The temperature dependence of the magnetic susceptibility, χ_M in the 2–300 K range, is shown in Fig. 4 and that of $\chi_M T$ in the Fig. 5. The overall behaviour is characteristic of a moderate antiferromagnetically coupled system. At 300 K, $\chi_M T$ is equal to 1.41 $cm^3\,K\,mol^{-1}$ which is close to the value expected for four non-interacting Cu^{II} ions. Upon cooling, this value decreases rather rapidly to reach zero below 20 K. The magnetic susceptibility shows a maximum at 85 K which is also a characteristic of dominant antiferromagnetic interactions. The low temperature behaviour of the magnetic susceptibility showing a minimum hump at 15 K goes on increasing which is indicative of a few paramagnetic impurities.

On the basis of the changes found in the magnetic susceptibility values on changing the temperature from 2 to 300 K, a sound

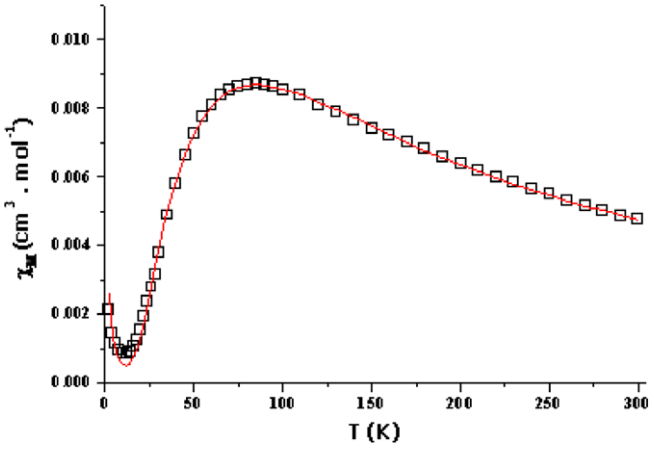

Fig. 4. Temperature dependence of the magnetic susceptibility (χ_M). The solid lines hold for the best fit of the data.

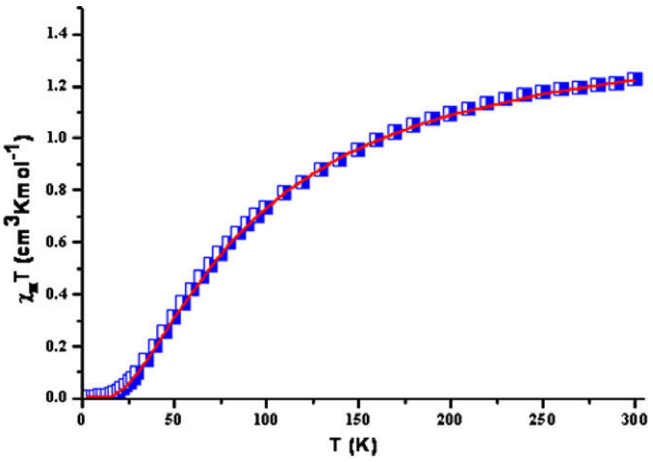

Fig. 5. Temperature dependence of $\chi_M T$ for **1**. The solid line corresponds to the best data fit.

magneto-structural correlation may be drawn successfully. A structural analysis carried out with the help of the Cambridge Structural Database [45] reveals the existence of three major types of cubane structures if they are classified according to the distribution of long Cu–Cu distances: (1) complexes with two short and four long Cu–Cu distances, and we call them 2 + 4 (2) complexes with four short and two long Cu–Cu distances, and may be labeled as 4 + 2 and finally (3) complexes where all six Cu–Cu distances are similar, and they will be termed 6 + 0. Magneto-structural correlations for the hydroxo- and μ-alkoxo-bridged Cu^{II} complexes were proposed earlier by Hatfield and co-workers [46]. From all the above works it is quite clear that the crucial geometrical parameters which can influence the magnetic susceptibility values are the Cu–O–Cu angles and the out-of-plane shift of the atom coordinated to the bridging oxygen [47]. Hence, in the case of the hydroxo-bridged complexes an angle of 98.5° marks the border between ferro- and antiferromagnetic complexes. Ferromagnetism is found in complexes with smaller angles, and antiferromagnetism for larger ones. Alkoxo-/phenoxo-bridged complexes show a similar trend: the larger the Cu–O–Cu angle, the stronger the antiferromagnetic coupling. We can therefore expect ideal cubanes with Cu–O–Cu angles close to 90° to be good candidates for being ferromagnetic.

In the reported complex, the analysis of the structural features within the tetranuclear Cu_4O_4 cubane core (Fig. 3) shows that the bridging system between the Cu^{II} ions is quite asymmetric. As may be anticipated for hexacoordinated Cu^{II} ions, there are short Cu–O(μ_3-phenoxo) bond lengths corresponding to the equatorial plane and long Cu–O(μ_3-phenoxo) bonds in the axial position. This

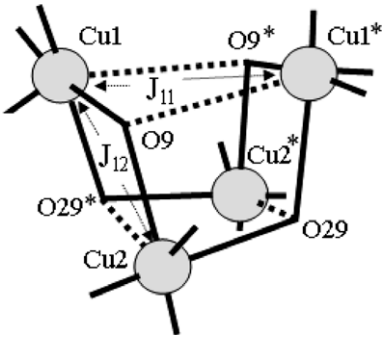

Fig. 6. Schematic representation of the exchange pathways [J_{11} = +13.6(4) cm^{-1}, J_{12} = −34.9(4) cm^{-1}].

asymmetry is also obvious from the Cu–Cu separations with the Cu1–Cu2, Cu1–Cu2* (and their symmetry related counterparts Cu1*–Cu2*, Cu1*–Cu2) distances being significantly shorter [3.229–3.253 Å] than the Cu1–Cu1* and Cu2–Cu2* distances [3.435–3.486 Å]. Therefore complex **1** clearly belongs to 4 + 2 category and the magnetic data have been analyzed considering two different magnetic coupling parameters such as J_{12} for the Cu1–Cu2 and Cu1–Cu2* interactions and J_{11} for the Cu1–Cu1* and Cu2–Cu2* interactions (Fig. 6).

From the following Hamiltonian operator:

$$\hat{\boldsymbol{H}} = -2J_{12}(\boldsymbol{S}_{Cu1}\cdot\boldsymbol{S}_{Cu2} + \boldsymbol{S}_{Cu1}\cdot\boldsymbol{S}_{Cu2*} + \boldsymbol{S}_{Cu1*}\cdot\boldsymbol{S}_{Cu2*} + \boldsymbol{S}_{Cu1*}\cdot\boldsymbol{S}_{Cu2}) - 2J_{11}(\boldsymbol{S}_{Cu1}\cdot\boldsymbol{S}_{Cu1*} + \boldsymbol{S}_{Cu2}\cdot\boldsymbol{S}_{Cu2*}).$$

The energies of the different spin states are then given by equation:

$$E(S_T) = -J_{12}[S_T(S_T+1)] + (J_{12}-J_{11})[S_{11*}(S_{11*}+1) + S_{22*}(S_{22*}+1)]$$
with $\boldsymbol{S}_T = \boldsymbol{S}_{11*} + \boldsymbol{S}_{22*}, \boldsymbol{S}_{11*} = \boldsymbol{S}_1 + \boldsymbol{S}_{1*}$ and $\boldsymbol{S}_{22*} = \boldsymbol{S}_2 + \boldsymbol{S}_{2*}$.

It leads to the following Van–Vleck equation [48]:

$$\chi_M = \frac{2N\beta^2 g^2}{kT} \times \left(\frac{2\exp(-2y) + \exp(-2x) + 5\exp(+2x)}{\exp(-4y) + 6\exp(-2y) + \exp(-4x) + 3\exp(-2x) + 5\exp(2x)}\right),$$

where, $x = J_{12}/kT$ and $y = J_{11}/kT$. The fitting of the experimental data have been carried out using this equation and taking in account an additional intermolecular interactions (zJ') in the molecular field approximation [49] and a paramagnetic impurity (S_{para} = 1/2).

$$\chi_{fit} = (1-P)\frac{\chi_M}{1 - \frac{2zJ'}{Ng^2\beta^2}\chi_M} + P\chi_{para}.$$

The best fit of the experimental data is obtained with J_{11} = +13.6(4) cm^{-1},

$$J_{12} = -34.9(4)\ cm^{-1},\quad g = 2.19(4),$$
$$zJ' = -7(2)\ cm^{-1} \text{ and } P = 1.4(3)\%.$$

The magnetic couplings thus found are in very good agreement with the structural features and also with earlier reported magneto-structural correlations in Cu^{II}-alkoxo-bridged polynuclear systems [50]. In case of the magnetic system with J_{11} exchange coupling parameter, i.e. Cu1–Cu1* and Cu2–Cu2*, the double phenoxo bridges between the Cu centers are made of one long and one short Cu–O bond lengths resulting in two long pathways [for Cu1–Cu1* system: Cu1–O9–Cu1* (or, symmetry related Cu1–O9*–Cu1*), 4.638 Å; for Cu2–Cu2* system: Cu2–O29–Cu2* (or, symmetry related Cu2–O29*–Cu2*), 4.656 Å] with the Cu–O–Cu angles in the range 94.3(3)–95.7(2)°. These structural parameters are not suitable for overlap and thus responsible for the ferromagnetic coupling [J_{11} = +13.6(4) cm^{-1}]. In contrast, both the bridges in the J_{12} type of magnetically coupled system, which includes Cu1–Cu2 (or, Cu1*–Cu2*) and Cu1–Cu2* (or, Cu1*–Cu2), are different from each other. Like the previous case, here also one bridge is made of one short and one long Cu–O bond lengths resulting in a long pathway [Cu1–O29*–Cu2, 4.662 Å; Cu1–O9*–Cu2*, 4.650 Å] with Cu–O–Cu angles in the range 86.2(3)-87.4(2)°. As mentioned before, this does not favour overlap. But here the second bridge is made of two short Cu–O bond lengths resulting in short pathway [Cu1–O9–Cu2, 3.930 Å, Cu1–O29*–Cu2*, 3.922 Å] with Cu–O–Cu angles comprising in the range 110.5(4)–112.1(3)° (Table 3). This certainly favours the overlap and explains well the antiferromagnetic coupling [J_{12} = −34.9(4) cm^{-1}].

Thus the magnetic susceptibilities have been fitted both with ferromagnetic and antiferromagnetic exchange couplings showing

a characteristic of overall antiferromagnetic behaviour due to the predominance of the antiferromagnetic interaction over the ferromagnetic one.

4. Conclusion

A novel tetranuclear Cu^{II} complex has been synthesized exploiting the tetradentate donor set of a dianionic hydrazone ligand. Single crystal X-ray diffraction analysis of the complex reveals the presence of four μ_3-phenoxo bridges connecting four different copper(II) centers in order to form an interesting Cu_4O_4 cubane core with an alternating array of copper and oxygen atoms. This kind of tetra(μ_3-phenoxo) bridged transition metal cubane core is quite rare and therefore needs further exploration. The cryomagnetic susceptibility measurements (2–300 K) demonstrate both ferromagnetic and antiferromagnetic interactions in a 2*J* model resulting in an overall antiferromagnetic behaviour of the magnetically coupled system. Here we have successfully drawn interesting magneto-structural correlations relating the bonding parameters with the magnetic exchange coupling parameters.

manifests an uncommon four-fold interpenetrated $4^2 6^3 8$–**sra** topology [15]. In these materials and other dpa-containing coordination polymer solids [16–19], the kinked orientation of the nitrogen donor atoms of the dpa and the hydrogen-bonding imparted by the central N–H group tend to act together as structure-directing agents during coordination polymer self-assembly.

In the present study, we report the significant effects of the presence of interstitial perchlorate ions on the topology of dual-ligand succinate or 2,2-dimethylsuccinate coordination polymers incorporating hydrogen-bonding capable dpa tethers. The structures of $\{[Co(suc)(Hdpa)_2(H_2O)_2](ClO_4)_2 \cdot 7.5H_2O\}_n$ (**1**), $\{[Cd_3(suc)_{2.5}(dpa)_2]\ (ClO_4)\}_n$ (**2**) and $\{[Cd_2(dmsuc)_2(dpa)(Hdpa)](ClO_4) \cdot 6H_2O\}_n$ (**3**) all vary very greatly from their perchlorate-free congeners. Complexes **1** and **3** adopt 1D straight chain and 2D (6,3) herringbone layer motifs, respectively; the structure of **2** manifests a unique 3D binodal coordination polymer lattice. Luminescent behavior within the d^{10} derivatives **2** and **3** are also discussed herein.

2. Experimental

2.1. General considerations

Hydrated metal perchlorates, succinic acid, and 2,2-dimethylsuccinic acid were obtained commercially from Aldrich. 4,4′-dipyridylamine (dpa) was prepared via a published procedure [16]. Water was deionized above 3 MΩ in-house. Elemental Analysis was carried out using a Perkin Elmer 2400 Series II CHNS/O Analyzer. IR spectra were recorded on powdered samples on a Perkin Elmer Spectrum One spectrum one instrument.

Caution! Perchlorate compounds can be explosive. Although no issues occurred during this work, minimum quantities were used and the materials were not subject to heating above the temperature of their synthesis.

2.1.1. Preparation of $\{[Co(suc)(Hdpa)_2(H_2O)_2](ClO_4)_2 \cdot 7.5H_2O\}_n$ (1)

$Co(ClO_4)_2 \cdot 6H_2O$ (100 mg, 0.273 mmol), dpa (94 mg, 0.54 mmol) and succinic acid (44 mg, 0.37 mmol) were added to 10 mL of distilled H_2O in a 23 mL Teflon lined Parr acid digestion bomb. The bomb was sealed and heated to 120 °C for 48 h at which point the bomb was gradually cooled to 23 °C. Pink crystals of **1** (63 mg, 0.071 mmol, 26% yield based on Co) were obtained after vacuum filtration and washing with distilled water and acetone, followed by air drying. Crystals of **1** were stable indefinitely in air. *Anal.* Calc. for $C_{24}H_{42}Cl_2CoN_6O_{21.5}$: C, 32.37; H, 4.98; N, 9.44. Found: C, 33.22; H, 4.70; N, 9.67%. IR (cm^{-1}): 3047m vbr, 1647w, 1606m, 1519s, 1483m, 1428w, 1411m, 1365m, 1230w, 1206m, 1087s, 1017m, 902w, 844w, 815s, 718w, 669m, 622s.

2.1.2. Preparation of $\{[Cd_3(suc)_{2.5}(dpa)_2](ClO_4)\}_n$ (2)

$Cd(ClO_4)_2 \cdot 6H_2O$ (150 mg, 0.358 mmol), dpa (165 mg, 0.963 mmol) and succinic acid (77 mg, 0.652 mmol) were added to 10 mL of distilled H_2O in a 23 mL Teflon lined Parr acid digestion bomb. The bomb was sealed and heated to 120 °C for 48 h at which point the bomb was gradually cooled to 23 °C. Colorless crystals of **2** (62 mg, 0.058 mmol, 49% yield based on Cd) were obtained. *Anal.* Calc. for $C_{30}H_{28}Cd_3ClN_6O_{14}$: C, 33.70; H, 2.64; N, 7.86. Found: C, 33.29; H, 2.55; N, 7.79%. 2.1.3. Preparation of $\{[Cd_2(dmsuc)_2(dpa)(Hdpa)](ClO_4) \cdot 6H_2O\}_n$ (3)

$Cd(ClO_4)_2 \cdot 6H_2O$ (100 mg, 0.238 mmol), dpa (110 mg, 0.642 mmol) and 2,2-dimethylsuccinic acid (47 mg, 0.322 mmol) were added to 10 mL of distilled H_2O in a 23 mL Teflon lined Parr acid digestion bomb. The bomb was sealed and heated to 120 °C for 48 h at which point the bomb was gradually cooled to 23 °C. Colorless crystals of **3** (55 mg, 0.052 mmol, 44% yield based on Cd) were obtained. *Anal.* Calc. for $C_{32}H_{45}Cd_2ClN_6O_{18}$: C, 36.19; H, 4.27; N, 7.91. Found: C, 36.40; H, 4.25; N, 7.94%. IR (cm^{-1}): 3291w br, 1595s, 1481m, 1443w, 1432m, 1404m, 1358m, 1301w, 1281w, 1257m, 1206m, 1094s, 1016m, 952w, 918w, 899m, 842w, 813s, 795m, 765w, 728w, 671w, 623s.

2.1.4. X-ray crystallography

A pink block of **1** (with dimensions 0.40 × 0.25 × 0.15 mm), a colorless block of **2** (0.25 × 0.20 × 0.16 mm) and a colorless plate of **3** (0.35 × 0.25 × 0.05 mm) were subjected to single-crystal X-ray diffraction using a Bruker-AXS SMART 1k CCD instrument. Reflection data was acquired using graphite–monochromated Mo-Kα radiation (λ = 0.71073 Å). Crystals of **1** and **2** were non-merohedral twins, with twin laws determined by CELLNOW [20]. The reflection data were integrated with SAINT [21]. Lorentz and polarization effect and empirical absorption corrections were applied with TWINABS or SADABS [22]. The structures were solved using direct methods and refined on F^2 using SHELTXL [23]. All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms bound to carbon atoms were placed in calculated positions and refined with isotropic thermal parameters using a riding model. The hydrogen atoms bound to any water molecules (except for the disordered cases in **1** and **3**) were found via Fourier difference maps, then restrained at fixed positions and refined with isotropic thermal parameters. One of the dmsuc carboxylate oxygen atoms in **3** is disordered over two positions in a 60/40 ratio. Relevant crystallographic data for **1**–**3** are listed in Table 1.

3. Results and discussion

3.1. Synthesis and spectral characterization

The coordination polymers **1–3** were obtained cleanly through the hydrothermal reaction of the appropriate metal perchlorate, either succinic acid or dimethylsuccinic acid, and dpa in a 1:1:2 mole ratio. The infrared spectra of **1–3** were consistent with their single-crystal structures. Medium intensity bands in the range of ~1600 to ~1200 cm^{-1} arise from stretching modes of the pyridyl rings of the dpa ligands. Features corresponding to pyridyl ring puckering exist in the region between ~930 and ~600 cm^{-1}. Asymmetric and symmetric C–O stretching modes of the fully deprotonated suc or dmsuc ligands were present at ~1520 and ~1360 cm^{-1}. The lack of bands in the region of ~1710 cm^{-1} indicates complete deprotonation of all carboxylate groups in **1–3**. Broad bands in the area of ~3400 to ~3200 cm^{-1} represent O–H stretching modes within water molecules of crystallization (**1** and **3**) and N–H stretching mdoes within the dpa or Hdpa ligands (all cases). The breadth of these features is attributed to hydrogen-bonding pathways (*vide infra*). Strong, broadened bands in the vicinity of 1090 cm^{-1} corroborate the presence of uncoordinated perchlorate anions in **1–3**.

3.1.1. Structural description of $\{[Co(suc)(Hdpa)_2(H_2O)_2](ClO_4)_2 \cdot 7.5H_2O\}_n$ (*1*)

Compound **1** contains an asymmetric unit of two crystallographically independent divalent cobalt atoms on inversion centers, two halves of two crystallographically distinct suc ligands, two singly protonated $Hdpa^+$ ligands, two aqua ligands, two uncoordinated perchlorate ions, and seven and a half water molecules of crystallization (Fig. 1). Operation of the inversion centers creates a $\{CoO_4N_2\}$ coordination environment at each cobalt ion, with trans nitrogen donor atoms from pendant, monodentate Hdpa ligands, trans aqua ligands and trans oxygen donor atoms belonging to *anti* conformation suc ligands. Bond lengths and angles about the cobalt ions are standard for a non-chelated octahedral coordination geometry (Table S1 in the Supplementary data).

The succinate ligands link adjacent cobalt ions with a bis(monodentate) bridging mode, to form two crystallographically independent 1D cationic $[Co(suc)(Hdpa)_2(H_2O)_2]_n^{2n+}$ coordination polymer chains arranged parallel to the *b* crystal direction (Fig. 2), heretofore denoted as chain-A (based on Co1) and chain-B (based on Co2). The Co···Co contact distances in both chain-A and chain-B are 10.062 Å, marking the *b* lattice parameter. Crystallographic distinction between the chains is provided by differences in the interring torsion angles within the Hdpa ligands (26.9° in chain-A, 29.0° in chain-B). Covalent connectivity within the chain-A and chain-B motifs is supplemented by hydrogen-bonding involving the central amine groups and protonated termini of the $Hdpa^+$ ligands and water molecules of crystallization. The unligated water molecules themselves form decorated short hydrogen-bonded chains with D3 classification [24], resembling the connectivity pattern of methylpropane. Uncoordinated perchlorate ions are anchored to the chains via hydrogen-bonding involving the water molecules of crystallization.

Aggregation of chain-A motifs into pseudolayers occurs through hydrogen-bonding involving water molecules of crystallization (O5W) bridging aqua ligands in one chain with unligated succinate oxygen atoms in an adjacent chain. Other interstitial water molecule of crystallization (O7W) links unligated succinate oxygen atoms with ligated succinate oxygen donors in a second chain-A motif (Fig. S1 in the Supporting Information). Interchain hydrogen-bonding patterns conjoining chain-B motifs are different. Here, water molecules of crystallization (O10W) located between the chains link unligated succinate oxygen atoms in both chains, and other unligated water molecules (O2W) bridge aqua ligands and ligated succinate oxygen atoms (Fig. S2). The pendant $Hdpa^+$ ligands permit interdigitation of neighboring pseudolayers and establishment of the three-dimensional structure of **1** through π–π stacking interactions with ring centroid-to-ring centroid distances of 3.721(2) and 3.744(2) Å (Fig. 3). Geometric parameters for the extensive hydrogen-bonding patterns in **1** are listed in Table S2 in the Supplementary data.

The structure of **1** contrasts greatly with that of its perchlorate-free congener $[Co(suc)(dpa)_2]_n$ despite the presence of *anti* conformation suc ligands in both cases. In the latter phase, the suc ligands adopt a bis(chelating) binding mode, made possible by the lack of any aqua ligands, thereby promoting homochiral 1D helical motifs which are connected to six others via dpa-mediated hydrogen-bonding [14]. The pendant dpa ligands in $[Co(suc)(dpa)_2]_n$ are not required to be protonated because of the absence of any unligated anionic species.

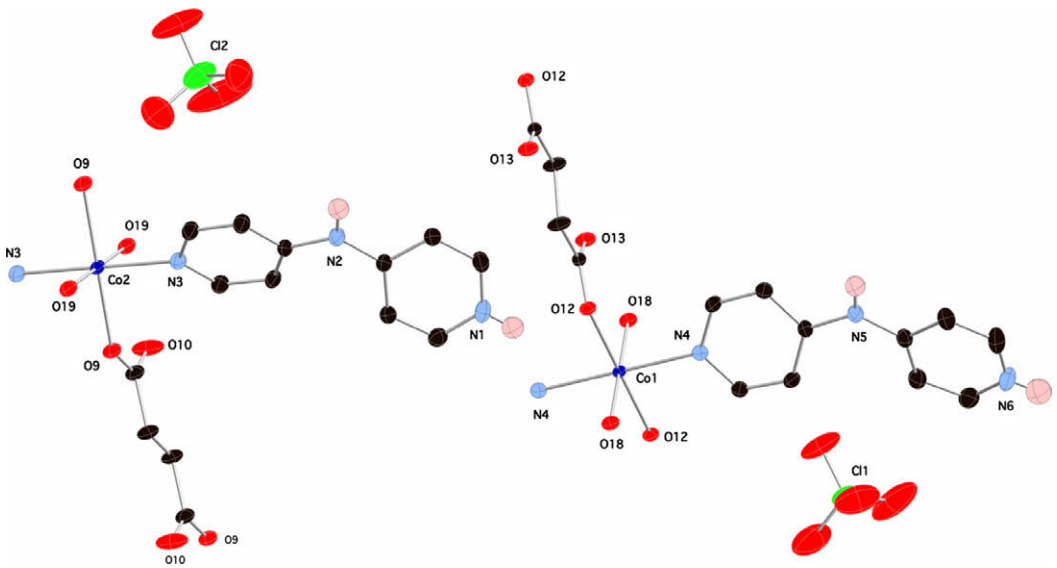

Fig. 1. Coordination environments in **1**. Thermal ellipsoids are drawn at 50% probability. Water molecules of crystallization are not shown.

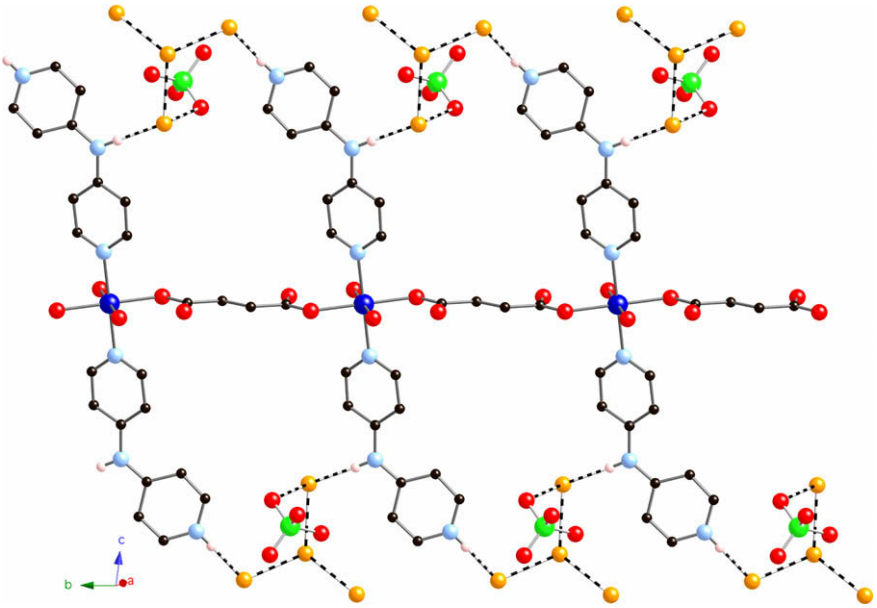

Fig. 2. A single chain-A motif in **1**, with neighboring perchlorate ions and water molecules of crystallization. Hydrogen-bonding is indicated as dashed lines. The chain-B motif is virtually identical except for a greater torsion within the pendant $Hdpa^+$ ligands.

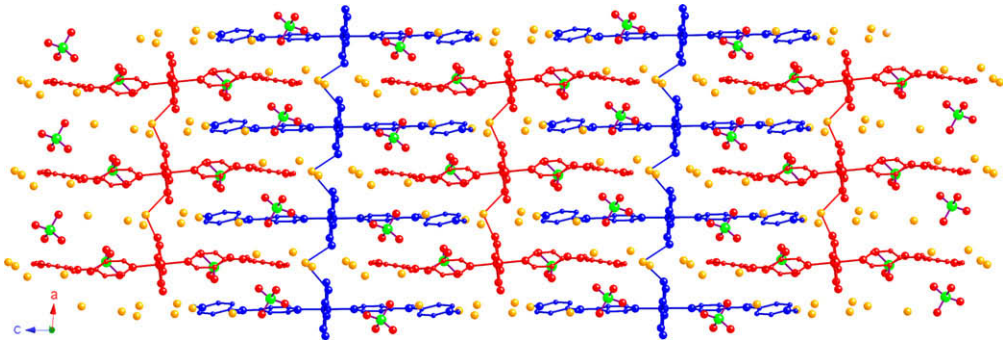

Fig. 3. Interdigitation of pseudolayers in **1**, shown in blue and red, respectively. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

*3.1.2. Structural description of $\{[Cd_3(suc)_{2.5}(dpa)_2](ClO_4)\}_n$ (**2**)*

The asymmetric unit of compound **2** consists of three crystallographically distinct cadmium ions [Cd1–Cd3], two dpa ligands [dpa-A, N1–N3; dpa-B, N4–N6], two and one half succinate dianions [suc-A, O5–O8; suc-B, O11–O14; suc-C, O9–O10], and one unligated perchlorate anion (Fig. 4). The coordination environment at Cd1 is a distorted $\{CdO_6\}$ octahedron, with two oxygen donors from a chelating terminus of suc-C ligands, and four oxygen donor atoms from two different suc-A and suc-B ligands. The coordination environments at Cd2 and Cd3 are both $\{CdN_2O_5\}$ pentagonal bipyramids with axially disposed nitrogen donor ligands from crystallographically distinct dpa ligands. The equatorial plane at Cd2 is defined by two oxygen donors from a chelating suc-B dicarboxylate group, two oxygen atoms from another suc-B ligand in a 1,4-chelating binding mode, and one oxygen atom donor from a suc-A ligand. Similarly, the equatorial plane at Cd3 is marked by two oxygen donors from a chelating suc-A dicarboxylate group, two oxygen atoms from another suc-A ligand in a 1,4-chelating binding mode, and one oxygen atom donor from a suc-B ligand. Relevant bond lengths and angles for **2** are listed in Table S3 in the Supplementary data.

Cd2 and Cd3 atoms are linked by the *gauche* conformation suc-A and suc-B (four-C atom torsion angles = 69.5° and 71.1°, respectively) dianions to construct a $[Cd_2(suc)_2]_n$ chain motif, which contains an "infinite" string of corner-shared $[Cd_2O_2]$ rhomboids (Fig. 5). The Cd2···Cd2, Cd2···Cd3, and Cd3···Cd3 contact distances across these $[Cd_2O_2]$ rhomboids are 3.938, 3.793 and 4.128 Å, respectively. The $[Cd_2(suc)_2]_n$ chain motifs based on Cd2 and Cd3 atoms are linked together by Cd1 atoms, each bound to two suc-A and two suc-B ligands, thus forming a cationic $[Cd_3(suc)_2]_n^{2n+}$ layer as seen in Fig. 5.

Neighboring $[Cd_3(suc)_2]_n^{2n+}$ layers are connected into the overall cationic $[Cd_3(suc)_{2.5}(dpa)_2]_n^{n+}$ 3D coordination polymer network of **3** (Fig. 6) through tethering dpa ligands which bridge Cd2 and Cd3 atoms, and also through *anti* conformation bis(chelating) suc-C ligands that link Cd1 atoms. The through-ligand interlayer Cd···Cd contacts are 12.058, 11.940 and 9.240 Å for dpa-A, dpa-B and suc-C, respectively. The different bridging distances for the dpa ligands are caused by variances in their inter-ring torsion angles (28.8° for dpa-A, 41.3° for dpa-B). Wider inter-ring torsion angles appear to promote shorter metal–metal through dpa contact distances. Covalent connectivity in **2** is supplemented by π–π ∗stacking of the dpa pyridyl rings in the interlayer region (ring centroid-to-ring centroid distances = 3.670(3) and 3.823(3) Å).

Unligated perchlorate ions are anchored to the cationic coordination polymer framework by hydrogen-bonding interactions

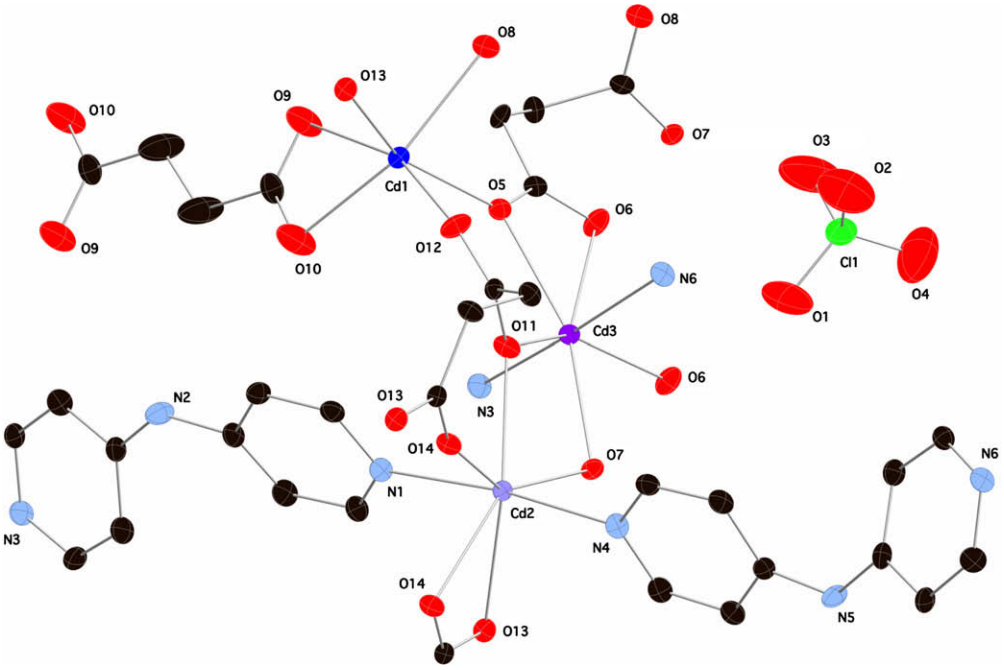

Fig. 4. Coordination environments in **2**. Thermal ellipsoids are drawn at 50% probability.

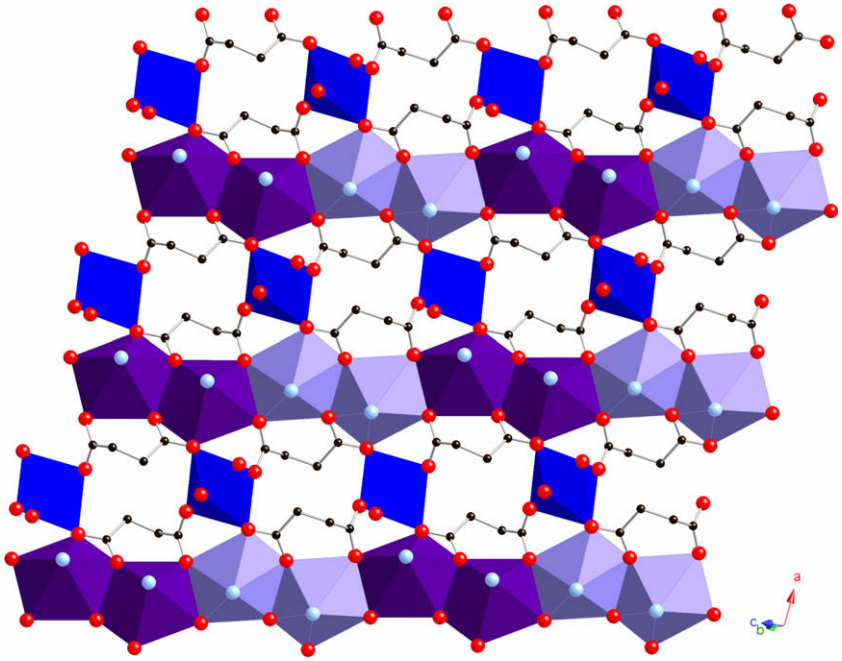

Fig. 5. A single $[Cd_3(suc)_2]_n^{2n+}$ layer in **2**. Cd1, Cd2 and Cd3 coordination spheres are shown as dark blue, light purple and dark purple polyhedra, respectively. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

fostered by the dpa central amine groups. Hydrogen-bonding parameters for **2** are given in Table S2 in the Supplementary data. According to a calculation performed with PLATON [25], the perchlorate ions occupy 10.7% of the unit cell volume of **2**.

Each Cd1 atom can be considered a 5-connected node, with connections within a single $[Cd_3(suc)_2]_n^{2n+}$ layer subunit to two Cd1 atoms and two $[Cd_2O_2]$ dimers through suc-A and suc-B ligands, and one connection to a Cd1 atom in an adjacent layer via the bis(chelating) suc-C ligands. The centroids of the $[Cd_2O_2]$ dimers can be treated as 6-connected nodes, linking two Cd1 atoms and two other $[Cd_2O_2]$ dimers within a single $[Cd_3(suc)_2]_n^{2n+}$ layer via suc-A and suc-B ligands, and two other $[Cd_2O_2]$ dimers in adjacent layers through dpa ligands. Thus the coordination polymer framework of **2** can be represented as a binodal (5,6)-connected lattice, whose topological symbol is $(4^6 6^4)(4^{10}6^5)$ as calculated by TOPOS software (Fig. 7) [26]. The long Vertex Symbol for this net is $(4.4.4.4.4.4.6_3.6_4.6_7.6_7)(4.4.4.4.4.4.4.4.4.4.6_2.6_3.6_4.6_7.6_7)$. To the best of our knowledge **2** is the first example of this binodal

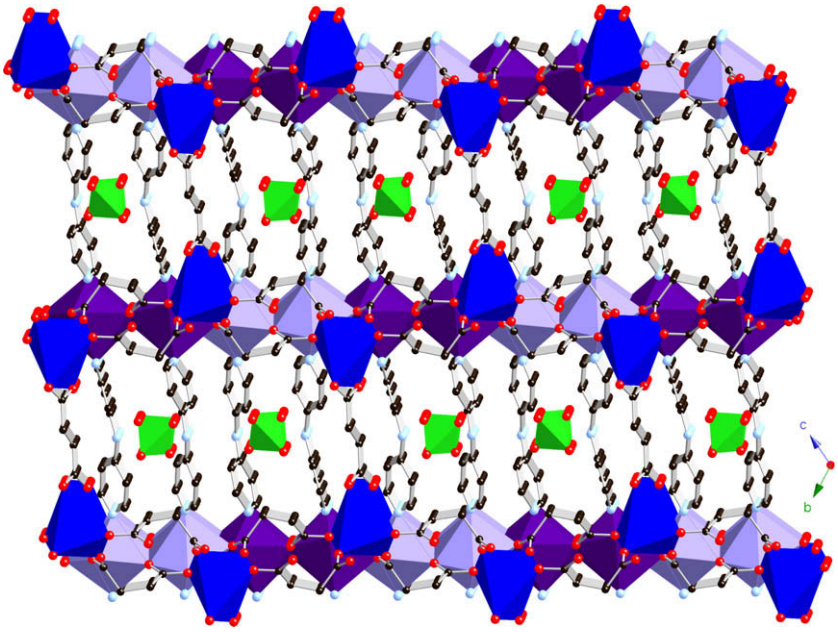

Fig. 6. The 3D coordination polymer network of **2**. Perchlorate ions can be seen in the incipient voids.

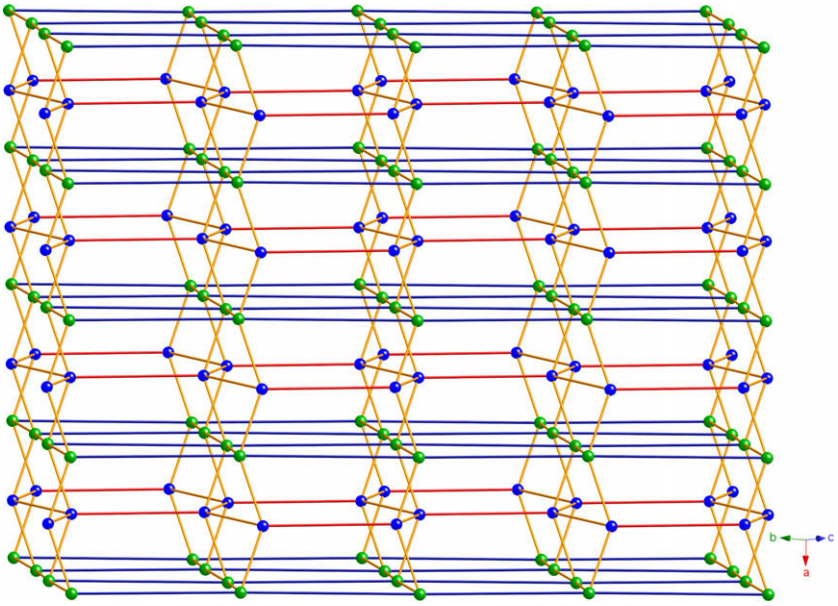

Fig. 7. Framework perspective of the $(4^6 6^4)(4^{10}6^5)$ (5,6)-connected binodal network in 2. Blue and green spheres represent the Cd1 atoms and $[Cd_2O_2]$ dimer centroids. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

topology. The network can also be viewed as alternating (4,4) rectangular and (6,3) hexagonal grids parallel to the *bc* crystal plane being joined by pillaring ligands along the *a* crystal direction.

The structure of **2** contrasts with that of its perchlorate-free analog, $\{[Cd(suc)(dpa)] \cdot H_2O\}_n$ [14], which possesses a twofold interpenetrated primitive cubic lattice formed from $[Cd(suc)]_n$ flat layers pillared by dpa ligands. In this material all of the suc ligands adopt strict *anti* conformations, with their carbon atoms resting on a crystallographic mirror plane. It is plausible that the necessity of accommodating the "spherical" perchlorate ligands into the framework forces the adjustment of some of the suc ligands into a more curved gauche conformation, resulting in a different 3D coordination polymer connectivity during self-assembly.

3.1.3. Structural description of $\{[Cd_2(dmsuc)_2(dpa)(Hdpa)](ClO_4) \cdot 6H_2O\}_n$ (3)

The asymmetric unit of compound **3** (Fig. 8) contains two divalent cadmium atoms, two dmsuc dianions [dmsuc-A, O1–O4; dmsuc-B, O5–O8], one dpa molecule, one protonated $Hdpa^+$ cation, one unligated perchlorate anion, and six water molecules of crystallization, one of which is split equally over two positions. The coordination environment at Cd1 is a distorted $\{CdO_6N\}$ pentagonal bipyramid, with a chelating carboxylate terminus from a dmsuc-B ligand occupying one axial and one equatorial position, a chelating carboxylate belonging to dmsuc-A filling two equatorial positions, and a chelating carboxylate group from a second dmsuc-A ligand taking up another equatorial site and the second

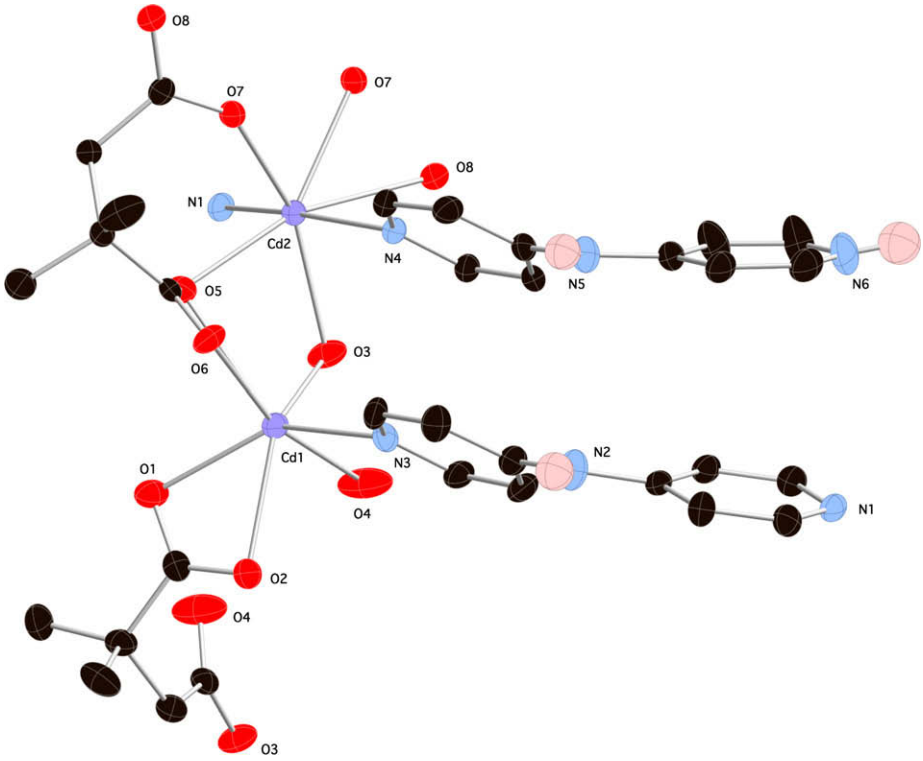

Fig. 8. Coordination environment of **3**, with thermal ellipsoids drawn at 50% probability. The perchlorate ion and water molecules of crystallization have been omitted.

axial position. The remaining equatorial site is defined by a nitrogen donor atom from an unprotonated dpa ligand. The divalent Cd2 atom also adopts a distorted pentagonal bipyramidal coordination geometry, but with a $\{CdO_5N_2\}$ arrangement. Its axial sites are occupied by nitrogen donor atoms from dpa and $Hdpa^+$ ligands. The equatorial positions at Cd2 are filled by two atoms from a dmsuc-B ligand in a 1,4-chelating binding mode, a chelating carboxylate endgroup of a second dmsuc-B ligand, and an oxygen donor atom belonging to a dmsuc-A ligand. Pertinent bond lengths and angles at the cadmium atoms are listed in Table S4 in the Supplementary data.

Each *gauche* conformation dmsuc-A ligand (four-C atom torsion angle = 57.9°) bridges two Cd1 atoms with a bis(chelating) binding mode, and also connects to a Cd2 atom via one of its carboxylate oxygen atoms. The dmsuc-B ligands also adopt a *gauche* conformation (66.8° torsion angle), and bridge Cd1 and Cd2 atoms in a bis(chelating) fashion, while binding to a second Cd2 via a 1,4-chelating arrangement. The dmsuc ligands with their divergent binding modes thus connect the cadmium atoms into a 1D $[Cd_2(dmsuc)_2]_n$ chain motif (Fig. 9). This chain contains an alternating pattern of three 4-membered{CdOCdO} and 14-membered $\{Cd(OC_4O)Cd(OC_4O)\}$ rings, across which the respective Cd···Cd contact distances measure 3.692, 3.846, 3.692 and 6.338 Å.

Conterminous $[Cd_2(dmsuc)_2]_n$ chains are connected into a 2D grid motif through tethering dpa ligands, forming (6,3) herringbone grid $[Cd_2(dmsuc)_2(dpa)(Hdpa)]_n^{n+}$ cationic layers (Fig. 10), which stack in an *AAA* pattern along the [101] crystal direction (Fig. S1). The pendant, monoprotonated $Hdpa^+$ ligands project across the grid apertures and engage in hydrogen-bonding to dmsuc-A carboxylate oxygen atoms through their protonated pyridyl termini. The water molecules of crystallization are situated between these layers, anchored to the coordination polymer framework by hydrogen-bonding donation to carboxylate oxygen atoms and hydrogen-bonding acceptance from dpa and $Hdpa^+$ central amine groups. Uncoordinated perchlorate anions are also situated in the interlamellar regions and engage in hydrogen-bonding with water molecules of crystallization. Hydrogen-bonding data for **3** is given in Table S2 in the Supplementary data. The water molecules of crystallization aggregate into a hydrogen-bonded six molecule cluster with a decorated D5 discrete five-molecule chain [24], with an additional water molecule positioned off the third molecule in the chain in a connectivity pattern reminiscent of 3-methylpentane (Fig. 11).

In contrast to **3**, its perchlorate-free analog $[Cd(dms)(dpa)]_n$ manifests a twofold interpenetrated (4,4)-grid acentric layered topology [16]. The presence of the protonated $Hdpa^+$ ligands lying

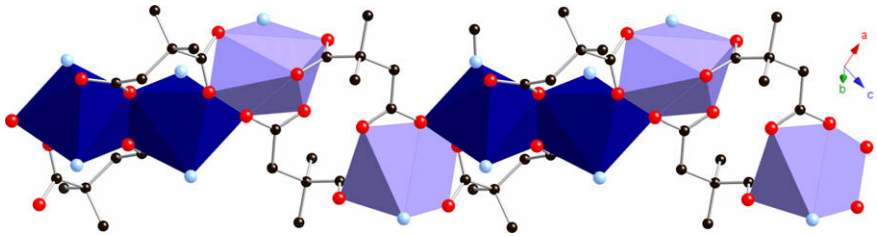

Fig. 9. A single $[Cd_2(dmsuc)_2]_n$ chain motif in **3**.

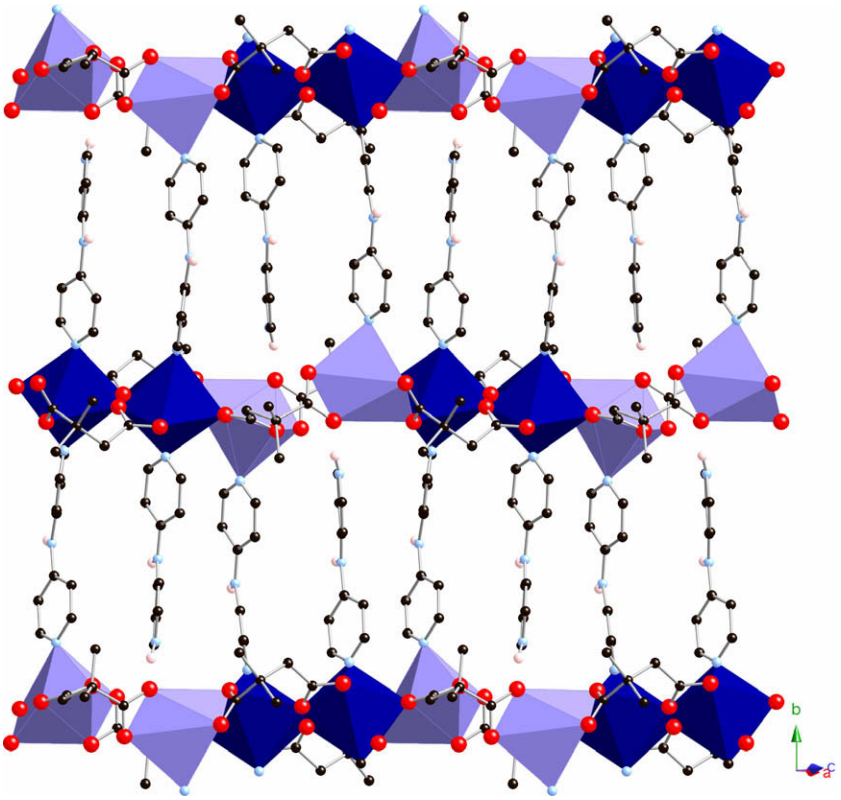

Fig. 10. A single (6,3) hexagonal grid $[Cd_2(dmsuc)_2(dpa)(Hdpa)]_n^{n+}$ cationic layer in **3**. Hydrogen-bonding is indicated as dashed lines.

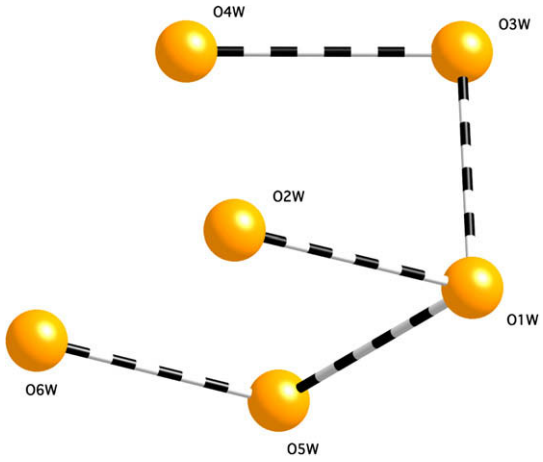

Fig. 11. The decorated D5 water molecule discrete chain in **3**.

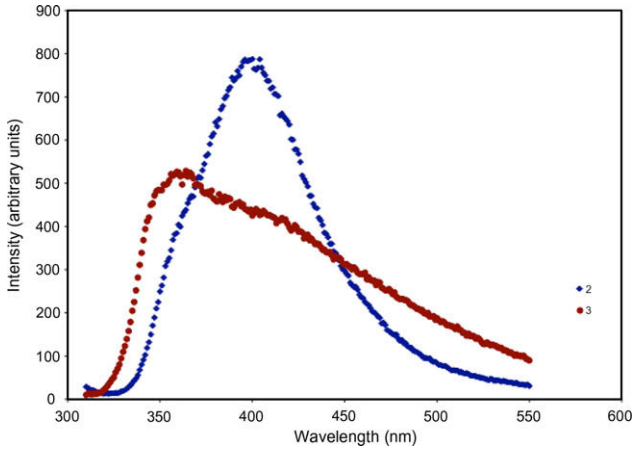

Fig. 12. Luminescence spectra of **2** and **3**.

within the grid apertures in **3** prevents interpenetration in the present case. These ligands also obviate the formation of a covalent (4,4)-grid because of their lack of covalent bridging via the distal pyridyl nitrogen atoms.

*3.1.4. Luminescent properties of **2** and **3***

In the solid state at room temperature both **2** and **3** exhibited blue-violet luminescence upon ultraviolet excitation (λ = 300 nm) (Fig. 12). The luminescent behavior of **2** and **3** is most likely attributable to ligand-centered $\pi \rightarrow \pi*$ or $\pi \rightarrow$ n orbital transitions within the aromatic rings of the dpa/Hdpa+ ligands, by comparison with other luminescent d^{10} coordination polymers [27]. The emission maximum for **2** (λ_{max} = 400 nm) is redshifted relative to that of **3** (λ_{max} = 360 nm). The spectral profile for **3** is much broader, plausibly a result of more energy loss due to radiative non-emissive pathways in the pendant $Hdpa^+$ ligands, which have greater vibrational degrees of freedom because of the absence of a metal atom at one terminus.

4. Conclusions

Incorporation of perchlorate ions into succinate/dpa dual-ligand coordination polymers has resulted in dramatic alterations in overall topology from those observed in prior anion-free derivatives. These changes are promoted either by the protonation of dpa ligands (in **1**) or the formation of a cationic 3D network (in **2**). While the perchlorate-free derivative of **2** possesses a common twofold interpenetrated primitive cubic lattice, **2** itself manifests a novel

binodal 3D cationic lattice featuring alternating (4,4) rectangular grid and (6,3) hexagonal grid layers linked through dpa ligands. Increasing the steric requirements of the dicarboxylate component resulted in a decrease in dimensionality from 3D in **2** to 2D in **3**, with concomitant protonation of the dpa ligands. The use of dipyridyl ligands containing hydrogen-bonding donating functional groups can assist in the inclusion of oxoanions during self-assembly, forcing the aliphatic α,ω-dicarboxylate ligands into different conformations and thus adjusting overall coordination polymer topology. Further efforts in this direction are currently underway.

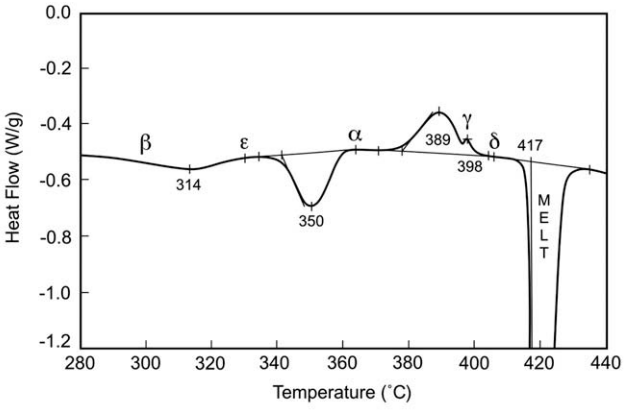

Fig. 4. Differential scanning calorimetry (DSC) curve for Alq_3. Temperatures of phase transitions are indicated on the plot. Labels indicate crystalline forms identified by *in situ* high-temperature XRD after heating to preset temperatures (β, 290 °C; ε, 330 °C; α, 365 °C; γ, 389 °C; δ, 405 °C).

2.1. Identification of Alq_3 phases by X-ray powder diffraction

X-ray powder diffraction (XRPD) is the primary technique used to assess polymorphism (same molecular species, different crystal structure) in crystalline materials. Five crystalline phases (α, β, γ, δ, and ε) of Alq_3 have been identified using XRPD [2–6] and their diffraction patterns are shown in Fig. 3.

2.2. Determination of the effect of thermal processing on Alq_3 phase transitions

To better understand thermal factors involved with the generation of the Alq_3 phases identified by XRPD, differential scanning calorimetry (DSC) was utilized. In Fig. 4, a DSC curve (heating rate 10 °C/min) for an Alq_3 sample (starting phase β Alq_3, Eastman Kodak Company) is shown. Multiple phase transitions that result from thermal processing of Alq_3 are evident.

At the temperatures where the endotherm (valley) and exotherm (peak) transitions occur in the DSC pattern, high-temperature X-ray powder diffraction (HTXRD) patterns were collected to identify the corresponding Alq_3 phase. Based on the HTXRD data, the five crystalline phases of Alq_3 identified previously are noted on the DSC pattern in Fig. 4. Each phase was identified by collecting XRD patterns immediately upon reaching a defined temperature slightly beyond the DSC transition temperature. As-received β Alq_3 was heated from 20 to 365 °C at a rate of 50 °C/min. At 365 °C 0 min (collected immediately after reaching temperature), the diffraction pattern shows Alq_3 as the α form (Fig. 5). This result is consistent with the DSC endotherm at 350 °C. After 5 min, there are small changes in the diffraction pattern that become better defined in the 15 min annealing data set, where the diffraction pattern for γ Alq_3 begins to emerge. After 1 h, γ Alq_3 is the only phase detected. Continued annealing (up to 14 h) does not produce any further change in the diffraction pattern. Upon cooling this specimen back to room temperature, XRPD data indicated that γ Alq_3 is still present.

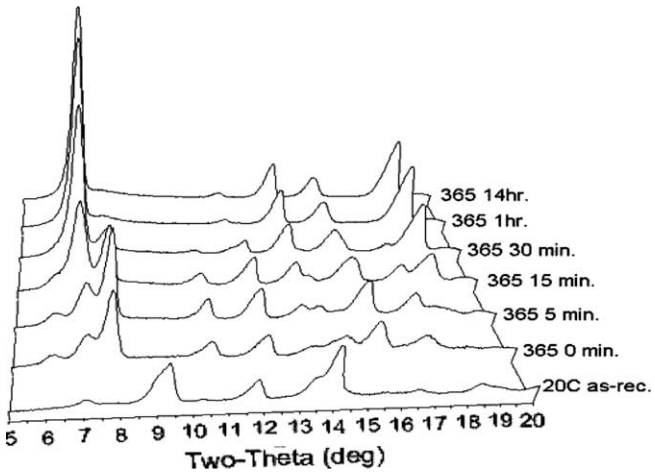

Fig. 5. High-temperature X-ray diffraction patterns for Alq_3 heated to 365 °C.

In thin films deposited using vapor deposition (VD) process, Alq_3 powder is heated at a defined temperature for a prolonged period of time, similar to what is shown in Fig. 5. The XRD patterns in Fig. 5 indicate that the phase conversion process in Alq_3 is dependent not only on the temperature but also on the time held at that temperature. We often use DSC as a method to define phase transition temperatures, noting the temperature for an observed endotherm or exotherm occurring at a specified heating or cooling rate. However, in some materials the kinetics are sluggish and, with time, phase transitions can take place at temperatures below those indicated by DSC data. A similar result was observed by HTXRD for annealing at 305 °C. Initially the sample was β Alq_3; however, upon reaching 305 °C, the sample was observed to convert to ε Alq_3. After 15 min, α Alq_3 was observed to be present, and after 1 h, the sample was completely converted to α Alq_3, even though the phase transition is observed by DSC at 350 °C. Observing the patterns for both ε Alq_3 and α Alq_3 at different temperatures during HTXRD experiments is evidence that these are two distinct Alq_3 phases. Further, contrary to the appearance of the DSC trace, α Alq_3 is thermodynamically the more stable of these two phases at temperatures as low as 305 °C.

Another important observation made during the thermal annealing studies of Alq_3 is that once the β and ε phases have been converted to the α, γ, or δ forms, or taken beyond the Alq_3 melting point (417 °C), β and ε Alq_3 will not be observed again after thermal processing by any means. In OLEDs, facial isomers are particularly desirable due to their blue-shifted fluorescence [11–13] and high quantum yield [11]. Procedures to convert from one crystalline form to another are described in detail in several patents and references [4,5,11,13]. Currently the most common method for depositing Alq_3 in OLED devices is VD, which results in formation of the α form in thin films. Efforts to make OLEDs with blue fluorescent Alq_3 films using solution processed deposition methods are being explored.

2.3. Determination of the crystal structures by single-crystal X-ray diffraction

Single-crystal X-ray diffraction was used to investigate four of the five crystalline phases of Alq_3 and the isomers that they contain. Crystals of ε Alq_3 were obtained using the HTXRD heating stage by heating β Alq_3 at 350 °C for 5 min while the Alq_3 sample on a platinum heating strip was covered with a beryllium foil [5]. The molecules in the crystal structure of ε Alq_3 are *meridional* as detailed in Ref. [5]. Crystals of δ Alq_3 for single-crystal structure determination were grown in our laboratory by a combination of sublimation and annealing in vacuum. This rather complicated procedure was developed, based upon our accumulated understanding of phase interconversions in Alq_3. The procedure is described in detail in Ref. [4]. Although thin, these crystals were found to be of acceptable quality for single-crystal data collection. The structure of δ Alq_3 was found to contain exclusively the *facial* isomer [3,4]. Although the γ phase has been identified [2] using powder XRD, to the best of our knowledge, a single-crystal XRD investigation of this phase has not been published. We too were unable to grow single crystals of the γ crystalline phase of Alq_3. Recent spectroscopic evidence (NMR, see below) has shown unambiguously that γ Alq_3 is *facial*. Chunky, excellent quality single crystals of β Alq_3 with perfectly formed surfaces can be easily obtained by subliming β Alq_3 powder in a tube furnace at 280 °C. The β Alq_3 structure was determined to contain exclusively the *meridional* isomer [2].

A structure of the α form, containing the *meridional* isomer, has been proposed on the basis of powder XRD data [2]. In the course of our HTXRD studies a thin beryllium foil is usually placed on top of the analyzed powder to prevent loss of sample through sublimation. When beryllium foil was not used, needle-like crystals identified as α Alq_3 were found to form on the cooler region of the platinum heating strip. The single crystals of α Alq_3 appeared to have the same unit-cell parameters as reported previously [2] using XRPD. The Alq_3, however, appeared to be present mostly as the *facial* isomer, with a high degree of disorder [5]. Powder XRD patterns were calculated for the present disordered structure of α Alq_3 and for the structure that was previously proposed [2]. The predictions are compared with experimental data in Figs. 6 and 7. Although both calculated patterns show rather good agreement with the observed data, upon close inspection the present

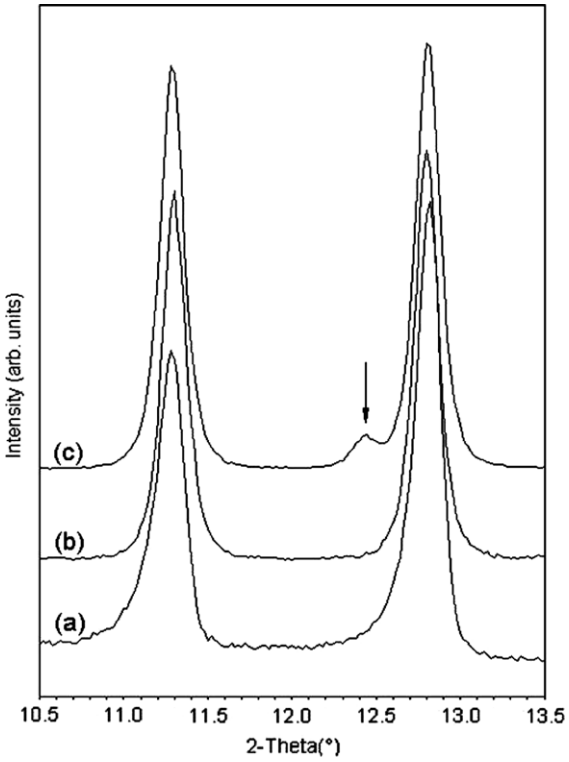

Fig. 6. Comparison of selected range powder XRD patterns for α Alq_3. (a) Observed pattern from Fig. 3; (b) calculated pattern based on the present disordered structure (c) calculated pattern based on the prior, fully ordered structure [2]. Arrow indicates an hkl (0–12) peak that is predicted only for the prior structure and is absent in the observed pattern.

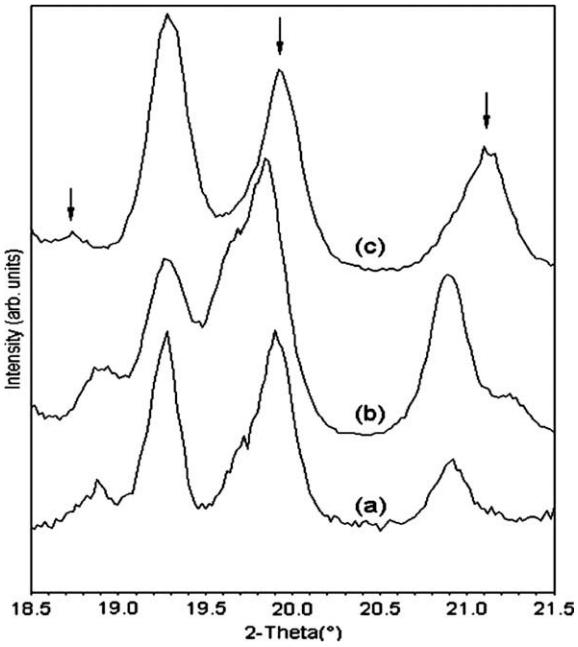

Fig. 7. Comparison of selected range powder XRD patterns for α Alq_3. (a) Observed pattern from Fig. 3; (b) calculated pattern based on the present disordered structure, (c) calculated pattern based on the prior, fully ordered structure [2]. Arrows indicate peaks that are predicted for the prior structure but are absent or shifted in both the predicted pattern for the present structure and in the observed pattern: hkl (1–21) at 18.7° 2θ, hkl (0–23) at 20.0° 2θ, and hkl (−112) at 21.1° 2θ.

disordered structure better reproduces the observed powder pattern.

Although the structure obtained by XRD appears to be predominantly or entirely *facial*, various spectroscopies are more consistent with a *meridional* composition (particularly NMR; see later sections). To resolve this contradiction, we have reconsidered the structural conclusions that can be drawn from the XRD. Somewhat overstated, our hypothesis is that α Alq_3 could be a disordered analog of ε Alq_3, with *meridional* conformation. A conclusive test of this model is not possible at present because of the difficulties involved in analyzing a disordered structure with weakly diffracting, imperfect, tiny crystals.

The unit-cell parameters for all five crystalline phases are compared in Table 1, and molecular packing is compared in Fig. 8. As illustrated in the packing diagrams (Fig. 8), the Alq_3 molecules in α, δ, and ε crystalline phases form stacks, and the propeller axes are approximately aligned with the stacking direction. As shown in Table 1 and Fig. 8, the unit-cell parameters and packing in α Alq_3 are also similar to those in δ Alq_3, even though the two forms contain different isomers. The structure of γ Alq_3 is unknown, but the packing in the β form is quite different from that in the other

For simplicity, the molecules of α Alq_3 are represented by the apparent majority *facial* structure. The structure of γ Alq_3 is not yet known.

crystal forms (see Fig. 8b). The molecules still form stacks along a crystallographic axis, but the propeller axes are far from parallel to the stack axis (~30°).

2.4. Raman, fluorescence, and NMR spectra for the isolated crystalline phases

Characterization of the Alq_3 crystalline phases by XRPD and single-crystal XRD allowed us to establish reference materials. These materials were then used to obtain Raman, fluorescence, and NMR spectra for each of the isolated phases.

2.4.1. Powder micro-Raman spectra of Alq_3 phases

The Raman spectra in Fig. 9 show features that are identifiable as unique for each Alq_3 crystalline phase in this study. These spectra were collected from polycrystalline powders at 4-cm^{-1} resolution. Where there are single-crystal Raman data in the literature, our powder spectra generally agree within their more limited resolution [2,11,14,15].

The spectra in Fig. 9 have been stacked in an order that juxtaposes different crystalline phases with similar Raman spectra. Overall, the spectra appear to fall into three groups: {β}, {α,ε}, and {δ,γ}. This grouping correlates with the assignment of β Alq_3 as a *meridional* structure, ε and (according to our hypothesis) α Alq_3 as *meridional* structures that are relatively similar to each other but markedly different from β Alq_3, and δ and γ Alq_3 as *facial* structures that may contain similar stacks of Alq_3 molecules. Although there are differences within each group, there are also differences within each group. The Raman data, taken together, indicate that there are observable signature differences among the five forms of Alq_3 in the 100–600 cm^{-1} region of the Raman spectra.

The similar Raman spectra of α and ε Alq_3 support the hypothesis that α Alq_3, like ε Alq_3 is *meridional*, and is similar in structure to ε Alq_3. The bigger differences between these two crystalline forms and β Alq_3 might be taken to indicate that α and ε Alq_3 are more similar to each other than to β Alq_3, which is also *meridional* but packs differently from either α or ε Alq_3. Although the unit-cell parameters of δ are similar to those of γ Alq_3 [2,3], the differences between their spectra must be attributed to significant differences in the packing of their *facial* Alq_3 molecules. The differences among the five crystalline forms are mostly rather subtle. Even with the very close similarity between the spectra of α and ε Alq_3, it would be risky to use the Raman spectra alone to identify the isomer in any of the crystalline phases.

2.4.2. Fluorescence spectra of Alq_3 phases

Interestingly, when exposed to UV light, all *facial* polymorph samples (δ and γ) exhibited blue-shifted fluorescence [11–13] relative to the yellow-green fluorescence of *meridional* polymorphs (β and ε) of Alq_3, whereas, α Alq_3 exhibits yellow-green fluorescence. Fig. 10 is a plot of the excitation and emission spectra of powders of Alq_3 crystalline forms, with the emission and excitation spectra from each crystalline form identified at their crossing point. As seen in Fig. 10, the fluorescence spectra of solid samples of different forms of Alq_3 exhibit substantial differences in emission band position [2,6,11].

The crossing points in Fig. 10, as well as red edges of the excitation and the blue edges of the emission spectra, exhibit a characteristic ordering in energy γ + δ > δ > ε > α > β (The nominal γ sample always contained a small fraction of δ in powder; hence the designation γ + δ). While the energies at the crossing points are dependent on the peak chosen for normalization of the excitation spectra, we have observed that this choice of normalization does not change the ordering in energy among the crystalline forms. Generally, the forms α and β are at lower energy, and γ and δ are at higher energy, with the form ε falling approximately midway in energy. The spectra also retain this order through repetition of the measurement on different packings of the crystalline powders in the sample holder, and on different batches of material. This suggests that the spectra are characteristic of the crystalline phase, and we have used them in other studies to identify the crystalline phases. The spectra of α Alq_3 lie between those of the unquestionably *meridional* β and ε phases, and all three occur at longer wavelengths than those of the *facial* γ and δ Alq_3. It is tempting to use these groupings as independent evidence that α Alq_3 contains the same isomer as β and ε Alq_3. Nevertheless, the spectra of β and ε Alq_3 themselves are significantly different, and so are those of γ and δ Alq_3. Evidently, it would be risky to assign the isomer in α Alq_3 on the basis of these spectra.

2.4.2.1. Fluorescence spectra of Alq_3 phases in solution. The maximum of the emission band varies from ~470 to ~515 nm, giving quite different perceived colors to the fluorescence, ranging from light blue (γ and δ) to yellowish green (α, β, and ε Alq_3). There are two fundamentally different explanations for the band shifts, attributing them to (i) molecular properties, i.e., distinctive spectra of *facial* and *meridional* isomers, or (ii) bulk material properties, where solid-state structure determines the absorption and

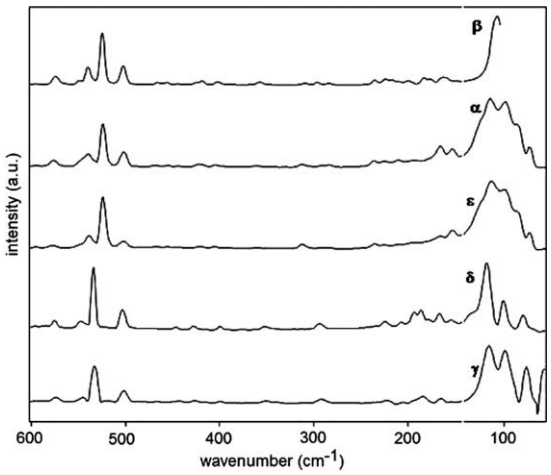

Fig. 9. Micro-Raman spectra for crystalline powders of five Alq_3 phases. The order of presentation is chosen to emphasize the similarities and differences among the crystalline forms.

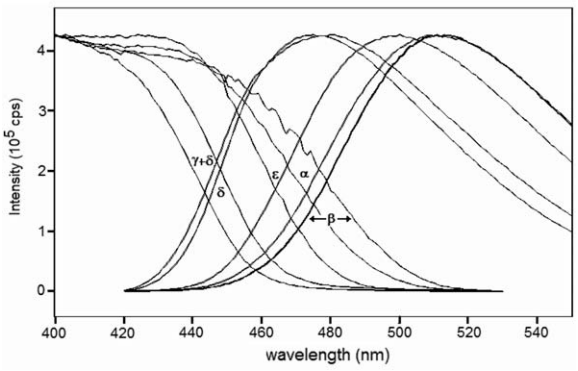

Fig. 10. Fluorescence excitation and emission spectra of Alq_3 powders of different crystalline forms. The spectra of each phase are labeled at their crossing point (as indicated by the double-headed arrow for the case of β Alq_3), without attributing a precise physical significance to that point.

emission band positions. These explanations are not mutually exclusive, and it is reasonable to expect that both molecular and bulk properties affect the optical spectra of Alq_3 samples. The differences between the two crystal forms of a single isomer (β and ε Alq_3) already indicate that solid-state effects can be important. Nonetheless, both *facial* polymorphs (γ and δ) exhibit blue shifts relative to the unequivocally *meridional* polymorphs (β and ε), and those shifts between isomers are considerably larger than the shifts between *meridional* isomers. Hence, it is important to understand whether differences between the isolated molecules also make a major contribution to the shifts.

To answer this question it is logical to examine the spectra of both isomers in solution. If molecular properties are playing a major role in the solid state, it is logical to expect comparable differences between the spectra in solution. Unlike the solution spectrum for *meridional* Alq_3, which is quite straightforward to obtain, measurements for the *facial* isomer are made difficult by the very low solubility of the available crystalline phase (δ) and the rapid conversion of the dissolved *facial* to the *meridional* isomer at room temperature. The low solubility not only decreases the intensity of the emission signal, but also requires precautions to avoid possible contamination with the *meridional* isomer, which can enrich the solution because of its higher solubility. It is also necessary to perform low-temperature filtration of the sample to exclude a relatively intense light blue fluorescence contribution originating from the Alq_3 solid particles.

In a typical experiment, ca. 1 mg of δ crystalline phase powder was placed into a vial cooled to −78 °C by a dry ice-methanol mixture. After 20 min, 15 ml of CD_2Cl_2, precooled by a dry ice-methanol mixture, was added. The sample was allowed to dissolve with occasional shaking while the temperature was maintained at −40 °C. After 1 h, the sample was cooled to −78 °C and ~2 ml was filtered through the precooled 0.25 μm PTFE membrane filter. The resultant solution was transferred into a precooled fluorimetric cuvette. The spectra were acquired using a Fluorolog-3 instrument with the right-angle geometry and 380 nm excitation wavelength. After acquiring the spectra, part of the solution was transferred into a precooled NMR tube and confirmed by proton NMR to contain a virtually pure *facial* isomer of Alq_3 (see below). The remaining solution in the fluorimetric cuvette was allowed to warm up to room temperature, kept at room temperature for 20 min to ensure complete conversion into the *meridional* isomer, and recooled before acquiring spectra to compare *facial* and *meridional* isomer spectra in identical conditions. Incidentally, we found that the spectrum of the *meridional* isomer obtained via solution conversion of the *facial* isomer, as described above, is virtually identical to the spectrum of a sample obtained directly by dissolution of a solid sample of the *meridional* isomer at room temperature and cooling to −40 °C.

The acquired fluorescence spectra are shown in Fig. 11. In notable contrast with the substantial *short*-wavelength shift observed for a solid sample of the *facial* δ crystalline phase relative to a solid sample of any *meridional* crystalline phase, the solution spectrum of *facial* Alq_3 is shifted to slightly *longer* wavelengths relative to that of *meridional* Alq_3. The emission maxima are 534 and 526 nm, respectively. Neither spectrum resembles that of the light blue emission from the solid δ phase. Not unlike the emission spectra, the excitation spectra of the *meridional* and *facial* isomers in solution are virtually identical (shifts <2 nm).

This finding appears contrary to a recent report by Muccini et al. [16] that the optical emission of *facial* Alq_3 in $CDCl_3$ solution is centered at 479 nm and has a bright blue color. However, the experimental procedure described by Muccini et al. does not include a filtration step and, therefore, yields a suspension of solid particles rather than a true solution. Considering the very low solubility of *facial* Alq_3, it is quite clear that the bright blue emission comes

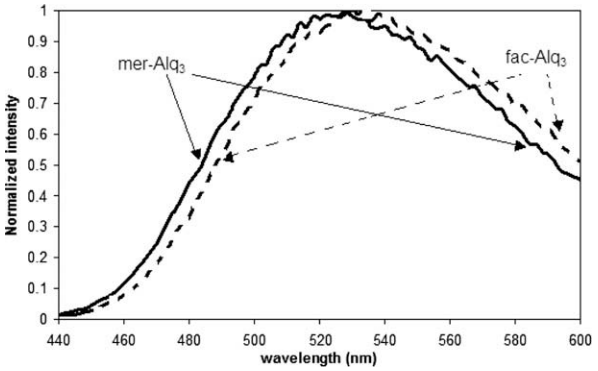

Fig. 11. Fluorescence spectra of *facial* and *meridional* isomers of Alq_3 in cold CD_2Cl_2.

from solid particles of the δ crystalline phase of *facial* Alq_3 material. In contrast, the visual appearance of emission of a solution of *facial* Alq_3 obtained by low-temperature filtration is neither bright nor blue. The present finding also disagrees with the stated conclusion of a recent study of Alq_3 molecules in an SiO_2 matrix by Levichkova et al. [17]. Emission spectra were analyzed into two components, and the bluer and greener components were identified with the *facial* and *meridional* isomers, respectively. No independent assay of the *facial* and *meridional* content of the samples was offered, nor was direct evidence that the Alq_3 is present as isolated molecules. Therefore, intriguing as the observations are, the identification of the emitting species must be regarded as speculative.

2.4.2.2. Fluorescence spectra of Alq_3 phases in powder form. It is now clear that the blue shifts of the spectra of γ and δ Alq_3 are not a consequence of distinctive spectra of the individual *facial* molecules but, rather, are largely a result of solid-state effects. Crystal packing may cause the geometry of the individual molecules to differ somewhat between the crystal and the solution, and their spectra could be shifted to an extent that depends on the isomer. There are, however, many other solid-state effects that may vary from one crystalline phase to another. Crystal packing fixes the alignment of neighboring static molecular dipoles, potentially causing the microscopic local field seen by the ground and excited states to be different for different isomers (and different polymorphs). The orientation of the ground- and excited-state dipole moments of an individual molecule, relative to the local field, probably also depend on the isomer (and the polymorph). The excitonic couplings [18,19] among the Alq_3 molecules probably vary as a consequence of differences between crystal structures and differences in the electronic structure of the *meridional* and *facial* isomers. Any of these effects might change the relative energies of the ground and excited states, leading to a shift in the absorption and emission spectra, as is evidently the case among the *meridional* crystalline phases. These solid-state factors can still be affected by differing properties of the two isomers, e.g., the ground- and excited-state dipole moments (both the magnitudes and the directions) or details of the ground- and excited-state wavefunctions (e.g., degree of delocalization of the excited state) that determine the excitonic coupling parameters. Thus, it is still possible that single-molecule properties contribute to the systematic hypsochromic shifts of the *facial* isomers relative to the *meridional*. Further, it is quite possible that the Alq_3 molecules may form similar stacks in the γ and δ crystalline phases. If so, the "systematic" shifts observed in the γ and δ crystalline phases may also be related to similarities in the molecular environments. In any case, however, it would have been demonstrably incorrect to argue that those shifts result from spectral shifts between isolated *facial* and *meridional* molecules, and to identify the isomer in α Alq_3 on that basis.

2.4.3. NMR spectra for Alq_3 crystalline phases

2.4.3.1. ^{27}Al solid-state NMR. Insight into the structures of Alq_3 crystalline phases can be gained from very-high-field ^{27}Al solid-state NMR experiments [20,21]. Spectra of three crystalline forms collected at 217.6 MHz are shown in Fig. 12. The spectrum for the β form, known from single-crystal XRD to comprise the *meridional* isomer with no disorder, is shown in Fig. 12a. This appears to be the first ^{27}Al spectrum of an unambiguously *meridional* Alq_3. The spectrum of the Alq_3 δ form *facial* isomer (Fig. 12b) is similar to spectra reported previously and is roughly as expected from the nominal molecular symmetry [20,21]. The reported spectrum of the γ form unambiguously identifies it with the *facial* isomer [21]. The spectrum of the α form (Fig. 12c) is similar to that of β Alq_3, but differs both in shape and central frequency. It is difficult to interpret this spectrum in terms of a mostly *facial* composition. On this basis, previous workers have identified the α form, instead, as *meridional* [2]. *Prima facie*, the observed difference between β and α forms could be ascribed to differences in molecular environment, as in the case of γ and δ Alq_3 [2].

2.4.3.2. Solid-state ^{13}C NMR spectra for Alq_3 isomers and polymorphs. ^{13}C NMR spectra and assignments are shown in Fig. 13. For the *facial* isomer we would expect one chemical environment, and for the *meridional*, three. Therefore, for each carbon nucleus in the quinolinolate group, naively we might expect one resonance for the *facial* and three resonances for the *meridional* isomer. However, the observed resonances are rather broad, and much of the anticipated structure is probably hidden in composite, overlapping resonances. ^{13}C is sensitive to intermolecular packing, as illustrated by the different spectra obtained for the β and ε forms. Both forms contain exclusively *meridional* Alq_3, but the molecules are arranged quite differently in their two structures. Because of the sensitivity to intermolecular interactions, a positive determination of the isomerism cannot readily be made on the basis of solid-state ^{13}C NMR spectra alone. Nevertheless, qualitative similarities and differences among the spectra are informative. The δ form, determined to be *facial* by other methods, has the narrowest resonances. The β form, determined to be *meridional* by other methods, appears to be the most complex. Thus, for the β and δ forms, the appearance of the spectra offers support for the isomer assignments. The spectra for the α and ε forms are nearly identical, while the comparison of the β with δ, and ε forms indicates the extent to which different isomers and different crystal structures can influence the spectra. Thus, while the spectra do not help to identify the isomers individually in the α and ε forms, they suggest structural similarities between the two.

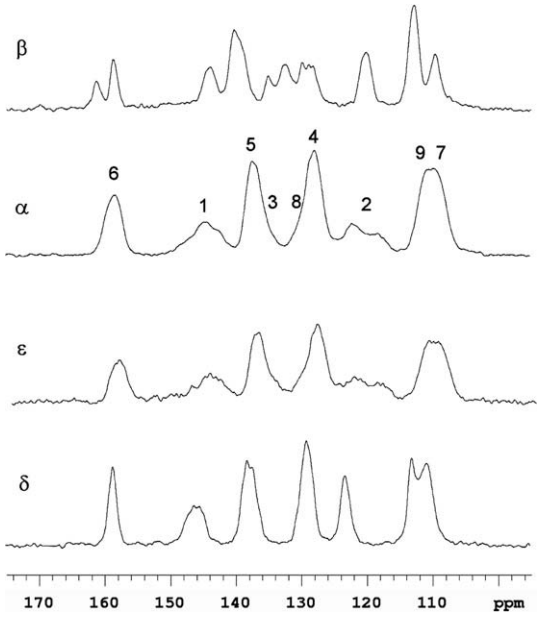

Fig. 13. ^{13}C CPMAS NMR spectra. The atom numbering is shown in Fig. 1. Assignments were not made directly on the solid samples, but are based on solution state spectra.

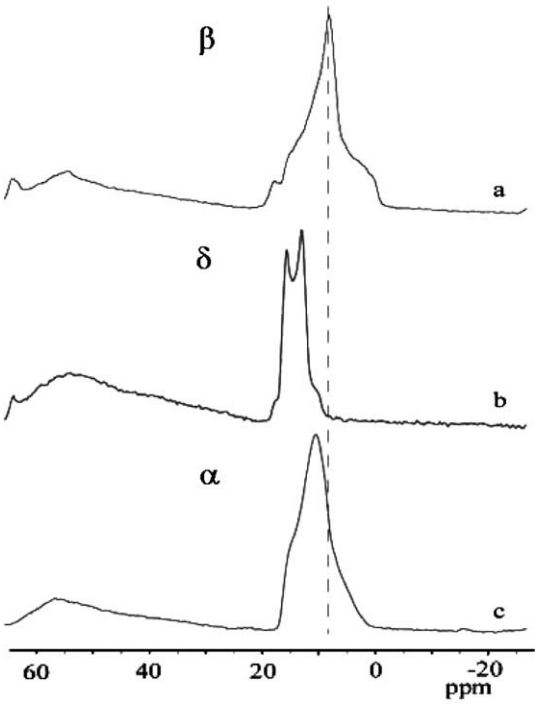

Fig. 12. ^{27}Al MAS NMR spectra of three Alq_3 crystalline forms: (a) β (*meridional*), (b) δ (*facial*), and (c) α polymorph.

Kaji et al. have reported solid-state ^{13}C NMR spectra for the α, γ, and δ crystalline forms [22]. Their spectra of α and δ Alq_3 are similar to ours. Their spectra of γ and δ Alq3 indicate that both comprise the *facial* isomer. They report modest differences between the γ and δ forms, again illustrating the sensitivity of ^{13}C NMR to molecular environment. Corresponding resonances in γ Alq_3 are split in δ Alq_3. Intermolecular packing must be responsible, as all ligands in the crystal are chemically equivalent. In fact, because of the low symmetry of the crystal structure, the three ligands in a δ Alq_3 molecule do occupy different environments.

For α Alq_3, Kaji et al. interpret the breadth of the resonances in terms of structural disorder. Clearly, if a crystal structure is ordered but possesses multiple molecular environments, and if the resolution of the spectra is limited, the result can also be the appearance of broad resonances. This point is illustrated by the generally broader resonances in our spectrum of ε Alq_3 relative to those for β Alq_3. While both polymorphs are fully ordered and comprise the same isomer, ε Alq_3 has three distinct molecular environments and β Alq_3 has only one.

2.4.3.3. ^{1}H NMR solution spectra obtained by low-temperature dissolution. When ^{1}H NMR spectra are acquired at 23 °C, solutions obtained by dissolving any of the five crystalline phases of Alq_3 (α, β, γ, δ, and ε) yield spectra consistent with the *meridional* isomer. However, if both dissolution in CD_2Cl_2 and subsequent acquisition of NMR spectra are performed at −35 °C, the α, β, and ε crystalline phases yield spectra consistent with the *meridional* isomer, while the δ and γ polymorphs yield spectra consistent with the *facial*

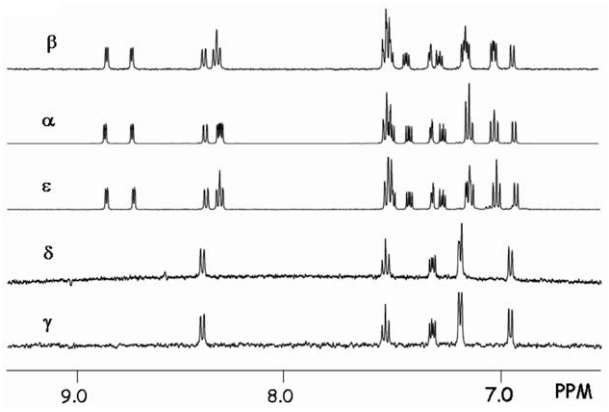

Fig. 14. Comparison of ^{1}H NMR spectra at −35 °C for solutions prepared from different crystalline forms of Alq_3.

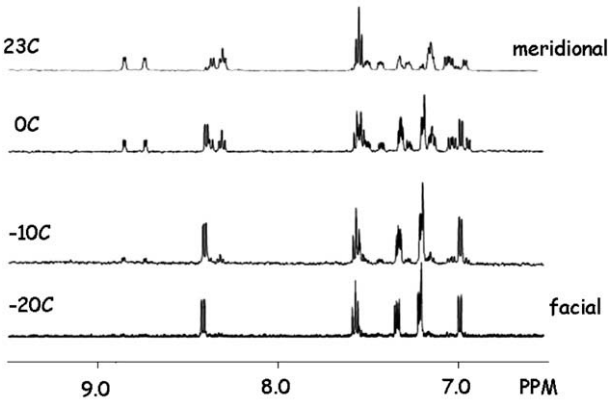

Fig. 15. ^{1}H NMR spectra for δ phase of Alq_3 dissolved in CD_2Cl_2, indicating isomerization (*facial* to *meridional* conversion) with increasing temperature.

isomer (see Fig. 14). It is known that the *meridional* isomer is the more stable in solution at room temperature, that isomerization is rapid at room temperature, and that the rate is strongly temperature-dependent [16]. To illustrate, a series of ^{1}H NMR spectra for the δ crystalline phase (*facial* isomer), dissolved in CD_2Cl_2 at −40 °C, was acquired (∼15 min/spectrum) in a step-wise fashion through a temperature range of −20 to 23 °C, as shown in Fig. 15. The *meridional* isomer begins to form at approximately −10 °C, and complete conversion to the *meridional* isomer is achieved by 23 °C. Therefore, the spectra obtained by dissolution and spectroscopy at −35 °C are most probably indicative of the isomeric state in each crystalline phase. In particular, the spectra in Fig. 14 strongly suggest that α Alq_3 is *meridional* and confirm that γ Alq_3 is *facial*. Incidentally, a solution of *meridional* Alq_3, upon cooling from room temperature to −30 °C, remained *meridional*.

3. Summary and conclusions

Five crystalline phases of Alq_3 have been identified using X-ray diffraction techniques. Single-crystal structures of four (α, β, δ, and ε) have been determined. High-quality single-crystal data indicate that β and ε Alq_3 contain the *meridional* isomer and that δ Alq_3 contains the *facial* isomer. Suitable crystals of γ Alq_3 have not been obtained, and the structure of this crystalline phase is unknown, although unit-cell parameters have been evaluated by powder XRD. Spectroscopic evidence identifies γ Alq_3 as a *facial* form. Only crystals of mediocre quality have ever been obtained for α Alq_3. As solved by conventional single-crystal XRD methods, the structure of these crystals appears to contain predominantly the *facial* isomer with a high degree of disorder. The fractional occupancies in this structure, however, combined with spectroscopic evidence point to a very different hypothesis. Most probably, α Alq_3 consists of the *meridional* isomer; the apparent disorder represents three orientations of the *meridional* molecules in the asymmetric unit; and, fortuitously, most of the atoms for each orientation occupy approximately the same location as the atoms in the apparent *facial* structure [23]. The asymmetric unit of ε Alq_3 also contains *meridional* molecules in three orientations, but with a regular ∼120° rotation between neighboring molecules. Both the crystallographic and the spectroscopic evidence suggest that the α and ε forms are structurally very similar, but that the ordered orientations in ε Alq_3 are supplanted by some form of disorder in α Alq_3.

Perhaps the simplest and most unambiguous indicator of the isomers present in α and γ Alq_3 is the characteristic proton NMR obtained by dissolving the various crystalline phases at low temperature. Strong additional evidence is provided by solid-state ^{13}C and ^{27}Al NMR. Raman spectra are consistent with the identifications. Although both γ and δ Alq_3 exhibit blue-shifted fluorescence and excitation (or absorption) spectra relative to α, β, and ε Alq_3, this comparison does not help to identify the isomers in each form. Hence, the spectral shifts are largely consequences of solid-state effects controlled by crystal packing.

Spectroscopic reference patterns for different crystalline phases were established. The Raman spectra clearly show features that are identifiable as unique for different crystalline forms. Nevertheless, the Raman spectra of α and ε Alq_3 are very similar, suggesting that the crystal structures of the two are also similar. The Raman spectra of γ and δ Alq_3 are also rather similar, providing some additional support for the conclusion that γ is a *facial* form.

The fluorescence and fluorescence-excitation spectra of powder samples exhibit substantial short-wavelength shifts for the *facial* crystalline species relative to the *meridional*. There are smaller, but still substantial shifts between the *meridional* β and ε polymorphs and between the *facial* γ and δ polymorphs, indicating the magnitude of solid-state effects. In solution, the fluorescence spectrum of *facial* Alq_3 is only slightly shifted, and is shifted to *longer* wavelengths relative to that of *meridional* Alq_3. The excitation spectra of the two isomers in solution are virtually identical. Evidently, the shifts seen in solid-state emission spectra are dominated by solid-state, intermolecular effects rather than by differences between the spectra of the individual molecules. Evidently, too, the powder spectra cannot be used to identify the isomer in α Alq_3. The apparently systematic spectral shifts of the *facial* polymorphs relative to the *meridional* polymorphs might even be misleading. If γ Alq_3 contains stacks of molecules similar to those in δ Alq_3, the shifts could be similar for this reason rather than because the two crystalline species contain the same isomer.

Solid-state ^{27}Al NMR spectra of an unambiguous *meridional* form, β, have been obtained for the first time. The spectrum of α is rather similar to that of β, and quite different from that of the unambiguously *facial* δ form. Unlike the spectrum of β Alq_3, the exact shape of the α spectrum cannot be modeled in terms of a *meridional* species in a single environment. These observations are consistent with an assignment of α Alq_3 as *meridional* with multiple molecular environments.

Solid-state ^{13}C NMR spectra of four crystalline phases have been presented. The spectra of β and δ Alq_3 support the crystallographic assignments as *meridional* and *facial*, respectively. The spectra of the α and ε forms cannot be used directly to identify the isomers, but they are very similar to each other. In view of the sensitivity of solid-state ^{13}C NMR to both the isomer and the molecular environment, the similar spectra of α and ε Alq_3 again suggests a close similarity of the two phases.

According to the ^{1}H NMR spectra, dissolution of any of the five crystalline forms of Alq_3 (α, β, γ, δ, and ε) yields a solution of the *meridional* isomer at room temperature. In contrast, when the experiment is repeated at −35 °C, the α, β, and ε crystalline forms yield solutions of the *meridional* isomer, while the γ and δ crystalline forms yield solutions of the *facial* isomer. At room temperature, the results are determined by a rapid conversion to the more stable (in solution) isomer. At low temperature, isomerization is suppressed, and the solution spectra report the isomers present in the respective solids.

Combined powder XRD and DSC studies indicate that some phase conversion processes in Alq_3 are so sluggish that the transition temperatures obtained by DSC exceed the thermodynamic values by 80° or more. In fact, γ can be converted to δ Alq_3 even at room temperature, ~380 °C below the DSC transition temperature, by solvent processing. The phase obtained by heating depends strongly on the incubation time. Once the β and ε phases have been converted to α, γ, or δ Alq_3, or taken beyond the melting point (~417 °C), the β and ε forms are not observed again after any means of thermal processing. A *facial* phase (δ) is the most stable form at high temperature. The progression of crystalline species observed upon heating is an indication of the relative stabilities of the different forms, but not at a common temperature. Because the phase transformations are sluggish, it has not been possible to determine which isomer forms the most stable phase at room temperature. It would be interesting to determine, perhaps calorimetrically, the relative stabilities of the five crystalline phases at a common temperature. For instance, is the *facial* δ form actually the most stable phase at room temperature? Dissolved in CD_2Cl_2 around room temperature, *meridional* Alq_3 is the more stable isomer. It would be interesting to learn whether the greater stability of *facial* Alq_3 in the solid state at high temperature and the greater stability of *meridional* Alq_3 in the solution at room temperature are consequences of packing and solvation forces in the two phases or a finely poised, temperature-dependent difference in the stability of the two isomers as isolated molecules.

4. Experimental

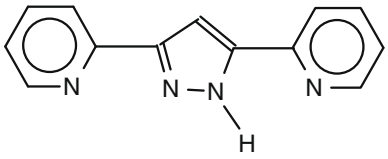
Powder diffraction data were collected using a Rigaku D2000 Bragg-Brentano diffractometer with graphite-monochromated Cu Kα radiation (1.54184 Å). To reduce peak asymmetry, incident-beam and diffracted-beam Soller slits were used. Using MDI JPOWD [24], powder XRD patterns were calculated for comparison to the observed pattern of α Alq_3.

Micro-Raman spectra were generated using a JY-Horiba LabRam spectrometer at an excitation wavelength of 633 nm and an MSPLAN 50X microscope objective. Micro-Raman spectra were collected for multiple crystallites of each sample to determine variability within and between crystallites.

Fluorescence excitation and emission spectra of polymorph powders were obtained using a Tau 3 Spex Fluorolog from JY/Horiba. A powder was either pressed or smeared against a quartz cover, and then measured in a "front-face" orientation in which the excitation light is normal to the surface of the powder, and the emission is collected at 22° relative to this normal.

^{27}Al solid-state NMR data were obtained at the National High Magnetic Field Laboratory (NHMFL) in Tallahassee, Florida. A field strength of 19.6 T, a magic angle spinning (MAS) rate of 10 kHz, and a sweep width of 40 kHz were used. ^{13}C NMR spectra were obtained on a Varian INOVA spectrometer operating at 100 MHz using MAS, cross polarization (CP), and high-power ^{1}H decoupling. Typical parameters used for acquisition were 12 kHz spinning speed, TPPM (Two Pulse Phase Modulation) decoupling, 60 s recycle delay, and 512 transients averaged.

All ^{1}H NMR spectra were obtained on a Varian Inova NMR spectrometer operating at ^{1}H observation frequency of 500 MHz, using a variable temperature 5 mm Indirect PFG (Pulse Field Gradient) probe. Solutions were prepared in CD_2Cl_2 at a consistent concentration, as well as referenced with respect to Tetramethylsilane, TMS (0.00 ppm).



Acknowledgements

The authors thank A. Lanzafame, C. Barnes, P. Reuter, R. Schultz, M. Robbins, J. Lippert, and J. Putrelo of Eastman Kodak Company for spectral measurements. We thank Drs. Zhehong Gan and Hyung-Tae Kwak of the National High Magnetic Field Laboratory (NHMFL) in Tallahassee, FL, for obtaining the ^{27}Al spectra. We thank Dr. Raymond Scaringe of Bristol Myers Squibb for useful discussions and Dr. Michael Cölle of Philips Research, The Netherlands, for useful discussions and help with some references.

a bidentate as well as tetradentate ligand depending on the ratio of metal-to-ligand used. The molecular structures of representative compounds are reported as well.

Ligand used in this study

2. Experimental

2.1. Physical measurements

Elemental analyses were performed on a Perkin–Elmer-2400 CHN/O analyzer. Infrared spectra were recorded on a Perkin–Elmer Model 983 spectrophotometer with the sample prepared as KBr pellets. The ^{1}H NMR spectra were recorded on a Bruker ACF-400 (400 MHz) spectrometer in $CDCl_3$ solvent with TMS as the internal reference. All chemicals used were of reagent grade. All reactions were carried out in distilled and dried solvents. Ruthenium trichloride trihydrate, iridium trichloride, rhodium trichloride and osmium tetraoxide (OsO_4) were purchased from Arora Matthey Ltd. The 3,5-bis(2-pyridyl)pyrazole (bpp-H) was prepared by following a literature procedure [40,41]. The precursor complexes [(η^5-C_5H_5)Ru(PPh_3)$_2$Cl] [33,42,43], [(η^5-C_5H_5)Os(PPh_3)$_2$Br] [44,45], [(η^5-C_5Me_5)Ir(μ-Cl)Cl]$_2$, [(η^5-C_5Me_5)Rh(μ-Cl)Cl]$_2$ [46], [(η^5-C_5Me_5)Ru(PPh_3)$_2$Cl] [47], [(η^6-C_6H_6)Ru(μ-Cl)Cl]$_2$ and [(η^6-*p*-^{i}PrC_6H_4Me)Ru(μ-Cl)Cl]$_2$ [48–50], were prepared by following the reported literature methods.

2.2. Single-crystal X-ray structure analyses

Crystals suitable for X-ray diffraction studies for compounds [**1**]PF_6 and [**5**]PF_6 were grown by slow diffusion of wet diethylether into a dichloromethane solution of [**1**]PF_6, and [**5**]PF_6, respectively. Whereas in the case of compound [**8**]BF_4, crystals were grown by slow diffusion of wet diethylether into an acetonitrile solution of [**8**]BF_4. A bright red crystal of [**1**]$PF_6 \cdot H_2O$ and a pale green crystal of [**5**]PF_6 were mounted on a Stoe-Image Plate Diffraction System equipped with a ϕ circle goniometer, using Mo Kα graphite monochromated radiation (λ = 0.71073 Å) with the ϕ range 0–200°, increment of 1.2°, $D_{max} - D_{min}$ = 12.45–0.81 Å. Whereas a crystal of [**8**]$BF_4 \cdot H_2O$ was mounted on a Bruker Apex CCD diffractometer in the full reciprocal sphere equipped with a CCD detector, X-ray intensity data were collected with Mo Kα graphite monochromated radiation at 120 (2) K, with a 0.3°ω scan mode and 10 s per frame. The intensity data were corrected for Lorenz and polarization effects. The structures were solved by direct methods using the program SHELXS-97 [51]. Refinement and all further calculations were carried out using SHELXL-97 [52]. The H-atoms were included in calculated positions and were treated as riding atoms using the SHELXL default parameters. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares on F^2. The data collection parameters and bond lengths and angles are presented in Tables 1 and 2, respectively.

2.3. Preparation of [(η^5-C_5H_5)M(bpp-H)(PPh_3)]PF_6 {M = Ru [**1**]PF_6, Os [**2**]PF_6}

A mixture of [(η^5-C_5H_5)M(PPh_3)$_2$X] {M = Ru, X = Cl and M = Os, X = Br} (100 mg, 0.11 mmol), 3,5-bis(2-pyridyl)pyrazole (bpp-H) (50 mg, 0.22 mmol) and NH_4PF_6 (36 mg, 0.22 mmol) in dry methanol (15 ml) were refluxed under dry nitrogen for 8 h until the color of the solution changed from pale yellow to orange. The solvent was removed under vacuum, the residue was dissolved in dichloromethane (10 ml) and the solution was filtered to remove ammonium halide. The orange solution was concentrated to 5 ml, and upon addition of diethylether the orange–yellow complex precipitated, which was separated and dried under vacuum.

ESI-MS (*m*/*z*): 722.3 [M−PF_6], 460.3 [M−PF_6−PPh_3]. UV–vis [(CH_3CN; λ_{max}, nm (ε, M^{-1} cm^{-1})]: 358 (17000).

2.5. Preparation of [(η^5-C_5Me_5)M(bpp-H)Cl]PF_6 {M = Rh [**4**]PF_6, Ir [**5**]PF_6}

A mixture of [(η^5-C_5Me_5)M(μ-Cl)Cl]$_2$ (M = Rh, Ir) (Rh dimer = 100 mg, 0.16 mmol and Ir dimer = 125 mg, 0.16 mmol), 3,5-bis(2-pyridyl)pyrazole (bpp-H) (70 mg, 0.325 mmol) and NH_4PF_6 (50 mg, 0.325 mmol) in dry methanol (15 ml) were stirred at room temperature for 6 h until the color of the solution changed from pale yellow to pale green. The solvents were removed in a rotary evaporator under reduced pressure, the residue was dissolved in dichloromethane (5 ml), and the solution filtered to remove ammonium chloride. The pale green solution was concentrated to 2 ml, when addition of excess hexane gave the orange–yellow complex, which was separated and dried under vacuum.

*Complex [**4**]PF_6*: Yield: 70 mg, 76%. Elemental *Anal.* Calc. for $C_{23}H_{25}N_4PClF_6Rh$: C, 37.8; H, 3.4; N, 7.7. Found: C, 38.0; H, 3.9; N, 7.0%. ESI-MS (*m*/*z*): 492.1 [M−BF_4], 491.1 [M−BF_4−H], 457.1[M−BF_4−Cl]. UV–vis [(CH_3CN; λ_{max}, nm (ε, M^{-1} cm^{-1})]: 430 (10000).

2.8. Preparation of [(η^6-C_6H_6)$_2$$Ru_2(bpp)Cl_2$]$BF_4$ [**8**]BF_4

A mixture of [(η^6-C_6H_6)Ru(μ-Cl)Cl]$_2$ (50 mg, 0.10 mmol), 3,5-bis(2-pyridyl)pyrazole (bpp-H) (22 mg, 0.10 mmol) and NH_4BF_4 (51 mg, 0.49 mmol) was stirred in dry methanol (15 ml) for 4 h at room temperature. The brown compound which formed was filtered, washed with methanol and diethylether, and dried under vacuum. Yield: 50 mg, 67.9%. Elemental *Anal.* Calc. for $C_{25}H_{23}N_4BCl_2F_4ORu_2$: C, 39.75; H, 3.07; N, 7.42. Found: C, 39.6; H, 3.0; N, 7.38%. IR (KBr pellets, cm^{-1}): 3416 (ν_{N-H}); 1613 ($\nu_{C=N}$); 1082 (ν_{B-F}). ^1H NMR ($CDCl_3$, δ): 8.91 (d, 1H), 8.5 (d, 1H), 8.35 (t, 2H), 8.12 (s, 1H), 7.92 (m, 2H), 7.7 (d, 1H), 7.55 (d, 1H), 6.35 (s, 6H), 6.1 (s, 6H). ESI-MS (*m*/*z*): 650.9 [M−BF_4], 649.9 [M−BF_4−H].

UV–vis [(CH_3CN; λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$)]: 328 (18000), 424 (3000).

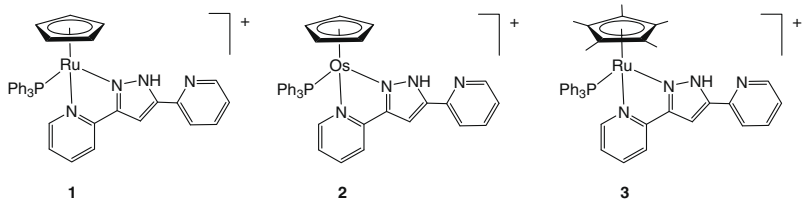
2.9. Preparation of $[(\eta^6\text{-}p\text{-}^iPrC_6H_4Me)_2Ru_2(bpp)Cl_2]BF_4$ [**9**]BF_4

A mixture of $[(\eta^6\text{-}C_{10}H_{14})Ru(\mu\text{-}Cl)Cl]_2$ (100 mg, 0.163 mmol), 3,5-bis(2-pyridyl)pyrazole (bpp-H) (36 mg, 0.16 mmol) and NH_4BF_4 (85 mg, 0.81 mmol) was stirred in dry methanol (15 ml) for 4 h at room temperature. The pale yellow compound which formed was filtered, washed with methanol and diethylether, and dried under vacuum. Yield: 95 mg, 68.44%. Elemental *Anal* . Calc. for $C_{33}H_{37}N_4BCl_2F_4Ru_2$: C, 46.66; H, 4.39; N, 6.60. Found: C, 46.5; H, 4.4; N, 6.7%. IR (KBr pellets, cm^{-1}): 3416 (ν_{N-H}); 1613 ($\nu_{C=N}$); 1082 (ν_{B-F}). ^1H NMR ($CDCl_3$, δ): 9.1 (s,1H); 8.8 (d, 1H); 8.77 (d, 1H); 8.37 (t, 1H); 7.95 (t, 2H); 7.93 (s, 1H); 7.68 (t, 1H); 6.46 (d, 1H); 6.09 (d, 1H, Ar_{p-cy}), 6.01 (d, 1H, Ar_{p-cy}), 5.99 (d, 2H, Ar_{p-cy}); 2.67 (sep, 1H), 2.17 (s, 3H), 1.04 (d, 6H). ESI-MS (*m*/*z*): 763 [$M-BF_4$], 762.0 [$M-BF_4-H$]. UV–vis [(CH_3CN; λ_{max}, nm (ε, $M^{-1}\,cm^{-1}$)]: 322 (19000), 425 (3000).

3. Results and discussion

The mononuclear η^5-cyclic hydrocarbon complexes $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)_2Cl]$, $[(\eta^5\text{-}C_5H_5)Os(PPh_3)_2Br]$ and $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)_2Cl]$ react with 3,5-bis(2pyridyl)pyrazole (bpp-H) in the presence of ammonium hexafluorophosphate in methanol to form the mononuclear cationic cyclopentadienyl ruthenium and cyclopentadienyl osmium complexes having the general formula $[(\eta^5\text{-}C_5H_5)M(bpp\text{-}H)PPh_3]^+$ (M = Ru [**1**]PF_6; M = Os [**2**]PF_6) and pentamethylcyclopentadienyl ruthenium complex having the formula $[(\eta^5\text{-}C_5Me_5)Ru(bpp\text{-}H)PPh_3]^+$ ([**3**]PF_6) (Chart 1). The complexes are orange–yellow, non-hygroscopic, air stable, crystalline solids. They are soluble in polar solvents such as methanol, dichloromethane, chloroform and acetone, but insoluble in hexane, petroleum ether and diethylether.

3.1. Cyclopentadienyl ruthenium [**1**]PF_6 and osmium [**2**]PF_6 complexes



The analytical data of these compounds are consistent with the formulations (Chart 1). These complexes are formed by the reaction of metal complexes with the bpp-H ligand, irrespective of the metal-to-ligand ratio, yielding only mononuclear compounds. Attempts to make dinuclear complexes by increasing the metal complex ratio were unsuccessful, which might be due to the steric bulkiness of the complex due to the presence of the triphenylphosphine group. The infrared spectra of the complexes [**1**]PF_6 and [**2**]PF_6 exhibit a chelated *N*,*N*′-bidentate ligand with strong bands at 3429, 3425, 1460 and 1474 cm^{-1} corresponding to the stretching frequencies of the N–H bond of the pyrazole ring and the C–N bond of the pyridine ring of the ligand. In addition, the infrared spectra contained a strong band at 850 cm^{-1} due to the stretching frequency of the P–F bond of PF_6 for both the complexes. The proton NMR spectra of these complexes exhibit a singlet at 4.75 and 4.69 ppm for the cyclopentadienyl ring protons, indicating a downfield shift from the starting complexes $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)_2Cl]$ and $[(\eta^5\text{-}C_5H_5)Os(PPh_3)_2Br]$ [42,45]. The downfield shift in the position of the cyclopentadienyl protons might result from a change in the electron density on the metal center due to chelation of the 3,5-bis(2-pyridyl)pyrazole (bpp-H) ligand through two nitrogen atoms. In addition to the other ligand peaks, as mentioned in the Section 2, a multiplet in the range 7.3–7.2 ppm, which corresponds to the phenyl protons of the triphenylphosphine group of these complexes, is observed.

The 3,5-bis(2-pyridyl)pyrazole (bpp-H) ligand reacts with the pentamethylcyclopentadienyl ruthenium(II) complexes in the presence of NH_4PF_6 in methanol, to yield the mononuclear cationic complex $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)(bpp\text{-}H)]PF_6$ ([**3**]PF_6) (Chart 1). The complex is an orange crystalline solid, soluble in polar solvents and air stable. The infrared spectrum displays a sharp band at 3424, 1613 and 850 cm^{-1}, corresponding to the stretching frequencies of the N–H bond of the pyrazole ring, the C–N bond of the pyridine ring and the P–F bond of the counter ion of the complex. In addition to the proton peaks of the ligand, as mentioned in the Section 2, the proton NMR spectrum also displays a singlet peak at 1.45 ppm corresponding to the methyl protons of the pentamethylcyclopentadienyl ring and a multiplet in the range 7.3–7.2 ppm which corresponds to the phenyl protons of the triphenylphosphine group. The $^{31}P\{^1H\}$ NMR spectra of the complexes [**1**]PF_6 and [**3**]PF_6 exhibit a single sharp resonance for triphenylphosphine at 50.8 and 49.7 ppm, respectively, whereas for the starting complexes $[(\eta^5\text{-}C_5H_5)Ru(PPh_3)_2Cl]$ and $[(\eta^5\text{-}C_5Me_5)Ru(PPh_3)_2Cl]$ the signals appear at 42.0 and 38.5 ppm, respectively [33,42,43,47]. The structure of a representative complex, [**1**]PF_6, was solved by a single crystal X-ray diffraction study (Fig. 1).

3.2. Pentamethylcyclopentadienyl rhodium [**4**]PF_6 and iridium complexes [**5**]PF_6

The dinuclear complexes $[(\eta^5\text{-}C_5Me_5)M(\mu\text{-}Cl)Cl]_2$ (M = Rh or Ir) undergo a bridge cleavage reaction with the *N*,*N*′-bidentate nitrogen base (bpp-H) ligand in methanol at room temperature, leading to the formation of the chloride displaced complexes [**4**]PF_6 and [**5**]PF_6, respectively (Scheme 1).

These complexes were isolated as their hexafluorophosphate salts. Here also we were only able to isolate the mononuclear complexes, despite the lack of triphenylphosphine groups. Change in concentration and longer reaction times do not change the reaction pathways. The orange–yellow complexes are air stable, soluble in polar solvents but insoluble in hexane, petroleum ether and diethylether. Complex [**4**]PF_6 exhibits a pale green color when dissolved in solution. The infrared spectra of the complexes [**4**]PF_6 and [**5**]PF_6 exhibit for the chelated *N*,*N*′-bidentate ligand, strong bands at 3426, 1612, 3429 and 1613 cm^{-1}, corresponding to the stretching frequencies of the C–N bond of the pyridine group and the N–H bond of the pyrazole ring. In addition, the infrared spectra contain a strong band at 850 cm^{-1} due to the ν_{P-F} stretching frequency of PF_6. The proton NMR spectra of compounds [**4**]PF_6 and [**5**]PF_6 displays a singlet at 1.48 and 1.45 ppm, corresponding to the protons

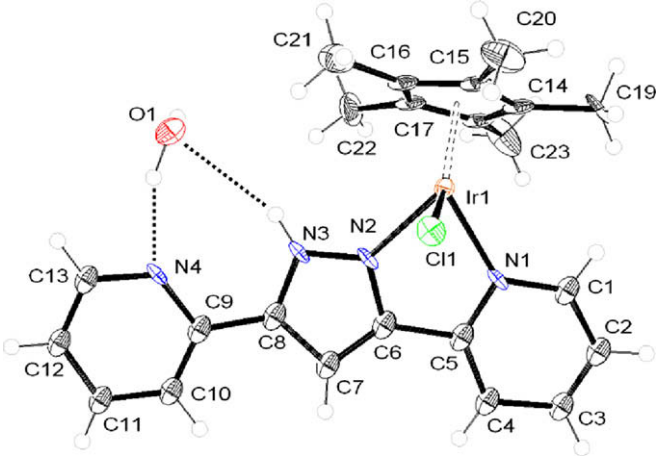
Scheme 1.

of the pentamethylcyclopentadienyl group. The molecular structure of the complex [**5**]PF_6 was solved by single crystal X-ray crystallography and the structure is presented in Fig. 2.

3.3. Mononuclear arene ruthenium complexes [6]BF_4 and [7]BF_4 and dinuclear complexes [8]BF_4 and [9]BF_4

The dinuclear arene ruthenium complexes $[(\eta^6\text{-arene})RuCl_2]_2$ (arene = benzene and *p*-cymene) react with the *N*,*N*′-based ligand (bpp-H) in methanol to produce the mononuclear cationic complexes [**6**]BF_4 and [**7**]BF_4 (Scheme 2) and the dinuclear cationic complexes [**8**]BF_4 and [**9**]BF_4 (Scheme 3). The complexes [**6**]BF_4



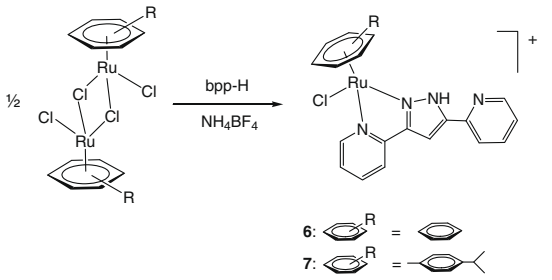


Fig. 2. ORTEP diagram with the labeling scheme for $[(\eta^5\text{-}C_5Me_5)Ir(bpp\text{-}H)Cl]^+$ ([**5**]$PF_6 \cdot H_2O$), at the 50% probability level, the PF_6 anion is omitted for clarity.

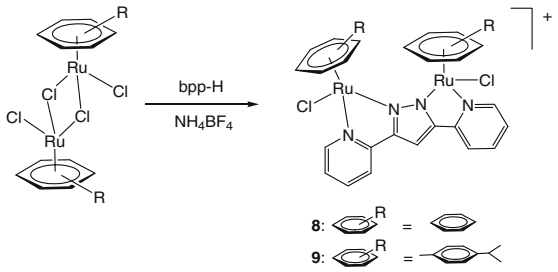
Scheme 2.



and [**7**]BF_4 are brown in color in solution, while they are yellow, non-hygroscopic, air stable solids. The complexes [**8**]BF_4 and [**9**]BF_4 are also yellow, non-hygroscopic, air stable solids, but they are sparingly soluble in polar solvents like dichloromethane, chloroform, acetone and acetonitrile, and are insoluble in non-polar solvents like hexane, diethylether and petroleum ether.

These complexes display strong bands at 3416 and 1613 cm^{-1} corresponding to the stretching frequencies of the N–H bond of the pyrazole ring and the C–N bond of the pyridine ring. In addition, the IR spectra of all these complexes contain a strong band at 1082 cm^{-1} due to the stretching frequency of the B–F bond of the counter ion of these complexes. In complex [**6**]BF_4, in addition to the proton peaks of the ligand, the NMR spectra also displays a singlet at around 6.25 ppm which corresponds to the six protons of the benzene ring. Whereas in the case of the dinuclear complex [**8**]BF_4, in addition to the ligand peaks, the spectra displays two singlet in the range of 6.3–6.1 ppm which corresponds to the protons of the two benzene rings. The formation of these compounds is also confirmed by ESI-MS spectrometry. The presence of peaks at m/z = 651.1, 740.3, 722.3, 658.5, 748.2, 437.2, 650.9, 492.1 and 763, which coincides with the molecular mass of the cationic complexes [**1**]PF_6 to [**9**]BF_4, also confirms the formation of these compounds.

An interesting point to make here is when the starting dimers $[(\eta^6\text{-arene})RuCl_2]_2$ (arene = benzene, *p*-cymene and hexamethylbenzene) are treated with terpyridine in methanol, rapid displacement of the arene group with terpyridine takes place to form a ruthenium terpyridine complex. In contrast, when [**8**]BF_4 or [**9**]BF_4 is treated with terpyridine, the reaction does not occur, i.e., the direct displacement of the arene group by terpyridine is not possible [53,54]. This could be due to the following reasons: (i) The formation of a mononuclear complex, as a solvated cationic complex in the case of $[(\eta^6\text{-arene})RuCl_2]_2$, is not possible in the case of [**8**]BF_4 or [**9**]BF_4. (ii) In these complexes the arene binds to the metal with *fac*-coordination, it is difficult then to replace this with *mer*-coordinating ligands such as terpyridine due to the frozen free rotation of ligands, unlike in the starting dimers. These complexes are prepared by different methods [38,39]. The dinuclear structure of representative complex [**8**]BF_4 was further confirmed by its molecular structure determination from a single crystal X-ray study (Fig. 3).

4. UV–vis spectroscopy

The UV–vis spectra of the representative complexes [**1**]PF_6, [**3**]PF_6, [**4**]PF_6, [**6**]BF_4, [**7**]BF_4, [**8**]BF_4 and [**9**]BF_4 were acquired in acetonitrile, and spectral data are summarized in the Section 2. Mononuclear complexes [**1**]PF_6, [**3**]PF_6, [**4**]PF_6 and [**6**]BF_4 displayed an intense transition in the UV region. The high energy absorption bands in the electronic spectra of [**1**]PF_6, [**3**]PF_6, [**4**]PF_6 and [**6**]BF_4 in the UV region at ~308–358 nm and have been assigned to ligand-centered $\pi \rightarrow \pi^*/n \rightarrow \pi^*$ transitions [55], whereas in the case of [**7**]BF_4, it shows a low energy absorption band in the visible

Scheme 3.

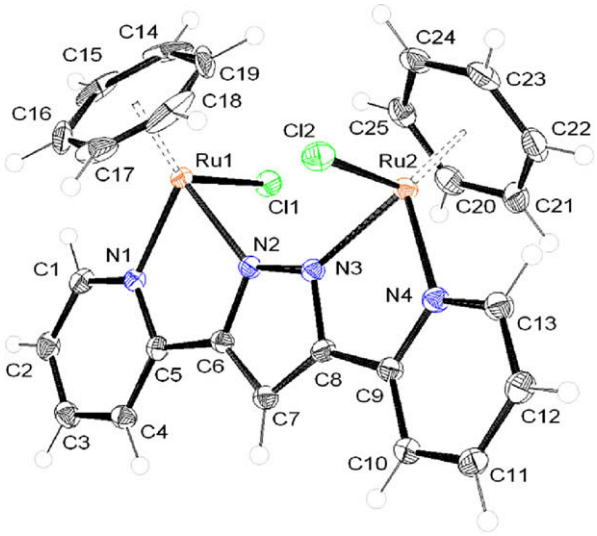


Fig. 3. ORTEP diagram with the labeling scheme for $[(\eta^6\text{-}C_6H_6)_2Ru_2(bpp)Cl_2]^+$ ([**8**]$BF_4 \cdot H_2O$), at the 50% probability level, the water and BF_4 anion are omitted for clarity.

region at ~430 nm which can be assigned to a MLCT transition. The dinuclear complexes [**8**]BF_4 and [**9**]BF_4 exhibited similar trends, with an additional band at ~425 nm that can be assigned to the MLCT band due to a $d\pi$M-arene → π^*_{bpp} transition [55], and they exhibit significant red shifts. In general, these complexes follow the normal trends observed in the electronic spectra of nitrogen bonded metal complexes, which display ligand based $\pi \rightarrow \pi^*/n \rightarrow \pi^*$ transitions in the UV region and metal-to-ligand charge transfer transitions in the visible region. The electronic spectra of these complexes are shown in Fig. 4.

5. Molecular structures

The molecular structures of $[(\eta^5\text{-}C_5H_5)Ru(bpp\text{-}H)PPh_3]PF_6$ ([**1**]PF_6) $[(\eta^5\text{-}C_5Me_5)Ir(bpp\text{-}H)Cl]PF_6 \cdot H_2O$ ([**5**]PF_6) and $[(\eta^6\text{-}C_6H_6)_2Ru_2(bpp)Cl_2]BF_4 \cdot H_2O$ ([**8**]BF_4) have been established by single-crystal X-ray analysis of their hexafluorophosphate and tetrafluoroborate salts. The complexes show a typical piano–stool geometry with the metal center coordinated by the cyclopentadienyl or arene ligand, a terminal chloride in complexes [**5**]PF_6 and [**8**]BF_4, triphenylphosphine in complex [**1**]PF_6 and the chelating bpp-H ligand. The metal atom is in an octahedral arrangement with two *cis*-nitrogen atoms of the bpp-H ligand acting as a bidentate chelating ligand through the neighboring pyridyl and pyrazolyl nitrogen atoms. In this study, the mononuclear complexes [**1**]PF_6 and [**5**]PF_6 were found to be coordinated to N1 and N2, and the dinuclear complex [**8**]BF_4 was found to have the first metal center coordinated to N1 and N2 and the second metal center coordinated

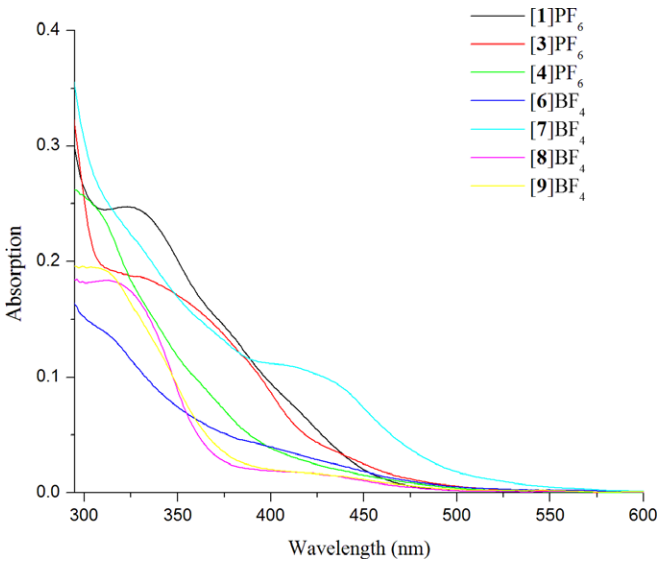

Fig. 4. UV–Visible spectra of the complexes [**1**]PF_6, [**3**]PF_6, [**4**]PF_6, [**6**]BF_4, [**7**]BF_4, [**8**]BF_4 and [**9**]BF_4 in acetonitrile at 298 K.

to N3 and N4 in a five-membered ring chelating fashion involving nitrogen atoms of the pyridine and the pyrazolyl moiety, respectively. The aromatic ring occupies three coordinate sites in these complexes to complete the octahedral geometry around the metal center. The molecular structures of complexes [**1**]PF_6, [**5**]PF_6 and [**8**]BF_4 are shown in Figs. 1–3, respectively. Selected bond lengths and angles are presented in Table 2.

The distances between the iridium atom and the centroid of the η^5-C_5Me_5 ring is 1.786 Å in complex [**5**]PF_6, whereas the distance betwen the ruthenium atom and the centroid of the η^5-C_5H_5 ring is 1.830 Å in complex [**1**]PF_6. These bond distances are comparable to those in the related complex cations $[(\eta^5\text{-}C_5Me_5)IrCl(C_5H_4\ N\text{-}2\text{-}CH{=}N\text{–}C_6H_4\text{–}p\text{–}X)]^+$, where X = NO_2 and Cl [56] and $[Ru(\eta^5\text{-}C_5H_5)(PPh_3)(\kappa^2\text{-paa})]^+$ and $[Ru(\eta^5\text{-}C_5H_5)(\kappa^1\text{-dppm})(\kappa^2\text{-paa})]^+$ [57]. Whereas in the complex [**8**]BF_4, the distances between the metal and the centeriod of the arene rings are 1.685 and 1.681 Å, which are in accordance with the values reported in other related complexes [58].

All these complexes crystallize in monoclinic space groups. The complexes [**5**]PF_6 and [**8**]BF_4 crystallize with a molecule of water per asymmetric unit. The M–N distance in complex [**5**]PF_6 appears to be significantly shorter than the M–N distances in complexes [**1**]PF_6 and [**8**]BF_4. There are no significant differences in the C–C bond lengths in the pentamethylcyclopentadienyl ring, all being about 1.337 Å and pointing to uniform π-electron delocalization in the ring. Furthermore, the five-membered ring is planar as evident in the nearly equal bond distances between metal atom and the ring carbons. The Ir–Cl bond distance is 2.398 Å, which is close to that in related iridium and rhodium complexes with two-coordinated chelating *N,N′*-based ligands [56]. An interesting structural feature of the homodinuclear complex [**8**]BF_4 is the presence of an orientational disorder for the location of the benzene ring C14–C19 (occupancy factor of 75). The ring C14–C19 is the major contribution of the disordered system, whereas the corresponding minor contribution is the orientational disorder ring C26–C31 (occupancy factor of 25) (not shown in Fig. 3). The refined site distribution of C14–19 to C26–31 is 75/25. The Ru(1)···Cl(1) 2.403(13) Å and Ru(2)···Cl(2) 2.4339(14) Å bond lengths are comparable to mononuclear complexes. However, the bond length of Ru(2)···Cl(2) is much longer than the other metal to chloride Ru(1)···Cl(1) distance despite there being no significant change in their environments.

6. Conclusion

The 3,5-bis(2-pyridyl)pyrazole (bpp-H) ligand, which posses two contiguous binding sites for metal ions, has been found to form mono- and binuclear complexes with metal precursors. However, arene ruthenium complexes yielded bimetallic complexes with bpp-H, whereas (η^5-C_5Me_5)M dimers and mononuclear triphenylphosphine complexes do not yield bimetallic complexes with bpp-H, and this could be due to the steric effect of the η^5-C_5Me_5 and PPh_3 ligands. The mononuclear complexes can be made available to bind with other less steric metal precursors to form homo or hetero bimetallic complexes through the other two nitrogen atoms of bpp-H and this work is still in progress and will be reported in the near future.

introduction of a blocking ligand. So, the tetracyano derivatives with general formula $[M(AA)(CN)_4]^-$ (M = Fe, Cr and Co; AA = bidentate ligand) have been proved to be well-suited building blocks to obtain low-dimensional cyano-bridged systems [9]. Taking the $[Fe(bipy)(CN)_4]^-$ entity as an illustrative example, its reaction with fully solvated transition metal ions, has led to single- and double-4,2-ribbon like $Fe^{III}_2M^{II}$ bimetallic chains (M = Mn, Ni, Co and Cu) [10a–e] as well as to heterometallic bi- [9], tri- [10a] and tetranuclear [10f] compounds. The extension of the coordination ability of the $[M(AA)(CN)_4]^-$ complex anion to 4f elements or conducting organic cations seems very appealing and it is a practically unexplored research area. The first attempts involving charged salts of TTF (tetrathiafulvalene) and the $[M(phen)(CN)_4]^-$ anion have led to metal-organic supramolecular systems $TTF[M(phen)(CN)_4]$ (M = Fe and Cr) with a semiconducting behaviour [11]. Also the structure and magnetic properties of the hexanuclear complex of formula $\{[Nd^{III}(NO_3)(H_2O)_3]_2[Fe^{III}(phen)(CN)_4]_4\} \cdot 2H_2O$ have been subject of a recent report [9a].

Stimulated by these preliminary results, we have tested the reactivity of the $[Fe(bipy)(CN)_4]^-$ complex toward lanthanide cations in the presence of the bpym ligand. It is worth to mention that non-covalent interactions are favoured in this type of association. At one hand, the oxophilic and highly coordinated lanthanide cations may incorporate several water molecules in their coordination sphere and, on the other hand, the cyanometallate anions are also good hydrogen acceptors. Consequently, hydrogen bonds may easily occur therein and even compete with the coordinative bonds to build supramolecular structures [12]. Bipy–bipy, bipy–bpym and bpym–bpym inter-ring stacking interactions are also possible.

These features have been checked in the 3d–4f heterobimetallic supramolecular systems $[Ln(bpym)(NO_3)_2(H_2O)_3][Fe(bipy)(CN)_4] \cdot H_2O \cdot CH_3CN$ [Ln = Sm (**1**), Gd (**2**), Tb (**3**), Dy (**4**) and Ho (**5**)] and $[Ln(bpym)(NO_3)_2(H_2O)_4][Fe(bipy)(CN)_4]$ [Ln = Pr (**6**), Nd (**7**), Sm (**8**) and Gd) (**9**)] whose preparation and structural characterization are presented here.

2. Experimental

2.1. General

All the chemicals were purchased from commercial sources as reagents pure for analysis and they were used as received. $PPh_4[Fe(bipy)(CN)_4] \cdot H_2O$ was prepared as described in the literature [10a]. The IR spectra of **1**–**9** as KBr pellets were registered on a Bruker IF S55 spectrometer. Elemental analysis (C, H, N) were performed at the Centro de Microanálisis Elemental from the Universidad Complutense de Madrid. The value of the Fe:Ln molar ratio (1:1) for **1**–**9** was determined by electron probe X-ray microanalysis at the Servicio Interdepartamental of the University of Valencia.

2.2. Synthesis

2.2.1. Preparation of $[Ln(bpym)(NO_3)_2(H_2O)_3][Fe(bipy)(CN)_4] \cdot H_2O \cdot CH_3CN$ [Ln = Sm (*1*), Gd (*2*), Tb (*3*), Dy (*4*) and Ho (*5*)]

Compounds **1**–**5** were obtained by the same general method: an acetonitrile solution (10 cm^3) of $PPh_4[Fe(bipy)(CN)_4] \cdot H_2O$ (0.05 mmol) was poured into another acetonitrile solution (10 cm^3) containing bpym (0.05 mmol) and the corresponding lanthanide salt as $Ln(NO_3)_3 \cdot nH_2O$ (0.05 mmol). The orange solid which separated immediately was removed by filtration. Slow evaporation of the filtered solution at room temperature afforded orange prisms of **1**–**5** after a few days. The yield is about 85%. *Anal.* Calc. for $C_{24}H_{25}N_{13}O_{10}FeLn$ [Ln = Sm (**1**), Gd (**2**), Tb (**3**), Dy (**4**) and Ho (**5**)]: C, 33.41; H, 2.90; N, 21.11 (**1**); C, 33.15; H, 2.87; N, 20.95 (**2**); C, 33.09; H, 2.87; N, 20.91 (**3**); C, 32.95; H, 2.86; N, 20.82 (**4**); C, 32.86; H, 2.85; N, 20.76 (**5**). Found: C, 33.20; H, 2.88; N, 20.87 (**1**); C, 33.11; H, 2.82; N, 20.62 (**2**); C, 32.93; H, 2.74; N, 20.65, (**3**); C, 32.87; H, 2.82; N, 20.72 (**4**); C, 32.95; H, 2.81; N, 20.51% (**5**). IR (cm^{-1}): 3418(m), 2927(w), 2856(w), 2128(m), 2057(m), 1636(s), 1560(m), 1519(w), 1470(w), 1444(m), 1382(s), 1310(w), 1280(w), 1032(m), 774(m), 739(w).

2.2.2. Preparation of $[Ln(bpym)(NO_3)_2(H_2O)_4][Fe(bipy)(CN)_4]$ [Ln = Pr (*6*), Nd (*7*), Sm (*8*) and Gd) (*9*)]

Compounds **6**–**9** were synthesized also following the same general method: slow inter-diffusion of mixed acetonitrile/water 1:1 (v/v) solutions of $PPh_4[Fe(bipy)(CN)_4] \cdot H_2O$ (0.03 mmol) and $Ln(NO_3)_3 \cdot nH_2O$ (0.03 mmol) and bpym (0.03 mmol) afforded X-ray quality crystals as red-orange prisms. The yield is about 90%. *Anal.* Calc. for $C_{22}H_{22}N_{12}O_{10}FeLn$ [Ln = Pr (**6**), Nd (**7**), Sm (**8**) and Gd (**9**)]: C, 32.54; H, 2.71; N, 20.70 (**6**); C, 32.40; H, 2.70; N, 22.34 (**7**); C, 32.16; H, 2.68; N, 20.46 (**8**); C, 33.09; H, 2.87; N, 20.91 (**9**). Found: C, 32.36; H, 2.70; N, 20.55 (**6**); C, 32.28; H, 2.65; N, 22.17, (**7**); C, 32.36; H, 2.61; N, 20.31, (**8**); C, 32.98; H, 2.79; N, 20.80% (**9**). IR (cm^{-1}): 3443(m), 2927(w), 2852(w), 2128(m), 2062(m), 1639(s), 1560(m), 1541(w), 1521(w), 1470(w), 1444(m), 1382(s), 1310(w), 1227(w), 1036(m), 778(m), 739(w).

2.3. X-ray data collection and structure refinement

Diffraction data set on single crystals of **1**–**9** were collected at 293(2) K (**1**–**7** and **9**) and 150(2) K (**8**) on a Nonius Kappa CCD diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). Orientation matrix and lattice parameters were determined by least-squares refinements of the reflections obtained by a $\theta-\chi$ scan (Dirac/lsq method). Data collection was done with the COLLECT [13] and the data reduction was done with EVALCCD [14] (**2**–**5** and **7**–**9**) and HKL2000 [15] (**1** and **6**) programs. Empirical absorption corrections were carried out using SADABS [16]. No significant variations were observed in the intensities of two checked reflections during data scaling. All the measured independent reflections were used in the analysis. The values of the minimum and maximum transmission factors were 0.6046/0.7159 (**1**), 0.6366/0.8859 (**2**), 0.6794/0.8587 (**3**), 0.6097/0.8103 (**4**), 0.7614/0.8460 (**5**), 0.5650/0.6732 (**6**), 0.6350/0.7127 (**7**), 0.6056/0.8230 (**8**) and 0.6050/0.6794 (**9**).

The structures of **1**–**9** were solved by direct methods through the SHELXS97 [17] computational program. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares technique on F^2 by using the SHELXL97 [17] program. The hydrogen atoms of bipy, bpym and acetonitrile molecules were placed in calculated positions and refined as riding atoms with a common fixed isotropic thermal parameter. The hydrogen atoms of the coordinated water molecules were neither found nor considered in the refinement. The values of the maximum and minimum final electron density peaks are 1.125/−1.468 (**1**), 0.830/−0.592 (**2**), 0.771/−0.686 (**3**), 0.832/−0.694 (**4**), 0.627/−0.395 (**5**), 0.708/−0.864 (**6**), 1.738/−0.842 (**7**), 0.953/−2.352 (**8**) and 0.651/−0.573 e $Å^{-3}$ (**9**). The final geometrical calculations and the graphical manipulations were carried out with the PARST97 [18], PLATON [19] and DIAMOND [20] programs. Information concerning the crystallographic data collection and structure refinement is summarized in Tables 1 (**1**–**5**) and 2 (**6**–**9**).

3. Results and discussion

3.1. Synthetic aspects and IR characterization

The versatility of the $[M(AA)(CN)_4]^-$ unit as a ligand is illustrated by Scheme 1. One can see therein the different low-dimensional species which have been materialized up to now, the ionic

salts on the top corresponding to the present work. Focusing on the reaction of the $[Fe(bipy)(CN)_4]^-$ anion with lanthanide cations in the presence of bpym as coligand, two types of 3D supramolecular heterobimetallic systems have been achieved, namely compounds **1**–**5** and **6**–**9**. The bpym molecule usually coordinates to the d and f type metal ions in a *bis*-chelating fashion [21–30], but this is not the case here where it exerts two structural functions: it acts as a bidentate ligand toward the Ln(III) ions and it is also a receptor of hydrogen atoms from the neighbouring water molecules.

The composition of the solvent induces changes in the coordination sphere of the lanthanide ions and also on the overall pattern of hydrogen bonds. So, if the reaction takes place in acetonitrile, the lanthanide ion is nine-coordinated (series **1**–**5**) whereas it is 10-coordinated (compounds **6**–**9**) when the synthesis is performed in an acetonitrile–H_2O 1:1 (v/v) mixture, the resulting three-dimensional supramolecular assemblies having different trends of the H-bonds. It is also possible that the distinct coordination geometries in complexes **1**–**5** and **6**–**9** are related to the different radii of the lanthanide ions, the smaller (Tb, Dy and Ho) being nine-coordinate and the larger (Pr and Nd) being 10-coordinate (Sm and Gd being intermediate). The infrared spectra of the compounds **1**–**9** exhibit two sharp absorptions characteristic of terminal cyanide groups at 2128 and 2057 cm^{-1}. The ring-stretching modes of coordinated bpym and bipy ligands overlap in the 1640–1560 cm^{-1} region. The medium intensity band at ca. 770 cm^{-1} is assigned to the chelating bipy ligand. Finally, the broad band observed in the high frequency region (ca. 3500–3200 cm^{-1}) is due to the presence of crystallization and coordinated water molecules which are interlinked by an extensive network of hydrogen bonds [31]. A weak intensity peak at ca. 2300 cm^{-1} in the IR spectra of **1**–**5** is assigned to the stretching vibration of the C≡N bond of the acetonitrile molecule. The spectral features of all nine compounds correspond with their single crystal X-ray structures (see below).

Scheme 1.

3.2. Description of the structure of $[Ln(bpym)(NO_3)_2(H_2O)_3][Fe(bipy)(CN)_4] \cdot H_2O \cdot CH_3CN$ [Ln = Sm (**1**), Gd (**2**), Tb (**3**), Dy (**4**) and Ho (**5**)]

Compounds **1**–**5** are isostructural and isomorphous and their structure consists of univalent $[Ln(bpym)(NO_3)_2(H_2O)_3]^+$ cations and $[Fe(bipy)(CN)_4]^-$ anions together with uncoordinated water and acetonitrile molecules which are interlinked through electrostatic forces and supramolecular interactions to afford a neutral three-dimensional network (see below). Bond lengths and angles around the Fe and Ln atoms are listed in Table 3 whereas the hydrogen bonds are given in Table 4.

The $[Ln(bpym)(NO_3)_2(H_2O)_3]^+$ cations are grouped by pairs which are interlinked through hydrogen bonds involving one coordinated water molecule [O(2w)], the crystallization water [O(4w)] and one coordinated nitrate-oxygen [O(1)] to afford a (4,4) layered motif extending in the *bc*-plane (Fig. 1a). $O_w \cdots N_{bpym}$ hydrogen bonds and slightly off-set π–π bpym–bpym interactions occur within each pair of cations, as shown in Fig. 1b. Dealing with these last interactions, the values of the centroid–centroid distance are 3.8910(2) (**1**), 3.8883(3) (**2**), 3.8838(4) (**3**), 3.8785(7) (**4**) and 3.8785(4) (**5**) Å and those of the angle between the normal of each bpym ring and the centroid–centroid vector are 19.87(11) (**1**), 19.68(11) (**2**), 19.88(11) (**3**), 19.67(10) (**4**) and 19.93(8)° (**5**).

The $[Fe(bipy)(CN)_4]^-$ anions are placed above and below the holes of the (4,4) layers (Fig. 2a) defining a *ABA* set of anionic and cationic layers which is repeating along the *a*-axis (Fig. 2b), the cations being anchored to the anions through $N_{cyanide} \cdots O_w$ hydrogen bonds where all the cyanide–nitrogen and coordinated water molecules are involved (see Table 4).

Finally, the *ABA* layers are interlinked along the *a*-axis through π–π type interactions between pairs of bipy ligands from adjacent *ABA* sets leading to a supramolecular three-dimensional network (Fig. 3). The bipy ligands are stacked in an slightly off-set conformation with values of the the centroid–centroid distances of 3.7521(1) (**1**), 3.7526(3) (**2**), 3.7452(4) (**3**), 3.7596(4) (**4**) and 3.7470(4) Å (**5**) and those of the angle between the normal of each pyridyl ring and the centroid–centroid vector being 25.56(8) (**1**), 25.71(10) (**2**), 25.49(9) (**3**), 25.46(9) (**4**) and 25.51(6)° (**5**).

Each crystallographically independent lanthanide atom is nine-coordinated: four oxygen atoms [O(1), O(2), O(4) and O(5)] belonging to two nitrate groups, two bpym-nitrogens [N(21) and N(24)] from a bidentate bpym molecule and three coordinated water molecules [O(1w), O(2w) and O(3w)] build a somewhat distorted monocapped square antiprism [mean bite value $b = 1.09$ (**1**), 1.08 (**2**–**4**) and 1.07 (**5**)] [32] around the rare-earth atom (Fig. 4). The square-planar base of the coordination polyhedron of each lanthanide atom in **1**–**5** is defined by the O(1), O(3w), N(21) and N(24) set of atoms, while the upper square-plane is built by the O(2), O(4), O(1w) and O(2w) atoms. The capping of the antiprism is achieved by the [O(5)] atom from a nitrato group. The largest $Ln–N_{bpym}$ bonds significantly contribute to the distortion polyhedron. The values of the Ln–O bond length cover the ranges 2.456(3)–2.521(3) (**1**), 2.422(3)–2.491(3) (**2**), 2.409(3)–2.479(2) (**3**), 2.392(3)–2.446(3) (**4**) and 2.379(2)–2.450(2) Å (**5**). The average values for the $Ln–O_w$ bond distances are 2.411(3) (**1**), 2.387(3) (**2**), 2.376(3) (**3**), 2.360(3) (**4**) and 2.349(2) Å (**5**), all of them being shorter than those of the mean $Ln–N_{bpym}$ bonds which are 2.619(3) (**1**), 2.596(3) (**2**), 2.575(3) (**3**), 2.564(3) (**4**) and 2.550(2) Å (**5**) (see Table 3).

These last bond lengths which cover the range 2.526(2)–2.632(3) Å are found to be somewhat smaller than those reported for similar coordination bonds in other ionic pair complexes [12b]. All distances concerning the coordination sphere of the trivalent lanthanide cations decrease with the ionic radius in the order Sm(III) (**1**) > Gd(III) (**2**) > Tb(III) (**3**) > Dy(III) (**4**) > Ho(III) (**5**) by following the lanthanide contraction.

Table 3
Bond lengths (Å) and angles (°) of the coordination environments of Fe and Ln in **1**–**5** [Ln = Sm (**1**), Gd (**2**), Tb (**3**), Dy (**4**) and Ho (**5**)].

[*] Symmetry code: [a] = $-2-x$, $-0.5+y$, $-0.5-z$; [b] = x, $-1.5-y$, $-0.5+z$; [c] = x, $-1+y$, z; [d] = $-2-x$, $-2-y$, $-z$.

Each iron atom in **1**–**5** is six-coordinated with two bipy–nitrogen and four cyanide–carbon atoms building a distorted octahedral surrounding (Fig. 4a). The reduced bite of the bidentate bipy group [(N(11)–Fe(1)–N(12) = 81.2(13) (**1**), 80.92(14) (**2**), 81.09(14) (**3**), 81.14(13) (**4**) and 81.18(9)° (**5**)] being one of the main factors accounting for this distortion. The values of the Fe(1)–N_{bipy} bonds in **1**–**5** [values varying in the range 1.980(3)–1.988(3) Å] compare well with those found in the related low-spin iron(III) complexes $PPh_4[Fe(bipy)(CN)_4]\cdot H_2O$ [1.98(2) and 2.00(2) Å] [10a], $K[Fe(bipy)(CN)_4]\cdot H_2O$ [1.990(3) and 1.991(3) Å] [10d] and $AsPPh_4[Fe(bipy)(CN)_4]\cdot CH_3CN$ [1.997(3) and 1.982(3) Å] [10e]. This agreement is also observed in the values of the Fe(1)–C_{cyano} bond lengths [values covering the range 1.904(5)–1.952(4) Å compared to 1.87(2)–1.91(2) (tetraphenylphosphonium derivative), 1.914(5)–1.958(5) (potassium salt) and 1.911(4)–1.955(4) Å (tetraphenylarsonium compound)]. The iron atom at each cyanide group in **1**–**5** is close to linearity, the values for the angle of the Fe(1)–C–N set of atoms varying in the range 177.4(5)–179.1(5)°.

Both bpym and bipy molecules are close to planarity, the first one exhibiting a somewhat greater deviation with maximum and minimum values of the inter-ring dihedral angle of 6.22(14)° (**4**) and 5.84(15)° (**1**) [the corresponding maximum and minimum values for the twisting between the pyridyl rings of bipy are 1.28(13) (**1**) and 1.69(12)° (**2**)]. The bond lengths and angles within the bipy and bpym ligands are in agreement with those reported for the free molecules [33,34].

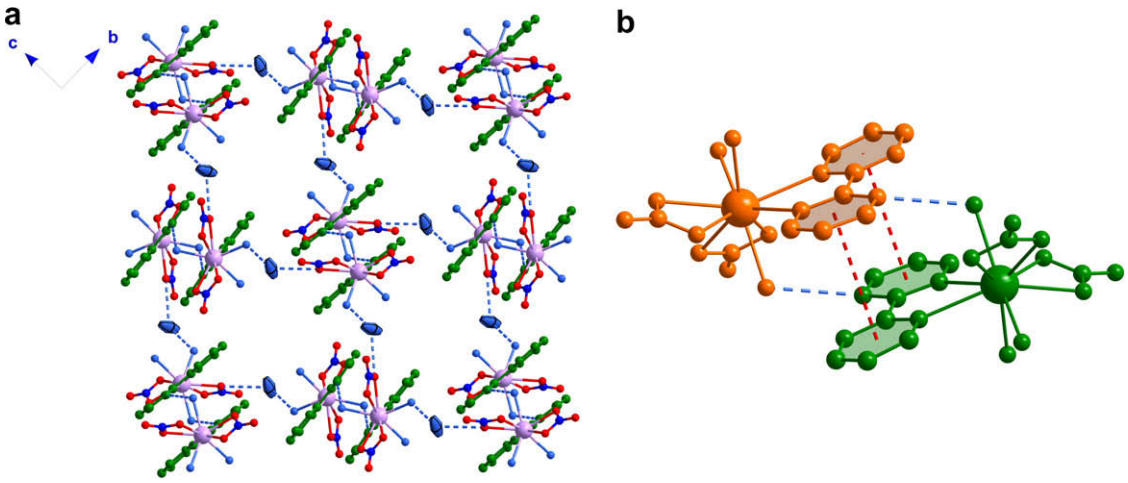

Fig. 1. (a) (4,4) rectangular supramolecular planes built by non-covalent pairs of $[Ln(bpym)(NO_3)_2(H_2O)_3]^+$ cations which are interlinked by $O_w\cdots O_w$ hydrogen bonds and (b) details of the non-covalent interactions between two $[Ln(bpym)(NO_3)_2(H_2O)_3]^+$ cationic synthons showing the $O_w\cdots N_{bpym}$ and intra-ring bpym–bpym contacts.

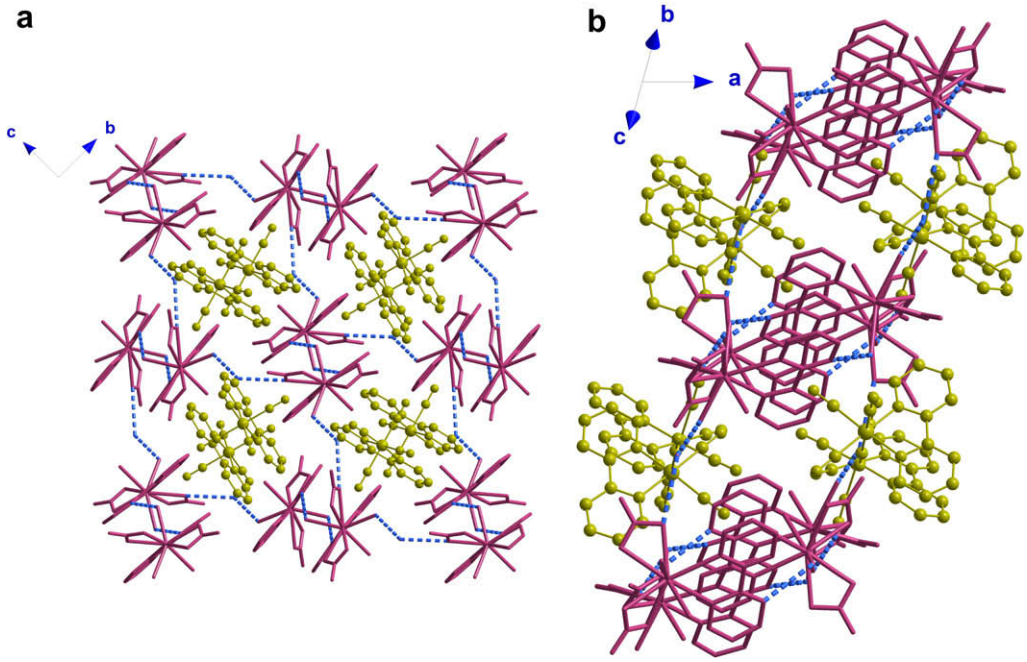

Fig. 2. Details of the crystal packing in the *bc*-plane (a) and along the *a*-axis (b) revealing the anchoring of the $[Fe(bipy)(CN)_4]^-$ anions in the 3D cavities defined by the lanthanide-based cationic synthons.

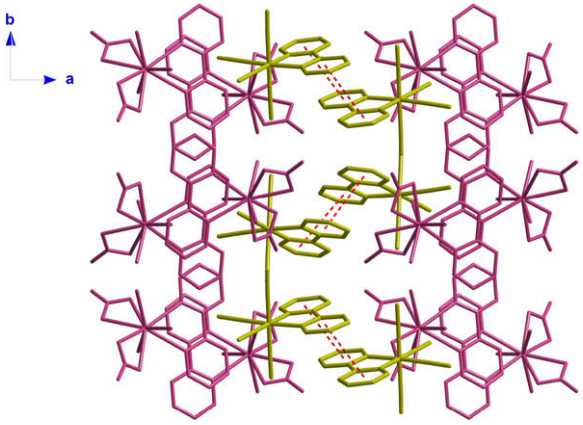

Fig. 3. Details of the crystal packing in the *ab*-plane revealing the inter-ring bipy–bipy interaction between adjacent anionic and cationic planes leading to a three-dimensional structure.

The crystallization acetonitrile molecules are stacked along the *b*-axis and they are located between layers. The shortest intermolecular separations between the iron and the lanthanide atoms occur through the C(3)–N(3)···O(3w) pathway and their values are 7.0359(6) (**1**), 7.0160(9) (**2**), 7.0110(9) (**3**), 7.0037(8) (**4**), 6.9958(7) Å (**5**) [Ln(1)···Fe(1)^d].

*3.3. Description of the structure of [Ln(bpym)(NO$_3$)$_2$(H$_2$O)$_4$][Fe(bipy)(CN)$_4$] [Ln = Pr (**6**), Nd (**7**), Sm (**8**), Gd (**9**)]*

Compounds **6**–**9** are isostructural and their structure is made up by anionic (*A*) and cationic (*B*) layers of $[Fe(bipy)(CN)_4]^-$ and $[Ln(bpym)(NO_3)_2(H_2O)_4]^+$, respectively, each one extending in the *bc*-plane, which are regularly stacked in the *ABAB* sequence along the *a*-axis through $O_w\cdots N_{cyano}$ hydrogen bonds (see Table 6) and off-set π–π bpym–bipy interactions [with values for the centroid–centroid distance of 3.8617(5) (**6**), 3.8506(4) (**7**), 3.8415(1) (**8**) and 3.8242(3) Å (**9**) and those of the angle between the normal

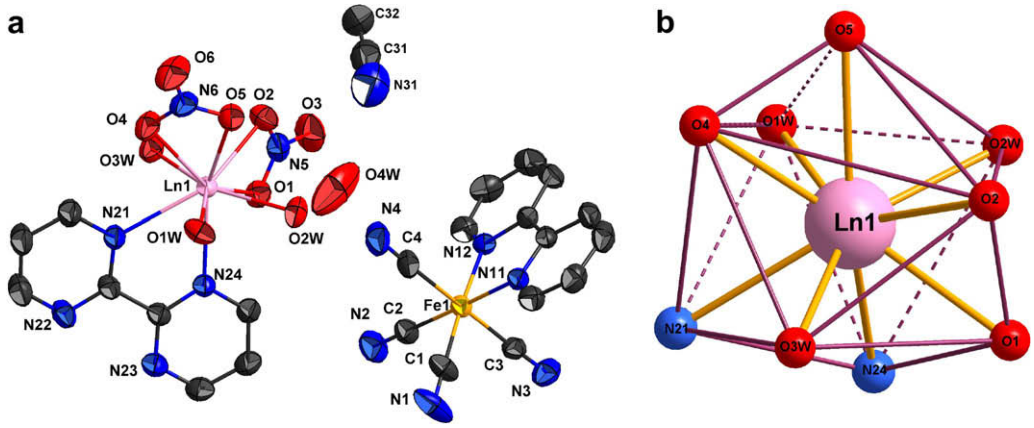

Fig. 4. (a) Perspective drawing of the crystallographically independent units of compounds **1**–**5** with the atom labelling (thermal ellipsoids are plotted at the 50% probability level) and (b) a view of the coordination polyhedron of the lanthanide atom in **1**–**5**. The hydrogen atoms have been omitted for clarity.

of the corresponding pyrimidyl ring and the centroid–centroid vector of 22.57(7) (**6**), 22.60(5) (**7**), 21.94(7) (**8**) and 22.64(5)° (**9**)] (Fig. 5). Both the anion and the cation have a C_{2v} symmetry.

Within each cationic layer, the $[Ln(bpym)(NO_3)_2(H_2O)_4]^+$ units are interlinked through $O_w\cdots N_{bpym}$ type hydrogen bonds along the *b*-axis and the resulting chains extend along the *c*-axis by means of $O_w\cdots O_{nitrate}$ hydrogen bonds (Fig. 6).

As far as the anionic layers are concerned, their $[Fe(bipy)(CN)_4]^-$ constituents are interlinked along the *c*-axis through π–π type interactions between the bipy ligands [values for the centroid–centroid distance of 3.9908(5) (**6**), 3.9808(3) (**7**), 3.9494(1) (**8**) and 3.9725(5) Å (**9**) and those of the angle between the normal of each pyridyl ring and the centroid–centroid vector of 28.29(8)° (**6**), 28.20(6) (**7**), 27.98(7) (**8**) and 27.89(5)° (**9**)] leading to supramolecular chains of iron atoms (Fig. 7).

The crystallographically independent structural units of **6**–**9** are shown in Fig. 8a. The 10-coordination of the lanthanide atom in **6**–**9** (Fig. 8b) versus the nine-coordination observed in **1**–**5** is the main difference between both families concerning these units and this structural feature determines the different supramolecular arrangement of the anions and cations in the resulting three-dimensional structures (Figs. 3 and 5) for **1**–**5** and **6**–**9**, respectively).

The bond lengths around the iron atom of the $[Fe(bipy)(CN)_4]^-$ anion in **6**–**9** [$Fe–C_{cyano}$ = 1.911(2)–1.948(3) Å and $Fe–N_{bipy}$ = 1.9880(2) and 1.992(2) Å] (see Table 5) compare well with those observed for this entity in **1**–**5**. The values of the Fe–C–N angles concerning the two *trans*-coordinated cyanide groups deviate somewhat from the strict linearity [172.0(3) and 172.5(3)°] whereas those coordinated in *cis* are very close to the linearity [177.7(2) and 177.9(3)°]. The lanthanide atoms in **6**–**9** are located on a twofold rotation axis and they are 10-coordinated with one chelating bpym, two bis-bidentate nitrato and four water molecules building a distorted bicapped square antiprism [*b*-mean value = 1.10 (**6**), 1.10 (**7**), 1.09 (**8**) and 1.09 (**9**)] [32]. The square-planar base of the polyhedron is defined by the O(1w), O(1), $O(2w)^b$ and $N(21)^b$ set of atoms while the upper square-plane is built by $O(1w)^b$, $O(1)^b$, O(2w) and N(21) atoms [(*b*) = $-x$, y, $1.5 - z$]. The O(2) and the symmetry-related $O(2)^b$ oxygen atoms cap the base and upper face of the square antiprism, respectively. The largest Ln–O bond distances concern these oxygen atoms [2.695(2) (**6**), 2.680(2) (**7**), 2.670(2) (**8**) and 2.678(2) Å (**9**)].

The bond lengths related with the trivalent lanthanide cations also decrease with the ionic radius, Pr(III) > Nd(III) > Sm(III) > Gd(III), as a result of the lanthanide contraction. The values of the $Ln–O_{nitrate}$ distances cover the range 2.4464(15)–2.695(2) Å, while those of the $Ln–O_w$ bonds are comprised between 2.3962(15) and 2.486(2) Å. The largest bond lengths at the coordination sphere of the lanthanide atom are observed for the $Ln–N_{bpym}$ bonds [2.774(3) (**6**), 2.756(2) (**7**), 2.741(3) (**8**) and 2.712(2) Å (**9**)] (see Table 5) and they are one of the sources of distortion of the coordination polyhedron of the rare-earth atom.

Focusing on the bidentate bipy and bpym ligands of **6**–**9**, their deviation from the planarity here is more accentuated than in the previous family. Although the bipy ligand is still quasi-planar [the values for the inter-ring dihedral angle vary in the range 3.63(9)–4.17(12)°], the bpym molecule is strongly distorted with values for the inter-ring dihedral angle covering the range 18.42(8)–23.32(12)°. Three factors contribute to create this significant distortion of the bpym molecule: its bidentate coordination, the $O_w\cdots N_{bpym}$ hydrogen bonds between $[Ln(bpym)(NO_3)_2(H_2O)_4]^+$ moieties (see Fig. 6) and the weak inter-ring bipy–bpym interactions [the values of the interplanar distances varying in the range 3.82–3.86 Å]. The large values for the inter-ring separation preclude any π–π bipy–bipy [interplanar distances above 3.96 Å] or bpym–bpym stacking interactions [ca. 4.2 Å].

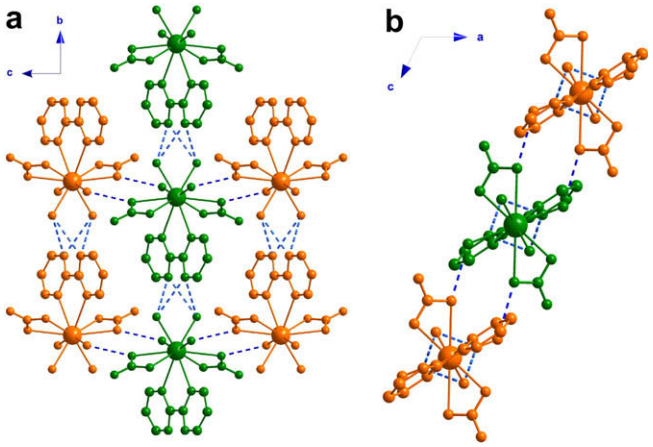

Fig. 6. Views in the (a) *bc* and (b) *ac*-planes of the supramolecular cationic layer in **6**–**9** which is built up by $O_{nitrate}\cdots O_w$ and and $N_{bpym}\cdots O_w$ hydrogen bond interactions. The hydrogen bonds are represented as blue dashed lines. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

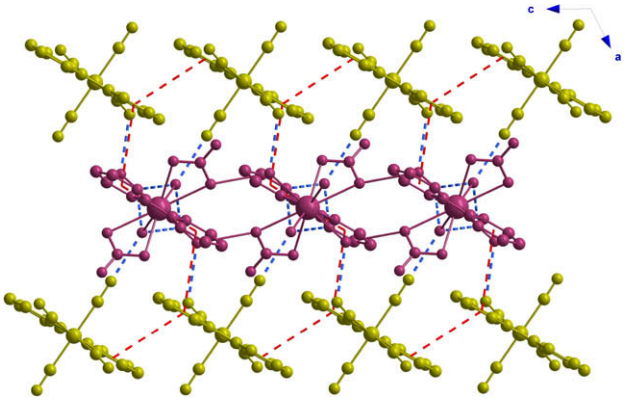

Fig. 5. A view of the crystal packing of **6**–**9** built up from H-bonds and π–π interactions. The hydrogen bonds and the π–π interactions are represented as blue and red dashed lines, respectively. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

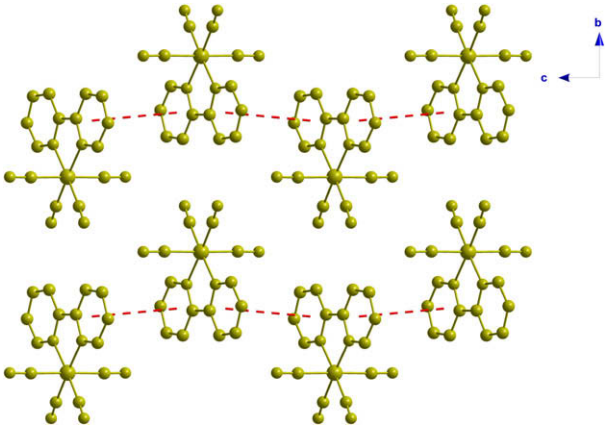

Fig. 7. A view of the supramolecular anionic sheets of **6**–**9** which are built up by π–π interactions among bipy ligands. The π–π bonds are represented as red dashed lines. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

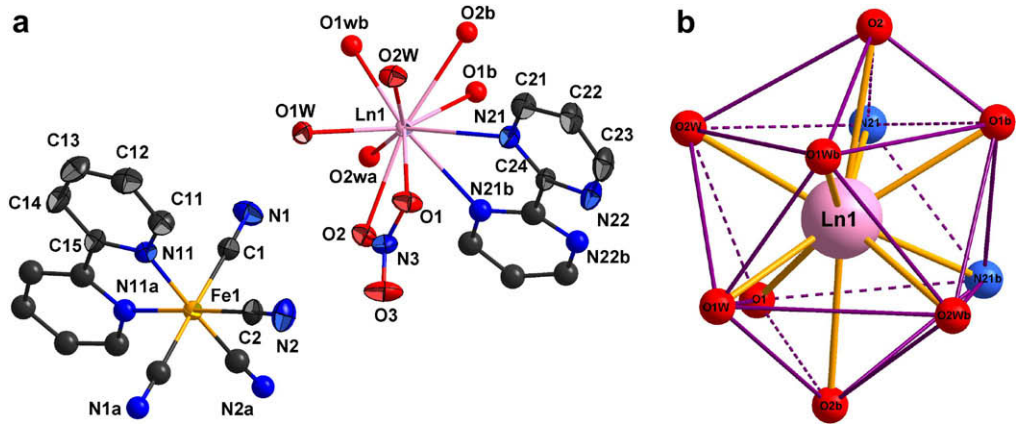

Fig. 8. (a) Perspective drawing of the ionic pair of compounds **6–9** complexes with the atom numbering scheme (thermal ellipsoids are plotted at the 50% probability level) and (b) a view of the coordination polyhedron of the lanthanide atom of **6–9**. The hydrogen atoms were omitted for clarity.

Table 5
Bond lengths (Å) and angles (°) of the coordination environments of Fe and Ln in **6–9** [Ln = Pr (**6**), Nd (**7**), Sm (**8**) and Gd (**9**)]*.

	6	7	8	9
Fe(1)–N(11)	1.991(3)	1.992(2)	1.990(3)	1.988(2)
Fe(1)–C(1)	1.944(3)	1.945(2)	1.948(3)	1.937(2)
Fe(1)–C(2)	1.916(3)	1.916(3)	1.913(4)	1.911(2)
Ln(1)–N(21)	2.774(3)	2.756(2)	2.741(3)	2.712(2)
Ln(1)–O(1)	2.537(2)	2.511(2)	2.483(2)	2.4464(15)
Ln(1)–O(2)	2.695(2)	2.680(2)	2.670(2)	2.678(2)
Ln(1)–O(1W)	2.463(2)	2.445(2)	2.412(2)	2.3962(15)
Ln(1)–O(2W)	2.486(2)	2.467(2)	2.427(2)	2.4028(14)
N(11)–Fe(1)–N(11)[a]	81.08(15)	81.23(13)	81.33(16)	81.31(10)
Fe(1)–C(1)–N(1)	177.5(3)	177.9(3)	177.5(3)	177.7(2)

N(21)–Ln(1)–N(21)[a]	59.82(11)	59.96(9)	60.76(12)	60.75(7)
O(1)–Ln(1)–O(2)	48.62(7)	48.86(6)	49.52(7)	49.25(5)

* Symmetry code: [a] = $-1-x, y, 0.5-z$.

Table 6
Selected intermolecular contacts (Å) in **6–9***.

	6	7	8	9
O(1w)···N(1)	2.709(3)	2.705(3)	2.706(3)	2.7021(2)
O(1w)···N(22)[d]	2.960(4)	2.973 (3)	2.935(4)	3.013(3)
O(1w)···N(22)[e]	3.120(4)	3.117(3)	3.118(4)	3.109(3)
O(2w)···N(2)[f]	2.848(4)	2.844 (4)	2.845(4)	2.836(3)
O(2w)···O(2)[g]	2.860(4)	2.864(3)	2.832(4)	2.868(3)

* Symmetry code: [d] = $x, 1+y, z$; [e] = $-x, 1+y, 1.5-z$; (f) = $-1-x, 1-y, 1-z$; [g] = $x, 1-y, 0.5+z$.

The shortest intermolecular iron···lanthanide separations are 6.7520(6) (**6**), 6.7350(6) (**7**), 6.7118(1) (**8**) and 6.6971(4) Å (**9**) [Fe(1)···Ln(1)[c]; (c) = $-x, 1-y, 1-z$], values which are close to those observed in **1–5.**

4. Conclusions

Two new families of 3d–4f three-dimensional supramolecular systems (compounds **1–5** and **6–9**; **1–9**) containing the ion pair $[Fe(bipy)(CN)_4]^-$ and $[Ln(bpym)(NO_3)_2(H_2O)_n]^+$ [Ln = Sm (**1**), Gd (**2**), Tb (**3**), Dy (**4**), Ho (**5**), Pr (**6**), Nd (**7**), Sm (**8**) and Gd (**9**)] with $n = 3$ (**1–5**) and 4 (**6–9**)] as constituents have been prepared and structurally characterized. The extensive network of hydrogen bonds and π–π type interactions which have their origin in the presence of coordinated water, terminally bound cyanide groups and aromatic rings, contribute to the stabilization of the resulting supramolecular three-dimensional architectures. In fact, both families can be seen as built by alternating cationic and anionic layers and their structural knowledge will orientate the future synthetic attempts to prepare cyanide-bridged 3d–4f heterometallic assemblies. For that, the nitrate anion has to be avoided in order to increase the positive charge on the lanthanide fragment and to make possible coordinative bond between the cyanide–nitrogen and the lanthanide atom. At that respect, it deserves to be noted that this coordinative bond is very common in the previous attempts where these cyanide-bearing units have been used as ligands toward first-row transition metal ions.

Acknowledgements

Funding for this work was provided by the Spanish Ministerio de Ciencia y Tecnología (CTQ2007-61690, MAT2007-60660 and Consolider Ingenio2010 "Factoria de Cristalización CSD2006-00015), the European Union through the Network QuEMolNa (Project MRTN-CT-2003-504880) and the Magmanet Network of Excellence (Contract 515767-2). O.F thank to the Spanish Ministerio de Ciencia y Tecnología for a predoctoral fellowship.

Appendix A. Supplementary data

CCDC 696695–696703 contain the supplementary crystallographic data for **1–9**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.12.032.

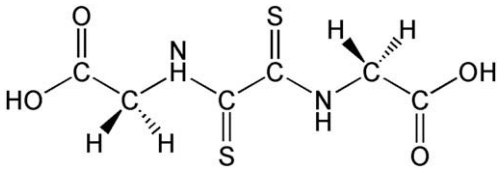

Fig. 1. N,N′-bis(carboxymethyl)dithiooxamide (H_4GLYDTO).

KBr pellets on a Perkin–Elmer 597 spectrophotometer and in the 700–100 cm^{-1} range using polyethylene-sandwiched Nujol mulls on a Bruker IFS-66v spectrophotometer. TGA analyses (25–750 °C) were recorded under an inert atmosphere (N_2) on a Hi-Res TGA 2950 TA Instruments. Evolved gases were detected by IR spectroscopy on a Bruker FTIR TENSOR-27 spectrophotometer. The electronic spectra of microcrystalline samples were obtained by the diffuse reflectance method on Shimadzu UV-3101PC spectrophotometers over the range 900–250 nm. EPR spectra were recorded between room temperature and 120 K on a Bruker ESP 300 spectrometer operating at X-band. The magnetic susceptibilities of polycrystalline samples were measured in the temperature range 2–300 K using a SQUID (Quantum Design) magnetometer. Diamagnetic corrections were made with Pascal's constants.

Caution: although difficulties were not encountered while working with metal perchlorates, they are potentially explosive and should be handled with care.

2.2. Synthesis

$[Mn(H_2GLYDTO)(H_2O)_2]_n$. A mixture of H_4GLYDTO (1.25 mmol, 0.30 g) and $Mn(ClO_4)_2 \cdot 6H_2O$ (2.25 mmol, 0.80 g) in water (50 ml) was stirred at room temperature for 30 min and then NaOH (1.25 mmol, 0.05 g) was added to the solution. The resulting pale brown powder was filtered off and washed with water and ethanol. Single crystals suitable for X-ray diffraction were obtained by slow evaporation (over a week) of the yellow mother liquor at room temperature. Their IR spectra show that the crystals and the original crystalline powder are the same compound. The yield for this reaction was 0.572 g (>95% based on total Mn). Mp. 141 °C (Dec). *Anal.* Calc. for $C_6H_{10}MnN_2O_6S_2$ (325.22): C, 22.2; H, 3.1; N, 8.6; S, 19.7. Found: C, 21.8; H, 3.1; N, 8.5; S, 20.4%. IR (ν_{max}/cm^{-1}): 3469m ν(OH), 3137m ν(NH), 1591s $\nu_{as}(COO^-)$, 1527s, 1437m, 1395s $\nu_s(COO^-)$, 1368s, 1301s, 1258w, 1078s, 980m, 923w, 879s, 865s, 763m, 711w, 646w, 547w, 502w, 468w, 394vw, 319w, 231w, 168w, 116w.

2.3. Crystal structure determination

A yellow plate crystal of $[Mn(H_2GLYDTO)(H_2O)_2]_n$ was mounted on a glass fibre and used for data collection. Crystal data were collected at 293(2) K using a Bruker SMART CCD 1000 diffractometer. Graphite monochromated Mo Kα radiation (λ = 0.71073 Å) was used throughout. The data were processed with SAINT [11] and corrected for absorption using SADABS (transmissions factors: 1.000–0.792) [12]. The structure was solved by direct methods using the program SHELXS-97 [13] and refined by full-matrix least-squares techniques against F^2 using SHELXL-97 [14]. Positional and anisotropic atomic displacement parameters were refined for all non-hydrogen atoms. Hydrogen atoms were located in difference maps and included as fixed contributions riding on attached atoms, with isotropic thermal parameters 1.2 times those of their carrier atoms. Criteria for a satisfactory complete analysis were ratios of *rms* shift to standard deviation of less than 0.001 and no significant features in final difference maps. Atomic scattering factors were obtained from "International Tables for Crystallography" [15]. A summary of the crystal data, experimental details and refinement results is given in Table 1.

Largest difference peak/hole	0.271/−0.278

3. Results and discussion

$[Mn(H_2GLYDTO)(H_2O)_2]_n$ was prepared using manganese(II) perchlorate hexahydrate as the metal source and $[H_2GLYDTO]^{2-}$ as a dianionic ligand in an aqueous medium. The product is air stable and is insoluble in common organic solvents.

An exhaustive comparison of the IR spectra of the ligand [10] and complex gave information about the mode of bonding of the ligand in the manganese(II) complex. The IR spectrum of the complex shows a broad absorption at 3469 cm^{-1}, corresponding to ν(OH) vibrations of the coordinated water molecules, and another medium intensity band at 3137 cm^{-1} that can be assigned to the –NH– vibrations. Three absorption bands at 1527, 1300 and 1078 cm^{-1} are the so-called thioamide bands, which are essentially related to the C=S stretching vibration strongly coupled to that of the C–N part of the thioamide group. The ν(C=S) band appears at 879 cm^{-1}. The band due to the carbonyl group at 1710 cm^{-1}, which is present in the spectrum of H_4GLYDTO, is absent in the spectrum of the complex and two bands due to asymmetric and symmetric stretching vibrations of COO^- are observed at 1591 and 1394 cm^{-1}, respectively. The $\Delta\nu = \nu_{as} - \nu_s$ separation value is 197 cm^{-1}, indicating that the carboxyl groups of the complex are coordinated with the manganese(II) ions in a *syn-anti* carboxylato-bridging mode [16]. The band at 335 cm^{-1} is assigned to the Mn–O stretching frequency.

Thermogravimetric analysis revealed that, under an inert atmosphere, the compound is stable up to 141 °C and undergoes the first weight loss (12.4%) from 141 to 231 °C, which may be due to the release of the coordinated water molecules (calcd. 11.1%) and partial decomposition of the ligand. The relatively high temperature for the loss of water molecules implies that hydrogen-bonding interactions occur in the crystal packing. The weight loss upon further heating to 740 °C occurs in three stages. This is due

to complete decomposition of the compound and corresponds to the production of CO, CH_3CHO and HNCS. However, other gases such as CO_2, CH_4 or NH_3 were also identified depending on the stage in question. The final residue of 24.9% is close to the calculated value of 21.9% based on MnO.

The diffuse reflectance spectrum of $[Mn(H_2GLYDTO)(H_2O)_2]_n$ showed absorption bands at around 15000, 20850 and 21900 cm^{-1}, which can be assigned to $^6A_{1g} \rightarrow {}^4T_{1g}$, $^6A_{1g} \rightarrow {}^4A_{1g}$ and $^4E_g(G)$ transitions, respectively. Other absorption bands at 25440, 28530 and 30210 cm^{-1} can also be assigned to $^6A_{1g} \rightarrow {}^4T_{2g}(D)$, $^4E_g(D)$ and $^4T_{1g}(P)$ transitions. These transitions are compatible with a distorted octahedral geometry around high-spin Mn(II) [17].

The X-band EPR spectrum of $[Mn(H_2GLYDTO)(H_2O)_2]_n$ shows an isotropic signal with a *g*-value of 2.0 at room temperature. This signal increases in intensity and becomes broad upon cooling to 120 K.

4. Structure description

A single-crystal X-ray diffraction study revealed that the asymmetric unit consists of one Mn^{II}, half a $H_2GLYDTO^{2-}$ dianion and one water molecule (Fig. 2). Each Mn^{II} ion is six-coordinated to four carboxylate oxygen atoms from four different $H_2GLYDTO^{2-}$ ligands and two symmetrically related water oxygen atoms (Fig. 3). As shown in Figs. 2 and 3, the Mn centre assumes a slightly distorted octahedral coordination geometry with the Mn–O bond distances in the range 2.169(1)–2.188(2) Å (Table 2). The carboxylate oxygen atoms are nearly coplanar and define the equatorial plane of the octahedron, with the bond angles around the neighbouring atoms close to 90° (89.26–90.74°). The oxygen atoms from symmetrically related aqua ligands occupy the axial positions of the octahedron, with bond angles to equatorial oxygen atoms in the range from 87.65(6)° to 92.36(6)°. $H_2GLYDTO^{2-}$ acts as a tetradentate ligand and the carboxylate functionality links the metal centres in a *syn-anti* fashion (Fig. 4). The carboxylate groups link the neighbouring manganese centres to form infinite one-dimensional helical channels that run along the crystallographic *b*-axis with an intrachannel Mn···Mn separation of 5.3176(9) Å (Fig. 5). These Mn atoms are shared by neighbouring helical channels that are alternately left- and right-handed. In addition, these channels are interconnected by the $O_2C–C–N–C–C–N–C–CO_2$ groups of $H_2GLYDTO^{2-}$ to form new alternate left- and right-handed helical chains, both with a distance between Mn atoms of 11.213 Å, and this gives rise to an infinite three-dimensional framework (Fig. 6). When viewed along the *a*-axis, such a 3D framework can also be viewed

N(1)–H(1)···S(1)^{e}	0.88	2.42	2.930(2)	116.9
N(1)–H(1)···S(1)^{a}	0.88	2.72	3.469(2)	144.0

Symmetry transformations: $^{a} = x, y - 3/2, z + 1/2$; $^{c} = -x, -y + 2, -z + 1$; $^{e} = -x + 1, -y + 2, -z + 1$; $^{f} = x, -y + 5/2, z + 1/2$.

as a 3D porous coordination polymer containing new rectangular-shaped channels with Mn–Mn distances of 6.060 and 8.726 Å (Fig. 7). Each Mn atom is therefore connected to four neighbouring Mn atoms through four $H_2GLYDTO^{2-}$ units in an undulated shape and the metal centres thus serve as linkers to produce 2D layers parallel to the (1 0 0) plane. Consequently, the carboxylate groups also act as pillars to support these layers, leading to an extended open 3D framework. In addition, an X-ray crystallographic study revealed a supramolecular assembly that is the result of hydrogen-bonding interactions between coordinated water molecules and the organic ligands, and between organic ligands (Table 3).

4.1. Magnetic properties

The magnetic susceptibility, χ, of $[Mn(H_2GLYDTO)(H_2O)_2]_n$ was investigated between 2 and 300 K. The room temperature effective magnetic moment μ_{eff} $[=(8\chi_M T)^{1/2}]$ is 5.93μ_B/Mn, which is consistent with the value of 5.92μ_B/Mn expected for a magnetically isolated high-spin Mn^{II} ($S = 5/2$) ion with $g = 2.00$. From the magnetic point of view, the complex can be considered as dinuclear, where two Mn(II) ions are linked by one carboxylate bridge. The magnetic susceptibilities are represented as a plot of $\chi_M T$ and χ_M versus T in Fig. 8. The experimental value at room temperature (4.40 cm^3 K mol^{-1}) decreases on decreasing the temperature, first slowly and then more rapidly. This behaviour is consistent with the presence of a weak antiferromagnetic interaction between the Mn(II) ions.

In order to quantitatively evaluate these magnetic interactions the data were fitted to an $S = 5/2$ dinuclear spin model (Eq. (1)) based on the isotopic Heisenberg exchange Hamiltonian $H = -2JS_1S_2$ (where $S_1 = S_2 = 5/2$ for Mn^{II} high-spin d^5 ion systems) [18]. N is Avogadro's number, β is Bohr magneton, g is the Landé g-value, k is the Boltzmann constant.

$$\chi_M = \frac{Ng^2\beta^2}{3kT}\frac{A}{B} \quad (1)$$

$$A = 6\exp[2J/kT] + 30\exp[6J/kT] + 84\exp[12J/kT] + 180\exp[20J/kT] + 330\exp[30J/kT]$$

$$B = 1 + 3\exp[2J/kT] + 5\exp[6J/kT] + 7\exp[12J/kT] + 9\exp[20J/kT] + 11\exp[30J/kT]$$

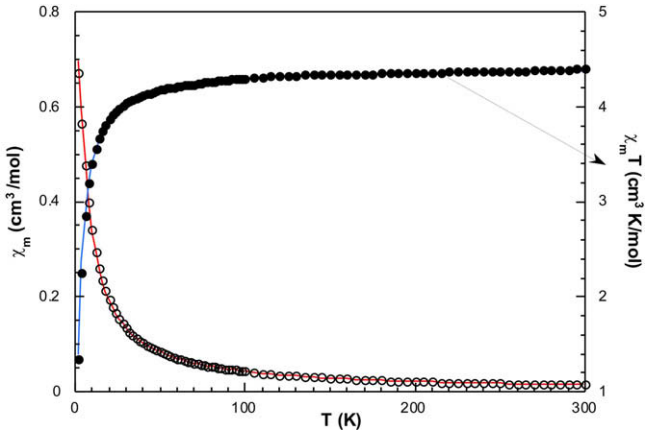

Fig. 8. Temperature dependence of χ_m and $\chi_m T$ for $[Mn(H_2GLYDTO)(H_2O)_2]_n$, solid lines represent the theoretical curves (see text).

The least-squares analysis of magnetic susceptibility data led to $J/k = -0.12$ K (-0.08 cm^{-1}) for $g = 2.01$. The agreement factor is around 6.58×10^{-5}, which corresponds to an excellent agreement between theory and experiment. This J value suggests that weak antiferromagnetic interactions between neighbouring Mn(II) ions are mediated through the double μ^2-carboxylate bridges. The J value is comparable to those reported for other manganese(II) complexes with the *syn-anti* bridging nature of the carboxylate, which generally mediates very weak magnetic interactions [19]. Due to the long superexchange pathway, the coupling through the compound is negligible.

5. Conclusions

A novel hexa-coordinate 3D manganese(II) polymer containing alternate left- and right-handed helical channels was synthesized and structurally characterized. Weak antiferromagnetic interactions between Mn^{II} ions were found with $J = -0.18$ K and $g = 2.00$. Further investigations are currently underway into magnetic materials based on N,N′-disubstituted dithiooxamide derivatives of amino acids as ligands with transition metals.

play an important role for structural holding via a hydrogen bonding interactions in proteins [35–39]. The role of hydrogen bonding in the stabilization of structures as well as in the functions of various metalloproteins is also well known in biochemistry [40–44]. In order to investigate the influence of different carboxylic acids on the geometrical structure of the central vanadium and probe into the importance of hydrogen bonding in this system, we designed and synthesised a series of vanadium complexes with poly(pyrazolyl)borate and carboxylic acid as ligands: TpVO(pzH)(2,4-Cl–C_6H_3–OCH_2COO) (**1**), TpVO(pzH)(C_6H_5–OCH_2-COO) (**2**), TpVO(pzH)(*p*-Cl–C_6H_4–COO) (**3**), TpVO(pzH)(3,5-NO_2–C_6H_3–COO) (**4**), Tp*VO(pzH*)(*p*-Cl–C_6H_4–COO) (**5**) and Tp*VO(pzH*)(*p*-Cl–C_6H_4–COO) · CH_3OH (**6**). Herein, we will report their spectra, crystal structures and thermal decomposition results. Particularly, the hydrogen bonding will be discussed in detail. In addition, the catalytic activities for bromoperoxidation have been determined and discussed by the UV–Vis spectra absorption method.

2. Experimental

2.1. Materials and methods

All the chemicals used were of analytical grade and were used without further purification. KTp and KTp* were synthesized according to the literature method [45,46] and all the other reactants were used as purchased. All synthetic manipulations were carried out in the atmosphere at room temperature. Elemental analyses (C, H and N) were performed on a PE 240C automatic analyzer. IR spectra were recorded with a JASCO FT/IR-480 spectrometer in the spectral range 4000–220 cm^{-1} with the samples in the form of potassium bromide pellets. The UV–Vis spectra were recorded on a PE Lambda 35 spectrometer.

2.2. Synthesis

2.2.1. Preparation of TpVO(pzH)(L) (L = 2,4-Cl–C_6H_3–OCH_2COO (**1**), C_6H_5–OCH_2COO (**2**), *p*-Cl–C_6H_4–COO (**3**) and 3,5-NO_2–C_6H_3–COO (**4**))

To a 10 ml solution of 2,4-dichlorophenoxyacetic acid (0.22 g, 1 mmol) (**1**) (phenoxyacetic acid (0.15 g, 1 mmol) (**2**), 4-chlorobenzoic acid (0.16 g, 1 mmol) (**3**) and 3,5-dinitrobenzoic acid (0.21 g, 1 mmol) (**4**)) in methanol, $VOSO_4 \cdot nH_2O$ (0.08 g, 0.3 mmol, based on 71% $VOSO_4$) in methanol (5 ml) was added, and the mixture was stirred for 30 min at room temperature to give a clear cyan solution, then a solution of KTp (0.09 g, 0.3 mmol) and pyrazole (0.02 g) in methanol (5 ml) was added to the cyan solution, and this reaction mixture was stirred at room temperature for 4 h to give a purple suspension. The precipitate was filtered out, the purple filtrate stored at room temperature for several days and violet-blue crystals suitable for X-ray diffraction were obtained from mother liquor. Yield (based on V): 0.12 g, 70.41% (**1**); 0.09 g, 60.10% (**2**); 0.11 g, 72.81% (**3**); and 0.14 g, 83.46% (**4**). *Anal.* Calc. for $C_{20}H_{19}BCl_2N_8O_4V$ (**1**): C, 42.29; H, 3.37; N, 19.72. 2.3. Single-crystal structure determination

The crystal data, data collection and refinement details are summarized in Table 1. Reflection data were collected at room temperature on a Bruker AXS SMART APEX II CCD diffractometer with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and $\omega-2\theta$ scan mode. All the measured independent reflections ($I > 2\sigma(I)$) were used in the structural analyses and semi-empirical absorption corrections were applied using the SADABS program [47].

The structures were solved by direct methods for **1**, **3**, **4**, **5** and **6**, respectively, and by the heavy-atom Patterson method for **2** and refined with the SHELXTL software package [48]. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms, except for the boron hydrogen atoms, were fixed at calculated positions with isotropic thermal parameters.

2.4. Thermal analysis

Thermogravimetric analyses (TGA) experiments were carried out on a Perkin–Elmer Diamond TG/DTA instrument. During the simple gradient experiment, weight changes were recorded as a function of temperature for a 20 °C/min temperature gradient between 50 and 1000 °C in a nitrogen environment.

2.5. Measurement of bromination activity in solution

The method of introducing four bromine atoms into the molecule of phenol red to form bromophenol blue was used to monitor bromination activity under peroxide conditions. Spectral changes were recorded in 1 cm path length quartz cells using a PE Lambda 35 UV−Vis spectrometer. Phenol red acts as an efficient trap of active bromine species without influencing the rate of reaction until it is exhausted. The reaction mixture contained phosphate buffer (50 mM, pH 5.8), KBr (2 M), phenol red (20 μM) and the vanadium complex (0.50 mM). The redox activity was tested by adding a solution containing the vanadium complex. Cells were transferred to the spectrophotometer immediately after mixing to record spectra in the range 375–650 nm.

3. Results and discussion

3.1. Synthesis

Although the coordination modes of the vanadium atoms in complexes **1**–**6** are similar to those of Tp*VO(pzH*)(C_6H_5COO) · 0.4toluene (**7**) [29] and Tp*VO(pzH*){(μ-η^5-$C_5H_4CO_2$)-Fe(η^5-C_5H_5)} (**8**) [30], their synthetic processes are different. The reaction courses of the complexes are presented as follows:

It is found that the order of addition of the reactants and the stoichiometric ratios can affect the final product. When the poly(pyrazolyl)borate and pyrazole are in excess, it is hard for the carboxylic acids to coordinate to the vanadium. All the compounds are air-stable and soluble in CH_2Cl_2, CH_3CN, THF, etc., and are insoluble in hexane and ether.

3.2. IR spectroscopy

The IR spectra of complexes **1**–**6** reveal B–H stretching vibrations of tris(pyrazolyl)borate in the range 2509–2533 cm^{-1}. For complexes **1**–**6**, the bands in the 1591–1622 cm^{-1} and 1403–1501 cm^{-1} regions are assigned to the asymmetric vas(COO^-) and symmetric vs(COO^-) vibrations of monodentate coordinated, deprotonated carboxylate groups, respectively. The calculated Δ values {vas(COO^-)–vs(COO^-)} of **1**–**6** are 135, 112, 197, 166, 162 and 142 cm^{-1}, respectively, which are all lower than the values expected for monodentate carboxylate ligands (larger than 200 cm^{-1}) but the relative reductions in the Δ values are typical where such carboxylate groups are involved in hydrogen bonding [49,50]. The bands of V=O were observed in the range 962–971 cm^{-1}, V–O in the range 433–475 cm^{-1} and V–N in the range 336–377 cm^{-1} [51].

3.3. UV–Vis spectroscopy

The electronic absorption spectra for complexes **1**–**6** were recorded in CH_2Cl_2 solution. As shown in Fig. 1, the two weak bands in the range 542–767 nm are assigned to d–d transitions within the oxovanadium(IV) moiety [30]. The strong bands in the range

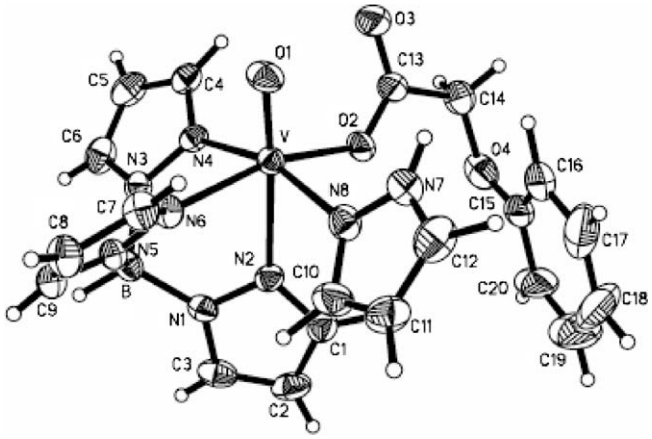

Fig. 3. The molecular structure and atom-numbering scheme for complex **2** with thermal ellipsoids drawn at the 30% probability level.

240–286 nm are related to intraligand charge transfer transitions [19].

3.4. Crystal structures

The X-ray structure analyses reveal that **1**–**4** are neutral complexes of VO–Tp–pz–carboxylate, and **5** and **6** are neutral complexes of VO–Tp*–pzH*–carboxylate. The molecular structures of complexes **1**–**5** are depicted in Figs. 2, 3 and 5–7 (the structure of complex **6** is the same as **5**, except for a lattice methanol molecule, and its structure is depicted in Fig. 1S). In all cases the vanadium atom is six-coordinated with a N_4O_2 donor set in a distorted-octahedral geometry. In complex **1**, two nitrogen atoms (N4, N6) from Tp^-, one nitrogen (N8) from a neutral pyrazole and one oxygen (O2) from carboxylate group of 2,4-dichlorophenoxyacetic acid in *cis* positions form the equatorial plane, and the axial positions

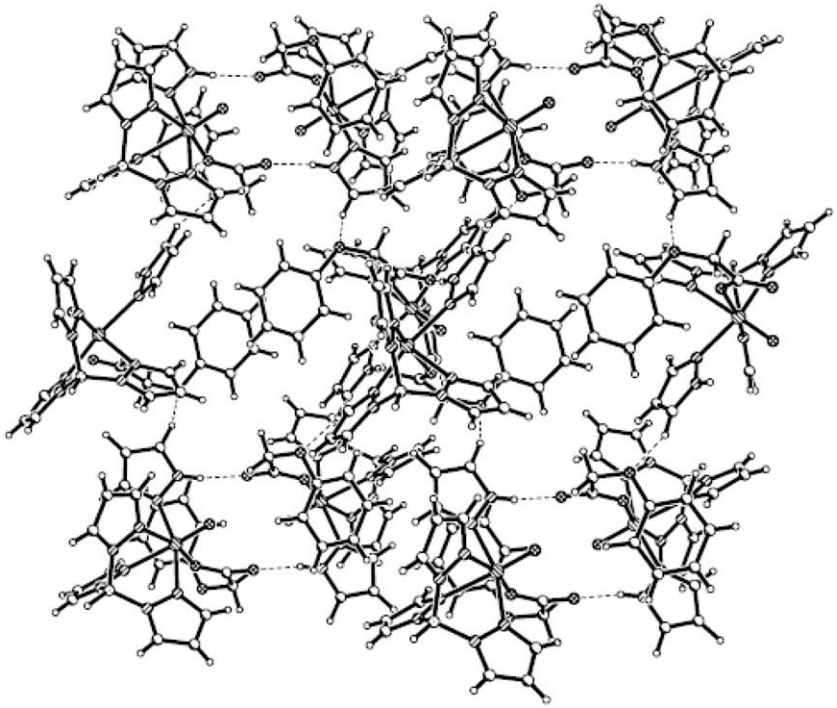

Fig. 4. Molecular packing of complex **2**.

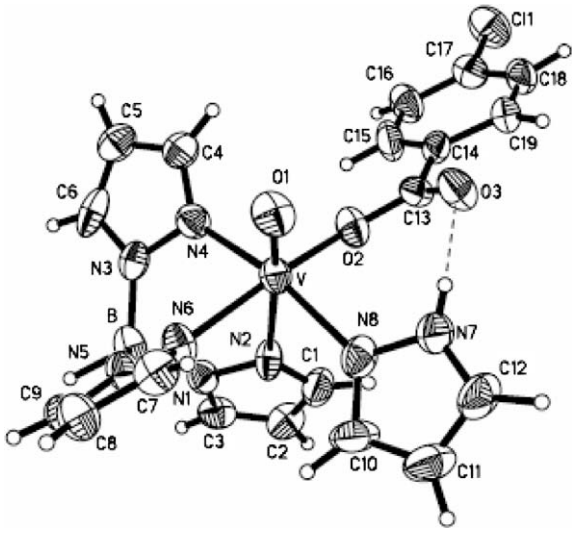

Fig. 5. The molecular structure and atom-numbering scheme for complex **3** with thermal ellipsoids drawn at the 30% probability level.

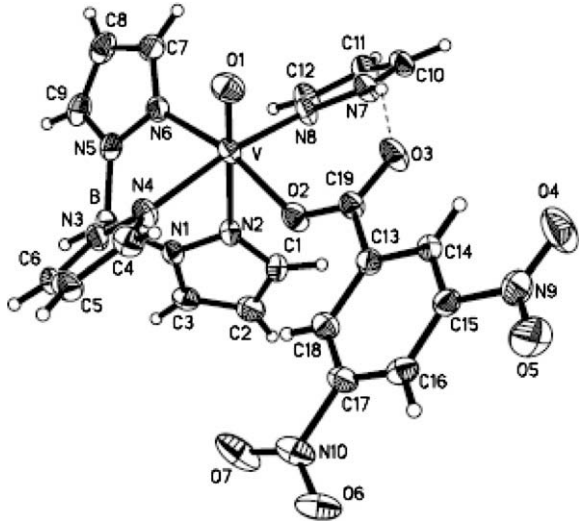

Fig. 6. The molecular structure and atom-numbering scheme for complex **4** with thermal ellipsoids drawn at the 30% probability level.

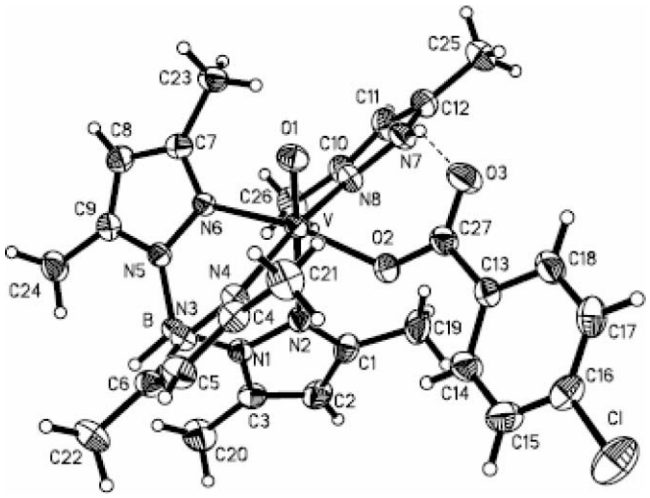

Fig. 7. The molecular structure and atom-numbering scheme for complex **5** with thermal ellipsoids drawn at the 30% probability level.

are occupied by the remaining nitrogen (N2) from Tp^- and a terminal oxygen atom (O1).

The deviations from the least-squares plane through the O2, N4, N6 and N8 atoms comprising the square plane are 0.0055(23), −0.0057(23), 0.0059(24) and −0.0057(23) Å, respectively, showing that these atoms are almost on one plane. The V, O1 and N2 from the apical positions lie 0.2859(24), 1.8702(48) and −2.0050(50) Å out of this plane, respectively, indicating that the vanadium atom is displaced towards the oxo oxygen O1. The V–O(terminal) bond length [V–O1, 1.594(3) Å] agrees well with those reported oxovanadium(IV) complexes containing poly(pyrazolyl)borate [14–16,26–33]. Because of the *trans* effect of the terminal oxo group, the bond length of V–N2 (2.291(4) Å) is considerably longer than those of V–N4, V–N6 and V–N8 (2.115(4), 2.109(4) and 2.136(4) Å, respectively). Such elongation is similar to that observed in comparable complexes [14–16,26–33]. The short V–N average bond length is 2.120(4) Å, which is comparable with V–N in V–BrPO (2.110 Å) [8]. The V–N(pz) and V–O(carboxylate) bond lengths are 2.136(4) and 1.996(3) Å, respectively, which are close to those of similar relevant complexes [29,30]. In addition, the two mononuclear molecules are held together by inter-molecular hydrogen bonds involving the N–H protons and O3 to form a quasi-dimeric structure as shown in Fig. 2. The corresponding hydrogen bonds lengths and angles of N7–H7A···O3$^{\#1}$ [#1: $-x$, $2-y$, $-z$] are 2.864(6) Å and 166.0(1)°.

As shown in Figs. 3 and 5–7, the structures of complexes **2**–**5** are similar to that of **1**, in each complex, the vanadium atom is in a distorted-octahedral environment with the Tp^- or Tp^{*-} occupying three facial sites. The other three sites are occupied by a terminal oxo group (O1), an oxygen atom (O2) from the carboxylate group and a nitrogen atom (N8) from a neutral pyrazole or 3,5-dimethylpyrazole ligand. Two nitrogen atoms (N4, N6) from Tp^- or Tp^{*-}, one nitrogen atom (N8) and one oxygen (O2), occupy the equatorial positions. The deviations of V, O1 and N2 out of the equatorial plane for complexes **2**–**6** are listed in Table 1S, indicating that the vanadium atoms are displaced toward the oxo oxygen O1. The *trans* effect of this terminal oxo group is responsible for the increased length of the V–N2 bond (2.266(9)–2.283(3) Å), which are slightly shorter than those of **7** and **8** (2.355(4) Å for **7**, and 2.3184(4) Å for **8**) and similar to those found in VO(κ^2-B(pz)$_4$)(κ^3-B(pz)$_4$)) and TpVO(Bp). The V–O(terminal) and V–N*cis* bond lengths are in the ranges 1.582(7)–1.593(2) and 2.086(10)–2.134(3) Å, respectively. Both the bond lengths for V–O(terminal) and V–N*cis* agree well with those reported oxovanadium complexes containing poly(pyrazolyl)borate (Table 2). As depicted in Fig. 4, two independent molecules of complex **2** form a dimer by inter-molecular hydrogen bonding as follows: N7–H7B···O3$^{\#2}$ [#2: $-x$, $1-y$, $1-z$; 2.777(6) Å, 164.7(3)°]. These dimeric units are connected to one another via weak inter-molecular C–H···O interactions between the phenoxyl oxygen atoms (O4) and C12 from the neutral pyrazole of an adjacent molecule to form a 2D network on the *bc*-face (Fig. 4). In complexes **3**–**5**, the intramolecular hydrogen bond N7–H7A···O3 [2.71(4) Å, 159.4(9)° for **3**; 2.70(2) Å, 142.3(2)° for **4** and 2.720(4) Å, 146.6(2)° for **5**] exists in each complex.

3.5. Thermal stability analyses

The TG–DTG–DTA curves of decomposition of **1** show two stages of thermal decomposition (Fig. 8). The first stage occurs within the temperature range 155–400 °C with a mass loss of 50.79% corresponding to the loss of a pyrazole molecule and a 2,4-dichlorophenoxyacetate moiety (theoretical value 50.68%). The DTA curve indicates an endothermic process. The second stage, in the temperature range 400–540 °C, was observed as mass loss of 13.69%, corresponding to the loss of $C_3H_4N_2B$, namely one pz moi-

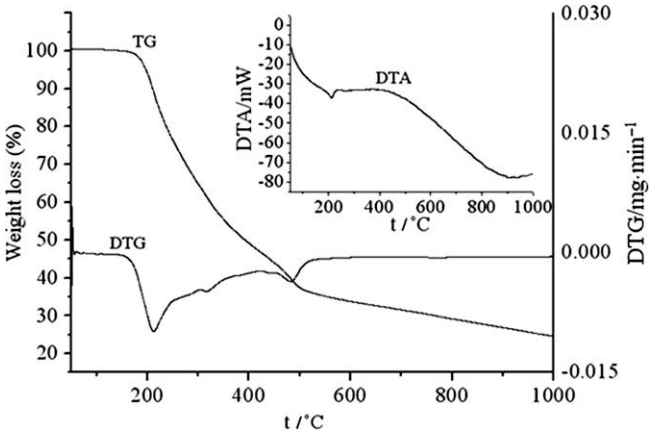

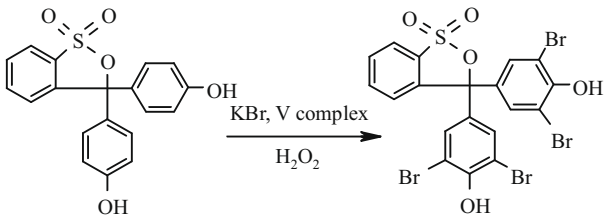

Fig. 8. The TG/DTG/DTA curves for complex **1**.

ety and one BH moiety (theoretical value 13.89%). The DTA curve of the complex indicates an exothermic process.

The TG–DTG–DTA curves of decomposition of **2**, **4** and **5** are shown in Figs. 3S–5S. The thermal decomposition of **2** also exhibits a two-step process. In the range 145–354 °C, there is a 44.05% weight loss, which is attributed to the release of one pyrazole moiety and one phenoxyacete moiety (43.84% theoretical weight loss). This step is followed by a weight loss of 22.30%, which can be attributed to the release of $C_5H_5N_3$, namely 1.6 pz moieties (theoretical value 21.46%) in the range 354–551 °C. As shown in Fig. 4S, the thermal decomposition process of complex **4** can be divided into three stages. The first weight loss corresponds to the release of one CO_2 and two NO_3 moieties and occurs in the temperature range 206–288 °C, the weight loss is 24.99% (calc. 24.32%). The second stage, in the temperature range 288–379 °C, was observed as a mass loss of 14.06%, corresponding to loss of one C_6H_3 moiety (theoretical value 13.41%). The third stage, in the temperature range 379–501 °C, was observed as a mass loss of 11.68% corresponding to loss of one pyrazole moiety (theoretical value 12.16%). As shown in Fig. 5S, the thermal decomposition of complex **5** exhibits a three-step process too. In the range 145–261 °C, there is a 15.95% weight loss, which is attributed to the release of one 3,5-dimethylpyrazole moiety (15.75% theoretical weight loss). In the temperature range 261–357 °C, about a 26.26% weight loss is observed, which may correspond to the release of one 4-chlorobenzoate moiety (theoretical value 25.33%). In the third stage, it experiences a 29.21% weight loss in the temperature range 357–700 °C, which is attributed to the release of two pz* moieties (theoretical value 30.85%).

3.6. Catalytic activity of the complexes in bromination reactions

It has been confirmed that vanadium compounds are able to mimic the reaction in which vanadium-dependent bromoperoxidases catalyze the bromination of organic substrates in the presence of H_2O_2 and bromide, for example, the bromination of trimethoxybenzene [52], salicylaldehyde, benzene and phenol by the VO_2^+ ion [53,54], and the bromination of phenol red by $[VO(O_2)H_2O]^+$ and related species [55]. Herein, we investigate the bromination reaction activity of the complexes using phenol red as the organic substrate, the reactive process as follows:

Addition of a solution of complex **2** to the standard reaction of bromide in phosphate buffer with phenol red as a trap for oxidized bromine resulted in a color change of the solution from yellow to blue. Fig. 9 shows the electronic absorption spectra collected during such a color change using **2** as a catalyst. The spectrum recorded showed

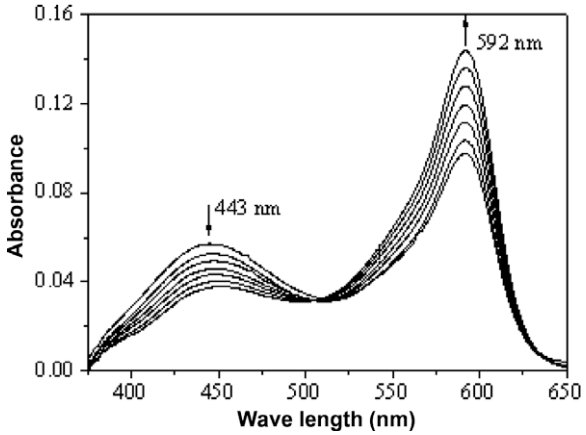

Fig. 9. Oxidative bromination of phenol red catalyzed by complex **2** (spectral changes at 10 min intervals. The reaction mixture contained phosphate buffer (50 mM, pH 5.8), KBr (2 M) and phenol red (20 μM)).

a decrease in absorbance of the peak at 443 nm due to loss of phenol red and a peak at 592 nm characteristic of the product bromophenol blue, showing that complex **2** possess obvious catalytic activity.

In addition, the results of the mimic catalytic activities for **1** and **3**–**6** are similar to that of **2**. It is probably due to the coordination environments of the vanadium atoms in **1** and **3**–**6** which are the same as **2**. Based on the information obtained from spectroscopic and catalytic experiments, we found that during the mimic catalysis reaction course, the concentration of KBr and vanadium, the pH value of the medium and the temperature are the main influencing factors. More detailed research for mimicking catalysis activities is in progress.

4. Conclusions

In order to mimic model complexes of V-HPOs, we designed and synthesized a series of oxovanadium complexes containing tris(pyrazolyl)borate as a supporting ligand and carboxylic acids as the second ligand. The one-step reaction of $VOSO_4 \cdot nH_2O$, pyrazole or 3,5-dimethylpyrazole, potassium poly(pyrazolyl)borate and carboxylic acids in methanol resulted in six new complexes, **1**–**6**. The synthetic process described here is different from those in the literature reports. Structural analyses show that in all of these complexes, the vanadium atoms are six-coordinated with a N_4O_2 donor set in a distorted-octahedral geometry, the carboxylate groups are coordinated as monodentate and the uncoordinated oxygen atom of the carboxylate groups form intra- or inter-molecular hydrogen bonds with the NH group of the corresponding coordinated neutral pyrazole (pzH/pzH*). Catalytic activity of the complexes in bromination reactions was discussed, which indicated that complexes **1**–**6** are in fact active in the bromination of phenol red in the presence of H_2O_2, Br^- and phosphate buffer, and hence may also be considered as potential functional model complexes.

Electronic absorption spectra were measured on a Shimadzu (UV-310PC) spectrometer. Luminescence spectra were recorded using a Perkin Elmer (LS 50 B) spectrometer.

2.1. Synthesis of $[(AgCN)_2 \cdot bpy]$ (1)

Seventy eight milligram (0.5 mmol) of bpy in 10 mL MeCN was added to 33 mg (0.25 mmol) of AgCN in 10 mL H_2O. The resulting mixture was heated at about 70°, while concentrated ammonia solution was added dropwise with stirring until the solution became clear. Prismatic colorless crystals appeared after standing at room temperature for two weeks. The crystals were recovered by filtration, washed with H_2O and dried in air (the yield was 65.5% with respect to AgCN).

Anal. Calcd for **1** ($C_{12}H_8N_4Ag_2$): C, 33.96; H, 1.88; N, 13.20. Found: C, 33.56; H, 1.79; N, 13.46. IR (KBr, cm^{-1}): 3048 (ν_{CH}), 2135 ($\nu_{C\equiv N}$), 1594 ($\nu_{C=N}$), 1529, 1481 ($\nu_{C=C}$), 1404, 1317 (δ_{CH}), 1218, 1063, 995, 803, 726, 618, 571, 471.

2.2. Synthesis of $[(AgCN)_3 \cdot (tbpe)_2 \cdot H_2O]$ (2)

Ninety one milligram (0.5 mmol) of tbpe in 10 mL MeCN was added to 33 mg (0.5 mmol) of KCN in 5 mL H_2O. The resulting mixture was added to 85 mg (0.5 mmol) of $AgNO_3$ in 10 mL H_2O. Concentrated ammonia solution was added dropwise with stirring to the previous mixture until the solution became clear. Yellow needle crystals appeared after standing at room temperature for two weeks. The crystals were recovered by filtration, washed with H_2O and dried in air (the yield was 85.6% with respect to $AgNO_3$).

Anal. Calc. for **2** ($C_{27}H_{22}N_7OAg_3$): C, 41.32; H, 2.80; N, 12.49. Found: C, 41.21; H, 2.37; N, 11.47%. IR (KBr, cm^{-1}): 3440 (ν_{H_2O}), 3046 (ν_{CH}), 2117 ($\nu_{C\equiv N}$), 1601 ($\nu_{C=N}$), 1555, 1498 ($\nu_{C=C}$), 1421, 1349 (δ_{CH}), 1219, 1067, 971, 826, 669, 550, 468.

2.3. Synthesis of $[(AgCN)_4 \cdot bpe]$ (3)

Ninety two milligram (0.5 mmol) of bpe in 10 mL MeCN was added to 33 mg (0.5 mmol) of KCN in 10 mL H_2O. The resulting mixture was added to 85 mg (0.5 mmol) of $AgNO_3$ in 10 mL H_2O and then concentrated ammonia solution was added dropwise with stirring to the previous mixture until the solution became clear. A colorless polycrystalline precipitate appeared after standing at room temperature for two weeks. The precipitate was recovered by filtration, washed with H_2O and dried in air (the yield was 70% with respect to $AgNO_3$).

Anal. Calc. for **3** ($C_{16}H_{12}N_6Ag_4$): C, 26.69; H, 1.66; N, 11.67. Found: C, 27.10; H, 1.59; N, 11.44%. IR (KBr, cm^{-1}): 3060, 2938, 2861 (ν_{CH}), 2130, 2160 ($\nu_{C\equiv N}$), 1600 ($\nu_{C=N}$), 1558, 1492, ($\nu_{C=C}$), 1453, 1416, 1339 (δ_{CH}), 1210, 1070, 830, 722, 610, 570 and 469.

2.4. X-ray structural determination

Structural measurements for SCPs **1**–**3** were performed on a Kappa CCd Enraf Nonius FR 90 four cycle geniometer with graphite monochromatic Mo Kα radiation {[λ Mo Kα] = 0.71073 Å} at 25 ± 2 °C. All the structures were resolved using direct-methods and all of the non-hydrogen atoms were located from the initial solution or from subsequent electron density difference maps during the initial stages of the refinement. After locating all of the non-hydrogen atoms in each structure the models were refined against F^2, first using isotropic and finally using anisotropic thermal displacement parameters. The positions of the hydrogen atoms were then calculated and refined isotropically, and then the final cycle of refinements was performed. The cyano groups of all structures were ordered unless otherwise stated. Crystallographic data for **1–3** are summarized in Table 1. Selected bond distances and bond angles are given in Tables 2–4. The C9 atom and N11 atom of the two bridging cyanide groups in **3** were located at inversion centers and were modeled as disordered over a pair of sites of equal occupancy. The disorder of these cyano groups in the asymmetric unit of **3** reflects the observation that R_w remains constant upon adopting a C atom or N atom at these sites.

3. Results and discussion

The novel SCPs **1–3** exhibit variable stoichiometries. The molar ratios of AgCN:L are 2:1 for **1**, 3:2 for **2** and 4:1 for **3** in MeCN/H_2O/NH_3 solution. It seems that self-assembly of either authentic or in situ prepared AgCN and the bipodal ligand takes place at the appropriate stoichiometry required by the extended framework

structure to adopt enough space demanded by the bipodal bridging ligand. The increased ratio of AgCN as the size specificity of the bridging ligand is increased can be considered as an essential requirement for the construction of unique $(AgCN)_n$ building blocks which create extended networks suitable for accommodating such long bridging ligands. In addition, these ligands behave as non-rigid spacers which are capable of displaying a variety of conformations. SCPs **1–3**, which are prepared at room temperature, can be also considered as unprecedented SCPs that may be compared with those prepared by hydrothermal reactions, described for $[(CuCN)_2.\ \mu\text{-L}]$ with L = bpy and tbpe [8] and $(CuCN)_2[(CuCN)_2(\mu\text{-}4,4'\text{-bpy})]$ [9]. Hydrothermal reactions, in spite of being exploited to prepare numerous SCPs, afford mostly the formation of mixtures of undesirable materials. The present procedure, in spite of being surprisingly simple, affords the formation of precipitates of **1–3** which consist exclusively of one discrete species and never of mixtures of different assemblies.

3.1. Crystal Structures

3.1.1. Crystal structure of $[(AgCN)_2 \cdot bpy]$ (1)

The asymmetric unit of **1** contains one fragment which consists of two silver atoms, two cyanide groups and one bpy molecule, Fig. 1a. The two silver atoms assume a distorted trigonal planar geometry where each is coordinated to two ordered cyanide groups and to the nitrogen atom of the bpy ligand. The two silver atoms are crystallographically different. Ag1 is strongly bonded to the cyanide groups, Ag1–C = 2.08 Å, but it is weakly coordinated to the bpy ligand, Ag1–N5 = 2.570 Å, which in spite of being weak is only slightly longer than those of previously reported silver complexes [5,7]. In this case the bpy ligand is at right angles to the C7–Ag1–C8 plane, N5–Ag1–C7 = 91.26°. On the other hand, whereas the Ag1–C distances are in the normal range, the bonds from the nitrogen atoms of the cyanide ligands to Ag2 are second-

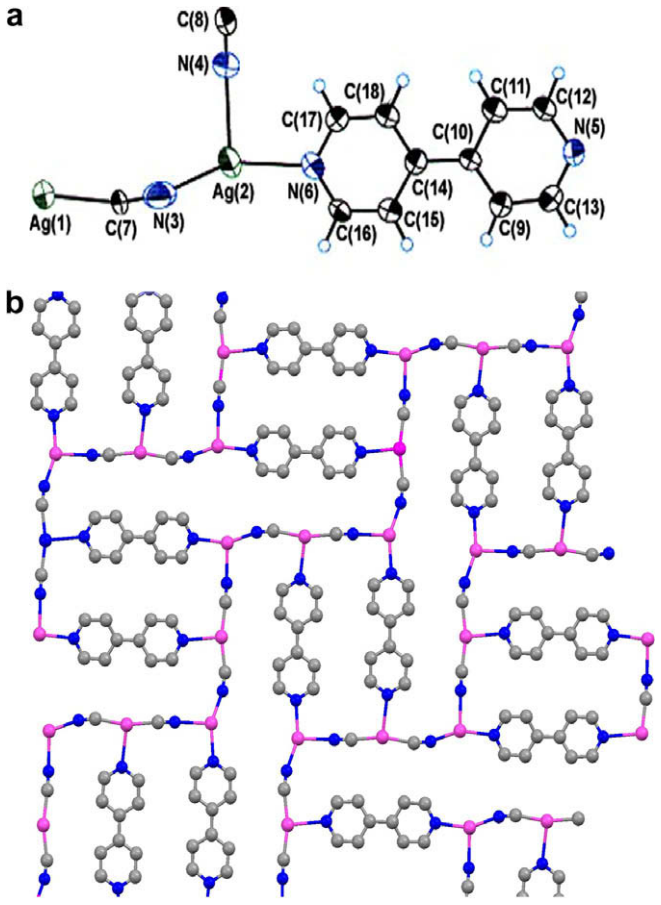

Fig. 1. (a) ORTEP plot of the asymmetric unit of **1**. (b) Structure of the 2D-layer of **1** along the diagonal of the unit cell. H-atoms have been omitted for clarity.

ary with a much longer range of distances, Ag2–N = 2.129–2.387 Å, while the Ag2–N6(bpy) bond is relatively strong with a distance equals to 2.249 Å. The extended structure of **1** consists of infinite puckered 1D-AgCN chains exhibiting a wave-like structure with a separation distance between the successive chains of 5.8093 Å, Fig. 1b. The wave-like appearance of the individual $[AgCN]_\infty$ chains results not only from the wide N(C)–Ag–C(N) angles at Ag1 and Ag2 (C7–Ag1–C8 = 164.85° and N3–Ag2–N4 = 110.43°) but also from the pronounced deviation from linearity for N3–C7–Ag1 = 163.3°, C7–N3–Ag2 = 166.0° and C8–N4–Ag2 = 161.7°. This deviation from linearity at the silver atoms in the $[AgCN]_\infty$ chains is in order to allow the coordination of the silver ions with the bidentate organodiimine ligand. These puckered chains are connected in a unique way by the bpy ligand via the Ag1 and Ag2 atoms creating corrugated 2D-layers with two types of fused rectangular rings; the first one consists of $Ag_8(CN)_6(bpy)_2$ with dimensions of 6.804 × 23.39 Å, while the second ring consists of $Ag_4(CN)_2(bpy)_2$ with dimensions of 6.526 × 12.142 Å, Fig. 1b. Analogous connectivity patterns in which infinite $[CuCN]_\infty$ chains are bridged by bpy have also been reported for [(CuCN)$_2$(μ-4,4′-bpy)], [{CuCN(μ-4,4′-bpy)}·2(μ-4,4′-bpy)] [8,10] and (CuCN)$_2$[(CuCN)$_2$(μ-4,4′-bpy)] [9]. Interestingly, only one type of hexagonal ring, $\{Cu_4(CN)_4(bpy)_2\}$, exists in the sheets forming the lamellar structure of [(CuCN)$_2$(μ-4,4′-bpy)], which differs however from those realized in **1**. Also, the layer's structure is stabilized by extensive H-bonding between the cyanide groups and hydrogen atoms of the bpy ligands, 2.583–3.056 Å, Table 2. The corrugated layers are arranged in parallel positions along the *b*-axis with a separation distance of almost 3.901 Å, creating channels, Fig. 2. These corrugated layers are interwoven along the *c*-axis causing stacking of the layers via interconnections of Ag–Ag interactions, Ag1–Ag2 = 3.2548 Å, meanwhile they are further packed by hydrogen bonding, N3–H18^d = 2.975 Å and C8–H15 = 3.056 Å, and π–π stacking, 3.120–3.379 Å, creating a novel 3D-network structure, Figs. 2 and 3. The Ag–Ag bonding interactions look like pillars between the layers. The argentophilic interaction as well as the close inter-layers Ag2–N5 and Ag1–N4 contacts of 3.120 and 3.236 Å, respectively, cause pyramidalisation of the silver atoms in such way that the angles of the planar trigonal geometry around the silver sites deviate significantly from 120° in spite of the sum of the angles being 360°, Table 2. Such behavior is also observed for Cu(I) in CuCN complexes [8].

