tetraldehyde as a precursor compound. Both complexes show good catalytic activity for the catechol oxidation reaction and remarkably promote the hydrolytic cleavage of supercoiled plasmid DNA under physiological conditions in the presence of H_2O_2 at pH 7.2 and 37 °C.

ABSTRACT

The complex [IrCl(η^1-$CH_2CH{=}CH_2$)(η^2-$MeO_2CC{\equiv}CCO_2Me$){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] (**1**) has been prepared by oxidative addition of allyl chloride to a solution of the complex [Ir(η^2-$MeO_2CC{\equiv}CCO_2Me$)$_2$){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] in acetone. The treatment of the complexes [Ir(η^2-C_2H_4)$_2$(κ^3-*N,N,N*-R-pybox)][PF_6] (R-pybox = 2,6-bis[4′-(*S*)-isopropyloxazolin-2′-yl]pyridine, 2,6-bis[4′-(*R*)-phenyloxazolin-2′-yl]pyridine) with (*E*)-3-chloro-1-phenyl-1-propene (cinnamyl chloride) (1:1 molar ratio) in methanol at −40 °C, followed by warming to room temperature, affords stereoselectively the complexes [IrCl(η^1-$CH_2CH{=}CHPh$)(η^2-C_2H_4)(κ^3-*N,N,N*-R-pybox)][PF_6] (R = (*S,S*)-^{i}Pr (**2**), (*R,R*)-Ph (**3**)). Warming of acetonitrile solutions of complexes **2** or [IrCl(η^3-C_3H_5){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] gives the complexes [IrCl(η^1-$CH_2CH{=}CHPh$)(MeCN){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] (**4**) and [IrCl(η^1-$CH_2CH{=}CH_2$)(MeCN){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] (**5**). Complex [Ir(η^2-C_2H_4)$_2$){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] undergoes the oxidative addition of RCOCl (R = Me, Ph) in acetonitrile leading stereoselectively to the complexes [IrCl(COR)(MeCN){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] (R = Me (**6**), Ph (**7**)). The structure of the complex **7** · CH_2Cl_2 has been determined by an X-ray monocrystal study.

1. Introduction

Iridium allyl-complexes display a rich chemistry and are widely used as synthetic reagents [1] as well as in catalysis [2]. Thus, the reaction of a π-allyl-iridium intermediate with nucleophiles is recognized as a useful reaction from a synthetic point of view [2a,b]. Helmchen reported, in 1997, the first iridium-catalyzed asymmetric allylic substitution and since then this field has experienced a pronounced growth [3]. Regarding the asymmetric iridium/pybox-catalyzed processes, the allylic substitution with nitrogen nucleophiles (e.g. oximes, amines, hydroxylamines) [4a–c] and the catalytic reductive aldol [4d] reactions catalyzed by mixtures of [Ir(μ-Cl)(cod)]$_2$/phenyl-pybox and [Ir(μ-Cl)(cod)]$_2$/indane-pybox, respectively, are the sole examples reported.

In this context, we have recently prepared η^3- and η^1-allyl complexes, [IrCl(η^3-C_3H_5)(κ^3-*N,N,N*-R-pybox)][PF_6] and [IrCl(η^1-$CH_2CH{=}CH_2$)(CO)(κ^3-*N,N,N*-R-pybox)][PF_6] (R = ^{i}Pr, Ph) [5], by oxidative addition of allyl chloride to the complexes [Ir(η^2-C_2H_4)$_2$(κ^3-*N,N,N*-R-pybox)][PF_6] and [Ir(CO){κ^3-*N,N,N*-*R*-pybox}][Y] (R = ^{i}Pr, Ph), respectively. We have observed that the coordination mode of the allyl group in the new complexes is highly dependent on the nature of the auxiliary ligands in the precursor complex.

On the ground of these results, we found interesting to explore the synthesis of novel allyliridium(III)–pybox complexes using different iridium(I) precursors and allyl and cinnamyl chloride ($RHC{=}CHCH_2Cl$, R = H, Ph). Unravelling the factors that favour the coordination mode of the allyl group (either η^1 or η^3) for discovering new precatalysts for enantioselective allylic substitution reactions. Moreover, the preparation of allyliridium– and acyliridium–pybox complexes having acetonitrile as a labile ligand is also reported.

2. Experimental

2.1. General procedure

The reactions were performed under an atmosphere of dry nitrogen using vacuum-line and standard Schlenk techniques. All reagents were obtained from commercial suppliers and used without further purification. Solvents were dried by standard methods and distilled under nitrogen before use. The complexes [Ir(η^2-C_2H_4)$_2$(κ^3-*N,N,N*-R-pybox)][PF_6] (R = (*S,S*)-^{i}Pr, (*R,R*)-Ph), [Ir(η^2-$MeO_2CC{\equiv}CCO_2Me$)$_2$){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] and [IrCl(η^3-C_3H_5){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] were prepared by previously reported methods [5]. Infrared spectra were recorded on a Perkin–Elmer 1720-XFT spectrometer. The conductivities were measured at room temperature, in ca. 5×10^{-4} mol L^{-1} acetone solutions, with a Jenway PCM3 conductimeter. The C, H and N analyses were carried out with a Perkin–Elmer 240-B microanalyzer

(inconsistent analyses was found for complex **4** due to incomplete combustion). Electrospray mass spectra (ESI-MS) were recorded on a Bruker MicroTof-Q instrument, operating in the positive mode and using methanol solutions. NMR spectra were recorded on a Bruker AC300 (DPX-300 or AC-300) instrument at 300 MHz (^{1}H) or 75.4 MHz (^{13}C) or a Bruker AMX-400 instrument at 400 MHz (^{1}H) or 100.6 MHz (^{13}C) and using $SiMe_4$ as standard. DEPT experiments were carried out for whole of the complexes reported. 2D-NMR (COSY, HSQC) were performed in selected complexes (AMX-400). Coupling constants *J* are given in Hertz. Abbreviations used: s, singlet; d, doublet; dd, doublet of doublets; t, triplet; m, multiplet; q, quartet; br, broad; pt, pseudotriplet.

2.2. Synthesis

2.2.1. Synthesis of complex [IrCl(η^1-$CH_2CH{=}CH_2$)(η^2-$MeO_2CC{\equiv}CCO_2Me$){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox)][PF_6] (**1**)

To a solution of complex [Ir(η^2-$MeO_2CC{\equiv}CCO_2Me$)$_2${κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF_6] (0.092 g, 0.1 mmol) in 10 mL of acetone, allyl chloride (0.016 mL, 0.2 mmol) was added. The resulting solution was stirred for 1 h at room temperature and the solvent was then removed under vacuum. The residue was extracted with dichloromethane and the resulting red solution was filtered and concentrated to ca. 2 mL. The addition of 30 mL of a mixture diethyl ether/hexane (1:1) afforded **1** as an orange solid, which was washed with hexane (3 × 5 mL) and vacuum-dried. Yield: 0.062 g (72%). *2.2.5. X-ray structure determination of **7** · CH_2Cl_2*

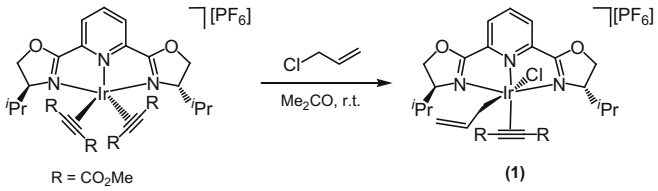
Crystals suitable for X-ray diffraction analysis were obtained by slow diffusion of hexane into a saturated solution of the complex **7** in dichloromethane. Data collection, crystal and refinement parameters are collected in Table 1. Diffraction data were recorded at 150(2) K on a Nonius Kappa CCD single crystal diffractometer, using Mo Kα radiation (*λ* = 0.71073 Å). Crystal–detector distance was fixed at 29 mm, and images were collected using the oscillation method, with 2° oscillation and 50 s exposure time per image. Data collection strategy was calculated with the program COLLECT [6]. Data reduction and cell refinement were performed using the programs HKL DENZO and SCALEPACK [7]. A semi-empirical absorption correction was applied using the program SORTAV [8].

The software package WINGX was used for space group determination, structure solution and refinement [9]. The space group determination was based on a check of the Laue symmetry and systematic absences, and ascertained from the structure solution. The structure was solved by Patterson interpretation and Phase expansion using DIRDIF [10]. Isotropic least-squares refinement on F^2 using SHELXL-97 [11]. During the final stages of the refinements, all positional parameters and the anisotropic temperature factors of all non-H atoms were refined. Hydrogen atoms were geometrically placed riding on their parent atoms with isotropic displacement parameters set to 1.2 times the Ueq of the atoms to which they are attached (1.5 for methyl groups). The function minimized was $([\sum wF_o^2 - F_c^2)/\sum w(F_o^2)]^{1/2}$ where $w = 1/[\sigma^2(F_o^2) + (0.0678P)^2 + 0.3718P]$ with $\sigma(F_o^2)$ from counting statistics and $P = (\text{Max}(F_o^2, 0) + 2F_c^2)/3$. The maximum residual electron density is located near to heavier atoms and to the solvent molecule. Atomic scattering factors were taken from International tables for X-ray Crystallography [12]. The crystallographic plots were made with PLATON [13].

Table 1
Crystal data and structure refinement for complex **7** · CH_2Cl_2.



Empirical formula	$C_{27}H_{33}Cl_3F_6IrN_4O_3P$
Fw	905.09
Temperature (K)	150(2)

3. Results and discussion

*3.1. Synthesis of complex [IrCl(η¹-$CH_2CH{=}CH_2$)(η²-$MeO_2CC{\equiv}CCO_2Me$){κ³-N,N,N-(S,S)-ⁱPr-pybox}][PF_6] (**1**)*

The reaction of complex [Ir(η²-$MeO_2CC{\equiv}CCO_2Me$)₂{κ³-N,N,N-(S,S)-ⁱPr-pybox}][PF_6] with allyl chloride (2 eq.) in acetone at room temperature produces stereoselectively the allyliridium(III) complex **1** isolated as an orange solid in 72% yield (Scheme 1). Its analytical and spectroscopic NMR data support the proposed formulation (see Section 2 for details). In particular the following data can be pointed: (a) the ^{1}H and ^{13}C NMR resonances of the allyl group are in accordance with a σ-coordination mode. The ^{1}H NMR spectrum shows the three olefinic hydrogens at 5.20 (m), 4.75 (dd,

Scheme 1.

J_{HH} = 9.8 Hz, J_{HH} = 2.5 Hz) and 4.52 (m) ppm and the $IrCH_2$ protons as two multiplets at 2.76, 2.24 ppm. Moreover, the $^{13}C\{^1H\}$ NMR spectrum shows the expected singlet resonances at 141.4, 110.4 and - 4.6 for the C_β, C_γ and C_α nuclei, respectively, of the η^1-allyl group. (b) The $MeO_2CC{\equiv}CCO_2Me$ (DMAD) ligand shows two singlets at 3.95 and 3.91 ppm (CO_2Me) in the ^1H NMR spectrum as well as six singlets [181.2 and 179.7 (CO_2Me); 129.9 and 111.0 (CCO_2Me); 56.1 and 52.0 (CO_2CH_3)] in the $^{13}C\{^1H\}$ NMR spectrum.

The reaction involves decoordination of one DMAD ligand and oxidative addition of allyl chloride to the iridium center to give **1** in which the allyl group participates as a monodentate ligand. Similar coordination of the allyl group has been recently found in the complexes $[IrCl(\eta^1\text{-}CH_2CH{=}CH_2)(CO)(\kappa^3\text{-}N,N,N\text{-R-pybox})][PF_6]$ (R = (*S,S*)-^{i}Pr, (*R,R*)-Ph) [5b] resulting from the reaction of complexes $[Ir(CO)(\kappa^3\text{-}N,N,N\text{-R-pybox})][PF_6]$ and allyl chloride. These η^1-allyl complexes do not evolve into the corresponding η^3-allyl complexes by loss of DMAD or CO. On the contrary, we reported recently that the complexes $[IrCl(\eta^3\text{-}C_3H_5)(\kappa^3\text{-}N,N,N\text{-R-pybox})][PF_6]$ [5a] are rapidly formed at room temperature from complexes $[Ir(\eta^2\text{-}C_2H_4)_2(\kappa^3\text{-}N,N,N\text{-R-pybox})][PF_6]$ and allyl chloride. Probably, the higher π-acceptor capability of either alkyne or CO ligands than that of the alkene makes their dissociation disfavoured and consequently the η^3-coordination of the allyl group is not observed.

An X-ray analysis to determine the real stereoisomer could not be performed since all attempts to crystallize complex **1** have been unsuccessful.

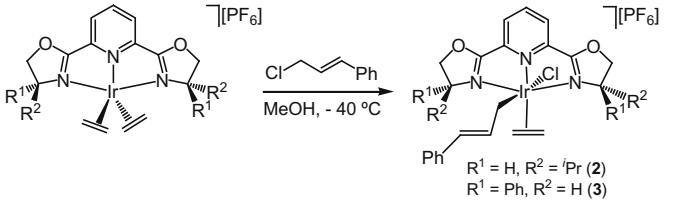
3.2. Synthesis of complexes [IrCl(η^1-$CH_2CH{=}CHPh$)(η^2-C_2H_4)(κ^3-N,N,N-R-pybox)][PF_6] (R = (S,S)-^{i}Pr (**2**), (R,R)-Ph (**3**))

The reaction of equimolecular amounts of the complexes $[Ir(\eta^2\text{-}C_2H_4)_2(\kappa^3\text{-}N,N,N\text{-R-pybox})][PF_6]$ (R-pybox = (*S,S*)-^{i}Pr-pybox, (*R,R*)-Ph-pybox) and (*E*)-3-chloro-1-phenyl-1-propene (cinnamyl chloride) (methanol, −40 °C to room temperature) produces the iridium(III) complexes $[IrCl(\eta^1\text{-}CH_2CH{=}CHPh)(\eta^2\text{-}C_2H_4)(\kappa^3\text{-}N,N,N\text{-R-pybox})][PF_6]$ (R = (*S,S*)-^{i}Pr (**2**), (*R,R*)-Ph (**3**)) in a stereoselective manner (Scheme 2). These complexes have been isolated as orange solids (86 and 88% yield, respectively) and characterized by elemental analyses, molar conductivity and NMR spectroscopy (see Section 2 for details). Significant spectroscopic data are: (a) the ^1H NMR spectrum shows two multiplets for the ethylene ligand [4.50 and 3.96 ppm (**3**)] while the corresponding carbon atoms are observed in the $^{13}C\{^1H\}$ NMR spectra as a singlet [ca. 72.0 ppm (**2**); 72.1 ppm (**3**)], (b) the ^1H and ^{13}C NMR resonances of the allyl group are in accordance with a σ-coordination mode. The ^1H NMR spectra show the olefinic hydrogens as two multiplets [6.00 and 5.75 ppm (**2**); 6.00 and 5.78 (**3**), the last ones being overlapped with the resonances of the oxazoline OCH_2] and the $IrCH_2$ protons as two multiplets [2.61 and 2.17 ppm (**2**); 2.50 and 1.83 ppm (**3**)]. In addition, the $^{13}C\{^1H\}$ NMR spectra show singlet signals at 134.8 (HC=CHPh), 125.9 (HC=CHPh) and 3.8 ($IrCH_2$) ppm for complex (**2**) and at 135.0 (HC=CHPh), 126.0 (HC=CHPh) and 3.8 ($IrCH_2$) ppm for complex (**3**).

Although three stereoisomers can be expected, a single reaction product was obtained in both cases according to the NMR data of the reaction crude. Unfortunately, an X-ray analysis could not be performed since all attempts to crystallize complexes **2** and **3** have been unsuccessful.

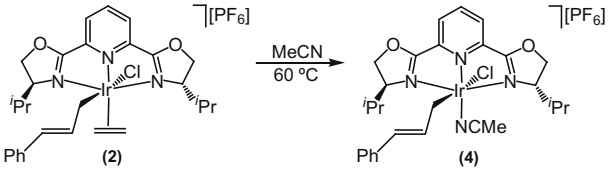
Attempts have been undertaken to obtain the cinnamyl complexes with η^3-coordination by warming methanol or acetone solutions of complexes **2** or **3** at 50 °C. In all cases, the analysis of the resulting solution reveals the presence of a η^3-coordination complex along with unidentified compounds. Probably, the tridentate coordination mode would be hampered in this case because of the sterically more demanding nature of the cinnamyl ligand.

3.3. Synthesis of complex [IrCl(η^1-$CH_2CH{=}HPh$)(MeCN){κ^3-N,N,N-(S,S)-^{i}Pr-pybox}][PF_6] (**4**)



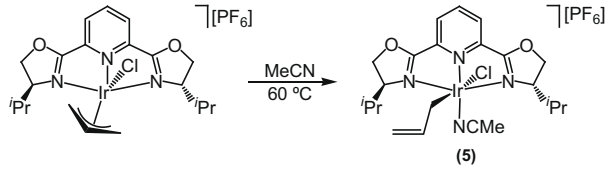
Warming a solution of complex **2** in acetonitrile at 60 °C during 3 h allows for the ethylene-acetonitrile ligand exchange leading to the complex $[IrCl(\eta^1\text{-}CH_2CH{=}CHPh)(MeCN)\{\kappa^3\text{-}N,N,N\text{-}(S,S)\text{-}^i\text{Pr-pybox}\}][PF_6]$ (**4**) which is isolated as red solid in 89% yield (Scheme 3). Its analytic and spectroscopic NMR data support the proposed formulation (see Section 2 for details). In particular the following data can be pointed: (a) The resonance of the acetonitrile ligand appears as a singlet at 3.05 ppm in the ^1H NMR spectrum. In addition the $^{13}C\{^1H\}$ NMR spectrum shows singlet signals for the acetonitrile carbons at 124.7 (CN) and 5.2 ppm (*Me*CN). (b) The resonance signals of the allyl ligand are in accordance with a η^1-coordination mode as it was found in the case of its precursor **2** (see Section 2 for details).

3.4. Synthesis of complex [IrCl(η^1-$CH_2CH{=}CH_2$)(MeCN){κ^3-N,N,N-(S,S)-^{i}Pr-pybox}][PF_6] (**5**)



When a solution of complex $[IrCl(\eta^3\text{-}C_3H_5)\{\kappa^3\text{-}N,N,N\text{-}(S,S)\text{-}^i\text{Pr-pybox}\}][PF_6]$ [5c] in acetonitrile is warmed at 60 °C during 3 h the complex **5** is isolated as a red solid in 72% yield (Scheme 4). Its analytic and spectroscopic NMR data support the proposed formulation (see Section 2 for details). In particular the following data can be pointed: (a) the ^1H and ^{13}C NMR resonances of the allyl group are in accordance with the η^1-coordination mode. Thus, the ^1H NMR spectrum shows the three olefinic hydrogens at 5.42 (m), 4.70 (dd, J_{HH} = 9.9 Hz, J_{HH} = 2.6 Hz) and 4.57 (m) ppm and the $IrCH_2$ protons as two pseudotriplets at 2.78 and 2.20 ppm (J_{HH} = 9.3 Hz). The $^{13}C\{^1H\}$ NMR spectrum shows the expected singlet resonances at 139.8, 109.1 and 1.7 ppm assigned to the C_β, Cγ, and C_α nuclei, respectively, of the η^1-allyl group. (b) The resonances of the acetonitrile ligand appear as singlets at 3.08 ppm (^1H NMR) and at 122.2 (CN) and 2.8 (*Me*CN) ppm (^{13}C NMR). The formation of the complex **5** presumably proceeds via the η^3-allyl-to-η^1-allyl isomerization reaction followed by coordination of acetonitrile to the resulting unsaturated iridium complex.

3.5. Synthesis of complexes [IrCl(COR)(MeCN){κ^3-N,N,N-(S,S)-^{i}Pr-pybox}][PF_6] (R = Me (**6**), Ph (**7**))

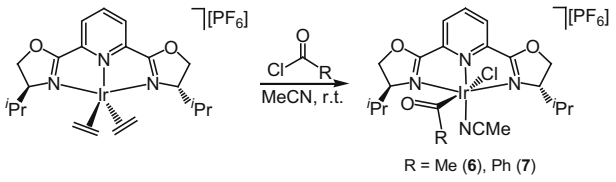


The oxidative addition of acetyl and benzoyl chloride to complex $[Ir(\eta^2\text{-}C_2H_4)_2\{\kappa^3\text{-}N,N,N\text{-}(S,S)\text{-}^i\text{Pr-pybox}\}][PF_6]$ has been also performed. Thus, the reaction of equimolecular amounts of that

Scheme 2.

Scheme 3.

Scheme 4.



complex and acetyl or benzyl chloride in acetonitrile at room temperature produces stereoselectively the complexes **6** and **7**, respectively (Scheme 5). These complexes have been isolated as orange solids in 83–85% yield. Their analytic and spectroscopic data (IR and ^{1}H, ^{13}C{^{1}H} NMR) support the proposed formulations (see Section 2 for details).

Significant spectroscopic data are given: (a) the carbonyl carbon of the acyl ligand appears in the ^{13}C{^{1}H} NMR spectra at low field as singlet signals (200.9 (**6**) and 200.1 (**7**) ppm); (b) the methyl group of the MeCN ligand is observed as a singlet at 3.15 (**6**) and 2.97 (**7**) ppm in the ^{1}H NMR spectra. In addition the ^{13}C{^{1}H} NMR spectra show singlet signals for the acetonitrile carbons at 123.7 (CN) and 3.4 (*Me*CN) ppm for complex (**6**) and at 126.0 (CN) and 5.2 ppm (*Me*CN) for complex (**7**). The reaction presumably involves the formation of a non-detected monoolefin acyliridium(III) complex, which in turn evolves by ethylene displacement and acetonitrile coordination to thus provide complexes **6** and **7**. When this reaction was carried out in less coordinating solvents a complex mixture of unidentified products was obtained.

3.6. Characterization structural: X-ray structure of complex [IrCl(COPh)(MeCN){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF$_6$] · CH_2Cl_2

Since the NMR data do not allow the unambiguous assignment of the stereochemistry of complexes **6**, **7** a single-crystal X-ray analysis of complex **7** has been performed. An ORTEP view of the molecular structure is shown in Fig. 1. The more significant bond length and angle values are collected in Table 2. The structure exhibits a distorted octahedral geometry around the iridium atom, and shows the bonding of iridium to the three nitrogen atoms of the ^{i}Pr-pybox ligand, the chlorine atom, the acetonitrile, and the benzoyl group. The chlorine atom and the benzoyl group are located in a *trans* arrangement. The distances Ir–N(1) (2.075(7) Å), Ir–N(2) (1.975(7) Å) and Ir–N(3) (2.039(6) Å), as well as the bond angles N–Ir–N (79.6(3)°, 78.3(3)° and 157.7(3)°) fall in the range observed for the related complexes [Ir(η^2-C_2H_4)$_2$(κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox)][PF$_6$] and [IrCl(η^3-C_3H_5)(κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox)][PF$_6$] [5a]. The Ir-benzoyl distances [Ir–C(18) (2.054(8) Å) and C(18)–O(3) (1.204(11) Å)] are in the range found for other acyliridium(III) complexes [14]. The acetonitrile group is almost linearly coordinated to iridium, as indicated by the C(25)–N(4)–Ir angle of 175.9(10)°; the distance Ir–N(4) is 2.024(8) Å.

We assume that the stereochemistry of complex **7** is maintained in complexes **1**–**5**, with the chloride and the allyl ligands *trans* to each other. A similar stereochemical environment was reported for the complex [IrCl(η^1-$CH_2CH{=}CH_2$)(CO)(κ^3-*N,N,N*-(*R,R*)-Ph-pybox)][PF$_6$] [5b].

Scheme 5.

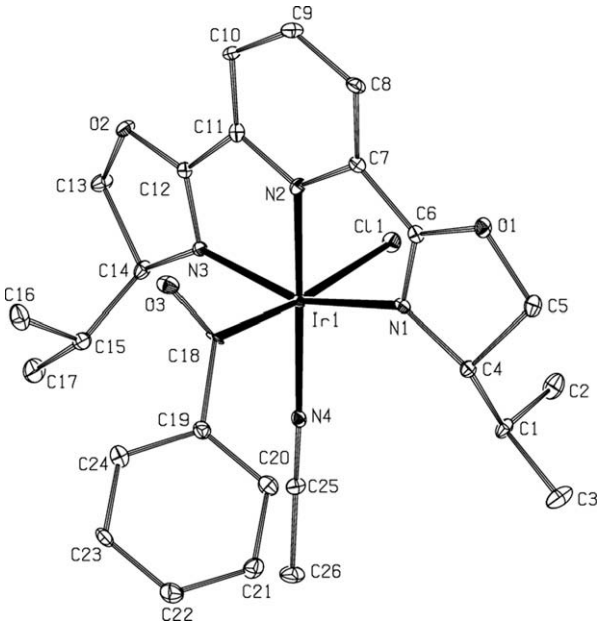


Fig. 1. An ORTEP type view of the molecular structure of the cation of complex [IrCl(COPh)(MeCN){κ^3-*N,N,N*-(*S,S*)-^{i}Pr-pybox}][PF$_6$] · CH_2Cl_2 (**7** · CH_2Cl_2); drawn at 10% probability level. Hydrogen atoms have been omitted for clarity.

Table 2
Selected bond distances (Å) and angles (°) for complex **7** · CH_2Cl_2.

Bond	Distance	Bond	Distance
Ir–N(2)	1.975(7)	C(18)–Ir	2.054(8)
Ir–N(1)	2.075(7)	C(18)–O(3)	1.204(11)
Ir–N(3)	2.039(6)	N(4)–C(25)	1.131(11)
Ir–N(4)	2.024(8)	C(25)–C(26)	1.450(13)

N(4)–C(25)–C(26)	175.9(10)		

4. Conclusions

In summary, we have accomplished the synthesis of enantiopure η^1-allyl and acyliridium(III) complexes of the types [IrCl(η^1-$CH_2CH{=}CHR$)(L)(κ^3-*N,N,N*-^{i}Pr-pybox)][PF$_6$] (R = H, L = $MeO_2CC{\equiv}C$-CO_2Me, MeCN; R = Ph, L = C_2H_4, MeCN), [IrCl(η^1-$CH_2CH{=}CHPh$)(η^2-C_2H_4)(κ^3-*N,N,N*-Ph-pybox)][PF$_6$] and [IrCl(COR)(MeCN)(κ^3-*N,N,N*-^{i}Pr-pybox)][PF$_6$] (R = Me, Ph) by the stereoselective oxidative addition of allyl or acyl chloride to the iridium(I) precursors or by ligand exchange on the allyliridium(III) complexes. The X-ray crystal structure of complex **7** · CH_2Cl_2 is reported and shows a *trans* disposition of the chlorine and benzoyl ligands. Although we have recently described the synthesis of complexes [IrCl(η^3-C_3H_5)(κ^3-*N,N,N*-R-pybox)][PF$_6$] from [Ir(η^2-C_2H_4)$_2$(κ^3-*N,N,N*-R-pybox)][PF$_6$] (R = (*S,S*)-^{i}Pr, (*R,R*)-Ph) and allyl chloride [5a], the results reported in this paper suggest that a η^1-coordination of allyl group is favoured in the presence of DMAD, MeCN and CO [5b]. On the other hand, the tridentate coordination is disfavoured for the cinnamyl group in comparison with the allyl group.

Attainment of new Te^{II} and Te^{IV} iodides by unexpected removal of the mesityl group of $[mesTeI_2]^-$: Synthesis and structural features of $[TeI_4][Co(en)_3] \cdot I$, $[TeI_6][Co(en)_3] \cdot I$, $[\{TeI_6\}\{Te_2I_{10}\}][Co(NH_3)_6]_2 \cdot 2I \cdot 6H_2O$ and $[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3] \cdot I_3 \cdot 2CHCl_3$ (mes = 2,4,6-trimetylphenyl; *en* = ethylenediamine; bpy = bipyridine)

ABSTRACT

$(MesTe)_2$ reacts with I_2 and $[CoL_n]I_3$ {L = $(NH_3)_6$, $(en)_3$} in a biphasic system (chloroform and water) to give, in the interface of the two phases, crystals of $[TeI_4][Co(en)_3] \cdot I^-$ (**1**), $[TeI_6][Co(en)_3] \cdot I^-$ (**2**) and $[\{TeI_6\}\{Te_2I_{10}\}]$ $[Co(NH_3)_6]_2 \cdot 2I^- \cdot 6H_2O$ (**3**), in a high yield. If the crystallization is carried out with $[Co(bpy)_3]I_3$ under addition of THF, the mesityl groups are retained and the final product is $[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3] \cdot I_3^- \cdot 2CHCl_3$ (**4**), which crystallizes in the organic phase. The already known species {mesTeI···I(mes)Te–Te(mes)$_2$} appears as subproduct in the syntheses of **1**, **2** and **3**, in the organic phase.

The X-ray structural characterization of the new complexes is discussed, together with some synthetic features related with the abstraction of the mesityl groups in the three first syntheses.

1. Introduction

It is not an overstatement when we classify the chemistry of organochalcogene halides, this subject of considerable current interest, as the "chemistry of the secondary bonds". The bonding in these compounds get away from simple description, and concepts like hypervalence, multicenter bonding, charge transfer interactions and secondary bonds have been arisen in the understanding of their structural and chemical features [1–5]. Intermolecular bonding effects of the type E···X and X···X (E = Se, Te; X = Cl, Br, I) of various strengths, together with hydrogen bonding (especially if pyridinium counter ions occur), lead to the formation of one, bi and three-dimensional polymeric chains, dimeric structures or monomers with fairly strong intermolecular interactions. Many of these halogen compounds lie close to the ionic/covalent borderline, and several identified species have been found to be dependent on variables like the substituents R, the donor atom, the identity of the halogen, and, in some cases, also on the dielectric constant of the solvent in which they have been prepared [6–9].

Newly we have described [10] the synthesis and the X-ray characterization of the new T-shaped [9,11] organotellurium dihalides (PyH)[mesTeI$_2$] (**A**), (PyH)[mesTeIBr] (**B**) and (PyH)[mesTeICl] (**C**), which were prepared starting from $(mesTe)_2$, with insertion – in **B** and **C** – of two different halogen atoms on tellurium and without the participation of ethylenethiourea, a coordinating solvent commonly used to mediate this type of reactions [12]. The anions [mesTeI$_2$] and [mesTeIBr] build dimers by reciprocal, secondary Te···X interactions and are also linked to the pyridinium cations through NH···X bonding; the anion [mesTeICl] do not interact with neighboring anionic moieties, but attains as well secondary NH···Cl bonding with the pyridinium cation. Following these experimental studies we have reported further [13] the analogous T-shaped organotellurium(II) dihalides (PyH)[mesTeBr$_2$], (PyH)[mesTeClBr] and (PyH)[mesTeCl$_2$], which do not reproduce the assembling of the above mentioned parent dihalides, e.g., there is no dimeric association of the anions, although the secondary NH···X bonds of the anionic moieties toward the pyridinium cations are maintained.

If the reaction milieu – in the synthesis of the two series of compounds described above – is anyway disturbed by using appropriated reagents, the final products can be essentially different, chemically and structurally. We have demonstrated [14] the effects of these controlled "disturbances" on the intermediary mesTeI, with the syntheses of the organotellurium iodides $[mesTeI(\mu\text{-}I)_2(TeImes)_2]_n$, $(C_5H_6N)_4[mesTeI_2]_2(I_3)_2$ and $\{(C_5H_6N)_3[(mesTeI_3)(\mu\text{-}I^-)(TeI_3mes)](I_3)_2\}_n$. All these compounds show unusual compositions and configurations, attaining secondary, interanionic $I_3^-\cdots I\text{–}Te^-$ bonds, $N^+\text{–}H\cdots I\text{–}Te^-$ interactions and $N^+\text{–}H\cdots I_3^-$ contacts. The last compound presents the tellurium atoms with mixed valence states, Te^{II} and Te^{IV}.

Because of the structural importance (multicenter and secondary bonding) and chemical properties of T-shaped organochalcogene dihalides [15–18], as well as their charge transfer interactions, we have attempted the recrystallization in two phases of an excess of [mesTeI](CHCl$_3$) plus I_2 with [CoL$_n$]I$_3$(H$_2$O) {L = (NH$_3$)$_6$, (*en*)$_3$} to obtain products related to **A**, but containing a Co^{III} complex as counter ion, as well as the already observed I_3^- interactions, with different stoichiometric relations. Instead, the obtained crystalline products, $[TeI_4][Co(en)_3]\cdot I^-$ (**1**), $[TeI_6][Co(en)_3]\cdot I^-$ (**2**) and $[\{TeI_6\}\{Te_2I_{10}\}][Co(NH_3)_6]_2\cdot 2I^-\cdot 6H_2O$ (**3**), are quite different of those expected, and all of them present a common feature: the absence of the mesityl group. When the reaction is carried out with [Co(bpy)$_3$]I$_3$, under addition of THF, the mesityl groups are retained and the final product is $[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3]\cdot I_3^-\cdot 2CHCl_3$ (**4**), which presents an iodine bridge between the two (mesTeI$_2$) anions. The already known [19], neutral species {mesTeI···I(mes)Te–Te(mes)$_2$} appears as subproduct in the syntheses of **1**, **2** and **3**.

We discuss now the synthetic procedures and the structural characterization of the title complexes, as well as possible reasons for the surprising withdrawal of the mesityl group in **1**, **2** and **3**.

2. Results and discussion

2.1. Structural features of *1*, *2*, *3* and *4*

The X-ray crystal data and the experimental conditions for the analyses of the complexes $[TeI_4][Co(en)_3]\cdot I^-$ (**1**), $[TeI_6][Co(en)_3]\cdot I^-$ (**2**), $[\{TeI_6\}\{Te_2I_{10}\}]\ [Co(NH_3)_6]_2\cdot 2I^-\cdot 6H_2O$ (**3**) and $[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3]\cdot I_3^-\cdot 2CHCl_3$ (**4**), are given in Table 1. Table 2 summarizes selected bond distances and angles for the title compounds. Figs. 1 and 2 represent the molecular structures of compounds **1** and **2** with their multiple secondary interactions (identified by dashed lines), which lead to the one-dimensional assembling of both compounds. Fig. 3 shows the two-dimensional assembly of the molecules in compound **3** (without the solvate molecules), with the secondary interactions also represented by dashed lines. Fig. 4 displays the structural composition of **4** (not including the chloroform molecules), with the iodine bridge as dotted lines, and Fig. 5 shows the one-dimensional assembly of **4**, attained by all the compound-forming entities.

In the complex $[TeI_4][Co(en)_3]\cdot I^-$ (**1**), the octahedral $[Co(en)_3]^{3+}$ ions are linked through angular (105.7°) NH···I$^-$···HN secondary bonding, with distances of 2.726(2) and 2.721(1) Å. Each octahedral moiety is connected to one semi planar $[TeI_4]^{2-}$ ion through a secondary NH···I bond, measuring 2.775(1) Å. The Te–I bonds are not symmetrical, ranging from 2.894(2) to 3.064(2) Å. The association of the ionic species through secondary interactions yields a one-dimensional chain along the bisector of the ac axes (see Fig. 1).

The complex $[TeI_6][Co(en)_3]\cdot I^-$ (**2**) presents two kinds of NH···I$^-$ interactions, H(2)″···I(7) {2.834(0)} and H(4)···I(7) {2.809(0) Å}, (see Fig. 2). The secondary iodine interactions of the tipe Te–I···I$^-$ {I(2)···I(7)} exhibit a distance of 3.934(1) Å, whereas the Te–I···I–Te contacts {I(2)···I(3′)} are somewhat shorter {3.907(0) Å}. The octahedral $[TeI_6]^{2-}$ ions are linked through iodine interactions, alternating $[Co(en)_3]^{3+}$ and I$^-$ ions in a zigzag configuration, which leads also to the assembly of the ionic species in a one-dimensional chain.

The unusual structure of the two-dimensional lattice of $[\{TeI_6\}\text{-}\{Te_2I_{10}\}]\ [Co(NH_3)_6]_2\cdot 2I^-\cdot 6H_2O$ (**3**) appears as a result of the transversal interlacement (in the same plane) of two kinds of chains: along a direction close on 20° to the *b* axis the ionic species $[TeI_6]^{2-}$ and $[Te_2I_{10}]^{2-}$ build parallel single chains through two I···I interactions {I(2)···I(7′)} with 3.930(2) Å. The $[Te_2I_{10}]^{2-}$ species attain also secondary bonding with two I$^-$ ions {I(6)···I(9)}, 3.674(2) Å}. With these shorter I···I$^-$ contacts, each two I$^-$ ions assemble a parallelogram with one $[Te_2I_{10}]^{2-}$ moiety, in the

Symmetry transformations used to generate equivalent atoms: **1** {(′) = 1 − *x*, 1 − *y*, 1 − *z*}; **2** {(′) = −*x*, −*y*, 1 − *z*; (″) = −1−*x*, −*y*, 1 − *z*}; **3** {(′) = 1 − *x*, 2 − *y*, 1 − *z*; (″) = −*x*, 1 − *y*, −*z*; (‴) = 1 + *x*, *y*, *z*}; **4** {(′) = −*x*, 1 − *y*, −*z*; (″) = 1 − *x*, *y*, 0.5 − *z*; (‴) −*x*, *y*, 0.5 − *z*; (⁗) = 0.5 − *x*, 0.5 + *y*, 0.5 − *z*}.

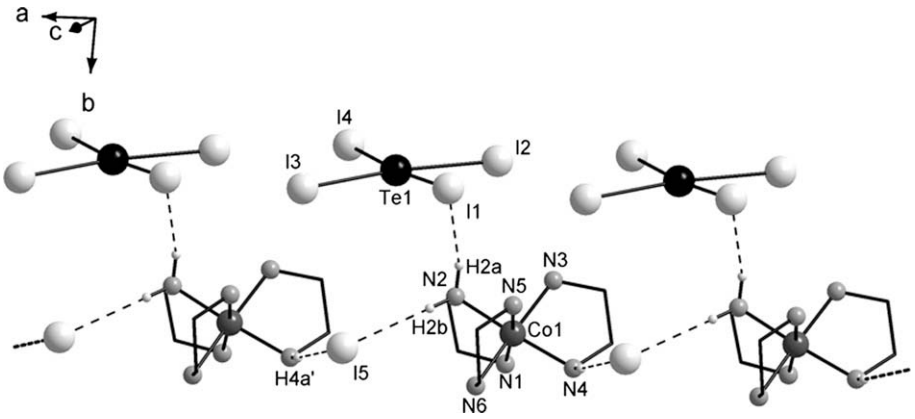

Fig. 1. Molecular/ionic structure and one-dimensional assembly of $[TeI_4][Co(en)_3]\cdot I^-$ (**1**). The dashed lines represent secondary interactions. Symmetry transformations used to generate equivalent atoms: (′) = 1 − *x*, 1 − *y*, 1 − *z*.

equatorial plane of the two octahedrons. An inversion center is located in the middle of the ring formed by the four Te(2) and I(5) atoms. The second set of chains crosses over the first one along the *a* axis, and is formed by $[Co(NH_3)_6]^{3+}$ octahedral moieties linked through NH···I$^-$ interactions. These non-symmetrical hydrogen bridges, H(1)‴···I(9) and I(9)···H(6), have distances of 2.843(1) and 2.800(3) Å, respectively (see Fig. 3).

The ionic species $[Te_2I_{10}]^{2-}$, counterbalanced by *N*,*N*-dimethylanilinium cations – with secondary I···I bonds building up a 3D network – was described for the first time by Ryan and Xu [20]. Also the analogous $[Te_2Cl_{10}]^{2-}$ ion is already known [21].

Complex **4**, $[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3]\cdot I_3^-\cdot 2CHCl_3$, the only product which retains the mesityl rings, is a typical T-shaped tellurium diiodide. The Te–I bonds show distances of 2.900(1) {Te(1)–I(2)} and 3.006(2) Å) {Te(1)–I(1)}. The I(1)–Te(1)–I(2) angle is 174.87(8)°, and the C(1)–Te(1)–I(1)/C(1)–Te(1)–I(2) angles measure 88.4(5) and 88.8(5)°, respectively. These angles characterize the classical T configuration of this type of compounds. As shown in Fig. 4, the two ($mesTeI_2$) ions are linked by a symmetrical iodine bridge of 3.225(1) Å.

The solvate I_3^- accomplishes the charge balance of **4** and shows identical I(4)–I(3)–I(4)″ interatomic distances, an uncommon feature in the case of poli-iodides {I(4)–I(3) = 2.9142(17) Å; the position of I(4)″ is obtained from I(4) through the symmetry transformation (″) = 1 − *x*, *y*, 0.5 − *z*}; the two bonds are virtually linear, with an angle of 177.28(11)° (see Table 2).

Also in the compound **4** secondary interactions produce a one-dimensional arrangement of the lattice, as shown in Fig. 5. The chain increases in a zigzag configuration along the direction which forms an angle of nearly 45° with the *a* axis. The molecules of the

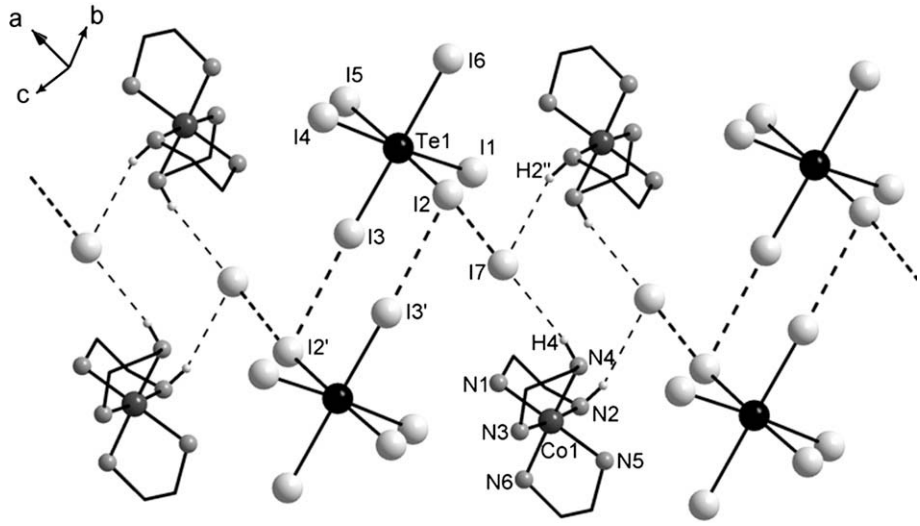

Fig. 2. Molecular/ionic structure and one-dimensional assembly of $[TeI_6][Co(en)_3] \cdot I^-$ (**2**). Secondary interactions are represented by dashed lines. Symmetry transformations used to generate equivalent atoms: (′) = −*x*, −*y*, 1 − *z*; (″) = −−1−*x*, −*y*, 1 − *z*.

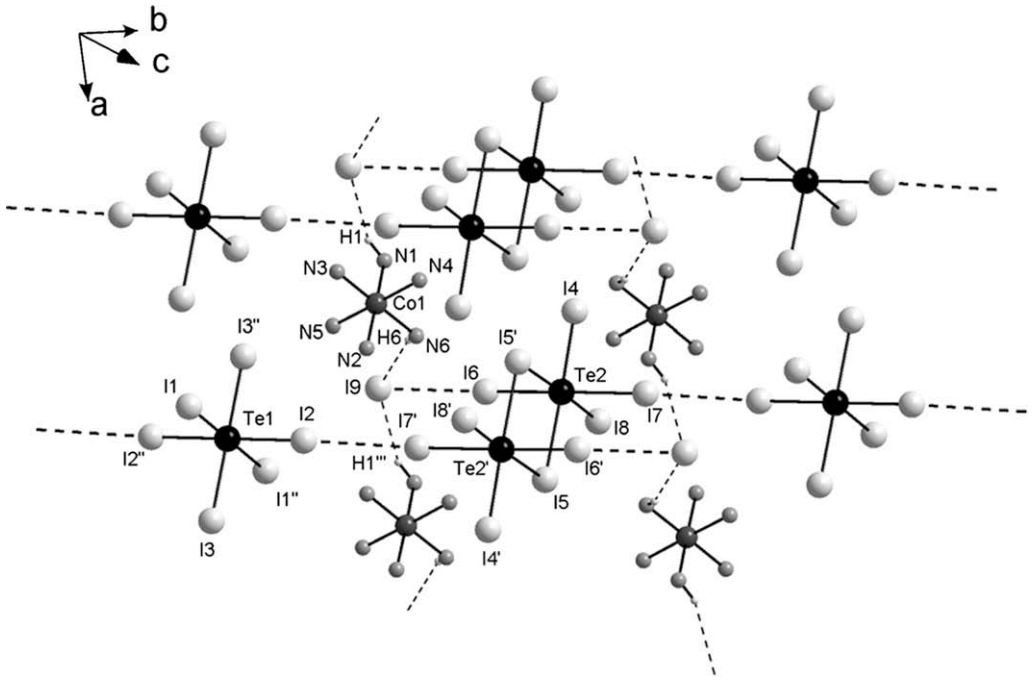

Fig. 3. The two-dimensional assembly of the species in $[\{TeI_6\}\{Te_2I_{10}\}][Co(NH_3)_6]_2 \cdot 2I^- \cdot 6H_2O$ (**3**). For clarity the water molecules are not displayed. The dashed lines represent secondary interactions. Symmetry transformations used to generate equivalent atoms: (′) = 1 − *x*, 2 − *y*, 1 − *z*; (″) = −*x*, 1 − *y*, −*z*; (‴) = 1 + *x*, *y*, *z*.

solvate $CHCl_3$ attain symmetrical, secondary interactions with I_3^- {Cl(3)‴···I(4), 3.862(8) Å} and with the single $(mesTeI_2)^-$ units {Cl(1)‴···I(2)⁗, 3.855(11) Å}, these last also connected through I_2 bridges. Each chain is delimited by two series of linear standing $[Co(bpy)_3]^{3+}$ ions, which do not interact ostensibly with any species.

2.2. Synthetic considerations

The syntheses of **1, 2**, **3** and **4** were carried out with basis on the formation of the intermediary {**mesTeI**} (see Section 3) and its further reactions and rearrangements.

The obtained products allow the conclusion that in the three first reactions (synthesis of **1**, **2** and **3**) has occurred partial decomposition of the intermediary mesTeI in the water/chloroform interface, due to the high difference of polarity. The action of the water dipoles probably has lead to the cleavage of C−Te bonds, what should explain the formation and crystallization, in the $H_2O/CHCl_3$ interface, of products without mesityl rings. Rearrangement reactions of mesityl rings and chemically altered mesTeI should also explain the crystallization, in the organic phase (for all the three first procedures), of the already known compound {mesTeI···I(mes)Te−Te(mes)$_2$} [19]. The preparation of **4** differs only in the addition of 5 mL of THF to the aqueous solution, together with iodine, in the second step of the synthesis. Since 5 mL of THF is the halve of the amount of water (10 mL) in the system, and THF and water are miscible in good extent, the addition of THF has reduced the polarity of the milieu, attenuating also the

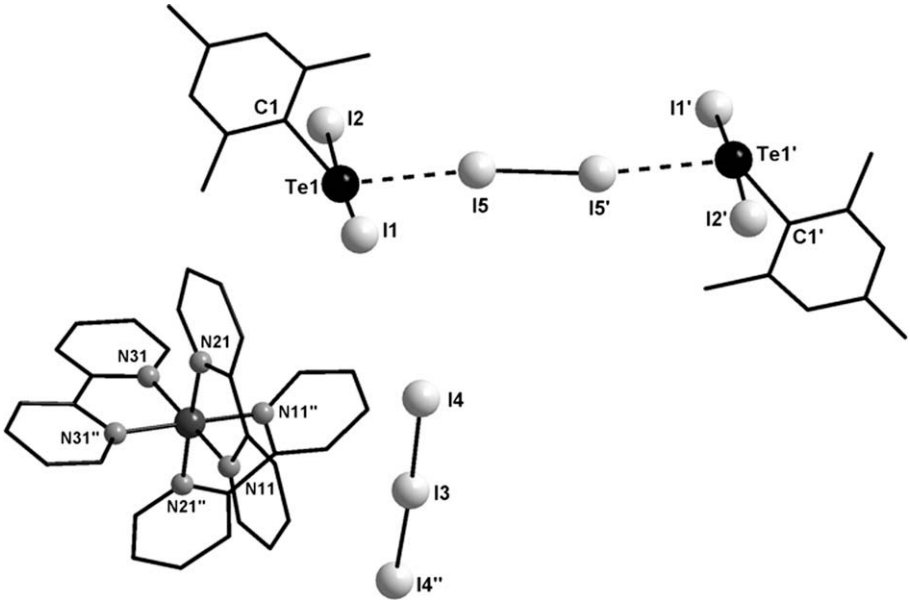

Fig. 4. Structural composition of $[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3] \cdot I_3^- \cdot 2CHCl_3$ (**4**), not including the chloroform solvate molecules. The dashed lines represent the iodine bridge. Symmetry transformations used to generate equivalent atoms: (′) = −*x*, 1−*y*, −*z*; (″) = 1 − *x*, *y*, 0.5 − *z*.

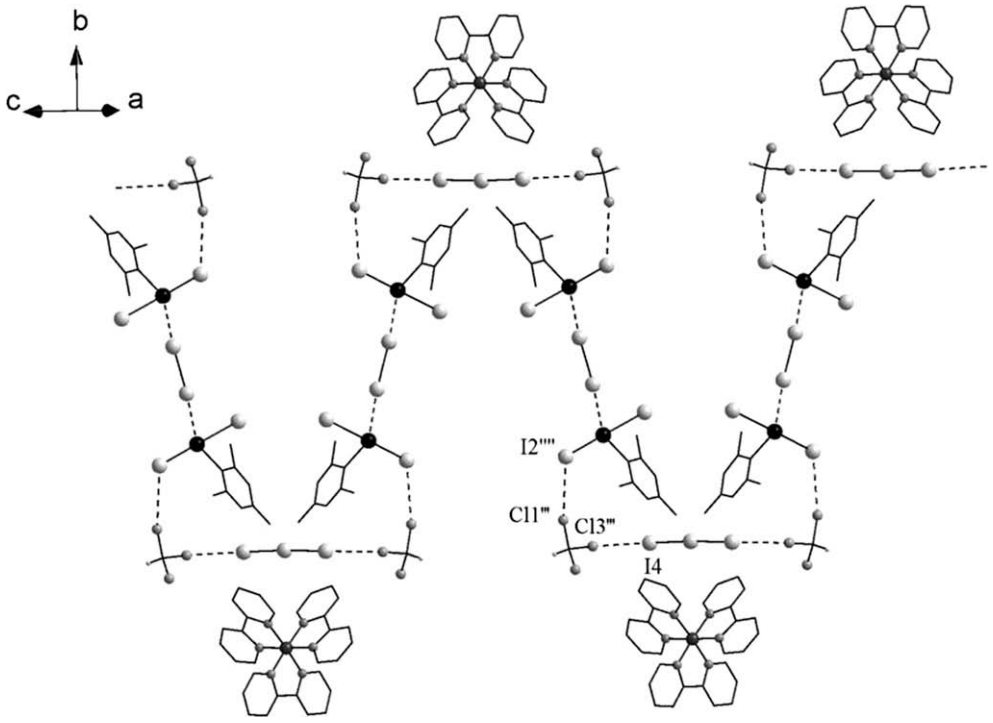

Fig. 5. Zigzag chain of **4**, delimited by the $[Co(bpy)_3]^{3+}$ ions, involving secondary interactions of the solvate molecules/ions and iodine bridges, in dashed lines. Symmetry transformations used to generate equivalent atoms: (‴) −*x*, *y*, 0.5 − *z*; (⁗) = 0.5 − *x*, 0.5 + *y*, 0.5 − *z*.

decomposition power of the water. This allowed the formation of compound **4** in the (mild) interface of the system and its resettlement to the organic phase, where the crystallization has occurred. From these considerations can be easily inferred that the solubility of these compounds is a strongly limiting factor for the availability of structural analytical methods. For example, the possibility of use of ^{125}Te NMR spectroscopy is remarkable reduced.

Finally, the title compounds here discussed represent also examples of supramolecular compounds. This is typical for a large amount of organotellurium halides, in which multiple secondary interactions are able to build chemical nets whose interpretation can be sometimes troublesome to puzzle out.

3. Experimental

3.1. Synthesis of $[TeI_4][Co(en)_3] \cdot I^-$ (**1**) and $[TeI_6][Co(en)_3] \cdot I^-$ (**2**)

To a solution of $(MesTe)_2$ (0.148 g, 0.3 mmol) in 5 mL $CHCl_3$, resublimed I_2 (0.077 g, 0.3 mmol) was added. The solution was

stirred by 30 min and the color turned blue, making evident the formation of the intermediary {mesTeI}. Over this solution 10 mL of an *aqueous* solution of $[Co(en)_3]I_3$ (0.125 g, 0.2 mmol) plus I_2 (0.052 g, 0.2 mmol) was added, remaining a biphasic system. After a few days, in the interface of the system arose the crystallization of two distinct crystalline products, **1** and **2**. In the organic phase occurs the crystallization of the adduct {(mes)2Te–TeI(mes)}-(mesTeI) [19]. Yield: 25% (**1**), 65% (**2**) based on $[Co(en)_3]I_3$.

$[TeI_4][Co(en)_3]\cdot I^-$ (**1**): red crystalline substance. $C_6H_{24}N_6CoI_5Te$ (1001.34). Melting point: 159.5–160.8 °C. *Anal.* Calc.: C, 7.20; H, 2.42; N, 8.39. Found: C, 7.24; H, 2.38; N, 8.43%.

IR (KBr): 3016.4 [ν(N–H)], 2917.2 [ν(C–H)], 1591.3 [δ(C–N–H)], 1438.8 [δ(C–C–H)], 849.8 cm^{-1} [$\delta_{out\,pl.}(NH_2)$].

$[TeI_6][Co(en)_3]\cdot I^-$ (**2**): black crystals. $C_6H_{24}N_6CoI_7Te$ (1255.14). Melting point: 105.5–106.2 °C. *Anal.* Calc.: C, 5.74; H, 1.93; N, 6.70. Found: C, 5.69; H, 1.96; N, 6.76%.

IR (KBr): 3014.2 [ν(N–H)], 2915.5 [ν(C–H)], 1592.5 [δ(C–N–H)], 1433.4 [δ(C–C–H)], 851.7 cm^{-1} [$\delta_{out\,pl.}$ (NH_2)].

3.2. Synthesis of $[\{TeI_6\}\{Te_2I_{10}\}][Co(NH_3)_6]_2\cdot 2I^-\cdot 6H_2O$ (**3**) and $[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3]\cdot I_3^-\cdot 2CHCl_3$ (**4**)

According to the former synthesis (**1** and **2**), under addition of $[Co(NH_3)_6]I_3$ (0.108 g, 0.2 mmol) (**3**), and $[Co(bpy)_3]I_3$ (0.181 g, 0.2 mmol) (**4**), in lieu of $[Co(en)_3]I_3$. In the preparation of **4** the second addition of iodine (to the aqueous solution) was preceded by its (I_2) dissolution in 5 mL of THF. The single product **3** crystallizes also in the interface of the biphasic system, while the crystallization of **4** occurs in the organic phase. In the case of **3**, crystalline {$(mes)_2$Te–TeI(mes)}(mesTeI) [19] was identified in the organic phase as well. Yield: 80% based on $[Co(NH_3)_6]I_3$ (**3**), 82% based on $[Co(bpy)_3]I_3$ (**4**).

$[\{½TeI_6\}\{½Te_2I_{10}\}][Co(NH_3)_6]\cdot I^-\cdot 3H_2O$ (**3**): black crystalline substance. $H_{24}N_6O_3CoI_9Te_{1.50}$ (1548.68). Melting point: 168.5–169.9 °C. *Anal.* Calc.: H, 1.55; N, 5.52; O, 3.17. Found: H, 1.51; N, 5.48; O, 3.14%.

IR (KBr): 3449.4 [ν(O–H)], 3147.7 [ν(N–H)], 1324.1 [$\delta(NH_2)$], 818.7 cm^{-1} [$\delta_{out\,pl.}(NH_2)$].

$[(mesTeI_2)_2(\mu\text{-}I_2)][Co(bpy)_3]\cdot I_3^-\cdot 2CHCl_3$ (**4**): dark red crystals. $C_{50}H_{48}N_6Cl_6CoI_9Te_2$ (2401.87). Melting point: 104.1–105.2 °C. *Anal.* Calc.: C, 25.00; H, 2.01; N, 3.50. Found: C, 25.04; H, 2.05; N, 3.56%.

IR (KBr): 3074.0 [$\nu(C–H)_{Ar.}$], 2958.4 [$\nu(C–H)CH_3$], 1601.0 [ν(C=C)], 1562.8 [ν(C=N)], 1445.1 [δ(C=C–H)], 758.4 cm^{-1} [$\delta_{out\,pl.}(NH)_2$].

3.3. X-ray structure determinations

Data were collected with a Bruker APEX II CCD area-detector diffractometer and graphite-monochromatized Mo Kα radiation. The structures were solved by direct methods using SHELXS [22]. Subsequent Fourier-difference map analyses yielded the positions of the non-hydrogen atoms. Refinements were carried out with the SHELXL package [22]. All refinements were made by full-matrix least-squares on F^2 with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were included in the refinement in calculated positions. Crystal data and more details of the data collections and refinements are contained in Table 1.

ABSTRACT

Reaction of the hexadentate N_4O_2-donor ligand 6,6′-bis(3-hydrazonobutan-2-one)-2,2′-bipyridine (**L**) with $Ag^{(I)}$ and $Zn^{(II)}$ affords a dinuclear double stranded helicate species $[Ag_2\mathbf{L}_2]^{2+}$ (**1a**) and $[Zn_2\mathbf{L}_2]^{2+}$ (**1b**), in which partitioning of the ligand into two bis-tridentate pyridyl-ketoimine chelating units allow each ligand to bridge both metal centres. X-ray crystallography, ESI-MS and UV–Vis spectrophotometric titration experiments reveal that the complex (**1a**) retains its solid-state structure in solution. The crystal structure of (**1a**) provides the first example of dinuclear silver(I) complex in which both of the metal centres can be approximated as a seven coordinate distorted mono-capped trigonal prism in which the Ag···Ag close contact of 3.034(4) Å is taken into account and forms the cap. The counter-ions do not interact with metal centres but hydrogen bond to N–H protons of the hydrazonic arms from the separate strands. The adjacent helical units are cross-linked together via NH···O_{keto} hydrogen bonding to maintain the supramolecular structure.

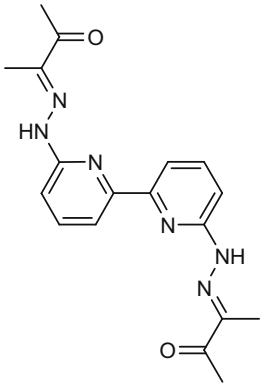
1. Introduction

Helical metal complexes [1–8] occupy a privileged position in metallosupramolecular chemistry. The basic principles of the formation of polynuclear helicates with a wide variety of metals and ligands have been well established. The development of new polydentate ligands which give optimized supermolecules upon complexation to two or more metal ions is thus a theme of considerable interest in supramolecular chemistry [9,10]. Particular interest has been shown in double-helical structures which may be generated by complexation of two ligands twisted around metal ions lying on the helical axis [11–14].



Oligo-bipyridine ligands containing 6,6′-disubstituted-bipyridyl (bpy) units, bridged by suitable spacers, and coordinated to a metal ion show a preference for tetrahedral geometry (such as Cu(I) or Ag(I)) to form double-stranded helicates [4–6,15–18]. However, in self-assembled polymeric Ag(I) complexes, the full diversity in coordination geometries exhibited by silver(I) is commonly observed. It has been shown that Ag(I) can adopt a range of coordination numbers between two and six, and exhibit coordination geometries from linear through trigonal to tetrahedral, square-planar, trigonal pyramidal and octahedral, and also very rarely in the case of coordination chemistry (there are numerous high coordination number Ag complexes known in cluster chemistry – some 150 in the Cambridge Crystallographic Database) seven- and eight-coordinate complexes [19–22]. On the other hand, a metal ion which has no fixed preference such as Zn(II) gives a triple helix at high ligand:metal ratios and a double helix at lower ratios [23]. There are some structurally characterised dizinc helical complexes described in the literature [24–31], but only two helicates (one triple and one double-stranded) contain Schiff bases. NMR spectroscopic studies have shown that Schiff bases with flexible spacers (e.g., 2,9-bis[(6-methyl-2,2′-bipyridin-6′-yl)methyleneoxymethylen-yl]-1,10-phenanthroline) can generate double-stranded zinc(II) helicates [8].

A considerable body of research now exists and has been reviewed in detail by Piguet et al. [4] and others [2,3]. Many such systems were reported by Lehn and his collaborators [32,33], who synthesized a series of oligo-bipyridyl ligands which form double-helicates containing as many as five Cu(I) ions, and by Dietrich-Bucheker and Sauvage [34,35] who used the double-helical complexes formed by Cu(I) with two oligo-phenanthroline ligands as precursor for the synthesis of the first molecular knot. In these systems, the coordinating possibilities of the ligand should match the stereochemical preferences of the metal ion. Thus, the reaction of the two binucleating ligands with cations favouring tetrahedral coordination can lead to a double-helical structure [10,23].

For oligobipyridine ligands, several spacers have been used to connect 2,2′-bipyridine or 1,10-phenanthroline units [1,4,6,36]. The binding of the linker is crucial in determining the nature of the resulting coordination. The linker must be short enough so that tetrahedral binding does not occur with one bpy unit of the same strand, yet sufficiently flexible that inter-strand coordination can occur without undue strain [6]. The formation of helicates is not only controlled by the coordination geometry of the metal ions and the flexibility of the spacer groups, but also by the linkage mode of the spacer units [37]. Following these criteria, a novel dinucleating ligand, 6,6′-bis(3-hydrazonobutan-2-one)-2,2′-bipyridine (**L**) presenting two N_2O-donor sites was designed and synthesized (*vide infra*).

The well-established coordination ability of the bpy ligand [38–40] suggests that the bulky substituents at the 6,6′-positions repel each other and prevent the ligand adopting a planar conformation to facilitate the self-assembly of mono-, double-, or triple-stranded helicates containing one or more transition metal cations with a variety of coordination geometries [5]. In such systems the metal centres will be organized in a well-defined array.

Early interest in the coordination chemistry of acylhydrazones led to the synthesis and structural characterization of a number of metal complexes of 2,6-diacetylpyridine aroylhydrazones (aroyl = benzoyl, picolinoyl, salicyloyl and thenoyl) [41–48]. These ligands were shown to be able to assume different conformations due to flexibility, and form mono-and bi-nuclear metal complexes.

A point of significant interest relating to the self-assembly of polynuclear complexes is to ascertain whether the double-helical structure found in the solid state is maintained in solution [3,5,7,49–51]. Thus, by means of classical spectrophotometric titrations and electrospray mass spectrometric (ESI-MS) measurements, we have investigated the nature of the species that **L** forms with $Ag^{(I)}$ and $Zn^{(II)}$. From these measurements stability constants and absorption spectra were used to gain insight into the distribution of the different species at a given [*M*]/[*L*] ratio and into the physicochemical features of their self-assembly process. A similar behaviour has been observed for both metal ions. Solution studies and X-ray analysis proved that the present ligand is a good helicant for Ag(I) and Zn(II) ions. Since, the keto oxygen atoms seem weakly interact with the metal centres, the double-helical structures may conveniently be transformed into molecular knots by condensation with simple diamine ligands. This will be addressed as an extension of the present study in future work. The zinc complex did not provide a suitable crystal for diffraction studies, but solution studies by ESI-MS and UV–Vis spectroscopy data show $[Zn_2\mathbf{L}_2]^{2+}$ that the idealized dinuclear double-stranded helical structure is maintained in solution.

2. Results and discussion

2.1. Synthesis of the ligand (*L*)

The bis(3-hydrazonobutan-2-one)-2,2′-bipyridine ligand was synthesized in high yield by condensation of 6,6′-dihydrazine-2,2′-bipyridine [52,53] with excess of butandione in dry thf in the presence of catalytic amount of glacial acetic acid under dry nitrogen atmosphere over molecular sieves. It is quite soluble in common organic solvents and acidic aqueous solutions. The ESI-MS of the free ligand in acetonitrile displays the expected singly charged species $[\mathbf{L}+H]^+$ and $[2L + CH_3CN + H_2O]^+$ adducts at *m*/*z* 353.4 and 763.3, respectively, (Fig. S1). The ^1H NMR spectrum measured in DMSO-d_6 confirmed the chemical structure as having C_2-symmetry (Fig. S2). In the aromatic region of the spectrum the NH proton appears as a singlet at 11.6 ppm, and the three distinguished bipyridinyl protons in the expected range (8.23–7.52 ppm), and two singlets in the aliphatic region at 2.5 and 2.3 ppm attributed to the methyl protons having different chemical environments due to having different electronegative atoms (N and O), adjacent to them.

2.2. Syntheses of the metal complexes

The metal complexes were prepared in similar manner with high yield: to a solution of **L** in dichloromethane was added equimolar AgOTf or $Zn(OTf)_2$ in MeCN at 40 °C with vigorous stirring under inert atmosphere for 12 h over molecular sieves (0.4 nm). The solutions were concentrated under vacuum and filtered from *Celite* into the test tubes and allowed to stand for crystallisation at r.t. The single crystals of **1a** were obtained by slow ether diffusion into the concentrated MeCN–CH_2Cl_2 solution in a well-isolated system at room temperature. These cationic d^{10} metal complexes are stable in the solid state and in solution, and are soluble in polar organic solvents such as DMF, DMSO, MeCN and MeOH. The physicochemical characterization proved that the hydrazonic ligand forms dinuclear complexes with AgOTf and $Zn(OTf)_2$, which well agrees with the general formulae $[M_2\mathbf{L}_2]^{2+}$.

2.3. Qualitative ESI-MS and spectrophotometric titration studies

The ESI-MS spectrum of the crystals of $[Ag_2\mathbf{L}_2][OTf]_2$ (**1a**) dissolved in MeCN revealed a peak at *m*/*z* 1068 which corresponds to the cationic fragment $[Ag_2\mathbf{L}_2(OTf)]^+$. The simulated isotopic pattern is in good agreement with the measured spectrum (Fig. S3). The isotopic pattern was also used for the characterization of the self-assembled dinuclear double-helical complexes in MeCN which represent typical cases for supramolecular complexes where the monomer $[M\mathbf{L}]^+$ and the dimer $[M_2\mathbf{L}_2]^{2+}$ display the same *m*/*z* ratio [54]. So, the elegant choice of alternative is to use of the isotopic pattern obtained by increasing resolution. The observation of singly charged peaks at *m*/*z* = 460 and 813 may be attributed to $[Ag\mathbf{L}]^+$ and $[Ag\mathbf{L}_2]^+$ species in solution. However, the formation of $[Ag_2\mathbf{L}_2]^{2+}$ can also not be excluded, since the resolution of the mass spectra is not good enough to discriminate between these two species with our experimental setup.

It is worthnoting that $[Ag_2\mathbf{L}_2]^{2+}$ displays a helical double-stranded structure in solution similar to that found for its Zn(II) analogue (*vide infra*). Such process was studied by UV–Vis spectrophotometric titration of **L** with AgOTf in MeCN (Fig. S4). Analysis of the titration data, using the SPECFIT/32 Global Analysis System [55–58] which performs a nonlinear best fit of the spectrophotometric data should provide the thermodynamic parameters for double-helicate formation. This programme calculates the binding constants β_{ml} for each M_mL_l species of a proposed chemical model by iterative comparison of calculated with experimental

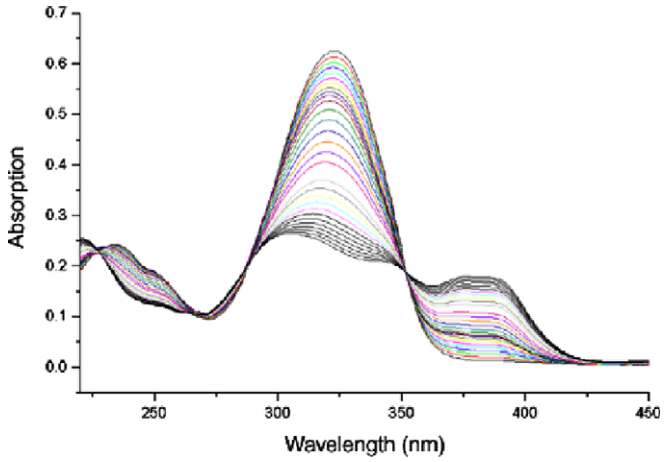

Fig. 1. Variation of the absorption spectra observed during the spectrophotometric titration of **L** with varying concentration of $Zn(OTf)_2$ in MeCN.

absorbance values, searching for the global minimum of the error function. The spectroscopic data can be satisfactorily fitted with the following equilibria (1)–(3), described by three stability constants β_{ml}.

$$Ag^+ + \mathbf{L} \rightleftharpoons [AgL]^+ \quad \log\beta_{11} = 3.5(1) \tag{1}$$

$$Ag^+ + 2\mathbf{L} \rightleftharpoons [Ag\mathbf{L}_2]^+ \quad \log\beta_{12} = 15(3) \tag{2}$$

$$2Ag^+ + 2\mathbf{L} \rightleftharpoons [Ag_2\mathbf{L}_2]^{2+} \quad \log\beta_{22} = 21(3) \tag{3}$$

These data allow the computation of the distribution diagram for the M_mL_l species and provide the basis for investigating the process of the formation of the $[Ag_2\mathbf{L}_2]^{2+}$ helicate **1a** (Fig. S5). The overall stability constant, β_{ml} values, towards silver(I) for the helicate compares quite well with the similar processes available in the literature [32]. The present equilibrium intermediates compare well to those observed in the ESI-MS spectrum. The helicate is also the stable form in the solid, as confirmed by X-ray analysis.

The ESI-MS spectrum of the zinc(II) complex (**1b**) measured in MeCN-CH_2Cl_2 solution (Fig. S6), shows peaks at $m/z = 208.2$, 415.2, 564.9 and 1283.5, which may be attributed to species $[Zn\mathbf{L}]^{2+}$, $[Zn\mathbf{L}_2]^{2+}$ adducts of MeCN and H_2O, singly charged $[Zn\mathbf{L}(OTf)]^+$ or doubly charged $[Zn_2\mathbf{L}_2(OTf)_2]^{2+}$, and finally the singly charged dimer $[Zn_2\mathbf{L}_2(OTf)_3]^+$. However, the peaks at 415.2 and 1146.7 demonstrate the additional coordination of keto oxygen atoms to form a pseudo-octahedral geometry at the $Zn^{(II)}$ centres, where the ligands are coordinated in the monoanionic form to reduce the overall positive charge on the complex ions. This occurs due to deprotonation after enolization as usually observed for similar kind of ligands possessing N_3O_2 [13] and N_2O or N_4O coordination modes [59–62]. It has been suggested that the effect of charge on the cation is important in the hydrolysis process of carbonyl ligands coordinated to metal centres, where the electron withdrawing effect of the metal ion will increase the polarisation of the carbonyl bond upon coordination [63,64]. Thus, the $Zn^{(II)}$ cations have an octahedral N_4O_2 coordination sphere assembled by using the two N_2O-donor set of **L** in the monoanionic form.

The formation of **1b** was followed by the spectrophotometric titration of **L** with $Zn(OTf)_2$ (Fig. 1). The data which allow the computation of the distribution diagram (Fig. 2) for the M_mL_l species indicate that upon increasing the metal ion concentration the dinuclear species becomes the major product in the final solution, as revealed by the qualitative ESI-MS studies. The calculated binding constants for the M_mL_l species can be satisfactorily fitted with the following equilibria (4)–(6):

$$Zn^{2+} + \mathbf{L} \rightleftharpoons [Zn\mathbf{L}]^{2+} \quad \log\beta_{11} = 1.6(1) \tag{4}$$

$$Zn^{2+} + 2\mathbf{L} \rightleftharpoons [Zn\mathbf{L}_2]^{2+} \quad log\beta_{12} = 13.9(1) \tag{5}$$

$$2Zn^{2+} + 2\mathbf{L} \rightleftharpoons [Zn_2\mathbf{L}_2]^{2+} \quad \log\beta_{22} = 19.5(2) \tag{6}$$

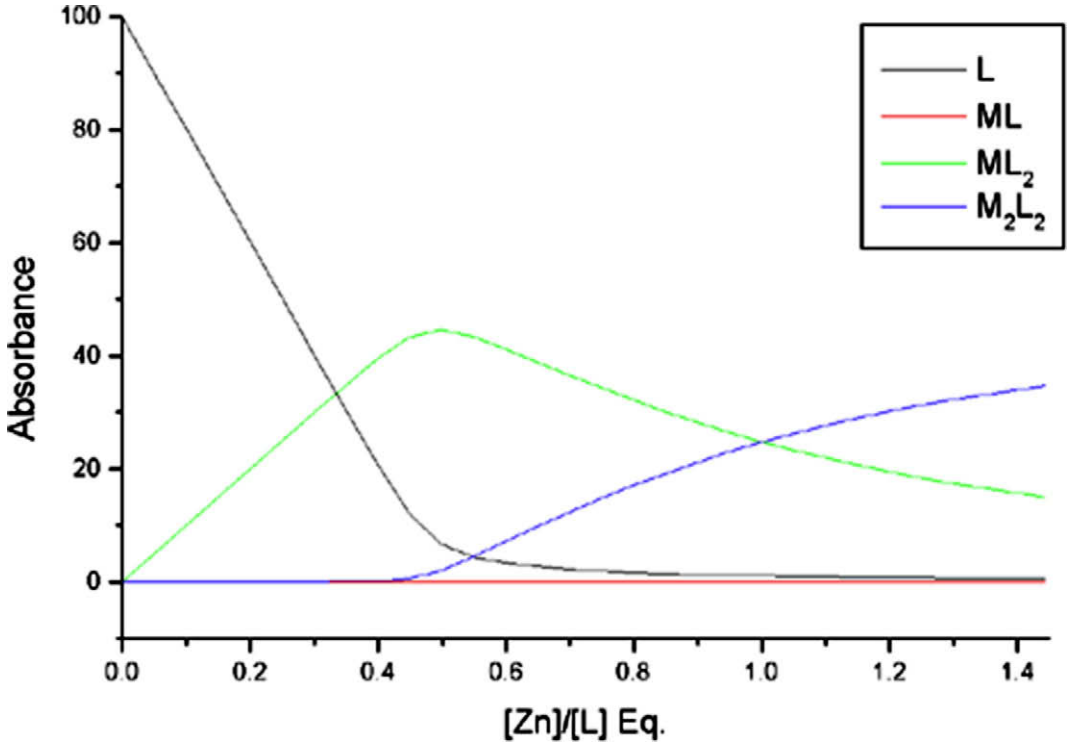

Fig. 2. Distribution curves predicted for the complexation of Zn(II) by **L**.

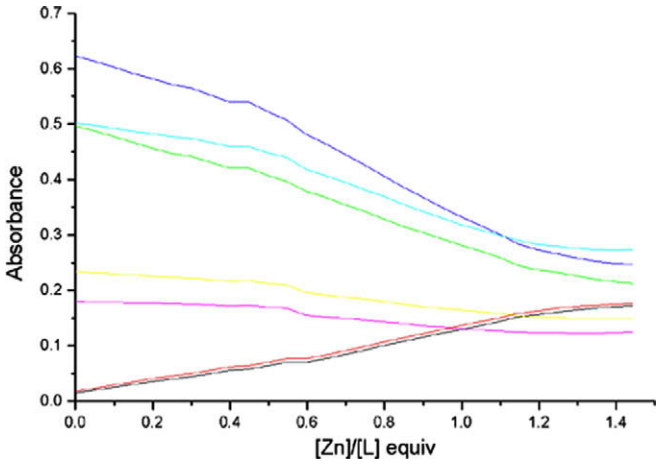

Fig. 3. EA plot, variation of observed absorbance during spectrophotometric titration of **L** with $Zn(OTf)_2$ in MeCN.

These data allow the computation of the distribution diagram for the M_mL_l species and provide the basis for investigating the process of the formation of the $[Zn_2\mathbf{L}_2]^{2+}$ helicate **1b**. The present equilibrium intermediates parallel to those observed in the ESI-MS spectrum. Furthermore, the excess absorbance diagrams (EA) [32] for several wavelengths shown in Fig. 3 confirms the existence of only two absorbing species, the ratio between which is less than 1.2. These features indicate the generation of the double-helical structure of **1b** [5].

2.4. X-ray crystal structure of *1a*

The double-helical structure of **1a** is depicted in Fig. 4. The crystal structure of **1a** shows the double helical cation $[Ag_2\mathbf{L}_2]^{2+}$, and two uncoordinated triflate anions (Fig. S7). Both these anions exhibit disorder; in one there is an overlay of a second fractionally occupied molecule over the original such that CF_3 moiety nearly overlaps with a SO_3 group; in the second there is a rotation about a 2-fold axis which generates two orientations where the C–S bonds cross each other with an angle of about 15°, which results in two O atoms in the SO_3 group overlapping directly with a symmetry generated pair and in the third case with a F atom, whilst the remaining F atoms in the CF_3 group nearly overlap with their symmetry related counterparts. As a result the triflate atoms exhibit high atomic displacement parameters and have been constrained to an idealised geometry.

In the dinuclear cation $[Ag_2\mathbf{L}_2]^{2+}$, the ligands act as neutral bis(terdentate) units bound to the silver atoms and wrap around a helical axis. This leads to a double-helical structure with a pseudo-C_2 axis defined by the Ag(I) atoms which are separated by 3.034(4) Å. It is noteworthy that this Ag···Ag separation is significantly shorter than the sum of the van der Waals radii of two silver atoms (3.44 Å) [65,66], indicating the presence of ligand supported Ag···Ag interactions which are often observed in $Ag^{(I)}$ complexes

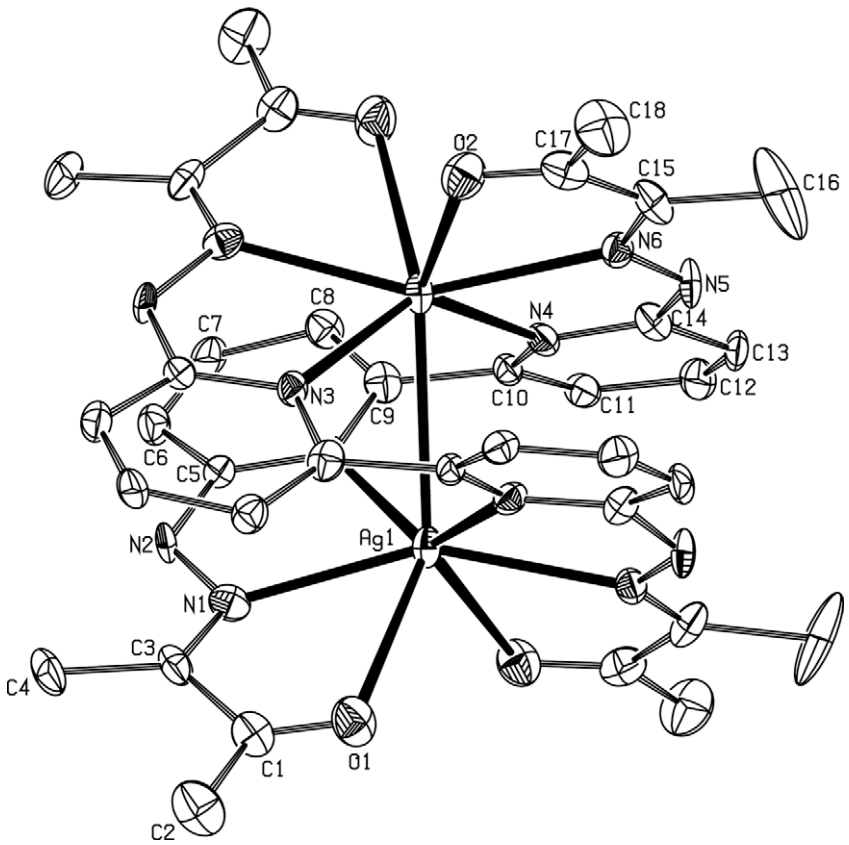

Fig. 4. ORTEP view of $[Ag_2L_2][OTf]_2$ (**1a**). Triflate ions and hydrogens have been omitted for clarity. Selected bond lengths (Å) and angles (°): Ag1–N3 2.389(1); Ag1–$N4^i$ 2.389(2); Ag1–N1 2.428(2); Ag1–N6 2.437(2); Ag1–O1 2.720(2); Ag1–O 2 2.722(2); Ag1–$Ag1^i$ 3.034(4); N3–Ag1–$N4^i$ 138.26(7); N3–Ag1–N1 67.88(5); $N4^i$–Ag1–N1 120.80(5); N3–Ag1–N6 124.43(5); $N4^i$–Ag1–N6 68.319(6); N1–Ag1–N6 153.14(7); $N4^i$–Ag1–O1 79.01(7); N3–Ag1–O1 129.01(7); N1–Ag1–O1 61.52(7); N6–Ag1–O1 98.99(7); N1–Ag1–O2 101.27(7); N3–Ag1–O2 80.31(7); N6–Ag1–O2 62.20(7); O1–Ag1–O2 100.94(7); N3–Ag1–$Ag1^i$ 70.48(5); $N4^i$–Ag1–$Ag1^i$ 67.84(5); N1–Ag1–$Ag1^i$ 104.29(5); N6–Ag1–$Ag1^i$ 102.47(5); O1–Ag1–$Ag1^i$ 129.59(5). Symmetry code for generated atoms with label = $-x+1, y, -z+1/2$.

[67–72]. The double helix nature of the complex gives rise to two ligands binding in an antiparallel fashion, with the angle between the mean planes of the two ligand strands (i.e., between the two moieties coordinated through N4, N6, O2 and the other two moieties coordinated through N1, N3, O1) averaging to approximately 13.3(2)° and separated by 3.55(3) Å. This suggests a significant π–π stacking interaction between the py ring from one ligand and the hydrazonic unit from the other (Fig. 5a). This is typical of π–π stacking interactions which along with hydrogen bonding and argentophilic interactions control the formation of the secondary double strand structure [73]. Despite OTf^- disorder in the lattice, the crystal structure provides no evidence of interaction between the $Ag^{(I)}$ centre and the remote OTf^- counter-ion. However, the triflate ions hold two strands in close proximity by intermolecular N–H···O, C–H···O and C–H···F weak interactions (Fig. S8). Further, the two hydrazonic NH groups of each strand also interact with the keto oxygen atoms of the adjacent helical cations to give rise to its supramolecular structure.

The ligand is a symmetrically substituted bpy incorporating two ketoiminohydrazone units at 6,6′-positions. These arms contain two donor atoms: one imine *N* atom and one keto oxygen atom. Although, Datta and his co-authors [74,75] have speculated that 'the keto oxygen atoms do not bind $Ag^{(I)}$ even in the solid' and the Cambridge Structural Database (January 2008)[1] contains no structures based on the AgN_4O_2 chromophore with an $Ag^{(I)}$–keto oxygen bond. There are also a very limited number of examples of structurally characterized $Ag^{(I)}$ complexes with aliphatic and aromatic ketones [64,76,77], di-2-pyridyl ketone [63] or 4-acyl-5-pyrazolone [78]. The carbonyl form is favoured in the $Ag^{(I)}$ complexes whereas in the $Zn^{(II)}$ complexes polarization of carbonyl bond is affected by the electron-withdrawing nature of the doubly charged ion [63].

It is clear from the X-ray structural analysis that the two ligand strands adopt a head-to-tail configuration. The twisting of the ligand strand (essential for helicate formation) takes place primarily about the central bond between the pyridine rings (dihedral angle = 52.5(2)°), and the planarity of the hydrazonic arms is significantly constrained by the Ag–O1 and the Ag–O2 interactions. The maximum deviation from the mean plane O1–C1–C3–N1–N2–C5 is 0.027 Å (for atom N2), and O2–C15–N6–N5–C14 is 0.062 Å (for atom C16). The former plane makes an angle of 9.81(9)° with the py ring C5–C9–N3, and the latter one an angle of 9.54(9)° with C10–C14–N4 py ring. The structure shows that the assembly of the helicate adopts an arrangement in which the steric hindrance is minimised. In this structure the bonds to the imino nitrogens (2.428(2), 2.437(2) Å) are significantly longer than those to the pyridyl nitrogens (2.392(2), 2.389(2) Å). The $Ag^{(I)}$–O_{keto} distances 2.720(2) and 2.722(2) Å are significantly greater than the sum of ionic radii (2.66 Å) [64] suggesting a weak bonding interactions between the $Ag^{(I)}$ and keto oxygen atoms O(1) and O(2). If these bonds are included [20–22], the $Ag^{(I)}$ centres could be considered to have a distorted mono-capped trigonal prismatic geometry as shown in Fig. 5b. Thus, the ligands which form four five-membered chelate rings around each metal atom resemble the complexes of bis[6,6′-(*N*-2″-pyridylmethylidenehydrazino)][2,2′-bipyridine] N_6-donor ligand [79,80] with a range of transition metal cations. A similarity may also be drawn with a polymeric silver(I) complex [81] in which one $Ag^{(I)}$ centre is in a distorted octahedral geometry coordinating to one thio-ether sulphur atom and one quinoline nitrogen atom of the ligand, and four oxygen atoms of three nitrate groups with two in monodentate and one in a bidentate coordination forms. However, the presence of a ligand supported argentophilic interaction in **1a** implies a weak binding and leads to the coordination geometry around Ag(I) best being described as a distorted mono-capped trigonal prism. As shown in Fig. 5b, the cap is formed through coordination to another silver centre (angles to N3, N4 and N6 = 70.48(5)°, 67.84(5)° and 102.47(5)°, respectively) and the prism is composed of the pyramidal coordination of N1, N3, O2 (angles about Ag of 67.88(5)°, 101.27(7)° and 80.31(7)°) and N4, N6, O1 (angles about Ag of 68.32(6)°, 98.99(7)° and 79.01(7)°, respectively).

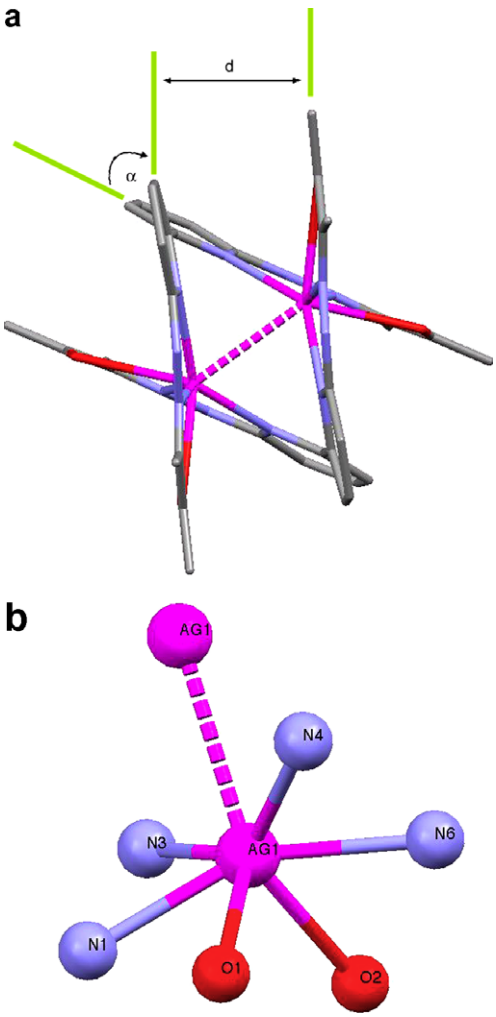

Fig. 5. (a) The Ag···Ag separation of 3.034(4) Å, the dihedral angles [α = 52.5(2)°] between the py rings and the aromatic π–π stacking interactions between the py rings [*d* = 3.5(3) Å]. (b) Depicting the spatial arrangements of the octahedral environment around the each silver(I) centre.

As the compound crystallises in a centrosymmetric space group, the crystal contains both left and right-handed helical cations. The helical structure is reminiscent of those reported by Schröder [79,80] and Wang [67,68]. A recent survey by Ziessel [5] proposed that the presence of two additional donor atoms in the vicinity of the central bipyridine frame will cause the conventional chelating coordination mode of the bipyridine to be that of a non-conventional character, where the ligand bridges two metal centres. The crystallographic structures of the helicates of imino-bipyridine ligands with Cu(I) cation clearly indicate that incorporation of imine groups at the α,α′-positions of a bpy causes the central unit to become non-chelating and, to adopt a bridging role. In those reported complexes, the bpy units was found to be twisted by 33° about the exocyclic central C–C bond, and in contradiction to the

[1] CSD version 5.29 (November 2007) has no hits for N_4O_2Ag–AgN_4O_2 motif with Ag–O_{keto} bond, but contains 18 hits for N_2O_2Ag–AgN_2O_2 motif (only two cases contain Ag–O_{keto} bonds derived from hexafluoropentane-2,4-dione and 2-pyridyl-3-methyl-4-trifluoroacetylpyrazol-5-one), and also shows 16 hits for the N_4Ag–AgN_4 query.

case presented here, the copper(I) centre was shown to be significantly closer to the imino *N* atom than to the adjacent pyridine unit. The unprecedented helicate **1a** is the first example to reveal the ability of the hexadentate ligand presenting two N_2O coordination sites to act selectively as a bridging ligand with d^{10} metal ions such as Ag(I) and Zn(II) ions.

3. Experimental

3.1. General

All commercially available chemicals were of reagent grade and used without further purification, unless otherwise stated. Tetrahydrofuran and diethyl ether were distilled from sodium benzophenone ketyl immediately prior to use. Dichloromethane was distilled over calcium hydride. Methanol and ethanol were of HPLC grade. Melting points were recorded on a Bushi Melting Points B-540 apparatus. The CHN microanalyses were performed with a Heraeus Rapid CHNO elemental analyzer. The electrospray ionisation mass spectral (ESI-MS) measurements were carried out on a LCQ (Finnegan MAT, USA) using MeCN as the mobile phase. The samples for ESI-MS measurements were prepared by redissolving the final isolated compounds in MeCN or methanol. Solutions containing **1a** and **1b** in MeCN (1.2×10^{-4} M) were injected into the mass spectrometer source with a syringe pump at a flow rate of 10 μL/min. ^{1}H NMR spectra were measured in DMSO-d_6 with a Bruker AC300 300 MHz spectrometer at room temperature. Chemical shifts are given in parts per million with reference to TMS. Abbreviations are as follows: s, singlet; d, doublet; dd, doublet of doublets; t, triplet; and m, multiplet. Spectrophotometric titrations were performed with a Shimadzu UV-1601 UV–Visible spectrophotometer connected to an external computer. In a typical experiment, 50 mL of ligand **L** in acetonitrile (1.05×10^{-5} M) was titrated with a 2.6×10^{-3} M solution of the trifluoromethanesulfonate salt of the appropriate metal ion [silver(I) and zinc(II)] in MeCN. Each addition (0.01 mL increments of the salt solution at 5 min. intervals) was carried out by using a precision micropipette at 25 °C. The absorbances at ten different wavelengths were recorded using a 1 cm quartz cell and transferred to the computer. The spectrophotometric data were analysed with SPECFIT programme [54], by which the absorptivities and the stability constants of the species formed at equilibrium were adjusted. The SPECFIT programme uses factor analysis (which confirms the number of different absorbing species) to reduce the absorbance matrix and to extract the eigenvalue prior to the multiwavelength fit of the reduced data set according to the MARQUARD algorithm [57,58]. The synthesis of the silver(I) complex was carried out in the dark.

3.2. Synthesis of bis(3-hydrazonobutan-2-one)-2,2′-bipyridine **L**

6,6′-Dihydrazine-2,2′-bipyridine (0.43 g, 2 mmol) was dissolved in dry thf (5 mL) containing molecular sieves (4 Å), and followed by addition of glacial acetic acid (5 mL). After dropwise addition of 2,3-butandione (0.173 g, 20 mmol, in excess) under nitrogen, the solution was set to reflux at 60 °C with vigorous stirring for 12 h. The off white precipitate was collected by filtration and washed with methanol and ether, and air-dried to give **L** (0.52 g, 74%), mp 286–288 °C (decomp.). ESI-MS: 353.3 $[\mathbf{L}+H]^+$ $C_{18}H_{20}N_6O_2$ requires 352.2; 763.3 $[2\mathbf{L}+CH_3CN+H_2O]^+$ $C_{38}H_{45}N_{13}O_5$ requires 763.4; 778.9 $[2\mathbf{L}+CH_3CN+2H_2O]^+$ $C_{38}H_{47}N_{13}O_6$ requires 781.4; δ_H (300 MHz; DMSO-d_6; Me_4Si): 2.03 (3H, s, CH_3), 2.41 (3H, s, CH_3), 7.40 (2H, d, H5,5′), 7.90 (4H, m, H3,3′ and H4,4′), 10.38 (2H, s, NH); *Anal.* Calc. for $C_{18}H_{22}N_6O_3$ ($\mathbf{L}+H_2O$) (370.41): C, 58.37; H, 5.99; N, 22.69. Found: C, 58.54; H, 5.76; N, 22.70%.

3.3. Synthesis of $[Ag_2L_2][OTf]_2$ **1a**

All procedures for synthesis and recrystallization were carried out in the dark. A degassed solution (10 mL) of CF_3SO_3Ag (72.9 mg, 0.28 mmol) in MeCN was added dropwise to a stirred solution of **L** (100 mg, 0.28 mmol) in dichloromethane (25 mL) at room temperature under N_2 atmosphere and stirred for over night at 40 °C. The solution was cooled to room temperature and filtered. Ether vapour diffusion into this solution gave yellow-orange crystals of **1a**. The synthesis of **1a** was repeated three times and recrystallisation by ether diffusion or slow evaporation of the solution for each time yielded the same type of crystals with identical diffraction data **1a** (0.128 mg, 75%). ESI-MS: 459.1 $[Ag\mathbf{L}]^+$ $C_{18}H_{20}N_6O_2Ag$ requires 459.1; 461.1 $[Ag_2\mathbf{L}_2]^{2+}$ $C_{36}H_{40}N_{12}O_4Ag_2$ requires 460.6; 812.7 $[Ag\mathbf{L}_2]^+$ $C_{36}H_{40}N_{12}O_4Ag$ requires 813.2; 1068.6 $[Ag_2\mathbf{L}_2(OTf)]^+$ $C_{37}H_{40}N_{12}SO_7F_3Ag_2$ requires 1069.1. *Anal.* Calc. for $Ag_2C_{41}H_{46}N_{14}O_{10}S_2F_6$: C, 38.21; H, 3.59; N, 15.21. Found: C, 38.02; H, 3.65; N, 15.10%.

3.4. Synthesis of $[Zn_2\mathbf{L}_2][OTf]_4$ **1b**

L (57 mg, 016 mmol) was dissolved in dichloromethane (10 mL) under inert atmosphere. A solution (25 mL) of $Zn(CF_3SO_3)_2$ (58 mg, 0.16 mmol) was added dropwise with continuous stirring. The colour was initially orange-red, and finally turned to yellow upon stirring. The filtered yellowish solution was bubbled wit N_2 for 10 min, and left for crystallization to afford **1b** (0.09 mg, 78%). ESI-MS: 208.2 $[Zn\mathbf{L}]^{2+}$ $C_{18}H_{20}N_6O_2Zn$ requires 208.1; 415.2 $[Zn\mathbf{L}]^+$ $C_{18}H_{20}N_6O_2Zn$ requires 416.1; 565.0 $[Zn\mathbf{L}(OTf)]^+$ $C_{19}H_{20}N_6SO_5F_3Zn$ requires 565.0; 566.9 $[Zn_2\mathbf{L}_2(OTf)_2]^{2+}$ $C_{38}H_{40}N_{12}S2O_8F_6Zn_2$ requires 567.6; 1146.7 $[Zn_2\mathbf{L}_2(OTf)_2]^+$ $C_{39}H_{40}N_{12}S_2O_{10}F_6Zn_2$ requires 1146.1; 1282.4 $[Zn_2\mathbf{L}_2(OTf)_3]^+$ $C_{39}H_{40}N_{12}S_3O_{13}F_9Zn_2$ requires 1283.0. *Anal.* Calc. for $Zn_2C_{40}H_{42}N_{12}O_{18}S_4F_{12}$: C, 32.77; H, 2.89; N, 11.47. Found: C, 32.7; H, 3.3; N, 11.3%.

3.5. Crystal structure determination of complex *1a*

Data were collected at 120K on a Nonius KappaCCD area detector situated at the window of a rotating anode (λ Mo kα = 0.71073 Å). The structure was solved by direct methods, SHELXS-97, and refined using SHELXL-97 [82]. Hydrogen atoms were included in the refinement, but thermal parameters and geometry were constrained to ride on the atom to which they are bonded. The data were corrected for absorption effects using SADABS [83]. The two trifluoromethanesulfonate anions exhibit positional disorder where two molecules occupy the same space in the crystal lattice (geometric constraints were applied for one case where a molecule inverted about the centre of the C–S bond lies almost on top of another and a second case where a two fold axis produces two partially overlapping orientations such that oxygen and fluorine atoms F(4) and O(7) nearly overlap). The crystallographic details of **1a** are summarised in Table 1. Selected bond lengths and angles are displayed in the caption of Fig. 4, and hydrogen bonds are displayed in Table 2.

4. Conclusions

This study shows that the reactions of a multidentate Schiff-based bipyridine ligand **L** with d^{10} metal ions such as $Ag^{(I)}$ and $Zn^{(II)}$ can afford dinuclear double-stranded helical complexes. These are characterized in solution by means of ESI-MS spectrometry and UV–Vis spectrophotometry. The spectrophotometric measurements allowed the calculation of binding constants for the complexes and indicate that the helicate formation process is through a $[M\mathbf{L}_2]^{2+}$ intermediate. Furthermore, the molecular structure of the $Ag^{(I)}$ complex **1a** was also investigated by X-ray crystallography, which confirmed that it indeed has a dimeric helical structure with a head-to-tail configuration where the silver(I) ion is coordinated to two pyridyl nitrogen atoms, two imino nitrogen atoms and weakly to two keto oxygen atoms from two ligands to afford a pseudo octahedral geometry about each $Ag^{(I)}$ centre which shares a short Ag···Ag contact to accomplish a seven coordinated mono-capped trigonal prismatic geometry. The triflate anions are not involved in coordination but form hydrogen bonds with the hydrazonic NH groups of the two ligands to stabilize the double stranded helical structure. The neighbouring units are cross-linked together by hydrogen bonding between the carbonyl groups and NH groups. The supramolecular structure is stabilised by N–H···O, C–H···O and C–H···F interactions (Table 1). In the solid state, the electrostatic forces, π–π stacking interactions and metal···metal contacts seem to control the secondary structure involving the double strand formation. On the other hand, the ESI-MS of the zinc(II) complex **1b** reveals that **L** is in the monoanionic form by deprotonation on coordination to $Zn^{(II)}$ to form a distorted octahedral geometry at each zinc centre. This is very much akin to those zinc(II) complexes with N_4O_2 donor ligands reported by McMorran [84] and with N_6-donor ligand by Schröder [79,80]. The importance of structural factors can be seen by comparing the formation constants for the helicate **1a** ($\log\beta_{22} = 21$) and **1b** ($\log\beta_{22} = 19.5$). Since two complexes are likely to contain comparable binding sites and be subject to similar electrostatic energies. The novel N_4O_2 coordination mode offers **L** as a building block for interesting frame works through self-assembly, and may find use in the design of molecular devices due to the stability in silver(I) and zinc(II) complexation.

Oxazolines
Exo and endo palladacycles

ABSTRACT

(*R*)-4-Ethyl-2-(1,1-dimethylpropyl)-2-oxazoline (**1**) and (*S*)-4-*tert*-butyl-2-(1,1-dimethylbutyl)-2-oxazoline (**2**) were synthesized in two steps from the corresponding enantiopure amino alcohols and acid chlorides in a total yield of 95% and 72%, respectively. (*S*)-2-(1-Adamantyl-1-methylethyl)-4-isobutyl-2-oxazoline (**3**) was obtained from adamantyl bromide and L-leucinol in five steps in a total yield of 82%. Reactions of oxazolines **1**–**3** with $Pd(OAc)_2$ in AcOH or CH_2Cl_2 followed by treatment with LiCl afforded the corresponding μ-Cl dimeric cyclopalladated complexes **15**, **17**, and **20** in good yield. Compounds **15**, **17**, and **20** reacted with PPh_3 to furnish the corresponding mononuclear complexes **16**, **19**, and **21**. The ^{31}P NMR spectra of trans(*N*,*P*) adducts **16**, **19**, and **21** contained signals of two diastereomers in a ratio of ca. 1.3:1.

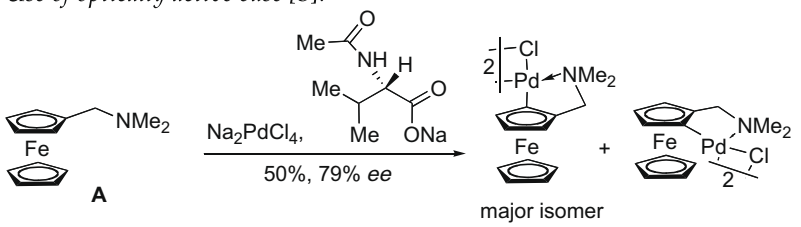
1. Introduction



Cyclopalladated complexes have been postulated as intermediates in some highly efficient Pd-catalyzed asymmetric reactions; therefore, understanding the factors governing stereoselectivity of cyclopalladation is of high importance [1,2]. There have been a number of reports on both enantio- and diastereoselective cyclopalladation. Three approaches have been used for enantioselective cyclopalladation (Chart 1). In the first method, prochiral substrates reacted with a source of Pd(II) in the presence of an optically active base. This approach was used by Sokolov et al. for enantioselective metalation of (dimethylamino)methylferrocene (**A**) using Na_2PdCl_4 in the presence of optically active salts of carboxylic acids [3]. The same group used this idea for enantioselective cyclopalladation of (dimethylamino)methylruthenocene [4], 6-ferrocenyl-2,2′-bipyridine [5], 2-ferrocenyl-1,10-phenanthroline [5], and ruthenocene-derived imines [6]. A second approach, the use of optically active Pd coordination complexes, *cis*-$PdCl_2L_2$ (L = (*R*)-methyl *p*-tolyl sulfoxide), was tested in cyclopalladation of (dimethylamino)methylferrocene **A**; however, no chiral induction was observed [7]. The third method is a cyclopalladated ligand exchange reaction (transcyclopalladation) between a substrate having prochiral groups and an enantiopure cyclopalladated complex, whose ligands play the chiral auxiliary role. This approach was effectively used by Dunina's group for preparation of optically active *CP*-palladacycles from prochiral phosphines, e.g. **B** [8,9]. In the reported studies of enantioselective cyclopalladation, almost exclusively, either planar or central chirality has been induced as a result of aromatic (sp^2)C–H bond activation. A few studies of enantioselective benzylic (sp^3)C–H bond activation have also been published. In one of them, transcyclopalladation of 8-ethylquinoline with an optically active cyclopalladated complex of *N*,*N*-dimethyl-α-methylbenzylamine proceeded with no asymmetric induction [10]. However, trans metalation of *tert*-butyldi(*o*-tolyl)phosphine using cyclopalladated α-*tert*-butylbenzylamine afforded the corresponding *CP*-complex in 91% *ee* [8].

The majority of the studies of diastereoselective cyclopalladation have been reported for substrates with the ferrocene backbone or compounds in which planar chirality can arise after metalation (Chart 2). As a rule, the chirality source was a stereogenic center in the ligand to be palladated and complexes with a (sp^2)C–Pd bond were formed. For example, Sokolov et al. used optically active 1-(dimethylamino)ethylferrocene (**C**) to obtain the corresponding cyclopalladated dimer with 70% de [11]. Similar results for the same substrate were reported by the López group [12]. Optically active ferrocene-derived imidozolines [13], hydrazones [14], and imines [15] also underwent cyclopalladation with very high or complete diastereoselectivity. Direct palladation of racemic ferrocene-based phosphinites by $(PhCN)_2PdCl_2$ was not diastereoselective [16], whereas reaction of racemic di-*tert*-butyl-1-ferrocenylethylphosphine with $Pd(OAc)_2$ proceeded with complete diastereoselectivity [17]. Diastereoselective cyclopalladation through (sp^3)C–H bond activation in the prochiral CMe_2 fragment was reported for a number of steroids and terpenoids, e.g. oxime **D** [18]. The only enantiopure oxazoline used for diastereoselective cyclopalladation was a (4*S*)-derivative with the prochiral (η^5-C_6H_4)(η^4-C_4Ph_4)Co fragment (**E**); it reacted with $Pd(OAc)_2$ to form

Use of optically active base [3]:

Use of optically active $PdCl_2L_2$, L = (R)-methyl p-tolyl sulfoxide [7]:

Enantioselctive transcyclopalladation [8,9]:

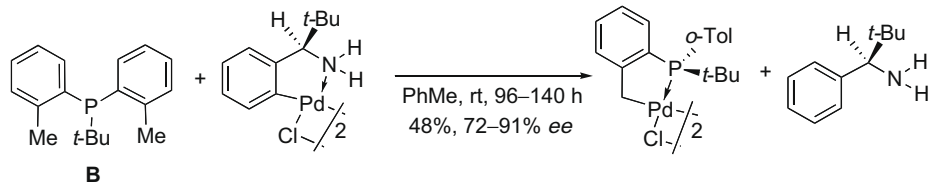

Chart 1. Examples of reported enantioselective cyclopalladation reactions [3,7–9].

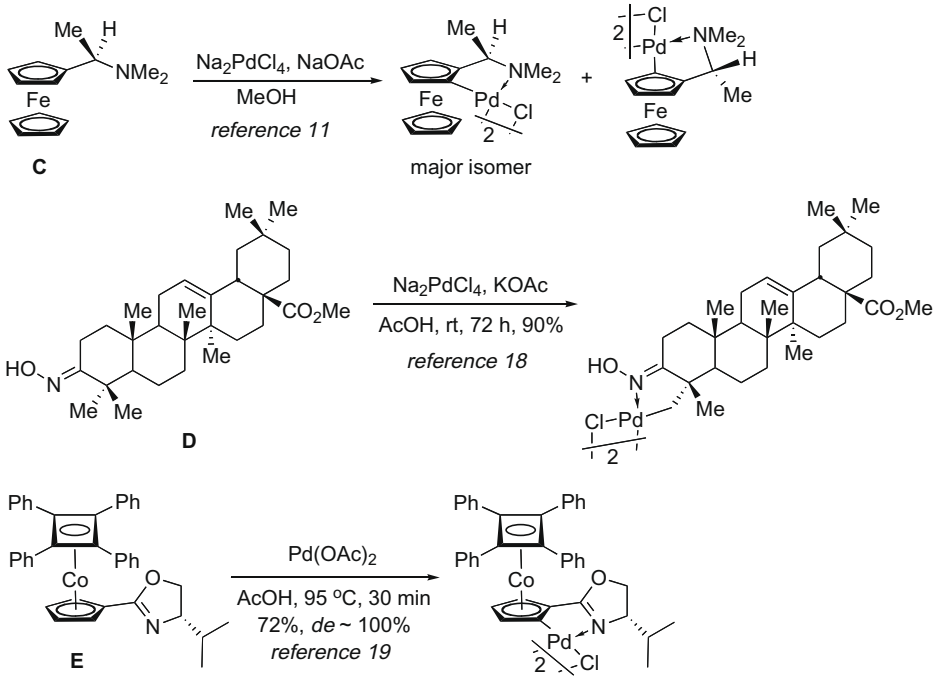

Chart 2. Examples of reported diastereoselective cyclopalladation reactions [11,18,19].

the corresponding palladacycle with complete diastereoselectivity [19].

In line with our interest in the study of cyclopalladated oxazolines [20–24], we report direct palladation of enantiopure oxazolines **1**–**3** having a chiral center at the 4-position and the prochiral CMe_2 fragment in the substituent at the 2-position of the heterocycle (Chart 3). We were interested in determining diastereoselectivity of these reactions and analyzing the effects of different factors on stereoselectivity.

2. Experimental

2.1. Materials

All reactions were carried out using standard bench top techniques. HPLC grade acetone and acetonitrile, as well as ACS reagent grade acetic acid were used without further purification. Other solvents were dried by distillation over CaH_2. Prior to use, $Pd(OAc)_2$ was dissolved in hot benzene followed by filtration and solvent

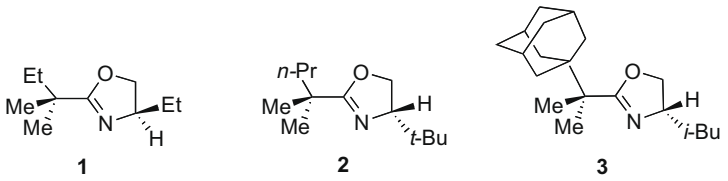

Chart 3. Enantiopure oxazolines **1**–**3** with the prochiral CMe_2 fragment.

removal in vacuum. All other chemicals were used as purchased from commercial sources (Sigma–Aldrich, Acros Organics or Alfa Aesar).

2.2. Chromatography

Column and preparative thin layer chromatography (TLC) was performed using Natland silica gel 60 (230–400 mesh). Analytical TLC was carried out on Whatman silica gel 60 (F_{254}) 250 μm precoated plates. Compounds on TLC plates were visualized using UV light (254 nm) and iodine stain (complexes) or vanillin/heat (ligands).

2.3. Physical measurements

Acquisition of ^1H (500 MHz), ^{13}C (126 MHz), ^{31}P NMR (202 MHz), DEPT, COSY, and HSQC spectra was performed in $CDCl_3$ using a Bruker AVANCE 500 spectrometer. Chemical shifts are reported in ppm relative to $SiMe_4$ as the internal standard (^1H and ^{13}C) or $P(OEt)_3$ as the external reference (^{31}P). Spin–spin coupling constants, *J*, are given in Hz. IR spectra were recorded on an ATI Mattson Genesis Series FT-IR. Melting points were determined on a Laboratory Devices Mel-Temp apparatus and are uncorrected. Optical rotations were measured in a 1 dm cell using an Autopol III automatic polarimeter. High resolution mass spectra were obtained on an Agilent 6200 LCTOF mass spectrometer at the Mass Spectrometry Facility, University of California Riverside, Riverside, CA, USA. Elemental analyses were performed by Atlantic MicroLabs Inc., Norcross, GA, USA.

2.4. Synthesis

2.4.1. Preparation of (R)-N-(1-hydroxybutan-2-yl)-2,2-dimethylbutanamide (**8**)

Compound **8** was obtained as a yellow solid in quantitative yield from (*R*)-(−)-amino-1-butanol (0.60 mL, 0.0063 mmol) and 2,2-dimethylbutyryl chloride (1.3 mL, 0.0095 mmol) according to a literature procedure reported for related compounds [25]. Mp 40–43 °C; R_f 0.35 (2:3 pet. ether–EtOAc); IR (thin film of $CHCl_3$ soln, *v*, cm^{-1}): 3342–3347 (OH, NH), 1640 (N–C=O); $[\alpha]_{633}^{25}$ +33.8, $[\alpha]_D^{25}$ +49.7 (*c* 0.208, CH_2Cl_2); ^1H NMR (δ, ppm): 0.86 (t, 3H, ^3J = 7.5, CMe_2CH_2Me), 0.95 (t, 3H, ^3J = 7.5, $NCHCH_2Me$), 1.17 (s, 6H, CMe_2), 1.49 (m, 1H, $NCHCH^AMe$), 1.56 (q, 2H, CMe_2CH_2Me), 1.62 (m, 1H, $NCHCH^BMe$), 3.40 (br. s, 1H, OH), 3.58 (dd, 1H, $^2J_{AB}$ = 10.9, ^3J = 5.8, OCH^A), 3.67 (dd, 1H, ^3J = 3.3, OCH^B), 3.86 (m, 1H, NCH), 5.84 (br. s, 1H, NH); ^{13}C NMR (δ, ppm): 9.2 (CMe_2CH_2Me), 10.6 ($NCHCH_2Me$), 24.2 ($NCHCH_2Me$), 25.0 and 25.1 (CMe_2), 33.9 (CMe_2CH_2Me), 42.5 (CMe_2), 53.4 (NCH), 65.8 (OCH_2), 179.0 (OCN). *Anal. Calc.* for $C_{10}H_{21}NO_2$: C, 64.13; H, 11.30; N, 7.48. Found: C, 63.66; H, 11.31; N, 7.26%.

2.4.2. Preparation of (S)-N-(1-tert-butyl-2-hydroxyethyl)-2,2-dimethylpentanamide (**9**)

Compound **9** was obtained as a cream-white solid from (*S*)-*tert*-leucinol (441.5 mg, 3.767 mmol) and 2,2-dimethylvaleroyl chloride (837.7 mg, 5.636 mmol) in 96% yield following a procedure reported for similar compounds [25]. Mp 94–97 °C; R_f 0.46 (2:3 pet. ether–EtOAc); IR (thin film of $CHCl_3$ soln, *v*, cm^{-1}): 3354 (NH), 3288 (OH), 1624 (N–C=O); $[\alpha]_D^{22.5}$ −22.9, $[\alpha]_{546}^{22.5}$ −27.6 (*c* 0.274, CH_2Cl_2); ^1H NMR (δ, ppm): 0.90 (t, 3H, ^3J = 7.3, CH_2Me), 0.96 (s, 9H, *t*-Bu), 2.21 and 2.22 (two s, 6H, CMe_2), 1.28 (m, 2H, CH_2Me), 1.52 (m, 2H, CH_2CMe_2), 3.54 (dd, 1H, $^3J_1$ = 7.9, $^3J_2$ = 10.7, OCH^A), 3.82–3.89 (m, 2H, NCH and OCH^B); ^{13}C NMR (δ): 14.6 (CH_2Me), 18.2 (CH_2Me), 25.49 and 25.54 (CMe_2), 27.0 (CMe_3), 33.3 (CMe_3), 42.6 (CMe_2), 43.7 (CH_2CMe_2), 59.7 (NCH), 63.8 (OCH_2), 179.8 (N–C=O). HRMS (TOF): calcd. for $[MH^+]$ 230.2120, found 230.2120.

2.4.3. Preparation of (R)-4-ethyl-2-(1,1-dimethylpropyl)-2-oxazoline (**1**)

Compound **1** was obtained from amide **8** (0.47 g, 2.5 mmol) and (diethylamino)sulfur trifluoride (0.36 mL, 2.8 mmol) as a colorless liquid in 89% (after distillation) using a procedure reported for other oxazolines [25]. Bp 82 °C/22 mm Hg; R_f 0.47 (6:1 pet. ether–EtOAc); IR (neat, *v*, cm^{-1}): 1658 (C=N); $[\alpha]_{633}^{23}$ +57.3, $[\alpha]_D^{23}$ +75.7, $[\alpha]_{546}^{23}$ +87.3, $[\alpha]_{435}^{23}$ +164.5, $[\alpha]_{365}^{23}$ +270.6 (*c* 0.210, CH_2Cl_2); ^1H NMR (δ, ppm): 0.84 (t, 3H, ^3J = 7.5, CMe_2CH_2Me), 0.90 (t, 3H, ^3J = 7.5, $NCHCH_2Me$), 1.17 (s, 6H, CMe_2), 1.49 (m, 1H, $NCHCH^AMe$), 1.54, (q, 2H, CMe_2CH_2Me), 1.65 (m, 1H, $NCHCH^BMe$), 3.86 (dd, 1H, ^3J = 7.2, $^2J_{AB}$ = 8.2, OCH^A), 4.02 (m, 1H, NCH), 4.23 (dd, 1H, ^3J = 9.4, OCH^B); ^{13}C NMR (δ, ppm): 9.1 (CMe_2CH_2Me), 9.5 ($NCHCH_2Me$), 25.5 (CMe_2), 28.4 ($NCHCH_2Me$), 33.4 (CMe_2CH_2Me), 36.8 (CMe_2), 67.0 (NCH), 71.5 (OCH_2), 172.7 (OCN); HRMS (TOF): calcd. for $[MH^+]$: 170.1543, found 170.1545.

2.4.4. Preparation of (S)-4-tert-butyl-2-(1,1-dimethylbutyl)-2-oxazoline (**2**)

Using a known procedure for related compounds [25], cyclization of amide **9** (3.113 g, 0.01357 mol) in the presence of (diethylamino)sulfur trifluoride (2.1 mL, 0.016 mol) afforded oxazoline **2** as a colorless liquid in 73% yield (after distillation). Bp 58–65 °C/1 mm Hg; R_f 0.64 (7:1 pet. ether–EtOAc); IR (neat, *v*, cm^{-1}): 1662 (C=N); $[\alpha]_{633}^{21}$ −54.8, $[\alpha]_D^{21}$ −64.3, $[\alpha]_{546}^{21}$ −77.1, $[\alpha]_{435}^{21}$ −140.2 (*c* 0.441, CH_2Cl_2); ^1H NMR (δ, ppm): 0.87–0.91 (m, 12H, 9H s of *t*-Bu and 3H of CH_2Me), 1.18 and 1.19 (two s, 6H, CMe^A and CMe^B), 1.27 (m, 2H, CH_2Me), 1.48 (m, 2H, CH_2CMe_2), 3.79 (dd, 1H, $^3J_1$ = 7.1, $^3J_2$ = 10.0, NCH), 4.03 (dd, 1H, $^2J_{AB}$ = 8.6, OCH^A), 4.09 (dd, 1H, OCH^B); ^{13}C NMR (δ): 14.7 (CH_2Me), 18.0 (CH_2Me), 25.8 (CMe_3), 25.9 and 26.3 (CMe^A and CMe^B), 33.7 and 36.6 (CMe_3, CMe_2), 43.2 (CH_2CMe_2), 68.3 (OCH_2), 75.4 (NCH), 172.7 (OCN). HRMS (TOF): calcd. for $[MH^+]$ 212.2014, found 212.2014.

2.4.5. Synthesis of methyl 2-adamantyl-2-methylpropanoate (**11**)

Compound **11** was obtained in 97% yield following a modified literature procedure [26]. $ZnCl_2$ (416 mg, 3.05 mmol) was sublimed under N_2 in a Schlenk flask, cooled to rt, and then agitated vigorously in CH_2Cl_2 (5.0 mL) before adding methyl trimethylsilyl dimethylketene acetal (2.0 mL, 9.8 mmol) via a syringe. The mixture was cooled to 0 °C in an ice-bath and a solution of 1-bromoadamantane (2.1242 g, 9.8736 mmol) in CH_2Cl_2 (10.0 mL) was added. The reaction mixture was stirred at rt for 28 h and then washed with distilled water (120 mL × 3). The combined aqueous

layers were extracted with CH_2Cl_2 (100 mL × 3). The combined organic solutions were dried over anhydrous $MgSO_4$. After solvent removal in vacuum, the product was isolated as a white solid. Mp 57–59 °C (lit. data [26] 58–59 °C); R_f 0.71 (9:1 benzene–EtOAc); IR (thin film of CH_2Cl_2 soln, ν, cm^{-1}): 1718 (C=O) [lit. data [26] 1710 (KBr)]; ^1H NMR (δ, ppm): 1.12 (s, 6H, CMe_2), 1.59–1.68 (m, 12H, CH_2 of Ad), 1.98 (br. s, 3H, CH of Ad), 3.64 (s, 3H, OMe); ^{13}C NMR (δ): 20.2 (CMe_2), 28.8 (CH of Ad), 36.6 (CMe_2), 36.95 and 36.97 (two s, two CH_2 groups of Ad), 48.8 (quat. C of Ad), 51.1 (OMe), 177.5 (C=O).

2.4.6. Synthesis of 2-adamantyl-2-methylpropionic acid (**12**)

Ester **11** (1.2366 g, 5.2321 mmol) was suspended in DMSO (21 mL) and NaSMe (0.8801 g, 12.56 mmol) was added. The mixture was stirred under N_2 at 84 °C (bath temp.) for 12 h. The yellowish slurry was treated with distilled water (140 mL) and extracted with Et_2O (100 mL × 3). Conc. H_2SO_4 was added dropwise to the aqueous solution to pH 3. The precipitated product (1.0609 g, 91%) was filtered off and dried under vacuum at rt. Mp 194–195 °C [lit. data [26] (164 °C)]; R_f 0.50 (4:1 benzene–EtOAc); IR (thin film of $CHCl_3$ soln, ν, cm^{-1}): 3500–2500 (OH), 1692 (C=O) [lit. data [26] 3300–2500 (OH), 1690 (C=O) (KBr)]; ^1H NMR (δ, ppm): 1.12 (s, 6H, CMe_2), 1.61–1.69 (m, 12H, CH_2 of Ad), 2.0 (br. s, 3H, CH of Ad), 11.34 (br. s, 1H, OH); ^{13}C NMR (δ): 20.4 (CMe_2), 29.2 (CH of Ad), 36.8 (CMe_2), 37.25 and 37.32 (two s, two CH_2 groups of Ad), 49.1 (quat. C of Ad), 183.4 (C=O).

2.4.7. Preparation of 2-adamantyl-2-methylpropionyl chloride (**13**)

A mixture of acid **12** (545.4 mg, 2.453 mmol) and $SOCl_2$ (0.27 mL, 3.7 mmol) was heated at 78 °C (bath temp.) under N_2 for 3 h. After removal of excess $SOCl_2$ in vacuum, the product was obtained as a pale-yellowish solid in quantitative yield. IR (thin film of CH_2Cl_2 soln, ν, cm^{-1}): 1788 (C=O); ^1H NMR (δ, ppm): 1.25–1.75 (m, 18H, CMe_2 and CH_2 of Ad), 2.03 (br. s, 3H, CH of Ad); ^{13}C NMR (δ): 21.7 (CMe_2), 28.7 (CH of Ad), 36.7 and 36.9 (two CH_2 groups of Ad), 37.9 (CMe_2), 59.3 (quat. C of Ad), 180.1 (C=O).

2.4.8. Synthesis of (S)-N-(1-isobutyl-2-hydroxyethyl)-2-adamantyl-2-methylpropanamide (**14**)

The synthesis of compound **14** was achieved according to a literature procedure for other amides [25]. Acyl chloride **13** (590.7 mg, 2.453 mmol) was added dropwise over 40 min to L-leucinol (**10**, 0.21 mL, 1.6 mmol) dissolved in a 1:1 mixture of CH_2Cl_2/H_2O containing K_2CO_3 (6.56 g, 0.0474 mol). The reaction proceeded at rt for 39 h. The product was obtained as a white solid in quantitative yield after crystallization from $CHCl_3$–pentane. Mp 113–115 °C; R_f 0.44 (3:2 pet. ether–EtOAc); IR (thin film of $CDCl_3$ soln, ν, cm^{-1}): 3456 (NH), 3386 (OH), 1633 (NC=O); $[\alpha]^{21}_{633}$ −39.8, $[\alpha]^{21}_{D}$ −49.3, $[\alpha]^{21}_{546}$ −62.3, $[\alpha]^{21}_{435}$ −105, $[\alpha]^{21}_{365}$ −153 (*c* 0.166, CH_2Cl_2); ^1H NMR (δ, ppm): 0.92 and 0.95 (two d, 6H, ^3J = 6.6, CHMe_2), 1.12 (s, 6H, CMe_2), 1.36 (m, 2H, CH_2CHMe$_2$), 1.59–1.69 (m, 13H, overlapping signals of C*H*Me$_2$ and CH_2 of Ad), 1.99 (br. s, 3H, CH of Ad), 2.59 (br. s, 1H, OH), 3.54 (dd, 1H, $^2J_{AB}$ = 10.9, ^3J = 6.4, OCH^A), 3.68 (dd, 1H, ^3J = 3.2, OCH^B), 4.03 (m, 1H, NCH), 5.63 (d, 1H, ^3J = 6.7, NH); ^{13}C NMR (δ): 20.3 and 20.4 (two s, CMe_2), 22.0 and 23.1 (two s, CHMe_2), 25.0 ($CHMe_2$), 28.8 (CH of Ad), 36.4 (CMe_2), 36.9 and 37.0 (two s, two CH_2 groups of Ad), 40.2 (CH_2CHMe_2), 48.2 (quat. C of Ad), 50.4 (NCH), 67.4 (OCH_2), 178.0 (C=O). Anal. Calc. for $C_{20}H_{35}NO_2$: C, 74.72; H, 10.97; N, 4.36. Found: C, 74.91; H, 11.11; N, 4.37%.

2.4.9. Synthesis of (S)-2-(1-adamantyl-1-methylethyl)-4-isobutyl-2-oxazoline (**3**)

Oxazoline **3** was obtained in quantitative yield as a viscous light yellow oil by the cyclization of amide **14** (494.8 mg, 1.539 mmol) with (diethylamino)sulfur trifluoride (0.22 mL, 1.7 mmol) according to a published procedure for other oxazolines [25]. The reaction mixture was stirred at −78 °C for 15.5 h and then slowly (11 h) warmed up to +5 °C. R_f 0.60 (5:1 pet. ether–EtOAc); IR (thin film of CH_2Cl_2 soln, ν, cm^{-1}): 1643 (C=N); $[\alpha]^{21}_{633}$ −37.9, $[\alpha]^{21}_{D}$ −43.9, $[\alpha]^{21}_{546}$ −53.6, $[\alpha]^{21}_{435}$ −92.4, $[\alpha]^{21}_{405}$ −114 (*c* 0.383, CH_2Cl_2); ^1H NMR (δ, ppm): 0.92 and 0.95 (two d, 6H, ^3J = 6.4, CHMe_2), 1.14 and 1.16 (two s, 6H, CMe_2), 1.28 (m, 1H, C*H*^{A}CHMe$_2$), 1.55–1.75 (m, 14H, overlapping signals of C*H*Me$_2$, C*H*^{B}CHMe$_2$ and CH_2 of Ad), 1.99 (br. s, 3H, CH of Ad), 3.91 (t, 1H, J = 7.7, OCH^A), 4.21 (m, 1H, NCH), 4.37 (t, 1H, J = 8.8, OCH^B); ^{13}C NMR (δ): 20.7 and 20.8 (CMe_2), 22.3 and 23.3 (CHMe_2), 25.4 ($CHMe_2$), 28.8 (CH of Ad), 36.9 (CMe_2), 37.0 and 37.03 (two CH_2 groups of Ad), 43.0 (C of Ad), 45.4 (CH_2CHMe_2), 63.2 (NCH), 73.0 (OCH_2), 173.8 (C=N); HRMS (TOF): calcd. for [MH^+] 304.2636, found 304.2640.

2.4.10. Synthesis of di-μ-chlorobis-[2-methyl-2-(4-ethyl-2-oxazolin-2-yl)butyl-C,N]dipalladium(II) (**15**)

Oxazoline **1** (79.7 mg, 0.471 mmol) was dissolved in MeCN (2.0 mL) and the solution was added to a suspension of $Pd(OAc)_2$ (107 mg, 0.476 mmol) and NaOAc (45.5 mg, 0.555 mmol) in MeCN (1.5 mL). The reaction mixture was stirred under N_2 at reflux for 4 h. The mixture was allowed to cool to rt and filtered through celite. After solvent removal, the crude μ-OAc dimer was dissolved in acetone (3 mL) and LiCl (22.0 mg, 0.519 mmol) was added. The mixture was stirred at rt for 24 h, then the solvent was evaporated and the crude μ-Cl dimer was purified by column chromatography using benzene and 98:2 benzene–EtOAc as the eluents. The pure product was isolated as a yellow powder in 77% yield. Data for a mixture of isomers: Mp 131–133 °C; R_f 0.52 (19:1 benzene–EtOAc); IR (thin film of $CDCl_3$ soln, ν, cm^{-1}): 1648 (C=N); ^1H NMR (δ, ppm): 0.87 (td, 3H, $J \approx 7.3$, $J \approx 2.9$, NCHCH$_2$*Me*), 0.87 and 0.94 (two t, 3H, ^3J = 7.5, PdCH$_2$C(Me)CH$_2$*Me*), 1.11 and 1.18 (two s, 3H, CMe), 1.44 (m, 1H, C(Me)C*H*^{A}Me), 1.51, (q, 1H, J = 7.6, C(Me)C*H*^{B}Me), 1.65 (m, 1H, NCHC*H*^{A}Me), 1.77–1.89 (m, 2H, NCHC*H*^{B}Me and PdCH^A), 2.10 and 2.11 (two d, 1H, ^2J = 7.7, PdCH^B), 3.96 (br. s, 1H, NCH), 4.17 (m 1H, OCH^A), 4.37 (m, 1H, OCH^B); ^{13}C NMR (δ, ppm): 8.2 and 8.6 (NCHCH$_2$*Me*), 9.2 and 9.5 (PdCH$_2$C(Me)CH$_2$*Me*), 25.1 and 25.6 (C*Me*), 25.7 and 26.0 (PdCH$_2$), 26.8 and 27.0 (NCH*C*H$_2$Me), 32.4 and 32.7 (C(Me)*C*H$_2$Me), 45.1 (*C*Me), 63.5 and 63.8 (NCH), 72.7 and 72.8 (OCH_2), 182.5 (OCN). *Anal. Calc.* for $C_{20}H_{36}Cl_2N_2O_2Pd_2$: C, 38.73; H, 5,85; N, 4.52. Found: C, 38.74; H, 5.95; N, 4.54%.

2.4.11. Synthesis of chloro-[2-methyl-2-(4-ethyl-2-oxazolin-2-yl)butyl-C,N](triphenylphosphine)palladium(II) (**16**)

The μ-chloro dimer **15** (52.0 mg, 0.0838 mmol) was dissolved in benzene (3 mL). PPh_3 (43.7 mg, 0.167 mmol) was added and the mixture was stirred under N_2 at rt for 24 h. After solvent removal, the crude product was purified by preparative TLC using 4:1 benzene–EtOAc as the eluent. Compound **16** was obtained as a white powder (73.9 mg, 77%) and as a 1:1 mixture (^{31}P NMR data) of diastereomers. Data for a 1:1 mixture of two diastereomers: Mp 145–148 °C; R_f 0.49 (4:1 benzene–EtOAc); IR (thin film of $CDCl_3$ soln, ν, cm^{-1}): 1649 (C=N); ^1H NMR (δ, ppm): 0.72 and 0.77 (two t, 3H, ^3J = 7.5, C(Me)CH$_2$*Me*), 0.86 (m, 1H, PdCH^A), 0.91 (td, 3H, J = 7.3, J = 1.7, NCHCH$_2$*Me*), 0.98 and 1.09 (two s, 3H, CMe), 1.26 (m, 1H, C(Me)C*H*^{A}Me), 1.43, (m, 2H, PdCH^B and C(Me)C*H*^{B}Me), 1.79 (m, 1H, NCHC*H*^{A}Me), 2.11 (m, 1H, NCHC*H*^{B}Me), 4.28 (m 1H, OCH^A), 4.40–4.49 (m, 2H, overlapping signals of OCH^B and NCH) 7.36–7.43 (m, 9H, *m*- and *p*-CH of PPh_3), 7.73 (m, 6H, *o*-CH of PPh_3); ^{13}C NMR (δ, ppm): 8.3 and 8.7 (NCHCH$_2$*Me*), 8.6 and 9.4 (C(Me)CH$_2$*Me*), 25.4 and 26.7 (C*Me*), 27.1 and 27.2 (NCH*C*H$_2$Me), 32.9 and 33.4 (PdCH$_2$), 33.9 and 34.1 (C(Me)*C*H$_2$Me), 45.05 and 45.11 (*C*Me), 62.7 and 63.0 (two d, $^3J_{CP}$ = 2.3 and 2.1, NCH), 73.5

and 73.7 (two d, $^4J_{CP}$ = 3.4, OCH_2), 128.1 (d, $^3J_{CP}$ = 10.6, *m*-CH of PPh_3), 130.2 (d, $^4J_{CP}$ = 2.0, *p*-CH of PPh_3), 131.5 and 131.6 (two d, $^1J_{CP}$ = 48.8 and 48.3, *ipso*-C of PPh_3), 134.7 (two d, $^2J_{CP}$ = 11.4, *o*-CH of PPh_3), 182.86 and 182.92 (two d, $^3J_{CP}$ = 2.8, OCN). ^{31}P NMR (δ, ppm): 32.91 and 32.94. *Anal. Calc.* for $C_{28}H_{33}ClNOPPd$: C, 58.75; H, 5.81; N, 2.45. Found: C, 58.62; H, 5.92; N, 2.49%.

*2.4.12. Synthesis of di-μ-chlorobis-[2-methyl-2-(4-tert-butyl-2-oxazolin-2-yl)pentyl-C,N]dipalladium(II) (**17**)*

$Pd(OAc)_2$ (73.2 mg, 0.326 mmol) and NaOAc (53.4 mg, 0.651 mmol) were added to a CH_2Cl_2 (5.2 mL) solution of oxazoline **2** (68.6 mg, 0.325 mmol). The mixture was stirred at rt for 5 days. The solvent was evaporated and the resulting μ-OAc dimer was reacted overnight at rt with LiCl (27.5 mg, 0.649 mmol) in acetone (5.7 mL). The acetone was removed and the residue was dissolved in CH_2Cl_2 and filtered. Evaporation of the solvent afforded a dark-yellow residue, which was purified by column chromatography using gradient elution with benzene and 95:5–1:1 benzene–CH_2Cl_2. This led to the isolation of 69 mg (61%) of compound **17** as a yellow powder. Data for the mixture of isomers: R_f 0.56 (19:1 benzene–EtOAc); IR (neat, *v*, cm^{-1}): 1639 (C=N); ^{1}H NMR (δ, ppm) 0.85 and 0.96 (two t, 3H, *J* = 6.9 and 7.3, CH_2*Me*), 1.00 (s, 9H, *t*-Bu), 1.02 (s, 3H, C*Me*), 1.12–1.27 (m, 1H, C*H*^{A}Me), 1.40 and 1.81 (m, 1H, C*H*^{B}Me), 1.62 (m, 2H, [C(Me)C*H*$_2$CH$_2$Me]), 1.81 and 2.17 (two d, 2H, ^2J = 8.3, $PdCH_2$), 3.63 (m, 1H, NCH), 4.18 and 4.23 (two t, 1H, *J* = 9.2, OCH^A), 4.41 (dd, 1H, $^2J_{AB}$ = 9.2, ^3J = 3.5, OCH^B); ^{13}C NMR (δ, ppm): 14.6 (CH_2*Me*), 17.2 and 18.7 (*C*H$_2$Me), 24.8 and 25.9 (C*Me*$_3$), 25.5 and 26.0 ($PdCH_2$), 26.0 and 26.9 ($PdCH_2$C*Me*), 34.2 and 34.4 (*C*Me$_3$), 41.1 and 42.9 [C(Me)*C*H$_2$CH$_2$Me], 44.7 and 45.0 ($PdCH_2$*C*Me), 70.4 and 70.7 (NCH), 70.5 and 71.0 (OCH_2), 181.9 and 182.5 (OCN). *Anal. Calc.* for $C_{26}H_{48}Cl_2N_2O_2Pd_2$: C, 44.33; H, 6.87; N, 3.98. Found: C, 44.90; H, 6.98; N, 4.07%.

*2.4.13. Synthesis of di-μ-chlorobis-{2-methyl-2-[2-(2-methylbutan-2-yl)-2-oxazolin-4-yl]propyl-C,N}dipalladium(II) (**18**)*

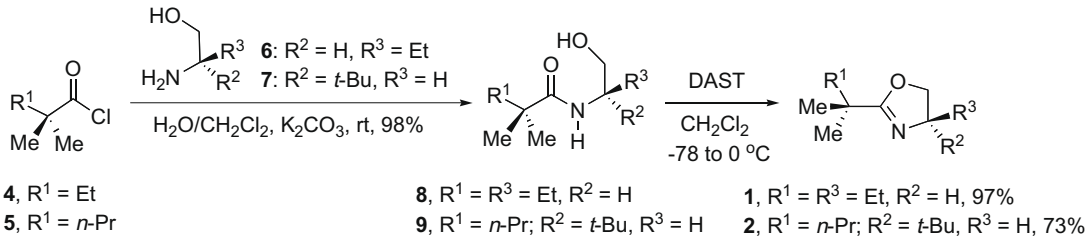
Compound **18** was isolated from the reaction of oxazoline **2** with $Pd(OAc)_2$ and NaOAc in AcOH (68 °C, 90 h) followed by treatment with LiCl in acetone in 11% yield (along with 28% of compound **17**). ^{1}H NMR (δ, ppm): 0.88 and 0.89 (two t, 3H, *J* = 7.25, CH_2C*H*$_3$), 0.96 (s, 6H, C(C*H*$_3$)$_2$), 1.15, 1.16, 1.17 (three s, 6H, C(C*H*$_3$)$_2$), 1.25 (m, 3H from CH_2CH_2), 1.47 (m, 2H from $PdCH_2$ and 1H from CH_2CH_2), 4.09 (m, 3H, OCH_2CHN); ^{13}C NMR (δ, ppm): 14.9 and 15.0 (*C*H$_3$CH$_2$), 18.5 and 18.6 (CH$_3$C*H*$_2$), 25.48, 25.50, 25.86 and 25.96 (C(*C*H$_3$)$_2$), 27.4 (C(*C*H$_3$)$_2$), 34.2 (*C*(CH$_3$)$_2$), 42.38 and 42.41 (*C*(CH$_3$)$_2$), 43.06 ($PdCH_2$), 43.63 ($CH_3CH_2CH_2$), 55.0 (NCH), 64.1 (OCH_2), 171.1 and 178.1 (OC=N).

*2.4.14. Preparation of chloro-[2-methyl-2-(4-tert-butyl-2-oxazolin-2-yl)pentyl-C,N](triphenylphosphine)palladium(II) (**19**)*

Complex **19** is obtained using a procedure described for compound **16** from pure dimer **17** in 95% yield. Data for a mixture of two diastereomers: R_f 0.27 (96:4 benzene–EtOAc); IR (thin film of $CDCl_3$ soln, *v*, cm^{-1}): 1643 (C=N); ^{1}H NMR (δ, ppm): ^{1}H NMR: 0.67 and 0.80 (two m, 4H, CH_2*Me* and PdCH^A), 1.06 and 1.07 (two s, 9H, *tert*-Bu), 0.94 and 1.22 (two s, 3H, Me), 1.00–1.45 (m, 4H, CH_2CH_2), 1.65 and 1.86 (two d, 1H, *J* = 9.45, PdCH^B), 4.29 (m, 2H, OCH_2), 4.49 (m, 1H, NCH), 7.35–7.40 (m, 9H, *m*- and *p*-CH of PPh_3), 7.71–7.74 (m, 6H, *o*-CH of PPh_3). ^{13}C NMR (δ, ppm): 14.5, 14.6 (CH_3), 25.9, 26.1 (*tert*-Bu), 28.6 (CH_3), 17.2, 18.7, 42.4 and 44.1 (CH_2CH_2), 34.3, 34.6, 45.1, 45.3 (*C*Me$_3$ and $PdCH_2$*C*), 34.5 and 35.4 ($PdCH_2$), 68.7 and 68.9 (two d, $^3J_{CP}$ = 2.8, OCH_2), 71.6 and 72.1 (two d, $^3J_{CP}$ = 2.8, NCH), 127.9 and 128.1 (*m*-CH of PPh_3), 130.13 and 130.14 (*p*-CH of PPh_3), 131.6 and 131.9 (two d, $^1J_{CP}$ = 4.0, *ipso*-C of PPh_3), 134.6 and 134.7 (*o*-CH of PPh_3), 181.8 and 182.2 (two d, $^3J_{CP}$ = 2.8, C=N); ^{31}P NMR (δ, ppm): 34.06 and 34.32.

*2.4.15. Synthesis of di-μ-chlorobis-[2-adamantyl-2-(4-isobutyl-2-oxazolin-2-yl)propyl-C,N]dipalladium(II) (**20**)*

A solution of oxazoline **3** (88.0 mg, 0.290 mmol) in acetic acid (4.0 mL) was added to a suspension of $Pd(OAc)_2$ (81.8 mg, 0.364 mmol) and NaOAc (26.2 mg, 0.319 mmol) in acetic acid (2 mL). The reaction mixture was stirred under N_2 at 80 °C (bath temp.) for 16 h. The solvent was evaporated and the resulting dark-brown residue was reacted under N_2 at rt for 22 h with a solution of LiCl (22.0 mg, 0.519 mmol) in acetone. The mixture was filtered through celite and the solvent was evaporated. Purification of the crude product by column chromatography with benzene as the eluent afforded the pure product (75% yield) as a yellow powder. Data for a mixture of isomers: Mp 180–184 °C; R_f 0.51 (benzene); IR (thin film of $CDCl_3$ soln, *v*, cm^{-1}): 1637 (C=N); ^{1}H NMR (δ, ppm): 0.83–2.37 (m, 29H, CH*Me*$_2$, CMe, $PdCH_2$, C*H*Me$_2$, C*H*$_2$CHMe$_2$, CH_2 and CH of Ad), 3.90 (m, NCH), 4.15 (m, 1H, OCH^A), 4.34 and 4.40 (two t, 1H, *J* = 9.1 and 8.9, OCH^B); ^{13}C NMR (δ, ppm): 20.0, 20.3, 21.6 and 21.8 (C*Me*$_2$), 23.6 and 23.7 (C*Me*), 24.3 and 24.5 ($PdCH_2$), 25.2, 25.4, 28.6 and 28.7 (*C*HMe$_2$ and CH of Ad), 36.4, 36.5, 36.6, 37.0 and 37.02 (CH_2 and C of Ad), 43.4 and 44.4 (*C*H$_2$CHMe$_2$), 50.8 and 51.1 (*C*Me), 61.0 and 61.2 (NCH), 72.9 and 73.9 (OCH_2), 181.6 and 181.7 (OCN). *Anal. Calc.* for $C_{40}H_{64}Cl_2N_2O_2Pd_2$: C, 54.06; H, 7.26; N, 3.15. Found: C, 54.30; H, 7.31; N, 3.21%.



*2.4.16. Preparation of chloro-[2-adamantyl-2-(4-isobutyl-2-oxazolin-2-yl)propyl-C,N](triphenylphosphine)palladium(II) (**21**)*

A solution of the μ-Cl dimer **20** (68.2 mg, 0.0767 mmol) and PPh_3 (42.8 mg, 0.163 mmol) in benzene (5.0 mL) was stirred under N_2 at rt for 43 h. The solvent was evaporated and the residue was purified by preparative TLC using 95:5 benzene–EtOAc as the eluent. The product (101.8 mg, 94%) was isolated as a white solid and as a 1:1 mixture of two isomers (^{31}P NMR data). Mp 123–128 °C; R_f 0.57 (4:1 benzene–EtOAc); IR (thin film of $CDCl_3$ soln, *v*, cm^{-1}): 1639 (C=N); ^{1}H NMR (δ, ppm, a mixture of two isomers): 0.70 and 1.48 (dd and m, $^2J_{HH}$ = 10.0, $^3J_{HP}$ = 7.2, PdCH^A and PdCH^B of one isomer), 0.99 and 1.15 (m and d, $^2J_{HH}$ = 10.0, PdCH^A and PdCH^B of the other isomer), 0.90–1.7 (m, 23H, CH_2 of Ad, C*H*^{B}C*HMe*$_2$ and $PdCH_2$C*Me*), 1.87 (br. s, 3H, CH of Ad), 2.34 (m, 1H C*H*^{A}CHMe$_2$), 4.25 (m, OCH^A), 4.40–4.51 (m, 2H, OCH^B and NCH); ^{13}C NMR (δ, ppm): 20.7 and 21.2 (C*Me*$_2$), 21.6, 21.7, 23.8 and 23.9 (CH*Me*$_2$), 25.3 and 25.5 (*C*HMe), 28.6 and 28.8 (CH of Ad), 32.4 and 32.6 ($PdCH_2$), 36.5, 36.9, 37.0 and 37.6 (two CH_2 groups of Ad), 36.7 and 37.5 (*C*Me$_2$), 43.5 and 44.3 (*C*H$_2$CHMe$_2$), 50.9 and 51.6 (C of Ad), 60.6 and 60.8 (two d, $^3J_{CP}$ = 2.4 and 2.1, NCH), 73.6 and 74.6 (two d, $^4J_{CP}$ = 3.0, OCH_2), 128.1 (d, $^2J_{CP}$ = 10.4, *o*-CH of PPh_3), 130.1 (d, $^4J_{CP}$ = 2.4, *p*-CH of PPh_3), 131.6 and 131.7 (two d, $^1J_{CP}$ = 47.6 and 47.9, *ipso*-C of PPh_3), 134.7 and 134.8 (two d, $^3J_{CP}$ = 7.5, *m*-CH of PPh_3), 181.9 and 182.5 (two d, ^3J = 2.3 and 2.7, OCN). ^{31}P NMR (δ, ppm): 32.7 and 32.3. *Anal. 3. Results and discussion

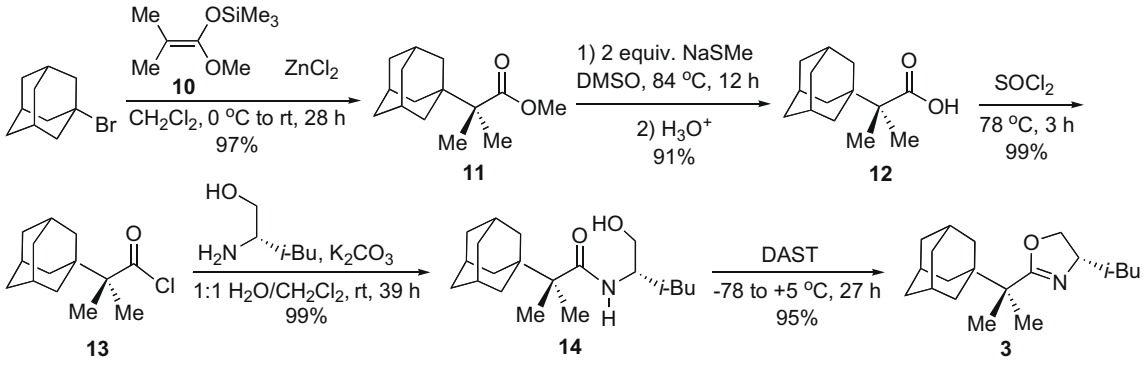
3.1. Oxazoline synthesis

(*R*)-4-Ethyl-2-(1,1-dimethylpropyl)-2-oxazoline, **1,** and (*S*)-4-*tert*-butyl-2-(1,1-dimethylbutyl)-2-oxazoline, **2**, were obtained from the corresponding acid chlorides **4** and **5** and commercially available optically enantiopure amino acids (*R*)-**6** and (*S*)-**7** following a two-step published procedure (Scheme 1). First, acid chlorides **4** and **5** were converted to the corresponding hydroxy amides **8** and **9** in quantitative yield. Then, compounds **8** and **9**

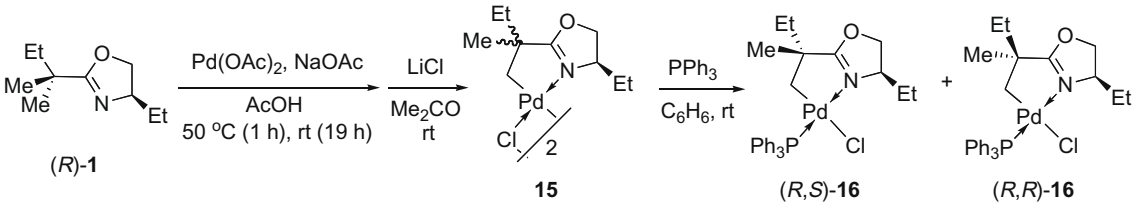
Scheme 1.

were subjected to the (diethylamino)sulfur trifluoride (DAST)-mediated cyclization [25] to afford oxazolines **1** and **2** in 97% and 73%, respectively.



Synthesis of (*S*)-2-(1-adamantyl-1-methylethyl)-4-isobutyl-2-oxazoline, **3**, was achieved from adamantyl bromide in five steps in 82% overall yield (Scheme 2). First, adamantyl bromide was converted to carboxylic ester **11** using methyl trimethylsilyl dimethylketene acetal **10** and $ZnCl_2$ in 97% yield [26]. The treatment of ester **11** with 2 equiv. of NaSMe in DMSO, followed by aqueous workup, afforded the corresponding acid **12** in 91% yield. The reaction of acid **12** with excess $SOCl_2$ provided acyl chloride **13** in quantitative yield. The acylation of commercially available (*S*)-leucinol by acyl chloride **13** furnished amide **14** in quantitative yield. In the last step, the DAST-mediated cyclization [25] of **14** afforded oxazoline **3** in quantitative yield.

3.2. Cyclopalladation of oxazolines *1–3*



Direct cyclopalladation of oxazoline **1** using $Pd(OAc)_2$ in acetic acid in the presence of NaOAc, followed by treatment of the crude product with LiCl, afforded dimer **15** in 68% yield after purification (Scheme 3). According to ^1H and ^{13}C NMR data, compound **15** was a complex mixture of two major isomers in a ratio of 1.3:1, with a trace amount of other isomers. It was impossible to assign the structures of two major isomers, because dimeric cyclopalladated complexes can exhibit trans/cis isomerism and each of these geometrical isomers contains two palladacycles with the same or opposite configuration of the new chiral center. Attempts to separate the isomers by column chromatography or preparative TLC on silica gel were unsuccessful. Reaction of dimer **15** with PPh_3 resulted in the formation of two diastereomeric mononuclear complexes, (*R,R*)-**16** and (*R,S*)-**16**. The ^{31}P NMR spectrum of complex **16** obtained from compound **15** contained two signals (δ 32.91 and 32.94 ppm) in a ratio of 1.3:1. All known PPh_3 adducts of cyclopalladated oxazolines have the trans(*N,P*) geometry [20–24,27]. The chemical shift of δ 32.9 ppm for the ^{31}P NMR signal of compound **16** is the same or very similar, δ 32.4, compared to the values reported for two PPh_3 mononuclear cyclopalladated complexes with a (sp^3)C–Pd bond and the trans(*P,N*) geometry proven by X-ray crystallographic analysis of solid samples [21,28]. Assuming that both signals in the spectrum of **16** belong to trans(*N,P*) isomers, the 1.3:1 signal ratio must correspond to the ratio of two diastereomers of **16**, which differ by the configuration of the chiral center created upon the cyclopalladation.

To investigate the solvent effect on the isomer ratio, cyclopalladation of oxazoline **1** using $Pd(OAc)_2$/NaOAc was also carried out in MeCN. The reaction was performed at reflux during 4 h and yielded 77% of dimer **15.** The diastereomer ratio of the corresponding PPh_3 adducts **16** obtained from a crude mixture of isomers **15** was similar, ca. 1.2:1 (^{31}P NMR data). Cyclopalladation of oxazoline **1** using $Pd(OAc)_2$/NaOAc in MeCN at room temperature (12 h) followed by treatment with LiCl, provided only traces of dimer **15** (TLC data). When heterocycle **1** reacted with Na_2PdCl_4 in MeOH in the presence of NaOAc at room temperature, the desired complex **15** was not detected (^1H NMR data) and the coordination complex $PdCl_2(\mathbf{1})_2$ was isolated in 62% yield.

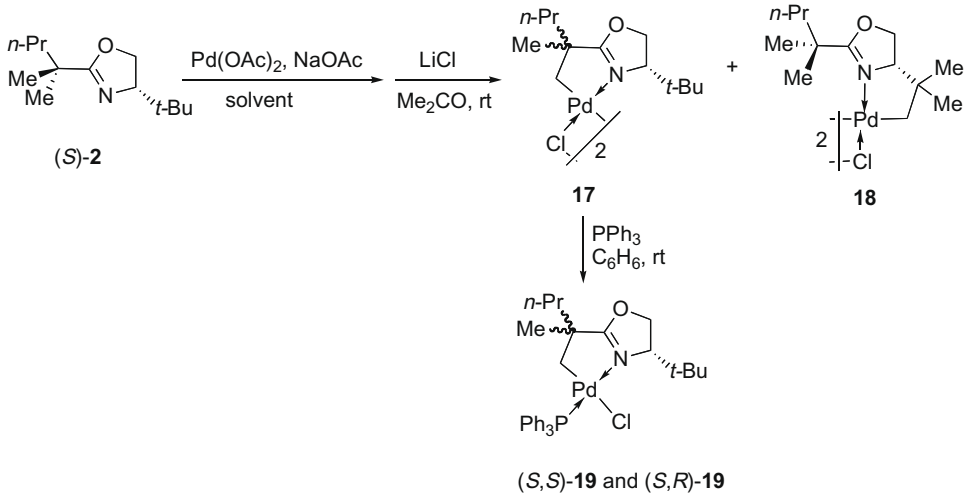
The poor diastereoselectivity observed with oxazoline **1** prompted us to test heterocycle **2** with the much bulkier *tert*-butyl group at the chiral center than the ethyl group in compound **1**. Reaction of compound **2** in acetic acid (68 °C, 90 h) provided two complexes, **17** and **18**, in a ratio of 5:2 and a total yield of 39%. Compounds **17** and **18** had completely different ^1H and ^{13}C NMR spectra. This suggests that the complexes have two different palladacycles, endo and exo. Previously, we reported that oxazolines have a strong tendency to form endo-cyclic complexes with the C=N bond within a palladacycle [21,23,24]. For example, cyclopalladation of (*S*)-2-*tert*-butyl-4-phenyl-2-oxazoline using $Pd(OAc)_2$ provided two products with the endo and exo metalacycles in a ratio of 13:1 in spite of the fact that the formation of the major endo complex required the (sp^3)C–H bond activation versus the usually more preferable (sp^2)C–H bond activation for the minor exo derivative [21]. Assuming the endo palladation preference in the reaction of oxazoline **2**, the major isomer **17** was assigned the endo structure of the palladacycle, while the minor isomer **18** must be the exo derivative. To support this assignment, ^{13}C NMR spectra of known oxazoline-based exo and endo palladacycles were com-

Scheme 2.

Scheme 3.

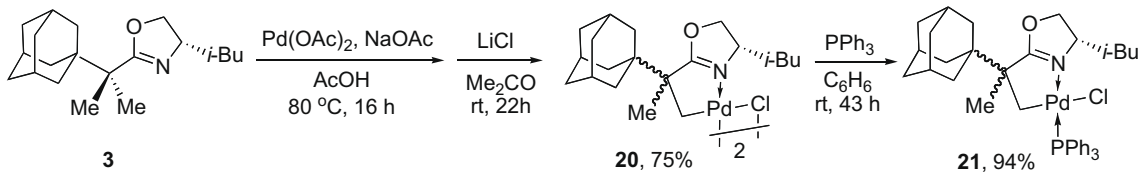
pared with those of complexes **17** and **18**. For the reported endo palladacycle obtained from 2-*tert*-butyl-4-phenyl-2-oxazoline, the ^{13}C NMR chemical shift of the $PdCH_2$ signal was δ 28.2 ppm [21]. The ^{13}C NMR signals of the same fragment in complexes **15**, **17**, and **20** (*vide infra*) appeared at δ 25.7, 25.5, and 24.3 ppm, respectively. For comparison, the only reported exo palladacycle with the $PdCH_2$ moiety exhibited a signal at δ 40.9 ppm [22]; this value is close to that for the signal at δ 43.06 ppm assigned to the same group in the spectrum of complex **18** (Scheme 4).

Cyclopalladation of oxazoline **2** using $Pd(OAc)_2$ in MeCN (76 °C, 11 h) also furnished a mixture of two types of complexes, **17** and **18**, in a ratio of 7:2 and a total yield of 58%. Unfortunately, the ^1H and ^{13}C NMR spectra of mixtures of **17** and **18**, as well as mixtures of the corresponding PPh_3 adducts, were too complicated for the analysis of possible stereoisomers. After many purifications, a pure sample of **17** was obtained; however, it could not be used for estimation of diastereoselectivity in reactions of oxazoline **2** with $Pd(OAc)_2$ in AcOH and MeCN.



When the reaction of oxazoline **2** with $Pd(OAc)_2$ was carried out in CH_2Cl_2 (rt, 120 h), only one cyclopalladated complex **17** was obtained (61% yield). For estimation of cyclopalladation diastereoselectivity, crude dimer **17** was converted to the corresponding PPh_3 adduct **19**. According to ^{31}P NMR data, the obtained complex **19** was a mixture of two diastereomers in a ratio of 1.3:1.

Reaction of oxazoline **2** with Na_2PdCl_4 in MeOH at rt was also tested; however, it produced no traces of either **17** or **18**. The corresponding coordination complex $PdCl_2(\mathbf{2})_2$ was isolated in 17% yield.



Since the replacement of the ethyl group at the chiral center in oxazoline **1** for the bulkier *tert*-Bu group in oxazoline **2** did not improve diastereoselectivity of cyclopalladation, reactions of heterocycle **3** were also investigated. In oxazoline **3**, a bulky adamantyl group was placed next to the prochiral CMe_2 center instead of the ethyl and *n*-propyl groups in compounds **1** and **2**, respectively. To avoid the exo palladacycle formation, the *tert*-butyl fragment in heterocycle **2** was replaced by the *iso*-Bu group in oxazoline **3**.

Cyclopalladation of oxazoline **3** with $Pd(OAc)_2$ in AcOH (80 °C, 16 h) followed by treatment with LiCl in acetone, provided complex **20** in 75% (Scheme 5). To estimate diastereoselectivity of the metalation, dimer **20** was converted to the PPh_3 adduct **21**. According to the ^{31}P NMR data, a ratio of two diastereomers of **21** was close to 1.3:1. Cyclopalladation of the adamantyl derivative **3** at rt in CH_2Cl_2 (65 h) followed by transformation of dimer **20** to mononuclear complex **21**, provided a diastereomeric mixture of the PPh_3 adduct of the same ratio.

The observed stereoselectivity for metalation of oxazolines **1**–**3** is significantly lower from that reported for palladation of ferrocenyl derivatives and structurally related compounds having the oxazoline [19], imidozoline [13], imine [15], or hydrazone [14] moiety with a N atom in the β-position to the prochiral metallocene fragment. The reason for excellent results in cyclopalladation of such systems is the possibility of only one rotamer of the Pd-coordinated ligand leading to the C–H bond activation [13–15,19]. Interestingly enough, excellent stereoselectivity for such systems was observed regardless the conditions used: Na_2PdCl_4 at rt [15] or $Pd(OAc)_2$ at 95 °C [19]. The reported highly diastereoselective palladation of the prochiral CMe_2 group in steroids and terpenoids [18] can be explained by a rigid polycyclic structure of the ligands. Such structures are expected to have preferred conformations with two prochiral Me groups positioned in two distinctly different faces of the chiral molecule. In the studied oxazolines **1**–**3**, there is unrestricted rotation around the $C^{ox}(2)$–CMe_2 bond; therefore, there is neither a preferred conformation of the $RCMe_2$ substituent relative to the Pd-coordinated oxazoline fragment nor a significant difference for the Pd atom to react with a C–H bond in either pro(*S*)-Me or pro-(*R*)-Me groups.

Scheme 4.

Scheme 5.

4. Conclusions

We have presented the synthesis of three enantiopure oxazolines **1**–**3** and their cyclopalladation using $Pd(OAc)_2$. The diastereoselectivity of cyclopalladation was estimated using ^{13}P NMR spectra of the corresponding PPh_3 adducts. It was found that, under the conditions used, cyclopalladation of enantiopure oxazolines **1**–**3** occurred with low diastereoselectivity. Neither the introduction of the bulky *tert*-butyl group at the chiral center in oxazoline **2**, nor the presence of the large adamantyl group next to the prochiral CMe_2 in compound **3** affected diastereoselectivity.

ABSTRACT

Bis(*O,O′*-ditolyl/dibenzyl dithiophosphato)cobalt(II) complexes with pyridine ligands of the type $[Co\{S_2P(OR)_2\}_2(C_5H_5N)_2]$ (R = *o*-, *m*-, *p*-C_6H_4Me, CH_2Ph) have been synthesized by the reaction of $CoCl_2(C_5H_5N)_2$ and the corresponding ammonium salt of *O,O′*-ditolyl/dibenzyl dithiophosphate in methanol. These newly synthesized adducts were characterized by elemental analysis, IR, UV–Vis spectroscopy, magnetic susceptibility measurements and single crystal X-ray diffraction. These structures confirm that in the pyridine complex the geometry around the cobalt metal centre is distorted octahedral, and in the amine complex it is distorted trigonal bipyramidal.

1. Introduction

The 1,1-dithiolate ligands, viz. *O,O′*-dialkyl/alkylene dithiophosphates, are versatile in nature and coordination complexes with cobalt have been reported in the literature [1–13]. In these complexes, the dithiophosphate ligand moieties are normally bidentate. X-ray crystal structures have been reported for a number of cobalt compounds with *O,O′*-dialkyl dithiophosphates including $Co[S_2P(OMe)_2]_3$ [14], $Co[S_2P(i\text{-}OPr)_2]_3$ [15], $[Co\{S_2P(OMe)_2\}_2 \cdot PPh_3]$ [16], $[NMe_4][CoCl\{S_2P(OMe)_2\}_2]$ [17], $Co[S_2P(OEt)_2]_3 \cdot 1/2H_2O$ [18], $[Co\{S_2P(OEt)_2\}_2(C_5H_5N)_2]$ [19], $[Co\{S_2P(OCy)_2\}_2(C_5H_5N)_2]$ [20] and $[Co\{S_2P(OEt)_2\}_2(C_{24}H_{26}O_2N_4)]$ [21]. Reports on metal complexes containing *O,O′*-ditolyl dithiophosphate ligands are relatively few [22–24]. Recently, we have used *O,O′*-ditolyl/dibenzyl dithiophosphate to examine the influence of bulkier groups on phosphorus and have reported the syntheses, spectroscopic studies and single crystal X-ray structures of $Ni[S_2P(OC_6H_4CH_3\text{-}o)_2]_2$ [25], $Ni[S_2P(OC_6H_4CH_3\text{-}m)_2]_2$ [25], $Ni[S_2P(OCH_2Ph)_2]_2$ [25], $[Ni\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(N_2C_{10}H_8)]$ [26], $[Ni\{S_2P(OC_6H_4Me\text{-}o)_2\}_2(N_2C_{14}H_{12})] \cdot C_6H_6$ [26] $Me_2Sn[S_2P(OC_6H_4Me\text{-}o)_2]_2$ [27], $Bu_2Sn[S_2P(OC_6H_4Me\text{-}o)_2]_2$ [27], $Mo_2O_3[S_2P(OC_6H_4Me\text{-}o)_2]_4$ [28], $Mo_2O_3[S_2P(OC_6H_4Me\text{-}m)_2]_4$ [28] and $MoO_2[S_2P(OC_6H_4Me\text{-}p)_2]_2$ [28].

In continuation of this interest, we report here the synthesis, and spectroscopic characterization of pyridine adducts of bis(*O,O′*-ditolyl/dibenzyl dithiophosphato)cobalt(II) complexes and a bis(*O,O′*-dibenzyl dithiophosphato)cobalt(II) complex. We also report the single crystal X-ray structures of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ and $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$.

2. Results and discussion

The reactions of cobalt chloride hexahydrate with ammonium salts of *O,O′*- ditolyl dithiophosphates in a 1:2 molar ratio were carried out in methanol. Initially a blue solution of bis(*O,O′*-ditolyl dithiophosphato)cobalt(II) was obtained, which soon turned green, indicating oxidation of Co(II) to Co(III), and finally turned brown. Various methods were adopted to avoid decomposition, such as carrying out the reaction in a foil wrapped flask at low temperature, but all failed, with the solid obtained slowly decomposing into a brown solid. Attempts were also made to avoid oxidation by carrying out the reactions with $CoCl_2 \cdot 6H_2O$ and the sodium salts of the *O,O′*-ditolyl dithiophosphates, but these again yielded the oxidized brown solids. However, the oxidation reactions were comparatively slow as compared to when the ammonium salts were used. Reactions were also carried out at lower temperature (5 °C), which again yielded cobalt(III) complexes. However, in one of these attempts plate-like blue crystals of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$ were isolated, which were relatively stable.

An indirect method was used to prepare adducts of bis(*O,O′*-ditolyl dithiophosphato)cobalt(II) with pyridine, This route readily

doi:10.1016/j.poly.2008.09.025

produced the expected compounds in good yields. Initially, the blue solid bispyridine cobalt(II) chloride was prepared and then a stoichiometric amount of ligand was added in situ, to give the purple pyridine adducts of the (*O,O′*-ditolyldithiophosphato)cobalt(II) complexes.

$$CoCl_2 \cdot 6H_2O + 2C_5H_5N \rightarrow CoCl_2(C_5H_5N)_2$$
$$CoCl_2(C_5H_5N)_2 + 2NH_4S_2P(OR)_2 \rightarrow [Co\{S_2P(OR)_2\}_2(C_5H_5N)_2]$$
$$(R = o-, m-, p- C_6H_4Me, CH_2Ph)$$

However, the cobalt(II) complex with dibenzyl dithiophosphate was prepared by the one step stoichiometric reaction of cobalt chloride hexahydrate with the ammonium salt of dibenzyl dithiophosphate in methanol on stirring at room temperature to give a blue solid product in good yield. This blue solid, on further reaction with pyridine, gave a purple coloured adduct.

$$CoCl_2 \cdot 6H_2O + 2NH_4S_2P(OCH_2Ph)_2 \rightarrow [Co\{S_2P(OCH_2Ph)_2\}_2]$$
$$[Co\{S_2P(OCH_2Ph)_2\}_2] + 2C_5H_5N \rightarrow [Co\{S_2P(OCH_2Ph)_2\}_2(C_5H_5N)_2]$$

In the case of the *O,O′*-dibenzyl dithiophosphate cobalt(II) complex, the decomposition rate to the brown coloured cobalt(III) complex is quite slow, giving enough time to isolate the tetrahedral blue coloured cobalt(II) complex at room temperature. The fact that the oxidation rate for the bis(*O,O′*-ditolyl dithiophosphato)cobalt(II) complexes is comparatively fast is probably because of the electron withdrawing effect due to the conjugation of the tolyl moiety which makes the phosphorous have a lower electron density and in turn withdraw electrons from the sulfur, giving rise to weaker bonding between the Co and S atoms, which aids the oxidation of Co(II) to Co(III). This conjugation effect is absent for the dibenzyl derivative.

All these pyridine adducts of the bis(*O,O′*-ditolyl/dibenzyl dithiophosphato)cobalt(II) complexes are soluble in common organic solvents such as benzene, chloroform and acetone. The products were characterized by elemental analysis, IR, UV–Vis spectroscopy and magnetic susceptibility measurements, along with the X-ray crystal structure determination of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ and $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$.

2.1. IR spectra

The relevant assignments of the IR bands (Table 1) have been made by a comparison with the spectra of the ammonium salts of the *O,O′*-ditolyl/dibenzyl dithiophosphates [29] and analogous adducts of cobalt(II) complexes [9]. The two strong to medium intensity bands present in the regions 1030–1068 and 897–993 cm^{-1} are assigned to ν[(P)–O–C] and ν[P–O–(C)] stretching vibrations, respectively. Bands due to ν(P=S) or $\nu(P–S)_{asymm}$ and ν(P–S) or $\nu(P–S)_{symm}$ are observed in the ranges 669–702 and 591–602 cm^{-1}. The metal sulfur ν(Co–S) weak bands in the 405–439 cm^{-1} region indicate coordination of the dithiophosphate ligands through the sulfur atoms. Weak to medium intensity bands due to ν(Co–N) are also seen in the region 351–388 cm^{-1}. Further, in the case of the pyridine adducts **1–4**, additional medium intensity bands in the region 1579–1634 cm^{-1} are due to the C–N vibrations of the aromatic ring, indicating the presence of the nitrogen base donors in the adducts.

2.2. Electronic absorption spectra

The electronic spectra of the pyridine adducts of the bis(*O,O′*-ditolyl/dibenzyl dithiophosphato)cobalt(II) complexes and the bis(*O,O′*-dibenzyl dithiophosphato)cobalt(II) complex were carried out in pyridine and CH_2Cl_2 solvents, respectively. The electronic spectra suggest a tetrahedral configuration for $[Co\{S_2P(OCH_2Ph)_2\}_2]$ which is supported by the presence of a strong absorption band at 613 nm [2]. This band is caused by the $^4A_2 \rightarrow {}^4T_1(F)$ transition whereas, the band at 579 nm is due to the $^4A_2 \rightarrow {}^4T_1(P)$ transition. Splitting is also observed in the main band at 613 nm due to spin–orbital coupling.

In the case of the octahedral adducts, the peaks corresponding to the transitions $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$, $^4T_{1g}(F) \rightarrow {}^4A_{2g}(F)$ and $^4T_{1g}(F) \rightarrow {}^4T_{2g}(F)$ are seen in the ranges 500–524, 574–746 and 1026–1138 nm, respectively. Almost identical electronic transitions for the pyridine adducts of bis(diethyldithiocarbamato) cobalt(II) [30] and benzathiazole and benzimidazole adducts of bis(diethyldithiophosphato)cobalt(II) [9] were observed, indicating an octahedral coordination.

2.3. Magnetic measurements

The conclusion about the tetrahedral and octahedral coordination in the complexes is further supported by the magnetic moment for $[Co\{S_2P(OCH_2Ph)_2\}_2]$ of 4.34 B.M., as compared with those of the pyridine adducts which range from 4.87 to 5.0 B.M.

2.4. Crystal Structures of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ and $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$

$[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ (**3**) and $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$ (**6**) crystallize in the monoclinic space groups $P2_1/c$ (centrosymmetric) and $P2_1/n$, respectively. The ORTEP diagram of the molecular structure of **3** in Fig. 1 displays a distorted octahedral geometry with the pyridine molecules occupying *trans* positions. In contrast, the ORTEP diagram of the molecular structure of **6** in Fig. 2 displays distorted trigonal bipyramidal geometry with N(1), S(1) and S(3) occupying the equatorial plane and S(2) and S(4) in the axial positions, similar to the structure of $[Co\{S_2P(OMe)_2\}_2 \cdot PPh_3]$ [16], with a phosphine electron donor instead of a nitrogen base. The Co–N bond distance of (2.162(2) Å) in **3** is essentially the same as that in $[Co\{S_2P(OEt)_2\}_2(C_5H_5N)_2]$ (2.164(3) Å) [19], which also has *trans* Co–N bonds. The shorter Co–N bond length of 2.052(2) Å in **6**, is closer to the average Co–N bond length of 2.041(7) Å in $[Co\{S_2P(OEt)_2\}_2(C_{24}H_{26}N_4O_2)]$ [21] where the Co–N bonds are *cis*.

In **6**, as is to be expected for a trigonal pyramidal structure, the $Co–S_{axial}$ bonds (ave. 2.567(5) Å) are longer than the $Co–S_{equatorial}$ bonds (ave. 2.3421(7) Å), as was found in $[Co\{S_2P(OMe)_2\}_2 \cdot PPh_3]$ [16]. The longer axial Co–S bonds are accompanied by relatively shorter S(2)–P(1) and S(4)–P(2) bonds (ave. 1.960(2) Å) than the

Table 1
IR spectral data (cm^{-1}) for the pyridine adducts of the bis(*O,O′*-ditolyl/dibenzyl dithiophosphato)cobalt(II) complexes[a] and the bis(dibenzyl dithiophosphato)cobalt(II) complex.

[a] *Key*: s = strong, m = medium, w = weak.

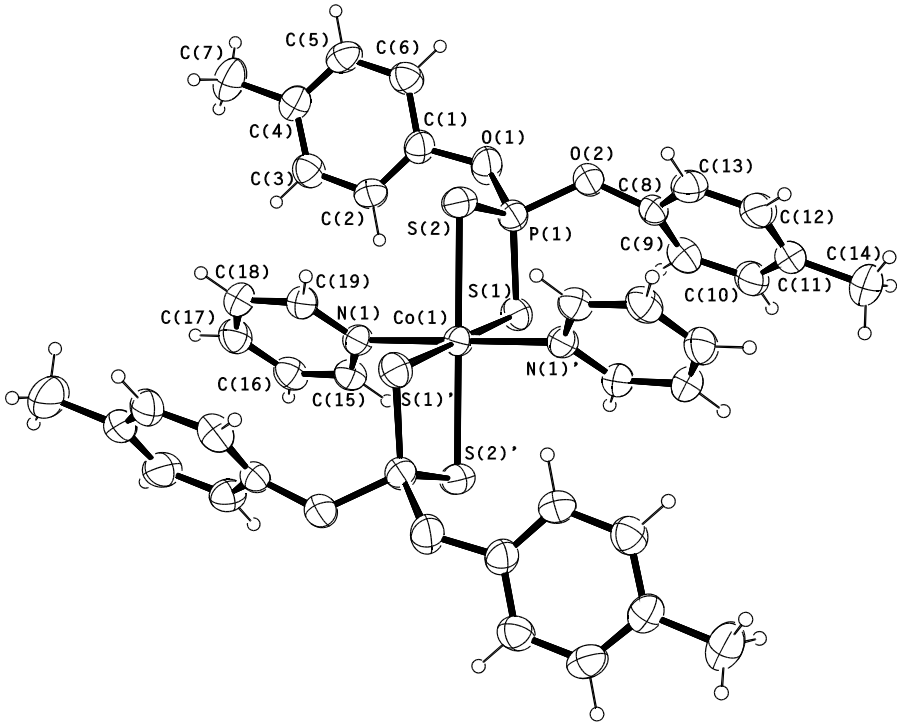

Fig. 1. ORTEP plot of the molecule $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$. The non-hydrogen atoms are drawn with 30% probability ellipsoids.

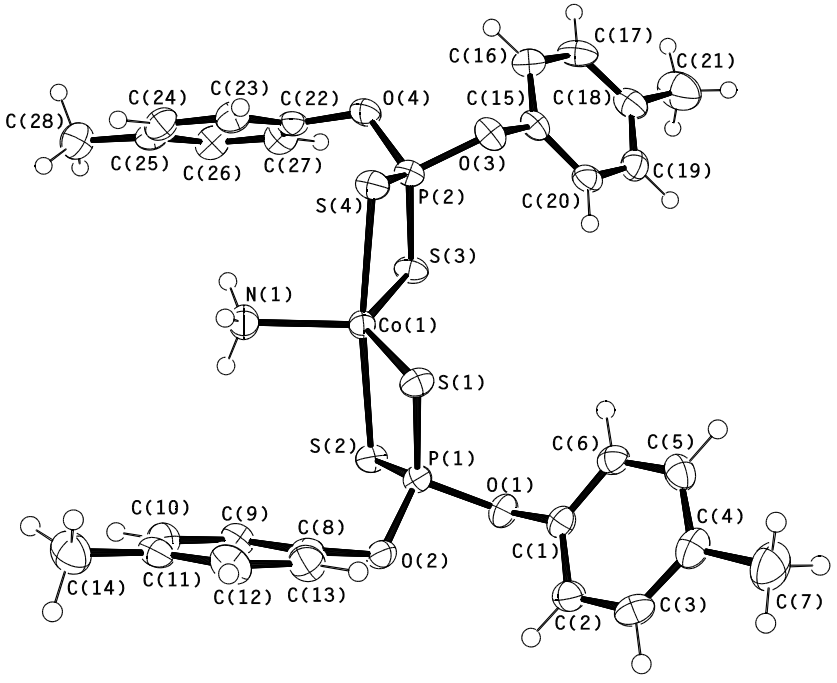

Fig. 2. ORTEP plot of $[Co\{S_2P(OC_6H_4CH_3\text{-}p)_2\}_2(NH_3)]$. The non-hydrogen atoms are drawn with 50% probability ellipsoids.

S(1)–P(1) and S(3)–P(2) bonds (ave. 1.994(9) Å) that accompany the shorter Co–S equatorial bonds. Similar trends were observed in $[Co\{S_2P(OMe)_2\}_2 \cdot PPh_3]$ [16].

When a monodentate coordinating moiety is sterically hindered, 5-coordinated Co(II) adduct formation is seen, viz. $[Co\{S_2P(OMe)_2\}_2 \cdot PPh_3]$ [16], as observed in **6**. NH_3 is a very small molecule but it may need considerable space for its coordination sphere. However, two molecules of monodentate coordinating ligands can be attached to Co(II) complexes when the coordinating moiety is planar (as in pyridine), viz. $[Co\{S_2P(OEt)_2\}_2(C_5H_5N)_2]$ [19].

In the octahedral complex **3**, there are again two sets of Co–S bonds, Co(1)–S(1) and Co(1)–S(1)′ (2.5053(8) Å) and Co(1)–S(2) and Co(1)–S(2)′ (2.5735(8) Å), although the differences are much smaller. There are no obvious signs of secondary interactions involving the sulfur atoms to account for the difference, so possibly it is indicative of a slight tetragonal distortion along the S(2)–Co(1)–S(2)′ axis; the one with the weakest bonds. The average

distance of all four Co–S bonds of 2.54(5) Å is comparable with the average Co–S distance of 2.52(2) Å reported in $[Co\{S_2P(OEt)_2\}_2(C_5H_5N)_2]$ [19].

In **3**, not unexpectedly, the longer Co(1)–S(2) bonds, are accompanied by relatively shorter S(2)–P(1) bonds (1.970(1) Å) and the shorter Co(1)–S(1) bonds by longer P(1)–S(1) bonds (1.974(1) Å). The P–O distances in **3** (ave. 1.599(2) Å), **6** (ave. 1.598(4) Å), $[Co\{S_2P(OEt)_2\}_2(C_5H_5N)_2]$ [19] (ave. 1.593(1) Å) and $[Co\{S_2P(OEt)_2\}_2(C_{24}H_{26}N_4O_2)]$ [21] (ave. 1.596(9) Å) are similar, regardless of their environment.

In **6**, the three angles in the equatorial plane, N(1)–Co(1)–S(1), N(1)–Co(1)–S(3) and S(1)–Co(1)–S(3) of 112.42(6)°, 112.96(6)° and 134.58(3)°, respectively, sum to exactly 360° as expected. The S(2)–Co(1)–S(4) angle of 172.23(2)° is not so far from 180°, given the planarity of the equatorial bonds and the requirements of the bite angles of the ligands, S(1)–Co(1)–S(2) and S(3)–Co(1)–S(4) of 83.88(2)° and 83.48(2)°, respectively In **3**, with the three 180° angles required by symmetry, the S(1)–Co(1)–S(2) and S(1)′–C(1)–S(2)′ bite angles (80.18(3)°) and the S(1)–Co(1)–S(2)′ and S(1′–Co(1)–S(2)′ (99.82(3)°) inter-ligand angles show the greatest deviation from 90°, the N–Co–S bond angles in the range of 88.82(6)–91.23(6)° showing only slight variation from a regular octahedral geometry.

3. Experimental

All chemicals (Emerk) were used after purification and solvents were dried before use by standard methods. $CoCl_2(C_5H_5N)_2$ was prepared by the reported method [30]. Literature methods were used for the preparation of the *O,O′*-ditolyl dithiophosphoric acids [29]. *O,O′*-dibenzyl dithiophosphoric acid was prepared by the reaction of P_2S_5 and benzyl alcohol in a 1:4 molar ratio. The ammonium salts of these dithiophosphoric acids were prepared by the reaction of the parent acids with an equimolar amount of ammonia in benzene. Cobalt and Sulfur were estimated by pyridine thiocyanate and Messenger's methods, respectively. Electronic spectra were recorded on a Perkin–Elmer UV–Vis–NIR spectrometer in pyridine (**1–4**) and dichloromethane (**5**). Infrared spectra were recorded on a Perkin–Elmer 983G spectrometer as Nujol mulls between CsI discs over the range 4000–180 cm^{-1}.

3.1. Preparations

3.1.1. $[Co\{S_2P(OC_6H_4Me\text{-}o)_2\}_2(C_5H_5N)_2]$ (**1**)

Typically, $CoCl_2(C_5H_5N)_2$ (0.254 g, 0.882 mmol) was dissolved in methanol (30 mL) and then a solution of $NH_4S_2P(OC_6H_4Me\text{-}o)_2$ (0.579 g, 1.825 mmol) in methanol (20 mL) was added, followed by refluxing for 1 h. The dark-pink precipitate that formed was filtered, washed and dried in vacuo. Yield: 0.644 g (87%); Calc. for $C_{38}H_{38}O_4N_2P_2S_4Co$: N, 3.35; S, 15.35; Co 7.05. Found: N, 3.40; S, 15.12; Co 6.94%; UV–Vis electronic absorption spectral data [$\lambda_{max.}$, nm(A); ε(L mol^{-1})] in 0.01 M pyridine solution 525(44), 653(42), 746(25), 915(31), 1126(22); μ_{eff} 4.91 B.M.

3.1.2. $[Co\{S_2P(OC_6H_4Me\text{-}m)_2\}_2(C_5H_5N)_2]$ (**2**)

Prepared as for $[Co\{S_2P(OC_6H_4Me\text{-}o)_2\}_2(C_5H_5N)_2]$. Yield: 0.544 g (71%); Calc. for $C_{38}H_{38}O_4N_2P_2S_4Co$: N, 3.35; S, 15.35; Co 7.05. Found: N, 3.23; S, 15.11; Co 7.14%; UV–Vis electronic absorption spectral data [$\lambda_{max.}$, nm(A); ε(L mol^{-1})] in 0.004 M pyridine solution 522(155), 574(147), 610(143), 642(135), 1138(120); μ_{eff} 4.87 B.M.

3.1.3. $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ (**3**)

Prepared as for $[Co\{S_2P(OC_6H_4Me\text{-}o)_2\}_2(C_5H_5N)_2]$. Yield: 0.531 g (76%); Calc. for $C_{38}H_{38}O_4N_2P_2S_4Co$: N, 3.35; S, 15.35; Co 7.05. Found: N, 3.44; S, 15.53; Co 7.22%; UV–Vis electronic absorption spectral data [$\lambda_{max.}$, nm(A); ε(L mol^{-1})] in 0.008 M pyridine solution 520(87), 568(80), 632(77), 715(60), 1033(57); μ_{eff} 5.0 B.M.

3.1.4. $[Co\{S_2P(OCH_2C_6H_5)_2\}_2(C_5H_5N)_2]$ (**4**)

Prepared as for $[Co\{S_2P(OC_6H_4Me\text{-}o)_2\}_2(C_5H_5N)_2]$. Yield: 0.531 g (76%); Calc. for $C_{38}H_{38}O_4N_2P_2S_4Co$: N, 3.35; S, 15.35; Co 7.05. Found: N, 3.29; S, 15.49; Co 7.12%; UV–Vis electronic absorption spectral data [$\lambda_{max.}$, nm(A); ε(L mol^{-1})] in 0.0057 M pyridine solution 500(135), 523(133), 668(98), 1038(114). μ_{eff} 4.95 B.M.

3.1.5. $[Co\{S_2P(OCH_2C_6H_5)_2\}_2]$ (**5**)

$CoCl_2 \cdot 6H_2O$ (0.289 g, 1.215 mmol) and $NH_4S_2P(OCH_2C_6H_5)_2$ (0.798 g, 2.437 mmol) were added to toluene (30 mL) and the solution was stirred for 30 min to give a blue solution which was concentrated before the addition of hexane (10 mL). The blue solid that formed was filtered, washed with hexane and dried in vacuo. Yield 0.539 g, (66%). Calc. for $C_{28}H_{28}O_4P_2S_4Co$; S, 18.93; Co, 8.70. Found: S, 18.64; Co, 8.57%; UV–Vis electronic absorption spectral data [$\lambda_{max.}$, nm(A); ε(L mol^{-1})] in 0.01 M in dichloromethane solution 579(57), 613(55), 635(49), 1043(35); μ_{eff} 4.34 B.M.

3.2. Crystallography

A purple block crystal of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ (**3**), and a blue block crystal of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$ **6** were mounted on glass fibres. Data for **3** were collected on a Siemens SMART System CCD diffractometer with the collection of a hemisphere of data in 1329 frames with 10 s exposure times. Data for **6** were collected on a Bruker-Nonius Kappa CCD area detector diffractometer, with ϕ and ω scans chosen to give a complete asymmetric unit. Cell refinements [31] gave cell constants corresponding to monoclinic cells for both, whose dimensions

are given in Table 2 along with other experimental parameters. An absorption correction was applied [32].

The structures were solved by direct methods [33] and were refined using the WINGX version [34] of SHELX-97 [35]. All of the non-hydrogen atoms were treated anisotropically. Hydrogen atoms were included in idealized positions with isotropic thermal parameters set at 1.2 times that of the carbon atoms to which they were attached. The final cycle of full-matrix least-squares refinement was based on 3418 (for **3**) and 7184 (for **6**) observed reflections, 2629 with $F^2 > 4\sigma(F^2)$ for **3** and 4823 with $F^2 > 4\sigma(F^2)$ for **6** and 234 (for **3**) and 365 (for **6**) variable parameters, and converged (the largest parameter shift was 0.001 times its esd).

The structure **6** is pseudo symmetric with a possible higher symmetry space group of $C2/c$. However refinement in $C2/c$ leads to physically less reasonable thermal parameters and the structure has therefore been left in $P2_1/n$. Selected distances and bond angles are given in Tables 3 and 4 and the molecules are displayed as an ORTEP diagrams in Figs. 1 and 2, respectively.

4. Conclusion

We have prepared and characterized the following complexes, $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ (R = *o*-, *m*-, *p*-C_6H_4Me, $CH_2C_6H_5$) and $Co[S_2P(OCH_2C_6H_5)_2]_2$. The IR and UV–Vis spectra and magnetic moments of these compounds are consistent with the proposed distorted octahedral structure. The molecular structures of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ (**3**) and $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$ (**6**) were determined to have distorted octahedral and distorted trigonal bipyramidal geometries, respectively, around the central cobalt atom.

ABSTRACT

The chiral diimine ligand C_5H_4N-2-C(C_6H_5)=N{(1*S*,2*S*)-C_5H_8-2-$OCH_2C_6H_5$)} (**1**) was prepared via the reaction of 2-benzoyl pyridine and (1*S*,2*S*)-(+)-2-benzyloxycyclopentylamine. **1** (=L) reacts with $M(CO)_6$ in toluene to give the respective metal(0) complexes [$M(CO)_4$(L-κ *N*,*N*′)] (M = Mo (**2**) and W(**3**)). **1**–**3** were fully characterized by elemental analyses, IR, multinuclear NMR spectroscopy and MS. The complexes **2** and **3** are isostructural and crystallize in the chiral hexagonal space group $P3_1$ with three molecules in the unit cell.

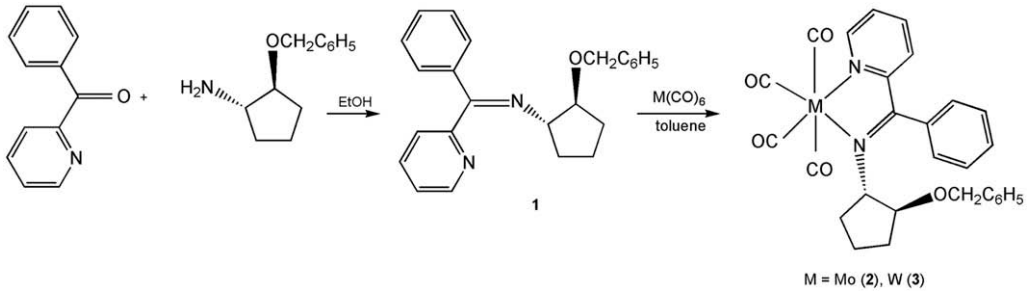
1. Introduction

The chemistry of Mo^0 and W^0 diimine complexes has attracted much attention due to the catalytic role of these compounds in allylic alkylations, metal–ligand charge transfer transitions, and due to their luminescence properties [1–7]. Especially molybdenum(0)-catalyzed allylic alkylations which show excellent chemoselectivity due to the high coordination number of molybdenum have been widely studied [7], and several Mo^0 and W^0 carbonyl diimine complexes have already been described [1,8–23]. A series of *meso* and C_2-symmetric tetracarbonyl Mo^0 and W^0 diimines was also reported [24], but the number of enantiomerically pure complexes is still small. Thus, the chiral molybdenum(0) and tungsten(0) carbonyl diimine complexes [$M(CO)_4C_5H_4NC(R)$=NCH(Me)Ph] (M = Mo, W; R = H, Me) and [$Mo(CO)_4C_9H_7NCH$=NCH(Me)Ph] were prepared, but their stereochemistry was discussed only on the basis of NMR data, and no X-ray data are available [1]. Examples of enantiomerically pure, structurally characterized complexes include (μ_2-*trans*-1,2-bis(2-pyridylmethylimine)cyclohexane-*N*,*N*′,*N*″,*N*‴)octacarbonyldimolybdenum dichloromethane solvate [25], tetracarbonyl-(*N*-(2-pyridylmethylene)-β-alanylvaline methyl ester-*N*,*N*′)tungsten [9] and piperidinium (*N*-(2-pyridylmethylene)-L-alanato)tetracarbonylmolybdenum [26].

In this paper, we report the synthesis and molecular structures of molybdenum(0) (**2**) and tungsten(0) (**3**) tetracarbonyl complexes containing the new chiral diimine ligand C_5H_4N-2-C(C_6H_5)=N{(1*S*,2*S*)-C_5H_8-2-$OCH_2C_6H_5$)} (**1**).

2. Results and discussion

2.1. Synthesis and characterization of the diimine ligand and its Mo^0 and W^0 complexes



The ligand C_5H_4N-2-C(C_6H_5)=N{(1*S*,2*S*)-C_5H_8-2-$OCH_2C_6H_5$)} (**1**) has been synthesized by condensation of 2-benzoyl pyridine and (1*S*,2*S*)-(+)-2-benzyloxycyclopentylamine in ethanol (Scheme 1). **1** was obtained as a pure yellow oil which was characterized by elemental analyses, IR, multinuclear NMR spectroscopy and MS (see Section 3). The ^1H and ^{13}C NMR spectrum of **1** confirm the formation of the diimine ligand, but exhibit two sets of signals corresponding to the *cis* and *trans* isomer. The EI mass spectrum shows the molecular ion peak at m/z = 356, and in the IR spectrum the characteristic C=N band is observed at 1665 cm^{-1}. These results are in good agreement with the experimental data reported before for similar compounds [13,27,28].

The corresponding Mo^0 and W^0 complexes were prepared by reaction of **1** with $M(CO)_6$ (M = Mo and W) in toluene (Scheme 1).

Complexes **2** and **3** were obtained as dark purple or blue crystals, respectively, in 55% or 46% yield. The ^1H NMR spectra show six multiplets between 1.4 and 2.8 ppm corresponding to the protons of the cyclopentyl ring. Three multiplets between ca. 4.0 and 5.0 ppm were assigned to the methine groups of the cyclopentyl ring and to the methylene group of the benzyl ligand, and a set of several multiplets between ca. 7.0 and 9.3 ppm corresponds to the aromatic protons of the phenyl and pyridyl groups. The carbonyl region of the ^{13}C NMR spectra exhibits four signals due to

doi:10.1016/j.poly.2008.10.004

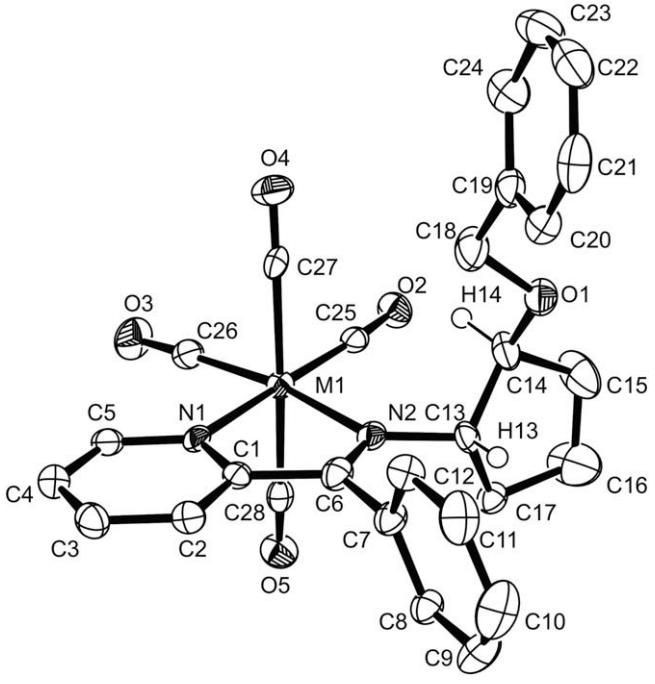
Scheme 1.

the presence of four inequivalent CO groups (203.5, 203.8, 222.3, 223.5 ppm for **2** and 199.1, 199.4, 214.7, 215.9 ppm for **3**). The chemical shift of Mo–CO resonances is typically observed at lower field than in the corresponding W–CO complexes [10,11]. The IR spectra of **2** and **3** display the characteristic absorption bands attributed to ν(CN) and the four CO stretching frequencies which are expected for these chiral molecules. The mass spectra (FAB) show the molecular ion peaks of **2** (m/z = 566) and **3** (m/z = 652).

2.2. Molecular structure of *2* and *3*

Complexes **2** and **3** crystallize in the chiral hexagonal space group $P3_1$ with three molecules in the unit cell. A disordered toluene molecule is also present in the asymmetric unit. The crystal structures of **2** and **3** are isotypical and isostructural (Fig. 1). In **2** and **3** the central atom (Mo or W) has an octahedral coordination with a chelating *cis*-diimine ligand and four carbonyl ligands. Due to the observed yields of 55% (**2**) and 46% (**3**) we assume that only the *cis* isomer of the diimine reacts and that isomerization of *trans* to *cis* is probably slow.

The M–N bond lengths (225.7(4) and 222.9(4) pm for **2** and 221.2(3) and 224.2(3) pm for **3**) are in the range observed for similar molybdenum and tungsten complexes [12,29], and the M–C



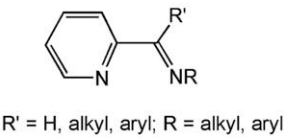


Fig. 1. Molecular structure of complex **2** with thermal ellipsoids at 50% probability level, hydrogen atoms, except at chiral centres, and a toluene molecule have been omitted for clarity. The tungsten complex **3** is isostructural and isotypical.

Scheme 2.

bond lengths (194.0(5), 194.6(6), 202.5(5) and 204.8(5) pm for **2** and 194.5(6), 195.3(5), 200.8(5) and 204.0(5) pm for **3**) are, as expected, similar to those observed in related molybdenum and tungsten carbonyl complexes [1]. The carbonyl ligands are nearly linear with M–C–O bond angles close to 180°. The five-membered MN_2C_2 ring (M1, N1, C1, C6 and N2) is almost planar (max. deviations from plane ca. 6 pm). The C–M–C bond angles of *cis*-CO groups are close to 90°, the C–M–C bond angle for the *trans* CO ligands deviate slightly from linearity (C27–Mo1–C28 171.3(2)° for **2** and C27–W1–C28 171.1(2)° for **3**). The short N1–C1 (135.4(5) for **2** and 136.0(5) for **3**) and N2–C6 bonds (132.0(5) for **2** and 129.9(5) for **3**) indicate multiple bond character, while the C1–C6 bond length (147.1(6) for **2** and 146.8(5) pm for **3**) is typical for a C–C single bond.