3.1.2. Crystal structure of $[(AgCN)_3 \cdot (tbpe)_2 \cdot H_2O]$ (2)

The reaction of the ternary system $AgNO_3$, tbpe and KCN in H_2O/MeCN/NH_3 media affords yellow needle crystals of $[Ag_3(CN)_3(\mu\text{-tbpe})_2 \cdot H_2O]$, (**2**). One molecule of **2** comprises the asymmetric unit of the structure which consists of two independent fragments containing three chemically and crystallographically different Ag(I)

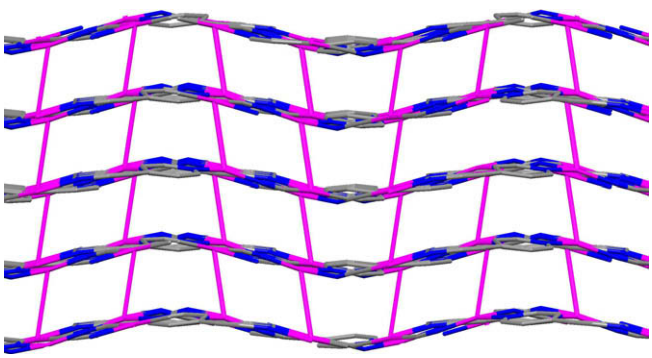

Fig. 2. 3D-dimensional structure of **1** showing the argentophilic interaction. H-atoms have been omitted for clarity.

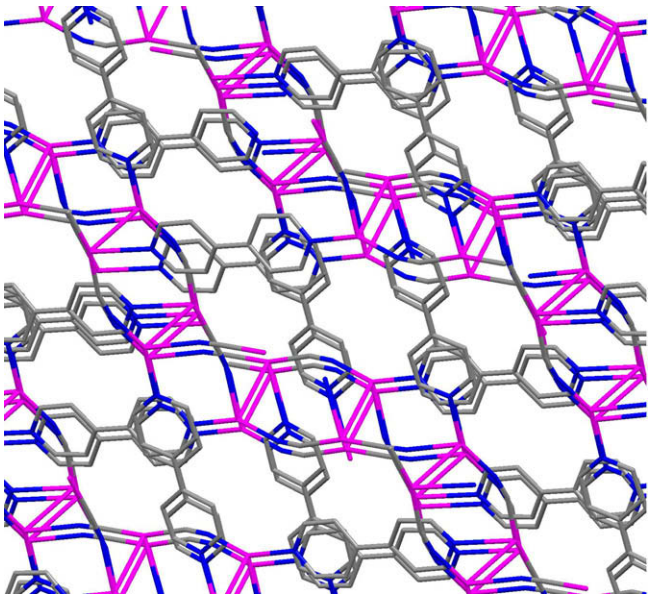

Fig. 3. 3D-structure of **1** along the *c*-axis showing the interwoven layers. H-atoms have been omitted for clarity.

atoms, Fig. 4a. The Ag(I) atoms are coordinated to ordered cyanide groups in a unique way representing the main building blocks of the structure of **2**. These building blocks form parallel ribbons connected by the tbpe ligands via silver atoms, Fig. 4b. Ag2 and Ag3 atoms are coordinated in tetrahedral fashion, while Ag1 atom exhibits a distorted planar trigonal configuration. Ag1 is strongly coordinated to two cyanide groups, Ag1–C31 = 2.076 Å, Ag1–C32 = 2.078 Å, and one nitrogen atom of the tbpe ligand, Ag1–N4 = 2.496 Å. The angles of the trigonal configuration at Ag1 assume a large deviation from the ideal value of 120° causing substantial pyramidal distortion which results essentially from the strong argentophilic interaction between Ag1 and Ag2, Table 3. The Ag2 atom exhibits a tetrahedral configuration via coordination to two cyanide groups and two tbpe ligands. On the other hand, the Ag3 atom assumes a strong coordination to the nitrogen atom of the tbpe ligand, Ag3–N25 = 2.211 Å, and to one cyanide group, Ag3–C26 = 2.062 Å, while it is weakly coordinated to the other cyanide groups that complete the distorted tetrahedral surroundings, Ag3–N33 = 2.716 Å, Ag3–N34 = 2.590 Å. The tetrahedral geometry around Ag3 is more distorted than that around Ag2 in consequence of the small chelate angles of 82.38° and 91.120°. In this case, two cyanide groups are asymmetrically bonded to three silver atoms, resulting in the μ_3-CN coordination mode forming a quadro minicycle $[Ag_2(\mu_3\text{-}CN)_2]$ motif, Fig. 5, similar to that found in the prototype CuCN coordination polymers [11].

Alternatively, the $(AgCN)_\infty$ building blocks create unusual parallel infinite ribbons which consist of fused hexagonal rings, $Ag_4(CN)_2$, with two double edge sides of the quadro minicyle $[Ag_2(\mu_3\text{-}CN)_2]$ motifs, Figs. 4b and 5. Surprisingly, the ribbons contain free terminal cyanide unit at Ag3, Ag3–C26–N27 = 176.0°. Four cyanide angles exhibit significant deviation from linearity, Ag2–N34–C32 = 132.8°, Ag2–N33–C31 = 148.6°, Ag3–N33–C31 = 118.0°, Ag3–N34–C32 = 132.5°, while the other Ag1–CN bonds are nearly linear, Table 3. The cyanide ligands turn out to be free of any disordered. **2** is the first example containing the minicycle $[Ag_2(\mu_3\text{-}CN)_2]$ motif, thus a comparison to CuCN complexes containing a similar type of the unusual minicycle $[Cu_2(\mu_3\text{-}CN)_2]$ motif is particularly pertinent. The minicycle $[Cu_2(\mu_3\text{-}CN)_2]$ motif is now realized as being the basic building block of an increasing number of 2D or 3D supramolecular assemblies [11,12]. The unusual character of the $[Cu_2(\mu_3\text{-}CN)_2]$ motif

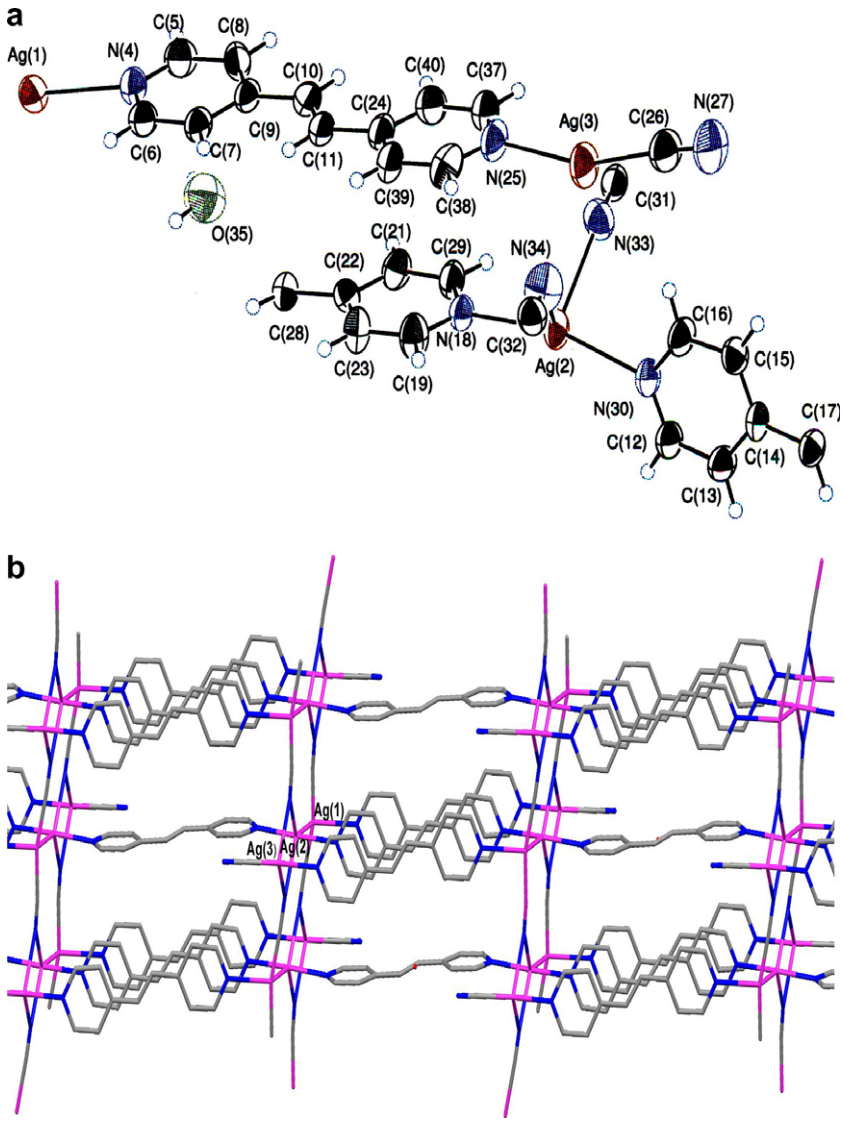

Fig. 4. (a) ORTEP plot of the asymmetric unit of **2**. (b) Structure of the layer of **2** along the *b*-axis showing the parallel ribbons. H-atoms have been omitted for clarity.

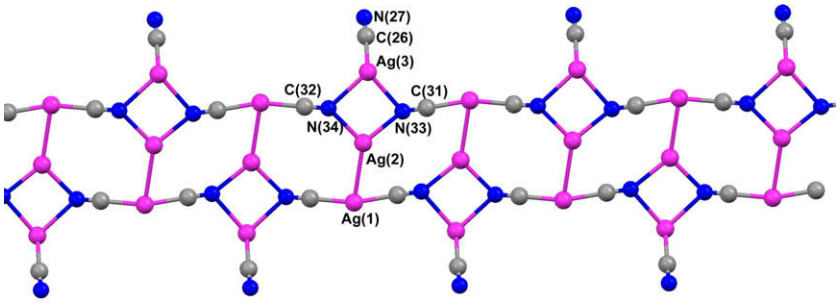

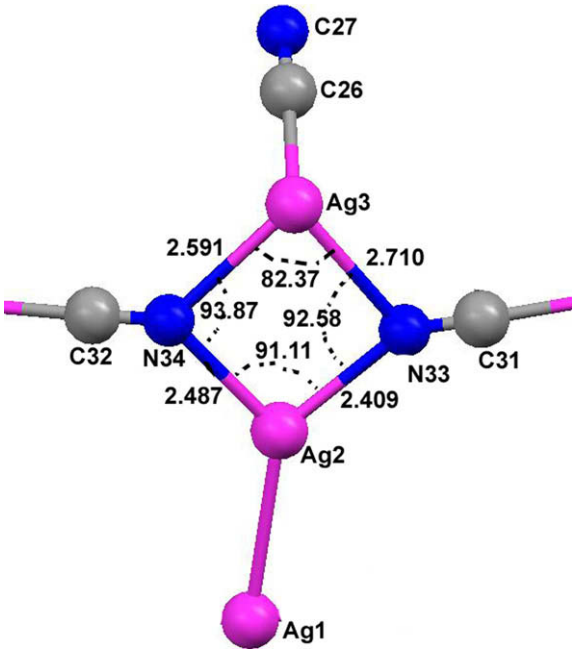

Fig. 5. View of the $(AgCN)_n$ ribbon showing the minicyclic $[Ag_2(\mu_3\text{-}CN)_2]$ motif along the *c*-axis.

comes from the fact that the carbon atoms bridge two copper atoms while the nitrogen atoms coordinate to one copper atom. In contrast, the nitrogen atoms in the $[Ag_2(\mu_3\text{-}CN)_2]$ motif act as μ_2-bridges, as should be expected. However, while the bifurcation of cyanide groups is no longer unusual, it greatly exceeds that in CuCN SCPs [12], while the Ag–N distances are not equal leading to the formation of a distorted rhombus with the sum of the internal angles being quite close to 360°, scheme 1. The bifurcated cyanide ligands can be considered as a consequence of the formation of the quadro minicycle $[Ag_2(\mu_3\text{-}CN)_2]$ motifs. Also, the $(AgCN)_\infty$ building blocks create a cluster-like structure consisting of three silver atoms exhibiting a strong Ag1–Ag2 interaction with a distance of 3.0145 Å and a weak Ag2–Ag3 interaction with a distance of 3.715 Å. Examples of weak Ag–Ag interactions with intermetallic distances from 3.40 to 3.724 Å are known [13]. The parallel ribbons are connected in a unique way by the tbpe molecules. One set of three nearly parallel tbpe

Scheme 1. Distorted $[Ag_2(\mu_3\text{-}CN)_2]$ rhombus in **2**.

ligands, with separation distances of 3.617–3.81 Å, and one tbpe ligand lying at right angles to the other ligands and to the plane defined by the $(AgCN)_n$ ribbon connect these ribbons in an alternate manner along the *a*-axis forming layers, Fig. 6. These layers contain polygons with dimensions of 9.843 × 14.602 Å. On the other hand, one type of the tbpe molecules fill the space of the hexagonal rings along the *c*-axis, alternatively one being vertical while the other one is horizontal, Fig. 7. The second type of tbpe ligands intermingle around both sides of the ribbon in horizontal positions while the terminal cyanide groups are directed to the space between the layers which form the 3D-network structure of **2**, Figs. 6 and 7. The structure of the layer is also stabilized by a wide range of intra-layer hydrogen bonding between the cyanide groups and the H-atoms of the pyridyl rings, 2.729–3.045 Å, Table 3. These parallel layers exhibit large channels in which water molecules thread, acting as guest molecules. The water molecules play an essential role in connecting the layers as they thread along the sides of the layers, H-bonding with the terminal cyanide groups belonging to one layer, tbpe ligand in the same layer and with the terminal cyanide groups of the adjacent layer, Table 3 and Fig. 6. This was further confirmed by TGA as SCP **2** starts decomposition by the loss of water molecules between 120 and 160 °C. The layers close packing was also achieved by weak but not negligible inter-layer hydrogen bonding, C37–H37^d = 3.061 Å and C26–H13 = 3.053 Å, as well as π–π stacking interactions between the pyridyl ring of tbpe from one layer and the ethylenic group from the adjacent layer, C10–C7 = 3.394 Å.

3.1.3. Crystal structure of $[(AgCN)_4 \cdot bpe]$ (3)

Half of the formula unit comprises the asymmetric unit of the structure of **3**, which contains two crystallographically different silver atoms, two cyanide groups and half of a bpe molecule, Fig. 8. Ag1 is coordinated to two ordered cyanide groups and to the nitrogen atom of the bpe ligand. Ag1 assumes a distorted trigo-

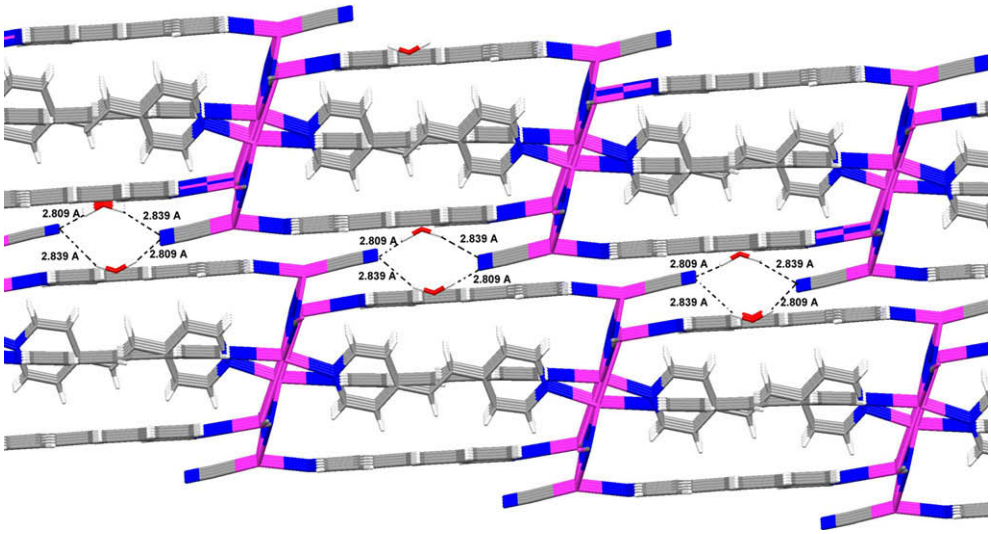

Fig. 6. View of packing of **2** along the *a*-axis showing H-bonding through water molecules.

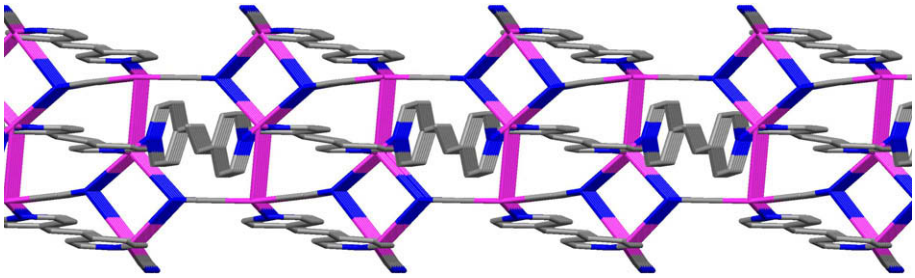

Fig. 7. View of one layer of **2** along the *c*-axis. H-atoms have been omitted for clarity.

nal planar geometry with the sum of bond angles equal to 360°, Table 4. The substantial pyramidal distortion of the essentially trigonal planar coordination sphere results mainly from the argentophilic interaction between Ag1 and Ag2, Table 4. Ag2 is coordinated to two disordered cyanide groups where it adopts a quasi-linear geometry, N(C)–Ag2–N(C) = 165.58°. This loss of linearity results from close Ag1–Ag2 and Ag2...C4 (3.031 Å) contacts.

The structure of **3** consists of two types of $(AgCN)_n$ chains, Fig. 9a and b. The first type, which runs in the ac-plane, is nearly linear and is composed of $\{Ag2–CN\}_n$ fragments. The second type, that runs along the *b*-axis, consists of corrugated chains of $\{Ag1CN\}_n$ and exhibits a wave-like structure with a separation distance between the chains of 11.132 Å. These chains are interconnected by the bpe ligands creating a 3D-network structure, while the two types of $(AgCN)_n$ chains are interconnected by the argentophilic interaction, Fig. 10. On the other hand, the 3D-structure is stabilized by extensive π–π stacking between the cyanide groups at both of the silver atoms and the pyridyl rings, 3.03 and 3.756 Å, and H-bonding between hydrogen atoms of the pyridyl rings and the cyanide groups at the silver atoms, 2.813, 3.159, 2.975 and 3.228 Å. The directions of propagation of the two chains are perpendicular to each other along the *a*-axis, Fig. 9b. The planes of the pyridyl rings are completely parallel in each set of the spacer ligands along the *b*-axis, while in the ac-plane each two sets of the spacer bpe ligands are interwoven in different conformations to accommodate a box-like structure of dimensions 9.161 × 11.132 Å, of intersecting $(AgCN)_n$ chains, Fig. 11.

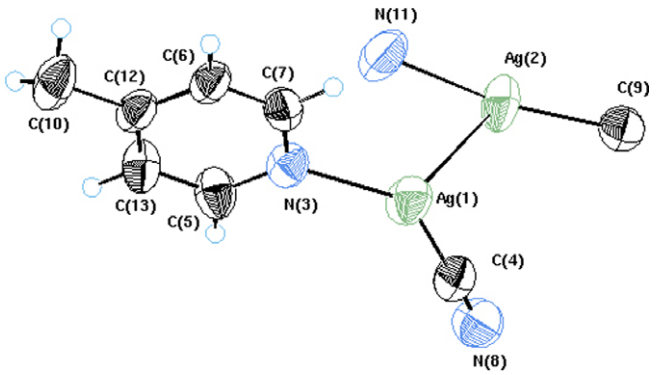

Fig. 8. ORTEP plot of the asymmetric unit of **3**.

3.2. Electronic absorption spectra and emission spectra of SCPs 1–3

The electronic absorption spectra of SCPs **1–3** display, generally, the absorption bands of the bipodal ligands in addition to the CT bands, Table 5. The bands due to $n–\pi^*$ transitions of the bipodal ligands disappear in the spectra of SCPs **1–3** due to the participation of the bipodal ligands in the coordination sphere of the silver(I) ions. The absorption spectra of SCPs **1** and **2** exhibit an additional broad band at 301–350 nm, respectively, corresponding to

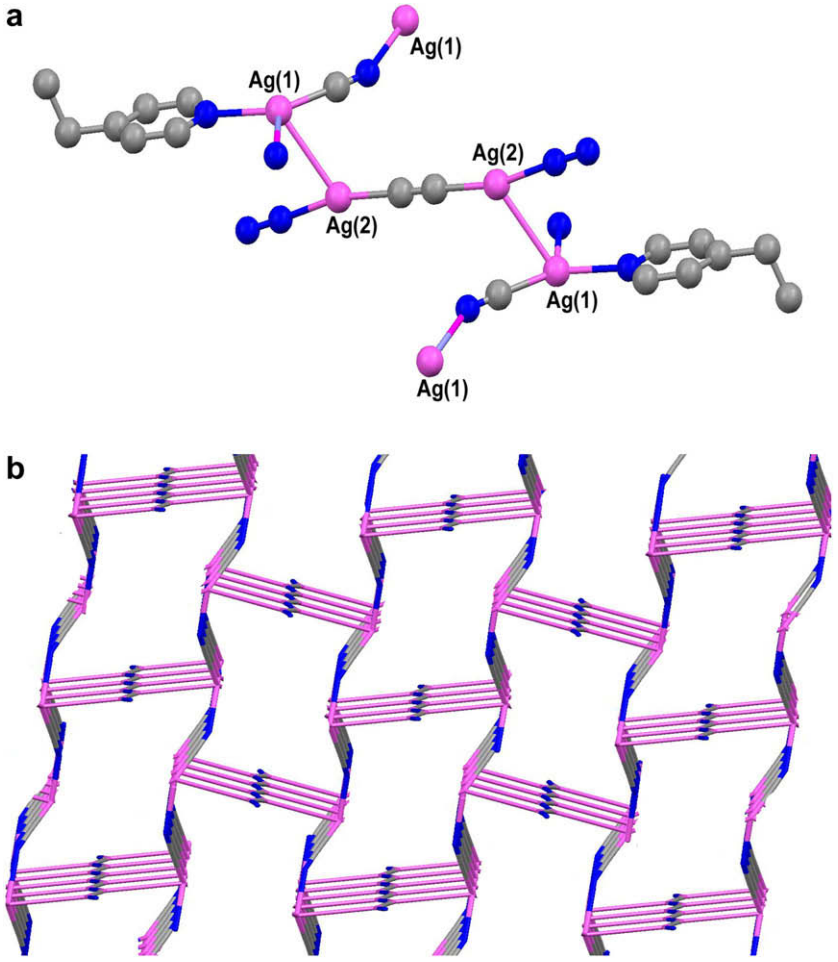

Fig. 9. (a) View of the basic building block of **3**. H-atoms have been omitted for clarity. (b) View of the connection of $(AgCN)_n$ chains in **3** to form a 3D-network, neglecting the bpe ligand.

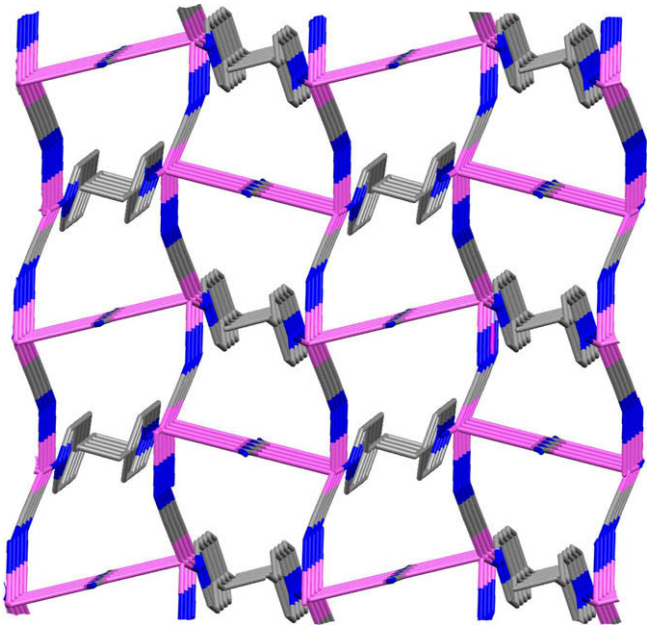

Fig. 10. View of the 3D-framework of **3** showing the argentophilic interaction. H-atoms have been omitted for clarity.

metalto-ligand charge transfer (MLCT), where the charge is transferred from the silver(I) center to the unoccupied π^*-orbital of the ligand. The emission spectra of the SCPs **1–3** together with the emission spectra of the bipodal ligands were measured in the solid state at room temperature and using the same excitation wavelength in each case, Fig. 12, Table 5. The emission spectra of the bipodal ligands display structural bands which correspond to the lowest (π–π^*) and close lying (n–π^*) states. On the other hand, the emission spectra of SCPs **1–3** display the structural bands of the bipodal ligands as well as additional bands at 600–640 nm, 584–624 nm and 600 nm, respectively. These bands may be attributed to MLCT or metal centered transitions of the type $4d^{10} \rightarrow 4d^9\,5s^1$ and $4d^{10} \rightarrow 4d^9\,5p^1$ on the silver(I) center. The emission spectra of SCPs **1–3** exhibit a slight red shift compared to those of the corresponding ligands, whereas the intensities of the bands of SCPs **2** and **3** increase significantly from those of the ligands.

3.3. Thermogravimetric analysis of SCPs *1–3*

The thermal decomposition bahaviour of SCPs **1–3** show broad similarity, but they are not identical, Table 6. They show the usual trend of similar early reported compounds [14]. Firstly dehydration occurs, followed by loss of the bipodal ligand and finally removal of the inorganic anions. After complete thermolysis the calculated and observed percentages of the residues are coincident with metallic silver. The loss of water molecules at 120–160 °C, for SCP **2**, confirms the involvement of the water molecules in hydrogen bonding with the cyanide groups, as depicted in the crystal structure (vide supra). The cyanide groups are lost in the form of cyanogen molecules at relatively high temperatures, indicating the bridging capability of the cyanide groups forming stable $(AgCN)_n$ frameworks.

4. General discussion

The SCPs **1–3** illustrate the rich diversity of structures that can be achieved by variation of the spacer bipodal ligand. The length and the molecular conformation of the spacer ligands affect significantly the self-assembly of the $(AgCN)_n$ building blocks to produce enough wide space to accommodate the spacer ligands via the formation of different rings and polygons. The bipodal ligands play the role of bridging the $(AgCN)_n$ building blocks creating 2D-layers which are interwoven, **1** and **2**, or intersecting, **3**, to produce 3D-structures via extensive H-bonding and π–π stacking, as well as Ag···Ag interactions. The structures of **1** and **2** are completely different from those of the analogous $[(Cu_2(CN)_2(\mu\text{-}4,4'\text{-bpy})]$, **1′** and $[(CuCN)_2(\mu\text{-tbpe})]$, **2′**. **1** exhibits an interwoven but non-interpenetrating open framework while **1′** contains two identical non-intersecting but interpenetrating frameworks with a rhombic (Cu_2X_2) motif. In spite of both **2** and **2′** containing the minicycle (Cu_2X_2) and (Ag_2N_2) motifs, **2′** contains large void spaces in the framework which results in interpenetration by a second independent framework, while **2** contains a cluster-like structure of $(AgCN)_n$ ribbons which are connected in a unique way by the tbpe ligands creating

a non-interpenetrating 3D-network with terminal cyanide ligands and threaded water molecules. The unprecedented structure of **3** consists of intersecting $(AgCN)_n$ chains forming a box-like structure with wide voids containing the interwoven bridging bpe ligands. In **1** and **2**, the Ag1–Ag2 and Ag1–N4 (in **1**) and Ag2–C4 (in **2**) contacts produce a distorted geometry at the silver sites. The coordination versatility of the silver atom is also in evidence as quasi-linear, [AgNC], distorted trigonal planar, [AgN_3], [AgC_2 N], [AgN_2C], and tetrahedral [AgN_4], [AgN_3C] geometries have been observed, in addition to the influence of the argentophilic interaction on the distortion of the geometry around the silver sites.

5. Conclusion

The results reinforce the observation that the cyanide group is an effective bridging ligand which can link together two or three silver centers, μ_2-1,2-CN or μ_3-1,2,2-CN. Ligand length and flexibility affect the AgCN–ligand ratio, where the proportion of the ligand decreases as the length and flexibility of the ligand increase. It is also clear that the organic ligands may be introduced as structural components of composite inorganic–organic materials and used, in addition to conventional and unconventional interactions, to propagate 3D-topologies.

Appendix A. Supplementary data

CCDC 682258, 682259 and 682260 contain the supplementary crystallographic data for **1**, **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.12.053.

aqueous interactions and ensuing chemistry of Ni(II) with the α-hydroxycarboxylate binder D-(−)-quinic acid. This chemistry is expected to (a) enlighten the type and nature of interactions emerging into the structural speciation of the requisite binary Ni(II)–hydroxycarboxylate cellular systems, and (b) provide insight into the chemical and physical properties on new Ni(II) species emerging as potential metallo(bio)targets in cellular physiology or toxicity. To this end, we, herein, report on the pH-specific synthesis, spectroscopic and structural characterization, and magnetic susceptibility studies of a new binary Ni(II)–quinate species $Na[Ni(C_7H_{11}O_6)_3] \cdot 2.75H_2O$ **(1)** closely tied to the aqueous speciation of the binary system and its significance in Ni(II) biologically relevant chemistry.

2. Experimental

2.1. Materials and methods

All manipulations were carried out under aerobic conditions. $NiCl_2 \cdot 6H_2O$ and D-(−)-quinic acid (purity 98%) were purchased from Fluka. Nano-pure quality water was used for all reactions run. NaOH and NaCl were supplied by Fluka.

2.2. Physical measurements

FT-IR measurements were taken on a 1760X FT-IR spectrometer from Perkin–Elmer, using KBr pellets. UV–Visible measurements were carried out on a Hitachi U2001 spectrophotometer in the range from 190 to 1000 nm. A ThermoFinnigan Flash EA 1112 CHNS elemental analyzer was used for the simultaneous determination of carbon and hydrogen (%). The analyzer is based on the dynamic flash combustion of the sample (at 1800 °C) followed by reduction, trapping, complete GC separation and detection of the products. The instrument is (a) fully automated and controlled by PC via the Eager 300 dedicated software and (b) capable of handling solid, liquid or gaseous substances. Magnetic susceptibility data were collected on powdered samples of **1** with a Quantum Design SQUID susceptometer in the 2–300 K temperature range, under various applied magnetic fields. Magnetization measurements were carried out at three different temperatures in the field range 0–5 T.

2.3. pH-potentiometric measurements

The protonation constants of quinic acid were determined by pH-potentiometric titrations of 30.0(1) ml samples in the pH range 2.8–11.4 under a purified argon atmosphere. The concentration of quinic acid was in the range of 1.3–5.0 mmol dm^{-3}. The stability constants of the Ni(II) complexes of quinic acid were determined by pH-potentiometric titrations of 30.0(1) ml samples in the pH range 2.4–8.7 under a purified argon atmosphere. Precipitation was observed at pH ~8.7, as in the case of the aqueous binary system of Co(II) with 2′-deoxyguanosine 5′-monophosphate [9].

All solutions were prepared using Fluka reagent grade quinic acid, $NiCl_2 \cdot 6H_2O$, and ultra-pure deionized water. The purity of quinic acid and the exact concentration of quinate and Ni(II) solutions, were determined by the Gran method [10–12]. The exact concentration of Ni(II) was checked by EDTA complexometric titrations as previously described [13]. The ionic strength was adjusted to 0.15 M with NaCl. The temperature was maintained at 25.0 ± 0.1 °C during the measurements. The titrations were carried out with a carbonate-free NaOH solution of known concentration (ca. 0.15 M). The base solution was prepared following a standard procedure: NaOH pellets were dissolved in nano-pure quality water under an argon atmosphere. Carbon dioxide was removed from water by boiling and cooling under a stream of purified argon. The NaOH solution was standardized using potassium hydrogen iodate ($KH(IO_3)_2$). The nickel concentration was 1.0 mM, and the employed metal:ligand ratios were 1:2, 1:3, and 1:4. In order to collect solution data at pH values lower than 3.0, a known amount of nitric acid was initially added. The pH was measured with a computer-controlled Crison titration system elaborated for titrations at such low concentrations [14] and a Mettler Toledo-Inlab 412 combined glass-electrode, calibrated for hydrogen ion concentration according to Irving et al. [15] by using the GLEE program [16]. The ionic product of water was found to be $pK_w = 13.76$ [17].

The one step protonation constants of quinic acid are given as $\log K_1$, consistent with the equilibrium $L^- + H^+ \rightleftarrows HL$, where $K_1 = [HL]/[L^-] \rightleftarrows [H^+]$. The stepwise protonation constants of quinic acid are given as $\log K_n$, consistent with the equilibrium $H_{n-1}L + H \rightleftarrows H_nL$, where $K_n = [H_nL]/[H_{n-1}L]\,[H]$. The initial computations were obtained in the form of overall protonation constants $\beta_n = [H_nL]/[L]\,[H]^n$, taking into account that $\beta_n = \prod K_n$. The concentration stability constants $\beta_{pqr} = [M_pL_qH_r]/[M]^p[L]^q[H]^r$ for quinic acid were calculated with SUPERQUAD [18], and those for Ni(II)–quinate complexes, arising in the investigated system, with the PSEQUAD computer program [19]. The pH-dependent species distribution curves and simulated titration curves were derived from the overall formation constants measured with the program HYSS [20].

Formation of Ni(II)–hydroxo complexes was taken into consideration in the employed calculations leading to the most plausible speciation model. The hydroxo species considered include the following: (a) $[NiH_{-1}]^+$ ($\log\beta_{1-1} = -9.74$), (b) $[Ni_2H_{-1}]^{3+}$ ($\log\beta_{2-1} = -9.6$), and (c) $[Ni_4(OH)_4]^{4+}$ ($\log\beta_{4-4} = -27.4$). Relevant information on the above species was taken from Plyasunova et al. [21] and corrected for an ionic strength of 0.15 M by use of the Davies equation [22].

2.4. Synthesis of sodium [tris(quinato)nickel(II)] hydrate: $Na[Ni(C_7H_{11}O_6)_3] \cdot 2.75H_2O$ (**1**)

$NiCl_2 \cdot 4H_2O$ (0.50 g, 2.1 mmol) and D-(−)-quinic acid (0.80 g, 4.2 mmol) were placed in a 25 mL round bottom flask and dissolved in 6 mL of water. The reaction mixture was then stirred at room temperature until both reactants were completely dissolved. Subsequently, the pH of the clear solution was adjusted to 5.5 with NaOH. The resulting reaction mixture was placed in the refrigerator at 4 °C and ethanol was added. Four months later, green crystalline material appeared on the bottom of the flask. The crystalline product was isolated by filtration and dried in vacuo. Yield 0.62 g (36%). *Anal.* Calc. for **1**, $Na[Ni(C_7H_{11}O_6)_3] \cdot 2.75H_2O$ ($C_{21}H_{38.50}O_{20.75}NaNi$, MW = 704.47): C, 35.7; H, 5.5. Found: C, 35.0; H, 5.8%.

2.5. X-ray crystal structure determination

X-ray quality crystals of compound **1** were grown from reaction mixtures upon addition of ethanol. A single crystal with dimensions 0.50 × 0.30 × 0.20 mm (**1**) was mounted on the tip of a glass fiber with epoxy glue. Single crystal analysis was carried out on a Bruker AXS SMART 1K CCD area detector diffractometer. The frame data were acquired at room temperature using the SMART-NT software and Mo Kα radiation ($\lambda = 0.71073$ Å) [23]. A total of 1325 45-s frames were collected in three sets with 0.3° ω-scan. The collected frames were then processed using the SAINT-NT software [24] to provide the *hkl* file corrected for Lorentz and polarization effects. An empirical absorption correction was applied through the program SADABS [23]. The structure was solved by direct methods using the SHELX-90 program and refined by least-squares methods on F^2, SHELXTL-93, incorporated in SHELXTL, Version 5.1 (Table 1) [25].

Table 1
Summary of crystal, intensity collection and refinement data for Na[Ni-($C_7H_{11}O_6$)$_3$] · 2.75H_2O (1).

Formula	$C_{21}H_{38.50}O_{20.75}NaNi$

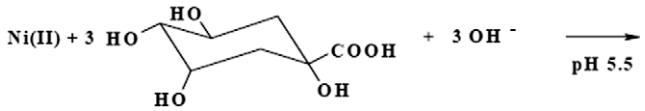
R indices[a]	R = 0.0653, R_w = 0.2038[b]

[a] R values are based on F values, R_w values are based on F^2. $R = \frac{\sum||F_0|-F_c||}{\sum(|F_0|)}$, $R_w = \sqrt{\sum[w(F_0^2 - F_c^2)^2]/\sum[w(F_0^2)^2]}$.



[b] For 7735 reflections with $I > 2\sigma(I)$.

All non-hydrogen atoms were refined anisotropically. Hydrogen atoms on carbon atoms were geometrically positioned and left riding on their parent atoms during structure refinement. Hydrogen atom positions, which belong to oxygen atoms, were first determined from E-maps, brought to reasonable distances from their parent oxygen atoms, and then fixed. The disordered oxygen-atoms of water were left as such (nascent form). The final assignment of hydrogen atoms satisfies the electroneutrality of compound **1**, with the understanding that Ni ions are formally in the +2 oxidation state. The associated CCDC reference number is 644650. Selected crystallographic data appear in Table 1. Further crystallographic details for **1**: $2\theta_{max}$ = 52°; reflections collected/unique/used, 23772/7735 [R_{int} = 0.0471]; 415 parameters refined; $[\Delta\rho]_{max}/[\Delta\rho]_{min}$ = 0.917/−0.399 e/Å^3; R/R_w (for all data), 0.0841/0.2127.

3. Results

3.1. Synthesis

Complex **1** was synthesized through a simple reaction between Ni(II) and D-(−)-quinic acid in a 1:2 molar ratio and isolated by addition of ethanol to the reaction mixture. The presence of NaOH helped to adjust the pH of the reaction mixture, while concurrently providing the appropriate counter ions to balance the arisen charge on the Ni(II)–quinate assembly (vide infra). The same reaction run with a Ni(II):quinic acid a 1:3 molar ratio led to a material identical to **1** by virtue of its FT-IR signature (yield 33%). A major advantage, however, of this reaction was that the crystalline product was obtained faster than that of the 1:2 Ni(II):quinic acid ratio. The stoichiometric reaction leading to the formation of compound **1** is shown below (Reaction 1):

D-(-)-quinic acid

$[Ni(C_7H_{11}O_6)_3]^-$ + 3 H_2O Reaction 1

Elemental analysis of the isolated green-colored crystalline material and FT-IR spectroscopy suggested the molecular formula Na[Ni-($C_7H_{11}O_6$)$_3$] · 2.75H_2O for **1**. Confirmation came from the X-ray crystallographic determination of its structure. Compound **1** is soluble in water, but insoluble in common organic solvents. Crystalline **1** is stable in the air at room temperature for long periods of time.

3.2. Description of X-ray crystallographic structure

Compound **1** emerges from a crystal lattice composed of discrete anionic Ni(II) complexes and Na^+ counter ions. The structure diagram for complex **1** is shown in Fig. 1. A list of selected bond distances and angles for **1** is given in Table 2. Complex **1** crystallizes in the orthorhombic space group $P2_12_12_1$ with four molecules per unit cell. The X-ray crystal structure of **1** reveals a Ni(II) assembly, with three quinate ligands coordinating to the metal ion through the alcoholic and carboxylate oxygens O(1) and O(5), O7 and O11, and O13 and O17, respectively. Each bound ligand is singly deprotonated, with the site of deprotonation being the carboxylic acid group. The three bound quinates formulate a distorted octahedral environment around Ni(II). Unlike other metal ions (e.g. Mn(II)) bound to the quinate ligand, the Ni(II) ion bears quinate ligands, the terminal alcoholic moieties of which do not participate in coordination to abutting metal ions in the crystal lattice of the title compound lattice.

The Ni–O bond distances are in the range from 2.009(4) to 2.069(4) Å for **1**, which are comparable with those in complexes, $(NH_4)_2[Ni_2(C_6H_5O_7)_2(H_2O)_4]_2 \cdot 2H_2O$ (2.020(3)–2.074(2) Å) (**2**) [26], $K_2[Ni(C_6H_5O_7)_2(H_2O)_4] \cdot 4H_2O$ (2.036(3)–2.125(3) Å) (**3**) [27], $[Ni(C_4H_4O_5)(H_2O)] \cdot H_2O$ (2.034(5)–2.101(5) Å) (**4**), $[Ni(C_4H_4O_5)(H_2O)(C_{12}H_8N_2)]$ (2.032(3)–2.048(3) Å) (**5**) [28], and $[(N(CH_3)_4)_5[Ni_4(C_6H_4O_7)_3(OH)(H_2O)] \cdot 18H_2O]_2$ (1.95(1)–2.12(1) Å) (**6**) [29].

The angles are in the range 77.99(15)–102.76(19)° for complex **1** and similar to those observed in (81.53(9)–96.7(2)°) (**2**), (86.8(1)–95.2(1)°) (**3**), (81.1(2)–95.0(2)°) (**4**), (89.2(2)–95.1(2)°) (**5**), (76.5(4)–102.1(4)°) (**6**), and also similar to those in the quinate organic–inorganic hybrid $[Mn_2(C_7H_{11}O_6)_4]_n \cdot nH_2O$ (69.56(15)–96.75(17)° and 73.02(13)–95.41(15)°, respectively) [30].

The octahedral Ni(II) ion in **1** correlates well with other octahedral divalent metal ions such as Zn(II) [31], Cu(II) [32], and Ni(II) [25], in analogous octahedral species bearing citrates. The M–O distances observed in those complexes are in line with those seen

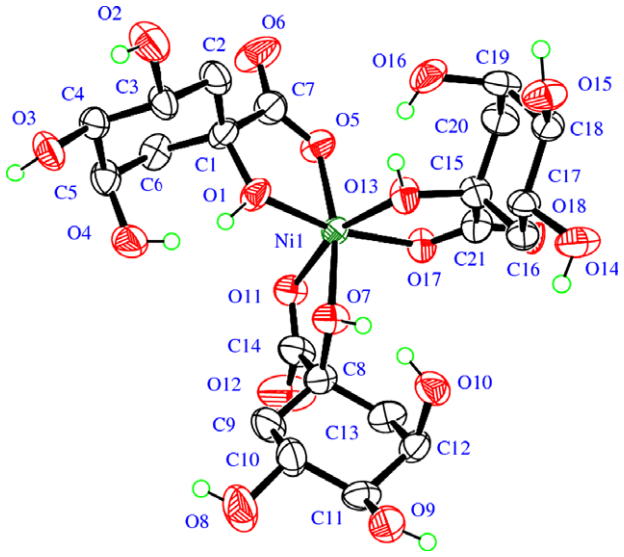


Fig. 1. The structure of the anionic assembly in Na[Ni($C_7H_{11}O_6$)$_3$]·2.75H_2O (**1**) with the atom-labeling scheme (50% thermal probability ellipsoids).

Table 2
Bond lengths (Å) and angles (°) in **1**.

Distances			
Ni(1)–O(1)	2.039(4)	Ni(1)–O(11)	2.041(4)
Ni(1)–O(5)	2.009(4)	Ni(1)–O(13)	2.069(4)
Ni(1)–O(7)	2.031(4)	Ni(1)–O(17)	2.005(4)
Angles			
O(17)–Ni(1)–O(5)	94.62(18)	O(7)–Ni(1)–O(11)	79.58(17)
O(17)–Ni(1)–O(7)	98.70(19)	O(1)–Ni(1)–O(11)	102.76(19)
O(5)–Ni(1)–O(7)	166.49(18)	O(17)–Ni(1)–O(13)	77.99(15)
O(17)–Ni(1)–O(1)	165.95(18)	O(5)–Ni(1)–O(13)	98.3(2)
O(5)–Ni(1)–O(1)	79.16(16)	O(7)–Ni(1)–O(13)	86.78(18)
O(7)–Ni(1)–O(1)	88.32(17)	O(1)–Ni(1)–O(13)	90.36(17)
O(17)–Ni(1)–O(11)	90.52(17)	O(11)–Ni(1)–O(13)	160.67(17)
O(5)–Ni(1)–O(11)	98.10(19)		

in **1** and range from 2.052(2) to 2.164(2) Å (Zn(II)) and from 2.021(3) to 2.072(3) Å (Ni(II)), while a wider range due to Jahn–Teller distortion is observed in the copper analog (1.969(3)–2.341(3) Å). Equally comparable are the M–O distances with those occurring in the congener quinate compounds $[Zn(C_7H_{11}O_6)_2]$ [33], $[Cd(C_7H_{11}O_6)_2]\cdot H_2O$, $[Cu(C_7H_{10}O_6)(H_2O)]_2(H_2O)_2$ [34], $\{[Cu(NO_3)(C_7H_{11}O_6)(H_2O)]\cdot 2H_2O\}_n$, $\{[CuCl(C_7H_{11}O_6)(H_2O)]\cdot H_2O\}_n$ [35], $[Pt(C_6H_{14}N_2)(C_7H_{10}O_6)]$ [36], and the trinuclear $(NH_4)_2\{[V(O)_2]_2[V(O)](\mu\text{-}C_7H_{10}O_6)_2\}\cdot H_2O$ [37].

In the lattice structure, the Na^+ ions counterbalance efficiently the anionic charge. They are in contact with the alcoholic oxygens of the quinate anion at distances in the range of 2.344(6)–2.423(5) Å (six contacts) (Fig. 2B). The crystal structure of **1** is composed of an infinite 3D network, where quinate ligands bridge each Ni-atom with its three neighboring Na-atoms. The three Na-atoms define a triangle, with the Ni-atom located above its center and the Ni–Na distance in the range 8.083(3)–8.096(3) Å (Fig. 2A). Each Na^+ ion is bound to three quinates, all originating from different $[Ni(C_7H_{11}O_6)_3]^-$ units.

3.3. UV–Visible spectroscopy

The UV–Visible spectrum of **1** was recorded in water (Fig. S1). The spectrum exhibits peaks at λ_{max} 725 (ε 2 M^{-1} cm^{-1}) and 662 nm (ε 2 M^{-1} cm^{-1}), and a distant shoulder around 395 nm rising into the UV. The absorption feature around 395 nm (ε 6 M^{-1} cm^{-1}) could be tentatively attributed to the $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transition. The observed multiple structure containing the 725 and 662 nm features, a region normally corresponding to the $^3A_{2g} \rightarrow {}^3T_{2g}$ transition, is in line with literature reports invoking the presence of an ^1E_g state lying so close to $^3T_{2g}$ that extensive mixing takes place. That mixing leads to the observation of a doublet band, where the spin forbidden transition picks up intensity from the spin-allowed transition, thus accounting for the complexity of the spectrum [38]. The spectrum bears similar features to that of $[Ni(H_2O)_6]^{2+}$ ion, signifying the effect of the O-containing ligands in the electronic structure of Ni(II).

3.4. FT-IR spectroscopy

The FT-IR spectrum of **1** exhibits strong absorptions for the carbonyls of the carboxylate groups in both the antisymmetric and symmetric vibration regions. The antisymmetric stretching vibrations $\nu_{as}(COO^-)$ appear close to 1602 cm^{-1}, whereas the symmetric stretches $\nu_s(COO^-)$ appear in the range 1450–1334 cm^{-1}. The frequencies for the carbonyl stretches in **1** are shifted to lower values compared to those of the free quinic acid. In addition to this, they indicate a change in the vibrational status of the quinate anion upon coordination to the metal ion. The difference between the symmetric and antisymmetric stretches, $\Delta(\nu_{as}(COO^-) - \nu_s(COO^-))$, was greater than 200 cm^{-1}, indicating that the carboxylate groups of the quinate ligand were either free or coordinated to the metal ion in a monodentate fashion [39,40]. The latter contention was further confirmed by the X-ray crystal structure of **1**. Similar trends in the frequencies of the carboxylate carbonyls have also been observed in the FT-IR spectra of other metal–quinate complexes as well as α-hydroxycarboxylate complexes with metal ions [41,42].

3.5. Magnetic susceptibility studies

Magnetic susceptibility measurements were carried out at different magnetic fields and in the temperature range 2–300 K. The data were fitted with the MAGPACK [43] program, employed with a nonlinear least-squares curve-fitting program, DSTEPIT [44]. The temperature dependence of $\chi_M T$ (χ_M being the magnetic suscepti-

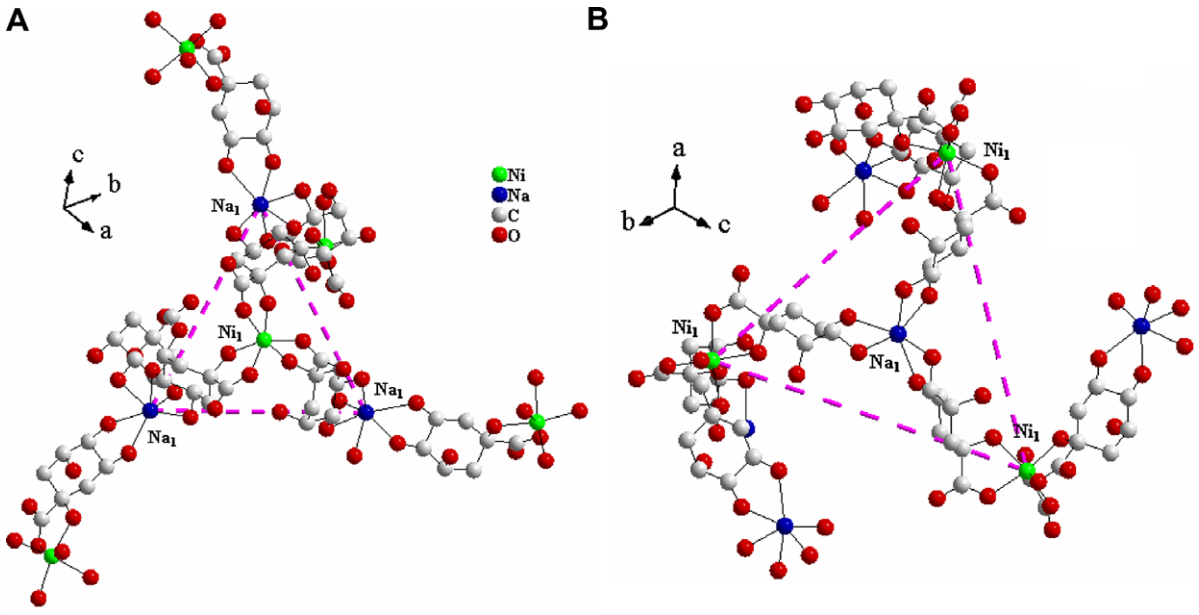

Fig. 2. Structural organization of **1**, showing the relationship between Na- and Ni-atoms (A and B) in the lattice composition (see text).

bility for one Ni(II) ion) for complex **1** is shown in Fig. 3 (solid circles). The $\chi_M T$ value is 1.78 emu mol^{-1} K at 300 K. From that temperature down to 10 K there is a smooth linear decrease, while after that temperature and until 2 K a more pronounced decrease occurs, reaching the value of 0.84 emu mol^{-1} K. The shape of this curve is characteristic of the occurrence of large zero field effects along with the temperature independent paramagnetism effect, TIP, which leads to a linear temperature dependence of the susceptibility data. The susceptibility data were fitted by the following equation:

$$H = D\left[S_z^2 - \frac{1}{3}S(S+1)\right] + E(S_x^2 - S_y^2) + g_z\mu_B H_z S_z + g_x\mu_B H_x S_x + g_y\mu_B H_y S_y, \quad (1)$$

where an isotropic g-value was used. The best fit (solid line in Fig. 3) is given by the parameters $D = 3.4$ cm^{-1} and $g = 2.2$, TIP = 1.8×10^{-3}. In the inset of the figure, simulations of the susceptibility function are shown for different values of the D parameter, where the g value and the TIP were kept at values obtained from the fitting procedure. Both axes are in logarithmic scale.

Isothermal magnetization curves at T 2 K in the applied field 0–5 T are shown in Fig. 4. The curves for the increasing and decreasing fields are identical. The data were fitted using (Eq. (1)) and the best fit (solid line in Fig. 4) is given by the parameters of $D = 2.8$ cm^{-1}, $g = 2.2$. The latter are very close to the values obtained from the susceptibility study, verifying the large zero-field character of the system.

3.6. Speciation studies

pH-potentiometric titrations of the ligand quinic acid alone, and Ni(II) with D-(−)-quinic acid in various metal ion to ligand molar ratios [Ni:L] = [1:2/1:3/1:4] were carried out. The titration curves were evaluated with different potential speciation models. The best fit between the experimental and calculated titration curves for the binary Ni(II)–quinic acid system was obtained by considering the species [Ni(II)], $[NiL_2]^o$ (HL = $C_7H_{12}O_6$; L = $C_7H_{11}O_6^-$), $[NiL_2H_{-1}]^-$, and $[NiH_{-1}]^+$. The fit is reasonably good in the overall pH and concentration range used, demonstrating that the adopted speciation model is satisfactorily defined. Other complexes, such as 1:1 and 1:2 Ni(II):quinate complexes or variably protonated and deprotonated species were rejected by the computer program (PSEQUAD) during the computation process. The species emerging from the speciation distribution of the binary system are in good agreement with the corresponding species synthesized and isolated in the solid state. The stability constants of the complexes formed are listed in Table 3. The uncertainties (3SD values) for the stability constants are given in parentheses. The pH range of the optimal formation of complexes is also reported. For the titratable quinate carboxylate group, the pK_a value of 3.34 was obtained and was found to be very close to the values reported by Clifford (3.40) [45] and Luethy-Krause et al. (3.36) [46]. For shikimic acid (3R, 4S, 5R)-3,4,5-trihydroxy 1-cyclohexanecarboxylic acid) the pK_a value is 4.15 [45]. The presence of an alcoholic moiety in a position α- to the carboxylate group of quinic acid increases its acid strength.

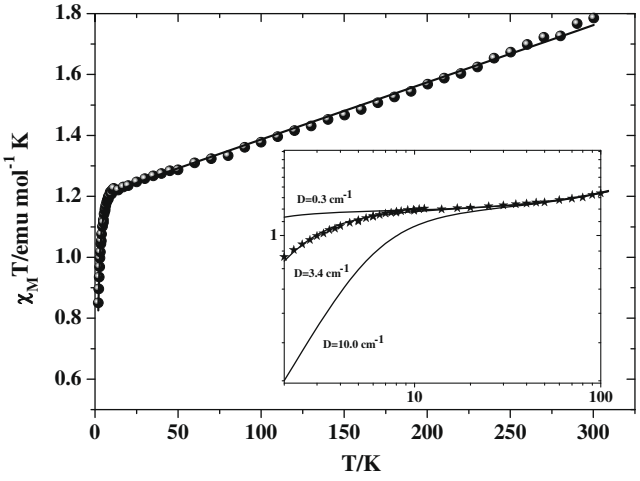

Fig. 3. Temperature dependence of the susceptibility data in the form of $\chi_M T$ vs. T (solid stars) and the fitting results using the theoretical formula discussed in the text (solid line). In the inset, simulations of the susceptibility function are shown, in the form of $\chi_M T$ vs. T, for different values of the D parameter. Both axes are in logarithmic scale.

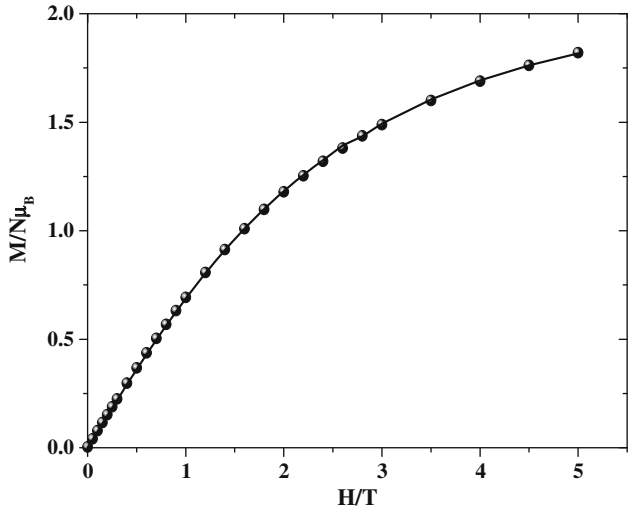

Fig. 4. Magnetization measurements in the field range 0–5 T, at temperature T 2 K, and the fitting results using the theoretical formula discussed in the text (solid line).

The titrimetric data were evaluated on the premise that complex formation between Ni(II) and quinate proceeds through binding of the quinate carboxylate and the α-alcoholic group moieties. The titration curves in the absence and presence of Ni(II) suggest formation of the $[NiL_2]^o$ species in the acidic region up to pH 8, and the $[NiL_2H_{-1}]^-$ species at pH values beyond 7. These studies also suggest that this ligand reacts expediently with Ni(II) ions, forming soluble metal chelate complexes. In the $[NiL_2]^o$ complex, the ligand appears to be deprotonated at the carboxylate moiety and as such both quinate ligands act in a bidentate fashion, coordinating Ni(II). The hexacoordination of Ni(II) ion is consistent with the presence of the $[Ni(H_2O)_6]^{2+}$ complex ion in the entire pH range investigated.

Table 3
Proton (log$K$) and Ni(II)–quinic acid complex formation constants (logβ) at $I = 0.15$ (NaCl) and 25 °C.

	Quinic acid	Ni–quinic acid	pH range for each species
Log$K$(HL)	3.34(1)		
Logβ (NiL_2)		4.95(3)	all domain
Logβ (NiL_2H_{-1})		−4.14(7)	>7.0
pK ($[NiL_2H_{-1}]/[NiL_2]$)		9.09	
Fitting[a]		9.656×10^{-3}	
Number of pts.		191	

Charges from the various species are omitted for clarity.
[a] Goodness-of-fit between the experimental and the calculated titration curves expressed in milliliters of titrant.

The overall stability constant of the mononuclear complex $[NiL_2]^o$ ($\log\beta$ 4.95) is similar yet greater than those in complexes of Ni(II) with some α-hydroxycarboxylic acids, such as 2-hydroxyacetic acid (glycolic acid) ($\log\beta$ 3.77) [47], 2-hydroxypropanoic acid (lactic acid) ($\log\beta$ 2.85) [48], 2-hydroxybutanoic acid ($\log\beta$ 2.89) [49], 2-hydroxy-2-methylpropanoic acid (2-hydroxyisobutyric acid) ($\log\beta$ 2.80) [50], and 2-hydroxy-2-phenylacetic acid (mandelic acid) ($\log\beta$ 2.48) [51].

In the pH range beyond 7 of the binary Ni(II)–quinic acid system, two species emerge, namely $[NiL_2H_{-1}]^-$ and the mononuclear $[NiH_{-1}]^+ = [Ni(OH)]^+$. Quinic acid contains one carboxylic acid group and four alcoholic hydrogens. The pK_a of the latter is >11. The dicationic metal ions (Co(II), Ni(II), etc.) are not sufficiently strong to deprotonate the alcoholic proton of quinic acid. As a consequence, it is very likely that one of the two water molecules coordinated to the nickel ion in the mononuclear species $[NiL_2H_{-1}]^-$ is possibly deprotonated. This is the species arising as the successor participant to the $[NiL_2]^o$ species at higher pH values in the speciation diagram. These two species coexist with the hexa-aquo nickel $[Ni(H_2O)_6]^{2+}$ species in the entire pH range studied, as that is shown in the speciation curves presented in Fig. 5. The maximum% content of $[NiL_2]^o$ appears to be 30% and stays constant in the pH range 4.5–7.5 of the binary Ni(II)–quinic acid system, where $c_{Ni} = 0.000657$ mol dm^{-3}, and $c_{ligand} = 0.002704$ mol dm^{-3}.

Beyond the pH range 8.2–8.8, depending on the molar ratio Ni(II):quinate, a precipitate appears and the pH rise ceases, most likely due to OH^- ions being consumed toward formation of $Ni(OH)_2$. The incipient precipitation at pH beyond 8.5 makes the observation of the next phase of the aqueous speciation doubtful, even in the presence of higher ligand-to-metal molar ratios (Fig. S2).

The presence of the hexa-aquo $[Ni(H_2O)_6]^{2+}$ species over the entire pH range, where the aqueous speciation was investigated, has been noted. In a similar system containing histidinehydroxamic acid, the Ni(II) ion is strongly bound to the ligand in mononuclear NiL ($\log\beta = 10.49$) and NiL_2 ($\log\beta = 18.80$) complexes [52]. From the speciation curves of that system, it can be seen that the hexa-aquo $[Ni(H_2O)_6]^{2+}$ species stays intact up to pH around 11. As was the case of the binary system of Ni(II) in presence of quinic acid, a precipitate appears beyond pH 9 in this system as well. In the Ni(II)–D-glucosamine system [53], the NiL_2 ($\log\beta = 6.43$) complex appears in the pH range 7–10. From the speciation curves of this system, it can be seen that the aquo $[Ni(H_2O)_6]^{2+}$ species stays as such up to pH around 11. Hexa-aquo Ni(II) ions are also the major species present in the binary system of Ni(II) with pycdpnen (a pyridylamido hexadentate ligand) up to pH 7 [54]. In the case of the aqueous binary system of Ni(II) with 2-(4-methylthiazol-2-yl)-2-(hydroxyimino)acetic acid, the binary NiL_2 complex also forms ($\log\beta = 11.83$), while at pH<6.5 hexa-aquo Ni(II) ions are present [55]. The stability constant of the $[NiL_2H_{-1}]^-$ ($\log\beta = -4.14$) species is higher than that of the monohydroxo species $[NiH_{-1}]^+$ ($\log\beta = -9.74$). That could help explain why at pH beyond 7, where both species form, the% content of the $[NiL_2H_{-1}]^-$ species appears to be higher than that of the $[NiH_{-1}]^+$ species in the same pH range [56].

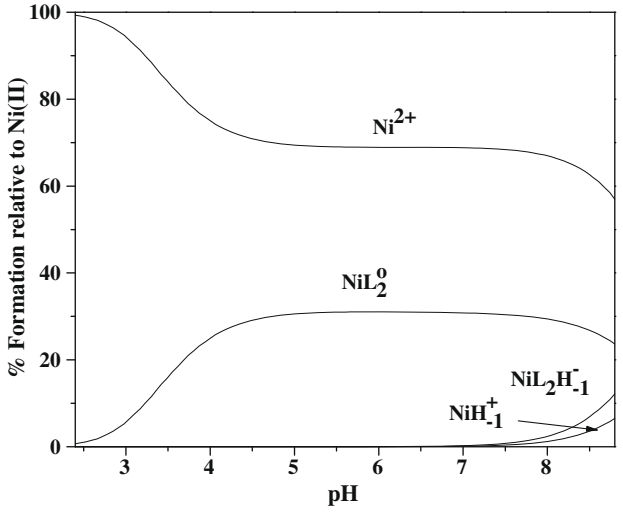

Fig. 5. Speciation curves for complexes forming in the binary Ni(II)–quinic acid system; $c_{Ni} = 0.000657$ mol dm^{-3}, $c_{ligand} = 0.002704$ mol dm^{-3}. Charges are omitted for clarity.

4. Discussion

4.1. The chemistry of the binary Ni(II)–quinate system in aqueous media

The synthesis of $Na[Ni(C_7H_{11}O_6)_3] \cdot 2.75H_2O$ (**1**) through the pH specific reaction of $NiCl_2$ with quinic acid at pH 5.5, emphasizes the distinct interaction of D-(−)-quinic acid with the divalent metal ion Ni(II). The analytical, spectroscopic, structural and magnetic susceptibility characterization of the derived material provided the physical and chemical properties of **1**, revealing a considerable number of structural details related to the reactivity of quinic acid toward Ni(II).

Associated with the distinct structural identity of **1** was the retention of the protonation of the α-alcoholic group in the quinate ligand upon binding to Ni(II). Each binding site around Ni(II) includes the oxygen from the carboxylate moiety bearing 1− charge, thus raising the total charge for the isolated mononuclear complex to 1−. Formation of a five-membered cyclic ring is most likely a source for stability in the isolated complex. The negative charge on the anionic complex $[Ni(C_7H_{11}O_6)_3]^-$ is counteracted by one sodium ion. Retention of the proton of the alcoholic group in the α-position to the carboxylate group has also been observed in the case of the congener α-hydroxycarboxylic acid, citric acid, upon binding of the latter to Ni(II) and Mn(II). In contrast to that behavior, binding of the α-hydroxycarboxylate ligand citrate to the higher oxidation state manganese ion Mn(III), led to a species in which the alcoholic group does not retain the proton despite the fact that citrate employs the same mode of coordination to Mn(III) as in Ni(II), through formation of a five-member cyclic ring [25,57].

Beyond the conventional contributions of the ligand to the reactivity of Ni(II), there appear to be general features potentially involved in the binary Ni(II)–quinic acid system linked to its aqueous chemistry. These include: (a) the coordination mode of all three quinate ligands to Ni(II) in **1**, and (b) the presence of the uncoordinated polyol functionalities in the quinates, signifying the unique chemical reactivity of Ni(II) ions toward α-hydroxycarboxylate ligands (central carboxylate and alcoholic groups) leading to a metal-cyclic motif formation. Even though both the α-hydroxycarboxylate and polyol functionalities in quinate are capable of promoting metal ion binding chemistries, the herein distinctly observed chemical reactivity and structural identity may indicate commensurably diverse chemical reactivity at the biological level. In such an environment, the natural metal ionic binder organic moieties are key molecular targets participating in essential biosynthetic pathways and likely influencing cellular integrity and survival.

Lastly, the employed synthetic strategy for the isolation of complex **1** reflects a chemical reactivity of Ni(II), because of which the title species crystallized out of solution. Key to the achievement of the solid state lattice of **1** appears to be (a) the low solubility of the anionic assembly $[Ni(C_7H_{11}O_6)_3]^-$ in the presence of the counter

ion Na^+, and (b) the involvement of water molecules in the assembly. To that end, solvent water molecules of crystallization contribute to the establishment of extensive hydrogen-bonding interactions throughout the lattice of **1** bestowing to it considerable stability.

4.2. The Ni(II)–quinic acid binary system speciation

A well-defined form of a metal–organic binary species such as **1** requires that an in-depth knowledge of its solution identity and properties is established. To this end, the aqueous solution study on the distribution of species arising in the binary system Ni(II)–quinic acid: (a) aids significantly in the understanding of the nature of various species forming as a function of pH and the stoichiometry of the reagent partners involved, and (b) provides a direct correlation of the physicochemical profile of the proposed species with the structure and properties of the species in the solid state (**1**). In this regard, the species prevailing in the requisite aqueous speciation bear a 1:2 Ni:L stoichiometry. In line with this stoichiometry, mononuclear $[NiL_2]^0$ and $[NiL_2H_{-1}]^-$ species emerge as competent participants in the pH distribution. Beyond that, mononuclear $[Ni(II)]^{2+}$ and $[NiH_{-1}]^+$ species emerge as complementary representative compounds of the aqueous binary distribution in different pH-ranges. Complex $[NiL_2]^0$ dominates in the low to physiological pH range. Its almost constant % fraction of total Ni(II) (30%) in the low and physiological pH range up to pH 8, indicates a preference over other species that could bear quinate ligands. It portrays a species containing a Ni(II) metal ion bearing two quinate ligands and likely two water molecules, thus bestowing an octahedral coordination environment to the central metal ion. In that respect, the $[NiL_2]^0$ species correlates the nature of the proposed solution species with that of **1** in the solid state. That, in turn, implies that compound **1** upon dissolution turns into $[NiL_2]^0$ giving up one quinate ligand. Consequently, **1** is likely not a species existing in solution, but rather one that emerges through favored lattice dynamics upon crystallization from the reaction mixture originally employed. It is worth noting that no 1:1 Ni:L species were proposed through the aqueous solution studies. Collectively, the data of the aqueous speciation relate the existence of the $[NiL_2]^0$ species at pH values around the specific pH value employed for the synthesis of that complex, with **1** ultimately crystallizing out of solution. This thesis is in line with recently isolated complexes of Co(II) with quinic acid at variable pH values in the corresponding binary aqueous speciation [58]. Hence, the idea of (a) synthesizing and isolating the proposed $[NiL_2]^0$ species, and (b) converting the $[NiL_2]^0$ species to **1** upon increasing the quinate:Ni(II) molar ratio (or influencing other factors) in the synthetic reaction mixture, are currently under investigation in our lab.

Moreover, the aqueous speciation studies suggest that other binary species exist at higher pH values (>7.5), including the $[NiL_2H_{-1}]^-$ complex. The composition of that complex presents a synthetic challenge that will shed light into that pH region of the aqueous speciation diagram, pinpointing specific structural features borne by quinate and the bound water molecules to Ni(II). The presence of Ni(II) bearing the same number of quinates at a higher pH as the $[NiL_2]^0$ dominant complex, but with an additional deprotonated aquo ligand (most likely), attests to its significance as a competent partner in the aqueous distribution diagram (albeit at a lower % fraction), explicitly projecting a variable chemical reactivity between Ni(II) and quinate as a function of pH.

4.3. Relevance of Ni(II) aqueous speciation to physiology and/or Ni(II) toxicity

The role of nickel in various structures and compartments in cells has been widely investigated and includes both normal physiological functions as well as toxic effects. As an exogenous inorganic cofactor, Ni(II) has been shown to exhibit physiological and/or aberrant effects (e.g. toxicity) with all the concomitant consequences to the integrity of organisms. As an enzyme metal cofactor and inducer of pathogenic physiologies, Ni(II) could exert influence on biochemical processes in cell structures or intercede in the chemistry of cellular (metal)homeostasis [59] by promoting binary and ternary interactions with cellular organic targets of both low and high molecular mass. Quinic acid is a suitable form of an organic substrate–ligand (a) present in plant fluids and circulating within plant structures, and (b) poised to seek chelation to divalent metal ions, such as Ni(II). In so doing, it establishes a binary Ni(II)–quinic acid system, which in the pH-range of plant physiological functions, generates a distribution of species with distinct physicochemical properties and potential (bio)chemical activity. Metal-linked biochemical activity has been observed in plants, emphasizing the ability of their cells to seek and identify metal ions or organic nutrients (a) essential to maintaining of their physiology [60], and/or (b) competent in combating (phyto)toxicity [61,62] events. To that end, the herein data signify the importance of the form, type and nature of Ni(II)–L (L = hydroxycarboxylate chelator) interactions potentially associated with the maintenance/compromise of cellular physiology or Ni(II) toxicity. In this respect, the well-characterized species **1** relates to the $[NiL_2]$ complex as the dominant species present in the aqueous speciation of the binary Ni(II)–quinic acid system. In plants, the chemistry of Ni(II), represented by well-defined soluble species such as $[NiL_2]^0$, may also reflect critical aspects of its interactive chemistry with other α-hydroxycarboxylic acids.

In humans, on the other hand, aberrant Ni(II) reactivity may influence processes (sister chromatid exchange, signaling pathways, transcription factor chemistry, etc.) linked to various manifestations of Ni(II) toxicity, potentially leading to allergic [63], respiratory and carcinogenic phenotypes [64]. In all of the aforementioned cases, soluble and bioavailable forms of Ni(II) constitute (a) the key to understanding the genetic and epigenetic (bio)chemistry unfolding in cellular compartments, organs and tissues, and (b) targets of ongoing research seeking to comprehend the intricate chemistry of Ni(II) toxicity at the molecular level. In this challenging field, efforts to understand further details of binary and ternary interactions of Ni(II), associated with soluble and bioavailable species currently eluding characterization, are ongoing in our labs.

5. Conclusion

The present endeavor (a) projects the complexity of the Ni(II)–quinic acid solution speciation in aqueous media and the diversity of species expected to arise as a function of pH and molecular Ni(II):quinate stoichiometry, (b) defines the physicochemical properties of a well-defined and characterized Ni(II)–quinate species **1** isolated at a specific pH value and its partner $[NiL_2]^0$ in solution projected through the aqueous speciation studies, and (c) links the pH-dependent bioinorganic chemistry of low molecular mass binary Ni(II)–(O-containing)organic substrate species with further binary and ternary interactions that might promote any potential activity relating to Ni(II) physiology or toxic effects on fundamental structures within cellular fluids.

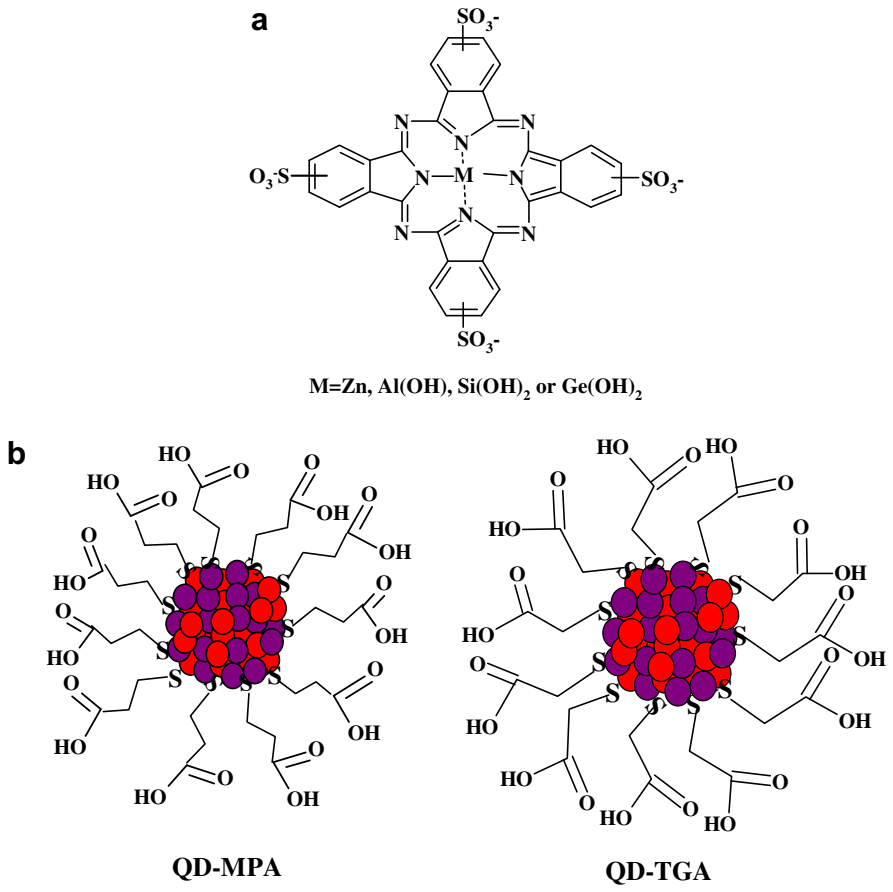

Fig. 1. (a) Molecular structure of the tetrasulfonated metallophthalocyanines ($MPcS_4$) and (b) Representation of the quantum dots studied, QD-MPA or QD-TGA: quantum dots capped with mercaptopropionic acid or thioglycolic acid, respectively.

to obtain QD-MPA of sizes 2.3 and 3.6 nm (represented as MPA1 and MPA2, respectively) and QD-TGA of 3.2 and 3.7 nm (represented as TGA1 and TGA2, respectively) in diameter. The sizes were estimated using a polynomial fitting function (Eq. (1)) derived in literature [30].

$$D = (9.8127 \times 10 - 7)\lambda^3 - (1.7147 \times 10 - 3)\lambda^2 + (1.0064)\lambda - (194.84), \quad (1)$$

where λ is the absorption maxima of the QDs. The fitting function is not valid for sizes of quantum dots outside the size range of 1–9 nm [30].

The QDs absorption maxima were 500, 550, 595 and 600 nm for MPA1, TGA1, MPA2 and TGA2, respectively, while the emission maxima were 550, 587, 649 and 632 nm, respectively. Rhodamine 6G was obtained from Sigma–Aldrich. Ultra pure water was obtained from a Milli-Q Water System (Millipore Corp., Bedford, MA, USA).

2.2. Equipment

Fluorescence excitation and emission spectra were recorded on a Varian Eclipse spectrofluoremeter. UV–Visible spectra were recorded on a Varian 500 UV–Vis/NIR spectrophotometer. Laser flash photolysis experiments were performed with light pulses produced by a Quanta-Ray Nd: YAG laser providing 400 mJ, 90 ns pulses of laser light at 10 Hz, pumping a Lambda-Physik FL3002 dye (Pyridin 1 dye in methanol). Single pulse energy ranged from 2 to 7 mJ. The analyzing beam source was from a Thermo Oriel xenon arc lamp, and a photomultiplier tube was used as detector. Signals were recorded with a digital real-time oscilloscope (Tektronix TDS 360). The triplet life times were determined by exponential fitting of the kinetic curves using the program ORIGINPRO 7.5. The flash photolysis experiments were performed at ±24 °C.

2.3. Photophysical studies

Fluorescence quantum yields (Φ_F) were determined by comparative method [31], (Eq. (2)):

$$\Phi_F = \Phi_{F(R)} \cdot \frac{F.A_R.n^2}{F_R.A.n_R^2}, \quad (2)$$

where F is the fluorescence intensity, A is the optical density at the excitation wavelength, and n is the refractive index of the solvent used. R refers to the reference fluorophore with known quantum yield. Rhodamine 6G ($\Phi_F = 0.94$ [32] in ethanol) and ZnPc ($\Phi_F = 0.20$ [33] in DMSO) were employed as standards for the QDs and MPcs, respectively. At least three independent experiments were performed for the quantum yield determinations. Both the sample and the reference were excited at the same relevant wavelength.

The determined fluorescence quantum yield values of the QDs and $MPcS_4$ were employed in determining the fluorescence quantum yields of $MPcS_4$ and QDs in each mixture ($\Phi^{Mix}_{F(MPcS_4)}$ and $\Phi^{Mix}_{F(QD)}$) using a modified form of Eq. (2) as shown by Eqs. (3a) and (3b).

$$\Phi^{Mix}_{F(QD)} = \Phi_{F(QD)} \frac{F^{Mix}_{QD}}{F_{QD}}, \quad (3a)$$

where $\Phi_{F(QD)}$ is the fluorescence quantum yield of the QDs alone, and was used as standard, F^{Mix}_{QD} is the fluorescence intensity of the

QDs in the mixture and F_{QD} is the fluorescence intensity of the QD in the absence of the respective $MPcS_4$ complexes. (λ_{exc} = 500 nm).

$$\Phi^{Mix}_{F(MPcS_4)} = \Phi_{F(MPcS_4)} \cdot \frac{F^{Mix}_{MPcS_4}}{F_{MPcS_4}}, \quad (3b)$$

where $\Phi_{F(MPcS_4)}$ is the fluorescence quantum yield of the $MPcS_4$ complexes alone, and was used as standard, $F^{Mix}_{MPcS_4}$ is the fluorescence intensity of the $MPcS_4$ complexes in the mixture and $F_{(MPcS_4)}$ is the fluorescence intensity of the $MPcS_4$ complexes alone (λ_{exc} = 620 nm).Triplet quantum yields were determined using a comparative method, Eq. (4):

$$\Phi^{Sample}_T = \Phi^{Std}_T \frac{\Delta A^{Sample}_T \varepsilon^{Std}_T}{\Delta A^{Std}_T \varepsilon^{Sample}_T} \quad (4)$$

where A^{Sample}_T and A^{Std}_T are the changes in the triplet state absorbance of the sample and the standard, respectively. ε^{Sample}_T and ε^{Std}_T are the triplet state extinction coefficients for the sample and standard, respectively. Φ^{Std}_T is the triplet state quantum yield for the standard. $ZnPcS_4$ in aqueous solution, Φ^{Std}_T = 0.56 [34] was used as standard. Solutions of samples in a H_2O:methanol (1:1) solvent mixture for triplet yield and lifetime measurements were purged of oxygen (by bubbling argon) for 20 min before laser irradiation.

2.4. Energy transfer (ET) study

The energy transfer efficiency (*Eff*) was determined experimentally from the fluorescence quantum yields of the donor (QDs) in the absence ($\Phi_{F(QD)}$) and presence ($\Phi^{Mix}_{F(QD)}$) of the acceptor and it is defined by Eq. (5) [12,35]:

$$Eff = 1 - \frac{\Phi^{Mix}_{F(QD)}}{\Phi_{F(QD)}}. \quad (5)$$

The Förster distance (R_0) is the critical distance between the donor and the acceptor molecules for which efficiency of energy transfer is 50% and it depends on the quantum yield of the donor, extinction coefficient of the acceptor, the degree of spectral overlap of the donor's fluorescence emission spectrum and the acceptor's absorption spectrum and a highly fluorescent donor is important [12,36], R_0 is expressed by Eq. (6):

$$R^6_0 = 8.8 \times 10^{23} \kappa^2 n^{-4} \Phi_{F(QD)} J \quad (6)$$

where κ is the dipole orientation factor, assumed to be 2/3; n is the refractive index of the medium; Φ_F is the fluorescence quantum yield of the donor in the absence of the acceptor; and J is the overlap integral calculated as (Eq. (7)):

$$J = \int f_{QD}(\lambda) \varepsilon_{MPc}(\lambda) \lambda^4 d\lambda \quad (7)$$

where f_{QD} is the normalized QDs emission spectrum; and ε_{MPc}, the molar extinction coefficient of the respective $MPcS_4$ complex.

The donor-to-acceptor distance, r is calculated by using Eq. (8) [12,36]:

$$r = R_0 \left(\frac{1}{Eff} - 1 \right)^{1/6}. \quad (8)$$

The above energy transfer parameters (J and R_0) were computed using the program PHOTOCHEMCAD [37] based on Eqs. (6) and (7).

3. Results and discussion

3.1. Electronic absorption and fluorescence spectra

Synthesis of tetrasulfonated metallophthalocyanine (Fig. 1) is known, and in this work, literature methods of synthesis and characterization were employed and gave expected results [28,29]. The CdTe QDs synthesized in this work, gave characteristic spectral behavior [5,16]. Shown in Fig. 2a are the absorption and emission spectra for MPA1 and TGA1 QDs.

Electronic absorption and fluorescence emission spectra of ($(OH)_2GePcS_4$) are shown in Fig. 2b in a mixture of H_2O and methanol (1:1). In this solvent mixture, the $MPcS_4$ complexes are monomeric. It has been documented that aggregation is accompanied by a reduction of photochemical activity in processes involving phthalocyanine excited states [38,39]. It is also known that the addition of organic solvents normally breaks the aggregates, resulting in monomeric species [40], hence the water:methanol solvent mixture was employed in this work. The $MPcS_4$ complexes obeyed Beer's law for concentrations less than 1×10^{-5} mol dm^{-3} in this solvent mixture. The excitation spectra of the $MPcS_4$ complexes were mirror images of the fluorescence emission spectra, Fig. 2b.

3.2. Photophysical behavior of $MPcS_4$ in the presence of QDs

Fluorescence quantum yield (Φ_F) values for the QDs and the $MPcS_4$ complexes were calculated using Eq. (2) and shown in Table 1. The Φ_F value of the QDs ranged from 0.19 to 0.62 at their different emission wavelength maxima (λ_{exc} 500 nm). It is known that the surface structure and the occurrence of charge carrier traps (which affect fluorescence) strongly depend on the size and symmetry of QDs [41]. Thus there is dependence of Φ_F values on the size of the QDs. However, the nature of the QDs (MPA versus TGA) was not found to significantly affect the Φ_F values [41]. The Φ_F values further decreased in the presence of the respective $MPcS_4$ complexes as shown in Table 1 ($\Phi^{Mix}_{F(QD)}$). This decrease in the fluorescence yield of the QDs in the presence of the $MPcS_4$

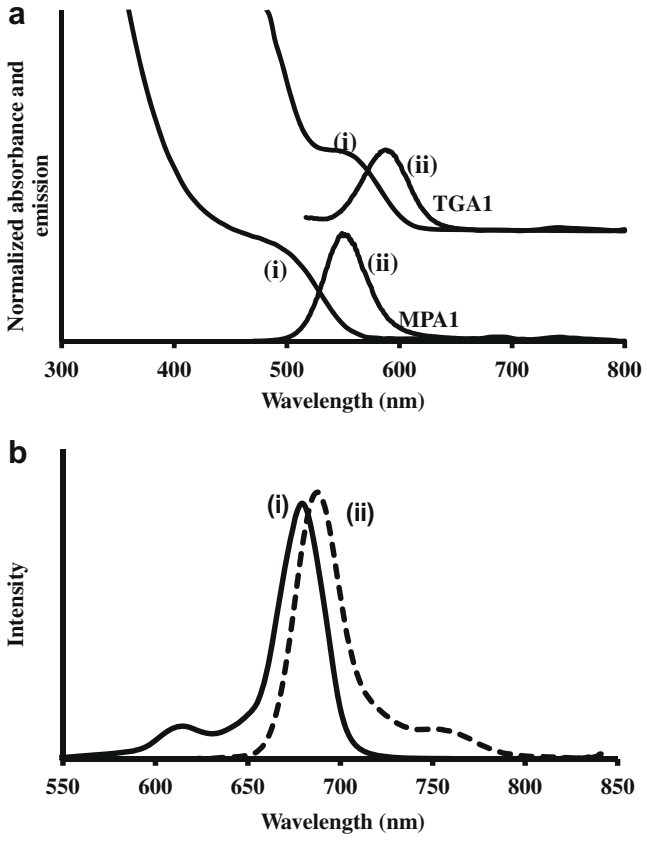

Fig. 2. Absorption (i) and emission (ii) spectra of TGA1 and MPA1 (a) and $(OH)_2GePcS_4$ (b) (λ_{exc} = 500 and 620 nm, respectively).

	TGA1	0.81	350	0.07	0.12
	TGA2	0.85	360	0.37	0.15

[a] Number in brackets are the quantum yields ($\Phi_{F(MPcS_4)}$ or $\Phi_{T(MPcS_4)}$) or triplet lifetimes $\tau_{T(MPcS_4)}$ of MPcS$_4$ alone.
[b] MPA = 3-mercaptopropionic acid and TGA = thioglycolic acid. Fluorescence quantum yields of quantum dots alone ($\Phi_{F(QD)}$): 0.19 (MPA1) 0.59 (MPA2), 0.30 (TGA1) and 0.62 (TGA2).

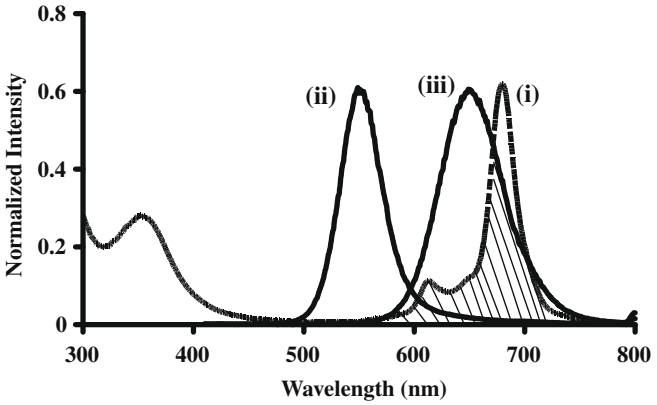

Fig. 3. Normalized absorption spectra of (OH)$_2$SiPcS$_4$ (i) and emission spectra of MPA1 (ii) and MPA2 (ii) (λ_{exc} = 500 nm).

complexes is due to the non-radiative transfer of energy from the QDs to the MPcS$_4$ complexes because as the QD particles fluoresce, the MPc molecules (acceptor) absorb the energy, thus reducing the fluorescence intensity of the QDs (donor) in the QD-MPc mixture. Φ_F values for the MPcS$_4$ complexes are listed in Table 1 (in parenthesis, λ_{exc} 620 nm). Apart from the (OH)$_2$SiPcS$_4$, Φ_F values decreases with the size of the central metal which is consistent with the strengths of spin–orbit (S–O) coupling induced by the respective central metals based on their relative masses.

There was generally a slight increase in the Φ_F values of the MPcS$_4$ complexes, except for (OH)$_2$SiPcS$_4$ (all sizes) and (OH)$_2$GePcS$_4$ (TGA1 and MPA1) in the presence of the QDs ($\Phi^{Mix}_{F(TSPc)}$, λ_{exc} 620 nm) compared to the values of the MPcS$_4$ complexes alone (in parenthesis, Table 1). The increase was more pronounced in the presence of the larger QDs (MPA2 and TGA2). For (OH)$_2$SiPcS$_4$, there was generally a small decrease in the Φ_F values. However, considering experimental errors, the changes in Φ_F values is insignificant in many cases. The decrease in Φ_F values could be due to the heavy atom effect of the QDs on the MPcS$_4$ complexes, and the slight increase in Φ_F values could be attributed to the possible shielding of the Pc by the QDs, thus decreasing quenching of the former.

An efficient overlap occurs between the absorption spectra of the MPcS$_4$ complexes with the emission spectra of QDs, Fig. 3. A decrease in the fluorescence emission intensity (on exciting at 500 nm, where the QDs absorb, but the MPcS$_4$ complexes have negligible absorbance) of the QDs on excitation of a mixture containing the respective QDs and respective MPcS$_4$ complex, and an emergence of the respective MPcS$_4$ complex fluorescence was observed as shown in Fig. 4. This suggests that energy transfer occurs from CdTe QDs to the MPcS$_4$ complexes. No significant fluorescence for the MPcS$_4$ complexes was observed on excitation at 500 nm in the absence of the QDs, so the fluorescence of the MPcS$_4$ complexes that emerged in this case must be due to the fluorescence induced by QDs unto the MPcS$_4$ complexes. The observation of FRET shows different behavior from the aggregation observed for MPcs substituted with alklthio substituted MPc complexes [19]. In this study, it is most likely that the QDs interact with the MPcS$_4$ complexes by adsorption.

The J values obtained as shown in Table 2 are of the order of 10^{-13} cm^6, for some porphyrin based molecules, J values of the order 10^{-14} cm^6 have been observed [35]. The J values were about the same for all the complexes in the presence of the various QDs except for ZnPcS$_4$ in the presence of MPA1 where the value was very low. The center-to-center separation distance between donor and acceptor (r, Å), were calculated using Eq. (8) and values are shown in Table 2. Most of the calculated r values were above the critical distance (R_0) at which energy transfer is 50% except for the complexes in the presence of TGA1 (with exception of (OH)AlPcS$_4$, and (OH)$_2$SiPcS$_4$ in the presence of MPA2). This gives an indication that the energy transfer in these combinations may not be optimum since for efficient energy transfer to occur r should be lower than R_0. The efficiency of energy transfer *Eff* was calculated with values stated in Table 2 and it was highest in each set for the MPcS$_4$ complexes in the presence of TGA1 except with (OH)AlPcS$_4$, as already predicted from the r values obtained. The values of *Eff* obtained for the MPcS$_4$ complexes in the presence of TGA2 and MPA2 were also very reasonable. However, bringing all the results together, TGA1 though exhibited high *Eff*, resulted in low fluorescence yield ($\Phi^{Mix}_{F(QD)}$) in the presence of the MPcS$_4$ complexes (Table 1) while TGA2 and MPA2, though with a lower *Eff*, maintained slightly higher fluorescence yields ($\Phi^{Mix}_{F(QD)}$) in the presence of the individual MPcS$_4$ complexes (Table 1). TGA2 and MPA2 QDs in the presence of MPcS$_4$ complexes may therefore be of better value in photosensitization reactions where detections will be needed since their fluorescence intensities will still be high enough to help in visualization.

Φ_T values provide a measure of the fraction of absorbing molecules that undergoes intersystem crossing to the triplet state (Φ_T). The efficiency of a phthalocyanine as a photosensitizer is determined by its triplet quantum yield (Φ_T) and lifetime (τ_T). The variation of Φ_T among the MPcS$_4$ complexes in Table 1 depends on heavy atom effect which encourages intersystem crossing to the triplet state. The observed trend for Φ_T corresponds to the increase in atomic masses of the central metals. (OH)$_2$SiPcS$_4$ behaves differently again in this case having a triplet yield that is of the same value with ZnPcS$_4$ even though there is a large difference in their relative atomic masses. This, however, explains the low Φ_F value obtained for the complex since most of the excited species were able to undergo ISC to the triplet state leading to a low Φ_F. The variation of Φ_T values of the MPcS$_4$ complexes in the presence of the QD is shown in Table 1. For (OH)AlPcS$_4$ and (OH)$_2$GePcS$_4$ slight increase in the Φ_T was observed compared to the respective MPcS$_4$ complexes alone. This slight increase in Φ_T in the presence of the QDs is attributed to the heavy atom effects of the QDs which contain heavy Cd and Te atoms. The increase in Φ_T of the MPcS$_4$

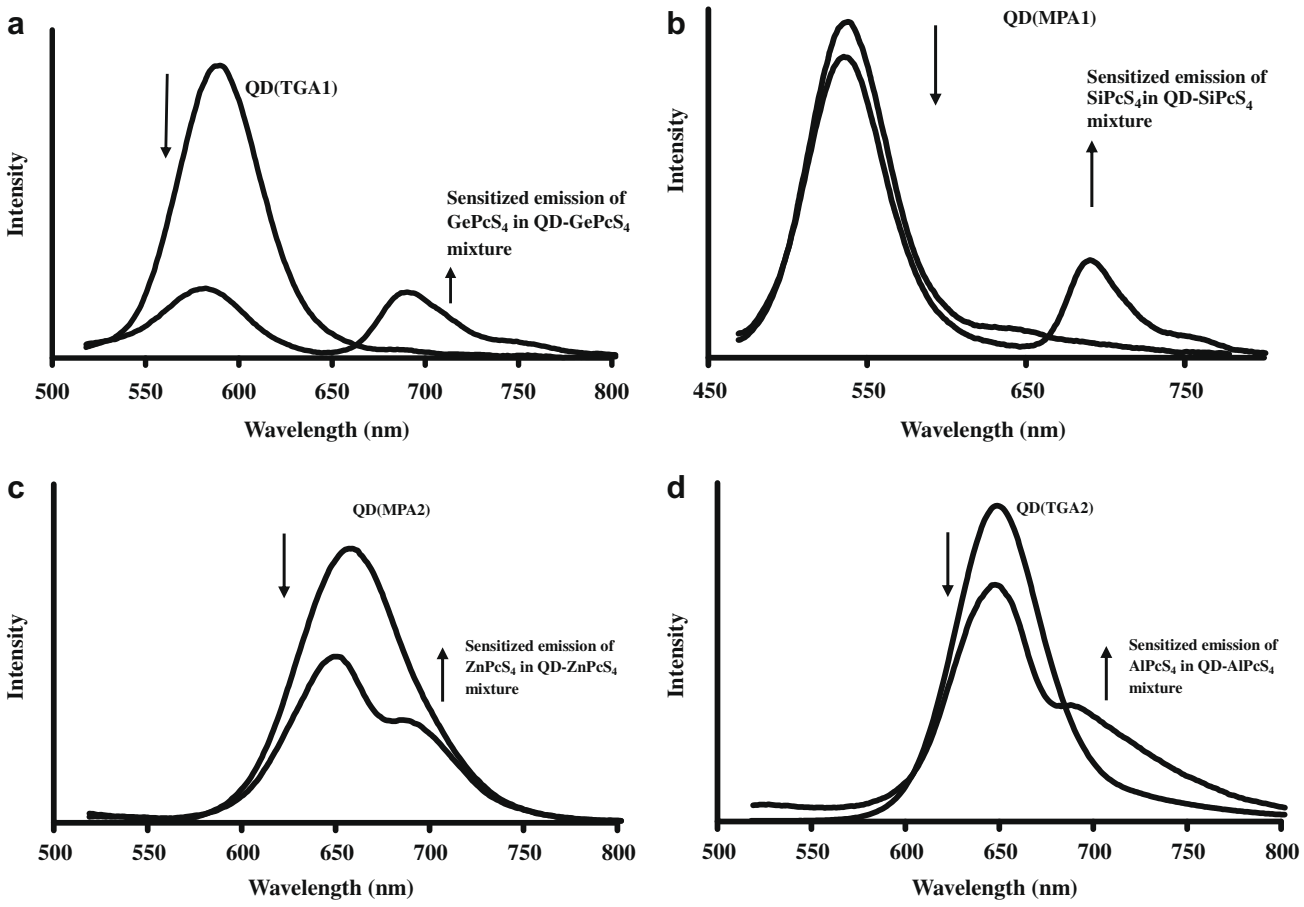

Fig. 4. Indirect activation of (a) $(OH)_2GePcS_4$ ($\sim 1 \times 10^{-5}$ mol dm^{-3}) by TGA1, (b) $(OH)_2SiPcS_4$ ($\sim 1 \times 10^{-5}$ mol dm^{-3}) by MPA1, (c) $ZnPcS_4$ ($\sim 1 \times 10^{-5}$ mol dm^{-3}) by MPA2 and (d) $(OH)AlPcS_4$ (6×10^{-6} mol dm^{-3}) by TGA2 through energy transfer, (λ_{exc} = 500 nm). [QD] = $\sim 1 \times 10^{-6}$ mol dm^{-3}.

complexes may be an advantage since it means the triplet state will be highly populated, thereby creating higher photosensitizing effect in photoactive reactions. The Φ_T values for $ZnPcS_4$ and $(OH)_2SiPcS_4$ complexes in the presence of QDs either decreased or remained the same, behaving contrary to what is expected on the basis of the heavy atom effect.

Table 2
Energy transfer parameters for TSPc-QD interactions in 1:1 water:methanol mixture.

MPc	QD	[a]J (10^{-13} cm^6)	[a]R_0 (Å)	r (Å)	*Eff*
$(OH)AlPcS_4$	MPA1	1.02	32.84	46.53	0.11

	MPA2	1.13	59.19	56.09	0.58
	TGA1	2.61	41.52	36.05	0.70
	TGA2	1.01	58.50	59.29	0.48
$(OH)_2GePcS_4$	MPA1	0.44	28.57	40.48	0.11
	MPA2	5.73	52.87	54.30	0.46
	TGA1	1.11	35.90	29.35	0.77
	TGA2	4.83	51.81	55.43	0.40

[a] Using Eqs. (5)–(8), J and R_0 were determined using the program PHOTOCHEMCAD then r and *Eff* were calculated.

The triplet state lifetime, τ_T values of the $MPcS_4$ complexes ranged from 180 to 560 μs. It was observed that there was a general increase in the τ_T values of the $MPcS_4$ complexes in the presence of the various QDs as seen in Table 1. This observation could be due to the fact that there is a reduction in the exposure of the phthalocyanine to the aqueous medium because of the presence of the QDs, since water is known as a quencher of the triplet states of MPcs [33]. The increase in the τ_T of the $MPcS_4$ complexes in the presence of the QDs contradicts what is expected by the heavy atom effect, whereby when Φ_T increases as observed above, the τ_T decreases but it is justified for the $ZnPcS_4$ and $(OH)_2SiPcS_4$ complexes, where there is a general decrease in Φ_T in the presence of QDs. These long τ_T values, however, shows that the $MPcS_4$ complexes will likely spend more time at the triplet state allowing for increased diffusional interactions which will be an advantage in photosensitized reactions.

4. Conclusion

Energy transfer from mercaptocarboxylic acid capped CdTe quantum dots (QDs) to various tetrasulfonated metallophthalocyanines in a H_2O:MeOH (1:1) solvent mixture occurred and was found to be dependent on the overlap of the absorption spectra of the $MPcS_4$ complexes and the emission spectra of the QDs. High triplet state quantum yields (Φ_T, ranging from 0.41 to 0.87) of the $MPcS_4$ complexes in the presence of the QDs with corresponding long triplet state lifetimes (τ_T, ranging from 140 to 610 μs) to allow for photosensitized reactions to occur was observed. The mixture

of $MPcS_4$ complexes with QDs may find use in photosensitization reactions.

reaction mixture was poured to 10 ml of water. And the filtered solid was washed with 30 ml of water by three times. Then the solid was dissolved in CH_2Cl_2 (50 ml), and the solution was dried in anhydrate sodium sulfate. After evaporation of the solvent, the crude product was purified via chromatography by using CH_2Cl_2 as eluent, and the Ir^{III} chloro-bridged dimer $(pdt)_2Ir(\mu\text{-}Cl)_2Ir(pdt)_2$ as yellow powder was obtained.

The dimer $(pdt)_2Ir(\mu\text{-}Cl)_2Ir(pdt)_2$ (469 mg, 0.41 mmol), Hphen5f (300 mg, 0.82 mmol) and anhydrous sodium carbonate (435.5 mg, 4.11 mmol) were refluxed in 2-ethoxyethanol (10 ml) under a N_2 atmosphere for 20 h. After cooling to room temperature, the mixture was poured into water. The crude product was obtained by filtration and then dissolved in CH_2Cl_2. The solution was dried in anhydrous sodium sulfate overnight. After evaporation of the solvent, the residue was purified via chromatography, using acetone for the elution. The pure product $Ir(pdt)_2(phen5f)$ was obtained as an orange-yellow powder (yield, 48%). ^1H NMR (400 MHz, DMSO–d_6): δ, ppm 8.80 (d, 1H, J = 8.0 Hz), 8.72 (d, 1H, J = 8.0 Hz), 8.31 (dd, 2H, J = 22, 8.8 Hz), 8.05 (d, 1H, J = 4.7 Hz), 7.89 (dd, 1H, J = 8.0, 5.1 Hz), 7.69 (d, 1H, J = 7.5 Hz), 7.46 (d, 1H, J = 8.0 Hz), 7.37 (d, 1H, J = 7.7 Hz), 7.05–7.01 (m, 1H), 6.97–6.93 (m, 1H), 6.85–6.81 (m, 1H), 6.73–6.70 (m, 1H), 6.25 (d, 1H,

Scheme 1. Synthetic routes of Ir^{III} complex and Ir^{III}–Yb^{III} complex.

J = 7.9 Hz), 6.15 (d, 1 H, J = 7.7 Hz), 4.21–4.14 (m, 4H), 4.04 (s, 3H), 1.58 (s, 3H), 0.83 (s, 3H). MALDI-TOF-MS: observed $[M+H]^+$, 905.2; calculated, 905.20. *Anal.* Calc. for $C_{37}H_{28}F_5IrN_8O_2 \cdot CH_3CH_2OH$: C, 49.31; H, 3.61; N, 11.80. Found: C, 49.39; H, 3.39; N, 11.79%.

2.2.2. Synthesis of Ir^{III}–Yb^{III} bimetallic complex

The complex-ligand $Ir(pdt)_2(phen5f)$ (0.3 mmol, 270 mg), $YbCl_3 \cdot 6H_2O$ (0.1 mmol, 38.8 mg) and ethanol (100 ml) were mixed in a round-bottom flask, and refluxed for 6 h. A crystallization from concentrated EtOH solution by slow diffusion of Et_2O led to microcrystalline $(pdt)_2Ir(\mu\text{-phen5f})YbCl_3$, which was deep-yellow solid. $(pdt)_2Ir(\mu\text{-phen5f})YbCl_3 \cdot 2H_2O$ *Anal.* Calc. for $C_{37}H_{32}N_8F_5O_4Ir$-$YbCl_3$: C, 36.45; N, 9.19; H, 2.65. Found: C, 36.47; N, 9.14; H, 2.65%.

2.3. X-ray crystallographic analyses

The X-ray diffraction data were measured on a Rigaku Micro-Max-007 CCD diffractometer by the ω scan technique at 131 K using graphite-monochromated Mo Kα (λ = 0.71073 Å) radiation. An absorption correction by multi-scan was applied to the intensity data. The structures were solved by direct method and the heavy atoms were located from E-map. The remaining non-hydrogen atoms were determined from the successive difference Fourier syntheses. The non-hydrogen atoms were refined anisotropically, whereas the hydrogen atoms were generated geometrically with isotropic thermal parameters. The structures were refined on F^2 by full-matrix least-squares methods using the SHELXTL-97 program package [17]. Crystallographic data and important refinement parameters for $Ir(pdt)_2(phen5f)$ and $[(pdt)_2Ir(\mu\text{-phen5f})YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and crystal structure

All synthetic routes for Ir^{III} complex and Ir^{III}–Yb^{III} complex are outlined in Scheme 1. The new cyclometalated ligand pdt was designed as the substitute for the previous used ligand ppy (2-phenylpyridinato-N,$C^{2'}$) in $Ir(ppy)_2(phen5f)$ [14]. The complex $Ir(pdt)_2(phen5f)$ was prepared from the reaction of the chloride-bridged Ir^{III} dimmer $(pdt)_2Ir(\mu\text{-Cl})_2Ir(pdt)_2$ and the ligand Hphen5f [18] under the similar conditions as those for the synthesis of $Ir(C^N)_2(O^O)$ [16]. The reaction conditions of $Ir(pdt)_2(phen5f)$ and $YbCl_3 \cdot 6H_2O$ and the crystal growth condition were similar as those used in the synthesis of bimetallic complex $\{[(dfppy)_2Ir(\mu\mu\text{-phen5f})]_3EuCl\}Cl_2$ [18], but the obtained crystal structure and the corresponding element analysis showed that the formation ratio between Ir^{III} and Yb^{III} was 1:1. This result confirmed that the bimetallic complex containing Ir^{III} and Ln^{III} with the ration of 1:1 could stably exist in such system.

The single crystals of $Ir(pdt)_2(phen5f)$ were grown from slowly evaporating solution of EtOH/acetone, and those of $[(pdt)_2Ir(\mu\text{-phen5f})YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ were obtained using the EtOH solution by slow diffusion of Et_2O. The two X-ray crystal structures are showed in Fig. 1, and both of the structure and metric parameters are shown in Tables 2 and 3. There was distorted octahedral coordination geometry around Ir^{III} ion. The C^N coordination sites were offered by two cyclometalated ligands and the N^N sites are contributed by the ancillary ligand phen5f. The O^O sites are free and in *trans*-form. Furthermore, the Ir–N bond lengths between Ir^{III} ion and the ancillary ligand phen5f is longer than those between Ir^{III} ion and the cyclometalated ligand pdt, which shows the combination of the Ir^{III} ion and C^N ligand anion was tighter than that of the Ir^{III} ion and N^N ancillary ligand. The bond lengths of O(1)–C(13) and O(2)–C(15) are 1.257(9) and 1.244(9) Å, respectively, which shows that the two carbonyl groups in β-diketone are averaged after the hydrogen was taken off in the reaction of the Ir^{III} dimer and Hphen5f.

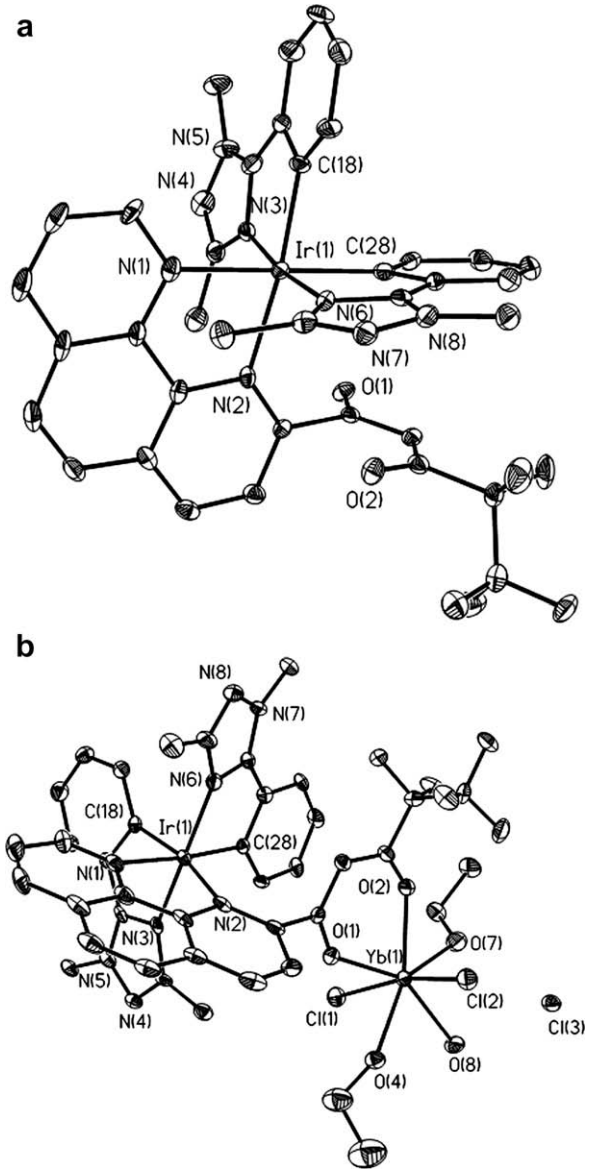

Fig. 1. ORTEP diagrams of $Ir(pdt)_2(phen5f)$ (a) and $[(pdt)_2Ir(\mu\text{-phen5f})Yb\text{-}Cl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ (b). Thermal ellipsoids are shown in (a) and (b) at 30% probability level and the hydrogen atoms and solvent molecules are omitted for clarity.

later. This is due to the fact that from Eu^{III} to Yb^{III}, the ionic radii become smaller contributed by the lanthanide contraction. The Yb^{III} ion tends to coordinate with the small molecules, such as ethanol and water, while keeps the coordination number unchanged. The configuration of the two carbonyl groups in the β-diketone has been changed from the *trans*-form to the *cis*-form upon coordination, but the bond length between carbon and oxygen slightly changed solely (Tables 2 and 3). It is obvious that the combination of β-diketone in $Ir(pdt)_2(phen5f)$ and Yb^{III} is tighter than that of EtOH or water and Yb^{III}. The non-bonding distances for Yb···Ir are 6.317 Å.

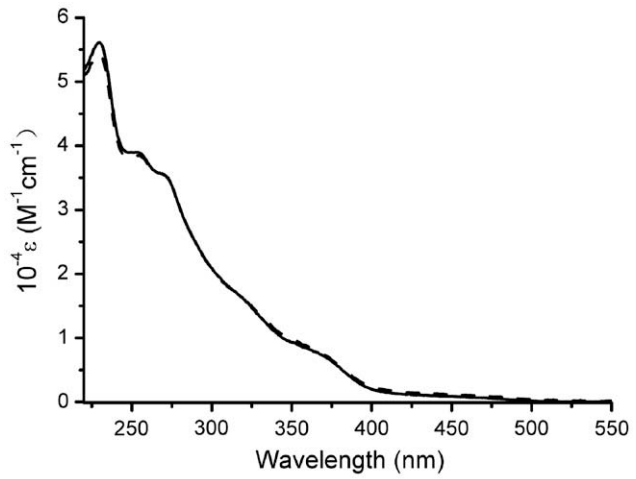

Fig. 2. UV–Vis absorption spectra of $Ir(pdt)_2(phen5f)$ (solid line) and $[(pdt)_2Ir(\mu\text{-phen5f})YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ (dashed line) in EtOH (1×10^{-5} M) at room temperature.

3.2. Photophysical properties

The absorption spectra of $Ir(pdt)_2(phen5f)$ and $[(pdt)_2Ir(\mu\text{-phen5f})YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ in ethanol are shown in Fig. 2. For $Ir(pdt)_2(phen5f)$, the short wavelength region below around 280 nm should be due to the π–π^* transitions of the ligands [15], while the longer wavelength region from 400 to 470 nm should be mainly assigned to the mixture of the ^{3}MLCT (metal-to-ligand charge transfer) transition in the $Ir(pdt)^{2+}$ moiety or the transition from Ir^{III} to phen5f. Moreover, $[(pdt)_2Ir(\mu\text{-phen5f})YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ exhibited such similar absorption properties as $Ir(pdt)_2(phen5f)$ because they had the same absorption ligand while the absorption of $YbCl_3$, ethanol and water in the range were quite small.

However, the complex $Ir(pdt)_2(phen5f)$ showed hardly observed emission in EtOH solution at room temperature. Both of the ^{3}MLCT from Ir^{III} to the cyclometalated ligand pdt [15] and to the ancillary ligand phen [19] should exhibit the corresponding phosphorescence emissions. The absence of emission might be caused by some special radiationless transitions which we have not still understood clearly. It might be induced by the rotation or vibration of the β-diketone part in the phen5f ligand, and this assume was supported by the following fact. When the EtOH solution was cooled down to 77 K, the low-temperature emission spectrum of $Ir(pdt)_2(phen5f)$ was observed in an EtOH rigid matrix as expected (Fig. 3). It showed the main peaks around 507 and 535 nm. This fact implied that the $Ir(pdt)_2(phen5f)$ complex-ligand might be suitable for the sensitization of Yb^{III} for NIR emission.

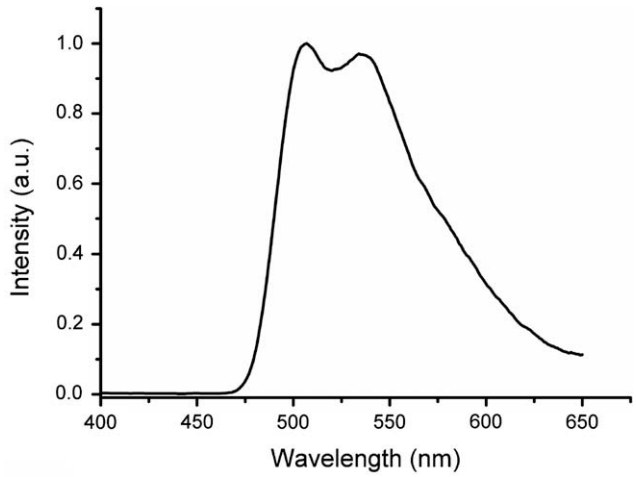

Fig. 3. Emission of $Ir(pdt)_2(phen5f)$ in an EtOH rigid matrix (1×10^{-5} M) at 77 K.

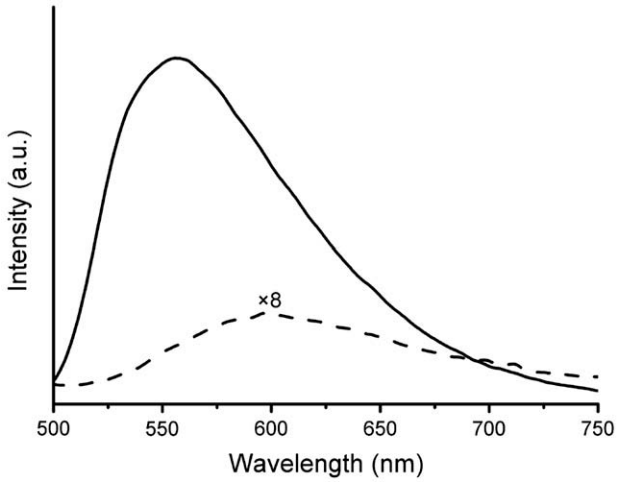

Fig. 4. Solid-state emission spectra (powdered samples) in visible region of $Ir(pdt)_2(phen5f)$ (solid line) and $[(pdt)_2Ir(\mu\text{-phen5f})YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ (dashed line).

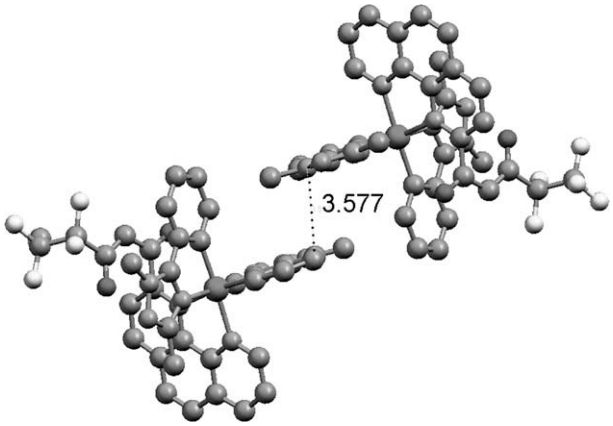

Fig. 5. Intermolecular π–π interaction in the crystal structure of $Ir(pdt)_2(phen5f)$.

The solid emissions at room temperature from $Ir(pdt)_2(phen5f)$ and $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ are shown in Fig. 4. Powdered $Ir(pdt)_2(phen5f)$ luminesced yellow-green with a maximum around 556 nm, which was red shifted when it was compared with what we observed in an EtOH matrix at 77 K (Fig. 3). This result might originate from the face to face π–π overlap interactions between aromatic molecules in the solid state and be ascribed to excimer formation [20], which is confirmed by the crystal packing of $Ir(pdt)_2(phen5f)$. The π–π spacing between the pdt ligands of adjacent molecules is *ca.* 3.58 Å (Fig. 5). Moreover, the solvent effect in the EtOH system should be another important factor for the differences between the emissions. When Yb^{III} ion

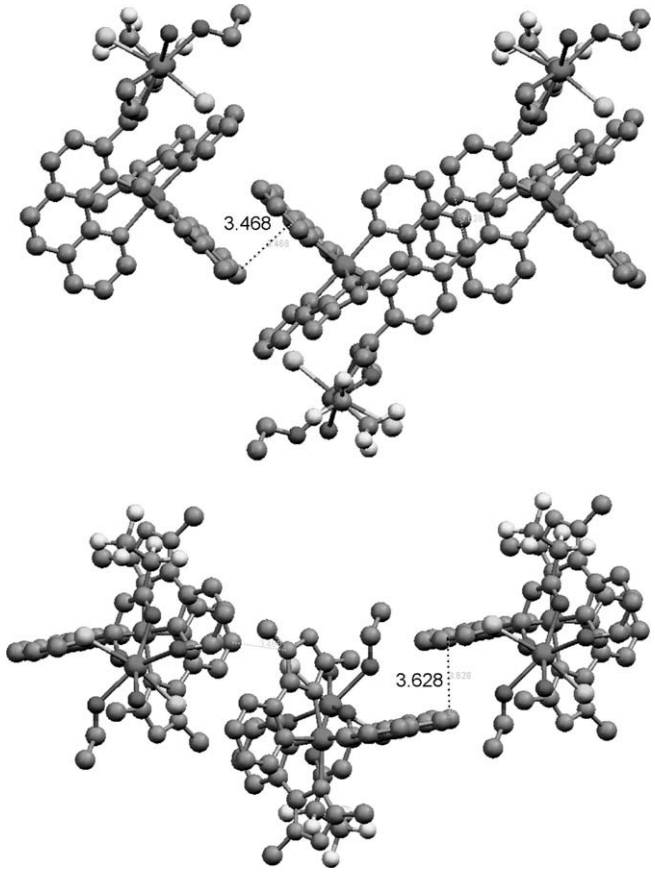

Fig. 6. Intermolecular π–π interaction in the crystal structure of $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$.

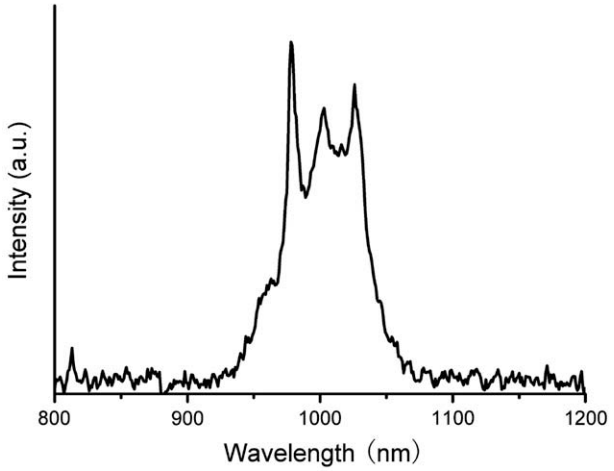

Fig. 7. Solid-state NIR emission spectrum (powdered samples) of $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$.

was incorporated in the complex and the bimetallic complex $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ was formed, one could find that the emission around 610 nm was very weak. From the packing of $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$, the π–π spacing between the pdt ligands and the phen5f ligands of adjacent molecules is *ca.* 3.47 and 3.63 Å, respectively (Fig. 6). The latter could cause the red shift in the emission maximum for bimetallic complex. Emission quenching implied that the energy transfer occurred in the analogous Ir^{III}–Ln^{III} bimetallic complexes.

Upon irradiation of the MLCT absorption of the Ir complex at 490 nm, the emission spectrum of $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3\text{-}CH_2OH \cdot H_2O]Cl$ was measured (Fig. 7). There is only one emission band around 978 nm affected by crystal-field splitting which is assigned to the $^2F_{5/2} \rightarrow {}^2F_{7/2}$ transition. The results of emission quenching in visible region and obtained NIR emission indicated that the energy transfer from Ir^{III} moiety to Yb^{III} center occurred.

However, the NIR emission from $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ was not very strong, and the emission from the solution was not obtained under our experiment conditions. The possible factors could be found from the structure of the bimetallic complex $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3\text{-}CH_2OH \cdot H_2O]Cl$. Firstly, there were ethanol and water molecules in the coordination environment, which might seriously quench the photoluminescence, especially the NIR emission. Secondly, there were only one Ir^{III} complex-ligand $Ir(pdt)_2(phen5f)$ in $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ while there were usually two or more ligands around the center Ln^{III} ion, which indicated that more antennae participating in the light harvesting would be favorable for emission. Moreover, the triplet state level of the complex $Ir(pdt)_2(phen5f)$ was a little higher than the energy level of Yb^{III}, which might make the energy transfer from the Ir^{III} center to the Yb^{III} center less efficient.

4. Conclusions

A new cyclometalated ligand 1,3-dimethyl-5-phenyl-1H-[1,2,4]-triazole (pdt) was synthesized, and the corresponding Ir^{III} complex $Ir(pdt)_2(phen5f)$ was obtained. The bimetallic complex $[(pdt)_2Ir(\mu\text{-}phen5f)YbCl_2 \cdot 2CH_3CH_2OH \cdot H_2O]Cl$ was synthesized by the approach of "complexes as ligands". Meanwhile, the emission quenching was observed in the solid state of the Ir^{III} and Ir^{III}–Yb^{III} complex. Upon irradiation of the MLCT absorption of $Ir(pdt)_2(phen5f)$, the characteristic emission of Yb^{III} was obtained with a peak around 978 nm. And the crystal packing of the Ir^{III}

and Ir^{III}–Yb^{III} complex implied that the similar combination principles between the cyclometalated ligands and bridge ligands might exist in these Ir^{III} systems sensitizing NIR lanthanide emission.

Scheme 1. Synthesis of mono and binuclear $V^{IV}O$ complexes.

complexes with unsymmetrical bicompartmental macrocyclic ligands (Scheme 1), which have one tetradentate compartment (N2O2) comprising of two piperazinyl nitrogens and two phenolic oxygens, and another tetradentate compartment (N2O2) comprising of two phenolic oxygens and two imine nitrogen atoms. The distance between the two vanadium centers is fixed by the two bridging phenolate ligands, while the distortion in geometry and stability of the complexes is varied by changing one of the compartmental ring sizes by condensing various aliphatic and aromatic diamines.

2. Experimental

2.1. Physical measurements

Elemental analysis was carried out on a Carlo Erba model 1106 elemental analyzer. FT-IR spectra were obtained on a Perkin Elmer FT-IR spectrometer with samples prepared as KBr pellets. UV–Vis spectra were recorded using a Perkin Elmer Lambda 35 spectrophotometer operating in the range 200–1400 nm with quartz cells and ε are given in M^{-1} cm^{-1}. Electrospray ionization mass spectral measurements were made using a Thermo Finnigan LCQ-6000 Advantage Max-ESI mass spectrometer. Cyclic voltammograms were obtained on a CH11008 Electrochemical analyzer using a three- electrode set-up comprising of a glassy carbon working, platinum wire auxiliary and a saturated Ag/AgCl reference electrode under oxygen-free conditions. The concentration of the complexes was 10^{-3} M. TBAP (Tetra(*n*-butyl)ammonium perchlorate) (10^{-1} M) was used as the supporting electrolyte. EPR spectra were recorded on powdered samples of **1a–1e** using a JEOL TES 100 ESR spectrometer. Low temperature measurements were made using a liquid nitrogen Dewar. The room temperature magnetic moment was measured on a PAR vibrating sample magnetometer model 155.

2.2. Materials

5-Methylsalicylaldehyde and the precursor compound 6,6′-piprazine-1,4-diyl-dimethylene bis (4-methyl-2-formyl-phenol) (**I**) were prepared by the literature methods [18,19]. Tetra(*n*-butyl)ammonium perchlorate (TBAP), used as the supporting electrolyte in the electrochemical measurements, was purchased from Fluka and recrystallized from hot methanol (Caution! All perchlorate salts are potentially explosive, hence care should be taken in handling TBAP). All the solvents were purified by the reported procedures [20]. The supercoiled pBR322 DNA and calf thymus (CT) DNA was purchased from Bangalore Genei (India). Superoxide dismutase (SOD), ethidium bromide (EB) and L-histidine were obtained from Sigma (USA). Tris(hydroxymethyl)aminomethane–HCl (Tris–HCl) buffer solution was prepared by using deionized, triple distilled water.

2.3. General methods

2.3.1. DNA binding and cleavage experiments

The DNA binding experiments were performed in Tris–HCl/NaCl buffer (50 mM Tris HCl/1 mM NaCl buffer, pH 7.5) using DMF (dimethylformamide) solution (10%) of the oxidovanadium(IV) complexes **1b**, **1d** and **1e**. The concentration of calf thymus (CT) DNA was determined from the absorption intensity at 260 nm with a ε value [21] of 6600 M^{-1} cm^{-1}. Absorption titration experiments were made using different concentrations of CT DNA, keeping the concentration of the complexes constant, with due correction for the absorbance of the CT DNA itself. Samples were equilibrated before recording each spectrum. The fluorescence spectral method using ethidium bromide (EB) as a reference was used to determine the relative DNA binding properties of the complexes **1d** and **1e** to calf thymus (CT) DNA (50 mM Tris HCl/1 mM NaCl buffer, pH 7.5). Fluorescence intensities of EB at 620 nm with an excitation wavelength of 450 nm were measured at different complex concentrations. Reduction in the emission intensity was observed with addition of the complexes. The relative binding tendency of the complexes to CT DNA was determined from a comparison of the slopes of the lines in the fluorescence intensity versus complex concentration plot. The apparent binding constant (K_{app}) was calculated using the equation $K_{EB}[EB]/K_{app}[complex]$, where the complex concentration was the value at a 50% reduction of the fluorescence intensity of EB and $K_{EB} = 1.0 \times 10^7$ M^{-1} ([EB] = 1.3 μM) [21]. The cleavage of supercoiled pBR322 DNA by the complexes was studied by agarose gel electrophoresis. The gel electrophoresis experiments were performed as follows: pBR322 DNA (0.2 μg, 33 μM) was treated with the complexes **1c** and **1e** in 50 mM Tris–HCl/NaCl buffer (pH 7.2) and H_2O_2, followed by dilution with Tris–HCl buffer to a total volume of 18 μL. All the samples were incubated for 1 h at 37 °C, followed by their addition to the loading buffer containing 25% bromophenol blue, 0.25% xylene cyanol and

30% glycerol (3 μL). The solution was finally loaded on 0.8% agarose gel containing 1.0 μg/mL^{-1} of ethidium bromide. Electrophoresis was done for 1 h at 50 V in TBE (45 mM Tris, 45 mM H_3BO_3, 1 mM-EDTA, pH 8.3) buffer. Bands were visualized by UV light and photographed.

2.3.2. Antibacterial and antifungal assays

The agar diffusion method was followed for antibacterial and antifungal susceptibility tests. Petri plates were prepared by pouring 10 ml of Mueller Hinton Agar for bacteria, and allowed to solidify. These agar plates were inoculated with 0.1 ml of a standardized bacterial suspension (2×10^6 cells/ml) and uniformly spread. A 6 mm well was cut at the center of the agar plate and the well was filled with a solution of the complexes (**1a**–**1e** separately). The diameter of the inhibition zone observed around the well was measure for each bacterium after 24 h of incubation at 37 °C. One well was filled with sterile distilled water to serve as a control. For fungus, Sabouraud Dextrose Agar medium was amended with the complexes (**1a**–**1e** separately) when the medium was warm, and poured into Petri plates. After solidification of the medium, mycelial disks (6 mm diameter) of the test fungi were inoculated at the center of the plates. The diameter of the inhibition zone for each fungus was measured after 48 h of incubation at 28 °C. The mechanism of inhibition was determined by measuring the change in the cell wall permeability. An increase in conductivity of the bacterial and fungal suspension treated with complexes (**1a**–**1e**) indicates an alteration in the cell wall permeability or injury to the cell wall leading to the non-specific release of electrolytes and free amino acids from the cells. The conductivity of the bacterial suspension and fungal mycelial suspension in sterile distilled water without the addition of complexes served as a control. The concentration of the bacterial cells and fresh weight of the fungal mycelia were kept constant. Conductivity was measured using a Conductivity Meter and expressed in micro Siemens.

2.4. Synthesis of mono and binuclear vanadyl complexes

To a solution of the precursor compound (**I**) (4.35 g, 10 mmol) in $CHCl_3$/MeOH (50 ml 1:1), a methanolic solution of vanadyl sulfate (2.52 g, 10 mmol) was added dropwise under constant stirring. A brown colored mononuclear complex precipitated. The solid was separated by filtration and washed with isopropyl alcohol and diethyl ether. Yield: 2.82 g (34%). The binuclear vanadyl complexes were prepared from a general procedure in which to a vigorously stirred suspension of the mononuclear complex (1 g, 2.4 mmol) in methanol (20 ml), a methanolic solution of vanadyl sulfate (0.6 g, 2.4 mmol) was added slowly, and the mixture was stirred for 15 min to obtain a clear solution. Then, a methanolic solution (5 ml) of the corresponding diamine (0.07 g, 1,2-diamino ethane; 0.08 g, 1,3-diaminopropane; 0.1 g, 1,4-diaminobutane; 0.13 g, 1,2-diaminobenzene; 0.19 g, 1,8-diaminonaphthalene; 1.2 mmol) was added dropwise to the above solution and refluxed for 6 h. The resulting solid that separated out on evaporating the solution at room temperature and the resulting compound was washed with ether and dried. All the compounds were recrystallized from acetonitrile solution. [Yield: ~80%]. For **1a**, green solid, Yield: 0.8 g (62%). *Anal.* Calc. for $C_{24}H_{28}N_4O_8SV_2$: C, 45.42; H, 4.41; N, 8.83. Found: C, 45.72; H, 4.61; N, 8.62%. ESI mass in CH_3CN: *m/z* 269.2 $[(VO)_2L^{1a}]^{2+}$. For **1b**, green solid, Yield: 0.86 g (64%). *Anal.* Calc. for $C_{25}H_{30}N_4O_8SV_2$: C, 46.29; H, 4.62; N, 8.64. Found: C, 46.34; H, 4.81; N, 8.73%. ESI mass in CH_3CN: *m/z* 276.3 $[(VO)_2L^{1b}]^{2+}$. For **1c**, pale green solid, Yield: 0.96 g (70%). *Anal.* Calc. for $C_{26}H_{32}N_4O_8SV_2$: C, 47.13; H, 4.83; N, 8.46. Found: C, 47.26; H, 4.96; N, 8.34%. ESI mass in CH_3CN: *m/z* 283.2 $[(VO)_2L^{1c}]^{2+}$. For **1d**, orange solid, Yield: 0.89 g (63%). *Anal.* Calc. for $C_{28}H_{28}N_4O_8SV_2$: C, 49.26; H, 4.11; N, 8.21. Found: C, 49.36; H, 4.28; N, 8.41%. ESI mass in CH_3CN: *m/z* 293.5 $[(VO)_2L^{1d}]^{2+}$. For **1e**, brown solid, Yield: 1.1 g (72%). *Anal.* Calc. for $C_{32}H_{30}N_4O_8SV_2$: C, 52.45; H, 4.09; N, 7.65. Found: C, 52.57; H, 4.15; N, 7.78%. ESI mass in CH_3CN: *m/z* 318.6 $[(VO)_2L^{1e}]^{2+}$.

3. Results and discussion

3.1. Spectral studies

The IR spectrum of the precursor compound shows a peak at 1650–1680 cm^{-1} due to the presence of a CHO group. The formation of an imine group (C = N) in the macrocyclic complexes by Schiff base condensation between CHO and NH_2 is evidenced by the appearance of a strong peak at 1610–1630 cm^{-1}. The strong peak around 1110–1120 cm^{-1} may due to the sulfate ion. The electronic spectra of all the complexes were measured in CH_3CN at 298 K for the range 300–800 nm. They all show a weak band in the range 570–600 nm due to metal centered d–d transitions [22,23]. Moderately intense charge transfer bands appear in the range 350–450 nm. These bands are due to charge transfer from the azomethine nitrogen and phenoxide oxygen to $V^{IV}O$ ion [24]. A strong peak in the range 250–290 nm is due to a intraligand transition (π–π^*). The absorption maxima for the d–d transition suggest that the geometry around the vanadyl ion is approximately square pyramid [25,26]. Further, the complexes reported in the present work show that on moving from **1a** to **1e** increase in λ_{max} (red shift) of the d–d transition of the $V^{IV}O$ ion is observed. It indicates that the coordination geometry of complex **1a** is less distorted [27,28] than that of the later complexes **1b**, **1c**, **1d** and **1e**. ESI mass spectral data of the binuclear $V^{IV}O$ complexes confirm the proposed formula of the complexes. The EPR spectra of the solid complexes **1a**–**1e** were recorded at liquid nitrogen temperature (LNT). All the binuclear complexes showed a single broad-band resonance (Fig. 1) at ca. *g* = 1.98–2.03 (Table 1) with the half field signal at 1500 G (*M* = ±2), which suggest magnetic interactions between two vanadyl ions through the phenolate bridge.

3.2. Cyclicvoltammetric studies

The electrochemical properties of complexes **1a–1e** were studied by cyclic voltammetry. The cyclic voltammogram of **3a** recorded in acetonitrile is given in Fig. 2. The electrochemical data are summarized in Table 2. For all the complexes two quasi-reversible waves were observed. Coulometric experiments indicated that each of the couples is involved in a one electron transfer process.

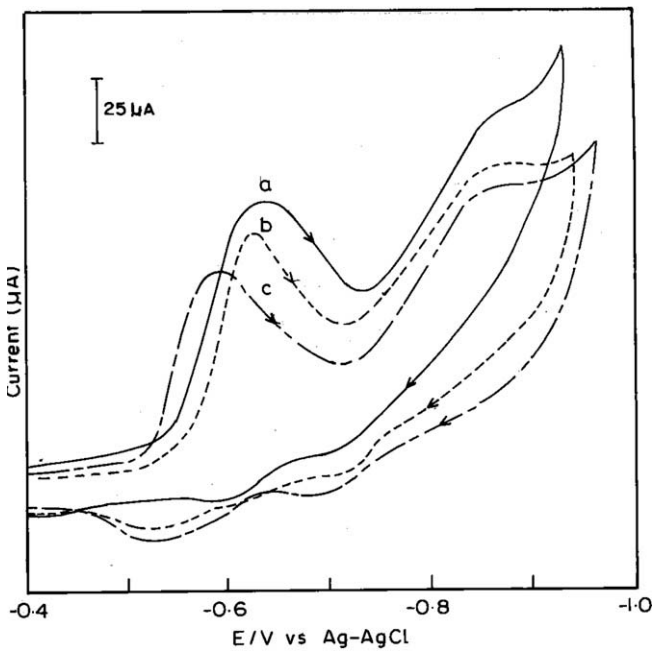

Fig. 2. Cyclicvoltammograms of the macrocyclic binuclear vanadyl(IV) complexes **1a**, **1b** and **1c** (1×10^{-3} M in DMF) in the cathodic region.

Based on these observations, it is reasonable to suggest that the reduction process may involve the stepwise redox processes depicted below:

$$(V^{IV}O)_2 \rightleftharpoons V^{III}OV^{IV}O_2 \rightleftharpoons (V^{III}O)_2.$$

The first redox potentials of the complexes are in the range ($E_{½}$) −0.51 to −0.63 V, and are assigned to the vanadyl ion present in the azomethine moiety. The second redox potentials of all the complexes were observed in the range ($E_{½}$) −0.74 to −0.78 V. The more negative potentials of the second quasi-reversible peaks are assigned to reduction of the vanadyl(IV) ion, which is located in the piperazinyl [29] moiety. As the size of the macrocycle is increased, an anodic shift of first reduction potential is observed for the binuclear $V^{IV}O$ complexes, which is consistent with reported observations [30]. As the chain length of the alkylimine compartment increases, the entire macrocyclic ring becomes more flexible, which enables easier reduction [31,32]. The ΔE_p values of first redox couple of the unsymmetrical $V^{IV}O$ complexes **1a**–**1c** decreases with the increasing chain between the two imine N atoms, easing the reduction process. The same trends were observed for the complexes of ligands **1d** and **1e**, which contain aromatic diimines. As the chelate ring size increases, the reduction potential shifts from $E^1_{pc} = -0.56$ to -0.54 V and $E^2_{pc} = -0.85$ to -0.83 V. From the cyclic voltammetric studies it can be stated that the complexes containing aromatic diimines get reduced at higher negative potentials than the complexes containing aliphatic diimines. The higher reduction potential can be attributed due to the greater planarity and electronic properties that are associated with aromatic rings [33].

In the positive potential region (+0.50 to +1.00 V) two quasi-reversible oxidation couples are observed for all the complexes. The cyclic voltammograms of the complexes are shown in Fig. 3 and the data are summarized in Table 3. A controlled potential electrolysis experiment indicates that the two oxidation peaks

Complex	E^1_{pc} (V)	E^1_{pa} (V)	$E_{½}$ (V)	ΔE_p (mV)	E^2_{pc} (V)	E^2_{pa} (V)	$E_{½}$ (V)	ΔE_p (mV)
1a	−0.67	−0.59	−0.63	80	−0.85	−0.71	−0.78	140
1b	−0.63	−0.54	−0.59	90	−0.83	−0.72	−0.77	110
1c	−0.59	−0.52	−0.56	70	−0.80	−0.69	−0.74	110
1d	−0.56	−0.49	−0.53	70	−0.85	−0.67	−0.76	180
1e	−0.54	−0.48	−0.51	60	−0.83	−0.66	−0.75	170

Table 3
Electrochemical data of the binuclear $V^{IV}O$ complexes in the anodic potential region.

Complex	E^1_{pc} (V)	E^1_{pa} (V)	$E_{½}$ (V)	ΔE_p (mV)	E^2_{pc} (V)	E^2_{pa} (V)	$E_{½}$ (V)	ΔE_p (mV)
1a	0.63	0.56	0.59	70	0.84	0.78	0.81	60
1b	0.65	0.57	0.61	80	0.85	0.77	0.81	80
1c	0.66	0.58	0.62	80	0.82	0.79	0.80	30
1d	0.72	0.65	0.68	70	0.93	0.81	0.87	120
1e	0.78	0.72	0.75	60	0.97	0.83	0.90	140

are associated with a stepwise oxidation process at the metal center

$$(V^{IV}O)_2 \rightleftharpoons V^{V}OV^{IV}O_2 \rightleftharpoons (V^{V}O)_2.$$

The first and second oxidation potentials of the complexes **1a**–**1c** shift towards more positive values from (E^1_{pc}) +0.63 to +0.78 V and (E^2_{pc}) +0.82 to +0.97 V as the number of methylene groups (chain length) increases in the imine compartment. This is because as the ring size increases, due to flexibility, the geometry around vanadium ion gets more distorted. For example the first oxidation potential of the complex **1c** is +0.66 V (E^1_{pc}). This potential is more positive when compared to the first and second oxidation potentials of complexes **1b** and **1a**. Similar trend has been observed for complexes **1d** and **1e**. This is because for complexes with aromatic diimines, an increase in unsaturation will decrease the electron density on the metal ions through delocalization, which prevents the easy oxidation of the metal ions in the macrocyclic ring.

3.3. DNA binding and cleavage studies

3.3.1. Absorption spectra studies

In the present investigation the interaction of the macrocyclic binuclear oxidovanadium(IV) complexes **1b**, **1d** and **1e** in DMF solutions (10%) with CT DNA have been investigated by UV absorption spectroscopy. Absorption titration experiments of $V^{IV}O$ complexes in buffer were performed by using a fixed complex concentration to which increments of the DNA stock solution were added. The binding ability of the complexes with CT DNA was studied by UV spectroscopy by following the intensity changes of the intraligand π–π^* transition band 200–220 nm. The binding of $V^{IV}O$ complexes to duplex DNA led to a decrease in the absorption intensities (Fig. 4) with a small amount of red shift in the UV–Vis absorption spectra. For the complexes **1b**, **1d** and **1e** the intrinsic binding constant K_b has been determined from the spectral titration data (Fig. 5) using the following equation [34]

$$[DNA]/(\varepsilon_a - \varepsilon_f) = [DNA]/(\varepsilon_b - \varepsilon_f) + 1/K_b(\varepsilon_b - \varepsilon_f).$$

Here, ε_a, ε_f and ε_b correspond to A_{obsd}/[$V^{IV}O$ complex], the extinction coefficient for the free complex, and the extinction coefficient for the complex in the fully bound form, respectively. The binding constants (K_b) of complexes **1b**, **1d** and **1e** are calculated as 3.02×10^4, 5.23×10^4 and 9.18×10^4 M^{-1}, respectively. The K_b values are lower than those reported for the typical classical intercalator ethidium bromide (EB) DNA, 3.3×10^5 M^{-1} in 50 mM Tris–HCl/1.0 mM NaCl buffer, pH 7.5 [35]. After intercalating the base pairs of DNA, the π^* orbital of the intercalated ligand can couple with the π orbital of the base pairs, thus decreasing the transition π–π^* energy and resulting in bathochromism. On the other hand, the coupling π orbital is partially filled by electrons, thus decreasing the transition probabilities and concomitantly resulting in hypochromism. [36]. The appreciable decrease in absorption intensity and significant red shift of the π–π^* band of complexes **1b**, **1d** and **1e** suggest that the complexes bind to DNA strongly. Complex **1e** show a minor bathochromic shift of the spectral band, of ~3 nm, suggesting a groove binding preference of the complex. Structurally, the ligand **1e** should provide an aromatic moiety to overlap with the stacking base pairs of the DNA helix by intercalation, which results in hypochromism and bathochromism. The higher binding propensity of complexes **1d** and **1e** may be probably due to the presence of more aromatic moieties [37] than the other $V^{IV}O$

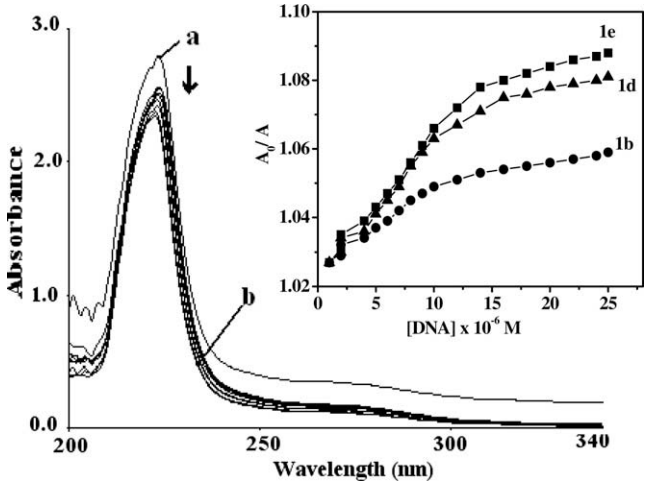

Fig. 4. Absorption spectra of the complex **1e** (1×10^{-5} M) in the absence (a) and presence of increasing amounts (b) of CT DNA (0–2.5×10^{-6} M) at room temperature in 50 mM Tris–HCl/NaCl buffer (pH 7.5). The arrow indicates decreasing absorbance with increasing DNA concentration. Insets shows the saturation in absorption intensity hypochromism (**1b**, **1d** and **1e**) is indicated by the plot of A_o/A versus [DNA].

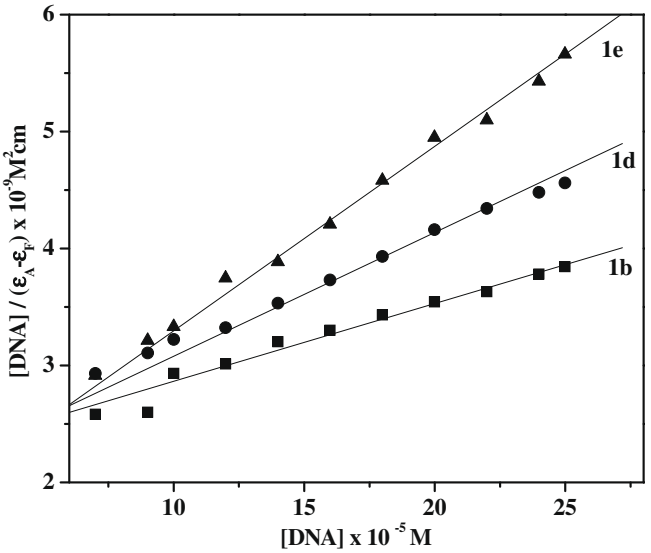

Fig. 5. The plots of [DNA]/(ε_a–ε_f) versus [DNA] for the titration of DNA with vanadyl(IV) complexes **1b**, **1d** and **1e**.

complex, **1b**. The increased aromatic moieties in the macrocyclic ligands of the oxidovanadium(IV) complexes facilitates their potential intercalative and/or DNA major groove binding, while complex **1b** may prefer minor groove binding.

3.4. Fluorescence spectra studies

Fluorescence measurements were performed to study the metal interaction with DNA using a Perkin Elmer spectrofluorimeter. Ethidium bromide (EB) is one of the most sensitive fluorescence probes that can bind with DNA [13]. The fluorescence of EB increases after intercalating into DNA. If the metal intercalates into DNA, it leads to a decrease in the binding sites of DNA available for EB, resulting in a decrease in the fluorescence intensity of the EB–DNA system [38]. The emission spectra of EB bound to DNA in the absence and presence of complex **1e** are shown in Fig. 6. The addition of the complex to DNA pretreated with EB causes an appreciable reduction in fluorescence intensity. This indicates that the complex **1e** binds with DNA. The reduction of the emission intensity gives a measure (Fig. 7) of the DNA binding propensity of the complex and the stacking interaction (intercalation) between the adjacent DNA base pairs [39]. The fluorescence quenching curves of DNA-bound EB by complexes **1d** and **1e** illustrates that the quenching of EB bound to DNA by the complexes are in good agreement with the linear Stern–Volmer equation. In the linear fit plot of I_0/I versus [complex]/[DNA], K is given by the ratio of the slope to intercept. The K values for the complexes **1d** and **1e** are 5.22 ($R = 0.989$) and 4.21 (0.991), respectively (I_0 is the emission intensity of EB–DNA in the absence of complex; I is the emission intensity of EB–DNA in the presence of complex). The concentrations of the complexes are taken when a 50% reduction of emission intensity of EB is observed [40]. From the data in Fig. 7, we know that 50% of the EB molecules were replaced from DNA-bound EB at a concentration ratio of [$V^{IV}O$ complex]/[EB] of 8.43 for **1d** and 9.96 for **1e**. By taking a DNA binding constant of $1.0 \times 10^7\ M^{-1}$ for EB [41], apparent DNA binding constants of 1.0×10^6 and $1.2 \times 10^6\ M^{-1}$ were derived {K_b(EB)/([$V^{IV}O$ complex]/[EB])} for the complexes **1d** and **1e**, respectively. The K_{app} values implies that both complexes can strongly interact with DNA and are protected by DNA efficiently, since the hydrophobic environment inside the DNA helix reduces the accessibility of solvent water molecules to the complex and the complex mobility is restricted at the binding site, leading to a decrease of the vibrational modes of relaxation [42]. The K_{app} value for complex **1e** is greater than the complex **1d**. This may be due to the presence of more aromatic moieties, which enhances the binding propensity of the molecule to DNA through the intercalative mode. The presence of a 4-methylphenol group and also the hydrophobic property of the rigid macrocycle ligands facilitate the DNA binding [43].

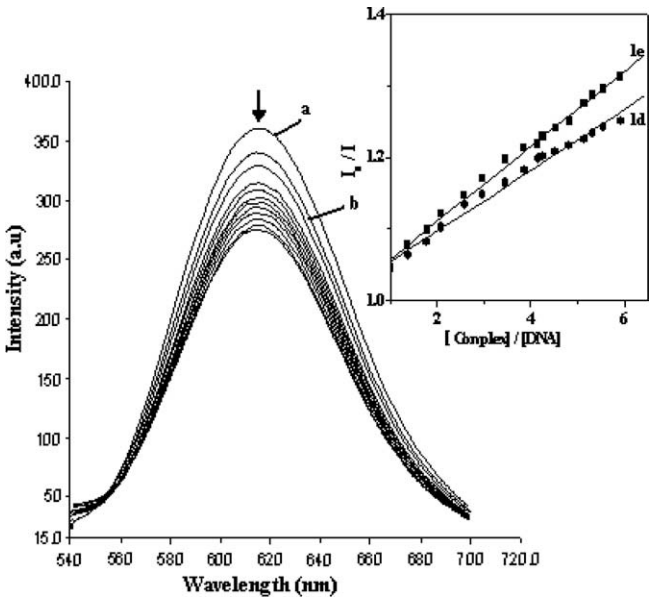

Fig. 6. Emission spectra of EB bound to DNA in the presence of **2e** ([EB] = 3.3 μM, [DNA] = 40 μM, [complex] = 0–25 μM, λ_{ex} = 510 nm). (a) Emission spectrum of DNA-bound EB. (b) The arrow indicates decreasing absorbance with increasing vanadyl(IV) complex (**1e**) concentrations. Inset shows the plots of emission intensity I_o/I versus [DNA]/[complex].

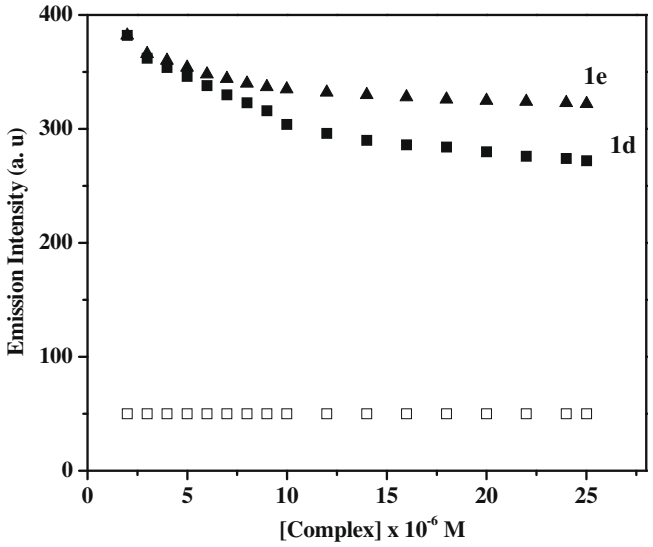

Fig. 7. The effect of addition of complexes **1d** (■) and **1e** (▲) on the emission intensity of 40 μM CT DNA-bound EB in Tris–HCl/NaCl buffer (50 mM, pH 7.5) at 25 °C; (□) on the emission intensity of EB in absence of CT DNA but at different concentrations of **1d** and **1e**.

3.5. DNA cleavage activity

The ability of complexes **1c** and **1e** to perform DNA cleavage in the presence of H_2O_2 has been studied by agarose gel electrophoresis using supercoiled pBR322 DNA (0.2 μg, 33 μM) in a medium of 50 mM Tris–HCl/NaCl buffer (pH 7.2). Both the complexes show considerable DNA cleavage ability at low concentrations (30 μM). When circular plasmid DNA is subjected to electrophoresis, relatively fast migration will be observed for the intact supercoil form (Form I). If scission occurs on one strand (nicking), the supercoil will relax to generate a slower moving open circular form (Form II). If both strands are cleaved, a linear form (Form III) that migrates between Forms-I and -II will be generated [44]. Fig. 8 shows the gel electrophoretic results of complexes **1c** and **1e** interaction with plasmid pBR322 DNA. Under similar conditions no cleavage of pBR322 DNA occurred for free H_2O_2 (Lane 2). In the presence of the $V^{IV}O$ complexes **1c** and **1e** (30 μM) with 60 μM H_2O_2, plasmid DNA was nicked as is evident from the formation of Form II (lanes 3 and 4) and the disappearance of the supercoiled form in the electrophoretic experiment. In lanes 5 and 6, using 50 μM of complexes **1c** and **1e** with 60 μM H_2O_2, bands could not be identified due to smearing. At higher concentrations of the dinuclear complexes (50 μM) the nicked DNA degraded completely into small pieces and only a smear was present and it could not induce the conversion of SC to the linear form at the tested concentrations. The cleavage mechanism of pBR322 DNA induced by complexes **1c** and **1e** was investigated and clarified in the presence of a singlet

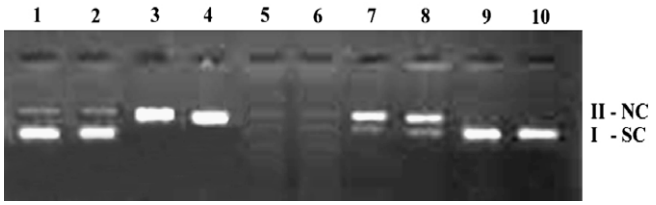

Fig. 8. Cleavage of SC pBR322 DNA (0.2 μg, 33.3 μM) by VO(IV) complexes **1c** and **1e** (0.03–0.05 mM) in the presence of H_2O_2 (60 mM) in 50 mM Tris–HCl/NaCl buffer (pH 7.2). lane 1, DNA control; lane 2, DNA + H_2O_2; lanes 3 and 4, DNA + H_2O_2 + **1c** and **1e** (0.03 mM), respectively; lanes 5 and 6, DNA + H_2O_2 + **1c** and **1e** (0.05 mM), respectively; lanes 7–8, DNA + H_2O_2 + L-histidine (0.04 M) + **1c** and **1e** (0.03 mM), respectively; lanes 9–10, DNA + H_2O_2 + DMSO (2μL) + **1c** and **1e** (0.03 mM), respectively (Gel image showing supercoiled (Form I) and circular relaxed (Form II) DNA).

oxygen quencher L-histidine [45] (lanes 6 and 7) and in the presence of the hydroxyl radical scavenger 0.4 M DMSO (lanes 9 and 10) [46]. Complete inhibition of DNA cleavage was observed from lane 9 to 10. These observations suggest the existence of diffusible radical species in the nuclease mechanism. This can be inferred by monitoring the quenching of DNA cleavage in the presence of DMSO, suggesting the possibility of the formation of HO· radicals as the reactive species [47]. Generation of a HO· radical adduct by the vanadyl(IV)–H_2O_2 system resembles the Fenton reaction (Fe^{2+}–H_2O_2) [48]. In the presence of H_2O_2, the macrocyclic ring containing $V^{IV}O$ ion(s) get oxidized and generates the HO· radicals [49] as follows: ($VO^{2+} + H_2O_2 \rightarrow VO_2^+ + OH + H^+$). These highly reactive hydroxyl radical species can cleave the DNA by abstraction of the hydrogen atom from the deoxyribose sugar [50]. It was also observed that vanadyl(IV) complexes were not able to cleave DNA under an oxygen-free atmosphere. It is remarkable that L-histidine also slightly inhibits the DNA cleaving activity of the complexes. This gives strong evidence of an oxidative process intervening in the DNA cleavage reaction. These results indicate that the presence of oxygen plays a fundamental role in the process of DNA cleavage by the binuclear oxidovanadium(IV) complexes. In the presence of H_2O_2 both the oxidovanadium(IV) complexes **1c** and **1e** degrade pBR322 DNA by oxidative cleavage.

3.6. Antifungal activity

Studies on the antifungal activity of macrocyclic ligands and their complexes are limited in the literature [51–53]. We have evaluated the antifungal activity of all the $V^{IV}O$ complexes against the pathogenic fungus *Aspergillus ochraceous*, *Paecilomyces variotii* and *Botrytis cineraia*. The three fungal species selected for this study are plant pathogens and they indirectly pose health problem in human beings. For example, *A. ochraceous* is a post-harvest fungus infecting the coffee bean and producing ochratoxin. *B. cineraia* infects grape wine and wines prepared from infected grapes yield inferior quality wines. *Paecilomyces variotii* causes paecilomycosis in man. The screening data were reported in Table 4. It is observed from the results that all the tested complexes show some antifungal activity. The activity reported by the present complexes was comparable with the antifungal activities of the macrocyclic ligand containing Cu(II) and Ni(II) ions. [54,55]. It is interesting to notice that the complexes **1d** and **1e** show higher activity than complexes **1a**–**1c**, which contain aliphatic diimines.

3.7. Antibacterial activity

All the binuclear oxidovanadyl complexes have been tested for antibacterial activity against three selected bacteria: *Serratia species*, *Micrococcus luteus* and *Proteus vulgaris*. All these three bacterial species are human pathogens. The screening results are shown in Table 4. *Proteus vulgaris*, used in this study, displayed more resistance to the complexes than the strain of *Serratia* sp. Even though *Serratia* sp. and *P. vulgaris* belongs to the Gram negative group, the difference in their response to oxidovanadium

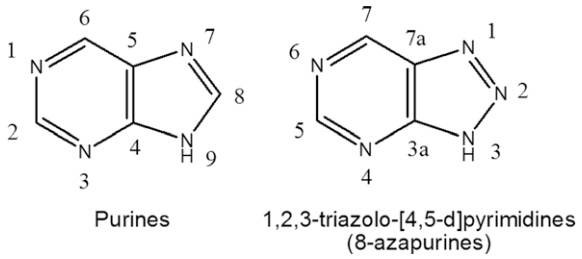
complexes could be attributed to their resistance pattern decided by the genetic factors. It is common among bacteria that different strains of bacterial species show different responses to a particular toxic material. The inhibition of bacterial and fungal cells by oxidovanadium complexes was due to the alteration in the cell permeability and subsequent injury to the cell membrane which led to leakage of electrolytes from the cells. This leakage caused an increase in conductivity of the suspended medium. The data from conductivity tests (Table 5) of the fungi clearly confirmed this fact. However, further more studies are needed to understand the functions which are responsible for the antifungal and antibacterial activities of the tested complexes.

4. Conclusion



In conclusion, it has been observed that the small variation in the chain length of the imine compartment: (i) shift the reduction potential anodically on increasing the chain length, (ii) shift the oxidation potential to a more positive potential as the chain length increases, (iii) aromatic diimine containing unsymmetrical macrocyclic binuclear $V^{IV}O$ complexes show better DNA binding ability than the aliphatic diimine containing complexes, (iv) these macrocyclic $V^{IV}O$ complexes significantly promote the oxidative cleavage of supercoiled plasmid DNA under physiological conditions in the presence of H_2O_2. All these studies on the complexes agree well with the established trend.

Scheme 1.

coordinated counteranion [16]. In the present work, we have extended this study, allowing the presence of the monodentate auxiliary ligand pyridine (py), and six new ternary complexes have been isolated and structurally characterized; for the Mn(II), Zn(II), Cd(II) and Co(II) complexes, only py is bound to the metal ion and $dmax^-$ acts as non-coordinated anion whereas for the Ni(II) and Cu(II) complexes, both ligands are directly bonded to the metal centres.

2. Experimental

2.1. Synthesis of the compounds

The synthesis of 4,6-dimethyl-1,2,3-triazolo[4,5-*d*]pyrimidin-5,7-dione (Hdmax) was carried out according to the published method of Nübel and Pfleiderer [17]. Other reagents were obtained form commercial sources and were used without further purification.

The metal complexes were obtained by mixing two 1:2 pyridine-aqueous solutions, 10 mL each, one containing 2 mmol of Hdmax and the other containing 1 mmol of the appropriate metal salt (sulfate for Mn and nitrate for the remaining metals). The mixture was allowed to evaporate at room temperature and, after several days, crystals suitable for X-ray studies were obtained in each case.

From elemental analyses, the following formulae were deduced for the isolated compounds:

$[Mn(H_2O)_4(py)_2](dmax)_2$ (**1**), colourless crystals. *Anal.* Calc. for $C_{22}H_{30}MnN_{12}O_8$: C, 40.9; H, 4.7; N, 26.0. Found: C, 40.9; H, 5.1; N, 26.8%.

$[Co(H_2O)_4(py)_2](dmax)_2$ (**2**), pale pink crystals. *Anal.* Calc. for $C_{22}H_{30}CoN_{12}O_8$: C, 40.7; H, 4.7; N, 25.9. Found: C, 40.6; H, 4.7; N, 26.1%.

$[Ni(dmax)_2(H_2O)_2(py)_2]\cdot 2H_2O$ (**3**), mauve crystals. *Anal.* Calc. for $C_{22}H_{30}N_{12}NiO_8$: C, 40.7; H, 4.7; N, 25.9. Found: C, 40.7; H, 5.2; N, 26.2%.

$[Cu(dmax)_2(H_2O)_2(py)_2]\cdot 2H_2O$ (**4**), blue crystals. *Anal.* Calc. for $C_{22}H_{30}CuN_{12}O_8$: C, 40.4; H, 4.6; N, 25.7. Found: C, 40.4; H, 4.6; N, 26.0%.

$[Zn(H_2O)_4(py)_2](dmax)_2$ (**5**), colourless crystals. *Anal.* Calc. for $C_{22}H_{30}N_{12}O_8Zn$: C, 40.3; H, 4.6; N, 25.6. Found: C, 40.8; H, 4.8; N, 26.3%.

$[Cd(H_2O)_4(py)_2](dmax)_2$ (**6**), colourless crystals. *Anal.* Calc. for $C_{22}H_{30}CdN_{12}O_8$: C, 37.6; H, 4.3; N, 23.9. Found: C, 37.5; H, 4.4; N, 24.2%.

2.2. Instrumentation

Microanalysis of C, H and N were performed in a Fisons Instruments EA-1008 analyser. Thermal behaviour was studied under an air flow in Shimadzu TGA-50 and Shimadzu DSC-50 equipment, at heating rates of 20 °C min^{-1} and 10 °C min^{-1}, respectively. Reflectance diffuse spectra were made on a VARIAN model CARY-5E spectrophotometer. EPR spectra of the powdered Cu sample was recorded at room temperature on a Bruker ESP-300E spectrometer, operating at X-band (9–10 GHz) (all this equipment is sited at the Centre of Scientific Instrumentation of the University of Granada). IR spectra were recorded on a ThermoNicolet IR 200 spectrometer using KBr pellets.

2.3. Crystallography

Data were collected at room temperature for **1**, **2** and **6** and at 100 K for **3**, **4** and **5**, in a Bruker SMART APEX CCD system with Mo Kα radiation (λ = 0.7107 Å). Data were corrected for absorption (multi-scan, transmission ranges, 0.897–0.789, 0.854–0.759, 0.859–0.743, 0.810–0.744, 0.901–0.781, 0.750–0.644 for **1** to **6,** respectively). The structures were solved by the heavy atom meth-

od and anisotropically refined in F^2 using SHELXL-97 [18]. Hydrogen atoms of the heterocycles were placed in ideal positions, whereas those of the water molecules were clearly spotted in the ΔF maps and refined with a restrained O–H distance (0.84(1) Å). Isotropic thermal parameters of all H-atoms were fixed to 1.2 times the equivalent isotropic thermal parameter of their parent atoms. Table 1 summarizes the crystallographic data for these compounds.

3. Results and discussion

3.1. X-ray structural studies

3.1.1. Complexes $[M(H_2O)_4(py)_2](dmax)_2$ (M=Mn, Co, Zn, Cd(II))

Compounds **1**, **2**, **5** and **6** are isostructural and therefore, may be discussed jointly. The unit cell of these compounds contains one $[M(H_2O)_4(py)_2]^{2+}$ cation (M = Mn, Co, Zn, Cd(II)) and two 4,6-dimethyl-1,2,3-triazolo[4,5-*d*]pyrimidin-5,7-dionato ($dmax^-$) non-coordinated anions, which have lost the acidic proton present in the free ligand at the N atom at position 2. Fig. 1 displays a view of the basic ionic unit in **5**, almost identical to those in the other three compounds. The metal atoms lie in crystallographic inversion centres and their environments are slightly distorted octahedra defined by two symmetry related py ligands in *trans* dispositions, and four water molecules. Distances and angles in the coordination sphere are listed in Table 2. The plane of the pyridine ligand is almost perpendicular to the $M(H_2O)_4$ plane, the corresponding dihedral angle ranging from 85.2° (**6**) to 87.2° (**1**). The conformation around the M–py bond is established with the projection of the pyridine plane almost bisecting the Ow–M–Ow angles (torsion angles C(py)–N(py)–M–O(w), 45 ± 6°), which probably optimizes the interactions between the aromatic ortho protons and the water oxygens, which may be considered as bifurcated weak intramolecular H-bonds, the corresponding C···O and H···O distances ranging from 3.1 to 3.6 Å and from 2.75 to 3.15 Å, respectively, these values being higher for the Mn and Cd compounds than for the Co and Zn ones. Surprisingly enough, there are very few previous references for $[M(H_2O)_4(py)_2]^{2+}$ cations, in fact for Mn, Zn and Cd, those presented here are the first examples; for Co, the geometrical parameters of the cation are almost identical to those in previous works [19].

The acidic proton of Hdmax is located at the nitrogen atom at position 2 in the crystal structure of the free ligand [20]. The ionization of this proton leads to the closing of the endocyclic angle at N2 (5.1–5.3°) and the opening of the adjacent endocyclic angles at N1 (3.6–3.8°) and N3 (4.5–4.7°). Changes in bond distances are probably less significant (maximum N1-C7a, around 0.02 Å).

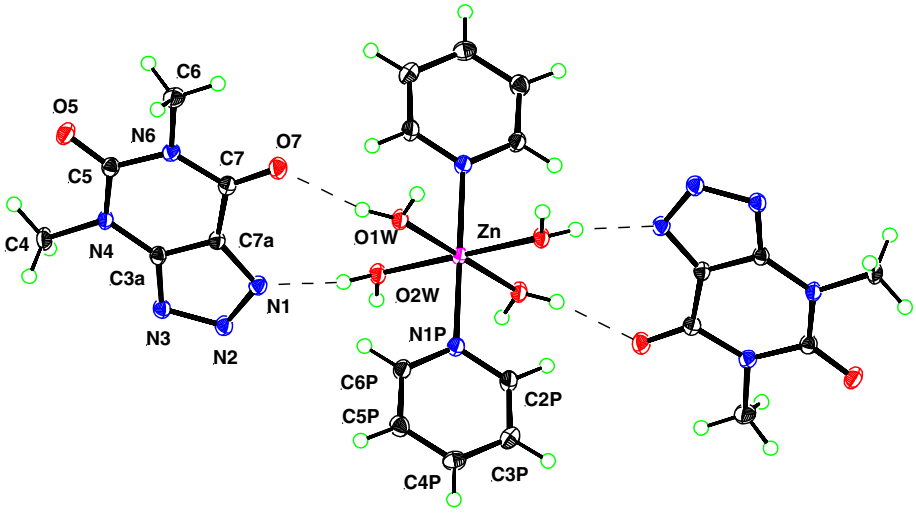

Fig. 1. View of the basic ionic unit of compound **5**.

Symmetry transformations used to generate equivalent atoms: #2: $x + 1, y, z$ #3: $-x, -y + 1, -z + 1$.

Nevertheless, the main interest of these structures lies probably more in the second coordination sphere than in the first. As it happens with the analogous hexa-aqua salts [16], the topology of the H-bonds are a good example of how concepts usually applied to the first coordination sphere find clear analogies in the second coordination sphere, so we may use terms like "monodentate", "bridging ligand", "chelate" and so on. All hydrogen atoms of coordinated water molecules, clearly spotted in the X-ray analysis, participate as donors in these H-bonds, four of five potential hydrogen acceptor sites (N1, N2, N3 and O7) being involved for the 4,6-dimethyl-1,2,3-triazolo[4,5-*d*]pyrimidin-5,7-dionato anions. The corresponding H-bond geometrical parameters are collected in Table 3.

All H-bond interactions between water molecules and anions take place in the equatorial plane of the complex. N2 and N3 interact with water molecules belonging to the same cation and this closes a ring which may be defined as a "chelate", where the ring includes seven atoms (the metal, two oxygens, two hydrogens and two nitrogens). This pattern may be represented in the condensed way as $R^2_2(7)$ according to the graph set notation proposed by Etter and Bernstein et al. [21,22]: R indicates a ring, the degree (in parentheses) is the number of atoms in the ring, and the super- and subscripts represent the number of hydrogen bond acceptors and donors in the motif, respectively. Likewise, N1 and O7 define another chelate (in this case $R^2_2(9)$) with another $[M(H_2O)_4(py)_2]^{2+}$ cation. These chelating interactions build tape structures that grow in the *a* direction (Fig. 2). A tape is defined as an infinite monodimensional structure in which the components are linked by more than one hydrogen bond, with the hydrogen bonds approximately copla-

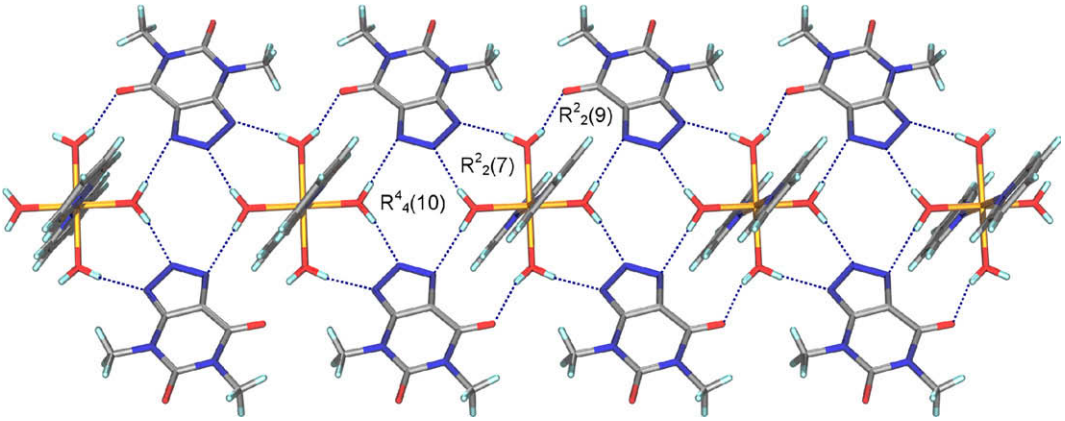

Fig. 2. Tape along the 100 direction built by the hydrogen bond interactions in compound **5**.

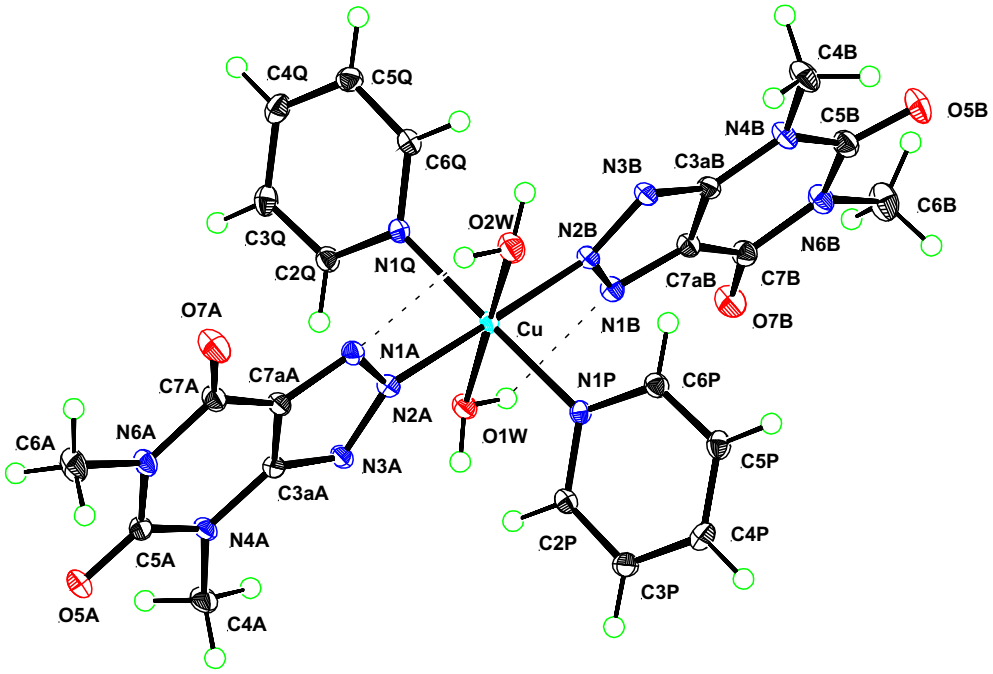

Fig. 3. Molecular structure of compound **4** (that of **3** is analogous to it).

nar [23]. A third ring motif $R_4^4(10)$ involving two cations and two anions appears in the tape around the crystallographic inversion centres. The anion is roughly coplanar with the tape.

Perhaps the most noteworthy feature of these tapes is that they are topologically identical to those present in the above mentioned hexa-aqua salts [16]. This fact prompted us to define this set of H-bond interactions as a case of molecular recognition between the square planar $[M(H_2O)_4]^{2+}$ subunits (M = Mn, Co, Zn, Cd) and the 4,6-dimethyl-1,2,3-triazolo[4,5-*d*]pyrimidin-5,7-dionato anions, letting us predict that in any compound containing these two species it is likely that the tape superstructure will be generated, regardless of the nature of the axial ligands. The stability of this superstructure may also explain, in principle, the surprising fact of the non-direct coordination between the divalent Mn, Co, Zn and Cd centres and the anion dmax$^-$, a species with several binding sites.

The tapes interact each other mainly through two types of π–π interactions: between parallel displaced pyridine moieties (3.4 Å) and between inversion centre related couples of dmax$^-$ anions (3.4 Å). Weak poorly defined H-bonds are also formed between the aromatic meta protons of pyridine and the carbonyl oxygen O5 of neighbouring tapes (C···O distances, around 3.4 Å).

Table 4
Hydrogen-bond distances (D-H···A, Å) in compounds **3** and **4**.

	3	**4**
O(Wc)–H···N(1)	2.7501(16)	2.8167(16)
		2.8328(16)
O(Wc)–H···O(Wi)	2.7286(15)	2.7868(15)
		2.7446(17)
O(Wi)–H···O(5)#1 (3) or O(5A)#2 (4)	2.8809(17)	2.8788(16)
O(Wi)–H···N(3B)		2.8918(17)

		2.8933(16)

O(Wc) = O atom of coordinated water (O1W for **3** and O1W, O2W for **4**).
O(Wi) = O atom of interstitial water (O2W for **3** and O3W, O4W for **4**).
Symmetry transformations used to generate equivalent atoms: #1: *x*, *y*, *z* + 1 #2: −*x* + 1, −*y* + 2, −*z* + 1 #3: −*x* + 2, −*y* + 1, −*z* + 1 #4: −*x*, −*y* + 1, −*z* #5: −*x* + 1, −*y* + 1, −*z* + 1.

3.1.2. Complexes $[M(dmax)_2(H_2O)_2(py)_2] \cdot 2H_2O$ (M=Ni, Cu(II))

In contrast to the compounds described in the previous paragraphs, in the case of Ni and Cu, there is direct coordination between the metal and the anion dmax$^-$. This is not too surprising, since divalent Ni and Cu usually form more stable complexes than Mn, Co and Zn, according to the well known Irving-Williams series. Direct (Ni,Cu)-dmax$^-$ binding seeming to be thermodinamically more favoured than the formation of the tapes described in Section 3.1.1. Both structures are built by neutral $[M(dmax)_2(H_2O)_2(py)_2]$ molecules (Fig. 3) plus two interstitial water molecules per complex unit. Nevertheless, the compounds are not isostructural, in **3** the nickel atom lies in a crystallographic inversion centre whereas the copper atom in **4** is placed in a general position, even if the molecule still presents local approximate C_i symmetry; the disposition of the ligands is therefore all-*trans* in both cases. The distortion of the octahedron is **3** is slight, whereas in **4** the expected tetragonal Jahn-Teller distortion is present, with the water molecules occupying the axial positions (Table 2). As in the previous compounds, the ionization of the acidic proton at position 2 leads to the closing of the endocyclic angle at N2 and the opening of the adjacent endocyclic angles at N1 and N3, but the differences with the free ligand are smaller (3.1–3.6°, 2.2–2.7° and 2.8–3.1°, respec-

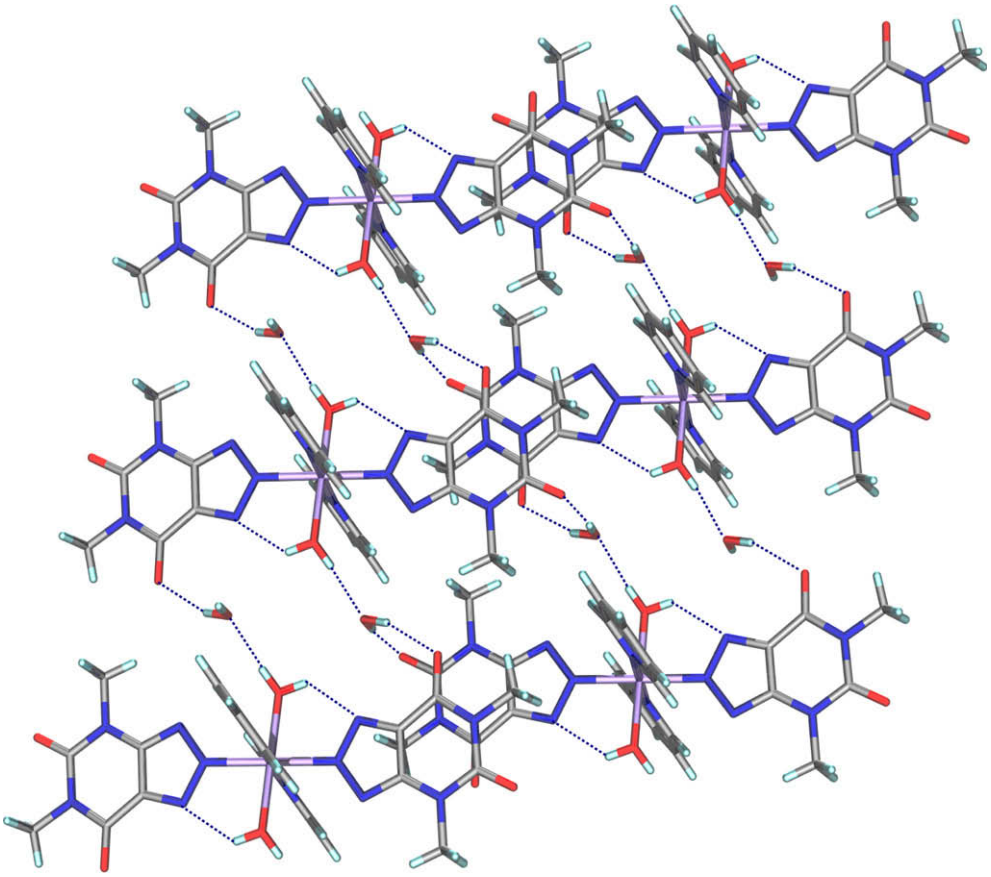

Fig. 4. Bidimensional H-bond superstructure in compound **3**.

tively) showing that the effect of the loss of the proton is partially compensated by the presence of the metal cation.

In both cases, one of the H-atoms of each coordinated water molecule forms an intramolecular H-bond with the N1 atom of one of the neighbouring dmax$^-$ anions (Table 4, Fig. 3), this leaves for each $[M(dmax)_2(H_2O)_2(py)_2]$ unit only two available donor H-atoms which are linked in all cases to interstitial water molecules. Therefore, these interstitial water molecules have the main responsibility for joining the molecules and to build the H-bond network. In the nickel compound, all non-coordinated water molecules are symmetry equivalent (O2W), their H-atoms being linked to carbonyl oxygen atoms of different complex molecules and building in this way a bidimensional corrugated superstructure in the *ac* plane (Fig. 4). For the copper complex, there are two crystallographically different interstitial water molecules (O3W and O4W): the two protons of O3W and one of OW4 also interact with carbonyl oxygens of different neighbouring molecules, whereas the second proton of O4W is linked to the N3 atom of a dmax$^-$ moiety belonging to the same complex as the coordinated water molecule for which O4W acts as a H-bond acceptor: this creates a –Cu–H_2O–H_2O-dmax $R_2^2(7)$ chelate ring. The water–carbonyl interactions also generate a bidimensional superstructure, growing in the $\bar{1}01$ crystallographic plane.

The layers in both compounds interact more weakly through normal Van der Waals contacts, weak C(aromatic)-H···O interactions and π-stacking interactions that take place between pyridine moieties (3.4 Å), but not between the dmax$^-$ anions.

3.2. Spectral, thermal and magnetic studies

The 1700–1500 cm^{-1} region of the infrared spectra of the free heterocycle Hdmax displays three bands at 1717, 1681 and 1604 cm^{-1}, assignable to carbonyl stretching and possibly to $\delta(H_2O)$, these bands being slightly displaced to lower (the first two) or higher (the last one) wavenumbers in the complexes. For all the complexes, a new band appears at 1544 cm^{-1}, characteristic of the anionic form of this ligand [16], and an intense band close to 1310 cm^{-1} is present in the region expected for vibrational modes of the aromatic ring. The main bands of pyridine [24,25] are slightly displaced to higher wavenumbers in the complexes.

The spectra also show broad bands in the 3500–3100 cm^{-1} region, assignable to υ(OH) of water, broadened and lower wavenumber displaced by the hydrogen bonds. The free ligand also displays a broad absorption around 2800 cm^{-1}, which disappears in the complexes, probably related to the acidic proton of the imidazole ring, extensively associated in H-bonding.

The first step of the thermal decomposition of the isolated complexes (except **4**) is the successive loss of four water molecules and two pyridine moieties with a well defined weight loss effect, the corresponding percentage agreeing well with the expected value. For **1**, **5** and **6** this process appears in the DSC diagrams as several overlapped endothermic peaks, and dehydration enthalpies cannot be reliably obtained, whereas for **2** and **3** the endothermic peaks are better defined and separated and, from the integration of the first one (102.4 and 113.0 °C, respectively), we can calculate the dehydration energies (45.5 kJ/mol and 48.7 kJ/mol, respectively). The second step is the pyrolytic decomposition around 400 °C, giving different metal oxides as inorganic residues. For the copper complex, the elimination of water and pyridine are well separated both in the TG and DSC diagrams. Dehydration takes place in a single step (endothermic peak at 80.4 °C) with dehydration energy of 47.4 kJ/mol. After this, the loss of two pyridine moieties takes place (endothermic peak at 176.2 °C) followed by the pyrolysis of the triazolopyrimidine derivative.

The diffuse reflectance spectra of **2–4** are typical of octahedral species [26]. The cobalt compound exhibits two main absorptions: a broad one centred at 8818 cm^{-1}, assigned to the $^4T_{2g}(F) \leftarrow {}^4T_{1g}(F)$ (υ_1) transition and another one at 19380 cm^{-1} assigned to the $^4T_{1g}(P) \leftarrow {}^4T_{1g}(F)$ (υ_3) transition. Ligand field parameters were calculated by Dou equations [27] on the basis of an octahedral geometry, giving $\Delta_o = 9953$ cm^{-1} and $B = 780$ cm^{-1}. The spectrum for the nickel compound shows two of the three typical bands expected for octahedral Ni(II) complexes at 11325 ($^3T_{2g}(F) \leftarrow {}^3A_{2g}(F)$, υ_1) and 17889 ($^3T_{1g}(F) \leftarrow {}^3A_{2g}(F)$, υ_2) cm^{-1}, from which the parameters $\Delta_o = 11325$ cm^{-1} and $B = 835$ cm^{-1} were calculated. Finally, the copper compound presents only one broad and asymmetric band with a maximum at 17153 cm^{-1} that can be assigned to a d–d transition with a d^9 configuration and a distorted octahedral geometry.

The X-band EPR spectrum has been recorded at room temperature for a polycrystalline powdered sample of compound **4**. The spectrum consists of a single very broad asymmetric band attributable to an unresolved anisotropic spectrum with an average *g* value of 2.06.

2.2. Preparation of $[Co_2(R\text{-}Hmal)(S\text{-}Hmal)(H_2O)_4]_n \cdot 2nH_2O$ (**2**)

R,*S*-malic acid (0.74 g, 5.5 mmol) was added to a stirred solution of $CoCl_2 \cdot 6H_2O$ (1.15 g, 5 mmol) in water (10 mL). The pH of the solution was adjusted to 5.0 with ammonium hydroxide. The mixture was heated in a 60 °C water bath for two days. Purple red crystals were obtained, washed with water and ethanol, then dried in air to give **2** in a yield of 0.74 g (60%). C and H elemental Anal. *Calc.* for $C_8H_{20}O_{16}Co_2$: C, 19.6; H, 4.1. Found: C, 19.7; H, 3.8%. IR (KBr, cm^{-1}): $\nu_{as}(CO_2)$ 1596_{vs}, 1567_{vs}; $\nu_s(CO_2)$ 1432_m, 1379_m.

2.3. Preparation of $K_4[Co_4(OH)_2(R\text{-}mal)_2(S\text{-}mal)_2(H_2O)_4] \cdot 10H_2O$ (**3**)

R,*S*-malic acid (0.81 g, 5.5 mmol) was added to a stirred solution of $CoCl_2 \cdot 6H_2O$ (1.18 g, 5 mmol) in 2:1 water–ethanol solution (15 mL). The pH value of the solution was adjusted to 7.0 with potassium hydroxide. Purple red crystals were obtained after standing at room temperature for several days, which were washed with water and ethanol, and dried in air to give **3** in a yield of 0.11 g (7.5%). C, H and N elemental Anal. *Calc.* for $C_{16}H_{42}O_{36}Co_4K_4$: C, 16.0; H, 3.5. Found: C, 15.5; H, 3.7%. IR (KBr, cm^{-1}): $\nu_{as}(CO_2)$ 1593_{vs}, 1564_{vs}; $\nu_s(CO_2)$ 1415_s, 1383_s, 1364_s.

2.4. X-ray structural data collections, structure solutions and refinements

Crystals of **1**–**3** were measured on a Bruker Smart Apex CCD diffractometer with graphite monochromate Mo Kα radiation (λ = 0.71073 Å) at 296 K. The data were corrected for Lorentz and polarization effects. An absorption correction was applied using the SADABS program [19]. The structures were solved by the WINGX package [20] and refined by full-matrix least-squares procedures with anisotropic thermal parameters for all the non-hydrogen atoms using SHELXL-97 [21]. Hydrogen atoms were located from difference Fourier maps and refined isotropically. Crystal data collections and refinement parameters are summarized in Table 1. Selected bond lengths and angles are listed in Table 2.

3. Results and discussion

3.1. Syntheses and conversions

The syntheses of the cobalt malato complexes were carried out in aqueous solutions under different pH values, molar ratios and counterions, as shown in Scheme 1. Complexes **1**–**3** exist in different forms of aggregates, in which **1** is a monomer, **2** forms a two-dimensional layered structure based on a dimeric unit, while **3** is in a tetranuclear species. In the synthesis of **1**, the high molar ratio of malic acid to cobalt chloride of 2:1 was applied to initiate the reaction. The presence of a small excess of malic acid in the reaction mixture was essential, since its deficiency caused the isolation of **2**. With a metal-to-ligand ratio of 1:1, $[Co_2(R\text{-}Hmal)(S\text{-}Hmal)(H_2O)_4]_n \cdot 2nH_2O$ (**2**) was isolated. When the pH value was less than 3.0, *cis*-$[Co(H_2mal)_2(H_2O)_2] \cdot 2H_2O$ or *trans*-$[Co(H_2mal)_2(H_2O)_2] \cdot 2H_2O$ (**4**) was obtained [7,8]. In weakly acidic and neutral conditions, **1** and **2** could be isolated from the solution in the pH ranges of 4.0–7.0 and 3.0–6.0, respectively. Use of various bases like ammonium hydroxide or potassium hydroxide not only supplied the necessary counterions to balance the negative charges of the cobalt malate complexes, but also made a contribution to the formation of monomeric and polymeric structures. As compared to the pH value and molar ratio, the sensitivity of the reactions to produce **1** and **2** with temperature is low under water bath conditions, unlike hydrothermal syntheses [4–6]. The synthesis of **3** is complete with the addition of ethanol at room temperature at pH 7.0. Complex **3** was isolated in a very low yield; this has not been reproduced at present.

Complexes **1** and **4** are soluble in water, while **2** and **3** are difficult to dissolve in water, even with strong heating. The chemical form and the structure of cobalt malate are dependent on the pH value and molar ratio. It is noted that water-soluble **1** exists in a physiological pH range, suggesting that it may serve as a model complex to study the coordination of cobalt with the biological malate system.

3.2. Description of the crystal structures

The X-ray crystal structure of complex **1** comprises two ammonium cations, the mesomeric anion $[Co(R\text{-}Hmal)(S\text{-}Hmal)]^{2-}$ and two water molecules. As illustrated in Fig. 1, the $[Co(R\text{-}Hmal)(S\text{-}Hmal)]^{2-}$ anion is octahedrally coordinated by two equivalent malates. The malato ligands bind in a tridentate fashion through the oxygen atoms of the α-hydroxy, α-carboxy and β-carboxy groups. Compared with the other water-soluble species *cis*-$[Co(H_2mal)_2(H_2O)_2] \cdot 2H_2O$ or *trans*-$[Co(H_2mal)_2(H_2O)_2] \cdot 2H_2O$ under acidic conditions, the deprotonation of the β-carboxylic acid group results in the tridentate coordination between pH 4.0–7.0. This type of coordination is also found in citrate complexes like $(NH_4)_4[M(Hcit)_2]$ (M = Co, Mn, Zn) [22–24], $(NH_4)_5[M(cit)_2] \cdot 2H_2O$ [M = Fe(III), Mn(III), Al(III), Ga(III)] [23,25,26] and $(NH_4)_3[Ga(Hcit)_2] \cdot 2H_2O$ [27]. The citrate ligand coordinates with the α-hydroxy or α-alkoxy, α-carboxy and β-carboxy groups, leaving the other β-carboxy or β-carboxylic acid group free. However, the present structure is a novel dimalato tridentate complex.

As illustrated in Fig. 2a, complex **2** comprises a dimeric unit of $[Co_2(R\text{-}Hmal)(S\text{-}Hmal)(H_2O)_4]$. Each Co^{II} ion in **2** exists in an octahedral environment and is surrounded by three different malates and two water molecules. The sixfold coordination polyhedron is severely removed from idealized octahedral symmetry. Specifically, the six apices of the oxygen coordination octahedron are occupied as follows. One malate ligand employs both of the α-hydroxy and α-carboxy oxygen atoms for two coordination positions, forming a five-membered chelate ring. Two additional malate ligands from two adjacently located octahedral Co^{II} ions coordinate through their β-carboxy oxygen atoms, O(4b) and O(5a). The remaining coordination sites are completed by two water molecules in a *cis*-configuration. Furthermore, both *R*- and *S*-malates exist in the dimeric unit.

In Fig. 2b, the dimeric unit labelled A connects Co(II) ions into macrocyclic loops labelled B. The B loop is formed by four dimeric A units. The two types of loops are arrayed alternately to form a 1D double-chain, which is similar to the one-dimensional structure of $[Zn_2(cpoa)_2(bpe)(H_2O)]$ [H_2cpoa = 4-carboxyphenoxy acetic acid, bpe = 1,2-bis(4-pyridyl)ethane] [28], and each A loop is further surrounded by four B loops, whereas two adjacent B loops are perpendicular to each other in parallel 2D layers.

Symmetric transformation for **1**: *a*, −*x* + 2, −*y*, −*z* + 2; **2**: *a*, *x* + ½, −*y* + ½, *z* + ½, *b*, −*x* + 2, −*y*, −*z* + 1; **3**: *a*, −*x* + 1, −*y*, −*z* + 2.

The difference between complex **2** and the other observed transition metal malate complexes, such as the one-dimensional structure of $[M(S\text{-Hmal})(H_2O)_2]_n\cdot nH_2O$ (M = Co, Ni) [3,29,30], is that each biionized malate moiety acts as a bidentate ligand coordinating to the Co^{II} ion *via* its α-hydroxy and α-carboxy groups. While the other β-carboxy group does not participate in the coordination to the same metal ion, instead it acts as a bridged ligand to bind another two Co^{II} ions simultaneously. This coordination mode of the dimeric unit $[Co_2(R\text{-Hmal})(S\text{-Hmal})(H_2O)_4]$ is novel among the cobalt malato complexes, but is similar to citrato cobalt and nickel cyclic dimers, such as $M_2[Co_2(Hcit)_2(H_2O)_4]\cdot 6H_2O$ (M = K or Na) and $M_2[Ni_2(Hcit)_2(H_2O)_4]\cdot nH_2O$ (M = K, *n* = 4; M = NH_4, *n* = 2) [31–33].

With the participation of alcohol, $K_4[Co_4(OH)_2(R\text{-mal})_2(S\text{-mal})_2(H_2O)_4]\cdot 10H_2O$ (**3**) is obtained at pH 7. The crystal structure of **3** comprises potassium cations, a tetranuclear malato cobalt anion and lattice water molecules. As shown in Fig. 3, the mixed-valence $Co^{II/III}$ ions in the cluster are held together by the bridging hydroxy and α-alkoxy groups. In the centrosymmetric tetramer, two types of octahedrally coordinated $Co^{II/III}$ ions can be distinguished as Co1 and Co2, which exist in normal octahedral environments. Two equivalent triionized malate ions coordinate with Co1 both *via* their α-alkoxy O(1) and O(6) atoms and α-carboxy O(2) and O(7) atoms, forming five-membered chelating rings. The oxygen atoms O(1) and O(6) are further coordinated to the adjacent Co^{III} ions. Moreover, the β-carboxy group does not participate in the coordination to the same metal ion, instead it binds the Co^{III} ion in the $Co_2(OH)_2$ unit [Co–O–Co = 96.3(2)°]. The remaining coordination sites of Co1 are completed by two water molecules in a *trans*-configuration. The two adjacent $Co^{II}(mal)_2$ and $Co_2^{III}(OH)_2$ units are further linked into a tetranuclear unit (Fig. 3). The distance between the two Co^{III} ions is 2.752(2) Å, which is close enough to involve metal–metal bonding interactions. This is similar to that [2.793(2) Å] of the dimeric Co^{III} complex $[Co_2(OH)_2(CH_3CO_2)_3(bpy)_2]\cdot ClO_4\cdot H_2O$ [34].

In the case of **3**, the partial aerial oxidation of the cobalt(II) ions is unexpected, which has not been previously observed for malic acid, but it has been found with other Schiff bases, like $[Co_2^{II/III}L(acac)(O_2CCH_2CO_2H)][Co_2^{II/III}L(acac)(OH)]\cdot 7H_2O$ [35]. It seems that this type of ligand favours the isolation of $Co^{II/III}$ mixed-valence complexes in a neutral or acidic medium. The oxidation of the initial cobalt(II) salt by atmospheric oxygen is highly dependent on the pH value of the medium.

The Co–O bond distances in **1**–**3** are summarized in Table 2. For **3**, the bond distances of the malate ligand to the cobalt ion range from 1.919(5) to 2.053(5) Å. The shortest Co–O bond in the malate ligand is observed for the α-alkoxy group with the Co^{III} ion, which is attributed to the deprotonation of the α-hydroxy group and the high valence cobalt ion. For the Co^{III} ion, the Co^{III}–O bond distances vary from 1.835(5) to 2.053(5) Å, which are shorter than the normal Co^{II}–O bonds.

$[(NMe_4)_3Na\{Co_4(cit)_4[Co(H_2O)_5]_2\}]\cdot 11H_2O$	2.075–2.142		2.055–2.157	[40]

Comparisons of the Co–O distances for malato and citrate cobalt complexes are given in Table 3. The tetranuclear complex **3** shows the shortest Co^{II}–O (α-carboxy) bond [2.009(5) Å] and **2** has the longest Co–O (α-hydroxy) bond [2.138(3) Å]. Other Co–O distances are shown in Table 3. The Co–O bond distances in malate cobalt are similar to the cobalt lactate $[Co(R\text{-Hlact})(S\text{-Hlact})(H_2O)_2]\cdot H_2O$ [2.018(3)–2.129(3) Å] (H_2lact = lactic acid) [36] and cobalt citrate in Table 3. Moreover, these Co–O distances are also comparable to those in the malato manganese and nickel complexes, for example $[Mn(S\text{-}H_2mal)_2(H_2O)_2]\cdot 4H_2O$ [2.134(1)–2.213(1) Å] [8] and $[Ni(S\text{-Hmal})(H_2O)_2]_n\cdot nH_2O$ [2.021(4)–2.082(5) Å] [29].

Bond valence calculations confirm the following information [41]. In the monomeric and dimeric complexes **1** and **2**, the bond valence values for the Co atoms are 2.19 and 2.06, respectively, indicating the +2 oxidation state for the Co ions. However, the bond valence values in **3** are 2.24 and 3.15 for Co1 and Co2, respectively, suggesting that Co1 has the +2 oxidation state, while the oxidation state for Co2 is +3. It is noted that there is partial oxidation of Co^{II} to Co^{III} in the reaction process, but the detailed mechanism is as yet unclear.

The FT-IR spectra of the title complexes display characteristic features of the coordinated malato ligand, shown in Figs. S1–S4. The absorptions for antisymmetric stretching carboxylate vibrations ν_{as} (COO) appear at 1591 and 1547 for **1**, 1596 and 1567 for **2**, 1593 and 1564 cm^{-1} for **3**, and the corresponding symmetric stretching vibrations ν_s (COO) appeared at 1364–1450 cm^{-1} for **1**–**3**. The frequencies of the coordinated carboxylate are shifted to lower frequencies compared to that of free malic acid, which is consistent with the absence of IR bands between 1700 and 1740 cm^{-1} for a typical undissociated carboxylic acid group. As shown in Figs. S5 and S6, the UV–Vis spectra of **1** and **4** in solution contain broad bands at 514 and 511 nm, respectively, which are assigned to the transition $^4T_{1\,g}(F) \rightarrow {}^4T_{2\,g}(P)$ and $^4T_{1\,g}(F) \rightarrow {}^4A_{2\,g}$ for an octahedral Co^{2+} ion, respectively [42]. The ^{1}H NMR spectra of **1** and **4** were tested in dilute solution. Due to the strong paramagnetic effect of the cobalt complexes, it was difficult to obtain the signals from the methylene and methenyl groups of the malate ligand.

4. Conclusions

From the above results, it was found that due to the flexibility of the H_3mal ligand, the complexes show interesting structures varying from monomer, dimer to tetramer, that are dependent on the pH value and molar ratio. The cobalt(II) malate complexes $(NH_4)_2[Co(R\text{-Hmal})(S\text{-Hmal})]\cdot 2H_2O$ (**1**), $[Co_2(R\text{-Hmal})(S\text{-Hmal})(H_2O)_4]_n\cdot 2nH_2O$ (**2**), $K_4[Co_4(OH)_2(R\text{-mal})_2(S\text{-mal})_2(H_2O)_4]\cdot 10H_2O$ (**3**) and *trans*-$[Co(R\text{-}H_2mal)(S\text{-}H_2mal)(H_2O)_2]\cdot 2H_2O$ (**4**) could be obtained in aqueous solution between pH 1.0 and 7.0. Compared to the other cobalt malate compounds previously reported, there are some remarkable features of these compounds: (a) although the starting malate was racemic, there is no enantiomer of malic acid coordinated with cobalt in these complexes. (b) Complex **2** shows a unique polymer structure with a novel dimeric unit that is different from the other cobalt malate complexes. (c) Complex **3** gives a unique tetranuclear mixed-valence structure, and the space between the two cobalt atoms Co2···Co2a is 2.752(2) Å, which is close enough to involve metal–metal bonding interactions. The solution isolation of the cobalt malates with pH and molar ratio dependence is helpful for the systematic understanding of the precursor method with malic acid.

exist predominantly in the G^+G^+ form [29,30], where the R groups are on opposite sides of the S–C–S plane. It is possible to distinguish between the two conformers with opposite helicity, generating the *P*- and the *M*-forms of optical antipodes. These characteristic twisted structures have implicit helicity in the spacer ligands and are of interest in terms of chiral crystal engineering.

The synthesis and structures of four new coordination polymers with 4bpytm, [Ag(4bpytm)](NO_3) (**1**), [Ag(4bpytm)](ClO_4) (**2**) and [Ag(4bpytm)](ClO_4) ½CH_2Cl_2 ½dmf (**2·Solv**), [Ag(CH_3COO)(4bpytm)]·H_2O (**3**) and [Ag(CF_3COO)(4bpytm)] (**4**), are described here. The NO_3^- and ClO_4^- anions do not coordinate to the silver(I) atoms and only act as counterions in complexes **1** and **2·Solv**. However, in complexes **3** and **4**, the carboxylate anions, $CH_3CO_2^-$ and $CF_3CO_2^-$, act as coordinating ligands, giving rise to a different degree of covalent polymerization and allowing the inclusion of crystallization water molecules in **3**.

2. Experimental

2.1. Materials and physical measurements

Bis(4-pyridylthio)methane was prepared as described previously [26]. The other starting materials and solvents were obtained commercially and were used as supplied. Elemental analyses (C, H, N, S) were carried out on a Fisons EA-1108 microanalyser. IR spectra were recorded from KBr discs (4000–400 cm^{-1}) on a Bruker Vector 22 spectrophotometer. A Shimadzu UV-3101PC spectrophotometer was used to obtain electronic spectra in the solid state. TGA analysis was carried out using a TA Instruments Hi-Res TGA2950 Thermobalance coupled to a Bruker Tensor 27 FT-IR apparatus. Powder X-ray diffraction data were obtained using Cu K_α radiation and were collected on a Siemens D-5000 diffractometer over the range 5.0–60.0° in steps of 0.20° (2θ) with a count time per step of 5.0 s.

Caution: Although problems were not encountered in this work, transition metal perchlorates are potentially explosive and should be handled with care.

2.2. Synthesis of the complexes

2.2.1. [Ag(4bpytm)](NO_3) (**1**)

Compound **1** was obtained by reaction of bis(4-pyridylthio)methane (4bpytm) (0.187 g, 0.80 mmol) in MeOH (10 mL) and $AgNO_3$ (0.80 mmol) in H_2O (10 mL). The resulting mixture was stirred for 24 h and the resulting white precipitate was filtered off, washed with EtOH and $CHCl_3$ and dried under vacuum. Single crystals were obtained by slow diffusion in a test tube of a solution of 4bpytm (23 mg, 0.10 mmol) in methanol (10 mL) and a solution of $AgNO_3$ (17 mg, 0.10 mmol) in water (10 mL). The X-ray power diffraction (XRPD) pattern of the resulting material do not show differences compared with that simulated from the crystal structure.

Data for **1**: Yield: 81%. *Anal.* Calc. for $C_{11}H_{10}N_3O_3S_2Ag$: C, 32.6; H, 2.4; N, 10.4; S, 15.9. Found: C, 31.9; H, 2.3; N, 10.0; S, 15.4%. IR (KBr, cm^{-1}): 1590s, 1537m, 1483m, 1361s, 1335s, 1222m, 1066m, 824m, 735m, 495m. UV–Vis (λ_{max}, cm^{-1}): 38 163.

2.2.2. [Ag(4bpytm)](ClO_4) (**2**) and [Ag(4bpytm)](ClO_4) ½CH_2Cl_2 ½dmf (**2·Solv**)

A solution of $AgClO_4$ (0.166 g, 0.80 mmol) in MeOH (10 mL) was added dropwise to a solution of 4bpytm (0.187 g, 0.80 mmol) in $CHCl_3$ (10 mL). The suspension was stirred for 24 h and the resulting white precipitate was filtered off, washed with $CHCl_3$ and dried under vacuum. Single crystals of **2·Solv** were obtained when a solution of bis(4-pyridylthio)methane (4bpytm) (59 mg, 0.25 mmol) in CH_2Cl_2 (3 mL) was slowly added to a solution of $AgClO_4$ (52 mg, 0.25 mmol) in CH_3CN (3 mL) layered with dmf (1.5 mL) in a test tube. The reagents were allowed to mix slowly by diffusion to form colorless crystals of **2·Solv**.

Data for **2**: Yield: 76%. *Anal.* Calc. for $C_{11}H_{10}N_2S_2O_4ClAg$: C, 29.9; H, 2.2; N, 6.3; S, 14.4. Found: C, 29.1; H, 2.0; N, 6.0; S, 13.9%. IR (KBr, cm^{-1}): 1596s, 1537m, 1481m, 1230s, 1144–1084s,b,sh, 797m, 734m, 630s, 492m. UV–Vis (λ_{max}, cm^{-1}): 38 461.

2.2.3. [Ag(CH_3COO)(4bpytm)]·H_2O (**3**)

Compound **3** was obtained by reaction of bis(4-pyridylthio)methane (4bpytm) (0.187 g, 0.80 mmol) in a 1:1 mixture of MeOH/$CO(CH_3)_2$ (10 mL) and Ag(CH_3COO) (0.134 g, 0.80 mmol) in H_2O (10 mL). The resulting mixture was stirred for 24 h and the resulting pale ochre precipitate was filtered off, washed with MeOH and dried under vacuum. Single crystals were obtained by slow evaporation of the colorless mother liquor. The XRPD pattern of the resulting material do not show differences compared with that simulated from the crystal structure.

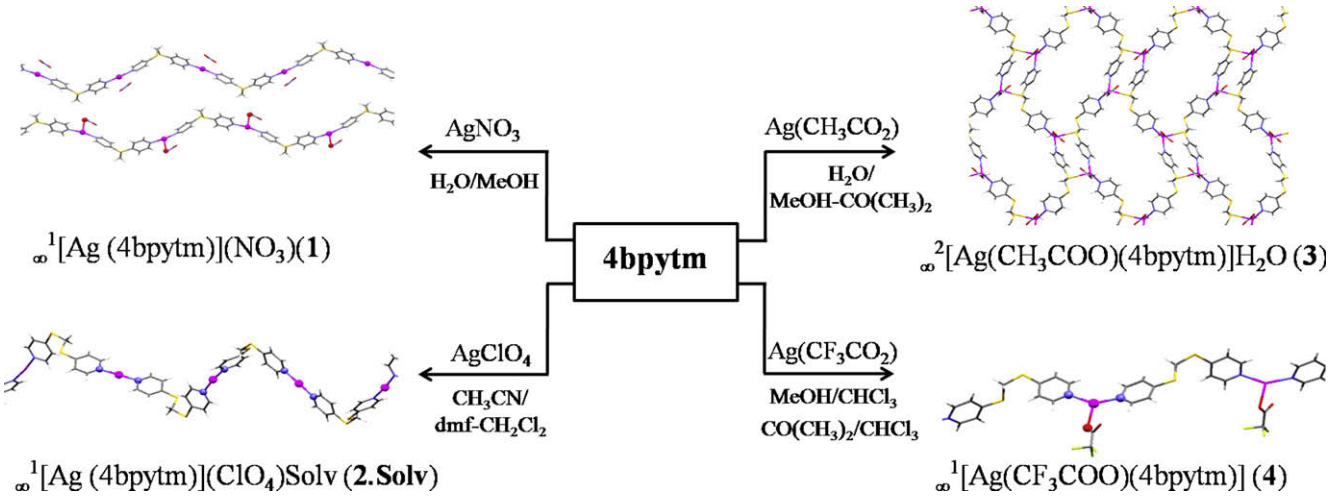
Data for **3**: Yield: 79%. *Anal.* Calc. for $C_{13}H_{15}N_2S_2O_3Ag$: C, 37.2; H, 3.6; N, 6.7; S, 15.3%. Found: C, 36.6; H, 3.4; N, 6.4; S, 14.9%. IR (KBr, cm^{-1}): 3418m, 1646m, 1576s, 1480m, 1410s, 1228m, 1063m, 797m, 735m, 491m. UV–Vis (λ_{max}, cm^{-1}): 38 461.

2.2.4. [Ag(CF_3COO)(4bpytm)] (**4**)

Compound **4** was obtained by reaction of bis(4-pyridylthio)methane (4bpytm) (0.187 g, 0.80 mmol) in $CHCl_3$ (10 mL) and Ag(CF_3COO) (0.177 g, 0.80 mmol) in MeOH (10 mL). The mixture was stirred for 24 h and the resulting white precipitate was filtered off, washed with $CHCl_3$ and dried under vacuum. Single crystals were obtained by slow evaporation of the colorless mother liquor. Crystals were also obtained by slow diffusion in a test tube of a solution of 4bpytm (70 mg, 0.30 mmol) in $CHCl_3$ (3 mL) and a solution of Ag(CF_3COO) (66 mg, 0.30 mmol) in $CO(CH_3)_2$ (3 mL). The XRPD pattern of the resulting material do not show differences compared with that simulated from the crystal structure.

Data for **4**: Yield: 80%. *Anal.* Calc. for $C_{13}H_{10}N_2S_2O_2F_3Ag$: C, 34.3; H, 2.2; N, 6.1; S, 14.1. Found: C, 34.2; H, 1.9; N, 5.9; S, 13.5%. IR (KBr, cm^{-1}): 1675s, 1578s, 1538m, 1482m, 1413s, 1202s, 1066m, 836m, 721m, 492m. UV–Vis (λ_{max}, cm^{-1}): 39 370.

2.3. Crystallography



Crystallographic data were collected on a Bruker Smart 1000 CCD diffractometer at 293 K using graphite monochromated Mo K_α radiation (λ = 0.71073 Å) and were corrected for Lorentz and polarization effects. The frames were integrated with the Bruker SAINT [31] software package and the data were corrected for absorption using the program SADABS [32]. The structures were solved by direct methods using the program SHELXS97 [33]. All non-hydrogen atoms were refined with anisotropic thermal parameters by full-matrix least-squares calculations on F^2 using the program SHELXL97 [34]. Hydrogen atoms were inserted at calculated positions and constrained with isotropic thermal parameters. Drawings were produced with MERCURY [35] and special computations for the crystal structure discussions were carried out with PLATON [36]. Crystal data and structure refinement data are listed in Table 1.

3. Results and discussion

All of the complexes were obtained as powders under quite similar reaction conditions in moderate to good yields (76–81%) from equimolar mixtures of silver(I) salts and the *N*,*N*′-ligand. A general reaction scheme is shown in Scheme 1. Single crystals of **1**, **2·Solv** and **4** were prepared by slow diffusion of different solutions of

Scheme 1.

the corresponding silver(I) salts into solutions of 4bpytm in MeOH or $CHCl_3$ at room temperature. Single crystals of **3** and **4** were prepared by slow evaporation of the mother liquors. The powder X-ray diffraction experiments of compounds **1**, **3** and **4** were compared with those simulated from the crystal structures to show that the crystals selected for crystallographic analysis are representative of the bulk materials. In almost all cases 1D coordination polymers (**1**, **2·Solv** and **4**) were obtained with the ligand acting in an *N*,*N*′-bis(monodentate) manner but the 2D coordination polymer **3** was obtained with the *N*,*N*′-ligand acting as a tridentate system. To the best of our knowledge, **1** and **2·Solv** are the first examples of 1D cationic coordination polymers with the 4bpytm ligand. All the complexes reported with this ligand are neutral coordination polymers, except the discrete binuclear species $[Cu_2(HmL)_4(4bpytm)]\cdot H_2O$ [28] and $[Cu_2(HL)_4(4bpytm)_3]$ [37]: (HmL = 2-methyllactate and HL = lactate).

The infrared spectra of these compounds show the characteristic absorption bands of the 4bpytm ligand [26], which is barely modified upon formation of the Ag(I) complexes. Intense absorptions at 1361 and 1335 cm^{-1} are observed for compound **1** and these are due to the nitrate anion. Complex **2·Solv** shows an absorption due to the perchlorate group as several bands in the range 1144–1084 and at 630 cm^{-1}, with the spectrum also having an absorption at 1674 cm^{-1} for the ν(C=O) band due to the dmf solvent molecule. The IR spectra of **3** and **4** show ν_{as}(C=O) bands at 1646 and 1675 cm^{-1} and ν_s(C=O) bands at 1410 and 1413 cm^{-1} in **3** and **4**, respectively. The value of the difference $\Delta\nu = (\nu_{as} - \nu_s)$ is greater than 200 cm^{-1}, which indicates that the carboxylate groups behave as monodentate ligands [38].

Microanalysis confirmed that, in each case, the 1:1 4bpytm ligand-to-metal ratio was conserved in these complexes. The diffuse reflectance spectra of the complexes exhibit a band in the range 38 100–39 400 cm^{-1} and this is characteristic of the 4bpytm ligand.

The thermal decomposition of the complexes was studied by thermogravimetric analysis. In the solvated compounds, the initial step is consistent with the escape of solvent molecules: a weight loss of 3.7% between room temperature and 135 °C in compound **3** corresponds to the release of the lattice water molecule (Calc.

4%) and in **2**·**Solv** the 16% loss between room temperature and 247 °C corresponds to the loss of the dmf and CH_2Cl_2 molecules (Calc. 14.3%). The second loss of 16% in **3** and 20% in **2**·**Solv** at 190 °C and 347 °C, respectively, agrees with the loss of weight corresponding to acetate (Calc. 14%) and perchlorate (Calc. 19.4%) anions, respectively. The final loss in both cases corresponds to the 4bpytm ligand. For compound **4** the decomposition occurs in only one step between room temperature and 216 °C, with a weight loss of 63% corresponding to the release of all the ligand content.

3.1. Structure of [Ag(4bpytm)](NO$_3$) (*1*)

Selected interatomic distances and angles and the main hydrogen bonds are listed in Tables 2 and 3. The coordination environment of the silver atom is shown in Fig. 1 together with the atom numbering scheme used. The structure is based on a 1D helical coordination polymer [Ag(4bpytm)](NO_3), which crystallized in the polar space group $Pca2_1$, with the Flack parameter being 0.10(3) [39].

Complex **1** is based on two different helical chains of the same helicity and each chain has silver atoms with a different environment. In one of the chains Ag1 is coordinated by two pyridine nitrogen atoms from different 4bpytm ligands and this gives a linear coordination geometry with an N–Ag–N bond angle of 171.9(3)° (Table 2). In the other chain Ag2 has a coordination close to a "T" shaped geometry [N21–Ag2–N11, 162.6(3)°; N21–Ag2–O31, 88.7(3)° and N11–Ag2–O31, 108.1(3)°] involving the NO_3^- anion in a weak coordination to Ag2, with an Ag···O distance of 2.688(6) Å, as observed in other silver(I) compounds [40,41]. Both silver atoms are bonded to nitrogen atoms of 4bpytm ligands with Ag–N distances in the range 2.144(7)–2.170(7) Å. The Ag···Ag distances in each chain separated by the bridging 4bpytm are 12.527 Å for Ag1 and 12.786 Å for Ag2. The chains run along the *c* axis and the 4bpytm ligands have C–S–C–S torsion angles of 64.3(5)° and 69.2(5)° in one chain and 68.4(5)° and 68.6(5)° in the other, with these values being smaller than those found in the free ligand [26] but in the range reported for other polymeric metal complexes [26–28]. The Ag(1) center presents secondary interactions with two nitrate anions, with Ag–O distances of 2.752(7) and 2.960(8) Å, and with a sulfur atom (S11) belonging to a neighboring chain at a distance of 3.352(2) Å (Table 2). The next closest atoms to the Ag2 center are an oxygen atom (O31) at a distance of 3.049(8) Å and a sulfur atom (S1) belonging to a neighboring chain at 3.234(2) Å. Both metal centers therefore have three secondary interactions at distances shorter than the corresponding sum of the van der Waals radii.

The chains are connected to give a 3D architecture by Ag···O and Ag···S interactions (Fig. 1, right). In this way, the nitrate anions, by means of Ag···O interactions, link chains of opposite helicity based on the same metal center (Ag1 or Ag2), the Ag2–S1 interaction also connects chains of opposite helicity but in this case they are based on a different silver cation and the Ag1–S11 linked chains of the same helicity and a different silver cation. The resulting 3D network is also stabilized by the effect of several hydrogen bonds

Table 2

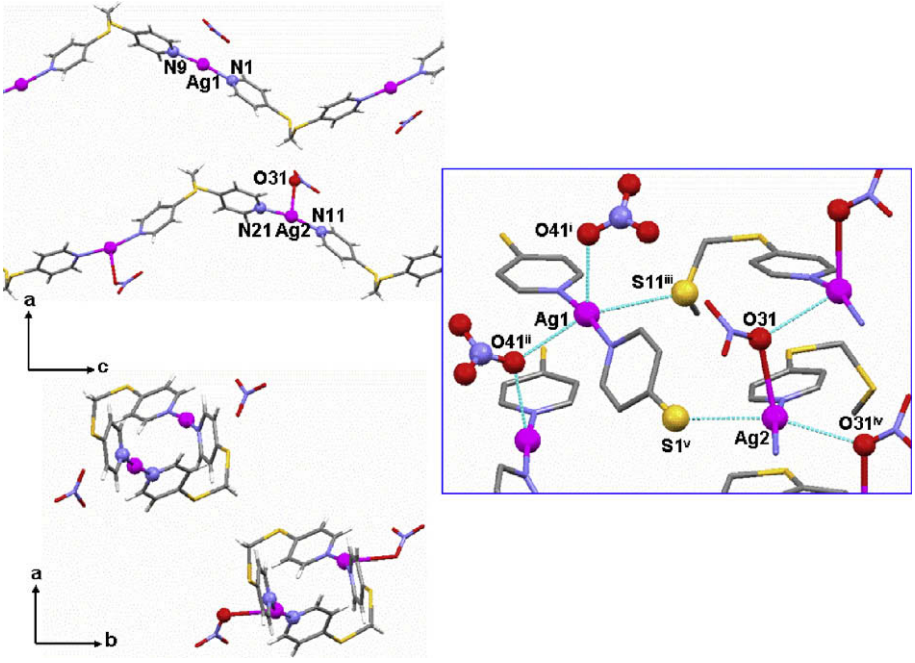

Fig. 1. Structure of [Ag(4bpytm)](NO$_3$) (**1**). Left: pictures showing the helical chains that run along the *c* axis. Right: Ag···S and Ag···O interactions between chains (some parts of the ligand have been omitted for clarity).

involving the –CH$_{py}$ and –CH$_2$ methyl groups of the ligand 4bpytm and the uncoordinated oxygen atom belonging to a nitrate anion (Table 3). The final 3D supramolecular architecture (Fig. 2) is racemic due to the existence of equal amounts of *P*- and *M*-helices.

It is clear that the nitrate anion plays a key role in the supramolecular assembly of **1**, which has a very efficient packing with a Kitaigorodskii packing index [42] of 75.6%, a value that is slightly greater than the index calculated for the coordination polymers previously reported with 4bpytm [26–28]. Although the nitrate anion could be classified as a potential coordinative anion [22], in this case the good solubility of AgNO$_3$ in water could be responsible for the semi-coordination or non-coordination of the anion to silver(I). According to these results it can be suggested that the solubility seems to be a major parameter for the crystallization [20].

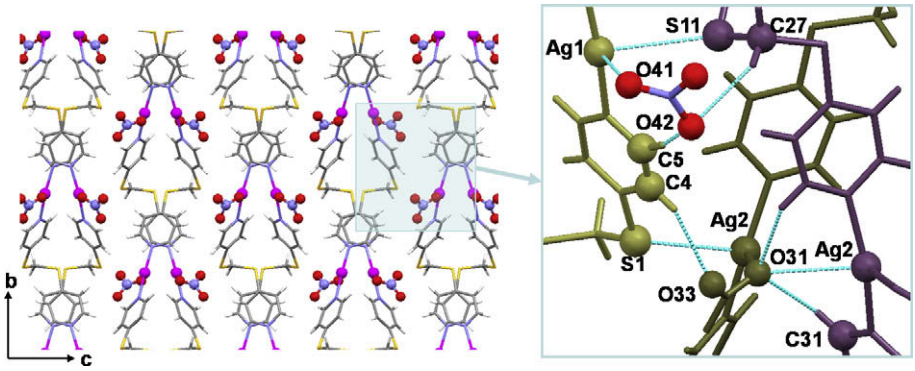

Fig. 2. View in the *bc* plane of the 3D architecture in **1**, showing in detail the main interactions (Ag···O, Ag···S and CH···O) between chains of opposite chirality.

3.2. Structure of [Ag(4bpytm)](ClO$_4$) ½CH$_2$Cl$_2$ ½dmf (**2·Solv**)

The coordination environment of the silver atoms in **2·Solv** is represented in Fig. 3 together with the atom numbering scheme. Selected bond distances and angles are listed in Table 2. The crystal structure of **2·Solv** consists of ClO_4^- anions, molecules of solvents and an $[Ag(4bpytm)]^+$ cationic chain. In the chain there are three crystallographically independent Ag^I centers, which are coordinated by two pyridine nitrogen atoms from two different 4bpytm ligands. Each silver center is in an almost linear coordination environment, with the Ag–N bond distances in the range 2.108(12)–2.191(11) Å, as expected for such coordination bonds [42,43,24], and with N–Ag–N angles of 172.7(5)° and 180.0(1)°. The ligand coordinates to the Ag^I centers in an *N,N*-bis-monodentate bridging mode with both *P*- and *M*-conformations, resulting in an infinite achiral chain with intramolecular Ag···Ag separations of 12.537 Å between Ag2–Ag3 and 12.177 Å between Ag2–Ag1. In the ligand the C–S–C–S torsion angles with values between 71.9(8)° and 174.6(7)° are larger than those found in the free ligand, in complex **1** and in the known polymeric complexes with the 4bpytm ligand [26–28]. These angles correspond to a TG conformation, which is much less common than the GG conformation [30,44]. This kind of conformation has only been observed in the molecular compound $[Cu_2(HL)_4(4bpytm)_3]$ (HL = lactate), where 4bpytm acts as monodentate ligand [37], meaning that **2·Solv** is the first example of a TG conformation in a coordination polymer with the 4bpytm ligand.

Another feature of **2·Solv** is the formation of a 3D network, as in **1**, by means of Ag···S and Ag···O interactions between adjacent chains (Fig. 3). The perchlorate anions are located next to the silver ions and are linked by Ag···O close contacts, with interaction distances in the range 2.940(9)–3.182(17) Å – i.e., shorter than the sum of van der Waals radii of silver and oxygen (3.24 Å) [47]. Ag1–S1 (3.357(4) Å) and Ag3–S12 (3.283(4) Å) are the next closest interactions between two different neighboring chains. The dmf molecule is linked to the Ag2 center at 3.107(13) Å, which indicates the presence of non-bonding Ag–O interactions. Therefore, the environments around the silver centers are different: Ag3 and Ag1 have four secondary interactions that involve two perchlorate anions and two adjacent chains towards semi-coordination with

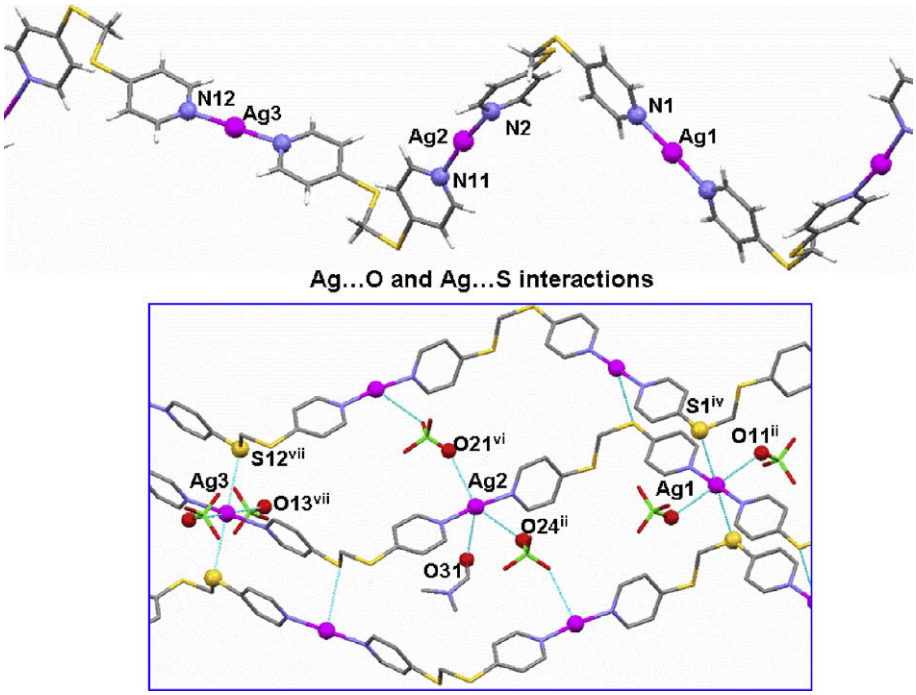

Fig. 3. Structure of [Ag(4bpytm)](ClO$_4$) ½CH$_2$Cl$_2$ ½dmf (**2·Solv**). Top: view of the silver atom environments with the corresponding labeling scheme. Bottom: view of the secondary interactions around each metal center.

the corresponding S atoms, but Ag2 only interacts with two perchlorate anions and one dmf solvent molecule (Fig. 3). The perchlorate anion is also linked to the framework by the effect of CH···O hydrogen bonds involving the pyridine rings and methyl groups of 4bpytm (Table 3, Fig. 4). In addition, the 3D association is reinforced by π–π stacking interactions (Fig. 4) between the [N2/C21/C22/C18/C19/C20] rings (coordinated to Ag3) of adjacent chains in a face-to-face mode with a centroid-to-centroid distance of 3.624(8) Å and an interplanar dihedral angle of 0.02°, which indicates the parallel disposition of the aromatic rings.

The resulting cavities in this network are filled by solvent molecules and perchlorate counterions as guest molecules (Fig. 4). The dmf and CH_2Cl_2 solvent molecules are involved in different weak interactions with the metal–organic framework. CH_2Cl_2 is only weakly linked by CH···Cl (with C–Cl distances greater than 3.5 Å) interactions to the metal–organic framework and, comparatively, this solvent is much more strongly connected to the perchlorate anions ($CH_{dichloromethane}$···$OClO_3$, C–O distance of 3.490(5) Å). On the other hand, dmf is linked to the network by means of several contacts, including Ag···O interactions, CH···O hydrogen bonds (Table 3) and CH···π interactions between one methyl group of dmf and the [N11/C12/C13/C14/C15/C16] ring of the 4bpytm ligand, with a CH···centroid distance of 3.527(18) Å and a CH···centroid angle of 123°. The volume occupied by the solvent is also evident in the corresponding values of the Kitaigorodskii packing index [42]: 59.4% when the solvent is omitted in the calculation and 73.3% when the solvent is included. The counterion and solvents filling the cavities of the network, which are weakly bonded to Ag(I), may act as a template for the formation of the network and consequently may contribute to the stability of the structure.

3.3. Structure of $[Ag(CH_3COO)(4bpytm)]\cdot H_2O$ (**3**)

The coordination environment of the silver atom in compound **3** is shown in Fig. 5 along with the atom numbering scheme used. The structure is based on 2D layers and water of crystallization. The AcO^- anion also acts as a coordinating monodentate anion. The Ag–O bond length (2.295(3) Å) is shorter than the normal range for Ag–O bond distances for silver carboxylate and oxalate complexes [48–50]. It is known that bidentate anions, such as AcO^-, have a higher density of negative charge on their peripheral, and therefore potentially interacting, atoms in comparison to NO_3^-, ClO_4^- and they are therefore able to coordinate more strongly [51]. The silver atom adopts a distorted tetrahedral geometry by coordination to two pyridine nitrogen atoms of each ligand, with $Ag–N_{py}$ distances of 2.245(4) and 2.263(4) Å, to an oxygen atom of acetate and to a sulfur atom from 4bpytm (Ag–O and Ag–S distances of 2.295(3) and 2.830(14) Å, respectively). In this way, each metal center is connected to three different ligand molecules and each ligand molecule is also coordinated by three Ag^I cations, thus generating the 2D network that is schematically represented in Fig. 5. The ligand adopts an *N,N,S*-tridentate bridging mode and it should be pointed out that this kind of coordination mode for 4bpytm has not been documented previously. The values for the C–S–C–S torsion angles in 4bpytm (79.1(3)° and 176.8(2)°) are similar to those found in **2·Solv** and they correspond to a TG conformation. Each Ag^I center is connected to four other Ag^I centers through the bridging ligand and, depending on the coordination mode of the ligand, the Ag···Ag distances are 7.376, 10.093 and 13.035 Å.

The 2D layer can be described as a rhombic grid with a major diagonal Ag···Ag distance of 20.65 Å and a minor diagonal Ag···Ag distance of 10.82 Å (Fig. 5). The crystallization water molecules are located in the void, as shown in Fig. 5, and they are undoubtedly responsible for the resulting 3D supramolecular organization, which is formed through hydrogen bonding involving the uncoordinated oxygen atoms of the carboxylato groups (Table 3). These layers are also linked by two kinds of weak interactions: CH···O hydrogen bonds, involving the water molecule and the coordinated oxygen of the acetate as acceptors (Table 3), and CH···π stacking

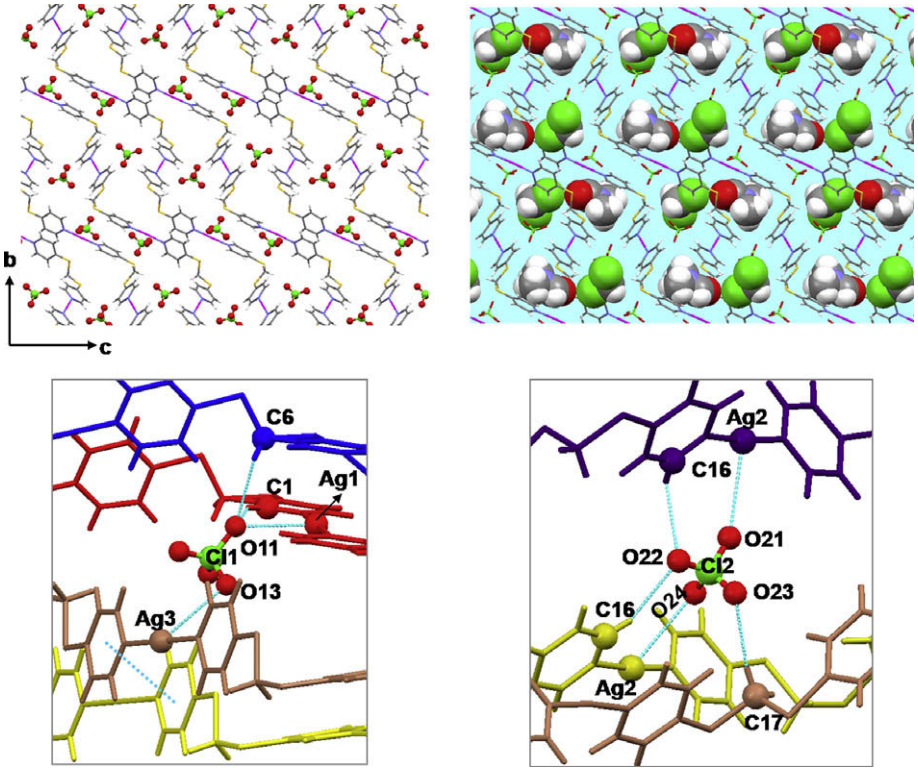

Fig. 4. View of the 3D architecture in **2·Solv** with perchlorate ions represented as "ball and stick" (top left) and solvent molecules shown as space filling representations (top right). Bottom: detail of main interactions that involve perchlorate anions.

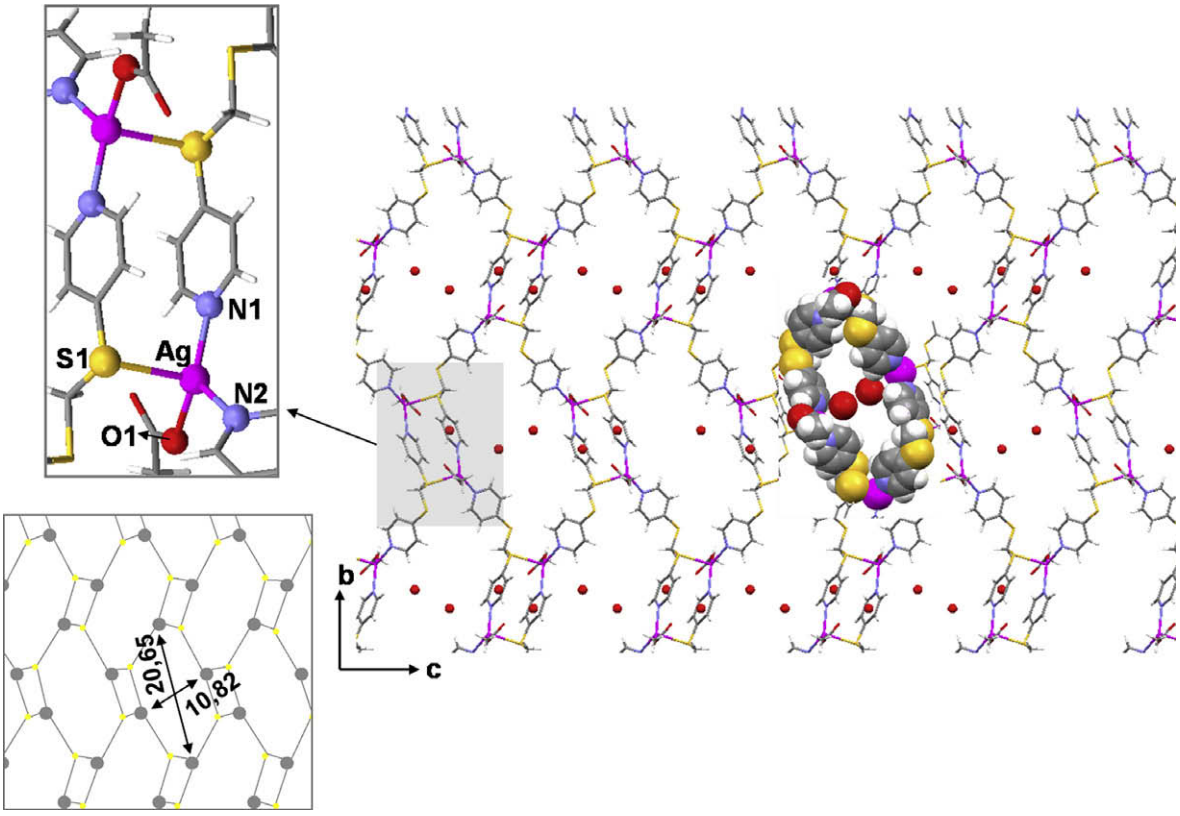

Fig. 5. View of the 2D coordination polymer [Ag(CH_3COO)(4bpytm)]·H_2O (**3**) together with the coordination environment of silver ions (top left) and a metric representation (bottom left).

interactions, involving the –CH belonging to the methyl group of the acetate ligand and the [N1/C1/C2/C3/C4/C5] ring of the 4bpytm ligand (Fig. 6). The CH···centroid distance is 3.884(5) Å with a C–H···centroid angle of 123°. These interactions link the 2D layer described above in an AB stacking mode (Fig. 6). In the resulting 3D network the molecules are packed very efficiently, with a Kitaigorodskii packing index [42] of 74.3%.

3.4. Structure of [Ag(CF_3COO)(4bpytm)] (**4**)

The structure of **4** is based on a 1D arrangement of Ag^I ions linked by 4bpytm ligands and trifluoroacetate anions. In this structure the Ag^I center is three coordinated by one oxygen atom of the organic anion and by two 4bpytm ligands through nitrogen donor atoms [Ag–N2 2.220(5), Ag–N1 2.230(6) Å] with a distorted trigonal planar coordination [N2–Ag–N1 139.6(2)°, N2–Ag–O1 116.2(2)°, N1–Ag–O1 102.7(2)°] (Fig. 7). The trifluoroacetate ion is coordinated to the silver atom in a monodentate manner with silver–oxygen distances of 2.354(6) Å. The Ag atom also interacts with one adjacent Ag atom, with an Ag–Ag distance of 3.2485(15) Å, and with an S atom from a neighboring chain, with an Ag–S distance of 3.359(5) Å. In both cases the distances are shorter than the sum of the corresponding van der Waals radii [47,51]. The Ag···Ag distance across the 4bpytm ligand is 13.903 Å, a slightly higher value than those found in the other complexes reported here. In the 4bpytm ligand the C–S–C–S torsion angle values of 81.5(4)° and 168.3(4)° are in the range reported for the polymeric metal complexes **2**·**Solv** and **3** and these adopt a TG conformation [45]. From the point of view of chirality, the 1D polymer consists of alternate linkages of the *M*- and *P*-forms of the ligand with the Ag^I ions. The chain is thus represented as –*M*–(Ag)–*P*–(Ag)–*M*–, resulting in an achiral structure running along the *b* axis.

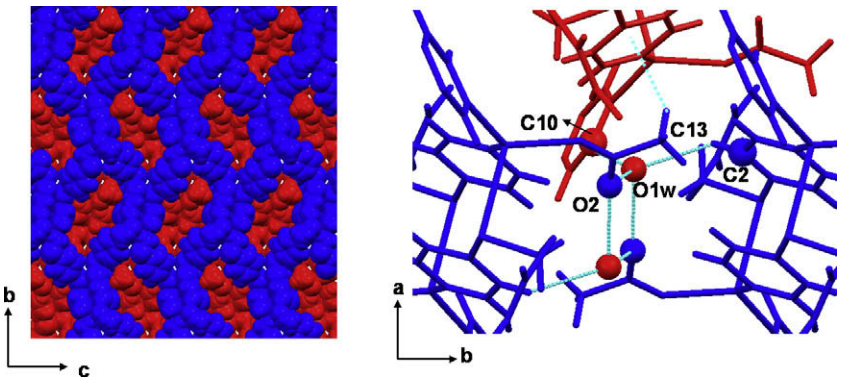

Fig. 6. View of the AB stacking mode of the layers (left) and details of the interactions with water of crystallization (right).

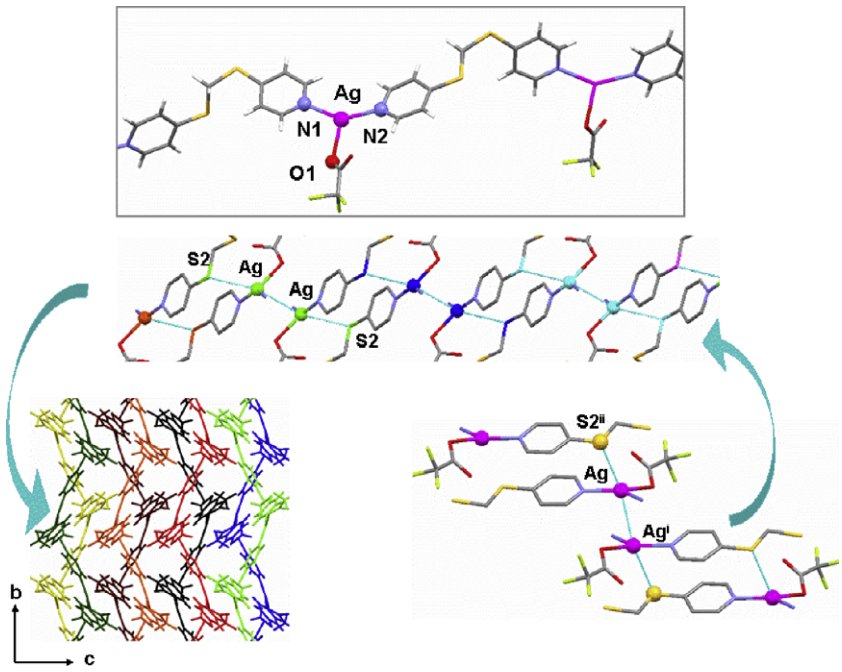

Fig. 7. View (top) of the 1D coordination polymer [Ag(CF_3COO)(4bpytm)] (**4**) together with the coordination environment of silver ions, showing detail of the S···Ag···Ag···S interactions. View in the *ab* plane of the 3D network (bottom left).

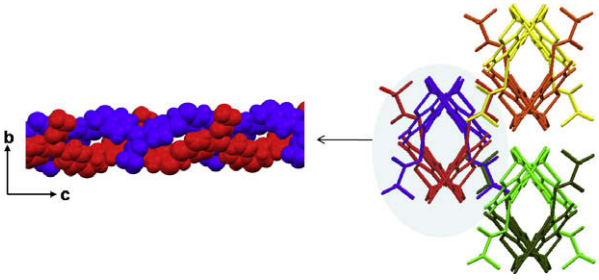

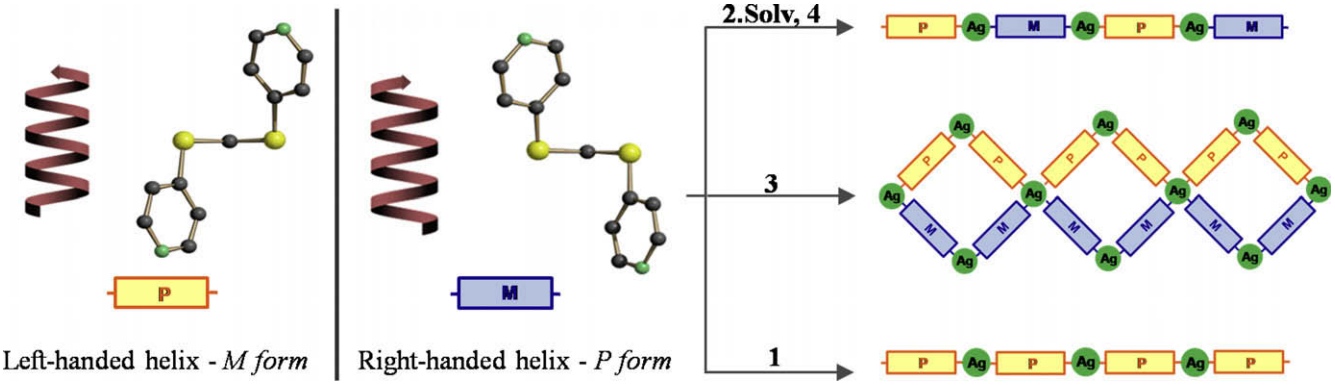

Fig. 8. View of the 3D organization showing details of the arrangement of the chains through Ag···Ag interactions.

The chains are interconnected through Ag–Ag and Ag–S interactions as well as weak CH···O hydrogen bonds (Table 3). Therefore, a specific combination of Ag–Ag and Ag–S contacts produces the pattern S···Ag···Ag···S (Fig. 7), which is mainly responsible for the 3D network. This network involves four chains in different points, as shown schematically in Fig. 7.

Taking into account only the effect of the argentophilic interactions, a double interweaved chain is formed, as shown in Fig. 8, and in turn these double chains are interconnected by means of the Ag···S interactions. In the resulting 3D network, the molecules are packed efficiently, with a Kitaigorodskii packing index [42] of 69.9%. Although electronegative atoms such as fluorine or oxygen, which are hydrogen bond acceptors, are present in the structure, weak CH···F or CH···O interactions do not play a significant role in the supramolecular organization.

4. Conclusions

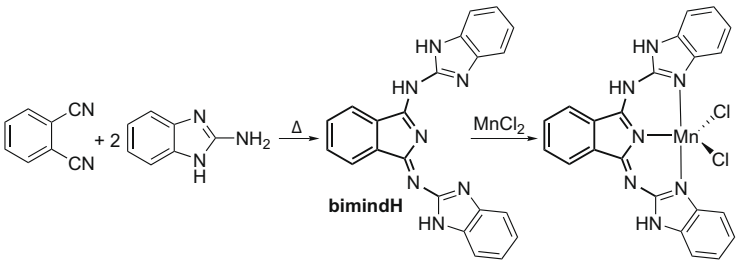
The Ag(I)/4bpytm system was investigated using inorganic and organic anions. $CH_3CO_2^-$ and $CF_3CO_2^-$ act as coordinating ligands giving rise to neutral coordination polymers, but with NO_3^- and ClO_4^- cationic chains are obtained. In all the compounds the cation is coordinated preferentially by the nitrogen atoms of 4bpytm in an *N*,*N*′-bis(monodentate) bridging mode and, only in one compound, the thioether sulfur is involved in coordination (*N*,*N*,*S*-tridentate bridging mode). From the viewpoint of chirality, the twisted structure of 4bpytm is accompanied by axial chirality (as shown in

Scheme 2.

Scheme 2) but the alternate linkage of the *M*- and *P*-forms affords achiral structures.

In the compounds with lower coordination number, the secondary interactions Ag···S and Ag···O play a crucial role in the self-organization of the supramolecular polymers and in one case the argentophilic interactions are also involved in the supramolecular organization. In one compound the Ag–S and Ag–O bonds are coordinating producing a 2D coordination polymer. When solvent is present, it influences the overall structure through its involvement in weak interactions or its role as a guest molecule in void space in the solid state.

Supplementary data



CCDC 702279, 702280, 702281 and 702282 contain the supplementary crystallographic data for **1**, **2**·**Solv**, **3** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

grown from dmf by diethyl ether diffusion. The intensity data were collected with Rigaku R-AXIS Rapid single-crystal diffractometer using Mo Kα radiation (λ = 0.71070 Å) at 130 K. Crystallographic data and details of the structure determination are given in Table 1, whereas selected bond lengths and angles are listed in Table 2. SHELX-97 [17] was used for structure solution and full matrix least squares refinement on F^2. The SQUEEZE function of PLATON was used to eliminate the contribution from the heavily disordered methanol solvent. Crystal structure has been deposited at the Cambridge Crystallographic Data Centre (Deposition no. 688573).

2.3. Synthesis of bimindH

It was prepared by fusing phthalonitrile (1.20 g, 9.4 mmol) and 2-amino-benzimidazole (2.5 g, 18.8 mmol) and maintaining a temperature of 190 °C until ammonia evolution ceased (~19 h). Extraction of the solid, which formed on cooling, into methanol gave yellow crystals on recrystallization (2.62 g, 71%). IR (KBr) cm^{-1}: 3278 m, 1642 m, 1630 s, 1614 vs, 1596 s, 1507 s, 1413 s, 1368 m, 1315 s, 1266 s, 1213 m, 1102 m, 1066 w, 997 w, 915 w, 821 m, 739 s, 694 s, 637 m, 563 w, 506 m. 2.4. Synthesis of [Mn(bimindH)Cl_2](dmf)

A solution of 0.59 g (3 mmol) of $MnCl_2 \cdot 4H_2O$ in 10 cm^3 CH_3OH was added to a suspension of 1.13 g (3 mmol) bimindH in 10 cm^3 CH_3CN and the orange yellow suspension was refluxed for 6 h. The solvent was removed by evaporation and the crude product was washed with cold CH_3OH and diethyl ether, and then dried under vacuum (1.28 g, 85%). The red product was recrystallized from dmf by ether diffusion. M.p. (Dec) 300 °C. IR (KBr) cm^{-1}: 3278 m, 1654 s, 1630 s, 1593 vs, 1569 s,1499 vs, 1421 s, 1315 m, 1283 w, 1184 m, 1091 m, 1037 m, 927 w, 784 w, 743 s, 702 s, 608 m, 522 w. UV–Vis (dmf) λ_{max} ($\log\varepsilon$/$dm^3\ mol^{-1}\ cm^{-1}$): 272 (4.15); 297 (4.23); 346 (4.288); 361 (4.313); 380.5 (4.229); 430 (4.333); 455 (4.394); 485.5 (4.192). ESR (toluene): g = 1.9998, A = 94.0 G. *Anal.* Calc. for $C_{22}H_{15}Cl_2MnN_7$: C, 52.51; H, 3.00; N, 19.48. Found: C, 52.23; H, 3.13; N, 19.28%.

2.5. Catalase-like activity

All reactions were carried out at 20 °C in a ~40 cm^3 reactor containing a stirring bar under air. The stoichiometry of the reaction was measured by simultaneous determination of the amount of O_2 and H_2O_2 concentrations. The evolved dioxygen was measured volumetrically, and amount of H_2O_2 was determined with the help of iodometric titration. In a typical experiment EtCN (30 cm^3) was added to the complex (0.04 mmol) and the flask was closed with a rubber septum. Dihydrogen peroxide (4–14 mmol) was injected through the septum with a syringe. The reactor was connected to a graduated burette filled with oil and dioxygen evolution was measured volumetrically at time intervals of 0.5 min. Observed initial rates were expressed as mol $dm^{-3}\ s^{-1}$ by taking the volume of the solution (30 cm^3) into account and calculated from the maximum slope of curve describing evolution of O_2 versus time.

3. Results and discussion

3.1. Synthesis and characterization of the [Mn(bimindH)Cl_2](dmf)

The synthetic route to the 1,3-bis(2′-benzimidazolylimino)isoindoline ligand involves the direct reaction of phthalonitrile and the 2-aminobenzimidazole at high temperature for 19 h followed

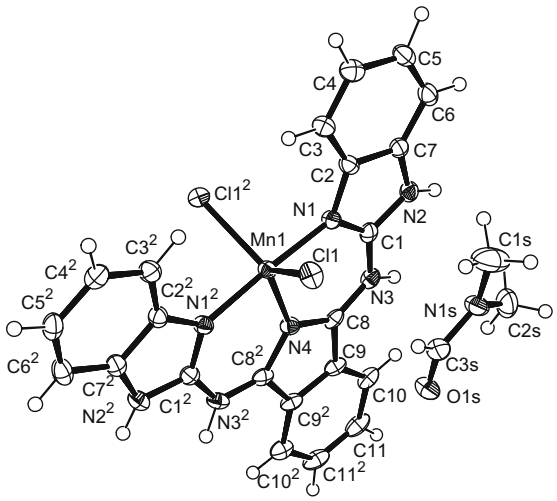

Fig. 1. Ellipsoid drawing of [Mn(bimindH)Cl_2](dmf) with the atom numbering scheme.

by extraction into methanol. This direct fusion method provides good yields and is a more efficient procedure than the syntheses involving 1,3-diiminoisoindoline as starting material. Reaction of equimolar amounts of 1,3-bis(2′-benzimidazolylimino)isoindoline and $MnCl_2 \cdot 4H_2O$ in methanol/acetonitrile resulted in the formation of [Mn(bimindH)Cl_2].

The Mn(II) ion is bound to a neutral tridentate isoindoline ligand and two chloride anions, forming a distorted trigonal bipyramidal environment around the metal ion. Analytical data, the infrared and the electronic spectrum of the complex are all consistent with the presence of a neutral nondeprotonated isoindoline ligand. Infrared spectra of metal complexes with deprotonated ligand versus nondeprotonated ligand show substantial differences in the region 1450–1660 cm^{-1} [18,19]. The infrared spectrum of [Mn(bimindH)Cl_2] has two strong absorptions at 1654 and 1630 cm^{-1}, and one weak at 3278 cm^{-1}, characteristic of a coordinated nondeprotonated isoindoline ligand. Complexes that contain deprotonated isoindoline ligands only exhibit weak bands above 1600 cm^{-1} [20,21]. The electronic spectrum of the [Mn(bimindH)Cl_2] complex is dominated by the π–π* transitions of the neutral ligand bimindH. Deprotonation of the pyrrole nitrogen could be reduced the difference in energy between occupied and unoccupied π–MOs of the ligand and resulted in a red shift of π–π* transitions (50–100 nm) [21].

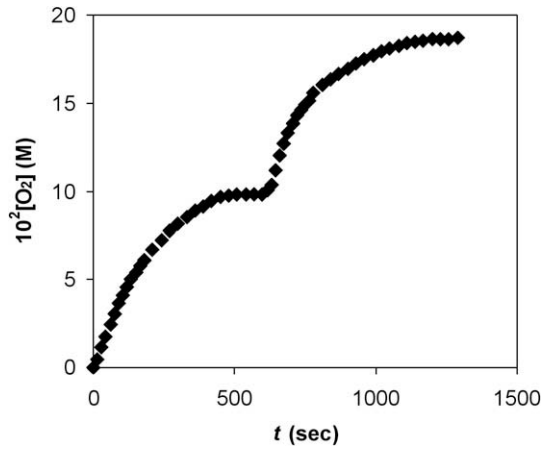

Fig. 2. Disproportionation of H_2O_2 in the presence of Mn(bimind)Cl_2 during the first two cycles at 20 °C in EtCN. [Mn(bimindH)Cl_2]$_0$ = 1.2×10^{-4} M, [H_2O_2]$_0$ = 2.0×10^{-1} M, [H_2O_2]$_{t\,=\,630\ s}$ = 2.0×10^{-1} M.

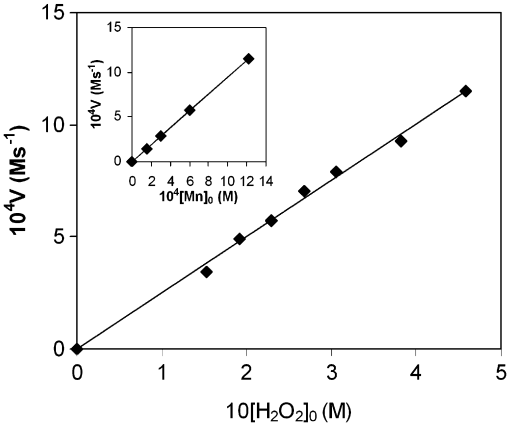

Fig. 3. Effect of the [H_2O_2] and [Mn(bimind)Cl_2] on the initial rate of H_2O_2 disproportionation at 20 °C in EtCN.

X-ray quality crystals of [Mn(bimindH)Cl_2](dmf) were grown from dmf by diethyl ether diffusion. The molecular structure of [Mn(bimindH)Cl_2](dmf) is shown in Fig. 1. The manganese(II) ion has a slightly distorted trigonal–bipyramidal geometry with $\tau = 0.93$ as judged by the method of Addison and co-workers [22]. Two chloride ions and one nitrogen atom of the isoindoline ligand occupy basal positions. The two other nitrogen atoms of the bimindH ligand are in apical positions. The Mn–N distance in the basal plane is shorter than those in apical positions.

3.2. Catalase-like activity

Compound [Mn(bimindH)Cl_2] is stable under ambient conditions and are not oxidized by atmospheric dioxygen. The catalase-like activity of the complex [Mn(bimindH)Cl_2] to disproportionate H_2O_2 into H_2O and O_2 was examined in EtCN at 20 °C by volumetric measurements of evolved dioxygen. Fig. 2 shows typical dioxygen uptake versus time curves for the disproportionation process during the first two cycles, supporting that the activity of the catalyst does not change under the conditions. At constant [H_2O_2]$_0$, the initial rate of H_2O_2 disproportionation varies linearly with the [catalyst], meaning that the reaction is first-order in catalyst (Fig. 3). The slope of the line gives a first-order rate constant (k) = 0.942 s^{-1} for a H_2O_2 concentration of 229 mM.

At low substrate concentrations, the reaction is also first-order in peroxide concentration as shown in Fig. 3, to establish a rate law of $-d[H_2O_2]/dt = k_{cat}[H_2O_2][Mn(bimindH)Cl_2]$. The slope of the line provides the bimolecular rate constant for a second-order reaction of 4.12 $M^{-1}\,s^{-1}$, which is somewhat slower than other published model compounds, but almost three times bigger than that of the Mn(indH)Cl_2–imidazole system (Table 3). This data suggest that the catalytic activity of the Mn(II) complex can be

controlled by the modification of electron donor properties on the ligand. On the basis of kinetic data and the lack of time-lag at the onset of the reaction suggest that the Mn(bimindH)Cl_2 is transformed from Mn(II) to Mn(IV)O on the addition of H_2O_2, which is reduced to its initial active form by another H_2O_2 molecule. Similar mechanism was proposed earlier for the Mn(indH)Cl_2–H_2O_2 system [14].

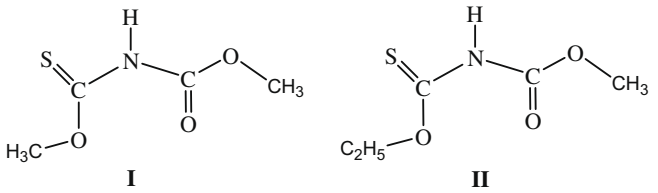
crystal structure and the FTIR spectra of O-ethyl benzoyl thiocarbamate ($R^1 = CH_3CH_2$, $R^2 = H$, $R^3 = C(O)C_6H_5$) were reported very recently, along with the first comparative quantum chemical study of the geometric and vibration properties of this type of compounds [16].

We report here a new method of synthesis for two simple O-alkyl N-methoxycarbonyl thiocarbamates, namely the O-methyl (**I**) and O-ethyl derivatives (**II**) (see Scheme 1), along with a complete characterization through GC–MS analysis and NMR (^1H and ^{13}C) and FTIR and FT-Raman vibration spectroscopy. The low-temperature crystal structure of $CH_3CH_2OC(S)N(H)C(O)OCH_3$ has been determined by X-ray diffraction methods. The experimental data were employed as references for quantum chemical calculations at the B3LYP/6-311++G** level of approximation.

2. Results and discussion

2.1. Synthesis



Kulkarni et al. [15,16] have reported a process for preparing N-alkoxy carbonyl isothiocyanate derivatives by reacting methyl chloroformate with metal thiocyanate salts in the presence of an organic solvent and a catalytic amount of a tertiary amine. This intermediate product is then converted to the corresponding thiocarbamate by reacting it with alcohols.

To avoid the use of methyl chloroformate, the $ROC(S)N(H)C(O)OCH_3$ species have been synthesized by the addition reaction between pure methoxycarbonyl isothiocyanate, $CH_3OC(O)NCS$ and the corresponding alcohol (ROH, R = CH_3– and CH_3CH_2–) without the use of solvent nor amine, according to Eq. (1)

$$CH_3OC(O)NCS + ROH \rightarrow ROC(S)N(H)C(O)OCH_3 \quad R = CH_3, CH_3CH_2 \qquad (1)$$

This method is an adaptation of those reported recently by Arslan et al. [16] for O-methyl N-benzyl thiocarbamate. Conventional vacuum techniques were used to condense pure $CH_3OC(O)NCS$ and an excess of methanol/ethanol in a Carius tube closed by a valve with PTFE stems (Young, London, UK). The reactions were performed at room temperature during 2 h. After removing the excess of ethanol in vacuum the remaining solid product was purified by sublimation in a 10^{-2} mbar vacuum at 50 °C, a procedure that afforded pure crystals of **II**. On the other hand, the O-methyl derivative was purified by column chromatography using a mixture of ether ethylic/hexane (3/1, v/v) as eluent solvent. The yield of O-methyl and O-ethyl N-methoxycarbonyl thiocarbamate was nearly quantitative. The final purity of the compounds was checked by IR and (^1H and ^{13}C) NMR spectroscopy.

$CH_3OC(O)NCS$ was prepared by thermal isomerization of $CH_3OC(O)SCN$. $CH_3OC(O)SCN$ was synthesized following the method reported by Haas and Reinke [17] for related XC(O)SCN (X = F and Cl) compounds. Accordingly, $CH_3OC(O)SCl$ (Aldrich, estimated purity better than 97%) was condensed in a tube containing AgCN (Aldrich, 97% purity) previously dried at 70 °C for 4 h. After 24 h at 20 °C, the volatile components were fractionated under dynamic vacuum through traps held at −10, −45 and −196 °C. Pure $CH_3OC(O)SCN$ was collected as a colorless liquid in the −10 °C trap, being the yield of the reaction of 95% (based on the quantity of $CH_3OC(O)SCl$ used). $CH_3OC(O)SCN$ is then heated at 50 °C for 4 h yielding an orange liquid which is further distilled in the same manner as described before. Pure $CH_3OC(O)NCS$ is obtained as a colorless liquid in the −10 °C trap. The yield of this isomerization reaction is *ca.* 60%. The final purity was confirmed by FTIR spectroscopy.

Scheme 1. O-methyl (**I**) and O-ethyl (**II**) N-methoxycarbonyl thiocarbamates.

2.2. Physical properties and spectroscopic characterization

Compounds **I** and **II** are white solids with melting points of 44(1) and 78(1) °C, respectively.

The ^1H NMR spectrum for $CH_3OC(S)N(H)C(O)OCH_3$ shows three singlet bands at $\delta = 8.39$ (*s*, N–H broad), 4.13 (s, $^1J_{HC} = 74.2$ Hz, $CH_3OC(O)$–) and 3.77 (s, $^1J_{HC} = 74.2$ Hz, $CH_3OC(S)$–) ppm, ($^1J_{HC}$ coupling constant values for both O–CH_3 groups were obtained from the ^{13}C satellites). The ^{13}C NMR spectrum shows signals at $\delta = 189.6$ and 149.8 ppm assigned to the C=O and C=S, respectively and signals at 59.5 and 53.4 ppm corresponding to the carbon atoms in the methoxy moieties, –OCH_3, respectively bonded to the C=S and C=O groups.

The ^1H NMR spectrum of $CH_3CH_2OC(S)N(H)C(O)OCH_3$ shows four signals at $\delta = 8.26$ (s, N–H broad), 4.60 (q, $^3J_{HH} = 7.1$ Hz, –CH_2–), 3.76 (s, $^1J_{CH} = 74.0$ Hz, CH_3O–) and 1.41 (t, $^3J_{HH} = 7.2$ Hz, –CH_3). The ^{13}C NMR spectrum shows five signals at $\delta = 188.8$, 149.7, 69.3, 53.3 and 13.9 ppm, assigned to the carbon atoms of the C=O, C=S, CH_2, CH_3O and CH_3 groups, respectively.

These assignments are clearly supported by HSQC (heteronuclear single quantum coherence) 2D-NMR spectroscopy as can be appreciated in the Supplementary data (Figs. S1 and S2). The ^1H and ^{13}C NMR spectral assignments are compatible with those previously reported for thiocarbamate compounds [2,5,18].

GC chromatogram shows a single peak at retention times of 7.3 and 10.6 min for compounds **I** and **II**, respectively. In the GC–MS spectra, both compounds show the molecular ion ($M^{\cdot+}$) peak as a strong intensity signal at *m/z* 149 for O-methyl and 163 for O-ethyl derivative compounds. The mass spectra were assigned to expected ionic fragments from logical ruptures of the corresponding $M^{\cdot+}$ molecular ions as shown in Table 1.

Additional evidences for identifying the synthesized compounds come from the analysis of their IR and Raman spectra in the solid phase (see Figs. 1 and 2 and Tables S2 and S3 of the Supplementary data). Thus, the characteristic broad band for amides assigned to the N–H bond stretching are observed at 3216 cm^{-1} and 3204 cm^{-1} in the IR spectra of the O-methyl and O-ethyl derivatives, respectively. One of the most intense bands observed in the IR and Raman spectra is centered at 1768 (1761 cm^{-1} in Raman)

Table 1
Main peaks observed in the mass spectra (70 eV electron ionization) of $CH_3OC(S)N(H)C(O)OCH_3$ (**I**) and $CH_3CH_2OC(S)N(H)C(O)OCH_3$ (**II**).

m/z	Intensity (%)		Fragments

and 1770 cm^{-1} (1768 cm^{-1} in Raman), characteristic of the carbonyl stretching mode of compounds **I** and **II**. Characteristic strong absorptions due to the stretching mode of the C═S groups appear at 1255 and 1266 cm^{-1} in the IR spectra of compounds **I** and **II**.

2.3. Quantum chemical calculations

Theoretical studies on carbamic acid and thiocarbamic O- and S-acids were undertaken by Remko et. al. [19] One of the important characteristic of these systems is the electronic resonance on the thioamide group [1]. However, there is only one previous work dealing with theoretical studies on thiocarbamate derivatives [16]. Following these works, the molecular geometry and vibrational spectra of $ROC(S)N(H)C(O)OCH_3$ ($R = CH_3-$ and CH_3CH_2-) were calculated by the B3LYP density functional method with 6-31G* and the more extended 6-311++G** basis sets.

In principle, the studied compounds may adopts several conformations, depending on the orientation around each of the C–O, O–C, C–N, N–C and C–O single bonds. Taking into consideration structural studies previously reported for the methoxycarbonyl –$C(O)OCH_3$ moiety [20–26], a *syn* orientation of the δ(O═C–OC) dihedral angle is preferred, being the *anti* form higher in energy. Thus, special attention was dedicated to the ROC(S)N(H)C(O)– moiety of the title compounds.

To analyze the conformational preferences of the compounds studied in the present work, the potential energy functions for internal rotation around the δ(C5C4–O3C3), δ(C4O3–C3S), δ(SC3–NC2) and δ(C3 N–C2O2) dihedral angles were calculated at the B3LYP/6-31G* level by allowing geometry optimizations with the respective dihedral angles (δ) varying from 0° to 360° in steps of 30°. The potential energy functions for compounds **I** and **II** are shown in Fig. 3 (see Fig. 4 for atoms numbering). The curve obtained for the δ(C5C4–O3C3) dihedral angle corresponding to the O-ethyl derivative (Fig. 3A) clearly indicates the presence of two minima, the most stable conformation corresponding to a mutual *anti* orientation of the C5–C4 and O3–C3 bonds in the ethyl group [δ(C5C4–O3C3) = 180°], while a second stable *gauche* form is located slightly higher in energy by *ca.* 0.89 kcal mol^{-1}. The other dihedral angles considered are common for both studied compounds and very similar potential curves are calculated, as shown in Fig. 3. The curve obtained as a function of the dihedral angle around the O3–C3 bond shows a deep minimum at δ(C4O3–C3S) = 0°, corresponding to a mutual *syn* orientation of the C4–O3 and C═S bonds. The potential energy curves for the rotation of the amidic-like groups characterized by the δ(SC3–NC2) and δ(C3 N–C2O2) dihedral angles present minima for both *syn* and *anti* planar forms. The *anti* conformation of the C═S bond with respect to the N–C2 bond is more stable by *ca.* 2.6 kcal mol^{-1} than the *syn* conformer [δ(SC3–NC2) = 0°]. On the other hand, the *syn* form is *ca.* 1.2 kcal mol^{-1} more stable than the *anti* conformation when the δ(C3 N–C2O2) dihedral angle is considered.

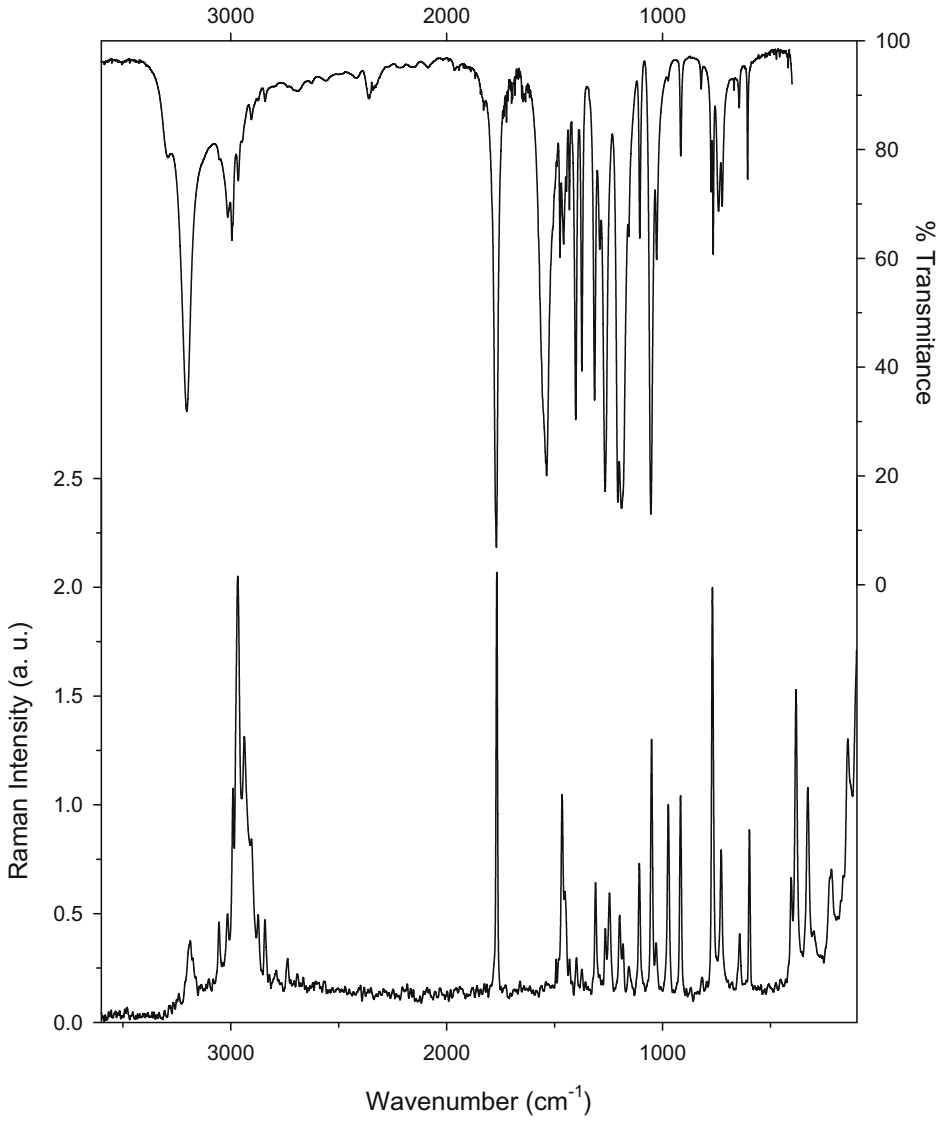

Fig. 2. Solid IR (in KBr pellet) and Raman spectra for $CH_3CH_2OC(S)N(H)C(O)OCH_3$.

Additionally, full geometry optimizations and frequency calculations were computed for each of the more stable structures of both compounds with the B3LYP method and the 6-31G* and 6-311++G** basis sets. Predicted relative energies, ΔE° (corrected by zero-point energy), are given in Table 2. The optimized molecular structures for the main conformers of the studied compounds are shown in Fig. 4. Accordingly, the most stable conformation for compound **II** is the one with alternated *anti–syn–anti–syn* (*a–s–a–s*) mutual orientations around the C4–O3, O3–C3, C3–N and N–C2 single bonds, respectively. The conformation with *syn*, *anti* and *syn* orientation around to the O3–C3, C–N and N–C2 single bonds, respectively –named as *syn–anti–syn* (*s–a–s*) in Fig. 3 is the most stable form of $CH_3OC(S)N(H)C(O)OCH_3$.

The second more stable conformation of compound II, higher in energy by only 0.89 kcal mol^{-1} (B3LYP/6-311++G**) with respect to the most stable form, corresponds to a conformer with *gauche* orientation of the δ(C5C4–O3C3) dihedral angle (*gauche–syn–anti–syn* form in Fig. 4). The next stable conformer (ΔE° = 1.48 kcal mol^{-1}) possesses *anti* orientation of the δ(C3 N–C2O2) dihedral angle (*anti–syn–anti–anti* conformation in Fig. 4). In the case of compound **I**, the second more stable conformer (ΔE° = 1.35 kcal mol^{-1}) exhibits its *anti* orientation of the δ(C3 N–C2O2) dihedral angle (*syn–anti–anti* conformation in Fig. 4).

Other conformers of $ROC(S)N(H)C(O)OCH_3$ (R = CH_3– and CH_3CH_2–) were found to be stable with calculated energies higher than 1.5 kcal mol^{-1} and are also included in the Table 2. Selected geometric parameters calculated (B3LYP/6-311++G**) for the most stable conformers of the title compounds are compared with the experimental values (see below) in Table 3.

2.4. Vibrational analysis

To our knowledge, neither experimental nor theoretical vibration analysis for $ROC(S)N(H)C(O)OCH_3$ (R = CH_3– and CH_3CH_2–) have so far been performed. The IR and Raman spectra of solid $CH_3OC(S)N(H)C(O)OCH_3$ and $CH_3CH_2OC(S)N(H)C(O)OCH_3$ are shown in Figs. 1 and 2, respectively. Experimental and calculated [B3LYP/6-311++G**] frequencies and intensities are given as Supplementary data (Table S2 and S3). A tentative assignment of the observed bands was carried out by comparison with spectra of related molecules [16,18,27–33]. The gas-phase molecular symmetry of the studied species is C*s* for both compounds and therefore all 42 (27A′ + 15A″) and 51 (32A′ + 19A″) normal modes for compounds **I** and **II**, respectively, are active in the IR and Raman spectra. The general features of the vibration spectra of solid $ROC(S)N(H)C(O)OCH_3$ (R = CH_3– and CH_3CH_2–) can be explained by supposing

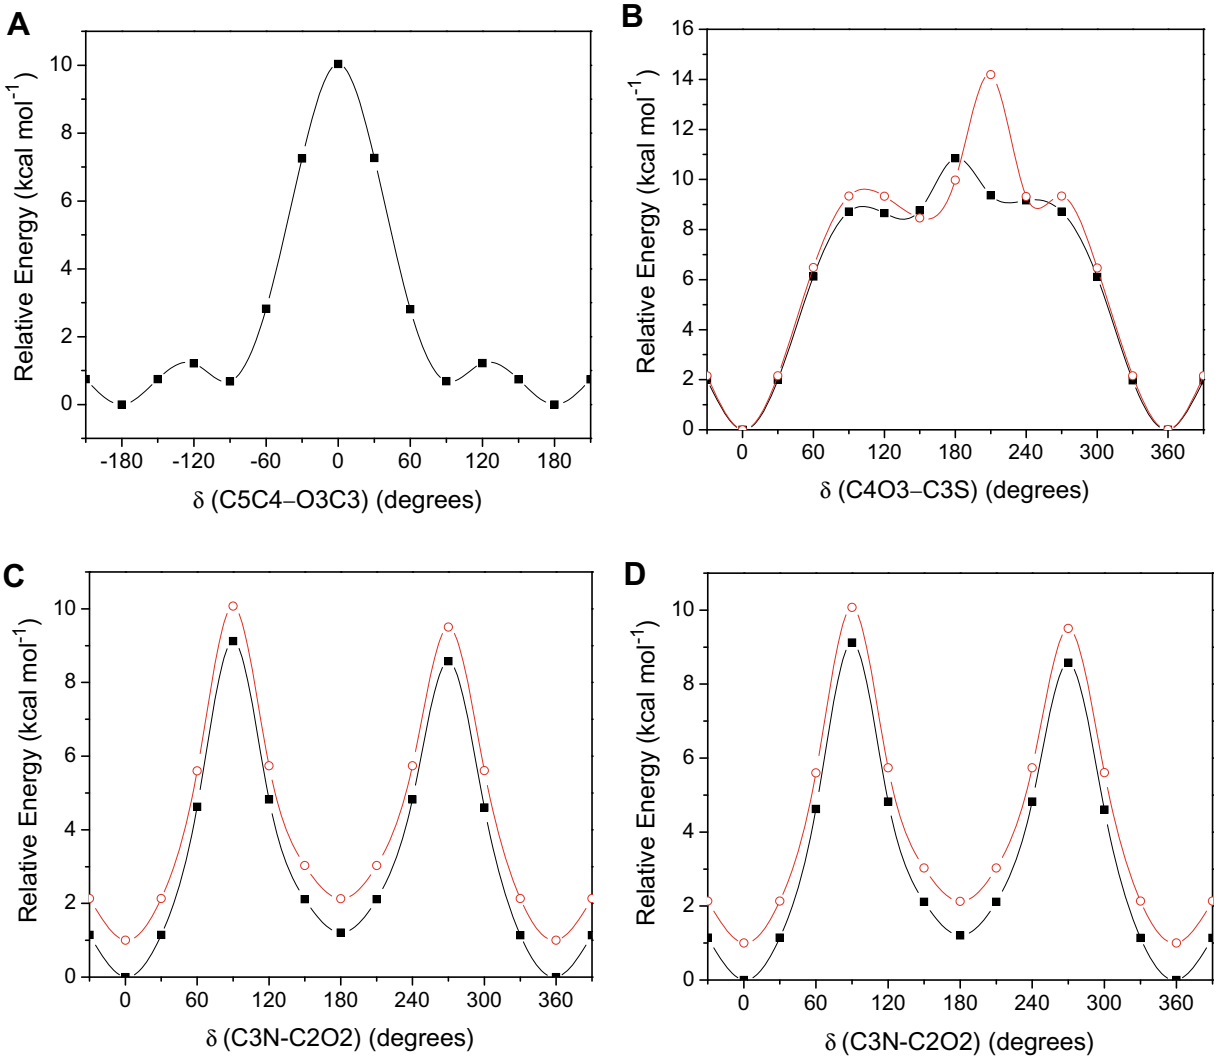

Fig. 3. Calculated (B3LYP/6-31G*) potential function for internal rotation of ROC(S)N(H)C(O)OCH$_3$ (—■— R = CH_3CH_2– and —○— R = CH_3–) as a function of the δ(C5C4–O3C3) (A), δ(C4O3–C3S) (B), δ(SC3–NC2) (C) and δ(C3N–C2O2) (D) dihedral angles. For the last two dihedral angles, the curve corresponding to the compound **I** was shifted by 1 kcal mol^{-1} in energy.

the solely presence of the most stable *syn–anti–syni* and *anti–syn–anti–syn* conformers, respectively. The assignment of the characteristic vibration modes of the main –OC(S)N(H)C(O)O– moiety is summarized in Table 4.

The intense IR absorptions at 3216 cm^{-1} (**I**) and 3204 cm^{-1} (**II**) are assigned to the N–H stretching mode. These values agree with the corresponding ones in the IR spectrum of O-ethyl benzoylthiocarbamate, where this mode is observed at 3256 cm^{-1} [16]. For other related molecule, namely N-(morpholinothiocarbonyl)benzamide, similar results were reported [34]. A single absorption is observed in the carbonyl stretching region for O-methyl and O-ethyl N-methoxycarbonyl thiocarbamates. Thus, the strong IR absorptions at 1768 and 1770 cm^{-1} with counterparts in the Raman spectra at 1761 and 1768 cm^{-1} were assigned to the ν(C=O) modes. Calculated (B3LYP/6-311++G**) frequencies for this mode are slightly higher: 1828 and 1826 cm^{-1} for O-methyl and O-ethyl N-methoxycarbonyl thiocarbamates, respectively. The IR absorptions observed at 1255 and 1266 cm^{-1} were assigned to the ν(C=S) mode for compounds **I** and **II**, in good agreement with the calculated values (Table 4). The formation of C=S···H–X intermolecular hydrogen bonds seems to strongly effect the frequency of the ν(C=S) mode. For example, a strong band at 1203 cm^{-1} was observed in the IR spectra of (E)-O-ethyl N-(4-chlorophenyl)thiocarbamate, a molecule which presents intermolecular hydrogen bonds [27], while the ν(C=S) stretching frequency for some free thioureas are reported lo lay in the region around 1325 cm^{-1} [31]. The relatively low frequency values for the ν(C=S) stretching mode observed in the IR spectra of the title compounds can be related to the formation of intermolecular hydrogen bonds involving the thiocarbonyl group. Indeed, C=S···H–N bonds are observed in the X-ray crystal structure of compound **II**, as will be discussed in the next section.

In connection with the amide- and thioamide-like groups, strong IR absorptions at 1548 and 1537 cm^{-1} of compounds I and II (Figs. 1 and 2) are assigned to the in-plane N–H deformation mode [δ(N–H), A′]. Medium intensity IR absorptions at 1345 and 1315 cm^{-1} (1345 and 1310 cm^{-1} in the Raman) are assigned to the C(S)–N stretching mode. Strong IR absorptions at 1205 and 1190 cm^{-1} are assigned to the N–C(O) stretching mode of O-methyl and O-ethyl N-methoxycarbonyl thiocarbamate, respectively, in agreement with reported data for related species [16,30].

Others clearly defined bands in the IR and Raman spectra (see Table 4) correspond to the C=O and N–H out-of-plane deformation modes, observed as strong Raman dispersions at 781 cm^{-1} (**I**) and

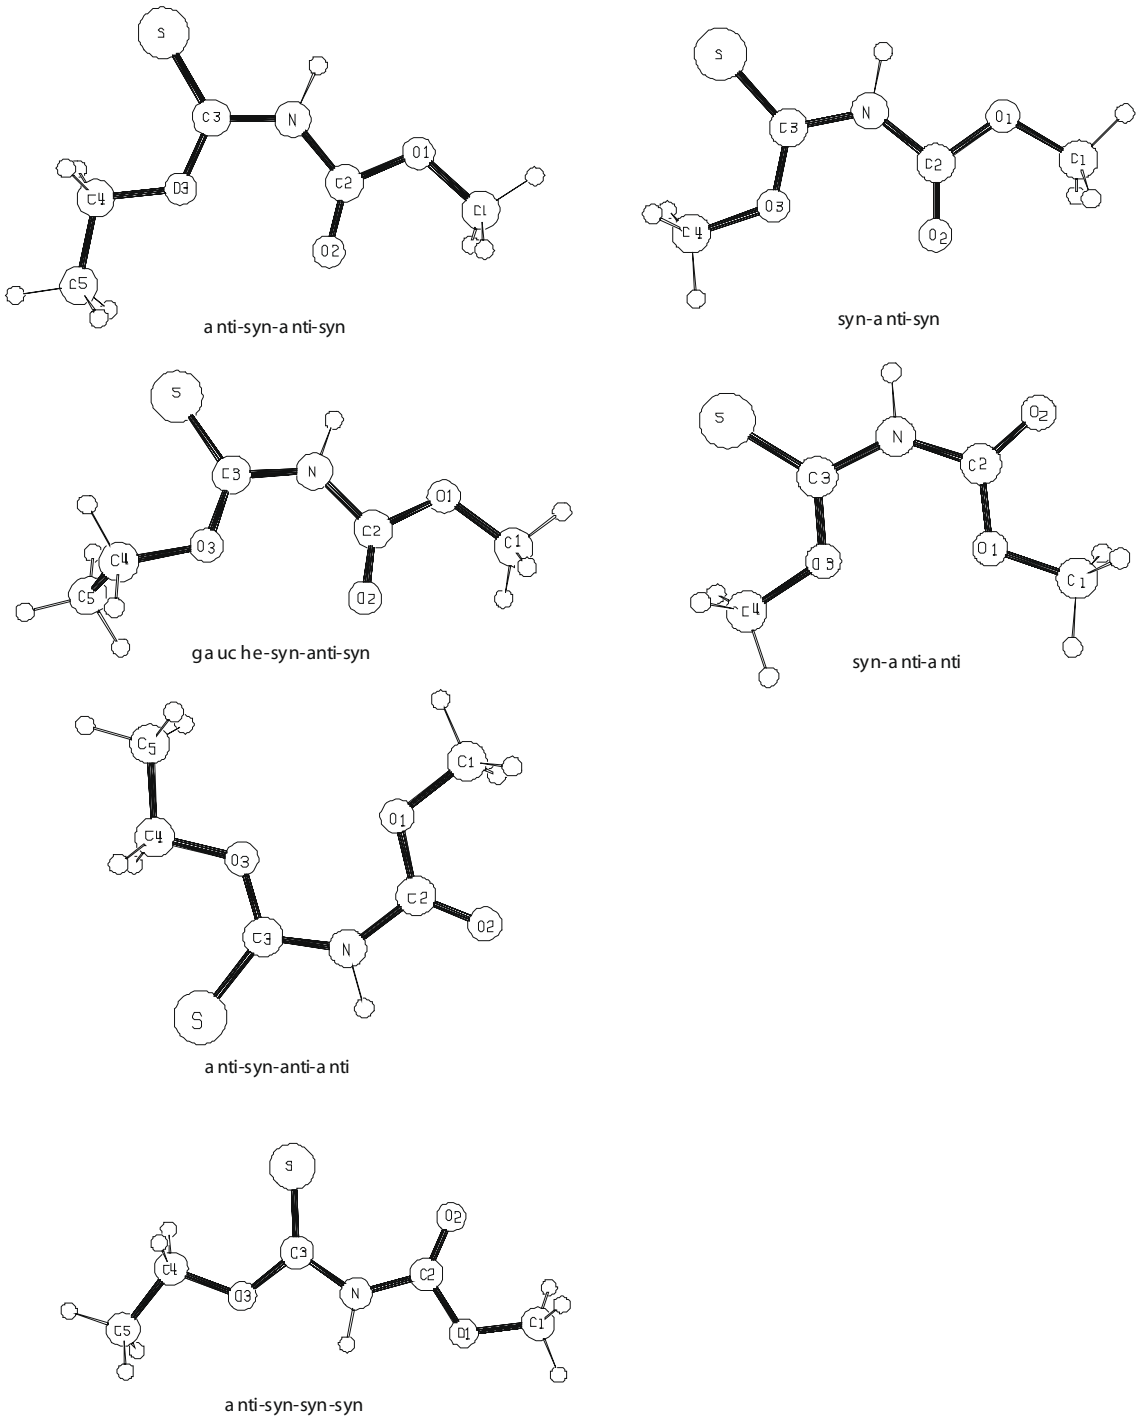

Fig. 4. Molecular structure of the main conformers of O-ethyl N-methoxycarbonyl thiocarbamate (left side) and O-methyl N-methoxycarbonyl thiocarbamate (right side) found theoretically with atom numbering.

766 cm^{-1} (**II**). The corresponding IR absorptions due to C═S out-of-plane deformation mode are observed at 590 and 646 cm^{-1} (583 and 643 cm^{-1} in Raman) for compounds **I** and **II**, respectively.

2.5. X-ray diffraction analysis

Crystal data and structure refinement results for O-ethyl N-methoxycarbonyl thiocarbamate are summarized in Table 5. An ORTEP [35] drawing of the molecule is shown in Fig. 5 and Table 3 includes the main geometric parameters derived from the structure refinement, as well as those obtained from quantum chemical calculations. In general, the parameter computed with theoretical calculations agree fairly well with those refined from the X-ray analysis.

Only molecules of **II** having the *anti–syn–anti–syn* conformation are found in the crystal. Thus, the molecules adopt a conformation with both O and S donor atoms in mutual *trans* orientations relative to each other, with torsion angles almost planar. Thus, experimental studies reported for related thiourea compounds show also an almost planar conformation around the –NC(S)N– unit [36,37]. The *trans* orientation of sulfur and oxygen donor atoms within the –C(S)NHC(O)– moiety has a significant role on the

molecular packing of the title compound. This conformation is stabilized in the crystal by the occurrence of intermolecular N–H···S=C hydrogen bonds [d(N···S) = 3.387(1) Å] between adjacent molecules. Pairs of molecules related by a crystallographic inversion center can interact forming a planar dimeric unit (see Fig. 5). This type of hydrogen-bond formation represents an example of π-bond cooperative behavior, frequently called "Resonance-Assisted Hydrogen Bonding" (RAHB) [38], which occurs when XH groups are polarized by charge flow through π-bonds. As a result of the dual donor and acceptor capacity of the thioamide unit, intermolecular N–H···S=C hydrogen bonds are common in thiourea compounds. Additionally, weak C=S···H–C interactions between dimeric structures involving methoxy groups are observed.

Interestingly, X-ray diffraction analysis carried out for the closely related O-ethyl benzoylthiocarbamate species [16] shows that the crystal packing is dominated by endless chains linked by C=O···N–H hydrogen bond interactions. The N–H···S=C intermolecular interaction are absent in the crystal, and the *syn–syn–syn* conformation is the only form observed in the crystal. On the other hand, theoretical studies predict the *syn–anti–syn* form as the most stable conformer of this molecule isolated in a vacuum [16], in

Table 4

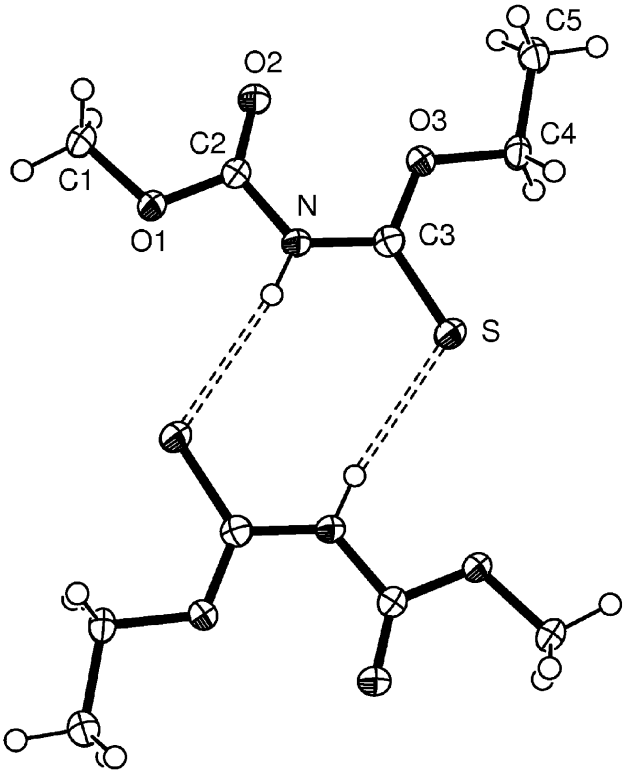

Fig. 5. Molecular plot of dimeric *anti–syn–anti–syn* $CH_3CH_2OC(S)N(H)C(O)OCH_3$ in the solid state showing the labeling of the non-H atoms and their displacement ellipsoids at the 50% probability level. The unlabeled monomer is related to the labeled one by a crystallographic inversion center. H-bonds are indicated by dashed lines.

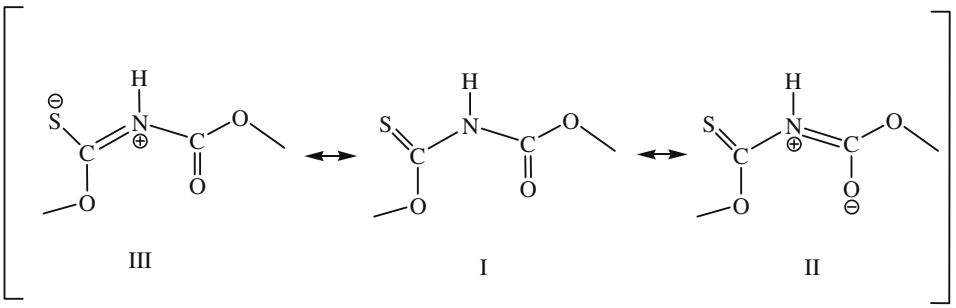
agreement with the preferred conformation found for both title compounds. Thus, the overall molecular structure of thiocarbamate species seems to be determined by the formation of N–H···X=C (X = O, S) hydrogen bonds between adjacent molecules. Depending on the substituents bonded to the central –OC(O)N(H)C(S)O– moiety, the acceptor group can be either C=S or C=O, leading to different crystal motif –chains or dimers– and to different molecular conformation in the solid thiocarbamate species.

To the best of our knowledge the present work is the first example of a thiocarbamate species forming such an N–H···S=C hydrogen bond network. Similar observations have been made for related compounds, such as thio- [39] and seleno-ureas [40]. The presence of this type of interactions strongly affects the C=S bond length, which is noticeably lengthened [d(C=S) = 1.654(2) Å. The comparison of the C=S bond length for a series of molecules possessing the –C(O)N(H)C(S)– moiety is shown in Table 6. Species

Table 6
Comparison of the C=S bond length in compounds that present and do not present N–H···S=C hydrogen bonds.



Species	Main moiety	C=S distance (Å)
$CH_3CH_2OC(S)N(H)C(O)OCH_3$	–C(O)N(H)C=SO–	1.654(2)[a]

[c] Related compounds which do not present N–H···S=C hydrogen bonds.

displaying N–H···S=C hydrogen bonds have longer C=S bond lengths by *ca.* 0.04 Å than similar species without intermolecular N–H···S=C interactions.

In addition, both C–N bond lengths (Table 3) are shorter than the average value of 1.472(5) Å [41]. In the title compounds, the C–N bond in the thiourea group (S)C–NH [N–C3 = 1.368 (2)°] is considerably shorter than the amide bond (O)C–NH [N–C2 = 1.401 (2)°]. This trend seems to be characteristic for thiocarbamate compounds [16,27,42]. However, for carboxyl substituted thioureas the above trend is the opposite, i.e., the C–N bond in the amidic-like group (O=C–NH–) is shorter than the C–N thiourea bond (S)C–NH [28–30,36,43]. The C=O double bond in compound **II** (1.194(2) Å) is very well reproduced by quantum chemical calculations (1.200 Å) with a value that is to some extent shorter than that reported for O-ethyl benzoylthiocarbamate [1.205(3) Å] [16]. Differences in the (O)C–O and (S)C–O single-bond lengths for the methoxy and ethoxy groups (1.343(2) and 1.318(2) Å for the O1–C2 and C3–O3 bonds, respectively) suggest that resonance interactions are extended over the whole planar structure.

The previous structural features can be rationalized considering that several resonant structures are feasible for the thiocarbamate central moiety. Three of them are showed in the Scheme 2. It is well-known that the traditional picture of amide resonance is more appropriate for thioamides than for oxoamides [44]. Moreover, previous studies showed that amide resonance in H_2 N(C=X)H species increases with a decrease in the electro-negativity of X (X = O, S, Se) [1]. By using *ab initio* molecular orbital calculations, Wiberg and Rablen [44] concluded that amide resonance is dependent on the charge polarization across the C=X double bond, the charge polarization across thiocarbonyl bond is weaker than that in C=O bond, hence the contribution from resonance structure is much more reduced for the oxygen analogs. In perfect agreement with these results, vibration and structural data for compounds **I** and **II** are consistent with a larger π resonant contribution of the thioamide group (structure **III**) when comparing with the amide group structure (structure **II**).

Scheme 2. Main resonance structures for the central thiocarbamate moiety.

3. Conclusions

Two O-alkyl N-methoxycarbonyl thiocabamates have been prepared in high yield and purity by treating $CH_3OC(O)NCS$ with the corresponding alcohols at room temperature. Conformational and structural properties were determined by using experimental techniques which include vibrational spectroscopy (IR and Raman) as well as X-ray diffraction analysis. For both substances, it was determined that the molecular skeleton is essentially planar. Results derived from the quantum chemical calculations show that the central –OC(O)N(H)C(S)– moiety adopts a planar structure with a preferred *syn–anti–syn* orientation around the O–C, C–N and N–C single bonds, respectively. This form is present in crystalline $CH_3CH_2OC(S)N(H)C(O)OCH_3$ (150 K) as centro-symmetric dimeric units held by resonance-assisted N–H···S=C hydrogen bonds.

4. Experimental

4.1. General procedure and reagents

Volatile materials were manipulated in a glass vacuum-line equipped with PTFE system (Young, London, UK) and capacitance pressure gauge (221 AHS-1000, MKS Baratron) for the control of the pressure. The vacuum line has a connection to an IR cell (optical path length 10 cm, Si windows 0.5 mm thick). This arrangement allowed us to observe the course of the isomerization in gaseous phase by FTIR spectroscopy (EQUINOX 55, Bruker). The pure compounds are air stable and they were stored in a glass tube under room temperature conditions.

4.2. Instrumentation

4.2.1. X-ray diffraction

The measurements were performed on an Enraf-Nonius Kappa-CCD diffractometer with graphite-monochromated Mo Kα ($\lambda = 0.71073$ Å) radiation. Diffraction data were collected (φ and ω scans with κ-offsets) with COLLECT [45]. Integration and scaling of the reflections was performed with HKL DENZO-SCALEPACK [46] suite of programs. The unit cell parameters were obtained by least-squares refinement based on the angular settings for all collected reflections using HKL SCALEPACK [46]. The data were corrected numerically for absorption with PLATON [47]. The structure was solved by direct methods with SHELXS-97 [48] and the molecular model refined by full-matrix least-squares procedure on F^2 with SHELXL-97 [48]. The hydrogen atoms were positioned stereo-chemically and refined with the riding model. The methyl hydrogen atoms locations were optimized during the refinement by treating them as rigid bodies which were allowed to rotate around the corresponding C–C or C–O bonds. Crystal structure data have been deposited at the Cambridge Crystallographic Data Centre (CCDC). Enquiries for data can be direct to: Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, UK, CB2 1EZ or (e-mail) deposit@ccdc.cam.ac.uk or (fax) +44 (0) 1223 336033. Any request to the Cambridge Crystallographic Data Centre for this material should quote the full literature citation and the reference number 695371.

4.2.2. Vibrational spectroscopy

Gas and solid-phase IR spectra were recorded with a resolution of 1 and 2 cm^{-1}, respectively, in the 4000–400 cm^{-1} range on a Bruker EQUINOX 55 FTIR spectrometer. FT-Raman spectra of the solid substances were run on a Bruker 66 with FRA 106 Raman accessory at a resolution of 2 cm^{-1}; the sample fitted in a 2 mm glass capillary was excited by the 1064 nm line of a 5 mW Nd:YAG laser.

4.2.3. NMR spectroscopy

The ^1H and ^{13}C NMR spectra were recorded with a Varian, Mercury Plus spectrometer operating at 200 and 50.3 MHz, respectively. The HSQC 2D-NMR measurement were recorded with observed ^1H at 200 MHz and decouple ^{13}C at 50.3 MHz. Pure sample dissolved in $CDCl_3$ was used as an external reference The spectra were recorded at room temperature in the 0–11 ppm and 0–220 ppm ranges for ^1H and ^{13}C NMR spectra, respectively.

4.2.4. GC–MS determination

The GC–MS measurements were recorded in a GCMS-QP2010 SHIMADZU instrument using gaseous Helium as mobile phase with the pressure in the column head equal to 100 kPa. The column used was a 19091J-433 HP-5 of 30 m × 0.32 mm × 0.25 mm film thickness. A 1-μL volume of the compounds dissolved in $CHCl_3$ was chromatographed under the following conditions: injector temperature was 200 °C, the initial column temperature (70 °C) was held for 2 min, then increased to 200 °C at 7 °C/min and held for 2 min after elevated to 300 °C at 5 °C/min and held for 2 min. In the spectrometer the source was kept at 200 °C.

4.2.5. Melting point determination

The melting points were determined in a capillary tube containing the pulverized sample, which was introduced in a BÜCHI-Glasapparatefabrik-flawil schmlzpunktestimmungsapparat (melting point apparatus) equipped with a thermometer (0–300 ± 1 °C).

4.2.6. Theoretical calculations

All quantum chemical calculations were performed with the GAUSSIAN 03 program package [49]. The molecular geometries were optimized to standard convergence criteria by using a DFT hybrid method with Becke's non local three parameter exchange and the Lee, Young and Parr correction (B3LYP) using 6-31G* and 6-311++G** basis sets.

volume) was sealed in a Teflon-lined stainless steel reactor, heated at 100 °C for 3 days and cooled to room temperature. Colorless plate-like single crystals of **1** were obtained and washed with distilled water. Yield: 35%. *Anal.* Calc. for $C_{24}H_{22}CdCl_3N_4O_4$: C, 44.40; H, 3.42; N, 8.63. Found: C, 44.21; H, 2.99; N, 8.86%. IR (KBr, cm^{-1}): 3341(m), 3279(m), 2987(m), 1618(s), 1584(vs), 1557(s), 1453(s), 1403(vs), 1368(s), 1028(w), 949(w), 902(w), 870(m), 812(m), 762(w), 688(m).

2.2.2. $[Cd(cqaH)(cqa)Br]_n$ (**2**)

Compound **2** was prepared by a similar method to **1**, except for using $CdBr_2 \cdot 4H_2O$ instead of $CdCl_2 \cdot 2.5H_2O$. Yield: 22%. *Anal.* Calc. for $C_{24}H_{22}CdCl_2BrN_4O_4$: C, 41.55; H, 3.20; N, 8.08. Found: C, 41.94; H, 3.21; N, 7.86%. IR (KBr, cm^{-1}): 3336(m), 3283(m), 2982(w), 1615(s), 1583(vs), 1559(s), 1453(s), 1402(s), 1367(vs), 1033(w), 949(w), 902(w), 865(m), 812(m), 763(w), 686(m).

2.2.3. $\{[Cd_2(cqa)_4] \cdot 3H_2O\}_n$ (**3**)

Compound **3** was prepared by a similar method to **1**, except for using $Cd(NO_3)_2 \cdot 4H_2O$ instead of $CdCl_2 \cdot 2.5H_2O$. Yield: 26%. *Anal.* Calc. for $C_{48}H_{42}Cd_2Cl_4N_8O_{11}$: C, 45.12; H, 3.31; N, 8.77. Found: C, 44.93; H, 3.07; N, 8.96%. IR (KBr, cm^{-1}): 3448(br), 3276(s), 2986(w), 1579(vs), 1456(m), 1406(s), 1368(s), 1041(w), 950(w), 914(m), 867(m), 812(m), 763(m), 660(w). This compound could also be obtained in various yields under the same hydrothermal conditions, by using $Cd(ClO_4)_2 \cdot 6H_2O$, $Cd(OAc)_2$, $Cd(SCN)_2$, CdI_2 and $CdSO_4 \cdot 8/3H_2O$ instead of $Cd(NO_3)_2 \cdot 4H_2O$.

2.3. Caution

Although we have experienced no problems in handling perchlorate compounds, these should be handled with great caution due to the potential for explosion.

2.4. X-ray structure determinations

X-ray intensity data of **1–3** were collected on a Bruker SMART APEX CCD diffractometer [20] using graphite monochromatized Mo Kα radiation (λ = 0.71073 Å) at 291(2) K. The raw data were reduced and corrected for Lorentz and polarization effects using the SAINT program and for absorption using the SADABS program. The structures were solved by direct methods and refined with the full-matrix least-squares technique using SHELXTL version 5.1 [21]. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. Hydrogen atoms were placed in calculated positions and refined using a riding model. The crystallographic data are shown in Table 1. Selected bond lengths and bond angles are given in Table 2.

3. Results and discussion

3.1. Preparation and IR analysis

Compounds **1–3** were synthesized under similar hydrothermal conditions by the reaction of the corresponding Cd salts and the Hcqa ligand. They are stable in air at ambient temperature and are insoluble in common solvents such as water, alcohol and acetonitrile. In the IR spectra, before the ligand coordinates to the Cd metal, the N–H stretching frequency is 3260 cm^{-1}. After it coordinates to the Cd metal, the N–H stretching frequencies are shifted to 3341 and 3279 cm^{-1} for compound **1**, 3336 and 3283 cm^{-1} for compound **2** and 3276 cm^{-1} for compound **3**. Obviously, additional absorptions at 3341 and 3336 cm^{-1} were observed for **1** and **2**, respectively, while the N–H stretching frequency of compound **3** is still slightly changed after the formation of the metal complex. Meanwhile, **1** and **2** show the characteristic bands of carboxylate groups with asymmetric vibrations at 1584 and 1583 cm^{-1}, and symmetric vibrations at 1403, 1368 and 1402, 1367 cm^{-1}, respectively. The Δ values representing the separation between $\nu_{as(COO)^-}$ and $\nu_{s(COO)^-}$ are all 181 and 216 cm^{-1}, respectively. In the IR spectrum of **3**, characteristic bands of the carboxylate groups are observed at 1579 cm^{-1} for the antisymmetric vibration and at 1406 and 1358 cm^{-1} for the symmetric vibration. The Δ values between $\nu_{as(COO)^-}$ and $\nu_{s(COO)^-}$ are 173 and 221 cm^{-1}, respectively. The results suggest that there exist two different coordination fashions for the carboxylate groups in **1–3**, which are consistent with the X-ray structural analysis results [22].

3.2. Structural description

3.2.1. Structures of $[Cd(cqaH)(cqa)Cl]_n$ (1) and $[Cd(cqaH)(cqa)Br]_n$ (2)

The X-ray crystal structure analyses of **1** and **2** reveal that they are isostructural. Therefore, only the crystal structure of **1** is described in detail. The asymmetric unit of **1** contains one Cd^{2+} cation, one Cl^- anion, one cqaH (the Hcqa ligand where the proton is transferred from the acid group to the imine group) ligand, and one deprotoned cqa^- ligand. As shown in Fig. 1, each Cd^{2+} ion adopts a distorted octahedral geometry and it is coordinated to one Cl^- anion, one nitrogen atom and two carboxylate oxygen atoms from cqaH and two carboxylate oxygens from cqa^-. The coordination fashion of the carboxylate oxygen from cqaH is in accordance with similar reported complexes [23]. The carboxylate oxygen atoms from cqaH (O1, O2), one nitrogen atom (N1A) and one carboxylate oxygen atom (O3) form the basal plane, whereas the axial positions are taken up by one chlorate anion (Cl1) and the other carboxylate oxygen atom (O4B). The carboxylate–oxygen atoms from cqaH join two Cd(II) atoms, yielding a Cd_2O_2 binuclear

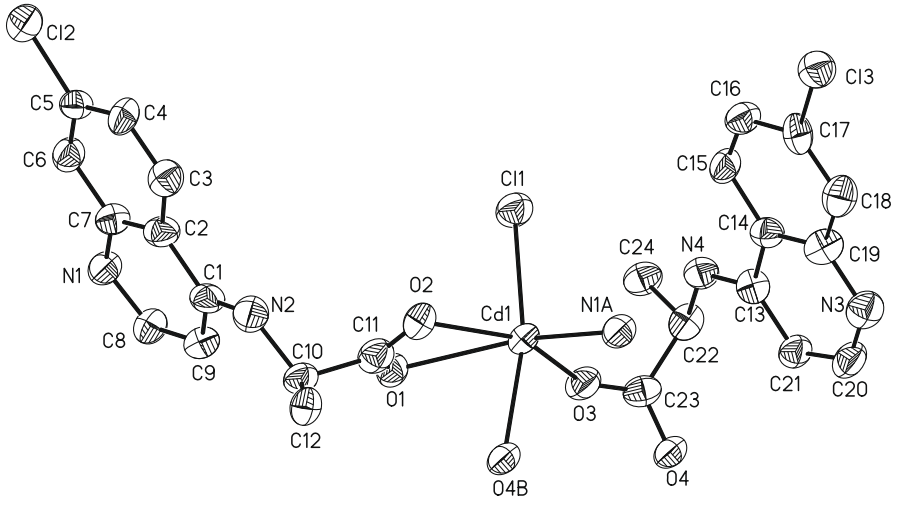

Fig. 1. View of the coordination environment of Cd(II) in complex **1**, thermal ellipsoids are drawn at the 50% probability level. Hydrogen atoms have been omitted for clarity.

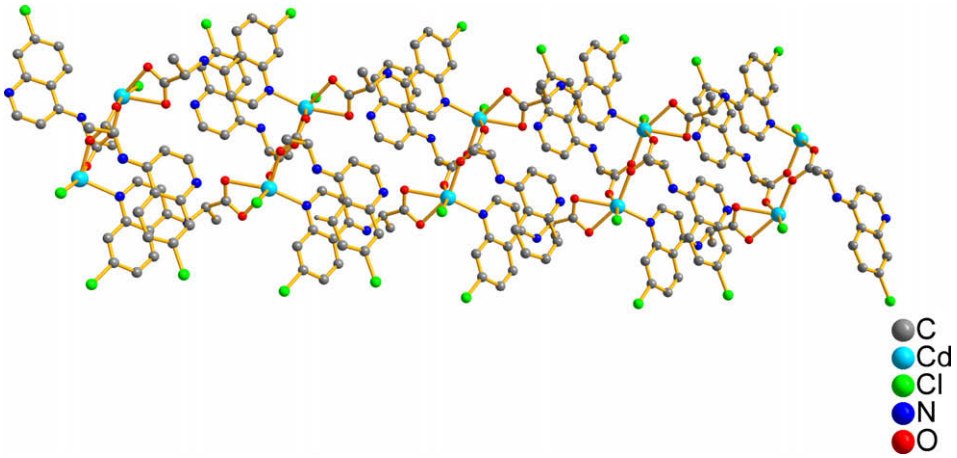

Fig. 2. The ribbon-like chain structure for complex **1**.

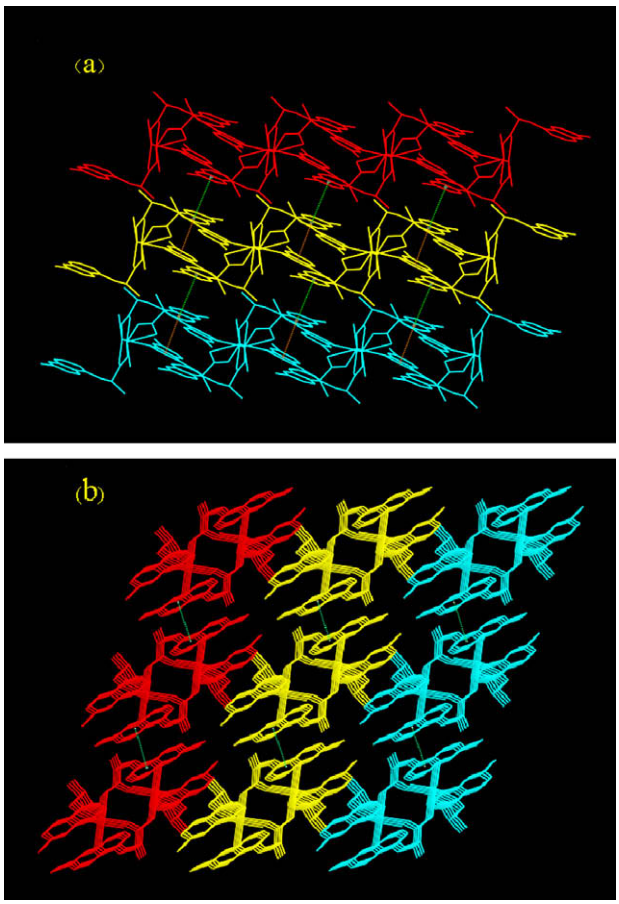

Fig. 3. (a) The 2D layered structure of **1** via π–π stacking interactions; (b) The 3D supramolecular architecture of **1** via π–π stacking interactions.

unit with an 8-membered metallacycle. Each dimer is further linked to give a one-dimensional ribbon-like polymer via one nitrogen atom and the carboxylate oxygen atoms from the cqa^- ligand (Fig. 2). The most remarkable feature of **1** is the existence of three types of π−π stacking interactions which connect the 1D ribbon-like chains into a 3D supramolecular framework. First, there are intrachain π–π stacking interactions of quinolyl rings with centroid–centroid separations of 3.554 Å. Then, the 1D ribbon-like chains are bridged to form a 2D supramolecular sheet through interchain π−π stacking interactions between the quinolyl rings, with centroid–centroid distances of 3.584 Å (Fig. 3a). Finally, every layer interacts with neighboring layers via π−π stacking interactions between quinolyl rings (centroid–centroid distances of 3.593 Å), further extending the 2D layers into a 3D supramolecular framework (Fig. 3b). A similar supramolecular framework formed by π−π stacking interactions can be observed in $[Pb_2(1,4\text{-}bdc)_2(dpdp)_2]\cdot H_2O$ (1,4-H_2bdc = benzene-1,4-dicarboxylic acid, dpdp = dipyrido[3,2-a:2′,3′-c]-phenazine) [24], which only have two types of π–π stacking interactions. Richer π−π stacking interactions are observed in **1** and it provides a practicable method to assembly the supramolecular framework. Additionally, the centroid–centroid distances of the π−π interactions gradually increases, which indicates these interactions gradually decrease when the dimensionality is expanded from one to three.

3.2.2. Structure of $\{[Cd_2(cqa)_4]\cdot 3H_2O\}_n$ (**3**)

In the asymmetric unit of **3** there is one Cd^{2+} ion, two deprotonated Hcqa ligands and one and a half disordered water molecules. Each Cd^{2+} ion sits in a distorted tetragonal–pyramidal arrangement, in which the equatorial plane is completed by one nitrogen atom (N1) and three carboxylate oxygens (O2A, O3B and O4B) from cqa^- and the vertex position is occupied by the other nitrogen atom (N3) from cqa^- (Fig. 4). Each Cd^{2+} center is connected by two ligands into a double-stranded chain with an 18-membered ring. It is noteworthy that there are two different 18-membered rings with Cd···Cd separations of 8.421 and 8.234 Å (Fig. 5). The intriguing structural feature of this compound comprises three sets of double-stranded polymer chains which extend in three non-coplanar directions ([1 1 1], [1 1 $\bar{1}$] and [1 $\bar{1}$ $\bar{1}$]). The chains are organized around the crystallographic 3-fold axes in the [0 0 1] direction and adopt an interwoven arrangement through three types of interchain π–π interactions between quinolyl rings, with centroid–centroid distances of 3.616, 3.644 and 3.669 Å (Fig. 6). The complicated and entangled repeated array ultimately leads to a

3D framework with 1D channels in the [001] direction (Fig. 7). Similar topological compounds constructed from three sets of chains have been reported for $[Ni(cyclam)(bpydc)] \cdot 5H_2O$ and $[\{Ni(C_{10}H_{26}N_6)\}_3(bpdc)_3] \cdot 2C_5H_5N \cdot 6H_2O$ (cyclam = 1,4,8,11-tetraazacyclotetradecane, bpydc = 2,2′-bipyridyl-5,5′-dicarboxylate, $C_{10}H_{26}N_6$ = 3,10-dimethyl-1,3,5,8,10,12-hexaazacyclotetradecane, bpdc = 4,4′-biphenyldicarboxylate), containing three sets of rigid chains, or $[Ag(sebn)](AsF_6)$ and $[Ag(sebn)](CF_3SO_3)$ (sebn = 1,10-decanedinitrile) containing three sets of flexible chains [25–27]. In contrast to these compounds, complex **3** is a rare example with both rigid and flexible chains. The chains are helpful for forming stronger π–π stacking interactions. The 1D channels with honeycomb-like windows have a diameter of ca. 7.6 Å (effective size 5.8 Å), which are occupied by disordered water guest molecules. After the removal of these guest solvents, the volume of the effective void, calculated using PLATON, is 11.0% of the unit-cell volume in **3**. The π–π stacking interactions further enhance the stability of this 3D framework.

The results suggest that the architectures of the coordination polymers are not only depended on the organic ligands, but also mediated by the anions and the cooperation effect from the anion and ligand. In our cases, the effects might be attributed to the following contributions: (i) Cl^-/Br^- ions and Cd^{2+} have a stronger electrostatic interaction and affinity than I^- and the other anions owing to the Cl^-/Br^- ions having a smaller ion radius [28]. The Cl^-/Br^- ions are easily involved in the affinity of the Cd centers and its self-organization. (ii) Previous studies suggested that Cl^-/Br^- ions usually cannot act as templating metal ions but they have a stronger capability of coordination than other anions in self-assembly reactions [29,30]. (iii) The cooperative effect of the ligand should also be very important. Generally, a stable metal–organic coordination polymer is good for a neutral framework [31,32]. If the anions show a weaker electrostatic affinity and weaker coordination ability to metal ions, the Hcqa ligand with both pyridyl and carboxylate groups can easily form a neutral and stable framework by itself.

3.3. Thermal stability

TG curves have been obtained under flowing N_2 for crystalline samples of **1–3** in the temperature range 25–750 °C. As shown in Fig. 8, for complex **3** a weight loss of 3.8% in the 75−150 °C range corresponds to the release of the lattice water molecules (calculated 4.2%). The decomposition of the residual components started beyond 500 °C. It can be seen from the TGA curves of **1** and **2**, the networks remain intact until they are heated to 350 °C and then they begin to collapse. The total observed weight loss at 730 °C is 38.9% and 41.3%, respectively, and the final residuals were not characterized.

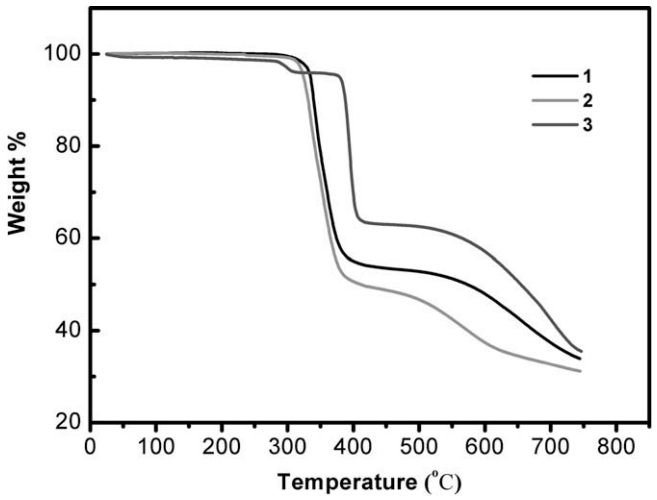

Fig. 8. Thermogravimetric curves for **1–3**.

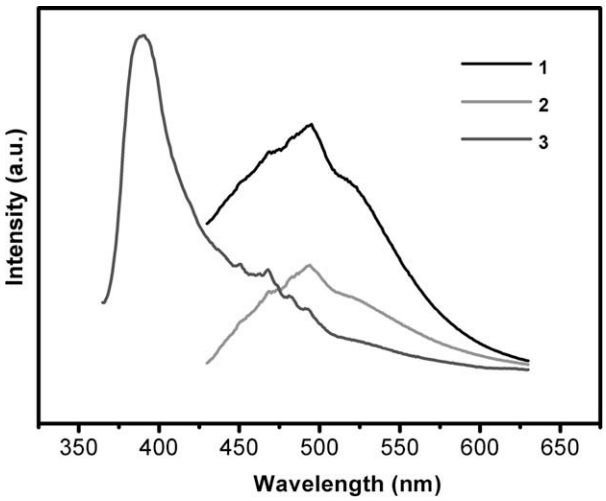

Fig. 9. Emission spectra of **1–3**.

3.4. Fluorescent emission properties

Metal–organic coordination polymers with the cadmium ion usually exhibit photoluminescent properties [33–36]. The photoluminescent properties of compounds **1–3** have been recorded in the solid state at room temperature. As shown in Fig. 9, complex **1** displays an intense emission maxima at 494 nm when excited at 400 nm. A similar emission band at 494 nm is also observed for **2** but the intensity is rather weak, which is reasonable because of the heavy atom (Br^-) that exists in compound **2** [37,38]. Complex **3** shows a very strong emission band located at 390 nm upon excitation at 350 nm. The bathochromic shift of the emission probably results from the differences of the coordination environment around the metal ions, since the photoluminescence behavior is nearly related to the coordination fashion of the ligands [39,40]. All the emissions could be attributed to the $\pi \rightarrow \pi^*$ intraligand fluorescence [41].

4. Conclusions and perspectives

In conclusion, three new coordination polymers based on the 7-chloroquinolin-4-alanine ligand have been successfully synthesized and characterized. The results revealed that the architectures of the coordination compounds are greatly affected by the anion and ligand: the cooperative effect induced the formation of 1D infinite molecular ribbon and the non-cooperative effect drove the generation of a 1D double-stranded chain. Hence, we believe that the cooperative effect of the anion and ligand may be considered in mediating the structure and it can play an important role in supramolecular chemistry and crystal engineering.

agents and solvents employed were commercially available and were used as received without further purification.

UV–Vis spectra were recorded on a SHIMADZU UV-2401 spectrometer and Fourier-transformer IR data on a SHIMADZU FTIR-8400 spectrometer. Mössbauer measurements were performed on a constant acceleration spectrometer from 20 to 150 K with an optional small field (Knox College).

2.2. Synthesis of [Na(2,2,2-crypt)][Fe^{II}(TpivPP)(N$_3$)] · 3C$_6$H$_5$Cl

[Fe^{III}(TpivPP)(SO$_3$CF$_3$)(H$_2$O)] [4] (100 mg, 0.081 mmol) and 1 mL of zinc amalgam were stirred for 1 h under argon in 10 mL of C$_6$H$_5$Cl. This deep red solution of [Fe^{II}(TpivPP)] was then filtered into a second solution that was made by stirring for 2 h a mixture of 150 mg (0.39 mmol) of cryptand-222 and 200 mg of NaN$_3$ (3.08 mmol) in 10 mL of C$_6$H$_5$Cl. The solution was filtered and crystals of the complex were prepared by slow diffusion of hexanes into the chlorobenzene solution. UV–Vis [C$_6$H$_5$Cl, λ_{max} in nm]: 359, 440, 568. IR (KBr disk, cm^{-1}): ν(N$_3$) 2024, 1996.

2.3. X-ray crystallography

Single crystal X-ray diffraction measurements were carried out at 223 K on a Bruker Nonius FR590 Kappa CCD area detector diffractometer employing graphite monochromatized Mo Kα radiation (λ = 0.71073 Å) in the ϕ scan mode. Final unit cell dimensions were obtained and refined on the entire data set. Integration and scaling resulted in the data set, corrected for Lorentz and polarization effects using DENZO/SCALEPACK [5]. The trial structure was obtained by direct methods using SIR-2004-1.0 [6], which revealed the position of the iron and sodium atoms, most atoms of the porphinato ligand, and the cryptand-222. The remainder of the structure was found in the subsequent difference Fourier syntheses. There are one [Fe^{II}(TpivPP)(N$_3$)]$^-$ anion, one sodium cryptand-222 counterion and three chlorobenzene solvent molecules in the asymmetric unit of the structure. The final structural refinement was made with F^2 data with the program SHELXL-97 [7].

A *tert*-butyl group of the picket occupies two alternative positions with converged occupancies of 0.58(1) and 0.42(1). Two oxygen atoms O5 and O6 of the cryptand-222 present two major positions with refined occupancy coefficients converged to 0.60(1) and 0.40(1) (for O5A and O5B) and 0.68(1) and 0.32(1) (for O6A and O6B). All non-hydrogen atoms were refined anisotropically, except the minor component of the disordered *tert*-butyl group as well as the two disordered oxygen atoms O5 and O6 of the cryptand-222. The hydrogen atoms were geometrically fixed and allowed to refine using a riding model. The crystal data and structural refinement parameters are given in Table 1 and selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. UV–Vis and IR

The electronic spectrum of the [Fe^{II}(TpivPP)(N$_3$)]$^-$ species exhibits a Soret band at 443 nm in chlorobenzene. The position of the Soret band is red-shifted, as seen for Fe(II) pentacoordinate *meso*-porphyrin complexes with ionic axial ligands (see Table 3). So, the UV–Vis spectrum of the azido-Fe(II) derivative alone suggests the formation of a five-coordinate iron(II) porphyrin species. The question of the spin state, however, remains. As shown in Table 3, the high-spin (S = 2) iron(II) halide and oxyanionic (RO$^-$) species have Soret maxima around 440 nm [8,9]. Interestingly, however, the Soret maximums for five-coordinated low-spin (S = 0) iron(II) porphyrinates [Fe^{II}(TpivPP)(NO$_2$)]$^-$ [10] and [Fe^{II}(TpivPP)(CN)]$^-$ [11] are also in the 435–450 nm area [10].

[a] Solvent: chlorobenzene.

The [Na(2,2,2-crypt)][Fe^{II}(TpivPP)(N_3)] · $3C_6H_5Cl$ complex shows a strong band in the IR spectrum at 1102 cm^{-1} which is attributed to the counterion (cryptand-222)sodium(+). The same spectrum exhibits a strong band at 1996 cm^{-1} and a weak band at 2024 cm^{-1} attributed to the asymmetric stretching frequency ν_{as} of the N_3^- ligand. Thus, the IR data are consistent with a Fe(II) mono-azido picket fence porphyrin species. IR data for azido-porphyrin and azido-hemoprotein iron(III) species are available in the literature [3]. McCoy and Caughey [13] observed infrared bands for MetMb-N_3 at 2045 and 2023 cm^{-1} and at 2047 and 2025 cm^{-1} for MetHb-N_3 in aqueous solution; both of these hemoprotein systems are spin-equilibrium systems with azide and histidine as the ligand set. These authors assigned the high frequency bands to the high-spin iron(III) forms and the low frequencies to the low-spin iron(III) forms. The bis-azide Fe(III) complex [Fe^{III}(TPP)(N_3)$_2$]$^-$ [3] presents two bands at 2014 and 2036 cm^{-1} attributed to ν_{as} of the N_3^- groups. These absorption bands are assigned to high and low-spin Fe(III) forms, respectively. The cobalt(III) bis-azide derivative: [Co^{III}(TpivPP)(N_3)$_2$]$^-$ [14] also exhibits two stretching frequencies attributed to the N_3^- ligands: a strong band at 1993 cm^{-1} and a weak band at 2019 cm^{-1}. This d^6 metal complex was found to be a low-spin species. Our iron(II) derivative [Fe^{II}(TpivPP)(N_3)]$^-$ (with a d^6 configuration), shows, as was mentioned above, two $\nu_{as}(N_3)$ bands at 1996 cm^{-1} (the strongest) and 2024 cm^{-1} for the weak band. Thus, both azido d^6 metals (Fe^{2+} and Co^{3+}) complexes present very similar $\nu_{as}(N_3)$ values but the Fe(II) derivative, as will be shown by the molecular structure and by Mössbauer spectroscopy, is high-spin ($S = 2$).

3.2. Crystal structure

The structure of the [Na(2,2,2-crypt)][Fe^{II}(TpivPP)(N_3)] · $3C_6H_5Cl$ compound was determined at 223 K. Fig. 1 is an ORTEP diagram of the [Fe^{II}(TpivPP)(N_3)]$^-$ complex ion. The iron(II) atom is coordinated to the N_3^- ligand from the pocket side of the TpivPP porphyrin.

The coordinated azide ion is linear with a N9–N10–N11 angle value of 178.0(3)°, the two N–N distances are definitely inequivalent: N9–N10 and N10–N11 bond lengths are, respectively, 1.194(3) and 1.169(4) Å. This difference is not unusual and reflects one resonance form of bound azide. The Fe–azide plane makes a dihedral angle of 28.0(1)° with the plane define by Fe, N9 and N3. This value is smaller than the one found in the related iron(III)

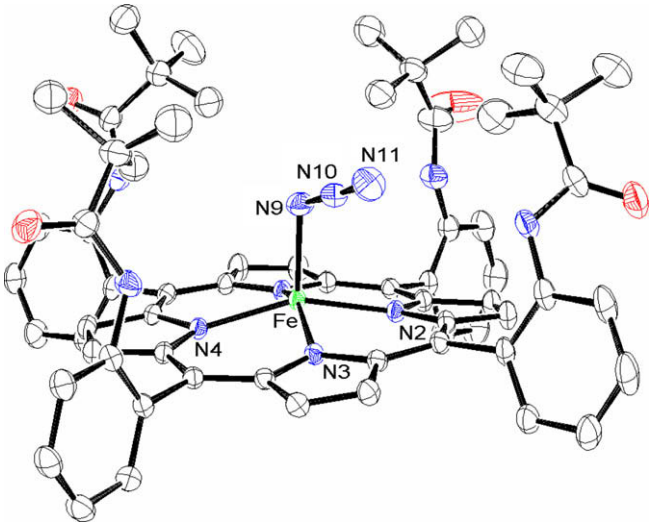

Fig. 1. ORTEP view of the ion complex [Fe^{II}(TpivPP)(N_3)]$^-$, thermal ellipsoids are drawn at the 30% probability level. Only the major positions of the disordered atoms are shown and hydrogen atoms have been omitted for clarity.

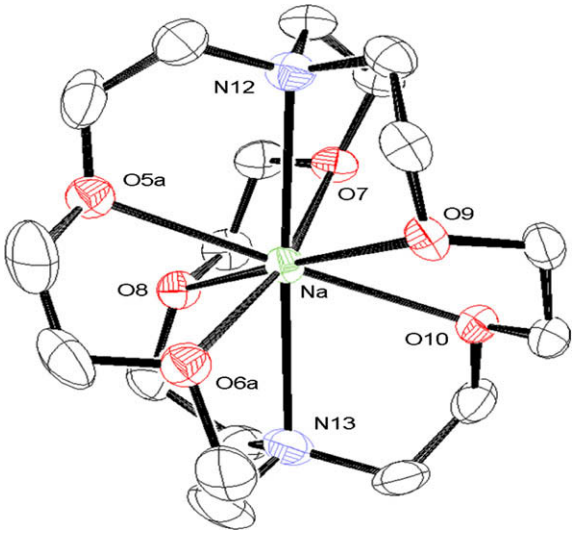

Fig. 2. ORTEP diagram of the [Na(2,2,2-crypt)]$^+$ cation. Thermal ellipsoids are drawn at the 30% probability level. Only the major positions of the disordered atoms are shown and hydrogen atoms have been omitted for clarity.

species [Fe^{III}(TPP)(N_3)$_2$]$^-$ (32°). The 116.8(2)° Fe–N9–N10 angle is significantly smaller than in either the five-coordinate [Fe^{III}(TPP)(N_3)] [15] species (121.8°) or the six-coordinate [Fe^{III}(TPP)(N_3)$_2$]$^-$ [3] ion complex (118.01°) but is within the range for the angle of a trigonally hybridized nitrogen. The negative charge of the [Fe^{II}(TpivPP)(N_3)]$^-$ anion is balanced by a [Na(2,2,2-crypt)]$^+$ counterion. An ORTEP drawing of this cation is given in Fig. 2. The eight-coordinate Na^+ ion is bonded to six O atoms and two N atoms. The average Na–O(2,2,2-crypt) distance is 2.500(3) Å, and the average Na–N(2,2,2-crypt) bond length is 2.760(3) Å.

As a consequence of the decreased charge, there is a small increase in the radius of Fe(II) compared to Fe(III), and this leads to increased bond lengths in the coordination group. Thus, the axial Fe–N(azide) bond length is 2.078(2) Å for our iron(II) species [Fe^{II}(TpivPP)(N_3)]$^-$, which is longer than those of all the reported iron(III) azido-porphyrin derivatives (see Table 4). The average equatorial Fe–N_p distance for the [Fe^{II}(TpivPP)(N_3)]$^-$ ion complex is 2.094(3) Å, and falls within the range found for five-coordinate high-spin iron(II) porphyrins (2.072–2.115 Å) [16]. This is a stereochemical proof that our synthetic compound is high-spin ($S = 2$). In order to accommodate the high-spin iron(II) atom, the porphinato cores undergo a significant radial expansion. This is very well illustrated by the long Fe–P_C (P_C = plane made by the 24-atom core of the porphyrin) and Fe–P_N (P_N = plane made by the four nitrogens of the porphyrin ring) distances shown by Fe(II) high-spin [Fe^{II}(Porph)(X)]$^-$ complexes (X is an anionic ligand). The values of these distances for the iron(II) azide species and for other iron porphyrinates are summarized in Table 4. As shown in Fig. 3, the porphyrin ring for [Fe^{II}(TpivPP)(N_3)]$^-$ exhibits a non-planar conformation that is domed and also shows major ruffling. The core conformation has also been analyzed by the normal structural decomposition (NSD) method provided by Shelnutt and co-workers [20]. These calculations confirm the major ruffling and doming distortions: *ruf* = 0.401 Å (~47%), *dom* = 0.190 Å (~22%), *sad* = 0.115 Å (~13%), *wav*(*x*) = 0.086 Å (~10%) and *wav*(*y*) = 0.069 Å (~8%) for a total out-plane-distortion D_{oop} = 0.471 Å.

3.3. Mössbauer spectrum

Fig. 4 represents the Mössbauer spectrum, taken at 20 K, of a sample of the azido-Fe(II) porphyrinate which shows one quadrupole doublet. The isomer shift (δ_{Fe}) and quadrupole splittings (ΔEq)

Table 4
Porphinato core parameters (Å) for selected Fe(III) high-spin ($S = 5/2$) and Fe(II) high-spin ($S = 2$) porphyrin complexes.

[a] Average equatorial iron–nitrogen pyrrole distance.
[b] Iron–axial ligand distance.
[c] Distance between the iron atom and the mean plane made by the 24-atom core of the porphyrin.
[d] Distance between the iron centre and the mean plane of the four pyrrole N atoms.
[e] OEP, octaethylporphyrin.
[f] TTP, tetratoluylporphyrin.

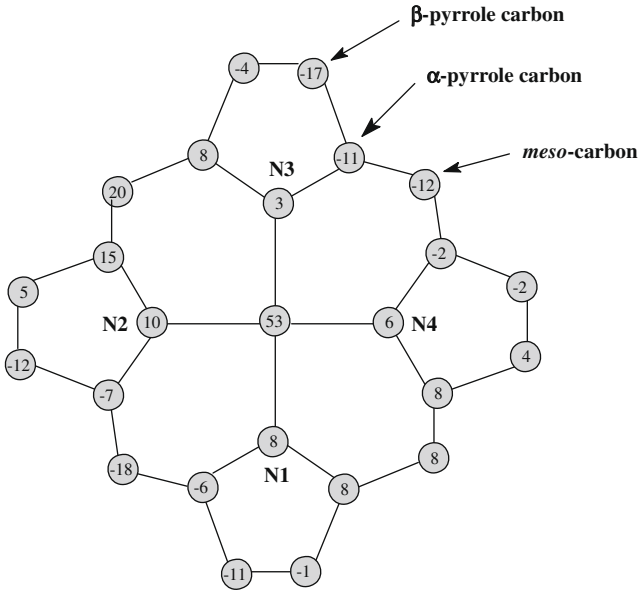

Fig. 3. Formal diagram of the porphinato core of $[Fe^{II}(TpivPP)(N_3)]^-$ illustrating the displacement, in units of 0.01 Å, of each atom from the mean plane of the 24-atom porphinato core. Positive values of displacement are toward the azide axial ligand.

values have been obtained by fitting these data to a set of two Lorentzian lines.

Mössbauer data for the complex ion $[Fe^{II}(TpivPP)(N_3)]^-$ are summarized in Table 5, along with some five-coordinated ferrous high-spin ($S = 2$) porphyrin complexes. As seen in this table, the ΔEq and δ_{Fe} values of the iron(II) azido-porphyrinate derivative are practically the same at 20, 77 and 150 K.

Porphyrin species with isomer shift values of ~0.8–1 mm/s are expected for high-spin iron(II) [21]. Indeed, the isomer shift for $[Fe^{II}(TpivPP)(N_3)]^-$ of 1.07 mm/s at 77 K strongly supports a high-spin-state assignment for this species. Previous studies (see Table 5) suggest that high-spin iron(II) porphyrinates of the general formula $[Fe^{II}(Porph)(X)]^-$, where X is a monodentate anionic ligand, have distinctively large quadrupole splittings (ΔEq ~ 3.5–4.5 mm/s). Indeed, the quadrupole splitting for $[Fe^{II}(TpivPP)(N_3)]^-$ of 4.22(1) mm/s (at 77 K) is consistent with their findings. These unusually large quadrupole splitting values arise from a significant bonding orbital contribution to the electric-field gradient from the anionic axial ligand, d_{xy} becomes the lowest d orbital in energy and

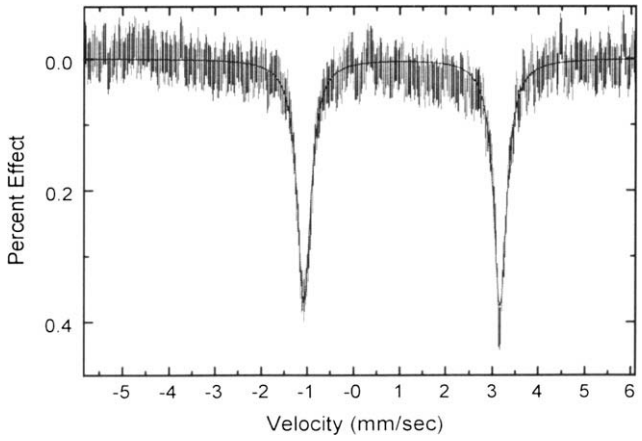

Fig. 4. Mössbauer spectrum of $[Fe^{II}(TpivPP)(N_3)]^-$ at 20 K in a weak applied field of 500 G.

Table 5
Mössbauer parameters for some five-coordinate high-spin ($S = 2$) iron(II) porphyrin complexes.

Complex	ΔEq (mm/s)	δ_{Fe} (mm/s)	T (K)	Reference
$[Fe^{II}(TpivPP)(N_3)]^-$	4.23(1)	1.08(1)	20	this work
	4.22(1)	1.07(1)	77	
	4.17(1)	1.04(1)	150	
$[Fe^{II}(TpivPP)(Cl)]^-$	4.36	1.01	77	[8]
$[Fe^{II}(TpivPP)(OMe)]^-$	3.64	1.00	77	[9]
$[Fe^{II}(TpivPP)(OAc)]^-$	4.19	1.03	77	[9]
$[Fe^{II}(TpivPP)(NO_3)]^-$	3.59	0.98	77	[12]

hence is doubly occupied. We believe that the electronic repulsion of the iron(II) in-plane d_{xy} orbital by the negative charge of the pyrrole nitrogens is thus expected to increase the magnitude of the iron atom displacement from the porphyrin plane with a concomitant increase in the values of the Fe–N_p, Fe–P_C and Fe–P_N distances, as is observed for our azido iron(II) porphyrin derivative.

4. Conclusion

The synthesis and characterization of the anionic iron(II) azido-porphyrin derivative, $[Na(2,2,2\text{-crypt})][Fe^{II}(TpivPP)(N_3)] \cdot 3C_6H_5Cl$, is described. Structural and Mössbauer data for this high-spin iron(II) species is consistent with a $(d_{xy})^2(d_{xz})^1(d_{yz})^1(d_{z^2})^1(d_{x^2-y^2})^1$

ground state electronic configuration. This study confirms the fact that the unusually large quadrupole splitting values found in the Mössbauer spectra for five-coordinate high-spin iron(II) $[Fe^{II}(Porph)(X)]^-$ species are structurally related to the large out-of-plane Fe displacement and the concomitant long $Fe–N_p$ bond lengths.

Scheme 1. Thiosemicarbazonato ligands used in the reactions.

2.2. IR spectra

All IR spectra were recorded as KBr pellets using a Perkin–Elmer Fourier-Transform Spectrum RX1 spectrophotometer in the region 4500–450 cm^{-1}.

2.3. Thermogravimetric analyses

All experiments were performed on a Mettler TG 50 thermobalance using aluminum crucibles under oxygen atmosphere with a heating rate of 5 °C min^{-1}. For all experiments the temperature ranged from 25 to 600 °C. The results were developed by applying the Mettler STAR^e 6.1. program.

Elemental analyses, yields, selected IR and thermal analysis data are given in Tables 1 and 2.

2.4. NMR experiment

All one-dimensional (^{1}H and APT) and gradient-selected two-dimensional (gCOSY, gHSQC and gHMBC) NMR spectra were recorded at ambient temperature on Bruker Avance DRX500 and Bruker Avance DPX 300 spectrometers equipped with a 5 mm inverse detection probe and a dual probe, respectively. The sample concentration in DMSO–d_6 was 20 mg ml^{-1}. TMS was used as the internal standard. The typical spectral conditions for one-dimensional ^{1}H and ^{13}C (APT) spectra were as follows. The spectra were recorded using 64 K data points and spectral widths of 7700 Hz and 32 000 Hz for ^{1}H and ^{13}C experiments, respectively. Digital resolution was 0.12 and 0.48 Hz per point, respectively. The number of scans was 16 for ^{1}H and 500–1000 for APT spectra. The COSY spectra were recorded under the following conditions: spectral width was 7700 Hz in both dimensions, 2 K data points were applied in the time domain and 512 increments were collected for each data set with linear prediction and zero filling to 2 K. Eight scans were applied for each increment. The digital resolution was 6.50 Hz per point in both dimensions. The gradient-selected inverse ^{1}H–^{13}C correlation experiments, gHSQC and gHMBC were recorded using the acquisition matrix of 1 K × 256 with 16 and 32 scans, respectively, and processed with a 2 K × 1 K transformed matrix. The spectral width was 6600 Hz in f2 dimension and 32000 Hz in f1 dimension for both experiments. The digital resolution was 3.25 Hz per point and 30.70 Hz per point in f2 and f1, respectively. HMBC spectra were recorded using a low-pass *J*-filter (3.4 s) and a delay for long-range coupling of 65 ms.

The NMR data of complexes are given in Table 3.

2.5. Reagents and apparatus for spectrophotometric determination of molybdenum

An aqueous solution of ammonium molybdate (c = 0.01 mol L^{-1}) was standardized gravimetrically with 8-hydroxyquinoline [6]. Working samples of lower concentrations were prepared by diluting aliquots of the stock solution. Cationic surfactants (benzethonium chloride (hyamine), cetyltrimethylammonium bromide (CTMA) or cetylpyridinium chloride (CPC)) were dissolved in reagent grade chloroform. All chemicals used were of the p.a. purity grade. A Varian double-beam spectrophotometer, Model Cary 3, equipped with 1-cm quartz cells, was used to determine absorption spectra and perform absorbance measurements. A Griffin flask shaker with a time switch served for extraction.

2.6. X-ray crystallography

Data were collected on an Oxford Diffraction Xcalibur CCD diffractometer with graphite-monochromated Mo K_α radiation at 293 K. Details of data collection and crystal structure refinement are presented in Table 4.

Programs CRYSALIS CCD and CRYSALIS RED [7] were employed for data collection, cell refinement and data reduction. The structures were solved by direct methods. The refinement procedure by full-matrix least squares methods based on F^2 values against all reflections included anisotropic displacement parameters for all non-H atoms. Calculations were performed with SHELXS97 [8] and SHELXL97 [9] (both operating under the WINGX [10] program package). Geometry calculations were done using PLATON [11] and PARST [12], and the molecular graphics were done with ORTEP [13] and MERCURY [14]. Selected bond distances and valence angles are listed in Table 5.

2.6.1. General procedure for the synthesis of $[MoO_2LD]$ D = pyridine (**1a** and **2a**) or γ-picoline (**1b** and **2b**) or imidazole (**1c** and **2c**)

The complex $[MoO_2(C_{12}H_{16}N_4OS)]_n$ (**1**) or $[MoO_2(C_9H_{11}N_3O_2S)]_n$ (**2**) (0.26 mmol) was suspended in dry methanol (10 mL) and an appropriate amine (pyridine, γ-picoline or imidazole) (2 mmol) was added in excess. The mixture was heated for 2 h. The solution was evaporated to one third of its volume under reduced pressure and left for 5–7 days at room temperature. The obtained products were filtered off, washed with tetrachloromethane and dried.

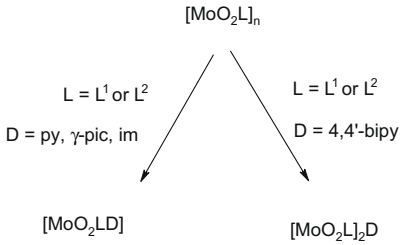
*2.6.2. General procedure for synthesis of [{MoO_2L}$_2$ D] D = bpy (**1d** and **2d**)*

The complex $[MoO_2(C_{12}H_{16}N_4OS)]_n$ (**1**) or $[MoO_2(C_9H_{11}N_3O_2S)]_n$ (**2**) (0.26 mmol) was suspended in dry ethanol (10 mL) and 4,4′-bipyridine (0.16 mmol) was added. The mixture was warmed up for 2 h. The solution was evaporated to one third of its volume under reduced pressure and left for several days at room temperature. The obtained products were filtered off, washed with tetrachloromethane and dried.

2.6.3. Procedure for spectrophotometric determination of molybdenum



The solution for spectrophotometric determination of molybdenum was obtained by wet ashing. An appropriate amount of the thiosemicarbazonato complexes containing 2–5 mg of molybdenum was weighed and transferred to a Kjeldahl flask. Concentrated sulfuric acid (1–2 cm^3) and a few drops of concentrated nitric acid were added and the solution was heated slowly at the beginning with constant swirling, and then it was boiled. The addition of concentrated nitric acid was repeated until all organic matter completely decomposed. After cooling, the digest was quantitatively transferred into a volumetric flask.

To an aliquot of solution containing the $Mo^{VI}O_2^{2+}$ ion (1×10^{-5} mol L^{-1}), hydrochloric acid, ascorbic acid and potassium thiocyanate were added in amounts to achieve the desired conditions in a final volume of 5 mL (HCl, 2 mol L^{-1}; ascorbic acid, 2%; KSCN, 0.2–0.6 mol L^{-1}). After 20 min, a solution of the cationic surfactant cetylpyridinium chloride (CPC) in chloroform (5.0 mL) was added in excess (molar ratio 1:200) to the previously prepared aqueous solution. Both phases were shaken with a mechanical shaker for 20 min and after separation of the phases the resulting solution was used for spectrophotometric determination of molybdenum. The absorbance of the organic phase was measured at 465 nm against a reagent blank prepared under the same experimental conditions.

3. Results and discussion

3.1. Synthesis of the complexes

New mononuclear [MoO_2L(py)] (**1a** and **2a**), [MoO_2L(γ-pic)] (**2a** and **2b**) and [MoO_2L(im)] (**1c** and **2c**) and dinuclear [{MoO_2L}$_2$D] (**1d** and **2d**) molybdenum(VI) complexes were obtained by the reaction of polimeric $[MoO_2L]_n$ (**1** or **2**) thiosemicarbazonato complexes with an appropriate amine (pyridine, γ-picoline, imidazole or 4,4′-bipyridine) (Scheme 2). In all the isolated complexes the thiosemicarbazonato ligands are coordinated to molybdenum as tridentate *ONS*-donors through phenolic–oxygen, imine–nitrogen and thiol–sulfur. The octahedral coordination around the Mo atom is completed by a N-donor molecule. The IR spectra of all the complexes showed a doublet characteristic of the presence of the *cis*-MoO_2 group in the range 892–932 cm^{-1}. Absence of an intensive band in the region 850–800 cm^{-1} in the spectra of the dinuclear complexes (**1d** and **2d**) indicates that the [{MoO_2L}$_2$D] complexes are formed by a simple linkage of two mononuclear species through the bridging 4,4′-bypiridine ligand ($LO_2Mo–NC_5H_5–C_5H_5N–MoO_2L$), and not *via* metal–oxygen bridging. The stretching frequencies found in that region in the IR spectra of **1d** and **2d** have a very small intensity and are not characteristic of the presence of a Mo_2O_b group [15]. All other frequencies characteristic for coordinated thiosemicarbazonato ligands are in accordance to the literature data [16] and are given in the Table 1.

Scheme 2. Reactions of polymeric $[MoO_2L]_n$ and amine, pyridine (py), γ-picoline γ-pic), imidazole (im) and 4,4′-bipyridine (bpy).

The thermal analysis data (Table 2) of the mononuclear complexes [MoO_2L(py)] (**1a** and **2a**) and [MoO_2L(γ-pic)] (**2a** and **2b**) exhibit two main processes. The first step is related to the loss of the coordinated N-donor molecule and conversion into stable species of the formula [MoO_2L]. The second step is associated with complex decomposition resulting in a solid residue identified as MoO_3. The decomposition of the complexes coordinated with imidazole [MoO_2L(im)] (**1c** and **2c**) or 4,4′-bipyridine [{MoO_2L}$_2$D] (**1d** and **2d**), proceeded without a stable intermediate product.

3.2. Structural studies

The structures of **2a**, **2b** and **2c** are shown in Fig. 1. In all the compounds the molybdenum atom has a distorted octahedral coordination, with two oxo groups *cis* to each other and the doubly deprotonated tridentate ligand equatorially oriented *via* O, N and S atoms. The octahedral coordination is completed by the N atom of the donor molecule (pyridine, γ-picoline or imidazole, in **2a**, **2b** and **2c**, respectively).

The interatomic distances Mo1–O1 and Mo1–O2 (Table 5) are typical of Mo–O double bonds. The corresponding bond angles O1–Mo1–O2 (which are significantly larger than 90°) indicate the greater repulsion between two oxygen atoms closely attached to the central metal atom. Repulsion between the terminal oxo atoms is accompanied by a contraction of the opposite angle N3–Mo1–N4. Values of the other coordination angles are in agreement with those found in similar structures [17,18], and with the fact that the ligand geometry, together with the donor atom size, has an influence on the final angle value. Such a sterically crowded environment in all the complexes causes a shift of the molybdenum atom from the equatorial plane towards the O2 atom (distances from the mean plane defined by S1, N3, O1 and O3 range from 0.2815(3) to 0.3439(5) Å). Also, the other bond distances of Mo1–S1, Mo1–O3 and Mo1–N3 resemble those found in other (similar) thiosemicarbazonato molybdenum complexes [4,5,19]. Owing to

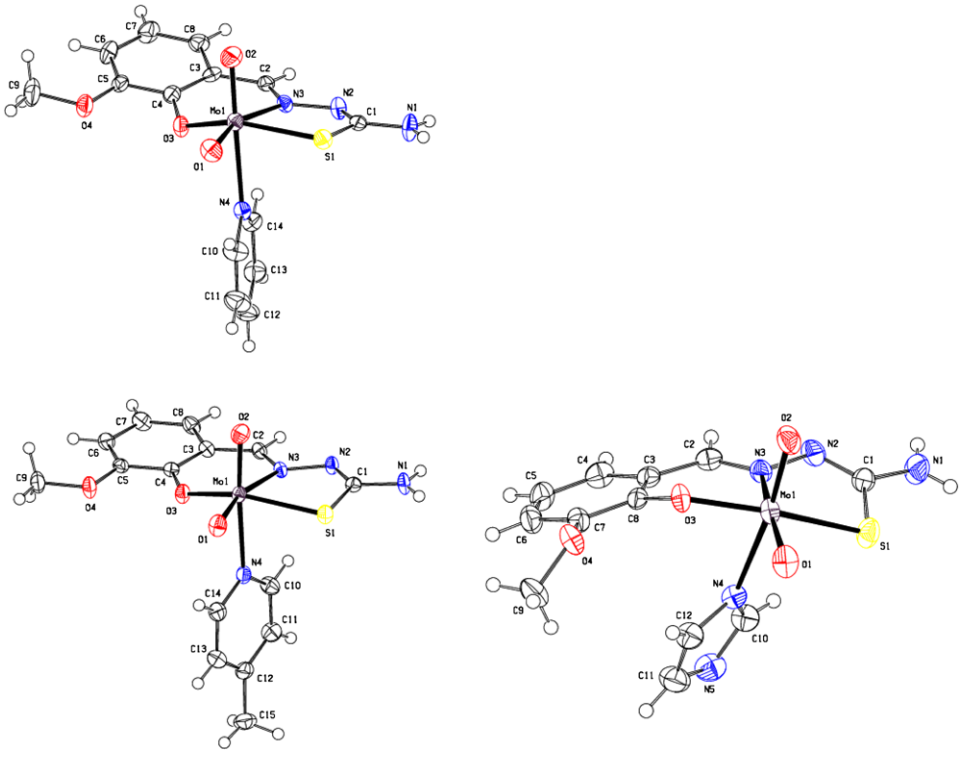


Fig. 1. View of the molecular structures of **2a**, **2b** and **2c** with the atom labelling scheme. Thermal ellipsoids are shown at the 50% probability level.

the *trans* influence of the terminal oxo ligands, the Mo–N4 bond from the amine donor ligand and the Mo–N3 bond from the thiosemicarbazonato ligand are longer than Mo–N bonds that are not under such an influence. A Cambridge Structural Database [20] survey gave 31 structures with similar *NOS* donors and with M=O *trans* to the Mo–N bond. The Mo-N bond lengths in those structures are in the range 2.224–2.325 Å. In contrast, the Mo–N bond distance is in the range 2.115–2.180 Å when the *trans* effect is not present (3 hits). The Mo–N bond to pyridine, γ-picoline or imidazole ligands is always longer, ranging from 2.372 to 2.475 Å in nine structures.

Ligand deprotonation and chelation causes the collapse of the intramolecular O–H···O and N–H···N hydrogen bonds which contribute to the planarity of the molecular skeleton (compared with the free ligand form in the solid state) [21]. As in many previously described cases, the *trans* configuration of the S1 atoms with respect to N3 changes upon chelation into a *cis* configuration [18,19]. In addition, the *cis* configuration of the N1 atom with respect to N3, which favors an intramolecular hydrogen bond in the free ligand form, changes to a *trans* configuration. This event is also associated with rotation around the C1–N2 and C2–C3 bonds together with lengthening of the C1–S1, C1–N1, N2–N3, C2–N3 and C3–C4 bonds and shortening of the C1–N2, C2–C3 and C4–O3 bonds in comparison with the ligand in the free form [19]. Other bond lengths and angles within the bound ligand are in agreement with the fact that, upon complexation to the metal atom, the system of conjugated bonds extends over the five- and six-membered chelate heterocycles. The conformations of the five-membered chelate rings in **2b** and **2c** are very flat envelopes on Mo1, whereas in **2a** the five-membered ring is planar. The six-membered chelate rings are found to be more puckered, with conformations near to envelope on Mo1 in **2a**, half-boat in **2b** and with the conformation close to screw-boat in **2c** (with Mo1 and O3 atoms found on the opposite sides of the mean plane [22,23]. The bound ligand in **2a** and **2c** is not planar. The angles between the planes of the salycilaldiminic and thiosemicarbazone

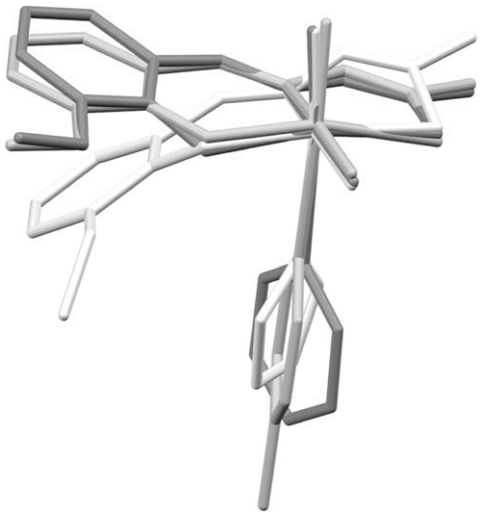

Fig. 2. Superposition of the molecules of **2a** (dark grey), **2b** (grey) and **2c** (light grey).

parts of the ligand [18.36(10)° and 32.93(6)° in **2a** and **2c**, respectively] indicate non-planarity of the ligand. These two planes are mutually coplanar in **2b**. Fig. 2 depicts the conformational changes between the molecules of **2a**, **2b** and **2c**.

The crystal structures of all the complexes are characterized with strong hydrogen bonding interactions of the N–H···N type. This type of structural motif, denoted with the graph-set notation $R_2^2(8)$ [24] is very usual in crystal structures of salicylthiosemicarbazone derivatives, as well as in their complexes. In addition to that, a great variety of weaker intermolecular interactions of the N–H···O, C–H···O, T shaped N–H···π and π···π type (Figs. 3–5) is also present.

In the crystal structure of **2a**, centrosymmetric dimers are held together by strong N–H···N^{i} (i = $x - 1/2$, $-y$, $1 - z$) hydrogen bonds

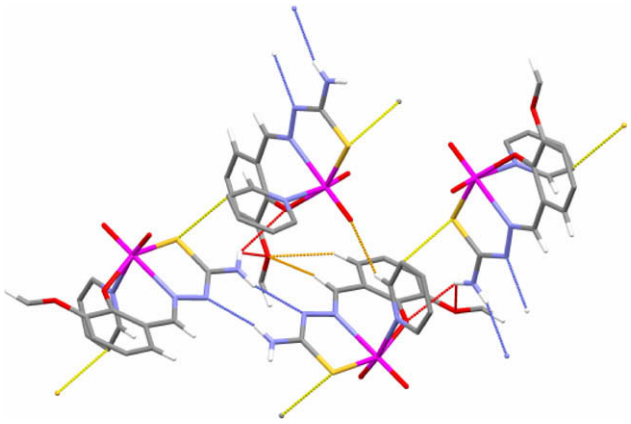

Fig. 3. Intermolecular interactions in **2a** are shown by dashed lines: N–H···N are blue, C···S yellow, N–H···O red and C–H···O orange colored. The molecules are projected down the [1 0 1] direction. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

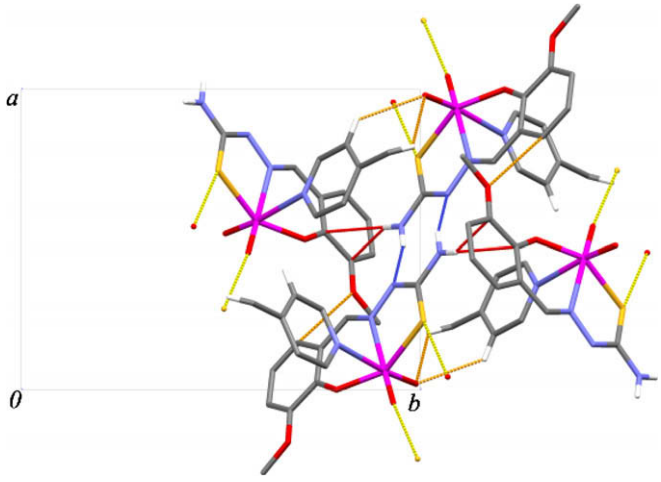

Fig. 4. Crystal packing of **2b**. The same color scheme as in Fig. 2 is applied, except that O···S is now yellow. The molecules are projected down the crystallographic *c*-axis. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

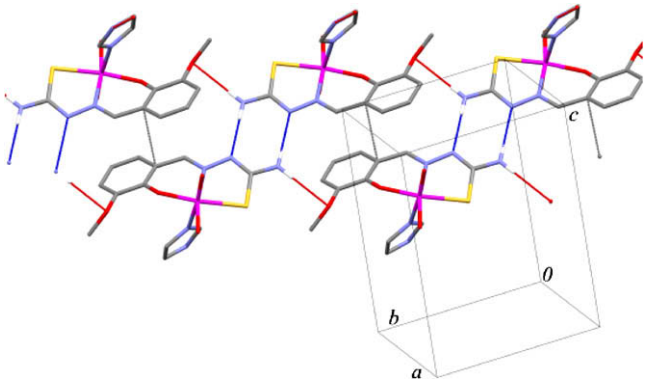

Fig. 5. Crystal packing of (**2c**). Same color scheme as in Fig. 2 is applied.

of the $R_2^2(8)$ type. Such dimers are further connected through N–H···O, C–H···O and S···π interactions forming zig-zag-like sheets of molecules with relatively close H···H contacts (Table 6, Fig. 3).

C12–H12···O1^{xii}	0.93	2.51	3.404(4)	161

Symmetry codes: i = l − *x*, −*y*, 1 − *z*; ii = 3/2 − *x*, −1/2 + *y*, 3/2 − *z*; iii = −1/2 + x, 1/2 − *y*, −1/2 + *z*; iv = l − *x*, 2 − *y*, 1 − *z*; v = 1/2 + *x*, 3/2 − *y*, 1/2 + *z*; vi = −1/2 − *x*, −1/2 + *y*, 1/2 − *z*: vii = 1/2 − *x*, −l/2 + *y*, 1/2 − *z*; viii = 1/2 + *x*, 3/2 − *y*, −1/2 + *z*, ix = 2 − *x*, 1 − *y*, 2 − *z*; *x* = 1 + *x*, −1 + *y*, *z*; xi = *x*, 1 + *y*, *z*; xii = l − *x*, 2 − *y*, 1 − *z*.

Similarly to **2a**, in the crystal structure of **2b**, there are also centrosymmetric dimers connected by weak hydrogen bonds of the N–H···N^{ii} type (ii = 1 − *x*, 2 − *y*, 1 − *z*). Chains of dimers are held together by van der Waals O···S contacts, similar to those found in the literature [25]. Like in the crystal structure of **2c**, one of the hydrogen atoms bound to N1 (the one not involved in N–H···N hydrogen bonding) is involved in T shaped N–H···π interactions, which together with the C–H···O interactions form a three dimensional network (Table 6, Fig. 4).

Molecules in the crystal structure of **2c**, like in the previously described structures, are connected with strong N–H···N hydrogen bonds forming dimers which are arrayed into chains through π···π stacking interactions. Single chains are held together by weaker interactions of the van der Waals (N···O) and C–H···O type (Table 6, Fig. 5).

3.3. NMR spectroscopy

The complete ^{1}H and ^{13}C atom assignments in DMSO–d_6 were made on the basis of the combined use of several one-dimensional (^{1}H and APT sequences) and two-dimensional homo- and heteronuclear experiments (COSY, HSQC and HMBC sequences). The proton and carbon chemical shifts of the ligands H_2L^1 and H_2L^2 (Scheme 1) and the polymeric complexes **1** and **2** are given in Table 3. The observed chemical shift values are similar to those reported previously for the related thiosemicarbazone ligands and their molybdenum(VI) complexes [4,5].

3.4. Spectrophotometric measurements

After decomposition of each molybdenum(VI) complex and addition of hydrochloric acid, the obtained solution containing the $Mo^{VI}O_2^{2+}$ ion was reduced to $[Mo^{V}O(SCN)_4]^-$ by addition of potassium thiocyanate and ascorbic acid. The formed thiocyanato molybdenum(V) complex was extracted using an excess of the extractant in chloroform. Three cationic surfactants were used to study the extraction behavior of the thiocyanato molybdenum(V) complex: benzethonium chloride (hyamine), cetyltrimethylammonium bromide (CTMA) or cetylpyridinium chloride (CPC). Among them CPC had the highest sensitivity and was selected for the study.

The optimum conditions for extractions of the thiocyanato molybdenum(V) complex (1×10^{-5} mol L^{-1}) were found to be:

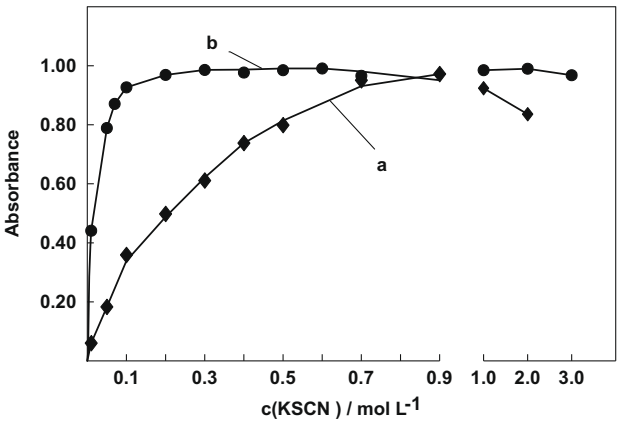

Fig. 6. The dependence of the absorbance of the $[MoO(SCN)_4]^-$ complex on thiocyanate concentration after extraction in the organic phase: (a) without ascorbic acid and (b) in the presence of 2% ascorbic acid.

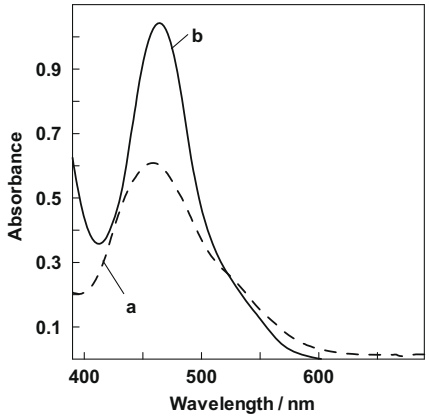

Fig. 7. Absorption spectra of the $[MoO(SCN)_4]^-$ complex *vs* reagent blank: (a) in water and (b) in chloroform after extraction with CPC.

2 mol L^{-1} hydrochloric acid, 2% solution ascorbic acid and an excess of CPC (molar ratio of at least 200:1). For the maximal and constant absorbances the required concentration of potassium thiocyanate depends on the presence of the reducing agent: the concentration was 0.2–0.6 mol L^{-1} in presence of 2% ascorbic acid, whereas in its absence the concentration was 0.9 mol L^{-1} (Fig. 6).

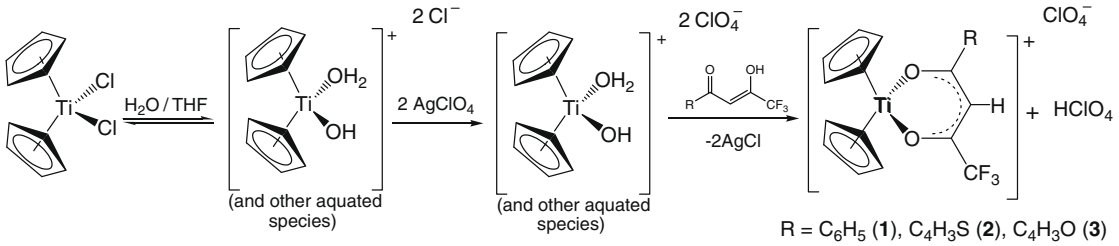
The composition of the ion pair formed by CPC and the thiocyanato molybdenum(V) complex was confirmed spectrophotometrically in the organic phase. The results obtained by the Job's method of continuous variation showed that the molar ratio of the cationic surfactant and the thiocyanato molybdenum(V) complex CPC was 1:1, with the most probable formula (CPC) $[MoO(SCN)_4]$.

The $[MoO(SCN)_4]^-$ complex formed in the aqueous hydrochloric acid solution has a sharp absorption maximum at 460 nm, whereas when extracted with CPC in chloroform a change in position, as well as in the value, of the molar absorptivity was observed (Fig. 7). The molar absorptivity of the complex was found to be 2.5×10^4 mol^{-1} dm^3 cm^{-1} at 465 nm.

The absorbance of the (CPC)$[MoO(SCN)_4]$ complex at 465 nm remained stable for at least 6 h. The results show that Beer's Law is verified for the range of concentrations from 5×10^{-6} to 7×10^{-5} mol L^{-1}. The relative standard deviation of the method was found to be ±0.9 for five repeated experiments.

The proposed method has been successfully applied for the determination of Mo in the new thiosemicarbazones complexes. The results obtained by the proposed method were in good agreement with calculated values and were comparable to those obtained by the thermogravimetric method. The anions used for wet ashing, sulfate and nitrate, were tolerated for a Mo(VI) to anion mole ratio exceeding 1:2500.

Supplementary data



CCDC 706547–706549 contains the supplementary crystallographic data for the structures 2a, 2b and 2c. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.12.026.

Scheme 1. Synthesis of $[Cp_2Ti(CF_3COCHCOR)]^+ClO_4^-$ complexes.

[10]. Addition of silver perchlorate ($AgClO_4$) removes the Cl^- ions by precipitating silver chloride (AgCl) while the hydrolysed perchlorate titanium salt, *e.g.* $[Cp_2Ti(H_2O)(OH)]^+ClO_4^-$ remains in solution. Finally, the β-diketone replaces the hydrolysed leaving groups, forming an ionic species, $[Cp_2Ti(\beta\text{-diketonato})]^+ClO_4^-$, with ClO_4^- as the counter-ion. The problem of the insolubility of the β-diketones in water was overcome by means of a mixed solvent system, using a 1:2 ratio of H_2O and THF. It was found that these salts could also be synthesized in anhydrous THF, in which case, instead of hydrolysis in water, a similar solvated species could be formed by displacement of the two Cl^- ligands in Cp_2TiCl_2 with OC_4H_4 instead of OH_2.

All the synthesized salts are insoluble in water, hexane and ether, slightly soluble in organic solvents such as chloroform, dichloromethane and are soluble in acetone, THF and ethanol. However, dissolving the product in ethanol caused it to decompose. The $[Cp_2Ti(\beta\text{-diketonato})]^+$ cation is very sensitive to moisture in solution, but has been found to be stable in the solid state.

2.2. X-ray structure analysis

The molecular diagrams showing the atomic labelling, accompanied by diagrams showing the molecular packing of **1**, **2** and **3**, respectively, are presented in Fig. 1. Crystal data and details of data collection and refinement are summarized in Table 1. Selected bond lengths and angles for the molecules are listed in Table 2. Structural data for similar complexes are also included in Table 2.

Geometrical aspects: The crystal structures of complexes **1**–**3** revealed a *pseudo*-tetrahedral structure with the centroids of the cyclopentadienyl rings and the two oxygen atoms of the β-diketonato ring in the ancillary positions of the central titanium(IV) atom. It is evident, from examination of the bond angles (see Table 2), that the coordination tetrahedron is distorted. The (centroid Cp1)–Ti–(centroid Cp2) angle is on average *ca.* 134° for complexes **1**–**3**, which is a significant deviation from the ideal tetrahedral bond angle of 109.5°. This large angle is attributed to steric hindrance between the Cp ligands. In contrast, the O1–Ti–O2 angle is on average *ca.* 86°, which is considerably smaller than the standard 109.5° angle. This small angle is attributed to constraints in accommodating the chelated β-diketonato ligand. The other angles around the Ti atom, ranging from 103.4° to 108.4°, approach those for an ideal tetrahedral geometry.

Typical C–C and C–O single and double bond lengths are: C–C (1.54 Å), C=C (1.34 Å), C–O (1.43 Å), C=O (1.23 Å) [11]. The large double bond character of the C–C and C–O bonds in the chelate ring of the β-diketonato ligand (see Table 2) emphasize effective electron delocalization in the *pseudo*-aromatic core of the β-diketonato ligand. This electron delocalization enhances electronic communication between the R-groups of the β-diketonato ligand and the Ti centre. The β-diketonato ligand in $[Cp_2Ti(\beta\text{-diketonato})]^+$ binds, within experimental error (taken as three times the bond e.s.d.), symmetrically to the titanium core in **1** and **2** and asymmetrically in **3**, with a difference between the two Ti–O bond lengths of 0.014, 0.000 and 0.023 Å, respectively. This implies that the electron donating properties of the substituted non-CF_3 groups Ph, C_4H_3S, C_4H_3O ($\chi_R = 2.21$ [12], 2.10 [13], unknown) of the β-diketonato ligand do not show an observed effect on the Ti–O bond length in the solid state compared to the stronger electron withdrawing property of the CF_3 group ($\chi_{CF_3} = 3.01$ [12]). The Ti–O bond lengths are shorter in the Ti^{IV} complexes (average 1.996 Å) compared to the Ti^{III} analogues (average 2.076 Å), see Table 2, and this indicates that the more electron deficient Ti^{IV} centre binds oxygen more strongly than Ti^{III}. The same trend is observed in the Ti–Cp bonds: the Ti–(centroid Cp) bonds (average 2.036 Å) for the Ti^{IV} complexes are *ca.* 0.03 Å shorter than those for the Ti^{III} complexes (average 2.062 Å).

The Cp rings of all the complexes tabulated in Table 2 are in a staggered conformation. From an examination of the Cambridge Structural Database (CSD) [14] it can be seen that the staggered sandwich conformation in bent metallocene $Cp_2Ti^{IV}(O\text{-ligand})_2$ and $Cp_2Ti^{IV}(O,O'\text{-ligand})$ complexes is highly favored, although in many cases it was found that the energy barrier to cyclopentadienyl rotation is very small [15]. It has been shown that the choice of conformation is attributed largely to crystal packing effects [16] highlighted in the crystals of Cp_2NbCl_2 and Cp_2MoCl_2, where both the staggered and eclipsed conformations are found in the same crystal.

Crystallographic aspects: The structures **1**–**3** are isomorphous, *i.e.* they crystallize in the same space group, $P2_1/n$, $Z = 4$, with unit cell parameters varying slightly to accommodate the differences in the substituted R-groups and are situated on fairly similar coordinates within the unit cell. The refinements of $[Cp_2Ti(tfba)]^+$ (**1**) and $[Cp_2Ti(tfth)]^+$ (**2**) showed large thermal vibrations on parts of the periphery of the molecules, such as the Cp ring and the CF_3 and ClO_4^- groups. These large thermal vibrations may be attributed to the fact that the collections were done at room temperature and possibly also to loose packing environments in the periphery of the molecules. The thermal vibrations were treated by disordered refinement techniques, involving geometric and anisotropic restraints to obtain more satisfactory refinement results. In the data collection of **3**, where sub-zero temperatures were utilized, these disorders became less pronounced and were considered negligible in the final refinements. Site occupancies for both disordered parts of **1** and **2** (indicated as A and B in Fig. 1) were refined freely but restricted to add up to one. These refined to ratios which are shown in Table 3.

Hydrogen-interactions, although relatively weak, also play a part in site occupation ratios. There are H-interactions between the atoms in the higher occupied site, *e.g.* the interactions C_2–$H_2\cdots F_{1A}$ have higher occupation rates of 56.9% and 83.7% (position A) for the disordered F atoms in $[Cp_2Ti(tfba)]^+$ (**1**) and $[Cp_2Ti(tfth)]^+$ (**2**), respectively. Similarly, H-interactions with perchlorate exist, which lead to the higher occupation rates of 80.0% and 58.9% (position A) for the disordered O atoms in the perchlorate ion.

The fact that the Cp ring, marked C_{21} to C_{26} in the molecular diagram of Fig. 1, is not disordered in all three cases, while the other

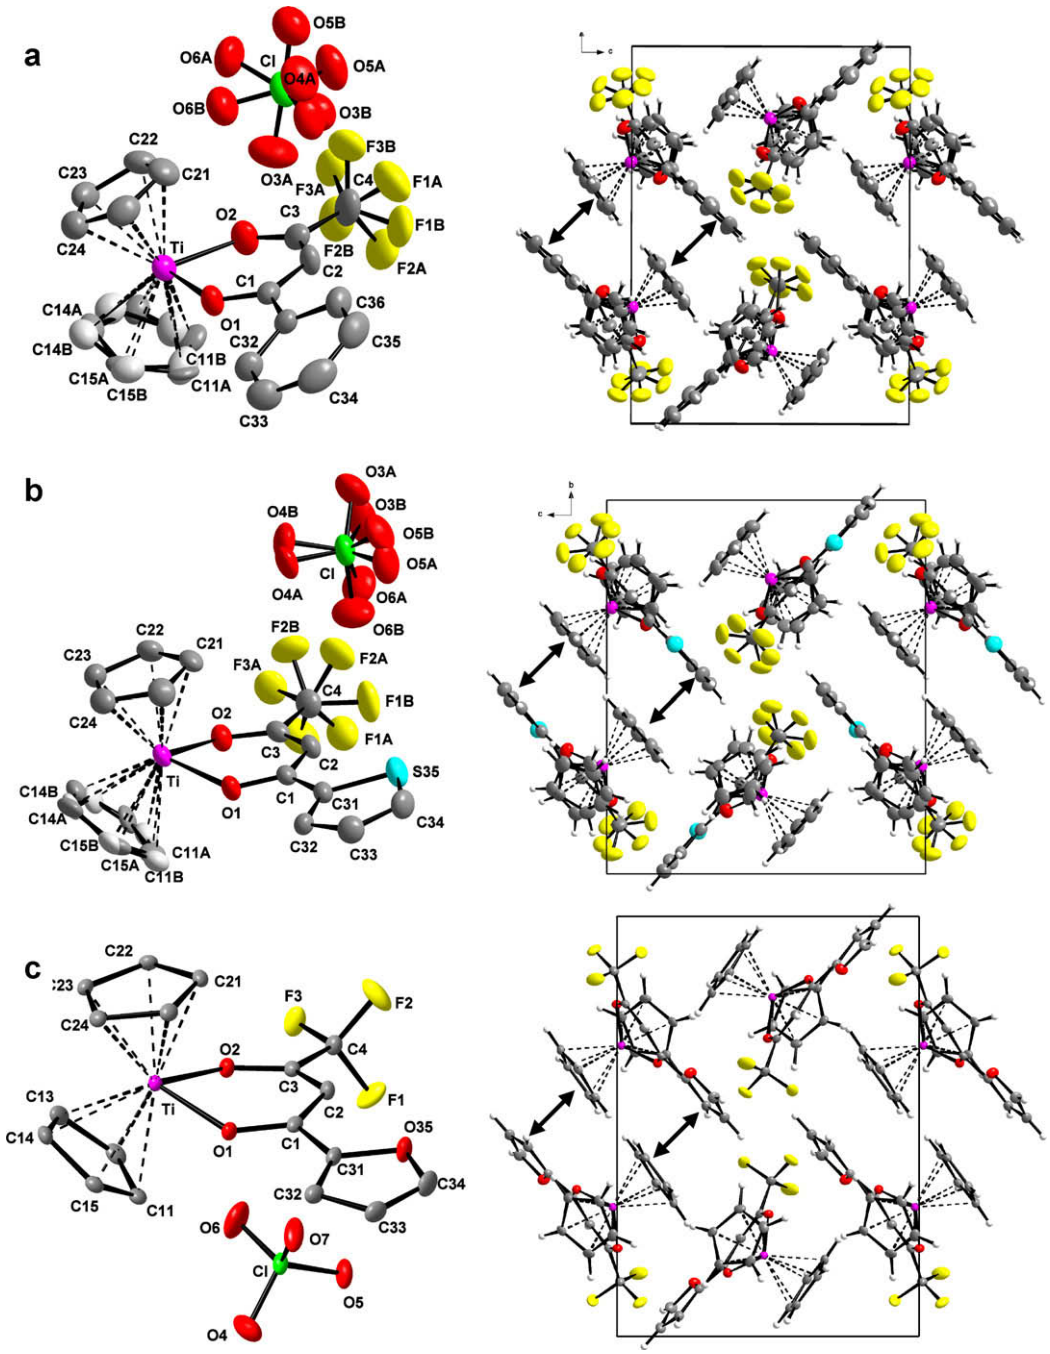

Fig. 1. Molecular structure indicating the numbering scheme (with 30% probability displacement ellipsoids, left) and packing viewed along the *a*-axis (right) of (a) $[Cp_2Ti(tfba)]^+ClO_4^-$ and (b) $[Cp_2Ti(tfth)]^+ClO_4^-$ at $T = 20°$ and (c) $[Cp_2Ti(tffu)]^+ClO_4^-$ at $T = -123°$. Monomeric cationic entities in the crystal are linked by π–π stacking interactions (indicated by double-headed arrows) forming dimeric units (perchlorate ions have been removed for the sake of clarity).

Cp ring (marked C_{11} to C_{16}) is disordered in $[Cp_2Ti(tfba)]^+$ (**1**) and $[Cp_2Ti(tfth)]^+$ (**2**) may be attributed to the fact that the non-disordered Cp rings are involved in the observed π-stacking as described below, forcing this ring (C_{21} to C_{26}) into a more restricted packing environment.

Packing features. The isomorphous complexes **1**–**3** have very similar packing arrangements, with π–π stacking between one Cp ring and the R-group ring of the β-diketonato ligand, *i.e.* the C_6H_5, C_4H_3S and C_4H_3O fragments of tfba, tfth and tffu, respectively. The π–π stacking interactions are between pairs of Ti complexes, forming dimeric units, see Fig. 1 (right).

The planes of the π–π stacked rings are nearly parallel in $[Cp_2Ti(tfth)]^+$ (**2**), with only a small deviation of 0.9° between the planes, compared to 7.4° and 11.0° in the corresponding complexes **3** and **1**, respectively. Geometrical parameters describing the π–π stacking [17] are given in Fig. 2. In all three cases (tfba, tfth and tffu), the rings are displaced from each other, in a slipped or offset alignment. The centroid–centroid separation, R_{cen}, of 3.724, 3.590 and 3.667 Å and the displacement (centre-normal) angle, θ, of 14.4°, 10.4° and 12.6° corresponds to a horizontal displacement of the ring centroids, *d*, of 0.926, 0.648 and 0.800 Å, respectively. The shortest C–H separations between the rings are 3.264, 3.486 and 3.217 Å. These parameters fall well within those required for effective π–π stacking [18]. The packing pattern observed here appears to be unique to the Ti^{IV} bis(cyclopentadienyl) mono(β-diketonato) complexes because the Ti^{III} analogues, *i.e.*

the ground state geometrical and electronic properties of the β-diketonato interactions with the titanium centre in monomeric complexes of the type $[Cp_2Ti^{IV}(R^1COCHCOR^2)]^+$. Since these density functional methods are applied to β-diketonato titanocenyl complexes for the first time and reported here, some measure on the reliability of the approach was obtained by comparing the calculated data with the known single crystal X-ray diffraction structural data of **1**–**4**. The root-mean-square distances (RMSD) calculated for non-hydrogen atoms for the best three-dimensional superposition of calculated structures on experimental structures give a qualitative measurement of the accuracy of the ground state geometry of the calculated structures. Excellent agreement between experimental and theoretical structures is obtained, as reflected by the RMSD values of 0.20, 0.08, 0.07 and 0.04 Å for **1**–**4**, respectively. For **1** and **2**, containing disordered parts, the parts with the highest site occupancy were used in the RMSD calculation. The largest deviation from the experimental structure was found for **1**, containing a large % of disordered parts. Fig. 3 displays the optimized structures of **1**–**4** with selected calculated geometrical parameters. All the bonds in the Ti-β-diketonato ring structure of **1**–**4** were reproduced by DFT calculations to within 0.01–0.03 Å of the experimental values. Since comparisons of experimental metal–ligand bond lengths with calculated bond lengths below a threshold of 0.02 Å are considered as meaningless [19], the computational method used thus gives a good account of the experimental bond lengths. The O1–Ti–O2 angles were calculated accurately to within 1°. The DFT optimized structures containing titanocene with the Cp rings in the staggered or in the eclipsed conformation are approximately equi-energetic, with no preference for either conformation. This result is in agreement with the experimental observation that the choice of conformation is attributed to crystal packing effects and is counter-ion dependant [16].

An interesting observation for experimental structure **2** is that the sulfur on the aromatic thienyl group is orientated towards the methine hydrogen of the β-diketonato ligand; this is in contrast to the orientation in the uncoordinated Htfth ligand [20]. The same result was found for the orientation of the O atom of the furyl group in the crystal structure of **3** [21]. Theoretical calculations, however, did not give any preference for the orientation of the thienyl or furyl group in the optimized ground state structure of **2** or **3**, respectively. The energy needed for rotation between the orientations is 11.3 kcal/mol for **2**, showing that this rotation may easily occur at room temperature [22], see Fig. 4.

Electronic structure: A bent Cp_2Ti^{2+} fragment has C_{2v} symmetry if the Cp ligands have an eclipsed geometry, and C_s symmetry if the

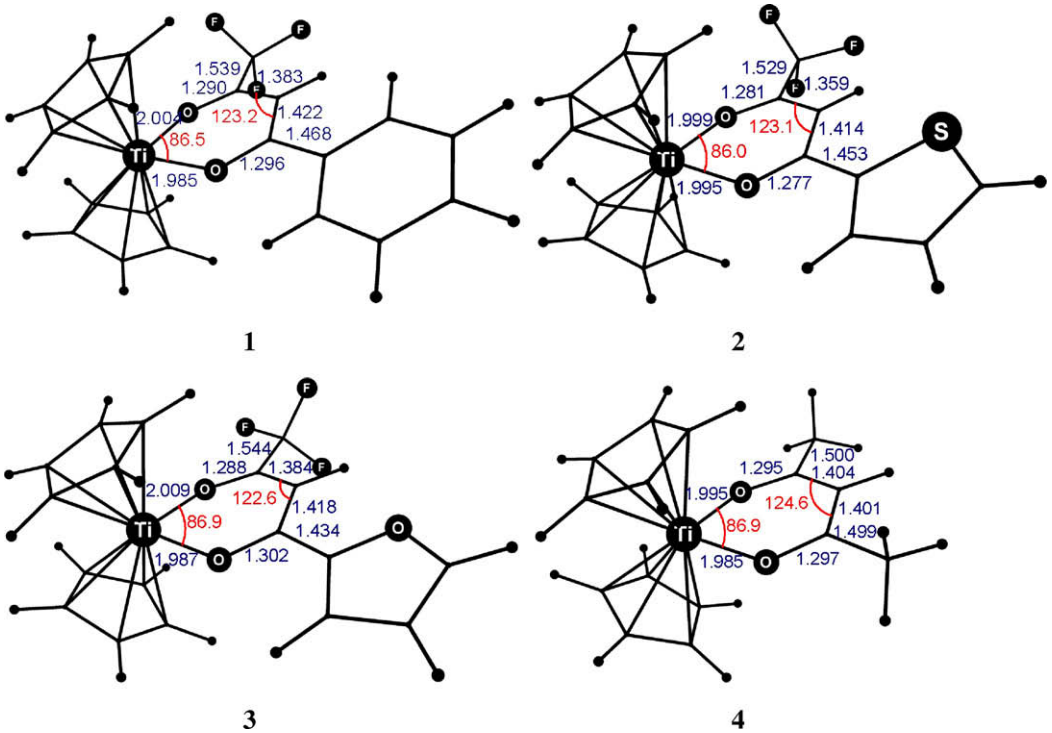

Fig. 3. The PW91/TZP calculated minimum energy geometries of **1**–**4**. Angles (°) and bond lengths (Å) are as indicated.

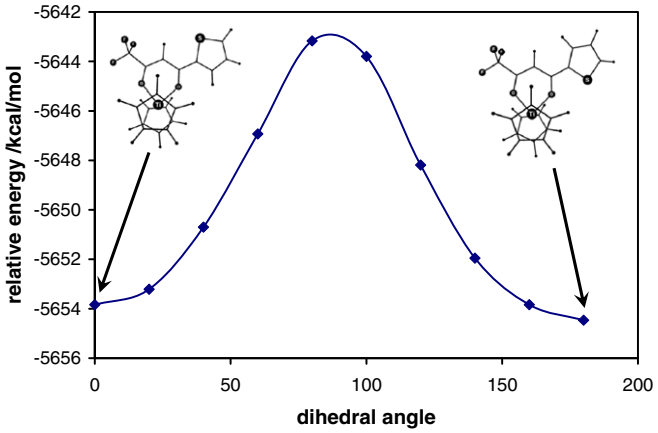

Fig. 4. Rotation of **2** from the isomer with the S orientated towards the methine H to the isomer with S orientated in the same direction as the O, as a function of the O1–C1–C31–S dihedral angle where all other internal coordinates have been optimized at each point.

rings are staggered. The C_s symmetry is preserved when a symmetrical β-diketonato ligand is complexed to Cp_2Ti^{2+}. The electronic structure of $[Cp_2Ti(acac)]^+$ with C_s symmetry is thus presented here as a representative example of the $[Cp_2Ti(\beta\text{-diketonato})]^+$ complexes **1**–**4**. To understand the way in which the acac$^-$ ligand binds, the interaction between the frontier orbitals of a bent Cp_2Ti^{2+} fragment [8] and the HOMOs of the acac$^-$ ligand is schematically illustrated in Fig. 5. The usual in-plane σ-type Ti–O interaction is observed where the unoccupied b_2 LUMO+1 of Cp_2Ti^{2+} interacts with the occupied b_2 HOMO of acac$^-$ (forming HOMO−5 of $[Cp_2Ti(acac)]^+$) and the unoccupied $2a_1$ LUMO+2 of Cp_2Ti^{2+} interacts with the occupied a_1 HOMO−2 of acac$^-$ (forming HOMO−6 of $[Cp_2Ti(acac)]^+$). The $[Cp_2Ti(acac)]^+$ complex is formally a 16-electron d^0 complex if only Ti–O σ-bonding is considered. The electron count is increased by Ti ← O π donation. A moderate to weak π-type interaction is observed in the HOMO−2 and HOMO−7 of the $[Cp_2Ti(acac)]^+$ complex, see Fig. 5 for a schematic presentation of the interaction and Fig. 6 for presentation of the orbitals involved in Ti–O bonding. The above described Ti–O interactions result in Ti–O bonds of an average 1.99 Å for **1**–**4**, slightly longer than that for determined for $Cp_2Ti^{IV}(OR)_2$ complexes containing two monodentate OR ligands, *i.e.* 1.96 Å for $Cp_2Ti(cyanoacetato)_2$ [23] and 1.93 Å for $Cp_2Ti(benzoato)_2$ [9] and comparable to the Ti–O bond length of 1.97 Å in $[\eta^2\text{-OC(Ph)=C(Ph)O]TiCp_2}$, containing a dioxolate bidentate ligand [24].

One interesting feature of the $[Cp_2Ti(\beta\text{-diketonato})]^+$ structures is the degree of out-of-plane folding of the β-diketonato ligand, as schematically shown in Fig. 7. The folding of $[Cp_2Ti(\beta\text{-diketonato})]^+$ along the O···O axis is $\omega = 7.9°$, 19.4°, 19.9° and 16.8° for **1**–**4**, respectively. Similar folding is observed in the series of d^0 penta metallacyclic structures, *i.e.* Cp_2Ti(dioxolene) [24], Cp_2Ti(dithiolene) [25] and Cp_2Ti(diselenolene) [26] complexes, with an increasing degree of folding along the O···O, S···S and Se···Se axes of 38°, 42–50° and 48–52°, respectively. It was rationalized by Lauher and Hoffmann [8] using extended Hückel (EH) calculations that the folding in the Cp_2Ti(dithiolene) complexes was due to a stabilizing interaction between the empty acceptor LUMO $1a_1$ orbital of the Cp_2Ti^{2+} fragment and the HOMO b_1 orbital of the dithiolene ligand, which was only possible by a symmetry lowering of the Cp_2Ti(dithiolene) complex to the C_2 conformation and associated folding of the TiS_2C_2 metallacycle. In this study we confirmed this Ti ← L (L = O, S, Se) π interaction (between the empty acceptor $1a_1$ LUMO of the Cp_2Ti^{2+} and the b_1 HOMO of the ligand) with DFT calculations for the above pentacyclic series, $Cp_2(TiO_2C_2R_2)$,

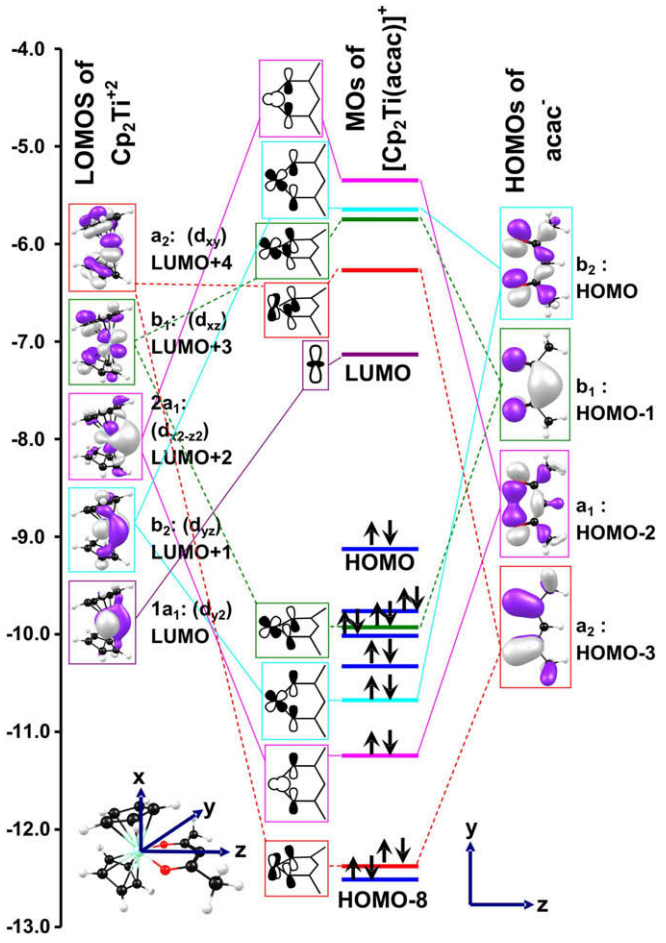

Fig. 5. A schematic molecular orbital (MO) diagram for the interaction between Cp_2Ti^{2+} and the acac$^-$ unit in **4**. The *y*-axis denotes the relative energy in eV for the molecular orbitals of the $[Cp_2Ti(acac)]^+$ complex **4**. The MO energy levels indicated in blue do not have any Ti–O interaction.

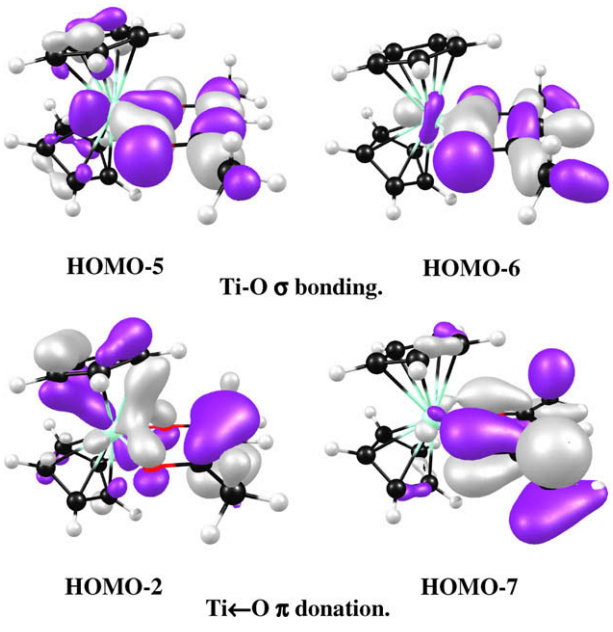

Fig. 6. Selected occupied MO's of **4**, illustrating the Ti–O σ and Ti ← O π interaction.

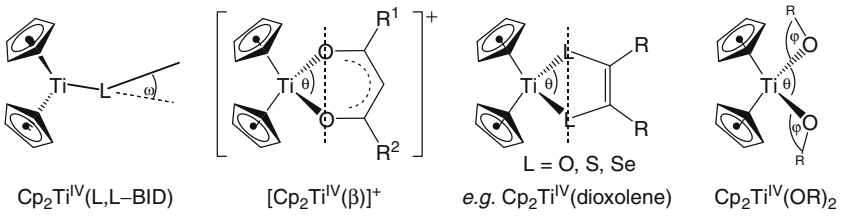

Fig. 7. Folding round the L···L axis in the Cp_2Ti(LL-BID) complexes (LL-BID = bidentate ligand with donor atoms L, L = O, S or Se) is described by the dihedral angle, ω, between the cyclic ligand plane and the L–Ti–L plane. In the $Cp_2Ti(OR)_2$ complexes containing monodentate ligands OR, the large θ and φ angles describe the degree of bending along Ti–O–R.

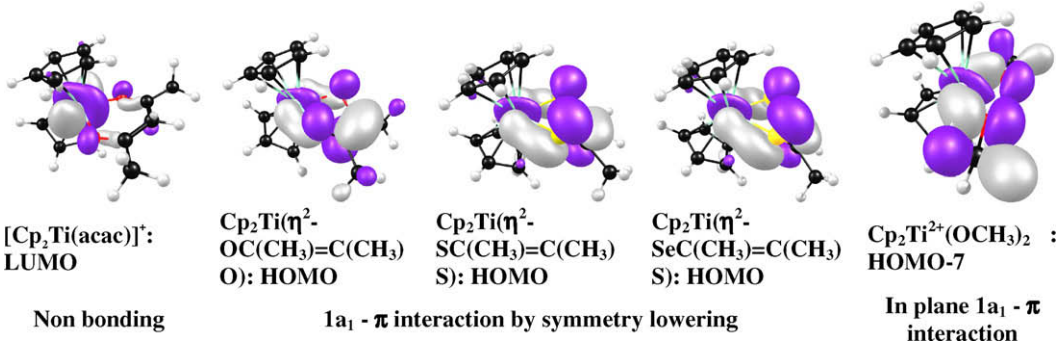

Fig. 8. The $1a_1$ type MO of the $[Cp_2Ti(\beta\text{-diketonato})]^+$, Cp_2Ti(dioxolene), Cp_2Ti(dithiolene), Cp_2Ti(diselenolene) and $Cp_2Ti(OR)_2$ complexes illustrating the $1a_1$–π interaction.

$Cp_2(TiS_2C_2R_2)$ and $Cp_2Ti(Se_2C_2R_2)$ (R = CH_3), see Fig. 8. However, no such Ti ← O π interaction was observed for the hexacyclic $[Cp_2Ti(\beta\text{-diketonato})]^+$ complexes **1–4** where the $1a_1$ LUMO of the Cp_2Ti^{2+} fragment remains non-bonding in $[Cp_2Ti(acac)]^+$, see Fig. 7. Thus we conclude that the folding in the $[Cp_2Ti(\beta\text{-diketonato})]^+$ complexes is not due to the stabilization of the same electronic interaction as in the Cp_2Ti(dioxolene) [24], Cp_2Ti(dithiolene) [25] and Cp_2Ti(diselenolene) [26] series.

Bending along Ti–O–R, stabilized by Ti ← O π interactions, is observed in $Cp_2Ti^{IV}(OR)_2$ complexes. Extended Hückel (EH) calculations [9] revealed that the in-plane Ti ← O π interaction involving the $1a_1$ LUMO of Cp_2Ti^{2+} and the b_1 HOMO of the ligand was made possible by the large O–Ti–O (θ = 89–91°) and Ti–O–R (φ = 143–148°) angles [9,23, 27]. The in-plane Ti ← O π interaction was reproduced with DFT in the present study for $Cp_2Ti^{IV}(OCH_3)_2$ and is illustrated in Fig. 8. The strain of the β-diketonato ring structure in $[Cp_2Ti(\beta\text{-diketonato})]^+$ complexes with a O–Ti–O angle of *ca.* 86°, however, makes large O–Ti–O and Ti–O–C angles impossible. Thus stabilization through in-plane Ti ← O π interaction is thus geometrically not possible for $[Cp_2Ti^{IV}(\beta\text{-diketonato})]^+$ complexes.

The potential energy as a function of the folding along the O···O, S···S and Se···Se axes, with all other internal coordinates being optimized at each point, was calculated for the model complexes $[Cp_2Ti(\beta\text{-diketonato})]^+$, Cp_2Ti(dioxolene), Cp_2Ti(dithiolene) and Cp_2Ti(diselenolene). A plot of potential energy as a function of folding indicates that it takes less than 1 kcal/mol to fold the $[Cp_2Ti(acac)]^+$ complex from the minimum energy conformation, with a folding angle of 17°, to planar. This energy is substantially increased in the pentacyclic series, where the energy needed is 7.4, 16.7 and 16.0 kcal/mol for the $Cp_2Ti(O_2C_2(CH_3)_2)$, $Cp_2Ti(S_2C_2(CH_3)_2)$ and $Cp_2Ti(Se_2C_2(CH_3)_2)$ complexes, respectively.

3. Conclusions

New titanocenyl complexes of the type $[Cp_2Ti(CF_3COCHCOR)]^+ClO_4^-$ with R = C_6H_5, C_4H_3S and C_4H_3O were synthesized and characterized. Crystallographic studies showed that all complexes exhibit π–π stacking between one Cp ring and the aromatic R-group ring, *i.e.* the C_6H_5, C_4H_3S and C_4H_3O fragments, respectively. DFT calculations show that $[Cp_2Ti^{IV}(\beta\text{-diketonato})]^+$ complexes behave differently to $Cp_2Ti^{IV}(OR)_2$ and Cp_2Ti^{IV}(dioxolene) complexes in that no significant bonding interaction between the $1a_1$ LUMO of the Cp_2Ti^{2+} fragment and the coordinating ligand is observed.

4. Experimental

4.1. Materials and apparatus

Solid reagents (Merck, Aldrich and Sigma) were used without further purification. Liquid reactants and solvents were distilled prior to use using standard purification techniques [28] and water was double distilled. Melting points were determined with a Reichert Thermopan microscope equipped with a Kofler hot-stage and are uncorrected. NMR measurements were recorded on a Bruker Advance DPX 300 NMR spectrometer. Chemical shifts are reported as δ values relative to $SiMe_4$ (0 ppm). IR spectra were recorded from neat samples on a Digilab FTS 2000 Fourier transform spectrometer utilizing a He–Ne laser at 632.6 nm.

4.2. Synthesis

Safety note: Perchlorate complexes are potentially explosive, should be treated with caution and handled in small quantities.

4.2.1. Preparation of $[Cp_2Ti(tfba)]^+ClO_4^-$ (*1*)

Titanocene dichloride, Cp_2TiCl_2 (249.0 mg, 1.0 mmol) was dissolved in H_2O/THF, 1:2 mixture (9 ml) and stirred under nitrogen for ½ h. The solution was cooled down on an ice-bath before silver perchlorate, $AgClO_4$ (406 mg, 1.96 mmol), dissolved in water (2 ml) was added. The cooled mixture was stirred for a further ½ h. $AgClO_4$ is light sensitive and the reaction must be shielded from light. Silver chloride, a white precipitate, was filtered off and washed with H_2O/THF (2 ml). Trifluorobenzoylacetone, Htfba (432 mg,

2.0 mmol), dissolved in cold THF (2 ml, *ca.* 4 °C) was added dropwise to the orange filtrate while stirring, causing a slight colour change. After ½ h of stirring the solution was removed and left for 7 days to precipitate (turned dark brown/black). The dark sticky precipitate was collected and washed with water (2 × 100 ml) and diethyl ether (4 × 50 ml). Recrystallisation from DCM/hexane afforded the pure product. Spectroscopically pure crystals suitable for single X-ray analysis were obtained by recrystallisation from DCM/hexane. Yield 51% (246 mg). M.p. = 200 °C. Colour: metallic brown. ν_{CO} = 1554 cm^{-1}. NMR: δ_H (300 MHz, acetone–d_6)/ppm: 7.16 (s, 10H, 2 × C_5H_5), 7.55 (s, 1H, CH), 7.68 (t, 2H, C_6H_5), 7.86 (t, 1H, C_6H_5), 8.35 (d, 2H, C_6H_5). *Anal.* Calc. for $TiC_{20}H_{16}O_6ClF_3$: C, 48.75; H, 3.27. Found: C, 48.13; H, 3.22%.

4.2.2. Preparation of $[Cp_2Ti(tfth)]^+ClO_4^-$ (**2**)

Preparation as for **1**, but replacing the trifluorobenzoylacetone with trifluorothenoylacetone, Htfth (461 mg, 2.0 mmol). Yield 48% (235 mg). M.p. = 191 °C. Colour: dark brown. ν_{CO} = 1566 cm^{-1}. NMR: δ_H (300 MHz, acetone–d_6)/ppm 7.13 (s, 10H, 2 × C_5H_5), 7.38 (s, 1H, CH), 7.50 (t, 1H, C_4H_3S), 8.42 (d, 1H, C_4H_3S), 8.56 (d, 1H, C_4H_3S). *Anal.* Calc. for $TiC_{18}H_{14}SO_6ClF_3$: C, 43.35; H, 2.83. Found: C, 43.77; H, 2.87%.

4.2.3. Preparation of $[Cp_2Ti(tffu)]^+ClO_4^-$ (**3**)

Preparation as for **1**, but replacing the trifluorobenzoylacetone with trifluorofuroylacetone, Htffu (412 mg/2.0 mmol). Yield 43% (203 mg). M.p. = 195 °C. Colour: brown. ν_{CO} = 1568 cm^{-1}. NMR: δ_H (300 MHz, acetone–d_6)/ppm: 7.00 (t, 1H, C_4H_3O), 7.13 (s, 10H, 2 × C_5H_5), 7.18 (s, 1H, CH), 8.07 (d, 1H, C_4H_3O), 8.28 (d, 1H, C_4H_3O). *Anal.* Calc. for $TiC_{18}H_{14}O_7ClF_3$: C, 44.79; H, 2.92. Found: C, 44.71; H, 2.87%.

4.3. X-ray crystal structure determination

The X-ray intensity data for **1** and **2** were measured on a Bruker SMART 1K CCD area detector and that for **3** on a Bruker X8 Apex II 4K CCD area detector. Both instruments were equipped with a graphite monochromator and a Mo Kα fine-focus sealed tube (λ = 0.71073 Å) operated at 1.5 kW power (50 kV, 30 mA). The detector was placed at a distance of 4.00 cm from the crystal. Data collection temperature for **1** and **2** was room temperature (293 K), whereas the temperature during the collection of **3** was 150(2) K, using an Oxford 700 series cryostream cooler.

The initial unit cell and data collection of **3** were achieved by the APEX2 software [29] utilizing COSMO [30] for optimum collection of more than a hemisphere of reciprocal space. A total of 948 frames were collected with a scan width of 0.5° in φ and ω with an exposure time of 20 s per frame. The initial unit cell and data collection for **1** and **2** were achieved by the SMART-NT software [31], set up for data collection of more that a hemisphere of reciprocal space. A total of 1350 frames were collected with a scan width of 0.3° in φ and exposure times of 10 s per frame. The frames were integrated using a narrow frame integration algorithm and reduced with the Bruker SAINTPLUS and XPREP software [32] packages, respectively. Analysis of all of the data collections showed no significant decay during the data collection. Data were corrected for absorption effects using the multi-scan technique SADABS [33].

All the structures were solved by the direct methods package SIR97 [34] and refined using the WINGX software package [35] incorporating SHELXL [36]. The largest peaks on the final difference electron densities and the deepest holes were all within 1 Å from non-hydrogen atoms and presented no physical meaning in the final refinements. Aromatic protons were placed in geometrically idealized positions (C–H = 0.93–0.98 Å) and constrained to ride on their parent atoms with $U_{iso}(H) = 1.2U_{eq}(C)$. Disorders on the perchlorate ions, CF_3 moieties and those on the Cp rings were treated with various geometrical and vibrational restraints.

Atomic scattering factors were taken from the International Tables for Crystallography Volume C [37]. The molecular plot was drawn using the DIAMOND program [38] with a 30% thermal envelope probability for non-hydrogen atoms. Hydrogen atoms were drawn as arbitrary sized spheres with a radius of 0.135 Å.

4.4. Quantum computational methods

Pure Density Functional Theory (DFT) calculations were carried out using the Amsterdam Density Functional 2007 (ADF) program system [39] with the PW91 (Perdew–Wang, 1991) exchange and correlation functional [40]. The TZP (Triple ζ polarized) basis set, a fine mesh for numerical integration (5.2 for geometry optimizations), a spin-restricted formalism and full geometry optimization (gas-phase) with tight convergence criteria, as implemented in the ADF 2007 program, were used. The accuracy of the computational method was evaluated by comparing the root-mean-square deviations (RMSD's) between the optimized molecular structure and the crystal structure, using the non-hydrogen atoms in the molecule. RMSD values were calculated using the "RMS Compare Structures" utility in CHEMCRAFT Version 1.5 [41]. Whether artificially generated atomic coordinates or coordinates obtained from X-ray crystal data were used in the input files, optimizations for each compound resulted in the same optimized geometry. The optimized structures were verified as a minimum through frequency calculations. Unless indicated, no symmetry limitations were imposed in the calculations.

Scheme 1. Schematic views of ligands.

excitation spectra were recorded on a Varian Cary Eclipse spectrometer.

2.2. Syntheses of the ligands and the complexes

2.2.1. Synthesis of 3,5-pmb and 3,4-pmb

3,5-Dihydroxybenzoic acid (15.4 g), ethanol (53 ml) and sulfuric acid (4 ml) were mixed and refluxed for 6–7 h. The excess ethanol was removed under vacuum, and then the reaction mixture was extracted with ethylacetate. The extracted solution was washed once with water, and then with $NaHCO_3$ aqueous solution. After drying with Na_2SO_4, the solvent was evaporated. To 20 mmol (3.64 g) of the product, 40 mmol (6.5 g) of 4-pycolyl chloride hydrochloride and 120 mmol (4.8 g) of NaOH and 10 ml DMF were added. The mixture was heated at 70 °C for 10 h, and then the product was washed with ethanol and filtered. The solid product was transferred to a 100 ml round bottom flask, 50 ml of 5% NaOH solution was added and the resulting solution was refluxed at 70 °C for 5 h, then the mixture was transferred into a 400 ml beaker. After adding 50 ml of distilled and concentrated HCl drop by drop, a light brown precipitate was obtained at about pH 6, which was washed with ethanol and filtered. Yield: 72%. *Anal.* Calc. for $C_{19}H_{16}N_2O_4$ (336.11): C, 67.85; H, 4.79; N, 8.33%. Found: C, 67.91; H, 4.98; N, 8.26%. M.p. for the crude product is 128 °C.

The synthetical method of 3,4-pmb was similar to the synthesis of 3,5-pmb, except that 3,4-dihydroxybenzoic acid was used instead of 3,5-dihydroxybenzoic acid. Yield: 60%. *Anal.* Calc. for $C_{19}H_{16}N_2O_4$ (336.11): C, 67.85; H, 4.79; N, 8.33. Found: C, 67.91; H, 4.98; N, 8.26%.

2.2.2. [Ni(3,4-pmb)(bdc)$_{0.5}$] (**1**)

Compound **1** was prepared from a mixture of $NiCl_2 \cdot 6H_2O$ (0.3 mmol, 0.066 g), 3,4-pmb (0.2 mmol, 0.073 g), bdc (0.2 mmol, 0.033 g) and NaOH (0.6 mmol, 0.024 g) in 8 ml distilled water. This mixture was heated in a sealed Teflon lined steel autoclave at 150 °C for three days. After the mixture was slowly cooled to room temperature at a rate of 10 °C/h, green crystals of **1** were obtained (yield: 58% based on Ni). *Anal.* Calc. for $C_{23}H_{15}N_2O_{10}Ni$ (538.08): C, 51.34; H, 2.81; N, 5.21. Found: C, 50.69; H, 2.79; N, 5.20%.

2.2.3. [Co(3,5-pmb)(bdc)$_{0.5}$] (**2**)

A mixture of $Co(OAc)_2 \cdot 2H_2O$ (0.3 mmol, 0.075 g), 3,5-pmb (0.2 mmol, 0.073 g), bdc (0.2 mmol, 0.033 g) and NaOH (0.6 mmol,0.024 g) was dissolved in 8 ml distilled water. The mixture was heated in sealed Teflon lined steel autoclave at 150 °C for three days. After cooling to room temperature at a rate of 10 °C/h, crystals of the product were obtained (yield: 52% based on Co). *Anal.* Calc. for $C_{23}H_{17}N_2O_6Co$ (476.32): C, 58.00; H, 3.60; N, 5.88. Found: C, 57.96; H, 3.20; N, 5.79%.

2.2.4. [Cd(3,5-pmb)(bdc)$_{0.5}$] (**3**)

The procedure was similar to the synthesis of complex **2** except that $Cd(OAc)_2 \cdot 2H_2O$ (0.3 mmol, 0.08 g) was used instead of $Co(OAc)_2 \cdot 2H_2O$. Yield: 64% based on Cd. *Anal.* Calc. for $C_{23}H_{17}N_2O_6Cd$ (529.79): C, 54.91; H, 3.41; N, 5.57. Found: C, 54.85; H, 3.32; N, 5.55%.

2.3. X-ray crystallography analysis

A suitable single crystal of each complex was mounted on a glass fiber and used for X-ray diffraction analyses. Data were collected at 293(2) K on a Bruker ApexII CCD diffractometer using the scan technique with Mo Kα radiation (λ = 0.71069 Å). Absorption corrections were applied using the multi-scan technique [30]. The structures were solved by the direct method and refined by full-matrix least-square techniques on F^2 using SHLXL-97 [31]. Further details of the X-ray structural analysis for compounds **1**–**3** are given in Table 1. Selected bond lengths and angles for **1**–**3** are listed in Table 2.

3. Results and discussion

3.1. Description of the structures

The hydrothermal reactions of H_2bdc and the corresponding metal salt with the pyridyl-containing ligands at 150 °C have afforded crystals of complexes **1**–**3**. H_2bdc is completely deprotonated to coordinate to the metal center. In each complex, the carboxylate groups of bdc and the carboxylate group of the pmb ligands adopt similar coordination modes.

3.1.1. [Ni(3,4-pmb)(bdc)$_{0.5}$] (**1**)

Single crystal X-ray diffraction analysis reveals that **1** has a 3D threefold interpenetrated adamantanoid structure. As is shown in Fig. 1, each Ni(II) center adopts a distorted octahedral geometry, supplied by two nitrogen atoms from different 3,4-pmb ligands (the average Ni–N distance is 2.037 Å and the N–Ni–N angle is 94.82°), and four oxygen atoms from two carboxylate groups of bdc and pmb in a chelating mode. The Ni–O bond distances are in the range 2.07–2.14 Å, and the O–Ni–O bond angles range from 62.3° to 98.1°. If each chelating carboxylate groups is treated as one connecting point, the nickel center has a pseudotetrahedral geometry [32]. Each Ni(II) atom is thus connected to four other Ni(II) centers, resulting in the formation of a diamondoid network. The

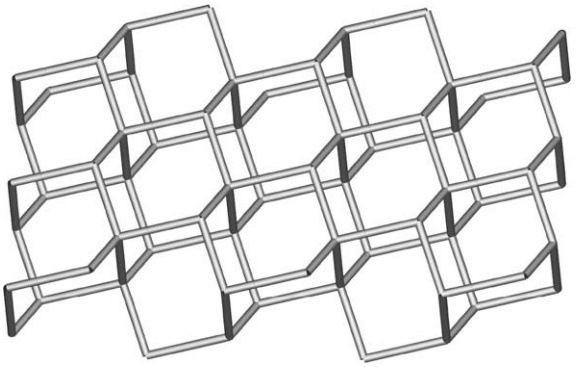

Fig. 2. The three-dimensional adamantanoid cages in complex **1**.

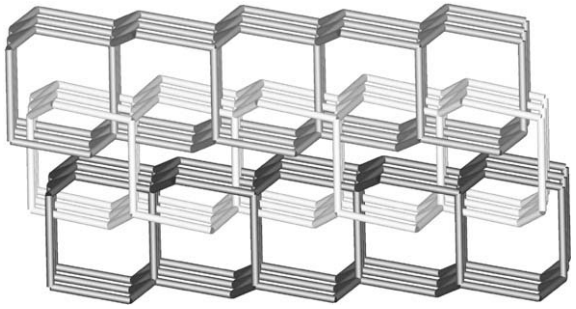

Fig. 3. The threefold interpenetrated adamantanoid architecture of **1**.

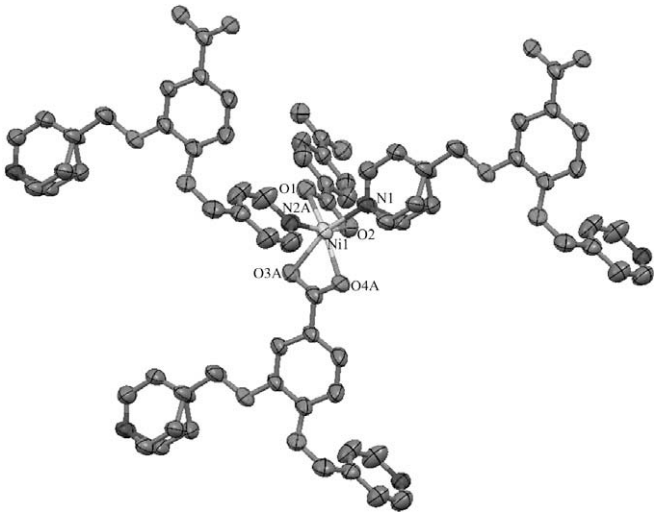

Fig. 1. The coordination environment of Ni(II) in complex **1**.

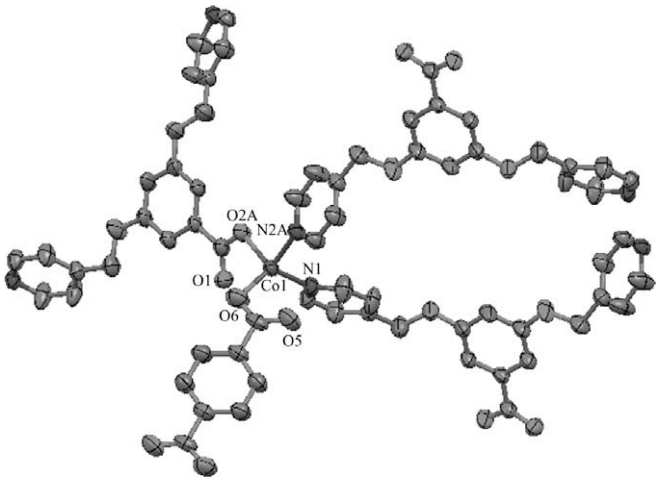

Fig. 4. The coordination environment of Co(II) in complex **2**.

Ni···Ni separations observed were in the range 10.65–13.13 Å. The long spacers between the coordination sites result in large cavities with adamantanoid cages (Fig. 2). In order to minimize the big void cavities and to stabilize the framework naturally, the potential voids are effectively filled by mutual interpenetration of other two independent equivalent frameworks, generating a threefold network (Fig. 3).

*3.1.2. [Co(3,5-pmb)(bdc)$_{0.5}$] (**2**)*

Unlike compound **1**, compound **2** has a 3D fourfold polyrotaxane structure. The network is constructed by binuclear molecules, in which each Co ion is tetrahedraly coordinated to two nitrogen atoms of different 3,5-pmb ligands (Co–N = 2.04 Å and N–Co–N = 102.06°) and two oxygen atoms of two different carboxylate groups in the monodentate mode from pmb and bdc ligands (Co–O = 1.95 Å and O–Co–O = 105.29°) (Fig. 4). The whole network is constructed from four equivalent independent fragments. Each individual fragment consists of a ring and rod chains, in which the ring is constituted by two metal atoms bridged by two pmb ligands. These rings connect with each other via bdc (the rod) to form a chain, and then two adjacent chains are linked by the monodentate carboxylic group of the pmb ligand to form a 3D network. Interestingly, each chain is entangled with one chain from another equivalent independent fragment through the rod to form the polyrotaxane topology (Fig. 5).

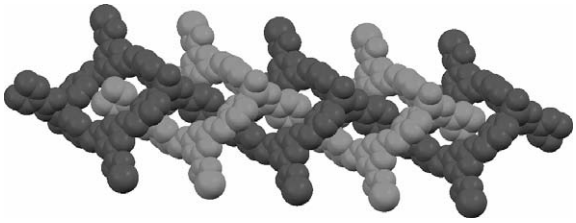

Fig. 5. The polyrotaxane architecture in complex **2**.

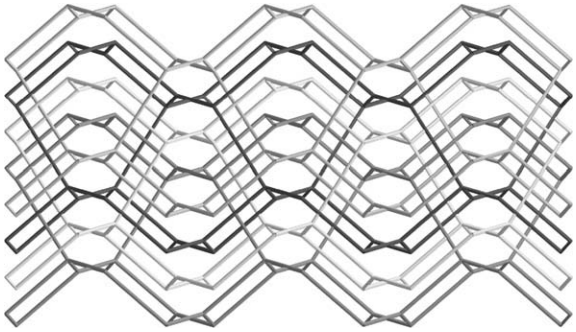

Fig. 6. The 3D fourfold interpenetrated structure of complex **2**.

The most fascinating structural feature of **2** is that four equivalent networks with rotaxane entanglement are then interwoven with each other to give a 3D fourfold structure (Fig. 6).

*3.1.3. [Cd(3,5-pmb)(bdc)$_{0.5}$] (**3**)*

For complex **3**, the X-ray diffraction analysis reveals that it has a unique 2D coordination network consisting of [$Cd_2(CO_2)_4$] units bridged by bdc and pmb ligands (Fig. 7). Each Cd(II) atom is coordinated by one nitrogen atom of a pmb ligand and four oxygen atoms from the carboxylate group of pmb and bdc, in which the four carboxylate oxygen atoms comprise the equatorial plane and the N atom occupies the vertex of square-pyramidal structure to give a square-pyramidal coordinated geormetry. The average Cd–O bond length is 2.233 Å and the Cd–N bond length is 2.239 Å. Two adjacent Cd(II) atoms are bridged equivalently by four carboxylate groups of different pmb and bdc ligands, forming a paddle wheel secondary building unit (SBU). The Cd···Cd separation is 3.12 Å, which is significantly shorter than those in reported discrete dimeric cadmium–tetracarboxylate complexes (3.278–3.452 Å) [33,34], but slightly longer than the sum of the van der Waals radii 3.04 Å [35,36], suggesting that there should be no Cd···Cd bond in the SBU. There exits a crystallographic inversion center between the two Cd cores in each dinuclear unit.

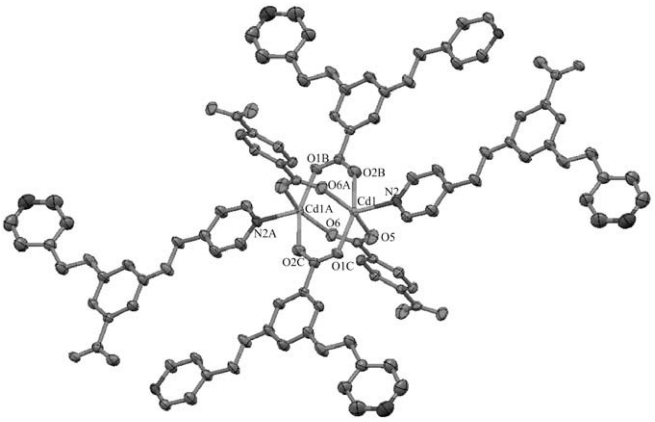

Fig. 7. The coordination environment of Cd(II) in complex **3** highlighting the dinuclear unit.

Two pmb ligands conect with two SBU units like arms to form a four membered ring with a Cd···Cd separation in the intersecting ring of 12.13 Å The rings are extended to form 1D fragments along the *c*-axis, which are extended into a ladder-like 2D network via the bdc ligand (Fig. 8). The arms of each fragment intervene with ones of adjacent fragments without any interlocking (Fig. 9).

3.2. Properties

3.2.1. IR spectroscopy

The IR spectrum of complex **1** shows typical antisymmetric and symmetric stretching bands of carboxylate groups at 1585 and 1384 cm^{-1}, respectively. The separation (Δ) $\upsilon_{asym}(CO_2) - \upsilon_{sym}(CO_2)$ is 200 cm^{-1}, which is consistent with the type of coordination of the carboxylate groups. The peaks of compound **2** centered at 1617 and 1389 cm^{-1} should be assigned to antisymmetric and symmetric stretching bands of carboxylate groups, respectively. The separation (Δ) value is 227 cm^{-1}, indicating the existence of a monodentate coordination mode [37]. In complex **3**, the characteristic bands of the carboxylate groups are shown at 1550 and 1390 cm^{-1} for the for the antisymmetric and symmet-

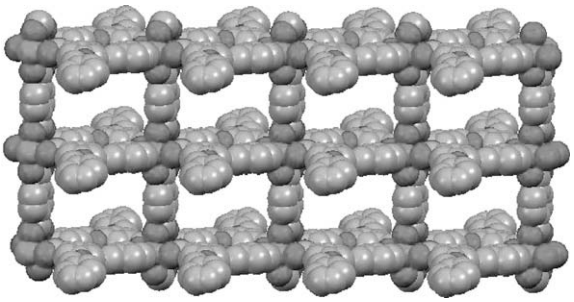

Fig. 8. The 2D ladder-like network of complex **3**.

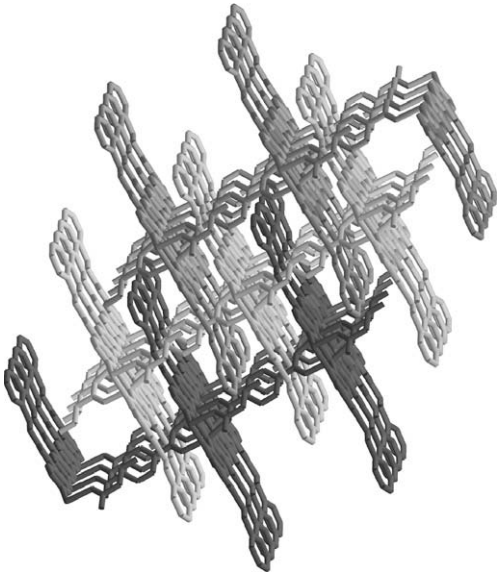

Fig. 9. The intervening fragments of **3**.

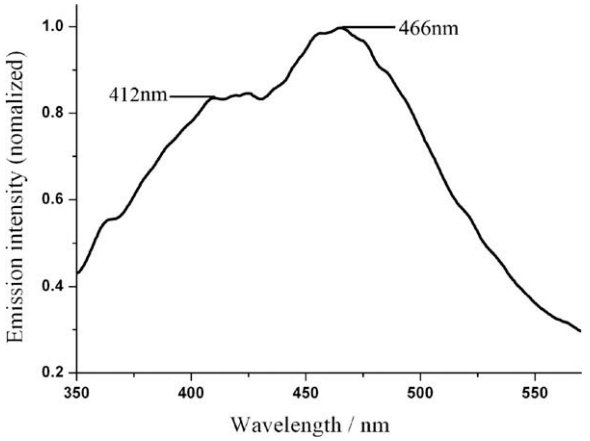

Fig. 10. The emission spectra of **3** in the solid state at room temperature.

ric stretching bands, respectively, with a Δ value of ca. 160 cm^{-1}, indicating the presence of a bis-bidentate coordination mode [37].

3.2.2. Luminescent properties

The solid-state luminescence property of complex **3** was investigated at room temperature. Interestingly, the emission spectrum for complex **3** shows a main peak at 466 nm with a shoulder at about 410 nm upon excitation at 373 nm (Fig. 10). In order to understand the nature of this emission band, we analyzed the photoluminescent property of the pmb ligand and found that the strongest emission peak for pmb apears at 406 nm upon excitation at 346 nm, whereas the emission peak for H_2bdc apears at 390 nm upon excitation at 350 nm [38]. So the shoulder peak of the emission spectrum at 410 nm of complex **3** is probably due to an intraligand energy transition, while the emission band at 466 nm may be assigned to a metal–ligand charge transfer.

4. Conclusion

Three new Ni(II), Co(II) and Cd(II) coordination polymers with different structural motifs based on mixed bdc and dipyridylbenzoates ligands (pmb) have been hydrothermally synthesized and structurally characterized. Complex **1** has a 3D threefold interpenetrated adamantanoid architecture, **2** has a 3D fourfold with rotaxane topology, and **3** is a 2D network with paddle wheel dimeric cadmium tetracarboxylate building units. In summary, our research demonstrates that the dipyridylbenzoates ligand (pmb) could be a potential bridging ligand to construct novel supramolecular architectures with different structures.

Scheme 1.

Magana 560 spectrometer with samples prepared as KBr pellets. A PE TGA thermogravimetric analyzer was used to obtain the TGA curve at a heating rate of 10 °C min^{-1}. Elemental analyses were carried out using the Perkin–Elmer elemental analyzer 2400CHN. The magnetic susceptibilities of the nickel and copper complexes were measured in the temperature range of 2–300 K with an applied field of 1000 Oe, as well as *M* versus H (0–6 T) at 2 K on a SQUID magnetometer by using polycrystalline sample. Experimental data were corrected for diamagnetic contributions employing both the subtraction of the sample holder and Pascal's constants [45]. 5-(4-Br)-ph-2,4′-bpy and the Co(II) complex were prepared as previously reported [43].

2.2. Synthesis

2.2.1. $[Ni(L1)(L2)_2 \cdot H_2O]_n$

This complex was prepared as light blue block crystals in *ca.* 40% yield according to a previously described procedure using $NiSO_4 \cdot 6H_2O$ in place of $CoSO_4 \cdot 7H_2O$ [43]. Brown powder was also obtained as reaction product. Elemental *Anal.* Calc. for $C_{39}H_{27}Br_2NiN_5O_5$: C, 54.20; H, 3.15; N, 8.10. Found: C, 54.71; H, 3.25; N, 7.95%. IR (KBr, cm^{-1}): 3413 s, 3066 s, 1653 s, 1567 vs, 1464 s, 1346 s.

2.2.2. $[Cu_4(L1)_4(L2)_4 \cdot 2H_2O$

Compound **$[Cu_4(L1)_4(L2)_4] \cdot 2H_2O$** was isolated as blue block crystals following the above procedure using $CuSO_4 \cdot 5H_2O$ in place of $NiSO_4 \cdot 6H_2O$, black powder was obtained as by product. Yield: ~45%. Elemental *Anal.* Calc. for $C_{92}H_{58}N_{12}O_{18}Br_4Cu_4$: C, 50.38; H, 2.67; N, 7.66. Found: C, 50.79; H, 2.99; N, 7.32%. IR (KBr, cm^{-1}): ν = 3422 m, 3081 m, 1632 s, 1465 m, 1427 m, 1368 m, 1270 m, 1213 m.

2.3. Crystal structure analysis

All diffraction data were collected at room temperature on a Bruker SMART APEX CCD area detector diffractometer using graphite a monochromated Mo Kα radiation (λ = 0.71073 Å). Intensity data were collected by ω scan technique. All data were corrected for Lorentz polarization effects [46]. The structures were solved by the direct method using SIR97 [47] and were refined on F^2 by full-matrix least-squares technique using the SHELXL-97 [48] program package. The non-hydrogen atoms were refined anisotropically. In **$[Ni(L1)(L2)_2 \cdot H_2O]_n$** and **$[Cu_4(L1)_4(L2)_4] \cdot 2H_2O$**, it was not practical to assign hydrogen atoms on the disordered water molecules. The other H atoms were added in ideal positions (C–H = 0.93 Å, U_{iso}(H) = 1.2U_{eq} (C)) and were not refined. The crystallographic parameters are listed in Table 1.

2.4. Theoretical calculations

DFT calculations were carried out for each nearest neighboring binuclear Cu complex with the B3LYP gradient-corrected density functional [49–51] and the Ahlrich's pVDZ [52] basis set, as implemented in GAUSSIAN 03 [53]. The broken-symmetry [54] procedure was used to evaluate the singlet state energy for each binuclear Cu complex. The value of the exchange parameter *J* was obtained as $J = [E(BS) - E(T)]$, where $E(T)$ is the energy for the triplet state, and $E(BS)$ is the energy for the broken symmetry singlet.

3. Results and discussion

We have previously reported the synthesis and the X-ray crystallographic studies of the Co^{II} complex **$[Co(L1)(L2)_2 \cdot H_2O]_n$** [43]. The structural analysis indicates that there are two crystallographically independent cobalt ions (Co1 and Co2) in **$[Co(L1)(L2)_2 \cdot H_2O]_n$**, and each cobalt ion exists in a distorted octahedral coordination environment. The two kinds of Co^{II} ions are bridged by pdc^{2-} anions to form two kinds of 1D coordination polymeric zigzag chains (the Co1 chain and the Co2 chain). The analytical data of **$[Ni(L1)(L2)_2 \cdot H_2O]_n$** suggests that the nickel(II) complex is analogous to the cobalt complex. However, the analytical data of the copper complex suggests that it is a tetranuclear cluster with formula **$[Cu_4(L1)_4(L2)_4] \cdot 2H_2O$**. Thus, a simple change of the metal center has yielded completely different nuclearity, structure, and magnetic behavior. The scheme for the above transformation is as following:

$$M^{2+} + pdc^{2-}\ (L1) + 5\text{-}(4\text{-}Br)\text{-}ph\text{-}2,4'\text{-}bpy\ (L2) + nH_2O \longrightarrow \begin{cases} \text{antiferromagnetic } [M(L1)(L2)_2 \cdot H_2O]_n\ (M=Ni \text{ or } Co) \\ \text{ferromagnetic } [M_4(L1)_4(L2)_4] \cdot 2H_2O\ (M=Cu) \end{cases}$$

3.1. Crystal structures

The crystal structure of **$[Ni(L1)(L2)_2 \cdot H_2O]_n$** (Fig. 1) is similar to the cobalt complex **$[Co(L1)(L2)_2 \cdot H_2O]_n$** [43]. There are two crystallographically independent nickel ions in the nickel complex, and each nickel ion exists in distorted octahedral coordination environment. The Ni^{II} ions are bridged by the bridging ligands pdc^{2-} to form 1D coordination zigzag polymeric chains along the *b*-axis. Thus, two kinds of 1D coordination zigzag polymeric chains (the Ni1 chain and Ni2 chain) exist in the nickel complex. In the

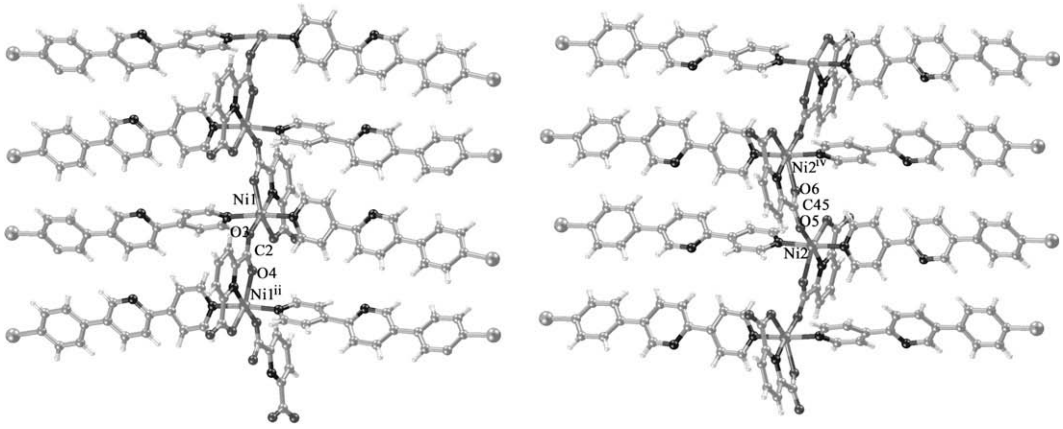

Fig. 1. The perspective view 1D zigzag polymeric chains in the complex $\mathbf{[Ni(L1)(L2)_2 \cdot H_2O]_n}$.

Ni1 chain, the equatorial Ni–N (1.990(8) Å) and Ni–O (2.052(7)–2.187(6) Å) (Table 2) bond distances are close (±0.01 Å) to those of the similar system with 5-ph-2,4′-bpy ligand [40], the two axial Ni–N distances (2.096(6) and 2.098(6) Å) are almost in the same length. For the Ni2 chain, the equatorial Ni–N bond distance is 2.000(7) Å, the equatorial Ni–O bond distances are in the range 2.044(7)–2.234(6) Å. The two axial Ni–N distances are unequal (2.082(5) and 2.096(6) Å), which is different from that of the Ni1 chain. Furthermore, Ni1 or Ni2 centered neighboring chains associate into a 2D layer by hydrogen bonds interactions, Ni1 and Ni2 layers are alternately arranged. Interestingly, in the Ni2 layer of $\mathbf{[Ni(L1)(L2)_2 \cdot H_2O]_n}$, both C–H groups and uncoordinated nitrogen atoms contribute to the hydrogen bonds formation (H···π, *ca.* 2.88 Å), whereas in the Ni1 layer only C–H groups form hydrogen bonds (H···π, *ca.* 2.78 Å) (see *Fig.* S1 in the Supplementary data). The intra-chain Ni1···Ni1 and Ni2···Ni2 distances are 5.57 and 5.61 Å, respectively. The torsion angle Ni1–O3–O4–Ni1^{iii} and Ni2–O6–O5–Ni2^{iv} (Symmetry codes: (iii) $1-x, -0.5+y, 1.5-z$; (iv) $-x, -0.5+y, 1.5-z$) are 177.2° and 172.9°, respectively. Therefore, the Ni2 chains are more twisted compared to those of the similar system with 5-ph-2,4′-bpy as L2 (Ni1–O3–O2–Ni1^{ii}, 175.3°) [40] by the introduction of bromide substituent on the pendant, though the Ni1 chains are less twisted.

The complex $\mathbf{[Cu_4(L1)_4(L2)_4] \cdot 2H_2O}$ can be engineered with the same ligands (L1 and L2) as in $\mathbf{[Ni(L1)(L2)_2 \cdot H_2O]_n}$ or $\mathbf{[Co(L1)(L2)_2 \cdot H_2O]_n}$, in the presence of the copper ions. Unlike the nickel or cobalt complex, there are two centrosymmetric $[Cu_4(L1)_4(L2)_4]$ tetramers in the unit cell of the copper complex. These two tetramers, **A** and **B**, have similar coordination spheres (see Fig. 2). In each tetramer, the two crystallographically independent copper ions possess distorted square pyramidal coordination. In the tetramer **A**, the four Cu^{II} ions are arranged symmetrically in a quadrilateral, in which neighboring Cu^{II} (Cu1···Cu2 or Cu1···Cu2A) ions are bridged alternately by the carboxylate group of two different pdc^{2-} ligands. Both Cu1 and Cu2 are penta-coordinated with same square-pyramidal coordinational mode. The basal plane is constructed by one N and two O atoms offered by one pdc^{2-} and one N atom from bpy ligand in trans position with pdc^{2-}, with normal Cu–O (2.014(6)–2.049(7) Å) and Cu–N (1.905(6)–1.966(7) Å) bond distances (Table 2) [24]. The apical sites are occupied by the O atom from other pdc^{2-} ligand, and Cu–O bond lengths are 2.182(7) and 2.164(6) Å, respectively, which are longer than those in the basal plane. In the tetramer **B**, the basal plane Cu–O (2.026(5)–2.053(6) Å) and the Cu–N (1.898(6)–1.950(5) Å) bond distances are similar to those in the tetramer **A**. The apical Cu–O distances are 2.192(5) and 2.195(7) Å, which are longer than the corresponding ones in the tetramer **A**. The length of each tetramer measured by the distance between the Br atoms in the trans position in $\mathbf{[Cu_4(L1)_4(L2)_4] \cdot 2H_2O}$ is ca. 32 Å. The tetramers **A** associate into a 1D chain through intercluster π···π stacking interactions (the face to face distance, 3.74 Å) between the pyridine rings of neighboring clusters (see *Fig. S2 in the Supplementary data*), while the tetramers **B** associate into a 1D chain through C–H···O hydrogen bonds (C···O, 3.269 Å) along the *a*-axis. The neighboring chains, **A** and **B**, self-assemble into a 2D layer by hydrogen bonds C–H···O (C···O, 2.641–3.442 Å) along the b-axis. In addition, the C–H···Br hydrogen bonds (C···Br, 3.624 Å) only exist in the chain **A**, which link the neighboring layers to form a 3D network (see *Fig. S3 in the Supplementary data*). The intercluster metal–metal distances are 5.138 Å, 8.643 Å, 9.045 Å, and 10.683 Å for Cu1···Cu1, Cu3···Cu4, Cu1···Cu4, and Cu2···Cu3, respectively. Obviously, 5.138 Å of intercluster Cu1···Cu1 distance is shorter than all intracluster Cu···Cu distances due to π···π stacking interactions between the pyridine rings of neighboring **A** clusters. This indicates that the intercluster π···π supramolecular interactions in the copper complex play a crucial role in the stabilization of the structure. The different coordination sphere around Ni (Co) and Cu is due to the fact that the weaker John–Teller effect in Ni^{II} (Co^{II}) than that of Cu^{II}, corresponding to distorted octahedral and distorted square pyramidal coordination structure in the complex $\mathbf{[Ni(L1)(L2)_2 \cdot H_2O]_n}$ ($\mathbf{[Co(L1)(L2)_2 \cdot H_2O]_n}$) and $\mathbf{[Cu_4(L1)_4(L2)_4] \cdot 2H_2O}$, respectively, therefore, 1D coordinational polymer and tetranuclear complex is obtained, respectively. Very recently we have obtained three mononuclear

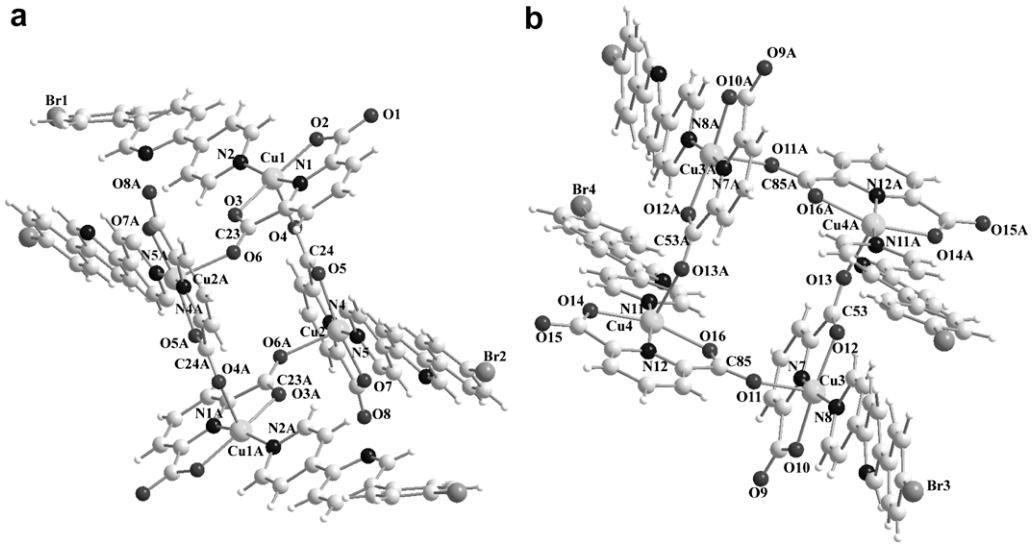

Fig. 2. The perspective view of tetramer **A** (a) and **B** (b) in the complex **[Cu$_4$(L1)$_4$(L2)$_4$]**. Cu1···Cu2, 5.608 Å; Cu1···Cu2A, 5.565 Å; Cu1···Cu1A, 9.135 Å; Cu2···Cu2A, 7.159 Å; Cu3···Cu4, 5.602 Å; Cu3···Cu4A, 5.628 Å; Cu3···Cu3A, 8.214 Å; Cu4···Cu4A, 7.658 Å. Atoms labeled 'A' are generated with $[1-x, -y, 1-z]$.

copper complexes constructed by pdc^{2-}, water molecule, and 2,4′-bipyridine as well as its derivative 5-phenyl-2,4′-bipyridine or 5-chloro-2,4′-bipyridine [55], where the copper ions also exhibit pentacoordinated environment with distorted square pyramidal geometry. Thus, both the Cu^{2+} and the pendant 5-(4-Br)-ph-2,4′-bpy ligand contribute to the formation of the tetranuclear complex **[Cu$_4$(L1)$_4$(L2)$_4$] · 2H$_2$O**.