Several other pyridyl-based diimine molybdenum and tungsten tetracarbonyl complexes with the type of diimine ligand shown in Scheme 2 have been structurally characterized and have similar structural features as complexes **2** and **3** [8,9,14–23,25,26,29].

3. Experimental

3.1. General remarks

When necessary, experiments were performed under an atmosphere of dry nitrogen using standard Schlenk techniques. The NMR spectra were recorded on a Bruker AVANCE DRX 400 spectrometer. ^{1}H NMR (400.13 MHz): internal standard solvent, external standard TMS; ^{13}C NMR (100.16 MHz): external standard TMS; IR spectra: KBr pellets were prepared in a nitrogen-filled glove box and the spectra were recorded with a Perkin–Elmer System 2000 FTIR spectrometer in the range 350–4000 cm^{-1}. FAB MS spectra were recorded with a MASPEC II spectrometer with 3-nitrobenzyl alcohol as matrix. EI MS spectra were recorded with a MAT-8230. All solvents were purified by distillation, dried and saturated with nitrogen. Elemental analyses were determined with a VARIO EL (Heraeus) and LECO-CHNS-O. Melting points (Gallenkamp) are uncorrected. $Mo(CO)_6$, $W(CO)_6$ and 2-benzoyl pyridine and (1*S*,2*S*)-(+)-2-benzyloxycyclopentylamine are commercially available.

3.2. X-ray crystallography

Data for **2** and **3** were collected on a CCD Oxford Xcalibur S (λ(Mo Kα) = 0.71073 Å) in ω and ϕ scans mode. Semi-empirical

from equivalents absorption corrections were carried out with SCALE3 ABSPACK [30]. The structures were solved with direct methods [31]. The structure refinements were carried out with SHELXL-97 [32]. All non-hydrogen atoms were refined anisotropically; H atoms were located in difference maps and refined isotropically. Crystallographic data for **2** and **3** are given in Tables 1 and 2.

3.3. Synthesis of C_5H_4N-2-$C(C_6H_5)$=N{(1S,2S)-C_5H_8-2-$OCH_2C_6H_5$)} (**1**)

2-Benzoyl pyridine (1.83 g, 10.00 mmol) was dissolved in EtOH (25 mL) and (1*S*,2*S*)-(+)-2-benzyloxycyclopentylamine (1.91 g, 10.00 mmol) was added dropwise via syringe. The reaction mixture was refluxed for 2 h. The solvent was then removed under vacuum to yield a yellow oily product. Yield 3.14 g (88%). *Anal.* Calc. for $C_{24}H_{24}N_2O$: C, 80.87; H, 6.79; N, 7.86. Found: C, 79.89; H, 6.17; N, 7.39%. ABSTRACT

A coordination polymer $\{[Mn(3\text{-pyt})_2(H_2O)_2][N(n\text{-Bu})_4]^+[3\text{-pyt}]^-\}_n$ (**3**) has been synthesized from the reaction of tetra-*n*-butylammonium[5-(3-pyridyl)-1,3,4-oxadiazole-2-thiolate] $\{[N(n\text{-Bu})_4]^+[3\text{-pyt}]^-\}$ and $Mn(OAc)_2 \cdot 4H_2O$. The ligand and the Mn(II) complex **3** have been characterized by elemental analyses, IR, ^1H and ^{13}C NMR spectroscopy, in addition **3** has also been studied crystallographically. The single crystal X-ray structure of the **3** shows that the ligand is bonded to Mn(II) via its pyridyl and oxadiazole nitrogen atoms. This bonding pattern connects the Mn(II) centres to afford an uniform two dimensional coordination frame work where the $[Mn(3\text{-pyt})_2(H_2O)_2]_n$ molecules are stacked in a parallel layers. The overall arrangement of molecules in crystal lattice results in open channels in which the enclosed tetra-*n*-butylammonium cations are stabilized by anionic oxadiazole molecules through $N^+\cdots S^-$ ionic interactions.

1. Introduction

There has been a considerable interest in the coordination polymers of 1,3,4-oxadiazole-2-thione because of their interesting role in supramolecular chemistry and crystal engineering [1–3]. This type of metal–organic framework with intriguing network structures [4–6] find potential applications in catalysis [7], gas storage [8] and photoluminescence [9,10]. Recently, pyridyl oxadiazoles have been systematically explored for their potential biological activities [11] and also as promising bridging ligands in coordination chemistry [12–14]. The design and assembly of supramolecular architectures with variable cavities or channels are currently of great interest owing to their novel topologies [15–17]. There are a few reports on the metal complexes of 5-phenyl-1,3,4-oxadiazole-2-thione [18–21], 5-(4-pyridyl)-1,3,4-oxadiazole-2-thione [12–14,22], 5-(2-pyridyl)-1,3,4-oxadiazole-2-thione [10] and 5-(3-pyridyl)-1,3,4-oxadiazole-2-thione [23]. The reported works mostly describe the coordination chemistry of symmetric bridging ligands used in the construction of network structures leading to porous coordination polymers [24]. Contrary to symmetrical bridging ligands, there is scanty of information on the coordination polymers of unsymmetrical organic ligands [12–14]. These unsymmetrical bridging ligands may show four types of binding modes involving monodentate (N_{oxo}) (I), bidentate (N_{py}, N_{oxo} or N_{py}, S) (II), tridentate (N_{py}, N_{oxo}, S) (III) and tetradentate (N_{py}, N_{oxo},S, S) (IV) as shown in Fig. 1. Such a type of multidentate module has been envisaged as useful building block for constructing coordination polymers [12]. As a part of our ongoing studies on metal complexes of unsymmetrical 1,3,4-oxadiazoles [18,23], we report herein the preparation, spectroscopic characterization of a new unsymmetrical heterocyclic oxadiazole bridging ligand $\{[N(n\text{-Bu})_4]^+[3\text{-pyt}]^-\}$ (**2**) and its Mn(II) complex **3**. Molecular structure of **3** has also been elucidated by X-ray crystallography.

2. Experimental

2.1. Materials and methods

All commercially available starting materials (analytical grade) were used as received and all experiments were carried out in open atmosphere. Nicotinamide was purchased from Sigma Aldrich and used as such. Carbon disulfide and hydrazine hydrate (SD fine Chemicals, India) and the solvents (Merck Chemicals, India) were used in the syntheses. Nicotinic acid hydrazide was synthesized according to the reported method [25].

2.2. Synthesis

2.2.1. Synthesis of potassium[N-(pyridine-3-carbonyl)-hydrazinecarbodithioate] $K^+(H_2L^-)$ (*1*)

$K^+(H_2L^-)$ was synthesized by the dropwise addition of CS_2 (4 ml, 53 mmol) to a solution of nicotinic acid hydrazide (7 g, 51 mmol)

and KOH (2.86 g, 51 mmol) in 35 ml of methanol (MeOH). The mixture was stirred continuously for 2 h at room temperature, thereafter the precipitated product was filtered off, washed twice with diethyl ether, m.p. 525 K. The analytical and spectroscopic data of **1** were identical to that reported previously [23].

*2.2.2. Synthesis of {[N(n-Bu)$_4$]$^+$[3-pyt]$^-$} (**2**)*

Potassium[N-(pyridine-3-carbonyl)-hydrazinecarbodithioate] (5.6 g, 22.5 mmol) was dissolved in a EtOH–H_2O mixture (75:25 v/v) (30 ml) and to it was added an EtOH solution (30 ml) of tetra-*n*-butylammonium bromide (7.2 g, 22.5 mmol). The resulting dirty yellow solution was concentrated at room temperature to afford the solid product. The separated solid was dissolved in a minimum amount of EtOH (25 ml) and water was added drop wise until the impurities settled down. The solution was decanted off and after evaporation of the solvent, a white solid product was obtained, m.p. 343 K (yield 3.60 g, 64%). Anal. Calc. for $C_{23}H_{40}N_4OS$ (420.66): C, 65.67; H, 9.58; N, 13.32; S, 7.62. Found: C, 65.73; H, 9.55; N, 13.46; S, 7.50%. IR (KBr, ν cm^{-1}): 1591 ν(C=N), 1188 ν_{as}(C–O–C), 1134 ν_s(C–O–C), 1035 ν(N–N), 905 ν(C–S); pyridine ring 626; ^{1}H NMR ($CDCl_3$, δ ppm): 7.35, 8.22, 8.59, 9.19 (4H, pyridine ring), 2.14 (m, 8H, CH_2 of N(*n*-Bu)$_4$), 1.63 (m, 8H, CH_2 of N(*n*-Bu)$_4$), 1.46 (m, 8H, CH_2 of N(*n*-Bu)$_4$), 0.97 (12H, CH_3 of N(*n*-Bu)$_4$); ^{13}C NMR ($CDCl_3$, δ ppm): 180.38 (C1), 160.21 (C2), 123.41 (C3), 132.66 (C4), 122.16 (C5), 146.93 (C6), 149.99 (C7), 58.97 (C11, C21, C31,C41), 24.06 (C12, C22, C32, C42A), 20.80 (C13, C23, C33, C43), 13.70 (C14, C24, C34, C44) (Ref. Fig. 4). UV–Vis [λ_{max}, MeOH, nm]: 322, 224. The tentative structure of the ligand based on the physico-chemical studies is shown in Fig. 2.

*2.2.3. Synthesis of the complex {[Mn(3-pyt)$_2$(H$_2$O)$_2$][N(n-Bu)$_4$]$^+$[3-pyt]$^-$}$_n$ (**3**)*

A methanolic solution (10 ml) of [$Mn(OAc)_2 \cdot 4H_2O$] (.249 g, 1 mmol) was mixed with the ethanolic solution (10 ml) of {[N(*n*-Bu)$_4$]$^+$[3-pyt]$^-$} (1.26 g, 3 mmol). The resulting yellow solution was filtered off and kept for crystallization. After 10 days, yellow crystals of **3** suitable for an X-ray crystallographic study were obtained.

Yellow crystals. *Anal.* Calc. for $C_{37}H_{52}MnN_{10}O_5S_3$ (868.01): C, 51.20; H, 6.04; N, 16.14; S, 11.08; Mn, 6.33. Found: C, 51.28; H, 6.10; N, 16.20; S, 11.12; Mn, 6.29%. μ_B = 5.93 BM. UV–Vis [λ_{max}, MeOH, nm]: 834, 434, 342, 298.

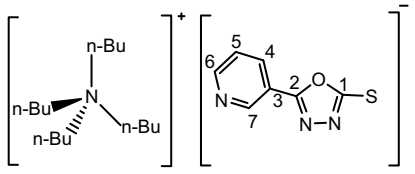

Fig. 2. Tentative structure of the ligand {[N(*n*-Bu)$_4$]$^+$[3-pyt]$^-$} (**2**).

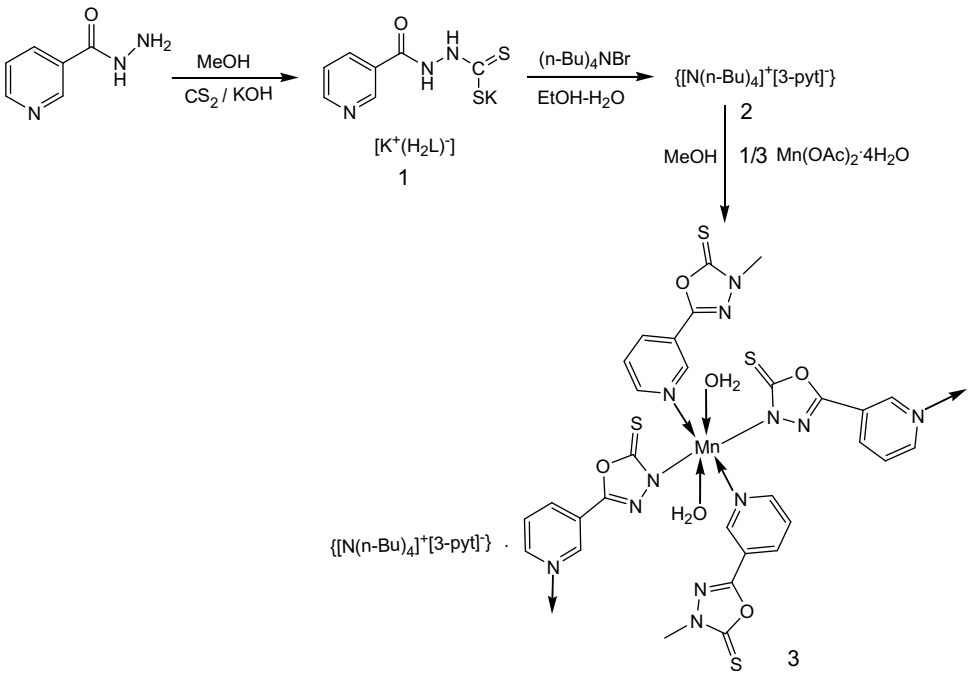
3. Analyses and physical measurements

Carbon, hydrogen, nitrogen and sulfur contents were estimated on a CHN Model CE-440 Analyzer and on an Elementar Vario EL III. Magnetic susceptibility measurement was performed at room temperature on a Cahn Faraday balance using Hg[Co(NCS)$_4$] as the calibrant and the electronic spectra were recorded on a UV-1700 Pharmaspec spectrophotometer. By following standard procedures, the complex was analyzed for its manganese content, after decomposition with a mixture of conc. HNO_3 and HCl, followed by conc. H_2SO_4 [26]. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a Varian 3100 FT-IR Excalibur series. ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ on a JEOL AL300 FT NMR spectrometer using TMS as an internal reference.

4. Crystal structure determination



X-ray single crystal refinement, diffraction data collection and data reduction for complex **3** were performed at 295(2) K with a graphite monochromated Mo Kα (λ = 0.71073 Å) radiation source using standard methods [27].

The structure was solved by direct methods (SHELX-97) and refined against all data by full-matrix least-squares on F^2 using anisotropic displacement parameters for all non-hydrogen atoms. All H atoms attached to C atoms were fixed geometrically and treated as riding with C–H = 0.98 Å (methyl), 0.97 Å (methylene) and 0.93 Å (aromatic) with U∼iso∼(H) = 1.2U∼eq∼(C) or 1.2U∼eq∼(methyl). H atoms of water molecules were initially located in difference Fourier maps and included in the subsequent refinement using restraints (O–H = 0.82(1) Å and H···H = 1.38(2) Å with U∼iso∼(H) = 1.5U∼eq∼(O). In the last stages of refinement they were treated as riding on their parent O atoms. One of the propyl groups is disordered over two positions with occupancy factors in the ratio 0.57/0.43. The occupancy factor has been determined by refining, in the first stage of refinement, a free variable fixing the two occupancies factor to sum to 1.0 and attributing all the disordered atoms a dummy isotropic temperature factor (2nd free variable). The atomic positions were refined using distances and angles restraints with the tools (PART and SAME) available in SHELXL-97. Once the occupancy factors were determined, they were fixed and the isotropic temperature factors were freely refined. In the last stages of refinement, the atomic positions were refined with anisotropic temperature factors. The refinement of the Flack's parameter gives a value of 0.55(2). Inverting the absolute structure gave a value of 0.45(2). In such a case, one may consider that the crystal is twinned by inversion and then the two domains were refined using the TWIN instruction in SHELXL-97.

MERCURY package was used for molecular graphics [28]. Crystal structure diagrams were generated by use of the ORTEP-3 for Windows program [29].

5. Results and discussion

The reaction of tetra-*n*-butylammonium[5-(3-pyridyl)-1,3,4-oxadiazole-2-thiolate] {[N(*n*-Bu)$_4$]$^+$[3-pyt]$^-$} (**2**) with $Mn(OAc)_2 \cdot 4H_2O$ in a 3:1 molar ratio generates a polymeric complex with

Scheme 1. Preparation of the ligand **2** and its Mn(II) complex.

the general formula $\{[Mn(3\text{-pyt})_2(H_2O)_2][N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}_n$ (Scheme 1) which has been confirmed by X-ray crystallography. The X-ray data show that the ligand is bridged between two Mn(II) centres via one pyridyl nitrogen and one oxadiazole nitrogen forming a novel coordination polymer. The ligand $\{[N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}$ (**2**) and the Mn(II) complex **3** are soluble in common organic solvents and are air stable.

5.1. IR spectra

The IR spectrum of compound **3** reveals five characteristics bands due to ν(C=N), ν(N–N), ν_{as}(C–O–C), ν_s(C–O–C) and ν(C–S) at 1612, 1084, 1196, 1156 and 942 cm^{-1} respectively. The IR spectra of **2** and **3** are devoid of any peak in the region of 3300–3200 cm^{-1} indicating the absence of –NH group.

The IR spectrum of compound **3** shows a positive shift of 49 cm^{-1} in ν(N–N) region due to the bonding of oxadiazole nitrogen atom to the metal ion. A further positive shift of 37 cm^{-1} in thioamide IV indicates a change of the C–S bond to C=S during complex formation. Thus ligand **2** adopts thiolato form in the free state but is present in the thione form in complex **3.** A band occurring at 3442 cm^{-1} shows the presence of water molecule(s) in the complex. A positive shift of 16 cm^{-1} in the pyridine ring vibration of the complex in comparison to the free ligand **2** suggests involvement of pyridine nitrogen in bonding with Mn(II).

The above IR data clearly indicates the participation of oxadiazole and pyridine nitrogens in bonding, conversion of the thiolato form of the ligand **2** to the thione form and the presence of water molecule(s), all of which are supported by X-ray analysis. The IR spectral bands of the co-crystallized part of the complex **3** are observed at 1584 ν(C=N), 1196 and 1134 ν(C–O–C), 1034 ν(N–N) and 901 cm^{-1} ν(C–S) which are very close to the corresponding bands of $[3\text{-pyt}]^-$ except that of the pyridine ring vibration. The pyridine ring vibration of co-crystallized $\{[N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}$ observed at 642 cm^{-1} shows a positive shift of 16 cm^{-1} in comparison to **2** due to the presence of hydrogen bonding between the pyridine nitrogen and hydrogen of water molecule.

5.2. Electronic spectra and magnetic moment

The UV–Vis spectrum of $\{[N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}$ (**2**) exhibits bands at 322 and 224 nm attributed to intraligand transitions. The magnetic moment and electronic spectrum of complex **3** suggests its distorted octahedral geometry. The complex $\{[Mn(3\text{-pyt})_2(H_2O)_2][N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}_n$ exhibits a μ_{eff} of 5.93 BM and shows two bands at 834 nm (11 990 cm^{-1}) and 434 nm (23 042 cm^{-1}) assigned to the $^5B_{1g} \rightarrow {}^5A_{1g}$ and $^5T_{2g}$ transitions, respectively, for high spin distorted octahedral Mn(II). The additional high intensity bands at 342 nm (29 240 cm^{-1}) and 298 nm (33 558 cm^{-1}) are tentatively assigned to charge transfer/intraligand transitions [30].

5.3. ^1H and ^{13}C NMR spectra

The ^1H NMR spectrum of $\{[N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}$ exhibits no signals between 10.5 and 13.5 ppm, indicating the absence of NH protons. The protons due to pyridine ring appear as multiplets between 9.19 and 7.35 ppm. The aliphatic protons for $-CH_2$ of tetra-*n*-butylammonium ion are observed at 2.14, 1.74 and 1.68 ppm while those of $-CH_3$ are located at 0.96 ppm. The ^{13}C NMR spectrum of $\{[N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}$ shows 11 peaks for 23 carbon atoms, out of which the signal due to >C–S appears at 180.38 ppm. The signals between 160.21 and 122.16 ppm are assigned the pyridine ring and oxadiazole carbons. The peaks appearing at δ 58.97, 24.06, 19.72 and 13.61 ppm are due to aliphatic carbons of tetra-*n*-butylammonium cation [31].

6. Crystal structure description of $\{[Mn(3\text{-pyt})_2(H_2O)_2][N(n\text{-}Bu)_4]^+[3\text{-pyt}]^-\}_n$

The crystal structure refinement data related to complex **3** are given in Table 1 and the main bond distances and bond angles of **3** are given in Table 2. The hydrogen bonds are listed in Table 3. The various possible binding sites of the ligand are represented in Fig. 1.

Table 1
Crystal refinement parameters of complex **3**.

Parameters	complex **3**
Empirical formula	$C_{37}H_{52}MnN_{10}O_5S_3$

Symmetry transformations used to generate equivalent atoms: #1: $x - 1/2$, $-y + 2$, z; #2: $x + 1/2$, $-y + 1$, z; #3: $x - 1/2$, $-y + 1$, z; #4: $x + 1/2$, $-y + 2$, z.

The X-ray study of complex **3** indicates the following characteristics of the ligand: (i) it exists in thione and thiolato forms (ii) it shows two preferential binding sites i.e. N_{py} (pyridyl nitrogen) and N_{ox} (oxadiazole nitrogen) and (iii) it has strong capability of forming hydrogen bonding i.e. O–H···N(3), O–H···S(1B), O–H···S(1A) and O–H···S#5 (Fig. 3). Single crystal X-ray analyses reveal that the complex **3** possesses a two dimensional (2-D) framework constructed of Mn(II) centres and two [3-pyt]$^-$ ligands. It is very interesting that the [3-pyt]$^-$ part of the ligand adopts a bidentate bridging mode (nitrogen atoms from pyridyl and oxadiazole groups, Fig. 4a). As evident from the bond angles [trans angles ranging from 174.74(8)° to 178.75(9)° and cis angles ranging from 84.57(7)° to 96.32(8)°], the Mn(II) is in a slightly distorted six coordinated octahedral environment formed by two identical oxadiazole N donors [2.265(2) and 2.2703(19) Å for Mn–N(3B) and Mn–N(3A)], and two pyridine N-donors [2.2671(18) and 2.2680(19) Å for Mn–N(1A) and Mn–N(1B)] in equatorial positions, two water molecules [2.1854(19) Å for Mn–O(2W) and 2.2055(18) Å for Mn–O(1W)] in the axial positions (Fig. 4). The two [3-pyt]$^-$ ligands in complex **3** act as bridging ligands, alternately employing oxadiazole or pyridine nitrogen donors to bond to a Mn(II) centre. The [3-pyt]$^-$ ligand is thus bonded in a N_{py}, N_{oxa} bidentate bridged coordination mode. The dihedral angle between the pyridyl plane and the oxadiazole ring is 13.65(2)°. Since all the bonding sites of 3-pyt occupy equatorial positions in the coordination sphere of each Mn, the result is a 2-D sheet in which the molecules are stacked in parallel layers, forming a supramolecular metal–organic framework (Fig. 4b). The coordinated axial water molecules, above and below this sheet, from hydrogen bonds [O–H···S#5 and O–H···N(3) with the occluded [N(*n*-Bu)$_4$]$^+$ and [3-pyt]$^-$ moieties (Fig. 4b). The tetra-*n*-butylammonium cation and oxadiazole anion are enclosed and stabilized in this rectangular cavity through ionic interactions ($N^+ \cdots S^+$) (Fig. 4b). The rectangular cavity formed by one dimensional chain of the complex molecules have a dimension of 9.823 × 13.650 Å^2 [adjacent Mn···Mn separation between inter (13.650 Å) and intra (9.823 Å) chain] (Fig. 4a). The enclosed {[N(*n*-Bu)$_4$]$^+$[3-pyt]$^-$} is stabilized by two types of C–H···π interactions occurring between C–H of tetra-*n*-butylammonium cation [N(*n*-Bu)$_4$]$^+$] and centroid (Cg) of pyridine ring and oxadiazole ring of [3-pyt]$^-$ at the distance of 3.430 Å and 3.334 Å, respectively. There are two types of intermolecular hydrogen bonding, C21-H21B···S#5 = 2.973 Å and C41-H41B···N1 = 2.326 Å which provide stability to the occluded [N(*n*-Bu)$_4$]$^+$ and [3-pyt]$^-$ (Fig. 4b).

The pyridine nitrogen and thiolato sulfur of occluded {[N(*n*-Bu)$_4$]$^+$[3-pyt]$^-$} are also involved in strong intermolecular hydrogen bonding [O–H···N_{py} and O(2W)–H(2W1)···S#5, 1.98 and 2.43 Å, respectively]. Further, the intramolecular hydrogen bonding O(1W)–H(1W1)···S(1B and O(2W)–H(2W2)···S(1A) having the distances of 2.38 and 2.33 Å, respectively, are also observed. These hydrogen bonding interactions add further stability to the overall structure.

A comparison of Mn–N_{py}, Mn–O_{water}, C=S and C=N bond lengths with similar systems show that the values are in good agreement with those reported in literature [32]. The bond lengths of 1,3,4-oxadiazole-2-thione/thiolate are intermediate between single and double bonds and provide evidence for a high degree of delocalization in the ring. The π-electron delocalization in the oxadiazole ring and inter/intra molecular hydrogen bonding interactions contribute to the stabilization of the molecular structure of

Table 3

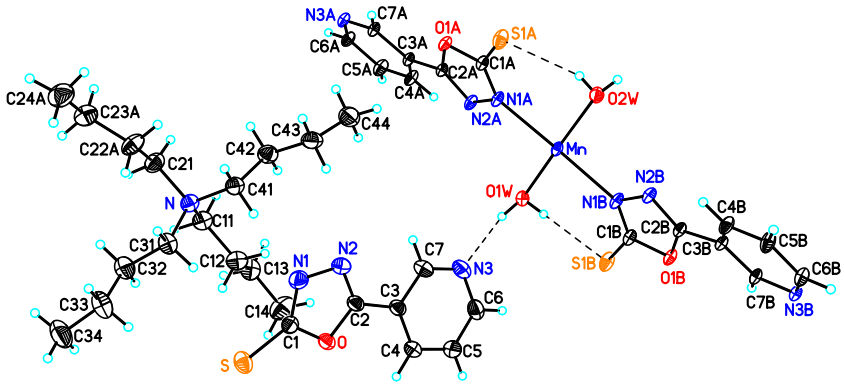

Fig. 3. Structure of the asymmetric formula unit of the complex $\{[Mn(3\text{-pyt})_2(H_2O)_2][N(n\text{-Bu})_4]^+[3\text{-pyt}]^-\}_n$ with the atom numbering scheme, showing O–H···N and O–H···S hydrogen bonding.

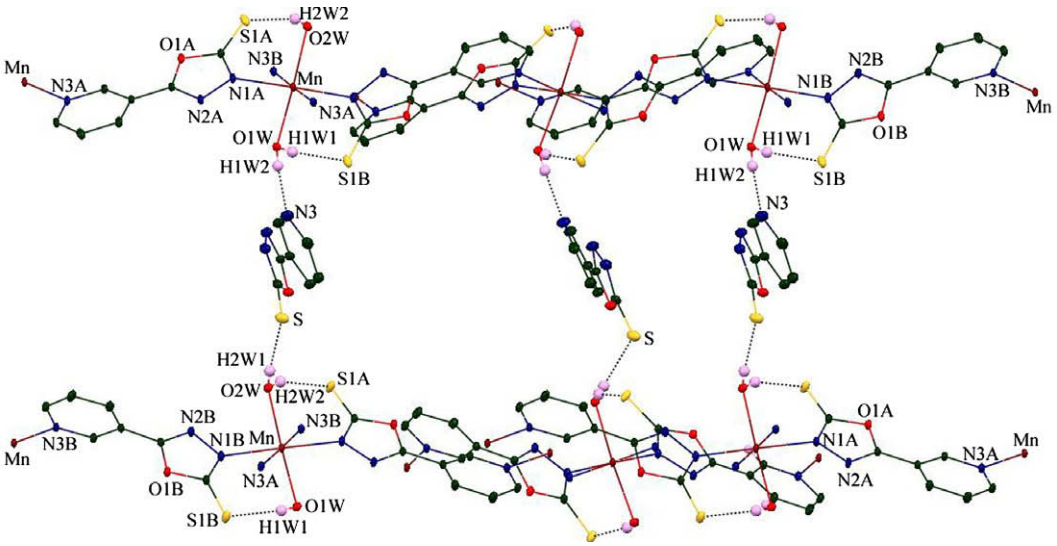

Fig. 4a. Mercury view of the crystal packing of complex **3**, showing O(1W)–H(1W1)···S(1B), O(2W)–H(2W1)···S(1A) intramolecular and O(1W)–H(1W2)···N(3), O(2W)–H(2W1)···S#5 intermolecular hydrogen bonding. Hydrogen atoms are omitted for clarity except those involved in hydrogen bonding.

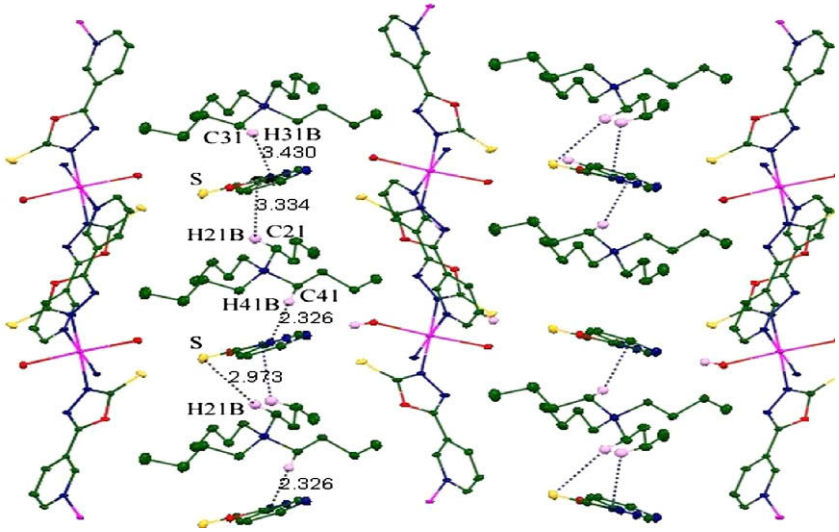

Fig. 4b. The supramolecular architecture of the complex **3,** view along *b* axis. Hydrogen atoms are omitted for clarity. Figure shows C–H···π interaction and C21–H21B···S#5 and C41–H41B···N1 intermolecular hydrogen bonding.

3. The specific arrangement of molecules along the *b* axis, gives rise to the 2-D sheet linked by strong hydrogen bonds formed between the axial water molecules and the occluded $N(n\text{-}Bu)_4]^+$ and $[3\text{-}pyt]^-$ moieties, resulting in a supramolecular architecture.

7. Conclusion

A new polymeric distorted octahedral Mn(II) complex $\{[Mn(3\text{-}pyt)_2(H_2O)_2][N(n\text{-}Bu)_4]^+[3\text{-}pyt]^-\}_n$ is synthesized from an unique ambidentate tetra-*n*-butylammonium [5-(3-pyridyl)-1,3,4-oxadiazole-2-thiolate] in which $[3\text{-}pyt]^-$ adopts the N_{py}, N_{oxa} coordination mode. The hydrogen bonding and arrangement of $[Mn(3\text{-}pyt)_2(H_2O)_2]_n$, along the *b* axis generates a rectangular cavity where tetra-*n*-butylammonium ion is enclosed and stabilized by anionic oxadiazole-2-thiolate through $N^+\cdots S^-$ ionic interaction.

ABSTRACT

Copper(I) complexes of short-bite aminobis(phosphonite), PhN{P(–$OC_{10}H_6$(μ-S)$C_{10}H_6O$–)}$_2$ (**1**) have been synthesized. Reactions of **1** with an excess of CuX (X = Cl, Br, and I) afforded the ligand-bridged binuclear complexes, [PhN(PR-κ*P*)$_2${Cu(μ-X)(MeCN)}$_2$] (**2**, X = Cl; **3**, X = Br; **4**, X = I; R = –$OC_{10}H_6$(μ-S)$C_{10}H_6O$–), whereas treatment with 0.5 equiv. of [Cu(MeCN)$_4$]PF_6 produces the mononuclear bischelated cationic complex, [{PhN(PR-κ*P*)$_2$}$_2$Cu](PF_6) (**5**). Single crystal X-ray structures of complexes **3** and **4** are reported. Complex **3** shows strong π–π stacking interactions between the naphthyl moieties, whereas complex **4** shows ligand-supported Cu···Cu metallophilic interactions.

1. Introduction

Short-bite ligands have drawn considerable attention over the last three decades owing to their novelty in organometallic chemistry and catalytic applications [1]. In such bidentate ligands, the donor atoms are generally separated by a single atom fragment such as CR_2, NR, O or S and can coordinate to metal centers in monodentate, chelating or bridging modes. In mononuclear chelate complexes, the ligand forms a highly strained four-membered ring with conformational rigidity whereas the bridging coordination mode brings the two metal centers into close proximity to facilitate a cooperative metallophilic interaction between two or more metal centers [2f]. Both of these factors, either conformational rigidity or metallophilic interaction, can activate the substrate molecules during catalysis [2]. Among the short-bite ligands, the P–C–P framework *i.e.* bis(diphenylphosphino)methane (dppm) and similar diphosphines has been widely investigated and achieved considerable success [1c,3]. In contrast, although the coordination chemistry of P–N–P framework ligands *i.e.* diphosphazane (or diphosphinoamine) has been well documented [1d,4], their catalytic applications have been much less explored. Recently, Faraone and co-workers have prepared diphosphazane ligands containing a dinaphthyl backbone between the phosphorus centers and used them in the enantioselective palladium-catalyzed allylic substitution reactions and the rhodium catalyzed hydroformylation of styrene [5]. However, diphosphazanes with donor atoms such as O, N or S incorporated into the ligand framework are less well known [6]. The development of such hybrid ligands is of particular significance because they can generate interesting coordination chemistry mainly for the synthesis of heterobimetallic and high-nuclearity complexes. In this context, we have recently synthesized a thioether-functionalized aminobis(phosphonite), PhN{P(–$OC_{10}H_6$(μ-S)$C_{10}H_6O$–)}$_2$ (**1**) and reported its reactivity with platinum metals where it exhibits interesting coordination behaviors producing neutral, cationic and anionic complexes (Chart 1) which show excellent catalytic activities [7].

Here we sought to examine the reactivity of this thioether-functionalized aminobis(phosphonite) with copper(I) derivatives as their complexes can be ideal candidates for luminescence studies. The dinaphthyl moiety was chosen as it is well known for exhibiting aromatic–aromatic π-stacking interactions which in turn can contribute to self assembly or molecular recognition processes [8].

As a part of our research in organometallic chemistry [9] and catalytic investigation [10] of phosphorus-based ligands, we report in this paper the copper(I) complexes of thioether-functionalized aminobis(phosphonite) (**1**).

2. Results and discussion

2.1. Copper derivatives

In our recent investigation on the coordination behavior of thioether-aminobis(phosphonite) **1** with platinum metal precursors, interesting anionic complexes with phosphorus and sulfur coordi-

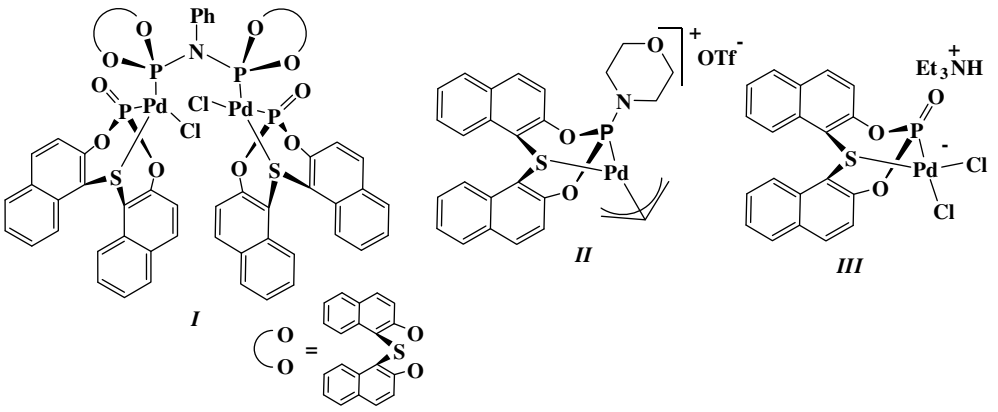

Chart 1.

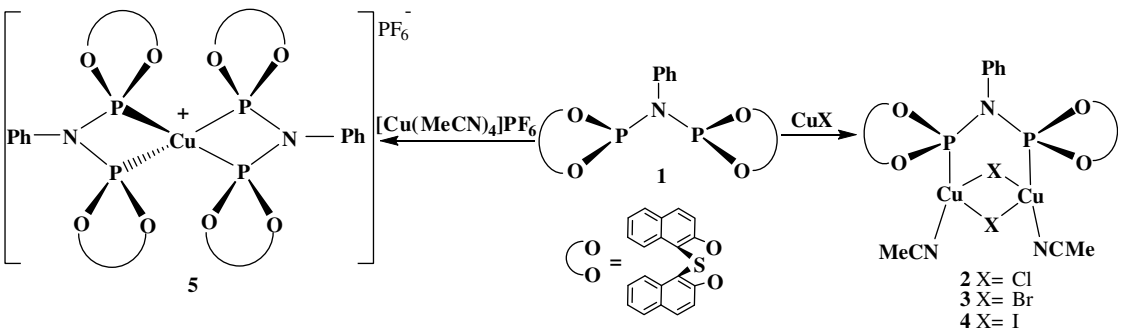

nation as well as neutral platinum complexes with highly strained four-membered chelate rings were produced and their catalytic applications were explored [7]. However, the reactivity of aminobis(phosphonite) with group 11 metal precursors is considerably different. Thus the reaction of **1** with an excess of CuX (X = Cl, Br, and I) in dichloromethane and acetonitrile afforded the corresponding binuclear complexes, [PhN(PR-κP)$_2${Cu(μ-X)(MeCN)}$_2$], (**2**, X = Cl; **3**, X = Br; **4**, X = I; R = −OC$_{10}$H$_6$(μ-S)C$_{10}$H$_6$O−) (Scheme 1). The bromo and iodo derivatives are highly soluble in dichloromethane whereas the chloro derivative is only partially soluble in dichloromethane. The ^{31}P NMR spectra of complexes **2**–**4** show single resonances at 102.9, 94.9 and 91.8 ppm, respectively. In the ^{1}H NMR spectra of all these complexes, a singlet is observed in the region 2.01–2.16 ppm which is assigned to the protons of the coordinated acetonitrile groups. Treatment of CuX with 1 equiv. of **1** did not give the four-membered chelate complexes; instead the same binuclear complexes **2–4** are obtained in excellent yield. The reaction of **1** with 0.5 equiv. of [Cu(MeCN)$_4$]PF$_6$ produces the mononuclear bischelated cationic complex, [{PhN(PR-κP)$_2$}$_2$Cu](PF$_6$) (**5**) in good yield. The ^{31}P NMR spectrum of complex **5** shows a single resonance at 100.7 ppm for the phosphorus of the aminobis(phosphonite) and a septet at −145.9 ppm for the PF_6^- group with a $^{1}J_{PF}$ coupling of 713 Hz. The structures of **3** and **4** are confirmed by single crystal X-ray diffraction studies.

2.2. Crystal structures of complexes *3* and *4*

Perspective views of the molecular structures of complexes **3** and **4** with the atom numbering schemes are shown in Figs. 1 and 2, respectively. The crystallographic data and details of the structure determinations are given in Table 1 while selected bond lengths and bond angles appear in Table 2.

In the molecular structures of **3** and **4**, the molecules consist of two copper atoms linked by one bridging aminophosphonite ligand and two bridging halides (bromide or iodide) with one acetonitrile coordinated to each copper center. Complex **3** has crystallographically-imposed mirror symmetry with all Cu, P, S and N atoms lying on the mirror. In both the complexes, the copper centers display distorted tetrahedral geometry with internal angles in the range 99.04(2)–115.13(2)° for complex **3** and 97.17(1)–127.82(1)° for complex **4**. The Cu–P distances (Cu1–P1 = 2.185(1), Cu2–P2 = 2.194(1) Å for **3** and Cu1–P1 = 2.214(1), Cu2–P2 = 2.220(1) Å for **4**) are shorter than those shown by other polynuclear copper (I) complexes containing dppm (Cu–P ≈ 2.277(6) Å) and dppf (Cu–P ≈ 2.306(7) Å) ligands [11]. The Cu···Cu distance in **3** (2.800(1) Å) is significantly longer than that in **4** (2.638(7) Å) with the latter somewhat shorter than the value of 2.695(1) Å found in [(PhN(PR$_2$)$_2$Cu$_2$(μ-Br)$_2$(L)]$_n$ (R = *o*-MeOC$_6$H$_4$O; L = 4,4'-bipy) [12a].

However, the span of Cu···Cu separations in {Cu(μ-X)$_2$Cu} moieties containing P–N–P type ligands is rather large and includes values of 2.742(2) Å in [(MeCN)$_2$(Cu(μ-Br)$_2$Cu)((R$_2$P)$_2$NC$_6$H$_4$N(PR$_2$)$_2$) (Cu(μ-Br)$_2$Cu) (MeCN)$_2$] and 2.920(3) and 2.941(3) Å in [(L)$_2$(Cu(μ-I)$_2$Cu)((R$_2$P)$_2$NC$_6$H$_4$N(PR$_2$)$_2$)(Cu(μ-I)$_2$Cu)(L)$_2$] (R = *o*-MeOC$_6$H$_4$O; L = HNC$_5$H$_9$C$_3$H$_3$N$_2$ [12b]. These last compare favorably with those found in trinuclear complexes of the type [Cu$_3$(μ^3-η^1-C≡CR)(μ-dppm)$_n$] (Cu···Cu = 2.997(3) Å) [11a]. In the case of complex **3**, the eight-membered ring containing phosphorus and sulfur atoms is in the *anti* chair-like conformation and the sulfur atom lies far away from the copper center thus preventing any S···Cu interaction. In contrast, the phosphorus- and

sulfur-containing eight-membered rings in complex **4** are in a *syn* boat-like conformation which places the sulfur atoms *syn* to the four-membered Cu_2I_2 ring. As the Cu1···S1 (3.459(8) Å) and Cu2···S2 (3.438(8) Å) separations are noticeably less than the sum of the corresponding van der Waals radii (4.12 Å), attractive Cu···S interactions are likely present. In the solid state **3** shows a strong π-π stacking interaction-ring involving the C1–C3;C8–C10 portion of one naphthyl group and the C11–C13;C18–C20 portion of the one in the molecule at $1-x, -y, 1-z$. There is a 9.91° dihedral angle between the mean planes of these two rings and the distance between their centroids (Cg) is 3.489(2) Å while the perpendicular distance from the Cg of the latter ring to the mean plane of the former is 3.299(3) Å [13]. In addition, there are C–H···Cg (π-ring) interactions involving the acetonitrile attached to Cu1 and the C3–C8 portion of one naphthyl group (C26–H26c···Cg(ring) = 2.71 Å; 151° (intramolecular) and C26–H26a···Cg (ring at $x, ½-y, z$) = 2.67 Å; 158°) as well as weak C–H···Br interactions (C6–H6···Br (at $1-x, -y, -z$) = 2.90 Å; 177° and C16–H16···Br (at $-x, -y, 1-z$) = 2.91 Å; 157°). Complex **4** shows a weak C37–H37···O1 (at $1-x, 1-y, -z$) interaction (2.67 Å; 162°) as well as intermolecular C–H···I interactions with the acetonitrile ligands in two adjacent molecules (I1···H48c–C48 (at $1-x, 1-y, 1-z$) = 3.05 Å; 176° and I1···H50b–C50b (at $2-x, 1-y, 1-z$) = 3.14 Å; 157°.

3. Conclusion

Copper(I) complexes of a thioether-functionalized aminobis(phosphonite) ligand have been synthesized. The aminobis(phosphonite) **1**, which contains a hemilabile thioether functionality, shows versatile coordination properties. By choosing appropriate metal reagents and reaction conditions both mononuclear and bridged binuclear complexes are obtained. In the solid state complex **3** shows strong π–π stacking interactions while in complex **4** there is a significant ligand-supported metallophilic interactions.

4. Experimental

All experimental manipulations were carried out under an atmosphere of dry nitrogen or argon using Schlenk techniques. Solvents were dried and distilled prior to use by conventional methods. Aminobis(phosphonite) (**1**) [7a], CuX (X = Cl, Br) [14] and $[Cu(MeCN)_4PF_6]$ [15] were prepared according to the published procedures. Other reagents were obtained from commercial sources and used after purification. The ^{1}H and ^{31}P{^{1}H} NMR (δ in ppm) spectra were obtained on a Varian VRX 400 spectrometer operating at frequencies of 400 and 162 MHz, respectively. The spectra were recorded in $CDCl_3$ (or DMSO-d_6) solutions with $CDCl_3$ (or DMSO-d_6) as an internal lock; TMS and 85% H_3PO_4 were used as internal and external standards for ^{1}H and ^{31}P{^{1}H} NMR, respectively. Positive shifts lie downfield of the standard in all of the cases. Microanalyses were carried out on a Carlo Erba (Model 1106) elemental analyzer. Melting points of all compounds were determined on Veego melting point apparatus and were uncorrected.

4.1. Synthesis of [PhN(PR-κP)$_2${Cu(μ-Cl)(MeCN)}$_2$] (**2**, R = –OC$_{10}$H$_6$(-S)C$_{10}$H$_6$O–)

A solution of CuCl (0.030 g, 0.303 mmol) in acetonitrile (4 ml) was added dropwise to a solution of **1** (0.059 g, 0.076 mmol) in dichloromethane (10 ml) and the reaction mixture was stirred for 1 h. The suspension was filtered to remove unreacted CuCl and the mother liquor was concentrated under vacuum, to give a crystalline product **2** at −25 °C. Yield: 85% (0.069 g), m.p.: 194–196 °C (dec.). ^{1}H NMR (400 MHz, DMSO-d_6): δ 8.70 (d, 4H, $^3J_{HH}$ = 9.2 Hz, Ar), 7.51–7.95 (m, 20H, Ar, 5H, Ph), 2.10 (s, 6H, CH_3CN). ^{31}P{^{1}H} NMR (121.4 MHz, DMSO-d_6): δ 102.9 (s). *Anal.* Calc. for $C_{50}H_{35}Cl_2N_3O_4P_2S_2Cu_2$: C, 56.34; H, 3.31; N, 3.94; S, 6.02. Found: C, 56.31; H, 3.29; N, 3.92; S, 5.99%.

4.2. Synthesis of [PhN(PR-κP)$_2${Cu(μ-Br)(MeCN)}$_2$] (**3**)

This was synthesized by a procedure similar to that for **2** using CuBr (0.050 g, 0.348 mmol) and **1** (0.068 g, 0.087 mmol). Yield: 87% (0.087 g), m.p.: 210 °C (dec.). ^{1}H NMR (400 MHz, $CDCl_3$): δ 8.51 (d, 4H, $^3J_{HH}$ = 8.8 Hz, Ar), 7.11–7.56 (m, 16H, Ar, 5H, Ph), 7.01 (d, 4H, $^3J_{HH}$ = 8.8 Hz, Ar), 2.16 (s, 6H, CH_3CN). ^{31}P{^{1}H} NMR (162 MHz, $CDCl_3$): δ 94.9 (s). *Anal.* Calc. for $C_{50}H_{35}Br_2N_3O_4P_2S_2Cu_2$: C, 52.00; H, 3.05; N, 3.64; S, 5.55. Found: C, 51.97; H, 2.99; N, 3.62; S, 5.51%.

4.3. Synthesis of [PhN(PR-κP)$_2${Cu(μ-I)(MeCN)}$_2$] (**4**)

This was synthesized by a procedure similar to that for **2** using CuI (0.050 g, 0.315 mmol) and **1** (0.062 g, 0.079 mmol). Yield: 91% (0.09 g), m.p.: 174 °C (dec.). ^{1}H NMR (400 MHz, $CDCl_3$): δ 8.87 (d, 4H, $^3J_{HH}$ = 9.2 Hz, Ar), 6.67–7.86 (m, 20H, Ar, 5H, Ph), 2.01 (s, 6H, CH_3CN). $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$): δ 91.8 (s). *Anal.* Calc. for $C_{50}H_{35}I_2N_3O_4P_2S_2Cu_2$: C, 48.09; H, 2.82; N, 3.36; S, 5.14. Found: C, 48.02; H, 2.79; N, 3.34; S, 5.11%.

4.4. Synthesis of [{PhN(PR-κP)$_2$}$_2$Cu](PF$_6$) (**5**)

To a solution of **1** (0.084 g, 0.107 mmol) in dichloromethane (12 ml) $Cu(MeCN)_4PF_6$ (0.020 g, 0.054 mmol) was added and the reaction mixture was stirred for 2 h. The colorless solution obtained was concentrated and diethyl ether (8 ml) was added to precipitate out the white product. This was then filtered off and dried under vacuum. Yield: 89% (0.085 g), m.p.: 180 °C (dec.). ^{1}H NMR (400 MHz, $CDCl_3$): δ 8.49 (d, 8H, $^3J_{HH}$ = 7.6 Hz, Ar), 7.14–8.23 (m, 40H, Ar, 10H, Ph). $^{31}P\{^1H\}$ NMR (162 MHz, $CDCl_3$): δ 100.7 (s, 4 P), −145.9 (septet, 1P, PF_6, $^1J_{PF}$ = 713 Hz). *Anal.* Calc. for $C_{92}H_{58}F_6N_2O_8P_5S_4Cu$: C, 62.07; H, 3.28; N, 1.57; S, 7.21. Found: C, 62.01; H, 3.25; N, 1.53; S, 7.18%.

5. X-ray crystallography

A crystal of **3** which proved to be twinned was mounted in a Cryoloop™ with a drop of Paratone oil and placed in the cold nitrogen stream of the Kryoflex™ attachment of the Bruker APEX CCD diffractometer. A full sphere of data was collected using 606 scans in ω (0.3° per scan) at Φ = 0°, 120° and 240° using the SMART software package [16]. The raw data were reduced to F^2 values using the SAINT+ software [17] and a global refinement of unit cell parameters using 9500 reflections chosen from the full data set was performed. Multiple measurements of equivalent reflections provided the basis for an empirical absorption correction as well as a correction for any crystal deterioration during the data collection (TWINABS [18]). The structure was solved by direct methods and refined by full-matrix least-squares procedure using the SHELXTL program package [19]. Hydrogen atoms were placed in calculated positions and included as riding contributions with isotropic displacement parameters tied to those of the attached non-hydrogen atoms.

A crystal of **4** was mounted on a OXFORD DIFFRACTION XCALIBUR-S CCD system equipped with graphite monochromated Mo Kα radiation (0.71073 Å). The data were collected in the ω–2θ scan mode and an absorption correction was applied by using multiscan techniques. The structure was solved by direct methods (SHELXS 97) and refined by full-matrix least-squares against F^2 using the SHELXL 97 software [19b]. Non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were geometrically fixed and allowed to refine using a riding model.

Acknowledgments

We are grateful to the Department of Science and Technology (DST), New Delhi for funding through Grant SR/S1/IC-02/2007. B.P. thanks CSIR for Research Fellowship (JRF and SRF). We also thank Department of Chemistry Instrumentation Facilities, Bombay, for spectral and analytical data and the Louisiana Board of Regents through Grant LEQSF (2002-03)-ENH-TR-67 for purchase of the CCD diffractometer and the Chemistry Department of Tulane University for support of the X-ray laboratory. National Single Crystal X-ray Facility Center, IIT Bombay is acknowledged for solving one of the structures.

Appendix A. Supplementary data

CCDC 673994 and 673995 contain the supplementary crystallographic data for **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.10.014.

ABSTRACT

A new dithioligand [N′-(2-methoxybenzoyl)hydrazinecarbodithioate] ethyl ester (H_2mbhce, **1**) formed complexes $[M(Hmbhce)_2]_n$ {M = Mn(II), Cd(II)} which have been characterized with the help of elemental analyses, magnetic susceptibility measurements, IR, UV–Vis, ^{1}H and ^{13}C NMR and mass spectrometry. $[Mn(Hmbhce)_2]_n$ (**2**) crystallized in monoclinic system with space group P_{21}/n. In the polymeric structure of **2**, the ligand acts as an uninegative tridentate N(1), O(1), S(3) donor and forms a five membered chelate ring with N(1), C(2) and O(1). The intermediate bond lengths (between single and double bond distances) O(1)–C(2) = 1.241(3), N(2)–C(2) = 1.325(3), N(1)–N(2) = 1.393(2), N(1)–C(8) = 1.311(3) Å and C(8)–S(3) = 1.704(2) Å suggest considerable delocalization of charge which develops slightly aromatic character in the chelate ring.

1. Introduction

Dithioligands are very promising compounds from the view point of coordination chemistry because of their ability toward complexation and involvement in a wide range of biological [1,2] and non-biological processes [3,4]. The metal dithiocomplexes frequently undergo facile and reversible one electron redox reaction and have been used as sensitizers in photoelectrochemical solar cells [5,6]. They also show solid state electrical conductivities and can be used as molecular conductors [7,8]. Some transition metal chelates of the derivatives of N and S substituted dithiocarbazates [9,10] such as S-alkyldithiocarbazates [11] and their Schiff's bases [12–16] have been widely studied for their unique antitumor, antibacterial and antifungal activities. The interest in these ligand systems is also stimulated by their unusual physicochemical [17,18] and chemotherapeutic properties [9]. Although N′-acylhydrazinecarbodithioates are structurally similar to the dithiocarbazates, not much data is available on the synthesis, characterization and biological activity of these ligands and their complexes. Following our interest in the study of the coordination properties of the ligands containing the HN–C(=S) group, we have recently reported synthesis and X-ray studies of N′-(pyridine-3-carbonyl)hydrazine carbodithioate (H_2pchc) and their Mn(II) complex [19]. Keeping in view the above points and with the aim of elucidating the coordination geometry of the complexes of this class of ligand, [N′-(2-methoxybenzoyl)hydrazine]carbodithioic acid ethyl ester (H_2mbhce) and its Mn(II) and Cd(II) complexes were synthesized and characterized by X-ray.

2. Experimental

2.1. Materials and methods

Commercial reagents were used without further purification and all experiments were carried out in open atmosphere. Methyl 2-methoxy-benzoate was purchased from Sigma Aldrich and used as such. Carbon disulfide and hydrazine hydrate (SD Fine Chemicals, India) and the solvents (Merck Chemicals, India) were used in the syntheses.

2.1.1. Preparation of the ligand $[K^+(H_2L)^-]$

The preparation and characterization of potassium [N′-(2-methoxybenzoyl)hydrazinecarbodithioate] ethyl ester $[K^+(H_2L)]$ has been published elsewhere [20].

2.1.2. Preparation of the ligand (H_2mbhce) (**1**)

The [N′-(2-methoxy-benzoyl)-hydrazine]-carbodithioic acid ethyl ester (H_2mbhce) was synthesized by drop wise addition of ethyl iodide (1.5 ml, 25.64 mmol) to a suspension of freshly prepared potassium [N′-(2-methoxybenzoyl)hydrazinecarbodithioate] ethyl ester $[K^+(H_2L)^-]$ (4 g, 14.29 mmol) in methanol (25 ml)

doi:10.1016/j.poly.2008.10.015

and stirring the reaction mixture continuously for 2 h at room temperature. On evaporation of the solvent and acidification of the product with CH_3COOH (20% v/v), white precipitate was obtained. This was suction filtered, washed with water, dried in vacuo and recrystallized from methanol–chloroform mixture (50:50 v/v).

*2.1.2.1. Compound (**1**).* White recrystalline compound of **(1)** suitable for spectroscopic analyses was obtained by slow evaporation of its MeOH–$CHCl_3$ solution. Yield (67%); m.p. 162 °C. *Anal.* Calc. for $C_{11}H_{14}N_2O_2S_2$ (270.36): C, 48.87; H, 5.22; N, 10.36; S, 23.72. Found: C, 48.38; H, 5.22; N, 10.01; S, 23.50.

IR data (ν cm^{-1}, KBr): ν(NH) 3244m, 3120m; ν(C=O) 1645s; thioamide I [β(NH) + ν(CN)] 1469s; thioamide II [ν(CN) + β(NH)] 1248s; ν(N–N) 1086m; ν(C=S) 968; (CH_3) 2929; (CH_2) 2873. ^{1}H NMR (DMSO-d_6; δ ppm): 11.46, 10.49 (2H, –NH), 2.50 (m, 2H, >CH_2), 1.30 (m, 3H, –CH_3), 3.88 (m, 3H, –OCH_3), 7.89–7.22 (4H, multiplets, benzene ring). ^{13}C NMR (DMSO-d_6, δ ppm): 202.96 (>C=S), 164.52 (>C=O), 28.28 (>CH_2), 14.38 (–CH_3), 120.85 (C1), 161.63 (C3), 130.70 (C4), 121.18 (C5), 133.46 (C6), 112.34 (C7), 56.27 (–OCH_3). UV–Vis [λ_{max}, DMSO, nm]: 307, 258. MS(FAB) m/z = 271 $[M]^+$. Based on the above data the tentative structure of the ligand is depicted in Fig. 1.

*2.1.3. Preparation of complexes (**2**–**3**)*

A solution of H_2mbhce (0.540 g, 2 mmol) in MeOH–$CHCl_3$ (8 ml) was added to a MeOH solution (10 ml) of $Mn(OAc)_2 \cdot 4H_2O$ (0.249 g, 1 mmol) and stirred the mixture for 2 h at room temperature. The resulting clear yellow solution of complex **2** was filtered off and kept for crystallization.

Complex **3** was prepared by adding a MeOH–$CHCl_3$ solution of H_2mbhce (2 mmol) to a MeOH solution (10 ml) of $Cd(OAc)_2 \cdot 2H_2O$ (1 mmol) and stirring the mixture for 3–4 h. The resulting precipitate was filtered off, washed thoroughly with ethanol and chloroform, dried at room temperature and stored in desiccators.

*2.1.3.1. [Mn(Hmbhce)$_2$]$_n$ (**2**).* Light yellow single crystals of **(2)** suitable for X-ray analyses were obtained by slow evaporation of the above methanol: chloroform solution over a period of 7 days.

Yield 58%; m.p. 230 °C, μ_{eff} = 5.98 BM. *Anal.* Calc. for $C_{22}H_{26}MnN_4O_4S_4$ (593.43): C, 44.51; H, 4.41; N, 9.44; S, 21.60; Mn, 9.25. Found: C, 44.12; H, 4.37; N, 9.04; S, 21.70; Mn, 9.20%. IR(ν cm^{-1}, KBr): ν(NH) 3162m; ν(>C=O) 1603s; thioamide I [β(NH) + ν(CN)] 1514s; thioamide II [ν(CN) + β(NH)] 1297s; ν(N–N) 1101m; ν(>C=S) 905; (CH_3) 2922; (CH_2) 2858. UV–Vis [λ_{max}, DMSO, nm]: 629, 393, 220. MS(FAB) m/z = 594 $[M]^+$.

*2.1.3.2. [Cd(Hmbhce)$_2$]$_n$ (**3**).* Yellowish white; Yield 65%; m.p. 175 °C; *Anal.* Calc. for $C_{22}H_{26}CdN_4O_4S_4$ (651.12): C, 40.58; H, 4.02; N, 8.60; S, 19.70; Cd, 17.26. Found: C, 40.77; H, 4.07; N, 8.24; S, 20.03; Cd, 17.63%. IR(ν cm^{-1}, KBr): ν(NH) 3166m; ν(>C=O) 1605s; thioamide I [β(NH) + ν(CN)] 1510s; thioamide II [ν(CN) + β(NH)] 1295s; ν(N–N) 1100m; ν(>C=S) 900; (CH_3) 2920; (CH_2) 2861. ^{1}H NMR (DMSO-d_6; δ ppm): 13.01, (1H, –NH), 3.00 (m, 2H, >CH_2), 1.07 (m, 3H, –CH_3), 3.34 (m, 3H, –OCH_3), 8.09–7.12 (4H, multiplets, benzene ring). ^{13}C NMR (DMSO-d_6, δ ppm): 180.65 (>C=S), 159.52 (>C=O), 27.41 (>CH_2), 14.86 (–CH_3), 120.03 (C1), 157.47 (C3), 130.91 (C4), 121.38 (C5), 133.64 (C6), 112.38 (C7), 56.55 (–OCH_3). UV–Vis spectrum [λ_{max}, DMSO, nm]: 304, 254. MS(FAB) m/z = 650 $[M]^+$.

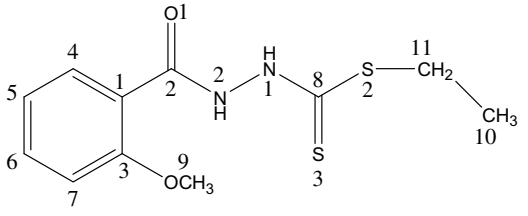

Fig. 1. [N′-(2-methoxybenzoyl)hydrazinecarbodithioate] ethyl ester (H_2mbhce).

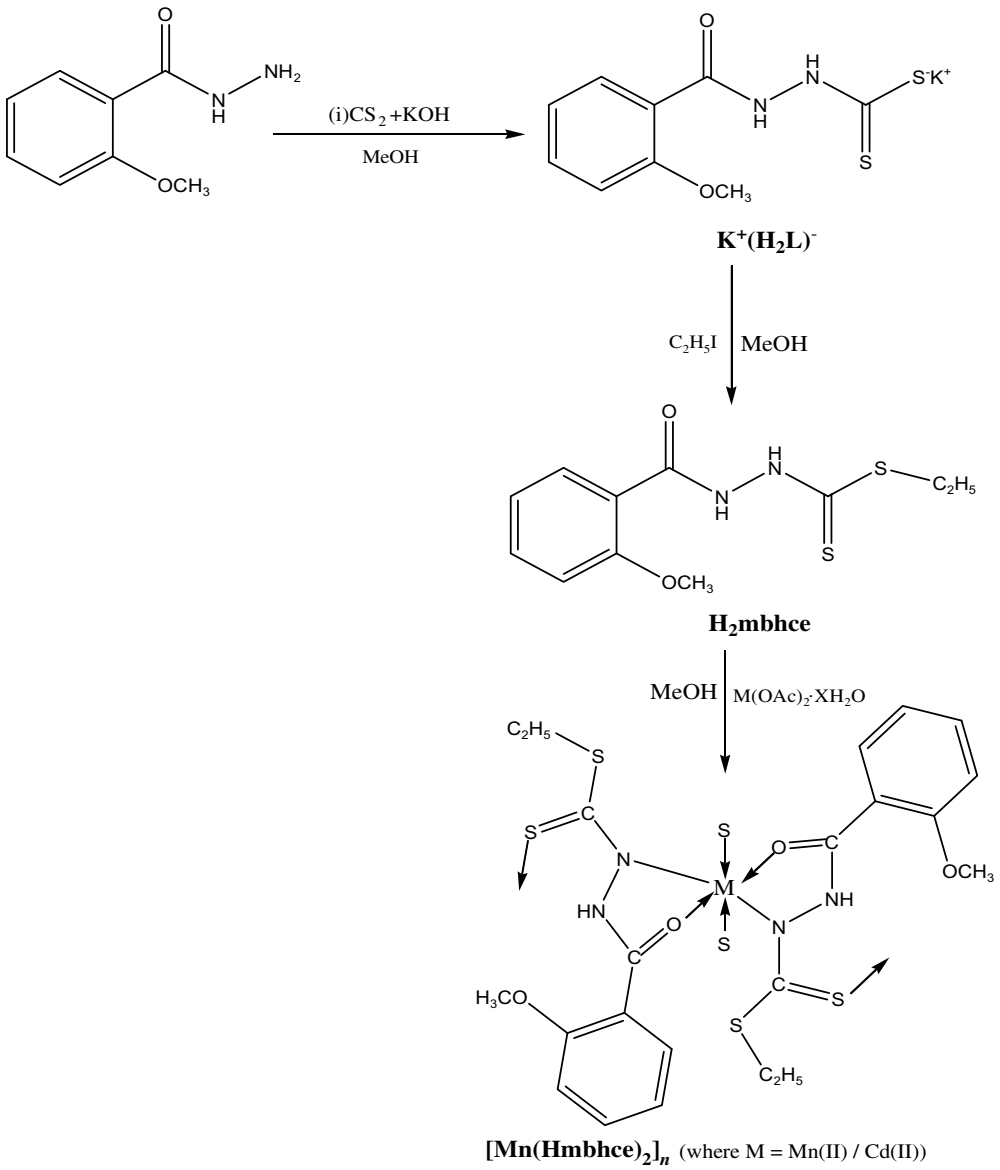
2.1.4. Physical measurements



Carbon, hydrogen, nitrogen and sulfur contents were estimated on a CHN Model CE-440 Analyzer and on an Elementar Vario EL III Carlo Erbo 1108. By following standard procedure, the complexes were analyzed for their metal content, after decomposition with a mixture of conc. HNO_3 and HCl, followed by conc. H_2SO_4 [21]. Magnetic susceptibility measurements were performed at room temperature on a Cahn Faraday balance using $Hg[Co(NCS)_4]$ as the calibrant and electronic spectra were recorded on an UV-1700 Pharmaspec spectrophotometer. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a Varian Excalibur 3100 FT-IR spectrophotometer. ^{1}H and ^{13}C NMR spectra were recorded in DMSO-d_6 on a JEOL AL300 FT NMR spectrometer using TMS as an internal reference. The FAB mass spectra were recorded on a Jeol SX 102/Da-600 mass spectrometer/data system using Argon/Xenon (6 kV, 10 m A0) as the FAB gas m-nitro benzyl alcohol (NBA) was used as the matrix.

3. Crystal structure determination

The X-ray data collection and processing for **2** were performed on Bruker Kappa Apex-CCD diffractometer by using graphite monochromated Mo Kα radiation (λ = 0.71070 Å) at 100 K. Crystal structures were solved by direct methods. Structure solution, refinement and data output were carried out with the SHELXTL program [22,23]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed at geometrically calculated positions by using a riding model. Diagrams were created with the DIAMOND program [24]. Hydrogen bonding interactions in the crystal lattice were calculated with both SHELXTL and MERCURY [25].

4. Results and discussion

With an aim to obtain N′-acylhydrazine carbodithioic acid ester, H_2mbhce was synthesized by the reaction of freshly prepared $[K^+(H_2L)^-]$ with C_2H_5I in equivalent molar ratio in methanolic solution. The synthetic route for the complexes **2** and **3** are given in Scheme 1. H_2mbhce having multidentate donor sites are expected to coordinate in neutral or anionic form. Owing to the presence of amide and thioamide functional groups, it can exhibit keto-enol and thione-thiol tautomerism [26]. But the IR (KBr) and ^{1}H NMR (DMSO-d_6) spectra of H_2mbhce are devoid of any peak to be attributed to SH for the thiol form indicating that it exists in thione form in solid (also by XRD) as well as in solution. Due to the more acidic character of HN(C=S), this proton undergoes deprotonation during complexation. It is seen that, H_2mbhce loses a proton directly from the nitrogen of HN(C=S) moiety to metal ion to fulfill the neutralization of positive charge of the metal ion. Thus, the ligand gets monodeprotonated to facilitate the formation of metal complexes **2**–**3.** Complex **2** has been obtained as single crystals and analyzed, which shows that the carbonyl oxygen, thione sulfur and hydrazinic nitrogen (after deprotonation) participate in bonding. The ligand and complexes are air-stable and can be kept in desiccators over a prolonged period without sign of decomposition. The complex 2 is soluble in DMF, DMSO, $CHCl_3$–MeOH mixture and other polar solvents while the Cd(II) complex is sparingly soluble in DMSO-d_6.

Scheme 1. Preparation of H_2mbhce and $[Mn(Hmbhce)_2]_n$.

4.1. IR spectra

The ligand H_2mbhce **(1)** contains the thioamide HN(C=S) group which should give rise to characteristic bands associated with thioamide I, thioamide II and thioamide IV having contributions from [β(NH) + *ν*(CN)], [*ν*(CN) + β(NH)], *ν*(C=S), modes of vibrations, respectively. The IR spectrum of H_2mbhce displays two bands at 3244 and 3120 cm^{-1} arising from two –NH groups attached to >C=O and >C=S groups, respectively, present in the ligand. The peaks at 1645, 1469, 1248, 1086, 968 cm^{-1} are assigned to *ν*(C=O), thioamide I [β(NH) + *ν*(CN)], thiamide II [*ν*(CN) + β(NH)], *ν*(N–N) and *ν*(C=S), respectively. The bands at 2929 and 2873 cm^{-1} correspond to *ν*(C–H) of ($–CH_3$) and $–CH_2$ groups, respectively, of H_2mbhce.

Comparison of the main vibrational bands of H_2mbhce (**1**) is used to establish its ligating behavior in the complexes **2**–**3**. Disappearance of one of the bands due to *ν*(NH) adjacent to thione sulfur in complexes **2**–**3** suggests loss of a proton from HN(C=S) group and participation of the deprotonated nitrogen in bonding with the metal ion. The *ν*(N–N) shows a positive shift of 14–15 cm^{-1} indicating bonding through hydrazinic nitrogen. The IR spectra of both complexes (**2**–**3**) show a strong band in 1594–1605 cm^{-1} region for amide I [mainly due to *ν*C(=O)]. A negative shift of 40–42 cm^{-1} in *ν*(C=O) indicates the involvement of carbonyl oxygen in bonding. A negative shift of 63–68 cm^{-1} in the *ν*(C=S) in the complexes **2** and **3** indicate involvement of the thione sulfur in bonding which is further supported by positive shifts of 41–45 and 47–49 cm^{-1} in thioamide I and II bands, respectively. Thus H_2mbhce behaves as uninegative tridentate O, N, S donor in the complexes **2** and **3**.

4.2. Magnetic moment and electronic spectra

The UV–Vis spectrum of H_2mbhce exhibits bands at 307 and 258 nm attributed to the intraligand transitions. $[Mn(Hmbhce)_2]_n$ exhibits a μ_{eff} of 5.98 B.M., indicating the presence of five unpaired electrons in the complex and shows three electronic bands at 629, 393 and 220 nm. The band at 629 nm is assigned to the $^6A_{1g} \rightarrow {}^4T_{1g}$, transition for a high spin octahedral geometry around Mn(II) [27]. The high energy bands at 393 and 220 nm may be assigned to the

intraligand/charge transfer transition. The high energy bands at 329 and 246 nm in the diamagnetic complex Cd(II) may be due to intraligand/charge transfer transitions [28].

4.3. ^1H and ^{13}C NMR spectra

The ^1H NMR spectrum of H_2mbhce exhibits signals at δ 10.49 and 11.46 ppm for the amide –NH(CO) and thioamide –NH(CS) protons, respectively. The protons due to the benzene ring appear as multiplets between δ 7.89, 7.70, 7.58, 7.22 ppm. The ^{13}C NMR spectrum of H_2mbhce shows 11 signals for 11 carbon atoms, out of which the signals at δ 202.96, 164.52 and 56.27 ppm are due to the >C=S, >C=O and $-OCH_3$ carbons, respectively. The expected structure of H_2mbhce is shown in Fig. 1. Due to the paramagnetic nature of **2** the ^1H and ^{13}C NMR spectra could not be studied. The ^1H and ^{13}C NMR spectra of $[Cd(Hmbhce)_2]_n$ in DMSO-d_6 was interpreted by comparing its spectra with that of H_2mbhce. The ^1H NMR of Cd(II) complex shows a signal at 13.01 ppm showing the presence of one hydrazinic proton while the signal due to another is found absent indicating deprotonation of the thioamide proton. The peaks at 3.34, 3.00 and 1.07 ppm corresponding to the $-OCH_3$, $-CH_3$, $-CH_2$ groups show slight variation during complexation as compared to the ligand. The signals due to the 2-methoxybenzene ring protons appear at 8.09, 7.62, 7.27, and 7.12 as multiplets. In the case of Cd(II), the peaks due to >C=S and >C=O appear at 180.65 and 159.52 ppm as compared to 202.96 and 164.52 ppm in the H_2mbhce, which suggests bonding through the thione sulfur and carbonyl oxygen.

4.4. Mass spectrometry

The ligand H_2mbhce is identified by FAB mass spectrum which shows many peaks due to various fragments. The molecular ion peak for $[H_2mbhce]^{+\cdot}$ is observed at m/z = 271. Other three important peaks at m/z = 242 (50% intensity), 209 (52% intensity) and 237 (35% intensity) correspond to fragments formed from H_2mbhce after the release of $-C_2H_5$, $-SC_2H_5$ and H_2S, respectively.

FAB mass spectral analyses of $[Mn(Hmbhce)_2]_n$ and $[Cd(Hmbhce)_2]_n$ show the presence of corresponding molecular ion peaks at m/z = 594 and 650, respectively, which correspond to the mol. wt. of one unit of the polymer. Other peaks at higher m/z values indicate their polymeric nature. Complex **2** gave four important peaks at m/z = 413 (50% intensity), 470 (90% intensity), 532 (50% intensity) and 560 (65% intensity) corresponding to the fragments formed from the $[Mn(Hmbhce)_2]_n$ after release of $2H_2S$, $2C_2H_5SH$, C_2H_5SH and H_2S, respectively. The fragmentation pattern of the Cd(II) complex shows peaks at m/z = 582 (25% intensity), 513 (25% intensity), 307 (30% intensity) and 268 (12.5% intensity) corresponding to fragments formed from

5. Structural description of $[Mn(Hmbhce)_2]_n$ (2)

The crystallographic data and structural refinement details of complex **2** are given in Table 1 whereas the important bond distances and bond angles are listed in Table 2. Compound **2** crystallized in monoclinic system with space group P_{21}/n and its thermal ellipsoidal view at 30% probability level is shown in Fig. 2. As shown in Fig. 2, the Mn(II) center is bonded to the ligand through the deprotonated hydrazinic nitrogen, carbonyl oxygen and thione sulfur forming a five membered chelate ring with oxygen and nitrogen atoms. The geometry around the Mn(II) ion is approximately octahedral. The H_2mbhce coordinates to Mn(II) center in meridonial configuration i.e. the carbonyl oxygen and hydrazinic nitrogen are *cis* to each other and thione sulfur *trans*. The Mn–N and Mn–O bond lengths are 2.2474(18) and 2.1280(15) Å, respectively. These values are in the ranges found for octahedrally coordinated Mn(II) with ONS donor ligands [29]. The Mn–S bond distance of 2.7053(7) Å is longer as compared to those found for $[Mn\{SSi(oBu^t)_3\}_2(o\text{-phen})]$, $[Mn\{SSi(oBu^t)_3\}_2(bpy)]$, $Mn(L_1)_2$ {L_1 = S-methyl-3-(2-S-methyl-6-methyl-4-pyrimidyl)methyl)dithiocarbazate} and $Mn(L_2)_2$ {L_2 = S-benzyl-3-(2-S-methyl-6-methyl-4-pyrimidyl)methyl)dithiocarbazate} [Mn–S = 2.4777(5)–2.555(2) Å] indicating that the Mn–S bond in the present complex is weaker than those cited above [29,30]. The C–S bond distances of 1.768(2) Å and 1.704(2) Å are intermediate between single C–S (1.82 Å) and double C=S (1.56 Å) bond distances. The lengthening of the C=S and shortening of the C–S bond may be caused due to the deprotonation of hydrazinic proton adjacent to the dithio group {–C(=S)S} and subsequent development of the negative charge on the nitrogen which is delocalized during complexation. The C–O, C–N and N–N bond distances are 1.241(3) Å, 1.325(3) Å and 1.392(2) Å, respectively, which are also intermediate between single and double bond character [31]. All these intermediate distances suggest extensive delocalization of charge in the five membered chelate ring of complex **2**, similar to the complexes of a few dithiocarbazates [32–34]. An angle of 180° is subtended at the Mn(II) ion {viz. the S(3)#2–Mn(1)–S(3)#3 angle} which is equivalent to the theoretical value. The angles N(1)–Mn(1)–O(1) and O(1)–Mn(1)–N(1) formed by two equatorial donors N(1) and O(1) at Mn(II) center are 74.60(6)° and 105.40(6)°, respectively, which shows deviation from an ideal value of 90° for an ideal octahedral structure. The metal center is bonded through two uninegative tridentate sites (N2O2S2) of $(Hmbhce)^-$ utilizing deprotonated hydrazinic nitrogen, carbonyl oxygen and thione sulfur, forming two five remembered chelate rings. The mean plane formed by O1C2N2N1Mn1 in the complex structure reveal the planar nature of both chelate rings. This chelate ring and the 2-methoxybenzene ring lie in the same plane and make an extended coplanar system (Fig. 3).

5.1. Crystal packing of complex 2

Fig. 3 shows the formation of one dimensional layer structure of polymeric complex $[Mn(Hmbhce)_2]_n$ due to the presence of weak interactions. The intramolecular N(2)–H(2)···O(2) (1.942 Å), C(4)–H(4)···O(1) (2.389 Å), C(11)–H(11B)···S(3) (2.686 Å) and N(2)–H(2)···S(3) (2.430 Å) hydrogen bonding in the molecule provide stability to complex **2**. The hydrogen of methyl group [$C(sp^3)$–H(s)] of one molecule shows weak van der Waals' interaction with the hydrogen of another methyl group causing the superimposition of molecules over each other. The crystal packing shows a special type of interaction between C2 and S2 with a distance of 3.402 Å and intermolecular hydrogen bonding O1···H11B (2.698 Å). There is no face to face (π–π) interaction and edge to face (C–H···π) interaction between two 2-methoxyphenyl rings in the crystal structure of **2**.

6. Conclusion

A new [N′-(2-methoxybenzoyl)hydrazinecarbodithioate] ethyl ester (**1**) and its Mn(II) (**2**) and Cd(II) (**3**) complexes have been synthesized. In the complex **2,** the chelate ring and the 2-methoxybenzene ring lie in the same plane making an extended coplanar system with the two chelate ring.

Solid porphyrin crystals
Self-assembly
2,4,6-Trinitrotoluene

ABSTRACT

In this article, we report on the formation of a photocatalytic porphyrin crystalline structure using two oppositely charged commercially available low cost porphyrins, [*meso*-tetra(*N*-methy-4-pyridyl)porphyrin tetratosylate (TMPyP) and zinc-tetrakis(4-sulfonatophenyl)porphyrin (Zn-TPPS)], by self-assembly at room temperature without acidification. Using optical microscopy, the crystals were determined to have a length of 30–55 μm and width of 2–50 μm, depending on the molar ratio of the porphyrins in the starting solution. The porphyrin crystals were characterized by means of powder X-ray diffraction and UV–Vis, fluorescence, and optical microscopic techniques. The UV–Vis absorbance spectrum of the crystalline structure is different than those of the monomer solutions, involving a broadened Soret band that is split into two blue-shifted and red-shifted peaks and broadened red-shifted Q-bands. The crystals exhibit a different emission spectrum from those of the porphyrin solutions in that they are red-shifted, split, and show a dramatic decrease in intensities. A hypothetical model for the crystal structure of the porphyrin crystals is developed. Illumination of the crystals in a 2,4,6-trinitrotoluene solution with a tungsten lamp results in TNT reduction to 1,3,5-trinitrobenzene and 4-amino-2,6-dinitrotoluene.

1. Introduction

Porphyrins and their derivatives possess particular photophysical and photochemical properties that depend on the substituents attached to the tetrapyrrolic ring as well as the metal linked to the nitrogen atoms in the core of the porphyrin ring [1,2]. Porphyrins play a principle role in many biochemical reactions including photosynthesis, drug detoxification, oxidation, and electron transfer [3]. Molecular self-assembly is a stratagem for the fabrication of many new materials involving the spontaneous aggregation of small molecular entities into specific structures in liquid or solid environments by a variety of cooperative and directional intermolecular interactions. Molecular self-assembly accomplishes the ordering of molecular components in space to form supramolecular entities with predefined dimensionality and connectivity [4]. Self-assembled, self-organized, and covalently-bound porphyrin arrays are of importance as attractive building blocks for the modular construction of tailored field-responsive materials and provide a versatile tool for potential applications in the design of sensors, catalysts, electronic and photonic devices, molecular sieves, and solar energy conversion devices [5,6]. Porphyrins have been used for the detection and degradation of hazardous, toxic gases, environmental pollutants, nitroaromatic compounds, insecticides, pesticides, and weapons of mass destruction [7–12]. Effort has been expanded in our laboratory to study the interaction between porphyrins and 2,4,6-trinitrotoluene to design efficient, low cost, and reusable photocatalytic porphyrin-based catalysts as well as sensitive detectors for explosives [13].

The nitroaromatic explosive 2,4,6-trinitrotoluene has been widely used in detonators, mines, rocket boosters, and plastic explosives [14]. 2,4,6-trinitrotoluene is found in the soil, ground water, and surface waters at the sites where it was manufactured [15]. TNT is toxic and is classified as priority EPA pollutant at concentrations above 2 μg/L [16].

Binding of 2,4,6-trinitrotoluene to porphyrins [17] as well as the degradation of TNT by porphyrins solutions using means of illumination [18] have been previously reported. Free base porphyrin and metalloporphyrin solutions have been shown to be a photocatalytic agent for TNT degradation [18]. The fact that porphyrins are inseparable from the solution after the degradation process such that they cannot be easily recovered and reused is a disadvantage of using porphyrin solutions in TNT degradation process. There is a need for a solid porphyrin-based catalyst for TNT degradation.

In this work we report on the formation of highly stable microscale solid porphyrin crystals using commercially available water-soluble porphyrins at room temperature without pH control. The ease of preparation, low cost, and speed of formation are three advantages of making these crystals. The solid crystalline structures reported in this article overcome the disadvantages of using porphyrin solutions in the TNT degradation process. The crystalline structure was investigated and characterized by light microscopy,

UV–Vis spectroscopy, fluorescence spectroscopy, and powder X-ray diffraction to determine the chemical structure and the nature of binding between the two different porphyrin molecules in the crystals. Prior to use as a photocatalyst, the porphyrin crystals were immobilized on microscope slides and used as a photocatalyst for aqueous 2,4,6-trinitrotoluene (TNT) degradation using light in the visible portion of the spectrum.

2. Experimental

2.1. Materials

meso-Tetra(*N*-methy-4-pyridyl)porphyrin tetratosylate (TMPyP) and zinc-tetrakis(4-sulfonatophenyl)porphyrin (Zn-TPPS), shown in Fig. 1, were obtained from Frontier Scientific (Logan, UT) and used without further purification. Porphyrin solutions were prepared at 1 mM stock concentration in 18 mΩ de-ionized water, stored refrigerated, and used within two weeks of preparation.

TNT (weapon grade) was obtained as a saturated water solution from the US Army Defense Ammunition Center at McAlester, OK.

2.2. Spectroscopic techniques

Absorbance spectra of the porphyrin monomers in pH 7.0 phosphate buffer and the absorbance spectra of the immobilized porphyrin crystals were collected using a Cary 5E UV–Vis spectrophotometer at 0.5 nm resolution using de-ionized water or a microscope slide as a reference depending on the sample being measured.

Fluorescence measurements were carried out with a SPEX FluoroMax-3 (Jobin-Yvon, Inc. Edison, NJ). Very dilute solutions (1 μM) were used to avoid spectral distortions due the inner filter effect and emission re-absorption. Before measuring fluorescence spectra of TMPyP, the cuvettes were first cleaned with nitric acid since TMPyP has a marked tendency to adhere on the cuvette walls.

Crystals were immobilized on a ProbeOn™ microscope slides obtained from Fisher Scientific. The immobilized crystals in aqueous 2,4,6-trinitrotoluene solution were illuminated at room temperature using an automotive headlamp (Osram HLX 46610, 50 W at 12 V) mounted with a flat rear reflector; the bulb was situated 2 cm from the lamp assembly. The total distance from the filament to the sample was 6 cm. The TNT aqueous solution was in a 16 mm diameter Pyrex test tube and stirred with a magnetic stirrer during illumination. The intensity of light at the sample was 5.1 mW/cm^2 as measured with an Optronics 740A photometer with the detector traceable to NIST standard no. 844/D-2 (Optronics Laboratories, Inc., Orlando, FL).

2.3. Chemical analysis

Organic intermediates and 2,4,6-trinitrotoluene were detected by HPLC chromatography using a Varian Prostar 210 HPLC with model 330 PDA detector fitted with a Supelcosil LC-18 column. A 40% acetonitrile/60% water solution was used as eluent at 0.7 mL/min flow rate. Identification of intermediates was performed by comparison of their UV–Vis spectra to the spectra of known specific compounds.

3. Results

3.1. Formation of porphyrin crystals

The porphyrin crystals were made by mixing 1:1 molar ratios of Zn-TPPS and TMPyP in 18 mΩ de-ionized water solutions at room temperature. The pH of the solution was not controlled or monitored. Crystals start forming immediately after mixing the two porphyrin monomers. The aqueous mixture of the two porphyrins solution was kept undisturbed in the dark for 24 h. After crystals formed in solution, the solid (dark purple color) crystals were filtered and washed three times with de-ionized water, ethanol, and pH 7.0 sodium phosphate (NaPi) buffer. Different porphyrin concentrations were used to make the crystals to study the effect of the porphyrin concentrations on the size and morphology of the crystals. The resulting crystals have a rod-like or needle-like structure using concentrations up to about 100 μM of each porphyrin in the formation process. The crystal length is 30–55 μm and the thickness is 2–3 μm as shown in Fig. 2a At porphyrin concentrations between 100 μM and 0.5 mM, the rod-like crystals have split ends. The length of the crystals is also 30–55 μm but the thickness increases to 3–4 μm as shown in Fig. 2b. At 0.5 mM porphyrin concentration, the crystals have a 'star-like' shape with length ranging from 30 μm to 40 μm, width ranging between 10 μm and 25 μm, and thickness 3–5 μm as shown in Fig. 2c.

3.2. UV–Vis spectroscopy

The absorbance spectra of *meso*-tetra(*N*-methy-4-pyridyl)porphyrin tetratosylate (TMPyP) in a 50 mM pH 7.0 phosphate buffer at room temperature exhibits an absorbance peak in the Soret region at 422 nm and four Q-bands at 519 nm, 553 nm, 585 nm, and 640 nm. The absorbance spectrum of zinc-tetrakis(4-sulfonatophenyl)porphyrin (Zn-TPPS) in 50 mM pH 7.0 phosphate buffer at room temperature exhibits a Soret absorbance peak at 421 nm and two Q-bands at 556 nm and 597 nm as seen in Fig. 3. The locations of the peaks were determined from the second derivatives of the absorbance spectra using Grams/32 (Galactic Industries, Salem,

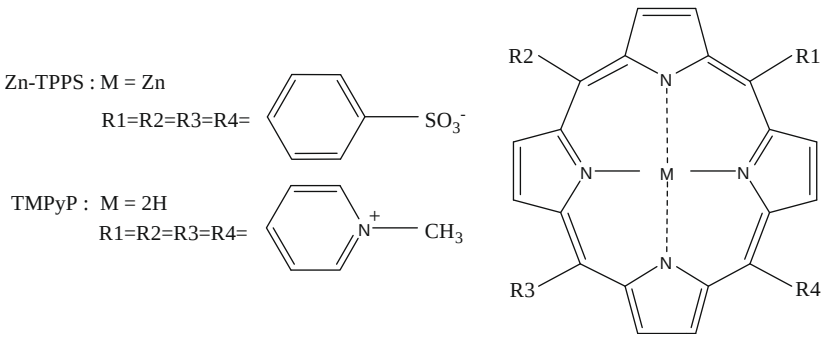

Fig. 1. Chemical structures of porphyrins used in making the porphyrin crystals.

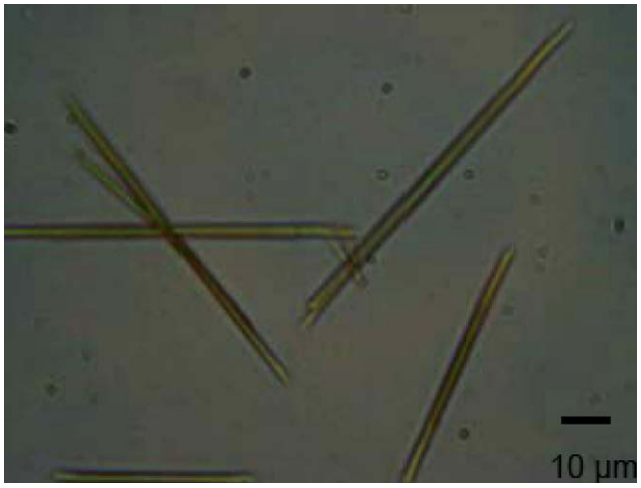

Fig. 2a. Optical microscope micrograph of porphyrin crystals: porphyrin concentration = 100 μM.

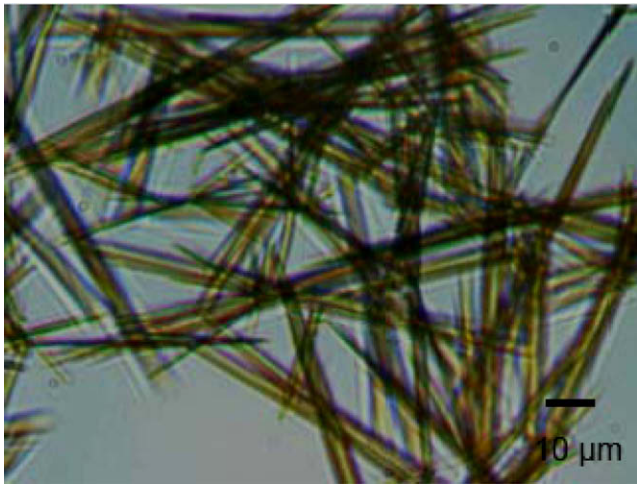

Fig. 2b. Optical microscope micrograph of porphyrin crystals: porphyrin concentration = 200 μM.

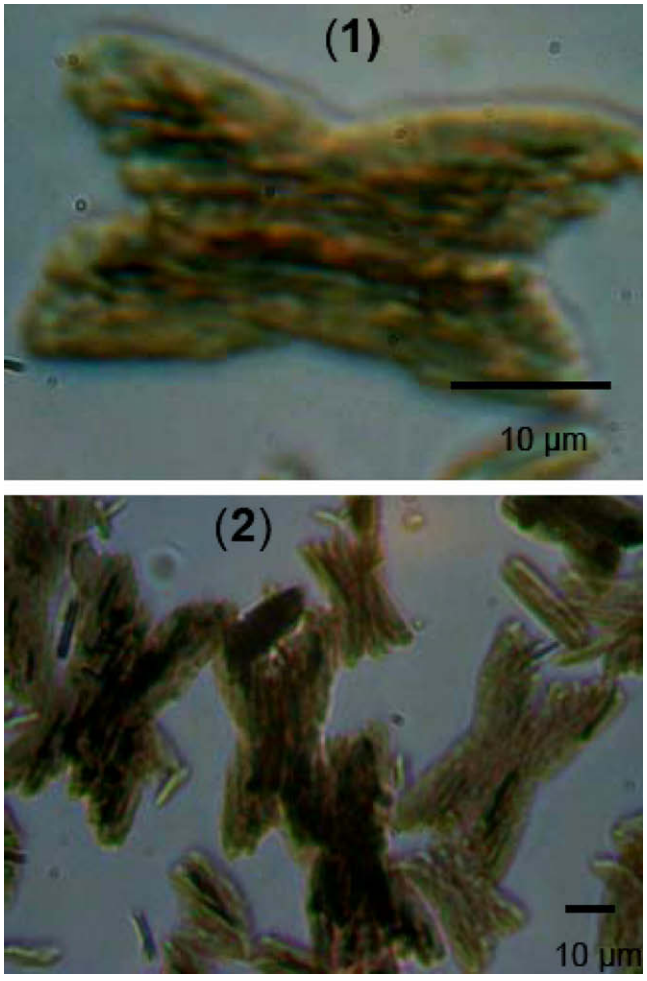

Fig. 2c. Optical microscope micrograph of porphyrin crystals: porphyrin concentration = 0.5 mM.

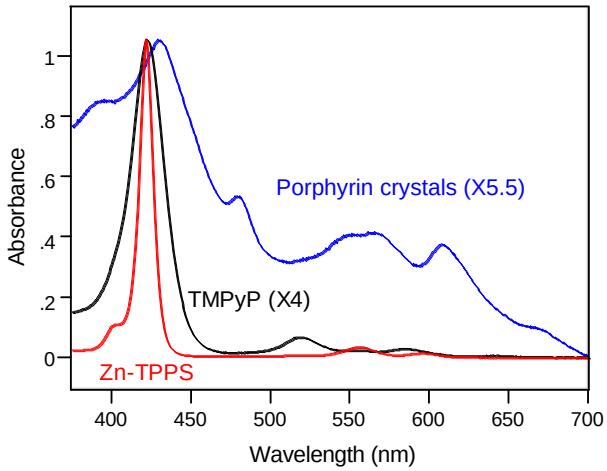

Fig. 3. Absorbance spectra of 1.6 μM *meso*-tetra(*N*-methy-4-pyridyl)porphyrin (TMPyP) and 1.6 μM zinc-tetrakis(4-sulfonatophenyl)porphyrin (Zn-TPPS) in 50 mM sodium phosphate (NaPi) buffer compared to the absorbance spectrum of the solid porphyrin crystals at room temperature (note the different scale).

NH). The Soret band of the porphyrin crystals is broadened and split into a blue-shifted band at 398 nm and a red-shifted band at 431 nm with a shoulder at 450 nm. The Q-bands of the porphyrin crystals are located at 486 nm, 548 nm, 552 nm, 577 nm, 612 nm, and 677 nm. The shape of the spectrum and the locations of the absorbance peaks are independent of the crystals size.

To determine the amount of porphyrins incorporated into the crystal structures, the absorbance spectrum of the solution remaining after crystal formation was measured and the intensity of the Soret peak was compared to those of the absorbance spectra of 1.6 μM of Zn-TPPS and TMPyP porphyrins in solutions at pH 7.0 sodium phosphate (NaPi) buffer at room temperature. The results indicate that 100% of TMPyP and 96% of Zn-TPPS starting solutions are incorporated into crystals (data not shown). The microcrystals are highly stable; crystals dissolve only in a 4 M HCl solution at room temperature for about 24 h or in a 2 M NaCl at 60 °C.

3.3. Fluorescence spectroscopy

The fluorescence spectra of TMPyP and Zn-TPPS are shown in Fig. 4 along with that of the crystalline structure with excitation at 422 nm, 421 nm, and 431 nm (Soret peak absorbance wavelengths), respectively. The positions of the emission peaks were determined from the second derivatives of the fluorescence spectra using Grams/32. The fluorescence spectrum of TMPyP consists of two broad and overlapping emission peaks centered at 654 nm

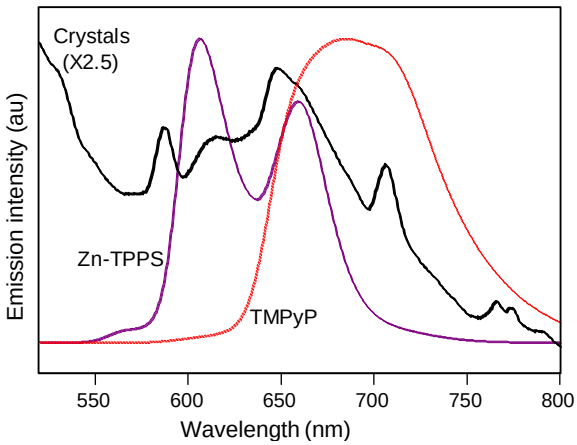

Fig. 4. Normalized emission spectra of Zn-TPPS, TMPyP, and crystals excited at 421 nm, 422 nm, and 431 nm, respectively.

with a shoulder at 683 nm and 713 nm. The fluorescence spectrum of Zn-TPPS consists of two well-defined emission peaks at 603 nm and 660 nm. The fluorescence spectrum of the porphyrin crystals is quenched and consists of seven emission peaks centered at 587 nm, 610 nm, 646 nm with a shoulder at 661 nm, 707 nm, 765 nm, 774 nm, and 791 nm. The three crystalline structures have similar fluorescence spectra.

3.4. Powder X-ray diffraction

Powder X-ray diffraction patterns of the two porphyrins, Zn-TPPS and TMPyP, used in making the solid porphyrin crystals have been obtained (data not shown). The porphyrin powders were used as supplied by the manufacturer. The X-ray diffraction patterns indicate that while Zn-TPPS is not in a crystalline form, TMPyP porphyrin is crystallized. We did not attempt to determine the crystal structure of the starting porphyrins since there is no standard procedure for crystallizing porphyrins. The crystal structure of the two monomer porphyrins could not be found in the literature.

The powder X-ray diffraction pattern of the porphyrin crystals is shown in Fig. 5. The diffraction pattern of the solid porphyrin crystals consists of only five peaks, which indicates that porphyrin crystals exist in a single phase. The diffraction pattern of porphyrin crystals is different from those of the monomer porphyrins suggesting the complexation of the two porphyrins to form the porphyrin crystals. The X-ray crystallography study reveals that the porphyrin crystals belong to the orthorhombic ($\alpha = \beta = \gamma = 90°$) system with unit cell dimensions of $a = 16.9416$ Å, $b = 14.5787$ Å, and $c = 4.8935$ Å. The volume of the unit cell is $V = a * b * c = 1208.616$ Å^3. Zinc porphyrins have been reported to crystallize in the orthorhombic system, for example, zinc(II)-tetrakis(4-methoxycarbonylphenyl)porphyrin–pyridine complex [30]. Crystal structure of multi-porphyrin structures could not be found in the literature. Since the negative charge on the anionic Zn-TPPS is held by the positive charge on the sodium ions (Na^+) and the positive charge on the cationic TMPyP porphyrin is held by the negative charge on the tosylate ions (Tos^-), sodium tosylate (or sodium toluene sulfonate) is formed in the process of developing the porphyrin crystals. This raises the possibility that sodium tosylate might be incorporated in the porphyrin crystals or exist side-by-side with the porphyrin crystals if has not been removed in washing/rinsing the crystals. Thus, for comparison reasons, a powder X-ray diffraction pattern of sodium tosylate crystals was obtained. The diffraction pattern of sodium tosylate is completely different from that of the porphyrin crystals (data not shown). The three prominent peaks of sodium tosylate XRD pattern at $\theta = 5°$, $\theta = 40°$, and $\theta = 45.5°$ do not exist in the porphyrin crystals XRD pattern which indicates that sodium tosylate is not incorporated in the porphyrin crystals and was removed in the washing/rinsing process of the porphyrin crystals.

3.5. 2,4,6-Trinitrotoluene degradation

The loss of 2,4,6-trinitrotoluene over time in presence of the immobilized star-like porphyrin crystalline structure is shown in

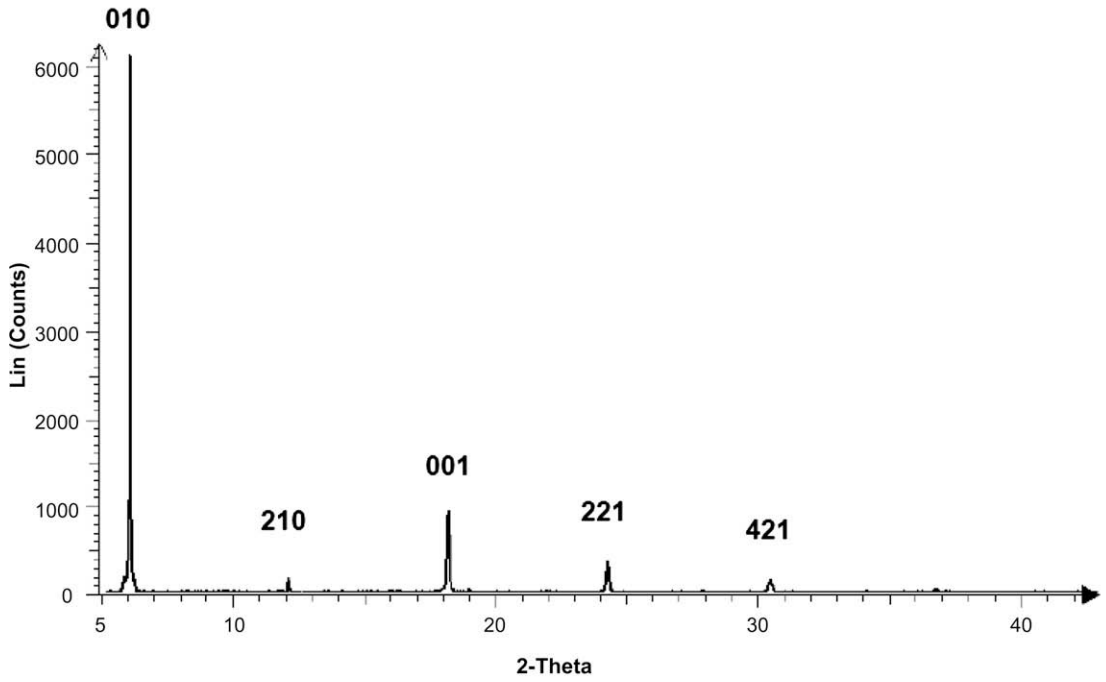

Fig. 5. Powder X-ray diffraction pattern of porphyrin crystals.

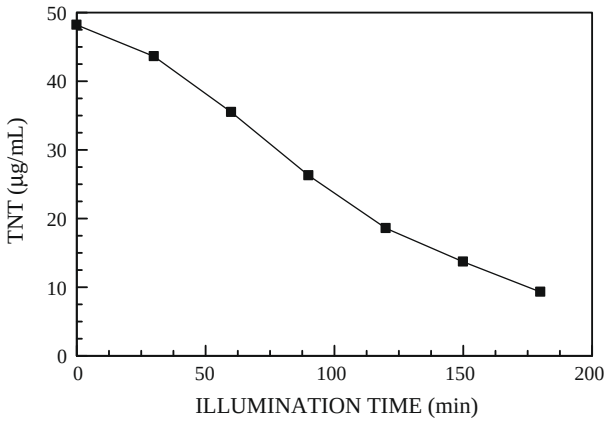

Fig. 6a. Time-dependent degradation of aqueous TNT solution using tungsten illumination in the presence of porphyrin crystals.

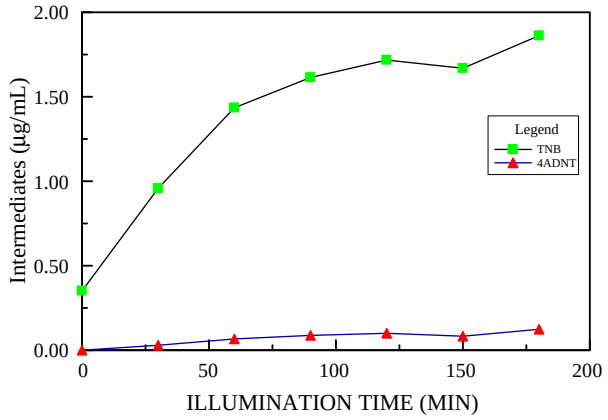

Fig. 6b. Time-dependent appearance of the TNT degradation products using tungsten illumination in the presence of porphyrin crystals.

Fig. 6a. Twenty percent of the original concentration (48 µg/mL) of TNT remained after 3 h of visible light exposure. The loss of TNT results in only two degradation products, 1,3,5-trinitrobenzene (TNB) and 4-amino-2,6-dinitrotoluene forming over time as shown in Fig. 6b, which were identified as such to greater than 99.9% probability on the basis of comparison of HPLC retention times and UV–Vis light spectra of pure standard compounds chromatographed under the same experimental conditions. Formation of other compounds was not observed. The degradation products seem to level off after 90 min of illumination even though the amount of TNT continues to decrease, possibly indicates that these intermediates are at a steady state level as they are degraded. After 90 min, intermediates are degraded as fast as or faster than they are generated. TNT degradation does not occur in the absence of light or the absence of crystals. The solid porphyrin crystals do not degrade over the course of the experiment.

4. Discussion

The formation of porphyrin aggregates can involve electrostatic forces between porphyrins molecules, hydrogen bonding, van der Waals, axial coordination, or other weak intermolecular interactions. These forces enhance the structural stability of the formed structures [19,20].

1:1 mixtures of tetrakis(4-methylpyridyl)porphyrin (TMPyP) and tetrakis(4-sulfonatophenyl)porphyrin (TPPS) in water results in the formation of precipitates that do not have a specific shape or structure [21]. This is in agreement with our results of mixing the same non-metallated porphyrins and confirms that zinc is needed for the production of the porphyrin crystals being reported in this article. We have attempted to make porphyrin crystals using different matalloporphyrins such as Cu-TPPS, Ni-TPPS, and Fe-TPPS instead of Zn-TPPS in de-ionized water. Mixing these porphyrins with TMPyP under the same experimental conditions results in the formation of non-crystalline precipitates (aggregates) with no specific morphology. Zinc in Zn-TPPS porphyrin solution exists as Zn^{2+} ions which makes it readily available for axial coordination with other species. Zinc is a good candidate for the use in making our porphyrin crystals in de-ionized water since it has high affinity for axial coordination bonding with water molecules than iron, copper, tin, and nickel.

Nanoporous metalloporphyrin crystalline solids as possible size- and shape-selective oxidation catalysts and zinc-porphyrin-doped polymethylmethacrylate (PMMA) used as a photochromic recording medium have been studied [22]. Fluorescent micro-scaled needle-shaped zinc–porphyrin crystals have been made via hydrothermal synthesis [23]. Porphyrin polymers have been previously reported to form by coordination bonding between a Zn^{2+} ion embedded in 5,15-di(4-nitrophenyl)-10,20-di(*p*-tolyl)porphyrin core and one of the oxygen atoms of the nitro groups on two neighboring molecules [24]. Homogeneous coordination polymers composed of metal chromophores without exocyclic linkers have also been reported [4,25] where the metal ion inserted in the core of the porphyrin exhibits a high propensity for octahedral coordination to the pyrrole groups of the porphyrin ligand at the four equatorial positions and to two adjacent porphyrin entities at the axial sites. Zn-TMPyP is a suitable example, in which the resulting assemblies represent two-dimensional nets composed of hexa-coordinated porphyrins that are nearly orthogonal with respect to one another. The negatively charged $[H_4TPPS_4]^{2-}$ porphyrin and the positively charged $[Sn–TPyP]^{4+/5+}$ porphyrin have been reported to form porphyrin nanotubes [26] in aqueous solution by ionic binding of the oppositely charged substituent groups with the aid of acidification. Porphyrin nanotubes form only at pH 2.0 and dissolve into monomeric porphyrins at pH 12.0. At pH 2.0, the anionic $[H_4TPPS_4]^{2-}$ porphyrin is protonated (the four nitrogen atoms in the core of the TPPS porphyrin molecule are bound to four hydrogen atoms), but the sulfonate groups (p*K*a = 1.6) are not. This would prevent the hydrogen bonding between the water molecules that are axially bonded to the metal ions embedded in $[Sn-TPyP]^{4+/5+}$ porphyrin, allowing only the formation of two-dimensional structures (sheets that roll into tubes) by the ionic binding of the oppositely charged substituents.

The two oppositely charged porphyrins (Zn-TPPS and TMPyP) used in the current study each possess four symmetrical substituent groups. Since the crystals were made in de-ionized water without acidification, deprotonation of the sulfonate groups ($pK \approx 1.6$) on the Zn-TPPS porphyrin could allow ionic binding of negatively charged sulfonate groups to the positively charged methylpyridinium groups of TMPyP porphyrin. As we mentioned above the Zn^{2+} ion in the core of Zn-TPPS could bind axially to two atoms of higher electronegativity above and below the plane of Zn-TPPS porphyrin. These two facts suggest the binding of the two porphyrins via at least two different types of chemical bonds that allow three-dimensional crystalline structures formation.

The absorbance spectrum of the porphyrin crystals is rather complicated than those of the porphyrin monomers. The Soret band of the porphyrin crystals is broadened and split into a blue-shifted band at 398 nm and a red-shifted band at 431 nm with a shoulder at 450 nm. The Q-bands are broadened and red-shifted. The large shifts, peak splitting, and the broadening in the absorbance peaks are expected for porphyrin architectures and multi-

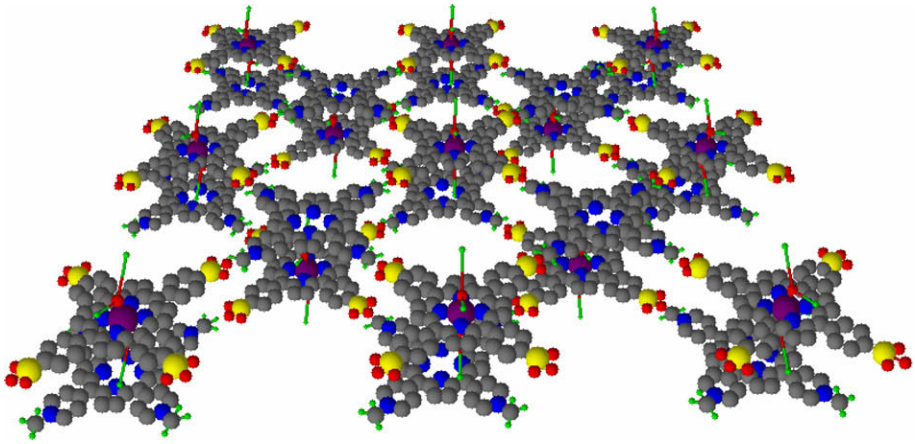

Fig. 7. Crystal packing of the solid porphyrin crystals showing the offset stacking mode between two neighboring layers. The axial water ligands of one layer protrude into the hydrogen bonding sites of the next layer to facilitate interlayer hydrogen bonding.

porphyrin systems [27,28]. The locations of both the Soret band and the Q-bands of the absorbance spectrum of the porphyrin crystals are different from those of the original porphyrin monomers consistent with the complexation of the two porphyrins to form the solid porphyrin crystals; if complexation had not occurred the spectrum of the crystals would be a simple additive combination of the two porphyrins spectra. The broadening, blue-shift, and red-shift in the Soret band in addition to the broadening and red-shift in the Q-bands of the porphyrin crystals absorbance spectrum indicate strong intermolecular and π–π interactions (marked orbital overlap) between the monomer porphyrins in forming the solid crystals [29–31]: This suggests the presence of both side-by-side (J-aggregation) and face-to-face (H-aggregation) interactions.

The different locations of the fluorescence peaks of the porphyrin crystals further suggest the complexation of the two monomer porphyrins to form the solid crystals. Furthermore, the fluorescence of the porphyrin crystals is quenched compared to those of the porphyrin monomers. This could be explained by the fact that in a composite molecule the internal conversion between the split singlet states is expected resulting in preventing fluorescence from the allowed excited state to the ground state [29]. The quenching of the fluorescence spectrum of the porphyrin crystals indicates the occurrence of π–π interactions [31].

The complexation of the Zn-TPPS and TMPyP porphyrins to form the porphyrin crystals is also highly suggested by the crystalline nature of the X-ray diffraction pattern of the porphyrin crystals which is different from those of the monomer porphyrins. Based on the crystallographic data and the chemical nature of the two porphyrins used in making the solid porphyrin crystals, we speculate that the formation of the crystals is achieved by the ionic bonding of the cationic and anionic porphyrins supported by the π–π interactions between *meso*-substituents (the phenyl group on the Zn-TPPS porphyrin and the methylpyridinium group on the TMPyP porphyrin) and the pyrrole rings of the two porphyrins.

The size of the porphyrin crystals is not suitable for performance of single-crystal X-ray diffraction in order to determine, to some extent, the exact crystal structure of these crystals. However, the dimensions of the unit cell, determined from the powder X-ray diffraction measurements, along with the chemical nature of the two porphyrins, suggest the ionic bonding between the two oppositely charged porphyrins resulting in the development of two-dimensional sheets of the two porphyrins with 1:1 stoichiometry. The dimensions of the unit cell (a = 16.9416 Å and b = 14.5787 Å) are of the order of the dimensions of a single porphyrin molecule. The small value of the third dimension of the unit cell (c = 4.8935 Å) suggests the co-facial offset stacking of the porphyrin sheets assisted by the axial coordination bonding of Zn^{2+} ions to two oxygen atoms of two water molecules (Zn^{2+}–O coordination) which in turn could bind to two unprotonated nitrogen atoms in the pyrrole ring of two TMPyP porphyrin molecules above and below the plane of this specific Zn-TPPS molecule via hydrogen bonding. This allows for formation of multiple interlayer links from the axial water ligands as shown in Fig. 7. Stacking of oppositely charged porphyrins in an alternated face-to-face geometry in porphyrin aggregates is well-known and has been reported by Lauceri et al. [31]. However in their study the cationic porphyrins are metallated (M-TMPyP) and the anionic porphyrin (TPPS) is protonated hindering the H-aggregation even though the metal ion in the cationic porphyrin is axially coordinated with two water molecules. This agrees well with our system and further suggests the growth of the porphyrin crystals by the mechanisms discussed above. The zinc atom at the center of porphyrins have been reported to lie out of the zinc porphyrins plane by 0.16–0.425 Å [32,33]. The oxygen atom has also been reported to form Zn–O bond in 5,10,15,20-tetrakis(4-(2-hydroxyethoxy)ethoxy)phenyl)porphyrin with a bond length of 2.124 Å [34] which is also similar to the bond length of Zn–N bond when zinc porphyrins bind to a pyridyl groups (Zn–N = 2.1 Å) [35]. The molecular diameter of a water molecule is 2.6–2.75 Å which is coincidentally is similar to a hydrogen bond [36]. The sum of the lengths of these bonds lies in the range from 4.88 Å to 5.299 Å. The value of the interplanar distance between the sheets in the porphyrin crystals (c = 4.89 Å) lies within the range of the sum of the lengths of the bonds mentioned above. Similar unit cell dimensions have been reported for single crystals of monomer porphyrin crystalline structures implicating the involvement of water molecules in the axial coordination of metlloporphyrins [33,37]. We suggest that the porphyrin crystals are likely formed via different bonding mechanisms: ionic bonding, π–π interactions, and hydrogen bonding in addition to the expected hydrophobic interaction of the aromatic macrocycles concur in holding the individual constituents together. All of these forces would result in a very stable complex (porphyrin crystals) formed with close face-to-face geometry. Porphyrin crystals were soaked in 95% ethanol, 1 M NaOH, 1 M NaCl, and 8 M urea for 24 h in order to examine their stability. The crystals did not dissolve in any of the listed solutions. However, the crystals dissolve completely by soaking them in 4 M HCl at room temperature for 24 h or in 2 M NaCl at 60 °C for 24 h further suggesting the involvement of both hydrogen and ionic bonds in making the crystals and the unusual stability of the solid crystals porphyrin reported in this work.

The increase of the size (rod-like or needle-like crystals to rod-like or needle-like with split ends and larger dimensions crystals to star-like with even larger dimensions crystals) of the porphyrin crystals with increasing porphyrin concentration in the solution may be explained by the higher binding probability at higher porphyrin concentrations. This is due to the relatively large electrostatic forces exerted by the neighboring porphyrin molecules at higher concentrations: increasing the concentration of porphyrins in the solution results in a smaller value of the intermolecular separation and in turn a greater electrostatic force. The different shapes of the crystals at different concentrations indicate the effect of the concentration on shaping the crystals; higher concentrations give rise to a specific binding mechanism (probably the ionic bonding between the porphyrin molecules) over the others as a result of decreasing the molecular spacing giving rise to crystalline structure with a flatter surface (star-like crystals). At low porphyrin concentrations, the ionic bonding between Zn-TPPS and TMPyP porphyrins is expected to be slower than that at high concentration allowing the porphyrin sheets to roll into tubes. However, the axial hydrogen coordination bonding of zinc with water in Zn-TPPS still can take place on the surface of these tubes resulting in rod-like or needle-like crystals that consist of numerous concentric tubes (rod-like or needle-like crystals).

Porphyrins have been previously used in 2,4,6-trinitrotoluene photodegradation. Harmon [18] reported on degrading diluted TNT solution using both free-base and metalloporphyrin solutions and showed that free-base porphyrin (TPPS) degrade TNT faster than metalloporphyrins with trinitrobenzene and trinitrobenzoic acid as degradation products and 37% of the original TNT concentration remained after 3.5 h of illumination. White et al. [38] have also reported on sunlight catalyzed conversion of TNT using porphyrin-embedded periodic mesoporous organosilica and showed that 32% of the original concentration of the diluted TNT solution remained after 5 h of illumination.

In the current work, 2,4,6-trinitrotoluene degradation data show that porphyrin solid crystals are able to degrade TNT when illuminated by visible light without addition of additional reductants. Only twenty percent of the original concentration of TNT solution remained after illumination with visible light for 3 h with trinitrobenzene (TNB) and 4-amino-2,6-DNT the only observed intermediates. The TNT degradation products suggest that the degradation of TNT occurs via two steps. First is the oxidation of the methyl group of TNT, which results in removing the methyl group, to yield TNB and second is the reduction of the 4-nitro group of TNT to an amino group to yield 4ADNT.

The immobilized porphyrin crystals used in the HPLC experiment were dissolved in 4 M HCl. The Soret band of the absorbance spectrum of the dissolved crystals was compared to the Soret band of a 1:1 molar ratio solution of the two monomer porphyrins in 4 M HCl to determine the concentration of porphyrin used in this specific run. The comparison revealed that 23 μM of each porphyrin was incorporated in theses crystals. Thus, in our system the porphyrins exist in approximately 1:8 mol/mol with respect to 2,4,6-trinitrotoluene (approximately 400 μM). The porphyrin crystals hydrolyze water resulting in production of protons and electrons. Thus the water molecules serve as the sacrificial electron donor [39–41].

Usually π-electron structure of porphyrin monocation is unstable [39] but the electron structure can be stabilized in the ground state in the case of dimeric form by coordination of the neighboring porphyrin molecule with the formation of water-porphyrin dimeric complex (donor–acceptor complex) via hydrogen bonds of two water molecules involved in the complex [40,41]. The stability of the porphyrin crystals is achieved via the donation of protons to the complexed porphyrin monomers by the water molecules as a result of formation of donor–acceptor complex.

We have previously reported on the binding of 2,4,6-trinitrotoluene to porphyrin by hydrogen bond(s) between a pyrrole-N(s) in the core of the porphyrin and a nitro-oxygen(s) of TNT at room temperature [13]. We suggest that the binding of TNT to the porphyrin crystals occurs by the same mechanism since the crystals will have both types of porphyrins, Zn-TPPS and TMPyP, which will provide larger number of binding sites for TNT that are closely packed. Based on the preferred reduction of the 4-nitro group of TNT to a 4-amino group [42] and that the reduction will occur via the pyrrole core of the porphyrin [43], we suggest that the hydrogen bond(s) form between the 4-nitro group of TNT and the pyrrole nitrogen atoms as O–H–N hydrogen bonds. Once the TNT binds to the crystals surface the degradation process takes place by either the demethylation of TNT (removal of the methyl group) [18] which will yield trinitrobenzene (TNB) or the reduction of one of the nitro group(s) of TNT to form amino group(s) to yield 4-amino-2,6-dinitrotoluene which has been previously reported [43,44].

5. Conclusion

The formation of highly stable micro-scale crystalline structures using two oppositely charged water-soluble porphyrins (TMPyP and Zn-TPPS) was investigated by means of optical microscopy, UV–Vis spectroscopy, fluorescence spectroscopy, and powder X-ray diffraction. The porphyrin crystals have different absorbance and fluorescence spectra from the porphyrin monomers used in making them which suggests the complexation of the two monomer porphyrins used in making the crystals. Porphyrin crystals photocatalytically degrade aqueous 2,4,6-trinitrotoluene solution upon illumination with a tungsten lamp (visible light). The porphyrin solid crystals do not dissolve or degrade over the course of the experiment.

ABSTRACT

The condensation of 3-amino-1*H*-1,2,4-triazole with benzaldehyde and terephthalaldehyde provides the bidentate and tetradentate Schiff bases 1,2,4-triazolo-3-imino-benzene L^1H and 1,4-bis(1,2,4-triazolo-3-imino)benzene L^2H_2, respectively. The well characterized Schiff bases were allowed to react with *cis*-$Ru(bpy)_2Cl_2 \cdot 2H_2O$. Isomers of the mononuclear complexes $Ru(bpy)_2L^1]PF_6 \cdot NH_4PF_6$ (**1a**, N4) and $[Ru(bpy)_2L^1]PF_6 \cdot 0.5NH_4PF_6$ (**1b**, N2), and the dinuclear Ru(II) complexes $[Ru(bpy)_2L^2Ru(bpy)_2](PF_6)_2 \cdot NH_4PF_6$ (**2a**, N4N4), $[Ru(bpy)_2L^2Ru(bpy)_2](PF_6)_2 \cdot NH_4PF_6 \cdot 2H_2O$ (**2b**, N2N2) and $[Ru(bpy)_2L^{2-}Ru(bpy)_2](PF_6)_3 \cdot NH_4PF_6$ (**2c**, Ru(II)-Ru(III)) were separated by column chromatography and characterized by their elemental analysis, FAB mass and spectral (IR, NMR, UV–Vis) data. The data obtained suggest that the ligands are bound to the metal centre via the N4 and N2 atoms of the triazole moiety along with the N (imine) atom. The complexes display metal-to-ligand charge-transfer (MLCT) transitions in the visible region from the $d\pi(Ru^{II}) \rightarrow \pi^*L$ transition. Highly intense ligand-based $\pi \rightarrow \pi^*$ transitions are observed in the UV region. A dual emission occurs from the N2 and N2N2 isomers.

1. Introduction

Ruthenium(II) polypyridyl complexes are at the centre of research owing to their well defined spectroscopic, photo-physical, photochemical and electrochemical properties [1]. These properties are exploited in the construction of supramolecular systems [2] as well as in the development of molecular devices [3]. Their incorporation into multinuclear structures capable of directing and modulating electron and or energy transfer processes has been extensively studied [3,4]. The ability of these complexes to tune their excited state properties lies in centre of their potential applications. In this context, a detailed and interesting investigation on the synthesis and characterization of multinuclear ruthenium(II) and osmium(II) polypyridyl complexes using negatively charged triazole based ligands have been reported [5,6]. Relatively strong interactions can be obtained between metal centres mediating both electron transfer and energy transfer processes efficiently [7]. Thus the synthesis and characterization of dinuclear complexes specifically with Schiff bases which are considered potential candidates to facilitate thermal and photon induced energy transfer processes [8], is considered as a challenging and interesting research area.

Recently, Vos et al. have extended these studies with the complex of *cis*-$Ru(bpy)_2Cl_2 \cdot 2H_2O$ with the ligand 3-(pyrazin-2-yl)-5-(pyridin-2-yl)-1,2,4-triazole (Hppt) [9]. The asymmetry of the ligand may result in the formation of four different mononuclear coordination isomers (N2 and N4). As expected, the reaction of one equivalent of the bridging ligand with two equivalents of a $[M(bpy)_2]$ precursor leads to the formation of a mixture of different coordination isomers. Hence identification of the different isomers is found challenging. However, it has been reported for several 1,2,4-triazoles that the presence of bulky substituents in the 5-position of the 1,2,4-triazole ring leads to the preferential formation of the N2 isomer. Thus, the amount of N4 bound isomers varies from 50% (5 position occupied by hydrogen) [10] to less than 5% (5 position occupied by Br) [11].

Based on these precedences and our earlier interest on triazole systems [12], an attempt has been made to synthesize, purify and characterize some mononuclear and dinuclear complexes of bidentate (L^1H) and tetradentate (L^2H_2) triazole based Schiff bases (Fig. 1) with the $Ru(bpy)_2$ unit. The different isomers obtained from complexes **1** and **2** are separated using column chromatography. The separated complexes are characterized using spectroscopic techniques.

In the present system, the 5-position of the triazole ring bears only a hydrogen atom, so equal amounts of N2 and N4 isomers are found.

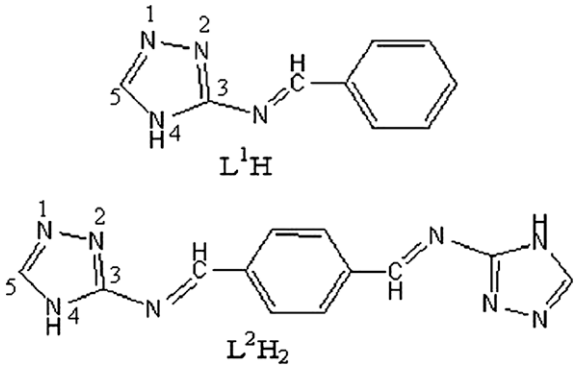

Fig. 1. Structure of the ligands.

2. Experimental

2.1. Materials and methods

All the preparations were carried out in a N_2 gas atmosphere at ambient temperature and pressure. All the solvents purchased from E. Merck were used without further distillation. However, $RuCl_3 \cdot 3H_2O$, 2,2′-bipyridine, 3-amino-1*H*-1,2,4-triazole and terephthalaldehyde purchased from Sigma–Aldrich were used as supplied. *cis*-$[Ru(bpy)_2Cl_2] \cdot 2H_2O$ [13] was prepared using the reported method. For electrochemical studies, HPLC-grade acetonitrile was used.

FAB mass data were obtained from SAIF-CDRI, Lucknow, India, using a JEOL SX-102/DA-6000 mass spectrometer and nitrobenzyl alcohol (NBA) as a matrix. IR spectra were recorded on a JASCO FT/IR 5300 or a Varian 3100 FTIR. ^{1}H NMR/^{13}C NMR spectra (in DMSO-d_6) were recorded on a JEOL-AL-300 MHz NMR spectrometer using $Si(CH_3)_4$ as an internal reference. UV–Vis spectra were recorded on a SHIMADZU UV-1601 spectrophotometer, whereas luminescence measurements were recorded on a LS-45 spectrophotometer (Perkin Elmer).

2.2. Synthesis of the ligands

The ligands L^1H and L^2H_2 were synthesized by the condensation of 3-amino-1*H*-1,2,4-triazole (10 mmol, 0.84 g) with benzaldehyde (10 mmol, 1.06 g) and terephthalaldehyde (5 mmol, 0.67 g), respectively, in methanol, containing a few drops of acetic acid. After refluxing for 4–6 h, the corresponding solid compounds thus obtained were filtered, washed with methanol, diethylether and dried in vacuo. The ligands were then characterized by IR, ^{1}H NMR, ^{13}C NMR, elemental analysis and FAB mass data. L^1H: A pure white powder. Yield = 1.049 g, 61%. M.p.: 212 °C. Elemental *Anal.* Calc. for $C_9H_8N_4$ (L^1H): C, 62.79; H, 4.65; N, 32.55. Found: C, 62.45; H, 4.41; N, 32.97%. IR (KBr pellet, cm^{-1}): 3245 (ν_{N-H}), 1595 ($\nu_{N=CH}$), 1335 cm^{-1} ($\nu_{triazole\ ring}$). ^{1}H NMR (DMSO-d_6, δ ppm): 14.05 (s, 1H; NH), 9.23 (d, 1H; HC=N), 8.33 (s, 1H; triazole CH), 8.00 (d, 2H; Ar-H), 7.57 (t, 3H; Ar-H). ^{13}C NMR (DMSO-d_6, δ ppm): 163.6 (N=*C*H), 144.9 (N–*C*N_2, triazole), 135.2 (N–*C*H, triazole), 132.3, 129.4, 129.1, 128.8 (aromatic). FAB-MS: *m/z:* 173 $[M+1]^+$. L^2H_2: A pure light yellow powder. Yield = 0.839 g, 73%. Elemental *Anal.* Calc. for $C_{12.5}H_{12}N_8O_{0.5}$ ($L^2H_2 \cdot 0.5CH_3OH$): C, 53.19; H, 4.25; N, 39.71. Found: C, 53.41; H, 4.01; N, 40.09%. IR (KBr pellet, cm^{-1}): 3152 (ν_{N-H}), 1608 ($\nu_{N=CH}$), 1271, 1219 ($\nu_{triazole\ ring}$). ^{1}H NMR (DMSO-d_6, δ ppm): 14.05 (s, 2H; NH), 9.30 (d, 2H; N=CH), 8.38 (s, 2H; trizole CH), 8.15 (d, 4H; Ar-H). ^{13}C NMR (DMSO-d_6, δ ppm): 163.1 (N=CH), 138.3 (N–CH, triazole), 129.8, 129.5 (aromatic). FAB-MS: *m/z:* 267 $[M+1]^+$.

2.3. Synthesis of the complexes

2.3.1. Mononuclear complexes: $[Ru(bpy)_2L^1] \cdot PF_6 \cdot NH_4PF_6$, **1a** and $[Ru(bpy)_2L^1] \cdot PF_6 \cdot 0.5NH_4PF_6$, **1b**

The ligand L^1H (1 mmol, 0.172 g) was mixed with *cis*-$Ru(bpy)_2Cl_2 \cdot 2H_2O$ (1 mmol, 0.520 g) in ethylene glycol and then refluxed for 13 h. A solution of the reaction mixture was then cooled to room temperature, followed by addition of an aqueous solution of NH_4PF_6, and then it was kept for 24 h. The crystalline solid thus obtained was filtered, washed with water followed by a few drops of methanol and diethylether, then dried in vacuo. The yield of the crude product was found to be 0.408 g (56%). After column chromatography on an alumina column using acetonitrile as the eluent, the complex was separated into two products after removing a light yellow band from the column. The second light brown band (isomer **1a**) was then collected followed by another dark brown fraction (**1b**) which was eluted using a mixture of acetonitrile, a saturated aqueous solution of KNO_3 and water in a 7:1:0.5 ratio (v/v). The last two fractions were then reprecipitated separately by the addition of an aqueous solution of NH_4PF_6. The corresponding crystalline solids thus obtained were then filtered, washed with water and methanol, and dried in vacuo. Both parts were further crystallized by dissolving them separately in acetonitrile containing a few drops of water, and kept for 5 days. The crystalline products were then collected, washed with water and dried. Fraction I was characterized as the N4 isomer and was designated as **1a**. Yield = 0.160 g, 22%. Elemental *Anal.* Calc. for $C_{29}H_{27}N_9P_2F_{12}Ru$ ($[Ru(bpy)_2L^1] \cdot PF_6 \cdot NH_4PF_6$): C, 39.01; H, 3.02; N, 14.12. Found: C, 38.69; H, 3.20; N, 14.50%. Λ_M (Ω^{-1} cm^2 mol^{-1}) 367.0. IR (KBr pellet, cm^{-1}): 1603 ($\nu_{N=CH}$), 1218 ($\nu_{triazole\ ring}$), 1465–1415 (ν_{bpy}), 557 (ν_{Ru-N}), 843 ($\nu_{PF_6^-}$); ^{1}H NMR (DMSO-d_6, δ ppm): 9.35 (N=CH), 8.10 (triazole N–CH), 8.02 (Ar-H), 7.80 (Ar-H), 8.70–7.35 (bpy-H); ^{13}C NMR (DMSO-d_6, δ ppm): 156.9 (N=*C*H), 151.4, 149.7, 127, 126, 122 (bpy-C), 137.9, 135.9 (triazole N–*C*), 126.1, 125.5, 123.6 (aromatic). FAB-MS: *m/z*: 729 $[M]^+$, 497, 413.

The second fraction **1b** was identified as the N2 isomer. Yield = 0.182 g 25%. Elemental *Anal.* Calc. for $C_{29}H_{25}N_{8.5}P_{1.5}F_9Ru$ ($[Ru(bpy)_2L^1] \cdot PF_6 \cdot 0.5NH_4PF_6$): C, 42.92; H, 3.08; N, 14.67. Found: C, 43.52; H, 3.00; N, 14.06%. Λ_M (Ω^{-1} cm^2 mol^{-1}) 257.0. IR (KBr pellet, cm^{-1}): 1606 ($\nu_{N=CH}$), 1224 ($\nu_{triazole\ ring}$), 1463, 1447 (ν_{bpy}), 557 (ν_{Ru-N}), 840 ($\nu_{PF_6^-}$). 1H NMR (DMSO-d_6, δ ppm): 9.37 (N=CH), 8.29 (triazole N–CH), 7.83, 7.43 (aromatic), 8.65, 8.20, 7.97, 7.33 (bpy). ^{13}C NMR (DMSO-d_6, δ ppm): 157.5 (N=CH), 153.1, 151.5, 138, 127, 120 (bpy), 137.8, 136 (triazole N–CN_2), 127.1, 124.2, 123.7 (aromatic). FAB-MS: *m/z*: 729 $[M]^+$, 497, 413.

2.3.2. Dinuclear complexes: $[Ru(bpy)_2L^2Ru(bpy)_2](PF_6)_2 \cdot NH_4PF_6$ (**2a**), $[Ru(bpy)_2L^2Ru(bpy)_2](PF_6)_2 \cdot NH_4PF_6 \cdot 2H_2O$ (**2b**) and $[Ru^{II}(bpy)_2L^2Ru^{III}(bpy)_2](PF_6)_3 \cdot NH_4PF_6$ (**2c**)

These complexes were prepared using the procedure as adopted for the synthesis of complex **1**, condensing the ligand L^2H_2 (1 mmol, 0.272 g) with $Ru(bpy)_2Cl_2 \cdot 2H_2O$ (2 mmol, 1.040 g) in ethylene glycol. The reaction mixture was then refluxed for 16 h in a N_2 gas atmosphere. After cooling to room temperature, an aqueous solution of NH_4PF_6 was added and then it was kept for 24 h. The crystalline solid thus obtained was then filtered, washed with water, methanol and diethylether, and dried in vacuo. The yield of the crude products was found to be 0.843 g (61%). The initial yellow solution, separated using column chromatography on an alumina column, was rejected. The next two bands, light and deep dark brown fractions, were separated using acetonitrile as the eluent. The third black fraction was separated using a mixture of acetonitrile, a saturated aqueous solution of KNO_3 and water in a ratio of 7:1:0.5, respectively. These three fractions were identified as N4N4, N2N2 and Ru(II)–Ru(III) isomers, symbolized as **2a**, **2b** and **2c**, respectively. These isomers were further purified

separately by the addition of an aqueous solution of NH_4PF_6 into their corresponding solutions in acetonitrile. The crystallized solids thus obtained were filtered, washed with water and dried in vacuo. Suitable crystals of both mononuclear and dinuclear complexes could not be obtained even after trying for many months.

Complex **2a**: Yield = 0.212 g, 16%. Elemental *Anal.* Calc. for $C_{52}H_{44}N_{17}P_3F_{18}Ru_2$ ($[Ru(bpy)_2L^2Ru(bpy)_2](PF_6)_2 \cdot NH_4PF_6$): C, 40.44; H, 2.85; N, 15.42. Found: C, 40.43; H, 3.13; N, 15.72%. Λ_M (Ω^{-1} cm^2 mol^{-1}) 541.0. IR (KBr pellet, cm^{-1}): 1605 ($\nu_{N=CH}$), 1282 cm^{-1} ($\nu_{triazole\ ring}$), 1459–1383 (ν_{bpy}), 556 (ν_{Ru-N}), 843 ($\nu_{PF_6^-}$). ^{1}H NMR (DMSO-d_6, δ ppm): 8.80 (N=CH), 8.02 (triazole N–CH), 7.95, 7.66 (aromatic), 8.86, 8.18, 7.74, 7.54, 7.46 (bpy). ^{13}C NMR (DMSO-d_6, δ ppm): 157.6 (N=CH), 153.1, 151.5, 137.8, 127.8, 123 (bpy), 137.5, 137.3 (triazole N–CH), 127.2, 126.8 (aromatic). FAB-MS: *m/z*: 1090 [M]$^+$, 413.

Complex **2b**: Yield = 0.186 g 14%. Elemental *Anal.* Calc. for $C_{52}H_{48}N_{17}O_2P_3F_{18}Ru_2$ ($[Ru(bpy)_2L^2Ru(bpy)_2](PF_6)_2 \cdot NH_4PF_6 \cdot 2H_2O$): C, 39.51; H, 3.03; N, 15.07. Found: C, 39.34; H, 2.81; N, 15.55%. Λ_M (Ω^{-1} cm^2 mol^{-1}) 493.0. IR (KBr pellet, cm^{-1}): 1603 ($\nu_{N=CH}$), 1217 cm^{-1} ($\nu_{triazole\ ring}$), 1459–1377 (ν_{bpy}), 557 (ν_{Ru-N}), 844 ($\nu_{PF_6^-}$). ^{1}H NMR (DMSO-d_6, δ ppm): 9.34 (N=CH), 8.42 (N–CH), 8.24, 8.09 (aromatic), 8.78, 8.58, 7.72, 7.35 (bpy). ^{13}C NMR (DMSO-d_6, δ ppm): 157.8 (N=CH), 151.3, 137.0, 127.3, 123, 122 (bpy), 145.8, 137.5 (triazole N–C), 127.1, 125.7 (aromatic). FAB-MS: *m/z*: 1090 [M]$^+$, 413.

Complex **2c**: Yield = 0.265 g, 21%. Elemental *Anal.* Calc. for $C_{52}H_{44}N_{17}P_4F_{24}Ru_2$, ($[Ru(bpy)_2L^2Ru(bpy)_2](PF_6)_3 \cdot NH_4PF_6$): C, 36.96; H, 2.60; N, 14.09. Found: C, 36.48; H, 2.80; N, 13.82%. Λ_M (Ω^{-1} cm^2 mol^{-1}) 584.0. IR (KBr pellet, cm^{-1}): 1604 ($\nu_{N=CH}$), 1223 ($\nu_{triazole\ ring}$), 1458–1383 (ν_{bpy}), 557 (ν_{Ru-N}), 844 ($\nu_{PF_6^-}$). ^{1}H NMR (DMSO-d_6, δ ppm): (broad spectrum) 8.89 (N=CH), 8.09 (N–CH), 8.06, 7.55 (Ar-H), 8.62-7.30 (bpy). FAB-MS: *m/z*: 1090 [M]$^+$, 413.

3. Results and discussion

All the complexes were found to be thermally stable at room temperature and were soluble in acetone, acetonitrile, DMSO and DMF. All the complexes contain NH_4PF_6, even after several washings with water, and are of an electrolytic nature in solution. The physicochemical and electronic properties of the complexes are shown in Table 1.

3.1. IR spectra

It is only νNH and νCH (both of triazole rings) together with νN=CH vibrations that can be used as diagnostics for the characterization of the binding pattern of the ligands with the metal ion. The peak observed at 1216–1285 cm^{-1} is assigned to the triazole ring skeletal vibration in view of an earlier report [14]. However the peak observed at ~1602–1606 cm^{-1} in the spectra of the complexes indicates that a change in the peak position of νN=CH of the free ligands (1595 and 1608 cm^{-1}) occurs upon complexation. The νNH (triazole) vibration observed at 3245 and 3152 cm^{-1} for free ligands L^1 H and L^2H_2, respectively, disappeared in the infrared spectra of their corresponding complexes, indicating that the ligands get deprotonated during their coordination with the metal ion. In this context, it is worth mentioning that it is only the change in the νCH (triazole ring) vibration which could be exploited as a diagnostic to distinguish the N2 and N4 isomers. For the N4 isomer, a change in the νCH vibration is supposed to occur while for the N2 isomer no significant change in νCH is expected. Additionally, peaks observed at 557 cm^{-1} in the spectra of all the isomers were assigned to νRu–N vibrations in view of an earlier report [15]. The peak observed at ~840–844 cm^{-1} was assigned to the $\nu_{PF_6^-}$ vibration. These assignments are further substantiated by the ^{1}H NMR spectra of the complexes.

Table 1
Electronic[a] data of the complexes

Complexes	λ_{max} in nm ($\varepsilon \times 10^4$ M^{-1} cm^{-1})	λ_{em} (nm) at 300 K
1a	465 (1.78), 346 (2.18), 290 (3.99),	520 (0.62)
1b	438 (1.70), 290 (4.00), 236 (3.98),	518 (0.59), 606 (0.86),
2a	456 (0.28), 344 (0.37), 288 (2.08), 245 (1.12)	603 (2.31)
2b	476 (0.35), 343 (0.53), 289 (2.41), 242 (1.32)	635 (1.52), 518 (0.84)
2c	471 (0.52), 343 (0.62), 289 (3.46), 244 (1.74)	675 (0.12)
$[Ru(bpy)_3]^{2+}$	451 (1.29)	608

[a] In acetonitrile at 298 K.

3.2. ^{1}H NMR spectra

The peak observed at δ 14.1 ppm in the spectra of the free ligands and assigned to the NH (triazole ring) proton disappears in the spectra of the complexes. Thus, it supports the proposal that the ligands have coordinated with the metal ion in the deprotonated form. However, a peak observed at δ 8.80–9.37 ppm and assigned to imine protons, also supports that the imine nitrogen of the ligands coordinates with the metal ion. As shown in the ^{1}H NMR spectrum of a representative complex **2a**, (Fig. 2a), the N–*CH* (triazole ring) proton appears at δ 8.02 ppm, whereas the same proton appears at 8.38 ppm in the spectrum of the free ligand L^2H_2. This difference in N–C*H* peak position could arise due to coordination of its neighbouring nitrogen atom. Hence complex **2a** is identified as the N4N4 isomer. However, in the spectrum of complex **2b**, the δ N–*CH* (triazole) proton appears at δ 8.42 ppm, which supports that the triazole rings coordinate via the N2 atom, and hence identifies it as the N2N2 isomer. However, in complex **2c**, the ^{1}H NMR spectral pattern was broad, with the N–*CH* proton of the triazole ring centred at δ = 8.09 ppm. Therefore, coordination via N4 of both triazole rings is considered and hence it is assigned as the N4N4 isomer. However in view of the broad NMR peak, combined with the elemental analysis, complex **2c** is proposed to be the mixed metal (Ru^{II}–Ru^{III}) isomer. For further support, the ^{13}C NMR spectra of the complexes have also been recorded and a representative spectrum of complex **2a** is shown in Fig. 2b.

3.3. ^{13}C NMR spectra

The peak observed at δ 163 ppm in the spectra of the free ligands is assigned to the carbon of the CH=N group which shifts to δ ~157 ppm in the spectra of the complexes (Fig. 2b). Thus, comparison of their ^{13}C NMR spectra directly support the participation of the nitrogen of CH=N in coordination with the metal ion.

3.4. Electronic properties

3.4.1. UV–Vis

UV–Vis spectral data recorded for all isomers in CH_3CN solution (10^{-4} M) are listed in Table 1 and the spectra are shown in Figs. 3a and 3b. The absorption peaks observed in the UV region at λ_{max} 285–346 nm are assigned to ligand-based π–π^* transitions. These bands are very intense in nature. The overall spectral properties are found to be similar to ruthenium bipyridyl as well as Ru-triazole, consistent with an earlier report [2]. The lowest energy MLCT band of $[Ru(bpy)]_3$ appears at 451 nm. The replacement of one bpy ligand by a symmetric coordination (N2N2 and N4N4) results in a red-shift of the same transition (456–476 nm). Since in these complexes, Ru^{II} is in the low-spin t_{2g}^6 state, the observed visible bands

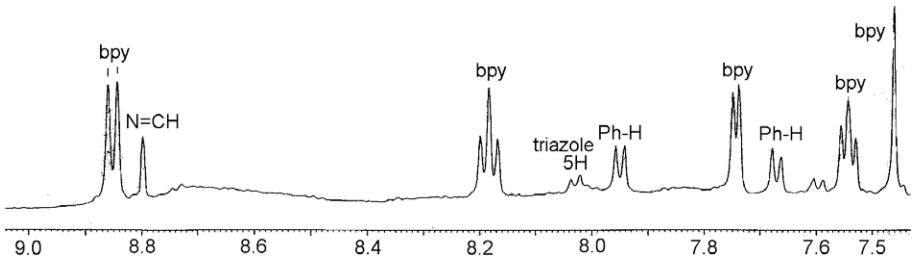

Fig. 2a. ^{1}H NMR spectrum of the representative dinuclear complex **2a**.

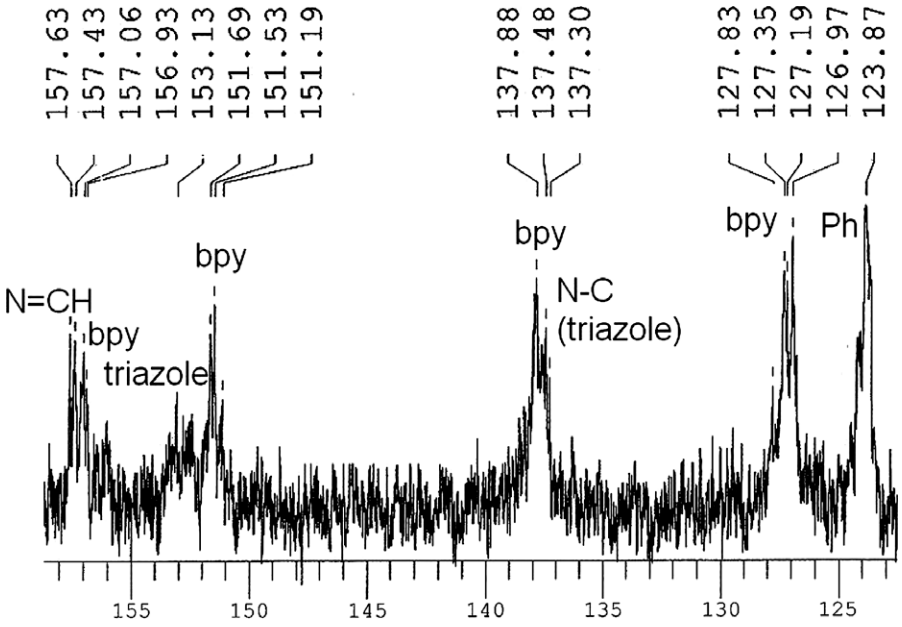

Fig. 2b. ^{13}C NMR spectrum of the representative dinuclear complex **2a**.

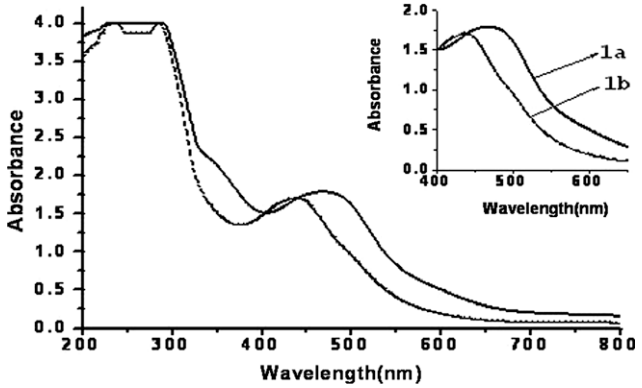

Fig. 3a. UV–Vis spectra of the complexes **1a** and **1b** in acetonitrile at 298 K.

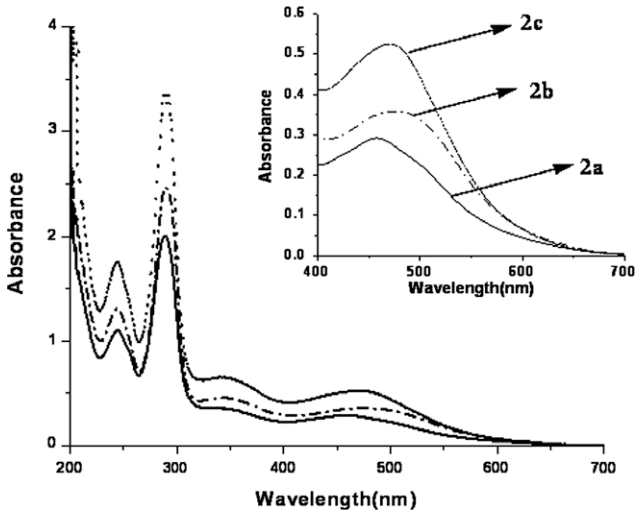

Fig. 3b. UV–Vis spectra of the complexes **2a**, **2b** and **2c** in acetonitrile at 298 K.

are considered to be metal-to-ligand charge-transfer (MLCT) transitions. The lowest energy band is assigned to the $d\pi(Ru^{II}) \rightarrow \pi^{*}(L)$ transition. This explains the observed shifts in this transition with the change in the bridging ligand in the complexes.

Since isomeric coordination compounds have also been distinguished from their emission behaviour, an attempt has been made to study the emission properties of both the mononuclear and dinuclear complexes. Thus, based on the elemental analysis and spectroscopic data, the structures of the complexes are shown in Fig. 4.

3.4.2. Luminescence

The emission spectra of the complexes, excited at λ_{ex} 450 nm and recorded in 10^{-4} M acetonitrile solution, are shown in Fig. 5. From the emission spectra, it is noticed that a dual emission arises at 518 and 606 nm from complex **1b**, whereas complex **2b** emits at 518 and 635 nm. Other isomers show a single emission, except

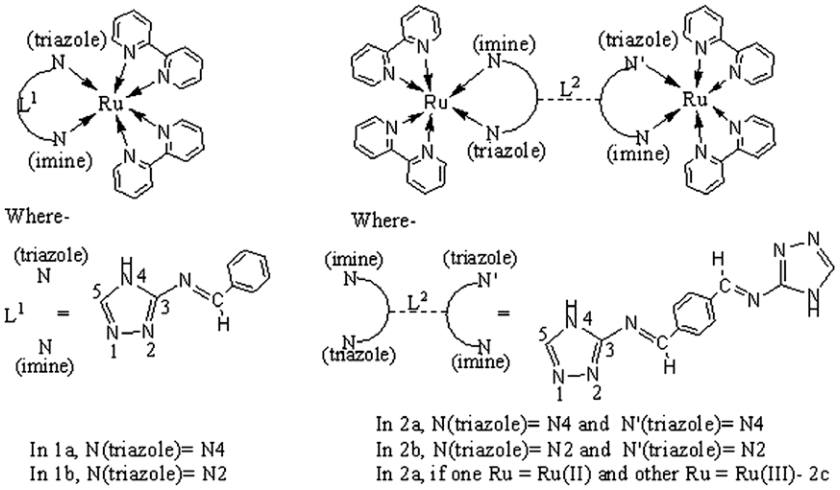

Fig. 4. Proposed structure of the complexes.

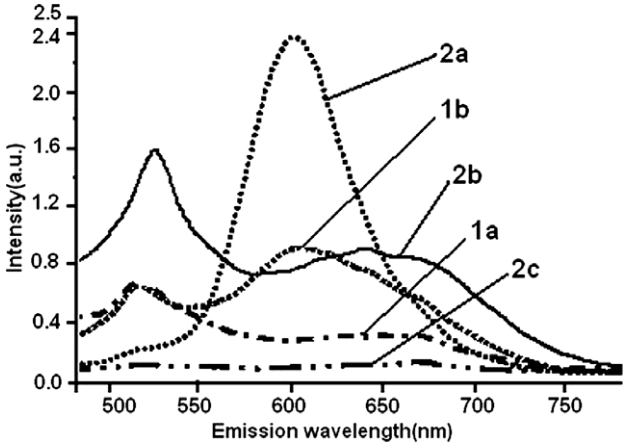

Fig. 5. Emission spectra of the complexes, λ_{ex} = 450 nm, in acetonitrile at 298 K.

complex **2c** which does not emit. Although dual emission is very rare, it has been reported earlier [16,17] in the region 518 and 625 nm, especially arising from triazole complexes with the ruthenium metal ion.

4. Conclusion

Triazolyl Schiff bases, upon their reaction with Ru(II)-2,2′-bipyridyl, provide isomeric metal complexes which are separated by column chromatography. These isomers are characterized by their spectroscopic properties. Dual emissions from metal complexes are rarely observed but the **1b** and **2b** isomers in the present system show dual emissions even at room temperature.

Authors are grateful to the authorities of CSIR, New Delhi, India, for the financial support and to Professor J.G. Vos Dublin City University, Ireland for reading the manuscript and giving useful suggestions in its preliminary stage of preparation.

Appendix A. Supplementary data

Cyclic voltametric measurements of the complexes in acetonitrile (5×10^{-4} M) containing tetrabutylammonium perchlorate as the supporting electrolyte were carried out using a CHI620c electrochemical analyzer. A glassy carbon working electrode, a platinum wire auxiliary electrode and an Ag/AgCl reference electrode were used in a three electrode configuration. The cyclic voltammograms thus obtained are shown as supporting informations (S1). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.09.012.

ABSTRACT

The present investigation reports the novel synthesis of copper nanocrystals using thermal reduction, and their physicochemical characterization. The copper nanocrystal powder has been prepared using [bis(2-hydroxyacetophenato)copper(II)] as a precursor. The effect of oleylamine and triphenylphosphine on the particle morphology has been investigated. Transmission electron microscopy (TEM) analysis has demonstrated that the copper nanocrystals have an average diameter of about 3 nm. The as-prepared copper nanocrystals were characterized by XRD, SEM, TEM, EDX, UV–Vis and FTIR.

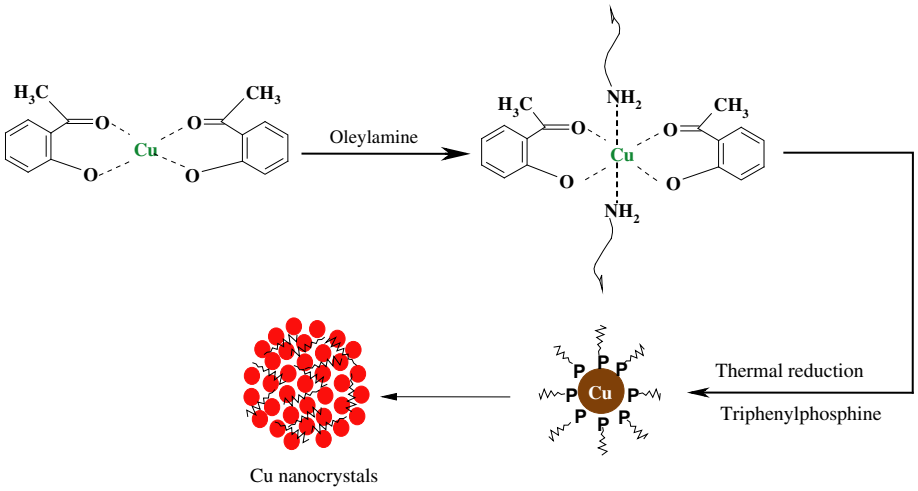
1. Introduction

Synthesis of metal nanoparticles other than those of silver and gold is often difficult due to the possibility of surface oxidation of the metal particles. Surface oxidation can be prevented by protecting the outer surface by the use of a suitable surfactant. The surfactant can also control the nucleation of particles and act as a particle growth terminator. Thus the surfactant has a dual role, i.e., to prevent surface oxidation of the particles and to control the growth of the particles. The study of nanoparticles of metals has been an extremely active area of research in recent years because of their unusual properties which are different from those of bulk materials. Since heterogeneous catalysis is a surface phenomenon and the surface to volume ratio increases with decreasing particle diameter, nanoparticles are vital for high catalytic activity. Copper metal has great significance in all industries, particularly in the electrical sector due to low cost. Copper nanoparticles have potential applications as fillers in polymers, as lubricants and they are used as ink and metallic coating [1,2]. For their application in electronics, the stability of the nanoparticles and their reactivity are two important factors. In addition, colloidal copper is also useful as an antibacterial agent.



Cu nanoparticles have been synthesized through different methods such as thermal decomposition [3–6], metal salt reduction [7], microwave heating [8], radiation methods [9], micro emulsion techniques [10], laser ablation [11], the polyol method [12], the solvothermal method [13], thermal and sonochemical reduction [14].

Among the various techniques developed for the synthesis of copper and copper oxide nanoparticles, thermal decomposition is a novel method to produce stable monodispersed species [15] and it is a rapidly developing research area. As compared to conventional methods, it is much faster, cleaner and economical. However, improvement in the thermal reduction process should be made in preparing copper nanoparticles with controllable size and shape in order to extend the application areas and to satisfy the needs of fundamental research.

The current synthetic procedure is a modified version of the method developed by the Hyeon group for the synthesis of various nanoparticles of metals and oxides, which employs the thermal decomposition of metal–surfactant complexes in hot surfactant solution [16]. More recently, our group reported the synthesis of metal oxide nanoparticles via thermal decomposition [17,18]. Fischer and coworkers synthesized monodisperse copper nanoparticles from the thermal decomposition of $Cu(OCH(Me)CH_2NMe_2)_2$ [19]. Hyeon and co-workers have reported the synthesis of copper nanoparticles by thermal decomposition of $[Cu(acac)_2]$ (acac = acetylacetonate) in oleylamine [20]. A major interest at the moment is in the development of organometallic or inorganic compound for preparation of nanoparticles. Using novel compounds opens a new way for preparing nanomaterials whilst controlling the nanocrystal size, shape and distribution size. We synthesized Cu nanoparticles by the thermal decomposition of the new precursor copper 2-hydroxyacetophenato in oleylamine (Scheme 1). In this process, oleylamine was used as both the medium and the

Scheme 1. Schematic depiction of the selective formation of Cu nanocrystals.

stabilizing reagent. To the best of our knowledge, this is the first report on the synthesis of Cu nanoparticles from [Cu(aceto)$_2$] (aceto = 2-hydroxyacetophenato). The aim of the present work is to prepare copper nanocrystals using the thermal reduction method, and their physicochemical characterization.

2. Experimental

2.1. Materials

The precursor complex, [bis(2-hydoxyacetophenato)copper(II)], was prepared according to the procedure described previously [21]. Oleylamine, triphenylphosphine (TPP), toluene, hexane and ethanol were purchased from Aldrich and were used as received.

2.2. Characterization

XRD patterns were recorded on a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Elemental analyses were obtained on a Carlo ERBA Model EA 1108 analyzer. Scanning electron microscopy (SEM) images were obtained on a Philips XL-30ESEM equipped with an energy dispersive X-ray spectroscope. Transmission electron microscopy (TEM) images were obtained on a Philips EM208 transmission electron microscope with an accelerating voltage of 200 kV. The compositional analysis was done by energy dispersive X-ray (EDX, Kevex, Delta ClassI). Thermogravimetric–differential thermal analyses (TG–DTA) were carried out using a thermal gravimetric analysis instrument (Shimadzu TGA-50H) with a flow rate of 20.0 mL min^{-1} and a heating rate of 10 °C min^{-1}. X-ray photoelectron spectroscopy (XPS) measurements of the as-prepared products were measured on an ESCA-3000 electron spectrometer with a non-monochromatized Mg Kα X-ray excitation source. Fourier transform infrared (FT-IR) spectra were recorded on a Shimadzu Varian 4300 spectrophotometer in KBr pellets. The electronic spectra of the complexes were taken on a Shimadzu UV–Vis scanning spectrometer (Model 2101 PC).

2.3. Synthesis of the Cu nanocrystals

In this synthesis, Cu nanocrystals were prepared by the thermal reduction of the [Cu(aceto)$_2$]–oleylamine complex as a precursor. The [Cu(aceto)$_2$]–oleylamine complex was prepared by the reaction of 0.5 g of [Cu(aceto)$_2$] with 5 mL of oleylamine. The mixed solution was placed in a 50 mL three-neck distillation flask and heated to 140 °C for 60 min under an argon atmosphere. The resulting metal-complex solution was injected into 5 g of triphenylphosphine, TPP, at 245 °C. As the thermal reduction proceeded, the dark green solution turned to red, indicating the formation of metallic copper. The reddish solution was aged at 245 °C for 35 min, and then cooled to room temperature. The reddish nanoparticles were precipitated by adding excess ethanol to the solution. The final product was washed with ethanol at least three times to remove impurities, if any, and dried at 100 °C. This product could easily be re-dispersed in non-polar organic solvents, such as hexane or toluene (Scheme 1).

3. Results and discussion

The thermal behaviour of the as-prepared precursor was investigated by thermal gravimetric analysis (TGA). Fig. 1 shows that [Cu(aceto)$_2$] starts to decompose at 195 °C and the weight loss occurs in the temperature range 195–330 °C. The weight loss may be ascribed to the decomposition of [Cu(aceto)$_2$]. The weight loss is about 25.58%, which is close to the theoretical value.

The X-ray powder diffraction (XRD) pattern of the Cu nanocrystals at room temperature is shown in Fig. 2. The XRD pattern is consistent with the spectrum of copper, and no peak attributable to possible impurities is observed. The peaks are very sharp due to the high nanocrystalline nature of copper. The peak positions are consistent with metallic copper. All possible peaks of copper

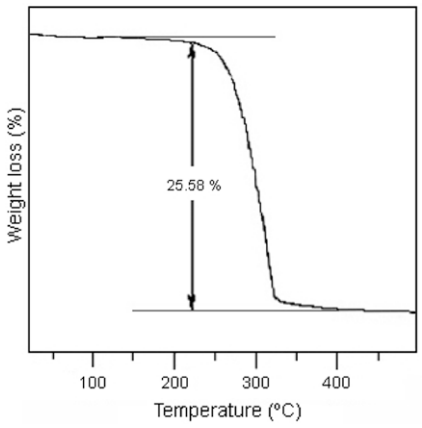

Fig. 1. TGA of the copper oxalate precursor, [Cu(aceto)$_2$].

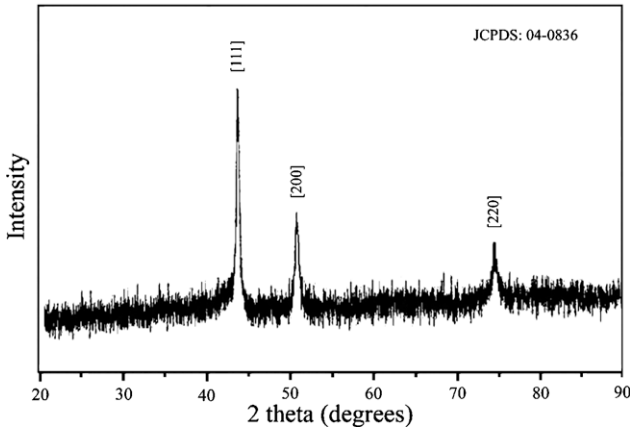

Fig. 2. XRD pattern of the copper nanoparticles.

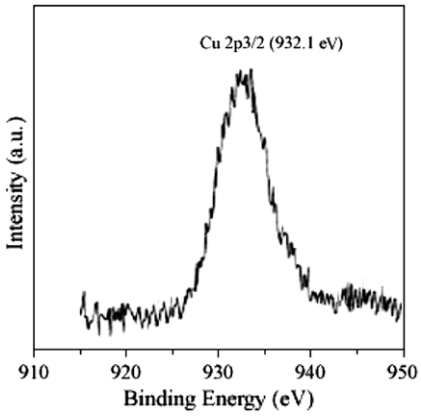

Fig. 4. XPS spectrum of the Cu nanocrystals.

are observed, which indicates the polycrystalline nature of the product. Bragg's reflections for the Cu nanocrystals are observed in the XRD pattern at 2θ values of 43.4°, 50.5° and 74.2°, representing [1 1 1], [2 0 0] and [2 2 0] planes of the *fcc* structure of copper with the space group *Fm3m* (JCPDS No. 04–0836). The size of the nanoparticles was estimated from the full width at half maxima (FWHM) of the [1 1 1] diffraction peak on the basis of the Scherrer formula: $D = 0.9\lambda/\beta\cos\theta$, and this gives a value of about 2 nm for the nanoparticles synthesized. Fig. 3 shows the EDX spectrum of the copper nanoparticles excited by an electron beam (24 kV). Peaks for the elements Cu, C and O were observed at 0.5469 (O_{ka}), 0.9698 (Cu_{La}), 0.9678 (Cu_{Lb}), 8.0977 (Cu_{ka}), 8.9050 (Cu_{kb}) and 0.2874 (C_{ka}).There is no impurity atom in the nanoparticles except oleylamine capped copper. Accordingly, from the EDX spectrum we could confirm that the nanoparticles in the TEM images are pure copper [22,23].

Surface information of the freshly obtained sample as shown in Fig. 4 can be properly provided by XPS analysis. The binding energies obtained in the XPS analysis were corrected with reference to C1s (284.6 eV). The spectrum of Cu 2p, Fig. 4, illustrates that the observed value of the binding energy for Cu $2p^{3/2}$ (932.1 eV) is consistent with the reported data for Cu^0 [24].

FT-IR spectroscopy is a useful tool to understand the functional group of any organic molecule (Fig. 5a and b). The presence of the oleylamine group on the Cu nanocrystals (Fig. 5b) is indicated by the N–H wagging mode from 650 to 900 cm^{-1}, NH_2 bending modes at 909, 964 and 993 cm^{-1}, and NH_2 scissor mode at 1568 cm^{-1} [25]. The spectrum, shown in Fig. 5b, also reveals the characteristic peak of the C–N stretch at 1042 cm^{-1} which suggests that the C–N bonds in the amine groups, and therefore the oleylamine ligands, remain intact, capping the Cu nanocrystals. The peak at 1468 cm^{-1} is associated with the C–H bending mode and the three peaks at 2865, 2921 and 2955 cm^{-1} represent the C–H stretching

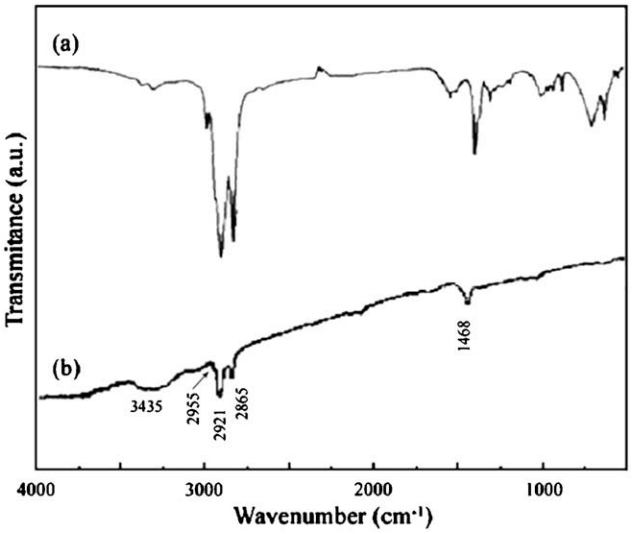

Fig. 5. FTIR spectra of (a) oleylamine and (b) Cu nanocrystals.

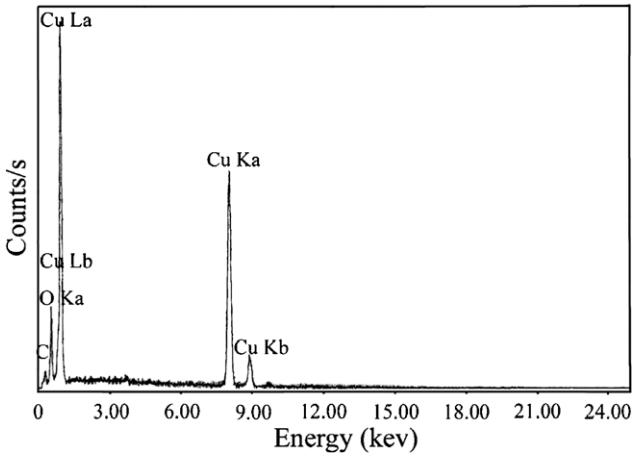

Fig. 3. EDX spectrum of the copper nanocrystals.

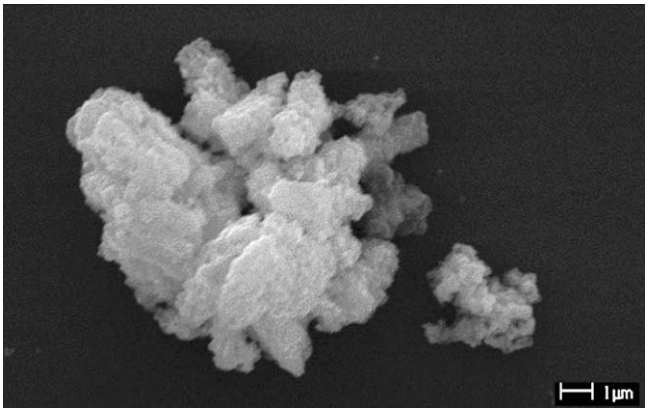

Fig. 6. SEM image of the Cu nanocrystals.

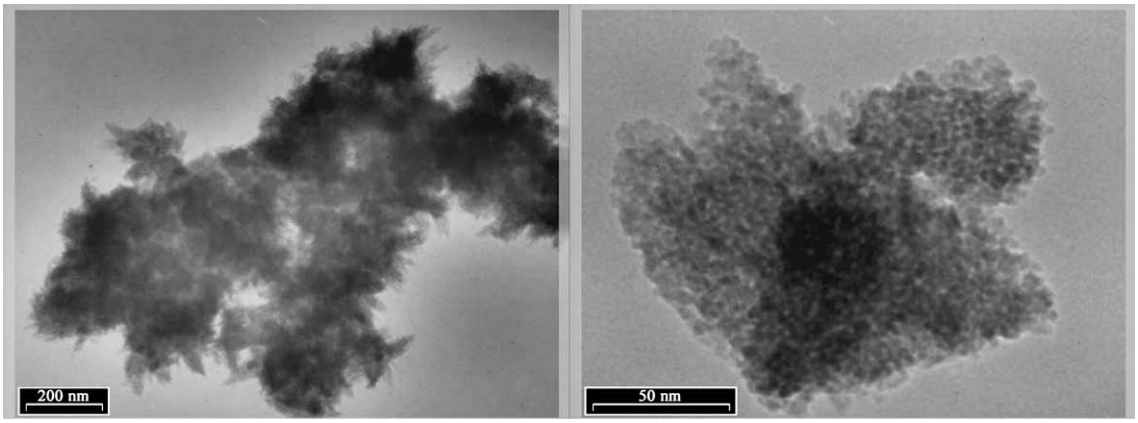

Fig. 7. TEM image of the Cu nanocrystals.

modes of the oleylamine carbon chain. The presence of various N–H peaks suggests that the amines are bound to the surface of the Cu nanocrystals. Based on the FTIR data, we deduce the following reaction mechanism. Upon injection of [Cu(aceto)$_2$] and oleylamine into hot TPP solution, the Cu–O bond is cleaved by the oleylamine group and Cu is subsequently reduced. The weak peak at 3435 cm^{-1} has been assigned to the EtOH used in the separation step. There was no evidence of the free precursor, copper 2-hydroxyacetophenato, in the sample, because the stretch vibration of C=O ($\upsilon_{C=O}$) and C–O (υ_{C-O}) disappeared. So the oleylamine serves as the capping ligand that controls growth.

The morphology of the product is examined by SEM. Fig. 6 depicts the SEM pictures of a sample of Cu nanoparticles. From the micrograph, it was observed that the nanoparticles are agglomerated. The transmission electron microscopic (TEM) photographs of the product are given in Fig. 7. The size of the nanocrystals obtained from the XRD diffraction patterns are in close agreement with the TEM studies which show sizes of 2–4 nm (Fig. 7). These sizes are nearly spherical. Some loose spheres formed by aggregation of small particles can be observed in the TEM images. We may consider that when the reaction was carried out at 245 °C, most organic molecules decomposed. Since only a few oleylamine molecules were adsorbed on the Cu nanocrystals, a loose solid flower-like morphology was finally produced.

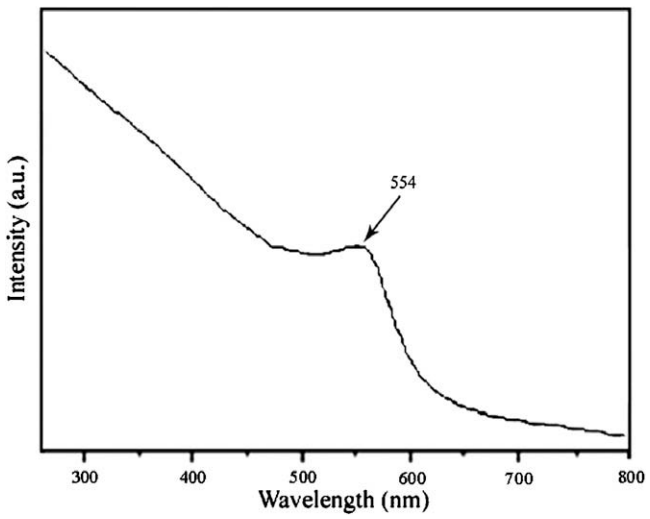

Fig. 8. The UV–Vis absorption spectrum of the Cu nanocrystals.

Since the surface areas of metal nanocrystals are enormously relative to their masses, they have an excess free energy surface comparable to the lattice energy, making them thermodynamically unstable. Protective agents are therefore essential in order to be able to outweigh the attractive van der Waals forces by repulsive steric forces. To achieve sufficient inter-particle separation, it can be helpful to use sterically demanding substituents [26]. In this work we have used TPP as a ligand stabilizing agent to make the nanocrystals stable and prevent their agglomeration. TPP is a high-boiling point surfactant with a patulous long-chain structure providing great steric hindrance. So, this agent might slow down the addition rate of materials to the nanoparticles during their growth, resulting in much smaller nanocrystals. Also we have used oleylamine as an additional surfactant in order to reduce the particle size much further and this resulted in uniform size (Fig. 7). Oleylamine has been known as a ligand that binds tightly to metal nanoparticle surfaces. The combined effects of TPP and oleylamine were much more profound than those of the individual contributions.

Nanosized particles exhibit unique optical properties with an exponential-decay Mie scattering profile with decreasing photon energy. Some transition metal nanoparticles show a distinct surface-plasmon resonance (SPR). The SPR is very sensitive to the metal size, dielectric constant of the metal and embedding medium (here it is oleylamine) [27,14]. For instance, Cu nanoparticles typically exhibit SPR at around 600 nm [28], however the fresh Cu nanocrystals synthesized here show an absorption peak at around 554 nm (2.24 eV) (Fig. 8). This peak can be assigned to the absorption of nanoparticles of copper [28]. A modest blue shift (about 46 nm) of the absorption edge relative to that of bulk copper powder is observed. This observation alludes to the size effect to the Cu nanoparticles. The synthesized particles were stable for ~12 days. This kind of stabilization of Cu nanocrystals is due to the capping of particles by oleylamine on thermal treatment. The arrangement of the capping agent, oleylamine, surrounding the nanoparticles is size dependent.

4. Conclusion

In summary, we have shown that a new simple, low cost thermal reduction precursor is particularly suited for the synthesis of copper nanocrystals. Because of the simplicity of the method, many opportunities may exist to further control the size and shape of the Cu nanoparticles. Furthermore, we suggest as a general principle that other organometallic decomposition precursors may be very good choices for the synthesis of nanometals.

ABSTRACT

The new complex bis(2-bromobenzoato-*O,O′*)-bis(methyl-3-pyridylcarbamate-*N*)-zinc(II), [Zn(2-$BrC_6H_4COO)_2mpc_2$] (**1**), has been prepared and characterized by elemental analysis, IR spectroscopy, thermal analysis and single-crystal X-ray diffraction. The bonding between the ligands and the central atom was investigated by DFT studies. The theoretical infrared spectrum of **1** was compared with the experimental data. The complex proved to be thermally stable up to 165 °C. Volatile intermediate products of its thermal decomposition were identified by mass spectrometry. The coordination environment of the zinc atom consists of two nitrogen atoms of two methyl-3-pyridylcarbamate ligands and is chelated by four oxygen atoms of two 2-bromobenzoate ligands (ZnO_4N_2 – chromophore).

1. Introduction

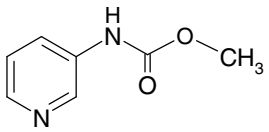
Several aromatic carboxylic acids (e.g. benzoic acid, salicylic acid) are known to have antibacterial and antifungal properties [1,2]. For metal carboxylate complexes it has been found that their antibacterial activity is higher than that of the parent carboxylic acid [3].

Our interest is aimed at studying compounds of halogenobenzoic acids with zinc, which can have a considerable effect on many biological processes. Zinc(II) complexes with organic ligands have proved to be useful in clinical medicine, e.g. for acne therapy [4]. Moreover, organic ligands can contribute to a better transport of metal ions through the lipophylic regions of cell membranes [5]. In addition, heterocyclic compounds play a significant role in many biological systems, e.g. vitamins. Therefore heterocyclic compounds such as nicotinamide, methyl-3-pyridylcarbamate and theophylline, incorporated in complexes as ligands have been investigated by many authors and their biological activities have been examined [6]. The thermal behaviour of several aliphatic zinc(II) carboxylate complexes with methyl-3-pyridylcarbamate was investigated by Szunyogová et al. [7]. Győryová et al. studied the thermal, spectral and structural properties of aliphatic zinc(II) carboxylates and halogenocarboxylates [8–11], and zinc(II) halogenosalicylates [12] with different bioactive ligands.

For the preparation of effective antimicrobial species it is important to gain information about the structure of the compound. It has been observed that the antibacterial effect can be enhanced when the ligands are chelated to the metal [13]. Zeleňák et al. [14] investigated Zn(II) benzoate complexes with pyridine based ligands. They found that for the zinc(II) benzoate complex with methyl-3-pyridylcarbamate, the metal atom is tetrahedrally coordinated by two monodentate benzoate and two heterocyclic ligands. Intermolecular hydrogen bonds connect the molecules to form a two-dimensional network. Maroszová et al. [15] studied the structural properties of a zinc(II) 2-chlorobenzoate complex with methyl-3-pyridylcarbamate. They found that the zinc atom is coordinated by two nitrogen atoms from two methyl-3-pyridylcarbamate ligands and four oxygen atoms from two bidentate 2-chlorobenzoate anions in a pseudo-octahedral geometry. The molecules are linked into a chain by hydrogen bonds.

The present work deals with the structural and bonding characterization, thermal and spectral properties of the new monomeric complex [Zn(2-$BrC_6H_4COO)_2mpc_2$].

2. Experimental



2.1. Materials and instrumentation

The following A. R. grade chemicals were used for the preparation of the studied compound: $ZnCl_2$ (Fluka), Na_2CO_3 (Mikrochem a.s. Pezinok), 2-bromobenzoic acid 97% (Aldrich), methyl-3-pyridylcarbamate (Merck) (Scheme 1).

The carbon, hydrogen and nitrogen content in the newly synthesised compound was determined on a CHN analyser PERKIN EL-

Scheme 1. Methyl-3-pyridylcarbamate (mpc).

MER 2400. The zinc content was determined by complexometry using Complexone III as an agent and Eriochrome black T as an indicator. The IR spectrum of the prepared zinc complex compound was recorded on an AVATAR 330 FT-IR Thermo Nicolet spectrometer using KBr pellets (2 mg/200 mg KBr), operating in the range 4000–400 cm^{-1}. The thermal measurements were carried out in air using ceramic crucibles under dynamic conditions on a NETZSCH STA 409 PC/PG Thermoanalyzer (heating rate 9 °C min^{-1}) with a sample mass of 24.970 mg, in the temperature range 26–900 °C. A GC/MS Agilent 7890A mass spectrometer (heating rate 30 °C min^{-1} from 100 °C up to 280 °C) was used for determination of volatile intermediate products of the thermal decomposition.

2.2. Synthesis

Compound **1** was synthesised as follows: $ZnCO_3$ was prepared by the reaction of an aqueous solutions of 1.35 g (10 mmol) $ZnCl_2$ and 1.06 g (10 mmol) Na_2CO_3. The freshly prepared aqueous suspension of $ZnCO_3$ was added in excess to the methanol solution of 2.58 g 97% 2-bromobenzoic acid under continual stirring. The reaction mixture was stirred for 1 h at 70 °C. Excess $ZnCO_3$ was filtered off using an S4 frit and the filtrate was left for crystallization at room temperature. After several days a white powdery compound of $[Zn(2\text{-}BrC_6H_4COO)_2]$ was formed (2.46 g, 5 mmol, yield: 83%). Afterwards, 1.61 g (10 mmol) of methyl-3-pyridylcarbamate was dissolved in methanol and added gradually to the methanol solution of zinc(II) 2-bromobenzoate. The reaction mixture was stirred for 2 h at 50 °C and the solution was reduced in volume at 70 °C in a water bath and left to crystallise at room temperature. After a few days colourless crystals of **1** were formed (2.69 g, 3.5 mmol, yield: 70%).

2.3. X-ray crystallographic study

Diffraction data for a suitable single crystal of **1** were collected on a Nonius Kappa CCD diffractometer (Mo Kα radiation, $\lambda = 0.71073$ Å) and processed by the HKL program package [16]. The phase problem was solved by direct methods (SIR97) [17], and refined by full-matrix least-squares on F^2 (SHELX97) [18]. Hydrogen atoms were refined isotropically, while all the other atoms anisotropically. The hydrogen atom on N17 was located from difference Fourier maps and refined without any constraints. Hydrogen atoms on the aromatic rings were included in ideal positions with C–H bonds fixed to 0.95 Å and U_{iso}(H) assigned to $1.2U_{eq}$ of the adjacent carbon atom; terminal methyl group hydrogen atoms were included in ideal positions with C–H bonds fixed to 0.98 Å and U_{iso}(H) assigned to $1.5U_{eq}$ of the pivot atom (Table 1).

Table 1
Crystal data and structure refinement for **1**

Empirical formula	$C_{28}H_{24}Br_2N_4O_8Zn$
Formula weight	769.70

c (Å)	13.4622(2)
V (Å^3)	2828.70(10)
Z, D_{calc} (Mg/m^3)	4, 1.807
Absorption coefficient (mm^{-1})	3.752
F(000)	1536
Crystal size (mm^3)	0.48 × 0.08 × 0.05
θ Range for data collection	2.00–27.47
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	3237/0/200
Final *R* indices [$I > 2\sigma(I)$]	$R_1 = 0.0300$, $wR_2 = 0.0581$
R indices (all data)	$R_1 = 0.0491$, $wR_2 = 0.0640$
Largest difference peak and hole (e Å^{-3})	0.435 and −0.413

2.4. Computational details

DFT studies have been carried out at the fermi cluster at the J. Heyrovský Institute of Physical Chemistry, Academy of Sciences of Czech Republic, using GAUSSIAN 03, Revision E.01 [19]. All calculations used the Becke exchange [20] and the Perdew/Wang 91 correlational [21] functionals. For a proper elucidation of the theoretical infrared spectrum, the solid-state structure has been optimized using the 6-311+G(3d,p) basis set [22] employed for all atoms and an analytical Hessian determined before the first step of the optimization procedure. Numerical integration was done on a pruned grid having 99 radial shells each of 590 angular points. The IR spectrum was computed after the optimization step yielded a proper stationary point where no imaginary frequencies were present. No scaling was employed for the obtained bands. Natural bonding analysis [23] was carried out by the NBO 3.1 [24] program integrated in Gaussian. To remove any side effects of possible near linear dependencies in the basis set due to the incorporation of diffuse functions, the NBO analysis and Mayer bond order [25] determination were carried out employing only the 6-311G(3d,p) basis set on the optimized geometry. Visualization and examination of molecular orbitals was accomplished by MOLDEN [26].

3. Results and discussion

3.1. Synthesis and properties of the prepared compound

Several methods of preparing zinc(II) carboxylate compounds are described in the literature [14,27,28]. Methods involving either the reaction of the sodium salt of the carboxylic acid with zinc sulfate, or the reaction between carboxylic acid and zinc(II) carbonate can be used.

The compound **1** was synthesised according to the following reactions:

$$ZnCl_2 + Na_2CO_3 \rightarrow ZnCO_3 \downarrow + 2NaCl$$

$$ZnCO_3 + 2(2\text{-}BrC_6H_4COOH) \rightarrow [Zn(2\text{-}BrC_6H_4COO)_2] + H_2O + CO_2 \uparrow$$

$$[Zn(2\text{-}BrC_6H_4COO)_2] + 2\ mpc \rightarrow [Zn(2\text{-}BrC_6H_4COO)_2mpc_2]$$

The prepared complex, $[Zn(2\text{-}BrC_6H_4COO)_2mpc_2]$, is colourless, and is stable to light and air at ambient temperature. It exhibits a very good solubility in methanol, acetone and DMSO, and is insoluble in chloroform and water.

3.2. Crystallographic characterization

Compound **1** crystallized with an orthorhombic lattice (space group *Pccn*) and with an exact molecular twofold symmetry, thus only one half of the molecule is located in the asymmetric part of the unit cell. The symmetrically dependent part of the molecule is generated by a twofold rotation around the axis passing through the central atom. The whole molecule is depicted in Fig. 1; selected bond distances and angles are listed in Table 2.

The coordination environment of the zinc atom consists of two nitrogen atoms from the mpc ligand and four oxygen atoms from the two 2-bromobenzoate carboxylate groups, making up an octahedral environment. This octahedron is however significantly distorted. Although the two least-squares planes, both containing one nitrogen and three oxygen atoms (cf. Table 3) do not suffer from large deviances of their constituent atoms, the geometry constrains imposed by the presence of the rather rigid carboxylate group leads to a large deflection of the oxygen atoms from the ideal positions at the octahedron vertices.

The driving force of the solid state packing is the presence of an infinite network of hydrogen bridges, chaining the hydrogen atom of one mpc NH group and one carboxylate oxygen atom from one neighbouring molecule (Table 4, Fig. 2).

Table 2
Selected bond lengths [Å] and angles [°] for **1**

Zn(1)–N(11); Zn(1)–N(11)^{i}	2.1151(19)

3.3. Spectroscopic and thermal properties

In the case of carboxylate compounds, the values of the asymmetric and symmetric vibrations of COO^{-} are important. In the prepared compound, $[Zn(2\text{-}BrC_6H_4COO)_2mpc_2]$, the stretching vibrations of the aromatic rings of 2-bromobenzoate and the heterocyclic ligand fall in the same region of the spectrum as the stretching vibrations of the carboxylate group, therefore the IR spectrum of $[Zn(2\text{-}BrC_6H_4COO)_2mpc_2]$ has been compared with the spectrum of $[Zn(2\text{-}BrC_6H_4COO)_2]$ and methyl-3-pyridylcarba-

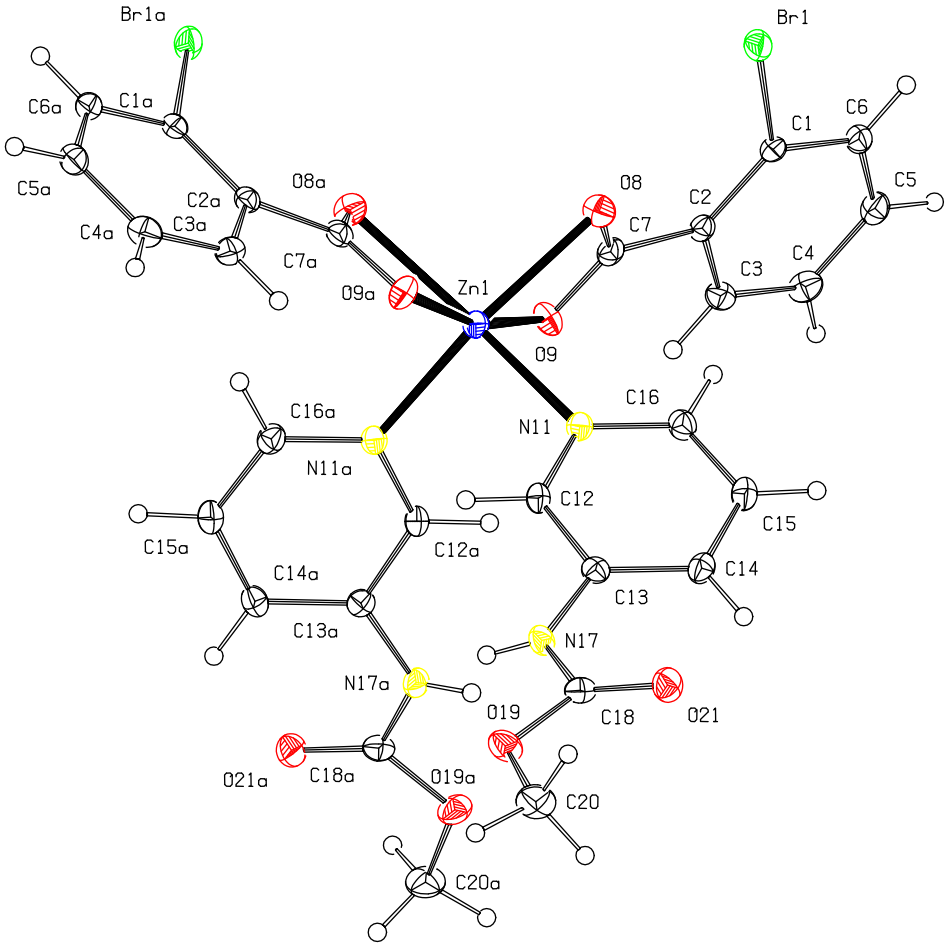

Fig. 1. Solid state structure of **1**. Displacement ellipsoids are drawn at the 30% probability level. Symmetrically dependant atoms are labelled with a terminal 'a'.

Table 3
Least-squares planes and deviations of individual atoms from them

Plane 1		Plane 2	
Atom	Deviation	Atom	Deviation
O9	0.0251(6)	$O9^{i}$	0.0251(6)
N11	−0.0308(7)	$N11^{i}$	−0.0308(7)
$O8^{i}$	−0.0383(10)	O8	0.0383(10)
$O9^{i}$	0.0440(11)	O9	0.0440(11)

The distance of Zn1 from both planes is 0.1379(9) Å, the angle between the two planes is 89.39(4)°.

Table 4
Hydrogen bonds with H···A < r(A) + 2.000 Å and DHA > 110° in solid state

D–H	d(D–H)	d(H···A)	∠DHA	d(D···A)	A
N17–H17	0.774 Å	2.115 Å	150.12°	2.813 Å	O8 [$-x+1/2, y, z-1/2$]

D denotes the donor and A the acceptor atom.

mate. The vibration observed at 1541 cm^{-1} was assigned as $\nu_{as}(COO^{-})$ and that at 1397 cm^{-1} as $\nu_{s}(COO^{-})$.

The strong absorption band of the carbonyl ν(C=O) vibration at 1732 cm^{-1} is slightly shifted to a higher wavenumber as compared with the free methyl-3-pyridylcarbamate (1727 cm^{-1}). This is in agreement with the results of Bellamy and Akbar Ali [29,30]. It can be explained by the fact that the pyridine nitrogen of methyl-3-pyridylcarbamate ligand is involved in coordination with zinc, therefore the electron density in the ligand is shifted towards the pyridine nitrogen, leading to the increase in the double bond character of the carbonyl group and shift the stretching vibration ν(C=O) to a higher value.

The most significant stretching and deformation vibrations are listed in Section 2.

Table 5
Comparison of the experimental and the theoretical values of the IR absorption bands

Assignment	Experimental (KBr) [cm^{-1}]	Theoretical [cm^{-1}]
ν(N–H)	3310s	3530
ν_{ar}(C–H)	3098m, 3066m	3164–3102
(ν(C–H)$_{-CH_3}$)	2951m	2990
ν(C=O)	1732s	1749
ν(C=C, C=N)	1593s, 1491s, 1467m	1596, 1527, 1476
$\nu_{as}(COO^{-})$	1542s	1563
(δ_{as}(C–H)$_{-CH_3}$)	1437s	1456
$\nu_{s}(COO^{-})$	1398s	1376
ν(C–Br)	1028s, 641m	1008, 637
$\delta(COO^{-})$	695s	697

The experimentally obtained and calculated IR spectra of [Zn(2-$BrC_6H_4COO)_2mpc_2$] are in good agreement (Table 5), with the notable exception of the N–H vibration. However, this particular hydrogen atom is part of a hydrogen bridge in the solid state (see above), which leads to a prolongation of the N–H bond. The latter phenomenon could not be reflected by the computational studies as these were performed on one single molecule only.

The results of thermogravimetric analysis are presented in Fig. 3. It was found that the studied complex compound is thermally stable up to 165 °C. Above this temperature the thermal decomposition is accompanied by the loss of methyl-3-pyridylcarbamate and CO_2 (calc. mass loss 51.07%, exp. 51.44%). The released methyl-3-pyridylcarbamate was confirmed by mass spectrometry (Fig. 4). The next step of the thermal decomposition is the release of bromobenzene (calc. mass loss 40.79%, exp. 42.67%). Zinc is the solid product of the thermal decomposition (calc. 8.49%, exp. 7.75%). The following reaction is proposed for the thermal decomposition of the investigated compound:

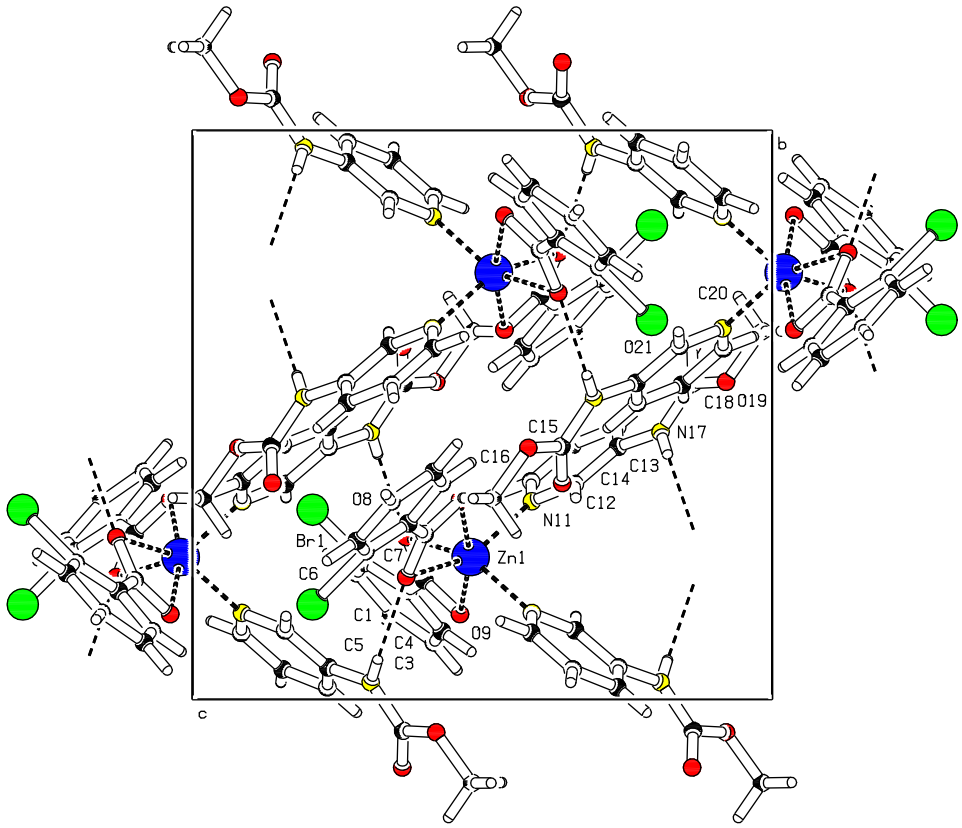

Fig. 2. Solid state packing of **1**. View along [100].

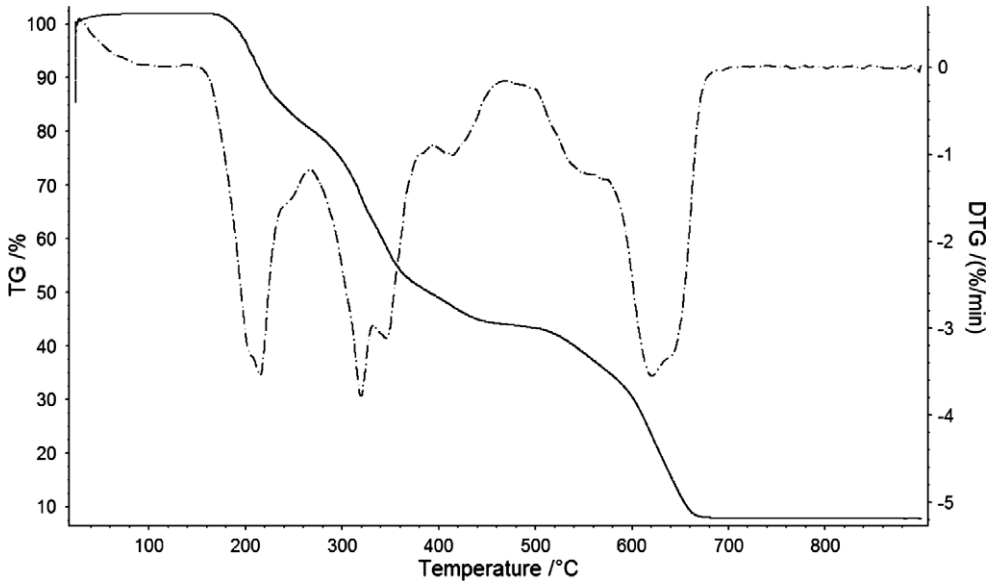

Fig. 3. Thermal decomposition of $[Zn(2\text{-}BrC_6H_4COO)_2mpc_2]$.

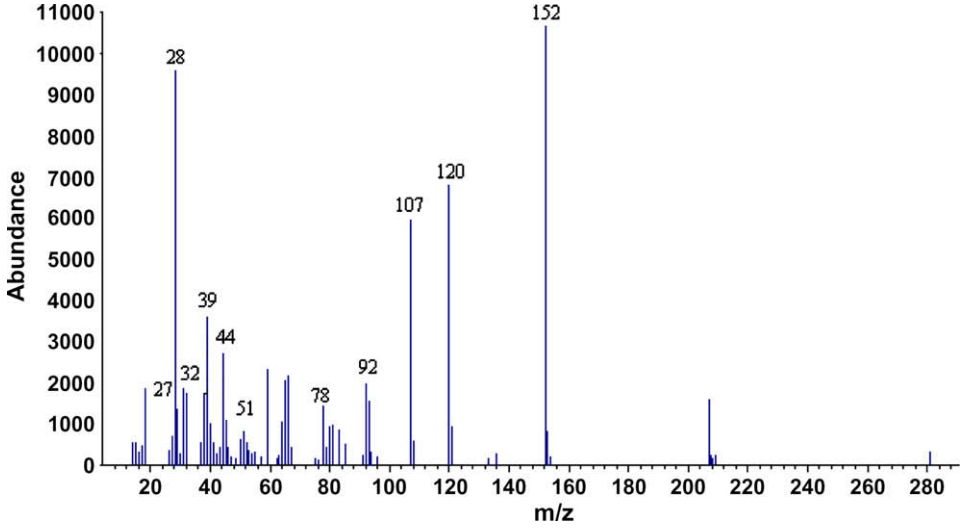

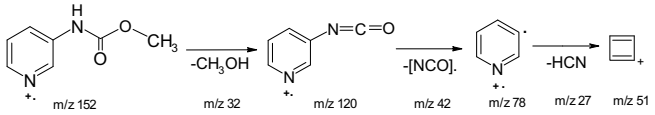

Fig. 4. Mass spectrum of $[Zn(2\text{-}BrC_6H_4COO)_2mpc_2]$ heated up to 280 °C.

$$[Zn(2\text{-}BrC_6H_4COO)_2mpc_2] \rightarrow 2\ mpc + 2\ CO_2 + 2\ C_6H_5Br + Zn$$

Based on the mass spectrum pattern, we propose the following fragmentation scheme for methyl-3-pyridylcarbamate:

This assumption is in a good agreement with the results of pyridine fragmentation proposed by Smith [31].

3.4. Computational studies

The IR spectrum of **1** (discussed above) and the nature of the bonding between the central atom and its ligands was investigated by DFT calculations. As expected for a Zn(II) compound, the calculations suggest a predominantly ionic character of the ligand coordination, with only a slight covalent contribution. The overall low ratio of the covalent contribution from the ligands can be conveniently deduced by examination of the crystal orbital overlap population (COOP) diagram (Fig. 5), depicting the value of the overlap integral between the ligands and the central atom versus orbital energies. In accordance with their lower electronegativity, an increased covalency ratio was observed for the two nitrogen atoms, since the total contribution from the 2-bromobenzoate ligand has to be partitioned among four oxygen atoms.

The apparent proximity of the carboxylate carbon atom and the central zinc atom could suggest a partial (covalent) bonding between them; however, Mayer bond order [25] analysis disproved any such possibility (Table 6). The carboxylate oxygen atoms thus coordinate as separate entities and the coordination environment of the central atom cannot be described as pseudotetrahedral by considering the centre of gravity of the carboxylate group only.

According to the results of natural bonding analysis [23], the electronic configuration of the central zinc atom is [Ar] $4s^{0.42}3d^{9.96}4p^{0.02}$, proving the presence of a zinc divalent cation, calling for primarily electrostatic interactions with the ligands.

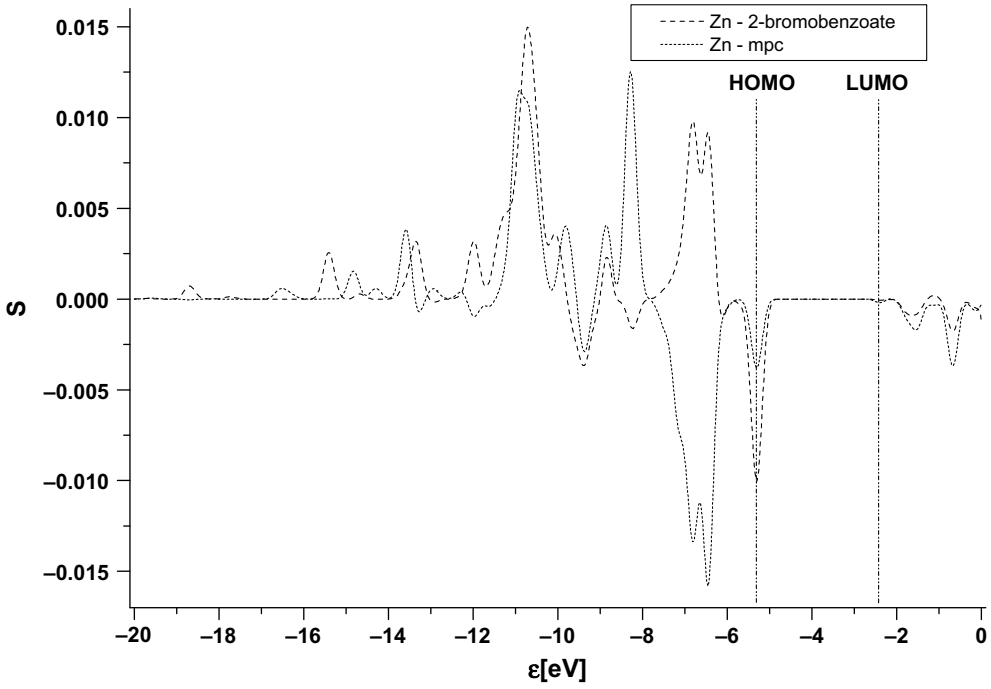

Fig. 5. The COOP diagram of **1**.

Table 6
Mayer bond orders between the central zinc atom and selected donors

Atoms	Mayer bond order(s)
Carboxylate oxygens	0.222, 0.204
Carboxylate carbons	0.015
mpc nitrogens	0.223

4. Conclusion

The present work describes the synthesis and characterization of $[Zn(2\text{-}BrC_6H_4COO)_2mpc_2]$. It was found out that the zinc is coordinated by two nitrogen atoms from two methyl-3-pyridylcarbamate ligands and by four oxygen atoms from two bidentate 2-bromobenzoates in a pseudo-octahedral geometry. The molecules are linked into a chain by hydrogen bridges between the NH group of methyl-3-pyridylcarbamate and one carboxylate oxygen atom from a neighbouring molecule.

According to our computational studies, the prevalence of an electrostatic interaction between the zinc divalent cation and two carboxylate anions of 2-bromobenzoate ligands was proved. A somewhat greater covalent contribution was observed only for the two nitrogen atoms of the methyl-3-pyridylcarbamate ligands. A notable bonding interaction between the two carboxylate carbon atoms and the central atom was disproved.

ABSTRACT

In this study, a new binary complex $[Cu(HCip)_2](NO_3)_2 \cdot 6H_2O$ (**1**) has been synthesized and then characterized by X-ray structure analyses. In this compound, each ciprofloxacin acts as a bidentate ligand resulting in a crystallographically planar configuration; the nitrate anions are located in apical positions with an axial distance significantly larger than the equatorial distances, which would be consistent with a very weak metal ion interaction due to the Jahn–Teller effect. In addition, both the synthesis and characterization of two new ternary complexes of ciprofloxacin–copper(II)–1,10-phenanthroline, $[Cu(phen)(Cip)](NO_3) \cdot 4H_2O$ (**2**) and $Cu(phen)(HCip)(NO_3)_2 \cdot H_2O$ (**3**), have been accomplished. We have also undertaken the single crystal structural determination of **2**, in which the ciprofloxacin acts as tridentate bridging ligand; the complex exhibits a five-coordinated motif in a distorted square pyramidal environment around the metal center. The chemical nuclease activity of compounds **2** and **3** has also been studied, revealing that both compounds behave as efficient chemical nucleases in the presence of ascorbate. Mechanistic studies, with various radical oxygen scavengers, indicate that the DNA cleavage reaction is mediated by hydroxyl radicals, singlet oxygen, and the superoxide anion.

1. Introduction

The biological activity of copper, a physiologically metal element that plays an important role in many biological processes [1], has been the subject of numerous studies [2–4]. Since Sigman et al. [5] discovered in 1979 that copper ions complexed to 1,10-phenanthroline were capable of cleaving DNA [6], copper complexes with a nitrogen donor heterocyclic ligand have been used widely to improve nuclease activity [6–11], mostly because their high nucleolytic efficiency is able to break the DNA chain in the presence of H_2O_2 and reducing agents [12]. In recent years, the study of quinolones–copper–1,10-phenanthroline complexes has become an increasingly important field due to the antibacterial properties of these compounds [13–19]. Quinolones, a commonly used term for the quinolone–carboxylic acids or 4-quinolones, are a group of synthetic antibacterial agents containing a 4-oxo-1,4-dihydroquinoline skeleton [20] which act by inhibiting the enzymes (topoisomerases) necessary for DNA synthesis. The spectrum of activity of these compounds has become increasingly broad, especially since the introduction of a fluorine atom at position 6 (fluoroquinolones) [21]. In 2002, Turel [22] reviewed the synthesis, physico-chemical properties, and structural characteristics of several binary and ternary fluoroquinolone compounds, together with their biological activity. Ciprofloxacin [HCip, 1-cyclopropyl-6-fluoro-1,4-dihydro-4-oxo-7-(1-piperazinil)-3-quinolone carboxylic acid], is a second generation fluoroquinolone that was synthesized for first time in 1987 [21]. A well known antibacterial drug with a wide spectrum of activity, it is extremely useful for the treatment of a variety of infections [22,23]. Over the past few years many studies have examined both the structure and chemical behavior of several complexes of cinoxacin and ciprofloxacin in which the bonding of the quinolones to the copper has been through the ring carbonyl group oxygen atom and one of the carboxylic atoms [24–28]. In addition, ciprofloxacin contains a nitrogen atom in its piperazinil group which is capable of attaching to the metal centers in a silver complex, as reported by Chen et al. [29]. Ternary complexes of copper(II), quinolones and 1,10-phenanthroline have also been isolated and characterized with the aid of X-ray diffraction methods. All of these ternary complexes have been found to be mononuclear species with a five-coordinate environment and a square pyramidal geometry around the copper center [4,30–35].

The DNAase activity of copper phenanthroline has been widely documented [36,37]. The $[Cu(phen)(nal)]^+$ compound likewise

doi:10.1016/j.poly.2008.09.018

acts as a powerful nuclease capable of degrading plasmid DNA under reductive conditions, and has an even stronger activity than that of the chemical nuclease copper phenanthroline [Cu(phen)$_2$]$^{2+}$ [38]. In the past few years, we have reported on the ability of two Cu(II)–norfloxacin–phenanthroline compounds to cleave DNA. Mechanistic studies with various inhibiting reagents indicate that hydroxyl radicals, singlet oxygen, and superoxide radicals are all involved in the DNA scission process mediated by these compounds [30]. In addition, several ternary copper(II)–quinolone–phenanthroline complexes have been screened for their activity against different strains of bacteria, exhibiting a higher inhibitory capacity than their individual components [32,34,39].

In this paper, we describe the synthesis, characterization and X-ray crystallographic structure of a new binary Cu(II) complex of ciprofloxacin. In addition, we report on the synthesis and characterization of two new ternary ciprofloxacin–copper(II)–1,10-phenanthroline complexes along with the crystal structure of [Cu(Cip)(phen)](NO$_3$) · 4H$_2$O. Data on the activity of the synthesized ternary compounds of ciprofloxacin as artificial nucleases is also included.

2. Experimental

Ciprofloxacin hydrochloride was provided by Sigma. Plasmid pUC18 (0.25 μg/μL in 10 mM Tris and 1 mM EDTA, pH 8.0) was purchased from Roche Diagnostics, Germany. Solutions of the metal complexes and other reagents for DNA strand scission were prepared fresh daily. All reagents used were of analytical grade.

2.1. Analyses

Cu was determined by means of atomic absorption spectroscopy with a Perkin–Elmer spectrometer model 2380. Elemental chemical analyses for C, H, N were performed on a Carlo Erba instruments EA 1110.

2.2. Physical measurements

Infrared spectra were recorded on a Satellite FTIR Mattson spectrophotometer with KBr pellets in the 4000–600 cm^{-1} range. UV–Vis absorption spectra were obtained on a Shimadzu 2101 PC spectrophotometer with the aid of the diffuse reflectance technique. Magnetic susceptibilities were measured on a Faraday magnetometer with Hg[Co(SCN)$_4$] as a standard; diamagnetic corrections were made with Pascal's constants. The electrospray ionization mass spectra of aqueous solutions of compounds **2** and **3** were obtained in positive mode [ESI$^+$] with an ESQUIRE 3000-plus Brucker ion trap mass spectrometer.

2.3. Synthesis of the complexes

2.3.1. [Cu(HCip)$_2$](NO$_3$)$_2$ · 6H$_2$O (**1**)

Adenine (34.29 mg, 0.25 mmol) was dissolved in 0.5 mL of 1 M HCl and the minimum amount of water. To this solution, an aqueous suspension of sodium ciprofloxacinate (102.24 mg, 0.25 mmol) was added and then stirred until total solution was achieved (pH 2.28). Next, a solution of 0.5 mmol (121.76 mg) of Cu(NO$_3$)$_2$ · 3H$_2$O in water was added. The final pH of the reaction mixture was approximately 5.45 for a final volume of 50 mL. The resulting blue solution was left to stand at room temperature. Pale blue crystals suitable for X-ray analysis formed after ca. 8 days.

Calc. for C$_{34}$H$_{48}$N$_8$O$_{18}$F$_2$Cu (**1**): C, 42.58; H, 5.01; N, 11.69; Cu, 6.63. Found: C, 42.08; H, 4.93; N, 11.62; Cu, 6.52%.

2.3.2. [Cu(Cip)(phen)](NO$_3$) · 4H$_2$O (**2**)

A solution of 1,10-phenantroline (49.6 mg, 0.25 mmol) was added to a suspension of sodium ciprofloxacinate (102.5 mg, 0.25 mmol). After 10 min of vigorous stirring, a solution of Cu(NO$_3$)$_2$ · 3H$_2$O (60.5 mg, 0.25 mmol) was added. The solvent used was a mixture of MeOH:H$_2$O (1:1) and the final volume was 50 mL. The pH was adjusted to 7.84 with 1 M NaOH and the resulting solution was stirred and filtered off. Green crystals suitable for X-ray structure determination formed after 10–15 days.

Calc. for C$_{29}$H$_{33}$N$_6$O$_{10}$FCu (**2**): C, 49.15; H, 4.66, N, 11.86; Cu, 8.97. Found: C, 48.58; H, 4.89; N, 11.80; Cu, 8.82%.

2.3.3. Cu(HCip)(phen)(NO$_3$)$_2$ · H$_2$O (**3**)

To an aqueous solution of 1,10-phenantroline (99.12 mg, 0.5 mmol), 0.5 mmol (204.18 mg) of sodium ciprofloxacinate and 0.5 mL of 1 M HNO$_3$ were added. After several minutes of stirring, an aqueous solution of Cu(NO$_3$)$_2$ · 3H$_2$O (120.8 mg, 0.5 mmol) was added to the mixture. The blue solution was stirred vigorously for approximately 10 min, after which a solution of 1 M NaOH was added. The final volume was 50 mL with a pH of 5.52. The resulting suspension was stirred and removed through filtration. After 8 days, the blue crystals that had formed were filtered off and air-dried.

Calc. for C$_{29}$H$_{28}$N$_7$O$_4$FCu (**3**): C, 48.52; H, 3.90; N, 13.66; Cu, 8.86. Found: C, 48.09; H, 4.16; N, 13.62; Cu, 8.74%.

2.4. X-ray structure determination

A summary of the crystallographic data for **1** and **2** is given in Table 1. First, green single-crystals of both **1** and **2** were selected. Data collection was performed at 293 K on a Nonius Kappa-CCD single-crystal diffractometer with Mo Kα radiation (λ = 0.7173 Å). The data collection strategy was determined with the aid of the program COLLECT [40]. Data reduction and cell refinement were car-

ried out with the HKL DENZO and SCALEPACK programmes [41]. Unit cell dimensions were determined from 2745 reflections between $\theta = 0.998°$ and 25.485° for **1** and 5857 reflections between $\theta = 0.998°$ and 27.485° for **2**. The crystal structures were solved by means of direct methods, with the program SIR-97 [42]. Anisotropic least-squares refinement was carried out with SHELXL-97 [43]. All non-hydrogen atoms were anisotropically refined. For compound **1**, some hydrogen atoms were located in a difference Fourier map and others located geometrically; the nitrate and water molecules how some kind of disorder. For compound **2**, all hydrogen atoms were located geometrically.

Geometrical calculations were made with PARST [44] and the crystallographic plots were made with ORTEP [45] (Figs. 1 and 2).

2.5. Cleavage of pUC18 by complexes [Cu(Cip)(phen)](NO$_3$) · 4H$_2$O (**2**) and Cu(HCip)(phen)(NO$_3$)$_2$ · H$_2$O (**3**)

Reactions were carried out in a total volume of 20 μL by mixing 7 μL of 0.1 M cacodylate buffer (pH 6), 6 μL of 10, 20, 30, or 40 μM complex solutions of **2** or **3** in 0.1 M cacodylate buffer (pH 6), 1 μL of 0.25 μg/μL pUC18; and 6 μL of ascorbate (2-fold molar excess relative to the concentration of the complexes) in 0.1 M cacodylate buffer (pH 6.0). The resulting mixtures contain 3, 6, 9, or 12 μM complex **2** or **3**, 0.012 μg/μL pUC18 (3.5 μM in nucleotides) and 6, 12, 18, or 24 μM ascorbate. The samples were then incubated at 37 °C for 60 min, after which 3 μL of a quench buffer solution (0.25% bromophenolblue, 0.25% xylene cyanole, and 30% glycerol) was added. The samples were then loaded on agarose gel (0.8%) containing 2 μL/100 mL of a solution of ethidiumbromide (10 mg/mL). Electrophoresis was carried out at 80 V for 2 h in 0.5 × TBE buffer (0.045 M Tris, 0.045 M boric acid and 1 mM EDTA). The gel was photographed on a capturing system gel printer plusTDI. To study mechanistic aspects of the DNA cleavage reaction performed by both compounds, scavengers of reactive oxygen intermediates [DMSO (0.4 M), sodium formate (0.4 M), sodium azide (20 mM), 2,2,6,6-tetramethyl-4-piperidone (0.4 M), SOD (15 units), tiron (10 mM)] and catalase (6.5 units) were added to the reaction mixtures. Assays in the presence of the minor groove binder distamycin (8 μM) and the major groove binder methyl green (2.5 μL of a 0.01 mg/mL solution) were also performed. The reduction of Cu(II) to Cu(I) was tested by adding 120 μM neocuproine, a ligand that chelates strongly to copper(I). Samples were treated as described above.

3. Results and discussion

3.1. Description of the structure of [Cu(HCip)$_2$] (NO$_3$)$_2$ · 6H$_2$O (**1**)

The structure of the complex is shown in Fig. 1 while selected bond lengths and angles are given in Table 2.

The structure consists of cationic monomeric units of [Cu(HCip)$_2$]$^{2+}$, two nitrate anions which neutralize the charge, and six lattice water molecules that provide crystalline stability through a network of hydrogen bond interactions. As in other previously reported ciprofloxacin compounds [27,46–51], the molecule of the ligand is zwitterionic in form with two hydrogen atoms attached to a nitrogen atom N(3). These hydrogen atoms are clearly visible in the difference Fourier map, and both form donor hydrogen bonds with water molecules. The Cu(II) ion is coordinated to two ciprofloxacin ligands that are related through an inversion center. Each ciprofloxacin acts as a bidentate ligand bonded to the cation through both its carboxylic oxygen atom and its carbonyl oxygen atom; this results in a CuO_4 chromophore in a crystallographically planar configuration (Σ(angles) = 360°). The nitrate anions are located in apical positions [O(1)–Cu(1)–O(13) 84.51(19)° and O(3)–Cu(1)–O(13) 79.13(19)°], with an axial distance Cu–O(13) (2.672(7)) Å. This is significantly larger than the equatorial distances, which would be consistent with a very weak metal ion interaction due to the Jahn–Teller effect. These equatorial bond Cu–O lengths (1.926(3) and 1.931(3) Å) are similar to those observed in related compounds [28,48]. The difference in the carboxylate distances O(1)–C(1) (1.265(6) Å) and O(2)–C(1) (1.245(6) Å) indicates the formation of a bond between the anionic carboxylate oxygen atom and the copper ion; these bond lengths are virtually identical in the uncomplexed ciprofloxacin ligand [49]. The quinolone moiety is practically planar with the exception of the cyclopropyl group sticking out of the plane, and the piperazine ring system is in the normal chair conformation [28,52]. The terminal nitrogen atom is protonated which explains why this atom fails to coordinate with the metallic ion.

Three interstitial water molecules complete the asymmetric unit. They are connected via hydrogen bonds with the protonated external nitrogen atom (N(3)) of the piperazine group as well as with the O(11) and O(13) from the nitrate group, the O(3)$_{keto}$ and the two *O*-carboxylate moieties. This bonding pattern contributes to the stability of the structure.

3.2. Description of the structure of $[Cu(Cip)(phen)](NO_3) \cdot 4H_2O$ (**2**)

Bond distances and angles for the compound **2** are given in Table 3 while Fig. 2 shows the ORTEP diagram for this copper complex.

Each crystallographically independent unit contains one copper(II) atom, one quinolone ligand in its anionic form (Cip^-), and one 1,10-phenanthroline, which together form cationic units $[Cu(Cip)(phen)]^+$, as well as one nitrate counteranion and four water molecules. The complex exhibits a five-coordinated motif in a distorted square pyramidal environment around the metal center. In the equatorial plane the metallic ion is coordinated by two nitrogen atoms (N(4) and N(5)) from a 1,10-phenanthroline molecule and by two oxygen atoms (O(1) and O(3)) from its quinolone ligand. The apical position is occupied by a third piperazinil nitrogen atom from a second ciprofloxacinate ligand, resulting in a CuN_3O_2 chromophore. It should be emphasised, that this ternary complex is the first time a quinolone has been found to act as a bridge-ligand by attaching two metallic centers.

The metal ion deviates from the mean least-squares basal plane in the direction of the apical piperazinil coordinated nitrogen atom by 0.2128(4) Å. The equatorial bond lengths between the copper ion and the two nitrogen atom (2.012(3) and 2.013(3) Å, respectively) are similar to those found in analogous compounds [53]. Furthermore, the axial distance Cu(1)–N(3)#1 (2.337(3) Å) is longer than those of the equatorial nitrogens. The equatorial oxygen bond lengths (1.923(3) and 1.931(2) Å) are similar to those found in previously reported structures of mixed copper–ciprofloxacin ternary complexes [28,33,48,54]. The O(1)–C(1) distance (1.282(4) Å) is longer than the O(2)–C(1) distance (1.231(4) Å) due to the formation of the Cu(1)–O(1) bond. The angles in the basal plane vary from 81.80(11)° to 92.66(10)°; these ranges are similar to those found in other previously described mixed copper–quinolone–1,10-phenantroline compounds [33,53]. In the apical direction, the Cu(1)–N(3)#1 vector is nearly perpendicular to the basal plane; the bond angles O_{basal}–Cu(1)–N(3)#1 and N_{basal}–Cu(1)–N(3)#1 are between 98.31(10)° and 93.03(10)°, respectively. The two basal ligands are planar with a dihedral angle between them of 7.75(07)° while the piperazinil ring, which is non-coplanar

with the quinolone ring, adopts a normal chair conformation [28,52].

The four interstitial water molecules are connected via hydrogen bonds, as well as with the two oxygen atoms of the nitrate anions, which helps stabilize the structure.

3.3. Spectroscopic properties

The IR spectra of the three compounds show a broad split band between 3600 and 2300 cm^{-1} which can be assigned to the O–H stretching vibrations of water molecules as well as to the N–H stretching vibration of the piperazinil moiety [28,51,55,56]. The latter signal appears between 2750 and 2300 in the IR spectra of complexes **1** and **3,** in which the ligand is in a neutral zwitterionic form (ν(N–H) of the NH_2^+ group). Furthermore, all the compounds present a slightly split band between 1640 and 1620 cm^{-1} which can be assigned to the ν(CO) vibrations of the ketonic group and ν_a(OCO) of the carboxylate group. At around 1383 cm^{-1} an intense band assigned to ν_s(OCO) + ν_3 (NO_3^-) is also visible, thereby confirming the presence of the nitrate group [49,57]. None of the IR spectra exhibit a band around 1730 cm^{-1} which would be assigned to the ν(C=O) vibration of the carboxylic group; this indicates the deprotonation of this moiety and its probable interaction with the metal ion [5,30,51,55]. The spectra of compounds **2** and **3** exhibit two new bands between 1610 and 1514 cm^{-1} which can be assigned to the vibrations ν(C=N) and ν(arC–C) of the phenantroline aromatic rings [30].

The diffuse reflectance spectra of the Cu(II)–ciprofloxacin complexes exhibit one asymmetric broad band centered around 15 000 cm^{-1} for compounds **2** and **3** and at 14368 cm^{-1} for compound **1**. These spectra suggest that compounds **2** and **3** have a distorted square-pyramidal geometry or tetragonal arrangement of the ligands donor atoms around the cupric ion while compound **1** presents a distorted octahedral arrangement [58].

At room temperature, the magnetic moments of all the complexes lie in the range 1.80–1.99 B.M., which is higher than the spin-only value of 1.73 B.M. Such divergence is not uncommon in mononuclear Cu(II) complexes due to the mixing-in of some angular moment from nearby excited states via spin–orbit coupling [59].

3.4. Nuclease activity of the complexes [Cu(Cip)(phen)] $(NO_3) \cdot 4H_2O$ (**2**) and Cu(HCip)(phen)$(NO_3)_2 \cdot H_2O$ (**3**)

The ability of [Cu(Cip)(phen)]$(NO_3)] \cdot 4H_2O$ (**2**) and Cu(HCip)-(phen)$(NO_3)_2 \cdot 3H_2O$ (**3**) to perform DNA cleavage has been investigated by means of gel electrophoresis with supercoiled pUC18 DNA in cacodylate buffer (pH 6.0). Reactions were carried out with ascorbate activation. Assays were also performed with Cu(II) due to the fact that Cu(II) ions in the presence of ascorbate are able to produce DNA damage. In addition, the DNA cleavage efficiency of **2** and **3** was compared with that of $[Cu(phen)_2]^{2+}$.

Fig. 3 shows the agarose gel electrophoresis of the oxidative cleavage of pUC18 plasmid DNA by the copper complexes, the Cu(II), and $[Cu(phen)_2]^{2+}$.

The DNA cleavage activity of the complexes was measured as the ability to convert supercoiled (form I) DNA to nicked circular (form II) or linear (form III) DNA.

The nuclease activity of the complexes was found to be dependent on complex concentration; thus, the activity of **2** and **3** increased at higher complex concentrations. At the lowest concentration assayed (3 μM), neither **2** nor **3** caused any damage to the DNA (lanes 8 and 12). However, at 6, 9 and at 12 μM, the compounds behaved as efficient chemical nucleases. At 6 μM, both **2** and **3** partially transformed the supercoiled DNA into its nicked circular form (lanes 9 and 13). At higher concentrations, the cleavage efficiency of complex **3** was found to be greater than that of **2**. Thus, at 9 μM, [Cu(Cip)(phen)]$(NO_3)] \cdot 4H_2O$ (**2**) promoted the partial conversion of form I DNA into nicked circular (form II) and a small amount of linear (form III) DNA (lane 10) while at the same concentration, Cu(HCip)(phen)$(NO_3)_2 \cdot 3H_2O$ (**3**) completely transformed the supercoiled DNA into its circular and linear forms (lane 14). The higher nuclease activity of **3** was even more evident at 12 μM, for at this concentration the compound was able to degrade form I DNA into linear DNA and small linear fragments that appeared as a smear (lane 15). The difference in the nuclease activity of the complexes is probably related to the difference in the amount of active copper species in solution able to promote DNA strand scission [60]. These species have been identified from the ESI^+ mass spectra of **2** and **3** as $[Cu(Cip)(phen)]^+$ (m/z = 573.2) and $[Cu(HCip)(phen)]^{2+}$ (m/z = 287.1), respectively. The presence of both species in solution is in good agreement with previous studies on the stability of ternary Cu:quinolone:phenantroline (1:1:1) compounds [61] which have concluded that Cu(HL)phen and Cu(L)phen are the predominant species under physiological conditions. We suggest that a higher amount of the active copper species is more easily produced in the monomeric compound **2** than in the polymeric compound **3,** which would explain the difference in cleavage activity. No cleavage was found with free Cu(II) (lanes 4–7). It is worth noting that the efficiency of compounds **2** and **3** at 12 μM was higher than that of $[Cu(phen)_2]^{2+}$ which, under identical reaction conditions, converted partially supercoiled DNA into circular and a small amount of linear DNA (lane 16). Similar results have been obtained for the [Cu(nal)-(phen)]$^+$ compound [38] and for the related [Cu(Nor)(phen)-(H_2O)](NO_3) and [Cu(HNor)(phen)(NO_3)]$(NO_3) \cdot 3H_2O$ compounds, which were all found to be more potent nucleases than $[Cu(phen)_2]^{2+}$ [30]. This fact clearly indicates that substituting

Marker, 3, lane 2: supercoiled DNA, lane 3 supercoiled DNA with ascorbate, lane 4: complex, lane 5: complex + DMSO (0.4 M), , lane 6: complex + sodium formate (0.4 M), lane 7: complex + NaN_3 (20 mM), lane 8: complex + 2,2,6,6-tetramethyl-4-piperidone (0.4 M), lane 9: complex + tiron (10 mM), lane 10: complex + SOD (15 units), lane 11: complex + neocuproine (120 μM), lane 12: complex + methyl green (2.5 μL of a 0.01 mg/mL solution), lane 13: complex + distamycin (8 μM), lane 14: catalase (6.5 units).

one phenanthroline with a quinolone ligand gives rise to a significant increase in nuclease activity.

In order to identify the reactive oxygen species that mediate the DNA strand scission brought about by compounds **2** and **3**, we decided to investigate the influence of different potentially inhibiting agents (Fig. 4).

The hydroxyl radical scavengers, dimethylsulfoxide and sodium formate both inhibited the scission reaction, which suggests that hydroxyl radicals are involved in the cleavage mechanism (lanes 5 and 6). Sodium azide and 2,2,6,6-tetramethyl-4-piperidone ($^1O_2$ scavengers) were also effective in blocking the DNA strand scission promoted by compounds **2** and **3** (lanes 7 and 8), indicating that either $^1O_2$ or a singlet-oxygen-like entity is one of the active oxygen intermediates responsible for the cleavage. In contrast, the presence of the superoxide radical scavengers tiron and SOD (lanes 9 and 10) attenuated the chemical nuclease activity of the complexes. These points to a cleavage pathway involving the formation of the reactive superoxide radical. Catalase (lanes 14) also inhibited the nucleolytic process, which confirms that hydrogen peroxide is also necessary for the DNA strand scission. With the Cu(I) chelator neocuproine, DNA damage was also significantly reduced (lanes 11); this suggests that the reduction of Cu(II) to Cu(I) is an important step in the cleavage process.

In summary, these results indicate that the cleavage reaction involves various oxygen species, including hydroxyl radicals, singlet-oxygen-like entities (e.g. Cu(I)–OOH) [62], and superoxide radicals. As is the case for other related compounds with nuclease activity, either a Fenton-type or a Haber–Weiss reaction leads to the formation of these oxygen active species, which, in turn, cleave the DNA [30,60].

$$(L)Cu^{2+} + Hasc^- \rightarrow (L)Cu^+ + acs^{\cdot -} + H^+$$
$$(L)Cu^+ + O_2 \rightarrow (L)Cu^{2+} + O_2{}^{\cdot -}$$
$$2O_2{}^{\cdot -} + 2H^+ \rightarrow H_2O_2$$
$$\text{Fenton}: (L)Cu^+ + H_2O_2 \rightarrow (L)Cu^{2+} + OH^- + {\cdot}OH$$
$$(L)Cu^+ + H_2O_2 \rightarrow (L)Cu^+ - OOH^- + H^+$$
$$\text{Haber–Weiss}: O_2{}^{\cdot -} + H_2O_2 \rightarrow {}^1O_2 + OH^- + OH$$

$(L)Cu^{2+}$ represents the active complex in solution.

The involvement of hydroxyl radicals in the DNA cleavage mechanism mediated by **2** and **3** suggests that the mode of action of these compounds differs from that of the Cu–phenanthroline compound [63].

In order to study how the complexes actually bind to DNA, the major groove binder methyl green and the minor groove binder distamycin were used. Treatment of pUC18 DNA with distamycin or methyl green prior to the addition of the complexes had no significant effect on the cleavage reaction, which indicate a lack of major or minor groove binding preferences for the complexes (lanes 12 and 13). Considering the cationic nature of the complexes in solution ($[Cu(Cip)(phen)]^+$ and $[Cu(HCip)(phen)]^{2+}$), their interaction with DNA must be primarily through electrostatic interactions with the phosphate backbone, although an intercalation involving the phenantroline and/or the ciprofloxacin ligands should not be ruled out.

4. Supplementary data

CCDC 702889 and 702890 contains the supplementary crystallographic data for compounds **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ABSTRACT

Three silver(I) complexes of the asymmetric tridentate ligand 8-((pyridin-3-yl)methylthio)quinoline (TQMP3), namely $[Ag_2(TQMP3)_2(NO_3)_2]$ (**1**), $[Ag_2(TQMP3)_2(CF_3CO_2)_2]$ (**2**) and $\{[Ag_2(TQMP3)_2](CF_3SO_3)_2(H_2O)\}_n$ (**3**), have been prepared by the method of layering and diffusing of diethyl ether. The structures of the complexes have been identified by elemental analysis (EA), infrared spectra (IR) and single-crystal diffraction, and are composed of discrete binuclear rings in complexes **1** and **2**, with π–π interactions or H-bonds further extending the structures into 2D nets, while in complex **3**, Ag···Ag interactions between the rings result in a 1D polymer chain. The antibacterial, antifungal and pesticide activities of the three complexes were tested.

1. Introduction

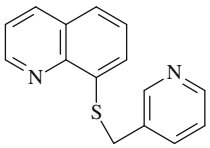
Ligands containing thioether or quinolinyl groups are well-established sources for structurally diverse and biologically active supramolecular complexes. Yuchi, Su, Luciano and Oh et al., have reported a series of transition metal complexes with symmetrical or asymmetrical thioether ligands containing quinolinyl groups [1–12]. Reports on the bioactivities of these kinds of complexes have also increased in recent years, and they show considerable antibactererial, antifungal and pesticide activities [13–15].

Referring to some reported heterocyclic N- and S-ligands [16–18], we designed a new kind of semi-rigid monothioether ligand, 8-((pyridin-3-yl)methylthio) quinoline (TQMP3) (Chart 1), and some discrete binuclear Ag(**I**) complexes were obtained using this ligand. We report herein the synthesis of the ligand and the structures of its three Ag(**I**) complexes. The antibacterial, antifungal and pesticide activities of the complexes have been tested.

2. Experimental

2.1. Materials and general methods

Silver nitrate, silver trifluoroacetate and silver trifluoromethylsulfonate were purchased from Aldrich Chemical Co. Inc., while sodium 8-mercaptoquinoline [19] and 3-chloromethylpyridine hydrochloride [20,21] were prepared according to reported procedures. All the other reagents and solvents were commercially available and employed as received or purified by standard methods prior to use. All reactions involving thiols were carried out under a nitrogen atmosphere. Elemental analyses were performed on a Germany Vario EL analyzer (Elementar) and IR spectra on an Avatar 330 FT-IR (Thermo Nicolet) spectrometer with KBr pellets. ^{1}H NMR spectra were recorded on a Mercury-Plus 300 spectrometer (VARIAN, 300 MHz) at 25 °C in $CDCl_3$ with tetramethylsilane as the internal reference. The UV–Vis spectra were recorded on a CARY-300 spectrometer (VARIAN).



2.2. Syntheses of the ligand and the complexes

2.2.1. Preparation of the ligand 8-[(pyridin-3-yl)methylthio]quinoline (TQMP3)

Sodium hydroxide (1.800 g, 45 mmol) and potassium iodide (0.322 g, 2 mmol) were dissolved in anhydrous ethanol (100 mL) in a 250 mL three-neck flask with a magnetic stirrer, a reflux condenser and an isobaric drop tundish. Sodium 8-mercaptoquinoline (4.045 g, 20 mmol) was added to the above mixture and dissolved by stirring under nitrogen. 3-Chloromethylpyridine hydrochloride (3.418 g, 21 mmol) in anhydrous ethanol (50 mL) was dropped into the mixed solution under nitrogen and heated in an oil bath at 80 °C for 8 h. Then it was cooled to room temperature, filtrated and washed with anhydrous ethanol (10 mL × 2). The filtrate was

2.2.2. Syntheses of the complexes

$[Ag_2(TQMP3)_2(NO_3)_2]$ (**1**). The linear tridentate ligand 8-[(pyridin-3-yl)methylthio]quinoline (TQMP3) (25 mg, 0.10 mmol) was dissolved in chloroform (3 mL) and acetone (2 mL), and the mixture was filtered into the bottom of a tube, then chloroform (1 mL) and acetonitrile (3 mL) were added very slowly onto the mixture, and silver nitrate (23 mg, 0.14 mmol) in absolute acetonitrile (3 mL) was layered on the top. The tube was sealed with film and put in dark for some days, and thus colorless crystals were obtained. The crystals were filtered and washed several times in anhydrous diethyl ether and then dried in vacuum. Yield 59% (25 mg). IR (KBr pellet, cm^{-1}): 3027 (w), 2923 (w), 1594 (m), 1575 (m), 1489 (m), 1456 (m), 1381 (vs), 1302 (m), 1190 (w), 1071 (w), 1027 (w), 985 (m), 822 (m), 788 (m), 754 (m), 711 (w), 657 (w). ^{1}H NMR (DMSO-d_6, 300 MHz): 8.86–8.88 (q, 1H), 8.58–8.59 (d, 1H), 8.41–8.42 (d, 1H), 8.38–8.39 (q, 1H), 7.81–7.82 (m, 2H), 7.79–7.80 (d, 1H), 7.73–7.75 (d, 1H), 7.58–7.62 (q, 1H), 7.52–7.55 (d, 1H), 7.29–7.33 (q, 1H), 4.38 (s, 2H). UV (CH_3CN, λ, nm): 250.0 ($\varepsilon = 8.5 \times 10^4$ dm^3 mol^{-1} cm^{-1}), 325.8 (2.4×10^4). *Anal.* Calc. for $C_{15}H_{12}AgN_3O_3S$: C, 42.67; H, 2.86; N, 9.95. Found: C, 42.42; H, 2.89; N, 10.04%.

$[Ag_2(TQMP3)_2(CF_3CO_2)_2]$ (**2**). The ligand 8-[(pyridin-3-yl)methylthio]quinoline (TQMP3) (25 mg, 0.10 mmol) was dissolved in chloroform (3 mL) and acetone (2 mL), and the mixture was filtered into the bottom of a tube, then chloroform (1 mL) and acetonitrile (3 mL) were added very slowly onto the mixture, and silver trifluoroacetate (28 mg, 0.13 mmol) in absolute acetonitrile (3 mL) was layered on the top. The tube was sealed with film and put in dark for some days, and thus colorless crystals were obtained. The crystals were filtered and washed several times in anhydrous diethyl ether, and then dried in vacuum. Yield 70% (33 mg). IR (KBr pellet, cm^{-1}): 3039 (w), 2917 (w), 1686 (vs), 1582 (w), 1484 (w), 1426 (m), 1369 (w), 1206 (s), 1130 (s), 987 (w), 802 (w), 718 (w), 652 (w). ^{1}H NMR (DMSO-d_6, 300 MHz): 8.85–8.87 (q, 1H), 8.62 (s, 1H), 8.41–8.42 (d, 1H), 8.35–8.38 (q, 1H), 7.82–7.85 (d, 1H), 7.74–7.77 (q, 1H), 7.66–7.68 (d,1H), 7.55–7.60 (m, 1H), 7.50–7.52 (d, 1H), 7.30–7.34 (q, 1H), 4.37 (s, 1H). UV (CH_3CN, λ, nm): 249.8 ($\varepsilon = 5.1 \times 10^4$ dm^3 mol^{-1} cm^{-1}), 329.0 (1.3×10^4). *Anal.* Calc. for $C_{34}H_{24}Ag_2F_6N_4O_4S_2$: C, 43.15; H, 2.56; N, 5.92. Found: C, 43.18; H, 2.56; N, 6.01%.

$\{[Ag_2(TQMP3)_2](CF_3SO_3)_2(H_2O)\}_n$ (**3**). A solution of $AgCF_3SO_3$ (28 mg, 0.11 mmol) in CH_3CN (3 mL) was added to a solution of TQMP3 (25 mg, 0.10 mmol) in $CHCl_3$ (3 mL) and CH_3COCH_3 (2 mL). Slow diffusion of diethyl ether into the resulting solution yielded colorless single crystals of **3**, which were filtered and washed several times in anhydrous diethyl ether, and then dried in vacuum. Yield 69% (36 mg) based on TQMP3. IR (KBr pellet, cm^{-1}): 3438 (w), 3028 (w), 2925 (w), 1596 (m), 1489 (m), 1457 (m), 1425 (m), 1375 (m), 1251 (vs), 1169 (s), 1048 (s), 985 (m), 820 (m), 788 (m), 712 (m), 657 (s), 579 (m), 520 (m). ^{1}H NMR (DMSO-d_6, 300 MHz): 8.85–8.87 (q, 1H), 8.63–8.64 (d, 1H), 8.41–8.43 (m, 1H), 8.33–8.36 (q, 1H), 7.84–7.86 (d, 1H), 7.71–7.74 (d, 1H), 7.62–7.65 (t, 1H), 7.54–7.59 (m, 1H), 7.48–7.51 (d, 1H), 7.30–7.34 (q, 1H), 4.37 (s, 2H). UV (CH_3CN, λ, nm): 250.4 ($\varepsilon = 3.9 \times 10^4$ dm^3 mol^{-1} cm^{-1}), 331.0 (9.4×10^3). *Anal.* Calc. for $C_{16}H_{13}AgF_3N_2O_{3.50}S_2$: C, 37.08; H, 2.53; N, 5.41. Found: C, 37.31; H, 2.48; N, 5.50%.

2.3. Antimicrobial assay

The complexes were dissolved in DMSO (dimethylsulfoxide) and tested against five aerobic reference strains for their inhibitory activities. The antimicrobial assays were performed using a modified version of the 2-fold serial dilution method of R.A. Fromtling (1993), in which two starting yeast inoculum sizes ($5 \times 10(4)$ and $2.5 \times 10(3)$ cells per ml) were compared, and readings were taken after 24 and 48 h of incubation. All other test conditions were standardized. The resultant turbidities in all tubes were estimated visually on a scale from 0 to ++++ turbidity, and MIC-0, MIC-1 and MIC-2 were defined as the lowest drug concentrations that reduced the growth to 0, + or ++ turbidity, respectively [22].

2.4. X-Ray diffraction analyses

Single-crystal X-ray diffraction measurements of complexes **1**–**3** were carried out on an Oxford Gemini S Ultra CCD diffractometer equipped with a graphite monochromator at 150 K. The determination of unit cell parameters and data collection were performed with Mo Kα radiation ($\lambda = 0.71073$ Å). The unit cell parameters were obtained with least-squares refinements and all structures were solved by direct methods [23]. The Ag atoms in each complex were located from *E*-maps. The other non-hydrogen atoms were located in successive difference Fourier syntheses. The final refinement was performed by full matrix least-squares methods with anisotropic thermal parameters for non-hydrogen atoms against F_0^2 [24]. Hydrogen atoms were added in calculated positions.

3. Results and discussion

3.1. Spectral analyses

3.1.1. ^{1}H NMR spectra

The ^{1}H NMR spectrum of the ligand is shown in Fig. 1 and the main data for both the ligand and the three complexes are listed in part 2. From the ^{1}H NMR data, we can see that in the complexes, the proton resonances on the $-CH_2$ linking group and the –CH groups far from the N atom on the heterocyclic rings shift to lower fields as compared to those in the free ligand (4.32 → 4.37–4.38 (s, 2H, Hg), 7.20–7.24 → 7.29–7.34 (q, 1H, Hb), 7.44–7.51 → 7.48–7.55 (m, 3H, Hd, e, i), which could be explained by the fact that upon coordination these groups are further shielded by another heterocyclic ring. In contrast, the other proton resonances on the heterocyclic rings shift to higher field as compared to those in the free ligand, which can be attributed to the packing effects amongst the rings.

3.1.2. IR spectra

The IR data for the ligand and the three complexes are listed in part 2. We can see that in the complexes, except for the peaks

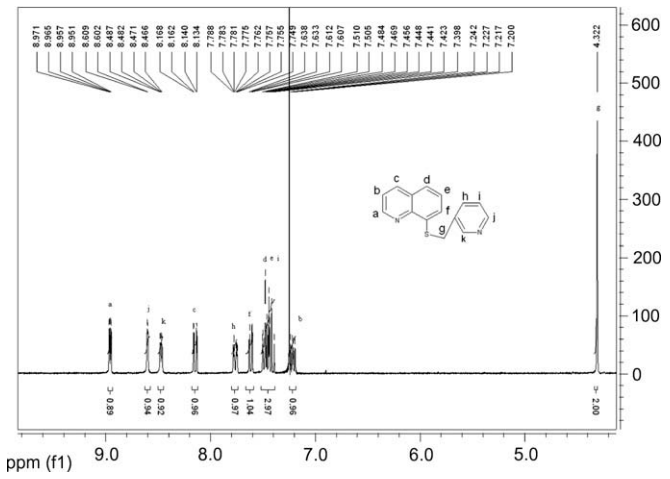

Fig. 1. ^{1}H NMR spectra of the ligand.

relevant to the ligand, they also show the typical peaks of the corresponding anions, i.e., 1575, 1381, 754 cm^{-1} for NO_3^- in complex **1**, 1686, 1484, 1206, 802, 718 cm^{-1} for $CF_3CO_2^-$ in complex **2**, and 1251, 1169, 1048, 657 cm^{-1} for $CF_3SO_3^-$ in complex **3**. These data prove the formation of coordination complexes.

3.1.3. UV spectra

The UV data for the ligand and the three complexes are also listed in part 2. We can see that in complexes **1** and **2**, the two absorbance peaks are caused by the characteristic $\pi \rightarrow \pi^*$ transition in the ligand, but they both show slight blue-shifts compared to those in the free ligand, which is due to strengthening in the π conjugate systems after coordination. In contrast, the two peaks in complex **3** show slight red-shifts, which can be attributed to the infinite polymer chain structure of the complex.

3.2. Crystal structures

The unit structures of complexes **1** and **2** are basically the same, composed of a dimetallic ring, as shown in Fig. 2. In the asymmetry unit, the Ag(I) center is in a distorted tetrahedral geometry, which is coordinated by two N atoms from one quinoline ring (Ag–N = 2.366(3) Å in **1** and 2.383(5) Å in **2**) and one pyridine moiety (Ag–N = 2.225(8) Å in **1** and 2.243(5) Å in **2**) from two different ligands. The remaining coordinated sites are occupied by a S atom from one ligand (Ag–S1 = 2.519(9) Å in **1** and 2.569(6) Å in **2**) and one O atom from NO_3^- (Ag–O1 = 2.366(3) Å) in **1** or the $CF_3CO_2^-$ anion (Ag–O1 = 2.539(6) Å) in **2**. In the $[Ag_2L_2(X)_2]$ ($X = NO_3^-$ or $CF_3CO_2^-$) unit, a twelve-membered ring is formed by the two Ag1 centers and the corresponding atoms on the two ligands.

In complex **1**, each molecular ring piles up with bordering rings by strong π-π interactions between the quinoline rings and pyridine rings, extending into a 2D structure in the *ac* plane. The central distance between the quinoline rings is 3.539 Å and that between the pyridine rings is 3.535 Å. While in complex **2**, the oxygen atoms in the $CF_3CO_2^-$ anion and hydrogen atoms on the quinoline ring form O1···H–C11 (Qui) and O2···H–C6 (CH_2) hydrogen bonds (3.312 and 3.370 Å), and a fluorine atom in the $CF_3CO_2^-$ anion

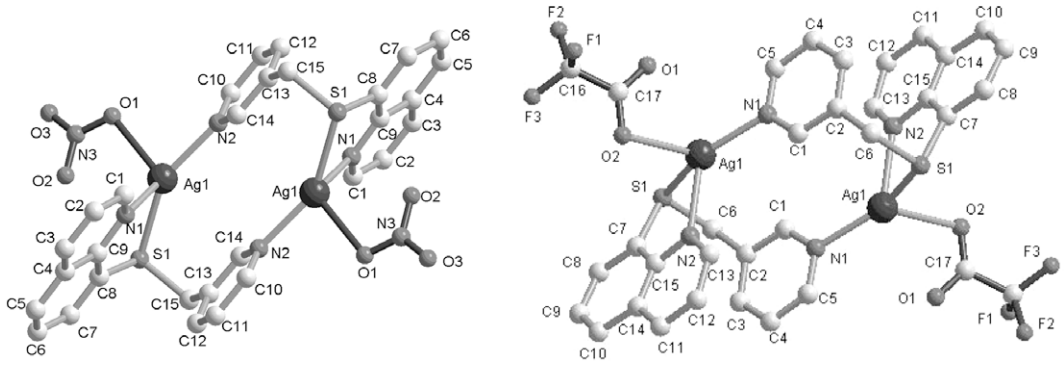

Fig. 2. Unit structures of complexes **1** (left) and **2** (right) (H atoms are omitted).

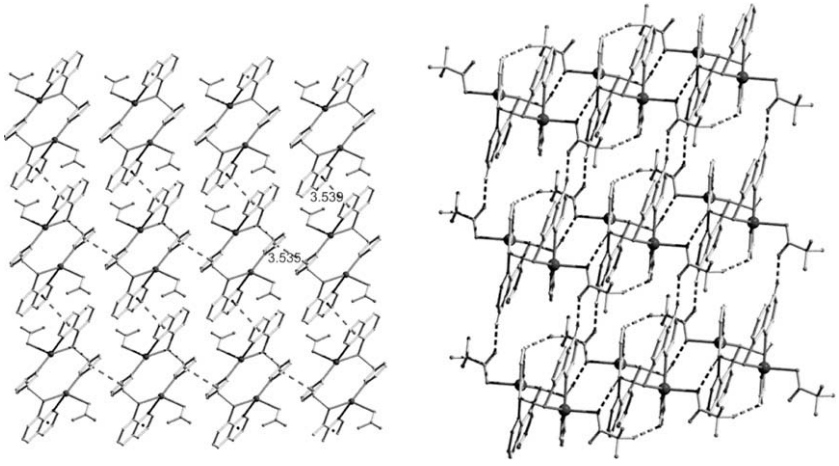

Fig. 3. Weak interactions and packing modes in complexes **1** (left) and **2** (right) (H atoms are omitted).

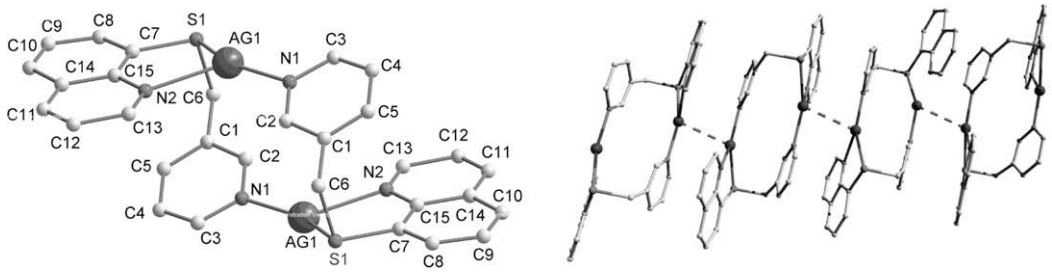

Fig. 4. Unit structure (left) and weak interactions (right) in complex **3** (H atoms and anions are omitted).

and a hydrogen atom on the pyridine ring form the F1···H–C5 (Py) hydrogen bond (3.243 Å), and thus a 2D net is formed along the *c* axis, as shown in Fig. 3.

In complex **3**, the self-assembly of Ag(I) ions and TQMP3 ligands gives the binuclear $[Ag_2(TQMP3)_2]$ $(CF_3SO_3)_2$ unit. Different from the above two complexes, the central Ag(I) is three coordinated by one S atom (d_{Ag-S} = 2.554(2) Å), one quinoline N atom (d_{Ag-N} = 2.347(2) Å) from one ligand, and one pyridyl N atom (d_{Ag-N} = 2.199(2) Å) from another ligand, forming a T-shaped configuration (Fig. 4 left). The $CF_3SO_3^-$ anions do not participate in the coordination and only act as counter anions for charge equilibrium. In the crystals, there exist Ag···Ag interactions between neighboring binuclear rings (d_{Ag-Ag} = 3.123(3) Å) and a 1D polymer chain is formed (Fig. 4 right). The data of the main bond lengths (Å) and angles (°) for complexes **1**–**3** are listed in Tables 1–3 and the crystallographic data and structure refinement summary are listed in Table 4.

3.3. The antibacterial, antifungal and pesticide activities of the three complexes

From the antibacterial results listed in Table 5, we can see that the three complexes show different inhibition activities against various kinds of bacteria. All of them have good efficiency in inhibiting *P. aeruginosa* and *Sarcina ureae*, while all are poor against *Escherichia coli*. Among them, complex **2** appears to be the most powerful one, showing quite good MIC values ($\leqslant$0.25 μg mL^{-1})

Table 6
Tests of pesticide activities of the complexes against five botanic bacteria.

Bacteria code	1		2		3	
	Percentage	Grade	Percentage	Grade	Percentage	Grade
C	38.18		52.73	+	56.36	+
F	11.11		77.78	++	55.56	+
U	52.94	+	82.35	++	52.94	+
I	67.09	+	82.28	++	51.90	+
D	52.00	+	68.00	+	60.00	+

Notes: (1) Biological activity is shown with killing or restraining percentage.
(2) Grades of biological activity to insect bacteria are +++ is ⩾90%; ++ is ⩾70–89%; + is ⩾50–69%; s- is <50%.
(3) C is cucumber fusarium wilt (*Fusarium oxysporum f. cucumerinum*); F is tomato early blight (*A. solani*); U is watermelon anthracnose (*C. lagenarium*); I is apple ring rot (*Physalospora piricola*); D is peanut brown spot (*Cercospora rachidicola*).

against both the bacteria with G^+ (*Staphylococcus aureus* and *S. ureae*) and those with G^- (*P. aeruginosa*), except for *E. coli*, providing potential applications in the broad spectrum of the anti-bacteria field.

The antifungal activities of the three complexes show that only complex **1** has considerable effect against *Saccharomyces cerevisiae* (*S. c*) and *Fusarium oxysporum f.sp.cubense* (*F. o*) (MIC = 31.25 μg mL^{-1}). The effects of the other complexes were poor in inhibiting fungal activities. The experimental results are also listed in Table 5.

The pesticidal activities of the three complexes against five botanic bacteria show that complexes **1**–**3** have distinct effects to inhibit cucumber fusarium wilt (*Fusarium oxysporum f. cucumerinum*, *C*), tomato early blight (*Alternaria solani*, F), watermelon anthracnose (*Colletotrichum lagenarium*, *U*), apple ring rot (*Physalospora piricola*, *I*) and peanut brown spot (*Cercospora rachidicola*, *D*), except that complex **1** has no effect against *C* and *F*. Complex **2** has the most powerful effect against *F*, *U* and *I*. The experimental results are listed in Table 6.

From the above results, we can see that for complexes **1** and **2**, with discrete binuclear rings aligned together by hydrogen bonds and π–π interactions, the bioactivities are comparatively better than complex **3** with a polymeric structure. This may be due to the fact that the relatively crowded packing of the heterocyclic rings in complex **3** makes it difficult to insert into the DNA helical chains in the bacterial or fungal molecules, and therefore makes it show worse inhibition results.

4. Conclusions

Three silver complexes from the ligand 8-((pyridin-3-yl)methylthio)quinoline (TQMP3) have been prepared and characterized, and they have been shown to have discrete or connected binuclear subunit rings in the crystal structures. Different kinds of intermolecular interactions, such as H-bonds, π–π interactions or Ag···Ag interactions, extend the structures into a 1D chain or 2D net. The antibacterial activity tests show that the three complexes are quite efficient at inhibiting certain bacteria, such as *P. aeruginosa* and *S. ureae*, while their antifungal activities are not quite so good. As for the pesticide activities, complexes **1**–**3** have distinctly inhibited several kinds of botanic bacteria, with complex **2** being the most powerful one against *A. solani* (F), *C. lagenarium* (U) and *P. piricola* (I). In general, complexes **1** and **2**, with discrete binuclear structures, show more efficient bioactivities than the polymeric complex **3**.

Supplementary data

CCDC 694468–694470 contain the supplementary crystallographic data for complexes **1**–**3**. ABSTRACT

The syntheses, FT-IR and UV–Vis spectra, thermal analyses and crystal structures of Mn(II) and Cu(II) orotate coordination polymers with 2-methylimidazole (2-meim) and *N,N,N′,N′*-tetramethylethylenediamine (tmen) ligands are described. The orotate ligand acts as a bridging ligand with two different coordination modes, the $\{mer\text{-}[Mn(\mu\text{-}HOr)(H_2O)(2\text{-}meim)_2]\}_n$ (**1**) complex displays an linear chain structure in which each Mn(II) ion exhibits a distorted octahedral coordination by a tridentate orotate, two 2-meim and one aqua ligand. In $\{[Cu(\mu\text{-}HOr)(tmen)] \cdot 1.5H_2O\}_n$ (**2**), the Cu(II) ion is coordinated by a tridentate orotate and one bidentate tmen ligand, and exhibits a square pyramidal geometry. These polymer chains are linked by hydrogen-bond interactions forming a three-dimensional network. Complex **2** exhibits an irreversible thermochromic effect. After dehydration, the color of the complex changes from blue to green.

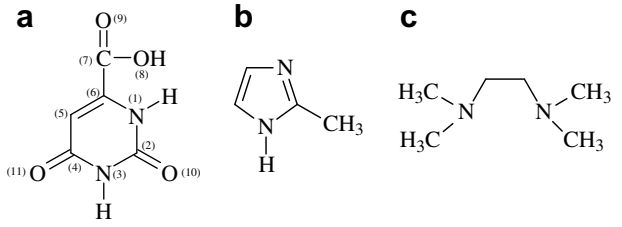
1. Introduction

The construction of novel supramolecular coordination polymers has been of increasing interest in recent years due to their potential applications in material sciences [1–5]. Organic molecules containing carboxylic acid have been used as building blocks in crystal engineering and many coordination polymers [6–8]. Orotic acid (2,6-dioxo-1,2,3,6-tetrahydropyrimidine-4-carboxylic acid, vitamin B13, and H_3Or) is a well-known versatile ligand able to chelate as well as to bridge metal ions, leading to the formation of polynuclear complexes [9–13], and it has been widely studied in recent years as a polyfunctional ligand because of its significance in the biosynthesis of pyrimidine bases, with antitumour activity displays for Ni(II), Pt(II), and Pd(II) complexes. The orotate ligand coordinates to metal ions by means of its four oxygen atoms of carboxyl or carbonyl groups and two nitrogen atoms, forming monodentate [14,15], bidentate [16–19], bis(bidentate) [20–22], tridentate bridging [23,24,7], tetradentate bridging [12] and mixed chelating-bridging coordination modes [25–27]. Until now, the crystal structures of two polynuclear Mn(II)–orotate complexes, $[Mn_2(HOr)_2(H_2O)_6]_n$ [12] and $[Mn(HOr)(H_2O)(bipy)]_n$ [13], and two mononuclear Mn(II)–orotate complexes, $[Mn(HOr)(H_2O)(phen)]$ [28] and $(enH_2)[Mn(HOr)_2(H_2O)_2]$ [20], have been reported, in which the orotate ligand acts as a tridentate bridging ligand and a bidentate ligand (N1, O1). Although there are many copper(II)–orotate complexes with mononuclear structures, $[Cu(HOr)(phen)]$ [29], $[Cu(HOr)(mea)_2]$ [30], $[Cu(HOr)(H_2O)(en)] \cdot H_2O$ [19], $[Cu(HOr)(tea)] \cdot H_2O$ [31], $[Cu(HOr)(bipy)(H_2O)] \cdot H_2O$ [32], and $[Cu(HOr)(etpy)]_2$ [33], only one polynuclear orotate complex of the Cu(II) ion has been reported, by Ha et al. [9].

Recently, we have reported the synthesis and structures of orotate complexes with different amines [19–22,30–47]. In the present study, we describe the preparation, spectral, thermal (TG, DTG, and DTA) and crystal structures of two novel supramolecular coordination polymers of Mn(II) and Cu(II) orotate with 2-methylimidazole and *N,N,N′,N′*-tetramethylethylenediamine ligands (Scheme 1.): *mer*-$[Mn(\mu\text{-}HOr)(H_2O)(2\text{-}meim)_2]_n$ (**1**) and $\{[Cu(\mu\text{-}HOr)(tmen)] \cdot 1.5H_2O\}_n$ (**2**).



2. Experimental

2.1. Preparation of the complexes

A solution of orotic acid monohydrate (0.871 g, 5 mmol) in water (50 mL) was added dropwise with stirring at 50 °C to a solution of $Mn(CH_3COO)_2 \cdot 4H_2O$ (1.23 g, 5 mmol) or $Cu(CH_3COO)_2 \cdot H_2O$ (1.00 g, 5 mmol) in distilled water (25 mL). The

Scheme 1. (a) Orotic acid, (b) 2-methylimidazole, (c) *N,N,N′,N′*-tetramethylethylene diamine.

solution immediately became a suspension and was stirred for 4 h at 50 °C. Then 2-methylimidazole (1.65 g, 20 mmol) for **1** and *N,N,N′,N′*-tetramethylethylenediamine (1.16 g, 10 mmol) for **2** in water (10 mL) was added dropwise to this suspension. The clear solution that formed was stirred for 2 h at 50 °C and then cooled to room temperature. The crystals that formed were filtered and washed with 10 mL of water and were dried in air.

2.2. Materials and measurements

All chemicals used were analytical reagents and were commercially purchased. IR spectra were obtained with a Perkin Elmer 100 FT-IR spectrometer using KBr pellets in the 4000–400 cm^{-1} range. The UV–Vis spectrum was obtained for an aqueous solution of the complex (10^{-3} M) with a Shimadzu UV-3150 spectrometer in the range 900–190 nm. Magnetic susceptibility measurements at room temperature were performed using a Sherwood Scientific MXI model Gouy magnetic balance. A Perkin Elmer Diamond TG/DTA Thermal Analyzer was used to record simultaneous TG, DTG and DTA curves in static air atmosphere at a heating rate of 10 °C min^{-1} in the temperature range 20–600 °C using platinum crucibles.

2.3. Crystallographic analyses

Diffraction experiments were carried out at 296 K on a Stoe IPDS diffractometer. The structures were solved by direct methods and refined using the programs SHELXS97 and SHELXL97 [48]. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares methods [48]. The hydrogen atoms were placed in geometrically idealized positions and refined as riding atoms. Data collection: X-AREA, cell refinement: X-AREA, data reduction: X-RED [49]; program(s) used for molecular graphics: ORTEP-3 for Windows [50]; software used to prepare material for publication: WINGX [51].

3. Results and discussion

3.1. UV–Vis spectrum and magnetic properties

The electronic spectrum of an aqueous solution of complex **2** displays a broad absorption band at 653 ($\varepsilon = 82$ L mol^{-1} cm^{-1}), which is assigned to the $a_1 \rightarrow b_1$ transition [52]. The strong absorption bands below 300 nm are due to $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions of the ligands in the complex.

The complexes exhibit magnetic moment values of 5.92 BM for **1** and 1.68 BM for **2**, which corresponds to five and one unpaired electrons, respectively.

3.2. IR spectra

The IR spectra of complexes **1** and **2** exhibit a medium intensity and broad band in the range of 3233–3133 cm^{-1} for **1** and 3109 cm^{-1} for **2**, which can be attributed to the N–H stretching vibration of 2-meim or/and HOr ligands. The presence of coordinated water molecules in **1** caused the appearance of a strong and broad absorption band with a maximum at 3342 cm^{-1}. The IR spectrum of **2** shows sharp bands at 3515 and 3453 cm^{-1}, the characteristic stretching of crystal water molecules. The weak bands observed in the 3085–2744 cm^{-1} region are due to CH/CH_2/CH_3 stretching vibrations. The separation $\Delta\upsilon$, defined as υ_{as}(COO)–υ_s(COO), provides some useful information on the bonding mode of the carboxylate groups [53]. The strong and broad bands appearing in the ranges 1683–1600 and 1408–1387 cm^{-1} for **1** and 1643–1558 and 1407–1337 cm^{-1} for **2** are ascribed to the asymmetric and symmetric stretching vibrations of the carboxylate group of the orotate ligand, respectively. The observed Δ values for the complexes are 306 and 264 cm^{-1}, respectively. This result indicates that the coordination mode of the carboxylate group is monodentate for **1** and bridging for **2**. These conclusions are also supported from the results obtained from X-ray diffraction measurements. The weak bands observed in the regions 427–569 cm^{-1} for **1** and 458–598 cm^{-1} for **2** are due to M–N and M–O stretching vibrations [53].

$$mer\text{-}[Mn(\mu\text{-HOr})(2\text{-meim})(H_2O)] \xrightarrow{164-211^{\circ}C} [Mn(\mu\text{-HOr})(im)_2] + 2CH_3 + H_2O$$

$$[Mn(\mu\text{-HOr})(im)2] \xrightarrow{211-322^{\circ}C} [Mn(\mu\text{-HOr})] + 2im$$

$$[Mn(\mu\text{-HOr})] \xrightarrow{322-450^{\circ}C} MnO + HOr$$

3.3. Thermal analyses

Thermal analyses of the complexes were performed in static atmosphere air in the temperature range 20–600 °C.

3.3.1. *mer*-[Mn(μ-HOr)(H_2O)(2-meim)$_2$]$_n$

This complex shows a three stage decomposition process. Although the complex contains the aqua ligand, it is stable up to 164 °C. In the first stage, the complex starts to lose the aqua ligand and two CH_3 radicals between 164 and 207 °C, with an experimental mass loss of 11.98% (calc. mass loss 12.28%). This type of behavior of methylimidazole ligands in the complexes [Zn(Han)$_2$(4-Meim)$_2$] (Han = *o*-aminobenzoate, 4-Meim = 4-methylimidazole) [54] and [Co(HOr)(H_2O)(4-Meim)$_3$] [41] has been reported earlier. The IR spectrum of the complex heated just to the end of this weight loss show no evidence of CH_3 bands. The second stage is related to the release of the remaining two imidazole ligands, giving an endothermic effect (calc. = 34.80, found = 34.02%). In the last extremely exothermic stage between 322 and 450 °C, the orotate ligand is abruptly burnt (DTA = 446 °C). The total mass loss of all the decomposition processes is 79.60% (calc. 81.86%), suggesting that MnO is the end product.

3.3.2. {[Cu(μ-HOr)(tmen)] · 1.5H_2O}$_n$

This complex exhibits four decomposition stages. In the first stage, endothermic removal of crystal water molecules occurs between 47 and 104 °C (calc. 7.60, found 7.48%, DTA$_{max}$ = 96 °C). The anhydrous complex is thermally stable up to about 234 °C and then undergoes complete exothermic decomposition after melting at 235 °C. The second stage in the temperature range 235–273 °C is related to the decomposition of the tmen ligand by exothermic effects (calc. 32.20, found 32.69%, DTA$_{max}$ = 262 °C). The exothermic effect between 273 and 360 °C is likely due to the release of CO_2 from the HOr ligand (calc. 12.19, found 11.92%). Similar behavior has been reported earlier [36,41,42]. The strong exothermic peak is associated with the decomposition of the uracil ligand in the range of 360–436 °C. The final decomposition product, namely CuO, was identified by IR spectroscopy by

$$[Cu(uracil)] \overset{360-436^{\circ}C}{\rightarrow} CuO + uracil$$

Thermochromic complexes showed abrupt color changes on heating in the solid state and these complexes are very important owing to their applicability as temperature sensors. Complex **1** exhibits irreversible thermochromism and on dehydration the color of the complex changes from blue to green. The thermochromism is proposed to be due to a decrease of the in-plane ligand field strength resulting from conformational changes of the diamine chelate rings.

3.4. Crystal structures of the complexes

The relevant crystal data and experimental conditions along with the final parameters are summarized in Table 1. Selected bond lengths and angles together with the hydrogen bonding geometries are given in Tables 2 and 3.

3.4.1. mer-[Mn(μ-HOr)(H$_2$O)(2-meim)$_2$]$_n$

The molecular structure of **1** with the atom labelling is shown Fig. 1. Selected bond lengths and angles are collected in Table 2. The crystallographic analyses reveal that the crystal structure of **1** is a one dimensional linear chain polymer along the *b* axis. The Mn(II) ion is coordinated by one orotate, two *trans*-2-methylimidazole and one aqua ligand, and is a *mer* isomer. The orotate ligand behaves as a tridentate bridging ligand through the oxygen atom of the carboxylate group and deprotonated nitrogen atom of the pyrimidine ring in a chelate manner, and the oxygen atom of another carbonyl group (Scheme 2a). The distorted octahedral geometry is completed with two nitrogen atoms of 2-methylimidazole and one aqua ligand. One carbonyl oxygen atom (O3) of a neighboring complex molecule and three nitrogen atoms (N1, N3, and N5) from the HOr and 2-meim ligands comprise the equatorial plane [N1–Cu1–N3 = 100.3 (4)°, N3–Cu1–N5 = 169.3 (3)°], while one oxygen atom of a carboxylate group (O1) of the HOr ligand and an oxygen atom (O5) of an aqua ligand occupy the axial positions. The Mn1–O1, Mn–O3 and Mn1–O5 bond distances are 2.131(6), 2.136(6), and 2.192(9) Å, and the Mn1–N1, Mn1–N3 and Mn1–N5 bond distances are 2.319(7), 2.265(10), and 2.288(9) Å, respectively. The Mn1–O$_{HOr}$ and Mn1–N$_{HOr}$ bond distances are significantly longer than that found in [Ni(HOr)(H$_2$O)$_3$]$_n$ (Ni–O = 2.064(2), 2.083(2) Å and Ni–N = 2.056(2) Å) [33] and [Co(HOr)(H$_2$O)$_3$]$_n$ (Co–O = 2.092(2), 2.133(5) Å and Co–N = 2.103(6) Å) [33]. However these bond distances are similar to the corresponding values found in the reported [Mn(HOr)(phen)-(H$_2$O)$_2$] [28], (enH$_2$)[Mn(HOr)$_2$(H$_2$O)$_2$] · 2.5H$_2$O [20], [Mn$_2$(HOr)$_2$-(H$_2$O)$_6$] [12], and [Mn(HOr)(bipy)(H$_2$O)] [13] complexes. The intermolecular Mn1–Mn1^{i} and Mn1–Mn1^{ii} ((i) $-1/2+x$, $1/2-y$, z; (ii) $1-x$, $1-y$, $1/2+z$) distances are 6.843 and 8.767 Å, respectively, and the intramolecular Mn1–Mn1^{iii} ((iii) x, $-1+y$, z) distance is 8.338 Å.

The crystal packing of the complex is stabilized through strong intermolecular hydrogen bonding (i) between the N atom of the 2-meim ligand and the uncoordinated oxygen atom of a carboxylate group [N(4)···O(2): 2.86 Å] and (ii) among the aqua ligand, coordinated and uncoordinated carboxylate oxygen atoms [O5···O(1): 2.944 and O5–O2 = 2.971 Å]. As a result of all these interactions, each chain is linked to other chains by hydrogen-bond interactions, forming a three dimensional network (Fig. 2).

3.4.2. {[Cu(μ-HOr)(tmen)] · 1.5H$_2$O}$_n$

A view of the molecule and its atom-numbering scheme are shown in Fig. 3 and selected bond lengths and bond angles are given in Table 3. Each Cu(II) center displays a square pyramidal coordination environment with two oxygen atoms and three nitrogen atoms: one oxygen atom (O4) of a carboxylate group and its adjacent nitrogen (N1) atom from the HOr ligand, one carbonyl oxygen atom from neighboring HOr ligand (Scheme 2b), and two nitrogen atoms from the tmen ligand (Fig. 3). One carboxylate oxygen atom (O3^{i}, (i) $-x+3/2$, $y+1/2$, $-z+3/2$) and three nitrogen atoms (N1, N3, and N4) from the HOr and tmen ligands comprise the equatorial plane [N1–Cu1–N4 = 169.95 (11)°, N3–Cu1–N4 = 90.06 (12)°], while one oxygen atom of a carboxylate group, O4, occupies the axial position. The Cu1–N1, Cu1–O4, Cu1–O3^{i}, Cu1–N3 and Cu1–N4 bond distances are 1.95, 2.26, 2.00, 2.02 and 2.10 Å, respectively. The Cu1–N1$_{HOr}$ bond distance is comparable to those reported for [Cu(HOr)(H$_2$O)$_2$]$_n$ *[1.975(2) Å]* [9], but the Cu1–O4 and Cu1–O3^{i} bonds distances are significantly different from the

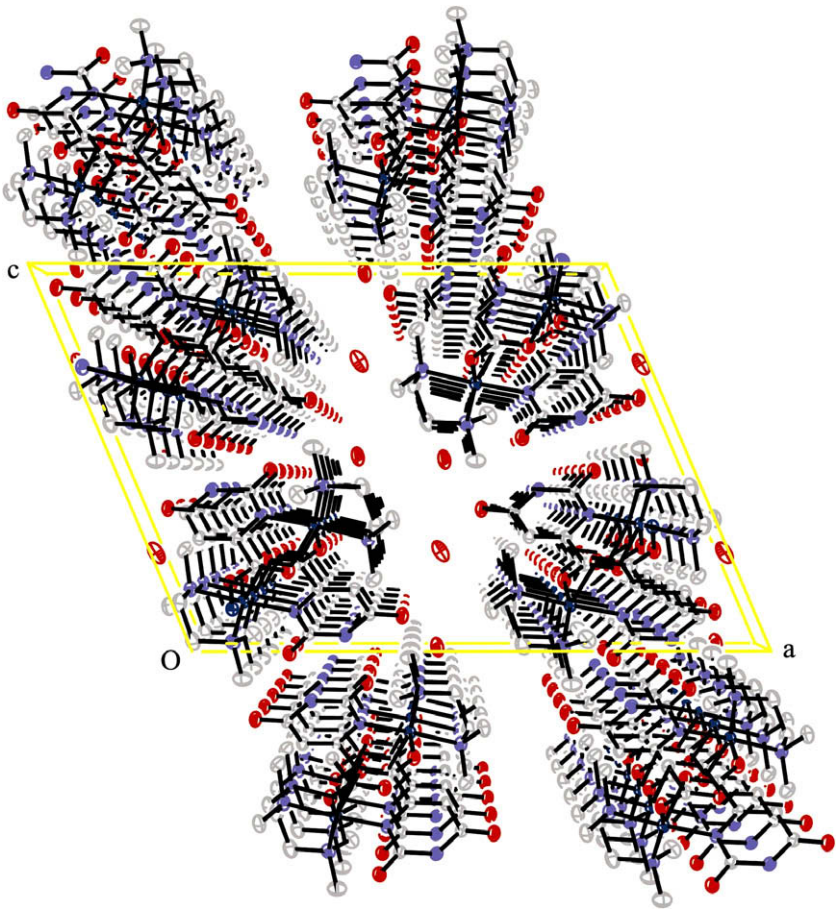

Fig. 5. Packing diagram of **2**.

corresponding distances of 1.948(2) and 2.337(2) Å, respectively. The intermolecular Cu1–Cu1^{i} = 8.622, ((i) $1.5 - x$, $1.5 - y$, $1 - z$) and Cu(1)–Cu(1)^{ii} = 7.828 Å ((ii) $1 - x$, $1 - y$, $1 - z$)] distances are longer than the intramolecular distance Cu1–Cu1^{iii} = 5.663 Å ((iii) = $1.5 - x$, $-1/2 + y$, $1.5 - z$).

The orotate ligand is essentially planar with a r.m.s. deviation of −0.0009 Å and the largest deviation from the mean plane is 0.0118 Å for the C4 atom. Of all the N–C bonds in the uracil ring of the orotato ligand, C1–N1 (1.357(2) Å), C1–N2 (1.373(2) Å) and C4–N1 (1.354(2) Å) are the shortest. This indicates significant π-electron delocalization within the uracil ring.

The details of the hydrogen bonding geometries are given in Table 3. The orotate anions can align to form a tail-to-tail cyclic dimer through strong N2–H···O1 hydrogen bonds, forming a DA:AD dimer [N2···O1^{iii} = 2.816 (2) Å, N2–H2···O1^{iii} = 172°, (iii) $-x + 3/2$, $-y + 1/2$, $-z + 1$]. This property establishes orotate as a significant candidate for designing supramolecular structures based on metal ion complexes [20]. In complex **1**, each of the HOr ligands are doubly hydrogen bonded to a corresponding HOr ligand of a neighboring complex, forming a cyclic dimer (Fig. 4a) and these motifs are linked to each other by water bridges (O5–H5···O2), generating a two dimensional network (Fig. 4b). These arrangement gives rise to eight membered rings that can be described as R_2^2 (8) and, R_3^3, respectively, in Etter's notation [55]. The two dimensional networks are linked to each other by water bridges (O6–H6···O2) (Fig. 4b). All these intermolecular interactions result in the formation of a three dimensional network (Fig. 5).

4. Conclusion

In this study, we have synthesized and structurally characterized two new Mn(II) and Cu(II) orotate coordination polymers with 2-methylimidazole and *N,N,N′,N′*-tetramethylethylenediamine ligands. In the *mer*-[Mn(μ-HOr)(H_2O)(2-meim)$_2$]} (**1**) and {[Cu(μ-HOr)(tmen)] · 1.5H_2O}$_n$ (**2**) complexes, the orotate dianion acts as a bridge between the metal ions forming one-dimensional polymeric chains, its coordination sites being the carboxylate oxygen atom (O8), nitrogen atom (N1) of the pyrimidine ring and oxygen atom O(11) for **1** and carboxylate oxygen atoms (O8 and O9) and nitrogen atom (N1) of the pyrimidine ring for **2**. These polymer chains are linked by hydrogen-bond interactions to form a three-dimensional network. The Cu(II) complex exhibits irreversible thermochromism and on dehydration the color of the complex changes from blue to green.

Appendix A. Supplementary data

CCDC 676222 and 676223 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly. 2008.09.024.

Fluorescence quenching
BSA

ABSTRACT

The interaction between colloidal $AgTiO_2$ nanoparticles and bovine serum albumin (BSA) was studied by using absorption, steady state, time resolved and synchronous fluorescence spectroscopy measurements. Absorption spectroscopy proved the formation of a ground state BSA···$AgTiO_2$ complex. Upon excitation of BSA, colloidal $AgTiO_2$ nanoparticles effectively quenched the intrinsic fluorescence of BSA. The number of binding sites ($n = 1.06$) and apparent binding constant ($K = 3.71 \times 10^5\ M^{-1}$) were calculated by the fluorescence quenching method. A static mechanism and conformational changes of BSA were observed.

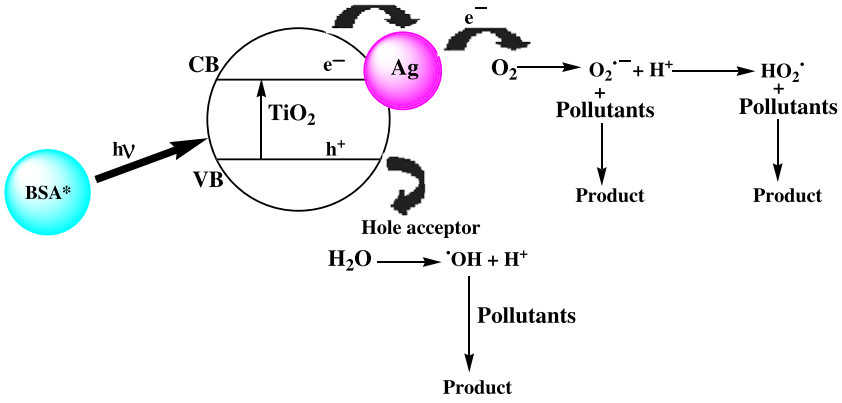
1. Introduction

One of the most important biological functions of albumins is their ability to carry drugs as well as endogenous and exogenous substances [1]. The binding capacity and sites of albumins have been characterized [2]. Serum albumins are the most abundant proteins in plasma [3]. As the major soluble protein constituents of the circulatory system, they have many physiological functions [4]. Among the serum albumins, BSA has a wide range of physiological functions involving binding, transport and delivery of fatty acids, porphyrins, bilirubin and steroids, etc. It is home to specific binding sites for metals and pharmaceutical dyes [5]. The binding properties of BSA with various drugs have been fully investigated by many researchers [6–10], which are useful for understanding the reaction mechanism as well as for providing guidance for the application and design of new drugs [11].

Bovine serum albumin (BSA) has been selected as our protein model due to its water-soluble nature which is important for interaction studies [12,13]. It contains 582 amino-acid residues with a molecular weight of 69,000, and two tryptophan moieties at positions 134 and 212 as well as tyrosine and phenylalanine [14]. The intrinsic fluorescence of BSA is due to aromatic amino-acid residues. Nanoparticle probes act as biosensors in the chemical and biochemical fields, and their applications are becoming more extensive. These probes have been applied to ultrasensitive detection of proteins, DNA sequencing, clinical diagnostics etc. Recently we reported the interaction of colloidal TiO_2 with bovine serum albumin using fluorescence spectroscopy [15].



Metal semiconductor nanoparticles have become an attractive topic of research because of their potential applications in different fields, such as charge-transfer processes [16], optoelectronics [17] and medicine [18]. Among such nanocomposite structures, $AgTiO_2$ has more attention paid to it because silver is an extremely attractive noble metal on the nanoscale due to its remarkable catalytic activity [19], size and shape-dependent optical properties, promising applications in chemical and biological sensing [20], and also due to its antimicrobial activity [21]. Elechiguerra et al. studied metal nanoparticle interactions with the human immunodeficiency virus-1 (HIV-1), and silver nanoparticles of the size 1–10 nm were attached to HIV-1, and this prevented the virus from binding to host cells [22].

Based on the above strategy we have investigated the interaction of BSA with colloidal $AgTiO_2$ nanoparticles (Scheme 1). This is the first challenge made to investigate the mode of interaction of colloidal $AgTiO_2$ nanoparticles with BSA.

BSA absorbs light energy around 280 nm, which is not absorbed by TiO_2. The excited state energy of BSA is transferred to the ground state TiO_2, thus TiO_2 gets excited and generates conduction band electrons and valence band holes (Scheme 1). The conduction band electrons are transferred to the metal core, and then the electrons in the metal and holes in the valence band of TiO_2 take part in subsequent redox reactions with the surface adsorbed molecules to yield the ultimate products. The photogenerated electrons have sufficient electronegativity to reduce dioxygen to superoxide/hydroperoxide radicals, effecting the deep oxidation of a wide range of organic pollutants to degraded products. In addition, the photogenerated holes are highly oxidizing which can split water into H^+ and $OH^{\bullet}$, and then the produced $OH^{\cdot}$ radicals can oxidize the organic pollutants.

Scheme 1. Interaction of colloidal $AgTiO_2$ nanoparticles with BSA.

2. Experimental

2.1. Materials

Bovine serum albumin and titanium-(triethanolaminato) isopropoxide were purchased from Aldrich. All measurements were performed at ambient temperature.

2.2. Methods

2.2.1. Preparation of colloidal $AgTiO_2$ nanoparticles

The method of preparation of colloidal $AgTiO_2$ nanoparticles in water is similar to the one reported earlier [23]. Colloidal $AgTiO_2$ nanoparticles were prepared by a one pot synthesis that involved reduction of metal ions and hydrolysis of titanium-(triethanolaminato)isopropoxide [TTEAIP] in dimethylformamide. The solvent, DMF, plays an important role in reducing the Ag^+ ions first, followed by the slow hydrolysis of TTEAIP to form colloidal $AgTiO_2$ nanoparticles.

2.2.2. Instrumentation

Samples for spectroscopic measurements were prepared by dissolving bovine serum albumin in water and administering the appropriate concentration of colloidal $AgTiO_2$ nanoparticles. The samples were carefully degassed using pure nitrogen gas for 15 min. Quartz cells (4 x 1 × 1 cm) with high vacuum Teflon stopcocks were used for degassing.

The fluorescence quenching measurements were carried out in a JASCO FP-6500 spectrofluorimeter. The slit width (each 5 nm) and scan rate (500 nm/min) were constantly maintained for all measurements. Absorption spectral measurements were recorded using a Cary 300 UV–Vis spectrophotometer. Fluorescence lifetime measurements were carried out in a picosecond time correlated single photon counting (TCSPC) spectrometer. The excitation source was the tunable Ti-sapphire laser (TSUNAMI, Spectra Physics, USA). The fluorescence decay was analyzed by using the software provided by IBH (DAS-6). The particle size of the prepared $AgTiO_2$ nanoparticles were analyzed by transmission electron microscopy (recorded using TECNAI G^2 model).

3. Results and discussion

3.1. Characterization of the $AgTiO_2$ nanoparticles

Transmission electron microscope pictures have been taken for the prepared Ag–TiO_2 nanoparticles (Fig. 1) to give an idea about the particle size and surface modifications effected during doping of the metal on TiO_2 nanoparticles. The TEM pictures permit easy differentiation of metal nanoparticles (small dark areas) and TiO_2 (large bright areas), that is, an Ag nanoparticle is seen on the surface of a TiO_2 particle as a dark dot. Also, there is the possibility of metal particles to be incorporated into the interstitial positions of the semiconductor particles. Further, it is observed that the average size of silver in the Ag–TiO_2 particles is in the range 10–20 nm.

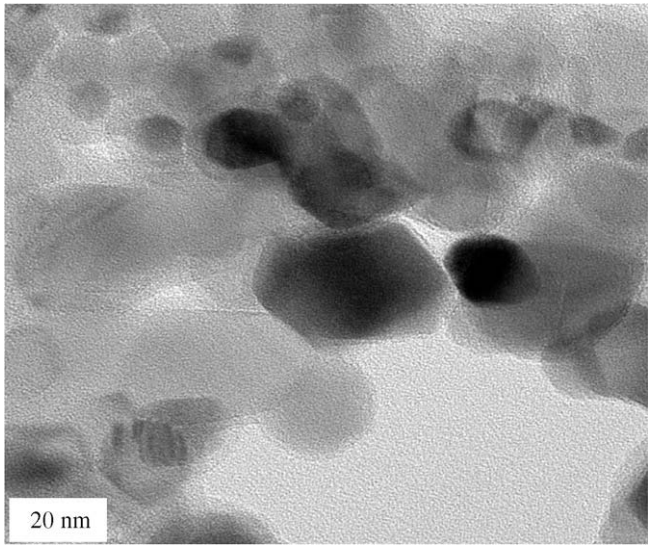

Fig. 1. TEM image of $AgTiO_2$ nanoparticles.

3.2. XRD characterization of $AgTiO_2$ nanoparticles

Fig. 2 shows the XRD spectrum of $AgTiO_2$ nanoparticles. Diffractions that are attributable to the anatase phase of TiO_2 crystals (101) are clearly detectable at $2\theta = 25°$ (JCPDS 21-1272) in Fig. 2. Peaks at $2\theta = 38.4°$, 44.5° and 64.6° in $AgTiO_2$ are assigned to (111), (200) and (220) planes of silver (JCPDS), which proves that the TiO_2 surfaces are covered with metal particles.

3.3. Absorption characteristics of BSA–$AgTiO_2$ nanoparticles

Fig. 3 shows the absorption spectra of BSA in the presence and absence of colloidal $AgTiO_2$ nanoparticles at different concentrations. From this study we observed that upon increasing the concentration of colloidal $AgTiO_2$ the absorption of BSA increases regularly with the peak shift of around 5 nm. It is due to the

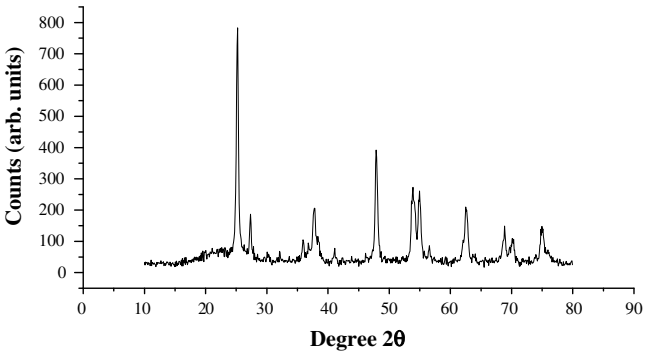

Fig. 2. XRD pattern of $AgTiO_2$ and nanoparticles.

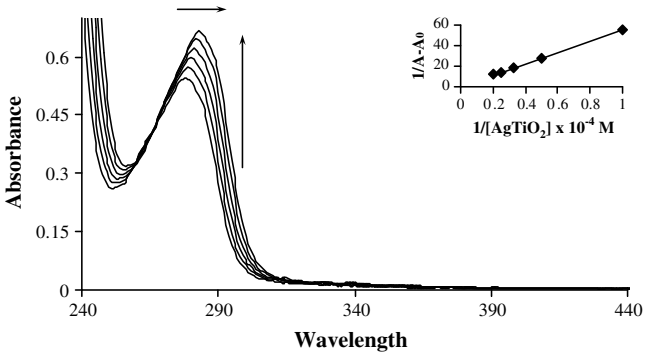

Fig. 3. Absorption spectrum of BSA in the presence of colloidal TiO_2 in the concentration range 0–5 × 10^{-4} M. Inset is the linear dependence of $1/A - A_0$ on the reciprocal concentration of colloidal $AgTiO_2$.

adsorption of BSA on the surface of colloidal $AgTiO_2$ nanoparticles, supported by similar observations reported earlier [24].

The equilibrium for the formation of complex between BSA and colloidal $AgTiO_2$ nanoparticles can be given by Eq. (1), where K_{app} represents the apparent association constant:

$$\mathrm{BSA} + \mathrm{AgTiO_2} \overset{K_{app}}{\rightleftharpoons} \mathrm{BSA}\cdots\mathrm{AgTiO_2} \quad (1)$$

$$K_{app} = \frac{[\mathrm{BSA}\cdots\mathrm{AgTiO_2}]}{[\mathrm{BSA}]\cdot[\mathrm{AgTiO_2}]}$$

The change in intensity of the absorption peak (280 nm) as a result of the formation of the surface complex were utilized to obtain K_{app} according to Benesi and Hildebrand [25]:

$$A_{obs} = (1-\alpha)C_0\varepsilon_{BSA}1 + \alpha C_0\varepsilon_c 1 \quad (2)$$

where A_{obs} is the observed absorbance of the solution containing different concentrations of colloidal $AgTiO_2$ at 280 nm, α is the degree of association between BSA and $AgTiO_2$, ε_{BSA} and ε_c are the molar extinction coefficients at the defined wavelength (λ = 280 nm) of BSA and the formed complex, respectively, in water. Eq. (2) can be expressed as Eq. (3), where A_0 and A_c are the absorbances of BSA and the complex at 280 nm, respectively, with a concentration of C_0:

$$A_{obs} = (1-\alpha)A_0 + \alpha A_c \quad (3)$$

At relatively high $AgTiO_2$ concentrations, α can be equated to $(K_{app}[AgTiO_2])/(1 + K_{app}[AgTiO_2])$. In this case, Eq. (3) can be changed to Eq. (4):

$$\frac{1}{A_{obs}-A_0} = \frac{1}{A_c-A_0} + \frac{1}{K_{app}(A_c-A_0)[\mathrm{AgTiO_2}]} \quad (4)$$

The enhancement of absorbance at 280 nm was due to absorption of the surface complex, based on the linear relationship between $1/(A_{obs} - A_0)$ vs reciprocal concentration of colloidal $AgTiO_2$ with a slope equal to $1/K_{app}(A_c - A_0)$ and an intercept equal to $1/(A_c - A_0)$ (Fig. 3, insert). The value of the apparent association constant (K_{app}) determined from this plot is 5.58 × 10^5 M^{-1}. Further, the reason for the higher association constant of $AgTiO_2$ compared to that reported for TiO_2 [15] may be due to the larger surface area of the $AgTiO_2$ nanoparticles.

3.4. Fluorescence quenching of BSA by colloidal $AgTiO_2$ nanoparticles

The fluorescence quenching is described by the Stern–Volmer relation:

$$I_0/I = 1 + K_{sv}[Q] = 1 + K_q\tau_0[Q] \quad (5)$$

where I_0 and I are the fluorescence intensities of BSA in the absence and presence of quencher, K_{SV} is Stern–Volmer constant, k_q is the bimolecular quenching rate constant, and τ_0 is the average lifetime of BSA, 10^{-8} s [26], [Q] is the concentration of quencher. Fig. 4 shows the effect of increasing the concentration of colloidal $AgTiO_2$ on the fluorescence emission spectrum of BSA. Addition of colloidal $AgTiO_2$ resulted in the quenching of BSA fluorescence emission and there is no peak shift and no new peak was observed. It is noted that a complex formed between colloidal $AgTiO_2$ and BSA is responsible for the quenching of BSA. According to Eq. (5), a linear plot [Inset, Fig. 4] between I_0/I against [$AgTiO_2$] was obtained and from the slope we calculated the quenching rate constant (k_q) as 1.64 × 10^{15} $M^{-1}s^{-1}$. In general, the maximum collisional quenching constant (k_q) of various kinds of quenchers to biopolymers is 2.0 × 10^{10} $M^{-1}s^{-1}$ [26], but for the BSA–$AgTiO_2$ system a higher quenching rate constant (1.64 × 10^{15} $M^{-1}s^{-1}$) was obtained. This shows that the quenching is not dynamic in nature, it depends on the formation of a complex between $AgTiO_2$ and BSA (Scheme 2). Further the type of interaction between BSA and colloidal $AgTiO_2$ was also confirmed by time resolved spectroscopy.

3.5. Fluorescence lifetime measurements

Fig. 5 shows the fluorescence decay of BSA in the absence and presence of colloidal $AgTiO_2$ nanoparticles. BSA exhibits single exponential decay not only in dilute solutions but also in the pres-

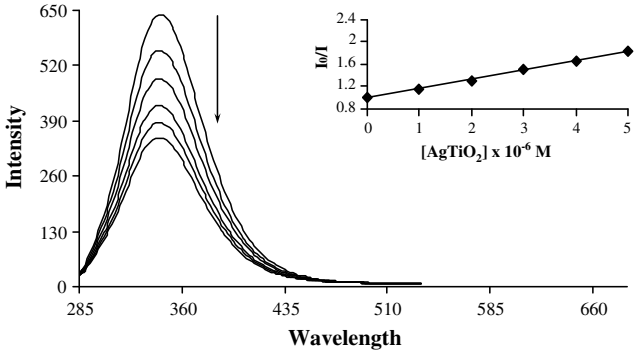

Fig. 4. Fluorescence Quenching of BSA in the presence of various concentrations of colloidal $AgTiO_2$ nanoparticles, [TiO_2] = 0, 1, 2, 3, 4 and 5 × 10^{-6} M. Insert shows the Stern–Volmer plot.

$$\mathrm{BSA} + \mathrm{AgTiO_2} \rightleftharpoons \mathrm{BSA}.....\mathrm{AgTiO_2}$$

$$\mathrm{BSA}.....\mathrm{AgTiO_2} \xrightarrow{h\nu} \mathrm{BSA}^{*}.....\mathrm{AgTiO_2}$$

Scheme 2. Mechanism of complex formation.

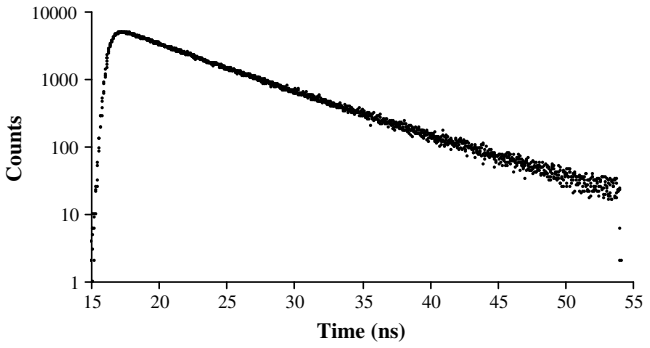

Fig. 5. Fluorescence decay curve of BSA in the absence and presence of colloidal $AgTiO_2$ in the concentration range 0–5 × 10^{-6} M.

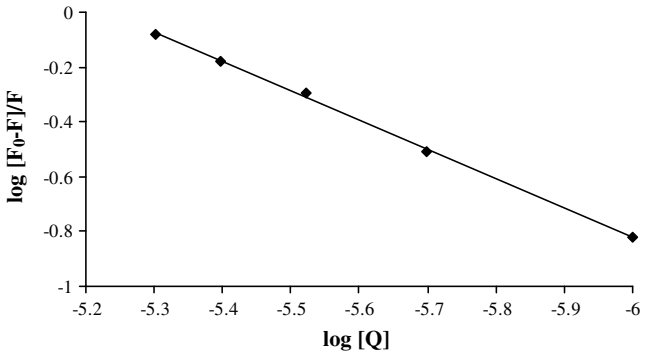

Fig. 6. Plot of $\log[(F_0 - F)/F]$ vs. log[Q].

ence of colloidal $AgTiO_2$ nanoparticles. On increasing the concentration of colloidal $AgTiO_2$ there is no change in the lifetime of BSA. This observation shows that the quenching follows a static mechanism. It also supports the formation of a ground state surface complex. (In Fig. 5 although the decay traces of BSA in the absence and presence of colloidal $AgTiO_2$ were actually plotted, the lifetime of BSA remained the same under both conditions, hence merging of the kinetic traces was observed, and the plot looks like a single decay curve.) For static quenching, we can deduce the binding constant (K) resulting from the formation of a ground state complex between fluorophore and the quencher.

3.6. Binding constant and number of binding sites

The relationship between the fluorescence intensity and quenching medium can be deduced from the following formula:

$$n\mathrm{Q} + \mathrm{B} \overset{K}{\rightleftharpoons} \mathrm{Q}_n \cdots \mathrm{B} \tag{6}$$

where B is the biomolecule with the fluorophore, Q is the quencher molecule, $Q_n \cdots B$ is the quenched biomolecules and the resultant constant K is given by

$$K = \frac{[\mathrm{Q}_n \cdots \mathrm{B}]}{[\mathrm{Q}]^n \cdot [\mathrm{B}]} \tag{7}$$

If the overall amount of biomolecules (bound or unbound with the quencher) is B_0, then $[B_0] = [Q_n \cdots B] + [B]$, here [B] is the concentration of unbound biomolecules. Thus the relationship between fluorescence intensity and the unbound biomolecule is $[B]/[B_0] = F/F_0$, that is

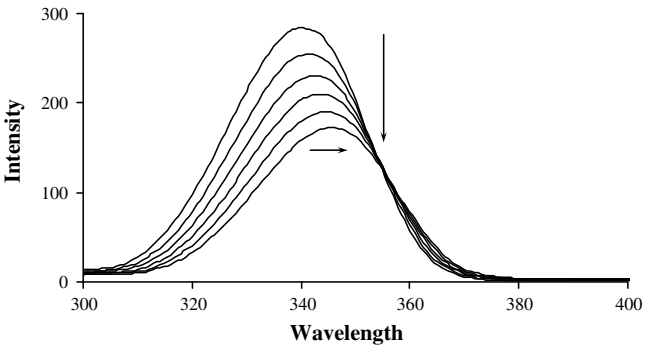
$$\log\left[\frac{F_0 - F}{\mathrm{F}}\right] = n\log[\mathrm{Q}] + \log K \tag{8}$$

where K is the binding constant of $AgTiO_2$ with BSA, which can be determined from the plot of $\log[(F_0 - F)/F]$ versus log[Q] as shown in Fig. 6. Thus we obtained the binding constant "K" as $3.71 \times 10^5\ M^{-1}$ and binding sites "n" (1.06) for $AgTiO_2$ with BSA from the intercept and slope of Fig. 5. The value of K obtained from the data of fluorescence quenching matches well with that determined from the absorption spectral changes. The good agreement between these values of K highlights the validity of assumption proposed for the association between BSA and colloidal $AgTiO_2$ nanoparticles.

3.7. Characteristics of synchronous fluorescence spectra

To explore the structural changes of BSA by the addition of colloidal $AgTiO_2$, we measured the synchronous fluorescence spectra of BSA with the concentrations of colloidal $AgTiO_2$ used for the fluorescence quenching study. Synchronous fluorescence spectra provide information on the molecular microenvironment, particularly in the vicinity of fluorophore functional groups [27]. The fluorescence of BSA is due to the presence of tyrosine, tryptophan and phenylalanine residues. Hence spectroscopic methods are usually applied to study the conformation of the serum protein. In synchronous fluorescence spectroscopy, according to Miller [28], the difference between the excitation and emission wavelength ($\Delta\lambda = \lambda_{emi} - \lambda_{exc}$) reflects the spectra of chromophores with the different natures. With larger $\Delta\lambda$ values, such as 60 nm, the synchronous fluorescence of BSA is characteristic of the tryptophan residue, and smaller $\Delta\lambda$ values, such as 15 nm, are characteristic of tyrosine [29]. The synchronous fluorescence spectra of BSA with various concentrations of colloidal $AgTiO_2$ were recorded at $\Delta\lambda$ = 15 nm (Fig. 7) and $\Delta\lambda$ = 60 nm (spectra not shown here). With an increasing concentration of colloidal $AgTiO_2$ the intensity of tyrosine decreased, and a red-shift of the emission wavelength (Fig. 7) was observed. At the same time, the tryptophan fluorescence emission decreased regularly, but no significant change in wavelength was observed. It suggests that the interaction of colloidal $AgTiO_2$ with BSA affects the conformation of the tyrosine region, but not the tryptophan micro-region. The tyrosine fluorescence spectrum may represent that the conformation of BSA has changed, leading to a strengthening of the polarity around the tyrosine residues and a weakening of the hydrophobicity [30]. It is important to note that colloidal $AgTiO_2$ affects only the tyrosine residues in the BSA moiety. This is because tyrosine contains one aromatic hydroxyl group, unlike tryptophan.

In our previous study, riboflavin was used as a sensitizer for colloidal TiO_2 [31] and it was observed that riboflavin interacted through the hydroxyl group of colloidal TiO_2. In addition, tyrosine can undergo an excited state ionization, resulting in the loss of a proton from the aromatic hydroxyl group. Hence it is clear that the presence of a hydroxyl group in the tyrosine residues may be



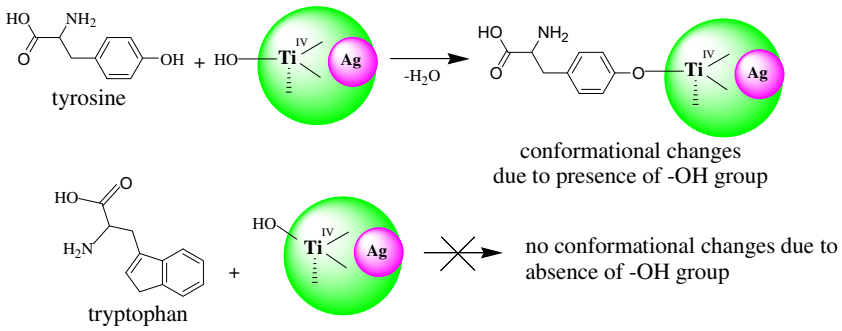


Fig. 7. Synchronous fluorescence spectrum of BSA with $\Delta\lambda$ = 15 nm in the absence and presence of colloidal $AgTiO_2$ nanoparticles.

Scheme 3. Mechanism for the interaction of $AgTiO_2$ nanoparticles with BSA.

responsible for the interaction of BSA with $AgTiO_2$, similar to 2,3-diazabicyclo [2.2.2] oct-2-ene (DBO) interacting with the aromatic hydroxyl group of tyrosine in BSA [32], as reported by Anbazhagan and Renganathan (Scheme 3).

4. Summary

The interaction between colloidal $AgTiO_2$ nanoparticles and BSA has been studied by various spectroscopic measurements. The results presented clearly indicate that colloidal $AgTiO_2$ nanoparticles quench the fluorescence emission of BSA through a static mechanism, which is further confirmed by the unaltered lifetime of BSA by time resolved measurements. The quenching rate constant, binding constant and number of binding sites were calculated according to the relevant fluorescence quenching data. From the synchronous fluorescence spectra, it is shown that the conformational change of BSA is induced by the interaction of colloidal $AgTiO_2$ nanoparticles with the tyrosine micro-region of the BSA molecules. The binding study of drugs with nanoparticles is of great importance in pharmacy, pharmacology and biochemistry. This study is expected to provide important insight into the interactions of the physiologically important protein BSA with metal nanoparticles. Information is also obtained about the effect of the environment on the BSA structure, which may be correlated to its physiological activity.

Bridging

ABSTRACT

Three new binuclear Ni(II) complexes [{Ni(L_{22py})Cl}$_2$](ClO_4)$_2$ (**1**), [{Ni(L_{23py})Cl}$_2$](ClO_4)$_2$ (**2**), and [{Ni(L_{33py})Cl}$_2$](ClO_4)$_2$ (**3**), {L_{22py} = *N*-(2-pyridylmethyl)-*N*-(2-aminoethyl)-1,2-diaminoethane, L_{23py} = *N*-(2-pyridylmethyl)-*N*-(2-aminoethyl)-1,3-diaminopropane, L_{33py} = *N*-(2-pyridylmethyl)-*N*-(3-aminopropyl)-1,3-diaminopropane} have been synthesized. Single crystal X-ray structure analysis showed that in each complex two distorted octahedral Ni(II) ions are bridged asymmetrically by a pair of chloride anions. Variable temperature magnetic susceptibility measurements of **1** and **3** revealed dominant ferromagnetic exchange interactions.

1. Introduction

The discovery that individual molecules can display a magnetic memory effect (such molecules are termed a Single Molecule Magnet or SMM) has perhaps been one of the biggest driving forces towards the synthesis of new polynuclear coordination complexes [1]. Many varied synthetic routes are employed to achieve such complexes, but most have a common feature: the use of bridging ligands for the assembly of transition metal ions into individual species. Such ligands are often simple mono or bidentate anions (Cl^-, HO^-, RO^-, N_3^-, $RCOO^-$ for example), and although uncomplicated in themselves, they can yield elaborate coordination complexes displaying numerous topologies [2,3]. One topology of particular current interest is composed of two metal ions bridged so as to form a diamond arrangement of metal ions and ligands ({ML}$_2$) [4]. From a magnetic stand point, Ni(II) clusters have received extensive recent interest [5]. When Ni(II) is five-coordinate, the magnetic coupling observed between the metal ions is usually dominantly antiferromagnetic in nature [6]. However, when the Ni center is six coordinate the situation is more complicated. In cases where there is pronounced tetragonal distortion, the degeneracy of the e_g level is removed and the coupling is therefore dominantly antiferromagnetic [7]. In cases where the metal center is octahedral or pseudo-octahedral, the degeneracy of the e_g level is maintained and the coupling is always dominantly ferromagnetic [8–13].

We have been involved in the synthesis of new tripodal tetraamine ligands [14–19], their macrocyclic [15,16] and macroacyclic [17–19] Schiff base complexes, determination of their stability constants [20] and their gas phase proton affinities [21,22]. In this work we set out to establish how the chelate sizes in a series of chloro-bridged binuclear Ni(II) complexes with tripodal ligands would affect their molecular structure and/or their magnetic properties. Thus we have used two ligands with pairs of identical alkyl-amino arms (L_{22py} and L_{33py}) and one with two different arms (L_{23py}) (Fig. 1) to prepare three bridged binuclear Ni(II) complexes with tetradentate ligands; [{Ni(L_{22py})Cl}$_2$](ClO_4)$_2$ (**1**), [{Ni(L_{23py})Cl}$_2$](ClO_4)$_2$ (**2**), and [{Ni(L_{33py})Cl}$_2$](ClO_4)$_2$ (**3**). We are reporting the single crystal X-ray structures of all three complexes, **1**–**3**, and the magnetic properties of **1** and **3**. To the best of our knowledge the Ni(II) complexes composed of the ligands L_{22py} and L_{23py} are previously unreported, with **2** being the first complex composed of the ligand L_{23py}, while a mononuclear Ni(II) complex of L_{33py}, [NiL(MeCN)$_2$]$^{2+}$, has been reported previously [23].

2. Experimental

2.1. General Information

$Ni(ClO_4)_2 \cdot 4H_2O$ was obtained from Aldrich and was used without further purification. The asymmetrical tripodal ligands were

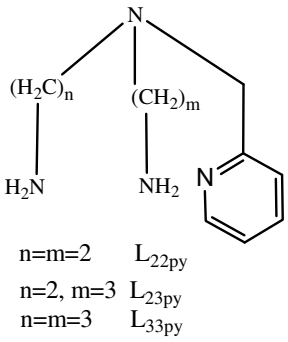

Fig. 1. Structure of the tripodal tetradentate ligands investigated here.

prepared as their hydrochloride salts *via* literature methods [14,24]. IR spectra were measured on a Perkin Elmer FT-IRGX spectrophotometer. Variable-temperature magnetic data were measured with a Cryogenic S600 SQUID magnetometer on polycrystalline samples in **1** (**300–35** K) and 0.1 (<35 K) T fields. Low temperature (1.5 K), variable-field (up to 12 T) magnetization measurements were measured on an Oxford Instruments vibrating-sample magnetometer. The data were corrected for the contribution of the sample holder and for the diamagnetism of the sample estimated from Pascal's constants.

2.2. X-ray crystal structure determination

A summary of the details of the crystal data, data collection and refinement details is given in Table 1. All structural determinations were carried out using a Bruker SMART-1000 CCD diffractometer equipped with Mo Kα X-radiation ($\lambda = 0.71073$ Å for all compounds) at 150(2) K for **1** and 100(2) K for **2** and **3**. In all cases, absorption corrections were applied using SADABS [25], and structure solution and refinement was carried out using SHELXS-97 and SHELXL-97, respectively, [26]. The structures were solved by direct methods and refined by full-matrix least-squares methods on F^2. Hydrogen atoms were placed geometrically and refined with a riding model, with U constrained to be 1.2 (1.5 for methyl groups) times U of the carrier atom. The lattice of **2** contained a disordered perchlorate anion that has been split over two sites (Cl2, O1–O4; 50:50 occupancy). The oxygen atoms of this residue have been left isotropic. All other non-hydrogen atoms were refined anisotropically.

2.3. Synthesis

2.3.1. Preparation of the complex $[\{Ni(L_{22py})Cl\}_2](ClO_4)_2$ (**1**)

A mixture of $L_{22py} \cdot 3HCl$ (0.1 g, 0.33 mmol) and NaOH (0.039 g, 0.99 mmol) in EtOH (15 cm^3) was heated under reflux for 1 h, allowed to cool and then filtered. A solution of $Ni(ClO_4)_2 \cdot 4H_2O$ (0.12 g, 0.37 mmol) in MeOH (5 ml) was added to the filtrate. The mixture was stirred at 50–60 °C for 1 h, during which time it turned blue in color. The solution was filtered and the filtrate reduced to ca. 10 cm^3. X-ray quality crystals were obtained by slow diffusion of Et_2O vapor into the latter solution. Yield: 0.15 g (57%). *Anal.* Calc. for $C_{20}H_{36}Cl_4N_8Ni_2O_8 \cdot CH_3OH$: C, 31.2; H, 5.0; N, 13.9. Found C, 31.8; H, 4.7; N, 13.4%. IR (Nujol, cm^{-1}): 3355 and 3302 (υ(N–H) stretching), 1605 and 1573 (υ(C=N and/or υ(N–H) bending), 1090 (υ(Cl–O) stretching).

2.3.2. Preparation of the complex $[\{Ni(L_{23py})Cl\}_2](ClO_4)_2$ (**2**)

Complex **2** was prepared in an analogous manner. Yield: 0.1 g (38%). *Anal.* Calc. for $C_{22}H_{40}Cl_4N_8Ni_2O_8 \cdot CH_3OH$: C, 33.0; H, 5.3; N, 13.4. Found C, 32. 4; H, 5.2; N, 12.6%. IR (Nujol, cm^{-1}): 3340 and 3290 (υ(N–H) stretching), 1606 and 1573 (υ(C=N and/or υ(N–H) bending), 1087 (υ(Cl–O) stretching).

*2.3.3. Preparation of the complex [{Ni(L_{33py})Cl}$_2$](ClO$_4$)$_2$ (**3**)*

Complex **3** was prepared in an analogous manner. Yield: 0.14 g (51%). *Anal.* Calc. for $C_{24}H_{44}Cl_4N_8Ni_2O_8 \cdot CH_3OH$: C, 34.8; H, 5.6; N, 13.0. Found C, 35.2; H, 5.4; N, 12.6%. IR (Nujol, cm^{-1}): 3335 and 3285 (υ(N–H) stretching), 1605 and 1573 (υ(C=N and/or υ(N–H) bending), 1092 (υ(Cl–O) stretching).

3. Results and discussion

Complexes **1**–**3** were readily synthesized by neutralization of the hydrochloric salts of the L_{22py}, L_{23py} and L_{33py} tripodal ligands with sodium hydroxide, followed by reaction with Ni(II) perchlorate, respectively. The IR spectra and analytical data are consistent with their structure and formulation. In the IR spectra of all the complexes a pair of sharp υ(N–H) bands at about 3200–3300 cm^{-1} correspond to the coordinated primary amine groups [27]. The stretching bands of the pyridine C=N groups and bending bands of primary amine groups appear, as expected, at about 1573–1606 cm^{-1}. A broad intense band at *ca.* 1100 cm^{-1} due to ClO_4^- shows no splitting, indicating the absence of anion coordination. This is consistent for all complexes.

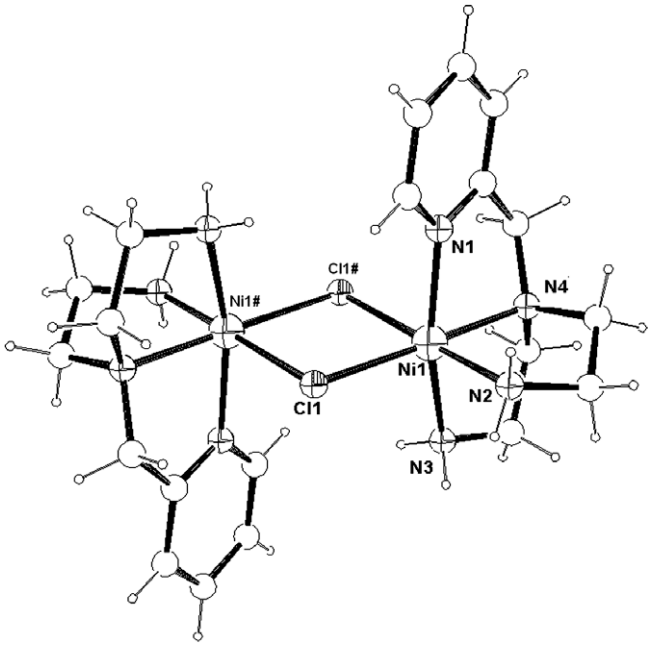

Fig. 2. Crystal structure of complex **1**. Perchlorate anions are omitted for clarity.

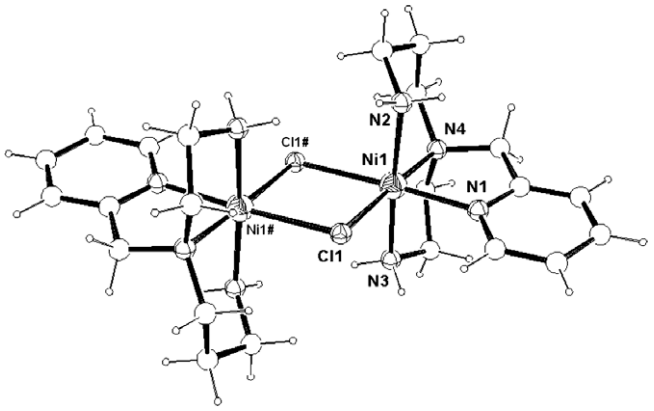

Fig. 3. Crystal structure of complex **2**. Perchlorate anions are omitted for clarity.

3.1. X-ray crystal structure analysis

Suitable crystals of **1**–**3** were obtained by slow diffusion of diethyl ether vapor into methanol–ethanol solutions. The structures of these compounds with the atomic numbering schemes are shown in Figs. 2–4, respectively. Single crystal X-ray structure analysis shows that all complexes have a solid state binuclear geometry, where two bridging chloride ions complete the octahedral coordination environments at the nickel atoms. Selected bond lengths and bond angles are given in Table 2. The Ni–N bond lengths are in the expected range from 2.0720(3) to 2.1110(3) Å (**1**), 2.0651(18) to 2.1212(19) Å (**2**) and 2.0727(18) to

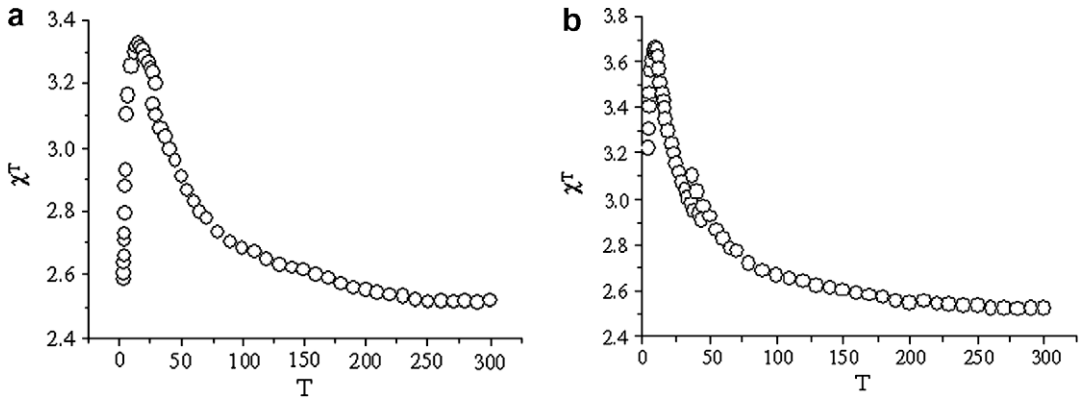

Fig. 5. Temperature-dependence of the magnetic properties for complexes **1**, (a), and **3**, (b), in the form of χT vs. T.

2.1237(17) Å (**3**). The N–Ni–N, Cl–Ni–N, and Cl–Ni–Cl bond angles in all three complexes are different, indicating a distorted octahedral coordination environment for each Ni atom.

The Ni–Cl bridges are asymmetric, (2.3739(9) and 2.5223(9) Å (**1**), 2.4518(6) and 2.4802(6) Å (**2**) and 2.5428(6) and 2.4904(5) Å (**3**)). In **1**, the bond to the monodentate ligand *trans* to N_{tert} [Ni–Cl1 2.3739(9) Å] is shorter than that to the ligand *cis* to N_{tert} [Ni–Cl1# 2.5223(9) Å]. The same situation can be seen in **2** and **3**, 2.4518(6) compared to 2.4802(6) Å and 2.4904(5) compared to 2.5428(6) Å, respectively. A similar observation has been reported for a binuclear Ni(II) complex of an asymmetric tripodal tetramine [28]. The distances between the nickel atoms in **1**, **2**, and **3** are 3.570, 3.616, and 3.737 Å, respectively, indicating the metal–metal distance increases with increasing ligand size. In complex **1** the bond length between a Ni atom and one of the primary amine groups, Ni(1)–N(3) [2.1110(3) Å], is the longest bond distance, but in both **2** and **3** the Ni(1)–N_{tert} bond length [2.1212(19) and 2.1237(17) Å, respectively] is longer than the other bond distances. On the other hand, in both **1** and **2** Ni(1)–$N_{pyridine}$ is the shortest bond distance, while for complex **3** the Ni(1)–N(3) distance is smaller than the other bond lengths. It is interesting that the variations of the Ni–N bond lengths in compounds **2** and **3** are very similar and are different to those of compound **1**. This may be related to the fact that in compound **1** all the chelates are five-membered rings. It should be noted that compounds **1** and **3** have the pyridine donors *trans* to a primary amino donor atom while compound **2** has the primary amino group *trans* to another primary amino donor.

We note that there are a number of isomeric possibilities for these complexes, especially for compound **2** which is an asymmetric compound. In addition to the observed structures for compounds **1**–**3** we can consider several different structures for the present binuclear complexes. Note that in each complex each of the three arms of the tripodal ligand can be located in a *trans* position relative to the other arms or relative to the bridging-chlorine atoms. Furthermore the present binuclear complexes are all centro-symmetric, but we can also consider some centro-asymmetric structures. We have no evidence to confirm that other possible isomers have been formed in our reaction system.

The N_{tert}–Ni–N bond angles for the five-membered chelate rings, as expected, are smaller than corresponding angles for the six-membered chelate rings in both complexes **2** and **3**.

3.2. Magnetic studies

The magnetic properties of compounds **1** and **3** are similar in nature. The room temperature values of χT are 2.52 and 2.53 emu K mol^{-1} respectively, in good agreement with that expected for two uncoupled Ni(II) spins [6,8] (Fig. 5). In both complexes χT increases with decreasing T, indicative of dominant ferromagnetic exchange interactions within the cluster. Further cooling from 3 to 8 K gives a sharp decrease of χT, suggesting a weak antiferromagnetic interaction at low temperature; this can be accounted for using the Weiss correction. In **1** χT reaches a maximum of 3.27 at 8 K before dropping to 2.59 at 3 K, and in **3** χT reaches a maximum of 3.67 at 8 K before dropping to 3.23 at 3 K. Using a simple exchange spin Hamiltonian we have modeled the magnetic data and obtain excellent fits with the parameters $J = 9.3$ cm^{-1}, $D = -12.9$ cm^{-1} and $g = 2.19$ for **1**, and $J = 6.8$ cm^{-1}, $D = -6.9$ cm^{-1} and $g = 2.2$ for **3**. The obtained values are consistent with those presented for related complexes [10].

In all the complexes, in spite of the differences in ring size, the magnetic properties are similar. The complex $[\{Ni(L_{22py})Cl\}_2]^{2+}$ has five-membered chelating rings whereas $[\{Ni(L_{33py})Cl\}_2]^{2+}$ has six-membered chelating rings, but both complexes display ferromagnetic coupling. $[\{Ni(_{L23py})Cl\}_2]^{2+}$ has five and six-membered chelating rings and we would also expect this complex to display similar magnetic properties.

4. Conclusion

The synthesis and characterization of three binuclear Ni(II) complexes (**1**–**3**) with tripodal tetradentate ligands are reported. The molecular structures of complexes **1**–**3** have been determined by single crystal X-ray diffraction studies and have been shown to exhibit distorted octahedral-coordinated nickel ions. In all the compounds the Ni(II) centers are bridged by two chlorides. The magnetic properties of **1** and **3** have been investigated and reveal dominant ferromagnetic interactions between the metal centers down to 8 K. The magnitude of these interactions has shown them to be ferromagnetic.

ABSTRACT

A mononuclear copper(I) complex, $[Cu(ca_2dapte)]ClO_4$ (**1**), and two dinuclear copper(I) complexes, $[\{Cu(PPh_3)(X)\}_2(ca_2dapte)]$ (X = I (**2**) and Br (**3**)), of a new tetradentate N_2S_2 donor Schiff-base ligand ca_2dapte have been prepared (ca_2dapte = *N*,*N*′-bis(*trans*-cinnamaldehyde)-1,2-di(o-iminophenylthio)ethane). These compounds have been characterized by elemental analyses (CHN), FT-IR, UV–Vis and ^{1}H NMR spectroscopy. The crystal structures of these copper(I) complexes have been determined by single-crystal X-ray diffraction. The coordination geometry around Cu(I) centers in these complexes is a distorted tetrahedron. The ca_2dapte is coordinated to Cu(I) as a tetradentate ligand in **1**, while it acts as a bis-bidentate bridging ligand in **2** and **3**.

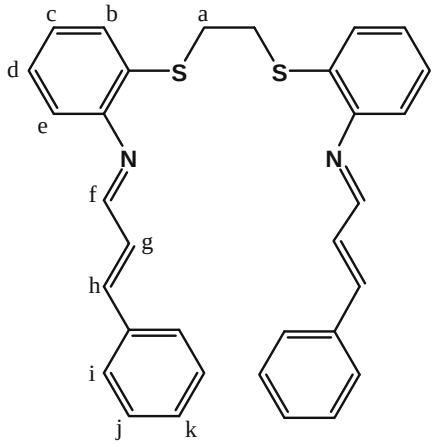
1. Introduction

There has been a growing interest in recent years toward the crystal structures and properties of copper(I) complexes with multidentate ligands [1–5], particularly in view of their potential applications in metallosupramolecular assemblies [6–10], bioinorganic chemistry [11] and catalysis [12]. Many efforts have been devoted to the design and synthesis of new multidentate ligands that are able to control the crystal structure and properties of copper(I) complexes [13–16]. With flexible ligands, the competition between bridging and chelating coordination modes is an important factor in producing mono, di, and polynuclear metal complexes [17,1,18,19]. We have recently studied the coordination behavior of the Schiff-base ligands such as ca_2en, Phc$a_2$en, and (Me-pk)$_2$en [20–29]. While ca_2en and Phc$a_2$en act as simple bidentate chelates [20–27], (Me-pk)$_2$en acts as a bidentate bridging ligand between two metal ions [28,29]. In this paper, we describe the synthesis and coordination behavior of the new Schiff-base ligand ca_2dapte (Scheme 1).

2. Experimental

2.1. General

All solvents and chemicals were of commercial reagent grade and used as received from Aldrich and Merck. 1,2-di(o-aminophenylthio)ethane (dapte) was prepared using the reported procedure [30]. Infrared spectra as KBr pellets were obtained on a FT-IR JASCO 680 PLUS spectrophotometer in the range 4000–400 cm^{-1}. UV–Vis absorption spectra were recorded on a JASCO V-570 spectrophotometer; λ_{max} (log ε) in nm. ^{1}H NMR spectra were measured with Bruker ACP-500 spectrometer at 500 MHz, and chemical shifts δ are reported in parts per million (ppm) relative to an internal standard of Me_4Si. Elemental analyses were performed using a Perkin–Elmer 2400II CHNS-O elemental analyzer.



2.2. Synthesis

2.2.1. Synthesis of the ligand ca_2dapte

To a solution of dapte (0.276 g, 1 mmol) in EtOH (20 ml) was added, with continuous stirring, cinnamaldehyde (0.264 g, 2 mmol). The mixture was stirred for about 30 min to give a yellow precipitate. The product was then filtered off and washed with EtOH. Yield 84%. M.p. 181 °C; *Anal.* Calc. for $C_{32}H_{28}N_2S_2$: C, 76.15; H, 5.59; N, 5.55. Found: C, 74.52; H, 5.38; N, 5.49%. IR (KBr pellet,

Scheme 1.

ν/cm^{-1}) 1624s (C=N). UV–Vis [chloroform; λ_{max} in nm ($\log\varepsilon$ in L mol^{-1} cm^{-1})] 357 (24772), 301 (76924). ^{1}H NMR ($CDCl_3$), δ (ppm) = 3.17(s, 4H$_a$), 6.92 (dd, 2H$_g$), 7.10–7.40 (m, 16H$_{b,c,d,e,h,j,k}$), 7.52 (dd, 4H$_i$), 8.14 (d, 2H$_f$).

2.2.2. Synthesis of [Cu(ca$_2$dapte)]ClO$_4$ (**1**)

To a solution of [Cu(CH$_3$CN)$_4$]ClO$_4$ (32 mg, 0.1 mmol) in CH$_3$CN (5 ml) was added, with continuous stirring, a solution of ca$_2$dapte (50 mg, 0.1 mmol) in the minimum amount of chloroform. The mixture was stirred at room temperature for about 10 min to give a clear dark-red solution. Dark-red single crystals suitable for X-ray analysis were obtained by diffusion of diethyl ether into the filtrate. Yield 79%. *Anal.* Calc. for $C_{32}H_{28}N_2S_2CuClO_4$: C, 57.56; H, 4.23; N, 4.20. Found: C, 57.43; H, 3.91; N, 4.20%. IR (KBr pellet, ν/cm^{-1}) 1613s (C=N), 1089 m (ClO$_4$). UV–Vis [chloroform; λ_{max} in nm ($\log\varepsilon$ in L mol^{-1} cm^{-1})] 340 (52164). ^{1}H NMR ($CDCl_3$), δ (ppm) = 2.95 (s, 4H$_a$), 7.00 (br d, 2H$_g$), 7.19–7.37 (m, 16H$_{b,c,d,e,h,j,k}$), 7.57 (d, 4H$_i$), 8.23 (d, 2H$_f$).

2.2.3. Synthesis of [{Cu(PPh$_3$)(I)}$_2$(ca$_2$dapte)] (**2**)

To a solution of PPh$_3$ (52 mg, 0.2 mmol) in CH$_3$CN (5 ml) was added a solution of CuI (38 mg, 0.2 mmol) in CH$_3$CN (5 ml) and the mixture was stirred at room temperature for about 10 min to give a clear colorless solution. The ligand ca$_2$dapte (50 mg, 0.1 mmol) was then added and a clear orange-red solution was obtained. Orange-red single crystals suitable for X-ray analysis were obtained by diffusion of diethyl ether into the filtrate. Yield 77%. *Anal.* Calc. for $C_{68}H_{58}N_2P_2S_2Cu_2I_2$: C, 57.92; H, 4.15; N, 1.99. Found: C, 57.48; H, 3.84; N, 2.15%. IR (KBr pellet, ν/cm^{-1}) 1620s (C=N). UV–Vis [chloroform; λ_{max} in nm ($\log\varepsilon$ in L mol^{-1} cm^{-1})] 332 (54889), 300 (64457). ^{1}H NMR ($CDCl_3$), δ (ppm) = 3.05 (s, 4H$_a$), 7.01 (br d, 2H$_g$), 7.11–7.42 (m, 46H$_{b,c,d,e,h,j,k}$, PPh$_3$), 7.57, 7.98 (d, 4H$_i$), 8.41 (d, 2H$_f$).

2.2.4. Synthesis of [{Cu(PPh$_3$)(Br)}$_2$(ca$_2$dapte)] (**3**)

This complex was prepared by a procedure similar to that for complex **2** except that CuI was replaced with CuBr. Orange-red single crystals suitable for X-ray analysis were obtained by diffusion of diethyl ether into the filtrate. Yield 84%. *Anal.* Calc. for $C_{68}H_{58}N_2P_2S_2Cu_2Br_2$: C, 62.05; H, 4.44; N, 2.13. Found: C, 61.49; H, 4.17; N, 2.23%. IR (KBr pellet, ν/cm^{-1}) 1622s (C=N). UV–Vis [chloroform; λ_{max} in nm ($\log\varepsilon$ in L mol^{-1} cm^{-1})] 332 (66740), 311 (71440). ^{1}H NMR ($CDCl_3$), δ (ppm) = 3.08 (s, 4H$_a$), 7.04–7.45 (m, 48H$_{b,c,d,e,g,h,j,k}$, PPh$_3$), 7.59, 8.018 (m, 4H$_i$), 8.33 (d, 2H$_f$).

2.3. Crystal structure determination

Data were collected using a Rigaku MM007 rotating anode/confocal optics (Mo Kα radiation λ = 0.71073 Å) and a Mercury CCD at 93(2) K. Data were corrected for Lorentz polarization and absorption effects. The structures were solved by direct methods and refined on F^2 (SHELXL). All non-hydrogen atoms were refined anisotropically. Crystal data and structure refinement are listed in Table 1.

3. Results and discussion

3.1. General characterization of ligand and corresponding complexes

The new tetradentate N_2S_2 donor Schiff-base ligand ca$_2$dapte was prepared by condensation reaction of 2 equiv. of cinnamaldehyde with 1 equiv. of dapte [30] in EtOH. The product precipitated and was readily isolated in approximately 80% yield; the ligand was characterized by CHN, FT-IR, UV–Vis and ^{1}H NMR spectroscopy. The IR spectrum of the free ligand ca$_2$dapte exhibits the characteristic band of the imine group, which appears at 1624 cm^{-1}.

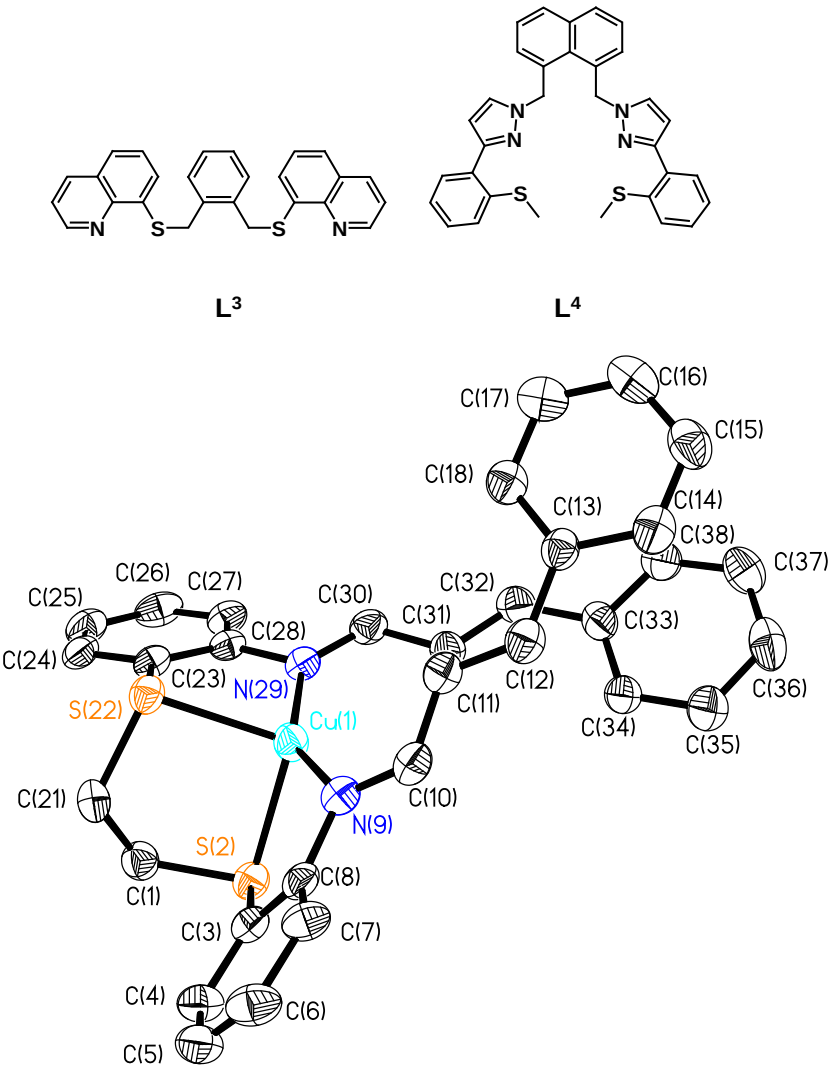

Fig. 1. View of the structure of $[Cu(ca_2dapte)]^+$ cation showing 50% probability ellipsoids.

This band is shifted to lower frequencies in the IR spectra of the corresponding complexes due to the coordination of the imine nitrogen [31], and appears at 1613 cm^{-1} in **1**, but at 1621 cm^{-1} in **2** and at 1622 cm^{-1} in **3** presumably due to weaker electron back donation by Cu(I) to the imine π^* in **2** and **3**. A strong band at about 1089 cm^{-1} in the spectrum of **1** is characteristic of the asymmetric Cl–O stretching mode of the perchlorate [32]. Since no d–d transitions are expected for d^{10} complexes, the UV–Vis bands are assigned to metal to ligand charge transfer (MLCT) or ligand-centered $\pi \rightarrow \pi^*$ transitions (Section 2) [33].

The ^1H NMR data and peak assignment are presented in Section 2. The ^1H signals of the coordinated ligand are commonly observed in all complexes, however, the aromatic H atoms of the coordinated PPh_3 ligands overlap to some extent with those of the phenyl H atoms of ca_2dapte. The two imine protons (H_f) appear as a doublet at 8.23 ppm in **1**, 8.41 ppm in **2** and 8.33 ppm in **3**. The downfield shift of iminic protons relative to the corresponding signals in the free ligand (8.14 ppm) can be attributed to the deshielding effect resulting from the coordination of the imine nitrogens.

3.2. Mononuclear copper(I) complex $[Cu(ca_2dapte)]ClO_4$ (*1*)

The crystal structure of the mononuclear $[Cu(ca_2dapte)]ClO_4$ (**1**) is shown in Fig. 1, and selected bond distances and angles are listed in Table 2. There are four similar but independent complex units in the asymmetric unit, one of which is only shown in Fig. 1. The complex is mononuclear and the central Cu(I) ion has the common irregular pseudo-tetrahedral geometry arising from the restricting bite angles of the chelating ligand (Table 2). In the absence of other coordinating ligands the ca_2dapte acted as a tetradentate ligand (*vide infra*). However, $[Cu(ca_2dapte)NCS]$ complex is formed in the presence of NCS [34] indicating that the ca_2dapte is capable of coordinating as a tridentate ligand leaving a free site for the NCS to coordinate. The Cu–N (1.982(4) and 1.996(4) Å) and Cu–S (2.3485(14) and 2.3489(13) Å) bond distances are similar to those found in $[Cu(L^3)][PF_6]$ [10] and $[Cu(L^4)][PF_6]$ [9].

*3.3. Dinuclear copper(I) complexes $[\{Cu(PPh_3)(I)\}_2(ca_2dapte)]$ (**2**) and $[\{Cu(PPh_3)(Br)\}_2(ca_2dapte)]$ (**3**)*

Complexes **2** and **3** were readily obtained by reactions of CuI or CuBr and PPh_3 with ca_2dapte in a molar ratio 2:2:1 under mild conditions. Elemental analyses (CHN) and spectroscopic data were consistent with the formation of the dinuclear species $[\{Cu(PPh_3)(I)\}_2(ca_2dapte)]$ **2** and $[\{Cu(PPh_3)(Br)\}_2(ca_2dapte)]$ (**3**). X-ray quality crystals of **2** and **3** were grown by diffusion of diethyl ether into a concentrated acetonitrile solution; the crystal structure of $[\{Cu(PPh_3)(I)\}_2(ca_2dapte)]$ **2** and $[\{Cu(PPh_3)(Br)\}_2(ca_2dapte)]$ (**3**) are shown in Figs. 2 and 3, respectively, and selected bond distances and angles are listed in Table 3. These complexes are centrosymmetric dimmers with pairs of $Cu(PPh_3)(X)$ (X = I, Br) units bridged by ca_2dapte. The central Cu(I) ion has the common irregular pseudo-tetrahedral geometry arising from the low intraligands N(9)–Cu(1)–S(2) chelate angles (80.72(8)° in (**2**) and 80.54(19)° in **3**. The Cu–N and Cu–S bond distances are larger than those found in $[Cu(L^3)][PF_6]$ [10] and $[Cu(L^4)][PF_6]$ [9]. The Cu–X (X = I and Br) and Cu–P are similar to those reported for similar copper(I) complexes [6,35,36].

Table 3
Selected bond distances (Å), and angles (°) for $[\{Cu(PPh_3)(I)\}_2(ca_2dapte)]$ (**2**) and $[\{Cu(PPh_3)(Br)\}_2(ca_2dapte)]$ (**3**).

4. Conclusion

This paper describes the synthesis of a new versatile tetradentate S_2N_2 Schiff-base ligand, ca_2dapte, with varying coordination capability, and three of its Cu(I) complexes. A mononuclear copper(I) complex with ca_2dapte acting as simple tetradentate ligand and two dinuclear complexes with ca_2dapte acting as a bis-bidentate bridging ligand was prepared.

Heterometallic paddlewheel complexes
X-ray structure
H-bonding

ABSTRACT

Bis-paddlewheel heterobimetallic complexes in which palladium(II) is connected to the rare-earth metals(III) $[Pd(\mu\text{-}OOCMe)_4Ln(OH_2)(\mu,\eta^2\text{-}OOCMe)]_2 \times 2HOOCMe$ (Ln = Nd, Sm, Eu, Yb and Tm) by four acetate bridges were synthesised by the reaction of $Pd_3(\mu\text{-}OOCMe)_6$ with the Ln^{III} acetates. The tetraacetate-bridged complexes were unexpectedly found to be readily transformed by the stoichiometric amount of pivalic acid into the mono-paddlewheel tetrapivalate-bridged analogues in which the paddlewheel structure $[Pd(\mu\text{-}OOCR)_4Ln]$ maintains as established by X-ray crystallography. The role of the intra- and intermolecular H-bonding in these complexes is discussed.

1. Introduction

Palladium-based mixed-metal materials, such as palladium–lanthanide alloys and catalysts present academic and industrial interest for material science and catalysis [l,2]. Traditional techniques of making palladium–lanthanide materials are based on direct fusion of the metallic components [1] or coimpregnation of a catalyst support with the constituent metal salts followed by redox treatments [2].

Recently we have synthesised in high yields and X-ray structurally characterised Pd^{II}-based heterobimetallic acetate-bridged complexes containing the complementary transition (Mn^{II}, Co^{II}, Ni^{II}), post-transition (Zn^{II}), alkaline earth (Ca^{II}, Sr^{II}, Ba^{II}) and rare-earth (Ce^{IV}, Sm^{III}, Nd^{III}, Eu^{III}) metals [3a–d]. These molecular systems in which the Pd^{II} and co-metal atoms are strongly linked by four acetate bridges (and in some cases possible metal–metal interactions[1]) seem to be favorable for keeping together the metal atoms during the deposition and redox treatments, giving promise for the preparation of heterometallic nanoclusters and catalysts.

For instance, the complex $Pd(\mu\text{-}OOCMe)_4Zn(OH_2)$ was readily reduced with H_2 under fairly mild conditions (150–250 °C, 5–10% H_2/He) both in the crystalline and carbon-supported states to afford a PdZn 1:1 nanoparticles as evidenced by ICP elemental analysis, EXAFS, XANES and XRD [4a]. The supported PdZn 1:1 nanoalloy prepared by this way from the heterobimetallic complex is an efficient and highly selective catalyst for acetylene to ethylene hydrogenation [4b].

The above heterobimetallic complexes were found to maintain the general shape of the Pd–co-metal moiety and nearly invariable metal–metal distance upon the attack of rather strong nucleophilic agents, as shown by the reactions of the complex $Pd(\mu\text{-}OOCMe)_4Co(NCMe)$ with such N-bases as 1,10-phenanthroline [5a] and pyridine [5b].

In this paper we report studies of the reaction of the tetraacetate-bridged Pd^{II}–Ln^{III} complexes with a weaker O-base, trimethylacetic (pivalic) acid. For this purpose we synthesised new heterobimetallic Pd^{II}-based carboxylate complexes with the early (Sm^{III}, Eu^{III}) and late (Tm^{III}, Yb^{III}) rare-earth metals whose distinctive features are the easy change of the Ln^{III}–Ln^{II} oxidation states in redox reactions and different atomic radii due to the lanthanide contraction. For comparison, the Pd^{II}–Nd^{III} acetate and pivalate complexes also were studied.

We unexpectedly found that all the tetraacetate-bridged complexes readily undergo total bridging acetate to pivalate metathesis, while the paddlewheel Pd–Ln motif remains practically unchanged.

2. Results and discussion

The reaction of palladium(II) acetate $Pd_3(\mu\text{-}OOCMe)_6$ with trivalent rare-earth metal acetates $Ln(OOCMe)_3 \times nH_2O$ (M = Nd^{III}, n = 1.5; Eu^{III}, Tm^{III}, Yb^{III}, n = 4) in hot acetic acid followed by concentration and slow cooling of the reaction solution to room temperature afforded in high yield the single-crystalline heterobimetallic complexes $[Pd(\mu\text{-}OOCMe)_4Ln(OH_2)(\mu,\eta^2\text{-}OOCMe)]_2 \times 2HOOCMe$

(Ln = Nd^{III} (**1**), Eu^{III} (**2**), Tm^{III} (**3**), Yb^{III} (**4**)) with a bis-paddlewheel structure (Scheme 1).

According to X-ray diffraction study (Fig. 1, Tables 1–5), molecules **1**–**4** containing different rare-earth metals consist of two tetraacetate-bridged fragments $Pd(\mu\text{-}OOCMe)_4Ln$ (Pd–O 1.995 (3)–2.002(4) Å, Nd–O 2.391(4)–2.416(3) Å for **1**; Pd–O 1.995(11)–2.003(8) Å, Eu–O 2.340(9)–2.361(8) Å for **2**; Pd–O 1.997 (3)–2.003(3) Å, Tm–O 2.282(2)–2.305(2) Å for **3**; Pd–O 1.993(5)–2.001(4) Å, Yb–O 2.265(4)–2.289(5) Å for **4**) linked by a pair of μ,η^2-acetate bridges (for **1**: Nd···Nd 4.1721(19) Å, Nd(1)–O(9) 2.558(3) Å, Nd(1)–O(10) 2.501(4) Å; for **2**: Eu···Eu 4.0764(15) Å; Eu(1)–O(9) 2.488(8) Å, Eu(1)–O(10) 2.433(7) Å; for **3**: Tm···Tm 3.9923(7) Å, Tm(1)–O(9) 2.433(2) Å, Tm(1)–O(10) 2.388(2) Å; for **4**: Yb···Yb 3.9823(6) Å, Yb(1)–O(9) 2.424(4) Å, Yb(1)–O(10) 2.382(5) Å).

The metal–metal distances Pd···Ln in the paddlewheel fragments (Pd···Nd 3.221(2) Å in **1**, Pd···Eu 3.1983(12) Å in **2**, Pd···Tm 3.1783(4) Å in **3**, Pd···Yb 3.1834(7) Å in **4**) are much shorter that the sum of the van der Waals radii of the corresponding metals, being close to the sum of the corresponding covalent radii (Pd–Nd 2.92 Å, Pd–Eu 3.13 Å, Pd–Tm 2.84 Å, Pd–Yb 3.02 Å). The coordination sphere of the rare-earth metal atoms is complemented with H_2O ligand, and the coordination number of these atoms is eight under suggestion of the absence of the direct Pd^{II}—Ln^{III} bond (Nd(1)–O(11) 2.462(3) Å, Eu(1)–O(11) 2.378(8) Å, Tm(1)–O(11) 2.310(2) Å, Yb(1)–O(11) 2.296(4) Å).

The Pd–O bond lengths in all complexes **1**–**4** are nearly the same, while the Ln^{III}–O distances are shortened with a decrease in the atomic radius of the Ln^{III} atom. Meanwhile, the Ln^{III}–O(9) bond length is noticeably longer compared to the other Ln^{III}–O distances likely due to the strong H-bonding between this atom belonging to η^2-acetate anion and the H atom of the solvate acetic acid molecule ((O(9)···O(12) 2.698(4), 2.671(7), 2.666(3), 2.665(4) Å, in **1**–**4**, respectively). However, the Ln^{III}–O(9) bond is slightly shorter than one bond of the bridging oxygen atom O(10) of the μ,η^2-coordinated acetate ligand (Nd(1)–O(10A) 2.570(3) Å, Eu(1)–O(10A) 2.500(9) Å, Tm(1)–O(10A) 2.446(2) Å, Yb(1)–O(10A) 2.427(4) Å).

Earlier we synthesised the relative bis-paddlewheel tetraacetate-bridged complexes $[Pd(\mu\text{-}OOCMe)_4Ln(THF)(\mu,\eta^2\text{-}OOCMe)_2]_2 \times 2THF$ (Ln = Eu, Nd; Pd···$Nd_{av.}$ 3.227, Nd···Nd_{av} 4.156 Å, Pd···Eu_{av} 3.208 Å, Eu···Eu 4.089 Å in two independent molecules) [3c] using the similar synthetic procedure, with the only exception that water and acetic acid were thoroughly removed from the primary reaction product by distillation with benzene followed by recrystallisation from hot THF [3c]. In contrast to crystals **1**–**4**, the crystals of these complexes have no intermolecular H-bonds and seemingly due to this fact, the metal–oxygen distances in the fragment $Ln(\mu,\eta^2\text{-}OOCMe)_2Ln$ are noticeably redistributed. The Ln–O(9) and Ln–O(10) bond lengths are close to each other (Nd–$O(9)_{av}$ 2.512 Å, Eu–$O(9)_{av}$ 2.472 Å Nd–$O(10)_{av}$ 2.553 Å, Eu–$O(10)_{av}$ 2.506 Å), while the Ln–O(10A) distances are shortened (Nd–$O(10A)_{av}$ 2.445 Å Eu–$O(10A)_{av}$ 2.401 Å) compared to those found in the H-bonded complexes **1** and **2** (Table 6).

Scheme 1.

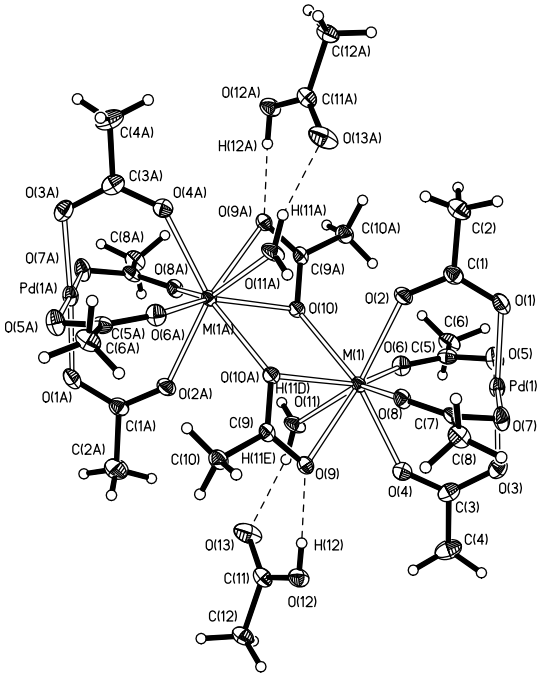

Fig. 1. Molecular structure of the bis-paddlewheel complexes $[Pd(\mu\text{-}OOCMe)_4\text{-}Ln(OH_2)(\mu,\eta^2\text{-}OOCMe)]_2 \times 2HOOCMe$ (Ln = Nd^{III} (**1**), Eu^{III} (**2**), Tm^{III} (**3**), Yb^{III} (**4**)) drawn with displacement ellipsoids at the 50% probability level.

The second O atom of the HOOCMe solvate molecule in **1**–**4** is linked to H atoms of the coordinated water molecules belonging to two adjacent complexes (O(13)···O(11)(11A) 2.819(4), 2.757(4) Å; 2.749(8), 2.787(9) Å; 2.789(3), 2.741(3) Å; 2.744(4), 2.798(5) Å for **1**–**4**, respectively), forming 1D polymeric chain (Fig. 2).

The geometry of molecules **1**–**4** is practically the same as that of the earlier synthesised complex $[Pd(\mu\text{-}OOCMe)_4Sm(OH_2)(\mu,\eta^2\text{-}OOCMe)]_2 \times 2HOOCMe$ [3a].

Complexes **1**–**4** and the earlier synthesised similar Pd^{II}-based acetate complexes are soluble and stable in water but poorly soluble in low-polarity organic solvents. To improve their solubility, it would desirable to change the acetate anions for the more lyophilic trimethylacetate (pivalate) ligands. The acetate-bridged palladium(II) acetate $Pd_3(\mu\text{-}OOCMe)_6$ is known to maintain its trinuclear structure upon changing all the acetate bridges by pivalate ligands [6a]. Meanwhile, the analogous acetate-bridged tetranuclear platinum(II) acetate $Pt_4(\mu\text{-}OOCMe)_8$ was transformed by pivalic acid or pivalate salts to the mixed-ligand complex $Pt_4(OOCBu^t)_4(OOCMe)_4$ only [6b].

In this context, we attempted to transform complexes **1**–**4** and the earlier synthesised [3b] complex $[Pd(\mu\text{-}OOCMe)_4Sm(OH_2)\text{-}(\mu,\eta^2\text{-}OOCMe)]_2 \times 2HOOCMe$ to the corresponding pivalates by refluxing in benzene solution of pivalic acid Bu^tCOOH. It was unexpectedly found that not only the solvate acetic acid and two μ,η^2-acetate bridges but also all the μ-acetate bridges undergo total ligand substitution by the reaction with a stoichiometric amount of pivalic acid to give the purely pivalate complexes in high yield:

$$[Pd(\mu\text{-}OOCMe)_4M]_2L + 4HOOCBu^t \rightarrow Pd(\mu\text{-}OOCBu^t)_4ML' + 4MeCOOH,$$

$$L = OOCMe^-,\ H_2O;\ L' = OOCBu^{t-},\ HOOCBu^t$$

which are well soluble in low-polarity organic solvents, including benzene and *n*-pentane.

Table 6
Comparison of geometries of the fragments Ln(μ,η^2-OOCMe)$_2$Ln in the bis-paddlewheel complexes [Pd(μ-OOCMe)$_4$Ln(OH$_2$)(μ,η^2-OOCMe)]$_2$ × 2HOOCMe (**1**,**2**) and [Pd(μ-OOCMe)$_4$Ln(THF)(μ,η^2-OOCMe)$_2$]$_2$ × 2THF (Ln = Eu, Nd).

	1	Ln = Nd (in two independent molecules) [3c]	**2**	Ln = Eu (in two independent molecules) [3c]
Ln(1)–O(9) (Å)	2.558(3)	2.512(5), 2.495(5); 2.520(5), 2.520(5)	2.488(8)	2.496(7), 2.469(8); 2.442(8), 2.480(7)
Ln(1)–O(10) (Å)	2.501(4)	2.561(5), 2.557(5); 2.547(5) 2.547(5)	2.433(7)	2.509(8), 2.495(7); 2.525(7), 2.497(7)
Ln(1)–O(10A) (Å)	2.500(9)	2.399(7), 2.423(5); 2.445(5), 2.420(7).	2.570(3)	2.449(5), 2.404(7); 2.382(7), 2.445(5)

The detailed geometry of the pivalate complexes depends on the size of the rare-earth metal atom. The early lanthanides form the complexes Pd(μ-OOCBu^t)$_4$Ln(OOCBu^t)(HOOCBu^t)$_3$ (Ln = Nd (**5**), Sm (**6**), Eu (**7**)) (Scheme 2).

According to X-ray diffraction data (Fig. 3, Tables 7–9) the Pd–co-metal distances in complexes **5**, **6** and **7** (3.2584(9) Å in **5**; 3.2548(6) Å in **6** and 3.2506(5) Å in **7**) are only slightly elongated compared to the corresponding bis-paddlewheel acetate complexes (*cf.* 3.221(2) Å in the Pd–Nd complex, 3.2047(9) Å in the Pd–Sm complex [3b] and 3.1983(12) Å in the Pd–Eu complex). The Pd–O distances are also nearly the same (1.998(6)–2.008(6) Å in **5**, 2.004(4)–2.008(4) Å in **6** and 1.996(4)–2.004(4) Å in **7**).

The coordination sphere of the Nd^{III}, Sm^{III} and Eu^{III} atoms is complemented with three coordinated molecules of pivalic acid and one terminal pivalate anion (Fig. 3, Tables 1 and 6–8). A special feature of this structure is the short intramolecular bonds between the H atoms of two axially coordinated molecules of pivalic acid and O atoms of two bridging pivalate anions, resulting in a noticeable (0.12–0.15 Å) loosing of two Nd(Sm,Eu)–O bonds, while all the H-bonded O···O distances have close values O(2)···O(10) (2.695(6), 2.678(4), 2.672(4) Å; O(4)···O(12) 2.660(6), 2.668(4), 2.657(4) Å) in complexes **5**, **6** and **7**, respectively). The H atom of the third pivalic acid forms a very short H bond with the O atom of the terminal pivalate anion (O(14)···O(16) 2.453(7) in **5** 2.455(4) Å in **6** and 2.434(4) Å in **7**).

The late lanthanides form the mono-paddlewheel complexes Pd(μ-OOCBu^t)$_4$Ln(η-OOCBu^t)(HOOCBu^t)$_2$ × HOOCBu^t (Ln = Tm (**8**), Yb (**9**) (Scheme 3).

When complexes **8**–**9** are formed, one of the coordinated pivalic acid ligands is displaced to become a solvate molecule because of the reduced atomic radii of the late lanthanides (Fig. 4, Tables 10 and 11). The coordinated pivalate anion becomes a η^2-terminal ligand, one of its O atoms being H-bonded with the O atom of the coordinated pivalic acid molecule. The H-bonding of the second coordinated pivalic acid molecule remains unchanged (O(2)···O(14) 2.657(4), 2.663(4) Å; Ln–O(2) 2.338(5), 2.334(3) Å in **8** and **9**, respectively). The metal–metal and metal–oxygen distances in

O(15)–Nd(1)–Pd(1)	133.96(15)	O(13)–Nd(1)–O(15)	92.5(2)

complexes **8** and **9** are almost the same as those in the corresponding bis-paddlewheel acetate complexes (Pd···Ln 3.1673(7), 3.1781(7) Å; Pd–O 1.992(5)–2.004(5) Å, 1.999(4)–2.006(3) Å; Ln–O 2.266(5)–2.291(5), 2.262(4)–2.285(4) Å in **8** and **9**, respectively).

However, unlike bis-paddlewheel acetates **1**–**4**, the solvate molecules of pivalic acid in **8** and **9** do not form H-bonds with the O atoms of the coordinated anions and acid molecules, but produce dimeric associates (O···O 2.654(5) and 2.660(4) Å for **8** and **9**, respectively) (Fig. 5).

Hence, the complete replacement of the bridging and terminal acetate ligands in the Pd^{II}–Ln^{III} heterobimetallic complexes by

the more basic pivalate ones does not change the paddlewheel structural motif of the complexes. The detailed structure of the molecules formed is determined by both the nature of the co-metal and the electronic and steric features of the carboxylate anions. The smaller acetate anions, unlike the larger pivalate anions, are prone to form bis-paddlewheel complexes and intermolecular H-bonds with the solvate carboxylic acid molecules. The bis-paddlewheel acetate complexes are formed from two mono-paddlewheel fragments due to a donor–acceptor bonding of the bridging oxygen atom of the η^2-acetate anion. Meanwhile, this structure remains unchanged upon refluxing in polar and donor solvents, such as THF, water and acetic acid.

The composition and structure of complexes **5**–**9** convey the suggestion on a plausible mechanism of the easy acetate to pivalate substitution observed in the complexes under question. When the molecule of pivalic acid approaches to the tetraacetate-bridged complex, it can be first coordinated to the rare-earth metal atom at the axial position; the subsequent formation of an intramolecular

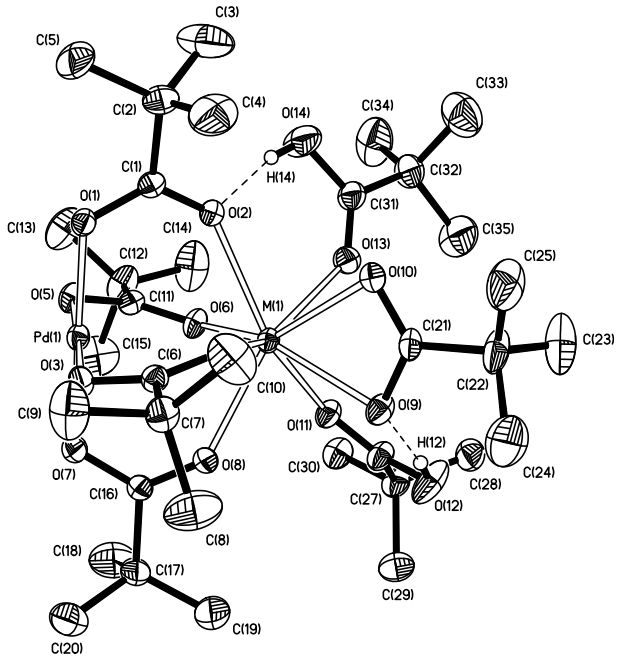

Fig. 4. Molecular structure of the tetrapivalate-bridged complexes with the late lanthanides $Pd(\mu\text{-}OOCBu^t)_4Ln(\eta\text{-}OOCBu^t)(HOOCBu^t)_2 \times HOOCBu^t$ (Ln = Tm^{III} (**8**), Yb^{III} (**9**)) drawn with displacement ellipsoids at the 30% probability level.

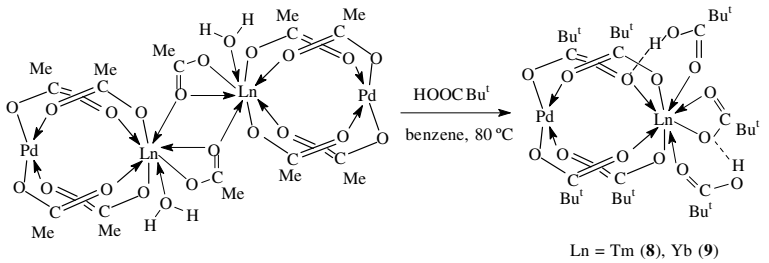

hydrogen bond with the bridging acetate ligand followed by proton transfer [7a–d] releases a molecule of acetic acid and produces a pivalate bridge (Scheme 4).

It is not inconceivable that the intra- and intermolecular bonds found in the crystals of complexes **1**–**9** are formed in intermediates during acetate to pivalate ligand metathesis, facilitating the removal of acetic acid.

3. Experimental

3.1. Reagents and solvents

Palladium(II) acetate $Pd_3(OOCMe)_6$ was prepared from $PdCl_2$ (purchased from Reakhim, Russia) by reduction with $NaBH_4$ followed by the oxidation of the Pd black that formed with concentrated HNO_3 in glacial acetic acid according to a procedure [8] and recrystallisation of $Pd_3(OOCMe)_6$ from hot acetic acid. Other chemicals (pivalic acid, $Sm(OOCMe)_3 \times 4H_2O$, $Eu(OOCMe)_3 \times 4H_2O$, $Nd(OOCMe)_3 \times 1.5H_2O$, $Tm(OOCMe)_3 \times 4H_2O$, $Yb(OOCMe)_3 \times 4H_2O$, all reagent grade, purchased from Reakhim, Russia) and solvents (glacial acetic acid, benzene, pentane and hexane, all reagent grade, purchased from Acros, Belgium) were purified by standard procedures [9].

3.2. Physical measurements

The elemental C,H,N analysis was performed on an automated C,H,N-analyzer (Carlo Erba Strumentazione, Italy). The IR spectra were recorded on a Nicolet Nexus spectrometer in KBr pellets.

3.2.1. X-ray diffraction analysis

Details of the data collection and structure refinement for complexes **1**–**9** are presented in Table 1. Single-crystal X-ray diffraction experiments were carried out on Siemens P4 (for complex **2**) and Bruker SMART and Bruker SMART APEX II diffractometers with a CCD area detector (graphite monochromator, Mo Kα radiation, $\lambda = 0.71073$ Å, ω-scans). The semi-empirical method SADABS [10] was applied for the absorption correction. The structures were solved by direct methods and refined by the full-matrix least-squares technique against F^2 with the anisotropic displacement parameters for all non-hydrogen atoms. All the hydrogen atoms in the complexes were placed geometrically and included in the structure factors calculation in the riding motion approximation. All the data reduction and further calculations were performed using the SAINT [11] and SHELXTL-97 [12] program packages.

3.3. Syntheses

3.3.1. [Pd(μ-OOCMe)$_4$Nd(OH$_2$)(μ,η^2-OOCMe)]$_2$ × 2HOOCMe (**1**)

In 50 ml water-jacketed flask equipped with reflux condenser and magnetic stirrer, $Pd_3(OOCMe)_6$ (100 mg, 0.45 mmol based on Pd atom), $Nd(OOCMe)_3 \times 1.5H_2O$ (156 mg, 0.45 mmol) and glacial acetic acid (15 ml) were stirred at 90 °C in an oil bath for ~40 min (more prolonged heating of the reaction mixture results in partial Pd^{II} to Pd^0 reduction). The light-yellow reaction solution was concentrated to 5 ml and slowly cooled in the bath to room temperature for crystallisation. Yellow crystals of complex **1** (194 mg) suitable for X-ray diffraction study were separated by decantation, washed with diethyl ether and dried in Ar flow. An additional amount of the smaller crystals were obtained by precipitation with ether from the mother liquid. Total yield of **1** was 250 mg (90% based on Pd). *Anal.* Calc. for $Pd_2Nd_2C_{24}O_{26}H_{42}$: C, 23.10; H, 3.39. Found: C, 22.76; H, 3.47%. IR spectrum (KBr, ν/cm^{-1}): 3420br, s, 3267w, 2940w, 2634w, 2553w, 1688m, 1628br, vs, 1546m, 1438s, 1415vs, 1346w, 1285m, 1050m, 1022m, 958w, 695s, 627m, 587w, 460w.

3.3.2. [Pd(μ-OOCMe)$_4$Eu(OH$_2$)(μ,η^2-OOCMe)]$_2$ × 2HOOCMe (**2**)

Compound **2** was prepared and crystallised by analogous procedure (see above) from $Pd_3(OCOMe)_6$ (100 mg, 0.45 mmol) and $Eu(OOCMe)_3 \times 4H_2O$ (177 mg, 0.45 mmol). Total yield of **2** was 253 mg (90% based on Pd). *Anal.* Calc. for $Pd_2Eu_2C_{24}O_{26}H_{42}$: C, 22.82; H, 3.35. Found: C, 22.69; H, 3.27%. 3.3.3. [Pd(μ-OOCMe)$_4$Tm(OH$_2$)(μ,η^2-OOCMe)]$_2$ × 2HOOCMe (**3**)

Compound **3** was prepared and crystallised by analogous procedure (see above) from $Pd_3(OCOMe)_6$ (100 mg, 0.45 mmol) and $Tm(OOCMe)_3 \times 4H_2O$ (188 mg, 0.45 mmol). Yield of crystals **3** was 257 mg (89% based on Pd). *Anal.* Calc. for $Pd_2Tm_2C_{24}O_{26}H_{42}$: C, 22.22; H, 3.26. Found: C, 21.98; H, 3.19%. IR spectrum (KBr,

*3.3.4. [Pd(μ-OOCMe)$_4$Yb(OH$_2$)(μ,η^2-OOCMe)]$_2$ × 2HOOCMe (**4**)*

Compound **4** was prepared and crystallised by analogous procedure (see above) from $Pd_3(OCOMe)_6$ (100 mg, 0.45 mmol) and $Yb(OOCMe)_3 \times 4H_2O$ (190 mg, 0.45 mmol). Yield of yellow crystals **4** was 265 mg (91% based on Pd). *Anal.* Calc. for $Pd_2Yb_2C_{24}O_{26}H_{42}$: C, 22.08; H, 3.24. Found: C, 21.89; H, 3.18%. IR spectrum (KBr, ν/cm^{-1}): 3417br, 3268w, 2929w, 2630w, 2550w, 1687m, 1628br, vs, 1545s, 1438s, 1413vs, 1346m, 1284m, 1049w, 1020m, 957w, 694 s, 625m, 590w, 461w.

*3.3.5. Pd(μ-OOCBu^t)$_4$Nd(OOCBu^t)(HOOCBu^t)$_3$ (**5**)*

A suspension of $Pd_3(OOCMe)_6$ (100 mg, 0.45 mmol) and $Nd(OOCMe)_3 \times 1.5H_2O$ (156 mg, 0.45 mmol) in 15 ml of glacial acetic acid was stirred at 90 °C for 40 min, cooled to room temperature and evaporated to dryness on a rotary evaporator (temperature of the water bath should be at most 60 °C). The dry residue was dissolved in warm benzene (10 ml), the solution was evaporated to dryness, and this operation was twice repeated to completely remove water and acetic acid. To the obtained dry yellow-orange powder was added a solution of pivalic acid (363 mg, 3.6 mmol) in benzene (15 ml) and refluxed for 0.5 h. The solution formed was evaporated to produce a yellow oil, which was thoroughly dried on a rotary evaporator to remove acetic acid formed by the acetate to pivalate metathesis. For the completion of the metathesis reaction a new portion of benzene (10 ml) was added and the solution was refluxed for 15 min followed by solvent evaporation. The oil residue was dissolved in 1 ml of warm pentane and stayed for 1–2 h for crystallisation either at room temperature or in a fridge at −10 °C. The yellow-orange crystals of **5** suitable for X-ray diffraction study were separated by decantation and dried in vacuum. Yield of **5** was 374 mg (79% based on Pd). *Anal.* Calc. for $PdNdC_{40}O_{16}H_{75}$: C, 45.21; H, 7.11. Found: C, 44.98; H, 6.93%. *3.3.6. Pd(μ-OOCBu^t)$_4$Sm(OOCBu^t)(HOOCBu^t)$_3$ (**6**)*

Compound **6** was prepared and crystallised by analogous procedure (see above) from $Pd_3(OCOMe)_6$ (100 mg, 0.45 mmol), $Sm(OOCMe)_3 \times 4H_2O$ (178 mg, 0.45 mmol) and HOOCBu^t (363 mg, 3.6 nmmol). Yield of **6** was 390 mg (82% based on Pd). *Anal.* Calc. for $PdSmC_{40}O_{16}H_{75}$: C, 44.95; H, 7.07. Found: C, 44.73; H, 6.92%. IR spectrum (KBr, ν/cm^{-1}): 3441br, m, 2967m, 2933w, 2875w, 1697s, 1595ws, 1573w, 1484m, 1459w, 1413s, 1372br, m, 1306w, 1227m, 1200w, 1030w, 869w, 787w, 647w, 450w.

*3.3.7. Pd(μ-OOCBu^t)$_4$Eu(OOCBu^t)(HOOCBu^t)$_3$ (**7**)*

Compound **7** was prepared and crystallised by analogous procedure (see above) from $Pd_3(OCOMe)_6$ (100 mg, 0.45 mmol), $Eu(OOCMe)_3 \times 4H_2O$ (177 mg, 0.45 mmol) and HOOCBu^t (363 mg, 3.6 nmmol). Yield of **7** was 343 mg (72% based on Pd). *Anal.* Calc. for $PdEuC_{40}O_{16}H_{75}$: C, 44.88; H, 7.06. Found: C, 44.59; H, 7.01%. 4. Conclusion

This and previous our studies [3a–d] showed that irrespectively of the complementary metal (transition, post-transition, alkaline earth or rare earth) acetates, palladium(II) readily forms similar Pd^{II}-based heterobimetallic complexes in high yields. The structure

of the complexes formed seems to be governed by the square planar palladium(II) atom that can be treated as a sort of a tetradentate chelating ligand towards the co-metal carboxylate to form a tetrabridged paddlewheel moiety $Pd(\mu\text{-}OOCR)_4M$ with rather short Pd–M distances.

Notwithstanding an apparent simplicity of the synthetic procedure, the reaction mechanism is rather complicated, as was shown by our recent kinetic study [13]. Therefore, it is somewhat surprising that the reaction products are such similar over a wide range of the complementary metals.

Unlike the mono-paddlewheel acetate complexes containing divalent transition, post-transition, alkali-earth metal, the trivalent rare-earth metal acetates form bis-paddlewheel heterobimetallic complexes. Meanwhile, when acetate ligands in the Ln^{III}-containing complexes are changed by pivalate anions, mono-paddlewheel compounds are formed.

A peculiarity of the Pd^{II}-based paddlewheel carboxylates is their ability to form intra- and intermolecular H-bonds in the crystals, which is particularly typical of the rare-earth metal complexes under study. The H-bonding induces the loosing of one or several Ln–O bonds with the bridging carboxylate ligands. It is possible that this bonding plays a significant role in the bridging acetate to pivalate metathesis. Although the reaction mechanism needs additional studying, we can note now that the tetraacetate-bridged Pd^{II}–Ln^{III} complexes readily react with a rather weak O-base, pivalic acid, resulting in the complete substitution of all $MeCOO^-$ anions by Bu^tCOO^- ones.

ABSTRACT

The feasibility of a novel and simple layer-by-layer chemical deposition method for the preparation of nano-sized metal 8-hydroxyquinolate complexes has been investigated and reported. Uniform nanocrystalline films have been synthesized via dipping a substrate alternately in metal ion solution followed by ligand solution. The stoichiometry of the as-grown anhydrous Fe(III), Co(II), Ni(II), Cu(II) and Zn(II) complex crystals were confirmed from the metal analysis and molar stoichiometric ratio of metal ion to 8-hydroxyquinoline. This was characterized as 1:2 for the Co(II), Ni(II), Cu(II) and Zn(II)–quinolate complexes. The Fe(III)–quinolate thin film was found to exhibit a 1:3 ratio. Electron impact-mass spectra (EI-MS) of all the synthesized thin film metal quinolate complexes were recorded and the results refer to the existence of the molecular ion peak at the corresponding *m*/*z* values. Confirmation of such stoichiometric 1:2 and 1:3 ratios were also evident from the (EI-MS) study. The deposited thin films were also subjected to analysis by a scanning electron microscope (SEM) and a particle size $\geqslant$50 nm was detected. FT-IR and UV–Vis spectroscopy were further used to confirm the structure of the metal 8-hydroxyquinolate complexes. Thermal gravimetric analysis (TGA) was also used to follow up the possible thermal decomposition steps and to calculate the thermodynamic parameters of the nano-sized metal complexes.

1. Introduction

Recently, more research efforts have been focused on the beneficial applications of the layer-by-layer deposition technique. This methodology has emerged and been found a more economic alternative for the direct preparation of thin films [1–3]. The highly sophisticated gas-phase layer deposition method can be easily replaced by this simple and direct liquid-phase solution-based layer-by-layer technique for thin film formation [4,5]. The formation of a variety of important compounds was successfully synthesized via the layer-by-layer thin film deposition approach. Polyelectrolyte thin films were prepared via alternately dipping the substrate into polycation and polyanion solutions to form polyelectrolyte multilayer films [6] as well as polymer-nanoclay multilayers [7]. The application of the layer-by-layer deposition method for the formation of various metal oxide [8–10] and metal sulfide thin films [11–13] have been reported and their optical properties investigated.

8-Hydroxyquinoline, 8HQ, also known as oxine, its derivatives as well as related metal complexes, are playing a uniquely important role in different disciplines of chemical research and applications. 8HQ, as a complexone or sequestering reagent, is considered second to EDTA and its analogues in binding with metal ions [14]. 8HQ was mainly applied for analytical purposes and separation techniques as an excellent reagent for the extraction of metal ions due to its extraordinary coordinating capabilities [15–20]. However, in coordination chemistry, versatile synthetic approaches for the formation of metal complexes of 8HQ and its derivatives were extensively used to open a wide range of di and tri-valent metal complexes that can be used as an arsenal for various impacts and applications in different fields. Among these applications are the utilization of 8-hydroxyquinoline as an interesting chelating agent for the formation of luminescent coordination compounds as light emitting devices. A review covering the applications of metal complexes of 8-hydroxyquinoline derivatives to obtain new supramolecular sensors, emitting devices or self-assembled aggregates was recently published [21]. Moreover, tris(8-hydroxyquinoline) aluminum (Alq3) is widely used in modern organic light emitting diodes (OLEDs) due to its excellent stability and electroluminescent properties via the high dependence on the injection behavior of the metallic contacts [22–24]. Most recent research efforts have also been focused on the synthesis of quinolate metal

complex nanomaterials by physical vapor deposition [25,26] and adsorbent assisted physical vapor deposition [27] techniques, with positive results at the end.

The strong necessity to fabricate thin films of various metal derivatives in the form of oxides, sulfides and complexes to desired shapes and sizes by an easy and simple technique has been previously reported [28]. Therefore, we present and describe in this work a simple and rapid method for the synthesis of nanomaterials derived from quinolate complexes of Fe(III), Co(II), Ni(II), Cu(II) and Zn(II) based on the application of a layer-by-layer technique via successive and alternative deposition of metal ions and ligand molecules from their aqueous and methanolic solutions, respectively, for the formation of a thin film loaded on a glass substrate. The structures of the thin film synthesized metal quinolate complexes were confirmed on the basis of scanning electron microscopy (SEM), electron impact-mass spectrometry (EI-MS) UV–Vis spectroscopy, Fourier Transform infrared spectroscopy (FT-IR) and thermal gravimetric analysis (TGA).

2. Experimental

2.1. Layer-by-layer thin film formation of 8HQ metal complexes

The formation of the 8HQ metal complexes was carried out by a chemical dipping method according to the following procedure. In this method, a clean glass micro-slide of the size 76.2 mm by 25.4 mm by 1 mm was used as the solid substrate. A solution of 0.1 M metal acetate or chloride was prepared in double distilled water and the 8HQ solution was also prepared (0.1 M) in methanol. The clean substrate was vertically immersed into the metal ion solution for a 30 s period to deposit the corresponding metal ion on the substrate surface. The substrate was then immersed in the ligand solution for another 30 s, where the pre-adsorbed metal ion on the glass substrate was allowed to react with the ligand. A colored and uniform thin film of the metal complex was formed after a few dipping cycles. The reaction substrate was rinsed with distilled water after each reaction cycle. This procedure was repeated several times (15–50 times) to increase the film thickness and homogeneity.

2.2. Instrumentation

A Shimadzu gas chromatography–mass spectrometer (GCMS-QP2010S) interfaced with a direct insertion probe (DIP) was used to acquire the electron impact-mass spectra (EI-MS) of the metal quinolate complexes, viz. Fe(III), Co(II), Ni(II), Cu(II) and Zn(II), by the application of 70-eV as the ionization energy. The heating temperature programming of the DIP was performed at 20 °C min^{-1} for all the metal quinolate complexes. The maximum temperature was set to 350 °C and the run time was completed in 20.0 min. The collected mass spectrum of each metal quinolate complex was library searched to obtain the best possible match.

Scanning electron microscopes (JSM-6360LA, JEOL Ltd.), (JSM-5300, JEOL Ltd.) and an ion sputtering coating device (JEOL-JFC-1100E) were used to examine the deposited thin film of the metal quinolate complexes. SEM specimens were coated with gold to increase the conductivity. The thermal gravimetric analysis (TGA) and thermoanalytical curves were obtained using a Perkin–Elmer TGA7 Thermobalance at Moubarak City, Egypt. The operating conditions were as follows: a temperature heating range of 20–1000 °C with a heating rate of 10 °C min^{-1}, a flow rate of 20 ml min^{-1} in a pure nitrogen atmosphere and a sample mass in the range 5–12 mg. The FT-IR spectra of the metal quinolate complexes were measured on a Shimadzu Fourier Transform infrared spectrophotometer (FTIR-8400S) in the range 4000–200 cm^{-1}. The metal contents of the quinolate complexes were determined on a Shimadzu (AA-6650) atomic absorption spectrophotometer after acid decomposition and suitable dilution. UV–Vis spectra of the metal quinolate complexes were measured on a Perkin–Elmer UV–Vis Spectrometer Lambda EZ210.

2.3. Chemical and materials

The metal salts were all of analytical grade and were purchased from Aldrich Chemical Company, USA and BDH limited, Poole, England. The acetate salts were cobalt acetate, $Co(OAc)_2 \cdot 4H_2O$, nickel acetate, $Ni(OAc)_2 \cdot 4H_2O$, copper acetate, $Cu(OAc)_2 \cdot H_2O$ and zinc acetate, $Zn(OAc)_2 \cdot 2H_2O$. Only iron was in the chloride form, $FeCl_3$. 8-Hydroxyquinoline (8HQ) and methanol were obtained from BDH limited, Poole, England and were used as received. The metal ion solutions (0.1 M) were prepared from doubly distilled water by dissolving the appropriate mass of the metal salt in a 500 ml flask. A 0.1 M methanolic solution of 8HQ was also prepared and used. The glass micro-slide glass substrate, of the size 76.2 mm by 25.4 mm by 1 mm, was cleaned as previously reported [10].

3. Results and discussion

3.1. SEM of the metal 8HQ complexes

Fig. 1 shows the SEM images of an 8HQ deposited thin film on a glass substrate for simple comparison with the thin film metal 8-quinolate complexes. It is evident that the 8HQ molecules are distributed into nano-sized tubes upon direct deposition on the glass substrate and the SEM images of 8HQ are somewhat similar to the SEM image of a carbon nanotube structure [29,30]. The diameter of the 8HQ-nanotube was found to be in the range 33–43 nm, as measured from the SEM images.

The detected SEM images of the various metal complexes were found to be completely different from that of 8HQ. Fig. 2(i)–(iii) shows the SEM images of the $Co(8HQ)_2$ complex deposited thin film on a glass substrate after 50 times of alternate dipping in metal ion solution and 8HQ ligand counter part solution. The $Co(8HQ)_2$ complex was observed to start forming uniform complex particles after only a few dipping cycles, indicating that a fast complex reaction is taking place for the formation of the desired thin films. Fig. 2(i) is a 30,000-times magnified image of the $Co(8HQ)_2$ complex particle, showing a number of deposited molecules under one particle aggregate. Fig. 2(ii) is a 7500 times magnified image of the $Co(8HQ)_2$ complex and clearly refers to the existence of several particles with different contributions of nano-sized aggregates.

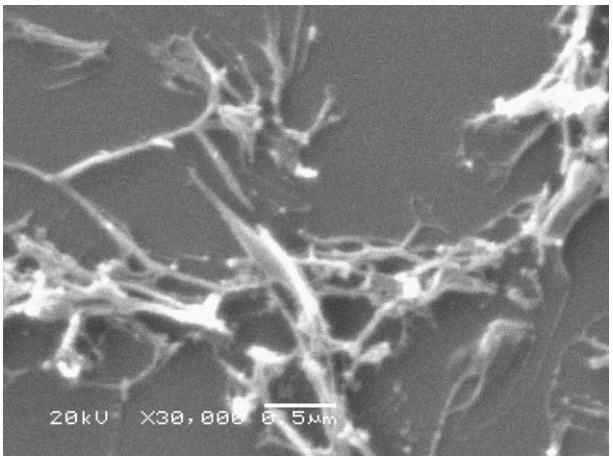

Fig. 1. SEM image of the 8HQ deposited thin film.

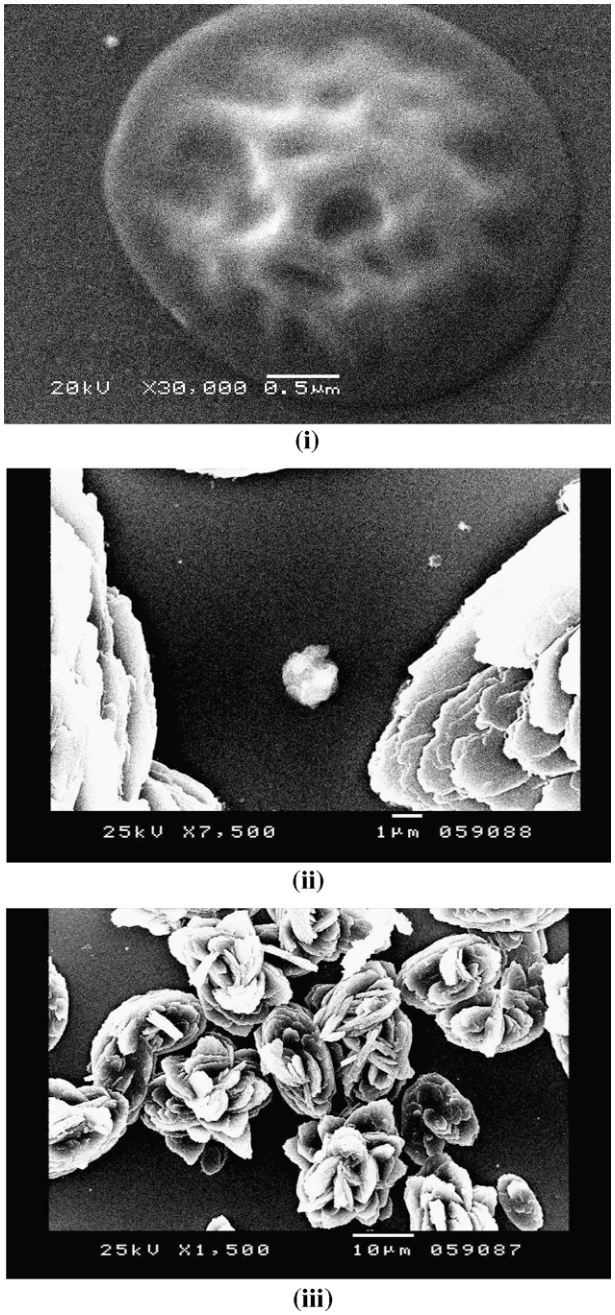

Fig. 2. SEM images of the thin film $Co(8HQ)_2$ complex on glass substrate based on 50-dipping cycles.

Finally, Fig. 2(iii) represents a 1500-times magnified SEM image of the $Co(8HQ)_2$ complex deposited thin film and refers to the high homogeneity and similarity in the $Co(8HQ)_2$ crystal growth based on layer-by- layer complex formation.

Fig. 3(i) and (ii) shows the SEM images of the deposited thin film of the $Fe(8HQ)_3$ complex after 50-dipping cycles in metal ion and 8HQ ligand solutions. Fig. 3(i) shows a homogeneous particle size distribution of the formed $Fe(8HQ)_3$ complex with 10,000-times magnification. Most of the $Fe(8HQ)_3$ complex particle sizes were identified as being under 200 nm. In a similar fashion to the thin film formation of the $Co(8HQ)_2$ complex, a fast complex formation reaction of $Fe(8HQ)_3$ thin film was characterized after only a few dipping cycles. Fig. 3(ii) represents a SEM image of the $Fe(8HQ)_3$ complex deposited thin film with a homogeneous

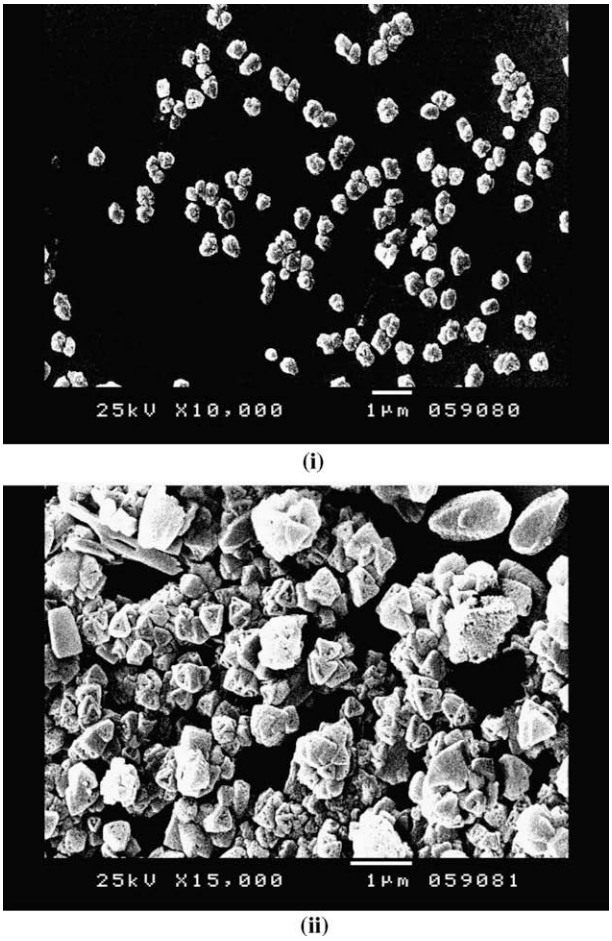

Fig. 3. SEM image of thin film $Fe(8HQ)_3$ complex on glass substrate based on 50-dipping cycles.

distribution of $Fe(8HQ)_3$ crystal growth based on layer-by-layer complex formation. The SEM images of the other metal complexes synthesized based on layer-by-layer thin film formation are shown in Figs. 4–6 for the $Ni(8HQ)_2$, $Cu(8HQ)_2$ and $Zn(8HQ)_2$ complexes, respectively. The numbers of dipping cycles are 30, 15 and 15 for the three tested complexes, respectively.

It is evident from the SEM study that all the synthesized metal quinolate complex crystals were found to grow up from just a single molecule to several molecules in an aggregate distribution with particle sizes starting from a few nanometers to several hundred nanometers. In addition, various characteristic shapes of metal

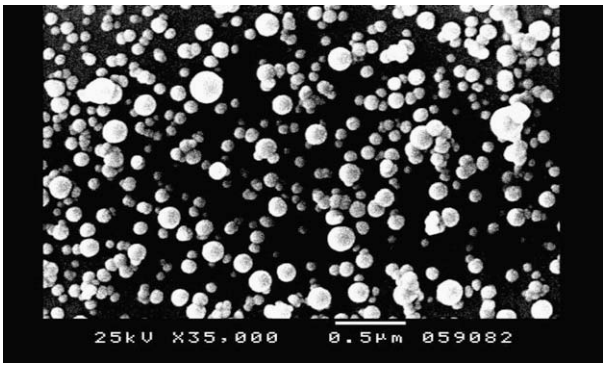

Fig. 4. SEM image of the thin film $Ni(8HQ)_2$ complex on glass substrate based on 30-dipping cycles.

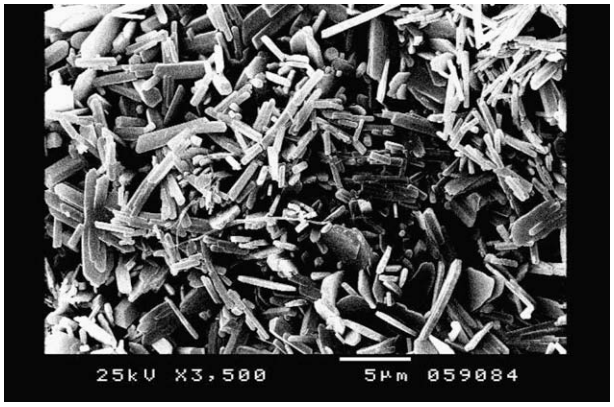

Fig. 5. SEM image of the thin film $Cu(8HQ)_2$ complex on glass substrate based on 15-dipping cycles.

quinolate complexes were identified and these SEM images are quite different from that of 8HQ alone. The shape difference of the metal quinolate complex crystal aggregates deposited on the thin films is mainly dependent on the reacted metal ions.

3.2. Stoichiometry based on metal analysis and EI-MS of the metal quinolate complexes

The molar stoichiometric ratios of the synthesized metal complexes, determined on the basis of the metal analysis, are listed in Table 1. The metal analysis of the characterized layer-by-layer thin film formation of the Co(II), Ni(II), Cu(II) and Zn(II) complexes proved a good similarity to the reactions with 8HQ providing a 1:2 stiochiometric ratio. It is important to report here that the two reaction species, metal ion and 8HQ, were prepared as 0.1 M and

Table 1
Some characteristic data of thin film metal quinolate complexes.