3.2. Magnetic properties

The global feature of $\chi_M T$ versus T curve of **[Ni(L1)(L2)$_2$ · H$_2$O]$_n$** suggests a weak intramolecular antiferromagnetic interaction between Ni(II) ions as shown in Fig. 3, which is similar to that of **[Co(L1)(L2)$_2$ · H$_2$O]$_n$** [43]. The value of $\chi_M T$ at 300 K is 1.41 cm^3 mol^{-1} K and thus higher than the spin-only value of 1.00 cm^3 mol^{-1} K expected for uncoupled high-spin Ni^{II} ion ($S = 1$, $g = 2$), in accordance with the well-documented orbital contribution of the octahedral Ni^{II} ion [56,57]. As the sample is cooled from room temperature, the $\chi_M T$ value smoothly decreases from 1.41 cm^3 mol^{-1} K to 1.37 cm^3 mol^{-1} K at 50 K and then decreases more rapidly at low temperatures, reaching a value of 0.26 cm^3 mol^{-1} K at 2 K. The low-temperature drop may be due to secondary effects such as inter-chain interactions and/or zero-field splitting effects. The magnetic data for **[Ni(L1)(L2)$_2$ · H$_2$O]$_n$** can be fitted to the Curie–Weiss law with $C = 1.44$ cm^3 mol^{-1} K, $\theta = -10.2$ K. The negative θ value for the nickel complex indicates the antiferromagnetic interactions between Ni^{II} ions. An empirical (Weng's) formula has been reported in the literature to analyze 1-D systems with $S = 1$, using numerical procedures [45,58]:

$$\chi_{chain} = \frac{N\beta^2 g^2}{kT}\frac{2.0 + 0.019x + 0.777x^2}{3.0 + 4.346x + 3.232x^2 + 5.834x^3}$$

where $x = |J|/kT$. Considering the weak inter-chain interactions, the susceptibility can be corrected by the mean-field, (zJ') [59].

$$\chi_M = \chi_{chain}/[1 - (zJ'/Ng^2\beta^2)\chi_{chain}]$$

The best-fit parameters for **[Ni(L1)(L2)$_2$ · H$_2$O]$_n$** are found to be $g = 2.0$ (fixed), $J = -3$ cm^{-1}, $zJ' = -0.5$ cm^{-1}, and $R = 1.44 \times 10^{-4}$. The J value of -3 cm^{-1} for the nickel complex indicates that the coupling between the Ni(II) centers through the syn-anti carboxylate bridge is weakly antiferromagnetic. Furthermore, the J value of the nickel complex is close to that of the similar carboxylate systems with 5-ph-2,4′-bpy as pendant (-3.99 cm^{-1}) [40], and less negative than the reported *syn–syn* carboxylate system (-13.3 cm^{-1}) [60].

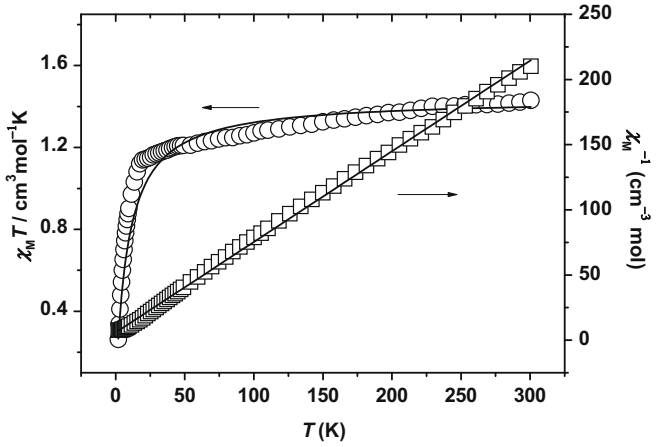

Fig. 3. Plots of $\chi_M T$ vs T and χ_M^{-1} vs T for the complex **[Ni(L1)(L2)$_2$ · H$_2$O]$_n$**. The solid line shows the best fit to the model (see text).

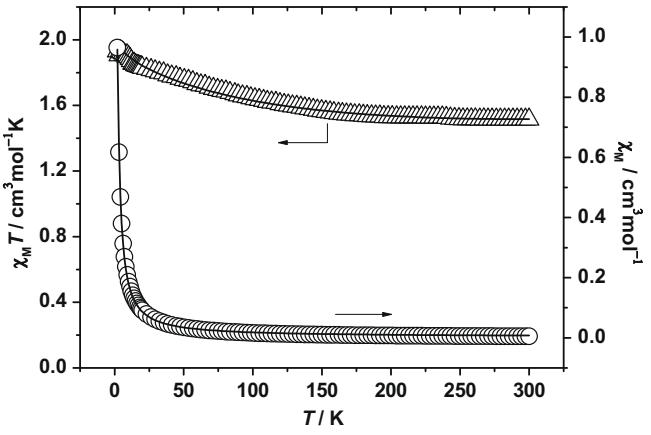

Fig. 4. Plots of $\chi_M T$ vs T and χ_M vs T for the complex **[Cu$_4$(L1)$_4$(L2)$_4$] · 2H$_2$O**. The solid lines represent the best fit of the data (see text for details).

The magnetic behavior for the complex **[Cu$_4$(L1)$_4$(L2)$_4$] · 2H$_2$O** is shown in Fig. 4. As the sample is cooled from room temperature, the value of $\chi_M T$ smoothly increases from 1.52 cm^3 mol^{-1} K to 1.53 cm^3 mol^{-1} K at 200 K and then increases rapidly at low temperatures, reaching a value of 1.93 cm^3 mol^{-1} K at 2 K, indicating the presence of intracluster ferromagnetic interactions. Taking into account the compound topology, three coupling parameters J_1, J_2, and J_3 can be considered to interpret the magnetic interactions in the copper complex, using the Hamiltonian:

$$H = -J_1(S_1 \cdot S_2 + S_3 \cdot S_4) - J_2(S_1 \cdot S_4 + S_2 \cdot S_3) - J_3(S_1 \cdot S_3 + S_2 \cdot S_4)$$

On the basis of the structural data of the tetramer, we set $J = J_1 = J_2$ and $J_3 = 0$ (see Chart 1). For this square disposition, the E_n value can be obtained by using the Kambe method [61,32] from the Hamiltonian:

$$H = -J(S_1 \cdot S_2 + S_3 \cdot S_4 + S_1 \cdot S_4 + S_2 \cdot S_3)$$

The analysis of the experimental susceptibility data has been performed by the use of the expression:

$$\chi_M T = Ng^2\beta^2 T(f(J,T)/3kT)$$

$$\text{where } f(J,T) = \frac{6\exp(J/kT) + 12\exp(2J/kT) + 30\exp(3J/kT)}{1 + 3\exp(J/kT) + 7\exp(2J/kT) + 5\exp(3J/kT)}.$$

The best-fit parameters are: $g = 2$, $J = 3$ cm^{-1}, and $R = 2.00\times10^{-5}$. The J value of 3 cm^{-1} for the copper complex suggests that the coupling between the Cu(II) ions through the *syn–anti* (basal–apical) O–C–O bridge is weakly ferromagnetic. In addition, the J value of copper complex is larger than that found in related structure [25], and smaller than those reported square Cu$_4$ systems [24,32]. Previous studies showed that the magnetic behaviors of a basal–apical O–C–O bridging complex related to the Addison parameter (τ) [62] of each square-pyramidal copper(II) center, representing the mixture of the magnetic $x^2 - y^2$ and z^2 orbitals. It is known that for $\tau = 0$ (pure square pyramidal), the interaction is strongly ferromagnetic but strongly antiferromagnetic when $\tau = 1$ (pure trigonal bipyramidal). In the copper complex, τ values for Cu1–Cu4 are 0.18, 0.12, 0.15, and 0.19, respectively. However, the basal–apical pathway was antiferromagnetic in similar system, where τ values were 0.14 and 0.25 [24].

DFT calculations are used in order to obtain insights into intracluster magnetic interactions in **[Cu$_4$(L1)$_4$(L2)$_4$] · 2H$_2$O**. Four binuclear copper(II) models (**a1**, **a2**, **b1**, and **b2**) are selected in our calculations to compute J value corresponding to each carboxylate bridging neighboring Cu ions in tetramers **A** or **B**. The model **a1** (**a2**) is obtained from the tetramer **A**, by taking the Cu1 and Cu2 (Cu2A) atoms, two pyridine ligands based on the structure of 5-(4-Br)-ph-2,4′-bpy, two pyridine-2,6-dicarboxylate ligands among which one serves as a bridge connecting the two copper atoms and the other one binds to Cu2 (Cu1), the formic acid molecule derived from the structure of pyridine-2,6-dicarboxylate binds to Cu1 (Cu2). Similarly, the model **b1** (**b2**) corresponding to the dimer containing atoms Cu3 and Cu4 (Cu3 and Cu4A) is taken from the tetramer **B**, where the 5-(4-Br)-ph-2,4′-bpy ligand is also replaced by a pyridine molecule for computational cost reasons. The J value obtained from [E(BS)−E(T)] (where E(BS) or E(T) denotes for the energy of broken symmetry singlet or triplet state, respectively) is 0.46 cm^{-1}/0.48 cm^{-1} for model **a1**/**a2**, and the J value is 0.54 cm^{-1}/0.48 cm^{-1} for **b1**/**b2**. These positive J values also demonstrate that the coupling between the Cu(II) ions through the basal–apical O–C–O bridge is weakly ferromagnetic, which differs from the antiferromagnetic coupling in similar system [24].The calculated J values of four model binuclear copper(II) complexes are similar to those found by the same DFT strategy in related structures (0−1.4 cm^{-1}) [63].

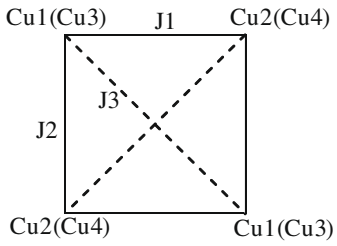

Chart 1. Schematic representation of the magnetic model in the tetramer **A** or **B** of **[Cu$_4$(L1)$_4$(L2)$_4$] · 2H$_2$O**.

The selected atom Mulliken spin populations obtained from our calculations in the triplet states for models **a1** and **a2** are presented in Table 3. In the triplet state of **a1**, the spin population on Cu1 is 0.596, and the spin populations on the directly coordinated atoms (N1, N2, O2, O3, O4) have the same sign as that on Cu1, corresponding to the spin delocalization from the spin center Cu^{II}. Furthermore, the spin population on Cu2 is 0.595, and the spin population on the directly coordinated atoms (N4, N5, O6A, O5, O7) also have the same sign as that on Cu2. The spin population on C24 atom of the bridging carboxylate ligand is negative. Obviously, the spin population distribution on the bridging carboxylate can be rationalized by the spin polarization mechanism. Thus, the path Cu1−O4−C24−O5−Cu2 is ferromagnetic in **a1**. Meanwhile, the spin population in **a2** indicates that Cu1−O3−C23−O6−Cu2A is also a ferromagnetic pathway. This behavior can also be observed for **b1** and **b2** (see *Table* S1 in the Supplementary data). Therefore, the paths Cu3−O11−C85−O16−Cu4 and Cu3−O12−C53−O13−Cu4A for **b1** and **b2**, respectively, are ferromagnetic. According to our DFT calculations, the O–C–O bridges in the basal–apical mode are responsible for the intracluster Cu^{II}···Cu^{II} ferromagnetic exchange which is reasonable for complex **[Cu$_4$(L1)$_4$(L2)$_4$] · 2H$_2$O**.

The X-ray crystallographic study suggests that the intercluster Cu1···Cu1 distance (5.138 Å) is shorter than all intracluster Cu···Cu distances due to the π···π stacking of Cu1 centered fragments of neighboring **A** clusters. Therefore, with the aim to understand the intercluster magnetic interactions in the copper complex, the Cu1 centered fragment was selected as model in our DFT calculation for the spin density distribution. As shown in Fig. 5, Cu1 and the directly coordinated atoms (N1, N2, O2, O3) have the positive density, demonstrating the spin delocalization from Cu1 to the ligands for the Cu1 centered fragment. For each Cu centered fragment, the alternating sign of the spin density is found on the ligand L1 and the bipyridine of L2. This is ascribed to the spin polarization effect to stabilize the high-spin state. The analysis of the spin densities shows opposite signs on two atoms in the face to face positions (C11 and C20, C15 and Cu1, C22 and C10) on

neighboring Cu1 centered fragments (*Fig.* 5 and Table S2 in the Supplementary data), which favors for the intermolecular ferromagnetic coupling according to the McConnell Model I [64]. Because the spin density on each interacting site except Cu1 (0.539) is pretty small (C11: 0.001, C20: −0.004, C15: −0.002, C22: −0.005, C10: 0.001), the intercluster interaction may also slightly contribute to the weakly ferromagnetic coupling for $\mathbf{[Cu_4(L1)_4(L2)_4]\cdot 2H_2O}$.

4. Conclusions

A series of complexes containing the identical bridging ligand and pendants and different metals such as Ni^{2+}, Co^{2+}, and Cu^{2+} was synthesized and characterized. In the nickel and cobalt complexes $\mathbf{[M(L1)(L2)_2\cdot H_2O]_n}$ (M = Ni^{2+} or Co^{2+}, L1 = pdc^{2-}, L2 =5-(4-Br)-ph-2,4′-bpy), the metal ions are hexa-coordinated with distorted octahedral geometries, and bridged by the L1 pdc^{2-} forming 1D backbone with L2 5-(4-Br)-ph-2,4'-bpy as pendants. However, in the copper complex $\mathbf{[Cu_4(L1)_4(L2)_4]\cdot 2H_2O}$, the metal ions adopt a distorted square pyramidal geometry and the O–C–O bridge of pdc^{2-} adopts a basal–apical disposition between metal ions to give a square planar backbone with L2 pendants. Antiferromagnetic coupling between metal ions in the nickel and cobalt complexes has been observed, the copper complex possesses weakly ferromagnetic coupling due to its tetranuclear cluster structure. DFT calculations suggested that the O–C–O bridges in a basal–apical mode are responsible for intermetallic ferromagnetic exchange for the tetranuclear copper cluster. The successful transform of magnetic property from antiferromagnetic $\mathbf{[Ni(L1)(L2)_2\cdot H_2O]_n}$ or $\mathbf{[Co(L1)(L2)_2\cdot H_2O]_n}$ to ferromagnetic coupling $\mathbf{[Cu_4(L1)_4(L2)_4]\cdot 2H_2O}$ can be simply traced back to the tuning of metal ions with investigated ligands. As a result, the metal ion plays the key role in the magnetic transform. This report may provide a reasonable way in the design and exploitation of new magnetic compounds for useful applications.

Scheme 1.

without attacking the 2-imidazolidinyl and imine carbon atoms, which would lead to ligand hydrolysis. The complex shows binding of the catechol molecule by replacement of the labile aqua bridge and its oxidation in air.

2. Experimental

2.1. Materials and instrumentation

All the starting chemicals and solvents were analytically pure and were used without further purification. Copper(II) carbonate, triethylenetetramine and salicylaldehyde were obtained from S.D. Fine Chem, India. The ligand H_3L was prepared according to a modified literature procedure [8]. ^1H and ^{13}C NMR spectra of the ligand were obtained on a Bruker AC 200 NMR spectrometer using TMS as the internal standard. The ^1H NMR spectrum of the complex was collected on a 250 MHz Bruker DXR 250 spectrometer. Infrared spectra were recorded as KBr pellets on a Nicolet Nexus-870 FT-IR spectrometer. The solution electrical conductivity and UV–Vis spectra were obtained using a Unitech type U131C digital conductivity meter with a solute concentration of about 10^{-3} M and a Shimadzu UV 3100 UV–Vis–NIR spectrophotometer, respectively. The room temperature magnetic susceptibilities in the solid state were measured using a home built Gouy balance fitted with a polytronic d.c. power supply. The experimental magnetic susceptibilities were corrected for the diamagnetic response using Pascal's constants [13]. Variable temperature magnetic measurements were carried out at the "Servei de Magnetoquímica (Universitat de Barcelona)" on polycrystalline samples (ca. 40 mg) using a Quantum Design MPMS XL-5 SQUID susceptometer operating at a constant magnetic field of 1T between 2 and 300 K. The experimental magnetic moment was corrected for the diamagnetic contribution from the sample holder. EPR experiments were performed on a Bruker ESR 300E (X-Band, 9.45 GHz) spectrometer, and spectra were collected at room temperature and ca. 77 K on powdered samples working with an Oxford make liquid helium cryostat for variable temperature measurements. Elemental analyses (C, H and N) were performed on a Perkin–Elmer model 240 C elemental analyzer.

Caution! Perchlorate salts are potentially explosive, only a small amount should be prepared, and handled with proper care.

2.2. Synthesis

2.2.1. $[\{Cu_2(\mu\text{-}L)(\text{-}H_2O)\}_2](ClO_4)_2 \cdot 4.5H_2O$ ($\mathbf{1} \cdot 4.5H_2O$)

To the ligand solution (0.50 g, 1.09 mmol) in 15 ml of DCM, a methanolic solution of triethylamine (0.55 ml, 4 mmol) was added dropwise to give a solution of pH 7–8. Then, a methanolic solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.80 g, 2.18 mmol) was added slowly to the ligand solution with magnetic stirring at ambient temperature for 10 min. The reaction mixture was then stirred for 2 h and the solvent was removed in air. The deep green precipitate obtained was filtered through a glass frit and washed with water followed by methanol and hexane, and finally dried in vacuum over P_4O_{10}. Yield: 1.16 g (72%). *Anal.* calc. for $C_{54}H_{67}N_8O_{20.5}Cu_4Cl_2$: C, 43.78; H, 4.55; N, 7.56; Cu, 17.16. Found: C, 43.62; H, 4.57; N, 7.46; Cu, 17.28%. Infrared spectrum, $\nu(cm^{-1}$, KBr disk) 3388(b), 2936(m), 1627(s), 1595(s), 1537(s), 1447(s), 1312(s), 1094(s), 914(s), 722(s). Molar conductance, Λ_M ($ohm^{-1}\,cm^2\,mol^{-1}$, MeCN solution) 130.3. UV–Vis spectra [λ_{max}, nm (ε, $l\,mol^{-1}\,cm^{-1}$), DMF solution] 640 (290), 380 (10365), 273 (22040). μ_{eff} (tot.): 2.43 μ_B; μ_{eff}/Cu: 1.71 μ_B at 298 K.

2.3. X-ray crystallography

Green block-like single crystals of $\mathbf{1} \cdot 4.5H_2O$ suitable for single-crystal diffraction were grown from a saturated MeCN-DCM solution mixture. The X-ray intensity data were collected at 295 K on a Nonius Kappa CCD diffractometer using a crystal of dimensions $0.48 \times 0.28 \times 0.10\,mm^3$ and with graphite monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) by the ω-scan method. A total of 6816 reflections were recorded with Miller indices $h_{min} = -14$, $h_{max} = 14$, $k_{min} = -15$, $k_{max} = 12$, $l_{min} = -29$, $l_{max} = 29$. In the final cycles of full-matrix least-squares on F^2 all non-hydrogen atoms were assigned anisotropic thermal parameters and refinement converged at $R = 0.0665$. The residual electron density is in the range +0.99 to −0.54 e $Å^{-3}$. The structure was solved using the program SIR97 [14]. The refinement was performed using full-matrix least-squares with all non-hydrogen atoms treated anisotropically and hydrogens included in calculated positions, riding on their carrier atoms. The asymmetric unit of $\mathbf{1} \cdot 4.5H_2O$ contains two crystallographic independent dinuclear cationic units $[\{Cu_2(\mu\text{-}L)(\mu\text{-}H_2O)\}_2]$ with significant geometric differences. The water molecule bridging the Cu(II) atoms in the cation **1**b displays a greater disorder than that in the cation **1**a, and was refined over two positions with occupancies of 0.7 and 0.3, respectively. The other non-coordinated water molecules display a high degree of disorder and most of them were refined over two positions. The hydrogen positions of the water molecules could not be determined. The disordered oxygens of the ClO_4^- anions were refined over two positions. All calculations were performed using SHELXL-97 [15] and PARST [16] implemented in the WINGX [17] system of programs. The crystallographic data are given in Table 1 and the bond lengths and bond angels are given in Table 2.

2.4. Catecholase activity

The catecholase activity was studied in MeCN at 25 °C by the reaction of $\mathbf{1} \cdot 4.5H_2O$ with 3,5-di-*tert*-butylcatechol (3,5-DTBC). For this purpose a 1.1×10^{-4} mol dm^{-3} solution of $\mathbf{1} \cdot 4.5H_2O$ in oxygen saturated MeCN was treated with 30 equiv of 3,5-DTBC under aerobic conditions. The increase in the absorption band at 395 nm, characteristic of the absorption band of the quinone

formed, was followed spectrophotometrically at various time intervals from 3 to 60 min.

3. Results and discussion

3.1. Synthesis and characterization

The ligand H_3L used in this work was prepared following a modified literature procedure [8] and was characterized by FTIR, ^1H and ^{13}C NMR spectra. The reaction in methanol of H_3L with $Cu(ClO_4)_2 \cdot 6H_2O$ in the presence of NEt_3 in a 1:2:3 molar ratio yielded the green complex $[\{Cu_2(\mu\text{-}L)(\mu\text{-}H_2O)\}_2](ClO_4)_2 \cdot 4.5H_2O$ (**1** · 4.5H_2O). The process was conducted in air and at room temperature. The complex was characterized by analytical, spectroscopic and single-crystal X-ray diffraction techniques. The molar conductivity value of **1** · 4.5H_2O in MeCN is 130 $ohm^{-1}cm^2\ mol^{-1}$ (28 °C), consistent with a 1:1 type electrolyte in solution. The FTIR spectrum of **1** · 4.5H_2O (Fig. S1) is in agreement with the coordination of the Schiff base and exhibits a broad medium band at 3388 cm^{-1} characteristic of ν_{OH} of an aqua bridge [18]. For the uncoordinated ClO_4^-, the stretching vibration appears at ~1094 cm^{-1}.

3.2. UV–Vis spectroscopy

The electronic spectrum of **1** · 4.5H_2O in DMF solution (Fig. S2) shows several intense absorption bands in the visible region that are assigned to allowed d–d and charge-transfer transitions. It exhibits a broad band at 640 nm (290 $lmol^{-1}\ cm^{-1}$) due to a d–d transition. Higher intensity charge-transfer transitions are obtained at 380 and 273 nm, with molar extinction coefficients of 10365 and 22040 $l\ mol^{-1}\ cm^{-1}$, respectively, attributed to $PhO^- \rightarrow Cu(II)$, $\sigma(amino) \rightarrow Cu(II)$ LMCT and intraligand charge-transfer transitions [19].

3.3. ^1H NMR spectroscopy

^1H NMR spectroscopy has been shown to be applicable for the characterization of the structure and reactivity of Cu_2 complexes with magnetic coupling that ranges from weakly ferromagnetic to strongly antiferromagnetic [20]. Therefore, few reports have described copper complexes that produce narrow ^1H NMR resonances [21–26]. Paramagnetic NMR spectra of Cu_2 complexes have been used extensively in order to establish their relevance as models for metal sites in copper enzymes [27]. Construction of a library of a compounds along with their NMR properties is beneficial in the context of bioinorganic modeling of naturally occurring metalloenzymes. 250 MHz ^1H NMR data of complex **1** · 4.5H_2O were collected in d_4-methanol at room temperature. This study benefited from an extensive investigation made with the related compound $[Cu_2(\mu\text{-}L')(\mu\text{-}OAc)]$, where L′ is a ligand very similar to the dinucleating ligand used here, possessing three methyl substituents in place of hydrogen atoms [9a]. The spectrum of **1** · 4.5H_2O shows a total of 17 hyperfine shifted peaks, as expected from the idealized C_s symmetry of the compound, spread over a very large window of chemical shift, spanning about 250 ppm. This reflects the fact that at room temperature the system remains largely paramagnetic as a result of the very weak nature of the observed antiferromagnetic coupling. In addition, peaks attributed to MeOH and free ligands were detected. The signals from the solvent were used as an internal reference. Inspection of the intensity integrals of these 17 resonances allowed their grouping into five sets of one (a), one (b), 10 (c), four (d) and one (e) signals, respectively, integrating for two, one, two, one and two protons, as predicted from the structure of **1** · 4.5H_2O (Fig. 1, top) consisting of two chemically identical $[Cu_2(\mu\text{-}L)(\mu\text{-}H_2O)]^+$ cations **1**a and **1**b. These groups correspond to the following categories of protons: group 'a', only one signal, which integrates to two protons, corresponding to the two equivalent hydrogens α to

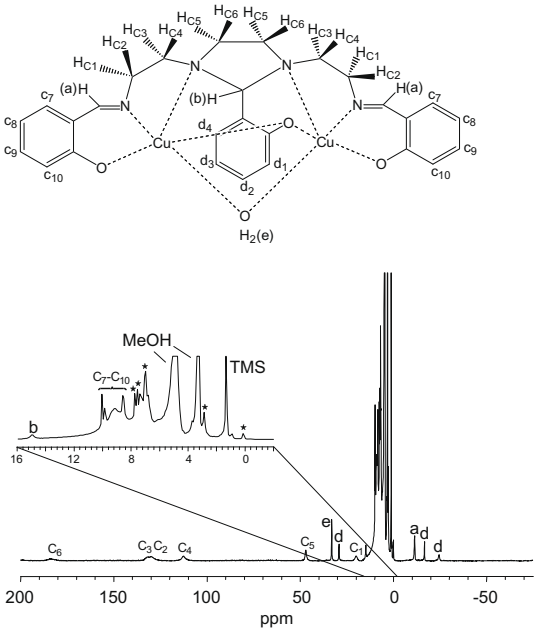

Fig. 1. Complex **1** · 4.5H_2O where all the protons have been labeled according to the groups a, b, c, d and e. At the bottom is a labeled 250 MHz ^1H NMR spectrum of **1** · 4.5H_2O as a mixture of two chemically equivalent $[Cu_2(\mu\text{-}L)(\mu\text{-}H_2O)]^+$ cations, **1**a and **1**b. * denote signals from the free ligand.

the imine N-atoms, and which was readily assigned; group 'b', one signal with an intensity equivalent to one proton, arising from the imidazolidinyl hydrogen; group 'c' is the most numerous. It includes 10 signals with intensity ratios for two H-nuclei. These results from the hydrogen atoms attached to the amine groups (six signals) and from those attached to the two external phenyl rings (which are equivalent). The peaks from the first sub-group are broader than these of the second, since the protons causing the former are crystallographically closer to the metal centers. The resonances of the other sub-group are sharper and show the alternation of chemical shifts characteristic of a π-delocalization mechanism [22]. Group 'd' includes the four peaks from the central phenyl ring of the ligand (one proton per signal). The mechanism of π-delocalization of the electronic spin is also evident here, which was useful in the assignment of the peaks. Group 'e' is the last set of signals, arising from the bridging water molecule. With this study, complex **1** · $4.5H_2O$ enters the small group of binuclear [Cu_2] complexes of which the ^1H NMR spectrum could be explained almost unambiguously and it is a valuable contribution to the growing body of spectroscopic data which can be useful in the functional and structural studies of the metalloenzymes.

3.4. Description of structure

Crystals of **1** · $4.5H_2O$ suitable for X-ray structure determination were obtained from mixtures of MeCN–DCM solvents. An ORTEP view of the cation **1**a is shown in Fig. 2. The crystallographic data are given in Table 1 the selected bond distances and angles are given in Table 2. The asymmetric part of the unit cell contains two crystallographically independent and chemically identical [Cu_2-(μ-L)(π-H_2O)]$^+$ cations (**1**a and **1**b), two perchlorate anions and 4.5 uncoordinated water molecules.

The cations represent the first example of a Cu_2 complex bridged by phenolate oxygen ($O_{ph}{}^b$), imidazolidinyl nitrogen (N_{md}) and water oxygen (O_{aq}) atoms. Several Cu(II) dimeric complexes containing an aquo-bridge between the metallic centers, sometimes coupled with a further hydroxo-bridge, can be retrieved from the recent structural literature [28]. Depending of the position, axial or equatorial, in the square-pyramidal coordination environment, the Cu–μ(OH_2) bond distances vary within the long range of about 1.99–2.74 Å, while the corresponding Cu–μ(OH) ones exhibit shorter values, from 1.88 to 1.99 Å. Accordingly, only on the basis of the bond lengths, the oxygens bridging the copper atoms in both **1**a and **1**b cations can be ascribed to water molecules, even if the positions of the hydrogen atoms could not be determined from X-ray data. The coordination from imine nitrogens (N_{im}) and terminal phenolate oxygens (O_{ph}) complete the distorted N_2O_3 square-pyramidal environments around each copper ions. The shared bi-square-pyramidal arrangement is assembled from two non-coplanar tetradentate coordination pockets of the ligand. This angular arrangement of the binding sites arises from the non-planar structure of the imidazolidinyl spacer, which in turn is responsible for aqua bridging instead of coordination of two monodentate ligands, as observed with phenolate spacer containing binucleating ligands. The bridging H_2O completes the triply bridging motif leading to intramolecular Cu···Cu separations of 3.335(2) and 3.355(1) Å in **1**a and **1**b, respectively. For each metal atom, two nitrogen atoms, one terminal and one bridging phenolate oxygen atoms give one five-membered (N–Cu–N) and two six-membered (N–Cu–O) terminal and bridging chelate rings. The average bite angles for the five-membered (N–Cu–N) chelate rings are 84.3(3)° and 83.9(3)° for **1**a and **1**b, respectively. The average bite angles for the six-membered (N–Cu–O) terminal chelate rings are 93.9(3)° and 93.8(3)°, whereas the average angles for the six-membered (N–Cu–O) bridging chelate rings are 91.5(3)° and 90.9(3)° for **1**a and **1**b, respectively.

The Cu(1)–O_{aq}–Cu(2) angles are 77.8(3)° for **1**a and 83.0(4)°/73.3(8)° for both the disordered bridging water molecules in **1**b. Small variations in the distances in Cu–$O_{ph}{}^b$ indicate that the monatomic phenolate oxygen bridges are nearly symmetric. The reported dinuclear complex [Cu_2(OH)(H_2O)L^1(ClO_4)$_2$]$^+$ (L^1 = a binucleating macrocyclic ligand) also has long Cu–O_{aq} linkages (2.519(12) Å) and an acute Cu–O_{aq}–Cu angle of 77.3(4)° [29]. The calculation of the least-square planes defined by the equatorial atoms around Cu(II) together with the metal atom shows the copper ions to be displaced from the basal planes toward the axial water molecule by 0.207(1) [Cu(1)] and 0.142(1) Å [Cu(2)] for **1**a and 0.181(1) [Cu(1)] and 0.126(1) Å [Cu(2)] for **1**b, respectively. As a result, the Cu centers could be considered to be in a square planar coordination environment, each with a weak axial bond to the water oxygen. The angles between the two CuN_2O_2 basal planes are 144.54(4)° for **1**a and 143.61(4)° for **1**b.

The central phenolate oxygen atom adopts a trigonal–pyramidal geometry (sum of the angles around O(2) is 331.6(4)° and 332.0(4)° for **1**a and **1**b, respectively. The symmetry of the coordination sphere around the two copper(II) ions in the dinuclear units, measured by the Addison parameter (τ) [30], are best described by distorted square pyramids with τ for Cu(1) and Cu(2) of 0.295 and 0.276, respectively for **1**a, and 0.275 and 0.236, respectively for **1**b. Based on the coordination sphere symmetry, it was proposed that in the square pyramid coordination limit (τ = 0) the magnetic orbitals are mainly $d_{x^2-y^2}$ and weak ferromagnetic interactions should result [31]. The Cu–N_{imd} distances (average 2.063(7) Å for **1**a and 2.072(7) Å for **1**b) are longer than the Cu–N_{im} distances (average 1.926(9) Å for **1**a and 1.939(9) Å for **1**b) [32–34]. The Cu–O_{ph} distances (av. 1.895(8) Å for **1**a and 1.891(8) Å for **1**b) are in the normal range for similar dicopper complexes, with longer average Cu–$O_{ph}{}^b$ distances of 1.967(6) and 1.963(6) Å for **1**a and **1**b, respectively.

The complex shows intricate unsymmetrical hydrogen bonding between an uncoordinated water molecule and two terminal phenolate oxygen atoms with average hydrogen binding distances of 2.687 Å for **1**a and 2.776 Å for **1**b. A second uncoordinated water molecule is hydrogen bonded to the first one at a distance of 2.794 Å for **1**a and 2.761 Å for **1**b, which is quite comparable to the O···O distance in ice (about 2.74 Å) [35]. The assignment of the apical bridge as water is supported by the long Cu–O distances [2.496(10) and 2.802(10) Å for **1**a, 2.491(13) and 2.571(14) Å (and 2.768(30) and 2.860(30) Å) for **1**b]. The variations in the distances in Cu–O_{aq} indicate that the monatomic aqua oxygen bridges are not symmetric. The long apical bridging bonds reflect weak axial interactions, as expected for copper complexes in a square-

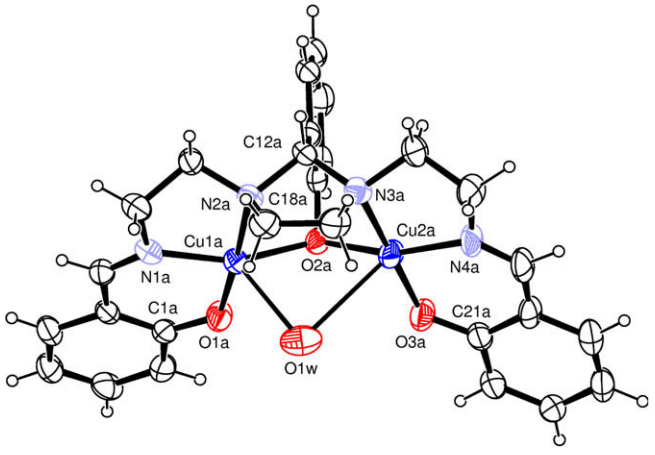

Fig. 2. An ORTEP view of the cation **1**a with the atom numbering scheme and thermal ellipsoids drawn at the 50% probability level.

pyramidal geometry. The geometry around the bridging water oxygen atom is distorted tetrahedral with a Cu(1)–O(W)–Cu(2) bond angle of 77.8(3)° and 83.0(4)°/73.3(8)° for **1**a and **1**b, respectively. The ClO_4^- counter anions in **1** · 4.5H_2O are disordered [36]. The average Cl–O distances are in the normal range, being 1.417 Å. The unit cell-packing pattern of **1** · 4.5H_2O indicates π–π interactions of the terminal phenyl rings of the ligand and the stacked cationic layers are uniformly separated by the ClO_4^- anions.

3.5. Magnetic behavior and EPR studies

The degree of the magnetic super-exchange interaction within the dinuclear complex [{Cu_2(μ-L)(μ-H_2O)}$_2$](ClO_4)$_2$ · 4.5H_2O (**1** · 4.5H_2O) was evaluated by means of variable temperature bulk magnetic susceptibility measurements under the influence of a constant magnetic field of 1T in the 2–300 K temperature range. The results are shown in Fig. 5 as a $\chi_m T$ versus T plot, after subtraction of diamagnetic contributions and a temperature independent paramagnetism (TIP) term of 120×10^6 cm^3 K mol^{-1}. The product $\chi_m T$ remains almost constant during practically the whole temperature range at a value very close to that expected for two independent Cu^{II} ions, and only experiences a decrease at very low temperatures (near 10 K) down to a value of 0.60 cm^3 K mol^{-1} at 2 K. This corroborates the fact that the coupling between the metal ions in complex **1** · 4.5H_2O is very weak and antiferromagnetic. This behavior could be modeled by fitting to the experimental data an expression of the type $\chi_m T = f(T)$ derived from the Bleaney–Bowers equation (Eq. (1)) where the g value obtained by EPR (2.09) was used

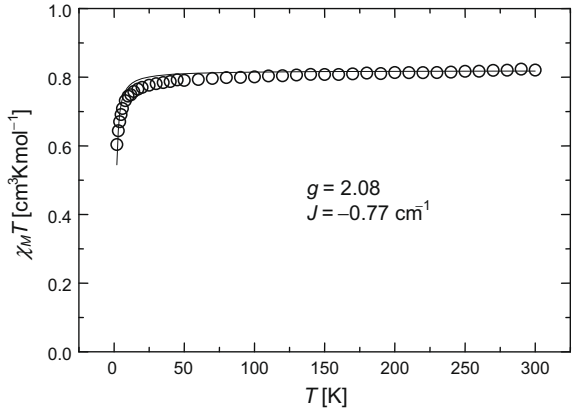

Fig. 3. Plot of $\chi_m T$ versus T for complex **1** · 4.5H_2O. The solid line is a fit of the data to the Bleaney–Bowers equation.

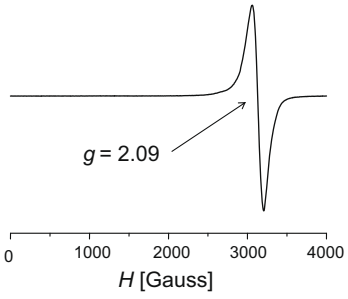

Fig. 4. X-band EPR spectrum for a powdered sample of **1** · 4.5H_2O at 4 K.

$$\chi_m = \frac{N_a g^2 \mu_B}{kT} \cdot \frac{2e^{2J/kT}}{1+3e^{2J/kT}}. \quad (1)$$

This equation is derived after considering the following Heisenberg spin-Hamiltonian (Eq. (2)) to describe the exchange within the complex

$$\hat{H} = -2J\hat{S}_1\hat{S}_2. \quad (2)$$

The best fit (Fig. 3, solid line) was obtained for $J = -0.77$ cm^{-1}. This result is in contrast with that observed for various analogous complexes featuring the same kind of dinucleating ligand as in **1** · 4.5H_2O, and various other exogenous ligands, such as AcO^-, HO^- or MeO^- [9e,f]. In all these cases moderately strong ferromagnetic coupling between the metals was found and this was attributed, following DFT calculations, to the counter-complementarity existing between the N–C–N bridge provided by the central ring of the ligand (always coordinated in basal positions of Cu^{II}) and the O-donors also bound to basal positions. In the present case, however, the geometry of the complex is different to any of the studied compounds and thus comparisons are hard to make. In addition, other examples of complexes featuring a phenoxide-type bridge together with an aqua bridge are non-existent. It was established, however, by DFT calculations that exchange of an OH^- bridge by an H_2O bridge has very drastic consequences from a magnetic point of view [37], and this could explain the disparity of behaviors observed here.

X-band (9.45 GHz) powder EPR spectra of complex **1** · 4.5H_2O were recorded at 4, 77 and 295 K. The spectra at each of these temperatures were very similar (Fig. 4), consisting of a broad isotropic signal centered at $g = 2.09$. This is consistent with the fact that the coupling between both Cu^{II} ions is very weak and thus the compound behaves apparently as the sum of two mononuclear independent $S = 1/2$ entities rather than a system experiencing super-exchange of the electronic magnetic moments.

3.6. Catecholase activity

Complex **1** · 4.5H_2O shows oxidation of 3,5-di-*tert*-butylcatechol (3,5-DTBC) in oxygen saturated acetonitrile solution at pH 7·5. The ability of the complex towards oxidation of catechol to quinone was examined and the time dependent growth of

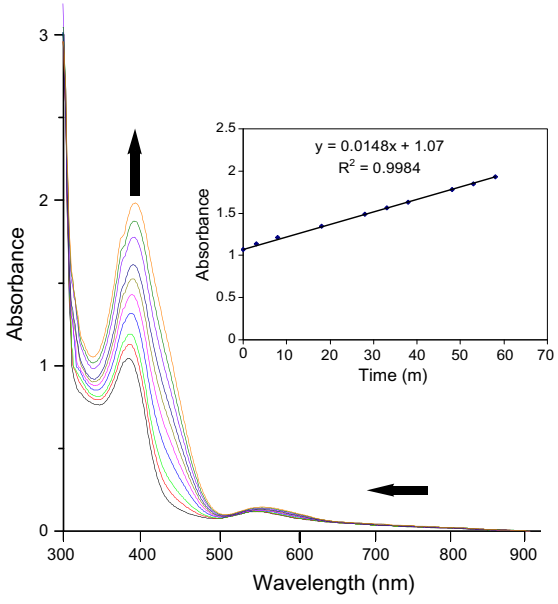

Fig. 5. Time dependent growth of 3,5-DTBQ at 395 nm in MeCN at 25 °C. Inset shows absorbance versus time plot.

3,5-DTBQ is shown in Fig. 5. The oxidation of 3,5-DTBC to the corresponding *o*-quinone was followed by the growth of a strong absorption band of the product at 395 nm, using UV–Vis spectroscopy. The complex simulates the short copper–copper distance of about ~3 Å in CO, as well as the N_2O_2 donor set from the binucleating ligand, which is formed in the enzymes by the pendant imidazoles of the amino acid histidine. The UV–Vis spectra of the original solution immediately after the addition of 3,5-DTBC and at regular intervals of time up to 1 h were recorded. The course of the oxidation of 3,5-DTBC and the reaction rate were determined by monitoring the time dependent increase of the quinone absorption band at 395 nm, which indicates the catechol oxidation ability of the aqua bridged complex [38]. The initial reaction rate obtained from the slope of the absorption versus time plot was found to be $2.46 \times 10^4\ h^{-1}$ (inset of Fig. 5), which is comparable to other exogenous μ-hydroxo and endogenous μ-phenoxo bridged dinuclear copper complexes [39]. This also points to the role of the angular and labile aqua bridging ligands for efficient catechol binding in the apical sites of two non-coplanar N_2O_2 chelated copper sites in $\mathbf{1} \cdot 4.5H_2O$.

4. Conclusion

Basal N,N′-imidazolidinyl (NCN) and *apical* aqua bridging moieties have been identified in a non-planar Cu_2 complex incorporating a N_4O_3 coordinating heptadenate ligand with a low $Cu{-}O_{aq}{-}Cu$ angle and an elongated $Cu{-}O_{aq}$ bond. The copper centers are at an average distance of 3.34 Å and show a weak antiferromagnetic interaction identified from variable temperature magnetic moment data. In a simulated copper–copper distance and N_2O_2 coordination environment, the complex shows catecholase like activity. The present study provides valuable insight into the biologically relevant coordination chemistry of copper. Currently we are engaged in synthesizing analogous complexes of other 3d and 4d metal ions to explore the role of bridging imidazolidine moiety and variety of apical groups in the molecular structure, the magnetic interactions and substrate reactivity.

Acknowledgments

We are thankful to DST, New Delhi, for the Single Crystal X-ray Diffractometer facility in the Department of Chemistry, IIT Kharagpur under its FIST program. We also thank Dr. Alok Ranjan Paital for growing the single crystals used in this study. We are very thankful to the reviewers at the revision stage.

Appendix A. Supplementary data

CCDC 695278 contains the supplementary crystallographic data for $\mathbf{1} \cdot 4.5H_2O$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk.

Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2008.12.063.

The $[VO(acac)_2]$ complex has already been directly immobilised on several solid matrixes, namely alumina, silica gel, mesoporous silicas and clays [16–19]. It has also been immobilised by microencapsulation in polystyrene [20] and by covalent grafting onto amine functionalised activated carbon [21] and clays [16] through Schiff base condensation between surface amine groups and the carbonyl groups of the acetylacetonate ligand.

Hexagonal mesoporous silicas are ordered mesoporous materials with wormlike pore structure [22,23]. Unlike the well-known MCM-41 materials, which are prepared using an anionic template, the HMS type materials are synthesised using a neutral template (long-chained alkylamines) [23,24]. The surface functionalisation of HMS materials with amine groups via reaction with APTES has been previously reported in the literature [25–29]. Both unmodified and amine functionalised HMS materials have already been used as supports for several transition metal catalysts such as manganese, copper and titanium [26–30].

Herein we report the immobilisation of $[VO(acac)_2]$ onto a synthetic HMS using three different methodologies, as depicted in Scheme 1: method A, direct complex immobilisation onto the parent material; method B, functionalisation of HMS with APTES followed by covalent complex grafting; and method C, reaction between the APTES modified HMS prepared in method B and TMS to deactivate eventually unreacted surface silanol groups and subsequent complex grafting. The novel $[VO(acac)_2]$ based materials were tested as heterogeneous catalysts in the epoxidation of geraniol, at room temperature, in dichloromethane, using *t*-BuOOH as the oxygen source; furthermore, the reusability of these heterogeneous catalysts was tested for four times. The main purpose of this work was to correlate different grafting methodologies for the immobilisation of $[VO(acac)_2]$ catalyst onto HMS with the corresponding catalytic activity and stability in the reaction media.

2. Experimental

2.1. Materials and solvents

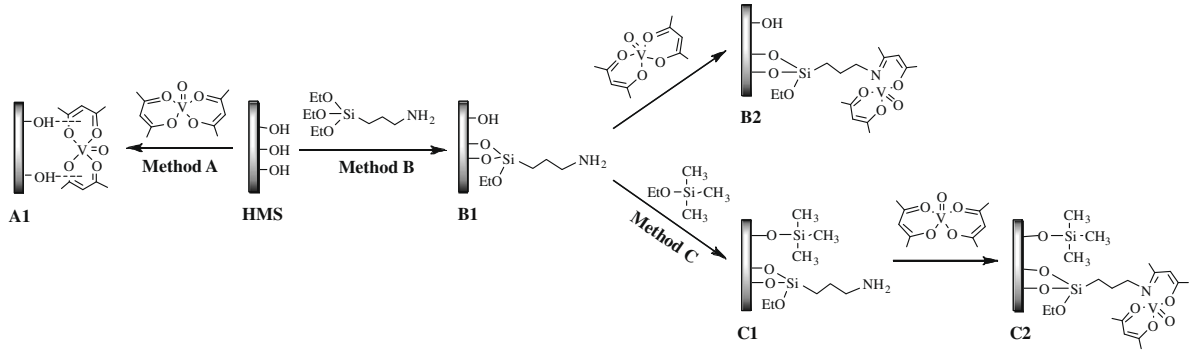
All the reagents and solvents used in the preparation and modification of the HMS material were used as received. $[VO(acac)_2]$, APTES, TMS, *t*-BuOOH solution in decane (5 mol dm^{-3}) and chlorobenzene were from Aldrich, tetraethoxysilane was from Lancaster, dichloromethane was from Romil (HPLC grade) and toluene and other solvents used in the synthesis procedures were from Fischer Scientific (analytical reagent grade).

2.2. Preparation of the heterogeneous catalysts

Synthesis of HMS: The HMS material was synthesised following a reported procedure [23]. Briefly, tetraethoxysilane (37.0 cm^3, 0.166 mol) was added to a stirred solution of ethanol (88.1 cm^3, 1.51 mol), water (88.5 cm^3, 4.91 mol) and 1-dodecylamine (10.3 cm^3, 0.0448 mol). The mixture was stirred at room temperature for 24 h. The white precipitate obtained was vacuum-filtered and washed with deionised water (100 cm^3) and ethanol (100 cm^3). In order to remove the template (1-dodecylamine), the precipitate was calcined at 600 °C for 24 h.

Immobilisation of $[VO(acac)_2]$: The immobilisation of $[VO(acac)_2]$ was performed by three different methodologies described below and summarised in Scheme 1.

Method A: A mixture of HMS (0.5 g) in dry toluene (50.0 cm^3) and $[VO(acac)_2]$ (0.0261 g, 0.09843 mmol) was refluxed for 24 h. The material was vacuum-filtered, washed by reflux in dichloromethane (50.0 cm^3) and methanol (50.0 cm^3) and dried overnight in an oven at 120 °C; the resulting material is denoted as A1.



Method B: A mixture of HMS (1.6 g) in dry toluene (100.0 cm^3) and APTES (0.80 mmol) was refluxed for 24 h and the resulting material (B1) was vacuum-filtered, washed with toluene (2 × 100 cm^3) and dried overnight in an oven at 120 °C. Afterwards, a mixture of B1 (0.6 g) in dry toluene and $[VO(acac)_2]$ (0.0322 g, 0.1214 mmol) was refluxed for 24 h and the resulting material was vacuum-filtered, washed by reflux in dichloromethane (50.0 cm^3) and methanol (50.0 cm^3) and dried overnight in an oven at 120 °C; the resulting material is denoted as B2.

Method C: A mixture of B1 (0.6 g) and TMS (1 mmol) was refluxed in dry toluene for 24 h and the resulting material (C1) was vacuum-filtered, washed with toluene (2 × 50 cm^3) and dried overnight in an oven at 120 °C. Afterwards, a mixture of C1 (0.4 g) and $[VO(acac)_2]$ (0.0233 g, 0.0879 mmol) was refluxed in dry toluene for 24 h and the final material was vacuum-filtered, washed by reflux in dichloromethane (50.0 cm^3) and methanol (50.0 cm^3) and dried overnight in an oven at 120 °C; the resulting material is denoted as C2.

2.3. Physico-chemical measurements

Vanadium bulk contents obtained by inductively coupled plasma emission spectrometry (ICP-AES) and nitrogen elemental analysis (EA) were performed at 'Laboratório de Análises', IST, Lisbon (Portugal). X-ray photoelectron spectroscopy (XPS) was performed at "Centro de Materiais da Universidade do Porto" (Portugal), in a VG Scientific ESCALAB 200A spectrometer using non-monochromatised Al Kα radiation (1486.6 eV). The materials were compressed into pellets prior to the XPS studies. To correct possible deviations caused by electric charge of the samples, the C 1s band at 285.0 eV was taken as internal standard. The surface atomic percentages were calculated from the corresponding peak areas and using the sensitivity factors provided by the manufacturer.

The nitrogen adsorption isotherms at −196 °C were measured in an automatic apparatus (ASAP 2010; Micromeritics). Before

Scheme 1. Methodologies for $[VO(acac)_2]$ immobilisation onto HMS materials.

the adsorption experiments the samples were outgassed under vacuum during 2.5 h at 150 °C.

The FTIR spectra of the materials were obtained with a Jasco FT/IR Plus spectrophotometer in the 400–4000 cm^{-1} region, with a resolution of 4 cm^{-1} and 32 scans, using pellets of the materials diluted with KBr.

Gas chromatography (GC) experiments were performed with a Varian CP-3380 chromatograph equipped with a FID detector and using helium as carrier gas and a fused silica Varian Chrompack capillary column CP-Sil 8 CB Low Bleed/MS (30 m × 0.25 mm i.d.; 0.25 μm film thickness). The chromatographic conditions were: 40 °C (3 min), 5 °C min^{-1}, 170 °C (2 min), 20 °C min^{-1}, 200 °C (10 min); injector temperature, 200 °C; detector temperature, 300 °C. The reaction parameters geraniol conversion (%C), 2,3-epoxygeraniol selectivity ($\%S_{2,3\text{-epoxygeraniol}}$) and 6,7-epoxygeraniol selectivity ($\%S_{6,7\text{-epoxygeraniol}}$) were calculated using the following formula, where A stands for chromatographic peak area: $\%C = \{[A(\text{geraniol})/A(\text{chlorobenzene})]_{t=0h} - [A(\text{geraniol})/A(\text{chlorobenzene})]_{t=xh}\} \times 100/[A(\text{geraniol})/A(\text{chlorobenzene})]_{t=0h}$, $\%S_{2,3\text{-epoxygeraniol}} = A(2,3\text{-epoxygeraniol}) \times 100/[A(2,3\text{-epoxygeraniol}) + A(6,7\text{-epoxygeraniol})]$, $\%S_{6,7\text{-epoxygeraniol}} = A(6,7\text{-epoxygeraniol}) \times 100/[A(2,3\text{-epoxygeraniol}) + A(6,7\text{-epoxygeraniol})]$.

2.4. Catalysis experiments

The reactions were carried out in 5.00 cm^3 of dichloromethane, at room temperature with constant stirring, and the composition of the reaction medium was 1.00 mmol of geraniol, 0.50 mmol of chlorobenzene (internal standard) and 0.10 g of heterogeneous catalyst. The oxidant, 1.50 mmol of *t*-BuOOH, was progressively added to the reaction medium using a Bioblock Scientific Syringe Pump at a rate of 0.5 cm^3 h^{-1}. For each material the %C was determined by withdrawing periodically 0.1 cm^3 aliquots from the reaction mixture. The reaction media composition was determined by GC, with geraniol, *t*-BuOOH, 2,3-epoxygeraniol, 6,7-epoxigeraniol and decane being quantified by the internal standard method (chlorobenzene). After the reaction, the catalysts were washed by reflux with 100 cm^3 of dichloromethane, and dried in an oven at 120 °C for 13 h, under vacuum. The catalysts were then reused for four times using the same experimental conditions. Control experiments using HMS, B1 and C1 materials as well as with $[VO(acac)_2]$ complex in the homogeneous phase were also performed under identical reaction conditions.

3. Results and discussion

3.1. Textural and chemical characterisation

The nitrogen adsorption–desorption isotherms at −196 °C for the different materials are depicted in Fig. 1. The curves do not show any hysteresis cycle, but the data analysis by the *t*-method [31] confirms the inexistence of microporosity. The isotherms can be considered of type IVc according to the IUPAC classification [31], being characteristic of mesoporous materials (pore widths between 2 and 50 nm). As described in more detailed elsewhere [32], type IVc isotherms, although they are obtained in mesoporous materials, they are completely reversible, that is, they do not present hysteresis. This type of isotherms was found by other authors in materials that are similar to those studied in this work, such as some samples of MCM-41 [32,33] and HMS type materials [34]. The specific surface areas (A_{BET}) and mesoporous volumes of the samples are given in Table 1. From this table it can be seen that the subsequent modifications performed on the parent HMS material lead to a concomitant decrease of the A_{BET} values. However, it is rather noticeable that after the immobilisation of the complex onto

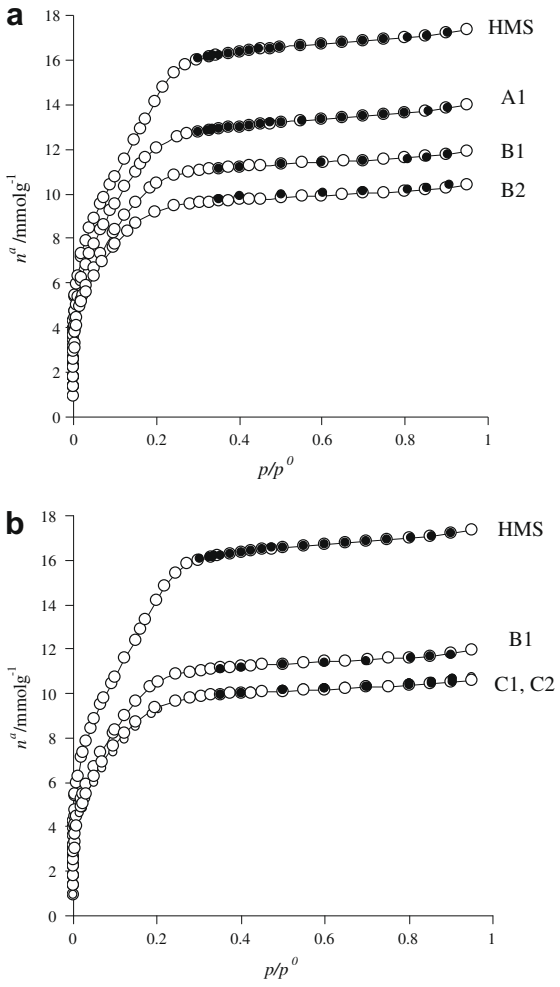


Fig. 1. Nitrogen adsorption–desorption isotherms at −196 °C of the materials prepared by: (a) methods A and B and (b) method C. Closed points are desorption points.

the supports even the lowest A_{BET} value (obtained for the B2 sample) is as high as 792 m^2 g^{-1}

In Fig. 2 the mesopore size distributions, obtained by the Broekhoff–de Boer method [35], are presented. As noticed from the HMS sample distribution, the mesopores present widths in the range of 2.4 and 3 nm. The direct complex immobilisation (A1) leads to an increase of the intensity of the peaks at the lowest pore diameter values (near 2.4 nm) and this effect is also observed for the remaining materials containing the vanadium complex (B2 and C2). In the case of C2, that is, the $[VO(acac)_2]$ based material where TMS was added, besides the peaks shift to lower values, the distribution seems to be more regular, that is, the different maxima become closer, suggesting that the TMS molecules, after reacting with the remaining silica OH groups, produce more uniform porous materials.

In Table 1 are also collected the N and V contents obtained by elemental and ICP-AES analysis, respectively, and by XPS. From the N bulk analysis and taking into account the initial amount of alkoxysilane used, it was possible to calculate the APTES grafting efficiency (amount of reacted alkoxysilane/amount in original solution × 100) for B1, which is 90%. Furthermore, the bulk (EA) and surface nitrogen (XPS) contents are similar, suggesting that APTES is uniformly grafted onto this material.

Upon complex immobilisation, the ICP-AES vanadium analysis in association with the peaks observation in the V $2p_{3/2}$ region of

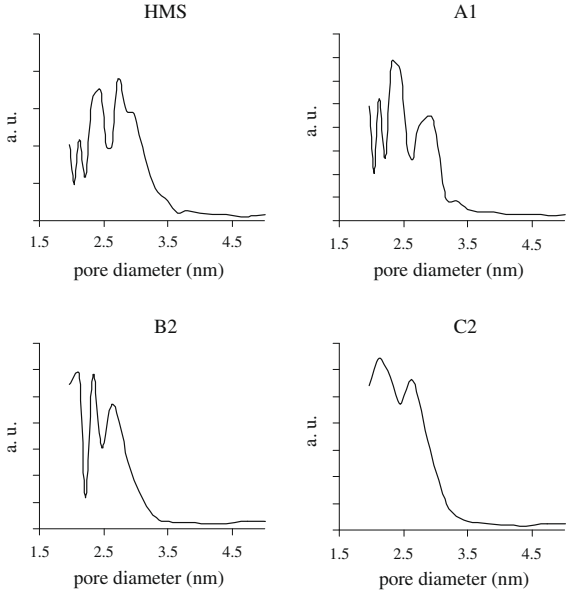

Fig. 2. Mesopore size distributions for HMS and for samples with anchored complex, obtained from the low temperature nitrogen adsorption data using the Broekhoff–de Boer method.

the high resolution XPS spectra of A1, B2 and C2 materials, confirm the presence of the metal complex in the HMS materials. From the vanadium contents determined by ICP-AES it was possible to determine the complex loadings for A1, B2 and C2 materials, which are 4, 128 and 51 μmol g^{-1}, respectively (Table 1), corresponding to complex immobilisation efficiencies (amount of immobilised complex/amount in original solution × 100) of 2%, 65% and 25%, respectively. As can be seen, the direct immobilisation of the complex onto the parent HMS (method A) leads to the lowest complex immobilisation efficiency, whereas the highest value is achieved for complex immobilisation onto the APTES functionalised HMS (method B). This is a consequence of the absence of chemical adsorption sites for the complex immobilisation in the parent HMS in contrast with the NH_2-functionalised HMS (B1), where the grafted NH_2 groups can act as specific sites for complex covalent anchorage. C1 material shows lower V content than B1, probably because the grafted TMS molecules hinder the reaction between APTES and the complex molecules.

Moreover, the comparison between the vanadium ICP-AES and XPS values can also provide some insights about the complex localisation within the HMS materials. In A1 material, [$VO(acac)_2$] is mainly immobilised in the outer pores of the parent HMS, since the total amount of vanadium per weight of material is lower than the vanadium surface content. On the other hand, in B2 material the VO complex is mainly grafted in the inner pores, since the bulk content is higher than the surface loading and finally, in C2, the metal complex appears to be homogeneously distributed throughout the HMS pores, since the vanadium bulk and surface contents are similar.

Analysis of A_{BET} values as a function of vanadium surface (XPS) and bulk (ICP-AES) contents for A1, B2 and C2 materials, Table 1, can give some interesting relations concerning the functionalised materials. In the case of the vanadium surface contents, the sample with higher complex loading (A1) is also the one which presents higher A_{BET} value since the surface inside the pores remains unoccupied to a large extent. More relevant, however, is the relation between the A_{BET} values and the vanadium bulk contents: in this case, as can be expected, the A_{BET} decreases with the increase in the vanadium total content: $A_{BET}(A1) > A_{BET}(C2) > A_{BET}(B2)$. However, for vanadium values of 51 and 128 μmol g^{-1} (for C2 and B2, respectively), the A_{BET} values only decrease from 808 to 792 m^2 g^{-1}, that is, in this vanadium content range, when the vanadium bulk amount increases 2.5 times the decrease in the surface area is only of 2%.

3.2. FTIR measurements

The infrared spectrum of the HMS parent material, Fig. 3, shows the typical Si–O lattice vibrations: two low intensity broad bands between 2100 and 1750 cm^{-1}, a broad and strong band in the 1390–900 cm^{-1} region and two strong bands between 900 and 400 cm^{-1} [26–29]. Moreover, it can also be observed a broad band at 3450 cm^{-1} assigned to O–H stretching vibrations and a very sharp peak at 3745 cm^{-1}, with medium intensity, due to stretching vibrations of isolated silanol groups [26–29]. A band at 1630 cm^{-1} is also observed in the spectrum and is attributed to H–O–H bending vibrations of physisorbed water [26–29].

Upon HMS functionalisation with APTES (B1), Fig. 3b, several changes can be observed in all the frequency range. The peak at 3745 cm^{-1} disappears, indicating the reaction between the surface silanol groups and the ethoxyl functionalities of APTES. A decrease in the broad band centred at 3450 cm^{-1} can also be observed due to a decrease in the adsorbed water content, as a consequence of the APTES grafting reaction. Furthermore, new bands due to N–H and C–H stretching vibrations can be observed in the 2970–2850 cm^{-1} region and the H–N–H and H–C–H bending vibrations are also observed in the range of 1560–1430 cm^{-1} [26–29].

Upon treatment of the APTES modified HMS with TMS (C1), Fig. 3c, no significant changes are detected; nevertheless a small decrease in the broad band centred at 3450 cm^{-1} due to OH stretching vibrations can be observed, suggesting the reaction between the remaining free silanol groups of the support and the ethoxyl groups of the TMS molecules. The presence of TMS in the material is also demonstrated by a small increase in the peaks corresponding to C–H stretching vibrations.

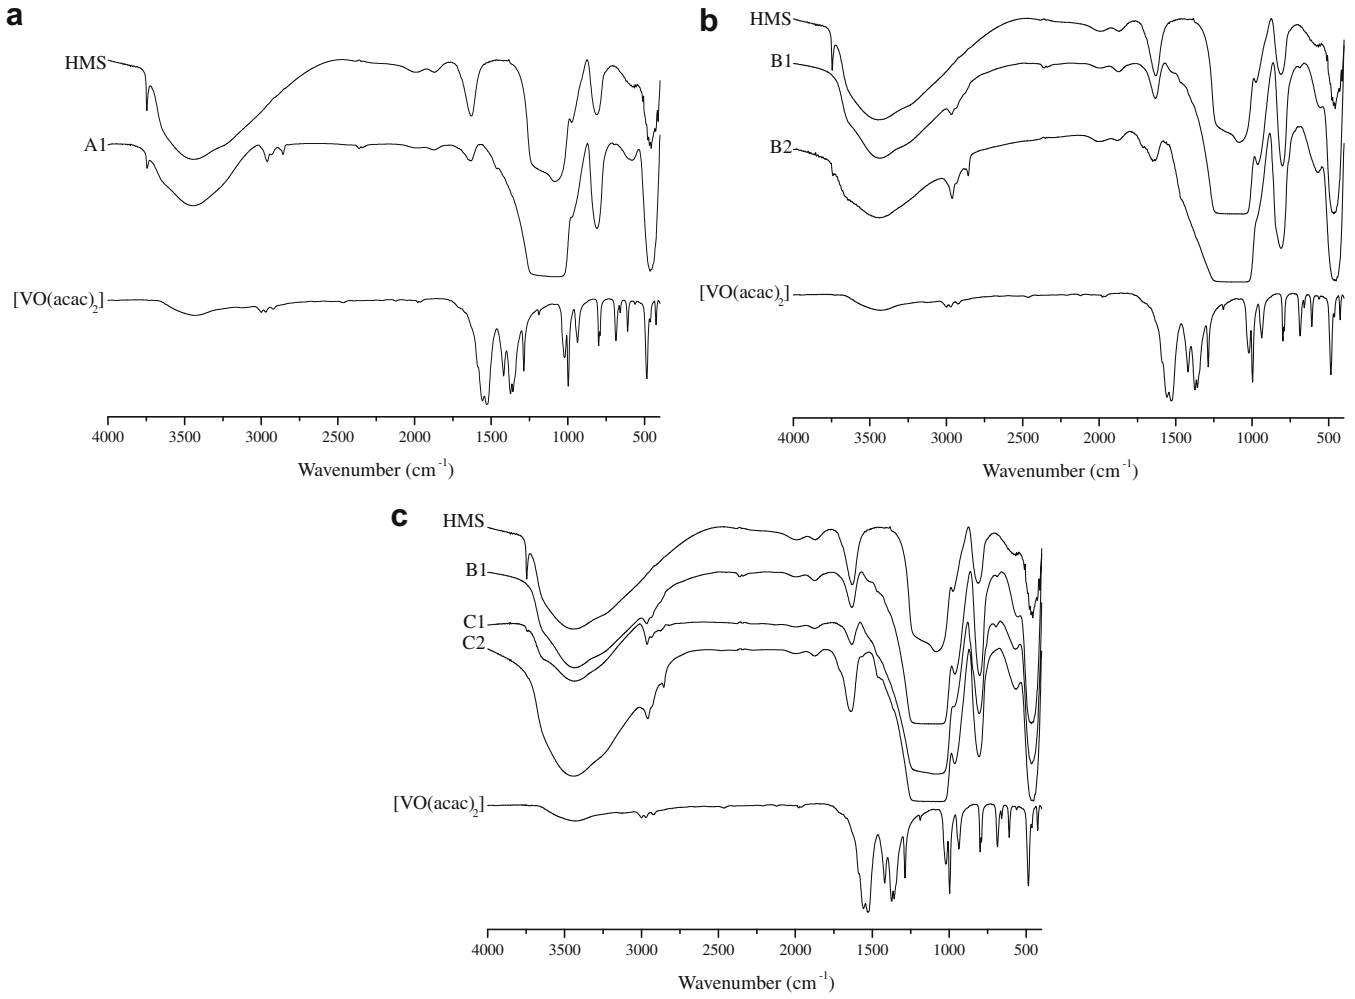

Fig. 3. FTIR spectra of the free [VO(acac)$_2$] complex and of parent and modified HMS materials prepared by methods: (a) A, (b) B and (c) C.

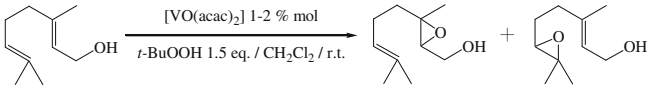
The FTIR spectra of the materials after complex immobilisation (A1, B2 and C2), Fig. 3a–c, present some changes in the ranges of 2970–2850 cm^{-1} and of 1780–1350 cm^{-1}, that can be unambiguously assigned to the immobilised complex; however, in all these spectra, the band due to the V=O stretching vibration, which appears at 997 cm^{-1} in the free complex could not be observed probably because it is masked by the strong and broad Si–O–Si band positioned in the 1390–900 cm^{-1} range. In fact, the free complex spectrum exhibits the most relevant bands in the ranges 3000–2920 cm^{-1} (C–H stretching vibrations), 1560–1350 cm^{-1} (stretching vibrations associated with the chelate ring) and at 997 cm^{-1} corresponding to the VO stretching vibrations [36].

The FTIR spectrum of A1, Fig. 3a, presents three new bands in the C–H stretching vibrations range, at 2960, 2932 and 2857 cm^{-1}, which are consistent with a band shift of the free complex bands situated at 3000, 2971 and 2923 cm^{-1}. This result, combined with the observed decreases in both the intensity of the broad band centred at 3450 cm^{-1} and the sharp peak at 3745 cm^{-1}, suggest that the HMS hydroxyl surface groups may be involved in the complex immobilisation through hydrogen bonds with the delocalised π-system of the acetylacetonate ligand, Scheme 1, as observed in the direct immobilisation of [VO(acac)$_2$] onto alumina, clays, silica gel and other mesoporous silicas [16,18,19].



When comparing the spectra of B2 and C2 with the correspondent parent materials (B1 and C1, respectively) it is possible to see several changes which are attributed to the grafted VO complex: (i) increase in the intensity of the C–H stretching vibrations in the 2970–2850 cm^{-1} region and a change in their profile, (ii) increase in the intensity and broadness of the band at 1630 cm^{-1} and (iii) the appearance of a shoulder on the latter band in the high energy side, at approximately 1710 cm^{-1}. The broadening of the band at 1630 cm^{-1} can be due to the presence of overlapped bands assigned to the grafted complex, as already seen in the grafting of the same VO(IV) complex and Cu(II) analogue in Laponite and K10-montmorillonite, using the same immobilisation procedure [16,37]. These new bands are assigned to chelate stretching vibrations, now containing the new C=N bond formed by Schiff condensation reaction between the amine groups of the grafted APTES and the C=O group from the coordinated acetylacetonate ligand, Scheme 1 [16,37]. Due to the high APTES grafting efficiency onto the parent HMS, no significant direct immobilisation of [VO(acac)$_2$] may occur in materials B1 and C1.

3.3. Epoxidation of geraniol catalysed by [VO(acac)$_2$] heterogeneous catalysts

The results obtained in the epoxidation of geraniol at room temperature using [VO(acac)$_2$] based materials as catalysts and *t*-BuOOH as the oxygen source, in dichloromethane, are summarised in Table 2. Data from homogeneous phase and blank experiments ran under identical conditions are also included.

The geraniol conversions for 48 h of reaction are 100%, 35% and 17% using B2, C2 and A1 materials, respectively (Table 2). This sequence follows the order of vanadium loadings obtained by

Table 2
Epoxidation of geraniol catalysed by $[VO(acac)_2]$ in homogeneous and heterogeneous phases.[a]

[c] Selectivity of the geraniol epoxides; yield calculated as: (%C × %S)/100.

ICP-AES (Table 1) onto the HMS materials: B2 ≫ C2 > A1. The regioselectivity towards the allylic double bond remains identical to the homogeneous counterpart for all the heterogeneous $[VO(acac)_2]$ based catalysts, being nearly 100% for 2,3-epoxygeraniol (Table 2). From the control experiments with the parent materials it is possible to conclude that the silica surface both unmodified and functionalised with APTES/TMS does not have relevant catalytic activity on its own, as can be confirmed by the geraniol conversion percentages of HMS, B1 and C1 materials, of only 7% and 4%, respectively.

All the reactions in the heterogeneous phase have higher reaction times when compared to the homogeneous reaction. This effect is due to diffusion constraints imposed to the substrate and reagents by the specific localisation of the active catalytic centres within the porous matrix [16,21,27].

With the exception of A1 which presents high catalyst leaching after the first cycle, detected by visual inspection of the colour of the reaction medium, the new heterogeneous catalysts were reused for further four catalytic cycles. During the catalytic cycles, B2 shows similar %C and $\%S_{2,3\text{-epoxygeraniol}}$ to those exhibited in the first cycle, but C2 shows some change in %C. In order to understand these different behaviours, leaching of the catalytic active phase was determined by measurement of vanadium contents by ICP-AES after the five catalytic cycles; the values are presented in Table 1. Materials B2 and C2 have complex leaching percentages of 73% and 20%, respectively, and thus it can be concluded that the constant high catalytic activity of B2 in all cycles may have a significant homogeneous component. In this context, C2 can be considered the most stable catalyst upon reuse, presenting a satisfactory geraniol conversion, but showing high selectivity for the desired product even after four reuse cycles.

As a summary, in terms of catalyst stability, the most effective immobilisation method is the one which uses TMS in combination with APTES (method C: covalent grafting, Scheme 1), leading to a homogeneous distribution of the complex throughout the support.

4. Conclusions

New heterogeneous catalysts were prepared by immobilisation of $[VO(acac)_2]$ onto HMS supports both directly and after functionalisation with amine groups. In the case of APTES functionalised supports, the effect of TMS addition before complex grafting was also studied.

The ICP-AES and XPS results of the final materials showed that the $[VO(acac)_2]$ immobilisation was achieved in all cases, with B2 presenting the highest grafting efficiency (highest complex loading). In the case of A1 (method A), the metal complex was mainly immobilised on the outer silica surface by hydrogen bonds between the HMS hydroxyl surface groups and the delocalised π-system of the acetylacetonate ligand. Complex immobilisation by methods B and C (materials B2 and C2) occurred by covalent bond formed by the reaction between the surface NH_2 grafted groups and the C=O group of the acetylacetonate ligand. In B2 the VO complex was mainly grafted in the inner pores of the solid matrix, but in the case of C2, the complex distribution in HMS pores was more homogeneous.

In the geraniol epoxidation, the material which led to the highest geraniol conversion was B2. One of the reasons that could justify the highest values for this material, in particular when compared with C2, could be its highest vanadium content for comparable specific surface area values. However, B2 material also resulted in a higher leaching percentage after five catalytic cycles when compared with C2. It could be concluded that the grafting process leading to C2 catalyst, although resulting in lower $[VO(acac)_2]$ content, was the most efficient one, giving rise to a heterogeneous catalyst with satisfactory substrate conversion, high regioselectivity until the fourth catalytic cycle and high stability,

corresponding to a leaching percentage of 20% after five consecutive catalytic cycles. Material A1 showed the lowest %C and the highest active phase leaching; this was a consequence of the lowest V content, determined by the absence of specific immobilisation sites and by weak non-covalent support interactions through hydrogen bonds, which can easily be disrupted by the oxidative nature of the catalytic reaction medium.

The SCPs **1**–**3**, were prepared by the same procedure under the same conditions. A solution of 85 mg (0.5 mmol) of $AgNO_3$ in 10 mL H_2O was being added at room temperature to the mixture of (0.5 mmol) of the bipodal ligand; **L**, in 10 mL MeCN and of 48 mg (0.5 mmol) of KSCN in 10 mL H_2O. White turbidity appeared then after concentrated ammonia solution was added to the hot mixture dropwise with stirring till clearness. The mixture was filtered off and the filtrate was left to stand for some days. Prismatic colorless crystals of **1** appeared after two weeks. After filtration, subsequent washing with small portions of water and MeCN and overnight drying, about 109 mg of [$(AgSCN)_2 \cdot$ bpy] **1** were obtained. *Anal.* Calc. for **1** ($C_{12}H_8N_4S_2Ag_2$): C, 29.50; H, 1.63; N, 11.47. Found: C, 29.32; H, 1.60; N, 11.55%. IR (KBr, cm^{-1}): 3045w, 2117s, 2090s, 1597s, 1528m, 1409s, 1372m, 1214m, 1067m, 799s, 622s, 562m, 508s, 452w and 431w. Also, brown prismatic crystals of [$(AgSCN)_2 \cdot$ (tbpe)], **2**, were formed after two weeks and filtered off then after washed with small portions of water and MeCN and dried overnight. Ninety-six milligrams of **2** were obtained. *Anal.* Calc. for **2** ($C_{14}H_{10}N_4S_2Ag_2$): C, 32.67; H, 1.94; N, 10.89. Found: C, 32.63; H, 1.97; N, 10.75%. IR (KBr, cm^{-1}): 3047w, 2925w, 2862w, 2099s, 1599m, 1419s, 1319m, 1295m, 1250m, 1207m, 980s, 827s, 754s, 552s, 448m. Brown needle crystals of **3** were formed after one week and filtered off then after washed with small portions of water and MeCN and dried overnight. Sixty-two milligrams of [$(AgSCN)_2 \cdot$ phenz], **3**, were obtained. *Anal.* Calc. for **3** ($C_{14}H_8N_4S_2Ag_2$): C, 32.80; H, 1.56; N, 10.93. Found: C, 32.64; H, 1.55; N, 11.09%. IR (KBr, cm^{-1}): 3048w, 3006w, 2867w, 2131s, 1513s, 1466m, 1432m, 1360m, 1119m, 905m, 823m, 748s, 654m, 594m, 439m.

2.2. X-ray structural determination

Structural measurements for the SCPs **1**–**3** were performed on a Kappa CCd Enraf Nonius FR 90 four cycle geniometer with graphite monochromatic Mo Kα radiation {[λMo Kα] = 0.71073 Å} at 25 ± 2 °C. All structures were resolved using direct-methods and

all of the non-hydrogen atoms were located from the initial solution or from subsequent electron density difference maps during the initial stages of the refinement. After locating all of the non-hydrogen atoms in each structure the models were refined against F^2, first using isotropic and finally using anisotropic thermal displacement parameters. The positions of the hydrogen atoms were then calculated and refined isotropically, and the final cycle of refinements was performed. The cyano groups of all structures were ordered. Crystallographic data for the SCPs **1**–**3** are summarized in Table 1. Selected bond distances and bond angles are given in Tables 2–4.

3. Results and discussion

3.1. Crystal structures

3.1.1. Crystal structure of $[(AgSCN)_2 \cdot bpy]$ (*1*)

The ORTEP plot of the novel SCP **1** shows one half of the chemical formula; Fig. 1a, while the formula unit contains two crystallographically identical silver atoms, two thiocyanate ligands and one bpy ligand. Each silver atom is bound to one S atom and one N atom of two thiocyanate ligands and one N atom of bpy ligand forming distorted trigonal planar geometry with N8–Ag1–N15

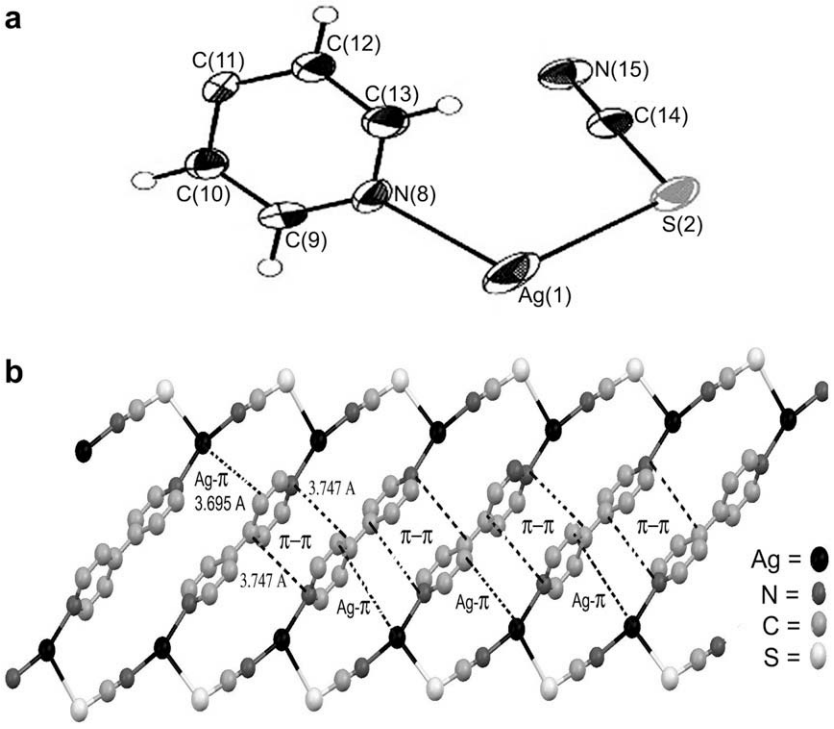

Fig. 1. (a) An ORTEP view of the asymmetric unit of the SCP **1**. (b)View of the ribbon structure of the SCP **1** along the *b*-axis; H-atoms are omitted for clarity.

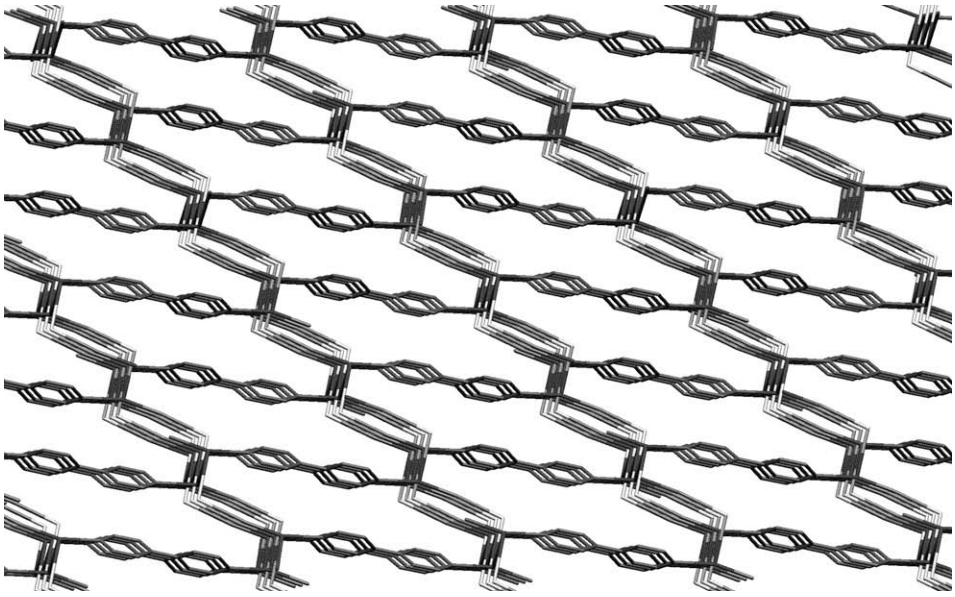

Fig. 2. View of the 3D-structure of the SCP **1** along the *b*-axis showing the crossing of the 2D-layers.

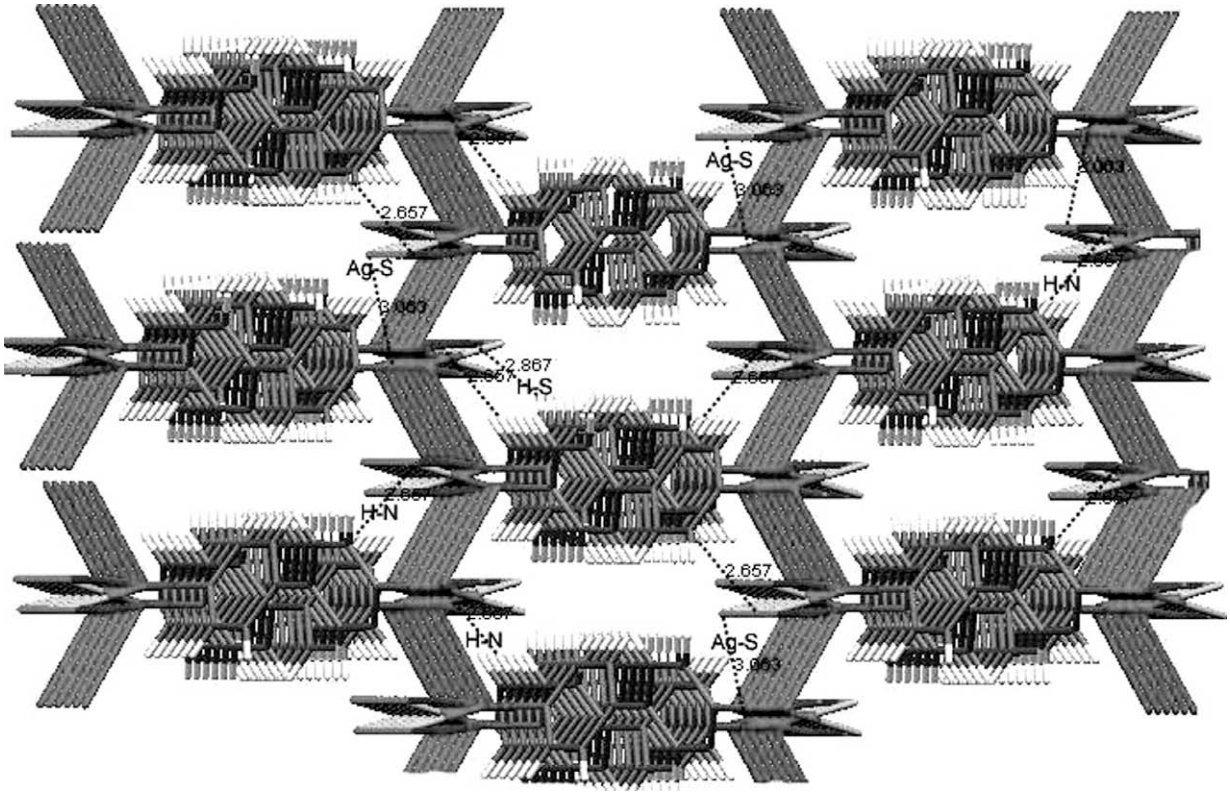

Fig. 3. View of the 3D-structure of the SCP **1** along the *c*-axis showing the Ag–Ag, Ag–S interactions and hydrogen-bonding.

angle equals to 161.52°, Table 2 and Fig. 1b. The thiocyanate ligand acts as μ_2-1,3-ligand connecting the silver atoms, Ag1–N15 = 2.158 Å, Ag1–S2 = 2.774 Å, which are in the range of the reported values [10,14]. On the other hand, the AgNC angle is nearly linear, while AgSC angle is nearly perpendicular; Table 2. The AgSCN building blocks create infinite parallel zig-zag chains with S2–Ag1–N15 = 98.99° and Ag1–S2–C14 = 103.06°. These zig-zag chains are bridged by the bpy bipodal ligand forming extended vertical 2D-ribbons along the *b*-axis, Fig. 1b. In this case, a polygon consisting of $[(Ag_4(SCN)_2(bpy)_2]$, of dimensions of 6.096 Å × 16.632 Å, is recognized as a typical fragment of **1**. These polygons are arranged in unique way that one pyridyl ring of the bpy ligand in one polygon is parallel to another pyridyl ring of bpy in the adjacent polygon with a separation distance of 3.74 Å suggesting the presence of weak but not negligible stacking interactions, between the pyridine rings, as well as Ag–π interaction between the silver(I) ion and the neighboring pyridyl ring; 3.695 Å; Fig. 1b. It is worth mentioned here that one pyridyl ring in each bpy ligand is tilted out of the plane defined by the other bpy ring by an angle of 43.93°. Alternatively, these ribbons can be considered as infinite non-interpenetrating 2D-layers that cross each other along the *b*-axis via the AgSCN fragments, Fig. 2. On the other hand, each ribbon can be considered as a compressed spring along the *c*-axis creating a unique shape, Fig. 3.

The ribbons are arranged parallel in unique way where one layer connect two ribbons above and two ribbons below by Ag–Ag interactions; Ag–Ag = 3.242 Å and by H-bonds between H-atoms of the pyridyl rings in one layer and thiocyanate groups in the neighboring layers; H–S = 2.867 and 3.016 Å, C–H = 2.907 Å and N–H = 2.657 Å, as well as considerable contacts between Ag atoms and S2 atoms in the adjacent layers Ag–S2[a] = 3.0627 and 3.393 Å forming 3D-network structure; Fig. 3. The Ag–Ag and Ag–S2 contacts cause pyramidalisation of Ag(I) sites.

*3.1.2. Crystal structure of [(AgSCN)$_2$ · tbpe] (**2**)*

The crystal structure of **2** consists of silver(I) thiocyanate and tbpe fragments in a 2:1 molar ratio creating a three-dimensional network formulated as $\infty^3[(AgSCN)_2 \cdot tbpe] \equiv \infty^3[Ag_2(\mu_3\text{-}SCN)_2(\mu\text{-}tbpe)]$. The asymmetric unit of **2** consists of only one Ag(I) ion, one SCN group and half of the tbpe ligand, Fig. 4a. Each Ag(I) ion is pseudo-tetrahedrally four-coordinated by a tbpe nitrogen atom; Ag1–N3 = 2.248 Å, two thiocyanate sulfur atoms Ag1–S2 = 2.753 Å, Ag1–S2^a = 2.772 Å and one nitrogen atom of another thiocyanate ligand; Ag1–N5 = 2.173 Å, with the bond angles at the silver atom in the range of 95.27–144.95°; Fig. 4b, Table 3. The extended structure of **2** consists of infinite parallel AgSCN zig-zag chains bonded at the sulfur atom; Ag1–S2–C10 = 96.37° and contains the unusual bifurcated cyanide fragment which exhibits bent AgCN angle, where Ag1–N5–C10 = 155.6°; Table 3. Each two close parallel AgSCN zig-zag chains are connected via two silver atoms and two sulfur atoms forming an array of fused polymer rings containing the unique quadro minicycle (Ag_2S_2) motif, in addition to the usual hexagonal rings of $Ag_2(SCN)_2$ with dimensions of 3.776 Å × 5.577 Å; Fig. 4b. These fused rings create stair-case like $\infty^1[Ag_2(SCN)_2]$ ribbons in which the minicycle (Ag_2S_2) motif represents the steps along the *a*-axis, Fig. 5a. The S–S distance in the minicycle is equal to 4.383 Å while the Ag–Ag distance is equal to 3.364 Å which is shorter than the sum of the van der Waals radii of two silver atoms (3.44 Å [26]),

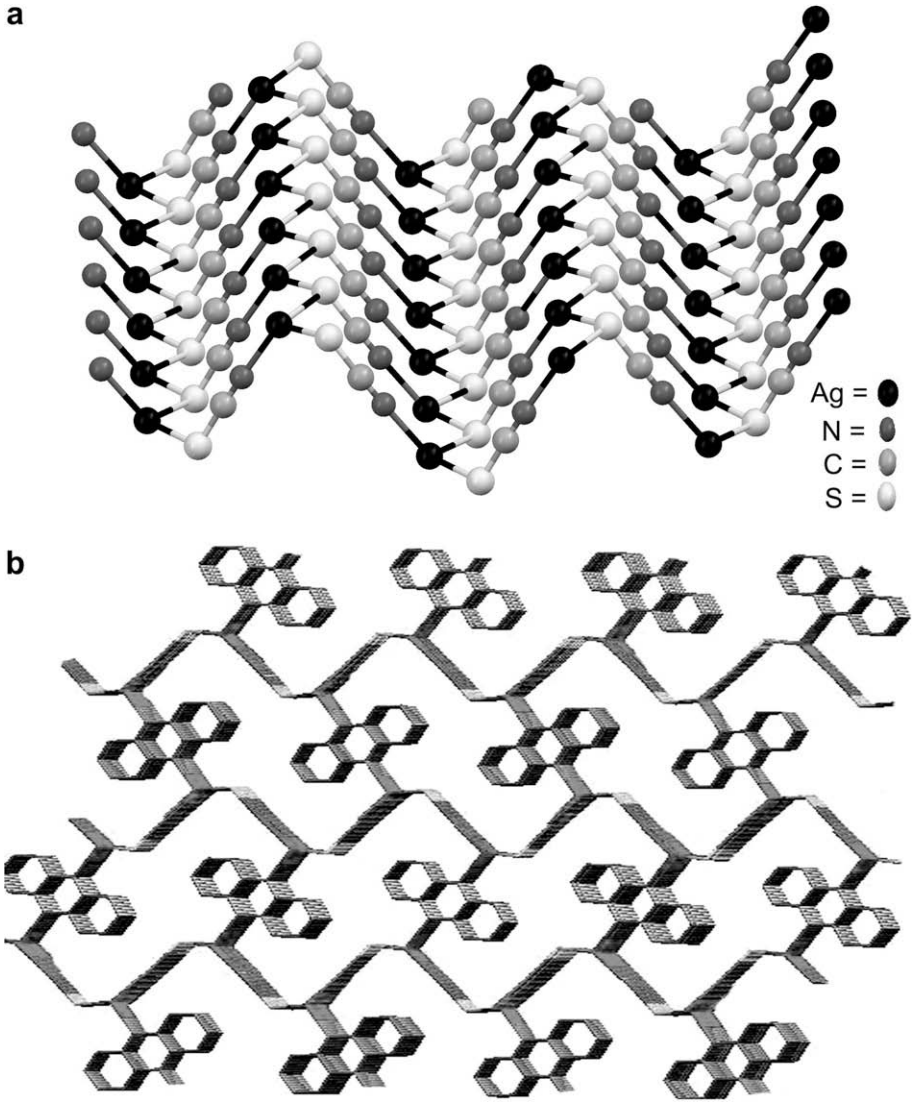

Fig. 8. (a) View of the parallel zig-zag $(AgSCN)_n$ chains showing the hexagonal $Ag_3(SCN)_3$ rings. (b) 3D-dimensional structure of the SCP **3** along the *a*-axis. H-atoms are omitted for clarity.

* b, broad.

indicating argentophilic interaction. The bifurcated silver-SCN fragment can be considered as a consequence of the formation of the minicycle (Ag_2S_2) motif which represents the essential building block in the structure of **2**.

These infinite parallel stair-case-like ribbons are arranged in a quasi-parallel fashion in the cell and separated by a distance of 13.606 Å. They are bridged by the tbpe ligands via silver atoms along the diagonal of the unit cell, forming infinite two-dimensional layered structure; Fig. 5b. In this case, one tbpe is directed to the space of the hexagonal ring $Ag_2(SCN)_2$ and the ethylenic moiety locates toward the quadro minicycle (Ag_2S_2) motif while the other pyridyl ring is directed to the next hexagonal ring in the adjacent stair-case chain. The bridging tbpe molecules are arranged in a parallel way with a distance between two successive tbpe ligands equal to 5.932 Å forming distorted polygon structure consisting of $[Ag_4(SCN)_2(tbpe)_2]$ with dimensions of 5.415 Å × 18.348 Å. It is interesting that the network structure of **2** consists of adjacent parallel infinite 2D-layers which are all related by translation in the *a*-axis direction in the solid state, being stacked in an ...AAAA... fashion to build up the three-dimensional structure with the inter-layer separation of about 6.5 Å; Fig. 6. The 3D-network structure of **2** is stabilized by extensive π–π stacking between the pyridyl rings, 3.360 Å, as well as hydrogen bonds between H-atoms of the ethylenic group and the sulfur atoms, 2.955 Å, and between the H-atom of the pyridyl rings and C10 of the thiocyanate group, 2.838 Å; see Table 3.

3.1.3. Crystal structure of $[(AgSCN)_2 \cdot phenz]$ (**3**)

The reaction of in situ prepared AgSCN with phenazine in aqueous ammonical solution affords the brown needle crystals $\infty^3[(AgSCN)_2 \cdot phenz]$, **3**. The crystal structure of **3** confirms the assignment of 2:1 stoichiometry for the silver(I) thiocyanate phenazine complex while the asymmetric unit of **3** comprises half of the formula unit, Fig. 7a. The asymmetric unit consists of one type of silver(I) which is four-coordinated assuming distorted tetrahedral geometry with angles in the range of 87.82–121.83°; Table 4. The silver site is coordinated to two sulfur atoms; Ag–S = 2.594 and 2.602 Å, a nitrogen atom of the thiocyanate ligand; Ag–N = 2.219 Å and nitrogen atom of the phenazine ligand; Ag–N = 2.438 Å, Fig. 7b. In this case, two silver atoms are bridged almost symmetrically by the S atom of the μ_3-1,1,3-SCN ligand. The structure of **3** is best described as AgSCN infinite chains which significantly perturbed at S atom to assume zig-zag conformation arranged parallelly to the crystallographic *c*-axis, Fig. 8a. The angles of the thiocyanate ligand are almost linear while the Ag1–S2–C6 acquires bent conformation, 110.80°; Table 4. These parallel zig-zag chains are bridged by the sulfur atoms where each S atom connects two silver atoms, one from its own chain and the other silver atom is from the adjacent chain, creating 2D-sheet containing fused hexagonal rings, 4.145 Å × 7.194 Å, that adopt chair conformation leading to the formation of corrugated layers consisting of $Ag_3(SCN)_3$ fragments, Fig. 8a. These hexagonal rings are interwoven along the *b*-axis.

The 2D-sheets of $(AgSCN)_n$ are further linked by the planar phenazine ligands creating distorted polygons consisting of $[Ag_6(SCN)_4(phenz)_2]$ with enough space to accommodate the phenyl rings of the phenazine ligand forming 3D-network structure. It is worth noting here that the phenazine ligands as well as the thiocyanate bridges are completely parallel assuming weak stacking interactions; 3.618 Å, while hydrogen bonds with S2; 2.84 and 2.97 Å, and the CN unit; 2.728–3.014 Å; Table 4, as well as short contacts between silver atom and carbon atoms of phenz and SCN ligands, 3.347 and 3.339 Å, lead to further stabilization of the 3D-network of **3**, Fig. 8b.

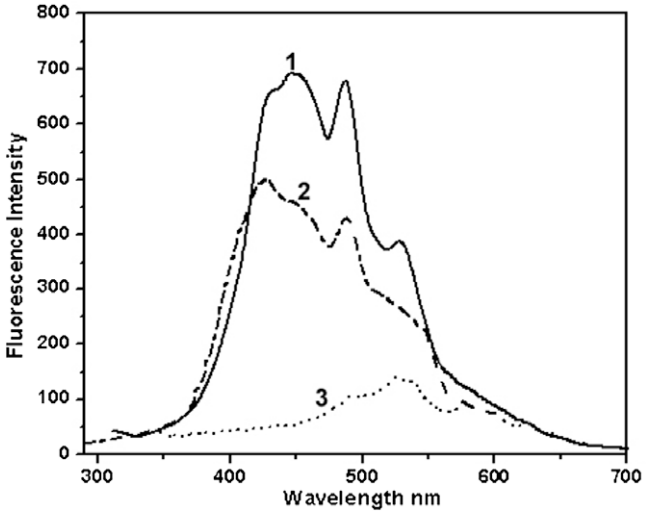

Fig. 9. Emission Spectra of the SCPs **1**–**3**; (λ_{ex} is 300 nm for **1**, 270 nm for **2** and 300 nm for **3**).

3.2. Electronic absorption spectra and emission spectra of SCPs *1*–*3*

The electronic absorption spectra of the ligands and the SCPs **1**–**3** were measured in the solid state at room temperature as reflectance spectra. The absorption spectra of the SCPs **1**–**3** display, generally, the absorption bands of ligands in addition to the CT bands. Thus, investigating the absorption spectra of the bpy and tbpe ligands reveals that the spectra display mainly three absorption bands at 218–232 nm ($^1L_a \leftarrow {}^1A$), 265–278 nm ($^1L_b \leftarrow {}^1A$), and 325 nm (π–π^*), in addition to a band at 390–450 nm (n–π^*), Table 5. On the other hand, the spectrum of phenazine shows several bands at 220, 275, 340, 394, 414, 510 nm; Table 5. It is a matter of fact that replacement of the methine group in anthracene by nitrogen atom in phenazine ligand results in relatively little changes in the spectrum of phenazine. This is especially true due to the fact that the replacement of N for CH of anthracene occurs at positions that it does not seriously affect the symmetry of anthracene. Thus, the phenz and anthracene are isoelectronic. In spite of the fact that transition ($^1C_b \leftarrow {}^1A$) in anthracene is forbidden the ($^1C_b \leftarrow {}^1A$) band in phenz is observed at 220 nm which is surprisingly intense for a forbidden transition [27]. The band at 270 nm exhibits red shift than $^1B_b \leftarrow {}^1A$ band of anthracene [27]. The bands at 340 and 394 nm should be assigned to $^1L_a \leftarrow {}^1A$ transition, whereas the band of phenz at 414 nm should be assigned to $^1L_b \leftarrow {}^1A$ transition. The relatively low intensity band at the long wavelength side is assigned to n–π^* transition. The bands due to n–π^* transitions disappear in the spectra of SCPs **1**–**3** due to participation of the bipodal ligands in the coordination sphere of silver(I) ions. The absorption spectra of the SCPs **1**–**3** exhibit an additional broad band at 345, 352 and 442 nm, respectively, corresponding to metal-to-ligand charge transfer (MLCT) where the charge is transferred from the silver(I) center to the unoccupied π^*-orbital of the ligand.

The emission spectra of the SCPs **1**–**3**, Fig. 9, together with the emission spectra of their ligands were measured using the same excitation wavelength in each case. The emission spectra of the bipodal ligands display structural bands, Table 5, which correspond to the lowest (π, π^*) and close lying (n, π^*) states. On the other hand, the emission spectra of the SCPs **1**–**3** display structural peaks of the bipodal ligands as well as additional bands which may assigned to MLCT or metal-centered transitions of the type $4d^{10} \rightarrow 4d^9\ 5s^1$ and $4d^{10} \rightarrow 4d^9\ 5p^1$ on the silver(I) center. The emission spectra of the SCPs **1**–**3** exhibit red shift compared to those of the corresponding ligands.

3.3. Thermogravimetric analysis of the SCPs *1*–*3*

The SCPs **1**–**3** are thermally stable until 150–200 °C, then after they start decomposition with the loss of ligand in the temperature range 150–300 °C, Table 6. The second decomposition step involves removal of one sulfur atom in the temperature rang 350–480 °C, for the SCP **1** and **2** and at 270–360 °C for the SCP **3**. The third step occurs at slow rate and over relatively large temperature range, 400–750 °C, where two cyanide groups are lost as cyanogen, Table 6. Finally above 750 °C the residue is obtained which is coincident with the silver sulfide. The relatively high temperature at which the SCN groups are released supporting the bridging capability of this group forming stable $(AgSCN)_n$ chains.

4. Conclusions

The general features of the structure of the SCPs **1**–**3** are the formation of AgSCN-L adducts in a 2:1 molar ratio forming 3D-networks containing the AgSCN building blocks connected via μ_2-1,3-SCN in **1** and μ_3-1,1,3-SCN in **2** and **3**. These AgSCN building blocks form zig-zag AgSCN chains which are bridged by the bipodal ligands creating polygons consisting of $[Ag_4(SCN)_2(L)_2]$; L = bpy or tbpe, and $[Ag_6(SCN)_4(phenz)_2]$. However, the parallel zig-zag chains assume different modes of interaction where in **1** they are bridged by Ag–Ag bonding interactions, in **2** via the formation of quaro minicycle Ag_2S_2 motif with weaker Ag–Ag interaction and in **3** by S atoms creating hexagonal rings which adopt chair conformation without any interaction between the silver atoms. The mode of bridging depends on the nature of the bipodal ligand, whereas the longest bipodal ligand tbpe; 9.412 Å, acquire wide space in the network structure of **2** which should be achieved by the formation of the minicycle motif and the bifurcated AgNC fragment which assumes quasi-linear fashion in **1**; 172.2° while it is almost linear in **2**; 177.7°. In the same direction, the AgSCN zig-zag chains are more puckered in **2** than in **1** and **3**; Table 7. The S–C–N fragment tends to be linear in all cases, whereas the Ag–N–C–S fragment is quasi-linear in **1** and **3** but nonlinear in **2**. On the other hand, the Ag–S distances in **1** and **2** are longer than that in molecular AgSCN (2.648 Å) [22], while they assume shorter distance in **3**. Thus, using bipodal ligands which would not be constrained to a planar conformation like bpy and tbpe which exhibit the two pyridyl rings in two parallel planes separated by ethylenic bond or the bulky planar phenazine ligand, would change the shape and geometry of the $(AgSCN)_n$ chains and allow the interconnection of chains and propagation of the microstructure in three dimensions.

Appendix A. Supplementary data

CCDC 682261–682263 contain the supplementary crystallographic data for SCPs **1**–**3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this

article can be found, in the online version, at doi:10.1016/j.poly.2009.01.005.

search Institute, Lucknow, India. The electronic spectra were recorded (in 10^{-5} M $CHCl_3$ solution) using a Simadzu UV-1601 spectrophotometer and Emission spectra were recorded in Perkin–Elmer L52 spectrophotometer using 10^{-5} M $CHCl_3$ solution at room temperature. Infrared spectral data were collected (KBr pellets) using a Perkin–Elmer L120-000A spectrophotometer and ^{1}H NMR spectra of the samples were measured in DMSO-d_6 at the Indian Institute of Chemical Biology, Kolkata, West Bengal, India using a Bruker-400 MHz instrument at room temperature.

2.1. Synthesis of ligands

The ligands, Hsmth and Hapmth, were synthesized by condensation of salicylaldehyde and 2-hydroxy acetophenone with morpholine *N*-thiohydrazide, respectively, using our previously published method [55].

2.2. Synthesis of the phenylmercury(II) complexes

[PhHg(Hsmth)] ***(1)***: Phenylmercury(II) acetate (0.676 g, 0.002 mol) was dissolved in dry ethanol (25 ml) and filtered directly into an ethanolic solution (15 ml) of the ligand, H_2smth (0.530 g, 0.002 mol). The mixture was heated under gentle reflux for about half an hour and filtered while hot. The filtrate, on concentration to ~20 ml and cooling, yielded a light yellow brown compound. It was recrystallized from dry ethanol to get suitable light yellow crystals for X-ray diffraction. Yield, 0.840 g, 70%; m.p. 168–170 °C. *Anal.* Calc. for $C_{18}H_{19}HgN_3O_2S$: C, 39.89; H, 3.53; N, 7.75. Found: C, 40.11; H, 3.45; N, 7.68%. νC=N, 1615 (m); λ_{max} = 243, 299, 343 nm; δ_{ph} 6.90–7.43 ppm.

[PhHg(Hapmth)] ***(2)***: Synthesized following the method similar that used for the compound (**1**) above using equimolecular portions of phenylmercury(II) acetate (0.676 g, 0.002 mol) and the ligand, H_2apmth (0.676 g, 0.002 mol) and recrystallized from dry ethanol to produce light yellow crystals for X-ray diffraction. Yield, 0.778 g, 70%; m.p. 175–180 °C. *Anal.* Calc. for $C_{19}H_{21}HgN_3O_2S$: C, 41.04; H, 3.81; N, 7.56. Found: C, 41.11; H, 3.75; N, 7.68%. νC=N, 1560 (m); λ_{max} = 244, 301, 344 nm; δ_{ph} 6.90–7.43 ppm, δ_{methyl} = 2.32 ppm.

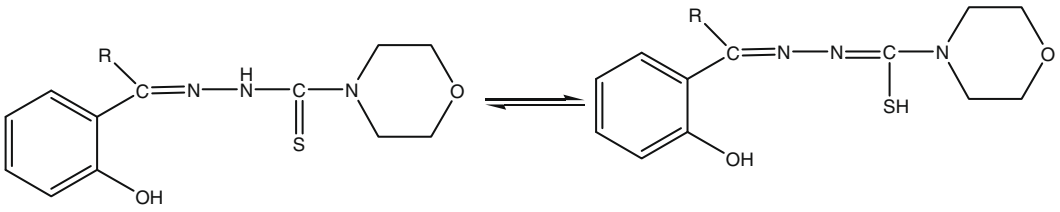
2.3. Crystallography

Crystallographic data and refinement details are given in Table 1. Diffraction intensities were measured at 100 K for both complexes **1** and **2** using a Bruker APEX CCD based diffractometer (Mo Kα radiation, λ 0.71073 Å) in the θ range (a) 1.82–28.31 for **1** (b) 1.93–28.33 for **2** using ω scans. Data processing was done using SAINT and absorption corrections using SADABS [56]. The structures were solved by direct methods [56]. Refinement (anisotropic displacement parameters, hydrogen atoms in riding model approximation and weighting scheme of the form $w = 1/[\sigma^2(F_o^2) + (0.0434P)^2]$, where $P = (F_o^2 + 2F_c^2)/3$) was on F^2. Graphics were obtained with ORTEP 3 for Windows and thermal ellipsoid plots are at the 50% probability level [57]. Additional figures were drawn with PLATON for Windows [58].

3. Results and discussion

The reactions of salisylaldehyde and 2-hydroxy acetophenone with morpholine *N*-thiohydrazide in 1:1 molar ratio in ethanol yielded the thiohydrazone ligands, which may remain in equilibrium with their thiol forms I and II, respectively, in solution [59,60].

The treatment of phenylmercury(II) acetate with salicylaldehyde morpholine *N*-thiohydrazone and 2-hydroxyacetophenone morpholine *N*-thiohydrazone (Fig. 1) in dry ethanol under gentle refluxing conditions resulted in deprotonation of the NH proton and formed light yellow to light yellow brown complexes [PhHg(Hsmth)] (**1**) and [PhHg(Hapmth)] (**2**). These two complexes are generally soluble in DMSO, acetonitrile and nitromethane, and partially soluble in acetone and chloroform. The crystal structures and spectroscopic properties of the complexes are described below.



3.1. Crystal and molecular structure of [PhHg(Hsmth)] (1)

The ORTEP drawing and the atomic numbering scheme of [PhHg(Hsmth)] (**1**) are shown in Fig. 2, and selected bond lengths and bond angles are given in Table 2. The X-ray analysis reveals that the complex (**1**) adopts a distorted T-shaped geometry around mercury(II) by the ligand (I) through the phenyl carbon, thiol sulfur and azomethine N atom of the ligand H_2smth.

Phenylmercury(II) makes bonds to thiol sulfur and azomethine N atoms of the ligand H_2smth. This N, S-chelate has a bite angle of 74.15(8)° with the result that azomethine N atom does not lie at 90° to the C_{ph}–Hg–S axis of PhHg(Hsmth). Due to the small bite, the C_{ph}–Hg–S angle is 166.83(10)°. Thus, the Hg complex does not acquire a T-shaped structure and is rather severely distorted

Table 2
Selected bond lengths and bond angles of phenylmercury(II) complexes.

Bond lengths		Bond angles	
Complex ***1***			
Hg1–S1	2.3779(11)	S1–Hg1–N1	74.15(8)
Hg1–N1	2.561(3)	S1–Hg1–C1	166.83(10)
Hg1–C1	2.070(4)	N1–Hg1–C1	118.93(12)
S1–C7	1.759(4)		
Complex ***2***			
Hg1–S1	2.357(2)	S1–Hg1–C1	173.6(2)
Hg2–S2	2.350(2)	S2–Hg2–C20	175.68(19)
Hg1–C1	2.068(8)		
Hg2–C20	2.063(7)		
S1–C7	1.768(8)		
S2–C26	1.785(8)		

[61,62]. It can be seen from earlier reported value that C–Hg–S angles vary (ca. 165–170°) [63–66] with the nature of the thiosemicarbazone. Variation in bite angle S–Hg–N1 and the angles at S, viz. Hg–S–C, do not show significant changes.

The Hg–C_{ph} bond length 2.070(4) Å in complex (1) is in the range of unperturbed Hg–C bonds (2.05–2.09 Å) [63]. This distance is slightly shorter than the Hg–C_{Me} bond distance (2.09 Å) but close to the values of Hg–C_{ph} bond lengths of previously reported similar phenylmercury(II) complexes [64–66]. The back donation of an electron from mercury(II) to the π^* orbital of phenyl ring is the key factor for shortening of this bond length. The Hg–S distance, 2.3779(11) Å and Hg–N bond distance 2.561(3) Å of complex (**1**) are similar to earlier reported values [67]. The coordination of the azomethine nitrogen and thiol sulfur atom to the mercury(II) atom leads to the formation of a stable five-membered chelate ring.

The complex (**1**) shows a C–S bond distance of 1.759 (4) Å which is shorter than the C–S single bond (1.81 Å) [68,69] but longer than the C–S double bond (1.62). This suggests partial double bond character of the C–S bond in this complex similar to the related thiosemicarbazonates of methylmercurey(II) and dimethylthallium(III) [67,70,71].

The intramolecular hydrogen bond O2–H2A····N2 leads to the formation of stable six-member ring with a H2A····N2 separation of 2.557(4) Å and O2–H2A····N2 angle 136°. The combination of C–H····π and Hg····π weak interactions form two-dimensional extended structure. The mercury(II) ion interacts with Cg3 (mid point of phenyl ring) with the formation of 1D square-box in which the Hg····Cg^a separation is 3.937 Å ($a = 1 - x, -y, -z$). The structure is further extended to 1D by the formation of edge to face C–H····π interaction. The Hg····π interaction forms supramolecular dimer which are joined through C6–H6····$Cg4^b$ ($b = 1 - x, -y, 1 - z$) stacking with the formation of 1D supramolecular chain. The C6–H6····Cg4 distance is 2.95 Å. The two-dimensional supramolecular structure is completed with the formation of C9–H9B····$Cg3^c$ weak bond ($c = -1 + x, 1 + y, z$) (Fig. 3) with H····Cg separation of 2.68 Å. The H6····Cg4 separation is slightly larger than the H9B····Cg3 separation.

3.2. Crystal and molecular structure of [PhHg(Hapmth)] (2)

The molecular structure of the complex [PhHg(Hapmth)] (**2**) is shown in Fig. 4 and selected bond lengths and bond angles are given in Table 2. The complex (**2**) crystallizes in space group $P2_1$.

The crystal structure of the complex [PhHg(Hapmth)] (**2**) adopts a familiar linear coordination geometry. The complex has two independent molecules comprising the asymmetric unit. Both the mercury atoms are coordinated by the thiol sulfur of the H_2apmth ligand and a carbon atom of the phenyl ring. Little difference in bond lengths and bond angles is shown by the two units. The

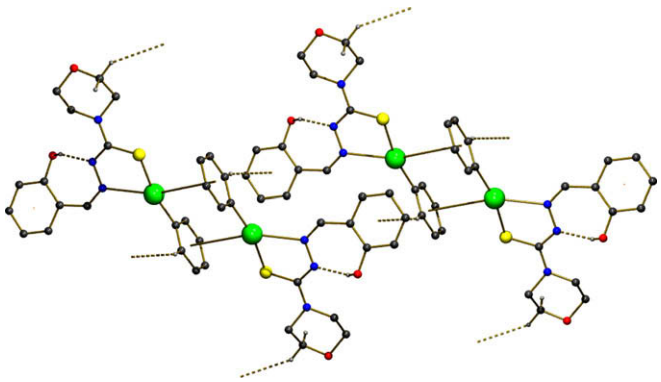

Fig. 3. Two-dimensional C–H–π and Hg–π interactions of the complex [PhHg(Hsmth)] (**1**).

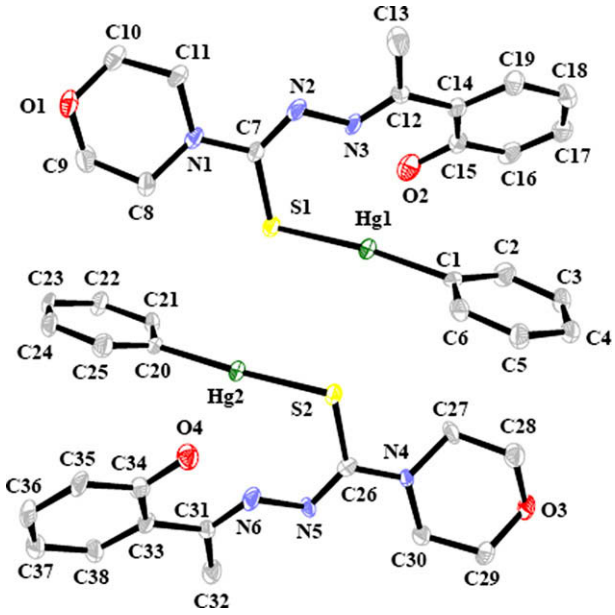

Fig. 4. Perspective view of complex [PhHg(Hapmth)] **(2)** with the numbering scheme. The thermal ellipsoids are drawn at the 50% probability level.

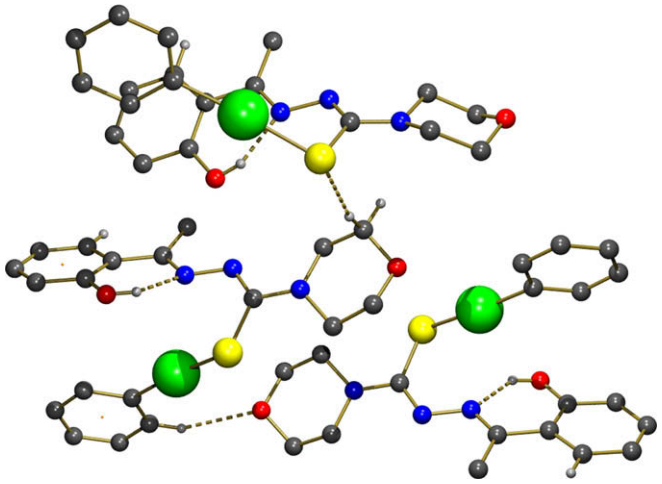

Fig. 5. Two-dimensional hydrogen bonding network of the complex [PhHg(Hapmth)] **(2)**.

$C_{ph}(1)$–Hg(1)–S(1) and $C_{ph}(20)$–Hg(2)–S(2) bond angles, 173.6(2)° and 175.68(19)°, respectively, are close to linear.

The Hg(1)–$C(1)_{ph}$ and Hg(2)–$C(20)_{ph}$ distances, 2.068(8) and 2.063(7) Å, respectively, are similar to the analogous phenylmercury(II) compound [65-67]. The average Hg–S bond length of 2.354(2) Å is within the range of Hg–S bonds of similar sulfur containing ligands [64–66].

The C(7)–S(1) bond distance [1.768(8) Å] is slightly shorter than the C(26)–S(2) distance [1.785(8) Å], but both are shorter than a C–S single bond (1.81 Å) [67–71] and longer than a C–S double bond (1.62). This small difference in C–S bond length may be due to C(10)–H(10B)–S(2) (see latter discussion) which is absent in the case of S(1). This observation suggests that both C–S bonds contain partial double bond character in the complex [67,70,71]. The C(7)–N(2) (1.301(11) Å) and C(26)–N(5) (1.269(11) Å) bond distances are close to the C–N double bond which confirms the deprotonation of the hydrazinic proton.

Both the unit form stable six-member rings via intramolecular O–H····N hydrogen bonding with O2–H2A····N3 and O4–H4A····N6 bond distances 2.550(8) and 2.542(8) Å and bond angles 145° and 144°, respectively. Several intermolecular weak interactions such as C–H····S, C–H····O hydrogen bonding, C–H····π and Hg····Hg form a two-dimensional extended structure. The intermolecular hydrogen bonding network of this compound forms a 2D supramolecular sheet which consists of C–H····S and C–H····O interactions (Fig. 5). This C6–H6····$O3^d$ hydrogen bond forms 1D supramolecular chain ($d = -1 + x, -1 + y, z$) with the D····A separation is 3.348(10) Å and D–H····A angle is 147°. This 1D chain is further extended to 2D extended structure by the formation of C10–H10B····$S2^e$ hydrogen bond ($e = -x, -1/2 + y, 1-z$) Two asymmetric units of the compound [PhHg(Hapmth)] (**2**) are joined together by the C10–H10B····S2 bond (Fig. 4). The D····A separation of this C–H····S hydrogen bond is 3.830(9) Å with the D–H····A angle 168°.

The two independent asymmetric units of the molecule [PhHg(Hapmth)] (**2**) are further interconnected by a weak Hg1····Hg2 interaction (Fig. 6). The Hg1····$Hg2^f$ [$f = x,-1 + y, z$] distance of 4.0216(10) Å is smaller than the sum of the van der Waal radius (5.0 Å) [72]. In addition to this Hg····Hg contact, the C–H····π interactions (Fig. 5) between C19–H19····$Cg5^g$ and C38–H38····$Cg2^h$ [$g = x, -1 + y, 1 + z$ and $h = x, 1 + y, -1 + z$] forms a three-dimensional ladder. The H····Cg distance is the same for both C–H····π interactions (2.94 Å), but the angle (C19–H19····Cg5) is 129° compared to 140° for C38–H38····Cg2.

3.3. Infrared and ^1H NMR spectra

The infrared spectra of the free ligands H_2smth and H_2apmth do not show any *ν*SH bands at 2570 cm^{-1} (Ref. [74–77]), but instead an intense band for *ν*C=S at 800 cm^{-1} is observed. This band disappears in the complexes and a new band around 760–750 cm^{-1} is observed for *ν*C–S suggesting mercury coordination through thiol sulfur. This mode is supported by the presence of a medium band around 350 cm^{-1} assignable to *ν*Hg–S.

The bands due to *ν*NH of the free ligands are located in the region 3300–3100 cm^{-1} but the *ν*OH band at 3500 cm^{-1} is not observed possibly due to strong hydrogen bonding which causes a

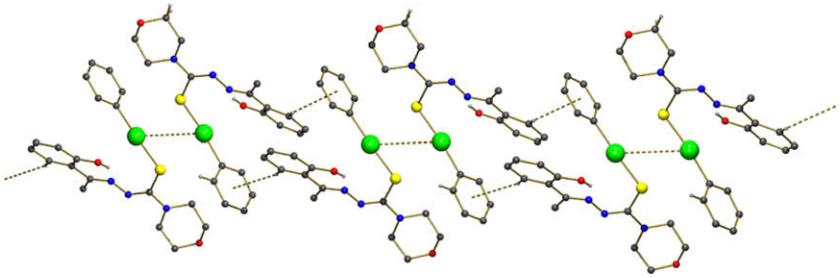

Fig. 6. Two-dimensional Hg–Hg and C–H–π interactions of the complex [PhHg(Hapmth)] **(2)**.

shift to a lower frequency. The νNH band of the free ligands disappeared in both complexes as a consequence of deprotonation.

Moreover, the νC=N stretching mode is at a slightly higher wave number in complex (**1**) and shows a similar spectroscopic pattern to previously reported phenylmercury(II) complexes with similar coordination modes. This band remains unchanged in complex (**2**) [70,71,77]. These observation for the two complexes suggests a similar S,N coordination mode for complex (**1**) and only S coordination for complex (**2**).

The bands at 1589 (sh), 1475 (m), 1015 (m), 995 (m), 720 (vs), 440 (s), 230 (s) and 180 (sh) for both of these complexes are characteristic of a phenylmercury ring [73–76].

The ^{1}H NMR spectra for the two phenylmercury(II) complexes do not show any chemical shift due to a NH proton in $CDCl_3$. The phenolic –OH signals of the ligands shift to lower field for both complexes but there is no deprotonation possibly due to strong hydrogen bonding. Thus both ligands coordinate to the phenylmercury(II) as singly charged anionic ligands. The phenyl ring proton signals appear in the range 6.90–7.43 ppm for both complexes. The methyl protons of complex (**2**) are observed at δ = 2.32 ppm. The chemical shifts of N–CH_2 (4 H) and O–CH_2 (4H) of the morpholine ring are observed at δ 3.17 ppm and δ 3.6 ppm, respectively [73–76].

3.4. Electronic and luminescent properties

Measured data for the electronic spectra of the free ligands, H_2smth, H_2apmth and their metal complexes are given in Table 3. The free ligands show absorption bands in the region 340–347 nm, 298–301 nm and 240–241 nm. The bands in the region 340–347 nm and 298–301 nm may be due to n–π^* and π–π^* transition, respectively [76,78]. The phenylmercury(II) complexes exhibit these bands but slightly shifted. The dependence of the solution absorption spectra on original Schiff bases suggests that the transitions are mainly ligand-centered transitions. Therefor, the electronic absorption spectra are probably dominated by intraligand π–π^* transitions possibly mixed with a small contribution from the metal in the HOMO and the LUMO [53,79].

The luminescent properties of the ligand and the complexes were studied in solution and solid state using different wavelengths. There is little change in emission spectra with variation of excitation wavelength, indicating that a single emissive state or multiple steps in equilibrium, is/are responsible for the observed emission. The emission energy is dependent on the nature of the Schiff bases but does not vary much with respect to the substituent. The similarity of the emission band shapes of the complexes and the parent Schiff bases are suggestive of a ligand dominated emissive state and the lowest emissive states in these complexes can be assigned as a metal perturbed intraligand π–π^* transition. In $CHCl_3$ solution, the free ligand H_2smth shows emission bands at 412 and 431 nm upon excitation with λ_{ex} = 343 nm. With respect to the free ligand H_2smth, the complex (**1**) in $CHCl_3$ shows similar peaks at 415 and 435 nm upon excitation with a similar wavelength. Besides these similar emission bands, the complex also shows a broad emission band at λ_{max} = 489 (λ_{ex} = 343 nm) as shown in Fig. 7. The luminescent spectra of the ligand, H_2apmth and corresponding phenylmercury(II) complex (**2**) are show in Fig. 8. The luminescent properties of H_2apmth and its corresponding phenylmercury(II) complex (**2**) is the same as that of H_2smth and its complex (**1**). The ligand, H_2apmth shows emission bands at λ_{max} = 412 and 434 nm, while the respective phenylmercury(II) complex shows emission bands at 410 and 430 nm. Like complex (1), complex (2) also shows an emission peak at 489 nm upon excitation with same wavelength. The emission bands near the 412 and 434 nm region of both complexes and the corresponding Schiff bases should be attributed to ligand center π–π^* transitions. The striking feature of the emission spectra in $CHCl_3$ (10^{-5} M) is the appearance of a new band at λ_{max} = 489 nm for complex (**1**) and λ_{max} = 500 nm for complex (**2**). The appearance of these new bands may result from an intermolecular interaction in $CHCl_3$ like solid state luminescence spectra [42–49,53,79].

In solution, both ligands and complexes show strongly solvent-dependent emission properties. The emission maxima shift toward shorter wavelength with an increase in the polarity of the solvent. The emission maxima of (**1**) are 415, 435 and 489 nm in $CHCl_3$ but is 427 nm in the polar solvent DMSO (λ_{ex} = 343 nm); for complex (**2**), the emission maxima in DMSO is 427 nm. This type of lumines-

Table 3
Photophysical data of phenylmercury(II) complexes.

	Absorbed λ (nm)	Excited λ (nm)	Emitted λ (nm)	Quantum yield	Conditions
Hsmth	244, 299, 343	343	412, 431, 519	0.035	$CHCl_3$ solid state
Hapmth	244, 301, 345	343	412, 434, 516	0.084	$CHCl_3$ solid state
Complex **1**	244, 299, 343	343	415, 435, 489, 488	0.041	$CHCl_3$ solid state
Complex **2**	244, 302, 347	343	410, 430, 500, 500	0.081	$CHCl_3$ solid state

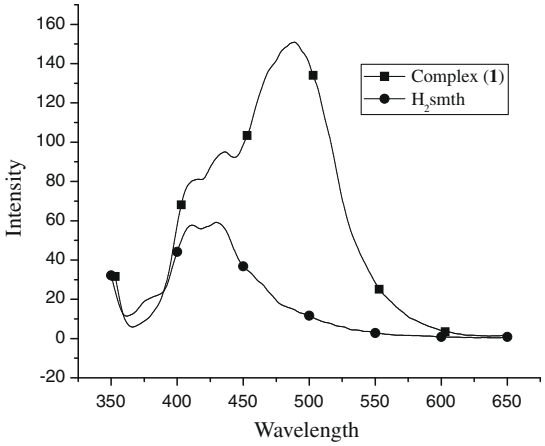

Fig. 7. Emission spectra of Ligand I, H_2smth and the complex (1) in $CHCl_3$ (λ_{ex} = 343 nm) at room temperature.

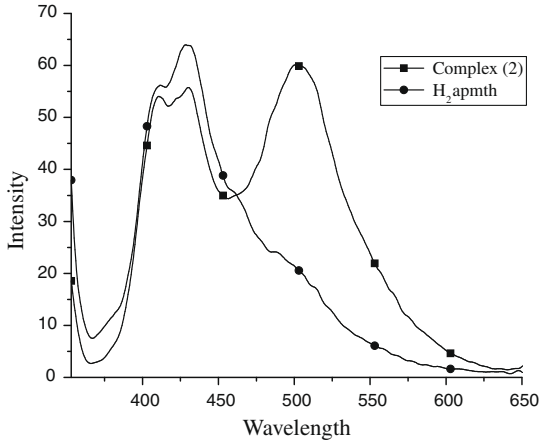

Fig. 8. Emission spectra of Ligand II, H_2apmth and the complex (2) in $CHCl_3$ (λ_{ex} = 343 nm) at room temperature.

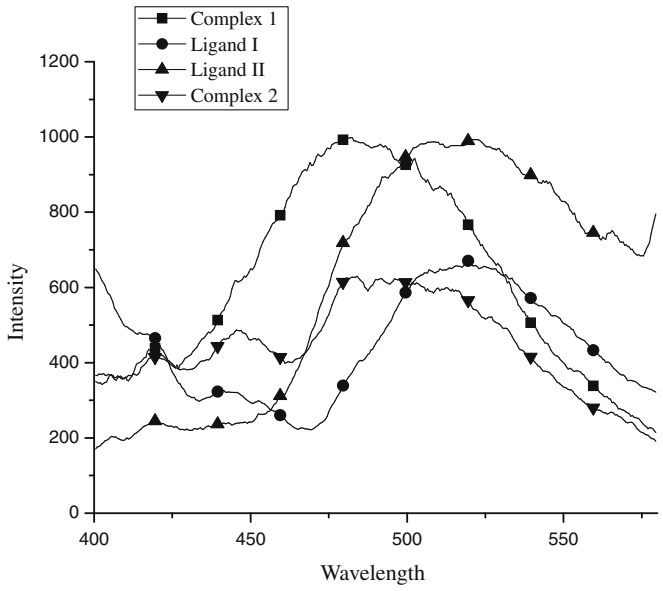

Fig. 9. Solid state emission spectra of the ligands, H_2smth, H_2apmth and the complexes (1) and (2) at room temperature (λ_{ex} = 343 nm).

cent property is a rare case as a red shift of the maxima is expected for most compounds when polarity increases. The observed blue-shift may be due to the presence of a highly polarized ground state [80,81].

The emission property of both complexes was also studied in solid state. The emission maxima of H_2smth, H_2apmth, complexes (**1**) and (**2**) are 519, 516, 488 and 500 nm, respectively (Fig. 9). The emission maxima of complexes (**1**) and (**2**) are blue-shifted in the solid state compared to emission maxima of the corresponding free ligands. This blue-shift may be due to the result of Hg····π and Hg····Hg stacking in solid state as shown in Figs. 3 and 6.

4. Conclusion

The thiohydrazone ligands used in the present investigation were previously used in this laboratory for the preparation of transition metal complexes. Based on the reaction conditions, the ligands were either found monobasic tridentate (NSO donor) or dibasic tridentate (NSO) donors [55]. However, in the present investigation with phenylmercury(II) species, the ligands either behave as monobasic bidentate NS or monobasic monodentate S-donor ligands. Depending on the nature of the ligands and the steric properties of Schiff bases, we are able to isolate two-dimensional solid state aggregate through Hg····π, Hg····Hg and C–H····π interactions. The Hg····Hg distance between adjacent molecules is such that both mercuriophilic and Hg····π interaction appear to be contributing to supramolecular aggregation. The emission properties of the complexes are dominated by mercury-perturbed organic π–π* transitions.

Acknowledgements

One of us (K.D.) is thankful to the University Grants Commission, New Delhi for Emeritus Fellowship and financial grants to conduct this work. We are also thankful to the Sophisticated Instrumentation Facility, Central Drug Research Institute, Lucknow, India for elemental analysis and spectroscopic data. Facilities provided by the DST, Govt. of India, New Delhi under FIST are also gratefully acknowledged.

Appendix A. Supplementary data

CCDC 677407 and 677408 contain the supplementary crystallographic data for [PhHg(Hsmth)] and [PhHg(Hapmth)]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.01.002.

KBr pellets. Elemental analyses were performed at the Ecole d'ingénieurs de Fribourg, Switzerland.

2.1. Synthesis

2.1.1. [$Ph_2PCH_2PPh_2CH_2C(O)Ph$]Br (**1**)

The phosphonium salt was prepared following the literature procedure [10] using $BrCH_2COPh$ (1.55 g, 7.8 mmol) and $PPh_2CH_2PPh_2$ (3.00 g, 7.8 mmol). Yield: 4.10 g (90%). M.p. 194–196 °C (Reported: 195–197 °C). IR (cm^{-1}): 1667 (νC=O). ^{1}H NMR ($CDCl_3$): δ 4.32 (d, 2H, PCH_2P, $^2J_{P-H}$ = 14.6), 5.93 (d, 2H, PCH_2COPh, $^2J_{P-H}$ = 12.5), 7.20–8.13 (m, 25H, Ph). ^{31}P NMR ($CDCl_3$): δ −26.18 (d, PPh$_2$, $^2J_{P-P}$ = 63.2), 24.07 (d, PCH$_2$COPh, $^2J_{P-P}$ = 63.2).

2.1.2. [$HgCl_2(Br)(PPh_2CH_2PPh_2CH_2C(O)Ph)$] (**2**)

A mixture of $HgCl_2$ (0.09 g, 0.34 mmol) and [$PPh_2CH_2PPh_2CH_2C(O)Ph$]Br (0.18 g, 0.34 mmol) in methanol (15 ml) was stirred for 3 h. The white precipitate obtained was isolated, washed twice with 15 ml methanol and recrystallised in dichloromethane. Yield: 0.25 g (86%). M.p. 158–160 °C. *Anal.* Calc. for $C_{33}H_{29}BrCl_2HgOP_2$: C, 46.36; H, 3.42. Found. C, 46.34; H, 3.35%. IR (cm^{-1}): 1672 (νC=O). ^{1}H NMR (DMSO–d_6): δ 4.43 (d, 2H, PCH_2P, $^2J_{P-H}$ = 15.5), 5.68 (d, 2H, PCH_2COPh, $^2J_{P-H}$ = 12.2), 7.26–7.99 (m, 25H, Ph). ^{31}P NMR (DMSO–d_6): δ −19.79 (d, PPh$_2$, $^2J_{P-P}$ = 63.2), 23.43 (d, PCH$_2$COPh, $^2J_{P-P}$ = 56.6).

2.1.3. [$HgBr_3(PPh_2CH_2PPh_2CH_2C(O)Ph)$] (**3**)

This complex was obtained using the same procedure as adopted for the preparation of **2** using $HgBr_2$ (0.12 g, 0.34 mmol). The product was recrystallized using dichloromethane containing a few drops of hexane. Yield: 0.29 g (90%). M.p. 135–137 °C. *Anal.* Calc. for $C_{33}H_{29}Br_3HgOP_2$: C, 41.99; H, 3.10. Found. C, 41.49; H, 3.00%. IR (cm^{-1}): 1671 (νC=O). ^{1}H NMR (DMSO–d_6): δ 4.27 (d, 2H, PCH_2P, $^2J_{P-H}$ = 15.4), 5.58 (d, 2H, PCH_2COPh, $^2J_{P-H}$ = 12.2), 7.26–7.97 (m, 25H, Ph). ^{31}P NMR (DMSO–d_6): δ −26.72 (d, PPh$_2$, $^2J_{P-P}$ = 65.4), 23.74 (d, PCH$_2$COPh, $^2J_{P-P}$ = 65.4).

2.1.4. [$HgBr_2(I)(PPh_2CH_2PPh_2CH_2C(O)Ph)$] (**4**)

A mixture of HgI_2 (0.08 g, 0.17 mmol) and [$PPh_2CH_2PPh_2CH_2C(O)Ph$]Br (0.10 g, 0.17 mmol) in methanol (15 ml) was stirred for 3 h. The clear colourless solution was evaporated to dryness giving an oily residue. Addition of diethyl ether (30 ml) resulted in the formation of a pale yellow solid. It was recrystallized in a mixture of dichloromethane–pentane and dried. Yield: 0.075 g (44%). M.p. 103–105 °C. *Anal.* Calc. for $C_{33}H_{29}Br_2HgIOP_2$: C, 40.00; H, 2.95. Found. C, 39.53; H, 2.90%. IR (cm^{-1}): 1675 (νC=O). ^{1}H NMR (DMSO–d_6): δ 4.24 (d, 2H, PCH_2P, $^2J_{P-H}$ = 15.4), 5.57 (d, 2H, PCH_2COPh, $^2J_{P-H}$ = 12.3), 7.24–7.97 (m, 25H, Ph). ^{31}P NMR (DMSO–d_6): δ −28.29 (d, PPh$_2$, $^2J_{P-P}$ = 67.0), 23.39 (d, PCH$_2$COPh, $^2J_{P-P}$ = 67.0).

2.1.5. [$HgCl_3(PPh_2CH_2PPh_2CH_2C(O)Ph)$] (**5**)

To a suspension of $HgCl_2$ (0.10 g, 0.36 mmol) in dichloromethane (10 ml) a solution of $Ph_2PCH_2PPh_2$=C(H)C(O)Ph [10] (0.21 g, 0.36 mmol) in dichloromethane (10 ml) was added dropwise. The clear suspension immediately turned turbid. After completion of the addition the solution became clear and the stirring was continued for two hours. The solution was reduced to about 5 ml and the addition of excess n-pentane resulted in a white precipitate. The solid was dissolved in CH_2Cl_2 and layered with n-pentane. After two days colourless diffraction quality crystals were obtained. Yield: 0.06 g (21% based on ylide). M.p. 184–186 °C. *Anal.* Calc. for $C_{33}H_{29}Cl_3HgOP_2$: C, 48.90; H, 3.61. Found. C, 48.84; H, 3.58%. IR (cm^{-1}): 1674 (νC=O). ^{1}H NMR (400 MHz, DMSO–d_6): δ 4.34 (d, 2H, PCH_2P, $^2J_{P-H}$ = 15.7), 5.64 (d, 2H, PCH_2COPh, $^2J_{P-H}$ = 12.2), 7.27–8.05 (m, 25H, Ph). ^{31}P NMR (162 MHz, DMSO–d_6): δ −22.78 (br, PPh$_2$), 23.55 (d, PCH$_2$COPh, $^2J_{P-P}$ = 60.2).

2.2. X-ray crystallography

All the crystallizations were carried out under aerobic conditions. Single crystals of **2**, **3** and **4** were obtained by slow evaporation of dichloromethane, dichloromethane/hexane and dichloromethane/pentane solutions, respectively. Well formed crystals of **5** were grown by layering pentane over a dichloromethane solution. The intensity data were collected at 173 K (−100 °C) on a Stoe Mark II-Image Plate Diffraction System [15] equipped with a two-circle goniometer and using Mo Kα graphite monochromated radiation. The structures were solved by direct methods using the programme SHELXS-97 [16]. The refinement and all further calculations were carried out using SHELXL-97 [16]. The H-atoms were included in calculated positions and treated as riding atoms using SHELXL default parameters. The non-H atoms were refined anisotropically, using weighted full-matrix least-squares on F^2. Further crystallographic data are given in Table 1. The molecular structure and crystallographic numbering schemes are illustrated in ORTEP [17] drawings, Figs. 1–3.

3. Results and discussion

3.1. Synthesis

The reactions of mercury(II) halides with the phosphine–phosphonium salt, [$Ph_2PCH_2PPh_2CH_2C(O)Ph$]Br in 1:1 molar ratio in methanol afford the zwitterionic complexes **2**–**4** as shown in Scheme 1.

While **2** and **3** are simple complexation products, the formation of **4** involves a halogen exchange followed by complexation as shown below,

$$2[Ph_2PCH_2PPh_2CH_2C(O)Ph]Br + HgI_2 \rightarrow [Br_2(I)Hg(PPh_2CH_2PPh_2CH_2C(O)Ph)] + [Ph_2PCH_2PPh_2CH_2C(O)Ph]I$$

The stability of **4** consisting of the $HgIBr_2$ moiety can be traced to the softness of Hg(II) and I^-. The non-formation of HgI_2Br^- or HgI_3^- may be ascribed to steric effects caused by I^- ion. Complex **5** has been obtained by the reaction of the ylide, $Ph_2PCH_2PPh_2$=C(H)C(O)Ph with $HgCl_2$ in dichloromethane and subsequent crystallization. The preferential formation of zwitterionic complexes as opposed to the formation of phosphonium metalates can be ascribed to the strength of Hg–P bond.

3.2. Spectroscopy

In the IR spectra of complexes **2**–**5**, a strong absorption around 1675 cm^{-1}, which is close to the same frequency in free phosphonium salt (1667 cm^{-1}) indicates the non involvement of the –$PCH_2C(O)Ph$ group in the reactions. The ^{31}P NMR spectra of complexes **2**–**5** exhibit two mutually coupled doublets corresponding to 'phosphonium' and 'phosphine' groups. The former peak remains sharp and unaltered, while the latter peak is relatively broad. In contrast to the ^{31}P NMR of Hg(II)–phosphine complexes [18], the coordination of phosphine to mercury in the present cases did not cause significant downfield shifts. Complexes **2** and **5** show downfield shifts (−19.79 and −22.78 ppm, respectively) compared to that of phosphine of the phosphonium salt (−26.18 ppm). The chemical shift for **3** (−26.72 ppm) appears close to that of the free ligand whereas **4** (−28.29 ppm) shows a slight upfield shift. These data indicate that the presence of a formal negative charge on the metal may effectively reduce the deshielding experienced by the phosphorus due to complexation. In the ^{1}H NMR spectra, the dou-

blet in the region of 4.30 ppm attributed to PCH_2P, and the doublet in the region of 5.62 ppm attributed to PCH_2COPh, remains unaffected due to complexation.

3.3. Molecular structures of complexes **2**–**5**

The crystal structures of **2** · CH_2Cl_2, **3** · CH_2Cl_2, **4** · CH_2Cl_2 and **5** · $2CH_2Cl_2$ have been determined and the relevant bond parameters are given in Table 2. The molecular structures of **2**, **3**, **4** are represented in Figs. 1–3, respectively. The structure of **5** is given as Supplementary data (Fig. S1). The Hg atom in all four structures is in a distorted tetrahedral environment with one P, and three halide ligands. The Hg–P distances in all of these zwitterionic complexes fall within the range of 2.39(1)–2.606(3) Å observed in

Hg(II)–phosphine complexes [19]. The Hg–Cl distances in **5** and **2** are comparable to those reported in the literature [20,21]. In complex **3**, one of the Hg–Br distances is shorter [2.550(1) Å] than the other two. It is worth mentioning that in **4**, both the Hg–Br and Hg–I [2.703(1) Å] distances are very similar. One of the P–Hg–halogen bonds in the complexes exhibits a major deviation from an ideal tetrahedral angle. The most striking feature is the large distortion shown by P–Hg–Cl bond angle in complex **5** (which contains three chlorides). It has been observed previously [22] that the weaker bonding of chlorine to mercury compared to that of bromine and iodine, allows the Hg–P bonding to be strengthened leading to a linear P–Hg–Cl arrangement. In accordance with this fact the Hg–P bond length is much shorter in complex **5** (containing three chlorides) and **2** (containing two chlorides) compared to that in **3** and **4** (containing no chloride). The structural features in the phosphonium moiety are very similar in all four complexes. The significant shortening of the C2–O1 bond, as well as the elongation of the P1–C1 and C1–C2 bonds in all four complexes, compared with ylide, $PPh_2CH_2PPh_2CHCOPh$ [12] indicates the absence of any significant additional resonance delocalization in the ylide moiety.

4. Conclusions

The reactions of the phosphine–phosphonium salt, $[PPh_2CH_2PPh_2CH_2COPh]Br$ with mercury(II) halides offers an easy method for the preparation of zwitterionic mixed halogen mercurates. Formation of the above complexes can be ascribed to the strength of Hg–P bond. In the ^{31}P NMR spectra the absence of significant downfield shifts due to complexation could be ascribed to the presence of formal negative charge on the metal which effectively reduces the desheilding experienced by the phosphine phosphorus atom. The crystal structures of the above complexes reveal a distorted tetrahedral geometry around the mercury atom.

phthalocyanine. These substituted platinum phthalocyanines have been prepared for the first time by using a novel route, with high purity. These compounds were characterized by elemental analysis, UV–Vis and infrared spectral analysis, magnetic susceptibility, powder X-ray diffraction and thermogravimetric studies. The electrical conductivity measurements of these compounds were analysed in the temperature range from ambient to 473 K.

2. Materials and methods

Platinic(IV) chloride, phthalonitrile, nitrophthalonitrile were of AR grade, obtained from Fluka, USA and were used as received. All the other reagents used were of analytical grade and were used as such without purification, unless otherwise mentioned.

2.1. Physico-chemical measurements

A domestic L.G. microwave oven, model MG-555F (max. 900 W, min. 180 W, L.G. electronics, India) with five select power levels was used for carrying out the reactions. Elemental analysis for carbon, hydrogen and nitrogen were done using a Vario EL-III CHN & S Elemental Analyser, Analytikjena, Germany. Electronic spectra in the UV–Vis region were recorded in analytical grade 28 M sulfuric acid using a Systronics type – 117 model spectrophotometer with 1 cm silica cells, Systronics, Ahmedabad, India. IR spectra were recorded in potassium bromide using a Shimadzu 8201 PC FT-IR spectrometer, Japan. Magnetic susceptibility measurements were done using a Gouy magnetic balance consisting of a NP-53 electromagnet with a DC power supply, type NP 1053, and a Keroy semimicro balance, supplied by the Universal Scientific Company, Mumbai, India. Pure mercury tetrathiocyanato cobaltate(II) was synthesized and used as a calibration standard [21]. Thermogravimetric analyses were done at the National Institute of Technology, Tiruchirapalli, India, using a TGA 7 Analyser, Perkin–Elmer, USA. Two to five milligram of the sample was used for the analysis and a heating rate of 10 °C/min was used in air atmosphere at a flow rate of 100 ml/min. A JEOL-JDX-8P X-ray diffractometer with Cu Kα radiation (λ = 1.934 Å) was used to study the powder X-ray diffraction pattern of the samples. Powdered complexes were compressed into pellets of 1.3 cm diameter and thickness ranging from 0.15 to 0.25 cm, using a Perkin–Elmer KBr Die under a pressure of 500 kg/cm^2. A KBr press, Techno Search Instruments, Thane, India, was used for applying the pressure. The diameter and thickness of the pellets were determined by using a screw gauge, readable up to 0.005 cm. Conducting silver paint (ELTECKS preparation No. 1228-C) was coated on both flat surfaces of the pellets and the electrical contacts to the samples were made using the same silver paint to the electrodes. The electrical contacts were checked to verify the ohmic connection and resistance measurements were done from room temperature to 473 K using a DOT 402 Digital Milli Ohm Meter and a DOT 425 Insulation Resistance Tester, Bhandari Electronics and Electricals, Bangalore, India.

2.2. Platinum phthalocyanine

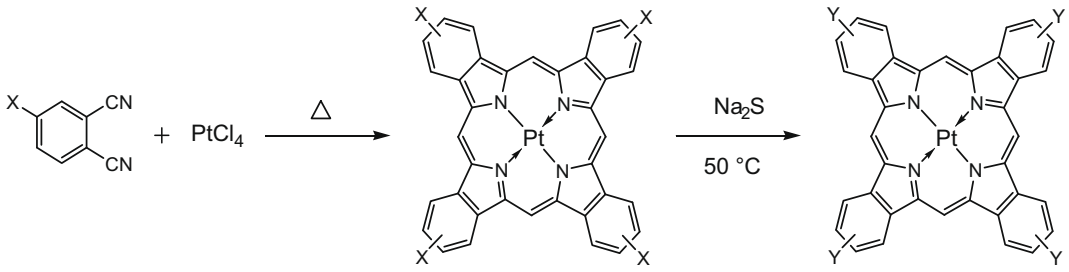
One gram (7.8 mmol) of phthalonitrile and 0.5 g (1.5 mmol) of platinic(IV) chloride were mixed well and then placed in a vessel with a small opening at the top. This vessel was then placed in a microwave and irradiated with at a power of 360 W for 2 min, whereupon the compound started to turn a slight bluish color, and then at 720 W for 3 min to complete the reaction. The compound turned totally to a bluish black color. The crude compound was ground well and washed with ethanol and water, and then with acetone in a Soxhlet extractor with 25 mL volume three times to remove the unreacted impurities. The product was then dried at 45 °C in an oven.

Anal. Calc. for platinum phthalocyanine, $C_{32}H_{16}N_8Pt$: C, 54.32; H, 2.26; N, 15.84. Found: C, 54.76; H, 2.35; N, 15.69%. IR absorption bands (cm^{-1}): 717 (s), 724 (w), 736 (s), 752 (w), 869 (s), 949 (w), 1068 (w), 1093 (m), 1118 (s), 1319 (s), 1359 (m), 1437 (w), 1481 (s), 1520 (s), 3061 (m). Yield: 93%.

2.3. Platinum tetranitro phthalocyanine

One gram (5.8 mmol) of nitrophthalonitrile and 0.45 g (1.34 mmol) of platinic(IV) chloride were mixed well and then placed in a vessel with a small opening at the top. This vessel was then placed in a microwave and irradiated with at a power of 540 W for 2 min, whereupon the compound started to turn a slight bluish color, and then at 720 W for 3 min to complete the reaction. The compound turned totally to a bluish black color. The crude product was ground well and washed with ethanol and water, and then with acetone in a Soxhlet extractor with 25 mL volume three times to remove the unreacted impurities. The product was then dried at 45 °C in an oven.

Anal. Calc. for platinum(II) tetranitro phthalocyanine, $C_{32}H_{12}N_{12}O_8Pt$: C, 43.29; H, 1.35; N, 18.94. Found: C, 42.97; H, 1.38; N, 19.15%. IR absorption bands (cm^{-1}): 3068 (m), 1610 (m), 1524 (s), 1483 (m), 1338 (s), 1252 (m), 1132 (s), 1084 (s), 931 (m), 846 (s), 748 (s), 730 (s), 671 (m). Yield: 90%.



2.4. Platinum tetramino phthalocyanine

For the preparation of the amino derivative of platinum, a similar procedure as used by Achar et al. to synthesize cobalt tetramino phthalocyanine [8] was followed, with a slight modification. 1.0 g (1.13 mmol) of platinum tetranitro phthalocyanine was dissolved in a 50 ml aqueous solution containing 2.5 g (10.42 mmol) of sodium sulfide nonahydrate. The slurry was stirred at 50 °C for 3 h. Then, the bluish complex was separated and washed repeatedly with 0.5 M hydrochloric acid, 1 M sodium hydroxide solution and finally with distilled water until the filtrate was neutral to litmus paper. The dark bluish green product was dried in an oven at 363 K.

Anal. Calc. for platinum(II) tetramino phthalocyanine, $C_{32}H_{20}N_{12}Pt$: C, 50.07; H, 2.61; N, 21.90. Found: C, 50.38; H, 2.54; N, 21.76%. IR absorption bands (cm^{-1}): 3354 (w), 3225 (w), 3057 (w), 1613 (s), 1490 (s), 1328 (s), 1122 (m), 1101 (m), 1033 (w), 962 (m), 867 (w), 745 (s). Yield: 88%.

3. Results and discussion

Platinum phthalocyanine and the tetranitro and tetramino derivatives were synthesized with very good quantitative yields, 88–93%. These phthalocyanines are dark bluish to greenish in color. The elemental analysis for carbon, hydrogen and nitrogen agreed very well with the theoretical calculations, indicating the very good purity of the synthesized compounds. The microwave radiations were carried out at different power levels, ranging from 180 to 900 W for different periods of time to evaluate the optimum conditions for the synthetic procedures. Completion of the reaction under the given microwave power was followed by recording FT-IR spectra at different time intervals. The reactions were carried in a microwave oven until the C≡N group stretching around 2230 cm^{-1} disappeared. The basic reaction and the structure of the synthesized complexes are as shown in Scheme 1. It is clear from the reaction conditions that microwave synthesis is considerably more advantageous with respect to the time required for the completion of the reaction compared to the conventional method. The synthetic yields are also found to be fairly good. Achar et al.

Scheme 1. Synthetic route and structure of the platinum phthalocyanine complexes.

have compared the synthesis of lead phthalocyanine and its derivatives by microwave irradiation and conventional synthesis and found that products obtained in both methods have similar purity, structure and properties [22]. These complexes are soluble in quinoline and chloronaphthalene. These complexes are even soluble in sulfuric acid without undergoing any degradation.

3.1. Electronic spectral study

Electronic absorption spectroscopy is an excellent tool for phthalocyanine investigation and characterization. The electronic spectral data for the three platinum complexes were recorded in the range 250–800 nm using 28 M sulfuric acid as the solvent. The UV–Vis absorption spectra for 1×10^{-5} M solutions of platinum phthalocyanine and the nitro and amino substituted derivatives in sulfuric acid are shown in Fig. 1. The absorption peaks observed for these complexes are shown in Table 1. These complexes showed a major Q-band absorption around 665–680 nm and a shoulder like absorption around 595–615 nm. Interpretation of the spectra is possible by using the analogy of the 18 π electron configuration of the porphyrin system and the mapping of the electronic molecular orbitals of standard metallophthalocyanines by using extended Huckel calculations [23]. The deep bluish to greenish color of the complexes are due to the absorption peaks in the Q-band region which may be assigned to $6e_g \rightarrow 2a_{1u}$ transitions [24]. A small shoulder peak observed at lower wavelengths than the main Q-band are additional components of the Q-band resulting from either vibronic fine structure or dimeric species in solution [25]. It is known that the vibronic structure in phthalocyanines is sensitive to the deviation of the phthalocyanine ring from the ring planarity [14,26]. Coordination of a metal to the phthalocyanine ring, compared to free base phthalocyanine, shifts the Q-band to shorter wavelengths. This is due to the interaction between the d-orbital of the metal and the phthalocyanine, i.e. strong metal to ligand π back-bonding [27]. This interaction increases the separation between the phthalocyanine HOMO and LUMO orbitals. The peaks obtained in the B-band region are around 275–295 nm. The broad absorption peaks observed around 425–450 nm may be due to the C_{4v} symmetry of the complexes [28].

3.2. Infrared spectral study

IR spectra of PtPc, PtTNPc and PtTAPc were recorded in the fundamental region 400–4000 cm^{-1} using the KBr disk technique. The IR spectra recorded for the three complexes are presented in Fig. 2. All the complexes showed absorption peaks around 745, 860, 950, 1060, 1095 and 1120 cm^{-1} which may be assigned to phthalocyanine skeletal vibrations [29]. The vibrational bands of PtPc match well with the reported values for PtPc in the literature [30]. The absorption bands at 1524 and 1338 cm^{-1} observed in the IR spectrum of PtTNPc complex may be assigned to the asymmetric (υ_{as}) and symmetric (υ_s) stretching due to the nitro groups present in the structure of the complex. Two weak absorption bands are ob-

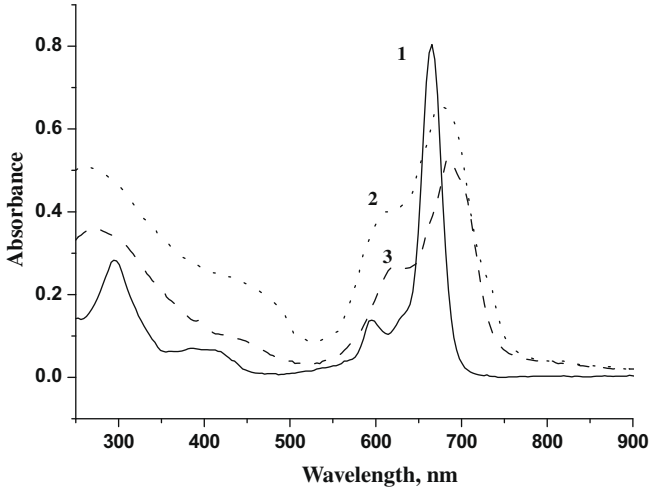


Fig. 1. UV–Vis absorption spectra of 1×10^{-5} M solutions of (1) PtPc, (2) PtTNPc and (3) PtTAPc in 28 M sulfuric acid.

PtTAPc	272 446 623 686	a = 27.7896 b = 3.9285 c = 19.8453 β = 119.827 V = 1268.3	1.43×10^{-7}	4.45×10^{-4}

served at 3354 and 3225 cm^{-1} for the PtTAPc complex which can be assigned to the asymmetric and symmetric stretching of the amino group. All the spectra showed absorption peaks in the range around 3060 cm^{-1} due to the aromatic C–H stretching as well as absorption bands around 1480 cm^{-1}, assignable to C–C bonds.

3.3. Magnetic susceptibility measurements

Magnetic susceptibility measurements of PtPc, PtTNPc and PtTAPc were investigated in the solid state at ambient temperature and varying magnetic field strengths ranging from 1.02 to 3.58 kG. A plot of magnetic susceptibility versus field strength is shown in Fig. 3. The experimental data are in agreement with the diamagnetic nature of the platinum complexes. The magnetic susceptibility values of these complexes showed a decreasing trend with the increase in the magnetic field strength. This may be due to a intermolecular effect [31]. Differences in magnetic susceptibility values and their variations may be due to the differences in intermolecular interactions which in turn may be due to the differences in spacing and inclination of the molecules in the crystal lattice.

3.4. Powder X-ray diffraction

The powder X-ray diffraction spectra of PtPc, PtTNPc and PtTAPc were obtained using Cu Kα radiation (λ = 1.934 Å). The X-ray powder diffraction spectra obtained are shown in Fig. 4. X-ray diffraction studies for the complexes were carried out for the 2θ angle ranging from 2° to 70°. The X-ray diffraction pattern of the complexes showed many sharp peaks in the spectra, indicating the crystalline nature of the sample. The 2θ values corresponding to the sharp peaks were noted down for all the complexes and analysed for the possible crystal structures of the compounds using the procedure DICVOL 91, as outlined elsewhere [32,33]. The crystal data obtained from this method for PtPc compared well with the lattice parameters obtained by Robertson for the single crystal of PtPc [12], which also indicates the superiority of the method used.

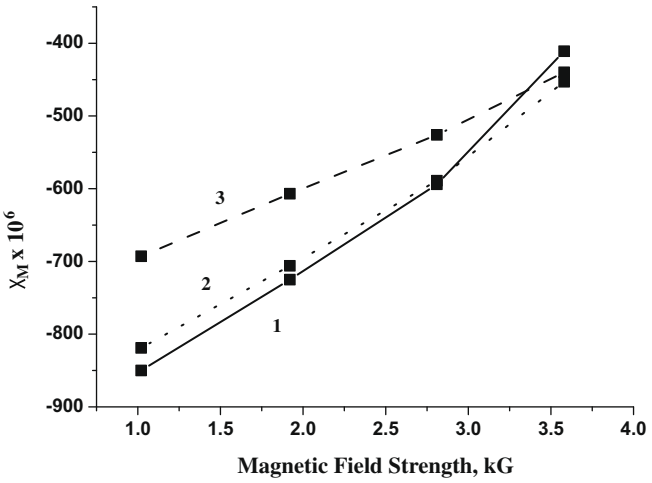

Fig. 3. Plot of magnetic susceptibility vs magnetic field strength.

The lattice constants obtained and the probable crystal structures are given in Table 1. The results obtained from the diffraction study indicated that all the three complexes have the monoclinic structure with different lattice constants and parameters.

3.5. Thermogravimetric studies

Thermal studies performed on platinum phthalocyanine by Konoshita et al., showed it is thermally stable up to 400 °C in air [34]. The dynamic thermogravimetric analyses were carried out in an oxidizing atmosphere for the PtPc, PtTNPc and PtTAPc complexes. The TGA curves are shown in Fig. 5a. All these complexes showed exceptional thermal stability. The nature of the analytical curves indicated that these complexes are degraded in one step in the temperature range 690–750 K. The weight losses are catastrophic in nature for these phthalocyanine complexes. The final

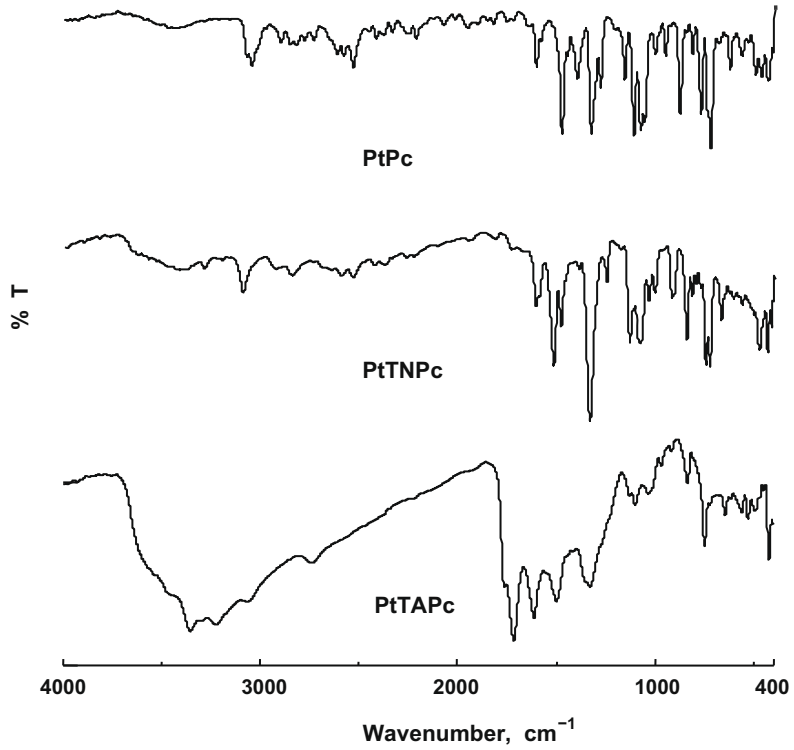

Fig. 2. FT-IR spectra of the complexes as KBr pellets.

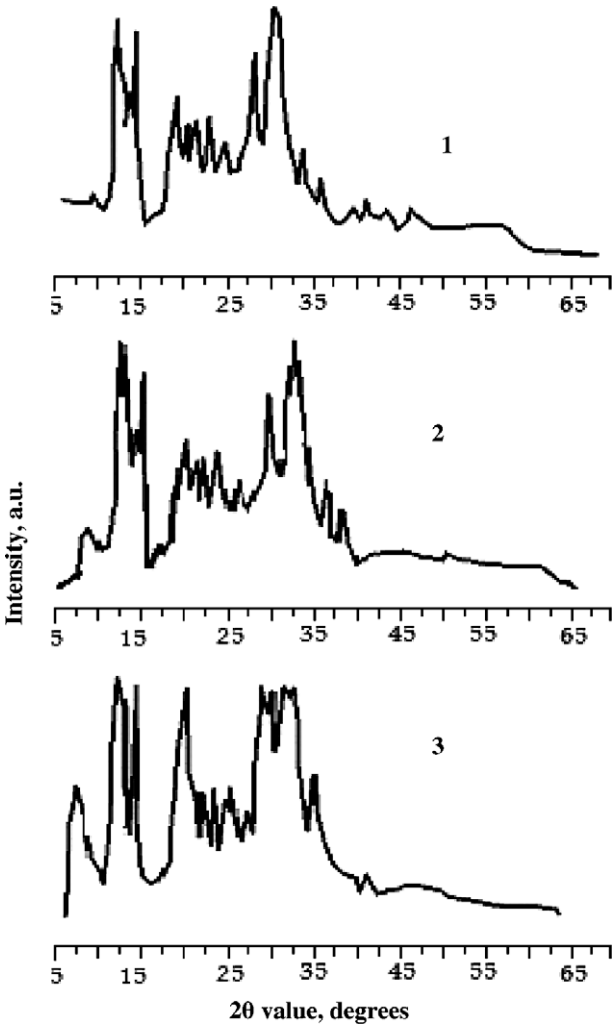

Fig. 4. Powder X-ray diffraction profiles of (1) PtPc, (2) PtTNPc and (3) PtTAPc.

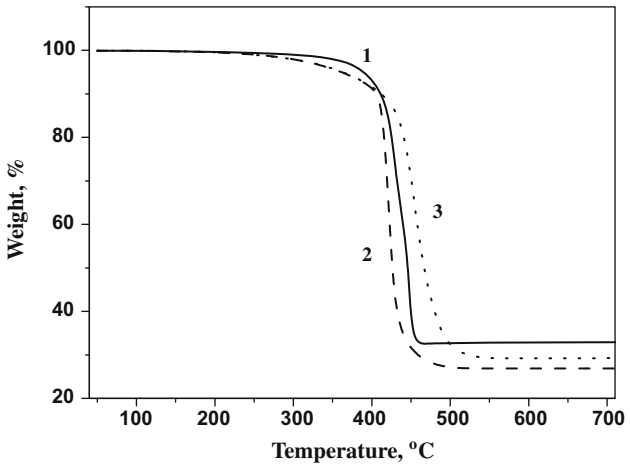

Fig. 5a. Thermogravimetric curves for (1) PtPc, (2) PtTNPc and (3) PtTAPc.

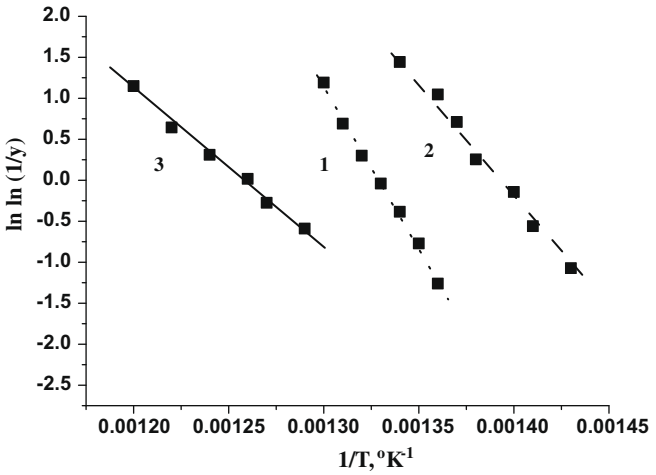

Fig. 5b. Plots of ln $(1/y)$ vs. $1/T$ for the thermal degradation of the phthalocyanine complexes: (1) PtPc, (2) PtTNPc and (3) PtTAPc.

residual weights in the TGA curves corresponded to platinum oxide, which agree very well with the theoretical calculations. The stabilities of these complexes in the oxidizing atmosphere are in the order PtTAPc > PtPc > PtTNPc. The greater thermal stability observed for PtTAPc may be due to the substituted electron donor amino groups which may enhance the resonance stability.

3.6. Kinetic parameters

Kinetic parameters were deduced using Broido's graphical procedure for the straight line decomposition portion of the thermogravimetric analytical curves [35]. Broido's equation is given by:

$$\ln(-\ln y) = -Ea/RT \quad \text{for } n = 1 \tag{1}$$

where y = fraction unreacted; E_a = activation energy (J/mol); R = universal gas constant (8.3145 J/mol K); T = absolute temperature (K).

The graphical plots of $\ln(1/y)$ versus $1/T$ obtained for the three complexes are shown in Fig. 5b. The plots indicate that all the three complexes undergo degradation through a first-order process. The slopes of the plots were used to evaluate the activation energies and the data are presented in Table 2. The activation energies are in the order PtTNPc > PtPc > PtTAPc. The activation energy depends on the chemical structure and the crystalline nature of the complex. If the crystallinity of the material is higher, then the activation energy will also be higher. The thermodynamic properties, like change in enthalpy (ΔH), entropy (ΔS), free energy (ΔG) and frequency factor A, are calculated using the equations as explained elsewhere [36,37]. The kinetic and thermodynamic parameters obtained are summarized in Table 2. The first-order rate constant is determined based on the weight change with time in the linear degradation range of the thermogravimetric curve. The rates of degradation for these complexes are of the same order as their activation energies. The degradation mechanism seems to be similar for all these complexes.

Table 2
Kinetic and thermodynamic parameters for the thermal degradation process of platinum phthalocyanine complexes using Broido's method.

Kinetic parameters	PtPc	PtTNPc	PtTAPc
n	1.0	1.0	1.0
E_a (kJ mol^{-1})	214.65	436.71	168.90
$\Delta H^{\neq}$ (kJ mol^{-1})	249.83	401.75	136.37
$\Delta S^{\neq}$ (J K^{-1} mol^{-1})	47.63	381.92	−78.38
$\Delta G^{\neq}$ (kJ mol^{-1})	209.66	134.57	232.18
A (s^{-1})	5.93×10^{16}	5.63×10^{19}	4.52×10^{8}

3.7. Electrical conductivity

A literature survey revealed that PtPc behaves like a semiconductor, like copper phthalocyanine, in the temperature range 300–500 K, with a room temperature conductivity $\sim 10^{-11}$ S cm^{-1} [20]. The partially oxidized salts of $PtPc(ClO_4)_{0.5}$ and $PtPc(AsF_6)_x$ showed an electrical resistivity of 10^{-2}–10^{-3} Ω cm at room temperature [19]. Electrical conducting properties of phthalocyanines are very sensitive to the presence of impurities. So, care has been taken to synthesize the complexes in a very pure form. The intrinsic electrical conductivity data of the synthesized PtPc, PtTNPc and PtTAPc were recorded from 298 to 473 K and $\log\sigma$ versus $1/T$ was plotted, Fig. 6. The relevant data are presented in Table 1. The plots indicate that these complexes are semiconducting in behavior and showed a linear relationship in the temperature range studied. The thermally activated varying conductivity with temperature was found to obey the expression:

$$\sigma = \sigma_0 e^{-E/KT} \quad (2)$$

where E is the activation energy, σ is the specific conductivity at T (K), σ_0 is a constant and 'K' is the Boltzmann constant. The room temperature specific conductivities of PtPc, PtTNPc and PtTAPc are 6.71×10^{-11}, 8.44×10^{-10} and 1.45×10^{-7} S cm^{-1}, respectively. The substitution of electron withdrawing $-NO_2$ groups increased the electrical conductivity by more than 10 times, whereas the amino substitution increased the electrical conductivity by more than 10^4 times, compared to the parent PtPc. The variations in electrical conductivities for these complexes are due to the nature of the substituent groups on the peripheral benzene ring of the phthalocyanine, the overlap of the π-electron system between the molecules and the differences in the stacking arrangement of phthalocyanine molecules. The improvement in the intrinsic electrical conductivity of substituted phthalocyanines may be due to the favorable stacking arrangement of the molecules with improved overlap of the π-electron systems. Decreasing the electron density on the phthalocyanine ring facilitates greater intermolecular contact because of decreased repulsion between the phthalocyanine rings. The highest increase in electrical conductivity for the electron donor amine substituted complexes is due to the smaller size of the amino group in comparison to the nitro group which is expected to stack the molecule with the smallest intermolecular distance resulting in greater intermolecular contact and increased interactions of 3d-orbitals with the π-orbitals of the neighboring phthalocyanine units. This greater intermolecular interaction provides a better pathway for the charge carriers, resulting in the improved electrical conductivity. The order of electrical conductivities observed for these complexes is PtTAPc > PtTNPc > PtPc. The small change in the slope and activation energy at different temperature ranges may be due to some phase transformations and variations in the intermolecular interactions.

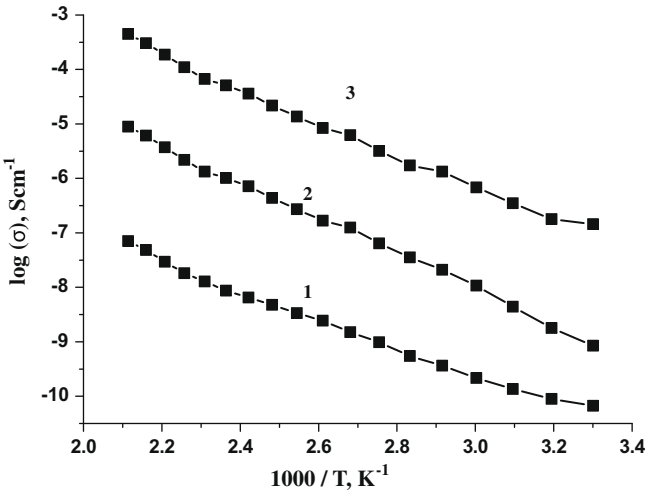

Fig. 6. Variations of electrical conductivities of (1) PtPc, (2) PtTNPc and (3) PtTAPc with temperature.

The electrical conductivity data of PtPc obtained here is similar to the data reported in literature for PtPc and CuPc [20] and the conductivity data obtained here for the substituted platinum phthalocyanines is similar to that of copper and other substituted phthalocyanines [8]. This leads to the conclusion that the angle with the (b) plane – which governs how the atoms in one molecule line up with those in another, behind or in front of it – has no important influence on the mobility of the charge carriers [20].

4. Conclusion

The PtPc, PtTNPc and PtTAPc complexes have been synthesized in the pure state with high yields for the first time by a novel route. The first two complexes were synthesized in dry conditions without using any solvent, urea or catalyst. The purification procedure used was very simple and not time consuming. These complexes have been characterized using elemental analysis, UV–Vis, FT-IR spectroscopy, powder X-ray diffraction and thermogravimetric analytical studies. Kinetic and thermodyanamic parameters associated with the thermal decomposition were calculated using the thermogravimetric data. PtTAPc showed an improvement in the intrinsic electrical conductivity by 4 orders of magnitude and PtTNPc by 1 order of magnitude greater than that of the parent complex.

Scheme 1.

Scheme 2.

interference of other factors, we maintained the same experimental conditions used in the Pb(II) reactions: namely, the same solvent, identical counter-ion (AcO^-) and similar temperature. As described below, if there is a direct relationship between cyclization capacity and acid behaviour in terms of the HSAB principle, then Ph_2Pb(IV) seems to be "harder" than Pb(II).

2. Experimental

2.1. Physical measurements

Elemental analyses were performed on a Fisons instruments EA1108CHNS-O microanalyser. Melting points (m.p.), uncorrected, were determined with a Büchi apparatus. The electrospray mass spectra of the complexes were measured on a Hewlett–Packard model LC-MSD 1100 instrument (positive ion mode, 98:2 MeOH/HCOOH as mobile phase, 20–100 V). IR spectra were recorded from KBr discs on a Bruker IFS66V FT-IR spectrometer and are reported in cm^{-1}. The ^1H, ^{13}C and ^{207}Pb NMR spectra of DMSO-d_6 solutions were recorded on Bruker DPX 250, AMX 300 or AMX 500 instruments; chemical shifts are expressed on the δ scale (downfield shifts positive) relative to tetramethylsilane using the solvent signal for ^1H and ^{13}C NMR spectra and using a saturated solution of Ph_4Pb in $CDCl_3$ (−178 ppm) as the external reference for ^{207}Pb spectra. All spectroscopic measurements were carried out at the RIAIDT services of the University of Santiago de Compostela.

2.2. Materials

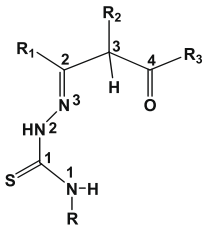
Thiosemicarbazide (Merck), N^1-ethylthiosemicarbazide (Merck), methyl acetoacetate (Aldrich), ethyl benzoylacetate (Aldrich), methyl 4-methoxyacetoacetate (Aldrich), methyl propionoylacetate (Aldrich), ethyl 2-methylacetoacetate (Aldrich), ethyl 2-ethylacetoacetate (Aldrich), acetoacetanilide (Merck), *o*-acetoacetanisidide (Aldrich), *p*-acetoacetanisidide (Aldrich), *o*-acetoacetotoluidide (Aldrich), silver acetate (Probus), and diphenyl- lead(IV) chloride (ABCR) were used as received. Diphenyllead(IV) acetate was prepared *in situ* by stirring diphenyllead(IV) chloride and silver acetate in methanol for 5 h. The resulting AgCl precipitate was filtered off and the solution containing the organolead(IV) acetate was used immediately in the preparation of the complexes.

2.3. Synthesis of ligands

The thiosemicarbazone ligands derived from β-dicarbonyl compounds (β-keto esters and β-keto amides) were prepared according to the method described by Jayasree and Aravindakshan [6]. Physical and analytical properties of $HTSC^n$ (n = 1–10) and HL^n (n = 1–7) have been reported elsewhere [3,7]. Recrystallization of $HTSC^{10}$ from EtOH gave crystals suitable for X-ray analysis.

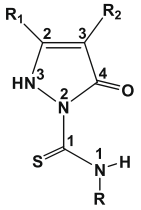
The synthesis and physical and spectroscopic properties of $HTSC^{11}$ are described below.

$HTSC^{11}$. A mixture of *0*-acetoacetotoluidide (1.90 g, 10 mmol) and thiosemicarbazide (0.90 g, 10 mmol) in ethanol (125 ml) was heated under reflux for 1 h. The resulting white solid was filtered off and dried under vacuum. M.p.: 158 °C. *Anal.* Calc. for $C_{12}H_{16}N_4OS$: C, 54.5; H, 6.1; N, 21.2; S, 12.1. Found: C, 54.6; H, 6.0; N, 20.8; S, 11.9%. IR (cm^{-1}): 3443 s, 3280 s, 3163 m, ν(N–H); 1651 s, ν(C=O); 1600 s, ν(C=N); 1497 s, 1247 w, ν(NH–Ph); 1023 m, 850 w, ν(C=S). ^1H NMR: 10.43 s, 10.15 s, 9.67 s, 9.44 s [(2), $N_{(2/4)}H$]; 8.14 s, 7.67 s, 7.63 s [(2), $N_{(1)}H_2$]; 7.36–7.08 m [(4), $H_{8\text{-}11}$]; 3.56 s, 3.40 s [(2), $C_{(3)}H_2$]; 2.20 s, 2.17 s [(3), $C_{(12)}H_3$]; 2.03 s, 1.99 s [(3), $C_{(5)}H_3$]. ^{13}C NMR: 178.8 [$C_{(1)}$]; 167.1 [$C_{(4)}$]; 149.0 [$C_{(2)}$]; 136.0–125.1 [$C_{(6-11)}$]; 46.0 [$C_{(3)}$]; 17.8 [$C_{(12)}$]; 16.7 [$C_{(5)}$].



2.4. Synthesis of complexes

General procedure [*Caution! Organolead(IV) compounds are very toxic*] [8]. A solution of freshly prepared $PbPh_2(OAc)_2$ in methanol was mixed in 1:2 or 1:1 molar ratio with a solution or suspension of the thiosemicarbazone ligand in the same solvent. The resulting mixtures were stirred for 6 h at room temperature or under reflux. The experimental conditions and the complexes obtained are summarized in Table 1. Only the reaction between $PbPh_2(OAc)_2$ and $HTSC^4$ gave unidentified products under all conditions. Details for each reaction are described in Supplementary data.



The analytical, physical and spectroscopic data for the complexes obtained are listed below.

Table 1
Reactions of $PbPh_2(OAc)_2$ with $HTSC^n$ in MeOH: conditions used and compounds obtained.

Ligand	M:L (mol ratio)	*T*	Compounds
$HTSC^1$	1:2	r.t.	HL[1a]
	1:1	r.t.	HL[1a]
$HTSC^2$	1:2	r.t.	unidentified product
		under reflux	$[PbPh_2(L^2)_2]$
	1:1	r.t.	$[PbPh_2Cl(L^2)]$
		under reflux	$[PbPh_2(OAc)(L^2)]$
$HTSC^3$	1:2	r.t.	$[PbPh_2Cl(TSC^3)]$
		under reflux	first fraction, $[Pb(L^3)_2]$
			second fraction, $[PbPh_2(L^3)_2]$
	1:1	r.t.	$[PbPh_2Cl(TSC^3)]$[b]
$HTSC^4$	1:1 and 1:2	r.t.	unidentified products
		under reflux	
$HTSC^5$	1:2	r.t.	first fraction, $[Pb(L^5)_2]$
			second fraction, $[PbPh_2(L^5)_2]\cdot H_2O$
		under reflux	$[Pb(OAc)(L^5)]$
	1:1	r.t.	unidentified product
		under reflux	first fraction, $[Pb(OAc)(L^5)]$
			second fraction, $[PbPh_2(OAc)(L^5)]\cdot MeOH$
$HTSC^6$	1:2	r.t.	$[PbPh_2(L^6)_2]$[c]
	1:1	r.t.	$[PbPh_2(OAc)(L^6)]$
$HTSC^7$	1:2 or 1:1	r.t.	$[PbPh_2(OAc)(L^7)]$[c]
$HTSC^8$	1:2 or 1:1	r.t.	$[PbPh_2(OAc)(TSC^8)]\cdot 2MeOH$[c]
$HTSC^9$	1:2	r.t.	$[PbPh_2(TSC^9)_2]$
	1:1	r.t.	first fraction, $[PbPh_2(TSC^9)_2]$[d]
			second fraction, $[PbPh_2(OAc)(TSC^9)]$[e]
$HTSC^{10}$	1:2 or 1:1	r.t.	$[PbPh_2(OAc)(TSC^{10})]\cdot H_2O$[c]
$HTSC^{11}$	1:2 or 1:1	r.t.	$[PbPh_2(OAc)(TSC^{11})]\cdot 0.75MeOH$[c]

[a] The same compound was obtained when the reaction mixture was heated under reflux for 6 h.
[b] The reaction of this ligand under reflux afforded unidentified products when a 1:1 molar ratio was used.
[c] The same compound was obtained when 1:2 or 1:1 molar ratios were heated under reflux for 6 h.
[d] The same compound was obtained when 1:2 or 1:1 (second fraction) molar ratios were heated under reflux for 6 h.
[e] The same compound was obtained when a 1:1 (first fraction) molar ratio was heated under reflux for 6 h.

The following crystals, which were suitable for X-ray diffractometry, were obtained from the mother liquors of the specified reactions: [$PbPh_2Cl(L^2)$] ($PbPh_2(OAc)_2$/$HTSC^2$ reaction, 1:1 molar ratio, room temperature), [$PbPh_2(OAc)(L^5)$] · MeOH ($PbPh_2(OAc)_2$/TSC^5 reaction, 1:1 molar ratio, under reflux), [$PbPh_2(OAc)$-(TSC^8)] · 2MeOH ($PbPh_2(OAc)_2$/$HTSC^8$ reaction, 1:1 molar ratio, room temperature), [$PbPh_2(OAc)(TSC^{10})$] · H_2O ($PbPh_2(OAc)_2$/$HTSC^{10}$ reaction, 1:1 molar ratio, room temperature) and [$PbPh_2$-$(OAc)(TSC^{11})$] · 0.75MeOH ($PbPh_2(OAc)_2$/$HTSC^{11}$ reaction, 1:2 molar ratio, room temperature).

2.5. X-ray crystallography

Crystal data for $HTSC^{10}$, [$PbPh_2(OAc)(TSC^{10})$] · H_2O, [$PbPh_2$-$(OAc)(TSC^{11})$] · 0.75MeOH, [$PbPh_2Cl(L^2)$] and [$PbPh_2(OAc)(L^5)$] · MeOH were collected on a Nonius Kappa CCD (São Carlos Institute of Physics, University of São Paulo), and data for [$PbPh_2$-$(OAc)(TSC^8)$] · 2MeOH were obtained on a Bruker SMART CCD-1000 (RIAIDT, University of Santiago de Compostela). Structures were solved using direct methods for the ligand and the Patterson method for the complexes, followed by normal difference Fourier techniques and refined using SHELXS-97 [9]. Data were corrected for absorption by multi-scan [10] or SADABS [11]. All hydrogen atoms were introduced in calculated positions. Molecular graphics were obtained with ORTEP-3 [12], PLATON [13] and MERCURY [14]. Experimental details and crystal and refinement data are listed in Table 2.

3. Results and discussion

3.1. Syntheses and physical properties of the complexes

Diphenyllead(IV) reacts with TSCs derived from β-keto esters through cyclization processes similar to those induced by Pb(II). Differences in the complexes obtained (Table 1) can be related to the apparently slightly higher tendency of $PbPh_2^{2+}$ to form heteroleptic [$PbPh_2(OAc)(L)$] compounds instead of the homoleptic [$PbPh_2(L)_2$] type, suggesting a somewhat lower affinity of $PbPh_2^{2+}$ for the pyrazolonate anion than the Pb(II) cation. This lower affinity is particularly evident in the reaction with $HTSC^1$, which leads to free pyrazolone (HL^1) with the organometallic cation under all of the conditions tested, whereas with Pb(II) the [$Pb(L^1)_2$] complex is formed. However, the dephenylation reactions in which the organometallic cation take part, which transform $PbPh_2^{2+}$ into Pb(II), paradoxically contribute most to the differences between the products obtained when these TSCs are cyclized in the presence of $PbPh_2^{2+}$ and Pb(II) cations. Although these dephenylation processes can give rise to lead(II) pyrazolonates, very often these reactions are incomplete and lead to mixed compounds that are very difficult to separate and identify. Similar but fully evolved processes have previously been observed for the $PbPh_3^+$ and $PbMe_2^{2+}$ cations in the presence of ferrocenyl TSCs [15] and these results were related to the weakness of the Pb–C bonds [16]. It is worth noting that, in some cases, a minimal amount of the heteroleptic complexes containing Cl^- ligands were also isolated, probably because the $PbPh_2(OAc)_2$ used in the reaction was contaminated with some $PbPh_2Cl_2$ used in the synthesis of the former species (see Section 2).

Regarding the reactions of diphenyllead(IV) acetate with TSCs derived from β-keto amides, cyclization did not occur in any case and only thiosemicarbazonates were isolated. Note that Pb(II) forms the corresponding pyrazolonate with HTSC[8], although not with HTSC[9] or HTSC[10] [2]. Thus, if there is a relationship between cyclization and "soft" character, then $PbPh_2^{2+}$, although a "borderline" ion, might be a little "harder" than Pb(II).

The complexes are all solids and are mostly yellow in colour. The complexes are insoluble in water, soluble in DMSO and DMF but only sparingly soluble in ethanol and acetone.

3.2. X-ray studies

3.2.1. HTSC[10]

The atomic numbering scheme for this TSC ligand is shown in Fig. 1 and selected bonds lengths and angles are listed in Table 3. The structure shows some disorder that affects the atoms of the ring [C(7), C(8), C(10) and C(11)], which are delocalized between two equally populated positions.

The thiosemicarbazone chain adopts the E configuration around the C(2)–N(3) and C(1)–N(2) bonds with the sulfur atom trans to the N–N bond. The bonds lengths and angles are similar to those previously found for this type of compound [17]. The atoms of the molecule are distributed in two planes, SN(1)C(1)N(2)-N(3)C(2)C(5)C(3) [rms = 0.0668] and C(4)N(4)C(6)C(7)C(8)C(9)-C(10)C(11) [rms = 0.0976] which form a dihedral angle of 76.94(0.42)°.

There is an intermolecular hydrogen bond [N(1)–H(1A)···N(3)] that limits the free rotation of the $-N(1)H_2$ group around the N(1)–C(1) bond (see below) and there is also a weak intermolecular N(1)–H(1B)···S^i interaction that associates the molecules into pairs. Another intramolecular hydrogen bond [N(4)–H(4)···$O(1)^{ii}$] connects the pairs to give parallel chains along the *a* axis (Table 4, Fig. 1S).

3.2.2. Complexes

The molecular structures of the complexes $[PbPh_2(OAc)(TSC^8)] \cdot 2MeOH$, $[PbPh_2(OAc)(TSC^{10})] \cdot H_2O$ and $[PbPh_2(OAc)(TSC^{11})] \cdot 0.75MeOH$ are shown in Figs. 2–4 together with the numbering schemes. Selected bonds lengths and angles are listed in Table 5. The three structures include solvent molecules (MeOH or H_2O) in the lattice. In $[PbPh_2(OAc)(TSC^{10})] \cdot H_2O$, the water molecule is disordered over two positions with occupancies of 0.75:0.25. Only the molecule in the high-occupancy position has been included in Table 4. This disorder is probably responsible for the low quality of the collected data.

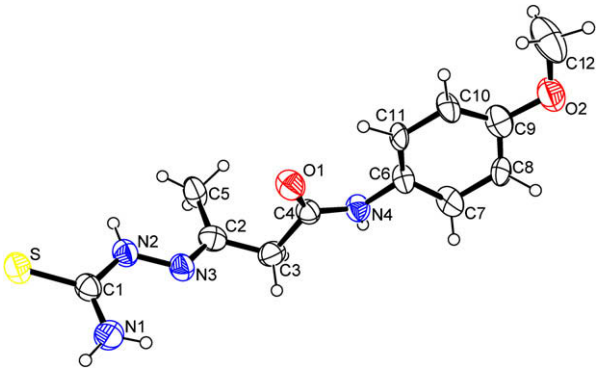

Fig. 1. Molecular structure of HTSC[10].

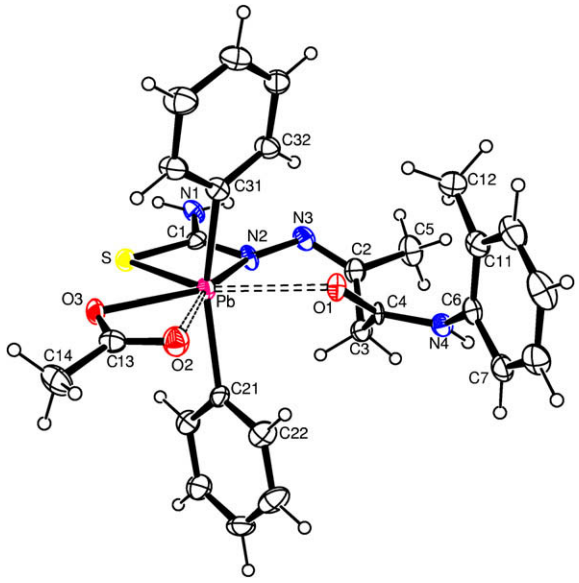

Fig. 4. Molecular structure of $[PbPh_2(OAc)(TSC^{11})] \cdot 0.75MeOH$ (methanol have been omitted for clarity).

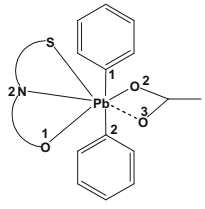
As can be seen from the figures, in all three heteroleptic complexes the diphenyllead(IV) cation is bound to a TSC^- ligand and to an anisobidentate acetate. The thiosemicarbazonate interacts via its S, N(2) and O(1) donor atoms, with the last interaction probably being a weak one. Similarly, one of the lead–acetate bonds [Pb–O(3)] seems to be even weaker than Pb–O(1) judging by the bond distance (cf. 2.83–2.77 Å). If these weak Pb–O bonds are taken into account, then lead has a pentagonal bipyramidal coordination, with the donor atoms of both TSC^- and AcO^- ligands equatorial and the carbon atom of the phenyl groups apical.

The deprotonation and coordination of the thiosemicarbazonate to the metal give rise to some changes with respect to the structure of the free $HTSC^8$ and $HTSC^{10}$ ligands [7a]. In both cases the bonding to the metal increases the carbon–sulfur bond distances, suggesting a thione to thiol evolution of the thioamide group. Also, in order to achieve the coordination of O(4) along with that of S and N(2), the ligands must change its conformation about the C(2)═N(3) bond in the free state from E to Z.



The most conspicuous characteristic of these structures is the N(2),S-coordination mode adopted by the TSC^- anion in place of the more usual N(3),S-coordination (see, e.g. Ref. [7b]). This leads to a four-membered chelate ring (see Figs. 2–4) instead of the five-membered ring that is formed when the thiosemicarbazonate binds in the usual N(3),S-mode. The N(2),S-coordination, initially observed in a dimethylthallium complex [18], is now well documented in more than thirty structures [19] and has been the subject of some experimental and theoretical discussion [20]. Nevertheless, in the present context, the relevance of the $[PbPh_2(OAc)(TSC^n)]$ structures resides not in the unusual character of the coordination mode of the TSC^- ligand, but in the fact that the involvement of the electron pair of N(2) in the bonding to the metal prevents its participation in the nucleophilic attack on the

$C(O)R_3$ group and the subsequent ring formation (see Section 1, the (II) → [III] evolution).

It is interesting to compare these structures with that of $[Zn(^TSC^9)_2]$ [7b]. In the zinc complex the ligand behaves in the more usual way and exhibits N(3),S-coordination; there is also an N(4)–H···N(2) hydrogen bond that involves the N(2) electron pair and the O(1) atom is located away from the metal centre, making any Zn–O(1) interaction impossible. Thus, it seems that, as suggested previously [21], small differences in weak interactions or in the steric requirements of the packing may determine which of the N(2),S- or N(3),S-coordination modes is adopted.

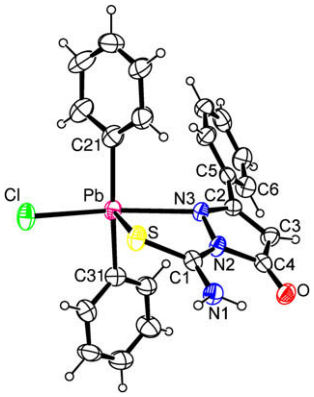
In the three complexes an intermolecular $[N(4)–H(4)\cdots O_{acetate}]$ hydrogen bond (Table 4) associates the molecules into chains; other bonds involving the solvent molecules (MeOH or H_2O) link these chains to form a layered network (Figs. 2S–7S).

With respect to the complexes containing the cyclized ligand, the arrangement of the dimers of $[PbPh_2(OAc)(L^5)]\cdot MeOH$ is shown in Fig. 5 and the asymmetric unit of $[PbPh_2Cl(L^2)]$ is represented in Fig. 6. Both figures include a numbering scheme in keeping with that used above for the uncyclized ligands. Selected bond lengths and angles are listed in Table 6.

In the former complex, the metallic atom is coordinated to the S and N(3) atoms of the monodeprotonated pyrazolone, to one oxygen atom of the acetate group [Pb–O(2) = 2.343(3) Å] and, more weakly, to the $O(3)^i$ (i = x, $-y+1$, $-z$) atom belonging to an acetate from a neighbouring molecule [$Pb–O(3)^i$ = 2.721(4) Å]. Thus, the acetate is bis-monodentate and bridges between the two diphenyllead(IV) units to give the dimeric arrangement displayed in Fig. 5. The intramolecular Pb···O(3) distance in the monomer (3.08 Å) is too long to represent a significant interaction.

The geometry around the metal is distorted octahedral and the pyrazolonate shows, in comparison to the free ligand [22], the expected structural evolution [2]. The intermolecular hydrogen bonds $N(1)–H(1B)\cdots O(1S)^{ii}$ and O(1S)–H(1S)···O(1), involving the solvent molecule and the amino and carbonyl groups of the L^- ligand (see Table 4), link the dimers to form a chain (Figs. 8S and 9S).

In $[PbPh_2Cl(L^2)]$ (Fig. 6) the monodeprotonated pyrazolone is N(3),S-coordinated to one diphenyllead(IV) cation and O(1)-bound to another, bridging between the metal centres and connecting the molecules to form a chain (Figs. 10S and 11S). The $Pb–O(1)^i$ distance [2.581(7) Å] is shorter than that in $[Pb(L^7)_2]$ [2.727(3) Å] [2], in which two intermolecular $Pb\cdots O(1)^x$ interactions also exist but the repulsive effect of a stereochemically active lone electron pair on Pb(II) also hinders the intermolecular approach. It is remarkable that the adopted structure contains only bridging pyrazolonates but not bridging chlorides, thus confirming the significant affinity of the diphenyllead(IV) cation with the oxygen donor centres.



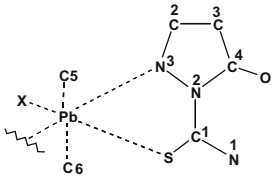


Fig. 6. Asymmetric unit of $[PbPh_2Cl(L^2)]$.

Table 6
Selected bond distances (Å) and angles (°) for pyrazolonate complexes.

Bond[a]	$[PbPh_2Cl(L^2)]$[b]		$[PbPh_2(OAc)(L^5)]\cdot MeOH$[c]
Pb–C(5)	2.173(13)		2.178(4)
Pb–C(6)	2.171(12)		2.166(4)
Pb–N(3)	2.562(8)		2.516(3)
Pb–S	2.686(3)		2.7031(10)
Pb–O(2)	–		2.343(3)
$Pb–O(3)^i$	–		2.721(4)
$Pb–O^i$	2.581(7)		–
Pb–Cl	2.625(3)		–
C–S	1.704(11)		1.710(4)
C(31)–Pb–C(21)	164.6(4)	C(15)–Pb–C(9)	162.67(16)
$N(3)–Pb–O^i$	104.5(2)	O(2)–Pb–S	72.72(8)
N(3)–Pb–S	70.35(18)	$O(2)–Pb–O(3)^i$	106.48(12)
O^i–Pb–Cl	101.07(18)	N(3)–Pb–S	70.33(8)
Cl–Pb–S	84.15(9)	$N(3)–Pb–O(3)^i$	110.36(12)

[a]

[b] i: $-x+3/2$, $y-1/2$, $-z+1/2$.
[c] i: $-x$, $-y+1$, $-z$.

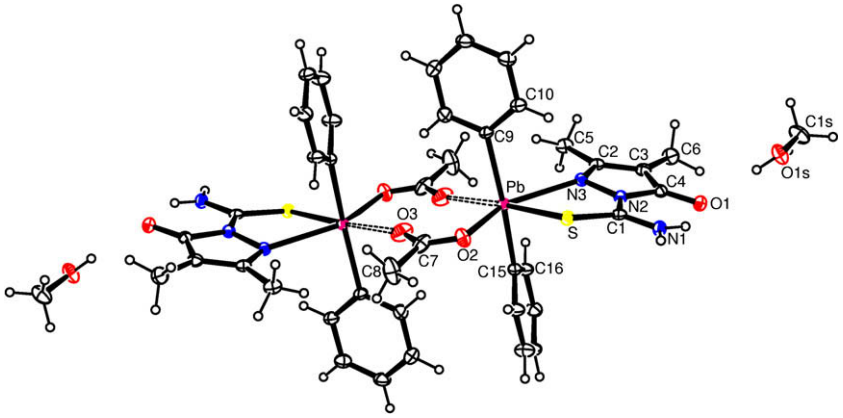

Fig. 5. Dimers of $[PbPh_2(OAc)(L^5)]\cdot MeOH$.

Once again the metal has octahedral coordination, with the main distortion caused by the C(21)–Pb–C(31) angle, which is 164.6(4)° rather than 180°, and the short N(3),S-bite of the ligand [N(3)–Pb–S = 70.35(18)°], which clearly differs from the ideal 90°.

In the crystal lattice, the chains interact via the N(1)–H(1B)···Cl^{ii} intermolecular hydrogen bond (Table 4) to give a layered arrangement (Figs. 10S and 11S).

3.3. IR spectroscopy

The most significant IR bands of the complexes are listed in Section 2 and were assigned according to a previous study [2].

In the spectra of the thiosemicarbazonates [$PbPh_2(OAc)(TSC^n)$] and [$PbPh_2(TSC^n)_2$], the ν(C=N) vibration remains close to its position in the spectra of the free ligands, which is consistent with N(3) not participating in the coordination to the metal. However, the ν(C=S) vibration is shifted to lower wavenumbers, as one would expect if there is a thione to thiol evolution due to the formation of a Pb–S bond. Thus, in this type of complex the TSC^- ligand is probably N(2),S-bound. The acetate ν_{as}(COO) and ν_s(COO) vibration modes lie at positions in keeping with a general anisobidentate OAc^- coordination [23].

In the pyrazolonate complexes the position of the band associated with the ν(C=S) changes upon metallation to lower wavenumber with respect to the free HL^n, suggesting the coordination of the sulfur atom to the metal in all of these pyrazolone complexes. The behaviour of the ν(C=N) mode is similar in all derivatives (a shift to higher wavenumber with respect to the free pyrazolone) and this is consistent with the coordination of N(3) as in [$PbPh_2(OAc)(L^5)$] · MeOH and [$PbPh_2Cl(L^2)$]. As indicated previously [7b], coordination of the oxygen atom of the carbonyl group to the metal cannot be confirmed by the modification of the band associated with ν(C=O) because this mode is also sensitive to the metallation of N(3) and to the changes in the hydrogen bonding interactions involving the carbonyl group. Thus, in [$PbPh_2(OAc)(L^5)$] · MeOH this signal is shifted by approximately 30 cm^{-1} to lower wavenumbers with respect to its position in HL^5, although the X-ray study showed (Fig. 5) that the C=O group is not involved in the coordination to the metal. However, in [$PbPh_2Cl(L^2)$], in which an O(1)–Pb bond exists, ν(C=O) was shifted to lower wavenumbers compared to the corresponding absorption in HL^2 and this shift was only marginally larger (*ca.* 40 cm^{-1}).

As far as the acetate ligand in the heteroleptic [$PbPh_2(OAc)(L^n)$] complexes is concerned, the value of $\Delta\nu$ (=[ν_{as}(COO)– ν_s(COO)]) (150–170 cm^{-1}) suggests a coordination behaviour similar to that described for [$PbPh_2(OAc)(L^5)$] [23].

3.4. ^{1}H, ^{13}C and ^{207}Pb NMR spectra

The ^{1}H, ^{13}C and ^{207}Pb NMR data for the complexes in DMSO–d_6 solution are included in Section 2. The corresponding data for the ligands $HTSC^n$ (n = 1–10) and HL^n (n = 1–7) have been published previously [3,7]. In cases where a long acquisition time was necessary to obtain a spectrum, some of the complexes decomposed to give a black precipitate (possibly PbS), benzene (as shown by new signals at 7.35 and 128.3 ppm in the ^{1}H and ^{13}C NMR spectra, respectively) and, in the case of heteroleptic complexes, diphenyllead acetate (according to the observed ^{207}Pb NMR signal at −863 ppm). This phenomenon was not explored further.

In the ^{1}H and ^{13}C NMR spectra of the thiosemicarbazonate complexes the signals belonging to the TSC^- moiety change with respect to those of the free ligand in the expected way: (i) that of the N(2)H group disappears due to deprotonation; (ii) the two bands associated with the –N(1)H_2 group [2] evolve to give a broad signal, in accordance with the free rotation of this group around the N(1)–C(S) bond as a result of the HTSC deprotonation and metallation; (iii) the C(2) signal is displaced to lower field (by between 6 and 16 ppm) upon complexation, probably due to the bonding of N(3) to the lead atom [7b].

In cases where the signals of the organometallic moiety did not overlap with the aromatic proton signals of the ligand, and therefore could be located, they showed chemical shifts that were very similar in all the complexes and also $^3J(^1H–^{207}Pb)$ values close to 112 Hz. In the ^{13}C NMR spectra the $^2J(^{13}C–^{207}Pb)$ coupling constants are between 87 and 88 Hz. These values are lower than those obtained for diphenyllead compounds with CN = 6 and even lower than those with CN = 5 [24,25], which suggests that in these compounds CN = 4. This low CN is also supported by the ^{207}Pb chemical shift (δ = −294 ppm), which is identical in all compounds and is displaced to lower field by almost 200 ppm with respect to the values reported for other diphenyllead complexes with CN 6 or 5 [24,25].

All of these data suggest that the solid state structures of the complexes [$PbPh_2(OAc)(TSC^n)$] (n = 8, 10 and 11), in which the metal exhibits a CN = 7, are modified in DMSO solution to form species in which the diphenyllead is probably only bound to the TSC^- anion via its S and N(3) atoms. If this is the case, it must be concluded that the NMR parameters of the diorganolead moiety are sensitive, as can been expected, to the CN of the metal and to the identity of the donor atoms, but is rather insensitive to the donor strength of these atoms.

In the pyrazolonate complexes, the main changes in the ^{1}H and ^{13}C NMR spectra of the pyrazolone moiety regarding the free HL^n ligands are: (i) the absence of the signal associated with the N(3)H group; (ii) the slight shielding of C(1) and (iii) the significant deshielding of C(2). The former modification is a consequence of the deprotonation of the ligand and the latter two suggest that the S,N(3)–Pb bonding is retained in DMSO solution.

The values of the $^3J(^1H–^{207}Pb)$ constants, in cases where they could be observed, are in the range 204–210 Hz and this is consistent with a CN of 6 or higher [24]. The limited availability of ^{207}Pb chemical shift data precludes any general conclusions, but this parameter in the cases of [$PbPh_2(L^3)_2$] (−738.1) and [$PbPh_2(L^6)_2$] (−706.4) also suggests a CN of 6 or higher [25–27]. However, the chemical shift value in [$PbPh_2(OAc)(L^6)$] (−869.5) indicates that during the acquisition of the spectrum this complex evolved to give diphenyllead acetate. The complex [$PbPh_2(OAc)(L^5)$] shows two signals, one at −575 and another at −871.9, and this underwent a partial or total displacement of the AcO^- ligand in solution to give a new complex with a lower CN and $PbPh_2(OAc)_2$.

Scheme 1.

2.2. Synthesis of ligand

L^2 was synthesized in an analogous way to L^1, which was described previously [17]. An ethanol solution (50 mL) of 1,3-dibromopropane (2.02 g, 10 mmol) was added to a dry ethanol solution (300 mL) containing 4-(pyridin-3-yl) pyrimidine-2-thiol (3.78 g, 20 mmol) and sodium hydroxide (0.80 g, 20 mmol). The solution was stirred and refluxed for 8 h. Yellow precipitates were filtered out, washed by water and ethanol, and dried in vacuum. Yield (3.12 g) 74.6%, M.p. 117–118 °C. *Anal. Calc.* for $C_{21}H_{18}N_6S_2$: C, 60.26; H, 4.33; N, 20.08. Found: C, 60.29; H, 4.27; N, 19.82%. IR (KBr, cm^{-1}): 1589 (m), 1562 (vs), 1533 (m), 1480 (w), 1440 (w), 1428 (w), 1419 (m), 1402 (m), 1343 (m), 1323 (s), 1206 (s), 1192 (m), 1023 (w), 824 (m). ESI-MS: 858.7 (100%) $[2L^2+Na]^+$, 441.2 (28%) $[L^2+Na]^+$, 419.3 (26%) $[L^2+H]^+$. ^1H NMR (δ, $CDCl_3$): 9.29 (s, 2H, pyridyl–H), 8.76 (d, 2H, pyrimidyl–H), 8.62 (d, 2H, pyridyl–H), 8.47 (d, 2H, pyridyl–H), 7.51 (t, 2H, pyridyl–H), 7.41 (d, 2H, pyrimidyl–H), 3.46 (t, 4H, methylene–H), 2.35 (m, 2H, methylene–H). Single crystals of L^2 suitable for X-ray diffraction were grown from its methanol solution by slow evaporation in air at room temperature.

2.3. Synthesis of complexes

*$[ZnL^2I_2]$ (**1**):* A solution of ZnI_2 (16.0 mg, 0.05 mmol) in methanol (5 mL) was very slowly dropped on the top of a solution of L^2 (20.9 mg, 0.05 mmol) in chloroform (5 mL) in a tube. Pale yellow crystals formed after 6 days (yield: 42%). *Anal.* Calc. for $C_{21}H_{18}I_2N_6S_2Zn$: C, 34.19; H, 2.46; N, 11.39. Found: C, 34.21; H, 2.51; N, 11.36%. IR (KBr, cm^{-1}): 1608 (w), 1559 (s), 1544 (s), 1482 (w), 1431 (m), 1406 (m), 1347 (m), 1325 (m), 1202 (m), 1180 (w), 1052 (w), 810 (w).

*$\{[CdL^2I_2]_2 \cdot CH_3OH\}_n$ (**2**):* **2** was prepared in a way like **1**. Yield, 40%. *Anal.* Calc. for $C_{43}H_{40}I_4N_{12}OS_4Cd_2$: C, 32.24; H, 2.51; N, 10.49. Found: C, 32.30; H, 2.57; N, 10.38%. IR (KBr, cm^{-1}): 3406 (w), 1602 (w), 1599 (s), 1543 (s), 1482 (w), 1430 (m), 1407 (m), 1348 (m), 1325 (w), 1202 (m), 1181 (w), 10468 (w), 809 (w).

*$\{[ZnL^2(H_2O)_4](ClO_4)_2\}_2$ (**3**):* A solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (37.2 mg, 0.10 mmol) in methanol (10 mL) was added to a solution of L^2 (41.8 mg, 0.10 mmol) in methanol (20 mL). The mixture was refluxed for half an hour and then cooled to room temperature. The solution was filtered, then complex **3** was obtained by slow evaporation of the filtrate at room temperature in 52% yield. *Anal.* Calc. for $C_{42}H_{52}N_{12}O_{24}S_4Cl_4Zn_2$: C, 33.41; H, 3.47; N, 11.13. Found: C, 33.28; H, 3.54; N, 11.08%. IR (KBr, cm^{-1}): 3460 (m), 1654 (m), 1608 (m), 1566 (vs), 1546 (s), 1484 (m), 1430 (m), 1403 (s), 1354 (s), 1332 (m), 1265 (w), 1206 (s), 1181 (m), 1110 (vs), 845 (w), 820 (m), 626 (s).

*$\{[CdL^2(H_2O)_4](ClO_4)_2\}_2$ (**4**):* Complex **4** was prepared by a similar way to complex **3**. Yield, 58%. *Anal.* Calc. for $C_{42}H_{52}N_{12}O_{24}S_4Cl_4Cd_2$: C, 31.45; H, 3.27; N, 10.48. Found: C, 31.40; H, 3.42; N, 10.41%. IR (KBr, cm^{-1}): 3449 (m), 1605 (m), 1566 (vs), 1546 (s), 1485 (w), 1432 (w), 1411 (m), 1355 (m), 1333 (w), 1306 (w), 1207 (m), 1119 (vs), 1048 (s), 813 (m), 623 (s).

*$[ZnL^1I_2]_n$ (**5**):* A solution of ZnI_2 (16.0 mg, 0.05 mmol) in methanol (5 mL) was very slowly dropped on the top of solution of L^1 (20.2 mg, 0.05 mmol) in chloroform (5 mL) in a tube. Pale yellow crystals formed after 6 days (yield: 45%). *Anal.* Calc. for $C_{20}H_{16}I_2N_6S_2Zn$: C, 33.19; H, 2.23; N, 11.61. Found: C, 33.20; H, 2.30; N, 11.58%. IR (KBr, cm^{-1}): 1608 (w), 1562 (s), 1540 (s), 1481 (w), 1430 (m), 1416 (m), 1346 (s), 1329(w), 1199 (m), 1178 (w), 1052 (w), 805 (w).

*$[CdL^1I_2]_n$ (**6**):* Complex **6** was prepared in an analogous way to complex **5**. Yield, 40%. *Anal.* Calc. for $C_{20}H_{16}I_2N_6S_2Cd$: C, 31.17; H, 2.09; N, 10.90. Found: C, 31.20; H, 2.04; N, 10.80%. IR (KBr, cm^{-1}): 1604 (w), 1560 (s), 1541 (s), 1481 (w), 1429 (m), 1416 (m), 1404 (w), 1346 (m), 1199 (m), 1181 (w), 1048 (w), 806 (w).

*$\{\{[ZnL^1_2(H_2O)_4](ClO_4)_2L^1\}_{0.5} \cdot CH_3OH\}$ (**7**):* A solution of $Zn(ClO_4)_2 \cdot 6H_2O$ (37.2 mg, 0.10 mmol) in methanol (15 mL) was added to a solution of L^1 (40.4 mg, 0.1 mmol) in methanol (20 mL). The mixture was refluxed for half an hour, and then cooled to room temperature. The solution was filtered, and complex **7** was obtained by slow evaporation of the filtrate at room temperature in 73% yield. *Anal.* Calc. for $C_{31}H_{32}N_9O_7S_3ClZn_{0.50}$: C, 46.14; H, 4.00; N, 15.62. Found: C, 46.20; H, 3.94; N, 15.56%. IR (KBr, cm^{-1}): 3456 (m), 3066 (m), 1599 (w), 1565 (vs), 1539 (s), 1480 (m), 1430 (m), 1403 (s), 1358 (m), 1345 (m), 1323 (s), 1224 (w), 1206 (m), 1195 (s), 1120 (s), 1088 (s), 832 (m), 809 (m).

2.4. Crystallographic analyses

Diffraction data for L^2 and complexes **1**–**8** were measured on a Bruker SMART 1K CCD diffractometer [18] at 291 K using graphite mono-chromated Mo Kα radiation (λ = 0.71073 Å). Lorentz polarization and absorption corrections were applied. The structures were solved by direct methods and refined with the full-matrix least-squares technique using SHELXTL version 5.1 [19]. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. The hydrogen atoms were geometrically fixed and allowed to ride on the attached atoms. The summary of the crystal data, experimental details and refinement results are listed in Table 1, while selected bond distances and bond angles are given in Table 2.

3. Results and discussion

3.1. Synthesis and characterization

Similar to solubility of L^1, L^2 is soluble in common polar organic solvents. Reactions of L^2 or L^1 with MI_2 (M = Zn^{2+} and Cd^{2+}) yielded the neutral species $[ZnL^2I_2]$ (**1**), $[CdL^2I_2]_n$ (**2**), $[ZnL^1I_2]_n$ (**5**) and $[CdL^1I_2]_n$ (**6**) by diffusion between solutions of the corresponding ligand and the metal salt. The other compounds were produced by refluxing L^2 or L^1 with metal salts in methanol. All complexes were prepared in 1:1 metal/ligand molar ratio, and it is found that the relative ratio between the two reagents will not affect the final products.

Symmetry code: 1 = *x*, 1 + *y*, *z* and 2 = *x*, −1 + *y*, *z* for **2**; a = −*x*, *y*, 1/2 − *z* for **5**; a = 1 − *x*, *y*, 1/2 − *z* for **6**; a = 2 − *x*, −*y*, −*z* for **7**; a = 2 − *x*, −*y*, −*z* for **8**.

Infrared spectra of **2**, **3**, **4**, **7** and **8** display middle peaks characteristic of the O–H stretching vibration in the 3470–3450 cm^{-1} region. In the 1400–1602 cm^{-1} region, the absorption bands are in accordance with the skeletal vibrations of aromatic rings for these five complexes. The weak absorption band appearing in the 800–820 cm^{-1} region can be assigned to the C–S stretching vibration. The strong bands of ClO_4^- appear near 1100 cm^{-1} in the IR spectra of **3**, **4**, **7** and **8**.

3.2. X-ray crystallographic studies of ligand and complexes

3.2.1. L^2

L^2 crystallizes in a triclinic system of a non-centrosymmetric space group $P\bar{1}$ (molecular structure shown in Supplementary data S1).

In the crystal structure of this ligand, pyrimidyl rings and pyridyl rings are slightly twisting, in which the dihedral angle between the neighboring two heterocyclic rings is ca. 8.4°. Adjacent molecules of L^2 are connected with each other via hydrogen bonds [C(18)–H(18)···N(6) (2 − *x*, −*y*, 2 − *z*), C(18)···N(6), 3.441(4) Å, C–H···N, 157.0°], as a consequence, forming dimers. These dimers are again stitched together to form a 3D supramolecular structure through π···π stacking interactions of 3.571 Å between the parallel neighboring dimers (see Supplementary data S2).

3.2.2. $[ZnL^2I_2]$ (**1**)

Single-crystal XRD study has revealed that $[ZnL^2I_2]$ (**1**) crystallizes in an orthorhombic system with space group *Pbca*. The asymmetric unit of **1** contains one ligand, one Zn(II) ion, and two coordinated iodide anions (shown in Fig. 1a).

The Zn(II) ion is coordinated by two iodide anions and two pyridyl N atoms of one ligand in a distorted tetrahedral configuration. The full dithioether molecule acts as an effectively bidentate ligand to link the metal atom and produce an 18-membered chelating metallomacrocycle. Probably owing to the steric requirement, the whole molecule adopts a distorted boat conformation. The ligand wraps around the Zn(II) ion, in which the dihedral angle between two pyridyl rings is ca. 83.6°. Bond angles of N–Zn–N and I–Zn–I are 102.2(2)° and 119.7(3)°, respectively, which are far from an ideal tetrahedral angle. It is worthy noting that two heterocyclic rings of the ligand, pyrimidyl and pyridyl rings, are not coplanar either, the dihedral angle between them is ca. 10.2° and 13.3°, respectively.

Additionally, as shown in Fig. 1b, effective π···π stacking is observed between the aromatic rings within the neighboring macrocycles with the centroid–centroid separation of 3.572 or 3.770 Å. Furthermore there are forces of van der Waals S···I contacts [S···I = 3.93 Å] [20,21]. So the adjacent modules are cemented together primarily with these "glue" leading to the formation of a 3D supramolecular structure (see Supplementary data S3).

3.2.3. $[CdL^2I_2]_n$ (**2**)

By replacing ZnI_2 with CdI_2 in the reaction with L^2, $[CdL^2I_2]_n$ (**2**) were obtained. Complex **2** crystallizes in a monoclinic system of

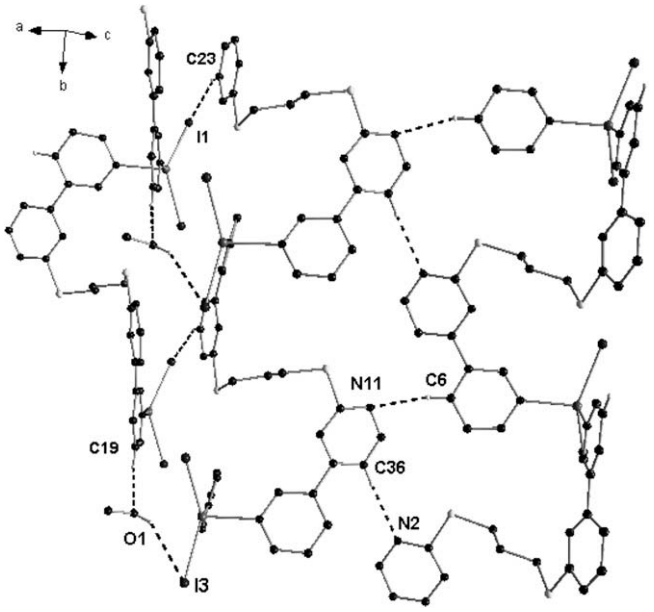

Fig. 2b. View of the structure of 2D planes of **2** showing the intermolecular and intramolecular hydrogen bonding.

space group $P2_1/n$. The asymmetric unit of **2** contains two *N,N′*-bidentate bridging ligands, two Cd ions, four iodide anions and one methanol molecule (Fig. 2a), which form two independent zig-zag polymers.

In complex **2** each Cd(II) ion is coordinated by two N donors from different ligands and two coordinated iodide anions, yielding a distorted tetrahedral coordination sphere with Cd–N and Cd–I distance in the range of those found in the other complexes [22,23]. Additionally, pyrimidyl and pyridyl units, are obviously not coplanar, the dihedral angles between the two heterocyclic units are ca. 17.7° and 17.2° for Cd1 chain, and 28.9° and 22.6° for Cd2 chain.

It is interesting to observe that C–H···N and C–H···I intermolecular hydrogen bonds are formed between adjacent 1D chains, resulting in a 2D fluctuant plane. As shown in Fig. 2b, two pyrimidine nitrogen atoms of L^2 and iodide anions serve as the acceptors to form two kinds of hydrogen bonds ($d_{C6\cdots N11}$ = 3.43 Å, C6–H···N11 = 153.0°; $d_{C36\cdots N2}$ = 3.53 Å, C36–H···N2 = 171.0°; $d_{C23\cdots I1}$ = 3.88 Å, C23–H···I1 = 150.0°). Then methanol molecules not only as hydrogen bonding donors take part in intramolecular hydrogen bonding pattern with iodide anions, but also as hydrogen bonding acceptors, participate in intermolecular hydrogen bonding pattern with C–H. As a result, methanol molecules, acting as glue, cemented the fluctuant planes to give rise to a 3D network.

3.2.4. $\{[ZnL^2(H_2O)_4](ClO_4)_2\}_2$ (**3**) and $\{[CdL^2(H_2O)_4](ClO_4)_2\}_2$ (**4**)

Interaction of $Zn(ClO_4)_2$ or $Cd(ClO_4)_2$ with L^2 led to the generation of dinuclear macrocyclic complexes, $\{[ZnL^2(H_2O)_4](ClO_4)_2\}_2$ (**3**) and $\{[CdL^2(H_2O)_4](ClO_4)_2\}_2$ (**4**). Both complexes **3** and **4** crystallize in a non-chiral space group $P\bar{1}$. Complex **3** contains a $\{[ZnL^2(H_2O)_4]^{2+}\}_2$ 36-numbered cation macrocycle (Fig. 3a), and four free ClO_4^- anions. Each Zn(II) ion exhibits a slightly distorted octahedral coordination geometry, which is completed by two pyridyl nitrogen atoms from different ligands and four water molecules. The basal plane consists of two water oxygen atoms and two nitrogen atoms, while the axial positions are occupied by other two water oxygen atoms with a bond angle (O1–Zn–O4) of 176.4°, which is much close to the linearity, as displayed in Fig. 3a.

In **3**, the Zn–O bond lengths are in the range from 2.082(3) to 2.166(3) Å, and the Zn–N bond lengths are 2.111(4) and 2.124(4) Å, respectively. Zn–O1 and Zn–O4 axial bond lengths are shorter than the equatorial ones, which mean that the metal ions are located in a compressed octahedral coordination geometry. In order to reduce steric hindrance, the adjacent coordinated pyridyl

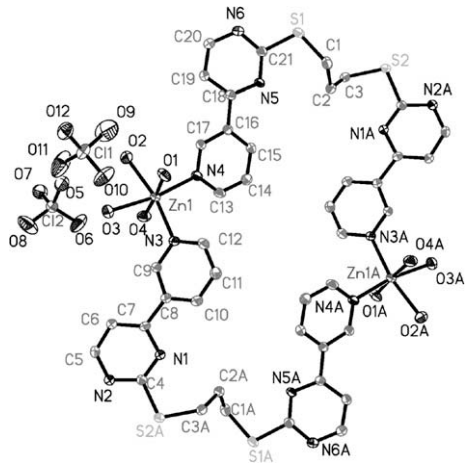

Fig. 3a. Molecular structure of **3** showing the numbering scheme and displacement ellipsoids at the 30% probability level, hydrogen atoms are omitted for clarity [symmetry code: 2 − *x*, −*y*, −*z* for **3**].