Structure	FW	Color	% Theoretical	% Experimental	Film (mg/cm^2)	Dipping cycles
$Co(8HQ)_2$	346.93	Orange	% Co = 16.99	% Co = 16.79	4.569	50×
$Ni(8HQ)_2$	347.01	Yellowish green	% Ni = 16.91	% Ni = 16.87	4.194	30×
$Cu(8HQ)_2$	351.87	Olive green	% Cu = 18.07	% Cu = 18.06	4.869	15×
$Zn(8HQ)_2$	353.39	Yellowish green	% Zn = 18.50	% Zn = 18.66	4.469	15×
$Fe(8HQ)_3$	488.33	Black	% Fe = 11.44	% Fe = 11.35	4.328	50×

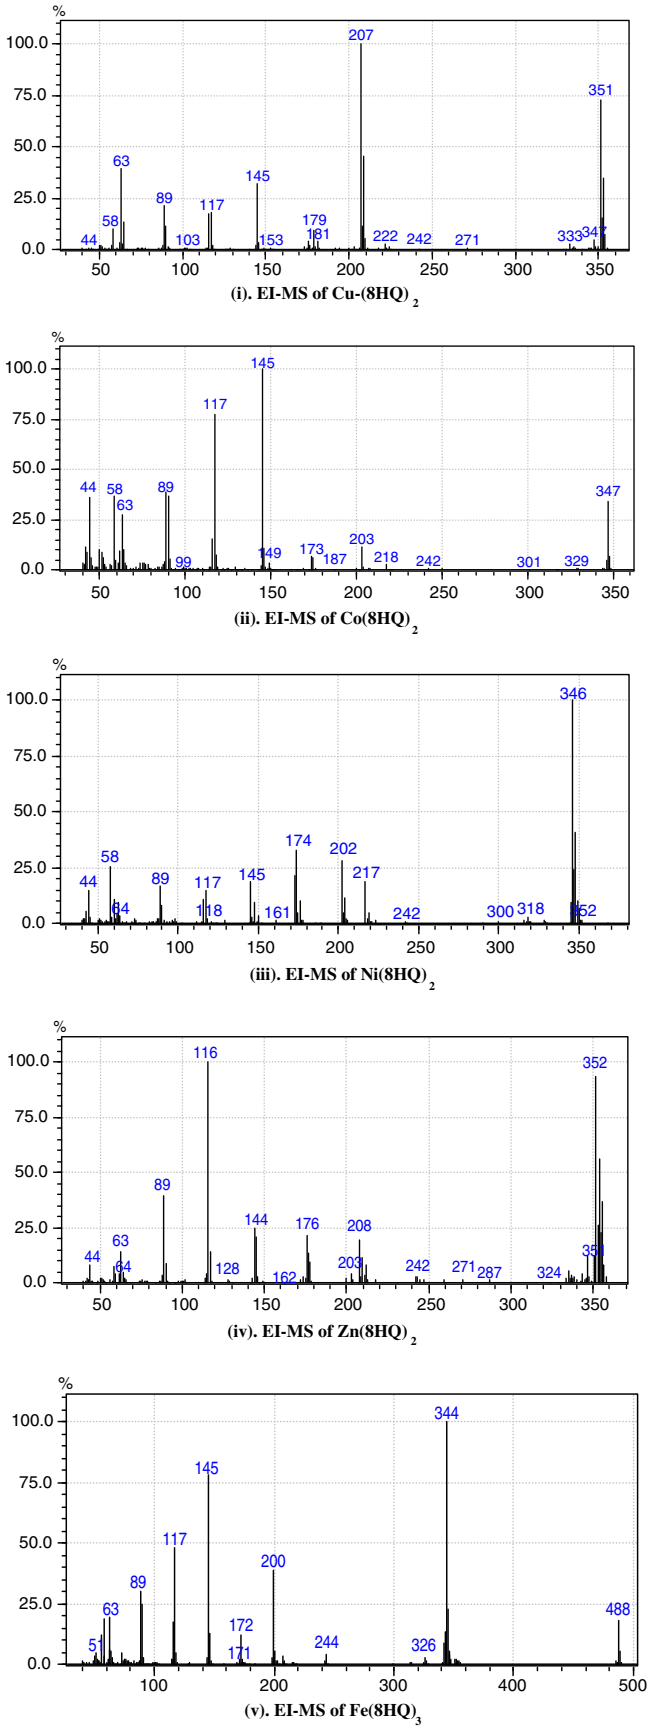

Fig. 7. EI-MS of layer-by-layer thin films of metal quinolate complexes.

when the glass substrate was first dipped in metal ion solution followed by the ligand solution, a rapid complexation reaction took place between the metal ion and 8HQ in a 1:2 ratio, respectively. Thus, the relative concentration of the two reacting species is considered of less importance when layer-by-layer thin film metal quinolate complexes are formed. In the same manner, the Fe(III) ion was characterized by its reaction with 8HQ in a 1:3 ratio based on the metal analysis of Fe(III) in the layer-by-layer thin film $Fe(8HQ)_3$ complex. The same observation of concentration independence can be also assigned in this case.

Electron impact-mass spectra (EI-MS) were also acquired to confirm the molecular masses of all the metal quinolate complexes. The collected spectra of the metal complexes were library searched for the best possible fit. The EI-MS of the $Cu(8HQ)_2$ complex, shown in Fig. 7(i), was found to exhibit a few characteristic ion peaks. A molecular ion peak at m/z 351 (rel. int. = 75%) was detected assuming ^{63}Cu as the most abundant copper isotope. The base peak in the EI-MS of the $Cu(8HQ)_2$ complex, m/z 207, is related to a loss of 144 amu as the deprotonated 8HQ ligand from the molecular ion peak. Some other fragment ion peaks were characterized in the EI-MS of the $Cu(8HQ)_2$ complex and these are directly related to direct and possible successive losses from the ligand ion. These ion peaks were identified at m/z 145, 117, 89 and 63, with relative abundances of 35%, 20%, 23% and 40%, respectively. The library search for the acquired EI-MS of the $Cu(8HQ)_2$ complex was found to strongly fit with the stored mass spectra of the copper 8-hydroxyquinoline complex.

Similar EI-MS of $Co(8HQ)_2$, $Ni(8HQ)_2$ and $Zn(8HQ)_2$ to that of $Cu(8HQ)_2$ were characterized. The molecular ion peaks of these metal quinolate complexes were characterized at m/z 347 (rel. int. = 100%), 346 (rel. int. = 35%) and 352 (rel. int. = 95%) assuming ^{59}Co, ^{58}Ni, ^{64}Zn as the most abundant isotopes of cobalt, nickel and zinc, respectively. These metal quinolate complexes were found to exhibit a loss of 144 amu, for the deprotonated 8HQ ligand, from the molecular ion peak, similar to $Cu(8HQ)_2$. In addition, the same characteristic ion peaks that are derived from 8HQ at m/z 145, 117, 89 and 63 are evident in the EI-MS of these metal complexes, as represented in Fig. 7(ii)–(iv).

The EI-MS of $Fe(8HQ)_3$ exhibited a molecular ion peak at m/z 488 (rel. int. = 20%). Two successive losses of 144 amu were identified and characterized in the mass spectrum of $Fe(8HQ)_3$ due to elimination of two deprotonated 8HQ ligand molecules from the molecular ion peak. These two fragment ion peaks are recorded at m/z 344 (rel. int. = 100%) and 200 (rel. int. = 40%). Fragment ion peaks at m/z 145, 117, 89 and 63 were also characterized in the EI-MS of the $Fe(8HQ)_3$ complex based on fragmentation parts of 8HQ as described above for $Cu(8HQ)_2$, $Co(8HQ)_2$, $Ni(8HQ)_2$ and $Zn(8HQ)_2$. The EI-MS of the $Fe(8HQ)_3$ complex is shown in Fig. 7(v).

3.3. FT-IR and UV–Vis spectrophotometric analysis of thin film metal 8HQ complexes

The FT-IR spectrum of 8HQ exhibited characteristic absorption peaks for ν(C=N) and ν(OH). In the FT-IR spectra of the five thin film complexes, the absorption peak ν(OH) disappeared with deprotonation of the H-atom of $C_{8\text{-OH}}$ while the ν(C=N) was shifted, indicating that coordination of 8HQ to the various metal ions has taken place via the nitrogen atom of the imine group and oxygen atom of the $C_{8\text{-OH}}$ group, consistent with the results outlined in Section 3.2. A comparison of the FT-IR spectra with

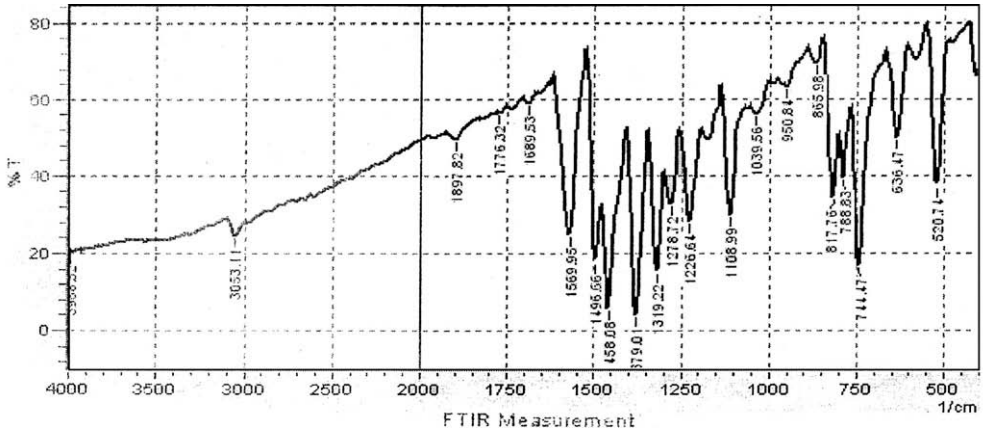

Fig. 8. FT-IR of Cu(II)–quinolate complex.

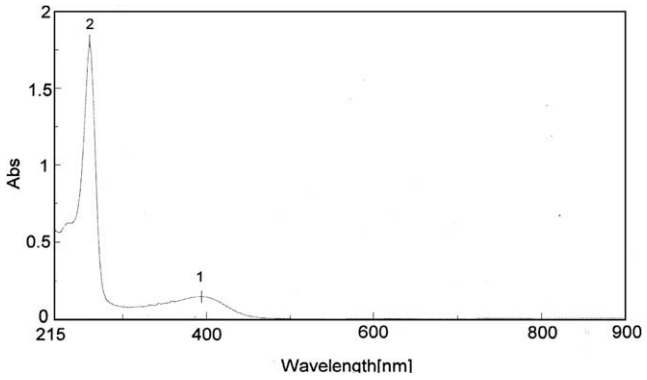

Fig. 9. UV–Vis of Cu(II)–quinolate complex in ethanol.

the molar stoichiometric ratio, metal analysis data and the EI-MS of the metal complexes revealed that 8HQ is behaving as a monobasic bidentate ligand in the process of layer-by-layer thin film formation of all the tested complexes. The metal ions are coordinated through two N,O metal-chelate rings in the case of Co(II), Ni(II), Cu(II) and Zn(II), indicating that these complexes have similar structures, and three N,O metal-chelate rings in $Fe(8HQ)_3$, proving the structure assigned for these thin film complexes by the stoichiometric metal analysis and the EI-MS. Fig. 8 is given as a representative FT-IR spectrum of the Cu(II)-8-hydroxyquinolate complex and the FT-IR assignments of the major peaks are given in Table 2.

The UV–Vis electronic spectra of the layer-by-layer thin film of metal quinolate complexes were also studied and proved to exhibit characteristic d–d transition bands. This band was centered at a wavelength of ~381 nm, with a shoulder band at ~433 nm, for the $Co(8HQ)_2$ complex. The $Zn(8HQ)_2$ complex showed a d–d transition band centered at a wavelength of ~371 nm with a shoulder band at ~427 nm. The d–d transition bands of the $Ni(8HQ)_2$ complex were centered at a wavelength of ~386 nm with a shoulder band at ~427 nm. The $Cu(8HQ)_2$ complex showed d-d transition bands at a wavelength of ~391 nm and two shoulder bands at ~235 and 427 nm. Finally, the $Fe(8HQ)_3$ complex exhibited three d–d transition bands centered at ~363, 461 and 578 nm. Fig. 9 shows a representative UV–Vis spectrum for the Cu(II)–8-hydroxyquinolate complex.

3.4. Thermal gravimetric analysis of the metal 8HQ complexes

Thermal gravimetric analysis of the layer-by-layer synthesized thin film metal quinolate complexes was performed and the thermal parameters are compiled in Table 3. Several thermal degradation steps were identified and are mainly due to the direct decomposition of 8HQ from the metal complexes. The $Co(8HQ)_2$ and $Zn(8HQ)_2$ complexes showed three possible degradation steps, with the final stable product expected to be the metal oxide at $\geqslant$985 K and $\geqslant$965 K, respectively. $Cu(8HQ)_2$ was found to decompose via two degradation steps in the temperature ranges 586–701 K and 765–977 K, due to the possible loss of 8HQ from the complex. The final product formed from the $Cu(8HQ)_2$ complex is also expected to be the metal oxide species at a temperature $\geqslant$977 K. On the other hand, $Ni(8HQ)_2$ and $Fe(8HQ)_2$ were characterized by their thermal gravimetric decomposition via four various degradation steps. These steps also refer to the direct decomposition of the bound 8HQ molecule from these two metal quinolate complexes, leaving the corresponding metal oxide at temperatures $\geqslant$919 K and $\geqslant$1018 K for the $Ni(8HQ)_2$ and $Fe(8HQ)_2$ complexes, respectively. The assigned temperature range of the metal oxide formations is very important if the study of the optical or electric applications of these layer-by-layer thin films of nano-sized particles is targeted, as previously reported for similar oxides [8–10].

4. Conclusion

The outlined results in this work directly refer to the suitability and applicability of the layer-by-layer chemical dipping method as a simple, efficient, low cost and rapid technique for the formation of nano-sized metal 8-hydroxyquinolinate complexes based on crystal growth and thin film formation. The reaction between the metal ion and 8HQ is very fast and a uniform thin film can be observed after only a few dipping cycles. The stoichiometry of the metal quinolate thin film is complete regardless of the concentration of these two interacting species. In addition, the assigned temperature for metal oxide formation is another dimension in this work owing to the possible extension of the presented method for such thin film oxide formation by simply annealing the metal complexes.

Several factors are considered to be of great importance upon application of the layer-by-layer thin film formation of metal complexes that must be explored in order to identify the optimum conditions and generalize the presented method for the formation of nano-sized metal complexes. These include the effect of (i) metal and ligand concentration on the stoichiometry of the metal complex and the particle size, (ii) number of dipping cycles on the particle size, (iii) immersion time on the particle size, (iv) pH of the metal and ligand solutions on the complex formation and (v) sol-

ABSTRACT

The 2,2′-bipyrimidine (bpm) adducts of the β-diketonate complexes of Eu(III), Sm(III), or Yb(III) with 2,2′,6,6′-tetramethyl-2,4-heptanedione (tmhd) resulted in the formation of dinuclear species. The synthesis and X-ray structure of these three new dinuclear lanthanide complexes are found to be similar. Each lanthanide ion is eight coordinate, bound to six O-atoms from the β-diketonates and 2N atoms from the bridging bpm ligand. They exhibit Ln–Ln distances (Sm(III): 6.935 Å, Eu(III): 6.901 Å, Yb(III): 6.679 Å) and Ln–ligand distances that are consistent with the decrease in radii across the lanthanide series. Absorption spectra of the complexes are dominated by ligand absorptions. Both the solution and solid state emission spectra of the complexes resemble ordinary monomeric lanthanide species, indicating independent ions in the dinuclear species. Cyclic voltammetry of all the complexes appear almost identical with discernable ligand centered redox reactions. The complex with Eu(III) ions, having the lowest possible lanthanide redox potential, was not found to display a signal corresponding to metal reduction.

1. Introduction

Many intriguing fundamental properties of the f-electron compounds arise from their electronic structure which leads to broad applications. The lanthanide (Ln) elements have been exploited for such commercial uses as lasers, phosphors, luminescent biological probes, MRI contrast reagents, NMR shift reagents, magnets, and medicines [1–3]. In addition, it is important to note the utilization of 4f electron compounds for magnetic materials and their potential use as high temperature superconductors [4]. The development of these and other Ln technologies is dependent on the elucidation of fundamental Ln properties, such as electronic and magnetic interactions. Electronic and magnetic inter-ion communications have been noted between Ln ions of a common oxidation state in dinuclear complexes [5,6], as well as extended solids in superconductors, lasers, and phosphors [4,7,8]. We are interested in generating dinuclear lanthanide complexes with bridging ligands that allow possible communication between lanthanide elements and thus provide insight into electron interactions in these f-electron ions. Elucidation of f-electron interactions can foster further development of Ln technologies [4].

Synthesizing dinuclear or polynuclear species with lanthanide ions is challenging due to the cationic repulsions. Coordination chemistry of the lanthanides is driven by ionic interactions between the ligands and the generally trivalent Ln ions. Furthermore, lanthanides typically adopt high coordination numbers and coordination geometries are heavily influenced by sterics [9]. The use of chelating ligands and hard donor atoms is important for generating stable complexes of the Ln ions.

The 2,2′-bipyrimidine (bpm) ligand has been used successfully in numerous transition metal complexes to bridge metal ions and functions as a channel for energy and electron transfer [10–16]. Bpm has also been used to form heterodinuclear metal complexes between Ln and transition metals [17–19]. In these studies, energy transfer was found to occur efficiently between the transition metal and the lanthanide ion [17]. Finally, there have been a few recent reports of crystallographically characterized dinuclear lanthanide complexes with bpm as the bridge [20–23]. Interestingly, there are still few examples of these dinuclear lanthanide species, and many complexes form mononuclear rather than the desired dinuclear structure.

We report the successful synthesis of more examples of dinuclear β-diketonate adducts of lanthanide complexes using bpm as the bridging ligand. Complexes of Eu(III), Sm(III), and Yb(III) ions with the β-diketone 2,2′,6,6′-tetramethyl-2,4-heptanedione (tmhd) were formed. The β-diketone was chosen to ensure complex solubility in organic solvents, a problem found with at least one β-diketonate complex [24]. Also, the higher electron donating ability of the β-diketone *tert*-butyl groups was hypothesized to encourage the formation of dinuclear complexes.

2. Experimental

2.1. Materials

Solvents and reagents were of commercial grade and used without further purification. Hexahydrates of the lanthanide chloride salts (Eu(III), Sm(III), and Yb(III)), 2,2′,6,6′-tetramethyl-2,4-heptanedione (tmhd) and 2,2′-bipyrimidine (bpm) were obtained from Strem Chemicals, ACROS, and Aldrich, respectively, without further purification. Elemental analysis data were collected by Atlantic Microlabs, Norcross, GA. bpm: IR (KBr): $\nu\sim$ = 508, 637, 668, 686, 766, 819, 986, 1097, 1140(m), 1194(w), 1237(w), 1257(w), 1406(s), 1433(w), 1557(s), 1653(m), 2973(w), 3027(w), 3060(w), 3126(w), 3436(br) cm^{-1}.

2.2. Synthesis

Powders of the dinuclear lanthanide complexes were all obtained by the same method of mixing Ln(III), bpm and β-diketone in ratios of 2:1:6, as described below. Sodium hydroxide in distilled and deionized water (8.4 mL of 0.0974 M solution, 0.82 mmol) was added drop-wise with stirring to a solution of absolute ethanol (7.1 mL), bpm (0.136 mmol) and tmhd (0.82 mmol) at room temperature (21 °C) in a 25 mL Erlenmeyer flask. The resulting solution was clear. A 3 mL solution of $LnCl_3 \cdot 6H_2O$ in absolute ethanol (0.272 mmol) was added a drop at a time with stirring every 1–2 min over the course of 45 min. With the first drop of Ln(III) salt solution, the solution became cloudy. A light-yellow colored precipitate formed upon further addition of metal. After the final drop of Ln(III) salt solution was added, the cloudy mixture was allowed to stir for another 30 min at room temperature. The light yellow precipitate was collected by filtration through a fine porcelain fritted funnel. The powder was washed with ~10 mL of cold absolute ethanol, dried under vacuum for 12–16 h, and weighed to determine yields. The powdered samples were further purified by dissolution in a minimum volume of room temperature $CHCl_3$ (~3 mL), immediately filtered to remove insoluble particulates with a fine-fritted porcelain funnel, and then re-precipitated by the addition of cold absolute ethanol (~10 mL). The precipitated solution was again filtered with a fine porcelain fritted funnel and dried under vacuum for 12–16 h. For all three Ln (Eu(III), Sm(III), and Yb(III)), diffraction quality crystals were formed by dissolving the complex in $CHCl_3$ with various amounts of CH_3OH as a precipitating co-solvent (from 1:1 to 1:10 $CHCl_3$:CH_3OH by volume). All solutions were clear initially and crystals formed in 1 to 10 days by allowing slow evaporation. Crystals removed from the mother liquor turned from clear and colorless to opaque over the course of 2–4 days. For this reason, crystals were left in solution until immediately before X-ray diffraction analysis or luminescence studies, whereupon they were quickly frozen in liquid nitrogen.

2.2.1. $[Eu(tmhd)_3]_2bpm$ (**1**)

A pale yellow powder was obtained in 91% average yield. Powder M.P.: 300 °C, crystal M.P.: 290 °C. Powder *Anal.* Calc. for $C_{74}H_{120}N_4O_{12}Eu_2$: C, 56.91; H, 7.75; N, 3.59. Found: C, 56.63; H, 7.65; N, 3.57%. IR (KBr): $\nu\sim$ = 474, 603, 659, 736, 758, 792, 815, 869, 961, 1020, 1065, 1139(m), 1181, 1226, 1246, 1284, 1359(s), 1388(sh), 1419(s), 1453(s), 1506(s), 1540(s), 1576(br), 2866(m), 2962(s) cm^{-1}.

2.2.2. $[Sm(tmhd)_3]_2bpm$ (**2**)

A pale yellow powder was obtained in 81% average yield. Powder M.P.: 306 °C, crystal M.P.: 303 °C. Powder *Anal.* Calc. for $C_{74}H_{120}N_4O_{12}Sm_2$: C, 57.03; H, 7.76; N, 3.59. Found: C, 57.15; H, 7.73; N, 3.42%. IR (KBr): $\nu\sim$ = 474, 602, 659, 735, 759, 793, 815, 868, 960, 1020, 1065, 1139(m), 1182, 1227, 1246, 1277, 1358(s), 1388(sh), 1418(s), 1452, 1506(s), 1539(s), 1575(br), 2866(m) 2954(s) cm^{-1}.

2.2.3. $[Yb(tmhd)_3]_2bpm$ (**3**)

A pale yellow powder was obtained in 78% average yield. Powder M.P.: 305 °C, crystal M.P.: 305 °C. Powder *Anal.* Calc. for $C_{74}H_{120}N_4O_{12}Yb_2$: C, 55.42; H, 7.54; N, 3.49. Found: C, 55.21; H, 7.49; N, 3.43%. IR (KBr): $\nu\sim$ = 478, 605, 662, 737, 758, 792, 816, 870, 963, 1023, 1065, 1143(s), 1182, 1228, 1246, 1286, 1358(s), 1388(sh), 1430(s), 1455(s), 1508(s), 1540(s), 1580(br), 2866(m), 2954(s) cm^{-1}.

2.3. Methods

UV–Vis absorption spectra were recorded on a Shimadzu UV2401 PC UV–Vis recording spectrophotometer at room temperature. Purified powder samples were run in $CHCl_3$ solution with 1 cm quartz cuvettes. Solution fluorescence spectra and emission decay curves were obtained with a Cary Eclipse Fluorescence Spectrophotometer equipped with a Cary Peltier temperature controller. Purified powder samples were run in $CHCl_3$ solution with 1 cm quartz cuvettes with excitation and emission slit widths of 5 nm. Solid state fluorescence data was recorded with a McPherson RS-10 spectrophotometer. Crystals of the complexes were placed in a 3 mm i.d. quartz tube and immersed in liquid N_2 held in a Wilmad quartz cold finger Dewar flask. The excitation source was the 365 nm line from a 100 W Osram mercury vapor lamp, selected by a glass filter. The spectrophotometer was calibrated before use with Hg emission lines. Electrochemistry measurements were obtained using a CH-Instruments 620B electrochemical analyzer with faraday cage. The working electrode was a 3 mm diameter glassy carbon disk purchased from CH-Instruments. The reference electrode was a Ag/AgCl electrode made with the same solvent and supporting electrolyte as the sample. Furthermore, ferrocene was added to each sample after initial data collection as an internal reference and displayed a midpoint potential of +0.750 V versus our Ag/AgCl electrode in DMF with 0.02 M tetrabutylammonium hexafluorophosphate ($TBAPF_6$). Purified powder samples and crystals of the homodinuclear complexes were dissolved in DMF solvent at 1 mM concentration with 0.02 M $TBAPF_6$ as supporting electrolyte. Solutions were added to a 2 mL cell with a Pt counter electrode, the reference electrode, and the working electrode. Anhydrous (<5 ppm H_2O) and degassed DMF was used and the sample was continuously bubbled with Argon during sample measurement. IR spectra were obtained on KBr pellets of purified powder samples with a Perkin Elmer Spectrum RX FT-IR spectrophotometer.

2.4. X-ray analysis

Single-crystal determinations were carried out using a Bruker SMART Apex II diffractometer using graphite-monochromated Cu Kα radiation [25]. The data were corrected for Lorentz and polarization [26] effects and absorption using SADABS [27]. The structures were solved by use of direct methods or Patterson map. Least squares refinement on F^2 was used for all reflections. Structure solution, refinement, and the calculation of derived results were performed using the SHELXTL [28] software package. The non-hydrogen atoms were refined anisotropically. The hydrogen atoms were located and then placed in theoretical positions. Images of molecular structures were created using ORTEP III [29].

3. Results and discussion

3.1. Synthesis

The Ln complexes were synthesized by mixing solutions of the lanthanide chloride salts of Eu(III), Sm(III), or Yb(III) with the β-diketonate and bpm in a 2:6:1 molar proportion. Precipitates

formed immediately and the resulting light-yellow powders were obtained in good yield. Elemental analyses of the powders indicated that the isolated complexes were dinuclear. These results parallel those of others [21,23], and represent a general way of synthesizing dinuclear lanthanide complexes with bridging bpm. This procedure differs slightly from an alternative procedure used to make dimers where bpm displaces water ligands of preformed mononuclear lanthanide(III) tris(β-diketonate) hydrates through ligand displacement reactions [20].

There are instances however where dinuclear species do not form and only mononuclear β-diketonate species assemble [30,31], or cases that go beyond the formation of dinuclear complexes with the formation of linear polymers of repeating Ln–bpm units [32,33]. The larger lanthanide ions have been observed to tend toward mononuclear complexes [21,24,30]. It is also apparent that the nature of the β-diketone makes a significant difference. β-diketones with groups capable of π–π interactions have been observed in crystal structures to stabilize dinuclear structures in the solid state by interacting above and below the bpm bridge [21–23].

The β-diketone tmhd was chosen for our studies based on the electron donating ability of *tert*-butyl groups versus other groups such as highly fluorinated alkyl groups. Tmhd was expected to encourage the formation of dinuclear complexes for two reasons. First, the greater charge neutralization of +3 lanthanide ions helps to minimize charge repulsions as the ions come in close proximity in the dimer. Second, the greater donating ability of the β-diketone allows less polarization of the bpm bridge and thus ensures the bpm can donate equally well from either side of the ligand. Stronger σ bonding on one side of bpm could withdraw charge density from the ligand and make the non-bonding electrons on the other side of bpm less available for complexation [31].

3.2. X-ray structures

Ready growth of X-ray quality crystals was accomplished from $CHCl_3$:CH_3OH solutions for all three lanthanide ions. The crystals were found to contain $CHCl_3$ solvent molecules trapped in the crystal lattice which evaporated over the course of days resulting in opaque crystals. For diffraction, crystals were removed from the mother liquor and quickly frozen in a cold stream of nitrogen to prevent solvent loss from the lattice.

All three crystallized lanthanide complexes were found to have dinuclear structures. The Eu(III) and Sm(III) structures were isomorphic, crystallizing in the chiral monoclinic $P2_1$ space group and having a single $CHCl_3$ solvate molecule. Both showed evidence of racemic twinning, with the Flack parameters being 0.503(2) and 0.121(2), respectively. The Yb(III) complex crystallized in the orthorhombic *Pbca* group with two $CHCl_3$ molecules in the lattice. Some minor rotational disorder was observed in the *tert*-butyl groups of the β-diketone ligand for all complexes. The Yb(III) complex contains a crystallographic center of symmetry at the bpm ligand. The crystal data (Table 1) and selected bond lengths and angles (Table 2) are reported for all three structures.

3.2.1. $[Eu(tmhd)_3]_2bpm$ (**1**) structure

The Eu complex crystallized as the dinuclear species bridged by a single bpm molecule (Fig. 1). In addition to the two Ln–N bonds to bpm, each Eu(III) center has six Ln–O bonds to three β-diketonate ligands. The resulting 8-coordinate structures adopt distorted square antiprismatic geometries for each Eu(III) ion, based on the method of Porai-Koshits and Aslanov (Table 3) [34]. The polyhedra exhibit slight distortion towards the bicapped trigonal prism. This coordination number and geometry is commonly found in many Ln(III) β-diketonate complexes [9]. The top square face of the antiprisms are defined by O1, O2, O3, O4 for Eu1 and N2,N4,O11,O12 for Eu2, with all four chelating rings spanning *s* edges [34]. Furthermore, the chelating ligands span *s* edges in a fashion such that the β-diketone ligands on either side of the bpm bridge are parallel and facing each other, thus minimizing steric conflicts. The average Eu–O distance is 2.339 Å, while the average Eu–N distance is 2.642 Å (Tables 2 and 4). Other reported dinuclear bpm bridged Eu(III) β-diketonate complexes exhibit very similar bond distance averages for Eu–O (2.355 [20], 2.354 [23], 2.370 [23], 2.343 [21], and 2.394 Å [21]) and Eu–N (2.610 [20], 2.609 [23], 2.646 [23], 2.677 [21], and 2.687 Å [21]). The Eu–Eu distance was found to be 6.901 Å, which is intermediate between other known bpm bridged Eu(III) dimers (6.8035 [23], 6.856 [20], 6.9212 [23], 6.993 [21], and 7.011 Å [21]).

It has been observed that the two rings of the bridging bpm ligand can be twisted from co-planarity in some complexes [21–23] while remaining co-planar in others [20,21,23]. Those complexes with co-planar bpm rings have crystallographic centers of symmetry centered on the bpm ligand. The two mean planes of

Table 4
Average Ln–O, Ln–N, and Ln–Ln bond lengths (Å) for complexes **1**, **2**, and **3**.

1		**2**		**3**	
Eu–O	2.339	Sm–O	2.350	Yb–O	2.263
Eu–N	2.642	Sm–N	2.658	Yb–N	2.542
Eu–Eu	6.901	Sm–Sm	6.935	Yb–Yb	6.679

the bridging bpm ligand in our complex were only slightly twisted from co-planarity by 0.63°. In addition, the bridging bpm ligand binds to each Eu(III) ion in a bidentate fashion, however each Eu(III) ion is not in the same plane as the bpm ligand. Eu1 and Eu2 bind to the bpm ligand above and below the mean plane defined by the bpm ligand by 0.518 and 0.373 Å, respectively. This results in a chair-like conformation for the six-membered ring defined by Eu1–N3–N4–Eu2–N2–N1 (Fig. 1).

3.2.2. $[Sm(tmhd)_3]_2$bpm (*2*) structure

The structure of **2** (Fig. 2) is largely similar to that of **1**. Both molecules crystallize in the same space group and contain a single solvent molecule. The Sm(III) ions are 8-coordinate with six Sm–O bonds to the three β-diketone ligands and two Sm–N bonds to the bridging bpm ligand. The geometry around each Sm(III) center is square antiprismatic with distortion towards a bicapped trigonal prism (Table 3) [34]. All chelating ligands span the *s* edges of the square antiprism. The angles defining the polyhedra are very similar to and parallel those of the complex **1**. The average Sm–O and Sm–N bond lengths are 2.350 and 2.658 Å, respectively (Table 2). Again, these are very similar to the average bond lengths for the Eu complex (Table 4). The slightly longer averages for the bond lengths in **2** however, are consistent with the well known decrease in ionic radii across the row. Finally, the Sm–Sm distance of 6.935 Å is longer than that in complex **1**.

The binding of the bridging bpm ligand is very similar between complexes **2** and **1**. The rings of the bpm ligand in **2** are slightly offset from co-planarity by 0.34°. Also, the Sm atoms are bound to the bpm ligand slightly above and below the plane defined by the bpm rings (Sm1: 0.527 Å, Sm2: 0.373 Å), creating a chair-like conformation. To our knowledge, there are no other published structures of dinuclear Sm(III) complexes with bridging bpm however this structure is not believed to be unusual due to its high similarity to the other known dinuclear complexes.

3.2.3. $[Yb(tmhd)_3]_2$bpm (*3*) structure

Complex **3** (Fig. 3) crystallizes in a different crystal system than the other dinuclear complexes reported here even though it has a similar ligand set and structure. The complex contains a crystallographic inversion center located at the center of the bridging bpm ligand and thus only half of the dimer is crystallographically independent. The Yb(III) center is a distorted square antiprism (Table 3) with six β-diketonate O atoms and two bpm N atoms chelating the *s* edges [34]. The average Yb–O and Yb–N bond distances are 2.263 and 2.542 Å, respectively. These distances are shorter than both **1** and **2** as expected from the contraction in radii across the

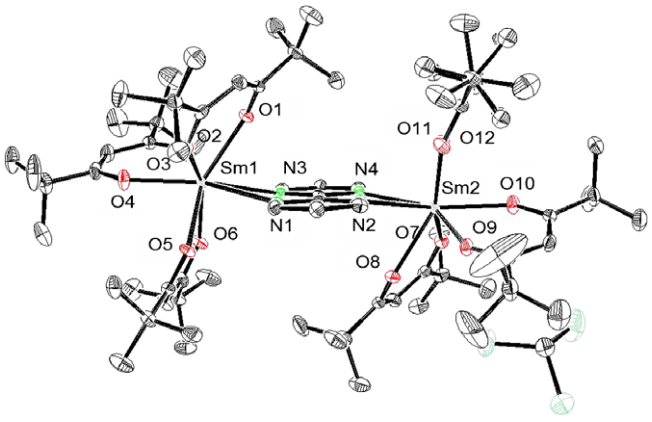

Fig. 2. Structure of $[Sm(tmhd)_3]_2$bpm, **2**. Thermal ellipsoids are shown at the 50% level.

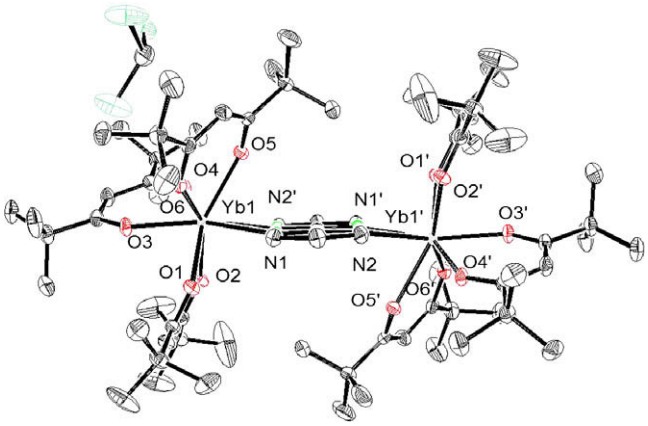

Fig. 3. Structure of $[Yb(tmhd)_3]_2$bpm, **3**. Thermal ellipsoids are shown at the 50% level.

lanthanide series. In addition, the Yb–Yb distance of 6.679 Å is shorter than in **1** and **2**. As required by symmetry, the bpm ligand is perfectly planar. However, the Yb(III) ions are coordinated to bpm 0.339 Å above and below the plane defined by bpm, resulting in the similar chair-like conformation seen with complexes **1** and **2**.

3.3. Absorbance and Luminescence spectroscopy

The UV–Vis absorption spectra of the complexes in $CHCl_3$ solution are dominated by the absorption of the β-diketonate and bpm ligands (Fig. 4). The spectra of all complexes are similar and have maxima around 280 nm. They exhibit higher energy absorption peaks and slightly smaller intensities than those observed in complexes utilizing aromatic side groups on the β-diketone ligands [21,23,30].

Solution luminescence spectra of the complexes in $CHCl_3$, with excitation into the 280 nm absorption band, result in spectra typical of the individual lanthanide ions (Fig. 5). The red-colored emission from the Eu(III) $^5D_0$ to the $^7F_0$, $^7F_1$, $^7F_2$, $^7F_3$, and $^7F_4$ states are observed near 580, 590, 612, 655, and 705 nm, respectively

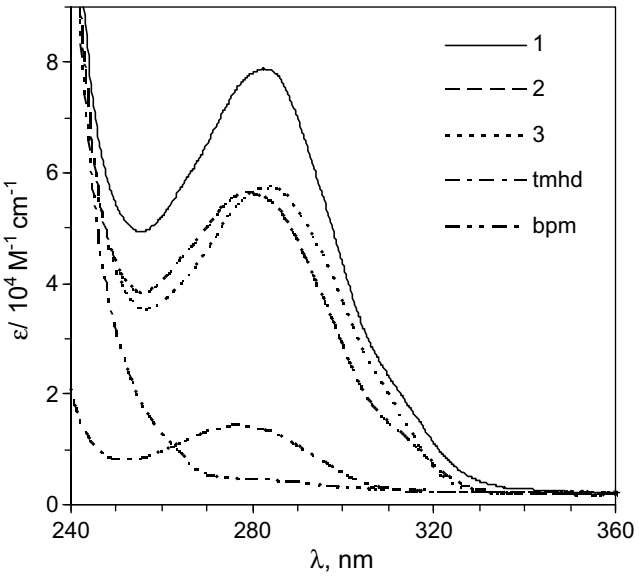

Fig. 4. The UV–Vis absorption spectra of 20 μM solutions of **1**, **2**, **3**, tmhd, and bpm in $CHCl_3$ at 22 °C.

(Fig. 5a). Lifetime measurements (data not shown) at 25 °C was fit closely with a first order, single exponential decay curve with rate constant value of 2.265 ms^{-1}. This decay rate constant is comparable to other mononuclear Eu(III) species as well as the few known dinuclear ones [23] when they are dissolved in solution. The Sm(III) complex, **2**, has four major emission peaks at 568, 607, 649, and 715 nm corresponding to transitions between its $^4G_{5/2} \rightarrow {}^6H_{5/2-11/2}$ levels (Fig. 5b) [35,36]. The NIR emissions from the Yb(III) ions $^2F_{5/2} \rightarrow {}^2F_{7/2}$ transitions [37] were not found, possibly due to inefficient energy transfer from ligand to metal. The emission peaks observed in **1** and **2** are similar to others observed from solutions of dissolved monomeric [35,37,38] and dimeric [36] complexes indicating that the bpm ligand has no significant effect on the luminescence. Furthermore, the labile nature in general of lanthanide coordination complexes precludes the conclusion that

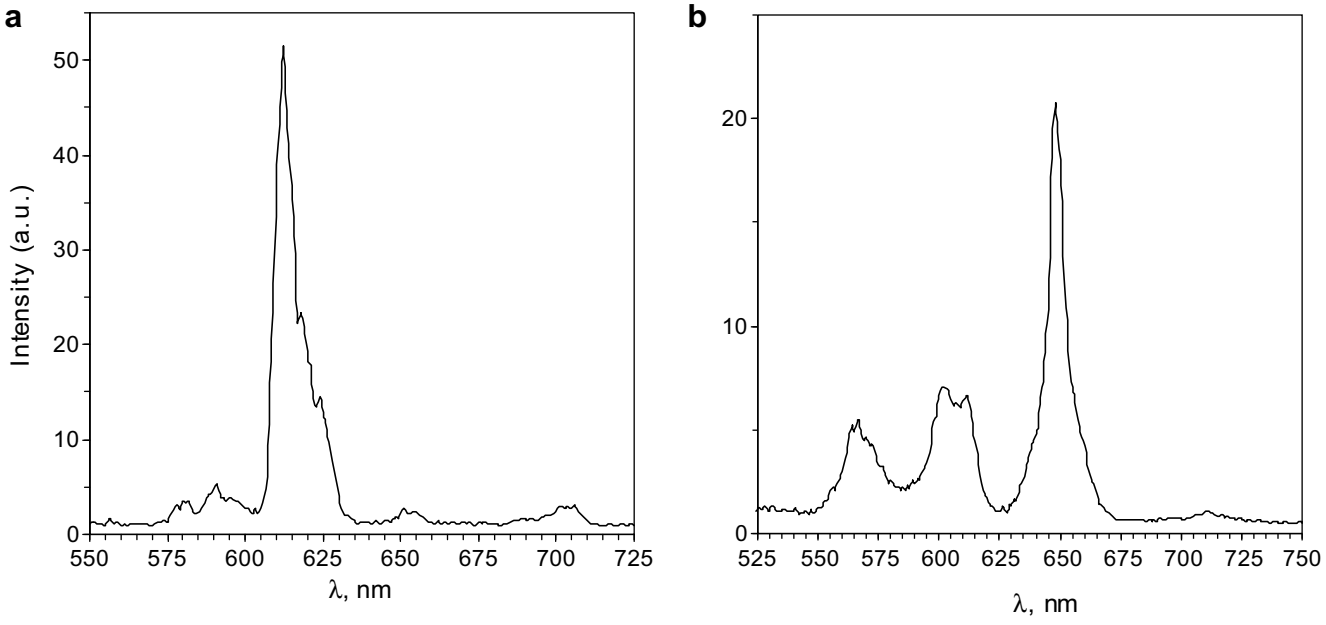

Fig. 5. The solution state luminescence spectra of *ca.* 20 μM solutions of (a) **1** and (b) **2** in $CHCl_3$.

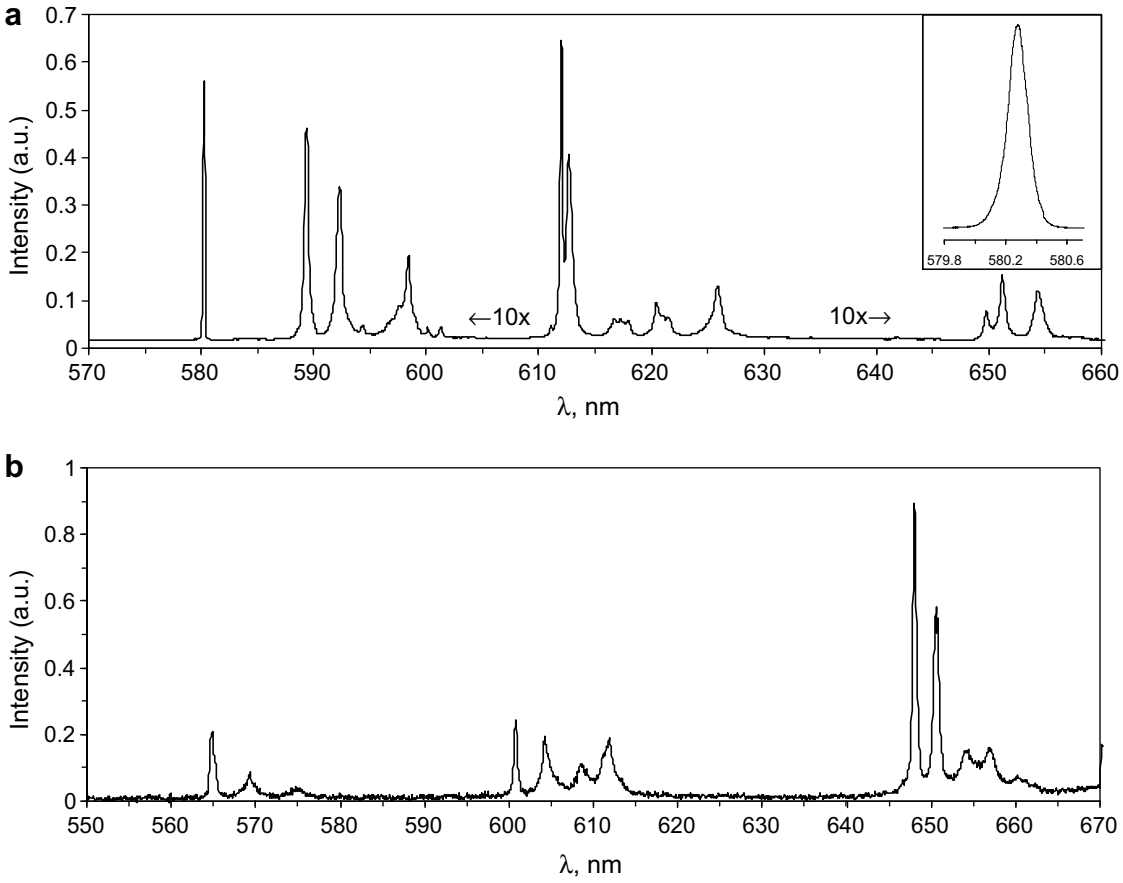

Fig. 6. The emission spectra for crystals of (a) **1** (inset view of the $^5D_0 \rightarrow {}^7F_0$ transition) and (b) **2** at 77 K.

dissolving dinuclear complexes in solution necessarily results in dinuclear solution species.

The solid state emission spectrum of crystals of **1** displays very sharp peaks for the $^5D_0$ to $^7F_{0-3}$ transitions (Fig. 6). The singly degenerate $^5D_0 \rightarrow {}^7F_0$ transition should have one peak for each Eu(III) center. The crystal structure indicates two different Eu centers, however the spectrum of the sample shows only one peak at 580.3 nm implying that both Eu(III) centers are located in similar ligand environments (Fig. 6, inset). Examination of the $^5D_0 \rightarrow {}^7F_0$ peak does reveal a small shoulder on the low energy side. The different Eu(III) environments must be similar enough to result in unresolved emission lines. The transitions from $^5D_0$ to the $^7F_{1\text{-}3}$ manifolds appear around 590, 615, and 650 nm, respectively. The clear splitting of these manifolds into their Stark components suggests low symmetry of the Eu(III) centers and is consistent with the structure. Crystals of the Sm(III) complex, **2**, gave similar results. Three major emission manifolds beginning near 565, 600, and 648 nm corresponding to transitions between its $^4G_{5/2} \rightarrow {}^6H_{5/2-11/2}$ levels (Fig. 5b). The NIR emissions from the Yb(III) ions were outside the range of our instrument.

3.4. Electrochemistry

The cyclic voltammograms of complexes **1**, **2**, and **3** in DMF solution are illustrated in Fig. 7. Three irreversible reduction waves are observed for each complex, with cathodic peak potentials *ca.* $E_{pc} = -1.24$, -1.5, and -2.0 V. To elucidate the origin of these peaks, we also studied cyclic voltammograms of solutions of 2,2′-bipyrimidine or deprotonated β-diketone with various molar equivalents Eu(III), Sm(III), and Yb(III) chloride (data not shown). It is interesting that complexes **1**, **2**, and **3** all yield very similar voltammograms. The peaks present in these data arise from the ligands, and no metal centered redox processes are apparent. The cathodic peaks at -1.24 and -1.5 V in complexes **1**, **2**, and **3** corresponds to bpm ligand reductions, which are shifted to more positive potentials relative to the free bpm (-1.64 V). Our studies

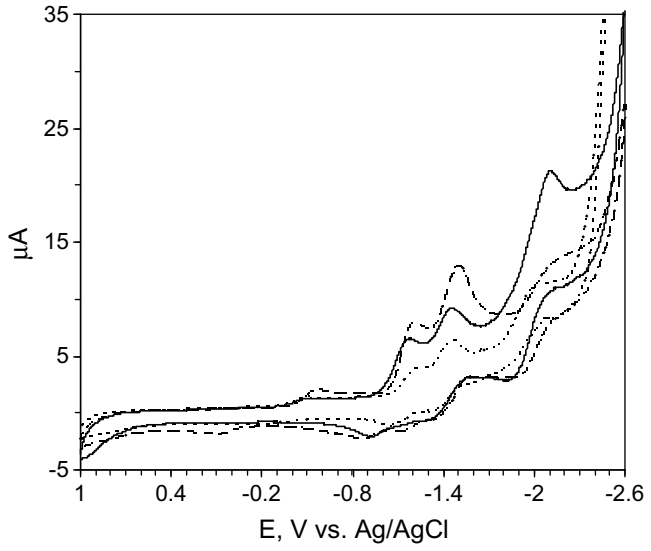

Fig. 7. Cyclic voltammograms for DMF solutions of 1 mM **1** (—), **2** (·····), and **3** (- - - -). All samples contain 0.02 M $TBAPF_6$ as electrolyte.

suggest that the peak at −1.24 V arises from the bpm ligand and not from the Eu(III) center [30]. All three of our complexes display this cathodic peak at ∼ −1.24 V and it is unlikely that all lanthanide centers are reduced here, given that the reported reduction potentials for ions of Eu(III) (−0.34 V versus NHE), Yb(III) (−1.05 V) and Sm(III) (−1.55 V) span more than a volt [3]. Furthermore, both of these peaks are present in the same ratio in solutions of bpm with 1–10 equiv. of added $LnCl_3$ and likely represent coordinated bpm reductions. The peak at −2.0 V in the complexes arises from the β-diketonate with a small contribution from the bpm ligand. Both bpm with $LnCl_3$ and the mixture of deprotonated tmhd with $LnCl_3$ were found to display peaks near −2.0 V.

4. Conclusions

We report the structures and spectroscopic properties of three new dinuclear lanthanide complexes using Sm(III), Eu(III), and Yb(III). The three β-diketonate complexes successfully assemble in the solid state as dimeric species through a bridging 2,2′-bipyrimidine ligand. The lanthanide ions are all 8-coordinate with square antiprismatic geometries, typical of such complexes. In addition, the fluorescence of the complexes in solution exhibits behavior similar to solutions of other known mononuclear and dinuclear complexes. The solid state fluorescence spectrum of the dinuclear Eu(III) complex indicates a single Eu(III) environment. Finally, cyclic voltammograms of the species in solution were dominated by cathodic peaks corresponding to ligand centered reductions and no peaks corresponding to the lanthanide ions were apparent. All the characterizations were consistent with independent lanthanide ions in the dimer and the bridging bpm ligand did not provide sufficient means for fostering M–M interactions.

Acknowledgments

The authors are grateful to the Research Corporation (Grant No. CC6396) for financially supporting this research and providing M.H.B with a summer stipend. M.H.B. and S.M.B. would like to thank the Swenson Family Foundation and UMD for a summer stipend and research support. J.D.D. thanks the UMD Department of Chemistry for the Moses Passer Fellowship. ABSTRACT

The ligand N^2-[bis(benzylsulfanyl)methylene]-2-methoxybenzohydrazide (N^2-bmbh) (**1**) on reaction with $CuCl_2.2H_2O$ yielded the mononuclear complex $[Cu(bzsmp)_2Cl_2]$ (**2**) (2-benzylsulfanyl-5-(2-methoxyphenyl)-1,3,4-oxadiazole, bzsmp). Complex **2** has been characterized by analytical, spectroscopic and X-ray data. X-ray study of **2** reveals that the cyclized ligand 2-benzylsulfanyl-5-(2-methoxyphenyl)-1,3,4-oxadiazole (bzsmp) acts as neutral bidentate ligand to form six membered chelate ring and the presence of C–H···π (face to edge) and C–H···S and two type of C–H···Cl weak interactions.

1. Introduction

The 1,3,4-oxadiazoles have found applications in several areas [1,2] such as anti tuberculostatic, anti-inflammatory, analgesic, antipyretic, anticonvulsant and medicine [3–6]. The syntheses of this type of heterocyclic compounds have attracted considerable attention and a number of methods have been used for their syntheses [7–9]. The widely used strategy involves the dehydrative cyclization of diacylhydrazides usually with strong acids [10–13]. The cyclization of potassium salt of 3-benzoyldithiocarbazate into the corresponding 5-phenyl-1,3,4-oxadiazole-2-thiol was first reported by Hoggarth [14]. The cyclization of 3-acyldithiocarbazates esters, N-aroyldithiocarbazates and their salts to 1,3,4-oxadiazoles in the presence of a base is also reported in the literature [15–18]. Several other methods are reported for the synthesis of oxadiazoles from acyclic precursor which includes oxidative cyclization of acylhydrazones [19], acylthiourea [20–22] and acylthiosemicarbazides [23–26]. Platinum assisted cyclization of S-methyl 3-acyl-2-methyldithiocarbazates under mild conditions was reported by Bergamini and co-workers [27]. Earlier we have reported the metal assisted cyclization of N-benzoyldithiocarbazate to 5-phenyl-1,3,4-oxadiazole-2-thiol and potassium[N′-(pyridine-3-carbonyl) hydrazine to 5-(3-pyridyl)-1,3,4-oxadiazole-2-thione in the presence of an excess ethylenediamine (en) [28,29]. A few papers are available on the syntheses and X-ray studies of [bis(benzylsulfanyl)methylene]-2-acidhydrazide [30,31] and (benzylsulfanyl)-1,3,4-oxadiazole [32,33], but for the first time we report here the metal complex of 2-benzylsulfanyl-5-(2-methoxyphenyl)-1,3,4-oxadiazole obtained from the cyclization of N^2-[bis(benzylsulfanyl)methylene]benzohydrazide (N^2-Hbmbh) during complexation. The cyclization of N^2-Hbmbh to 2-benzylsulfanyl-5-(2-methoxyphenyl)-1,3,4-oxadiazole has been performed under normal condition without the use of any other reagents viz. base or acid as already described in the case of other oxadiazoles. The spectroscopic and single crystal X-ray studies of the resulting Cu(II) complex obtained by the reaction of Cu(II)chloride and N^2-[bis(benzylsulfanyl)methylene]-2-methoxy-benzohydrazide [N^2-Hbmbh] is reported in the present paper.

2. Experimental

2.1. Materials and methods

Commercial reagents were used without further purification and all experiments were carried out in open atmosphere. Methyl 2-methoxy benzoate (Sigma Aldrich, USA) and hydrazine hydrate (S.D. Fine Chemicals, India) were used as such. All solvents were purchased from Merck Chemicals, India and used after purification.

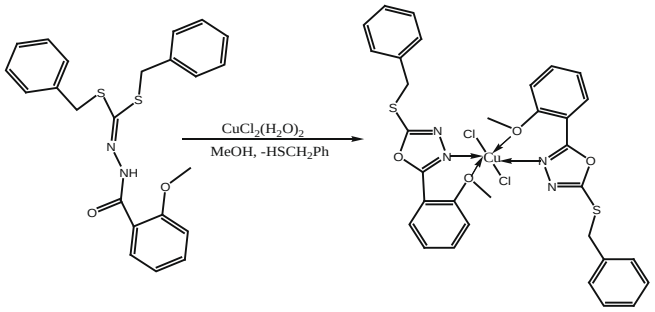
2.2. Preparation of the ligand N^2-Hbmbh (**1**)

The ligand N^2-Hbmbh was synthesized as described previously [30].

2.3. Preparation of the complex $[Cu(bzsmp)_2Cl_2]$ (**2**)

A solution of N^2-Hbmbh (**1**) (2 mmol) in MeOH (15 ml) was added to a solution of $CuCl_2 \cdot 2H_2O$ (1 mmol) in 10 ml of MeOH and the mixture was stirred for 2 h at room temperature. The resulting green color solution was filtered off and kept for crystallization. Green Crystals of **2** suitable for X-ray analyses were obtained by slow evaporation of its methanolic solution over a period of 21 days. Yield 64%; m.p. 145 °C. *Anal.* Calc. for $C_{32}H_{28}N_4CuO_4S_2Cl_2$ (731.17): C, 52.57; H, 3.86; N, 7.66. Found: C, 52.42; H, 4.12; N, 7.60%. I.R. data (ν cm^{-1} KBr) ν(C=N) 1603 s; ν(C–O–C) 1254 w; ν(N–N) 1133 s; ν(C–S) 869 m; $\nu(CH_2)$ 2979; ν(Cu–N) 478, ν(Cu–O) 420, ν(Cu–Cl) 325.

2.4. Physical measurements



Carbon, hydrogen and nitrogen contents were estimated on a CHN Analyser Model CE-440. Magnetic susceptibility measurement was performed at room temperature on a Cahn Faraday balance using $Hg[Co(NCS)_4]$ as the calibrant and electronic spectra were recorded on UV-1700 Pharmaspec spectrophotometer. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a Varian Excalibur 3100 FT-IR spectrophotometer.

3. Crystal structure determination

The X-ray data collection and processing for **2** were performed on Bruker Kappa Apex-CCD diffractometer by using graphite monochromated Mo Kα radiation (λ = 0.71070 Å) at 273(2) K. Crystal structure was solved by direct methods. Structure solution, refinement and data output were carried out with the SHELXTL program [34,35]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in geometrically calculated positions by using a riding model. Images were created with the DIAMOND program [36]. Hydrogen bonding interactions in the crystal lattice were calculated with both SHELXTL and MERCURY [37].

4. Results and discussion

The $[Cu(bzsmp)_2Cl_2]$ [bzsmp = 2-benzylsulfanyl-5-(2-methoxyphenyl)-1,3,4-oxadiazole] was obtained by stirring the methanolic solution of N^2-Hbmbh (**1**) and $CuCl_2 \cdot 2H_2O$ in a 2:1 molar ratio at room temperature. A ring closure reaction takes place due to cleavage of C–S bond followed by elimination of $PhCH_2SH$ during complexation resulting in the formation of complex **2** (Scheme 1). The green solution obtained after the reaction was filtered off and on

slow evaporation of the solvent the resulting complex **2** crystallized. Crystals of complex **2** were obtained after three weeks in 64% yield. Complex **2** has been structurally characterized by single crystal X-ray. The molecular structure of **2** is shown in Fig. 1. The physical and analytical data of compound **2** supports the X-ray structure.

4.1. IR spectra

A comparative study of the IR spectral data of the complex with ligand **1** gives meaningful information regarding bonding sites and its cyclization during complexation. The IR spectrum of **1** shows bands at 3252, 2969, 1658, 1071, 1598 and 877 which correspond to ν(NH), δ(CH_2), ν(CO), ν(N–N), ν(C=N) and ν(C–S), respectively [30]. The bands due to ν(NH) and ν(CO) are absent in **2** and a new band appears at 1254 cm^{-1} due to ν(C–O–C) which suggests cyclization [28,29] of acyclic {–C(O)–NH–N=C=} moiety by elimination of $HSCH_2C_6H_4$ during complexation with Cu(II). Thus I.R. data of **2** supports cyclization of **1** and formation of 1,3,4-oxadiazole moiety in the complex. A positive shift of 62 cm^{-1} in ν(N–N) as compared to the ligand suggests the involvement of this group as a bonding site.

4.2. UV spectra

The electronic spectrum of the ligand N^2-Hbmbh shows bands at 337, 252 and 213 nm assigned to the $n\rightarrow\pi^*$ and $\pi\rightarrow\pi^*$ transitions. The magnetic moment of 1.82 B.M. for **2** is normal as expected for the presence of one unpaired electron. The complex [Cu(bzsmp)$_2$Cl$_2$] displays electronic bands at 557, 316, 297, 257 nm. A Cu(II) complex with d^9 configuration is expected to experience Jahn–Teller distortion which leads to further splitting of the ^{2}Eg and $^2T_{2g}$ levels and give rise to the $^2B_{1g}\rightarrow{}^2A_{1g}$ (ν_1), $^2B_{2g}$(ν_2), ^2E_g (ν_3) transitions which is expected to be close in energy and generally appear as a broad band. Therefore the broad band at 557 nm is assigned to the envelope of $^2B_{1g}\rightarrow{}^2A_{1g}$, $^2B_{2g}$ and ^2E_g transitions [38]. The strong absorptions found for complex **2** in the range 316–257 nm is due to the ligand to copper(II) charge transfer and intraligand transitions.

4.3. Crystal structure of complex *2*

The crystal structure refinement data related to complex **2** are given in Table 1 and the main bond distances and bond angles of **2** are given in the Table 2. The hydrogen bonds are listed in Table 3. In the centrosymmetric mononuclear [Cu(bzsmp)$_2$Cl$_2$], each Cu(II) ion is located at the inversion center. The six membered [CuO1C3C4C19N1] chelate ring is not coplanar (rms deviation from mean plane = 0.207 Å) but the two six membered chelate rings are parallel to each other separating a distance of 0.532 Å. Two ligands coordinate to Cu(II) center in meridonial fashion i.e. the carbonyl oxygen and hydrazinic nitrogen are cis to each. The bite angle for both C_3NCuO chelate rings is 75.28°. Cu(II) is bonded octahedrally with two methoxy oxygens, two oxadiazole nitrogens and two chlorine atoms with Cu–N, Cu–O and Cu–Cl distances of 1.9999(10) Å, 2.5080(4) Å, 2.2830(4) Å}, respectively (Fig. 1). Thus the ligand behaves as a neutral bidentate chelating ligand (Scheme 1). The Cu–N bond length in complex **2** agrees well with those

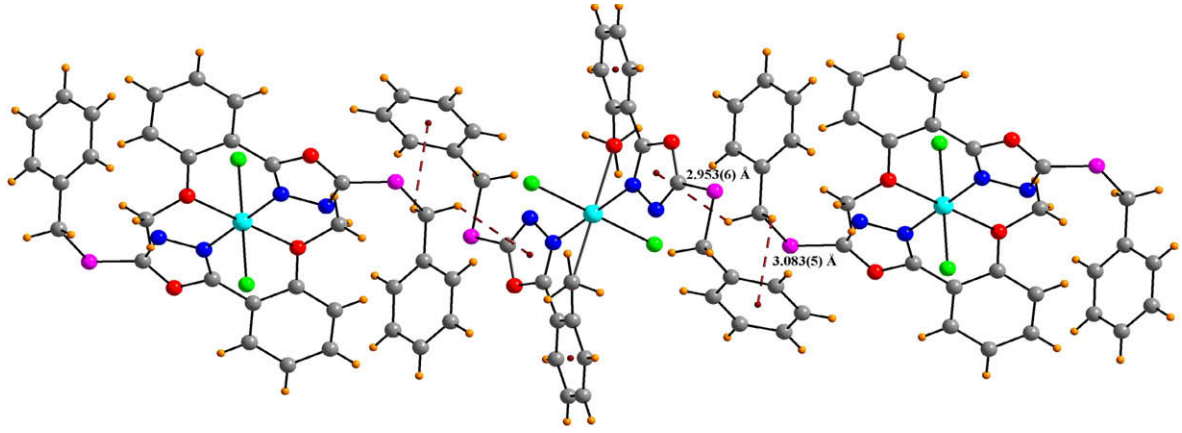

Fig. 2. One dimensional chain formed by C–H···π interaction (brown dotted) in the complex. Color code: C, grey; H, orange; N, blue; O, red; S, purple; Cl, green; Cu, cyan. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

found for compounds e.g. [Cu(2-PBZM)MoO_4] {2-PBZM = 2-(2-pyridyl)benzimidazole) [39] and [Cu_2(EGTA)$(Him)_2]_n$, [Cu_2(EGTA)$(Him)_4] \cdot 4H_2O$ {Him = imidazole, EGTA = ethylenebis(oxyethylnitrilo)tetraaceticacid)}. The Cu–O bond length is comparably shorter than the sum of van der Waal's radii of oxygen and copper atoms (1.50 + 1.40 = 2.90 Å), indicating comparatively strong Cu–O bonding [40]. The 2-methoxybenzene and oxadiazole rings make a dihedral angle of 23.57°. Similarly, the dihedral angle between benzyl and oxadiazole rings is 57.46°. The plane containing the oxadiazole ring equally divides the 2-methoxy benzene ring in equal halves.

The crystal packing of **2** reveals the existence of C–H···π, C–H···S and C–H···Cl intermolecular interactions. There are two C–H···π interactions, one occurring between a hydrogen atom of the methylene group and the π-electrons of the oxadiazole ring and the second one between other hydrogen of the same methylene group and the π-electrons of benzyl group from the adjacent molecule with a distance of 2.953(6) and 3.083(5) Å, respectively. These two C–H···π interactions provide one dimensional chain (Fig. 2). Additionally, two molecules of the complex are also linked by C–H···S interaction (2.970(3) Å) formed between C–H of 2-methoxy phenyl

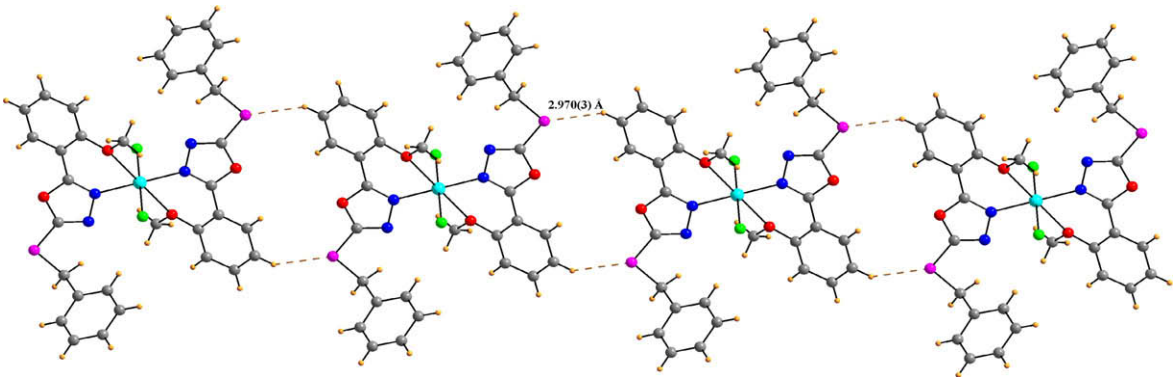

Fig. 3. One dimensional chain formed by C–H···S interaction (orange dotted) in complex. Color code: C, grey; H, orange; N, blue; O, red; S, purple; Cl, green; Cu, cyan. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

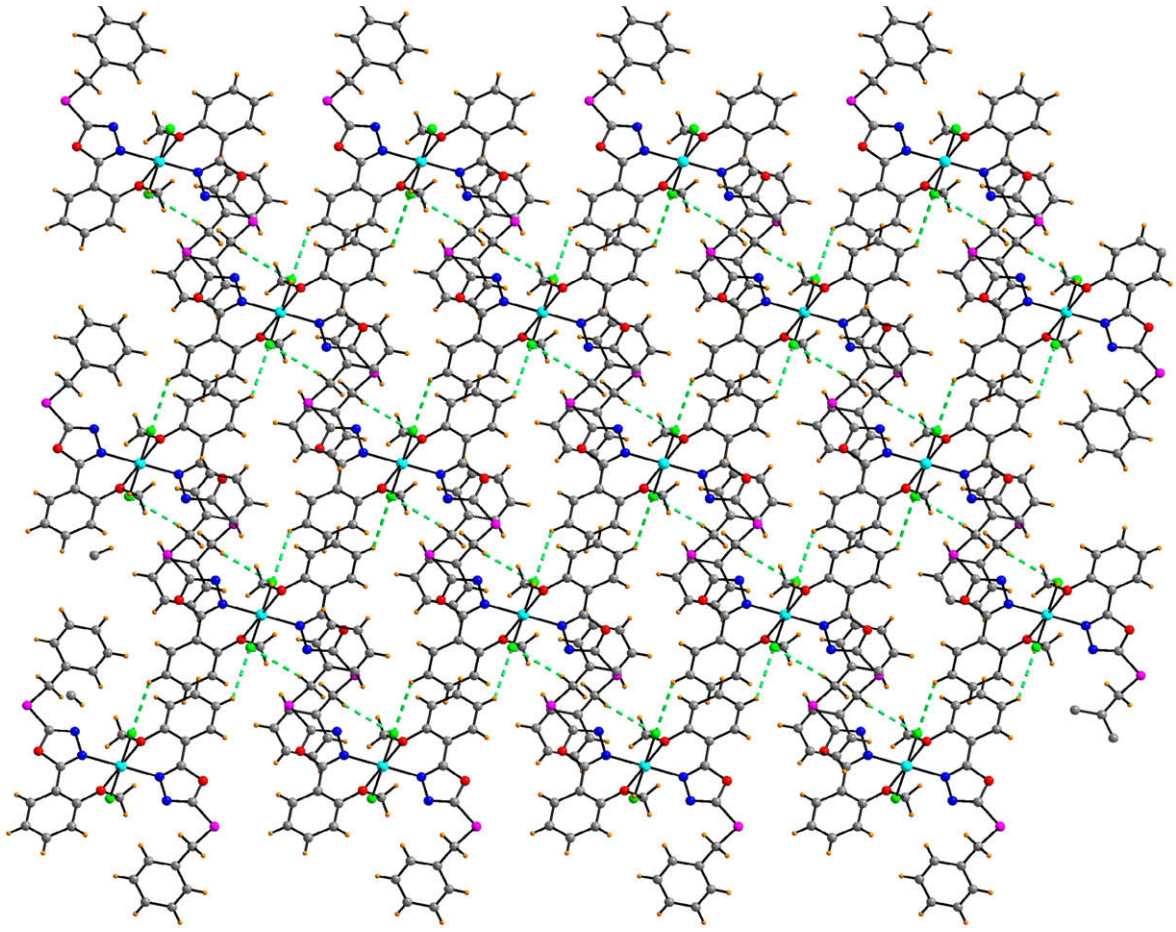

Fig. 4. Three-dimensional packing of complex [$Cu(bzsmp)_2Cl_2$] showing C–H···Cl interactions (green dotted). Color code: C, grey; H, orange; N, blue; O, red; S, purple; Cl, green; Cu, cyan. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

ring and sulfur atom which extend in one dimensional chain (Fig. 3). The three dimensional packing in the complex is also stabilized by two types of C–H···Cl interactions (one between hydrogen atom of methoxy phenyl ring and chlorine atom and other between hydrogen atom of benzyl ring and chlorine atom) with a distances of 2.951(6) and 2.900(12) Å, respectively (Fig. 4).

5. Conclusion

We have reported that acyldithocarbazates derivatives undergo cyclization during complex formation in the presence of en [13]. The present work indicates that the presence of Cu(II) is required for the cleavage of C–S bond leading to the elimination of $C_6H_5CH_2SH$ and cyclization of the cleaved product. As a conclusion of this work we describe a very facile route to obtain 2-benzylsulfanyl-1,3,4-oxadiazole as a stable Cu(II) complex.

ABSTRACT

The first alkaline earth metal complexes of a dibenzoyl derivative of clodronic acid were prepared and characterised by X-ray crystallography, elemental analysis and infrared spectroscopy. The complexes were $[Mg\{[Cl_2C(PO_2O(C(O)C_6H_5))_2](H_2O)_5\}\cdot H_2O]$ (**1**), $[Sr_2\{[Cl_2C(PO_2O(C(O)C_6H_5))_2]_2(H_2O)_9\}\cdot H_2O]_n$ (**2**) and $[Ba\{Cl_2C(PO_2O(C(O)C_6H_5))_2\}(H_2O)_2]_n$ (**3**). The monomeric units of **1** and the polymeric chains of **2** and **3** form 2D layer-like structures through intermolecular hydrogen bonds. The $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligand acts as a bridging and chelating ligand, forming six- and eight-membered chelate rings with metal atoms. In addition, the previously determined polymeric calcium complex of clodronate, $[Ca_2\{Cl_2C(PO_3)_2\}(H_2O)_6\cdot 4.5H_2O]_n$ (**4**), was synthesised by hydrolysis method from the dibenzoyl derivative of clodronic acid.

1. Introduction

The research on metal phosphonates has resulted in many interesting structures and applications in the field of solid state chemistry. Applications have been found in sorption, catalysis and ion exchange [1–4]. The investigation of metal bisphosphonates is an interesting extension of this work. In general, metal bisphosphonates adopt two-dimensional (2D) layered [5–14] or three-dimensional (3D) pillared layered structures [8,12–23], though one-dimensional (1D) chain structures [9–14,24–26] are also reported. In addition, bisphosphonates and other polyfunctional phosphonates enable the formation of 3D crystalline structures with open frameworks, containing predominantly 1D pores [13,14,16–23,27]. The structures of metal bisphosphonates typically include an inorganic hydrophilic part, in which metal atoms are bonded to the organobisphosphorus ligand by the phosphonate oxygens, whilst the hydrophopic organic part projects to the interlayer section. The dimensionality depends on the number of donor atoms of the ligand, on the length and structure of the organic tether between the phosphonate groups and on the degree of protonation of the phosphonate groups. However, prediction of metal bisphosphonate structures is not straightforward [2].

Bisphosphonates (BPs) have important pharmaceutical applications [28]. One of the best known methylenebisphosphonate derivatives is disodium (dichloromethylene)bisphosphonate tetrahydrate, clodronate, which is used to inhibit the bone resorption [29]. Several metal complexes of clodronate [30–34], its symmetrical diethyl [34,35] and diisopropyl ester [36,37] derivatives, and the methyl ester of piperidine derivative of clodronate [38] have been prepared and characterised to study the properties of solid materials. Clodronate and its derivatives form molecular compounds and polymeric chain and layer structures [30–38]. 3D structures are formed when the Na^+ cation participates in structure formation [32,37]. Few metal complexation studies on derivatives of clodronate have been published. We recently reported the hydrolysis product of the polymeric Mg complex of the clodronic acid dianhydride *P*,*P*′-diacetyl(dichloromethylene)bisphosphonate disodium salt $Na_2Cl_2C[PO_3(COMe)]_2$ [32], and the results have encouraged us to study in more detail the metal complexes of clodronic acid dianhydrides and their metal complexation behaviour.

In this paper we present the metal complexation properties of the clodronic acid dianhydride *P*,*P*′-dibenzoyl(dichloromethylene)bisphosphonate disodium salt $Na_2Cl_2C[PO_3(COC_6H_5)]_2$ (**L1**). Magnesium, strontium and barium complexes of this dianhydride, namely, monomeric $[Mg\{[Cl_2C(PO_2O(C(O)C_6H_5))_2]\}(H_2O)_5\}\cdot H_2O]$ (**1**), polymeric $[Sr_2\{[Cl_2C(PO_2O(C(O)C_6H_5))_2]_2(H_2O)_9\}\cdot H_2O]_n$ (**2**) and polymeric $[Ba\{Cl_2C(PO_2O(C(O)C_6H_5))_2\}(H_2O)_2]_n$ **(3)** were crystallised under carefully controlled conditions by gel and liquid crystallisation methods. In addition, the previously published [33] polymeric calcium complex of clodronate, $[Ca_2\{Cl_2C(PO_3)_2\}(H_2O)_6\cdot 4.5H_2O]_n$ **(4)**, was synthesised by hydrolysis method from the dibenzoyl derivative. The structures of the complex crystals were determined by single-crystal X-ray methods.

2. Experimental

2.1. General

All reagents used for the synthesis and characterisation of compounds **1–4** were of analytical reagent grade. The synthesis and characterisation of *P*,*P*′-dibenzoyl (dichloromethylene)bisphosphonate disodium salt $Na_2Cl_2C[PO_3(COC_6H_5)]_2$ (**L1**) have been reported earlier [39]. Infrared spectra were recorded on a Nicolet Magna-IR™ spectrometer 750 by the KBr pellet technique. The metal complexes of **L1** were crystallised by gel crystallisation method, and, additionally, compound **1** was prepared by liquid crystallisation method. In the gel crystallisation, carefully weighed amounts of **L1** and the metal salt were separately dissolved in water (2×0.45 ml) and the **L1** solution was warmed to 40 °C in a water bath. The solutions were mixed together, the TMOS (0.1 ml) was added, and the two-phase system was shaken until homogeneous. After the gel formation, organic precipitant was added. Exceptionally, in the preparation of **2**, a pure 20% supplemental TMOS layer (0.225 ml) was placed above the gel and allowed to gelate before the precipitant was added.

2.2. Syntheses of complexes

2.2.1. $[Mg\{[Cl_2C(PO_2O(C(O)C_6H_5))_2](H_2O)_5\} \cdot H_2O]$ (**1**)

Compound **1** was prepared by mixing the water solutions of **L1** (0.0101 mmol/0.45 ml, pH 4.01) and $Mg(NO_3)_2 \cdot 6H_2O$ (0.0101 mmol/0.45 ml, pH 5.17) with TMOS (0.1 ml). After the gel (pH 3.92) was formed, ethanol was added above the gel. Colourless and plate-like crystals were formed in the gel (pH 4.00) in one day. After two weeks the crystals dissolved in the gel through the effect of ethanol. In air atmosphere the dried crystals degraded during a few hours, probably due to the loss of water molecules. The crystals of **1** were also grown by liquid crystallisation method in 4/9:5/9 acetone/water solution (4.5 ml) of the ligand (0.050 mmol) and the metal salt (0.050 mmol) at 5 °C. *Anal.* Calc. for $C_{15}H_{22}MgCl_2O_{14}P_2$ (583.48): C, 30.88; H, 3.80; Mg, 4.17. Found: C, 30.97; H, 4.24; Mg, 3.91%. IR/cm^{-1} (KBr pellet, characteristic region): 1735 (s), 1604 (m), 1592 (m), 1505 (w), 1454 (s), 1273 (vs), 1181 (m), 1147 (m), 1105 (m), 1087(s), 1062 (s), 1026 (s), 1002 (m), 858 (s), 764 (s), 698 (s), 682 (s).

2.2.2. $[Sr_2\{[Cl_2C(PO_2O(C(O)C_6H_5))_2]_2(H_2O)_9\} \cdot H_2O]_n$ (**2**)

In the preparation of **2** the water solutions of **L1** (0.0019 mmol/0.45 ml, pH 4.00) and $SrCl_2 \cdot H_2O$ (0.0019 mmol/0.45 ml, pH 4.95) were mixed with TMOS (0.1 ml). A pure 20% TMOS layer (0.225 ml) was placed above the gel and allowed to gelate before the precipitant, 1:1 acetone/water solution, was added above the gel (pH 3.95). The plank-like and colourless crystals were formed in the gel (pH 4.60) in two days. *Anal.* Calc. for $C_{15}H_{20}SrCl_2O_{13}P_2$ (628.80): C, 28.65; H, 3.21; Sr, 13.94. Found: C, 28.71; H, 3.10; Sr, 13.72%. IR/cm^{-1} (KBr pellet, characteristic region): 1721 (s), 1601 (m), 1587 (m), 1494 (w), 1452 (m), 1281 (vs), 1181 (m), 1132 (s), 1107 (s), 1083 (s), 1061 (s), 1060 (s), 1027 (s), 1002 (m), 858 (s), 770 (s), 765 (sh), 755 (sh), 701 (s), 684 (s).

2.2.3. $[Ba\{Cl_2C(PO_2O(C(O)C_6H_5))_2\}(H_2O)_2]_n$ (**3**)

Compound **3** was prepared by mixing water solutions of **L1** (0.0010 mmol/0.45 ml, pH 4.05) and $Ba(NO_3)_2$ (0.0010 mmol/0.45 ml, pH 5.00) with TMOS (0.1 ml). After the gel (pH 3.90) was formed, ethanol was added above it. Colourless and thin plate-like crystals were formed in the gel (pH 4.69) in few days. Like the crystals of **1**, the crystals of **3** degraded in air atmosphere within a few hours. *Anal.* Calc. for $C_{15}H_{14}BaCl_2O_{10}P_2$ (624.44): C, 28.85; H, 2.26; Ba, 21.99. Found: C, 28.50; H, 2.41; Ba, 21.80%. IR/cm^{-1} (KBr pellet, characteristic region): 1721 (vs), 1714 (s), 1602 (m), 1588 (w), 1498 (w), 1455 (m), 1281 (vs), 1182 (m), 1136 (s), 1089 (s), 1066 (s), 1027 (s), 1110 (s), 1001 (w), 860 (s), 768 (s), 750 (sh), 700 (s), 685 (s).

2.2.4. $[Ca_2\{Cl_2C(PO_3)_2\}(H_2O)_6 \cdot 4.5H_2O]_n$ (**4**)

The preparation of **4** from the clodronate ligand has been described earlier [33], but now **4** was prepared by mixing water solutions of **L1** (0.0013 mmol/0.45 ml, pH 4.08) and $CaCl_2 \cdot 2H_2O$ (0.0026 mmol/0.45 ml, pH 5.40) with TMOS (0.1 ml). After the gelation (pH 4.10), acetone was added. Colourless, plank-like crystals formed above the gel during one month (pH 4.75). *Anal.* Calc. for $CH_{21}Ca_2Cl_2O_{16.5}P_2$ (510.18): C, 2.35; H, 4.15; Ca, 15.71. Found: C, 2.11; H, 3.90; Ca, 15.62%.

2.3. X-ray crystallographic study

X-ray diffraction data were collected with a Nonius Kappa CCD diffractometer using Mo–Kα-radiation ($\lambda = 0.71073$ Å). DENZO and SCALEBACK [40] programs were used for cell refinements and data reduction. The structures were solved by direct methods with SHELXS 97 [41], and structural refinements were carried out with SHELXL 97 [42]. The H_2O hydrogen atoms of the structures **1** and **3** were located from the difference Fourier map but constrained to ride on their parent atom, with $U_{iso} = 1.5$. The H_2O hydrogen atoms of the structure **2** are disordered and therefore they are omitted from the structure. The other hydrogen atoms of the structures **1–3** were positioned geometrically and were also constrained to ride on their parent atoms, with $U_{iso} = 1.2 \cdot U_{eq}$ (parent atom). Crystallographic data of compounds **1–3** are summarised in Table 1.

3. Results and discussion

3.1. Complex synthesis

Moderately stable crystals of metal complexes of dibenzoyl derivative of clodronic acid (**L1**) were formed by gel and liquid crystallisation methods. Because the rate of the hydrolysis of the ligand is dependent on the pH [39], the pH was followed in every step of the crystallisation: at the beginning when the water solutions of ligand and metal salt were mixed together, after gelation

with tetramethoxysilane TMOS and after the crystals were formed. The pH values of all syntheses were in the range where the ligand should not hydrolyse fast. The results established that there were no significant difference in the pH change in the syntheses of compounds **1–3** and the hydrolysis product **4**. In all cases, the pH decreased slightly when the water solutions of ligand and metal salt were mixed together, and the pH rose during the formation of the crystals. Thus, the crystallisation time is the most important factor in the syntheses. The crystals of the clodronate dianhydride complexes need to form within a few days, or otherwise the hydrolysis product may form instead. The crystallisation tests were done by varying the precipitant and the ratio of the concentrations of the metal salt and the ligand.

3.2. Crystal structures

Compound **1** consists of monomeric units. The asymmetric unit contains one independent Mg^{2+} atom, one $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligand, five aqua ligands and one lattice water molecule (see Fig. 1a). The geometry around the six-coordinated magnesium atom is a distorted octahedron having Mg–O bond lengths of 2.010(2)–2.139(2) Å. The $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligand is coordinated to the Mg atom monodentately via the phosphonate O11 atom, and the remaining coordination sites of the Mg atom are occupied by aqua ligands. The other phosphonate oxygen atoms of the ligand are unprotonated. Intramolecular hydrogen bond contacts are formed between the O1···O21, O2···O6 and O6···O22 having the distances 2.684(3), 2.748(3) and 2.854(2) Å, respectively, and the angles 150.8–174.5°. The monomeric units of **1** form parallel to the (010) plane a 2D layer-like structure where the units are placed with hydrophilic parts against each other (see Fig. 1b). The monomeric units are held together by intermolecular hydrogen bonds involving all aqua ligands and lattice water molecules as donors and O atoms of $Cl_2C(PO_2O(C(O)C_6H5))_2^{2-}$ as acceptors. The O4···O12^{i}, O5···O6^{i}, O1···O12^{i}, O2···O22^{ii}, O6···O21^{ii}, O5···O24^{ii}, O3···O5^{iii}, O3···O14^{iv}, O1···O22^{i}, O4···O24^{v}, O6···O1^{ii} distances are 2.615(3)–3.254(2) Å (symmetry code: i, *x*, y + 1, *z*; ii, −*x*, y + 1/2, −*z* + 1/2; iii, −*x*, −*y* + 2, −*z*; iv, −*x*, −*y* + 1, −*z*; v, *x*, −*y* + 1/2, *z* − 1/2) and the angles 123.5–172.8°. The benzene rings and chlorine atoms point out from the layers making the external parts hydrophobic with no intermolecular hydrogen bonds between the layers.

Compounds **2** and **3** consist of polymeric chains. The asymmetric unit of compound **2** contains two Sr^{2+} atoms on the mirror plane, one $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligand, 4.5 aqua ligands and 0.5 lattice water molecules (see Fig. 2a). The $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligand acts as a bridging ligand bonding to the Sr1 atom via phosphonate oxygen O11 and to the Sr2 atom via phosphonate oxygen O21 leaving two phosphonate oxygen atoms unprotonated. The other coordination sites of the Sr1 and Sr2 atoms are occupied by aqua ligands and by the bridge oxygen μ-O1 between the Sr atoms. The hydrogen atoms of the aqua ligands O3, O4, O4A, O6 and O7 and the lattice water molecule O8 are in disorder, therefore they are omitted from the structure **2**. The Sr1–O bond distances vary from 2.555(3) to 2.827(5) Å, but there exists the Sr1–O5A distance of 3.049(5) Å. This indicates a strong interaction between the Sr1 and O5A atoms, thus the Sr1 atom has a sphere with a coordination character of nine. The Sr2–O distances of the eight-coordinated Sr2 atom vary from 2.530(7) to 2.679(4) Å. According to the preceding indication, the polymeric chains consist of dimeric units linked together via one monoatomic bridge O5/O5A and two μ-aqua bridges (O2/O2B and O2A/O2C) between Sr atoms. The geometry around the Sr1 atom can be described as tricapped trigonal prism and around the Sr2 atom as distorted bicapped trigonal prism. The chains are formed parallel to the *a*-axis and are bonded together in the direction of the *a*- and *c*-axis by intermolecular hydrogen bonds between the lattice water molecules, aqua ligands and phosphonate oxygen atoms (see Fig. 2b). The O8···O6^{i}, O2···O12^{ii}, O5···O2^{ii}, O6···O22^{iii}, O7···O3^{iv}, O4···O24^{v}, O2···O21^{ii}, O8···O4^{vi}, O6···O2^{vi}, O8···O7^{v} and O8···O21^{vi} distances are estimated to be 2.7050(5), 2.7635(5), 2.7967(5), 2.8012(6), 2.838(10), 2.892(5), 2.9611(9), 2.962(8), 2.9877(6), 3.003(10) and 3.0200(8) Å (symmetry code: i, 1 + *x*, 1/2 − *y*, −1 + *z*; ii, −1 + *x*, 1/2 − *y*, *z*; iii, 1 + *x*, 1/2 − *y*, *z*; iv, *x*, *y*, 1 + *z*; v, *x*, *y*, −1 + *z*; vi, −1 + *x*, *y*, *z*), respectively. In addition, the phosphonate oxygen atoms, aqua ligands, lattice water molecule and carbonyl oxygen atoms form intramolecular hydrogen bonds. The O3···O14, O2B/O2C···O21/O21A, O5···O11, O8···O4/O4A, O7···O21, O7···O24, O3···O11, O1···O2 and O1···O5 distances are 2.902(4), 2.957(4), 2.9586(4), 2.962(8), 3.0868(5),

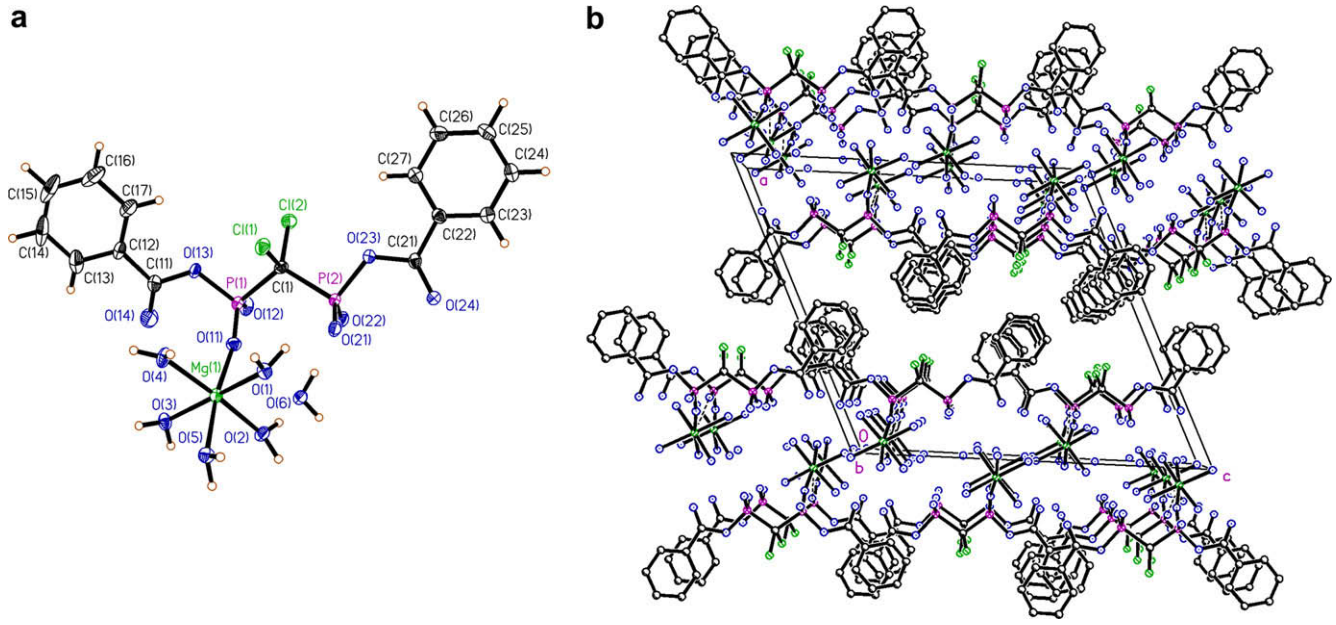

Fig. 1. (a) The structure of **1** with numbering scheme and thermal ellipsoids (50%) and (b) packing of the monomeric units of **1**. Hydrogen atoms are omitted for clarity. Selected bond distances (Å): Mg–O1 2.079(2), Mg–O2 2.034(2), Mg–O3 2.052(2), Mg–O4 2.066(2), Mg–O5 2.139(2), Mg–O11 2.010(2).

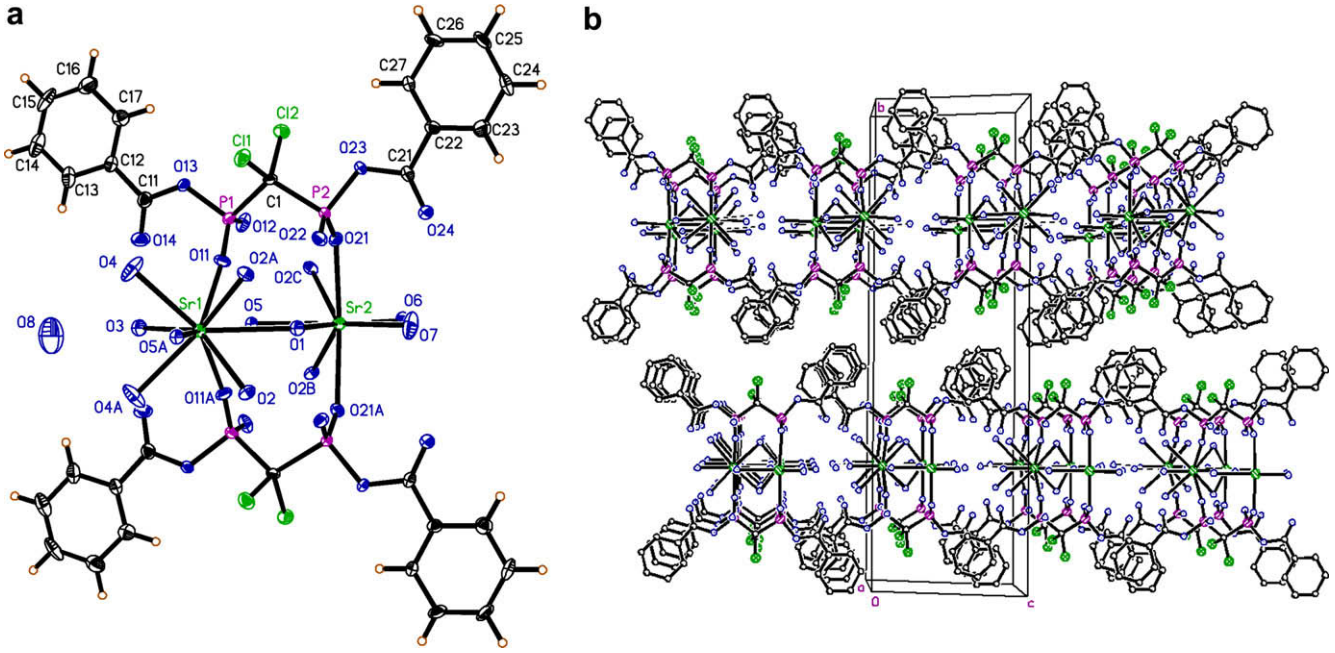

Fig. 2. (a) Part of the polymeric structure of **2** with numbering scheme and thermal ellipsoids (50%). The H_2O hydrogen atoms are disordered and thus omitted. (b) Packing of the chains of **2**. Hydrogen atoms are omitted for clarity. Selected bond distances: Sr1–O11 2.555(3), Sr1–O11A 2.555(3), Sr1–O3 2.621(5), Sr1–O4 2.628(3), Sr1–O4A 2.628(3), Sr1–O2 2.633(3), Sr1–O2A 2.633(3), Sr1–O1 2.827(4), Sr1–O5A^{i} 3.049(5), Sr2–O7 2.530(7), Sr2–O6 2.574(7), Sr2–O21 2.612(3), Sr2–O21A 2.612(3), Sr2–O5 2.668(4), Sr2–O2B 2.675(3), Sr2–O2C 2.675(3), Sr2–O1 2.679(4). In the figure, A refers to atoms at ($x-1, y, z$), A^{i} to atoms at ($x+1, y, z$), B to atoms at ($x-1, -y+1/2, z$) and C to atoms at ($x-1, y, z$).

3.0960(6), 3.1211(5), 3.1801(5) and 3.232(1) Å, respectively. The inner space between the 2D layers is filled by hydrophobic benzene rings and chlorine atoms of the ligands.

The asymmetric unit of compound **3** consists of one independent Ba^{2+} atom, one $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligand and two aqua ligands (see Fig. 3a). The geometry around the eight-coordinated Ba atom can be described as a distorted square antiprism where three independent $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligands are bidentately coordinated to the Ba atom through their phosphonate oxygen atoms forming six- and eight-membered chelate rings. The phosphonate oxygen O11 also acts as a bridging atom between two Ba atoms. The remaining two coordination sites of the Ba atom are occupied by aqua ligands O1 and O2. The Ba–O bond lengths range from 2.682(3) to 2.850(3) Å. The polymer chains are formed in the direction of the crystallographic *a*-axis (see Fig. 3b). Intramolecular hydrogen bonds are formed between the aqua ligand oxygen O1, carbonyl oxygen O24 and phosphonate oxygen O21. The hydrogen atoms of the aqua ligand O1 are disordered having the population parameter 0.5. In every second molecule the intramolecular hydrogen bond interaction from the aqua ligand oxygen O1 is directed towards the phosphonate oxygen O21, with shortest O1···O21 distance 2.680(4) Å and smallest angle 110.8°, and towards the carbonyl oxygen O24 having the O1···O24 distance 3.917(5) Å and angle 163.8°, whilst in the other molecules the intramolecular hydrogen bonds do not exist. Intermolecular hydrogen bonds formed between aqua ligand oxygens O1 hold the polymer chains together in the direction of the *b*-axis and, in addition, there are intermolecular hydrogen bonds between the aqua ligand oxygen O2, the carbonyl oxygen O24 and the phosphonate oxygen O12. The O2···O24^{i}, O2···O12^{ii}, O1···O1^{iii}, O1···O24^{i} distances are 2.808(4), 2.817(4), 2.823(4) and 3.073(5) Å (symmetry code: i, $-x+1, -y, -z$; ii, $-x, -y+1, -z$; iii, $-x+2, -y, -z$), respectively, and the angles are 148.4–171.0°. There are no intermolecular hydrogen bonds between the polymer chains in the direction of *c*-axis, only benzene rings, and the chlorine atoms point towards each other.

3.3. Spectroscopic properties

The characteristic absorption region and bands of the ligand **L1** and the compounds **1–3** were determined by IR spectroscopy. The assignments are based on published values for similar compounds and IR tables [43–45]. For all compounds the characteristic region was at 1735–700 cm^{-1}. The significant difference between the IR spectrum of **L1** and the IR spectra of its metal complexes were the bands for the water molecules. Strong, broad bands of $\nu(H_2O)$ around 3300 cm^{-1} and weaker absorptions of δ(H–O–H) in the region 1653–1623 cm^{-1} were present in the spectra of the metal complexes **1–3**, but were lacking in the spectrum of **L1**. Otherwise the absorptions and their intensities in the spectra of **L1** and **1–3** were closely similar.

A C=O stretching vibration overtone appeared around 3550 cm^{-1} for all compounds, and a very strong absorption band due to the stretching vibration of the carbonyl group, ν(C=O), appeared in the region 1735–1720 cm^{-1}. There was a strong asymmetric C–O stretching vibration, with weak shoulder at 1281 cm^{-1}, the symmetric ν(C–O) vibration appeared at 1130–1150 cm^{-1}. A series of strong bands in the 1300–1000 cm^{-1} region was attributed to the stretching vibrations of phosphonate PO_3 groups, and strong absorptions in the region 861–847 cm^{-1} to asymmetric and symmetric ν(P–C–P) vibrations. The aromatic ring carbon carbon stretching vibrations, ν(C=C), occurred at 1602 cm^{-1}, 1587 cm^{-1}, 1494 cm^{-1} and 1454 cm^{-1} and the stretching vibrations of the ring C–H bonds appeared with four weak peaks at around 3080–3010 cm^{-1}. The strongest absorptions for the monosubstituted aromatic ring, due to the out-of-plane C–H vibrations were at ca. 750 cm^{-1} and 700 cm^{-1}.

4. Conclusion

The dibenzoyl derivative of clodronic acid forms typical metal bisphosphonate complexes with alkaline earth metals. The

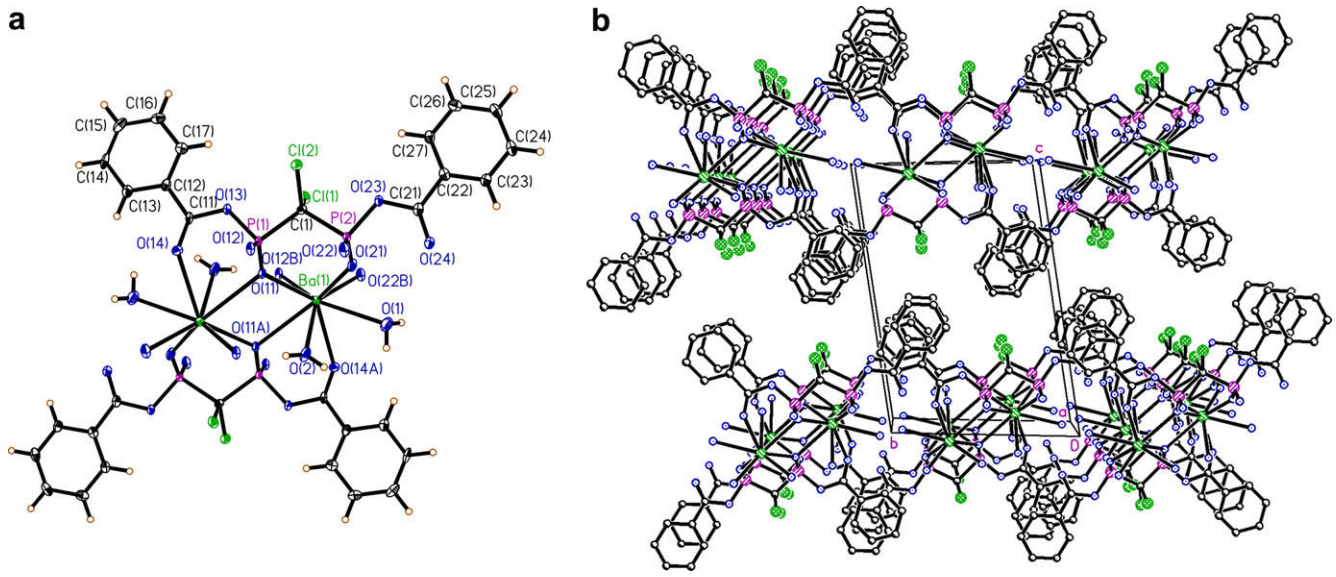

Fig. 3. (a) Part of the polymeric structure of **3** with numbering scheme and thermal ellipsoids (50%) and (b) packing of the chains. Hydrogen atoms are omitted for clarity. Selected bond distances: Ba1–O21 2.682(3), Ba1–O2 2.728(3), Ba1–O22B 2.732(3), Ba1–O1 2.795(3), Ba1–O14A 2.814(3), Ba1–O12B 2.758(3), Ba1–O11 2.840(3), Ba1–O11A 2.850(3). In the figure, A refers to atoms at $(-x+1, -y+1, -z)$ and B to atoms at $(x+1, y, z)$.

monomeric units of **1** and the polymer chains of **2** and **3** form 2D layer-like structures through intermolecular hydrogen bonds. In all structures the benzene rings and chlorine atoms of the ligand point to the interlayer part making the outer surfaces of the layers hydrophopic. The structures are packed efficiently and there are no porous channels. The $Cl_2C(PO_2O(C(O)C_6H_5))_2^{2-}$ ligand acts as both a bridging and a chelating ligand. It forms six- and eight-membered chelate rings with metal atoms via the four available phosphonate oxygens and via two carbonyl oxygens of the dibenzoyl groups. Studies on the complexing properties of other dianhydride derivatives of clodronate are in progress.

5. Supplementary data

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC Nos. 702609 (**1**), 702610 (**2**) and 702611 (**3**). These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

ABSTRACT

The oligomeric potassium complex $[(Me_2pzH)(Me_2pz)_2(18\text{-crown-6})(THF)K_2]_2$ (**1**) and the lithium dimer $[(^tBu_2pz)(THF)Li]_2$ (**2**) were synthesized. Both complexes were fully characterized by spectroscopic methods and single crystal X-ray diffraction. Complex **1** crystallized in the triclinic space group $P\bar{1}$, the structure shows an oligomer capped with 18-crown-6 and THF in both ends. This oligomer may be thought as the result of exscind an infinite single ladder structure in which η^2-coordinated pyrazolate ligands to potassium ions are the steps of the stair, and the crown ether acting as a scissor. The potassium ions that form the truncated stair are coordinated in a η^5-fashion to one pyrazolate ligand and in a η^1-fashion to one pyrazolate and one pyrazolyl ligand, respectively. The potassium ions in the cavity of the 18-crown-6 ligand complete their coordination spheres with η^5-coordination to one pyrazolate ligand and one THF molecule. Complex **2** is formed from the nucleophilic addition of THF to the lithium pyrazolate tetramer, $[(^tBu_2pz)Li]_4$. Complex **2** crystallized in the monoclinic space group *C*2/*c*. The molecular structure shows a dimer in which the pyrazolate ligands are coordinated in a $\mu\text{-}\eta^1{:}\eta^1$ fashion to two Li ions. These ions complete their respective coordination spheres with THF.

1. Introduction

It is currently being recognized that the cation-π interactions of alkali metals with aromatic rings are an important class of non-covalent binding modes that should play an important role in molecular biology and could have repercussions even in the design of new materials and molecular devices [1]. Alkali and other Main Group cyclopentadienyl complexes have recently been the subject of intense experimental and theoretical work [2]. These results have advanced our understanding of the nature of the bonding and the factors that prompt Cp to bind a Main Group metal in a high hapticity fashion [3]. The Main Group coordination chemistry of its heterocyclic analogues such as the pyrazolyls has attracted considerable attention due to the discovery of several coordination modes to alkali and alkaline ions, including the $\pi\text{-}\eta^5$ coordination mode [4–11]. 18-crown-6 complexes that incorporate pyrazolates and alkali ions should favor the expression of the η^5-coordination mode, due the fact, that the crown ether blocks in plane coordination sites without a high demand of steric bulk, leaving the pyrazolate ligand coordinate the ion axially in the best circumstances. The known examples with Na and K show the pyrazolate ligand coordinating the ion in a η^2 fashion, more likely as a consequence of big alkyl groups on the pyrazolate and/or competition for the same coordination site occupied by the pyrazolate by another ligand [4,7–9]. On this vein, the structure of the complex previously reported by us $[(^tBu_2pz)K]_\infty$ [8] that shows η^5 coordination of potassium in a 1D extended chain, inspired us to use 18-crown-6 ligand as a scissor and a small pyrazolate, expecting to witness the highest possible hapticiy of the ligand in a olygomeric or monomeric structure. On the other hand, the isolation of the dimeric lithiumpyrazolates $[(^tBu_2pzH)(^tBu_2pz)Li]_2$ [8] and $[(Ph_2pz)(OEt_2)Li]_2$ [9], rise the question if a similar structure may be obtained from nucleophilic addition of THF to $[(^tBu_2pz)Li]_4$. The results obtained are presented herein.

2. Results and discussion

From the mixture of $pzMe_2K$ with 18-crown-6 in THF, it was isolated a colorless crystalline complex with a formulation $[(Me_2pzH)(Me_2pz)_2(18\text{-crown-6})(THF)K_2]_2$ (**1**), which was established with spectroscopic methods and single crystal X-ray diffraction analysis (crystal data and structural parameters are shown in Table 1). The incorporation of the pyrazol, Me_2pzH, to complex **1** may be due to the introduction of adventitious water into the potassium pyrazolate, Me_2pzK.

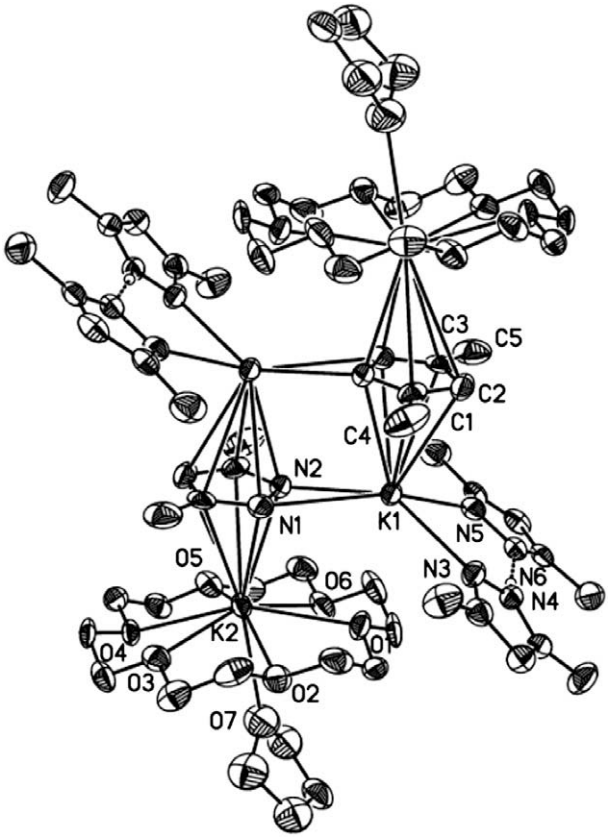

Fig. 1. Perspective view of complex [(Me$_2$pzH)(Me$_2$pz)$_2$(18-crown-6)(THF)K$_2$]$_2$ (**1**), showing thermal ellipsoids at the 50% probability level. Most hydrogen atoms were omitted for clarity. Symmetry transformation used to generate equivalent atoms: $-x+1$, $-y+2$, $-z+1$.

Complex **1** crystallized in the triclinic $P\bar{1}$ space group, the structure, which is presented in Fig. 1, shows an oligomer capped with 18-crown-6 and THF in both ends (Fig. 1). Apart from the intramolecular interactions described below (selected bond lengths and angles are given in Table 2), there are no significant intermolecular contacts in the crystal structure. The molecular structure of **1** is somehow related to the crystal structure of the potassium pyrazolate [(^{t}Bu$_2$pz)K]$_\infty$ [8] that has an infinite single ladder like structure. For **1** the single ladder structure is truncated as the result of the action of the crown ether and hydrogen bonded pyrazolate-pyrazol moiety acting as the scissors. The potassium ions that form the truncated stair (K1A and K1B) are coordinated in a η^5-fashion to one pyrazolate ligand and in a η^1-fashion to one pyrazolate and one pyrazolyl ligand, respectively. These η^1-coordinated pyrazolyl and pyrazolate ligands are bonded by unsymmetrical hydrogen bonding (N4–H100 0.87(2) Å, N6···H100 1.84(2) Å, N4···N6 2.712(7) Å, N4–H100···N6 176(7)). The potassium ions in the cavity of the 18-crown-6 ligand (K2A and K2B) are above by 0.603 Å to the best-fit plane formed by the oxygen atoms of the crown ether toward a η^5-coordinated pyrazolate ligand, and complete their coordination spheres with one THF molecule. Interestingly, both K1 and K2 ions are π-bound to one pyrazolate ring in a η^5-fashion. Both ions are oriented to the C_3N_2 ring centroid (distance K-ring centroid 2.922 Å), but marginally slipped toward the two nitrogen atoms as reflected by the shorter K–N bond lengths compared to the K–C bond lengths of 2.723(5)–2.989(5) and 3.181(6)–3.365(7) Å, respectively. These bond lengths are in the range observed for the π-bound potassium complexes [Tp^{CF3,CH3}CuK(CO$_3$)KTp^{CF3,CH3}]$_2$ (K–N 3.277(2)–3.339(3), K–C 3.339(3)–3.424(4) Å) [5], and [(^{t}Bu$_2$pz)K]$_\infty$ (K–N 2.803(2)–2.967(3), K–C 3.177(4)–3.431(3) Å) [8]. Moreover, the π-bound pyrazolate ligands further coordinate the K1 ions in a η^2-fashion resulting in an unusual binding mode μ_3-η^5:η^5:η^2, which to our knowledge has not been previously observed. The pyrazolate ring best-fit plane compared to the best-fit plane formed by the 18-crown-6 ligand with K2 in the cavity is almost coplanar (tilted by 10.5°). Comparison of the same angle in the related complexes [K(η^2-3,5-Ph$_2$pz)(η^6-18-crown-6)] 85.0° [12], [K(η^2-3,5-Me$_2$pz)(H$_2$O)(η^6-18-crown-6)] 25.4° [12], and [(^{t}Bu$_2$pz)Na(18-crown-6)] 52.3° [8] suggests that electronic and steric factors are operating in the perpendicular or coplanar orientation of the pyrazolate ligand in these complexes. In a previous report we showed with *ab initio* calculations at the MP2 level of theory that η^5-coordination of the C3N2 ring in simple alkalipyrazolates (C_s symmetry) is more favored with K in the series Li, Na, K [8]. In addition, the smaller steric requirements of the Me groups on the C3N2 ring versus the requirements of the ^{t}Bu and Ph groups should favor also in

#1 $-x+1$, $-y+2$, $-z+1$.

the former case a C_s symmetry. Both factors appear to favor in **1** the observed η^5-coordination of the pyrazolate ligand to the K2 ions. In contrast, it is the steric hindrance of the phenyl groups attached to the pyrazolate ligand in [K(η^2-3,5-Ph_2pz)(η^6-18-crown-6)] that may favor the observed perpendicular configuration. Thus, the intermediate perpendicular-coplanar configuration observed in [(^{t}Bu_2pz)Na(18-crown-6)] accounts again for the interplay of both the electronic and steric factors previously discussed.

The ^{1}H and ^{13}C NMR spectra of complex **1** in benzene-d_6 account partially with the formulation found in the solid state by X-ray diffraction. In particular the resonance signals ascribed to THF by NMR are most likely due to uncoordinated THF (^{1}H δ 1.43 and 3.58 ppm, ^{13}C δ 68.2 and 26.3 ppm). It appears that complex **1** easily release coordinated solvent as evidenced by the crystal structure obtained by X-ray, which shows partial occupancy of THF (0.5). In the ^{1}H NMR, a broad singlet resonance at considerably low field δ 16.25 ppm is ascribed to the N–H proton of the hydrogen bonded pyrazolate-pyrazol moiety (*cf.* free Me_2pzH 12.29 ppm).

Dimeric complex [(^{t}Bu_2pz)Li(THF)]$_2$ (**2**) was obtained by the opening of the lithium pyrazolate tetramer [(^{t}Bu_2pz)Li]$_4$ via nucleophilic addition of THF (Scheme 1). Similar nucleophilic additions were previously reported using the pyrazol ^{t}Bu_2pzH and diethyl ether affording complexes [(^{t}Bu_2pz)Li(^{t}Bu_2pzH)]$_2$ [8] and [(Ph_2pz)Li(OEt_2)]$_2$ [9], respectively. The spectroscopic and X-ray analysis (crystal data and structural parameters are shown in Table 1) evidence is consistent with the formulation proposed for **2**.

Complex **2** crystallized in the monoclinic space group C2/c, selected bond lengths and angles are given in Table 3. The molecular structure presented in Fig. 2, shows a dimer in which the pyrazolate ligands (^{t}Bu_2pz) are coordinated in a μ-η^1:η^1 fashion to two Li ions. These ions complete their respective coordination spheres with THF in a pyramidal coordination geometry around the lithium atom. The related complexes [(^{t}Bu_2pz)Li(^{t}Bu_2pzH)]$_2$ [8] and [(Ph_2pz)Li(OEt_2)]$_2$ [9] show μ-η^2:η^1 coordination of the pyrazolate ligand to Li. As a consequence of the lower hapticity of the pyrazolate ligand in **2,** a six-membered ring Li_2N_4 in a chair conformation is formed. The THF moieties occupy anti-axial positions of the chair, which in turn minimize steric bulk in the complex. Although the torsion angles Li–N–N–Li (50.8 and −49.1°) in **2** are more acute than those of [(^{t}Bu_2pz)Li(^{t}Bu_2pzH)]$_2$ and [(Ph_2pz)Li(OEt_2)]$_2$ (69.3 and 60.2°, respectively),[8–9] the chair conformation adopted by Li_2N_4 ring prevents steric crowding of the ^{t}Bu groups. The Li–N bond length values found in **2** (1.942(5) and 1.952(5) Å) are statistically similar compared to the sum of covalent radii of Li and N (1.99 Å)[1] [13] and those found in [(Ph_2pz)Li(OEt_2)]$_2$ (1.945(3)–1.954(3) Å) [9], but somehow shorter than those reported in [(^{t}Bu_2pz)Li(^{t}Bu_2pzH)]$_2$ (2.009(4)–2.048(4) Å) [8]. Although in the pyrazolates [(^{t}Bu_2pz)Li(^{t}Bu_2pzH)]$_2$ and [(Ph_2pz)Li(OEt_2)]$_2$ there is η^2 coordination, in **2** is precluded due to rather long Li···N contacts (2.471(2)–2.820(1) Å) if compared to the sum of covalent radii of Li and N (0.48–0.83 Å difference).

Scheme 1.

2.1. Conclusions

We have prepared the oligomeric complex **1** that can be envisioned as the result of exscind the parent compound [(Me_2pz)K]$_\infty$ [8] with 18-crown-6 ether and the hydrogen bonded pyrazolyl-pyrazolate moiety. Complex **1** shows strong π binding in a η^5 fashion between pyrazolate rings and potassium, which in strength is comparable to what it has been observed for [η^5-CpK]$_\infty$ (K–C bond lengths: 2.995(5)–3.080(7) Å; K-ring centroid: 2.816 Å) [14].

[1] Covalent radii of Li and N: 1.28(7) and 0.71(1) Å, respectively. Data from Ref. [13].

Additionally, the structure of **1** display a new binding mode of the pyrazolate ligand to potassium of the type μ_3:η^5:η^5: η^2.

The crystal structure of **2** and others related reported elsewhere, demonstrate that coordination of a better nucleophile is highly favored in the tetramer $[(R_2pz)Li]_4$, resulting in dimeric structures with the nucleophile coordinating the lithium atom.

3. Experimental

3.1. General methods

All experiments were carried out under argon using standard Schlenk techniques in a dual argon/vacuum line in conjunction with an inert atmosphere glovebox. THF and toluene were distilled from Na/benzophenone and stored under N_2 prior to use. [^{t}Bu$_2$pzLi]$_4$ and ^{t}Bu$_2$pzK were prepared as described in the literature [8]. All other chemicals were purchased from Aldrich and used as received.

3.1.1. Instrumentation

The ^{1}H, ^{13}C{^{1}H}, and ^{7}Li{^{1}H} NMR (δ in ppm) were obtained on a Varian Gemini-200 MHz spectrometer (200 MHz for ^{1}H, 50.30 MHz for ^{13}C, and 77.7 MHz for ^{7}Li) at ambient probe temperature (293 K). ^{1}H and ^{13}C NMR chemical shifts were determined by reference to the residual solvent peaks. ^{7}Li NMR chemical shifts are reported versus LiCl in D_2O. IR data were recorded as KBr pellets on a FT-IR Bruker spectrometer and are reported in cm^{-1}.

3.2. Single crystal X-ray diffraction analysis

Crystals of **1** and **2** were mounted directly from solution under argon using an inert oil, which protects them from atmospheric oxygen and moisture. X-ray intensity data were collected using the program SMART [15] on a Bruker APEX CCD diffractometer with monochromatic Mo Kα radiation (λ = 0.71073 Å). Cell refinement and data reduction were carried out with the use of the program SAINT, the program SADABS was employed to make incident beam, decay and absorption corrections in the SAINT-PLUS v. 6.0 suite [16]. Then, the structures were solved by direct methods with the program SHELXS and refined by full-matrix least-squares techniques with SHELXL in the SHELXTL v. 6.1 suite [17]. Crystals of **1** show half a molecule of THF that was refined accordingly with an occupancy of 0.5. Statistical disorder was found for the two THF molecules of **2**, refinement of each molecule into two split positions gave an occupancy factor level of 0.48. Except for H100, all hydrogen atoms in complex **1** were generated in calculated positions and constrained with the use of a riding model. H100 was located by the difference Fourier synthesis and refined isotropically restraining the N4-H100 distance to a target value of 0.88 Å. The final models involved anisotropic displacement parameters for all non-hydrogen atoms. Further details of the structure analyses are given in Table 1.

3.2.1. Synthesis of bis[(η^1:η^6-18-crown-6)(μ_3:η^5:η^5:η^2-Me$_2$pz)(η^1-Me$_2$pz)(η^1-Me$_2$pzH)(η^1-THF)K$_2$] (**1**)

A Schlenk flask was charged with a solution of [^{t}Bu$_2$pzK] (0.26 g, 1.39 mmol) in toluene (20 mL) and THF (5 mL). Then, 18-crown-6 was added (0.18 g, 0.7 mmol) and the reaction mixture was stirred 1 h at ambient temperature. The solution was concentrated to 10 mL and stored under argon at −20 °C. Once the compound crystallized, it was isolated by cannula filtration and dried under vacuum. Yield: 50 mg (10.64%). ^{1}H NMR (benzene-d_6, 25 °C): δ 16.24 (bs, 1H, N*H*), 6.07 (s, 3H, C*H*), 3.58 (m, 4H, THF), 3.17 (s, 24H, 18-crown-6), 2.59 (s, 18H, C-C*H*$_3$), 1.43 (m, 4H, THF). ^{13}C NMR (benzene-d_6, 25 °C): δ 145.84 (s, *C*-CH$_3$), 102.06 (s, *C*H), 70.49 (s, 18-crown-6), 68.24 (s, THF), 26.27 (s, THF), 14.81 (s, C-*C*H3).

3.2.2. Synthesis of bis[(μ:η^1:η^1-^{t}Bu$_2$pz)(η^1-THF)-Li] (**2**)

A Schlenk flask was charged with a solution of (^{t}Bu$_2$pz)Li (0.26 g, 1.39 mmol) in toluene (20 mL) and THF was added (0.1 g, 1.39 mmol). The reaction mixture was stirred 30 min at ambient temperature. The solution was then concentrated until the solution shows signs of precipitation. After this, it was stored under argon at −20 °C for several days. Upon crystallization, **2** was isolated by cannula filtration and dried under vacuum leaving a white solid residue (0.34 g, 97%). M.p. >350 °C, ^{1}H NMR (benzene-d_6, 25 °C): δ 6.084 (s, 1H, C*H*), 3.50 (m, 4H, O-C*H*$_2$), 1.35 (m, 4H, O-CH$_2$-C*H*$_2$), 1.02 (s, 18H, C*H*$_3$). ^{13}C NMR (THF, 25 °C): δ 163.72 (s, *C*-^{t}Bu), 97.15 (s, *C*H), 67.41 (s, O-*C*H$_2$), 31.74 (s, *C*-CH$_3$), 31.37 (s, C-*C*H$_3$), 25.55 (s, O-CH$_2$-*C*H$_2$). ^{7}Li NMR (THF, 25 °C): δ −0.88 (s). IR (KBr, cm^{-1}): 2960 (s), 2902 (m), 2866 (m), 1565 (w), 1503 (m), 1462 (m), 1402 (w), 1360 (m), 1308 (w), 1250 (m), 1208 (w), 1047 (m), 1024 (m), 1001 (m), 896 (w), 782 (w), 730 (w), 473 (m), 432 (m).

Acknowledgments

We are indebted to CONACYT-México (Grant UI-54151) for generous financial support of this work, Ph.D. scholarships to S.A.C.L. and M.-A.V.-C. (165618 and 186755, respectively), and a postdoctoral grant to A.J.M.-M (050287).

Appendix A. Supplementary data

CCDC 695529 and 695530 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.10.041.

ABSTRACT

Novel bis(acetylacetonato-*O*,*O*′)(biphenyldiolato-*O*,*O*′)titanium(IV) is synthesized and characterized by 'X-ray crystallography and other physical methods. The kinetics of substitution of bidentate 2,2′-biphenyldiolato for the two monodentate Cl^- ligands in $Ti(CH_3COCHCOCH_3)_2Cl_2$ proceeds *via* a 7-coordinated transition state according to an associative mechanism. The $Ti(CH_3COCHCOCH_3)_2$biphen complex exhibits high hydrolytic stability.

1. Introduction

Complexes of titanium(IV) are widely studied for a variety of purposes, mainly serving as a catalyst in different organic reactions as well as for antitumor activity [1,2]. Titanium alkoxides are excellent precursors for the deposition of metal oxides used in optoelectronics, high-T_c superconductors and ceramic materials [3,4]. Titanium alkoxy systems are, for example, effective catalysts in a variety of processes such as the Diels–Alder reaction [5], C–C bond forming reactions [6], esterification reactions including ones involved in the production of dialkyl phthalate plasticisers [7], polymerization of alkenes and alkynes [8,9], asymmetric and enantioselective reactions [10–12] and many more [12–14]. However, since titanium alkoxides are very sensitive to hydrolysis, a problem frequently encountered when used as catalysts, is that as the catalytic reaction commences, there is some cleavage of the Ti–OR bonds due to the reaction with water that is produced as by-product in the reaction, for example in esterification reactions [15]. Studies on sol–gel systems involving $[Ti(OR)_4]$ have shown that the rate of hydrolysis of the metal alkoxide can be significantly reduced by the presence of bulky [16], or chelating ligands as acetylacetonate and glycols [17]. Thus, producing titanium(IV) complexes exhibiting enhanced water resistance, is extremely valuable. Electron-rich oxygen-based ligands may lead to resistance towards hydrolysis. The *O*,*O*′-chelate bidentate 1,1-bi-2-naphthol ligand in the (BINOLate)TiX_2 catalysts have resulted in development of an impressive number of highly enantioselective processes [18] such as the cyanosylation of aldehydes [19], Diels–Alder cycloadditions [20] hetero Diels–Alder cycloaddition [21], carbonyl-ene reaction [22], Mukaiyama aldol condensation [23] and asymmetric addition of alkyl groups to aldehydes, to name a few [24]. In this paper we describe the synthesis of a remarkably hydrolytically stable catalytic complex containing three electron donating *O*,*O*′-chelate bidentate ligands: bis(acetylacetonato-*O*,*O*′)(biphenyldiolato-*O*,*O*′)titanium(IV).

2. Results and discussion

2.1. Reactivity of $Ti(acac)_2Cl_2$ with 2,2′-biphenyldiol

The complex $Ti(acac)_2Cl_2$ **1** (Hacac = acetylacetone = $CH_3COCHCOCH_3$) was prepared by treating $TiCl_4$ with two equivalents of acetylacetone and isolated and purified by recrystallization before use [25,26]. Reaction of complex **1** with 2,2′-biphenyldiol in 1:1 ratio in CH_3CN yielded the mixed ligand complex, $Ti(acac)_2$(biphen) **2** (H_2biphen = 2,2′-biphenyldiol = $HOC_6H_4C_6H_4OH$). Even with the use of higher ligand ratios, 1:2 or 1:3, the reaction yielded **2** rather than a product possessing more than one biphenolato ligand in the coordination sphere of Ti. This is similar to what was found for the reaction between $Ti(acac)_2Cl_2$ and 1,1′-methylenedi-2-naphtol [27]. Stoichiometric amounts of $Ti(acac)_2Cl_2$ and H_2biphen (representing second-order reaction conditions), stirred at room temperature for 25 h under an inert atmosphere, generated the product $Ti(acac)_2$(biphen) **2** in low yields (<10%).

2.2. Spectral study of Ti(acac)$_2$(biphen) **2**

The proton NMR spectrum of **2** showed methyl protons of acac as a singlet at 2.05 ppm and the methine proton of acac also as a singlet at 5.81 ppm. The biphenolato ring protons were arranged in a 2:2:2:2 ratio (d; t; t; d pattern) at 6.88; 7.00; 7.21; 7.39 ppm, compared to the 4:4, m; m pattern at 7.07; 7.33 ppm in the uncoordinated ligand. The disappearance of the phenolic–OH protons in the spectrum of **2**, compared to the uncoordinated ligand, suggests that the bidentate ligand is chelated through the two oxygens to the Ti(IV) centre. The methine proton of the chelated ring in both Ti(acac)$_2$biphen (5.81 ppm) and parent complex, Ti(acac)$_2$Cl$_2$ (6.00 ppm) is slightly downfield shifted relative to the uncoordinated Hacac (5.50 ppm). This is due to the formation of the six-membered, planar *pseudo*-aromatic system when acetylacetone coordinates to the Ti(IV) centre.

2.3. X-ray structure of (**2**)

A molecular diagram showing the numbering scheme of the title compound Ti(acac)$_2$biphen, **2**, is presented in Fig. 1a. Crystal data and details for data collections and refinements are summarized in Table 1. Selected bond lengths and angles for **2** and for comparison, also of **1**, are displayed in Fig. 1b and c, respectively.

The Ti(acac)$_2$biphen, **2**, structure consists of an octahedrally coordinated titanium atom with all three ligands acting as bidentate. The octahedral coordination around titanium is distorted to accommodate the three chelated ligands, *i.e.*, the two six-membered acetonato and seven-membered biphenolato rings. The bond angles vary from 83° to 103° compared to 90° in a perfect octahedron. Due to the strain in the ring, the ligand O–Ti–O angle increases from 82.8° for the six-membered acetonato chelated ligand to 89.9° for the seven-membered biphenolato ring, which is in the same trend as the angle of 94.0° found for an eight-membered 1,1′-methylenedi-2-naphtol (mbinaph) ring in the structure of Ti(acac)$_2$mbinaph [27]. The Ti–O bond lengths in **2** are in the order Ti–O$_{biphen}$ (1.860 Å) < Ti–O$_{acac\ axial}$ (1.985 Å) < Ti–O$_{acac\ equatorial}$ (2.013 Å) as illustrated in Fig. 1b. The formal Ti–O single bond is 1.94–1.99 Å (Ti–O distances found in rutile, TiO$_2$ [28]) and Ti=O double bond is 1.61–1.68 Å [29]. Therefore the shortest Ti–O distance is clearly shorter than one expected for a single bond, suggesting that this Ti–O bond possesses partial double bond character arising from donation of the electrons from the p_y and p_z filled oxygen orbitals to the empty titanium *d* orbitals [30]. The Ti–O$_{acac}$ bonds *trans* to another acac oxygen, are shorter (*ca.* 1.99 Å) than those *trans* to the oxygen of the chelated dianion biphenalato ligand (*ca.* 2.01 Å). The Ti–ligand bond lengths in **1** are in the order Ti–O$_{acac\ axial}$ (1.924–1.936 Å) < Ti–O$_{acac\ equatorial}$ (1.967–1.978 Å) < Ti–Cl (2.277 Å) as illustrated in Fig. 1c. Both Ti–O$_{acac\ axial}$ and Ti–O$_{acac\ equatorial}$ are slightly longer in **2** than in **1**, but the Ti–O$_{biphen}$ bond in **2** is considerably shorter than any Ti–O$_{acac}$ bond in either 1 or 2. Therefore, a strong electron donation to the titanium centre is expected due to the short Ti–O$_{biphen}$ bond.

The compound Ti(acac)$_2$biphen, **2**, crystallizes in the monoclinic centrosymmetric space group $C2/c$ with Z = 4, resulting in only half the molecule necessary for the asymmetric unit as it is situated on a twofold rotational axis. Intermolecular π–π stacking of the chelated β-diketonato acac moieties is clearly observed in Ti(acac)$_2$biphen (Fig. S1a Supplementary material). The planes of the π–π stacked rings are parallel with the rings displaced from each other in a slipped or offset alignment resulting in a centroid–centroid

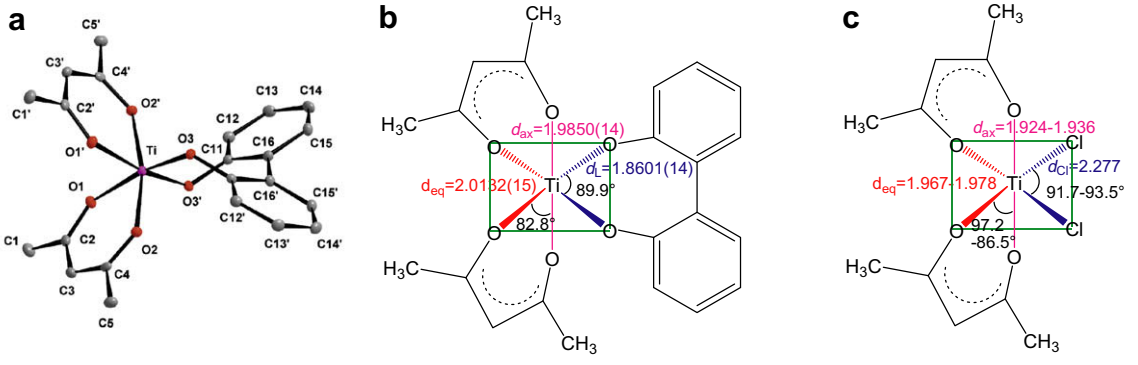

Fig. 1. (a) The molecular structure (30% probability displacement ellipsoids) of Ti(acac)$_2$biphen (**2**) showing the numbering scheme (primed labels indicate atoms generated by symmetry operations). separation of the acetylacetono backbones of 3.619 Å and a centre-normal angle θ of 8.6°. The geometrical parameters describing π–π stacking [31,32] are given in Supplementary material Fig. S1b.

2.4. Hydrolytic stability of (**2**)

Complex **1** is extremely moisture sensitive and hydrolyzes easily [33]. The final stage of hydrolysis is the formation of TiO_2. Keppler and Heim [33] evaluated the rate of hydrolysis, showing that complex **1** precipitates within 5 s when dissolved in dry acetonitrile treated with 0.01% water. Complex **2**, however, exhibits a high hydrolytic stability and is "air stable" for more than 3 years. The solution stability was tested under the same conditions as Keppler and Heim, *i.e.*, 0.01% water/CH_3CN, and it was found that **2** does not precipitate within 6 weeks. The strong electron donation to the titanium centre observed in the form of a short Ti–O_{biphen} bond may contribute to the enhanced hydrolytic stability of **2** relative to **1**.

2.5. Substitution kinetics

The kinetics of substitution of bidentate 2,2-biphenyldiolato for the two monodentate Cl^- ligands in $Ti(CH_3COCHCOCH_3)_2Cl_2$ takes place in two kinetically distinct steps, including a solvent pathway.

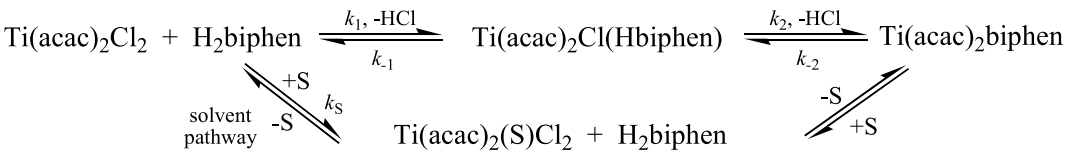

Table 2
Kinetic data and activation parameters for the substitution of 2,2′-biphenyldiolato for the two monodentate Cl^- ligands in $Ti(acac)_2Cl_2$.

T (°C)	k_1 ($dm^3\ mol^{-1}\ s^{-1}$)	$10^3\ k_S$ (s^{-1})	$\Delta H^{\#}$ (kJ mol^{-1})	$\Delta S^{\#}$ (J $mol^{-1}\ K^{-1}$)	$\Delta G^{\#}$ (kJ mol^{-1})
15.0	0.062(2)	0.12(3)			
25.0[a]	0.153(4)	4.61(7)	59.6	−60.8	77.7
36.2	0.365(5)	13.3(1)			

[a] $k_2 = 0.0015(2)\ s^{-1}$ for the second step at 25°.

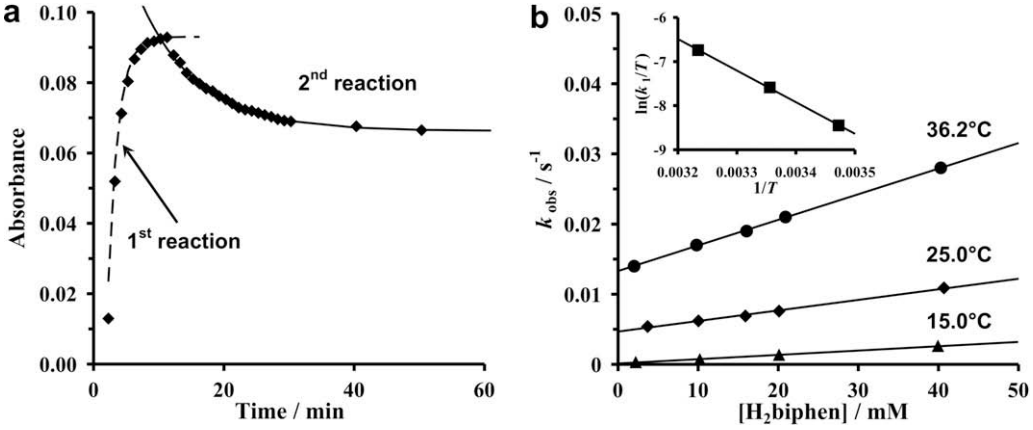
are given in Table 2 and the results plotted as a function of the incoming H_2biphen concentration in Fig. 2b.

The general rate law applicable to the first [H_2biphen] dependent step is given by Rate = $\{k_S + k_1[H_2biphen]\}[Ti(acac)_2Cl_2] = k_{obs}[Ti(acac)_2Cl_2]$ [35,36] with the pseudo-first-order rate constant $k_{obs} = k_S + k_1[H_2biphen]$ and k_1 the second-order rate constant for the substitution process and k_S the first-order rate constant for a solvent pathway. A noticeable solvent path is observed, *e.g.* $k_S = 0.00461(7)\ s^{-1}$ at 25 °C. That $Ti(CH_3COCHCOCH_3)_2Cl_2$ **1** indeed forms a solvent coordinated species is also confirmed on ^1H NMR. ^1H NMR in $CDCl_3$ (a non-coordinating solvent) showed one set of proton signals corresponding to the signals of the protons of the methyl groups and the methine protons of the acac ligand coordinated to $Ti(CH_3COCHCOCH_3)_2Cl_2$, but in CD_3CN solution (a coordinating solvent), two sets of signals were observed, see Supporting material Fig. S2. Since the ^1H NMR spectrum in $CDCl_3$ confirmed the purity of **1**, the second species in CD_3CN must correspond to the seven-coordinate $[Ti(CH_3COCHCOCH_3)_2(Cl_2)(CD_3CN)]$ solvent coordinated species. Each signal of the solvent coordinated species split since the methyl and methine groups are not chemical equivalent in $[Ti(CH_3COCHCOCH_3)_2(Cl_2)(CD_3CN)]$.

(1)

Both reaction steps were observed when following the reaction on a UV–Vis spectrophotometer, see Fig. 2a. The rate constant for the second step (0.0015(2) s^{-1} at 25 °C) is *ca.* 10 times slower than that of the first step (0.153(4) $dm^3\ mol^{-1}\ s^{-1}$ at 25 °C). The first step was followed at 340 cm^{-1} where the second reaction did not have a change in absorbance. The two stages and the rate constants were determined independently. The H_2biphen was in excess, so first-order kinetics in [H_2biphen] was observed for the first step. The second step was [H_2biphen] independent, consistent with the second step being rate-limiting ring closure [34]. Rate constants for the first and second stages of substitution at $Ti(acac)_2Cl_2$

The activation parameters, the entropy of activation, $\Delta S^{\#}$, and activation enthalpy, $\Delta H^{\#}$, were determined from a temperature dependence study. The large negative activation entropy of



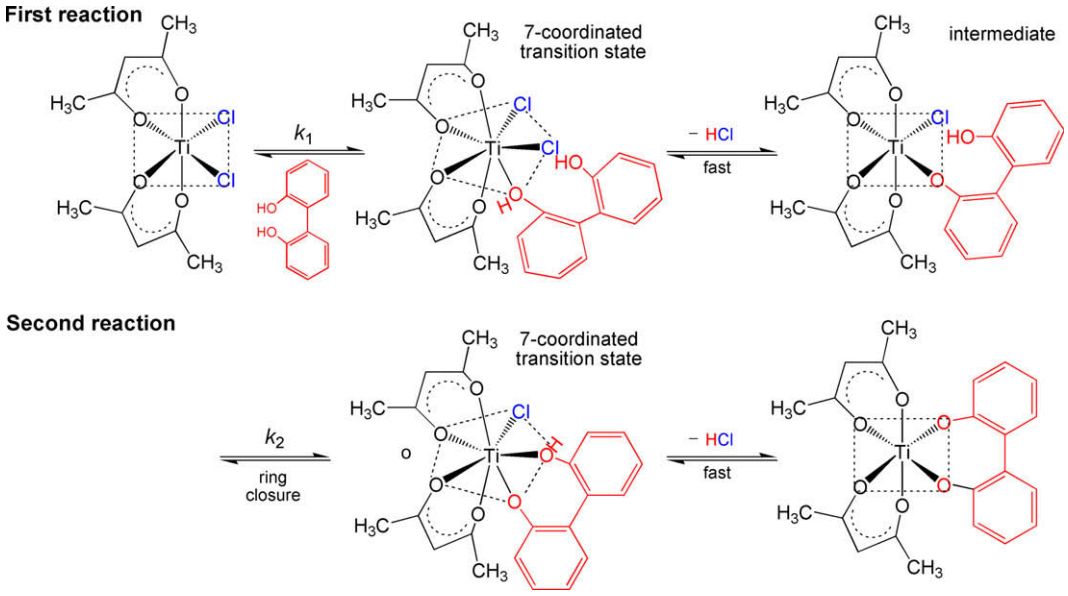


Fig. 2. (a) Absorbance *vs.* time data of the UV monitoring of the reaction between 0.0002 mol dm^{-3} $Ti(CH_3COCHCOCH_3)_2Cl_2$, **1**, and 0.040 mol dm^{-3} H_2biphen at 336 nm illustrating the two reaction steps observed. (b) Temperature and H_2biphen concentration dependence of the first reaction step of the substitution of 2,2-biphenyldiolato for the two monodentate Cl^- ligands in $Ti(CH_3COCHCOCH_3)_2Cl_2$. Inset: linear dependence between $\ln(k_1/T)$ and $1/T$, as predicted by the Eyring equation (k_1 is the second-order rate constant for the first reaction step in Eq. (1)).

Scheme 1. Schematic presentation of the proposed associative mechanism of the substitution reaction between Ti(acac)Cl_2 (**1**) and H_2biphen to afford Ti(acac)$_2$(biphen) (**2**).

−60.8 J mol^{-1} K^{-1}, suggests that the substitution process proceeds *via* an associative mechanism. This is expected, since octahedral complexes of Ti^{IV} (d^0) are coordinatively unsaturated, *i.e.*, Ti(acac)$_2Cl_2$ is a 12-electron species, and therefore would prefer an associatively activated pathway. The incoming H_2biphen ligand is thus expected to compete with the solvent to form a 7-coordinated transition state. When considering the nature of the transition state of the first reaction, an activated complex in which the biphenolato binds to the Ti nucleus through only one of the O-atoms, is expected to form first. This transition state may then convert to another transition state in which the biphenol ligand becomes bidentate. Stable Ti(IV) complexes with coordination numbers greater than six, for example, 7- and 8-coordination, are known [37]. The common geometry for 7-coordinated Ti(IV) complexes is pentagonal bipyramidal, as in the case of Ti(dithioacetato)$_3$Cl [38] and Ti(N,N-diethyldithiocarbamato)$_4$ [39]. In a dissociative mechanism, the 5-coordinated cationic species, [Ti(acac)$_2$Cl]$^+$, formed by breaking the first Ti–Cl bond, is considerably less likely. The proposed reaction pathway for the substitution the reaction between Ti(acac)$_2Cl_2$ and H_2biphen may thus be presented as in Scheme 1 where the first [H_2biphen] dependent step is the formation of a 7-coordinated [Ti($CH_3COCHCOCH_3$)$_2$(Cl_2)(H_2biphen)] complex, and the second [H_2biphen] independent step being rate-limiting ring closure.

3. Conclusions

The substitution of bidentate 2,2-biphenyldiolato for the two monodentate Cl^- ligands in Ti($CH_3COCHCOCH_3$)$_2Cl_2$ proceeded *via* a 7-coordinated transition state according to an associative mechanism. The product of the substitution reaction, Ti($CH_3COCHCOCH_3$)$_2$biphen, is "air stable" and also exhibits high resistance towards hydrolysis.

4. Experimental

4.1. Materials and apparatus

Solid reagents used in preparations (Merck, Aldrich and Fluka) were used without further purification. Liquid reactants and solvents were distilled prior to use; water was doubly distilled. Organic solvents were dried according to published methods [40].

4.2. Synthesis of **2**

Complex **1** was synthesized according to published methods [25,26]. To 15 ml CH_3CN, 2,2′-biphenyldiol (0.186 g, 1 mmol) was added and stirred at RT. Complex **1** (0.317 g, 1 mmol) in 15 ml CH_3CN was added drop by drop to give an orange red solution which was refluxed for 4–6 h. The reaction mixture was then cooled to RT and filtered. The precipitate was washed in MeOH to remove unreacted biphenol, filtered, dried and stored under N_2 atmosphere. Yield: 0.333 g (77.5%). M.p. >250 °C. ^{1}H NMR (δ/ppm, $CDCl_3$): 2.05 (s, 12H, 4 × CH_3); 5.81 (s, 2H, acacH); 6.88 (d, 2H, biphenH); 7.00 (t, 2H, biphenH); 7.21 (t, 2H, biphenH); 7.39 (d, 2H, biphenH). λ_{max}(CH_3CN)/nm 334 (ε/dm^{+3} mol^{-1} cm^{-1} 4890(30)). Elemental *Anal.* Calc. for $C_{22}H_{22}O_6Ti$: C, 61.4; H, 5.2. Found: C, 61.2; H, 5.1%.

4.3. Spectroscopy and spectrophotometry

NMR measurements at 25 °C were recorded on a Bruker Advance II 600 NMR spectrometer [1H(600.130 MHz)]. The chemical shifts were reported relative to $SiMe_4$ (0.00 ppm). Positive values indicate downfield shift. IR spectra were recorded from neat samples on a Digilab FTS 2000 infrared spectrophotometer. UV–Vis spectra were recorded on a Cary 50 Probe UV–Vis spectrophotometer.

4.4. Kinetic measurements

The substitution reaction was monitored on the UV–Vis (by monitoring the change in absorbance at the indicated wavelength) spectrophotometer. All kinetic measurements were monitored under pseudo-first-order conditions with [H_2biphen] 10–200 times the concentration of the Ti(acac)$_2Cl_2$ complex in CH_3CN solution. The concentration Ti(acac)$_2Cl_2$ ≅ 0.0002 mol dm^{-3}. Kinetic measurements, under pseudo-first-order conditions for different concentrations of Ti(acac)$_2Cl_2$ at a constant [H_2biphen], confirmed that the concentration of Ti(acac)$_2Cl_2$ did not influence the value of the observed kinetic rate constant. A linear relationship between

UV absorbance, A, and concentration, *C*, confirmed the validity of the Beer–Lambert law ($A = \varepsilon Cl$ with l = path length = 1 cm) for the complexes **1** and **2** at experimental wave lengths λ_{max} = 340 nm (ε/dm^3 mol^{-1} cm^{-1} is 1830(20) for **1** and 4890(30) for **2**). The observed first-order rate constants were obtained from least-square fits of absorbance *versus* time data [41].

4.5. Calculations

Pseudo-first-order rate constants, k_{obs}, were calculated by fitting kinetic data [41] to the first-order equation [42] $[A]_t = [A]_0 e^{(-kobs\ t)}$ with $[A]_t$ and $[A]_0$ the concentration of the indicated species at time t and at $t = 0$ (UV–Vis). The experimentally determined pseudo-first-order rate constants were converted to second-order rate constants, k_1, by determining the slope of the linear plots of k_{obs} against the concentration of the incoming biphenolato ligand. Non-zero intercepts implied that $k_{obs} = k_1[\text{biphen}] + k_{-1}$ and that the first-order rate constant for a solvent pathway, k_{-1}, in the proposed reaction mechanism exists. All kinetic mathematical fits were done utilizing the fitting program MINSQ [41]. The error of all the data are presented according to crystallographic conventions, for example $k_{obs} = 0.0236(1)\ s^{-1}$ implies $k_{obs} = (0.0236 \pm 0.0001)\ s^{-1}$. The activation parameters were determined from the Eyring relationship [42] and the activation free energy $\Delta G^{\#} = \Delta H^{\#} - T\Delta S^{\#}$.

4.6. X-ray crystal structure determination

Crystals of Ti(acac)$_2$biphen (**2**) were obtained from recrystallization in chloroform. X-ray intensity data for **2** was measured on a Bruker X8 Apex II 4K CCD area detector, equipped with a graphite monochromator and Mo Kα fine-focus sealed tube (λ = 0.71073 Å) operated at 1.5 kW power (50 kV, 30 mA). The detector was placed at a distance of 3.75 cm from the crystal. Sample temperature was kept constant at 100(2) K using an Oxford 700 series cryostream cooler.

The initial unit cell and data collection of **2** were achieved by the Apex2 software [43] utilizing COSMO [44] for optimum collection of more than a hemisphere of reciprocal space. A total of 948 frames were collected with a scan width of 0.5° in φ and ω with an exposure time of 20 s per frame. The frames were integrated using a narrow frame integration algorithm and reduced with the Bruker SAINTPLUS and XPREP software [45] packages respectively. Analysis of the data collections showed no significant decay during the data collection. Data were corrected for absorption effects using the multi-scan technique SADABS [46].

The structure was solved by the direct methods package SIR97 [47] and refined using the WINGX software package [48] incorporating SHELXL [49]. The largest peaks on the final difference electron densities and the deepest holes were all within 1 Å from non-hydrogen atoms which presented no physical meaning in the final refinements. Aromatic protons were placed in geometrically idealized positions (C–H = 0.95 Å) and constrained to ride on their parent atoms with *U*iso(H) = 1.2 *U*eq(C). Initial positions of the methyl protons were obtained from a Fourier difference map and refined as fixed rotors with *U*iso(H) = 1.5 *U*eq(C) and C–H = 0.98 Å.

Atomic scattering factors were taken from the International Tables for Crystallography Volume C [50]. The molecular plot was drawn using the DIAMOND program [51] with a 30% thermal envelope probability for non-hydrogen atoms. Hydrogen atoms were drawn as arbitrary sized spheres with a radius of 0.135 Å.

ABSTRACT

A structurally distinct, multi-copper(II)-substituted silicotungstate $K_3H_4Cu_{0.5}\{Cu[Cu_{7.5}Si_2W_{16}O_{60}(H_2O)_4(OH)_4]_2\} \cdot 9H_2O$ (**1**) has been synthesized and characterized by FT-IR spectroscopy, elemental analysis, variable-temperature magnetic measurements, electron spin resonance, and X-ray diffraction. Green crystalline plates of **1** were obtained by the reaction of $K_8[\gamma\text{-}SiW_{10}O_{36}] \cdot 12H_2O$ with 8 equiv. of Cu(II) in a 50% ethylene glycol solution. A cationic copper center connects the terminal oxygen atoms of neighboring polyanions, resulting in a one-dimensional structure. Magnetic susceptibility measurements indicate weak ferromagnetic superexchange between the Jahn–Teller-distorted $S = 1/2$ Cu(II) centers.

1. Introduction

Polyoxometalates (POMs) substituted with one or more d-electron metal centers constitute a large class of electronically highly tunable and structurally robust multinuclear compounds [1–3] with applications in catalysis [2,4–11] and potential applications in electroactive materials [12–14], magnetism [15–20], medicine (diagnostics or therapeutics) [21–27], and other fields. The incorporation of transition metals into lacunary POM precursors is generally simple and straightforward; however, the exact mechanisms by which metal-substituted POMs are formed are complex and not well understood. Most frequently, the d-electron metals fill the vacant positions of the lacunary POM forming a saturated (or plenary) structure. Complicating plenary structure reconstitution is the fact that multi-vacant (di-lacunary or tri-lacunary) POM precursors can isomerize under different synthetic conditions, leading to a range of metal-substituted structures. The di-vacant silicotungstate, $[\gamma\text{-}SiW_{10}O_{36}]^{8-}$, readily isomerizes to α and β structures in aqueous solution [28–30], and these processes result in the formation of a diverse set POM structures [31–42] upon reaction with transition metals.

Several research groups have investigated the reactions of $[\gamma\text{-}SiW_{10}O_{36}]^{8-}$ with first-row transition metal salts [31–48]. Early work to prepare disubstituted $\{\gamma\text{-}M_2SiW_{10}\}$ (M = V, Cr, Mn), where the γ-isomer polyoxoanion structure is retained, was performed by Pope and co-workers [32,33,44]. These di-metal substituted structures contain the two d metals in adjacent positions as either "in-pocket" or "out-of-pocket" isomers. The in-pocket isomers contain bonds between the central heteroatom oxygens and the incorporated d-electron centers. In contrast, the out-of-pocket isomers do not contain this bond, and consequently the d-electron metals are displaced from the center of the polyanion and frequently multiply bonded to other adjacent polyanions or distinct structural units. Subsequently $\{\gamma\text{-}M_xSiW_{10}\}$ structures were reported by the research groups of Mizuno [43,45,46], Mialane [39], Peng [47], and others. By slightly changing the synthetic conditions, Kortz and co-workers [36] prepared a series of sandwich dimers, $[\beta\text{-}(M_2SiW_9O_{34})_2]^{(2n+4)-}$ (M = Mn, Cr, Zn). Further investigation of the reactions of d-electron-metals with $[\gamma\text{-}SiW_{10}O_{36}]^{8-}$ by this group afforded several other d-electron-metal-substituted silicotungstates [37,38,40,41,48,49]. Meanwhile, Mialane and co-workers [39,50,51] reported several different metal-substituted silicotungstates with complicated structures by adding azide and/or other ligands to the reaction system. Peng and co-workers [47] described dimers, $[\{K(H_2O)\}_2\{(\mu_3\text{-}H_2O)M(H_2O)\}(\gamma\text{-}Si_2W_{20}O_{70})]^{8-}$ (M = Mn^{2+}, Co^{2+}, and Ni^{2+}), prepared in acidic aqueous solution, that retain the $\{\gamma\text{-}SiW_{10}\}$ unit of the precursor.

Recently, we obtained a di-copper substituted dimeric silicotungstate complex, $K_9Na_2Cu_{0.5}[\gamma\text{-}Cu_2(H_2O)SiW_8O_{31}]_2 \cdot 38H_2O$ from the reaction of a copper(II) salt with $K_8[\gamma\text{-}SiW_{10}O_{36}] \cdot 12H_2O$ in an acetate-buffered 50% ethylene glycol solution [52]. This copper substituted silicotungstate cluster contains two pseudo-planar Cu_2O_2 motifs, and strong ferromagnetic superexchange between the $S = 1/2$ Cu(II) centers was observed. Simultaneously, Peng and co-workers obtained a similar complex via a different synthetic

doi:10.1016/j.poly.2008.09.031

approach [53]. We report here that reaction of $[\gamma\text{-}SiW_{10}O_{36}]^{8-}$ and $Cu(NO_3)_2$ in unbuffered aqueous solution followed by crystallization out of water:ethylene glycol (1:1) produces a one-dimensional polymeric structure comprising $\{Cu_{16}Si_4W_{32}\}$ polyanions interlinked by additional individual Cu(II) centers, $K_3H_4Cu_{0.5}\{Cu[Cu_{7.5}Si_2W_{16}O_{60}(H_2O)_4(OH)_4]_2\}\cdot 9H_2O$ (**1**). Magnetic susceptibility and ESR measurements of **1** show that this multi-copper substituted silicotungstate exhibits more complicated magnetic properties. As we were reporting our work, Su and co-workers [53] reported a similar multi-copper polyanion, $Na_{16}[Cu_{14}(OH)_4(H_2O)_{16}(SiW_8O_{31})_4]\cdot 20.5H_2O$, but here the structure features discrete polyanion units, and no magnetic data were reported. Herein, we describe the synthesis, structure, and magnetic properties of **1**.

2. Experimental

2.1. General methods and materials

$K_8[\gamma\text{-}SiW_{10}O_{36}]\cdot 12H_2O$ was prepared according to literature procedure [30] and the purity was checked by infrared spectroscopy. Copper nitrate, acetonitrile and ethylene glycol were obtained from Aldrich and used without further purification. Elemental analyses for K, Cu, Si and W were performed by Galbraith Laboratories (Knoxville, Tennessee). The infrared spectrum (2 weight% sample in KBr pellet) was recorded on a Nicolet 6700 FT-IR spectrometer. Thermogravimetric data were collected on an ISI TGA 1000 instrument. ESR measurements were performed on a powder sample at 290 K using a Magnettech Miniscope MS-100 spectrometer and DPPH as an external standard. Magnetic susceptibility measurements were performed at 0.1–5.0 T for $T = 1.8$–290 K using a Quantum Design MPMS-5S SQUID magnetometer. Experimental susceptibility data were corrected for diamagnetic and (significant) temperature-independent paramagnetic contributions that were determined from measurements on a range of diamagnetic γ-Keggin polyoxotungstate compounds ($\chi_{dia/TIP}$(**1**) = -1.10×10^{-3} emu/mol).

2.2. Synthesis of $K_3H_4Cu_{0.5}\{Cu[Cu_{7.5}Si_2W_{16}O_{60}(H_2O)_4(OH)_4]_2\}\cdot 9H_2O$ (**1**)

A 5 mL aliquot of acetonitrile solution containing 0.5 g (2.66 mmol) of $Cu(NO_3)_2$ was dissolved in 20 mL of deionized water. To this solution 1.0 g (0.33 mmol) of $K_8[\gamma\text{-}SiW_{10}O_{36}]\cdot 12H_2O$ was added with stirring. After stirring for 20 min, the undissolved residues were removed from the solution by a medium frit and the filtrate (25 mL) was collected. A 5 mL portion of the filtrate was transferred to a 15 mL vial and 5 mL of ethylene glycol was added. The mixture was stirred for an additional 5 min and then placed into a dark cabinet. Green plate-like diffraction quality crystals of **1** grew from this 1:1 water:ethylene glycol mixed solution after two weeks (0.12 g, yield 14.4%). IR (2% KBr pellet, 1200–400 cm^{-1}): 1082 (w), 1039 (w), 990 (w, sh), 950 (m), 878 (s, sh), 787 (w), 736 (s), 696 (w), and 519 (w, sh), 491 (w). Elemental composition *Anal.* Calc. for $K_3H_4Cu_{0.5}\{Cu[Cu_{7.5}Si_2W_{16}O_{60}(H_2O)_4(OH)_4]_2\}\cdot 9H_2O$: Cu, 11.00; K, 1.23; Si, 1.18; W, 61.75. Found: Cu, 11.9; K, 1.07; Si, 1.22; W, 58.2%. [MW = 9527.6 g/mol].

2.3. X-ray crystallography of **1**

A green plate crystal of **1** with dimensions of $0.19\times0.17\times0.04$ mm^3 coated in Paratone-N oil was mounted on a small fiber loop for index and intensity data collection. The data were collected at 30 K under a helium stream on a Bruker-AXS SMART 1000 CCD single-crystal diffractometer using Mo K_α (0.71073 Å) radiation. Indexing, and initial cell refinements of the collected data were performed by the SMART [54] program. The frame integration and final cell refinements were carried out by using the SAINT [55] program. The final cell parameters were determined from the least-squares refinement of 79 664 reflections. From these unique reflections ($2\theta_{max} = 46.52°$), 13 924 reflections ($R_{int} = 0.2197$) were considered to be observed. The structure was determined through direct methods (SHELXS97) via locating the tungsten atoms and difference Fourier maps (SHELXL97). The hydrogen atoms of the water molecules were not located in the difference Fourier maps. The final cycle of refinement resulted at $R = 0.0979$ and $R_w = 0.1513$ ($I > 2\sigma(I)$) (Table 1). In the final difference map, a residual electron density maximum of 3.954 e $Å^{-3}$ and a minimum of -3.304 e $Å^{-3}$ were observed.

3. Results and discussion

3.1. Synthesis

The potassium salt of **1** was prepared by mixing 8:1 mole ratio of $Cu(NO_3)_2$ and $K_8[\gamma\text{-}SiW_{10}O_{36}]\cdot 12H_2O$ in a 1:1 water–ethylene glycol solution. Green crystalline plates of **1** were obtained after two weeks in ca. 14% yield. If the same synthetic procedure is followed but without the addition of ethylene glycol, small green needle-like crystals appear after several hours in significantly higher yield (ca. 46%). The FT-IR spectrum of these needles are very similar to that of **1** except that there is an absence of two peaks at 1082 and 1039 cm^{-1}, which are attributed to the C–O stretch of ethylene glycol. Unfortunately, the needles diffracted X-rays poorly providing commensurately low quality datasets. Complex **1** was synthesized in an acidic environment (pH 4.2) without buffer and the blue needle-like crystals were obtained when HOAc/NaOAc buffer was used to maintain the same pH value. X-ray diffraction established that the blue crystals are a dimeric silicotungstate which contains a $\{\gamma\text{-}Cu_2(H_2O)SiW_8O_{31}\}$ motif in each subunit. Both **1** and the dimeric POM contain the tetra-vacant $\{B\text{-}\beta\text{-}SiW_8O_{31}\}$ fragment in their structures. The appearance of this $\{B\text{-}\beta\text{-}SiW_8O_{31}\}$ fragment in both multi-copper-containing POM products may indicate that Cu^{2+} ions facilitate conversion of the di-vacant $[\gamma\text{-}SiW_{10}O_{36}]^{8-}$ into $\{B\text{-}\beta\text{-}SiW_8O_{31}\}$ *in situ* and/or stabilize the latter unit via coordination. It is reasonable that the excess acetate from the buffer and the polytungstate intermediates compete to coordinate to the hydrated Cu^{2+} ions, and this competition leads to the formation of the recently reported dimeric cluster [52,56] which contains fewer copper centers per polyanion.

Kortz and co-workers [38,48] recently reported several POM structures that contain the {B-β-SiW_8O_{31}} unit in their study of the Co(II)/[γ-$SiW_{10}O_{36}$]$^{8-}$ system, where a large excess $CoCl_2$ was reacted with [γ-$SiW_{10}O_{36}$]$^{8-}$ in aqueous solution buffered at pH 5.5 and heated to 50 °C for 30 min. This procedure resulted in the cobalt-substituted silicotungstate trimer [{$Co_9Cl_2(OH)_3(H_2O)_9$(β-$SiW_8O_{31})_3$}]$^{5-}$ of D_{3h} symmetry. Each subunit of this trimer contains a {B-β-SiW_8O_{31}} unit, which coordinates with three cobalt atoms and forms a {M_3SiW_8} motif. By changing the pH to 4.8 and the molar ratio of Co:[γ-$SiW_{10}O_{36}$]$^{8-}$ to 2:1, another cobalt-substituted silicotungstate, [{Co_3(B-β-SiW_9O_{33})(OH))(B-β-SiW_8O_{29}-$(OH)_2$}$_2$]$^{22-}$, was obtained which also contains the {M_3SiW_8} motif [38,48].

Mialane and co-workers [39,51,57] have investigated the reaction of transition metals and [γ-$SiW_{10}O_{36}$]$^{8-}$ in the presence of azide and documented several instances where azide interacts with metal centers, resulting in the formation of new POM structures. They obtained a copper-substituted trimer, [{$SiW_8O_{31}Cu_3$-$(OH)(H_2O)_2(N_3)$}$_3(N_3)$]$^{19-}$, that is structurally analogous to the Co-substituted trimer obtained by Kortz and co-workers when an excess of azide was used. Their study of the Co/[γ-$SiW_{10}O_{36}$]$^{8-}$ system afforded several different cobalt-substituted silicotungstates, including the dimer polyanion [{(B-β-SiW_9O_{33})(OH)(β-SiW_8O_{29}-$(OH)_2$)$Co_3(H_2O)$}$_2$$Co(H_2O)_2$]$^{20-}$. Each subunit of this dimer contains a {B-β-SiW_8O_{31}} and a {B-β-SiW_9O_{34}} motif connected by three cobalt atoms, and the {B-β-SiW_8O_{31}} motif in each subunit is linked to another by a six-coordinated cobalt center. The general polyanion framework of this Co-substituted POM is similar to our sixteen-copper-containing polyanion, **1**. Very recently, Zhang et al. [53] reported a 14-copper-containing silicotungstate by the reaction of 12 mol equiv. of copper salt with [γ-$SiW_{10}O_{36}$]$^{8-}$ in a pH 5.5 boiling aqueous solution containing D-proline for 2 h. This Cu_{14} silicotungstate is structurally analogous to **1** but contains less copper since the polyanions are not linked by Cu centres into a one-dimensional material as it is the case in **1** (*vide infra*).

3.2. Structural features

The new polymeric multi-copper-substituted silicotungstate, **1**, crystallizes in the monoclinic space group, *C2/c*. The polyanion unit contains 2 equiv. [$Cu_7Si_2W_{16}O_{60}(H_2O)_4(OH)_4$]$^{6-}$ subunits related by a four-coordinate copper located on the C_2 axis (C_2 local symmetry; Fig. 1). The inversion center is not located at this copper, but lies in the center of the unit cell. Each subunit contains two multi-copper substituted {B-β-SiW_8O_{31}} motifs (Fig. 2). The two motifs connect to each other via three five-coordinate copper atoms: Cu2, Cu3 and Cu4. O30 is a μ_3-oxo bridging Cu3, Cu4 and Si1; O35 is a μ_4-oxo bridging Cu2, Cu3, Cu4 and Si2. In the {B-β-SiW_8O_{31}} motif containing Si1, two of the copper atoms, Cu3 and Cu4, exist as a {Cu_2O_6} unit which resides in the position of the conventional {W_2O_6} group, thus forming a {γ-$Cu_2SiW_8O_{31}$} unit that maintains the γ isomerism of the [γ-$SiW_{10}O_{36}$]$^{8-}$ precursor. Alternatively, the {B-β-SiW_8O_{31}} motif with Si2 contains these three copper atoms, Cu2, Cu3 and Cu4, as a {Cu_3O_5} unit that defines a β-Keggin structure, {β-$Cu_3SiW_9O_{34}$}. The remaining lacunary (vacant) position of the {β-$Cu_3SiW_9O_{34}$} motif is filled by Cu6. Two more copper atoms, Cu5 and Cu7, are also five coordinate each forming a pyramidal unit linked to Cu6. The three copper atoms linked via four μ_3-oxo groups form a nearly planar Cu_3O_4 motif. The pyramidal units share the terminal O1 and O7 with the {γ-$Cu_2SiW_8O_{31}$} motif located on the other subunit, thus connecting the β and γ motifs in different subunits to form the large cluster. Cu1, the only four-coordinate copper in the structure which is located on the C_2 axis, fills the lacunary position opposite to Cu3 and Cu4 on each γ motif. In each subunit, a copper atom, Cu8, is bonded to three oxygens on the outside (away from the central multi-copper region) of the γ motif. One more cationic copper, Cu9, connects to the terminal oxygen of W15 and W15′ located on two neighboring molecules thereby linking the clusters to form the one-dimensional array (Fig. 3).

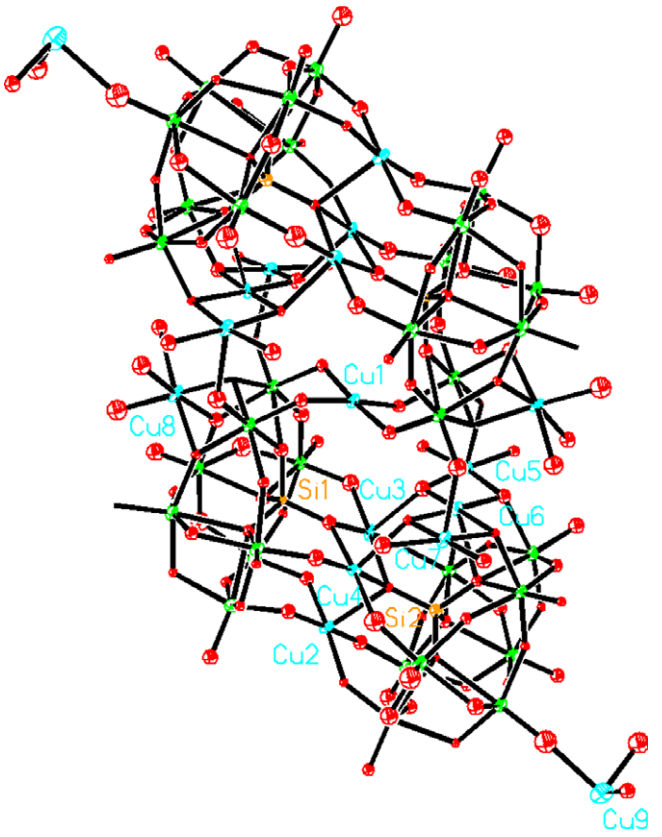

Fig. 1. Ball and stick representation of [$Cu\{Cu_{7.5}Si_2W_{16}O_{60}(H_2O)_4(OH)_4\}_2$]$^{8-}$ (**1a**, the polyanion of **1**) showing 50% probability ellipsoids and selected atomic labels. Cu: blue; O: red; Si: orange; W: green. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

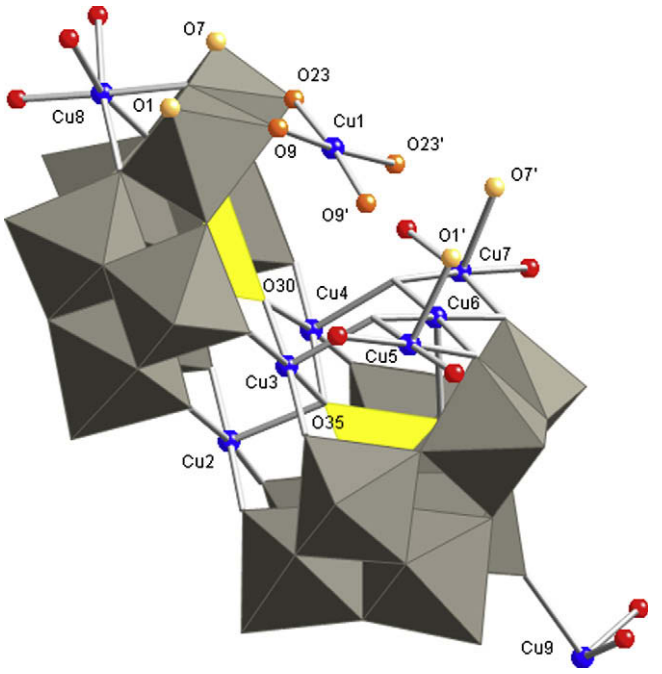

Fig. 2. A combination polyhedral/ball-and-stick representation of the {Cu_9Si_2-$W_{16}O_{60}(H_2O)_4(OH)_4$} subunit of **1**.

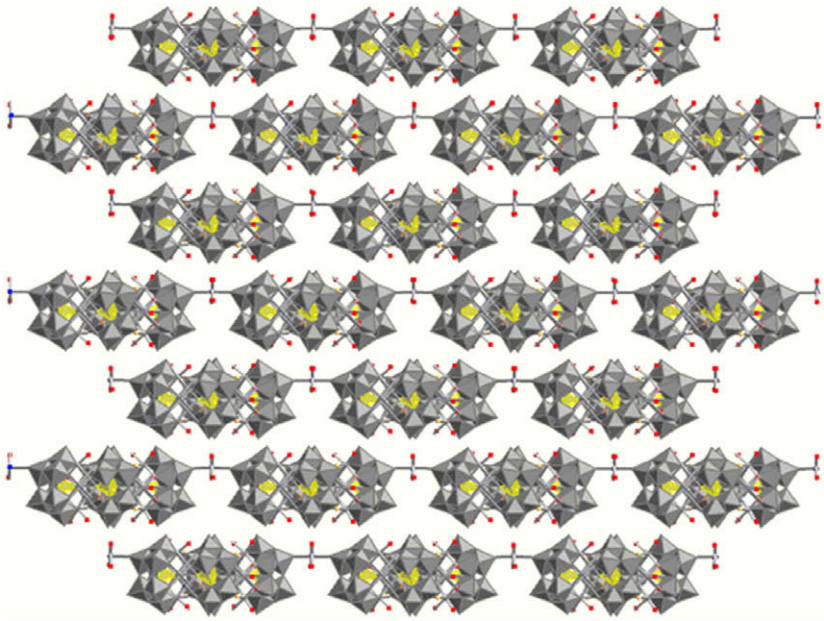

Fig. 3. Structural view of the one-dimensional array of **1** from *c* axis direction.

3.3. Electron spin resonance

The X-band ESR spectrum of **1**, measured as a powder, displays an overlay of several different Cu(II) environments, resulting in a very broad signal (Fig. 4). The resulting convoluted response can be understood as an average of Jahn–Teller-distorted Cu(II) signals characterized by vertical and parallel g tensor components, $g_{\perp} = (g_{xx} + g_{yy})/2$ and $g_{||} = g_{zz}$, characteristic for Cu(II) centers in such distorted environments. From the average values $g_{\perp} = 2.04$ and $g_{||} = 2.48$, an average isotropic $g_{iso} = 2.19$ is derived. Note that limited solubility of **1** in polar and nonpolar solvents prevented recording of an ESR spectrum of **1** in solution of possibly higher resolution.

3.4. Magnetic properties

The low-field (0.1 T) magnetism of compound **1** indicates dominating weak ferromagnetic intramolecular superexchange between the Jahn–Teller-distorted $s = 1/2$ Cu(II) centers that are spaced apart less than 3 Å (Table 2). Note that ferromagnetic interactions of comparable strength are also observed in Cu(II)-substituted polyoxometalates such as $\{Mo_{57}Cu_6\}$-type clusters [58] in which the spin centers are bridged by O–Mo–O fragments and where the orthogonality of the magnetic Cu(3d) orbitals necessary for ferromagnetic exchange is achieved by rotation of their colinear local orbital coordinate frameworks by 60° around the local z axis, i.e. the elongated Jahn–Teller axis. In **1** the coupling within a subunit (characterized by the exchange energy J_1 between Cu3 and Cu4) is mediated via a μ_3-oxo group (O30) and a μ_4-oxo group (O35), whereby the Cu(II) centers form a nearly planar Cu_2O_2 motif with oxo groups in the equatorial coordination plane. Very similar and coplanar Cu_2O_2 motifs result for the triad formed by Cu5, Cu6, and Cu7. The geometry of the $Cu_2(\mu\text{-}O)_2$ fragments are expected to result in ferromagnetic exchange based on the empirical correlation studies of oxo-bridged Cu(II) dimer compounds [59–62]. We expect that both of these effects, the rotation of the coordinate systems and the Cu–O–Cu bond angles in the subunits, are the primary source for the observed ferromagnetic coupling. However, additional weaker antiferromagnetic coupling is likely to be present, too, e.g. for contacts involving O–W–O exchange pathways such as Cu1–Cu8. On the other hand, we expect Cu9, interlinking the POM units, to be magnetically isolated as any pathways to other Cu centers involve at least five non-magnetic centers. Furthermore, also Cu2 has to be assumed to be magnetically isolated: the magnetic Cu(3d) orbital will be of $d_{x^2-y^2}$ character due to the observed Jahn–Teller distortion so that virtually no exchange will be active via the apical oxo center (O35), and exchange with any

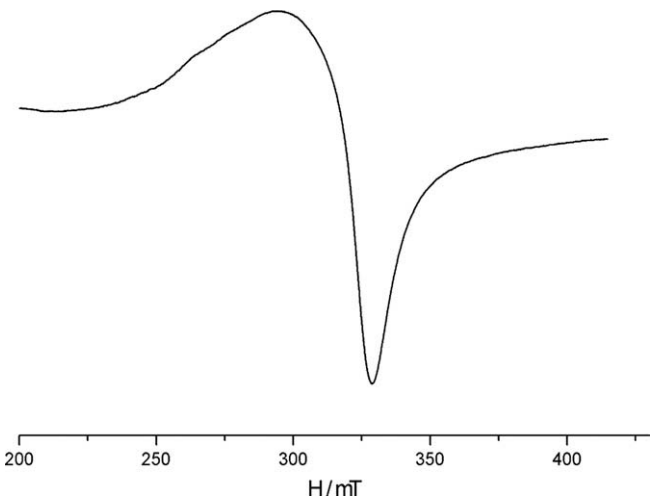

Fig. 4. X-band ESR spectrum of compound **1**, measured as a microcrystalline powder at 290 K.

adjacent Cu centers via the equatorial oxo ligands will, on the other hand, again involve more than five non-magnetic centers. For the same reasons, the interaction between the Cu3/Cu4 dimer and the Cu5/Cu6/Cu7 triad will be very weak as well. In summary, in terms of magnetic interactions **1** can be approximated as several independent entities: magnetically isolated centers, Cu2 and Cu9, a weakly antiferromagnetically coupled symmetric trimer, Cu8–Cu1–Cu8′, a ferromagnetically coupled dimer, Cu3–Cu4, and a ferromagnetically coupled trimer, Cu5–Cu6–Cu7. The high nuclearity and the large number of intramolecular exchange contacts in **1** precludes, however, the unambiguous determination of coupling constants J_n based on the susceptibility data, even if only a simple isotropic Heisenberg-type model Hamiltonian is employed.

The high-temperature limit of χT of 7.6 emu K/mol (at 290 K) corresponds to the spin-only moment of 16.9 spin-1/2 centers (assuming the ESR-derived $g_{iso} = 2.19$). This value indicates an additional fraction of approx. 0.9 isolated Cu(II) centers per formula unit in the cationic lattice. Below ca. 100 K, χT rises continually, and even at 1.8 K (15.3 emu K/mol) the χT versus T graph does not show any signs of approaching a maximum (Fig. 5). This steep increase is, however, quenched at higher fields. At 5.0 Tes/a, χT reaches a maximum at ca. 12 K.

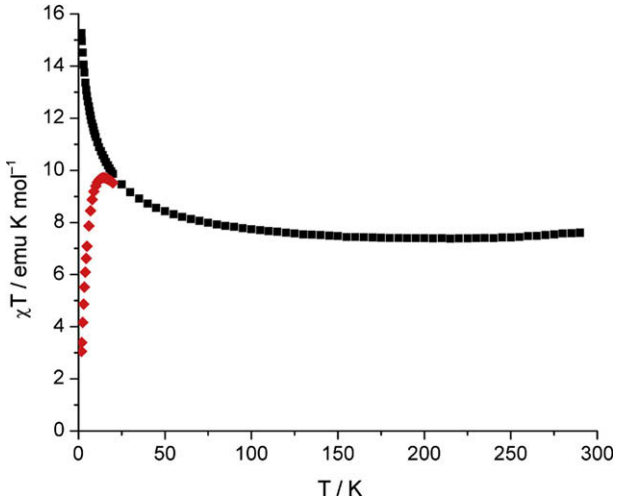

Fig. 5. Temperature dependence of χT of **1** at 0.1 T (black squares) and at 5.0 T (red carets, the data follows the 0.1 T curve for higher temperatures). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

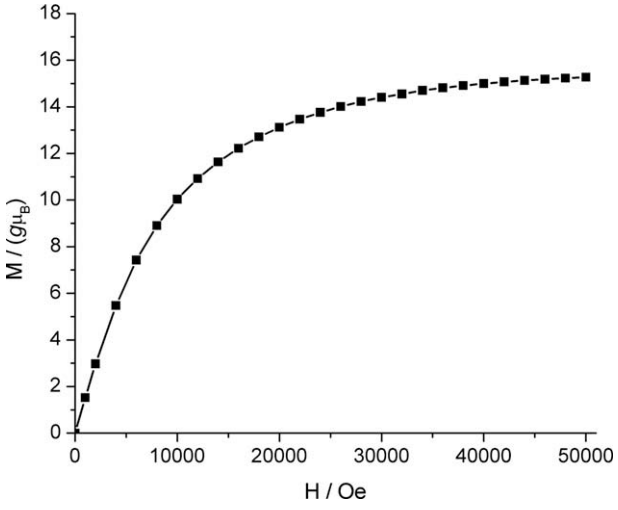

Fig. 6. Field dependence of the magnetization, M, of **1** at 1.8 K.

Field-dependent magnetization measurements at 1.8 K (Fig. 6) indicate the expected magnetic saturation. However, the aforementioned magnetically isolated entities all contribute to the low-temperature magnetization; therefore, the spin ground state of an individual POM cluster unit cannot be determined with certainty from these data. In addition, as evident from the very broad ESR spectrum, the coordination environments of the Cu(II) centers differ significantly and thus contribute to the overall magnetization to a different extent. We are currently working to characterize this system using large-scale simulation techniques (Quantum Monte Carlo simulations) and will present a more detailed description of the magnetism of **1** in forthcoming work.

Supplementary data

CSD 418999 contains the supplementary crystallographic data for **1**. Further details of the crystal structure investigation may be obtained from Fachinformationszentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen, Germany (fax: (+49)7247-808-666; e-mail: crysdata@fiz-karlsruhe.de, http://www.fiz-karlsruhe.de/request_for_deposited_data.html) on quoting the appropriate CSD number.

ABSTRACT

A novel lead(II) complex with the Schiff base benzil bis(semicarbazone), $[Pb(LH_2)_2(NO_3)]NO_3 \cdot 1/2H_2O$, has been synthesised and structurally characterized as well as the free ligand. The coordination number of Pb(II) is seven provided by two neutral ligand molecules and one nitrato group. The most interesting characteristic of this complex is the different behaviour observed in the two bis(semicarbazone) molecules. One of them is a N_2O_2 chelate ligand, whereas the other one is bonded to the lead ion only through one of the semicarbazone branches. The seventh position in the lead coordination sphere is provided by one oxygen atom from a nitrato ligand.

1. Introduction

In the course of our studies on the coordination ability of ligands derived from 1,2-diphenylethanedione (benzil) with thiosemicarbazides to bind to transition and main group metals, we have established the importance of the working conditions and the preferred coordination geometries of the metal ion in the structure of the final complexes. A combination of both factors permits the synthesis of mono, binuclear, hexanuclear or extended coordination polymers [1–5]. Control of the structural properties is essential, since they will determine the potential applications of the metal complexes [6–8].

Relatively less attention has been devoted to the synthesis and biological properties of their structurally analogous semicarbazones and their metal complexes, and excluding derivatives from 2,6-diacetylpyridine there is almost nothing reported with bis(semicarbazones), despite the fact that, some of these compounds have shown considerable anticonvulsant, antimicrobial and antitumor activities and some VO_2^+ complexes can act as insulin-mimetic agents [9–12]. The great advantage of semicarbazone derivatives over their thiosemicarbazone analogues seems to be their lower toxicity. One reason for the lack of complexes containing bis(semicarbazone) ligands might be the fact that they frequently undergo cyclization reactions, particularly in the presence of metal ions. This has also been observed for benzil bis(semicarbazone) LH_2, which even in the absence of metal cyclises when heated [13]. With rhenium at room temperature it readily loses one of its semicarbazone arms to yield a triazine-3-one, which forms complexes with different triazine binding modes depending on the precursor used [14].

On the other hand, the Pb(II) ion is a heavy p-block metal that possess variable coordination behaviours, coordination numbers ranging from 2 to 10 and diverse coordination geometries, caused by the stereo-chemical active lone pair [15–21]. With respect to the large number of thiosemicarbazone complexes with many main group and transition metals, the number of structurally characterized lead complexes with such ligands is relatively small [22–26] and as far as we know, only five crystal structures of lead semicarbazones have been reported [27–30]. In order to compare the reactivity of benzil bis(semicarbazone) with the analogous benzil bis(thiosemicarbazone) [2,31], we have explored the reaction of LH_2 with lead nitrate and here we report its lead derivative, which has been crystallographically characterized, as well as the crystal structure of the free ligand.

2. Experimental

2.1. Physical measurements

Microanalyses were carried out using a Perkin-Elmer 2400 II CHNS/O Elemental Analyser. IR spectra in the 4000–400 cm^{-1} range were recorded as KBr pellets on a Jasco FT/IR-410 spectrophotometer. Fast atom bombardment mass spectra were recorded on a VG Auto Spec instrument using Cs as the fast atom and *m*-nitrobenzylalcohol (*m*NBA) as the matrix. ^1H spectrum was recorded on a Bruker AMX-300 spectrometer using THF-d_8 and CD_3CN as solvents; chemical shifts are expressed on the δ scale relative to TMS as internal reference. ^{13}C CP/MAS NMR spectra

doi:10.1016/j.poly.2008.10.058

were recorded at 298 K in a Bruker AV400WB spectrometer equipped with a 4 mm MAS NMR probe (magic-angle spinning) and obtained using cross-polarization pulse sequence. For the recorded spectra a contact time of 4 ms were used and recycle delays of 4 s were used. Chemical shifts are reported relative to TMS, using the CH group of adamantano as a secondary reference (29.5 ppm).

2.2. Synthesis of benzil bis(semicarbazone), LH_2

This was prepared by reaction between benzil and semicarbazide hydrochloride in the presence of $LiOH \cdot H_2O$ [13]. Selected spectroscopic data for LH_2: IR (KBr): ν = 3411(s), 3325(s), 3255(s), 3158(s) ν(N–H), 1682(s) amide I, 1584(w) ν(CN), 1569(s) $\delta(NH_2)$ cm^{-1}. ^1H NMR (25 °C, DMSO-d_6, 300 MHz): δ = 9.09 (s, 2H, NH), 7.65 (m, 4H, Ph), 7.51–7.25 (m, 6H, Ph), 6.59 (s, 4H, NH_2) ppm. ^{13}C CP/MAS NMR (300 MHz): δ = 158.9 (CO), 141.1 (CN), 128.9 (Ph) ppm. Crystals suitable for X-ray studies were obtained by recrystallization in methanol.

2.3. Synthesis of $[Pb(LH_2)_2(NO_3)]NO_3$ (**1**)

A solution of $Pb(NO_3)_2$ (165 mg, 0.5 mmol) in distilled water (5 mL) was mixed with a suspension of LH_2 (324 mg, 1 mmol) and $LiOH{\cdot}H_2O$ (42 mg, 1 mmol) in methanol (50 mL). The mixture was stirred for 6 h under reflux. A crystalline yellow material was formed after partial evaporation of the yellow solution (389 mg, 80%). *Anal.* Calc. for $C_{32}H_{32}N_{14}O_{10}Pb$ (979.45): C, 39.21; H, 3.29; N, 20.02. Found: C, 39.45; H, 3.08; N, 19.87%. IR (KBr): ν = 3398(s), 3335(s), 3231(s), 3188(s) ν(N-H), 1691(s), 1667(s) amide I, 1614(m) ν(CN), 1539 (s) $\delta(NH_2)$ cm^{-1}. Single crystals suitable for X-ray analysis were grown from THF.

2.4. X-ray crystallography

Crystal data and refinement results are listed in Table 1. Data for LH_2 were collected on a Bruker SMART 6K CCD area-detector three-circle diffractometer with a MAC Science Co., Ltd. Rotating Anode (Mo Kα radiation, λ = 1.54178 Å) and for **1** on a Bruker AXS Kappa Apex-II diffractometer equipped with an Apex-II CCD area detector using a graphite monochromator (Mo Kα radiation, λ = 0.71073 Å). The substantial redundancy in data allows empirical absorption corrections (SADABS) [32] to be applied using multiple measurements of symmetry-equivalent reflections. The raw intensity data frames were integrated with the SAINT program, which also applied corrections for Lorentz and polarization effects [33].

The software package SHELXTL version 6.10 was used for space group determination, structure solution and refinement. The structures were solved by direct methods (SHELXS-97) [34], completed with difference Fourier syntheses, and refined with full-matrix least squares using SHELXL-97 minimizing $\omega(F_0^2 - F_c^2)$. Weighted *R* factors (R_w) and all goodness of fit *S* are based on F^2; conventional *R* factors (*R*) are based on *F* [35], All non-hydrogen atoms were refined with anisotropic displacement parameters and hydrogen atoms were located by difference maps although were positioned geometrically after each cycle refinement .All scattering factors and anomalous dispersions factors are contained in the SHELXTL 6.10 program library.

In complex **1** the hydrogen atoms of the molecule of water could not be located in the difference Fourier map, presumably as a result of disorder. In addition, the difference Fourier map showed a number of peaks of additional electron density, which were identified as the N and O of half a nitrate anion, but as a consequence of the disorder they could not be satisfactorily modelled. Its contribution was removed from the observed data using SQUEEZE in the software program PLATON [36], but the atom count from this $1/2NO_3$ is included in the empirical formula. The water hydrogen atoms and the half a nitrate molecule have been omitted from the model, but included in calculations of the formula, weight etc. The other half a nitrate is also disordered, but only over two sites, so it could be modelled.

3. Results and discussion

The crystal structure of the bis(semicarbazone) consists of discrete molecules of LH_2 with two molecules of methanol (Fig. 1). Both semicarbazone branches are identical due to a crystallographically imposed symmetry, with the bond distances and angles corresponding to an imine–ketone disposition, which is supported by the presence of hydrazinic hydrogens (Table 2). To difference with the analogue thiosemicarbazone ligand [1], the two semicarbazone arms are not *trans* with respect to the single bond C(2)–C(2A), and the angle between them is 75.5°, being close to be perpendicular. The angle between the aromatic rings is 73.4°, so they are in a perpendicular disposition, thus minimizing the phenyl intramolecular interaction. The semicarbazone core can be considered planar with a maximum deviation of 0.02 Å for C(2) and forms an angle of 22.5° with the phenyl ring. The molecular conformation of the oxygen atom and the hydrazinic hydrogen H(2) is *cis* with respect to C(1)–N(2). Starting from the free ligand the N_2O_2 chelate formation can only take place via 180° rotation about the C–$N_{hydrazinic}$ single bond, which is in an *E* disposition, and an additional rotation around the C(2)–C(2A) bond. The ligand molecules are held together in the crystal packing through hydrogen bonds involving the amine nitrogen atom N(1) and the oxygen atom O(1) (Table

3, Fig. 2). This forms zigzag chains running along the *b* axis. The chains are also linked through hydrogen bonds running in the direction of *a* and through C(7)–H(7)···O(1) interactions (3.333 Å, 159.5°) along *c*, leading a 3D network. It seems that along *c* there are some π–π interactions, although the distance of 3.999 Å between centroids avoids π–π stacking. The methanol molecules are also connected through hydrogen bonds acting both as donor and acceptor, with the hydrazinic nitrogen N(2) and O(1) (Table 3), reinforcing the 3D structure, although they are not necessary for the formation of the 3D network.

The lead complex $[Pb(LH_2)_2(NO_3)]NO_3$ was prepared by reaction of LH_2 and $Pb(NO_3)_2$. Its analytical data indicate a 2:1 ligand:Pb ratio, as well as the presence of two NO_3^-. The mass spectrum does not show a peak corresponding the cationic part $[Pb(LH_2)_2(NO_3)]^+$, but peaks corresponding to the loss of LH_2 and/or NO_3^- are observed. The infrared spectrum shows the same number of bands corresponding to the N–H stretching vibrations, suggesting the ligand is not deprotonated, although they are shifted with respect to LH_2. There are two bands corresponding to the amide I, one almost in the same place than in the free bis(semicarbazone) and another shifted to lower wavenumber, suggesting that there exist both free and coordinated C=O groups. This is also observed in the case of the C=N moieties. The presence of NO_3^- is confirmed by a strong band at 1386 cm^{-1}. ^1H NMR spectrum in THF-d_8 or CD_3CN shows that the ligands are not deprotonated, as well as the presence of semicarbazone arms with different behaviour. Due to the low solubility of $[Pb(LH_2)_2(NO_3)]NO_3$, which is only soluble in an amount enough for ^{13}C studies in DMSO-d_6, but with decomposition, ^{13}C/CP MAS spectrum of the complex and the free ligand were recorded. In the complex there are two signals corresponding to C=O and two to C=N, confirming the presence of two types of CO and CN groups, as was deduced form the IR.

The crystal structure of **1** shows an asymmetric unit containing one $[Pb(LH_2)_2(NO_3)]^+$ cation, one nitrate and half a molecule of water (Fig. 3). In the cation the lead atom is in a hepta-coordinate geometry formed by one N_2O_2 tetradentate ligand, one NO bidentate and the oxygen of one nitrato in a distorted capped octahedron arrangement and represents, as far as we know, the first complex containing two bis (semicarbazone) ligands with a different coordination mode and the second containing one coordinated and

one free arm [37]. The difference between our complex and the one previously described is that in those the two bis(semicarbazone) ligands act as tridentate monodeprotonate molecules. The N(1)–C(1)–N(2)–N(3)–C(2)–C(3)–N(4)–N(5)–C(4)–N(6) core of the tetradentate ligand is almost flat, with a maximum deviation of 0.15 Å for N(4). The Pb(II) is 0.50 Å over this plane and the oxygens O(2) and O(1) are 0.19 Å over and 0.26 Å under the plane respectively. The dihedral angle between the phenyl rings in this ligand

is 64.4°. In the bidentate ligand, where one semicarbazone arm is coordinated and the other is free, the branches have a similar disposition than the free ligand and are virtually perpendicular, 89.3°. Whereas in the free arm the semicarbazone, including the aromatic ring (dihedral angle 3.3°), is flat, in the bidentate one the phenyl ring is canted 29.2°. This difference in the position of the phenyl rings makes that they are not exactly perpendicular and form an angle of 80.3° Another difference is that in the free arm the imine nitrogen N(10) and O(4) are in a *trans* disposition, as well as in the free ligand, whilst in the coordinated one they are *cis*.

Within both ligands bond distances and angles correlate well with an imine-ketone form (Table 4), and as a consequence of their behaviour as neutral molecules, there is not a great deal of electronic delocalization, being quite similar to those of the free bis(semicarbazone). Pb–N bond distances with the tetradentate ligand are almost identical [2.551(5) and 2.557(5) Å], whilst N(9) is significantly larger [2.870(5)]. Although this bond is long, is supported by the *cis* disposition of O(3) and N(9). In contrast, Pb–O bond distances with the N_2O_2 LH_2 are quite different [2.497(4) and 2.643(4) Å]. The distance with the bidentate branch is significantly the shortest [2.427(5) Å] and the one with the nitrato the largest [2.701(5) Å].

All of the NH and NH_2 groups participate in hydrogen bonding with both the nitrato and the modelled nitrate groups, as well as with and the oxygen atoms of the water molecules, acting as acceptors to give a 3D network (Table 5). This 3D network can be obtained only through the hydrogen bonds existing between the $[Pb(LH_2)NO_3]^+$ units. The water molecules also have additional short non-bonded contacts, presumably also indicative of hydrogen bonding, although as their H atoms could not be located, these are ambiguous.

4. Conclusions

In this paper we have synthesised and structurally characterised a lead(II) bis(semicarbazone) complex, which represents the first complex containing two bis(semicarbazone) ligands with different behaviour. This structure points out the preference of lead to bind to oxygen instead of to sulphur, since the complex obtained with benzil bis(thiosemicarbazone), under the same reaction conditions, leads a 1:1 complex with the lead atom in a tetracoordinated arrangement and with the ligand doubly deprotonated [2].

In this reaction, the pH does not seem to determine the ligand behaviour on the contrary to the analogue bis(thiosemicarbazone) ligand.

ABSTRACT

The luminescent Pt(II) complex [Pt(4,4′-^{t}Bu$_2$-bipy){CC-(5-pyrimidinyl)}$_2$] (**1**) was prepared by coupling of [Pt(4,4′-^{t}Bu$_2$-bipy)Cl$_2$] with 5-ethynyl-pyrimidine, and contains two pyrimidinyl units pendant from a Pt(II) bipyridyl diacetylide core; it shows luminescence at 520 nm which is typical of Pt(II) luminophores of this type. Reaction with [Ln(hfac)$_3$(H$_2$O)$_2$] (hfac = anion of hexafluoroacetylacetone) affords as crystalline solids the compounds [**1** · {Ln(hfac)$_3$(H$_2$O)}{Ln(hfac)$_3$(H$_2$O)$_2$}] (Ln = Nd, Gd, Er, Yb), in which the {Ln(hfac)$_3$(H$_2$O)} unit is coordinated to one pyrimidine ring *via* an N atom, whereas the {Ln(hfac)$_3$(H$_2$O)$_2$} unit is associated with two N atoms, one from each pyrimidine ring of **1**, *via* N···HOH hydrogen-bonding interactions involving the coordinated water ligands on the lanthanide centre. Solution spectroscopic studies show that the luminescence of **1** is partly quenched on addition of [Ln(hfac)$_3$(H$_2$O)$_2$] (Ln = Er, Nd) by formation of Pt(II)/Ln(III) adducts in which Pt(II)→Ln(III) photoinduced energy-transfer occurs to the low-lying f–f levels of the Ln(III) centre. Significant quenching occurs with both Er(III) and Nd(III) because both have several f–f states which match well the ^{3}MLCT emission energy of **1**. Time-resolved luminescence studies show that Pt(II)→Er(III) energy-transfer (7.0×10^7 M^{-1}) is around three times faster than Pt(II)→Nd(III) energy-transfer ($\approx 2 \times 10^7$ M^{-1}) over the same distance because the luminescence spectrum of **1** overlaps better with the absorption spectrum of Er(III) than with Nd(III). In contrast Yb(III) causes no significant quenching of **1** because it has only a single f–f excited level which is a poor energy match for the Pt(II)-based excited state.

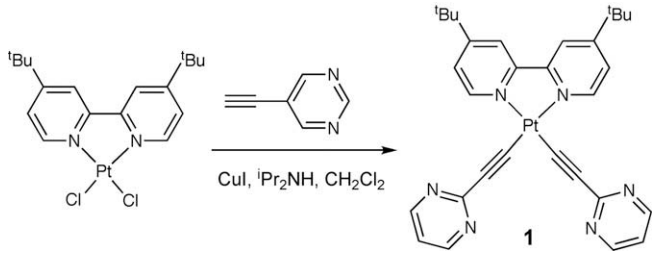
1. Introduction

There has been extensive recent interest in the preparation and photophysical properties of d–f dinuclear complexes in which d-block chromophores, generally with long-lived MLCT excited states, are used as energy-donors to generate sensitised near-infrared luminescence from lanthanide(III) ions such as Nd(III) and Yb(III) which have low-lying emissive f–f states [1–4]. The intense and fully allowed ^{1}MLCT absorptions of the d-block unit allow light to be absorbed at a range of wavelengths in the visible region, overcoming the inability of lanthanide(III) ions to absorb light themselves due to the f–f transitions being Laporte-forbidden. Two recent results of particular significance are (i) that d→f energy-transfer occurs by the Dexter mechanism over long distances (up to 20 Å) when conjugated bridging ligands are used to link the d-block and f-block components [3], and (ii) there is a clear correlation of energy-transfer rate with donor/acceptor spectroscopic overlap [4], which is to be expected but was nonetheless clearly demonstrated in some Pt(II)/Ln(III) dyads in which the ^{3}MLCT energy of the Pt(II) unit varied [4].



In this paper we report a new series of Pt(II)/Ln(III) dyads based on a luminescent Pt(II)-diimine-diacetylide chromophore [4,5] which bears two pendant pyrimidinyl groups. These groups in turn provide four N-donor sites which could potentially act as sites of attachment to {Ln(diketonate)$_3$} centres to allow buildup of polynuclear Pt(II)/Ln(III) assemblies. We describe the synthesis and structure of the new Pt(II) unit, the unexpected structure of a trinuclear PtEr$_2$ adduct, and the photophysical properties of some 1:1 Pt/Ln assemblies (Ln = Gd, Er, Nd, Yb) in solution, in which Pt→Ln energy-transfer occurs to varying extents depending on the nature of the Ln(III) centres.

2. Results and discussion

The new Pt(II) complex **1** (Scheme 1) was prepared from the Cu(I)-catalysed coupling of 4-ethynylpyrimidine with [Pt(^{t}Bu$_2$bipy)Cl$_2$] according to the literature method [5], followed by

chromatographic purification to give pure **1** in 64% yield. Satisfactory spectroscopic and analytical data were obtained (see Section 3). X-ray quality crystals were grown by slow evaporation of a CH_2Cl_2 solution of **1**; the crystal structure is shown in Fig. 1. The Pt(II) ion is in the usual square planar coordination environment, with the Pt–N(py) bond lengths being significantly longer than the Pt–C bond lengths, as is typical for complexes of this type. One pyrimidine ring [containing N(32) and N(34)] is twisted out of the plane of the ^{t}Bu$_2$bipy ligand by 30°; this deviation of a ring from overall planarity prevents the molecules from forming well-defined columnar stacks. Stacking between adjacent molecules involves the {Pt(bipy)} cores, separated by (on average) 3.4 Å and is shown in Fig. 1(b); there are no short Pt···Pt contacts.

The UV–Vis absorption spectrum of **1** in CH_2Cl_2 shows absorption maxima at 378 nm (ε, 8.7×10^3 M^{-1} cm^{-1}) and 287 nm (ε, 44×10^3 M^{-1} cm^{-1}) which can be assigned to ^{1}MLCT and ligand-centred π–π^* transitions, respectively. Excitation of the complex into the ^{1}MLCT absorption band generates typical strong luminescence at 520 nm with t = 105 ns and ϕ = 3.7% (in air-equilibrated CH_2Cl_2) which may be ascribed to a ^{3}MLCT process [4,5]. Thus, the complex has the potential to act as an energy-donor to Ln(III) ions whose f–f states are lower in energy than the ^{3}MLCT energy of **1** [1–4].

Reaction of **1** with [Ln(hfac)$_3$(H$_2$O)$_2$] (Ln = Gd, Nd, Er, Yb) in CH_2Cl_2 solution, followed by layering heptane on to the reaction mixture and leaving the solutions to stand for several days, afforded reasonable yields of orange crystalline products for which elemental analysis was consistent with a 1:2 association of Pt(II) complex **1** and {Ln(diketonate)$_3$} units, respectively. This reaction exploits the lability of the two water ligands of [Ln(hfac)$_3$(H$_2$O)$_2$] units and their tendency to be replaced by N-heterocyclic donors [1–4].

We had expected that the pyrimidine rings might act as bridging ligands, each spanning two Ln(III) centres to generate network structures. However the crystal structure of [**1** · {Er(hfac)$_3$(H$_2$O)}{Er(hfac)$_3$(H$_2$O)$_2$}] (Figs. 2 and 3) reveals a trinuclear PtEr$_2$ species in which the {Er(hfac)$_3$} units interact with the pyrimidine rings of **1** by a combination of conventional N–Er dative bonds, and N···HOH hydrogen bonds to the water molecules that are in turn coordinated to the Er(III) centres. Thus Er(1) is 8-coordinate from three diketonate ligands, one water ligand, and one directly coordinated pyrimidine N atom [N(4)]. Er(2) is also 8-coordinate, from three diketonate and two water ligands, and is associated with both pyrimidine rings of **1** by a pair of N···HOH hydrogen-bonding interactions: effectively complex **1** behaves as a chelating bidentate H-bond acceptor to this {Er(hfac)$_3$(H$_2$O)$_2$} unit. The non-bonded N···O distances in these hydrogen bonds are N(2)···O(2 W), 2.764(7) Å and N(12)···O(3 W), 2.770(7) Å. The N···H–O angles are 168.8° and 161.8°, respectively. The

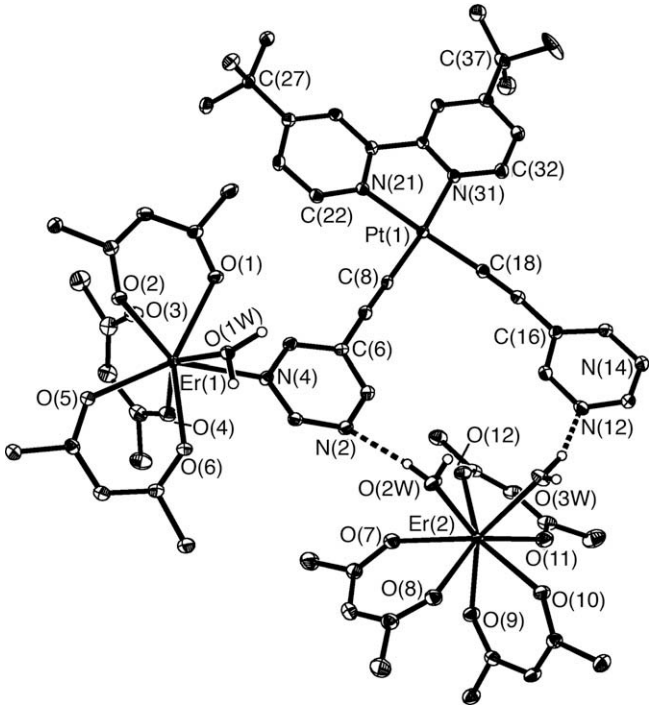

Fig. 2. An ORTEP view of a molecule of [**1** · {Er(hfac)$_3$(H$_2$O)}{Er(hfac)$_3$(H$_2$O)$_2$}], with thermal ellipsoids at the 30% level. The dashed lines are hydrogen bonds between pyrimidine N atoms and water molecules coordinated to Er(2). H atoms (apart from those on the water ligands), F atoms on the hfac ligands, and the minor disorder component of the methyl groups on the ^{t}Bu substituents, ate not shown for clarity.

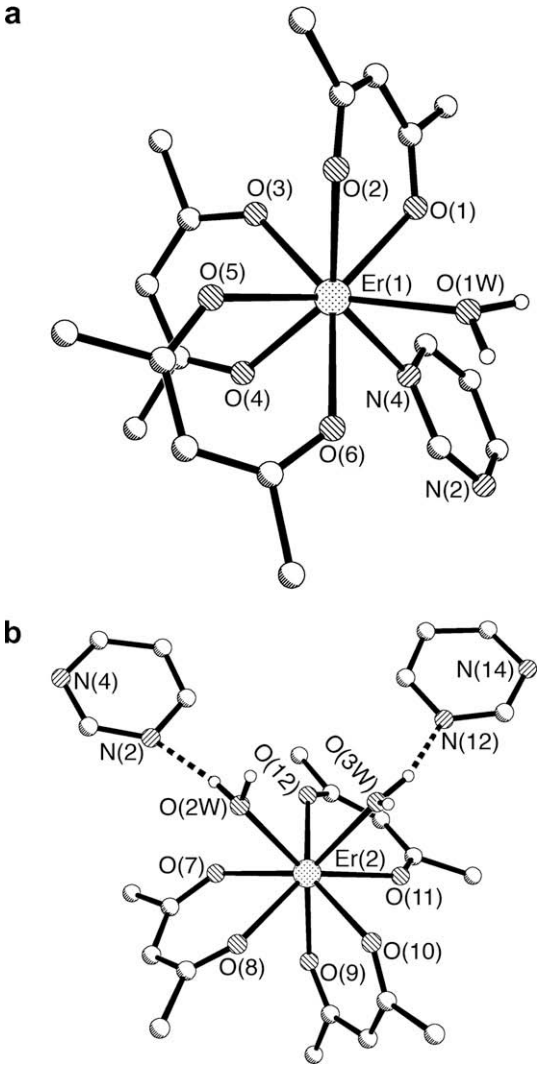

Fig. 3. Coordination environments around (a) Er(1) and (b) Er(2) in the structure of [**1** · {Er(hfac)$_3$(H$_2$O)}{Er(hfac)$_3$(H$_2$O)$_2$}]. The dashed lines are hydrogen bonds between pyrimidine N atoms and water molecules coordinated to Er(2).

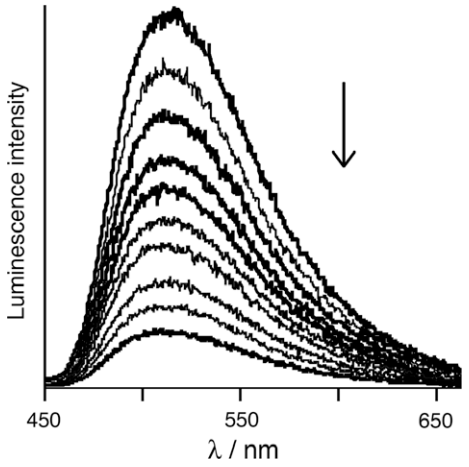

Fig. 4. Steady decrease in the luminescence intensity of **1** (0.6 μM solution in CH_2Cl_2) as portions of [{Er(hfac)$_3$(H$_2$O)$_2$}] (up to 9 equiv) are added. Excitation was at 345 nm, a wavelength at which the absorbance of the solution did not change significantly during the titration.

arrangement of this pair of pyrimidine N atoms [N(2) and N(12)], both oriented inwards towards the same cavity, makes an ideal hydrogen-bond accepting site for the {Er(hfac)$_3$(H$_2$O)$_2$} unit. We have seen a similar hydrogen-bonding interaction between a coordinated water ligand and a weakly basic N-heterocyclic donor, in which the heterocycle does not coordinate directly to the Ln(III) centre, in previous work [6].

The geometry around both Er(III) centres is approximately square antiprismatic, as shown in Fig. 3 which emphasises their immediate coordination environments. For Er(1) the two square planes consist of O(1)/O(3)/O(4)/N(4) and O(2)/O(5)/O(6)/O(1 W); for Er(2) the two planes consist of O(8)/O(10)/O(3 W)/O(2 W) and O(7)/O(9)/O(11)/O(12). The two Er(III) units are 8.99 Å apart; the Pt···Er separations are 8.67 Å to Er(1) and 8.81 Å to Er(2). The tendency we see in this complex of the pyrimidine N atoms not to coordinate fully to the Ln(III) centres presumably reflects the poorer basicity of pyrimidine compared to pyridine.

Spectroscopic titrations were then performed in which small portions of [Ln(hfac)$_3$(H$_2$O)$_2$] were added to a solution of **1** (5×10^{-5} M) in CH_2Cl_2. This addition resulted in no perceptible change to the position or intensity of the ^{1}MLCT absorption band at 378 nm, but resulted in significant changes in luminescence intensity depending on the nature of Ln(III). The decrease in luminescence during the titration when Ln = Er is shown in Fig. 4. During this titration the luminescence intensity from **1** was slightly blue-shifted from 520 to 510 nm, and steadily diminished in intensity. The blue-shift is consistent with the energy of the ^{3}MLCT state being increased by the coordinated Er(III) centre attached to a pyrimidine ring (*cf.* the crystal structure). This arises because of the electron-withdrawing effect of the electropositive Er(III) ion, which inductively stabilises the Pt(II) d(π) orbitals and slightly increases the Pt(II)→bipy MLCT energy gap [4]. The steady reduction in luminescence intensity during the titration, on the other hand, must arise from Pt(II)→Er(III) energy-transfer which quenches the Pt(II)-based excited state by generation of an f–f excited state at Er(III).

A plot of decrease in luminescence intensity of **1** *versus* amount of added [Er(hfac)$_3$(H$_2$O)$_2$] produced a curve which fitted well to a 1:1 binding isotherm, from which an association constant of 7×10^3 M^{-1} could be calculated. We do not know what the solution structure of the adduct (denoted **1** · Er) is: it may differ significantly from what was observed in the solid state (a kinetic species) although adduct formation is clearly occurring. The most likely behaviour – based on extensive previous work [4,7] – is that an {Er(hfac)$_3$} fragment is bound to **1** *via* one of the weakly basic pendant pyrimidine N atoms, *cf.* atom Er(1) in Fig. 2. An association constant of 7×10^3 M^{-1} involving binding of an {Er(hfac)$_3$} fragment to a single pyrimidine ring is reasonable given that we have obtained association constants of the order of 10^5 M^{-1} for binding to a chelating 2,2′-bipyrimidine site in a neutral complex [7b]. We could not find any evidence for a 1:2 Pt:Er adduct (*cf.* the crystal structure) in which a second {Ln(hfac)$_3$} fragment is associated *via* hydrogen bonding. Presumably the second association constant is too low to have any noticeable effect at the low concentrations used for photophysical studies.

As a control experiment we performed the same titration of **1** with [Gd(hfac)$_3$(H$_2$O)$_2$]. Gd(III) cannot quench the excited state of **1** because its lowest energy f–f excited state is at 32 000 cm^{-1}, in the UV region. Thus Gd(III) behaves the same as other Ln(III) ions in terms of electrostatic and steric effects, but without being able to cause quenching by energy-transfer. In this experiment, addition of portions of [Gd(hfac)$_3$(H$_2$O)$_2$] to a solution of **1** resulted in a slight *increase* in emission intensity – consistent with the increase in energy of the ^{3}MLCT state – and a corresponding increase in emission lifetime to 141 ns. This lifetime of 141 ns for the ad-

duct between **1** and {Gd(hfac)$_3$} is then used as the basis for comparison with other **1** · Ln$_2$ adducts in solution.

$$k_{EnT} = 1/\tau_1 - 1/\tau_2 \quad (1)$$

At the end of the titration of **1** with [Er(hfac)$_3$(H$_2$O)$_2$], the partially-quenched Pt(II)-based emission of **1** displayed dual-exponential decay with lifetimes of 96 ns (major component) and 13 ns (minor component). Given that the titration did not go to completion, because of the relatively low association constant of 7×10^3 M^{-1}, we assign the 96 ns component to luminescence from free **1** which was measured as 105 ns in the absence of any added [Er(hfac)$_3$(H$_2$O)$_2$] (the slight reduction from 105 ns to 96 ns may be ascribed to collisional quenching between **1** and increasing amounts of [Er(hfac)$_3$(H$_2$O)$_2$] even when adduct formation is not occurring). The 13 ns component may be ascribed to nearly-quenched emission from the Pt(II) centre in the adduct **1** · Er. From Eq. (1) [in which k_{EnT} is the energy-transfer rate, and τ_1 (13 ns) and τ_2 (141 ns) are the partially-quenched and unquenched Pt(II)-based luminescence lifetimes, respectively], we can determine the Pt(II)→Er(III) energy-transfer rate to be 7.0×10^7 s^{-1}.

An exactly similar experiment with [Yb(hfac)$_3$(H$_2$O)$_2$] resulted in no significant quenching, with **1** · Yb$_2$ showing essentially identical properties to **1** · Gd$_2$ with a final lifetime of 137 ns. Application of Eq. (1) gives $k_{EnT} \approx 2 \times 10^5$ s^{-1}, although given the very small difference between the values of τ_1 (137 ns) and τ_2 (141 ns), each individually having a margin of error of at least 2%, this calculation is of little significance and we can just say that there is essentially no Pt(II)→Yb(III) energy-transfer.

When [Nd(hfac)$_3$(H$_2$O)$_2$] was used in the titration, the luminescence from **1** was again steadily, but not completely, quenched. At the end of the titration – after addition of 10 equiv. of [Nd(hfac)$_3$(H$_2$O)$_2$] – the decay curve showed signs of dual-exponential decay, although it this was difficult to deconvolute into two components with confidence. If we fixed one component at 105 ns, being unchanged luminescence from the substantial amount of free **1**, the second component refined to being *ca.* 30–40 ns from several independent measurements. If we take an estimate of 35 ns for the partially-quenched luminescence of **1** · Nd we get from Eq. (1) a Pt(II)→Nd(III) energy-transfer rate constant of *ca.* 2×10^7 s^{-1}, about one-third the value of the value Pt(II)→Er(III) energy-transfer rate constant (7.0×10^7 s^{-1}).

The ability of these different lanthanide(III) ions to accept energy from the ^{3}MLCT state of **1** is therefore in the order Er > Nd > Yb, which agrees with what we have seen before in Pt(II)/Ln(III) dyads where the Pt(II) emission is quite high in energy [4]. The results can be rationalised on the basis of overlap between the donor's emission spectrum and the acceptor's absorption spectrum. Yb(III) only has a single f–f absorption at 10200 cm^{-1} which has negligible overlap with the tail end of the luminescence spectrum of **1**. Nd(III) is much richer in f–f excited states in the relevant region (Figs. 5 and 6), with 10 f–f levels lying between 11000 and 20000 cm^{-1} (910 and 500 nm) spanning the region where the Pt-based emission occurs; however, the Nd(III)-based f–f absorptions are weak in the area where the Pt(II) emission is at its most intense (Figs. 4 and 6). In contrast, the region of maximum f–f absorption intensity for Er(III) – between 520 and 530 nm (Fig. 6) – exactly matches the emission maximum of **1** (Fig. 4), giving good donor/acceptor overlap which results in Er(III) being the best energy acceptor from complex **1** from this set of Ln(III) ions.

We note also that the absolute values of these energy-transfer rates are slower than we observed before in other Pt(II)–Ln(III) dyads [4], despite the inter-metallic distances being shorter. This is likely to be a consequence of the bridging pathway which provides the necessary electronic coupling for Dexter energy-transfer [3]. In the crystal structure of **1** · Er$_2$ we can see that one {Er(hfac)$_3$} unit is only connected to **1** *via* hydrogen bonding, through which

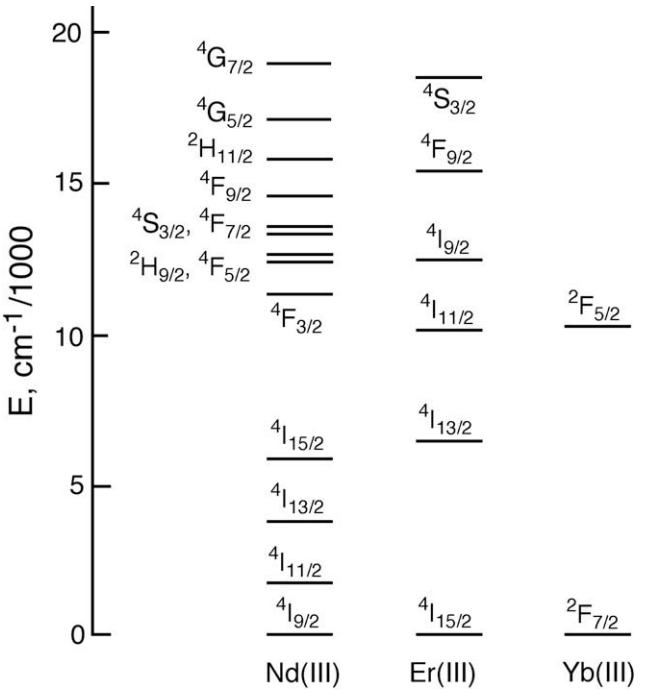

Fig. 5. Excited f–f levels of Nd(III), Er(III) and Yb(III).

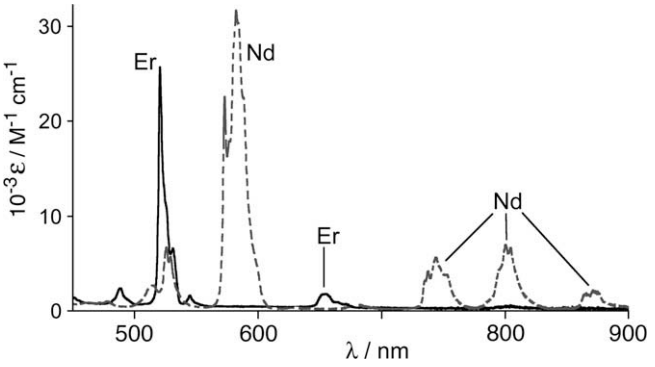

Fig. 6. Absorption spectra of [Ln(hfac)$_3$(phen)] in CH_2Cl_2 (Ln = Nd, Er). Note the exact correspondence of the strong Er(III)-based absorption maximum in the 520–530 nm region with the ^{3}MLCT emission maximum of **1** at 520 nm.

electronic coupling will necessarily be weak, and the other is connected to the N atoms of a pyrimidine ring which has a *meta* relationship to the acetylide 'wire'. The relative weakness of electronic couplings across *meta*-substituted aromatic rings compared to *para* linkages is well known [8].

Even though it is relatively slow, Pt(II)→Ln(III) energy-transfer is clearly occurring to Nd(III) and Er(III). We attempted therefore to see if we could see sensitised Ln(III)-based emission from these centres following excitation of the MLCT absorption of **1** at 450 nm. We could not detect any significant sensitised Nd(III)-based or Er(III)-based luminescence under these conditions however, which is likely to be a consequence of (i) slow energy-transfer leading to only a fraction of the Ln(III) centres being excited by this mechanism, (ii) the relatively low absorbance of the adducts at 450 nm, and (iii) the presence of water molecules in the coordination spheres of these ions (according to the crystal structure) which will make any luminescence weak and short-lived. It is well known that directly coordinated OH oscillators are very effective at quenching low-energy luminescence from lanthanide(III) ions [9].

We could however detect weak Nd(III)-based emission using 337 nm excitation which directly excites the Ln(III) centres *via* the diketonate π–π^* absorptions in a region where the extinction coefficient is much higher, and in this case we could detect weak luminescence from Nd(III) at its characteristic wavelengths of 1060 and 1340 nm; this emission clearly showed dual-exponential decay with lifetimes of *ca.* 1.0 and 0.2 μs, in agreement with the presence of two environments for Nd(III), one with two coordinated water molecules (to which can be ascribed the shorter-lived lifetime component) [4] and the other with only one coordinated water molecule (to which can be ascribed the longer-lived lifetime component). Similarly, direct excitation of the {Er(hfac)$_3$} centre in **1** · Er$_2$ using 337 nm excitation revealed very weak luminescence at 1530 nm characteristic of Er(III) (too weak for lifetime measurements to be reliable, due to the coordinated water ligands).

In conclusion, the new luminescent complex **1**, with two pendant pyrimidinyl units, forms adducts with {Er(hfac)$_3$(H$_2$O)$_n$} fragments (n = 1, 2) which in the solid state are associated by a combination of direct Pt–Er dative bonds, and N···HOH hydrogen bonds between pyrimidine rings and the water molecules coordinated to Er(III). This association results in Pt→Ln photoinduced energy-transfer to lanthanide(III) ions having low-lying f–f states, with energy-transfer rates in the order Pt→Er > Pt→Nd > Pt→Yb, in agreement with expectations based on the availability of f–f states on these lanthanide ions which can act as energy-acceptors and how well they overlap with the luminescence from **1**. The presence of coordinated water molecules still attached to the Ln(III) centres however means that the resulting sensitised near-infrared luminescence is very weak.

3. Experimental

3.1. General details

The following were prepared using the literature methods: [Ln(hfac)$_3$(H$_2$O)]$_2$ [10], [Pt(^{t}Bu$_2$bipy)Cl$_2$] [4]. The following instruments were used for routine spectroscopic measurements: UV–Vis spectra, a Cary 50 spectrophotometer; luminescence spectra, a Perkin–Elmer LS-50 fluorimeter; luminescence lifetimes in the visible region, an Edinburgh Instruments 'mini-τ' time-resolved fluorimeter equipped with a 405 nm pulsed diode laser excitation source; EI mass spectra, a VG AutoSpec magnetic sector instrument; ^{1}H NMR spectra, a Bruker AC-250 spectrometer. Lanthanide-based luminescence lifetimes in the near-infrared region were measured using a setup described previously [11].

3.2. X-ray crystallography

X-ray crystallographic data are summarised in Table 1. For each compound a suitable crystal was coated with hydrocarbon oil and attached to the tip of a glass fibre and transferred to a Bruker-SMART 1000 or APEX-2 CCD diffractometer (graphite-monochromated Mo Kα radiation, λ = 0.71073 Å) under a stream of cold N$_2$. Data were corrected for Lorentz and polarisation effects and for absorption by semi-empirical methods (SADABS) [12] based on symmetry-equivalent and repeated reflections. The structures were solved by direct methods or heavy atom Patterson methods and refined by full-matrix least-squares methods on F^2. Hydrogen atoms were placed geometrically and refined with a riding model and with U_{iso} constrained to be 1.2 (1.5 for methyl groups) times U_{eq} of the carrier atom. Structures were solved and refined using the SHELX suite of programs [13]. Significant bond distances and angles for the structures of the metal complexes are in Tables 2 and 3. The structure determination of **1** presented no significant problems. In [**1** · {Er(hfac)$_3$(H$_2$O)$_2$} {Er(hfac)$_3$(H$_2$O)}] however there was rotational disorder involving both some of the CF$_3$ groups of the hfac ligand, and some of the ^{t}Bu groups of the ^{t}Bu$_2$bipy ligands. Specifically the CF$_3$ groups involving C atoms C(55), C(61), C(65) and C(85) exhibited disorder of the attached F atoms, with two or three F atoms at each of these CF$_3$ groups disordered over two positions with site occupancies of 51% and 49%. Likewise the methyl groups C(38) and C(39) were disordered over two sites each with the same fractional occupancies. These disordered atoms, with fractional site occupancies, were refined with isotropic displacement parameters.

3.3. Preparation of 5-ethynylpyrimidine

This is based on a literature method [14] but with some modifications. To a mixture of 5-bromopyrimidine (5.03 g, 31.6 mmol), $Pd(PPh_3)_2Cl_2$ (150 mg) and CuI (25 mg) in THF (15 mL) under N_2, was added 2-methyl-3-butyn-2-ol (2.60 g, 31.0 mmol) and diethylamine (30 mL). After stirring for 5 h at room temperature, the solvent was evaporated to dryness. Recrystallisation from ethylacetate/diethylether afforded yellow microcrystalline needles of 2-methyl-4-(5-pyrimidine)-3-butyn-2-ol in 84% yield. EI-MS: *m*/*z* 162 [M^+]. ^{1}H NMR (250 MHz, $CDCl_3$): δ 9.10 (s, 1H; pyrimidine H^2), 8.75 (d, 2H; pyrimidine H^4/H^6), 1.60 (s, 6H; $2CH_3$): the OH peak could not be observed.

To a solution of 2-methyl-4-(5-pyrimidine)-3-butyn-2-ol (3.50 g, 33.7 mmol) in a mixture of toluene (30 mL) and diethylether (15 mL), was added finely powdered NaOH (0.80 g, 20 mmol). The mixture was refluxed for 3 h and was then cooled to room temperature and filtered. The solvent was concentrated in vacuum to 10 mL and cooled in the fridge. Pale yellow microcrystalline needles were isolated in 80% yield. EI-MS: *m*/*z* 104 [M^+]. ^{1}H NMR (250 MHz, $CDCl_3$): δ 9.15 (s, 1H; pyrimidine H^2), 8.80 (s, 2H; pyrimidine H^4/H^6) and 3.40 (s, 1H; CH).

3.4. Preparation of complex **1**

A mixture of [Pt(4,4-^{t}Bu$_2$bipy)Cl_2] (0.63 g, 1.20 mmol), anhydrous CuI (175 mg, catalyst), and dry iPr$_2$NH (30 mL) in dry, degassed dichloromethane (150 mL) under N_2 was stirred for 10 min, after which time 4-ethynylpyrimidine (0.63 g, a large excess) was added. The resulting suspension was stirred under N_2 at room temperature for 5 days whilst being protected from light. The solvent was evaporated and the solid residue was dried *in vacuo* to remove traces of ^{i}Pr$_2$NH. The product was purified by column chromatography (2% MeOH–CH_2Cl_2/alumina) to give 0.53 g (64%) of the desired product. EI-MS: *m*/*z* 669 [M^+]. ^{1}H NMR (250 MHz, $CDCl_3$): δ (ppm) 9.50 (2H, d; bpy H^6), 8.90 (2H, s; pym H^2), 8.74 (4H, s; pym $H^{4,6}$), 7.96 (2H, d; bpy H^3), 7.58 (2H, dd; bpy H^5) and 1.41 (18H, s; $C(CH_3)_3$). $PtC_{30}H_{30}N_6$ requires C, 53.8; H, 4.5; N, 12.5. Found: C, 53.3; H, 4.3; N, 12.2%. X-ray quality crystals were grown by slow evaporation of a CH_2Cl_2 solution.

3.5. Preparation of trinuclear complexes *[1 · {Ln(hfac)$_3$(H$_2$O)$_2$}{Ln(hfac)$_3$(H$_2$O)}] (1 · Ln$_2$)*

A solution of complex **1** (50 mg, 0.07 mmol) in CH_2Cl_2 was added to a solution of the appropriate [Ln(hfac)$_3$(H$_2$O)$_2$] (2 equiv.) in CH_2Cl_2 and the mixture was stirred overnight. A small layer of heptane was placed over the solution and the system left to evaporate slowly until orange needles of the desired compounds grew in a few days. The crystals were filtered off, washed with hexane and dried.

Data for [**1** · {Nd(hfac)$_3$(H$_2$O)$_2$}{Nd(hfac)$_3$(H$_2$O)}]. Yield: 50%. $C_{60}H_{42}N_6O_{15}F_{36}PtNd_2$ requires C, 32.0; H, 1.9; N, 3.7. Found: C, 32.2; H, 1.8; N, 3.8%.

Data for [**1** · {Er(hfac)$_3$(H$_2$O)$_2$}{Er(hfac)$_3$(H$_2$O)}]. Yield: 53%. $C_{60}H_{42}N_6O_{15}F_{36}PtEr_2$ requires C, 31.3; H, 1.8; N, 3.7. Found: C, 31.8; H, 1.9; N, 3.9%.

Data for [**1** · {Yb(hfac)$_3$(H$_2$O)$_2$}{Yb(hfac)$_3$(H$_2$O)}]. Yield: 44%. $C_{60}H_{42}N_6O_{15}F_{36}PtYb_2$ requires C, 31.2; H, 1.8; N, 3.6. Found: C, 31.3; H, 1.8; N, 3.7%.

Data for [**1** · {Gd(hfac)$_3$(H$_2$O)$_2$}{Gd(hfac)$_3$(H$_2$O)}]. Yield: 48%. $C_{60}H_{42}N_6O_{15}F_{36}PtGd_2$ requires C, 31.6; H, 1.8; N, 3.7. Found: C, 31.8; H, 1.9; N, 3.7%.

ABSTRACT

In this study, we report a new ligand, 6-hexyloxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin, and its fluorescent tetrasubstituted phthalocyanines {M[Pc(OBzCou)$_4$], M = 2H, Zn(II), Co(II); Bz: Benzene}. The effect of the coumarin derivative on the intensity of the fluorescence spectra of the metal-free (H_2Pc) and zinc phthalocyanine (ZnPc) derivatives was investigated. The change of the emission properties of both the coumarin moieties and the phthalocyanine core in the presence of the metal ion and the ring-opening reaction of the coumarin were studied by means of steady-state fluorescence spectroscopy. The radiative decay of the Pcs and the treated coumarin substituents bound to the Pcs was examined. The novel chromogenic compounds were characterized by elemental analysis, ^{1}H NMR, ^{13}C NMR, Maldi-TOF, IR and UV–Vis spectral data. The photophysical properties of the Pcs are extensively affected by their state of aggregation: in particular, dimerization and aggregation result in a remarkable modification of the absorption and emission bands and may induce significant quenching of the usually strong Pc fluorescence. The electronic spectra exhibit a band of coumarin identity together with characteristic Q and B bands of the phthalocyanine core.

1. Introduction

Phthalocyanines have been discovered to be versatile functional materials and have been applied in biological as well as electronic areas for many years [1–4]. The benefits of phthalocyanines (Pc's) in terms of technological applications is beyond question, such as sensing elements in chemical sensors, photoconducting agents in photocopying machines, carrier generation materials in near-IR, etc. [5–10]. They exhibit excellent chemical and photochemical properties, but poor fluorescent properties [11–13]. On the other hand, coumarins (2*H*-1-benzopyran-2-one), found naturally in many higher plants and essential oils including tonka beans, sweet clover and lavender [14,15], are used as anticoagulants, additives in food and cosmetics, in the preparation of insecticides, optical brighteners and dispersed fluorescent, laser dyes, anti-HIV activities, etc. [16–18]. The family of functional phthalocyanines has been an interesting target for chemists for the development of further chemical reactions on phthalocyanine complexes [19–23]. Therefore in this paper we have, in particular, combined these two functional materials into a single compound via synthetic methodology to obtain soluble fluorescent phthalocyanines. The experimental results demonstrate that the introduction of coumarin derivatives into the peripheral ring of phthalocyanines increases the fluorescent properties of phthalocyanines. Phthalocyanines coupled with the coumarin moiety may exhibit biological activities and, after cleavage of the lactone ring of the peripheral 2*H*-1-benzopyran-2-one (coumarin), the solubility can also be increased.

In this study, the phthalocyanines {M[Pc(OBzCou)$_4$], M = 2H, Zn(II), Co(II)}, with four peripheral 6-hexyloxy-3-(4-oxyphenyl)-coumarin substituents, were prepared via cyclotetramerization from the 6-hexyloxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin and the products resulting from lactone ring-opening reactions on the periphery of H_2Pc (**3**) and ZnPc (**4**) were synthesized. In addition, we report here the effect of the coumarin substituent on intensity of the fluorescence emission spectra of **3**, **3a**, **4** and **4a**, as well as the effect of the phthalocyanine core on the coumarin emission.

2. Experimental

Chloroform ($CHCl_3$), tetrahydrofuran (THF), $Zn(O_2CMe)_2 \cdot 2H_2O$, $CoCl_2 \cdot 6H_2O$, 1,8-diazabicyclo-[5,4,0]undec-7-ene (DBU) were purchased from Merck and Alfa Aesar, and were used as received. All other reagents were obtained from Fluka, Aldrich Chemical Co.

doi:10.1016/j.poly.2008.10.066

and were used without purification. *p*-(3,4-Dicyanophenoxy)-phenylacetic acid [21] and 4-nitro-1,2-dicyanobenzene [24] were prepared according to reported procedures. The purity of the products was tested in each step by TLC (silica gel: $CHCl_3$ and MeOH). Routine IR spectra were recorded on a Shimadzu Fourier Transform FTIR-8300 Infrared spectrophotometer using KBr pellets, and electronic spectra on a Shimadzu UV-1601 UV–Vis spectrophotometer. ^{1}H NMR and ^{13}C NMR spectra were recorded on a Bruker 300 spectrometer instrument using TMS as an internal reference at Sakarya University. Elemental analysis was performed by the Instrumental Analysis Laboratory of TUBITAK Ankara Test and Analysis Laboratory. Mass spectra were performed on a Bruker Autoflex III mass spectrometer. Fluorescence excitation and emission spectra were recorded on a Jasco FP-750 spectrofluorimeter. Fluorescence measurements utilized 10 μM samples, 5-nm band-pass in both excitation and detection paths, and right-angle geometry.

2.1. 6-Hydroxy-3-[p-(3′,4′-dicyanophenoxy)phenyl]coumarin (**1**)

A mixture of *p*-(3,4-dicyanophenoxy)phenylacetic acid (2.00 g, 7.19 mmol), 2,5-dihydroxybenzaldehyde (0.99 g, 7.19 mmol), sodium acetate (2.95 g, 36 mmol), anhydrous acetic anhydride (15 mL) was heated and stirred at reflux temp. in a sealed glass tube for 8 h under N_2. After cooling to room temperature, water was added and the mixture stirred overnight. The resulting solid, 6-acetoxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin, was filtered, washed with water and dried. The crude product 6-acetoxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin was suspended in methanol. 10% HCl was added until the pH of the solution was 3 and the mixture was heated and stirred at 60 °C for 4 h under N_2. At the end of the reaction, the resulting powder, 6-hydroxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin, was filtered, washed with water and dried. It was purified by silica gel column chromatography with chloroform as the eluent.

Yield: 1.61 g (59%); m.p. 284–286 °C. IR ν(cm^{-1}): 3440 (OH), 3105–3044 (Ar-H), 2924–2843 (alkyl-CH), 2229 (–C≡N), 1709 (C=O lactone), 1626 (C=C), 1589–1488 (Ar C=C), 1258 (Ar-O-Ar). ^{1}H NMR (DMSO-d_6) δ (ppm): 9.78 (s, Ar-OH, 1H, deuterium exchangeable), 8.22 (s, 1H, *meta* to lactone, Cou-H), 8.12 (d, 1H, *ortho* to CN, Phenyl H2), 7.84 (d, isomer, 1H, *ortho* to CN; H3), 7.42 (Bz_2; dd, 4H, Ar-H), 7.27 (d, 1H, *meta* to Cou-OH), 7.06 (d, 1H, *ortho* to Cou-OH), 7.05 (Bz_1; dd, 1H, *meta* to CN; H2), 7.02 (dd, 1H, *ortho* to Cou-OH). ^{13}C NMR (300 MHz, DMSO-d_6) δ (ppm): 164.32 (Ar-C=O), 160.55 (Ar-H, *ortho* to Ar-OH), 145.23, 141.80 (Cou), 140.65 (Bz_1), 136.11 (Bz_2), 135.58, 134.44, 133.92, 131.16, 128.42, 127.34, 125.65 (Cou), 123.85, 123.10, 116.57 (Bz_1), 115.78, 115.09, 114.63, 40.45 (DMSO). *Anal.* Calc. for $C_{23}H_{12}N_2O_4$ (380 g/mol): C, 72.63; H, 3.16; N, 7.37. Found: C, 72.56; H, 3.32; N, 7.43%. UV–Vis (DMF): λ_{max} (nm) (log ε): 326 (4.22), 380 (3.90 Coumarin).

2.2. 6-Hexyloxy-3-[p-(3′,4′-dicyanophenoxy)phenyl]coumarin (**2**)

6-Hydroxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin **1** (1.61 g, 4.24 mmol) and 1-bromohexane (0.70 g, d 1.11 g/ml, 4.24 mmol) were dissolved in dry DMF (50 mL), and K_2CO_3 (0.60 g, 4.34 mmol) and tetrabutylammoniumbromide (0.02 g, excess) as a catalyst were added. After refluxing for 5 days under nitrogen the reaction mixture was poured into iced water and acidified with aq. HCl solution. The precipitate that formed was filtered, washed with water and the crude product dried. It was purified on silica gel column chromatography with chloroform as the eluent.

Yield: 1.76 g (89%); m.p. 164–166 °C. IR ν(cm^{-1}): 3090–3044 (Ar-H), 2962–2858 (alkyl-CH), 2226 (–C≡N), 1701 (C=O lactone), 1607 (C=C), 1585–1496 (Ar C=C), 1281 (Ar-O-Ar), 1242–1130 (Ar-O-C). ^{1}H NMR (DMSO-d_6) δ (ppm): 8.23 (s, 1H, *meta* to lactone, Cou-H), 8.12 (d, 1H, *ortho* to CN, Phenyl H2), 7.83 (d, isomer, 1H, *ortho* to CN; H3), 7.80 (d, 1H, *meta* to Cou-OR), 7.43 (Bz_2; dd, 4H, Ar-H), 7.36 (d, 1H, *ortho* to Cou-OR), 7.26 (Bz_1; dd, 1H, *meta* to CN; H2), 7.20 (dd, 1H, *ortho* to Cou-OR), 3.98 (t, 2H, OCH_2–), 1.74–1.69 (m, 2H, –OCH_2CH_2–), 1.42–1.21 (m, 6H, $CH_2CH_2CH_2CH_3$), 0.90 (t, 3H, CH_3). ^{13}C NMR (300 MHz, DMSO-d_6) δ (ppm): 162.11 (Ar-C=O), 160.06 (Ar-H, ortho to Ar-OH), 144.98, 140.40 (Cou), 140.07 (Bz_1), 135.77 (Bz_2), 134.34, 133.70, 130.28, 129.40, 127.62, 126.08 (Cou), 123.85, 122.01, 116.18 (Bz_1), 115.95, 115.24, 114.04, 66.38 (CH_2O–), 40.45 (DMSO) 29.67 ($CH_2CH_2CH_3$), 28.43 (OCH_2CH_2), 25.66 ($OCH_2CH_2CH_2$), 23.47 (CH_3CH_2) 14.70 (CH_3). *Anal.* Calc. for $C_{29}H_{24}N_2O_4$ (464 g/mol): C, 75.00; H, 5.17; N, 6.03. Found: C, 75.21; H, 5.12; N, 6.08%. UV–Vis ($CHCl_3$): λ_{max} (nm) (log ε): 308 (4.30), 362 (4.01 Coumarin).

2.3. 2,9,16,23-Tetrakis[6-hexyloxy-3-(4-oxyphenyl)coumarin] metal-free-phthalocyanine (**3**)

Compound **2** (0.10 g, 0.22 mmol) and anhydrous *N*,*N*-dimethylaminoethanol (1.0 mL) were refluxed with stirring for 48 h in a sealed glass tube under N_2. After cooling to room temperature, methanol (2 mL) was added in order to precipitate the product. The green product was filtered and washed with water, MeOH, CH_3CN, EtOH, acetone, ethyl acetate and diethyl ether, and dried.

Yield: 0.025 g (25%); m.p. > 300 °C. 2.3.1. 2,9,16,23-Tetrakis[(E)-hexyl-3-(2,5-bis(hexyloxy)phenyl-2-(4-oxyphenyl)acrylate] metal-free-phthalocyanine (**3a**)

To a solution of 2,9,16,23-tetrakis[6-hexyloxy-3-(4-oxyphenyl)coumarin] metal-free-phthalocyanine (**3**) (0.025 g, 0.014 mmol) in dry DMF (5 mL), hexanol (5 mL) and lithium metal (0.0012 g, 0.17 mmol) were added. The mixture was refluxed for 24 h, and then it was cooled to room temperature. 1-Bromohexane (0.3 mL) was added to the reaction mixture and it was heated at 50 °C for 3 days under N_2. After cooling to room temperature, the mixture was treated with 2 M HCl under ice-cooling. The precipitate that formed was collected by filtration, washed with H_2O, MeOH, EtOH, CH_3CN, acetone, ethyl acetate and diethyl ether, and dried.

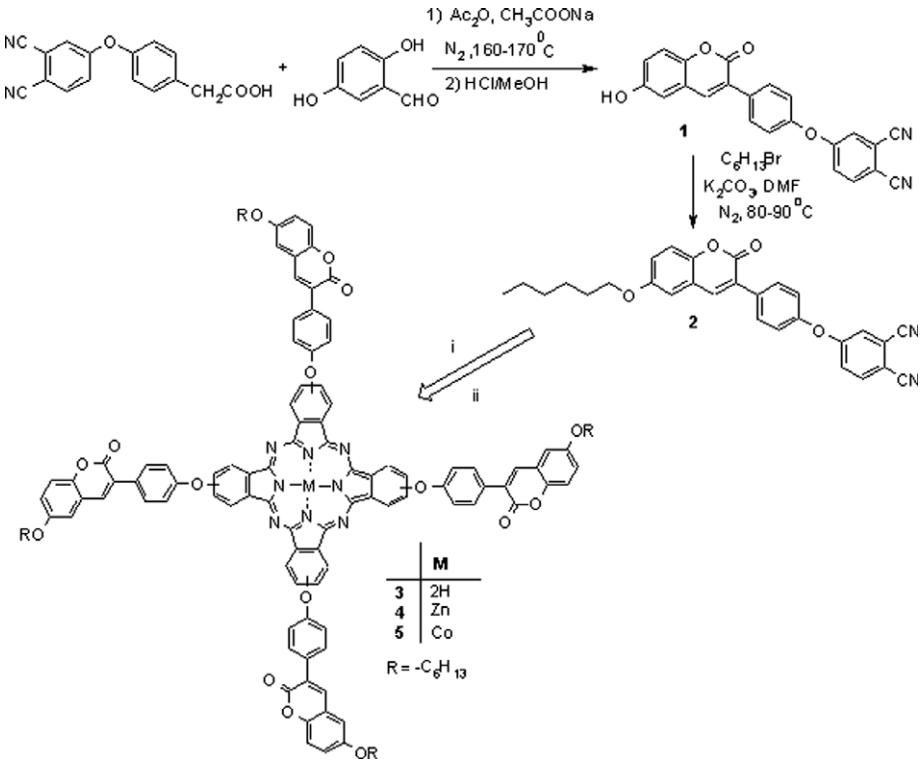
2.5. 2,9,16,23-Tetrakis[6-hexyloxy-3-(4-oxyphenyl)coumarin]phthalocyaninatocobalt (II) (**5**)

A mixture of compound **2** (0.10 g, 0.215 mmol), $CoCl_2$ (0.0134 g, 0.054 mmol) and 1,8-diazobicyclo[5.4.0]undec-7-ene (DBU) (0.07 mL, 0.04 mmol) in hexanol (1.5 mL) was heated and stirred at 160 °C for 24 h under N_2. The resulting green mixture was cooled to room temperature and then methanol (2 mL) was added in order to precipitate the product. The product was filtered and washed with water, methanol, acetonitrile, ethanol, acetone, ethyl acetate and diethyl ether, and dried.

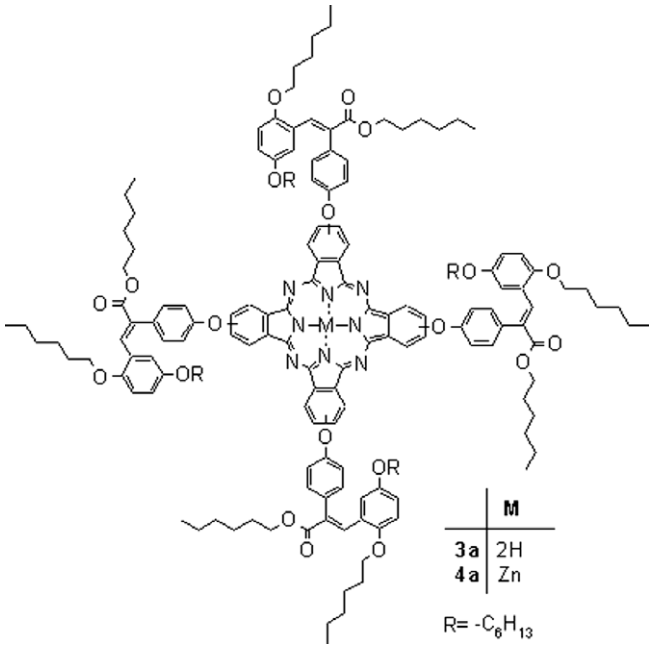
Yield: 0.031 g (30%); m.p. > 300 °C. IR $\nu(cm^{-1})$: 3067–3036 (Ar-H), 2932–2858 (alkyl-CH), 1713 (C=O lactone), 1601 (C=C), 1506–1469 (Ar C=C), 1323–1234 (Ar-O-Ar), 1191–1096 (Ar-O–C); *Anal.* Calc. for $C_{116}H_{96}N_8O_{16}Co$ (1915 g/mol): C, 72.69; H, 5.01; N, 5.85. Found: C, 72.15; H, 5.22; N, 5.54%. UV–Vis (DMSO): λ_{max} (nm) ($\log\varepsilon$): 358 (4.84), 470 (4.23), 606 (4.62), 668 (4.97). MS (Maldi-TOF, α-CHCA as matrix) *m*/*z*: 1916.12 $[M+H]^+$, 1935.05; $[M+H_2O]^+$.

3. Results and discussion



Fluorescence functional metallophthalocyanines (**3**–**5**) bearing coumarin were accomplished by heating a mixture of 6-hexyloxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin with anhydrous $Zn(O_2CMe)_2$ and $CoCl_2$ salts at ca. 170–180 °C under a N_2 atmosphere in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) in hexanol, while metal-free (**3**) was obtained in anhydrous *N*,*N*-dimethylaminoethanol solvent (Scheme 1). In addition, the lactone ring of the synthesized 2,9,16,23-tetrakis[6-hexyloxy-3-(4-oxyphenyl)coumarin] metal-free-phthalocyanine (**3**) and 2,9,16,23-tetrakis[6-hexyloxy-3-(4-oxyphenyl)coumarin]phthalocyaninatozinc(II) (**4**) was opened and the released hydroxyl group was hexylated (Scheme 2). The yields of **3**–**5** were rather low (25% for **3**, 30% for **4** and **5**). The structures of the phthalocyanines **3**–**5** were verified by FTIR, ^1H NMR, UV–Vis and MALDI-TOF MS spectroscopic methods, as well as by elemental analysis. All the analytical and spectral data are consistent with the predicted structures.

Cyclotetramerization of the dinitrile derivative, 6-hexyloxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin to the phthalocyanines **3**–**5** was confirmed by the disappearance of the sharp –C≡N vibration at 2226 cm^{-1} in compound **2**. The strong C=O (lactone) vibration at 1701, Ar-H and Aliph-H at above and below 3000 cm^{-1} together with the Ar-O-Ar band at ca. 1240 cm^{-1} in the compound **2** underwent small shifts. The ester stretching bands in the FTIR spectra of **3a** and **4a** at ca. 1710 cm^{-1} are evidence for the formation of **3a** and **4a**.



The ^1H NMR spectra of compounds **3**–**4** are somewhat broader than the corresponding signals in the starting dinitrile derivative. This broadening is likely due to chemical exchange caused by aggregation–disaggregation equilibria and the fact that the product obtained in these reactions is a mixture of positional isomers which are expected to show chemical shifts that differ slightly from each other. The inner NH protons of **3** and **3a** were also identified in the ^1H NMR spectra with a broad chemical shift, $\delta = -3.43$ and −3.45 ppm, respectively, as a consequence of the 18π-electron systems of the planar molecule, and this signal disappears on deuterium oxide (D_2O) exchange [12]. The other resonances related to aliphatic and aromatic (OCH_2, CH_2, CH_3, Ar-H) protons in the ^1H NMR spectra of **3** and **3a** are similar to each other, except for the esteric protons. The ^1H NMR spectra of **3a** and **4a** indicated characteristic aromatic protons (Bz_1, Bz_2 and Bz_3) at 8.33–6.75 and 8.38–6.92 ppm, ethilenic protons at 6.60 and 6.75 ppm and aliphatic ester protons at 4.30–4.10 and 4.30–4.12 ppm, respectively. The signals belonging to aromatic protons in the downfield region of the spectra for **3**, **3a**, **4** and **4a** are broader than the aliphatic ones in the highfield region of the spectra.

3.1. UV–Vis absorption spectra

UV–Vis spectra of the phthalocyanine complexes exhibit characteristic Q and B bands, one in the visible region at ca. 600–750 nm (Q-band) attributed to the π–π^* transition from the HOMO to the LUMO of the Pc^{2-} ring, and the other in the UV region at ca. 300–400 nm (B-band) arising from deeper π–π^* transitions [25]. While the zinc and cobalt phthalocyanines (**4**, **4a** and **5**) gave a single Q-band of high intensity due to a single π–π^* transition, as expected as a result of D_{4h} symmetry, H_2Pc (**3** and **3a**) displayed a split Q-band as a result of D_{2h} symmetry with shoulders at the slightly higher energy side of the Q-band for each phthalocyanine in addition to B-bands in the UV region [12,18,25]. The Q-band absorptions of **3**, **4** and **5** were observed at 703, 675 (Qx and Qy), 685 and 668 nm, respectively, with shoulders at the slightly higher energy side of the Q band for each phthalocyanine (Fig. 1). The shoulder between 400 and 450 nm may be due to a charge transfer

Scheme 1. Synthetic route to **3**, **4** and **5**, {M[Pc(OBzCou)$_4$], M = 2H, Zn(II) and Co(II)}. (i) *N*,*N*-Dimethylaminoethanol and (ii) anhydrous $Zn(O_2CMe)_2$, $CoCl_2$, hexanol and dbu.

Scheme 2. Schematic representation of 2,9,16,23-tetrakis[(*E*)-hexyl-3-(2,5-bis(hexyloxy)phenyl-2-(4-oxyphenyl)acrylate]metal-free (**3a**), and zinc(II) phthalocyanine (**4a**).

from the electron-rich ring to the electron-poor acceptor metal. The B bands are broad due to the superimposition of the B1 and B2 bands in the 330–350 nm region in the case of compound **2** [25]. Therefore the B bands are more intense than the Q bands because of the absorption contribution of the coumarin derivatives peripherally substituted on Pc.

The protonated molecular ion peak for **3** (α-cyano-4-hydroxycinnamic acid matrix, α-CHCA) was observed at 1858 Da from the monoisotopic masses of the elements in compound **3** (H_2Pc), with the other isotopic peaks (between 1857 and 1460 with about 1 Da mass differences) mainly resulting from the isotopic distribution of carbon, which exactly overlapped with the mass of the ligand calculated theoretically from the elemental composition of the ligand. The mass spectrum of compound **3a** also confirmed the proposed structure, giving MS (Maldi-TOF (α-cyano-4-hydroxycinnamic acid matrix) at *m*/*z*: 2603.54 $[M+H]^+$. The protonated molecular ion peaks were identified at *m*/*z*: 1922.69 $[M+H]^+$ for **4**, at *m*/*z*: 2666.22 $[M+H]^+$ for **4a** and at *m*/*z*: 1916.12 $[M+H]^+$, 1935.05 $[M+H_2O]^+$ for **5**, by using α-cyano-4-hydroxycinnamic acid matrix in MS Maldi-TOF. Isotopic peaks resulting from the isotopic distribution of the protonated molecular ion of the **4** were observed between 1922 and 1927 Da with 1 Da increments in the high mass range (Fig. 2). Following the protonated molecular ion peak, a peak group was observed at 36 Da mass higher than the protonated molecular ion peak group, with almost the same pattern. This peak is the result of two moles of H_2O adduct on the neutral molecule of **4**.

3.2. Fluorescence spectra and quantum yields

Excitation and emission spectra of the phthalocyanine derivatives substituted with coumarin groups were obtained in DMSO solution. The reason for using DMSO as the solvent for spectral measurement is that DMSO, with a relatively high dipole moment of 3.96, more easily dissolved the compounds synthesized in our work. Also, we could not observe enough aggregation behavior in different solvents such as THF, $CHCl_3$ and DMF, showing that a hypsochromic shift with increasing solvent polarity was not a pronounced effect for the Q band maxima of the Pc derivatives.

The excitation spectra of the coumarin substituted phthalocyanine derivatives (**3**, **3a**, **4** and **4a**) at 460 nm emission wavelength are shown Fig. 3A. As seen from the figure, the Pc derivatives exhibit excitation maximum wavelength at 380 nm where the couma-

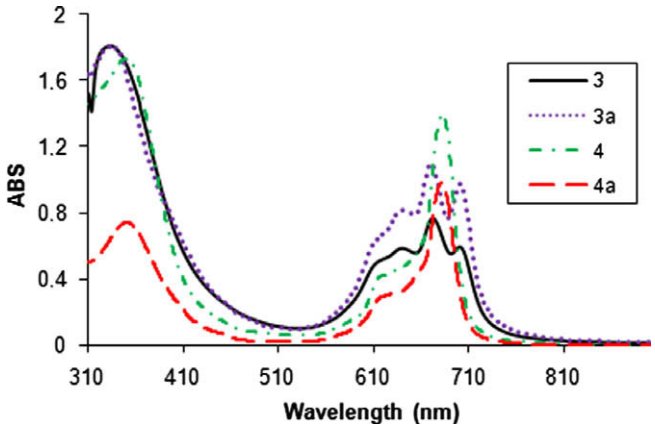


Fig. 1. UV–Vis spectra of 10 μM **3**, **3a**, **4** and **4a** in DMSO.

rin moiety shows high excitation intensity alone (spectrum not shown). The excitation spectrum of the coumarin substituent does not shift in the position of the maximum, though its excitation intensity was diminished when the coumarin moiety was bound to Pc core. The intensity of the **3a** and **4a** species were more decreased because of restricted conjugation due to the ring-opened molecular structure [26,27]. Fig. 3B shows the fluorescence spectra of Pc derivatives in DMSO at room temperature upon excitation at 380 nm, where the coumarin moiety in Pc absorbs almost all of the light, whereas the Pc core absorbs only several percent [28]. Therefore, the fluorescence emissions around 460 nm occur almost entirely from coumarin derivatives substituted on the Pc core. The fluorescence intensity from the peripherally bonded coumarin derivatives is decreased because of radiative energy transfer resulting from the inner filter effect of the Pc core [29]. Since the core of **4a** gives poorer spectral overlap compare with that of the core of **3a**, the decrease in emission is much more in the case of **3a**. The decrease in emission intensity of the coumarin derivative which was chemically treated is more pronounced, because the increase in the spectral overlap causes the inner filter effect. On the other hand, the emission spectra of **3**, **3a**, **4** and **4a** show 15 nm, 1 nm, 13 nm and 18 nm Stokes shifts, respectively, compared with that of the coumarin moiety itself. These red shifts indicate very little molecular rearrangement in the excited state because of intramolecular interactions [30]. Fig. 4A shows the excitation spectra monitoring the emission at 730 nm of the Pc derivatives. The excitation spectra of **4** and **4a** are nearly identical with their ground-state absorption spectra. This indicates that the energy-transfer process is nearly quantitative, showing the unaggregated forms of the **4** and **4a** species [31,32]. On the other hand, the excitation spectra of **3** and **3a** do not closely match their absorption spectra from 450 to 710 nm, indicating that these three species are essentially aggregated in this medium [33,34]. The steady-state fluorescence spectra of the coumarin substituted Pc derivatives were performed in DMSO, upon excitation at the 620 nm Q-band vibration (Fig. 4B). Emission around 700 nm occurs almost entirely from the phthalocyanine moiety. As seen from the figure, the **3** and **4** species with the same coumarin derivative exhibit higher emission intensity than those of the **3a** and **4a** species. This decrease in emission of the Pc core which has an appended coumarin derivative with a ring-opened structure suggests that the Pc core excited state rapidly decays through radiationless conversion to the ground state. On the other hand, a spectral shift in emission wavelength was not observed. This shows that there is no effect of the different coumarin substituents on the fluorescence emission from the S1 singlet excited state of the Pc core with or without a metal ion [35].

The fluorescence quantum yields (Φ) were determined using the classical formula: $\Phi_x = (\Phi_s x F_x x A_s x n_x^2)/(F_s x A_x x n_s^2)$, where A is the absorbance at the excitation wavelength, F is the area under the fluorescence curve and n is the refraction index. Subscripts s and x refer to the standard and to the sample of unknown quantum yield, respectively. Fluorescence quantum yields in DMSO were determined by a comparative method, using coumarin **1** ($\Phi_s = 0.73$ [36]) in ethanol as the fluorescence standard for the coumarin moiety (390–600 nm region). The excitation wavelength was 380 nm for the coumarin derivative substituted on Pc. The fluorescence quantum yield obtained for the coumarin derivative substituted on ZnPc ($\Phi_f = 0.21$) can be attributed to reduced aggregation on comparison to that of H_2Pc ($\Phi_f = 0.18$). On the other hand, Φ_f values for the ring-opened structure of coumarin derivatives **3a** and **4a** ($\Phi_f = 0.12$ and 0.11, respectively) are substantially decreased compared to compound **3** and **4** and are in

Benzo[1,2-*b*;4,3-*b*′]dithiophene

ABSTRACT

New silver complexes of general formula $[Ag(O_3SCF_3)(PPh_2\{bzt\})_n]$ (n = 1–3, bzt = benzo[1,2-*b*;4,3-*b*′]dithiophene) have been synthesized and characterized. Spectroscopic studies shown neutral ligand fluxionallity, typical of silver(I) complexes. The solid state structure of the complexes was determined by X-ray crystallographic studies, showing a decrease in structure complexity with increasing number of neutral ligands in silver coordination sphere: $[Ag(O_3SCF_3)(PPh_2\{bzt\})]$ is a dimer with two bridging triflate anions, further linked into polymeric bidimensional chains along *bc* plane, through Ag···Ph close contacts; $Ag(O_3SCF_3)(PPh_2\{bzt\})_2]$ is also a dimmer with two bridging triflate anions, displaying an interesting packing feature, with *zig-zag* alignment of bzt groups along direction *b*; $[Ag(O_3SCF_3)(PPh_2\{bzt\})_3]$ is a monomer.

1. Introduction

The chemistry of poly-nuclear coordination complexes of coinage metals is a field of continuous growing due to the almost unlimited possibilities of chemical designs, ranging from simple molecules to polymeric arrangements [1,2]. Within this area, silver(I) complexes of the type $AgX/(PR_3)_n$, where X is a oxyanion such as NO_3^-, ClO_4^-, NO_2^- and $CF_3SO_3^-$, are known to show interesting structural variations arising from different coordination modes of the anions [3–7]. Despite the intense investigation on the $AgX/(PR_3)_n$ complexes, specially for R = Ph [3–7], complexes of the type $AgX/(PR_2R')_n$ were only sporadically investigated [6,8], nonetheless revealing that the identity of R′ has a large influence both on silver(I) nuclearity and/or solid state packing features. Benzo[1,2-*b*;4,3-*b*′]dithiophen-2-diphenylphosphine is an interesting ligand, in this respect, to study structural features induced by the large volume and moon-shape of the benzo[1,2-*b*;4,3-*b*′]dithiophene (bzt) group and also due to the possibility of this ligand to act as P,S-donor in a bridging bidentate fashion. In this paper we report the synthesis and spectroscopic characterization (^1H, ^{31}P RMN) of novel silver(I) complexes of general formula $[Ag(O_3SCF_3)(PPh_2\{bzt\})_n]$ (n = 1–3), fully supported by single-crystal X-ray studies to understand the relationships between silver(I) nuclearity, $CF_3SO_3^-$ coordinating ability and $PPh_2\{bzt\}$ coordination modes. Also, comparison is made with related compounds to get some insight on the influence of the bzt group on silver nuclearity and solid state packing. Our results show that $PPh_2\{bzt\}$ acts, in this case, only as P-donor and unravel beautiful and unexpected solid state packing features for these complexes.

2. Results and discussion

The ligand benzo[1,2-*b*;4,3-*b*′]dithiophen-2-diphenylphosphine (**L1**) was synthesized based on the procedure reported for the synthesis of the analogue benzo[1,2-*b*;4,3-*b*′]dithiophen-2-carbaldehyde [9], by generation of the benzodithiophene α-anion with *n*-BuLi and subsequent treatment with $(C_6H_5)_2PCl$, affording **L1** in good yield (60%), as a colorless oil.

The silver complexes $[Ag(CF_3SO_3)(PPh_2\{bzt\})_n]$ (**nAg**: n = 1, 2 and 3) were prepared by reaction of $AgCF_3SO_3$ and an adequate molar ratio of **L1** (0.96, 2 and 3, respectively), in dichloromethane. The compounds were obtained as crystalline white solids, stable to air but slightly unstable to light in solution, soluble in dichloromethane, chloroform, acetone, acetonitrile and insoluble in tetrahydrofuran, ethyl ether and hydrocarbons.

The ^1H NMR spectra of the complexes only show the ligand resonances, slightly deshielded upon coordination to the metal center.

For compounds *[Ag(CF$_3$SO$_3$) (PPh$_2$ {bzt})]* **1Ag**, *[Ag(CF$_3$SO$_3$)(PPh$_2${bzt}$)_3$]* **3Ag** and for free **L1**, the resonances of proton H_3 are doublets, with coupling constants ranging from 6.8 to 11.2 Hz, attributed to P(–C–C–)H coupling, while it appears as a singlet in *[Ag(CF$_3$SO$_3$)(PPh$_2${bzt}$)_2$]* **2Ag**.

Although the ^{31}P NMR spectra of **L1** show a resonance at −17.06 as a sharp singlet, the complexes spectra obtained at room temperature revealed no resonances. This behavior is attributed to complexe's fluxionallity, due to the exchanging phenomena involving neutral ligands, typical of silver coordination chemistry [6]. At

doi:10.1016/j.poly.2008.11.013

−60 °C the spectra are resolved, showing the phosphorus resonances as two doblets, with Ag–P coupling constants ranging from 321.0 to 788.5 Hz, although for **1Ag** the second doublet isn't resolved. The large difference between Ag–P coupling constants is attributed both to the different s contribution to the hybridization of the silver centers [10] and to the different phosphorus/oxygen ratio in the silver coordination sphere [11].

2.1. Crystallographic studies

X-ray diffraction studies constitute an unambiguous way to determine both the nuclearity and the geometry of the silver compounds synthesized. In this case, infrared spectra are not useful to distinguish trifluoromethanesulfonate coordination modes, due to ambiguity in the attribution of CF_3, SO_3 and **L1** vibrational modes [12].

Crystals of compounds **1Ag**, **2Ag** and **3Ag** were obtained by slow diffusion of *n*-hexane into dichloromethane solutions. Compound **1Ag** crystallizes in a centrosymmetric spatial group ($P2_1/c$, monoclinic). This compound is a dinuclear derivative of $[Ag_2(CF_3SO_3)_2(PPh_2\{bzt\})_2]$, in which two silver centers are bridged by two equivalent triflate anions using two donor oxygen atoms, O(1) and O(21), forming an eight-atom cycle (Fig. 1). Silver atoms deviate from planarity with the three coordinated atoms.

Table 1 presents selected bond lengths and angles for compound **1Ag**. The Ag(1)–P(1) distance is similar to the Ag-P distances determined for the analogous compounds $[Ag(CF_3SO_3)(PPh_3)]$ (2.3619(10)–2.3736(10) Å) and $[Ag(CF_3SO_3)(PPh_2Me)]$ (2.3628(11)–2.3637(10) Å) [6]; Ag–O distances are also in the interval verified for the referred compounds: 2.250(2)–2.572(3) Å and 2.2792(19)–2.573(2) Å, respectively.

Each silver atom of the dimer $[Ag_2(CF_3SO_3)_2(PPh_2\{bzt\})_2]$ establishes a short contact with a Ph carbon atom (C(125)) of a distinct dimer, the distance between the atoms being of 2.688(2) Å. This contact is not of the usual Ag···(aromatic bond) type, such as in the $AgClO_4$–benzene complex [13] since Ag···C contacts to C neighbor atoms are significantly longer. The Ag(1)···C(125) contact is almost perpendicular to the Ph ring, with angles between this bond and other Ph carbon atoms ranging from 81.97° to 101.97°. A similar Ag···Ph close contact was found for compound $[Ag(CF_3SO_3)(PPh_2Me)]$ (2.721(3)) [6]. The arrangement of **L1** accounts for the establishment of the Ag(1)···C(125) short contact: the large bzt groups are almost perpendicular to the O(1)–Ag(1)–O(21) plane, minimizing the sterical hindrance on the silver center in the opposite side; also, a significant difference (approximately 36°) between angles O–Ag–P is verified, thus allowing the alignment of Ag(1) with C(125). Each dimeric unit interacts with four other units, leading to the formation of a bidimensional polymeric chain along the *bc* plane, packed along the *a* direction. This polymeric arrangement is illustrated in Fig. 2.

Compound **2Ag** is also a dinuclear derivative (Fig. 3) in which the molecule possesses an inversion center, with silver atoms displaying distorted tetrahedral coordination geometry. Each metal center is bonded to two phosphorus atoms of **L1** and two oxygen atoms of distinct, but crystallographically equivalent, triflate anions, forming an eight member cycle similar to the one found for **1Ag**. This structural arrangement is quite common in complexes of general formula $[AgX(PPh_3)_2]$ [6,11]. Table 2 presents selected

Table 1
Selected bond lengths and angles for compound **1Ag**.

Bond lengths (Å)			
Ag1–O1	2.3045(17)	S1–O1	1.4492(17)
Ag1–O3#1	2.5028(17)	S1–O2	1.425(2)
Ag1–P1	2.3738(6)	S1–O3	1.4354(17)
Ag1–C125#2	2.687(2)		
Bond angles (°)			
O1–Ag1–O3#1	83.49(6)	O3–S1–O1	113.83(11)
P1–Ag1–O3#1	110.82(4)	S1–O1–Ag1	120.29(10)
O1–Ag1–P1	147.05(5)	S1–O3–Ag1#1	147.81(11)
O3#1–Ag1–C125#2	77.28(7)	O1–Ag1–C125#2	90.45(7)
P1–Ag1–C125#2	121.09(6)		

Symmetry transformations used to generate equivalent atoms: #1: $-x+1, -y, -z$; #2: $x, -y+1/2, z-1/2$.

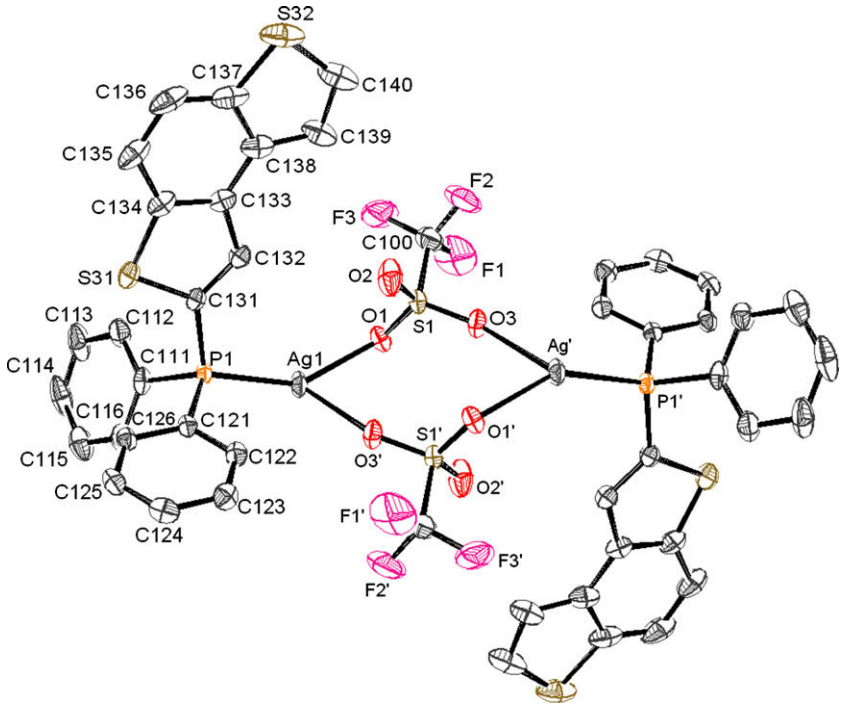

Fig. 1. Molecular diagram of **1Ag** with 50% thermal ellipsoids, showing the labeling scheme. Hydrogen atoms have been omitted for clarity.

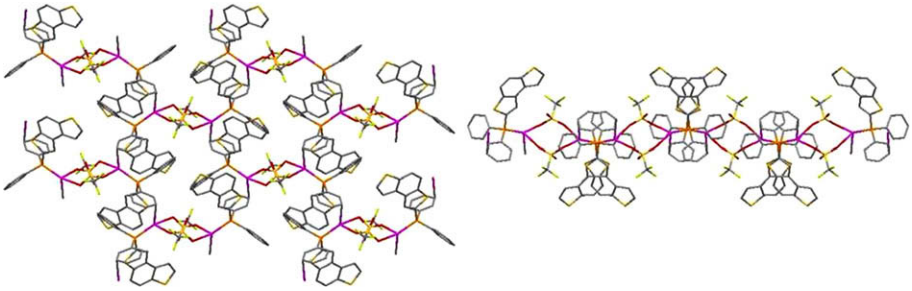

Fig. 2. Perspective of the bidimensional polymeric chain of **1Ag** along *a* (left) and *c* (right).

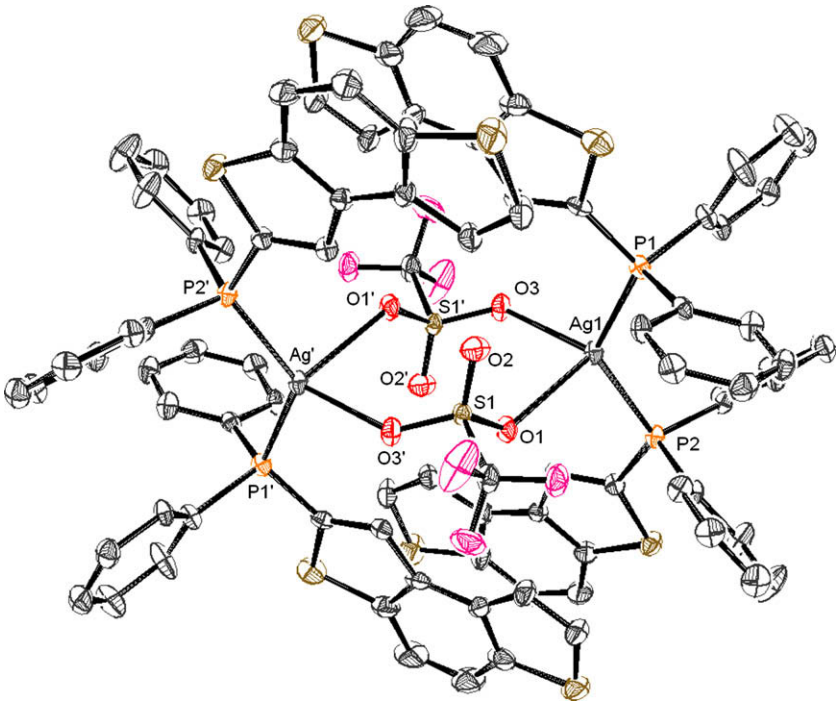

Fig. 3. Molecular diagram of **2Ag** with 40% thermal ellipsoids, showing the labeling scheme. Hydrogen atoms have been omitted for clarity.

bond lengths and angles for compound **2Ag**. Both Ag–P (2.439(2) and 2.434(2) Å) and Ag–O distances are comparable to the ones found for compound $[Ag(O_3SCF_3)(PPh_3)_2]$ (2.409(5) and 2.572(5)) (Ag–P: 2.4321(12) and 2.4339(12); Ag–O: 2.385(13) to 2.578(5) [6]; Ag–O distances resemble the dissimilarity found in compound $[Ag(O_3SCF_3)(PPh_3)_2]$.

Worth noticing the effect of the substitution of one Ph ring by the larger bzt group: compounds $[Ag(O_3SCF_3)(PPh_3)]$ and $[Ag(O_3SCF_3)(PPh_2\{bzt\})]$ (**1Ag**) have totally different solid state arrangements ($[Ag(O_3SCF_3)(PPh_3)]$ is a trinuclear derivative [6,14] while **1Ag** is a bidimensional polymer), compounds $[Ag(O_3SCF_3)(PPh_3)_2]$ and $[Ag(O_3SCF_3)(PPh_2\{bzt\})_2]$ (**2Ag**) have similar arrangements.

Table 2
Selected bond lengths and angles for compound **2Ag**.

Bond distances (Å)			
Ag1–O1	2.572(5)	S1–O1	1.442(5)
Ag1–O3	2.411(5)	S1–O3#1	1.434(5)
Ag1–P1	2.439(2)	S1–O2	1.414(5)
Ag1–P2	2.434(2)

O3–Ag1–P2	117.78(14)		

Symmetry transformations used to generate equivalent atoms: #1: $-x+1$, $-y$, $-z+1$.

The four bzt groups of each dimer have an almost parallel alignment. This parallel alignment between bzt groups is maintained along direction *a*, through weak hydrogen bonding between the Ph groups and fluorine and oxygen atoms of neighbor dimers (C(225)–H(225)···F2 {2.669(6) Å}, (C(113)–H(113)···O3 {2.657(5) Å} and C(114)–H(114)···F(1) {2.635(6) Å}), forming a columnar packing. The column packing along the *b* direction is made, alternately, between columns symmetrically generated trough an 180° rotation around the *a* axis in relation to the neighbor ones, which results in a *zig-zag* alignment of the bzt groups along *b*, as illustrated in Fig. 4.

Compound **3Ag** · **0.5CH_2Cl_2** crystallizes in the triclinic centrosymmetric space group $P\bar{1}$. The asymmetric unit (Fig. 5) is the monomeric formula unit with the half solvent molecule of CH_2Cl_2. Selected bond lengths and angles are presented in Table 3.

The silver atom is coordinated to three phosphorus atoms of **L1** ligands and to an oxygen atom (O1) of trifluoromethanesulfonate, displaying a distorted tetrahedral coordination. The Ag–P bond distances range from 2.4780(12) to 2.5113(11) Å and are shorter

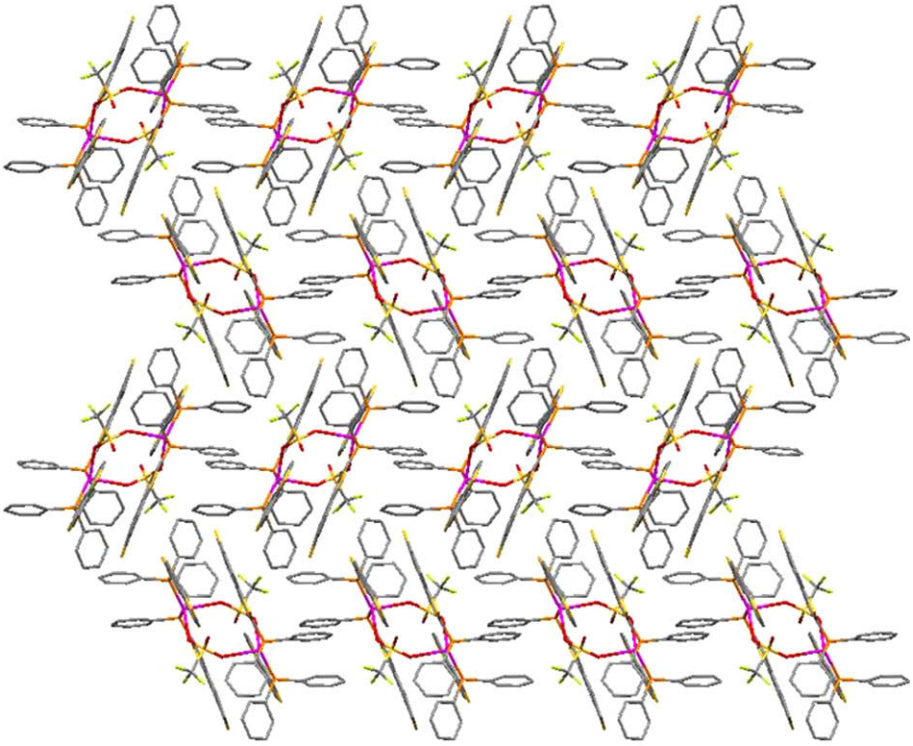

Fig. 4. Perspective of the supramolecular arrangement of **2Ag**, along direction *c*: dimer alignment along direction *a* (horizontal) and *zig-zag* alignment of bzt groups along *b* (vertical).

than the ones found for compounds $[AgX(PPh_3)_3]$ (X = Cl: 2.558(5)–2.582(4); Br: 2.528(3)–2.549(7); I: 2.544(2)–2.780(3) [15]; NO_3: 2.525(1)–2.630(2) [11]; $CO_2C_2F_5$: 2.5432(7)–2.6026(8) Å [16]). P–Ag–P angles range between 111.49(4) and 124.67(4) Å: the angle P(1)–Ag(1)–P(3) is higher (~23 Å) than the other two P–Ag–P angles, minimizing the interaction between **L1** ligands and the anion, and opposite to the longer Ag–P(2) distance, as expected.

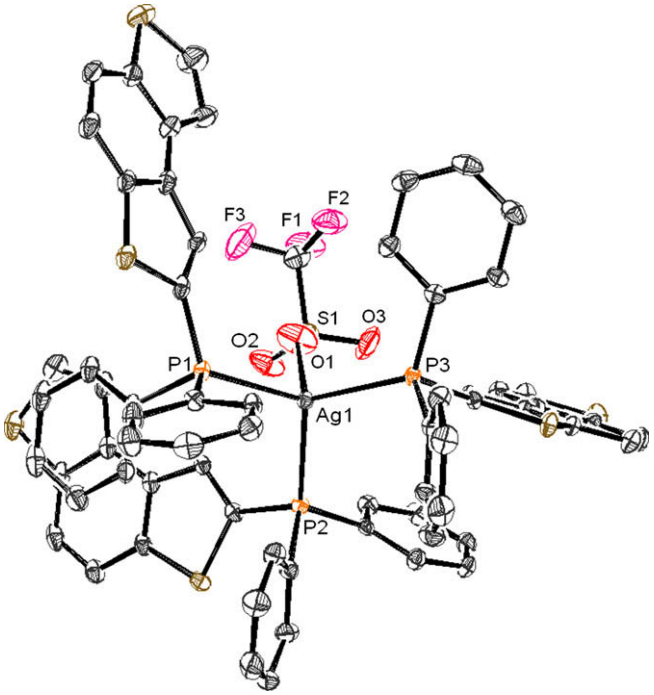

Fig. 5. Molecular diagram of **3Ag** with 40% thermal ellipsoids, showing the labeling scheme. Hydrogen atoms have been omitted for clarity.

3. Experimental

3.1. General procedures

All the experiments were carried out under a dinitrogen atmosphere, using standard Schlenk techniques. All solvents used were dried using standard methods [17]. $AgCF_3SO_3$ and $(C_6H_5)_2PCl$ were purchased from Aldrich and used without further purification. ^1H and ^{31}P NMR spectra were recorded on a Bruker Avance 400 spectrometer at probe temperature, unless stated otherwise. The ^1H NMR (chloroform-*d*) chemical shifts are reported in parts per million (ppm) downfield from internal Me_4Si and the ^{31}P NMR (chloroform-*d*) spectra are reported in ppm downfield from external standard, 85% H_3PO_4. Elemental analyses were obtained at *Laboratório de Análises*, *Instituto Superior Técnico*, using a Fisons

3.2. Synthesis of benzo[1,2-b;4,3-b′]dithiophen-2-diphenylphosphine (*L1*)

To a THF solution (15 mL) of benzo[1,2-*b*;4,3-*b*′]dithiophene (0.19 g, 1 mmol) cooled at −78 °C, was slowly added a 2.0 M *n*-BuLi pentane solution (0.55 mL, 1.1 mmol). The mixture was stirred at −78 °C for 5 min and for 15 min at room temperature. The resulting yellow solution was cooled at −78 °C and treated with Ph_2PCl (0.22 mL, 1.2 mmol). After 1 h under agitation at −78 °C, the solution was warmed to room temperature and quenched with a saturated solution of NH_4Cl (5 mL). The THF was removed under reduced pressure, the crude material was taken up with CH_2Cl_2 (20 mL) and washed with saturated aqueous solution of NH_4Cl (3 × 10 mL) and water (3 × 10 mL). The organic phase was dried over $MgSO_4$, the solvent was removed under reduced pressure and the crude material was purified by means of flash column chromatography (eluent: light petroleum/CH_2Cl_2 4:1). Yield: 60%. Colorless oil. *Anal.* (%): Calc. for $C_{22}H_{15}PS_2$: C, 70.56; H, 4.04; S, 17.13. Found: C, 70.01; H, 3.95; S, 17.35. ^{1}H NMR: 7.30 (m, 6H, Ph), 7.38 (m, 4H, Ph), 7.47 (d, 1H, H_{10}, J_{HH} = 5.2 Hz), 7.59 (d, 1H, H_{11}, J_{HH} = 5.2 Hz), 7.62 (d, 1H, H_7, J_{HH} = 8.4 Hz), 7.71 (d, 1H, H_6, J_{HH} = 8.4 Hz), 8.02 (d, 1H, H_{10}, J_{HP} = 6.8 Hz). ^{31}P NMR: −17.06 (s).

3.3. Synthesis of the complexes [Ag(CF_3SO_3)(PPh_2{bzt})$_n$]

Complexes of general formula [Ag(CF_3SO_3)(PPh_2{bzt})$_n$] were prepared from $AgCF_3SO_3$ (0.128 g, 0.5 mmol) in CH_2Cl_2, in the presence of an adequate quantity of benzo[1,2-*b*;4,3-*b*′]dithiophen-2-diphenylphosphine (n = 1: 0.180 g, 0.49 mmol; n = 2: 0.374 g, 1.00 mmol; n = 3: 0.562 g, 1.5 mmol). The mixtures were stirred overnight at room temperature, protected from light. After filtering and reducing the solvent volume to ≈5 mL), the complexes were recrystallized by slow diffusion of n-hexane, affording white crystalline products.

3.3.1. [Ag(CF_3SO_3)(PPh_2{bzt})] (*1Ag*)

Yield: 94%. White. *Anal.* (%): Calc. for $C_{23}H_{15}S_3O_3PF_3Ag$: C, 43.75; H, 2.39; S, 15.24. Found: C, 44.12; H, 2.39; S, 15.92. ^{1}H NMR: 7.50 (m, 6H, PPh_2), 7.59 (m, 4H, PPh_2), 7.61 (d, 1H, H_{10}, J_{HH} = 4.8 Hz), 7.70 (d, 1H, H_7, J_{HH} = 8.8 Hz), 7.76 (d, 1H, H_{11}, J_{HH} = 5.2 Hz), 7.88 (d, 1H, H_6, J_{HH} = 8.4 Hz), 8.39 (d, 1H, H_3, J_{HP} = 11.2 Hz). ^{31}P NMR (−60 °C): 3.23 (d, J(^{109}Ag–P) = 788.5 Hz).

3.3.2. [Ag(CF_3SO_3)(PPh_2{bzt})$_2$] (*2Ag*)

Yield: 89%. White. *Anal.* (%): Calc. for $C_{45}H_{30}S_5O_3P_2F_3Ag \cdot 0.3CH_2Cl_2$: C, 52.76; H, 2.99; S, 15.54. Found: C, 52.84; H, 3.11; S, 15.60. ^{1}H NMR: 7.38 (m, 4H, PPh_2), 7.48 (m, 2H, PPh_2), 7.53 (d, 1H, H_{10}, J_{HH} = 5.2 Hz), 7.59 (m, 4H, PPh_2), 7.63 (d, 1H, H_{11}, J_{HH} = 4.8 Hz), 7.64 (d, 1H, H_6, J_{HH} = 8.8 Hz), 7.85 (d, 1H, H_6, J_{HH} = 8.8 Hz), 8.46 (s, 1H, H_3). ^{31}P NMR (−60 °C): 0.79 (dd, J(^{109}Ag–P, ^{107}Ag–P) = 553.3, 488.4 Hz).

3.3.3. [Ag(CF_3SO_3)(PPh_2{bzt})$_3$] (*3Ag*)

Yield: 82%. White. *Anal.* (%): Calc. for $C_{67}H_{45}S_7O_3P_3F_3Ag \cdot 0.4CH_2Cl_2$: C, 57.24; H, 3.26; S, 15.87. Found: C, 57.12; H, 3.32; S, 15.88. ^{1}H NMR: 7.08 (m, 4H, PPh_2), 7.23 (m, 2H, PPh_2), 7.38 (d, 1H, H_{10}, J_{HH} = 5.6 Hz), 7.40 (d, 1H, H_{11}, J_{HH} = 5.6 Hz), 7.42 (m, 4H, PPh_2), 7.51 (d, 1H, H_6, J_{HH} = 8.8 Hz), 7.75 (d, 1H, H_6, J_{HH} = 8.8 Hz), 8.34 (d, 1H, H_3, J_{HP} = 7.2 Hz). ^{31}P NMR (−60 °C): 2.90 (dd, J(^{109}Ag–P, ^{107}Ag–P) = 362.5, 321.0 Hz).

3.4. Crystal structure determination

X-ray data for compounds **1Ag**, **2Ag** and **3Ag · 0.5CH$_2$Cl$_2$** were collected on a Bruker AXS APEX CCD area detector diffractometer at 150(2) K using graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation. Intensity data were corrected for Lorentz polarization effects. Empirical absorption correction using SADABS [18] was applied and the data reduction was done with SMART and SAINT programs [19].

All structures were solved by direct methods with SIR97 [20] and SIR2004 [21] and refined by full-matrix least-squares on F^2 with SHELXL97 [22], all included in the package of programs WINGX-Version

1.70.01 [23]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were placed in idealized positions and allowed to refine riding on the parent C atom. Graphical representations were prepared using ORTEP [24], and MERCURY 1.1.2 [25]. A summary of the crystal data, structure solution and refinement parameters are given in Table 4. In compound **2Ag** a severely disordered solvent molecule was found that could not be modeled so it was removed using SQUEEZE [26]. SQUEEZE calculated an electron count/cell of 143 which matches well with a n-hexane or a dichloromethane molecule per asymmetric unit. Before SQUEEZE $R_1 = 0.0801$, afterwards $R_1 = 0.0764$.

ABSTRACT

The ternary copper(II) complexes [Cu(L-trp)(bpy)](ClO_4) (**1**) and [Cu(L-trp)(phen)] (ClO_4)·$3H_2O$ (**2**) (where L-trp = L-tryptophan, bpy = bipridyl, phen = phenanthroline) have been synthesized. The single crystal X-ray structures for these complexes revealed that the monocationic Cu^{II}-units are interlinked through Cu–OCO–Cu connectivity and exist as helical coordination polymers. The two different helical strands composed with Cu1 and Cu2 independently, possess a similar pitch distance of 7.713 Å in complex **1**. For complex **2**, existing in the hydrated form, the Cu(II) polymeric strand and the hydrated water molecules have gained a supramolecular helical architecture with a similar pitch distance of 8.133 Å. The two helical strands in complex **1** are associated with right handed (*PP*) supramolecular chirality, while the helical water chain and the Cu^{II}-strand in **2** are self assembled into left handed (*MM*) helicity in the solid state. The solid state CD recorded for **1** and the dehydrated form of **2** exhibit a positive optical sign at their respective d–d band [λ_{max} = 667 nm, **1**; λ_{max} = 630 nm, **2**], the solution state CD for both these complexes are found to be inverted into a negative optical sign, which could be attributed to inversion of their associated supramolecular helicity. The TGA curve illustrates two distinct weight losses at 60 °C and 87 °C, equivalent to one and two water molecules, respectively. The PXRD pattern for the hydrated and dehydrated forms of **2** indicated a change, on comparison with the simulated diffractograph. The fluorescence properties of both these complexes, possessing tryptophan and bipy/phen, were investigated.

1. Introduction

Helicity is of paramount importance in nature and in synthetic materials [1–3], and the helical architecture has inspired the syntheses of a variety of helical coordination polymers [4–8], metallohelicates [9], and organohelices [10]. Chiral coordination polymers and helicates composed of chiral building blocks are important supramolecular compounds in view of enantio-selective catalysis [11,12], chiral separation [13–15], and material chemistry [16]. Intensive efforts to investigate the chiroptical properties of supramolecular helices, upon introduction of various chiral residues, such as chiral spacers [17–22], amino acids [23–28], and chiragens [25–28] in the helical skeleton, have been carried out by a number of researchers, including Raymond et al. [29–32], Albrecht et al. [33–35], Kuroda and Telfer [36], and Zelewsky and Ziegler [37]. A number of ternary [Cu(II)(DA)(AA)] [38–51] type complexes composed of optically active D- and L-amino acids (AA) are been known and their optical properties in solution have been studied extensively with intensive focus on structure–reactivity correlation. The rich literature on such complexes indicating the formation of folded and extended conformations, and the present investigation on their supramolecular helical architecture and solid state chiroptical properties are expected to enhance further understanding. In this direction, and in continuation of our recent report [52], we have synthesized and characterized the complexes [Cu(L-trp)(bpy)](ClO_4) (**1**) and [Cu(L-trp)(phen)](ClO_4)·$3H_2O$ (**2**), with a view to investigate the structures and chiroptical properties. The structural analysis of these complexes illustrates that they are single stranded helical coordination polymers. Both these coordination polymers possess the chiral L-tryptophan as a supramolecular building block. The potential chiral sources, *i.e.* the (*P*)/(*M*) sense of supramolecular helicity [53,54], the geometrical chirality (Λ/Δ) [55–58] due to the non-coplanarity at the Cu^{II}-center and conformational chirality λ/δ [59–63] of the chelate rings of the amino acids are analyzed in detail along with CD spectra recorded both in the solid and solution states. These complexes, when composed of the chiral amino acid (L-trp), resulted in single stranded supramolecular helical structures. The solid state optical activity in combination with the solution state CD of these complexes exhibit interesting chiroptical properties. Further, the cooperative self-assembly process of the "helical aqua chain in-between the helical coordination network" observed in **2** signifies that these complexes are parallel with a recent report on water chains. Chakravarty and co-workers [64,65], Vittal and Sreenivasulu [66], and Das and

doi:10.1016/j.poly.2008.10.072

co-workers [67] have reported both right and left handed helical water chains. In this direction, the present complex demonstrates the formation of a left handed helical water chain [68–75], similar to the one in the complex $[Cu(sHis)_2] \cdot 4H_2O$ reported by Hong and co-workers [76] The present manuscript, in addition to investigating the structural aspect of the coordination polymers, has further attempted to explore the involvement of the water chain on the supramolecular architecture. Indole is an important fluorophore for monitoring many bio-clinical and catalytic experiments, the fluorescence obtained for these complexes in the present study asserts them as better candidates for photoactive materials.

2. Experimental

2.1. Materials and methods

All reagents and solvents employed were commercially available and were used without further purification. Elemental analysis was performed on a Perkin–Elmer 4100 elemental analyzer. Variable temperature Powder diffraction spectra were recorded using a Philips X-pert MPD Powder X-ray Diffractometer with a 2θ angle ranging from 5° to 40°. Thermogravimetric analysis with heating rate of 5 °C/min was performed using a Mettler Toledo Star SW 7.01. Simulated powder patterns were obtained from the crystallographic software MERCURY version 1.4. The KBr pellets for the CD spectra were prepared with a 1:20 w/w ratio of complex to KBr, and the spectra were measured on a JASCO 815 Spectrometer; fluorescence spectra were recorded on a Perkin Elmer Luminescence Spectrometer LS 50B.

2.1.1. Crystal structure determination

Data collections of **1** and **2** were performed with Mo Kα radiation ($\lambda = 0.71073$ Å) on a Bruker Apex CCD diffractometer at $T = 100(2)$ K. Absorption corrections were applied by using SADABS [77]. The structures were solved by direct methods and all non-hydrogen atoms were refined anisotropically by least-squares on F^2 using the SHELXTL program [78]. Hydrogen atoms of the ligand moiety were geometrically fixed in both complexes, and we could not locate the lattice water hydrogens from the difference Fourier map for O8 and O9.

2.2. Synthesis

2.2.1. [Cu(L-trp)(bpy)](ClO$_4$) (**1**)

A mixture of L-tryptophan (1.02 g, 5 mmol) and NaOH (0.2 g, 5 mmol) dissolved in 10 mL of distilled water was added to an aqueous solution (25 mL) of $CuSO_4 \cdot 5H_2O$ (1.25 g, 5 mmol) with constant stirring for 1 h. The light blue precipitate that formed was dissolved upon addition of a 10 mL ethanol solution of bipyridyl (0.78 g, 5 mmol). To this mixture, $NaClO_4 \cdot H_2O$ (0.7 g) dissolved in distilled water was added gradually. The solution was stirred for another 2 h with heating at 333 K. Slow evaporation of the reaction mixture at 298 K yielded dark blue, needle shaped crystals after a couple of weeks. Yield, 76%. *Anal. Calc.* for $C_{21}H_{19}N_4O_6CuCl$: C, 48.28; H, 3.67; N, 10.72. Found: C, 48.55; H, 3.99; N, 10.80%. IR (ν, cm^{-1}): 3386–2933 (s), 1626, 1595 (ν_{COO}, s), 1445, 1407 (m), 1317 (m), 1110, 1070, 1052 (s, ClO_4), 755, 663 (m).

2.2.2. [Cu(L-trp)(phen)](3H$_2$O)(ClO$_4$) (**2**)

This complex was synthesized following the above procedure, using 1,10-phenanthroline monohydrate (0.94 g, 5 mmol) in place of bipyridyl. Yield 85%. *Anal.* Calc. for $C_{23}H_{25}N_4O_9CuCl$: C, 46.01; H, 4.20; N, 9.33. Found. C, 46.20; H, 4.25; N, 9.50%. IR (ν, cm^{-1}): 3566–2954 (s, br), 1635, 1590 (ν_{COO}, s), 1523, 1433, 1395 (m), 1140, 1112, 1080 (s, ClO_4), 841, 757 (m).

CAUTION! Perchlorate salts of metal complexes are potentially explosive and should be handled with great care.

3. Results and discussion

3.1. Crystal structures and molecular association

Complexes **1** and **2** crystallized in the chiral space groups $P2_1$ and $P2_12_12_1$, respectively. ORTEP diagrams with the atom numbering schemes for **1** and **2** are depicted in Fig. 1 and a summary of the crystallographic data, selected bond distances and bond angles are given in Tables 1 and 2, respectively. The Cu^{II} ion in both these complexes possesses a distorted square pyramidal geometry, the square base around the metal center is occupied by pyridyl nitrogens of the bpy/phen moiety, and NH_2 and COO groups of the amino acid (L-trp). The fifth axial site is occupied by the second oxygen of the carboxylate unit, which bridges the neighboring metal center in a "*syn–anti*" mode and constructs a single stranded one-dimensional helical polymeric network. The *syn–anti* carboxylate coordination of the tryptophan unit in **1** and **2** repeatedly self assembled in screw related 2_1 symmetry, through a spiral coordination polymeric arrangement running through the OCO···Cu^{II}···OCO bridge. The indole moiety of L-tryptophan in the present complexes, possessing some sort of weak intramolecular interaction with the aromatic rings of the diamines and bpy/phen, exists in a folded conformation, as observed in various [Cu$^{(II)}$(DA)(AA)] type complexes.

Complex **1** consists of two independent molecules in the asymmetric unit, with Cu1 and Cu2 as the central metal ions. The carboxylate oxygens O2 and O4 of the tryptophan ligand in **1** [Cu1–O2 = 2.206(3), Cu2–O4 = 2.203(3) Å] interconnect the adjacent Cu^{II} centers and generate two independent helical strands running through Cu1–OCO–Cu1 and Cu2–OCO–Cu2. The Cu^{II} metal ions are placed in the respective polymeric helical strands with intrahelical Cu^{II}–Cu^{II} distances of 5.579 (Cu1–Cu1) and 5.628 Å (Cu2–Cu2). Both these parallel helical strands, possessing a similar pitch distance, exist as screw related right handed (*PP*) helices, as shown in Fig. 2a.

Similar to complex **1**, adjacent Cu^{II} metal ions in **2** are interlinked through the carboxylate oxygen O2 [Cu1–O2 = 2.254(4) Å] and are extended as a one-dimensional helical polymeric strand. Further, complex **2**, crystallizing with three lattice water molecules per Cu(II) unit, exists in the hydrated form. These hydrated water molecules O7, O8, and O9 are entrapped between the Cu^{II}-helical strand and are self assembled into a helical aqua chain. Thus, the molecular packing in **2** is comprised of two different helical assemblies *i.e.* the robust Cu^{II}–OCO–Cu^{II} chiral polymeric strand and the one-dimensional helical water chain. Although these two helical strands differ in their chemical constituents, they possess a similar pitch distance, 8.133 Å, and it is revealed that they are left handed homohelices (*MM*). Unlike complex **1**, the Cu^{II} metal centers in **2** are placed in the helical chain (Cu1–OCO–Cu1) and possess a constant intrahelical Cu^{II}···Cu^{II} distance of 5.946 Å. Adjacent Cu^{II}-helical strands are packed along the *ab* plane, incorporating the infinite helical water chain between them as shown in Fig. 2b.

3.2. Molecular stacking and stereoregular arrangement

Since the π–π stacking interactions [11–16] observed in [Cu(-DA)(AA)] type complexes has been of significant interest, the present complexes, composed of aromatic rings of tryptophan and bpy/phen, and their molecular association mediated through inter and intramolecular interactions like π–π stacking and hydrogen bonding are analyzed in view of their involvement in the construction of the helical arrangement. Accordingly, crystallographically

generated centroids Cg_1 to Cg_5 and Cg_1' to Cg_5' were assigned to the various aromatic rings around the Cu^{II} centers as indicated in Fig. 3.

Cg_1, Cg_2, and Cg_5 represent the centroids of the respective aromatic rings of bpy and phen, and Cg_c represents the centroid of the metal-chelate ring. The centroids for the phenyl and pyrrole rings of the tryptophan moiety in complexes **1** and **2** are assigned as Cg_3 and Cg_4, respectively. The various inter and intramolecular offset π···π stacking interactions between the aromatic rings and the respective distances derived from the crystallographic data are depicted in Table 3. The intramolecular π–π stacking interaction measured between the various aromatic rings of bpy/phen with the phenyl (Cg_3) and pyrrole (Cg_4) rings of the tryptophan moiety are found to be in the range 3.60–3.94 Å, and the corresponding stacked rings are oriented almost parallel to each other. Interestingly, for these complexes existing in the folded conformation, the five membered chelate ring Cg_c (metal-chelate ring of bpy/phen) in **1** and **2** revealed the shortest distance with the phenyl ring of the tryptophan and illustrate the existence of an aryl-metal-chelate ring interaction [43,79–81] (complex **1**, $Cg_c\cdots Cg_4$ = 3.452 Å; $Cg_c\cdots Cg_3$ = 3.37 Å and complex **2**, $Cg_c\cdots Cg_3$ = 3.385 Å; $Cg_c\cdots Cg_4$ = 3.661 Å]. This aryl-metal-chelate interaction between the phenyl ring of the tryptophan and the metal chelate, ring $Cg_c\cdots Cg_3$ = 3.37 Å in **1** and $Cg_c\cdots Cg_3$ = 3.385 Å in **2**, presumably might have helped in stabilizing the folded conformation in both these complexes. Thus, while the inter and intramolecular π–π stacking interactions, along with aryl-metal-chelate interactions, favors the formation of a folded conformation, the carboxylate moiety interconnects the Cu^{II}-units through its Cu–OCO–Cu bridge in a stereoregular manner and gains a helical arrangement.

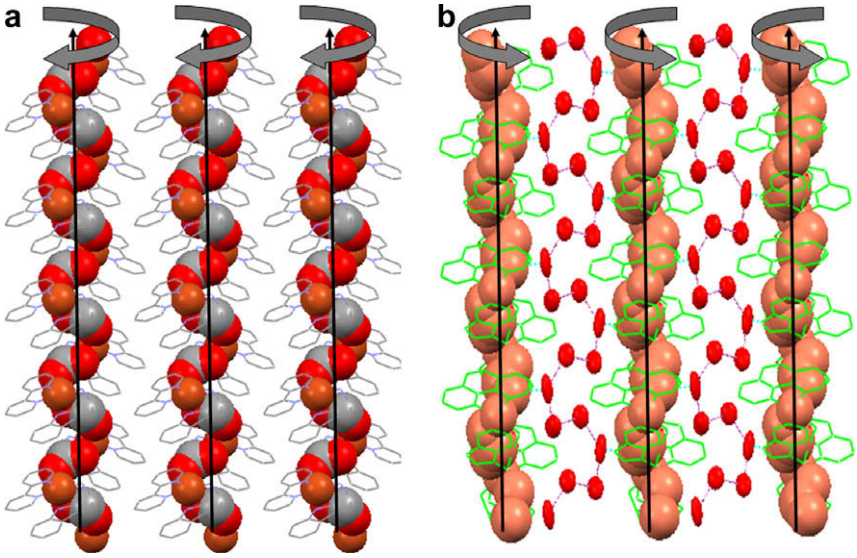

Fig. 2. Helical coordination polymers **1** and **2** along with helical rotation. (a) Complex **1** (*PP*)-helices. (b) Complex **2**. Table 3
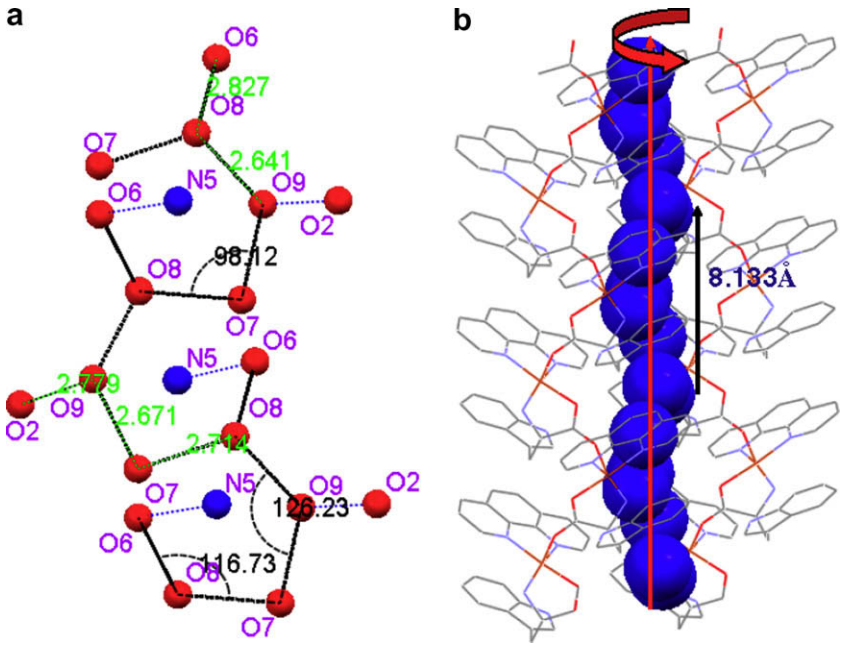
Inter and intramolecular π···π stacking distances in **1** and **2**.

Complex	**1** (Å)	**2** (Å)
Intra π···π	$Cg_1\cdots Cg_4$ = 3.606	$Cg_3\cdots Cg_4$ = 3.940
	$Cg_2\cdots Cg_3$ = 3.715	$Cg_2\cdots Cg_4$ = 3.893
	$Cg_c\cdots Cg_4$ = 3.452	$Cg_c\cdots Cg_3$ = 3.385
	$Cg_c\cdots Cg_3$ = 3.370	$Cg_c\cdots Cg_4$ = 3.661
Inter π···π	$Cg_3\cdots Cg'$ = 3.759	$Cg_4\cdots Cg'_5$ = 3.499

3.3. Helical water chain

The trimeric acyclic water molecules containing O7, O8, and O9 in complex **2** are interconnected themselves through their O–H···O interactions (S1). Selected bond distances and bond angles regarding the helical water chain are depicted in Fig. 4a. Even though the data collection was carried out at liquid nitrogen temperature (100 K), only the hydrogen atoms attached to O7 were located, whereas the hydrogen atoms of O8 and O9 were not obtainable from the difference Fourier map. However, the hydrogen bonding



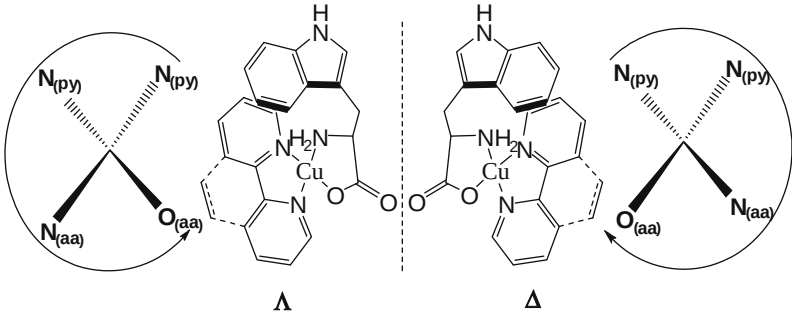


Fig. 4. Lattice helical water chain between the Cu^{II}-helical strands. (a) Water helix with atom numbering, bond distances and bond angles. (b) Pitch distance and left handed helical rotation.

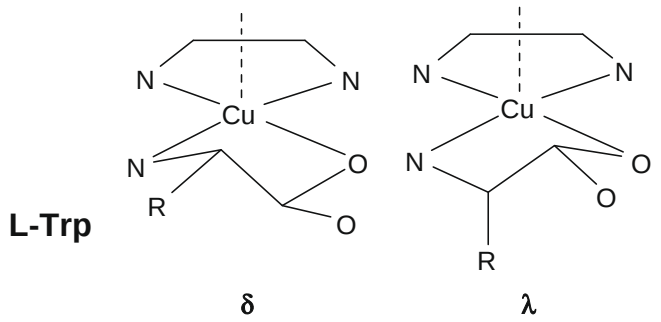
distances and angles (∠O7–H71···O9 = 122°; ∠O7–H72···O8 = 151°) between the 2_1 screw related water oxygens (O7, O8, O9) unequivocally establish the infinite hydrogen bonded helical water chain. The average O···O (2.675 Å) distance and the average angle of 112.30° matches well with reported helical water chains [76,79–82]. The water oxygen O9 further acts as both a donor and an acceptor and makes effective H-bonding with the tryptophan carboxylate oxygen O2 [O9···O2 = 2.779 Å] and phenyl hydrogen H2 [C2···O9 = 3.396 Å; ∠C2–H2···O9 = 146°] of the phenanthroline ring oriented along the periphery of Cu^{II}-strand. O7 water is involved in N–H···O interaction with the tryptophan amino nitrogen N4 [N4···O7 = 3.07 Å; N4–H4···O7 = 151°], whereas O8 water acts as a donor in hydrogen bonding with the perchlorate oxygen O6 [O8···O6 = 2.827 Å]. Thus the adjacent Cu^{II}-helical strands within the interhelical space force the trimeric acyclic water molecules through their contact mediated *via* C–H···O, N–H···O, and O–H···O hydrogen bonds, and stabilize them in the helical arrangement. Interestingly, the helical water chain and the Cu^{II}-strand in complex **2** are associated in a left handed (*MM*) sense of superstructure. In general, the supramolecular helices are usually pack in a racemic fashion [30], comprising of both right and left handed helices. Accordingly, recent literature [22–24] illustrating the packing of both right and left handed helical water chains in schiff base complexes, the present helical water chain, possessing solely left handedness (Figs. 2b and 4b), resembles the water chain similar to the one in $[Cu(sHis)_2]\ 4H_2O$ complex reported by Hong and co-workers [76]. Thus, the observation suggest, that the complex 1 and 2 stabilizes with L-tryptophan in homochiral (*PP*) and (*MM*) helices predominantly is worth mentioning.

3.4. Chiral components and chiroptical properties



For the complexes **1** and **2** (hydrated), possessing a chiral amino acid, their diastereo-selective crystallization provide homochiral right handed (*PP*) and left handed (*MM*) superstructures in their solid states, respectively. The change in the CD optical sign of these L-tryptophan complexes, in solution and in the solid state, inspired us to investigate their chiroptical properties. Accordingly, the CD spectra for complex **1** and the hydrated and dehydrated forms of complex **2** were recorded both in solution and on ground crystals. An attempt to derive a correlation between the various chiral components in the complexes and their chiroptical properties was carried out. In general, the source of the optical activity could be derived from various chiral sources such as the (*P*)/(*M*) supramolecular helical descriptors, the molecular Δ/Λ descriptors of the chiral metal centers (Scheme 1) and the λ/δ conformational chiral-

Scheme 1. Geometrical descriptors.

ity of the non-planar amino acid chelate ring (Scheme 2). The stereochemical descriptors (*P*) and (*M*) could be assigned to the supramolecular helical assemblies for complexes **1** and **2** depending upon the clockwise and anticlockwise rotation of the helical strand. Further, the existence of molecular chirality can be attributed to the non-coplanar arrangement of the Cu^{II} chromophoric donor atom at the base of the square pyramid or the asymmetric arrangement of the ligand conformation. Accordingly, the molecular descriptors Δ and Λ are assigned for the present complexes depending upon the clockwise (Δ-enantiomer) and anticlockwise (Λ-enantiomer) operation of the ligand coordination around the Cu^{II} center as shown in Scheme 1. The structural analysis for both these complexes denote that the indole ring of the tryptophan and the bipy/phen moieties project outwards and revolved around the helical axis, drawn between the metal centers, with considerable intra and intermolecular π–π stacking interactions, as shown in Fig. 3a and b. The folded isomers in complex **1**, sitting alternatively in a ΔΛΔΛ··· fashion, generate two helical strands *i.e.* Cu1–OCO–Cu1 and Cu2–OCO–Cu2 strands. Thus, the stereoregularly arranged adjacent polymeric Cu1 and Cu2 homohelices are associated with right handed rotation and produce (*PP*) helices as shown in Fig. 2a. Our analysis in complex **1** indicates that this complex preferred the formation of (*PP*) homohelices predominantly.

As stated above, the two helical strands in complex **2** (helical water chain and Cu(II)-strand) are stereospecifically self assembled into left handed (*MM*) helices in the solid state. The supramolecular chiralities associated with complexes **1** and **2**, existing in the folded form, are different and opposite to each other, *i.e.* right handed (*PP*) in **1** and left handed (*MM*) helices in **2** (hydrated). Based on the structural investigation, the molecular chirality at the metal center obviously demonstrates the presence of both Δ and Λ isomers in the helical strand and hence the chirality associated with the molecule is cancelled out. The solid state CD recorded for complex **1** illustrates a broad band centered at ≈660 nm with a positive optical sign, while complex **2**, in its hydrated form, exhibited a negative optical sign at ≈609 nm, as shown in Fig. 5a. As complexes **1** and **2** have very similar chemical compositions, the difference in the stereoregular arrangement observed in their superstructures *i.e.*, right handed (*PP*) in **1** and left handed (*MM*) in **2** (hydrated) must have caused the opposite sign. The bpy rather than phen ring and the helical water chain are the only differences between these complexes, the change observed in their respective helical superstructures is identified as an appropriate candidate for these changes. Hence as a first step, to understand the involvement of the water chain and supramolecular helicity, the water molecules from complex **2** were removed following the thermogravimetric analysis described below. Hence upon dehydrating complex **2** at 110 °C, the corresponding solid state-CD spectra was recorded [Fig 5a (iii)]. Fascinatingly, the CD spectrum obtained for this dehydrated form of complex **2** bears a positive optical sign, which is almost opposite to the respective optical sign obtained for its hydrated counterpart (Fig 5a (ii)). Thus, the hydrated and dehydrated forms of complex **2** produce almost opposite optical signs in their respective solid state-CD spectra, the corresponding structural changes *i.e.* (*MM*) in the hydrated form into (*PP*) in the dehydrated form may tentatively be assigned to the supramolecular helical inversion. This observation indicates that the helical water chain entrapped in between the Cu^{II}-strands, retains the (*MM*) helices, but upon dehydration the left handed Cu^{II}-strand rearranges into right handed (*P*) helices. Thus, the change in the optical sign can be attributed to the hydrated and dehydrated forms. Our attempt to solve the crystal structure for this dehydrated form of complex **2** was unsuccessful.

Scheme 2. Conformations of the amino acid chelate rings.

In general, the five membered amino acid chelate rings can exhibit a dynamic λ ⇌ δ conformational equilibrium [20] in the solution state (Scheme 2). The well documented literature [21] indicates that the position of the equilibrium would be determined by the distortion on the chiral center influenced by various factor such as aromatic rings, bulkiness of the side chain substitution and polarity of the solvent. As mentioned above, phen rather than bpy and the helical water being the only difference between **1** and **2**, they are considered to play a significant role in determining the λ/δ conformation in the solid state. Accordingly, the torsion angles involving the C12C11O1Cu1 and C33C32O3Cu2 motifs measured using the crystal structure of **1** are −6.53° and −3.88°, whilst the respective chelate ring C14C13O1Cu1 in complex **2** shows +10.28°. This observation clearly supports that complex **1** predominantly stabilizes the δ conformation, while **2** favors the λ conformation in the solid state. For complex **2**, possessing a comparatively bulky phenanthroline moiety and the polar water chain in the solid state, the respective λ conformation induces the formation of a (*M*) helix, while complex **1** with a δ conformation induces the (*P*) helix, resembling our earlier reports.

The CD spectra recorded in both the solid state (Fig. 5a) and in solution (Fig. 5b) for complexes **1** and **2** at room temperature give broad signals in the visible region at 450–800 nm. Whilst the solid state-CD spectrum for **1** exhibits a positive sign (λ_{max} = 660 nm), the corresponding solution state CD spectrum gives a negative sign at 598 nm ($\Delta\varepsilon = -1.38\ M^{-1}\ cm^{-1}$). However the respective solid state-CD spectra of the hydrated and dehydrated (λ_{max} = 630 nm) forms of **2** produce opposite optical signs. Interestingly, the solution state CD spectra recorded in methanol solvent for **1** and **2** behave similarly in the visible region, exhibiting a d–d band at 598 nm ($\Delta\varepsilon = -1.38\ M^{-1}\ cm^{-1}$) for **1** and 603 nm ($\Delta\varepsilon = -1.64\ M^{-1}\ cm^{-1}$) for **2**. This shift in the d–d band and the change in the optical sign together suggest that the polymeric helical assembly is destroyed in the solution state and the complexes may exist as monomeric species.

As observed from the single crystal X-ray structures, the supramolecular helical assemblies of complexes **1** and **2**, containing the L-tryptophan ligand, lead to (*PP*) and (*MM*) homohelices. In complex **2**, for the hydrated form, where the metal-chelate ring exists in the λ conformation, the Cu^{II} strand results in (*M*) helices, while the δ conformation is stabilized in (*P*) helices in the dehydrated form. In complex **1**, with a folded conformation, the chelate ring exists in the λ conformation and induces a (*M*) helix, while in complex **2**, due to the incorporation of the left handed helical water chain, the Cu^{II}-strand exists in the (*P*) helix. Astonishingly, upon removing the water molecules the resultant dehydrated form of complex **2** behaves similarly to compound **1** by inverting from the (*P*) into a (*M*) helix, as can be attributed to the changes observed in the CD spectra (Fig. 5).

3.5. Fluorescence property

Cu(II) complexes with phenanthroline and tryptophan [83,84] are extensively used as fluorescent probes to monitor the DNA

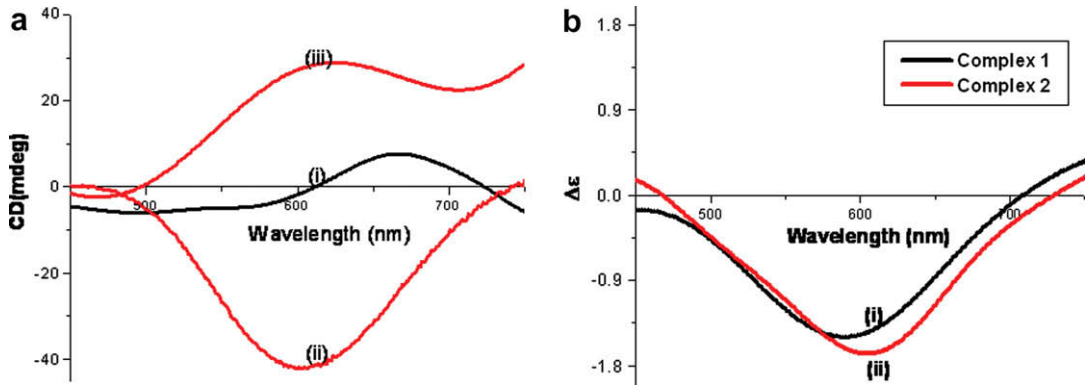


Fig. 5. (a) Solid state-CD spectra for (i) complex **1**, (ii) complex **2**, (iii) complex **2** (dehydrated) in the visible region measured as a KBr discs. (b) Solution state CD spectra for (i) complex **1**, (ii) complex **2** in the visible region measured in methanol.

cleavage. Accordingly, the emission observed both in solution and in the solid state (S2) for **1** and **2** around 350 ± 3 nm (excited at 280 nm) could be attributed to an intra-ligand charge transfer.

3.6. Thermal analysis

To ascertain the thermal stability of the helical water chain, thermogravimetry analysis and powder diffraction studies for the hydrated and dehydrated samples of complex **2** were performed. The TGA curve (S3), indicates two distinct weight losses in the temperature range 40–110 °C. The first endothermic curve showing 2.26% (calc = 2.99) weight loss at 60 °C corresponds to 0.75 water molecule, while the second curve appearing at 87 °C was equivalent to 5.71% (calc = 5.98%), representing 1.9 water molecules. This discrepancy between the observed and theoretical values could be attributable to the evaporation of water molecules and such differences are usual in such hydrated complexes. The two sets of weight loss may be attributable to two distinguishable bindings of trimeric water molecules for "strong" and "weak" H-bonding contacts with the Cu^{II}-helical strand. The water molecules O8, O9, make strong O–H···O interactions with the lattice perchlorate (O6) and carboxylate (O2), whilst the water molecule O7 is involved in weaker N–H···O interactions, making it more labile as observed from the TGA curve.

In addition to the TGA experiment, X-ray powder diffractograms were recorded for complex **2** at different temperatures. Fig. 6 represents the PXRD pattern for simulated, hydrated and dehydrated forms of complex **2**. Evidently, the simulated PXRD pattern from the single crystal X-ray structure, using the crystallographic software package MERCURY 1.4, and the PXRD recorded at room temperature are similar to each other. This similarity in the diffraction pattern confirms that the crystals in the bulk and the single crystal, for which crystal structure was solved, are the same. Diffractogram (ii) and (iii), representing the PXRD recorded at 30 and 110 °C, can be attributed to the hydrated and dehydrated forms of complex **2.** While the diffractogram of the simulated and hydrated forms of complex **2** are similar, the diffraction pattern with respect to the dehydrated form showed some significant changes, which reflects some structural changes upon losing the helical water chain. Structural changes upon loss of water molecules are expected for this complex as the water molecules are an integral part of the supramolecular network. The change in the PXRD pattern recorded for dehydrated form, shown by an arrow compared to the hydrated form at 30 °C, indicates that upon losing all three water molecules the supramolecular crystal system undergoes a major change, which could be attributed to the opposite optical sign observed from the CD spectrum for the dehydrated sample.

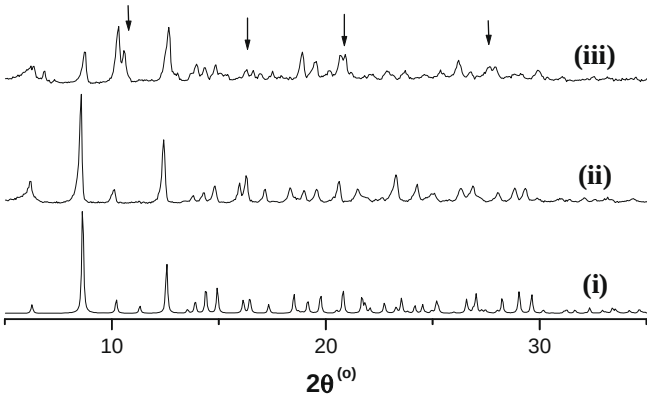

Fig. 6. PXRD of complex **2** (i) simulated, (ii) hydrated form, (iii) dehydrated form.

4. Conclusions

In conclusion, we have shown the formation of two self-assembled single stranded supramolecular Cu^{II} helical coordination polymers. Complexes **1** and **2**, containing L-tryptophan, are found to crystallize in the right handed (*PP*) and left handed (*MM*) sense of helices, respectively. A self-assembled infinite left handed helical water chain entrapped between the Cu^{II} helical strands in complex **2** is meticulously analyzed using various physico-chemical techniques such as TGA and PXRD, and includes a single crystal X-ray structure. The solid state-CD spectra of complex **1** and the dehydrated form of complex **2** exhibit a positive optical sign, whereas the corresponding solution state CD spectra are found to be inverted, with a negative optical sign. The CD activity of complex **2** in its hydrated form, similar to its solution state, infers that the left handed helical water chain entrapped in the lattice inverts its supramolecular chirality. Although the right handed (*PP*) and left handed (*MM*) supramolecular helices are actually observed in the present crystals of **1** and **2**, the formation of the respective (*MM*) and (*PP*) counterpart cannot be ruled out. In this direction, to gain further understanding on the formation of supramolecular helical assemblies, the synthesis of a similar coordination polymer with D-tryptophan is under progress in our laboratory. Both these helical coordination polymers display luminescent properties in solution as well as the solid state and their emission properties signify these compounds as potential fluorescent materials.

Real-time observation

ABSTRACT

Real-time observation of a morphologies of a multi-component tubular giant vesicle (tGV), which is a self-assembly composed of plural amphiphiles with different packing parameters, was carried out under application of a magnetic field. A tGV, one of the terminals of which was fixed to a bottom of a cell, exhibited the bending deformation under a magnetic field along the perpendicular direction of the long axis. Moreover, the hysteretic behavior in this deformation was observed associated with the increase and decrease of the magnetic fields repeatedly, regardless of the presence or absence of a paramagnetic species. To understand the hysteretic behavior, the molecular cooperative effect, which stabilizes the bending deformation by replacing of the plural kinds of amphiphiles with different packing parameters within a membrane, must be taken into consideration.

1. Introduction

Researchers in the field of 'molecular magnetism' are usually interested in para-, ferro- or antiferromagnetic materials composed of organic radicals or transition metal ions [1,2], and they deduce the magnetic properties characteristic to the molecular magnetism from those materials. The contribution of a paramagnetic term of an organic radical with $S = 1/2$ dominates over others at cryogenic temperatures, but the situation becomes different at ambient temperature. The absolute value of a paramagnetic term arisen from a paramagnetic spin and that of a diamagnetic term from a whole molecule are comparable with each at ambient temperature [1]. Hence, one can not ignore the diamagnetic contribution to the entire magnetism of a paramagnetic radical. If the method of magnetic manipulation of diamagnetic materials is explored, it would be utilized in various fields, including medical sciences, because every material is invested with diamagnetism unexceptionally.

Recently, we have studied the non-linear dynamics of giant vesicles [3–6] constructed by amphiphiles through a self-assembling process in water [7]. Our interest, in particular, has been focused on magnetic field response of tubular giant vesicles (tGVs) [8,9] with an anisotropic structure, their lengths and diameters being 10–100 μm and several μm, respectively [10]. A merit of this anisotropic shape of diamagnetic tGV lies in the facile detection of morphological changes under a magnetic field. For instance, tGVs align parallel to the external magnetic field due to a torque exerted by a static magnetic field [11]. Since this magnetic response is merely caused by the magnetic orientation, the scope of its application is rather limited [11–16]. In contrast, the magnetic response of collagen containing tGVs, which we have recently studied [8], can not be explained by the simple magnetic orientation, but their characteristic curved structures exhibited under a magnetic field are recognized as 'elastica' on the basis of dynamical analysis [8]. To note that such curved structures emerge only when the elastic energy of tGV is balanced with the magnetic energy [17].

$$\frac{d^2}{ds^2}\Theta = -A\sin\Theta, \quad A = \frac{\pi r^2 B}{2\mu_B}\cdot\frac{|\Delta\chi|}{K} \tag{1}$$

Here s is a length from the origin, Θ is twice of the degree of inclination of the infinitesimal unit against the applied field, B, r is a radius of the specimen, K is a module of curvature-elasticity of the specimen and $\Delta\chi$ is an anisotropy of the effective diamagnetic susceptibility of the specimen.

In general, the effect of elasticity of tGV is much smaller than that of a magnetic field. This magnetic manipulation of tGV to curved structures is archived by the following trick. When collagen

doi:10.1016/j.poly.2008.11.010

is introduced into tGV, the magnetic response of tGV is suppressed because the diamagnetic anisotropy of collagen fibrils competes with that of tGV and they align perpendicular to the magnetic field [14].

In this study, we carried out real-time observation of a bending deformation of multi-component tGV, one of the terminals of which is fixed on a surface of cover glass, under application of a magnetic field along the perpendicular direction of its long axis. We also notice that the bending deformation exhibits the hysteretic behavior, associated with increase and decrease of the magnetic fields. Incidentally, this non-linear dynamics occurs regardless of the presence or absence of a paramagnetic additive (a spin-probe). Notably, this hysteretic response can not be explained by regarding tGV as an uni-component elastic rod, but by the cooperative effect of plural components of amphiphiles.

2. Experimental

Chemicals were purchased from commercial sources and used without further purification. Oleyl nitronyl nitroxide (ONN) was synthesized from oleylaldehyde by the regular procedure [18]. Thin films, composed of 1,2-dioleoyl-*sn*-glycero-3-phosphocholine (DOPC; 0.5 μmol) and 1-palmitoyl-2-oleoyl-*sn*-glycero-3-[phospho-*rac*-(1-glycerol)] sodium salt (POPG; 0.5 μmol) or of DOPC:POPG:ONN = 5:5:1 (molar ratio) were formed on a glass surface at room temperature, respectively. The films were swelled by 1 mL of phosphate-buffered saline (PBS). The dispersion of tGV was prepared between a pair of glass covers and a spacer with approximately 300 μm thickness and 25 μL volumes (Frame Seal Chamber, MJ Research Inc., Waltham) (Fig. 1). The mount was placed on a 500× objective lens unit (VH-501, KEYENCE, Japan) of a digital microscope camera, and it was inserted in a center of the magnetic field of a perpendicular-type superconducting magnet with a bore radius of 12 cm ($B = \pm 5$ T, sweep time 1 T/min, Microstat BT, Oxford Instruments, Oxon, UK). The direction of the magnetic field was perpendicular to the glass surface of the mount. The morphological change of the specimen during application and removal of the magnetic fields was observed directly under a digital microscope set (VH-5000, KEYENCE, Japan) with a digital video recorder (DDR-TRV50, SONY, Japan).

3. Results and discussion

3.1. Real-time observation of deformation of a tubular vesicle

A buffered dispersion of tGV with or without ONN were prepared in a mount following a procedure described in the experimental section. As an object of real-time observations, we selected tGV a terminal of which was fixed on the bottom. Magnetic field was applied along the perpendicular direction to the long axis of tGV (Fig. 1).

A series of photo-images recording the deformation dynamics of tGV were shown in Fig. 2. As the magnetic field increased, the length of tGV was shortened and it was recovered to the original length associated with removal of the magnetic field. This shortening and the restoration dynamics of tGV occurred repeatedly more than 10 times. Reproducibility of the geometrical changes was confirmed in many batches, regardless of the presence or absence of a paramagnetic additive (ONN).

3.2. Hysteretic behavior of deformation of tubular vesicle

Magnetic field dependence of the virtual length of tGV was shown in Fig. 3. The length of tGV was kept constant until the magnetic field exceeded a certain threshold value (e.g. *ca.* 3 T), but thereafter it became shortened as the magnetic field increased, and the change was gradually saturated at higher magnetic fields than *ca.* 4.5 T. In the descending process of the magnetic field, the length of tGV remained the same until the magnetic field passed a critical value (e.g. *ca.* 2.5 T), and it started to increase and restored to the original length at null magnetic field, showing the hysteretic behavior: The threshold magnetic field in descending process is lower than that in rising process. This hysteretic behavior is reproducible in other butches, although the absolute value of the critical magnetic field showed sample-dependence.

3.3. Mode of deformation

If tGV is really shortened keeping its volume, the diameter of tGV has to be enlarged. However it is not the case. Hence the shortening of tGV in a microscopic image must come from the observational limitation, that is the depth of field (DOF) of a camera lens. When a magnetic field is applied, tGV deforms as a cantilever beam and the free terminal moves out of DOF of the lens. Such deformation makes the observed length of tGV shorter virtually. The virtual length, L, is determined by a, which is the distance between the center line of tGV at an ambient field ($B = 0$) and the maximum depth of on-focus area (Fig. 4). The maximum value of a is esti-

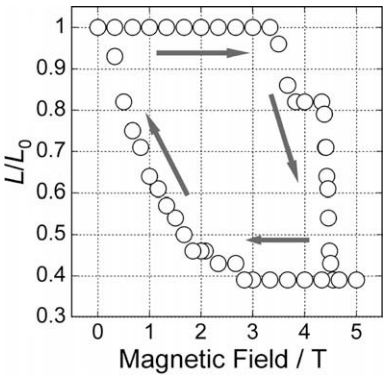

Fig. 3. Magnetic field dependence of virtual length of tGV containing phospholipids and ONN (see Fig. 2). Magnetic field was applied in a sequence of 0 T → 5 T → 0 T.

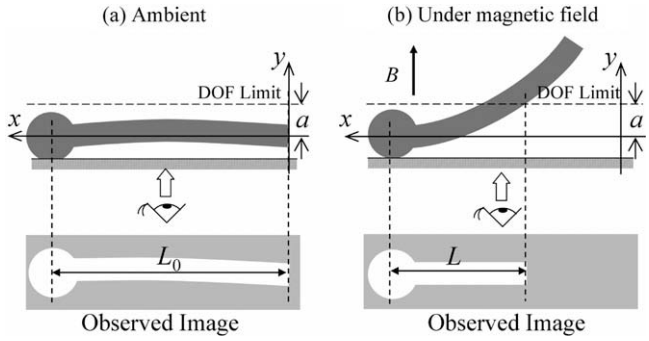

Fig. 4. tGV as a cantilever beam and its objective images.

mated to be 30 μm if the center of tGV is focused. Consequently, the absolute values of the critical magnetic fields are dispersed depending of the accuracy of the focusing positions of each sample, but relative values for the observed lengths of the same tGV is highly reproducible.

3.4. Mechanical analysis of deforming tGV

In order to analyze the virtual length of a tGV upon application or removal of a magnetic field, a mechanical analysis on bending tGV was carried out using a cantilever model. In general, deformation of a cantilever is approximated by the following formula (Eq. (2) and Fig. 4),

$$\frac{d^2}{dx^2}y(x) = -\frac{1}{EI}M(x) \tag{2}$$

where, $M(x)$ is a bending moment, E is a module of elasticity and I is a second moment of area (a product of E and I is defined as a rigidity of tGV). Since a magnetic field is applied uniformly on tGV, this system can be regarded as a uniformly distributed loading system. Hence the bending moment is defined by Eq. (3),

$$M(x) = -\frac{\rho}{2}x^2 \tag{3}$$

where, ρ is a constant, corresponding to an effective magnetic sensitivity. From Eqs. (2) and (3), the displacement y at coordinate x is expressed by Eq. (4), where L_0 is a whole length of tGV.

$$y(x) = \frac{\rho}{2EI}\left(\frac{x^4}{12} - \frac{L_0^3}{3}x + \frac{L_0^4}{4}\right) \tag{4}$$

Since the influence of a magnetic sensitivity, ρ, upon diamagnetism is proportional to the square of the magnetic field, the magnetic field dependence of the virtual length of tGV can be simulated numerically as shown in Fig. 5, considering DOF of a lens. The calculated curves reproduce the observed phenomenon that the virtual length of tGV changes abruptly at the critical magnetic field and it is gradually saturated at higher magnetic fields.

3.5. Origin of hysteretic behavior

According the above analysis, the bending deformation of tGV under a magnetic field can be interpreted in terms of a cantilever model, but the hysteretic behavior, which is another important characteristic of this dynamics, cannot be rationalized by this mechanical model. Then we examine this bending dynamics of tGV using a multi-component tGV model proposed by Stavans and co-workers [19]. When tGV is deformed as an elastic bar, the elastic energy rises. It means a straight tGV is most stable. However, if tGV is made of multi-components with different packing parameters [20], the energy-cost caused by bending can be relaxed by the displacement of individual amphiphiles as schematically depicted by Fig. 6.

Since the current experiments utilize multi-components vesicles made of DOPC:POPG or DOPC:POPG:ONN, optimization of the bending geometry is possible, although apparent shapes of DOPC and POPG do not differ much. In fact, the observed hysteretic behavior indicates that the bent tGV maintains its shape under a

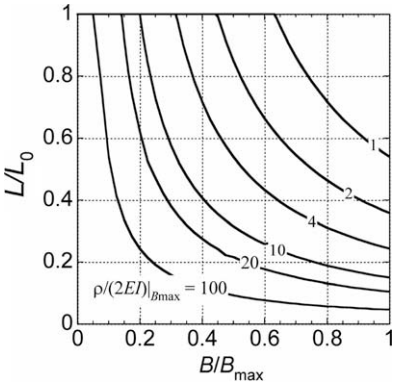

Fig. 5. Numerical-simulation of magnetic filed dependence of observed length of tGV. Parameters, $\rho/(2EI)|_{B=B_{max}} = 1 - 100$, $L_0 = 1$ and $y(x) = a = 0.1$ are used for the calculations.

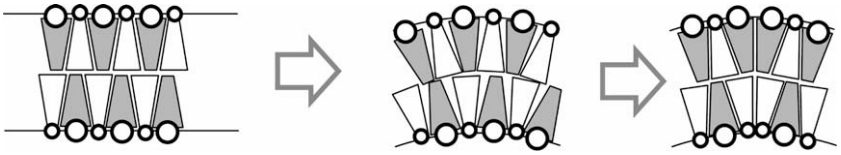

Fig. 6. Stabilization of a curved lipid-bilayer of bent tGV by relocation of membrane molecules with different packing parameters, provided that molecules move freely along the horizontal direction within a single membrane layer. Molecular migration of the vertical direction hardly happens, because the rate of a flip-flop motion is much slower than that of a horizontal diffusion.

lower magnetic field in the field-decreasing processes than that in the increasing processes. The fact that a helical tGV can be formed by egg-yolk lecithin [21], which is a mixture of phospholipids, is indicative of the validity of the multi-components tGV model. We have not examined unicomponent vesicles yet due to the difficulty in preparation of tGVs, there is a possibility to observe a similar behavior because various conformations are conceivable even for a single phospholipid.

In the current study, we have not detected any extra effect caused by the paramagnetic additive, e.g. ONN. This insensibility may be rationalized by the following reasons. (1) Since a spin of nitronyl nitroxide is of a Heisenberg type, the magnetic anisotropy is too small to show the anisotropic magnetic response [22], (2) the diamagnetic susceptibility of ONN (-2.7×10^{-3} emu/mol, estimated by Pascal additive rule) and the paramagnetic one (1.25×10^{-3} emu/mol at 300 K) are comparable with each other. Accordingly, the effect caused by paramagnetic spins is negligibly small, if any.

4. Conclusion

We revealed that tGV deformed toward the perpendicular direction to its long axis under the external magnetic field ($\sim$5 T) due to the diamagnetic anisotropy. Moreover, tGV made of DOPC and POPG exhibited hysteretic response in the bending deformation and its relaxation process with increasing and decreasing magnetic field. Appearance of this hysteretic behavior is derived from the collaborative dynamics of two kinds of membrane molecules (DOPC and POPG) with different packing parameters. If a self-assembly of membrane molecules in which a membrane-affinitive transition metal complex of a large quantum number is buried, the self-assembly, e.g. tubular vesicles, or fibrils, may exhibit more drastic response towards an external magnetic field.

ABSTRACT

A novel alcohol-soluble ionophore ligand and its non-peripherally tetrasubstituted functional 1,8,15,22-tetrakis(6-hydroxyhexylsulfanyl) metallophthalocyanines M[Pc(α-$SC_6H_{12}OH)_4$] (M = Cu(II), Zn(II), Co(II); Pc = phthalocyanine) are reported. The aggregation and cation binding behaviors of the phthalocyanine compounds in the presence of soft Ag^{I} and Pd^{II} metal ions were investigated by using UV–Vis spectroscopy. The new compounds have been characterized by elemental analysis, IR, ^{1}H, ^{13}C NMR, UV/Vis spectroscopy, ESI and MALDI–TOF–MS mass spectra. Voltammetric and in-situ spectroelectrochemical studies show that while copper and zinc phthalocyanine complexes give well-defined ring-based reduction and oxidation processes, the cobalt phthalocyanine gives both metal-based and ring-based redox processes which have reversible and diffusion controlled character.

1. Introduction

The benefit of phthalocyanines (Pcs) in terms of technological applications is beyond question [1,2]. The family of functional phthalocyanines has been an interesting target for chemists for the development of further chemical reactions on Pc complexes [3,4]. Functional Pcs perturbs the Pcs optical transitions by shifting the absorption from the visible to near-IR or UV-region. Phthalocyanines bearing thia functionalities show optical changes when they bind transition metal ions, while crown-ether substituted ones are well-suited to bind alkaline and alkaline-earth metal ions [5,6]. Although several Pcs bearing different substituents either on the β position or at an axial position have been synthesized and characterized [5,7], papers on the synthesis, electrochemistry and spectroelectrochemistry of non-peripherally functional phthalocyanines are scarce because of the preparation and purification required [8].

In the past few years we have directed our attention to the construction of phthalocyanine-based functional systems [3,9,10]. The introduction of functional groups having rich electron-donor units on the phthalocyanine ring is not only expected to improve its solubility but also to enhance optical or electrochemical properties of the phthalocyanine.

In this study, we therefore report a new ligand and its non-peripherally α-substituted MPcs, M[Pc(α-$SC_6H_{12}OH)_4$] {M = Cu(II) (**2**), Zn(II) (**3**), Co(II) (**4**)}. The cation binding capabilities of the functional substituents on the periphery of MPcs (**2**)–(**4**) as well as voltammetric and in-situ spectroelectrochemical characterization are also reported.

2. Experimental

Chloroform ($CHCl_3$), 4-nitrophthalonitrile, tetrahydrofuran (THF), tetrabutyl ammoniumperchlorate (TBAP), $Zn(OAc)_2$, $CuCl_2$, $CoCl_2$ and all other reagents were purchased from Alfa Aesar and were used as received. The purity of the products was tested in each step by TLC (thin-layer chromatography) (SiO_2, $CHCl_3$, hexane and MeOH). FT-IR (Fourier transform infrared) spectra were recorded on a Perkin–Elmer spectrophotometer with samples were dispersed in KBr discs. Chromatography was performed with silica gel (Merck grade 60 and sephadex) from Aldrich. Elemental analysis (C, H and N) was performed at the instrumental Analysis Laboratory of Marmara University. Time- and applied-resolved UV–Vis spectra were recorded on an Agilent Model 8453 diode array spectrophotometer. ^{1}H NMR, and ^{13}C NMR spectra were recorded on a Bruker 300 spectrometer instrument. The cyclic voltammetry (CV) and differential pulse voltammetry (DPV) measurements were carried out with a Gamry Reference 600 potentiostat/galvanostat controlled by an external PC and utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt disc with a surface area of 0.071 cm^2. The surface of the working electrode was polished with a diamond suspension before each run. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and this was separated from the bulk of the solution by a double bridge. Ferrocene was used as an internal reference. Electrochemical grade

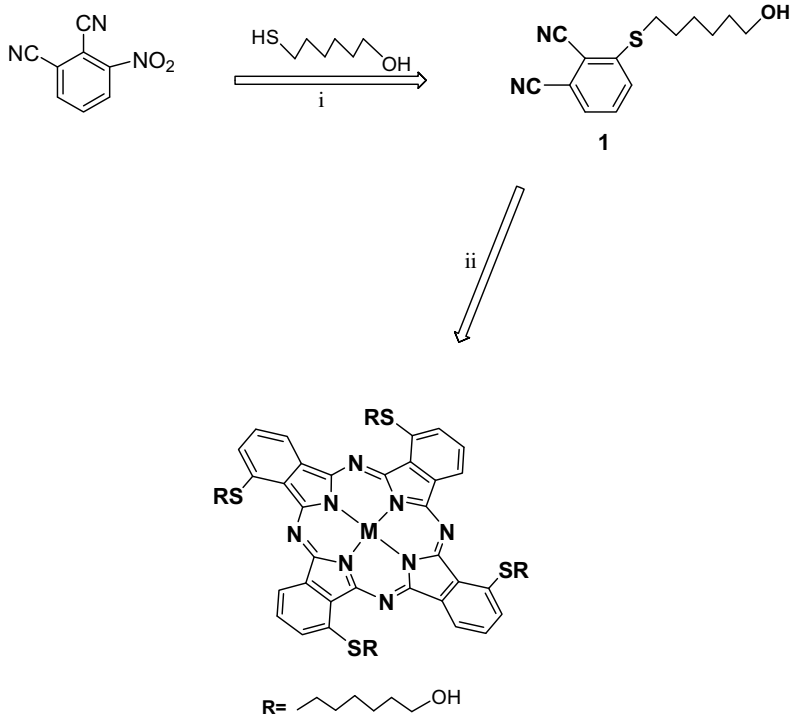
doi:10.1016/j.poly.2008.11.035

tetrabutylammonium perchlorate (TBAP) in extra pure dimethylsulfoxide (DMSO) was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}. High purity N_2 was used to remove dissolved O_2 prior to each run and to maintain a nitrogen blanket during the measurements. IR compensation was also applied to the CV scans to minimize the potential control error.

The spectroelectrochemical measurements were carried out with an Ocean-optics QE65000 diode array spectrophotometer equipped with a potentiostat/galvanostat utilizing the three-electrode configuration of a thin-layer quartz spectroelectrochemical cell at 25 °C. The working electrode was Pt tulle. A Pt wire counter electrode separated by a glass bridge and a SCE reference electrode separated from the bulk of the solution by a double bridge were used.

Matrix-assisted laser desorption/ionization-time-of-flight (MALDI–TOF) mass spectra were measured using a Bruker Autoflex III mass spectrometer equipped with a nitrogen UV-Laser operating at 337 nm. Spectra were recorded in the reflectron mode with an average of 50 shots. An α-cyano 4-hydroxycinnamicacid (CHCA) (20 mg/mL in THF) matrix was used. MALDI samples were prepared by mixing the complex (2 mg/mL in THF) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® micro tube. Finally, 1 μL of the mixture was deposited on the sample plate, dried and then analyzed.

2.1. Synthesis



2.1.1. 3′(6-hydroxyhexylthio)-1,2-dicyanobenzene (*1*)

6-Mercapto–1-hexanol (1.55 g, 12.00 mmol, excess) was dissolved in dry DMF and finely ground anhydrous K_2CO_3 (~2.40 g, 17.00 mmol) was added. Then 3-nitrophthalonitrile (2.00 g of 11.56 mmol) was added to this mixture dropwise at 35–40 °C under a N_2 atmosphere. The reaction mixture was stirred efficiently and monitored by TLC ($CHCl_3$) under an inert atmosphere at 40–45 °C for 2 days. After the reaction mixture was cooled to room temperature, it was poured into ca. 300 cm^3 ice-water. The creamy precipitate that formed was filtered and washed with water until the washings became neutral. The crude product was dissolved in $CHCl_3$ and washed with 5% $NaHCO_3$ to remove the unreacted starting thiol compounds. The creamy solution was then dried with anhydrous Na_2SO_4, and filtered. The solvent, $CHCl_3$, was removed under reduced pressure. The final product was chromatographed over a silica gel column using a mixture of $CHCl_3$: MeOH (100/5) as eluent, giving a hydroscopic oily solid. Finally the pure powder was dried in vacuum.

Yield: 0.93 g (61.89 %). M.p.: 77 °C. IR (thin film) /cm^{-1}: 2236 (–CN), 3280 (CH_2–OH), 3080, 3045 (Ar–H), 2933, 2885, 2854 (Aliph-CH_2) 1707 (H–O···H, weak), 1585 (s), 1555, 1476, 1384, 1277, 1145, 1067, 980, 852, 735, 570. ^{1}H NMR ([D6]-DMSO) δ (ppm): 7.85–7.62 (m, 3H, Ar–H, Phenyl Ar–H H3, H4 and H5), 4.19 (t, br, –CH_2–OH, D_2O exchangeable), 3.55 (t, 2H, –CH_2OH), 2.85 (CH_2–CH_2–S–), 1.65 (m, 2H, CH_2–S–Ar), 1.50 (m, 2H, $CH_2CH_2CH_2$–OH), 1.37 (m, 2x$CH_2CH_2CH_2$). ^{13}C NMR (ATP test) (300 MHz, [D6]-DMSO) δ (ppm): 143.23, 135.45, 132.76, 130.09, 116.12, 115.16, 116.95, 116.82, 62.76 (–CH_2 OH), 40.42 (DMSO), 37.16 (S-CH_2), 33.40 (CH_2CH_2OH), 29.12 (SCH_2CH_2), 28.80 ($SCH_2CH_2CH_2$), 25.26 ($CH_2CH_2CH_2CH_2$OH). *Anal.* Calc. for $C_{14}H_{16}N_2OS$ (%): C, 64.62; H, 6.15; N, 10.77. 2.1.2. 1(4),8(11),15(18),22(25)-(6-Hydroxyhexylthio)-zinc(II)phthalocyanine (*2*)

3′-(6-hydroxyhexylthio)-1,2-dicyanobenzene (**1**) (0.25 g, 0.96 mmol) and anhydrous $ZnCl_2$ (0.022 g), in the presence of quinoline and 1,8-diazabicyclo [5.4.0.] undec–7-ene (DBU, 0.05 ml) as a strong base (Scheme 1), were heated to reflux in a sealed tube

Scheme 1. Synthetic route of the 1,8,15,22-tetrakis{6-hydroxyhexylsulfanyl) metallophthalocyanines M[Pc(α-$SC_6H_{12}OH)_4$] {M = Zn(II) (**2**), Cu(II) (**3**), Co(II) (**4**)}. (i) K_2CO_3, 6-mercapto-1-hexanol, DMF, 40–45 °C, 2 days. (ii) Anhydrous, $Zn(O_2CMe)_2$, $CuCl_2$, $CoCl_2$, DBU.

under a N_2 atmosphere for 6 h. The color of the mixture turned green-blue over this time. After heating for an additional 3 h, the green–blue product was cooled to room temperature. The crude product formed was washed several times, successively with i-PrOH and then cold CH_3CN, to remove impurities. Finally, the product was further purified by silica gel chromatography {$CHCl_3$ and then with $CHCl_3$/MeOH (20:1 v/v)}. After washing the resulting oily product with copious amounts of hexane, diethylether and *i*-PrOH, finally it was dried in vacuum. This product is soluble in MeOH, THF, DMF, DMSO, pyridine and insoluble in diethylether.

Yield of **2**: 0.087 g (32.80%). Anal. Calc. for $C_{56}H_{64}N_8O_4S_4Zn$ (1105.0 g/mol): C, 60.81; H, 5.79; N, 10.14. Found: C, 60.28; H, 5.80%; N, 9.77. 3. Results and discussion

3.1. Synthesis and characterization

The introduction of 6-mercapto-1-hexanol groups, having rich electron-donor units, on the Pc ring is not only expected to improve the solubility of phthalocyanines in polar medium such as MeOH, EtOH, THF, DMF, DMSO and *i*-PrOH, but also to enhance the optical or electrochemical properties of the phthalocyanine. In the present work, 3'-(6-hydroxyhexylthio)-1,2-dicyanobenzene (**1**) can be readily synthesized by nucleophilic aromatic substitution reactions of 6-mercapto-1-hexanol on 3-nitrophthalonitrile [11]. MPc complexes (**2**–**4**) were obtained from the reaction of **1** with the appropriate anhydrous metal salts in the presence of quinoline and DBU as a strong base (Scheme 1), followed by chromatographic purification on silica gel columns. The purification steps were tedious because of the peripheral polar functional end-group. The new compounds were characterized by UV–Vis, IR, NMR spectroscopies, MALDI–TOF mass spectra and elemental analysis. All the analytical and spectral data are consistent with the predicted structures.

The sharp peak in the IR spectra for the –C≡N vibrations of **1** at 2230 cm^{-1} disappeared after conversion into the MPcs, indicative of the MPcs formation. A primary aliphatic –OH peak at around 3280 cm^{-1} and the remainder of the spectra for **2**–**4** are closely similar and diagnosed easily. Broad signals in the NMR spectrum of **2** are probably due to chemical exchange associated with aggregation–disaggregation equilibria which occurred at the high concentrations used in the NMR measurements. A broad signal belonging to primary aliphatic exchangeable –OH protons appeared at ca. 4.21 ppm, and this disappeared after addition of D_2O. Splitting of the aromatic protons in the downfield region is less for α-substituted compounds when compared to β-substituted ones [12–15].

The UV/Vis spectra of the MPcs **2**–**4** exhibited characteristic absorptions in the Q-band region at around 695–710 nm, attributed to the π–π^* transition from the HOMO (highest occupied molecular orbital) to the LUMO (lowest unoccupied molecular orbital) of the Pc^{2-} ring, and in the B band region (UV region) at around 300–400 nm, arising from deeper π–π^* transitions [14]. In the UV/Vis absorption spectra of MPcs **2**–**4**, the Q-band absorptions were observed as a single band with high intensity at 709, 710 and 695 nm respectively. There was also a shoulder at the slightly higher energy side of the Q-band at 668, 662 and 654 nm for each phthalocyanine respectively. The Q-band absorptions are shifted to the lower energy side as a result of the electron-donating thioether substituents on periphery of the Pcs compared to those of MPcs bearing oxo substituted moieties, whereas the position of the Soret-like π–π^* bands of all the MPcs are slightly shifted [5,6,9,14,15]. The Q-band of the α (non-peripheral) substituted Pcs is red-shifted by about 20 nm, when compared to the corresponding β (peripheral)-substituted complexes in the same solvent [9,11–13,14]. The observed red spectral shift is typical of Pcs bearing substituents at the α positions and has been explained by the linear combinations of the atomic orbital (LCAO) coefficients at

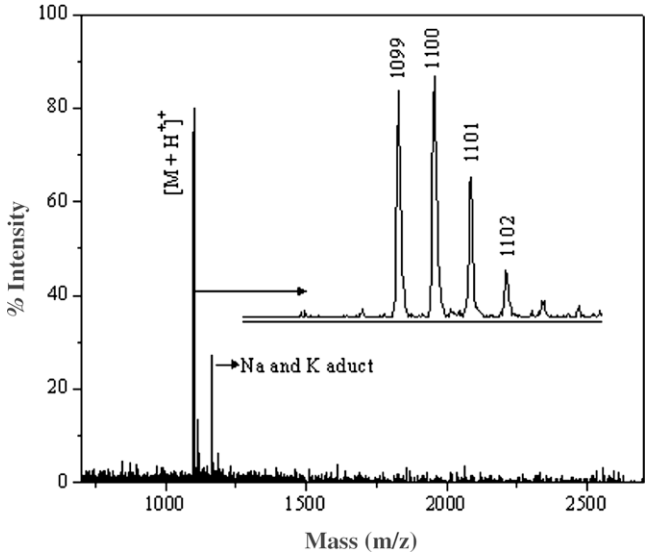

Fig. 1. Positive ion and reflectron mode MALDI–MS spectrum of **4** obtained in α-cyano-4-hydroxycinnamic acid (CHCA) as the MALDI matrix. Inset spectrum shows the expanded molecular mass region of **4**.

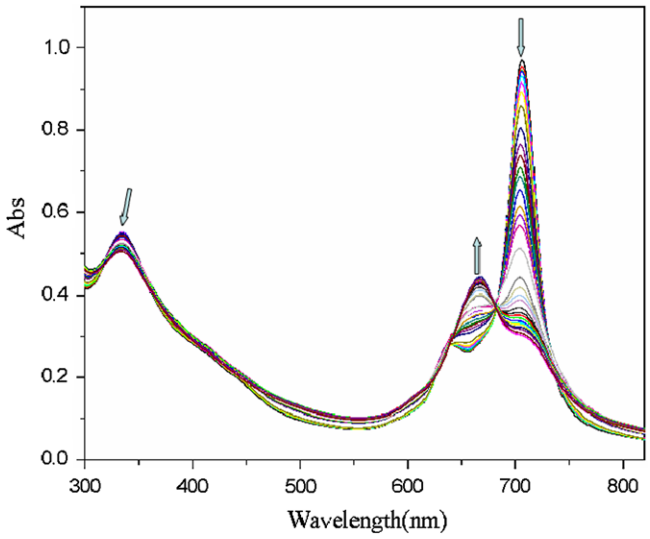

Fig. 2. UV–Vis spectra of **3** in THF/MeOH (90/10 (v/v)) during titration with Ag^{I} (in MeOH).

the α positions for the HOMO [12,13]. As a result, the HOMO level is destabilized more for an α position than a β position. Moreover, the B bands of the complexes in the UV/Vis absorption spectra are broad due to the superimposition of the B1 and B2 bands in the 325–340 nm regions.

The mass spectra of **2**–**4** confirmed the proposed structures. The protonated molecular ion peaks (MALDI matrix; α-cyano-4-hydroxycinnamic acid (CHCA)) were easily identified at *m*/*z*: 1104.20 $[M+H]^+$ for **2**, 1105.78 $[M+H]^+$ for **3** and 1100.30 $[M+H]^+$ for **4** (Fig. 1) and they exactly overlapped with the mass of the complexes calculated theoretically from their elemental compositions [9].

3.2. UV/Vis spectroscopic titrations

We have employed UV/Vis spectroscopic titrations to monitor the capability of our MPcs in sensing/coordinating transition metal ions of different sizes. The room temperature gradual addition (μl) of Ag^{I} and Pd^{II} to solutions of **2** and **3** caused a gradual color change, from blue–green to intractable dark-green, suggesting complex formation of the Mpcs with Ag^{I} and Pd^{II}. Addition of small increments of Ag^{I} to **3** (Fig. 2) leads to the gradual disappearance of monomeric species, which show absorptions at 710 and 708 nm, and simultaneously enhances the intensity of the oligomeric aggregated species at around 662 and 668 nm. Similar spectroscopic changes were observed during the titration of **3** with Pd^{II}, and **2** with Ag^{I} and Pd^{II}. This type of spectroscopic behavior probably results from the complexation of Ag^{I} and Pd^{II} with the Pc complexes. These spectroscopic changes indicate the coordination of Ag^{I} and Pd^{II} with the S donor atoms of the phthalocyanines and the formation of polymer units due to the aggregation of the complexes [2,6,9].

3.3. Electrochemical and spectroelectrochemical measurements

The solution redox properties of the complexes **2–4** were studied using cyclic voltammetry (CV) and differential pulse voltammetry (DPV) in DMSO on a platinum electrode. Table 1 lists the assignments of the redox couples recorded and the estimated electrochemical parameters, which included the half-wave peak potentials ($E_{1/2}$), the ratio of anodic to cathodic peak currents ($I_{p,a}/I_{p,c}$), the peak to peak potential separations (ΔE_p) and the difference between the first oxidation and first reduction processes ($\Delta E_{1/2}$).

When we compare the redox potentials of **2–4** with those of the unsubstituted MPcs [16], MPcs carrying tetrakis-(6-hydroxyhexylsulfanyl) [9] and tetrakis-6-(-thiophene-2-carboxylate)-hexylthio moieties [17], it is clearly shown that the redox potentials of **2–4** shift to negative potentials due to the electron releasing effect of the tetrakis-(6-hydroxyhexylsulfanyl) substituents on the α position of the complexes (Table 1). Within the electrochemical window of TBAP/DMSO, **2** and **3** undergo a one-electron oxidation (two oxidations for **3**) and two one-electron reduction reactions having reversible and diffusion controlled mass transfer processes. Because of the electro-inactive metal center of the complexes, all of these processes are attributed to successive removal of electrons from, or addition of electrons to, the macrocycle orbitals. Fig. 3 shows the CV and DPV of CoPc (**4**) as a representative example of the redox behaviors of the complexes. Within the electrochemical window of TBAP/DMSO, **4** undergo two reversible one-electron oxidation processes and two reversible one-electron reduction processes. The first reduction and first oxidation processes of **4**, recorded at −0.43 and 0.40 V, could be easily assigned to the Co^{II}/Co^{I} and Co^{II}/Co^{III} redox couples respectively and the remaining processes to the phthalocyanine ring. Assignments of the redox couple are confirmed by the spectroelectrochemical measurements given below. For the couples, the ΔE_p values changed from 60 to 120 mV with scan rates from 10 to 500 mVs^{-1} ($\Delta E_{p'}$, 60 to 110 mV, were obtained for the ferrocene reference), supporting reversible electron transfer. Reversibility is illustrated by the similarity in the forward and reverse DPV scans (Fig. 3B) [18]. Unity of the $I_{p,a}/I_{p,c}$ ratio at all scan rates indicated the purely diffusion controlled mass transfer of the complex.

Spectroelectrochemical studies were employed to confirm the assignments in the CVs of the complexes. The complexes **2** and **3** have redox inactive metal centers. Therefore, in-situ UV–Vis spectral changes of **4** are only given as a representative example of the spectral changes of a MPc having a redox active metal center (Fig. 4). Fig. 4A shows the in-situ UV–Vis spectral changes during

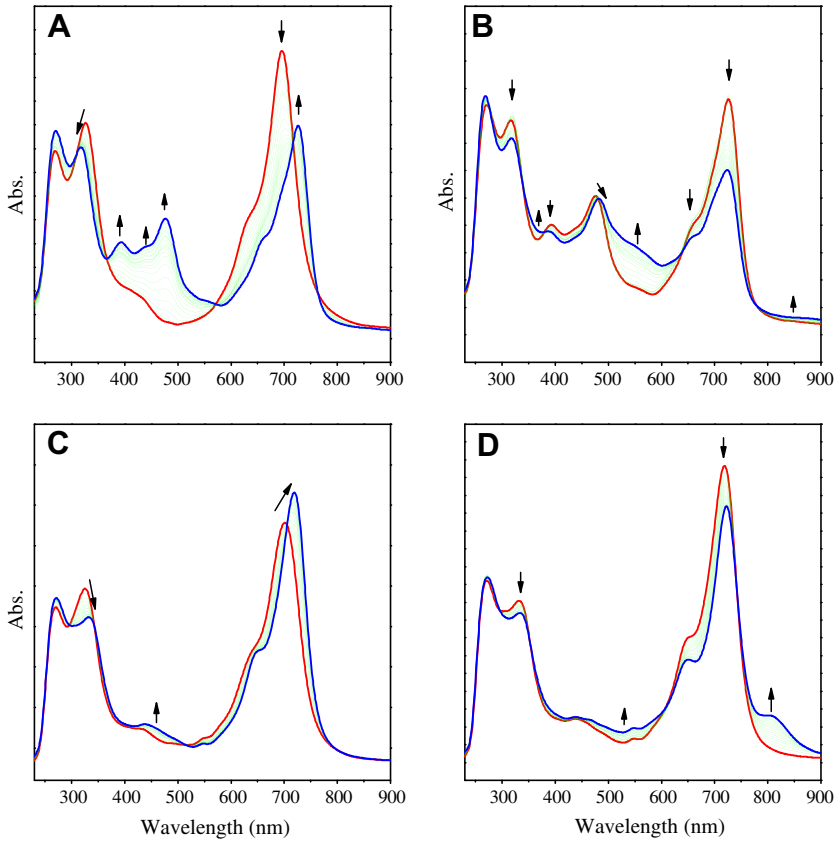

Fig. 4. In-situ UV–Vis spectral changes of **4** (A) E_{app} = −0.50 V. (B) E_{app} = −1.45 V. (C) E_{app} = 0.45 V. (D) E_{app} = 1.00 V.

the controlled potential reduction of **4** at −0.50 V, corresponding to the redox process labelled R_1. The Q-band at 695 nm shifts to 725 nm, while two new bands at 390 and 477 nm appear, as the reduction process continues. At the same time, the B band shifts from 327 to 317 nm with decreasing intensity. The bands at 390 and 477 nm and the red shifting of the Q-band indicate the formation of the $[Co^{I}Pc^{-2}]^{1-}$ species and confirm the CV assignment of the couple R_1 to the $[Co^{II}Pc^{-2}]/[Co^{I}Pc^{-2}]^{1-}$ process [20–25]. Clear isosbestic points at 311, 365, 571, 715 and 764 nm in the spectra and a color change from blue to greenish yellow were observed during this process. Fig. 4B shows the spectral changes during the second reduction process of **4**. During this process, while the Q-band at 725 nm, the band at 390 nm and the B band at 317 nm decrease in intensity, a new band at around 557 nm appears. Clear isosbestic points at 341, 381, 484, 640 and 780 nm in the spectra and a color change from greenish yellow to red were observed during this process. These spectral changes are characteristic of a ring reduction process and are easily assigned to the reduction of the $[Co^{I}Pc^{-2}]^{1-}$ species to $[Co^{I}Pc^{-3}]^{2-}$ at the potential of the couple R_2. Fig. 4C shows the spectral changes observed when the potential corresponding to the process O_1 was applied to the solution of $[Co^{II}Pc^{-2}]$. The Q-band at 695 nm increases in intensity with a red shift to 720 nm, while a new band at 450 nm appears as the oxidation process continues. The intensity of the B band decreases with a red shift from 325 nm to 335 nm. These spectral changes occur with clear isosbestic points at 297, 342, 516 and 706 nm in the spectra. A color change from blue to dark blue was also observed during the process. The band at 443 nm and the increase of the Q-band with a red shift are typical of a metal-based oxidation in cobalt Pc complexes. The final spectrum in Fig. 4C is therefore assigned to the $[Co^{II}Pc^{-2}]/[Co^{III}Pc^{-2}]^{+}$ process, confirming the CV assignments. Fig. 4D shows the further oxidation of the $[Co^{III}Pc^{-2}]^{+}$ species. During this process, the Q-band decreases in intensity without shift and a new band at 809 nm is recorded. The MLCT region between 500 and 600 nm increases slightly in intensity. These spectral changes shows the ring oxidation process and are therefore assigned to the $[Co^{III}Pc^{-2}]^{+}/[Co^{III}Pc^{-1}]^{2+}$ process [20–25].

4. Conclusion

Non-peripheral 6-hydroxyhexylthio substituents of metal (II) phthalocyanines, (M[Pc(α-$SC_6H_{12}OH)_4$](M = Cu(II), Zn(II), Co(II))), exhibited interesting solubility and metal sensing properties. It is important to mention here that the solubility of phthalocyanines is important in terms of high-technological applications. The phthalocyanines synthesized are considerably soluble in polar solvents, such as MeOH, DMSO and DMF. The red shift of the complexes compared to the parent phthalocyanine is due to the electron-donating thioether substituents on the periphery and non-periphery of the Pc. The stronger electron-releasing 6-hydroxy hexylthio substituents on the non-periphery of the Pc also affect the electrochemical behavior of the complexes, shifting to more negative potentials. This redox feature may be useful for the application of the complexes as electro-catalysts for the reduction and/or oxidation of many target species, which will be the subject of our future interest.

ABSTRACT

(1,10-Phenanthroline)bis(piperidinecarbodithioato-*S*,*S*′)cadmium(II), [Cd(pipdtc)$_2$(1,10-phen)] (**1**) and (2,2′-bipyridine)bis(piperidinecarbodithioato-*S*,*S*′)cadmium(II), [Cd(pipdtc)$_2$(bipy)] (**2**) adducts were prepared and the crystal structures are reported. Cd–S and Cd–N distances and the angles subtended at cadmium are almost the same in both complexes but the Cd–S distances in the adducts are longer than those in Cd(pipdtc)$_2$ (**3**) complexes due to the presence of an additional neutral ligand. Thioureide C–N distance in **1** and **2** are supported by *ν*C–N bands observed at 1471 and 1470 cm^{-1}, respectively. S2p binding energies for the adducts show a significant reduction in value compared to the parent dithiocarbamate indicating the weakening of the Cd–S bond on adduct formation. The observed reduction in binding energy is due to the increased electron density on the metal in the adducts. The cyclic voltammetric study on the complexes also show an increase of electron density on cadmium in the adducts compared to Cd(pipdtc)$_2$.

1. Introduction

Dithiocarbamates of zinc and cadmium have continued to attract attention in recent years on account of their recent industrial application [1,2] and biological profiles [3]. Cadmium dithiocarbamate complexes have been used as a precursor for the synthesis of CdS nanoparticles [4,5]. The dithioacid complexes of CdL_2 (LH_2 X-CS_2H or X_2PS_2H) type are coordinately unsaturated; this leads to the formation of compounds of higher coordination number either by the addition of one or two molecules of a Lewis base or by polymerization of CdL_2 [6,7]. In our efforts to compare electron density on cadmium in CdS_4 and CdS_4N_2 chromophore, in this paper we report the synthesis, XPS and cyclic voltammetric studies on [Cd(pipdtc)$_2$(1,10-phen) (**1**), [Cd(pipdtc)$_2$(bipy)] (**2**) and [Cd(pipdtc)$_2$] (**3**) complexes and single crystal X-ray structures of **1** and **2**.

2. Experimental

All the reagents and solvents employed were commercially available analytical grade materials (BDH) used as supplied without further purification.

2.1. Preparation of the complexes

The simple bis(piperidinecarbodithioato-*S*,*S*′)cadmium(II) was prepared by established procedure [8]. The adducts were prepared by adding a hot solution of 1,10-phenanthroline (2 mmol, 0.4 g) or 2,2′-bipyridine (2 mmol, 0.31 g) in ethanol to a hot solution of [Cd(pipdtc)$_2$] (1 mmol, 0.43 g) in chloroform. The resulting solution was cooled and then added to petroleum ether (boiling range 40–60 °C). Yellow precipitate of the adducts separated out. Single crystals were obtained by recrystallization from a solvent mixture of $CHCl_3$ and CH_3CN.

2.2. Physical measurements

IR spectra were recorded on a JASCO IR-700 spectrophotometer (range 4000–400 cm^{-1}) as KBr pellet. An STA 1500 PL Thermal Sciences instrument was used for thermogravimetric analysis. The heating rate of the furnace was 10 °C per minute.

XPS spectra were recorded on a VG mark II ESCA spectrometer equipped with a twin anode of aluminium and magnesium. Samples were studied by using Mg Kα radiation and the resolution of the instrument was 0.2 eV. The overall minimum peak width is 1.0–1.1 eV. Samples were well powdered and packed tightly in nickel stubs. All measurements were made at room temperature (25 °C) and at 10^{-9} Torr pressure. The peaks were calibrated by

doi:10.1016/j.poly.2008.11.019

the methods described earlier for the dithiocarbamato complexes [9].

2.3. Cyclic voltammetric studies

A bioanalytical system 100 electrochemical analyzer was used for all measurements. Working electrodes were of HMDE and platinum; the counter electrode was platinum wire and reference electrode was Ag/AgCl. The solvent used, DMF, was purified by distillation methods [10]. The supporting electrolyte was tetrabutylammonium perchlorate. The experimental solution was thermostated at 28±1 °C and oxygen free atmosphere was provided by bubbling purified nitrogen through the solution.

2.4. X-ray crystal structure analysis

Details of the crystal data, data collection and refinement parameters are summarized in Table 1. The structures were solved by direct methods with SIR97 program [11] and refined by full matrix least squares with SHELX93 [12]. Excepting C3, C6, C7 in **1** and C3, C7 in **2** all other non-hydrogen atoms were refined anisotropically and the hydrogen atoms were refined isotropically. Both the complexes are partially disordered. In complex **1** the C3, C4, C6 and C7 carbon atoms of the piperidine ring were found disordered in two different positions and were anisotropically refined with occupancy factors of 0.64(03) and 0.36(03), respectively. Their hydrogen atoms were put in calculated position. In complex **2** the C3′–C7′ carbon atoms were isotropically refined in two disordered positions with respective occupancy factors of 0.55(04) and 0.45(04). Their hydrogen atoms were not localized. Selected bond distances and angles are given in Table 2.

3. Results and discussion

3.1. IR spectral and thermogravimetric studies

The stretching frequencies associated with the ν_{C-N} bond are listed in Table 3. The ν_{C-N} has been used as a measure of the contribution of the thioureide form to the complexes [13]. In the present study complexes **1**, **2** and **3** show the ν_{C-N} bands around 1470 cm^{-1}, indicating the partial double bond character. However, ring frequencies associated with 1,10-phenanthroline and 2,2′-bipyridine are observed in the range of 1600 and 1000 cm^{-1}. In the present study, compound **1** shows bands at 1620 and 1510 cm^{-1} whereas **2** shows a prominent band at 1590 cm^{-1}. Other bands are masked by those due to the dithiocarbamate ligand.

The thermogravimetric studies on the complexes were performed to confirm their stoichiometry. The final product of thermal decomposition was a mixture of CdS and $CdSO_4$ in all complexes. Loss of bipyridine was indicated by a well defined step, whereas the corresponding 1,10-phenanthroline analogue showed a single step decomposition.

Table 3

Table 4
Binding energies (FWHM)[a] and binding energy shifts[b].

	$Cd(pipdtc)_2$	ΔE	$[Cd(pipdtc)_2$ (1,10 phen)]	ΔE	$[Cd(pipdtc)_2(bipy)]$	ΔE
N1s[c]	400.5(1.7)	−1.1	399.0(2.0)	−2.6	398.8(1.8)	−2.8
S2p[d]	163.0(1.9)	−1.8	162.2(2.4)	−2.8	161.6(2.4)	−3.2
Cd3d	405.5(2.1)	+1.8	404.1(2.1)	+0.4	404.3(2.3)	+0.6
	412.3(1.0)	+1.8	410.8(2.3)	+0.3	411.3(2.3)	+0.8

[a] Full width at half maximum given in parentheses.
[b] Shift in bindings energies (ΔE = observed BE − bare atom BE) with respect to 'bare' atom values quoted in the operation manual for the VG ESCA mark II spectrometer, count rate: 10^3 counts s^{-1}.
[c] Binding energy values for the adducts are unresolved and include those due to 1,10-phenanthroline and bipyridine.
[d] $S2p_{1/2,3/2}$ spin orbit components are not well resolved and the S2p binding energy is the peak maximum of the overall band envelope close to that of the $S2p_{3/2}$ component [27].

3.2. X-ray photoelectron spectroscopy

Binding energy values of core level electrons in different complexes and binding energies (ΔE) of the electrons with respect to the elemental state binding energies are listed in Table 4.

For the adducts, S2p binding energies show a significant reduction in magnitude compared to the parent dithiocarbamate. The observation is a clear indication of the weakening of Cd–S bond on adduct formation. Such a weakening is indicated by the lengthening of Cd–S bond and is observed in the crystal structures of the adducts. The bindings energy values associated with Cd3d electrons in the parent compound are observed at 405.5 and 412.3 eV [14]. On adduct formation, a highly significant reduction in binding energy of 1.5 eV is evident. The observed shift in binding energy very clearly shows the increased electron density on the metal in the adducts.

The metal-dithiocarbamate complexes are known to be highly covalent with effective bonding [15,16]. Unlike the truly planar nickel dithiocarbamate complexes, tetrahedral cadmium dithiocarbamate complexes are dimeric because of less effective charge transfer from the ligands to the metal. On adduct formation, the cadmium dithiocarbamate complexes become hexa-coordinated and the electron density on cadmium increases relatively due to the presence of the nitrogen bases. Weakening of the Cd–S bond on adduct formation is shown by the reduction in Cd3d electron binding energies. Therefore, the present XPS study supports the weakening of the Cd–S bond and the increase of electron density on cadmium as a result of the adduct formation.

3.3. Cyclic voltammetric studies

Representative cyclic voltammograms of $[Cd(pipdtc)_2(bipy)]$ at a HMDE and at a platinum electrodes are given in Fig. 1. In the cyclic voltammogram of $Cd(pipdtc)_2$ at a HMDE electrode, a new redox couple (−0.575 V/−0.400 V) is observed [17]. The magnitude of process 1 depend on the time the electrode is held at the initial potential. This is not observed unless HMDE is used. The process is conspicuously absent when CV is recorded with a platinum working electrode. This suggests that the process 1 (−0.575 V/−0.400 V) might be due to the formation of bimetallic complex such as $[HgCd_2(dtc)_6]$ as follows:

$$Hg(dtc)_2 + 2Cd(dtc)_2 \rightleftharpoons HgCd_2(dtc)_6$$

Synthetically, the formation of bimetallic complexes has been reported earlier [18]. Formation of the bimetallic complexes in all the dithiocarbamate complexes during electrochemical studies is due to the inherent nature of the mercury electrode to undergo exchange reaction with the metal dithiocarbamate complexes to ultimately form $Hg(dtc)_2$ and related complexes [19,20]. This is because of the soft–soft interaction between Hg and S containing ligands.

However, process 2 (−0.825/−0.675 V) in the cyclic voltammogram is for the 2 electron reduction reaction observed before. The process 2 can be written as

$$Cd(dtc)_2 + 2e^- + Hg \rightleftharpoons 2(dtc)^- + Cd(Hg)$$

In the case of the $[Cd(pipdtc)_2(1,10\text{-phen})]$ adduct, the cyclic voltammogram under identical conditions shows two reductive responses *viz.*, −0.725/−0.525 V and −1.750 V. The two reduction processes are identified by process 3 and 4. Process 3 is a redox couple with a large voltage separation (−200 mV). The couple does not appear unless a HMDE electrode is used for the CV studies. The response is totally absent when a platinum electrode is used. Therefore the redox couple identified by process 3 must be due to an electroactive species produced as a result of the interaction of Hg with other species.

Process 4 must be due to the electron addition process such as

$$[Cd(dtc)_2(1,10\text{-phen})] + 2e^- \rightleftharpoons [Cd(dtc)_2(1,10\text{-phen})]^{-2}$$

Controlled potential electrolysis could not be carried out because the response was observed close to the solvent decomposition potential. But, a comparison of the current per unit concentration of the complex with that of the parent dithiocarbamate indicates the nature of the reduction to be a two electron process. The absence of a corresponding oxidative couple for the reduction process is noteworthy. An earlier polarographic study [21] on similar compounds has also indicated the reduction to be a two electron addition process.

Similarly, for $[Cd(pipdtc)_2(bipy)]$ two reductive responses are also observed, indicated by process 5 and 6. Process 5 appears as a redox couple (−0.775/−0.555 V) whereas, the process 6 shows a reduction potential of −1.225 V with the respective oxidative couple missing. Process 5 is not observed if the CV is recorded with

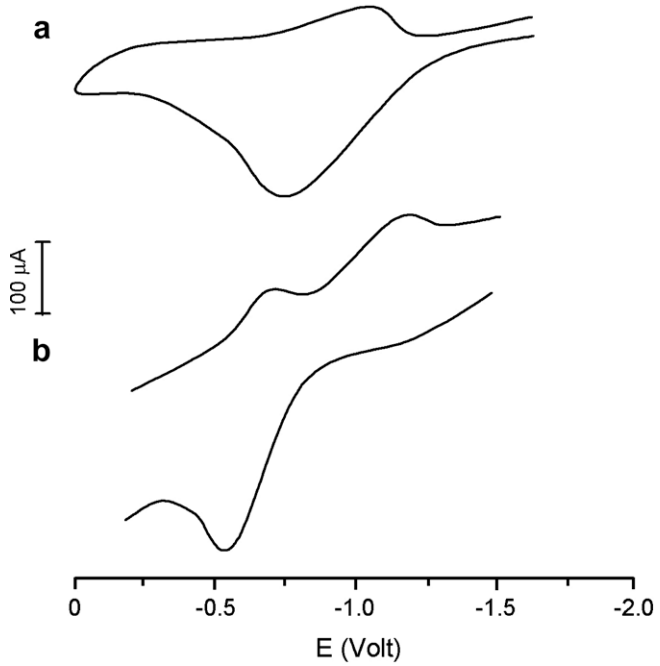

Fig. 1. Cyclic voltammograms of [Cd(pipdtc)$_2$(bipy)] at (a) HMDE and (b) platinum electrode.

a platinum working electrode. Process 6 is similar to the process 4 of the 1,10-phenanthroline analog and hence, must correspond to the two electron addition process.

The most important outcome of the observations is that in both the adducts the electron addition process becomes more difficult compared to the parent bisdithiocarbamate complex. This fact is supported by the very large shift in reduction potentials of the adducts compared to the parent dithiocarbamate (process 4 and 6 versus 2). The observation clearly indicates the presence of excess electron density on cadmium in the adducts compared to the parent dithiocarbamates. As the electron density increases, the electron addition is more difficult and hence a higher negative reduction potential is observed. Of the two adducts, the one involving bipyridine shows a lower reduction potentials than the other indicating less effective electron donation compared to 1,10-phenanthroline [22,23].

The new redox couple observed around −0.700/−0.500 V in both the adducts is not observed when CV are recorded with a platinum electrode. The potential associated with the redox couple is totally different from the values recorded for the corresponding parent complex involving simple dithiocarbamate or the nitrogen bases under identical conditions. This observation clearly also supports the involvement of Hg in the formation of a new electroactive species. In addition, the absence of a reductive response for Hg(dtc)$_2$ (−0.500 V) is an indication of the involvement of the new electroactive species.

3.4. Structure analysis

The ORTEP of [Cd(pipdtc)$_2$(1,10-phen)] and [Cd(pipdtc)$_2$(bipy)] are shown Figs. 2 and 3, respectively. The structures of **1** and **2** contain four and eight discrete monomeric units, respectively per unit cell. In both complexes the cadmium atoms are situated at the centre of a distorted tetragonal bipyramidal arrangement with two sulfur atoms from the chelating dithiocarbamate groups [S2, S2′] and two nitrogen atoms from the chelating neutral ligand [N8, N8′] on the basal plane and the two remaining sulfur atoms as vertices. Selected geometrical parameters for **1–3** are given Table 5.

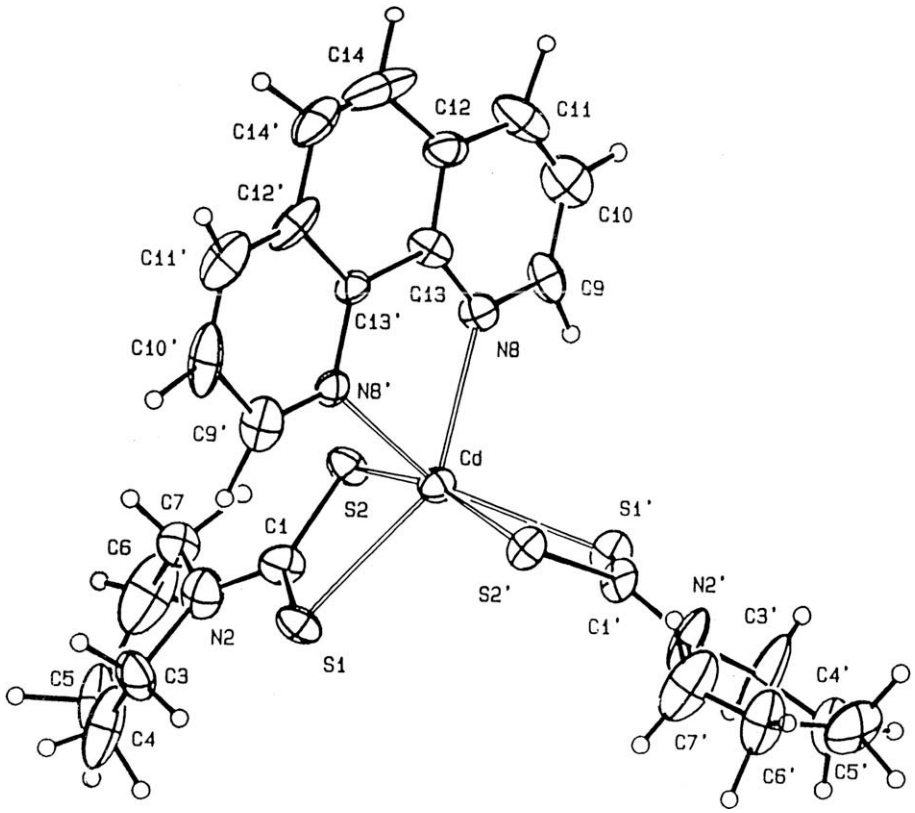

Fig. 2. ORTEP (30% ellipsoids) of [Cd(pipdtc)$_2$(1,10-phen)] **1**.

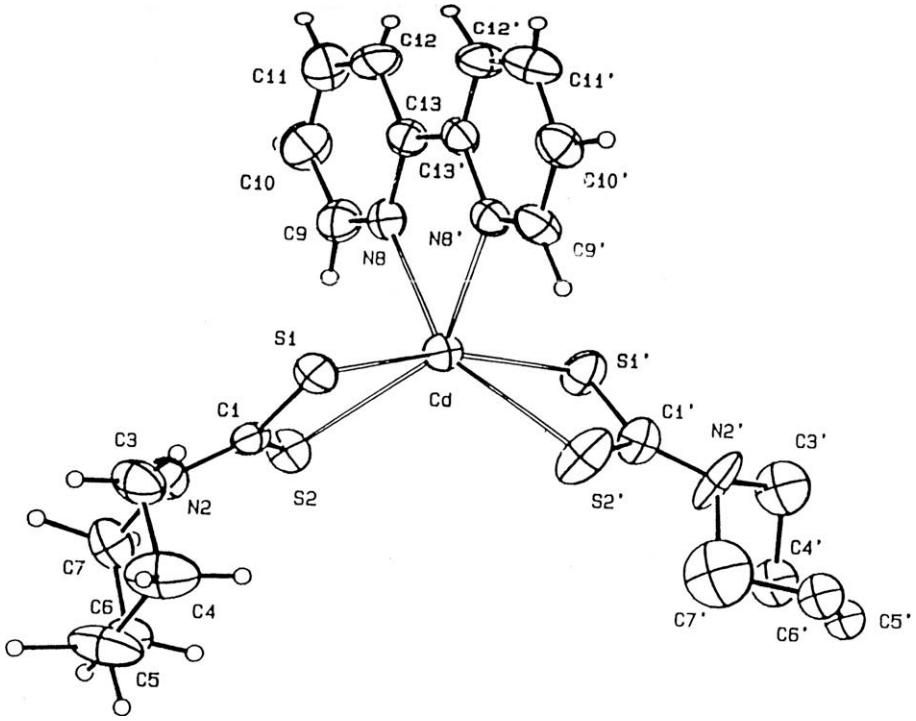

Fig. 3. ORTEP (30% ellipsoids) of [Cd(pipdtc)$_2$(bipy)] **2**.

Table 5
Comparative structural parameters for cadmium compounds.

Compound	Coordination number	S–Cd–S (°)	S–C–S (°)	C–S (Å)	Cd–S (Å)	S_2C–N (Å)	Ref.
Cd(pipdtc)$_2$	4[a]	68.0 (1)	118.7	2.566 (1)	1.734 (3)	1.33 (1)	[6]
[Cd(pipdtc)$_2$ (1,10-Phen)]	6	67.4(1)	119.7(2)	2.666(1)	1.711(2)	1.35(5)	This work
[Cd(pipdtc)$_2$(2,2′-bipy)]	6	67.7(1)	118.6(7)	2.659(4)	1.718(13)	1.32(2)	This work

[a] It has been suggested that the coordination number is essentially five due to the presence of very long Cd–S bond in the dimer.

Table 6
Comparative structural parameters involving the bidentate nitrogen ligands for related cadmium compounds.

Compound	N–Cd–N (°)	Cd–S (Å)	Cd–N (Å)	Ref.
[Cd(S_2COEt$_2$)$_2$(1,10-Phen)]	69.5(3)	2.687(3)	2.386(8)	[25]
[Cd(S_2CSBu)$_2$(2,2′-bipy)]	69.0(1)	2.684(1)	2.363(3)	[26]
[Cd(pipdtc)$_2$(1,10-Phen)]	68.7(5)	2.666(5)	2.415(3)	This work
[Cd(pipdtc)$_2$(2,2′-bipy)]	68.2(3)	2.659(4)	2.424(7)	This work

The bond distances and angles are mean values.

The Cd–S distances observed in **1** and **2** are longer than those observed in **3**. This is attributed to the change in coordination number from 4 to 6 and the steric effect exerted by 1,10-phenanthroline or 2,2′-bipyridine. No significant changes in C–N, C–S bond lengths and in the S–Cd–S and S–C–S angles are observed. In complex **2**, there are considerable differences between the pairs of Cd–S and S–C bonds and it is interesting to note that the shorter Cd–S bonds [2.657(3), 2.635(4) Å compared to 2.682(3), 2.646(4) Å] are associated with the longer S–C distances [1.730(12), 1.738(12) Å versus 1.703(13), 1.707(13) Å]. The fact is that the dithiocarbamate ligand is asymmetrically linked to cadmium and the asymmetric C–S distances are shorter than the typical C–S single bond distance [1.81 Å]. Therefore, all the C–S bonds in the present structure are of partial double bond character as observed in most of the dithiocarbamates [24]. Average C–N distances of **1** and **2** are 1.327(4) and 1.308(17) Å, respectively, which clearly indicates the contribution of the thioureide form to the dithiocarbamate ligand. This contrast well with adjacent typical single bonded N–C distances.

Selected structural parameters involving, 1,10-phenanthroline and 2,2′-bipyridine are also given in Table 6. Cd–N bonds are a symmetric and are longer than those observed in two similar adducts derived from xanthate and thioxanthate complexes [25,26]. The Cd–S distances observed in both the complexes **1** and **2** are the shortest compared to others listed in Table 6. Relatively, as the Cd–S bonds are shorter the Cd–N bonds are long. Therefore, the strength of Cd–S bond is decided at the cost of Cd–N bond and vice versa. The presence of relatively bulky piperidine ring sterically hinders the close approach of the neutral ligands.

Supplementary data

CCDC Nos. 245559 and 245937 contain the supplementary crystallographic data for complexes **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.com.ac.uk/costs/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

ATR-FTIR

ABSTRACT

Aquation of the 1:2 complex between Cr^{III} and nitrilotriacetic acid (NTA) was monitored using a combination of capillary electrophoresis (CE), ultraviolet–visible (UV–vis) spectrophotometry, and attenuated total reflectance-Fourier transform infrared (ATR-FTIR) spectroscopy. To our knowledge, this is the first published report of the use of either CE or ATR-FTIR to monitor the kinetics of ligand exchange reactions of Cr^{III}–aminocarboxylate complexes. The aquation products were identified as the 1:1 Cr^{III} complex with NTA and "free" NTA. The 1:1 complex dimerized to form a 2:2 complex in a slower subsequent reaction step. Rates of disappearance of the 1:2 complex were first-order under all experimental conditions. First-order rate constants for aquation, k_{obs} (h^{-1}), measured using all three techniques were similar at equivalent pH conditions, and with values reported previously in the literature. Measured k_{obs} values exhibited a complicated pH dependence with three distinct regions: (i) at pH < 6.5, k_{obs} values increased with decreasing pH, (ii) between pH 6.5 and 8.0, k_{obs} values were relatively constant, and (iii) at 8.0 < pH < 10.0, k_{obs} increased with increasing pH and then leveled off. A kinetic model incorporating five distinct aquation pathways was successfully employed to model the pH dependence of k_{obs} from 0.0 < pH < 10.0. These results show that CE and ATR-FTIR can be used as tools for better understanding ligand exchange processes occurring in aqueous solution.

1. Introduction

Chromium(III) is classically known as a substitution-inert metal ion [1]. This categorization is largely based upon measurements of the rate of water exchange from the first coordination shell of Cr^{III} and other metal aqua ions [2]. The pseudo first-order rate constant for water exchange for $[Cr^{III}(H_2O)_6]^{3+}$ (hexaaquo Cr^{III}) is $2.4 \times 10^{-6}\ s^{-1}$ ($t_{1/2}$ = 3.2 days) [3], one of the smallest in magnitude for all metals. Since replacement of a water molecule from the first coordination shell is an important step in complex formation and many redox processes, many aqueous systems containing hexaaquo Cr^{III} take long periods of time to reach equilibrium [4]. Rate constants for exit of coordinated water/entry of simple inorganic ligands (e.g., Cl^-, Br^-, NO_3^-) vary, but most range between 10^{-6} and $10^{-8}\ M^{-1}\ s^{-1}$ [2].

Replacement of water by hydroxide ion does not involve ligand exchange because it can be achieved via deprotonation of a coordinated water molecule. Consequently, formation of hydroxo species occurs rapidly upon raising the pH of aqueous solutions containing hexaaquo Cr^{III} [5]. This not only alters the speciation of Cr^{III}, but also has been found to increase ligand exchange rates. For example, replacing a coordinated water molecule of hexaaquo Cr^{III} with hydroxide ion to form $[Cr^{III}(H_2O)_5(OH)]^{2+}$ decreases the half-life of water exchange from 3.2 days to approximately 8 h [3]. Rate constants for Cr^{III} oligomerization increase by about a factor of 10^2 with each replacement of a coordinated water molecule by hydroxide ion [6].

Aminocarboxylate chelating agents complex strongly with most metals, thus altering metal bioavailability and mobility in the environment [7]. These compounds are used as laundry detergent builders, boiler scale inhibitors, in metal plating and cleaning operations, in textile manufacture, and in paper and cellulose production. When aminocarboxylate chelating agents occupy two, three, four, or five coordination positions of Cr^{III}, rates of exchange at remaining positions occupied by water can be quite rapid [8–10]. For example, exit of a water molecule and entry of NCS^- (thiocyanate ion) into the inner coordination shell of hexaaquo Cr^{III} has a rate constant of $1.8 \times 10^{-6}\ M^{-1}\ s^{-1}$ [11]. However, replacement of a coordinated water molecule by NCS^- in $[Cr^{III}(edta)(H_2O)]^-$ and $[Cr^{III}(hedta)(H_2O)]^0$ (edta = ethylenediaminetetraacetic acid, hedta = N-(2-hydroxyethyl)-ethylenediaminetriacetic acid) is much more rapid, exhibiting rate constants of 13.7 and $3.32\ M^{-1}\ s^{-1}$, respectively [12].

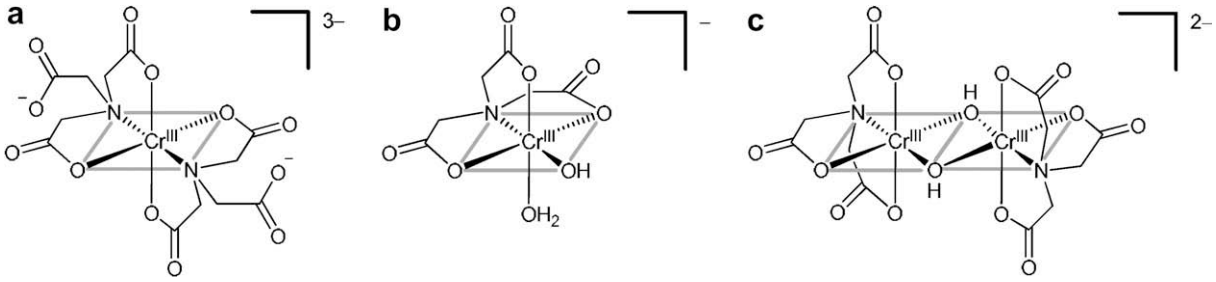

Fig. 1. Structures and stoichiometries and of Cr^{III} complexes with NTA. Identity: (a) *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, b) $[Cr^{III}(H_2O)(OH)(nta)]^{-}$, c) *trans*-$[Cr^{III}_2(\mu\text{-}OH)_2(nta)_2]^{2-}$.

Nitrilotriacetic acid (NTA), a member of the aminocarboxylate family, is of particular interest from a chemical perspective because of the multiple stoichiometries and protonation levels that result when it coordinates metal ions. Cr^{III} complexes with NTA are known to exist in 1:1, 1:2 and 2:2 stoichiometries (Fig. 1). These species interconvert in solution, exhibiting a wide range of reaction rates that are dependent upon pH [13–15]. However, nearly all previous examinations of these complexes have been conducted in acidic media, making it difficult to predict the rates and mechanism of transformation under environmentally-relevant pH conditions.