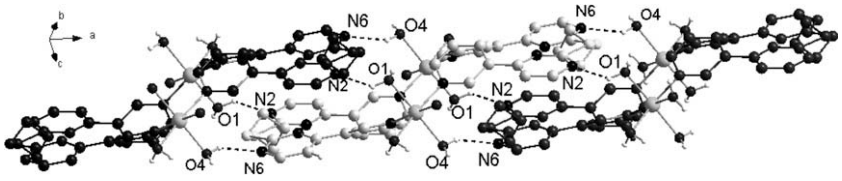

Fig. 3b. View of the structure of 1D chains of **3** showing the intermolecular hydrogen bonding along *a*-axis.

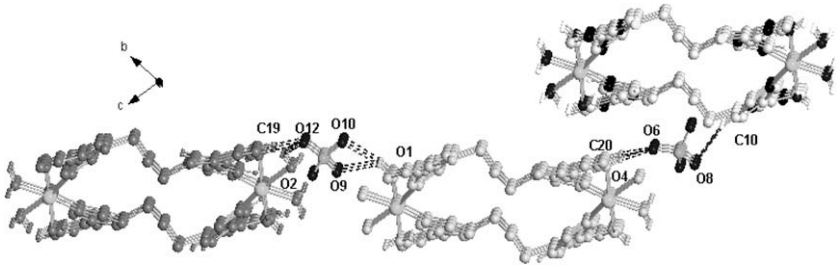

Fig. 3c. View of the structure of a 3D supramolecular framework of **3** showing the intermolecular and intramolecular hydrogen bonding.

rings are inclined to each other with a dihedral angle of 51.6° and a N–Zn–N bond angle of 100.9(2)°, and the dihedral angle between the adjacent pyridyl ring and the pyrimidine ring is 28.5°. In addition, the coordinated pyridyl rings in the symmetrical positions are parallel to each other. By adopting a *N*,*N*′-bidentate bridging coordination pattern, two ligands bridge two Zn(II) ions via N atoms of pyridyl ring in a *cis* conformation to form a M_2L_2 36-numbered macrocycle structure with a Zn···Zn distance of 10.938 Å [24–26].

Complex **4** takes a similar molecular structure to **3** (see Supplementary data S4). The coordination geometry around a Cd(II) atom is analogous to that of a Zn atom in **3**, which is surrounded by four water molecules and two nitrogen atoms from different L^2. The Cd–O bond lengths fall in the range from 2.261(6) to 2.320(6) Å and Cd–N are 2.300(6) and 2.304(6) Å, respectively. The axial bond lengths are also shorter than the equatorial bond lengths with an axial angle of 177.5(2)°. The neighboring coordinated pyridyl rings are inclined to each other with a dihedral angle of 49.9° and a N–Cd–N bond angle of 102.7(2)°. In the macrocycle, the Cd···Cd distance is 10.993 Å.

Although the actual assembly process may happen all at once rather than stepwise, it is particularly interesting and more convenient to describe the 3D structure of **3** or **4** formed by hydrogen bonds in a three-step procedure.

For complex **3**, two independent macrocycle units are linked each other via intermolecular hydrogen bonds O1–H···N2 and O4–H···N6 [O1–H···N2 ($-1+x, y, z$), O1···N2, 2.735(5) Å, O1–H···N2, 137.0°; O4–H···N6 ($1+x, y, z$), O4···N6, 2.835(5) Å, O4–H···N6, 144.0°], forming a tiled chain along *a*-axis. As shown in Fig. 3b, the hydrogen bonds are involved with *cis* nitrogen atoms of pyrimidine rings and the hydrogen of coordinated water molecules, O1 and O4. On the other hand, free perchlorate anions are moored to chains *via* intermolecular hydrogen bonds, O1–H···O9, O1–H···O10, O4–H···O6 and C10–H···O8 [O1–H···O9, O1···O9, 2.970(6) Å, O1–H···O9, 114.0°; O1–H···O10, O1···O10, 3.067(5) Å, O1–H···O10, 169.0°; O4–H···O6, O4···O6, 2.917(5) Å, O4–H···O6, 168.0°, C10–H···O8 ($x, y, -1+z$), C10···O8, 3.481(7) Å, C10–H···O8, 163.0°]. Then the neighboring chains self-assemble through intermolecular hydrogen bonds, O2–H···O12 [O2···O12, 2.886(5) Å, O2–H···O12, 107.0° ($1-x, 1-y, 1-z$)] and C19–H···O12 [C19···O12, 3.305(5) Å, O1–H···O9, 166.0° ($1-x, 1-y, 1-z$)] interactions forming fluctuant layers along *b*-axis.

Furthermore another interesting feature of **3** is the 3D network, formed by intermolecular hydrogen bonds of the adjacent layers between oxygen atoms of anions and hydrogen atoms of aryl rings through C20–H···O6 [C···O6, 3.411(6) Å, C20–H···O6, 1148.0° ($-1+x, y, z$)] and C10–H···O8 [C10···O8, 3.481(7) Å, C10–H···O8, 163.0° ($x, y, -1+z$)] interactions along *c*-axis (as shown in Fig. 3c).

Analogously, complex **4** takes the same molecular packing stack model in a supramolecular structure to **3**.

3.2.5. $[ZnL^1I_2]_n$ (**5**) and $[CdL^1I_2]_n$ (**6**)

Both **5** and **6** pack into the same centrosymmetric space group *C2/c*. The X-ray structures show clearly that **5** (shown in Fig. 4a) and **6** (see Supplementary data S5) are one-dimensional architectures. Each metal atom is bound to two pyridyl N atoms and two iodide anions to attain a pseudo-tetrahedral coordination geometry with M–N distances of 2.059(9)–2.275(5) Å and M–I 2.5416(15)–2.6764(8) Å. The dihedral angles for the two coordination pyridyl rings about Zn1 and Cd1 are 86.3° and 89.1°, respectively. Coordination to the metal center forces serious twisting

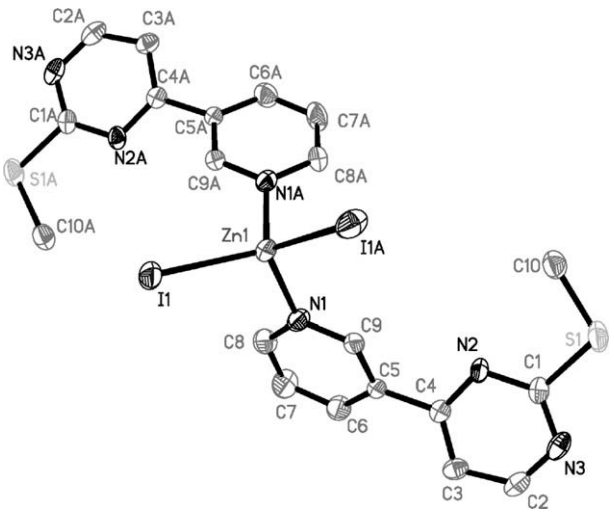

Fig. 4a. ORTEP diagrams (30% thermal probability) of the molecular structure of **5** with the atom-numbering scheme; hydrogen atoms are omitted for clarity.

between the pyridyl ring and the pyrimidyl unit with dihedral angles of 33.2° in **5** and 35.3° in **6**. Compared with the free ligand [17], the ligand in these complexes is much more contorted (see Fig. 4b).

In the crystal packing of **5** and **6**, there are effective face-to-face π···π interactions among the aromatic rings. In **5** the centroid–centroid distances of the π···π interactions are 3.389–3.445 Å. While in **6**, the centroid–centroid distances range from 3.389 to 3.483 Å.

Furthermore there are forces of van der Waals S···I contacts [S···I = 3.776 Å] among adjacent modules to build a supramolecular structure in **6** (see Supplementary data S6).

3.2.6. $\{\{[ZnL^1_2(H_2O)_4](ClO_4)_2\}_{0.5} \cdot L^1_{0.5} \cdot CH_3OH\}$ (**7**) and $\{\{[Cd_{0.5}L^1(H_2O)_2](ClO_4)\}_2 \cdot CH_3OH \cdot L^1\}$ (**8**)

Complexes **7** and **8** pack into the same centrosymmetric space group $P\bar{1}$ with similar crystal structures (molecular structure of **7** as the example shown in Fig. 5a). Two ligands and one metal ion, lattice methanol molecules and counter-anions as well as a free ligand are present in a symmetric unit of **7**. In these two complexes, the metal center is coordinated by four water molecules and two pyridyl N atoms from different ligands, adopting slightly distorted octahedral coordination geometry. Notedly different from the coordination model of L^1 in **5**–**6** or other complexes [17], L^1 is monodentate coordinated to a metal atom in **7**. Intermolecular face-to-face π···π contacts are observed between the heterocycle rings of the free ligand and the ligand binding to metal atom, although they are not strictly coplanar (mean plane angles between the corresponding heterocycle rings are 3.6° and 6.8° in **7**). The centroid–centroid distance of these π···π interactions are 3.754 and 3.787 Å in **7**.

It is also noted that hydrogen binding caused by free anions and methanol molecules with ligands or water molecules play important roles to connect with near molecules in **7** (shown in Fig. 5b).

It is found that L^1 in **7** or **8** only adopts a monodentate coordination pattern, while both L^1 and L^2 through nitrogen atoms from pyridyl rings adopt a *N, N′*-bidentate bridging coordination pattern to connect metal atoms in other complexes. This bidentate coordination fashion is similar to those of Hg(II) complexes with L^1 [17]. For complexes **1** and **2**, systematic variation in dimensionality may be due to the different size of metal atoms, indicating a metal-directed synthesis. Compared complexes **3** and **4** with complexes **1** and **2**, perchlorate anions probably play an important template role in the formation of macrocyclic complexes, indicating an anion-directed synthesis. Complexes resulted from L^1 and L^2 with different molecular structures prove that the role of ligands is much more important than other factors in the assembly process, minor modifications of the ligands will lead to conspicuous changes of the molecular structures of their metal complexes.

3.3. Thermogravimetric properties

Thermogravimetric analysis data for all complexes are given in Fig. 6. For complex **1**, a stable region is observed between RT and 198 °C, while it is between RT and 285 °C for complex **2**. The thermal model of complex **3** shows that the thermal decomposition takes place in two distinct stages. In the first stage, the weight loss corresponds to the loss of eight coordinated water molecules per

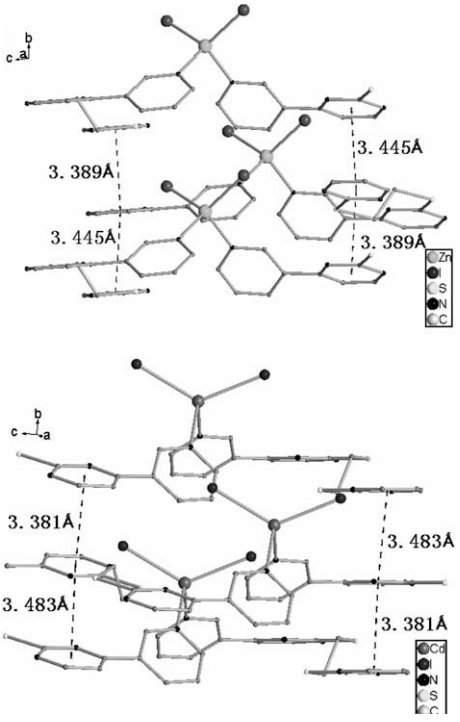

Fig. 4b. Perspective views of the π···π stacking interactions in **5** (top) and **6** (bottom).

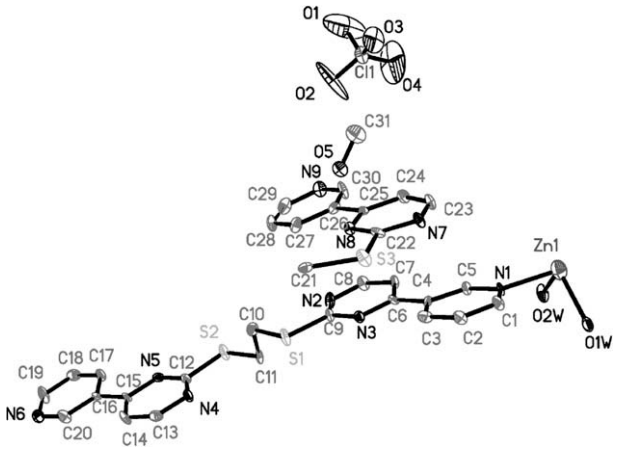

Fig. 5a. ORTEP diagrams (30% thermal probability) of the molecular structure of **7** with the atom-numbering scheme, hydrogen atoms are omitted for clarity.

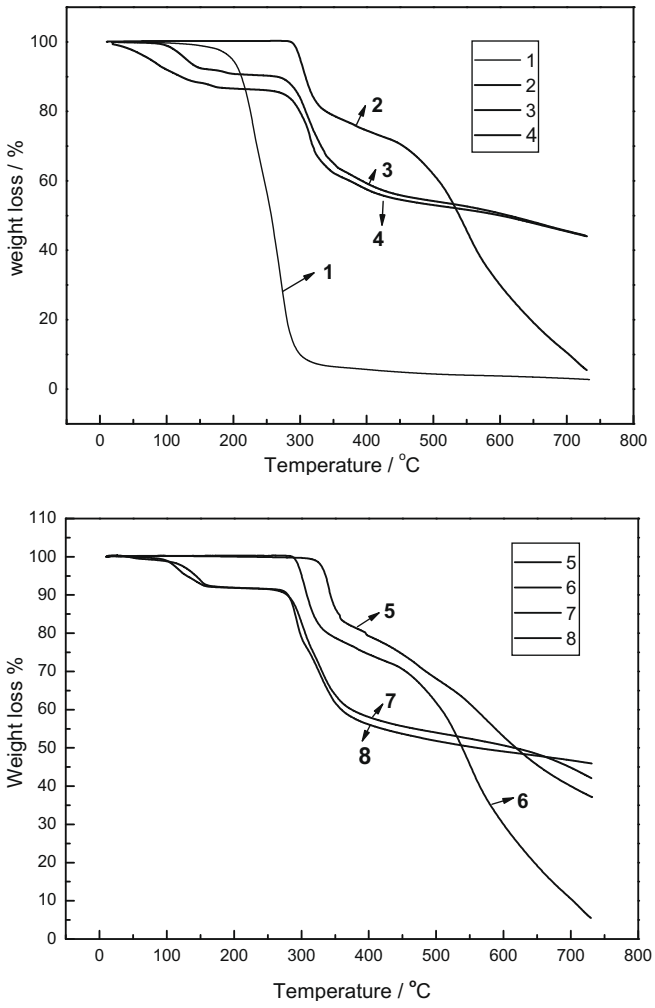

Fig. 6. *Top:* TGA curves of complexes **1**–**4**; *bottom:* TGA curves of complexes **5**–**8**. Heating rate: 20 °C min^{-1}.

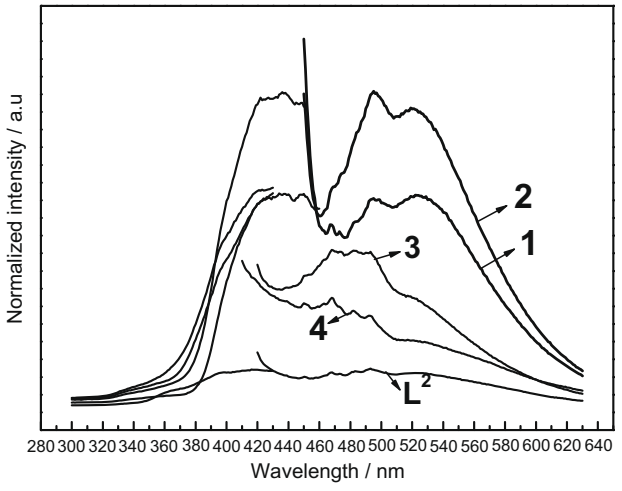

Fig. 7. Excitation and emission spectra of **1**, **2**, **3**, **4** and $\mathbf{L^2}$ in the solid state at room temperature.

formula between 25 and 230 °C. Then the complex begins to decompose. As for the decomposition of complex **4**, the weight loss attributed to the gradual release of eight-coordinated water molecules is observed between RT and 240 °C, then the decomposition happens. As for **5** and **6**, they are very stable in a temperature region between RT and 310 °C. For complexes **7** and **8**, the TGA curves show that the thermal decomposition takes place in two distinct stages. Thermal decompositions first occur to lose water molecules or free solvent molecules between 25 and 250 °C, then the subsequent decomposition starts.

3.4. Luminescence properties

The excitation and emission spectra of complexes **1**–**4**, and L^2 in the solid state at room temperature are shown in Fig. 7. These complexes exhibit intense blue fluorescence emission bands at ca. 494 and 521 nm for **1**, 495 and 520 nm for **2**, 468 and 493 nm for **3**, 467 and 493 nm for **4**, respectively, while weaker blue-fluorescent emission bands are observed at 467 and 493 nm for L^2, under the same conditions. These emissions are neither metal-to-ligand charge transfer nor ligand-to-metal charge transfer in nature, because Zn(II) or Cd(II) ions are difficultly oxidized or reduced due to their d^{10} configurations. These emissions are assigned to the intraligand $\pi\cdots\pi_*$ fluorescence emission since the corresponding ligand also shows a similar emission, i.e., they belong to ligand-to-ligand charge transfer (LLCT) [27,28]. Compared with those of L^2, the increase of emission occurred in complexes **1**–**4** may be ascribed to effective increase of the rigidity and asymmetry of the ligand due to its chelation to the metal atom, which reduces the loss of energy by radiationless decay process [29–32]. Furthermore in complexes **1**–**4** and the free ligand, existences of $\pi\cdots\pi$ interactions between the adjacent aromatic rings may be favorable for reduction of the energy of the $\pi\cdots\pi_*$ transition to some extent and thus help the luminescence [33]. However, complexes **5**–**8** and L^1 did not show any luminescence properties under the same conditions, this is probably due to the short alkyl chain of L^1, which leads to the weak $\pi\cdots\pi$ stacking interactions between neighboring molecules in the crystal structure. As a result, it is inferred that complexes **1** and **2** may be suitable as candidates for blue fluorescent materials.

4. Conclusion

In summary, eight novel complexes with different architectures were constructed from 1,3-bis (4-(pyridin-3-yl) pyrimidin-2-ylthio) propane (L^2) and 1,2-bis (4-(pyridin-3-yl) pyrimidin-2-ylthio) ethane (L^1). Although the difference of L^2 from L^1 lies in the length of alkyl chains, complexes derived from L^2 showed quite distinct coordination architectures and excellent fluorescent properties compared with those derived from L^1. The present study proves that a minor modification about the ligand can give rise to great changes not only in structures but also in properties. Meanwhile, geometric needs of metal atoms and anion effects also play important roles in the formation of the supramolecular architectures. In addition, complexes **1**–**4** exhibit blue fluorescence emissions, and complexes **1** and **2** may be suitable as candidates for potential photoactive materials.

2.2. Methods

2.2.1. Product analysis

HPLC was employed to detect the reaction products under the conditions used in the kinetic measurements (excess of Glc3Me over Cr^{VI}). The chromatograms were obtained on a KNK-500 A chromatograph provided with a 7125 HPLC pump. The separation was carried out on a Supelcogel C-610H HPLC column (300×7.8 mm, Bio-Rad Laboratories) using 0.1% P/V H_3PO_4 as eluent and a flow rate of 0.5 mL/min, at 30 °C. The effluent was monitored with refractive index (ERC-7522, ERMA INC) and UV (115 UV Gilson, $\lambda = 220$ nm) detectors. The $[H^+]$ of the reaction mixtures (Glc3Me:Cr^{VI} ratios of 25:1, 50:1 and 100:1) was adjusted to 0.2 mol/L by addition of 2 mol/L $HClO_4$ and then the samples were filtered through a 0.2 μm membrane prior to injection into the chromatographic system.

Standard samples of 2-methyl-D-arabinose (Ara2Me), 3-methyl-D-gluconic acid (Glc3MeA) – prepared following published procedures [19,20] – and formic acid were prepared individually and the chromatographic retention times determined separately.

Chromatograms of the reaction mixtures showed two peaks with retention times (t_R) of 13′ 44″ and 17′ 11″, in addition to the peak of unreacted Glc3Me at t_R = 11′ 55″. The retention times of the new peaks are coincident with those of the standard solutions of Ara2Me and formic acid, respectively. No peak corresponding to Glc3MeA was detected in the reaction mixture. Furthermore, co-chromatography of a Cr^{VI}/Glc3Me reaction mixture and Ara2Me or formic acid resulted in the increase of peaks at 13′ 44″ or 17′ 11″, respectively. Additionally, the presence of HCO_2H acid was confirmed through the $HgCl_2$ reaction [21].

For the Glc3Me to Cr^{VI} ratios used in the kinetic studies (higher than 50:1), carbon dioxide was never detected as a reaction product.

2.2.2. Glc3Me stability

The stability of Glc3Me under conditions used in the kinetic studies was checked by monitoring the optical rotation changes on a JENA polarimeter with thermostated 20-cm tubes using the sodium D line. Reactant solutions were previously thermostated and transferred into the cell immediately after mixing. The optical rotations were recorded at different times after the preparation of the solutions and were identical to that of freshly prepared Glc3Me solutions. The specific rotation of Glc3Me was found to be $[\alpha]^{33}_D = +54.1° \pm 0.5°$ ($c = 3.88$ g/100 mL, 1.0 M $HClO_4$, $t = 10$ min to 30 h), a value similar to that measured for Glc3Me in aqueous solution: $[\alpha]^{20}_D = +55.7° \pm 0.5°$ ($c = 4.51$ g/100 mL).

The stability of the Glc3Me at 33 °C was also confirmed by HPLC after incubation of the solutions at fixed $[H^+]$.

2.2.3. Polymerization test

Polymerization of acrylamide was investigated during the reaction of Glc3Me with Cr^{VI} as a test for free radical generation. Acrylamide (0.6 g) was added to a reaction mixture containing $K_2Cr_2O_7$ (3×10^{-3} mmol) and Glc3Me (0.3 mmol) in 2 mL of 0.5 mol/L $HClO_4$, at 33 °C. When the color of Cr^{VI} disappeared, 1 mL of the mixture was diluted with 1 mL of methanol and a white polymer precipitated. Control experiments showed that no polymerization of acrylamide takes place under the experimental conditions with either $HCrO_4^-$ or the Glc3Me alone. The possible reaction of Cr^V or Cr^{IV} with acrylamide was tested with $Na[Cr^VO(ehba)_2]$ and $Na_2[Cr^{IV}O(ehba)_2]$. No precipitation occurred on mixing the Cr^V or Cr^{IV} complexes with acrylamide under the same conditions as those used in the Cr^{VI} + Glc3Me reaction.

2.2.4. Spectrophotometric measurements

Kinetic measurements were performed by monitoring absorbance changes using a Jasco V-550 UV/VIS spectrophotometer with a fully thermostated cell compartment (±0.2 °C). The reactions were followed under pseudo-first-order conditions, at 33 °C, using at least a 50-fold molar excess of Glc3Me over Cr^{VI} and different $[HClO_4]$. Reactant solutions were previously thermostated at 33 °C and transferred into a 1-cm pathlength cell immediately after mixing.

The disappearance of Cr^{VI} was followed spectrophotometrically at 350 nm until at least 80% conversion. In the kinetic measurements, the initial concentration of Cr^{VI} and I were kept constant at 8.0×10^{-4} mol/L and 1.02 mol/L, respectively, while $[HClO_4]$ was varied from 0.15 to 1.02 mol/L, at various [Glc3Me].

The experimental pseudo-first-order rate constants (k_{exp}), determined from the absorbance versus time curves at 350 nm, were deduced from multiple determinations and were within ±5% of each other. The first-order dependence of the rate upon $[Cr^{VI}]$ was verified in a set of experiments where the $[Cr^{VI}]_0$ was varied between 4.0×10^{-4} and 8.0×10^{-4} mol/L but T, $[Glc3Me]_0$, $[H^+]$ and I were kept constant.

The formation of Cr^{III} was monitored by following changes in the 570 nm absorption band. In these experiments the $[Cr^{VI}]_0$ was kept constant at 8.0×10^{-3} mol/L, (Glc3Me:Cr^{VI} ratio of 50) and the $[H^+]$ was varied between 0.40 and 1.02 mol/L. Rate constants obtained at this wavelength are in agreement with those calculated from data at 350 nm for the same experimental conditions.

Cr(VI) esters were investigated by UV–Vis spectrophotometry in the 350–500 nm region in which chromate esters show characteristic absorption bands. Reactions were performed at pH 3.52, where the redox reaction is slow enough to enable the observation of the ester formation. The instrument was zeroed to an arrangement of the reference and sample beams passing through matched cuvettes, both containing 6×10^{-4} mol/L Cr^{VI} at pH 3.52. The solution in the sample cell was replaced with the reaction solution containing 6×10^{-4} mol/L Cr^{VI} and 0.30–0.60 mol/L Glc3Me at pH 3.52, I = 1.02 M, and T = 33 °C. Spectra obtained within 40 min after mixing revealed a distinctive absorption at 373 nm.

The possible formation of Cr^{II} was examined by UV–Vis spectrophotometry in the 200–500 nm region in which CrO_2^{2+} show characteristic absorption bands. This experiment was performed at 22 °C, by periodic scanning of solutions containing 0.21 mol/L Glc3Me, 0.049 mmol/L Cr^{VI} and 1.26 mmol/L O_2, in 0.84 mol/L $HClO_4$. Under these conditions, the Cr^{VI} absorption band at 350 nm decreased in intensity, while new peaks at 293 nm and 247 nm, characteristic of CrO_2^{2+} [22], grew in.

2.2.5. EPR measurements

The EPR spectra were obtained on a Bruker EMX spectrometer operating at X-band frequencies (9–10 GHz). The microwave frequency was generated with a Bruker 04 ER and measured with a Bruker EMX 048T frequency meter. The magnetic field was measured with a Bruker EMX 035M NMR-probe gaussmeter. Spectra were recorded as first derivatives of the microwave absorption in 1024 points at ambient temperature (20 ± 1 °C). g-Values were determined by reference to diphenylpicryhydrazyl radical ($g = 2.0036$) as an external standard. Reactions were carried out by mixing Glc3Me and $K_2Cr_2O_7$ (ratio 49:1, $[Cr^{VI}] = 0.025$ mol/L) in 0.3 and 0.5 mol/L $HClO_4$; and by addition of $Na[Cr^VO(ehba)_2]$ (1.0 mmol/L), or Na_2CrO_4 (1.0 mmol/L) + glutathione (1.0 mmol/L), to solutions of Glc3Me (100 mmol/L) in acetate buffer (0.1 mol/L, pH 5.5) or HEPES buffer (0.1 mol/L, pH 7.5). Stock solution of $Na[Cr^VO(ehba)_2]$ (0.1 mol/L) was prepared in *N*,*N*-dimethylformamide. All of the EPR spectra were simulated using the program PEST WINSIM [23], assuming 100% Lorentzian line shapes.

The spectral parameters for each Cr^{V} species were consistent within all simulation, with maximum deviations in the g_{iso} values being ±0.0001 units. In the simulations, values for ^{1}H superhyperfine coupling constant a_H were included only where the a_H value was greater than the LW (line width) of the Cr^{V} species, since the signal is not significantly affected where the a_H value is ⩽LW.

3. Results and discussion

3.1. Products of the reaction of Glc3Me with Cr^{VI}

Under conditions used in the kinetic studies, excess of Glc3Me over Cr^{VI} in acid medium, HCO_2H and Ar2Me were identified by HPLC as the oxidation products of Glc3Me, while EPR and UV–Vis spectroscopies showed that aqueous Cr^{III} was the final Cr species in the reaction mixture. Thus, the reaction of Glc3Me and Cr^{VI} can be written as in Scheme 1.

This result implies that, in this reaction, C1–C2 bond break prevails over C1–H cleavage. A fact that differentiates the reactivity of the 3-*O*-methyl derivative towards Cr^{VI} from glucose that yields the corresponding aldonic acid as the only reaction product [10].

3.2. Detection of an intermediate Cr^{VI}-ester

At pH 3.52, the redox reaction of Cr^{VI} with Glc3Me proceeds very slowly, with negligible reduction of Cr^{VI} in the first 40 min. Thus, at this pH, the ester formation can be distinguished clearly from the electron transfer reaction. Differential UV–Vis spectra of mixtures of Cr^{VI} and Glc3Me exhibit, immediately after mixing, a distinctive absorption band with λ_{max} = 373 nm consistent with that ascribed to Cr^{VI} oxo-esters [24] that can be assigned to Glc3Me–Cr^{VI} species. Continued scanning over 40 min showed no further change in the spectra. The absorbance of this band increased with the increasing concentration of Glc3Me when the [Glc3Me] was varied at pH 3.5 (Fig. 1), probably as a result of a shift toward the ester in the esterification equilibrium.

3.3. Intermediacy of Cr^{II}

Involvement of Cr^{II} in the mechanism of the oxidation of a number of alcohols, saccharides and hydroxyacids by Cr^{IV} and Cr^{VI} in $HClO_4$ has been demonstrated by conversion into CrO_2^{2+} upon reaction with molecular oxygen [22,25–27]. At high [O_2] and low [Cr^{VI}] the reaction of Cr^{II} with O_2 can compete successfully with the reaction of Cr^{II} with Cr^{VI} and the autocatalytic consumption of CrO_2^{2+} by Cr^{II}, and if formed, Cr^{II} should yield the CrO_2^{2+} product [25,26,28,29]. We examined the presence of intermediate Cr^{II} in the reaction of Glc3Me with Cr^{VI}, by monitoring the formation of CrO_2^{2+}, using $[Cr^{VI}]_0$ low enough to avoid the Cr^{VI} + Cr^{II} competitive reaction. A periodic scanning of the O_2-saturated solution (1.26×10^{-3} mol/L O_2) of a Cr^{VI} + Glc3Me reaction mixture in 0.84 mol/L $HClO_4$ over a period of 3 h, showed that the band at 350 nm, characteristic of Cr^{VI}, decreased in intensity while two absorption bands at λ_{max} = 247 and 293 nm appeared (Fig. 2). These two bands are characteristic of CrO_2^{2+} formed as a long-lived intermediate [22] that then slowly transforms into the final Cr^{III}. Since

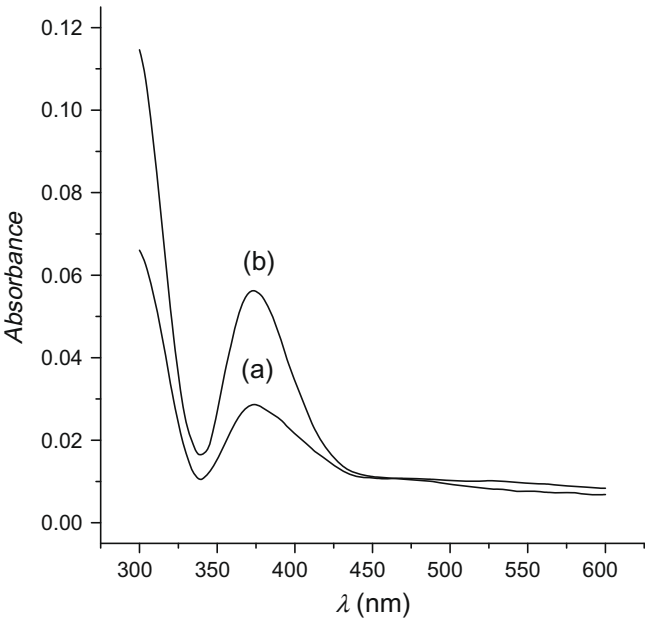

Fig. 1. UV–Vis difference spectra of Glc3Me/Cr^{VI} solutions at pH 3.52, showing the increasing band at 373 nm with increasing [Glc3Me]: (a) 0.30 and (b) 0.60 mol/L. $[Cr^{VI}] = 6.0 \times 10^{-4}$ mol/L, I = 1.02 mol/L, T = 33 °C. Spectra taken 30 min after preparation of the reaction mixture.

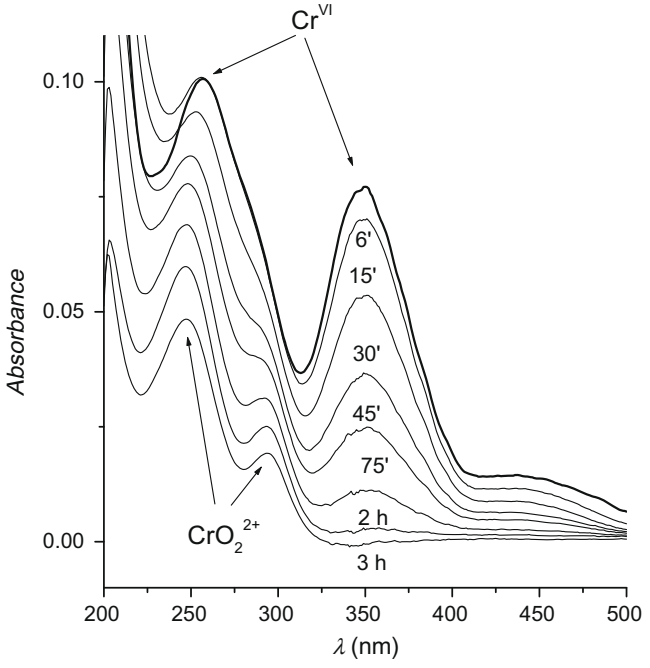

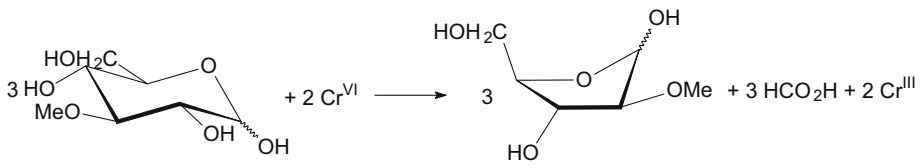

Fig. 2. Formation of CrO_2^{2+} (λ_{max} 293, 247) from the reaction between 0.21 mol/L Glc3Me, 1.26 mmol/L O_2 and 4.9×10^{-2} mmol/L Cr^{VI}, in 0.84 mol/L $HClO_4$. T = 22 °C.

Scheme 1.

CrO_2^{2+} can be exclusively formed by reaction of Cr^{II} with O_2, and, in turn, Cr^{II} had previously been demonstrated to form exclusively through two-electron reduction of Cr^{IV} [26,28], our spectroscopic results provide evidence that Cr^{II} and Cr^{IV} are involved in the redox mechanism of the reaction between Cr^{VI} and Glc3Me.

3.4. Detection of intermediate Cr^V

The most common means of detecting Cr^V complexes in solution is EPR spectroscopy, where strong isotropic signals are observed at room temperature in X-band spectra. The reduction of Cr^V by Glc3Me is $[H^+]$ dependent, and at the high $[H^+]$ used in the kinetic measurements, Cr^V–Glc3Me redox processes are fast and, consequently, high modulation amplitude is required to observe Cr^V. With a modulation amplitude of 4 G, the EPR spectra of solutions from the reaction between Cr^{VI} and 50-times excess of Glc3Me in 0.3–0.5 mol/L $HClO_4$, consisted of two signals: a major one centered at g_{iso1} 1.9788, and an additional weak signal at g_{iso2} 1.9712 (Fig. 3) with relative intensity ⩽10% of the main signal. The high modulation amplitude used to observe Cr^V species at this $[H^+]$, disabled the resolution of the signal superhyperfine (shf) pattern (the ^1H shf splitting (a_H) for Cr^V–alcoholato species is usually <1 G [4,9]). Given that the g values of Cr^V species are very sensitive to the co-ordination number and the nature of the donor groups bound to Cr^V [4,9,30], an estimation of the intermediate Cr^V species formed in the reaction of Cr^{VI} with Glc3Me was made based on g_{iso} values of the EPR signals. The g_{iso} value of 1.9788 is typical of five-coordinate oxochromate(V) complexes formed with *O*-donor ligands, while the value of 1.9712 is typical of a six-co-ordinate oxo-Cr^V complex with two alcoholato donor sites and three water molecules, and can be assigned to $[Cr(O)(O^1,O^2\text{-Glc3Me})(H_2O)_3]^+$ (**I**, Fig. 4) [4,9,30]. The positive charge of this species is also consistent with its appearance at high $[H^+]$ and it is possibly responsible for the higher rates observed for the Cr^V–Glc3Me redox reactions at pH < 1.

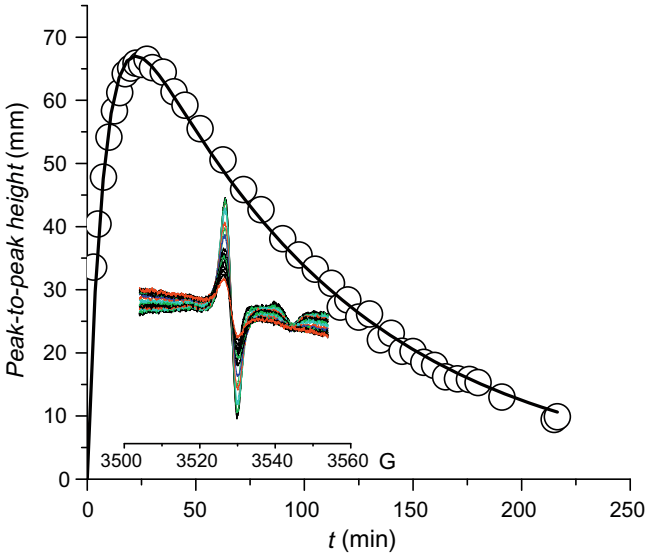

Fig. 3. Peak-to-peak heights of Cr^V EPR signals *vs.* time. $[Cr^{VI}] = 0.025$ mol/L, [Glc3Me] = 1.225 mol/L, $[H^+] = 0.3$ mol/L, $I = 1.02$ mol/L, $T = 20$ °C. Inset: time evolution of X-band EPR spectra from the reaction mixture in 0.3 mol/L $HClO_4$. $\nu = 9.766887$, mod. ampl. = 4 G.

At pH > 3 the redox reaction between Cr^V with Glc3Me becomes slow, Cr^V species remain in solution for longer periods of time and the shf pattern of the Cr^V EPR signals can be resolved using a modulation amplitude lower than the ^1H shf splitting. With this in mind, Cr^V–Glc3Me complexes formed upon addition of 100-times molar excess of Glc3Me to Cr^V generated in either the one-electron reduction of Cr^{VI} by glutathione or the ligand-exchange reaction of $[Cr^VO(ehba)_2]$ were investigated in the 5.5–7.5 pH range by EPR spectroscopy. The Cr^V EPR signals are more intense at pH 5.5 than at pH 7.5, probably because Cr^V disproportionation is slower at the lower pH [31]. In this pH range, the EPR spectra taken at the beginning of the reaction were dominated by a triplet at g_{iso1} 1.9792 ($a_H = 1.0 \times 10^{-4}$ cm^{-1}), with a minor component at g_{iso2} 1.9794 (quintet, $a_H = 0.9 \times 10^{-4}$ cm^{-1}). Fifteen minutes after mixing, the two components at g_{iso1} and g_{iso2} were present in 71% and 29%,

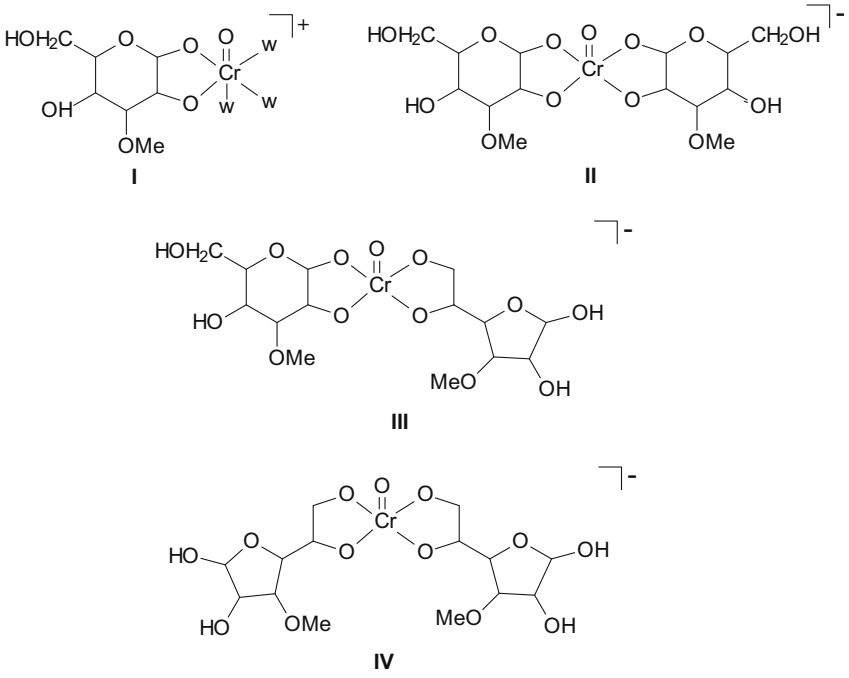

Fig. 4. Structures of Cr^V complexes formed with Glc3Me.

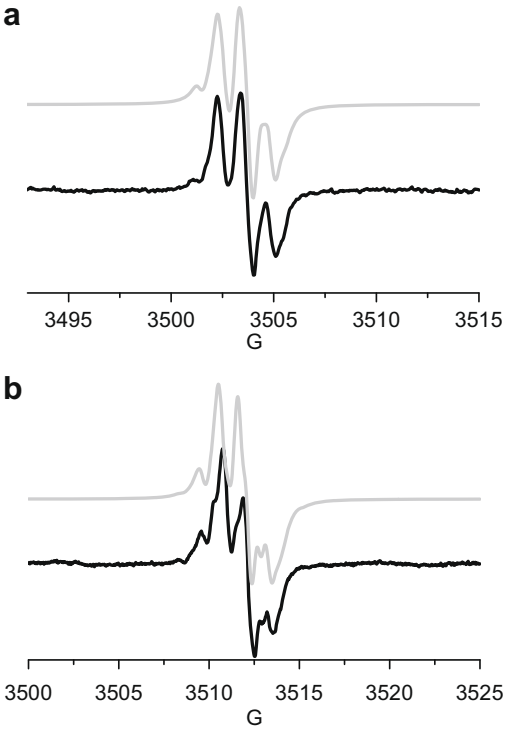

Fig. 5. Experimental (——) and simulated (——) X-band EPR spectra from mixtures of 1 mmol/L glutathione + 1mmol/L Cr^{VI} and 100 mmol/L Glc3Me, pH 5.5; taken (a) 15 min (ν = 9.705912 GHz) and (b) 1 h (ν = 9.728655) after mixing. Mod. ampl. = 0.2 G. T = 20 °C.

respectively (Fig. 5a). It is known that the EPR spectrum of a Cr^{V}-diolato species of six-membered ring *cis*-diols yields a doublet, since only one proton is in the plane of the unpaired electron density of the Cr^{V} ion. Consequently, the EPR spectral multiplicity of bis-chelate Cr^{V}-diolato$_2$ species formed between Cr^{V} and pyranosic *cis*-diols exhibit a triplet with two (one from each chelate ring) carbinolic protons coupled to the Cr^{V} electronic spin. In the present case, the major component of the EPR signal can be attributed to the bis-chelate [Cr(O)(*cis*-O^1,O^2-Glc3Me)$_2$] (**II**, Fig. 4). This result is in line with the reported higher ability of the *cis*- versus the *trans*-diolato for binding Cr^{V} [4,9,32]. The minor component at g_{iso2} 1.9794 can be attributed to the bis-chelate formed with the pyranose and furanose forms of Glc3Me: [Cr(O)(*cis*-O^1,O^2-Glc3Me)(O^5,O^6-Glc3Me-furanose)] (**III**, Fig. 4), with four protons coupled to the electronic spin of Cr^{V}. The assignment of the minor component to [Cr(O)(*cis*-O^1,O^2-Glc3Me-furanose)$_2$] was disregarded based on the a_H values – a_H values expected for Cr^{V}-diolato$_2$ species of five-membered ring *cis*-diols are lower than found here [33,34]. With time, the EPR spectral pattern slowly changed, the proportion of the components varied and a third component appeared. The EPR spectrum taken 1 h after mixing, shown in Fig. 5b, could be deconvoluted into a triplet at g_{iso1} 1.9792 ($a_H = 1.0 \times 10^{-4}$ cm^{-1}), a quintet at g_{iso2} 1.9794 ($a_H = 0.9 \times 10^{-4}$ cm^{-1}) and a septuplet at g_{iso3} 1.9793 ($a_H = 1.0 \times 10^{-4}$ cm^{-1}), in 6:3:1 ratio. Other minor species were also present, but they were not included in the simulations to avoid over-parameterization. Based on the shf coupling, the three components could correspond to [Cr(O)(*cis*-O^1,O^2Glc3Me)$_2$] (**II**), [Cr(O)(*cis*-O^1,O^2-Glc3Me)(O^5,O^6-Glc3Me-furanose)] (**III**) and [Cr(O)(O^5,O^6-Glc3Me-furanose)$_2$] (**IV**) (Fig. 4). At longer times, the proportion of the species at g_{iso1} decreased and the spectra were dominated by species at g_{iso2} and g_{iso3}. These five-coordinate Cr^{V} bis-chelates were still observed 15 h after mixing. Thus, initially, Cr^{V} bis-chelate is formed with Cr^{V} bound to the 1,2-*cis*-diolato moiety of the pyranose form of Glc3Me (kinetic control); but, with time, it transforms into bis-chelates with Cr^{V} bound to the 5,6-*vic*-diolato moiety of the furanose form of the ligand.

3.5. Rate studies

The kinetics of the reaction of Glc3Me with Cr^{VI} was examined by monitoring the [Cr^{VI}] consumption under conditions of excess of Glc3Me over Cr^{VI}, in the 0.15–1.02 mol/L $HClO_4$ range. UV–Vis spectra of the reaction mixtures showed an absorbance band at 350 nm and a shoulder at 420–500 nm, characteristic of Cr^{VI} in acidic medium. At 350 nm, the absorbance versus time curves exhibited a monotonic decrease and the rate constants were calculated from the absorbance changes at this wavelength. As stated before, Cr^{V} species are formed in the chromic oxidation of Glc3Me, and it is known that these species absorb at 350 nm and may superimpose Cr^{VI} absorbance [35]. However, if Cr^{V} reacts faster than Cr^{VI} and exists in solution in a sufficiently small concentration, changes in absorbance at 350 nm essentially reflect changes in Cr^{VI} concentration. The relative values of the Cr^{VI} versus Cr^{V} reduction rate constants obtained from the Cr^{V} EPR signal intensity variation during the reaction course demonstrated this is the case for the reaction studied here (discussed below).

The kinetic profiles at 350 nm could be adequately described by a single exponential decay from which Cr^{VI} pseudo-first order rate constants (k_{exp}) were calculated. Table 1 summarizes values of k_{exp} for various concentrations of Glc3Me and $HClO_4$. Plots of k_{exp} versus [Glc3Me] at constant [H^+] gave good straight lines (Fig. 6) from which values of k_h were determined (Table 1, right). Values of k_h showed quadratic dependence on [H^+] (Fig. 6, inset), and the rate constant k_6, calculated by non-linear least-square fit of {k_h, [H^+]} data pairs, was found to be $(6.35 \pm 0.02) \times 10^{-4}$ mol^{-3} L^3 s^{-1}. Consequently, the complete rate law for the Cr^{VI} consumption can be expressed as in Eq. (1):

$$-d[Cr^{VI}]/dt = k_6[H^+]^2[Glc3Me][Cr^{VI}]. \quad (1)$$

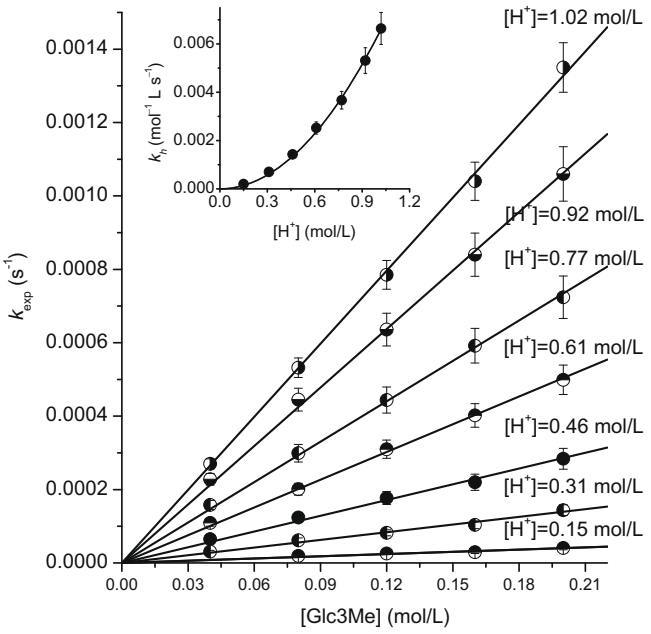

Fig. 6. Effect of [Glc3Me] on k_{exp} at 33 °C, I = 1.02 mol/L, λ = 350 nm and different [H$^+$]. Inset: dependence of k_h on [H$^+$].

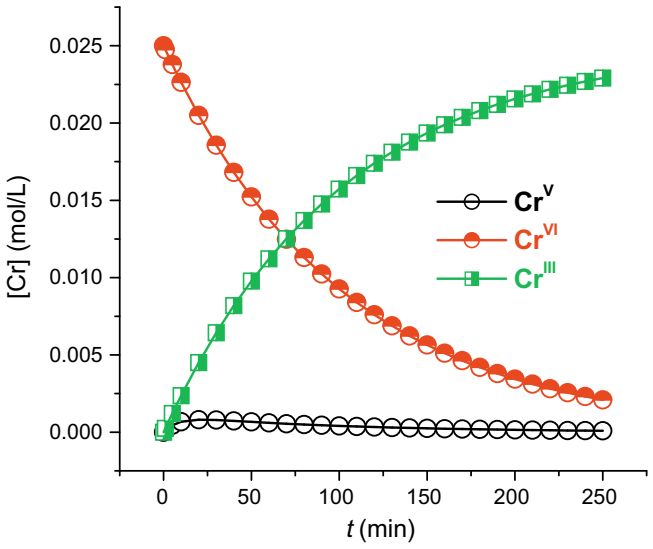

Fig. 7. Simulated kinetic profiles for Cr species. [Cr] calculated using k_a = 0.00496 min^{-1} and k_b = 0.1224 min^{-1} obtained from EPR data in 0.3 mol/L $HClO_4$. [Cr]$_T$ = 0.025 mol/L.

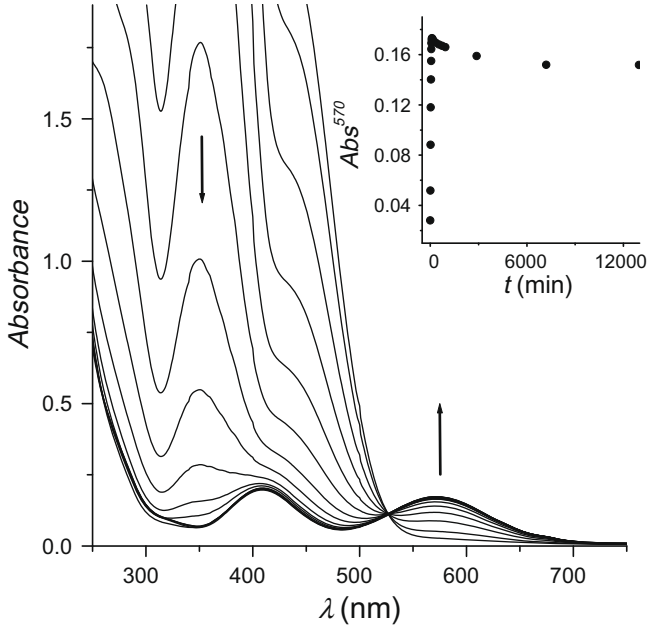
The kinetic results were independently confirmed by following the redox reaction by EPR spectroscopy. Fig. 3 shows a typical curve for the growth and decay of the Cr^V EPR signal peak-to-peak height as a function of time. The kinetic profiles could be adequately fitted with the rate expression derived from a two-step reaction sequence involving two consecutive first-order reactions (Scheme 2 and Eq. (2)) [11,36]:

$$EPR_{area} = Ak_a\{\exp(-2k_at) - \exp(-k_bt)\}/(k_b - 2k_a), \quad (2)$$

where A depends on the spectrometer settings, and k_a and k_b refer to the rate of disappearance of Cr^{VI} and Cr^V, respectively, and were evaluated from a non-linear least-squares fit of Eq. (2). In the 0.3 to 0.5 mol/L $HClO_4$ range, the calculated values of k_a were more than ten-times lower than k_b. For conditions in Fig. 3, k_a = 0.00496 min^{-1} and k_b = 0.1224 min^{-1}. The fact that $k_b > k_a$ implies that the slow redox step involves the reduction of Cr^{VI}. The simulation of the kinetic profiles employing k_a and k_b values obtained from EPR data in 0.3 mol/L $HClO_4$ (Fig. 7), shows that the maximal [Cr^V] represents 3% of the total Cr in solution. These results confirm that [Cr^V] is low throughout the reaction and should not interfere absorbance at 350 nm, which essentially reflects changes in [Cr^{VI}]. Rate constants calculated by this technique were consistent with those obtained from the spectrophotometric measurements at 350 nm, under the same experimental conditions. For 1.225 mol/L Glc3Me and 0.3 mol/L $HClO_4$, the value determined spectrophotometrically for k_{exp} was 1.90×10^{-4} s^{-1}, that compares well with $2k_a = 1.65 \times 10^{-4}$ s^{-1} obtained from EPR measurements.

Sequential absorption spectra of the reaction mixture showed the appearance and growth of two d–d bands at λ_{max} = 409 and 572 nm (Fig. 8). Kinetics traces at 570 nm showed that at this wavelength, the absorbance grew to intensities higher than expected for the free Cr^{3+} and then slowly decayed to the value corresponding to $[Cr(H_2O)_6]^{3+}$ (409 nm, ε = 17.7 mol^{-1} L cm^{-1} and 572 nm, ε = 15.2 mol^{-1} L cm^{-1}) [37], as shown in the inset of Fig. 8. This behavior suggests the formation of an intermediate Cr^{III}–Glc3Me complex, which then hydrolyzes to the final product [30,38]. EPR spectra taken at the end of the reaction confirm that Cr^{3+} is the final Cr species in the reaction of Cr^{VI} with excess Glc3Me in acid medium.

In order to determine the rate of Cr^{III} formation relative to that of the Cr^{VI} consumption, the formation of Cr^{III} was followed at 570 nm, in the presence of excess of Glc3Me in the 0.40–1.02 mol/L $HClO_4$ concentration range. Under these conditions, the first order dependence of the rate upon [Cr^{VI}] was verified. For [Glc3Me]$_0$ = 0.4 mol/L, values of k_{exp} calculated at this wavelength



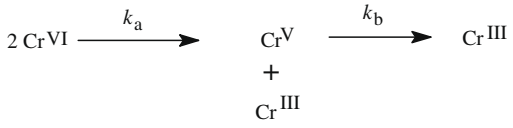


Fig. 8. Time evolution of the UV–Vis spectra of a mixture of 0.4 mol/L Glc3Me and 0.01 mol/L Cr^{VI} over a period of 16 h. [$HClO_4$] = 1.02 mol/L, T = 33 °C. Inset: growth and slow decay of Abs^{570} over a period of 9 days.

Scheme 2.

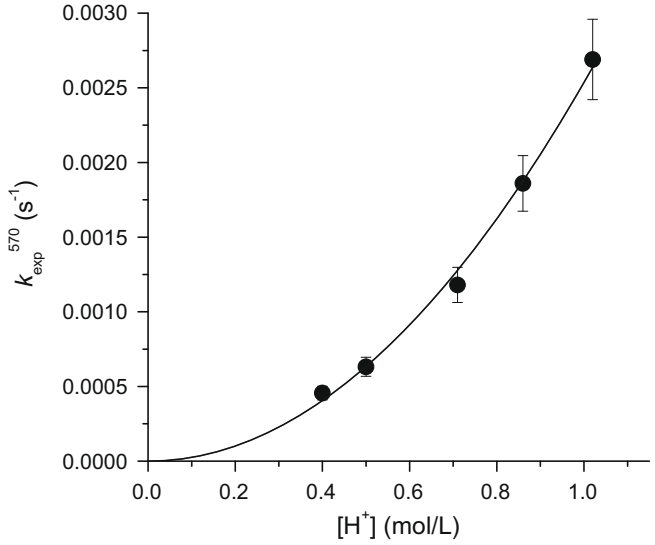

Fig. 9. Effect of acidity on k_{exp} calculated from absorbance data at 570 nm. $[Cr^{VI}] = 8 \times 10^{-3}$ mol/L, [Glc3Me] = 0.4 mol/L, I = 1.02 mol/L, T = 33 °C.

were plotted against $[H^+]$ (Fig. 9). The rate constant calculated by non-linear least-square fit of $\{k_{exp}, [H^+]\}$ data pairs was found to be 25.4×10^{-4} mol^{-2} L^2 s^{-1}, which is the same as that calculated from data at 350 nm. This indicates that the rate of formation of Cr^{III} equals the rate of consumption of Cr^{VI} and that the slow redox path effectively implies the reduction of Cr^{VI}, which should react slower than Cr^V does. This is also consistent with the observation of an isosbestic point at 527 nm (Fig. 8) and implies a low Cr^V concentration throughout the reaction in the $[H^+]$ range used in the kinetics studies.

3.6. Mechanism of the Glc3Me + Cr^{VI} reaction

In the range of substrate and acid concentration used in the kinetics measurements, the oxidation of Glc3Me by Cr^{VI} is a complex reaction that yields Cr^{III}, HCO_2H and Ara2Me as final redox products. The fact that CrO_2^{2+} is detected in the reaction of Glc3Me with Cr^{VI} together with the observation of Cr^V species and the successful trap of organic radicals using acrylamide indicates that the reaction occurs through both one- and two-electron pathways involving Cr^{IV} and Cr^V intermediate species. However, under conditions used in the kinetic measurements, Cr^{IV} and Cr^V react with Glc3Me faster than Cr^{VI} and do not accumulate in the reaction mixture. Therefore, Cr^{IV} and Cr^V, although formed in the Cr^{VI} + Glc3Me, should be involved in fast steps of the reaction pathway. Thus, the absorbance-time profiles reflect the $[Cr^{VI}]$ monotonic decay (at 350 nm) or the $[Cr^{III}]$ monotonic growth (at 570 nm) without interference of $[Cr^{IV}]$ or $[Cr^V]$. In Scheme 3, we propose a mechanism that combines $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{II}$ and $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{III}$ pathways, and takes into account: (a) kinetic results, (b) the polymerization of acrylamide added to the reaction mixture, (c) detection of intermediate of Cr^{VI} esters and oxochromate(V) species, (d) observation of CrO_2^{2+} and (e) the reaction products.

The first step of the mechanism proposed in Scheme 3 involves the formation of a Glc3Me–Cr^{VI} mono-chelate (Eq. 3), in agreement with the observation of the absorption band at 373 nm characteristic of chromate oxo-ester, immediately after mixing Glc3Me and Cr^{VI} under conditions where the redox reaction is extremely slow. Therefore, such a chromate ester should be formed rapidly prior to the redox steps. The formation of the chromate ester is followed by the slow redox step where the C–C bond cleavage is proposed to occur through an acid catalyzed two-electron redox process to

$$\text{Glc3Me} + Cr^{VI} \underset{}{\overset{\text{fast}}{\rightleftharpoons}} \text{Glc3Me-}Cr^{VI} \quad (3)$$

$$\text{Glc3Me-}Cr^{VI} \xrightarrow{k_6,\ 2\,H^+} Cr^{IV} + HCO_2H + \text{Ara2Me} \quad (4)$$

$$Cr^{IV} + \text{Glc3Me} \xrightarrow{\text{fast}} Cr^{III} + HCO_2H + \text{Glc3Me}^{\bullet} \quad (5)$$

$$Cr^{IV} + \text{Glc3Me} \xrightarrow{\text{fast}} Cr^{II} + HCO_2H + \text{Ara2Me} \quad (6)$$

$$Cr^{II} + Cr^{VI} \xrightarrow{\text{fast}} Cr^{V} + Cr^{III} \quad (7)$$

$$Cr^{VI} + \text{Glc3Me}^{\bullet} \xrightarrow{\text{fast}} Cr^{V} + \text{Ara2Me} + HCO_2H \quad (8)$$

$$\text{Glc3Me} + Cr^{V} \xrightarrow{\text{fast } (k_b)} Cr^{III} + HCO_2H + \text{Ara2Me} \quad (9)$$

$$Cr^{II} + O_2 \xrightarrow{\text{fast}} CrO_2^{2+} \longrightarrow Cr^{III} \quad (10)$$

$$O_2 + \text{Glc3Me}^{\bullet} \xrightarrow{\text{fast}} \text{Glc3Me}_{ox} \quad (11)$$

Scheme 3.

yield Cr^{IV}, HCO_2H and Ara2Me (Eq. 4). The initial two-electron reduction of Cr^{VI} by Glc3Me is in agreement with previous reports on a number of oxygenated compounds that were selectively oxidized by Cr^{VI} to the lower homolog [30,35]. In the mechanism, we have included two competitive one- and two-electron reductions of Cr^{IV} by Glc3Me. Thus, Cr^{IV} is proposed to react with excess Glc3Me to yield Cr^{III}, HCO_2H and Glc3Me$^{\bullet}$, or Cr^{II}, HCO_2H and Ara2Me, through two alternate fast steps (Eqs. 5 and 6). The first is supported by the observed polymerization of acrylamide when it is added to the Cr^{VI}/Glc3Me reaction mixture, while the second, by the observation of CrO_2^{2+} (the product of the reaction of Cr^{II} with O_2). Cr^V can form by fast reaction of Cr^{II} with Cr^{VI} (Eq. 7) and, alternatively, by rapid reaction of the Glc3Me$^{\bullet}$ with Cr^{VI} (Eq. 8). Cr^V can further oxidize Glc3Me to yield Cr^{III}, HCO_2H and Ara2Me as final redox products (Eq. 9). In the mechanism, one half of the Cr^{VI} reaches Cr^{III} through the Cr^V intermediate, in accordance with Scheme 2 used to fit the time evolution of the Cr^V EPR signal.

In O_2-saturated solutions (1.26 mmol/L) and $[Cr^{VI}]_0 < 0.1$ mmol/L, reactions 7 and 8 can be neglected because Glc3Me$^{\bullet}$ and Cr^{II} intermediates formed in reactions 5 and 6 should be rapidly trapped by O_2 (reactions 10 and 11) [39]. The proposed mechanism is in accordance with the observation that O_2 has not kinetic effect on this reaction, because when $[Cr^{VI}]_0 \geqslant 0.5$ mmol/L (as employed in the kinetic measurements), both Cr^{II} and Glc3Me$^{\bullet}$ react with Cr^{VI} faster than they do with O_2, and reactions 10 and 11 can be neglected [27,40,41].

4. Conclusion

The reaction of Glc3Me with Cr^{VI} strongly depends on pH. In acid medium, redox reaction occurs and reactive Cr^V, Cr^{II} and Cr^{IV} intermediate species are generated in the redox process, together with free radicals, HCO_2H and Ara2Me. At pH > 3, Glc3Me oxidation by Cr^{VI} or Cr^V is very slow and long-lived oxo-Cr^{VI} or oxo-Cr^V–Glc3Me species form. EPR spectroscopy shows that at pH 5.5–7.5 Glc3Me is able to trap Cr^V through the 1,2-diolato moiety to yield

a Cr^V bis-chelate that then slowly converts into species with Cr^V bound to the 5,6-diolato moiety of its furanose form. The selective C1–C2 bond cleavage of Glc3Me upon reaction with high valent chromium in acid medium, distinguishes the 3-OMe derivative from glucose that, under the same experimental conditions, is oxidized to the gluconic acid at comparable rate [10].

Acknowledgments

We thank the National Research Council of Argentina (CONICET), the National University of Rosario (UNR), the National Agency for Sciences Promotion (FONCyT) and the ALFA Program (CROCON Network, Project ALR/B7-30.11/94-7.0064.9) for financial support. MIF thanks V. Andreu for helping with the kinetic measurements.

2.2. ESI-MS

Mass spectral data were acquired on a LCQ Deca ion trap mass spectrometer from ThermoFinnigan (San Jose, CA, USA) equipped with an electrospray ionization (ESI) interface operated in the positive and negative ion modes, mass range 150–2000. Stock samples were prepared in CH_3OH or DMSO, further diluted to a concentration of about 0.05 mg/mL in CH_3CN, CH_3OH or water, and directly injected. Infusion into the mass spectrometer was performed by the built-in syringe pump at a flow rate of 5 μL/min. Nitrogen was used as the auxiliary and sheath gas. Helium was used as the collision gas in the ion trap. The sheath gas flow was set at 85 and the auxiliary gas flow at 30 (arbitrary units). The spray voltage was set at 4.5 kV, while the capillary temperature was 250 °C and the capillary voltage 17 V. Full mass spectra were acquired over the mass range *m/z* 150–2000. Additional solvent cluster studies were performed by varying the capillary voltage (10 V) and temperature (250 °C). For MS/MS investigations, characteristic molecular ions were isolated in the ion trap and collisionally activated with different collision energies (CE) to find the optimal CE for a distinct fragmentation. Product ions in the MS/MS spectra were chosen to perform further MS^3 and MS^4 experiments, relevant to the confirmation of investigated compounds.

2.3. Synthesis

2.3.1. Preparation of ligand *1*

Synthesis of the ligand 1-(*p*-toluenesulfonyl)cytosine (**1**) was performed according to the procedure reported by Kašnar-Šamprec et al. [11]. 1-(*p*-Toluenesulfonyl)cytosine (**1**) had been synthesized previously by the reaction of silylated cytosine and *p*-toluenesulfonyl chloride in acetonitrile, according to Scheme 1. The phenyl-proton (Ph) assignments were confirmed by carbon-proton connectivity in $^1H/^{13}C$ heteronuclear correlation spectra (HETCOR). Additionally, in the NOESY spectrum of **1**, the assignment of Ph-c protons was proved by their interaction with methyl-protons. IR (KBr) ν_{max}/cm^{-1}: 3369 (m), 3100 (m), 3074(m), 1703 (m), 1673 (s), 1524 (s), 1489 (m), 1376 (m), 1353 (m), 1285 (m), 1236 (w), 1184 (m), 1173 (s), 1138 (w), 1116 (m), 1088 (m), 1023 (w), 967 (m), 806 (w), 765 (m), 707 (m), 689 (m), 657 (w), 602 (w), 585 (w), 555 (m), 542 (m); ^1H NMR (DMSO–d_6) δ/ppm: 8.14 (d, 1H, $J_{6,5}$ = 7.8 Hz, H-6), 7.95 (brs, 2H, NH_2), 7.87 (d, 2H, $J_{b,c}$ = 8.1 Hz, Ph-b), 7.46 (d, 2H, $J_{c,b}$ = 8.1 Hz, Ph-c), 5.98 (d, 1H, $J_{5,6}$ = 7.8 Hz, H-5), 2.42 (s, 3H, CH_3); ^{13}C NMR (DMSO–d_6) δ/ppm: 166.27 (s, C-4), 151.22 (s, C-2), 145.61 (s, Ph-d), 139.73 (d, C-6), 134.47 (s, Ph-a), 129.80 (d, Ph-c), 129.02 (d, Ph-b), 97.50 (d, C-5), 21.20 (q, CH_3); MS (EI) exact mass calculated for $C_{11}H_{11}N_3O_3S$: *m/e* 265.051565 ($[M]^+$), found: 265.040053.

2.3.2. Preparation of the complex Pd(1-TosC–N3)$_2$Cl$_2$ (*2*)

To a solution of 1-(*p*-toluenesulfonyl)cytosine (**1**) (0.1061 g, 0.4 mmol) in methanol (9 mL), K_2PdCl_4 (0.0653 g, 0.2 mmol) was added. The reaction mixture was stirred and refluxed for 2 h. The red suspension was cooled to room temperature and a pale yellow solid product was filtered off, washed with methanol and dried over vacuo to give 102 mg (76%) of a pale yellow powder **2**: IR (KBr) ν_{max}/cm^{-1}: 3406 (s), 3313 (s), 3288 (s), 3247 (m), 3207 (m), 3107 (m), 3067 (m), 1686 (s), 1650 (s, br), 1613 (s), 1609 (s), 1514 (s), 1503 (s), 1380 (s), 1363 (s), 1276 (s), 1252 (m), 1191 (s), 1171 (s), 1145 (m), 1122 (m), 1107 (m), 1084 (s), 1045 (s), 1017 (m), 974 (m), 815 (m), 792 (s), 766 (s), 706 (s), 695 (s), 673 (s), 613 (s), 590 (s), 552 (s), 541 (s), 480 (m), 361 (m). *Anal.* Calc. for $C_{22}H_{22}Cl_2N_6O_6PdS_2$ xH_2O (M_r = 725.91): C, 36.40; H, 3.33; N, 11.58; S, 8.83. Found: C, 36.05; H, 2.93; N, 11.55; S, 8.54%.

2.3.3. Complex *2* in DMSO-d_6 solution

The first set of signals (marked o in Fig. 4): ^1H NMR (DMSO–d_6) δ/ppm: 8.10 (d, 1H, $J_{6,5}$ = 8.0 Hz, H-6), 7.88 (d, 2H, J = 8.7 Hz, NH_2), 7.84 (d, 2H, $J_{b,c}$ = 8.1 Hz, Ph-b), 7.44 (d, 2H, $J_{c,b}$ = 8.0 Hz, Ph-c), 5.94 (d, 1H, $J_{5,6}$ = 7.9 Hz, H-5), 2.41 (s, 3H, Ph–CH_3); ^{13}C NMR (DMSO–d_6) δ/ppm: 165.90 (s, C-4), 150.87 (s, C-2), 145.28 (s, Ph-d), 139.41 (d, C-6), 134.19 (s, Ph-a,), 129.51 (d, Ph-c), 128.72 (d, Ph-b), 97.25 (d, C-5), 21.11 (q, Ph–CH_3).

Scheme 1. Synthesis of 1-(*p*-toluenesulfonyl)cytosine (**1**).

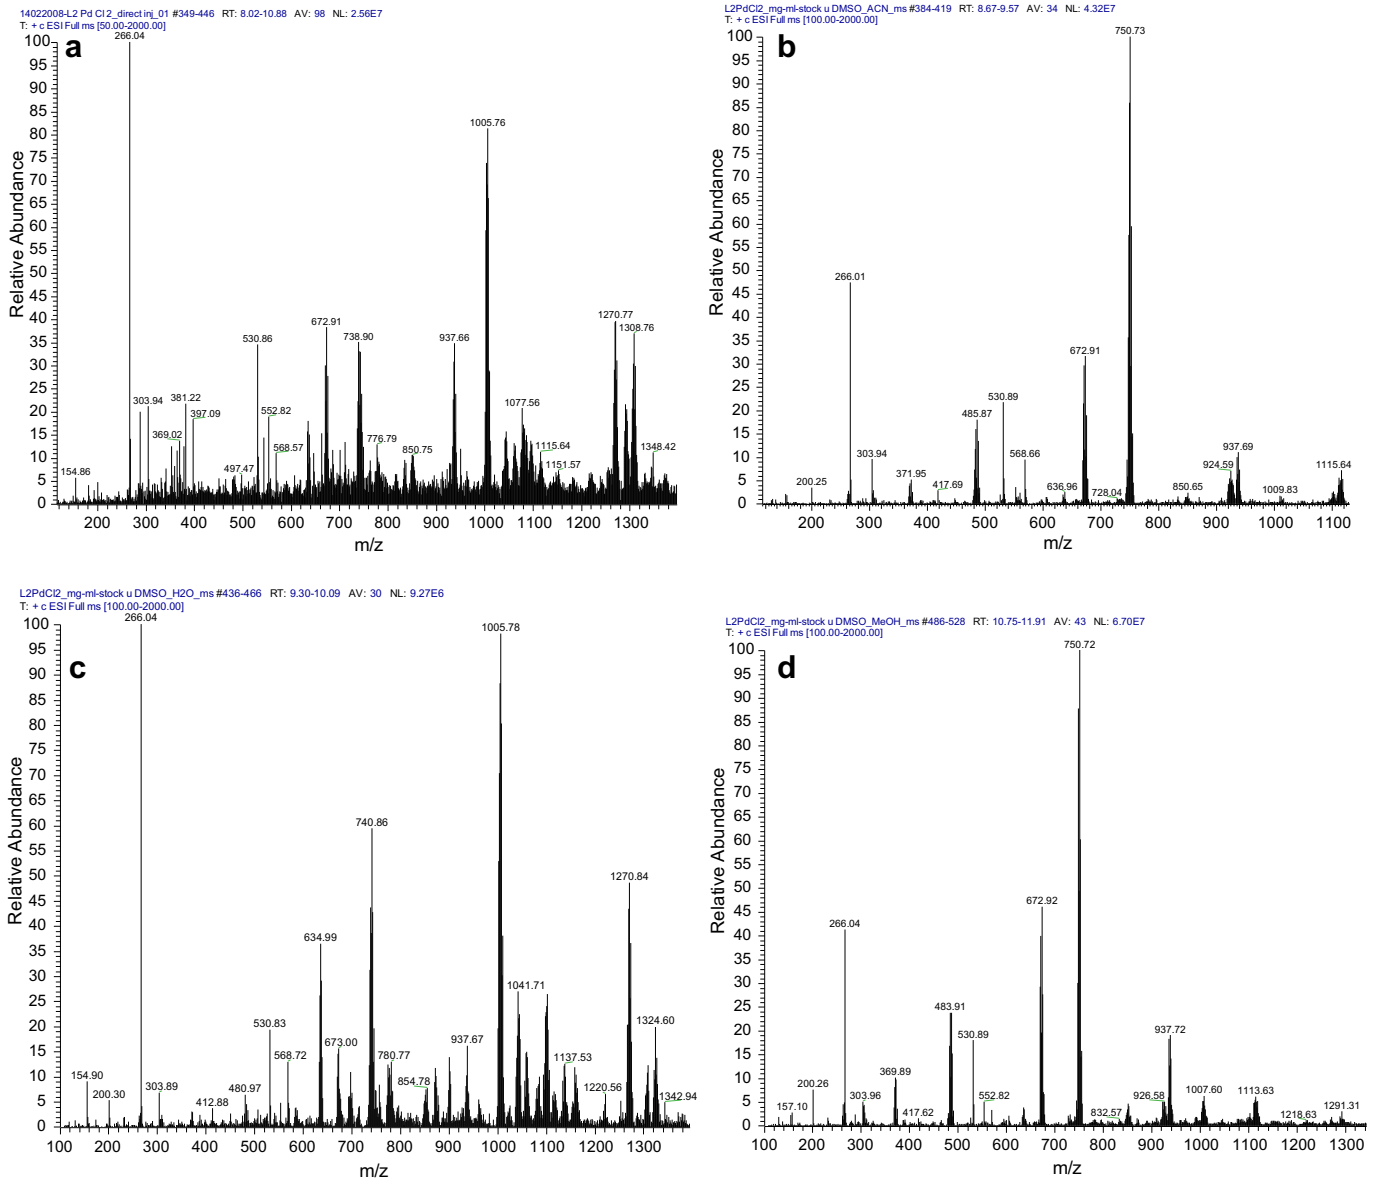

Fig. 3. ESI-MS spectra of the yellow solid Pd**L**$_2$Cl$_2$ (**2**): (a) dissolved in CH_3OH; (b) dissolved in DMSO and diluted with CH_3CN; (c) dissolved in DMSO and diluted with water and (d) dissolved in DMSO and diluted with CH_3OH.

The second set of signals (marked x in Fig. 4): ^{1}H NMR (DMSO–d_6) δ/ppm: 9.34, 9.25, 9.21, 8.89 (4 x brs, 2H, NH), 8.22 (m, 1H, H-6), 7.94 (m, 2H, Ph-b), 7.50 (m, 2H, Ph-c), 6.07 (m, 1H, H-5), 2.43 (s, 3H, Ph–CH_3); ^{13}C NMR (DMSO–d_6) δ/ppm: 163.82 (s, C-4), 148.99 (s, C-2), 146.39 (s, Ph-d), 139.46 (d, C-6), 132.64 (s, Ph-a), 129.92 and 129.77 (d, Ph-c), 129.23 and 129.20 (d, Ph-b), 97.20 (d, C-5), 21.22 (q, Ph–CH_3).

2.3.4. Preparation of complexes *3* and *4*

Slow evaporation of the DMF solution of solid material **2** at room temperature gave, after 10 days, orange needles of complex **3**, whereas a 60-day-long crystallization from the DMSO solution of solid material **2** at room temperature gave crystals of complex **4**. Single crystals of **3** and **4** were characterized by X-ray crystallography.

Complex Pd$_2$(1-TosC$^-$–N3,N4)$_2$DMSO$_2$Cl$_2$ (***4***): IR (KBr) ν_{max}/cm^{-1}: 3407 (w), 3247 (w), 3103 (w), 3012 (w), 2919 (w), 1670 (s), 1648 (s), 1569 (s), 1475 (m), 1396 (m), 1354 (m), 1282 (s), 1236 (m), 1188 (s), 1172 (s), 1148 (s), 1128 (s), 1087 (s), 1043 (s), 1025 (s), 954 (w), 808 (w), 757 (w), 723 (m), 680 (m), 651 (w), 607 (vw), 560 (s), 546 (m), 491 (m), 426 (m), 370 (br, m), 360 (m, sh), 249 (m); ^{1}H NMR (DMSO–d_6) δ/ppm: 7.85 (d, 2H, $J_{b,c}$ = 8.3 Hz, Ph-b), 7.52 (d, 1H, $J_{6,5}$ = 8.0 Hz, H-6), 7.45 (d, 2H, $J_{c,b}$ = 8.2 Hz, Ph-c), 7.26 (brs, 1H, NH-4), 5.92 (d, 1H, $J_{5,6}$ = 8.0 Hz, H-5), 2.93 (s, 3H $(CH_3)_2SO$–Pd), 2.54 (s, 3H $(CH_3)_2SO$–Pd), 2.42 (s, 3H, Ph–CH_3).

2.4. X-ray structural analysis

Crystal data, data collection and refinement parameters for compounds **1**, **3** and **4** are summarized in Table 1. Data collections were performed on an Enraf Nonius CAD4 diffractometer using graphite monochromated Cu Kα radiation (λ = 1.54179 Å). Data reduction and cell refinement were carried out using the procedures incorporated into the WINGX package [12]. Intensities were measured at room temperature. All structures were solved using direct methods with SIR2002 [13] and refined using the full matrix least-squares refinement based on F^2 with SHELXL [14]. Molecular illustrations were prepared using ORTEP-III [15]. All non-hydrogen

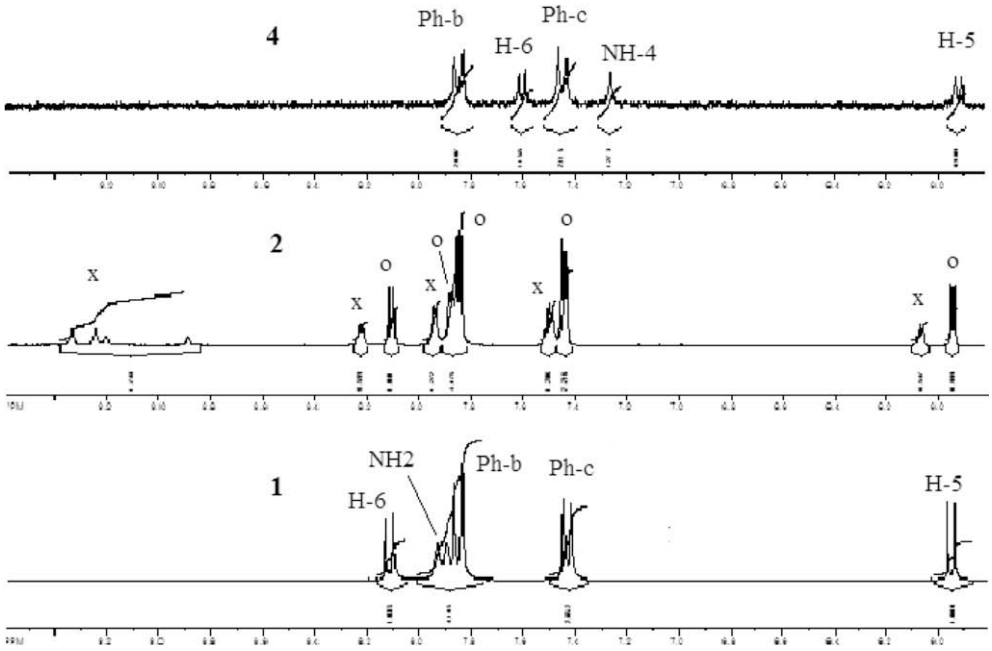

Fig. 4. (DMSO–d_6) ^{1}H NMR spectra of ligand **1** (bottom), complex Pd**L**$_2$Cl$_2$ (**2**) at room temperature (middle) and complex Pd$_2$(1-TosC$^-$–*N*3,*N*4)$_2$DMSO$_2$Cl$_2$ (**4**) (top).

atoms in the structures were refined anisotropically; hydrogen atoms were included in their geometrically calculated positions (except for some hydrogen atoms included in hydrogen bonding) and refined according to the riding model. In the structure of **3**, the substantial residual electron density due to the unresolvable disorder of solvent molecules was reduced by the SQUEEZE [16] routine incorporated into PLATON [17].

3. Results and discussion

3.1. Synthesis and crystal structure of ligand *1*

The synthesis of the ligand 1-(*p*-toluenesulfonyl)cytosine (**1**), (1-TosC), was performed according to the procedure reported by Kašnar-Šamprec et al. [11]. Silylation of cytosine was accomplished with *N*,*O*-bis(trimethylsilyl)acetamide in acetonitrile at 80 °C. Condensation of silylated cytosine with *p*-toluenesulfonyl chloride in acetonitrile gave ligand **1** in 80% yield after recrystallization from methanol (Scheme 1).

In our previous report, we have shown that *N*-1-sulfonyluracil derivatives can adopt chiral conformations, possessing *M* and *P* helicities in the crystalline state [18]. A partial and a total spontaneous resolution upon crystallization was observed for 1-(*p*-toluenesulfonyl)uracil and 1-(1-naphthylsulfonyl)uracil, respectively, while the structurally closely related 1-(*p*-toluenesulfonyl)thymine crystallized as a racemic compound. Unlike its uracil counterpart, 1-tosylcytosine (ligand **1**) does not exhibit *à la Pasteur* separation of conformational enantiomers upon crystallization,

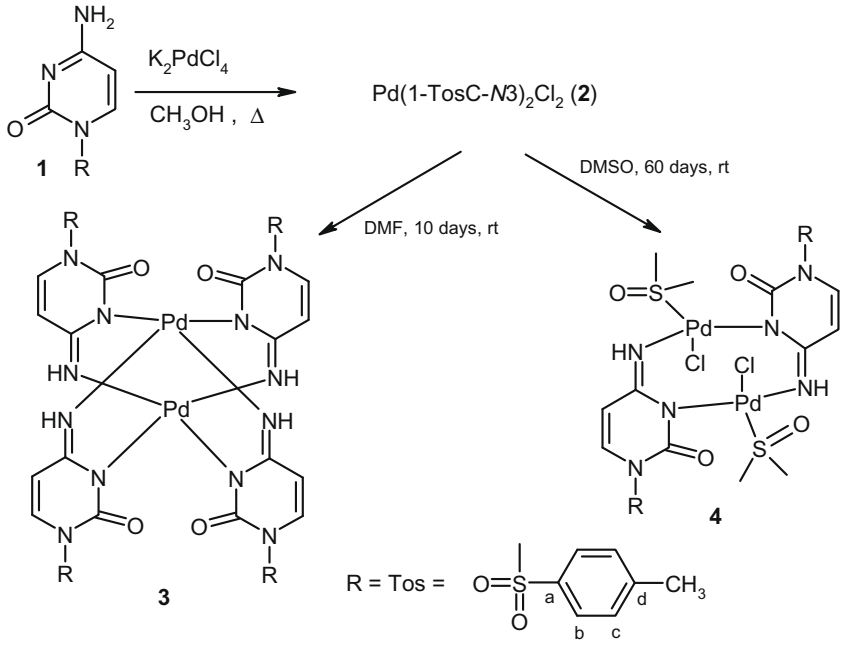
and crystallizes in the centrosymmetric space group $P2_1/a$. However, it exhibits analogous conformational chirality in the solid state with respect to the S–N bond. This is due to the enhanced hydrogen bonding potential of the cytosine, where the presence of a double hydrogen bond donor (amino nitrogen N4) instead of a single H bond donor (endocyclic N3–H) in the case of the uracil derivative, enables the formation of centrosymmetric dimers and tetramers, and finally leads to a centrosymmetric crystal arrangement. The crystal structure of the ligand **1** is characterized by hydrogen-bonded centrosymmetric dimers of the graph set motif $R_2^2(8)$ [19], formed by hydrogen bonds N4–H4b···N3*i*, and centrosymmetric tetramers of the graph set motif R_4^4 including hydrogen bonds N4–H4b···N3*i* and N4–H4a···O2*ii* (Fig. 2). Thus, these two hydrogen-bonded centrosymmetric rings share the common edge made by the hydrogen bond N4–H4B···N3*i* and form an infinite double layer along the crystallographic *a*-axis.

3.2. Synthesis and characterization of complexes **2**, **3** and **4**

3.2.1. Synthesis

1-(*p*-Toluenesulfonyl)cytosine (**1**) and K_2PdCl_4 in a 2:1 molar ratio were refluxed for 2 h in methanol and, upon cooling to room temperature, the pale yellow solid **2** was obtained. Solid **2** is soluble in polar coordinative solvents like DMF and DMSO, and insoluble in most other organic solvents and in water. The same solid product **2** was obtained using DMF instead of methanol, as proved by the X-ray powder diffraction method (data not shown). Slow evaporation of a DMF solution of solid material **2** over 10 days at room temperature gave orange needles of complex **3**, whereas a 60 day crystallization of the DMSO solution at room temperature gave crystals of complex **4** (Scheme 2). The structures of complexes **3** and **4** were confirmed by X-ray structural analysis.

The molecular formula of the pale yellow solid **2** ($Pd\mathbf{L}_2Cl_2$, where **L** = 1-(*p*-toluenesulfonyl)cytosine) (**1**) was confirmed by elemental analysis and ESI-MS spectrometry.



3.2.2. ESI-MS studies

Since ESI-MS is the softest desorption/ionization method, it is ideally suited to investigate the coordination behaviour of transition metal complexes [20,21]. The mass spectrum reflects the composition of the species present in the solution. Franska studied cytosine platinum(II) complexes by ESI-MS in DMSO and observed the formation of cationic complexes with Pt(II). Singly charged [cytosine + PtCl + 2DMSO]$^+$ ions were detected at a low cone voltage [22].

Our MS studies (ESI-MS and HRMS) confirmed the molecular formula of complex **2**. The spectra were taken at a low cone voltage (10 V). Molecular ions containing palladium gave rise to a number of peaks showing the characteristic natural isotope percent distribution of the compounds containing one or two palladium atoms. Masses of the complexes reported in this paper are those containing the most abundant stable isotope of each element in the complex. Since the examined solid, complex **2**, had a low solubility in CH_3OH or CH_3CN, these being the common solvents used for ESI-MS studies, it was dissolved in DMSO and then diluted with CH_3OH, water or CH_3CN in our experiments (Fig. 3). The obtained spectra were compared with the theoretical spectra, matching completely the molecular peak percent distribution caused by the Pd isotopes.

The presence of the complex $Pd\mathbf{L}_2Cl_2$ (**2**) was confirmed by detection of the ions from CH_3OH solutions: at *m/z* 635.00 assigned as the [Pd**L**(**L**–H)]$^+$ ion and at *m/z* 672.91 assigned as [Pd$\mathbf{L}_2$Cl]$^+$, or DMSO solutions: at *m/z* 730.78 assigned as the [(Pd$\mathbf{L}_2Cl_2$)Na]$^+$ ion and at *m/z* 748.75 assigned as the [(Pd$\mathbf{L}_2Cl_2$)K]$^+$ ion, in the ES$^+$ mode. The mononuclear complex $Pd\mathbf{L}_2Cl_2$ exchanged chloride quickly with another ligand forming a $Pd\mathbf{L}_3Cl$ type complex. The presence of that complex was confirmed after detection of the ions from CH_3OH solution: at *m/z* 937.75 assigned as the (Pd$\mathbf{L}_3$Cl)$^+$ ion. Dissolving complex **2** in DMSO and further diluting with water, methanol or acetonitrile showed clearly that the species present in the solutions depend strongly on the added solvent properties. The formation and stability of the formed species were monitored by ESI-MS and LC–MS. Interaction between complex **2** and DMSO was detected as a new species eluted at a retention time of 48.67 minutes with *m/z* 1086 and assigned as [Pd$_2\mathbf{L}_3$(DMSO)]$^+$.

It was also found that when complex $Pd\mathbf{L}_2Cl_2$ was dissolved in DMSO, new dinuclear Pd(II) complexes **4** containing two DMSO molecules in the structure were detected (complex **4** at *m/z*

Scheme 2. Synthesis of complexes: Pd(1-TosC–*N*3)$_2$Cl$_2$ (**2**), Pd$_2$(1-TosC$^-$–*N*3,*N*4)$_4$ (**3**) and Pd$_2$(1-TosC$^-$–*N*3,*N*4)$_2$DMSO$_2$Cl$_2$ (**4**).

992.59 assigned as the $[Pd_2(\mathbf{L}–H)_2(DMSO)_2Cl_2Na]^+$ ion or at *m/z* 1009.46 assigned as the $[Pd_2(\mathbf{L}–H)_2(DMSO)_2Cl_2K]^+$ ion, and its fragments). Complex **3** or its fragments were detected by MS at *m/z* 1268.77 assigned as the $[Pd_2(\mathbf{L}–H)_4]^+$ ion or at *m/z* 1290.80 assigned as the $[Pd_2(\mathbf{L}–H)_4]Na^+$ ion or at *m/z* 1308.76 assigned as the $[Pd_2(\mathbf{L}–H)_4]K^+$. A detailed MS study of the complex $Pd\mathbf{L}_2Cl_2$ will be described elsewhere.

3.2.3. Solution studies

Compound **2** is generally insoluble in common organic solvents, except DMF and DMSO. The molar conductivity value in DMSO proves that complex **2** is a non-electrolyte. This finding indicates that both the chloride anions and the organic ligands are located in the internal coordination sphere of the Pd(II) complex. Despite the fact that most palladium complexes (PdL_2Cl_2) exhibit a fast exchange of axial ligands with solvent molecules, **2** is stable in DMSO–d_6 for several days at room temperature.

With respect to the ^{1}H NMR spectrum of ligand **1**, the spectrum (DMSO–d_6) of complex **2** exhibits two pairs of signals for each proton in a 2:1 ratio (Fig. 4). The first set of resonances of **2** (marked o in Fig. 4) displays two sets of doublets in the aromatic region, corresponding to the H-6 and H-5 protons (δ 8.10 and 5.94 ppm) and phenyl Ph-b and Ph-c protons (δ 7.84 and 7.44 ppm). Two amino protons at N-4, readily exchangeable with deuterium by addition of D_2O, appear as a broadened doublet at δ 7.88 ppm. These data are in accord with the keto-amino form of the ligand in the complex Pd(1-TosC–*N*3)$_2$Cl$_2$ (**2**). On the other hand, all the protons of the second set of resonances in the DMSO solution of **2** (marked x in Fig. 4) were shifted upfield. Signals of the H-6 and H-5 (δ 8.22 and 6.07 ppm) and Ph-b and Ph-c protons (δ 7.94 and 7.50 ppm) show significant additional splitting of the H-5, H-6 and Ph doublets and the broadened singlets at δ 9.34, 9.25, 9.21 and 8.89 ppm are assigned to NH protons. The latter observations may be explained by the existence of two possible rotamers in **2**, which is also evident from the infrared spectra.

The ^{1}H NMR spectrum of the dipalladium complex Pd_2(1-TosC$^-$–*N*3,*N*4)$_2$DMSO$_2$Cl$_2$ (**4**) is considerably different and shows only one signal for each H5, H6, Ph-b, Ph-c and NH-4 proton, due to the high symmetry of the complex and large upfield shifts for the H-6 (δ 7.60 ppm, doublet $J_{6,5}$ = 8 Hz) and the NH-4 (δ 7.26 ppm, broad singlet) protons.

3.2.4. Infrared spectra

The infrared spectra with tentative band assignments (ν/cm^{-1}) for cytosine, according to the literature [23], some characteristic changes in ligand **1** and the bands in the spectra of complexes **2** and **4** are shown in Table 2. The strong to weak bands, observed between 3407 and 3100 cm^{-1}, are associated with ν(N–H). Ligand **1** (keto-amino tautomer) shows characteristic $\nu_{as}(NH_2)$ and $\nu_s(NH_2)$ vibrations at 3369 and 3100 cm^{-1} for the C4 amino group, while the ketoimino form of the ligand anion in **4** shows the N–H stretching of the imine group at 3407, 3247 and 3103 cm^{-1}, which is also indicated by the ^{1}H NMR spectrum.

Solid $Pd\mathbf{L}_2Cl_2$ (**2**) shows six bands between 3406 and 3107 cm^{-1}, supporting the existence of two rotamers [24]. The band assigned to ν(C(2)=O), which appears around 1703 cm^{-1} in the free ligand spectrum, is appreciably shifted to lower frequencies. This modification and changes in the zone between 1700 and 1400 cm^{-1}, involving the stretching of ν(C=O, C=C, C=N, ring, C–N, etc.), are related to the new charge distribution in the ring of the complexes. For the palladium complex $Pd\mathbf{L}_2Cl_2$ (**2**), three bands at 280, 306 and 360 cm^{-1}, and for complex **4** one split band within 360–370 cm^{-1} are attributed to the ν(Pd–Cl) vibrations, while the bands within the 426–480 cm^{-1} range are assignable to the ν(Pd–N) stretching vibrations [25].

3.2.5. Crystal structure of *3*

The molecular structure of **3** includes two Pd atoms, 2.6210(15) Å apart, with the interatomic Pd1–Pd2 vector along the twofold symmetry axis parallel to the crystallographic *b*-axis. The relatively short interpalladium distance is probably caused by steric hindrance of the bulky ligands. The coordination spheres of both Pd atoms inside the binuclear metal complex are virtually identical. They both consist of two exocyclic imino N4 [Pd1–N4, 1.970(9) Å; Pd2–N4, 2.039(12) Å] and two endocyclic N3 [Pd1–N3, 2.067(10) Å; Pd2–N3, 2.090(9) Å] atoms. The coordination spheres of the two palladium atoms are inseparable since they involve four ligand molecules, each of which binds to one Pd atom through its endocyclic N3 and to the other one through the exocyclic N4; hence each of the four ligand molecules bridges two palladium atoms *via* its N–C–N moiety. The asymmetric unit contains two ligand molecules (**A** and **B**), as well as two Pd atoms with half-site occupancy. The asymmetric unit is then repeated by a twofold symmetry axis operation to give a paddlewheel binuclear structure where the adjacent ligand molecules are head-to-tail oriented with respect to the twofold axis, *i.e.* with respect to the interpalladium vector (Fig. 5).

The complete geometries of both coordination spheres of complex **3** are given in Table 3. The atom numbering in the ligand molecule **B** is composed of a prefix "2" and the second digit, corresponds to the numbering scheme defined for the ligand molecule **A**. Thus, for example, N3 of the ligand molecule **A** corresponds to N23 of the ligand molecule **B**. It is evident that the Pd–N3 (endocyclic nitrogen) contacts are somewhat longer than the Pd–N4 (exocyclic imino-nitrogen) ones. The four nitrogens forming the first coordination sphere around Pd1 (N23, N23*i*, N4 and N4*i*) are in an almost perfect square-planar arrangement. The maximum deviation from the least square plane defined by Pd1 and the four nitrogen atoms is only 0.0891(11) Å, whereas the least square plane defined only by these four nitrogen atoms reveals a maximum deviation of 0.025(11) Å.

Similarly, the Pd2 coordination sphere least square plane including palladium reveals a maximum deviation of 0.0878(9) Å, excluding Pd2, 0.013(11) Å. In addition, remarkable planarity is re-

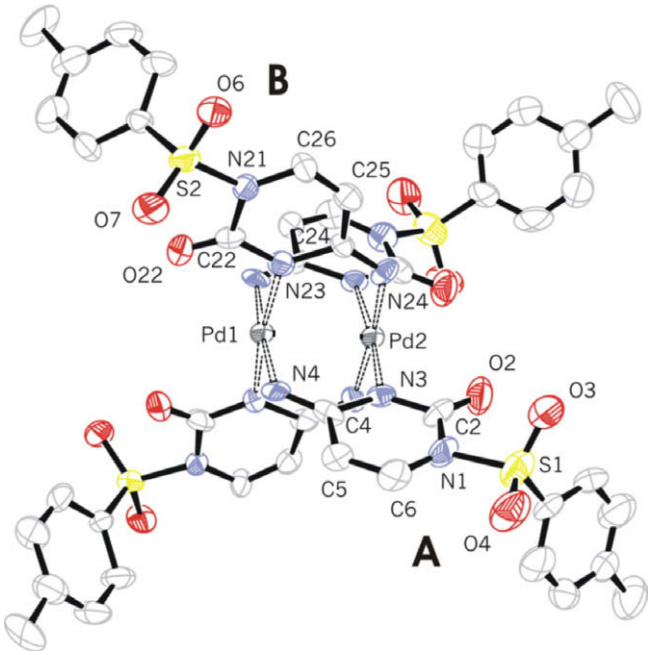

Fig. 5. ORTEP drawing of complex **3** with a partial atom numbering scheme and 30% ellipsoid probability. Hydrogen atoms are omitted for clarity.

vealed by the two planes defined by N3, C4, N4, Pd1, N4*i*, C4*i*, N3*i* and Pd2 [max. deviation of the least square plane, 0.038(10) Å] and N23, C24, N24, Pd1, N24*i*, C24*i*, N23*i* and Pd2 [max. deviation of the least square plane, 0.061(9) Å]. These two planes intersect at the Pd1–Pd2 vector, forming an interplanar angle of 89.3(3)°. This class of ligands reveals a conformational chirality along the N–S bond, as previously described by us [17]. Although **3** crystallizes in the centrosymmetric space group *Pnab*, discrete complex molecules do not contain an intramolecular inversion centre, and all the ligand molecules present inside the single complex molecule are of the same chirality. However, the crystal structure contains complex molecules of both chiralities, related by the extramolecular inversion centers.

The cytosine ring geometries for ligand **1** as well as for complexes **3** and **4** are given in Table 4. In both symmetrically independent ligand molecules **3A** and **3B**, the bond distances inside the cytosine rings reveal remarkable alterations compared to the analogous values in the structure of ligand **1**. This is due to the stabilization of the iminooxo form of the ligand anion upon Pd coordination. While the length of the N3–C4 bond in ligand **1** clearly reflects its double bond character, this bond is significantly longer in both coordinated ligand molecules in complex **3**, suggesting an increase of its single bond character. This implies that the

negative charge at the endocyclic N3 atoms compensates the positive charge of the Pd atom in the complex structure.

3.2.6. Crystal structure of *4*

Molecular structure of **4** is given in Fig. 6 as an ORTEP drawing. Complex **4** is a dinuclear bridging molecule where two palladium atoms, being 2.9358(10) Å apart, are each coordinated by one exocyclic imino-nitrogen N4 and one endocyclic nitrogen N3. The coordination spheres are each completed by one DMSO molecule (through its sulfur atom) and one chlorine atom. Two ligand molecules bridge two Pd atoms in such a manner that each ligand complexes one Pd atom with its exocyclic imino-nitrogen N4 and the other one with its endocyclic N3. The positive charge of the Pd atoms (+2) is compensated by one chlorine and one deprotonated endocyclic nitrogen, bearing a negative charge, as a consequence of the iminooxo form stabilization upon Pd complexation (*vide supra*).

The geometry of the cytosine ring is given in Table 4. A comparison with the analogous values observed in the ligand structure reveals an increase of the single bond character of the N3–C4 bond, similarly to the case of complex **3**. In both cases, stabilization of the iminooxo form took place upon the coordination of Pd(II). The two bridging rings involve both palladium atoms, as well as N3, C4 and N4 of both ligand molecules, and the corresponding planes form an interplanar angle of 89.9(2)°. The molecule contains two DMSO molecules coordinated to the Pd atoms through their sulfur atoms. A search of the current version of *CSD* (2007 release) shows that the abundance of O-bonded and S-bonded Pd–DMSO adducts is almost equal. Details of the coordination sphere geometries are given in Table 5. The maximum deviation from the coordination sphere least square plane, defined by Pd1, S3, Cl1, N3 and

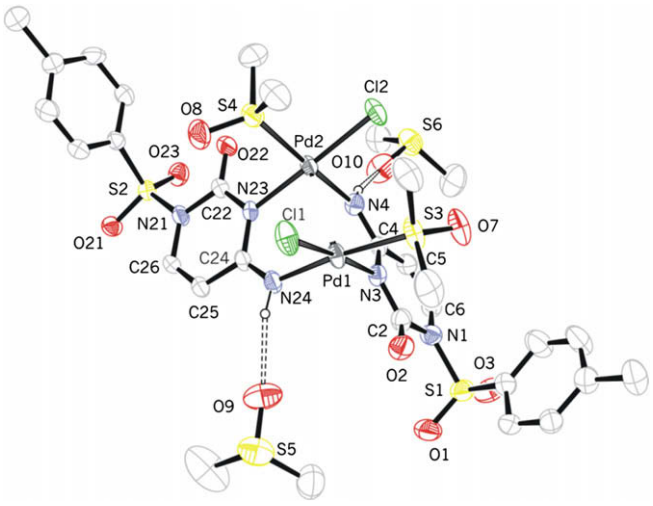

Fig. 6. ORTEP drawing of **4**. Ellipsoids are given on a 30% probability scale. The atom numbering is provided partially and hydrogens are omitted for clarity, except for those included in hydrogen bonding. The solvent molecule connected by the hydrogen bond N24–H···O9 is included.

Table 5
Geometry of the coordination spheres around Pd1 and Pd2 in **4**.

	Pd1	Pd2
Bond lengths (Å)		
Pd–S	2.263(3)	2.252(3)
Pd–Cl	2.292(3)	2.299(2)
Pd–N3 (N23)	2.029(7)	2.034(7)

Angles (°)		
S–Pd–Cl	91.10(10)	90.29(10)
S–Pd–N3 (N23)	89.7(2)	89.1(2)
S–Pd–N4 (N24)	173.8(2)	172.5(2)
Cl–Pd–N3 (N23)	176.1(2)	178.5(2)
Cl–Pd–N4 (N24)	90.7(2)	90.3(2)
N3 (N23)–Pd–N4 (N24)	88.1(3)	90.2(3)

N24, is 0.0722(6) Å, whereas in the case of the one defined by Pd2, S4, Cl2, N4 and N23, it is 0.076(7) Å.

The crystal structure is characterized by discrete complex molecules, each of which is connected to two DMSO molecules (in addition to those included in the coordination around Pd), *via* the imino-nitrogens N4 and N24 and the oxygen atoms of the neighbouring non-coordinated solvent molecules [N4–H···O10, 2.965(12) Å, 166°; N24–H···O9, 3.074(15) Å, 146°] (Fig. 6).

4. Conclusions

Complexation of Pd(II) with 1-(*p*-toluenesulfonyl)cytosine ligand (**1**) leads initially to the formation of a kinetically favoured mononuclear complex **2**, regardless of the solvent used. This, initially formed complex undergoes rearrangements in aprotic polar solvents, resulting in the formation of two different dinuclear bridging species (**3** from DMF and **4** from DMSO), where the ligand anion (1-TosC$^-$) exists in a rare iminooxo form and is coordinated to Pd(II) through both its exocyclic (N4) and endocyclic nitrogen atom (N3).

Supplementary data

CCDC 695234, 695235 and 695236 contains the supplementary crystallographic data for compounds **1**, **3** and **4**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

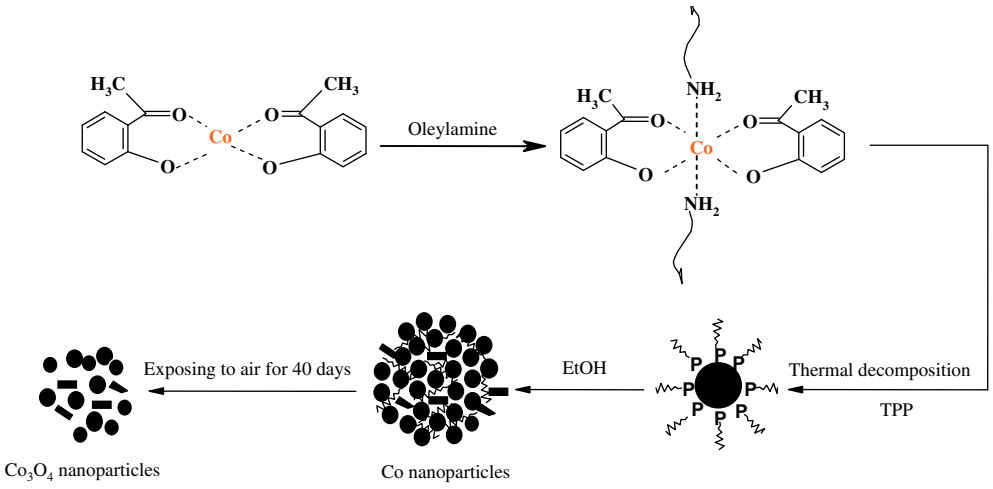
2. Experimental

2.1. Materials and physical measurements



The precursor complex [bis(2-hydroxyacetophenato)cobalt(II)], [Co(aceto)$_2$], was prepared according to the procedure described previously [17]. Oleylamine, triphenylphosphine (TPP), toluene, hexane, and ethanol were purchased from Aldrich and used as received. XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Transmission electron microscopy (TEM) and energy dispersive X-ray (EDX) images were obtained on a Philips EM208 transmission electron microscope with an accelerating voltage of 200 kV. The high-resolution transmission electron microscopy (HRTEM) image was recorded on a JEOL-2010 TEM at an acceleration voltage of 200 kV. Fourier transform infrared (FT-IR) spectra were recorded on Shimadzu Varian 4300 spectrophotometer in KBr pellets. The magnetic measurement was carried out in a vibrating sample magnetometer (VSM) (BHV-55, Riken, Japan) at room temperature.

2.2. Synthesis of Co nanoparticles

The current synthetic procedure is a modified version of the method developed by Hyeon group for the synthesis of various nanoparticles of metals and oxides, which employ the thermal decomposition of metal-surfactant complexes in hot surfactant solution [19]. The synthetic pathway is shown in Scheme 1. In the typical synthesis, a stock solution of co-surfactant complex, prepared by reacting 0.6 g of [Co(aceto)$_2$] with 5 mL of oleylamine at 140 °C, was injected into 5 g of triphenylphosphine (TPP) under vigorous stirring at 250 °C under argon atmosphere. The color of the solution changed from orange to black, indicating that colloidal nanoparticles were generated and then the black solution was aged at 240 °C for 60 min. The reaction mixture was then cooled to room temperature in air and the black products were retrieved by adding 30 mL of anhydrous ethanol, followed by centrifugation. The final product was washed with ethanol for at least three times to remove impurities, if any. The retrieved powder of the nanoparticles could be easily redispersed in nonpolar organic solvents such as hexane or toluene (Scheme 1).

3. Results and discussion

Fig. 1 presents the XRD patterns of the as-prepared samples. The discernible peaks in Fig. 1a can be indexed to (100), (111), (101), (200) and (220) planes of hcp-Co (JCPDS: 89-4308). It is well known that nanometer sized cobalt particles are easy to be oxidized in air. However, from XRD pattern, except for pure hcp-Co, no other cobalt oxide phase were detected, which might result from the protection of oleylamine and TPP on the surface of nanoparticles. The diffraction peaks are clearly broadened, which can be the result of the reduced particle size. This indicates that the Co is all nanoparticle. The average particle diameter can be estimated using Scherrer's formula. The average sizes calculated is 13 nm.

Scheme 1. The overall synthetic procedure of the formation Co_3O_4 nanoparticles.

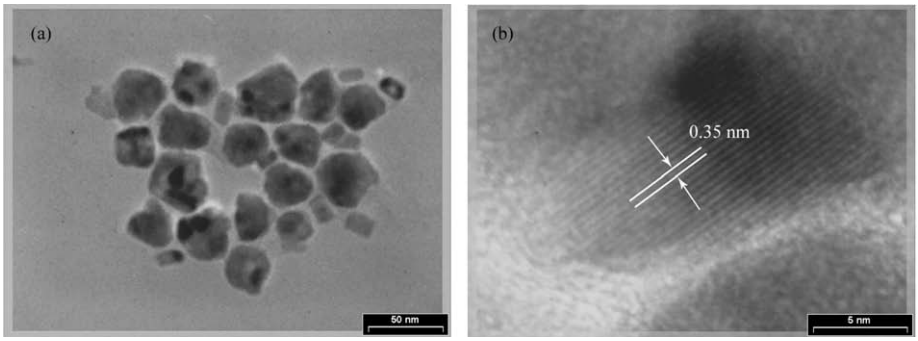


Fig. 2. (a) TEM image and (b) HRTEM image of Co nanoparticles.

The diffractogram shown in Fig. 1b presents the XRD pattern of nanoparticles after exposing the nanoparticles to air; no peak was related to the cobalt element in the XRD pattern. All the reflection peaks can be indexed to a cubic phase of Co_3O_4 spinel with lattice parameter $a = 8.0850$ Å, which is consistent with the reported value (JCPDS: 78-1969). No other peaks for impurities were detected. The spectrum consists of well-defined diffraction peaks indicating that very thin crystalline single phase is formed with cubic crystal structure.

Fig. 2a is TEM image of the Co nanoparticles. Most of the Co particles are irregular (Fig. 2a). The mean size of Co nanoparticles is 20 nm. In the HRTEM (high-resolution transmission electron microscopy) image (Fig. 2b), the distance between the two adjacent planes, d, is measured to be 0.355 nm.

Time-dependent FT-IR studies indicate that oxidation of the as-synthesized cobalt nanoparticles in air is slow. Fig. 3a is the FT-IR spectrum of the freshly prepared cobalt nanoparticles. Characteristic peaks of oleylamine (CH stretching) are observed. Because cobalt is the only product of the decomposition reaction and all the residual surfactant is removed by washing the precipitate with ethanol several times, the characteristic peaks of the oleylamine are introduced from the oleylamine coated surface of cobalt nanoparticles. According to the literature oleylamine should react or coordinate with the surface atoms of the Co nanoparticles to prevent oxidation or aggregation of the Co nanoparticles. Also, adding amounts of hexane at the end of the reaction helps to coat any exposed crystal surface, improving passivation against oxidation. The weak peaks at 3417 cm^{-1} are assigned to the stretching vibration of absorption water. Fig. 3b and c is the FT-IR spectrum of the cobalt nanoparticles from dispersion kept under air for 30 days (curve b) and 40 days (curve c). FT-IR on cobalt nanoparticles kept in hexane under air for 30 days shows the same peaks with Fig. 3a, without any peaks in the 400–600 related to Co–O stretching, from the typical valence state of Co^0, indicating that the Co nanoparticles in hexane are very stable against further oxidation. However, after it is kept in hexane under air for 40 days (Fig. 3c) we observed a valency change of cobalt from the Co nanoparticle sample. The spectra (Fig. 3c) also contained two strong absorption bands at 662 and 581 cm^{-1} which confirm the spinel structure of Co_3O_4. The former peak at 662 cm^{-1} is attributed to the stretching vibration mode of M–O in which M is Co^{2+} and is tetrahedrally coordinated. The band at 581 cm^{-1} can be assigned to the M–O in which M is Co^{3+} and so coordinates octahedrally [20]. Also, Fig. 3 shows two weak stretch vibrations at 2923 and 2852 cm^{-1} attributing to the C–H stretching models of the oleylamine carbon chain, indicating oleylamine molecules are absorbed on the surface of Co_3O_4 nanocrystals. If there is adsorption of $[Co(aceto)_2]$ on the surface of the Co_3O_4 particles, a distinct carbonyl peak around 1640 cm^{-1} should appear in the FT-IR spectrum. Moreover, this peaks which also indicates a change in the valency of the cobalt nanoparticles. Chemical purity and stoichiometry of the Co_3O_4 (the Co nanoparticles kept for 40 days) was tested by EDX. The strong peaks related to Co and O is found in the spectrum Fig. 4. EDX spectrometry for nanoparticles shown oxygen that confirm sample was oxidize in air for 40 days. The Cu peaks are due to the 300 mesh copper grid.

In the presence work as shown in Scheme 1 because of the symmetry of precursor we have sites with same potential energy levels

on the surface of metallic core. TPP is a high-boiling point surfactant with three phenyl groups providing great steric hindrance to control the size of nanomagnetic metal nanoparticles. The addition of TPP into the mixture of oleylamine and complex as an additional surfactant reduced the particle size much further and resulted in nanoparticles. Oleylamine is known as a ligand that binds tightly to the metal nanoparticles surface. The combined effects of TPP and oleylamine were much more profound than those of individual contributions.

The superparamagnetic behavior is documented by the hysteresis loop measured at 300 K as shown in Fig. 5a. There is almost immeasurable coercivity for Co nanoparticles at room temperature, which is a very typical behavior for a soft magnet. This indicates that the Co particles are superparamagnetic and nanosized. The saturation magnetization, M_s, is 63.9 emu/g for Co nanoparticles, which is lower than that of bulk Co particles (M_{bulk} = 166 emu/g) [21]. The decrease in M_s of Co nanoparticles is due to superparamagnetism of magnetite particles that occurs when the particle size decreases below 8 or 20 nm [12] and oleylamine that coated on the surface of Co nanoparticles. The hysteresis loops (Fig. 5b) measured at room temperature shows a ferromagnetic behavior of the Co_3O_4 nanoparticles. At 25 °C the remanent magnetization, (M_r) is 12.23 emu/g, the coercive field (H_c), is 911.34 Oe and the magnetization at saturation (M_s) is estimated to be only 24.94 emu/g (the saturation magnetization M_s was determined from the extrapolation of curve of H/M versus H). Cobalt oxide nanoparticles are made of small crystalline domains. Each crystalline domain is characterized by its own magnetic moment oriented randomly. The total magnetic moment of the nanoparticles is the sum of these magnetic domains coupled by dipolar interactions. As a result, a low value of M_s is obtained. The magnetic properties of nanomaterials have been believed to be highly dependent on the sample shape, crystallinity, magnetization direction, and so on.

4. Conclusion

In summary, Co and Co_3O_4 nanoparticles were successfully prepared using thermal decomposition of [Co(aceto)$_2$] as new precursor in the presence of TPP and oleylamine. The as-synthesized cobalt particles show very good crystallinity and are stable in hexane as solvent against air oxidation. This method is nontoxic, facile and inexpensive. Co nanoparticles have common features of superparamagnetic at room temperature. This work is easily extended to other metals.

dried according to the standard literature procedures [10], freshly distilled, and saturated with nitrogen prior to use. All starting reagents were purchased from commercial sources and used without further purification or synthesised from published methods. The 4-(4-pyridyl)-1,3-dithiol-2-one was synthesised according to literature reports [8,11].

Elemental analyses of the compounds isolated in theses studies were performed at ITN analytical services using an EA 110 CE Instruments automatic analyser. Melting points were performed on a Stuart Scientific SMP2.

2.2. Synthesis

2.2.1. Tetraphenylphosphonium salt of bis[1-(4-pyridin-4-yl)-1,2-ethylenedithiolato]nickel, $PPh_4[Ni(4\text{-}pedt)_2]$ (**1**)

The 4-(4-pyridyl)-1,3-dithiol-2-one (0.50 g; 2.56 mmol) was added to a sodium methoxide solution (0.147 g; 6.40 mmol; 13 mL) After 45 min of stirring, $Ni(NO_3) \cdot 6H_2O$ (0.37 g, 1.28 mmol) was added. One hour later the red solution was filtered to an aqueous PPh_4Cl solution (0.96 g, 2.56 mmol, 100 mL). A black precipitate appeared immediately from the brown solution. The solid was recovered by filtration, washed with water and recrystallised from acetonitrile to afford black crystals of the nickel salt suitable for X-ray diffraction. 50% yield (0.47 g, 0.64 mmol); m.p. 217–218 °C. $C_{38}H_{30}NiN_2PS_4$ (Mol. Wt.: 732.59). Elemental *Anal.* Calc.: C, 62.30; H, 4.13; N, 3.82; S, 17.51. Found: C, 62.09; H, 4.06; N, 3.77; S, 17.31%.

2.2.2. Tetraphenylphosphonium salt of bis[1-(4-pyridin-4-yl)-1,2-ethylenedithiolato]copper $PPh_4[Cu(4\text{-}pedt)_2]$ (**2**)

The oxo compound (0.10 g; 0.51 mmol) was added to a freshly made sodium methoxide solution (0.023 g; 1.02 mmol, 3 mL) and stirred at room temperature, until total dissolution, followed by drop wise addition of a solution of $CuCl_2 \cdot 2H_2O$ (0.043 g; 0.25 mmol) in methanol (2 mL). The solution was stirred for 1 h and filtered to a PPh_4Br methanol solution (0.214 g, 0.51 mmol, 3 mL). No precipitate formation was observed. The reaction vial was opened to the air, a few H_2O drops were slowly added until start of incipient precipitation and the mixture was left overnight at 4 °C. The oil that formed was separated from the mixture by centrifugation, dried under vacuum (P_2O_5) and recrystallised from dichloromethane/hexane to be recovered as a microcrystalline precipitate. 48% yield (0.089 g, 0.12 mmol); m.p. 162–163 °C. $C_{38}H_{30}N_2CuS_4$ (Mol. Wt.:737.44). Elemental *Anal.* Calc.: C, 61.89; H, 4.10; N, 3.80; S, 17.39. Found: C, 61.72; H, 4.92; N, 3.84; S, 18.03%.

2.2.3. Tetrabutylammonium salt of bis[1-(4-pyridyl)-1,2-ethylenedithiolato]nickel $n\text{-}Bu_4N[Ni(4\text{-}pedt)_2]$ (**3**)

The procedure was similar to the described above. The oxo compound was added (0.10 g; 0.51 mmol) to a freshly made sodium methoxide solution (0.023 g; 1.02 mmol, 3 mL) and stirred at room temperature, until total dissolution, followed by dropwise addition of a solution of $NiCl_2 \cdot 6H_2O$ (0.061 g; 0.25 mmol) in methanol (2 mL). The red solution was stirred for 1 h and then filtered into n-Bu_4NBr methanol solution (0.165 g, 0.51 mmol, 3 mL). No precipitate formation was observed. The reaction vial was opened to the air, a few H_2O drops were slowly added until start of incipient precipitation and the mixture was left overnight at 4 °C. The reddish oil formed was separated from the mixture by centrifugation, dried under vacuum (P_2O_5) and recrystallised from acetone to be recovered as a microcrystalline precipitate. 65% yield (0.105 g, 0.16 mmol); m.p. 133–134 °C. $C_{30}H_{46}N_3NiS_4$ (Mol. Wt.: 635.66) Elemental *Anal.* Calc.: C, 56.68; H, 7.29; N, 6.61; S, 20.18. Found: C, 56.01; H, 7.89; N, 6.12; S, 19.75%.

2.2.4. Tetrabutylammonium salt of bis[1-(4-pyridyl)-1,2-ethylenedithiolato]copper, $n\text{-}Bu_4N[Cu(4\text{-}pedt)_2]$ (**4**)

Following the same general procedure used for n-$Bu_4N[Ni(4\text{-}pedt)_2]$, the oxo compound was added (0.10 g; 0.51 mmol) to a freshly made sodium methoxide (0.023 g; 1.02 mmol, 3 mL) stirred until total dissolution, followed by drop wise additio of a solution of $CuCl_2 \cdot 2H_2O$ (0.043 g; 0.25 mmol) in methanol (2 mL). The solution was stirred for 1 h and afterwards filtered onto an n-Bu_4NBr methanol solution (0.165 g, 0.51 mmol, 3 mL). No precipitate formation was observed. A few H_2O drops were slowly added until start of incipient precipitation and the mixture was left overnight at 4 °C. The oil formed was separated from the mixture by centrifugation, dried under vacuum (P_2O_5) and recrystallised from dichloromethane/hexane to be recovered as a microcrystalline precipitate. 41% yield (0.065 g, 0.10 mmol); m.p. 160–162 °C. $C_{30}H_{46}N_3CuS_4$ (Mol. Wt.: 640.51) Elemental *Anal.* Calc.: C, 56.26; H, 7.24; N, 6.56; S, 20.02. Found: C, 55.83; H, 7.01; N, 6.12; S, 19.84%.

2.2.5. Tetrabutylammonium salt of bis[1-(4-pyridyl)-1,2-ethylenedithiolato]gold $n\text{-}Bu_4N[Au(4\text{-}pedt)_2]$ (**5**)

Following the same general procedure used for n-$Bu_4N[Ni(4\text{-}pedt)_2]$, the oxo compound (0.10 g; 0.51 mmol) was dissolved in a freshly prepared methoxide solution (0.024 mg; 1.02 mmol, 3 mL). The total dissolution of the oxo compound was followed by drop wise addition of a $KAuCl_4 \cdot 4H_2O$ methanol solution (0.097 g; 0.25 mmol, 2 mL). The brown solution was filtered into an n-Bu_4NBr methanol solution (0.165 g, 0.51 mmol, 3 mL). After the addition of a few milliliters of water, the reaction vial was kept for several hours at 4 °C. The brown oil formed was recovered by centrifugation, dried under vacuum (P_2O_5) and recrystallised from diclorometha/hexane to be recovered as a microcrystalline precipitate. 60% yield (0.115 g, 0.15 mmol); m.p. 127–129 °C. $C_{30}H_{46}N_3AuS_4$ (Mol. Wt.: 773.93). Elemental *Anal.* Calc.: C, 46.56; H, 5.99; N, 5.43; S, 16.57. Found: C, 46.21; H, 5.52; N, 5.25; S, 16.39%.

2.2.6. Crown ether [Na(18C6)] salt of bis[1-(4-pyridyl)-1,2-ethylenedithiolato]nickel $[Na(18C6)][Ni(4\text{-}pedt)_2]$ (**6**)

The oxo compound (0.20 g; 1.03 mmol) was added to a freshly prepared methoxide solution (0.047 g, 2.05 mmol, 5 mL). After stirring until total dissolution, $NiCl_2 \cdot 6H_2O$ methanol solution (0.122 g; 0.51 mmol, 5 mL) was added. The red solution was stirred for 1 h and then filtered into an 18-crown-6 methanol solution (0.271 g, 1.03 mmol, 1 mL). The mixture was left at 4 °C for two weeks. A mixture of amorphous brown and darker polycrystalline precipitate was recovered by vacuum filtration. The mixture was dissolved in dichloromethane and an insoluble precipitate was removed. By slow diffusion of hexane into the dichloromethane solution, it was possible to recover compound **6** as a dark brown polycrystalline material. 58% yield (0.197 g; 0.29 mol) m.p. 260–261 °C. $C_{26}H_{34}N_2NaNiO_6S_4$ (Mol. Wt.: 680.5). Elemental *Anal.* Calc.: C, 45.89; H, 5.04; N, 4.12; S, 18.85. Found: C, 45.43; H, 5.35; N, 4.12; S, 18.30%.

2.2.7. Crown ether [Na(18C6)] salt of bis[1-(4-pyridyl)-1,2-ethylenedithiolato] gold $[Na(18C6)][Au(4\text{-}pedt)_2]$ (**7**)

The oxo compound (0.10 g, 0.51 mmol) was added to a freshly prepared sodium methoxide solution (0.0235 g, 1.02 mmol, 5 ml) and stirred for 45 min. The dark red solution was removed from the inert atmosphere and solid $KAuCl_4 \cdot 4H_2O$ (0.097 g, 0.25 mmol) was added. The mixture was stirred for 2 h, filtered over Celite to a solution of 18C6 (0.0677 g, 0.25 mmol) in methanol (1 ml), layered with pentane and left at 4 °C. A few days later, an amorphous brown precipitate was recovered by vacuum filtration. From an attempt to recrystallise from dichloromethane/hexane, an oil was

obtained which was dried and characterised. Yield 0.088 g, 0.11 mmol (44%); m.p. 145–146 °C. $C_{26}H_{34}O_6N_2S_4AuNa$ (Mol. Wt.: 818.08). Elemental *Anal.* Calc.: C, 38.14; H, 4.19; N, 3.42; S, 15.63. Found: C, 38.38; H, 4.91; N, 3.50; S, 15.28%.

2.3. Physical characterisation

Cyclic voltammetry data were obtained using a BAS C3 Cell Stand. The measurements were performed at room temperature in CH_2Cl_2 solutions, containing [*n*-Bu_4]PF_6 (0.1 M) as supporting electrolyte, with a scan rate of 100 mV/s using platinum wire working and counter electrodes and a Ag/AgCl reference electrode. The $[(Me_5C_5)_2Fe]^+/[Me_5C_5)_2Fe]$ ($[Fc^*]^+/[Fc^*]$) couple was used as the internal reference and the potentials of the redox couples observed were referenced to that.

Single crystals suitable for X-ray crystallographic analyses were obtained by recrystallisation in acetonitrile, for compound **1**, and by slow diffusion of hexane into a saturated solution of dichloromethane, for compounds **2**, **3**, **5** and **6**. In compound **6** two water molecules were incorporated in the crystal structure to yield compound **6** · **2H$_2$O**, due to the presence of air humidity.

The data for compounds **1**, **2**, **3**, **5** and **6** · **2H$_2$O** were collected on a Bruker AXS APEX CCD area detector X-ray diffractometer equipped with an Oxford Cryosystems low-temperature device at 150 K in the ω and φ scans mode. A semi empirical absorption correction was carried out using SADABS [12]. Data collection, cell refinement and data reduction were done with the SMART and SAINT programs [13]. The structures were solved by direct methods using SIR97 [14] and refined by fullmatrix least-squares methods with the SHELXL97 [15] program using the WINGX software package [16]. Non-hydrogen atoms were refined with anisotropic thermal parameters whereas H-atoms were placed in idealised positions and allowed to refine riding on the parent C atom. In **3** and **5** one of the butyl groups on the cation show disorder that was modelled over two positions with the following occupation factors: 52%:48% and 55%:45%, respectively. The final difference Fourier map revealed the existence of residual electron densities of: 2.4/−0.89 e A^{-3} for compound **5**, which are located near the Au atom. Molecular graphics were prepared using ORTEP3 [17] and MERCURY 1.4.2 [18]. A summary of the crystal data, structure solution and refinement is listed in Table 1.

EPR spectra were obtained at room temperature on powders using a conventional X-band spectrometer (Bruker ESP 300E) equipped with a microwave bridge ER041XK, a rectangular cavity operating in T102 mode and a field controller ER 032M system. The modulation amplitude was kept well below the linewidth and the microwave power well below saturation.

Static magnetic susceptibility measurements in the range 2–300 K were performed using a superconducting longitudinal Faraday system (Oxford Instruments) under a magnetic field of 5 T and field gradient of 1 T/m. A polycrystalline sample (~20 mg) was placed inside a previous calibrated thin-wall Teflon bucket. The force was measured with a microbalance (Sartorius S3D-V), applying forward and reverse field gradients. Magnetisation data were corrected for contributions due to the core diamagnetism, estimated from tabulated Pascal constants as -385×10^{-6}, -379×10^{-6} and -348×10^{-6} emu/mol for **1**, **3** and **6**, respectively.

3. Results and discussion

3.1. Synthesis

The synthesis of the nickel, copper and gold complexes **1**–**7** were performed following standard procedures for complexes with this type of dithiolene ligands (Scheme 1). The dithiolate ligand (**L**) was obtained from the corresponding oxo compound by hydrolytic cleavage with sodium methoxide and without intermediate isolation it was reacted with the selected metal salt to give an anionic complex which is precipitated as a salt in the presence of the selected cation. The presence of water was necessary to precipitate the bisdithiolene complex from the solution. In case of **1**, a water solution of the cation was added and the bisdithiolene complex precipitated immediately as a black precipitate. In the case of compounds **2**, **3**, **4** and **5** a few drops of water were added at the end of the reaction until the start of incipient precipitation and after keeping the reaction mixture at 4 °C it was possible to collect the product as fine precipitate which tends to form an oil. Compounds **6** and **7** were obtained without adding water after keeping the solution a few days at 4 °C until complexes precipitated. These complexes were obtained after recrystallisation from acetonitrile, acetone or dichloromethane/hexane in overall yields between 41% and 65%.

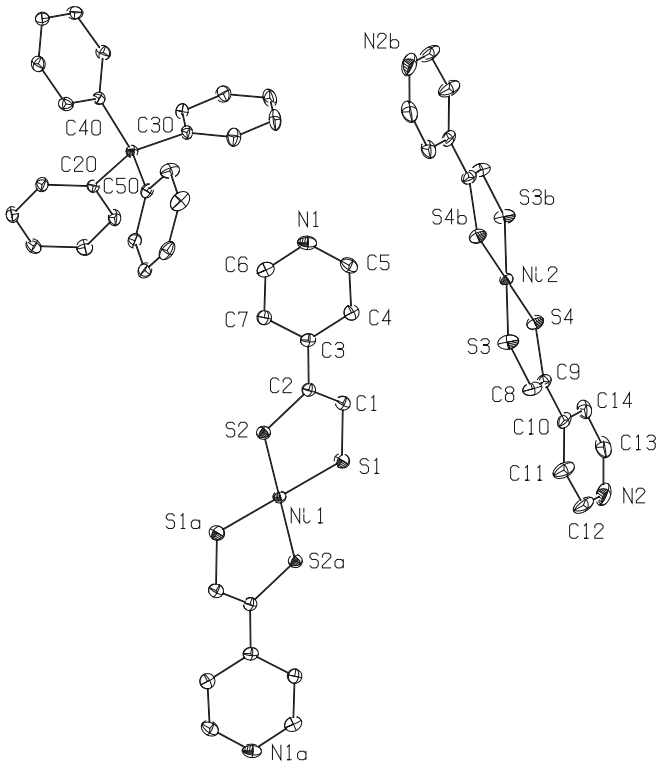
Complexes **1**–**7** were characterised by elemental analyses and cyclic voltammetry studies. The elemental analyses after the recrystallisations are consistent with a 1:1 cation:anion stoichiometry, in agreement with the X-ray crystal structure determination of the diffracting single crystals. While this is expected for M = Au, for Cu and Ni even though starting from a $Ni^{II}Cl_2$ or $Cu^{II}Cl_2$ salt, the dianionic bisdithiolene complexes could not be obtained, even under nitrogen atmosphere and the monoanionic dithiolene complexes were obtained as evidenced by the X-ray structure determination or by the electronic paramagnetic resonance (EPR) spectroscopy. Whereas complexes **1**, **2**, **3**, **5** and **6** · **2H$_2$O** were unambiguously characterised by single X-ray structure determination, compounds **4**, **6** and **7** could not be studied by single X-ray diffraction due to their poor crystal quality.

3.2. Crystal structure

Compounds **1**, **2**, **3**, **5** and **6** · **2H$_2$O** have been characterised by single crystal X-ray diffraction technique. The ORTEP views of these compounds are shown in Figs. 1–5. Selected bond angles and distances are given in Table 2.

The monoanionic Ph_4P salts **1** and **2** are isostructural and crystallise in the monoclinic system, space group $C2/c$, $Z = 8$, the asymmetric unit comprising one cation $[PPh_4]^+$ located in a general position and two independent half-anions $[M(4\text{-pedt})_2]^-$ (M = Ni and Cu for compounds **1** and **2**, respectively) both with the metals located at an inversion centre. The angle between the two $[M(4\text{-pedt})_2]^-$ units mean planes is about 49.47° and 49.52° for compounds **1** and **2**, respectively.

The monoanionic *n*-Bu_4N salts **3** and **5** are isostructural and crystallise in the triclinic system, $P\bar{1}$ space group, $Z = 2$. The asymmetric unit comprises two independent half-anion units. Both the metal atoms located at inversion centres and with one cation unit located at a general position. The angle between the anionic units mean planes is between 88.98° and 89.81° for **3** and **5**, respectively.



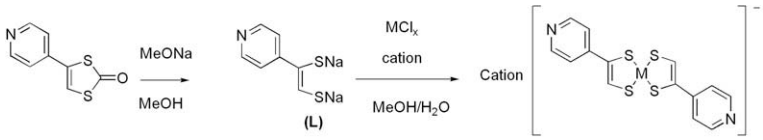


Fig. 1. ORTEP views of the cation and the two independent anion units of $Ph_4P[Ni(4\text{-pedt})_2]$, (**1**), showing the atomic numbering scheme. Displacement ellipsoids are drawn at the 30% probability level. H atoms have been omitted for clarity. [Symmetry codes: (a) $2 - x$, $1 - y$, $1 - z$; (b) $1.5 - x$, $1.5 - y$, $1 - z$].

The compound **6** · **2H$_2$O** crystallises in the monoclinic system, space group $P2_1/n$, $Z = 2$. The asymmetric unit comprises one independent half-anion unit and one independent half-cation unit located at inversion centres.

In all complexes, the centrosymmetric anion $[M(4\text{-pedt})_2]^-$ (M = Ni, Cu or Au) adopts a square-planar coordination geometry and a *trans* conformation. The central core of the anions, constituted by the metal atom, the four sulfur atoms and the four carbon atoms, is essentially planar (rms deviations of fitted atoms are 0.0091 and 0.0057 Å for compound **1**; 0.0182 and 0.0237 Å for compound **2**; 0.0152 and 0.0268 Å for compound **3**; 0.0537 and 0.0250 Å for compound **5**; 0.0125 Å for compound **6** · **2H$_2$O**).

Important bond lengths within the MS_2C_2 metallocycle are collected in Table 2. The average M–S bond lengths are in good agreement with values found in other Ni, Cu and Au monoanionic bisdithiolene complexes, respectively [1c,19–21]. While the central core of the complexes is planar, the two pyridine rings are rotated out of the central core plane with dihedral angles between

$\delta = 100(b - b')/b$.

13° and 33°; depending on the complex, with the majority of them between 21° and 33°, only one of the anionic units in the Ph_4P salts **1** and **2** presents a smaller angle of about 13°. The rotation of the pyridine rings is induced by steric hindrance between hydrogen atoms at the 2-position of the pyridine ring and in the metallocycle carbon but this rotation is also assisted by the interaction with neighbouring molecular units in the solid. The salts **5** and **6** · **2H$_2$O** present the higher pyridine rotation values (~33°) and this large value can be ascribed to cation interactions (and also anion interactions in the case of complex **5**) as denoted by several short contacts (see Tables S1 and S2 and Figs. S1 and S2).

The smaller pyridine rotations of only ~13°, in **1** and **2**, are associated with anionic and cationic interactions, including π–π interactions between the pyridine groups of the $[M(4\text{-pedt})_2]^-$ units: (see Tables S3 and S4 and Fig. S3). The two pyridine rings involved are coplanar with distances close to the sum of the van der Waals radii, clearly denoting significant π–π interactions (Fig. S3c).

A feature related to the unsymmetrical nature of the 4-pedt ligand, is the S–C bond length difference within the metallocycle (Table 2). The shortening of the **b**′ bond when compared with the **b** bond can be evaluated in terms of a parameter $\delta = 100(b - b')/b$, as previously done on other unsymmetrical bisdithiolene complexes such as the $[Ni(adt)_2]^-$ (adt = acrylonitrile-1,2-dithiolate) or $[Ni(tfadt)_2]^-$ (tfadt = 2-(trifluoromethyl)acrylonitrile-1,2-dithiolate) [6,22]. In our case δ values are between 1.26% and 2.03% in the four structures analysed and it can be attributed to the mesomeric effect of the pyridine group.

A long debated aspect of the dithiolene complexes is the so called "non-innocence" of the ligands, which may lead to formal ambiguities in the description of the different oxidation sates of

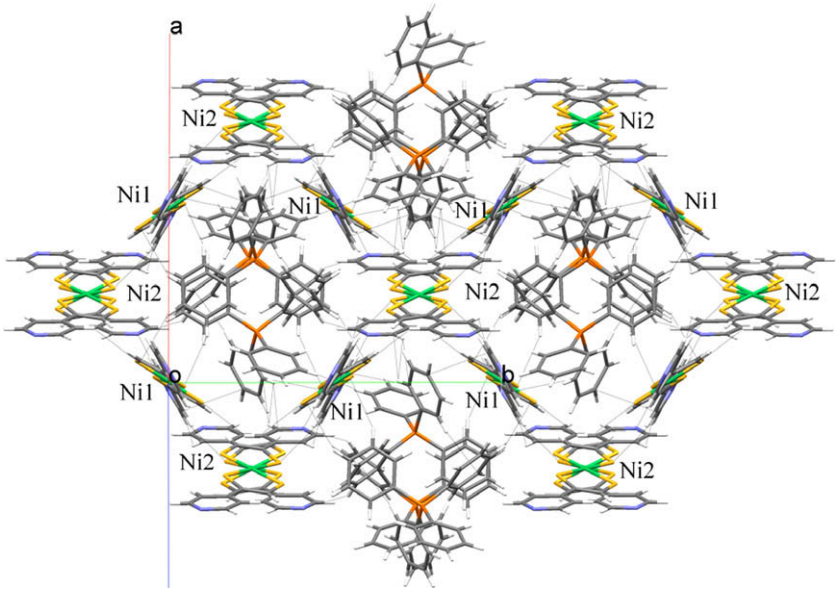

Fig. 6. Crystal structure of **1**, viewed along the cation stacking axis.

these complexes [19]. In these monoanionic complexes the ligand may have a significant contribution to the frontier orbitals and can be viewed as being present in one of two extreme forms: the dianionic ene-1,2-dithiolate or the neutral dithioketone [1a,19]. In this particular case of the $[M(4\text{-pedt})_2]^-$ dithiolenes where the dithiole ring is not fused to any aromatic ring the lengths of the C–C and C–S bonds provide a direct indication on the nature of a dithiolene ligand. In all complexes studied the C=C (1.32–1.36 Å) and C–S (1.71–1.77 Å) bond lengths were found in the range typical of sp^2 C hybridisation [23] indicative of the ene-1,2-dithiolate form of the dithiolene and M(III) oxidation state. In the solid state, the monoanionic $[M(4\text{-pedt})_2]^-$ species with M = Ni, Cu and Au,

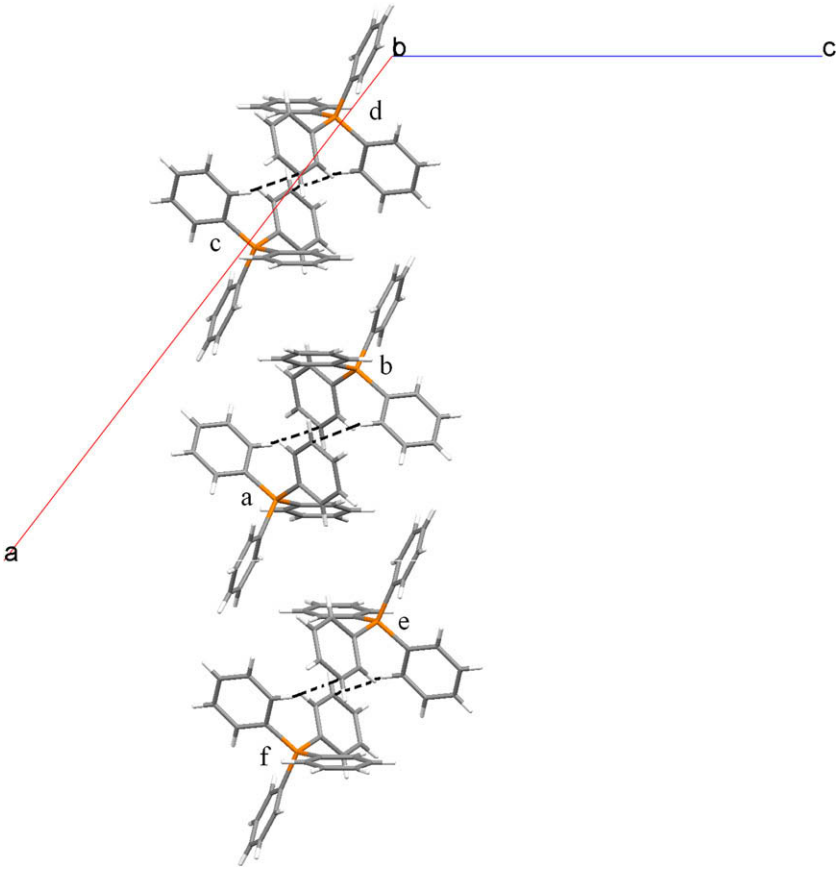

Fig. 7. Chain of $[PPh_4]^+$ cations in compound **1** viewed along *b*. [Symmetry codes: (a) *x*, *y*, *z*; (b) 1.5 − *x*, ½ − *y*, 1 − *z*; (c) −1/2 + *x*, 1/2 − *y*; −½ + *z*; (d) 1 − *x*, *y*, 1/2 − *z*; (e) 2 − *x*, *y*, 1.5 − *z*; (f) 1/2 + *x*, 1/2 − *y*, 1/2 + *z*].

present different packing patterns and interactions depending on the cation type complexes. The compounds **1** and **2** are isostructural with the previously reported $(PPh_4)[Au(4\text{-pedt})_2]$ [9]. A characteristic of their crystal structure is the occurrence of cation columns along $b + c$, isolated by a alveolar anion arrangement (Fig. 6). As **1** and **2** are isostructural, we will only focus our structural analysis on the compound **1**. In the cation column, it is possible to observe cation pairs and the only intra column short contact is H25···C54 (2.785(3) Å) (Fig. 7). Such inversion-centred arrangements of PPh_4^+ cations are a recurrent feature among molecules bearing at least three phenyl rings on the same atoms [24]. In the alveolar anionic arrangement there are no S–S short contacts, but there are several other N···H, S···H, H···H short contacts and π–π interactions (Table S3). Of particular note are the C52–H52···N2 (3.514(4) Å) and C6–H6···N2 (3.537(3) Å) weak hydrogen bonding interactions.

The crystal structure of the two tetrabutylammonium salts (**3** and **5**) can be seen as made from parallel mixed chains constituted by pairs of cations alternating with an anion. The parallel chains alternate with sheets of anions (Fig. 8). These two compounds have several short intermolecular contacts but none of them corresponds to S–S interactions (for compound **5** Table S1).

The crystal structure of compound **6** · **2H$_2$O** can be described in terms of parallel alternated layers of $[Ni(4\text{-pedt})_2]^-$ anions and $Na(18C6)^+$ cations. The coordination sphere of the sodium cation is completed by two water molecules, one on each side (Fig. 9). The angle between the anionic units mean plan is about 44.53. Only between anions and cations, there are relevant interactions. Besides several N···O, N···H, C···H, O···S, S···H short contacts a hydrogen bond N1···H4A–O4 (2.916(4) Å) is present, which is the most important, governing the chain-like arrangement anion–cation–anion(...) as depicted in Fig. 10.

3.3. Redox behaviour

The redox behaviour of the different complexes was studied by cyclic voltammetry in CH_2Cl_2 solution containing $[n\text{-}Bu_4N]PF_6$ (0.1 M) as electrolyte. Each of the compounds **1**, **3** and **6** containing the Ni complex (cyclic voltammogram of compound **6**, Supplementary data, Fig. 4S) exhibit two quasi reversible redox waves, at circa −0.52 V and 0.30 V versus $[Fc]^+/[Fc]$ which are ascribed to the couples $[Ni(4\text{-pedt})_2]^{2-}/[Ni(4\text{-pedt})_2]^-$ and $[Ni(4\text{-pedt})_2]^-/[Ni(4\text{-pedt})_2]^0$ (Table 3). The $E^{1/2}$ potentials for the Ni complexes in these three compounds are identical. The variation in the scan rate (from 10 to 200 mV s^{-1}) monitoring the wave profile, the separation of the peak potentials ($\delta E > 59$ mV), and the ratio of the cathodic and anodic currents ($-I_p^c/I_p^a \approx 1$) indicate that the processes are quasi reversible. The low values of the first process explain the difficulty in preparing the dianionic complex, which can be spontaneously oxidised by minor amounts of oxygen or other oxidising agents. On the other hand the low value of the second process predicts that the neutral complex can be prepared. However attempts to isolate it were so far not successful.

The compounds **2** and **4** containing the Cu complex (cyclic voltammogram of compound **2**, Supplementary data, Fig. 5S) show also identical cyclic voltammograms with one quasi reversible redox process at ca −0.38 V, ascribed to the couples $[Cu(4\text{-pedt})_2]^{2-}/[Cu(4\text{-pedt})_2]^-$ (Table 3). Scans to higher positive potentials

Table 3
Redox potentials (mV, vs. $[Fc]^+/[Fc]$) of **1**–**6** at room temperature in CH_2Cl_2 containing $[n\text{-}Bu_4N]PF_6$ (0.1 M) with a 100 mV s^{-1} scan rate.

Compound	$[ML_2]^{2-}/[ML_2]^-$	$[ML_2]^-/[ML_2]^0$
[*n*-Ph$_4$P][Ni(4-pedt)$_2$] (**1**)	−519	297
[*n*-Ph$_4$P][Cu(4-pedt)$_2$] (**2**)	−374	676
[*n*-Bu$_4$N][Ni(4-pedt)$_2$] (**3**)	−523	303
[*n*-Bu$_4$N][Cu(4-pedt)$_2$] (**4**)	−379	771
[*n*-Bu$_4$N][Au(4-pedt)$_2$] (**5**)		585
[Na(18C6)][Ni(4-pedt)$_2$] (**6**)	−518	298
[Na(18C6)][Au(4-pedt)$_2$] (**7**)		588

(∼0.6 V versus $[Fc]^+/[Fc]$) reveal the existence of an irreversible process which should correspond to the couple $[Cu(4\text{-pedt})_2]^-/[Cu(4\text{-pedt})_2]^0$.

Compounds **5** and **7** containing the $[Au(4\text{-pedt})_2]^-$ complex (cyclic voltammogram of compound **7**, Supplementary data, Fig. 6S) both exhibit one oxidation and a reduction process, assigned to the couples $[Au(4\text{-pedt})_2]^-/[Au(4\text{-pedt})_2]^0$ (Table 3). For both gold compounds, the $E^{1/2}$ potentials are very similar. A variation in the scan rate (from 10 to 200 mV s^{-1}) monitoring the wave profile, the separation of the peak potentials ($\delta E > 59$ mV), and the ratio of the cathodic and anodic currents ($-I_p^c/I_p^a = 1$) indicate that the oxidation is not electrochemically reversible.

It is known that the nature of the R substituent in the complexes $Ni(S_2C_2R_2)_2$ affects the redox potentials and even a small variation in the electron withdrawing substituent can tune the redox potential [1a,25]. In this case we observe that the pyridine groups, which are only partially rotated relatively to the central bisdithiolene plane, thus retaining the possibility of interacting via their π systems, make the 4-pedt complexes easier to oxidise than phenyl substituted or even unsubstituted edt ligands [5].

3.4. EPR measurements

While the monoanionic Cu and Au complexes are diamagnetic the monoanionic Ni, complexes, as d^7 system in a square planar coordination are expected to be paramagnetic $S = 1/2$ systems. Indeed the EPR spectra of **1**, **3** and **6** as powders, show a signal typical of monoanionic Ni dithiolene complexes [1,26,27,28] with rhombic symmetry, with $g_1 = 2.1035$, $g_2 = 2.0518$, $g_3 = 2.0128$ compound **1** and $g_1 = 2.1153$, $g_2 = 2.0480$, $g_3 = 2.0087$ for the compound **6**. In the case of compound **3** the EPR spectrum denotes the existence of two Ni sites with different g_1 (2.0849 and 2.0834) and g_3 (2.0183 and 2.0113) values but with the same (or very close) g_2 value (2.0701). This should be related with the different crystallographic environments of the two anionic Ni units in the asymmetric unit of the compound **3**. In fact Ni1 unit besides quite asymmetric Ni–S bonds lengths has several short S···H–C contacts with cations which are absent in unit Ni2. In spite of the existence of two different anionic Ni^{III} units in the asymmetric unit of **1**, the two sets of g principal values for this compound are not distinguishable within experimental error in agreement with the fact that the two Ni units present comparable short contacts between the S atoms.

3.5. Magnetic susceptibility

The magnetic susceptibility measurements of the compounds **1** and **3** in the range 2–300 K indicate a paramagnetic behaviour with effective magnetic moments essentially temperature independent down to ∼15 K with values at room temperature of 1.72 and 1.79 BM, respectively. For compound **6**, the room temperature magnetic moment is 1.67 BM, but it slightly increases upon cooling down to 11 K (1.85 BM), denoting weak ferromagnetic interactions that are not effective at lower temperature (confirmed by magnetisation versus magnetic field at 3.1 K – see Supplementary data). These values are consistent with a $S = 1/2$ state, due to an unpaired electron of a d^7 system in an quadrangular coordinating geometry. The calculated magnetic moment for the three compounds assuming a Curie law for $S = ½$ and g values g_{av} from EPR is 1.78 BM.

4. Conclusion

The new paramagnetic complex, $[Ni(4\text{-pedt})_2]^-$, with the dithio-azo 4-pedt ligand has been synthesised, and isolated as the $[PPh_4]^+$, $[n\text{-}Bu_4N]^+$ and Na^+(18C6) salts, which were characterised by single crystal X-ray diffraction, cyclic voltametry EPR and magnetic susceptibility. These three compounds present three distinct crystal structures and similar magnetic and redox behaviour, characteristic of monoanionic Ni complexes with quadrangular coordinating geometry and exhibit two quasi reversible redox waves, attributed to the $[Ni(4\text{-pedt})_2]^{2-}/[Ni(4\text{-pedt})_2]^-$ and $[Ni(4\text{-pedt})_2]^-/[Ni(4\text{-pedt})_2]^0$ redox processes.

Two other complexes with the same dithio-azo ligand have been synthesised, $[Au(4\text{-pedt})_2]^-$ and $[Cu(4\text{-pedt})_2]^-$, isolated as the $[n\text{-}Bu_4N]^+$ and Na^+(18C6) salts in case Au and as the $[PPh_4]^+$ and $[n\text{-}Bu_4N]^+$ salts in case Cu, all of them exhibiting diamagnetic behaviour.

The $[n\text{-}Bu_4N]^+$ and $[PPh_4]^+$ salts of Au and Cu complexes are isostructural with the correspondent Ni ones. Both Ni and Cu complexes present a similar quasi reversible redox process corresponding to the couple $[ML_2]^{2-}/[ML_2]^-$ but they differ in the couple $[ML_2]^-/[ML_2]^0$ which is a quasi reversible process for Ni and an irreversible one for Cu. For the Au complexes only the couple $[ML_2]^-/[ML_2]^0$ is observed.

The ability of the pyridine groups of these complexes to coordinate other metals is presently under study and will be reported subsequently.

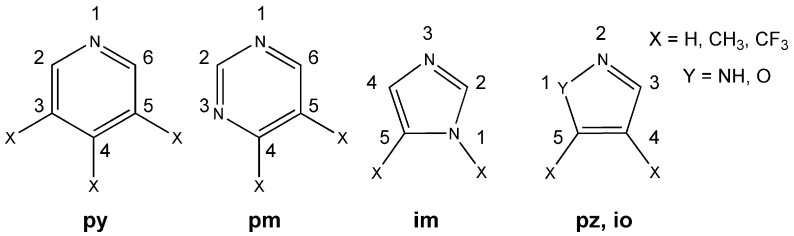

Fig. 1. Pyridine-, pyrimidine-, pyrazole-, isoxazole- and imidazole-based ligand skeletons and positional numbering.

the reactivity of $AuCl_3$(4R-py) {4R-py = *para*-substituted pyridines} are highlighted. Moreover, to avoid mixing of the electronic effects on the stability of the M–N bond with well-known steric effects, no group was put in an α-position with respect to the coordinating nitrogen atom [2,3].

The proton affinities (PA) of the ligands have been computed on the basis of Eq. (1) as the total energy difference between the heterocycle L (E_L) and its protonated counterpart $[LH]^+$ ($E_{[LH]^+}$). These energy values have been corrected for zero-point vibrational energies (ZPVE) and the thermal contributions to enthalpy at 298 K ($\Delta H^{0\rightarrow 298}$). Finally, the pressure–volume work term $-RT$, where R is the gas constant, which is equal to -0.6 kcal mol^{-1} at 298 K, has been added to Eq. (1) [10]. All the energy data, obtained using the DFT B3LYP/6-31G** method, are reported in Table 1:

$$PA = E_L + ZPVE_L + \Delta H_L^{0\rightarrow 298} - E_{[LH]^+} - ZPVE_{[LH]^+} - \Delta H_{[LH]^+}^{0\rightarrow 298} - RT \quad (1)$$

Hwang et al. studied the correlation between experimental and B3LYP/6-31G** computed proton affinities for 16 N-heterocycles, constituted by pyridine, imidazole and pyrazole derivatives [11], observing that the PA variations are correctly predicted by the *ab initio* simulations, even if the calculated absolute values are about 3% too large.

In our case the maximum PA value, 238.0 kcal mol^{-1}, corresponds to 1,5-dimethyl-1*H*-imidazole, 1,5-$(CH_3)_2$-im, while the lowest, 189.2 kcal mol^{-1}, is that of 4,5-bis-trifluoromethyl-isoxazole, 4,5-$(CF_3)_2$-io. Even if the considered PA range is relatively wide, about 49 kcal mol^{-1}, the computed N–H bond lengths of the protonated species are all quite similar, falling in a range between 1.011 and 1.019 Å. Also the difference of the zero-point vibrational energy (ZPVE) between $[LH]^+$ and L, attributable to the N–H vibrations in the protonated form of the ligands, is rather constant for all the considered heterocycles, ranging between 7.9 and 9.0 kcal mol^{-1}. The difference between the thermal contributions to enthalpy ($\Delta H^{0\rightarrow 298}$) of L and $[LH]^+$ is quite small, affecting the PA to a maximum of 1.3 kcal mol^{-1}.

2.2. Mulliken charges and charge-proton affinity relationship

Once the desired proton affinities of the various ligands L were computed, the geometries of the corresponding $AuCl_3L$ complexes were optimised using the hybrid B3PW91 density functional. The Mulliken charges of the $AuCl_3$ fragment (Q_{AuCl_3}), which are simply the sums of the Mulliken charges of the three chlorine atoms and the gold centre, were computed and the values are reported in Table 2.

Very good linear relationships between the Mulliken charge of the $AuCl_3$ fragment in the $AuCl_3L$ complexes and the computed proton affinity of L have been found for all the groups of the considered monodentate nitrogen ligands (pyridines, pyrimidines, imidazoles, pyrazoles and isoxazoles), as depicted in Figs. 2–6. The PA values are, in all cases, referred to the nitrogen atom that coordinates the metal centre.

Besides the $AuCl_3$ charge, the PA variation of the ligands also affects the geometry of the considered compounds. On reducing the ligand proton affinity, the coordinated heterocycle tends to be more perpendicular with respect to the $AuCl_3$ plane. In the pyridine-complexes the Cl_{cis}–Au–N–C_α dihedral angle ranges from 130.8° for the 3,4,5-$(CH_3)_3$-py derivative to 138.2° for {3,4,5-$(CF_3)_3$-py}. In the isoxazole-complexes the same angle ranges between 143.4° {4,5-$(CH_3)_2$-io} and 153.6° {4,5-$(CF_3)_2$-io}, while in the imidazole derivatives it varies between 159.4° {1,5-$(CH_3)_2$-im} and 164.0° {1,5-$(CF_3)_2$-im}. The Cl_{cis}–Au–N–C_α dihedral angle is scarcely affected by the PA in the pyrimidine-complexes, where it is around 136.5°, and in the pyrazole-complexes, where the heterocycle is on about the same plane as $AuCl_3$.

The general equation describing the linear correlation between the ligand proton affinity PA and the $AuCl_3$ charge Q_{AuCl_3} is Eq. (2):

$$Q_{AuCl_3}^L = \alpha^L PA^L + \beta^L \quad (2)$$

Both the α^L and β^L parameters, reported in Table 3, depend upon the nature of the considered class of the ligands. The slopes α^L represent the variations of electron density on the $AuCl_3$ fragment on varying the proton affinity of L, that is, on changing the σ-donor ability of the considered ligands. The β^L values formally represent the $AuCl_3$ Mulliken charges in complexes where the coordinated N-ligand has zero proton affinity. From these two parameters it is easy to compute the proton affinity value corresponding to a zero charge of the $AuCl_3$ fragment, PA_0^L, on the basis of Eq. (3):

$$PA_0^L = -\beta^L/\alpha^L \quad (3)$$

This last parameter represents the ligand minimum basicity for a charge variation in $AuCl_3$, and therefore it can be considered as the minimum proton affinity to have a meaningful bond between the heterocycle and the metal ion. Table 3 reports the α^L, β^L and PA_0^L values for the five groups of considered ligands.

The increasing basicity of the free ligands L, expressed by the PA values, corresponds to a rise of the σ-donor ability, which leads to a more negative Mulliken charge on the $AuCl_3$ fragment. From Table 3 it is observable that the slopes of the plots corresponding to different types of N-ligands, α^L, are not the same: the pyridine and pyrimidine ligands show the greatest $AuCl_3$ charge variations on changing the basicity of L, while the other N-donors show lower variations. This means that the different slopes found on changing the N-donor type represent a measure of the π-acidity of these nitrogen ligands once coordinated to $AuCl_3$. In fact, the π-acceptor ability tends to keep the charge on the $AuCl_3$ fragment as constant as possible on varying the σ-donation: the greater the π-acidity, the lower the charge variation on changing the proton affinity. The α^L gradients are therefore representative of the relative π-back-donation potential of a group of coordinated ligands: lower values correspond to poorer π-acidities. On this basis, on comparing the slopes of the linear relationships a new π-acidity scale can be built:

Pyridines ≈ pyrimidines < imidazoles < pyrazoles ≈ isoxazoles.

The α^L values are compared in the histogram in Fig. 7. From Table 3 and Fig. 7 it is to be stressed that this theoretical approach

Table 1
Total energies (E_L and $E_{[LH]^+}$), zero-point vibrational energies ($ZPVE_L$ and $ZPVE_{[LH]^+}$) and thermal contributions to enthalpy at 298 K ($\Delta H_L^{0\rightarrow 298}$ and $\Delta H_{[LH]^+}^{0\rightarrow 298}$) of the ligands L and their conjugated acids $[LH]^+$ and computed proton affinities (PA). highlights the greater π-acceptor ability of the five-membered N-donor heterocycles compared to the six-membered ligands, a different behavior which was already supposed on the basis of kinetic measurements. In particular, in a previous work regarding the displacement of N-donors by chloride from $AuCl_3$ (N-ligands) [3d] a difference of about 1 kcal mol^{-1} between the free energies of activation of pyridines and five-membered N-donors with equivalent pK_a values was found, the pyridines showing a greater lability. The lower reactivity of the coordinated five-membered heterocycles was mainly attributed to the enforcement of the Au–N bond caused by π-back-donation, in agreement with the results reported in this paper.

Finally, some words should be given on the PA_0^L values reported in Table 3. As already described, PA_0^L represents the ligand minimum proton affinity for a charge variation in $AuCl_3$, therefore it is interpretable as the minimum ligand basicity for a meaningful bond between the heterocycle and the metal ion. Surprisingly, the PA_0^L values are substantially comparable for all the groups of ligands considered in this work, falling around 150 kcal mol^{-1}. Therefore, PA_0^L seems a parameter more related to the electronic features of $AuCl_3$ than those of the coordinating nitrogen donors. In particular, it is presumable that PA_0^L could be related to the electrophilicity of the metal fragment, but further experiments must be carried out to strengthen this hypothesis.

3. Conclusions

On the basis of the linear relationships between the $AuCl_3$ Mulliken charges in $AuCl_3L$ complexes and the proton affinities of several groups of N-donor heterocycles L, it has been possible to build a new theoretical π-acidity scale for pyridines, pyrimidines, imidazoles, pyrazoles and isoxazoles referred to a specific metal fragment. A different π-back-bonding ability between five- and six-membered ligands has been highlighted, in perfect agreement with already reported experimental evidences. Finally, the minimum proton affinity value to have a meaningful bond between $AuCl_3$ and N-donor heterocycles, like those considered in this work, has been estimated.

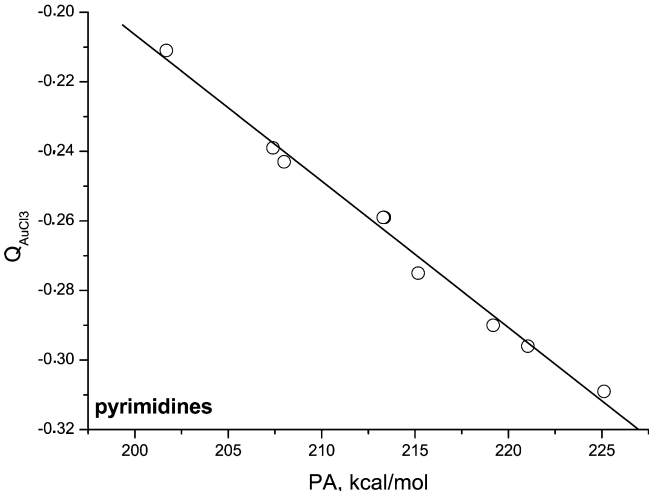

Fig. 3. $AuCl_3$ Mulliken charge (Q_{AuCl_3}) against the ligand proton affinity PA for $AuCl_3L$ complexes, L = pyrimidines.

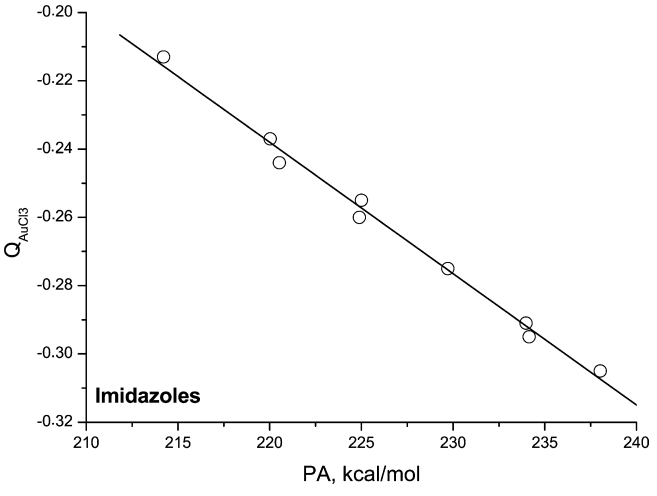

Fig. 4. $AuCl_3$ Mulliken charge (Q_{AuCl_3}) against the ligand proton affinity PA for $AuCl_3L$ complexes, L = imidazoles.

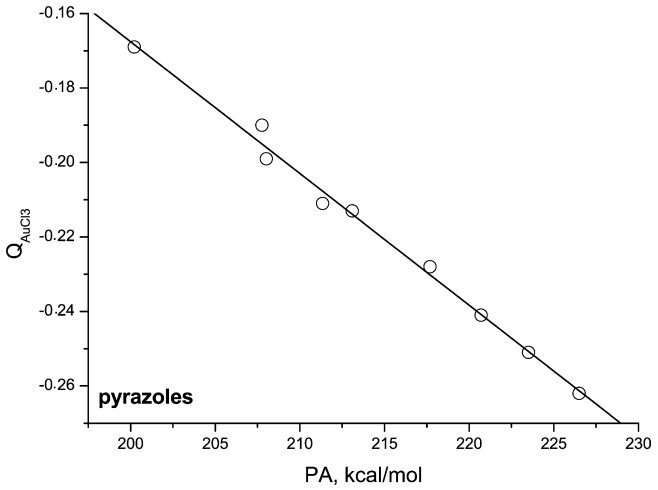

Fig. 5. $AuCl_3$ Mulliken charge (Q_{AuCl_3}) against the ligand proton affinity PA for $AuCl_3L$ complexes, L = pyrazoles.

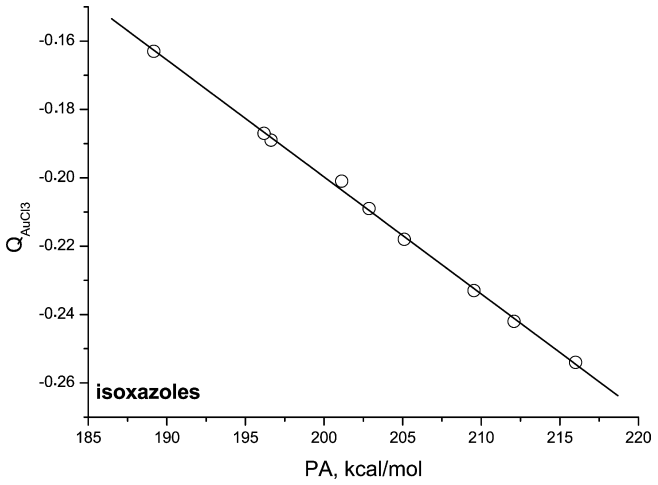

Fig. 6. $AuCl_3$ Mulliken charge (Q_{AuCl_3}) against the ligand proton affinity PA for $AuCl_3L$ complexes, L = isoxazoles.

Table 3
α^L, β^L and PA_0^L values for the five groups of considered ligands.

Ligand	α^L (mol kcal^{-1})	β^L	PA_0^L (kcal mol^{-1})
Pyridines (py)	−0.0045 ± 0.0001	0.69 ± 0.03	150 ± 10
Pyrimidines (pm)	−0.0042 ± 0.0002	0.64 ± 0.04	150 ± 10
Imidazoles (im)	−0.0039 ± 0.0001	0.61 ± 0.03	160 ± 10
Pyrazoles (pz)	−0.0035 ± 0.0001	0.54 ± 0.02	150 ± 10
Isoxazoles (io)	−0.00342 ± 0.00005	0.48 ± 0.01	142 ± 5

These studies will continue, changing both the metal centre and the ancillary ligands, in order to discover if this kind of computational approach could be a useful tool to gain more information on the role of π-back-bonding in d^8 metal complexes and on the relative electrophilicity of different metal fragments.

4. Computational details

The ground-state computational geometry optimisations of the $AuCl_3L$ complexes {L = pyridines (py), pyrimidines (pm), imidazoles (im), pyrazoles (pz) and isoxazoles (io)} were carried out using the hybrid DFT B3PW91 method [12] without symmetry constrains, in combination with the Dunning's split-valence double-ζ D95V basis set on the light atoms [13] and the ECP-based SDD basis set on Au and Cl [14]. The geometry optimisations of

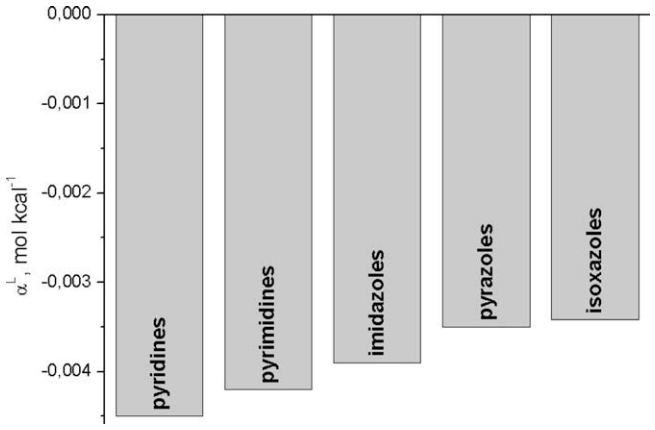

Fig. 7. α^L values of the $AuCl_3$-coordinated ligands.

the free ligands L and of their conjugate acids $[LH]^+$ were carried out with the hybrid B3LYP functional [15] using Pople's split-valence double-ζ polarised 6-31G** basis set [16]. The "restricted" formalism was applied in all calculations and no solvation model was added. A standard accuracy of 10^{-3} Å and 10^{-1}° was used in all the geometry optimisations and all the resulting stationary points were characterized as true minima (*i.e.*, no imaginary frequencies). From the IR simulations, carried out with the harmonic oscillator approximation, the zero-point vibrational energies (ZPVEs) were computed. The thermal contributions to enthalpy have been calculated on the basis of statistical mechanical standard formulas (rigid-rotor approximation). Charge distributions were derived from Mulliken population analysis [17]. Mulliken charges are reported, as usual, as the differences between the number of protons and the number of electrons. Unfortunately, as already observed in a previous work [9], the Natural Bond Orbitals analysis [18] does not properly work for the systems considered in this paper: the software separates the $AuCl_3L$ complexes into three different fragments, $[AuCl_2]^{x+}$, $[Cl]^{y-}$ and $[L]^{(y-x)+}$, leading to wrong results, including an apparent d^{10} configuration of the gold centre. We did not succeed in obtaining any useful results by trying to perform Bader's atoms-in-molecules (AIM) analysis [19] on the $AuCl_3L$ complexes.

All calculations were carried out at CINECA (Centro Italiano di Supercalcolo, Bologna, Italy) using IBM p5-575 computers with 64-bit IBM Power5 processors operating at 1.9 GHz frequency. The software used was GAUSSIAN'03 [20].

Scheme 1. Some of the ligands discussed in the text. The ligand used in this work is the maleamate(−1) ion (**VII**, HL^-).

instead of a carboxylate group, is expected – due to different charge, electronic properties and hydrogen bonding capabilities – to significantly affect the chemical and structural identity of the resultant metal complexes in comparison with that of the α,ω-dicarboxylate complexes.

With the above considerations in mind, we had explored "ligand blend" reaction systems involving the succinamate(−1) ligand ($n = 2$ in **V** of Scheme 1; $Hsucm^-$) and various aromatic chelating *N*,*N*′-donors as a means to dinuclear and polymeric copper(II) complexes [4]. In a subsequent step we used the maleamate(−1) (**VII** in Scheme 1; HL^-)/phen ligand combination in copper(II) chemistry [5]. The coordination chemistry of maleamic acid (H_2L) was unknown before those studies. It was expected that the presence of the double bond between the central carbon atoms would alter the coordination chemistry of H_2L as compared to that of succunamic acid (H_2sucm). The HL^-/phen ligand "blend" led to interesting mononuclear, dinuclear and polymeric copper(II) complexes containing intact HL^-. We also reported that the $Cu(ClO_4)_2 \cdot 6H_2O/H_2L$/phen reaction systems in MeOH, in the absence of external OH^- ions, affords complex $[Cu_2(L')_2(ClO_4)(phen)_2(MeOH)](ClO_4)$ in which the maleamate(−1) ion has been transformed to the monomethyl maleate(−1) ligand L'^- (**IX** in Scheme 1) via a novel, Cu^{II}-promoted process and through the intermediate formation of the HL^--free coordination polymer $[Cu(ClO_4)(phen)(MeOH)_2]_n$ [5b].

We illustrate herein how the reactions of $Cu(ClO_4)_2 \cdot 6H_2O$ with H_2L *and* bpy yield a series of interesting complexes containing the intact HL^- or ligands derived from the metal ion-assisted transformation of the primary amide group. The use of bpy allows direct structural comparison with the complexes featuring the corresponding α,ω-dicarboxylate (**III** in Scheme 1; maleate) and the succinamate(−1) ligand ($n = 2$ in **V** of Scheme 1; $Hsucm^-$), i.e. the $Cu^{II}/^-OOC–CH{=}CH–COO^-$/bpy and $Cu^{II}/Hsucm^-$/bpy complexes. We have also wondered if isostructural bpy analogues of the Cu^{II}/HL^-/phen complexes [5] could be prepared and if the bpy versus phen difference would lead to different Cu^{II}-assisted reactivity chemistry on HL^-. The answers of these questions are provided in this work.

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials as received (Aldrich Co.). All chemicals and solvents were of reagent grade. Elemental analyses for C, H and N were performed on a Perkin–Elmer 2400/*II* automatic analyzer. IR spectra were recorded from KBr pellets in the range 4000–400 cm^{-1} on a Bruker Equinox 55/S FT-IR spectrophotometer.

Safety note: Perchlorate salts are potentially explosive; such compounds should be synthesized and used in small quantities, and treated with utmost care at all times.

2.2. Compound preparation

2.2.1. $[Cu_2(HL)_2(bpy)_2(H_2O)_2](ClO_4)_2$ (**1**) and $[Cu(L'')(bpy)]_n \cdot 2nH_2O$ (**2** $\cdot 2nH_2O$) in a mixture

A colorless aqueous solution (1.5 ml) of $LiOH \cdot H_2O$ (0.018 g, 0.44 mmol) was added to a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeCN (20 ml) to give a white suspension. Solid bpy (0.045 g, 0.29 mmol) was then added to afford a colorless solution. A blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.107 g, 0.29 mmol) in MeCN (10 ml) was finally added to obtain a blue solution. X-ray quality blue prismatic crystals and light blue long plate-like crystals in an approximate ratio of 1:1 formed by layering of the blue solution with a mixture of Et_2O/*n*-hexane (40 ml, 1:1 v/v). The crystals were separated manually and dried in air. X-ray crystallography revealed that blue prisms correspond to complex **1** and light blue plates correspond to complex **2** $\cdot 2nH_2O$. FT-IR for **1** (KBr pellet, cm^{-1}): 3442sb, 3354sb, ~3190mb, 2922w, 2850w, 1676s, 1640s, 1603vs, 1598vs, 1496m, 1473s, 1447vs, 1382m, 1308m, 1249w, 1198w, 1177w, 1112vs, 1082vs, 1022vw, 877w, 820m, 764s, 728s, 655m, 624s, 490w, 478w. *Anal.* Calc. for $C_{28}H_{28}N_6O_{16}Cl_2Cu_2$ (902.56): C, 37.26; H, 3.12; N, 9.31. Found: C, 36.97; H, 3.63; N, 9.16%. FT-IR for **2** $\cdot 2nH_2O$ (KBr pellet, cm^{-1}): 3385mb, 3109w, 3072w, 3032vw, 2360w, 1648w, 1591vs, 1560vs, 1542sh, 1494w, 1474w, 1448m, 1432m, 1404m, 1315m, 1286w, 1249w, 1199w, 1175w, 1160vw, 1112vw, 1055w, 1031w, 1017w, 987w, 913w, 875vw, 859w, 836w, 782m, 732w, 679vw, 650w, 596w, 448vw. *Anal.* Calc. for $C_{14}H_{14}N_2O_6Cu$ (369.82): C, 45.47; H, 3.82; N, 7.57. Found: C, 45.35; H, 3.74; N, 7.64%.

2.2.2. $[Cu_2(HL)_2(bpy)_2(H_2O)_2](ClO_4)_2$ (**1**)

Solid $LiOH \cdot H_2O$ (0.018 g, 0.43 mmol) was added to a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeOH (20 ml) to give again a colorless solution. Solid $Cu(ClO_4)_2 \cdot 6H_2O$ (0.159 g, 0.43 mmol) was then added to obtain a light blue solution. A colorless solution

of bpy (0.067 g, 0.43 mmol) in MeOH (5 ml) was then added to give a final blue solution, which was layered with a mixture of Et_2O/*n*-hexane (30 ml, 1:1 v/v) to afford X-ray quality blue prismatic crystals. The crystals were collected by filtration under vacuum, washed with cold MeOH (2 ml) and Et_2O (2 ml), and dried in air. Typical yields were in the 55–60% range. The identity of the blue crystals was established as **1** by unit cell determination (a = 7.421(4), b = 10.273(5), c = 11.868(6) Å, α = 83.43(2), β = 87.90(2), γ = 77.59(2)°; see Table 1). The IR spectrum of the crystals was identical to that of the authentic material prepared in a mixture with **2** · 2*n*H_2O. *Anal.* Calc. for $C_{28}H_{28}N_6O_{16}Cl_2Cu_2$ (902.56): C, 37.26; H, 3.12; N, 9.31. Found: C, 36.87; H, 3.32; N, 9.28%.

*2.2.3. [$Cu_2(HL)_2(bpy)_2(H_2O)_2$]($ClO_4$)$_2$ · 2H_2O (**1** · 2H_2O)*

A colorless aqueous solution (2 ml) of LiOH · H_2O (0.018 g, 0.44 mmol) was added to a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeCN (20 ml) to give a white suspension. Solid $Cu(ClO_4)_2 \cdot 6H_2O$ (0.159 g, 0.43 mmol) was then added to give a light blue suspension, which was stirred for 30 min. A colorless solution of bpy (0.067 g, 0.43 mmol) in MeCN (6 ml) was finally added to obtain a blue mixture, which was filtered to give a clear blue solution. X-ray quality blue prismatic crystals of **1** · 2H_2O were obtained by layering of the blue solution with a mixture of Et_2O/*n*-hexane (40 ml, 1:1 v/v). The crystals were collected by filtration under vacuum, washed with cold MeCN (2 ml) and Et_2O (2 ml), and dried in air. Typical yields were in the 55–60% range. FT-IR for **1** · 2H_2O (KBr pellet, cm^{-1}): 3394sb, 3197sb, 2359w, 1679s, 1641m, 1602vs, 1496m, 1473m, 1445vs, 1374m, 1303s, 1250w, 1196w, 1171w, 1098vs, 932vw, 907vw, 890vw, 863vw, 822m, 776s, 730m, 658w, 625s, 503w, 479w. *Anal.* Calc. for $C_{28}H_{32}N_6O_{18}Cl_2Cu_2$ (938.59): C, 35.83; H, 3.44; N, 8.95. Found: C, 35.96; H, 3.28; N, 8.77%.

*2.2.4. [Cu(L″)(bpy)]$_n$ · 2nH_2O (**2** · 2nH_2O)*

2.2.4.1. Method A. Solid LiOH · H_2O (0.018 g, 0.43 mmol) was added to a colorless aqueous solution (25 mL) of H_2L (0.049 g, 0.43 mmol). A solution of bpy (0.034 g, 0.22 mmol) in MeOH (5 mL) was then added to the above solution. An aqueous light blue solution (5 mL) of $Cu(ClO_4) \cdot 6H_2O$ (0.080 g, 0.22 mmol) was finally added to afford a light blue solution. Slow evaporation of the final solution yielded turquoise needle-like crystals of **2** after one week. The identity of the crystals was confirmed by unit cell determination (a = 7.352(3), b = 19.945(9), c = 10.099(5) Å, β = 98.39(1)°) and IR spectroscopy. The crystals were collected by filtration under vacuum and dried in air. Typical yields were 60%. *Anal.* Calc. for $C_{14}H_{14}N_2O_6Cu$ (369.82): C, 45.47; H, 3.82; N, 7.57. Found: C, 45.65; H, 3.94; N, 7.74%.

2.2.4.2. Method B. A colorless aqueous solution (3 ml) of LiOH · H_2O (0.037 g, 0.88 mmol) was added to a colorless solution of H_2L'' (0.051 g, 0.44 mmol) in MeCN (25 ml) to give a white suspension. Solid bpy (0.069 g, 0.44 mmol) was then added to give a new white suspension. A light blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.163 g, 0.44 mmol) in MeCN (15 ml) was finally added to obtain a blue suspension which was filtered to give a final blue solution. Turquoise needle-like crystals of **2** · 2*n*H_2O were obtained in closed vials at ~4 °C after *ca* 30 days. The identity of the product was revealed by IR spectroscopy. The crystals were collected by filtration under vacuum and dried in air.

*2.2.5. [$Cu_2(L'')(bpy)_2(H_2O)_2$]$_n$(ClO_4)$_{2n}$ · 0.5*n*H_2O (**3** · 0.5*n*H_2O)*

The procedure is identical to that of Method B above. X-ray quality blue prismatic crystals of **3** · 0.5*n*H_2O were obtained by layering of the blue solution with Et_2O (50 ml). The crystals were collected by filtration under vacuum and dried in air. Typical yields were ~55%. FT-IR for **3**: (KBr pellet, cm^{-1}): 3446mb, 3114w, 3087w, 1647w, 1601m, 1583vs, 1561vs, 1496m, 1473s, 1446vs, 1416m, 1320s, 1282w, 1270w, 1250m, 1209m, 1176sh, 1162sh, 1089vs, 1033w, 1017w, 930w, 912w, 857w, 830m, 771vs, 730s, 702w, 664w, 623vs, 576w, 457vw, 441w, 418w. The dried product analyzed as **3**. *Anal.* Calc. for $C_{24}H_{22}N_4O_{14}Cl_2Cu_2$ (788.45): C, 36.56; H, 2.81; N, 7.11. Found: C, 36.38; H, 2.79; N, 7.07%. Vapor diffusion of Et_2O (10 ml) into the blue reaction solution yielded light blue needle-like crystals of **4**, which were not suitable for X-ray crystallography. The FT-IR spectrum of this material is identical to that of **7b** (vide infra).

*2.2.6. [$Cu_2(L'')_2(bpy)_2$] · 2MeOH (**5** · 2MeOH)*

2.2.6.1. Method A. Solid LiOH · H_2O (0.036 g, 0.86 mmol) was added to a colorless solution of H_2L'' (0.050 g, 0.43 mmol) in MeOH

Table 1

(20 ml) to give a white suspension. Solid bpy (0.067 g, 0.43 mmol) was added and the resultant new suspension was stirred under heating for 30 min. Finally a light blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.159 g, 0.43 mmol) in MeOH (10 ml) was added to give a dark blue suspension, which was filtered to obtain a dark blue solution. Layering of the final reaction solution with a mixture of Et_2O/*n*-hexane (50 ml, 1:1 v/v) gave large blue prismatic crystals, which were collected by filtration under vacuum, washed with cold MeOH (5 ml) and Et_2O (5 ml), and dried in air. Typical yields were in the 65–70% range. FT-IR (KBr pellet, cm^{-1}): 3385sb, 3108m, 3072vw, 3061vw, 3033vw, 2031vw, 1826vw, 1647vs, 1590vsb, 1561vsb, 1541ssh, 1494m, 1474m, 1446s, 1423m, 1402vs, 1314s, 1286m, 1250m, 1223w, 1193m, 1176m, 1157m, 1113w, 1100w, 1073vw, 1057m, 1037m, 1018m, 988w, 911m, 860, 836m, 781s, 732s, 681w, 664wsh, 650w, 643wsh, 601mb, 448vw. The dried product was analyzed as solvent free. *Anal.* Calc. for $C_{28}H_{20}N_4O_8Cu_2$ (667.58): C, 50.38; H, 3.02; N, 8.39. Found: C, 50.22; H, 3.21; N, 8.19%.

2.2.6.2. Method B. Solid $LiOH \cdot H_2O$ (0.036 g, 0.86 mmol) was added to a colorless solution of H_2L'' (0.050 g, 0.43 mmol) in MeOH (20 ml) to give a white suspension. Solid bpy (0.067 g, 0.43 mmol) was then added and the new resultant suspension was stirred under heating for 30 min. Finally a light blue solution of $Cu(NO_3)_2 \cdot 2.5H_2O$ (0.100 g, 0.43 mmol) in MeOH (10 ml) was added to give a blue suspension, which was filtered to obtain a blue solution. Layering of the final solution with Et_2O (30 ml) gave cubic blue crystals, which were collected by filtration under vacuum, washed with cold MeOH (5 ml) and Et_2O (5 ml), and dried in air. Typical yields were in the 65–70% range. The identity of the crystals was confirmed by unit cell determination (a = 18.49(1), b = 7.885(5), c = 21.31(1) Å, β = 98.26(2)°; see Table 1) and by IR comparison with the authentic material prepared using Method A. *Anal.* Calc. for $C_{28}H_{20}N_4O_8Cu_2$ (667.58): C, 50.38; H, 3.02; N, 8.39. Found: C, 50.52; H, 3.18; N, 8.31%.

*2.2.7. $[Cu_2(L')_2(bpy)_2(ClO_4)_2]$ (**6**)*

Solid bpy (0.045 g, 0.29 mmol) was dissolved in a colorless solution of H_2L (0.050 g, 0.43 mmol) in MeOH (20 ml). A light blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.107 g, 0.29 mmol) in MeOH (8 ml) was then added to obtain a light blue solution which was layered with a mixture of Et_2O/*n*-hexane (30 ml, 1:1 v/v). Slow mixing initially gave a light blue polycrystalline solid (**7a**). Upon storage of the closed layering tube at room temperature for two weeks, the polycrystalline powder was transformed into blue, X-ray quality crystals of the product (**6**). The crystals were collected by filtration under vacuum and dried in air. Typical yields were >55%. FT-IR (KBr pellet, cm^{-1}): 3414mb, 3118w, 3088w, 3036vw, 2959w, 2856vw, 2027vw, 1719vs, 1648sh, 1601sb, 1568s, 1497m, 1474m, 1447s, 1432s, 1361m, 1324sh, 1317m, 1237s, 1174m, 1162m, 1117vs, 1046s, 995w, 967w, 926m, 900w, 828m, 817w, 771s, 746w, 728s, 684w, 666w, 651w, 624s, 493w. The IR spectrum of the light blue powder is completely different compared to that of **6**. *Anal.* Calc. for $C_{30}H_{26}N_4O_{16}Cl_2Cu_2$ (896.55): C, 40.19; H, 2.92; N, 6.25. Found: C, 40.30; H, 2.87; N, 6.17%.

*2.2.8. $[Cu(ClO_4)_2(bpy)(MeCN)_2]$ (**7b**)*

A colorless solution of bpy (0.069 g, 0.44 mmol) in MeCN (12 ml) was added to a light blue solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.163 g, 0.44 mmol) in the same solvent (40 ml) to give a light blue-turquoise solution. X-ray quality, light blue crystals of the product formed by layering of the final solution with a mixture of Et_2O/*n*-hexane (50 ml, 1:1 v/v). The crystals were collected by filtration under vacuum, washed with cold MeCN (2 ml) and Et_2O (3 ml), and dried in air. Typical yields were in the 55–60% range. FT-IR (KBr pellet, cm^{-1}): 3440mb, 3106w, 2362vw, 1869vw, 1742vw, 1636w, 1609sh, 1600s, 1566m, 1496m, 1472s, 1443s, 1326m, 1317m, 1285w, 1246m, 1144vsb, 1091vsb, 1023s, 1013sh, 940m, 904m, 774s, 728s, 658w, 653sh, 627vs, 472vw, 417m. *Anal.* Calc. for $C_{14}H_{14}N_4O_8Cl_2Cu_2$ (564.29): C, 29.80; H, 2.50; N, 9.93. Found: C, 29.67; H, 2.64; N, 9.86%.

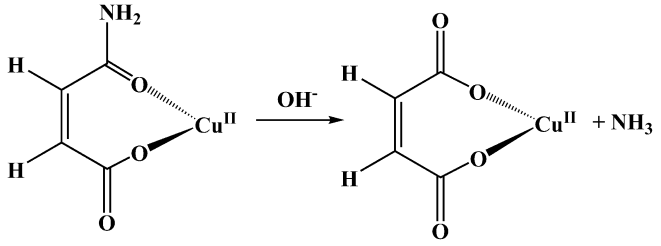
2.3. Single-crystal X-ray crystallography

A blue prismatic crystal of **1** (0.10 × 0.20 × 0.40 mm) and a light blue prismatic crystal of **2** · $2nH_2O$ (0.18 × 0.25 × 0.45 mm) were mounted in air. Blue prismatic crystals of **1** · $2H_2O$ (0.20 × 0.30 × 0.45 mm), **5** · 2MeOH (0.20 × 0.30 × 0.55 mm), **6** (0.25 × 0.35 × 0.50 mm) and **7b** (0.10 × 0.10 × 0.45 mm) were mounted in capillaries. A blue prismatic crystal of **3** · $0.5nH_2O$ (0.08 × 0.13 × 0.51 mm) was taken directly from the mother liquor and immediately cooled to −93 °C. Diffraction measurements for **3** · $0.5nH_2O$ and **7b** were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Cu Kα radiation. Data for **1**, **1** · $2H_2O$, **5** · 2MeOH and **6** were collected on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions (for **1**, **1** · $2H_2O$ **2** · $2nH_2O$, **5** · 2MeOH, **6**) were determined and refined by using the angular settings of 25 automatically centred reflections in the range $11 < 2\theta < 23°$. Intensity data were recorded using a $\theta-2\theta$ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using CRYSTAL LOGIC software. For **3** · $0.5nH_2O$ and **7b**, data collection (ω-scans) and processing (cell refinement, data reduction and empirical absorption correction) were performed using the CRYSTALCLEAR program package [6]. Important crystallographic and refinement data are listed in Table 1. Compound **2** · $2nH_2O$ has been reported earlier [7] and will not be further discussed from the crystallographic point of view.

The structures were solved by direct methods using SHELXS-97 [8] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [9]. Further crystallographic details for **1**: $2\theta_{max} = 50°$; reflections collected/unique/used, 3238/3075 [R_{int} = 0.0126]/3075; 337 parameters refined; $(\Delta/\sigma)_{max}$ = 0.009; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.351/−0.304 e/Å^3; R/R_w (for all data), 0.0369/0.1082. Further crystallographic details for **1** · $2H_2O$: $2\theta_{max} = 50°$; reflections collected/unique/used, 3449/3241 [R_{int} = 0.0208]/3241; 317 parameters refined; $(\Delta/\sigma)_{max}$ = 0.003; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.954/−1.392 e/Å^3; R/R_w (for all data), 0.0689/0.1858. Further crystallographic details for **3** · $0.5nH_2O$: $2\theta_{max} = 130°$; reflections collected/unique/used, 19328/4944 [R_{int} = 0.0471]/4944; 499 parameters refined; $(\Delta/\sigma)_{max}$ = 0.002; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.891/−0.760 e/Å^3; R/R_w (for all data), 0.06256/0.1713. Further crystallographic details for **5** · 2MeOH: $2\theta_{max} = 50°$; reflections collected/unique/used, 2785/2696 [R_{int} = 0.0082]/2696; 264 parameters refined; $(\Delta/\sigma)_{max}$ = 0.002; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.266/−0.281 e/Å^3; R/R_w (for all data), 0.0416/0.0864. Further crystallographic details for **6**: $2\theta_{max} = 50°$; reflections collected/unique/used, 3228/3135 [R_{int} = 0.0595]/3135; 287 parameters refined; $(\Delta/\sigma)_{max}$ = 0.014; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.744/−0.911 e/Å^3; R/R_w (for all data), 0.0682/0.1769. The crystals of **7b** had poor quality with large ω-widths, which probably came from two different domains. As a result, the data set contained reflections with large F_o^2 compared to the expected F_c^2 value; these reflections have been omitted during the refinement. Further crystallographic details for **7b**: $2\theta_{max} = 130°$; reflections collected/unique/used, 4987/1405 [R_{int} = 0.1150]/1405; 144 parameters refined; $(\Delta/\sigma)_{max}$ = 0.001; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 1.198/−0.799 e/Å^3; R/R_w (for all data), 0.0881/0.1869. In all structures, all non-H atoms were refined anisotropically. Hydrogen atoms were located by difference maps and were refined isotropically, except those of the methyl group in **6** and those in **7b** which were introduced at calculated positions as riding on bonded atom.

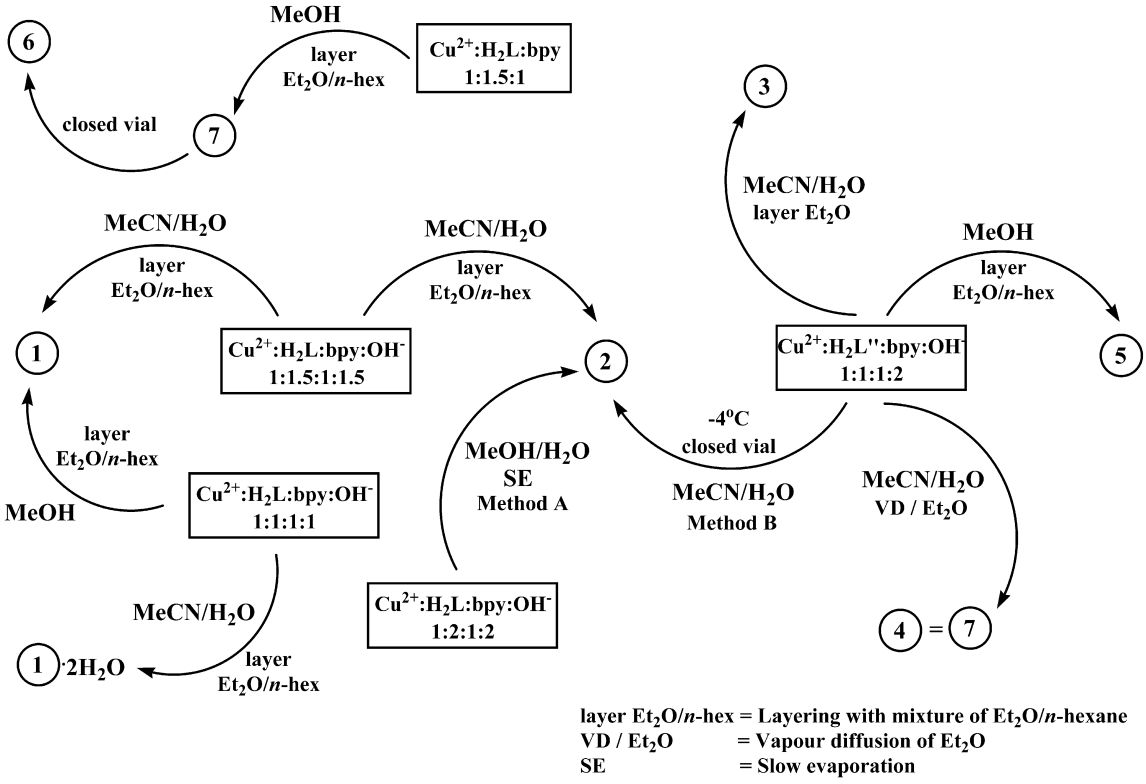
3. Results and discussion

3.1. Syntheses



Our previous investigation of the tertiary Cu^{II}/H_2L/phen reaction system [5] has led to interesting results concerning the chemical and structural properties of the compounds isolated. In order to examine to what extent the nature of the aromatic ligand might affect the identity of the products isolated, we have expanded our research on the investigation of the Cu^{II}/H_2L/bpy reaction system. The influence of the same synthetic parameters, i.e., the solvent, the absence or presence of external hydroxides, the inorganic anion in the copper(II) salts and the stoichiometry of the reactants, has been investigated. In the present work we have kept constant the inorganic anion of the copper(II) source; we have explored reactions employing $Cu(ClO_4)_2 \cdot 6H_2O$ which contains an anion with a weak coordinating capability.

Our initial efforts involved the reaction of $Cu(ClO_4)_2 \cdot 6H_2O$ with 1.5 equivalents of H_2L and one equivalent of bpy in the presence of 1.5 equivalents of $LiOH \cdot H_2O$ in MeCN/H_2O (20:1 v/v). Blue prismatic crystals of **1** and light blue plate-like crystals of the known [7] polymeric complex **2** have been simultaneously isolated in an approximate 1:1 ratio (Scheme 3). Assuming the formation of equimolar quantities of the two products, the preparation of **1** and **2** can be summarized in the balanced Eq. (1):



$$3n\mathrm{Cu(ClO_4)_2 \cdot 6H_2O} + 3n\mathrm{H_2L} + 3n\mathrm{bpy} + 4n\mathrm{LiOH \cdot H_2O} \xrightarrow{\mathrm{MeCN/H_2O}} \underset{\mathbf{1}}{n[\mathrm{Cu_2(HL)_2(bpy)_2(H_2O)_2](ClO_4)_2}} + \underset{\mathbf{2}}{[\mathrm{Cu(L'')(bpy)}]_n} \cdot 2n\mathrm{H_2O} + 4n\mathrm{LiClO_4} + n\mathrm{NH_3} + 21n\mathrm{H_2O} \quad (1)$$

The dianion L''^{2-} in **2** is the maleate(−2) ligand (**III** in Scheme 1) that formed in situ by the hydrolysis of the primary amide group to carboxylate function, accompanied by simultaneous release of ammonia. It is well known that such hydrolysis reactions are accelerated by metal ions [10]. Coordination of the oxygen atom of the amide group to the Cu^{II} centre in solution modifies the reactivity of that group. The metal ion polarizes the carbonyl group increasing the $\delta+$ character of the amide carbon, and the OH^- ion can attack this carbon to generate the tetrahedral intermediate, which collapses – with loss of NH_3 – to give the maleate(−2) ligand containing two carboxylate groups. Avoiding any detailed mechanistic scheme and assuming the formation of a seven-membered chelating ring, the $HL^- \rightarrow L''^{2-}$ transformation is depicted in Scheme 2. We believe that the little amount of water added in the reaction mixture – in order to dissolve $LiOH \cdot H_2O$ and to prevent contamination of the product by $LiClO_4$ which is insoluble in anhydrous MeCN – or contained in the starting materials is beneficial to the hydrolysis of the primary amide group and the formation of the maleate(−2) ligand followed by its subsequent coordination affording **2**.

With the identity of compound **1** established by crystallographic studies, we have employed the 'correct' stoichiometric ratio of the reactants to obtain pure **1**. However, from the strictly 1:1:1:1 $Cu(ClO_4)_2 \cdot 6H_2O/H_2L$/bpy/$LiOH \cdot H_2O$ reaction mixture in MeCN/H_2O (20:1 v/v) we have isolated compound **1** · $2H_2O$ upon

Scheme 2. The maleamate(−1) to maleate(−2) transformation observed during the preparation of complex **2** from the $Cu(ClO_4) \cdot 6H_2O/H_2L$/bpy/$OH^-$ reaction system in MeCN/H_2O.

Scheme 3. Diagram of the reaction pathways, showing the various combinations of stoichiometries and crystallization methods, and the products obtained by each.

layering of the resultant blue solution with mixture of Et_2O/*n*-hexane (Scheme 3). The structure of the dinuclear cation in **1** · $2H_2O$ is completely similar to that of the corresponding cation in **1**, see Eq. (2). The presence of two water solvate molecules in the structure of the former leads to a completely different crystal structure due to hydrogen bonding interactions. In order to study the influence of the solvent on the reaction that leads to **1** · $2H_2O$, we have performed the above stoichiometric reaction in MeOH and have isolated pure **1** [Eq. (3)]; its identity was established by unit cell determination:

$$2Cu(ClO_4)_2 \cdot 6H_2O + 2H_2L + 2bpy + 2LiOH \cdot H_2O \xrightarrow{MeCN/H_2O} \underset{\mathbf{1} \cdot 2H_2O}{[Cu_2(HL)_2(bpy)_2(H_2O)_2](ClO_4)_2 \cdot 2H_2O} + 2LiClO_4 + 12H_2O \quad (2)$$

$$2Cu(ClO_4)_2 \cdot 6H_2O + 2H_2L + 2bpy + 2LiOH \cdot H_2O \xrightarrow{MeOH} \underset{\mathbf{1}}{[Cu_2(HL)_2(bpy)_2(H_2O)_2](ClO_4)_2} + 2LiClO_4 + 14H_2O \quad (3)$$

The next question addressed was whether, and in what manner, changes in the reactants' ratio might affect the product identity. Thus, reaction of $Cu(ClO_4)_2 \cdot 6H_2O$ with two equivalents of H_2L and one equivalent of bpy in the presence of two equivalents of $LiOH \cdot H_2O$ in MeOH/H_2O (1:6 v/v) afforded a blue solution, which yielded light blue crystals of **2**, see Eq. (4). The identity of the crystals was confirmed by unit cell determination (see preparation of **2**, Method A, Scheme 3):

$$Cu(ClO_4)_2 \cdot 6H_2O + nH_2L + nbpy + 2nLiOH \cdot H_2O \xrightarrow{MeOH/H_2O} \underset{\mathbf{2} \cdot 2nH_2O}{[Cu_2(L'')(bpy)]_n \cdot 2nH_2O} + 2nLiClO_4 + nNH_3 \uparrow + 7nH_2O \quad (4)$$

Three features of the reaction represented by Eq. (4) deserve comments: First, the isolation of complex **2** containing the maleate(−2) ligand is in agreement with our previous conclusion that the presence of water in the reaction mixture is responsible (together with the presence of OH^- ions) for the hydrolysis of the maleamate(−1) ligand to maleate(−2). Second, the 'wrong' Cu^{II} to HL^- ($H_2L + OH^-$) reaction ratio (1:2) employed for the preparation of **2** (see Section 2), compared to that required by Eq. (4) (1:1), did not prove detrimental to the clean isolation of the product. And third, our inability to isolate complexes containing HL^- from the above reaction solution does not corroborate its quantitate hydrolysis to L''^{2-}; other more soluble species could be present in the reaction mixture, although not isolated in the solid state.

In order to prepare pure **2** in a rational manner we have used maleic acid, H_2L'' as starting material. Reaction of $Cu(ClO_4)_2 \cdot 6H_2O$ with one equivalent of H_2L'' and one equivalent of bpy in the presence of two equivalents of $LiOH \cdot H_2O$ in MeCN/H_2O (20:1 v/v) gave a blue solution which upon standing in closed vials at −4 °C afforded a turquoise microcrystalline solid which was characterized as **2** by infrared spectroscopy [Eq. (5)]. Layering of the blue reaction solution with Et_2O afforded blue crystals of **3** · 0.5*n*H_2O [Eq. (6)], whereas vapor diffusion of Et_2O onto the above blue solution afforded light blue microcrystals of **4** – not suitable for X-ray analysis – which were characterized by infrared spectroscopy as complex **7b** (vide infra). The isolation of **2**, **3** and **4** from the same reaction solution is an impressive example of the dramatic influence of the crystallization method on the product identity (Scheme 3):

$$nCu(ClO_4)_2 \cdot 6H_2O + nH_2L'' + nbpy + 2nLiOH \cdot H_2O \xrightarrow{MeCN/H_2O(-4\ ^\circ C)} \underset{\mathbf{2} \cdot 2nH_2O}{[Cu(L'')(bpy)]_n \cdot 2nH_2O} + 2nLiClO_4 + 8nH_2O \quad (5)$$

$$2nCu(ClO_4)_2 \cdot 6H_2O + nH_2L'' + 2nbpy + 2nLiOH \cdot H_2O \xrightarrow{MeCN/H_2O} \underset{\mathbf{3} \cdot 0.5nH_2O}{[Cu_2(L'')(bpy)_2(H_2O)_2]_n \cdot (ClO_4)_{2n} \cdot 0.5nH_2O} + 2nLiClO_4 + 13.5nH_2O \quad (6)$$

In a next step, we wondered whether the reaction solvent might affect the isolation of **2** prepared by the direct use of H_2L'' and we performed a reaction analogous to (5) in MeOH (Scheme 3). The resultant blue solution was layered with a mixture of Et_2O/*n*-hexane to afford blue crystals of **5** (as its MeOH solvate) according to Eq. (7). In our efforts to further investigate the parameter space of the above reaction, we employed $Cu(NO_3)_2 \cdot 2.5H_2O$ as starting material keeping all the other reaction parameters unchanged. We thought that the presence of the more coordinatively active NO_3^- in the reaction mixture might lead to new chemical and structural types. However, we isolated only compound **5**; the presence of other more soluble nitrate-containing species in the reaction solution cannot be ruled out [Eq. (8)]:

$$2Cu(ClO_4)_2 \cdot 6H_2O + 2H_2L'' + 2bpy + 4LiOH \cdot H_2O + 2MeOH \xrightarrow{MeOH} \underset{\mathbf{5} \cdot 2MeOH}{[Cu_2(L'')_2(bpy)_2] \cdot 2MeOH} + 4LiClO_4 + 20H_2O \quad (7)$$

$$2Cu(NO_3)_2 \cdot 2.5H_2O + 2H_2L'' + 2bpy + 4LiOH \cdot H_2O + 2MeOH \xrightarrow{MeOH} \underset{\mathbf{5} \cdot 2MeOH}{[Cu_2(L'')_2(bpy)_2] \cdot 2MeOH} + 4LiNO_3 + 13H_2O \quad (8)$$

Our final efforts involved the study of the influence of the externally added OH^-s on product identity, based on our previous experience with the $Cu(ClO_4)_2$? $6H_2O$/H_2L/phen reaction system, where the absence of external OH^-s leads to a novel transformation of HL^- in alcohols [5b]. Thus, reaction of $Cu(ClO_4)_2$? $6H_2O$ with two equivalents of H_2L and one equivalent of bpy in MeOH afforded a light blue solution which was layered with a mixture of Et_2O/*n*-hexane to yield a light blue polycrystalline solid (**7a**). This solid completely transformed to blue crystals upon storage of the closed layering tube for two weeks. X-ray crystallography revealed (vide infra) that the blue crystals had the formula $[Cu_2(L')_2(bpy)_2(ClO_4)_2]$ (**6**) [Eq. (9)] (Scheme 3), where L'^- is the monoanion of monomethyl maleate, $^-$OOC–CH=CH–COOMe (**IX** in Scheme 1). This $H_2L \rightarrow HL'$ ligand transformation had been established crystallographically for the first time during our previous work on phen-containing $Cu(ClO_4)_2 \cdot 6H_2O$/H_2L reaction mixtures in MeOH in the absence of OH^-s. This process is metal-ion promoted/assisted as we have shown by certain 'blind' experiments [5b]. We have performed numerous experiments in order to obtain X-ray quality crystals of the 'intermediate' compound **7a**, which were all unsuccessful. The IR spectrum of this material showed the typical bpy and ClO_4^- bands, and the ν(OH) band of MeOH at ~3440 cm^{-1}; no bands attributable to amide, carboxylate or ester groups of HL^- or/and L'^- ligands were visible. Analytical data repeatedly indicated the empirical formula $Cu(ClO_4)_2(bpy) \cdot x$MeOH (x = 2–3). As expected, the polycrystalline product **7a** could be isolated by the direct 1:1 reaction of $Cu(ClO_4)_2 \cdot 6H_2O$ and bpy in MeOH in high yields (>60%). With the goal to obtain better crystals of a compound that would be structurally analogous to **7a**, we performed the 1:1 reaction between $Cu(ClO_4)_2 \cdot 6H_2O$ and bpy in MeCN. We were lucky enough to obtain X-ray quality, light blue crystals of $[Cu(ClO_4)_2(bpy)(MeCN)_2]$ (**7b**) by layering of the light blue-turquoise reaction solution with a mixture of Et_2O/*n*-hexane [Eq. (10)]. The IR spectra of **7a** and **7b** are almost identical – except the bands due to the coordinated solvent – suggesting that the former is structurally similar to the latter:

$$2Cu(ClO_4)_2\cdot 6H_2O + 2H_2L + 2bpy + 2MeOH \xrightarrow{MeOH} \times [Cu_2(L')_2(bpy)_2](ClO_4)_2 + 2NH_4ClO_4 + 12H_2O \quad (9)$$
6

$$Cu(ClO_4)_2\cdot 6H_2O + bpy + 2MeCN \xrightarrow{MeCN} \times [Cu(ClO_4)_2(bpy)(MeCN)_2] + 6H_2O \quad (10)$$
7b

The fact that complex **7a** does not contain HL^- or any ligand derived from H_2L does not allow us to draw direct mechanistic conclusions for the Cu^{II}-assisted/promoted [5b] transformation of HL^- to L'^- in MeOH. Again coordination of the oxygen atom of the amide group in solution is likely to modify the reactivity of that group [10]. The metal centre polarizes the carbonyl group and MeOH can attack the amide carbon to generate the tetrahedral intermediate **X** (Scheme 1), which may collapse after intramolecular proton transfer to the amido group and loss of NH_3 to give the ligand L'^- that contains both an ester and a carboxylate group. In accordance with our belief that the observed ligand transformation does not take place through hydrolysis of the amide group and esterification of one of the carboxylate groups, the Cu^{II}/L''^{2-}/bpy reaction systems in MeOH or MeOH/H_2O ([7b], this work) give ternary complexes containing only the maleate (L''^{2-}, **III** in Scheme 1) ligand and not complexes of L'^-; however, a strict comparison between our system that led to **6** and the other reaction mixtures (which use H_2L'' as starting material) is not possible, because the latter contained a considerable OH^- concentration.

Alcoholysis of free amides in organic chemistry is possible but it is seldom observed, except for the imidazolide type of amide [11]. Czarnik has reported [12] that Ni^{II} can be used to accelerate the conversion of a pyridyl substituted acrylamide to the corresponding ethyl acrylate at 78 °C, i.e., the ethanolysis of a primary amide. Although no mechanistic details were reported, the study provided strong evidence that preactivation of the amide group, through O-coordination, is necessary for the conversion of the amide group to the corresponding ester in EtOH, i.e., for the ethanolysis reaction. A similar activation is possible for the observed $HL^- \rightarrow L'^-$ tranformation during the preparation. Metal ion (Zn^{II}, Cd^{II}, Hg^{II})-assisted alcoholysis reactions of *secondary* amides *in the presence of external OH^-s* have been reported [13]. The proposed mechanism [13c] involves reaction of the deprotonated-amide intermediate complex with MeOH to yield a structure involving both amide and methoxide nucleophile coordination to the metal centre; attack of the nucleophile at the amide carbonyl carbon and breakdown of the resulting intermediate initiates the amide cleavage which produces the free ester and the corresponding amine-ligated complex.

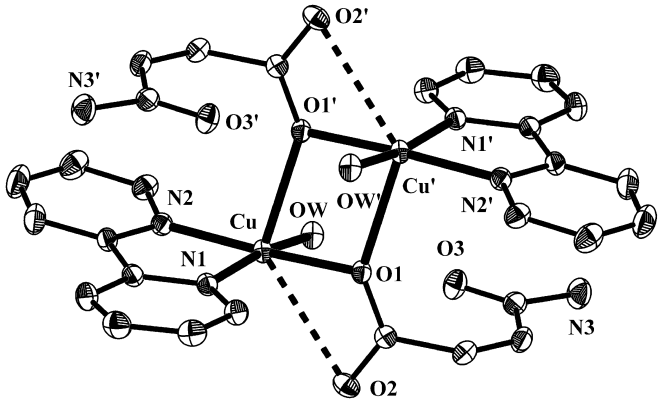


Fig. 1. Partially labeled ORTEP plot of the cation of **1** with ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity. Primed atoms are generated by symmetry (′) = 1 − *x*, 2 − *y*, −*z*.

We believe that this mechanism is not possible in our case because amide deprotonation of the coordinated HL^- is unlikely due to the absence of external OH^-s in the reaction mixture.

To investigate the possible role of bpy in the Cu^{II}-assisted/promoted $HL^- \rightarrow L'^-$ tranformation, 1:2 reactions between $Cu(ClO_4)_2\cdot 6H_2O$ and H_2L in MeOH, and in the absence of external OH^-s, were performed. No crystalline solids suitable for single-crystal X-ray crystallography could be isolated. Analytical results were not reproducable, but the IR spectra of the isolated powders all exhibit the characteristic strong $\nu(C{=}O)_{ester}$ band at 1718 cm^{-1}, which is the diagnostic spectral feature of L'^-. Thus, the bpy co-ligand does not seem to be crucial for the amide–ester transformation.

3.2. Description of structures

The molecular structures of the dinuclear cations that are present in complexes **1** and **1** · $2H_2O$ are very similar. We give below a comparative structural description for the cations of **1** (Fig. 1, Table 2) and **1** · $2H_2O$ (Fig. S1, Table 2). The structure of the cation in both complexes consists of two centrosymmetrically related Cu^{II} ions bridged by the carboxylate groups of two HL^- ligands which present the less common η^2 coordination mode. A chelating bpy and a water molecule complete five-coordination around each Cu^{II} atom. The neutral primary amide groups of the HL^- ligands remain uncoordinated. The Cu···O(2) distance of 2.847 Å (dashed line in Fig. 1) provides evidence for weak interaction, as has sometimes [14] (but not always [15]) observed for monoatomic bridging carboxylate groups. The coordination geometry about each metal ion in both complexes is well described as square pyramidal with the bridging carboxylate oxygen atoms occupying the apical positions for the two Cu^{II} centres; for example, in **1**, atoms O(1′) and O(1) occupy the apical positions for Cu and Cu′, respectively. Analysis of the shape-determining angles using the approach of Reedijk and coworkers [16] yields trigonality index, τ, values of 0.09 and 0.26 for the Cu^{II} ions in **1** and **1** · $2H_2O$, respectively (τ = 0 and 1 for perfect *sp* and *tbp* geometries, respectively). As expected, the axial bonds are the longest.

In the crystal lattice of **1**, the cations are hydrogen bonded and form chains extending parallel to the *a*-axis [Ow···O(2) (−*x*, 2 − *y*, −*z*)], which are further associated through ClO_4^- ions to form a 2D network parallel to the (0 1 1) plane (Fig. 2, Table 5).

Symmetry transformations used to generate equivalent atoms: in **1**, (′) = 1 − *x*, 2 − *y*, −*z*; in **1** · $2H_2O$, (′) = 1 − *x*, −*y*, 2 − *z*.

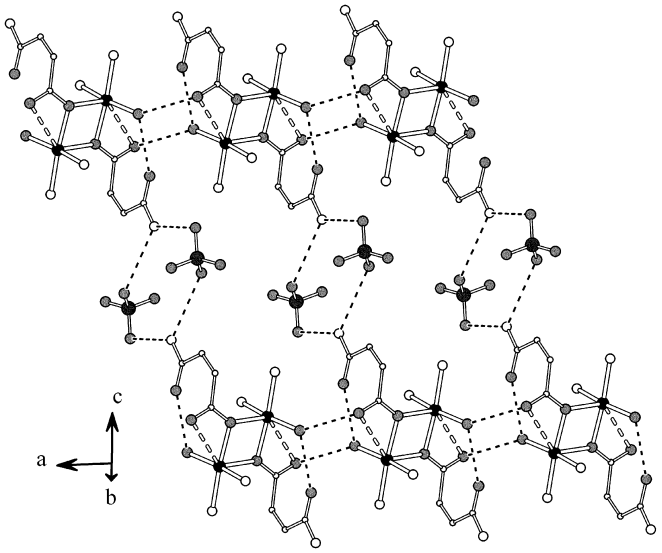

Fig. 2. A part of the 2D structure of **1** due to H-bonding interactions. Colour code: Cu, black; O, medium grey; N, large white; C, small white; Cl, dark grey. H bonds are presented by dashed lines. Only the N atoms of the bpy ligands are shown.

In the crystal lattice of **1** · $2H_2O$, the cations are hydrogen bonded and form chains extending parallel to the *b*-axis [N(3)···O(3) $(1-x, 1-y, 2-z)$], which are further associated to form a 2D network parallel to the (001) plane (Fig. 3, Table 5).

The crystal structure of **3** · $0.5nH_2O$ consists of 1D polymeric chains based on dinuclear $[Cu_2(L'')(bpy)_2(H_2O)_2]^{2+}$ cations (L''^{2-} = the dianion of maleic acid) (Fig. 4, Table 3), perchlorate counterions and H_2O solvate molecules; the latter two will not be further discussed. The structure of the dinuclear repeating unit in **3** consists of two Cu^{II} atoms bridged by two *syn,syn* $\eta^1:\eta^1:\mu_2$ carboxylate groups belonging to two L''^{2-} anions. Each L''^{2-} anion bridges two neighboring $[Cu_2^{II}]$ units through its two carboxylato groups thus promoting the formation of a helical chain along the *b*-axis. A chelating bpy molecule and an aquo ligand complete five-coordination around each Cu^{II} atom. The coordination geometry about each metal ion is well described as square pyramidal with a coordinated H_2O molecule occupying the apical position. Analysis of the shape-determining angles using the approach of Reedijk and co-workers [16] yields trigonality index, τ, values of 0.21 and 0.11 for Cu(1) and Cu(2), respectively. As expected, the axial bonds are the longest. There is a significant intramolecular stacking interaction

Symmetry transformations used to generate equivalent atoms: (′) = $0.5-x, 0.5+y,$

between the aromatic ligands; the mean distance and the angle between the two bpy planes in *syn* positions are 3.83 Å and 5.2°, respectively. We strongly believe that the structure of the dinuclear subunit is maintained by these intramolecular, attractive interactions [4,17]. For a detailed discussion of such structural phenomena in complexes containing the $\{M_2^{II,II}(\eta^1:\eta^1:\mu_2\text{-}O_2CR)_2\}^{2+}$ core, see Ref. [17]. In the crystal lattice of **3**, there are intra-chain hydrogen bonding interactions, as well as intermolecular interactions which lead to the connection of the chains through the solvate water and the perchlorate oxygen atoms (Table 5).

The structure of the dinuclear molecule that is present in complex **5** · 2MeOH consists of two centrosymmetrically related Cu^{II} ions bridged by two carboxylato groups from two maleate(−2)

ligands (Fig. 5, Table 4). The bridging carboxylate group adopts the rather rare η^2 coordination mode. The second carboxylate group of each L''^{2-} ligand is monodentately coordinated to Cu^{II} giving rise to a remarkable seven-membered $CuO_{carboxylate}C–C=C–CO_{carboxylate}$ chelating ring. A chelating bpy completes five-coordination around each metal ion, creating an almost perfect square pyramidal geometry ($\tau = 0.04$). The apical position of the square pyramid is occupied by a bridging carboxylate oxygen atom; thus, O3 and O3′ occupy the apical positions of Cu1′ and Cu1, respectively. In the crystal lattice of **5**, each dinuclear complex is hydrogen bonded to two adjacent methanol solvate molecules (Table 5). Complex **5** bears striking similarity to the various solvates of $[Cu_2(L'')_2(phen)_2]$ [18].

The structure of the dinuclear complex **6** (Fig. 6, Table 4) consists of centrosymmetrically related Cu^{II} ions bridged by the carboxylato group of two L′ anions, where L'^- is the monomethyl maleate(−1) ligand (**IX** in Scheme 1) formed by the Cu^{II}-assisted/promoted transformation of HL^-. The L'^- ion behaves as a carboxylate-type ligand, i.e., the ester group remains uncoordinated in accordance with the known weak coordinating capacity of the ester function. In the molecule of **6**, the carboxylate group of the L'^- ligands is in the familiar *syn,syn* $\eta^1:\eta^1:\mu_2$ coordination mode. A chelating bpy molecule and one coordinated ClO_4^- complete five-coordination at each Cu^{II} centre. The metal coordination geometry is well described as square pyramidal with the terminal monodentate ClO_4^- occupying the apical position; the parameter τ is 0.14. Perchlorate coordination is rare in copper(II) chemistry; however, there exist examples of structurally characterized copper(II) perchlorato complexes [17,19]. There is a significant intramolecular stacking interaction between the aromatic ligands; the mean distance and the angle between the two bpy planes in *syn* positions are 3.61 Å and 2.1°, respectively. As in the dinuclear subunits of **3** · 0.5*n*H_2O, we do believe that the structure of the dinuclear molecule is maintained by these intramolecular, attractive aromatic stacking interactions [17]. Complex **6** joins a small family of structurally characterized compounds possessing the $\{Cu_2(\eta^1:\eta^1:$

μ_2-$O_2CR)_2\}^{2+}$ core (R = H, CH_3, C_2H_5, $CH_2CH_2C_6H_5$) and stacked aromatic ligands in *syn* positions [4,17,20].

The structure of **7b** consists of mononuclear molecules [Cu(bpy)$(ClO_4)_2$(MeCN)$_2$] (Fig. 7, Table S1). The coordination sphere of the Cu^{II} ion consists of four N atoms belonging to one bpy and two coordinated *cis* MeCN molecules and two O atoms from two *trans* perchlorate ions. The coordination geometry can be described as distorted octahedral with the perchlorate oxygen atoms in the apical positions at Cu(1)–O(1) = 2.515(1) and Cu(1)–O(4) = 2.548(7) Å. The Cu–N bond distances in the equatorial plane are Cu(1)–N(1) = 1.971(5) and Cu(1)–N(2) = 1.988(6) Å. There is a mirror plane of symmetry passing through Cu(1), Cl(1), Cl(2), O(1), O(2), O(4) and O(6) which is perpendicular to the equatorial plane of the distorted octahedron.