In our previous work, a capillary electrophoresis (CE) method was developed to speciate various Cr^{III} complexes with aminocarboxylate chelating agents [16]. CE is an effective tool for measuring Cr^{III} speciation because time scales of complex dissociation are longer than the time scale of the CE separation itself. Injections of pure solutions of the 1:1 and 2:2 complexes of Cr^{III} with NTA resulted in distinct, sharp peaks. In this study, we apply this CE method together with complementary ultraviolet–visible (UV–Vis) and attenuated total reflectance-Fourier transform infrared (ATR-FTIR) spectroscopy analyses to study the kinetics and mechanism of the inter-conversion of Cr^{III}–NTA complexes amongst the various forms shown in Fig. 1. ATR-FTIR spectroscopy provides an in situ probe for changes in the molecular properties of metal–organic complexes because many organic functional groups are infrared-active at characteristic vibrational frequencies (e.g., carboxylate, phenolate) [17,18], and spectral features of individual functional groups are sensitive to protonation, metal coordination, and hydrogen bonding [19–22]. Thus, ATR-FTIR spectral changes during Cr^{III}–NTA ligand exchange reactions can be traced to specific changes in metal-binding ligand groups. The ATR sampling technique is particularly suited for probing aqueous solutions because it provides a small highly reproducible spectral pathlength (~few μm), which is necessary because water completely absorbs infrared radiation over longer pathlengths [23]. ATR-FTIR spectroscopy has been used successfully to characterize the structures of carboxylate ligands complexed to aqueous metal ions and adsorbed to mineral surfaces [19–22,24–26].

This contribution examines the kinetics for aquation of the 1:2 complex between Cr^{III} and NTA using the novel combination of techniques described above. The products of the aquation reaction are the 1:1 complex and a "free" NTA molecule. Since ligand exchange rates of Cr^{III}–aminocarboxylate complexes are known to be pH dependent, experiments were conducted over a wide pH range and models that consider changing protonation levels of the reacting complex were developed to quantitatively interpret observed kinetic trends. To our knowledge, this is the first published report of the use of either CE or ATR-FTIR to monitor the kinetics of ligand exchange reactions of Cr^{III}–aminocarboxylate complexes. Additional kinetic experiments were performed using UV–Vis spectrophotometry, the sole method used in earlier studies [13], as a way to verify CE and ATR-FTIR results. Although the experimental system and reaction studied here is very simple in nature, elucidation of the aquation mechanism in this model system has implications for a variety of more complex homogeneous and heterogeneous phenomena involving metal–organic complexes (e.g., metal ion transport, bioavailability, and toxicity).

2. Experimental

All solutions were prepared using distilled, deionized water (DDW) with a resistivity of 18 MΩ cm (Millipore Corp. or Barnstead International). All stock solutions were stored in polypropylene bottles prior to use. All glassware and plasticware were soaked in 5 M HNO_3 or 1 M HCl (Fisher Scientific) and rinsed several times with DDW prior to use.

Nitrilotriacetic acid (NTA) was purchased from Acros Chemicals. N,N′-Diethylpiperazine (DEPP, 4.0 < pH < 5.3), 2-morpholinoethanesulfonic acid (MES, 5.5 < pH < 6.7), 3-(N-morpholino)propanesulfonic acid (MOPS, 6.7 < pH < 7.7), 4-(2-Hydroxyethyl)-1-piperazinepropanesulfonic acid (EPPS, 7.7 < pH < 8.8), and 2-(cyclohexylamino)ethanesulfonic acid (CHES, 8.8 < pH < 10.0) were used as pH buffers. These buffers were selected specifically because they are believed to interact minimally with metal ions in solution [27]. NaCl (sodium chloride), HNO_3 (nitric acid), HCl (hydrochloric acid) and NaOH (sodium hydroxide) were purchased from Fisher Scientific.

Solid *s-fac*-$K_3[Cr^{III}(nta)_2] \cdot 2H_2O$ was synthesized according to the method of Kallen et al. [13]. $K_2[Cr^{III}_2(\mu\text{-}OH)_2(nta)_2] \cdot 2H_2O$ was synthesized according to the method of Koine et al. [28]. Solution standards of $[Cr^{III}(H_2O)_2(nta)]^0$ were prepared by dissolving $K_2[Cr^{III}_2(\mu\text{-}OH)_2(nta)_2] \cdot 2H_2O$ in 0.01 M HCl for 1.0 h as described by Visser et al. [29]. Purity of Cr^{III} salts was ensured by dissolving them in pH buffered solutions and comparison of their UV–Vis spectral features (λ_{max} and ε_{max}) with literature values [15]. Capillary electrophoresis analysis provided a final check since impurities would result in unidentifiable peaks in electropherograms.

2.1. Capillary electrophoresis experiments

Capillary electrophoresis experiments were conducted by adding pre-weighed amounts of solid *s-fac*-$K_3[Cr^{III}(nta)_2] \cdot 2H_2O$ to a 100 mL solution containing 10 mM NaCl and 5.0 mM pH buffer. The resulting initial concentration of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ was 172 μM. Small amounts of 0.1 M HCl or NaOH were then added to achieve specific pH values. A 500 μL aliquot of this solution was then added to a polypropylene sample tube for analysis by CE. The pH of the solution was measured in the remainder of the solution at the beginning and end of each experiment to ensure that it stayed at a constant value. The samples were maintained at a constant 25 °C via the thermostatted internal sample chamber of the instrument. Repeated injections of the sample were then made at various time intervals. CE experiments were performed over the range $3.72 \leqslant pH \leqslant 10.02$.

A P/ACE MDQ (Beckman Coulter, Fullerton, CA) capillary electrophoresis instrument equipped with a UV–Vis diode array detector was used. Underivatized fused-silica capillaries (75 μm i.d.) were purchased from Polymicro Technologies (Phoenix, AZ). Samples were introduced into the capillary by hydrostatic injection using a pressure of 0.5 psi for 10 s. *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, $[Cr^{III}(H_2O)(OH)(nta)]^-$, and *trans*-$[Cr^{III}_2(\mu\text{-}OH)_2(nta)_2]^{2-}$ were analyzed by CE using methods described in Carbonaro and Stone [16]. Direct detection of these complexes at a wavelength of 214 nm was employed.

2.2. Ultraviolet–visible spectrophotometry experiments

Solutions of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ used in UV–Vis spectrophotometry experiments were prepared in a similar manner to the CE experiment except the initial concentration was 4.3 mM. Immediately after pH adjustment, a 2.0 mL aliquot of the reaction solution was added to a plastic cuvette (1 cm pathlength) which was then loaded into the UV–Vis spectrophotometer (DU 800, Beckman Coulter). The sample chamber of the spectrophotometer was maintained at 25 °C via a Peltier thermostat system. Repeated measurements of the sample absorbance were then made at selected time intervals at a wavelength of 506 nm. A solution of 10 mM NaCl was used as a blank for background correction. UV–Vis experiments were performed over the range $2.07 \leqslant pH \leqslant 3.48$. An organic pH buffer was not employed in these experiments. Experiments were not performed at higher pH values because of dimerization of the product which occurs at neutral to alkaline pH.

2.3. ATR-FTIR spectroscopy experiments

ATR-FTIR spectra of aqueous samples containing NTA and Cr^{III}–NTA complexes were collected at room temperature (22 ± 2 °C) using a Nicolet Nexus 670 FTIR spectrometer (Thermo Scientific) outfitted with an ATR cell containing a horizontal 45° AMTIR crystal (Pike Technologies), a mid IR source, a KBr beam splitter, and a deuterated triglycine sulfate (DTGS) detector. All reference standard and reaction solutions were prepared in a stirred batch reactor with 10 mM ligand concentration (e.g., 5 mM of the 1:2 complex yields 10 mM ligand) and sufficient NaCl concentration to yield 100 mM total Na^+ in the solution. The pH of the batch reactor was continuously monitored to ensure pH stability during the aquation reaction (no adjustment was necessary). At desired time intervals, a small aliquot of the reactor solution was transferred to the ATR sample cell and an infrared spectrum was obtained by averaging 100 spectral scans acquired at 4 cm^{-1} resolution.

2.4. Data analysis

It was not possible to generate accurate CE or UV–Vis calibration curves for *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ because standard solutions undergo the same transformation reactions we are investigating. Reaction time courses resulting from CE experiments were plotted in terms of corrected peak area instead of concentration. Corrected peak area is defined as the peak area divided by the analyte migration time [30]. Normalizing to migration time has been found to increase reproducibility and lower %RSD of repeated injections of standard solutions [30]. The CE corrected peak area of Cr^{III}–aminocarboxylate complexes is depends linearly upon concentration with a near-zero intercept [16]. Therefore, changes in corrected peak area with time can be used as a surrogate for concentration for determining rate constants [31]. Electropherograms resulting from CE separations are usually reported as absorbance versus electromigration time [30]. However, to correct for run-to-run variability in electroosmotic flow, the electromigration time axis was transformed to effective electrophoretic mobility [30]. Analysis of UV–Vis absorbance data is described after presentation of the experimental results.

ATR-FTIR spectra were analyzed using OMNIC (Version 6.1; Thermo-Nicolet). Spectra of NTA-containing solutions were collected against a deionized water background and spectral contributions from the background electrolyte were manually subtracted using the spectra of 100 mM NaCl solutions that were measured in between measurements of NTA-containing samples; background subtraction factors for individual raw spectra, which varied from 0.1 to 0.98, were selected to minimize spectral noise from water vapor. The resulting spectra were then baseline corrected to remove spectrometer drift. Although care was taken to subtract spectral features of water, contributions from a strong water bending mode ($\delta_{H\text{–}O\text{–}H}$) at ~1630 cm^{-1} cannot be completely eliminated with confidence, so this region of the spectra was used only for qualitative analysis of peak positions and was not considered when conducting quantitative analysis. Spectra of solutions spiked with *s-fac*-$K_3[Cr^{III}(nta)_2] \cdot 2H_2O$ that were collected after different reaction times (0–6 h) were fit with a stoichiometry-constrained linear combination of reference spectra for *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, $[Cr^{III}(H_2O)(OH)(nta)]^-$, and free NTA collected at the same pH condition. Spectral fitting was performed by method of least square residuals using SCIENTIST (Version 3.0; Micromath Scientific).

All observed first-order rate constants for s-fac-$[Cr^{III}(nta)_2]^{3-}$ aquation, k_{obs} (h^{-1}), were determined via linear regression using the slope function of EXCEL (Version 2007; Microsoft). Reaction progress was followed for a minimum of two half-lives. Confidence intervals on rate constants at the 95% confidence level were determined using standard statistical methods facilitated through the use of EXCEL. Model fits of k_{obs} versus pH data were performed using SCIENTIST. Confidence intervals on model parameters (pK_a values and reaction rate constants) were determined at the 95% confidence level using numerical algorithms available in SCIENTIST.

2.5. Notation

The notation used here for Cr^{III} complexes is consistent with that used in the inorganic chemistry literature. When the identity of the metal ion and chelating agent are known, but the protonation level, or overall charge is not established, all of the letters of the abbreviation for a chelating agent are written in upper-case, e.g., Cr^{III}–NTA and Cr^{III}–NTA_2. Lower-case abbreviations for chelating agents correspond to their lowest protonation levels (e.g., nta^{3-}). Protonation of nta^{3-} therefore results in $Hnta^{2-}$, H_2nta^-, and H_3nta. Brackets are used when the chelating agent stoichiometry, protonation level, and overall charge of the metal complex are known, e.g., $[Cr^{III}(nta)_2]^{3-}$ and $[Cr^{III}(H_2O)_2(nta)]^0$. The overall charge of the complex is placed outside the brackets. Since the kinetics of conversion of one complex to another is the focus of study, denotation of the concentration of these complexes requires further delineation and is indicated using a second set of brackets. Thus, $[[Cr^{III}(nta)_2]^{3-}]$ and $[[Cr^{III}(H_2O)_2(nta)]^0]$ represent the concentrations in mol/L of $[Cr^{III}(nta)_2]^{3-}$ and $[Cr^{III}(H_2O)_2(nta)]^0$, respectively.

3. Results and discussion

3.1. Capillary electrophoresis studies

Results from a typical *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ aquation experiment are shown in Fig. 2 for a reaction buffered at pH 6.91. In Fig. 2a, stacked electropherograms are shown at increasing sample injection times. The peak area for *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ (Peak 1) decreased over time from the onset of the reaction. Loss of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ peak area corresponded with an increase in the areas of Peak 2

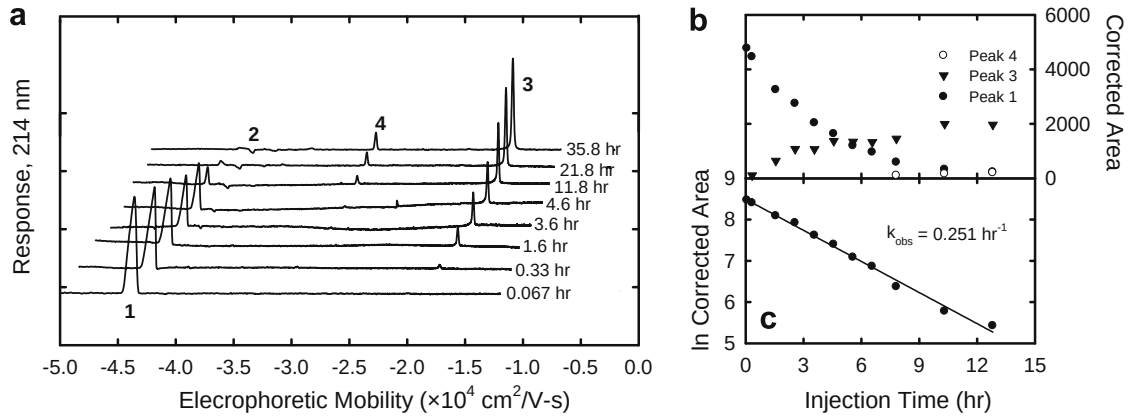

Fig. 2. Aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ at near-neutral pH monitored using capillary electrophoresis. In (a) electropherograms resulting from successive injection and separation of a pure solution of 172 μM *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ at pH 6.91 (5.0 mM MOPS, 10 mM NaCl). Peak identity: 1. *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, 2. free NTA, 3. $[Cr^{III}(H_2O)(OH)(nta)]^{-}$, 4. $[Cr_2^{III}(\mu\text{-}OH)_2(nta)_2]^{2-}$. In (b) the corrected areas of Peaks 1, 3 and 4 are shown as function of the injection time. In (c), the natural log of the corrected area of Peak 1 is shown vs. the injection time.

(a negative peak) and Peak 3. Peaks 2 and 3 were confirmed to be free NTA and $[Cr^{III}(H_2O)(OH)(nta)]^{-}$, respectively, by spiking samples with known standards of these compounds. A peak corresponding to $[Cr_2^{III}(\mu\text{-}OH)_2(nta)_2]^{2-}$ (Peak 4), typically appeared very slowly after a significant lag period. In Fig. 2b, the corrected peak area of Peaks 1, 3 and 4 are plotted versus time for the same experiment as shown in (a). The corrected peak area for *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ (Peak 1) decreased exponentially with time. Similar results were obtained for all experiments performed using CE.

Based upon the changes in corrected peak area with injection time, the following general "reactions in series" scheme was observed:

$$\textit{s-fac}\text{-}[Cr^{III}(nta)_2]^{3-} \xrightarrow{-NTA} [Cr^{III}(H_2O)(OH)(nta)]^{-} \xrightarrow{(slow)} [Cr_2^{III}(\mu\text{-}OH)_2(nta)_2]^{2-} \quad (1)$$

As *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ aquates to $[Cr^{III}(H_2O)(OH)(nta)]^{-}$, one NTA molecule becomes completely dissociated. A more subtle change occurs in the other NTA molecule still attached to Cr^{III}. As can be seen in the structures shown in Fig. 1, the number of Lewis base groups of the NTA ligand attached to the Cr^{III} center increases from 3 to 4. It is also important to note the nature of the product of the aquation reactions. $[Cr^{III}(H_2O)(OH)(nta)]^{-}$ is the dominant form of the 1:1 Cr^{III} complex with NTA at pH 7.1 (the pH of the CE buffer). However, at moderately-low pH, the coordinated hydroxide ion of $[Cr^{III}(H_2O)(OH)(nta)]^{-}$ protonates to form $[Cr^{III}(H_2O)_2(nta)]^{0}$ [14,32,33]:

$$[Cr^{III}(H_2O)_2(nta)]^{0} \rightleftharpoons [Cr^{III}(H_2O)(OH)(nta)]^{-} + H^{+} \quad pK_{a1} = 5.87 \quad (2)$$

At moderately-high pH, the coordinated water molecule of $[Cr^{III}(H_2O)(OH)(nta)]^{-}$ deprotonates to form $[Cr^{III}(OH)_2(nta)]^{2-}$ [32,33]:

$$[Cr^{III}(H_2O)(OH)(nta)]^{-} \rightleftharpoons [Cr^{III}(OH)_2(nta)]^{2-} + H^{+} \quad pK_{a2} = 8.74 \quad (3)$$

Interconverison of these species occurs typically in sub-millisecond time-scales because Cr^{III} ligand exchange is not involved [5]. Thus, the predominant form of the 1:1 complex depends strongly upon solution pH. For simplicity, Cr^{III}–NTA is used throughout the remainder of this work to denote all protonation levels of the 1:1 complex.

Conversion of Cr^{III}–NTA to $[Cr_2^{III}(\mu\text{-}OH)_2(nta)_2]^{2-}$ (Eq. (1)) is a dimerization reaction which has been investigated in a previous study [34]. Since the concentration of Cr^{III}–NTA is affected by both its formation and dimerization reactions, we chose to determine observed rate constants solely from the loss of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$. Fig. 2c shows that the natural logarithm of the *s-fac*-$[Cr^{III}(nta)_2]^{3-}$

[a] Reactions conducted at 25 °C unless otherwise indicated. Uncertainty represented at the 95% confidence level.
[b] Experiment conducted at room temperature (22 ± 2 °C).

corrected area versus time is linear, indicating first-order loss of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$. The negative slope of the linear regression line yielded an observed first-order rate constant, k_{obs}, equal to $0.251 \pm 0.015\ h^{-1}$. In general, linear regression provided excellent fits to the data from all experiments performed using CE ($3.6 < pH < 9.4$), yielding k_{obs} values with small confidence intervals (95% confidence level) ranging from 0.220 to $3.93\ h^{-1}$. A summary of all measured k_{obs} values is provided in Table 1.

Attempts at stabilizing *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ by adding "free" NTA (1.0 mM) to solutions buffered at pH 7.0 were unsuccessful. In all cases *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ corrected peak area decreased exponentially as a function of time. Values for k_{obs} were approximately the same as when additional NTA was not added. Thus, back reaction of Cr^{III}–NTA with NTA is kinetically limited and is unimportant under the experimental conditions employed in this study.

3.2. UV–Vis spectrometry studies

At low pH conditions ($pH < 3.6$), rates of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ aquation were too rapid to be monitored by CE. Instead, UV–Vis spectrophotometry was used in the low-pH experiments to examine reaction progress by measuring the solution absorbance as a function of time. In the experiments where UV–Vis was employed, the absorbance increased as a function of time until it leveled off at a particular value (Fig. 3a for three separate experiments performed at pH 2.35, 2.96, and 3.27).

For an irreversible first-order reaction in a system where the reactant and product(s) have appreciable UV–Vis absorbance, k_{obs} is related by the following equation [31,35]:

$$\ln\left(\frac{D_0 - D_\infty}{D_t - D_\infty}\right) = k_{obs}t \quad (4)$$

where D_0 is the initial sample absorbance, D_∞ is the sample absorbance at infinite time, and D_t is the sample absorbance at time t.

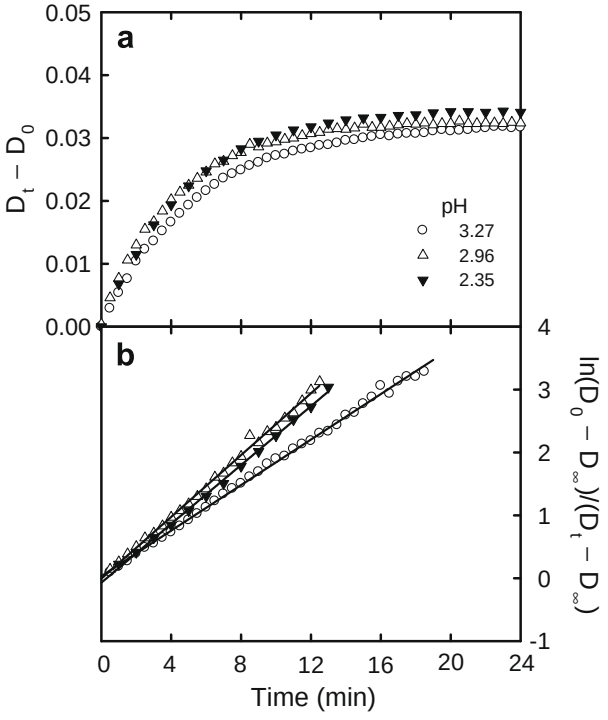

Fig. 3. Aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ at low pH monitored using UV–Vis spectrophotometry. In (a), the corrected absorbance, $D_t - D_0$, is shown vs. time for three separate solutions of 4.30 mM *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ at pH 2.35, 2.96 and 3.27 (10 mM NaCl). In (b) the data shown in (a) is linearized (see text) to obtain values of k_{obs}.

Although Cr^{III}–NTA dimerizes to form $[Cr_2^{III}(\mu\text{-}OH)_2(nta)_2]^{2-}$ thereby affecting values of D_t and D_∞, previous work has shown that this reaction is relatively unimportant at the low total chromium concentration and pH used in these experiments [15]. Plots of the left-hand side of Eq. (4) versus time were linear (Fig. 3b). The slope resulting from linear regression through data points corresponding to the first 95% of the reaction yielded values of k_{obs} ranging from 8.23 to $15.89\ h^{-1}$ (Table 1).

3.3. ATR-FTIR studies

A kinetic experiment was also performed at pH 7.0 using ATR-FTIR spectroscopy to compare with the results obtained with CE and confirm that the products formed are spectroscopically consistent with expected aquation reaction that generates $[Cr^{III}(H_2O)(OH)(nta)]^-$ and liberates a free NTA molecule. Reference spectra for the reactant and both of the expected products are provided

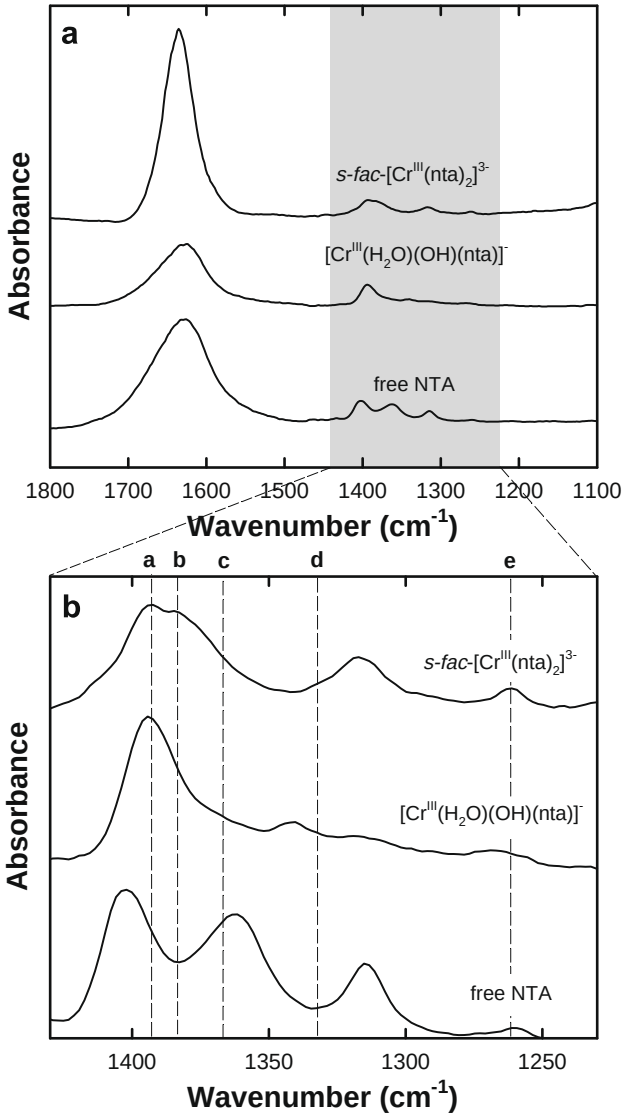

Fig. 4. Reference ATR-FTIR spectra for 10 mM aqueous NTA solutions where the ligand is present predominantly as *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, $[Cr^{III}(H_2O)(OH)(nta)]^-$, and free NTA at pH 7.0 (0.1 M NaCl). Panel A shows the full fingerprint region of the spectra that contains both asymmetric and symmetric carboxylate stretching regions. Panel B shows a close-up of the symmetric carboxylate stretching region used for kinetic analysis. Labels a–e in inset refer to wavenumbers where spectral changes were observed during the aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ (Fig. 5).

in Fig. 4a. The spectra of NTA species are dominated by contributions from the infrared-active carboxylate groups and are sensitive to protonation, metal coordination, and hydrogen bonding of these groups [36]. The asymmetric stretching mode of the carboxylate group (ν^{as}_{C-O}) occurs near 1600 cm^{-1} and the symmetric modes (ν^{s}_{C-O}) occur in combination with other modes (e.g., C–H stretching modes) in the region between 1300 and 1450 cm^{-1}. Not much difference in the position of ν^{as}_{C-O} is observed for the reference compounds, and variations in the mode's intensity are difficult to interpret here because ν^{as}_{C-O} overlaps with a very strong water bending mode (δ_{H-O-H}) that is difficult to completely subtract out during background correction procedures. Thus, only the spectral region containing ν^{as}_{C-O} was used for quantitative spectral fitting and kinetic analysis.

Fig. 4b shows a close-up on the symmetric stretching region highlighted in Fig. 4a. This region shows several differences between *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ and the two reaction products that reflect changes in the average carboxylate coordination environment. At pH 7.0, free NTA has three deprotonated carboxylate groups and a single protonated bridging nitrogen that can form intramolecular hydrogen bonds with the free carboxylate groups [37]. In the Cr^{III}-coordinated state, the bridging nitrogen is not protonated and intramolecular hydrogen bonding between ligand donor groups is also prevented. Thus, changes in this region of ATR-FTIR spectra can be used to track the progress of the *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ aquation reaction (Fig. 5). A few notable spectral trends are observed during the reaction. The peak at 1393 cm^{-1} (a; letter refers to noted vertical lines in Figs. 4 and 5) blue shifts while a prominent shoulder at 1385 cm^{-1} (b) and peak at 1261 cm^{-1} (e) diminish as the reaction proceeds. At the same time, peak shoulders grow in at both 1367 cm^{-1} (c) and 1336 cm^{-1} (d). Each of these spectral changes are consistent with conversion of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ into a mixture of $[Cr^{III}(H_2O)(OH)(nta)]^{-}$ and free NTA.

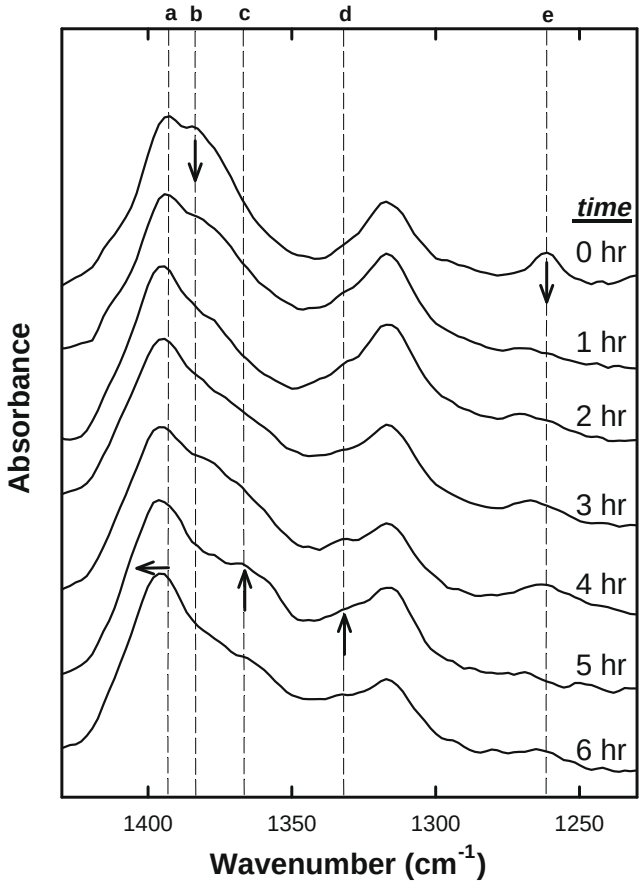

Fig. 5. Time-dependent changes in ATR-FTIR spectra of aqueous solutions initially containing 5.0 mM *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ at pH 7.0 (0.1 M NaCl). Arrows indicate direction of spectral changes during the aquation reaction. Labels a–e indicate wavenumbers at which major spectral shifts were observed and coincide with the same subscripts used in Fig. 4.

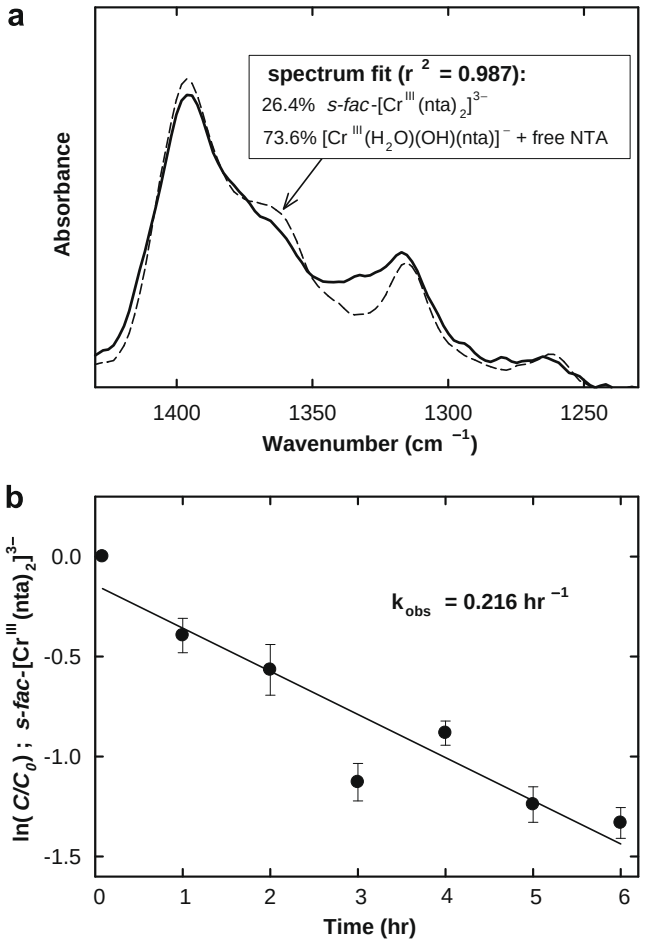

Fig. 6. (a) Comparison of experimental spectrum collected at $t = 6$ h ($C_o = 5$ mM *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, pH 7.0, 0.1 M NaCl) with a model fit-derived spectrum calculated by linear combination of reference spectra for *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, $[Cr^{III}(H_2O)(OH)(nta)]^{-}$, and free NTA shown in Fig. 4. (b) Natural log of the fraction of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ remaining vs. time and pseudo-first-order kinetic model fit. Error bars represent 95% confidence levels.

The extent of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ aquation as a function of time was quantified by fitting the observed carboxylate symmetric stretching region spectra in Fig. 5 with a linear combination of the reference spectra shown in Fig. 4b. Similar spectral fitting procedures have previously been used to characterize both homogeneous and heterogeneous kinetic processes [38,39]. Model fits were stoichiometrically constrained by assuming that dissociation of 1 mol of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ yields 1 mol each of $[Cr^{III}(H_2O)(OH)(nta)]^{-}$ and free NTA. A representative fit of the spectrum collected at $t = 6$ h is provided in Fig. 6a, showing a generally close agreement between the measured and simulated spectrum. The best fit was obtained with 73.6% aquation (that is, a linear combination of 26.4% *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ plus 73.6% $[Cr^{III}(H_2O)(OH)(nta)]^{-}$ and free NTA). It is worth noting that the fit-derived extent of aquation was not found to be significantly different when the stoichiometric constraints were removed during spectral fitting. Fig. 6b shows that decreasing concentrations of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, determined from spectral fits, followed a first-order rate law, and the k_{obs} value obtained from the slope of

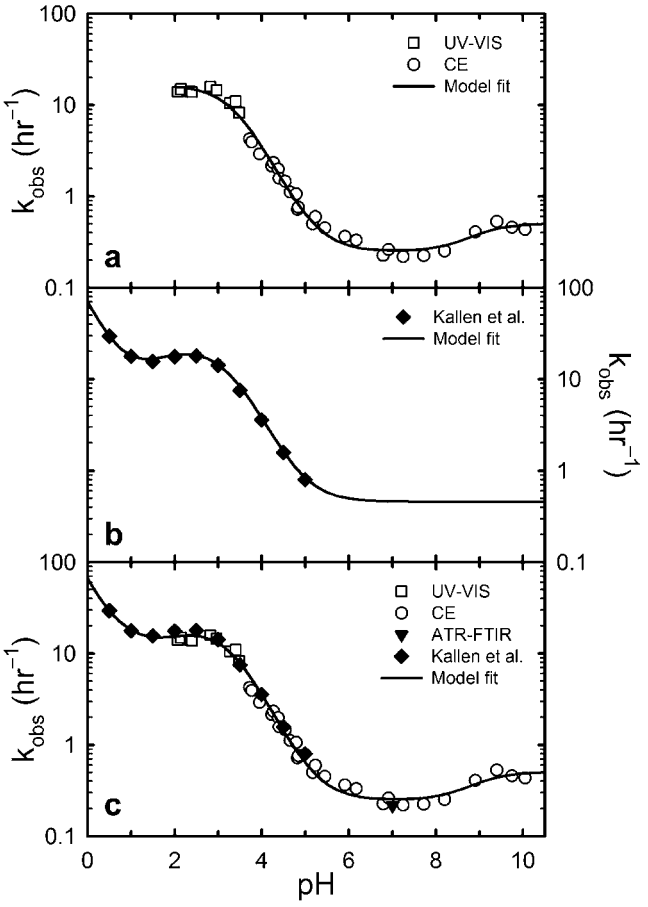

Fig. 7. Observed first-order rate constants, k_{obs}, for aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ vs. pH. In (a), CE and UV–Vis data from this study is shown with the corresponding model fit according to Eq. (15). In (b), UV–Vis data from Kallen et al. [13] is shown along with the corresponding model fit (conditions: initial [*s-fac*-$[Cr^{III}(nta)_2]^{3-}$] = 172 μM, 25 °C, I = 0.10 M). In (c) CE, UV–Vis, and ATR-FTIR data from this study and UV–Vis data from Kallen et al. is shown with the corresponding model fit according to Eq. (24).

the regression line is equal to 0.216 ± 0.090 h^{-1}. This value agrees closely with the values determined by CE at similar pH conditions (Table 1). The close agreement also indicates that the rate constant for aquation is insensitive to changes in the initial *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ concentration and solution ionic strength since both of these parameters were more than 10-fold higher in the ATR-FTIR experiments than in the CE experiments.

3.4. Modeling the k_{obs} pH dependence from CE and UV–Vis experiments

The k_{obs} values from all CE and UV–Vis experiments are shown as a function of pH in Fig. 7a. The pH dependence is complicated, exhibiting three distinct regions: (i) at pH < 6.5, k_{obs} values increased with decreasing pH, (ii) between pH 6.5 and 8.0, k_{obs} values were relatively constant, and (iii) at 8.0 < pH < 10.0, k_{obs} increased with increasing pH and then leveled off. The solid line in Fig. 7a is a model fit to the k_{obs} data, obtained as described below.

The following three reaction sequences successfully modeled the pH dependence of k_{obs} over the pH range of 2.0–10.0, and are consistent with previously proposed mechanisms for aquation of Cr^{III}–aminocarboxylate complexes [13,40]. Alternate kinetic formulations were explored but did not adequately fit the data (these will be discussed subsequently). Note that *s-fac* has been dropped for simplicity, and the product of the aquation is written as $[Cr^{III}(H_2O)_2(nta)]^0$ in all cases for consistency.

Sequence i:

$$[Cr^{III}(nta)_2]^{3-} + H^+ \underset{(fast)}{\overset{1/K_{a2}}{\rightleftharpoons}} [Cr^{III}(Hnta)(nta)]^{2-} \quad (5)$$

$$[Cr^{III}(Hnta)(nta)]^{2-} + 2H_2O \xrightarrow{k_1} [Cr^{III}(H_2O)_2(nta)]^0 + Hnta^{2-} \quad (6)$$

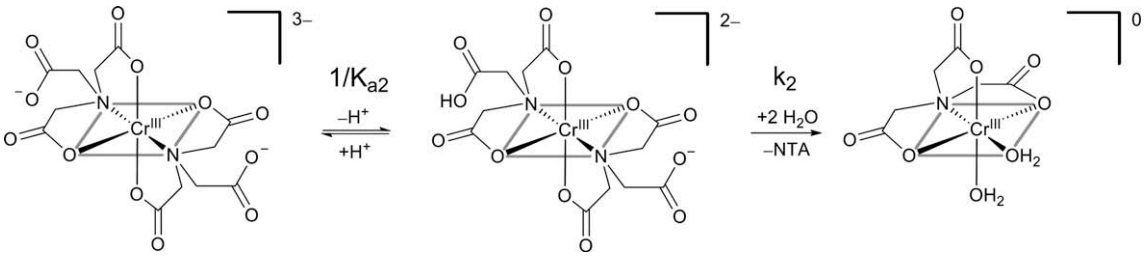
Sequence ii:

$$[Cr^{III}(nta)_2]^{3-} + 2H_2O \xrightarrow{k_2} [Cr^{III}(H_2O)_2(nta)]^0 + nta^{3-} \quad (7)$$

Sequence iii:

$$[Cr^{III}(nta)_2]^{3-} + H_2O \underset{(fast)}{\overset{K_{a3}}{\rightleftharpoons}} [Cr^{III}(OH)(nta)]^{4-} + H^+ \quad (8)$$

$$[Cr^{III}(OH)(nta)_2]^{4-} + H_2O + 2H^+ \xrightarrow{k_3} [Cr^{III}(H_2O)_2(nta)]^0 + Hnta^{2-} \quad (9)$$



In sequence (i), a reversible protonation reaction is followed by a second reaction where one NTA molecule is replaced by two water molecules. Since *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ has two carboxylate groups that are not coordinated to protons or metal ions (Fig. 1a), one or both of these are expected to protonate in mildly-acidic solution. Equilibrium between $[Cr^{III}(nta)_2]^{3-}$ and $[Cr^{III}(Hnta)(nta)]^{2-}$ is expected to be rapid, and can be described by its law of mass action:

$$K_{a2} = \frac{\left[[Cr^{III}(nta)_2]^{3-}\right][H^+]}{\left[[Cr^{III}(Hnta)(nta)]^{2-}\right]} \quad (10)$$

where K_{a2} is an acidity constant. The second reaction in sequence (i) is an overall reaction which involves exit of NTA and entry of two water molecules into the inner coordination shell of Cr^{III}. Also note that all three carboxylate groups in the complexed ligand become attached to Cr^{III} in the product. Sequence (i) is illustrated below in Scheme 1.

Entry of two water molecules and exit of NTA is expected to be much slower than the preceding protonation step since ligand exchange at the Cr^{III} central ion is involved. Since we do not know whether entry of the first or the second water is the rate limiting step, the k_1 reaction has been written as an overall reaction.

In sequence (ii), an overall reaction is shown where NTA is replaced by two water molecules, thereby forming $[Cr^{III}(H_2O)_2(nta)]^0$ and a "free" NTA molecule. The rate of aquation via sequence (ii) is

Scheme 1.

not dependent upon pH because H^+ or OH^- does not participate prior to or during the rate limiting step. Note however that the nta^{3-} will protonate in a rapid subsequent reaction step.

In sequence (iii), hydroxide ion enters the inner coordination shell of Cr^{III} thereby replacing one Lewis base group of NTA. The equilibrium can be described by its law of mass action:

$$K_{a3} = \frac{\left[[Cr^{III}(OH)(nta)_2]^{4-}\right][H^+]}{\left[[Cr^{III}(nta)_2]^{3-}\right]} \quad (11)$$

where K_{a3} is an acidity constant. The resulting $[Cr^{III}(OH)(nta)_2]^{4-}$ has one NTA molecule coordinated by only 2 Lewis base groups. In the second slower step, the NTA molecule is completely replaced by an incoming water molecule and the last remaining carboxylate group of the other NTA molecule. Sequence (iii) is illustrated below in Scheme 2.

A similar reaction mechanism has been proposed for the aquation of *s-fac*-$[Cr^{III}(ida)_2]^-$ at mildly-alkaline pH [40].

Summing the contributions of these three pathways, the rate of aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$, R (mol L^{-1} h^{-1}), becomes:

$$R = k_1\left[[Cr^{III}(Hnta)(nta)]^{2-}\right] + k_2\left[[Cr^{III}(nta)_2]^{3-}\right] + k_3\left[[Cr^{III}(OH)(nta)_2]^{4-}\right] \quad (12)$$

To simplify this result, $[Cr^{III}–NTA_2]$ was used to represent the sum of the concentrations of $[Cr^{III}(nta)_2]^{3-}$, $[Cr^{III}(Hnta)(nta)]^{2-}$ and $[Cr^{III}(OH)(nta)_2]^{4-}$:

$$\left[Cr^{III}–NTA_2\right] = \left[[Cr^{III}(Hnta)(nta)]^{2-}\right] + \left[[Cr^{III}(nta)_2]^{3-}\right] + \left[[Cr^{III}(OH)(nta)_2]^{4-}\right] \quad (13)$$

Substitution of Eqs. (10), (11), and (13) into Eq. (12) yields the following expression for the rate of aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$:

$$R = -\frac{d[Cr^{III}–NTA_2]}{dt} = \frac{k_1[H^+]^2 + k_2K_{a2}[H^+] + k_3K_{a2}K_{a3}}{[H^+]^2 + K_{a2}[H^+] + K_{a2}K_{a3}}\left[Cr^{III}–NTA_2\right] \quad (14)$$

which produces an expression for k_{obs} which is written in terms of the constants K_{a2}, K_{a3}, k_1, k_2 and k_3:

$$k_{obs} = \frac{k_1[H^+]^2 + k_2K_{a2}[H^+] + k_3K_{a2}K_{a3}}{[H^+]^2 + K_{a2}[H^+] + K_{a2}K_{a3}} \quad (15)$$

Eqs. (14) and (15) assume interconversion between the three protonation levels of Cr^{III}–NTA_2 is much faster than the aquation reactions. Values of k_{obs} therefore represent the loss of Cr^{III}–NTA_2 rather than the loss of any one individual species. Best-fit values for K_{a2}, K_{a3}, k_1, k_2 and k_3 were obtained using a SCIENTIST fit of Eq. (15) to the $\log k_{obs}$ versus pH data obtained from all three experimental methods. The resulting values of K_{a2}, K_{a3}, k_1, k_2 and k_3 are listed in Table 2 as Model 1.

Table 2
Parameters obtained from k_{obs} versus pH model fits.

Parameter	Model fit 1	Kallen et al.[a]	Model fit 2
pK_{a1}		1.87	2.16 ± 1.61
pK_{a2}	3.40 ± 0.10	3.20	3.32 ± 0.14
pK_{a3}	8.94 ± 0.96		8.94 ± 0.88
k_1 (h^{-1})	(1.64 ± 0.24) × 10^1	2.25 × 10^1	(1.91 ± 0.46) × 10^1
k_2 (h^{-1})	(2.48 ± 0.36) × 10^{-1}	4.61 × 10^{-1}	(2.47 ± 0.32) × 10^{-1}
k_3 (h^{-1})	(5.08 ± 0.15) × 10^{-1}		(5.08 ± 0.14) × 10^{-1}
k_4 (h^{-1})		1.10 × 10^1	(1.26 ± 0.74) × 10^1
k_5 (L mol^{-1} h^{-1})		5.98 × 10^1	(5.38 ± 4.49) × 10^1

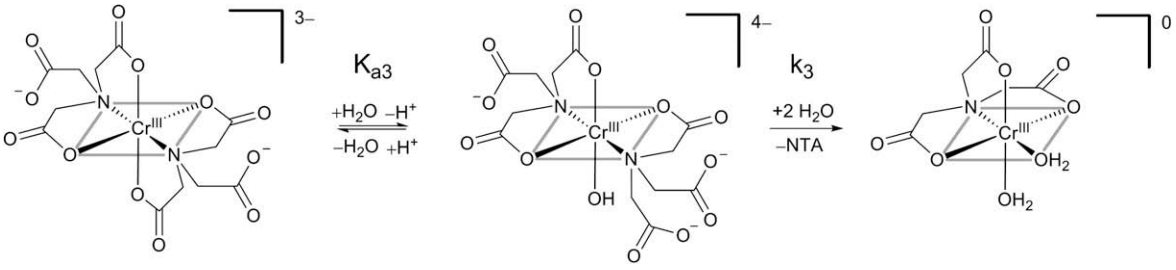
[a] In Kallen et al. [13], different notation is employed: $K_{a1} = 1/K_1$, $K_{a2} = 1/K_2$, $k_1 = k_4$, $k_2 = k_1$, $k_4 = k_5$, $k_5 = k_H$.

Kinetic schemes where either H^+ or OH^- appear as a reactant often result in a first-order dependence of the reaction rate with respect to these solution constituents. Kinetic models which involve such functional dependences could not reproduce the pH dependence of k_{obs} values in either region (i) or (iii). Since the concentration of H^+ increases by a factor of 10 for every unit decrease in pH, k_{obs} would need to show a similar increase if a reaction sequence was first-order with respect to $[H^+]$. Likewise with OH^-, a unit increase in pH increases $[OH^-]$ by a factor of 10 which would result in a similar increase in k_{obs}. A first-order dependence on $[OH^-]$ is clearly not present in the data as there is a clear leveling out of the value of k_{obs} that occurs at 9.0 < pH < 10.0.

3.5. Modeling the k_{obs} pH dependence using data from Kallen et al.

Observed rate constants for aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ are available at 25 °C and 1.0 M ionic strength for 0.0 < pH < 5.0 from the UV–Vis kinetic study of Kallen et al. [13]. In their work, observed first-order rate constants showed a unique pH dependence where k_{obs} values increased with decreasing pH, leveled off and then increased again (diamonds, Fig. 7b). The reaction sequence proposed by these authors to explain this pH dependence is compatible with the sequence proposed in this work and is described below.

At low pH, *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ is proposed to undergo two successive protonation steps, whereby each uncoordinated carboxylate group of NTA is protonated [13]:



$$[Cr^{III}(nta)_2]^{3-} \overset{1/K_{a2}+H^+}{\underset{-H^+}{\rightleftharpoons}} [Cr^{III}(Hnta)(nta)]^{2-} \overset{1/K_{a1}+H^+}{\underset{-H^+}{\rightleftharpoons}} [Cr^{III}(Hnta)_2]^- \quad (16)$$

The $[Cr^{III}(Hnta)_2]^-$ which results from the second protonation step was proposed to aquate at its own characteristic rate to form Cr^{III}–NTA (Sequence iv):

Sequence iv:

$$[Cr^{III}(nta)_2]^{3-} + 2H^+ \rightleftharpoons [Cr^{III}(Hnta)_2]^- \quad (17)$$

$$[Cr^{III}(Hnta)_2]^- + 2H_2O \overset{k_4}{\rightarrow} [Cr^{III}(H_2O)_2(nta)]^0 + Hnta^{2-} + H^+ \quad (18)$$

Scheme 2.

This sequence alone, however, did not fully explain the pH dependence shown in the k_{obs} data [13]. Therefore, the following acid-catalyzed aquation of $[Cr^{III}(Hnta)_2]^-$ was proposed (Sequence v):

Sequence v:

$$[Cr^{III}(nta)_2]^{3-} + 2H^+ \rightleftharpoons [Cr^{III}(Hnta)_2]^- \quad (19)$$

$$[Cr^{III}(Hnta)_2]^- + H^+ + H_2O \xrightarrow{k_5} [Cr^{III}(H_2O)(Hnta)(H_2nta)]^0 \quad (20)$$

$$[Cr^{III}(H_2O)(Hnta)(H_2nta)]^0 + H_2O \xrightarrow{(fast)} [Cr^{III}(H_2O)_2(nta)]^0 + H_2nta^- + H^+ \quad (21)$$

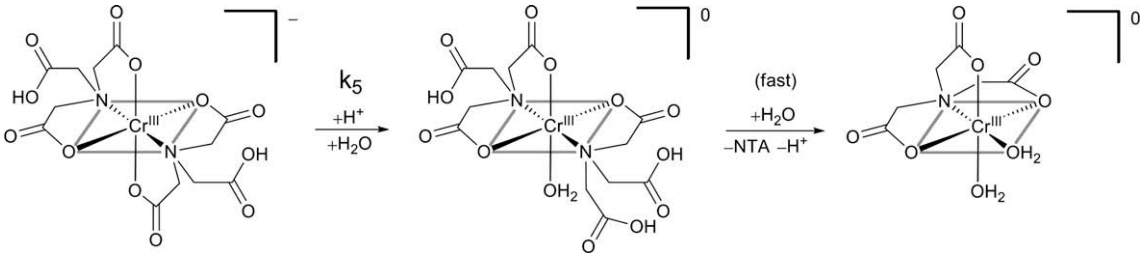
The reaction shown as Eq. (20) involves exit of a carboxylate group of NTA from the inner coordination shell of Cr^{III}, and entry of a water molecule. This is followed by rapid entry of a second water molecule, exit of one NTA molecule and full attachment of the other NTA molecule. Sequence (v) is illustrated below in Scheme 3:

The solid line shown in Fig. 7b is a SCIENTIST simulation of k_{obs} versus pH using the rate constants and model of Kallen et al. [13] given in Table 2.

Inclusion of Eqs. (17)–(21) into our previously described kinetic model yields five distinct pathways for aquation of Cr^{III}–NTA_2:

$$R = k_1\left[[Cr^{III}(Hnta)(nta)]^{2-}\right] + k_2\left[[Cr^{III}(nta)_2]^{3-}\right] + k_3\left[[Cr^{III}(OH)(nta)_2]^{4-}\right] + k_4\left[[Cr^{III}(Hnta)_2]^-\right] + k_5\left[[Cr^{III}(Hnta)_2]^-\right][H^+] \quad (22)$$

To incorporate the contributions of sequences (iv) and (v) to the rate law, we allow $[Cr^{III}$–$NTA_2]$ to represent the sum of the concentrations of $[Cr^{III}(Hnta)_2]^-$, $[Cr^{III}(Hnta)(nta)]^{2-}$, $[Cr^{III}(nta)_2]^{3-}$, and $[Cr^{III}(OH)(nta)_2]^{4-}$, and substitute the mass action laws corresponding to K_{a1}, K_{a2}, and K_{a3}. The rate of aquation of Cr^{III}–NTA_2 becomes:



$$R = \frac{k_5[H^+]^4 + k_4[H^+]^3 + k_1K_{a1}[H^+]^2 + k_2K_{a1}K_{a2}[H^+] + k_3K_{a1}K_{a2}K_{a3}}{[H^+]^3 + K_{a1}[H^+]^2 + K_{a1}K_{a2}[H^+] + K_{a1}K_{a2}K_{a3}} \times [Cr^{III}\text{—}NTA_2] \quad (23)$$

which yields an observed first-order rate constant written in terms of K_{a1}, K_{a2} K_{a3}, k_1, k_2, k_3, k_4, and k_5:

$$k_{obs} = \frac{k_5[H^+]^4 + k_4[H^+]^3 + k_1K_{a1}[H^+]^2 + k_2K_{a1}K_{a2}[H^+] + k_3K_{a1}K_{a2}K_{a3}}{[H^+]^3 + K_{a1}[H^+]^2 + K_{a1}K_{a2}[H^+] + K_{a1}K_{a2}K_{a3}} \quad (24)$$

This result is similar to that derived by Kallen et al. [13] with the exception that it includes the contribution of $[Cr^{III}(OH)(nta)]^{4-}$ to the overall rate of aquation. Using the CE, UV–Vis, and ATR-FTIR data generated as part of this study, along with the values measured by Kallen et al. using UV–Vis, a global fit of the k_{obs} versus pH data to Eq. (24) was performed using SCIENTIST. The model fit is shown as the solid line in Fig. 7c. The best-fit values for the three equilibrium constants and five rate constants are shown in Table 2 under Model 2.

Our values for k_{obs} measured with UV–Vis, CE, and ATR-FTIR, supplemented by those of Kallen et al. [13], provide a clear picture

Scheme 3.

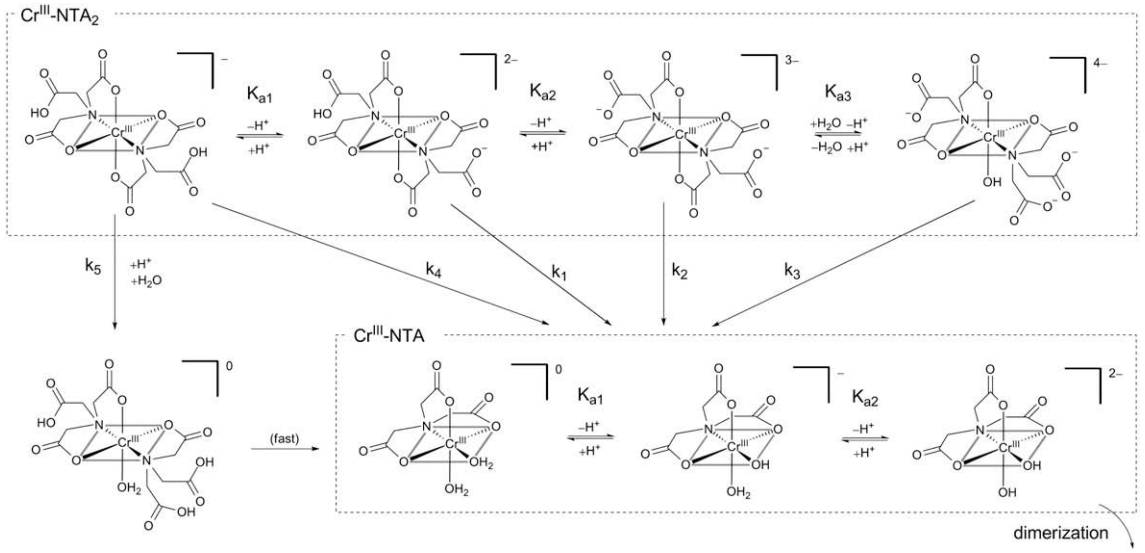


Fig. 8. Proposed kinetic scheme for aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ for $0.0 \leqslant pH \leqslant 10.0$. Species enclosed in dashed lines are assumed to interconvert rapidly compared to the time scale of aquation.

of the pH dependence of the aquation reaction. These three methods use different initial concentrations of the complex (and different ionic strengths), but k_{obs} values fall nearly on top of one another, and are well replicated by the model line produced from Eq. (24). This fact provides evidence that the observed reaction rate constants are not sensitive to the concentration of the 1:2 complex within the concentration range investigated. This is expected because the reaction is first-order with respect to Cr^{III}–NTA_2. Rate constants obtained by CE are biased low when compared to those reported by Kallen et al. [13] indicating a small ionic strength effect. Model parameters (pK_a values and rate constants) determined from the kinetic models are very similar to one another (Table 2) because of the consistency of the k_{obs} values with those of Kallen et al. [13]. The only large discrepancy is in the value of k_2 (0.461 versus 0.247 h^{-1}). Our k_2 value was fit utilizing k_{obs} values measured by CE at pH values over the entire pH range (Fig. 7c), and therefore provides a better estimate of this parameter.

A visual illustration of the full proposed reaction scheme is shown in Fig. 8. Dashed lines are used to indicate reactions which involve rapid interconversion of either Cr^{III}–NTA_2 or Cr^{III}–NTA. Also indicated on the scheme is an arrow for dimerization of Cr^{III}–NTA to form *trans*-$[Cr_2^{III}(\mu\text{-}OH)_2(nta)_2]^{2-}$. The intermediate product of the acid-catalyzed aquation (Eq. (18)), $[Cr^{III}(H_2O)(Hnta)(H_2nta)]^0$, is indicated with the coordinated water molecule axial to the two nitrogen Lewis base groups. A non-equivalent structure could have been drawn with the coordinated water equatorial to the nitrogen groups. Both of these structures are possible intermediates, but formation of only one was included in the kinetic model for simplicity. Kallen et al. [13] uses the same structure for this intermediate, but does not discuss possibilities for alternate structures.

4. Conclusion

The rate of aquation of *s-fac*-$[Cr^{III}(nta)_2]^{3-}$ and its related forms to produce Cr^{III}–NTA was successfully monitored using a combination of CE and ATR-FTIR. This work is the first published report of the use of either technique to monitor the kinetics of such reactions. Observed first-order rate constants obtained from these techniques were remarkably consistent with those obtained using traditional UV–Vis spectrophotometry. This indicates that CE and ATR-FTIR are viable tools for monitoring Cr^{III} ligand exchange reactions.

As discussed earlier, ligand exchange rates of inorganic Cr^{III} complexes generally increase with increasing pH due to the labilizing effect of coordinated hydroxide ion. For aquation of Cr^{III}–NTA_2, the opposite pH dependence is observed, and the lowest aquation rates occur at circum-neutral pH. This is potentially important for environmental systems (i.e. groundwater, surface water, sediments), which are usually buffered in this same region. In such systems, Cr^{III} speciation in the presence of aminocarboxylate chelating agents may be under kinetic rather than equilibrium control as a result of slow ligand exchange kinetics.

Inorganic chemists have long used substitution-inert metal complexes to gather information about ligand exchange mechanisms and trends in chemical reactivity. In this relatively simple system containing a monomeric Cr-^{III} complex, five rate constants and three equilibrium constants were required to describe the pH dependence of aquation. In natural aquatic environments, there are other ligands (both organic and inorganic) and surfaces present which greatly increases the number of potential ligand exchange reactions that can occur. Which reactions control ligand exchange rates in these more complicated systems? Can we make accurate predictions of ligand exchange rates in natural systems using kinetic models developed from laboratory systems?

We do not have the answers to these questions for many important ligand exchange processes occurring in aqueous solution and at mineral–water interfaces. To begin to answer these questions for processes of environmental interest, it is beneficial to start with well-constrained systems. Knowledge of the acid–base chemistry and structure of the parent complex is required to propose well-supported reaction mechanisms and kinetic models. Metals which exhibit slow ligand exchange kinetics are better suited for study because there are more tools available for observing changes in metal ion speciation during experiments.

ABSTRACT

Oxo/hydoxo zirconium(IV) complex of the general formula $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ has been isolated, when $Zr(O^iPr)_4$ reacted with a 2-fold excess of 3,3-dimethylbutyric acid. Single crystal X-ray diffraction data, collected at 103 and 153 K, showed that the studied compound crystallizes in hexagonal system ($P6_3/m$ (no. 176)). Structure consists of dimers composed of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9]$ sub-units, linked by six μ_2-OH bridges. Infrared spectroscopic studies proved the presence of hydroxo groups in the structure of studied clusters and formation of different types of oxo/hydroxo bridges. The application of variable temperature infrared spectroscopy and differential scanning calorimetry revealed that the structure of this complex undergoes the phase transitions at 143–183 and 203–293 K. Comparison of spectral and crystallographic data suggests that these phase transitions might be related to changes in the strength of Zr–O bonds of μ_2-OH bridges linking complex sub-units, and change in symmetry of the crystal lattice (from hexagonal to trigonal). Analysis of thermogravimetric data showed that decomposition of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ proceeds with complete conversion to ZrO_2 (monoclinic form) between 603 and 803 K.

1. Introduction

Synthesis, structure, and properties of zirconium oxo clusters have been studied extensively in a search of the novel types of hybrid materials having interesting optical, magnetic, and catalytic properties [1–5]. Recently Kickelbick, Schubert et al. have described syntheses and crystal structures of the group of multinuclear Ti(IV) and Zr(IV) oxo acrylate or methacrylate derivatives, which were efficiently used as sol–gel precursors in the fabrication of organic–inorganic materials [6–8]. According to these reports, the reaction of Zr(IV) isopropoxides with corresponding organic acids, using a molar ratio 1:4 and 1:16, respectively, leads to the formation of carboxylate derivatives of general formulas $[Zr_6(OH)_4O_4(OMc)_{12}]$ or $[Zr_4O_2(OMc)_{12}]$ [6–8]. In the structure of $[Zr_6(OH)_4O_4(OMc)_{12}]$, zirconium atoms (coordination number 8) form hexanuclear cores with μ_3-oxo and μ_3-hydroxo bridges, which are stabilized by 12 methacrylate ligands. Three carboxylate ligands form the chelate interactions with Zr(IV) atoms, while other nine participate in *syn–syn* bridges. The reaction of $Zr(O^iPr)_4$ with a 6.5-fold excess of acrylic acid, under the same conditions, proceeds with a formation of approximately 1:3 mixture of an amorphous powder and crystals [8]. The X-ray structural studies revealed the formation of dimers, composed of two $[Zr_6(OH)_4O_4(OAcr)_{12}]$ units linked by four carboxylate bridges. Zr(IV) compounds, also formed by two multinuclear Zr(IV) sub-units linked by alkoxide bridges, were synthesized in the reaction of $Zr(O^nBu)_4$ with 1.6 equiv. of methacrylic acid [9]. The use of ~16-fold excess of the methacrylic acid led to the formation of $[Zr_4O_2(OMc)_{12}]$ [6]. Literature reports concerning oxo zirconate acrylate or methacrylate derivatives, suggest that the type of the formed cluster depends on (a) the $M(OR)_4$/HOOCR′ ratio and (b) the kind of OR groups [9]. The application of sterically diverse carboxylic acids (HOOCR′; R′ = H, CH_3, ^{i}Pr, ^{t}Bu, $CH_2{}^t$Bu) in the reaction with zirconium(IV) isopropoxide ($[Zr(O^iPr)_4 \cdot HO^iPr]_2$, molar ratio 1:1) leads to the formation of the following products: $[Zr_4O_2(O_2CH)_2(O^iPr)_{10}]$, $[Zr_3O(O_2CCH_3)_5(O^iPr)_5]$, $[Zr_2(O^iPr)_6(O_2C^iPr)_2]_2$, $[Zr_2O(O_2C^tBu)(O^iPr)_7](HO^iPr)_2$, $[Zr_2O(O_2CH_2{}^tBu)_2(O^iPr)_6](HO^iPr)$ [10]. The use of the 2-fold excess of organic branched acids (HOOCR′; R′ = ^{t}Bu, $C(CH_3)_2Et$) in the above reaction results in a formation of $[Zr_6(OH)_4O_4(OOCR')_{12}]$ (R′ = ^{t}Bu, $C(CH_3)_2Et$) clusters [11]. Also in this case, the hexanuclear zirconium core was linked by four μ_3-oxo and four μ_3-hydroxo bridges and stabilized by 12 carboxylate *syn–syn* bridges. Simultaneously, spectroscopic studies revealed that the more complicated type of multinuclear Zr(IV) oxo clusters was formed during the 1:2 reaction of $Zr(O^iPr)_4$ with $HOOCCH_2{}^tBu$ [11]. Although the stability of single crystals at room temperature was sufficient, their crystal structure has not been solved. Therefore, the aim of the presented paper is the structural and spectral characterization of the multinuclear Zr(IV) oxo

carboxylate derivatives, obtained in a reaction of $Zr(O^iPr)_4$ with 2-fold excess of 3,3-dimethylbutyric acid under the inert atmosphere.

2. Results and discussion

2.1. Synthesis and spectral characterization

The studied complex was obtained in the 1:2 reaction of the zirconium isopropoxide ($Zr(O^iPr)_4$, with 3,3-dimethylbutyric acid under Ar atmosphere at room temperature. The colorless crystals were isolated by slow evaporation (glovebox) of the solvent after 1 day. The general formula defined on the basis of the elemental analysis is $Zr_6O_{29}C_{54}H_{103}$, suggesting the possible formation of a similar type of cluster as described for $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCR')_{12}]$ ($R' = {}^t$Bu, $C(CH_3)_2Et$). However, the clear differences between IR spectra of synthesized compound and those reported in [11] indicate the formation of different type of structure (Fig. 1).

The synthesized complex has been characterized by multinuclear NMR spectroscopy in the solid phase and solution ([D_6] benzene) and chemical shifts of the resonance signals are listed in Table 1. The coordination effects were studied mainly as a result of the chemical shift of resonance signals descended from carbon atoms of carboxylate ligands. Three resonance signals attributed to carbon atoms of COO group were found at δ = 174.7, 178.1, and 179.4 ppm (Table 1). Coordination of carboxylate groups caused the shift of resonance signals towards lower fields in comparison to the spectrum of 3,3-dimethylbutyric acid (δ (COO) = 179.9 ppm). Simultaneously, analysis of chemical shifts of carboxylate carbon in spectra of dimeric complex and $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCR')_{12}]$ ($R' = {}^t$Bu, δ = 184.5, 183.9 ppm, $C(CH_3)_2Et$), δ = 184.3, 183.9 ppm [11]) reveals that the shift of the resonance signals of COO group is significantly influenced by the type of the carboxylate ligand. Moreover, splitting of the resonance signals of carboxylate atoms suggests that carboxylate ligands form non-equivalent interactions with zirconium ions of $[Zr_6\text{-}(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4]$ cores.

Analysis of ^{13}C NMR data, registered in [D_6] benzene solution (Table 1) revealed no significant difference in chemical shifts of resonance signals attributed to the methyl, methylene, and buthyl moiety of the $-CH_2C(CH_3)_3$ group. Simultaneously, only a single peak assigned as the COO group (δ = 179.0 ppm) has been found. This indicates that the stable and highly symmetrical molecules of the synthesized complex exist also in solution.

Table 1
Results of NMR studies of compound synthesized in the reaction $Zr(O^iPr)_4$ with $HOOCCH_2{}^t$Bu, reported in this paper.

Method	δ (ppm)			
	CH_2	CH_3 (^{t}Bu)	C (^{t}Bu)	C (COO)
^{13}C–s.st	50.6	30.3	43.5	179.4 178.1 174.7
$^{13}C\text{–}C_6D_6$	50.7	30.2		179.0
$^{1}H\text{–}C_6D_6$	2.3	1.5		

The XRD patterns, collected one week and one month after crystallization, proved the high stability of crystalline powders stored at room temperature on the air. The obtained compound was insoluble in aliphatic and sparingly soluble in aromatic solvents.

2.2. Description of the structures

Multiple attempts to determine the X-ray crystal structure at room temperature showed that the studied compound crystallized in the trigonal space group *P*3 (no. 143). Although X-ray diffraction measurements at room temperature have been carried out for numerous crystals, their structure has not been solved due to the poor data quality. Therefore, the low temperature measurements at 103 K and 153 K have been carried out. The details of the X-ray analysis are listed in Table 2, selected bond lengths and angles are listed in Table 3.

Low temperature X-ray crystal structure determination revealed that the studied compound crystallizes in the hexagonal system ($P6_3/m$). Its structure consists of dimers composed of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCR')_9]$ sub-units, linked by six oxygen bridges (Fig. 2). Average distances between Zr–Zr atoms, within the sub-unit are 3.56 Å and between neighboring units are 3.58 Å at 103 K and 3.57 Å at 153 K. Simultaneously, these distances are slightly larger than analogous average distances within

$[Zr_6(OH)_4O_4]$ core of $[Zr_6(OH)_4O_4(OMc)_{12}]_2$ (3.52 Å [8]). All zirconium atoms in the structure of $[Zr_6O_4(OH)_4(OOCCH_2{}^tBu)_9]$ are eight-coordinate and form two types of surroundings. The $[Zr1O_8]$ polyhedra consist of four oxygen μ_3-O bridges, formed by oxo/hydoxo ligands, and four μ-O of carboxylato ones, whereas $[Zr2O_8]$ are formed by two oxygen atoms of μ_3-O (O/OH), four μ-O (OOC), and two μ_2-O of O/OH bridges (Table 2).

The localization of hydrogen atoms in the zirconium-oxide of dimers core was not possible on the basis of obtained X-ray diffraction data. However, the charge balance requires the presence of hydroxo groups (that problem is also discussed in the next part of this paper, where the IR spectroscopy results are analyzed). Significant differences in Zr–O distances of μ_3-O bridges suggest that oxo and hydroxo bridges can be identified on the basis of this criterion. Analysis of X-ray data, collected at 103 K (Table 2), revealed the formation of four types of μ_3-O bridges per sub-unit (1 × O1, 3 × O2, 1 × O6, and 3 × O3). Short distances between O2 and Zr1, $Zr1^{ii}$, $Zr2^{ii}$ atoms (Zr–O2, 2.044(11)–2.062(12) Å) indicate the formation of μ_3-O bridges [6]. In contrast, O3 is asymmetrically bonded and forms three longer Zr–O bonds, two of them are significantly shorter (2.256(12) and 2.255(11) Å) than the third one (2.327(11) Å). According to previous reports, this type of interactions has been assigned to μ_3-OH bridges [6]. The symmetrical location of oxygen atoms is also observed in bridges formed by O1 (2.242(7)–2.244(7) Å) and O6 (2.189(4) Å). Judged from the length of metal–oxide bonds, bridges formed by O1 can be attributed to μ_3-OH bridges, while the O6 to μ_3-O bridges (Table 2). The electrostatic compensation requires the presence of 14 hydroxo groups in the studied complex. Therefore, bridges formed by O4 and O5 atoms should also correspond to μ_2-OH ligands. Considering these data, the neutral sub-unit cluster should be built with 4:4 systems of oxo/hydroxo bridges, linked by 6 μ_2-OH bridges ($[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2Bu^t)_9(\mu_2\text{-}OH)_3)]_2$). According to data presented in Table 2, carboxylate ligands form two types of bridges. In one of them no significant differences in the length of Zr–O bonds were observed (Zr1–O61, 2.226(13) and $Zr1^{i}$–O62, 2.246(12) Å), while in the second type (asymmetric bridge) the shorter Zr–O bonds Zr1–O72, 2.176(12), $Zr1^{i}$–O82, 2.169(16) Å, and longer bonds Zr2–O81, 2.220(14), Zr2–O71, 2.233(9) Å were observed.

Analysis of data presented in Table 3 revealed that no significant differences were observed in the crystal system and unit cell parameters of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ between 103 and 153 K. Moreover, the comparison of the average Zr–Zr distances within $Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4$ cores suggests the lack of significant differences in geometry of clusters at 103 and 153 K. The noticeable differences in the structure of this complex were detected, when the length of Zr–O distances and Zr–O–Zr angles of μ_2-OH bridges were compared at both temperatures. At 103 K, similar values of analogous Zr–O distances (Zr2–O4 = 2.174(6) Å and Zr2–O5 2.173(8) Å) and Zr–O–Zr, O–Zr–O angles (Zr2–O4/5–Zr2 = 110.78(6)° and 110.87(6)°, O4–Zr2–O5 = 66.49(4)°) prove the formation of symmetrical μ_2-OH bridges linking two sub-units. Increase of the temperature up to 153 K causes the clear changes both in the Zr–O bond distances (Zr2–O5 = 2.150(7) Å; Zr2–O4 = 2.169(7) Å) and Zr–O–Zr, O–Zr–O angles (Zr2–O4/5–Zr2 110.7(4)° and 112.2(5)°, O5–Zr2–O4 = 65.2(4)°) of μ_2-OH bridges. These changes influenced also values of dihedral angle between Zr2–O4–Zr2 (x, y, $-z + 1/2$) and Zr2–O5–Zr2 (x, y, $-z + 1/2$) planes being 30.11(0.86)° and 33.57(0.84)° for 103 and 153 K models, respectively. Moreover, the differences in the Zr–O distances of Zr2 coordination sphere were also found (Table 3). Results of these investigations show that the decrease of the strength of metal–oxide bonds in μ_2-OH bridges, linking $[Zr_6O_4(OH)_4(OOCR')_9]$ sub-units is the main effect associated with the temperature increase.

2.3. Analysis of infrared spectra

IR spectroscopy analysis has been carried out in order to detect the hydroxide groups in the structure of the complex, as well as to determine the nature of μ_2-O bridges linking $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCR')_9]$ sub-units. IR spectra were registered between 103 and 293 K to study influence of the temperature increase on the structure of the synthesized complex. Results of spectroscopic investigations are presented in Table 4.

Detection of the band at 3668 cm^{-1}, which was attributed to stretching ν(OH) band, explicitly confirms the presence of hydroxo groups in the structure of the studied complex. According to literature data, the position of the ν(OH) band at higher wavenumbers indicates that OH groups are not involved in hydrogen bonds [11–13]. Only slight changes of ν(OH) motions, which were found in spectra registered at 293 and 103 K, indicate the high stability of hydroxo ligands in the zirconium oxo/hydroxo clusters. Simultaneously analysis of ν(OH) band shape using curve fit method, revealed the slight splitting of this band in the spectrum registered at ~103 K (Fig. 3). This effect can be explained by the presence of nonequivalent hydroxo groups in the complex molecule, resulting in the formation of μ_3-OH and μ_2-OH bridges in the molecule of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$.

Bands attributed to ν_{as}(COO) and ν_s(COO) vibrations have been detected at 1572 cm^{-1} and 1426 cm^{-1} in spectra registered at 298 K (Table 4). Values of the $\Delta\nu[\nu_{as}(COO) - \nu_s(COO)]$ parameter, being 146 cm^{-1}, is characteristic for bidendate carboxylate groups participating in *syn–syn* bridges [13,17]. Single bands, descended from asymmetric and symmetric vibrations, indicate the lack of significant differences in the strength of carboxylate groups interaction in $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9]$ sub-unit. Splitting of bands descended from OCO bending and rocking vibrations can result from the asymmetry of carboxylate ligand interactions in *syn–syn* bridges. The slight changes in the way of OOC groups interaction with zirconium atoms with increase of temperature

Symmetry codes: For structures determined at 103 K and 153 K – (i) $1-y, 1+x-y, z$; (ii) $-x+y, 1-x, z$; (iii) $x, y, 0.5-z$.

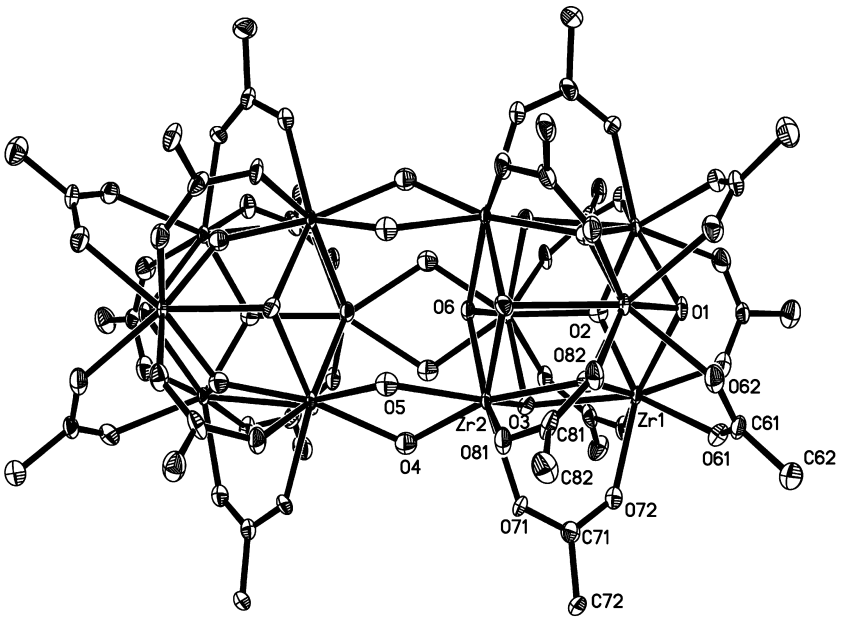

Fig. 2. The zirconium-oxide/hydroxide core of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$. For clarity, the thermal ellipsoid are plotted at 30% probability, and $CH_2{}^tBu$ groups are omitted. The numbering scheme of the asymmetric unit is identical for both structures reported in the paper. The molecule symmetry includes the 3-fold axis and the center of symmetry. Therefore the alternating OH groups bridging two halves of the complex are labeled O4 and O5.

(Table 3) explain the minor differences in spectra registered between 103 and 293 K (Table 4).

The bands corresponding to vibrations of OH groups and Zr–(μ_3-O/OH), Zr–(μ_2-O/OH) bridges were detected between 400 and 1000 cm^{-1} [14–16]. The medium intensity band, which can be assigned to stretching vibrations of metal–oxide/hydroxide bridges (Zr–O/OH–Zr), has been found at 707 cm^{-1} (293 K). In comparison to IR data of $[Zr_6O_4(OH)_4(OOCR')_{12}]$ (R = ^{t}Bu, $C(CH_3)_2Et$), frequency of this band is shifted towards lower wavenumbers (R = $C(CH_3)_2Et$, ν(Zr–O/OH–Zr) = 724 cm^{-1}, R = ^{t}Bu, ν(Zr–O/OH–Zr) = 728 cm^{-1}) [13]. The restrictions of proton migration between oxygen bridges at liquid nitrogen temperature (LNT) and the formation of non-equivalent Zr–(μ_3-O/OH) and Zr–(μ_2-OH) bridges contribute to the splitting of ν(Zr–O–Zr) bands in the spectrum registered at 103 K (Table 4). The splitting of this band decreases at higher temperatures and in the spectrum registered at room temperature the components at 707 and 715 cm^{-1} were observed. The study of the dependencies between integral intensity of ν(OH) and ν_{as}(Zr(O/OH)Zr) bands versus temperature revealed the possible phase transitions in the structure of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ at 143–183 K and 203–293 K (Fig. 4) [18]. Considering crystallographic data, the above phase transitions can be coupled to the changes in the strength of Zr–O bonds in μ_2-OH bridges linking $[Zr_6O_4(OH)_4(OOCR')_9]$ sub-units (143–183 K) and the transition of

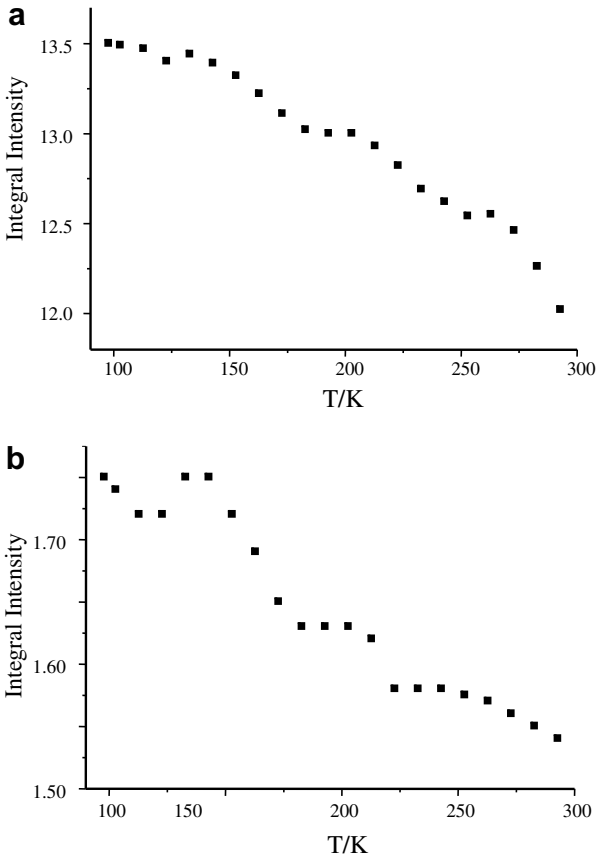

Fig. 4. Variation of the integral intensity of (a) ν(OH) and (b) ν(Zr–O/OH–Zr) bands versus temperature.

crystal system from the hexagonal (stable at 103–203 K) to the trigonal one detected at 293 K. The phase transitions in the structure of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ have been also studied using the DSC method (Fig. 5). The obtained results show the phase transition in the structure of this complex at 165 K. However, another phase transition was observed at 189 K, The course of the diagrams presented in Fig. 4 and DSC results indicate the high instability of crystal structure of studied complex between 143 and 293 K. It can be caused by the changes in the strength of Zr–O bonds of μ_2-OH bridges linking $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9]$ sub-units, as confirmed by the crystal structures reported in this paper.

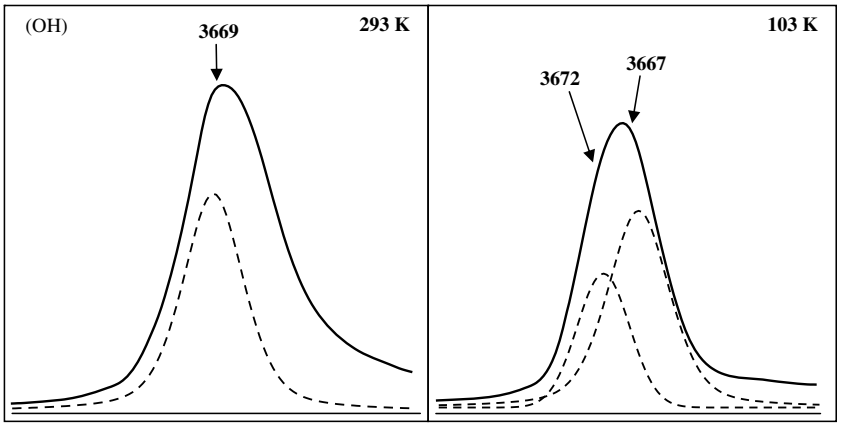

Fig. 3. Curve fit of the band corresponding to the stretching vibrations of OH groups.

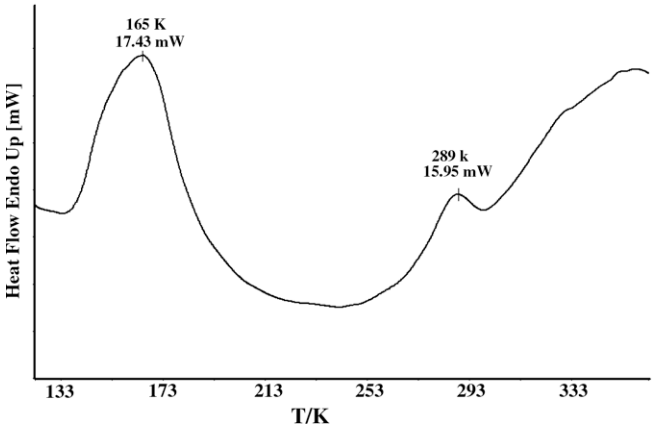

Fig. 5. Results of DSC studies of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2Bu^t)_9(OH)_3]_2$.

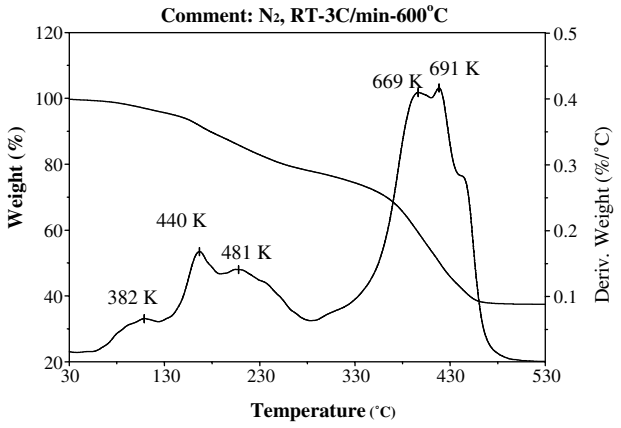

Fig. 6. Thermal analysis of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(OH)_3]_2$.

2.4. Thermogravimetric analysis

Thermal behavior of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ was studied using thermogravimetric methods (TGA/DTA) over the temperature range 303–803 K (Fig. 6). Five endothermic steps, with maxima at 382, 440, 481, 669 and 691 K have been detected during the thermolysis of this compound. The weight loss of 63.6% indicates that decomposition of this compound proceeds with complete conversion to ZrO_2 (calculated weight loss 64.1%) in the whole temperature range. It is interesting that the temperature of complete decomposition of dimeric complex is significantly lower than that for $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCR')_{12}]$, which was 742 and 783 K for R′ = ^{t}Bu and C(CH$_3$)$_2$Et, respectively [11]. The formation of ZrO_2 as the main decomposition product of the studied compound has been confirmed using X-ray diffraction (XRD) methods. Analysis of XRD data proved the formation of the monoclinic form of ZrO_2 (literature reports [19]: 28.18 ($\bar{1}11$), 31.47 (111), 34.16 (002), 34.42 (020), 35.31 (200), 49.27 (022), 50.12 (220), found: 28.18 ($\bar{1}11$), 31.46 (111), 34.15 (002), 34.42 (020), 35.30 (200), 49.30 (022), 50.12 (220)).

3. Conclusions

Dimeric hexanuclear zirconium(IV) oxo/hydroxo carboxylato complex, of general formula $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ has been synthesized in a reaction of Zr(O^{i}Pr)$_4$ with 3,3-dimethylbutyric acid in a molar ratio 1:2. The low temperature crystal structures of this compound were solved with X-ray diffraction data collected at 103 and 153 K. Analysis of X-ray data exhibits that the complex crystallizes in hexagonal system. At the investigated temperature range, the structure of this complex is composed from the $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4]_2(\mu_2\text{-}OH)_6$ core, stabilized by 18 *syn–syn* bidendate carboxylate ligand bridges. The cluster geometry does not change significantly with temperature, at which the experiments were conducted. The linkage of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9]$ sub-units by six μ_2-OH bridges leads to the formation the dimeric structure of this complex. Comparison of the crystallographic data collected at 103 and 153 K revealed the significant differences in the strength of Zr–O bonds involving μ_2-OH bridges. The phase transitions in the structure of this complex have been detected at 143–183 K and 203–293 K using VT IR spectroscopy and DSC methods. Comparison of spectral and crystallographic data suggests that changes in the strength of Zr–O bonds formed by μ_2-OH bridges and the transformation from hexagonal (103–203 K) to trigonal symmetry (observed at 293 K) are the main factors affecting the structural stability of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$. TGA/DTA studies have shown that thermal decomposition of this complex proceeds with formation of ZrO_2 monoclinic form between 382 and 703 K.

4. Experimental

4.1. Materials and physical measurement

The employed reagents ($[Zr(O^iPr)_4 \cdot HO^iPr]_2$ and $CH_2{}^tBuCOOH$) were commercially available and used as received without further purification. Studied compounds were synthesized at room temperature under argon atmosphere, using standard Schlenk line and glovebox techniques. The reactions were carried in the 1:1 mixture of *n*-hexane and *i*-propanol used as a solvent. Solvents applied in the synthesis of this complex were freshly distilled and stored over the molecular sieves in the inert gas atmosphere. Infrared (IR) spectra were recorded on Perkin Elmer Spectrum 2000 spectrometer within range 400–4000 cm^{-1} with a medium slit width and peak resolution of 4.0 cm^{-1}. The samples of analyzed compounds were studied as a powder dispersed in a KBr pellet. Variable temperature IR spectra were registered between 98 K and 353 K using the SPECAC variable temperature cell. Solid-state ^{13}C NMR spectra were registered on Bruker AMX 300. The solution ^{1}H and ^{13}C NMR spectra ([D$_6$]-benzene) were recorded using a 5 mm solution probe on Varian Gemini 200. Thermogravimetric analysis (TGA/DTA) was carried out using SDT 2960 TA Instruments, in nitrogen atmosphere between 303 K and 873 K at a ramp rate 3 K^{-1}. Differential scanning calorimetry methods have been used in order to phase transition studies between 103 and 373 K. The measurements were carried out using Diamond DSC PerkinElmer, in Helium atmosphere at the ramp rates 50, 100, and 200 K^{-1}. X-ray powder diffraction (XRD) data were collected with a Philips X'PERT diffractometers; 2Θ ranges 30–50°, Cu Kα radiation and sample spinning (step size – 0.1°, program. res. slit – 0.5, measuring time – 11 s per point).

4.2. Reaction of $Zr(O^iPr)_4$ with $CH_2{}^tBuCOOH$

70% solution of Zr(O^{i}Pr)$_4$ in *i*-propanol (1 g of Zr(O^{i}Pr)$_4$ (2.58 mmol)) was added dropwise to a solution of 3,3-dimethylbutyric acid (0.6 g; 5.16 mmol) in the 3 cm^3 of mixture of *n*-hexane and *i*-propanol (1:1), and stirred for 24 h. Crystals were grown by slow evaporation of the reaction mixture under argon atmosphere (glovebox). The colorless crystals were obtained after 1 day. Yield: 65%. The Zr amount was gravimetrically determined as ZrO_2. *Anal.* Calc. for $C_{108}H_{206}O_{58}Zr_{12}$: C, 36.79; H, 5.84; Zr, 31.05. Found: C, 36.98; H, 5.78, Zr, 31.19%. IR (KBr, cm^{-1}): 724 (ν_s(Zr–O–Zr)),

1478, 1577 (νCOO); 631 δ(OCO) 13C NMR (solid-state, δ, ppm) 30.8 and 30.2 ($CH_3(^tBu)$); 39.5 ($C(^tBu)$); 179.4, 178.1 and 174.7 (COO).

4.3. Single-crystal structure determination

The diffraction data of studied compound were collected at 153 K for the single crystals (0.24 × 0.13 × 0.03 mm) using Oxford Diffraction KM4 CCD diffractometer, Mo Kα radiation λ = 0.71073 Å. The reflections have been measured with ω–2θ method. The numerical absorption correction was applied for studied crystals (RED171 package of programs, Oxford Diffraction, 2000) [20]. At 103 K the diffraction data were collected for the single crystal (0.20 × 0.17 × 0.15 mm) on ID14-1 (EH1) synchrotron beamline (ESRF, Grenoble) at wavelength λ = 0.93400 Å. The data were processed using XDS package [21]. The absorption correction was applied for both studied structures with XDS [21] for 103 K and RED171 package [21] for 153 K structures of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}O)_3]_2$ were solved by the direct methods and refined with full-matrix least-squares procedure on F^2 using SHELX-97 program package [22,23]. Details of the data collection and structure refinement are presented in Table 2.

ABSTRACT

In the treatment of cyclometallated dimer $[Pd(dmba)(\mu\text{-Cl})]_2$ (dmba = N,N-dimethylbenzylamine) with $AgNO_3$ and acetonitrile the result was the monomeric cationic precursor $[Pd(dmba)(NCMe)_2](NO_3)$ (NCMe = acetonitrile) (**1**). Compound **1** reacted with *m*-nitroaniline (*m*-NAN) and pirazine (pz), originating $[Pd(dmba)(ONO_2)(m\text{-NAN})]$ (**2**) and $[\{Pd(dmba)(ONO_2)\}_2(\mu\text{-pz})] \cdot H_2O$ (**3**), respectively. These compounds were characterized by elemental analysis, IR and NMR spectroscopy. The IR spectra of (**2**–**3**) display typical bands of monodentade O-bonded nitrate groups, whereas the NMR data of **3** are consistent with the presence of bridging pyrazine ligands. The structure of compound **3** was determined by X-ray diffraction analysis. This packing consists of a supramolecular chain formed by hydrogen bonding between the water molecule and nitrato ligands of two consecutive $[Pd_2(dmba)_2(ONO_2)_2(\mu\text{-pz})]$ units.

1. Introduction

Over the past years the chemistry of cyclopalladated compounds, mainly of those derived from N-donor ligands, has been investigated by numerous research groups [1], due to important applications of these compounds in various fields, such as organic and organometallic synthesis [2], new materials (e.g. metallomesogens) [3], catalysis [4] and medical science (e.g. antitumor drugs) [5].

The relatively low cost and ready availability [6] of $[Pd(dmba)(NCMe)_2](NO_3)$ (**1**), with two of its *cis* coordination sites occupied by quite easily removable ligands, prompted us to try this compound in reactions of the self-assembly type. The general idea had been set forth by Fujita by using traditional transition metal complexes and bidentated nitrogen ligands [7]; moreover, Huck already succeeded in producing dendrimers from cyclopalladated compounds [8], and Spek, van Koten and their group advanced the features of 90° square planar platinum and palladium (II) metallated complexes as corner acceptors units [9]. Therefore, compound **1** seemed suitable for the preparation of tetramers and higher nuclearity compounds, if one could bridge two distinct terminal diamines to the $[Pd(dmba)]^{2+}$ fragments. However, only one terminal amine was allowed to be coordinated to the metal atom in **1**, originating monomers from monoamines and dimer compounds from the addition of diamines to its solutions. The behavior of **1** toward the used nitrogen ligands is discussed below, and the solid state structure of the pyrazine dimer **3** is presented.

2. Experimental

2.1. General comments

The syntheses were performed at room temperature. Commercial reagents and solvents were employed without further purification. The precursor $[Pd(dmba)(NCMe)_2](NO_3)$ (**1**) was prepared according to procedures described in the literature [6].

2.2. Synthesis of $[Pd(dmba)(ONO_2)(m\text{-NAN})]$ (**2**)

0.0720 g (0.0520 mmol) of *m*-nitroaniline (*m*-NAN), dissolved in 10 cm^3 of dichloromethane was added to 15 cm^3 of solution **1** (0.100 g, 0.260 mmol), in the same solvent. The mixture was stirred for 30 min, and the resulting yellow precipitate was isolated by filtration. The product was thoroughly washed with ether and pentane and dried *in vacuo*. The yield was about 90% after recrystallization from dichloromethane and pentane. $PdN_4O_5C_{15}H_{18}$ (**2**) requires: C, 40.87; H, 4.08; N, 12.71. Found: C, 40.3; H, 3,93; N, 12.4%.

2.3. Synthesis of $[\{Pd(dmba)(ONO_2)\}_2(\mu\text{-pz})]$ (**3**)

A solution of 0.389 mmol (0.031 g) of pirazine (pz) in 5 cm^3 of dichloromethane was added to a solution of 0.15 g (0.389 mmol)

of [Pd(dmba)(MeCN)2](NO$_3$) (**1**) in 10 cm^3 of dichloromethane. The mixture was stirred for 1 h. The yellow solid which precipitated was filtered, washed with acetone and pentane and dried *in vacuo*, and re-crystallized. The yield was about 80%. Calc. for $Pd_2N_6O_6C_{22}H_{28}$: C, 38.5; H, 4.08; N, 12.26. Found: C, 39.0; H, 2.95; N, 13.5%.

2.4. Physical measurements

Infrared spectra were recorded as KBr pellets on a Nicolet Impact 400 spectrophotometer (range 4000–400 cm^{-1}). ^{1}H and ^{13}C NMR spectra were obtained as DMSO-d_6 solutions and referred to the high field $SiMe_4$ signal, on a Varian INOVA 500 spectrometer. Molar conductivities were measured in nitromethane solutions ($c \approx 1 \times 10^{-3}$ mol L^{-1}) with a Digimed-DM-31 conductimeter. Elemental analyses were performed by the Central Analítica at IQSC/University of São Paulo.

2.5. X-ray structure determination for compound **3**

A single crystal of the compound [{Pd(dmba)(ONO_2)}$_2$(μ-pz)] (**3**) was mounted on a Enraf-Nonius CAD4 diffractometer at room temperature using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). The data collection was taken in the ω–2θ scan mode. The unit cell parameters were determined using 25 automatically centered reflections. Table 1 shows the data collection and refinement conditions. The intensity data were reduced to F_0 and corrected by absorption factors using the PSISCAN method [10]. The structures were solved by the WINGX system [11], using SIR92 [12] and SHELX97 [13]. The hydrogen atoms belonging to compound **3** were located in their ideal positions. The water H atoms were placed at calculated positions using the HYDROGEN [14]. All non-hydrogen atoms were refined anisotropically. The geometric analysis was performed by the PLATON system [15].

3. Results and discussion

3.1. Characteristics of [Pd(dmba)(NCMe)$_2$](NO$_3$) (**1**) and [Pd(dmba)(ONO_2)}(***m***-NAN)] (**2**)

[Pd(dmba)(NCMe)$_2$](NO$_3$), (**1**), can be easily prepared from dichloromethane solutions of [Pd(dmba)Cl$_2$] upon the addition of silver nitrate dissolved in a mixture of dichloromethane and acetonitrile [6]. This precursor is very interesting on its own, due to its exquisite physical properties, which seems to be somewhat dictated by the physical conditions to which it is submitted. For instance, the ionic formulation for **1** seems to be evident from its formulae, and from its solid state IR spectrum, which shows low intensity bands at 2308 and 2249 cm^{-1}, attributed mainly to A_{1g} CN stretches and CCN combination bands of coordinated nitriles [16,17], and quite intense bands for the presence of ionic nitrates [18,19] at 1387 (ν ONO, vs) and 852 cm^{-1} (δ ONO, s). Nevertheless, ready solubility of this compound in solvents such as chloroform is not characteristic of a purely ionic compound. Indeed, molar conductance measurements of **1** made in nitromethane indicated a value of 27.55 μS cm^{-1}, which collocates that species among those considered non-electrolytes [20].

In this context, it is also interesting to research the ^{1}H and ^{13}C NMR spectra of **1**. In spite of the ubiquitous square planar coordination geometry of the [Pd(dmba)(NCMe)$_2$] core, the 125 MHz ^{13}C NMR of **1** in $CDCl_3$ at room temperature seemed to be exceedingly simple, for it did not show the magnetic inequivalence of the ^{13}C nuclei of the acetonitriles. This magnetic inequivalence was expected on the grounds that the acetonitriles must be accommodated, one in the *trans* position to the dmba's nitrogen, and the other, *trans* to the metallated carbon anchor of that ligand. However, in the NMR spectrum there is only one singlet NMR resonance for the two nitriles' CH_3CN at ca. 119, and another singlet resonance CH_3CN carbon at 3 ppm. The other ^{13}C resonances of that spectrum are indicated in Fig. 1.

Upon N-coordination with the palladium metal in cyclopalladated complexes such as **1**, is formed a puckered five-membered ring with a low barrier of inversion. Therefore, fast exchanges from axial to equatorial position are possible, and the benzylic (–N–CH_2–) protons, as well the protons of the [–NMe_2] group of dmba usually appear as singlets in the proton NMR spectrum, and this analysis is valid for complex **1**, where those groups resonate at 3.91 and 2.78 ppm. However, this fast inversion on the NMR time scale does not explain the equivalence of the ^{13}C NMR signals of the coordinated acetonitriles. The 500 MHz ^{1}H spectrum of **1** showed two separated signals for the two distinct acetonitrile groups at 2.78 and 2.36 ppm. The downfield shifted signal at 2.78 ppm was assigned to the methyl group of the acetonitrile in cis position to the metallated aromatic ring since, it is located in the deshielding area generated by the metallated aromatic ring. This signal appeared in the spectrum overlapped by the six-proton singlet of the [–NMe_2] fragment of dmba. A closer examination on other acetonitrile substituted cyclopalladates point to a similar difficulty in a proper assignment of their NMR spectra [21].

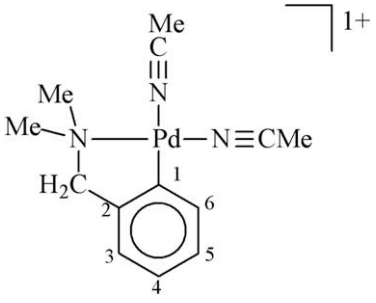

Fig. 1. Additional ^{13}C resonances for the metal containing core of **1**: Me_2N = 51; H_2C = 73; 1 = 147; 2 = 143; 3,6 = 123; 4 = 134; 5 = 123 ppm.

In the first attempt to test the capacity of the precursor compound **1** to react with heterocyclic nitrogen donors, it was chosen the *m*-nitroaniline ligand only as monosubstituted compound; despite the 1:2 stoichiometry of the addition. The IR spectrum of the product suggested the coordination of the *m*-nitroaniline ligand by the disappearance of the bands assigned to *ν*CN of the precursor. However, new bands for a different type of nitrate ligand were also readily assigned in that spectrum, at 1417 and 1305 (*ν*ONO), and at 806 cm^{-1} (*δ*NO), evidencing the presence of a monodentate O-bound nitrate group [18,19].

The ^1H NMR spectrum of **2** showed four multiplets, two at 7.37 and 7.23 ppm assigned to the *m*-nitroaniline, and two at 7.05 and 6.9 ppm, relative to the H-3 to H-5 dmba protons. The upfield shift of dmba's H-6 proton at 5.79 ppm should be the result of the shielding effect of the nearby aromatic ring of the *m*-NAM ligand, a conclusion which allows to allocate the nitrogen ends of *m*-NAM and dmba, *trans* to each other in the complex [22]. Thus, the nitrato ligand, which acts as pseudo-halogen in the structure of compound **2**, is in trans position to the metallated carbon, according to the antisymbiotic effect [x]. The (–N–CH_2–) protons of the dmba ligand resonate at 4.03 ppm, and the [N–$(CH_3)_2$] fragment was indicated by the proton resonance at 2.63 ppm. In the ^{13}C NMR spectrum of **2** there are three important signals: the metallated, the benzylic and the [–NMe_2] carbons, resonating at 148.7, 71.4 and 50.5 ppm, respectively, indicating the presence of dmba in the complex. These evidences and the microanalysis data pointed to the monomeric structure [Pd(dmba)(ONO_2)(*m*-NAN)] for compound **2**.

3.2. Characteristics of cyclopalladated complex [{Pd(dmba)(ONO_2)}$_2$(μ-pz)] (**3**)

The ability of precursor **1** to act as a corner acceptor unit for self-assembled species was tested with the potential bridging ligand pz.

The reactions of **1** with pyrazine were the simplest, in the way that only one type of compound could be detected by the occurrence of only one precipitate, after the mixture of reactants was stirred at room temperature. This compound was determined as μ-pz dinuclear, O-bound NO_3 palladium complex of the type [{Pd(dmba)(ONO_2)}$_2$(μ-pz)], (**3**). For instance, the IR spectrum showed the expected bands at 1621 and 1031 cm^{-1} attributed to the CN stretch and CH deformation of pz, respectively; and the characteristic trio of absorptions for the –ONO_2 coordinated nitrate at 1424, 1296 and 810 cm^{-1} [18,19]. The ^{13}C NMR spectrum of **3** showed the metallated carbon from dmba at 148.1 ppm. The proton NMR spectrum confirms the presence of the pyrazine by signals at 8.84 and 8.74 ppm. Although the signal for symmetrically coordinated pyrazine occurs above 8.6 ppm [23], the presence of two signals for **3** indicated some kind of molecular arrangement as they were the pz protons magnetically non-equivalent. The signals for the diastereotopic protons of the –CH_2– and [–NMe_2] groups of metallated dmba appear in the ^1H NMR spectrum of **3** as slightly broadened resonances at the normal positions of 4.01 and 2.84 ppm, respectively.

3.3. X-ray structure of [{Pd(dmba)(ONO_2)}$_2$(μ-pz)] · H_2O (**3**)

Suitable crystals of [{Pd(dmba)(ONO_2)}$_2$(μ-pz)] · H_2O (**3**) were grown by slow evaporation of a water–acetone solution. The X-ray structure showed that the asymmetric unit consists of a Pd(dmba)(ONO_2) unit linked to half of the pyrazine ring, forming a dimer made by two fold crystallographic axis (Fig. 1). In the asymmetric unit it is also found half water molecule, with the oxygen atom lying in other twofold axis Fig. 2.

The X-ray diffraction study permitted the correct interpretation of the analytical and NMR data, by showing the molecule as a dinuclear compound, with one pz bridging the two metals. The square planar coordination of each palladium atom is composed by the metallated carbon and the nitrogen atom from the dmba, the nitrogen from pz, and the coordinated oxygen of the NO_3 group. This feature could be inferred, but it was not explicit from previous spectroscopic studies. This coordination may reflect the powerful trans-influence of the C–Pd bond, which would labilize a bond between the metal and any incoming σ-donor, neutral L ligand, inducing the coordination to conform to a C–Pd–L *cis* environment in the final compound. In the solid structure, the palladium atom occupies a position slightly below the mean squares plane defined by C_1, N_1, O_1 and N_2 (0.537(1) Å).

Selected interatomic bond lengths and angles are given in Tables 2 and 3. In molecule of **3**, the various bonds and angles involving the metals and directly coordinated atoms agree with previous reports found in the literature for this class of metallated compounds [24–29], but a few particular characteristics of **3** must be discussed. For instance, the short Pd–C_1 bond length of 1.971(4) Å is shorter than a Pd(II)–C sp^3 bond of 2.14 Å [21]. This value may reflect a typical Pd(II)–C sp^2 bond, but there seem to be a consensus that the Pd–C bonds in metallated benzenoid rings must involve some multiple bond character, which would cause a further shortening of this peculiar Pd–C bond [30a]. Also, the trans Pd–O bond

Cg3: benzene ring.

(2.208(4) Å) is in good agreement with a square planar Pd(II) complex structure [29].

The most striking features of the crystal structure of **3** is the tilt (57.6(2)°) of the plane of pz relative to the square plane of the two palladium atoms (C_1, N_1, O_1 and N_2). The pyrazine ring is highly symmetric because it is formed by symmetry operation.

The solid state shows the presence of hydrogen bonds (Table 4). Molecules of **3** self-assemble into a supramolecular chain through intermolecular hydrogen bonds between crystallization water molecules and nitrato ligands of **3**, as can be observed in Fig. 3. As a result of the oxygen atom (from the water molecule) being positioned on the crystallographic twofold axis the polymeric chain is generate by symmetry.

In addition to this hydrogen bond, there are two C–H···O (3.195(9) and 3.460(6) Å) and two C–H···π (3.804(5) and 3.492(5) Å) interactions contributing to the stabilization of the crystal packing, which results in a complex three-dimensional framework.

As mentioned above, the other noteworthy feature of **3** which was disclosed by the X-ray analysis was the severe tilt of the pz plane of 57.6(2)° relative to the square planes defined by the metals and their four immediate bonded atoms. In this geometrical arrangement around a d^8 transition metal, the crystal field theory predicts that the metal's empty $d_{x^2-y^2}$ orbital shall be antibonding, with the other four d orbitals lying close in energy, with the d_{z^2} orbital assuming the role of the HOMO of the ML_4 molecule. In this way, following the σ coordination, there will be essentially two modes through which d–π interactions may develop. The two modes involve the metal and ligand B_{1g} and B_{2g} orbitals. The interaction of the empty B_{1g} $d_{x^2-y^2}$ with the pz HOMO B_{1g} should lower the energy of that otherwise essentially antibonding orbital, and this d←π interaction may thus help in further stabilization of the whole molecular assembly. On the other hand, the full d_{xy} orbital, of B_{2g} symmetry, may interact with the LUMO of pz, which is also B_{2g}, allowing for the development of an effective mechanism for d→π* back donation. The interesting thing is that the d←π and d→π* overlaps can only develop if the plane of pz is severely tilted in relation to the *xy* plane defined by the ML_4 core, a tilting that, in the present case, is 57.6(2)°. These d←π interactions may be found in the half-filled $d_{x^2-y^2}$ of Cu(II) atoms and the B_{1g} HOMO of pz which had been held responsible for magnetic processes in copper dimers and supramolecules [31]. A number of other metal pyrazine compounds which have been analyzed by X-ray crystallography also showed variations in the orientation of the plane of the complexes and the plane of coordinated pz, although the stabilizing effect of such canting has not always been emphasized [32].

4. Conclusions

The nitrate group from the ionic [Pd(dmba)(MeCN)$_2$](NO_3), (**1**), seem to render this compound to be susceptible to a double substitution to yield [Pd(dmba)L_2]$^+$ complexes only with very strong σ donating L such as bipy, in which the interactions enables the detection of polycations from strongly conducting nitromethane solutions [33]. With poorer σ donors such as *m*-NAM or pz only complexes of the type [Pd(dmba)(ONO_2)L] are formed. The biligand nature of pz ensures the formation of the dinuclear compound [Pd(dmba)(ONO_2)]$_2$(μ-pz). This complex showed the square planes defined by the metals ML_4 cores severely tilted in relation to the

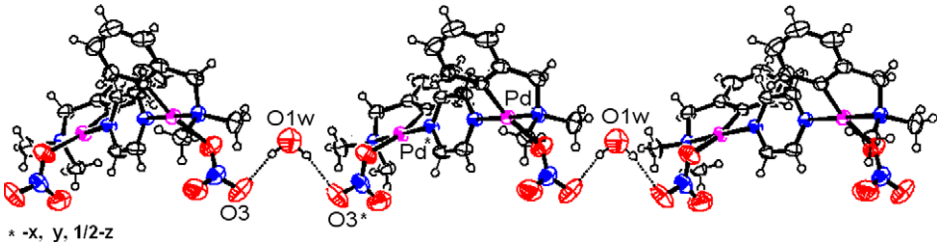

Fig. 3. Supramolecular chain formed by hydrogen bonding in the crystal structure of [{Pd(dmba)(ONO_2)}$_2$(μ-pz)] · H_2O.

plane of pz, suggesting the operation of strong $d\leftarrow\pi$ and $d\rightarrow\pi^*$ interactions between the metals and the pyrazine ring.

ABSTRACT

Solution phase reaction of silver nitrate with various hydrogen-bonding capable dipyridyl ligands has resulted in three 1-D coordination polymers and one discrete cationic species with diverse silver coordination spheres. $[Ag(NO_3)(4,4'\text{-dpk})]_n$ (**1**, 4,4′-dpk = 4,4′-dipyridylketone), $\{[Ag(4\text{-bpmp})](NO_3)\cdot 6H_2O\}$ (**2**, 4-bpmp = bis(4-pyridylmethyl)piperazine) and $\{[Ag_2(NO_3)(3\text{-bpmp})(H_2O)_2]NO_3\}_n$ (**3**, 3-bpmp = bis(3-pyridylmethyl)piperazine) all display 1-D coordination polymer chain or ribbon motifs. Long-range Ag···O interactions and/or hydrogen-bonding promote the formation of different supramolecular aggregations such as a 2-D double layer slab in **1**, a threefold interpenetrated 3-D diamondoid network in **2**, and a 2-D single layer in **3**. Compound **2** manifests "infinite" 1-D T(5)2 water molecule tapes within its incipient voids. $\{[Ag(2,4'\text{-pmpp})_2](NO_3)\cdot H_2O\}$ (**4**, 2,4′-pmpp = 2-pyridyl(4′-methylpyridyl)piperazine) contains discrete cationic species connected by nitrate-mediated Ag···O interactions into a supramolecular 1-D zig-zag chain. Complexes **1** and **4** undergo weak blue–violet luminescence upon irradiation with ultraviolet light.

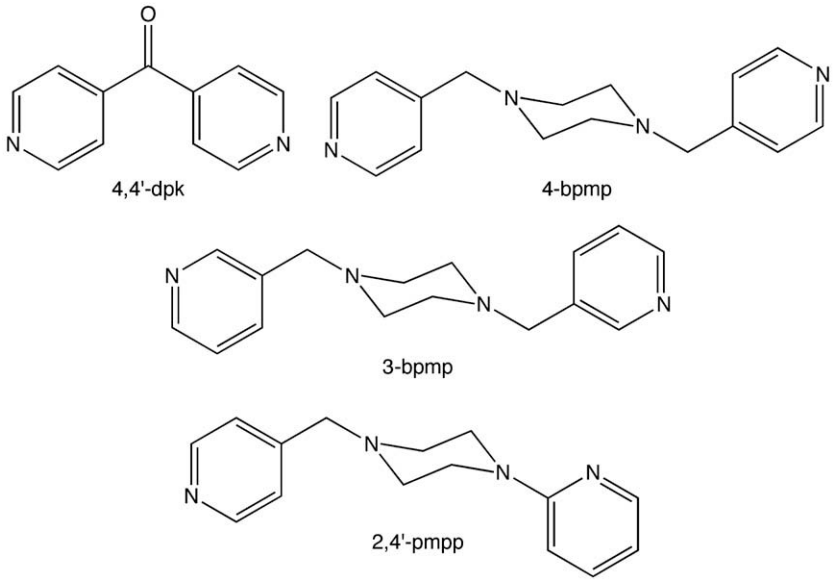
1. Introduction



Exploratory synthesis of coordination polymers remains an intensive area of research because of these materials' potential utility in gas storage [1] and luminescence [2], and also as selective absorbents [3], ion-exchange substrates [4] and catalysts [5]. While most of the focus has rested on coordination polymers incorporating divalent transition metal cations, extended inorganic/organic phases based on monovalent silver have also exhibited diverse patterns of covalent and supramolecular connectivity [6–10], in addition to luminescent [11], ion-exchange [7] and even antibacterial properties [12]. The lack of crystal field stabilization at the d^{10} configuration monovalent silver cation allows different coordination environments depending on the particular steric and electronic requirements of the employed tethering ligands, thereby allowing a variety of coordination polymer morphologies [6–10].

A commonly used tethering ligand for the construction of monovalent silver coordination polymers is the rigid-rod spacer 4,4′-bipyridine (4,4′-bpy), giving rise to a variety of structural topologies. While $\{[Ag(4,4'\text{-bpy})(H_2PO_4)]\cdot 2H_2O\}_n$ [6] and $[Ag(4,4'\text{-bpy})(BF_4)]_n$ [7] are simple 1-D coordination polymer chains, $\{[Ag(4,4'\text{-bpy})_{1.5}(CH_3CN)](SbF_6)\}_n$ displays a non-interpenetrated (6,3) honeycomb 2-D grid with large ~17 × ~26 Å rings [8]. Higher dimensionality structures that feature interpenetration are also possible in this system, as $[Ag(4,4'\text{-bpy})(NO_3)]_n$ manifests a triply interpenetrated (10,3) $ThSi_2$ lattice [9] and $\{[Ag(4,4'\text{-bpy})_2](CF_3SO_3)\}_n$ possesses a fourfold 3-D diamondoid network constructed from tetrahedrally coordinated silver cationic connecting nodes [10]. In comparison, there are fewer examples of related silver-based coordination polymers constructed from dipyridyl ligands possessing hydrogen-bonding capable functional groups. In addition to their covalent ligating capabilities, members of this class of ligand can promote structure direction by permitting supramolecular interactions with ligated or unligated counteranions, resulting in structures different from their 4,4′-bpy analogues [13,14]. For instance, $[Ag(2,3'\text{-dpa})(NO_3)]_n$ (2,3′-dpa = 2,3′-dipyridylamine) [13] and $[Ag(4,4'\text{-dpa})(NO_3)]_n$ (4,4′-dpa = 4,4′-dipyridylamine) [14] both exhibit 1-D helical chain structures, although the latter forms a fourfold interpenetrated α-Po primitive cubic-type supramolecular net via long-range Ag···O interactions and hydrogen-bonding mechanisms.

In this study we present three 1-D silver nitrate coordination polymers and one discrete cationic complex containing the potentially ditopic hydrogen-bonding capable pyridyl ligands 4,4′-dipyridylketone (4,4′-dpk), bis(4-pyridylmethyl)piperazine (4-bpmp), bis(3-pyridylmethyl)piperazine (3-bpmp) or 2-pyridyl(4′-methylpyridyl)piperazine (2,4′-pmpp) (Scheme 1). Although our group has recently reported some divalent metal aromatic dicarboxylate coordination polymers including 4-bpmp [15] and 3-bpmp [16],

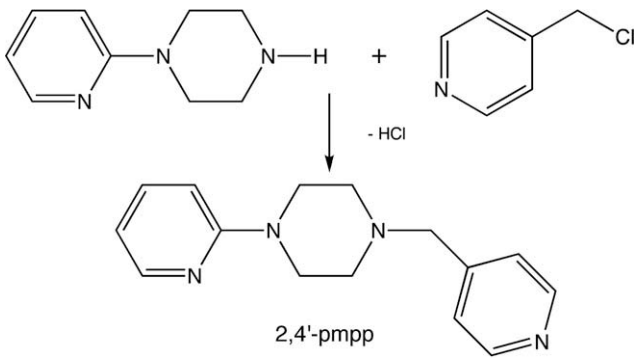

Scheme 1.

the coordination polymer chemistry of 4,4′-dpk and 2,4′-pmpp remains undeveloped. The 0-D discrete cationic species and 1-D coordination polymer chains aggregate into 1-D chain, 2-D layer, 2-D double slab or interpenetrated 3-D supramolecular morphologies via specific long-range Ag···O or hydrogen-bonding interactions, reflecting a degree of structural control exerted by the particular dipyridyl ligand used. Luminescent behavior for two of these phases (**1** and **4**) is also observed.

2. Experimental

2.1. General considerations

Silver nitrate was obtained from Alfa Aesar. The ligands 4,4′-dpk [17], 4-bpmp and 3-bpmp [18] were prepared via published procedures. The ligand 2,4′-pmpp was synthesized by a modification of the procedure for 4-bpmp, through the combination of 2-pyridylpiperazine with 4-chloromethylpyridine (Scheme 2). Water was deionized above 3 MΩ in-house. Elemental analysis was carried out using a Perkin Elmer 2400 Series II CHNS/O Analyzer. IR spectra were recorded on a Perkin Elmer Spectrum One instrument on ground powdered samples. Luminescence spectra were obtained with a Hitachi F-4500 Fluorescence Spectrometer on solid crystalline samples anchored to quartz microscope slides with Rexon Corporation RX-22P ultraviolet-transparent epoxy adhesive.

Scheme 2.

2.2. Preparation of [Ag(NO$_3$)(4,4′-dpk)] (**1**)

Silver nitrate (0.017 g, 0.10 mmol) was dissolved in 1.5 ml H_2O in a glass vial. To this solution was added a 0.75 mL aliquot of 1:1 water–ethanol solution, followed by 1.5 mL of a solution of 4,4′-dpk (0.040 g, 0.22 mmol) in ethanol. Colorless plates of **1** (18 mg, 0.051 mmol, 51% yield based on Ag) formed after standing at 25 °C for two weeks in a dark environment. These were isolated after washing with distilled water, ethanol, acetone and drying in air. *Anal.* Calc. for $C_{11}H_8AgN_3O_4$ (**1**): C, 37.31; H, 2.28; N, 11.87. Found: C, 36.79; H, 2.15; N, 11.76%. IR (cm^{-1}): 3046 (w), 2923 (w), 1745 (w), 1668 (m), 1603 (w), 1554 (w), 1496 (w), 1419 (w), 1392 (m), 1329 (s), 1296 (m), 1280 (s), 1252 (s), 1222 (m), 1155 (m), 1104 (m), 1059 (m), 1040 (m), 1010 (m), 949 (m), 879 (m), 860 (m), 819 (m), 756 (s), 740 (m), 708 (m), 684 (s), 651 (s).

2.3. Preparation of {[Ag(NO$_3$)(4-bpmp)] · 6H$_2$O} (**2**)

A similar procedure as for **1** was followed, with the use of 4,4′-bpmp (0.032 g, 0.12 mmol) as the dipyridyl ligand. Colorless plates of **2** (30 mg, 0.055 mmol, 55% yield based on Ag) formed after standing at 25 °C for two weeks in a dark environment. *Anal.* Calc. for $C_{16}H_{32}AgN_5O_9$ (**2**): C, 35.18; H, 5.90; N, 12.82. Found: C, 34.97; H, 5.60; N, 12.81%. IR (cm^{-1}): 3359 (m, br), 2850 (w), 1650 (w), 1619 (m), 1561 (w), 1468 (w), 1433 (m), 1366 (s, sh), 1330 (vs), 1303 (s, sh), 1268 (m), 1231 (m), 1136 (m), 1118 (m), 1103 (w), 1070 (w), 1032 (w), 993 (m), 972 (w), 939 (m), 857 (m), 835 (m), 804 (s), 684 (s).

2.4. Preparation of {[Ag$_2$(NO$_3$)(3-bpmp)(H$_2$O)$_2$]NO$_3$}$_n$ (**3**)

A similar procedure as for **1** was followed, with the use of 3-bpmp (0.032 g, 0.12 mmol) as the dipyridyl ligand. Colorless plates of **3** (21 mg, 0.032 mmol, 32% yield based on Ag) formed after standing at 25 °C for two weeks in a dark environment. *Anal.* Calc. for $C_{16}H_{24}Ag_2N_6O_8$ (**3**): C, 29.83; H, 3.76; N, 13.05. Found: C, 29.39; H, 3.60; N, 12.91%. IR (cm^{-1}): 3404 (m, br), 2971 (w), 2857 (w), 1628 (w), 1603 (w), 1485 (w), 1463 (w), 1437 (w), 1307 (vs), 1269 (m), 1233 (w), 1216 (w), 1198 (w), 1119 (w), 1104 (m), 1057 (m), 1037 (m), 1002 (w), 981 (m), 947 (w), 937 (w), 836 (w), 824 (w), 804 (s), 708 (s), 668 (w), 659 (w).

2.5. Preparation of {[Ag(2,4′-pmpp)$_2$](NO$_3$) · H$_2$O} (**4**)

A similar procedure as for **1** was followed, with the use of 2,4′-pmpp (0.032 g, 0.13 mmol) as the dipyridyl ligand. Colorless plates of **4** (8.0 mg, 0.011 mmol, 17% yield based on 2,4′-pmpp) formed after standing at 25 °C for two weeks in a dark environment. *Anal.* Calc. for $C_{30}H_{36}AgN_9O_4$ (**4**): C, 51.88; H, 5.22; N, 18.15. Found: C, 50.53; H, 5.26; N, 17.62%. IR (cm^{-1}): 3463 (w, br), 2938 (w), 2810 (w), 1613 (m), 1594 (m), 1560 (w), 1480 (m), 1440 (m), 1428 (m), 1322 (vs), 1313 (s), 1287 (m), 1246 (m), 1231 (m), 1163 (m), 1141 (m), 1105 (m), 1063 (m), 1029 (w), 1009 (m), 977 (m), 946 (m), 930 (w), 839 (w), 825 (m), 801 (w), 781 (s), 739 (m), 722 (w), 667 (w).

3. X-ray crystallography

X-ray diffraction data were collected on single crystals of **1**–**4** at 173 K using either a Bruker-AXS SMART 1k CCD or a Bruker-AXS APEX2 CCD instrument. Reflection data were acquired using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). Crystals of **2** and **4** were non-merohedrally twinned; the twin laws were found using CELLNOW [19]. The data was integrated via SAINT [20]. Lorentz and polarization effect and absorption corrections were applied with SADABS (**1**, **3**) or TWINABS (**2**, **4**) [21]. The structures were solved using direct methods and refined on F^2 using SHELXTL [22]. For **2** and **4**, reflections from both major twin components were used in the refinements. All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms bound to carbon atoms were placed in calculated positions and refined with isotropic displacement parameters with a riding model. Hydrogen atoms belonging to bound or unbound water molecules were located via Fourier difference map, placed at fixed positions, and refined with isotropic displacement parameters, with the exception of those in **4** which could not be found. Although a structural check indicated the possibility of *I*-centering for **3**, the triclinic space group forbids this. Relevant crystallographic data for **1**–**4** is listed in Table 1.

4. Results and discussion

4.1. Synthesis and spectral characterization

Slow diffusion of aqueous solutions of silver nitrate with ethanolic solutions of the requisite pyridyl ligands cleanly produced single crystals of **1**–**4**. The syntheses were carried out in the dark to avoid photodecomposition. Once formed, the crystalline solids remained insoluble in water and common organic solvents. The infrared spectra of all materials were consistent with their crystal structures. Features corresponding to pyridyl ring puckering mechanisms were observed in the region between 600 cm^{-1} and 820 cm^{-1}. Medium intensity bands in the range of ~1600 cm^{-1} to ~1200 cm^{-1} arise from stretching modes of the pyridyl rings [23]. Bands between 3050 cm^{-1} and 3150 cm^{-1} represent C–H stretching modes. The ketone C=O stretching frequency in **1** was observed at 1668 cm^{-1}. Features corresponding to the N–O stretching frequencies of the nitrate anions are observed in the region of ~1300 cm^{-1} to ~1500 cm^{-1} in all four spectra.

4.2. Structural description of [Ag(NO$_3$)(4,4′-dpk)]$_n$ (**1**)

The asymmetric unit of compound **1** consists of a monovalent silver ion, one monodentate nitrato ion, and one 4,4′-dpk ligand with an inter-ring torsion angle equaling 39.6° (Fig. 1). Despite the use of achiral starting materials, compound **1** crystallizes in the acentric space group $P2_1$. As seen in previous phases incorporating the related amine ligand 4,4′-dpa [14], the locked torsion angle between the aromatic rings of kinked dipyridyl ligands can promote the generation of chiral coordination polymers during

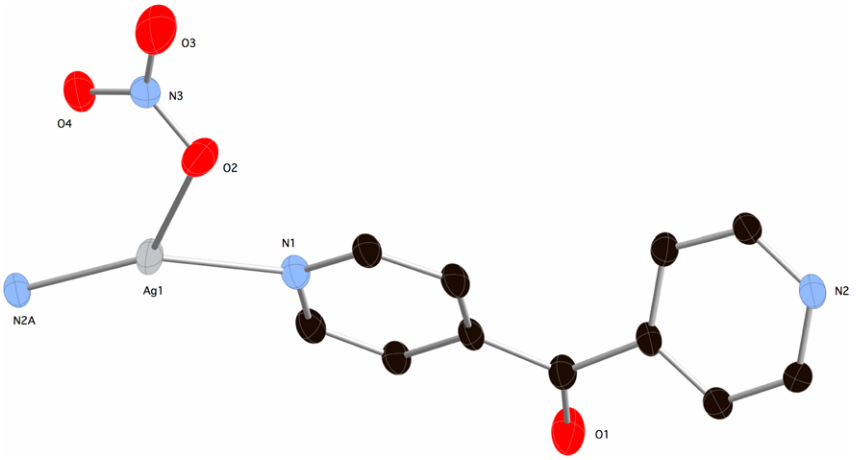

Fig. 1. Coordination environment of **1** with thermal ellipsoids shown at 50% probability. Hydrogen atoms have been omitted for clarity.

their self-assembly. It is thus likely that the kinked nature of 4,4′-dpk allows it to act similarly. Enantiomeric purity within the crystal is indicated by the Flack parameter [24] value of 0.016(19).

The silver ion in **1** adopts a very distorted $\{AgON_2\}$ trigonal planar-type geometry, with bond angles varying between 91.7° and 135.7°. Bond lengths and angles about the silver ion are given in Table 2. Extension of the structure through the 4,4′-dpk ligands generates a 1-D $[Ag(NO_3)(4,4'\text{-dpk})]_n$ coordination polymer chain, in which the nearest neighbor Ag···Ag distance is 11.677 Å (Fig. 2). Adjacent $[Ag(NO_3)(4,4'\text{-dpk})]_n$ chains are connected into a pseudo 2-D slab through long-range Ag···O interactions (2.760 Å) between unligated nitrate oxygen atoms in one chain and silver ions in another (Fig. 3). Within a single slab, the two sets of 1-D chains are arranged parallel to the [1–10] and [−1 −10] directions, respectively. The closest Ag···Ag contact between the sets of chains within the slab is 5.130 Å, well outside of the range of active argentophilic interactions [25]. Neighboring pseudo slabs stack in an *AAA* pattern (Fig. S1) along the *c* crystal direction through non-classical C–H···O hydrogen-bonding (H···O distance = 2.413 Å; C···O distance = 3.319 Å) between the pyridyl rings in one slab and the ketone functional groups of the 4,4′-dpk ligands in another slab.

Table 2
Selected bond distance (Å) and angle (°) data for **1**.

Ag1–N2	2.2072(17)	N2–Ag1–N1	130.60(6)

4.3. Structural description of $\{[Ag(NO_3)(4\text{-bpmp})] \cdot 6H_2O\}$ (**2**)

As revealed by single-crystal X-ray diffraction the asymmetric unit of **2** contains one silver ion, one unligated nitrate anion disordered over two positions in a 60/40 ratio, two halves of two crystallographically distinct 4-bpmp molecules ligated via their pyridyl nitrogen atoms, and six water molecules of crystallization (Fig. 4). The centroid of each of the chair conformation piperazinyl rings of the 4-bpmp ligands rests on a crystallographic inversion center. The silver coordination environment is virtually linear (Table 3). Unlike **1**, compound **2** crystallizes in a centrosymmetric space group ($P2_1/c$). Monovalent silver cations are connected through tethering 4-bpmp ligands to construct sets of 1-D $[Ag(4-bpmp)]_n^{n+}$ coordination polymer chains that are oriented parallel to the [−1 3 0] and [1 −3 0] crystal directions (Fig. 5). Within these chains, the Ag···Ag distances through the two crystallographically distinct types of 4-bpmp ligands alternate between 16.062 and 16.148 Å.

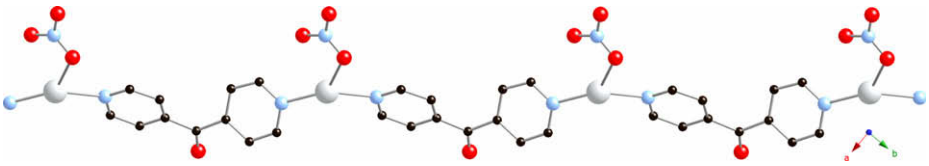

Fig. 2. A single $[Ag(NO_3)(4,4'\text{-dpk})]_n$ coordination polymer chain in **1**.

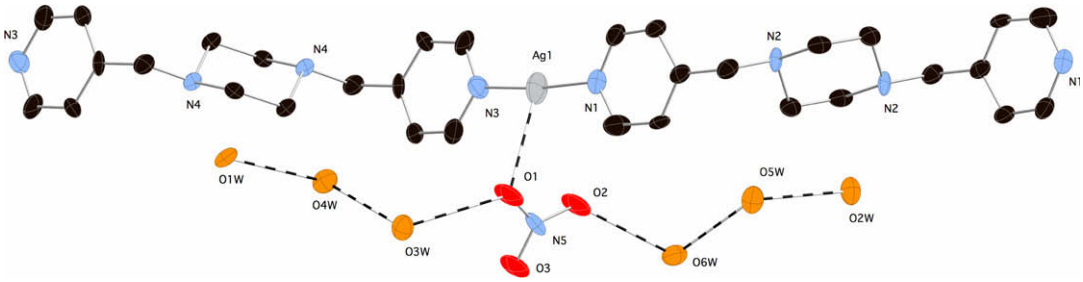

Fig. 4. Coordination environment of **2** with thermal ellipsoids shown at 50% probability. Hydrogen atoms have been omitted for clarity. Hydrogen-bonding and Ag···O long-range interactions are depicted as dashed lines.

Table 3
Selected bond distance (Å) and angle (°) data for **2**.

Ag1–N3	2.127(10)	N3–Ag1–N1	174.6(4)
Ag1–N1	2.129(10)		

The subtle difference between these values is attributed to variances in the conformations of the flexible 4-bpmp bridging ligands, especially in the N–C–C angles (109.8° and 110.8°) defining the connection of the piperazinyl rings to the pyridyl rings.

Neighboring $[Ag(4-bpmp)]_n^{n+}$ chains are linked together through long-range Ag···O interactions (2.918 and 2.927 Å) provided by the charge-balancing nitrate anions. Thus, each silver cation can be considered a 4-connected node, with two connections through 4-bpmp ligands within a $[Ag(4-bpmp)]_n^{n+}$ chain and two others through the long-range supramolecular Ag···O interactions. The 4-connected 3-D supramolecular network thereby formed has a 6^6 topology, corresponding to the diamond lattice. Incipient voids within a single network allows interpenetration of two identical networks, thus resulting in an overall threefold interpenetrated diamondoid net supramolecular topology for **2** (Fig. 6). While many coordination polymers possessing diamondoid networks with odd-numbered interpenetration levels are chiral [26], the presence of the crystallographic inversion centers within the 4-bpmp ligands precludes chirality in this case.

Entrained in the void spaces within the triply interpenetrated supramolecular network, which occupy 27.2% of the unit cell volume according to PLATON [26], are 1-D water tapes belonging to the commonly encountered T(5)2 classification [27] in which cyclic water pentamers share two water molecules between them. The water molecule tapes are conjoined into a supramolecular layer topology via hydrogen-bonding interactions with the unligated nitrate anions (Fig. 7). Geometrical parameters for the hydrogen-bonding interactions in **2** are listed in Table 4. NO void space when all solvent molecules included.

4.4. Structural description of $\{[Ag_2(NO_3)(3\text{-bpmp})(H_2O)_2]NO_3\}_n$ (**3**)

The asymmetric unit of complex **3** contains two monovalent silver cations, one monodentate nitrato ligand, two aqua ligands, two halves of two crystallographically distinct 3-bpmp ligands and one unbound nitrate anion (Fig. 8). Dissimilar to **1** and **2**, there are two crystallographically distinct silver ions in **3**. One (Ag1) is coordinated in an extremely distorted tetrahedral $\{AgN_2O_2\}$ environment, where the two oxygen donors are provided by the two aqua ligands. The nitrogen donors belong to the pyridyl ring of one 3-bpmp ligand and the piperazinyl ring of a second 3-bpmp ligand. The other silver atom (Ag2) adopts a very distorted T-shaped $\{AgN_2O\}$ coordination sphere wherein the nitrogen donor atoms arise from a similar binding pattern as at Ag1; the coordination environment is completed by a nitrato oxygen atom. Pertinent bond lengths and angles for **3** are given in Table 5.

Exotetradentate 3-bpmp ligands connect the silver atoms into a cationic $[Ag_2(NO_3)(3\text{-bpmp})(H_2O)_2]_n^{n+}$ 1-D coordination polymer

ribbon, which can be visualized as being formed from the *spiro* junction of 12-membered $\{AgNCCCN\}_2$ rings with 6-membered {NCCNCC} piperazinyl rings (Fig. 9). The Ag···Ag through-space distance across the 12-membered circuits is 5.362 Å, again beyond the usual range of argentophilic d^{10}–d^{10} interactions. In the very limited coordination polymer chemistry of the 3-bpmp ligand [16], compound **3** appears to be the first instance of metal binding by the piperazinyl nitrogen atoms.

The chain motifs, which are co-linear with the [1 −1 −1] crystal direction, are connected together into a supramolecular pseudo layer pattern (Fig. 10) by means of hydrogen-bonding donation from the aqua ligands to the ligated nitrato anions (Table 4). Supplementary structural stability of the supramolecular layer is provided by long-range Ag···O interactions to the formally unligated nitrates (Ag···O distance = 2.863 Å). Pseudo layers further stack

into 3-D in an *AAA* pattern by hydrogen-bonding donation between aqua ligands and oxygen atoms from ligated nitrato anions (Fig. S2).

4.5. Structural description of {[Ag(2,4′-pmpp)$_2$](NO$_3$) · H$_2$O} (**4**)

The asymmetric unit of compound **4** consists of a monovalent silver cation, two 2,4′-pmpp molecules ligated to silver through their 4′-pyridyl termini, one unligated nitrate anion, and one water molecule of crystallization (Fig. 11). Neither the 2-pyridyl nor piperazinyl nitrogen atoms bind to silver, perhaps due to steric encumbrances failing to permit the orientation of their lone pairs toward a metal center. The silver atom is coordinated in a {AgN$_2$} pseudo-linear fashion as in **2**, with bond length and angle information listed in Table 6.

Individual molecules of **4** are linked into a pseudo 1-D chain through long-range Ag···O interactions (2.908 Å) to nitrate oxygen atoms and hydrogen-bonding pathways between the nitrate anions and the water molecules of crystallization. The chain motifs lie parallel to the *b* crystal direction, wherein the closest Ag···Ag distance of 6.073 Å corresponds to the *b* lattice parameter. Neighboring pseudo chains interdigitate with each other, constructing a pseudo 2-D layer motif parallel with the *ac* crystal plane (Fig. 12).

4.6. Luminescence studies

As numerous silver-based coordination polymers have been found to possess luminescent properties [28], solid samples of **1**–**4** were subjected to ultraviolet irradiation. Although samples of **2** and **3** failed to exhibit any appreciable visible light emission, possibly due to dehydration and loss of crystallinity upon long-term storage, crystals of **1** and **4** showed modest emission of blue–violet light (Fig. 13) upon excitation with ultraviolet light (λ_{ex} = 300 nm). In comparison to previously reported silver-containing coordination polymers, the emissive behavior is ascribed to metal to ligand charge transfer [28c].

5. Conclusion

Employment of long-spanning dipyridyl ligands with hydrogen-bonding capable centers has generated four distinct silver coordination complexes, three of which form 1-D coordination polymer chains. The specific electronic environment enforced by the nitrogen donor disposition and the central amine groups of the ligands during self-assembly results in 1-D, 2-D, or 3-D supramolecular lattices, different from those obtained with the commonly used rigid-rod tether 4,4′-bpy. Although the hydrated species apparently dehydrate over time, compromising crystal quality, the luminescent properties of **1** and **4** reinforce the potential of silver/diimine coordination polymers as substrates in optical devices. Variance of the anionic component in this system is likely to influence and alter molecular-level coordination polymer structure and macroscopic properties. Work in this vein continues in our laboratory and will be reported in due course.

ABSTRACT

Three polynuclear transition metal complexes $[Mn_8(DMF)_8(L1)_8]\cdot 4DMF$ (**1**), $[Mn_6(DMF)_6(L2)_6]\cdot[Mn_6(DMF)_4(H_2O)_2(L2)_6]\cdot 2DMF$ (**2**), $[Cu_3(L3)_2(py)_2]$ (**3**) of the pentadentate ligands *N*-acyl-salicylhydrazides were synthesized and characterized, their crystal structures were investigated. The oxidation state and properties of the central metal ions are important in crystal structure formation, trivalent Mn(III) ion which easily form stable octahedral coordination metallamacrocycle complexes, metallacrowns **1** and **2** were obtained; while bivalent Cu(II) ion is easier to form square planar, trinuclear complexes **3** was obtained. The steric effect of the *N*-acyl side chains also plays an important role in the structures of these polynuclear complexes. The magnetic property of **1** was also investigated.

1. Introduction

Polynuclear transition metal complexes containing nitrogen and phenolic oxygen donor atoms are of considerable interest in inorganic and biomimetic chemistry due to their potential application in catalysis, their biological relevance, and potentially interesting magnetic properties [1]. To prepare such polynuclear complexes with desired structures and properties, it becomes important to understand the delicate factors influencing the formation of those systems [2,3]. The trianionic pentadentate *N*-acyl-salicylhydrazide ligands, a good example of these ligands, have been utilized to construct many interesting polynuclear complexes. Trivalent metal ions such as Ga, Co, Fe and Mn that can generally form stable octahedral coordination are found to yield hexanuclear, octanuclear, decanuclear and dodecanuclear metallamacrocycles with these ligands, known as metallacrowns [4–7], where the ring size and nuclearity of the metallacrowns could be modulated by controlling the steric repulsion of the *N*-acyl side chains. The ligands with flexible linear or β-branched *N*-alkyl groups that have sterically flexible Cα methylene groups tend to yield 18-membered hexanuclear metallacrowns; while for the ligands of α-branched *N*-alkyl groups, metallacrowns with extended nuclearity have been prepared [8]. When the central atoms are bivalent metal ions that can easily form planar square coordination, several trinuclear nickel(II), copper(II) and zinc(II) compounds and one hexanuclear nickel(II) compound with these types of ligands have been reported [9]. Regardless of the ring size, metal ions, nuclearity or stereochemistry of these polynuclear complexes, the binding mode of the ligands around the metal centers are the same, it is the different connectivities of the ligands between the two kinds of metal ions that lead to the formation of metallacrowns and trinuclear complexes.

With the aim of understanding the coordination chemistry of the *N*-acyl-salicylhydrazide with metal ions, and side effect of the *N*-acyl on the formation and structures of these polynuclear complexes, we report three pentadentate ligands *N*-2-methylacryloyl-5-bromosalicylhydrazide (H_3L1), *N*-(phenylacetyl)-5-bromosalicylhydrazide (H_3L2) and *N*-(3-*t*-butylbenzoyl)-5-bromosalicylhydrazide (H_3L3) (Scheme 1) and three polynuclear complexes $[Mn_8(DMF)_8(L1)_8]\cdot 4DMF$ (**1**), $[Mn_6(DMF)_6(L2)_6]\cdot[Mn_6(DMF)_4(H_2O)_2(L2)_6]\cdot 2DMF$ (**2**), $[Cu_3(L3)_2(py)_2]$ (**3**) from these ligands.

Scheme 1. The ligands and their same binding modes.

^{13}C NMR spectra were recorded on a Varian Inova 600 MHz NMR spectrometer at 25 °C. Chemical shifts were referenced to the residual solvent peak. IR spectra were recorded on AVATAR 360 FT-IR spectrophotometer in the range 4000–400 cm^{-1} (KBr pellets). Element analyses were performed on a Perkin–Elmer 2400 CHN elemental analytical instrument. Temperature-dependent magnetic susceptibility measurements were carried out on powdered samples between 2 and 300 K using a Quantum Design (SQUID) magnetometer MPMS-XL-5 in a field of 1 kOe.

2.2. Synthesis of the ligands and metal complexes

2.2.1. N-2-Methyl-acryloyl-5-bromosalicylhydrazide (H_3L1)

2-Methyl-acryloyl chloride (1.9 ml, 19.7 mmol) was added to a solution of chloroform (100 ml) containing water (0.36 ml, 20.0 mmol) and triethylamine (5.7 ml, 40.0 mmol) at 0 °C. The reaction mixture was slowly warmed to ambient temperature. Then a further amount of 2-methyl-acryloyl chloride (1.9 ml, 19.7 mmol) was added to the mixture and stirred for a further 1 h. At the completion of the above reaction, 5-bromosalicylhydrazide (3.7 g, 16.4 mmol) was added to the reaction mixture. The resulting mixture was stirred at ambient temperature for 1 day. The solution was diluted with hexane (90 ml), kept under refrigeration overnight, filtered, and washed with ether (30 ml × 3), dried in vacuo over P_2O_5. Yield: 2.50 g, 83.5%. *Anal.* Calc. for $C_{11}H_{11}N_2O_3Br$: C, 44.17; H, 3.71; N, 9.37. Found: C, 44.06; H, 3.68; N, 9.41%. 2.2.3. N-(3-t-Butylbenzoyl)-5-bromosalicylhydrazide (H_3L3)

The ligand H_3L3 was prepared in a manner analogous to that used for H_3L1, except that 3-*t*-butylbenzoyl chloride was used instead of 2-methyl-acryloyl chloride. Yield: 4.18 g, 65.2%. *Anal.* Calc. for $C_{18}H_{19}N_2O_3Br$: C, 55.24; H, 4.86; N, 7.16. Found: C, 55.18; H, 4.79; N, 7.21%. 2.2.4. [$Mn_8(DMF)_8(L1)_8$] · 4DMF (**1**)

H_3L1 (29.9 mg, 0.1 mmol) was dissolved in 30 ml of 2:1 methanol + DMF, and manganese acetate tetrahydrate (24.5 mg, 0.1 mmol) was added to it, stirred for 2 h with the color of the solution changing to dark brown, then the mixture was filtered. After slow evaporation of the mother liquor over several weeks, dark brown block crystals suitable for X-ray diffraction were obtained. Yield: 65.3%. IR (KBr pellet, cm^{-1}): 3430 (s, br); 1650 (s); 1600 (m); 1560 (m); 1510 (s); 1430 (m); 715 (m); 629 (m).

2.2.5. [$Mn_6(DMF)_6(L2)_6$]·[$Mn_6(DMF)_4(H_2O)_2(L2)_6$] · 2DMF (**2**)

Complex **2** was prepared in a manner analogous to that of **1**, use H_3L2 as the ligand. Yield: 72.7%. IR (KBr pellet, cm^{-1}): 3440 (s, br); 1650 (s); 1600 (s); 1550 (s); 1500 (s); 1430 (s); 1380 (s); 729 (m); 633 (m).

2.2.6. [$Cu_3(L3)_2(py)_2$] (3)

H_3L3 (39.0 mg, 0.1 mmol) was dissolved in 30 ml of 1:1 methanol/DMF, and then copper acetate monohydrate (19.9 mg, 0.1 mmol) was added, followed by four drops of pyridine. The mixture was stirred for 1 h, the resulting solution was filtered. After slow evaporation of the mother liquor for several days, blue block crystals suitable for X-ray diffraction were obtained. Yield: 67.5%. *Anal.* Calc. for $C_{46}H_{42}Cu_3N_6O_6Br_2$: C, 49.10; H, 3.76; N, 7.47. Found: C, 49.01; H, 3.71; N, 7.51%. IR (KBr pellet, cm^{-1}): 1610 (m); 1590 (m); 1500 (s); 1410 (s); 634 (w); 559 (w).

2.3. Crystallographic data collection and refinement of the structures

X-ray single-crystal diffraction data for compounds **1**–**3** were collected on a Bruker Smart APEX diffractometer at 293 (2) K with Mo Kα radiation (λ = 0.71073 Å). There was no evidence of crystal decay during data collection of complex **3**. In the data collection of complexes **1** and **2**, suitable crystal was mounted in glass

capillaries with mother liquor to prevent the loss of the structure solvent molecules. In the complexes **1** and **2**, the crystals diffracted poorly, with a relatively low percentage of observed intensities above the threshold of $2\sigma(I)$ within the 1.73–25.00° (**1**) and 0.97–25.00° (**2**) θ ranges. In complex **2**, the non-coordinated solvent molecules are severely disordered which could not be modeled by discrete atoms in the complexes. Correspondingly, the contribution of the solvent to the diffraction pattern was subtracted using SQUEEZE procedure of the PLATON [10]. These voids consist of about 11.8% of the crystal volume (6492(5) per unit cell). Conventional least-squares refinement of the same solvent-exclude structure model against the original data set converged only at $R_1 = 0.22$. Refinement calculations with the modified data converged at $R_1 = 0.0831$ for 7965 reflections with intensities above the threshold of $2\sigma(I)$. In the three complexes, the structures were solved by direct methods and all non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were located in calculated positions and/or in the position from difference Fourier map. The positions and anisotropy from difference of non-hydrogen atoms were refined on F^2 by full-matrix least-squares techniques with the SHELXTL program package [11,12]. Crystal data of complexes **1**–**3** are listed in Table 1.

3. Results and discussion

3.1. Spectral characterization

In the IR spectra, the ligands H_3L1, H_3L2 and H_3L3 show stretching bands attributed to C=O, PhO–H (phenolic, including intramolecular and intermolecular hydrogen bond) and N–H at 1620, 1670, 2670–3130, 3440 cm^{-1}; 1610, 1640, 2670–3170, 3440 cm^{-1} and 1610, 1650, 2490–3190, 3440 cm^{-1}, respectively [13]. The infrared

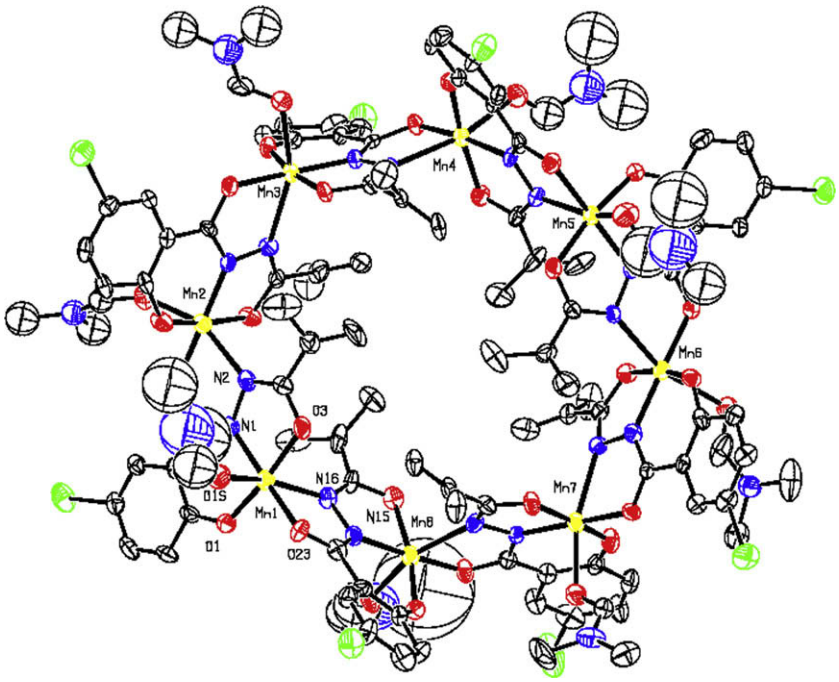

Fig. 1. Ortep plot of complex **1,** H-atoms have been omitted for clarity.

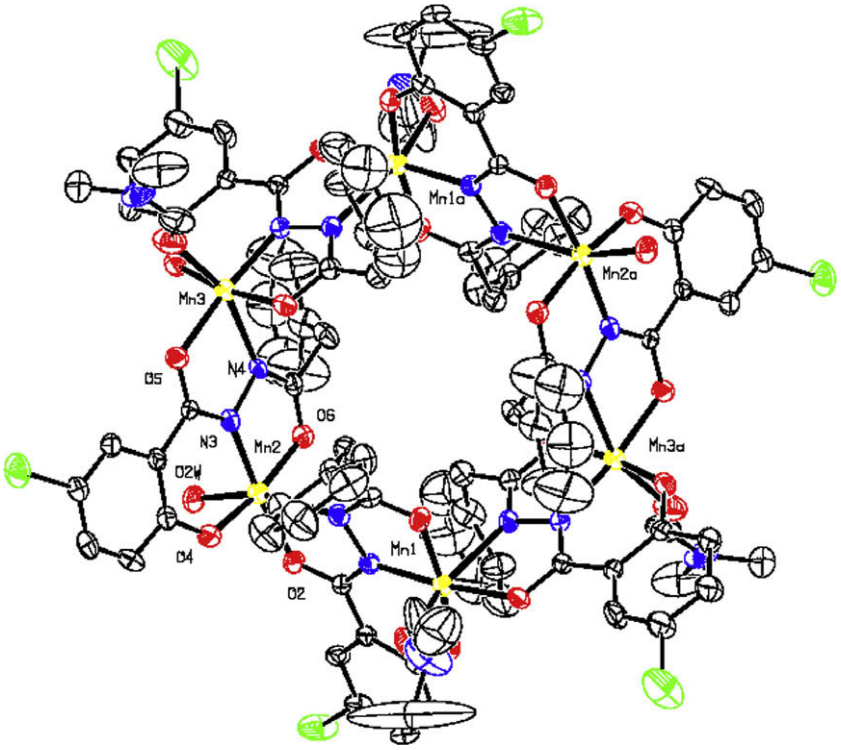

Fig. 2. Ortep plot of complex **2a,** H-atoms have been omitted for clarity.

stretching bands for compounds **1**–**3** are quite similar. The absence of the N–H band and the weakness of the C=O stretching bands are consistent with the deprotonation of the CONH groups and coordination to the Mn(III) and Cu(II) ions, which indicate the same chelating mode of the ligands to metal ions. The deprotonation and coordination are also confirmed in complexes **1**–**3** by the bands at 715, 729 and 634 cm^{-1}, attributed to M–O linkages; bands at 629, 633 and 559 cm^{-1}, attributed to M–N linkages [14]. The C=N–C=N framework bands are found at 1430 and 1410 cm^{-1}, respectively [15].

3.2. Description of the structures of *1*–*3*

The structure of complex **1** is illustrated in Fig. 1. The neighboring Mn···Mn interatomic distance are 4.886–4.935 Å. The Mn···Mn···Mn interatomic angles in the 24-membered core ring are in the range of 124.37–130.96°. These values are very close to the value of the interior angle in an *n*-octagon (135°). The flex-

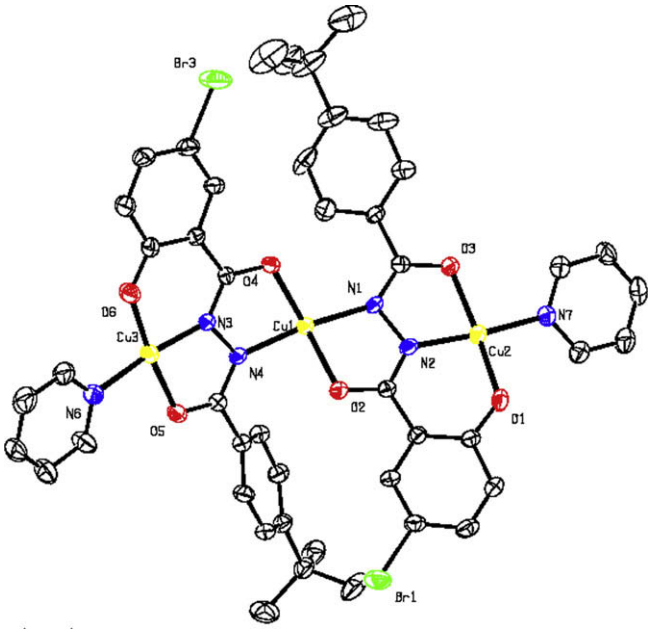

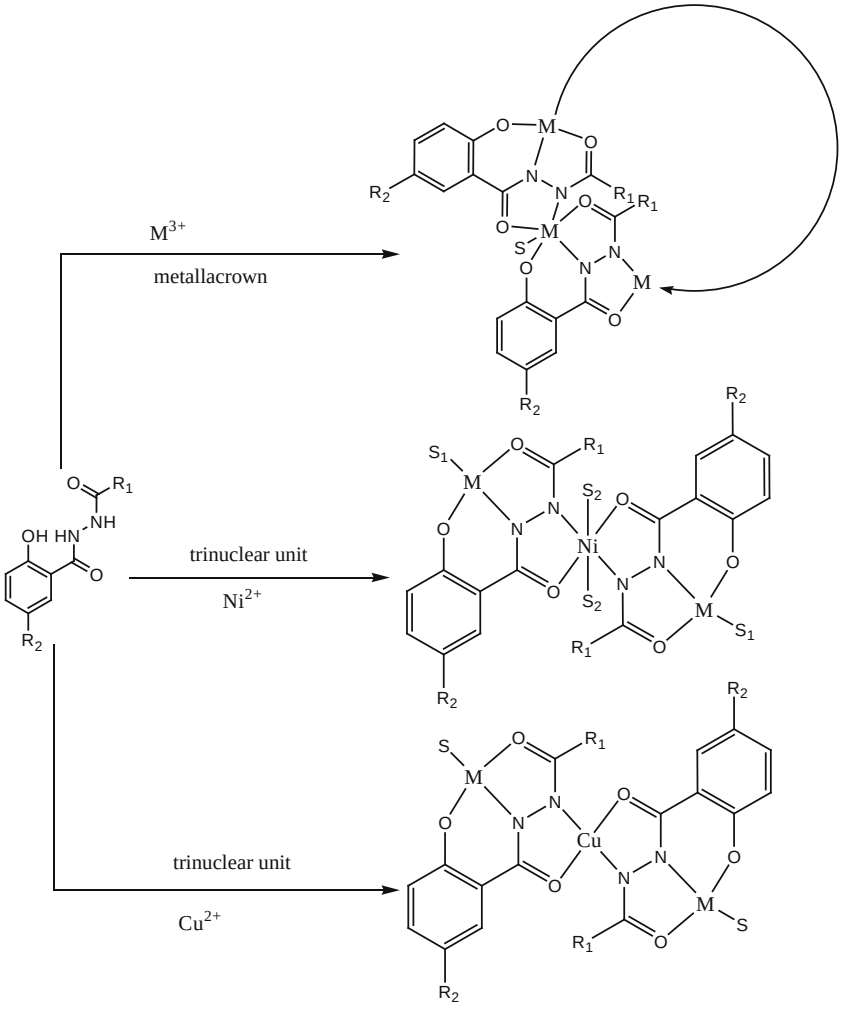

Fig. 4. Ortep plot of complex **3,** H-atoms have been omitted for clarity.

Scheme 2. Connective modes of metallacrown and trinuclear complex.

ibility around the N–N single bond and the conformational adaptability of the deprotonated pentadentate ligand $(L1)^{3-}$ assist the formation of the complex **1** and its propeller configuration of the Mn(III) ions. The chiralities of the manganese ions alternate between the Λ and Δ forms. The four DMF molecules coordinated to Mn centers with Λ configuration are on one face of the metallacrown, while the remaining four DMF molecules coordinated to the other Mn centers with Δ configuration on the other face of the metallacrown. The two faces of each metallacrown molecule have opposite chiralities. All manganese ions in 1 are in a distorted octahedral MnN_2O_4 geometry. In each octahedral environment around Mn(III), the mean axial distance of Mn–O/N is approximately 0.36 Å longer than the mean value of the basal distances due to the Jahn–Teller elongation of the octahedrons.

The X-ray structure analysis results shown in Figs. 2 and 3 reveal that complex **2** is a hexanuclear Mn(III) metallacrown with a $[Mn–N–N]_6$ unit, it has two independent molecules(**2**a and **2**b) in each crystallographic asymmetric unit. All manganese ions of **2** are in an octahedral MnN_2O_4 environment, with the rest axial sites occupied by O atoms from six DMF molecules in **2**b, and four DMF molecules, two H_2O molecules in **2**a. The mean axial distances are about 0.33 Å longer than the average basal bond lengths for each Mn(III) center, which indicates that the elongation of the octahedrons takes place in the axial direction due to the Jahn–Teller distortion of the high-spin d^4 electronic configuration of Mn(III) ion. The pentadentate ligand $(L2)^{3-}$ not only bridge the adjacent manganese ions by –N–N–, but also forces the stereochemistry of the metal ions into a propeller configuration because of the meridional coordination of the neighboring ligands. As a result, the complex **2** exhibits a combination of ΔΛΔΛ chiral configuration. The Mn···Mn distances fall in the range of 4.899–4.938 Å and the Mn···Mn···Mn angles of 112.63–116.02°.

Complex **3** is composed of three Cu(II) ions, two $(L3)^{3-}$ ligands and two pyridine molecules, as shown in Fig. 4. The chelating modes of the ligands to Mn(III) ions and Cu(II) ions are the same, they serve as both bidentate ligand for one metal ions, and at the same time, tridentate ligand for the adjacent metal ions. Central copper ion and two terminal copper ions are connected by two bridging deprotonated $(L3)^{3-}$ ligands, forming a bent trinuclear copper structure unit with a Cu–N–N–Cu–N–N–Cu core. The coordination geometry of the central Cu(1) is distorted square, it is bound to carbonyl oxygen atoms, O(2) and O(4), two hydrazine nitrogen atoms N(1), N(4) from two ligands. For two terminal Cu(II) ions, the square geometry is realized with carbonyl oxygen, hydrazine nitrogen, phenolic oxygen and pyridine nitrogen atoms. The bent angle of Cu(2)···Cu(1)···Cu(3) is 162.7°.

3.3. Coordination architectures

From the structures of complexes **1**–**3** and other trinuclear complexes obtained by us: $[Ni_3(H_2O)_2(DMA)_2(acbshz)_2]\cdot 2DMF$ [9b], $[Cu_3(3,5\text{-dmbzshz})_2(py)_2$, $[Ni_3(pabshz)_2(DMF)_2(py)_2$, $[Ni_3(3\text{-}t$-

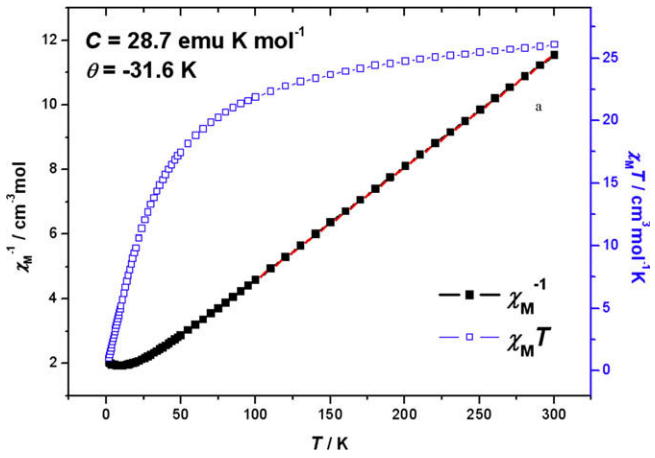

Fig. 5. Temperature dependence of $\chi_M T$ and Ψ_M^{-1} of **1** at $H = 1$ kOe from 2 to 300 K. The line a represents the best fit to the Curie–Weiss law.

bbzshz)$_2$(py)$_4$ · 2H$_2$O [9c], [Ni$_3$(H$_2$O)$_2$(DMA)$_2$(acshz)$_2$] · 2DMF [4i], [Cu$_3$(mashz)$_2$(py)$_2$], [Ni$_3$(mashz)$_2$(py)$_4$] [9e], [Ni$_3$(3,5-dmbzshz)$_2$(py)$_4$] · DMF[1] [9d]. It is obvious that the *N*-acyl-salicylhydrazide ligands act as pentadentate ligands to metal ions, with bidentate to one metal ion centre and tridentate to the adjacent metal ion. The chelating modes of the ligands around the metal centers are the same, but the different connectivities of them lead to the formation of metallacrowns or trinuclear complexes. For trivalent metal ions Mn(III), Fe(III), Co(III) and Ga(III) that can easily form stable octahedral coordination, the two adjacent ligands serve as pentadentate to the central metal ion, and the one-by-one connectivity of these units forms a metallamacrocycle, known as metallacrowns. While for bivalent metal ions such as Cu(II), Ni(II) that are easier to form planar square geometry, the two adjacent ligands serve as tetradentate ligands to the central metal ions, but tridentate ligands to the terminal metal ions forming an isolated unit, so it can only form trinuclear complex (Scheme 2). The steric effect of the *N*-acyl side chains can also effect the formation of these polynuclear complexes. β-branched *N*-alkyl groups that have sterically flexible Cα methylene groups yield 18-membered hexanuclear metallacrown and linear trinuclear Ni(II) complex; while α-branched *N*-alkyl groups yield the 24-membered octanuclear Mn(III) metallacrown and bent trinuclear Ni(II) complex. In the trinuclear Cu(II) complexes, Cu(II) ions all take distorted planar square geometry, while in the trinuclear Ni(II) complexes, two terminal Ni(II) are distorted planar square, the central Ni(II) ions are octahedral. This difference reflects the steric requirement of coordination, and the presence of inter- and intra-molecular interactions. Further research on why the significantly bent molecular conformation is formed is still under way.

3.4. Magnetic properties

The magnetic behavior of complex **1** is illustrated in Fig. 5. The value of $\chi_m T$ decreases slight with decreasing temperature from 26.07 cm^3 mol^{-1} K at 300 K to 18.16 cm^3 mol^{-1} K at 55 K. Below 55 K, $\chi_m T$ decreases rapidly and reaches 0.98 cm^3 mol^{-1} K at 2 K. The $\chi_m T$ value at 300 K is slightly larger than the sum value (24 cm^3 mol^{-1} K) expected for eight spin-only Mn(III) systems with $S = 2$. This behavior is characteristic of antiferromagnetic exchange coupling between the Mn(III) centers. This is further confirmed by a negative Weiss constant $\theta = -31.6$ K, which is calculated from the data within $T > 55$ K. The magnetic data were not fitted based on an eight Mn(III) ring model owing to the computing difficulties of dealing with such a large system. In order to evaluate the exchange interaction values of Mn(III) ions, the data were fitted to a one-dimensional chain model [16] since the ring is large and approximates a one-dimensional chain. The magnetic susceptibility of **1** can be written as [17]:

$$\chi = \frac{NS(S+1)}{3kT} g^2\beta^2 \frac{1-u(K)}{1+u(K)} \times 8 \qquad (1)$$

where $u(K)$ is $1/K - \coth(K)$, $K = 2JS(S+1)/kT$, $S = 2$ for Mn(II) and N, β, K, g and T have their usual meanings. The best fitting was obtained with $g = 2.14(2)$, $J = -1.94(4)$ K. The negative J value indicates the antiferromagnetic couplings between the Mn(III) centers.

4. Conclusion

Three complexes with the ligands derived from *N*-acyl-salicylhydrazides were reported. The 3d Metal coordination architectures of these kinds of ligands were also studied. For trivalent Mn(III), Fe(III), Co(III), Ga(III), which can easily form stable octahedral coordination, metallacrowns were obtained. While for bivalent Cu(II), Ni(II), Zn(II) that are easier to form planar square geometry, trinuclear complexes were obtained. The steric effect of the *N*-acyl side chains can also effect the formation of these polynuclear complexes. Antiferromagnetic couplings were observed between the Mn(III) centers in complex **1**.

Acknowledgment

We greatly thank Prof. Song Gao for his kind help in the magnetic analysis.

Appendix A. Supplementary data

CCDC 678388, 678405 and 665860 contain the supplementary crystallographic data for **1–3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.10.055.

ABSTRACT

Novel phosphorus compounds of bisphosphoramidate, phosphoramidate and phosphoric triamide derivatives were synthesized using the starting materials PCl_5 and $POCl_3$. The products were then characterized by ^1H, ^{13}C, ^{31}P, ^{19}F NMR, IR spectroscopy and CHN elemental analysis. It is noticeable that the reaction of 4-aminobenzamide with PCl_5 in different molar ratios yields different products, bisphosphoramides and phosphoric triamides. Moreover, we were taken by surprise that the interaction of $POCl_3$ with the first-type aromatic amines gave bisphosphoramidates with P–N–P linkages that exhibited $^2J(P,P) \approx 20.0$ Hz in the ^{31}P NMR spectra. In fact, two simple one-pot pathways are presented here for the synthesis of new bisphosphoramidates, and to the best of our knowledge these are the first instances of bisphosphoramidates that have been obtained up until now. The structures of compounds **I** (4-OCH_3–C_6H_4–CH_2–C_9H_{13}–NH_2Cl), **34** and **44** were further determined by X-ray crystallography. All of these structures produced three dimensional polymeric chains through strong- and weak hydrogen bonds. The presence of chiral aminoacidester moieties in the phosphoric triamides lead to chiral molecules that showed two sets of signals for the two groups. Interestingly, in phosphoric triamides containing cyanoacetamide moieties, the existence of aromatic amine substituents on the P atoms created central chiral phosphorus atoms, i.e. the two aromatic groups revealed two sets of peaks in the ^1H and ^{13}C NMR spectra, while compounds with aliphatic moieties did not display this effect.

1. Introduction

Phosphorus chemistry covers a wide area of sciences, including synthesis, coordination, biomedicine and theoretical matters. Phosphoramidates, bisphosphoramidates and phosphoric triamides are some important instances of phosphorus derivatives whose chemistry plays a significant role in various parts of science. Among the phosphoramidates, N-phosphorylated aminoacids have revealed high antitumor, antiviral and anti-HIV activities [1–4]. So far the syntheses and coordination chemistry of many bisphosphoramidates have been reported, containing P–N–P bonds via multi-step reactions [5–9], but here a simple one-pot method is presented to prepare such compounds. These types of compounds are potential bidentate ligands for the coordination to the metal atoms [10,11]. There are some reports on the synthesis of bisphosphoramides containing P(O)–$(CH_2)_n$–P(O) or P(O)–N(CH_3)–(binaphthyl)–N(CH_3)–P(O) moieties [12], as well as the P–$(CH_2)_n$–P group [13,14]. In addition, it is expected that due to the presence of the two phosphorus atoms in their structures, they will show more anticancer, antibacterial and enzyme inhibitory properties than phosphoramidates. Besides, the coordination chemistry of phosphoramidates [15–18], their biological applications [19–22], quantum chemical calculations on their structures [23,24], and their spectroscopic and X-ray crystal structures [25–27] are frequently studied. In the present work, following on from our previous research, we have synthesized and characterized several new phosphorus compounds of phosphoramidates, bisphosphoramidates (including P(O)NHC_6H_4-C(O)NHP(O) and P–N–P linkages), and phosphoric triamides. It is noteworthy that two simple one-pot pathways are presented for the synthesis of the new bisphosphoramidates and, as far as we know, these are the first examples of bisphosphoramidates that have been prepared so far. Furthermore, their NMR, IR and mass spectroscopic features as well as X-ray crystal structures are discussed and compared with our previous data.

2. Experimental

2.1. X-ray measurements

X-ray data of compound **34** were collected on a Bruker APEX II [28] and Siemens P3/PC [29] and those of compounds **I** and **44** on a

Bruker SMART 1000 CCD [30] single crystal diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å). The structures were refined with SHELXL-97 [31] by full matrix least-squares on F^2. The positions of hydrogen atoms were obtained from the difference Fourier maps. Routine Lorentz and polarization corrections were applied and an absorption correction was performed using the SADABS program for compounds **I** and **44** [32].

2.2. Spectroscopic measurements

^{1}H, ^{13}C and ^{31}P spectra were recorded on a Bruker Avance DRS 500 spectrometer. ^{1}H and ^{13}C chemical shifts were determined relative to internal Me_4Si, ^{31}P and ^{19}F chemical shifts relative to 85% H_3PO_4 and $CFCl_3$ as external standards, respectively. The field strengths for the acquisition of ^{1}H, ^{13}C, ^{31}P and ^{19}F NMR spectra were 500.13, 125.77, 202.46 and 470.54 MHz, respectively. Infrared (IR) spectra were recorded on a Shimadzu model IR-60 spectrometer. Elemental analyses were performed using a Heraeus CHN-O-RAPID apparatus. Melting points were obtained with an electrothermal instrument. The spectroscopic data of the synthesized compounds can be found in the online Supplementary data.

2.3. Syntheses

2.3.1. N,N′-4-Carboxyamidophenyl-bis phosphoramidic tetrachloride (**1**)

A suspension of 16 mmol PCl_5 in 40 mL CCl_4 was prepared and then 4.0 mmol of 4-aminobenzamide was slowly added to the mixture at room temperature. After 24 h stirring, the temperature was raised to 80–90 °C to reflux the flask contents. After 5 h, the yellow solution was cooled to 4 °C and 16.0 mmol of formic acid was added dropwise at −5 °C to oxide the product, releasing CO and HCl. The mixture was stirred for 2 h under these conditions and then the white product was washed with CCl_4 and dried under vacuum. Yield: 76%. m.p. = 115 °C. *Anal.* Calc. for $C_7H_6Cl_4N_2O_3P_2$: C, 22.73; H, 1.64; N, 7.57. Found: C, 22.70; H, 1.64; N, 7.56%. ^{31}P {^{1}H} NMR (CD_3CN): δ 5.44 (s), 6.69 (s). ^{31}P NMR (202.46 MHz; CD_3CN; 85% H_3PO_4): δ 5.44 (m), 6.69 (m). ^{1}H NMR (CD_3CN): δ 7.37 (d, ^3J(H,H) = 8.7 Hz, 2H, Ar–H), 7.93 (d, ^3J(H,H) = 8.7 Hz, 2H, Ar–H), 7.16 (d, ^2J(PNH) = 11.9 Hz, 1H, NH_{amine}), 9.41 (s, 1H, NH_{amide}). ^{13}C NMR (CD_3CN): δ 120.04 (d, ^3J(P,C) = 8.9 Hz), 127.92 (d, ^3J(P,C) = 10.6 Hz), 131.19 (s), 131.45 (s), 134.93 (s), 143.79 (s), 167.25 (d, ^2J(P,C) = 3.5 Hz, C=O). IR (KBr, cm^{-1}): 3405 (s, νNH), 3170 (s, νNH), 3005 (s), 2835 (s, CH), 2595 (s, CH), 2350 (m), 1644 (s, C=O), 1611 (s), 1453 (s), 1272 (s), 1211 (s, νP=O), 1176 (s, νP=O), 1156 (s), 1121 (s), 1098 (s), 1071 (s), 1049 (s), 994 (s, νP–N), 964 (s, νP–N), 750 (m), 537 (m), 478 (s, νP–Cl).

2.3.2. N-(4-Carboxy amidophenyl) phosphoramidic dichloride (**2**)

This compound was prepared in the same way as compound **1**, but the molar ratio of 4-aminobenzamide to PCl_5 was 1:1. Yield: 95%. m.p. = 80 °C. *Anal.* Calc. for $C_7H_7Cl_2N_2O_2P$: C, 33.23; H, 2.79; N, 28.02. Found: C, 33.22; H, 2.78; N, 28.03%. ^{31}P NMR (DMSO-d_6): δ 0.14 (m). ^{1}H NMR (DMSO-d_6): δ 7.38 (d, ^3J(H,H) = 8.2 Hz, 2H, Ar–H), 7.93 (d, ^3J(H,H) = 8.2 Hz, 2H, Ar–H), 9.36 (b, 3H, $NH_{amine,amide}$). ^{13}C NMR (DMSO-d_6): δ 122.05 (s), 128.94 (s), 132.50 (s), 136.29 (s), 167.11 (s, C=O). IR (KBr, cm^{-1}): 3385 (s, νNH), 3185 (s, νNH), 2795 (s, νCH), 2560 (s), 1649 (s, νC=O), 1601 (s), 1577 (s), 1524 (s), 1419 (m), 1293 (m), 1209 (m, νP=O), 1176 (m), 1115 (m), 837 (m, νP–N), 758 (s), 720 (m), 556 (m), 525 (m).

2.3.3. General procedure for the synthesis of compounds **3**–**12**

A solution of 8 mmol of corresponding amines in acetonitrile was added dropwise to a suspension of 1 mmol of compound **1** at −5 °C. After 24 h stirring, the product was filtered and washed with distilled water and recrystallized from a methanol-acetonitrile solution to yield molecules **3–8** and **10**. For the synthesis of diazaphosphole **9**, a solution of 4 mmol diamine plus 4 mmol triethylamine was added to the suspension. Compounds **11**–**13** were synthesized in the same way, but the molar ratio of the corresponding amines to compound **2** was 4:1.

2.3.4. N,N′-4-Carboxyamidophenyl-bis [bis (N″,N‴-isopropyl) phosphoric triamide] (**3**)

Yield: 61%. m.p. = 131.5 °C. *Anal.* Calc. for $C_{19}H_{38}N_6O_3P_2$: C, 49.56; H, 8.32; N, 18.26. Found: C, 49.54; H, 8.31; N, 18.26%. ^{31}P NMR (CD_3OD): δ 9.16 (m), 9.26 (m). ^{1}H NMR (CD_3OD): δ 0.99 (d, ^3J(H,H) = 6.5 Hz, 6H, CH_3), 1.00 (d, ^3J(H,H) = 6.5 Hz, 6H, CH_3), 1.01 (d, ^3J(H,H) = 6.4 Hz, 6H, CH_3), 1.02 (d, ^3J(H,H) = 6.4 Hz, 6H, CH_3), 3.43 (m, 4H CH), 7.17 (d, ^3J(H,H) = 8.7 Hz, 2H, Ar–H), 7.76 (d, ^3J(H,H) = 8.7 Hz, 2H, Ar–H). ^{13}C NMR (CD_3OD): δ 25.41 (d, ^3J(P,C) = 4.7 Hz, CH_3), 25.56 (d, ^3J(P,C) = 5.4 Hz, CH_3), 25.72 (d, ^3J(P,C) = 3.4 Hz, CH_3), 25.77 (d, ^3J(P,C) = 2.1 Hz, CH_3), 44.33 (s, CH), 44.36 (s, CH), 118.05 (d, ^3J(P,C) = 7.0 Hz), 126.20 (d, ^3J(P,C) = 8.0 Hz), 129.48 (s), 130.21 (s), 148.28 (s), 159.98 (s), 170.84 (s, C=O). 2.3.15. General procedure for the synthesis of compounds **14**–**21**

A solution of 7 mmol of the corresponding amine in acetonitrile was added dropwise to a solution of 1 mmol *N*-(4-X-phenyl) phosphoramidic dichloride (X = H, F, Cl, and Br) in acetonitrile at −5 °C. The flask contents were stirred for 48 h and then the precipitate was filtered, washed with water and dried in air to yield molecules **14**–**17**. To synthesise compounds **18**–**21**, this procedure was ap-

plied, but a solution of 4 mmol of 4-X-aniline (X = H, F, Cl, and Br) in acetonitrile was added dropwise to a solution of 1 mmol 2-pyridinyl phosphoramidic dichloride in acetonitrile.

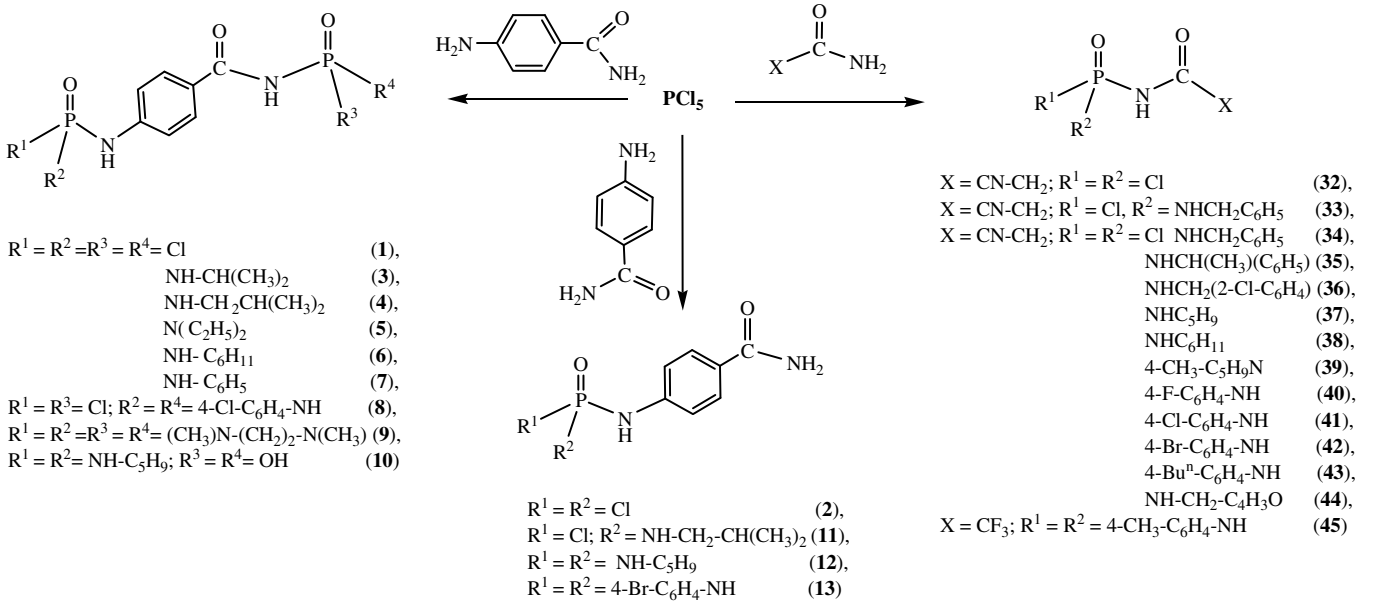
3. Results and discussion

3.1. Spectroscopic study



In this work a number of new phosphoramidate derivatives of bisphosphoramidates and phosphoric triamides were synthesized using PCl_5 and $POCl_3$ as starting materials, Schemes 1 and 2. Here, the spectroscopic features of these compounds are studied.

3.1.1. Bisphosphoramidates *1*, *3*–*10*

The syntheses of the bisphosphoramidates **1** and **3–10** (containing the (O)P–NH–C_6H_4–C(O)NH–P(O) linkage) were performed by the reaction of PCl_5 with 4-aminobenzamide in a 1:4 molar ratio to initially yield the bisphosphoramide $Cl_2P(O)NHC_6H_4C(O)NHP(O)Cl_2$ (**1**) that was used as an intermediate to react with different amines to give molecules **3–10**, Scheme 1. As far as we know, these compounds are the first examples of bisphosphoramidates that have been obtained up until now in such a simple one-step reaction.

The ^{31}P{^{1}H} NMR spectrum of compound **1** displays two singlet peaks for the two phosphorus atoms, at 5.44 and 6.69 ppm, and the substitution of different cyclic and acyclic aliphatic amines for the chlorine atoms shifts the δ (^{31}P) downfield, while substitution with phenyl groups leads to upfield shifts. The δ (^{31}P) in this series varies between −3.42 and −3.74 ppm (in **7** containing an aromatic aniline moiety) to 20.03, 20.16 ppm (in **9** containing a heterocyclic aliphatic diazaphosphole ring). The ^{1}H NMR spectrum of **3** displayed four doublet signals for the four types of CH_3 groups of isopropyl moieties due to the fact that the carbon atom of the CH group in the iso-propyl substituent is prochiral, and so the two methyl groups bonded to this group are different and show two signals in both the ^{1}H and ^{13}C NMR spectra. The ^{13}C NMR spectra of compounds **1** and **3–10** displayed six separate signals for the aromatic carbon atoms of the 4-aminobenzamide group and ^2J(P,C=O) = 3.5 Hz for the C=O group in **1**, while this constant was zero for the other compounds.

Compound **6**, with cyclohexyl substituents, displayed 12 peaks in the aliphatic region of the ^{13}C NMR spectrum, with four ^3J(P,C) coupling constants for CH_2 groups, four singlet signals for CH_2 groups and four ^2J(P,C) coupling constants for the CH groups. These results indicate that due to the different spatial orientation of the aliphatic six-membered rings, the four CH groups of the four cyclohexyl groups are different, but other related carbon atoms on one side of the molecule are equal to each other while being unequal to their related carbon atoms on the other side. The ^{13}C NMR spectrum of bis diazaphosphole **9** displayed two ^2J(P,C) = 5.0, 4.9 Hz for the CH_3 groups, two ^2J(P,C) = 7.3, 5.7 Hz for CH_2 moieties, two singlets for CH_3 as well as two singlets for CH_2 groups. A reason for this may be that for the phosphorus and carbon atoms a simple splitting is seen on one side of the molecule, while for the carbon atoms on the other side no coupling is observed. According to the Karplus relationship between the ^3J(P,X), X = H, C coupling constant and the P–N–C–X torsion angle [33], this is due to the P–N–C–H torsion angle values. The ^{13}C NMR spectrum of **10** showed three signals in the aliphatic region for the cyclopentyl moieties and the proton integrals in the ^{1}H NMR spectrum indicate that only two cyclopentyl groups are connected to one of the phosphorus atoms, while for

Scheme 1. Preparation pathway for compounds using PCl_5 as a starting compound.

Scheme 2. Preparation pathway for compounds using $POCl_3$ as a starting compound.

the other phosphorus atom the two cyclopentyl substituents are replaced by OH groups. This is probably due to the acquisition of the NMR spectra in D_2O solvent, and hence hydrolysis of the molecule occurs. A comparison of δ (^{31}P) in compounds **4** and **11** revealed that in the bisphosphoramide **4** the P atom is far more deshielded than in the phosphoric triamide **11**.

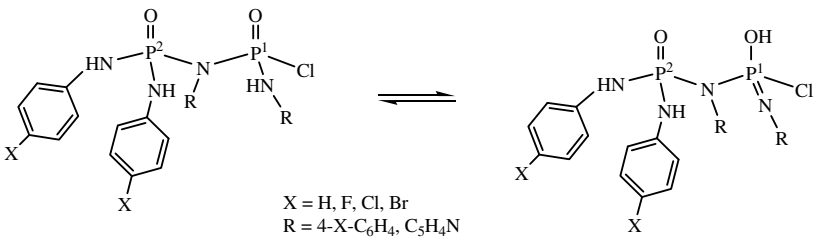
The IR spectra indicated two ν (P=O) for the two P=O bonds and a ν (C=O) in each compound. The $^2J(PNH_{amine})$ coupling constant for compounds **1**, **5** and **6** are 11.9, 9.1 and 7.6 Hz, respectively, and the corresponding $\nu(P–N)$ values are 994, 941 and 907 cm^{-1}. These data reveal that the more the ν(P–N) value increases, i.e., a shorter P–N bond with more s character in the nitrogen hybridization, the more the $^2J(PNH_{amine})$ coupling constant is enhanced.

3.1.2. Bisphosphoramidates *14–21*

The bisphosphoramidates **14–21** (containing the (O)P–N–P(O) linkage) were prepared by the reaction of $POCl_3$ with different first-type aromatic amines, Scheme 2. To our knowledge, this is the first attempt that has been made to obtain these types of

compounds using time-dependent reactions. That is, the synthesis procedure of these molecules is similar to that of phosphoric triamides, but these compounds are obtained after 48 h stirring and if the reaction mixture was allowed to stir for about one or two weeks, the corresponding phosphoric triamides would be yielded. In fact, these compounds are kinetically stable products of the reaction and are not stable with time. Thus after a relatively long time they convert to their related thermodynamically stable phosphoric triamides. The ^2J(P,P) coupling constants observed in the $^{31}P\{^1H\}$ NMR spectra are about 20 Hz. The two phosphorus atoms are not connected directly to each other, because the ^1J(P,P) coupling constants in other similar compounds are reported to be about 200 Hz [34]. The ^2J(P,P) coupling constant in compound **14** was measured as 19.7 Hz in DMSO-d_6 and it decreased to 17.5 Hz in the solvent CD_3OD, probably due to the different hydrogen bonding interactions in this solvent. The ^{31}P NMR spectra of compounds **14** and **18** (containing the anilinium substituent) indicated two signals, the upfield one of them being a multiplet and the other being only a doublet peak. This trend is reverse for compounds **15–17** and **19–21**, including *para*-haloanilinium groups. It is clear that the doublet peak is related to the P^1 atom and the multiplet peak to the P^2 atom (Scheme 3), and the reason for the reduced splitting of P^1 with the NH group of the aromatic amine may be described by the resonance interaction in Scheme 3. The downfield shift of δ (^{31}P) for the P^2 atom in compounds containing *para*-haloanilinium groups is related to the electron withdrawing nature of the electronegative halogen atoms in comparison with the inert H atom.

Comparison of δ (^{31}P) in compounds **14–17** and also in **19–21** revealed that the shielding of the P^1 and P^2 atoms decreases with the decreasing halogen electronegativity from F to Cl to Br (i.e., from **15** to **17** and from **19** to **21**). The shielding of the phosphorus atoms in compounds **14** and **18** containing anilinium moieties are greater than that of compounds containing 4-fluoroanilinium groups, and the shielding order is Br > Cl > H > F. The reason for the greater shielding of the P atoms in compounds with 4-Cl and 4-Br substituents relative to the H substituent can be explained by the electron release of the halogens through resonance. The ^{13}C NMR spectra of **15** and **19** indicate ^{1-4}J(F,C) coupling constants as well as ^3J(P,C) coupling constants. The IR spectra revealed two ν(P=O) frequencies for the two P=O bonds and we can relate the smaller ν(P=O) to the weaker P=O bond and vice versa. In molecules **14** and **18**, the upfield signal is related to P^2 and in compounds **15–17** and **19–21**, it is related to P^1.



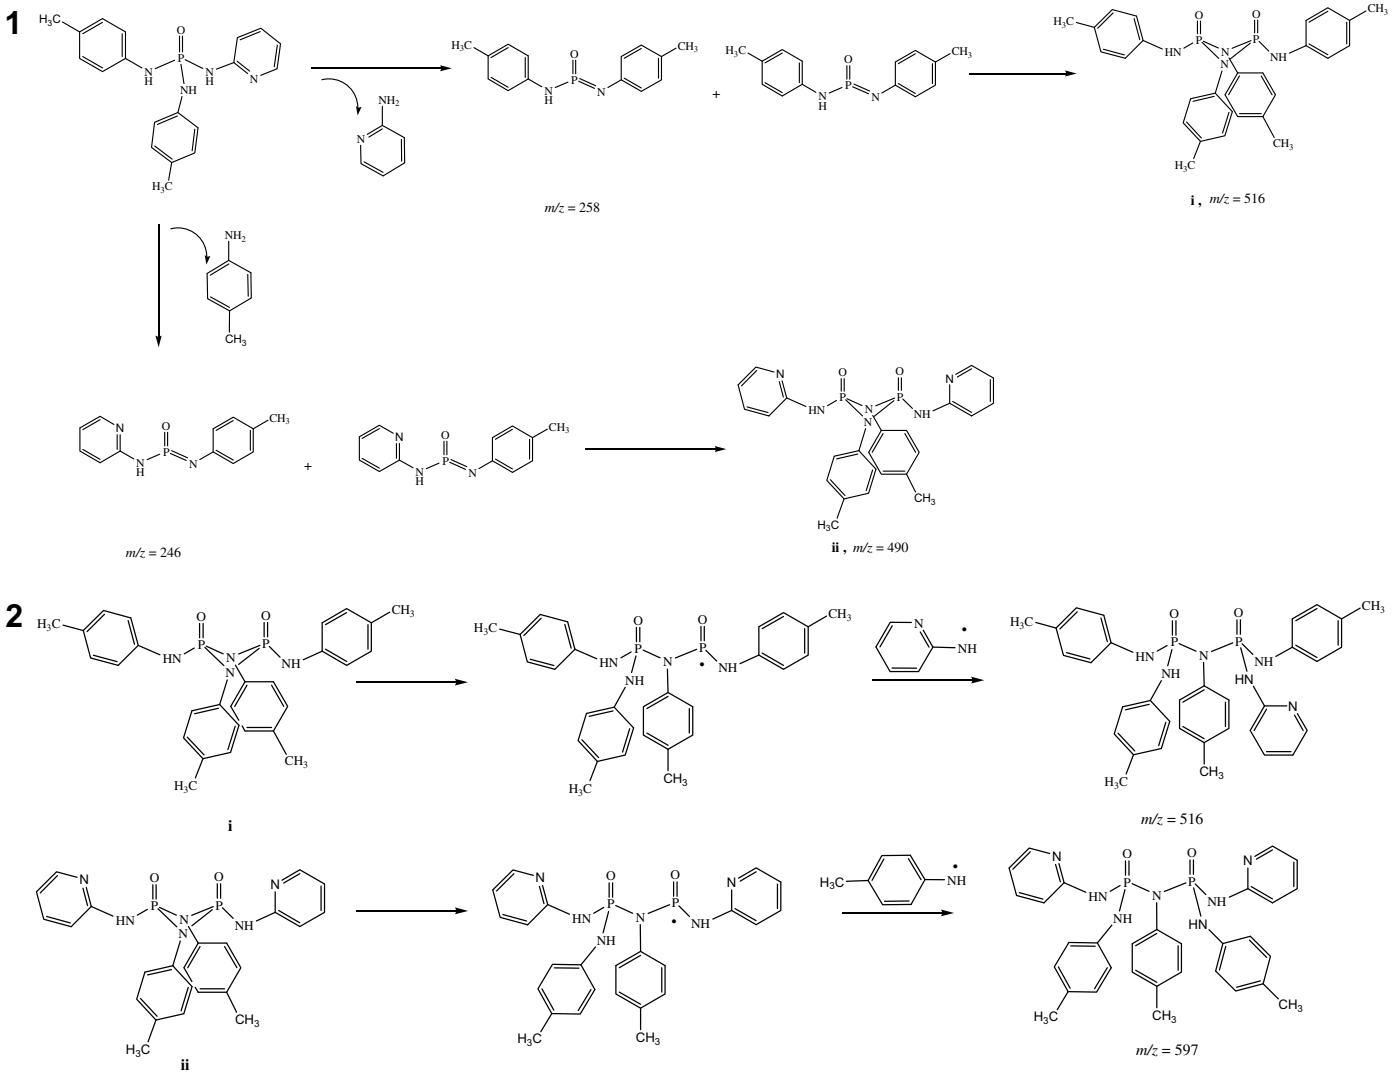
3.1.3. Phosphoramidates and phosphoric triamides

The phosphoramidates **2** and **11–13** were prepared by the reaction of PCl_5 with 4-aminobenzamide in a 1:1 molar ratio and we may judge that the P–N bond is formed from the anilinium NH_2 group not from the amidic $C(O)NH_2$. This is because stronger P–N bonds always have been observed for $P–N_{amine}$ compared to $P–N_{amide}$ in our other synthesized compounds, and also the C(O) group causes weakening of the P–N bond via resonance interactions. A comparison of δ (^{31}P) in these molecules indicated that substitution of aliphatic electron donor amines with the chlorine atoms of **2** leads to a more positive P atom (in **11** and **12**), while the aromatic 4-bromoaniline (in **13**) had the opposite effect. In the ^{13}C NMR spectra of these compounds four singlet signals were observed for the benzamidic ring, while in their related bisphosphoramidates six different signals were obtained for the six carbon atoms of the ring. Replacement of an amine group by a chlorine atom gives a ν(P–N) value indicating a stronger P–N bond and a ν(C=O) value indicating a weaker C=O bond.

For the synthesis of compounds **23–26**, first the hydrochloride salt of the phenylalanine benzylester was obtained for subsequent reaction with an $RP(O)Cl_2$ intermediate, where R = amine or phenol. Phosphoric triamides of this type have shown antitumor, antiviral and anti-HIV properties [1–4] and for this reason we have been interested in studying such molecules. In the case of compound **23**, it is concluded from the ^1H and ^{13}C NMR spectra that the phenylalanine benzylester is hydrolyzed and the phenylalanine is connected to the phosphorus atom. The ^1H and ^{13}C NMR spectra of molecules **23–26** displayed two unequivalent aminoester (or aminoacid) moieties, probably owing to the presence of chiral CH groups as well as the spatial hinderance caused by these two huge substituents. However, this is not observed in the ^1H and ^{13}C NMR spectra of **29** that also contain two chiral aminoester groups. Therefore, the chirality of these moieties is not the reason for the difference between these groups in compounds **23–26**, but it is the various spatial orientations of the aminoester/aminoacid groups (the huge groups are far away from each other due to the repulsion) which result in the creation of a central chiral phosphorus atom.

The ^{31}P NMR spectra exhibited an upfield shift for δ (^{31}P) in compounds including electron donor groups such as *p*-tolyl (**24**), while it is shifted downfield with electronegative 4-nitroanilinium or 4-chloroanilinium groups (**25** and **26**). Both compounds **23** and **27** contain a *p*-toluidinium substituent and their difference is the replacement of the aminoacid groups in **23** with aminoester groups (**27**). The δ (^{31}P) in **23** is upfield, and the P=O bond shows a weaker ν(P=O), whereas the C=O bond has a stronger ν(C=O) relative to those of **27**. The δ (^{31}P) in compound **28** is upfield relative to that of **29**, perhaps due to the greater electron donation of the two chlorine atoms via resonance in comparison to the two *p*-toluidinium groups.

A huge amino group is bonded to the phosphorus atom in molecules **30** and **31**. This kind of amine group has indicated possible clinical applications [35–37] and significant importance in medicine. Our attempts to obtain a single crystal of compound **30** in a methanol/acetonitrile mixture resulted in structure **I**, which is most likely a hydrolyzed product of **30** in the solution (perhaps the P–N bond of this giant amino group is labile due to steric repulsion). The δ (^{31}P) of **30** is at a much higher field relative to that of **31**. Therefore, it could be concluded that the phenyl ring plays an important role as an electron withdrawing group in compound **31**.



Scheme 3. The resonance interaction in bisphosphoramidates **14–21**.