Compounds **1** and **1** · $2H_2O$ join a small family of structurally characterized maleamate complexes. In all the previously reported complexes, the aromatic co-ligands were 1,10-phenanthroline (phen) [5] or 2,6-bis(pyrazol-1-yl)pyridine (bppy). It should be mentioned at this point that few metal complexes of *N*-substituted

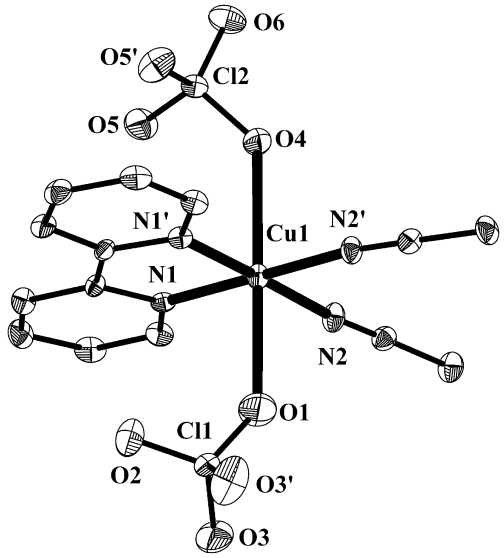

Fig. 7. Partially labeled ORTEP plot of **7b** with ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity. Primed atoms are generated by symmetry (′) = *x*, 0.5 − *y*, *z*.

maleamate ligands have been structurally characterized [21]. These are $[Bu^n_3Sn^{IV}(L1)]_n$ [21a], where $L1^-$ is the *N*-(1-naphthyl)maleamate(−1) ligand, and $[Mo^{II}(\eta^3\text{-}C_3H_4\text{-Me-2})L2)(CO)_2$(phen)] [21b], where $L2^-$ is the *N*-(*p*-tolyl)maleamate(−1) ligand. $L1^-$ behaves as an O(carboxylate)O(amide) bidentate bridging ligand leading to polymeric chains, while $L2^-$ acts as an O(carboxylate) monodentate ligand.

Complex **6** is the third structurally and *published* complex of any metal containing the anionic L'^- ligand (**IX** in Scheme 1). The two previously reported complexes are $[Cu_2(L')_2(ClO_4)$(phen)$_2$(MeOH)](ClO_4) and $[Cu_2(L')_2$(bppy)$_2](ClO_4)_2$ [5b]. All the three compounds have been prepared using maleamic acid (H_2L) as one of the starting materials and MeOH as solvent. However, search in the CCDC database reveals that Winpenny and co-workers have deposited [22] the structure of $[Co^{II,II,II}_3$(cpyol)$_4(L'_2)_2$(MeOH)$_6$] · 2MeOH, where cpyol$^-$ is the 6-chlropyridine-2-olate(−1) ligand; the monomethyl maleate(−1) ligand L'^- exhibits a *syn*,*syn* η^1:η^1:μ_2 carboxylate-type coordination in the four compounds. It is worth mentioning that the polymeric compound $[Sr_2(L_A)_3(H_2O)_4]_n(L_A)_n$, where L_A^- is the monomethyl fumarate(−1) (**XI** in Scheme 1), i.e., the isomer of L'^-, has recently been structurally characterized [23]. The complex was prepared from the reaction of $SrCO_3$ and methyl fumarate (HL_A) in H_2O; the L_A^- ions exhibit no less than three different ligation modes (μ_2, μ_3, μ_4) in this compound.

Complexes **3** · 0.5*n*H_2O and **5** · $2H_2O$ are the third and fourth members of a small group that has Cu^{II}/L''^{2-}/bpy complexes as members. The previously characterized members are the mononuclear complex [Cu(L″)(bpy)(H_2O)] · $2H_2O$ [24] and the coordination polymer [Cu(L″)(bpy)]$_n$ · 2*n*H_2O [7]. The latter has also been obtained in the present work (complex **2** · 2*n*H_2O) using either H_2L (Sections 2.2.1 and 2.2.4 – Method A) or H_2L' (Section 2.2.4 – Method B) as starting materials.

3.3. IR spectra

Dried samples of complexes **1**, **1** · $2H_2O$, **3**, **5**, **6**, **7a** and **7b** were characterized by IR spectroscopy. Complexes **1**, **1** · $2H_2O$ and **3** exhibit a very broad band covering the whole 3450–3150 cm^{-1} range, assignable to ν(OH) vibrations of lattice or/and coordinated H_2O [25]. The broadness and relatively low frequency of this band are both indicative of H-bonding.

The ν(C⋯C) and ν(C⋯N) bands of free bpy in the 1600–1400 cm^{-1} region are sensitive to chelation [26]. The 1578 and 1556 cm^{-1} bands of free bpy shift to higher frequencies in the complexes. Other characteristic vibrations of free bpy are the C–H out-of-plane deformations which appear as a strong band at 756 cm^{-1} and a weak satellite at 739 cm^{-1}; upon chelation two strong bands appear at ~770 and ~730 cm^{-1} [26].

In the spectra of **1**, **1** · $2H_2O$ and **3**, the strong band at 1080–1100 cm^{-1} and the medium-intensity band at ~625 cm^{-1} are attributed to the $\nu_3(F_2)$ [ν_d(ClO)] and $\nu_4(F_2)$ [δ_d(OClO)] modes, respectively, of the uncoordinated T_d ionic perchlorates [27]. The large number of ClO_4^- bands at around 1100 and 630 cm^{-1} in the spectra of **6**, **7a** and **7b** are consistent with the presence of coordinated ClO_4^- groups in these compounds [27].

The strong band at 1719 cm^{-1} in the spectrum of **6** is assigned to the carbonyl stretching vibration of the ester group [28].

The IR spectra of **1** and **1** · $2H_2O$ exhibit the typical bands of the primary amide and carboxylate groups [28]. Tentative assignments of few diagnostic bands attributed to these groups are given in Table 6. The assignments have been given in comparison with the data obtained for sodium maleamate, Na(HL), assumed to contain a "free" carboxylate group [29], oxamato(−1) [**XII** in Scheme 1] [30], malonamato(−1) [**V** in Scheme 1; *n* = 1] [31] and succinamato(−1) [**V** in Scheme 1; *n* = 2] [4] metal complexes. As a general remark, we must emphasize that some of the vibrational modes

Table 6
Diagnostic amide and carboxylate IR bands (cm^{-1}), and their tentative assignments for sodium maleamate[a] and complexes **1** and **1** · $2H_2O$.

Vibration	Na(HL)	**1**	**1** · $2H_2O$
$\nu_{as}(NH_2)$	3385sb	3354sb[c]	3394sb[c]
$\nu_s(NH_2)$	3160mb	3180mb[c]	3197sb[c]
$\nu(C{=}O)_{amide}$	1677s	1676s	1679s
$\delta(NH_2)$	1636m[b]	1640s[b]	1641m[b]
$\nu(C{=}C)$	1636m[b]	1640s[b]	1641m[b]
$\nu_{as}(CO_2)$[d]	1576s	1603vs	1602vs
$\nu(CN)_{amide}$	1449s	1447vs	1445vs
$\nu_s(CO_2)$	1407m	1382m	1374m

Abbreviations: b, broad; m, medium; s, strong; v, very.
[a] Prepared from the 1:1 reaction between H_2L and NaOH in EtOH, followed by precipitation with Et_2O.
[b] Overlapping bands.
[c] These bands are components of the ν(OH) manifold.
[d] These vibrations may include an aromatic stretching character.

Table 7
The carboxylate stretching IR bands (cm^{-1}) for complexes **3**, **5** and **6**.

Compound[a]	$\nu_{as}(CO_2)$	$\nu_s(CO_2)$
3	1561vs	1416m
5	1647vs[b], 1590vsb[c]	1423m, 1402vs
6	1568s[c]	1432s

[a] Solvate molecules have not been included.
[b] This vibration has also a ν(C=C) character.
[c] This vibration may include an aromatic stretching character.

shown in Table 6 are strongly coupled and thus the proposed assignments must be regarded as approximate descriptions of the vibrations [28]. The typical bands of the neutral amide group, i.e., $\nu_{as}(NH_2)$, $\nu_s(NH_2)$, ν(C=O) and ν(CN), in the spectra of **1** and **1** · $2H_2O$ are situated at the same wavenumber to those in the spectrum of Na(HL), confirming the crystallographically established non-participation of the amide group in coordination. The difference Δ, where $\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)$, for **1** (221 cm^{-1}) and **1** · $2H_2O$ (228 cm^{-1}) is more than that of Na(HL), as expected for the crystallographically confirmed, essentially monoatomic bridging mode of the carboxylate ligation [29,32].

The carboxylate stretching vibrations for **3**, **5** and **6** are listed in Table 7. The difference Δ for **3** (145 cm^{-1}) is less than that of the "free" maleate(−2) ion (200 cm^{-1} [7a]), as expected for the bidentate bridging mode of the carboxylate ligation [29]. Owing to the presence of two different types (monodentate, monoatomic bridging) of carboxylate ligation in **5**, two $\nu_{as}(CO_2)$ and two $\nu_s(CO_2)$ appear in its spectrum. The 1647, 1402 cm^{-1} pair (Δ = 245 cm^{-1}) are assigned to the monoatomically bridging carboxylate groups, while the 1590, 1402 cm^{-1} pair (Δ = 188 cm^{-1}) to the monodentate carboxylate groups.

4. Concluding comments and perspectives

The initial use of the HL^-/bpy "ligand blend" in reactions with $Cu(ClO_4)_2 \cdot 6H_2O$ has yielded the new complexes **1**, **1** · $2H_2O$ and **6**, and the known [7] coordination polymer **2** · $2nH_2O$. The HL^- ion has been tranfrormed to L''^{2-} and L'^- in **2** · $2nH_2O$ and **6**, respectively, via Cu^{II}-assisted hydrolysis (**2** · $2nH_2O$) and methanolysis (**6**) of the primary amide group. The reaction that yields **6** takes place through the formation of **7a**, whose structure has been assigned on the basis of its spectral similarity with the structurally characterized complex **7b**. The $Cu(ClO_4)_2 \cdot 6H_2O/L''^{2-}$/bpy reaction system has also led to the new complexes **3** · $0.5nH_2O$ and **5** · 2MeOH. The dinuclear complexes **1**, **1** · $2H_2O$, **5** · 2MeOH and **6** have bridging carboxylate units that rarely appear in $Cu_2^{II,II}$ chemistry, while **3** · $0.5nH_2O$ is an interesting 1D polymer composed of dinuclear subunits.

The chemistry of the $Cu(ClO_4)_2 \cdot 6H_2O/HL^-$/bpy system, as detailed in the above discussion for **1**, **1** · $2H_2O$, **6**, **7a** and **7b**, shows similarities and differences to that of the corresponding $Cu(ClO_4)_2 \cdot 6H_2O/HL^-$/phen system [5].The HL^- to L'^- transformation occurs for both systems in MeOH in the absence of external OH^-s. Complexes $[Cu_2(L')_2(bpy)_2(ClO_4)_2]$ (**6**) and $[Cu_2(L')_2(phen)_2(ClO_4)(MeOH)](ClO_4)$ have similar structural motifs based on the $\eta^1{:}\eta^1{:}\mu_2$ mode of the carboxylate ligation and on intramolecular stacking interactions between the *syn* aromatic ligands. However, the intermediates to this transformation have different structures; complex $[Cu(ClO_4)_2(bpy)(MeOH)_2]$ is mononuclear, whereas compound $[Cu(ClO_4)(phen)(MeOH)_2]_n(ClO_4)_n$ is an 1D coordination polymer. Both $Cu(ClO_4)_2 \cdot 6H_2O/HL^-$/bpy and $Cu(ClO_4)_2 \cdot 6H_2O/HL^-$/phen systems favour the formation of dinuclear cationic complexes. However, in the phen-containing cation $[Cu_2(HL)_3(phen)_2]^+$, bridging of the two Cu^{II} centres is achieved through three HL^- ligands, whereas complexes **1** and **1** · $2H_2O$ have only two HL^- bridges with one H_2O ligand completing five-coordination at each metal centre. A final difference between the two reaction systems is that the HL^- to L''^{2-} transformation established in **2** · $2nH_2O$ was not observed in the phen-containing [5] reaction mixtures.

The reactivity and structural chemistry of the $Cu(ClO_4)_2 \cdot 6H_2O/HL^-$/bpy system is different to that of the $Cu(ClO_4)_2 \cdot 6H_2O/Hsucm^-$ (n = 2 in **V** of Scheme 1)/bpy system [4,33]. The dinuclear complex $[Cu_2(Hsucm)_3(bpy)_2](ClO_4)$ [33], which is structurally similar with complex $[Cu_2(HL)_3(bpy)_2](ClO_4)$ [5b], is the main product from the $Hsucm^-$-containing reaction mixture. No esterification of the primary amide group of $Hsucm^-$ was observed during our synthetic investigations in the $Cu(ClO_4)_2 \cdot 6H_2O/Hsucm^-$/bpy reaction system [4,33]. We attribute this difference to the ability of HL^- to form a seven-membered $CuO_{carboxylate}C{-}C{=}C{-}CO_{amide}$ chelating ring (see left part of Scheme 2) in solution; such a ring, whose formation is not possible in $Hsucm^-$ (due to free rotation), activates strongly the amide carbon atom towards nucleophilic attack in the case of HL^-.

Finally, the structural chemistry of the $Cu(ClO_4)_2 \cdot 6H_2O/HL^-$/bpy system, as detailed in the above discussion for **1** and **1** · $2H_2O$, does not show similarities to the corresponding L''^{2-} system (see Refs. [7,24], and complexes **3** and **5** of this work), due to the different nature (charge, donor groups) of HL^- and the maleate(−2) [L''^{2-}] ligand.

Complexes of other 3d- or 4f-metal perchlorates with the HL^-/bpy ligand combination are not known to date, and it is currently not evident whether the chemical identity and structure of such compounds, and the $HL^- \rightarrow L'^-$, L''^{2-} transformations are dependent on the particular nature of the metal ion. It is also clear that the metal ion/HL^- chemistry warrants expansion to monodentate and tridentate aromatic *N*-heterocycles. Of particular interest would be the synthetic investigation of the metal ion/monoamide of acetylenedicarboxylate (**VIII** in Scheme 1)/aromatic *N*-donors. We currently study these matters. Experimental work at the time of writing also reveals that replacement of ClO_4^- with NO_3^- in the Cu^{II}/HL^-/bpy system has a dramatic influence on the identity of the products and it is an excellent source of polynuclear and polymeric complexes with interesting structures and magnetic properties; our results will be reported soon.

AFCBP1 bipotentiostat [17]. Solutions of the compounds were 2 mM in anhydrous acetonitrile (Aldrich, used as received) with 0.1 M tetra-*n*-butylammonium hexafluorophosphate. Data are reported from cyclic voltammograms recorded at a 0.5 mm Pt disc working electrode at a scan rate of 100 mV s^{-1}. Electrochemical potentials are quoted relative to the ferrocene–ferrocenium couple measured under the same experimental conditions (same concentrations, solvent, support electrolyte, electrodes, temperature and scan rate).

2.2. Synthesis of ligands, HL^1–H_2L^3 and their precursors

2.2.1. (3-Indolyl-2-ethyl)[bis(2-pyridylmethyl)]amine (HL^1)

Tryptamine (1.6 g, 0.01 mol) in tetrahydrofuran (10 mL) was combined with pyridine-2-carboxaldehyde (2.14 g, 0.02 mol) and sodium triacetoxyborohydride (4.87 g, 0.02 mol). After diluting with tetrahydrofuran (50 mL), the reaction mixture was stirred under dinitrogen for 3 days. Then, the reaction mixture was quenched by adding aqueous saturated sodium bicarbonate, and the product extracted with diethylether. The extract was dried over magnesium sulfate and the solvent removed on a rotary evaporator. The residue was purified by column chromatography (silica gel; eluent 1:9 methanol/dichloromethane). The major yellow band afforded a brown oil (2.5 g, 75%).

m/z (ESI-MS) 345 (M^+, 2%), 252 (100), 248 (4); δ_H ($CDCl_3$) 8.56 (2H, d, Py), 8.12 (1H, br s, NH), 7.58 (2H, d, Py), 7.52 (2H, d, Py), 7.45 (1H, d, Ind), 7.35 (1H, d, Ind), 7.13 (2H, t, Py), 7.02 (1H, t, Ind), 6.94 (1H, t, Ind), 6.90 (1H, s, Ind), 4.03 (4H, s, CH_2-CH_2), 3.01 (4H, s, CH_2); ν/cm^{-1} (KBr disc) 1592s, 1569m, 1474m, 1455m, 1434s, 1360m, 1149w, 1002w.

2.2.2. (3-Indolyl-2-ethyl)[bis(2-pyridyl-2-ethyl)]amine (HL^2)

2-Vinylpyridine was purified by passing through a short silica column with diethylether as eluent followed by removal of the diethylether by rotary evaporation. To 2-vinylpyridine (1.64 g, 15.6 mmol) in methanol (20 mL) was added tryptamine (0.5 g, 3.12 mmol) in methanol along with glacial acetic acid (15 mL). The mixture was stirred and heated at reflux under dinitrogen for 5 days. The mixture was then cooled and the solvent removed using a rotary evaporator. The residue was re-dissolved in chloroform. This solution was washed with saturated sodium carbonate and saturated brine solutions, and then dried over magnesium sulfate. The solvent was removed on a rotary evaporator and the oily residue purified by column chromatography (silica support; eluent 2:8 methanol–dichloromethane) to afford the product as a brown oil (0.84 g, 72%).

m/z (ESI-MS) 371 (M^+, 50%), 332 (100), 266 (90), 252 (30); δ_H ($CDCl_3$) 9.47 (1H, br s, NH), 8.43 (2H, d, Py), 7.49 (3H, m, Ar), 7.28 (1H, d, Ind), 7.04 (6H, m, Ar), 6.89 (1H, d, Ind), 3.01 (2H, t, CH_2), 2.97 (2H, t, CH_2), 2.89 (4H, s, CH_2).

2.2.3. (3-Indolyl-2-ethyl)(4-imidazolylmethyl)(2-pyridylmethyl)amine (H_2L^3)

2.2.3.1. (3-Indolyl-2-ethyl)(2-pyridylmethyl)amine. To tryptamine (6.5 g, 0.04 mol) dissolved in methanol (10 mL), was combined with pyridine-2-carboxaldehyde (4.3 g, 0.04 mol). After diluting the mixture with methanol (70 mL), the solution was hydrogenated under hydrogen (1 atm) in the presence of 10% Pd–C catalyst (0.6 g) over night. After removal of the catalyst by filtration through a silica plug, the solvent was removed by rotary evaporation to give a pale yellow oil (8.24 g, 82%), which was used without further purification in the synthesis of H_2L^3.

2.2.3.2. H_2L^3. (3-Indolyl-2-ethyl)(2-pyridylmethyl)amine (410 mg, 1.63 mmol) dissolved in 1,2-dichloroethane (10 mL) was added 4(5)-imidazolylcarboxaldehyde (156 mg, 1 eq.) and sodium triacetoxyborohydride (800 mg). Additional 1,2-dichloroethane (30 mL) was added and the reaction mixture was stirred under dinitrogen for 3 days. The mixture was quenched by adding aqueous saturated sodium bicarbonate, and the product was extracted with diethylether. The combined extracts were dried over anhydrous magnesium sulfate and the solvents removed on a rotary evaporator; the residue was placed under high vacuum to afford a light brown oil (0.46 g, 85%).

m/z (ESI-MS) 334 (M^+, 25%), 252 (100); δ_H (D_2O) 8.42 (1H, s, Im), 8.23 (1H, d, Py), 8.03 (1H, d, Py), 7.52 (2H, d, Ind), 7.34 (2H, m, Py & Ind), 7.12 (2H, t, Ind), 7.04 (1H, s, Im), 6.91 (1H, t, Py), 4.17 (2H, s, CH_2), 4.11 (2H, s, CH_2), 3.09 (2H, d, CH_2), 2.84 (2H, d, CH_2).

2.3. $[Cu(L)Cl_2]$ ($L = HL^1$–H_2L^3) complexes

2.3.1. $[Cu(HL^1)Cl_2]$ (**1**)

$CuCl_2 \cdot 2H_2O$ (25 mg, 1 eq.) in iso-propanol (10 mL) was layered on HL^1 (50 mg, 0.14 mmol) in dichloromethane (2 mL). After several days, a deep green crystalline solid (47.7 mg, 71%) deposited from the mixture.

(Found: C, 54.85; H, 4.90; N, 11.49%. $C_{22}H_{22}Cl_2CuN_4 \cdot 0.5H_2O$ requires C, 54.38; H, 4.77; N, 11.53%); λ_{max}/nm (MeOH) 219 (ε/$dm^3\ mol^{-1}\ cm^{-1}$ 14833), 256 (12472), 282 (9722), 676 (148); EPR (frozen MeOH solution, 77 K) $g_{||} = 2.23$, $g_{\perp} = 2.04$, $A_{||} = 178$ G; $\overline{\nu}$/cm^{-1} (KBr disc) 1608s, 1573w, 1480w, 1459m, 1443s, 1471m, 1343m, 1284m, 1092m, 1055m, 1024m.

2.3.2. $[Cu(HL^2)Cl_2]$ (**2**)

HL^2 (94.4 mg, 0.255 mmol) in iso-propanol (2 mL) was layered on $CuCl_2 \cdot 2H_2O$ (43 mg, 1 eq.) in iso-propanol (10 mL); upon standing for several days a dark green precipitate formed (92.3 mg, 72%).

(Found: C, 49.63; H, 5.81; N, 9.37%. $C_{24}H_{26}Cl_2CuN_4 \cdot 4H_2O$ requires C, 49.96; H, 5.94; N, 9.71%); λ_{max}/nm (MeOH) 214 (ε/$dm^3\ mol^{-1}\ cm^{-1}$ 12382), 263 (8470), 674 (158); EPR (frozen MeCN solution, 77 K) $g_{||} = 2.35$, $g_{\perp} = 2.09$, $A_{||} = 159$ G; $\overline{\nu}$/cm^{-1} (KBr disc) 3335br, 1607s, 1570m, 1484m, 1445s, 1313w, 1108w, 1027w.

2.3.3. $[Cu(H_2L^3)Cl_2]$ (**3**)

H_2L^3 (100 mg, 0.227 mmol) in methanol (5 mL) was added slowly to a solution of $CuCl_2 \cdot 2H_2O$ (38.7 mg, 1 eq.) in methanol (5 mL). After stirring for 10 min, the solution was left to stand under a diethylether atmosphere for a few days; a green crystalline solid (74 mg, 75%) formed.

(Found: C, 49.71; H, 4.87; N, 13.87%. $C_{20}H_{21}Cl_2CuN_5 \cdot H_2O \cdot 0.5CH_3OH$ requires C, 49.25; H, 5.04; N, 14.01%); λ_{max}/nm (MeOH) 220 (ε/$dm^3\ mol^{-1}\ cm^{-1}$ 14222), 263 (10444), 280 (911), 653 (100); EPR (frozen MeOH solution, 77 K) $g_{||} = 2.23$, $g_{\perp} = 2.05$, $A_{||} = 175$ G; $\overline{\nu}$/cm^{-1} (KBr disc) 3248br, 2895s, 1609s, 1572w, 1503w, 1456s, 1445s, 1350m, 1271m, 1104m.

2.4. X-ray crystallography

As good quality crystals of complexes **1**–**3** were not obtained, each complex was separately treated with an excess $K[PF_6]$, $Na[BF_4]$ or $Li(ClO_4)$ in methanol and the resulting green solutions left to stand under an atmosphere of diethylether. Single crystals of $[Cu(HL^1)Cl](ClO_4).0.5Et_2O \cdot 0.25H_2O$ (**4**), $[Cu(HL^2)F]_2[BF_4]_2$ (**5**) and $[Cu(H_2L^3)Cl][PF_6]$ (**6**) were obtained. X-ray reflection data for **4**–**5** were measured with an Enraf-Nonius CAD-4 diffractometer in ω–2θ scan mode at 294 K. Crystal structure and refinement data are collected in Table 1. A summary of key bond lengths and bond angles is given in Table 2. The CIF files have been deposited at the Cambridge Crystallographic Data Centre and allocated the deposition numbers CCDC 710201–710203.

3. Results and discussion

3.1. Syntheses

Two new indole-substituted ligands, HL^1 and H_2L^3, were easily synthesized by reductive amination using an appropriate aldehyde and tryptamine with sodium triacetoxyborohydride in dry 1,2-dichloroethane [18]. HL^2 was produced by reaction of excess 2-vinyl pyridine with tryptamine. Copper(II) complexes, $[Cu(L)Cl_2]$ (**1**: L = HL^1, **2**: L = HL^2; **3**: L = H_2L^3) were obtained by adding the ligand (L) in dichloromethane to $CuCl_2\cdot 2H_2O$ in iso-propanol. After several days, the green–blue microcrystalline complexes **1**–**3** precipitated. Unfortunately, none of the complexes gave crystals of sufficient quality for an X-ray crystal structure determination.

3.2. X-ray crystallography

As crystals of **1**–**3** were unavailable, in separate reactions, each of these complexes was treated with excess $K[PF_6]$, $Na[BF_4]$ or $Li(ClO_4)$ in methanol and the resulting green solutions were left to stand under an atmosphere of diethylether. Single crystals of $[Cu(HL^1)Cl](ClO_4)\cdot 0.5Et_2O\cdot 0.25H_2O$ (**4**), $[Cu(HL^2)F]_2[BF_4]_2$ (**5**) and $[Cu(H_2L^3)Cl][PF_6]$ (**6**) were obtained that were satisfactory for X-ray structure determinations. Fig. 1 presents views of the structures and selected bond length and angle data are gathered in Table 2.

Complex **4** exhibits a distorted square planar copper(II) centre formed by the binding of the two pyridine and amine nitrogen atoms, and a chloro co-ligand, Fig. 1a. The sum of the six less-than-180° angles about the Cu centre is 704°, which compares with 720° (and 645°) for perfect square planar (and tetrahedral) centre(s) [19,20]. The Cu–Cl1 (2.241(5) Å), Cu–N(amine) (2.052(13) Å), and Cu–N(py) (1.907(11) and 1.909(12) Å) distances are all in the anticipated range for copper(II) complexes. The indole substituent does not bind to the copper(II) centre and lies offset π-stacked with the pyridine ring containing N2. The inter-ring separation of the offset π-stacked pyridinyl and indolyl rings is 3.38 Å, which is comparable to the Trp 236···His 291 separation in cyto-

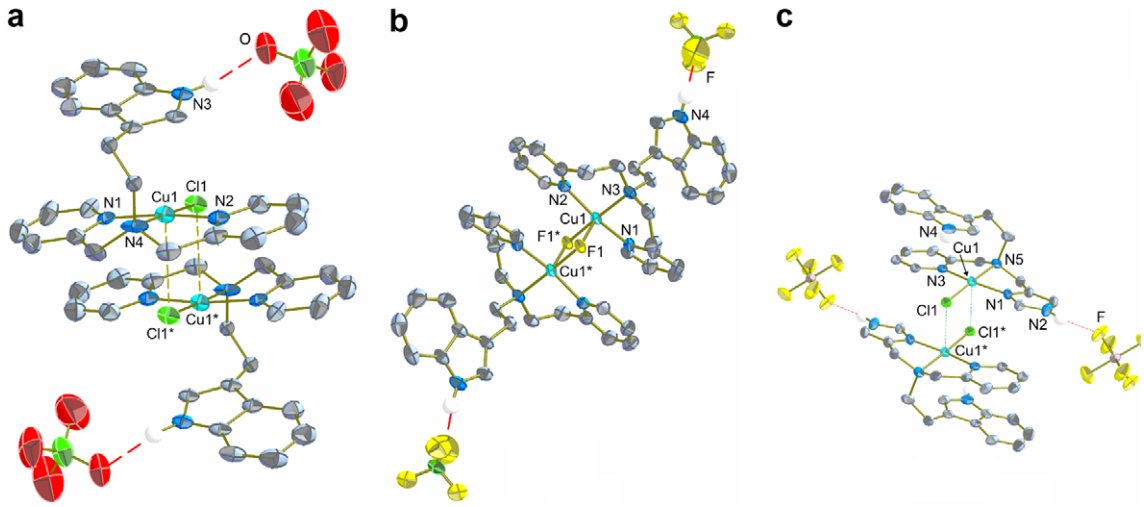

Fig. 1. Views of the paired cations and closely associated anions in the X-ray crystal structures of: (a) $[Cu(HL^1)Cl](ClO_4)$, **4**; (b) $[Cu(HL^2)F]_2[BF_4]_2$, **5**; (c) $[Cu(H_2L^3)Cl][PF_6]$, **6**. In all views, 50% thermal ellipsoids are shown and hydrogen atoms bonded to carbon have been omitted for clarity; in each case, atoms labelled with an asterisk are related by a crystallographic inversion to the corresponding atom labelled without the asterisk.

chrome *c* oxidases (see above) [1]. In the crystal structure, adjacent cation pairs of **4** are connected by weak (3.10 Å) Cu···Cl1 interactions. The inter-copper distance between neighbouring cations is 3.75 Å. The indole N–H forms a hydrogen bond to the perchlorate counterion (N3···O 2.97 Å).

Fig. 1b shows the centrosymmetric $[Cu(HL^2)F]_2^{2+}$ dimers and associated $[BF_4]^-$ counterions in the crystal structure of **5**. Fluoride abstraction reactions in transition metal complexes containing the tetrafluoroborate anion are well-known [21]. The copper(II) centre in **5** has a typical distorted square pyramidal geometry with a trigonality index [22] $\tau = 0.25$ [F1–Cu1–N3 = 176.011(1)° is the largest bond angle and N1–Cu1–N2 = 161.712(1)° the next largest]. Axial Cu–F1* bonds (2.212(2) Å) link to the adjacent Cu* to give a dimeric structure. The axial Cu–F1* bond is longer than the in-plane Cu–F1 (1.911(2) Å) and Cu–N bonds (2.029 Å average). The Cu···Cu* distance in the dimer is 3.125(2) Å. The indole substituent of HL^2 is not coordinated to the copper centre and is without any π-stacking interactions within the complex ion. There is an hydrogen bond between the indole N–H and F on tetrafluoroborate (N···F 3.04 Å).

The molecular structure of **6**, Fig. 1c, reveals the copper(II) ion to be distorted square planar bound by the amine, imidazolyl and pyridyl nitrogen atoms and by a chloro co-ligand. The sum of the six less-than-180° bond angles about the copper(II) centre is 701.7° [19,20]. The indolyl ring is offset π-stacked with the pyridyl ring consistent with the larger π-surface area and electron density of pyridyl *cf.* imidazolyl rings. The separation between the π-stacked indolyl and pyridyl rings is 3.11 Å. The Cu1–Cl1 and Cu1–Cu1* (adjacent cation) distances are 3.14 and 3.72 Å, respectively. The $[PF_6]^-$ counterion forms a F···H–N hydrogen bond (2.94 Å) with the coordinated imidazolyl N–H rather than with the pendant indole.

3.3. Physicochemical data for complexes *1*–*3* in solution

Numerous studies reveal $[Cu(N_3\text{–}L)Cl_2]$ complexes, analogous to **1**–**3**, to contain five-coordinate $Cu^{II}Cl_2N_3$ centres that display characteristic EPR and UV–Vis spectra [17–22,24–26]. Available data are indicative for five-coordinate $Cu^{II}Cl_2N_3$ centres in **1**–**3**. The FTIR of spectrum of each complex (see Supplementary data) shows characteristic pyridyl stretches at ~1604 and 1571 cm^{-1} indicative for all pyridines binding to the Cu(II) ion. The fingerprint regions of the IR spectra show characteristic indole peaks between 1400 and 1500 cm^{-1} [23]. The Vis/NIR spectra of **1**–**3** in methanol solution show a broad band having a maximum at ~640–750 nm and a prominent tail to lower energy, consistent with each complex adopting a tetragonally-elongated, square pyramidal ($CuCl_2N_3$) structure, Table 3. Likewise EPR spectra of complexes **1**–**3** in frozen

Table 3
Electronic and X-band EPR spectroscopic data for the Cu(II) complexes in methanol.

	UV-NIR (297 K) [λ_{max}/nm] (ε/dm^3 mol^{-1} cm^{-1})	EPR (77 K)
1	676 (148)	$g_{\|\|} = 2.23$, $g_\perp = 2.04$, $A_{\|\|} = 178$ G
2	674 (158)	$g_{\|\|} = 2.35$, $g_\perp = 2.09$, $A_{\|\|} = 159$ G
3	653 (100)	$g_{\|\|} = 2.23$, $g_\perp = 2.05$, $A_{\|\|} = 175$ G

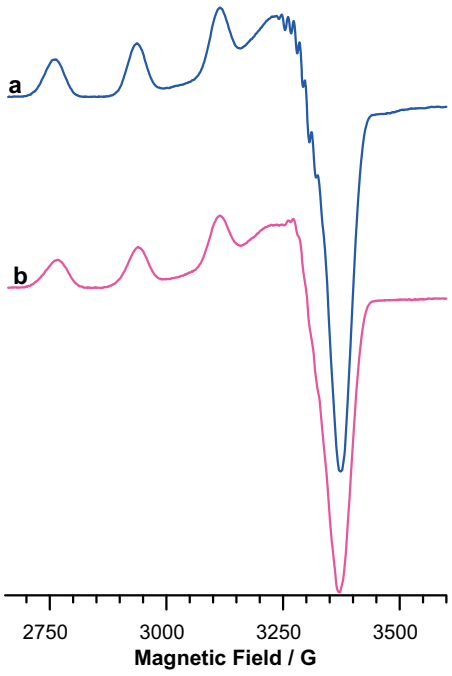

Fig. 2. X-band EPR spectra of complexes **1** (a) and **3** (b) in frozen methanol solution at 77 K; ν/GHz = 9.448.

methanol at 77 K are axial ($d_{x^2-y^2}$ ground-state) fully consistent with square pyramidal $CuCl_2N_3$ structures, *e.g.* Fig. 2 and Table 3. *N*-Superhyperfine coupling is also apparent in the spectra: *e.g. N*-superhyperfine peaks ($A_{N-Cu} \approx 12$ G) from three Cu(II)-bound *N*-donors are clearly discerned in the spectrum of **1**, Fig. 2a.

3.4. Electrochemistry of complexes 1–3

Cyclic voltammograms (CVs) of **1**–**3** in acetonitrile were acquired to characterize the redox properties of the indole and copper centres in each complex. The CVs show quasi-reversible Cu(II)/Cu(I) couples, at −0.57 V for the methylene-bridged amine complexes **1** and **3** and at −0.25 V for the ethylene-linked amine complex **2** (*e.g.* see Fig. 3). Lower potential Cu(II)/Cu(I) couples are expected for complexes of bis(pyridylmethyl)amine ligands compared to complexes of bis(pyridylethyl)amines [24–26]. On scanning to positive potentials, the CVs of **1**–**3** all show a broad anodic peak at +0.64 V followed closely by an peak at +0.77 V for an oxidation process that appears to have some reversibility (a broad cathodic peak is discernable ca. at +0.71 V in the return scan: $i_{p,c}/i_{p,a} = 1.1$). The broad anodic peak at +0.64 V is found in CVs of both bis(triphenylphosphoranylidene)ammonium chloride (PPNCl) and [(Bz-bpa)$CuCl_2$] and, therefore, may be attributed to oxidation of 'free' chloride anion (in the complexes, from dissociation of chloro ligand) [27–29]. The second peak at +0.77 V in the CVs of **1**–**3** is absent in the CVs of PPNCl and [(Bz-bpa)$CuCl_2$] and therefore must be an indole substituent-centred oxidation. For comparison, CVs of indole, Fig. 3a, reveal a broad anodic peak at +0.80 V and CVs of 3-methylindole, Fig. 3b, show a sharp anodic peak at +0.57 V that is followed by a broad peak at +0.80 V; the irreversibility arises from rapid coupling reactions of the indolyl radical [30,31]. Thus, the peaks in this region for **1**–**3** can be attributed to oxidation of the indole substituent. Notably, although the merging of chloride- and indole-centred oxidation processes complicates the electrochemistry, the potential of the indole oxidation is only slightly, if at all, affected by coordination of the indole-substituted ligand to the copper(II) centre.

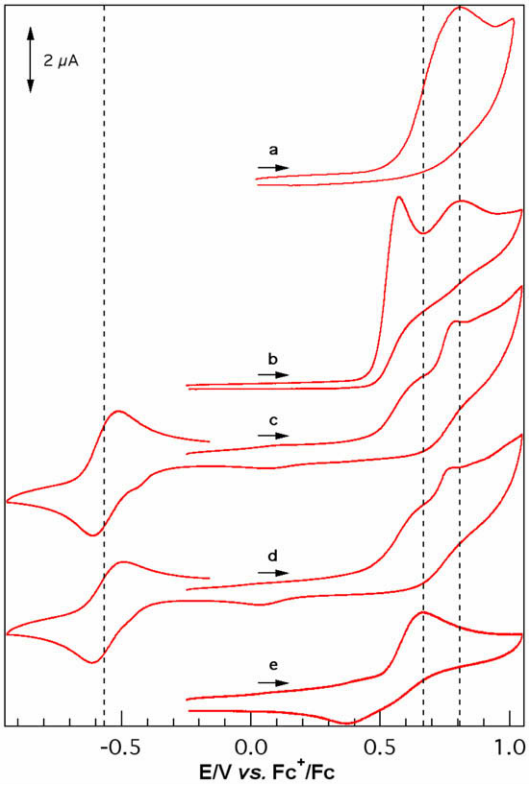

Fig. 3. Cyclic voltammograms of indole (a), 3-methylindole (b), **1** (c), **3** (d) and PPNCl (e) in acetonitrile with 0.1 M [Bu_4N][PF_6] at 295 K; 1.0 mm Pt disc working electrode; scan rate = 100 mV s^{-1}.

4. Conclusions

Three new indole-substituted ligands (HL^1–H_2L^3) were synthesized from tryptamine and copper(II) complexes (**1**–**6**) were successfully obtained from them. The results of the electrochemistry for complexes **1**–**3** show coordination of the ligands to a copper centre and the proximity of the indole and copper(II) centres does not affect the Cu^{II}/Cu^{I} couples or the indole-centred oxidation processes. This finding contrasts with our previous results for some complexes wherein copper(II) centres closely related to those reported here were substituted with ferrocenyl (Fc) substituents; in these Fc ∼ Cu(II) complexes significant mutual perturbations of the electron donor properties of each centre were observed that lead to new reactivity [26]. The crystal structures of **4** and **6** reveal offset π-stacking between the indolyl group and the ring of a pyridinyl or imidazolyl donor bound to the Cu(II) ion. The inter-ring separation is ca. 3.1–3.3 Å, which is analogous to that observed for the Trp 236···His 291 sidechains within CcO. In solution, π-stacking of the indolyl and ligand heterocyclic donor rings in complexes **1**–**6** is possible, but much less likely due to the disrupting effect(s) of solvent molecules. Thus model systems of considerably more sophistication will be needed if the effects of π-stacking between an indolyl group and a Cu(II)-bound heterocyclic ligand donor are to be explored further.

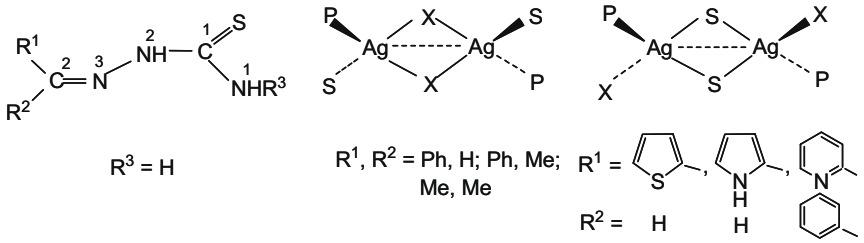

Chart 1.

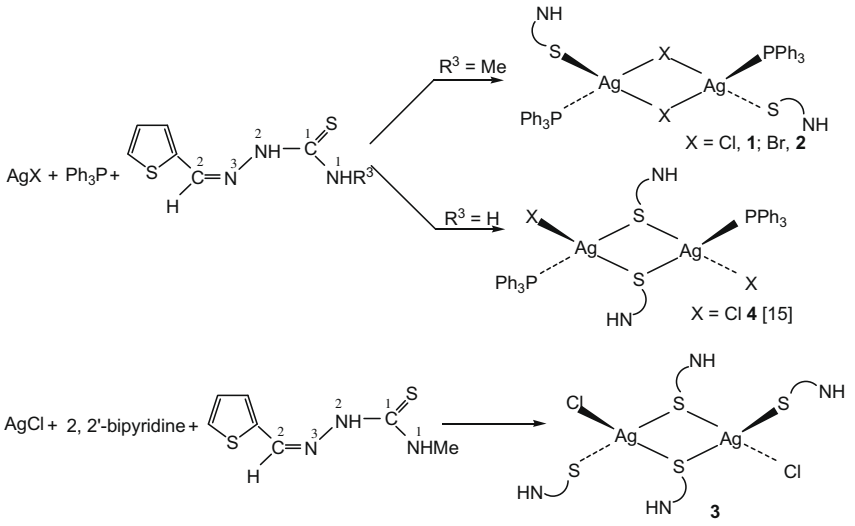
4000–200 cm^{-1} on a Pye-Unicam SP-3-300 spectrophotometer. Melting points were determined with an electrically heated Gallenkamp apparatus. ^1H NMR were recorded on a JEOL AL-300 FT spectrometer operating at a frequency of 300 MHz using $CDCl_3$ as the solvent with TMS as an internal standard. ^{31}P NMR spectra were recorded on a Bruker ACP-300 spectrometer operating at a frequency of 121.5 MHz with H_3PO_4 as an external standard with $\delta = 0$.

2.2. Synthesis of the complexes

2.2.1. $[Ag_2(\mu\text{-}Cl)_2(\eta^1\text{-}S\text{-}HttsMe)_2(PPh_3)_2]$ (**1**)



To AgCl (0.025 g, 0.17 mmol) suspended in acetonitrile (15 mL) was added solid Ph_3P (0.046 g, 0.17 mmol), and the reaction mixture was stirred for 2 h. The white precipitates that formed were filtered to remove acetonitrile, and to the white solid suspended in chloroform was added the solid HttscMe ligand (0.035 g, 0.17 mmol). The contents stirred for a further period of 10 min and the yellow colored clear solution thus formed was allowed to crystallize. Slow evaporation at room temperature yielded crystals of $[Ag_2(\mu\text{-}Cl)_2(\eta^1\text{-}S\text{-}HttsMe)_2(PPh_3)_2]$ (**1**) (**1** yellow, 72%, m.p. 175–177 °C). *Anal.* Calc. for $C_{50}H_{48}Ag_2Cl_2N_6P_2S_4$: C, 49.26; H, 4.35; N, 6.92. Found: C, 49.67; H, 4.0; N, 6.95%. IR data (KBr, cm^{-1}): ν(N–H) 3340(s); ν(–NH–) 3160(m); $\nu(C\text{–}H)_{Ph}$ 2951(m); $\nu(C\text{–}H)_{Me}$ 2733(w); ν(C=N) + ν(C=C) 1620(m), 1565(m), 1530(m); $\nu(P\text{–}C_{Ph})$ 1093(s); ν(C–N) 1031(s); ν(C=S) 854(s). ^1H NMR ($CDCl_3$, δ ppm): 12.42s ($-N^2H$), 8.66s (C^2H), 7.32–7.52m ($C^{4,6}H$ + 15H, PPh_3 + N^1H), 7.05dd (C^5H), 3.23d ($-CH_3$). ^{31}P NMR ($CDCl_3$, δ ppm): 10.5, $\Delta\delta$ (δ complex – δ ligand) 14.7.

2.2.2. $[Ag_2(\mu\text{-}Br)_2(\eta^1\text{-}S\text{-}HttsMe)_2(PPh_3)_2]$ (**2**)

To AgBr (0.025 g, 0.13 mmol) suspended in acetonitrile (15 mL) was added solid Ph_3P (0.035 g, 0.13 mmol), and the reaction mixture was stirred for 2 h. The white precipitates that formed were filtered to remove acetonitrile, and to the white solid suspended in chloroform was added the solid HttscMe ligand (0.027 g, 0.13 mmol). The contents were stirred for a further period of 10 min and the yellow colored clear solution thus formed was allowed to crystallize. Slow evaporation at room temperature yielded crystals of $[Ag_2(\mu\text{-}Br)_2(\eta^1\text{-}S\text{-}HttsMe)_2(PPh_3)_2]$ (**2**) (**2** yellow, 69%, m.p. 195–198 °C). *Anal.* Calc. for $C_{50}H_{48}Ag_2Br_2N_6P_2S_4$: C, 46.47; H, 3.92; N, 6.92. Found: C, 46.28; H, 3.70; N, 6.47%. IR data (KBr, cm^{-1}): ν(N–H) 3345(s); ν(–NH–) 3150(m); $\nu(C\text{–}H)_{Ph}$ 2975(m); $\nu(C\text{–}H)_{Me}$ 2753(w); ν(C=N) + ν(C=C) 1632(m), 1555(m), 1532(m); $\nu(P\text{–}C_{Ph})$ 1094(s); ν(C–N) 1029(s); ν(C=S) 853(s). ^1H NMR ($CDCl_3$, δ ppm): 11.59s ($-N^2H$), 8.61s (C^2H), 7.32–7.52m ($C^{4,6}H$ + 15H, PPh_3 + N^1H), 7.06dd (C^5H), 3.23d ($-CH_3$). ^{31}P NMR ($CDCl_3$, δ ppm): 6.2, $\Delta\delta$ (δ complex – δ ligand) 10.9.

2.2.3. $[Ag_2Cl_2(\mu\text{-}S\text{-}HttscMe)_2(\eta^1\text{-}S\text{-}HttscMe)_2] \cdot 2CHCl_3$ (**3**)

To AgCl (0.025 g, 0.17 mmol) suspended in acetonitrile (15 mL) was added solid 2,2′-bipyridine (0.034 g, 0.17 mmol) and the reaction mixture was stirred for 2 h. The light purple precipitates that formed were filtered to remove acetonitrile, and to the purple precipitates suspended in chloroform was added the solid ligand HttscMe (0.035 g, 0.17 mmol). The contents were stirred for a further period of 10 min and the solution was allowed to crystallize. Slow evaporation at room temperature yielded crystals of $[Ag_2Cl_2(\mu\text{-}S\text{-}HttscMe)_2(\eta^1\text{-}S\text{-}HttscMe)_2]$ (**3**) (yellow, 65%, decomposed at 180–185 °C). *Anal.* Calc. for $C_{28}H_{36}Ag_2Cl_8N_{12}S_8$: C, 27.86; H, 3.20; N, 19.0. Found: C, 27.23; H, 2.90; N, 19.4%. IR data (KBr, cm^{-1}): ν(N–H) 3347(s); ν(–NH–) 3142(m); $\nu(C\text{–}H)_{Ph}$ 2981(m); $\nu(C\text{–}H)_{Me}$ 2757(w); ν(C=N) + ν(C=C) 1638(m), 1566(m), 1530(m); ν(C–N) 1029(s); ν(C=S) 854(s). ^1H NMR ($CDCl_3$, δ ppm): 11.68s ($-N^2H$), 8.56s (C^2H), 7.86sb (N^1H) 7.32–7.39m ($C^{4,6}H$), 7.06dd (C^5H), 3.24d ($-CH_3$).

3. X-ray crystallography

The data for **1** and **2** were measured on a Bruker AXS SMART APEX CCD diffractometer. Data were reduced and corrected for absorption using SMART and SAINT [42]. The structures were solved by direct methods and refined by full matrix least squares based on F^2 with anisotropic thermal parameters for non-hydrogen atoms using SHELXTL (structure solution, refinement and some molecular graphics). All non-hydrogen atoms were refined anisotropically. All hydrogen atoms were placed in calculated positions and were refined with an isotropic displacement parameter 1.5 (methyl) or 1.2 (all others) times that of the adjacent carbon or oxygen atom.

A prismatic crystal of complex **3** was mounted on an automatic Enraf–Nonius CAD-4 diffractometer equipped with a graphite monochromator and Mo Kα radiation (λ = 0.71073 Å). The unit cell dimensions and intensity data were measured at 200 K. The structure was solved by direct methods and refined by full matrix least squares based on F^2 with anisotropic thermal parameters for non-hydrogen atoms using XCAD-49 (data reduction), and SHELXL (absorption correction, structure solution refinement and molecular graphics) [43]. The thiophene rings of the terminally bonded HttscMe ligand in complex **3** are disordered and the data is 99% complete to a theta value of 25° (2θ of 50°), which meets the criterion. The reason for the 90% completion figure is that data was collected out to a theta value of 32.51°, but at this angle the data is incomplete due to the shape of the detector (this is normal for area detector data).

4. Results and discussion

4.1. Synthesis

Scheme 1 gives a pictorial representation of formation of the silver(I) halide complexes with thiophene-2-carbaldehyde N^1-methylthiosemicarbazone (HttscMe). To silver(I) chloride suspended in acetonitrile was added triphenylphosphine, and the contents were stirred for 2 h, which formed white precipitates. The ligand HttscMe was added to these precipitates suspended in chloroform and stirred for 10 min. The clear solution was allowed to evaporate at room temperature, which formed crystals of the stoichiometry, $[Ag_2(\mu\text{-}Cl)_2(\eta^1\text{-}S\text{-}HttsMe)_2(PPh_3)_2]$ **1**. A similar reaction with silver(I) bromide yielded $[Ag_2(\mu\text{-}Br)_2(\eta^1\text{-}S\text{-}HttsMe)_2(PPh_3)_2]$ **2**. The use of 2,2′-bipyridine in lieu of Ph_3P in the reaction of silver(I) chloride with HttscMe yielded $[Ag_2(\mu\text{-}S\text{-}HttscMe)_2(\eta^1\text{-}HttsMe)_2] \cdot 2CHCl_3$ **3**. There was no coordination by 2,2′-bipyridine in this reaction. Reactions of silver(I) halides with thiosemicarbazones in the absence of Ph_3P or 2,2′-bipyridine yield insoluble complexes. Thus the presence of the co-ligand is necessary to get crystalline compounds.

It was reported earlier that thiophene-2-carbaldehyde thiosemicarbazone (Httsc, R^3 = H) with silver(I) chloride formed a sulfur-bridged complex, $[Ag_2Cl_2(\mu\text{-}S\text{-}Httsc)_2(Ph_3P)_2] \cdot 2CH_3CN$ **4** [15], and the replacement of one hydrogen at the N^1 nitrogen with a methyl group has changed the nature of bonding from sulfur-bridging (**4**) to halogen-bridging (**1** and **2**). Complex **3** shows S-bridging, as in **4**, and probably is dominated by the presence of four

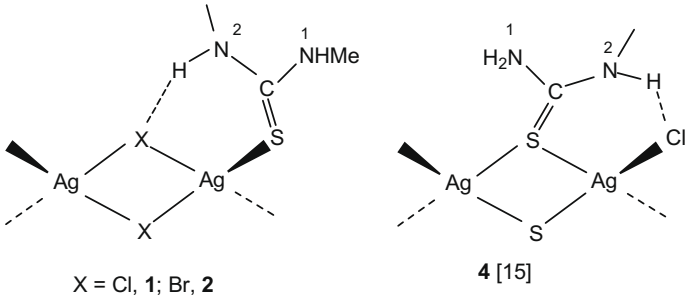
1–**3** supports the coordination of HttscMe as a neutral ligand. The (N–H) band of the –N^1HR group showed a high-energy shift in the complexes vis-à-vis the free ligand (3326 cm^{-1}). The most characteristic thioamide band due to ν(C=S) lies in the range 852–854 cm^{-1} in complexes **1**–**3** and is at a somewhat low energy region (free ligand, 860 cm^{-1}). This indicates the coordination of sulfur to the silver center. The $\nu(P–C_{Ph})$ bands in complexes **1** and **2** at 1093 and 1094 cm^{-1}, respectively, support the presence of coordinated triphenylphosphine in these complexes [15,16].

4.2. Structures of the complexes



The crystallographic data and important bond parameters (bond lengths and bond angles) of complexes **1**–**3** are given in Tables 1 and 2, respectively. The molecular structures along with the numbering scheme are given in Figs. 1–3, respectively. All the three complexes crystallized in the monoclinic crystal system with space group $P2_1/n$.

4.3. Structures of the dimers *1*–*3*

Complexes **1** and **2** have similar structures. In each complex, silver(I) is coordinated to two bridging halogen atoms, one terminal S atom and one terminal P atom. The central $Ag(\mu\text{-}X)_2Ag$ cores of these dimers are almost square planar as the X–Ag–X and Ag–X–Ag angles are close to 90° (90.15(12), 89.85(2)° **1**; 93.717(15), 86.284(15)° **2**), while similar cores of complexes **5**–**8** form parallelograms (Table 3). In complex **3**, two bridging sulfurs, one terminal sulfur and one terminal chloride atom are coordinated to the silver(I) centers. The central core $Ag(\mu\text{-}S)_2Ag$ is a parallelogram (S–Ag–S, Ag–S–Ag, 109.49°, 83.76°). The geometries around each silver atom in complexes **1**–**3** can be treated as distorted tetrahedral. The Ag–X–Ag and X–Ag–X or Ag–S–Ag and S–Ag–S bond angles vary in a complementary fashion, the larger the angle at the bridging halogen/sulfur, the greater is the Ag···Ag contact. The Ag···Ag separation (3.487 Å) in sulfur-bridged complex **3** is close to twice the sum of the van der Waal's radius of silver atoms (3.40 Å [44]) and this separation is less than that (3.734(4) Å for **1**; 3.746(5) Å for **2**) in the halogen-bridged dimers.

4.4. H-bonded networks

Scheme 2 shows the intra-molecular interactions in complexes **1** and **2**. Complex **4** has S-bridging and the imino group is H-bonded to the terminal chlorine. The presence of the methyl group at the N^1 atom modulates the bonding property of HttscMe, probably by way of higher steric crowding if it was in a sulfur-bridged dimer. This paves way for halogen-bridging and the imino group now H-bonds to this halogen (N^2H···Cl, 2.45 Å **1**; N^2H···Br, 2.614 Å **2**). The two chloro-bridged dimeric units of **1** are interconnected

Scheme 2.

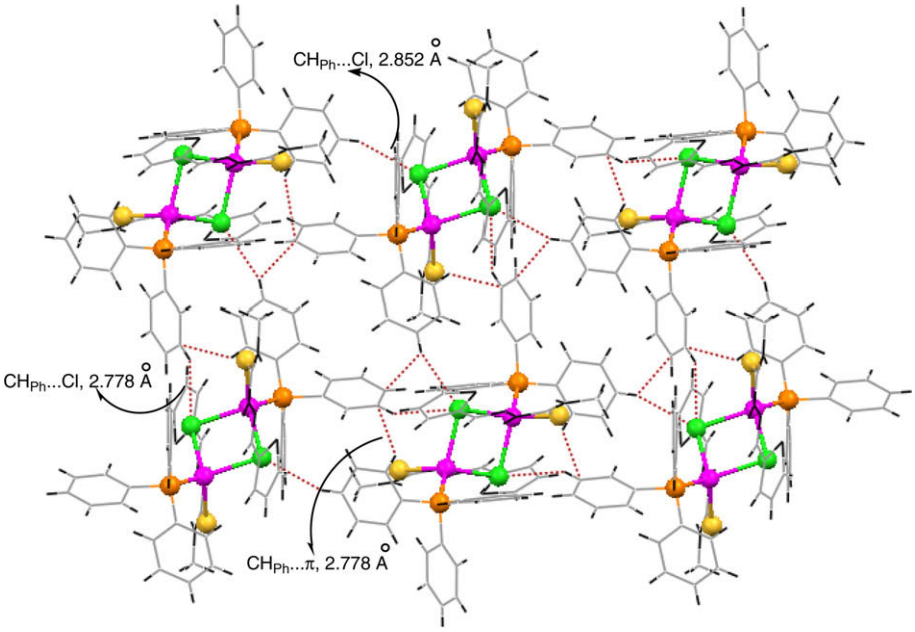


Fig. 4. Packing diagram of $[Ag_2(\mu\text{-}Cl)_2(\eta^1\text{-}HttsMe)_2(Ph_3P)_2]$ **1**.

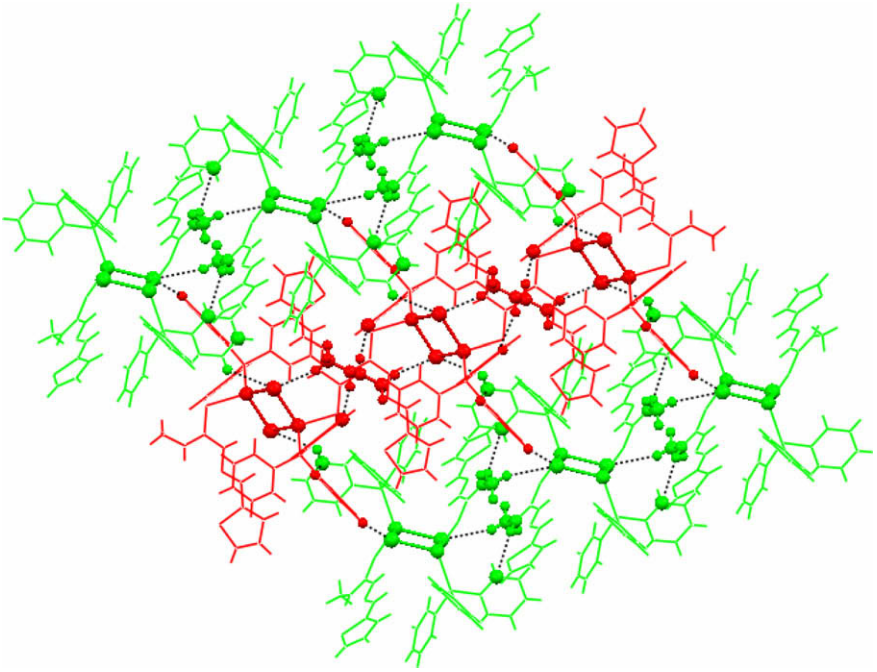

Fig. 5. Packing diagram of $[Ag_2(\mu\text{-}Br)_2(\eta^1\text{-}HttsMe)_2(Ph_3P)_2]$ **2**.

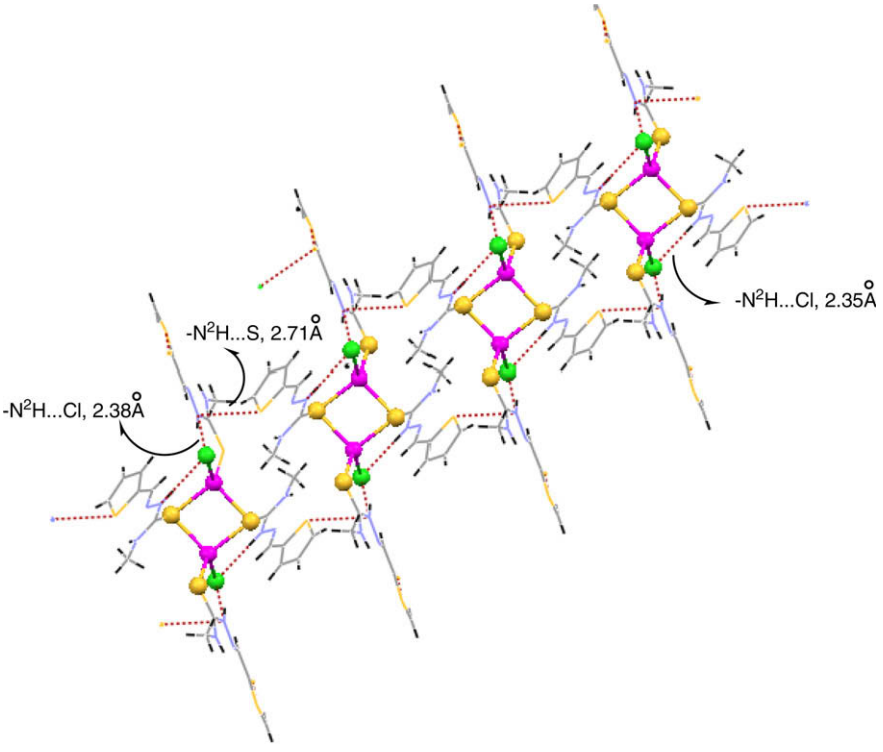

Fig. 6. Packing diagram of $[Ag_2(\mu\text{-}S\text{-}HttscMe)_2(\eta^1\text{-}HttsMe)_2] \cdot 2CHCl_3$ **3**.

via phenyl hydrogen–chlorine ($CH_{Ph}\cdots Cl^{\#1}$, 2.852 Å) and phenyl hydrogen–π, ($CH_{Ph}\cdots\pi$, 2.626 Å) interactions to form a linear chain along the *a*-axis (Fig. 4). Two such linear chains are further interconnected by a phenyl hydrogen–chlorine ($CH_{Ph}\cdots Cl^{\#2}$, 2.778 Å) interaction which forms a H-bonded 2D polymer. In the dimer **2**, two units are H-bonded via MeN^1H–π (2.768 Å) and methyl-bromine, ($H_2CH\cdots Br$, 2.972 Å) interactions, which form a H-bonded linear chain. Two linear chains are connected via phenyl hydrogen–bromine ($CH_{Ph}\cdots Br^{\#1}$, 2.996 Å) interaction and form a H-bonded 2D polymer (Fig. 5).

The imino hydrogen atom of terminal as well as bridging ligands forms a strong intra-molecular H-bond with the chlorine

atom (–N^2H_{ter}···Cl, 2.38 Å; –N^2H_{bri}···Cl, 2.35 Å) in complex **3**. Two dimeric units are interconnected via the imino hydrogen of a terminal ligand of one unit and the sulfur atom of a bridging ligand of the second unit (–N^2H_{ter}···S_{bri}, 2.71 Å), which forms a linear chain polymer (Fig. 6). The lack of Ph_3P, which provides CH–π interactions, limits the dimensionality of **3** to 1D.

4.5. Solution phase behaviour

The ^{1}H NMR spectra of complexes **1**–**3** show shifts in the N^2H proton signal to low field (δ 12.42, 11.60 and 11.68 ppm, respectively) relative to the free ligand (δ 9.15 ppm). The presence of the N^2H proton signals in these complexes ensures that no deprotonation occurred during complexation. The C^2H proton signals also appear shifted to low field: δ 8.66 (**1**), 8.61 (**2**) and 8.56 ppm (**3**) (free ligand, 7.93 ppm). The ring protons of Ph_3P in complexes **1** and **2** appear in the range δ *7.32–7.51* ppm and appear to have obscured the N^1HMe proton signals. The methyl protons of –N^1HCH_3 appear as a doublet in the range, δ *3.22–3.25* ppm in **1**–**3**. The C^5H protons of the thiophene ring appeared as a doublet of doublets in the range, δ *7.07–7.1* ppm in these complexes, while the other ring protons are obscured by proton signals for triphenyl phosphine in complexes **1** and **2** and N^1HMe proton signals (δ 7.34–7.86 ppm) in complex **3**.

Complexes **1** and **2** showed ^{31}P NMR bands at δ 10.05 and 6.2 ppm, respectively. The coordination shifts, ($\Delta\delta = \delta_{complex} - \delta_{ligand}$) are 14.7 (**1**) and 10.9 ppm (**2**). These coordination shifts are similar to those found in halogen-bridged dimers in silver(I)–thiosemicarbazone chemistry [15].

5. Conclusion

For the mixed ligand complexes $[AgX_2(Htsc)_2(Ph_3P)_2]$ it is interesting to note that for R = H at N^1HR of (C_4H_4S)CH=N–NH–C(=S)–N^1HR, a sulfur-bridged dimmer, **4**, was formed [15], while for R = Me at N^1HR, halogen-bridged dimers **1** and **2** have been obtained. It demonstrates the influence of methyl substituents at the N^1 nitrogen on the bonding properties of thiophene-2-carbaldehyde thiosemicarbazones, which would enhance the steric crowding if the ligand were sulfur-bridged. In the absence of a co-ligand, as in compound **3**, the presence of four sulfur donor atoms prefers S-bridging over chloride-bridging. This also enhances the argentophilicity, with a relatively short Ag···Ag contact induced by the S-bridging. It is the first example of a complex of the stoichiometry $[Ag_2Cl_2(HttscMe)_4]$ among thiosemicarbazone/heterocyclic thioamide chemistry of coinage metals. Compounds **1**–**3** present the first report of complexes of N^1-substituted thiosemicarbazones with silver(I).

position of $[Ni(O_4C_2)(H_2O)_4]$, without any additional reducing agents. This precursor is a cheap and easy prepared complex with low toxicity.

2. Experimental

All the chemical reagents used in our experiments were of analytical grade and were used as received without further purification. XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Transmission electron microscopy (TEM) images were obtained on a Philips EM208 transmission electron microscope with an accelerating voltage of 200 kV. Fourier transform infrared (FT-IR) spectra were recorded on Shimadzu Varian 4300 spectrophotometer in KBr pellets. The elemental analysis (carbon, hydrogen and nitrogen) of the materials was obtained from Carlo ERBA Model EA 1108 analyzer. Thermogravimetric-differential thermal analysis (TG-DTA) were carried out using a thermal gravimetric analysis instrument (Shimadzu TGA-50H) with a flow rate of 20.0 mL min^{-1} and a heating rate of 10 °C min^{-1}. The electronic spectra of the complexes were taken on a Shimadzu UV–visible scanning spectrometer (Model 2101 PC).

Nickel oxalate precursor was synthesized according to this procedure: the $Ni(COOCH_3)_2 \cdot 4H_2O$ was dissolved in 10 mL of distilled water to form a homogeneous solution. A stoichiometric amount of potassium oxalate dissolved in an equal volume of distilled water, was dropwise added into the above solution under magnetic stirring. The solution was stirred for about 15 min and a green precipitate was isolated, washed and dried at 50 ℃. The obtained product was characterized by FT-IR, elemental analyses and thermogravimetric analysis (TGA) [5]. *Anal.* Calc. for $[Ni(O_4C_2)(H_2O)_4]$: C, 10.98; H, 3.69; Ni, 26.83. Found: C, 10.89; H, 3.57; Ni, 26.74%.

The main synthetic procedure in order to approach to final products is a modified version of the method developed by Hyeon and others for the synthesis of metal nanocrystals that employ the thermal decomposition of transition metal complexes [23,24]. In current synthesis, NiO nanoclusters were prepared by the thermal decomposition of nickel oxalate as precursor. First 0.6 g of $[Ni(O_4C_2)(H_2O)_4]$ and 5 mL of $C_{18}H_{37}N$ were mixed to produce $[Ni(O_4C_2)(H_2O)_2]$–oleylamin as suggested intermediate precursor. The solution was placed in a 50 mL three-neck distillation flask and heated up to 140 ℃ for 60 min. Then 5 g of $C_{18}H_{15}P$ was injected into the resulting metal-complex solution at 240 ℃. The color of the solution changed from green to black, indicating generation of colloidal products. The black solution was aged at 240 ℃ for 45 min, and was then cooled to room temperature. The black products were precipitated by adding excess C_2H_5OH to the solution. The NiO nanoclusters were washed with C_2H_5OH. These products could easily be re-dispersed in nonpolar organic solvents, such as C_6H_{12} (Scheme 1). The synthesized nanoclusters were characterized by XRD, TEM, FT-IR and UV–Vis techniques.

3. Results and discussion

In order to make sure of the precursor composition, elemental analysis was done. The TGA curve of the as-prepared precursor is shown in Fig. 1. It can be seen that there are two distinct weight loss steps. The first weight loss occurs at 110–190 ℃, which corresponds to the evaporation of crystallized water, that is to say, nickel oxalate in the stage. The second weight loss step occurs at the temperature range 210–370 ℃. The weight loss at 210–370 ℃ may be ascribed to the decomposition of the oxalate. The weight loss of two steps is about 17.80% and 41.18%, which is close to the theoretical value.

The XRD diffraction patterns of the sample of nickel oxides were recorded for the identification of the products (Fig. 2). The main diffraction peaks were observed at 37.18°, 43.42°, 62.82°, 74.20° and 79.2° in the XRD pattern of the nickel oxide which confirm that the formed material is nickel oxide. The diffraction peaks match with the standard values and they can be indexed to pure cubic phase of NiO (*Fm3 m*) with lattice parameter $a = 4.1771$ Å (JCPDS: 78-0429). The crystal size of the NiO nanoclusters was estimated by Debye–Scherrer equation ($d = 0.9\lambda/\beta\cos\theta$) and it was about 2.7 nm, which is in agreement with the other observation results. The diffraction peaks are clearly broadened, which can be the result of the reduced particle size.

To investigate whether the surface of the nanoparticles was capped with organic surface, the Fourier transformed infrared (FT-IR) of the as-synthesized samples was performed. Fig. 3 shows the FT-IR spectra of NiO nanoclusters and progressive formatted

materials within the procedure. The board peaks at ca. 3350–3400 cm^{-1} in all three spectra are representative of H_2O. Curve c shows that the surface was hydroxylated because the sample was exposed to the ambient after calcinations and some water was adsorbed probably on the external surface of the samples during handling to record the spectra. In our measurement, number of weak peaks between ν1000–1400 and ν2800–3000 cm^{-1} are attributable to the symmetric and asymmetric stretching of the $-CH_2$ groups, terminal $-CH_3$ and $=CH$ of $C_{18}H_{37}N$. The H–OH bending vibration appears at 1635 cm^{-1}. The sharp peak at 1430 cm^{-1} can be assigned to the phenyl stretching mode υ(P–ph) (curve c). Also a characteristic broad band due to the C–N stretching mode was present at about 1150 cm^{-1}. So the oleylamine and TPP serves as the capping ligand that controls growth. Triphenylphosphine (TPP) was widely used in the synthesis of phosphine-stabilized metal nanoparticles [25]. Finally, the peak at 458 cm^{-1} in spectrum (curve c), showing Ni–O bonds, gave clear evidence about the presence of the crystalline NiO. In curve a, the narrow band at 465 cm^{-1} is attributed to the bending mode of –COO group [26]. The spectra of NiO nanoclusters shows two weak stretch vibrations at 2921 and 2865 cm^{-1} attributing to the C–H stretching modes of the $C_{18}H_{37}N$ carbon chain, indicating that $C_{18}H_{37}N$ molecules have been absorbed on the surface of NiO nanoclusters. So, the $C_{18}H_{37}N$ serves as the capping ligand that controls growth [24].

The surface morphological study of the nickel oxide nanoclusters was carried out using SEM images. Fig. 4a shows the SEM images of the nickel oxide samples. From the SEM analyses, one can conclude the formation of nanoclusters flower-like structure (Fig. 4a). The transmission electron microscopic (TEM) photographs and selected area electron diffraction (SAED) pattern of the product have been given in Fig. 4b and c. The size of nanoclusters obtained from the XRD diffraction patterns are in close agreement with the TEM studies which show sizes of 2–10 nm (Fig. 4c). The particle size distributions are shown as insets in Fig. 4b and c. Most of the particles in Fig. 4b and c have diameters of 3 and 5 nm, respectively, which compare well with the values calculated from the XRD pattern. These sizes are nearly spherical. Some loose spheres formed by aggregation of small particles can be observed in TEM images. We may consider that when the reaction was carried out at 240 ℃, most organic molecules such as oleylamine and triphenylphosphine were decomposed. Since only a few $C_{18}H_{37}N$ molecules were adsorbed on NiO nanoclusters loose solid was finally produced. The SAED pattern in the inset in Fig. 4b reveals that the NiO nanoclusters are crystalline.

Since the surface areas of metal nanoclusters are enormously relative to their masses, they have an excess free energy surface comparable to the lattice energy, making them thermodynamically unstable. Protective agents are therefore essential in order to be able to outweigh the attractive van der Waals forces by the repulsive steric forces. To achieve sufficient inter-particle separation, it can be helpful to use sterically demanding substituents [22]. In this work we have used $C_{18}H_{15}P$, (TPP) and as a ligand stabilizing agent to make nanoclusters stable and prevent their agglomeration. $C_{18}H_{15}P$ is a high-boiling point surfactant with a patulous structure providing greater steric hindrance. So, this agent might slow down the rate of agglomeration of the nanoparticles during their growth, resulting in much smaller nanoclusters. Also we have used $C_{18}H_{37}N$ as an additional surfactant in order to reduce the particle size much further and resulted in uniform size distribution (Fig. 4).

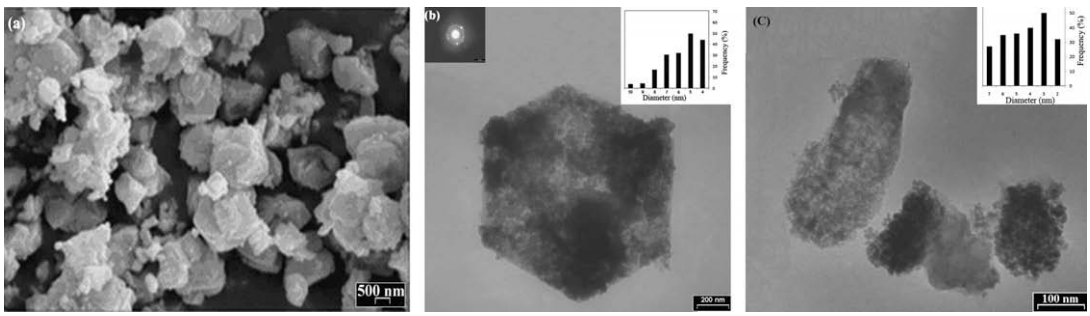

Fig. 4. (a) SEM; (b) and (c) TEM images of NiO nanoclusters (the inset shows the SAED pattern and the histograms of the particle size distributions).

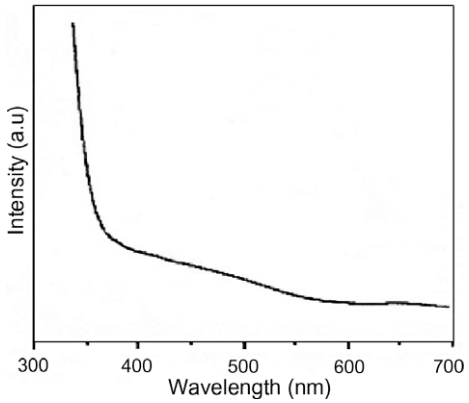

Fig. 5. UV–Vis absorption spectrum of the NiO nanoclusters dispersed in C_2H_5OH.

Table 1
Preparation of NiO under different conditions.

Sample	Capping agent	Temperature (℃)	Time	Particles size
1		450	2 h	9 nm [5]
2	oleylamine	240	45 min	agglomeration
3	TPP	240	45 min	no product
4	oleylamine + TPP	240	45 min	2.7 nm

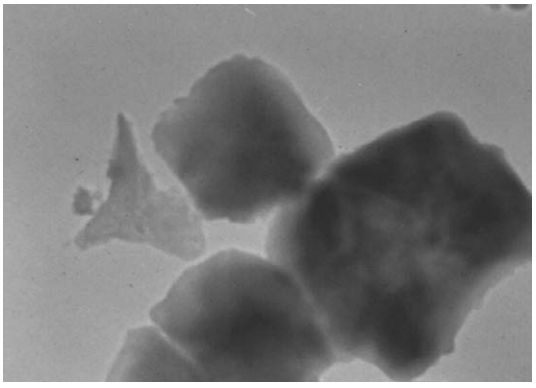

Fig. 6. NiO agglomerations (sample 2) synthesized in presence of oleylamine.

$C_{18}H_{37}N$ has been known as a ligand that binds tightly to the metal nanoparticles surface. The combined effects of TPP and $C_{18}H_{37}N$ were much more profound than those of individual contributions. Furthermore, as capping agents, TPP and oleylamine surround initial nuclei and result in decomposition of precursor in lower temperature (240 ℃). However, the decomposition without these capping agents (see Fig. 1) occurs in higher temperature (370 ℃) [27,28].

Fig. 5 is the UV–Vis spectrum of the as-synthesized NiO nanoclusters dispersed in ethanol. A strong absorption in the UV region is observed at wavelengths about 365 nm, while a broad absorption appears in the visible region. These absorptions can be attributed to intra-3d transition of Ni^{2+} in the cubic structure of NiO [29,30].

In addition, the nickel oxide nanoparticles have been prepared under different condition (Table 1). By controlling the quality of nanoparticles, NiO with various sizes can be formed. $[Ni(O_4C_2)(H_2O)_4]$ calcined at 450 ℃ for 2 h and resulted 9 nm nanoparticles (sample 1) [5], 0.5 g $[Ni(O_4C_2)(H_2O)_4]$ and 5 mL of oleylamine were mixed and heated in 240 ℃ for 45 min so led to NiO agglomerations which show size of more than 1000 nm (sample 2) (Fig. 6). Also 0.5 g $[Ni(O_4C_2)(H_2O)_4]$ and 5 g of TPP were heated together in 240 ℃ for 45 min, after washing with ethanol no precipitations were obtained. To prepare NiO nanoclusters (sample 4), the procedure mentioned in Section 2, including $C_{18}H_{37}N$ and TPP, was done. Considering different condition employed to prepare these samples, it is obvious that using both $C_{18}H_{37}N$ and TPP as capping agent is preferred for NiO nanoclusters synthesis.

4. Conclusion

NiO nanoclusters have been successfully synthesized through a thermal decomposition of new precursor $[Ni(O_4C_2)(H_2O)_4]$ in the presence of TPP and $C_{18}H_{37}N$. The as-synthesized nickel oxide nanoclusters show NiO with cubic structure without any other impurities. From the results of XRD, FT-IR and TEM, the NiO nanoclusters show good morphologies corresponding to nanosize about 2–10 nm, relatively.

carrying ortho hydroxy naphthaldimine parts **(3)**, and present the complexation properties of the ligand with a series of metal cation. The complex stability constants and complex compositions of metal cations with the ligand were determined by using spectrofluorimetric titrations in acetonitrile-dichloromethane (9.5/0.5).

2. Experimental

2.1. Chemicals

Acetonitrile and dichloromethane from Merck (spectrometric grade) were the solvents for absorption and fluorescence measurements. All metal perchlorates purchased from Acros were of the highest quality available and vacuum dried over blue silica gel before use.

2.2. Apparatus

^{1}H NMR and ^{13}C NMR spectra were recorded on a Varian 200 A spectrometer, using $CDCl_3$ with TMS as the internal reference. IR spectra were recorded on a Perkin–Elmer 1600 FTlR spectrophotometer using KBr pellets. The absorption spectra of the solutions were recorded using a Unicam UV2 spectrophotometer. Mass spectra of the ligand was measured on a Micromass Quattro LC-MS/MS spectrometer. Elemental analysis was performed on Costech 4010 CHNS instrument. A Photon Technologies International Quanta Master Spectrofluorimeter (model QM-4/2006) was used for all fluorescence measurements.

2.3. Measurements

Absorption spectra of fluoroionophore **(3)** with a concentration of 2.58×10^{-5} M in acetonitrile-dichloromethane solution (9.5/0.5) containing 100 molar equivalents of appropriate metal perchlorate salt were measured using 1-cm long absorption cell. Fluorescence spectra of the ligand solutions of 2.58×10^{-6} M were measured in 1-cm quartz cell. Excitation wavelength was 380 nm for **(3)**. Fluorescence emission spectra were recorded in the range 400–600 nm with slit width 1.0 nm.

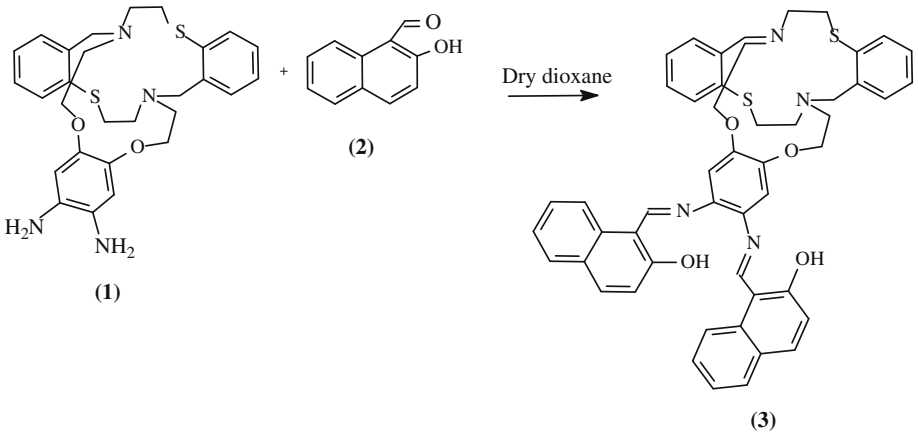
The stoichiometry of the complexes was determined by using the molar-ratio method. The stability constants were calculated according to the procedure described in literature [25].

2.4. Synthesis

2.4.1. Synthesis of ligand *(3)*

Compound **(1)** [26] (0.195 g, 0.37 mmol) was dissolved in dry dioxane (15 mL) and purged under nitrogen atmosphere in a Schlenk system connected to a vacuum line. A solution of 2-hydroxy-1-naphthaldehyde **(2)** (0.128 g, 0.74 mmol) in dry dioxane (15 mL) was added dropwise to this solution for 30 min. at 40 °C. The reaction mixture was refluxed and stirred at reflux temperature for 32 h, monitored by TLC [silica gel (ethyl alcohol)]. At the end of this period, the red solution was concentrated on an evaporator to 10 mL and the dark red solid formed was filtered off, washed with hot ethanol and cold diethyl ether, then dried *in vacuo*. The dark red solid product (yield 96%) was obtained by recrystallization from ethanol, mp 233–235 °C. *Anal.* Calc. for $C_{50}H_{46}N_4O_4S_2$: C, 72.26; H, 5.58; N, 6.74; S, 7.72. IR (KBr pellets, cm^{-1}): 3433 (O–H), 3053 (Ar–H), 2928–2797 (C–H), 1620 (C=N). ^{1}H NMR ($CDCl_3$): (δ) 15.26 (s, 2H, O–H), 9.35 (s, 2H, CH=N), 7.51–8.16 (m, 12H, napht.-H), 6.80–7.47 (m, 10H, macrocyc.-H) 4.25 (s, 4H, Ar–CH_2), 3.41 (t, 4H, O–CH_2), 3.35–2.61 (m, 8H, N–CH_2), 2.57 (t, 4H, S–CH_2). ^{13}C NMR ($CDCl_3$): (δ) 167.68, 155.30, 148.01, 140.81, 135.93, 135.25, 135.01, 132.98, 132.49, 132.44, 132.01, 129.34, 127.82, 127.48, 123.44, 121.72, 119.14, 109.36, 103.17, 66.22, 59.97, 53.25, 51.26, 33.65, MS (EI): m/z = 831.32 $[M]^+$.

3. Results and discussion



3.1. Characterization of the ligand *(3)*

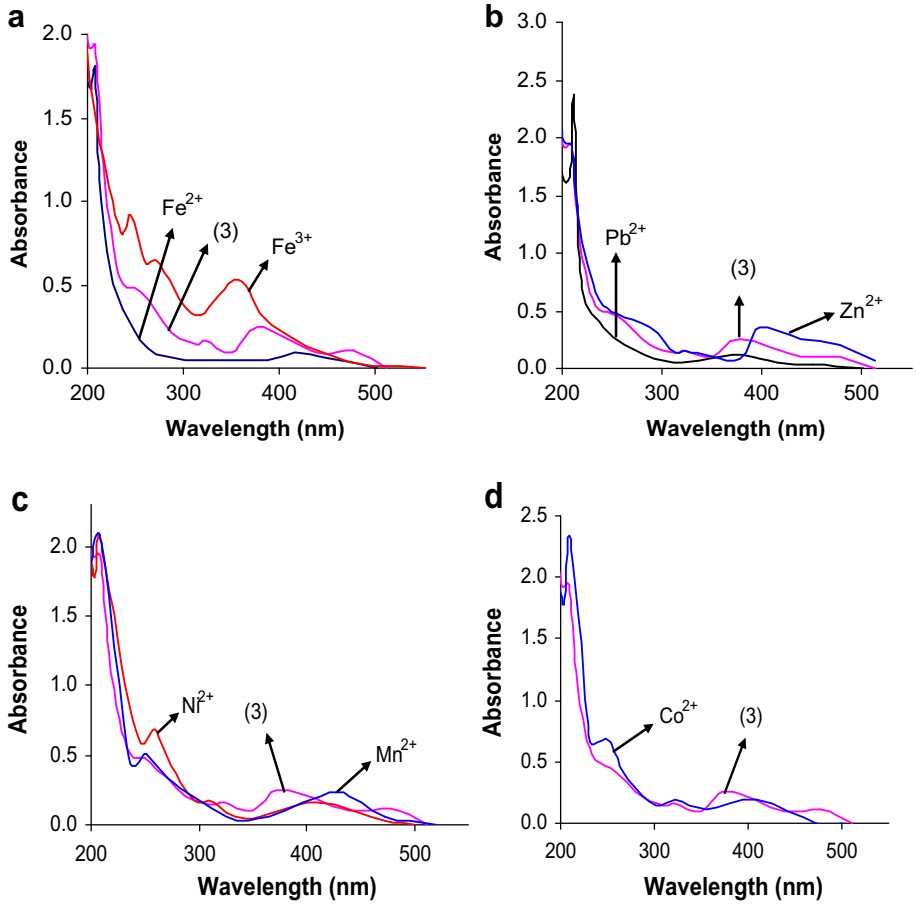
The synthetic pathway to new Schiff base ligand **(3)** is summarized in Scheme 1. Compound **(1)** was prepared according to the previous papers [26].

Compound **(3)** was synthesized by reaction of compound **(1)** with 2-hydroxy-1-naphthaldhyde **(2)** in dry dioxane. IR spectra of the diamine Schiff base naphthaldimine **(3)** show a broad band at 3435 cm^{-1} for OH stretching vibration. This band shifts towards 2791 cm^{-1} due to the increasing strength of the OH···N hydrogen bond. In the IR spectrum of compound **(3)**, the C=N stretching vibration was observed at 1620 and 1602 cm^{-1} as a strong absorption. The coexistence of two different hydrogen bond types within Schiff base molecule can be possible. There is such example of diamine Schiff base naphtaldimine molecule in which one naphtaldimine part exists in enol-imine (A form), while the other exists in keto-amine (H form) [17]. The bands at about 1541 and 1507 cm^{-1} stems from the stretching vibrations of the skeleton NH–C=C–C=O, which belongs to the keto-amine tautomer. The absence of primary aromatic amine groups belonging to compound **(1)** and carbonyl groups belonging to compound **(2)** has also supported the structure. In the ^{1}H NMR spectrum of **(3)**, the chemical shifts belong to HC=N protons at δ = 9.35 ppm. The absence of the singlet at δ = 5.23 ppm belonging to primary aromatic amine groups of the starting material, supports the formation of compound **(3)**. The resonance of moving hydroxyl group was observed at δ = 15.26 ppm for this compound. ^{13}C NMR spectral data is also in good agreement with this structure. For ligand **(3)**, the value of the chemical shift of the phenolic carbon atom at δ = 167.68 ppm suggests the coexistence of enol-imine and keto-amine forms. The carbon resonance of azomethine group was observed at δ = 155.30 ppm. The result of the mass spectral data at m/z = 831.06 $[M]^+$ confirms the formation of compound **(3)**.

3.2. Absorption spectra

As seen from Fig. 1, ligand **(3)** possesses five absorption bands with maximums at 200, 260, 323, 377 and 475 nm in acetonitrile-dichloromethane (9.5/0.5). Molar absorption coefficients are 7.5×10^4, 1.8×10^4, 8.7×10^3, 1.0×10^4 and 4.8×10^3 cm^{-1} M^{-1} in these wavelengths, respectively. The presence of 100 equivalents of Mn^{2+}, Ni^{2+} and Co^{2+} cations produces modest changes in the absorption of the ligand (Fig. 1c and d). These metal cations caused a decrease of absorption at 377 nm. On the other hand, there was a red shift in this wavelength for Mn^{2+}. These results suggest that the mentioned cations affected the keto–enol tautomeric equilibrium of the ligand (Scheme 2). Especially, that new broad band at about 450 nm caused by Mn^{2+} may have resulted from the shifting of the tautomeric equilibrium from the enol to the keto form. The effects of Fe^{2+} and Fe^{3+} ions on the absorption spectra of the ligand are pronounced. As seen from Fig. 1a, the interaction of Fe^{3+} with the ligand markedly increased absorptions in all parts of the spectrum except for the one at about 475 nm. However, Fe^{2+} caused a decrease of absorption above 220 nm. Similar effect was also observed for Pb^{2+} (Fig. 1b). Fe^{3+} gives a new strong absorption band at 344 nm with the molar absorptivity coefficient of 1.6×10^5 cm^{-1} M^{-1}. Namely, there was a blue shift by 33 nm in the 377 nm absorption band for

Scheme 1. Synthetic pathway to new macrocyclic ligand **(3)** used in this study.



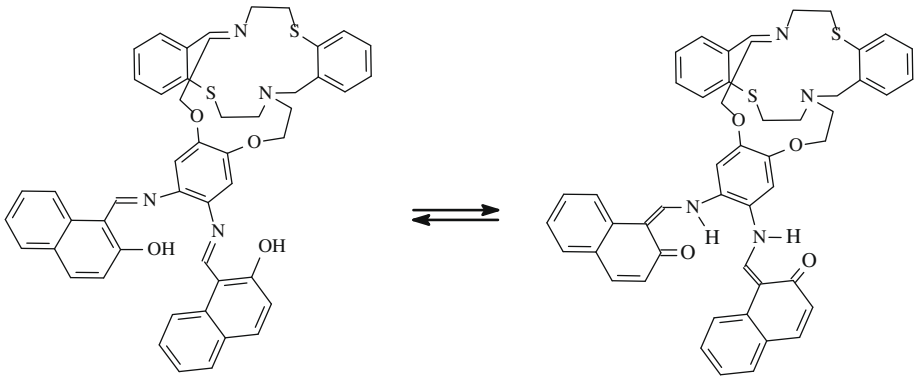


Fig. 1. The effect of metal cations on the absorption spectra of **(3)** in acetonitrile-dichloromethane solution (9.5/0.5): (a) for Fe^{2+} and Fe^{3+}; (b) for Zn^{2+} and Pb^{2+}; (c) Mn^{2+} and Ni^{2+}; (d) for Co^{2+}. Ligand concentration: 2.58×10^{-5} M. Metal perchlorate concentrations: 2.58×10^{-3} M.

Fe^{3+} cation. The absence of the 475 nm absorption band shows that Fe^{3+} caused the tautomeric equilibrium shift to the enol-imine form.

The absorption spectrum around 260 nm, attributed to the benzo-cryptand moiety, showed an enhancement of absorbance for Fe^{3+}, Co^{2+} and Ni^{2+}. This result can be explained by the disruption of the π-conjugated system between benzene and naphthaldimine groups. Similar changes in the absorption spectrum of benzo-15-crown-5 possessing 1-naphthaleneacetamide moiety in the binding of cation were observed in literature [27].

The change in the absorption spectra of ligand **(3)** with increasing concentrations of Zn^{2+} is shown in Fig. 2. Fig. 2a shows the change in the absorption spectra between 190 and 320 nm. There were two isobestic points at 215 and 240 nm. This result indicates that there were two equilibriums during the complexation. The decrease of absorbance at 220 nm provided the determination of the complex composition of Zn^{2+}-ligand **(3)**. There was a good relationship between $A_o - A$ and $[M]/[L]$ at 220 nm. A_o and A are the absorbance of free ligand and the absorbance of the solution involving Zn^{2+} cation, respectively. As seen from Fig. 2a (inset), the complex

Enol-imine (A form) Keto-amine (H form)

Scheme 2. Tautomeric forms (enol-imine and keto-amine) of the new macrobicyclic Schiff base ligand **(3)**.

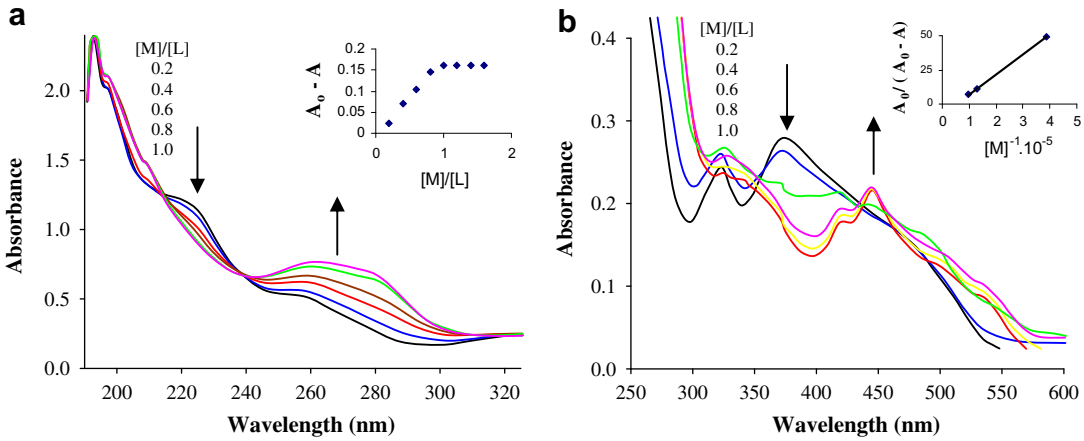

Fig. 2. Absorption spectra of **(3)** complexed with Zn^{2+}. (a) Between 190 and 320 nm and (b) between 250 and 600 nm. The spectral changes during the addition of 0–1 equivalent of $Zn(ClO_4)_2$. Ligand concentration: 2.58×10^{-5} M. Insets: measurements were carried out at 220 nm.

composition was 1:1 (*M*:*L*). The absorbance around 280 nm resulted from the naphthalene moieties accordingly increased during the complexation. This result suggests that a large conformational change occurred around the naphthalene groups. Fig. 2b shows the change in the absorption spectra between 250 and 500 nm with increasing amounts of Zn^{2+} ions. There was no isobestic point observed between these wavelengths. However, there were regular absorption changes at 377 and 450 nm. Pronounced decreases of absorbance with increases of the Zn^{2+} ion concentration was observed at 377 nm. On the contrary, there was regular absorption increases at 425 nm with increases of the Zn^{2+} ion concentration. This shows that the complexation shifts the equilibrium from the enol-imine form to keto-amine form.

The change in the absorption spectra of ligand **(3)** with increasing concentrations of Co^{2+} is shown in Fig. 3. Fig. 3a shows the change in the absorption spectra between 190 and 320 nm. The changes in the absorption spectra were very similar to that in the case of Zn^{2+} ion. The absorption decrease was observed at 220 nm with increases of the Co^{2+} ion concentration. Fig. 3a (inset) shows the molar-ratio plot for Co^{2+}. A_o and A are the absorbance of free ligand and the absorbance of the solution involving Co^{2+} cation, respectively. The inflection point was 1.0 ([*M*]/[*L*]). It can thus be concluded that ligand **(3)** formed a stable 1:1 (*M*:*L*) complex with Co^{2+}. The isobestic point at 237 nm was not clear when it was observed in detail. This seems to be due to the presence of small amounts of free ligand. Fig. 3b shows the change in the absorption spectra between 250 and 500 nm with increasing amounts of Co^{2+} ions. As seen from the Fig. 3b, two well-pronounced isobestic points were observed at 350 and 400 nm. Totally, three isobestic points were found in the absorption spectrum as a result of the Co^{2+} binding. These results indicate that there were three equilibriums during the complexation.

In order to determine the complex stability constant, the ratio of $A_o/(A_o - A)$ was plotted versus $[M]^{-1}$, as in Figs. 2b and 3b, which gave a good straight line. The stability constant was calculated from the ratio intercept/slope [25]. The values of Log *K* were 4.87 and 4.22 for the Zn^{2+}- and Co^{2+} complex, respectively. The calculations were carried out at 220 nm (Table 1).

3.3. Fluorescence spectra

Excitation at 380 nm gives an emission band with a maximum 463 nm for the ligand **(3)**. Fig. 4 shows the effects of the metal cations on the fluorescence spectra of ligand **(3)**. As seen from Fig. 4, the maximum emission band intensities of the ligand **(3)** accordingly reduced over the interaction with the metal cation except for Fe^{3+} and Zn^{2+}. There is a blue shift and an enhancement in the fluorescence intensity upon the addition of guest cations Fe^{3+} and Zn^{2+}. PET (photo-induced electron transfer) is hindered by the use of one electron pair of N of the imine group because of the complexation of these cations. Namely, fluorescence intensity is enhanced upon cation binding. Similar fluorescence enhance-

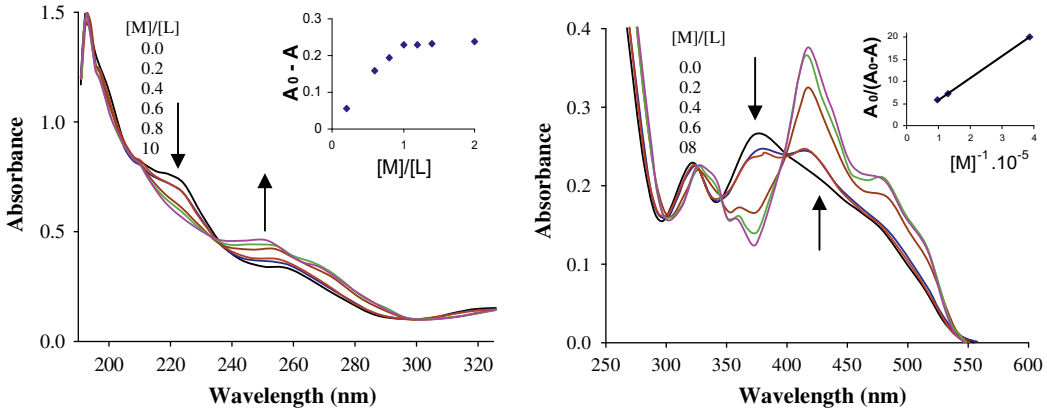

Fig. 3. Absorption spectra of **(3)** complexed with Co^{2+}. (a) Between 190 and 320 nm and (b) between 250 and 600 nm. The spectral changes during the addition of 0–1 equivalent of $Co(ClO_4)_2$. Ligand concentration: 2.58×10^{-5} M. Insets: Measurements were carried out at 220 nm.

ments were observed in the complexation of the Schiff base derived from salicylaldehyde with Zn^{2+} cation [28].

The transition metal cations such as Pb^{2+}, Co^{2+}, Ni^{2+}, Mn^{2+} and Fe^{2+} caused strong quenching of the fluorescence emission of the ligand. A decrease of the fluorescence intensity caused by these cations is probably a result of the "heavy atom effect" [29]. The incorporation of heavy metal cation into the structure leads to increase the rate of intersystem crossing (ISC) by spin-orbit coupling. This effect is known as "heavy atom effect". Especially, there was an important quenching for Ni^{2+} and Co^{2+}. The quenching effect after the formation of the Co^{2+} and Ni^{2+}-complex can be ascribed to either a naphthyl-to-metal energy transfer (ET) or a metal-to-naphthyl electron transfer (et) mechanism [30].

The effect of Fe^{2+} and Fe^{3+} is opposite on the fluorescence spectra of the ligand. While Fe^{2+} causes a strong quenching, Fe^{3+} causes an enhancement with a blue shift by 30 nm on the spectra. This result shows that the emission mechanism occurring through the complexation is different for these cations. The blue shift was about 13 nm for Zn^{2+} cation. This result shows that increasing the charge density of the transition metal cation causes more blue shift.

The complex formation was monitored by the effect of gradual addition of perchlorate salts to the solution of the ligand. The successive decrease of the emission intensity with addition of Co^{2+} was observed for the fluorimetric titrations. Fig. 5 shows the decrease of the emission of ligand **(3)** with addition of Co^{2+} ion. The values of $I_o - I$ at 463 nm was plotted against the ratio of [metal]/[ligand]. I_o and I are the fluorescence intensity of free ligand and the fluorescence intensity of the solution involving Co^{2+} cation, respectively. The curve obtained (Fig. 5 inset) clearly shows the formation of a 1:1 (M:L) complex for the ligand **(3)** with Co^{2+}.

Similarly, the decrease of the emission intensity with addition of Ni^{2+} was observed for the fluorimetric titrations. Fig. 6 shows

Table 1
Complex stability constants and complex composition of ligand **(3)** with metal cations in acetonitrile-dichloromethane (9.5/0.5).

Cation	Complex composition[a] (M:L)	Stability constant[a]	
		(Log K)[b]	(Log K)[c]
Zn^{2+}	1:1		4.87 ± 0.30
Co^{2+}	1:1	4.22 ± 0.14	4.22 ± 0.41
Ni^{2+}	2:1	4.68 ± 0.04

[b] Obtained from the fluorescence measurements.
[c] Obtained from the absorbance measurements.

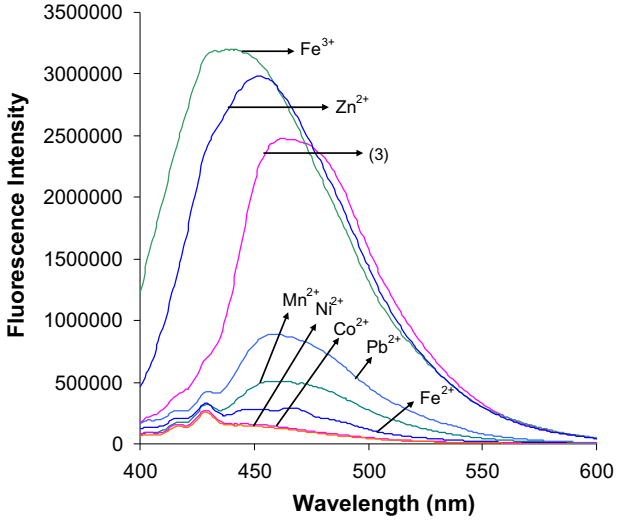

Fig. 4. Effects of metal cations on fluorescence spectra of ligand **(3)** in acetonitrile-dichloromethane solution (9.5/0.5). (Ligand concentration = 2.58×10^{-6} M. Metal perchlorate concentrations = 2.58×10^{-3} M. Excitation at 380 nm.)

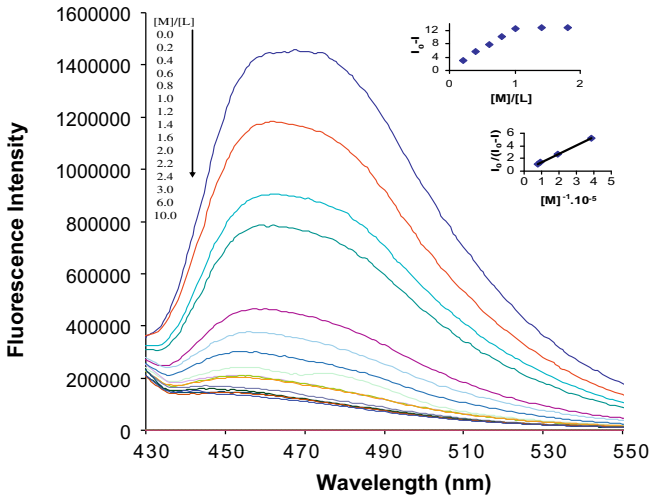

Fig. 5. Fluorescence spectra (λ_{exc}: 380 nm, λ_{em}: 463 nm) of ligand **(3)** in acetonitrile-dichloromethane (9.5/0.5) with increasing amounts of Co^{2+} ions. [L]: 2.58×10^{-6} M.

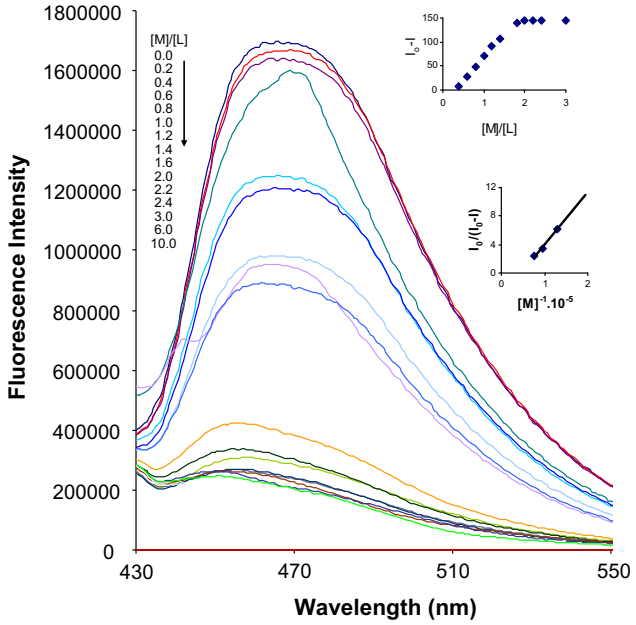

Fig. 6. Fluorescence spectra (λ_{exc}: 380 nm, λ_{em}: 463 nm) of ligand **(3)** in acetonitrile-dichloromethane (9.5/0.5) with increasing amounts of Ni^{2+} ions. [*L*]: 2.58×10^{-6} M.

the decrease of the emission of ligand **(3)** with addition of Ni^{2+} ion. The $I_o - I$ values at 463 nm was plotted against the ratio of [metal]/[ligand]. I_o and I are the fluorescence intensity of free ligand and the fluorescence intensity of the solution involving Ni^{2+} cation, respectively. The curve obtained (Fig. 6 inset) clearly shows the formation of a 2:1 (*M*:*L*) complex for the ligand **(3)** with Ni^{2+}. We did not observe a regular change in the fluorescence spectra of the ligand in the titrations with other tested metal cations. As seen from Table 1, the values of Log *K* were 4.68 and 4.22 for the Ni^{2+}- and Co^{2+} complex, respectively. The values of stability constant from obtained absorption and emission measurements for the Co^{2+} complex with 4.22 were in agreement (Table 1).

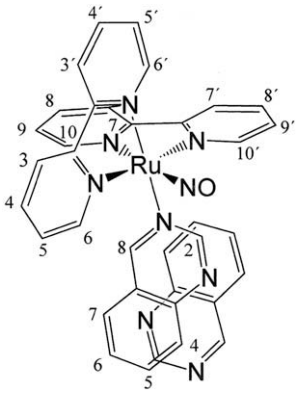

Fig. 1. Pictorial view of the *cis*-$[Ru(bpy)_2(qui)NO](PF_6)_3 \cdot (qui)$ structure and NMR labels.

Then, 303 mg of *cis*-$[Ru(bpy)_2(qui)(NO_2)]PF_6$ were dissolved in 20 mL of methanol. Next, 4 mL of HPF_6 were added to this solution and the reaction mixture was allowed to react for 1 h. The resulting yellowish solid was collected by filtration, washed with methanol and diethyl ether, and dried under vacuum. Yield 311 mg (74%). FT-IR (KBr): ν(NO) = 1944 cm^{-1}. *Anal.* Calc. for $RuC_{36}H_{28}N_9OP_3F_{18}$: C, 38.3; H, 2.7; N, 11.2. Found: C, 38.0; H, 2.5; N, 11.1% (*Caution:* The compound must be handled with care because it appears to be hygroscopic and sensitive to light exposure).

2.2. Physical measurements

All the UV–Vis spectra were recorded on a Hitachi U-3501 spectrophotometer in different solvents, at solution concentrations of approximately 10^{-5} mol L^{-1}. The infrared spectra were registered on an FT-IR/Nicolet spectrometer, model Protegé 460, from KBr pellets. The ^1H and COSY NMR measurements were performed from a 10^{-2} mol L^{-1} CD_3CN solution, in a Bruker DRX 500 MHz spectrometer and the NOESY spectrum were recorded on a Bruker DPX 300 MHz, under the same solution conditions, with mixing time t_m = 700 ms. The ESI MS mass spectrum were acquired using a high-resolution hybrid quadrupole (q) and orthogonal time-of-flight (TOF) mass spectrometer (QTOF from Waters Micromass, UK) operating in the positive ion mode at ca. 5000 resolving power. The temperature of the nebulizer was 150 °C, the cone voltage was 30 V and the sample were dissolved in a water/ethanol 1:1 (v:v) mixture. Photolysis of the complex was carried out in a water/ethanol 1:1 (v:v) deaerated mixture. The light source was the output from a 200 mW high-pressure mercury lamp and a 400 nm interference filter, to enable selection of the desired irradiation wavelength range. A sample of known volume was placed in a 1-cm quartz cuvette at 25 °C and maintained under continuous stirring while irradiated. UV–Vis spectra were recorded after pre-defined time intervals. NO release from the complex during visible irradiation was measured using a specific NO-selective electrode (ISO-NOP NO meter, World Precision Instruments, Sarasota, FL, USA). The calibration curve of the NO-selective electrode was prepared by using several dilutions of a known volume of a saturated NO solution in 10.0 mL of deaerated acetate buffer solution (pH 7.4). The current value in nA was recorded for each added volume. NO concentration was calculated according to the NO molar fraction solubility of NO (2.1×10^{-3} mol L^{-1} at 25 °C). The sensitivity of this apparatus ranged from 1 nM to 20 μM, with a 2-mm sensor, which directly detected NO concentration by an amperometric technique. Photolysis in aqueous media under physiological conditions was carried out as described above, using a solution of complex in PBS buffer.

pH values were recorded on a Labmeter pH meter model PH2. In order to evaluate the pK_a of the quinazoline ligand in the complex and the pH for the conversion of coordinated NO^+ into NO_2^-, absorption spectra of the complex solutions at different pH values were registered. Variations in the absorbance values of the bands, recorded in the visible region, were plotted against the pH. The curves were differentiated for determination of the pK_a values. Mcllvaine buffer solutions were used for the pH range 2.5–7.5 while the Kolthoff buffer was used for pH 10 [19]. For the pH range 0–2.5, trifluoroacetic acid and NaOH 0.1 mol L^{-1} solutions were employed. Other pH values were obtained by combinations of NaOH and HCl solutions. All solutions were prepared from KCl 0.1 mol L^{-1} solutions.

3. Results and discussion

3.1. NMR and ESI MS structural characterization

Compound *cis*-$[Ru(bpy)_2(qui)NO](PF_6)_3 \cdot (qui)$ was obtained following a synthetic procedure previously reported for analogous nitrosyl complexes [18]. Elemental analysis results suggest that the complex was isolated with an additional *qui* molecule. Contamination was excluded on the basis of the apparent 1:1 stoichiometric relation between the complex and non-coordinated *qui*, not to mention the fact that the complex was washed with methanol after filtration, a solvent in which the ligand is fully soluble. To verify whether the investigated complex was associated with this additional quinazoline molecule in solution, its structural characterization was performed by ^1H 1D and COSY 2D NMR. Table 1 summarizes the tentative assignment of the signals observed in the ^1H NMR spectrum of the *cis*-$[Ru(bpy)_2(qui)NO](PF_6)_3 \cdot (qui)$ complex. Assignments are based on literature data for related species [20], and comparison with chemical shift values (δ) of the free ligands was carried out [21]. Correlations observed in the COSY

Table 1

spectra also aided the characterization (see Supplementary material for the spectra).

The spectrum of the compound *cis*-[Ru(bpy)$_2$(qui)NO](PF$_6$)$_3$ · (*qui*) displays a large number of peaks as a consequence of the non-equivalence of the aromatic rings of the quinazoline and bipyridine ligands. As seen in Fig. 1, the ring labeled (2–3–4–5–6) should exert direct influence (from ring current effects) on proton **10**, while the (7′–8′–9′–10′–11′) ring should affect the signal of proton **6**′. In turn, the coordinated quinazoline ring should affect proton **6**, while proton **10**′ would be subjected to induced current effects of the nitrosyl ligand. The δ values of the protons belonging to the [Ru(bpy)$_2$] moiety follow the same pattern observed for the [Ru(bpy)$_3$]$^{2+}$ complex [22,23]. Due to coordination to the ruthenium ion, free rotation of the bpy rings is not possible. In addition, protons **3**, **3**′, **7** and **7**′ are sterically strained, so the van der Waals interaction between them causes a deshielding effect, shifting their signals to lower field compared with other protons in that ligand [23]. An interesting feature is the signal at 9.40 ppm, ascribed to proton **10**′. This large shift to lower field has also been observed in other mononuclear ruthenium complexes. It arises from the close proximity of that proton with the adjacent NO ligand and has been attributed to inductive effects from the latter ligand. This kind of anisotropy is known to occur from chemical units such as NO or CN, where the π electrons of the multiple bond are disturbed by the applied magnetic field. These electrons respond to this external perturbation by circulating in order to generate an opposed magnetic field in the axis of the multiple bond. In the region below and above this bond there is an induced magnetic field adding to the applied one, causing a deshielding effect on protons near this region [24–27]. Finally, protons **6**, **6**′, and **10** are subjected to *ring current* effects, since they are located in the shielding region of the pyridinic aromatic rings and therefore have their signals shifted to higher field compared with the free ligand. As expected, protons **5**, **5**′, **9**, and **9**′ appear as triplets, with δ values varying from 7.67 to 8.24 ppm due to the non-equivalence of the bpy rings. The same discussion can be applied to protons **4**, **4**′, **8** and **8**′, except that the signals of **4**, **4**′ are superimposed.

However, the most important feature emerging from these measurements is that the experimental value of I (the sum of the integral value of the signals observed in the ^{1}H spectrum) is 28.2, which matches the calculated value of 28, obtained when one considers the total number of H nuclei present in the complex structure (22) plus an additional molecule of *qui*, which contributes with 6 protons. Moreover, it was possible to assign the signals of both the coordinated and the non-coordinated *qui* ligands, which leads to the conclusion that there is an interaction sustaining the complex:*qui* association in solution in 1:1 stoichiometry.

The analysis of the NOESY spectrum (Supplementary material) was rather inconclusive, since there is a large superimposition of signals in the aromatic region of the spectrum and, consequently, large superimpositions of the observed correlations. However, the spectrum presents some inter – molecular correlations, such as between protons Hq5–Hq2 and Hq6–Hq2 (coordinated and un-coordinated quinazoline protons, respectively) that suggest the interaction between the coordinated and the un-coordinated quinazoline molecule in the compound. Although in solution a dynamic equilibrium for that interaction is expected, the observed correlations also suggest that the main site of interaction of the unbound *qui* is the coordinated *qui* molecule.

Under the experimental conditions employed in this work for the acquisition of the ESI MS spectrum (30 eV for cone voltage), it is not expected to detect the molecular peak corresponding to the charged species [Ru(bpy)$_2$(qui)(NO)]$^{3+}$ · (*qui*), in which the ruthenium complex is weakly associated to the additional *qui* molecule. Actually, the compound suffered an extensive fragmentation process at the source, and consequently the MS spectrum displayed peaks corresponding to fragments originated from the cleavage of stronger bonds such as Ru–NO or Ru–qui (coordinated molecule) (the ESI MS spectrum as well as the assignment of the main peaks observed are available as Supplementary material).

3.2. UV–Vis spectroscopy and solvent effect

The absorption spectrum of the *cis*-[Ru(bpy)$_2$(qui)NO](PF$_6$)$_3$ · (*qui*) complex in acetonitrile solution displays absorption bands in the UV region ($\pi \rightarrow \pi^*$ intraligand and Ru$_{d\pi} \rightarrow$ NO$_\pi^*$) [18] and a lower energy band centered at 430 nm (ε = 5741 cm^{-1} mol^{-1} L). This last band could be assigned to a metal to ligand charge transfer transition (MLCT, possibly Ru$_{d\pi}$–qui$_\pi^*$), to a low lying nπ transition of the quinazoline ligands or even to a transition related to the association of the additional quinazoline molecule to the complex. To probe these hypothesis, the absorption spectrum of the compound *cis*-[Ru(bpy)$_2$(qui)NO](PF$_6$)$_3$ · (*qui*) was acquired in aqueous medium, in two different pH values (Fig. 2), assuming that the protonation of the nitrogen heteroatoms of both the coordinated and non-coordinated *qui* molecules could contribute to the association disassembly. In fact, at pH 1 the sites available in the complex are protonated (pK_{a1} = 3.5 and pK_{a2} = 3.2 for free quinazoline, and pK_a = 2.75 for the coordinated *qui* ligand) and, under this condition, there is no absorption in the visible region of the UV–Vis spectrum. At pH 3.7, the lower energy absorption band is restored.

Both Ru$_{d\pi}$–qui$_\pi^*$ MLCT or a low lying nπ transition would respond to the protonation of the non-coordinated N heteroatoms. The MLCT band would be red shifted since the protonation would stabilize to some extent the π^* levels of the quinazoline, lowering the transition energy. Such shift is not observed (Fig. 2). Alternatively, the involvement of the non-ligand electron pair of the quinazoline nitrogen atoms in the bond with the protons would further stabilize the non-ligand levels, promoting a hypsochromic shift of a nπ transition. This is observed (Fig. S9, Supplementary material), however, the quinazoline transitions occur in a higher energy region of the spectrum than the observed for the complex transitions (Fig. 2). Thus, the assignment of the 430 nm band as a MLCT or as a nπ transition was ruled out.

Based on the previous discussion and considering that this kind of mononuclear ruthenium–nitrosyl complex typically presents transitions in the higher energy region of the UV–Vis spectrum, it was concluded that the 430 nm band is due to the association of the *qui* molecule with the complex. As shown in Fig. 2, this absorption, and most probably the kind of interaction that sustains the assembly of the complex, is dependent on the protonation of the quinazoline nitrogen heteroatoms.

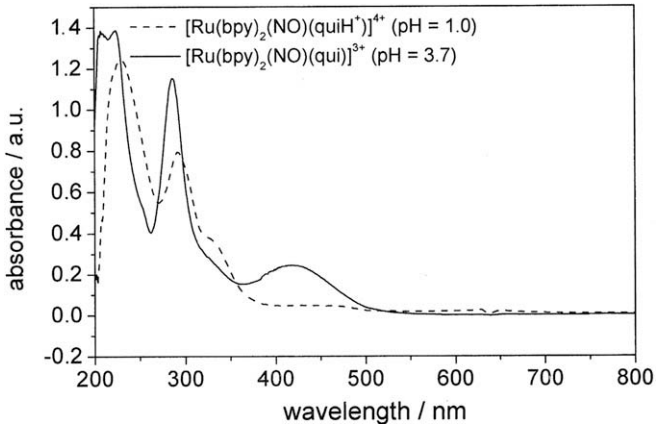

Fig. 2. Electronic spectra of the *cis*-[Ru(bpy)$_2$(qui)NO](PF$_6$)$_3$ · (*qui*) compound in aqueous medium, at pH 1.0 and 3.7.

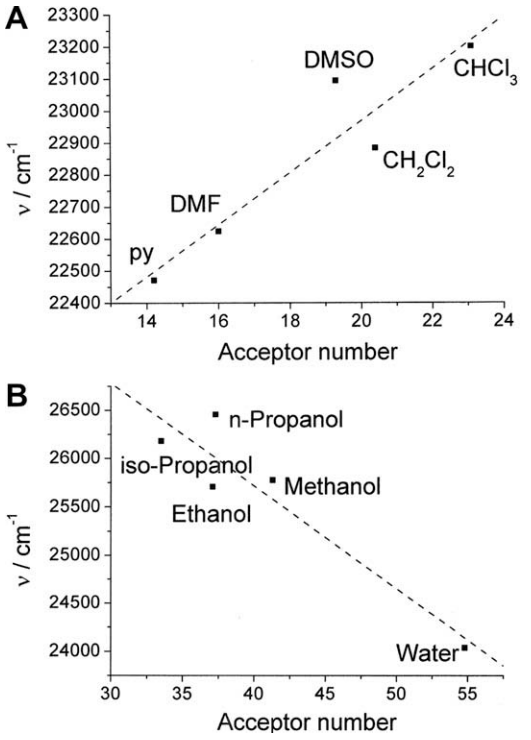

Fig. 3. CT absorption energy of the *cis*-[Ru(bpy)$_2$(qui)NO](PF$_6$)$_3$ · (*qui*) complex vs. the acceptor number of (A) an aprotic and (B) a protic group of solvents.

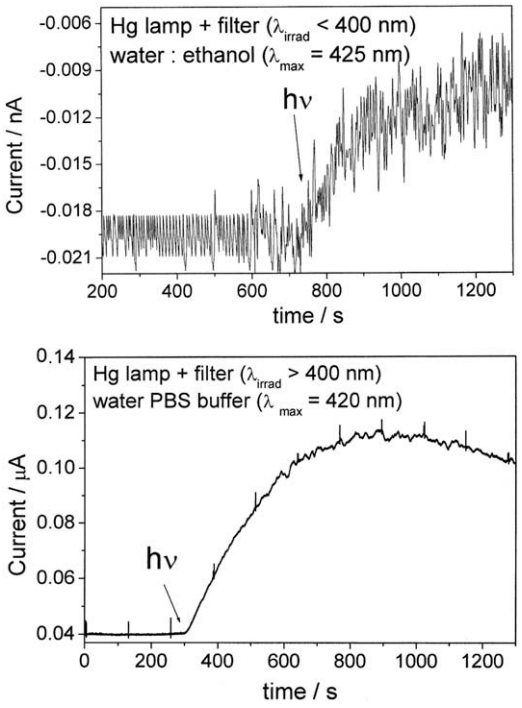

Fig. 4. Chronoamperogram of *cis*-[Ru(bpy)$_2$(qui)NO](PF$_6$)$_3$ · (*qui*) solutions in different conditions, irradiated with visible light.

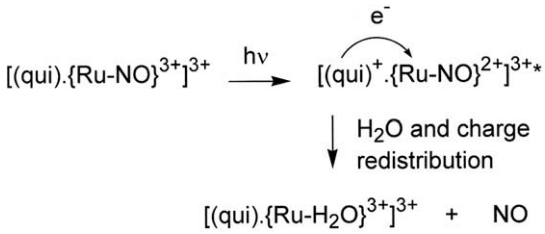
It is worth mentioning that the coordinated NO^+ ligand constitutes a site for nucleophilic attack in higher pH values (pH 6.63 for the conversion of coordinated NO^+ to NO_2^-), but at pH 3.7 it is actually coordinated in the form of NO^+, as probed by its typical IR stretching band at 1935 cm^{-1} (see Supplementary material for the pK_a determination curves, the IR and UV–Vis spectra at pH 7.4).

Aiming at further characterizing this visible absorption band, a solvent effect experiment was carried out. In the solvents used in this work, the lower energy band in the spectra of the complex displays a well behaved correlation with the solvent parameter "acceptor number" (AN, Fig. 3) [28,29]. This shows that the complex sites that probably interact with the solvent are the nitrogen electron lone-pairs of the quinazoline ligands, which should be involved in a "donating type" interaction with the solvent molecules. This kind of solvatochromism is characteristic of charge transfer transitions that require a large reorganization of the solvation sphere because of the charge density redistribution over the molecule. This result, together with the spectral region of the studied transition and its ε value (in the order of 10^3), suggests that this is a charge transfer transition (CT). Interestingly, the dependence of the band energy on the AN of the solvent features a different correlation pattern ongoing from an aprotic to a protic group of solvents. This reveals that protonation or a proton donating interaction, such as the formation of hydrogen bond (a possible event in protic solvents), plays an important role in the spectral behavior of the compound [Ru(bpy)$_2$(qui)NO]PF$_6$ · (*qui*).

Therefore, the observed spectral dependence on pH and solvent leads to the conclusion that the assembly of the aggregate complex:*qui* in solution is a reversible event. Additionally, due to the hydrophobic and planar nature of the quinazoline ligand, this aggregation is possibly driven by π-stacking interactions between the ligands. The most dramatic effect is seen when the protonation of the quinazoline ligands is promoted. This creates charge on these ligands, what would disrupt the π-stacking interaction that holds the solution arrangement.



Preliminary molecular modeling results based on DFT calculations[1] suggest that the HOMO is a molecular orbital centered at the non-coordinated quinazoline ligand, with a little contribution from the {RuNO}^{6} moiety [30]. The LUMO, in turn, has a large metal character, with its major contribution from the metallic unit {RuNO}^{6}. Therefore, this result strongly suggests that the lower energy band of absorption spectrum of the complex (430 nm in acetonitrile), that is the HOMO–LUMO transition, has a charge transfer character, corroborating the spectroscopic results discussed above.

On a qualitative basis, at this point it is interesting to further analyze the assignment of this transition. Keeping in mind that the HOMO has a ligand character and the LUMO has a metal character, this CT band could be considered as belonging to a ligand-to-metal charge transfer (LMCT) transition type, even though the quinazoline ligand involved in the transition is not coordinated to the central metal ion, in other words this transitions is an outer sphere charge transfer [31–34]. On the other hand, it would be counter-intuitive, if one thinks that the complex is formally a Ru(II) com-

[1] All calculations were performed using the GAUSSIAN 03 (Multiprocessor Version) package. Geometry optimizations were carried out without any symmetry constraints, using the double-ζ LANL2DZ basis set with the relative pseudopotential for ruthenium, and the DGDZVP basis set of double-ζ and polarization quality, for the other atoms. The B3LYP hybrid functional was employed in all the calculations. The TD-DFT excitation spectrum was computed for 40 excited states in vacuum only. In this case, the DGDZVP basis set was substituted with the larger DGDZVP2, of double polarization. The stabilization energy, without corrections, for the formation of the stacked complex was calculated by the relation:

$$E(complex + quinazoline) = E(complex) - E(quinazoline),$$

where E(complex + quinazoline) is the total stabilization energy (in atomic units) calculated for the stacked complex (−88 kJ/mol), E(complex) is the total energy for the complex without an additional quinazoline, and E(quinazoline) is the total energy calculated for an isolated quinazoline molecule. For the geometry optimization of the complex without the additional quinazoline, the same atomic basis sets used for optimization of the stacked complex were employed. The geometry optimization of quinazoline was carried out using the DGDZVP basis set for all the atoms. Further details focusing on the molecular modeling results are the subject of another work that is being carried out in our laboratories.

Scheme 1.

pound. Nevertheless, it has already been discussed that ruthenium ions might have an ambiguous behavior, regarding its oxidation state, when coordinated to nitrogen species (especially NO) [35–38]. Thus, a Ru(II) ion coordinated to NO^+ has its Lewis acidity increased to such a limit that it might behave as Ru(III). This seems to be the case here, so it is reasonable to assign the 430 nm band as an outer sphere LMCT transition.

3.3. Photophysics

A simple way to test the CT nature of this transition is to evaluate its ability to promote the photorelease of the coordinated NO. Fig. 4 presents the photolysis results when aqueous/ethanolic or PBS buffered (pH 7.4) aqueous solutions of the complex are irradiated with visible light ($\lambda > 400$ nm).

Irradiation of this complex in both conditions is effective to release NO, which is detected by an amperometric measurement. It has already been described that the NO^+ ligand must be reduced to NO^0, so that it can be released from ruthenium compounds [2–6,10–16]. One way to do this is to irradiate the compound in a CT transition, usually the $Ru_{d\pi} \rightarrow NO_{\pi}^{*}$, a photoredox state that leads to NO^0 generation in the excited state. This seems to be the case in the present work. Assuming that the 430 nm band is an LMCT transition that directly addresses a molecular orbital with {RuNO} character, one possible mechanism is presented in Scheme 1. Irradiation on this CT band generates the reduced NO form, which is released. The complex further decays, suffering a charge redistribution where the Ru^{2+} ion is oxidized to Ru^{3+}, in order to restore the neutral form of the adjacent quinazoline ligand. The aquation reaction then takes place.

It is worth mentioning that the proposed mechanism holds for the nitrosyl species and, at physiological pH, the species actually present in the solution has a NO_2^- ligand coordinated to the ruthenium ion ($pK_a = 6.63$). Although the photolysis carried out in this work is a qualitative experiment, chronoamperometric curve in Fig. 4B demonstrates that NO release seems to be more efficient, considering that the conditions of both experiments were the same, except for the reaction medium. Probably this is so because other mechanisms of NO release should be involved in this second experiment. In fact, it has already been demonstrated that nitro bipyridine ruthenium compounds are also able to release nitric oxide, due to a photoinduced homolytic dissociation of NO from a coordinate NO_2^-, yielding a Ru^{2+}–H_2O complex and NO as photoproducts [39].

4. Conclusions

In summary, the use of the quinazoline ligand has led to the isolation of a ruthenium–nitrosyl complex that delivers NO under visible light irradiation. The visible absorption band has a charge transfer nature, involving a second quinazoline molecule which is associated with the ruthenium complex by means of weak interactions, possibly of the π-stacking nature. Spectroscopic experiments, such as solvent effect and pH dependence of the spectral behavior, corroborate the charge transfer assignment of the transition. Therefore, the interaction of the complex ion with a *qui* molecule in solution introduces new spectroscopic features into the compound, constituting an example of the use of weak interactions (non-covalent interactions) to create interesting properties in inorganic/organic molecular systems.

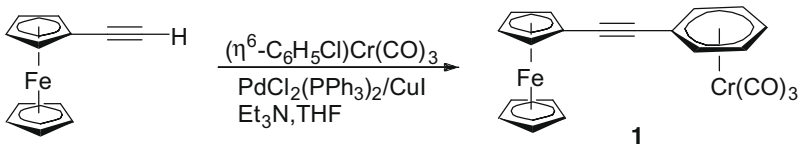
2.5. X-ray diffraction analysis

The structure of **1** was determined by Robert Burrow (Universidade de Santa Maria, RS, Brazil). The structure of **3** was determined by V.G. Young Jr. (University of Minnesota, USA). Crystal data, data collection details, and solution and refinement procedures are provided in Table 1 [27–29]. For complex **3** all non-H atoms were refined with anisotropic displacement parameters unless stated otherwise. All hydrogen atoms were placed in ideal positions and refined as riding atoms with relative isotropic displacement parameters [27,28].



On p. 6, line 19, the description of the treatment of the hydrogen atoms is correct only for **3**. For structure **1**, the cif file indicates that all of the hydrogen atom coordinates were refined and their Uiso values were fixed. The term in the cif file for **3** which describes the hydrogen treatment (_refine_ls_hydrogen_treatment) should be changed from "mixed" to "constr" for **3** and to "refxyz" for **1**. The reference 29 (Otwinowski & Minor) is not applicable to hydrogen atoms.

3. Results and discussion

The reaction of $Cr(CO)_3(\eta^6\text{-}C_6H_5Cl)$ with 1.4 equiv of ethynylferrocene in the presence of a catalytic amount of $Pd(PPh_3)_2Cl_2$/CuI in a gently refluxing THF/NEt_3 for 13 h affords the corresponding starting heterobimetallic compound $[Cr(CO)_3(\eta^6\text{-}C_6H_5)C\equiv C\text{-}\{(\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5)\}]$(**1**) [22], which was isolated as a dark solid (78%, Scheme 1). The identity of **1** was confirmed on the basis of elemental analysis, multinuclear (^1H, ^{13}C) NMR data, and by an X-ray diffraction study.

Scheme 1.

The IR spectrum of **1** shows three bands of the carbonyl stretching frequencies determined by a splitting of the asymmetric mode (E), which can be rationalized in terms of a small perturbation of C_{3v} symmetry by alkyne–ferrocene fragment on the benzene ring [30,31]. The ^{1}H NMR spectrum of **1** contains three sets of arene resonances in the region between 5.50 and 5.23 ppm, and two singlets at 4.52 and 4.27 ppm attributable to the cyclopentadienyl protons of ferrocene unit. As expected, the resonances of the alkyne carbons appear at 85.4 and 81.3 ppm.

Crystals of complex **1** suitable for an X-ray diffraction study were grown from slow diffusion of hexane into the CH_2Cl_2 solution containing **1** at −20 °C. Details of crystal and refinement data are reported in Table 1. Selected bond distances and angles are listed in Table 2. The crystal structure of **1** consists of two structural sub-units "$Cr(CO)_3((\eta^6\text{-}C_6H_5\text{–})$", and "$(\text{-}C{\equiv}C\text{–}C_5H_4)Fe(C_5H_5)$", which adopts a *cisoid* conformation as displayed in Fig. 1.

The $Cr(CO)_3$ group shows the well-known piano-stool conformation found in half-sandwich tricarbonyl complexes. The bond angles OC–Cr–CO (88.8° average) and Cr–C bond distances (1.848 Å average) are comparable to the (η^6-arene)tricarbonylchromium complexes $YCH_2C{\equiv}CPh[Cr(CO)_3]$ (Y = NMe_2, 88.4°, 1.841 Å; Y = N(Me)(CH_2Ph), 88.8°, 1.840 Å) [23]. On the other hand, the Cr–Ct(1) distance (1.723 Å, Ct(1) = centroid of C31–C36) is slightly longer than in (η^6-arene)tricarbonylchromium compounds incorporating propargyl amine units (average 1.701 Å) [23], which can be associate to the presence of an electron-donating ferrocenyl group. The C≡C bond distance (1.194 Å) falls in normal range for similar arene tricarbonyl chromium complexes [32,33]. The $Cr(CO)_3$ tripod is arranged in a nearly staggered conformation with the dihedral angles of the projected Cr-CO with respect to the aromatic carbon atoms varying from 37° to 40° (Figs. 2 and 4). The alkyne fragment is found lying in the mean plane of the arene and cyclopentadienyl rings, whereas the C_{ipso}–C≡C linkages are almost linear (C(31)–C(2)–C(1) = 174.2 (2)°; C(21)–C(1)–C(2) = 176.3 (2)°). The ferrocene unit shows an almost eclipsed conformation (average torsion angle 13.9°) with characteristic Fe–Ct distances (Fe–Ct(2) = 1.654 Å, Ct(2) = centroid of C21–C25); Fe–Ct(3) = 1.649 Å, Ct(3) = centroid of C11–C15) [34–36].

Selected bond distances and angles are listed in Table 2. The crystal structure of **1** consists of two structural sub-units "$Cr(CO)_3((\eta^6\text{-}C_6H_5\text{–})$", and "$(\text{-}C{\equiv}C\text{–}C_5H_4)Fe(C_5H_5)$", which adopts a *cisoid* conformation as displayed in Fig. 1.

The 1-(ferrocenylethynyl)(η^6-arene)tricarbonylchromium (**1**) reacts with an equimolar amount of $[Co_2(CO)_8]$ in THF at room temperature to give, after workup, the heterotetrametallic complex $[Cr(CO)_3(\eta^6\text{-}C_6H_5)\{Co_2(CO)_6\text{-}\mu^2\text{-}\eta^2\text{-}C{\equiv}C\text{-}\}(\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5)\}]$ (**2**) as dark solid in 80% yield (Scheme 2). The structure of **2** was assigned based on elemental analysis, IR, and multinuclear (^{1}H, ^{13}C) NMR data.

The characterization of **2** was first provided by the IR ν(CO) spectrum. In solid state, complex **2** shows six bands of the carbonyl stretching frequencies. The three CO stretching bands at higher frequencies are attributed to the carbonyl bonded to cobalt atoms [37]. In the case of the (η^6-arene)$Cr(CO)_3$ unit, three bands are expected: the A_1 band at higher frequency and the E band, split due to the deviation from idealised C_{3v} symmetry [30,31]. In addition, the IR spectrum of **2** displays the vibration mode of the C≡C unit at 1564 cm^{-1}, indicating a weakening of the C≡C bond upon coordination of the dicobalt compound [38,39]. From IR data we can assume that the $Co_2(CO)_6$ moiety coordinated to alkyne moiety acts as an electron-withdrawing substituent. The positive value of the

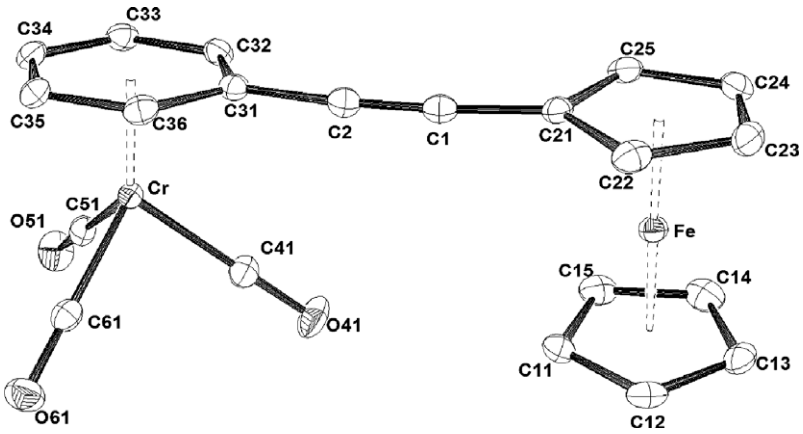

Fig. 1. Molecular structure of **1** (H atoms omitted) with thermal ellipsoids at the 30% probability level.

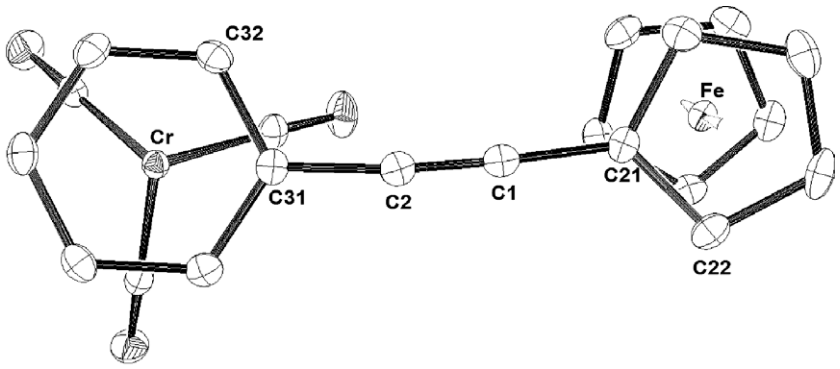

Fig. 2. Ortep view of complex **1** with the $Cr(CO)_3$ tripod projected onto the arene ring.

parameter $\Delta\nu_M$ (10 cm^{-1}) [40] calculated for E-mode carbonyl absorption bands strongly suggests a slight electronic density transfer from the chromium fragment to the dicobalt-alkyne unit.

As expected, the ^1H NMR spectrum of **2** shows the usual three set of resonances in the range of 6.14–5.23 ppm attributable to the arene protons, and three singlets at 4.46, 4.40 and 4.18 ppm corresponding to the cyclopentadienyl protons of the ferrocene unit. In addition, the ^1H NMR spectrum of **2** displays the low frequency shift of the arene protons with respect to those of the cor-

Scheme 2.

Scheme 3.

responding complex **1** as result of electron-withdrawing characteristic of $Co_2(CO)_6$ fragment. The $^{13}C\{^1H\}$ NMR spectrum of **2** contains one sharp peak at 232.2 ppm related to the carbonyl groups bound to the chromium atom and a typical broad shape resonance at 199.2 ppm corresponding to the two equivalent sets of carbonyl ligands coordinated to the cobalt metal centres.

The 1:1 reaction of **1** with "$Mo_2Cp_2(CO)_4$" in di-*n*-butyl ether/CH_2Cl_2 at room temperature for 12 h affords the corresponding heterotetrametallic complex $[Cr(CO)_3(\eta^6\text{-}C_6H_5)\{Mo_2Cp_2(CO)_4\text{-}\mu^2\text{-}\eta^2\text{-}C{\equiv}C\text{-}\}(\eta^5\text{-}C_5H_4)Fe(\eta^5\text{-}C_5H_5)]$ (**3**) (Scheme 3), which was isolated as dark red solid in moderate yield (41%). The identity of **3** was established on the basis of elemental analysis, IR, multinuclear (^1H, ^{13}C) NMR data, and by an X-ray diffraction study.

The IR spectrum of **3** shows six ν(CO) bands in the range of 2004–1865 cm^{-1} corresponding to the terminal CO groups coordinated to molybdenum and chromium metal centres, and one lower-frequency band at 1846 cm^{-1} assigned to the semi-bridging carbonyl group. In this case the value of the parameter $\Delta\nu_M$ cannot be calculated due to difficulty assigning precisely the carbonyl stretching E band related to the $Cr(CO)_3$ moiety.

The ^1H NMR spectrum of **3** shows three set of arene resonances at 6.40, 5.52 and 5.31 ppm in a 2:1:2 intensity ratio, one singlet at 5.24 ppm assigned to the molybdenum cyclopentadienyl protons, and three singlets at 4.40, 4.30 and 4.23 ppm in a 2:2:5 intensity ratio related to the cyclopentadienyl protons of the ferrocene unit. Similarly found for complex **2**, the flow of electronic density from arene ligand to the "$Mo_2Cp_2(CO)_4$" fragment is reflected by the low field of the ^1H NMR signals of the arene group. The $^{13}C\{^1H\}$ NMR spectrum displays one singlet at 234.2 ppm related to the carbonyl groups coordinated to chromium metal center, and two weak singlets at 230.2 and 229.7 corresponding to the carbonyl groups bonded to molybdenum metal center as result of a fluxional process these ligands.

Crystals of complex **3** suitable for an X-ray diffraction study were grown from slow diffusion of hexane into the CH_2Cl_2 solution containing **3** at 25 °C. Crystal data and structure refinement for **3** are summarized in Table 1, and selected bond distances and angles are listed in Table 3. The molecular geometry and atom-labeling scheme is shown in Fig. 3. The compound **3** consists in three structural sub-units "$Cr(CO)_3(\eta^6\text{-}C_6H_5\text{-})$", "$Mo_2Cp_2(CO)_4(\eta^2, \mu^2\text{-}C{\equiv}C\text{-})$", and "$(\text{-}C_5H_4)Fe(C_5H_5)$". The Cr–Ct(1) (Ct(1) = centroid of C8–C13) and CrC–O bond distances in **3** (1.763 Å, average 1.173 Å(10)) are slightly longer than those observed in complex **1** (1.723 Å, average 1.152 Å(3)); this is likely due to the electron-withdrawing capacity of the "$Mo_2Cp_2(CO)_4$" as already indicated by the ^1H and ^{13}C NMR data.

As a general trend, the cluster core $Mo_2(\text{-}C{\equiv}C\text{-})$ shows the common tetrahedron geometry where the alkyne unit is almost perpendicular to the Mo–Mo bond. The Mo(1)–Mo(2) bond distance of 3.0036 (12) Å is comparable to those found in similar molybdenum complexes [41]. The coordination of the alkyne ligand to the Mo_2 unit is quite symmetrical, which can be evidenced by similar Mo–C bond distances [Mo(1)–C(14) = 2.220 (8) Å, Mo(1)–C(15) = 2.230 (7) Å; Mo(2)–C(14) = 2.251 (8) Å, Mo(2)–C(15) = 2.230 (7) Å]. The smallish Mo(1)–Mo(2)–C(3) angle of 69.5 (2)°, slightly bent Mo(2)–C(3)–O(3) angle (171.0 (7)°), away from Mo(1), and close non-bonding Mo(1)–C(3) bond distance (2.969(8)Å) are characteristic of a weakly interacting type II semi-bridging carbonyl [24,42]. The angle between the Mo(1)–Mo(2) and C(14)–C(15) vectors is 90.6°. The cyclopentadienyl rings, which have an average C-C bond distance of 1.442 Å are in the *trans*-position with respect to each other (pseudo torsion angle Ct(1)–Mo(1)–Mo(2)–Ct(2) = 152.2° (Ct(1) = centroid of C26–C30; Ct(2) = centroid of C31–C35). The Mo(1)–Ct(1) distance (2.037 Å) is slightly shorter than the Mo(2)–Ct(2) distance (2.059 Å), which can be attributable to the donation of electronic density from Mo(1) to the semi-bridging carbonyl of Mo(2). Neither ring shows slippage and both distances are in agreement with values observed for similar compounds [43].

In alkyne–dimolybdenum cluster, the R_1–C≡C–R_2 [R_1 = $Cr(CO)_3$-(η^6-C_6H_5–), R_2 = (–C_5H_4)Fe(C_5H_5)] moiety is no longer linear [C(16)–C(15)–C(14) = 140.2 (7)°, and C(8)–C(14)–C(15) = 129.5 (7)°] and the substituents are bent back by *ca.* 45°. In addition, the presence of substituents leads a twisting of the C(8)–C(14) bond relative to the C(15)–C(16) vector to give a dihedral angle of 4.8(15)°. As expected, the coordinated triple bond C(14)–C(15) = 1.399(10) Å) is significantly longer than the uncoordinated one in **1** (1.193(3) Å) indicating the reduction of the C≡C bond to a C=C bond upon coordination to the two molybdenum metal centers. In the ferrocene unit, the Fe-centroid distances are essentially equal (Fe–Ct(1) = 1.674, Fe–Ct(2) = 1.675 Å)(Ct(1) = centroid of C16–C20; Ct(2) = centroid of C21–C25), and the Ct(1)–Fe(1)–Ct(2) angle is almost linear (177.6(7)°). The average Fe–C separations for both rings are identical at 2.08 Å and slightly longer than those found in **1** (average 2.04 Å).

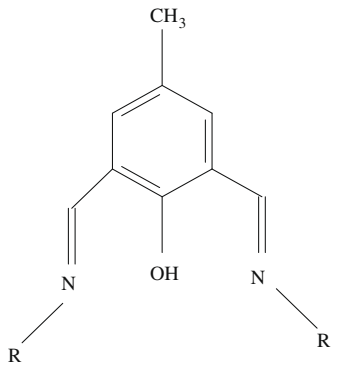
Comparing the molecular structures of **1** and **3** it was observed that the coordination of dimolybdenum moiety to the alkyne unit changes the orientation of the carbonyl groups coordinated to the chromium metal center [from 38.6° (staggered) in **1** to 12.2° (eclipsed) in **3**] as well as the torsion angle of the Cp rings bounded to the iron metal center [from 13.9° in **1** to 4.7° in **3**]. Furthermore, the Cr–C_{ipso} and Fe–C_{ipso} bond lengths in **3** (Cr(1)–C(8) = 2.336(7) Å; Fe(1)–C(16) (2.132(7) Å) are longer than those ones found in **1** (Cr–C(31) = 2.246(2) Å; [**1**, Fe–C(21) = 2.052(2) Å). These results are consistent with the ability of "$Mo_2Cp_2(CO)_4$" moiety to withdraw some electronic density from the arene and Cp rings.

It is interesting to note that the *cisoid* conformation presented in **1** (torsion angle defined by Cr–C(31)–C(21)–Fe of 6.4°) no longer exist after the coordination of the alkyne ligand to the Mo_2 unit. In **3**, the torsion angle of 94.8° (defined by Cr(1)–C(8)–C(16)–Fe(1)) indicates that **1** has twisted in order to form the alkyne–dimolybdenum cluster, maybe by rotation about the C(2)–C(31) bond and/or rotation about the C(1)–C(21) bond.

4. Conclusion

We have shown that two novel heterotetrametallic complexes (**2 and 3**) are readily synthesized by reacting **1** with the respective binuclear compounds [$Co_2(CO)_8$] and [$Mo_2Cp_2(CO)_4$]. Structural data from **1** reveal that the two structural sub-units $Cr(CO)_3$((η^6-C_6H_5–) and (–C≡C–C_5H_4)Fe(C_5H_5) adopts a *cisoid* conformation. The X-ray structural analysis of **3** shows that the conformation of the tricarbonyl tripod with respect to the aromatic ring as well as the disposition of the Cp rings bounded to the iron metal centre changes significantly after the coordination of the Mo_2 unit to the alkyne ligand.

Acknowledgments



We gratefully acknowledge financial support from the CNPq and Pronex/FAPERGS (Brazil). Elton L.S. Gomes thanks CNPq for PhD fellowship. The X-ray structural analysis of **1** was performed by Dr. Robert Burrow (Universidade de Santa Maria, RS, Brazil). The X-ray structural analysis of **3** was performed by Dr. V.G. Young, Jr (University of Minnesota, USA).

HL[1], R = cyclohexylmethyl
HL[2], R = 1-naphthylylmethyl

Scheme 1.

studied on a Perkin–Elmer LS 55 Luminescence spectrometer. Fluorescence life times were determined from time-resolved intensity decay by the method of time-correlated single-photon counting using a picosecond diode laser at 403 nm as the light source.

2.2. Synthesis of 4-methyl-2,6-bis(cyclohexylmethyliminomethyl)-phenol (*HL*[1])

The Schiff-base ligand **HL**[1] has been prepared by following the published procedure with a slight modification [16]. To a solution of 4-methyl-2,6-diformylphenol (0.821 g, 5 mmol) in 20 mL of acetonitrile was added cyclohexanemethylamine (1.132 g, 10 mmol) in 5 mL acetonitrile. The reaction mixture was refluxed for 4 h. The mixture was filtered, concentrated on rotary evaporator to dryness. The solid compound was obtained after keeping it at 4 °C overnight. It was recrystallized from toluene (yield = 95%). Data for **HL**[1]: *Anal*. Calc. for $C_{23}H_{34}N_2O$: C, 77.92; H, 9.67; N, 7.90. Found: C, 77.88; H, 9.56; N, 7.96%; FT-IR (KBr phase) (cm^{-1}): 2920 vs, 2849 s, 1637 vs, 1599 s, 1465 s, 1448 s, 1309 m, 1037 w, 889 w, 844 w (w, weak; m, medium; s, strong; vs, very strong). ^1H NMR (300 MHz, $CDCl_3$; δ): 0.94–1.05 (t, 4H), 1.14–1.32 (m, 8H), 1.65–2.0 (m, 10H), 2.29 (s, 3H), 3.47 (t, 4H), 7.41 (s, 2H), 8.48 (s, 2H); HRMS [$(M+H^+)/z$ (%)]: simulated for $C_{23}H_{34}N_2O$; 355.53; found 355.53.

2.3. Synthesis of 4-methyl-2,6-bis(1-naphthalylmethyliminomethyl)-phenol (*HL*[2])

HL[2] was synthesized according to a similar process as that followed for **HL**[1]. In this case 1-naphthalenemethylamine was used instead of cyclohexanemethylamine (yield = 92%). Data for **HL**[2]: *Anal*. Calc. for $C_{31}H_{26}N_2O$: C, 84.13; H, 5.92; N, 6.33. Found: C, 84.06; H, 5.87; N, 6.30%; FT-IR (KBr phase) (cm^{-1}): 2914 w, 2864 w, 1635 vs, 1596 vs, 1460 s, 1436 m, 1392 m, 1307 m, 1256 s, 1027 w, 875 w, 795 vs, 777 vs, 731 w, 663 w. ^1H NMR (300 MHz, $CDCl_3$; δ): 2.26 (s, 3H), 5.27 (s, 4H), 7.42–7.58 (m, 12H), 7.79–7.93 (m, 4H), 8.12 (d, 2H); HRMS [$(M+H^+)/z$ (%)]: simulated for $C_{31}H_{26}N_2O$; 443.56; found 443.56.

2.4. Synthesis of $[Zn_6(L^1)_2(OH)_2(CH_3COO)_8] \cdot CH_3CN$ (**1** · CH_3CN)

Zinc(II) acetate dihydrate (0.198 g, 0.9 mmol) in 10 mL acetonitrile was added slowly to a magnetically stirred 10 mL acetonitrile solution of the ligand (**HL**[1]) (0.106 g, 0.3 mmol). The mixture was stirred in air for 45 min and then refluxed for 1 h. It was filtered and kept in air at ambient temperature. Crystals of **1** suitable for a structure determination by X-ray crystallography were obtained by slow evaporation of the filtrate within few days (yield: 70%). *Anal*. Calc. for $C_{64}H_{95}N_5O_{20}Zn_6$: C, 45.55; H, 5.67; N, 4.15. Found: C, 45.49; H, 5.63; N, 4.19%. FT-IR (KBr phase) (cm^{-1}): 2925 s, 2851 s, 1626 s, 1593 vs, 1556 s, 1446 s, 1423 vs, 1342 m, 1043 w, 823 w, 667 m.

2.5. Synthesis of $[Zn_6(L^2)_2(OH)_2(CH_3COO)_8] \cdot 4CH_3CN$ (**2** · $4CH_3CN$)

Complex **2** · $4CH_3CN$ was also prepared similarly as for the previous procedure. To a 10 mL acetonitrile solution of **HL**[2] (0.133 g, 0.3 mmol) was added 10 mL acetonitrile solution of zinc(II) acetate dihydrate (0.198 g, 0.9 mmol). The mixture was stirred for 45 min and refluxed for 1.5 h. It was cooled, filtered and the filtrate was kept at room temperature. Yellow colored single crystals of **2** · $4CH_3CN$ were obtained from the filtrate within 2 days (yield: 60%). *Anal*. Calc. for $C_{78}H_{76}N_4O_{20}Zn_6$: C, 52.58; H, 4.30; N, 3.14. Found: C, 52.49; H, 4.26; N, 3.19%. FT-IR (KBr phase) (cm^{-1}): 3049 w, 2925 w, 1595 vs, 1578 s, 1414 s, 1342 m, 1232 w, 1020 w, 794 m, 777 m, 669 m.

2.6. X-ray data collection and structure determination

The crystal data of both complexes are summarized in Table 1. The structures of the complexes were determined by the single crystal X-ray diffraction method. The diffraction experiments were carried out on a Bruker SMART CCD area-detector diffractometer at 295 K for **1** · CH_3CN and at 150 K for **2** · $4CH_3CN$. No crystal decay was observed, so that no time-decay correction was needed. The collected frames were processed with the software SAINT [17], and an empirical absorption correction was applied (SADABS) [18] to the collected reflections. The calculations were performed using the Personal Structure Determination Package [19] and the physical constants tabulated therein [20]. The structure was solved by direct methods (SHELXS) [21] and refined by full-matrix least-squares using all reflections and minimising the function $\sum w(F_o^2 - F_c^2)^2$ (refinement on F^2). All the non-hydrogen atoms were refined with anisotropic thermal factors. The hydrogen atoms of the acetato ligands were detected in the final Fourier maps and were not refined. All the other hydrogen atoms were placed in their

3. Results and discussion

The crystals of the complexes **1** · CH_3CN and **2** · $4CH_3CN$ are highly unstable. They contain solvent molecules, i.e. acetonitrile, in the crystal. The crystal looses its solvent molecules when they are dry. This is also evident from the elemental analysis, where the results show the absence of any acetonitrile molecule(s).

The electronic spectra of the ligands along with complexes **1** and **2** were recorded in acetonitrile at room temperature. Both of the ligands exhibit similar behavior. They show bands at around 320 and 387 nm. These may be assigned to π–π*/n–π* transitions. The complexes show an intense band at around 390 nm which may be assigned due to π–π*/n–π* transitions. A relatively weak transition at around 440–445 nm is assigned to a MLCT band [6].

3.1. Description of the structure of $[Zn_6(L^1)_2(OH)_2(CH_3COO)_8] \cdot CH_3CN$ (**1** · CH_3CN)

Complex **1** crystallizes in the triclinic system, space group $P\bar{1}$ from acetonitrile solvent. A perspective view of the complex is shown in Fig. 1. The selected bond distances and bond angles are listed Table 2. The molecule is a hexametallic neutral monomer, lying on a crystallographic inversion center. The asymmetric unit of the complex comprises three Zn^{2+} ions, one binucleating ligand 4-methyl-2,6-bis(cyclohexylmethyliminomethyl)-phenolate ($\mathbf{L^{1-}}$), one μ_3-hydroxo anion (bonded to the three metal atoms) and four acetato anions. The Zn1 atom is linked by a μ_2-phenoxo oxygen atom (O2) and the N1 atom of the ligand $\mathbf{HL^1}$, a μ_3-hydroxo oxygen atom (O1) and two μ_2-acetato oxygen atoms (O3, O5). It has an almost perfect square pyramidal geometry, as is evident from the τ value of Zn1 which is found to be 0.04. The value of τ is defined as the difference between the two largest donor–metal–donor angles divided by 60, a value which is 0 for an ideal square pyramid geometry and 1 for a trigonal bipyramidal geometry [22]. The Zn1 atom is displaced out the best plane formed by O2, O1, O5 and N1 by 0.226 Å. The O2, O1, O5 and N1 atoms are coplanar to within 0.018 Å. On the other hand, the Zn2 atom is coordinated to a μ_2-phenoxo oxygen atom (O2) and the N2 atom of the ligand $\mathbf{HL^1}$, a μ_3-hydroxo oxygen atom (O1) and two μ_2-acetato oxygen atoms (O6 and O7). The Zn2 atom has a distorted square pyramidal geometry. This is clear from the value of the trigonal index of Zn2, which is found to be 0.38. The square plane is formed by O2, O1, O7 and N2, and the O6 atom occupies the apical position. These atoms are coplanar to within 0.234 Å, whereas the Zn2 atom is out the square plane by 0.488 Å. The apical Zn–O6 bond distance is slightly shorter than the other bond distances. The Zn3 atom is connected to a μ_3-hydroxo oxygen atom (O1) and three μ_2-acetato oxygen atoms (O3, O8 and O9). It has a distorted tetrahedral geometry. The bond angles vary from 104.1(1)° to 124.9(1)°. The two Zn3 units are bridged by two acetato ions. Thus it may be summarized that out the three Zn atoms, two are five-coordinated (one almost perfect square pyramidal and one distorted trigonal bipyramidal) and the third has a tetrahedral four-coordinated geometry. All the bond distances are in good agreement with previously reported values [8,23].

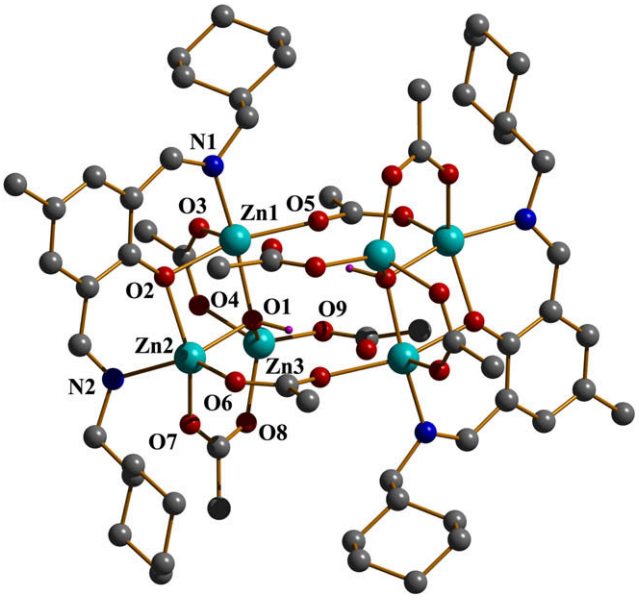

Fig. 1. A perspective view of complex **1** with partial atom numbering scheme and color codes (carbon, grey; oxygen, red; nitrogen, blue; hydrogen, pink; zinc, cyan). All the hydrogen atoms (except the hydrogen atoms of hydroxo ions) and solvent molecule are omitted for clarity. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

3.2. Description of the structure of $[Zn_6(L^2)_2(OH)_2(CH_3COO)_8] \cdot 4CH_3CN$ (**2** · $4CH_3CN$)

The crystals of $[Zn_6(\mathbf{L^2})_2(\mu_2\text{-}OH)_2(\mu_2\text{-}CH_3COO)_8] \cdot 4CH_3CN$ (**2** · $4CH_3CN$) were obtained in the in monoclinic crystal system, *C 12/c*1 space group from acetonitrile. A perspective view of the complex is shown in Fig. 2. Selected bond lengths and bond angles are listed in Table 3. The complex is a hexanuclear monomer lying on a crystallographic twofold axis. The asymmetric unit comprises three Zn^{2+} ions, one binucleating ligand, 4-methyl-2,6-bis(1-naphthalylmethyliminomethyl)-phenolate ($\mathbf{L^{2-}}$), four acetato ligands and one μ_3-hydroxo anion (bonded to the three metal atoms). The Zn1 atom is coordinated to the N1 and O2 atoms of the binucleating ligand, O1 (μ_3-hydroxo oxygen atom) and two oxygen atoms (O3 and O5) of two acetato ions. It is in a distorted octahedral geometry. The *cis* angles around Zn1 range from 79.1(1)° to 98.7(1)°. The Zn1–O3 distance (2.241(1) Å) is quite a lot longer compared to the other Zn1–O or Zn1–N bond distances. The Zn2 atom is linked to one μ_2-phenoxo oxygen atom (O2) and the N2 atom of the ligand $\mathbf{HL^2}$, one μ_3-hydroxo oxygen atom (O1) and two oxygen atoms (O4 and O9) of two acetato ions. Zn2 has a 4 + 1 distorted square pyramidal geometry, whose basal plane is constructed by O1, O2, N2 and O9. O4 occupies the apical position

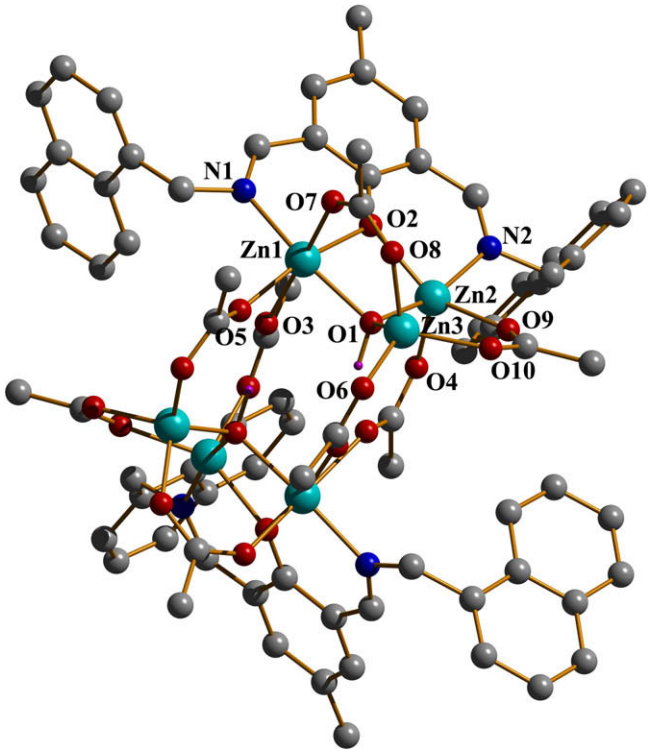

Fig. 2. A perspective view of complex **2** with partial atom numbering scheme and color codes (carbon, grey; oxygen, red; nitrogen, blue; hydrogen, pink; zinc, cyan). All the hydrogen atoms (except the hydrogen atoms of hydroxo ions) and solvent molecules are omitted for clarity. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.).

of the square pyramid. The O1, O2, N2 and O9 atoms are coplanar to within 0.222 Å, whereas the Zn2 atom is out of basal plane by 0.453 Å. The distortion in the square pyramidal geometry is supported by the trigonal index value of Zn2 which is calculated to be 0.35. The Zn2–O4 distance (1.988(1) Å) is the shortest distance among all the Zn2–donor distances. Zn3 is connected to one μ_3-hydroxo oxygen atom (O1) and three oxygen atoms (O6, O8 and O10)

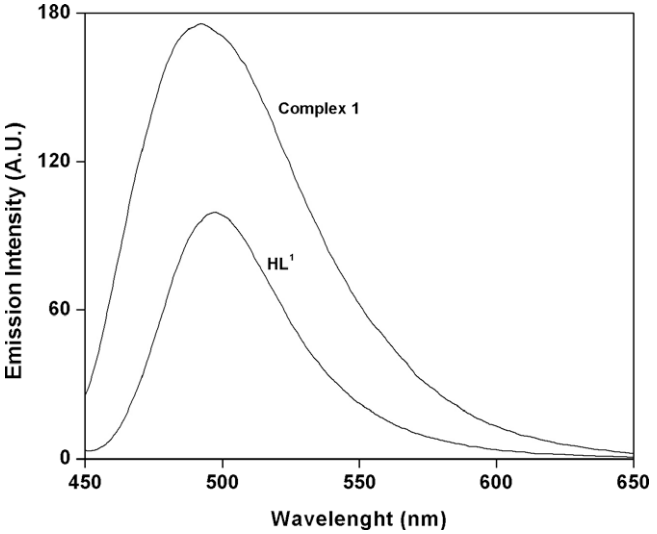

Fig. 3. Emission spectra of equimolar solutions (1×10^{-3} M) of **HL^1** and complex **1** in acetonitrile with an excitation wavelength of 395 nm.

of three different acetato moieties. It is in a distorted tetrahedral geometry. The donor–metal–donor angles range from 100.5(1)° to 120.8(1)°. The Zn3–O bond distances are in the range 1.935(1)–1.960(1) Å. All the metal–donor bond distances are in good agreement with the reported values [8,23]. It may be summarized that of these three independent Zn atoms, one is octahedrally six coordinated, one irregularly five coordinated and one distorted tetrahedrally four coordinated. This is a rare occasion in chemistry when all the three Zn atoms in a complex have different coordination environments [8].

3.3. Fluorescence properties

The fluorescence spectra of the ligands and their zinc(II) complexes are recorded in acetonitrile at room temperature on excitation at 395 nm. The ligands **HL^1** and **HL^2** show emission bands at 497 and 503 nm, respectively. Complexes **1** and **2** exhibit their emission maxima at 492 and 474 nm, respectively. The complexes, having the same molar concentrations as the ligands, display enhanced emission intensities compared to their corresponding ligands when excited with the same amount of energy. Fig. 3 shows the emission of **HL^1** together with its complex as a representative case. The peak of emission band of the complex, as compared to that of the free ligand, is quite unexpected, as one would expect the emission band of the free ligand to be at a higher energy related to that of the complex because of its relatively high energy excitation band. This anomaly can be explained by the fact that excited states resulting from complexes of Zn^{2+} are typically ligand-centered (LC) in nature, owing to the inability of the d^{10} metal center to participate in low-energy charge-transfers for metal-centered transitions [24]. Therefore, the emission from the complex is believed to arise from an excited state centered on the ligand which contains a phenolic proton [8,25]. It is well known that 4-methyl-2,6-diformylphenol undergoes a blue shift of its own band (from 530 to 445 nm) in the presence of a base B (e.g. piperidine or triethylamine), and this observation is believed to support the existence of an equilibrium between the phenol and a proton-transferred species of phenol with the formation of phenoxide and BH^+ ions [26,27]. The same analogy can be applied to the present system because the phenolic proton of the ligand is removed upon complexation with Zn^{2+}, and this proton should be transferred to the anion of the precursor zinc(II) acetate in the solution. We performed an emission experiment on the free ligand in the presence

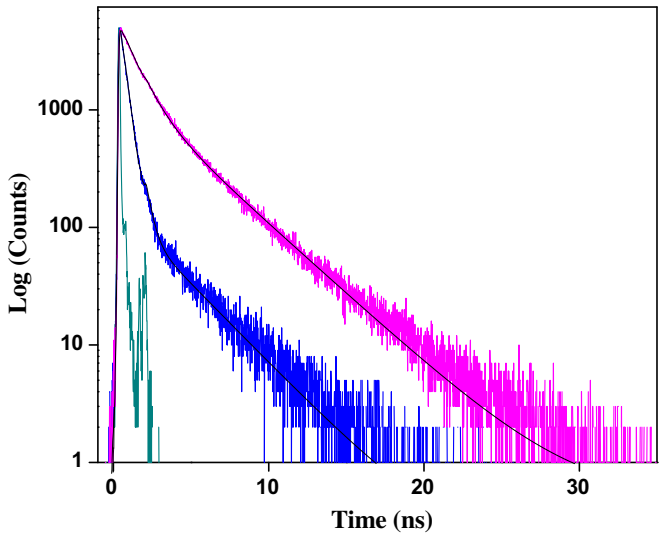

Fig. 4. Time-resolved fluorescence decay of **HL**[1] (blue) and its complex (magenta) in acetonitrile at room temperature (λ_{ex} = 403 nm). The sharp profile on the left (olive) is the lamp profile. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

Table 4
Fluorescence quantum yields[a] and radiative and total non-radiative rate data of the ligands and their complexes with Zn^{2+}.

Compounds	Quantum yield	τ_f (ns)	k_r (10^7 s^{-1})	k_{nr} (10^7 s^{-1})
HL[1]	0.05	1.14	4.4	83.3
Complex **1**	0.12	1.68	71.1	58.5
HL[2]	0.03	0.96	3.1	103.8
Complex **2**	0.15	1.37	10.9	71.9

[a] Standard used is Cumarin 343, Φ = 0.63.

of an added base, e.g. triethylamine, in acetonitrile and found that on addition of triethylamine, a new band appeared at around 445 nm. This indicates the existence of an equilibrium between undissociated **HL**[1] and a proton-transferred species of **HL**[1].

The quantum yields measured for all the ligands and complexes are listed in Table 1. The results clearly reveal that the quantum yields of complexes **1** and **2** are increased by 2.4 and 5 times compared to that of the free ligands.

We have also studied the fluorescence decay behavior of the ligands and their complexes (Fig. 4, Supplementary data, Fig. S1). The fluorescence lifetimes (τ) of the ligands and their corresponding complexes in acetonitrile are given in Table 4. The results of fluorescence lifetime measurements indicate that changes in the lifetime would be associated with any number of possible mechanisms for fluorescence enhancement, not only PET (photo-induced electron transfer). The time-resolved spectrum appears to display at least two components. Since the mechanism of fluorescence enhancement is a change in the rigidity upon binding of the zinc ion, a different mechanism other than PET may be of significance. According to the equation [28] $\tau^{-1} = k_r + k_{nr}$ and $k_r = \Phi_f/\tau$, the radiative rate constant k_r and the total non-radiative rate constant k_{nr} of the ligands and their complexes with Zn^{2+} were calculated and listed in Table 4. The data suggest that k_{nr} is just changed by a small amount, but the factor that induces fluorescent enhancement is mainly ascribed to the increase of k_r. Thus, the enhancement in the emission intensity of the complex compared to free ligand may be assigned to the fact that complexation would impose rigidity to the ligand and hence increase the value of the radiative rate constant.

4. Conclusion

We have prepared two hexanuclear zinc(II) complexes with N_2O donor Schiff-base ligands and the complexes have been characterized by single crystal X-ray analysis along with elemental analysis and spectroscopic methods. Three zinc atoms are present in both the complexes. In complex **1**, two zinc atoms are five-coordinated (one distorted square pyramidal and one distorted trigonal bipyramidal) whereas the third is tetrahedrally four-coordinated. In complex **2**, three zinc atoms are present in three different coordination environments (distorted octahedral, irregularly five coordination and distortedly tetrahedral geometry) leading to a rare situation in chemistry. Both complexes showed greater emission intensity compared to their ligands. They emit at around 470–490 nm on excitation at 395 nm.

Appendix A. Supplementary data

CCDC 703376 and 703377 contains the supplementary crystallographic data for this article. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.01.042.

reduction to dihydrogen. In this work, we prepared and characterized two diiron dithiolate complexes [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_5$L] (L = PPh_3, **2**; P(Pyr)$_3$, **3**) containing a functionalized C_2 bridge with two vicinal basic sites. We found that the reaction of the complex [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_6$] (**1**) with two equivalents of bis(diphenylphosphino)methane (dppm) in refluxing toluene afforded a desulfurized complex [(μ-S)(μ-dppm)$_2Fe_2(CO)_4$] (**6**) via a dppm mono-dentate intermediate [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_5(\kappa^1$-dppm)] (**4**) and a dppm μ-bridging species [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_4$(μ-dppm)] (**5**). The complexes **2** and **3** can be protonated by mild acids CCl_3COOH and CF_3COOH in acetonitrile, resulting in a 610–650 mV anodic shift of the Fe^IFe^I/Fe^IFe^0 reduction potentials. Here, we report the preparation and characterization of **2**–**6**, the molecular structures of **2**, its protonated species [(**2**H$_N$)(OTf)], and **6**, the protophilicity of **2** and **3**, as well as the electrochemical properties of **2** and **3** compared with the analogous diiron azadithiolate complex [{(μ-$SCH_2)_2N(CH_2C_6H_5)$}$Fe_2(CO)_5$P(Pyr)$_3$] (**7**).

2. Experimental

2.1. General procedures and materials

All reactions and operations related to organometallic complexes were carried out under dry, oxygen-free dinitrogen with standard Schlenk techniques. Solvents were dried and distilled prior to use according to the standard methods. Commercially available chemicals, $Me_3NO\cdot 2H_2O$, HOTf, CCl_3COOH, CF_3COOH, PPh_3, and dppm, were of reagent grade and used as received. Ligand P(Pyr)$_3$, diiron carbonyl complexes [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_6$] (**1**) and [{(μ-$SCH_2)_2N(CH_2C_6H_5)$}$Fe_2(CO)_5$P(Pyr)$_3$] (**7**) were prepared following the literature methods [20–22].

Infrared spectra were recorded on JASCO FT/IR 430 spectrophotometer. Proton and ^{31}P NMR spectra were collected with a Varian INOVA 400 NMR Instrument. Mass spectra were recorded on an HP1100 MSD mass spectrometer. Elemental analyses were performed with a Thermoquest-Flash EA 1112 elemental analyzer.

2.2. Synthesis of [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_5$L] (L = PPh_3, **2**; P(Pyr)$_3$, **3**)

CO-Removing reagent $Me_3NO\cdot 2H_2O$ (0.11 g, 1.0 mmol) was added to a solution of **1** (0.58 g, 1.0 mmol) in MeCN (20 ml). The red solution was stirred for 5 min and the color turned dark red. Triphenylphosphine (0.27 g, 1.0 mmol) was added to the solution, and it was stirred for 30 min. The solvent was removed under reduced pressure. The residue was purified by chromatography on a silica gel column with hexane/CH_2Cl_2 (2:1, v/v) as eluent. The complex **2** was obtained as red powder from the collected red band after removal of solvent. Yield: 0.70 g (86%). *Anal.* Calc. for $C_{39}H_{31}Fe_2N_2O_5PS_2$: C, 53.99; H, 3.71; N, 3.15. Found. C, 53.78; H, 3.78; N, 3.07%. IR (KBr): ν(CO) 2048 (s), 1988 (s), 1938 (m) cm^{-1}. ^{1}H NMR ($CDCl_3$): δ 7.00–7.52 (25H, 5Ph), 4.54, 4.39 (2d, J_{H-H} = 15.8 Hz, 2H, C=NCH_2), 3.87, 3.59 (2d, J_{H-H} = 13.8 Hz, 2H, NHCH_2) 3.11 (s, 1 H, SC*H*), 2.10 (s, 1 H, N*H*) ppm. ^{31}P NMR ($CDCl_3$): δ 60.24 ppm.

The complex **3** was prepared according to the above-described protocol. Yield: 0.50 g (80%). IR (KBr): ν(CO) 2059 (s), 2007 (s), 1991 (s) cm^{-1}. ^{1}H NMR ($CDCl_3$): δ 7.13–7.27 (10H, 2Ph), 6.63, 6.21 (2s, 12H, 3Pyr), 4.79, 4.73 (2d, J_{H-H} = 14.4 Hz, J_{H-H} = 27.2 Hz, 2H, C=NCH_2), 3.94, 3.70 (2d, J_{H-H} = 8.8 Hz, 2H, NHCH_2), 3.28 (s, 1H, SC*H*), 2.21 (s, 1H, N*H*) ppm. ^{31}P NMR ($CDCl_3$): δ 140.01 ppm.

2.3. Synthesis of [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_5PPh_3$](OTf)

HOTf (1.5 equivalents) was added to a solution of **2** (0.81 g, 1.0 mmol) in diethyl ether (50 ml). The red solution was stirred for 5 min and stood for 3 h. Protonated species [(**2**H$_N$)(OTf)] was precipitated as red powder from the solvent and washed three times with cold diethyl ether. Yield: 0.83 g (87%). *Anal.* Calc. for $C_{40}H_{32}F_3Fe_2N_2O_8PS_3$: C, 49.81; H, 3.34; N, 2.90. Found: C, 49.43; H, 3.42; N, 2.65%. IR (KBr): ν(CO) 2061 (s), 2009 (s), 1948 (s) cm^{-1}. ^{1}H NMR ($CDCl_3$): δ 7.09–7.43 (25H, 5Ph), 4.77, 4.58 (2d, J_{H-H} = 13.2 Hz, 2H, C=NCH_2), 4.40–4.80 (br, 2H, NH_2), 4.10, 3.87 (2d, J_{H-H} = 12.8 Hz, 2H, NHCH_2), 3.59 (s, 1H, SC*H*) ppm. ^{31}P NMR ($CDCl_3$): δ 59.10 ppm.

2.4. Synthesis of [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_5$(dppm)] (**4**)

Ligand dppm (0.39 g, 1.0 mmol) was added to a solution of **1** (0.58 g, 1.0 mmol) in toluene (20 ml). The mixture was refluxed for 0.5 h. The resulting solution was evaporated to dryness under reduced pressure, and the residue was chromatographed on an alumina column with hexane/CH_2Cl_2 (2:1, v/v) as eluent. The complex **4** was obtained as red powder from the collected red band after removal of solvent. Yield: 0.66 g (69%). IR (KBr): ν(CO) 2045 (s), 1986 (vs), 1934 (m) cm^{-1}. ^{1}H NMR ($CDCl_3$): δ 7.10–7.35 (30H, 6Ph), 4.52, 4.20 (2d, J_{H-H} = 15.8 Hz, 2H, C=NCH_2), 3.92, 3.61 (2d, J_{H-H} = 13.2 Hz, 2H, NHCH_2), 3.40 (s, 1H, SC*H*), 3.18 (d, J_{H-H} = 8.0 Hz, 2H, PCH_2P), 2.17 (s, 1H, N*H*) ppm. ^{31}P NMR ($CDCl_3$): δ 53.18 (d, J_{P-P} = 91.5 Hz, coordinated dppm), −26.31 (d, J_{P-P} = 91.5 Hz, non-coordinated dppm) ppm. ESI-MS: *m/z* 937.1 [M+H]$^+$.

2.5. Synthesis of [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_4$(μ-dppm)] (**5**)

The toluene solution (20 ml) of **1** (0.58 g, 1.0 mmol) and dppm (0.39 g, 1.0 mmol) was refluxed for 1.5 h. Complex **5** was obtained by chromatography of the residue on an alumina column with hexane/CH_2Cl_2 (1:1, v/v) as eluent. Yield: 0.60 g (66%). IR (KBr): νCO 1995 (s), 1964 (vs), 1931 (s) cm^{-1}. ^{1}H NMR ($CDCl_3$): δ 7.11–7.55 (30H, 6Ph), 4.92, 4.73 (2br, 2H, C=NCH_2), 4.35, 4.01 (2br, 2H, NHCH_2), 4.10 (s, 2H, PCH_2P), 3.46 (s, 1H, SC*H*), 2.20 (br, 1H, N*H*) ppm. ^{31}P NMR ($CDCl_3$): δ 57.23 (d, J_{P-P} = 59.9), 56.31 (br), 56.03 (br), 54.30 (d, J_{P-P} = 53.4) ppm. ESI-MS: *m/z* 909.1 [M+H]$^+$.

2.6. Synthesis of [(μ-S)(μ-dppm)$_2Fe_2(CO)_4$] (**6**)

Ligand dppm (0.78 g, 2.0 mmol) was added to a solution of **1** (0.58 g, 1.0 mmol) in toluene (20 ml). The solution was refluxed for 6 h. The complex **6** was precipitated as red powder from the solution and washed three times with acetone. Yield: 0.72 g (70%). *Anal.* Calc. for $C_{54}H_{44}Fe_2O_4P_4S$: C, 63.30; H, 4.33. Found: C, 63.27; N, 4.35%. IR (KBr): νCO 1967 (m), 1925 (s), 1898 (m), 1875 (w) cm^{-1}. ^{31}P NMR (CH_2Cl_2): δ 44.20 ppm.

2.7. X-ray crystal structure determination

Single crystals of **2**, [(**2**H$_N$)(OTf)], and **6** were obtained by recrystallization from dichloromethane/hexane. All of the single crystal X-ray diffraction data were collected on a Bruker Smart Apex II CCD diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 298 K using the $\omega-2\theta$ scan mode. Data processing was accomplished with the SAINT program. Intensity data were corrected for absorption by the SADABS program. The structures were solved by direct methods and refined on F^2 against full-matrix least-squares methods by using the SHELX-97 program package. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed by geometrical calculation and refined in a riding model, and the proton on the N atom of [(**2**H$_N$)(OTf)] was

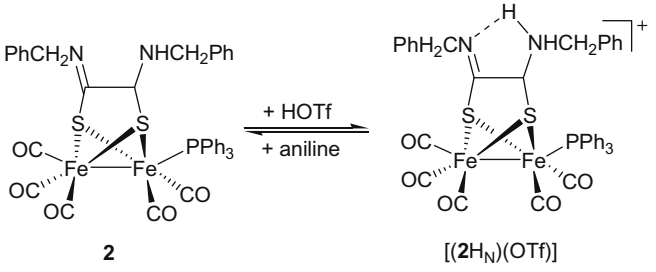
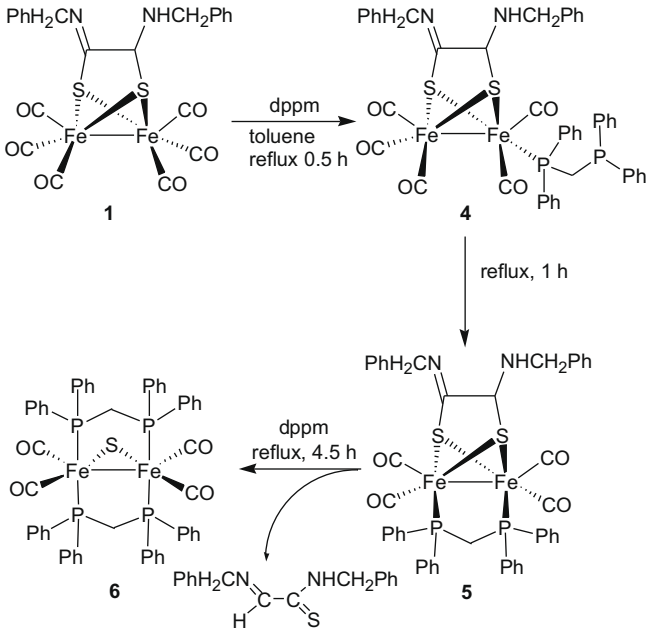
located by the difference Fourier map. Crystal data and parameters for data collections and refinements of complexes **2**, [(**2**H_N)(OTf)], and **6** are listed in Table 1. The quality of the single crystal of the complex **6** containing solvent was not good, resulting in the large R_{int} value (0.1613).



2.8. Electrochemistry

Acetonitrile (Aldrich, spectroscopy grade) used for electrochemical measurements was dried with molecular sieves and then freshly distilled from CaH_2 under N_2. A solution of 0.05 M n[NBu_4][PF_6] (Fluka, electrochemical grade) in CH_3CN was used as electrolyte, which was degassed by bubbling with dry argon for 10 min before measurement. Electrochemical measurements were recorded using a BAS-100W electrochemical potentiostat at a scan rate of 100 mV/s. Cyclic voltammograms were obtained in a three-electrode cell under argon. The working electrode was a glassy carbon disc (diameter 3 mm) successively polished with 3 and 1 μm diamond pastes and sonicated in ion-free water for 10 min. The reference electrode was a non-aqueous Ag/Ag^+ electrode (0.01 M $AgNO_3$ in CH_3CN) and the auxiliary electrode was a platinum wire. All potentials are reported relative to the Fc^+/Fc potential.



3. Results and discussion

3.1. Preparation and spectroscopic characterization of the complexes **2**, **3**, and [(**2**H_N)(OTf)]

The parent complex [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_6$] (**1**) was prepared according to the literature method [20], which is an oil and very sensitive to air and moisture. More stable diiron complexes [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_5PPh_3$] (**2**) and [{μ-SC(NBn)CH(NHBn)S-μ}$Fe_2(CO)_5P(Pyr)_3$] (**3**) were obtained by treating **1** with a phosphine ligand in the presence of the CO-removing reagent $Me_3NO \cdot 2H_2O$ in CH_3CN. The complexes **2** and **3** are stable in the solid state and in the solution. They were characterized by IR, ^1H and ^{31}P NMR spectroscopy, and the elementary analysis. The complex **2** displays three ν(CO) bands at 2048, 1988, and 1938 cm^{-1} in the IR spectrum, and the ν(CO) bands of **3** appear at 2059, 2007, and 1991 cm^{-1}. Comparison of the ν(CO) bands of **2** and **3** is clearly indicative of the weaker electron donating capability of the $P(Pyr)_3$ ligand as compared to the PPh_3 ligand. The ^1H

Scheme 1.

Scheme 2.

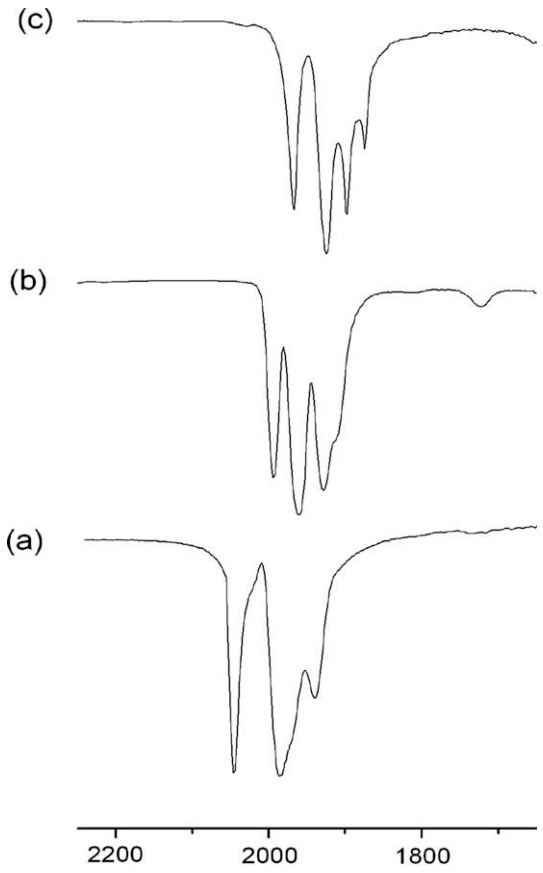


Fig. 1. The IR spectra of complexes **4** (bottom), **5** (middle), and **6** (top).

signals for the two CH_2 groups, the CH, and the NH group in the complex **3** are all move to down-field by 0.11–0.17 ppm compared to the corresponding signals of **2**. The complexes **2** and **3** display ^{31}P signals at 60.2 and 140.0 ppm, respectively.

Protonation of **2** in diethyl ether with addition of 1.5 equivalents HOTf afforded the N-protonated species [(**2**H_N)(OTf)] as red precipitate in a good yield (87%) after being washed with cold diethyl ether and recrystallization in hexane/CH_2Cl_2. In comparison to the ν(CO) bands of **2**, the ν(CO) bands of [(**2**H_N)(OTf)] is shifted to higher frequencies by ca. 15 cm^{-1} in average, indicating that protonation of the amino-N atom on the C_2 bridge has apparent influence on the electron density of the iron atoms. This shift value of the ν(CO) bands is comparable to those reported for N-protonation of other analogous diiron complexes [8–15]. The proton resonance of the SCH group directly attached to the protonated-N atom is moved down-field by ca. 0.31 ppm in the ^1H NMR spectrum of [(**2**H_N)(OTf)]. The spectroscopic evidence strongly supports the protonation of the N atom in the complex **2**. Upon addition of an equivalents of aniline to the solution of [(**2**H_N)(OTf)], the ^{31}P signal at 58.0 ppm for the N-protonated species completely disappeared, and in the same time the signal at 60.2 ppm for the complex **2** appeared as the only peak in the ^{31}P NMR spectrum, indicating a reversible protonation and deprotonation process between **2** and [(**2**H_N)(OTf)] (Scheme 1).

3.2. CO-displacement of *1* by dppm

The reaction of the complex **1** with an equivalents of bis(diphenylphosphino)methane (dppm) in refluxing toluene for 0.5 h afforded the complex [{μ-SC(NBn)CH(NHBn)S-μ}Fe_2-$(CO)_5$(κ^1-dppm)] (**4**), in which dppm acts as a simple monodentate ligand. When the toluene solution of **4** was further refluxed for 1 h, an intramolecular CO-displacement occurred to form a μ-dppm bridging complex [{μ-SC(NBn)CH(NHBn)S-μ}Fe_2-$(CO)_4$(μ-dppm)] (**5**). The complex with a chelating dppm ligand was not detected during the reaction by ^{31}P NMR monitoring, which is different from the reaction of (μ-pdt)[$Fe_2(CO)_6$] and dppm [23,24]. If another equivalents of dppm was added to the toluene solution of **5**, an unexpected complex [(μ-S)(μ-dppm)$_2Fe_2(CO)_4$] (**6**) was obtained after 4.5 h reflux. The complex **6** was formed by simultaneous CO-displacement and desulfurization of **5** (Scheme 2). Sulfur-containing organic compound $PhCH_2N{=}CHC(S)NHCH_2Ph$ was detected in the reaction solution by HPLC–MS analysis. The first two steps for the reaction of **1** and dppm to form the complexes **4** and **5** are just similar to the reaction of (μ-pdt)[$Fe_2(CO)_6$] and dppm [23,24], while the third step, desulfurization reaction, is special for **1**. The complex (μ-pdt)[$Fe_2(CO)_4$(μ-dppm)], in analogy to **5**, did not react with dppm even in refluxing toluene for 72 h. The results show that the [μ-SC=NBnCH(NHBn)(μ-S)] bridge in **1** is apparently less stable than the pdt bridge. The complexes **4**–**6** were characterized by IR, MS, ^1H and ^{31}P NMR spectroscopy, and the molecular structure of **6** was determined by X-ray diffraction study.

Except for the additional ^1H signals of dppm, the complex **4** displays a similar ^1H NMR spectrum with that of **2**. In addition to the signals at 7.10–7.35 ppm for phenyl groups of dppm and the C_2 bridge, a typical doublet at 3.18 ppm (J = 8.0 Hz) for the CH_2 group of dppm is found in the ^1H NMR spectrum of **4**. Two doublets, at 53.2 ppm for the coordinate phosphorus and −26.3 ppm for the non-coordinate one, appear in the $^{31}P\{1H\}$ NMR spectrum of **4**. As the free phosphorus of dppm in **4** is coordinated to the other iron atom by replacement of a CO ligand, the ^1H signal for the

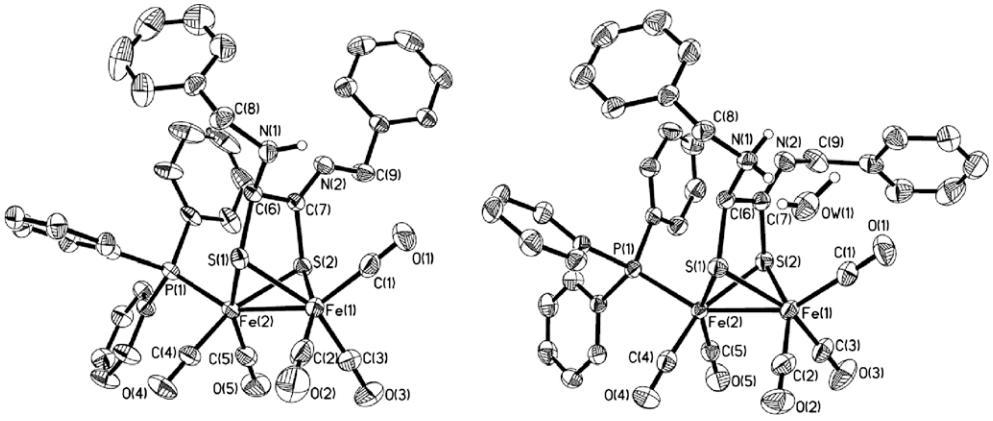

Fig. 2. Molecular structures of **2** (left) and $(2H_N)^+/H_2O$ with the thermal ellipsoids at 30% probability.

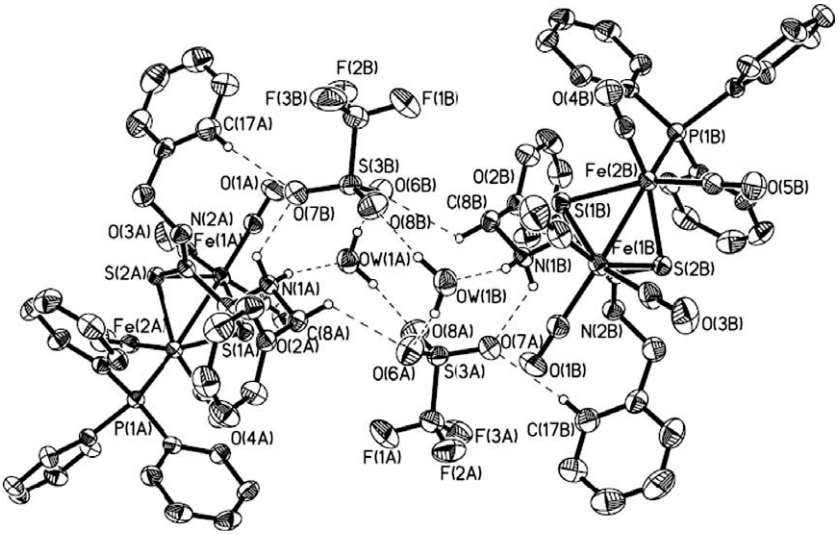

Fig. 3. Diagram of the dimeric structure of [(**2**H_N)(OTf)] encircling two water molecules by hydrogen bonds (ellipsoids at 30% probability).

CH_2 group of dppm ligand is moved from 3.18 to 4.10 ppm. There are two doublets at 57.23 ppm (J_{P-P} = 59.9) and 54.30 ppm (J_{P-P} = 53.4) as well as two broad signals at 56.31 and 56.03 ppm in the ^{31}P spectrum of **5**, indicative of existence of two conformation isomers for the complex **5** in solution in an approximate equal ratio. The isomerization caused by swing of the μ-bridging dppm ligand is similar as that found for (μ-pdt)(μ-PNP)[Fe(CO)PMe_3]-[$Fe(CO)_2$] in our previous studies [25]. Because of the non-symmetric bridge of **5**, the chemical shifts should be different for the two phosphorus centers of the μ-dppm ligand. Therefore four ^{31}P signals are observed, and the two broad signals at 56.31 and 56.03 ppm result from the overlap of two doublets. The complex **6** displays only one ^{31}P signal at 44.2 ppm for four coordinate phosphorus atoms, indicating that **6** has a symmetric molecular structure.

C(6)–C(7)–S(2)	115.3(3)	114.1(2)

The complex **4** displays three ν(CO) bands in the region of 2061–1948 cm^{-1} (Fig. 1), which are shifted by ca. 50 cm^{-1} in average to lower frequency as compared to the ν(CO) bands of the complex **1**. The subsequent intramolecular CO/phosphine replacement results in a further red-shift of the ν(CO) bands to 1995–1931 cm^{-1}. The complex **6** with two μ-bridging dppm ligands exhibits four ν(CO) bands in the region of 1967–1875 cm^{-1}. The IR, MS, ^1H and ^{31}P NMR data give clear evidence for the formation of phosphine mono-, di-, and tetra-substituted complexes **4**, **5**, and **6**, in the different stages of the CO-displacement of **1**.

3.3. Molecular structures of *2*, *[(2H$_N$)(OTf)]*, and *6*

To obtain unambiguous evidence for the N-protonation of **2**, the molecular structures of **2** and its N-protonated species [(**2**H_N)(OTf)] were determined by X-ray analyses of single crystals, which are depicted in Figs. 2 and 3. The selected bond lengths and angles are summarized in Table 2. The central 2Fe2S skeletons of **2** and (**2**H_N)$^+$ are both in the butterfly framework and each Fe atom is coordinated in the pseudo-square-pyramidal geometry similar to previously reported 2Fe2S models [9–14,23,26]. The protonation of **2** occurs at the nitrogen atom [N(1)] of the secondary amine. The N···N distance (2.704 Å) is proper for intramolecular N–H···N interaction, which can considerably promote the stability of the N-protonated species. After protonation, both the bond lengths of N(1)–C(6) and N(1)–C(8) are elongated by 0.037 and 0.034 Å, respectively, while the bond length of N(2)–C(7) is shortened by 0.01 Å.

Fig. 3 shows that two molecules of water are caged by two [(**2**H_N)(OTf)] molecules through hydrogen bonds. In the solid state of [(**2**H_N)(OTf)], each asymmetric unit contains a molecule of [(**2**H_N)(OTf)] and a molecule of water. The molecule of water is close to the iron atom of the [$Fe(CO)_3$] unit with the Fe(1)···O(H_2O) distance of 4.199 Å. It is proposed that H_2O is coordinated to the distal iron atom in the H_{ox} state of the natural H-cluster [2,24]. The bond lengths and angles related to hydrogen bonds are given in Table S1 (see Supplementary data).

The molecular structure of **6** was also determined by single crystal X-ray analyses, which is shown in Fig. 4, and selected bond lengths and angles are given in Table 3. The central iron atoms of **6** are coordinated in the trigon-bipyramidal geometry, consistent with the structure of [(μ-CO)(μ-dppm)$_2$$Fe_2(CO)_4$] [27]. Each iron atom is coordinated with two terminal carbonyls, which are

[a] $[NBu_4][PF_6]$ (0.05 M) in CH_3CN under Ar; scan rate 0.1 V s^{-1}.

essentially co-planar with the bridging-sulfur atom. This plane is perpendicular to the plane defined by the four phosphorus atoms and the two iron atoms. The Fe(1)–Fe(2) bond length of 2.8383(16) Å in **6** is notably longer than that (2.742 Å) in [(μ-CO)(μ-dppm)$_2$Fe$_2$(CO)$_4$], resulting from the replacement of the μ-CO bridge by μ-S bridge [28].

3.4. Cyclic voltammograms of the complexes *2*, *3*, and *7*

To compare the electrochemical property and the protophilicity of **2** and **3** with the azadithiolate-bridging complex, [{(μ-$SCH_2)_2N(CH_2C_6H_5)$}Fe$_2$(CO)$_5$P(Pyr)$_3$] (**7**) was prepared. The cyclic voltammograms (CVs) of **2**, **3**, and **7** were studied in CH_3CN using 0.05 M $[NBu_4][PF_6]$ as electrolyte. The redox potentials versus Fc^+/Fc are summarized in Table 4. The first reduction peaks of **2** and **3** appear at −1.66 and −1.51 V, respectively, using ferrocene as an internal standard. The approximately equal current height in the CVs of complexes **2** and **3** and ferrocene with an identical molar concentration suggests that the primary reduction of complexes **2** and **3** is a one-electron process (Fe^IFe^I/Fe^IFe^0). The reduction potential of **3** is 110 mV more positive than that (−1.62 V) found for the analogous diiron azadithiolate complex **7**. The oxidation peaks, at +0.60 and +0.83 V for **2** and **3**, respectively, and +0.59 V for **7**, are attributed to the Fe^IFe^I to $Fe^{II}Fe^I$ process [29,30].

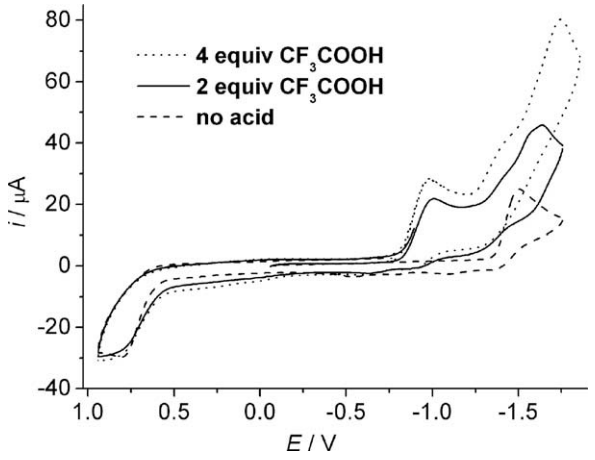

Fig. 5. Cyclic voltammograms of **3** (1.0 mM) in the presence of CF_3COOH in CH_3CN.

Upon addition of one equivalents of HOTf to the CH_3CN solution of **3**, a new peak is observed at −0.90 V in the CV, attributed to the reduction of the protonated species [(**3**H_N)(OTf)] (*Fig.* S1, Supplementary data). Essentially identical CVs were obtained for protonation of **2** with a new peak at −1.01 V. In comparison, the reduction peak of [(**7**H_N)(OTf)] appears at −1.11 V (*Fig.* S1). Protonation of **2** and **3** leads to the 610–650 mV anodic shifts of the reduction peaks, while after protonation, the reduction peak of **7** is shifted by 450 mV. It shows that protonation of the internal base of **2** and **3** exhibits a larger influence on the reduction potential of the iron atoms compared to that displayed by the protonation of the azadithiolato bridge of **7**. It is noteworthy that the complexes **2** and **3** can be protonated by mild acids CCl_3COOH and CF_3COOH (Fig. 5). In contrast, no new peak is detected in the CV when CF_3COOH is added to the solution of **7** (*Fig.* S2). The protonation of **2** and **3** is further verified by in situ ^{31}P NMR spectroscopy with stepwise addition of CCl_3COOH to the $CDCl_3$ solution of **2** or **3** (*Fig.* S3). The results indicate that the complexes **2** and **3** are more protophilic than the diiron azadithiolate the complex **7**. In fact, in organic solvents the internal bases of the FeFe-Hase mimics reported so far can be protonated only in the presence of strong acids, such as $HClO_4$ [11,13], HBF_4 [12,16,19], and HOTf [10,14,18].

4. Conclusion

The ^{31}P NMR spectra and CVs show that the complexes **2** and **3** with a C_2 bridge containing two basic sites are more protophilic than other internal bases in the FeFe-Hase mimics reported so far. The omplexes **2** and **3** can be protonated by CCl_3COOH and CF_3COOH in organic solvent. Protonation and deprotonation

processes between **2** and [(**2**H_N)(OTf)], as well as **3** and [(**3**H_N)(OTf)], are instant and reversible. The protonated species [(**2**H_N)(OTf)] is relatively stable because of the proper distance for intramolecular N–H···N interaction, which is structurally characterized. It is noteworthy that each asymmetric unit of [(**2**H_N)(OTf)] containing a molecule of water close to the iron atom of the [Fe(CO)$_3$] subunit (Fe(1)···O(H_2O) 4.199 Å), which reminds us of H_2O coordinating to the distal iron atom in the H_{ox} state of the natural H-cluster. The reduction potential of the complex **3** is 110 mV more positive than that of the analogous azadithiolate complex **7**, and protonation of the internal base of **2** and **3** exhibits a larger influence on the reduction potential of the iron atoms than that displayed by the protonation of the azadithiolato bridge of **7**. In addition, a desulfurization reaction is found in the reaction of the complex **1** and two equivalents of dppm ligand to afford the complex **6** in refluxing toluene. The reaction undergoes by three steps via a dppm mono-dentate intermediate **4** and a dppm μ-bridging species **5**.

2. Experimental

2.1. General

Standard techniques for handling of air- and moisture-sensitive materials were used [1,3]. $HBBr_2 \cdot SMe_2$ and $H_2BBr \cdot SMe_2$ (1 M solutions in CH_2Cl_2), as well as $HBCl_2 \cdot SMe_2$ (in excess Me_2S) were purchased from Sigma–Aldrich, and were used as supplied. 4-Octene (Sigma–Aldrich) was dried with 3 Å molecular sieves prior to use. 1-Octene (Sasol Ltd.) and CH_2Cl_2 (Merck), used as solvent for preparation of solutions, were dried as mentioned elsewhere [1,3].

2.2. Kinetic measurements

^{11}B NMR spectra were recorded on Varian Unity Inova 500 spectrometer, using 5 mm quartz tubes, at 160 MHz and referenced externally against $BF_3 \cdot OEt_2$. The kinetic reactions were monitored as previously reported, as was the product characterization [1,3].

All kinetic runs were carried out under pseudo-first-order conditions with respect to the haloboranes. The concentration of $HBBr_2 \cdot SMe_2$ was kept constant at 0.025 M, whilst that of $HBCl_2 \cdot SMe_2$ and $H_2BBr \cdot SMe_2$ was fixed at 0.05 and 0.0125 M, respectively. All haloborane solutions were prepared by diluting known concentrations from the stock solution with freshly distilled CH_2Cl_2, the same solvent that was used to prepare the nucleophile solutions. The nucleophile employed in concentration-dependence studies ranged from 10 to 50 times that of the haloborane concentration. In the case of $H_2BBr \cdot SMe_2$ complex, concentrations of the nucleophile were doubled due to the presence of two hydroboration sites on the boron complex.

The observed pseudo-first-order rate constants, k_{obs}, were obtained by fitting a first-order exponential decay equation, through the data points using Origin 5.0 statistical software. Activation parameters, $\Delta H^{\neq}$ and $\Delta S^{\neq}$, were determined from temperature dependence studies over the temperature range of 15–30 °C, at 5 °C intervals. A wider temperature range could not be investigated because of the constraint imposed by the boiling point (40 °C) of the solvent, CH_2Cl_2.

3. Results and discussion

On hydroboration with $HBBr_2 \cdot SMe_2$ and $HBCl_2 \cdot SMe_2$ the disappearance of the ^{11}B NMR doublet peaks ($\delta^{11}B = -7$ ppm at 25 °C, $J_{B\text{-}H} = 162$ Hz and $\delta^{11}B = 2$ ppm at 25 °C, $J_{B\text{-}H} = 158$ Hz) and the emergence of singlet peaks ($\delta^{11}B = 6.3$ ppm and $\delta^{11}B = 14.8$ ppm), respectively, correspond to a reaction that can be described by Eq. (1). The doublet represents the $HBX_2 \cdot SMe_2$, whilst the singlet represents BX_2-octyl·SMe_2.

$$HBX_2 \cdot SMe_2 + \underset{X_2=Br_2 \text{ or } Cl_2}{4\text{-octene}} \rightarrow BX_2\text{-octyl} \cdot SMe_2 \quad (1)$$

In the case of $H_2BBr \cdot SMe_2$, the conversion of the ^{11}B NMR triplet peak ($\delta^{11}B = -10.5$ ppm, at 25 °C, $J_{B\text{-}H} = 134$ Hz) into a singlet peak at $\delta^{11}B = 33.5$ ppm is an indication that the reaction monitored can be described by Eq. (2). The triplet peak represents the $H_2BBr \cdot SMe_2$, whilst the singlet peak represents BBr-$(octyl)_2 \cdot SMe_2$.

$$H_2BBr \cdot SMe_2 + 2\ 4\text{-octene} \rightarrow BBr\text{-}(octyl)_2 \cdot SMe_2 \quad (2)$$

Representative ^{11}B NMR arrays are similar to those reported previously [1,3]. In all the three cases, the products of hydroboration were confirmed by quenching the reactions using H_2O_2/NaOH mixture to form the alcohol, which was characterised using GC, as before [1].

Integration of ^{11}B NMR spectral arrays allowed for the determination of pseudo-first-order rate constants, k_{obs}. First-order exponential decay curves were fitted over the data points to generate the k_{obs}. A representative plot of concentration against time is shown in Fig. 1.

The k_{obs} values, obtained were plotted against the concentration of the entering nucleophile, [Nu], *i.e.* 4-octene. Linear dependence on [Nu] with insignificant *y*-intercepts was observed for both $HBBr_2 \cdot SMe_2$ and $HBCl_2 \cdot SMe_2$. In the case of $H_2BBr \cdot SMe_2$, significant *y*-intercepts were observed, indicative of the presence of a back or parallel reaction. Representative plots are shown in Figs. 2 and 3, for the dihaloboranes and the monohaloborane, respectively. These graphs demonstrate that the reactions are first-order with respect to incoming nucleophile.

For $HBBr_2 \cdot SMe_2$ and $HBCl_2 \cdot SMe_2$, the overall process can be described by the rate law given in Eq. (3):

$$K_{obs} = k_2'[Nu] \quad (3)$$

In the case of $H_2BBr \cdot SMe_2$, the overall process is described by Eq. (4):

$$K_{obs} = k_2'[Nu] + k_{-2} \quad (4)$$

To account for the observed results, a mechanism (Eq. (5)) similar to that already reported [1], is applicable in these investigations. The hydroboration involving the $H_2BBr \cdot SMe_2$ goes through the same

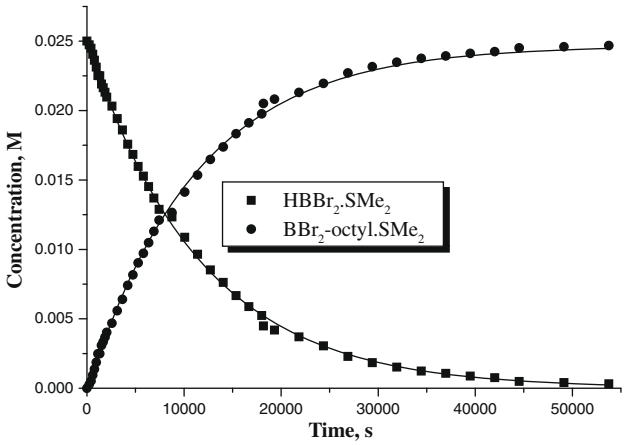

Fig. 1. Exponential decay curve for hydroboration of 4-octene with $HBBr_2 \cdot SMe_2$ in CH_2Cl_2 at 25 °C.

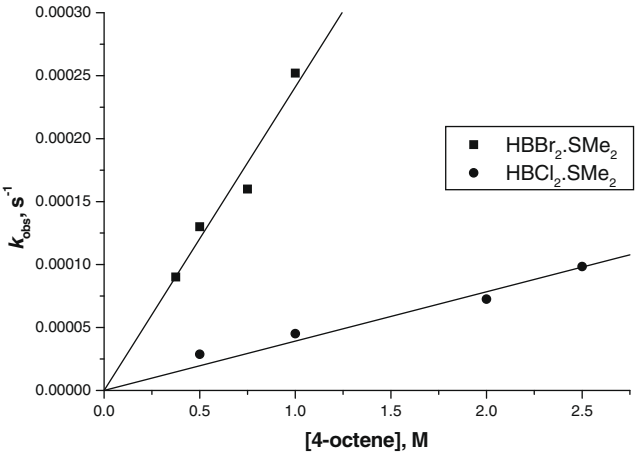

Fig. 2. Dependence of k_{obs} on [4-octene] in the hydroboration reactions of 4-octene with $HBBr_2 \cdot SMe_2$ and $HBBr_2 \cdot SMe_2$ in CH_2Cl_2 at 25 °C.

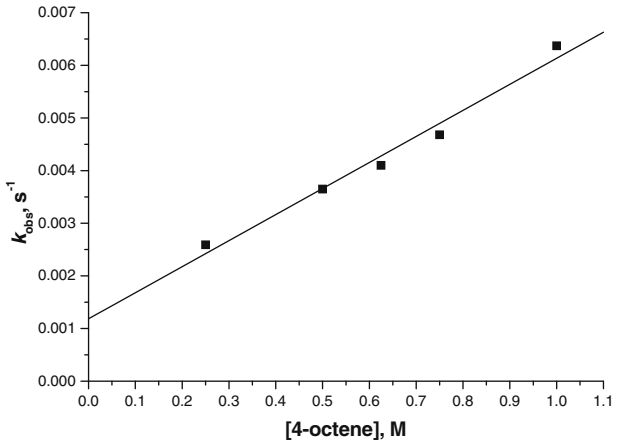

Fig. 3. Dependence of k_{obs} on [4-octene] in the hydroboration reaction of 4-octene with $H_2BBr \cdot SMe_2$ in CH_2Cl_2 at 25 °C.

process twice, with the second hydroboration step being too fast to be monitored within the NMR time.

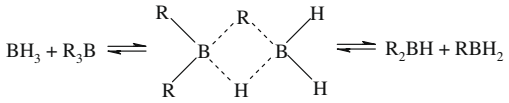
$$BH_iX_j \cdot SMe_2 \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} BH_iX_j + SMe_2$$

$$BH_iX_j + nR \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} R_nBX_j \quad (5)$$

$$R_nBX_j + Me_2S \overset{Fast}{\rightleftharpoons} R_nBX_j \cdot SMe_2$$

where i,j and n represent the number of that particular atom(either 1 or 2) and X represents the type of halogen atom (either Br or Cl).

Overall, the mechanism of hydroboration of 4-octene with haloborane addition complexes involves prior dissociation of the complex into the Me_2S and either HBX_2 or H_2BX, which is followed by the reaction of the free HBX_2 or H_2BX with entering nucleophile to, respectively, form RBX_2 or R_2BX. The rate law emanating from the proposed mechanism is that given in Eq. (6):



$$K_{obs} = \frac{k_1k_2[R] + k_{-1}k_{-2}[Me_2S]}{k_{-1}[Me_2S] + k_2[R]} \quad (6)$$

Due to the presence of excess Me_2S in the system, $k_{-1}[Me_2S] > k_2[R]$, reducing Eq. (6) to Eq. (7):

$$K_{obs} = \frac{k_1k_2[R] + k_{-1}k_{-2}[Me_2S]}{k_{-1}[Me_2S]} \quad (7)$$

The reactions involving dihaloboranes do not undergo any reverse or parallel reaction, implying that $k_{-2} = 0$, thus resulting into Eq. (3). The opposite is true for the monohaloborane, describing Eq. (4). This means that k_2' in both instances is a composite parameter made up of $k_1k_2/k_{-1}[Me_2S]$.

It can be agued that the mechanism should include an exchange between $R_2BBr \cdot SMe_2$, once it is formed, and $H_2BBr \cdot SMe_2$, resulting into $RHBBr \cdot SMe_2$ as the most active hydroborating reagent in the system. This is not possible because of a number of reasons when one looks at the mechanistic pathway through which such redistribution would occur. A generally accepted mechanistic pathway for the redistribution equilibria that involve boron-containing species, *e.g.* BH_3 as shown in Eq. (8), proceed through formation of hydrogen-bridge dimer that eventually go through dispropotionation by means of a four-centre transition state as shown in Scheme 1 [19]:

Scheme 1. A boron-based four-centred transition state for the disproportionation process.

$$\left.\begin{aligned} &BH_3 + R_3B \rightleftharpoons R_2BH + RBH_2 \\ &2RBH_2 \rightleftharpoons R_2BH + BH_3 \\ &2R_2BH \rightleftharpoons RBH_2 + R_3B \end{aligned}\right\} \quad (8)$$

In our case, such a route was not possible as the boron complex is stabilised by the coordination of the Lewis base as well as π-back donation from the halogen into the boron, which impedes the formation of dimeric adducts. This is supported by the thermodynamic stability of haloboranes in the presence of a donor (Lewis base) which is well documented in literature [19]. Moreover, Pasto et al. [20] have established that the dissolution of diborane in THF produces a solution of $BH_3 \cdot THF$ in THF. In addition, on reacting tetramethylethylene (TME) with borane in THF they observed that the possibility of TME reacting with diborane, which might have been formed through dimer–monomer equilibrium, and could have lead to redistribution complications, was non-existent.

To further invalidate the possibility of formation of a hydrogen-bridged centred transition state that would facilitate the redistribution, it is important to note that in the current systems of haloborane addition complexes, after hydroboration no hydrogen is available to allow for such a bridge to form since all the hydrogens will have been used in the hydroboration process.

The other reason that must be taken into consideration is whether a dehydroboration process is possible under the experimental conditions employed. Based on literature information, under the current conditions it is not possible to have dehydroboration taking place, since the temperature range investigated (15–30 °C) was too low to allow for the breakage of a B–C bond whose energy has been approximated to be 84 kcal mol^{-1} [2].

For the purposes of determining the activation parameters, the composite second order rate constants (k_2'), given in Table 1, were determined by least-square analysis of the plots for different temperatures, ranging from 15–30 °C. These values were used in plotting the Erying plots shown as in Fig. 4. Using the slope and the

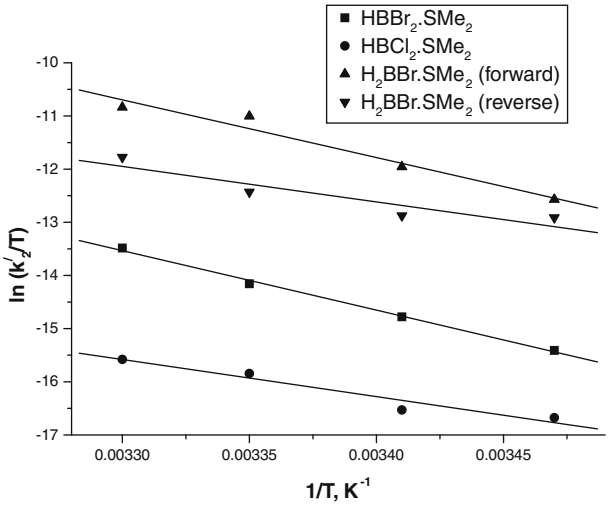


Fig. 4. Erying plots for hydroboration of 4-octene with $HBBr_2 \cdot SMe_2$, $HBCl_2 \cdot SMe_2$ and $H_2BBr \cdot SMe_2$ in CH_2Cl_2 under pseudo-first-order conditions.

intercepts of the graphs, we were able to calculate the entropies and enthalpies of activation, shown in Table 1.

In our previous work, we compared the rates of hydroboration of different haloboranes using 1-octene and making sure that the amount of the Lewis base was the same. In this paper, our main interest is to compare the hydroboration reaction of 4-octene and that of 1-octene [1,3] with different haloboranes. Therefore, it is important to mention that this paper compares the reactivity between 4-octene and 1-octene with a specific haloborane and not the differences among haloboranes. Consequently, making sure that the different haloborane systems were at same level of excess Lewis base was of no necessity. Even so, the reactivity between $HBBr_2 \cdot SMe_2$ and $H_2BBr \cdot SMe_2$ can be compared since these two systems had the same amount of excess Me_2S.

3.1. Reactivity of 1-octene and 4-octene

Looking at the data in Table 1, the composite second order rate constants, k_2' for hydroboration of 1-octene are larger than those of the hydroboration of 4-octene. This implies that the rate of hydroboration of 1-octene is faster than that of 4-octene, which is in agreement with what Brown et al. [16–18] discovered through relative reactivity studies.

A quantitative analysis of the rate constants, reveal that on average hydroboration of 1-octene with $HBBr_2 \cdot SMe_2$ and $HBCl_2 \cdot SMe_2$ is 16 times faster than that of the 4-octene, whilst in the case of $H_2BBr \cdot SMe_2$ this factor is reduced to 8 times. This difference is due to the difference in the reactivity of the haloboranes, as reported in our previous work [1,3] where we showed that the rate-controlling step on hydroboration with dimethyl sulfide haloborane addition complexes is the dissociation of the Me_2S. The comparison between the mono- and the dihaloborane showed that the rate of dissociation of Me_2S from $H_2BBr \cdot SMe_2$ is 34 times faster than that from $HBBr_2 \cdot SMe_2$. This was accounted for in terms of the magnitude of the inductive effect the boron atom experiences due to the presence of bromine atoms in the two environments.

The difference in reactivity between 1-octene and 4-octene within a haloborane is due to the contribution of k_2 to the k_2' term. This value is controlled by the steric hindrance of the incoming nucleophile, with the internal double bond being more sterically hindered than the terminal one.

Hydroboration reactions involving $H_2BBr \cdot SMe_2$ were observed to have a y-intercept, as shown in Eq. (4), which resulted in k_{-2} values that are given in Table 1. From the mechanism, these values represent a rearrangement process which has previously been proposed [21] to occur (either through dehydroboration or through a stereospecific migration by means of a π-complex or three-centred intermediate) as a means of isomerization. In this study, the temperatures employed were much lower than those at which dehydroboration is expected to occur as already explained above [22], therefore we can assume that the k_{-2} values observed represent the stereospecific migration of boron from one carbon to the next, as opposed to complete dehydroboration.

3.2. Activation parameters

In analysing the activation parameters, as previously stated [1,3], it is important that caution is exercised since the values originate from the composite rate constants, k_2'. This is because the values obtained are a sum of two processes taking place, *i.e.* dissociation of the Me_2S from the boron atom and subsequently the hydroboration reaction.

Therefore, the moderate $\Delta H^{\neq}$ values, accompanied by small $\Delta S^{\neq}$ values imply a process that is dissociatively dominated. However, the magnitude of the $\Delta S^{\neq}$ values is indicative of an overall interchange (I) mechanism. The large errors associated with entropy values are due to the intrinsic extrapolation involved in their determination. The activation enthalpy values are similar in magnitude, an indication that these reactions go through a similar mechanistic process. The rearrangement process (which is means of isomerization) has small values of $\Delta S^{\neq}$. These can also be interpreted to represent an interchange (I) mode of activation. This further supports the proposal that at lower temperatures, isomerization may occur by means of stereospeific rearrangement through a π-complex [21].

4. Summary

The results reported in this paper show that hydroboration of 1-octene with dimethyl sulfide dihaloborane addition complexes ($HBBr_2 \cdot SMe_2$ and $HBCl_2 \cdot SMe_2$) is 16 times faster than hydroboration of 4-octene. This factor is reduced to 8 times when a monohaloborane ($H_2BBr \cdot SMe_2$) is used. This certainly is in agreement and in support of the findings reported by previous workers, *i.e.* hydroboration of internal olefins is sluggish compared to that of terminal olefins. Steric hindrance accounts for the difference in hydroboration reactivities of 1-octene and 4-octene.

The activation parameters obtained for hydroboration of both 1-octene and 4-octene with $HBX_2 \cdot SMe_2$ and $H_2BBr \cdot SMe_2$ are indicative of a mechanistic mode that is dominated by the dissociation of the Me_2S as opposed to the associative nature of the coming in of the nucleophile. The overall mode of activation is interchange (I) in nature. The observed k_{-2} values for $H_2BBr \cdot SMe_2$ is an indication of a rearrangement process most probably through a π-complex, which facilitates isomerization.

Acknowledgements

The authors wish to acknowledge the funding of this project by Sastech R&D, DTI/Thrip, as well as the University of KwaZulu Natal. Our special gratitude goes to Mr. C.D. Grimmer for recording the NMR spectra, as well as assistance with regard to NMR queries. Dr. A. de Klerk of Sasol Ltd. is also acknowledged for his contribution.

2.2. Synthesis

In a typical synthesis, a solution of $Ni(NO_3)_2 \cdot 6H_2O$ (0.67 mmol) in 10 ml formamide for **1**, or $Ni(NO_3)_2 \cdot 6H_2O$ (0.67 mmol) and 4,4′-bipyridine (1.34 mmol) in 10 ml formamide for **2** was transferred into a Teflonlined autoclave and then heated under autogenous pressure at 70 °C for 72 h, followed by cooling to room temperature naturally. Green large single crystals in regular cubic shape were collected and washed with ethanol several times, yield 75% for **1** and **2** upon Ni. *Anal.* Calc. for **1**: N, 23.08. Found: N, 23.05%. *Anal.* Calc. for **2**: C, 39.13; H, 2.63; N, 18.26. Found: C, 39.03; H, 2.93; N, 18.32%.

2.3. Characterization

Elemental analyses for C, H, and N were performed on an EA 1110 elemental analyzer. The IR spectra were obtained on a FT/IR-6100 (JASCO) spectrometer. The variable temperature magnetic susceptibilities were measured using a PPMS 6000 (Quantum Design Inc., USA) instrument.

2.4. X-ray crystallography

Data for compounds were collected on a Bruker SMART AXS diffractometer equipped with a monochromator in the Mo Kα (λ = 0.71073 Å) incident beam. The crystals were mounted on a glass fiber. The CCD data were integrated and scaled using the Bruker-SAINT software package, and the structures were solved and refined using SHEXTL V6.12 [32]. Hydrogen atoms were located in the calculated positions. The crystallographic data for **1** and **2** is listed in Table 1.

3. Results and discussion

3.1. Synthesis

Recently, hydro(solvo)thermal synthesis has gained impressive progress. This technique provides a powerful tool for the construction of materials containing unique structures and special properties. In this work, using solvothermal reaction between $Ni(NO_3)_2 \cdot 6H_2O$ and formamide for **1**, $Ni(NO_3)_2 \cdot 6H_2O$ and 4,4′-bipyridine in formamide for **2** at 70 °C for 72 h yields green cubic crystals. This synthetic procedure gave a good yield of about 75% based on nickel in the both cases. Anion NO_2^- in the compounds may come from reduction of NO_3^- by formamide [33]. Indeed, at high temperature and pressure of the solvothermal condition, the reaction is suggested to be as follows:

$$NO_3^- + NH_2{-}CHO \rightarrow NO_2^- + NH_2{-}COOH.$$

To evidence the reaction mechanism above, the analysis of nitrite anion was carried out by a standard method, spectrophotometric determination. A liquid part of the reaction products was isolated and analyzed by using sulfanilamide and *N*-(1-naphthyl)ethylenediamine as indicators with using light at 543 nm. The analysis results showed that almost NO_3^- was reduced to NO_2^-. The oxidation of *N*,*N*-dimethylformamide to form carbamic acid by oxidant such as Ag^+ was also reported in the previous literature [33]. Compounds **1** and **2** can be obtained in a wide temperature range from 70 to 150 °C.

3.2. Structure description

Compound **1** crystallizes in monoclinic space group $C2/c$ with two-dimensional framework (Fig. 1). In this structure, there is only one crystallographical type of Ni^{2+} ion with a nearly octahedral environment surrounded by six oxygen atoms. Each Ni^{2+} ion is bridged with four neighboring Ni^{2+} ions through NO_2^- ligands. The Ni1–O1, O1–N1, N1–O2($0.5 - x$, $-0.5 + y$, $0.5 - z$) and O2–Ni1 lengths are 2.075(3), 1.273(6), 1.256(5), and 2.083(3) Å; and the Ni1–O1–N1, O1–N1–O2($0.5 - x$, $-0.5 + y$, $0.5 - z$) and N1($0.5 - x$, $0.5 + y$, $0.5 - z$)–O2–Ni1 angles are 123.6(3)°, 122.6(4)°, and 22.0(3)°, respectively. The distance between two neighboring Ni^{2+} ions is 5.873(1) Å. These bond lengths and angles may play an important role to the magnetic coupling between the Ni^{2+} ions. The relative Ni1–O1–N1–O2 and O1–N1–O2–Ni1 torsion angles are 177.7(1)° and 174.06(1)°. This means that Ni1, O1, N1, and O2 atoms are arranged nearly in a plane. Linking Ni^{2+} ions and bridging NO_2^- ligands forms a two-dimensional framework. In addition, each Ni^{2+} ion also coordinates with two NO_2 molecules with bond lengths Ni–O3 (2.080(3) Å), N2–O3 (1.251(7) Å), N2–O4 (1.192(11) Å). Compared with N2–O3 bond, shorter length of N2–O4 may be due to double bond of this terminal link. The double bond can be evidenced further by a comparison of the IR data for 4,4′-bipyridine, **1**, and **2** (Fig. S1). Compound **2** crystallizes in tetragonal space group $P4_32_12$. Asymmetric unit contains half metal atom, half 4,4′-bipy ligand, and a NO_2^- ligand. Symmetry operations ($x - 1$, $y - 1$, z), ($x - 1/2$, $-y+1/2$, $-z + 1/4$), ($-y + 1/2$, $x - 1/2$, $z - 1/4$), (y, x, $-z$), ($x + 1$, $y + 1$, z), and ($y + 1/2$, $-x + 1/2$, $z + 1/4$) generate three-dimensional structure (Fig. 2). There is only one type of Ni^{2+} ion in the structure, coordinated by six atoms. The coordination environment of Ni can be considered as a octahedron compressed along N1–Ni1–N2($x - 1$, $y - 1$, z) axis with Ni–N bond lengths for Ni1–N1 (2.051(8) Å) and Ni1–N2($x - 1$, $y - 1$, z) (2.063(7) Å) are shorter than those of four equatorial bonds Ni–O (2.124(5)–2.126(5) Å). Each Ni^{2+} ion is bridged with four neighboring Ni^{2+} ions via NO_2^- ligands. The Ni1–O1, O1–N3, N3–O2 and O2–Ni1($y + 1/2$, $-x + 1/2$, $Z + 1/4$) lengths are 2.126(5), 1.236(7), 1.275(8), and 2.124(5) Å; and the Ni1–O1–N3, O1–N3–O2 and N3–O2–Ni1($y + 1/2$, $-x + 1/2$, $Z + 1/4$) angles are 126.6(5)°, 127.8(8)°, and 120.0(5)°, respectively. The distance between two neighboring Ni^{2+} ions bridged by NO_2^- is 5.893(1) Å. The relative Ni1–O1–N3–O2 and O1–N3–O2–Ni1($y + 1/2$, $-x + 1/2$, $Z + 1/4$) torsion angles are −178.1(5)° and −156.6(6)°. This shows that the configuration of NO_2^- for **2** is different from that for **1**. Along direction N1–Ni1–N2, two neighboring Ni^{2+} ions are bridged by a ligand 4,4′-bipy molecule with a torsion angle of two pyridine rings to be 47.7(2)°. The distance between these two Ni^{2+} ions is 11.187(1) Å. Two 4,4′-bipyridine molecules of two neighboring Ni^{2+} ions bridged by NO_2^- have perpendicular N–N directions.

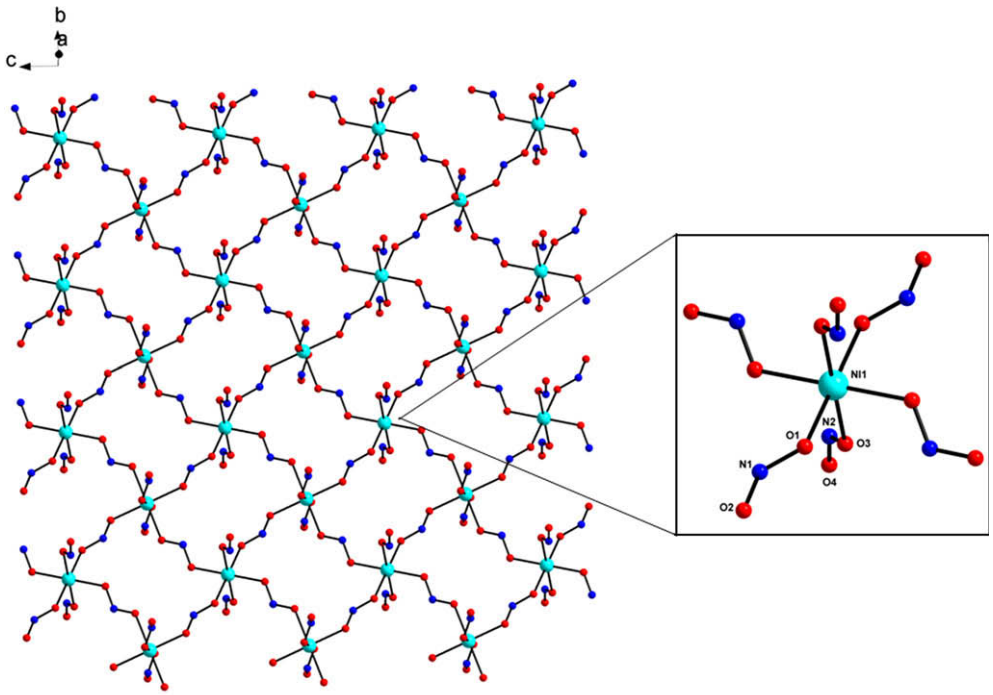

Fig. 1. Two-dimensional structure of **1**.

3.3. Magnetic properties

The $\chi_M T$ versus T plots for **1** and **2** are shown in Figs. 3 and 4 with χ_M being the molar magnetic susceptibility per Ni^{II} ion. At room temperature, the $\chi_M T$ values for **1** and **2** are 1.36 and 1.21 $cm^3\ K\ mol^{-1}$, respectively, which exceed the spin-only value for uncorrelated Ni^{II} ($S = 1$) center (1.0 $cm^3\ K\ mol^{-1}$). The observed $\chi_M T$ values are similar to that found in the end-to-end azide-bridged Ni(II) chain [34]. Upon cooling, a decrease in the $\chi_M T$ product was observed at temperatures down to 20 K (0.62 $cm^3\ K\ mol^{-1}$) for **1** and 26 K (0.53 $cm^3\ K\ mol^{-1}$) for **2**. This suggests the presence of antiferromagnetic interactions in the both compounds. The

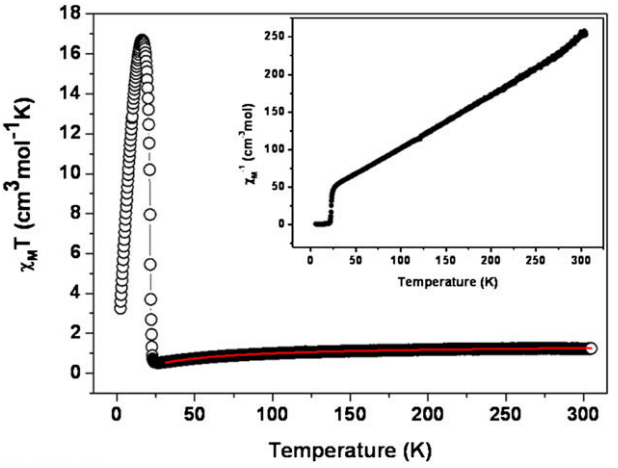

Fig. 4. Plots of the temperature dependence of $\chi_M T$ and $1/\chi_M$ (inset) for **2** at 500 Oe field.

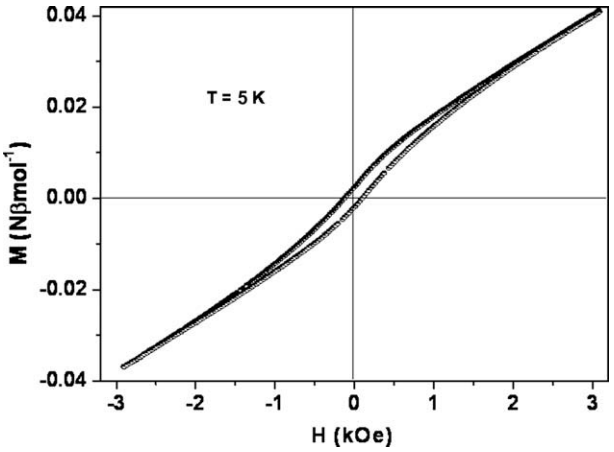

Fig. 5. Hysteresis loop of **1** at $T = 5$ K.

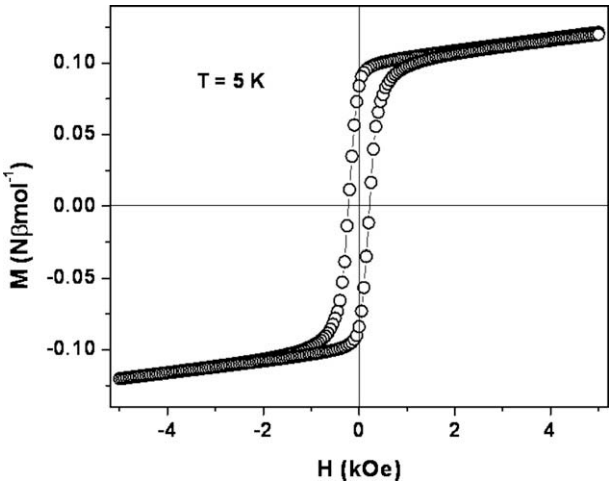

Fig. 6. Hysteresis loop of **2** at $T = 5$ K.

subsequent cooling leads to a abrupt increase to a maximum at 15 K (1.55 cm^3 K mol^{-1}) and 16 K (16.69 cm^3 K mol^{-1}), followed by a drop down to 0.60 cm^3 K mol^{-1} and 7.70 cm^3 K mol^{-1} at 5 K for **1** and **2**, respectively. This overall magnetic behavior is related to the occurrence of spin-canting [34]. Fit of the data ($T > 50$ K) with the Curie–Weiss law [$\chi_M = C/(T - \theta)$] provides parameters of $C = 1.54$ cm^3 K mol^{-1}, $\theta = -31$ K for **1**; and $C = 1.39$ cm^3 K mol^{-1}, $\theta = -41$ K for **2**. Based on the structural feature, we adopted the equation of the Heisenberg model ($H = -2J\Sigma_{ij}S_i - S_j$) for a two-dimensional plane square derived by Rushbrooke and Wood [35]. The deduced expression for $S = 1$ is given by

$$\chi_M = (2Ng^2\beta^2/3kT)[\Sigma_{n=0^6}(p_n/x^n)]^{-1}$$

where $p_0 = 1$, $p_1 = 5.3333$, $p_2 = 9.7778$, $p_3 = 9.4815$, $p_4 = 19.0617$, $p_5 = 45.0897$, $p_6 = 25.4639$, and $x = kT/J$. From the structural considerations of **1** showing a two-dimensional lattice, the high-temperature magnetic data of **1** at $T > 25$ K were fitted to the equation, giving parameters of $g = 2.37$, $J = -2.84$ cm^{-1}. In χ_M versus T plots (Figs. S2 and S3) a long-range magnetic phase transition was observed at low temperature. The critical temperatures are present at 19 K for **1** and 21 K for **2** as evidenced by the peak in the $d\chi_M/dT$ versus T curve (the inset of Figs. S2 and S3). Because four $\mu_{1,3}$-nitrito bridges around each Ni center link four neighboring Ni atoms and then forms the three-dimensional network, the equation for a two-dimensional square lattice was not applied for **2**. The magnetic couplings via 4,4′-bipy can be ignored due to the long mediating distance. Using the mean-field approximation, $T_N = 2z|J|S(S + 1)/3k_B$ with $T_N = 21$ K, $z = 4$, and $S = 1$, J through the nitrite bridges is calculated to be -2.74 cm^{-1}. The obtained J value is compatible with those of **1** and $[Co(pyrazine)_2NO_2]ClO_4$ [11]. Characteristic hysteresis loops are observed at 5 K with a remnant magnetization (M_r) of 0.0025 Nβ mol^{-1} and a coercive field (Hc) of 127 Oe for **1** (Fig. 5), and M_r of 0.084 Nβ mol^{-1} and Hc of 220 Oe for **2** (Fig. 6).

4. Conclusion

We successfully synthesize molecule-based magnetic materials with two- (for $Ni(NO_2)_2(NO_2)_2$) and three- (for $Ni(4,4'\text{-bipyridine})(NO_2)_2$) dimensional coordination polymer frameworks by solvothermal method in formamide using salt $Ni(NO_3)_2 \cdot 6H_2O$ as a precursor. Both complexes mark the first two- and three-dimensional examples constructed from purely nitrite bridges. Magnetic measurements show weak ferromagnetism within framework of the two compounds, in which the magnetization of **2** with 3D network is much stronger than that of **1** with 2D structure. Bridging ligand NO_2^- formed by reducing NO_3^- in the presence of formamide may play an important role in the observed weak ferromagnetism generating T_N values of 19 K for **1** and 21 K for **2**.

2. Results and discussion

HL^1P was synthesized adopting a previously published procedure [14]. Some modifications in the experimental conditions, however, increased the yield significantly. The ^{31}P NMR spectrum of the yellow solid shows a resonance at −12.9 ppm. A doublet at 9.1 ppm (J_{PH} = 4.88 Hz) in the ^1H NMR spectrum suggests the presence of the HC=N unit. Oxidation of HL^1P with H_2O_2 in THF results in the formation of HL^1PO in good yields. The ^{31}P NMR signal of the phosphorus atom in the phosphine oxide is found at 31.6 ppm, which corresponds to a low-field shift of 44 ppm compared to the value for HL^1P. The aminophosphine H_2L^2 was prepared by the reduction of HL^1P with an excess of $NaBH_4$ in boiling EtOH. The course of the reaction can readily be tracked by ^1H NMR, where signal of the CH=N protons disappears and a doublet of the methylene protons appears at 4.4 ppm (J_{HH} = 5.24 Hz).

HL^1P reacts with oxorhenium(V) precursors such as $[ReOCl_3(PPh_3)_2]$ or $(NBu_4)[ReOCl_4]$ by almost immediate changes of the colors of the reaction mixtures. However, all our attempts to isolate crystalline products from such mixtures failed. ^{31}P NMR studies of the reaction solutions showed several new signals at negative and positive chemical shift values for each reaction. Number and positions of the signals were strongly dependent on the solvent and the reaction time, which indicates an ongoing decomposition of HL^1P and/or oxidation of the phosphine under formal reduction of the metal ion. The latter type of reaction is not without precedent and has frequently been observed during the interaction of oxorhenium(V) compounds and phosphines, and can principally simply be initiated by released PPh_3 [7]. A detailed analysis of such oxygen transfer reactions has been carried out by Conry and Mayer [15].

In order to simplify the reaction and to minimize the risk of the formation of Re(III) products by a reaction of HL^1P with the oxo oxygen and subsequent formation of HL^1PO in the reaction mixture, we used the phosphine oxide directly. While the course of even this reaction with $(NBu_4)[ReOCl_4]$ remained unclear, HL^1PO reacted within 1 h in boiling THF with the sparingly soluble $[ReOCl_3(PPh_3)_2]$ under formation of a clear green solution. The heating was stopped after 2 h and two crystalline products, the red $[ReOCl_2(PPh_3)(L^1PO–O,N)]$ (**1**) and the green $[Re(NC_6H_4OH)Cl_3(PPh_3)_2]$ (**2**) could be isolated in an approximate ratio of 1:2 (Scheme 1). The amount of compound **2** can be increased by a prolonged reaction time.

The ^{31}P NMR spectrum of **1** exhibits two resonances at 26.8 and 29.4 ppm indicating the presence of L^1PO^- and coordinated PPh_3. The $\nu_{C=N}$ band of the uncoordinated imine compound is bathochromically shifted in the spectrum of the complex and appears at 1566 cm^{-1}. Single crystals of the complex were studied by X-ray diffraction. Fig. 1 shows an ellipsoid representation of **1**. Selected bond lengths and angles are summarized in Table 1. The coordination sphere of the complex is a distorted octahedron with the Schiff base as a singly deprotonated O,N chelate ligand binding via the imine nitrogen and the phenolic oxygen atoms. The oxygen atom O2 is found in *trans* position to the oxo ligand. Such a coordination mode is typical for chelating ligands systems with oxygen donor atoms [7] and goes along with a considerable transfer of electron density from the terminal Re=O bond into the relatively short Re-O2 bond of 1.958(6) Å. The phosphine oxide unit does not contribute to the coordination of the metal atom. This results in a bulky complex molecule, which produces relatively large voids between the molecules, which is also expressed by the relatively low density of the rhenium complex of 1.48 g/cm^3. These holes are almost unoccupied. The highest peaks of electron density located there count approximately 1 $e^-/Å^3$. A refinement with each one water molecule which is disordered in over four positions in such a void improves the *R* value only marginally and is not justified by other experimental data.

The formation of the green phenylimido complex **2** is an unexpected feature of the reaction, but confirms the decomposition of HL^1PO during the reaction with $[ReOCl_3(PPh_3)_2]$. The fact that the amount of **2** formed increases with a prolonged reaction time, also indicates a considerable instability of **1**. The presence of the metal complex is mandatory for the observed ligand decomposition, and all our attempts to decomposed pure HL^1PO in boiling THF failed. The compound resisted such a treatment for 5 h without degradation as has been proven by ^{31}P NMR and TLC experiments. The released 2-aminophenol finally reacts with the oxorhenium core under formation of a phenylimido unit. It is interesting to note that the isolated complex **2** contains two PPh_3 ligands and, consequently, the triphenylphosphine released from $[ReOCl_3(PPh_3)_2]$ is not oxidized immediately by a secondary reaction with the oxo

ligand as has been observed previously, but remains in the solution. This fact is supported by ^{31}P NMR spectra of the reaction mixture. Reactions of anilines with oxo complexes are common and many phenylimido complexes have been prepared in this way, but there are only a few structurally characterized examples of rhenium compounds with (2-hydroxyphenylimido) ligands [16]. Fig. 2 depicts an ellipsoid representation of **2**, selected bond lengths and angles are given in Table 2. Main structural features of the compound are similar to the corresponding 'parent complex' $[Re(NPh)Cl_3(PPh_3)_2]$ [17]. The only remarkable feature in the molecular structure of **2** is an intramolecular hydrogen bond (O1–H1: 0.82 Å, H1–Cl2: 2.25 Å, O1–Cl2: 3.037(7) Å, O1–H1–Cl2: 161.3°), which is established between the phenolic oxygen atom and one of the chloro ligands.

Cleavage of the backbone of the organic ligand is avoided, when the Schiff base is reduced prior reaction with the metal complex. The resulting phosphine amine H_2L^2P is a robust chelating system, which readily reacts with $[ReOCl_3(PPh_3)_2]$ under formation of *fac*-$[ReOCl_2(HL^2P)]$ (**3**) (Scheme 2). The same product is obtained by heating a reaction mixture of H_2L^2P and $(NBu_4)[ReOCl_4]$ in MeOH. The coordination of the phosphorus atom is confirmed by a single resonance in the ^{31}P NMR spectrum at −4.6 ppm, which corresponds to a 12 ppm shift compared to the resonance of uncoordinated H_2L^2P. The IR spectrum contains a medium intense absorption at 968 cm^{-1} related to the Re=O vibration. The broad band at 3452 cm^{-1} is consistent with the stretching vibrations of the NH unit and indicates that the amine donor function is not deprotonated.

The conclusions of the spectroscopic studies are confirmed by an X-ray structure determination of the compound. Fig. 3 depicts the molecular structure of **3** with a facially coordinated HL^2P^- ligand. Expectedly, the oxygen atom occupies the position *trans* to the oxo ligand, and the Re–O1 bond length of 1.973(3) Å is shorter than expected for a rhenium–oxygen single bond. More bond lengths and angles of **3** are summarized in Table 3. The coordination sphere around the metal atom is a distorted octahedron. Main distortions from an ideal octahedron come from the requirements of the four- and five-membered chelate rings, as can clearly be seen at the N1–Re–O1 angle of 77.2°. The Re–Cl2 bond is slightly longer than the Re–Cl1 bond, which is in accord with the stronger structural *trans* influence of the phosphine function compared with the amine.

Concluding it can be stated that a stable tridentate ligand is obtained by the reduction of a Schiff base derived from (2-formylphenyl)diphenylphosphine, while the imine itself undergoes a rapid hydrolysis when reacted with rhenium(V) oxo complexes. This concept can be extended to ligand systems of higher denticity starting from the Schiff bases derived from bis(2-formylphenyl)phenylphosphine or tris(2-formylphenyl)phosphine. Such studies are currently done in our laboratory.

3. Experimental

$(NBu_4)[ReOCl_4]$ [18] and $[ReOCl_3(PPh_3)_2]$ [19] were prepared by literature procedures. IR spectra were measured as KBr pellets on a Shimadzu FTIR-spectrometer 8300. FAB^+ mass spectra were recorded with a TSQ (Finnigan) instrument using a nitrobenzyl alcohol matrix. Elemental analysis of carbon, hydrogen and nitrogen were determined using a Heraeus (vario EL) elemental analyzer. ^1H, ^{13}C and $^{31}P\{^1H\}$ NMR spectra were taken with a JEOL 400 MHz multinuclear spectrometer.

3.1. Synthesis of HL^1P

A mixture of (2-formylphenyl)diphenylphosphine (1.5 g, 5.2 mmol) and 2-aminophenol (0.57 g, 5.2 mmol) were suspended in 10 mL of ethanol and heated under reflux for 1.5 h. The product precipitated as a yellow powder, which was filtered off and washed with cold ethanol. Yield 1.8 g (93%). Elemental *Anal.* Calc. for $C_{25}H_{20}NOP$ (381.13): C, 78.73; H, 5.29; N, 3.67%. Found: C, 78.92; H, 5.29; N, 3.51%. ^1H NMR (400 MHz, DMSO-d_6, ppm): δ 6.72–8.30 (m, 18H, aromatic), 8.78 (s, 1H, OH), 9.14 (d, 1H, HC=N, J_{PH} = 4.88 Hz). ^{13}C NMR (DMSO-d_6, ppm): δ 115–136 (aromatic), 156 (HC=N). ^{31}P NMR (DMSO-d_6, ppm): δ −12.9 s. IR (KBr, cm^{-1}): 3283 (st), 3043 (m), 3013 (w), 2881 (w), 1632 (st), 1581 (m), 1481 (st), 1431 (m), 1369 (w), 1281 (w), 1250 (st), 1270 (m), 1122 (w), 1026 (w), 968 (w), 883 (w), 856 (w), 744 (st), 698 (st), 602 (w), 509 (m), 482 (m). MS (EI): *m/z* 381 ($[M]^+$, 83%), 304 ($[M-Ph]^+$, 100%).

3.2. Synthesis of HL^1PO

HL^1P (1 g, 2.6 mmol) was dissolved in 5 mL of THF and H_2O_2 (0.3 mL, 30% wt.) was added. After stirring the reaction mixture for 10 min, 10 mL brine solution was added. The organic phase was separated and dried over $MgSO_4$. HL^1PO was isolated as an analytically pure, yellow powder after removal of the solvent. Yield 0.98 g (95%). Elemental *Anal.* Calc. for $C_{25}H_{20}NO_2P$ (397.41): C, 75.56; H, 5.07; N, 3.52%. Found: C, 75.68; H, 5.05; N, 3.61%. ^1H NMR (400 MHz, DMSO-d_6, ppm): δ 6.55–8.30 (m, 18H, aromatic), 8.9 (s, 1H, HC=N), 10.05 (s, 1H, OH). ^{31}P NMR (DMSO-d_6, ppm): δ 31.6 s. ^{13}C NMR (DMSO-d_6, ppm): δ 164.1 (s, HC=N). IR (KBr, cm^{-1}): 3420 (w), 3058 (m), 3024 (m), 1632 (m), 1578 (m), 1485 (s), 1435 (m), 1377 (w), 1354 (w), 1292 (m), 1223 (m), 1257 (st), 1157 (m), 1130 (m), 1111 (m), 1072 (m), 1029 (w), 968 (w), 767 (m), 748 (st), 702 (s), 578 (m), 540 (st).

3.3. Synthesis of H_2L^2

HL^1P (1.4 g, 3.6 mmol) and $NaBH_4$ (0.91 g, 24 mmol) were suspended in 20 mL of EtOH and heated for 10 min. After the reaction solution became colorless, the solvent was removed under vacuum and the product was extracted with 15 mL of Et_2O. The organic phase was washed with water and dried over $MgSO_4$. A colorless solid was obtained after removing the solvent under vacuum. Yield 1.2 g (88%). Elemental *Anal.* Calc. for $C_{25}H_{22}NOP$ (383.4): C, 78.31; H, 5.78; N, 3.65%. Found: C, 77.05; H, 5.42; N, 3.14%. ^1H NMR (400 MHz, DMSO-d_6, ppm): δ 4.36 (d, 2H, CH_2, J_{HH} = 5.24 Hz), 5.4 (t, 1H, NH J_{HH} = 5.84 Hz), 6.05–7.6 (m, 18H, aromatic), 9.2 (s, 1H, OH). ^{31}P NMR (DMSO-d_6, ppm): δ −16.6. IR (KBr, cm^{-1}): 3514 (w), 3425 (m), 3055 (m), 2866 (w), 1604 (st), 1515 (st), 1438 (m), 1242 (m), 1192 (m), 1041 (w), 737 (st), 698 (m).

3.4. Synthesis of $[ReOCl(PPh_3)(L^1PO)]$ (**1**) and $[Re(NC_6H_4OH)Cl_3(PPh_3)_2]$ (**2**)

$[ReOCl_3(PPh_3)_2]$ (0.17 g, 0.2 mmol) and HL^1PO (79 mg, 0.2 mmol) were dissolved in 20 mL of THF and heated under reflux for 2 h. The volume of the solution was reduced to 3 mL and cooled to −10 °C. Two different types of crystalline products, red **1** and green **2**, deposited and were separated mechanically. Overall yield of both compounds: 74 mg (ca. 80%). After a reaction time of 2 h an approximate ratio of 1:2 between the compounds **1** and **2** was obtained. The relative amount of **2** increased with prolonged reaction times.

3.4.1. Data for **1**

Elemental *Anal.* Calc. for $C_{43}H_{34}Cl_2NO_3P_2Re$ (1·THF) (931.7): C, 55.43; H, 3.68; N, 1.50%. Found: C, 53.87; H, 3.66; N, 1.62%. ^1H NMR (400 MHz, DMSO-d_6, ppm): δ 6.85–8.04 (m, 38H, aromatic), 10.58 (s, 1H, HC=N). ^{31}P NMR (DMSO-d_6, ppm): δ 26.08 (s, PPh_3), 29.44 (s, $OPPh_3$). IR (KBr, cm^{-1}): 3055 (m), 2851 (w), 1697 (w), 1589 (w), 1566 (w), 1477 (m), 1431 (st), 1194 (m), 1161 (m), 1095 (m), 1068 (w), 1026 (w), 941 (w), 748 (st), 694 (st), 517 (st). MS (FAB^+): *m/z* 896 ($[M-Cl]^+$, 1%), 635 ($[M-C_{18}H_{14}PCl]^+$, 3%).

3.4.2. Data for **2** · *THF*

Elemental *Anal.* Calc. for $C_{42}H_{35}Cl_3NOP_2Re$ (924.2): C, 54.58; H, 3.82; N, 1.52%. Found: C, 55.18; H, 4.19; N, 1.27%. ^1H NMR (400 MHz, $CDCl_3$, ppm): δ 6.17−7.87 (m, 34H, aromatic). ^{13}C NMR ($CDCl_3$, ppm): δ 127.8–138.7 (aromatic). ^{31}P NMR ($CDCl_3$, ppm): δ −20.68 s. IR (KBr, cm^{-1}): 3132 (w), 3055 (w), 2970 (w), 2851 (w), 1593 (w), 1473 (m), 1431 (m), 1342 (w), 1238 (w), 1200 (m), 1153 (w), 1092 (m), 1061 (w), 1030 (w), 999 (w), 744 (m), 694 (st), 652 (w), 517 (st).

3.5. Synthesis of fac-$[ReOCl_2(HL^2P)]$ (**3**)

$[ReOCl_3(PPh_3)_2]$ (83 mg, 0.1 mmol) was dissolved in 20 mL of THF and H_2L^2P (38 mg, 0.1 mmol) was added as solid. The mixture was stirred under reflux for 1 h, whereupon an olive-green suspension was obtained. The solvent was removed under reduced pressure and the residue was suspended in 5 mL of MeOH. The olive-green solid was filtered through a Celite pad and washed twice with MeOH. Recrystallization from CH_2Cl_2/MeOH gave green plates. Yield: 46 mg (71%). Elemental *Anal.* Calc. for $C_{25}H_{21}NO_2Cl_2PRe$ (656.5): C, 45.74; H, 3.38; N, 2.13%. Found: C,

MS (FAB$^+$): 654.9 ([M]$^+$, 7%), 620 ([M−Cl]$^+$, 48%).

3.6. X-ray structure determinations

The intensities for the X-ray determinations were collected on a STOE IPDS with Mo Kα radiation. The structures were solved by direct methods using SHELXS-86 [20] or SHELXS-97 [20]. Subsequent Fourier-difference map analyses yielded the positions of the non-hydrogen atoms. Refinement was performed using SHELXL-97 [20]. Hydrogen atom positions were calculated for idealized positions and treated with the 'riding model' option of SHELXL. Crystal data and more details of the data collections and refinements are contained in Table 4.

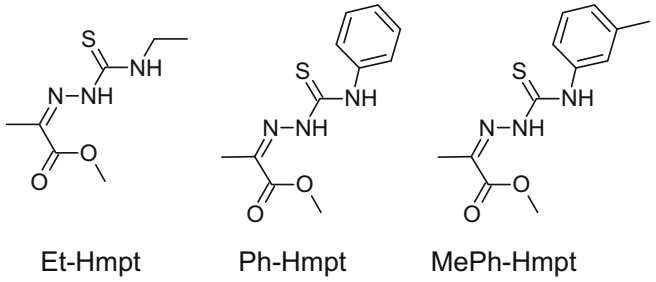
Scheme 1. R^1, R^2 and R^3 can be either H or organic radicals.

Scheme 2. Chemical drawing of Hmpt ligand (R1 = ethyl, phenyl and 3-methylphenyl).

These ligands were then reacted with bis(triphenylphosphine)copper (I) nitrate and acetate and the complexes so obtained, $[Cu(PPh_3)_2(Et\text{-}Hmpt)]_2(NO_3)_2$ **1**, $[Cu(PPh_3)_2(Ph\text{-}Hmpt)]NO_3$ **2**, $[Cu(PPh_3)_2(MePh\text{-}Hmpt)]NO_3$ **3**, $[Cu_2(O_2CCH_3)(Et\text{-}pt)(PPh_3)_2]\cdot H_2O$ **4**, $[Cu(Ph\text{-}mpt)(PPh_3)]$ **5** and $[Cu_2(MePh\text{-}mpt)_2(PPh_3)_2]$ **6**, are reported here. All of them have been characterized by elemental analysis, IR, ^1H NMR spectroscopy and compounds **1**, **2**, **4**, and **6** also by X-ray crystallography. Compound **4** contains two copper atoms with two totally different geometries suggesting, together with the charge balance, the presence of two different oxidation states. For this compound also an EPR spectroscopy analysis was carried out.



2. Experimental

2.1. Materials and techniques

$[Cu(PPh_3)_2NO_3]$ and $[Cu(PPh_3)_2(CH_3COO)]$ were prepared by reduction of the corresponding Cu(II) salt using a fourfold excess of PPh_3 in CH_3OH at reflux temperature for 1 and 3 h, respectively. The white powder formed in the reaction flask was filtered to separate the product from Ph_3PO and washed first with EtOH and then with diethyl ether. $Cu(NO_3)_2\cdot 3H_2O$ and $Cu(CH_3COO)_2\cdot H_2O$ were procured from Carlo-Erba, while PPh_3 was purchased from Aldrich. C, H, N, S analyses were obtained with a Carlo-Erba 1108 instrument. IR spectra were recorded using KBr pellets on a Nicolet 5PC FT-IR spectrophotometer in the 4000–400 cm^{-1} range. ^1H NMR spectra were recorded on a Bruker AC300 spectrometer at 300 MHz in d_6–DMSO with TMS as the internal reference. EPR spectra, both at room and liquid nitrogen temperature, were recorded in phase-sensitive detection by a X-band (9-GHz) Varian V-4502 spectrometer with a 100 kHz field modulation.

2.2. Preparation of the ligands

Methylpyruvate thiosemicarbazones were prepared by condensation of methylpyruvate with N^1-substituted thiosemicarbazides in a 1:1 molar ratio in methanol using the procedure reported in the literature [24]. In this way methylpyruvate-N^1-ethylthiosemicarbazone (Et-Hmpt $\cdot H_2O$, used to prepare complexes **1** and **4**), methylpyruvate-N^1-phenylthiosemicarbazone (Ph-Hmpt, used to prepare complexes **2** and **5**) and methylpyruvate-N^1-(3-methyl)phenylthiosemicarbazone (MePh-Hmpt, used to prepare complexes **3** and **6**) were synthesised. Scheme 3 reports the structure of the used ligands.

Scheme 3. Schematic view of the used ligands.

2.3. Synthesis of the complexes

To a hot stirred methanolic 40 mL solution of the proper ligand was added an amount of solid $[Cu(PPh_3)_2NO_3]$ for **1** (0.502 g of the ligand, 2.47 mmol, and 1.606 g of metal salt, 2.47 mmol), for **2** (0.610 g of the ligand, 2.43 mmol, and 1.580 g of metal salt, 2.43 mmol), for **3** (0.484 g of the ligand, 1.82 mmol, and 1.187 g of metal salt, 1.82 mmol) together with additional 40 mL of methanol. Similarly, to a hot stirred methanolic 40 mL solution of the proper ligand was added an amount of solid $[Cu(PPh_3)_2CH_3COO]$ for **4** (0.610 g of the ligand, 3.00 mmol, and 3.890 g of metal salt, 6.00 mmol), for **5** (0.480 g of the ligand, 1.91 mmol, and 1.238 g of metal salt, 1.91 mmol), for **6** (0.505 g of the ligand, 1.91 mmol, and 1.233 g of metal salt, 1.91 mmol) together with additional 40 mL of methanol. The mixture was allowed to reach the reflux temperature. When the inorganic salt was completely dissolved, the resulting solution appeared dark yellow and was left under magnetic stirring for 2 h. The solution was then cooled down to room temperature and by slow evaporation of the solvent, crystals suitable for X-ray diffraction were obtained for complexes **1**, **2**, **4** and **6**.

2.3.1. $[Cu(PPh_3)_2(Et\text{-}Hmpt)]_2(NO_3)_2$ ***1***

Yield: 2.01 g, 75% (based on metal). Mp: 166 °C. 2.3.4. $[Cu_2(O_2CCH_3)(Et\text{-}pt)(PPh_3)_2] \cdot H_2O$ **4**

Yield: 5.38 g, 75% (based on metal). Mp: 178 °C. FT-IR (KBr, cm^{-1}) 3442, m, ν (NH); 1650, s, ν (C=O) pyruvate; 1618, m, ν (CN); 1567, m, ν (CO) coordinated carboxylates; 695, m, ν (CS). *Anal.* Calc. for $C_{44}H_{44}N_3O_5P_2SCu_2$: C, 57.70; H, 4.84; N, 4.59; S, 3.50. Found: C, 57.11; H, 4.76; N, 4.44; S, 3.50%.

2.3.5. $[Cu(Ph\text{-}mpt)(PPh_3)]$ **5**

Yield: 0.72 g, 65% (based on metal). Mp: 158 °C. FT-IR (KBr, cm^{-1}) 3400, mb, ν (NH); 3048, m, ($CH_{aromatic}$); 1735, m, ν (CO); 1564, m, ν (CN); 746, ms, ν (CS). *Anal.* Calc. for $C_{29}H_{27}N_3O_2PSCu$: C, 60.46; H, 4.72; N, 7.29; S, 5.57. Found: C, 59.98; H, 4.96; N, 7.01; S, 5.23%. ^{1}H NMR data (δ, ppm; DMSO–d_6): 2.20 (s, 3H, CH_3CN–), 3.75 (s, 3H, CH_3O–), 7.25 (t, b, 9H, PPh_3 $H_p + H_o$); 7.37 (t, 6H, PPh_3 H_m); 7.55–7.72 (m, 5H, aromatic ligand H), 10.08 (bs, 1H, N*H*).

2.3.6. $[Cu_2(MePh\text{-}mpt)_2(PPh_3)_2]$ **6**

Yield: 0.68 g, 60% (based on metal). Mp: 197 °C. FT-IR (KBr, cm^{-1}) 3400, mb, ν (NH); 3025, m, ($CH_{aromatic}$); 1715, m, ν (CO); 1610, m, ν (CN); 742, ms, ν (CS). *Anal.* Calc. for $C_{60}H_{58}N_6O_4P_2S_2Cu_2$: C, 61.06; H, 4.95; N, 7.12; S, 5.43. Found: C, 61.18; H, 4.87; N, 7.13; S, 5.73%. ^{1}H NMR data (δ, ppm; DMSO–d_6): 2.21 (s, 3H, CH_3CN–), 2.35 (s, 3H, CH_3Ph), 3.80 (s, 3H, CH_3O–), 7.25 (t, b, 9H, PPh_3 $H_p + H_o$); 7.35 (t, 6H, PPh_3 H_m); 7.55–7.70 (m, 5H, aromatic ligand H), 10.17 (bs, 1H, N*H*).

2.4. X-ray crystallography

Relevant data concerning data collection and details of structure refinement are summarized in Tables 1a and 1b. Intensity data for **1** were collected on a CAD4 diffractometer with Cu Kα radiation, those of **2** on a Philips PW1100 and those of **4** and **6** on a SMART 1000 Bruker AXS diffractometers with Mo Kα radiation. Data from crystals of compound **1** were affected by twinning and were not corrected for absorption, while for compounds **2, 4** and **6** absorption corrections were carried out using the psi-scan procedure for the first and the SADABS [25] procedure for **4** and **6**. The crystals of compounds **4** and **6** gave very poor diffraction and data could be collected only up to 23.30° of theta. The structures were solved using direct methods (SIR-97 [26]). Refinements were carried out by full matrix least-squares cycles SHELXL97 [27] for all compounds. Most hydrogen atoms were calculated with standard geometry and refined in riding position. The program PARST [28] was employed for the geometrical description and PLUTON [29] and MERCURY [30] for the drawings.

3. Results and discussion

3.1. Synthesis and spectroscopy

Ligands were synthesized according to the procedure reported in [24] and complexes by reacting these ligands with bis(triphenylphosphine)copper(I) nitrate and with bis(triphenylphosphine) copper(I) acetate. Both ligands and complexes were produced in good yields. In complexes **1**, **2** and **3**, obtained from the nitrate salt, the ligand is protonated while in complexes **4**, **5** and **6**, that are obtained from the acetate salt, it is deprotonated. The syntheses were carried out in methanol in order to deter possible problems arising from transesterification or hydrolysis processes that could modify the ligands. Compound **4** was isolated with difficulty and only after many attempts. The best conditions were found using a 2:1 ratio of ligand with respect to the metal content. Moreover, in comparison with the syntheses of the other complexes, compound **4** was exposed to atmospheric oxygen and moisture more than the other ones being recalcitrant to crystallize. The higher acetate content stabilizing the anionic form of the ligand, together with the increased acidity of the hydrazine nitrogen due to copper(I) oxidised to copper(II), promoted the hydrolysis of the methyl group from the ester improving the electrophilicity of the carboxyl carbon and speeding up the process of demethylation.

The ^{1}H NMR spectrum of complex **1** exhibits the NHC=S signal at about 11.40 ppm, showing that the ligand is present in its neutral

form and the structure of the complex in the solid state persists in DMSO solution; the deshielded N*H*CH_2CH_3 signal at 8.53 ppm upon complexation can be related to the change from an *E* to a *Z* conformation of the ligand and the coordination to the metal of the S and N3 atoms of the ligand [24]. Even for complexes **2** and **3** the signal attributed to NHC=S and the deshielded resonance of the N*H*R nucleus reveals that the ligands are in their neutral form and in a *Z* conformation showing that the three complexes behave in a similar way. The ^{1}H NMR spectra of complexes **4** and **5** show the lack of the signal of the N*H*C=S group confirming that in solution the ligand is deprotonated. The resonances at *ca* 10.10 ppm, downfield with respect to the resonances of the same N*H* group in the free ligand, show that also these compounds are in a *Z* conformation. Due to its paramagnetism, it was not possible to record the ^{1}H NMR spectra of complex **4**. As regards as IR spectra, the absorptions in the region 3510–3150 cm^{-1} usually attributed to ν(OH) and ν(NH) stretching frequencies are assigned with difficulty, because of numerous hydrogen bonding interactions involving amino and imino groups (NH···S, NH···ONO_2^- and NH···OH_2). No relevant shifts are observed by the comparison of the vibrational stretching C=O bonds of complexes with the absorption of the free ligands [24], showing that the metal centre does not bind via pyruvate oxygen. An exception is reported for complex **4**, where the C=O absorption at 1650 cm^{-1} (*ca* 70 cm^{-1} at lower frequencies with respect the free ligand) shows that the C=O group is involved in coordination. For all complexes ν(C=N) and ν(C=S) are significantly shifted at lower frequencies showing that every ligand bind the metal ion via N,S. For complexes **1**, **2** and **3** the nitrate group vibration can be easily find at 1384 cm^{-1} with a strong absorption, while for complex **4**, the typical stretching bands (symmetrical and asymmetrical) for CH_3COO^- are identified. In agreement with diffraction and/or NMR data, no counterion can be observed in the IR spectra of compounds **5** and **6**.

An electron paramagnetic resonance study was also performed for compound **4** in order to provide information about the electronic structure of the metal and its immediate surrounding. The sample was in polycrystalline form because we experienced some difficulty to find single crystals of dimensions large enough to give an acceptable signal to noise ratio. The resulting derivative absorptions, with superimposed a DPPH (diphenyl-β-picrylhydrazyl) marker (g = 2.0036), are shown in Fig. 1a and b. The two spectra are quite similar, apart from the observation at the liquid nitrogen temperature of a more intense signal with some emphasization of a number of not completely resolved weak peaks of a possible superhyperfine nature, see below. The increase of the peak-to-peak intensity in decreasing temperature is usual in EPR, reminiscent of the fact that a simple isolated paramagnetic centre follows the $1/T$ Curie's law.

Both resonance signals appear typical for a Cu^{2+} ion in octahedral field with tetragonal distortion and show a well resolved four lines hyperfine pattern in the low field range. They may be described by a spin Hamiltonian of the form:

$$\mathscr{H} = \mu_B \vec{S} \cdot \overleftrightarrow{g} \cdot \vec{H} + \vec{S} \cdot \overleftrightarrow{A} \cdot \vec{I}, \quad \text{with } S = 1/2,\ I_{Cu} = 3/2. \tag{1}$$

Here the first term represents the Zeeman interaction of the copper unpaired spin S = 1/2 with the applied static magnetic field H (μ_B = Bohr magneton) and the second one describes the hyperfine interaction of the unpaired electron with the copper nucleus (I = 3/2).

The $\overleftrightarrow{g}$ and $\overleftrightarrow{A}$ tensors are approximately axial with maximum values:

$$g_{//} = 2.274 \pm 0.002 \quad \text{and} \quad |A_{//}| = (104 \pm 2) \times 10^{-4}\ cm^{-1} \tag{2}$$

However, the presence of a rhombic contribution is also evident, more pronounced in the high temperature spectrum, but the overlap of various non-resolved hyperfine peaks prevents a precise determination of the in-plane constants.

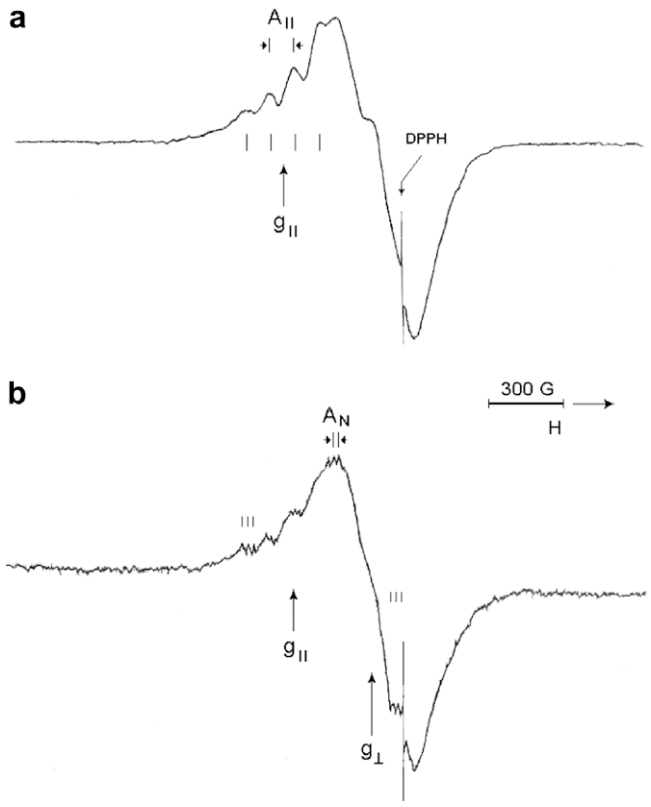

Fig. 1. Derivative X-band EPR spectra of a polycrystalline sample of **4** at room temperature (a) and at T = 77 K (b). The observed intensities of the signals a and b were in the approximate ratio 1:4.

Assuming complete axial symmetry, we estimate:

$$g_\perp \approx 2.065 \pm 0.007 \quad \text{and} \quad |A_\perp| \leqslant 30 \times 10^{-4}\ cm^{-1} \tag{3}$$

Although in general the measured g values may not coincide with the local single-ion values if exchange is present, here we have no doubt about this because the $\overline{1}$ point symmetry makes the two copper(II) per unit cell magnetically undistinguishable.

The g values are strongly indicative of a magnetically isolated Cu^{2+} ion with unpaired spin in a substantially $d_{x^2-y^2}$ ground state orbital. In this case, in fact, it should roughly be [31]:

$$\begin{aligned} g_{//} &= g_0 - 8\alpha^2\lambda/\Delta_1, \\ g_\perp &= g_0 - 2\alpha^2\lambda/\Delta_2, \end{aligned} \tag{4}$$

where g_0 is the free electron g value 2.0023, λ is the spin-orbit coupling constant for the free copper ion with a vale close to $-828\ cm^{-1}$, and Δ_1 and Δ_2 stand for the optical energy splittings due to the crystal-field between the ground state and the d_{xy} and $d_{xz,yz}$ orbitals, respectively.

The reducing α^2 factor measures the fraction of time spent by the unpaired electron at the copper ion and is directly related to the covalence of the bonds [32–34]. A light anisotropy of this factor arising from the excited orbitals d_{xy} and $d_{xz,yz}$ in (Eq. (4)) has been neglected for simplicity.

The value $|A_{//}|$ appears somewhat low as compared with usual axial values for copper(II) complexes, frequently found in the range $150–200 \times 10^{-4}\ cm^{-1}$. The reduced value has possibly to be related to the strong spin delocalization due to the Cu(II)–S very covalent bond. In fact, this should result in two distinct effects. A low presence of the unpaired spin at the copper nucleus with reduction of both the dipolar and Fermi-contact terms of the hyperfine interaction, and an induced in-plane rhombic distortion with mixing between the $d_{x^2-y^2}$

and $d_{3z^2-r^2}$ orbitals which should also reduce the axial dipolar term [34].

As a further experimental fact, we observe that the powder spectrum at liquid nitrogen temperature shows the presence of several groups of three equiintense weak peaks, see Fig. 1b. The measured splittings correspond to energies in the range 13–16 $\times 10^{-4}$ cm^{-1}. Both the number of peaks and the energy splitting involved seem to suggest the presence of a superhyperfine interaction between the magnetic copper and one nitrogen nucleus ($I_N = 1$), in line with the structure of Fig. 5.

In conclusion, all the results of this EPR study on a polycrystalline sample of compound **4** appear to strictly support the proposed crystallographic view based on two copper centres in different oxidation states.

3.2. Crystal structures of the complexes

A PLUTON drawing representing complex $[Cu(PPh_3)_2(Et\text{-}Hmpt)]_2(NO_3)_2$ **1** is reported in Fig. 2. The structure can be described as formed by two cationic complex molecules with two bridging nitrates that act as counterions. The copper(I) ion coordinates two triphenylphosphines and an N^1-ethyl methylpyruvate thiosemicarbazone molecule in its neutral form. The thiosemicarbazones bind to the metal through the sulfur and the iminic nitrogen and form a five-term chelation ring. The coordination bonds have distances of 2.165(6) and 2.148(6) Å for the Cu–N bonds and 2.365(2) and 2.368(2) Å for the Cu–S bonds. The Cu–P bonds range instead from 2.254(2) to 2.281(2) Å. The angles N–Cu–S of 82.3(2)° and 82.9(2)° are fairly small, while the P–Cu–P angles are wide (129.60(8)° and 130.54(8)°). The copper coordination is slightly distorted from the ideal tetrahedron but less than expected in the presence of a potentially terdentate planar ligand. The non-methylated oxygens of the ligand and the copper atom are 2.802(6) and 2.799(6) Å apart and do not seem to influence the copper coordination geometry. Noteworthy in both molecules that the centroids between the coordinated N and S atoms lie on the plane defined by P–Cu–P, as in a typical tetrahedral coordination geometry.

The thiosemicarbazone moieties, expected to be planar because of the extended conjugated system of double bonds, in one of the cations are in fact fairly planar with a distortion of only 9.8(4)° between the average thiosemicarbazide plane and that of the terminal carboxylate, but in the other the molecule are significantly distorted: the angle between the average plane of the terminal carboxylate and that of the thiosemicarbazide fragment is 23.0(4)°.

Table 2
Selected parameters of the hydrogen bonds involving the nitrate ions in compound **1**.

Donor···acceptor (Å)	Angle (°)	Donor···acceptor (Å)	Angle (°)
N1···O4	N1–H1···O4	N1A···O4	N1A–H1A···O4
3.01(2)	149.5(6)	3.18(1)	131.6(6)
N1···O6	N1–H1···O6	N1A···O6	N1A–H1A···O6
2.87 (1)	134.0(6)	3.17(2)	139.3(6)
N2···O4	N2–H2···O4	N2A···O4	N2A–H2A···O4
3.18(2)	135.9(5)	3.13(1)	137.4(5)
N2···O6	N2–H2···O6	N2A···O6	N2A–H2A···O6
3.19(1)	131.6(4)	2.85(1)	142.6(5)

A peculiarity of this structure is the way the two nitrate ions link the two cationic moieties. A system of loose bifurcated hydrogen bonds binds each thiosemicarbazone amino and hydrazine NH groups to two different oxygen atoms from the nitrate ions (see Fig. 2). These interactions are quite loose and this is reflected in the long bond distances (see Table 2) observed in the structure and also in the high thermal parameters presented by the nitrate ions.

Another feature that characterizes the packing of these molecules is a sixfold phenyl embrace (6PE) [35–38] (P1···P1^I $I = (x, 1 + y, z)$ distance 7.354 Å) (see Fig. 3) between molecules related by a translation along y. More precisely the phenyls of the triphenylphosphines involved in this interaction present what the aforementioned paper calls an "offset sextuple phenyl embrace" (OSPE) conformation. To complete the description of the packing it is noteworthy to observe that the hydrogen bonds with the nitrate ions together with these OSPE create a ribbon of molecules that develops along the y-axis.

The structure of compound **2**, $[Cu(PPh_3)_2(Ph\text{-}Hmpt)]NO_3$, is reported in Fig. 4. The asymmetric unit is formed by a complex cation, $[Cu(PPh_3)_2(Ph\text{-}Hmpt)]^+$, and a disordered nitrate anion bound through a loose charge-assisted hydrogen bond. In the cation complex, the copper(I) ion coordinates two triphenylphosphines and an N^1-phenyl methylpyruvate thiosemicarbazone molecule in its neutral form. Also in this case the thiosemicarbazone binds to the metal through the sulfur and the iminic nitrogen and forms a five-term chelation ring. The angle N–Cu–S is 81.70(7)° while the

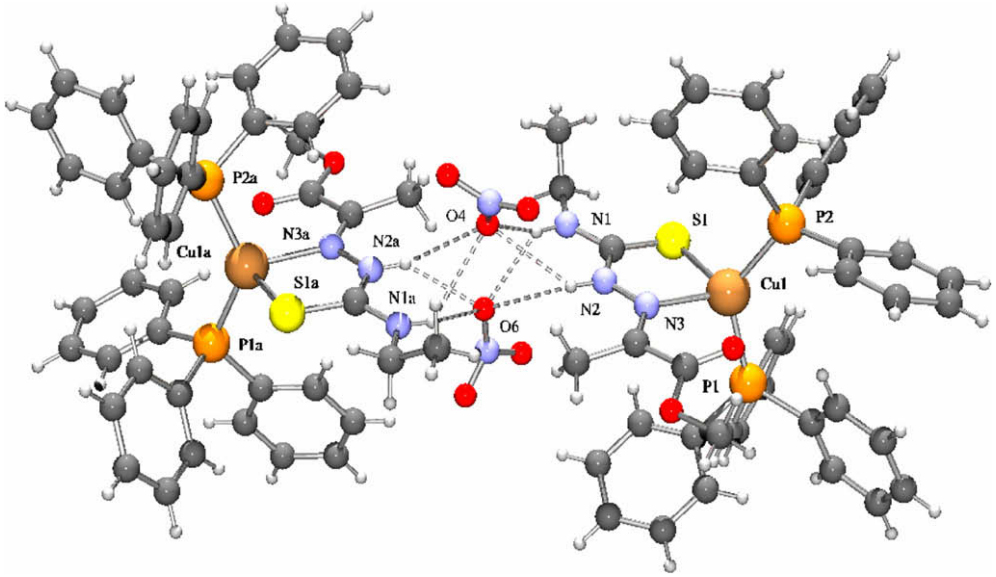

Fig. 2. PLUTON rendering of complex $[Cu(PPh_3)_2(Et\text{-}Hmpt)]_2(NO_3)_2$ **1**.

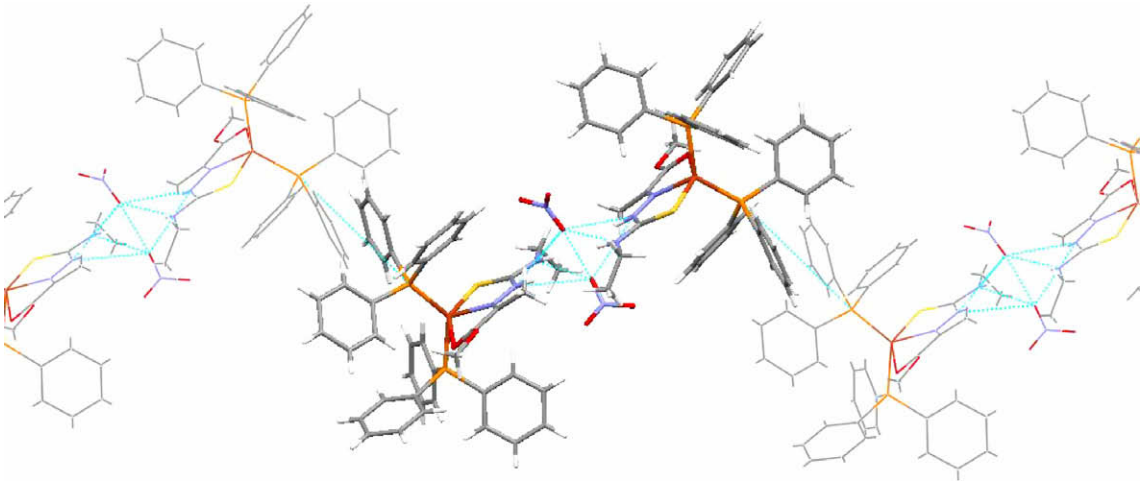

Fig. 3. MERCURY drawing showing compound **1** with two adjacent molecules linked through the six phenyl embrace.

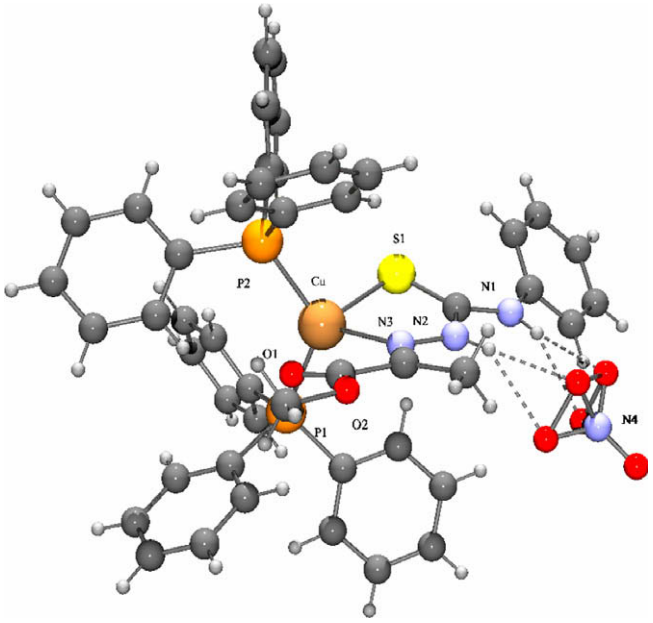

Fig. 4. PLUTON rendering of complex $[Cu(PPh_3)_2(Ph\text{-}Hmpt)]NO_3$ **2** showing the disordered nitrate hydrogen bond interaction (on the right-hand side).

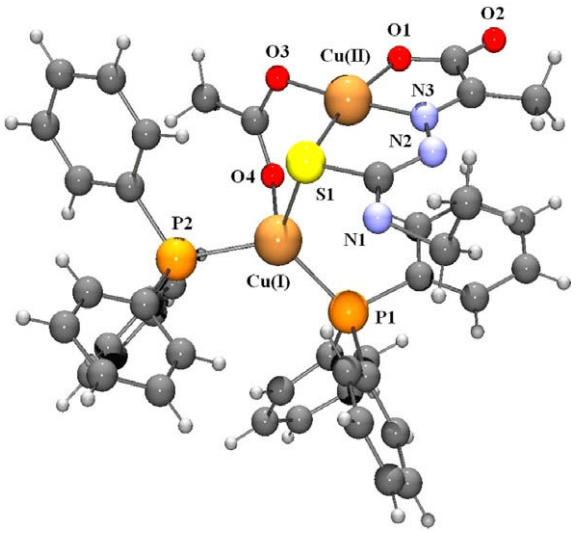

Fig. 5. PLUTON rendering of compound **4** complex fragment $[Cu_2(O_2CCH_3)(Et\text{-}pt)(PPh_3)_2]$.

P–Cu–P is slightly narrower than the previous ones, being 124.28(3)°. Compared to compound **1** the copper tetrahedral coordination is therefore slightly more regular. The coordination bonds have values of 2.156(2) Å for Cu–N, 2.400(1) Å for Cu–S and the Cu–P bonds are of 2.282(1) and 2.277(1) Å.

The thiosemicarbazone ligand is strongly distorted from the expected planarity and the angle between the thiosemicarbazide average plane and that of the carboxylate fragment is of 24.10(9)°; also the average plane of the phenyl ring is tilted of 36.3(1)° with respect to the thiosemicarbazide group. Also here, one carboxylate oxygen is oriented in the direction of the copper atom but presents a long distance Cu–O of 2.780(2) Å.

The crystal structure of compound **4** $[Cu_2(O_2CCH_3)(Et\text{-}pt)(PPh_3)_2] \cdot H_2O$ is reported in Fig. 5. The solution of this structure shed light on the anomalies that were observed in the elemental analysis and the IR spectra. This compound was particularly recalcitrant to crystallise and, probably due to the long exposure to oxygen and to air moisture, copper(I) has been partially oxidised to copper(II) and the ligand has hydrolysed and lost the ester methyl group and has become a carboxylic acid. The asymmetric unit, as a consequence, contains two metal centres in two different oxidation states. The two copper atoms are bridged by an acetate ion and by a shared sulfur from the thiosemicarbazone. The copper(II) atom coordinates in a square planar fashion the thiosemicarbazone ligand. In this case the ligand behaves as O,N,S terdentate using also its carboxylic oxygen. The fourth position site is occupied by an acetate oxygen atom. The coordination distances are: Cu(II)–N 1.912(4), Cu(II)–S 2.267(1), Cu(II)–O 1.949(3) and Cu(II)–O(ac) 1.895(3) Å. Those of the tetrahedral copper(I) fragment are: Cu(I)–O(ac) 2.248(4), Cu(I)–S1 2.351(1) Å, and the two with the phosphorus atoms of the tpp ligands are Cu–P1 2.238(1) and Cu–P2 2.277(1) Å.

The packing is formed by ribbons of molecules held together by hydrogen bonds involving the water molecule [N1–H···O1 W 2.936(7) Å 158.8(4)° and O1 W···O1W^{i} 2.982(7) Å i = $-x, -y, -z + 2$] and by a weak interaction between the copper(II) atom with the hydrazine nitrogen atom of a nearby molecule (Cu2···N2^{i} 3.406(5) Å i = $-x + 1, -y, -z + 2$) as can be seen in Fig. 6. These ribbons are then joined together by a 6PE (sixfold phenyl embrace)

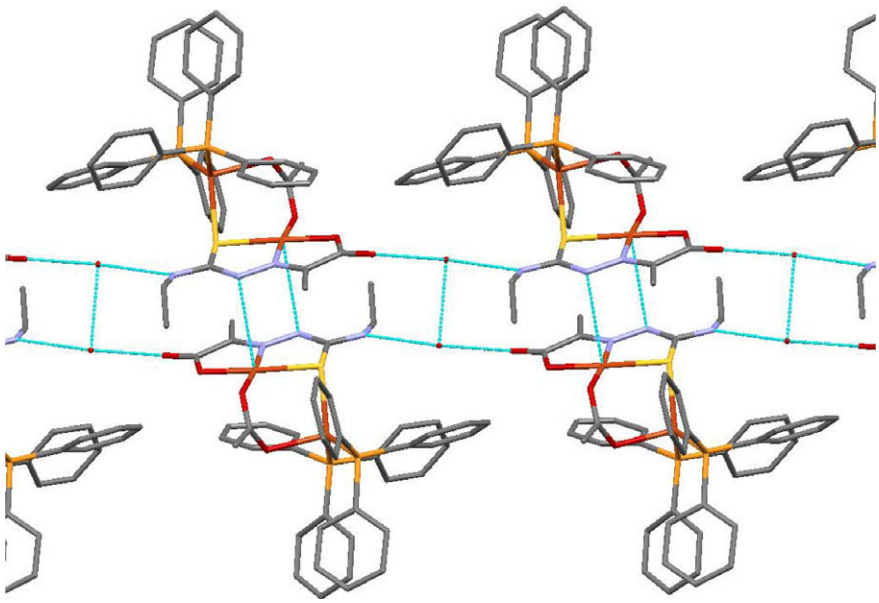

Fig. 6. MERCURY drawing of the packing of compound **4** showing the ribbon of complex molecules held together through hydrogen bonds formed by water molecules and by a long interaction between copper(II) and the hydrazine nitrogen of an adjacent molecule.

interaction with a distance P···P of 7.234 Å that involves the triphenylphosphines.

The crystal structure of compound **6** $[Cu_2(MePh\text{-}mpt)_2(PPh_3)_2]$ is reported in Fig. 7. The asymmetric unit contains two independent enantiomeric complex molecules. Both are planar 2Cu–2S clusters made up of two copper ions with interatomic distances of 2.845(1) and 2.844(1) Å, bridged by two sulfur atoms belonging to two thiosemicarbazone ligands. These ligands are deprotonated and located on the same face of the cluster plane, bind through the sulfur and the iminic nitrogen (see Table 3) and are perpendicular to each other and oriented head to tail (see Fig. 7). The triphenylphosphines are on the opposite side and two phenyls interact edge

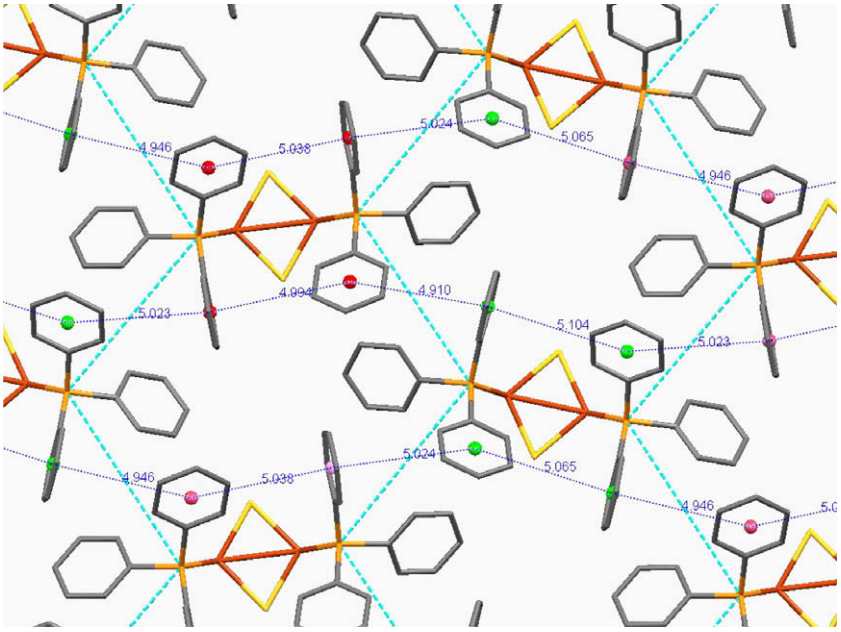

Fig. 8. MERCURY drawing of the packing of compound **6** showing the phenyl–phenyl edge to face interactions extending in the *xy* plane.

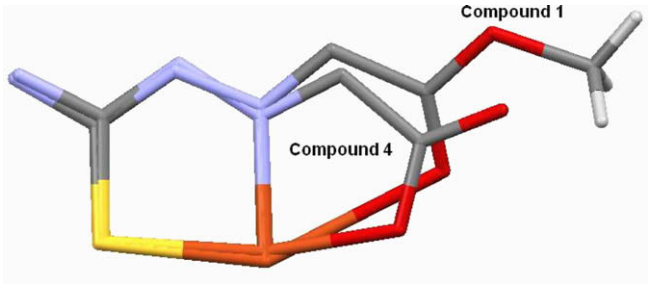

Fig. 9. PLUTON rendering of the methylpyruvate thiosemicarbazone group deformation observed passing from a Cu(I) in **1** to a Cu(II) coordination in **4**.

to face with those of an adjacent molecule forming parallel quadruple phenyl embrace (PQPE) [35–38] (see Fig. 8).

4. Conclusions

Copper(I) ions, with their d^{10} electronic configuration, do not have an energetically preferred geometry and their coordination is therefore mainly governed by steric repulsions. Aside from the two donor species P and S, the remaining space around the copper ion, in bistriphenylphosphine complexes present in the Cambridge Structural Database [39], is usually occupied by a fourth ligand, usually a halide. In previous experiments we have verified that the absence of other soft species can influence the coordination and in particular that the imino nitrogen can become a suitable donor for coordination on a soft metal ion in the absence of softer competitors. What is apparent in the structures reported in this paper is that the control on the coordinating behaviour of a ligand is tuned by a series of factors among which the predominant is the hard soft nature of the atoms involved in the interactions with the metal centre. In our case it is striking the comparison between compounds **1** and **4**. Compound **4** was recalcitrant to crystallisation and the crystals were obtained after many attempts leaving the compound exposed to atmospheric oxygen and moisture. The copper(I) oxidised to copper(II) increases both the acidity of the hydrazine nitrogen stabilizing the anionic form and promotes the hydrolysis of the methyl group from the esther improving the electrophilicity of the carboxyl carbon and speeding up the process of demethylation. This phenomenon of demethylation had been previously observed in a work where an analogous ligand was coordinated by zinc(II) [40]. The ligand is therefore the same but the effects are dramatically different in the coordination of copper(I) versus copper(II). The fairly rigid ligand is markedly deformed upon coordination on copper(II) in **4** (see Fig. 9) to allow the carboxylic oxygen to bind to the metal ion, while it remains almost unaltered upon coordination of copper(I) in **1**.

investigations may be of interest for the multi-purpose rational theoretical design of new magnetic high-spin compounds.

The compound $[Cr_{10}(OCH_3)_{20}(CH_3COO)_{10}]$ ($n = 10$) is well known because of its highly unusual magnetic properties, which were experimentally evaluated [10]. The results of the study show that this compound possesses a very high-spin ground state ($S = 15$). The authors argue that very few examples of ferromagnetic Cr···Cr exchange in such molecular systems had been reported previously [13,14] and, furthermore, there are only four examples of ferromagnetically coupled cyclic complexes of metal ions [15]. From this point of view, compounds that are similar to the above mentioned compounds may serve to obtain a better understanding of some nano-properties of molecular magnets.

The main aim of our study is to investigate the relative stability of $[Cr_n(OCH_3)_{2n}(CH_3COO)_n]$ depending on the number n of its interior groups by means of calculations that are carried out in accordance with well known quantum-chemistry methods such as the HF and DFT approaches.

2. Calculational methods

Carboxylate methoxy clusters of the 'wheel'-type, $[Cr_n(OCH_3)_{2n}(CH_3COO)_n]$ ($n = 4$, 6, 8, 10, 12 and 14), were studied theoretically in order to determine the most stable compound, first. Then the results obtained from the theoretical study were compared with the corresponding experimental data reported previously. All the calculations on their geometries and electronic properties have been performed with the aim of finding the total energy, E_{tot}, and then to determine the ratio E_{tot}/n. The latter value corresponds to one Cr-containing coordination section of these compounds and is considered as a measure of the *relative stability* for the compounds. All the complexes were studied in their ferromagnetic state, which was found as the ground state for the experimentally obtained compound with $n = 10$ [10,12] (spins of all the chromic ions were considered as parallel).

Their geometries were obtained on the basis of the molecular mechanics MM+ method from the GAUSSIAN-03 computational package [19]; for $n = 10$, the data calculated were found to be very close to the known X-ray data [10]. Their electronic properties were calculated by means of the MO LCAO Hartree–Fock–Roothaan and DFT (hybrid B3LYP functional) methods, using the STO-3G and 6-31G(d) basis sets.

3. Results and discussion

The X-ray structure of the molecule $[Cr_{10}(OCH_3)_{20}(CH_3COO)_{10}]$ and the structure found from the MM+ method are both shown in Fig. 1, in two different projections. The values of the geometrical parameters for the model molecule and its X-ray analogue are presented in Table 1.

As one can see from Fig. 1, both projections are very similar to each other except for the positions of the CH_3 groups belonging to the $-OCH_3$ bridges. The CH_3 groups of the X-ray structure are insufficiently oriented inside the ring. However, the data of Table 1 indicate that the average length of the Cr–O bonds found from the MM method correlates with the experimental value well enough. It should be noted that the most substantial difference in bond lengths exists for the Cr–O bonds whose oxygen atoms belong to CH_3COO groups. The average value of the bond lengths is equal to 1.82 Å in the calculated model structure; in the X-ray structure, the lengths considered vary from 1.98 to 2.01 Å. At the same time, different valence and torsion angles, found by means of the MM+ method, are very close to the corresponding experimental values (see the values given in Table 1).

Our package of programs was chosen for the reason that it contains a generic model (in the frameworks of the force field MM+), which can be applied even when some required parameters of the force field are absent. This is a typical situation in coordination compound modeling. When comparing various series of related molecules, this approach gives fully reasonable results and does not require great calculation efforts. However, the *ab initio* HF and DFT methods used in our case for the calculation of the single point energy and especially for the optimization of molecular geometry of large systems that contain transition metal ions and

Table 1

Geometry characteristics	Found by MM+	X-ray data
$Cr-O_{(CH_3COO)}$ (Å)	1.82	1.98–2.01
$Cr-O_{(CH_3O)}$ (Å)	1.87	1.94–1.98
Cr···Cr (Å)	2.90	2.99
$Cr-O_{(OCH_3)}$···Cr (°)	101.50	98.41–99.91
Cr···Cr···Cr (°)	143.99	142.81

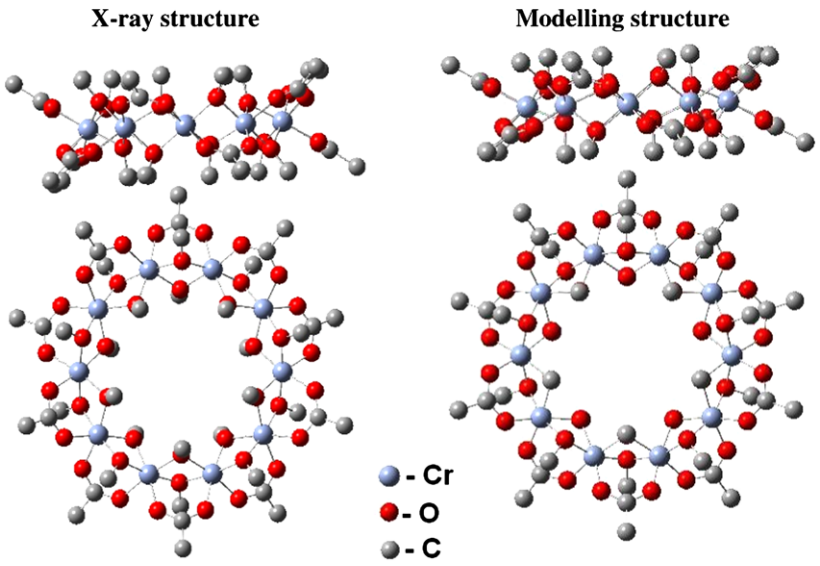

Fig. 1. Two projections of the chromic wheel $[Cr_{10}(OCH_3)_{20}(CH_3COO)_{10}]$ structure (hydrogen atoms omitted for clarity).

labile organic ligands, require huge computational efforts (even for the minimal basis set STO-3G). There is no guarantee that the molecular geometries found from these two methods are better than the geometries obtained on the basis of an adequately selected MM method (see [20]). The electronic characteristics of the compound with $n = 10$ were calculated by both the HF method and DFT from its X-ray geometry, and the geometries obtained by means of the MM+ method and DFT are given in Table 2.

A comparison of the total energies and charge distributions, which have been obtained by means of the two quantum-chemistry methods indicated above, tells us that these values are in good agreement with each other. The charges on the chromium ions vary in the ranges 1.09–1.12 for HF and B3LYP (6-31G(d)) and 0.81–0.87 for B3LYP (STO-3G) basis set, and thus they are far from the formal charge of +3 for the chromium(III) ions. This tells us about the electron density delocalization in the molecular system. The values of the local magnetic moments correspond to three unpaired electrons on any chromium center, which possesses the $3d\uparrow^3 d\downarrow^0$ spin configuration.

Some theoretical electronic characteristics of the compounds with $n = 4$, 6, 8, 10, 12 and 14 calculated by both MO LCAO methods, i.e. HF and DFT (B3LYP), are presented in Table 3. The table contains data on the total molecular energy per one Cr-containing coordination section, E_{tot}/n, and the difference $E_{tot}/n - E_{tot}/10$. $E_{tot}/10$ is the minimal value of the energy of one coordination section for the most stable 'wheel' with $n = 10$. Previously obtained data [10] show that this compound is really being formed under the experimental conditions. It should be noted that calculations with the 6-31G(d) basis also give a lower minimum of energy for $n = 10$ than those with the STO-3G basis. One of the significant advantages of the DFT method, being based on unrestricted determinants for open-shell systems, is that the method is not very prone to "spin contamination", i.e. (S^2) is normally close to $s_z(s_z + 1)$. This is mainly a consequence of electron correlation being included in the single determinantal wave function.

It follows from the calculations that for our systems with three unpaired electrons on each Cr atom, the system multiplicity increases with the growth of number of Cr atoms. Thus, in the series of complexes $[Cr_n(OCH_3)_{2n}(CH_3COO)_n]$ with $n = 4$, 6, 8, 10, 12 and 14, the multiplicity takes the corresponding values equal to 9, 19, 25, 31, 37, 43, and calculated values of S^2 are 22, 90, 156, 240, 342 and 462. The distribution of the spin density in the system with $n = 10$ is shown in Fig. 2.

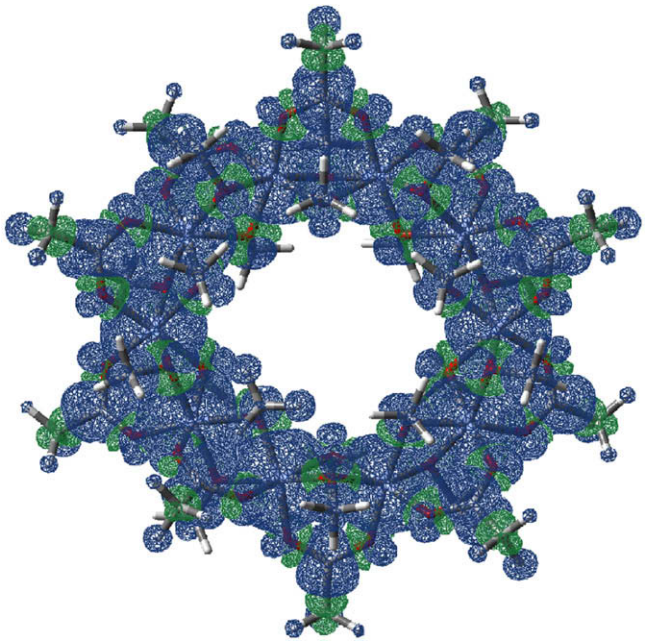

Fig. 2. Spin density distribution for the $[Cr_{10}(OCH_3)_{20}(CH_3COO)_{10}]$ molecule.

To estimate the stability of the systems under study, an analysis of some energy parameters is needed. As follows from Table 3, the E_{tot}/n values that have been calculated by both of the above mentioned methods agree very well with the above given experimental data on the stability of our complexes.

In Fig. 3, one can see the dependence of E_{tot}/n on the number n. It should be noted that the energy values of the compounds with $n = 10$ and $n = 12$ are very close to each other. It means that by changing either the experimental conditions of their syntheses or the molecular volumes of their organic ligands, one can shift the chemical equilibrium to the formation of the desired compound.

In order to understand the reason for the relative stability of $[Cr_n(OCH_3)_{2n}(CH_3COO)_n]$ with $n = 10$ we have compared various electron characteristics of the compounds under study. However, a comparison of characteristics such as atomic charges, spin densities, energies and energy gaps of the MO's of the active zones of the complexes (including their HOMO, LUMO and all the singly occu-

pied MO's, containing the 3d-electrons of the Cr atoms) does not allow us to find any correlations between the above parameters and the relative stability of these compounds.

Luckily, we paid attention to the following circumstance. The X-ray data show [10] that the varying oxygen surroundings of the Cr ions in the structure $[Cr_{10}(OCH_3)_{20}(CH_3COO)_{10}]$ violate the octahedral form. In this connection, we have supposed that possible geometrical distortions of the 'CrO_6' octahedrons in the structures with $n \neq 10$ are more significant than those in the structure with $n = 10$.

As the first stage of our investigation, the following expression was used for the description of the degree of geometrical distortion (δ) of the octahedrons:

$$\delta = 3 * 180 - (\varphi 1 + \varphi 2 + \varphi 3) \quad (1)$$

where φ_i ($i = 1$–3) are the values of the three O–Cr–O angles taken along the three main axes of the octahedrons. A comparison of the data presented in the first line of Table 4 with the data of Table 3 shows, however, that there is no clear-cut correlation between the δ and E_{tot}/n values.

It should be noted that the quantity δ describes geometrical distortions within any coordination octahedron, which must be caused by the electronic repulsion which exists between the electronic pairs belonging to the six Cr–O bonds of the octahedrons. At the same time, there is one more type of electronic repulsion between neighboring coordination units, which belong to any pair of neighboring Cr ions in the compounds under study. In other words, this repulsion exists within any pair of the neighboring coordination sections.

Table 4
The values of the parameters δ and ξ, depending on n.

n	4	6	8	10	12	14
δ (°)	122.163	49.741	34.948	40.001	47.530	55.289
ξ (°)	182.193	109.747	80.008	76.005	77.517	81.006

The total number of such pairs (taken along the wheels considered) equals the number of all Cr-containing coordination sections for any investigated structure. Thus, the influence of this repulsion may be properly taken into account as an addendum to the value of δ that describes the deposit of the above repulsion type relative to one coordination section.

Fig. 4 and Table 1 show that the average repulsion of the coordination units belonging to a pair of their neighboring Cr ions will depend on the average value of the angle $\varphi 4$: Cr–Cr–Cr, where all Cr ions are neighbors. As the Cr–Cr distance remains practically constant (~2.90 Å) for all the investigated structures, it is clear that any decrease in the value of $\varphi 4$ (from the value of 180) will lead to a corresponding increase in the above mentioned repulsion between these coordination units. Thus, bearing in mind all these reasons, we have applied to the description of the total electronic repulsion per coordination section the following quantity, ξ:

$$\xi = 4 * 180 - (\varphi 1 + \varphi 2 + \varphi 3 + \varphi 4) \quad (2)$$

From Table 4 (line 2) and also from a comparison of Figs. 3 and 5, it is seen that the main reason for the compound $[Cr_{10}(OCH_3)_{20}(CH_3COO)_{10}]$ to be relatively stable is that its electronic repulsion per one coordination section takes a minimal

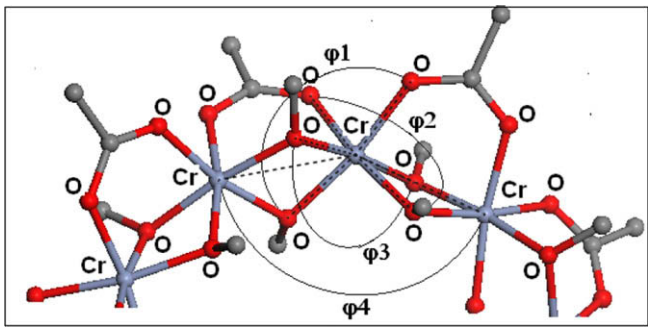

Fig. 4. Angles $\varphi 1$–$\varphi 4$ in a molecular fragment selected for the ξ value calculation.

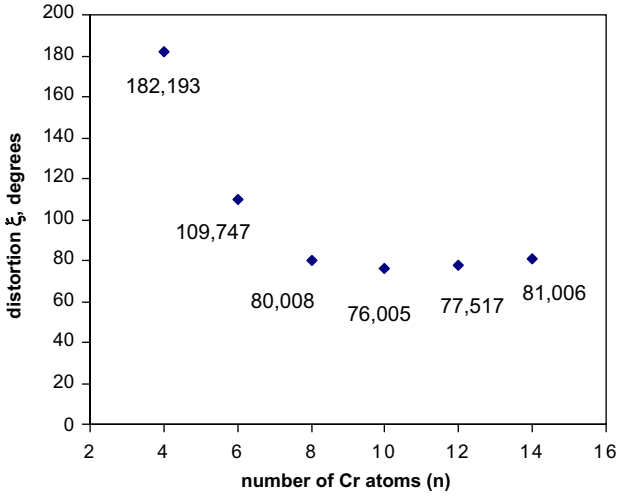

Fig. 5. The ξ vs. n dependence curve.

value. In turn, the electronic repulsion per $\{Cr(OCH_3)_2CH_3COO\}$ coordination section can be properly taken into account for any compound by means of the above given simple geometrical parameter ξ.

4. Conclusion

The results obtained from the study of a series of macro-coordination compounds show that both the HF and DFT methods describe the known experimental data adequately. The values of a simple structural (geometrical) parameter ξ determined from the results of the MM+ method, and data obtained from the quantum-chemistry calculations of the above mentioned nano-clusters, are both in very good agreement with the experimentally known data on the stability of chromic wheels. Hopefully, the parameter ξ can be used in future to forecast the relative stability of different coordination compounds of the wheels type from the nature of their ligands and, perhaps, the nature of their metal ions (i.e. without using voluminous quantum-chemistry calculation methods). However, this assumption requires additional research applied to new series of similar compounds of the wheel-type.

2.3. Synthesis of [(μ-O){ReOCl(amp)}$_2$] (**1**)

To a suspension of 0.100 g (120 μmol) of *trans*-[ReOCl$_3$(PPh$_3$)$_2$] in 20 cm^3 of acetone was added 0.053 g (243 μmol) of Hamp. After the mixture was heated under reflux for 4 h, it was cooled to room temperature and a brown precipitate was removed by filtration. Recrystallization from acetonitrile gave red crystals, which were suitable for X-ray diffraction study. Yield = 71% (0.039 g), m.p. 249 °C. *Anal.* Found: C, 33.92; H, 3.81; N, 6.15. $C_{26}H_{34}Cl_2N_4O_5Re_2$ requires C, 33.73; H, 3.70; N, 6.05%. IR (cm^{-1}): ν(Re=O) 961w, ν(Re–O–Re) 692vs, ν(NH$_2$) 2911 m, 2963 m, ν(Re–NH$_2$) 422 m, ν(Re–N(2)) 449 m, ν(Re–Cl) 312 m. ^{1}H NMR (ppm): 7.82(m, 2H, Ph), 7.38(m, 3H, Ph), 5.64(s, 1H, H(4)), 1.18(d, 1H, H(1)), 1.39(d, 2H, H(2)), 2.03(s, 3H, H(12)), 2.09(s, 3H, H(13)).

2.4. Synthesis of [ReOCl$_2$(ada)] (**2**)

A mass of 0.041 g (240 μmol) of Hada was added to *trans*-[ReOCl$_3$(PPh$_3$)$_2$] (0.100 g, 120 μmol) in 20 cm^3 of methanol under a nitrogen atmosphere. The resulting suspension was heated under reflux for an hour, and then cooled to room temperature. A red-brown precipitate was filtered off. The solvent was reduced to about 3 cm^3, and dark red crystals (unsuitable for X-ray diffraction) appeared upon standing overnight. Recrystallization of the precipitate from dichloromethane/diethyl ether gave dark red plates, which were of a poor quality and an X-ray measurement was not possible. Yield = 48% (0.026 g), m.p. 241 °C. *Anal.* Found: C, 24.83; H, 3.91; N, 6.68. $C_9H_{17}Cl_2N_2O_2Re$ requires C, 24.44; H, 3.87; N, 6.33%. IR (cm^{-1}): ν(Re=O) 966vs, ν(NH$_2$) 2941 m, 2992 m, ν(C=N) 1605vs, ν(Re–N) 451 m, 459 m, ν(Re–Cl) 328 m. ^{1}H NMR (ppm): 3.24(s, 2H, C(6)H$_2$), 2.44(s, 3H, C(4)H$_3$), 1.88(s, 3H, C(9)H$_3$), 1.95(s, 2H, C(7)H$_2$, 1.28(s, 3H, C(11)H$_3$), 0.79 (s, 3H, C(12)H$_3$), 4.22(d, 1H, N(2)H), 4.14(d, 1H, N(2)H).

2.5. Synthesis of fac-[Re(CO)$_3$Br(Hada)] (**3**)

Hada (0.084 g, 493 μmol) was dissolved in 10 cm^3 of ethanol, and added to 0.100 g (246 μmol) of [Re(CO)$_5$Br] in 5 cm^3 of ethanol. The resulting solution was heated under reflux for an hour and then cooled to room temperature. It was filtered and left to evaporate slowly at room temperature. After 4 days light yellow crystals, suitable for X-ray diffraction studies, were collected by filtration. Yield = 62% (0.079 g), m.p. 217–219 °C. *Anal.* Found: C, 27.83; H, 3.61; N, 5.44. $C_{12}H_{18}BrN_2O_4Re$ requires C, 27.70; H, 3.49; N, 5.38%. IR (cm^{-1}): ν(C≡O)$_{fac}$ 2010s, 1902s, ν(NH$_2$) 2937 m, 2980 m, ν(Re–N(1)) 435 m, ν(Re–N(2)) 408 m, ν(C=O) 1622 m. ^{1}H NMR (ppm): 3.34 (s, 2H, C(6)H$_2$), 2.52(s, 3H, C(4)H$_3$), 1.96(s, 3H, C(7)H$_3$), 1.86(s, 2H, C(9)H$_2$), 1.28(s, 3H, C(11)H$_3$), 0.76(s, 3H, C(12)H$_3$), 4.08(d, 1H, N(2)H), 3.90(d, 1H, N(2)H).

2.6. X-ray crystallography

Intensity data collection was performed at 200 K on a Nonius Kappa CCD detector system using the ω scan technique with Mo Kα radiation. Intensities were corrected for Lorentz and polarization effects. The structures were solved by direct methods and were refined by full-matrix least-squares procedures using the SHELXL-97 package [17]. Crystal and structure refinement data for **1** and **3** are given in Table 1. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were idealized and fixed. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. [(μ-O){ReOCl(amp)}$_2$] (**1**)

The complex was synthesized by the reaction of *trans*-[ReOCl$_3$(PPh$_3$)$_2$] with two molar equivalents of Hamp in refluxing acetone in air with trace amounts of water present. It is an established fact that monomeric octahedral oxorhenium(V) complexes prefer the position *trans* to the oxo group to be occupied by an anionic oxygen donor atom like an alcoxide or phenoxide [12,18,19]. Tautomer *c* of amp (Scheme 1) can provide such an oxygen donor (after deprotonation) to produce a monomeric complex of formula [ReOCl$_2$(amp)], as was observed previously with NNO-donor chelates [20–22]. However, the fact that the μ-oxo dimer **1** is formed therefore precludes the existence of amp as the tautomer *c*. Complex **1** is possibly formed *via* the intermediate [ReOCl$_2$(amp)] (with

Scheme 1. Schematic representation and tautomerization of the ligands.

amp in a deprotonated form of tautomer *a* or *b*), with a labile chloride *trans* to the oxo group, which is then substituted by a water molecule, the double deprotonation of which leads to the formation of **1**. The initial occupation of the *trans* site by the anionic oxygen atom of amp would prevent this process of formation. Complex **1** is diamagnetic and a non-electrolyte in DMF, and is only soluble in acetonitrile, DMSO and DMF.

The infrared spectrum of **1** displays the Re=O stretch as a weak band at 961 cm^{-1}. Weak intensity absorptions corresponding to ν(Re=O) have been observed previously for dimeric Re(V) species [23,24]. However, the dominant feature of the spectrum is the presence of a strong and intense absorption at 692 cm^{-1}, ascribed to the asymmetric Re–O–Re stretch [23,24]. The tridentate coordination of amp is manifested by the medium intensity peaks at 449 [ν(Re–N(2)], 422 [ν(Re–NH_2)] and 378 cm^{-1} [ν(Re–O)]. The ^1H NMR spectrum consists of sharp, well-resolved peaks with no detectable paramagnetic shifts or line broadening of signals. The most informative aspect of the spectrum is a one-proton singlet at 5.64 ppm, which is assigned to a single proton on C(4) (see Fig. 1 for atom labelling), implying a C(3)=C(4) double bond and the presence of tautomer *a* in complex **1**. The phenyl protons appear as two multiplets at 7.82 and 7.38 ppm, and the signals of the two methyl groups occur at 2.03 and 2.09 ppm. In addition, there are a two proton signal at 1.39 ppm [C(2)H_2] and a one-proton peak at 1.18 ppm [C(1)H].

The molecular structure of **1** is illustrated in Fig. 1. The axis of the molecule is formed by the O=Re–O–Re=O moiety, with an improper rotation (rotation of 98.93° followed by a reflection) depicting the symmetry of the two halves relative to each other. The corresponding bond lengths and angles of the two [ReOCl(amp)] halves are identical. The Re–O–Re angle is 179.7(3)°, and the two O–Re=O are equal [172.2(2)°], showing significant deviation from linearity (Table 2). Each rhenium atom is centred in an octahedron with the equatorial plane formed by a N_2OCl donor set. The octahedron is severely distorted, with the N(2) and O(1) donor atoms being displaced significantly away from the Re=O(3) bond [O(3)–Re–N(2)=96.6(2)°, O(3)–Re–O(1)=99.2(1)°], while the O(3)–Re–N(1) [89.7(2)°] and O(3)–Re–Cl [91.8(1)°] angles are close to orthogonality. The result of these distortions is an O(3)–Re–O(2) angle of 172.2(2)°, with the Re atom displaced from the mean equatorial plane by 0.162 Å towards the O(3) oxo atom. The axial Re=O(3) and Re–O(2) distances of 1.706(3) and 1.9098(2) Å, respectively, are typical of this backbone. The Re–N(1) bond length of 2.144(4) Å is typical of Re(V)–NH_2 bonds, which vary in the range 2.12–2.20 Å [13]. The Re–N(2) length of 2.042(4) Å falls within the range observed [1.94(1)–2.05(1) Å] for rhenium(V)–amide bonds [27–30], implying that N(2) is deprotonated. Bond lengths of neutral secondary amine and imine nitrogens to rhenium(V) fall in the range 2.08–2.15 Å, with an average value of 2.11(1) Å [23–32]. The amp ligand therefore acts as a monoanionic tridentate chelate, with coordination through the neutral amino group N(1)H_2, the deprotonated amido nitrogen N(2), and the neutral ketonic oxygen O(1) [Re–O(1) = 2.028(3) Å], as depicted as tautomer *a* in Scheme 1.

The intraligand bond distances illustrate π-delocalization in the phenyl rings [average C–C distance = 1.384(9) Å]. The C(1)–N(1) bond is single [1.482(6) Å], with the bond angles around C(1) typical of sp^3 hybridization. There is considerable π-delocalization over the N(2)–C(3)–C(4)–C(5) backbone of amp, with bond lengths longer than formal double bonds, but shorter than typical C–C and C–N single bonds. The C(5)–O(1) bond length of 1.298(5) Å is considerably shorter than single C–O^- bond lengths in octahedral

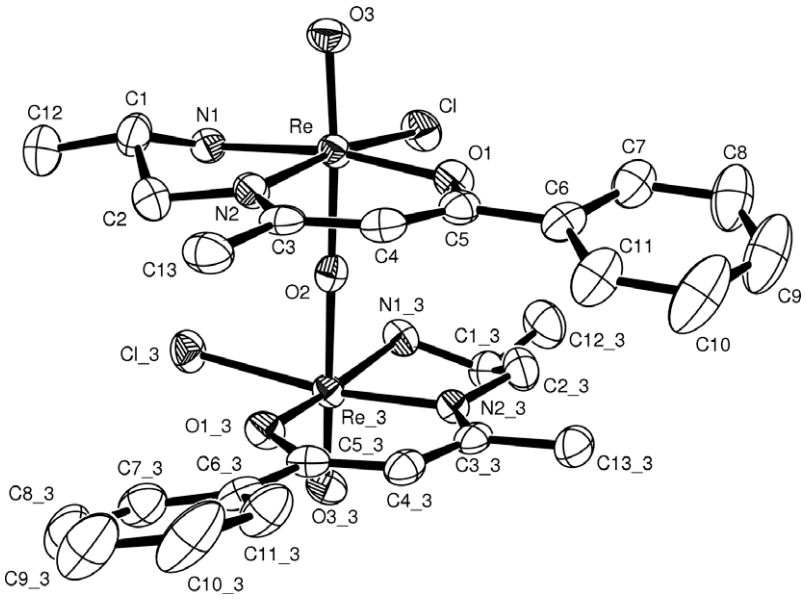

Fig. 1. Structure of complex **1**. Thermal ellipsoids are shown at 50% probability, and hydrogen atoms are omitted for clarity.

rhenium(V) complexes with the oxygen coordinated *cis* to the oxo group [average 1.35(1) Å] [10–15], but longer than the uncoordinated ketonic C=O group in complex **3** [1.22(1) Å]. The bite angle formed by the six-membered metallocycle [O(1)–Re–N(2) = 92.9(1)°] is, as expected, larger than the bite angle of the five-membered one [N(1)–Re–N(2) = 81.3(2)°]. The spatial arrangement of the phenyl rings is governed by the intramolecular hydrogen bond C(7)H···O(1) and the intermolecular bonds C(8)H···Cl and C(10)H···Cl (see Table 3).

A previous study of an oxorhenium(V) complex with the acetylacetone-derived Schiff base, the tridentate ONS-donor ligand 4-[2-(methylthio)aniline]-3-penten-2-one (Hmap), had led to the isolation of the product (n-Bu_4 N)[$ReOCl_3$(map)] (**4**) [12c]. The X-ray crystal structure shows that the map ligand is coordinated bidentately as a monoanionic N,O-donor, with a dangling thioether functionality. This result corresponds to the existence of tautomer *c* in **4,** in which the phenolate group is deprotonated.

3.2. [$ReOCl_2$(ada)] (**2**)

Complex **2** was prepared by the reaction of *trans*-[$ReOCl_3(PPh_3)_2$] with a twofold molar excess of Hada in methanol. With equimolar ratios of reactants, only the product [$ReOCl_2$(OMe)$(PPh_3)_2$] was isolated.

Table 3
Hydrogen bonding distances (Å) and angles (°) for **1** and **3**.

D–H···A	D–H	H···A	D···A	∠D–H···A
1				
N(1)–H(1A)···O(3)	0.92	2.23	3.144(5)	174
N(1)–H(1B)···Cl	0.92	2.51	3.388(4)	160
C(7)–H···O(1)	0.95	2.32	2.659(7)	100
C(8)–H···Cl	0.95	2.81	3.665(7)	149
C(10)–H···Cl	0.95	2.73	3.497(6)	138
3				
N(2)–H(2A)···O(3)	0.92	2.50	3.243(8)	138
N(2)–H(2B)···Br	0.92	2.58	3.491(5)	171
C(6)–H(6A)···Br	0.99	2.93	3.859(8)	157
C(6)–H(6B)···O(4)	0.99	2.57	2.97(1)	104
C(9)–H(9A)···Br	0.99	2.92	3.474(7)	116

Spectroscopic evidence suggests that ada acts as a tridentate N_2O-donor chelate, with deprotonation of the alcoholate oxygen to coordinate as tautomer *c* (Scheme 1) in the complex. In the infrared spectrum the asymmetric Re=O stretching frequency appears as a very strong band at 966 cm^{-1}, which falls in the range (947–968 cm^{-1}) normally observed for neutral six-coordinate monooxorhenium(V) complexes with an anionic oxygen atom coordinated *trans* to the oxo group [11,12,18–22]. An absorption at 328 cm^{-1}, with a shoulder at 322 cm^{-1}, is observed for ν(Re–Cl), which falls outside the range of 295−310 cm^{-1} observed for complexes with the chloride coordinated *trans* to the oxo group. A very strong band at 1605 cm^{-1} is typical of ν(C=N), and medium intensity bands at 2941 and 2992 cm^{-1} indicates the presence of the neutral amino group.

3.3. *fac*-[$Re(CO)_3Br$(Hada)] (**3**)

The rhenium(I) complex was prepared by the reaction of [$Re(CO)_5Br$] with two equivalents of Hada in refluxing ethanol. The infrared spectrum exhibits a sharp, strong band at 2010 cm^{-1} and a broad, intense absorption at 1902 cm^{-1}, attributed to ν(C–O) of the *fac*-$[Re(CO)_3]^+$ unit [33,34]. Two medium intensity peaks at 435 and 408 cm^{-1} are assigned to ν(Re–N(1)) and ν(Re–N(2)H_2), respectively. In the ^{1}H NMR spectrum four three-proton singlets are observed for the methyl groups, and two two-proton singlets appear at 3.34 and 1.86 ppm for the methylene groups. Interestingly, two one-proton doublets are observed for the N(2)H_2 protons, which are hydrogen-bonded to O(3) and Br in the solid state (see Table 3).

A perspective view of the asymmetric unit is shown in Fig. 2. The X-ray results show that the complex contains the chemically robust *fac*-$[Re(CO)_3]^+$ core in a distorted octahedral geometry. The metal is coordinated to three carbonyl donors in a *facial* orientation, to the neutral amino nitrogen N(2), the imino nitrogen N(1), and a bromide. The ketonic oxygen O(4) is uncoordinated. The Re–CO bond distances [average of 1.911(8) Å] fall in the range observed [1.900(2)–1.928(2) Å] for similar complexes [35,36]. The Re–N(1) bond [2.218(5) Å] is marginally longer than the Re–N(2) one [2.194(5) Å], and they are typical to other similar bonds [25,26,37]. The distortion from octahedral ideality in the complex is mainly the result of the *trans* angles, which fall in the range

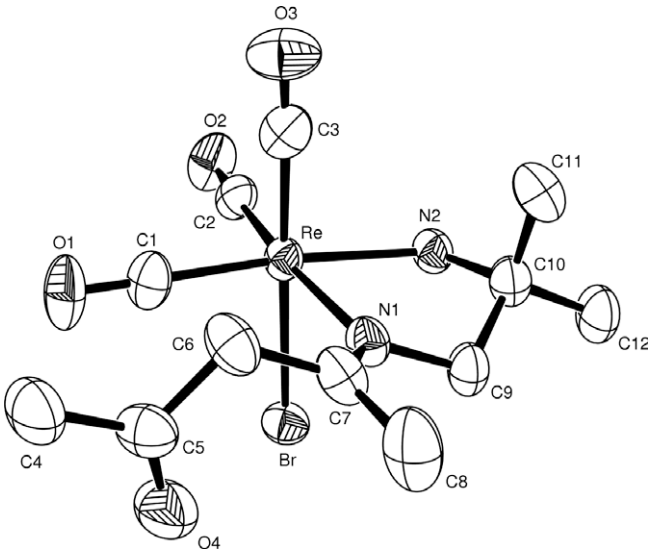

Fig. 2. ORTEP drawing of complex **3** with numbering scheme.

170.6(2)–178.7(2)° (Table 2). These distortions are mainly the result of the constraints imposed by the bidentate coordination of Hada, which has a bite angle of 77.0(2)°. As a result the bromide distorts the two nitrogen atoms less [average Br–Re–N angle is 84.0(1)°] than the two carbonyl carbons [average Br–Re–C angle is 91.5(2)°].

The Hada intraligand bonding distances confirm its coordination to the metal as the neutral tautomeric form *b* in Scheme 1. The two double bonds in Hada are C(5)–O(4) [1.22(1) Å] and C(7)–N(1) [1.292(8) Å], with the O(4)–C(5)–C(6) and C(7)–N(1)–C(9) bond angles equal to 121.9(7)° and 118.2(5)°, respectively. All the other bonds are single, and all the carbon atoms (except C(5) and C(7)) are sp^3 hybridized.

In addition to those formed by the amine group, there are also the intramolecular hydrogen bonds C(6)H(A)···Br, C(6)H(A)···O(4) and C(9)H···Br (see Table 3).

Previously, the reaction of $[Re(CO)_5Cl]$ with the potential tridentate ligand 1-amino-1'-hydroxybinaphthyl (H_2ahb) produced $[Re(CO)_3(Hahb)(H_2O)]$, in which Hahb acts as a monoanionic bidentate N,O-donor chelate *via* the coordination of an imine nitrogen and deprotonated oxygen atom [1d].

4. Conclusion

The characterization of the product $[(\mu\text{-}O)\{ReOCl(amp)\}_2]$ from the reaction of *trans*-$[ReOCl_3(PPh_3)_2]$ with the benzoylacetone-derived ketoamine ligand Hamp shows that the latter is coordinated as a monoanionic NNO-donor chelate in the tautomeric form *a* (Scheme 1). By repeating this reaction with Hada in methanol under nitrogen, $[ReOCl_2(ada)]$ was isolated as product, in which ada is coordinated tridentately as tautomer *c*, with an anionic alcoholate oxygen atom *trans* to the oxo group. However, the reaction of $[Re(CO)_5Br]$ and Hada gives *fac*-$[Re(CO)_3Br(Hada)]$, with Hada coordinated as a neutral bidentate NN-donor as tautomer *b*.

Supplementary data

CCDC 708330 and 708331 contain the supplementary crystallographic data for **1** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

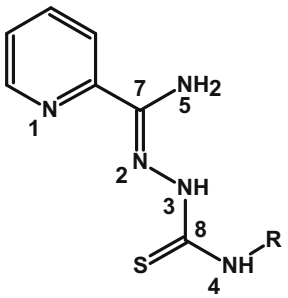

Fig. 1. Generic structure of 2-pyridineformamide thiosemicarbazones.

source at room temperature. The samples were analyzed at 80 K. All spectra were computer-fitted assuming Lorentzian curves.

Tin tetrachloride (Sigma–Aldrich), 2-cyanopyridine (Sigma–Aldrich), thiosemicarbazide (Sigma–Aldrich) and its *N*(4)-methyl (Sigma–Aldrich), *N*(4)-ethyl (Sigma–Aldrich) and *N*(4)-phenyl (Merck) derivatives were purchased and used without further purification. All other chemicals and solvents were of analytical grade.

2.2. Synthesis of [Sn(2Am4DH)Cl_3] (**1**), [Sn(2Am4Me)Cl_3] (**2**), [Sn(2Am4Et)Cl_3] (**3**) and [Sn(2Am4Ph)Cl_3] (**4**)

The 2-pyridineformamide thiosemicarbazones were prepared as described in the literature [15]. The tin(IV) complexes were obtained by stirring an ethanol solution of the desired ligand (3.0 mmol) with a slight excess of $SnCl_4$. The solids were washed with diethylether and then dried *in vacuo*. Crystals of complexes **1** and **2** suitable for X-ray diffraction were obtained by crystallization from ethanol.

2.2.1. Trichloro(2-pyridineformamide-thiosemicarbazonato)tin(IV) [Sn(2Am4DH)Cl_3] (**1**)

Yellow solid. *Anal. Calc. for* $C_7H_8Cl_3N_5SSn$ (419.30): C, 20.05; H, 1.92; N, 16.70. Found: C, 20.07; H, 1.77; N, 16.37%. Molar conductivity (1×10^{-3} mol L^{-1} DMF): 16.0 Ω^{-1} cm^2 mol^{-1}. Melt point: 283–284 °C. IR (CsI/nujol, cm^{-1}): *ν*(NH) 3456s, *ν*(C=N) 1652s, *ν*(CS) 718 m, ρ(py) 645 m, *ν*(M–N) 383 m, *ν*(M–S) 339 m, *ν*(M–Npy) 326 m, *ν*(M–Cl) 290w 258w. The main signals in ^{1}H NMR (DMSO-d_6): *δ* (ppm) = 9.09 (1H, d, H6), 8.16 (1H, t, H5), 8.61 (1H, t, H4), 8.70 (1H, d, H3), 7.23 (2H, s, N4H), 8.6–8.0 (2H, broad, N5H). ^{13}C NMR (DMSO-d_6): *δ* (ppm) = 162.30 (C8), 138.10 (C7), 144.26 (C6), 129.07 (C5), 144.11 (C4), 123.61 (C3), 141.70 (C2). ^{119}Sn NMR (DMSO-d_6): *δ* (ppm) = −480 (s). Yield 65%.

2.2.2. Trichloro(N(4)-methyl-2-pyridineformamide-thiosemicarbazonato)tin(IV) [Sn(2Am4Me)Cl_3] (**2**)

Yellow solid. *Anal.* Calc. for $C_8H_{10}Cl_3N_5SSn$ (433.33): C, 22.17; H, 2.33; N, 16.16. Found: C, 22.25; H, 2.22; N, 16.08%. Molar conductivity (1×10^{-3} mol L^{-1} DMF): 17.1 Ω^{-1} cm^2 mol^{-1}. Melt point: 291–292 °C. IR (CsI/nujol, cm^{-1}): *ν*(NH) 3437 m, *ν*(C=N) 1652 m, *ν*(CS) 768 m, ρ(py) 612 m, *ν*(M–N) 391w, *ν*(M–S) 329w, *ν*(M–Npy) 326w, *ν*(M–Cl) 290w, 279w. The main signals in ^{1}H NMR (DMSO-d_6): *δ* (ppm) = 9.08 (1H, d, H6), 8.15 (1H, t, H5), 8.62 (1H, t, H4), 8.72 (1H, d, H3), 7.71 (1H, q, N4H), 8.8–7.9 (2H, broad, N5H), 2.97 (3H, d, H9). ^{13}C NMR (DMSO-d_6): *δ* (ppm) = 29.09 (C9), 161.06 (C8), 138.15 (C7), 144.28 (C6), 129.07 (C5), 144.11 (C4), 123.55 (C3), 141.94 (C2). ^{119}Sn NMR (DMSO-d_6): *δ* (ppm) = −486 (s). Yield 68%.

2.2.3. Trichloro(N(4)-ethyl-2-pyridineformamide-thiosemicarbazonato)tin(IV) [Sn(2Am4Et)Cl_3] (**3**)

Yellow solid. *Anal.* Calc. for $C_9H_{12}Cl_3N_5SSn$ (447.36): C, 24.16; H, 2.70; N, 15.65. Found: C, 24.20; H, 2.48; N, 15.25%. Molar conductivity (1×10^{-3} mol L^{-1} DMF): 15.3 Ω^{-1} cm^2 mol^{-1}. Melt point: 296–297 °C. IR (CsI/nujol, cm^{-1}): *ν*(NH) 3425 m, *ν*(CN) 1655 m, *ν*(CS) 782 m, ρ(py) 605w, *ν*(M–N) 402w, *ν*(M–S) 345w, *ν*(M–Npy) 315w, *ν*(M–Cl) 288w. The main signals in ^{1}H NMR (DMSO-d_6): *δ* (ppm) = 9.10 (1H, d, H6), 8.16 (1H, t, H5), 8.61 (1H, t, H4), 873 (1H, d, H3), 7.71 (1H, t, N4H), 8.33 (2H, broad, N5H), 3.53 (2H, m, H9), 1.18 (3H, t, H10). ^{13}C NMR (DMSO-d_6): *δ* (ppm) = 14.61 (C10), 37.36 (C9), 160.65 (C8), 138.56 (C7), 144.68 (C6), 129.44(C5), 144.29 (C4), 123.94 (C3), 142.20 (C2). ^{119}Sn NMR (DMSO-d_6): *δ* (ppm) = −483(s). Yield 74%.

2.2.4. Trichloro(N(4)-phenyl-2-pyridineformamide-thiosemicarbazonato)tin(IV) [Sn(2Am4Ph)Cl_3] (**4**)

Yellow solid. *Anal.* Calc. for $C_{13}H_{12}Cl_3N_5SSn$ (495.40): C, 31.52; H, 2.44; N, 14.14. Found: C, 31.82; H, 2.52; N, 14.08%. Molar conductivity (1×10^{-3} mol L^{-1} DMF): 13.2 Ω^{-1} cm^2 mol^{-1}. Melt point: 296–297 °C. IR (CsI/nujol, cm^{-1}): *ν*(NH) 3424 m, *ν*(CN) 1655 m, *ν*(CS) 761 m, ρ(py) 653w, *ν*(M–N) 411w, *ν*(M–S) 355w, *ν*(M–Npy) 305w, *ν*(M–Cl) 290w. The main signals in ^{1}H NMR (DMSO-d_6): *δ* (ppm) = 9.15 (1H, d, H6), 8.22 (1H, t, H5), 8.68 (1H, t, H4), 8.86 (1H, d, H3), 9.80 (1H, s, N4H), 8.55 (2H, broad, N5H), 7.79 (2H, d, H10,14), 7.34 (2H, t, H11,13), 7.04 (1H, t, H12). ^{13}C NMR (DMSO-d_6): *δ* (ppm) = 119.89 (C14, C10), 128.79 (C13, C11), 122.42 (C12), 139.79 (C9), 157.66 (C8), 137.82 (C7), 144.33 (C6), 129.58 (C5), 144.33 (C4), 124.22 (C3), 143.44 (C2). ^{119}Sn NMR (DMSO-d_6): *δ* (ppm) = −491(s). Yield 71%.

2.3. X-ray crystallography

Crystals of [Sn(2Am4DH)Cl_3] (**1**) and [Sn(2Am4Me)Cl_3] (**2**) were mounted on a glass fiber and used for data collection. Crystal data were collected at 293(2) K, using a Bruker SMART CCD 1000 diffractometer [25]. Graphite monochromated Mo Kα radiation (*λ* = 0.71073 Å) was used throughout. The data were processed with SAINT [25], and corrected for absorption [26]. The structures were solved by direct methods using the program SHELXS-97 [27] and refined by full-matrix least-squares techniques againts F^2 using SHELXL-97 [28]. Positional and anisotropic atomic displacement parameters were refined for all non hydrogen atoms. Hydrogen atoms were located in difference maps and included as fixed contributions riding on attached atoms with isotropic thermal parameters 1.2 times those of their carrier atoms. Criteria of a satisfactory complete analysis were the ratios of rms shift to standard deviation less than 0.001 and no significant features in final difference maps. Molecular graphics were obtained from PLATON [29] and SCHAKAL [30]. A summary of the crystals data, experimental details and refinement results are listed in Table 1.

2.4. In vitro antimicrobial activity

Antifungal activity was evaluated by minimum inhibitory concentration (MIC) using the macrodilution test [31]. *Candida albicans* ATCC18804 stored in Sabouraud broth was subcultured for testing in the same medium and grown at 37 °C. Then, the yeast cells were suspended according to the McFarland protocol [31] in saline solution, to produce a suspension of about 10^5 CFU (colony-forming units) mL^{-1}. Serial dilutions of the compounds, previously dissolved in dimethyl sulfoxide (DMSO), were prepared in test tubes to final concentrations of 512, 256, 128, 64, 32, 16, 8, 4, 2 and 1 mg mL^{-1}. A 24-h old inoculum (100 μL) was added to each tube. The MIC, defined as the lowest concentration of the compound which inhibits the visible growth after 18 h, was determined visu-

Table 1
Crystal data and refinement results for [Sn(2Am4DH)Cl_3] (**1**) and [Sn(2Am4Me)Cl_3] (**2**).

Compound	[Sn(2Am4DH)Cl_3]	[Sn(2Am4Me)Cl_3]
Empirical formula	$C_7H_8Cl_3N_5SSn$	$C_8H_{10}Cl_3N_5SSn$

ally after incubation for 18 h at 37 °C. Tests using fluconazole as reference and DMSO as negative control were carried out in parallel. No inhibition was observed with 5% v/v DMSO. All tests were performed in triplicates with full agreement between the results.

Antibacterial activity was evaluated by minimum inhibitory concentration (MIC) using the macrodilution test [32]. *Pseudomonas aeruginosa* ATCC27853 stored in Brain Heart Infusion (BHI) broth were subcultured for testing in the same medium and grown at 37 °C. Then the bacterial cells were suspended, according to the McFarland protocol [32] in saline solution, to produce a suspension of about 10^5 CFU mL^{-1}. Serial dilutions of the compounds, previously dissolved in DMSO, were prepared in test tubes to final concentrations of 512, 256, 128, 64, 32, 16, 8, 4, 2 and 1 mg mL^{-1}. A 24-h old inoculum (100 μL) was added to each tube. The MIC, defined as the lowest concentration of the test compound, which inhibits the visible growth after 20 h, was determined visually after incubation for 20 h at 37 °C. Tests using tetracycline as reference and DMSO as negative control were carried out in parallel. All tests were performed in triplicates with full agreement between the results.

2.5. Assay of toxicity against Artemia salina

The *A. salina* (brine shrimp) lethality test was employed as an antitumor prescreen. Lethality towards brine shrimp was assayed using procedures related in the literature [33,34]. Lethal dose (LD_{50}) is the amount of a substance which causes the death of 50% of a group of test animals. Determination of LD_{50} is an indication of the short-term poisoning potential (acute toxicity) of a compound.

Artemia salina encysted eggs (10 mg) were incubated in 500 mL of seawater under artificial light at 28 °C, pH 7–8. After incubation for 24 h, nauplii were collected with a Pasteur pipette and kept for an additional 24 h under the same conditions to reach the metanauplii stage. The samples to be assayed were dissolved in 1% DMSO (dimethylsulfoxide) and diluted in five different concentrations in seawater. About 10 nauplii were added to each set of tubes containing the samples. Controls containing 1% DMSO in seawater were included in each experiment. Forty-eight hours later, the number of survivors was counted, recorded and the lethal dose 50% (LD_{50} value) and 95% confidence intervals were calculated by Probit analysis [35]. The repeatability of the method was evaluated using nine replicates of concentration of each sample.

3. Results and discussion

Microanalyses and molar conductivity data suggest the formation of the following complexes: [Sn(2Am4DH)Cl_3] (**1**), [Sn(2Am4Me)Cl_3] (**2**), [Sn(2Am4Et)Cl_3] (**3**) and [Sn(2Am4Ph)Cl_3] (**4**), in which an anionic thiosemicarbazone is attached to the metal centre and the remaining coordination sites are occupied by three chloride ions. Diffraction X-ray analysis confirms the structures of **1** and **2.**

3.1. Spectroscopic characterization

The vibrations attributed to ν(C=N) at 1663–1587 cm^{-1} in the infrared spectra of the free thiosemicarbazones shift to 1655–1652 cm^{-1} in the spectra of complexes **1–4**, in agreement with coordination of the azomethine nitrogen [10,11,13,14]. The ν(C=S) absorption which lays at 860–854 cm^{-1} in the spectra of the ligands shifts to 768–718 cm^{-1} in the spectra of complexes **1–4**, hence indicating coordination of the sulfur. The 92–136 cm^{-1} shift is compatible with complexation upon deprotonation and formation of a thiolate sulfur [10,13,14]. The in-plane deformation mode of the pyridine ring at 618–600 cm^{-1} in the spectra of the uncomplexed thiosemicarbazones shifts to 653–605 cm^{-1} in complexes **1–4** suggesting coordination of the hetero-aromatic nitrogen [10,11,13,14].

In the spectra of **1–4** the absorptions at 383 and 411 cm^{-1} were assigned to the ν(Sn–N_{imine}) vibration mode. Bands at 329 and 355 cm^{-1} were attributed to ν(Sn–S), and the absorptions at 305–326 cm^{-1} and 258–290 cm^{-1} were attributed to the ν(Sn–Npy) and ν(Sn–Cl) modes, respectively [10,14].

Therefore, the thiosemicarbazones are attached to the metal through the N_{py}–N–S chelating system and chloride ions occupy the remaining coordination positions.

NMR spectra of the thiosemicarbazones and their tin(IV) complexes were recorded in DMSO-d_6 because this is the only solvent in which the free thiosemicarnazones and complexes are soluble. The ^{1}H resonances were assigned on the basis of chemical shifts, multiplicities and coupling constants. The carbon type (C, CH) was determined by using distortionless enhancement by polarization transfer (DEPT135) experiments. The assignments of the protonated carbons were made by 2D hetero-nuclear multiple quantum coherence experiments (HMQC). A ^{119}Sn NMR study was performed for all complexes.

In the ^{1}H spectra of the uncomplexed thiosemicarbazones the N3–H chemical shifts in DMSO-d_6 occur at δ 10.45–10.05 ppm, indicating hydrogen bonding with the solvent [10–14]. This signal is absent in the spectra of **1–4**, according to deprotonation and formation of an anionic ligand. Upon coordination the signals of the pyridine hydrogens undergo significant shifts. Variations also occur in the ^{13}C NMR spectrum for the signals of C8, C7 and the pyridine carbons, in accordance with coordination of the sulfur, the imine nitrogen and the hetero-aromatic nitrogen, leading to

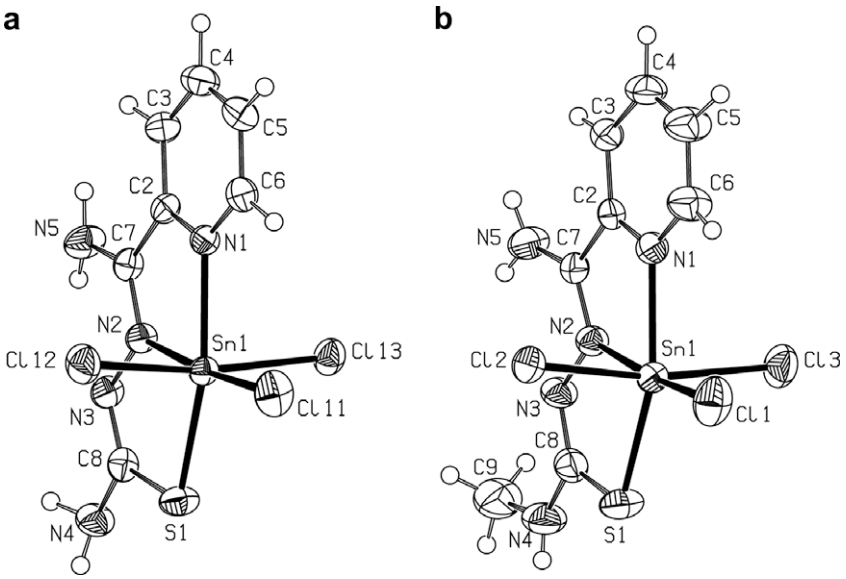

Fig. 2. Molecular plot of [Sn(2Am4DH)Cl_3] (**1**) and [Sn(2Am4Me)Cl_3] (**2**) showing the labeling scheme of the non-H atoms and their displacement ellipsoids at the 50% probability level.

compounds in which the thiosemicarbazone adopts the *E* configuration in relation to the C7–N2 bond.

In the ^{119}Sn NMR spectra of complexes **1**–**4** (DMSO-d_6) only one signal was observed at $\delta = -480$ (**1**), $\delta = -486$ (**2**), $\delta = -483$ (**3**) and $\delta = -491$ (**4**) ppm, compatible with the presence of one tin site. The values of the ^{119}Sn signal are in agreement with data reported in the literature for hexa-coordinated tin complexes [6]. In previous works, we found δ in the –(471–491) ppm range in the same solvent for [Sn(L)Cl_3] (HL = 2-benzoylpyridine-derived thiosemicarbazones) [6,7,13] which also contain an anionic tridentate thiosemicarbazone along with three chloride ions in the metal coordination sphere.

The Mössbauer isomer shifts are very similar for the four complexes, in agreement with the similar s-density around the metal centre in the three compounds. The isomer shifts decrease upon coordination due to the variation in the percentage of s-character as tin changes from approximately sp^3 hybridization (25% s-character) in the tin salt to sp^3d^2 (17% s-character) in the octahedral complexes **1**–**4** [6,7,13]. Hence, δ-values are 0.82(1) mm s^{-1} for $SnCl_4$ [7] and 0.58(5), 0.61(5), 0.63(5) and 0.55(5) mm s^{-1} for **1**–**4,** respectively.

Table 2
Selected bond lengths and angles for [Sn(2Am4DH)Cl_3] (**1**) and [Sn(2Am4Me)Cl_3] (**2**).

Bond	(**1**) (Å)	(**2**) (Å)	Angle	(**1**) (°)	(**2**) (°)

Sn–S1	2.466(1)	2.451(1)	N1–Sn–Cl1	100.38(8)	99.43(7)
Sn–N1	2.240(3)	2.234(3)	N1–Sn–Cl2	88.32(8)	84.27(7)
Sn–N2	2.136(3)	2.148(3)	N1–Sn–Cl3	83.32(8)	85.93(7)
Sn–Cl1	2.368(1)	2.358(1)	N2–Sn–S1	79.81(8)	79.97(7)
Sn–Cl2	2.414(1)	2.4614(9)	N2–Sn–Cl1	174.13(8)	171.88(8)
Sn–Cl3	2.464(1)	2.4297(9)	N2–Sn–Cl2	89.04(9)	87.43(7)
			N2–Sn–Cl3	90.88(9)	94.30(7)
			Cl1–Sn–Cl2	90.35(4)	88.01(3)
			Cl1–Sn–Cl3	88.85(4)	88.93(4)
			Cl2–Sn–Cl3	171.32(3)	169.11(3)

The quadrupole splitting values for **1**–**4** were 0.46(5), 0.55(5), 0.58(5) and 0.67(5) mm s^{-1}, respectively, suggesting an increase in asymmetry of charge distribution with increasing the volume of the substituent attached to N4. This variation is probably due to spatial effects but differences in the electronic contribution among the three groups could also take place.

3.2. X-ray diffraction analysis

In Fig. 2 are perspective views of [Sn(2Am4DH)Cl_3] (**1**) and [Sn(2Am4Me)Cl_3] (**2**)**.** Selected intra-molecular bond distances and angles for **1** and **2** are given in Table 2. The distances and angles observed for the two compounds are very similar (see Table 2). In the two complexes tin(IV) is coordinated by a tridentate anionic ligand and three chloride ions in a distorted octahedral environment.

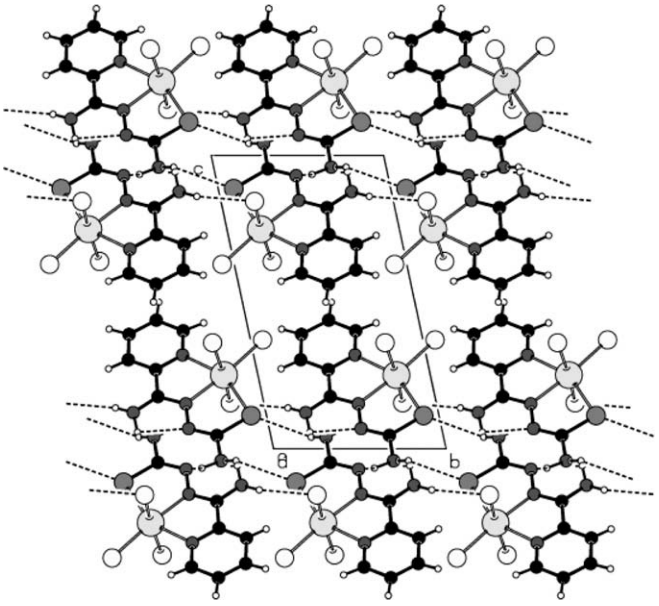

Fig. 3. Molecular packing of [Sn(2Am4DH)Cl_3] (**1**) showing the labeling scheme of the non-H atoms and their displacement ellipsoids at the 50% probability level.

Table 3
Hydrogen bonds distances (Å) and angles (°) for [Sn(2Am4DH)Cl_3] (**1**), [Sn(2Am4-Me)Cl_3] (**2**), with d(H···A) < *r* (Å) + 2.00 Å and <D–H···A> 110°.

	N5–H5B···Cl3	0.89	2.51	3.316(3)	151.9	[*x*, *y* − 1, *z*]
(**2**)	N4–H4A···Cl2	0.77	2.70	3.381(3)	148.7	[−*x* + 1, −*y* + 1, −*z* + 1]
	N5–H5A···Cl1	0.79	2.84	3.511(3)	143.0	[*x*, *y* − 1, *z*]
	N5–H5B···Cl3	0.80	2.83	3.474(3)	139.5	[−*x*, −*y* + 1, −*z* + 1]
	N5–H5B···Cl2	0.80	2.91	3.577(3)	142.4	[−*x* + 1/2, *y*−1/2, −*z* + 3/2]

Molecular structures of H2Am4DH and H2Am4Me have been determined previously [15,17]. The expected lengthening of the C8–S bonds from 1.698 Å in H2Am4DH [15] to 1.768(4) Å in **1** and from 1.699 Å in H2Am4Me [17] to 1.753(2) Å in **2**, together with the shortening of the N3–C8 bonds from 1.340 Å and 1.358 Å in H2Am4DH and H2Am4Me to 1.302(4) and 1.306(4) Å in **1** and **2,** respectively were observed. Therefore, the C8–S bond changes from a double to a predominantly single bond whereas N3–C8 acquires some double bond character. The bond distances between tin and the imine nitrogens, 2.136(3) Å in **1** and 2.148(3) Å in **2**, are slightly shorter than the distance between tin and the pyridine nitrogen, 2.240(3) Å in **1** and 2.234(3) Å in **2**.

A twisting of approximately 180° in the N3–C8 bond of the thiosemicarbazone to match the steric requirements of tridentate coordination was evidenced. Hence, some angles undergo significant changes on complexation. The C8–N3–N2 angle goes from 118.4° in H2Am4DH [15] to 115.1(3)° in **1** and from 117.2° in H2Am4Me [17] to 114.6(3)° in **2**; N3–C8–S goes from *ca.* 120.1° in the free bases [15,17] to 127.4(2)° in **1** and to 127.5(3)° in **2**; N4–C8–S varies from *ca.* 123.5° in the free bases [15,17] to 115.3(3)° in **1** and to 114.5(3)° in **2**. In complexes **1** and **2,** the metal is located in a pseudo-octahedral environment in which the N1–Sn–S1 angle (*ca.* 153°) deviates markedly from the ideal value of 180°. The N2–Sn–Cl1 and Cl2–Sn–Cl3 angles are aproximately 170°.

The molecular packing of [Sn(2Am4DH)Cl_3] (**1**) (Fig. 3) reveals that a number of weak inter-molecular hydrogen bonds occur between N4–H and different atoms: Cl3, N3 and S1, and N5–H and Cl3 (see Table 3). In the molecular packing of [Sn(2Am4Me)Cl_3] (**2**) (Fig. 4) only inter-molecular hydrogen bonds involving N4–H, N5–H and chlorine atoms of neighboring chains occur (see Table 3). In both cases these interactions give rise to bi-dimensional networks.

3.3. Antimicrobial activity

The minimum inhibitory concentrations (MICs) against *P. aeruginosa* and *C. albicans* of the thiosemicarbazones and their tin(IV) complexes are reported in Table 4. Upon coordination to tin(IV) the activities against *C. albicans* and *P. aeruginosa* substantially increase. Although the antimicrobial activity of $SnCl_4$ could not be evaluated due to its extreme reactivity in air, a synergistic effect

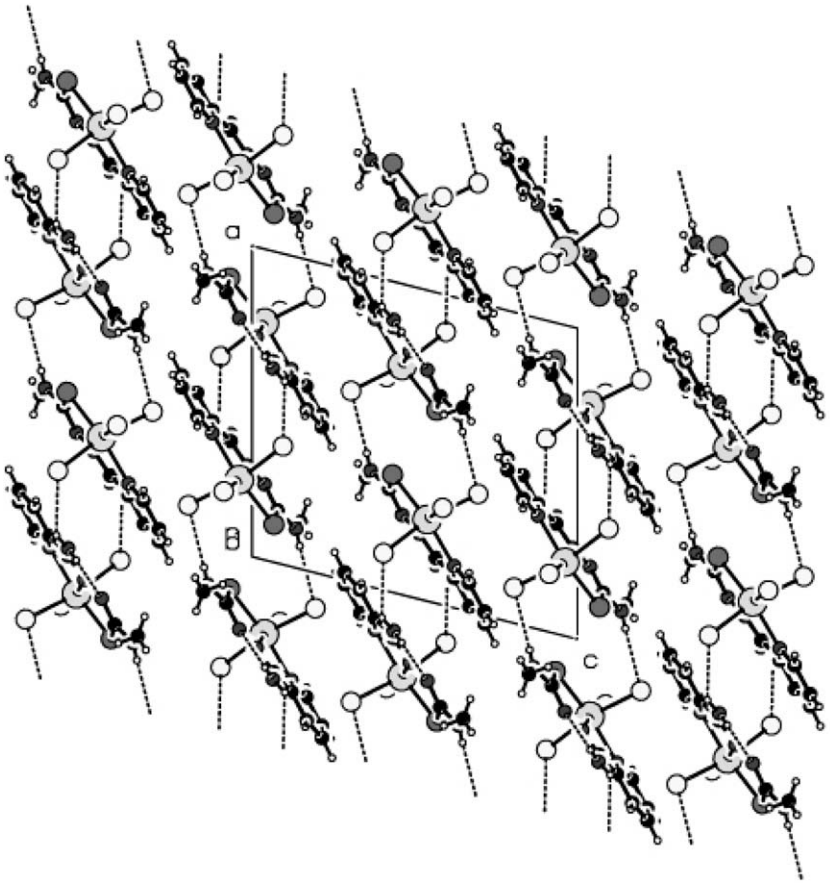

Fig. 4. Molecular packing of [Sn(2AmMe)Cl_3] (**2**) showing the labeling scheme of the non-H atoms and their displacement ellipsoids at the 50% probability level.

Table 4
Minimum inhibitory concentration (MIC) against *Candida albicans* and *Pseudomonas aeruginosa* for 2-pyridineformamide-derived thiosemicarbazones and their tin(IV) complexes.

Compound	MIC/μmol L^{-1} *C. albicans*	MIC/μmol L^{-1} *P. aeruginosa*
H2Am4DH	1312	1320
[Sn(2Am4DH)Cl_3] (**1**)	611	604
H2Am4Me	2448	1330
[Sn(2Am4Me)Cl_3] (**2**)	295	581
H2Am4Et	2294	1220
[Sn(2Am4Et)Cl_3] (**3**)	267	534
H2AmPh	1887	>2060
[Sn(2Am4Ph)Cl_3] (**4**)	>1014	>1022
Tetracycline		29
Fluconazole	18	

involving the metal and the thiosemicarbazone probably takes place. Also, the rigid structure of the thiosemicarbazone in the complexes could facilitate its interaction with the biological target. Finally, changes in lipophilicity upon coordination could also be in part responsible for the activity improvement in the complexes. It is worth comparing the values of MIC against *C. albicans* obtained in the present work for [Sn(2Am4DH)Cl_3] (**1**) (MIC = 611 μM), [Sn(2Am4Me)Cl_3] (**2**) (MIC = 295 μM) and [Sn(2Am4Et)Cl_3] (MIC = 267 μM) (**3**) with those previously determined for [(*n*-Bu)Sn(2Am4DH)Cl_2] (MIC = 290 μM), [(*n*-Bu)Sn(2Am4Me)Cl_2] (MIC = 281 μM) and [(*n*-Bu)Sn(2Am4Et)Cl_2] (MIC = 273 μM) (*n*-Bu stands for the *n*-butyl group) [14]. In both cases upon coordination to tin the antimicrobial activity increases. However, the presence of a chloride instead of the *n*-butyl group does not appreciably affect the antifungal activity.

3.4. Toxicity against Artemia salina

LD_{50} average values for the thiosemicarbazones and their tin(IV) complexes are reported in Table 5. We obtained LD_{50} in the 36.6–2.2 μM range for the free thiosemicarbazones and in the 25.5–1.6 μM range for the tin(IV) complexes. The tested compounds were found to be more active than lapachol (LD_{50} = 281 μM), which is known as reference compound [36]. Among the free thiosemicarbazones H2Am4Ph proved to be the most toxic against *A. salina*. Upon coordination the values of LD_{50} decrease, indicating higher toxicity for the complexes.

The toxicity against *A. salina* bioassay has a good correlation with cytotoxic activity in some human tumors [37]. The low values of LD_{50} obtained for the studied compounds in this assay indicate that they could present antineoplastic properties. H2Am4Ph and its tin complex (**4**) proved to be the most promising compounds.

Table 5
LD_{50} values for 2-pyridineformamide-derived thiosemicarbazones and their tin(IV) complexes against *Artemia salina*.

Compound	LD_{50}[a], μmol L^{-1} ± SD
H2Am4DH	36.6 ± 4.4
[Sn(2Am4DH)Cl_3] (**1**)	25.5 ± 1.7
H2Am4Me	30.0 ± 3.8
[Sn(2Am4Me)Cl_3] (**2**)	13.8 ± 1.3
H2Am4Et	26.0 ± 5.3
[Sn(2Am4Et)Cl_3] (**3**)	12.9 ± 0.6
H2Am4Ph	2.2 ± 0.5
[Sn(2Am4Ph)Cl_3] (**4**)	1.6 ± 0.5

[a] LD_{50}, lethal dose which causes the death of 50% of a group of test animals; SD, standard deviation.

4. Conclusions

Coordination to tin(IV) could be an interesting strategy for increasing the antimicrobial or cytotoxic activity of 2-pyridineformamide thiosemicarbazones. The very low LD_{50} values determined for H2Am4Ph and its tin(IV) complex (**4**) against *A. salina* suggest that the cytotoxicity of these compounds should be further investigated against human tumor cell lines.

Scheme 1. Structure of the ligand = 1,8-bis-(2-pyridyl)-3,6-dithiaoctane (***pdto***).

2. Experimental

2.1. Chemicals

All chemicals and solvents for the synthesis and electrochemical studies were purchased from Aldrich Chemical Co. and were used without further purification.

2.2. Synthesis

Ligand 1,8-bis(2-pyridyl)-3,6-dithioctane (***pdto***) was prepared by the method described by Goodwin and Lions. Yield 70% [6]. Elemental *Anal.* Calc. for $C_{16}H_{20}N_2S_2$: C, 63.1; H, 6.6; N, 9.2; S, 20.1. Found: C, 63.1; H, 6.2; N, 9.7; S, 20.5%.

Aquo 1,8-bis(2-pyridyl)-3,6-dithiaoctane copper(II) hexafluorophosphate, [Cu(***pdto***)(H_2O)](PF_6)$_2$ 0.304 g (1.0 mmol) of ***pdto*** was added to 0.294 g of $Cu(NO_3)_2 \cdot 2.5H_2O$ (1.0 mmol) previously dissolved in 50 mL of methanol. The solution was stirred strongly and a deep blue color was observed. This solution was treated with two equivalents of ammonium hexafluorophosphate (0.0088 g). A blue precipitate was isolated. Elemental *Anal.* Calc. for $CuC_{16}H_{21}N_2S_2OP_2F_{12}$: C, 28.4; H, 3.1; N, 4.2; S, 9.5. Found: C, 28.1; H, 3.0; N, 4.7; S, 9.3%.

2.3. Measurement of cell growth inhibition

The antiproliferative effect was analyzed on cervix human tumor cell line HeLa obtained from American Type Culture Collection (ATCC, Rockville (MD) USA). Once the cells reached a constant rate of proliferation, approximately 2×10^4 cells/well were plated in a 96-well microplate with Dulbecco's modified eagle medium (DMEM) supplemented with 10% of fetal bovine serum (FBS), and allowed to attach, incubating at 37 °C and 5% CO_2 for 24 h. At the end of incubation timing the medium was removed and cells were exposed to drugs in five different concentrations (0, 1, 10, 100 and 300 μg/mL) with fresh supplemented media for 24 h. *cis*-platin was employed as drug control at same mentioned concentrations. Cell growth was determined according to the sulforhodamine B assay, described by Skehan et al. [7,8]. Absorbance was measured at 564 nm (*Microplate reader BIO-RAD 550*) and percentage cell growth by each concentration of drug was calculated as: percentage growth = $100 * [T/C]$; where T is the absorbance of treated wells and C is the absorbance of untreated wells. The software PROBIT (*Log Probit Analysis by Maximum Likelihood/Novartis)* was used to calculate the concentration to inhibit the proliferation of the cells in a 50% (IC_{50}).

2.4. Elemental analysis

Fissons Instruments Analyzer model EA 1108 was used for elemental analysis determination, using a sulfanilamide standard.

2.5. Electrochemistry

All electrochemical measurements were performed in acetonitrile, MeCN, (HPLC grade) solution containing 0.1 M tetra-N-butylammonium tetrafluoroborate ($TBABF_4$) as supporting electrolyte. All electrochemical experiments were obtained at sample concentrations of 1×10^{-3} M in the presence of supporting electrolyte. A potentiostat/galvanostat EG&G PAR model 263 controlled by a PC software was used. A typical three-electrode array was employed for all electrochemical measurements: platinum disk as working electrode $\phi = 2$ mm, platinum wire as counter-electrode, and a silver wire as pseudo reference electrode. The silver electrode was immersed in a MeCN solution with 0.1 M tetra-N-butylammonium chloride (TBACl) in a separate compartment that was connected to the working cell through a BAS vycor™ tip. All potentials were reported versus the couple Fc/Fc^+ according to IUPAC.

Cyclic voltammetry was initiated from open circuit potential (E_{ocp}), the scan rate employed was 0.1 V/s. One step chronoamperometry experiments were performed, initiating at $E_1 = E_{ocp}$ to different potential values, E_2, using a pulse width of 3 s. Electrochemical impedance spectra were measured using a BAS-ZAHNER IM6 potentiostat–galvanostat which was controlled by the software THALES SYSTEM™ version 3.0 previously installed in a PC Pentium III. All the spectra were obtained at open circuit potential and applying to the electrochemical cell an alternant perturbation having an amplitude of 10 mV and frequencies, f, between 100 kHz and 1 Hz. Fitting data to the Randles equivalent circuit were carried out by means of the spectra simulator SIM, which is a routine also supplied by the THALES SYSTEM software.

3. Results and discussion

3.1. Cell growth inhibition studies of [Cu(*pdto*)H_2O]$^{2+}$ complex

The antiproliferative effect of the compound [Cu(***pdto***)H_2O]$^{2+}$ was determined as IC_{50} in human cervix tumor cell line HeLa. From Table 1 it can be seen the similarity between the IC_{50} value of [Cu(***pdto***)H_2O]$^{2+}$ (41.8 ± 1.2 μM) and *cis*-platin (40.1 ± 0.9 μM). An inspection of values, show that the biological activity is due to [Cu(***pdto***)H_2O]$^{2+}$ complex, and not to its precursors. This fact can be related to redox properties, which may correspond to possible Cu-SOD dismutase reactions. In order to explain how the redox properties affect the biological activity, in the next sections we present a complete electrochemical characterization of the [Cu(***pdto***)H_2O]$^{2+}$ complex, and $Cu(NO_3)_2 \cdot 2.5H_2O$.

3.2. Electrochemical behavior of $Cu(NO_3)_2 \cdot 2.5H_2O$

Cyclic voltammogram of a 1×10^{-3} M $Cu(NO_3)_2 \cdot 2.5H_2O$ acetonitrile solution is shown in Fig. 1. When the scan was initiated in negative direction two reduction signals **Ic** and **IIc**, and two oxidation signals **Ia** and **IIa** are observed. The dependence of the signals **Ic** with **Ia** and **IIc** with **IIa** was established by modifying the switching potentials E_{-i}. The cathodic and anodic peak potential values for signals **Ic**, **IIc**, **Ia** and **IIa** are: E_{pc}(**Ic**) = 0.401 V, E_{pc}(**IIc**) = −0.914 V, E_{pa}(**Ia**) = 0.615 V and E_{pa}(**IIa**) = −0.667 V, respectively.

The electrochemical processes **I** and **II** can be attributed to the consecutive reductions Cu(II) + 1e → Cu(I) and Cu(I) + 1e → Cu(0).

Table 1
IC_{50} mean values (μM) and standard deviation (SD) obtained for [Cu(***pdto***)H_2O]$^{2+}$, $Cu(NO_3)_2 \cdot 2.5H_2O$, and *cis*-platin against tumor cell line HeLa.

	IC_{50} (μM) ± SD
cis-Platin	40.1 ± 0.9
[Cu(***pdto***)H_2O]$^{2+}$	41.8 ± 1.2
$Cu(NO_3)_2 \cdot 2.5H_2O$	No activity
pdto	No activity

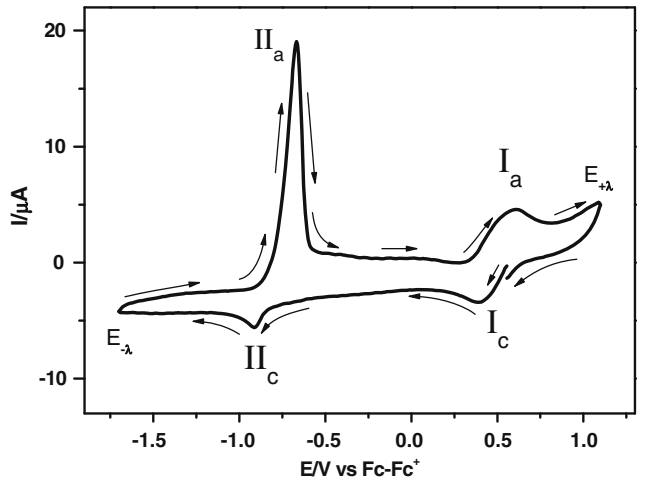

Fig. 1. Cyclic voltammogram of 1×10^{-3} M $Cu(NO_3)_2 \cdot 2.5H_2O$ in MeCN in presence of 0.1 M $TBABF_4$. The scan potential was initiated from E_{ocp} to negative direction. Scan rate 0.1 V s^{-1}. Platinum electrode was used.

However, to confirm this idea one step chronoamperometry experiments were also carried out.

From current-sampled versus potential plot $I(t) - E$, at current sampling time of 1.5 s, two reduction and one oxidation diffusion controlled limit zones are detected: $Id_{Ic}(t)$, $Id_{IIc}(t)$ and $Id_{Ia}(t)$ (see Fig. 2). This is a typical current–potential curve when soluble species of a redox couple are initially presented. Using the ratio $Id_{Ic}(t)/Id_{Ia}(t)$, it was established 90% of Cu(II) and 10% of Cu(I) in solution. The presence of the last species is attributed to its stability in acetonitrile solution [9,10].

The equation that describes the voltammogram in sampled-current voltammetry in the semi-infinite linear diffusion region with two soluble species of a redox couple is:

$$E = E_{1/2} + \frac{RT}{nF}\ln\frac{[Id_{OX}(t) - I(t)]}{[I(t) - Id_{RED}(t)]} \quad (3)$$

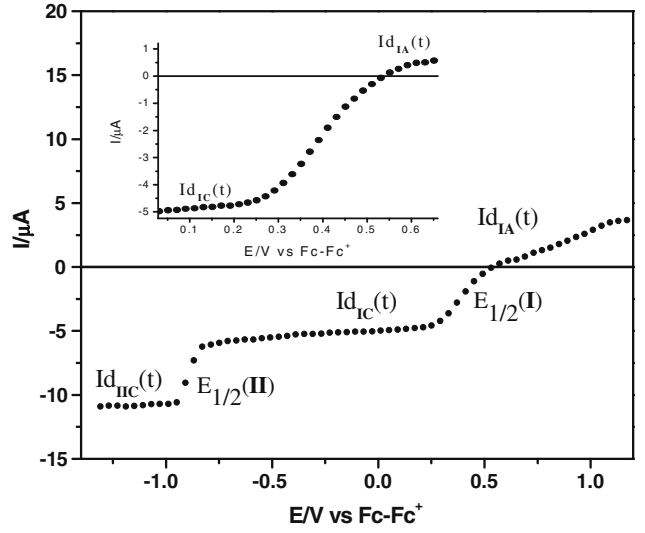

Fig. 2. Current-potential curves $I(t)$–E, constructed from chronoamperograms at different potentials E_2 from −1.560 to 1.571 V/Fc − Fc^+, corresponding to the electrochemical behavior of the copper salt $Cu(NO_3)_2 \cdot 2.5H_2O$. The $I(t)$–E plot was constructed for current sampling times 1.5 s. Inset corresponds to an expanded $I(t)$–E scale.

For a reversible system the slope value should be 0.059/n V at 25 °C and the intercept corresponds to the half wave potential $E_{1/2}$. The half wave potential is usually a very good approximation of E^0 for a reversible couple, whenever the diffusion coefficients ratio is close to the unity Eq. (4):

$$E_{1/2} = E^0 + \frac{RT}{nF}\ln\frac{D_R^{1/2}}{D_O^{1/2}} \quad (4)$$

The slope and the intercept of E versus $\log[Id_{OX}(t) - I(t)]/[I(t) - Id_{RED}(t)]$ plot were found to be 0.122 and 0.387 ($r = 0.999$) for process **I**, and 0.047 and −0.892 ($r = 0.999$) for process **II**. The slope values suggest that non-reversible behavior for processes **I** and **II** is observed.

Due to the non-reversible behavior of both processes, no formal potential E^0, can be evaluated. Instead of E^0, the values of $E_{1/2}$ for processes **I** and **II** were obtained, $E_{1/2}(I) = 0.387$ V and $E_{1/2}(II) = -0.892$ V. Considering the preferential geometry of Cu(II) and Cu(I) complexes and with all arguments presented above, the following electrochemical reactions in MeCN solution are proposed:

I $[Cu^{II}(MeCN)_n]^{2+} + 1e \rightarrow [Cu^{I}(MeCN)_{n-1}]^{+} + MeCN$
$E_{1/2}(I) = 0.387$ V

II $[Cu^{I}(MeCN)_{n-1}]^{+} + 1e \rightarrow Cu(0) + (n-1)MeCN$
$E_{1/2}(II) = -0.892$ V

4. Electrochemical behavior of the complex $[Cu(\textit{pdto})H_2O]^{2+}$

Fig. 3 shows a typical cyclic voltammogram of $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ in acetonitrile solution, started from open circuit potential to negative direction. Before the potential switch, $E_{-\lambda}$, two reduction signals **Ic′** and **IIc′** can be observed. When the scan was completed four oxidation signals (**IIa′**, **IIa′*** , **Ia′** and **IIIa′**) and one additional reduction signal (**IIIc′**) were detected. The cathodic peak potential values E_{pc}(**Ic′**), E_{pc}(**IIc′**) and E_{pc}(**IIIc′**) for signals **Ic′**, **IIc′** and **IIIc′** are: 0.180, −1.106 and 0.340 V, respectively. On the other hand, the values of anodic peaks potentials E_{pa}(**Ia′**), E_{pa}(**IIa′**) and E_{pa}(**IIIa′**) for signals **Ia′**, **IIa′** and **IIIa′** were 0.268, −0.650 and 0.543 V.

A comparison of these peak potential values, and those obtained from Fig. 1, suggests that the signals **IIIa′** and **IIIc′** are attributed to

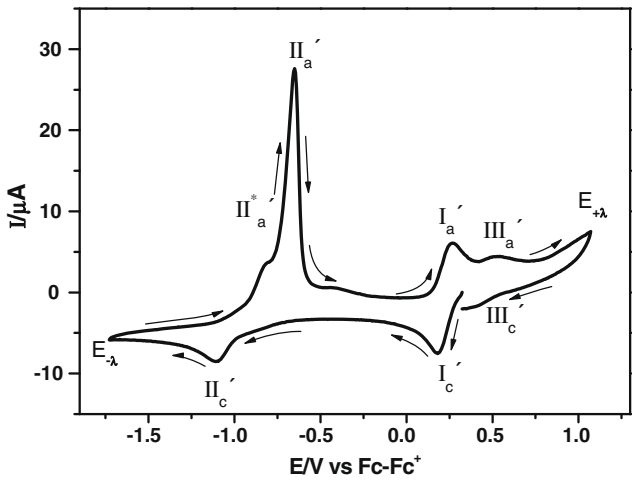

Fig. 3. Cyclic voltammogram of 1×10^{-3} M $[Cu(\textbf{\textit{pdto}})H_2O](PF_6)_2$ in MeCN in presence of 0.1 M $TBABF_4$. The scan potential was initiated from E_{ocp} to negative direction. Scan rate 0.1 V s^{-1}. Platinum electrode was used.

non-coordinated Cu(II) that comes form the dissociation of the complex. The signal **IIa**′* can be explained as the dissolution of deposited elemental copper in the presence of the ligand [11].

In order to obtain the number of electrons exchanged in the principal processes **I**′ and **II**′, current-sampled versus potential plot $I(t) - E$ was constructed from chronoamperometric experiments at current sampling time of 1.5 s. Two diffusion controlled limit zones $Id_{I}(t)$ and $Id_{II}(t)$ with their corresponding half wave potential $E_{1/2}$(I) and $E_{1/2}$(II) are observed.

For a reversible system when only one oxidized species is present in solution, a plot E versus $\log[I_d(t) - I(t)/I(t)]$ should be linear with a slope value of 0.059/n V and with an intercept value that corresponds to the formal potential E^0. Using linear fit with correlation coefficient of 0.999 for both processes, the calculated slopes were 0.065 for process **I**′, and 0.069 for process **II**′. These values clearly suggest that both systems are practically reversible with a value of one electron exchanged in both cases. From the intercept, the obtained values of formal potentials E^0(I′) and E^0(II′) for processes **I**′ and **II**′ were 0.165 and −1.110 V, respectively.

To confirm the number of exchanged electrons in these processes, Cottrell's analysis is presented. It is well known that for a two consecutive electron transfer, the diffusion limit currents are established with the Cottrell Equations: for the first step, Eq. (5), the slope is proportional to n_1, Eq. (7), and for the second step, Eq. (6), the slope is proportional to $(n_1 + n_2)$, Eq. (8) [12]:

$$Ox_1 + n_1 \rightarrow Red_1 \quad (5)$$

$$Red_1 + n_2 \rightarrow Red_2 \quad (6)$$

$$Id(t) = n_1 FAD_o^{1/2}\pi^{1/2}Co^* t^{-1/2} \quad (7)$$

$$Id(t) = (n_1 + n_2)FAD_o^{1/2}\pi^{-1/2}Co^* t^{-1/2} \quad (8)$$

Two linear relationships of current $I(t)$ and $t^{-1/2}$ were obtained within the two diffusion controlled zones, with the equations $I(t) = -4.9t^{-1/2} + 0.36$ ($r = 0.999$) and $I(t) = -10.0t^{-1/2} + 0.9$ ($r = 0.999$) for processes **I**′ and **II**′, respectively. Considering the same value of diffusion coefficient in Eqs. (7) and (8), the ratio $Id_{II}(t)/Id_{I}(t) = 2$ confirms the values $n_1 = 1$ and $n_2 = 1$. With all the evidences the electrochemical processes **I**′ and **II**′ can be attributed to:

I′ $[Cu^{II}(\boldsymbol{pdto})H_2O]^{2+} + 1e \rightarrow [Cu^{I}(\boldsymbol{pdto})]^{+} + H_2O$

$E^0(I') = 0.165\ V/Fc - Fc^+$

II′ $[Cu^{I}(\boldsymbol{pdto})]^{+} + 1e \rightarrow Cu(0) + \boldsymbol{pdto}$ $E^0(II') = -1.110\ V/Fc - Fc^+$

The coordination spheres for Cu(I) and Cu(II) complexes are proposed based on previously reported X-ray structures. [13]. The reversibility presented in the electrochemical processes Cu(II)/Cu(I) is in agreement with the high flexibility of the ligand ***pdto*** towards the preferential geometry of the central atom [4–6,13–24].

In order to complete the electrochemical characterization of the complex $[Cu(\boldsymbol{pdto})H_2O]^{2+}$, and its precursor $Cu(NO_3)_2 \cdot 2.5H_2O$, electrochemical impedance spectroscopy experiments were performed. These results are discussed in the next section.

4.1. Electrochemical impedance spectroscopy studies of $[Cu(\boldsymbol{pdto})H_2O]^{2+}$ $Cu(NO_3)_2 \cdot 2.5H_2O$

Fig. 4 shows typical Nyquist plots for $Cu(NO_3)_2 \cdot 2.5H_2O$ and $[Cu(\boldsymbol{pdto})H_2O]^{2+}$. The presence of a semi-loop at high frequencies in these plots indicates that an electrochemical reaction exists at the open circuit potential (E_{ocp}). This reaction is attributed to the Cu(II)/Cu(I) equilibrium. But, according to the shape of the spectra at the low frequency range, the main contribution to the impedance is due to a semi-infinite diffusion process, which controls the overall reaction rate. It seems that the species involved in this equilibrium diffuse at the interface metal–solution. However these species remains unidentified.

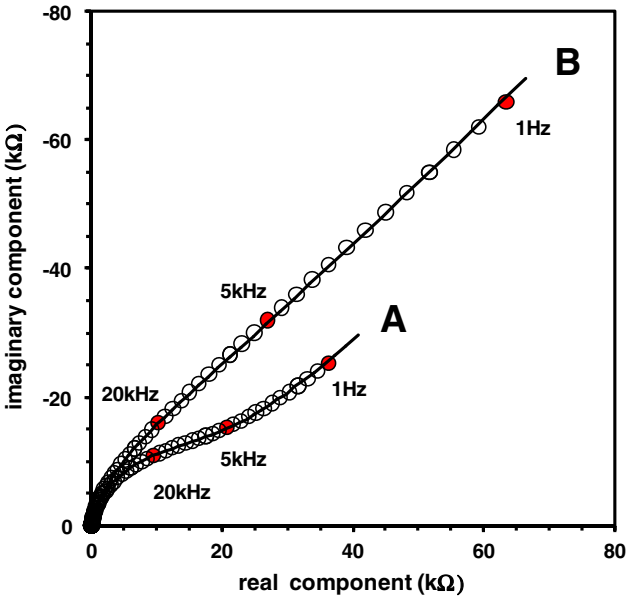

Fig. 4. Nyquist diagram for (A) $Cu(NO_3)_2 \cdot 2.5H_2O$ and (B) $[Cu(\boldsymbol{pdto})H_2O](PF_6)_2$. The concentration of samples was 1×10^{-3} M, in supporting electrolyte (0.1 M $TBABF_4$ in MeCN). EIS spectra were obtained at open circuit potential $E_{i=0}$ vs. $Fc - Fc^+$ couple with alternant perturbation 10 mV.

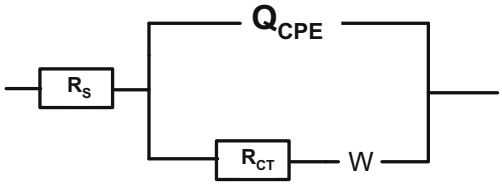

Both impedance spectra have been analyzed using a classical Randles equivalent circuit, displayed on Scheme 2. In this circuit, R_s stands for the resistance of the electrolyte, R_{tc} is the charge transfer resistance of the electrochemical reaction, *CPE* (constant phase element) and n are related to the double layer capacitance C_{dl} (see Eq. (9)) and, W is the Warburg parameter, related to diffusion processes (see Eq. (10)) [25,26]:

$$Z_{CPE} = \frac{1}{Q_{CPE}}(j\omega)^{-n} \quad (9)$$

where $\omega = 2\pi f$, $j = \sqrt{-1}$, and $0 \leqslant n \leqslant 1$ If $n = 1$ $Z_{CPE} = Z_{C_{dl}}$

$$Z_W = W(j\omega)^{-1/2} \quad (10)$$

Fig. 4 shows a good fitting (continuous line) of the Randless circuit to the experimental spectra in both cases. Fitted parameters are presented in Table 2. It is seen that R_{tc} is similar for both $Cu(NO_3)_2 \cdot 2.5H_2O$ and $[Cu(\boldsymbol{pdto})H_2O]^{2+}$ spectra, showing no significant difference in the kinetics of charge transfer of both species. In contrast, there is a significant difference in the Warburg parameter, being more important the diffusion process for the $[Cu(\boldsymbol{pdto})H_2O]^{2+}$ complex. This means that a deeper concentration gradient is built in this case, as a result of a faster electrochemical reaction. Such behavior is related to a more reversible Cu(II)/Cu(I) equilibrium, thus confirming the voltammetric and chronoamperometric results.

Scheme 2. Randles-type equivalent circuit used for fitting EIS spectra.

Table 2
Parameters of the Randles circuit fitted to the impedance spectra.

Compound	Proposed parameters
$Cu(NO_3)_2 \cdot 2.5H_2O$	$R_s = 212.4 \pm 5.5\ \Omega$, $R_{ct} = 17.9 \pm 0.2\ k\Omega$, $C_{dl} = 0.336 \pm 0.005\ \mu F$ $n = 0.933 \pm 0.002$, $W = 86.57 \pm 1.59\ k\Omega/s^{1/2}$
$[Cu(\textbf{\textit{pdto}})H_2O](PF_6)_2$	$R_s = 213.8 \pm 16.3\ \Omega$, $R_{ct} = 18.7 \pm 0.6\ k\Omega$, $C_{dl} = 0.258 \pm 0.007\ \mu F$ $n = 0.924 \pm 0.004$, $W = 246.30 \pm 2.88\ k\Omega/s^{1/2}$

It is totally clear that the complex $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ presents more reversible electrochemical behavior than its precursor $Cu(NO_3)_2 \cdot 2.5H_2O$, due to the high flexibility of the ***pdto*** ligand towards the preferential geometry of the central atom. This is in good agreement with the fact that the value of the self-exchange electron transfer rate constant for the couple Cu(II)L/Cu(I)L (L = tetradentate ligands N_2S_2) is larger than the corresponding value of the non-coordinated couple Cu^{2+}/Cu^{+} [27]. In a simple way, we proposed that the electrochemical reversibility presented in the complex $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ increases the reaction of electron exchange with superoxide molecule (Eqs. (1) and (2)). According to the Marcus theory, the π system in the ligand ***pdto*** and the smaller molecular reorganization in the couple $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}/[Cu(\textbf{\textit{pdto}})H_2O]^{+}$ support the idea of an easy transfer of electrons from $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ to other chemical species in solution [28]. A correlation between the antiporoliferative effect and electrochemical reversibility of the Fe(II)/Fe(III) couple in Fe(II) complexes with thiohydrazones has been recently proposed by Kalinowski et al. [29].

Due to the nature of the studies presented in this work, it cannot be neglected that the biological activity of the complex $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ is also related with other properties, like intercalation properties with DNA [3]. But, by simple electrochemical techniques, it is possible to proposed that electrochemical reversibility is an important factor in the antitumoral activity of the $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ complex.

5. Conclusion

The similar antiproliferative effects of the complexes $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ and *cis*-platin in human cervix tumor cell line HeLa, suggest that the copper compound could be used against other tumor cell lines. We have established, by using cyclic voltammetry chronoamperometry and electrochemical impedance spectroscopy, an electrochemical reversibility for complex $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$, and irreversibility for the starting material $Cu(NO_3)_2 \cdot 2.5H_2O$ in acetonitrile solution. This fact confirms the flexibility of the ***pdto*** ligand, towards the preferential geometry of Cu (II) and Cu(I) in their corresponding complexes. It can be proposed that antitumoral activity of the complex $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ is related with electrochemical reversibility. Due to the studies performed in this work, additional effects like the interaction of $[Cu(\textbf{\textit{pdto}})H_2O]^{2+}$ with DNA reported before, cannot be neglected in the full understanding of the biological activity of this copper complex.

$CDCl_3$ δ = 77.55). Infrared spectra were collected on Bruker Vector 22 in KBr at room temperature. Elemental analysis was performed on a Perkin–Elmer 240 C elemental analyzer. ThermoGravimetric (TG) and Differential Scanning Calorimetric (DSC) studies were carried out with a NETZSCH STA 449 C with a constant heating rate of 10 °C min^{-1} under Argon (1.0 cm^3 min^{-1}). Melting points were observed in sealed capillaries and are uncorrected.

2.2. Synthesis

2.2.1. Synthesis of $AgNC_4H_4O_2$ (**1**)

Silver oxide (5.0 g, 22 mmol) was added in one portion to a boiling solution of succinimide (3.8 g, 38 mmol) in 100 ml water. The reaction vessel was wrapped with aluminum foil in order to exclude as much light as possible. After the stirred solution was heated to reflux for 45 min and the silver oxide disappeared, the suspension was filtered through a heated Büchner funnel into a filter flask, also wrapped with aluminum foil. The filtrate was allowed to stand at room temperature overnight, during which time *N*-silver(I) succinimide crystallized. The *N*-silver(I) succinimide was separated on a Büchner funnel, dried in a vacuum oven for 1 h at 110 °C. The product was stored under nitrogen and kept in dark place. Yield: 3.1 g (40%, based on Ag_2O) [33].

2.2.2. Synthesis of $Ph_3P \cdot AgNC_4H_4O_2$ (**2a**)

Triphenylphosphine (0.1318 g, 0.5 mmol) dissolved in 20 mL of CH_2Cl_2 was added dropwise into a stirred solution of *N*-silver(I) succinimide (0.1029 g, 0.5 mmol) suspended in 20 mL of CH_2Cl_2 at 0 °C. A clear solution was obtained by filtration through a pad of celite after stirring the reaction mixture for 6 h at 0 °C. A white solid product was obtained after removing all the volatiles with an oil-pump vacuum, yield: 0.22 g (94% based on *N*-silver(I) succinimide). Mp.: 182–183 °C dec. *Anal. Calc.* for $C_{22}H_{19}O_2AgPN$: C, 56.43; H, 4.09. Found: C, 56.36; H, 4.04%. ^{1}H NMR ($CDCl_3$): δ 2.7 (s, 4 H, CH_2–H), 7.4–7.6 (m, 15 H, Ph-H). ^{13}C{H} NMR ($CDCl_3$): δ 32.1 (CH_2), δ 191.4 (C), 134.0 (J_{PC} = 16.0 Hz, C_6H_5), 131.3 (C_6H_5), 129.9 (C_6H_5), 129.2 (J_{PC} = 10.9 Hz, C_6H_5). IR (KBr) data (cm^{-1}): 3049 (m), 2963 (m), 1709 (m), 1611 (s), 1436 (s), 1348 (s), 1282 (s), 1157 (m), 1096 (s), 1026 (m), 806 (m), 745 (s), 693 (s), 507 (s), 451 (m).

2.2.3. Synthesis of $(Ph_3P)_2 \cdot AgNC_4H_4O_2$ (**2b**)

Complex **2b** was obtained by following the above procedure, only using *N*-silver(I) succinimide (0.1379 g, 0.67 mmol) and triphenylphosphine (0.3515 g, 1.34 mmol) instead. Yield: 0.47 g (96% based on *N*-silver(I) succinimide). Mp.: 196–197 °C. *Anal. Calc.* for $C_{40}H_{34}O_2AgP_2N$: C, 65.77; H, 4.69. Found: C, 65.63; H, 4.63%. ^{1}H NMR ($CDCl_3$): δ 2.6 (s, 4 H, CH_2–H), 7.3–7.5 (m, 30 H, Ph-H). ^{13}C{H} NMR ($CDCl_3$): δ 32.5 (CH_2), δ 192.4 (C), 133.9 (J_{PC} = 16.8 Hz, C_6H_5), 132.6 (J_{PC} = 24.1 Hz, C_6H_5), 130.0 (C_6H_5), 128.7 (J_{PC} = 9.5 Hz, C_6H_5). IR (KBr) data (cm^{-1}): 3655 (m), 3049 (m), 2962 (m), 2361 (w), 1700 (m), 1603 (s), 1583 (m), 1478 (m), 1434 (s), 1345 (s), 1285 (s), 1247 (s), 1183 (w), 1095 (s), 1026 (m), 996 (m), 803 (m), 746 (s), 695 (s), 512 (s), 436 (m).

2.2.4. Synthesis of $(Ph_3P)_3 \cdot AgNC_4H_4O_2$ (**2c**)

Complex **2c** can be synthesized in the same manner as **2a** (Section 2.2.2). In this respect, triphenylphosphine (0.4328 g, 1.65 mmol) was reacted with *N*-silver(I) succinimide (0.1132 g, 0.55 mmol). After appropriate work-up (see Section 2.2.1), complex **2c** was obtained as a white solid. Yield: 0.51 g (93% base on *N*-silver(I) succinimide). Mp.: 194–196 °C dec. *Anal. Calc.* for $C_{58}H_{49}AgO_2P_3N$: C, 70.17; H, 4.98. Found: C, 69.91; H, 4.73%. ^{1}H NMR ($CDCl_3$): δ 2.5 (s, 4 H, CH_2–H), 7.3–7.5 (m, 45 H, Ph-H). ^{13}C{H} NMR ($CDCl_3$): δ 32.5 (CH_2), δ 192.5 (C), 134.0 (J_{PC} = 4.8 Hz, C_6H_5), 133.8 (J_{PC} = 8.6 Hz, C_6H_5), 129.6 (C_6H_5), 128.6 (J_{PC} = 8.8 Hz, C_6H_5). IR (KBr) data (cm^{-1}): 3047 (m), 1703 (m), 1598 (s), 1477 (m), 1434 (s), 1344 (s), 1282 (s), 1245 (s), 1157 (m), 1096 (s), 1026 (m), 998 (m), 806 (m), 743 (s), 694 (s), 513 (s), 465 (m).

2.2.5. Synthesis of $(EtO)_3P \cdot AgNC_4H_4O_2$ (**2d**)

Complex **2d** can be synthesized by a similar procedure used for the synthesis of **2a** (Section 2.2.1). In this respect, [$(EtO)_3P$] (1.87 g, 11.27 mmol) was reacted with *N*-silver(I) succinimide (2.32 g, 11.27 mmol). After appropriate work-up, complex **2d** was isolated as a white solid. Yield: 3.81 g (91% based on *N*-silver(I) succinimide). Mp.: 53–54 °C. *Anal. Calc.* for $C_{10}H_{19}O_5AgPN$: C, 32.28; H, 5.15. Found: C, 32.16; H, 5.02%. ^{1}H NMR ($CDCl_3$): δ 1.3 (t, 9H, CH_3/CH_3CH_2–, J_{HH} = 7.0 Hz), δ 2.6 (s, 4H, CH_2–H), 4.0 (m, 6 H, CH_2/CH_3CH_2–). ^{13}C{H} NMR ($CDCl_3$): δ 31.9 (CH_2), δ 191.0 (C), 16.1 (J_{PC} = 6.7 Hz, CH_3/CH_3CH_2–), 61.3 (J_{PC} = 3.8 Hz, CH_2/CH_3CH_2–). 2.2.6. Synthesis of $[(EtO)_3P]_2 \cdot AgNC_4H_4O_2$ (**2e**)

Complex **2e** can be synthesized in the same manner as **2a** (Section 2.2.2). In this respect, [$(EtO)_3P$] (1.4044 g, 8.46 mmol) was reacted with *N*-silver(I) succinimide (0.8708 g, 4.23 mmol). After appropriate work-up (see Section 2.2.1) complex **2e** was obtained as a colorless liquid. Yield: 2.09 g (92% based on *N*-silver(I) succinimide). *Anal. Calc.* for $C_{16}H_{34}O_8AgNP_2$: C, 35.70; H, 6.37. Found: C, 35.57; H, 6.38. ^{1}H NMR ($CDCl_3$): δ 1.2 (t, 18 H, CH_3/CH_3CH_2–, J_{HH} = 7.0 Hz), δ 2.5 (s, 4 H, CH_2–H), 3.9 (m, 12 H, CH_2/CH_3CH_2–). ^{13}C{H} NMR ($CDCl_3$): δ 31.8 (CH_2), δ 191.0 (C), 16.1 (J_{PC} = 6.1 Hz, CH_3/CH_3CH_2–), 60.0 (J_{PC} = 5.7 Hz, CH_2/CH_3CH_2–). IR (KBr) data (cm^{-1}): 3440 (m), 2979 (s), 2934 (m), 2901 (m), 2358 (w), 1715 (m), 1612 (s), 1477 (m), 1441 (m), 1391 (s), 1348 (s), 1287 (s), 1245 (s), 1162 (m), 1097 (m), 1022 (s), 937 (s), 771 (s), 669 (m), 536 (s), 442 (m).

2.2.7. Synthesis of $[(EtO)_3P]_3 \cdot AgNC_4H_4O_2$ (**2f**)

Complex **2f** was synthesized in a similar procedure to that used for the synthesis of **2a** (Section 2.2.1). In this respect, [$(EtO)_3P$] (1.5538 g, 9.36 mmol) was reacted with *N*-silver(I) succinimide (0.6423 g, 3.12 mmol). After appropriate work-up, complex **2d** was isolated as a colorless liquid. Yield: 2.03 g (92% based on *N*-silver(I) succinimide). *Anal. Calc.* for $C_{22}H_{49}O_{11}AgP_3N$: C, 37.51; H, 7.01. Found: C, 37.32; H, 6.89%. ^{1}H NMR ($CDCl_3$): δ 1.3 (t, 27H, CH_3/CH_3CH_2–, J_{HH} = 7.0 Hz), δ 2.6 (s, 4 H, CH_2–H), 4.0 (m, 18 H, CH_2/CH_3CH_2–). ^{13}C{H} NMR ($CDCl_3$): δ 32.1 (CH_2), δ 191.5 (C), 16.2 (J_{PC} = 5.9 Hz, CH_3/CH_3CH_2–), 59.5 (J_{PC} = 6.6 Hz, CH_2/CH_3CH_2–). IR (KBr) data (cm^{-1}): 3414 (m), 2979 (s), 2926 (m), 2898 (m), 1701 (m), 1598 (s), 1437 (m), 1441 (w), 1391 (m), 1348 (s), 1295 (s), 1252 (s), 1162 (m), 1097 (m), 1023 (s), 933 (s), 773, (s), 669 (m), 556 (m), 454 (m).

2.3. Single crystal structure of $(Ph_3P)_3 \cdot AgNC_4H_4O_2$ (**2c**)

Single crystals of **2c** could be obtained by cooling a saturated dichloromethane solution to −20 °C. Suitable crystals for X-ray determination were placed in glue under N_2 due to their sensitive nature to oxygen and moisture. The X-ray structure measurement was performed on a BRUKER SMART Apex CCD, detector equipped with graphite monochromatic Mo Kα radiation (λ = 0.71073 Å), at room temperature. The program SMART [34] was used for determination of the unit cell. Data reduction and integration was carried out with SAINT [34] and absorption corrections were applied using the program SADABS [35]. The structure was solved using direct methods and refined by full-matrix least-squares procedures on

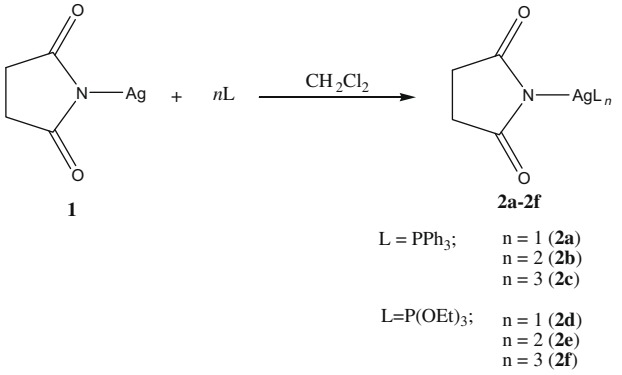
$\Delta\rho_{min}$ (e Å^{-3})	−0.78



[a] $R_1 = \sum(||F_o| - |F_c||)/\sum|F_o|$; $wR_2 = [\sum(w(F_o^2 - F_c^2)^2)/\sum(wF_o^4)]^{1/2}$.
[b] $w = 1/[\sigma^2(F_o^2) + (0.064P)^2]$, $P = (F_o^2 + 2F_c^2)/3$.
[c] $S = [\sum w(F_o^2 - F_c^2)^2]/(n-p)^{1/2}$, n = number of reflections, p = parameters used.

F^2 (SHELX-97) [36]. All of the non-hydrogen atoms were refined with anisotropic displacement parameters. Crystallographic data and details on refinement are presented in Table 1. The crystal structure of **2c** is drawn using ORTEP [37].

3. Results and discussion

3.1. Synthesis

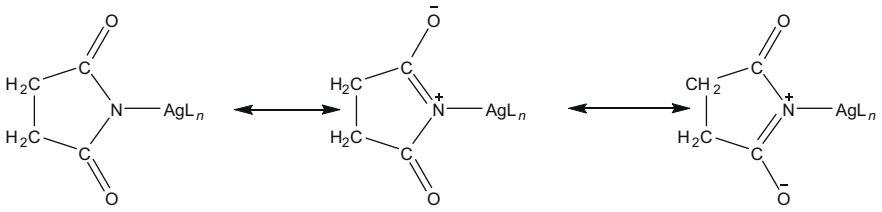
The phosphine/phosphite stabilized *N*-silver(I) succinimide complexes of the type $[L_n \cdot AgNC_4H_4O_2]$ (L = PPh_3, n = 1, **2a**; n = 2, **2b**; n = 3, **2c**; L = $P(OEt)_3$; n = 1, **2d**; n = 2, **2e**; n = 3, **2f**) were prepared by reacting $Ph_3P/(EtO)_3P$ with *N*-silver(I) succinimide in dichloromethane in stoichiometric amounts at 0 °C in high yield (Scheme 1). The complexes were isolated as white solids (**2a**–**2c**) or colorless liquids (**2d**–**2f**). They are very sensitive to moisture, oxygen as well as light. The complexes are insoluble in cold non-polar solvents such as petroleum, whereas they are highly soluble in polar or unsaturated hydrocarbons such as methylenechloride, benzene and tetrahydrofuran. All the products obtained gave satisfactory elemental analysis results and were characterized by FT-IR, ^{1}H NMR and ^{13}C {H} NMR spectroscopy.

Scheme 1. Synthesis of complexes **2a**–**2f**.

The spectra of succinimide were investigated by Woldbaek, Klaeboe and Christensen [38]. Assignments are proposed by comparison with the normal-coordinate interpretation presented by the authors mentioned above. So far, discussion of the IR spectra of the metal complexes has been restricted to the stretching carbonyl band (1700 cm^{-1}) [39].

In the IR spectra, the broad N–H stretching band (~3170 cm^{-1}) in succinimide disappears in the complexes obtained, as well as the sharp band at 820 cm^{-1} assigned to the out-of-plane N–H bending mode [38]. The in-plane N–H bending vibration has been tentatively associated with a sharp peak at 1418 cm^{-1} in succinimide, with an overtone at ~2800 cm^{-1}. The overtone is absent from the spectra of the complexes. This illustrates the formation of a Ag–N bond.

In the 1600–1800 cm^{-1} region, succinimide contains sharp peaks at 1773 and 1695 cm^{-1} for the in-phase and out-of-phase stretching motions of the C=O groups [38]. In the *N*-silver(I) succinimide complexes, these bands are found at 1700–1710 and 1580–1615 cm^{-1}, respectively. These changes, which are correlated with those found for the uracil moiety [38], could be ascribed to the delocalization of the anionic charge to the ring and carbonyl groups, thus decreasing the C=O bond order (Scheme 2). The (C=O) region is very sensitive to proton substitution, but rather insensitive to whether the C=O groups are involved in metal coordination [38]. A weak band at 420 cm^{-1}, believed to involve the C=O in-plane bending vibration, was shifted to 436–475 cm^{-1} in the complexes. However, the weakness of these bands in the infrared spectra complicates their use for diagnostic purposes.



The NMR spectra (^{1}H and ^{13}C{H}) were recorded for all six complexes (see Section 2) at room temperature, The ^{1}H NMR spectra are consistent with the stoichiometries of the complexes. The protons of complexes **2a**–**2c** in the aryl proton region were in the range 7.2–7.6 ppm. The complexes (**2d**–**2f**) are easily distinguished because the resonances of the protons show only two groups. The proton of $-CH_2-$ in $C_4H_4NO_2-$ appeared at 2.5–2.7 ppm, which agrees well with that previously reported [40]. In the ^{13}C{H} NMR spectra, the triphenylphosphine carbon resonances of **2a**–**2c** are easily distinguished (128.6–134.1 ppm) from the resonance of $-CH_2-$ on $C_4H_4NO_2-$ (31.8–32.1 ppm).

3.2. Single crystal structure of *2c*

Single crystals of $[(Ph_3P)_3 \cdot AgNC_4H_4O_2]$ (**2c**) could be grown by slowly cooling a saturated dichloromethane solution containing **2c** to −20 °C. The molecular structure of **2c** is depicted in Fig. 1. Selected bond distances (Å) and bond angles (°) are given in Table 2.

Complex **2c** crystallizes in the triclinic space group $P\bar{1}$, and is composed of one molecule of $[(Ph_3P)_3 \cdot AgNC_4H_4O_2]$ and three molecules of dichloromethane (Fig. 1). In the complex, a four-coordinated silver(I) ion is present with three PPh_3 ligands occupying three of the coordination sites (PPP) and the nitrogen atom of succinimide occupying the fourth site, forming a distorted tetrahedral geometry around silver. The N–Ag–P(1) (107.29(1)°) and N–Ag–P(3) (94.95(1)°) angles are smaller than that of the ideal tetrahedral angle, while the P(1)–Ag–P(2) (113.70(5)°) and P(2)–Ag–P(3) (113.32(5)°) angles are larger (Table 2).

The succinimide ring is roughly planar; the N atom is 0.027 Å above the C(55)–C(56)–C(57)–C(58) plane, producing a slight "envelope" distortion in the ring. The succinimide ring is similar to the reported complex $[Li(Ag(Suc)_2) \cdot H_2O]$ [38]. The carbonyl oxygen, however, show different distances to the plane, implying the no coordinating interactions with silver.

Scheme 2. Delocalization of the anionic charge into the ring and carbonyl groups, decreasing the C=O bond order.

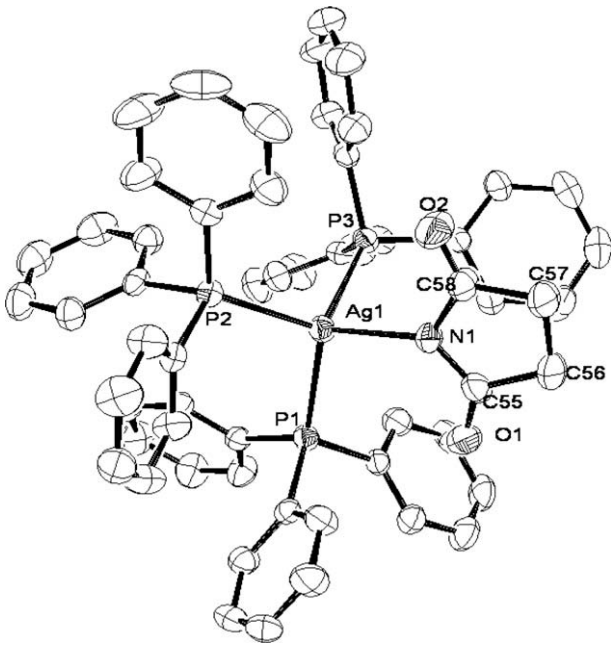


Fig. 1. ORTEP drawing of **2c**, showing 30% probability displacement ellipsoids. The hydrogen atoms and solvent molecules are omitted for clarity.

Table 2
Selected bond lengths (Å) and bond angles (°) for the $(Ph_3P)_3 \cdot AgNC_4H_4O_2 \cdot 3CH_2Cl_2$.

Bond lengths (Å)			
Ag(1)–P(1)	2.619(2)	Ag(1)–P(2)	2.561(1)

C(7)–P(1)–C(13)	101.9(2)	O(1)–C(55)–C(56)	122.6(6)
C(7)–P(1)–Ag(1)	113.9(2)	N(1)–C(55)–C(56)	111.2(6)
C(1)–P(1)–Ag(1)	116.9(2)	C(57)–C(56)–C(55)	103.8(5)
C(13)–P(1)–Ag(1)	117.7(2)	C(8)–C(7)–P(1)	118.2(4)
C(19)–P(2)–C(31)	103.3(3)	C(20)–C(19)–P(2)	119.0(4)
C(19)–P(2)–C(25)	102.8(2)	C(24)–C(19)–P(2)	123.3(5)
C(19)–P(2)–Ag(1)	115.2(2)	C(55)–N(1)–Ag(1)	123.5(4)
C(31)–P(2)–Ag(1)	121.1(2)	C(58)–N(1)–Ag(1)	124.1(4)
C(25)–P(2)–Ag(1)	111.1(2)	C(6)–C(1)–P(1)	122.6(4)
C(37)–P(3)–C(49)	102.6(2)	C(2)–C(1)–P(1)	117.7(4)
C(37)–P(3)–C(43)	103.0(3)	C(12)–C(7)–P(1)	124.1(4)
C(37)–P(3)–Ag(1)	114.7(2)	O(2)–C(58)–N(1)	125.6(6)
C(49)–P(3)–Ag(1)	111.7(2)	O(2)–C(58)–C(57)	122.6(7)
C(56)–C(57)–C(58)	103.4(6)	N(1)–C(58)–C(57)	111.9(6)
C(55)–N(1)–C(58)	109.6(5)	C(43)–P(3)–Ag(1)	120.6(2)

The C–N–C and N–C–C angles, depending on the substituent on nitrogen, are roughly correlated with the electrophilic character of the substituent. For instance, the C–N–C angle progressively decreases with decreasing substituent electrophilic character (115.0(15)°, C1; 111.6(7)°, Br; 112.6(6)°, H; 109.6(5)°, Ag; 108.3(4)°, Ni), whereas the adjacent N–C–C angles increase, but to a lesser extent (106.5(15)°, C1; 107.4(8)°, Br; 108.3(6)°, H; 111.9(6)°, Ag; 112.1(5)°, Ni) [38].

The Ag–P distances [2.619(2), 2.561(1), 2.575(2) Å] are longer than the sum of covalent radii of the P and Ag atoms (2.44 Å) [40] and that of $[(R_3P)_2AgPI]$ (PI = $C_8H_4NO_2$) [2.4944(7) Å] [41]. The Ag–N distance [2.313(4) Å] is much longer than that of $[(R_3P)_2AgPI]$ (PI = $C_8H_4NO_2$) [2.223(3) Å] [41] and the angles of P–Ag–P [113.70(5)° and 109.46(5)°] are much smaller than that of $[(Ph_3P)_2AgPAZ]$ [130.88(5)° and 125.49(8)°] (PAZ = $C_8H_5N_2O$) [41].

3.3. Thermal analysis

The complex was studied by ThemoGravimetry (TG) to obtain information on transition, decomposition temperatures and frequencies and then by Differential Scanning Calorimetry (DSC) to determine the change of entropy during thermolysis. These studies are also required to optimize the temperature at which the respective single silver precursor should be maintained during the CVD experiments. For an example, the TG and DSC curves of complex **2d** are shown in Fig. 2. It can be seen from the DSC curve that there

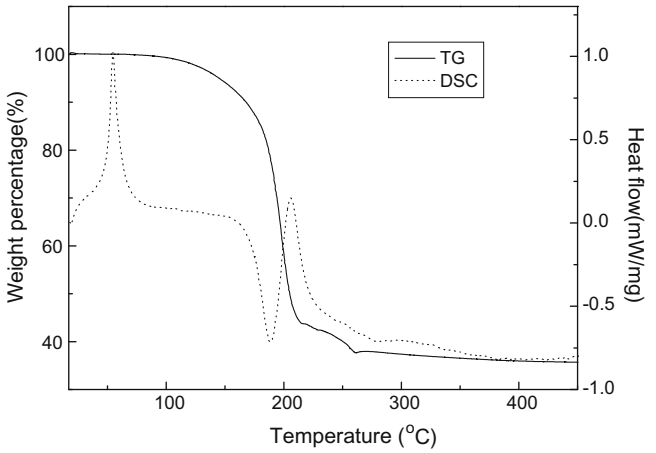

Fig. 2. TG and DSC curves of **2d** (heating rate 10 °C min^{-1}, argon atmosphere).

is one apparent endothermic process with a peak temperature of 55 °C, which could be attributed to the melting process of complex

2d. There are two continuous exothermic/endothermic processes from 163 to 210 °C, with peak temperatures of 189 and 207 °C. As seen from the TG curve, it is very difficult to distinguish from one step to another and know the sequence of decomposition of $P(OEt)_3$ and succinimide. The total weight losses are about 65.09%. The final percentage of the residue is 34.91%, which is higher than the theoretical value of silver (29.01%), which may be due to the some impurities in the complex. The complex exhibits a proper thermal decomposition temperature indicating that it could be a promising candidate as a precursor for growing silver films using the chemical vapor deposition technique.

4. Supplementary data

CCDC 687312 contains the supplementary crystallographic data for **2c**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

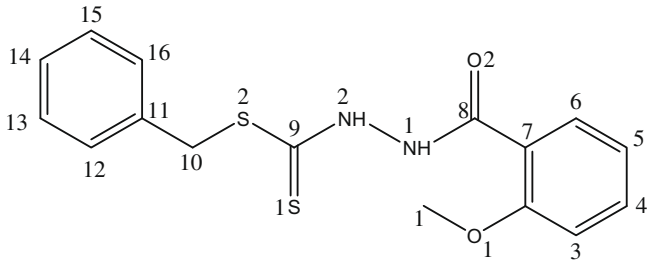

Fig. 1. Benzyl *N*′-(2-methoxybenzoyl)hydrazinecarbodithioate.

3.65 (m, 3H, $-OCH_3$), 7.76–7.10 (9H, aromatic protons). ^{13}C NMR (d_6-DMSO, δ ppm): 56.25 ($-OC^1H_3$), 157.25 (C^2), 112.31 (C^3), 136.97 (C^4), 121.09 (C^5), 129.08 (C^6), 119.21 (C^7), 164.55 (>C^8=O), 202.22 (>C^9=S), 38.04 (>$C^{10}H_2$), 133.91 (C^{11}), 128.42 (C^{12}, C^{16}), 130.63 (C^{13}, C^{15}), 127.26 (C^{14}). UV–Vis [λ_{max}, DMSO, nm]: 330, 301, 278, 242.

2.3. Preparation of the complexes

2.3.1. Preparation of $[M(Hmbhcd)_2]_n$ {M = Mn(II) **2**, Co(II) **5** and Ni(II) **6**}

The complexes **2**, **5** and **6** were prepared by stirring a solution of H_2mbhcd (2 mmol) in MeOH/$CHCl_3$ (25 ml) with a solution of $M(OAc)_2 \cdot XH_2O$ (1 mmol) in MeOH for 3–4 h at room temperature. The resulting precipitate was filtered off, washed with an ethanol–chloroform mixture and dried at room temperature under vacuum. The yield ranged from 58% to 67%.

*2.3.1.1. $[Mn(Hmbhcd)_2]_n$ (**2**).* Mustard yellow, yield 58%; M.p. 190 °C, μ_{eff} = 5.98 BM. *Anal. Calc.* for $C_{32}H_{30}MnN_4O_4S_4$ (717.39): C, 53.55; H, 4.21; N, 7.81; S, 17.87; Mn, 7.65. UV–Vis [λ_{max}, DMSO, nm]: 668, 457, 331, 298, 259. MS(FAB) *m*/*z* = 721 $[M]^{+\cdot}$.

2.3.2. Preparation of $[Mn(Hmbhcd)_2(o\text{-phen})] \cdot DMSO$ (**3**)

Complex **2**, as prepared above, was stirred with a solution of *o*-phen (0.198 g, 1 mmol) in methanol (15 ml) for 1 h. The yellowish turbid suspension obtained was made clear after adding a few drops of DMSO. The clear yellow solution of the complex was kept for crystallization which yielded light yellow transparent crystals of **3** after 16 days.

Light yellow, yield 67%; M.p. 200 °C, μ_{eff} = 6.10 BM. *Anal. Calc.* for $C_{46}H_{44}MnN_6O_5S_5$ (976.11): C, 56.60; H, 4.54; N, 8.61; S, 16.42; Mn, 5.63. Found: C, 56.12; H, 4.07; N, 8.11; S, 16.40; Mn, 6.01%. IR (ν cm^{-1}, KBr): ν(NH) 3181 m; ν(>C=O) 1602s; thioamide I [β(NH) + ν(CN)] 1501s; thioamide II [ν(CN) + β(NH)] 1300s; ν(N–N) 1101 m; ν(>C=S) 910; ν(CH_2) 2933; (*o*-phen) 1240; ν(SO) of DMSO 1018. UV–Vis [λ_{max}, DMSO, nm]: 585, 461, 338, 317, 289.

2.3.3. Preparation of $[Mn_2(Hmbhcd)_2(2,2'\text{-bpy})_2(\mu\text{-OAc})_2]$ (**4**)

Complex **4** was prepared by stirring a solution of H_2mbhcd (2 mmol) in MeOH/$CHCl_3$ (25 ml) with a solution of $Mn(OAc)_2 \cdot 4H_2O$ (1 mmol) in MeOH for 2 h at room temperature followed by the addition of 2,2′-bpy (0.156 g, 1 mmol) to yield a clear yellow solution. This solution was filtered and kept for crystallization for 25 days, which gave yellow transparent crystals of **4**.

Light yellow, yield 61%; M.p. 245 °C, μ_{eff} = 5.90 BM. *Anal.Calc.* for $C_{56}H_{52}Mn_2N_8O_8S_4$ (1203.18): C, 55.90; H, 4.36; N, 9.31; S, 10.66; Mn, 9.13. Found: C, 55.48; H, 4.30; N, 9.89; S, 10.59; Mn, 9.96%. IR (ν cm^{-1}, KBr): ν(NH) 3181 m; ν(>C=O) 1601s; thioamide I [β(NH) + (CN)] 1512s; thioamide II [ν(CN) + β(NH)] 1312s; ν(N–N) 1106 m; ν(>C=S) 905; ν(CH_2) 2922; (bpy) 1181; $\nu_{as}(CH_3COO)^-$ 1561; $\nu_s(CH_3COO)^-$ 1480. UV–Vis [λ_{max}, DMSO, nm]: 632, 343, 234.

3. Analyses and physical measurements

Carbon, hydrogen, nitrogen and sulfur contents were estimated on a CHN Model CE-440 Analyzer and on an Elementar Vario EL III Carlo Erbo 1108. By following standard procedures, the complexes were analyzed for their metal content, after decomposition with a mixture of conc. HNO_3 and HCl, followed by conc. H_2SO_4 [22]. Magnetic susceptibility measurements were performed at room temperature on a Cahn Faraday balance using $Hg[Co(NCS)_4]$ as the calibrant and electronic spectra were recorded on an UV-1700 Pharmaspec spectrophotometer. IR spectra were recorded in the 4000–400 cm^{-1} region as KBr pellets on a Varian Excalibur 3100 FT-IR spectrophotometer. ^1H and ^{13}C NMR spectra were recorded in DMSO-d_6 and on a JEOL AL300 FT NMR spectrometer using TMS as an internal reference. The FAB mass spectra were recorded on a Jeol SX 102/Da-600 mass spectrometer/data system with argon/xenon (6 kv, 10 m A0) as the FAB gas and *m*-nitrobenzyl alcohol (NBA) was used as the matrix.

4. Crystallographic data collection and structure refinement

X-ray single crystal refinement, diffraction data collection and data reduction for complexes **3** and **4** were performed at 200(2) K with a graphite monochromated Mo Kα (λ = 0.71073 Å) radiation source using standard methods [23]. The MERCURY package was used for molecular graphics [24]. Crystal structure diagrams were generated by use of the ORTEP-3 for Windows program [25]. The structures were solved by direct methods (SHELX-97) [26] and refined against all data by full-matrix least-squares on F^2 using anisotropic displacement parameters for all non-hydrogen atoms. Crystallographic data and refinement details for the structural analysis of the complexes are summarized in Table 1 and selected bond lengths and bond angles for complexes **3** and **4** are given in Tables 2 and 4, respectively. The hydrogen bonds are listed in Tables 3 and 5 for complexes **3** and **4**, respectively.

5. Results and discussion

The ligand H_2mbhcd reacts with $M(OAc)_2 \cdot XH_2O$ in a $CHCl_3$–MeOH mixture to give polymer complexes with a metal:ligand composition of 1:2. The CHNS elemental analyses and mass spectrometry results are in full agreement with the calculated values of mass percent of elements and molecular weights. In the case of the ligand, the presence of the thioamide functional group –

NH–C(=S)SR, indicates that the ligand can exhibit thione–thiol tautomerism. The solid state IR spectrum and XRD of H$_2$mbhcd do not reveal the presence of –(SH), indicating that in the solid state it remains in the thione form. The ^{1}H NMR spectrum in DMSO-d_6 is devoid of any signal attributed to the SH proton, indicating that in solution also it remains as the thione form. The ligand behaves as uninegative tridentate/bidentate and facilitates the formation of the metal complexes [M(Hmbhcd)$_2$]$_n$ {where M = Mn(II) **2**, Co(II) **5** and Ni(II) **6**}, [Mn(Hmbhcd)$_2$(*o*-phen)] · DMSO (**3**) and [Mn$_2$(Hmbhcd)$_2$(2,2′-bpy)$_2$(μ-OAc)$_2$] (**4**). These are stable towards air and moisture for several days. All the compounds are soluble in a methanol–chloroform mixture and other polar solvents such as DMF and DMSO.

5.1. IR spectra

The IR spectrum of H$_2$mbhcd in KBr shows two bands at 3127 and 3068 cm^{-1} due to the presence of two –NH groups. The presence of the thioamide functional group –NH–(C=S)SR gives rise to characteristic bands associated with thioamide I [β(NH) + ν(CN)] [mainly due to βNH], thioamide II [ν(CN) + β(NH)] [high ν(CN)] and thioamide IV [mainly due to ν(C=S)]. The bands at 1641, 1467, 1250, 1046 and 905 cm^{-1} are assigned to ν(C=O), thioamide I, thioamide II, ν(N–N) and ν(C=S), respectively. The bands at 2938 cm^{-1} correspond to ν(CH$_2$) of the benzyl ring. An exhaustive comparison of the IR spectra of the ligand and the complexes gave information about the mode of bonding of the ligand in the metal complexes **2–6**. The IR spectra of the complexes [Mn(Hmbhcd)$_2$]$_n$ (**2**), [Co(Hmbhcd)$_2$]$_n$ (**5**) and [Ni(Hmbhcd)$_2$]$_n$ (**6**) show only one peak at 3177–3179 cm^{-1}, suggesting the loss of one hydrazinic proton and participation of the resulting deprotonated nitrogen in bonding with the metal ion. A negative shift of 40–43 cm^{-1} in amide I indicates the involvement of the carbonyl oxygen in bonding for complexes **2**, **5** and **6**. A negative shift of 58–63 cm^{-1} in the ν(C=S) band indicates the involvement of the thione sulfur in bonding for complexes **2, 5** and **6**. Furthermore, the bands at 1511–1514, 1295–1301 and 1102–1105 cm^{-1} due to thioamide I, thioamide II and ν(N–N) undergo a shift to higher frequencies of 44–47, 45–51 and 56–59 cm^{-1}, respectively, showing the involvement of the thione sulfur and hydrazinic nitrogen in bonding.

In the IR spectra of complexes **3** and **4**, the bands at 3180–3181, 1601–1603, 1501–1512, 1300–1312, 1101–1106, 906–910 and 2922–2933 cm^{-1} are assigned to ν(NH), ν(C=O), thioamide I, thioamide II, ν(N–N), ν(C=S) and ν(CH$_2$), respectively. The ν(C=S) band at 906–910 cm^{-1} remains practically unchanged in the complexes in comparison to the ligand, suggesting non-involvement of the thione sulfur in bonding, while a negative shift of 38–40 cm^{-1} for ν(C=O) indicates the involvement of this group in bonding. A positive shift in ν(N–N) indicates the involvement of the hydrazinic nitrogen in bonding. This is also supported by the positive shift in thioamide I and II. The IR spectra of each of complexes **3** and **4** show a band at 1240 and 1181 cm^{-1}, respectively, for coordinated *o*-phen and 2,2′-bpy [27]. The peak corresponding to the SO stretching of non-bonded DMSO occurs at 1018 as a strong and broad band [28]. Thus, H$_2$mbhcd behaves as a uninegative bidenate ligand in complexes **3** and **4** and a uninegative tridentate ligand in complexes **2**, **5** and **6**. The symmetric (1480 cm^{-1}) and asymmetric (1561 cm^{-1}) stretching bands of the acetate anion in complex **4** indicate its bridging bidentate nature [29].

5.2. Magnetic moments and electronic spectra

The μ_{eff} values of 5.98, 6.10 and 5.90 B.M. for complexes **2**, **3** and **4**, respectively show the presence of a high spin Mn^{2+} ion having five unpaired electrons with the $^6A_{1g}$ ground state. Their UV–Vis spectra exhibit one d–d band at 632–550 nm due the $^6A_{1g} \rightarrow {}^4T_{1g}(G)$ transition, suggesting an octahedral geometry around Mn(II) [30]. An additional band at 461 nm in [Mn(Hmbhcd)$_2$(*o*-phen)] · DMSO (**3**) is assigned to an intraligand/charge transfer transition. The magnetic moment of 5.11 B.M. and the presence of two well resolved bands at 592 and 445 nm corresponding to the $^4T_{1g} \rightarrow {}^4A_{2g}$ and $^4T_{1g}$ transitions, respectively, is indicative of a cobalt(II) ion in an octahedral environment for complex **5** [30]. An absorption band at 320 nm in the high-energy region is assigned to an intraligand transition. The magnetic moment of 2.99 B.M. for [Ni(Hmbhcd)$_2$]$_n$ (**6**) is typical of a high spin octahedral Ni(II) complex and the presence of two bands at 668 and 457 nm are considered to arise from the $^3A_{2g} \rightarrow {}^3T_{2g}(F)$ and $^3T_{1g}(P)$ transitions in an octahedral geometry around Ni(II). The high-energy bands at 331, 298 and 259 nm in the spectrum of [Ni(Hmbhcd)$_2$]$_n$ are probably due to charge transfer/intraligand transitions [30].

Table 3
Hydrogen bonds for complex **3** (Å and °).

D–H···A	d(D–H)	d(H···A)	d(D···A)	<(DHA)
N(1A)–H(1AD)···O(1A)	0.88	1.94	2.5950(16)	130.0
N(1B)–H(1BD)···O(1B)	0.88	2.00	2.6541(15)	130.5
C(1A)–H(1AB)···O(1S)	0.98	2.55	3.339(3)	138.0

Symmetry transformations used to generate equivalent atoms.

5.3. ^1H and ^{13}C NMR spectra

The ^1H NMR spectrum of H_2mbhcd shows two signals at 10.73 and 10.55 ppm due to the presence of –NH(CO)– and –NH(CS)– protons, respectively. The peaks at 4.45 and 3.91 ppm correspond to $–CH_2$ and $–OCH_3$ protons. The protons due to the two aromatic rings, i.e. the 2-methoxybenzene ring and the benzyl ring, appear as multiplets between 7.76 and 7.10 ppm. The ^{13}C NMR spectrum of H_2mbhcd shows 16 signals due to the presence of 16 carbon atoms. The peaks at δ 202.22 and 164.14 ppm are attributed to the >C=S and >C=O carbons, respectively. The ^1H and ^{13}C NMR of complexes could not be recorded due to their paramagnetic nature.

5.4. Mass spectrometry

FAB mass spectral analyses of $[Mn(Hmbhcd)_2]_n$ (**2**), $[Co(Hmbhcd)_2]_n$ (**4**) and $[Ni(Hmbhcd)_2]_n$ (**6**) show the presence of the molecular ion peaks at m/z = 718 $[M]^{+\cdot}$, 722 $[M]^{+\cdot}$ and 721 $[M]^{+\cdot}$, respectively which correspond to the molecular weight of one unit of the polymer. Other peaks at higher m/z values indicate their polymeric nature. Complex **2** gave several important peaks at m/z 684 (45% intensity), 610 (35% intensity), 593 (25% intensity), 509 (35% intensity), 470 (98% intensity) and 386 (75% intensity) corresponding to fragments formed from $[Mn(Hmbhcd)_2]_n$ after release of H_2S, $C_6H_4(–OCH_3)$, $PhCH_2S–$, $[C_6H_4(OCH_3)–C(O)–NHN–C(S)–]$, $2(PhCH_2S–)$ and $[C_6H_4(OCH_3)C(O)NH–N–C(S)–S–]$, respectively. The fragments at m/z = 689 (12.5% intensity), 598 (25% intensity), 571 (25% intensity) and 390 (35% intensity) correspond to the fragments formed from $[Co(Hmbhcd)_2]_n$ (**4**) after release of HS, $PhCH_2S–$, $[C_6H_4(OCH_3)–C(O)–NH)–]$ and $C_6H_4(OCH_3)–C(O)–NH–N–C(S)S–]$, respectively from one unit of the complex. Complex **6** gave important peaks at m/z = 597 (50% intensity), 473 (48% intensity) and 389 (75% intensity), corresponding to the fragments formed from one unit of $[Ni(Hmbhcd)_2]_n$ after release of $PhCH_2S–$, $2PhCH_2S–$ and $[C_6H_4(OCH_3)C(O)NH–N–C(S)–S–]$, respectively.

On the basis of the analytical data and spectroscopic studies, tentative structures of the complexes $[M(Hmbhcd)_2]_n$ are given in Fig. 2.

6. Crystal structure description

6.1. Crystal structure description of complex 3

Fig. 3 shows a Mercury view of the Mn(II) complex together with the atom numbering scheme. The metal center in complex **3** is coordinated by an N_4O_2 core from two uninegative bidentate ligands using the hydrazinic nitrogens (N2, after loss of a proton) and carbonyl oxygens. Various bond distances found within the chelate rings are intermediate between single and double bond lengths and shorter or longer than the corresponding bond lengths in comparison to the ligand. The average bond lengths in complex **3** are: O(2A)–C(8A) = 1.2503(18); O(2B)–C(8B) = 1.2569(17), N(1A)–C(8A) = 1.3363(19), N(1B)–C(8B) = 1.3303(19), N(1A)–N(2A) = 1.3872(16), N(1B)–N(2B) = 1.3851(15) Å, which suggest considerable delocalization of charge [31] in the chelate ring.

Transition metal complexes in which bonding of the ligand takes place through a carbonyl oxygen and nitrogen and also bonded with N-heterocyclic bases such as *o*-phen or 2,2′-bpy are prone to exhibit metalloaromaticity [32–36]. The above criteria of metalloaromaticity are fulfilled in complex **3**. The most noteworthy structural feature of complex **3** is that two *ortho*-H atoms from the *o*-phen ring point towards the center of the corresponding Mn–OCN1N2 chelate rings [37]. This delocalized charge in the chelate ring forms an unusual intramolecular C–H···π interaction with the *ortho* hydrogen of the adjacent *o*-phen ring [19,37] (Fig. 4).

$[M(Hmbhcd)_2]_n$ {M = Mn(II) (2), Co(II) (5), Ni(II) (6), R' = CH_2Ph

Fig. 2. Tentative structure of the complexes $[M(Hmbhcd)_2]_n$ {M = Mn(II), Co(II) and Ni(II)}.

The shortest centroid to centroid separation found between parallel benzyl and *o*-phen rings is 4.038 Å within the molecule, which rules out the possibility of intramolecular face to face (π···π) interactions in **3**. The chelate rings around Mn(II) formed by $(Hmbhcd)^-$ display a dihedral angle of 73.50° (between the mean planes MnN2AN1AC8AO2A and MnO2BC8BN1BN2B) and indicate strain in both chelate rings. This strain between the chelate rings is also supported by the dihedral angle between the 2-methoxy benzene ring and the chelate rings. The chelate ring O2BMnN2BN1BC8B and the corresponding 2-methoxy benzene ring lie in the same plane while another chelate ring O2AMnN2AN1AC8A and its corresponding 2-methoxy benzene ring are nearly planar with a dihedral angle of 14.11°. The dihedral angle between a benzyl ring (mean plane C16BC15BC14BC13BC12BC11B) and one chelate ring (mean plane MnO2BC8BN1BN2B) is 24.30° and between another chelate ring (mean plane MnN2AN1AC8AO2A) and benzyl ring (mean plane C14AC13AC12AC11AC16AC15A) is 62.81°.

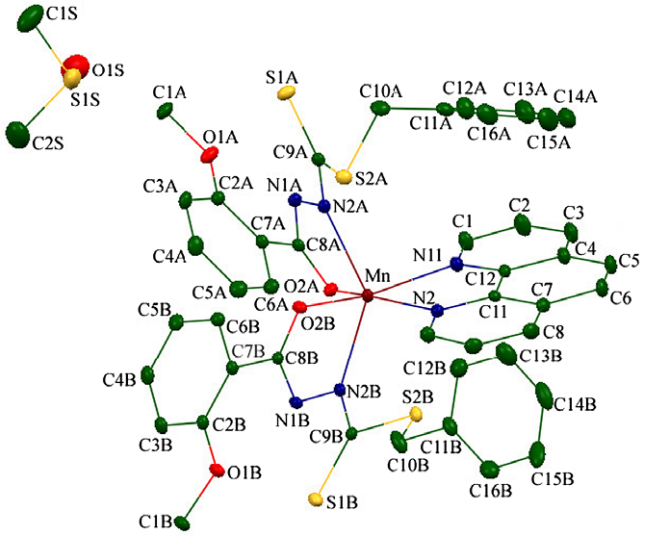

Fig. 3. Mercury view of $[Mn(Hmbhcd)_2(o\text{-phen})]\cdot DMSO$ showing the atomic numbering scheme with ellipsoids of 20% probability. Hydrogen atoms are omitted for clarity.

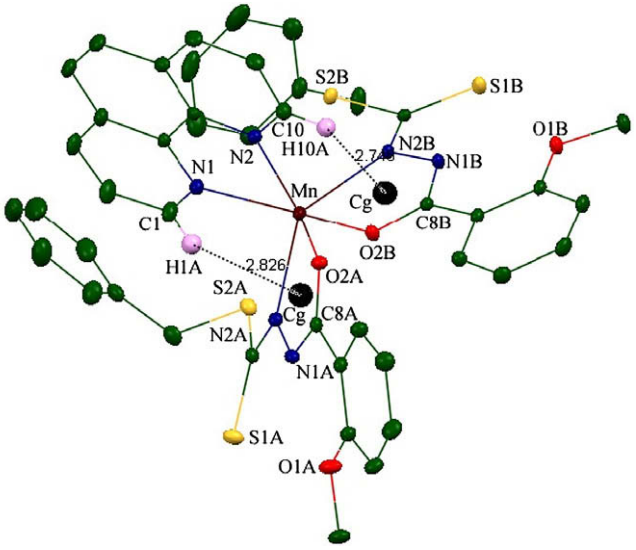

Fig. 4. Crystal structure of $[Mn(Hmbhcd)_2(o\text{-phen})]$, showing an unusual intramolecular C–H···π interaction with the Mn(II) chelate ring. For clarity other hydrogen atoms and the DMSO molecule are omitted.

6.2. Crystal packing of complex **3**

The weak intermolecular interactions are listed in Table 6. The presence of intramolecular hydrogen bonding, N(1B)–H(1BD)···O(1B) = 1.99 Å and N(1A)–H(1AD)···O(1A) = 1.94 Å, provide stability to complex **3**. The two-dimensional framework is formed with the help of intermolecular hydrogen bonding, C10–H10A···O1S (2.604 Å), C1A–H1AB···O1S (2.546 Å) and C3A–H3AA···S1B (2.908 Å). The whole arrangement of molecules in the crystal packing creates channels which enclose DMSO molecules (Fig. 5).

6.3. Crystal structure description of complex **4**

Each Mn(II) center is six coordinately bonded through two N atoms of one 2,2′-bpy, one deprotonated nitrogen from a hydrazinic moiety and three oxygen atoms, belonging to two different acetates and one carbonyl oxygen of the ligand **1** (Fig. 6). The two neighboring Mn(II) centers are connected by two bridging acetate ions which results in the formation of a distorted rectangular shaped cavity of size 3.151 × 3.017 $Å^2$, labeled as [Mn–O12–C12A–O11–Mn–O12–C12A–O11] (Fig. 6). One molecular unit of $[Mn_2(Hmbhcd)_2(2,2'\text{-bpy})_2(\mu\text{-OAc})_2]$ shows the presence of an intramolecular N–H···O hydrogen bond, with a distance and angle of 2.614(3) Å and 111.2°, respectively. The $Mn–O_{acetate}$ bond lengths of 2.0929(17) and 2.1737(18) Å are relatively shorter than the reported bond length values for bridged Mn–OAc = 2.144(2)–2.203(2) Å, indicating relatively stronger bonding between Mn(II) and oxygen in this system [38]. The bond distance of $Mn–O_{carbonyl}$ = 2.1890(17) Å is comparable to the bond lengths found for $[Mn(Hpchc)_2(o\text{-phen})]$ [19]. The $Mn–N_{bpy}$ distances [2.238(2) and 2.277(2) Å] are slightly longer than the reported values for $Mn–N_{bpy}$, 2.038(3)–2.254(3) Å [39], but the bite angle N(1A)–Mn–N(2A) = 72.96(7)° is close to 73°, as observed for chelating 2,2′-bpy complexes [39]. The C–O, C–N and N–N bond distances of 1.262(3), 1.326(3) and 1.406(3) Å, respectively, are intermediate between single and double bond character. All these intermediate distances suggest extensive delocalization of charge in the five-membered chelate ring of complex **4** [31] and is the basis of metalloaromaticity.

6.4. Crystal packing of **4**

A view of the crystal packing along the b axis gives a linear arrangement of Mn(II) centers and increases the chain in one dimension with a Mn···Mn separation of 10.001 Å in

$[Mn_2(Hmbhcd)_2(2,2'\text{-bpy})_2(\mu\text{-OAc})_2]$. The chain grows infinitely in 1 D along the a axis with the help of C4A–H4AA···O11 and π···π interactions between two successive 2,2′-bpy rings (Fig. 7). The distance between the centroids (Cg) of two 2,2′-bpy ligands of two adjacent units of $[Mn_2(Hmbhcd)_2(2,2'\text{-bpy})_2(\mu\text{-OAc})_2]$ is 3.262 Å, which is within the range of π···π stacking interactions (3.3–3.7 Å). The π···π stacking interactions between the two units of molecules, intermolecular hydrogen bonding, C4A–H4AA···O11 = 2.641 Å, and short contact of C4A–H4AA···C11A = 2.562 Å connect the sheets into a 1D coordination framework (Fig. 7).

The 2,2′-bpy ligand forms C–H···π interactions with the phenyl ring of the 2-methoxy benzene ring with a distance of C–H···$Cg_{(2\text{-methoxy ring})}$ of 2.907 Å (Fig. 8). There is intermolecular hydrogen bonding, C1–H1$C_{(2\text{-methoxy benzene ring})}$···S1 = 2.931 Å and C10–H10B···O11 (CH_2 of benzyl ring) = 2.394 Å, which extends the crystal packing and gives a three dimensional framework. The weak intermolecular interactions are listed in Table 6.

Looking at the crystal data and structure of the complexes, it is found that the bond lengths and bond angles in the ligand H_2mbhcd are very similar, but the torsional angles of compounds **3** and **4** differ widely (Table 7). The basic change observed in the structure of the ligand due to metal coordination is in the orientation of the benzyl ring. One benzyl ring, C11A–C12A–C13A–C14A–C15A–C16A, in complex **3** and both benzyl rings, C11–C12-C13–C14–C15–C16, in complex **4** show major deviation in torsional angles [C9A–S2A–C10A–C11A = −93.19°, C9B–S2B–C10B–C11B = 177.96° for complex **3**, C9–S2–C10–C11 = –80.34°, C9–S2–C10–C11 = 80.34° for complex **4**] in comparison to the ligand H_2mbhcd [C9–S2–C10–C11 = −173.79°]. The O(2)–C(8) bond length in the ligand, 1.222(3) Å, is shorter than the corresponding length {O(2A)–C(8A) = 1.2503(18) Å (**3**), O(2B)–C(8B) = 1.2569(18) Å (**3**) and O(2)–C(8) = 1.262(3) (**4**)} in the complexes, indicating that the single bond character of the C–O bond has increased due to delocalization of charge. There are slight variations in the N(1)–C(8), N(1)–N(2) and N(2)–C(9) bond lengths in complexes **3** and **4** as compared to the respective bond lengths of H_2mbhcd.

The C–N and N–N bond lengths in the ligand and the complexes show intermediate between single and double bond character, which is also indicative of considerable delocalization of charge in the chelate ring formed by the coordination of the deprotonated hydrazinic nitrogen and carbonyl oxygen in complexes **3** and **4**. This delocalization generates aromaticity in the chelate ring of both complexes.

7. Conclusion

In this work, the synthesis and spectral studies of Mn(II), Co(II) and Ni(II)} complexes derived from benzyl *N*′-(2-methoxybenzoyl)hydrazine carbodithioate (H_2mbhcd) are presented. $[Mn(Hmbhcd)_2(o\text{-phen})]\cdot DMSO$ (**3**) and $[Mn_2(Hmbhcd)_2(2,2'\text{-bpy})_2(\mu\text{-OAc})_2]$ (**4**) have been studied by single crystal X-ray crystallography, which indicate that the complexes involve delocalization of charges in the chelate ring.

(200 mg, 1 mmol) in methanol (10 ml). The resulting precipitate that formed immediately was dissolved in hot absolute methanol (20 ml). The filtered solution was cooled in the dark, giving the complex as light yellow needles, which were washed successively with ice-cooled absolute methanol (5 ml) and ether (25 ml), and dried in a vacuum desiccator overnight. Yield: 92%. *Anal.* Calc. for $C_{24}H_{18}F_2Hg_2N_6O_6$: C, 31.14; H, 1.96; N, 9.08. Found: C, 31.17; H, 1.95; N, 9.05%. UV–Vis: $\lambda(\log\varepsilon)$ (DMSO): 243(4.11), 275(3.92), 295(3.91). IR (KBr/ν, cm^{-1}): 1596 (C=N).