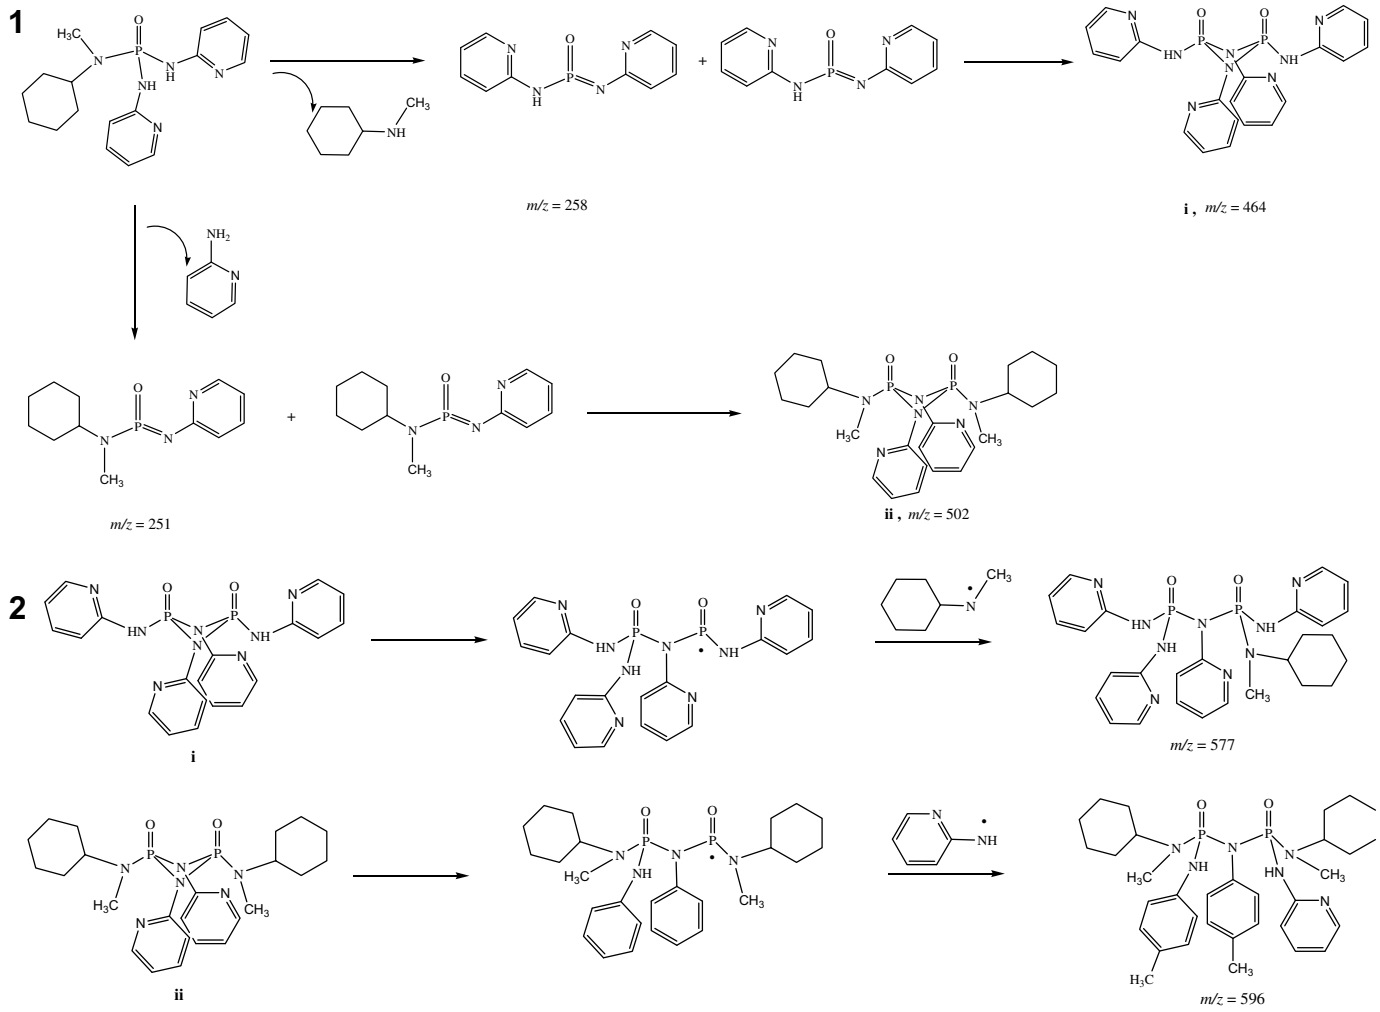
The ^{31}P NMR spectra of the phosphoramidates **32**–**44**, containing the cyanoacetamide substituent, demonstrated that substitution of the chlorine atoms in compound **32** by aliphatic amino groups result in deshielded phosphorus atoms, while replacing with aromatic amino groups of the formula 4-X–C_6H_4NH, X = F, Cl, Br, $(CH_2)_3CH_3$, leads to much more shielded phosphorus atoms. The connection of *p*-butylaniline to the phosphorus atom causes its shielding, and the δ (^{31}P) is the most upfield in this series. Also, the δ (^{31}P) of the *p*-haloanilinium substituents becomes more positive on decreasing the halogen electronegativity. δ (^{31}P) changed in the order of Br > Cl > F > $(CH_2)_3CH_3$ for compounds **40**–**43**. An interesting feature in the ^{1}H and ^{13}C NMR spectra of compounds **40**–**43**, having *p*-substituted anilinium substituents, is that the two aromatic groups are different and present two sets of signals in the spectra, whereas when aliphatic amino groups are replaced by the two Cl atoms in **32**, they are equal. This characteristic was not seen in the spectra of compound **45**.

The ^{13}C NMR spectra of **32**–**44** revealed that the ^2J(P,C) coupling constant, i.e., the coupling of the amidic CH_2 carbon atom with the P atom, is decreased from 10.5 Hz (in **32**) to about 8.9 Hz (in **33**–**44**). Therefore, replacement of the chlorine atoms by different amino groups reduces the ^2J(P,C) coupling constant. Compound **35** contains α-phenylethyl substituents that have a chiral carbon atom at the CH groups, leading to the appearance of two sets of peaks in its ^{1}H and ^{13}C NMR spectra. The ^{13}C NMR spectrum of compound **37** exhibited five signals for the five carbon atoms of the two aliphatic cyclopentyl moieties owing to the fact that the two aliphatic rings are equal, but the five carbon atoms of the ring are different. The ^{13}C NMR spectra of compounds **38** and **39** display eight separate signals for the aliphatic carbon atoms of the cyclohexyl and 4-methylpiperidinyl groups due to the fact that the two aliphatic groups are not equal. A ^4J(P,C) coupling constant of 1.6 Hz was observed for the splitting of the C≡N carbon atom with the phosphorus atom in **32**, but this coupling did not occur in molecules **33**–**44**.

The mass spectrum of compound **29** indicates ionic fragments corresponding to this molecule as well as a base peak at *m/z* = 352 (100%). There are also some peaks at *m/z* > 352 related to dimerization of the ionic fragments [38]. The following rearrangements are proposed for the mechanism of the dimerizations (Scheme 4(1 and 2)).

(a) The P–N bond of the aminopyridinium group is broken, an aminopyridine group is released and a P=N bond is formed. Then, conjugation of the two similar fragments, i.e. a cycloaddition reaction, will yield the diazadiphosphetidine **i** with *m/z* = 516. (b) If a *p*-toluidine group is separated from the molecule and the resulting

Scheme 4. The proposed fragmentation mechanism of compound **29** in the mass spectrum.



similar fragments are bonded to each other, another diazadiphosphetidine (**ii**) is obtained with $m/z = 490$. (c) If one of the P–N bonds in the cyclic diazadiphosphetidines **i** breaks then an aminopyridinium radical cation is bonded to it, a bisphosphoramidate with $m/z = 516$ could be produced. (d) If one of the P–N bonds in the diazadiphosphetidine **ii** breaks then a *p*-toluidinum radical cation is bonded to it, a bisphosphoramidate with $m/z = 597$ is obtained. This fragmentation pathway is also proposed for the mass spectrum of compound $(C_5H_4N–NH)_2P(O)[N(CH_3)(C_6H_{11})]$ [39] in which there are some molecular ion peaks at m/z greater than the base peak, and a similar mechanism could be considered for its fragmentation (Scheme 5(1 and 2)).

3.2. X-ray crystallography

Single crystals of compounds **I** (4-OCH_3–C_6H_4–CH_2–C_9H_{13}–NH_2Cl), **34** and **44** were obtained from a solution of methanol/chloroform or methanol/acetonitrile/water at room temperature. The crystallographic data and the details of the X-ray analysis of these compounds are represented in Table 1, and selected bond lengths and angles are given in Table 2. Hydrogen bonding data of these structures are presented in Table 3. Molecular structures (ortep views) have been shown in Figs. 1–3.

There are two symmetrically independent molecules in the crystalline lattice of compound **I** due to the differences in the related torsion angles of these two conformers. The torsion angles N(2)–C(1)–C(8A)–C(4A) and N(2′)–C(1′)–C(8′A)–C(4′A) are 6.6(3)° and 8.7(3)° (also, compare the torsion angles N(2)–C(1)–C(9)–C(10), N(2′)–C(1′)–C(9′)–C(10′) and C(14)–C(13)–O(1)–C(16), C(14′)–C(13′)–O(1′)–C(16′) that are −68.0(3)°, −61.0(3)° and −11.4(4)°, −1.8(4)°, respectively). This phenomenon was observed for some of our previously reported structures [17,18,23]. Although there is a C=C double bond between the two unsaturated six-membered rings, they are not planar and show a puckered shape. The C(5)–C(10) and C(5′)–C(10′) carbon atoms of the phenyl ring as well as their corresponding hydrogen atoms in compound **34** revealed disorder in the structure that can be described by free rotation along the C(4)–N(3) bond, causing uncertainty in the determination of the carbon and hydrogen locations of the phenyl ring.

The P=O bond lengths in molecules **34** and **44** are 1.483(16) and 1.491(15) Å, which are larger than the normal P=O bond length (1.450 Å) [40]. The P atoms have slightly distorted tetrahedral configurations, e.g. the surrounding angles around the P atoms of the two symmetrically different molecules in compound **34** are in the range 103.16(10)–117.34(10)°. The P–N_{amide} bond lengths are longer than the P–N_{amine} bond lengths because of the interaction of the N_{amide} atom with the π resonance system of the C=O group, which results in a shorter C–N_{amide} bond length, i.e., 1.687(19) > 1.616(19), 1.620(2) (in **34**), and 1.685(17) > 1.622(18), 1.621(18) Å (in **44**). All of these P–N bonds are shorter than the typical P–N single bond length (1.770 Å) [40]. The nitrogen envi-

Symmetry transformations used to generate equivalent atoms: (#1) x, y, z, (#2) $x+1, y, z$, (#3) $x-1, y, z$, (#4) $x+1, y-1, z$, (#5) $-x, -y+1, -z+2$, (#6) $-x, -y+1, -z+1$, (#7) $x-1, y, z$, (#8) $x+1, y, z$.

are 360.07° and 359.11°, respectively. Similar results were obtained for the nitrogen atoms in the structure of **44**, which indicate sp^2 hybridization for the nitrogen atoms, although because of the repulsion and steric effects, some angles were either greater or smaller than 120°. It is noticeable that the P═O and C═O bonds indicate an *anti* configuration with respect to each other in compounds **34** and **44**, which is in agreement with our previously reported results [17,18,25–27].

The two symmetrically independent molecules of **I** are connected to each other through two intermolecular N(2)–H(2A)···Cl(1) and N(2′)–H(2′A)···Cl(1) hydrogen bonds and each of these independent molecules is linked to its symmetrically independent molecules via intermolecular N(2)–H(2B)···Cl(2) and N(2′)–H(2′B)···Cl(2) hydrogen bonds. Considering the weak intermolecular C–H···O and C–H···Cl hydrogen bonds, this creates a three dimensional polymeric chain in the crystalline lattice. Intermolecular N(1)–H(1N)···O(1) hydrogen bonds between the two adjacent molecules in compound **34** create a non-centrosymmetric dimer (because of the disorder in one molecule, the dimer is not centrosymmetric). This dimer is connected to similar dimers by intermolecular N(2)–H(2N)···O(2) and N(3)–H(3N)···O(1) hydrogen bonds. Beside these H-bonds, there are also weak intermolecular hydrogen bonds such as C(16)–H(16A)···O(2), and all of them produce a three dimensional network. The intermolecular N(2)–H(2A)···O(2) and N(3)–H(3A)···O(1) hydrogen bonds in the structure of **44** connect the neighboring molecules to each other to construct a linear chain. The molecules in this polymeric chain are linked to other molecules through intermolecular N(1)–H(1A)···O(1) hydrogen bonds. Repetition of the H-bonds generates a one dimensional polymeric chain. If weak intermolecular C–H···O and C–H···N hydrogen bonds [like C(12)–H(12A)···O(2), C(2)–H(2B)···N(4) and C(13)–H(13A)···N(4)] are taken into account, a 3-D polymeric chain is obtained.

4. Conclusion

Using PCl_5 and $POCl_3$ as starting materials, a number of novel phosphorus derivatives of bisphosphoramidates, phosphoramidates and phosphoric triamides were synthesized. The reaction of 4-aminobenzamide with PCl_5 in different molar ratios yielded different products, bisphosphoramides and phosphoric triamides. Furthermore, the interaction of $POCl_3$ with first-type aromatic

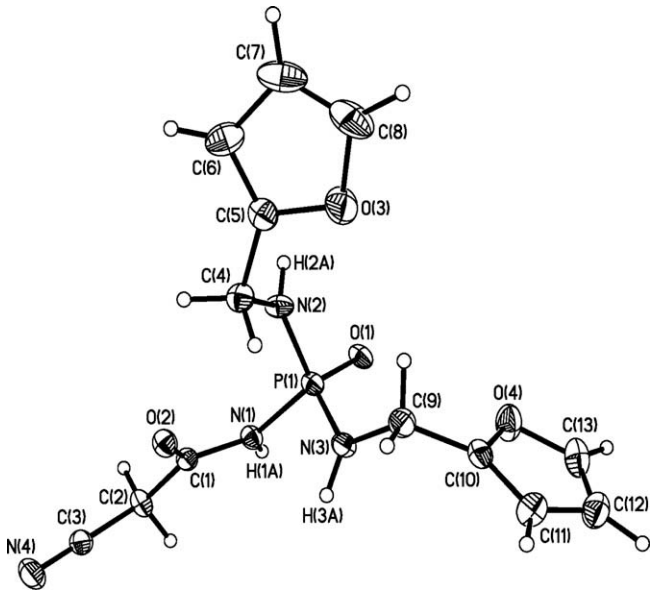

Fig. 3. Molecular structure and atom labelling scheme for C≡N–CH_2C(O)NH-P(O)($NHCH_2C_4H_3O)_2$, compound **44** (50% probability ellipsoids) that shows two conformers in the crystal lattice.

amines gave bisphosphoramidates with a P–N–P linkage that demonstrated $^2J(P,P) \approx 20.0$ Hz in the ^{31}P NMR spectra. Indeed, two simple one-pot pathways are presented here for the synthesis of the new bisphosphoramidates that are, to our knowledge, the first examples of bisphosphoramidates that have been obtained so far. The X-ray crystal structures of compounds **I** (4-OCH_3–C_6H_4–CH_2–C_9H_{13}–NH_2Cl), **34** and **44** were further investigated and all of these structures displayed three dimensional polymeric chains through strong- and weak hydrogen bonds. The presence of chiral amino-acidester moieties in the phosphoric triamides lead to chiral molecules which showed two sets of signals for the two groups.

ABSTRACT

Diphenylphosphinecyrhetrene ligand (η^5-$C_5H_4PPh_2$)$Re(CO)_3$ (**1**) reacts with 1 equiv. of $PdCl_2(NCPh)_2$ to form, after workup, the square-planar *trans*-[(η^5-$C_5H_4PPh_2$)$Re(CO)_3$]$PdCl_2$(NCMe) (**2**). Similarly, reaction of **1** with (tetrahydrothiophene)AuCl produces, in excellent yield, the bimetallic complex [(η^5-$C_5H_4PPh_2$)$Re(CO)_3$]AuCl (**3**) with a linear P–Au–Cl moiety. From the reaction of 2 equiv. of **1** with $CuBr(SMe_2)$ the planar-trigonal complex [(η^5-$C_5H_4PPh_2$)$Re(CO)_3$]$_2$CuBr (**4**) was obtained. ^{31}P NMR and X-ray crystallography demonstrate, for the three cases, that (η^5-$C_5H_4PPh_2$)$Re(CO)_3$ acts as a monodentate ligand. The structural parameters of the bimetallic complexes are compared with related diphenylphosphinoferrocene metal complexes, described in the literature.

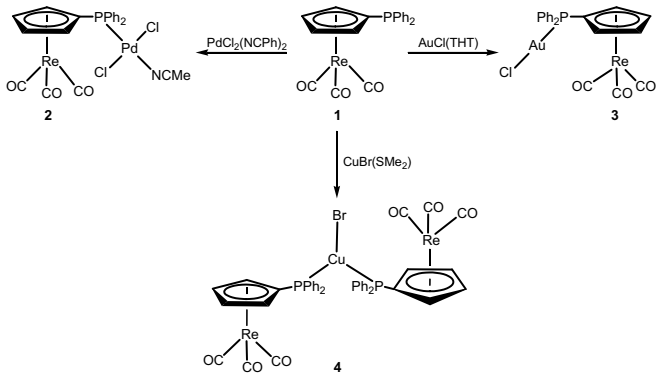
1. Introduction

The diphenylphosphinocyclopentadienyl group η^5-coordinated to metal fragments has proved to be a versatile unsymmetrical mono- or bidentate ligand to form homo- and heterobimetallic complexes [1–3]. Complexes of this type include those which have two metal centers of a very different nature (for example, early and late transition metals) held together through a bridging ligand [4,5] or both a bridging ligand and a metal–metal bond [6–9]. The most common synthetic approach to form simple bridging bimetallic compounds has been to bind first the cyclopentadienyl moiety to one of the transition metals, thus producing a metallo ligand derivative, which may then act as a monodentate phosphorous ligand [4,5]. Several examples of metallo ligands of the type (η^5-$C_5H_4PPh_2$)MLn, M = Fe, Ti, Zr, Co, Mo, Rh, etc. have been used to prepare a large number of bimetallic complexes with interesting chemical, electrochemical and catalytic properties [1,2,10]. Nevertheless, examples of group 7 metallo ligands remain relatively unexplored. (η^5-$C_5H_4PPh_2$)$M(CO)_3$ M = Mn and Re, were first reported by Rausch and Spink in 1989 [11] by reaction of diphenylphosphinocyclopentadienylthallium with $BrM(CO)_5$. Much more recently, Gladysz and co-workers [12] prepared (η^5-$C_5H_4PR_2$)$Re(CO)_3$, R = Ph and *tert*-Bu, by direct reaction of (CpLi)$Re(CO)_3$ with PR_2Cl. Although, the phenyl derivative was used in a palladium-base catalytic system for Suzuki coupling reactions, the bimetallic Re–Pd complex, which is probably involved in the catalytic system, was neither isolated nor characterized *in situ*. The lack of information about the coordination chemistry of (η^5-$C_5H_4PPh_2$)$Re(CO)_3$ (**1**) and the unknown structural data for bimetallic complexes containing this metallo ligand, encouraged us to prepare and fully characterize by spectroscopic and crystallographic techniques the square-planar *trans*-[(η^5-$C_5H_4PPh_2$)$Re(CO)_3$]$PdCl_2$(NCMe) (**2**), linear [(η^5-$C_5H_4PPh_2$)$Re(CO)_3$]AuCl (**3**) and trigonal [(η^5-$C_5H_4PPh_2$)$Re(CO)_3$]$_2$CuBr (**4**) complexes.



2. Results and discussion

The preparation of diphenylphosphinocyclopentadienyl rhenium tricarbonyl (**1**) was carried out according to the Gladysz procedure [12]. Bimetallic complex (**2**) is formed by the reaction of (η^5-$C_5H_4PPh_2$)$Re(CO)_3$ with commercially available $PdCl_2(NCPh)_2$ (1:1 molar ratio) in $CHCl_3$ under reflux for 4 h. Upon cooling the mixture to room temperature, a red solid is formed which was slightly soluble in chloroform but soluble in MeCN. Crystallization from MeCN–Et_2O yielded orange-red microcrystals of **2** (Scheme 1).

This reaction probably involves in a first step, the formation of the chloro-bridged dimeric complex [$Pd(\mu$-Cl)Cl(η^5-$C_5H_4PPh_2$)-$Re(CO)_3$]$_2$ which then, in the crystallization step, reacts with MeCN to form the observed product. We were unable to characterize the red solid in solution; nevertheless, the elemental analysis is consistent with the proposed formula. Similar palladium chloro-bridged

Scheme 1.

complexes containing the phosphinoferrocene ligand have been reported [13–15].

Compound **2** is air and moisture stable and moderately soluble in polar organic solvents and insoluble in non polar solvents. The elemental analysis of this compound is in good agreement with the proposed structure. The ^{1}H NMR spectrum (in CD_3CN) of **2** showed in addition to the resonances of the metallo ligand, the presence of coordinated MeCN as a singlet at δ 1.98. The ν(CN) absorption band observed at 2297 cm^{-1} (KBr disc) in the IR spectrum is further evidence for coordinated MeCN. A single resonance in the ^{31}P NMR spectrum indicates a single phosphorous environment due to the presence of the metallo ligand. This resonance is shifted to lower field when compared to the free ligand ($\Delta\delta$ = 38.3). Similar shift have been observed in analogous palladium complexes possessing the diphenylphosphinoferrocene ligand [14].

The Re–Au bimetallic complex (**3**) was formed by reacting the ligand **1** with the recommended gold precursor chloro(tetrahydrothiophene)gold(I) [16] in CH_2Cl_2, at room temperature (Scheme 1). It was isolated as white crystals in 90% yield. The mass spectrum and elemental analysis of this compound agrees well with the presence of a single cyrhetrenylphosphine.

The ^{1}H NMR spectrum of this complex showed, apart from the multiplet from the phenyl protons, the signal of the cyrhetrenyl unit as two multiplets for the cyclopentadienyl protons ring. Like the previous case, the phosphorous resonance (observed at δ 25.7) in the ^{31}P NMR spectrum is shifted to lower field upon coordination to Au(I). $\Delta\delta$ = 42.7, this value is comparable to those observed in diphenylphosphinoferrocenes coordinated to the Au–Cl fragment [17,18].

With regard to the complex (**4**) and considering that the reaction of copper(I) halide, with tertiary organo-phosphines gives a wide range of products of variable stoichiometry and molecular structure [19], we decided to carry out the reaction of $CuBr(SMe_2)$ with an excess of ligand **1** (1:4 molar ratio) (Scheme 1). After overnight stirring (in CH_2Cl_2 at room temperature) followed by solvent evaporation, a white solid was obtained, which showed two resonances in the ^{31}P NMR spectrum (δ −17.0 and δ *−13.5)* due to the presence of uncoordinated **1** and a new compound. Column chromatography allowed the separation of the two compounds; a mixture of CH_2Cl_2/hexane (1:1) moved unreacted **1** whereas the new complex was eluted with acetone. The solid obtained after evaporation of acetone showed the same spectroscopic parameters as the one isolated from the direct reaction of **1** and $CuBr(SMe_2)$ in a 2:1 molar ratio. From the latter procedure, complex **4,** was isolated as white crystals in 81% yield, after crystallization from CH_2Cl_2/hexane. The elemental analysis of **4** is in good agreement with the proposed structure. The ^{31}P NMR spectrum of **4** is consistent with the presence of a single compound in solution (δ −13.5). The small downfield shift from that of the parent ligand ($\Delta\delta$ = 3.5) is comparable to those found in other three-coordinated complexes of copper(I) [20,21].

3. X-ray crystallography

The numbering scheme of the bimetallic Re–Pd complex **2** is presented in Fig. 1. Crystallographic data are presented in Table 1, whereas selected bond lengths and angles are shown in Table 2. In complex **2** the palladium atom exhibits a slightly distorted square-planar geometry which is supported by (i) the displacement of palladium atom by 0.06 Å away from the $PNCl_2$ least-squares plane and (ii) the sum of the four angles around the palladium atom which is 361°. The phosphine and the acetonitrile ligand are found in a *trans* orientation with angles P(1)–Pd–N(1) 175.71°(15), Cl(1)–Pd–Cl(2) 171.25°(9). In the phosphine ligand the phosphorous atom is tetrahedrally surrounded by the two phenyl rings (P–C(14) = 1.808(5) Å and P–C(15) = 1.827(6) Å), and the cyrhetrenyl ligand (P–C(1) = 1.807(5) Å). The latter distance compares well to 1.803(3) Å found in (*trans*-[PdMeCl(PPh_2Fc)$_2$], (PPh_2Fc = ferrocenyldiphenylphosphine) [14]. The bond length Pd–P (2.2217(13) Å) is quite short when compare to the similar distance measured in related phosphinoferrocene complexes (*trans*-[PdMeCl(PPh_2Fc)$_2$], Pd–P = 2.3328(10) Å [14] *trans*-[$PdCl_2$-(PPh_3)$_2$] Pd–P = 2.337(1) Å [22] but it resembles to the one observed in the dimer *trans*-[Pd(μ-Cl)Me(PPh_2Fc)]$_2$ (avg. 2.223(9) Å) [13]. The Pd–N bond length (2.085(5) Å) compares well with those obtained for other square-planar Pd(II) complexes containing coordinated acetonitrile with a *trans* P–Pd–N moiety, such as (MeCN)$PdCl_2$(μ-dpmp)$PdCl_2$ [23].

The C–P–Pd angles are all larger than the ideal 109.5°, and range from 110.48(17)° to 118.25(18)°, while all C–P–C are smaller than expected for normal tetrahedra, i.e. 101.3(2)–104.5(2)°. Similar deviation has been reported for related Pd-complexes and explained in term of the valence shell electron pair repulsion theory [14,24].

The molecular structure of complex **3** is shown in Fig. 2 and selected bond distances and angles are presented in Table 2. Taking into account the gold(I) environment this compound exhibits a very regular linear geometry, with a P–Au–Cl angle of 178.24(4)°

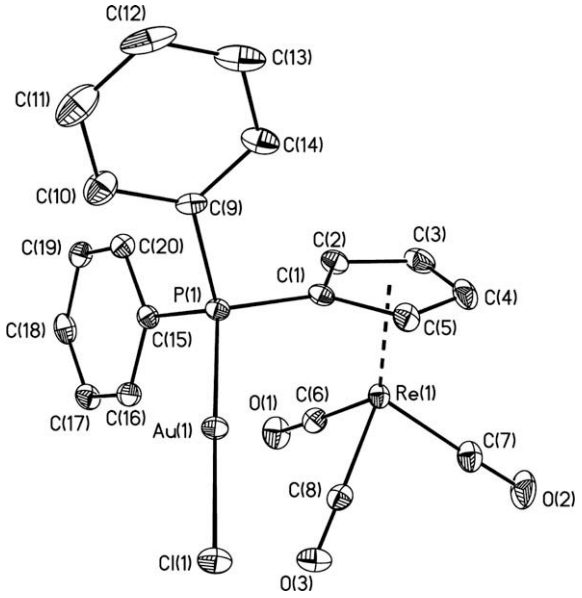

Fig. 2. ORTEP's plots of complex **3** with displacement ellipsoids at the 30% probability level.

which is slightly larger to those found in related ferrocenyl phosphine derivatives, for example, 177.12(10)° in AuCl(PPh$_2$Fc), [17] 176.1(1)° in AuCl(PPhFc$_2$) [25] and 176.01(7)° in AuCl(PPh$_2$CH$_2$Fc) [26]. The Au–Cl and Au–P bond distances of 2.2798(13) Å and 2.2214(13) Å are similar to the ones measured in AuCl(PPh$_2$Fc) and AuCl(PPhFc$_2$) [17,25]. The shortest gold–gold distance in the lattice is 6.640 Å, which excludes the possibility of any bonding interaction between gold atoms.

Crystals of complex **4** were obtained from a of CH$_2$Cl$_2$/hexane mixture (1:5) at room temperature. A view of the molecular structure is presented in Fig. 3 with the relevant interatomic distances and angles summarized in Table 2. The coordination geometry about the copper atom is almost idealized trigonal planar according to (i) the negligible displacement of copper atom away from the P$_2$Br plane and (ii) the sum of the three angles around the copper atom which is 360°. These two last observations are consequences of symmetry operator (C_2 axis) in the Cu–Br bond. The bulky cyrhetrenyl groups adopt an *anti* conformation respect to the trigonal plane. The Cu–Br distance of 2.3416(10) Å is comparable to those observed in other three-coordinated copper(I) compounds [20,21,27]. The Cu–P distance of 2.2346(11) Å is somewhat shorter than that measured previously in copper(I) bromide complexes containing tertiary organo-phosphines [20,21,27]. Within the cyrhetrenyl group the average Re–Cp (centroid) and Re–C(O) distances and Re–C–O angles are comparable to the one observed in complexes **2** and **3**, and are also concordant with the corresponding values reported for other complexes containing the cyrhetrenyl group [28–30].

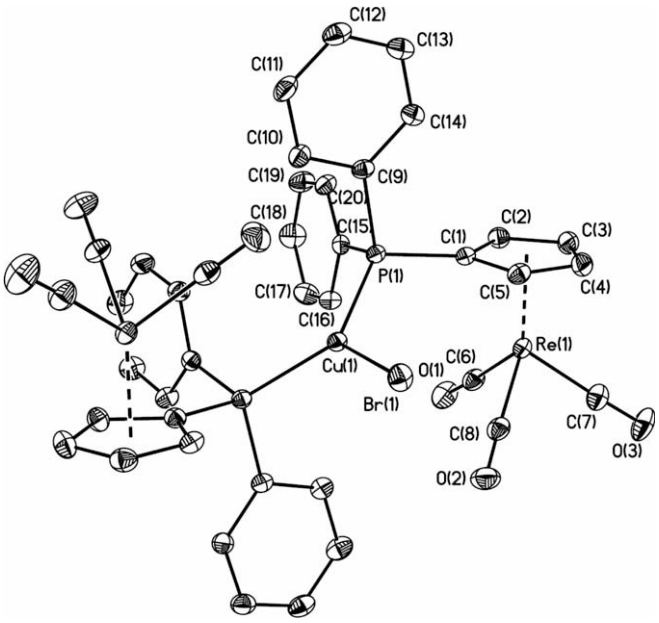

Fig. 3. ORTEP's plots of complex **4** with displacement ellipsoids at the 30% probability level.

4. Experimental

All reactions were carried out under nitrogen atmosphere using standard Schlenk techniques. Solvents were purified as follow: hexane and tetrahydrofuran by distillation from sodium/benzophenone ketyl; dichloromethane, chloroform and acetonitrile by distillation from P_2O_5. $PdCl_2(NCPh)_2$ and $CuBr(SMe_2)$ (Aldrich) were use as received. $(\eta^5\text{-}C_5H_4PPh_2)Re(CO)_3$ (**1**) [12] and (tht)AuCl (tht = tetrahydrothiophene) [16] were prepared following published procedures. Infrared spectra were recorded with a Perkin–Elmer FT-IR Spectrum One spectrophotometer. NMR spectra were recorded with a Bruker Avance 400 spectrometer. ^1H NMR chemical shifts were referenced using the chemicals shifts of residual solvent resonances, and $^{31}P\{^1H\}$NMR chemical shifts were referenced to 85% H_3PO_4 as external standard. The mass spectrum of **3** was obtained on a Thermo-Finnigan MAT 900XP, at the Facultad de Ciencias Químicas y Farmacéuticas, Universidad de Chile.

4.1. trans-[(η^5-$C_5H_4PPh_2$)Re(CO)$_3$]PdCl$_2$(NCMe) (**2**)

To 60 mg (0.116 mmol) of $(\eta^5\text{-}C_5H_4PPh_2)Re(CO)_3$ (**1**) dissolved in 15 mL of chloroform were added 44 mg (0.115 mmol) of solid $PdCl_2(NCPh)_2$ and the mixture was refluxed for 4 h. After cooling at room temperature a red precipitate was formed, this was filtered out and washed with chloroform. The elemental analysis of this material reveals a dimeric nature (*Anal.* Calc. for $[C_{20}H_{14}O_3PCl_2\text{-}RePd]_2 \cdot CHCl_3$: C, 32.52; H, 1.91. Found: C, 32,49; H, 1.89%). Crystallization from acetonitrile/diethylether (1:3) yielded orange-red microcrystals (suitable for analysis of X-ray diffraction) of **2** (62 mg, 0,084 mmol, 73%).

IR (cm^{-1}, CH_3CN) $\nu_{(CO)}$ 2029 (s); 1936 (vs). IR (cm^{-1}, KBr) $\nu_{(CN)}$ 2297 $\nu_{(CO)}$ 2032 (s); 1943 (vs); 1933 (vs). ^1H NMR (CD_3CN) δ: 1.98 (s, 3H, C*H*$_3$CN), 5.60 (m, 2H, C_5H_4), 5.81 (m, 2H, C_5H_4), 7.50–7.74 (m, 10H, C_6H_5). $^{31}P\{^1H\}$ NMR (CD_3CN) δ: 21,3 (s, *P*Ph$_2$). Elemental *Anal.* Calc. for $C_{22}H_{17}O_3NPCl_2RePd$: C, 35.87; H, 2.31. Found: C, 35.79; H, 2.30%.

4.2. [(η^5-$C_5H_4PPh_2$)Re(CO)$_3$]AuCl (**3**)

To a solution of **1** (100 mg, 0.193 mmol) dissolved in 10 mL of CH_2Cl_2 were slowly added 61 mg (0.193 mmol) of (tht)AuCl dissolved in 5 mL of CH_2Cl_2. The transparent mixture was stirred at room temperature for 4 h. Solvent was pumped off and the colorless oil produced was crystallized from CH_2Cl_2/hexane (1.5) to give white crystals of **3** (130 mg, 0.173 mmol, 90%).

IR (cm^{-1}, CH_2Cl_2) $\nu_{(CO)}$ 2032 (s); 1942 (vs). ^1H NMR ($CDCl_3$) δ: 5,56 (m, 2H, C_5H_4), 5,69 (m, 2H, C_5H_4), 7.48–7.62 (m, 10H, C_6H_5). $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ: 25.7 (s, *P*Ph$_2$). Mass spectrum (^{187}Re and ^{35}Cl) *m*/*z*: 752 [M^+], 520 [M^+−AuCl], 492 [M^+−AuCl−CO], 435 [M^+−AuCl−3CO]. Elemental *Anal.* Calc. for $C_{20}H_{14}O_3PClReAu$: C, 31.87; H, 1.86. Found: C, 31.92; H, 1.90%.

4.3. [(η^5-$C_5H_4PPh_2$)Re(CO)$_3$]$_2$CuBr (**4**)

To a solution of ligand **1** (120 mg, 0.231 mmol) in 15 mL of CH_2Cl_2 were added 24 mg (0.115 mmol) of solid $CuBr(Sme_2)$. The pale purple suspension formed was stirred overnight at room temperature. After this time the mixture became a colorless solution. Solvent evaporation to dryness produced a white solid which was crystallized from CH_2Cl_2/hexane (1:5) generating transparent crystals of complex **4** (112 mg, 0.095 mmol, 81%).

IR (cm^{-1}, CH_2Cl_2) $\nu_{(CO)}$ 2028 (s); 1933 (vs). ^1H NMR ($CDCl_3$) δ: 5.36 (broad signal, 2H, C_5H_4), 5.86 (broad signal, 2H, C_5H_4), 7.28–7.40 (m, 10H, C_6H_5). $^{31}P\{^1H\}$ NMR ($CDCl_3$) δ: −13.5 (broad signal, *P*Ph$_2$). Elemental *Anal.* Calc. for $C_{40}H_{28}O_6P_2BrReCu$: C, 40.54; H, 2.36. Found: C, 40.39; H, 2.35.

4.4. X-ray crystal structure determination of complexes **2**, 3 and **4**

Single crystals of complexes **2**, **3** and **4**, obtained as mentioned above, were mounted on the tip of a glass fiber in a random orientation. Intensity data were collected on a Bruker Smart Apex diffractometer equipped with a bidimensional CCD detector using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Semi-empirical corrections, via ψ-scans, were applied for absorption for complexes **2** and **3,** and face indexing absorption correction was applied to complex **4**. The diffraction frames were integrated using the SAINT package [31] and corrected for absorption with XPREP in SHELXTL-PC [32] and SADABS [33]. The structures were solved using XS in SHELXTL-PC [32] by direct methods and completed (non-H atoms) by difference Fourier techniques. Refinement was performed by the full-matrix least-squares method based on F^2. All non-hydrogen atoms were anisotropically refined. Hydrogen atoms were placed in their calculated positions, assigned fixed isotropic thermal parameters and allowed to ride on their respective parent atoms. A summary of the data collection and structure refinement parameters is given in Table 1. ORTEP plots of complexes **2**, **3** and **4** with displacement ellipsoids at the 30% probability level were generated with XP in SHELXTL-PC [32].

ABSTRACT

The complexes formed by 2,6-pyridinedicarboxylic acid (H_3X^+, $pK_{a1} \ll 0.4$, $pK_{a2} = 2.10 \pm 0.01$, $pK_{a3} = 4.383 \pm 0.004$, neutral form H_2X) and 2,6-pyridinediacetic acid (H_3A^+, $pK_{a1} = 2.32 \pm 0.01$, $pK_{a2} = 3.08 \pm 0.01$, $pK_{a3} = 5.92 \pm 0.01$, neutral form H_2A) with Al(III) and Fe(III) were studied by means of potentiometric titrations, UV–Vis, and NMR measurements (for Al(III)), at 25 °C in (Na)Cl 0.6 m aqueous solution. Stoichiometry (and stability constants) of the complexes are the following: AlX^+ (4.72 ± 0.01), $AlXH_{-1}$ (0.37 ± 0.07), AlX_2^-(7.85 ± 0.02), and $AlX_2H_{-1}^{2-}$(2.6 ± 0.3) for Al(III)/H_2X; FeX^+ (8.840 ± 0.003), $FeXH_{-1}$ (6.44 ± 0.05), and FeX_2^- (14.82 ± 0.03) for Fe(III)/H_2X; $AlAH^{2+}$ (8.4 ± 0.1), AlA^+ (5.2 ± 0.1), AlA_2^-(9.1 ± 0.1), and $AlA_2H_{-1}^{2-}$(3.3 ± 0.3) for Al(III)/H_2A; FeA^+ (7.53 ± 0.03), FeA_2H (16.5 ± 0.3), FeA_2^-(13.81 ± 0.04), $FeA_2H_{-1}^{2-}$(10.0 ± 0.1), and FeA_3H^{2-}(22.32 ± 0.08) for Fe(III)/H_2A. An Al(III)/H_2X complex, probably $AlXH_{-1}$, was characterised in the solid state.

H_2X forms stronger complexes towards Al(III) and Fe(III) than does H_2A. The main metal/H_2X complexes can be hypothesised to display a partial tridentate coordination, and the nitrogen of H_2X appears to be involved in the metal chelation. For Al(III)/H_2A, the most probable structure of the complexes AlA^+ and AlA_2^- is a bidentate one involving the two acetate arms.

1. Introduction

There is a strong interest in studying the complexes of 2,6-pyridinedicarboxylic acid (dipicolinic acid, H_3X^+, neutral form H_2X, Fig. 1) ([1–11] and references in [6]). Interesting features of H_2X are its biological activity, its ability to stabilize unusual oxidation states, and its usefulness in corrosion inhibition and in decontamination of nuclear reactors [3]. H_2X has been used as reactant for the determination of Al(III), Fe(III), and other biologically and environmentally relevant metal ions, by capillary electrophoresis and ion chromatography ([12,13] and references therein). A vanadium complex with H_2X has been proposed as insulin-mimetic compounds [5,7]. H_2X has been proposed also as proton transfer systems, which can be used in designing of novel layered crystalline materials ([14] and references therein).

Conversely, there is no literature data dealing with the complexing properties of 2,6-pyridinediacetic acid (H_3A^+, neutral form H_2A, Fig. 1). Preliminary metal ion solubility data obtained by Chen et al. [15] indicate that H_2A is a stronger Fe(III) chelator than H_2X. Due to the similar structure, H_2A can in principle display similar properties as H_2X, and it can be proposed for the same applications listed above for H_2X.

Al(III) and Fe(III), as typical hard metal ions, prefer coordination of oxygen donors, especially negatively charged ones, such as carboxylates, phosphates and alcoholates [16]. If a molecule has suitable geometric properties, amine nitrogens can coordinate Al(III) and Fe(III) together with oxygen donors, forming polydentate chelates as, *e.g.* it is the case with ethylenediaminetetraacetic acid (EDTA).

The aim of this paper is to evaluate and to compare the complexing properties of H_2X and H_2A towards hard metal ions like Al(III) and Fe(III). The complexation study has been performed by means of potentiometric titrations, and e.m.f. data have been supported by NMR and UV–Vis measurements. As H_2A is not commercially available, it has been synthesised and characterised.

2. Experimental

2.1. Chemicals

All chemicals were commercially available and of pure grade. Chloroform was purchased by Janssen and absolute Ethanol by Sigma Aldrich (ACS reagent, ⩾99.5%). Magnesium sulphate

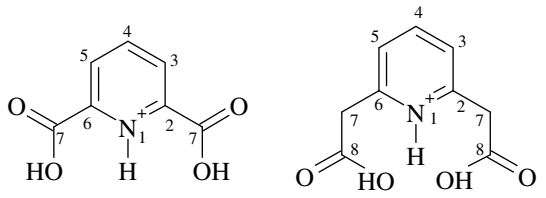

Fig. 1. 2,6-Pyridinedicarboxylic acid (H_3X^+, left) and 2,6-pyridinediacetic acid (H_3A^+, right), shown in the completely protonated form.

anhydrous and HCl (36–38%) were Baker Analyzed Reagent (Holland) products. HBr (ppa ACS reagent 48%), NaCN (ppa ACS reagent) and NaOH (nominal purity 99%+, CO_2 max. 0.5%) were purchased by Fluka. 2,6-Pyridinedicarboxylic acid (H_2X, 99%) was an Acros Organics product. Aluminium wire (Aldrich, nominal purity 99.999%) and iron granules (Aldrich, nominal purity 99.999%) were used to prepare solutions for potentiometric and UV–Vis measurements. For the NMR measurements, D_2O (Sigma, 99.9 atoms% D) $AlCl_3$ (Fluka, 99.5%) KOD (Aldrich, 40% sol. in D_2O, 99.9 at.% D) and DCl (Janssen, 20 wt.% sol. in D_2O, 99+ at.% D) were used.

2.2. Apparatus

IR spectra were registered on a FT-IR Perkin–Elmer spectrophotometer mod. 237 as a nujol suspension. The ^1H and ^{13}C NMR measurements were made at room temperature with a Bruker Avance 300 operating in FT mode using 5 mm tubes. The chemical shifts were given with respect to Me_4Si (TMS) when organic deuterated solvents were employed, and to $Me_3SiCH_2CH_2COONa$ (TSP) when D_2O was used as solvent. HPLC-MS analyses were made with an Agilent instrument mod 1100 equipped with a Luna C-108 column (15 cm × 5 mm i.d.) and an ion-trap quadrupolar mass detector. The eluent was a solution of $HCOONH_4$ 2.1 mM and HCOOH 0.026 mM.

All potentiometric measurements were performed with a Metrohm 765 Dosimat apparatus. UV spectra were recorded with a Perkin–Elmer Lambda 25 spectrophotometer.

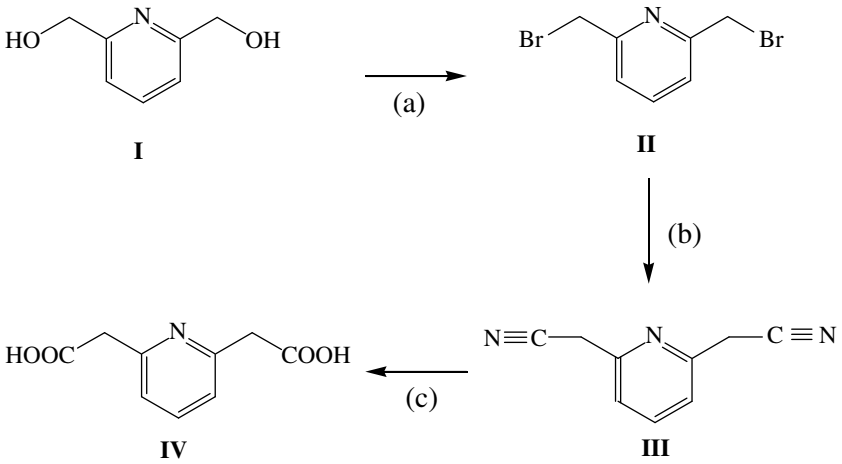
2.3. Synthesis of 2,6-pyridinediacetic acid (H_2A)

The synthesis of the H_2A has been performed following a procedure reported in the literature [15], starting from 2,6-pyridinedimethanol (**I**) through the *a–c* steps reported in scheme 1.

2.3.1. Synthesis of 2,6-bis(bromomethyl)pyridine (*II*)

7.0 g (35.9 mmol) of **I** were added with 50 mL of a 48% HBr solution at room temperature in a 250 mL flask, equipped with condenser and magnetic stirrer. The yellow stirred solution was quickly heated and refluxed for 18 h. After cooling, it was reduced to small volume in rotary evaporator under vacuum. A further addition of 20 mL of a 48% HBr solution followed by heating for 18 h was necessary to improve the recovery yield. After solvent removal, 7.6 g of crude product was obtained, containing about 10% of the monobromurated derivative as impurity. The elution of the crude product with $CHCl_3$ on a glass column filled with 20 cm of silica gel (230–400 mesh) yielded 6.0 g (22.6 mmol; 63% yield) of pure **II** · **0.5 HBr** (m.p. 87–89 °C; Lit 84–89 °C [17]).

Anal. Calc. for **II** · **0.5 HBr**: C, 27.13; H, 2.31; N, 4.44. Found: C, 27.52; H, 2.47; N, 4.59%. NMR chemical shifts (ppm) in $CDCl_3$ and TMS as internal standard: ^1H NMR: 7.71 (t, 1H, pyridine), 7.37 (d, 2H, pyridine), 4.54 (s, 4H, methylene); ^{13}C NMR: 156.76, 138.12, 122.80 (pyridine), 33.45 (methylene).



2.3.2. Synthesis of 2,6-pyridinyldiacetonitrile (*III*)

5.0 g (18.9 mmol) of **II** · **0.5 HBr**, 3.5 g (71.4 mmol) of NaCN, and 60 mL of water, were mixed in a 250 mL flask equipped with condenser and magnetic stirrer, and heated (85 °C) for 5 h under stirring. On heating, the colour of the resulting solution changed from yellow to green. After cooling and addition of 30 mL of water, the reaction product was extracted three times, each with 50 mL of $CHCl_3$. The collected organic phases were dried on anhydrous $MgSO_4$ overnight. After filtration and removal of the solvent, a solid green crude product (2.1 g) was obtained (m.p. 85–90 °C), which was crystallized by EtOH to give 1.6 g (10.2 mmol, 53.9% yield) of pure compound **III**, as colourless needles melting at 96–97 °C.

Anal. Calc. for **III**: C, 68.34; H, 4.41; N, 26.56. Found: C, 68.77; H, 4.49; N, 26.74%. NMR chemical shifts (ppm) in $CDCl_3$ and TMS as internal standard: ^1H NMR: 7.8 (t, 1H, pyridine), 7.42 (d, 2H, pyridine), 3.94 (s, 4H, s, 4H, methylene); ^{13}C NMR: 150.98, 138.80, 121.55 (pyridine), 116.61 (–CN group), 26.48 (s, 4H, methylene).

2.3.3. Synthesis of 2,6-pyridinediacetic acid (H_2A, *IV*)

2.7 g (17.2 mmol) of **III** were added with 50 mL of a 37% HCl solution at room temperature in a 250 mL flask, equipped with condenser and magnetic stirrer. The solution was quickly heated at 100 °C for 18 h under stirring. After cooling, the solution was added with 50 mL of water and 1.5 g of activated carbon. After filtration, the clear solution was brought at pH 2 by drop wise addition of a 1 M NaOH solution, then evaporated to about 5 mL under

Scheme 1. Synthesis of 2,6-pyridinediacetic acid (H_2A).

reduced pressure, and held at 4 °C overnight. White needles crystals of pure **IV** were separated from the solution. Yield: 56.4% (1.9 g, 9.7 mmol, m.p.: 211–212 °C).

Anal. Calc. for **IV**: C, 55.75; H, 4.82; N, 7.32. Found: C, 55.39; H, 4.65; N, 7.18%. NMR chemical shifts (ppm) in D_2O and TSP as internal standard: ^{1}H NMR: 8.31 (t, 1H, pyridine), 7.69 (d, 1H pyridine); ^{13}C NMR: 172.97, 150.20, 146.43 (pyridine). The methylenic protons and carbons of the alkyl chain are not observed in D_2O because of a rapid exchange between the protons of the methylenic group and the solvent. The ^{1}H and ^{13}C NMR signals of the methylenic group are detected when the measurements are performed in H_2O using an insert containing D_2O and the solvent presaturation technique: the proton signal resonates at 4.18 ppm, the carbon signal at 39.56 ppm.

2.4. Synthesis of an Al(III)/H_2X complex

Fifty milliliters of a H_2X solution (167.12 mg, 20 mmol/L, pH 3.37) were mixed with 50 mL of an $AlK(SO_4)_2 \cdot 12H_2O$ solution (237.20 mg, 10 mmol/L, pH 1.90). The pH of the resulting solution was 2.40. The solution was slowly basified upon addition of KOH 1 M. A white precipitate (solid A) formed immediately when the pH reached 4.57.

50 mL of another H_2X solution (167.12 mg, 20 mmol/L, pH 3.30) were mixed with 50 mL of an $AlCl_3 \cdot 6\ H_2O$ solution (120.71 mg, 10 mmol/L, pH 1.90). The resulting pH was 1.89. The solution was slowly basified upon addition of NaOH 1 M. A white precipitate (solid B, apparently identical to solid A) formed immediately when the pH reached 5.00. Solids A and B were filtered, washed and dried overnight under vacuum.

Melting points: H_2X 249.6 °C, solid A (decomposition) = 357–359 °C, solid B (decomposition) = 355–357 °C.

IR (nujol mull, KBr): for H_2X: 1690 cm^{-1} (COO asimm. stretching), 1560 cm^{-1} (aromatic CC stretching), 1450 cm^{-1} (COO simm. stretching). For solids A and B: 1640 cm^{-1} (COO asimm. stretching), 1580 cm^{-1} (aromatic CC stretching), and 1375 cm^{-1} (COO simm. stretching).

AAS measurements (26.00 mg solid A + 1 mL HNO_3 conc. in 10 mL, 10.10 mg solid B + 1 mL HNO_3 conc. in 10 mL, both solutions diluted 100 times) verified the absence of K^+ in solid A and of Na^+ in solid B.

Elemental analyses: four different samples of solid A and two of solid B were prepared and elementally analysed. Aluminium content was determined colorimetrically at 535 nm by reaction with eriochromocianine R [18]. Mean values (±standard deviation of the mean) are reported. For solid A, (36.4 ± 0.4)% C, (2.26 ± 0.05)% H, (6.15 ± 0.09)% N, (11.05 ± 0.2)% Al. For solid B, (36.4 ± 0.4)% C, (2.30 ± 0.08)% H, (6.12 ± 0.09)% N, (11.38 ± 0.2)% Al (theoretic values for $AlC_7H_8NO_7$: 34.2% C, 3.26% H, 5.71% N, 11.0% Al). For both solids, the molar ratio Al:C:N is *ca.* 1:7:1.

2.5. Solution equilibria

All analyte concentrations were expressed in the molality scale (mol/kg of water, m). For potentiometric and UV measurements, working solutions of HCl (0.1 m), NaOH (0.1–0.2 m), H_2X (0.008 m), H_2A (0.01 m), $AlCl_3$ (0.04 m, containing HCl 0.3 m) [19] and $FeCl_3$ (0.05 m, containing HCl 0.3 m) [20] were prepared and standardised. The starting solution for each titration and all working solutions contained known amounts of NaCl to assure a constant (Na)Cl 0.6 m (0.594 M) ionic strength during the titrations. Solutions for ^{1}H NMR measurements were prepared by dissolving in D_2O weighed amounts of ligand, $AlCl_3$ and NaCl. The pD was adjusted by the addition of concentrated KOD and/or DCl solutions.

Potentiometric titrations are summarised in Table 1. Temperature was 25.0 ± 0.1 °C. Duplicate potentiometric measurements were executed by using two glass electrodes (VWR 662-1792) and a Ag/AgCl/0.6 m NaCl reference electrode [21,22] with a J-shaped junction. Titrations were discarded if the relative e.m.f. values measured by the two electrodes differed by more than 0.2 mV (*ca.* 0.003 pH units). The acidic liquid junction potential of the reference electrode has been determined previously [20], and it can be represented by the equation [22] $E_j = -S\log(1 + J \cdot [H^+])$, with $J = 3.69 \pm 0.08$ m^{-1}. As a check of the accuracy of the entire experimental system, the pK_w value for water in (Na)Cl 0.6 m was computed from HCl + NaOH titrations. The values obtained from different series of experiments (pK_w = 13.699 ± 0.003 and 13.706 ± 0.001) compare well with the literature value [23] in Na(Cl) 0.6 M at 25 °C (13.727 ± 0.001). All stability constants were calculated using the computer program PITMAP [24]. The following metal-hydroxo species have been considered and the corresponding logβ values kept fixed during the elaboration of the data: AlH_{-1} (logβ = −5.52), AlH_{-2} (−11.3), AlH_{-3} (−17.3), AlH_{-4} (−23.46), Al_3H_{-4} (−13.57), $Al_{13}H_{-32}$ (−109.2) [25], FeH_{-1} (logβ = −2.87), FeH_{-2} (−6.16) [20], FeH_{-3} (−12.2), FeH_{-4} (−22.2), Fe_2H_{-2} (−2.9), Fe_3H_{-4} (−6.3) [26].

Table 1
Potentiometric titrations.

Solution	$C_{metal}/10^{-3}$ m	$C_{ligand}/10^{-3}$ m	C_{ligand}/C_{metal}	pH
1. H_2X		0.41–5.10		2.5–10.0
2. Al(III)/H_2X	0.64–0.91	0.93–2.73	1, 2, 4, 8	2.1–5.2
3. Fe(III)/H_2X	0.45–1.91	1.00–5.05	1, 2, 3, 4, 6, 9	2.1–5.0
4. H_2A		1.98–5.59		2.1–9.0
5. Al(III)/H_2A	0.37–1.70	1.93–5.49	1, 2, 3, 4, 5, 8	1.7–5.5
6. Fe(III)/H_2A	0.36–1.62	1.87–5.61	1, 2, 3, 4, 8	1.8–4.5

Table 2
UV–Vis measurements.

Solution	$C_{metal}/10^{-3}$ m	$C_{ligand}/10^{-3}$ m	pH	λ (nm) for calcul.
1. H_2X		0.94	0.40–2.00	244; 270; 278
2. Al(III)/H_2X	0.99	0.98	2.13–3.49	243; 270; 274
3. Fe(III)/H_2X	0.99	0.99	0.30–1.51	310

UV measurements (Table 2) were carried out for solutions containing the ligand alone, and for solutions containing the ligand and the metal ion, at various pH values (cell path 0.1 cm). When the pH of the solution was below 2.5, it was computed from the stoichiometric concentration of HCl, because the [H$^+$] modifications produced by the other species were negligible under these conditions. In other cases the pH was measured with the same electrodes and procedures as for potentiometric titrations. The logβ values for the metal–ligand complexes were computed by the program PITMAP.

NMR spectra of H_2X and of H_2A were collected at various pD values in D_2O solutions containing only the free ligand, and the ligand together with Al(III). The pD was measured with a Crison 5014 combined glass electrode previously calibrated in buffered solutions at pH 4 and pH 7, and 0.41 pH units were added to the pH-meter readings to correct for isotopic and solvent effects [27].

3. Results and discussion

3.1. Potentiometric results

Both H_2X and H_2A are triprotic acids (see Fig. 1). Table 3 summarises the pK_a values obtained from our potentiometric titrations. The first two deprotonations of H_3X^+ are due to the benzoic groups, and the third one is due to the pyridinium, as the former functional groups are intrinsically much more acidic than the latter. For H_3A^+

Table 3
Acidic properties of H_2X and H_2A at 25 °C, (Na)Cl 0.6 m. Here and in the following tables, values are shown as the mean and standard deviation of the mean[a].

Species	pK_a	Species	pK_a
H_3X+	≪0.4	H_3A^+	2.32 ± 0.01
H_2X	2.10 ± 0.01	H_2A	3.08 ± 0.01
HX^-	4.383 ± 0.004	HA^-	5.92 ± 0.01

[a] The standard deviation of the mean is a measure of the repeatability of our results, not of their accuracy.

Table 5
Log β values for Al(III)/H_2A and Fe(III)/H_2A complexes at 25 °C, (Na)Cl 0.6 m ($pM^{3+} + qA^{2-} + rH^+ = M_pA_qH_r^{3p-2q+r}$).

(*p*, *q*, *r*)	Log β for Al(III)/H_2A	Log β for Fe(III)/H_2A
1, 1, 1	8.4 ± 0.1	
1, 1, 0	5.2 ± 0.1	7.53 ± 0.03
1, 2, 1		16.5 ± 0.3
1, 2, 0	9.1 ± 0.1	13.81 ± 0.04
1, 2, −1	3.3 ± 0.3	10.0 ± 0.1
1, 3, 1		22.32 ± 0.08
1, 3, 0		18.76 ± 0.06

this deprotonation order is less sure as the intrinsic acidity of the acetic arms is comparable to that of pyridinium. The pK_{a2} and pK_{a3} values of H_3X^+ are in reasonable agreement with those reported in the literature (for example, pK_{a2} = 2.09 and pK_{a3} = 4.53 in $NaClO_4$ 0.5 M [2], 2.03 and 4.49 in KCl 0.4 M [5]). Like the cited authors we were not able to determine pK_{a1}: UV–Vis spectra (not shown) at pH values between 0.4 and 2.3 allowed to determine only one pK_a value, 2.02 ± 0.01, which is clearly the pK_{a2}. Thus we can assume that pK_{a1} ≪ 0.4.

The three pK_a values of H_3A^+ are higher than those of H_3X^+ because the resonance effect of the pyridinic ring, which stabilizes the deprotonated form of the carboxylic groups in H_3X^+, is missing in H_3A^+. For this ligand no data is reported in the literature to allow a comparison. We found a data for pyridine-2-acetic acid: here pK_{a1} = 2.73 and pK_{a2} = 5.81 [28]. As expected, pK_{a1} of pyridine-2-acetic acid is higher than pK_{a1} of H_3A^+ due to statistical effects, whereas pK_{a2} of pyridine-2-acetic acid is very similar to pK_{a3} of H_3A^+.

The potentiometric titrations of solutions containing the metal and the ligand allowed the identification of several complexes. The stoichiometry of the complexes and the values of their stability constants are reported in Tables 4 and 5. Typical distribution diagrams drawn from our data are reported in Fig. 2 (2a for Al(III)/H_2X, 2b for Fe(III)/H_2X, 2c for Al(III)/H_2A, 2d for Fe(III)/H_2A).

3.1.1. Al(III)/H_2X

The main Al(III)/H_2X complexes in solution are AlX^+ and $AlXH_{-1}$. AlX_2^- and $AlX_2H_{-1}^{2-}$ are minor species. The acidity of AlX^+ and AlX_2^- (the pK_a value for the reaction $AlX_n^{3-2n} = AlX_nH_{-1}^{2-2n} + H^+$ is 4.35 for AlX^+ and 5.3 for AlX_2^-) is significantly lower than that of $Al(H_2O)_6^{3+}$ (5.52). A similar effect has been observed by Jøns and Johansen [29], who found that the pK_a of the 1:2 Al(III)/picolinate complex (picolinic acid = 2-pyridinecarboxylic acid) is 4.12. The involvement of the pyridinic nitrogen in the metal chelation can represent a possible explanation for these acidity increments, as the Al–N^+ bond can lower the electronic density of the metal center in AlX^+ and in AlX_2^- with respect to $Al(H_2O)_6^{3+}$. It is interesting to observe that the pK_a of the water coordinated to the metal center in Al(III)/pyridine-like complexes is significantly larger than 5.52 when the pyridinic nitrogen is surely not involved in the Al(III) chelation (*e.g.* for the Al(III)/1-methyl-3-hydroxy-4-pyridinecarboxylate and Al(III)/1-methyl-4-hydroxy-3-pyridinecarboxylate complexes [30]).

Al(III)/H_2X titrations had to be stopped at pH ≈ 5–6 due to the precipitation of a white solid. The same observation is reported by Napoli [2], who however did not characterise the precipitate. Our data (see Section 2) demonstrate that the precipitate is not the metal hydroxide $Al(OH)_3$ but a metal/ligand complex in which the metal/ligand ratio is 1:1. This complex is probably the neutral species $AlC_7H_8NO_7$ ($AlXH_{-1}$) with the co-presence of *ca.* 5% of free ligand. The experimental observation of the start of the precipitation at different stoichiometric metal and ligand concentrations can be well modeled considering that the stability constant for the reaction $AlXH_{-1(s)} + H^+ = Al^{3+} + X^{2-}$ is 3.7×10^{-4}. The distribution diagram in Fig. 2a was computed taking into account this data.

Napoli [2] found only two Al(III)/H_2X complexes, AlX^+ and AlX_2^- (Table 4). Data were obtained by potentiometric titrations, and e.m.f. values were elaborated graphically by the Bjerrum method. A paper electrophoretic investigation showed that the Al(III) complexes display opposite charges, mainly positive at pH ⩽ 3 and mainly negative at pH > 4 in the presence of 10^{-2} M H_2X. Unfortunately the Al(III) concentration used for the electrophoretic runs is not reported, but Napoli's data can qualitatively be well interpreted also by our speciation model, according to which the free metal ion and AlX^+ predominate at acidic pH, and the other complexes (neutral or negatively charged) predominate at higher pH values. Also Napoli's UV–Vis results, *i.e.* that at pH 3 only the species AlX^+ exists in solution with a log β value of 4.85 ± 0.03, agree very well with our speciation model and with our UV–Vis results (see below). Nitzsche and Röbisch [10] analysed Al(III)/H_2X solutions at pH 3–5 by means of UV–Vis, and they found the complexes $AlXH^{2+}$ and AlX^+ (Table 4). However, the log β value given for AlX^+ (11.37) is abnormally large, and it implies a not-measurable pK_a value of $AlXH^{2+}$ (7.4 − 11.37 = −4).

3.1.2. Fe(III)/H_2X

The main Fe(III) complexes are FeX^+ and FeX_2^-. FeX^+ already forms at very acidic pH values, and its stability constant can be determined only by UV–Vis measurements at pH values lower than 1 (see below). A water molecule coordinated to the metal center in FeX^+ deprotonates to give $FeXH_{-1}$. The pK_a of FeX^+ (2.40) is lower

Table 4
Log β values for Al(III)/H_2X and Fe(III)/H_2X complexes ($pM^{3+} + qX^{2-} + rH^+ = M_pX_qH_r^{3p-2q+r}$). Literature values are reported for comparison.

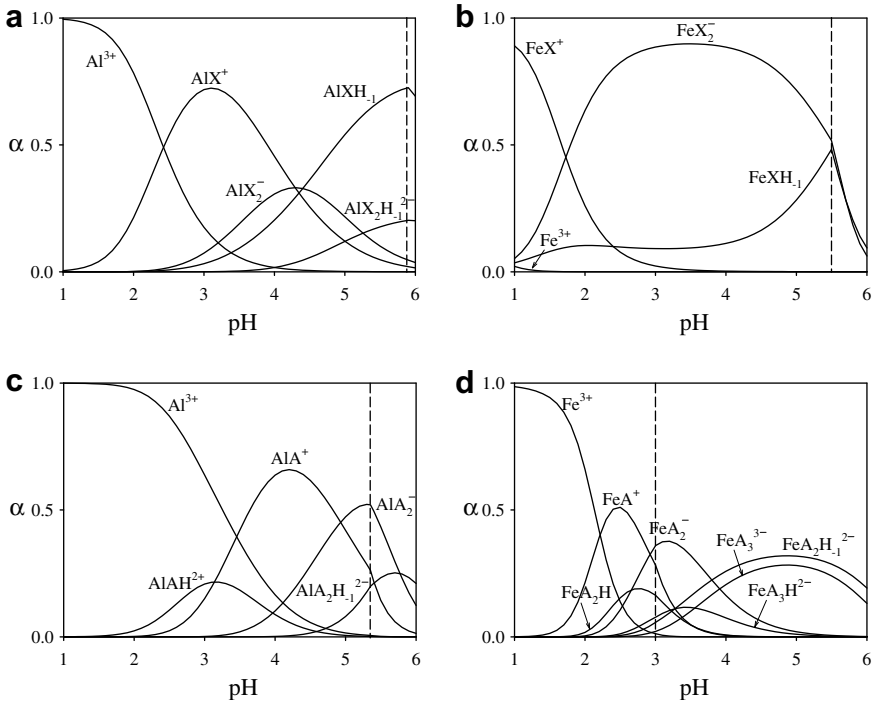

Fig. 2. Distribution diagrams of Al(III)/H_2X (a), Fe(III)/H_2X (b), Al(III)/H_2A (c), and Fe(III)/H_2A (d) complexes in aqueous (Na)Cl 0.6 m, T = 25 °C; $C_{metal} = 10^{-3}$ m, $C_{ligand} = 3 \times 10^{-3}$ m. The dotted line indicates the theoretic start of metal hydroxide (b, c, d) or $AlXH_{-1}$ (a) precipitation.

than that of $FeH_2O_6^{3+}$ (2.87). For the Fe(III) complexes of other pyridine derivatives, when the metal ion is coordinated by carboxylate and hydroxo substituents, we always found pK_a values significantly larger than 2.87 ([31] and references therein). As hypothesised for AlX^+ and AlX_2^-, the high acidity of FeX^+ can be due to the involvement of the nitrogen in the metal chelation.

Fe(III)/H_2X solutions are known to form a mixed FeX^+/FeX_2^- green precipitate if they are allowed to stand for few days at acidic pH values [32]. In our titrations, which we completed within *ca.* 1 h, we did not observe this solid: at pH values larger than *ca.* 5 (depending on metal and ligand concentrations), the precipitation of a brown powder was observed, which we considered to be iron hydroxide.

Bridger et al. [11] studied Fe(III)/H_2X complexes by the Job method at very acidic pH values (between *ca.* 0 and 1.4), and they observed only the species FeX^+ (Table 4). Both the acidic pH speciation (*e.g.* see Fig. 2b) and the log β value of FeX^+ (Table 4) agree very well with our results. Anderegg [1] found the complexes FeX^+ and FeX_2^- (Table 4). The Anderegg's stability constant of FeX^+ appears to be overestimated with respect to our value (Table 4): the absence of $FeXH_{-1}$ in his speciation model likely produced this effect. Anderegg's stepwise stability constant of FeX_2^- (17.13 − 10.91 = 6.22), on the other hand, agrees well with our value (14.82 − 8.84 = 5.98). Napoli [2] showed by paper electrophoresis that the Fe(III) complexes are always negatively charged at pH ⩾ 2. His data can be very well modeled also by our speciation model, according to which FeX_2^- predominates at pH values larger than 2 (Fig. 2b).

3.1.3. Al(III)/H_2A

In Al(III)/H_2A solutions the main species is AlA^+. $AlAH^{2+}$ forms in low amount at acidic pH, AlA_2^- and $AlA_2H_{-1}^{2-}$ become significant at pH close to the start of $Al(OH)_3$ precipitation. The pK_a value of $AlAH^{2+}$ (3.2, it can be calculated from data in Table 5) is almost identical to the pK_{a2} of the free ligand (3.08, Table 3), indicating that in $AlAH^{2+}$ the deprotonating group is a carboxylate. For AlA_2^- the deprotonation can occur only at the coordinated water molecule, so that $AlA_2H_{-1}^{2-}$ is a hydroxospecies. Differently than for AlX_2^-, the pK_a of AlA_2^- (5.8) is larger than that of $Al(H_2O)_6^{3+}$. It is therefore suggested that in the complex AlA_2^- the nitrogen of the ligand is not involved in the metal chelation.

3.1.4. Fe(III)/H_2A

The main Fe(III) complexes are FeA^+, FeA_2H and FeA_2^-. The remaining Fe(III) species can be detected in significant amounts only at large ligand-to-metal ratios and at pH values close to the start of $Fe(OH)_3$ precipitation. The pK_a of the water molecule coordinated to Fe(III) is very similar to that of the unbound carboxylate: for $Fe(H_2O)_6$ pK_a = 2.87 [20], for H_2A pK_a = 3.08 (Table 3). On this basis, for FeA^+, FeA_2^-, and FeA_3^{3-}, two microspecies probably coexist in solution, one having the ligand completely deprotonated, the other one having one protonated carboxylate and one coordinated water molecule deprotonated.

3.1.5. pM calculations

It is useful to compare the complexation strength of the ligands H_2X and H_2A towards Al(III) and Fe(III). The comparison is extended to 2-pyridinecarboxylic acid (picolinic acid), in order to show if the presence of a second carboxylate in H_2X has an effect on the metal complexation. The quantitative comparison can be accomplished by computing pM (=−log[M^{3+}]) *vs.* pH at a given metal and ligand concentration (e.g. $C_{metal} = 10^{-6}$ m and $C_{ligand} = 5 \times 10^{-5}$ m [16]). pM *vs.* pH graphs are reported in Fig. 3. Data for Al(III)/picolinate (25 °C, KNO_3 0.15 M [29]) and Fe(III)/picolinate (35 °C, $NaClO_4$ 1.00 M [33]) are taken from the literature.

A slight difference (0.5 log units) can be observed in the complexation strength of H_2X and H_2A towards Al(III): H_2X is a better Al(III) chelator than H_2A. This difference can be due to the chelation ring size, *i.e.* the 5-membered ring formed by H_2X is more stable than the 6-membered ring formed by H_2A. A similar pAl difference is observed between Al(III)/H_2X and Al(III)/picolinate: this difference can be due to the tridentate coordination mode of

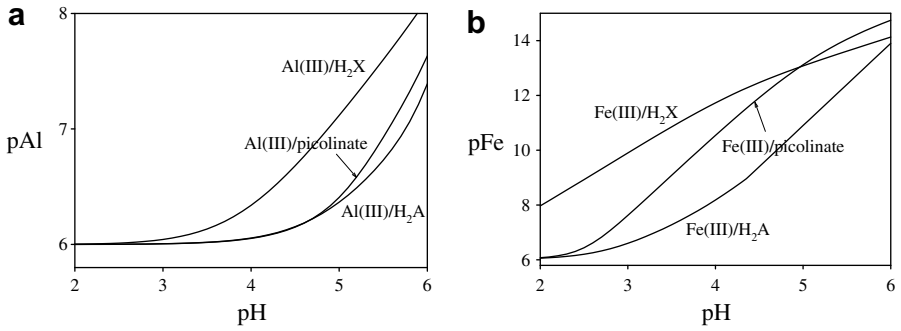

Fig. 3. pM *vs.* pH for various Al(III)/ligands (a) and Fe(III)/ligands (b) ($C_{metal} = 10^{-6}$ m, $C_{ligand} = 5 \times 10^{-5}$ m).

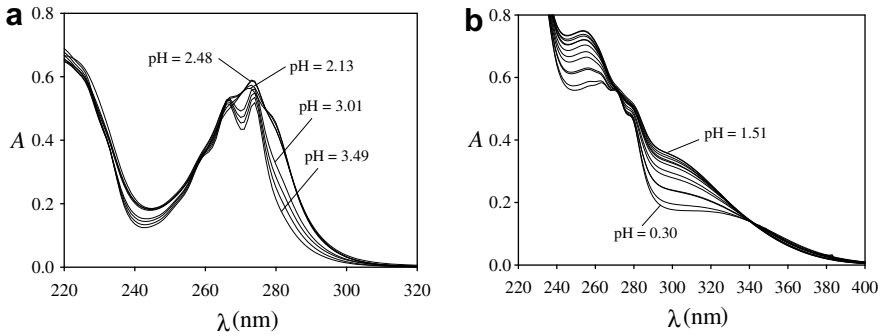

Fig. 4. (a) UV–Vis spectra of Al(III)/H_2X solutions, pH 2.13, 2.30, 2.48, 2.71, 3.01, 3.21, 3.35, 3.49. (b) UV–Vis spectra of Fe(III)/H_2X solutions, pH 0.30, 0.39, 0.59, 0.79, 0.87, 1.02, 1.05, 1.16, 1.22, 1.36, 1.42, 1.51.

AlX^+ and AlX_2^-, which stabilizes Al(III)/H_2X complexes slightly more than Al(III)/picolinate ones. Tridentate coordination is however likely to be only partial, i.e. in equilibrium with a bidentate coordination predominating over the tridentate one, due to the very small pAl difference and to the relative weakness of the Al(III)/H_2X complexes (pAl values are quite low).

As no complexation data of pyridine-2-acetic acid towards Al(III) and Fe(III) is available, it is not possible to verify the role of the second carboxylate of H_2A in the metal complexation. However, due to the weakness of Al(III)/H_2A and Fe(III)/H_2A complexes, we can confidently exclude that these species display a tridentate coordination.

Also Fe(III)/H_2X complexes are more stable than Fe(III)/H_2A ones, the pFe difference is up to 3 log units. The preliminary data of Chen et al. [15], cited above, are therefore not confirmed by our results. Fe(III)/H_2X complexes are also significantly more stable than Fe(III)/picolinate ones at pH values lower than 5: the tridentate coordination of H_2X towards Fe(III) represents the most probable explanation to this data (at pH larger than 5 polynuclear species form in Fe(III)/picolinate solutions [33], so that the pFe increases significantly). It is worth noting that the species FeX_2 was isolated as crystal, and it was showed that the ligand acts as tridentate coordinating through the heterocyclic nitrogen and two carboxyl oxygens [34].

3.2. UV–Vis results

UV–Vis spectra for the Al(III)/H_2X and Fe(III)/H_2X solutions are reported in Fig. 4a and b. In the case of Al(III)/H_2X, the increase of pH causes a general decrease of the absorption coefficients of the aromatic band, especially at around 270 and 280 nm. This effect can be explained by the gradual formation of the metal complex AlX^+, assuming the involvement of the pyridinic ring in the metal complexation and the consequent perturbation of the electronic distribution in the aromatic ring. In the case of Fe(III)/H_2X, the complex formation is revealed by two weak charge-transfer peaks which appear at *ca.* 250 and 310 nm.

The elaboration of the UV–Vis data is complicated by a change of the free ligand ε values with concentration at every wavelength, because of the presence of concentration-dependent ligand–ligand interactions in solution [35]. This problem applies specifically for Al(III)/H_2X spectra, as here the absorption of the complexes overlaps with that of the free ligand. The formation constant of only one Al(III)/H_2X complex, AlX^+, was optimised. For this species, $\log\beta = 4.96 \pm 0.01$. Taking into account the uncertainty of the absorption of the free ligand, this value compares reasonably well with the corresponding potentiometric one ($\log\beta_{1,1,0} = 4.72 \pm 0.01$, Table 4). For Fe(III)/$H_2X$ solutions the problem of the ε change of free ligand can be overcome by elaborating the spectra at a wavelength where the ligand does not absorb (310 nm). From spectra at acidic pH values, the formation constant of FeX^+ was optimised ($\log\beta_{1,1,0} = 8.84 \pm 0.01$, Table 4).

3.3. NMR results

The ^{1}H NMR spectra of H_2X and Al(III)/H_2X solutions are shown in Fig. 5. The ^{13}C NMR spectra of H_2X and Al(III)/H_2X solutions are reported in Fig. 6. The ^{1}H NMR spectra of H_2A and Al(III)/H_2A solutions are shown in Fig. 7.

3.3.1. NMR spectra of H_2X and H_2A

The ^{1}H NMR spectra of the ligands display a typical X_2Y pattern: the doublet is assigned to H_3 and H_5, the triplet to H_4 (refer to Fig. 1 for atom numbering). The methylenic protons of H_2A do not appear in the spectra as they rapidly exchange with the solvent (see Section 2). The H_4 protons of both H_2X and H_2A resonate at very low

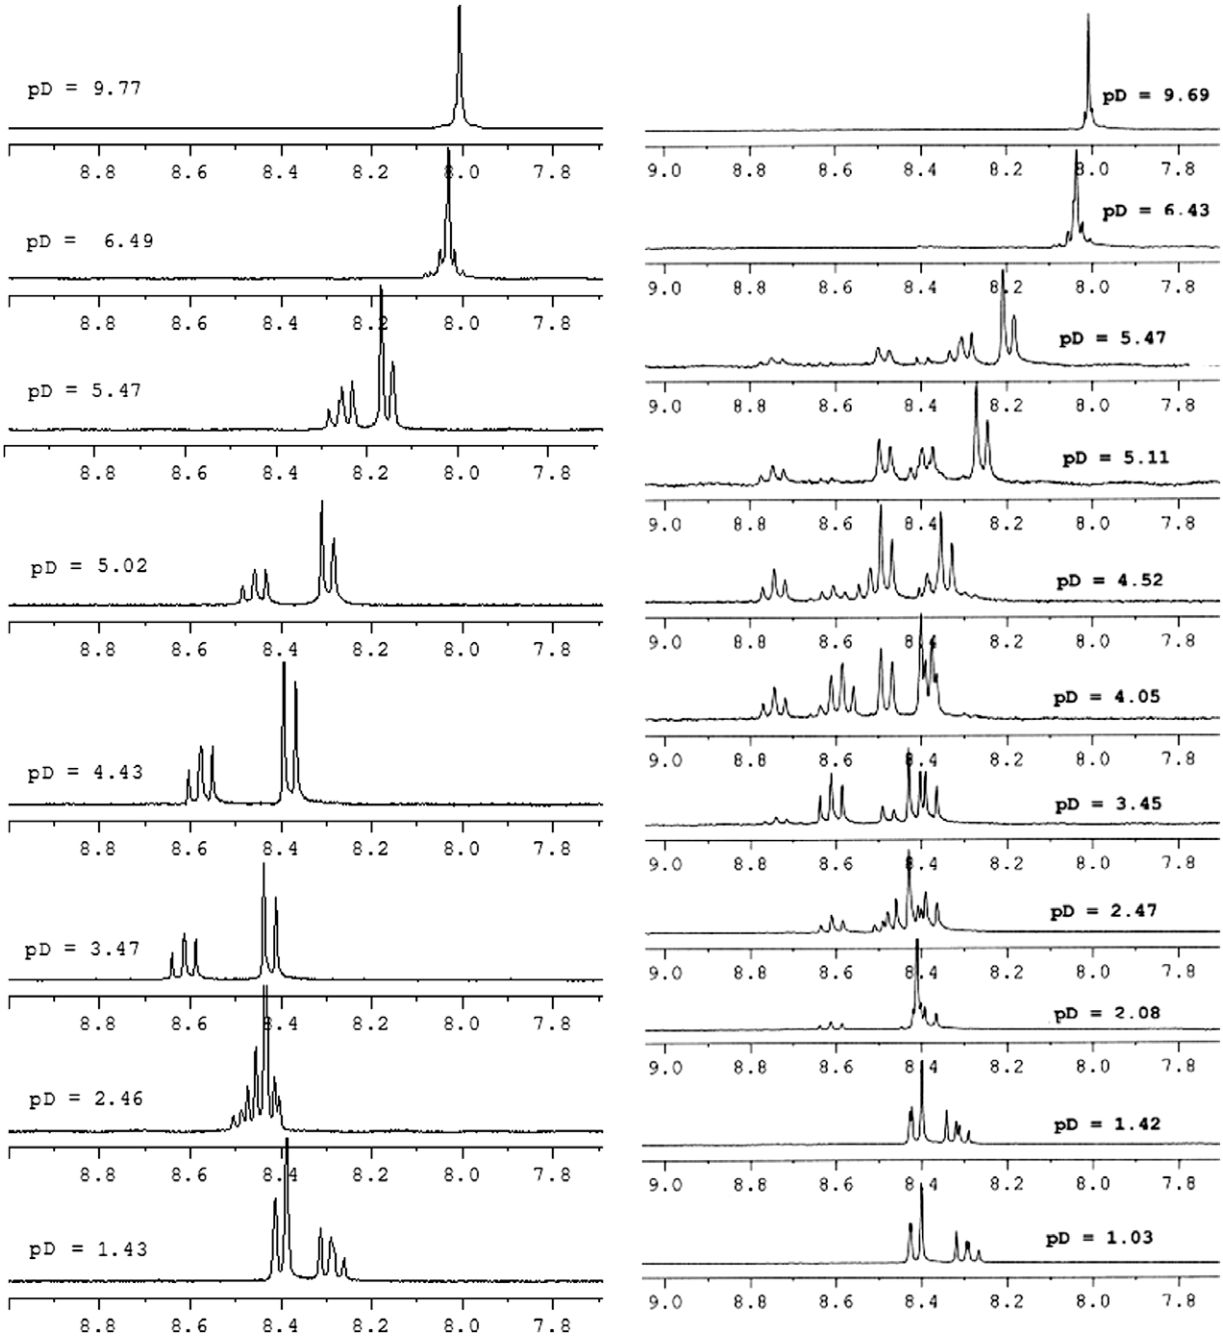

Fig. 5. ^{1}H NMR spectra of D_2O solutions at various pD values containing H_2X 0.0017 m (left), Al(III) 0.0017 m + H_2X 0.0035 m (right).

fields at acidic pH ($\delta > 8.2$) because of the electron-attracting effect of the positively charged pyridinium. The two carboxylic groups in H_2X shift downfield also the signals of H_3 and H_5, whereas the two acetic groups in H_2A do not have a significant electron-attracting effect.

The carboxylate groups have a very strong pD-dependent effect in H_2X (Fig. 5). For this ligand, at pD lower than pK_{a2} (corresponding to the deprotonation of the second carboxylate: pK_{a2} = 2.12 + 0.34 = 2.46 in D_2O according to Rule and La Mer [36]) H_3 and H_5 resonate at lower fields than H_4. At pD ≈ pK_{a2} the two proton signals collapse and the spectrum becomes of the second-order. At pD larger than pK_{a2} and lower than pK_{a3} (pK_{a3} = 4.36 + 0.46 = 4.82 in D_2O [36]) the carboxylate groups are negatively charged and the electron-attracting effect of the positive nitrogen predominates, so that H_3 and H_5 resonate at higher fields than H_4. Finally, when pyridinium deprotonates (pD ≈ pK_{a3}), all signals move upfield and finally collapse again to give a second-order spectrum.

The ^{1}H signals of H_2A do not have any pD-dependent shift (Fig. 7) because the carboxylate can affect only slightly the electronic distribution in the pyridinic ring, and the nitrogen does not deprotonate in the investigated pD range (pK_{a3} = 5.92 + 0.52 = 6.44 in D_2O [36]).

3.3.2. NMR spectra of Al(III)/H_2X 1:2

At pD 2.47 the addition of Al(III) gives rise to two new sets of ^{1}H signals (Fig. 5), a triplet centered at δ 8.6 and a doublet at δ 8.35–8.4. These signals can be attributed to H_4 and to H_3 + H_5 of the com-

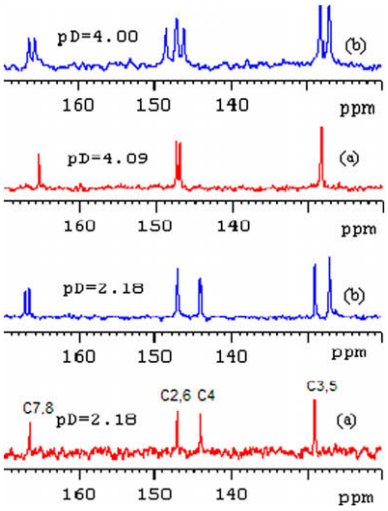

Fig. 6. ^{13}C NMR spectra of D_2O solutions at two pD values containing H_2X 0.15 m (a), Al(III) 0.075 m + H_2X 0.15 m (b).

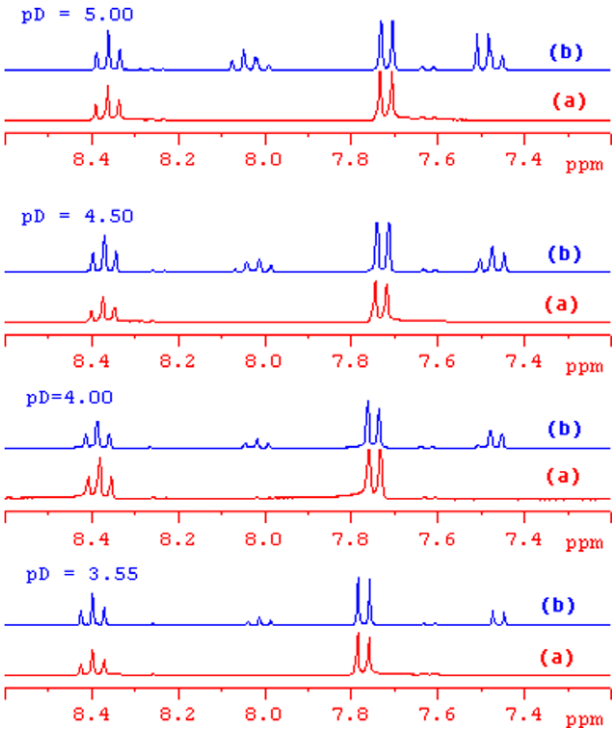

Fig. 7. ^1H NMR spectra of D_2O solutions at various pD values containing H_2A 0.03 m (a), Al(III) 0.01 m + H_2A 0.03 m (b).

plex AlX^+, as according to potentiometric data this species predominates at acidic pD values. Also in the ^{13}C NMR spectrum at pD 2.18 (Fig. 6) three new signals appear in the presence of Al(III), which can be assigned to the same complex.

The signals of AlX^+ are still present in the ^1H NMR spectrum at pD 3.45, even if the triplet is completely overlapped by the triplet of the free ligand (as indicated by the abnormally high intensity of the latter). At this pD a new group of signals appears: a triplet at δ 8.7–8.8, and a doublet at δ 8.45–8.5. According to the potentiometric results, these new sets of signals are assigned to the complex AlX_2^-. Also in the ^{13}C NMR spectrum at pD 4.00 two new signals of $C_{2,4,6}$ appear, suggesting the formation of two complexes (AlX^+ and AlX_2^-).

The same sets of ^1H signals are observed at pD larger than 3.45. Here the change of pD causes a shift of the signals of the free ligand and a change of relative intensities of the peaks of free ligand, AlX^+, and AlX_2^-. Between pD 3.45 and pD 5.47 the ^1H signals of AlX_2^- do not shift, suggesting no deprotonation for this complex in the investigated pD range. The relatively high pK_a value of AlX_2^- expected in D_2O ($pK_a = 5.3 + 0.50 = 5.8$ [36]) is consistent with this data. The signals of AlX^+ ($pK_a = 4.35 + 0.46 = 4.81$ [36]) do not shift with pD, probably because the deprotonation of AlX^+, occurring at a water coordinated to the metal center to produce $AlXH_{-1}$, does not affect significantly the electronic distribution in the aromatic ring.

The signals of the complexes disappear at pD > *ca.* 6–6.5, as expected on the basis of the potentiometric results, due to the precipitation of the metal hydroxide and the formation of $Al(OH)_4^-$.

3.3.3. NMR spectra of Al(III)/H_2A 1:3

Upon addition of Al(III) to a solution containing H_2A at pD 3.55, a new set of signals appears, a doublet at δ 7.45, and a triplet at δ 8.0. These peaks are clearly $H_3 + H_5$ and H_4 of a complex, which according to the potentiometric results is AlA^+. At pD 4.00, pD 4.50 and 5.00, new signals appear, which are partially overlapped with those of AlA^+, and which are attributed to AlA_2^-. The peak intensity of increases with pD, whereas that of AlA^+ and of the free ligand decrease. This behaviour agrees with the potentiometric results.

3.3.4. Structural information

The NMR spectra in the presence of Al(III) show two features which help to understand the structure of the Al(III) complexes. First, in the ^1H spectra H_3 and H_5 resonate as doublets for both ligands, for any complex and at any pD value. Therefore, both ligands bind the metal ion in a symmetric manner (in the NMR time scale), *i.e.*, either the ligand acts as tridentate, or as bidentate with two arms rapidly exchanging with the third one. Second, ^1H spectra show a quite different behaviour for the two ligands. In the case of H_2X, the signal of H_4 in the complexes AlX^+ and AlX_2^- is significantly shifted downfield with respect to the same signal of the free ligand, and the signals of H_3 and H_5 are slightly shifted upfield (at least at acidic pD values). In the case of H_2A, all signals of AlA^+ and AlA_2^- ($H_3 + H_5$ and H_4) are significantly shifted upfield with respect to the same signals of the free ligand. The formation of an Al–N^+ bond (which affects primarily H_4) only in the Al(III)/H_2X complexes, as suggested from thermodynamic data, can explain also this NMR difference.

4. Conclusions

Our results show that the main complexes formed by 2,6-pyridinedicarboxylic acid (H_2X) and by 2,6-pyridinediacetic acid (H_2A) with Al(III) and Fe(III) have a metal:ligand 1:1 and 1:2 stoichiometry. Potentiometric titrations, UV–Vis and NMR measurements gave consistent results. The complexes formed by H_2X with both metal ions are stronger than those formed by H_2A. On the basis of all our data, the main metal/H_2X complexes can be hypothesised to display a partial tridentate coordination, and the nitrogen of H_2X appears to be involved in the metal chelation. For Al(III)/H_2A, the most probable structure of the complexes AlA^+ and AlA_2^- is a bidentate one involving the two acetate arms.

Oxo-rhenium(V) complexes
Hydrospirophosphorane ligand
Diaza ligand
Dinuclear compound

ABSTRACT

Two neutral mono and dinuclear rhenium(V) complexes, *cis*-$ReOCl_2(P{\sim}O)(pym)$ (**1**) and *cis*-$[ReOCl_2(P{\sim}O)]_2(\mu$–pym) (**2** · $(CH_3)_2CO$), with the hydrospirophosphorane ligand HP∼O (HP∼O = octamethyl-2,2,3,3,7,7,8,8-tetraoxa-5λ^5 1,4,6,9-phosphaspiro-4,4-nonane) have been prepared. The coordination geometry of the complexes has been determined in solution by NMR and UV–Vis spectroscopy, as well as in the solid state by IR, FIR spectroscopy and single crystal X-ray diffraction. The complexes display distorted octahedral geometries. X-ray structures of **1** and **2** reveal that the $ReCl_2NP$ fragments are equatorially disposed and the oxygens, terminal oxo and alcoholato, lie in axial positions. The pyrimidine coordinates as a monodentate or bridging ligand. Detailed temperature dependent ^1H NMR analysis for both **1** and **2** shows that in solution the diaza moiety exhibits hindered rotation about the Re–N bond. Furthermore two concomitant conformation changes, one in the metallacycle and the second in the phosphorus cycle, are also observed for dimer **2**.

1. Introduction

Attention to the chemistry of bicyclic hydrospirophosphoranes stems not only from their application as convenient reagents providing routes to bolaform- and gemini-type phosphorus acid surfactants, but also as peptide coupling agents as well [1–3]. Tetraoxaspirophosphoranes, represented by 2,2′-spirobi(1,3,2-benzodioxaphosphole), can easily induce the formation of peptide bonds in the process of the construction of dipeptides, polypeptides and proteins with a reduced effect of racemization [4]. Furthermore, it was recently reported that spiro-[10-P-5]-phosphoranes derived from amino acids exhibit a distinct inhibition activity to tyrosinase, a meaningful enzyme in the formation of melanin pigment found in plants and animals [5]. It is worth mentioning that a spirophosphorane compound containing the Ileucine residue reveals a 96% rate of inhibition, better than the whitening reagent Arbutin (88%) used in cosmetology.

A novel application of spirophosphoranes was demonstrated by Gavrilov and coworkers, using P,N and P,O bidentate derivatives of hydrospirophosphoranes as ligands for the synthesis of a range of new systems including Rh, Pd and Pt complexes. Applications of these ligands in metal-promoted homogenous catalyst systems have been described too [6].

In recent years, work in our laboratory has also centred on the coordination chemistry of hydrospirophosphoranes. As a part of the continuing investigations on the spirophosphorane ligand HP∼O [(HP∼O = $HP(OCMe_2CMe_2O)_2$) 2,2,3,3,7,7,8,8-octamethyl-1,4,6,9-tetraoxa-5λ^5 phosphaspiro[4,4]nonane], we were fruitful in our efforts to obtain a class of new rhenium(V) complexes: $ReOX_2(P{\sim}O)L$ (X = Cl, Br, I; L = py, PPh_3, $OPPh_3$) [7,8].

Keeping in mind that metal ions entailment in medicine and biology often needs coordination of planar N-donor ligands such as purines, imidazoles or pyrimidines, we have made an afford to widen the family of oxo-rhenium(V) complexes with the HP∼O ligand. Introducing the diaza molecule along with the bifunctional $P{\sim}O^-$ ligand in the metal complexes should provide stable compounds which might also be considered as biologically non-innocent systems. Spatial orientation of the N-donors with respect to other ligands and their distribution in the molecule is the second reason for incorporation of the diaza molecule into rhenium complexes. This interest has led us to construct new pyrimidine complexes of intermediate oxidation state, mono- and diore oxo-rhenium(V) compounds with the hydrospirophosphorane derived chelate ligand HP∼O. This report includes the description of the synthesis, molecular structure, spectroscopic characterization and fluxionality of two complexes, *cis*-$ReOCl_2(P{\sim}O)pym$ and *cis*-$[ReOCl_2(P{\sim}O)]_2(\mu$-pym).

2. Experimental

2.1. General procedure

Chemicals and deuterated solvents were purchased from Aldrich and Fluka, and were used as received. All preparations were

doi:10.1016/j.poly.2008.10.045

performed in an atmosphere of dry, oxygen-free nitrogen, using conventional Schlenk techniques. Solvents were carefully dried and deoxygenated by standard methods [9]. The ligand precursor $HP(OCMe_2CMe_2O)_2$ 2,2,3,3,7,7,8,8-octamethyl-1,4,6,9-tetraoxa-5λ^5 phosphaspiro[4,4]nonane, abbreviated as HP∼O, was prepared according to the literature method [10]. $ReOCl_2(OEt)(pym)_2$ and *trans*-$ReOCl_2(P{\sim}O)(PPh_3)$ were synthesized as previously reported [11,7].

IR and FIR measurements were performed in KBr pellets either with a Nicolet FTIR Impact 400 or in Nujol with a Bruker IFS 113V. ^1H, $^{31}P\{^1H\}$ NMR spectra were obtained on a Bruker AMX and Avance III spectrometers (300 MHz for ^1H NMR). The chemical shifts δ are given in ppm towards TMS (^1H) and H_3PO_4 (^{31}P) using deuterated solvent CD_2Cl_2 as the lock and reference (^1H), respectively. UV–Vis spectra in CH_2Cl_2 solution were obtained on a Carry 500. Elemental analyses were performed on a Vario EL III apparatus.

2.2. Synthesis of the complexes

2.2.1. *cis*-$ReOCl_2(P{\sim}O)(pym)$ (**1**)

Method (a): The hydrospirophosphorane ligand HP∼O (0.24 g, 0.91 mmol) was added to a suspension of *trans*-$ReOCl_2(OEt)(pym)_2$ (0.20 g, 0.42 mmol) in toluene (7 cm^3). The reaction mixture was heated and stirred vigorously for 4 h until the starting compound reacted and a light violet crystalline solid was afforded. The crude product was filtered, washed with diethyl ether and dried *in vacuo* (0.22 g, 85%). Single crystals suitable for X-ray analysis were obtained by re-crystallization from a dichloromethane/ethyl ether solution.

Anal. Calc. for $C_{16}H_{28}Cl_2N_2O_5PRe$: C, 31.17; H, 4.58; Cl, 11.50; N, 4.54. Found: C, 31.29; H, 4.51; Cl, 11.80; N, 4.52%; ν_{max}(KBr)/cm^{-1} 955vs ν(Re═O), 926s and 1018s ν(C–O–P), 1553w and 1558w ν(C═N); ν_{max} (Nujol)/cm^{-1} 149w, 238m, 269m, 289s, 326s (Re–P), (Re–N), (Re–Cl); $\lambda_{max}(CH_2Cl_2)$/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$) 242 (15040), 344 (4030), 498 (190).

Method (b): A suspension of *trans*-$ReOCl_2(P{\sim}O)(PPh_3)$ (0.20 g, 0.25 mmol) and pyrimidine (0.06 cm^3, 0.76 mmol) in decahydronaphthalene (7 cm^3) was refluxed for 4 h until the starting compound reacted and a light-violet solid was obtained. The product was filtered, washed with diethyl ether and dried *in vacuo* (0.12 g, 78%).

2.2.2. *cis*-$[ReOCl_2(P{\sim}O)]_2(\mu$-pym) ($2\cdot(CH_3)_2CO$)

A toluene suspension (10 cm^3) of *cis*-$ReOCl_2(P{\sim}O)(pym)$ (0.22 g, 0.36 mmol) and *trans*-$ReOCl_2(P{\sim}O)(PPh_3)$ (0.29 g, 0.36 mmol) was refluxed for 3 h, during which time the dark violet suspension turned into a red solution. The solvent was partially removed by evaporation under vacuum. On standing in a fridge for several days, dark red crystals of *cis*-$[ReOCl_2(P{\sim}O)]_2(\mu$-pym) were collected. The product was filtered, washed with diethyl ether and dried (0.25 g, 60%). Crystals appropriate for X-ray analysis were obtained by re-crystallization from acetone/ethyl ether solution.

Anal. Calc. for $C_{28}H_{52}Cl_4N_2O_{10}P_2Re_2$: C, 29.17; H, 4.55; Cl, 12.13; N, 2.43. Found: C, 30.20; H, 4.49; Cl, 12.11; N, 2.14%); ν_{max}(KBr)/cm^{-1} 956vs ν(Re═O), 922s and 1018s ν(C–O–P), 1603w ν(C═N); ν_{max} (Nujol)/cm^{-1} 150w, 231m, 246m, 289m, 310s cm^{-1} (Re–P), (Re–N), (Re–Cl); $\lambda_{max}(CH_2Cl_2)$/nm (ε/$dm^3\,mol^{-1}\,cm^{-1}$) 240sh (15020), 319 (3645), 525 (401);

2.3. Crystal structure determination

The data, collected on KM4CCD diffractometer, were corrected for Lorentz and polarization effects. Data reduction was carried out using the Oxford Diffraction (Poland) programs. The structure was solved by the Patterson method using SHELXS-97 and refined by the full-matrix least-squares method on F^2 using SHELXL-97 software [12]. Non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were set in calculated positions and refined using the riding model with a common fixed isotropic thermal parameter.

3. Results and discussion

3.1. Preparation and spectroscopic characterization

The mononuclear complex *cis*-$ReOCl_2(P{\sim}O)$pym **1** can be prepared according to the method recently published for the analogue *cis*-$ReOCl_2(P{\sim}O)$py [13]. Treatment of the $ReOCl_2(OEt)(pym)_2$ precursor with a two fold excess of the HP∼O ligand, that reacts in its tautomeric deprotonated form as an uninegative bidentate chelate $(OCMe_2CMe_2O)POCMe_2CMe_2O^-$, leads to the replacement of both EtO^- and pym ligands, affording complex **1**. Alternatively **1**

Complex	^{1}H NMR δ/ppm (int., mult., J/Hz)		^{31}P{^{1}H} NMR δ/ppm
	Methyl groups	Pyrimidine ligand	
$ReOCl_2(P{\sim}O)(pym)$ **1**	0.95, 0.98, 1.20, 1.40, 1.45 1.48, 1.56, 1.58 (24H, s's)	7.66 (1H, tm, 5), 8.86 (1H, m) 9.10 (1H, dm, 2), 9.52 (1H, s)	87.79
$[ReOCl_2(P{\sim}O)]_2(\mu\text{-pym})$ **2**	1.25, 1.42, 1.52, 1.58 (48H, s's)	8.12 (1H, tm, 6), 9.51 (2H, dm, 3) 9.87 (1H, s)	93.44

can be obtained in a substitution reaction of the labile triphenylphosphine ligand for pyrimidine in *trans*-$ReOCl_2(P{\sim}O)(PPh_3)$ (see Chart 1). The synthesis was performed in decahydronaphthalene in order to lower the solubility of the product that precipitates from the reaction mixture. **1** was also employed as the substrate in the preparation of the dinuclear compound *cis*-$[ReOCl_2(P{\sim}O)]_2(\mu\text{-pym})$ **2**. The equimolar reaction of **1** with *trans*-$ReOCl_2(P{\sim}O)(PPh_3)$ in refluxing toluene gave rise to the dimer **2**, which can merely be achieved in a prolonged dimerization process of **1** performed in boiling toluene. Both complexes **1** and **2** were isolated as air-stable, microcrystalline solids, well soluble in dichloromethane, and sparingly in acetone and chloroform.

Compounds **1** and **2** consist of one and two discrete $ReOCl_2(P{\sim}O)N$ units, respectively. Dimer **2** comprises of two subunits of opposite configuration around the stereogenic rhenium centre. The *trans* O═Re–O– entity gives rise to a strong characteristic stretching vibration in the infrared spectra. For mono and dimeric compounds with the $P{\sim}O^-$ ligand, described earlier, the ν(Re═O) stretching vibrations appear at 956 and 975 cm^{-1} [7,14]. The values are roughly the same as reported for other $ReOCl_2(OR)(N\text{-heterocycle})_2$ complexes, usually observed in the 950–975 cm^{-1} region [11,15]. In the FIR area the ambiguity in the assignment of the stretching vibrations ν(Re–P), ν(Re–N) and ν(Re–Cl) can be solved based on the results of our prior experimental and theoretical work [8]. The absorptions of weak and medium intensity (at 149 and 238 or 269 cm^{-1} for **1**; 150 and 231 or 246 cm^{-1} for **2**) might be considered as ν(Re–P) and ν(Re–N) stretching vibrations, respectively. Meanwhile, the higher frequency values at 289 and 326 cm^{-1} (for **1**), and 289 and 310 cm^{-1} (for **2**) can carefully be ascribed as ν_{as}(Re–Cl) and ν_s(Re–Cl) absorptions.

Proton nuclear magnetic resonance (^{1}H NMR) spectroscopy is a powerful method for structural as well as molecular dynamic studies of the mono and dinuclear complexes **1** and **2**. The spectroscopic studies at room temperature reveal two sets of signals relevant to $P{\sim}O^-$ and the pyrimidine ligand. In addition they allow recognition between the monomer and dimer compounds. Eight equal intensity resonance signals for **1**, observed in the aliphatic range (0.6–1.8 ppm), correspond to eight magnetically non-equivalent methyl groups of the spirophosphorane $P{\sim}O^-$ and point to C_1 symmetry around the metal centre (Table 1). Coordination of the pyrimidine ring to the $ReOCl_2(P{\sim}O)$ unit, manifested by four resonances in the aromatic region, both lowers the symmetry of the diaza molecule and shifts the signals downfield.

Variable temperature spectra were recorded at temperatures between ambient and 193 K (Fig. 1). On cooling a solution of **1** to 233 K, all the NMR spectral lines broadened, with the exception of the H4 and H5 signals, due to the *para*- and *meta*-ring protons. Then the resonance lines coalesced at 223 K, and finally sharpened at 203 K. Further reduction of the temperature to 193 K causes widening of some aromatic protons (δ 0.86, 0.935 ppm) and splitting of the *meta*-H5 signal.

In order to obtain more information concerning the capability of the aromatic ring to rotate around the Re–N bond, we measured the variable-temperature ^{1}H NMR spectra of the two isomers *cis*-$ReOCl_2(P{\sim}O)py$ and *trans*-$ReOCl_2(P{\sim}O)py$.[1] A similar splitting of the resonances both in the aliphatic and the aromatic region at lower temperatures was detected for isomer *cis*-$ReOCl_2(P{\sim}O)py$ (Supplementary data, Fig. S1). The resulting pattern of the aliphatic signals for *cis*-$ReOCl_2(P{\sim}O)py$ was roughly the same as for *cis*-$ReOCl_2(P{\sim}O)pym$. Moreover analogous splitting in aromatic range upon freezing to 193 K was noticed for the *ortho*- and *meta*-proton signals of *cis*-$ReOCl_2(P{\sim}O)py$ as well.

The fact that the *o*- and *m*-protons split into non-equal intensity pairs and that there is no temperature changes on the *p*-protons indicates that two different topomers of complex **1** of disparate population may exist in solution (Chart 2). The N-heterocycle occurs in two 'frozen out' environments and the pyrimidine interchanges between these location rapidly at ambient temperature.

While the pyrimidine ligand possesses a pair of nitrogen donor atoms, we also have to take account of the 1,3-metallotropic shift phenomenon, especially as fluxionality of transition metal–azine complexes has been determined previously [16–18]. However ^{1}H NMR spectra performed from room temperature up to 333 K in $CDCl_3$ show no evidence of fluxionality for both **1** and **2**.

The NMR spectra of *cis*-$[ReOCl_2(P{\sim}O)]_2(\mu\text{-pym})$ **2** (Fig. 2) reveal temperature dependant changes too. At the temperature of 298 K four signals (versus eight for **1**) in the aliphatic resonances range, attributed to 16 methyl groups, appear. As the temperature is decreased the signals broaden, and at 223 K they approach coalescence. Eight methyl group resonances of almost equal intensity observed at 213 K split further as the temperature is lowered. At 193 K the structure seems to be frozen and 12 signals (δ 0.96, 1.03, 1.06, 1.11, 1.18, 1.20, 1.29, 1.40, 1.50, 1.59, 1.66, 1.68 ppm) of different intensity were detected. As an inference from this fact we can conclude that in this temperatures range at least two concomitant conformational changes, one in the metallacycle and the second in the phosphorous cycle appear in the system. Our previous studies on *trans*-$ReOCl_2(P{\sim}O)(PPh_3)$ (at rt exist four methyl signals) have shown that low-temperature NMR spectra can detect such dynamic exchange processes, so the proposed conclusion is in accordance with the earlier statement [7].

The aromatic region of the spectrum undergoes changes as well. Three instead of four (for **1**) resonances (at 298 K) for protons H2-pym, H4,6-pym and H5-pym, implying that the pyrimidine ring acts as bridging ligand, were observed. Such a bridging coordination mode of the diaza ligand corroborates the signals integration as well. On freezing, the two resonances at δ 9.51 and 9.87 ppm, assignable to H4,6 and H2 protons, broaden and approximately coalescence at 213 K. Each splits further into two signals of the same intensity, detected at 193 K. The most distant proton H5 of the coordinated ligand experiences the least influence by the rhenium coordination sphere. The changes in the spectra again imply that the pyrimidine H4,6 and H2 protons experience dissimilar chemical environments due to the fixed position of the molecule

[1] Complexes *cis*-ReOCl2(P∼O)(py) and *trans*-ReOCl2(P∼O)(py) were synthesized according to the procedure previously reported elsewhere [8].

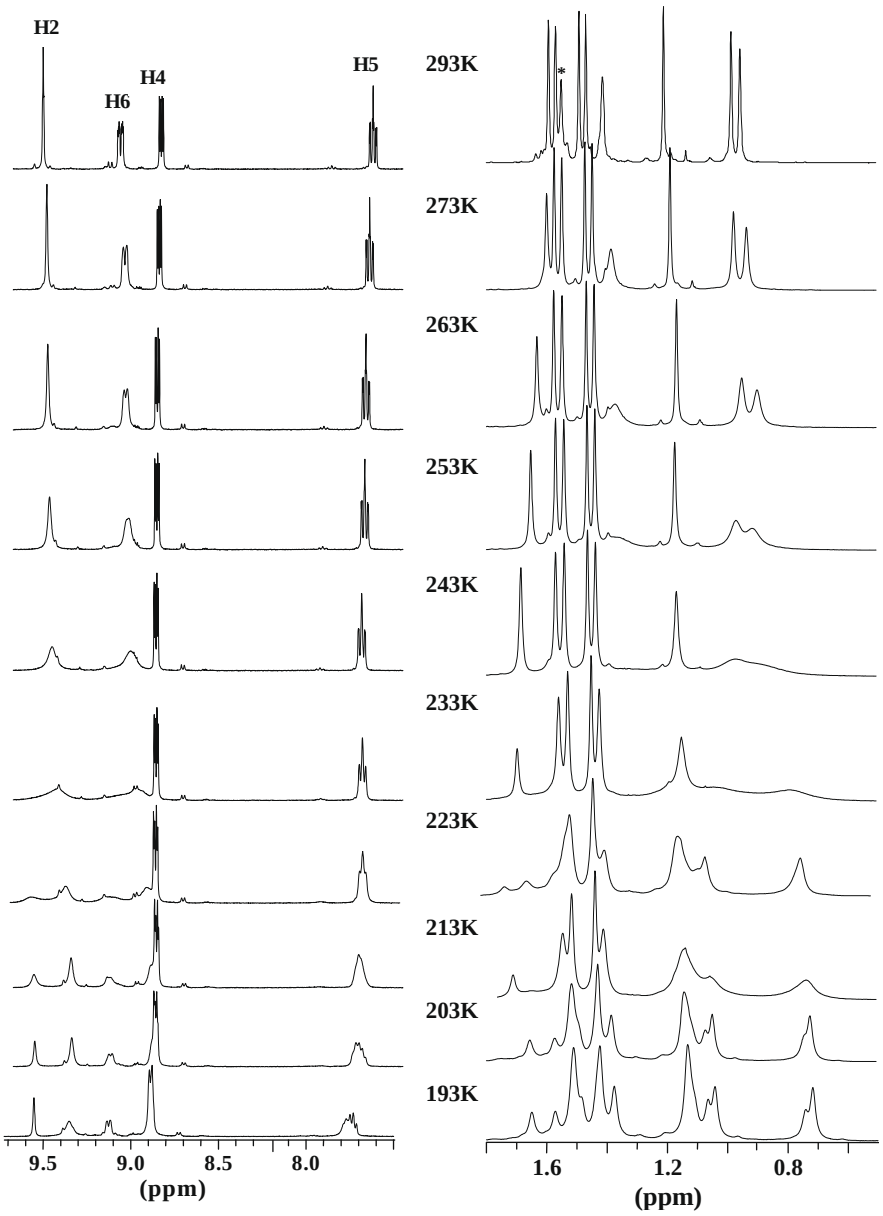

Fig. 1. ^{1}H NMR spectra of **1** run at different temperatures. * denotes H_2O impurity in CD_2Cl_2.

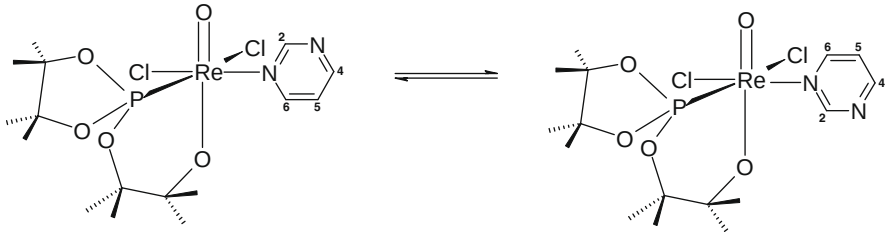

Chart 2. The proposed solution topomers of complex *cis*-$ReOCl_2$(P∼O)(pym) **1**.

upon freezing. The steric hindrance of the rhenium moiety ReOCl2(P∼O) appears to play a determinant role for the pyrimidine rotation.

The electronic spectra of the pink-violet complexes **1** and **2** display relatively weak bands at 525 nm, that are distinct from that reported for *cis*-$ReOCl_2$(P∼O)(py). These transitions are thought to have significant ligand field character d–d (π^*) with a contribution of a metal-to-oxo ligand charge transfer (MLCT). The excitations at about 320 and 340 nm with large absorption coefficients are tentatively assigned to CT bands.

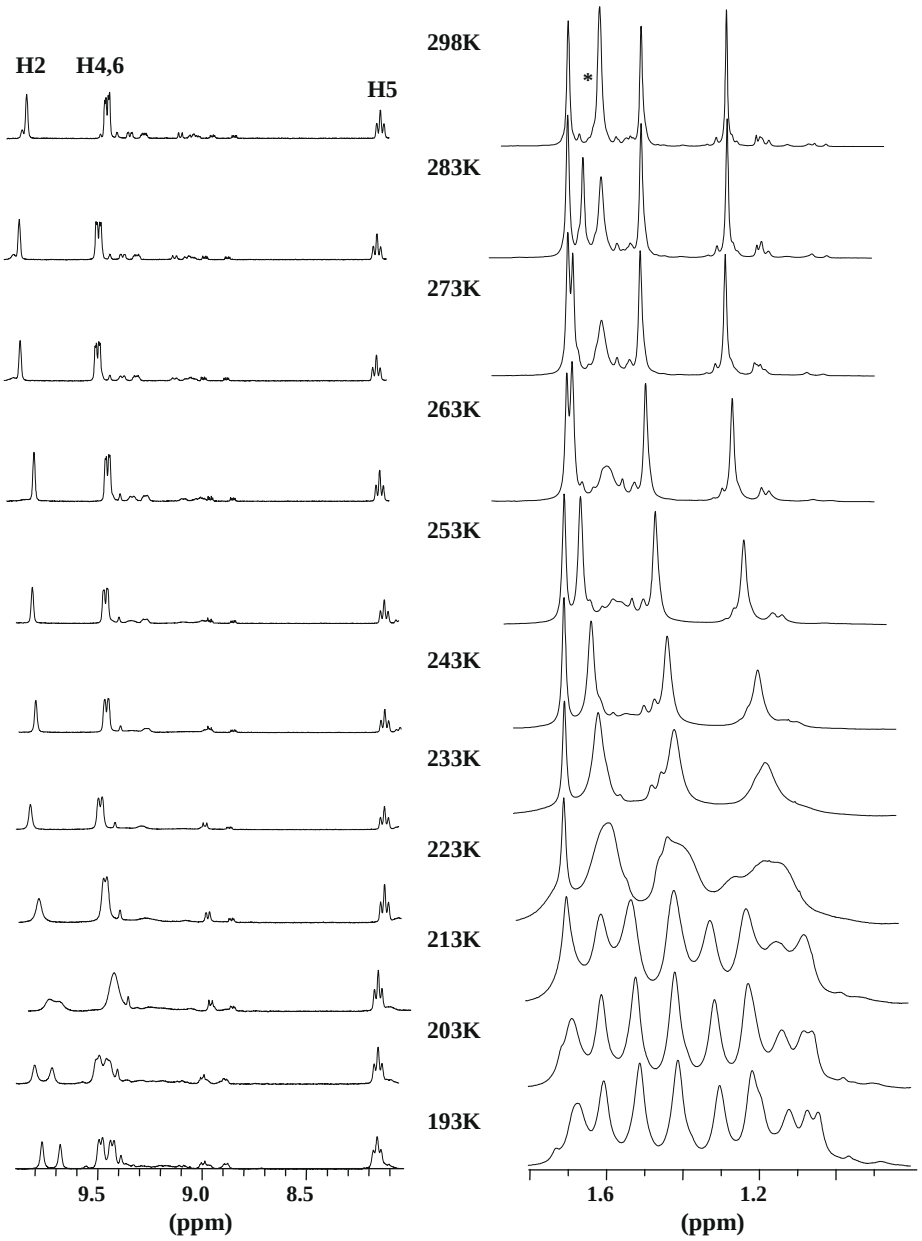

Fig. 2. ^{1}H NMR spectra of **2** run at different temperatures. * denotes overlapped impurity of H_2O in CD_2Cl_2. (The low intensity signals in the aromatic range are due to an impurity of **1**.)

4. X-ray structure analysis of complexes 1 and 2

The crystal structures of the complexes *cis*-$ReOCl_2$(P∼O)(pym) **1** and *cis*-[$ReOCl_2$(P∼O)]$_2$(μ-pym) (**2** · $(CH_3)_2CO$), resolved by X-ray analysis, corroborates that the stereochemistries of the molecules are nearly like those anticipated from the spectroscopic studies in solution for **1** and **2**. The crystallographic data of **1** and **2** are given in Table 2. A perspective drawing of the structures showing the atom numbering are depicted in Figs. 3 and 4, while selected bond lengths and angles are listed in Table 3.

Complex **1** generates enantiomorphic crystals belonging to the orthorhombic space group $P2_12_12_1$, whilst the dinuclear compound **2** crystallizes in the triclinic $P\bar{1}$ space group. The overall geometry about the central rhenium atoms for both complexes **1** and **2** can be best described as a distorted octahedral, with similar $ReOCl_2$(P∼O)N atomic arrangements. The equatorial positions are occupied by two chlorides, one phosphorous and one nitrogen atom in both cases. The apical positions are filled up by oxygens: terminal oxo and alcoholato oxygens. The rhenium atoms are displaced 0.095 and 0.069 Å towards the oxo ligands from the equatorial plane formed by the Cl1Cl2N1P1 atoms for complex **1** and **2**, respectively, and 0.080 Å from the equatorial plane formed by Cl3Cl4N2P2 found for second half of molecule **2**. The short Re–O1 bond lengths of 1.699(5) and 1.700(3) Å, and Re–O2 of 1.703(3) Å are typical for rhenium(V) monooxo complexes and indicate multiple-bond character [19,20]. The Re–$O_{pinacolato}$ bond distances of 1.894–1.898 Å are comparable to that of the alcoholate ligand [21,22] with a *trans* O=Re–O arrangement, in that the total bond order is close to four. The oxygen atoms are not aligned with the metal. The O=Re–O angles are equal to 168.7(3)° for **1** and 166.9(1)° and 164.6(1)° for **2**. Whereas the Re–Cl bond distances appear to be in the normal range (2.35–2.45 Å), the Re–Cl1 and

$wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/[w(F_o^2)^2]\}^{1/2}$.
$w = 1/[\sigma^2(F_o^2) + (aP)^2]$ where $P = (F_o^2 + 2F_c^2)/3$, a = 0.0220 (**1**), 0.0331 (**2**).

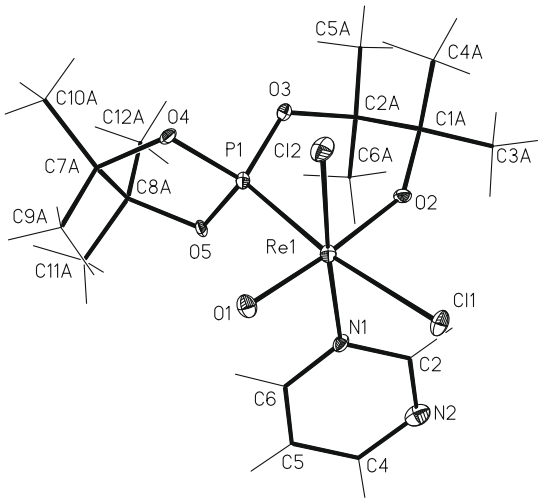

Fig. 3. Molecular structure of *cis*-$ReOCl_2(P{\sim}O)pym$ (**1**).

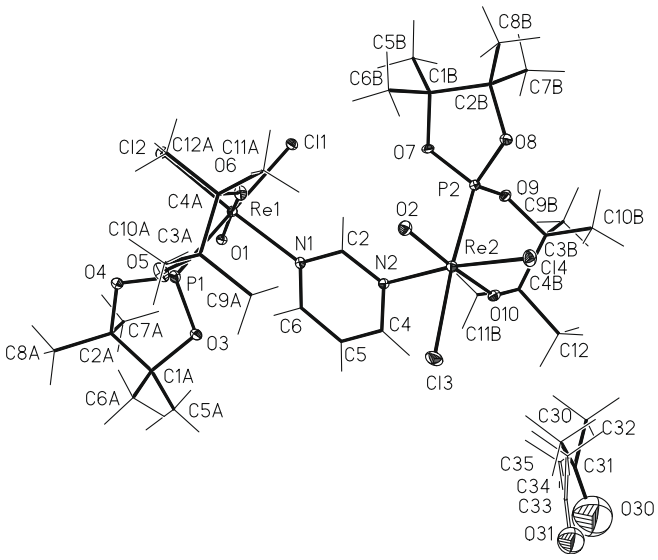

Fig. 4. Molecular structure of *cis*-$[ReOCl_2(P{\sim}O)](\mu\text{-pym})$ ($\mathbf{2}\cdot(CH_3)_2CO$).

Re–Cl3 bonds are moderately elongated by ca. 0.04 Å in comparison with Re–Cl2 and Re–Cl4. One can explain this strengthening as the expense of the steric *trans* effects to the Re–P bond [23], caused by the strong π-acceptor character of the phosphite ligand.

Both the five-membered POCCO and six-membered RePOCCO cycles are puckered. The five-membered rings with tetrahedrally coordinated phosphorous atoms adopt a slightly deformed envelope conformation with a deviation of the C8A atom by 0.52 Å for **1**, C1A and C2B atoms by 0.518 and 0.516 Å from the main planes for **2**. The metallacycles reveal half chair conformations with torsion angles equal to O2Re1P1O3 = −15.08° for **1**, O6Re1P1O5 = 8.16° and O10Re2P2O9 = 5.87° for **2**. As expected, comparison of the bond lengths and bond angles in **1** and **2** with the previously obtained by us congeners *cis*-$ReOCl_2(P{\sim}O)py$ or *trans*-$ReOCl_2(P{\sim}O)py$ shows that the values are in good agreement and the structures do not differ significantly [8,13].

5. Conclusions

The reaction of the oxo starting material $ReOCl_2(OEt)(pym)_2$ with the $HP(OCMe_2CMe_2O)_2$ ligand in toluene has produce *cis*-$ReOCl_2(P{\sim}O)(pym)$ **1**. Attempts to obtain a dinuclear analogue pro-

vided a dimer with the diastereomeric configuration *cis*-[$ReOCl_2$(P∼O)](μ-pym) **2**. X-ray analysis corroborates a distorted octahedral geometry of the rhenium atoms and the existence of a *trans* O═Re–O– arrangement of the terminal oxygen and pinacolato atoms, determining their high stability. The two complexes, either mono or dinuclear, are new components of the oxo–rhenium(V) complex set, where coordination of hydridospirophosphorane occurs with the breakage of the P–O bond and formation of an opain–chain P(III) derivative. In solution the complexes are fluxional. The low-temperature ^{1}H NMR data for **1** and **2** reveal dynamic exchange process concerning the aza protons. Its resonances are sensitive to the fluxional motion and suggest that interconversion occurs between two topomers. Additionally NMR data show that dimer **2** undergoes two dynamic exchange processes contemporaneously, pertinent for the P∼O^- ligand, one in the metallacycle coupled with the second in the phosphorocycle.

Appendix A. Supplementary data

CCDC 694051 and 694052 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.10.045.

ABSTRACT

The binding affinity for Pb^{2+}, Cd^{2+} and Hg^{2+} of the sinapic acid–calix[4]arene hybrid **2**, having four sinapyl pendants at the upper rim, has been investigated *via* an UV–Vis study. Compound **2** has better complexing ability than the monomeric *p*-phenetidine derivative **1**. This highlights that the clustering of sinapyl units in a basket-like structure, dictated by the calixarene scaffold, greatly enhances the complexing properties. Ligand **2** forms complexes even with Hg^{2+}, which is not complexed by **1** at all; the complexes formed by **2** with Pb^{2+} and Cd^{2+} are much stronger than the analogous complexes formed by **1**. The UV–Vis investigation shows that the hybrid **2** markedly favors Pb^{2+} over Cd^{2+} and Hg^{2+}. Information on the structural properties of the complex species was obtained by ^{1}H NMR spectroscopy. NMR data show that all three metal ions are placed into the cavity consisting of the calixarene scaffold and the sinapyl pendants, though their binding affects the coordinating regions to a different extent.

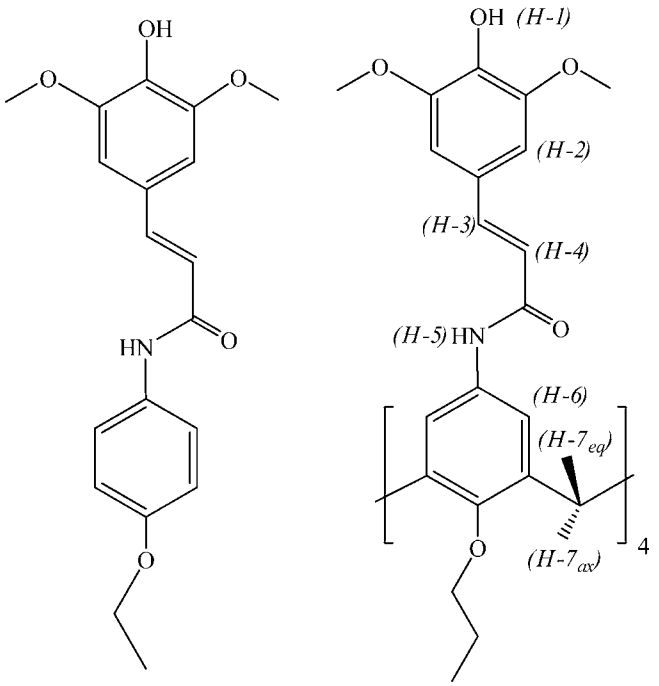
1. Introduction

The increasing interest in environmental contaminants as Pb^{2+}, Cd^{2+} and Hg^{2+} is documented by the large number of papers appearing about these specific metal ions [1]. These metal ions are largely present in the environment due to fossil fuel combustion, paint, battery and fertilizer industries as well as oil refineries, smelting plants and municipal wastes [2]. Exposure to these non-essential elements remains a serious problem, especially in many developing countries [3]. These highly toxic metals are known to cause health problems such as brain damage [4], nephropathy [5], sluggishness [6], hyperirritability [7], restlessness [8], infertility [9] and a number of diseases in pre-school aged children [4c,10].

Thus, the design and development of efficient ligands that may be used to selectively extract and/or probe these metal ions are turning out to be extremely important. To this end, macrocyclic ligands have been extensively studied [11].



Hydroxycinnamic acids are a class of compounds of biomedical interest widely spread in the plant kingdom [12]. Their biological activity relates not only to their capability to act as antioxidants or enzyme inhibitors but also to their metal chelating properties [13]. Recently, we have reported on the synthesis, the radical scavenging and antioxidant activities of calix[4]arene derivatives bearing hydroxycinnamic acid residues [14].

Calixarene-based macrocycles have been widely used in supramolecular chemistry as platforms to build receptors able to bind ions and molecules of biological and environmental relevance [15]. Among the calix[*n*]arenes, the smallest tetrameric oligomer, calix[4]arene, has attracted significant attention since it may be *ad hoc* tailored to have unique tri-dimensional structures (*cone*, *partial cone*, *1,2-* and *1,3-alternate* conformations) [15a].

Here, we report on the binding ability of the sinapyl–calix[4]arene **2** towards the toxic metals Pb^{2+}, Cd^{2+} and Hg^{2+}. Ligand **2** has the potential to act as a selective binder by virtue of the arrangement of the synapyl units which are anchored onto the calixarene platform in the *all-syn* orientation. In this respect, we compare the chelating ability of **2** to that of the homologous "monomer" *p*-phenetidine derivative **1**.

1 **2**

2. Experimental

2.1. General

CH_3CN for spectrophotometry (Merck, Uvasol) was employed throughout. Lead and mercury perchlorates were obtained from Aldrich and were used without any further purification. Cadmium perchlorate solutions were obtained by dissolving a weighed amount of cadmium oxide (Carlo Erba) in CH_3CN, then adding a stoichiometric amount of perchloric acid. Perchlorate solutions were standardized according to the procedures described in the literature [16]. Safer counter ions (*e.g.* tetrafluoroborates) could not be employed owing to their interfering absorption. (**Caution!** *Perchlorates may be explosive and should be handled with caution*). Grade A glassware was used throughout. All reagents for the syntheses and deuterated solvents were purchased from Aldrich and were used without any further purification.

2.2. Synthesis

The *p*-phenetidine derivative **1** was synthesized according to the procedure described by Rajan et al. [17]. Compound **2** was synthesized as described previously [14]; its purity was checked thermogravimetrically as described by Arena et al. [18].

Compound **2**: ^{1}H NMR (400 MHz, CD_3CN/acetone-d_6, 80:20, v/v) δ 1.03 (t, CH_3, J = 7.60 Hz, 12H), 2.32 (CH_2 overlapped CD_3CN), 3.18–4.48 (AX system, $ArCH_2Ar$, J = 13.60 Hz, 8H), 3.74 (s, OCH_3, 24H), 3.87 (t, OCH_2, 8H), 6.49 (d, CH=CH, J = 15.20 Hz, 4H), 6.71 (s, OH, 4H), 6.72 (s, ArH, 8H), 7.04 (s, ArH, 8H), 7.46 (d, CH=CH, J = 15.20 Hz, 4H), 8.31 (s, NH, 4H).

2.3. Spectroscopic measurements

2.3.1. UV–Vis spectra

UV–Vis titrations were carried out as described [19] by using a diode-array spectrophotometer (Agilent 8453) and a precision burette (Hamilton, 1 ml). All measurements were performed in CH_3CN at 25 °C. Addition, equilibration time and data reading were controlled by homemade software. Time intervals for equilibration and reading were systematically changed to avoid artefacts. The titrate concentration ranged from 2.5×10^{-5} to 4.0×10^{-5} mol dm^{-3} and from 1.3×10^{-5} to 1.7×10^{-5} mol dm^{-3} for **1** and **2**, respectively. The titrant (metal ion) concentration was chosen so as to reach the metal/ligand ratio needed to have enough curvature in the molar ratio plot. 55–60 points were recorded for each independent titration run. At least four independent runs were collected for each M–ligand system (M = Hg^{2+}, Pb^{2+} or Cd^{2+}; ligand = **1** or **2**).

Experiments for **1**, carried out with solutions prepared more than 3 h before the titration, showed discrepancies that were time-dependent. For this reason, all **1** solutions had to be freshly prepared and employed immediately. For both ligands the data were collected over the range 215–450 nm for all the cations investigated and were analyzed by using HYPERQUAD [20] and SPECFIT [21]. Both programs allow a multiwavelength treatment of the data. HYPERQUAD follows a procedure that does not imply matrix compression and allows simultaneously refinement of the data from different experimental measurements, whilst SPECFIT combines a chemometric analysis (*Factor Analysis* and Evolving *Factor Analysis*) [22] with a non-linear least squares minimization procedure [23]. Unlike SPECFIT, HYPERQUAD offers the possibility to refine all the titrations simultaneously, which accounts for the smaller standard deviations associated with the values shown in Tables 1 and 2.

2.3.2. NMR spectra

^{1}H NMR (400.13 MHz) spectra were recorded at 25 °C using a Bruker Avance™ 400 spectrometer. Chemical shifts (δ) are expressed in parts per million (ppm) and were referenced to TMS. The complex formation of **2** with Pb^{2+}, Cd^{2+} and Hg^{2+} was studied by adding different aliquots of a stock solution of the metal perchlorate (Pb^{2+} = 2.2×10^{-2} mol dm^{-3}, Hg^{2+} = 0.13 mol dm^{-3} and Cd^{2+} = 0.2 mol dm^{-3} in acetone-d_6) into the NMR tube containing the ligand **2** (5.5×10^{-4} mol dm^{-3}, in CD_3CN/acetone-d_6, 80:20, v/v). NMR spectra were recorded after each addition of metal ion salt (0.5, 1, 1.5 and 3 equiv. for Pb^{2+}; 5, 10, 15 and 25 equiv. for Cd^{2+}, and 3, 6, 9 and 15 equiv. for Hg^{2+}). Changes in the chemical shifts were measured using the free ligand as a reference.

Table 2
$\log\beta$ values[a] for the complex formation of Hg^{2+}, Cd^{2+} and Pb^{2+} with **2** in CH_3CN at 25 °C.

Reaction	$\log\beta$	
	HYPERQUAD	SPECFIT
$Hg^{2+} + \mathbf{2} \leftrightarrows [Hg(\mathbf{2})]^{2+}$	3.84(3)	3.9(2)
$2\,Hg^{2+} + \mathbf{2} \leftrightarrows [Hg_2(\mathbf{2})]^{4+}$	8.14(5)	8.0(1)
$Cd^{2+} + \mathbf{2} \leftrightarrows [Cd(\mathbf{2})]^{2+}$	4.40(9)	4.4(1)
$2\,Cd^{2+} + \mathbf{2} \leftrightarrows [Cd_2(\mathbf{2})]^{4+}$	8.40(8)	8.40(9)
$Pb^{2+} + \mathbf{2} \leftrightarrows [Pb(\mathbf{2})]^{2+}$	7.2(3)	7.2(3)
$2\,Pb^{2+} + \mathbf{2} \leftrightarrows [Pb_2(\mathbf{2})]^{4+}$	11.3(3)	11.3(3)
$Pb^{2+} + 2\,\mathbf{2} \leftrightarrows [Pb(\mathbf{2})_2]^{2+}$	13.3(7)	13.3(7)

[a] σ in parentheses.

3. Results and discussion

3.1. Binding constants

Figs. 1 and 2 show typical titration spectra obtained by titrating a CH_3CN solution of $Cd(ClO_4)_2$ or $Pb(ClO_4)_2$ into a solution of **1** in CH_3CN. Mercury addition does not cause any significant change of the absorption spectrum, indicating that this cation does not form detectable complexes with ligand **1**. The insets of both figures give an immediate perception of how the spectrum changes from the beginning (free ligand) to the end (complex) of the titration.

The spectral changes resulting from the addition of the metal ion were corrected for dilution and analyzed by using two different computer programs (see Section 2). Both programs resort to a multiwavelength treatment of the absorption data; however they use a different refinement strategy. The use of different algorithms and calculation methods minimizes the risk of creation of artefacts [19].

The value of SPECFIT [21] in analysing the data, that is the Evolving Factor Analysis employed by this package, provides a limit to the number of species necessary to explain the changes, *i.e.*, it provides an objective mean of obtaining a chemical model for the system; if the model provided by SPECFIT is also accepted by HYPERQUAD [20], the speciation of the system has to be considered highly reliable. Both packages indicate that the spectrophotometric data may be fitted with a $[M–\mathbf{1}]^{2+}$ ($M = Cd^{2+}$ or Pb^{2+}) species only and that Pb^{2+} binds **1** more efficiently than Cd^{2+}; they also indicate that there are no evidences for the formation of Hg^{2+} complexes (Table 1).

Figs. 3–5 show the UV–Vis titration curves obtained for the hydroxycinnamic acid–calix[4]arene hybrid **2**. It is noteworthy that mercury does not form complexes with the *p*-phenetidine derivative **1**, but it does form complexes with **2**. Furthermore, the shape of molar ratio curves (see insets) show that **2** forms complexes with the three cations having both different stoichiometries and formation constants of different magnitudes. Indeed, this is confirmed by the data analysis that leads to the set of values listed in Table 2.

To obtain molar ratio plots with a curvature suitable for the determination of stability constant values, different metal/ligand ratios had to be reached for the three metal ions, depending upon the magnitude of the stability constants; these ratios were smaller for Pb^{2+} (*i.e.* the metal ion forming the strongest complexes) whereas they were larger for cadmium and mercury. All three cations form species of the type ML and M_2L; Pb^{2+} forms also a species of the type ML_2.

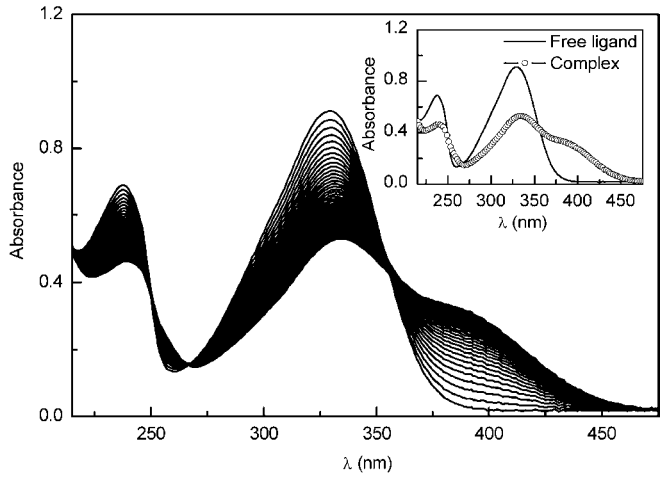

Fig. 1. UV–Vis titration curves for the Cd^{2+}–**1** system in CH_3CN at 25 °C. The inset shows the ligand spectrum before (—) and after (–O–) the metal ion addition.

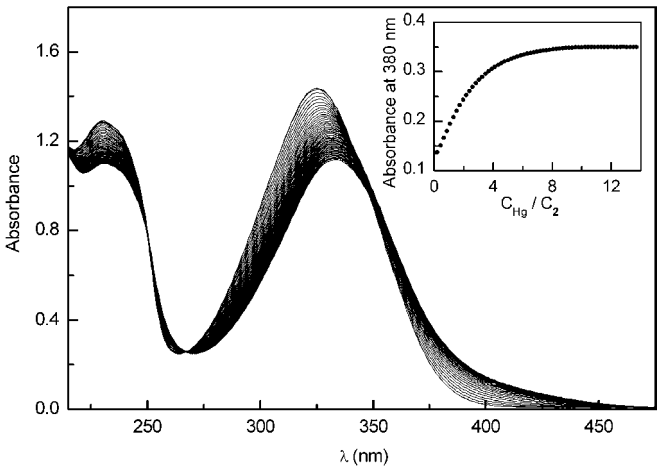

Fig. 3. UV–Vis titration curves and molar ratio curve for the Hg^{2+}–**2** system in CH_3CN at 25 °C.

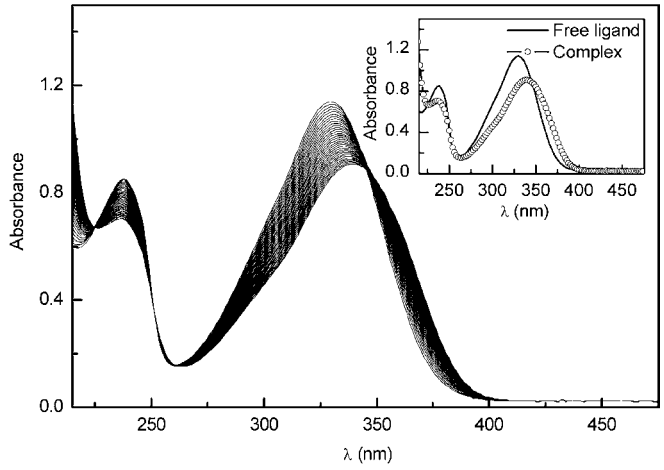

Fig. 2. UV–Vis titration curves for the Pb^{2+}–**1** system in CH_3CN at 25 °C. The inset shows the ligand spectrum before (—) and after (–O–) the metal ion addition.

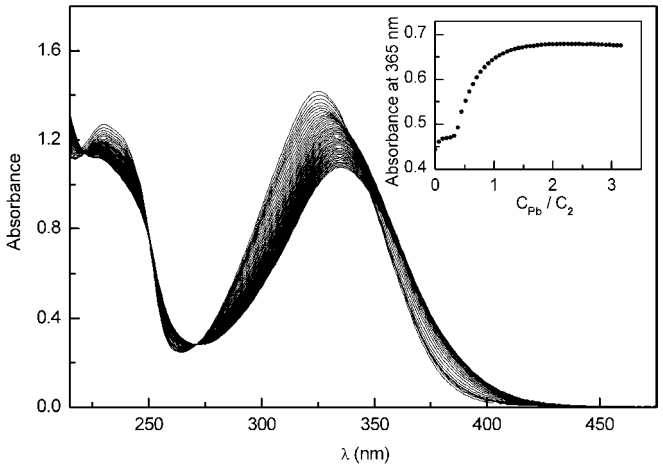

Fig. 5. UV–Vis titration curves and molar ratio curve for the Pb^{2+}–**2** system in CH_3CN at 25 °C.

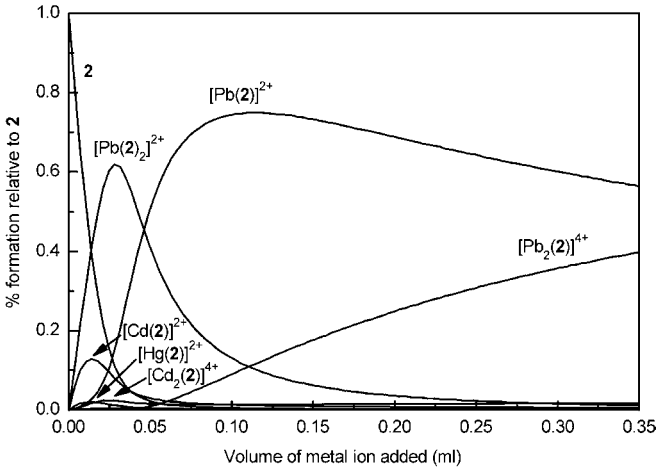

Fig. 6. Species distribution diagram for a M^{2+}–**2** (M = Hg^{2+}, Cd^{2+} and Pb^{2+}) system. $C_{Hg} = 1.10 \times 10^{-3}$ mol dm^{-3}; $C_{Cd} = 2.0 \times 10^{-3}$ mol dm^{-3}; $C_{Pb} = 4.50 \times 10^{-4}$ mol dm^{-3}; $C_2 = 1.50 \times 10^{-5}$ mol dm^{-3}. Initial volume = 1.8 ml.

Among the three cations, Pb^{2+} forms the most stable species. The determination of such values (especially for the ML and ML_2 complexes) required the use of diluted solutions; this likely accounts for the relatively large standard deviation associated with the binding constants of Pb^{2+}, *i.e.* the cation that requires the lowest concentration since it forms the strongest complexes.

Though several calixarene-based ligands have been proposed as sensors [24] or, more in general, as selective ligands [25–27], only a few papers [19b,27] report studies of the stability constants of the proposed ligands with the metal ion(s) of interest, which are the only parameters that really reflect the true binding ability of the receptors. Unlike the 1,3-alternate calix[4]arene derivative reported by us previously [19b], although it forms complexes with large stability constants ($\log\beta > 7$), it is not able to discriminate Pb^{2+} from Hg^{2+}, whereas ligand **2** interacts with Pb^{2+} selectively.

The $\log\beta$ values show that the complexation follows the order $Pb^{2+} > Cd^{2+} > Hg^{2+}$. The same stability order has been found in acetonitrile for a calix[4]arene containing ester and ketone functional groups at the lower rim [27]. However, a straight comparison between the present results and the data reported in Ref. [22] is not possible since the ligands investigated by Danil de Namor et al. are reported to form only 1:1 species. On the other hand, through extraction studies based on a calix[4]arene tetracarboxylic derivative, Ohto et al. [26] have inferred that lead may form a Pb_2L species, which is in line with our results.

The marked selectivity of **2** for Pb^{2+} over Cd^{2+} and Hg^{2+} is clearly shown by the distribution diagram reported in Fig. 6. The figure shows how the three metal ions compete for the ligand in a solution of **2**; even with Pb^{2+} concentrations as low as 1.2×10^{-5} mol dm^{-3} and Hg^{2+} and Cd^{2+} concentrations of 2.7×10^{-5} and 5.4×10^{-5} mol dm^{-3} respectively (*i.e.* at $v = 0.05$ ml, see Fig. 6), the ligand would form almost exclusively species with lead.

There are two more aspects that deserve some comments. Firstly Hg^{2+}, that does not form any species with **1**, does complex **2**, even though to a smaller extent; in addition Pb^{2+} and Cd^{2+} form complexes with **2** that are much more stable than those formed with **1**. This indicates that there is a cooperative effect resulting from the simultaneous presence of four sinapyl units on the calixarene platform. The arrangement of sinapic acid pendants in a bowl-like structure brings the complexing moieties in close proximity and this greatly enhances the complex formation ability of the single monomeric unit. This is supported not only by the magnitude of the binding constant but also by the formation of species other than the simple ML complexes, the only species detected for both Pb^{2+} and Cd^{2+} with **1**.

Secondly, the binding constant values follow the order $Pb^{2+} > Cd^{2+} > Hg^{2+}$, which does not follow the cation size order ($Pb^{2+} > Hg^{2+} > Cd^{2+}$) [28] but parallels the *hard–soft* characteristics of the three metal ions (*hardness* follows the order $Pb^{2+} > Cd^{2+} > Hg^{2+}$) [29]. This leads to the thinking that the donor atoms of the ligand play a different role in the binding of the three metal ions.

Unfortunately, the spectrophotometric experiments do not indicate whether the different coordination modes result from preferences for the phenolic or amide sites. Attempts to monitor (and eventually to model) the extra-proton displacement that would result from the deprotonation at the phenolic or amide sites failed as the ΔpH change measured following the addition of the metal ion was well within the experimental error. On the other hand, the investigation of larger concentrations is hampered by the limited solubility of **2**.

3.2. ^{1}H NMR experiments

To gain insight into the structures of the complexes formed by **2**, we carried out ^{1}H NMR measurements. Unfortunately, the concentrations usually needed to perform NMR experiments could not be reached, due to the scarce solubility of **2** in CD_3CN.

A well resolved spectrum of the ligand was obtained by adding CD_3OD to CD_3CN (30:70, v/v). However, addition of Pb^{2+}, Cd^{2+} or Hg^{2+} perchlorates did not result in significant changes of the chemical shifts of the ligand in this solvent mixture, probably owing to the competitive effect of the protic solvent (CD_3OD). A CD_3CN/acetone-d_6 (80:20 v/v) mixture turned out to be the best solvent for the NMR experiments since it gave both a well resolved ligand spectrum and chemical shifts that changed upon metal ion addition. The amount of metal ion added to ligand **2** reproduced the metal/ligand ratios explored in the UV–Vis experiments. Attempts to explore metal ion concentrations larger than those used in the present NMR study were hampered by the formation of a precipitate and the simultaneous appearance of a yellowish colour.

The chemical shift changes of olefinic (H-3 and H-4), bridging methylene (H-7_{eq} and H-7_{ax}), aromatic (H-2 and H-6), OH (H-1) and NH (H-5) protons were followed to gain information on the sites of **2** involved in the metal binding (see Table 3).

The addition of up to 4–5 equiv. of Cd^{2+} results in significant downfield shifts of the OH, NH, H-3, H-4, H-6, H-7_{eq} and H-7_{ax} proton signals (Fig. 7). At these metal/ligand ratios, the free ligand and ML species predominate while M_2L forms to a lesser extent, as

Table 3
^{1}H NMR chemical shift (δ) and chemical shift changes ($\Delta\delta$) of the ligand protons of **2** by the addition of Pb^{2+}, Cd^{2+} and Hg^{2+} in CD_3CN/acetone-d_6 (80:20, v/v) at 25 °C.

Protons	δ (ppm)	δ (ppm)						
	Free ligand	Pb^{2+}			Cd^{2+}		Hg^{2+}	
		0.5 equiv.	1 equiv.	3 equiv.	5 equiv.	25 equiv.	3 equiv.	15 equiv.
H-1	6.72	0.11	0.25	0.37	0.06	0.21	nd[a]	nd[a]
H-2	6.73	0.00	0.01	0.03	0.00	0.04	0.00	0.00
H-3	6.49	0.03	0.09	0.15	0.01	0.07	0.00	0.08
H-4	7.46	0.09	0.13	0.14	0.01	0.04	0.02	0.13
H-5	8.31	0.26	0.54	0.72	0.13	0.36	0.51	0.91
H-6	7.04	0.04	0.08	0.10	0.05	0.14	0.00	0.00

[a] not detectable.

shown by the distribution diagram (see Supplementary data). As we increase the metal/ligand ratio, a deshielding of the H-2 proton ($\Delta\delta$ 0.04 ppm) is observed in addition to a more pronounced deshielding of the all above mentioned signals; such deshielding is particularly significant for the OH ($\Delta\delta$ 0.21 ppm) and NH ($\Delta\delta$ 0.36 ppm) protons. These data suggest that, in the presence of larger metal/ligand ratios, two cadmium cations interact with the amide region as well as with the upper part of the sinapyl residue.

The addition of Pb^{2+} to **2** causes shifts of the same protons involved in the cadmium complexation (Fig. 8); remarkably, the OH protons show a pronounced shift ($\Delta\delta$ 0.11 ppm) at a 0.5:1 metal/ligand ratio. This shift may be associated to the formation of a ML_2 structure in which one Pb^{2+} ion holds together two molecules of ligand by binding the external sinapyl OH groups. At the same metal/ligand molar ratio, a small amount of ML species is already present in solution (see distribution diagram in the Supplementary data). The deshielding observed for the NH ($\Delta\delta$ 0.26 ppm) and olefinic ($\Delta\delta$ 0.03 and 0.09 ppm) protons, suggests that the lead ion is positioned in the proximity of the carbonyl region. The affinity of Pb^{2+} for the carbonyl oxygen is in line with the relatively *harder* nature of this metal ion. As the metal/ligand molar ratio is increased to 3:1, the progressive deshielding of the protons, that are diagnostic for the complexation, supports the formation of the M_2L species. The shifts of the calixarene NH, H-6, H-7_{eq}, H-7_{ax} and the sinapyl H-3, H-4, H-2 and OH proton signals ($\Delta\delta$ 0.72, 0.10, 0.15, 0.14, 0.15, 0.14, 0.03 and 0.37 ppm, respectively) show that both the wide rim of the scaffold and the sinapyl pendants are involved in the complexation process. Likely, the first lead ion that is taken up is forced towards the macrocycle wide rim by the coordination of the second lead ion. The tentative structures for the ML_2, ML and M_2L complexes are depicted in Fig. 9.

A different behaviour is shown by Hg^{2+}; the interpretation of the NMR spectrum is somehow difficult due to the coexistence of a significant amount of free ligand in addition to the ML and M_2L species. However, the downfield shifts of H-3, H-4 ($\Delta\delta$ 0.08 and 0.13 ppm, respectively) and NH ($\Delta\delta$ 0.91 ppm) protons show that

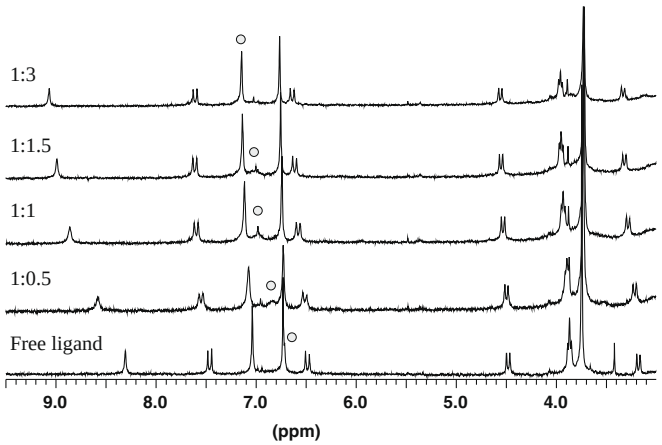

Fig. 8. Changes of the ^{1}H NMR (400 MHz) spectra of **2** in CD_3CN/acetone-d_6 (80:20, v/v) upon addition of Pb^{2+}; the circle labels the OH signals.

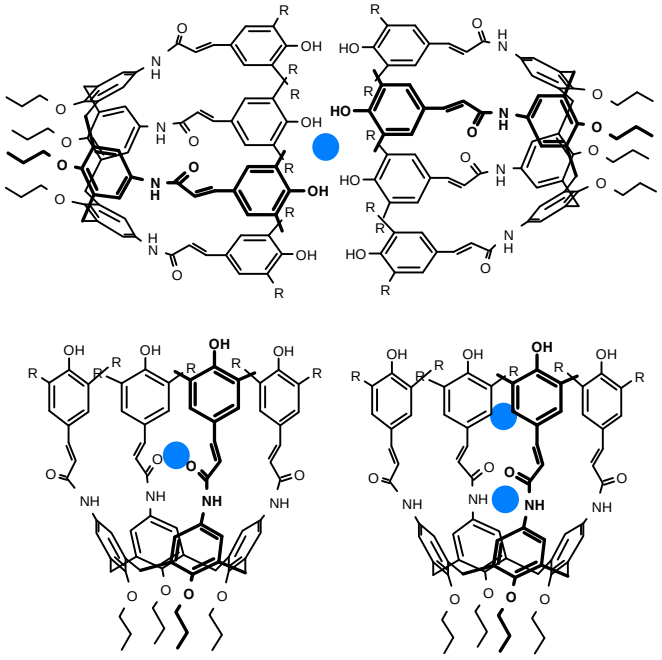

Fig. 9. Tentative structures of the ML_2, ML, and M_2L species for the Pb^{2+}–**2** system.

Hg^{2+}, the *softest* among the three metal ions, has a marked preference for the olefinic *(softer* region) and NH groups of the ligand.

X-ray diffraction analysis is currently underway to obtain more details on the structures of the complexes.

4. Conclusion

This work shows the first example of a sinapic acid–calixarene hybrid capable of forming strong complexes not only with Pb^{2+} and Cd^{2+} but also with Hg^{2+}. The latter metal ion does not form any complex with the monomeric homologous compound **1**. Our results indicate a cooperative effect resulting from the simultaneous presence of multiple sinapyl units arranged on the calix[4]-arene wide rim. The three metal ions show some preference for specific coordination sites of the ligand. Pb^{2+} complexes with ligand **2** are so stable that in principle they are the only ones that would show up in a solution containing a mixture of the three metal ions. The marked preference of ligand **2** for Pb^{2+} may pave the way for new applications of this ligand as an ion-selective sensor.

Isocyanides

ABSTRACT

The quinolinylcyclopalladated complexes **3a–b** were synthesised in good yields (81% and 77%) by the insertion reaction of the prepared dinuclear palladium complexes [Pd(*C,N*-2-C_9H_4N-CHO-3-R-6)Cl(PPh_3)]$_2$ [(R = H (**2a**), R = OMe (**2b**)] with isonitrile XyNC (Xy = 2,6-$Me_2C_6H_3$). The cyclopalladated complexes **3a–b** were also obtained in low yields (39% and 33.5%) via a one pot oxidative addition reaction of quinoline chloride **1a–b** with isonitrile XyNC:Pd(dba)$_2$ (4:1). The reactions of **3a–b** with Tl(TfO) (TfO = triflate, CF_3SO_3) in the presence of H_2O or EtOH causes depalladation reactions of the complexes to provide the corresponding organic compounds **4a–b**, **5a–b** and **6a–b** in yields (41%, 27% and 18–19%). The products were characterized by satisfactory elemental analyses and spectral studies (IR, ^{1}H, ^{13}C and ^{31}P NMR). The crystal structures of **2a**, **3a** and **3b** were determined by X-ray diffraction studies.

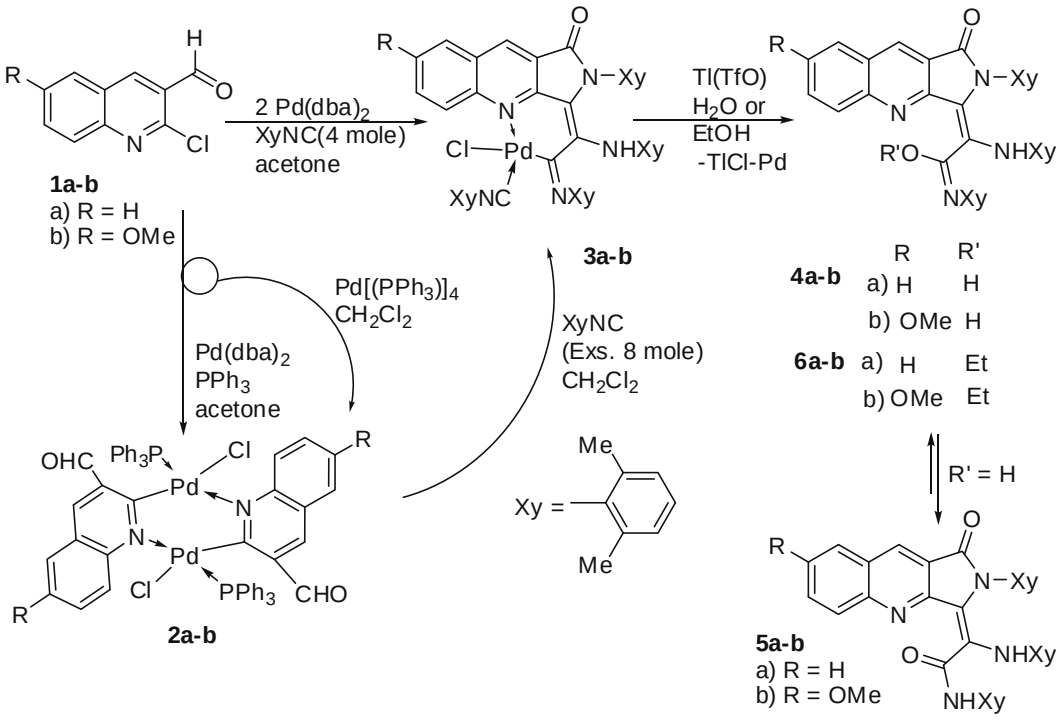
1. Introduction

The chemistry of arylpalladium complexes is a topic of great interest because such compounds participate in many organic reactions [1–12]. Cyclopalladated complexes (CPCs) are one of the most popular classes of organopalladium derivatives, which are widely applied in organic synthesis, organometallic catalysis and new molecular materials. Among them, the most investigated cyclopalladated complexes are five- or six-membered rings fused with an aromatic ring, and the metallated carbon is usually an aromatic sp^2 carbon [13–17]. However, six-membered palladacycles with iminoyl (C=N–) sp^2 carbon are rather rare [18]. This is probably due to poor stability which brings difficulties of preparation, isolation and characterization of these complexes. The limitation can be overcome by changing the nature of the metallated carbon atom, the type of donor groups and their substituents. Some of these reactions involved *ortho*-functionalized aryl complexes that after insertion of isocyanides gave heterocyclic products in which the ortho group is included [19–21]. Establishing synthetic procedures for these complexes invariably involve the presence of other strongly coordinated ligands, such as PPh_3 [22–24], and these are attracting our interest. There is relatively little known concerning the cyclometallation of aldehyde functionalities [25–34]. The interest of this subject has prompted us to prepare arylpalladium complexes containing *ortho*-–CHO functionalized groups. In this contribution we present the synthesis and characterization of novel mono- and dimeric palladacycles as well as their utility as precursors for the synthesis of valuable organic products. The structure of dimeric [*N*-aryl-Pd-Cl(PPh_3)]$_2$, **2a–b**, with non common '$Pd_2C_2N_2$' central cores formed by oxidative addition of the chloroquinolines **1a–b** to a Pd(0) is supported by X-ray structures. The utility of the cyclopalladated complexes **3a–b** in organic synthesis via their depalladation reactions to provide amidic acid or esters (**4a–b**, **5a–b** and **6a–b**) are the most outstanding points of this manuscript. The sequence of the reactions led eventually to compounds that could potentially possess pharmacological properties [35–53].



2. Results and discussion

Oxidative addition reactions of 2-chloro-6-R-3-quinolinecraboxaldehydes R = H (**1a**), R = OMe (**1b**) toward a stoichiometric amount of [Pd(dba)$_2$] = ([Pd$_2$(dba)$_3$] · dba; dba = dibenzylideneacetone) [54] in the presence of a neutral ligand such as PPh_3 (1:2:1) under nitrogen in degassed acetone gave the dimeric palladium complexes{Pd[C_9H_5-CHO(3)]Cl(PPh_3)}$_2$ **2a**, {Pd[-6-OCH_3-C_9H_4-CHO(3)]Cl(PPh_3)}$_2$ **2b** in moderate yields (43% and 31%), through the coordination of the quinolinyl nitrogen. Subsequently, the insertion reaction of 2,6-dimethylphenyl isocyanide XyNC (Xy = 2,6-$Me_2C_6H_3$) into the dinuclear complexes in CH_2Cl_2 at room temperature eventually formed the monuclear complexes **3a–b** in high yields (81% and 77%). These palladacycles **3a–b** could also be obtained in low yields (39% and 33.5%) by direct oxidative addition of 2-chloro-6-R-3-quinolinecraboxaldehydes **1a–b** toward Pd(dba)$_2$ in the presence of a stoichiometric amount of isocyanide XyNC in degassed acetone at room temperature, as depicted in Scheme 1.

It was envisaged that the oxidative addition reaction of **1a–b** with Pd(dba)$_2$/PPh_3 could give the expected complex in a *transoid* form (**A**). However, isolation of the *trans* complexes failed, and only a yellow powder solid was isolated in the pure form that

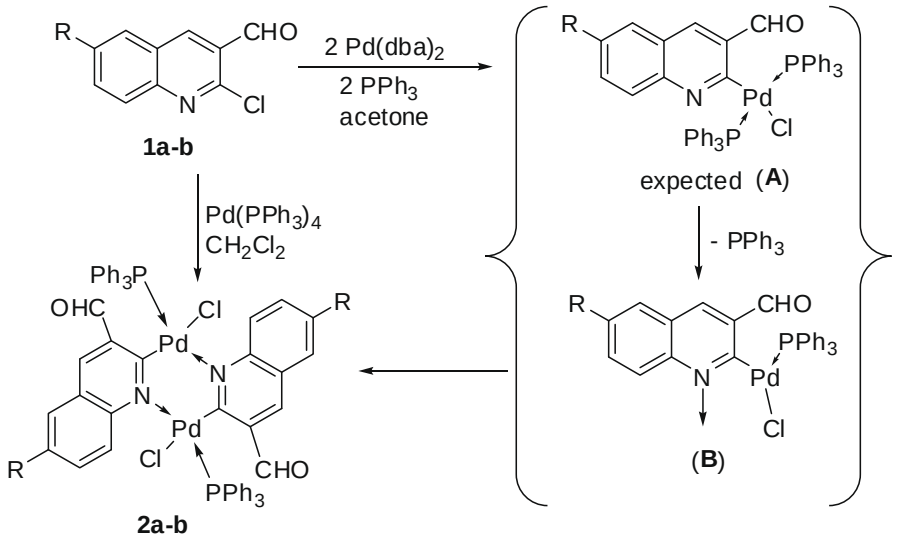

Scheme 1.

corresponded to the dimeric palladium complexes **2a–b**, as outlined in Scheme 2. This is probably due to the result of the interchange between the nitrogen donor of the quinoline ring and the PPh_3 ligand of palladium, which is a very well-known process [55]. One might believe that complexes (**A**) and (**B**) are intermediates for the formation of complexes **2a–b** and also suggest that the presence of PPh_3 as a ligand could be responsible for the interchange of the ligands and existence of complex **2a** or **2b** in solution as a mixture of complexes derived from two *trans* forms. The formation of the dimeric complexes **2a–b** are consistent with the related dimeric palladium complex $[Pd(\mu\text{-pyridine})Cl(PPh_3)]_2$, formed by the oxidative addition of 2-chloropyridine to the complex $Pd(PPh_3)_4$ [56].

These complexes were confirmed by the appearance of one singlet signal in their ^{31}P NMR spectra. The reaction products were identified by comparison of the ^{31}P NMR spectra of the reaction mixture with those of related reported complexes which showed two AB resonance patterns. The ^{31}P NMR spectra recorded in case of R = H (**2a**) and R = OMe (**2b**) showed resonances at δ 20.67 and 21.37 ppm.

The ^{1}H NMR spectra did not show the presence of any impurities for either of the complexes **2a** or **2b**, although the quinoline backbone shows slight variations when complexes **2a** or **2b** are compared. However, we feel that not enough was known about palladium–carbon bonds of these complexes, through four bonds. This promoted us to place emphasis on these data. While this

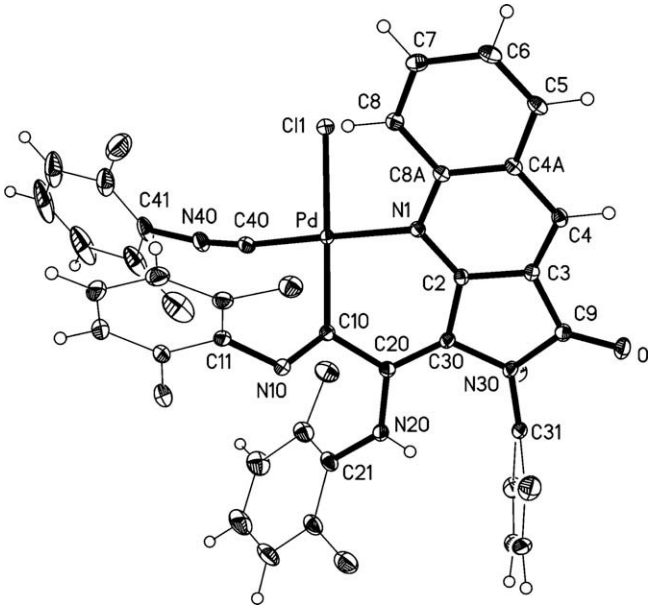

Fig. 2. Thermal ellipsoid plot (50% probability level and solvent omitted) of **3a**. The hydrogen atom attached to N(20) has been displayed for clarity. Selected bond lengths (Å) and angles (°): Pd–C(40) = 1.9425(18), Pd–C(10) = 1.9999(17), Pd–N(1) = 2.0864(14), Pd–Cl(1) = 2.4398(4), N(1)–C(2) = 1.325(2), N(1)–C(8A) = 1.388(2), N(10)–C(10) = 1.270(2), N(10)–C(11) = 1.420(2), N(20)–C(20) = 1.372(2), N(20)–C(21) = 1.418(2), N(30)–C(9) = 1.389(2), N(30)–C(30) = 1.429(2), N(30)–C(31) = 1.434(2), N(40)–C(40) = 1.151(2), N(40)–C(41) = 1.409(2), C(2)–C(30) = 1.452(2), C(3)–C(9) = 1.479(2), C(9)–O = 1.221(2), C(10)–C(20) = 1.505(2), C(20)–C(30) = 1.366(2), C(40)–Pd–C(10) = 91.93(7), C(40)–Pd–N(1) = 178.97(6), C(40)–Pd–Cl(1) = 84.21(5), C(10)–Pd–N(1) = 87.11(6), C(10)–Pd–Cl(1) = 173.33(5), N(1)–Pd–Cl(1) = 96.78(4), C(2)–N(1)–C(8A) = 116.44(14), C(2)–N(1)–Pd = 116.23(11), C(8A)–N(1)–Pd = 126.75(11), C(10)–N(10)–C(11) = 123.11(15), C(20)–N(20)–C(21) = 129.41(17), C(9)–N(30)–C(30) = 112.76(14), C(9)–N(30)–C(31) = 122.82(15), C(30)–N(30)–C(31) = 124.29(14), C(40)–N(40)–C(41) = 171.2(2), N(1)–C(2)–C(3) = 123.94(15), N(1)–C(2)–C(30) = 127.31(15), C(3)–C(2)–C(30) = 108.75(15), C(2)–C(3)–C(9) = 108.26(14), O–C(9)–N(30) = 125.39(17), O–C(9)–C(3) = 129.47(16), N(30)–C(9)–C(3) = 105.12(14), N(10)–C(10)–C(20) = 116.45(15), N(10)–C(10)–Pd = 127.94(13), C(20)–C(10)–Pd = 115.61(11), C(30)–C(20)–N(20) = 122.27(16), C(30)–C(20)–C(10) = 118.02(15), N(20)–C(20)–C(10) = 118.83(15), C(20)–C(30)–N(30) = 127.76(15), C(20)–C(30)–C(2) = 126.11(16), N(30)–C(30)–C(2) = 104.88(13), N(40)–C(40)–Pd = 171.71(16).

observation can be rationalized for **2a–b**, we were surprised that the cyclopalladated product showed almost no change in view of the angular distortion involved in forming the six-membered palladacycles. The IR (Nujol, cm^{-1}) bands assignable to the ν(C=O), ν(C=N) and ν(C=C) modes in **2a–b** indicating the non-coordination of the carbonyl group in these complexes. In complex **2a**, the IR spectrum shows bands at 1688, 1612 and 1582 cm^{-1} and for **2b** these bands appear at slightly lower values at 1678, 1584 and 1546 cm^{-1} respectively. The complexes **2a–b** show in their IR spectra a strong band at ca. 1688 and 1678 cm^{-1} assignable to ν(C=O) of the formyl group. These frequencies are similar to that observed in the starting materials **1a–b**, indicating that there is no coordination of the formyl group to the metal atom.

2.1. Insertion of 2,6-dimethylphenyl isocyanide XyNC (Xy = 2,6-$Me_2C_6H_3$)

Oxidative addition of 2-chloro-6-R-3-quinolinecarboxaldehydes **1a–b** [R = H (**1a**), R = OMe (**1b**)] (1.5) to a mixture of $Pd(dba)_2$ and XyNC (Xy = 2,6-$Me_2C_6H_3$) in 1:4 ratios in acetone at room temperature yields the tri-inserted iminoacyl palladium complexes **3a–b** in low yields (39%, 33.5%). Instead of the required 4:1.5:1 molar ratios of reagents XyNC:**1a–b**:$Pd(dba)_2$ for the formation of **3a–b**, the stoichiometric amounts of this mixtures used were 3:1.5:1, 2:1.5:1, 2:1:1, 1:1.5:1, 1:1:1 (**3a**) and 3:1.5:1, 2:1.5:1, 2:1:1, 1:1.5:1, 1:1:1 (**3b**), unfortunately, it was not possible to isolate the inserted products in this regard.

A mechanistic proposal depicts the formation of the possible intermediates [Pd{C(=NXy)$_3$Ar}Cl(CNXy)] [**I**] which are quickly cyclized to give iminoacyl quinolinylpalladium **3a** and **3b**, and not the expected complex [**II**]. We believe that a nucleophilic attack of the nitrogen of the primarily inserted isocyanide at the formyl carbon could give the isoindole ring [**III–V**]. The intermediate [**IV**] could evolve to [**V**], bearing a carbon–carbon double bond, which could undergo an intermolecular proton migration from the OH group of the intermediate [**V**] to the nitrogen of the second inserted isocyanide. There is no precedent for this type of structure conformation with migration of the proton to the nitrogen atom of the second inserted isocyanide, it was supported by X-ray structures, displaying the nitrogen proton at N(20)–H (**3a**, Fig. 2) and N(5)–H (**3b**, Fig. 3). The favored attack of the quinolinyl nitrogen at the (Pd) metal center in intermediate [**VI**] could turn into iminoacyl quinolinylpalladium **3a** or **3b**. The reported [57–62] synthesis of a highly functionalized ketenimine from di-insertion of XyNC into an (*o*-formylaryl) palladium complex is consistent with the result described here. The formation of such a ketenimine is also the result of the attack of the nitrogen of the primarily inserted isocyanide at the formyl carbon. A mechanistic proposal consistent with literature data [63], is given in Scheme 3.

The reactivity of the dinuclear palladium complexes **2a–b** were examined toward the bulky isocyanide XyNC (Xy = 2,6-$Me_2C_6H_3$),

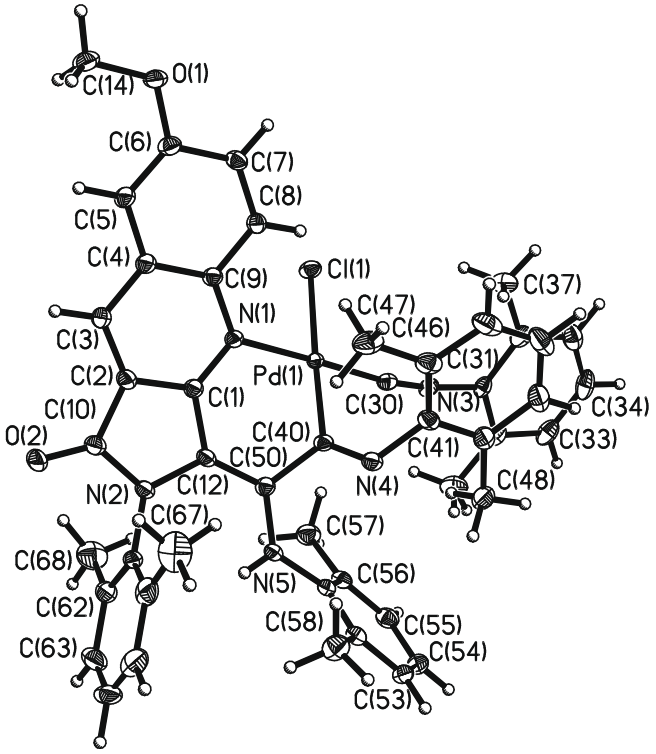

Fig. 3. Thermal ellipsoid plot (50% probability level and solvent omitted) of **3b**. The hydrogen atom attached to N(5) has been displayed for clarity. Selected bond lengths (Å) and angles (°): Pd(1)–C(30) = 1.944(2), Pd(1)–C(40) = 2.002(2), Pd(1)–N(1) = 2.0905(18), Pd(1)–Cl(1) = 2.4283(5), N(1)–C(1) = 1.332(3), N(1)–C(9) = 1.382(3), N(2)–C(10) = 1.383(3), N(2)–C(12) = 1.432(3), N(2)–C(61) = 1.438(3), N(3)–C(30) = 1.153(3), N(3)–C(31) = 1.404(3), N(4)–C(40) = 1.266(3), N(4)–C(41) = 1.429(3), N(5)–C(50) = 1.363(3), C(30)–Pd(1)–C(40) = 91.67(8), C(30)–Pd(1)–N(1) = 178.75(8), C(40)–Pd(1)–N(1) = 87.14(8), C(30)–Pd(1)–Cl(1) = 84.53(6), C(40)–Pd(1)–Cl(1) = 175.94(6), N(1)–Pd(1)–Cl(1) = 96.64(5), C(1)–N(1)–C(9) = 116.68(18), C(1)–N(1)–Pd(1) = 116.25(14), C(9)–N(1)–Pd(1) = 126.45(14), C(10)–N(2)–C(12) = 112.44(18), C(10)–N(2)–C(61) = 119.09(18), C(12)–N(2)–C(61) = 127.39(18), C(30)–N(3)–C(31) = 170.0(2), C(40)–N(4)–C(41) = 120.57(18), C(50)–N(5)–C(51) = 129.11(19), C(6)–O(1)–C(14) = 116.23(18), N(1)–C(1)–C(2) = 122.76(19), N(1)–C(1)–C(12) = 128.49(19).

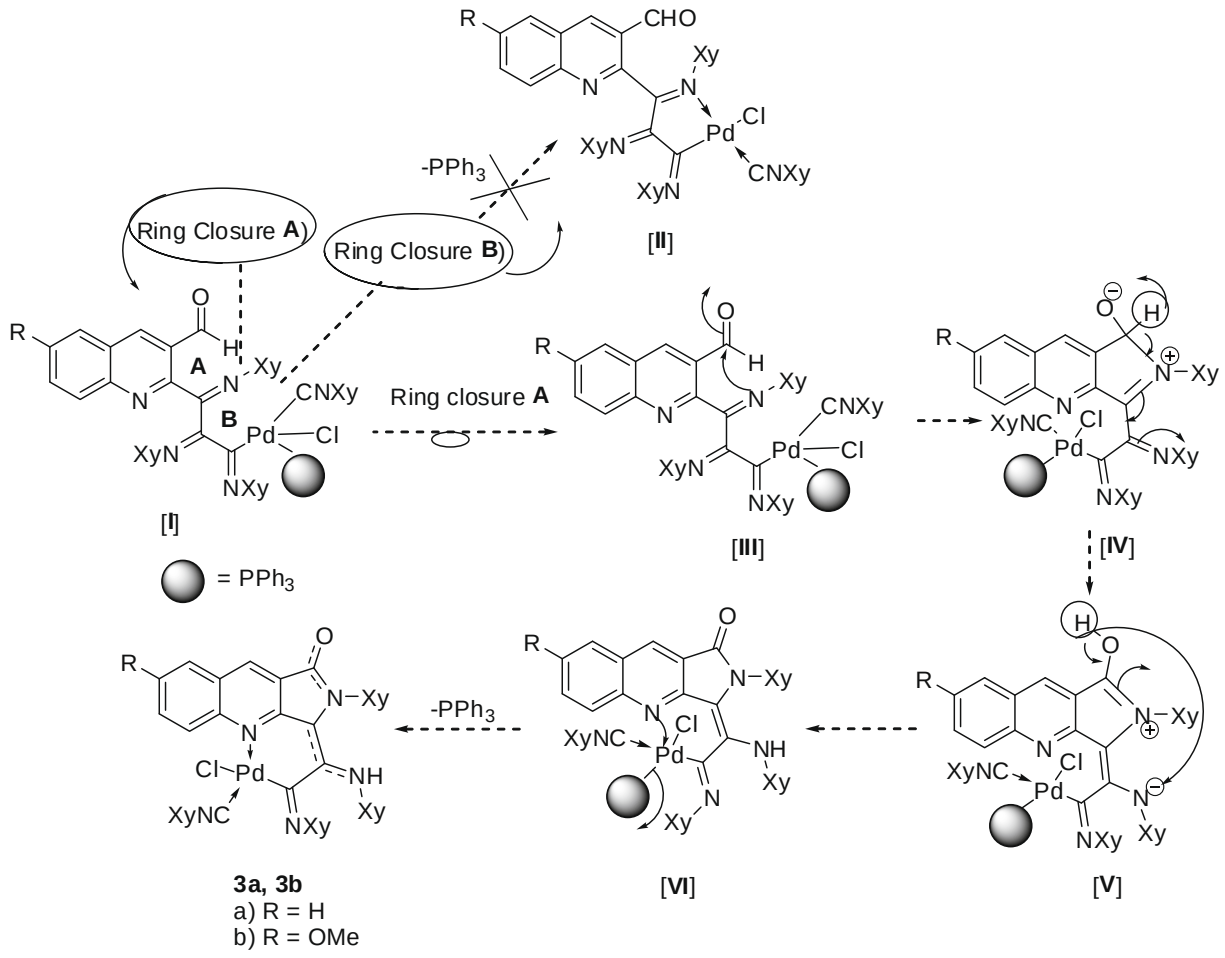
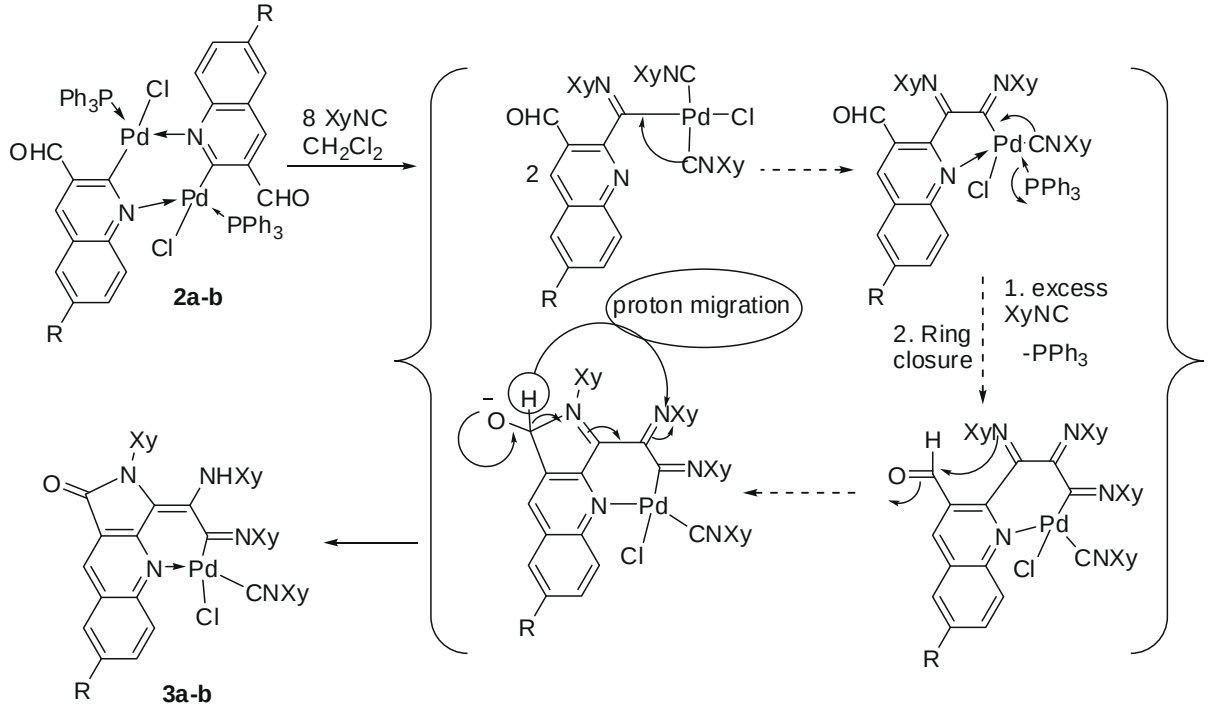


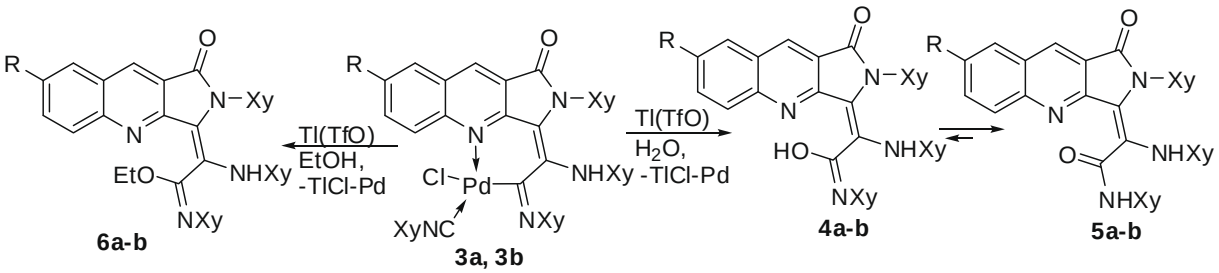
and it depends on nature of the ligands and on the reaction conditions. Thus when the insertion reaction takes place at different molar ratios of XyNC to complex, the inserted products obtained are the result of tri-insertion processes. The mono-insertion and di-insertion of XyNC at 1:1 or 1:2 molar ratios are not being isolated. The reaction of the dinuclear palladium complexes **2a–b** with 8 equiv. of XyNC at room temperature with a longer reaction time (16 h) provided the inserted products of iminoacyl quinolinylpalladium complexes **3a–b**. Instead of the required (8:1) equivalents of XyNC:**2a–b**, the stoichiometric amounts of 3:1, 4:1, 5:1, 6:1 and 7:1 were used, and it was not possible to isolate complexes **3a–b** in case of 3:1, 4:1 and 5:1 molar ratios.

The inserted products were formed from the insertion of 2,6-dimethylphenyl isocyanide (XyNC) into the C–Pd bond and the displacement of PPh_3 by the XyNC ligand. These kinds of complexes are very poorly represented in the iterature, the only example being those recently prepared by Vicente et al. [63] and suggested that the presence of PPh_3 during the insertion of XyNC into the dinuclear palladium complexes **2a–b** could be responsible for the change of reactivity of the intermediate complexes. It is possible that free PPh_3 coordinates in the intermediate complexes, forcing the insertion of the two isocyanide ligands. A mechanistic scheme depicting the formation of the various products, including possible intermediates, consistent with literature data [63] is given in Scheme 4.

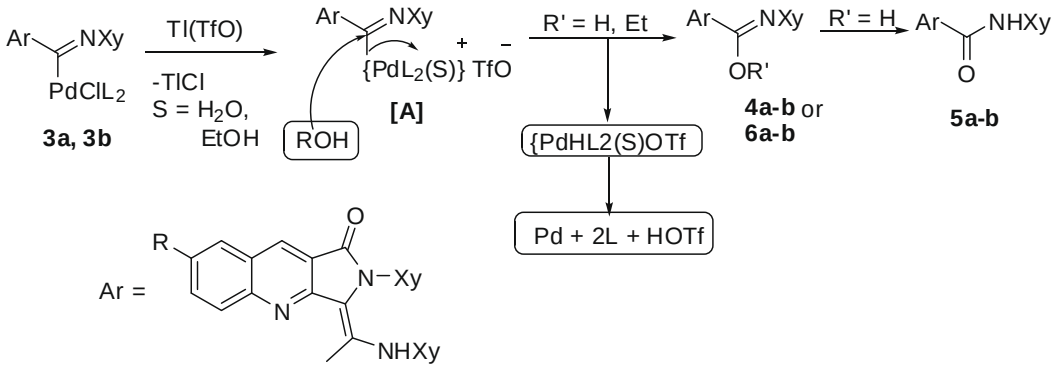


The products were analyzed by IR, ^1H NMR spectroscopy and single-crystal X-ray diffraction studies. IR (Nujol, cm^{-1}) bands were assignable to ν_{NH}, $\nu_{C\equiv N}$, $\nu_{C=O}$ and $\nu_{C=N,}$ for the iminoacyl quinolinylpalladium complexes **3a** and **3b** with no significances differences, indicating the cyclization of the carbonyl group within those complexes. In the case of **3a** the bands appear at ν(NH, broad band) 3338, ν(C≡N) 2361, ν(C=O) 1716 and ν(C=N) 1558 cm^{-1}, and in the case of **3b** the bands appear at ν(NH, broad band) 3360, ν(C≡N) 2182, ν(C=O) 1704 and ν(C=N) 1602 cm^{-1}. This suggests little change in the carbonyl stretching frequency of **3a** or **3b** due to complexation, and the electron releasing methoxyl group could confer special properties to the formyl group, for example, facilitating its coordination to the primarily inserted isocyanide (C=NXy) intermediate and nucleophilic attack of the nitrogen on the formyl carbon could give cyclometallated species of the important isoindolinone. The complexes **3a** and **3b** show a strong band in their IR spectra at 1716 and 1704 cm^{-1} assignable to ν(C=O). This frequency is not similar to that observed in the starting materials **1a–b** or **2a–b** and indicates the coordination of the carbonyl group to the isoindolinone ring. The ^1H NMR spectrum of complex **3a** in $CDCl_3$ was recorded and found to contain seven singlet resonances at different chemical shifts, each corresponding to methyl groups, appearing at δ 2.55 (s, Me, 3H), 2.49 (s, Me, 3H), 2.30 (s, Me, 3H), 2.19 (s, Me, 6H), 2.11 (s, Me, 3H), 1.58 (s, Me, 3H) and 0.62 (s, Me, 3H) ppm. There is one singlet signals integrated for 2 equiv. methyl groups of the coordinated isocyanide (CNXy) which appears at δ 2.19. The ^1H NMR spectrum of complex **3b** in $CDCl_3$ was recorded and found to contain six singlet resonances at different chemical shifts, each corresponding to methyl groups, appearing at δ 2.54 (s, Me, 3H), 2.49 (s, Me, 3H), 2.29 (s, Me, 3H), 2.18 (s, Me, 6H), 2.12 (s, Me, 6H) and 0.62 (s, Me, 3H) ppm. There are two singlet signals for the four methyl groups appearing at δ 2.18 (s, 6H, 2Me(Xy)) and 2.12 (s, 6H, 2Me(Xy)), one of which is for the inserted XyNC, indicating a *cis* geometry and no free rotation of the Xy groups. The other of the two singlet signals integrated to 2 equiv. methyl groups is from the coordinated isocyanide. This suggests steric hindrance that prevents the rotation of three xylyl groups, while the fourth one rotates freely.

2.2. Depalladation via reactions with Tl(TfO)



The reaction of complexes **3a–b** with Tl(TfO) was carried out in CH_2Cl_2 to give after 20 h at room temperature a precipitate of TlCl plus metallic palladium and a solution from which the highly functionalized **4a**–**b** and **5a–b** could be isolated (70% total yield, Scheme 5). These tautomers could not be separated by chromatography, but they displayed an exploitable difference in solubility. Thus, when a solution of both products in Et_2O was evaporated to dryness and Et_2O added again, the major tautomer did not redissolve and could be isolated by filtration, while the other tautomer could be similarly separated from the mother liquor. In the solid state **5a–b** and **4a–b** are stable and they do not interconvert. However, if **4a–b** are dissolved in CH_2Cl_2 and refluxed for 16 h, they transform completely into **5a–b**. The latter are stable at room temperature in $CDCl_3$ for several days, while under the same conditions **4a–b** transform partially into **5a–b**. The addition of an acid does not accelerate the interconversion of these products. Several reviews dealing with imidoyl compounds have discussed the question of whether imidic acids can exist in general [64]. They are unstable compounds that may be in equilibrium with the stable amide (**5a–d**) molecules. This is confirmed by theoretical investigations, which demonstrate that the amide form is about 11 kcal/mol more stable than the tautomeric imidic acid (**4a–d**) [65]. When the reaction of **3a–b** with Tl(TfO) was carried out in CH_2Cl_2 plus a drop of EtOH, **6a–b** were obtained and the yields varied from 18% to 40%, depending on the amount of added of EtOH.



Scheme 3.

Scheme 4.

Scheme 5.

Scheme 6.

Therefore, the depalladation of these inserted complexes represents a stoichiometric synthesis of functionalized arene, *N*-heterocyclic compounds from chloroarenes. As mentioned above, we fruitlessly attempted the synthesis of some of these organic compounds under catalytic conditions. However, catalytic applications of these stoichiometric reactions could still be an objective for future studies. We believe that all depalladation reactions reported here share three common steps, as outlined in Scheme 6

(i) The substitution of the chloro ligand in the iminoacyl quinolinylpalladium complexes **3a–b** by TfO to give the intermediates [**A**], which are formulated as cationic species, assuming that the very labile TfO is substituted by H_2O or EtOH.
(ii) The nucleophilic attack of the iminoacyl carbon (C=NXy)-Pd of intermediate [**A**] by EtOH alcoholysis or H_2O hydrolysis, the latter coming from atmospheric or solvent moisture.
(iii) The decomposition of the resulting adduct (probably through an intermediate) gives the hydrido palladium complex, metallic palladium, neutral ligand L, HOTf and Ar C(=NXy)OR′.

Although the very simple reaction pathways proposed in Scheme 6 allow systematization of the formation of such products, some questions remain unanswered because too many factors can influence the results. Finally, we do not attempt to explain the formation of the enol or ketone form and which of these is more stable, as we cannot account for the influence of the impurities present in the starting material. A mechanistic scheme depicting the formation of various products, including possible intermediates, is outlined in Scheme 6.

2.3. X-ray crystal structures

To further confirm the structures of the products, the molecular structures of yellow crystals of **2a** (Fig. 1), red crystals of **3a** · CH_2Cl_2 (Fig. 2) and reddish crystals of **3b** · CH_2Cl_2 · C_2H_6O (Fig. 3) were determined by X-ray analysis. The Pd–C bond distances of the iminoacyl ligands decrease, in agreement with the decreasing electron delocalization influence of the extended of electron donating group (OMe) located in position (6), as shown in complexes **3a–b** compared with **2a**, or may be decreased due to the *trans* influence of the ligands, thus these values are (in Å): Pd(1)–C(12) 2.0081(16), Pd(2)–C(2) 1.9919(17) (**2a**); Pd–C(40) = 1.9425(18), Pd–C(10) = 1.9999(17) (**3a**); Pd–C(30) = 1.944(2), Pd–C(40) = 2.002(2) (**3b**).

The Pd–Cl distances in (Å) are: Pd(1)–Cl(1) 2.3816(6), Pd(2)–Cl(2) 2.3812(5) **2a**; Pd–Cl 2.4398(4) **3a**, Pd–Cl 2.4283(5) **3b**. Similarly, the Pd–N bond distance in complexes **2a**, **3a** and **3b** were compared: Pd(1)–N(1) 2.0944(14), Pd(2)–N(2) 2.1115(14) **2a**; Pd–N(1) 2.0864(14) **3a** and 2.0905(18) **3b**. Those show the greater *trans* influence of the carbon-donor iminoacyl ligand with respect to the chloro ligand. Looking at these scales, our proposal that the *transphobia* could be directly related to the *trans* influence is reinforced [66] under this assumption; the two ligands with a great *trans* influence will suffer a great *transphobia* [67].

The structure of **2a** (Fig. 1) clearly shows the formation of a palladium atom in a square-planar environment due to the coordination environment consisting of *trans* phosphine, chloro ligands and nitrogen, carbon quinolinyl ligands. The mean deviation of atoms Pd(1), P(1), N(1), Cl(1), C(1) and Pd(2), P(2), N(2), Cl(2), C(2) from the best plane is [Pd(2)–C(2)–Pd(1)–C(12) = 0.0162 Å], [Pd(2)–P(2)–Pd(1)–P(1) = 0.7912 Å], [Pd(2)–Cl(2)–Pd(1)–Cl(1) = 0.004 Å] and [Pd(2)–N(11)–Pd(1)–N(1) = 0.0171 Å]. As expected, for the Pd–C bond distances, Pd(2)–C(2) (2.0081(16) Å) is significantly longer than Pd(1)–C(12) (1.9919(17) Å), the difference being 0.0162 Å. The Pd–N bond distance Pd(2)–N(11) (2.1115(14) Å) is significantly longer than that for Pd(1)–N(1) (2.0944(14) Å), and the difference here is 0.0171 Å, as a result of coordination of the nitrogen atom to Pd(II). However, the Pd–Cl bond distance Pd(2)–Cl(2) (2.3812(5) Å) is just a little bit longer than Pd(1)–Cl(1) (2.3816(6) Å), the difference being 0.004 Å. The Pd–P distance

Pd(2)–P(2) (3.0818(5) Å) is significantly longer than Pd(1)–P(1) (2.2906 Å) and the difference is 0.7912 Å. The reason for the deviation of the Pd(2) compared to Pd(1) in the bond distances for all the ligands around it is due to the greater steric hindrance of PPh_3 and also the trigonal pyramids for the phosphine atom. The angles around Pd(1) and Pd(2) have been compared: C(2)–Pd(2)–N(11) (84.88(6)°) is significantly larger than C(12)–Pd(1)–N(1) (82.22 (6)°) and the difference is 2.66°; C(2)–Pd(2)–P(2) (93.24(5)°) is slightly larger than C(12)–Pd(1)–P(1) (92.32(5)°) and the difference is 0.92°; N(11)–Pd(2)–P(2) (175.12(4)°) is slightly larger than N(1)–Pd(1)–P(1) (174.53(4)°) and the difference is 0.59°; C(2)–Pd(2)–Cl(2) (174.14(5)°) is slightly larger than C(12)–Pd(1)–Cl(1) (173.90(5)°) and the difference is 0.24°; N(11)–Pd(2)–Cl(2) (90.20(4)°) is smaller than N(1)–Pd(1)–Cl(1) (92.30(4)°) by 2.10°; P(2)–Pd(2)–Cl(2) (91.91(2)°) is smaller than P(1)–Pd(1)–Cl(1) (93.14(2)°) by 1.23°; C(2)–Pd(2)–Pd(1) (66.30(5)°) is slightly larger than C(12)–Pd(1)–Pd(2) (66.01(5)°) and the difference is 0.29°; N(11)–Pd(2)–Pd(1) (63.27(4)°) is very slightly larger than N(1)–Pd(1)–Pd(2) (63.12(4)°) and the difference is 0.15°; P(2)–Pd(2)–Pd(1) (111.854(17)°) is smaller than P(1)–Pd(1)–Pd(2) (114.865(14)°) by 3.015°; Cl(2)–Pd(2)–Pd(1) (114.188(16)°) is slightly larger than Cl(1)–Pd(1)–Pd(2) (113.865(19)°) and the difference is 0.323°. These results suggest a delocalization of π electron density around N(1) and P(1) as compared to N(2) and P(2) and distortion of the bond angles around the Pd(1) and Pd(2) due to the greater steric hindrance of PPh_3.

Fig. 2 clearly shows the structure of the red crystalline quinolinepalladium complex **3a**, with the Pd–C distances Pd–C(40) 1.9425(18) Å and Pd–C(10) 1.9999(17) Å. The Pd–Cl(1) distance is 2.4398(4) Å and the Pd–N(1) bond distance is 2.0864(14) Å; these show the greater *trans* influence of the C-donor iminoacyl ligand is with respect to the chloro ligand. The *transphobia* [*T*] is directly related to the *trans* influence of the two ligands and the complex suffers a great *transphobia* effect. The [Pd]C═NXy bond distance of the iminoacyl ligand in complex **3a** is N(10)–C(10) 1.270(2) Å; N(20)–C(20) 1.372(2) Å and N(30)–C(30) 1.429(2) Å are the C═N distances corresponding to the inserted molecule of XyN═C and N(40)–C(40) 1.151(2) Å is the C═N distance corresponding to the inserted molecule of CNXy. All these lengths are as expected for a C═N bond [mean values for the C(aryl)–C═NR distances lie in the range 1.432–1.382 Å] [68–70]. The aryl C═N(Xy)[Pd] distance corresponding to the third inserted molecule of XyNC in **3a** is significantly longer than the other related distances, N(10)–C(10) 1.270(2) Å and N(1)–C(2) 1.325(2) Å, as a result of coordination of the nitrogen atom to Pd(II). This fact, the angles around Pd (C(40)–Pd–C(10) 91.93(7)°, C(40)–Pd–N(1) 178.97(6)°, C(10)–Pd–N(1) 87.11(6)°, C(40)–Pd–Cl(1) 84.21(5)°, C(10)–Pd–Cl(1) 173.33(5)°, N(1)–Pd–Cl(1) 96.78(4)°) and the short C(20)–C(30) bond 1.366(2) Å compared with C(10)–C(20) 1.505(2) Å, suggest a delocalization of π electron density around C(20)–C(30)–N(30) (angle (127.76(15)°) as compared to N(30)–C(30)–C(2) (angle 104.88(13)°), N(20)–C(20)–C(30) (angle 122.27(16)°) and N(20)–C(20)–C(10) (angle 118.83(15)°). The coordination environment of the Pd(II) centre is almost square planar.

Red crystals of **3b**, also suitable for X-ray analysis, were obtained in a similar manner to its analogue **3a**, and the structure of **3b** (Fig. 3) is identical to **3a** except for the different substituents of the OMe group. The Pd–C distances of the iminoacyl quinolinylpalladium complex **3b** are Pd(1)–C(30) 1.944(2) Å and Pd(1)–C(40) 2.002(2) Å. The Pd–Cl distance (Pd(1)–Cl(1) 2.4283(5) Å) and the Pd–N bond distance, Pd(1)–N(1), is 2.0905(18) Å; these again show the greater *trans* influence of the C-donor iminoacyl ligand is with respect to the chloro ligand. Looking at these scales, our proposal that the *transphobia [T]* could be directly related to the *trans* influence is reinforced under this assumption; the two ligands with a great *trans* influence will suffer a great *transphobia [T]* [67]. The [Pd]C═NXy bond distance of the iminoacyl ligand in complex **3b** is N(4)–C(40) 1.266(3) Å; N(5)–C(50) 1.363(3) Å and N(2)–C(12) 1.432(3) Å are the C═N distances corresponding to the inserted molecule of XyN═C and N(3)–C(30) 1.153(3) Å is the C═N distance corresponding to the inserted molecule of CNXy. All these lengths are as expected for a C═N bond [mean values for the C(aryl)–C═NR distances lie in the range 1.432–1.382 Å] [68–70]. The aryl C═N(Xy)[Pd] distance corresponding to the third inserted molecule of XyNC in **3b** is significantly longer than the other related distance, N(4)–C(40) 1.266(3) Å, as a result of coordination of the nitrogen atom to Pd(II). This fact, the angles around Pd (C(30)–Pd(1)–C(40) 91.67(8)°, C(30)–Pd(1)–N(1) 178.75(8)°, C(40)–Pd(1)–N(1) 87.14(8)°, C(30)–Pd(1)–Cl(1) 84.53(6)°, C(40)–Pd(1)–Cl(1) 175.94(6)°, N(1)–Pd(1)–Cl(1) 96.64(5)°) and the short C(12)–C(50) bond 1.365(3) Å compared to C(40)–C(50) 1.507(3) Å, suggest a delocalization of π electron density around the C(50)–C(12)–N(2) (angle 127.34(19)°) as compared to N(2)–C(12)–C(1) (angle 105.08(18)°), N(5)–C(50)–C(12) (angle 123.2(12)°) and N(5)–C(50)–C(40) (angle 119.57(19)°). The coordination environment of the Pd(II) centre is almost square planar.

3. Experimental

Reactions were carried out without precautions to exclude light, atmospheric, oxygen and moisture, unless otherwise stated. Melting points were determined on a Reicher apparatus and are uncorrected. Elemental analyses were carried out with a Carlo Erba 1106 microanalyzer. IR spectra were recorded on a Perkin–Elmer 16F P CFT-IR spectrometer with Nujol mulls between polyethylene sheets or KBr pellets. NMR spectra were recorded in a Bruker AC 200, Avance 300 or a Varian Unity 300 spectrometer at room temperature unless otherwise stated. Chemical shifts were referenced to TMS (^1H and ^{13}C) and H_3PO_4 (^{31}P). The NMR probe temperature was calibrated using ethylene glycol ^1H NMR standard methods. Chromatographic separations were carried out by TLC on silica gel (70–230 mesh). Some of the preparations required the use of highly hazardous Tl(I) salts and they should be handle with caution.

3.1. General method for the synthesis of aryl palladium complexes (*2a–b*)

A mixture of [Pd(dba)$_2$] (432 mg, 0.75 mmol), PPh_3 (393.45 mg, 1.5 mmol) and 2-chloro-6-R-3-quinolinecarboxaldehyde **1a–b** (0.75 mmol) was mixed under N_2 in dry acetone (25 ml). The reaction mixture was stirred for 3–5 h at room temperature, then was concentrated (ca. 2 ml) and CH_2Cl_2 (25 ml) was added. The solution was passed through a pad of silica gel/$MgSO_4$ (3:1) in a fritted funnel, and then evaporated under reduced pressure, and Et_2O (15 ml) was added. The resulting solution was concentrated (ca. 2 ml); a mixture of the complex and dba was precipitated with *n*-hexane. The suspension was stirred for 10 min at RT, filtered off, washed with Et_2O (5 ml), and air-dried to give the yellow solid of **2a–b**.

3.1.1. {Pd[C_9H_5-CHO-(3)]Cl(PPh_3)}$_2$ (*2a*)

Purification via flash column chromatography silica gel (1:1 CH_2Cl_2/acetone) afforded a yellow solid **2a**, Yield: 398 mg, 43%. M.p.: 177–179 °C dec. A diffraction-quality crystal was grown by slow diffusion of Et_2O into a CH_2Cl_2 solution. IR (Nujol, cm^{-1}); *ν*(HC═O) 1688.4, *ν*(C═N and C═C) 1612.0, 1582.0, 1572.0 and 1538.0. ^1H NMR (400 MHz, $CDCl_3$); *δ* 10.39 (s, 2H, CHO), 7.34–7.90 (m, 17H, Ar–H), 7.25–6.91 [(m, 23H, Ar–H and (PPh_3)$_2$], 5.28 [(s, 1H, 1/2 (CH_2Cl_2)] ppm. ^{31}P {^1H} NMR (121 MHz, $CDCl_3$); 20.67 ppm. *Anal.* Calc. for $C_{56}H_{42}N_2O_2Cl_2Pd_2P_2$ (1120.62): C, 60.02; H, 3.78; N, 2.50. Found; C, 60.01; H, 3.75; N, 2.35%.

*3.1.2. [Pd[-6-OCH_3-C_9H_4-CHO-(3)]Cl(PPh_3)}$_2$ (**2b**)*

Purification via flash column chromatography silica gel (1:1 CH_2Cl_2/acetone) afforded a yellow-solid **2b**, Yield: 277 mg, 31.2%. M.p.: 180–182 °C dec. A diffraction-quality crystal was grown by slow diffusion of Et_2O into a CH_2Cl_2 solution of **2b**. IR (Nujol, cm^{-1}); ν(HC=O) 1678.0, ν(C=N and C=C) 1584.0, 1546.0. ^1H NMR (400 MHz, $CDCl_3$); δ 10.43 (s, 2H, CHO), 7.79–7.46 (m, 15H, Ar–H), 7.41–7.05 [(m, 22H, Ar–H and $(PPh_3)_2$], 6.60 (d, 1H, J = 2.6Hz), 3.84 (s, 6H, OMe) ppm. ^{31}P {^1H} NMR (121 MHz, $CDCl_3$); 21.37 ppm. *Anal.* Calc. for $C_{58}H_{46}N_2O_4Cl_2Pd_2P_2$ (1180): C, 59.00; H, 3.93; N, 2.37. Found; C, 59.08; H, 4.04; N, 2.32%.

*3.2. 4-(2,6-Dimethyl-phenyl)-3-(2,6-dimethyl-phenylamino)-2-(2,6-dimethyl-phenylimino)-1-[(2,6-dimethyl-phenylisonitrile)]-2,4-dihydro-1H-4,10b-diaza-acephenanthrylene-5-one-1-palladium(II)chloride complex (**3a**)*

3.2.1. Method (A)

To a suspension of 'Pd(dba)$_2$' (300 mg, 0.52 mmol) and XyNC (274 mg, 2.09 mmol) in acetone (15 ml), 2-chloro-3-quinoline carboxaldehyde **1a** (149.4 mg, 0.78 mmol) was added under nitrogen. The suspension was stirred for 5 h at room temperature, then the solvent was evaporated. The resulting residue was extracted with CH_2Cl_2 (25 ml) and the extract filtrate was filtered over anhydrous $MgSO_4$/silica gel (1:3) in a fritted funnel. The resulting red solution was evaporated and the residue was triturated with Et_2O (15 ml). The precipitate was filtered, washed with Et_2O (2 × 5 ml), and air-dried, giving the red compound **3a**, yield, 254 mg, 39%. Diffraction-quality crystals were grown by slow diffusion of Et_2O into a CH_2Cl_2 solution of **3a**. M.p.: Dec. pt: 255 °C. IR (Nujol, cm^{-1}):): ν(NH, broad band) 3353, ν(C=O) 1716, 1699, ν(C≡N) 2361, 2338, ν(C=N) 1558, 1541. ^1H NMR (200 MHz, $CDCl_3$) δ 8.87 (s, 1H, NH), 8.83–8.78 (d, 1H, *J* = 8.6 Hz), 7.99–7.87 (q, 2H, *J* = 8.6 Hz), 7.63–7.55 (t, 1H, *J* = 7.6 Hz), 7.35–7.22 (m, 3H), 7.19–6.97 (m, 5H), 6.91–6.73 (m, 4H), 6.40–6.37 (d, 1H, *J* = 7.2 Hz), 2.55 (s, Me, 3H), 2.49 (s, Me, 3H), 2.30 (s, Me, 3H), 2.19 (s, Me, 6H), 2.11 (s, Me, 3H), 1.58 (s, Me, 3H) 0.62 (s, Me, 3H) ppm. *Anal.* Calc. for $C_{46}H_{42}N_5OClPd$ (822): C, 67.15; H, 5.15; N, 8.50. Found: C, 67.04; H, 5.09; N, 8.14%.

3.2.2. Method (B)

To a suspension of {Pd[C_9H_5-CHO (3)]Cl(PPh_3)}$_2$ **2a** (268 mg, 0.24 mmol) in CH_2Cl_2 (15 ml), XyNC (248 mg, 1.92 mmol) was added. The suspension was stirred for 24 h at room temperature. The color changed from pale yellow into pale red and then dark red whilst the reaction mixture was monitored. The solvents were filtered over a pad of anhydrous $MgSO_4$/silica gel (1:3) in a fritted funnel. The resulting red solution was evaporated and the residue was triturated with Et_2O (15 ml). The precipitate was filtered, washed with Et_2O (2 × 5 ml), and air-dried, giving the red compound **3a**. Yield: 160 mg, 81%. Diffraction-quality crystals were grown by slow diffusion of Et_2O into a CH_2Cl_2 solution of **3a**.

*3.3. 4-(2,6-Dimethyl-phenyl)-3-(2,6-dimethyl-phenylamino)-2-(2,6-dimethyl-phenylimino)-1-[(2,6-dimethyl-phenylisonitrile)]-8-methoxy-2,4-dihydro-1H-4,10b-diaza-acephenanthrylene-5-one-1-palladium(II) chloride complex (**3b**)*

3.3.1. Method (A)

2-Chloro-6-methoxy-3-quinoline carboxaldehyde **1b** (172.86 mg, 0.78 mmol) was added to a suspension of 'Pd(dba)$_2$' (300 mg, 0.52 mmol) and XyNC (274 mg, 2.09 mmol) in acetone (15 ml) under nitrogen. The suspension was stirred for 5 h at room temperature. The solvents were evaporated, the residue was extracted with CH_2Cl_2, and the extract filtrate was filtered over a pad of anhydrous $MgSO_4$/silica gel (1:3) in a fritted funnel. The resulting red solution was evaporated and the residue was triturated with Et_2O (15 ml). The precipitate was filtered, washed with Et_2O (2 × 5 ml), and air-dried, giving the red solid compound **3b**.Yield: 223 mg, 33.5%. Diffraction-quality crystals were grown by slow diffusion of Et_2O into a CH_2Cl_2 solution of **3b**. M.p.: 238–240 °C. IR (Nujol, cm^{-1}): ν(NH, broad band) 3360, ν(C≡N) 2182.7, ν(C=O) 1704.5, ν(C=N) 1602.4, 1570.1. ^1H NMR (200 MHz, $CDCl_3$) δ 8.75 (s, 1H, NH), 8.71 (d, 1H, $^3J_{HH}$ = 8.6 Hz), 7.67–7.57 (dd, 1H, $^4J_{HH}$ = 2.6, $^3J_{HH}$ = 9.6 Hz, quinoline-H_8), 7.27–7.18 (m, 5H), 7.14–7.11 (s, 1H), 7.07–6.96 (m, 3H), 6.89–6.80 (m, 4H), 6.40–6.36 (d, 1H, $^3J_{HH}$ = 7.6 Hz, quinoline-H), 3.96 (s, 3H, OMe), 2.54 (s, Me, 3H), 2.49 (s, Me, 3H), 2.29 (s, Me, 3H), 2.18 (s, Me, 6H), 2.12 (s, Me, 6H), 0.62 (s, Me, 3H) ppm. *Anal.* Calc. for $C_{47}H_{44}N_5O_2ClPd$ (852) + H_2O = (870.79): C, 64.83: H, 5.32: N, 8.04. Found: C, 64.91: H, 5.12: N, 8.04%.

3.3.2. Method (B)

To a suspension of {Pd[6-OCH_3-C_9H_5-CHO (3)]Cl(PPh_3)}$_2$ (**2b**) (283 mg, 0.24 mmol) in CH_2Cl_2 (15 ml), XyNC (248 mg, 1.92 mmol) was added. The suspension was stirred for 24 h at room temperature and the color changed from pale yellow into pale red and then dark red whilst the reaction mixture was monitored. The solvents were filtered over a pad of anhydrous $MgSO_4$/silica gel (1:3) in a fritted funnel. The resulting red solution was evaporated and the residue was triturated with Et_2O (15 ml). The precipitate was filtered, washed with Et_2O (2 × 5 ml), and air-dried, giving the red compound **3b**. Yield, 158 mg, 77%. Diffraction-quality crystals were grown by slow diffusion of Et_2O into a CH_2Cl_2 solution of **3b**.

4. Depalladation procedure

*4.1. General procedure for the acetamidic acids (**4a**–**b**) and acetamide (**5a**–**b**)*

Tl(TfO) (314 mg, 0.89 mmol) was added to a suspension of **3a–b** (0.89 mmol) in Me_2CO (20 ml). The resulting red suspension was stirred for 20 h. During this time decomposition to metallic palladium was observed and a dark brownish suspension formed. This was filtered over Celite, and the filtrate was concentrated and applied to a preparative TLC plate (eluant: *n*-hexane/Et_2O, 1:2). A yellow band at R_f = 0.25 was collected and extracted with Me_2CO (30 ml). The resulting solution was dried with anhydrous $MgSO_4$ for 1 h and filtered, and the filtrate was evaporated to dryness, giving a 2:3 mixture of both tautomers **5a–b** and **4a–b**. A sample of this mixture (200 mg) was dissolved in Et_2O (30 ml), the solution was evaporated to dryness, and the residue was treated with Et_2O (30 ml), causing the precipitation of a solid, which was filtered and air-dried to give yellow **4a–b** (41%). The same process was repeated with the mother liquor, giving **5a–b** (27%).

*4.2. N-(2,6-Dimethylphenyl)-2-(2,6-dimethylphenylamino)-2-[2-(2,6-dimethylphenyl)-1-oxo-1,2-dihydro-pyrrolo[3,4-b]quinolin-3-ylidene]-acetimidic acid (**4a**)*

M.p.: 206–208 °C. 4.6. General Procedure of the ethyl esterification of acetamidic acids (**6a**–**b**)

Tl(TfO) (374 mg, 1.06 mmol) and EtOH (one drop) were added to a solution of **3a–b** (1.06 mmol) in CH_2Cl_2 (20 ml). The resulting black suspension was stirred for 20 h and filtered over Celite, and the yellow filtrate was concentrated and applied to a preparative TLC plate (eluant: *n*-hexane/Et_2O, 1:2), where two main yellow bands separated. From the band at R_f = 0.25 a 2:1 mixture of **5a–b** and **4a–b** was obtained in moderate yield. The band at R_f = 0.62 was collected and extracted with Me_2CO (30 ml). The extract was treated with anhydrous $MgSO_4$ for 1 h, filtered and evaporated to dryness, affording the yellow ester **6a–b** in low yields (18–19%).

4.7. N-(2,6-Dimethylphenyl)-2-(2,6-dimethylphenylamino)-2-[2-(2,6-dimethylphenyl)-1-oxo-1,2-dihydro-pyrrolo[3,4-b]quinolin-3-ylidene]acetimidic acid ethyl ester (**6a**)

A suspension solution of **3a** (871.32 mg, 1.06 mmol) in CH_2Cl_2 (20 ml) was used under the reaction conditions to produce **6a** in the yield 122 mg, 19%. M.p.: 210–212 °C. IR (cm^{-1}): ν(NH) 3384, ν(C=O), ν(C=N) 1698, 1694, 1660. ^{1}H NMR (200 MHz, $CDCl_3$) δ 8.86 (d, 1H, quinol-H_4), 8.34 (dd, 1H, $^4J_{HH}$ = 1.6, $^3J_{HH}$ = 8.4 Hz, quinol-H_8), 7.87 (d, 1H, $^3J_{HH}$ = 8.4 Hz, quinol-H_5), 7.73 (dd, 1H, $^3J_{HH}$ = 8.4 and 6.8 Hz, quinol-H_7), 7.45 (dd, 1H, $^3J_{HH}$ = 8.4 and 6.8 Hz, quinol-H_6), 7.10–7.05 (m, 3H), 6.80–6.69 (m, 6H), 4.79 (s, NH, 1H), 4.39 (q, CH_2Me, 2H, $^2J_{HH}$ = 7 Hz), 2.22 (s, 2 × Me, 6H), 1.48 (bs, 4 × Me, 12H), 1.39 (t, CH_2Me, 3H, $^2J_{HH}$ = 7 Hz) ppm. *Anal.* Calc. for $C_{39}H_{38}N_4O_2$ (594.7): C, 78.76; H,6.44; N, 9.42. 4.8. N-(2,6-Dimethylphenyl)-2-(2,6-dimethylphenylamino)-2-[2-(2,6-dimethylphenyl)-7-methoxy-1-oxo-1,2-dihydro-pyrrolo[3,4-b]quinolin-3-ylidene]acetimidic acid ethyl ester (**6b**)

A suspension solution of **3b** (903.12 mg, 1.06 mmol) in CH_2Cl_2 (20 ml) was used under the reaction conditions to produce **6b** in the yield 120 mg, 18%. M.p.: 206–208 °C. IR (cm^{-1}): ν(NH) 3384, ν(C=O), ν(C=N) 1698, 1694, 1660. ^{1}H NMR (300 MHz, $CDCl_3$) δ 8.86 (d, 1H, quinol-H_4), 8.34 (dd, 1H, $^4J_{HH}$ = 1.6, $^3J_{HH}$ = 8.4 Hz, quinol-H_8), 7.87 (d, 1H, $^3J_{HH}$ = 8.4 Hz, quinol-H_5), 7.73 (dd, 1H, $^3J_{HH}$ = 8.4 and 6.8 Hz, quinol-H_7), 7.45 (dd, 1H, $^3J_{HH}$ = 8.4 and 6.8 Hz, quinol-H_6), 7.10–7.05 (m, 3H), 6.80–6.69 (m, 6H), 4.79 (s, NH, 1H), 4.39 (q, CH_2, 2H, $^2J_{HH}$ = 7 Hz), 2.22 (s, 2 × Me, 6H), 1.48 (bs, 4 × Me, 12H), 1.39 (t, CH_2Me, 3H, $^2J_{HH}$ = 7 Hz) ppm. *Anal.* Calc. for $C_{40}H_{40}N_4O_3$ (624.8): C, 76.90; H, 6.45; N, 8.97. Found: C, 76.83; H, 6.42; N, 9.02%.

4.9. X-ray crystallographic studies

Details of data collection and refinement are given in Table 1. The crystal structures from the single-crystal X-ray diffraction studies for **2a**, **3a** and **3b** were carried out on a Bruker SMART 1000 CCD diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). Cell parameters were obtained by global refinement of the positions of all collected reflections. Intensities were corrected for Lorentz and polarization effects and empirical

absorption. The structures were solved by direct methods and refined by full-matrix least-squares on F^2. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms placed in calculated positions. Structure solution and refinement were performed by using the SHELXL-97 package. [71] Crystal data and processing parameters for **2a**, **3a** and **3b** are summarized in Table 1.

5. Conclusion

We successfully developed a new type of iminoacyl quinolinyl palladium complexes and palladacycles that allows the preparation of new carbocycles via a depalladation reaction. Overall, this methodology provides an alternative approach to novel quinolinylpalladium complexes and amide **5a–b** or imidic acid **4a–b** from three simple and readily available building blocks via a one-pot, multi-component process. These novel arylpalladium complexes are air- and moisture stable, and further scope of this class of arylpalladium complexes and applications are currently under investigation in our laboratory.

Acknowledgments

This work has been supported by the Ministry of Education and Science Spain and FEDER (EU) during the sabbatical leave of the author as a visiting professor. The author wishes to thank Professor Peter G. Jones' Institut für Anorganische und Analytische Chemie der Technischen Universität, Postfach 3329, 38023 Braunschweig, Germany for the measurement of the single crystal by X-ray analysis.

Appendix A. Supplementary data

CCDC 680962, 680963, 680964 contain the supplementary crystallographic data for **2a**, **3a**, **3b**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. ^{1}H and ^{31}P NMR spectra for compounds **2a**, **3a** and **3b**. Atomic coordinates, bond lengths, bond angles and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre (CCDC). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.10.054.

Templating

ABSTRACT

Metal complexes of 2-quinoxalinol salen (salqu) ligands can be prepared in a one-pot metal templated synthesis resulting in significantly enhanced yields than if the ligand were prepared and isolated prior to introducing the metal for complexation. Using this method, 12 salqu metal complexes have been prepared and characterized from +2 metal ions.

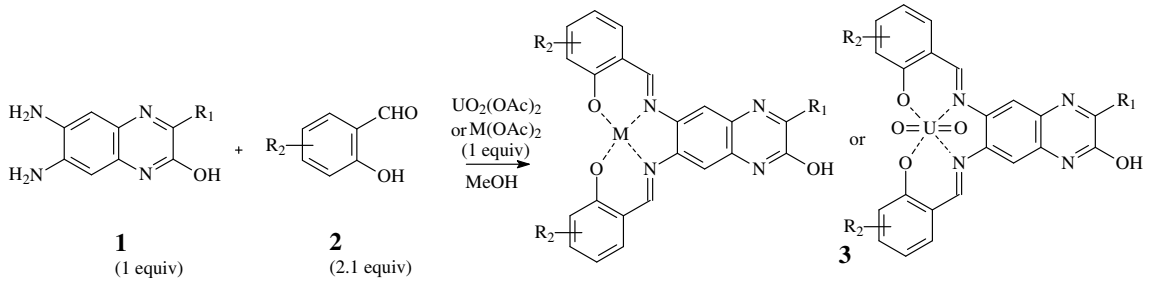
One-pot multicomponent syntheses have received increasing attention of late, because they not only address fundamental principles of synthetic efficiency and reaction design [1–3], but they also expand the possibilities for extending one-pot reactions into combinatorial and solid-phase methods [3,4]. This presents a new way of thinking about "greener" chemistry by allowing for the reduction of synthetic steps, purification solvents, and wastes. A one-pot metal templated strategy for the preparation of metal complexes for use in applications offers the distinct advantages of reduced environmental impacts and easier procedures for workup.

Salen or salph complexes have been used widely in applications for everything from catalysts to molecular recognition. For example, salen Cu, Mn, or Ru complexes have been used as catalysts in the catalytic oxidation of secondary amines [5], as the basis for enantioselective catalysts [6], and as catalysts for ring-opening metathesis [7]. Uranyl (UO_2^{2+}) salophen complexes have been used in molecular recognition studies [8–10]. In addition, salen Mn complexes can act as catalytic scavengers of hydrogen peroxide and have been demonstrated to have a degree of cytoprotectivity [11].



Symmetric and unsymmetric 2-quinoxolinol salen ligands (abbreviated *salqu, e.g.* 3) have been synthesized for use in catalysis using solution phase and combinatorial strategies [12,13]. A disadvantage of this reaction scheme was an extended reaction time required to obtain the optimal yields. Metal complexes of this series of ligands were then prepared by a standard proton transfer procedure [14]. Because applications in solid-phase extraction and catalysts of salqu metal complexes have been developed [15,16], it was thought that it would to be advantageous to find a more efficient, economical method to prepare salqu metal complexes. Here, a one-pot synthetic method based on a metal template synthesis to access salqu metal complexes will be introduced. With this method, 12 salqu metal complexes have been synthesized from diamino-2-quinoxalinol (**1**, Scheme 1) in significantly higher yields in a shorter time than when the ligand is isolated and purified prior to complexation.

Previously, to prepare the salqu metal complexes, two steps were required. The first being the preparation of salqu ligands followed by preparation of the salqu metal complex. In the synthesis of symmetric salqu ligands, the final optimized conditions required that the diamino-2-quinoxalinol intermediate **1** be reacted with 10 equiv. of the desired salicylaldhyde derivatives (**2**) at reflux temperature in methanol for 48 h [12]. The ligand must then be isolated prior to the addition of the metal to prepare the metal complex, resulting in yields around 60.0%. Metal complexes are then prepared from a reaction of the salqu ligand (**3**) with 1.2 equiv. of the desired metal acetate at reflux temperature in either DMF or DCM with MeOH reacted for 2–12 h [14]. The final yields for this step are around 85.0%, resulting in an overall yield for both reactions close to 50%.

Using a metal templating strategy for a one-pot synthetic method, the diamino-2-quinoxalinol intermediate **1** is reacted with 2.1 equiv. of the salicylaldhyde derivative (**2**) and 1.1 equiv. of metal acetate is added directly to the reaction mixture. This also does not require a mixed solvent system, only methanol is used. The mixture was then heated to reflux temperature and allowed to react for 6 h. After the reaction was determined to be complete,

Scheme 1. Method for a one-pot synthesis of salqu metal complexes.

Table 1
Salqu metal complexes synthesized using a one-pot metal templated method.

	$[M]^{2+}$	R_1	R_2	Yield
3a	Cu^{2+}		3,5-di-*tert*-butyl	72.8
3b	Cu^{2+}		H	80.0
3c	Mn^{2+}		3,5-di-*tert*-butyl	76.5
3d	Co^{2+}		3,5-di-*tert*-butyl	69.4
3e	Ni^{2+}		3,5-di-*tert*-butyl	62.7
3f	UO_2^{2+}		3-OH	84.5
3g	UO_2^{2+}		3,5-di-*tert*-butyl	62.0
3h	UO_2^{2+}		H	61.2
3i	UO_2^{2+}		3,5-di-*tert*-butyl	65.3
3j	UO_2^{2+}		H	63.4
3k	UO_2^{2+}		H	67.0
3l	UO_2^{2+}		H	69.8

a large quantity of red or black solid was found to precipitate from solution. The precipitates were filtered and washed with ethanol five times. The solids were dried to obtain salqu metal complexes with purity greater than 95% (purity was identified by NMR and TLC.) Yields were found to range from 60% to 85%. The results are listed in Table 1.

The IR spectral results are indicative of metal complexation. Broad peaks in free ligands seen around 3400 cm^{-1} (3400–3448 cm^{-1}) are indicative of the presence of the hydroxyl groups on the free ligand. These broad signals are seen to be absent in the Cu, Mn, Co, Ni, and UO_2 metal complexes indicating the formation of the metal complex with these oxygens. Coordination through the phenolic hydroxyl unit in the salicylaldehyde coordination site can also be shown a shift in the C–O band for the metal complexes between 1199 and 1213 cm^{-1} as compared to the sharp peak in the free ligands (1263–1276 cm^{-1}) [18]. (**3j** is lower 1146 cm^{-1} although there is not a peak seen as in the range characteristic of the C–O stretch in the starting material.)

The spectra of the free ligands have peaks around 1654–1658 cm^{-1} for the carbon–nitrogen imine stretch. This is seen to shift to 1599–1620 cm^{-1} (**3f–3l**) for the uranyl complexes and is indicative of coordinated imine nitrogens [16,17]. This peak is seen at 1616–1614 cm^{-1} in the Ni^{2+} and Co^{2+} complexes, and in the Cu^{2+} complex (**3b**) but is not as well defined in the Mn^{2+}or in the Cu^{2+} (**3a**) in which the metal may not be strongly coordinating to the imines. Bands around 900 cm^{-1} (897–903 cm^{-1}) seen in the uranyl complexes (**3f–3l**) are due to the asymmetric and symmetric UO_2 stretching characteristic of linear uranyl ion in the complex [17].

In the ^1H NMR spectra of the uranyl (UO_2^{2+}) complexes, a significant shift in the imine CH=N proton is observed in the uranyl metal complexes (9.5–9.8 ppm for **3f–3l**) as compared to the free ligands (8.9–9.3 ppm). This is indicative of the imine nitrogen lone pairs coordinating to the metal center. In a similar fashion, there are three hydroxyl peaks in the ^1H NMR spectra of the free ligands (12.1–13.3 ppm) while in the uranyl (UO_2^{2+}) complexes, only one from the quinoxolinol hydroxyl group remains (12.6–12.7 ppm for **3f**, **3h**, and **3j–3l**, 12.2–12.3 ppm for **3g** and **3i**). (The slight difference seen in the data for **3g** is presumably due to the difference in solvation of the more subsituted and is comparable to **3i**.)

The advantages of the one-pot synthetic method for preparing salqu metal complexes are the shortened reaction time from more than 2 days to 6 h and improved final yields from less than 50.0% to over 60–85%. This also allows us to simplify the procedure and to conserve the amounts of the salicylaldhyde derivatives (2) used while avoiding the use of the more troublesome solvent DMF. This method could be a method for synthesis of these complexes using combinatorial methods because of the simple procedure and high yields.

In conclusion, a one-pot methodology based on a metal templating synthesis using +2 metal ions to more easily and rapidly prepare salqu metal complexes is an efficient method to prepare these metal complexes. With this method, several salqu metal complexes have been synthesized and identified. This will be a more convenient synthetic method in exploring the use of such metal complexes. In the future, a new salqu metal complex library will be prepared in this way.

General procedure and data

All amino acid methyl esters, DFDNB, HCl (37%) and aldehydes were purchased from Acros. Ammonium hydroxide (5.0 N), palladium on carbon (wet, 5%) were purchased from Aldrich. Starting materials were used as received. All organic solvents were purchased from Fisher Scientific and were used directly for synthesis. ^1H and ^{13}C NMR spectra were recorded on Bruker AC 250 spectrometer (operated at 250 and 62.5 MHz, respectively) or Bruker

AV 400 spectrometer (operated at 400 and 100 MHz, respectively). Chemical shifts are reported as δ values (ppm). The solvents used are indicted in the experimental details. Electrospray ionization mass spectrometry was performed on a Micromass QTOF mass spectrometer (Waters Corp, Milford MA). Direct probe samples were on a VG-70S mass spectrometer (Waters Corp, Milford MA). Reaction progress was monitored by thin-layer chromatography (TLC) using 0.25 mm Whatman Aluminum silica gel 60-F254 precoated plates with visualization by irradiation with a Mineralight UVGL-25 lamp. IR spectroscopic data were collected using a SHIM-SDZU Inc. IR, Prestige-21 Fourier Transform Infrared Spectrophotometer and KBr solid samples.

To a 5 ml methanol solution of intermediate **1** (0.05 mmol), 2.1 equiv. of the desired salicylaldehyde derivatives (e.g., **2** 0.105 mmol) and 1.1 equiv. of metal acetate (0.055 mmol) are added. The mixture was heated to reflux temperature with stirring and allowed to react for 6 h. At this time, a dark red or black solid precipitates out, indicating the completion of the reaction. The precipitates were filtered from the reaction solution. They were then washed with ethanol five times. Finally, the solids were dried under high vacuum.

ABSTRACT

The $\{UO_2(DPPMO_2)_2\}^{2+}$ dication (where $DPPMO_2$ = bis(diphenylphosphino)methane) contains the linear uranyl group, $\{UO_2\}^{2+}$, with two bidentate P=O donor ligands. Previously, we have shown that the weakly coordinating oxoanions $[ReO_4]^-$ and $[TcO_4]^-$ (as well as Cl^-) will fill a fifth equatorial coordination site yielding complexes of general formula $[UO_2(DPPMO_2)_2X][X]$ (where X = $[ReO_4]^-$, $[TcO_4]^-$ and Cl^-), with the X^- anion acting in both monodentate coordinated and uncoordinated modes. Seven coordinate pentagonal bipyramidal uranyl complexes with the same general formula have now also been prepared with both the bistriflimide, $((CF_3SO_2)_2N^-, NTf_2^-)$ and triflate ($CF_3SO_3^-$ OTf^-) anions and we report the structural characterisation of both $[UO_2(NTf_2)(DPPMO_2)_2][NTf_2]$ (**1**) and $[UO_2(OTf)(DPPMO_2)_2][OTf]$ (**2**). In the case of **1** the anion is coordinated through a terminal oxygen, representing the first structural characterization of an actinide-bistriflimide complex. Both the solid state uranium-anion bond lengths (for O-donor ligands only) and $^{31}P\{^1H\}$ NMR solution competition studies indicate that the strength of the uranyl-anion bond decreases along the series $Cl^- > [ReO_4]^- > [OTf]^- > [NTf_2]^-$. In addition, $^{31}P\{^1H\}$ NMR competition studies show that both nitrate and excess $DPPMO_2$ will readily displace the weakly coordinating X^- anions.

1. Introduction

Interest in uranium coordination chemistry has increased in recent years, with the discovery of novel reagents, reactivity and structural features. This increase in synthetic chemistry is linked with ever improving computational techniques and evolving nuclear fuel processing, waste management and environmental challenges [1]. One area of research that our laboratory have focussed on is the interaction of actinide cations with a range of 'weakly coordinating' anions [2]. In the case of pertechnetate, $[TcO_4]^-$, (and perrhenate, $[ReO_4]^-$) the chemistry has been directed towards improving our understanding of Tc behaviour in the PUREX process (Plutonium and Uranium Recovery by Extraction) [3]. In the case of bis(trifluoromethylsulfonyl)amide (bistriflimide, $(CF_3SO_2)_2N^-$, NTf_2^-) and trifluoromethanesulfonate (triflate, $CF_3SO_3^-$ OTf^-) our initial interest was related to the application of ionic liquids in the electrochemical separation of actinide cations [4].

For many years NTf_2^- was considered to just be a very weak or non-coordinating anion [5], which in turn has led to the extensive use of this anion in ionic liquid research (where NTf_2^- salts with organic cations tend to produce relatively low viscosity ionic liquids) [6]. However, in the absence of more strongly coordinating ligands complexes with *d*-transition metals have been synthesised with a range of bidentate and monodentate coordination modes observed, including η^1-O, η^1-N, η^2-O,O′ and η^2-O,N [7]. This chemistry has also recently been extended to the *f*-elements, although structurally characterised bistriflimide-*f*-element complexes are currently restricted to the lanthanides [8–11], with no reports of structurally characterised actinide bistriflimide complexes. In contrast, there have now been numerous studies into the coordination chemistry of uranium with the triflate anion, with both monodentate and bidentate coordination modes observed [12–17].

We have previously reported the synthesis of a series of isostructural uranyl complexes with the bidentate phosphine oxide ligand $DPPMO_2$ (where $DPPMO_2$ = bis(diphenylphosphino)methane) [18]. These complexes have the general formula $[UO_2(X)(DPPMO_2)_2][X]$, where X = $[TcO_4]^-$, $[ReO_4]^-$ or Cl^-. Perhaps of most interest was the spectroscopic evidence that the cationic species, $[UO_2(TcO_4)(DPPMO_2)_2]^+$ and $[UO_2(ReO_4)(DPPMO_2)_2]^+$ are stable in solution. In the presence of more strongly coordinating anions, F^- and NO_3^-, more than one anion coordinates in the uranyl equatorial plane, forming $[UO_2(\mu\text{-}F)(F)(DPPMO_2)]_2$ and $[UO_2(NO_3)_2(DPPMO_2)]$, respectively [19,20]. In the presence of

doi:10.1016/j.poly.2008.10.070

bidentate bis(β-diketonates) the $DPPMO_2$ ligand is forced into monodentate or bridging coordination modes [20]. Recently, bidentate $DPPMO_2$ coordination has also been observed in the β-diketiminate cationic complex, $[UO_2(Ar_2nacnac)(DPPMO_2)]$, where Ar_2nacnac = (2,6-^{i}Pr$_2$- C_6H_3)*NC*(Me)CHC(Me)*N*(2,6-^{i}Pr$_2C_6H_3$) [21]. It would thus appear that the $\{UO_2(DPPMO_2)_2\}^{2+}$ fragment (two bidentate P=O donor ligands) is only stable in the absence of strongly coordinating anions and can accommodate another monodentate less strongly coordinating anion (*i.e.* 5 coordinate in the $\{UO_2\}^{2+}$ equatorial plane). The chemistry of this $\{UO_2(DPPMO_2)_2\}^{2+}$ dication has been investigated further with the fifth coordination site filled with triphenyl phosphine oxide to form $[UO_2(DPPMO_2)_2(Ph_3PO)]^{2+}$, both as the triflate and BF_4^- salts. The BF_4^- salt can react further to form a mixture of two dimeric uranyl complexes with bridging F^- (abstracted from the anion), with only chelating $DPPMO_2$ observed in one complex and both bridging and chelating $DPPMO_2$ observed in the second complex [22].

In this paper we report the synthesis, structural and spectroscopic characterisation of two more complexes in the $[UO_2(X)(DPPMO_2)_2][X]$ series, where $X = NTf_2^-$ and OTf^-. In addition, a ^{31}P NMR solution spectroscopic study has been undertaken to probe the stability of both $[UO_2(NTf_2)(DPPMO_2)_2]^+$ and $[UO_2(OTf)(DPPMO_2)_2]^+$ in the presence, and absence, of competing anionic ligands.

2. Experimental

Caution: The natural uranium used during the course of this work is a radioactive toxic metal and care should be taken with all manipulations.

2.1. General considerations

All reactions were carried out under an argon atmosphere using standard Schlenk techniques or an inert atmosphere glovebox. All solvents employed were reagent grade and dried by refluxing over appropriate drying agents. $DPPMO_2$, $[UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ and $[UO_2(Cl)(DPPMO_2)_2][Cl]$ were prepared as described previously, [18] with all other reagents used as received (except for $[Bu_4N][ReO_4]$ – see below). $^{31}P\{^1H\}$, $^{19}F\{^1H\}$ and ^1H NMR spectra were recorded on a Bruker Avance Ultrashield 400 instrument at 161.91, 376.47 and 400 MHz, respectively. Chemical shifts were measured relative to external references H_3PO_4 (85%) (^{31}P), $CFCl_3$ (^{19}F) and TMS (^1H) and. Raman and IR spectroscopy were performed on a Bruker Equinox 55 FTIR/Raman machine. Elemental analysis was performed on a Carlo ERBA Instruments CHNS-O EA1108 elemental analyzer for C, H and N and on a Fisons Horizon Elemental analyser ICP-OED spectrometer for U and P.

2.2. Synthesis of $[Bu_4N][ReO_4]$

$HReO_4$ (0.83 mL, 0.91 mmol) was added dropwise to a solution of $[Bu_4N][Cl] \cdot H_2O$ (0.26 g, 0.91 mmol) in EtOH (15 mL), and the resulting mixture left to stir for 1 h. Evaporation in air afforded colourless plates of the title compound after 10 d which were collected, washed with EtOH (10 mL) and dried *in vacuo* (1.87 g, 93%). IR (solid on ATR cell) (cm^{-1}): 2963 (w), 2876 (w), 1473 (m), 1383 (w), 1165 (w), 1036 (w), 898 (vs), 737 (m). *Anal.* Calc. for $C_{16}H_{36}NO_4Re$: C, 39.02; H, 7.32; N 2.85. Found: C, 38.05; H, 7.52; N, 2.74%.

2.3. Synthesis of $[UO_2(NTf_2)(DPPMO_2)_2][NTf_2]$ (**1**)

UO_3 (0.26 g, 0.91 mmol), $(CF_3SO_2)_2NH$ (0.49 g, 1.80 mmol) and $DPPMO_2$ (0.73 g, 1.80 mmol) were dissolved in MeCN (10 mL), and heated. After stirring at room temperature for 2 days, the resultant yellow solution was filtered to remove trace UO_3 and taken to dryness *in vacuo* yielding a dark yellow powder which was recrystallised from dichloromethane (0.95 g, 63%). ^1H NMR (CD_2Cl_2 – 298 K): δ *4.1–4.3* (t, 4H, CH_2, $^2J_{P-H}$ 12 Hz), 7.2–7.6 and 7.8–8.0 (m, 20H, Ph); $^{31}P\{^1H\}$ NMR (CD_2Cl_2 – 298 K): δ 41.7(s); ^{19}F NMR (CD_2Cl_2 – 298 K): δ −78.6 (s) ppm. Raman (solid in glass capillary) (cm^{-1}): 3068(vs), 2904(s), 1592(m), 1165(w), 1030(m), 1000(s), 854(m), 743(m), 682(w), 617(w). *Anal.* Calc. for $C_{54}H_{44}F_{12}N_2O_{14}P_4S_4U$: C, 38.94; H, 2.64; N, 1.68; P, 7.45; S, 7.69; U, 14.30. Found: C, 38.66; H, 2.67; N, 2.10; P, 7.26; S, 7.52; U, 14.10%.

2.4. Synthesis of $[UO_2(OTf)(DPPMO_2)_2][OTf]$ (**2**)

UO_3 (0.25 g, 0.87 mmol), HSO_3CF_3 (151 μL, 1.74 mmol) and $DPPMO_2$ (0.72 g, 1.74 mmol) were dissolved in acetonitrile (6 mL) and stirred for a week at room temperature. The resulting solution was taken to dryness *in vacuo* yielding a light yellow powder which was purified by recrystallisation from dichloromethane at −15 °C over 5 days (1.18 g, 97%). ^1H NMR (CD_2Cl_2 – 298 K): δ *4.2–4.4* (t, 4H, CH_2, $^2J_{P-H}$ 12 Hz), 7.1–7.5 and 7.8–8.1 (m, 20H, Ph). $^{31}P\{^1H\}$ NMR (CD_2Cl_2 – 298 K) δ 40.6 (dd); ^{19}F NMR (CD_2Cl_2 – 298 K): δ −79.4 (s) ppm. Raman (solid in glass capillary) (cm^{-1}): 3066 (vs), 1592(m), 1031(m), 1000(s), 849(m), 683(w). *Anal . Calc.* for $C_{52}H_{44}F_6P_4S_2U$: C, 44.57; H, 3.14; F, 8.14; P, 8.86; S, 4.57; U, 17.00. Found: C, 44.39; H, 3.21; F, 8.08; P, 8.79; S, 4.16; U, 16.48%.

2.5. Single crystal X-ray diffraction

The crystallographic data for **1** and **2** · $4CH_2Cl_2$ are summarised in Table 1. Diffraction data for 1 were collected on a Bruker Apex CCD diffractometer while those for 2 were measured on an Oxford Diffraction Crysalis CCD diffractometer, both at 100 K using Mo Kα radiation (λ = 0.71073 Å). Both structures were solved by direct methods using SIR-92 and refined using full matrix least squares on F^2 with SHELXL-97 [23,24]. All non-hydrogen atoms were refined anisotropically, while hydrogen atoms were included in calculated positions. Restraints were used motion on the anisotropic thermal of all C-atoms for both structures.

3. Results and discussion

The yellow solids $[UO_2(NTf_2)(DPPMO_2)_2][NTf_2]$ (**1**) and $[UO_2(OTf)(DPPMO_2)_2][OTf]$ (**2**) were prepared by reaction of UO_3 with two equivalents of $DPPMO_2$ and 2 equiv. of the corresponding acid ($HNTf_2$ for **1** and HOTf for **2**) in acetonitrile (MeCN). Both products could be recrystallised from dichloromethane to yield crystals suitable for single crystal X-ray diffraction the latter as a CH_2Cl_2 solvate.

Compounds **1** and **2** both contain monocationic, monomeric uranyl complexes (see Figs. 1 and 2, respectively). The pentagonal bipyramidal geometry around the uranium metal centres are constructed from the two axial uranyl oxygens, two bidentate P=O donor $DPPMO_2$ ligands and either monodentate O-coordinated NTf_2^- (**1**) or monodentate OTf^- (**2**). The charge is balanced by an additional uncoordinated NTf_2^- (**1**) or OTf^- (**2**). Both structures are very similar to the previously structurally characterized perrhenate and chloride complexes, $[UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ and $[UO_2(Cl)(DPPMO_2)_2][Cl]$ [18]. Selected bond distances and angles given in Table 2.

The uranyl bond lengths for **1** and **2** (range between 1.765(3) Å and 1.771(3) Å) and O_{axial}–U–O_{axial} bond angles (179.7(3)° for **1** and 178.70(13)° for **2**) are as expected for 7-coordinate uranyl complexes, and comparable to those observed in $[UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ and $[UO_2(Cl)(DPPMO_2)_2][Cl]$ [18]. Turning to the two bidentate coordinated $DPPMO_2$ ligands, the bite angles of both groups (73.52(19)° and 73.0(2)° for **1** and 72.17(10)° and 72.94(10)° for **2**) are slightly more obtuse than those found in the analogous choride complex (70.32(17)° and 71.56(16)°), but similar to the values observed for the perrhenate species (73.1(2)° and 72.9(2)°) [18]. This supports our previous rationale that the larger radius of the fifth equatorial bound anion atom (Cl versus O) leads to the more acute $DPPMO_2$ bite angle.

The U–O bond lengths for coordinated anion is longer for U–$O_{bistriflimide}$ (2.457(6) Å – **1**) versus U–$O_{triflate}$ (2.408(3) Å – **2**) giving some indication that the U–$O_{triflate}$ bond is the stronger of the two. However, uranium–oxygen bond lengths are not always the best measure of comparing bond strength and caution should be taken when making this comparison. The U–$O_{triflate}$ bond length in **2** is significantly longer than the shorter U–$O_{triflate}$ bond length in $UO_2(OTf)_2(thf)_3$ (2.372(6) Å) [17], and also in $UO_2(OTf)_2(py)_3$ (2.372(6) Å) [15], perhaps reflecting the stronger donor properties of the co-ligand in **2**.

O(5)–U(1)–O(6)	73.0(2)	72.94(10)

For $[bmpyr]_2[Ln(NTf_2)_5]$ (Ln = Nd or Tb) an increase in S–O bond length for NTf_2^- on coordination to the trivalent lanthanide (mean values of 1.47 Å coordinated versus 1.42 Å uncoordinated) has been observed [11]. For the Pr complex, $[bmpyr]_2[Pr(NTf_2)_5]$, a similar trend is also observed (mean values of coordinated and uncoordinated S–$O_{bistriflimide}$ bond lengths are 1.45 and 1.43 Å) [10]. In addition, significant changes in NTf_2^- bond lengths are observed on N-donor coordination in $[(C_5H_5)Fe(CO_2)(NTf_2)]$ (N–S increases from 1.56–1.57 to 1.630(4)/1.643(4) Å and on O-donor coordination in $(C_5H_5)_2Ti(NTf_2)_2$, where the S–O coordinated bond lengths are quoted as 1.467(4) and 1.468(3) Å) [7a]. However, in our case the S(1)–O(7) (coordinated – 1.450(6) Å) and S(1)–O(8) (uncoordinated – 1.433(7) Å) bond lengths are comparable and we see no systematic change in any of the NTf_2^- bond lengths on coordination, as also previously observed for $La(NTf_2)_3(H_2O)_3$ [8]. In comparison, the S(1)–O(7) bond length (1.455(3) Å) for the triflate oxygen coordinated to uranium in **2** is significantly longer than the S(I)–O(8) and S(I)–O(9) – uncoordinated bond lengths (1.434(4) and 1.435(4) Å, respectively).

The solid state Raman spectra were collected for both **1** and **2** (see Supplementary material). Of most interest was the ν_1 uranyl symmetric stretching frequency, assigned to peaks at 854 and 848 cm^{-1} for **1** and **2**, respectively. These vibrations come at slightly higher frequency than two other structurally similar

uranium $DPPMO_2$ based complexes $([UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ and $[UO_2(TcO_4)(DPPMO_2)_2][TcO_4]$ (where ν_1 O=U=O = 840, 844 cm^{-1}, respectively), and at a significantly higher value than observed for $[UO_2(Cl)(DPPMO_2)_2][Cl]$ (where ν_1 O=U=O = 824 cm^{-1}) [18]. The higher energy vibration probably reflects a more limited weakening of the O=U=O bond through anion coordination.

Previously we have reported that the room temperature $^{31}P\{^1H\}$ NMR spectra of $[UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ and $[UO_2(TcO_4)(DPPMO_2)_2][TcO_4]$ both exhibit one single broad peak at 42.2 and 40.8 ppm, respectively in CD_2Cl_2 (shifted from 25.1 ppm for uncomplexed $DPPMO_2$ in the same solvent). As the temperature is lowered the broad peak splits into four bands, with a "roof effect" typical of two doublets when the chemical shift difference between the two different P environments (from the P=O groups distal and adjacent to the perrhenate or pertechnetate anion) is similar to the J_{P-P} coupling constant (an AA′BB′ system). Clearly at higher temperatures there must be an exchange process(es) taking place at a rate comparable to the NMR timescale which could be ring flipping in the 6 membered chelate ring formed from complexed $DPPMO_2$ and/or exchange of coordinated and uncoordinated $[ReO_4]^-$ or $[TcO_4]^-$ anions.

The $^{31}P\{^1H\}$ variable temperature NMR spectra for $[UO_2(OTf)(DPPMO_2)_2][OTf]$ (**2**) in CD_2Cl_2 are shown in Fig. 3a. In contrast with the perrhenate and pertechnetate complexes, the expected AA′BB′ pattern is observed at room temperature. As the temperature is lowered the bands firstly broaden before again sharpening as the temperature is lowered still further. At room temperature the resonances are centred at 40.6 ppm, shifting slightly downfield as the temperature is lowered. We postulate that at room temperature triflate ligand exchange is too rapid to allow the $DPPMO_2$ groups to relax back into the D_{4h} geometry that might be expected for $\{UO_2(DPPMO_2)_2\}^{2+}$ and triflate exchange occurs at the same site in the uranyl equatorial plane (assuming a dissociative mechanism for ligand exchange dominates). As the temperature is lowered there are a range of possible chemical processes with kinetics within the NMR timescale, including flipping between monodentate and bidentate coordination for triflate and coordination of a triflate anion to the uranyl centre *trans* to a leaving triflate group. A minor peak is also observed at *c.a.* 39.1 ppm as the temperature is lowered, with another two minor broad resonances also resolved at −70 °C between 41 and 42 ppm. The variable temperature ^1H NMR spectra of **2** in CD_2Cl_2 simply show a gradual loss of resolution of the phenyl and methylene resonances as a function of temperature, probably a result of decreasing the rate of $P–C_{phenyl}$ bond rotation and $UO_2P_2C_2$ ring flipping. Similar variable temperature ^1H NMR spectra in CD_2Cl_2 are also observed for **1**. The ^{19}F NMR spectrum for **2** at 25 °C reveals just a single resonance at −79.6 ppm (*c.f.* −79.3 ppm for $[UO_2(DPPMO_2)_2(OPPh_3)][OTf]$-[22]) indicating a rapid exchange between coordinated and uncoordinated triflate. At −65 °C, this resonance appears to be splitting into two peaks of comparable intensity, presumably corresponding to coordinated OTf in **2** and uncoordinated OTf (see Fig. 3b).

The $^{31}P\{^1H\}$ variable temperature NMR spectra for $[UO_2(NTf_2)(DPPMO_2)_2][NTf_2]$ (**1**) in CD_2Cl_2 are shown in Fig. 4. As the temperature is lowered a single resonance at 41.7 ppm broadens and then splits into 5 peaks. The major peak is at 41.5 ppm with the four other peaks appearing to form two coupled doublets centred at 42.1 and 42.7 (J_{P-P} = 14.9 Hz). We assign the two doublets to $[UO_2(NTf_2)(DPPMO_2)_2]^+$ and the singlet to the dicationic species $[UO_2(DPPMO_2)_2]^{2+}$. Integration at −70 °C leads to an 1:1.2 ratio of $[UO_2(NTf_2)(DPPMO_2)_2]^+$:$[UO_2(DPPMO_2)_2]^{2+}$. It would thus appear that even in the presence of two molar equivalents of NTf_2^- there is incomplete coordination of NTf_2^- in solution. The ^{19}F NMR of **2** at 25 °C reveals a broad resonance at −78.6 ppm (*c.f.* −80.2 ppm for $XNTf_2$), which is resolved into two peaks at −65 °C. From the incomplete coordination of NTf_2^- in solution observed by $^{31}P\{^1H\}$ NMR we assigned the more intense resonance to uncoordinated NTf_2^- and the less intense resonance to $[UO_2(NTf_2)(DPPMO_2)]^+$.

From the structural and solution $^{31}P\{^1H\}$ NMR studies, it would appear that the order of strength of coordination of weakly

coordinating anion to $\{UO_2(DPPMO_2)_2\}^{2+}$ is probably $[ReO_4]^- > OTf_2^- > NTf_2^-$. In addition, chloride, nitrate and excess $DPPMO_2$ should also be able to displace all three of these anions. To prove this hypothesis we undertook competition reactions using $[Bu_4N]^+$ salts of competing anions. The reactions were monitored by ^{31}P NMR spectroscopy in CD_2Cl_2 solution. Firstly, addition of one equivalent of $[Bu_4N][OTf]$ or $[Bu_4N][ReO_4]$ to $[UO_2(NTf_2)(DPPMO_2)_2][NTf_2]$ led to the clean formation of $[UO_2(OTf)(DPPMO_2)_2]^+$ or $[UO_2(ReO_4)(DPPMO_2)_2]^+$ in solution. It took the addition of two molar equivalents of $[Bu_4N][ReO_4]$ to completely displace triflate from the coordination sphere of uranyl when added to a CD_2Cl_2 solution of **2**. It would thus appear that the order of coordinating ability of anion to $\{UO_2(DPPMO_2)_2\}^{2+}$ in solution is $[ReO_4]^- > OTf_2^- >> NTf_2^-$. Example spectra are shown in Fig. 5 where triflate is shown to coordinate to $\{UO_2(DPPMO_2)_2\}^{2+}$ in preference to bistriflimide.

While it was not possible to record the ^{31}P NMR spectrum of $[UO_2(Cl)(DPPMO_2)_2][Cl]$ in CD_2Cl_2 due to solubility issues it was possible to add $[Bu_4N][Cl]$ to CD_2Cl_2 solutions of **1**, **2** and $[UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$. Addition of 1 molar equivalent of $[Bu_4N][Cl]$ to **1** led to spectral changes consistent with almost complete formation of $[UO_2(Cl)(DPPMO_2)_2]^+$. The addition of 2 equiv. of $[Bu_4N][Cl]$ to **2** were required for complete formation of the same product. Finally, addition of two equivalents of $[Bu_4N][Cl]$ to $[UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ led to the almost complete formation of $[UO_2(Cl)(DPPMO_2)_2]^+$ with $[UO_2(ReO_4)(DPPMO_2)_2]^+$ present as a minor product. In all cases the expected AA'BB' system for $[UO_2(Cl)(DPPMO_2)_2]^+$ was observed at *ca.* 39 ppm. Clearly Cl^- is a more strongly coordinating ligand to $\{UO_2(DPPMO_2)_2\}^+$ than either perrhenate, triflate or bistriflimide. For example spectra see the supporting information.

The addition of one molar equivalent of $[Bu_4N][NO_3]$ to **1**, **2** or $[UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ in CD_2Cl_2 led to quite distinctive complex spectra. However, the addition of two molar equivalents of $[Bu_4N][NO_3]$ to all three complexes in solution yielded very similar spectra with numerous separate peaks resolvable at low temperature, indicative of complete displacement of weakly coordinating anion by nitrate. As an example, the addition of two equivalents of $[Bu_4N][NO_3]$ to **2** led to a spectrum with 6 peaks (−70 °C) at 44.5, 42.2, 40.6, 40.2, 39.3 and 27.0 ppm (Fig. 6). This system contains 2 NO_3^- and 2 $DPPMO_2$ ligands per $\{UO_2\}^{2+}$. We assign the peak at 39.3 ppm to $[UO_2(NO_3)_2(DPPMO)]$,[20] having recorded a $^{31}P\{^1H\}$ NMR spectrum of this complex in the same solvent. The peaks at 44.5, 42.2 and 27.0 ppm have equivalent intensities and are assigned to a complex containing two monodentate coordinated $DPPMO_2$ ligands and one bidentate coordinated $DPPMO_2$ ligand, $[UO_2(\eta^1\text{-}DPPMO_2)_2(DPPMO_2)]^{2+}$. The peak at 27.0 ppm relates to the uncoordinated P═O groups and the peak at 44.5 ppm relates to the coordinated P═O groups for the two monodentate $DPPMO_2$ ligands. As will be discussed below the two broad peaks for monodentate coordinated $DPPMO_2$ can, in some instances, be resolved into a pair of coupling doublets. The coordinated bidentate $DPPMO_2$ ^{31}P resonance is assigned to a peak at 42.2 ppm. The two peaks at 40.6 and 40.2 ppm are more difficult to assign and our suggested assignments are tentative. One of the two peaks, possibly the broader peak at 40.6 ppm, could well be due to $[UO_2(NO_3)(DPPMO_2)_2]^+$. Alternative, both peaks could relate to complexes with this formula, with both monodentate and bidentate nitrate containing species present in solution.

Finally, the addition of one, and then two molar equivalent of $DPPMO_2$ to **1**, **2** or $UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ in CD_2Cl_2 led to very similar spectra. Perhaps the best resolved spectrum was recorded at −70 °C on a CD_2Cl_2 solution containing $UO_2(ReO_4)(DPPMO_2)_2][ReO_4]$ and 2 equiv. of $DPPMO_2$ (Fig. 7). As described for the nitrate system, peaks assigned to $[UO_2(\eta^1\text{-}DPPMO_2)_2(DPPMO_2)]^{2+}$ are observed at 45.7 and 28.7 ppm for monodentate coordinated $DPPMO_2$. On this occasion both peaks are clearly split into doublets, as expected for coupling between inequivalent P environments for the same $DPPMO_2$ ligand (J_{P-P} = 14.6 Hz). The peaks for bidentate and uncoordinated $DPPMO_2$ are observed at 43.2 and 27.5 ppm, respectively. These results clearly indicate that monodentate coordinate $DPPMO_2$ P═O donor ligand more strongly coordinates to $\{UO_2\}^{2+}$ than perrhenate, triflate or bistriflimide.

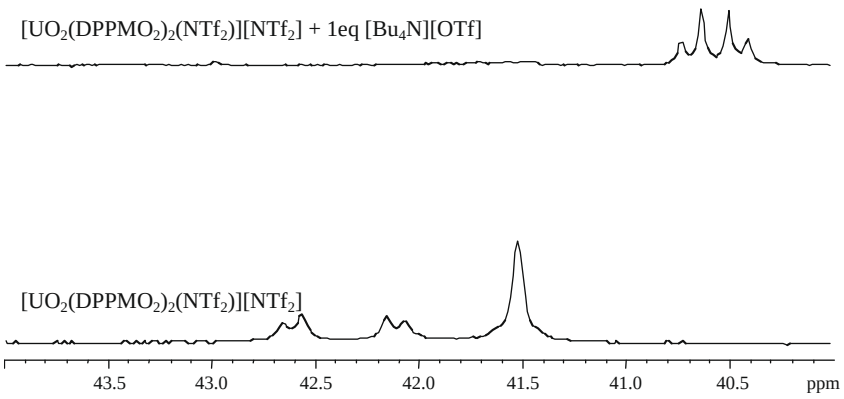

Fig. 5. $^{31}P\{^{1}H\}$ NMR spectra $[UO_2(NTf_2)(DPPMO_2)_2][NTf_2]$ (**1**) before, and after, the addition of one molar equivalent of $[Bu_4N][OTf]$. The spectra were recorded at −70 °C in CD_2Cl_2.

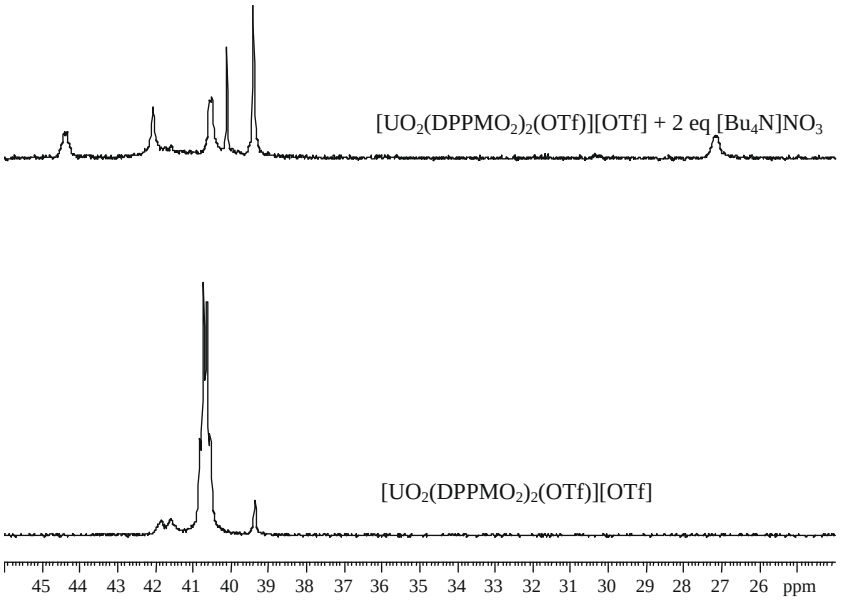

Fig. 6. $^{31}P\{^{1}H\}$ NMR spectra of $[UO_2(OTf)(DPPMO_2)_2][OTf]$ (**2**) before, and after, the addition of two molar equivalents of $[Bu_4N]NO_3$. The spectra were recorded at −70 °C in CD_2Cl_2.

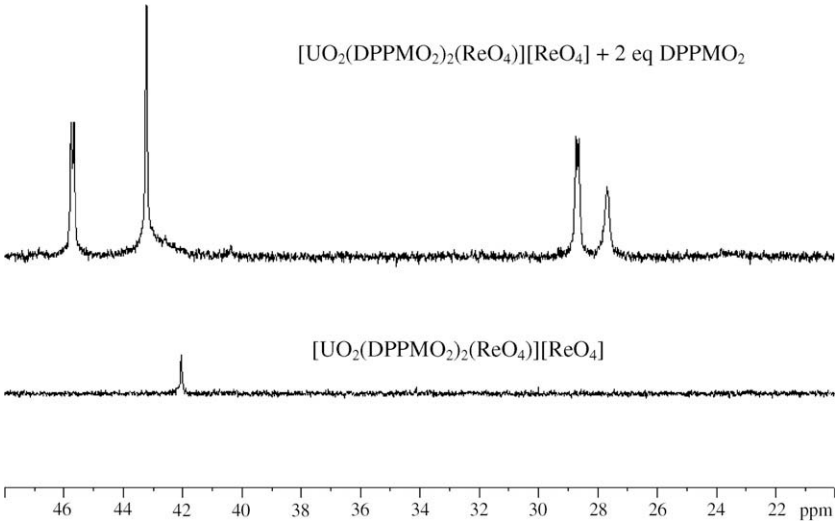

Fig. 7. $^{31}P\{^{1}H\}$ NMR spectra $[UO_2(DPPMO_2)_2(ReO_4)][ReO_4]$ before, and after the addition of two molar equivalents of $DPPMO_2$. The spectra were recorded at −70 °C and −45 °C, respectively in CD_2Cl_2.

4. Conclusions

The $\{UO_2(DPPMO_2)_2\}^{2+}$ dication yields a uranyl equatorial bonding site which can accommodate 'weakly' coordinating anions, as we have now demonstrated by characterising a series of complexes of general formula $[UO_2(DPPMO_2)_2X][X]$ (where $X = [ReO_4]^-$, $[TcO_4]^-$, NTf_2^-, OTf^- and Cl^-). Both $[UO_2(NTf_2)(DPPMO_2)_2][NTf_2]$ (**1**) and $[UO_2(OTf)(DPPMO_2)_2][OTf]$ (**2**) have been prepared in the course of this current study. We have shown this series to be an excellent probe of uranyl – anion bond strength. Solid state structural and solution state ^{31}P NMR studies are in agreement with respect to the order of the strength of the uranyl – anion bonding interaction which decreases along the series $[Cl]^- > [ReO_4]^- > [OTf]^- > [NTf_2^-]^-$. Further ^{31}P NMR competition studies show that both nitrate and excess $DPPMO_2$ will readily displace the weakly coordinating anions that have been investigated, forming complexes in which the $[UO_2(DPPMO_2)_2X][X]$ structural type no longer prevails.

ABSTRACT

The complexes $[Co(N\hat{}O)_2]$ (**1**) and $[Cu(N\hat{}O)_2]$ (**2**) {N^O = η^2-(N,O) coordinated 2-pyrazinecarboxylic acid} have been synthesized and characterized by elemental (including metal) analyses, FT-IR spectroscopy and powder X-ray diffraction. The molecular structure of complex **2** was determined by single X-ray crystallography. In the molecule, the Cu atom occupies the center of a square planar geometry, which consists of two *trans*-O atoms and two *trans*-N atoms of two 2-pyrazinecarboxylic acid ligands. The complexes **1** and **2** were well encapsulated into zeolite–Y super-cage to yield the corresponding zeolite–Y encapsulated metal complexes, abbreviated herein as $[Co(N\hat{}O)_2]$–Y (**3**) and $[Cu(N\hat{}O)_2]$–Y (**4**). Similarly, the metal complexes **1** and **2** were immobilized on alumina and organically modified silica surfaces to lead to the formation of immobilized metal complexes $[Co(N\hat{}O)_2]$–Al_2O_3 (**5**); $[Cu(N\hat{}O)_2]$–Al_2O_3 (**6**); $[Co(N\hat{}O)_2]$–AMPS (**7**) and $[Cu(N\hat{}O)_2]$–AMPS (**8**) (AMPS = aminopropyl silica). Elemental (including metal) analyses, FT-IR spectroscopy, powder X-ray diffraction and thermal analysis have been used to characterize these materials. The catalytic activity of all the catalysts **1**–**8** towards the oxidation of cyclohexene into different chemically and pharmaceutically important products were evaluated under homogeneous and heterogeneous conditions. In order to obtain a maximum conversion of cyclohexene, the reaction parameters, like reaction temperature and time, were optimized. Under the optimized conditions, a maximum of 90.47% cyclohexene conversion was achieved with $[Cu(N\hat{}O)_2]$–Y (**4**) with a 1:2 molar ratio reaction of cyclohexene and H_2O_2.

1. Introduction

Oxidation of olefins to give oxygen containing value added products like alcohols, aldehydes, ketones, acids, epoxides, etc. is an extremely important and useful reaction in both chemical and pharmaceutical industries [1,2]. Amongst the different oxidants used in oxidation catalysis, hydrogen peroxide is ideally suitable due to its low cost. Furthermore, hydrogen peroxide is readily available and creates no hazardous by-products during the reaction [2]. In the last few years, homogeneous catalysts have received great attention in the effective use for oxidation of olefins [3,4]. Despite this interest, such materials suffer from some drawbacks like difficulty in separation from the reaction mixture, catalyst deactivation by dimerization through the formation of oxygen bridges, the high cost of the complex and lack of recycling method, etc., which make them difficult for application on a large scale [1,3]. The search for new oxidation catalysts is one of the most important current topics for both industrial and academic research. The heterogenization of homogeneous catalysts found to exhibit some attractive features like the site isolation effect is a field of continuing interest [5]. To avoid the problems with homogeneous catalysis, various strategies are employed like encapsulation in zeolites, grafting on polymers and MCM-41 silica, and immobilization in polysiloxane membranes, etc., which are offering moderate to excellent results [1,3]. A molecule encapsulated in a zeolite cage is characterized by steric restriction and if the size of the molecule is well fitted within the zeolite cage, the molecule may show interesting properties, which would not be observed under ordinary conditions [6]. Immobilization of transition metal complexes on solid supports such as alumina and organically modified silica has also been studied extensively in order to prepare heterogeneous catalysts with the desired structure and functionality [7]. The supporting tendency of acidic alumina might arise from the presence of oxygen groups on the surfaces, which coordinate easily to metal ion centers [3]. Modified silica is also important due to its chemical and thermal stability and strong ability to bind the metal complexes. Some reported efficient copper containing heterogeneous catalysts for oxidation reactions are Cu(II)-phthalocyanine incorporated inside Y-faujasite and MCM-41 [8], Cu(II)-complexes of 1,2-diaminocyclohexane based ligands encapsulated into zeolite–Y [6], Cu(II)-bis(2-mercaptoanil)benzil complexes supported on alumina [9], Cu(II)-coordination polymers constructed from phthalate–imidazole [2], copper–pyridine complexes encapsulated

doi:10.1016/j.poly.2008.10.063

into a zeolite super-cage [7], (3,10-dialkyl-dibenzo-1,3,5,8,10,12-hexaazacyclotetradecane)Cu(II) encapsulated into zeolite [5], alumina supported Cu(II) *N,N*-bis(salicylidene)-2,2-dimethylpropane-1,3-diamine complexes [3], a copper complex with 8-hydroxyquinoline immobilized on an organically modified silica surface [10], Cu(II)/X and Y zeolite [11], $Cu(OH)_2$/silica [12], etc. Some other supported catalysts of Ni(II), Co(II), Mn(II) and oxovanadium(IV) are also as potentially important as copper complexes in heterogeneous oxidation catalysis [1–3,6,9,13].

The present investigation deals with the encapsulation and immobilization of Co(II) and Cu(II) complexes of 2-pyrazinecarboxylic acid ligand in zeolite–Y, alumina and organically modified silica supports. The neat and supported materials have been screened as catalysts for the oxidation of cyclohexene into different value added products with hydrogen peroxide as the oxygen donor. The effects of different experimental parameters like reaction time and temperature on the catalytic conversion were also investigated in order to optimize the reaction conditions.

2. Experimental

2.1. Materials

Analytical reagent grade cyclohexene, 30% aqueous hydrogen peroxide, copper(II) acetate monohydrate, cobalt(II) acetate tetrahydrate, 3-aminopropyltriethoxysilane, etc. were purchased from Wako Pure Chemical Industries, Ltd., Japan. 2-Pyrazinecarboxylic acid, reference samples of 1,2-epoxycyclohexane, 2-cyclohexen-1-ol, 2-cyclohexen-1-one and 1,2-cyclohexanediol were obtained from Tokyo Kasei Kogyo Co., Ltd. The zeolite–Y, namely HSZ-390HUA ($SiO_2/Al_2O_3 = 750$), was supplied by Tosoh Corporation and alumina and silica supports were supplied by the Catalytic Society of Japan. All other chemicals and solvents used in the present study were of AR grade and were used without further purification.

2.2. Characterization techniques

FT-IR spectra in the range 400–4000 cm^{-1} were recorded using a Jasco 460 plus spectrophotometer in KBr disks. Powder X-ray diffraction patterns were recorded on a Rigaku Miniflex with Cu Kα filtered radiation (30 kV, 15 mA) at a scanning speed of 2°/min. Metal contents were measured by Inductively Coupled Plasma-atomic emission Spectroscopy (ICPS-7500, Shimadzu) after leaching the metal ions with conc. nitric acid and diluting with distilled water. The carbon and nitrogen contents were measured using an Atomic High Sensitive NC analyzer (Sumigraph NC-22A, Sumika Chemical Analysis Service (SCAS)). Thermal analyses of the supported complexes were carried out on a Shimadzu Thermal Analyzer at a heating rate of 10 °C/min. All catalyzed reaction products were analyzed using a Gas Chromatograph (GC-17A, Shimadzu) fitted with a DB-1 capillary column (30 m × 0.25 mm × 0.25 μm) and FID detector. The identities of the products were confirmed by Gas Chromatography Mass Spectroscopy (GCMS-QP5050A, Shimadzu).

2.3. Preparations

2.3.1. Preparation of $[Co(N\hat{}O)_2]$ (**1**) and $[Cu(N\hat{}O)_2]$ (**2**); $N\hat{}O = \eta^2$-(N,O) coordinated 2-pyrazinecarboxylic acid

2-Pyrazinecarboxylic acid (10 mmol, 1.241 g) dissolved in 10 mL warm methanol was added to a solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (5 mmol, 1.245 g) in methanol (10 mL) and reaction mixture was refluxed with stirring on a water bath for 5 h. A light yellow solid of $[Co(N\hat{}O)_2]$ slowly separated out within a few hours on cooling the solution at room temperature. The solid was filtered off, washed repeatedly with methanol and dried at 50 °C in an oven for 10 h. Yield: 79%.

$Cu(CH_3COO)_2 \cdot H_2O$ (5 mmol, 0.998 g) and 2-pyrazinecarboxylic acid (10 mmol, 1.241 g) were treated following the same experimental procedure and conditions as above to obtain a blue solid of $[Cu(N\hat{}O)_2]$. Yield: 88%.

2.3.2. X-ray crystallography

A crystal of complex **2** suitable for X-ray crystallographic analysis was grown from a methanol–water solution. Data collection was performed using a Rigaku Saturn (Rigaku AFC10) diffractometer, full sphere of data with 0.3° slices, −150 °C, Mo Kα radiation and empirical absorption corrections. All non-hydrogen atoms were refined anisotropically with the hydrogen atoms being refined in idealized geometries. The structure refinements were done by full matrix least square on F^2 using the SHELXTL97 computer program [14]. The crystal data and structure refinement for the complex are listed in Table 1.

2.3.3. Preparation of zeolite–Y encapsulated metal complexes

2.3.3.1. Preparation of M–Y (M = Co, Cu). Zeolite powder (H–Y) was activated at 100 °C overnight before use. Three grams of activated zeolite were added to a 100 mL methanolic solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (12.50 mmol, 0.05 M) or $Cu(CH_3COO)_2 \cdot H_2O$ (12.52 mmol, 0.05 M) and suspensions were stirred at ca. 60 °C for about 72 h under dry conditions. The solid compounds of Co–Y and Cu–Y were filtered off and washed repeatedly with warm methanol in order to remove uncomplexed metal ions, and were dried at 100 °C for 24 h.

*2.3.3.2. Preparation of encapsulated $[Co(N\hat{}O)_2]$–Y (**3**) and $[Cu(N\hat{}O)_2]$–Y (**4**).* Co–Y or Cu–Y (2 g) and 2-pyrazinecarboxylic acid (1 g) were transferred to a round bottom flask containing 50 mL of methanol. Then the reaction mixtures were heated at 65 °C under

reflux for 12 h with continuous stirring under dry conditions. The resulting yellow solid of [Co(N^O)$_2$]–Y (**3**) and blue solid of [Cu(N^O)$_2$]–Y (**4**) were filtered off and washed with methanol repeatedly to remove excess ligand and uncomplexed metal ions that may be contained in the cavities as well as in the external surface of the zeolite. The purification process was continued by refluxing the powder samples of **3** and **4** in methanol (50 mL) for 2 h. The unreacted metal ions if any, in the cavity of the zeolite were removed by stirring with aqueous 0.01 M NaCl solution (150 mL) for 10 h. The resulting solids were filtered and washed with distilled water until free from chloride ions. The solids were finally dried at 100 °C for 24 h.

*2.3.4. Preparation of immobilized [Co(N^O)$_2$]–Al$_2$O$_3$ (**5**) and [Cu(N^O)$_2$]–Al$_2$O$_3$ (**6**) complexes*

Alumina was activated at 100 °C overnight before immobilization of the metal complexes. Solutions of [Co(N^O)$_2$] and [Cu(N^O)$_2$] (2.5 g) in 250 mL $CHCl_3$ were added to a 3 g alumina suspension in 25 mL $CHCl_3$. The resulting reaction mixtures were refluxed with stirring for about 12 h. The corresponding yellow solid of complex **5** and blue solid of complex **6** were filtered off and washed with $CHCl_3$. The catalysts [Co(N^O)$_2$]–Al$_2$O$_3$ and [Cu(N^O)$_2$]–Al$_2$O$_3$ were dried at 100 °C for 24 h prior to use.

2.3.5. Preparation of immobilized metal complexes on silica surface

2.3.5.1. Modification of silica by the organic functionality 3-aminopropyltriethoxysilane. Amorphous silica (3 g) was ground and suspended in an ethanolic solution of 3-aminopropyltriethoxysilane $\{(OC_2H_5)_3SiCH_2CH_2CH_2NH_2\}$ such that 2.0 mmol silane/g silica could be obtained. The mixture was refluxed with stirring for 12 h to obtain organically modified silica. The solid was then filtered off and washed with methanol and ether respectively several times. The resulted material is designated as aminopropyl silica (AMPS).

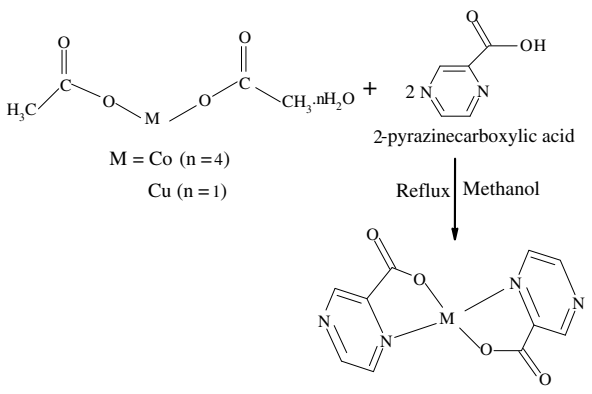
*2.3.5.2. Preparation of immobilized [Co(N^O)$_2$]-AMPS (**7**) and [Cu(N^O)$_2$]-AMPS (**8**).* The AMPS was refluxed with 250 mL aqueous solution of $Co(CH_3COO)_2 \cdot 4H_2O$ (12.50 mmol, 0.05 M) or $Cu(CH_3COO)_2 \cdot H_2O$ (12.52 mmol, 0.05 M) for about 12 h and respective solids of Co–AMPS and Cu–AMPS were filtered and washed thoroughly with water. The Co–AMPS and Cu–AMPS samples were then reacted with 2-pyrazinecarboxylic acid dissolved in methanol to produce the immobilized metal complexes **7** and **8**.

2.3.6. Homogeneous oxidation of cyclohexene

The catalytic oxidation of cyclohexene under homogeneous conditions was carried out using complexes **1** and **2** in a 100 mL flask fitted with a water circulated condenser. In a typical 1:1 molar ratio reaction of substrate to oxidant, neat metal complexes **1** or **2** (0.035 g) in 10 mL acetone and 30% H_2O_2 (1.14 g, 10 mmol) were added to a solution of cyclohexene (0.82 g, 10 mmol). The resulting mixture was then heated at 75 °C for 8 h with continuous stirring in a water bath. The solvent was evaporated under reduced pressure and the crude product analyzed by GC and GC–MS. The corresponding amounts of H_2O_2 for 1:2 and 1:3 molar ratio catalytic reactions were 2.28 g (20 mmol) and 3.42 g (30 mmol). A temperature of 75 °C and reaction period of 8 h were the optimum values for maximum conversion of cyclohexene, and the optimization reactions were carried out separately by changing the temperature and time with a fixed amount of catalyst.

2.3.7. Heterogeneous oxidation of cyclohexene

The reaction conditions as well as the experimental set-up were essentially the same as out lined for the homogeneous catalysis, except for the amount of catalyst used. In all the heterogeneous catalytic reactions, 0.1 g of each catalyst **3**–**8** was used.



3. Results and discussion

3.1. Synthesis and characterization of catalysts

The reactions of $Co(CH_3COO)_2 \cdot 4H_2O$ or $Cu(CH_3COO)_2 \cdot H_2O$ with 2 M equiv. of 2-pyrazinecarboxylic acid ligand in refluxing methanol yielded the corresponding chelate complexes [Co(N^O)$_2$] (**1**) and [Cu(N^O)$_2$] (**2**); N^O = η^2-(N,O) coordinated 2-pyrazinecarboxylic acid (Scheme 1). The metal as well as C and N contents (Table 2) of the complexes **1** and **2** are in agreement with their general formula, as mentioned above. The preliminary identification of these two complexes was made on the basis of their FT-IR spectra. A sharp band at 1724 cm^{-1} due to the $\nu(COO)_{as}$ stretch of the free ligand shifts to the lower energy region, at 1637 cm^{-1} for **1** and 1645 cm^{-1} for **2**, indicating five membered chelate ring formation through the O- and one of the N-donors of the ligand [15,16]. Some moderately intense bands appeared in the 400–500 cm^{-1} region are assigned to new ν(M–N) and ν(M–O) (M = Co, Cu) bands, which further suggest bond formation between the metal and N- and O-donors of the ligand [17,18]. Powder X-ray diffraction patterns (Fig. 1) of complexes **1** and **2** were recorded over the range 2θ = 5–80°, which infer the well-crystalline nature of each complex.

In order to confirm the structures and to determine the detailed geometries, we tried to grow crystals of the complexes. A good crystal suitable for X-ray structural determination was obtained for complex **2**. The IR and elemental analyses data agree well with the molecular structure of the complex. The arrangements and numbering of the atoms in the crystal are shown in Fig. 2 and important bond lengths and bond angles are summarized in Table 3. In the molecule, the copper atom has a square planar coordination with two *trans*-O atoms and two *trans*-N atoms of two 2-pyrazinecarboxylic acid ligands. One vacant position is occupied by a loosely bonded water molecule, which will not change the coordination environment of the copper atom.

The zeolite–Y encapsulated complexes **3** and **4** (Scheme 2) are the result of the exchange of Co(II) and Cu(II) ions with H^+ ions associated with H–Y, followed by a metal exchange reaction of Co–Y or Cu–Y with the ligand 2-pyrazinecarboxylic acid in solution. Due to flexible nature, the ligand enters into the zeolite–Y nano-cavity and reacts with the previously exchanged metal ions. The purification of the solids by refluxing with a excess of methanol removed excess free ligand that remained uncomplexed in the cavities of the zeolite along with the neat complex formed on the external surface of the zeolite. The excess metal ions that may be present in the cavity were removed by exchange back with aqueous NaCl solution. The metal, C and N contents in each of the catalysts are determined and presented in Table 2, along with their

expected formula as well as their corresponding colour. As the complexes were purified well, the metal and element contents found after encapsulation are only due to the presence of the metal complexes in the cavity of the zeolite–Y. The chemical analysis of the encapsulated complexes also reveals a metal/N ratio roughly similar to that of the neat complexes **1** and **2** (Table 2), suggesting the same stoichiometry of the neat complexes after encapsulation. The catalysts $[Co(N^O)_2]$–Y (**3**) and $[Cu(N^O)_2]$–Y (**4**) are also well characterized by IR spectroscopy (Fig. 3). These complexes exhibit IR spectral bands essentially similar to their corresponding neat complexes **1** and **2**. The chelating mode of the ligand in these supported complexes is evident from the appearance of $\nu(COO)_{as}$ bands at 1634 and 1641 cm^{-1} for complexes **3** and **4,** respectively, which are shifted to a lower wavenumber (about 83–90 cm^{-1}) compared to the corresponding free ligand band (1724 cm^{-1}). Similar to complexes **1** and **2**, some new moderately intense bands located in the range 400–500 cm^{-1} further corroborate the chelate formation through one of the N- and O-donor sites of the ligand [17,18]. It is worth mentioning that the intensities of all the bands in the encapsulated complexes are weak compared to the corresponding neat complexes, which could be due to the low loading of the complexes into the zeolite matrix [6,19]. The powder X-ray diffraction pattern of H–Y and supported complexes **3** and **4** are presented in Fig. 4. The X-ray patterns are essentially similar, except the intensities of the bands in the encapsulated complexes are slightly lower compared to the parent H–Y, which could be due to the insertion of only a small amount of the metal complexes in the cavity of the zeolite–Y. This is in agreement with the low percentage metal content obtained for the encapsulated complexes **3** and **4** (Table 2). This observation indicates that the framework of the zeolite has not undergone any significant structural change during the encapsulation. This is expected as the ligand, being flexible in nature, enters slowly through the pores of the zeolite and fits nicely in the cavity upon coordination with the metal ions. Similar conclusions were also drawn by previous workers from their XRD patterns of different zeolite–Y encapsulated metal complexes [6,19]. One new but weak peak detected at 2θ values of 12.17° and 12.14° for complexes **3** and **4,** respectively was due to the externally loaded metal complexes. Fig. 5 represents the decomposition

Scheme 2. Metal complexes encapsulated into a zeolite–Y super-cage.

patterns of different groups associated with the complexes on thermogravimetric analysis. Table 4 lists the percent mass loss at different steps and their possible assignments. The decomposition of different groups in the catalysts **3** and **4** occurs in three overlapping steps. The removal of externally trapped water is indicated by endothermic peaks at ca. 60 °C, with a corresponding mass loss of 7.25% (in **3**) and 1.05% (in **4**). The first step is followed by a mass loss of 8.52% and 9.12% for the corresponding complexes **3** and **4**, which could be due to decomposition of water associated with the zeolite framework. The removal of coordinated water molecules from the respective metal ion is also expected to be overlapped in this step [6,19]. The final step is exothermic for both the complexes, and corresponds to the decomposition of the externally loaded metal complexes. The low mass loss percentage (11.73% in **3** and 11.53% in **4**) is consistent with insertion of only a small amount of the metal complexes in the cavity of the zeolite–Y, which is also evident from the metal and elemental analyses results [6,19].

The immobilized catalysts **5** and **6** (Scheme 3) on the alumina surface have been characterized by metal and elemental analyses, FT-IR, XRD and thermal analysis, similar to the encapsulated catalysts **3** and **4**. The chemical composition data (Table 2) confirmed the purity and stoichiometry of these immobilized catalysts. The metal/N ratios in the catalysts are very similar to the corresponding neat complexes, ensuring immobilization of the complexes on the alumina. In the FT-IR spectra, the band corresponding to the $\nu(COO)_{as}$ vibration appears at 1641 and 1644 cm^{-1} for **5** and **6** respectively, suggesting a chelating mode of the ligand. Appearance of moderate intensity bands in the region 400–500 cm^{-1} indicates the coordination of N- and O-donors to the respective metal center. Powder X-ray diffraction patterns (Fig. 6) were also recorded to ensure immobilization. Two new but weak peaks with 2θ values of 11.55° and 14.32° (in **5**) and one weak peak at 11.65° (in **6**) were detected, which could be due to externally loaded metal complexes [3]. These new peaks further ensure the support of $[Co(N\hat{}O)_2]$ and $[Cu(N\hat{}O)_2]$ on the alumina surface. The DTA and TGA curves of the catalysts **5** and **6** have been shown in Fig. 7, and Table 4 presents the percentage of mass loss and possible assignments of different groups that decomposed during pyrolysis. The curves comprise of decomposition in three overlapping steps. First step is due to removal of just trapped water and the subsequent second and third steps indicate the decomposition of coordinated water molecules and metal complex respectively. The percentage of mass loss due to decomposition of the metal complex is low (20.16% in **5**; 18.62% in **6**), suggesting low loading of complexes.

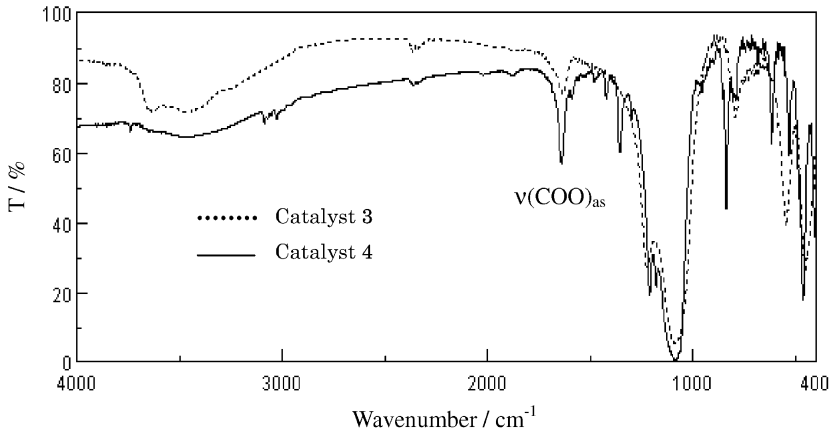

Fig. 3. FT-IR spectral pattern of zeolite–Y encapsulated catalysts $[Co(N\hat{}O)_2]$–Y (**3**) and $[Cu(N\hat{}O)_2]$–Y (**4**).

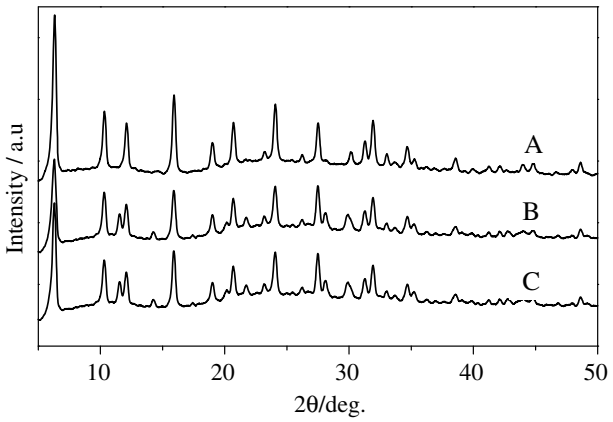

Fig. 4. XRD pattern of (A) H–Y, (B) [Co(N^O)$_2$]–Y (**3**) and (C) [Cu(N^O)$_2$]–Y (**4**).

In order to immobilize metal complexes on a silica surface, it was modified with a common organic functionality 3-aminopropyltriethoxysilane {$(OC_2H_5)_3SiCH_2CH_2CH_2NH_2$}, which gives rise to organically modified silica, designated as aminopropyl silica (AMPS). A preliminary investigation performed by elemental analysis indicates the presence of N (1.22%) and C (3.59%) in AMPS, suggesting the interaction between the organic moiety and the silica surface as pure silica is without C and N. AMPS was further characterized by FT-IR spectroscopy. A comparison of the IR spectra of pure silica as well as AMPS (Fig. 8) reveals that AMPS exhibits all the characteristic bands of 3-aminopropyltriethoxysilane (Table 5), which are not detected in pure silica. These new bands further substantiate the coordination of $(OC_2H_5)_3SiCH_2CH_2CH_2NH_2$ through a Si-bonding site with silica surface [10].

Treatment of AMPS with metal (Co or Cu) followed by 2-pyrazinecarboxylic acid yields the immobilized catalysts **7** and **8** (Scheme 4). The percentages of Co or Cu, N and C are listed in Table 2. The metal/N ratios are comparable with the neat metal complexes, which indicate immobilization of the metal complexes on AMPS. The FT-IR spectra of these catalysts (Fig. 9) exhibit all the characteristic bands of AMPS along with some new bands characteristic for the immobilized metal complexes. The intensities of the characteristic bands of AMPS in the catalysts are relatively weak compared to the parent AMPS. The band due to the $\nu(COO)_{as}$ vibration occurs at 1637 cm^{-1} (in **7**) and 1644 cm^{-1} (in **8**), suggesting a chelating mode of the ligand. These vibrations are almost in same position as that of the corresponding neat complexes **1** and **2** (Fig. 9), which indicates immobilization of the metal complexes on AMPS. The immobilization of the metal complexes on AMPS was further confirmed by a powder X-ray diffraction study (Fig. 10). Similar to the catalysts **3**-**6**, an additional weak peak is detected for both catalysts at 2θ values ~12.04°, indicating immobilization of the metal complexes on the AMPS surface. The DTA and TGA profiles of the catalysts **7** and **8** are presented in Fig 11. Details about the mass loss and possible assignments of the groups lost are illustrated in Table 4. Similar to the catalysts **3**–**6**, a low mass loss percentage corresponding to decomposition of the metal complex is in agreement with the low percentage of metal content obtained for the immobilized complexes.

The actual loading of the metal complex **1** or **2** on the different supports is related to catalytic activity of the supported catalysts

Table 4

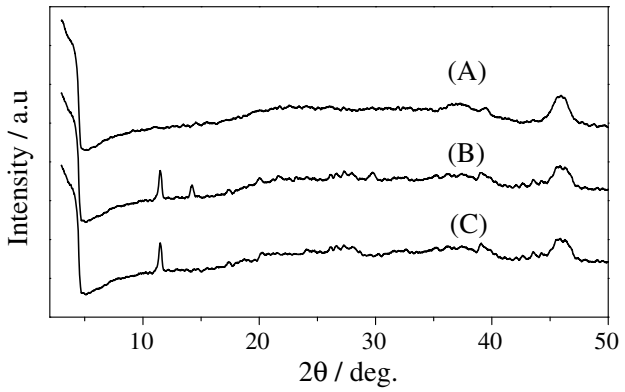

Fig. 6. XRD pattern of (A) parent Al_2O_3, (B) $[Co(N^O)_2]$–Al_2O_3 (**5**) and (C) $[Cu(N^O)_2]$–Al_2O_3 (**6**).

3–**8**. The complex, either **1** or **2**, does not directly interact with the supports. The metal ion loading step was followed by ligand loading. Excess metal ion and also ligand were removed by purification, it is a fact that the metal ion remaining after purification will react with 2 equiv. of the ligands in order to form the metal complex. This indicates that the determination of the metal ion loading on the supported catalysts **3**–**8** is essential, which in turn allows the determination of the catalytic activity in terms of turnover number of the catalysts. The metal ion loading values on the catalysts **3**–**8** are presented in Table 2. The Co loading on the different supports follows the trend zeolite–Y > alumina > silica whereas Cu loading follows the reverse trend under the same experimental conditions. Another important observation is that Cu loading is higher compared to Co loading on each of the supports.

3.2. Catalytic oxidation of cyclohexene using catalysts ***1–8***

Oxidation of cyclohexene to different commercially important products like 1,2-epoxycyclohexane, 2-cyclohexen-1-ol, 2-cyclohexen-1-one and 1,2-cyclohexanediol (Scheme 5) has been investigated by several workers using homogeneous as well as heterogeneous catalysts [1–3,6,9,10,13,20–23]. The catalytic activities of some of these catalysts which are closely related to the investigated ones are presented in Table 6 for a comparison in terms of total conversion of cyclohexene into products. The investigated catalysts **1**–**8** also satisfactorily catalyze the oxidation of cyclohexene in the presence of H_2O_2 as the oxidant. In order to achieve maximum conversion of cyclohexene, the catalytic reactions were carried by varying the reaction temperature and time whilst keeping catalyst amount constant (0.1 g for heterogeneous conditions, 0.035 g for homogeneous conditions). The neat catalyst $[Co(N^O)_2]$ (**1**) and its immobilized catalyst on silica $[Co(N^O)_2]$–AMPS (**7**) were tested as representative catalysts under homogeneous and heterogeneous conditions respectively in order to optimize the conditions. Reaction mixture having cyclohexene

(0.82 g, 10 mmol), catalyst **1** (0.035 g) or catalyst **7** (0.1 g) and 30% H_2O_2 (2.28 g, 20 mmol) in 10 mL acetone were refluxed with stirring at four different temperatures (40, 65, 75 and 80 °C) in order to find a suitable reaction temperature. At 75 °C, the catalysts **1** and **7** show the highest conversion of cyclohexene into products (79.45% by **1** and 90.25% by **7**) with an 8 h reaction time. No further improvement in conversion was obtained at 80 °C. Furthermore, at this reaction temperature, the heterogeneous catalytic mixture became colloidal, making the separation of the catalysts from the reaction mixture difficult. Consequently, 75 °C is considered to be the best suited temperature to carry out the catalytic reactions. Similarly, the representative catalysts exhibit the highest conversion of cyclohexene with a 8 h reaction time, which was selected after carrying out the catalytic reactions for different times, keeping the other conditions as above.

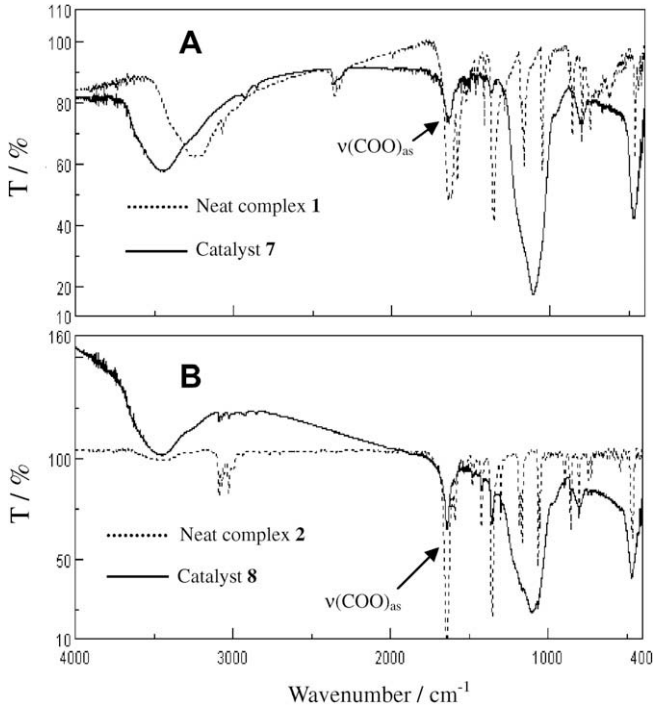

Fig. 9. FT-IR spectra of (A) neat complex **1** and catalyst **7**; (B) neat complex **2** and catalyst **8**.

Applying the optimum reaction conditions (reaction temperature 75 °C, reaction time 8 h, catalyst amount 0.035 g or 0.1 g,

acetone 10 mL), the catalytic potential of all the catalysts were evaluated at three different molar ratios viz. 1:1, 1:2 and 1:3 of cyclohexene to H_2O_2. The catalysts **1** and **2** are homogeneous in nature and dissolved readily in the reaction mixture under the catalytic conditions. The selectivity of various oxidation products and the activity results are presented in Table 7 and Fig. 12. It is clear from the data that for the 1:1 molar ratio reaction between cyclohexene and H_2O_2, a maximum conversion of only 60.14% was shown, by catalyst **8**, which reveals poor catalytic ability of the catalysts. In contrast, all the catalysts exhibit highest efficiency at a 1:2 molar ratio, and a maximum of 90.47% conversion was noted with catalyst **4**. The catalytic ability of the catalysts **1**–**8** at a cyclohexene to H_2O_2 molar ratio of 1:3 is higher than that for the 1:1 molar ratio and the maximum cyclohexene conversion was 84.21% when using catalyst **3**. The most important observation is that compared to the 1:2 molar ratio reaction, the catalytic potential of all the catalysts was reduced remarkably at the 1:3 molar ratio, indicating that a large amount of oxidant is not an essential condition to achieve maximum oxidation. The suppression of conversion for the 1:3 molar ratio reaction may be due to the presence of excess water supplied by H_2O_2 under the catalytic conditions, which blocks the catalysts active sites [6,13,24]. In any molar ratio reaction between cyclohexene and H_2O_2, alumina supported catalysts **5** and **6** exhibit poor catalytic activity compared to the zeolite and silica supported catalysts. Under the optimized reaction conditions, the catalyst [Co(N^O)$_2$]–Al_2O_3 (**5**) shows a maximum of only 37.99% conversion for the 1:2 molar ratio reaction. In general, the selectivity of the products follows the order 2-cyclohexen-1-one > 2-cyclohexen-1-ol > 1,2-cyclohexanediol > 1,2-epoxycyclohexane. The most promising observation is that 2-cyclohexen-1-one is found to be the major product in most of the catalytic reactions. The highest selectivity of 64.16% for 2-cyclohexen-1-one is obtained using the zeolite–Y encapsulated catalyst **4**. Moreover, 1,2-epoxycyclohexane is not a product in some of the catalytic reactions, and it is only formed to a small extent in the remaining catalytic reactions. For the 1:1 molar ratio reaction, a maximum of only 14.46% selectivity of the product 1,2-epoxycyclohexane is obtained using the catalyst [Co(N^O)$_2$]–Al_2O_3 (**5**). Salavati-Niasari [3] reported that epoxidation of cyclohexene by alumina-supported metal complex catalysts occurs effectively in the presence of H_2O_2. It is expected that, under the mentioned reaction conditions, the allylic hydrogen is more reactive than the C=C double bond, irrespective of the supports. Due to this fact the reaction proceeds to yield 2-cyclohexen-1-one as the major product and 1,2-epoxycyclohexane as the minor product in all the catalytic reactions [2,3,9]. For the zeolite–Y supported catalysts **3** and **4**, such allylic oxidation infers that metal complexes **1** or **2** are loaded mainly in the internal pores of the zeolite–Y. The nanospace constraints experienced by complex **1** or **2** located within the pores of the zeolite–Y support suppress the epoxidation pathway and favour allylic oxidation [22]. The heterogeneous catalysts **3**, **4**, 7 and **8** are found to exhibit higher catalytic performance compared to that of the corresponding neat complexes **1** and **2**, mostly due to site isolation of the complexes [1,3]. Another important observation is that performance of the cobalt catalysts towards to cyclohexene oxidation is good compared to the copper catalysts.

Salavati-Niasari et al. reported the highest efficiency by Cu(II), Co(II) and Mn(II) catalysts supported on alumina for oxidation of cyclohexene in dichloromethane solvent [1]. Therefore, in order to investigate the effect of solvent on catalytic performance, the solvent was changed from acetone to dichloromethane whilst keeping the other conditions the same. The catalytic activity of the zeolite encapsulated catalyst **4** in the 1:2 molar ratio reaction of cyclohexene and H_2O_2 is 87. 33%, which is lower than the value of 90.47% obtained using acetone as the solvent. Similarly, the catalytic activity of the alumina supported catalyst **5** reduced from 37.99 to 34.78% when dichloromethane is used as the solvent instead of acetone. The solvent effect has also been investigated

[a] Activity after first reuse.

using a catalyst on a silica support using a 1:2 molar ratio of substrate and oxidant. The catalytic activity of the silica supported catalyst **7** is 86.34% in dichloromethane while it shows 90.25% activity in acetone. In each case, 2-cyclohexen-1-one and 1,2-epoxycyclohexane are found to be the major and minor products respectively, similar to the catalytic reactions run in acetone.

At the end of the heterogeneous reaction, the catalysts were recovered from the reaction mixture and washed thoroughly with solvent. The FT-IR spectral patterns of the recovered catalysts were quite similar to fresh catalysts, suggesting the purity and also the stoichiometry of the recovered catalysts. Under the similar conditions, the activity of the refreshed catalysts **3–8** after first cycle remains nearly the same as fresh catalysts (Table 7). Thus, high catalytic activities as well as other characteristics like stability, recycling ability and operational flexibility make the supported catalysts superior over neat complexes. A comparison of Tables 6 and 7 will justify the suitability of the investigated catalysts in the cyclohexene oxidation reaction.

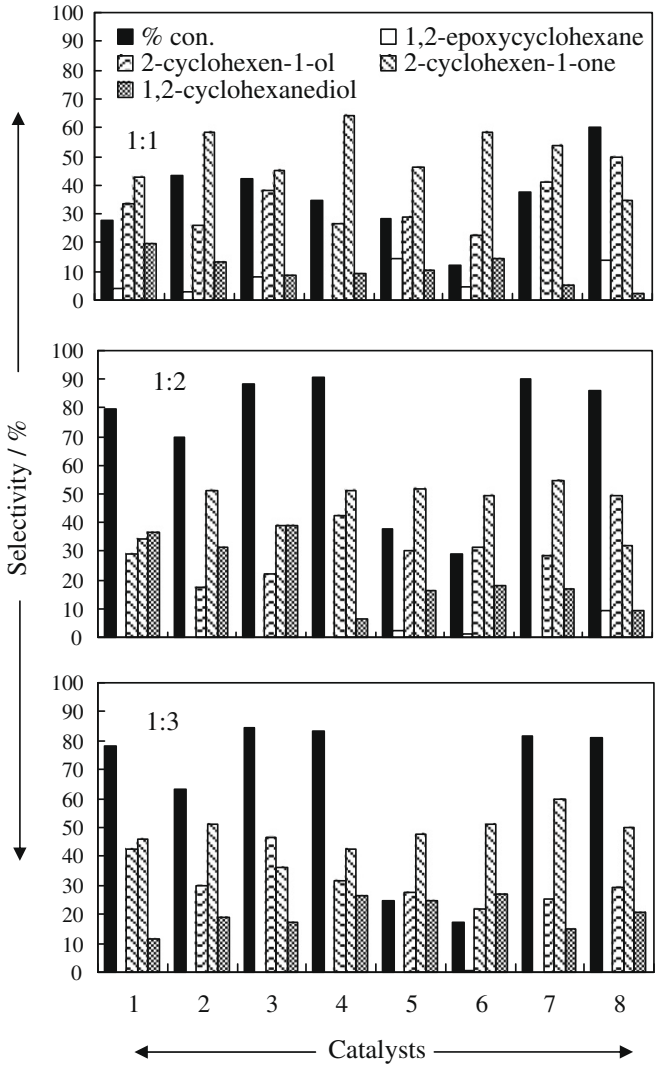

Fig. 12. Oxidation products distribution and total conversion with the catalysts **1–8** in 1:1, 1:2 and 1:3 molar ratio reactions of cyclohexene and H_2O_2.

4. Conclusions

The complexes $[Co(N^O)_2]$ and $[Cu(N^O)_2]$ have been supported on zeolite–Y, alumina and organically modified silica supports and their encapsulation or immobilization have been ensured by different studies. The catalytic activities of the complexes were tested for the oxidation of cyclohexene using H_2O_2 as the oxidant. A maximum of 90.47% cyclohexene conversion with 51.00% selectivity of 2-cyclohexen-1-one has been achieved with the catalyst $[Cu(N^O)_2]$–Y for a 1:2 molar ratio reaction between cyclohexene and H_2O_2. The heterogeneous catalysts $[Co(N^O)_2]$–Y, $[Cu(N^O)_2]$–Y, $[Co(N^O)_2]$–AMPS and $[Cu(N^O)_2]$–AMPS were found to exhibit higher catalytic activity compared to the corresponding neat complexes $[Co(N^O)_2]$ and $[Cu(N^O)_2]$. Oxidation occurs mainly at the allylic site, giving rise to 2-cyclohexen-1-one and 1,2-epoxycyclohexane as the major and minor products, respectively. The high percentage yield of the reactions in the presence of the cobalt complexes compared to the copper complexes seems promising.

Acknowledgements

The authors are thankful to the Tosoh Corporation and Catalytic Society of Japan for supplying zeolite–Y, alumina and silica supports. The authors also wish to record their sincere feelings of appreciation and gratitude to all the reviewers whose comments have helped in publishing this work.

ABSTRACT

The platinum(II) complex [$PtMe_2$(bpy)] (bpy = 2,2′-bipyridine) reacted with a large excess of dihaloalkanes $X(CH_2)_nX$ (n = 1, X = Cl; n = 4, X = Br) to form the platinum(IV) complexes [$PtMe_2X\{(CH_2)_nX\}$(bpy)] (n = 1, X = Cl, **1a**; n = 4, X = Br, **1b**). The reaction of complexes **1a** and **1b** with $SnBr_2$ resulted in insertion of $SnBr_2$ into Pt–X (X = Cl, Br) bond to afford the trihalostannyl complexes [$PtMe_2(SnBr_2X)\{(CH_2)_nX\}$(bpy)] ($n$ = 1, X = Cl, **2a**; n = 4, X = Br, **2b**). The synthesis of such trihalostannylplatinum(IV) complexes is reported for the first time. The complex **2a** was decomposed in CH_2Cl_2 solution and single crystals of [$PtBr_2$(bpy)] (**3a**) were obtained. The X-ray structure determination of **3a** revealed a new polymorphic form of [$PtBr_2$(bpy)]. The molecules undergo a remarkable stacking along the *b*-axis to form a zigzag Pt···Pt···Pt chain containing both short (3.799 Å) and long (5.175 Å) Pt···Pt separations through the crystal. The crystal structure is compared to that of the yellow modification of [$PtBr_2$(bpy)].

1. Introduction

Polymetallic complexes of tin and platinum are of particular interest because of their potential use in many catalytic processes such as olefin hydrogenation, isomerization and hydroformylation [1]. In this respect, much attention has been directed to the insertion of $SnCl_2$ into Pt–Cl bond of the dichloroplatinum(II) complexes [1–4]. Many studies on the role of $SnCl_2$ "co-catalyst" were reported, but its role is still uncertain [5]. There is a limited range of reported Pt–Sn complexes containing a mixture of halides at the same time [6,7]. We have recently reported the reaction of *cis* and *trans*-[$PtCl_2(SMe_2)_2$] with $SnBr_2$ to form *cis* and *trans*-[$PtBr_4(SMe_2)_2$] in which $SnBr_2$ acts as both oxidizing and bromination agent [8]. There are already several interesting examples of organoplatinum(IV) complexes containing stannyl group, for example, the reaction of trialkylplatinum(IV) complexes [$PtMe_2Cl$(R)(bpy)] (R = allyl, Me, benzyl) with $SnCl_2$ results in the formation of [$PtMe_2(SnCl_3)$(R)(bpy)] or the oxidative addition of tin(IV) halides to dimethylplatinum(II) complexes which yields [$PtMe_2(SnCl_3)Cl$(NN)], in which NN = bpy or bu_2bpy (bu_2bpy = 4, 4′-di-*tert*-butyl-2,2′-bipyridine) [9–11].

Dimethylplatinum(II) complexes undergo oxidative addition with different reagents, e.g. alkyl halides and dihaloalkanes leading to stable dimethylplatinum(IV) complexes [12–14]. These complexes have been shown to be precursors in the synthesis of new materials with novel properties [12]. There is no report on the reaction of organoplatinum(IV) complexes with $SnBr_2$. In the present study, the insertion of $SnBr_2$ into Pt–X (X = Cl, Br) bond of chloro and bromoalkyl complexes of dimethylplatinum(IV) are investigated.

There is much current interest in the formation of linear chains of square planar diimineplatinum(II) complexes in the solid state. The resulting stacks are often particularly topical due to the remarkable spectroscopic properties. These complexes are polymorphic and can be classified into three categories; monomers with no Pt···Pt interaction and two types of linear chains with platinum centers stacked along an axis to form dimers by predominantly either by Pt···Pt or π···π interaction [15]. It has been known that [$PtCl_2$(bpy)] forms both yellow and red solids. The red color of the latter is due to the very short separations (3.45 Å) while in the former, the molecules are widely separated [16]. We have recently reported the crystal structure of [$PtBr_2$(bpy)] which was isomorphous to the yellow modification of [$PtCl_2$(bpy)] [17]. We now obtained new yellow crystals of [$PtBr_2$(bpy)] adopting a third form, which is different from the red and yellow forms of [$PtCl_2$(bpy)].

2. Experimental

2.1. General remarks

All procedures were performed under an atmosphere of argon. Diethyl ether was distilled from sodium/benzophenone ketyl.

doi:10.1016/j.poly.2008.11.008

Acetone and the other reagents were used without further purification. Elemental analyses were performed by a Heraus CHN or Perkin–Elmer 2400 II elemental analyzer. NMR data were recorded using Bruker Avance DRX 500 or DPX 250 MHz spectrometers. All the chemical shifts and coupling constants are reported in ppm and Hz, respectively, with respect to residual solvent signal. The complex [$PtMe_2$(bpy)] was prepared according to the literature [18].

2.2. Synthesis of cis and trans-[$PtMe_2Cl(CH_2Cl)$(bpy)], **1a**

This complex was synthesized by a modified procedure of Kuyper [19]. A solution of [$PtMe_2$(bpy)] (60 mg, 0.16 mmol) in dichloromethane (15 mL) was stirred at room temperature for 24 h. The red solution turned pale yellow. The solvent was removed under the vacuum and the resulting pale yellow solid was washed with diethyl ether. Yield: 90%; m.p. 216–8 °C. *Anal.* Calc. for $C_{13}H_{16}Cl_2N_2Pt$: C, 33.5; H, 3.5; N, 6.0. Found: C, 33.5; H, 3.4; N, 6.0%. 2.3. Synthesis of [$PtMe_2Br\{(CH_2)_4Br\}$(bpy)], **1b**

A solution of [$PtMe_2$(bpy)] (0.06 g, 0.16 mmol) in acetone (40 mL) was treated with an excess of 1,4-dibromobutane (0.5 mL). The reaction mixture was stirred for 8 h after which time a pale yellow solution had developed. The solvent was removed under vacuum and the resulting off white-yellow solid was crystallized from CH_2Cl_2/diethyl ether solution. Yield: 90 %; m.p. 205–7 °C. *Anal.* Calc. for $C_{16}H_{22}Br_2N_2Pt$: C, 32.2; H, 3.7; N, 4.7. Found: C, 32.0; H, 3.6; N, 4.8%. NMR data (250 MHz, $CDCl_3$): δ (^{1}H) (*trans* isomer) 1.38 [s, 6H, ^2J(PtH) = 70.1 Hz, Pt–Me]; 1.50 [t, 2H, ^2J(PtH) = 43.3 Hz, ^3J(HH) = 7.0 Hz, $PtCH_2$]; 0.63 [m, 2H, $PtCH_2CH_2$]; 1.27 [m, 2H, CH_2CH_2Br]; 3.08 [t, 2H, ^3J(HH) = 6.8 Hz, CH_2Br]; bpy protons 7.61 [t, $^4J(H^5H^3)$ = 0.9 Hz, H^5]; 7.97 [t, $^3J(H^4H^5)$ = 7.5 Hz, H^4]; 8.24 [d, $^3J(H^3H^4)$ = 8.1 Hz, H^3]; 8.89 [d, $^3J(H^6H^5)$ = 5.5, ^3J(PtH) = 12.0 Hz, H^6]; (*cis* isomer) 0.49 [s, 3H, ^2J(PtH) = 75.0 Hz, Pt–Me]; 1.41 [s, 3H, ^2J(PtH) not observed, Pt–Me]; 3.55 [t, 2H, ^3J(HH) = 7.0 Hz, CH_2Br]; δ (^{13}C) (*trans* isomer) −3.5 [s, ^1J(PtC) = 644 Hz, Pt–CH_3]; 17.9 [s, ^1J(PtC) = 697 Hz, Pt–CH_2]; 33.4 [s, ^2J(PtC) = 90 Hz, $PtCH_2CH_2$]; 28.7 [s, ^3J(PtC) = 29 Hz, CH_2CH_2Br]; 33.8 [s, ^4J(PtC) = 9 Hz, CH_2Br]; bpy carbons 155.0 (C_2); 123.8 (C_3); 139.1 (C_4); 127.0 (C_5); 147.1 (C_6).

2.4. Synthesis of cis and trans-[$PtMe_2(SnBr_2Cl)(CH_2Cl)$bpy)], **2a**

To a solution of a mixture of *cis* and *trans*-[$PtMe_2\{CH_2Cl\}$(bpy)Cl] (70 mg, 0.15 mmol) in dicholoromethane (10 mL) was added a solution of $SnBr_2$ (47 mg, 0.17 mmol) in THF (1 mL). The reaction mixture was stirred for 2 h under Ar atmosphere. The orange solution turned pale yellow. The solvent was removed at reduced pressure leaving a yellow solid. This was washed with *n*-hexane. Yield: 75 %; m.p. 134 °C. *Anal.* Calc. for $C_{13}H_{16}Br_2Cl_2N_2PtSn$: C, 21.0; H, 2.2; N, 3.8. Found: C, 21.1; H, 2.5; N, 3.5%. NMR data (500 MHz, $CDCl_3$): δ (^{1}H) (*trans* isomer) 1.45 [s, 6H, ^2J(PtH) = 68.9 Hz, ^3J(SnH) = 15.2 Hz, Pt–Me]; 3.56 [s, 2H, ^2J(PtH) = 51.5 Hz, ^3J(SnH) not observed, $PtCH_2$]; bpy protons 7.66 [t, $^3J(H^5H^4)$ = 6.2 Hz, H^5]; 8.08 [t, $^3J(H^4H^5)$ = 7.8 Hz, H^4]; 8.23 [d, $^3J(H^3H^4)$ = 8.0 Hz, H^3]; 8.90 [d, $^3J(H^6H^5)$ = 6.0 Hz, ^2J(PtH) = 20.0, H^6]; (*cis* isomer) 0.82 [s, 3H, ^2J(PtH) = 75.3 Hz, Pt–Me, *trans* to $SnBr_2Cl$]; 1.46 [s, 3H, ^2J(PtH) = 68.6 Hz, Pt–Me, *trans* to N]; 3.38 [s, 2H, ^2J(PtH) = 44.3 Hz, $PtCH_2$]; 9.39 [d, $H^{6'}$]. Single crystals of [$PtBr_2$(bpy)], **3a,** suitable for X-ray crystallographic study were obtained when the complex **2a** was remained in dichloromethane solution for two weeks.

2.5. Synthesis of cis and trans-[$PtMe_2(SnBr_3)\{(CH_2)_4Br\}$(bpy)], **2b**

Following the same procedure as for the preparation of **2a,** this was prepared similarly using [$PtMe_2Br\{(CH_2)_4Br\}$(bpy)] (78 mg, 0.13 mmol) and $SnBr_2$ (40 mg, 0.14 mmol). Yield: 70%; m.p. 139–140 °C. *Anal.* Calc. for $C_{16}H_{22}Br_4N_2PtSn$: C, 21.9; H, 2.5; N, 3.2. Found: C, 21.1; H, 2.5; N, 2.9%. ^{1}H NMR data (500 MHz, $CDCl_3$): δ (^{1}H) (*trans* isomer) 1.41 [s, 6H, ^2J(PtH) = 69.8 Hz, ^3J(SnH) = 23.9 Hz, Pt–Me]; 1.57 [m, 2H, $PtCH_2$]; 0.68 [m, 2H, $PtCH_2CH_2$]; 1.22 [m, 2H, CH_2CH_2Br]; 3.14 [t, 2H, ^3J(HH) = 6.7 Hz, CH_2Br]; bpy protons 7.67 [t, $^3J(H^5H^4)$ = 6.5 Hz, $^4J(H^5H^3)$ = 0.9 Hz, H^5]; 8.08 [t, $^3J(H^4H^5)$ = 8.1 Hz, H^4]; 8.24 [d, $^3J(H^3H^4)$ = 8.1 Hz, H^3]; 8.97 [d, $^3J(H^6H^5)$ = 5.5 Hz, ^3J(PtH) = 15.0 Hz, H^6]; (*cis* isomer) 0.54 [s, 3H, ^2J(PtH) = 74.4 Hz, ^3J(SnH) = 20.4 Hz, Pt–Me]; 1.45 [s, 3H, ^2J(PtH) not observed, Pt–Me]; 3.58 [t, 2H, ^3J(HH) = 7.1 Hz, CH_2Br]; δ (^{119}Sn) in $CH_2Cl_2 \cdot THF \cdot CDCl_3$: −485 [s, $^1J(^{195}Pt–^{119}Sn)$ = 22355 Hz].

2.6. X-ray structure determination

A yellow plate shaped crystal, air stable at room temperature was used for the crystallographic measurements. The measurements on crystals of **3a** were performed on a Bruker APEX CCD area detector using Mo Kα radiation (λ = 0.71073 Å) covering a whole sphere in reciprocal space. Intensities were corrected for Lorentz and polarization effects. An empirical absorption correction was applied using SADABS based on the Laue symmetry of the reciprocal space [20]. The structure was solved by direct methods and refined against F^2 with a Full-matrix least-squares algorithm using the SHELXTL-plus V 6.10 software package [21]. The hydrogen atoms were treated using appropriate riding models. The crystallographic data are listed in Table 1.

3. Results and discussion

3.1. Oxidative addition of dihaloalkanes to [$PtMe_2$(bpy)]

The reaction of [$PtMe_2$(bpy)] with a large excess of dihaloalkanes $X(CH_2)_nX$ (n = 1, X = Cl; n = 4, X = Br), as illustrated in Scheme 1, gave the platinum(IV) products with a general formula [$PtMe_2X\{(CH_2)_nX\}$(bpy)] (n = 1, X = Cl, **1a**; n = 4, X = Br, **1b**) in high yield. Complex [$PtMe_2Cl(CH_2Cl)$(bpy)], **1a**, was characterized as described elsewhere [19,22]. NMR data indicate that the complex **1a** has formed as a mixture of *cis* and *trans* isomers in an approximately 1.2:1 ratio.

The complex [$PtMe_2Br\{(CH_2)_4Br\}$(bpy)], **1b**, was fully characterized by ^{1}H and ^{13}C NMR spectroscopy. NMR data show that complex **1b** is predominately formed as *trans* isomer with a trace amount of the *cis* isomer. The ^{1}H NMR spectrum of complex **1b** in $CDCl_3$ solution contained a signal at δ = 1.38 accompanying with platinum satellites with ^2J(Pt–H) = 70.1 Hz which was assigned to the protons of the methyl groups of the *trans* isomer of complex **1b**, whereas the less symmetrical complex (*cis* isomer) gave two signals at δ = 0.49 with ^2J(Pt–H) = 75.0 Hz and δ = 1.41 which its platinum satellites could not be resolved. The characteristic triplet

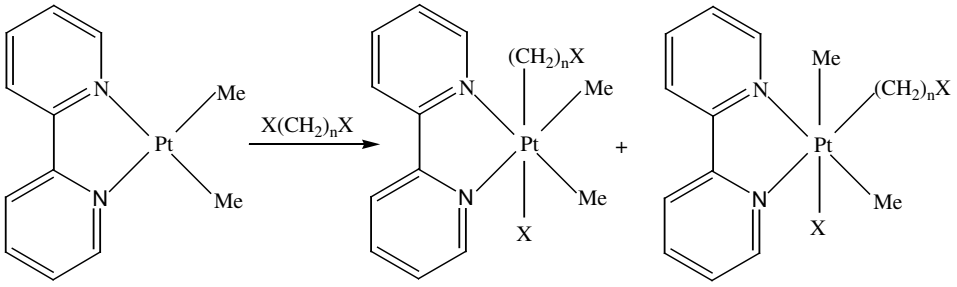
in the region δ = 3.08 with ^3J(HH) = 6.8 Hz was assigned to the protons of CH_2Br while the $PtCH_2$ protons centered as a triplet at δ = 1.50 with ^2J(Pt–H) = 43.3 Hz. Furthermore, the $PtCH_2CH_2$ and CH_2CH_2Br protons appeared as the multiplets at δ = 0.63 and 1.27, respectively. A small triplet at δ = 3.55 with ^3J(HH) = 7.0 Hz was assigned tentatively to the CH_2Br resonance of the trace of the *cis* isomer. The ^{13}C NMR spectrum of the *trans* isomer of complex **1b** shows a signal at δ = −3.5 with diagnostic ^1J(Pt–C) = 644 Hz in agreement with the symmetry of the product while the carbon atom of Pt–CH_2 group resonated at δ = 17.9 with ^1J(Pt–C) = 697 Hz. The remaining assignments for haloalkyl chain are made on the basis of the magnitude of Pt–C coupling constants, assuming that the coupling decreases the further the carbon is from the platinum. The assignment for bpy ligand was made according to the closely related analogues [13–14]. Full data for **1a**–**1b** are collected in Section 2.

3.2. Insertion of $SnBr_2$ into Pt–X (X = Cl, Br) bond of *1a*–*1b*



Addition of a tetrahydrofurane solution of $SnBr_2$ to a dichloromethane solution of **1a** or **1b** gave complexes **2a** or **2b**, respectively, as yellow solids (Eq. (1)). NMR data show that complex **2a** exists as a mixture of *cis* and *trans* isomers in an approximately 1:7 ratio while in the case of **2b**, only a trace of the *cis* isomer was observed. It is probable that the steric effects due to the $SnBr_2X$ and $(CH_2)_nX$ ligands do not favor them to be located in *cis* position to each other. Therefore, in the case of **2a**, a mixture of isomers are obtained with the *trans* isomer being formed predominantly while for **2b** having two bigger ligands $SnBr_3$ and $(CH_2)_4Br$, only a trace of the *cis* isomer is formed.

$$\mathbf{1a{-}1b} \xrightarrow{SnBr_2} cis \text{ and } trans - [PtMe_2(SnBr_2X)\{(CH_2)_nX\}(bpy)] \quad \begin{matrix} n = 1, X = Cl & \mathbf{2a} \\ n = 4, X = Br & \mathbf{2b} \end{matrix} \tag{1}$$

The complex **2a** was identified by elemental analysis. The complex **2a** was slowly decomposed in $CDCl_3$ solution. The ^{1}H NMR spectrum of a freshly prepared solution of complex **2a** contained a singlet at δ = 1.45 accompanying with platinum satellites ^2J(Pt–H) = 68.9 with ^3J(SnH) = 15.2 Hz which was assigned to the protons of the methyl groups of *trans*-[$PtMe_2(SnBr_2Cl)(CH_2Cl)$(bpy)], **2a**. The *cis* isomer gave two singlets at δ = 0.82 and 1.46 showing platinum satellites with ^2J(Pt–H) = 75.3 (*trans* to $SnBr_2Cl$) and 68.6 Hz (*trans* to N), respectively. This confirms that the N ligating atoms of bpy ligand has a higher *trans* influence than the $SnBr_2Cl$ group. The CH_2 protons of the *cis* and *trans* isomers of **2a** appeared as singlets at δ = 3.38 and 3.56 ppm with ^2J(Pt–H) = 44.3 and 51.5 Hz, respectively. The complex **2a** was decomposed in CH_2Cl_2 solution and single crystals of [$PtBr_2$(bpy)] (**3a**) were obtained after two weeks.

The complex **2a** has a very low solubility and decomposes in polar solvents, e.g. acetone or nitromethane, and thus no satisfactory ^{119}Sn NMR spectrum could be obtained.

The identity of complex **2b** was established by elemental analysis, ^{1}H and ^{119}Sn NMR spectroscopy. Complex **2b** has very low solubility in different solvents and so its ^{119}Sn NMR spectrum was obtained using an *in situ* solution. The NMR sample was prepared directly in the NMR tube by adding a tetrahydofurane solution of $SnBr_2$ to a dichloromethane solution of **1b** with an approximately 1:1.1 mole ratio of Pt:Sn. The ^{119}Sn NMR spectrum of **2b** reveals a central resonance at δ = −485 flanked by ^{195}Pt satellites with $^1J(^{195}Pt-^{119}Sn)$ = 22 355 Hz which is very close to the reported value for [$PtClMe_2(SnCl_3)(bu_2bpy)$] ($\delta$ = −402 with $^1J(^{195}Pt-^{119}Sn)$ = 25 864 Hz) [11]. The presence of platinum satellites in the ^{119}Sn NMR indicates that the platinum–tin bond is maintained in solution. Moreover, there were several weak signals at δ = −56, −57 and −89 ppm which are tentatively assigned to the halogen scrambling between $SnBr_2$ and chlorinated solvents. This complex

represents the first example of tribromostannylplatinum(IV) complex which has been prepared through $SnBr_2$ insertion into the Pt–Br bond.

3.3. Description and discussion of the crystal structure of *3a*

Selected bond lengths and angles are given in Table 2. The crystal structure of complex **3a,** which shows that the platinum center adopts the expected square planar geometry, is given in Fig. 1. The average deviation from the coordination plane is only 0.01 Å. In the crystal structure of complex **3a** (form **A**), two inequivalent Pt–Br distances (2.411 and 2.413 Å) and two inequivalent Pt–N distances (2.017 and 2.021 Å) are noted in contrast to the yellow modification of [$PtBr_2$(bpy)] (form **B**) which has 2 equiv. Pt–Br and 2 equiv. Pt–N bonds (2.414 and 2.017 Å, respectively) [17]. The Pt–N bond lengths are between 2.029 Å in [PtI_2(bpy)] [23] and 2.001 Å in the red form of [$PtCl_2$(bpy)] [24] or 2.006 and 2.011 Å in the yellow form of [$PtCl_2$(bpy)] [16]. This is in accordance with the *trans* influence of halogens which increases in the order of Cl < Br < I [25].

The N–Pt–N and Br–Pt–Br angles are 80.48 and 88.80°, respectively, which are consistent with the previously reported values for form **B** which are 80.54 and 88.93°, respectively [17]. The platinum–platinum vector in the form **A** inclines only by 25.1° with respect to the perpendicular of the coordination plane but it is inclined by 48.6° in the form **B.** This is the major difference of both forms and leads to significantly different Pt–Pt and bpy–bpy distances. Interestingly, in the new polymorph **A**, the flat molecules stack in the *b* direction in a head to tail fashion with two different Pt···Pt distances (see Fig. 2). In this arrangement, the short Pt···Pt distance is 3.80 Å. As mentioned before, the platinum atoms are not placed orthogonal on top of one another. Instead of they are shifted 1.19 Å in the direction towards the bipyridine ligand and 0.58 Å sidewards. Most of the reported values for Pt···Pt interaction is in the range of 3.09–3.40 Å [24]. The Pt···Pt separation is too long to support a significant metal–metal interaction. The corresponding separation between the parallel bipyridine ligand planes is 3.27 Å. However, the bipyridine moieties are anti to each other and they are not overlapping. The second Pt···Pt distance is much longer (5.175 Å). In return for these stacking contacts, there

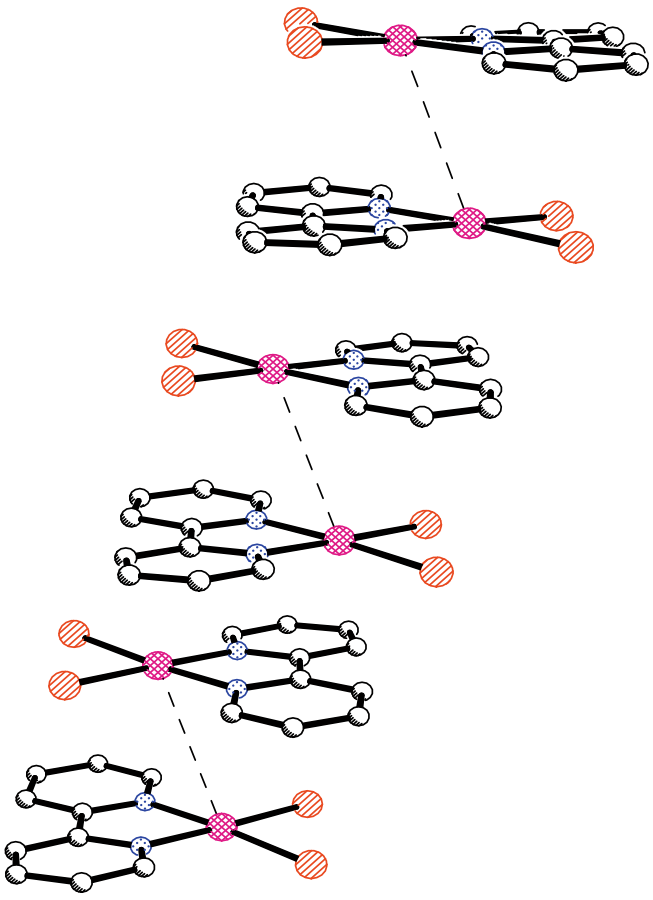

Fig. 2. Crystal packing of [$PtBr_2$(bpy)] (**3a**), the stacking occurs along the *b*-axis.

are partially overlapping bipyridine groups with a distance between the parallel planes of 3.640 Å. In the form **B**, there was a repeat of platinum units with symmetry equivalent contacts, stacking along the crystallographic *c* axis. Moreover, the distances between two planes were 3.400 Å and the Pt centers were 5.164 Å apart [17]. The modification of complex [$PtBr_2$(bpy)], presently investigated, has a crystallographic density (3.01 g/cm^3) which is slightly lower than that of the reported value of form **B** (3.14 g/cm^3) which is consistent with the concept that the form

A has a less efficient mode of packing compared to the form **B**. The red form [$PtCl_2$(bpy)] also has a lower density (D_{calc} = 2.56 g/cm^3) as compared to the yellow form (D_{calc} = 2.65 g/cm^3). It was found that the red form has a lower stability compared to the yellow form and could easily be converted to the latter at room temperature [16,24].

The interaction between bpy ligands is preferred in the yellow form of [$PtCl_2$(bpy)] but in the red form, interaction between platinum atoms is privileged [16,24]. It has been known that the ligand electronics and sterics play the significant roles in Pt···Pt stacking [26]. The formation of a short Pt···Pt distance in form **A** is probably inhibited due to the bromine ligands being rather bulkier than chlorine atoms.

Acknowledgements

We thank the Science Research Council of K.N. Toosi University of Technology for financial support. We also wish to thank Johnson Matthey for a generous loan of platinum salt.

Appendix A. Supplementary data

CCDC 698981 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.11.008.

ABSTRACT

The novel pyrazole-containing tetradentate ligand 2,2′-bis[[(3,5-dimethylpyrazol-1-yl)methyl]amino]-1,1′-biphenyl (N_4-mpz), **1**, was synthesized and three Cu(II) complexes, **2**–**4**, were prepared from this compound. These complexes were characterized by a combination of elemental analysis, FAB-MS and electrochemistry and were shown to have the structure of [Cu(N_4-mpz)(Pz)]X_2 where X = BF_4 or ClO_4 or [Cu(N_4-mpz)(Cl)]Cl. The X-ray structure of [Cu(N_4-mpz)(Pz)] $(ClO_4)_2 \cdot CH_3OH$, **2**, was determined and it showed the Cu(II) coordinated by the four nitrogen donors from the ligand along with an exogenous pyrazole donor that had been extracted from another molecule of the ligand. Cyclic voltammetry studies indicated that the complexes undergo quasi-reversible one-electron reductions in acetonitrile at potentials between 396 and 422 mV versus Ag/AgCl.

1. Introduction

Defining the geometry around a metal ion by using the steric and electronic aspects of ligand sets is a powerful way to generate new and interesting metal complexes. Prudent choice of the electronic and steric features of the donor sets can lead to an immense assortment of metal complexes. We currently are interested in tetradentate ligands as they can be designed from a tremendous variety of motifs and can lead to a vast number of different structures. Using tetradentate ligands, four coordinate metal complexes can be produced that range from tetrahedral to square planar while five-coordinate species cover the spectrum from square pyramidal to trigonal bipyramidal geometries. Much of our inspiration for the preparation of these complexes comes from the variety of structures found in biological systems. As one example, Cu(II) complexes coordinated to multidentate heterocyclic amine donors are found in the type 3 copper proteins hemocyanin and tyrosinase [1–4]. Through the preparation of multidentate ligands, numerous complexes have been prepared and their properties compared to the biological systems [5–7].

We particularly are interested in exploiting the properties of the biphenyl moiety in designing tetradentate ligands as these ligands can be designed to force metal ions into specific geometries in their resultant metal complexes [8]. In the parent biphenyl, the two aromatic rings are not co-planar but rather have a dihedral angle between the rings of 42° [9]. This will force the substituents on the adjacent rings out of plane and any coordinated metal ion will become more tetrahedral-like and less planar-based. Since metals which have Jahn–Teller distortions present (such as Cu(II)) prefer planar-based geometries, complexes formed from these biphenyl-based ligands with metals such as Cu(II) will have to balance the tension between the preferences of the ligand set with those of the metal ion.

We are involved in a systematic study of the impact of structural changes on the physical and chemical properties of synthetic Cu(II) complexes in order to better understand these natural systems [10–13]. We published the results obtained for a biphenyl-based ligand with N_2S_2 donors that spontaneously reduced Cu(II) to Cu(I) upon complexation while a similar N_4 ligand remained in the Cu(II) form [11]. These results confirmed that in order for the spontaneous reduction to occur, the presence of the sulfur donors and the biphenyl rings were essential. We wanted to explore further this premise so we have prepared other tetradentate biphenyl-based ligands with a variety of donor sets. In this work, we report the synthesis of the new ligand, 2,2′-bis[[(3,5-dimethylpyrazol-1-yl)methyl]amino]-1,1′-biphenyl (N_4-mpz). The synthesis and characterization of Cu(II) complexes from this ligand of the type [Cu(N_4-mpz)(Pz)]X_2 where X = BF_4 or ClO_4 and [Cu(N_4-mpz)(Cl)]Cl are presented along with their spectroscopic and electrochemical properties. The molecular structure of [Cu(N_4-mpz)(Pz)]

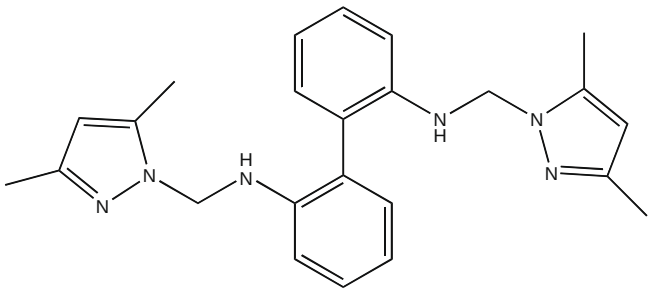

Fig. 1. N_4-mpz ligand.

$(ClO_4)_2 \cdot CH_3OH$ has been determined and comparisons to the pyridine analog explored (Fig. 1).

2. Experimental

Unless otherwise noted, all solvents and reagent grade starting materials were used as received from commercial sources (Aldrich/Sigma). The solvents used for electrochemistry (methanol and acetonitrile) were spectroscopic grade from Aldrich and were dried using activated molecular sieves. Elemental analyses were performed by Oneida Research Services. $^1H/^{13}C$ NMR spectra were recorded on a Varian FT-NMR spectrometer running at 400 MHz. FAB-MS was run at the Midwest Center for Mass Spectrometry in Lincoln, NE.

Cyclic voltammetry (CV) and differential pulse voltammetry (DPV) data were collected using a PAR Model 283 potentiostat and PowerCV electrochemical analysis software. The three-electrode system consisted of a glassy carbon disc electrode, a platinum wire counter electrode and an Ag/AgCl reference electrode (BAS, West Lafayette, IN). The electrodes were polished with alumina on microcloth pads, washed with distilled water, sonicated for five minutes in water and washed with acetone. All solutions were 1–2 mM in **2**–**4** using spectroscopic grade methanol (Aldrich, dried with activated molecular sieves) that contained 100 mM tetrabutylammonium hexafluorophosphate (TBAH, 99%, Aldrich) as the supporting electrolyte. Prior to scanning, all solutions were deoxygenated with methanol-saturated argon for roughly 10 min. All potentials were scaled to the Ag/AgCl electrode (+0.194 V from NHE). Peak currents and peak potentials were estimated with the PowerCV peak analysis software. Using this electrode system, the $E_{1/2}$ of ferrocene was 0.45 V (CH_3CN/0.1 M TBAH).

Caution: Although there were no incidents in our laboratory, transition metal perchlorates may explode violently. They should be prepared in small quantities and handled with care.

2.1. Preparation of 2,2′-bis[[(3,5-dimethylpyrazol-1-yl)-methyl]amino]-1,1′-biphenyl (**1**)

To 2.0 g (15.8 mmol) of 1-hydroxymethyl(3,5-dimethyl)pyrazole in 100 ml of acetonitrile was added 1.396 g (7.92 mmol) of 2,2′-diaminobiphenyl. The solution was stirred at room temperature for 72 h. The solution was reduced under reduced pressure. The resultant oil was crystallized from ethyl acetate/hexanes to give white crystals which were collected by filtration and washed with cold hexanes. Yield, 2.18 g (68.8%), m.p. 106–107 °C. ^1H NMR (400 MHz, $CDCl_3$); δ 2.10 (s, 6H), 2.11 (s, 6H), 4.20 (broad s, 2H), 5.32 (d, 4H), 5.72 (s, 2H), 6.83–7.23 (m, 8H). ^{13}C NMR (400 MHz, $CDCl_3$); δ 149.0, 146.2, 140.3, 128.8, 128.5, 118.2, 117.8, 115.3, 103.2, 50.2, 17.3, 14.3. *Anal.* Calc. for $C_{24}H_{28}N_6$: C, 71.97; H, 7.06; N, 20.97. Found: C, 71.64; H, 6.88; N, 20.68%.

2.2. Preparation of $[Cu(N_4\text{-mpz})(Pz)](ClO_4)_2 \cdot CH_3OH$ (**2**)

To 0.10 g (0.25 mmol) of **1** in 10 ml of MeOH was added a solution of 0.0925 g (0.25 mmol) of $Cu(ClO_4)_2 \cdot (H_2O)_6$ in 10 ml of MeOH. The mixture immediately turned green. The solution was cooled to 0° from which green crystals appeared overnight. The crystals were collected and washed with cold MeOH. Yield, 0.075 g (38.0%). *Anal.* Calc. for $C_{30}H_{39}Cl_2CuN_8O_9$: C, 45.60; H, 4.99; N, 14.17; Cu, 8.04. Found: C, 45.93; H, 5.15; N, 13.88, Cu, 8.22%. FAB-MS (*m*/*z*, %): 562 (26), 463 (68), 367 (100), 317 (15), 271 (66), 209 (10), 159 (24).

2.3. Preparation of $[Cu(N_4\text{-mpz})(Pz)](BF_4)_2 \cdot CH_3OH$ (**3**)

To 0.10 g (0.25 mmol) of the N_4-mpz ligand in 10 ml of MeOH was added a solution of 0.086 g (0.25 mmol) of $Cu(BF_4)_2 \cdot (H_2O)_6$ in 10 ml of MeOH. The mixture immediately turned green. The solution was cooled to 0° from which green crystals appeared over 48 h. The crystals were collected and washed with cold MeOH. Yield, 0.079 g (41.5%). *Anal.* Calc. for $C_{30}H_{39}B_2CuF_8N_8O$: C, 47.10; H, 5.15; N, 14.64; Cu, 8.31. Found: C, 47.50; H, 5.22; N, 14.71; Cu, 8.57%. FAB-MS (*m*/*z*, %): 646 (12), 550 (20), 463 (68), 366 (74), 307 (30), 271 (46), 180 (18), 154 (100).

2.4. Preparation of $[Cu(N_4\text{-mpz})(Cl)]Cl$ (**4**)

To 0.10 g (0.25 mmol) of the N_4-mpz ligand in 10 ml of MeOH was added a solution of 0.043 g (0.25 mmol) of $CuCl_2 \cdot 2H_2O$ in 10 ml of MeOH. The mixture immediately turned pale green. The solution was cooled to 0° from which green crystals appeared over 7 days. The crystals were collected and washed with cold MeOH. Yield, 0.049 g (36.5%). *Anal.* Calc. for $C_{24}H_{28}Cl_2CuN_6$: C, 53.88; H, 5.29; N, 15.70; Cu, 11.88. Found: C, 53.65; H, 5.20; N, 15.53; Cu, 12.03%. FAB-MS (*m*/*z*, %): 498 (38), 463 (45), 367 (62), 271 (23), 154 (100).

2.5. X-ray crystallographic analysis

Single crystals of compound **2** were mounted on quartz capillaries by using paratone oil and were cooled in a nitrogen stream on the diffractometer. Data were collected on a Bruker P4 diffractometer with an APEX area detector. Peak integrations were performed with the Bruker SAINT software package. Absorption corrections were applied using the program SADABS. Space group determinations were performed by the program XPREP. The structure was solved by direct methods and refined with the SHELXTL software package [14]. Hydrogen atoms were fixed at calculated positions or located from difference maps and refined with isotropic thermal parameters, and all non-hydrogen atoms were refined anisotropically unless otherwise noted.

3. Results and discussion

Pyrazole donors have found extensive use in a variety of multidentate ligands coordinated to metal ions [15,16]. The ligand 2,2′-bis[[(3,5-dimethylpyrazol-1-yl)methyl]amino]-1,1′-biphenyl (N_4-mpz) was synthesized using the reaction between a primary amine and 1-hydroxymethyl(3,5-dimethyl)pyrazol-1-ylmethyl. In this case, only one pyrazolylmethylene arm adds to each 1° amine probably as a result of the precipitation of the product as it is formed under the reaction conditions used. Further condensation of the N_4-mpz ligand with 2-picolylchloride or other aromatic amines to give N_6 ligands has been successful and will be reported elsewhere [17]. The ligand has been characterized by ^1H and ^{13}C

NMR and elemental analysis and the data is consistent with the formulated structure.

The copper complexes **2**–**4** were prepared by treating the N_4-mpz ligand with the appropriate copper salt. For complex **4**, elemental and mass spectral analyses data were consistent with the anticipated structure, [Cu(N_4-mpz)(Cl)]Cl. This was not the case for complexes **2** and **3** so single crystals of complex **2** were grown and its X-ray structure solved (vide infra). The elemental analysis and mass spectra were consistent with the formulation of the complexes as [Cu(N_4-mpz)(Pz)]X_2 where X = BF_4 or ClO_4 with an additional pyrazole donor coordinated to the copper in complexes **2** and **3**.

In the FAB-MS, there are many peaks that are diagnostic for the anticipated structures. For complex **2**, the highest mass peak is found at 562*m*/*z* which corresponds to $[Cu(N_4\text{-mpz})^{2+}](ClO_4)^-$. A prominent peak is found at 463*m*/*z* which corresponds to [Cu(N_4-mpz)$^+$]. No evidence for the additional pyrazole donor is found in the mass spectrum of complex **2**. Similar patterns exist for complex **3** where the peak at 550*m*/*z* is consistent with $[Cu(N_4\text{-mpz})^{2+}](BF_4)^-$ and the peak at 463*m*/*z* matches [Cu(N_4-mpz)$^+$]. However, the major difference is that a peak is found at 646*m*/*z* that corresponds with $[Cu(N_4\text{-mpz})(Pz)]^{2+}(BF_4)^-$ showing the presence of the additional pyrazole donor in complex **3**. Although the mass spectral results do not include the exogenous pyrazole donor in complex **2**, the crystallographic results (vide infra) do show its presence. For complex **4**, diagnostic peaks are found at 463*m*/*z* for the [Cu(N_4-mpz)$^+$] and at 498*m*/*z* for the $[Cu(N_4\text{-mpz})^{2+}]Cl^-$ moiety.

The existence of the additional pyrazole in complexes **2** and **3** was unexpected as there was no free pyrazole in the reaction mixture so its presence in the complex must be the result of its extraction by the copper during complexation. There are other examples of this phenomenon [18–23]. We have seen other instances of unusual results for biphenyl-based ligands upon complexation to Cu(II) as the Cu(II) is forced by the biphenyl ligand into a relatively undesirable form with the metal in a non-planar environment. In prior examples of biphenyl-based ligands, the Cu(II) responded to this imposition by spontaneously reducing the Cu(II) to its Cu(I) form in order to relieve the severe steric constraints imposed by the ligand [11]. In the study reported here, the copper in complexes **2** and **3** takes on an additional donor to modify its structure. In this case, the result is a five-coordinate Cu(II) complex with an additional pyrazole nitrogen coordinated. In comparison, complex **4** behaves in a more predictable way by coordinating the ligand and the anion from the copper salt resulting in a five-coordinate complex with the chloride bound.

3.1. Crystallographic analysis of [Cu(N_4-mpz)(Pz)] (ClO_4)$_2$ · CH_3OH (**2**)

Single crystals of [Cu(N_4-mpz)(Pz)] (ClO_4)$_2$ · CH_3OH (**2**) suitable for X-ray diffraction structural determination were grown by vapor diffusion of ether into a solution of the complex in CH_3OH. The molecular structure of complex **2** is shown in Fig. 2. It crystallizes in a triclinic crystal system with space group $P\bar{1}$. The relevant details of the crystals, data collection and structure refinement are found in Table 1. Selected bond distances and bond angles are presented in Table 2. The complete list of bond distances, bond angles, atomic coordinates and anisotropic thermal parameters are presented in supporting information.

Complex **2** is a five-coordinate complex with the copper coordinated by five nitrogen donors. The coordination geometry around the copper is best described as distorted trigonal bipyramidal as revealed by the magnitude of the trigonality index *t* of 0.61. For perfect pyramidal and trigonal bipyramidal geometries, the *t-values* are zero and unity, respectively [24], so this complex only slightly favors the trigonal bipyramidal form. The axial positions are taken up by the pyrazole donors N(6) and N(1) from the pyrazoles of the multidentate ligand while the non-aromatic nitrogens N(4) and N(3) and the exogenous pyrazole N(7) make up the equatorial donors. All bond distances are within expected values with the nitrogen from the exogenous pyrazole at a slightly longer distance (1.99 Å) than the other two pyrazole donors (1.95 Å). In other examples of copper complexes with a pyrazole donor attached to the copper, the Cu–N distance is usually found in the range of 1.99–2.00 Å. The impact on the structure due to the biphenyls is

also manifested in the smaller bond angles found for N(6)–Cu(1)–N(4) (80.6°) and for N(1)–Cu(1)–N(3) (80.5°).

It is striking that in other examples where decomposition of pyrazole-based ligands occurs upon reaction with metal salts [18–23], the decomposition typically occurs only with sterically encumbered ligands such as pyrazolylborates or diphenyldipyrazolylmethanes. This also is the case here as the biphenyl ring is forcing the nitrogen donors out of planar type environments when bound to the metal. The mechanism of the decomposition has been hypothesized to involve metal-mediated cleavage of the pyrazole nitrogen–X bond (where X = boron or carbon) [18,19,21]. To determine whether the metal is essential for the decomposition process, we stirred the ligand overnight in the absence of copper and found it to be unperturbed indicating that Cu(II) is required for the pyrazole decomposition [18].

3.2. Electrochemistry

The cyclic voltammogram scans for fresh solutions of complexes **2**–**4** in methanol (Fig. 3) start at positive potentials versus Ag/AgCl and proceed to more negative potentials at a scan rate of 50 mV s^{-1}.

The first cathodic current peaks (E_{pc} in Table 3) are assigned to the reduction of Cu(II) to Cu(I) based on a comparison to our previous studies with the pyridine containing Cu(N_4-mpy) complexes [6]. Reversing the scan direction at a negative potential (−0.1 V) gives the corresponding reoxidation of Cu(I). Table 3 summarizes the electrochemical CV data for all the complexes, along with the peak potentials obtained from DPV (we were not able to get a result for complex **3**). One notes several trends from the electrochemical parameters. First, the $E_{1/2}$ values and ΔE_p values are different for the three complexes, which suggests that the complexes do not have identical coordination spheres around Cu(II) in MeOH. Complexes **2** and **3**, possessing weakly coordinating ClO_4^- or BF_4^-, have similar $E_{1/2}$ values, yet **3** has much larger peak splitting (306 mV) indicating more quasi-reversible redox chemistry and/or more kinetic problems at the electrode compared to complexes **2** and **4**. Complex **4** is slightly harder to reduce than **2** based on the DPV peaks (426 mV versus 456 mV), implying that the electron donating chloride ion has some influence at the metal center. These observations imply that the counterion in **2**–**4** influences the electronics of the metal center. It is not clear from these data that the pyrazole remains in the fifth coordination site during the redox event.

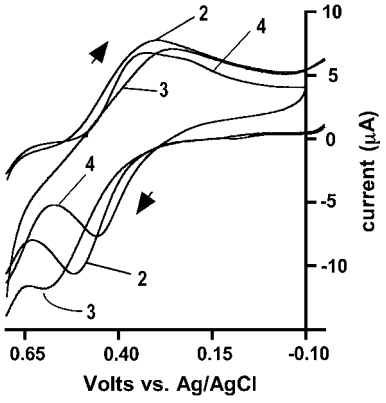

Fig. 3. Cyclic voltammograms at 50 mV s^{-1} using a glassy carbon electrode for complexes **2**, **3**, and **4** dissolved in degassed methanol. All solutions contained 1 mM complex and 0.100 M TBAH.

Table 3
CV and DPV data for complexes **2**–**4**.

Complex	E_{pc}/mV	E_{pa}/mV	ΔE_p/mV	$E_{1/2}$/mV versus Ag/AgCl	$i_{pc}i_{pa}^{-1}$	DPV, E_p/mV
2	318	507	189	422	1.02	456
3	280	586	306	430	1.08	N/A
4	341	451	110	396	1.11	426

CV: methanol containing 0.1 M TBAH, [Cu(II)] = 1–2 mM at a scan rate of 50 mV s^{-1}. DPV: scan rate 5 mV s^{-1}, pulse amplitude/time of 25 mV/50 ms, step height/time of 1 mv/200 ms.

The second point is that all the complexes show quasi-reversible redox behavior that is most likely related to structural changes upon going from Cu(II) to Cu(I) where a tetrahedral geometry is favored. The solvent or a counter ion may slowly exchange into the fifth coordination site as we note the appearance of small shoulder after the DPV reduction peak for complex **4** that increases in intensity after 24 h at room temperature (no change is apparent upon continuous cycles using CV). Finally, the $E_{1/2}$ for complexes **2**–**4** occur at much more positive potentials compared to the pyridine-based [Cu(N_4-mpy)(X)]X complexes studied earlier [11]. For example, [Cu(N_4-mpy)(Cl)]Cl gives an $E_{1/2}$ of +100 mV (ΔE_p = 80 mV) versus Ag/AgCl in methanol compared to +396 mV (ΔE_p = 110 mV) for complex **4**. This result is consistent with the better donor properties of pyridine compared to the dimethylpyrazole-based chelating ligand.

3.3. Conclusions

A new tetradentate pyrazole-containing ligand (N_4-mpz) has been synthesized and three Cu(II) complexes prepared and characterized from it. The crystal structure and spectroscopic data show complexes **2** and **3** to be five-coordinate with the ligand bound along with an additional pyrazole donor. The origin of this pyrazole is due to the abstraction of a pyrazole from an uncomplexed ligand. This is the second example where we have found Cu(II) complexes formed from biphenyl-based ligands behave in unusual ways. We attribute these results to the steric constraints enforced on the metal by the non-planarity of the biphenyl rings and we continue to probe related biphenyl derived ligands and their metal complexes.

Dioxovanadium(V)
Thiosemicarbazones
Anti-*Mycobacterium tuberculosis* activity

ABSTRACT

The development of more efficient anti-tuberculosis drugs is of interest. Three oxovanadium(IV) and three *cis*-dioxovanadium(V) complexes with thiosemicarbazone derivatives bearing moieties with different lipophilicity have been prepared and had their inhibitory activity against *Mycobacterium tuberculosis* H_{37}Rv ATCC 27294 evaluated. The analytical methods used by the complexes' characterization included IR, EPR, ^{1}H, ^{13}C and ^{51}V NMR spectroscopies, elemental analysis, cyclic voltammetry, magnetic susceptibility measurement and single crystal X-ray diffractometry. [VO(acac)(aptsc)], [VO(acac)(apmtsc)] and [VO(acac)(apptsc)] (acac = acetylacetonate; Haptsc = 2-acetylpyridinethiosemicarbazone; Hapmtsc = 2-acetylpyridine-N(4)-methyl-thiosemicarbazone and Happtsc = 2-acetylpyridine-N(4)-phenyl-thiosemicarbazone) are paramagnetic and their EPR spectra are consistent with the monoanionic *N,N,S*-tridentate coordination of the thiosemicarbazone ligands, resulting in octahedral structures of rhombic symmetry and with the oxidation state +IV for the vanadium atom. As result of oxidation of the vanadium(IV) complexes above, the diamagnetic *cis*-dioxovanadium(V) complexes [VO_2(aptsc)], [VO_2(apmtsc)] and [VO_2(apptsc)] are formed. Their ^{1}H, ^{13}C and ^{51}V NMR spectra were acquired and support a distorted square pyramidal geometry for them, in accord with the solid state X-ray structures determined for [VO_2(aptsc)] and [VO_2(apmtsc)]. In general, the vanadium compounds show comparable or larger anti-*M. tuberculosis* activities than the free thiosemicarbazone ligands, with MIC values within 62.5–1.56 (μg/mL).

1. Introduction

Tuberculosis (TB) is a contagious disease with high mortality worldwide. The statistics indicate that three million people worldwide die annually from complication of tuberculosis and about eight million new cases are estimated to occur every year, 95% of them in developing countries [1]. Therefore, the incidence of tuberculosis is raising at alarming rates, which are coincident with the increase of AIDS cases. In addition, the expanding number of multi drug resistant TB cases does not only create problems for the treatment, but also the costs are ever-increasing. Thus, new drugs are necessary to overcome the current problems of therapy [1,2].

Biological properties of thiosemicarbazones (TSCs) have been studied since 1946, when Domagk et al. [3] reported their activity against *Mycobacterium tuberculosis*. The compound *p*-acetamidobenzaldehyde thiosemicarbazone, commercially available as thiacetazone, has long been employed in the treatment of tuberculosis [4]. Otherwise, its purely bacteriostatic activity *in vivo* and the fast appearance of strains resistant to the thiacetazone during the treatment, besides collateral effects like the induction to the *diabetes mellitus*, limit its utilization [5]. Since then, this and other biological properties of TSCs have been extensively studied owing to their wide variety of biological activities [6]. The mechanism of action of TSCs is closely related to their ability to inhibit the biosynthesis of DNA, possibly by blocking the enzyme ribonucleotide diphosphate reductase; binding to the nitrogen base of DNA, hindering or blocking base replication; creation of lesions in DNA strands by oxidative rupture [7]. Structure–activity relationships evidence not only that the complexation enhances the antimicrobial activity of bioactive ligands against some tested microorganisms but also that the presence of a metal center may

doi:10.1016/j.poly.2008.11.017

also play a relevant role in the activity of coordination compounds [8,9].

In recent years the medicinal applications of oxovanadium(IV) and dioxovanadium(V) complexes with *N*-, *O*- and *S*-donor chelating ligands have been investigated in special about their potential insulin-mimetic effects [10–15]. Besides these effects, other pharmacological activities of vanadium compounds include tumor growth inhibition and prophylaxis against carcinogenesis [16]. Some vanadium complexes are known to inhibit several enzymes, including phosphatases, ATPases, nucleases, kinases and other enzymes [17].

The antimicrobial activity of vanadium complexes has been explored too little and till this moment we have notices about only two studies on vanadium complexes activities against *M. tuberculosis* [18,19]. Furthermore, once observed that the treatment of the tuberculosis with free thiosemicarbazones ligands may induct *diabetes mellitus* [5], the coordination to vanadium may be advantageous both to the enhancement of the anti-*M. tuberculosis* activity and to the prevention of *diabetes*.

This work describes the preparation, structural characterization, both in solution and in the solid state, of the oxovanadium(IV) complexes [VO(acac)(aptsc)] (**1**), [VO(acac)(apmtsc)] (**2**), and [VO(acac)(apptsc)] (**3**), as well as the *cis*-dioxovanadium(V) complexes [VO_2(aptsc)] (**4**), [VO_2(apmtsc)] (**5**), and [VO_2(apptsc)] (**6**), which involve the thiosemicarbazone derivatives 2-acetylpyridine-thiosemicarbazone (Haptsc), 2-acetylpyridine-N(4)-methyl-thiosemicarbazone (Hapmtsc) and 2-acetylpyridine-N(4)-phenyl-thiosemicarbazone (Happtsc). The activity of complexes, free ligands and common vanadium salts against *M. tuberculosis* H37Rv ATCC 27294 was evaluated. Literature data is available for complex **3**, concerning to its preparation and characterization [20]. A somewhat different preparation route was used here for **3** and the complex characterization was extended by using additional methods.

2. Experimental

2.1. Materials and methods

[$VO(acac)_2$] (ACROS ORGANICS), 2-acetylpyridine, thiosemicarbazide, N(4)-methyl-thiosemicarbazide, N(4)-phenyl-thiosemicarbazide and analytical reagents grade chemicals and solvents were obtained commercially and used without further purification. The ligands were prepared as described by literature methods [21]. FTIR spectra were recorded on a BOMEM FTIR model BM 100 spectrometer. NMR spectra were acquired on a Varian MERCURY plus spectrometer operating at 300.07, 75.46 and 78.92 MHz for ^{1}H, ^{13}C and ^{51}V, respectively. The ^{1}H and ^{13}C{^{1}H} spectra were internally referenced to TMS. The ^{51}V spectrum was externally referenced to $VOCl_3$ ($\delta = 0$), checked against an aqueous $(NH_4)VO_3$ solution containing capillary ($\delta = -541.2$ for VO_4^{3-}). A BAS 100B electrochemical analyzer was used for the cyclic voltammetry studies. Elemental analyses (CHNS) were determined with FISONS EA-1108 analyzer. EPR spectra were collected on an X-band Bruker ER-580 spectrometer equipped with Oxford low temperature system. The spectra were simulated with the EasySpin program [22]. The measurement conditions include microwave frequency of 9.472 GHz, modulation frequency and amplitude of 100 kHz and 0.1 mT, respectively, magnetic field scan range of 248–429 mT, gain of 45 db, microwave power of 8 μW, time constant of 20.48 ms and conversion time of 81.92 ms. Solid samples were measured at room temperature and liquid sample diluted in DMSO solvent were measured at 25 K to prevent microwave power saturation. Magnetic susceptibilities were measured on a JOHNSON MATTHEY MSB balance at 298 K and converted into the corresponding molar susceptibilities in the usual way [23]. Diamagnetic corrections, applied to the molar susceptibilities of the paramagnetic substances, are reported as χ_{diam}. The latter corrections were calculated using the standard Pascal's constants [23]. Enraf-Nonius CAD4 and Nonius Kappa CCD diffractometers equipped with graphite monochromators were used for the X-ray structure analyses, applying standard procedures.

2.2. Preparations

Synthesis of the ligands: The ligands Haptsc, Hapmtsc and Happtsc were prepared by refluxing an equimolar methanolic solution of the desired thiosemicarbazide (10 mmol) and 2-acetylpyridine (10 mmol) for 1 h.

Haptsc: Yellow crystalline solid. Yield 1.50 g (77%). M.p.: 161–162 °C. ^{1}H NMR (DMSO-d_6, δ): 2.39 (s, CH_3), 7.38 (ddd, $J_{2,3}$ = 8 Hz, $J_{2,1}$ = 5 Hz, $J_{2,4}$ = 1 Hz, 1H), 7.79 (ddd, $J_{3,4}$ = $J_{3,2}$ = 8 Hz, $J_{3,1}$ = 2 Hz, 1H), 8.15 (s, NH), 8.42 (s, NH), 8.44 (ddd, $J_{4,3}$ = 8 Hz, $J_{4,2}$ = 1 Hz, 1H), 8.58 (ddd, $J_{1,2}$ = 5 Hz, $J_{1,3}$ = 2 Hz, 1H), 10.33 (s, NH). ^{13}C{^{1}H} NMR (DMSO-d_6, δ): 12.4, 121.1, 124.2, 136.6, 148.4, 148.6 154.9, 179.3.

Hapmtsc: White crystalline solid. Yield 1.52 g (73%). M.p.: 178–179 °C. ^{1}H NMR (DMSO-d_6, δ): 2.38 (s, CH_3), 3.06 (d, $J_{6,5}$ = 5 Hz, N–CH_3), 7.39 (ddd, $J_{2,3}$ = 7, $J_{2,1}$ = 5, $J_{2,4}$ = 1 Hz, 1H), 7.82 (ddd, $J_{3,4}$ = 8, $J_{3,2}$ = 7, $J_{3,1}$ = 1 Hz, 1H), 8.42 (dq, $J_{4,3}$ = 8, $J_{4,2}$ = 1 Hz, 1H), 8.58 (dq, $J_{1,2}$ = 5, $J_{1,3}$ = 1 Hz, 1H), 8.64 (d, $J_{5,6}$ = 5 Hz, 1H), 10.35 (s, 1H). ^{13}C{^{1}H} NMR (DMSO-d_6, δ): 12.0, 31.1, 120.7, 123.8, 136.2, 147.8, 148.4, 154.6, 178.6.

Happtsc: Bright white solid. Yield 2.14 g (79%). M.p.: 171–174 °C. ^{1}H NMR (DMSO-d_6, δ): 2.47 (s, CH_3), 7.24 (ddd, $J_{7,6}$ = 7 Hz, $J_{7,5}$ = 1 Hz, 1H), 7.34–7.44 (m, 3H), 7.55 (dd, $J_{5,6}$ = 9 Hz, $J_{5,7}$ = 1 Hz, 2H), 7.82 (ddd, $J_{3,4}$ = $J_{3,2}$ = 8 Hz, $J_{3,1}$ = 2 Hz, 1H), 8.54 (ddd, $J_{4,3}$ = 8 Hz, $J_{4,2}$ = $J_{4,1}$ = 1 Hz, 1H), 8.61 (ddd, $J_{1,2}$ = 5 Hz, $J_{1,3}$ = 2 Hz, $J_{1,4}$ = 1 Hz, 1H), 10.21 (s, NH), 10.67 (s, NH). ^{13}C{^{1}H} NMR (DMSO-d_6, δ): 12.6, 121.3, 124.2, 125.6, 126.2, 128.2, 136.5, 139.1, 148.5, 149.2, 154.5, 177.3.

Synthesis of the V(IV) complexes: Solutions of 0.133 g (0.5 mmol) [$VO(acac)_2$] and (0.5 mmol) of the desired ligand were prepared separately in minimal amounts of MeCN and then mixed. After stirring for 15 min, the solutions had their volume reduced to half by heating and were then cooled by standing at room temperature. The precipitates formed were filtered off and dried in vacuum.

*[VO(acac)(aptsc)] (**1**):* Dark green precipitate. Yield 0.08 g (46%). M.p. not observed up to 300 °C. (Found: C, 42.90; H, 4.43; N, 15.29; S, 9.02. Calc. for $C_{13}H_{16}N_4O_3SV$: C, 43.46; H, 4.49; N, 15.59; S, 8.92%).

*[VO(acac)(apmtsc)] (**2**):* Dark green precipitate. Yield 0.13 g (72%). M.p. not observed below 300 °C. (Found: C, 44.91; H, 4.98; N, 15.17; S, 8.76. Calc. for $C_{14}H_{18}N_4O_3SV$: C, 45.04; H, 4.86; N, 15.01; S, 8.59%).

*[VO(acac)(apptsc)] (**3**):* Dark brown precipitate. Yield 0.143 g (66%). M.p. not observed below 300 °C. (Found: C, 51.89; H, 4.71; N, 13.02; S, 7.44. Calc. for $C_{19}H_{20}N_4O_3SV$: C, 52.41; H, 4.63; N, 12.87; S, 7.36%).

Synthesis of the V(V) complexes: The compounds were prepared in a similar approach as applied for **1–3**, but preparing more diluted final mixtures (around 100 mL) in MeOH or MeCN, which were stirred during 5 days in order to complete the oxidation process.

*[VO_2(aptsc)] (**4**):* Yellow-brown solid. Yield 0.10 g (70%). M.p. not observed until 300 °C. (Found: C, 34.31; H, 3.34; N, 20.12; S, 11.77. Calc. for $C_8H_9N_4O_2SV$: C, 34.79; H, 3.28; N, 20.29; S, 11.61%). ^{1}H NMR (DMSO-d_6, δ): 2.53 (s, CH_3), 7.62 (dd, $J_{2,3}$ = 8 Hz, $J_{2,1}$ = 5 Hz, 1H), 7.83 (s, NH_2), 8.03 (d, $J_{4,3}$ = 8 Hz, 1H), 8.28 (dd, $J_{3,2}$ = $J_{3,4}$ = 8 Hz, 1H), 8.64 (d, $J_{1,2}$ = 5 Hz, 1H). ^{13}C{^{1}H} NMR (DMSO-d_6, δ): 13.9, 123.7, 125.4, 142.9, 152.9, 154.2, 155.4, 176.0 ppm.

[VO_2(apmtsc)] (**5**): Yellow solid. Yield 0.07 g (50%). M.p. not observed below 300 °C. (Found: C, 36.90; H, 3.72; N, 18.86; S, 10.93. Calc. for $C_9H_{11}N_4O_2SV$: C, 37.25; H, 3.82; N, 19.31; S, 11.05%). ^{1}H NMR (DMSO-d_6, δ): 2.57 (s, CH_3), 2.92 (d, J = 5 Hz, N–CH_3), 7.63 (t, $J_{2,1}$ = 6 Hz, 1H), 8.02–8.14 (m, 2H), 8.29 (t, $J_{3,4}$ = 8 Hz, 1H), 8.65 (d, $J_{1,2}$ = 6 Hz, 1H). ^{13}C{^{1}H} NMR (DMSO-d_6, δ): 13.8, 31.0, 123.9, 125.6, 143.0, 153.1, 154.3, 156.8, 173.3 ppm.

[VO_2(apptsc)] (**6**): Yellow solid. Yield 0.10 g (65%). M.p. not observed below 300 °C. (Found: C, 47.44; H, 3.83; N, 15.59; S, 9.27. Calc. for $C_{14}H_{13}N_4O_2SV$: C, 47.73; H, 3.72; N, 15.90; S, 9.10%). ^{1}H NMR (DMSO-d_6, δ): 2.68 (s, CH_3), 7.07 (t, $J_{7,6}$ = 8 Hz, 1H), 7.37 (dd, $J_{6,5}$ = $J_{6,7}$ = 8 Hz, 2H), 7.71 (dd, $J_{2,3}$ = 7 Hz, $J_{2,1}$ = 5 Hz), 7.76 (d, $J_{5,6}$ = 8 Hz), 8.17 (d, $J_{4,3}$ = 8 Hz, 1H), 8.34 (ddd, $J_{3,4}$ = 8 Hz, $J_{3,2}$ = 7 Hz, $J_{3,1}$ = 2 Hz, 1H), 8.72 (d, $J_{1,2}$ = 5 Hz, 1H), 10.17 (s, NH). ^{13}C{^{1}H} NMR (DMSO-d_6, δ): 14.7, 120.1, 123.0, 124.8, 126.4, 128.7, 140.2, 143.2, 153.2, 153.8, 160.4, 170.3 ppm.

2.3. Crystal structure determinations

Brown crystals of **4** were grown by slow interdiffusion of CH_3CN solutions of [VO(acac)$_2$] and of the corresponding thiosemicarbazone ligand. Light brown crystals of **5** were obtained by slow concentration of an acetonitrile solution of the compound at room temperature. The structures were solved with SHELXS97, by using direct methods [24] and all non-hydrogen atoms were refined with anisotropic displacement parameters with SHELXL97 [25]. Absorption corrections were applied in both cases, as given in Table 1, together with more detailed information about the structure determinations.

Table 1
Crystal data and structure refinement for the complexes [VO_2(aptsc)] (**4**) and [VO_2(apmtsc)] (**5**).

2.4. Determination of MICs

According to the methodology of Franzblau et al. [28], the anti-*M. tuberculosis* activity of the tested compound and standard drug isoniazid (Difco Laboratiories, Detroit, MI, USA) were determined in triplicate by using of the Microplate Alamar Blue Assay (MABA). In this technique, the Minimal Inhibitory Concentration (MIC) of compounds necessary to inhibit in 90% the mycobacterial growth was determined using Alamar Blue as a fluorescent vital dye. The bacterial suspension used was prepared by adjusting its turbidity by the McFarland No. 1 scale, and further dilution (1:25 v/v) in the culture medium 7H9. Concentrations of the complex and isoniazid in DMSO ranged from 1.00 to 100 μg/mL and 0.50 to 0.015 μg/mL, respectively. A negative control was run without bacterial *inoculum* in the medium to confirm that there is no reaction of the complexes themselves with Alamar Blue. The fluorescence of the dye (indicative of bacterial growth) was measured in a SPECTRAfluor Plus microplate reader (Tecan®) in bottom reading mode with excitation at 530 nm and emission at 590 nm.

3. Results and discussion

3.1. Synthesis of the complexes

The oxovanadium(IV) complexes **1**, **2** and **3** form readily in concentrated acetonitrile solutions at room temperature. The compound **3** can be also obtained from a methanol solution, while **1** and **2** suffer oxidation quickly in this solvent. The *cis*-dioxovanadium(V) complexes **4**, **5** and **6**, otherwise, are prepared from more diluted solutions of the corresponding complexing agents and [VO(acac)$_2$] at room temperature, with longer reaction times. In all complexes the thiosemicarbazone derivatives are found to coordinate *N,N,S*-tridentate as monoanionic, deprotonated ligands.

3.2. Magnetic measurements and EPR spectroscopy

The oxidation state of the central vanadium atom in the complexes was confirmed by measurements of the magnetic susceptibility and by EPR spectroscopy. The compounds **1**, **2** and **3** are paramagnetic in the extension of one unpaired electron (d^1) with values of μ_{eff} equal to 1.57 μ_B ($\chi_{diam} = -168.5 \times 10^{-6}$ cm^3 mol^{-1}), 1.60 μ_B ($\chi_{diam} = -180.3 \times 10^{-6}$ cm^3 mol^{-1}) and 1.50 μ_B ($\chi_{diam} = -217.0 \times 10^{-6}$ cm^3 mol^{-1}) at 298 K, respectively, which are typical for vanadium(IV) complexes [29]. The EPR spectra of the paramagnetic samples were measured in powder and diluted samples in DMSO solvent. The anisotropic EPR spectra of powder samples of **1**, **2** and **3** at room temperature are given in Fig. 1. It is possible to see that only one line is observed for each complex, suggesting that the packing in solid state is accompanied by magnetic exchange interaction between neighbour molecules. This phenomenon is very known in Cu(II)-aminoacids, -peptides and other molecules compounds [30–36].

Comparing the line width of the three spectra, it is possible to suggest that the magnetic exchange interaction is greater in **3**, which show the sharper line width, followed by **2** and then by **1**, which shows the broader line width, but it is possible that the line width differences explain differences in relaxation mechanism. To explore better these line width differences, single crystals EPR studies with angular line width variation will be desired. These

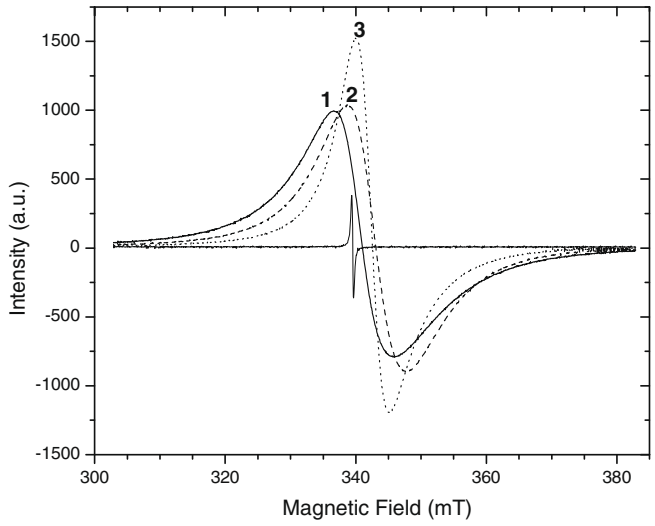

Fig. 1. Experimental EPR spectra of the complexes **1** (solid line), **2** (dashed line) and **3** (dotted line) in solid state. Simulation of these spectra were done using EasySpin program and the EPR parameters are shown in Table 2. The sharp line is a Cr(III) in MgO g-marker (g = 1.9797).

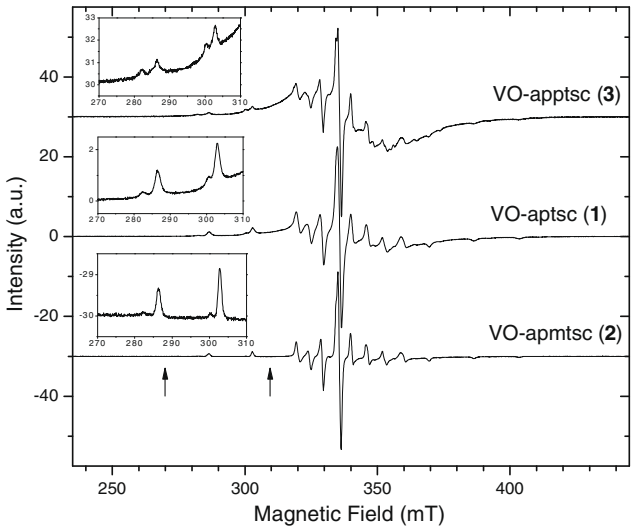

Fig. 2. EPR spectra of **1**, **2** and **3** in DMSO solution at 25 K. The inserts amplifies the magnetic fields region between the arrows, in order to show the two components.

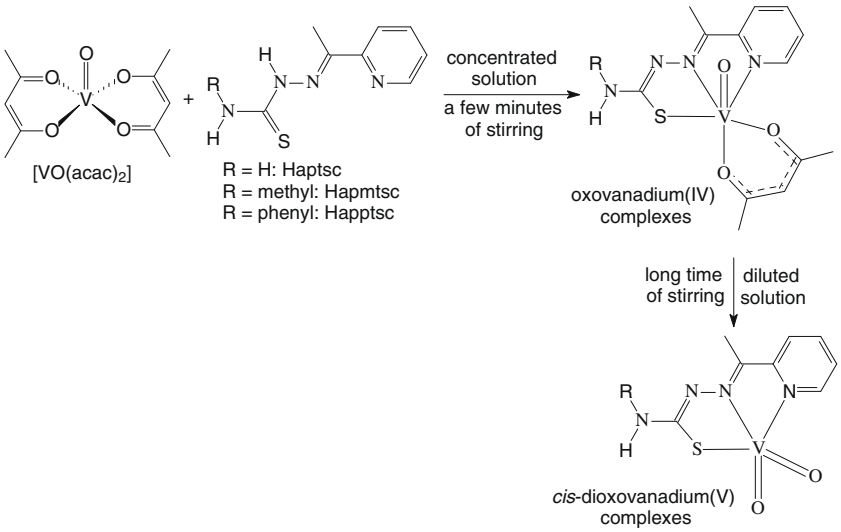
spectra were simulated and the EPR parameters of the best fittings are given in Table 2. Fig. 2 shows the EPR spectra of the DMSO solved paramagnetic samples, collected at 25 K. All spectra are consistent with small rhombic distortion from the axial symmetry structures proposed for **1**, **2** and **3** in Scheme 1. It is important to note that for the compounds **1** and **3** a broaden line, superposed to the diluted compound, is apparent, suggesting that the magnetic exchange interaction are partially persistent for these samples under the experimental conditions or the complete dilutions of these two samples are not achieved. The EPR parameters, specially the g-values, are the same as obtained from the powder samples, but the lines widths (ΔH) are broaden in both cases. For complex **2**, however, a complete dissolution in DMSO solvent is observed.

Additionally, the EPR spectra of the three compounds indicate a second diluted paramagnetic species, also with rhombic distortion, which is present in much lower concentration (see insert in Fig. 2). These more diluted species are supposed to be formed probably by coordination of a DMSO molecule to the vanadium center, displacing one of the oxygen donor atoms from the acac ligand, similarly as observed during the voltammetry studies, described in the next section, which were also conducted by using a coordinating solvent. A component analysis by spectral simulation was done and is shown in Fig. 3, for complex **3**, as an example. The percentage of the components is calculated by numerical double integration of the simulated components with an estimate error of 5%. The complete results showing the EPR parameters and component percentages are shown in Table 2.



The compounds **4**, **5** and **6** lead to silent EPR signals, which is consistent with the oxidation state +V (d^0) for the vanadium centers.

3.3. Electrochemistry

The cyclic voltammogram (CV) studies for the oxovanadium(IV) complexes **1**, **2** and **3** were realized in DMF solutions. The electrochemical processes are consistent with the oxidative reactions observed for the vanadium(IV) compounds in alcoholic solution, forming the *cis*-dioxovanadium(V) complexes **4**, **5** and **6**, respectively, with loss of the acetylacetonate ligand. As shown in Fig. 4 for the CV curve of complex **1**, the V^{IV}–V^{V} redox processes are irreversible, in accord with the observed behavior for other similar vanadium(IV) complexes [11,12]. Moreover, three oxidation processes are observed for **1**–**3**, which were analyzed applying differential pulse voltammetry (DPV), as depicted in Fig. 5. The anodic peaks for the oxidation processes of the species **1**–**3** are seen with large intensity at 600, 604 and 652 mV, respectively. The two additional oxidation peaks observed for each complex (at 1088 and 1320 mV for **1**; 1080 and 1220 mV for **2**; 1096 and 1284 mV for **3**), with small intensities, are supposed to be originated by species formed upon coordination of one or two DMF molecules in the coordination sites occupied originally by $acac^-$ ligand in **1**–**3**. Under

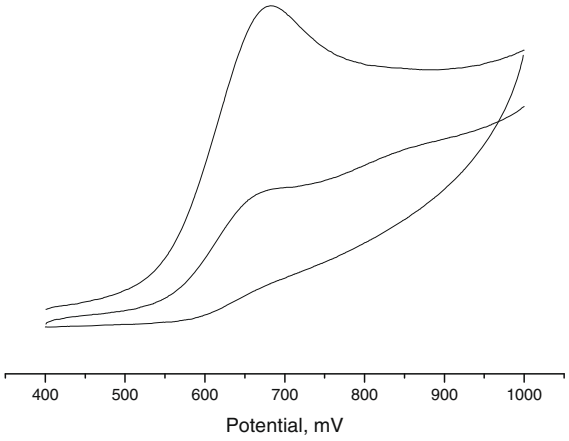

Fig. 4. Cyclic voltammogram of **1** (Ag/AgCl, 0.1 mol/L PTBA, DMF, 100 mV/s). An example of the irreversible redox processes observed for the vanadium(IV).

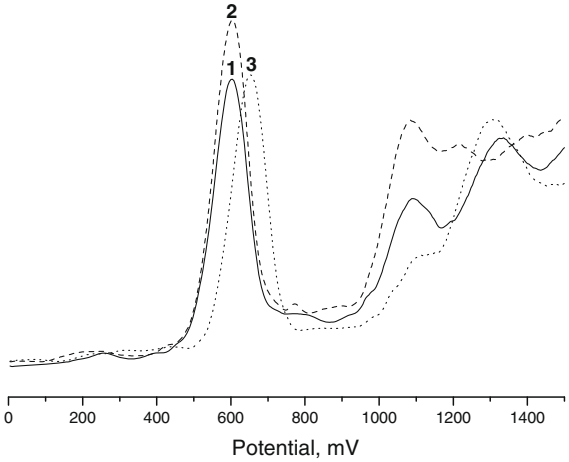

Fig. 5. Differential pulse voltammetry (Ag/AgCl, 0.1 mol/L PTBA, DMF, 20 mV/s) of the complexes **1** (solid line), **2** (dashed line) and **3** (dotted line).

excess of acetylacetone these additional peaks disappear and a new oxidation process is observed at 748 mV, referring to the oxidation of $[VO(acac)_2]$, which is formed in the solution under these circumstances. The formation of $[VO(acac)_2]$ was confirmed by the evaluating the DPV of $[VO(acac)_2]$ lonely under the same experimental conditions. The oxidation of $[VO(acac)_2]$ in equilibrium with the complexes **1**, **2** or **3** in DMF solution under excess of acetylacetone is reported in Fig. 6.

3.4. IR and NMR spectroscopies

Selected IR absorption bands assigned for the free ligands as well as for their vanadium complexes, given in Table 3, evidence *N,N,S*-coordination of the thiosemicarbazone ligands The ν(V=O) absorption band, observed at 998 cm^{-1} for $[VO(acac)_2]$, are observed at 953, 939 and 952 cm^{-1} for **1**, **2** and **3**, respectively. Two ν(O=V=O) absorption bands corresponding to the symmetric and anti-symmetric stretching modes are satisfactorily assigned for the dioxovanadium(V) complexes [15,16].

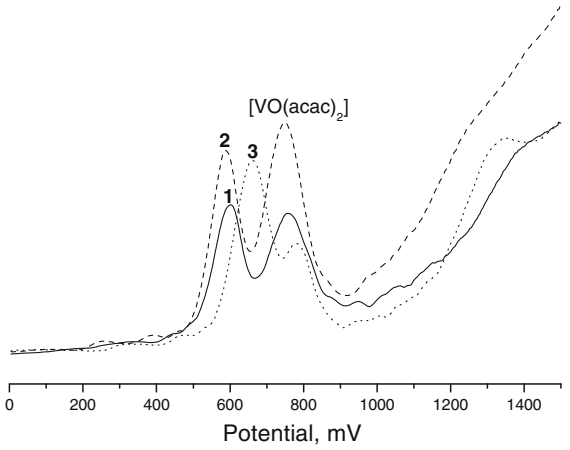

Fig. 6. Differential pulse voltammetry (Ag/AgCl, 0.1 mol/L PTBA, DMF, 20 mV/s) of the complexes **1** (solid line), **2** (dashed line) and **3** (dotted line) and excess of acetylacetone.

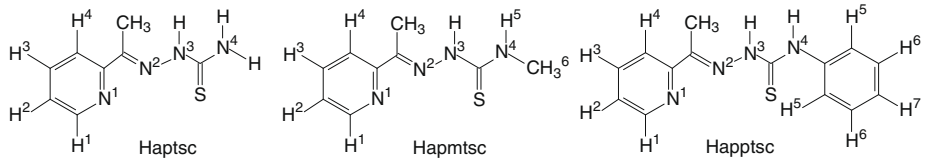
The ^{1}H chemical shift values of the free ligands and the diamagnetic complexes **4**, **5** and **6** are given in the experimental section. The Scheme 2 shows the numbered structures of the free ligands. The three new V(V) complexes show similar ^{1}H- and ^{13}C-chemical shift behavior. ^{1}H NMR integrations and signal multiplicities are in agreement with the proposed structures.

In the ^{1}H NMR spectra of the complexes, a down field shift of around ~0.2 ppm for the methyl hydrogens (C–CH_3), compared to the free ligands, evidences the coordination through the azomethine nitrogen atom. In the pyridine ring, the resonance of the hydrogen atoms follows the sequence H1, H4, H3 and H2 for the free ligands, but H1, H3, H4 and H2 for **4**, **5** and **6**, which is consistent with literature data [37]. This up-field shift of proton H4 could be the result of the decreasing of the azomethine anisotropic effect on this proton in the coordinated form of the ligands [38,39]. The values of δ for the azomethine and for the thione/thiolate carbons show clearly the coordination of the thiosemicarbazone ligands in the ^{13}C NMR spectra of the complexes. The δ for the azomethine carbons are found at 148.4, 148.4 and 149.2 ppm for the free ligands Haptsc, Hapmtsc and Happtsc, respectively, and at 154.2, 154.3 and 153.8 ppm for their respective V(V) complexes **4**, **5** and **6**, while the δ for the thione/thiolate carbons are observed at 179.1, 178.6 and 177.3 ppm for the free ligands and at 176.0, 173.3 and 170.3 ppm for the complexes. The ^{51}V NMR spectra of the complexes **4**, **5** and **6** in DMSO-d_6 present single peaks at δ −402.8, −404.2 and at −413.1 ppm, respectively, consistent with the proposed structures of the mononuclear *cis*-dioxovanadium(V) chelate-complexes. The values are in agreement with other penta-coordinated VO_2^+ complexes which involve one sulfur and two nitrogen donor atoms, occupying the three remaining positions at the vanadium coordination sphere [40]. The shielding order $[VO_2(aptsc)] < [VO_2(apmtsc)] < [VO_2(apptsc)]$ is verified for the three complexes, in accordance to the up-shielding effect generally found for semi- and thiosemicarbazone vanadium complexes, which is directly proportional to the volume of the group bound to the N^4 atom [41].



3.5. Crystal structures of the cis-dioxocomplexes $[VO_2(aptsc)]$ (**4**) and $[VO_2(apmtsc)]$ (**5**)

The perspective view of the dioxocomplexes **4** and **5** along with the atom labels is given in Figs. 7 and 8, respectively. The complexes present 5-coordinated vanadium(V) centers bonded to two oxo ligands in a *cis* arrangement, two nitrogen atoms and one sulfur atom from aptsc$^-$, which coordinates monoanionic in the *N,N,S*-tridentate mode, forming two five-membered quelate rings around the vanadium atom. The geometry around the vanadium centers are better defined as distorted square pyramids, as observed by $\tau = 0.23$ for **4** and $\tau = 0.22$ for **5** ($\tau = 1$ for an ideal trigonal bipyramid, $\tau = 0$ for an ideal square pyramid) [6,10]. The basal plane is occupied by the sulfur atom and by the nitrogen atoms N(1) and N(2) from the thiosemicarbazone ligand in both structures, while the fourth corner of the pyramid base is occupied by the oxygen O(1) in **4** and by the oxygen O(2) in **5**. The apical positions are engaged by the oxygen atoms O(2) and O(1) in **4** and **5**, respectively. The bond lengths between the vanadium center and the donor atoms are comparable with the values found in oxovanadium complexes involving structurally similar ligands previously described [42]. Additional information about bond lengths and angles for **4** and **5** can be seen in Table 4.

In the complex **4**, the crystal is stabilized by a net of intermolecular hydrogen bonds, which are shown in Fig. 7. Classic (N–H···O and N–H···N) and non-classic (C–H···O) hydrogen bonds are

Scheme 2. Numbering scheme for ^{1}H NMR data.

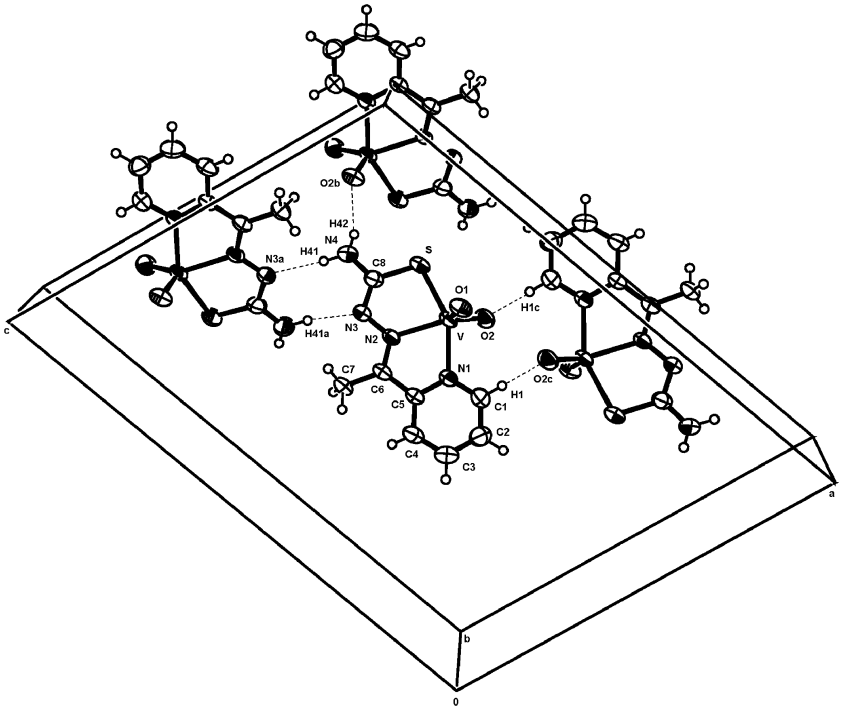

Fig. 7. Crystalline and molecular structure of $[VO_2(aptsc)]$ (**4**) with atom labels. [N(4)···N(3a) = 3.076(4) Å, N(4)–H(41)···N(3a) = 165(3)°], [N(4)···O(2b) = 2.876(3) Å, N(4)–H(42)···O(2b) = 162(3)°] and [C(1)···O(2c) = 3.397(4) Å, C(1)–H(1)···O(2c) = 162(2)°]. Symmetry operations used: (a) $-x, y, -z + 1/2$; (b) $-x + 1/2, y-1/2, -z + 1/2$; (c) $-x + 1/2, -y + 1/2, -z$.

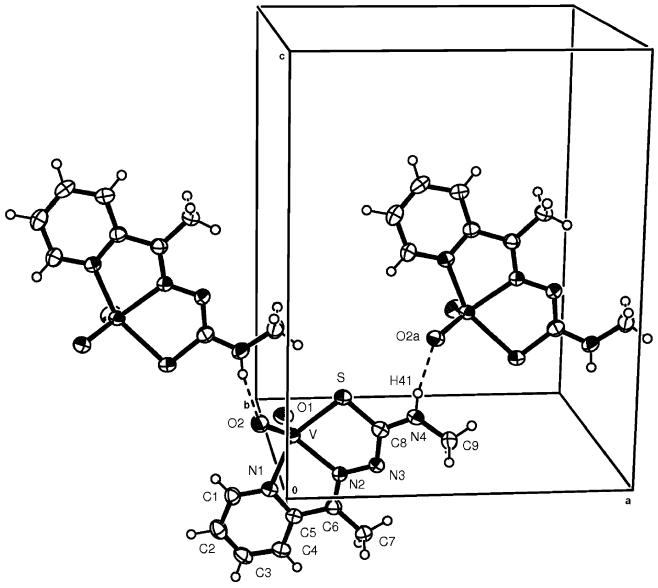

Fig. 8. Hydrogen bonds observed in the crystalline structure of $[VO_2(apmtsc)]$ (**5**), toward the direction [100]. [N(4)···O(2a) = 2.847 Å, N(4)–H(41)···O(2a) = 165.4°]. Symmetry operation used: (a) $x + 1/2, y, -z + 1/2$.

found. The nitrogen atom N(4), of the NH_2 group, is H-bonded through H(41) to the N(3a) atom from a symmetry related molecule, while H(42) interacts with the vanadyl oxygen atom O(2b) of a third complex molecule. Furthermore, the aromatic carbon atom C(1) is H-bonded to the vanadyl oxygen atom O(2c) of a fourth complex molecule.

The crystalline structure of the complex **5** is stabilized by N–H···O hydrogen bonds involving the nitrogen atom N(4) and the oxo ligand O(2a) of a symmetry related molecule, building a zigzag alignment of the complex molecules toward the direction [100], parallel to the *a* axis, as shown in the Fig. 8.