*2.2.2. Synthesis of $[Hg_2(B)_2](NO_3)_2$ (**2**)*

This complex was prepared by a procedure similar to that for **1** using 21.7 mg (0.1 mmol) of **B**. Light yellow crystals were collected by filtration and dried in *vacuo*. Yield: 93%. *Anal.* Calc. for $C_{24}H_{18}Cl_2Hg_2N_6O_6$: C, 30.07; H, 1.89; N, 8.77. Found: C, 30.09; H, 1.87; N, 8.74%. UV–Vis: $\lambda(\log\varepsilon)$ (DMSO): 240(4.21), 273(3.84), 297(3.71). IR (KBr/ν, cm^{-1}): 1601 (C=N).

*2.2.3. Synthesis of $[Hg_2(C)_2](NO_3)_2$ (**3**)*

This complex was prepared by a procedure similar to that for **1** using 26.1 mg (0.1 mmol) of **C**. Light yellow crystals were collected by filtration and dried in *vacuo*. Yield: 86%. *Anal.* Calc. for $C_{24}H_{18}Br_2Hg_2N_6O_6$: C, 27.52; H, 1.73; N, 8.02. Found: C, 27.50; H, 1.72; N, 8.05%. UV–Vis: $\lambda(\log\varepsilon)$ (DMSO): 239(4.23), 269(3.86), 298(3.86). IR (KBr/ν, cm^{-1}): 1599 (C=N).

*2.2.4. Synthesis of $[Hg_2(D)_2](NO_3)_2$ (**4**)*

This complex was prepared by a procedure similar to that for **1** using 30.8 mg (0.1 mmol) of **D**. Light yellow crystals were collected by filtration and dried in *vacuo*. Yield: 89%. *Anal.* Calc. for $C_{24}H_{18}Hg_2I_2N_6O_6$: C, 25.25; H, 1.59; N, 7.36. Found: C, 25.28; H, 1.56; N, 7.34%. UV–Vis: $\lambda(\log\varepsilon)$ (DMSO): 238(4.20), 272(3.81), 296(3.95). IR (KBr/ν, cm^{-1}): 1602 (C=N).

2.3. X-ray analyses

Crystals of **1** and **3**, which were suitable for X-ray crystallography, were obtained as described above. A summary of the key crystallographic information is given in Table 1. Diffraction data for **1** was collected on a Bruker–Nonius Kappa-CCD diffractometer using monochromated Mo Kα radiation and measured using a combination of ϕ scans and ω scans with κ offsets to fill the Ewald sphere. The data was processed using the Denzo-SMN package [21]. Absorption corrections were carried out using SORTAV [22]. The structure was solved and refined using SHELXTL V6.1 [23] for full-matrix least-squares refinement based on F^2. All H-atoms were included in calculated positions and allowed to refine in a riding-motion approximation with U_{iso} tied to the carrier atom. Diffraction data for **3** collected on a Bruker SMART APEX2 CCD area detector using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Preliminary orientation matrices were obtained from the first frames using APEX2 [24]. The structures were solved using direct methods and refined by the full-matrix least-squares method on F^2 data using SHELXTL [25]. All H-atoms were geometrically positioned and refined using a riding model with d (C–H) = 0.93 Å, U_{iso} = 1.2U_{eq}(C).

3. Results and discussion

3.1. Synthesis and spectral properties

The mercury(I) complexes were prepared by reacting equimolar quantities of mercury(I) nitrate and the ligands in methanol. These complexes are light yellow solids, which are insoluble in chloroform, methanol, ethanol and acetone, and are stable under ambient conditions. While most mercury(I) complexes containing nitrogen donor ligands undergo disproportionation reactions, some imines are known to form stable mercury(I) complexes [4,13]. The existence of stable iminopyridine complexes of mercury(I), which have

Table 2

		Hg1–Hg1′–O1′	124.29(14)
		N3′–O1′–Hg1′	110.1(4)

been confirmed in this study, is consistent with an earlier suggestion that mercury(I) complexes should favor π-acceptor ligands. The IR spectra of the free ligands exhibit the characteristic band of the imine group in the 1621–1631 cm^{-1} region [20]. This band is shifted to lower frequencies in the IR spectra of the corresponding complexes due to the coordination of the imine nitrogen, and appears in the 1596–1602 cm^{-1} region.

The absorption spectra of the complexes **1–4** have absorption bands in the 200–300 nm range (see experimental section) attributed to ligand-centered $\pi \rightarrow \pi^*$ or/and charge transfer transitions.

3.2. Crystal structures

The crystallographic data of compounds **1** and **3** are summarized in Table 1 and selected bond distances and angles are given in Table 2.

3.2.1. $[Hg_2(A)_2](NO_3)_2$ (**1**)

A view of the complex $[Hg_2(A)_2](NO_3)_2$, **1**, along with the atom-numbering scheme is shown in Fig. 2. Complex **1** has crystallographic $\bar{1}$ symmetry and the inversion center is located at the midpoint of the Hg–Hg bond. Each mercury atom has essentially four nearest neighboring atoms, namely the other mercury atom, two nitrogen atoms of the diimine molecule and one oxygen atom belonging to a nitrate ion. The Hg atoms in **1** have an irregular coordination environment. The N1–Hg1–O1 and the intraligand N1–Hg1–N2 angles are only 81.9(3)° and 70.4(3)°, respectively. On the contrary, the Hg1a–Hg1–N1 and Hg1a–Hg1–N2 angles are 145.7(3)° and 134.9(2)°, respectively.

The average Hg–N bond distance (2.372 Å) is similar to that found in structurally related complexes ($[L^2HgHgL^2]^{2+}$ with two N-donor atoms per Hg); for example: 2.335 Å for $[Hg_2(phen)_2](OTf)_2$, 2.39 Å for $Hg_2(phen)(NO_3)_2$ [12], 2.356 Å for $[Hg_2(L^{pPh})][ClO_4]_2$, (L^{pPh} = terdentate ligand, [bis(pyrazol-3-yl)pyridine] derivative) [16] and 2.335 Å for $[Hg_2(phen)_2](OTf)_2$ and 2.352 Å for $Hg_2(4\text{-benzyl-py})_4ClO_4)_2$ [13,14]. However, the Hg–N bond lengths in complexes of the type $[L^2HgHgL^2]^{2+}$ lie between the same bond lengths in complexes of the type $[L^1HgHgL^1]^{2+}$ and $[(L^2)_2HgHg(L^2)_2]^{2+}$. The Hg–N bond lengths observed for complexes of the type $[L^1HgHgL^1]^{2+}$ exhibit values in the 2.10–2.20 Å range [4]. A mean value of 2.521 Å is observed for the complex $[Hg_2(phen)_4]^{2+}$ with four N-donor atoms per Hg [13]. The diimine ligands in **1** are coordinated in a slightly asymmetric bidentate manner: The difference between the bond lengths of Hg1–N1 and Hg1–N2 is 0.11 Å. A similar asymmetry has been reported for $[Hg_2(phen)_2](OTf)_2$, with a difference of 0.14 Å [13].

The Hg1–O1 distance is 2.490(9) Å, compared to the sum of the van der Waals radii of 3.02–3.25 Å. This distance is slightly shorter than those in $Hg_2(phen)(NO_3)_2$, (2.59 and 2.91 Å) [12] and in $Hg_2(quinoline)_2(NO_3)_2$, (2.818, 2.786 and 2.802 Å) [26–29].

The Hg–Hg bond length of **1** is 2.5334(11) Å, compared to 2.513(5) Å for $[Hg_2(phen)_2](OTf)_2$, 2.516(7) Å for $Hg_2(phen)(NO_3)_2$ and 2.551(2) Å for $Hg_2(quinoline)_2(NO_3)_2$ [12,13,27].

The geometry of imine and pyridine nitrogen atoms is planar. The planarity is measured by three N atom bond angles. The sums

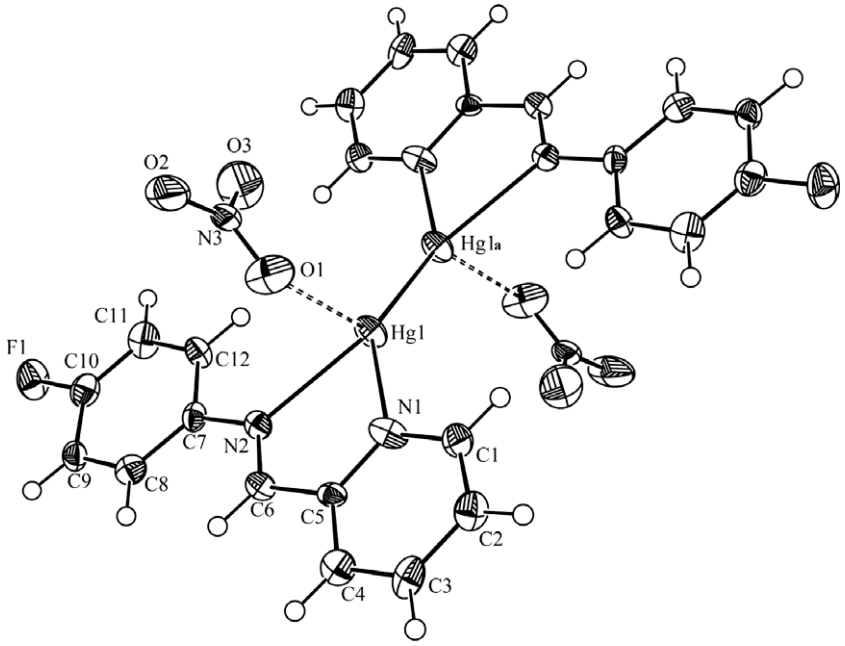

Fig. 2. Structure of **1** in the crystal, showing the atom-labelling scheme. Thermal ellipsoids are at 50% probability.

Table 3
Geometry of the pyridine, chelate and benzene ring in compounds **1** and **3**.

	1	**3**	
		Ligand 1	Ligand 2
Planes 1 (pyridine ring)	N1–C5–C6–N2	N1–C5–C6–N2	N1′–C5′–C6′–N2′
Planes 2 (chelate ring)	N1–C2–C3–C4–C5.– N2	N1–C2–C3–C4–C5	N1′–C2′–C3′–C4′–C5′
Planes 3 (benzene ring)	C7–C8–C9–C10–C11–C12	C7–C8–C9–C10–C11–C12	C7′–C8′–C9′–C10′–C11′–C12′
Dihedral angle/° between planes 1 and 2	1.29(4)	5.88(3)	5.20(4)
Dihedral angle/° between planes 2 and 3	2.10(3)	9.45(3)	7.59(3)
Dihedral angle/° between planes 1 and 3	2.65(4)	6.19(3)	11.21(3)
Distance/Å of Hg (1) to the plane 1	0.1091(5)	0.1193(5)	0.0492(4)
Distance/Å of Hg (1a) to the plane 1	1.089(5)	0.127(4)	0.816(4)
Torsion angle/° N–C=C–N (lig 1)	4.848(2)	4.197(2)	−9.073(2)
Angel between plane 1 and Hg–Hg line	67.25(4)	84.35(3)	69.90(3)

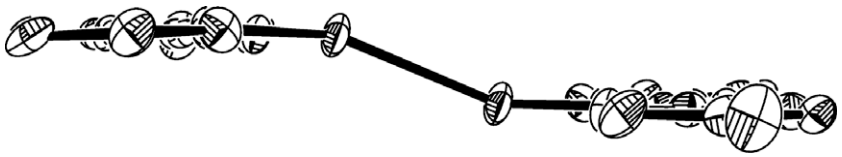

Fig. 3. View of the $[Hg_2(A)_2]^{2+}$ cation of complex **1** perpendicular to the Hg–Hg bond.

of these angles (ΣN) are 359.5° and 360° for N1 and N2, respectively. Despite the fact that the imine nitrogen atoms in **1** are sp^2 hybridized, some strain in the chelate ring is suggested by the deviation from the 120° angle about the nitrogen, Hg1–N2–C6 (114.6(7)°), Hg1–N2–C7 (124.3(7)°), and C6–N2–C7 (121.1(9)°).

Surprisingly, the dihedral angles between the planes of the pyridine ring, chelate ring and the benzene ring (best plane of 1, 2 and 3, Table 3) in **1** show coplanarity of these planes, leading to a considerable planarity of the ligands. The coplanarity of the pyridine and chelate ring results in a bite size of 2.74 Å for d(N1–N2).

While the ligand is planar, the $[L^2HgHgL^2]^{2+}$ cation of **1**, as a whole, is not coplanar. The mercury atom is closely within the plane of the corresponding chelate diimine ligand (max. deviation from this plane is 0.11 Å). However, the inversion-related mercury is displaced by 1.1 Å out of this plane, so that the $[L^2HgHgL^2]^{2+}$ unit has an appreciable 'step' in the Hg–Hg bond (Fig. 3).

$[Hg_2(A)_2](NO_3)_2$, **1**, exhibits a supramolecular structure as a result of the π–π stacking of the diimine ligands, and this may be responsible for the insolubility of the complex. Each diimine ligand has two diimine neighbors within the stacks, which are oriented along the crystallographic, 1 1 1 plane (Fig. 4). The mean inter-ring distances between corresponding atoms of the diimine ligands and the two neighboring ligands are almost equal and amount to 3.42 Å for the stacks involving the rings formed by the pyridine ring and the neighboring benzene ring. A related stacking of the phenanthroline ligands was observed for $[Hg_2(phen)_2](OTf)_2$ with separations of approximately 3.45 Å [13] and 3.50 Å for $Hg_2(phen)(NO_3)_2$ [12].

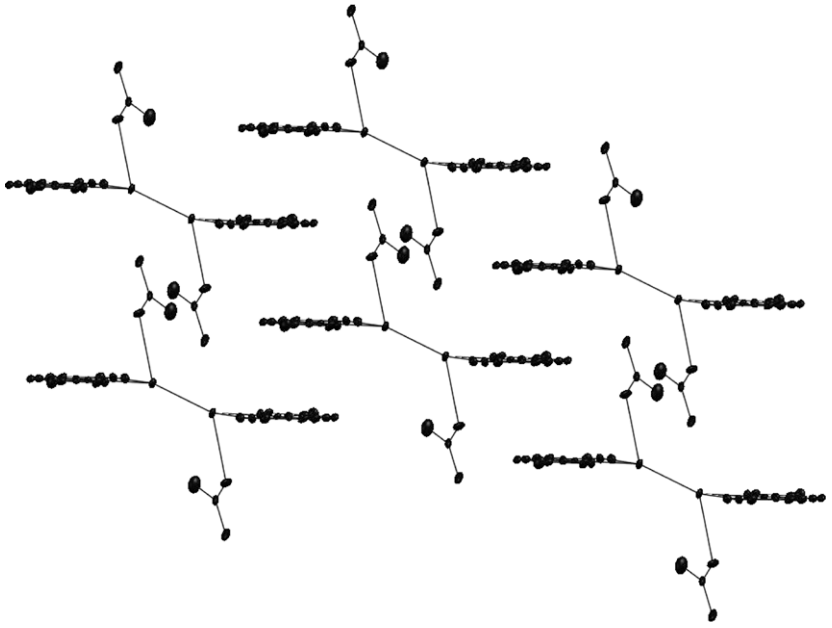

Fig. 4. Packing of $[Hg_2(A)_2](NO_3)_2$, **1**.

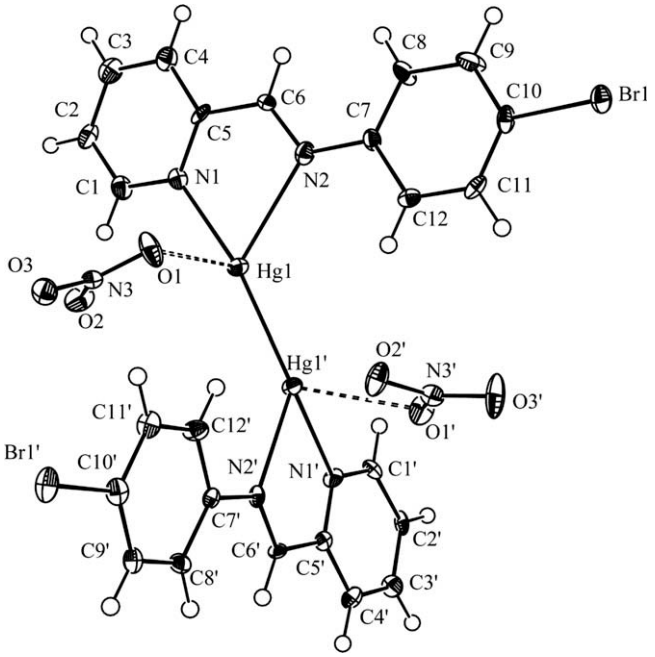

Fig. 5. Structure of **3** in the crystal, showing the atom-labelling scheme. Thermal ellipsoids are at 50% probability.

3.2.2. $[Hg_2(C)_2](NO_3)_2$ (**3**)

The molecular structure of **3** is illustrated in Fig. 5, where each mercury atom is coordinated by the bidentate diimine ligand and another mercury atom. The Hg–N distances of **3** cover the range 2.219(6)–2.565(7) Å, which is well within the van der Waals limit of 3.05–3.28 Å, depending on the van der Waals radius of mercury (1.50–1.73 Å) [28,29], while the Hg–N distances of **1** cover a shorter range (2.317–2.427 Å). The diimine ligands in **3** are coordinated in a considerably asymmetric bidentate manner: The difference between the bond lengths Hg1–N1 and Hg1–N2 is 0.346 and 0.137 Å between Hg1′–N1′ and Hg1′–N2′ (Table 2). However, the average Hg–N bond length of 2.376 Å agrees well with the same distance in the **1** ($Hg–N_{ave}$ = 2.372 Å).

The Hg–Hg bond length of 2.5190(7) Å in **3** is slightly shorter than the same bond length in complex **1**. However, the average Hg–Hg bond distance of **1** and **3** is 2.526 Å, and the Hg–Hg bond lengths in these complexes ($[L^2HgHgL^2]^{2+}$) lie between the same bond lengths in complexes of the type $[L^1HgHgL^1]^{2+}$ (2.51 Å with the exception of $Hg_2(quinoline)_2(NO_3)_2$, exhibiting a value of 2.551(2) Å) and complexes of the type $[(L^2)_2HgHg(L^2)_2]^{2+}$ (2.549 Å).

The environment of each mercury atom differs in terms of mercury–oxygen contacts. The Hg–O distances are 2.698(6) and 2.569(6) Å for Hg1–O1 and Hg1′–O1′, respectively. Whereas Hg1 is four coordinate, Hg1′ has an additional relatively weak interaction with another oxygen of the same nitrate atom [Hg1′···O2′, 3.03 Å]. However, the Hg–O distances are longer than those in **1**.

The dihedral angle between the plane of the chelate ring and the pyridine ring (Table 3) indicate the coplanarity of these moieties, resulting in a bite size of 2.788 and 2.735 Å for d(N1–N2) and d(N1′–N2′).

A comparison of the dihedral angles between the planes of the pyridine, chelate and the benzene ring (best plane of 1, 2 and 3, Table 3) in **3** indicate that the ligand is distorted from planarity, with an average twist of 8.5° between the chelate and the benzene planes.

In contrast with complex **1**, the chelate ring of ligand 1 in complex **3** twists around the Hg–Hg bond, such that it is approximately perpendicular to the chelate ring of ligand 2, resulting in a dihedral angle of 84.58° between the chelate rings (Fig. 6).

The mercury atom, Hg1 is closely coplanar with the diimine ligand. Deviation of the Hg (1) atom from this plane is 0.05 Å. However, Hg1′ deviates considerably from this plane, by 0.816 Å.

As in complex **1,** a related stacking of diimine ligands was observed for **3** with separations of approximately 3.50 Å [13]. In the structure of **3**, each of the two diimine ligands is stacked with one diimine ligand of a neighboring complex.

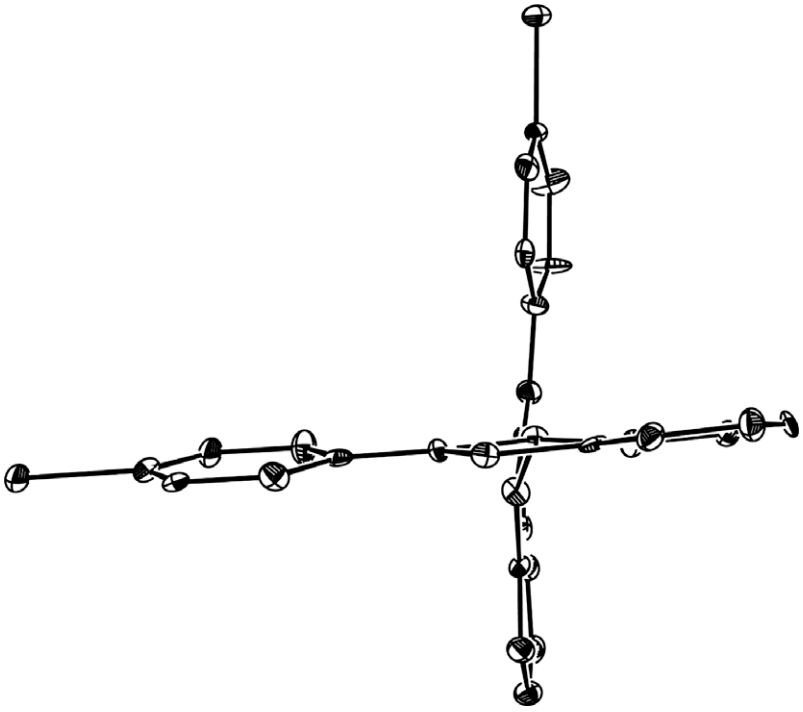

Fig. 6. View of the $[Hg_2(B)_2]^{2+}$ cation of complex **3** along the Hg–Hg bond.

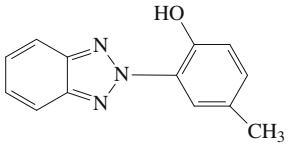
4. Supplementary data



CCDC 714916 and 714917 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Structure of 2-(2′-hydoxy-5′-methylphenyl)benzotriazole (Hhmpbta).

phenyl)benzotriazole in the presence of PPh_3 resulted in failure. In contrast to 8-hydroxyquinoline and quinoline-2-carboxylic acid, the both above mentioned reactions lead to the monosubstituted chelates. Only few crystals of $[ReOCl(hmpbta)_2]$ were isolated from the reaction of $[ReOCl_3(AsPh_3)_2]$ with ligand excess in acetonitrile.

Here, we present the synthesis, structural and spectroscopic characterization of $[ReOCl_2(hmpbta)(AsPh_3)] \cdot MeCN$ (**1** · MeCN), $[ReOBr_2(hmpbta)(AsPh_3)] \cdot MeCN$ (**2** · MeCN), $[ReOCl_2(hmpbta)(PPh_3)] \cdot MeCN$ (**3** · MeCN), $[ReOBr_2(hmpbta)(PPh_3)] \cdot MeCN$ (**4** · MeCN) and $[ReOBr_2(hmpbta)(PPh_3)] \cdot MeCN$ (**4** · Me_2CO) complexes. The paper reports also X-ray structure of $[ReOCl(hmpbta)_2]$ (**5**) and DFT calculations for **1** and **5**.

Currently density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [14]. Gancheff et al. [15] have performed extended tests of the ability of the B3LYP method in LANL2DZ basis set for rhenium compounds in a geometry optimization and calculation of spectral properties. Although this is not a very extended basis set, its use with DFT has shown to be sufficient for the geometry optimization and calculation of spectral properties. The correctness of B3LYP method with LANL2DZ basis set for rhenium complexes has been also proven in this paper. The experimental geometries of **1** and **5** are well reproduced and the calculated electronic spectrum of **1** is in good accordance with the experimental one.

2. Experimental

2.1. General procedure

All the reagents used to the synthesis were commercially available and were used without further purification. The $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)_2]$ complexes were prepared according to the literature methods [16].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–Vis 8500 in the range 1100–180 nm in acetonitrile solution. Elemental analyses (CHN) were performed on a Perkin–Elmer CHN-2400 analyzer.

2.2. Preparation of $[ReOCl_2(hmpbta)(AsPh_3)] \cdot MeCN$ (**1** · MeCN)

$[ReOCl_3(AsPh_3)_2]$ (0.5 g, 0.54 mmol) was added to 2-(2′-hydoxy-5′-methylphenyl)benzotriazole (0.125 g, 0.55 mmol) in acetonitrile (50 ml) and the reaction mixture was refluxed for 2 h. The resulting solution was allowed to cool to room temperature and reduced in volume to ~10 ml. A greenish-brown crystalline precipitate of [Re-

2.7. Crystal structures determination and refinement

The X-ray intensity data of **1** · MeCN, **2** · MeCN, **3** · MeCN, **4** · MeCN, **4** · Me_2CO and **5** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and numerical absorption correction [17] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 (non-methyl) and 1.5 (methyl) times the value of equivalent temperature factor of the parent atom. The methyl groups were allowed to rotate about their local threefold axis. SHELXS97 [18], SHELXL97 [19] and SHELXTL [20] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.8. Computational details

The gas phase geometries of **1** and **5** were optimized without any symmetry restrictions in the singlet ground-state with the DFT method using the hybrid B3LYP functional of GAUSSIAN03 [21–23]. The calculations were performed by using ECP basis set on the rhenium atom, the standard 6–31+G** basis for chlorine, arsine, oxygen and nitrogen, 6–31G* for carbon and 6–31G for hydrogen atoms [24,25]. The Xe core electrons of Re were replaced by an effective core potential and DZ quality Hay and Wadt Los Alamos ECP basis set (LANL2DZ) [26] was used for the valence electrons. Additional d function with exponent α = 0.3811 and *f* function with exponent α = 2.033 on the rhenium atom were added [27]. All vibrations in the calculated vibrational spectrum of **1** and **5** were real, thus the both geometries correspond to true energy minimum.

The electronic spectrum of **1** was calculated with the TDDFT method, and the solvent effect was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM) [28].

Natural bond orbital (NBO) calculations were performed with the NBO code [29,30] included in GAUSSIAN03.

3. Results and discussion

3.1. Preparation and infrared data

The $[ReOX_2(hmpbta)(EPh_3)] \cdot MeCN$ (X = Cl, Br; E = As, P) and $[ReOBr_2(hmpbta)(PPh_3)] \cdot Me_2CO$ complexes were prepared in high yield by a route analogous to that used for the synthesis of the $[ReOX_2(hqn)(EPh_3)_2]$ and $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)_2]$, namely by ligand exchange reactions starting from $[ReOX_3(EPh_3)_2]$ complexes and 2-(2′-hydoxy-5′-methylphenyl)benzotriazole in molar ratio 1:1 [9–12]:

$$[ReOX_3(EPh_3)_2] + Hhmpbta \rightarrow [ReOX_2(hmpbta)(EPh_3)] + HX + EPh_3 \quad X = Cl, Br; \quad E = As, P$$

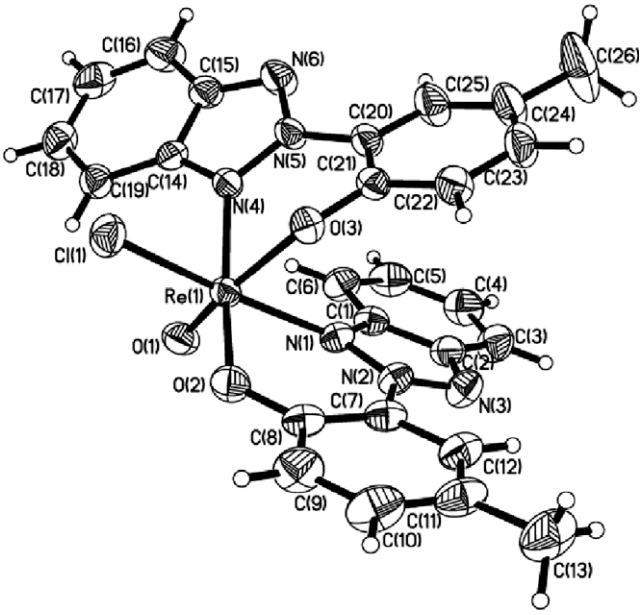

Fig. 2. The molecular structure of **5**. Displacement ellipsoids are drawn at 50% probability.

Formation of the monosubstituted chelates were also observed in the reactions of NH_4ReO_4 with 2-(2′-hydoxy-5′-methylphenyl)benzotriazole in the presence of PPh_3 as reductant.

Attempts of preparation of the disubstituted $[ReOX(hmpbta)_2]$ chelates by refluxing of $[ReOX_3(EPh_3)_2]$ with ligand excess or in the reactions of NH_4ReO_4 with excess of 2-(2′-hydoxy-5′-methylphenyl)benzotriazole in the presence of PPh_3 resulted in failure. In contrast to 8-hydroxyquinoline and quinoline-2-carboxylic acid, the both mentioned above reactions lead to the monosubstituted chelates. We managed to isolate only few crystals of $[ReOCl(hmpbta)_2]$ from the reaction of $[ReOCl_3(AsPh_3)_2]$ with ligand excess refluxed in acetonitrile for two days.

The $[ReOX_2(hmpbta)(EPh_3)]$ · solvent (solvent = MeCN, acetone) complexes are air stable and slightly soluble in acetonitrile, dichloromethane, chloroform, acetone, sparingly soluble in benzene and toluene. In general, the elemental analyses of the examined complexes are in good agreement with their formulation, some discrepancies of the hydrogen and nitrogen percentages between the calculated and found values are likely due to the solvate nature of the oxocompounds.

The selected frequencies observed in the IR spectra of $[ReOX_2(hmpbta)(EPh_3)]$ complexes are given in Section 2. The strong ν(Re=O) stretching bands of the $[ReOX_2(hmpbta)(EPh_3)]$ compounds are found in the narrow range 965–970 cm^{-1}. They are in the higher end of the range observed for $\{ReO\}^{3+}$ core complexes. It suggests that the Re–hydoxy bond *trans* to the oxo ligand does not compete effectively for the d_{Re} orbitals and indicates the presence of the {O≡Re–O} structural subunit in the examined structures. A similar trend is observed for the $[ReOX_2(hqn)(EPh_3)_2]$ and $[ReOX_2(quin\text{-}2\text{-}c)(EPh_3)_2]$ [9–12].

3.2. Crystal structures

The crystallographic data of **1** · MeCN, **2** · MeCN, **3** · MeCN, **4** · MeCN, **4** · Me_2CO, and **5** complexes are summarized in Table 1. All the $[ReOX_2(hmpbta)(EPh_3)]$ complexes are isostructural, crystallise as acetonitrile or acetone solvates in the triclinic $P\bar{1}$ space group, whereas the disubsituted $[ReOCl(hmpbta)_2]$ chelate – in the orthorhombic *Pbca* space group. In both solvates of **4** the complex molecule atoms occupy the same (in the range of experimental error) positions of unit cell, and MeCN/Me_2CO occupies the same solvent accessible void. The short intra- and intermolecular contacts [31,32] detected in the **1** · MeCN, **2** · MeCN, **3** · MeCN, **4** · MeCN, **4** · Me_2CO, and **5** are gathered in Table 2.

The perspective drawing of $[ReOCl_2(hmpbta)(AsPh_3)]$ · MeCN (**1** · MeCN) is presented in Fig. 1, and the selected bond distances and angles of **1** · MeCN, **2** · MeCN, **3** · MeCN, **4** · MeCN, and **4** · Me_2CO are collected in Tables 3 and 4. Fig. 2 presents the molecular structure of $[ReOCl(hmpbta)_2]$ (**5**), and the selected bond distances and angles of **5** are gathered in Table 5.

The geometry of $[ReOX_2(hmpbta)(EPh_3)]$ and $[ReOCl(hmpbta)_2]$ compounds reveal typical features of quasi-octahedral oxorhenium(V) complexes with oxygenated bidentate ligands. In each $[ReOX_2(hmpbta)(EPh_3)]$ complex, the rhenium atom is coordinated by a terminal oxygen atom (O_t), two halide ions in *cis* arrangement, the phosphorus or arsine atom from EPh_3 molecule, and the biden-

tate N,O-donors of the 2-(2′-hydoxy-5′-methylphenyl)benzotriazolato ligand. The oxygen atom of 2-(2′-hydoxy-5′-methylphenyl)benzotriazolato ligand occupies *trans* position to the terminal oxo ion. The rhenium atom of $[ReOCl(hmpbta)_2]$ is coordinated by two bidentate $hmpbta^-$ ligands, one chloride ion and terminal oxo (O_t) ligand. Clear distortions of the pseudooctahedral environment of Re center in $[ReOX_2(hmpbta)(EPh_3)]$ and $[ReOCl_2(hmpbta)_2]$ are induced by the multiple bonding ligand (O_t) and narrow bite angle of the chelating ligand. The high concentration of electronic density along the Re–O_t axis strongly influences the positions of the adjacent atoms (two halogen atoms in $[ReOX_2(hmpbta)(EPh_3)]$ and Cl(1), O(2) in $[ReOCl(hmpbta)_2]$), which are pushed away.

In complexes **1** · MeCN, **2** · MeCN, **3** · MeCN, **4** · MeCN, **4** · Me_2CO the rhenium atom is displaced, respectively, 0.1153(25), 0.1268(6), 0.1252(7), 0.1273(8), 0.1238(11) Å from the plane formed by the two halogen, one nitrogen and one P or As atoms (plane A), 0.0697(26), 0.0708(6), 0.0752(7), 0.0741(9), 0.0735(12) Å from the plane formed by the two oxygen, one halogen and one P or As atoms (plane B) and 0.0526(34), 0.0521(9), 0.0267(9), 0.0162(12), 0.0181(14) Å from the plane formed by two oxygen, one halogen and one nitrogen atoms (plane C). Least squares plane A is inclined at 89.61(20)°, 89.89(5)°, 89.88(5)°, 89.80(7)°, 89.62(8)° to plane B and at 87.89(20)°, 87.82(5)°, 87.99(5)°, 87.83(7)°, 87.90(9)° to plane C; planes B and C are inclined at 88.66(12)°, 89.49(3)°, 89.06(3)°, 89.55(4)°, 89.29(8)°, respectively.

For complex **5** the rhenium atom is displaced 0.1896(9) Å from the equatorial plane formed by the two nitrogens, one oxygen and one chloride atoms (plane A) and 0.0749(9) and 0.0562(8) Å from the axial planes formed, respectively, by the three oxygen, one

Positive values of the orbital contour are represented in blue (0.04 au) and negative values – in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

nitrogen atoms (plane B) and two oxygens, one chloride and one nitrogen atoms (plane C). Least squares plane A is inclined at 89.24(5)° to the plane B and at 89.19(4)° to the plane C. The planes B and C are inclined at 88.76(4)°.

The Re–O_t bond lengths of [$ReOX_2$(hmpbta)(EPh_3)] and [ReOCl(hmpbta)$_2$] complexes fall in the range 1.639–1.76 Å, typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicate the presence of a triple bond Re≡O [33]. The interatomic distances between the rhenium atom and the oxygen atom of 2-(2′-hydoxy-5′-methylphenyl)benzotriazolato ligand are somewhat shorter than an ideal single Re–O bond length (*ca.* 2.04 Å) [34], It indicates small delocalization in the O(2)–Re(1)–O(1) moi-

Table 7
The occupancy and composition of the calculated natural bond orbitals (NBOs) between the rhenium and the oxo ligand for **1** and **5**.

BD	Occupancy	Composition of NBO	BD*	Occupancy
1				
Re–O_t	1.993	$0.567(d)_{Re} + 0.824(p)_O$	$0.824(d)_{Re} - 0.567(p)_O$	0.270
Re–O_t	1.987	$0.571(d)_{Re} + 0.821(p)_O$	$0.821(d)_{Re} - 0.571(p)_O$	0.313
5				
Re–O_t	1.991	$0.558(d)_{Re} + 0.830(p)_O$	$0.830(d)_{Re} - 0.558(p)_O$	0.284
Re–O_t	1.990	$0.569(d)_{Re} + 0.822(p)_O$	$0.822(d)_{Re} - 0.569(p)_O$	0.322

BD denotes two-center bond.
* Denotes antibond NBO.

ety. The similar trend is observed for many Re(V)-oxo complexes with an monoanionic oxygen *trans* to the oxo group.

In the [ReOCl(hmpbta)$_2$] complex, the interatomic distance between the rhenium atom and the oxygen atom of 2-(2′-hydoxy-5′-methylphenyl)benzotriazolato ligand in *trans* position to the terminal oxo ion is somewhat longer than the corresponding Re–O bond in the equatorial plane. This structural *trans* influence is common in mononuclear six-coordinate oxo Re(V) complexes with an monoanionic oxygen *trans* to the oxo group [9–12].

The elongation of the Re(1)–X(1) distances *trans* to the phosphorus or arsine atom of EPh_3 molecule in comparison with Re(1)–X(2) bonds *trans* to the nitrogen atom of the 2-(2′-hydoxy-5′-methylphenyl)benzotriazolato ligand in the [$ReOX_2$(hmpbta)(EPh_3)] complexes is a consequence of *structural trans* effect of the EPh_3 ligands.

3.3. Geometry optimization, charge distribution, electronic structure and NBO analysis

The geometries of **1** and **5** were optimized in a singlet state by the DFT method with the B3LYP functional. The optimized geometric parameters of **1** and **5** are gathered in Tables 3 and 5, respectively. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations. The largest differences are found for the Re–As and Re–Cl bond distances. It may come from the basis sets which are approximated to a certain extent or may indicate the influence of the crystal packing on the values of the experimental bond lengths. The theoretical calculations do not consider the effects of chemical environment.

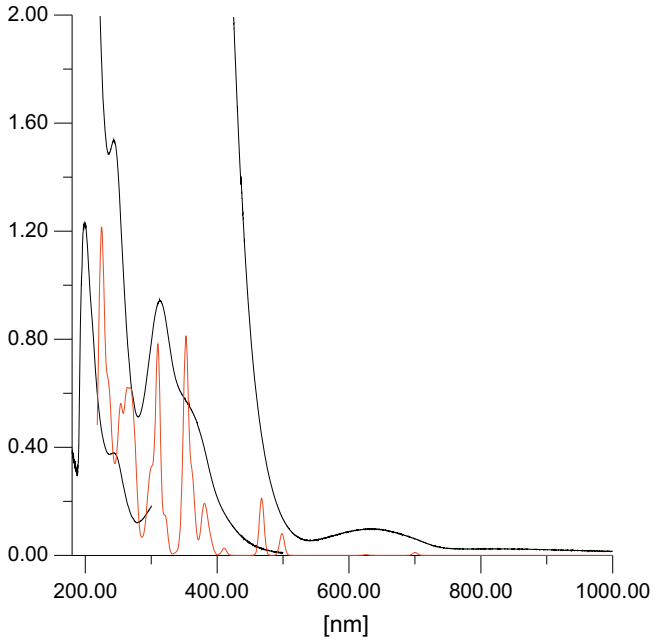

Fig. 5. The experimental (black) and calculated (red) electronic absorption spectra of **1**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Table 6 presents the atomic charges from the Natural Population Analysis (NPA) for **1** and **5**. The calculated charge on the rhenium atom in complex **5** is somewhat larger in comparison with the monosubstituted compound. However, the both values are considerably lower than the formal charge +5, which results from significant charge donation from the oxygen atoms, chloride ions and triphenylarsine. In both complexes **1** and **5**, the considerable differences in values of charges are observed for the terminal oxo ligand and the oxygen atom of hmpbta$^-$ ligand – less negative are the terminal oxo ligands, which indicates the higher electron density delocalization from the terminal ligands towards the rhenium centers and corresponds to differences in the Re–O_t and Re–O_{hmpbta} bonds lengths.

The **1** and **5** are closed-shell structures. Their partial molecular orbital diagrams with several highest occupied and lowest unoccupied molecular orbital contours are presented in Figs. 3 and 4, respectively.

Two highest occupied MOs of **1**, are of d_{xy} type with some contributions from pπ chloride and hmpbta$^-$ orbitals. The LUMO and LUMO + 1 are predominately localized on the rhenium atom (d_{xz} and d_{yz} orbitals) with some contribution of pπ oxygen orbitals. The LUMO + 3 is of $d_{x^2-y^2}$ character, and d_{z^2} rhenium orbital contributes mainly to the LUMO + 12. The value of the energy separation between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) equals to 3.10 eV. This value is considerable higher in comparison with the HOMO–LUMO gap of [$ReOX_2$(hqn)(EPh_3)$_2$] and [$ReOX_2$(quin-2-c)(EPh_3)] {[$ReCl_2$(quin-2-c)(PPh_3)] – 2.93 eV; [$ReOX_2$(hqn)(EPh_3)$_2$] – 2.87 eV}. The bigger absolute value of the energy gap means better stability, and explains high stability of the title monosubstituted chelates.

The qualitative molecular orbitals scheme of **5** is almost the same as for **1**. HOMO and HOMO−2 of **5** are of d_{xy} type with some contributions from pπ chloride and hmpbta$^-$ orbitals. The LUMO and LUMO + 1 are predominately localized on the rhenium atom (d_{xz} and d_{yz} orbitals) with some contribution of pπ oxygen orbitals. The LUMO + 4 is of $d_{x^2-y^2}$ character, and d_{z^2} rhenium orbital contributes to the higher unoccupied MO. The HOMO–LUMO gap of **5** is equal to 3.06 eV, and is somewhat smaller in comparison with value calculated for **1**. It seems to explain difficulty in synthesis of the disubstituted chelates.

The nature of rhenium-terminal oxygen interaction in **1** and **5** has been studied by NBO analysis. The occupancy and composition of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 7.

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

ε, molar absorption coefficient ($dm^3\ mol^{-1}\ cm^{-1}$); f, oscillator strength; H, highest occupied molecular orbital; L, lowest unoccupied molecular orbital.

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A + c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [29,30].

The detected natural Re–O_t bond orbitals of **1** and **5** are π orbitals – the p_x and p_y oxygen orbitals and d_{xz} and d_{yz} rhenium orbitals are involved in their formation. Not detected σ_{Re-O_t} bond has character of predominant Coulomb-type interactions between the central ion and ligands [35]. The terminal oxo ligand of **1** and **5** has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital. Accordingly, NBO analysis confirms a triple bond between the rhenium and the terminal oxygen ligand in **1** and **5**.

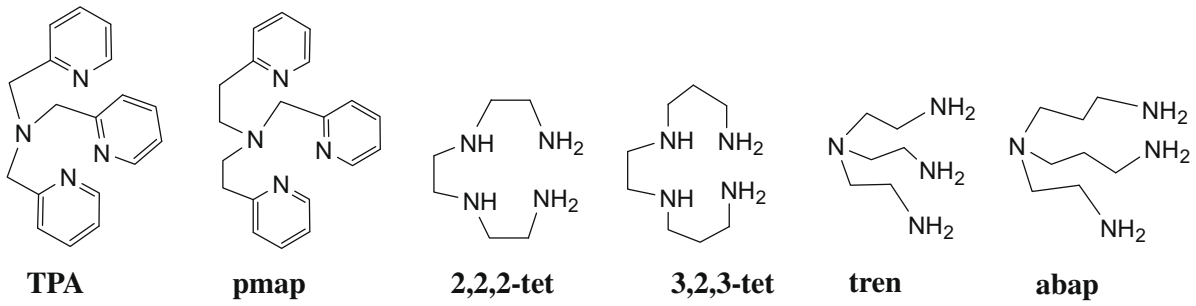
3.4. Electronic spectra

The experimental and calculated electronic spectra of **1** are presented in Fig. 5. Each calculated transition is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}. The positions and molar absorption coefficients of electronic bands for the other [ReOX_2(hmpbta)(EPh_3)] complexes are given in Experimental part. The electronic spectra of [ReOX_2(hmpbta)(EPh_3)] complexes are very similar in terms of the position, intensity and shape of the bands in the whole region 1000–180 nm.

Table 8 presents the most important electronic transitions calculated with the TDDFT method assigned to the observed absorption bands of **1**. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy to the orbitals HOMO and LUMO involved in the electronic transitions. The simplified molecular orbital diagram of **1** with several contours of occupied and unoccupied MOs (active in the electronic transitions) is presented in Fig. 3.

The TDDFT/PCM calculations show that the longest wavelength experimental band of **1** at 630.0 nm originates in the HOMO → LUMO and HOMO−1 → LUMO transitions. As can be seen from the Fig. 3, the LUMO orbital is mainly formed from rhenium d atomic orbital, the HOMO−1 and HOMO orbitals are delocalized among rhenium ion, chloride and hmpbta$^-$ ligands. Accordingly, the transitions assigned to the longest wavelength experimental band can be seen as mixed chloride/hmpbta → Re (*Ligand–Metal Charge Transfer; LMCT*) and d → d (*Ligand Field; LF*) transitions.

The experimental absorption band at 346.2 nm can be assigned to *Ligand–Metal Charge Transfer* transitions occurring from the chloride, triphenylarsine and hmpbta$^-$ ligands to d rhenium orbitals.



The absorption bands at 315.2, 243.2 and 200.8 nm result mainly from *Ligand–Ligand Charge Transfer* and interligand (*IL*) transitions. However, some contribution of the *Ligand–Metal Charge Transfer* from the chloride, triphenylarsine and hmpbta$^-$ orbitals to the d rhenium orbitals in these bands is also confirmed by the calculations.

Acknowledgement

The GAUSSIAN03 calculations were carried out in the Wrocław Centre for Networking and Supercomputing, WCSS, Wrocław, Poland under calculational grant No51/96.

Scheme 1.

supplement, tris(picolinato)chromium(III), [Cr(pic)$_3$] showed nicking of DNA in absence of oxidant [22].

Careful inspection of the literature data reveals that most of the hydrolytic activity of DNA and RNA were produced with Cu(II) and Co(III) complexes. Therefore, we believe that it would be interesting to perform a systematic study on the catalytic cleavage of DNA using a series of Co(III) complexes derived from tetraamine ligands of varied skeletal structures to see how the nature of the blocking amine ligands might enhance or prohibit the DNA hydrolysis. In other words, to determine the structural features in the Co(III) complexes that rapidly and efficiently promote the cleavage of DNA. For this reason, three categories of tetradentate-N-donor ligands were synthesized as well as their Co(III) complexes. These include: linear tetradendate amines (2,2,2-tet, 3,2,3-tet),[1] tripod amines with three aliphatic amine arms (tren, abap) and with three pyridyl arms (TPA, pmap). The structures of these amines are illustrated in Scheme 1.

The common feature between TPA, tren and 2,2,2-tet is the presence of three ethylenic groups between the N-donor atoms of these ligands and hence their ability to form five-membered chelate rings upon their coordination with Co^{III} center whereas the pmap, abap and 3,2,3-tet contain two arms with three methylene groups and one with an ethylenic group. These will lead to the formation of one five- and two flexible six-membered chelate rings when bind Co^{III} center. This study should allow us to evaluate the role of the pyridyl groups and the length of arms between the N-donor atoms of the coordinated amines in promoting the cleavage of the double-stranded DNA.

2. Experimental

2.1. Materials and methods

The compounds 2-(2-aminoethyl)pyridine, 2-picolylchloride hydrochloride, N-(2-bromoethyl)-phthalimide and 2-vinylpyridine were obtained from Aldrich Chemical Co., USA, 4,7-diaza-1,10-decanediamine (3,2,3-tet) was purchased from Strem Chemical Company, USA whereas 2-pyridylmethylamine and di-(2-pyridylmethyl)amine (DPA) were obtained from TCI, America. All other materials were reagent grade quality. Infrared spectra were recorded on JASCO FT/IR-480 plus spectrometer as KBr pellets. Electronic spectra were recorded on an Agilent 8453 HP diode UV–Vis spectrophotometer. Mass spectra were obtained on a HP 5890 series II GC spectrometer coupled to a HP 5972 Mass Selective Detector (MSD). Elemental analyses were performed at the Atlantic Microlaboratory, Norcross, Georgia USA.

Caution: Salts of perchlorate and their metal complexes are potentially explosive and should be handled with great care and in small quantities.

2.2. Synthesis of the compounds

2.2.1. Synthesis of the amine ligands

The three triopd amine ligands tris(2-pyridylmethyl)amine (TPA), bis[2-(2-pyridyl)ethyl]-(2-pyridylmethyl)amine (pmap) and N-(2-aminoethyl)-N,N-bis(3-aminopropyl)amine tetrahydrochloride trihydrate (abap · 4HCl · 3H$_2$O) were synthesized and characterized following the procedures described elsewhere [42–45].

2.2.2. Synthesis of Co(III) complexes

[Co(pmap)CO$_3$]ClO$_4$. A cold aqueous solution of bis[2-(2-pyridyl)ethyl]-(2-pyridylmethyl)amine (3.20 g, 10 mmol dissolved in 10 mL H$_2$O) was neutralized with 5 M HClO$_4$ to pH ~ 7 and then added drop-wise to an ice cold mixture of a well stirred slurry of Na$_3$[Co(CO$_3$)$_3$] · 3H$_2$O [46] (3.62 g, 10 mmol) in H$_2$O (50 mL). The temperature of the solution was gradually raised to 75 °C over a period of 1 h and stirring was continued at this temperature for 3 h, during which volume of the solution was reduced to ca 30 mL. The resulting reddish-orange solution was allowed to cool to room temperature, filtered through celite and left to crystallize at ambient temperature. After one week, the red precipitate which separated was collected by filtration, washed with absolute ethanol, then air dried and re-crystallized from H$_2$O (overall yield: 3.78 g, 71%). Slow evaporation of the dilute aqueous solution of the complex at room temperature afforded well-shaped crystals suitable for X-ray analysis. Characterization: *Anal.* Calc. for C$_{21}$H$_{22}$N$_4$ClCoO$_7$ (MM = 536.82 g/mol): C, 46.99; H, 4.13; N, 10.44. Found: C, 46.89; H, 4.12; N, 10.41%. UV–Vis. in H$_2$O (λ_{max} in nm, ε in M^{-1} cm^{-1}): 515 nm (144) and ~365 nm (sh). Selected IR bands (KBr, cm^{-1}): ν(C–O) 1665 (s); ν(C=C) 1637 (s); ν(Cl–O) (ClO$_4^-$) 1102 (vs) cm^{-1}.

The carbonato complexes [Co(tren)CO$_3$]ClO$_4$ and [Co(3,2,3-tet)-CO$_3$]ClO$_4$ · H$_2$O were synthesized using a procedure similar to that described above for [Co(pmap)CO$_3$]ClO$_4$ and were characterized according to the published procedures [47,48]. The remaining complexes [Co(abap)Cl$_2$]ClO$_4$ · H$_2$O, [Co(abap)(H$_2$O)Cl]Cl(ClO$_4$), [Co(TPA)Cl$_2$]ClO$_4$, *cis*-β-[Co(2,2,2-tet)Cl$_2$]-ClO$_4$ and [Co(tren)-(H$_2$O)$_2$](ClO$_4$)$_3$ were synthesized and characterized as reported elsewhere [43,49,50].

2.2.3. Preparation of aqua–Co(III) solutions

Aquahydroxo complex ions, [Co(N$_4$)(OH)(H$_2$O)]$^{2+}$ (N$_4$ = TPA, **1**; pmap, **2**; 2,2,2-tet, **3**; 3,2,3-tet, **4**; tren, **5** and abap, **6**) used for studying the hydrolytic cleavage of DNA were generated in aqueous solutions by two methods:

[1] *Ligand abbreviations:* TPA, tris(2-pyridylmethyl)amine; pmap, bis[2-(2-pyridylethyl)]-(2-pyridylmethyl)amine; 2,2,2-tet, triethylenetetraamine; 3,2,3-tet, 4,7-diaza-1,10-decanediamine; tren, tris(2-aminoethyl)amine; abap, N-(2-aminoethyl)-N,N-bis(3-aminopropyl)amine; cyclen, 1,4,7,10-tetraazacyclododecane.

(1) From the carbonato complexes by treating a weighed amount of the corresponding carbonato compound with 0.12 mL of 1.0 M $HClO_4$ solution. The resulting mixture was warmed for 5 min at 60 °C to expel CO_2 [19a,51]. This was then diluted with deionized water and transferred to 10.0 mL volumetric flask where $NaClO_4$ was added to adjust the ionic strength to 0.1 M and completed to the mark to give a solution of final concentration of 3.00 mM. The pH of these solutions were adjusted to 7.0 with 1 M NaOH or 1 M $HClO_4$ solution using glass stick "dotting" where the volume changes were negligible [52].
(2) From the chloro complexes by dissolving a weighed sample of the complex in 0.01 M $HClO_4$ solution, and allowing them to hydrolyze by heating on a steam-bath for 30 min, then ionic strength and pH 7.0 were adjusted as described above.

The stock solutions of the aquahydoxo–cobalt(III) complexes (3.00 mM of complex, pH 7.0, I = 0.1) were prepared and stored in the refrigerator at −20 °C. These solutions were used within period of two weeks.

2.3. X-ray structure determination of [Co(pmap)(CO_3)]ClO_4

The single crystal data were collected on a Bruker-AXS SMART APEX CCD diffractometer with graphite crystal-monochromatized Mo Kα radiation (λ = 0.71073 Å) at 100(2) K. The data were corrected for Lorentz-polarization effects, and for absorption by using the SADABS program [53]. The structure was solved by direct methods and refined by full-matrix least-squares techniques on $|F|^2$ using SHELX system of programs [54]. In case of disordered oxygen atoms of perchlorate counter ion split occupancies of 0.555(4) for O(4) to O(7) and 0.445(4) for O(8) to O(11), respectively, were applied. All hydrogen atoms belonging to the complex were in their calculated positions and refined using a riding model. All non-hydrogen atoms were refined anisotropically [total 344 parameters, R_1 = 0.0643, wR_2 (all data) = 0.2072, *S = 1.190,* largest difference peak and hole: 0.698 and −0.593 e/Å^3]. The crystallographic parameters are: $C_{21}H_{22}ClCoN_4O_7$ (formula weight = 536.74), monoclinic, space group *C*2/*c*, *a* = 17.617(3), *b* = 18.028(4), *c* = 14.515(3) Å, β = 109.72(1)°, *V* = 4340(2) Å^3, *Z* = 8, D_{calc} = 1.643 Mg/m^3, μ = 0.968 mm^{-1}, 15417 reflections measured (Θ_{max} = 24.99°), 3813 unique (R_{int} = 0.0389), and of these 3548 had $I > 2\sigma(I)$.

2.4. DNA study

2.4.1. Plasmid DNA isolation

pUC19 plasmid was introduced into DH5α competent cells based on manufactory protocol (Invitrogen Corporation, Carlsbad, California 92008, USA). Single colony was selected from standard Luria Bertani (LB) plate and cultured in 5 mL of LB medium at 37 °C in a shaker at speed of 300 rpm for overnight. This starter cell culture was diluted 1:500 using freshly prepared LB medium and grew at 37 °C in a shaker at speed of 300 rpm for 16–18 h. Cells were harvested at 4000 rpm for 5 min. The plasmid DNAs were purified from the cell culture using Qiagen plasmid purification column based on manufactory protocol (QIAGEN Inc., Valencia, CA 91355, USA). All the LB medium and LB plate contained 100 μg/mL ampicillin. The plasmid DNA concentrations were determined spectrophotometrically by measuring the absorbance at 260 nm.

2.4.2. Plasmid DNA hydrolysis by Co(III) complexes and agarose gel electrophoresis

Approximately 1.0 μg of pUC19 plasmid DNA was incubated with Co(III) complexes with indicated concentrations in a total volume of 20 μL at 37 °C water-bath for a varying of incubation time. At the end of incubation, bromophenol blue loading buffer was added. The samples were then loaded on a 1.0% agarose gel containing approximately 2.0 μg/mL ethidium bromide. Electrophoresis was carried out at 150 V for approximately 20 min in Tris–Borate–EDTA (TBE) buffer. Bands were visualized by UV light and photographed by a Bio-Rad gel documentation system (Bio-Rad Laboratories, Hercules, CA 94547). The intensity of the different forms (**I**, **II** and **III**) of plasmid DNA was quantified using Quantity One software (Bio-Rad Laboratories). Experimental data were analyzed using graphic and statistical software PRISM 4.0. Differences of $p < 0.05$ by analysis of variance (ANOVA) and Dunnett's post test were considered to be significantly different from controls.

2.4.3. Kinetic measurements for the DNA cleavage by aquahydroxo–cobalt(III) complexes ***1*** and ***3***

DNA cleavage rates at varying concentration of cobalt(III)–tetraamine complexes {0 (control), 50, 100, 150, 300 and 450 μM} were carried out in 1.0 mM Tris–Cl buffer, pH 7.0 and I = 0.1 M ($NaClO_4$) at 37 °C for different interval of time. The percentage of form **II** quantified by QUANTITY ONE software was plotted against time for each catalyst concentration. The data were fitted with single-exponential curve (pseudo-first-order kinetics) using ORIGIN 7.5 and Eq. (1) to extract the hydrolysis rate or apparent rate constant, k'_{obs} [34]:

$$y = (100 - y_0)(1 - \exp(-k'_{obs}t)) \quad (1)$$

$$k'_{obs} = V'_{max}[\text{catalyst}]/(K_M + [\text{catalyst}]) \quad (2)$$

where y_0 and y represent the percentages of DNA form **II** at zero time and at any time t, respectively. The values of k'_{obs} were then plotted against the concentrations of cobalt(III) complexes (catalyst = [Co(III]) (Eq. (2)) allowing a pseudo-Michaelis–Menten analysis and the determination of the maximal reaction velocity V'_{max} and K_M [34]. It is important to emphasize here that Cowan and co-workers indicated that for comparison of rates of reactions, the pseudo-Michaelis–Menten rate constant, k'_{cat} which represents the rate at saturation levels (i.e., V'_{max}) would be used [34].

Similar experiments with constant Co(III) concentration (150 μM) and varying DNA (substrate) concentrations (8.53, 25.6, 76.8 and 203.4 μM DNA bps) were also performed ("true" Michaelis–Menten kinetics). Experimental data were analyzed using graphic and statistical software PRISM 4.0. Differences of $p < 0.05$ by analysis of variance (ANOVA) and Dunnett's post test were considered to be significantly different from controls.

3. Results and discussion

3.1. Syntheses the complexes

One general method was used to synthesize the carbonato complexes, [Co(N_4)CO_3]ClO_4 where N_4 = pmap, tren and 3,2,3-tet. They were obtained in reasonably good yield (60–80%) by the reaction of an aqueous solution of the tetraamine (pre-neutralized to pH ~ 7 with 5 M $HClO_4$ solution) with to an equimolar amount of $Na_3[Co(CO_3)_3] \cdot 3H_2O$. Re-crystallization of these compounds from

Table 1
UV–Vis spectral data for the carbonato–tetraamine–cobalt(III) complexes in H_2O.[a]

Complex	λ_{max}, nm (ε_{max}, M^{-1} cm^{-1})
[Co(pmap)CO_3]ClO_4	515 (144), ~365 (sh)
[Co(tren)CO_3]ClO_4	504 (132), 354 (110)
[Co(3,2,3-tet)CO_3]$ClO_4 \cdot H_2O$	518 (136), 360 (133)

[a] Values are comparable to those reported in Refs. [47,48].

aqueous solutions afforded the complexes in high pure forms. The purity of the complexes was checked by comparing their electronic spectra in H_2O (Table 1) with literature values [47,48]. However, it should be noted that $[Co(3,2,3\text{-tet})CO_3]ClO_4$ and $[Co(tren)CO_3]ClO_4$ complexes were previously prepared by $PbO_2/NaHCO_3$ method [49]. The chloro complexes $[Co(abap)Cl_2]ClO_4 \cdot H_2O$, $[Co(abap)(H_2O)Cl]Cl(ClO_4)$ and $[Co(TPA)Cl_2]ClO_4$ were synthesized and characterized according to the literature methods [43,47,50].

3.2. Characterization of the carbonato-Co(III) complexes

The electronic spectra of the carbonato complexes under investigation $[Co(N_4)CO_3]ClO_4$ display two bands over the wavelength range 550–360 nm. These spectral features are consistent with octahedral *cis*-geometry and the bands arise from $^1T_{1g}$ (Oh) ← $^1A_{1g}$ (Oh) and $^1T_{2g}$ (Oh) ← $^1A_{1g}$ (Oh) transitions. Although the actual field is of lower symmetry (C_{4v}), this has a small effect upon the model and the $^1T_{1g}$ state is split into $^1E_{1g}$ and $^1A_{2g}$ (octahedral labels were retained for simplicity) [56]. Inspection of the data in Table 1 clearly indicates that λ_{max} of the low energy d–d band increases in the order: tren < pmap < 3,2,3-tet. This is due to the reduction in the ligand field strength on going from tren to 3,2,3-tet.

3.3. Crystal structure of $[Co(pmap)CO_3]ClO_4$ complex

The complex $[Co(pmap)CO_3]ClO_4$ was structurally characterized by single crystal X-ray diffraction technique. The structure of the complex consists of a discrete monomeric $[Co(pmap)(CO_3)]^+$ cation and a disordered perchlorate counter ion. A perspective view of the complex cation is shown in Fig. 1. Selected bond distances and angles are given in Table 2. The Co(1) center is octahedrally coordinated by the four nitrogen donor atoms of the pmap blocking ligand and by O(1) and O(2) of the chelating carbonato group. The Co–N bond distances are in the range from 1.925(4) to 1.991(5) Å, the Co(1)–O(1) and Co(1)–O(2) bond lengths are 1.902(3) and 1.906(3) Å, respectively. The cobalt center lies only 0.015 Å out of the plane of the carbonato group, which forms dihedral angles of 9.8°, 84.2° and 95.3°, respectively, with the planes of the three pyridyl rings of the pmap ligand. The shortest separation between Co(1) centers of monomeric complex cations is 7.6779(19) Å. It should be noted that although the crystal structure of $[Co(pmap)CO_3]ClO_4$ was determined by Blackman and his group [48], more details for the structural parameters are reported here. The O–Co–O bond angle of $[Co(pmap)CO_3]^+$ (69°) is comparable to that observed in the corresponding carbonato complexes of tren (68.5°), cyclen (68.4°) and trpn (68.4°) [11a,49].

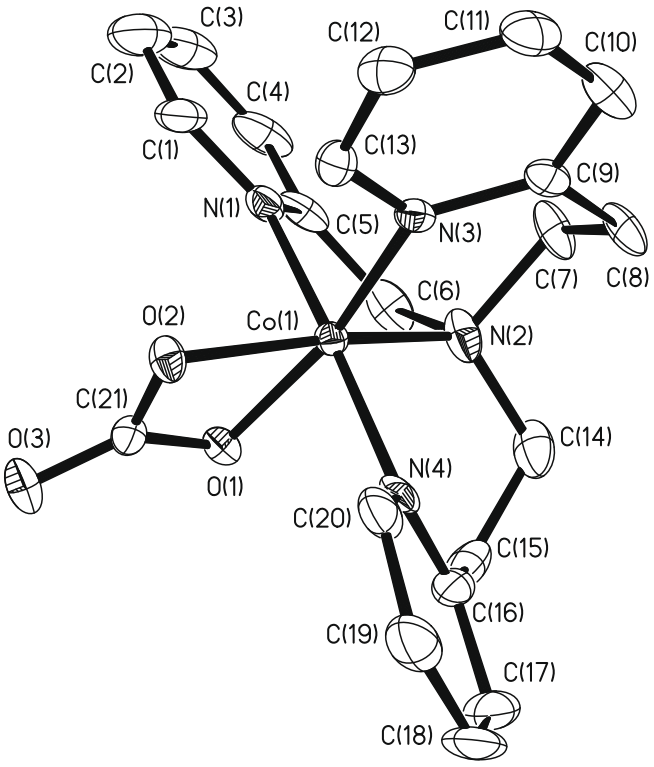

Fig. 1. Perspective view of $[Co(pmap)(CO_3]^+$ cation showing the atom labeling scheme and 50% probability displacement ellipsoids.

3.4. Aquaamine–Co(III) complexes

The diaqua complex ions, $[Co(N_4)((H_2O)_2]^{3+}$ which were used for DNA studies after adjusting their pHs to 7.0, were generated in the acidic medium by hydrolyzing the corresponding carbonato- or the chloro-Co(III) compounds [43,47–50]. Phosphate buffers were not used to avoid their possible interaction with the aqua complex species [58]. The electronic spectra of the prepared diaqua solutions displayed two absorption maxima, almost at the same positions as their parent carbonato compounds which indicates the formation of complexes with *cis*-geometry [57] and were also identical to those obtained for the corresponding isolated diaqua compounds [10,57,58]. Moreover, the solutions adjusted to pH 7.0, showed no sign of significant spectral changes due to hydrolysis and/or redox reactions during the entire period of preservation in the refrigerator (four weeks), except in the case of 3,2,3-tet compound which reveals pronounced tendency for isomerization to the *trans* isomer. The two λ_{max} detected at 360 and 520 nm in the fresh solution of *cis*-$[Co(3,2,3\text{-tet})(H_2O)_2]^{3+}$ (pH ~ 7.0) were disappeared and instead, three new bands of lower intensities, typical for *trans*-disubstituted tetraamine–cobalt(III) complexes [56] were observed at ca 442, 614 and 742 nm. The process was also associated with color change from red to green.

In the neutral pH region, the acid–base equilibrium studies performed on the aqua–tetraamine–cobalt(III) complexes, reveal that the predominant species under these conditions is the aquahydroxo complex ion, $[Co(N_4)(H_2O)(OH)]^{2+}$ [11a,19a,57,59,60]. The tripodal nature of the amine ligands (TPA, Pmap, abap and tren) encountered in the Co(III) complexes used in this study presents some advantages which make them suitable candidates for studying the hydrolytic cleavage of DNA. They provide two available coordination sites that are relatively rapid towards substitution reactions [7,11,12,19,61]. Also, the geometrical nature of these amines enforces the formation of complexes with *cis*-geometry. On the other hand, in the linear tetraamines 2,2,2-tet and 3,2,3-tet the *cis*/*trans* isomerization may occur where this tendency is

higher in case of 3,2,3-tet as indicated above. Consequently, the presence of high proportion of *trans*-[Co(3,2,3-tet)(OH)(H_2O)]$^{2+}$ in solution reduces the hydrolytic efficiency of **4** to catalyze the DNA cleavage.

3.5. Hydrolytic cleavage of plasmid DNA by aqua–Co(III) complexes

3.5.1. Hydrolysis of plasmid DNA

A wide range of octahedral *cis*-aquahydroxo–tetraamine–Co(III) complexes of different structural amine skeletons were used to test the hydrolytic cleavage of DNA at pH 7.0, I = 0.1 M ($NaClO_4$) and at 37 °C. Among the six complexes used in this study, only three complex ions [Co(TPA)(OH)(H_2O)]$^{2+}$ (**1**), [Co(pmap)(OH)(H_2O)]$^{2+}$ (**2**) and [Co(2,2,2-tet)(OH)(H_2O)]$^{2+}$ (**3**) showed significant DNA cleavage where the supercoiled DNA (form I) was cleaved to the relaxed open circular DNA (form II) over a period of 24 h as illustrated in Fig. 2. During this long incubation period, complex **1** showed pronounced capability to further cleave form II to linear DNA (form III) while significant changes of form III were not observed for **2** and **3**. The cleavage ability of the complexes decreases in the order **1** > 3 ≫ 2, where very low catalytic cleavage was obtained in complex **2** (pmap). On the other hand, the remaining Co(III) complexes did not exhibit any detectable DNA cleavage as indicated by the fact that the percentages of all forms were almost unchanged with each complex over a period of 24 h (Fig. 1S in the Supplementary data).

As a result of the very low efficiency of the complex ion [Co(pmap)(OH)(H_2O)]$^{2+}$ (**2**) in hydrolyzing the plasmid DNA, no more study was performed on this complex but instead the two aqua complexes [Co(TPA)(OH)(H_2O)]$^{2+}$ (**1**) and [Co(2,2,2-tet)(OH)(H_2O)]$^{2+}$ (**3**) were the subject of further detailed kinetics studies in order to explore their activities in the catalytic cleavage of plasmid DNA. The migration position of the form III cleaved by **1** was confirmed by the EcoRI digestion of pUC19, which is known to contain only one site in pUC19 plasmid and expected to produce one linearized DNA (Fig. 3).

3.5.2. Kinetics of plasmid DNA hydrolysis

The kinetics of DNA cleavage by complexes [Co(TPA)(OH)(H_2O)]$^{2+}$ (**1**) and [Co(2,2,2-tet)(OH)(H_2O)]$^{2+}$ (**3**) were carried out by following the conversion of form **I** to form **II** over various concentrations of the complexes (50–450 μM) and constant pUC19 DNA concentration (76.8 μM) at different time intervals at pH 7.0, I = 0.1 M ($NaClO_4$) and 37 °C. The percentages of form **II** were plotted against time and plots are represented in Figs. 4 and 5 for complexes **1** and **3**, respectively. It should be noted that significant increase of form **III** was not observed until 16 h of DNA incubation with **1** therefore form **III** cleaved by **1** was not included in Fig. 4. However, longer incubation (Fig. 2) results in cleavage of form **I** into form **II** first by **1**, and then continues to cleave form **II** to form **III**. Each of these plots follows pseudo-first-order kinetic

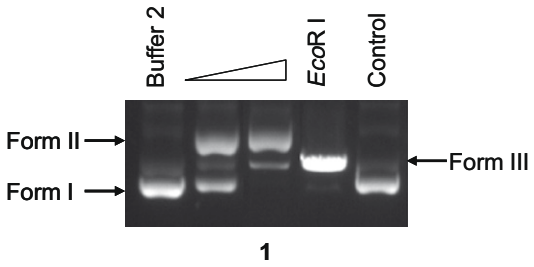

Fig. 3. Electrophoretic separations of pUC19 plasmid DNA cleavage by complex **1** and by EcoRI. Plasmid DNA (76.8 μM) was incubated with Co(III) complexes (50 and 150 μM) or 2.0 U EcoRI for 24 h in 1 × buffer 2 (NEB), I = 0.1 M ($NaClO_4$) at 37 °C.

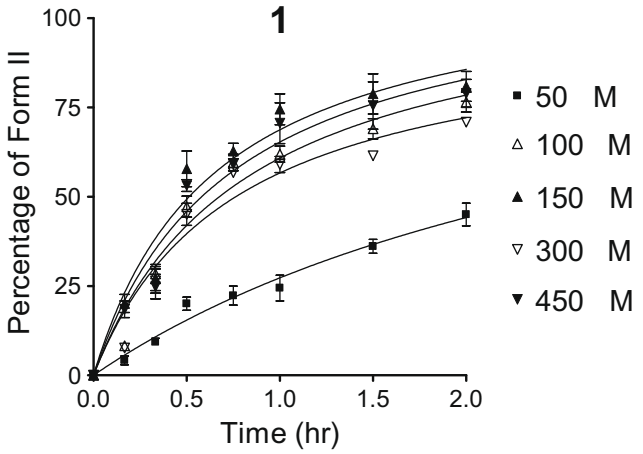

Fig. 4. Cleavage profile of pUC19 plasmid DNA by **1**. DNA (76.8 μM) was incubated with varying concentrations of **1** in 1.0 mM Tris–Cl buffer pH 7.0, I = 0.1 M ($NaClO_4$) at 37 °C.

profile and was fitted well to a single-exponential curve using Eq. (1). From these curves, the cleavage rate constant, k'_{obs} at each complex concentration was calculated and data are collected in Table 3. The kinetic parameters for the pseudo-Michaelis–Menten conditions were derived from the plots of k'_{obs} versus [Co(III)] (=[catalyst]) and fit to Eq. (2). Under these experimental conditions, values of $k''_{cat} = 3.49 \times 10^{-4}\ s^{-1}$ and $K_M = 159$ μM for **1** and $k''_{cat} = 5.08 \times 10^{-5}\ s^{-1}$ and $K_M = 296$ μM for **3** were obtained (Table 3), where these values represent pseudo-Michaelis–Menten conditions. The calculated values of K_M and k'_{cat} fall into the range reported for the cleavage of DNA by other metal complexes ($K_M = 3.0 \times 10^2$–2.0×10^3 μM, and $k'_{cat} = 5.0 \times 10^{-5}$–$2.0 \times 10^{-4}\ s^{-1}$) [16,31,37,55,62–64]. The DNA cleavage by [Co(TPA)(OH)(H_2O)]$^{2+}$, **1** is about six times much faster than the corresponding complex [Co(2,2,2-tet)(OH)(H_2O)]$^{2+}$, **3**. Interestingly, the rate

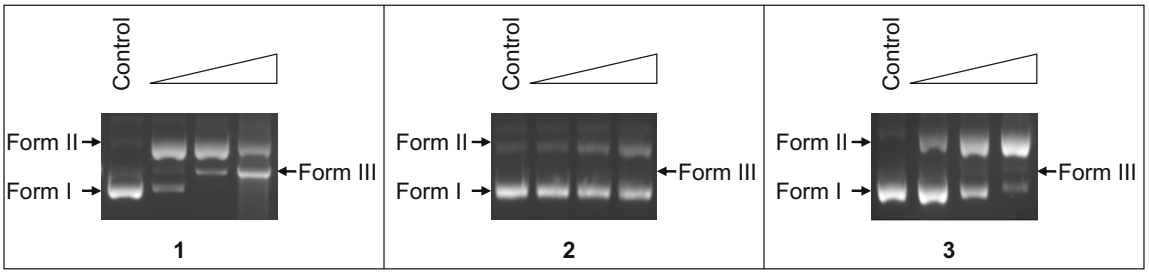

Fig. 2. Electrophoretic separations of pUC19 plasmid DNA cleavage by aquaamine–cobalt(III) complexes: (**1**) TPA (left panel), (**2**) pmap (middle panel) and (**3**) 2,2,2-tet (right panel). Plasmid DNA (76.8 μM) was incubated with varying [Co(III)] (0, 50, 150 and 450 μM, from left lane to the right lane) for 24 h in 1.0 mM Tris–Cl buffer pH 7.0, I = 0.1 M ($NaClO_4$) at 37 °C.

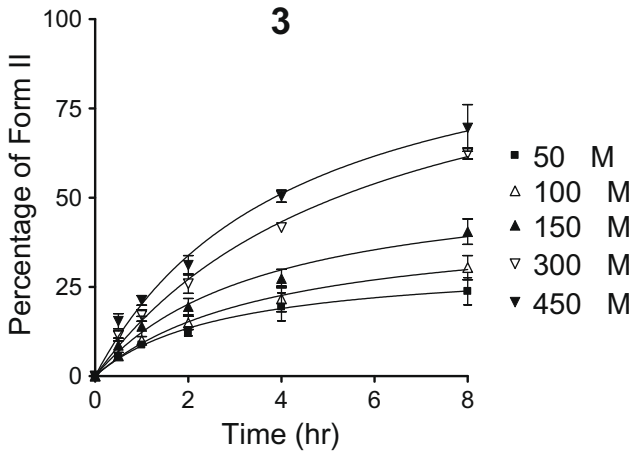

Fig. 5. Cleavage profile of pUC19 plasmid DNA by complex **3**. DNA (76.8 μM) was incubated with varying Co(III) concentrations of **3** in 1.0 mM Tris–Cl buffer pH 7.0, I = 0.1 M ($NaClO_4$) at 37 °C.

Table 3
Pseudo-Michaelis–Menten kinetic data for the cleavage of pUC19 plasmid DNA by aquahydroxo–amine–Co(III) complexes.

Complex	[DNA] (μM)	[Co(III)] (μM)	k'_{obs} (s^{-1})	V'_{max} [a] (s^{-1})	K_M (μM)
1 (TPA)	76.8	50	7.99×10^{-5}	3.49×10^{-4}	159
		100	1.54×10^{-4}		
		150	1.89×10^{-4}		
		300	2.09×10^{-4}		
		450	2.20×10^{-4}		
3 (2,2,2-tet)	76.8	50	7.77×10^{-6}	5.08×10^{-5}	296
		100	1.08×10^{-5}		
		150	1.52×10^{-5}		
		300	3.17×10^{-5}		
		450	3.81×10^{-5}		

[a] At the saturation level, $V'_{max} = k'_{cat}$ [34].

enhancements obtained here with **1** and **3** correspond to 3.5×10^7 and 5.1×10^6, respectively, over the non-catalyzed DNA ($k = 1.0 \times 10^{-11}$ s^{-1} at 37 °C [1]) clearly reveals the efficiency of these complexes to cleave the double-stranded DNA. Comparable rate enhancements by cobalt(III)–polyamine complexes derived from cyclen ($k'_{cat} = 2.2 \times 10^{-4}$ s^{-1}) [7] and tamen ($k'_{cat} = 5.0 \times 10^{-5}$ s^{-1}) [65] have been reported for the hydrolysis of DNA when rates were compared at the saturation levels under pseudo-Michaelis–Menten kinetics.

Plasmid DNA cleavage was also monitored under 'true' Michaelis–Menten kinetic conditions using a constant Co(III) concentration (150 μM) and varying substrate DNA concentration (8.53–203 μM). A typical cleavage profile of pUC19 plasmid DNA by Co(III) complex is shown in Fig. 6 (and in Fig. 2S in the Supplementary data). The cleavage rate constants, k_{obs} were estimated in a similar fashion as that shown by Eq. (1) and the plots of k_{obs} versus [DNA] [34] for the two complexes are depicted in Fig. 7. These

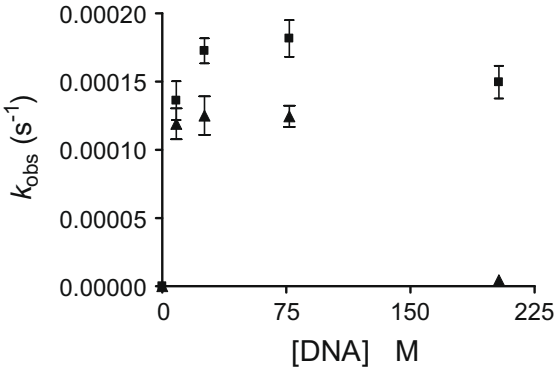

Fig. 7. Kinetics of the cleavage of pUC19 plasmid DNA by **1** (■) and **3** (▲). Varying concentrations of DNA were incubated with 150 μM of **1** or **3** in 1.0 mM Tris–Cl buffer pH 7.0, I = 0.1 M ($NaClO_4$) at 37 °C.

plots did not fit Michaelis–Menten equation. Therefore, K_M and k_{cat} ($k_{cat} = V_{max}/[E]_0$, where $[E]_0$ = [catalyst] = [Co(III)] [34]) were not calculated under these conditions. The data for the two complexes **1** and **3** presented in Fig. 7 show that k_{obs} increases slightly at the very low DNA concentrations reaching a maximum at ca [DNA] = 50 μM and then starts to decrease at higher DNA concentrations. The decrease of k_{obs} in **3** is faster than in **1**. This kinetic behavior is very similar to that reported in some copper complexes [55] and at the same time is different from a perfect saturation behavior observed in other metal complexes [34]. Thus, in order to reach a maximum DNA cleavage activity, a certain number of Co(III) complexes appears to be required to bind to each plasmid DNA; a situation which probably was not achieved with these two complexes. Finally we should indicate that in some of the previous work, V_{max} have been inappropriately used to calculate rate enhancement instead of k_{cat} [7,17a] and this point was addressed by Cowan and co-workers [34].

In order to clarify the DNA cleavage mechanism by the complexes **1** and **3** (hydroxyl radical mechanism, O_2-dependent versus hydrolytic mechanism, O_2-independent), the cleavage of DNA was further investigated in presence and absence of hydrogen peroxide (0.1 mM) and in presence of radical scavengers like DMSO (0.4 M). The DNA cleavage was almost the same as that obtained either with H_2O_2 or with DMSO for both complexes **1** and **3** (Fig. 8). This demonstrates the absence of hydroxyl radical in the cleavage reaction. Therefore, DNA cleavage by the complexes **1** and **3** is most likely proceeding *via* a hydrolytic pathway.

Many of the mononuclear *cis*-diaqua–Co(III) complexes are known to be good promoters in the catalysis of phosphate diesters and of ATP [3,12,19,20]. These complexes also exhibit their highest activity in the neutral pH region (pH ~ 7), where only one of the coordinated water molecule is deprotonated, giving the *cis*-aquahydroxo species [3,12,19]. Therefore, a similar mechanism can be proposed here for the hydrolytic cleavage of the phosphodiester bonds of DNA by the *cis*-aquahydroxo–Co(III) complexes used in this study. The mechanism of reaction involves the coordination

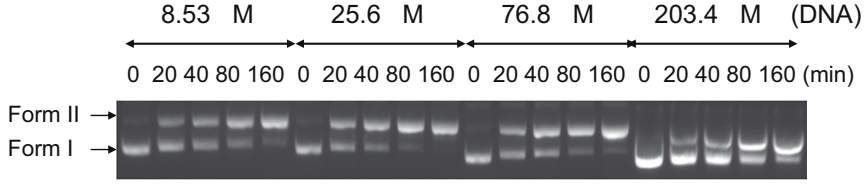

Fig. 6. Cleavage profile of pUC19 plasmid DNA by **1**. Varying concentrations of DNA (8.53, 25.6, 76.8 and 203.4 μM) were incubated with 150 μM of **1** for 0, 20, 40, 80 and 160 min in 1.0 mM Tris–Cl, pH 7.0 at 37 °C.

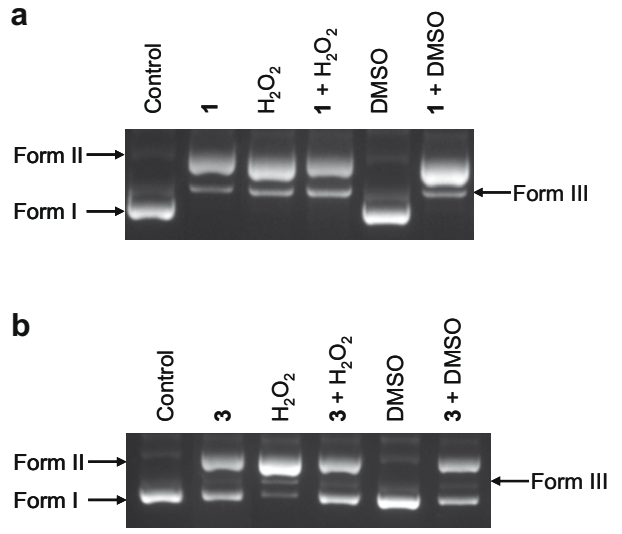

Fig. 8. Electrophoretic separations of pUC19 plasmid DNA cleavage by: (a) complex **1** and (b) complex **3** under the addition of H_2O_2 or of scavenger DMSO. Plasmid DNA (76.8 μM) was incubated with 150 μM of the complex and 0.1 mM H_2O_2 or 0.4 M DMSO for 24 h at 37 °C.

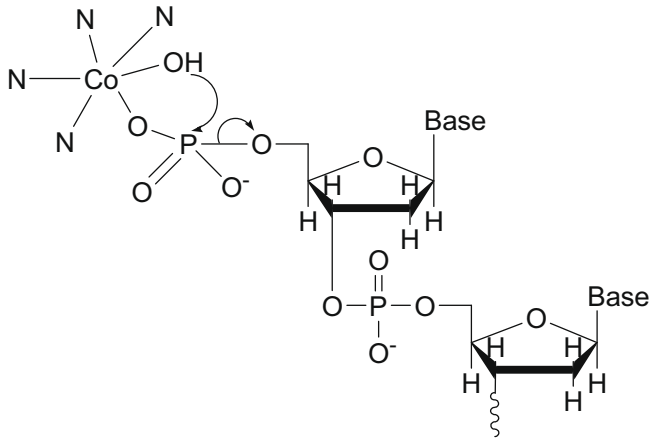

Fig. 9. Proposed intermediate in the DNA cleavage by *cis*-aquahydroxo–tetraamine–cobalt(III) complexes (charge on the cobalt complex cation was omitted for simplicity).

of the phosphate onto the metal followed by an intramolecular nucleophilic attack of the hydroxo ligand on the metal-bound DNA strand, forming a four-membered ring intermediate and hence the cleavage of DNA. It should be emphasized here that this hydroxide ion plays a critical role in the phosphoryl transfer hydrolysis process. The proposed intermediate is illustrated in Fig. 9.

4. Concluding remarks

In this study, we demonstrated the efficiency of the aquahydroxo–Co(III) complexes derived from TPA (**1**) and 2,2,2-tet (**3**) in promoting the hydrolytic cleavage of DNA. Under pseudo-Michaelis–Menten conditions and at the saturation kinetic level, the former complex enhances the rate of cleavage of the double-stranded DNA by a factor that is about 35-million-fold greater than the uncatalyzed DNA. The rate enhancement by **1** compared to **3**, most likely is attributed to the presence of the pyridyl groups in **1** which may undergo ring stacking with the DNA nucleic bases. This interaction was confirmed in the reactions M^{2+}-polypyridyl complexes with AMP, ADP and ATP [66]. Moreover, the stacking interaction is also known to accelerate the rates of hydrolysis of ADP and ATP systems [20a,67]. Small alteration in the ligand skeleton by inserting methylene groups into the arms between the N-donor groups in TPA and 2,2,2-tet to increase the chain lengths as in pmap and 3,2,3-tet, respectively, led to dramatic depression in the cleavage rates of DNA. Very low catalytic activity was observed with **2** and almost no hydrolysis in **4**. This indicates that increasing the arms in these two complexes could be responsible for such reduction in rates. Another interesting conclusion which should be addressed when comparing the rates of DNA cleavage by compounds **1** and **2** is the improper orientation of the pyridyl groups in **3**. This may lead to poor π–π interaction with the N-heterocyclic bases of DNA and hence lowers catalytic efficiency. In summary, the TPA–Co(III) complex is a very promising model to catalyze the hydrolytic cleavage of DNA and more work has to be directed to improve the reactivity of this system by incorporating substituted pyridyl groups into the TPA skeleton.

HL^{Me} R = methyl
HL^{iBu} R = *i*-butyl
HL^{nBu} R = *n*-butyl
HL^{nHe} R = *n*-hexyl

Chart 1.

VG MM16 operating in electron ionisation mode at 70 eV electron beam energy and an ion source temperature of 180 °C. TGS–DSC analysis were performed with a Perkin–Elmer TGS-2, DSC-4 apparatus.

X-ray photoelectron spectroscopy (XPS) analyses were performed with a Perkin–Elmer Φ 5600ci spectrometer, with monochromatised Al Kα radiation (1486.6 eV), calibrated vs. $Au4f_{7/2}$ at 83.9 eV [10]. XRD data were collected with a Philips diffractometer with thin film equipment (Cu Kα, λ = 1.54 Å, incident angle 1°).

2.2. Synthesis of the ligands

The β-enaminodiones (MeCO)(MeOCO)C=C(NH_2)R (R = Me (**HL^{Me}**); R = *i*-Bu (**HL^{iBu}**); R = *n*-Bu (**HL^{nBu}**); R = *n*-hexyl (**HL^{nHe}**)), were prepared by reaction of methyl acetoacetate with the appropriate nitrile in the presence of a stoichiometric amount of $SnCl_4$, with the same procedure already reported for **HL^{Me}** [11,12].

HL^{nBu}: ^{1}H NMR (in $CDCl_3$): δ = 0.93 (t, 3H, C*H*$_3$), 1.30–1.75 (m, 4H, 2C*H*$_2$), 2.26 (s, 3H, C*H*$_3$CO), 2.45 (m, 2H, C*H*$_2$), 3.76 (s, 3H, C*H*$_3$OCO), 5.68 (s, 1H, N*H*), 11.21 (s, 1H, N*H*). FTIR [cm^{-1}, KBr]: 3370 [ν(NH)], 2959–2872 [δ(CH)], 1709 [ν(MeOC=O)], 1603 [ν(C=O)].

HL^{iBu}: ^{1}H NMR (in $CDCl_3$): δ = 0.91 (d, 6H, CH(C*H*$_3$)$_2$), 1.84 (m, 1H, C*H*), 2.20 (s, 3H, C*H*$_3$CO), 2.32 (d, 2H, CH$_2$), 3.70 (s, 3H, C*H*$_3$OCO), 6.00 (s, 1H, N*H*), 11.18 (s, 1H, N*H*). FTIR [cm^{-1}, KBr]: 3364 [ν(NH)], 2961–2872 [δ(CH)], 1703 [ν(MeOC=O)], 1603 [ν(C=O)].

HL^{nHe}: ^{1}H NMR (in $CDCl_3$): δ = 0.87 (m, 3H, C*H*$_3$), 1.20–1.70 (m, 8H, 4C*H*$_2$), 2.24 (s, 3H, C*H*$_3$CO), 2.44 (m, 2H, C*H*$_2$), 3.75 (s, 3H, C*H*$_3$OCO), 5.64 (s, 1H, N*H*), 11.21 (s, 1H, N*H*).

2.3. Synthesis of the complexes

Complexes **1–6** were obtained by reaction of the metal acetate with the appropriate ligand in 1/2 molar ratio, in anhydrous ethanol, at room temperature under argon; the resulting solutions were left under stirring for variable times and the complexes can either precipitate spontaneously from the reaction mixture or be recovered from the solution evaporated to dryness. In many cases the compounds are isolable in different forms, distinguished as **a** or **b**, which exhibit identical composition but different spectroscopic properties; the symbols **a** and **b** indicate only the order in which the complexes have been isolated.

[Pd(**L^{Me}**)$_2$] (**1a, 1b**). [Pd(OAc)$_2$] (0.17 g, 0.76 mmol) and **HL^{Me}** (0.25 g, 1.60 mmol) were dissolved in anhydrous ethanol (20 ml) and the resulting solution was stirred for 4 h at room temperature, then filtered. The solid was recrystallised from dichloromethane/hexane, affording pure (**1a**) as a bright yellow solid (0.090 g, 27% yield). The yellow alcoholic filtrate was evaporated to small volume under reduced pressure and treated with diethylether (10 ml), giving (**1b**) as a light yellow solid, which was filtered and dried under vacuum (0.157 g, 47% yield). *Anal.* Calc. for $C_{14}H_{20}N_2O_6Pd$ (*MW* = 418.72): C, 40.16; H, 4.81; N, 6.69. Found for (**1a**): C, 40.28; H, 4.71; N, 6.37. Found for (**1b**): C, 39.57; H, 4.76; N, 6.68%. (**1a**). ^{1}H NMR (in $CDCl_3$), two species, labelled **a** and **a′**, in approximately 2/1 ratio are present in solution: δ = 2.09 (s, 3H, C*H*$_3$CO, **1a**), 2.16 (s, 3H, C*H*$_3$, **1a**), 2.18 and 2.19 (2s, 3H, C*H*$_3$CO and C*H*$_3$, **1a′**), 3.76 (s, 4.5H, C*H*$_3$OCO, **1a** and **1a′**), 6.34 (s, 0.5H, N*H*, **1a′**), 6.79 (s, 1H, N*H*, **1a**). ^{13}C NMR (in $CDCl_3$): δ = 25.6 and 26.7 (*C*H$_3$ and *C*H$_3$CO, **1a**), 26.1 and 27.0 (*C*H$_3$ and *C*H$_3$CO, **1a′**), 51.6 (*C*H$_3$OCO, **1a** and **1a′**), 106.0 ((CH$_3$CO)*C*, **1a** and **1a′**), 164.7 (*C*NH, **1a**), 165.4 (*C*NH, **1a′**), 170.9 (CH$_3$O*C*O, **1a′**), 171.1 (CH$_3$O*C*O, **1a**), 179.5 (CH$_3$*C*O, **1a**), 181.4 (CH$_3$*C*O, **1a′**). FTIR [cm^{-1}, KBr]: 3322 [ν(NH)], 1692 [ν(MeOC=O)], 1577 [ν(C⟷O)]. FTIR [cm^{-1}, $CDCl_3$]: 3348, 3316(sh) [ν(NH)], 1702 [ν(MeOC=O)], 1587 [ν(C⟷O)]. UV–Vis (λ_{max}/nm, $CHCl_3$): 328 (ε = 6400 ± 500 dm^3 mol^{-1} cm^{-1}), 260 (ε = 21 100 ± 2100 dm^3 mol^{-1} cm^{-1}). MS-EI: *m/z* 418 ([Pd(**L^{Me}**)$_2$]$^+$). (**1b**). ^{1}H NMR (in $CDCl_3$): δ = 2.15 (s, 3H, C*H*$_3$CO), 2.17 (s, 3H, C*H*$_3$), 3.75 (s, 3H, C*H*$_3$OCO), 6.80 (s, 1H, N*H*). ^{13}C NMR (in $CDCl_3$): δ = 25.9 and 26.7 (*C*H$_3$ and *C*H$_3$CO), 51.6 (*C*H$_3$OCO), 106.0 ((CH$_3$CO)*C*), 165.2 (*C*NH), 171.0 (CH$_3$OCO), 180.7 (CH$_3$CO). FTIR [cm^{-1}, KBr]: 3325 and 3310 [ν(NH)], 1684 and 1675 [ν(MeOC=O)], 1584 and 1576 [ν(C⟷O)]. FTIR [cm^{-1}, $CDCl_3$]: 3348 and 3313 [ν(NH)], 1702 [ν(MeOC=O)], 1576 [ν(C⟷O)]. UV–Vis (λ_{max}/nm, $CHCl_3$): 326 (ε = 7400 ± 500 dm^3 mol^{-1} cm^{-1}), 260 (ε = 22 300 ± 1600 dm^3 mol^{-1} cm^{-1}). MS-EI: *m/z* 418 ([Pd(**L^{Me}**)$_2$]$^+$). Complex (**1a**) decomposes at 178 °C at atmospheric pressure, while it sublimes at 156 °C at 4 × 10^{-2} mbar; FTIR analysis reveals that both the sublimate (FTIR: 3321 [ν(NH)], 1689 [ν(MeOC=O)] and 1576 [ν(C⟷O)]) and the residue are still (**1a**) (FTIR: 3322 [ν(NH)], 1690 [ν(MeOC=O)], 1574 [ν(C⟷O)]). Complex (**1b**) decomposes at 210 °C at atmospheric pressure, while it sublimes at 156 °C at 4 × 10^{-2} mbar; FTIR analysis reveals that the sublimate is (**1a**) (FTIR: 3320 [ν(NH)], 1688 [ν(MeOC=O)] and 1576 [ν(C⟷O)]) while the residue is still (**1b**) (FTIR: 3323 and 3310 [ν(NH)], 1685 and 1673 [ν(MeOC=O)], 1574 [ν(C⟷O)]).

[Pd(**L^{iBu}**)$_2$] (**2a, 2b**). [Pd(OAc)$_2$] (0.17 g, 0.76 mmol) was dissolved in anhydrous ethanol (15 ml) and the resulting solution was additioned with **HL^{iBu}** (0.30 g, 1.50 mmol, in 15 ml anhydrous ethanol). The reaction mixture was left under stirring for 2 h at room temperature, then evaporated under reduced pressure. The residue was dissolved with dichloromethane (15 ml) and filtered through Celite. The filtrate was again evaporated to small volume and finally, treated with diethylether (20 ml), affording a yellow precipitate (**2**), which was filtered and dried under vacuum (0.24 g, 63% yield). *Anal.* Calc. for $C_{20}H_{32}N_2O_6Pd$ (*MW* = 502.88): C, 47.77; H, 6.41; N, 5.57. Found: C, 46.96; H, 6.40; N, 5.38%. (**2**): FTIR [cm^{-1}, KBr]: 3297, 3270 and 3248 [ν(NH)], 1715 [ν(MeOC=O)], 1584 [ν(C⟷O)]. UV–Vis (λ_{max}/nm, $CHCl_3$): 330 (ε = 6600 ± 500 dm^3 mol^{-1} cm^{-1}), 260 (ε = 19 000 ± 1400 dm^3 mol^{-1} cm^{-1}). MS-EI: *m/z* 502 ([Pd(**L^{iBu}**)$_2$]$^+$). The NMR spectra revealed that the isolated solid was a mixture of two isomers (**2a**, **2b**) in 2.5/1 ratio. (**2a**). ^{1}H NMR (in $CDCl_3$): δ = 0.89 (d, 6H, (C*H*$_3$)$_2$CHCH$_2$, $^3J_{HH}$ = 6.6 Hz), 1.83 (m, 1H, (CH$_3$)$_2$C*H*CH$_2$), 2.18 (s, 3H, C*H*$_3$CO), 2.37 (d, 2H, (CH$_3$)$_2$CHC*H*$_2$, $^3J_{HH}$ = 7.4 Hz), 3.74 (s, 3H, C*H*$_3$OCO), 6.34 (s, 1H, N*H*). ^{13}C NMR (in $CDCl_3$): δ = 22.8 ((*C*H$_3$)$_2$CHCH$_2$), 26.6 (*C*H$_3$CO), 28.1 ((CH$_3$)$_2$CHCH$_2$), 49.5 ((CH$_3$)$_2$CHCH$_2$), 52.2 (*C*H$_3$OCO), 106.2 ((CH$_3$CO)*C*), 169.0 (*C*NH), 171.6 (CH$_3$O*C*O), 181.7 (CH$_3$*C*O). ^{15} N NMR (in $CDCl_3$): δ = 145.4. (**2b**). ^{1}H NMR (in $CDCl_3$): δ = 0.92 (d, 6H, (C*H*$_3$)$_2$CHCH$_2$, $^3J_{HH}$ = 6.6 Hz), 1.83 (m, 1H, (CH$_3$)$_2$C*H*CH$_2$), 2.09 (s, 3H, C*H*$_3$CO), 2.33 (d, 2H, (CH$_3$)$_2$CHC*H*$_2$, $^3J_{HH}$ = 7.4 Hz), 3.74 (s, 3H, C*H*$_3$OCO), 6.74 (s, 1H, CN*H*). ^{13}C NMR (in $CDCl_3$): δ = 22.9 ((*C*H$_3$)$_2$CHCH$_2$), 26.2 (*C*H$_3$CO), 27.9 ((CH$_3$)$_2$*C*HCH$_2$), 49.0 ((CH$_3$)$_2$CHCH$_2$), 52.2 (*C*H$_3$OCO), 106.4 ((CH$_3$CO)*C*), 168.0 (*C*NH), 171.8 (CH$_3$O*C*O), 179.9 (CH$_3$*C*O). ^{15} N NMR (in $CDCl_3$): δ = 166.9. Complex (**2**) decomposes at 195 °C at atmospheric pressure, while it sublimes at 155 °C at 6 × 10^{-2} mbar; FTIR analysis reveals that the sublimate is (**2b**) (FTIR [cm^{-1}, KBr]: 3270 and 3248 [ν(NH)], 1713 [ν(MeOC=O)], 1585 [ν(C⟷O)]) while the residue is still a mixture of (**2a**) and (**2b**) (FTIR: 3298, 3270 and 3248 [ν(NH)], 1715 [ν(MeOC=O)], 1584 [ν(C⟷O)]).

[Pd(**L^{nBu}**)$_2$] (**3**). A yellow solid was obtained with the same experimental procedure of complex (**2**) (0.29 g, 77% yield). *Anal.*

Calc. for $C_{20}H_{32}N_2O_6Pd$ (MW = 502.88): C, 47.77; H, 6.41; N, 5.57. Found: C, 46.89; H, 6.30; N, 5.41%. ^{1}H NMR (in $CDCl_3$): δ = 0.87 (t, 3H, $CH_3(CH_2)_3$, $^3J_{HH}$ = 7.2 Hz), 1.28 (m, 2H, $CH_3CH_2(CH_2)_2$), 1.52 (m, 2H, $CH_3CH_2CH_2CH_2$), 2.14 (s, 3H, CH_3CO), 2.42 (t, 2H, $CH_3(CH_2)_2CH_2$, $^3J_{HH}$ = 8.0 Hz), 3.72 (s, 3H, CH_3OCO), 6.38 (s, 1H, N*H*). ^{13}C NMR (in $CDCl_3$): δ = 13.8 ($CH_3(CH_2)_3$), 22.7 (CH_2), 25.6 (CH_3CO), 30.4 (CH_2), 39.3 (CH_2), 51.7 (CH_3OCO), 105.7 ((CH_3CO)*C*), 168.7 (*C*NH), 171.1 (CH_3OCO), 179.3 (CH_3CO). UV–Vis (λ_{max}/nm, $CHCl_3$): 342 (ε = 3500 ± 300 dm^3 mol^{-1} cm^{-1}), 272 (ε = 30200 ± 2800 dm^3 mol^{-1} cm^{-1}), 244 (ε = 36500 ± 3000 dm^3 mol^{-1} cm^{-1}). MS-EI: *m/z* 370 ([Ni($\mathbf{L^{Me}}$)$_2$]$^+$). Complex (**5**) decomposes at 193 °C at atmospheric pressure, while it sublimes at 130 °C at 4 × 10^{-2} mbar; FTIR analysis reveals that the sublimate is a mixture of (**5**) and another isomer (FTIR: 3342 and 3320 [ν(NH)], 1690 [ν(MeOC=O)], 1591 and 1572 [ν(C⟷O)]), while the residue is complex (**5**) (FTIR: 3320 [ν(NH)], 1688 [ν(MeOC=O)], 1570 [ν(C⟷O)]).

[Ni($\mathbf{L^{iBu}}$)$_2$] (**6**). A solution of $\mathbf{HL^{iBu}}$ (0.25 g, 1.60 mmol) in anhydrous ethanol (20 ml) was added to a solution of [Ni(OAc)$_2$]·4H$_2$O (0.19 g, 0.78 mmol, in 15 ml anhydrous ethanol). The resulting mixture was stirred for 12 h at room temperature and then evaporated to small volume under reduced pressure. The resulting residue was treated with ethanol (20 ml) under stirring for 1 h and the solvent was again removed. Treatment with diethylether (20 ml) afforded a reddish precipitate, which was filtered and dried under vacuum. The solid was recrystallised from dichloromethane/diethylether, affording pure (**6**) as a pink solid (0.26 g, 75% yield). *Anal.* Calc. for $C_{20}H_{32}N_2NiO_6$ (MW = 455.19): C, 52.77; H, 7.09; N, 6.15. Found: C, 51.44; H, 7.01; N, 5.98%. ^{1}H NMR (in $CDCl_3$): δ = 0.90 (d, 6H, $(CH_3)_2CHCH_2$, $^3J_{HH}$ = 6.8 Hz), 1.72 (m, 1H, $(CH_3)_2CHCH_2$), 1.94 (s, 3H, CH_3CO), 2.28 (d, 2H, $(CH_3)_2CHCH_2$, $^3J_{HH}$ = 7.2 Hz), 3.70 (s, 3H, CH_3CO_2), 5.37 (s, 1H, CN*H*). ^{13}C NMR (in $CDCl_3$): δ = 22.8 ((CH_3)$_2$CHCH$_2$), 26.7 (CH_3CO), 27.9 ((CH_3)$_2$CHCH$_2$), 49.0 ((CH_3)$_2$CHCH$_2$), 51.8 (CH_3OCO), 106.1 ((CH_3CO)*C*), 170.7 (*C*NH), 171.1 (CH_3OCO), 181.5 (CH_3CO). ^{15}N NMR (in $CDCl_3$): δ = 162.7. FTIR [cm^{-1}, KBr]: 3279 and 3268 [ν(NH)], 1709 [ν(MeOC=O)], 1582 [ν(C⟷O)]. UV–Vis (λ_{max}/nm, $CHCl_3$): 346 (ε = 3000 ± 200 dm^3 mol^{-1} cm^{-1}), 272 (ε = 26300 ± 1700 dm^3 mol^{-1} cm^{-1}), 244 (ε = 34600 ± 2300 dm^3 mol^{-1} cm^{-1}). MS-EI: *m/z* 454 ([Ni($\mathbf{L^{iBu}}$)$_2$]$^+$). Complex (**6**) decomposes at 180 °C at atmospheric pressure, while it sublimes at 125 °C at 7.5 × 10^{-2} mbar; FTIR analysis reveals that both the sublimate (FTIR: 3279 and 3268 [ν(NH)], 1707 [ν(MeOC=O)], 1582 [ν(C⟷O)] and the residue (FTIR: 3279 and 3268 [ν(NH)], 1709 [ν(MeOC=O)], 1582 [ν(C⟷O)]) are complex (**6**).

2.4. Vapour deposition of complex [Ni($\mathbf{L^{Me}}$)$_2$] (**5**)

All deposition experiments were performed in a cold wall reactor using O_2, N_2, N_2/O_2 or $N_2/O_2/H_2O$ mixtures as gas carrier (purity 99.999%). The precursor was sublimed from a small crucible located close to the reactor (for a similar reactor see Ref. [13]).

Deposition on silicon under N_2: temperature of precursor 132 °C, of substrate 450 °C, total pressure 0.08 mbar, gas flow 8.1 cc min^{-1}; deposition on glass under O_2: temperature of precursor 130 °C, of substrate 450 °C, total pressure 0.08 mbar, gas flow 8.1 cc min^{-1}; deposition on silicon under $O_2 + H_2O$: temperature of precursor 133 °C, of substrate 450 °C, total pressure 0.03 mbar, gas flow 10 cc min^{-1}; deposition on glass under $O_2 + H_2O$: temperature of precursor 133 °C, of substrate 450 °C, total pressure 0.03 mbar, gas flow 10 cc min^{-1}.

The Si(100) substrate before the deposition was degreased using boiling trichloroethylene and rinsed with isopropyl alcohol.

3. Results and discussion

The results obtained in this study confirm the validity of the procedure for the synthesis of β-imino carbonyl enolato complexes starting from metal(II) acetates and β-enaminodiones (Eq. (1)). The factors governing the success of this exchange reaction have been recently fully

$$M(OAc)_2 + 2(R'CO)(R''CO)C{=}C(NH_2)R \rightarrow [M((R'CO)(R''CO)CC(NH)R)_2] + 2HOAc \quad (1)$$

exploited and depend on: (i) the relative stabilities of metal acetates and metal complexes and on (ii) the acidity of the β-enaminodiones compared with that of acetic acid [2a]. The chain length in the series of investigated β-enamino ketoesters (MeCO)(MeOCO)C=C(NH$_2$)R (R = Me, *i*-Bu, *n*-Bu, *n*-hexyl) has practically no effect on the output of the synthetic procedure so that complexes [M$\mathbf{L}_2$] (**1–6: 1**, Pd, $\mathbf{L^{Me}}$;

2, Pd, $\mathbf{L^{iBu}}$; **3**, Pd, $\mathbf{L^{nBu}}$; **4**, Pd, $\mathbf{L^{nHe}}$; **5**, Ni, $\mathbf{L^{Me}}$; **6**, Ni, $\mathbf{L^{iBu}}$) are obtained always in good yields. In most cases the complexes precipitate spontaneously otherwise the reaction is forced toward the desired products by co-distillation from the reaction mixture of solvent and the acetic acid produced in the ligand exchange process.

The results are coherent with those obtained with the ethyl substituent at the imino group [3]. The potentially tridentate N,O,O ligand acts in all cases as bidentate through the nitrogen and the keto oxygen atoms to give monomeric square planar neutral complexes. These are air and moisture stable solids, which can be stored safely under inert atmosphere; they are soluble in common organic solvents, such as ethanol, CH_2Cl_2, and $CHCl_3$, but mostly insoluble in *n*-hexane or diethylether.

The IR spectra in KBr of all complexes are very similar as the whole, being characterised by: (i) the N–H band approximately around 3300 cm^{-1}, (ii) a band at 1570–1585 cm^{-1}, which can be easily attributed to the coordinated acetyl carbonyl, (iii) an absorption in the range 1675–1719 cm^{-1} due to the C=O stretching vibration of the uncoordinated ester. In fact, the wavenumber values for O,O′-chelation in β-diester complexes are always close to 1600 cm^{-1}, as an effect of electronic delocalisation which occurs in the metallocycle ring [14]. These features confirm N,O ligand to metal coordination.

In addition the ^1H and ^{13}C NMR spectra are consistent with the proposed picture; in particular the ketonic carbonyl C signal (179.3–181.7 ppm) is shifted upfield in comparison with the signal of the corresponding carbon in the free ligand [2b,3]. No information can be gained instead from the chemical shift values of the C=N and C(O)OMe carbons which remain practically unchanged. Preferential coordination of the keto group with respect to the ester one has been widely observed in analogous complexes [1–3].

The palladium complexes (**1**) and (**2**) have been isolated in two forms, labelled **a** and **b**, whereas palladium(II) complexes (**3**) and (**4**) and the nickel ones (**5**) and (**6**) have been isolated only in one form.

This explains some small differences between the NMR spectra of samples (**1a**) and (**1b**) or (**2a**) and (**2b**). NOE experiments carried out on sample **2a** revealed a strong dipolar interaction between the protons of the *i*-butyl substituent and the imino hydrogen. Moreover a strong dipolar interaction between the hydrogen atoms of the acetyl and methyl ester groups indicates that they are spatially very close to each other (conformation **A** in Fig. 1). The same experiments carried out on sample (**2b**), indicate that the oxo and methoxy substituents on (**2b**) are turned and the methyl ester is preferentially faced toward the *i*-butyl group (conformation **B**). Thus the small differences observed in the solution NMR spectra of (**2a**) and (**2b**) can be easily attributed to these conformational changes of the ester substituent of the chelate ring. Similar considerations may apply to the solution chemistry of the palladium complex (**1**) for which three different sets of signals relative to **a**, **a**′ and **b** are observed. NOE experiments are not conclusive for this complex; in fact a sample of (**1b**) shows strong dipolar interactions consistent with conformation **B**. However sample (**1a**) shows two N–H proton signals of different intensity relative to the two species labelled **a** and **a**′, both correlating only with the corresponding imino methyl substituent, and no other spatial correlations are evident. The absence of these expected correlations may be due perhaps to a turning away of the methyl oxo. It should be underlined that the position of the N–H signal attributable to the minor species labelled **a**′ strongly depends on the type of solvents and, for example, passing from $CDCl_3$ to anhydrous C_6D_6 moves from 6.34 to 5.10 ppm, thus suggesting the possibility of intermolecular hydrogen bonding. With more sterically demanding groups, like *n*-butyl or *n*-hexyl, only one species has been isolated, thus indicating that the rotation of the ester group is hindered and that acetyl and methyl ester groups are preferentially faced to each other (conformation **A** in Fig. 1)

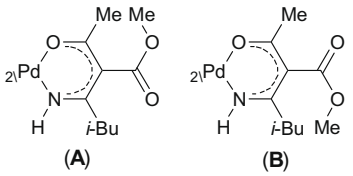

Fig. 1. Proposed conformations of complex (**2**).

In the UV–Vis spectra, palladium(II) complexes (**1**)–(**4**) show two maxima at ca. 330 and 260 nm of medium and strong intensities respectively. The shortest wavelength absorption at 260 nm may be assignable to $\pi \rightarrow \pi^*$ transition of the ligand, while the absorption at 330 nm ca. may be due to metal-to-ligand charge transfer transitions. The nickel compounds (**5**) and (**6**) present a third absorption at 240 nm ca., which is still assigned to a $\pi \rightarrow \pi^*$ transition of the ligand.

The complexes are volatile and remarkably stable as it appears evident from the presence of very intense molecular ions in the mass spectra of all compounds (**1**)–(**6**) (see Supplementary Information). The primary fragmentations are the same for both forms (**a** and **b**) and can be divided in two main categories: fragmentations of the ligand moiety anchored to the metal and those of the "free" ligand. The mass spectra of all the complexes are also characterised by the presence of HML^+ ions containing only one coordinated ligand and related fragmentations.

The high stability of this type of complexes is also confirmed by melting point measurements and TGA analysis (Table 1 and Fig. 2). The effect of the length of R chain on the melting point is rather limited, even if a decrease of the value with the lengthening of the chain is observed, probably due to reduced H-bonding interactions. Comparing palladium(II) and nickel(II) complexes it is evident a greater stability of the former ones, as indicated by the somewhat higher melting point values (215–178 °C versus 193–180 °C). TGA studies of the palladium complexes (**1**)–(**4**) show that they decompose in two steps; the first around 300 °C gives a residue (ca. 30%), which transforms in palladium black upon heating at 950 °C. Also in the case of nickel complexes (**5**)–(**6**) there are two losses of weight: the major one takes place between 110–350 °C and gives a residue that vaporizes almost completely at temperatures below 750 °C.

DSC measurements show a markedly different behaviour for the two metal centres. Nickel complexes are characterised by a strong endothermic peak (31.3 and 54.3 kJ mol^{-1}) at approximately the fusion temperatures 193 (**5**) and 180 (**6**) °C. For the palladium complexes the ΔH versus temperature diagram is much more complicated: low energy endothermic peaks (ca. 3 kJ mol^{-1}), probably associated to conformational processes, are observed, in addition to very intense peaks in the correspondence of state changes like fusion and evaporation.

The nickel complex (**5**) has been tested under MOCVD conditions to verify its suitability as precursor in the formation of thin films over glass or silicon substrates. Its high volatility allows rather accessible temperatures (130–133 °C) and pressures (3×10^{-2}–8×10^{-2} mbar), whereas the substrate was kept at 450 °C to ensure fast decomposition of the complex.

The film surface morphology was investigated by SEM (Fig. 3), confirming a uniform substrate coverage, typical of a three-dimensional growing, characterised by well-interconnected agglomerates with mean sizes around 100 nm.

The nature of the thin films depends on the employed carrier gases: use of N_2 and of O_2 gives nickel metal and nickel oxide respectively, whereas a mixture of water with either N_2 or O_2 affords a co-deposition of both. The presence of nickel oxide in the

films obtained under nitrogen can not be detected by X-ray technique, even if ESCA analysis indicates the presence of NiO (see further); these results suggest an amorphous phase for NiO [15]. X-rays analysis on the deposited films reveals a preferential

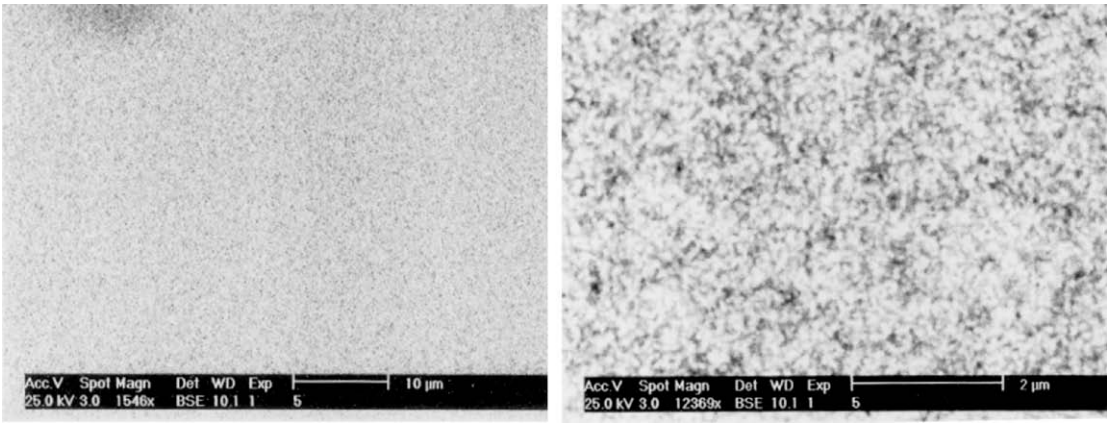

Fig. 3. Selected SEM images of the thin films deposited on glass using $O_2 + H_2O$ carrier.

Ni/%	15.4	32.9	24.7	22.0
N/%	2	0	1	1
Si/%	0	5.0	0	0

orientation (1 1 1) for nickel metal and (2 0 0) plus (1 1 1) for nickel oxide.

The superficial composition determined by ESCA (Table 2) shows in all cases a high carbon content, mostly due to a superficial contamination, and very low quantity of nitrogen derived from ligand decomposition.

Silicon is practically absent in the surface so ensuring a good homogeneity of the deposit. The Ni/O ratio is within the experimental errors close to 1. Analysis of the films deposited in the presence of water reveals two contributions to the O1s peak: the first one at 529.9 eV is attributed to Ni–O bonds in the NiO, whereas the contribution at higher binding energy (531.6 eV) suggest the presence of OH groups present on the NiO surface [16–18]. The Ni2p peaks are found at a value consistent with literature data for NiO with hydroxyl groups on the surface [17]; the NiO (1 1 1) faces can be in fact stabilised by hydroxylation [19].

4. Conclusions

In conclusion, the synthesis of β-imino carbonyl enolato complexes of palladium(II) and nickel(II), by reaction of the acetato salt and the required β-enaminodione, appears rather general. The obtained complexes are square planar, stable and volatile, with a limited effect of the imino alkyl chain on their thermal behaviour. The N,O square planar coordination observed also for nickel(II) complexes is particularly interesting, because it makes possible to utilize, for example, [Ni($\mathbf{L^{Me}}$)$_2$], as convenient MOCVD precursor for the production of Ni or NiO thin films. It should be underlined that O,O coordination to nickel(II), as in β-carbonyl enolato complexes, gives rise to octahedral high melting, non volatile, oligomeric *via* O-bridges structures [20].

Scheme 2. Possible routes of formation of the haloalcoholato fragment.

by studying the reactions of $NbCl_5$ with styrene oxide and epoxycyclohexane (vide infra).

The compounds **2a**–**h** have been characterized spectroscopically (IR and NMR), by elemental analyses, and by X-ray diffraction in the case of **2h** (Fig. 1 and Table 1).

The unit cell contains discrete dinuclear $[TaBr_2(OCH_2CH_2Br)_2(\mu\text{-}OCH_2CH_2Br)]_2$ molecules, which reside on a crystallographic inversion centre. The dimeric species adopts an edge sharing bioctahedral geometry, with four terminal bromide ligands in the axial positions (*trans* geometry). Conversely, the equatorial plane is occupied by four terminal and two bridging haloalcoholates. All bonding distances are comparable with those previously reported for Ta(V)–Br and Ta(V)–OR containing complexes [6]. The bridging ligand is almost symmetric [Ta(1)–O(1) 2.091(11) Å; Ta(1)–O(1)#1 2.107(10) Å], and these contacts are considerably elongated compared to the ones referring to the terminal haloalcoholates [Ta(1)–O(2) 1.818(9) Å; Ta(1)–O(3) 1.822(10) Å].

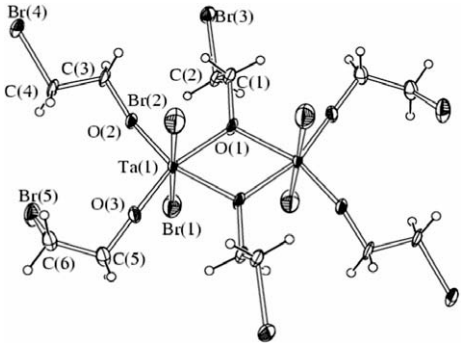

Fig. 1. Molecular structure of $[TaBr_2(OCH_2CH_2Br)_2(\mu\text{-}OCH_2CH_2Br)]_2$, **2h**. Thermal ellipsoids are drawn at the 30% probability level. Only independent atoms are labelled.

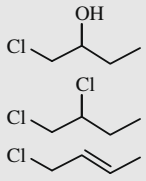
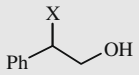
Symmetry transformations used to generate equivalent atoms: #1 $-x+1/2, -y+1/2, -z+2$.

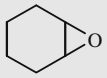
Compounds **2** add to the family of transition metal alcoholato complexes [7], which have found various applications (film-deposition [8], nanotechnology [9], polymerization catalysis [10] and the preparation of materials with notable properties [11]); and in more detail, cases of structurally characterized metal complexes containing 2-haloalcoholates are available in the literature, including both late [12] and early transition [13] metal species.

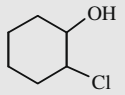
Regarding niobium(V) and tantalum(V), although examples of pentaalcoholates are numerous [14a–e], only a few mixed halide-alcoholates $[MX_n(OR)_{5-n}]_2$ have been crystallographically characterized so far [14f–i]. Complexes **2** belong to this rather uncommon class of compounds [15], and represent the first case of structurally characterized coordination compounds of the heavier Group 5 elements containing halo-substituted alcoholates.

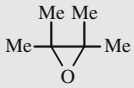
The NMR spectra of **2a**, **c**, **e** and **f** exhibit slightly distinct resonances for the terminal and bridging ligands (see Section 4) [13], and agree with the dinuclear structure $[MX_2(OR)_2(\mu\text{-}OR)]_2$. For instance, the methyl units belonging to the $OC(Me)_2$ moieties in **2c** give rise to resonances at 1.70 (bridging ligands) and 1.58 ppm (terminal) in the ^1H NMR spectrum, and at 29.1 (bridging) and 28.9 ppm (terminal) in the ^{13}C NMR spectrum. On the other hand, the ^1H NMR spectra of **2b**, **d** and **g** display only broad resonances, for which discrimination between terminal and bridging ligands has not been possible. In contrast to the previous observations on some niobium or tantalum alkoxides, no dimer–monomer equilibria [13,16] have been detected in solution at room temperature for compounds **2**.[2]

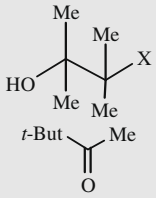












It is worthy noting that the formal insertion of 1,2-epoxybutane into the metal–halide bond could in principle generate two isomeric forms, according to the site of attack of the halide, see Scheme 2.

A careful reading of the 1D and 2D NMR spectra of **2a** and **f** has evidenced the absence of resonances attributable to $-OCH_2$-CH(Et)Cl units [6c,6d], suggesting that multiple 1,2-epoxybutane insertion into the metal–chloride bonds of MCl_5 (M = Nb, Ta) occurs in a highly regioselective mode (Scheme 2, path B), placing the halide on the less hindered carbon atom.

The NMR spectra of **2b** and **d**, obtained by reacting NbX_5 (X = Cl, Br) with styrene oxide, do not allow, unambiguously, the formation of any of the species obtainable by the two potential modes of insertion to be ruled out (see Scheme 2). Nevertheless, the hydrolysis of $CDCl_3$ solutions of complexes **2b** and **d**, and subsequent GC–MS and NMR analyses on the organic phase, have pointed out that either **2b** or **2d** contain the $[OCH_2CH(Cl)Ph]$ fragment (entry 2, Table 2). In other words, the insertion of styrene oxide to give **2b** and **d** seems to proceed, differently from the insertion of 1,2-epoxybutane, according to path A of Scheme 2, the halide going to the more hindered carbon atom. This feature may be attributable to the steric hindrance of the phenyl ring, which would force this ligand to occupy the farthest position from the metal centre.

[2] NMR experiments could not be run on complex **2h**, because of its low solubility in suitable deuterated solvents ($CDCl_3$, CD_2Cl_2).

Table 2
Products of hydrolysis of compounds **2a**–**h**.

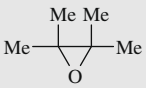
Entry	Epoxide	Haloalkoxo derivative	Hydrolysis product
1		**2a**, **f**[a]	
2		**2b**, **d**[b]	
3		**2g**	
4		**2c**, **e**[b]	
5		**2h**	

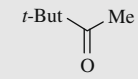
[a] 1,2-Dichlorobutane and 1-chloro-2-butene have been detected probably due to the action of HCl, product of the hydrolysis, on 1-chloro-2-butanol.
[b] X = Cl, Br.

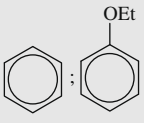
The identities of products **2a**–**h** have been corroborated by combined GC–MS and NMR analyses on concentrated $CDCl_3$ solutions of these compounds after treatment with H_2O, see Section 4 and Table 2. The addition of water causes the quick precipitation of a white solid (probably metal oxides), and release of the organic material. The hydrolysis of **2c** (entry 4, Table 2) deserves more comment: beside 2,3-dimethyl-3-chloro-2-butanol, minor amounts of *t*-butylmethylketone have been observed by NMR and GC–MS analyses, suggesting that pathways alternative to the insertion (see Scheme 1) may be operating, at least for the reaction of 2,3-dimethyl-2,3-epoxybutane with $NbCl_5$.

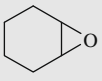
With the purpose of extending the series of halo-2-haloalcoholato complexes of type **2**, we studied the reactivity of $NbBr_5$ with 1,2-epoxybutane and with epoxycyclohexane. Unfortunately, these reactions afforded mixtures of compounds which could not be separated and characterized. Nonetheless, GC–MS and NMR analyses on the reaction mixtures treated with water led to the identification of 1,2-dibromobutane and 1-bromo-2-butene from $NbBr_5$ and 1,2-epoxybutane, and of 2-bromocyclohexanol and 1,2-dibromocyclohexane from $NbBr_5$ and epoxycyclohexane. These results indicate that the reactions of 1,2-epoxybutane and epoxycyclohexane with $NbBr_5$ proceed *via* epoxide insertions, analogously to that discussed for **2a**–**h**.

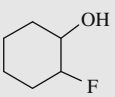
2.2. Reactivity of MF_5 (M = Nb, Ta) with epoxides: isomerisation of 2,3-dimethyl-2,3-epoxybutane to 3,3-dimethyl-2-butanone











According to our recent reports, the reactivity of niobium and tantalum pentahalides with oxygen-donor ligands is strongly influenced by the metal–halide bond energy [6a,6b], and the fluorides often show a chemistry quite different from that of the other halides. Therefore, we decided to investigate the reactivity of MF_5 (M = Nb, Ta) with epoxides, with the aim to see whether insertion reactions could take place, despite the high value of the metal–fluoride bond energy [17].

Niobium pentafluoride and 2,3-dimethyl-2,3-epoxybutane react to afford the ketone complex $NbF_5[O{=}C(Me)(^tBu)]$, **3**, in *ca.* 90% yield. This reaction is strictly stoichiometric: the same reaction, carried out by using variable epoxide to metal ratios greater than 1, resulted in the formation of **3** in an admixture with the unreacted epoxide. Complex **3**, which belongs to the restricted family of carbonylic adducts of Group 5 pentahalides [6a], has been characterized spectroscopically (^1H, ^{13}C and ^{19}F NMR, IR) and by GC–MS analysis carried out on the organic material obtained by hydrolysis of **3** (entry 1, Table 3). A salient spectroscopic feature is given by a strong IR absorption at 1647 cm^{-1}, ascribed to the carbon–oxygen double bond (uncoordinated *t*-butylmethylketone shows the C=O stretching vibration at 1708 cm^{-1}, recorded as a liquid film). The ^1H NMR spectrum displays one set of two resonances, attributed to the methyl unit (s, 2.84 ppm) and the *t*-butyl group (s, 1.41 ppm). The major ^{13}C NMR aspect is given by the carbonylic resonance, seen at 245.6 ppm, *i.e.* significantly downfield-shifted with respect to the resonance of the uncoordinated ketone (δ = 213.81 ppm). Furthermore, the ^{19}F NMR spectrum shows uniquely a broad resonance at 145.8 ppm, accounting for the five fluorines of the $[NbF_5]$ moiety, and indicating the monomeric, neutral nature of **3**.

In contrast to that discussed about the reaction of $NbCl_5$ with 2,3-dimethyl-2,3-epoxybutane, which affords some *t*-butylmethylketone as result of HCl release and subsequent hydrolysis (vide infra), the formation of *t*-butylmethylketone in the case of NbF_5 is probably the consequence of direct epoxide isomerisation promoted by niobium fluoride. This latter rearrangement has been reported to occur under the assistance of various metal species, including high valent vanadium [18], cobalt [19], erbium [20], bismuth [21] and lithium [22] compounds.

We tried to extend the chemistry of niobium and tantalum pentafluorides to a series of epoxides (1,2-epoxybutane, styrene oxide and epoxycyclohexane). At variance with that reported

Table 3
Reactants and main products (after hydrolysis) of the reactions of MF_5 with epoxides.

Entry	M	Epoxide	Hydrolysis product

3	Ta		
4	Ta		

above about the synthesis of **3**, the reactions of MF_5 with epoxides other than 2,3-dimethyl-2,3-epoxybutane led to complicated mixtures of products. We did not succeed in the characterization of the inorganic species, but we were able to identify some of the organic compounds produced in the course of the reactions, and released from the metallic frames upon hydrolysis (see Table 3). Thus, ethylmethylketone has been recognized in the mixture obtained from NbF_5 or TaF_5 and 1,2-epoxybutane (entry 2, Table 3): accordingly, this reaction proceeds with epoxide rearrangement, similar to that described for 2,3-dimethyl-2,3-epoxybutane (entry 1, Table 3).

Conversely, no traces of acetophenone and cyclohexanone have been found in the hydrolyzed mixtures generated from the reactions of TaF_5 with styrene oxide and epoxycyclohexane, respectively. Therefore, alternative pathways are likely to be operating in these two cases. More precisely, benzene and ethoxybenzene have been recognized (GC–MS and NMR) as the main products from the treatment of TaF_5 with styrene oxide followed by hydrolysis (entry 3, Table 3). Furthermore, GC–MS and NMR analyses on a sample obtained by addition of epoxycyclohexane to TaF_5, and successive hydrolysis, revealed the presence of small amounts of 2-fluorocyclohexanol (entry 4, Table 3). All these organics prove that C–C and C–H bond activation, together with C–O and C–F bond formation, are possible processes taking place in the course of the reactions of MF_5 (M = Nb, Ta) with epoxides.

3. Conclusions

The strong oxophilicity of niobium and tantalum pentahalides is tested in the room temperature reactions with epoxides, in a 1:3 molar ratio, which proceed rapidly, exothermically and regioselectively. Multiple epoxide ring opening and insertion into metal–chloride (or bromide) bonds give novel stable dinuclear species containing both halide and 2-haloalcoholato ligands. Although MF_5 (M = Nb, Ta) are very reactive towards epoxides, the relatively high metal–fluoride bond energy inhibits insertion reactions. Several alternative pathways appear to be operative concurrently; among them, epoxide to ketone isomerization prevails in some cases.

4. Experimental

4.1. General procedures

All manipulations of air and/or moisture sensitive compounds were performed under an atmosphere of pre-purified argon using standard Schlenk techniques. The reaction vessels were oven dried at 150 °C prior to use, evacuated (10^{-2} mm Hg) and then filled with argon. All the reagents, including MX_5 (M = Nb, Ta, X = Cl; M = Nb, Ta, X = F), were commercial products (Aldrich) of the highest purity available. $NbBr_5$ and $TaBr_5$ were prepared according to published procedures [23]. Epoxides were liquid commercial products stored under an argon atmosphere as received. Solvents were distilled before use under an argon atmosphere from appropriate drying agents: CH_2Cl_2 and $CDCl_3$ from P_4O_{10}, pentane from $LiAlH_4$.

Infrared spectra were recorded at 298 K on a FT-IR Perkin–Elmer Spectrometer equipped with a UATR sampling accessory (solid samples). NMR measurements were performed at 298 K on Varian Gemini 200BB and Mercury Plus 400 instruments. The chemical shifts for ^1H, ^{13}C and ^{19}F NMR spectra were referenced to TMS and to $CFCl_3$, respectively. The chemical shifts were assigned *via* DEPT experiments and ^1H, ^{13}C correlation through gs-HSQC and gs-HMBC experiments [24]. NMR assignments related to terminal and bridging ligands have been specified only where a distinction has been possible. GC/MS analyses were performed on a HP6890 instrument, interfaced with a MSD-HP5973 detector and equipped with a Phenonex Zebron column. Carbon and hydrogen analyses were performed at the Dipartimento di Chimica Farmaceutica of the University of Pisa on a Carlo Erba mod. 1106 instrument, paying particular attention to the sensitive compounds, which were weighed and directly introduced into the analyzer. The halide content refers to the metal-bound halides, and was determined by the Volhardt method [25] after exhaustive hydrolysis of the sample. Metals were analyzed as M_2O_5, obtained by hydrolysis of the sample followed by calcination in a platinum crucible. Every elemental analysis was repeated twice in order to get reproducible results.

4.2. Preparation of $[MX_2(OR)_2(\mu\text{-}OR)]_2$ [M = Nb, X = Cl, R = –CH(Et)CH_2Cl, **2a**; M = Nb, X = Cl, R = –CH_2CH(Ph)Cl, **2b**; M = Nb, X = Cl, R = –C(Me)$_2$C(Me)$_2$Cl, **2c**; M = Nb, X = Br, R = –CH_2CH(Ph)Br, **2d**; M = Nb, X = Br, R = –C(Me)$_2$C(Me)$_2$Br, **2e**; M = Ta, X = Cl, R = –CH(Et)CH_2Cl, **2f**; M = Ta, X = Cl, R = –$\overline{CH(CH_2)_4CHCl}$, **2g**; M = Ta, X = Br, R = –CH_2CH_2Br, **2h**]

General procedure: A suspension of MX_5 (M = Nb, Ta; X = Cl, Br; 1.00 mmol), in CH_2Cl_2 (15 mL) inside a Schlenk tube, was treated with the appropriate epoxide (3.00 mmol). In the case of the synthesis of **2h**, ethylene oxide was added as a CH_2Cl_2 solution (50 mg/mL). Dissolution of the solid and a colour change occurred rapidly and exothermically. The mixture was stirred for an additional 30 min, then the final solution was concentrated (3 mL), layered with pentane (15 mL) and stored at −20 °C. The product was obtained as a solid after 48–72 h. In a different experiment, MX_5 (0.50 mmol) was introduced into a NMR tube, then $CDCl_3$ (0.85 mL) and epoxide (1.50 mmol) were added in the order given. The ^1H NMR analysis was performed once the solid dissolved: complete consumption of the epoxide occurred. Afterwards, the mixture was treated with a large excess of H_2O (*ca.* 20 mmol): precipitation of a colourless solid took place nearly instantaneously. The content of the resulting solution was determined by means of ^1H and ^{13}C NMR spectroscopies, and by GC–MS analysis.

2a: orange, from $NbCl_5$ and 1,2-epoxybutane. *Anal.* Calc. for $C_{24}H_{48}Cl_{10}Nb_2O_6$[3]: C, 29.63; H, 4.97; Nb, 19.10; Cl, 14.58. Found: C, 29.44; H, 5.06; Nb, 18.90; Cl, 14.19%. Hydrolysis (entry 5, Table 2): 2-bromoethanol (NMR and GC–MS).

4.3. Reactivity of $NbBr_5$ with 1,2-epoxybutane and epoxycyclohexane

General procedure: A suspension of $NbBr_5$ (1.00 mmol), in $CDCl_3$ (0.80 mL) inside a NMR tube, was treated with the appropriate epoxide (3.00 mmol). The tube was sealed, and left at room temperature overnight. Then, a ^{1}H NMR spectrum revealed that complete consumption of the epoxide had occurred, and formation of a complicated mixture of products had taken place. This mixture was treated with water (*ca.* 30 mmol), resulting in quick formation of a white precipitate. The precipitate was separated from the solution, which was analyzed by both GC–MS and ^{1}H NMR. From $NbBr_5$ and 1,2-epoxybutane: 1-bromo-2-butene, 1,2-dibromobutane (ratio 1:1). From $NbBr_5$ and epoxycyclohexane: 2-bromocyclohexanol, 1,2-dibromocyclohexane (ratio 3:1).

4.4. Preparation of $NbF_5[O{=}C(Me)(Bu^t)]$, **3**

A suspension of NbF_5 (0.120 g, 0.639 mmol) in CH_2Cl_2 was treated with 2,3-dimethyl-2,3-epoxybutane (0.082 mL, 0.64 mmol). The resulting mixture was stirred for 90 min, then the volatile materials were removed *under vacuum*. Compound **3** was obtained as a crystalline colourless solid by storing a CH_2Cl_2 solution (3 mL), layered with pentane (10 mL), at −20 °C for one week. Yield: 0.166 g, 90%. *Anal.* Calc. for $C_6H_{12}F_5NbO$: C, 25.02; H, 4.20; Nb, 32.25. Found: C, 24.90; H, 4.26; Nb, 32.11%. ^{1}H NMR ($CDCl_3$) δ = 2.84 (s, 3H, Me); 1.41 (s, 9H, Bu^t) ppm. ^{13}C NMR ($CDCl_3$) δ = 245.6 (CO); 48.5 (CMe_3); 26.7 (Me); 26.2 (CMe_3) ppm. ^{19}F NMR ($CDCl_3$) δ = 145.8 (br, 5F) ppm. IR (solid state): ν = 2979w-m, 2947w, 2881w, 1647s (C=O), 1482m, 1466m, 1404w-m, 1368m, 1293w, 1226w, 1146vs, 1054m, 994m, 923s, 797vs, 684vs cm^{-1}. In a different experiment, NbF_5 (0.55 mmol), $CDCl_3$ (0.85 mL) and 2,3-dimethyl-2,3-epoxybutane (0.50 mmol) were added in the order given in a NMR tube and the tube was sealed. The ^{1}H NMR spectrum, recorded when the solid dissolved (about 2 h), evidenced the clean formation of **3**. The tube was opened, and an excess of water was introduced (*ca.* 30 mmol). Precipitation of a colourless solid occurred nearly instantaneously. 3,3-Dimethyl-2-butanone was recognized in solution by both ^{1}H NMR and GC–MS.

The reaction of NbF_5 (0.05 mmol) with 2,3-dimethyl-2,3-epoxybutane (0.50 mmol), in $CDCl_3$ inside a sealed NMR tube, resulted in the clean formation of **3**, in an admixture with a large quantity of unreacted epoxide (ratio: 1:80 *ca.*). The ratio did not change on heating the solution at 120 °C for 30 min.

4.5. Reactivity of MF_5 (M = Nb, Ta) with epoxides (1,2-epoxybutane, styrene oxide, cyclohexene oxide)

General procedure: To a suspension of compound MF_5 (M = Nb, Ta; 0.50 mmol) in $CDCl_3$ (0.80 mL) inside a NMR tube, the appropriate epoxide was added (0.50 mmol). The tube was sealed, and left at room temperature overnight. A ^{1}H NMR spectrum revealed the complete consumption of the epoxide and the formation of a complicated mixture of unidentifiable products. The tube was opened, then the mixture was treated with a large excess of water (*ca.* 15 mmol), resulting in the quick precipitation of a solid from the pale yellow solution. The latter was analyzed by both GC–MS and ^{1}H NMR. From NbF_5 or TaF_5 and 1,2-epoxybutane (entry 2, Table 3): ethylmethylketone. From TaF_5 and cyclohexene oxide (entry 3, Table 3): 2-fluorocyclohexanol. From TaF_5 and styrene oxide (entry 4, Table 3): benzene, ethoxybenzene (ratio *ca.* 1:1).

4.6. X-ray crystallographic study

Crystal data and collection details for $[TaBr_2(OCH_2CH_2Br)_2(\mu\text{-}OCH_2CH_2Br)]_2$, **2h**, are reported in Table 4. The diffraction experiments were carried out on a Bruker APEX II diffractometer equipped with a CCD detector using Mo Kα radiation. Data were corrected for Lorentz polarization and absorption effects (empirical absorption correction SADABS) [26]. The structure was solved by direct methods and refined by full-matrix least-squares based on all data using F^2 [27]. The asymmetric unit contains only half of the molecule, whereas the second half is generated by an inversion centre. Hydrogen atoms bonded to C-atoms were fixed at calculated positions and refined by a riding model. All non-hydrogen atoms were refined with anisotropic displacement parameters.

Table 4
Crystal data and experimental details for **2h**.

Complex	**2h**
Formula	$C_{12}H_{24}Br_{10}O_6Ta_2$
Formula weight	1425.31
T (K)	100(2)
λ (Å)	0.71073
Crystal system	monoclinic
Space group	$C2/c$
a (Å)	12.2223(13)
b (Å)	10.4276(12)
c (Å)	23.080(3)
α (°)	90
β (°)	95.602(2)
γ (°)	90
Cell volume (Å^3)	2927.5(6)
Z	4
D_{calc}, g cm^{-3}	3.234
μ (mm^{-1})	21.144
$F(000)$	2560
Crystal size (mm)	0.17 × 0.15 × 0.14
θ limits (°)	2.57–25.03
Reflections collected	13415
Independent reflections [R_{int}]	2595 [0.0379]
Data/restraints/parameters	2595/100/192
Goodness on fit on F^2	1.051
R_1 ($I > 2\sigma(I)$)	0.0561
wR_2 (all data)	0.1835
Largest difference in peak and hole (e Å^{-3})	2.569/−4.554

The bridging $-CH_2CH_2Br$ group and a terminal one are disordered. Disordered atomic positions were split and refined using one occupancy parameter per disordered group and restrained to have similar geometries (SAME line in SHELXTL). Similar U restraints were applied to the C, Br and O atoms.

Supplementary data

CCDC 710805 contains the supplementary crystallographic data for $[TaBr_2(OCH_2CH_2Br)_2(\mu\text{-}OCH_2CH_2Br)]_2$, **2h**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgments

The authors wish to thank the Ministero dell'Istruzione, dell'Università e della Ricerca (MIUR, Roma), Programmi di Ricerca Scientifica di Notevole Interesse Nazionale, Cofinanziamento 2004–2005, and the Consiglio Nazionale delle Ricerche (C.N.R.) Progetto CNR-MIUR "Sviluppo di microcelle a combustibile", for financial support.

by solvent system and metal to ligand ratio. In some cases, a small change in any of these factors can lead to new complexes with different structural topologies and different functions. Through controlling and tuning these effect factors, we have prepared a series of novel coordination polymers from zinc-benzoate [52,53], but metal-organic complexes from various metal ions with mixed-ligand system of benzoate and bipyridyl groups have been seldom reported [54].

As an extension of our previous work, in this study, we have investigated the complex formation of various metal benzoates with the bridging ligand 4,4′-bipyridine (4,4′-bpy) in order to further prepare functional coordination polymers with intriguing structures and potential applications especially in catalysis and to systematically investigate the influence of the metal ion effects less studied on the assembly processes of coordination polymers containing various metal benzoates.

We report here the syntheses and structures of six novel M(II) coordination polymers (**1**-Co, **2**-Ni, **3**-Cu, **4**-Zn, **5**-Zn, and **6**-Cd), comparison of coordination modes of metal ions including the previously known compound **7**-Mn, and their novel catalytic activities for transesterification reactions.

2. Experimental

Materials: Acetone, methanol, ethanol, methylene chloride, DMF, *para*-substituted phenyl acetate, *para*-substituted phenyl benzoate, methylacetate, methylbenzoate, 4,4′-bipyridine (4,4′-bpy), ammonium benzoate, $Cd(NO_3)_2 \cdot 4H_2O$, $Zn(NO_3)_2 \cdot 6H_2O$, $Cu(NO_3)_2 \cdot 5/2H_2O$, $Ni(NO_3)_2 \cdot 6H_2O$, $Co(NO_3)_2 \cdot 6H_2O$, and $Mn(NO_3)_2 \cdot H_2O$ were purchased from Aldrich and were used as received. 4-Fluorophenyl acetate and 4-nitrophenyl benzoate were obtained from Lancaster.

Instrumentation: Elemental analysis for carbon, nitrogen, and hydrogen was carried out by using an EA1108 (Carlo Erba Instrument, Italy) in the Organic Chemistry Research Center of Sogang University, Korea. IR spectra were measured on a BIO RAD FTS 135 spectrometer as KBr pellets. Product analysis for the transesterification reaction was performed on either a Hewlett–Packard 5890 II Plus gas chromatograph interfaced with Hewlett–Packard Model 5989B mass spectrometer or a Donam Systems 6200 gas chromatograph equipped with a FID detector using 30-m capillary column (Hewlett–Packard, HP-1, HP-5, and Ultra 2).

Synthesis of $[Co_2(O_2CPh)_4(4,4'\text{-bpy})_2]_n$ (**1**-*Co):* 37.0 mg (0.125 mmol) of $Co(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL water and carefully layered by 4 mL ethanol solution of 4,4′-bipyridine ligand (40.0 mg, 0.25 mmol). The yield was 48.0 mg (42.1%) for compound **1**-Co. Slow evaporation of the diffused mixture provided suitable crystals of **1**-Co for X-ray crystallography in two months. *Anal.* Calc. for $C_{48}H_{36}Co_2N_4O_8$ (914.67), **1**-Co: C, 63.03; H, 3.98; N, 6.13. Found: C, 63.25; H, 3.54; N, 5.88%. IR (KBr): $\nu(cm^{-1})$ = 3062(m), 1606(s), 1549(s), 1490(w), 1419(s), 1221(m), 1070(m), 1024(w), 857(m), 813(m), 722(s), 681(m), 630(m), 478(w). The decomposed temperature is 260 °C.

Synthesis of $[Ni(O_2CPh)_4(H_2O)_2(4,4'\text{-bpy})]_n$ (**2**-*Ni):* 36.0 mg (0.125 mmol) of $Ni(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL water and carefully layered by 4 mL solution of a mixture of acetone, methanol and ethanol (2/2/2) of 4,4′-bipyridine ligand (40.0 mg, 0.25 mmol). The yield was 18.5 mg (31.0%) for compound **2**-Ni. Slow evaporation of the diffused mixture provided suitable crystals of **2**-Ni for X-ray crystallography in a month. *Anal.* Calc. for $C_{24}H_{22}N_2NiO_6$ (479.03), **2**-Ni: C, 60.17; H, 4.64; N, 5.85. Found: C, 59.85; H, 4.48; N, 6.07%. IR (KBr): $\nu(cm^{-1})$ = 3391(br), 3065(w), 1604(s), 1540(s), 1491(w), 1392(s), 1219(m), 1174(w), 1069(m), 1045(w), 1024(w), 858(w), 815(s), 720(s), 676(s), 636(m), 439(w). The decomposed temperature is 250 °C.

Synthesis of $[Cu_2(O_2CPh)_4(4,4'\text{-bpy})]_n$ (**3**-*Cu):* 24.0 mg (0.125 mmol) of $Cu(NO_3)_2 \cdot 5/2H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL DMF and carefully layered by 4 mL methanol solution of 4,4′-bipyridine ligand (40.0 mg, 0.25 mmol). The yield was 27.0 mg (28.1%) for compound **3**-Cu. Slow evaporation of the diffused mixture provided suitable crystals of **3**-Cu for X-ray crystallography in a few days. *Anal.* Calc. for $C_{38}H_{28}Cu_2N_2O_8$ (767.72), **3**-Cu: C, 59.45; H, 3.68; N, 3.65. Found: C, 59.01; H, 3.94; N, 3.55%. IR (KBr): $\nu(cm^{-1})$ = 3446(br), 1675(w), 1627(s), 1573(s), 1403(s), 1218(m), 1070(w), 813(m), 719(s), 686(s), 631(w), 485(m).

Synthesis of $[Zn_2(O_2CPh)_2(OH)_2(4,4'\text{-bpy})_2]_n$ (**4**-*Zn) and* $[Zn_3(O_2CPh)_4(\mu\text{-}OH)_2(4,4'\text{-bpy})_2]_n$ (**5**-*Zn):* For **4**-Zn, 38.0 mg (0.125 mmol) of $Zn(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL methanol and carefully layered by 4 mL methylene chloride solution of 4,4′-bipyridine ligand (40.0 mg, 0.25 mmol). The yield was 25.0 mg (28.2%) for compound **4**-Zn. Slow evaporation of the diffused mixture provided suitable crystals of **4**-Zn for X-ray crystallography in two months. *Anal.* Calc. for $C_{34}H_{28}N_4O_6Zn_2$ (719.34), **4**-Zn: C, 56.77; H, 3.93; N, 7.79. Found: C, 56.53; H, 4.12; N, 8.07%. IR (KBr): $\nu(cm^{-1})$ = 3062(br m), 2361(m), 1632(s), 1613(s), 1492(w), 1403(br s), 1221(m), 1173(w), 1072(m), 1047(w), 1024(w), 840(m), 815(s), 717(s), 684(s), 643(m), 457(m). For **5**-Zn, 38.0 mg (0.125 mmol) of $Zn(NO_3)_2 \cdot 6H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL water and carefully layered by 4 mL acetone solution of 4,4′-bipyridine ligand (40.0 mg, 0.25 mmol). The yield was 43.0 mg (33.6%) for compound **5**-Zn. Slow evaporation of the diffused mixture provided suitable crystals of **5**-Zn for X-ray crystallography in two months. *Anal.* Calc. for $C_{48}H_{36}N_4O_{10}Zn_3$ (1024.98), **5**-Zn: C, 56.24; H, 3.55; N, 5.47. Found: C, 56.30; H, 3.42; N, 5.65%. IR (KBr): $\nu(cm^{-1})$ = 3061(br m), 2363(m), 2341(w), 1611(s), 1570(s), 1493(w), 1419(w), 1375(s), 1226(m), 1074(m), 1045(w), 815(br m), 718(s), 685(s), 641(s). The decomposed temperature of **4**-Zn is 200 °C.

Synthesis of $[Cd_2(O_2CPh)_4(4,4'\text{-bpy})_2]_n$ (**6**-*Cd):* 39.0 mg (0.125 mmol) of $Cd(NO_3)_2 \cdot 4H_2O$ and 36.0 mg (0.25 mmol) of $C_6H_5COONH_4$ were dissolved in 4 mL water and carefully layered by 4 mL methanol solution of 4,4′-bipyridine ligand (40.0 mg, 0.25 mmol). The yield was 37.0 mg (27.2%) for compound **6**-Cd. Slow evaporation of the diffused mixture provided suitable crystals of **6**-Cd for X-ray crystallography in several months. *Anal.* Calc. for $C_{50}H_{44}Cd_2N_4O_{10}$ (1085.7), **6**-Cd: C, 55.30; H, 4.09; N, 5.16. Found: C, 55.19; H, 3.92; N, 5.24%. IR (KBr): $\nu(cm^{-1})$ = 3060(m), 1598(s), 1555(s), 1410(s), 1221(m), 1071(m), 1008(m), 854(m), 809(s), 716(s), 684(s), 628(s), 496(w). The decomposed temperature is 300 °C.

Catalytic activity of compounds ***1*****–*****7****:* Catalytic reaction conditions: ester (0.05 mmol) was dissolved in methanol (1 mL), and the compounds **1**–**7** (1.0 mg, 1.09×10^{-3} mmol for **1**-Co, 1.0 mg, 2.09×10^{-3} mmol for **2**-Ni, 1.0 mg, 1.28×10^{-3} mmol for **3**-Cu, 1.0 mg, 1.39×10^{-3} mmol for **4**-Zn, 1.0 mg, 0.96×10^{-3} mmol for **5**-Zn, 1.0 mg, 0.92×10^{-3} mmol for **6**-Cd, and 1.0 mg, 2.21×10^{-3} mmol for **7**-Mn) were added, respectively, and shaken at 50 °C (450 rpm). Reaction conversion was monitored by GC/mass analysis of 20 μL aliquots withdrawn periodically from the reaction mixture. All reactions were run at least three times and the average conversion yields are presented.

X-ray crystallography: The X-ray diffraction data for all five compounds were collected on a Bruker SMART APX diffractometer equipped with a monochromater in the Mo Kα (λ = 0.71073 Å) incident beam. Each crystal was mounted on a glass fiber. The CCD data were integrated and scaled using the Bruker-SAINT software package, and the structure was solved and refined using SHEXTL V6.12 [55]. All

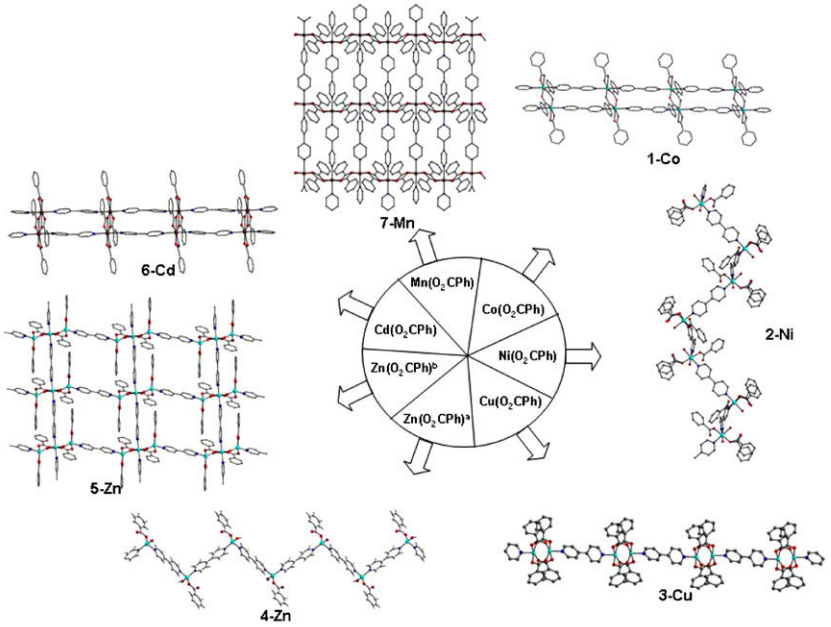
[a] The crystal structure of complex **7**-Mn $[Mn(O_2CPh)_2(4,4'\text{-bpy})]_n$ was re-determined, and all the parameters were same with the results reported by Chen et al. [56].



hydrogen atoms were placed in the calculated positions. The crystallographic data for compounds **1**–**7** are listed in Table 1.

3. Results and discussion

Synthesis and spectral characterization: To investigate structures of metal complexes containing 4,4′-bpy and benzoate coligands, six transition metal ions have been chosen: Co(II), Ni(II), Cu(II), Zn(II), Mn(II), and Cd(II) cations. The Mn(II)-benzoate complex with 4,4′-bpy was reported previously [56], but we re-measured the data for the crystal structure of the complex $[Mn(O_2CPh)_2(4,4'\text{-bpy})]_n$ (**7**-Mn) to compare their structures and the coordination modes with those of other metal complexes. We found all the parameters are same with the results reported by Chen et al. [56]. Although we used the same 4,4′-bpy and benzoate coligands, each metal cation provided the different structure, respectively. All seven compounds are shown in Scheme 1. The infrared spectra of **1**–**7** were fully consistent with their formulations. Asymmetric and symmetric C=O stretching modes of the ligated benzoate moieties were evidenced by very strong, slightly broadened bands at ~1600 and ~1400 cm^{-1} [57–59]. The absence of any bands in the area of ~1710 cm^{-1} indicates full deprotonation of all carboxylate groups in **1**–**7** [57–59], which is consistent with the results of the X-ray analysis.

*Structure description of $[Co_2(O_2CPh)_4(4,4'\text{-bpy})_2]_n$ (**1**-Co):* Asymmetric unit contains a Co atoms, two benzoate ligands, and a 4,4′-bpy ligand, and there is a crystallographic inversion center between the cobalt atoms. Symmetry operations $(-x+2,-y,-z+1)$, $(x-1,y,z-1)$, and $(x+1,y,z+1)$ produce a one-dimensional chain **1**-Co. Benzoate groups coordinate to the Co ions in two different ways: bridging mode and chelating mode. Two benzoate ligands bridge two Co ions, and each Co ion has a chelating benzoate ligand. These $Co_2(O_2CPh)_4$ units are connected by two 4,4′-bpy bridging ligands to form a ladder-type double chain (Fig. 1a). The structure of **1**-Co contains no solvent molecules. The packing diagram along *a-axis* is shown in Fig. 1b. The coordination geometry of Co ion is distorted octahedral constructed by four oxygen atoms from benzoate ligands and two nitrogen atoms from 4,4′-bpy ligands. The two pyridyl rings of 4,4′-bpy ligand are nearly coplanar by the dihedral angle of 7.0°. The Co–$O_{bridging}$ bond distances are 2.006(3) and 2.014(3) Å, typical in Co complexes containing 4,4′-bpy ligands [44,60]. These Co–O bond distances for bridging benzoate ligands are shorter than those for chelating benzoate ligands (Co–$O_{chelating}$ 2.170(3) and 2.191(3) Å). The Co–N bond distances are 2.163(3) and 2.158(3) Å (Table 2), similar to those found in the reported Co complexes [44,60]. The Co···Co distance is 4.057(2) Å, similar to that found in the reported Co complex (4.02(1) Å) [44].

*Structure description of $[Ni(O_2CPh)_2(H_2O)_2(4,4'\text{-bpy})]_n$ (**2**-Ni):* Asymmetric unit contains a Ni atom, two benzoate, two water, and a 4,4′-bpy ligand, and symmetry operations $(-y+2, -x+2, -z+1/2)$ and $(y,x,-z)$ produces a helical structure **2**-Ni (Fig. 2a). One of benzoate ligands is disordered with two sets of benzoate. The similar helical structure $[Ni(O_2CPh)_2(CH_3O)_2(4,4'\text{-bpy})]_n$ **2′** has been reported by Biradha et al. [61]. The crystals of **2**-Ni for X-ray analysis were obtained with the similar cell parameters to those of **2′**. Both compounds **2**-Ni and **2′** have a tetragonal cell with the $P4_32_12$ space group (Table 1). The difference between two compounds is the coordination environment around the Ni ion. The Ni ion in **2**-Ni is N2O4 hexa-coordinated from two benzoate oxygen atoms, two water oxygen atoms and two nitrogen atoms to form a distorted octahedral geometry. In **2′**, the geometry of a Ni ion is also distorted octahedral, but methanol molecules coordinate to the Ni ion instead of water molecules in **2**-Ni. The $Ni(O_2CPh)_2(H_2O)_2$ units in **2**-Ni are connected by 4,4′-bpy to form a helical compound. The right-handed and the left-handed helices are packed alternatively to form a racemic mixture (Fig. 2b) while the crystal packing of **2′** induced spontaneous resolution of the helices. Cavities between helices (1912 Å^3 in volume, 31% of unit cell volume) are larger than those of compound **2′**, and there is no guest molecule in **2**-Ni. Two pyridyl rings are tilted by 17.2°

Scheme 1.

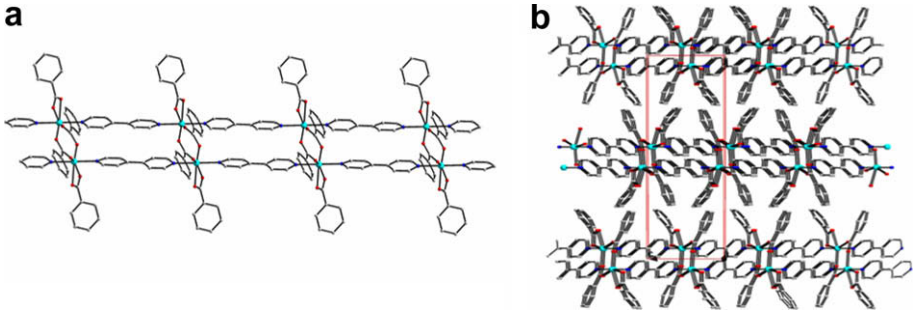


Fig. 1. (a) Structure of ladder-type $[Co_2(O_2CPh)_4(4,4'\text{-bpy})_2]_n$ **1**-Co. All hydrogen atoms were omitted for clarity. (b) Packing diagram of **1**-Co.

and 20.2°. The Ni–$O_{benzoate}$ bond distances are 2.031(5) and 2.042(5) Å, and the Ni–O_{water} bond distances are 2.085(4) and 2.089(4) Å. The Ni–N bond distances are 2.077(5) and 2.097(5) Å (Table 2).

*Structure description of $[Cu_2(O_2CPh)_4(4,4'\text{-bpy})]_n$ (**3**-Cu):* The crystal structure of **3**-Cu is shown in Fig. 3a. The paddle-wheel type units are bridged by 4,4′-bpy ligand to form a one-dimensional polymeric compound **3**-Cu. View along the crystallographic *b-axis* of **3**-Cu is shown in Fig. 3b. The octahedral coordination around the Cu ion consists of four oxygen atoms from benzoate ligands (1.947(4)–2.004(4) Å), a nitrogen atom of the 4,4′-bpy ligand (Cu–N 2.147(4) and 2.150(4) Å) and the second copper atom (Cu···Cu 2.642(1) Å) (Table 2). The Cu–N bond distances are similar to those found in the reported Cu(II) complexes, $[Cu_2(Hsal)_4(4,\text{-bpy})]_n$ (H_2sal = salicylic acid) [62], $[Cu_2(O_2CPh)_4(pyz)]_n$ (pyz = pyrazine) [63], $[Cu_2(OAc)_4(bpe)]\cdot 2H_2O$ (bpe = 1,2-bis(4-pyridyl)ethane) [64]. The Cu···Cu distance in the paddle-wheel unit is comparable with the reported Cu complexes (2.66 Å [62], 2.5899(7) Å [63], 2.6424(7) Å [64]). The Cu–O bond distances are usually observed in the similar Cu complexes [62–64]. The Cu′–Cu–N bond angle (171.3(1)°) shows a nearly linear chain structure. The two pyridyl rings of the 4,4′-bpy ligand are twisted by the dihedral angle of 28.2°. The coordination mode of benzoate shows only bridging type as shown in Fig. 2. It is worthwhile to mention that while $[Cu(maa)_2(bpp)]$ (Hmma = 2-methylcrylic acid and bpp = 1,3-bis(4-pyridyl)propane) system [65] with 1:1 ratio of bpp:$[Cu_2(maa)_4\cdot 2H_2O]$ contains a zigzag chain containing a dinuclear paddle-wheel type structure and with 2:1 ratio do a triple-stranded molecular braid that contains a mononuclear node, our system under 2:1 ratio of 4,4′-bpy:Cu-benzoate generate a 1-D polymer with a dinuclear paddle-wheel type structure. In addition, Long and co-workers showed the pH effects on the structures of Cu complexes containing benzoate and 4,4′-bpy ligands, ranging from a 0-D mononuclear complex to a 2-D network [54]. Therefore, these results suggest that the compound **3**-Cu could be converted to unknown compounds by further change of the reaction conditions such as pH, solvent, and ligand-to-metal ratio.

*Structure description of $[Zn_2(O_2CPh)_2(OH)_2(4,4'\text{-bpy})_2]_n$ (**4**-Zn) and $[Zn_3(O_2CPh)_4(\mu\text{-}OH)_2(4,4'\text{-bpy})_2]_n$ (**5**-Zn):* The reactions of Zn-benzoate with 4,4′-bpy ligands produced two different structures in different solvent systems. The methylene chloride solution of zinc-benzoate can react with the methanol solution of 4,4′-bpy ligand to form a one-dimensional zigzag chain **4**-Zn. The aqua solution of zinc-benzoate can react with the acetone solution of 4,4′-bpy ligand to form two-dimensional compound **5**-Zn. For compound **4**-Zn, asymmetric unit contains two crystallographi-

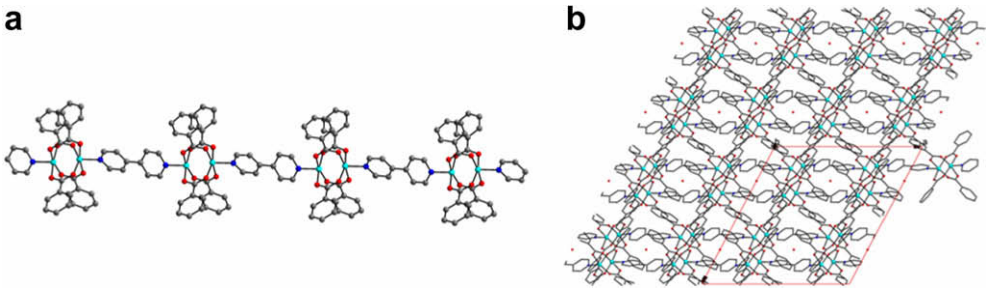

Fig. 3. (a) Structure of $[Cu_2(O_2CPh)_4(4,4'\text{-bpy})]_n$ **3**-Cu containing paddle-wheel type dinuclear Cu units. All hydrogen atoms were omitted for clarity. (b) View along the crystallographic *b*-axis of **3**-Cu.

cally independent Zn atoms, two benzoate ligands, two hydroxyls, and two 4,4′-bpy ligands, and there are inversion centers in the middle of 4,4′-bpy ligands. Symmetry operations $(-x+2,-y+1,-z+1)$ and $(-x+1,-y,-z+2)$ produce a zigzag chain (Fig. 4a). The individual chains are cross each other to form infinite channels as shown in Fig. 4b. The Zn atom is four-coordinated by two nitrogen atoms from 4,4′-bpy ligands and two oxygen atoms from one benzoate and one hydroxyl ligand to form a distorted tetrahedral geometry. One of 4,4′-bpy bridging ligands is nearly planar with the dihedral angle of 3.8°, and others are exactly planar. The Zn–N bond distances range from 2.037(5) to 2.059(5) Å, similar to those found in previously reported Zn compounds $[Zn(OAc)_2(\mu\text{-bpe})]\cdot 2H_2O$ [66], $\{[Zn_2(4,4'\text{-bpy})_2(4\text{-aba})_4](H_2O)_5\}_n$ (4-aba = 4-aminobenzoic acid) [67], and $[\{(F_3CCO_2)(\mu\text{-}O_2CCH_3)Zn\}_2(\mu\text{-bpe})_2]_n$ [47]. The Zn–$O_{benzoate}$ bond distances range from 1.924(5) to 1.951(5) Å (Table 2), similar to

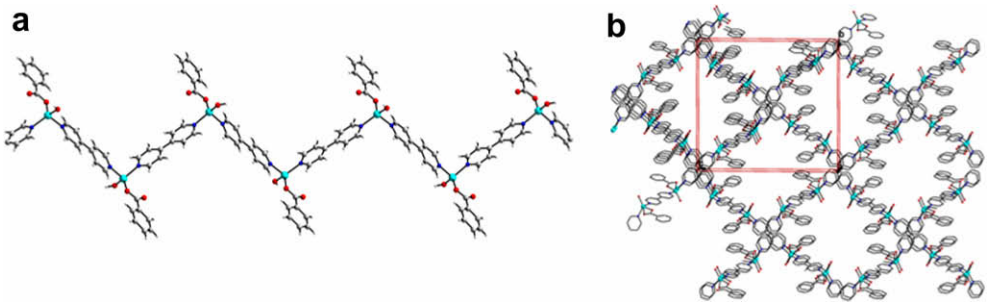

Fig. 4. (a) Structure of $[Zn_2(O_2CPh)_2(OH)_2(4,4'\text{-bpy})_2]_n$ **4**-Zn. All hydrogen atoms were omitted for clarity. (b) View along the crystallographic *a*-axis of **4**-Zn.

those found in the reported Zn compounds [28–30]. The Zn–$O_{hydroxyl}$ bond distances are 2.051(7) and 2.060(1) Å. The Zn···Zn distances in **4**-Zn are 11.190(13) and 11.208(6) Å.

For compound **5**-Zn, asymmetric unit contains one and half Zn atoms, two benzoate ligands, a hydroxyl, a 4,4′-bpy ligand, and a water solvent molecule, and there is an inversion center on central Zn atom. Symmetry operations $(-x+1,-y+1,-z+2)$, $(-x+1,-y,-z+2)$, and $(-x+2,-y+1,-z+1)$ produce a two-dimensional sheet **5**-Zn. The $Zn_3(O_2CPh)_4(\mu\text{-}OH)_2$ units are connected by bridging 4,4′-bpy ligands to form a two-dimensional sheet (Fig. 5a). Out of three Zn centers the central Zn atom is N2O4 coordinated from two bridging benzoate ligands, two bridging hydroxyl ligands, and two bridging 4,4′-bpy ligands to form a distorted octahedral geometry. The other two Zn centers are symmetric to each other, and each is NO3 coordinated from a bridging benzoate, an asymmetric chelating benzoate, a μ-hydroxyl, and a bridging 4,4′-bpy ligand to form distorted trigonal-bipyramidal geometry. View along the crystallographic *b-axis* of **5**-Zn is shown in Fig. 5b. The topological feature of compound **5**-Zn is most unusual because it features a previously unobserved trinuclear motif that is catenated with adjacent ones to form a 2-D supramolecular structure. The Zn–$O_{bridging}$ bond distances are 1.992(3) and 2.183(3) Å, similar to those found in the related Zn(II)-4,4′-bpy coordination polymer, $[Zn_4O(ip)_3(4,4'\text{-bpy})]$ (ip = isophthalate) [68], and the asymmetric Zn–$O_{chelating}$ bond distances are 1.987(4) and 2.62(1) Å. The Zn–$O_{hydroxyl}$ bond distances are 1.922(3) and 2.081(3) Å which can be comparable with those found in a coordination network containing $Zn_3(OH)_3$ units, $[Zn_3(OH)_3(bpp)_3[NO_3]_3\cdot 8.67H_2O$ [69] and our previous 2-D compound containing hexanuclear $Zn_6(OH)_8$ units, $[Zn_6(OH)_8(bpp)_4](OTf)_4\cdot 3H_2O$ (bpp = 1,3-bis(4-pyridyl)propane) [70]. The Zn–N bond distances are 2.054(4) and 2.140(4) Å (Table 2), similar to those found in previously reported compounds $[Zn(OAc)_2(\mu\text{-bpe})]\cdot 2H_2O$ [66], $\{[Zn_2(4,4'\text{-bpy})_2(4\text{-aba})_4](H_2O)_5\}_n$ [67], and $[\{(F_3CCO_2)(\mu\text{-}O_2CCH_3)Zn\}_2(\mu\text{-bpe})_2]_n$ [47]. Two pyridyl rings of the 4,4′-bpy ligand are exactly coplanar with an inversion center in the middle C–C bond between two rings. The Zn···Zn distance in **5**-Zn is 3.326(7) Å, shorter than those found in the related Zn compound containing trinuclear $Zn_3(O_2CPh)_6$ units (3.370(2) and 3.347(2) Å) [53]. It is interesting to note that despite the prevalence of coordination polymers containing 4,4′-bpy and acetate ligands, the structure of the complexes described here has not been previously reported.

*Structure description of $[Cd_2(O_2CPh)_4(4,4'\text{-bpy})_2]_n$ (**6**-Cd):* Asymmetric unit contains a Cd atom, two benzoate ligands, a 4,4′-bpy ligand, and a methanol solvent molecule, and symmetry operations $(-x+2,-y+1,-z+1)$, $(x-1,y-1,z)$, and $(x+1,y+1,z)$ produce an one-dimensional compound. The benzoate-bridged Cd_2 units are connected to form a ladder-type chain **6**-Cd (Fig. 6a). The packing diagram along *a-axis* is shown in Fig. 6b. The structure of **6**-Cd is very similar to that of **1**-Co showing ladder-type double chains. While two benzoate ligands in **1**-Co connect Co atoms with a bridging coordination mode, the benzoate ligands in **6**-Cd connect two Cd atoms with a chelating/bridging bidentate coordination mode in which a benzoate ligand chelates to one Cd atom and simultaneously bridges to the other Cd atom. Each Co atom in **1**-Co or each Cd in **6**-Cd has another chelating benzoate ligand, respectively. The coordination geometry of Co atom in **1**-Co is distorted octahedral, and that of Cd in **6**-Cd can be described as a distorted pentagonal pyramid with five oxygen atoms of benzoate ligands and two nitrogen atoms of 4,4′-bpy ligands (N2O5 coordinated). The Cd–$O_{chelating/bridging}$ distances are 2.328(3) and 2.577(4) Å which can be comparable with those in the related Cd/4,4′-bpy compounds, [Cd(tp)(4,4′-bpy)] (2.287(2)–2.653(2) Å, tp = terphthalate) [71], $[Cd(4,4'\text{-bpy})(oba)]_n$ (2.383(3)–2.749(3) Å, H_2oba = 4,4′-oxybis(benzoic acid)) [72], and $[Cd_6(MeCO_2)(4,4'\text{-bpy})_2(H_2bna)_4]\cdot 3.5H_2O$ (2.262(2)–2.550(3) Å, H_2bna = 2,2′-dihydroxyl-[1]-binaphthalene-3,3′-dicarboxylate) [73]. The Cd–

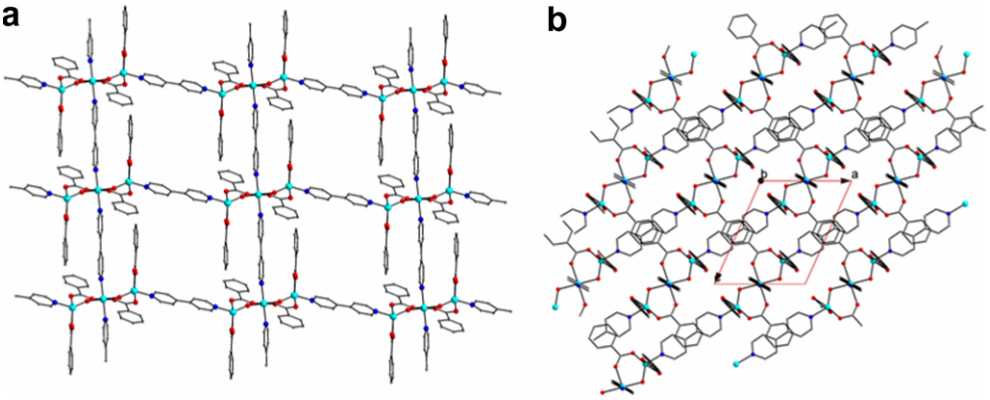

Fig. 5. (a) Structure of $[Zn_3(O_2CPh)_4(\mu\text{-}OH)_2(4,4'\text{-bpy})_2]_n$ **5**-Zn. All hydrogen atoms were omitted for clarity. (b) View along the crystallographic *b*-axis of **5**-Zn.

$O_{chelating}$ distances of 2.362(4) and 2.432(3) Å are similar to those found in Cd related compounds (2.329(3)–2.432(3) Å) [72,73] but different from those found in Cd(tp)(4,4′-bpy) in which two oxygen atoms asymmetrically coordinate to Cd atoms (2.263(2) and 2.608(2) Å) [71]. The Cd–N bond distances are 2.310(4) and 2.323(3) Å (Table 2), similar to those found in the related Cd/4,4′-bpy compounds [71–73]. The Cd···Cd distance is 3.925(10) Å which is also comparable with those found in the related Cd/4,4′-bpy compounds (3.908(1) Å [71], 3.872(2) Å [72], and 3.873(1)–4.514(1) Å [73]), and is shorter than that of Co···Co in **1**-Co since benzoate ligands connect Cd atoms with chelating/bridging bidentate coordination mode in compound **6**-Cd. The two pyridyl rings are twisted by 27.5°, in contrast to those in Co complex in which they are nearly coplanar.

3.1. Coordination geometry around each metal

Six metal cations have been employed to investigate how the change of metal cations influences on construction of metal-benzoate complexes with 4,4′-bpy ligand. Each metal cation provides different structure, respectively (Scheme 1), and so it is clear that selection of appropriate metal ions plays a key role in controlling the structures of the complexes.

The coordination geometries of metal atoms in metal-benzoate complexes are shown in Scheme 2. **1**-Co and **6**-Cd show similar double chain structures, but the coordination around each metal ion is different. The coordination geometry of Co atom in **1** is distorted octahedral constructed by four oxygen atoms from benzoate ligands and two nitrogen atoms from 4,4′-bpy ligands, and that of Cd in **6** is a distorted pentagonal pyramid with five oxygen atoms of benzoate ligands and two nitrogen atoms of 4,4′-bpy ligands. The Ni atom in the helical structure of **2**-Ni is N2O4 hexa-coordinated from two benzoate oxygen atoms, two water oxygen atoms and two nitrogen atoms to form a distorted octahedral geometry. The coordination of Cu atom in **3**-Cu is octahedral with four oxygen atoms in the equatorial plane completed by nitrogen atom of 4,4′-bpy ligand and by the second copper atom. In Zn-benzoate complexes, different solvent systems provide different crystal structures (**4**-Zn and **5**-Zn). The coordination around Zn atom in **4**-Zn is distorted tetrahedral constructed by two nitrogen atoms from 4,4′-bpy ligands and two oxygen atoms from one benzoate and one hydroxyl ligand. In compound **5**-Zn, the central Zn atom has a distorted octahedral geometry formed by two bridging benzoate ligands, two bridging hydroxyl ligands, and two bridging 4,4′-bpy ligands, and the other two symmetric Zn atoms have a distorted tetrahedral geometry formed by one bridging benzoate ligand, one dangling benzoate ligand, and one bridging 4,4′-bpy ligand. The Mn atom in the two-dimensional structure of **7**-Mn is N_2O_4 coordinated by two nitrogen atom from 4,4′-bpy ligands and four oxygen atoms from two benzoate ligands to form a slightly distorted octahedral geometry [56]. These results show the systematic change in the coordination geometries of the metal ions: from a tetrahedral (four-coordinate) **4**-Zn ion, a trigonal-bipyramidal (five-coordinate) **5**-Zn ion, an octahedral (six-coordinate) **1**-Co, **2**-Ni, and **7**-Mn ions to a pentagonal-bipyramidal (seven-coordinate) **6**-Cd ion. Since different structure provides different coordination geometry of each metal ion, it is clear that selection of appropriate metal ions can control the coordination geometry of each metal ion to form different crystal structures.

Scheme 2.

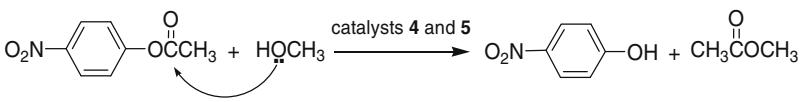
Scheme 3.

3.2. Carboxylate coordination modes of each polymer

Benzoate groups can coordinate to the metal atoms in four different ways: monodentate (a), chelating (b), bridging (c), and chelating/bridging (d) modes (Scheme 3) [74–76]. In **1**-Co and **6**-Cd, 4,4′-bpy bridged single chains are connected by benzoate ligands with the bridging mode for **1**-Co and with the chelating/bridging mode for **6**-Cd to form ladder-type double chains, and each metal ion has a chelating benzoate ligand. In the helical structure **2**-Ni, benzoates coordinate to Ni atoms as monodentate ligands. In **3**-Cu, benzoate groups bridge two Cu atoms to form paddle-wheel type dinuclear units, and these units are connected by 4,4′-bpy ligands to form an one-dimensional compound. For Zn-benzoate complexes with 4,4′-bpy ligands, two different structures are obtained in different solvent systems. In zigzag chains **4**-Zn, benzoate groups coordinate Zn atoms as monodentate ligands while in the $Zn_3(O_2CPh)_4(\mu\text{-}OH)_2$ units of **5**-Zn, benzoate and hydroxyl groups bridge Zn atoms and terminal two Zn atoms are also coordinated by monodentate benzoate ligands. In **7**-Mn, benzoate ligands bridge Mn atoms to form double zigzag one-dimensional chains, and 4,4′-bpy ligands connect those double zigzag chains to form two-dimensional sheets.

3.3. Solvent effect

The reactions of Zn-benzoate with 4,4′-bpy ligands produced two different structures in different solvent systems, and Cu-benzoate may also show solvent effect based on this work and the previously reported results [54], while the reactions of other metal benzoates (for Co, Ni, Cd, or Mn ions) with 4,4′-bpy ligands did not show solvent effects. The methylene chloride solution of zinc-benzoate can react with the methanol solution of 4,4′-bpy ligand to form an one-dimensional zigzag chain **4**-Zn. The aqua solution of zinc-benzoate can react with the acetone solution of 4,4′-bpy ligand to form two-dimensional compound **5**-Zn. This phenomenon shows the similar result to that found in the our previous Zn-benzoate complexes with bpe ligands (bpe = 1,4-bis(4-pyridyl)ethane) in which the solvent and the ligand-to-metal ratio are simultaneously playing a controlling role over the structure [53].



3.4. Conformations of 4,4′-bpy in these seven compounds

Conformations of 4,4′-bpy in these seven compounds are very different depending on crystal structures of different metal ions. Dihedral angles between the two pyridyl rings of 4,4′-bpy are listed in Table 3. The compound **1**-Co and **6**-Cd shows similar structures with different coordination modes of carboxylate ligands, and the dihedral angles between two planes of pyridyl rings are 7.0° and 27.5°, respectively. Two pyridyl rings are nearly coplanar in **1**-Co while those are twisted in **6**-Cd since the chelating/bridging mode of benzoates in **6** may make two pyridyl rings more tilted than those in **1**-Co having the bridging mode. In the helical structure of **2**-Ni, two pyridyl rings are tilted by 17.5° and 20.3°. The bridging 4,4′-bpy ligands in **4**-Zn and **5**-Zn are either nearly planar or exact planar to form a zigzag chain and a two-dimensional structure, respectively. In one-dimensional structure for Cu-benzoate, **3**-Cu containing paddle-wheel type dinuclear units, two pyridyl rings are tilted by 28.2°. In the two-dimensional network of **7**-Mn, two pyridyl rings are much tilted by 39.0°.

3.5. Catalytic transesterification reactions by the compounds **1**–**7**

While an enormous number of the polymeric coordination compounds have been developed and reported over the past 10 years, their application as homogeneous or heterogeneous catalysts is relatively very scarce [18–27]. Therefore, the application of the polymeric compounds as catalysts for various organic reactions is important and meaningful. We have previously reported that the Cu-containing polymeric compounds were found to be a good heterogeneous catalyst for epoxide ring-opening reactions [18,20] that offers the practical advantages of simplifying the separation and isolation of products, and of the potential for catalyst recycling [18–27]. Moreover, we have recently reported that various Zn-containing coordination polymers could carry out the homogeneous and heterogeneous catalytic transesterifications of a range of esters with methanol under the mild conditions [77,78]. While these catalyst systems constitute a promising class of catalysts that appears to be an efficient, mild, and sometimes easily-recyclable method for the alcoholysis of esters and the epoxide ring opening, there is still more demand to develop new type of catalysts that show a high efficiency. Based on the previous results, therefore, we began to examine the reactivity of the Cu-containing polymeric compound **3**-Cu as potential catalysts for the ring opening of epoxides under mild conditions [18,20]. Unfortunately, the reaction was proceeded with only a few percents in several days when a mixture of **3**-Cu and epoxide in methanol was shaken at room temperature. The rest compounds also showed the similar results.

Next, we have tested the catalytic activity of those compounds **1**–**7** for transesterification of phenyl acetate, since we have recently observed that Zn-containing coordination polymers could perform the catalytic transesterification of a variety of esters [77,78]. First of all, the zinc-containing polymeric compounds **4**-Zn and **5**-Zn have been employed as catalysts for transesterification reaction in methanol. The ester, *p*-nitrophenyl acetate, was initially used as a substrate (Eq. (1)):

(1)

Table 3
The dihedral angles (°) between two pyridyl rings of 4,4′-bpy in compounds **1**–**7**.

Compounds	Dihedral angles (°)
1-Co	7.0
2-Ni	17.5, 20.3 (helix)
3-Cu	28.2
4-Zn	3.8, 0.0 (coplanar)
5-Zn	0.0 (coplanar)
6-Cd	27.5
7-Mn	39.0

The polymeric compounds **4**-Zn and **5**-Zn were somewhat soluble in methanol, resulting in a homogeneous condition. Treatment of 4-nitrophenyl acetate and methanol in the presence of **4**-Zn and **5**-Zn at 50 °C produced methyl acetate quantitatively within 0.29 and 0.21 days, respectively, under the neutral conditions (see entry 1 in Table 4). Little transesterification occurred without **4**-Zn and **5**-Zn in the same time period. These efficient reactivities are one of best among the catalytic systems reported previously in Zn-containing coordination and polymeric compounds, to our best knowledge [77–84]. These promising results led us to examine further the transesterification of other esters including *p*-substituted phenyl acetates and benzoates by **4**-Zn and **5**-Zn. The results are also shown in Table 4. The substrates *p*-nitrophenyl acetate and benzoate with the electron-withdrawing substituent at the *para*-position have undergone faster transesterification (entries 1 and 5), while the esters *p*-methylphenyl acetate and benzoate with the electron-donating one such as a methyl group have shown slow reaction (entries 4 and 8). Furthermore, vinyl acetate, which is often used as a precursor for synthesis of various esters [85–87], was converted effectively to the product methyl acetate within 0.5 and 0.5 days, respectively, by **4**-Zn and **5**-Zn. These results suggest that the compounds **4**-Zn and **5**-Zn could be efficient catalysts for ester synthesis by transesterification.

As Zn-containing polymers have shown a good catalytic activity, Cd-containing polymer **6**-Cd, positioned in the same group in the periodic table, was next tested for the transesterification. Surprisingly, the catalyst **6**-Cd catalyzed the conversion of 4-nitrophenyl acetate to the products within 0.62 day. This result is interesting because it is well known that the second period transition metals are much less labile for the substitution reaction [88]. More importantly, this is the first example that a Cd-containing coordination polymer catalyzed the transesterification of esters, to our knowledge. Therefore, this result offers the opportunity to use many Cd-containing polymeric compounds reported to date as a potential catalyst for the transesterification reactions. The catalyst **6**-Cd also catalyzed the transesterification of a variety of substrates including 4-substituted phenyl acetates and 4-substituted benzoates, and its reactivity is comparable to **4**-Zn and **5**-Zn, as shown in Table 4.

After this test, the rest polymeric compounds, **1**-Co, **2**-Ni, **3**-Cu, and **7**-Mn, containing redox-active metals (Co, Ni, Cu, and Mn) were also tested for transesterification reactions of *p*-nitrophenyl acetate. Unexpectedly, **1**-Co, **3**-Cu, and **7**-Mn have shown efficient catalytic reactivities for the transesterification reactions, while **2**-Ni has displayed a very slow conversion (see Table 4). This result suggest that the polymeric compounds **1**-Co, **3**-Cu, and **7**-Mn, well known as redox-active catalysts [89,90], could be employed as a solvolytic catalyst. To our knowledge, this is the first example that redox-active metal-containing coordination polymers catalyzed the transesterification of esters. This result also offers the opportunity to use many redox-active metal-containing polymeric compounds reported to date as a potential catalyst for the transesterification reactions. On the other hand, it deserves to mention the fact that Cu-containing polymeric compound, **3**-Cu, could catalyze transesterification reactions, because we previously reported that Cu-containing polymeric compounds did not catalyze transesterification reactions but do catalyze the epoxide ring-opening reaction [18,20], while our previous Zn-containing polymer-supported catalysts carried out the transesterification reactions efficiently but do not catalyze the epoxide ring-opening reaction [79–84,91]. Therefore, we concluded that the nature of metals plays an important role to perform the specific reactions, for example, transesterification with Zn [79–84,91] versus epoxide ring opening with Fe, Ru, and Cu [18,20,92,93]. However, this observation that **3**-Cu used in this study did catalyze the transesterification reactions suggests that we need more data to have a general conclusion.

These positive results with **1**-Co, **3**-Cu, and **7**-Mn led us to investigate further the transesterification of various *p*-substituted phenyl acetates and benzoates. As shown in Table 4, the substrates with the electron-withdrawing substituents have undergone faster transesterification reactions (entries 1 and 5), while those with the electron-donating ones have shown slow reactions (entries 4 and 8). In addition, *p*-nitrophenyl acetate and *p*-nitrophenyl benzoate, known to be problematic substrates for the transesterification reaction due to undesirable side reactions such as isomerization or polymerization [94], were also converted quantitatively to the corresponding products. Vinyl acetate was used as an acylating agent and, expectedly, converted efficiently to the product methyl acetate within 0.06–1.5 day by **1**-Co, **2**-Ni, **3**-Cu, and **7**-Mn (entry 9), suggesting that these catalytic systems can be useful for preparing various esters by transesterification.

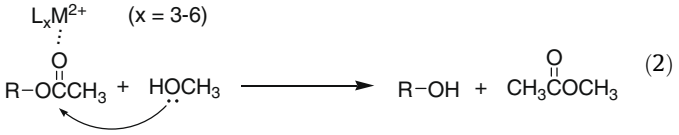


Table 4
Transesterification of esters by methanol in the presence of compounds **1**–**7** at 50 °C.[a]

Entry	Substrate	**1**-Co (time/days)[b]	**2**-Ni (time/days)[b]	**3**-Cu (time/days)[b]	**4**-Zn (time/days)[b]	**5**-Zn (time/days)[b]	**6**-Cd (time/days)[b]	**7**-Mn (time/days)[b]
1	4-nitrophenyl acetate	1	0.71	1.35	0.29	0.21	0.62	0.04

9	vinyl acetate	1.5	1	1	0.5	0.5	0.5	0.06

[a] All esters were completely converted to the corresponding products, methyl acetate and methyl benzoate. *Reaction conditions:* esters, 0.05 mmol; catalyst, 1.09×10^{-3} mmol for **1**-Co, 2.09×10^{-3} mmol for **2**-Ni, 1.28×10^{-3} mmol for **3**-Cu, 1.39×10^{-3} mmol for **4**-Zn, 0.96×10^{-3} mmol for **5**-Zn, 0.92×10^{-3} mmol for **6**-Cd, and 2.21×10^{-3} mmol for **7**-Mn; solvent, methanol (1 mL). See Section 2 for the detailed reaction conditions.
[b] Time necessary for the complete conversion of substrate to product.
[c] The solvent was a mixture of CH_3OH/CH_2Cl_2 (1/1) because of low solubility of substrate in CH_3OH.

The reactivities of the compounds used in this study are in the order of **5**-Zn > **4**-Zn > **6**-Cd > **7**-Mn ~ **3**-Cu > **1**-Co > **2**-Ni with the consideration of the concentration of each complex (see Section 2), indicating that the non-redox metal-containing compounds, **5**-Zn, **4**-Zn, and **6**-Cd, show better activity than the redox-active metal-containing compounds, **7**-Mn, **3**-Cu, **1**-Co, and **2**-Ni. Based on these results, it is possible to tune the catalytic activities by changing from Zn to those metals such as Cd, a kinetically inert metal, and Cu, Mn, and Co, the redox-active metals.

Though we do not know, at this moment, about the exact reactive species and the reaction mechanism for the transesterification reaction by the catalysts, it has been proposed that the mechanism of metal ion catalyzed transesterification probably involves electrophilic activation of the carbon center of the carbonyl moiety by binding of the metal to the carbonyl oxygen [95–99]. Therefore, Lewis acidity of the metal center may be important in catalytic transesterification. Based on this idea, a possible transesterification mechanism in this catalyst system can be proposed [78]. The substrate phenyl acetate substitutes a labile ligand, maybe benzoate, to give the adduct $L_xM^{2+}\cdots O{=}CR_1(OR_2)R$ (L is 4,4′-bpy or benzoate; x = 3 (**4**-Zn), 4 (**3**-Cu), 5 (**1**-Co, **2**-Ni, **5**-Zn, and **7**-Mn), and 6 (**6**-Cd)) (Eq. (2)). Then, the nucleophile methanol would attack the carbon atom of carbonyl moiety of the adduct to produce the product methyl acetate. Detailed mechanistic studies are currently under investigation:

(2)

4. Conclusions

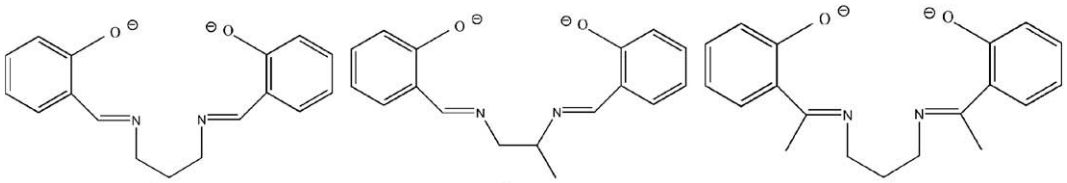
We have presented a systematic investigation on the coordination polymers assembled from metal benzoates and 4,4′-bpy. Their structures show various coordination modes depending on metal ions: from a tetrahedral (four-coordinate) **4**-Zn ion, a trigonal-bipyramidal (five-coordinate) **5**-Zn ion, an octahedral (six-coordinate) **1**-Co, **2**-Ni, and **7**-Mn ions, a pentagonal-bipyramidal (seven-coordinate) **6**-Cd ion. **1**-Co and **6**-Cd show ladder-type double chains, **2**-Ni does a helical structure, **3**-Cu does a one-dimensional chain containing paddle-wheel units, **4**-Zn does a zigzag chain, **5**-Zn and **7**-Mn do a two-dimensional sheet. Since different structures provide different coordination geometry of each metal ion, it is clear that selection of appropriate metal ions can control the coordination geometry of each metal ion to form different crystal structures.

We have also shown that the compounds **1**–**7** catalyzed the transesterification of a variety of esters. Importantly, the transesterification reactivity shown by the catalysts **4**-Zn and **5**-Zn are very efficient and one of the best among the catalytic efficiencies reported previously with Zn-containing coordination and polymeric compounds. In addition, the catalyst **6**-Cd containing Cd ion, well known as an inert metal ion for the ligand substitution, also catalyzed efficiently the transesterification of a variety of esters, and its reactivity is comparable to **4**-Zn and **5**-Zn. Moreover, the redox-active metal-containing polymers, **1**-Co, **3**-Cu, and **7**-Mn, have shown efficient catalytic reactivities for the transesterification reactions, while **2**-Ni has displayed a very slow conversion. This result suggests that the polymeric compounds **1**-Co, **3**-Cu, and **7**-Mn, well known as redox-active catalysts, could be employed as a solvolytic catalyst. To our knowledge, this is the first example that redox-active metal-containing coordination polymers catalyzed the transesterification of esters. This result also offers the opportunity to use many redox-active metal-containing polymeric compounds reported to date as a potential catalyst for the transesterification reactions.

The reactivities of the compounds used in this study are in the order of **5**-Zn > **4**-Zn > **6**-Cd > **7**-Mn ~ **3**-Cu > **1**-Co > **2**-Ni, indicating that the non-redox metal-containing compounds, **5**-Zn, **4**-Zn, and **6**-Cd, show better activity than the redox-active metal-containing compounds, **7**-Mn, **3**-Cu, **1**-Co, and **2**-Ni. These results suggest that it is possible to tune the catalytic activities by changing from Zn to those metals such as Cd, a kinetically inert metal, and Cu, Mn, and Co, the redox-active metals.

Supplementary data

CCDC 695227–695232 contain the supplementary crystallographic data for **1**-Co, **2**-Ni, **3**-Cu, **4**-Zn, **5**-Zn, and **6**-Cd. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.



Acknowledgements

Financial support from Korea Ministry Environment "ET – Human Resource Development Project", the Korea Research Foundation (2007-314-C00159), the Korean Science and Engineering Foundation (R01-2008-000-20704-0), The SEOUL R&BD Program, and the SRC program of the Korea Science and Engineering Foundation (KOSEF) through the Center for Intelligent Nano-Bio Materials at Ewha Womans University (Grant R11-2005-008-00000-0) is gratefully acknowledged.

Scheme 1.

To the resulting solution, NaOCN (0.130 g, 2.00 mmol) dissolved in a minimum amount of water was added, stirring continued for 3 h, to complete the aerial oxidation of Mn^{II}. The filtered solution was kept in a refrigerator (5 °C) for 1 week when dark green crystals deposited. Yield: 0.234 g (0.62 mmol, 62%). *Anal. Calc.* for $C_{36}H_{32}N_6O_6Mn_2$: C, 57.1; H, 4.27; N, 11.14. Found: C, 57.20; H, 4.23; N, 11.23%. Characteristic IR absorptions (cm^{-1}): ν_a(NCO) 2160, ν_s(NCO) 1313, δ(NCO) 615, $\nu_{schiff\ base}$(C=N) 1620. Electronic absorption bands ($\bar{\nu}_{max}/10^3\ cm^{-1}$, $\varepsilon_{max}/100\ cm^{-1}\ M^{-1}$): 17.11, 3.47(sh); 26.34, 66.0; 32.94, 108(sh); 35.65, 180.

2.2.2. [Mn(salmen)N_3]$_2$ (**2**)

In a beaker open to the atmosphere, salicylaldehyde (0.244 g, 1.00 mmol) and 1,2-diaminopropane (0.074 g, 1.0 mmol) were stirred in 40 mL of methanol. $Mn(CH_3COO)_2 \cdot 4H_2O$ (0.245 g, 1.00 mmol) was added, and stirring was continued for about 1 h. To the resulting solution, NaN_3 (0.130 g, 2.00 mmol) dissolved in a minimum amount of water was added and stirring continued for 3 h to complete the aerial oxidation of Mn^{II}. The resulting microcrystalline precipitate was filtered off and dried. Yield: 0.306 g (0.81 mmol, 81%). It was recrystallized by slow evaporation of an acetonitrile solution at room temperature yielding dark-brown X-ray quality crystals. *Anal. Calc.* for $C_{36}H_{32}N_{10}O_4Mn_2$: C, 54.12; H, 4.27; N, 18.57. Found: C, 54.19; H, 4.32; N, 18.98%. Characteristic IR absorptions (cm^{-1}): $\nu_a(N_3)$ 2035, $\nu_s(N_3)$ 1309, $\delta(N_3)$ 599, $\nu_{schiff\ base}$(C=N) 1612. Electronic absorption bands ($\bar{\nu}_{max}/10^3\ cm^{-1}$, $\varepsilon_{max}/100\ cm^{-1}\ M^{-1}$): 20.20, 12.1(sh); 24.44, 45.7; 28.35, 61.5(sh); 32.16, 124, 35.87,192.

2.2.3. [Mn(acphpn)N_3]$_2$ (**3**)

In a beaker open to the atmosphere, $Mn(CH_3COO)_2 \cdot 4H_2O$ (0.245 g, 1.00 mmol) and NaN_3 (0.130 g, 2.00 g) were dissolved in 30 mL methanol and filtered. 2-Hydroxyacetophenone (0.272 g, 2.00 mmol) and 1,3-diaminopropane (0.071 g, 1.0 mmol) were dissolved in 30 mL methanol and filtered. The two solutions were mixed and stirred for 2 h to complete the aerial oxidation of Mn^{II}. The filtered solution was kept at room temperature for three days to obtain dark green crystals. Yield: 0.254 g (0.63 mmol, 63%). *Anal. Calc.* for $C_{38}H_{40}N_{10}O_4Mn_2$: C, 56.25; H, 4.98; N, 17.26. Found: C, 56.45; H, 4.98; N, 17.36%. Characteristic IR absorptions (cm^{-1}): $\nu_a(N_3)$ 2038, $\nu_s(N_3)$ 1300, $\delta(N_3)$ 522, $\nu_{schiff\ base}$(C=N) 1587. Electronic absorption bands ($\bar{\nu}_{max}/10^3\ cm^{-1}$, $\varepsilon_{max}/100\ cm^{-1}\ M^{-1}$): 18.00, 8.04; 26.32, 67.0(sh); 30.01, 89.0; 36.67, 191.

2.3. Magnetic studies

The magnetic susceptibility was measured in the 1.98–300 K temperature range using a Quantum Design MPMS SQUID susceptometer. The samples were pressed into pellets to avoid orientation effects of the microcrystals during magnetic measurements. Diamagnetic corrections were applied using Pascal's constants [24]. The magnetic susceptibilities have been computed both with the program SUSCEP [25] based on the expression derived from the isotropic spin-exchange Hamiltonian, $\hat{H} = -2J\hat{S}_1\hat{S}_2$ ($S1 = S_2 = 2$) and van Vleck's equation [26], and by exact calculations of the energy levels associated to the spin Hamiltonian through diagonalization of the full matrix with a general program for axial symmetry [27]. In the latter case, least-squares fittings were accomplished with an adapted version of the function-minimization program MINUIT [28].

2.4. X-ray crystallography

X-ray data were collected for compounds **1–3** on a Bruker SMART APEX CCD X-ray diffractometer, using graphite-monochromated Mo K radiation ($\lambda = 0.71073$ Å). Data were reduced using SAINTPLUS [29], and a multi-scan absorption correction using SADABS [30] was performed. The structures were solved using SHELXS-97 and full matrix least-squares refinements against F^2 were carried out using SHELXL-97 [31]. All ring hydrogen atoms were assigned on the basis of geometrical considerations and were allowed to ride upon the respective carbon atoms. All hydrogen atoms were assigned fixed U_{iso} values, equal to $1.2U_{eq}$ of the parent atom for ring and $1.5U_{eq}$ for methyl hydrogens. Crystallographic data and structure refinement parameters are presented in Table 1. Selected bond distances and angles are collated in Tables 2–4.

3. Results and discussion

3.1. Crystal structures

All three complexes crystallize in the $P2_1/n$ space group. Complexes **1** and **2** have almost identical formula weights and nearly equal unit cell dimensions, even though their chemical compositions are different. The crystals of all three complexes contain dinuclear Mn^{III} entities (Fig. 1), wherein the two centrosymmetrically related five-coordinate metal centers are held by two weak phenoxo bridges (Mn···O in the 2.49–2.59 Å range). Within each five-coordinate unit, the tetradentate Schiff base ligand chelates in the equatorial mode, while the axial position is occupied by a nitrogen atom from the pseudo-halide ion, azide or cyanate, coordinating in a bent mode. The equatorial donor atoms (O_2N_2) are very nearly coplanar even though the manganese atom deviates significantly from this plane (0.16 Å in **1**; 0.20 Å in **2**; 0.13 Å in **3**). The mean planes of the two halves of the Schiff base ligands (excluding the methylene groups) are inclined with respect to each other by 15° in the three crystals. There are only slight differences in the Mn–(N,O) distances in the three complexes: Mn–O($eq.$)$_{av}$, Mn–N($eq.$)$_{av}$, Mn–N($ax.$) are, respectively, 1.90, 2.01, 2.14 Å in **1**; 1.88, 1.99, 2.14 Å in **2**; 1.89, 2.01, 2.17 Å in **3**. The overall coordination geometry of each Mn^{III} ion is thus distorted octahedral with the Jahn–Teller elongation along the OCN/NNN–Mn···O axis.

Coming to the dimer formed by bridging the five-coordinate complex molecules, the plane of the Mn_2O_2 bridge is nearly perpendicular to the equatorial coordination plane: dihedral angle, 88.5° in **1**, 87.4° in **2**, 89.7° in **3**. The axial N atom deviates only slightly from the bridging plane (0.08 Å in **1**; 0.16 Å in **2**; 0.03 Å in **3**). The most important difference between the three dimers

Table 1
Crystallographic data and structure refinement for **1**, **2** and **3.**

	1	**2**	**3**
Formula	$C_{36}H_{32}Mn_2N_6O_6$	$C_{34}H_{32}Mn_2N_{10}O_4$	$C_{38}H_{40}Mn_2N_{10}O_4$
Formula weight	754.56	754.58	810.68

arises from the bridging bond lengths (Å) and angles (°): Mn–O, Mn···O, Mn–O···Mn are, respectively, 1.92, 2.51, 100.6 in **1**; 1.90, 2.59, 98.5 in **2**; 1.91, 2.49, 101.2 in **3**. The Mn···Mn distance in the three dimers is 3.43 Å. In summary, the bridge geometry in compound **3** is characterized by a shorter Mn···O distance coupled with a wider Mn–O···Mn angle while the longer Mn···O distance goes with a more acute Mn–O···Mn angle in compound **2**; compound **1** has a bridge geometry intermediate between those of **2**

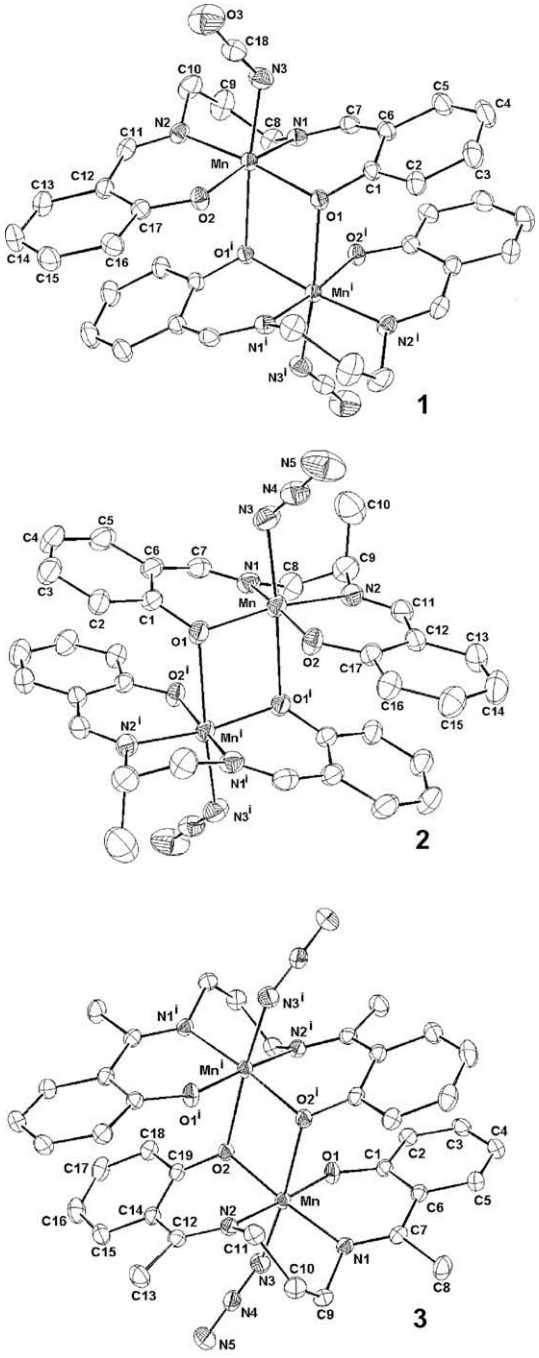

Fig. 1. ORTEP view of the dimers in $[Mn(salpn)NCO]_2$ (**1**) $[Mn(salmen)N_3]_2$ (**2**) $[Mn(acphpn)N_3]_2$ (**3**). Hydrogen atoms are omitted, and the thermal ellipsoids are represented at the 30% probability level. i = $-x+1$, $-y+1$, $-z+1$ for **1**; $-x+1$, $-y+1$, $-z+1$ for **2**; $-x,-y+2,-z$ for **3**.

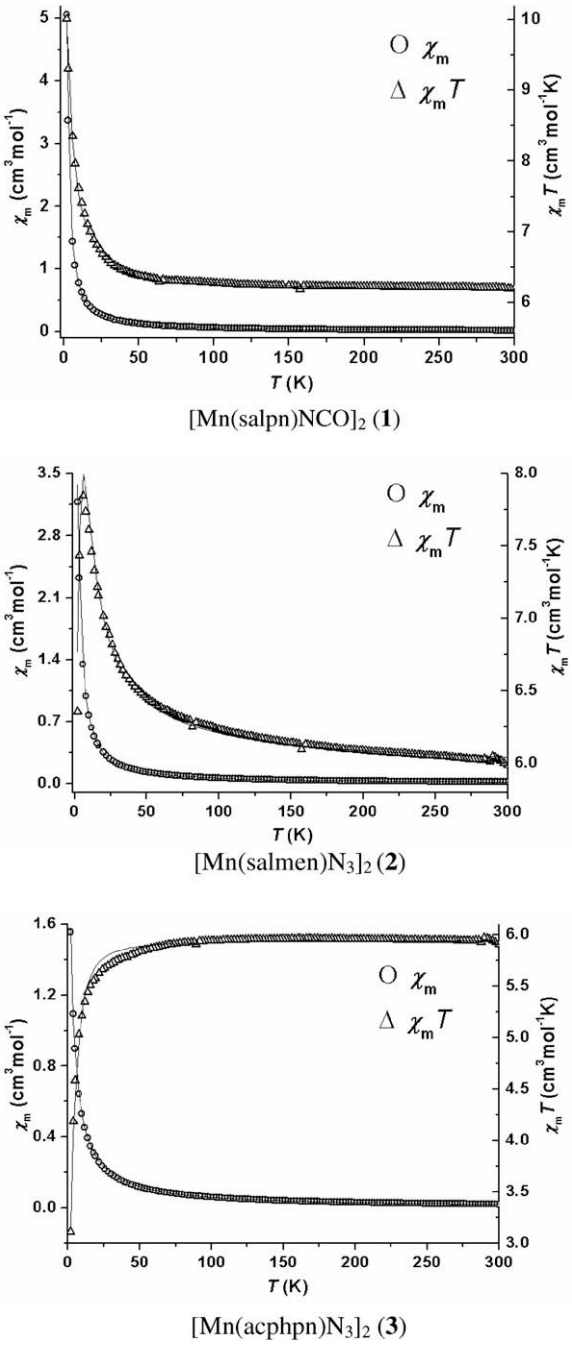

Fig. 2. Temperature variation of the magnetic susceptibility χ_m and $\chi_m T$ product (per dimeric unit) for compounds **1**–**3**. Magnetic field strength used: 1000 Oe (**1**); 5000 Oe (**2**); 3000 Oe (**3**).

and **3**. These differences have an important bearing on the magnetic properties.

3.2. Magnetic properties

The variations of the molar magnetic susceptibility χ_m, and of the product $\chi_m T$ in the temperature range 1.98–300 K for the three complexes are shown in Fig. 2. The room temperature $\chi_m T$ values ($cm^3\ mol^{-1}\ K$) are nearly equal for the three dimers and comparable to the expected spin-only value of 6.00 $cm^3\ mol^{-1}\ K$ per dinuclear Mn^{III} unit: 6.19 for **1**; 5.99 for **2**; 5.90 for **3**. However, the three compounds behave differently when the temperature is lowered. In the case of compound **1**, $\chi_m T$ increases continuously to reach a value of 10.01 $cm^3\ mol^{-1}\ K$ at 1.98 K. Since the expected value for the $S = 4$ ground state is 10.00 $cm^3\ mol^{-1}\ K$, the above result proves the ferromagnetic coupling within the dimer and the absence of significant competing effects from Mn^{III} single ion zero-field splitting and/or antiferromagnetic inter-dimer interactions. Compound **2** also shows an increase upon lowering the temperature. However a maximum $\chi_m T$ of 7.85 $cm^3\ mol^{-1}\ K$ is reached at 5.82 K. Further cooling leads to a rapid decrease to 6.34 $cm^3\ mol^{-1}\ K$ at 2 K. Therefore, while the intra-dimer interaction in compound **2** is ferromagnetic like in **1**, there are competing Mn^{III} single

ion zero-field splitting (zfs) effects and/or antiferromagnetic inter-dimer interactions leading to a rapid fall in $\chi_m T$ below 6 K. In sharp contrast to **1** and **2**, compound **3** is clearly an antiferromagnetically coupled dimer with the $\chi_m T$ value decreasing continuously upon cooling from room temperature to reach a value of 3.11 $cm^3\ mol^{-1}$ K at 2 K.

The magnetic susceptibilities were therefore computed through exact diagonalisation of the spin Hamiltonian including Zeeman and zfs terms and isotropic exchange [27] and fitted to the experimental magnetic data by least-squares techniques [28]. The calculations employed the Hamiltonian, $\beta H \cdot \mathbf{g} \cdot (S_1 + S_2) - 2JS_1 \cdot S_2 + D(S_{z1}^2 + S_{z2}^2)$. Although **g**-tensor was assumed to be axial, the difference between its parallel and perpendicular components was not significant. The single ion zero-field splitting parameter, D is identical for the two centrosymmetrically related Mn^{III} ions in the dimer. The best sets of parameters obtained by least square fitting were: **1**, $J = 0.\ 42(2)\ cm^{-1}$, $D = 0.0006(2)\ cm^{-1}$, $g = 2.022(1)$, LSE (least-squares error) = 0.00007; **2**, $J = 0.58(1)\ cm^{-1}$, $D = -2.32(4)\ cm^{-1}$, $g = 2.000(3)$, LSE = 0.0001; **3**, $J = -0.20(2)\ cm^{-1}$, $D = -0.009(3)\ cm^{-1}$, $g = 1.997(2)$, LSE = 0.00003. The solid lines in Fig. 2 were computed using the above parameters. The differences between the three compounds are further illustrated in Fig. 3, by plotting together their effective magnetic moments as a function of temperature. While the differences in J values are in agreement with the differences in bridge geometry in the molecular structures of **1–3**, the large zfs difference between **1** and **3** on the one hand, and **2** on the other hand, is difficult to explain in view of their very similar coordination geometries. This apparent discrepancy suggests that Mn^{III} zfs may not be the unique effect competing with the isotropic spin–spin interactions, but that possibly inter-dimer magnetic interactions also operate in these complexes. As a first step to check this hypothesis, we also computed the magnetic susceptibilities using the dimer model [26] including inter-dimer interactions within the molecular field approximation [32]. The best sets of parameters obtained by least square fitting were: **1**, $J = 0.364(6)\ cm^{-1}$, $zj = 0.0020(3)\ cm^{-1}$, $g = 2.025$(fixed), LSE = 0.002; **2**, $J = 0.853(9)\ cm^{-1}$, $zj = -0.0576(2)\ cm-^{1}$, $g = 1.99$(fixed), LSE = 0.001; **3**, $J = -0.1385\ (5)\ cm^{-1}$, $zj = -0.0561\ (5)\ cm^{-1}$, $g = 2.00$(fixed), LSE = 0.0004. The quality of the fits, although satisfactory, was not as good as the previous ones, suggesting the operation of both Mn^{III} zfs and antiferromagnetic inter-dimer interactions, at least for **2** and **3**. As a further step, we also computed the magnetic susceptibilities through exact diagonalisation of the spin Hamiltonian including axial Zeeman and zfs terms, isotropic exchange, and inter-dimer interactions within the molecular field approximation. Although the quality of the fits was excellent, D and zj were correlated preventing us to safely estimate independently the respective contribution of these two factors to the magnetic susceptibilities in this series of dimeric Mn^{III} compounds. Considering the similar Jahn–Teller elongation in complexes **1–3** the D is expected to be similar and negative in all the three compounds. Therefore, based on the observed temperature dependence of the magnetic moments and the fitting results, it is reasonable to conclude that the magnitude of D is very small for these compounds so that the variation of the magnetic moment at low temperatures is dominated by inter-dimer interactions.

It is worthwhile to examine the reason for the conspicuous difference in the inter-dimer interactions in compounds **1** and **2**. The intermolecular interactions between dimers are shown in Fig. 4. The shortest Mn···Mn separation between dimers is nearly the same in both compounds: 8.86 Å in **1** and 8.68 Å in **2**. A close examination of the crystal packing shows that the important inter-dimer interactions present in both compounds are (i) =CH···N_c (2.52 Å in **1**; 2.47 Å in **2**), (ii) =CH···O_t/N_t (2.62 Å in **1**; 2.57 Å in **2**) and (iii) Ph-H···Cπ (2.83 Å in **1**; 2.66 Å in **2**) where, suffixes c and t refer to coordinated and terminal atom of the pseudohalide ion. The only difference between the two compounds is the presence of a π-stacking interaction (3.36 Å) [33] in **1** while such an interaction is blocked in **2** by the methyl group. Instead, a hydrogen atom of the methyl group in **2** is involved in a C–H···Phπ interaction (2.88 Å) [34]. The above two contacts which distinguish the packing in the two compounds are shown by red dotted lines in Fig. 4. Correlation of these observations with the magnetic data seems to suggest that the methyl group interaction in **2** is responsible for the antiferromagnetic inter-dimer pathway, while the π-stacking in **1** is ferromagnetic and all other contacts common to both compounds may be of the antiferromagnetic type. This leads to a near-cancellation of the inter-dimer interactions so that the dimer in **1** remains ferromagnetically coupled down to 2 K. The methyl C–H···Phπ interaction is also present in **3** (3.02, 3.13 Å) while the other interactions listed above are absent. The terminal azido in this compound is involved in a Ph-H···N interaction (2.59 Å). As noted above, the inter-dimer exchange interaction determined by the fitting of magnetic susceptibility is antiferromagnetic in this

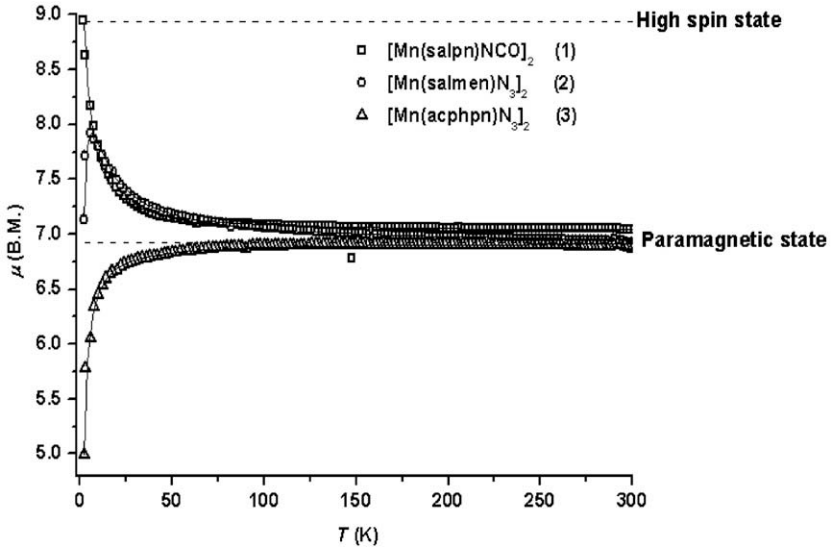

Fig. 3. Temperature variation of magnetic moment (μ_{eff} per dimeric unit) for the three compounds (**1**, **2** and **3**).

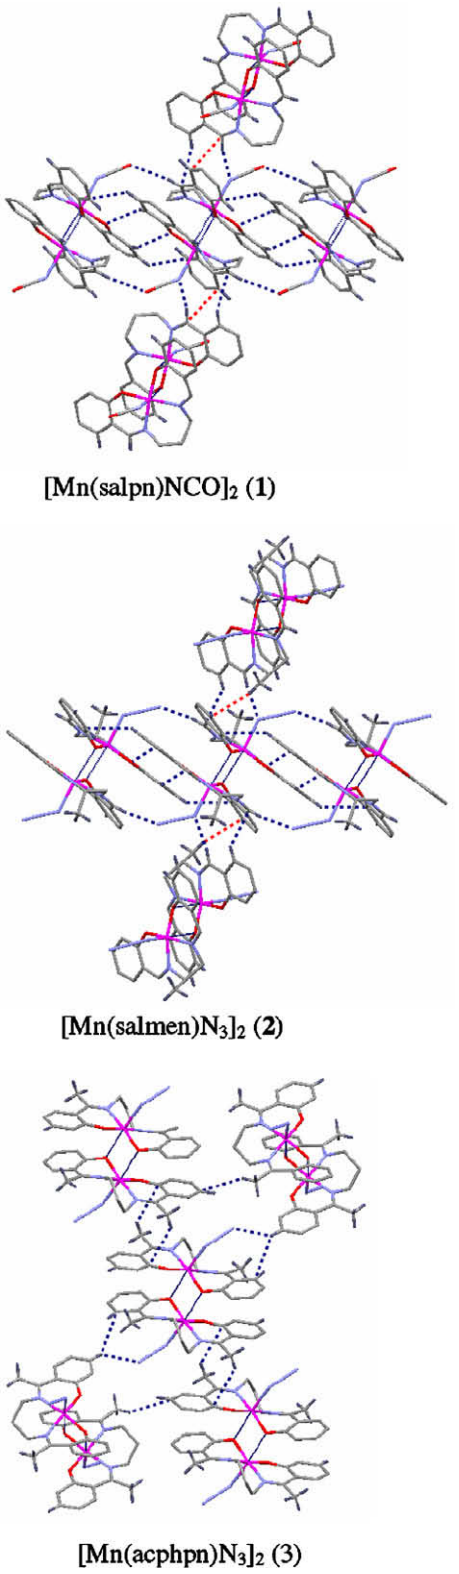

Fig. 4. Intermolecular interactions between dimers in complexes **1**, **2** and **3**.

compound as well. *dc*-Magnetisation measurements were done for **1** and **2** mainly to check for hysteresis. Attempts to fit the magnetisation data (Fig. S1) using the parameters previously derived from temperature variation of molar susceptibility gave satisfactory result only for **2**. It seems that a larger anisotropic term (D) will be needed for **1**. The reason for this discrepancy is not evident. The absence of hysteresis indicates that inter-dimer interactions do not lead to long range order in **1** and **2**, above 1.9 K.

A look at the 20-odd phenoxo-bridged dinuclear Mn^{III} compounds reported [2–21] to date shows that the exchange splitting, $2J$, falls in the range, -3.4 to 12.6 cm^{-1}, with only two instances of $2J > 4$ cm^{-1}. Further, the small magnitude of the interaction energy may reduce the precision with which it can be determined from least-squares analysis when competing influences from zero-field splitting and inter-dimer interactions are present. Therefore, a precise correlation of exchange interactions with molecular structure is difficult to evaluate in this class of compounds. In the case of several dimers having water, thiocyanate or chloride as axial ligands and showing ferromagnetic interaction, it was found that the $2J$ value has a reciprocal correlation with the Mn···O bond distance (2.4–3.7 Å) [5]. However, for the present compounds, the relationship is reversed, with the following respective Mn···O distances (Å) and $2J$ (cm^{-1}) values: 2.49, −0.4 (**3**); 2.51, 0.84 (**1**); 2.59, 1.16 (**2**). Because four magnetic orbitals are involved on each centre, it is unlikely that the exchange interaction may be controlled by just one structural parameter. In this respect, it is worth noting that the increase in $2J$ (cm^{-1}) parallels the decrease in Mn–O···Mn angle (°), with the

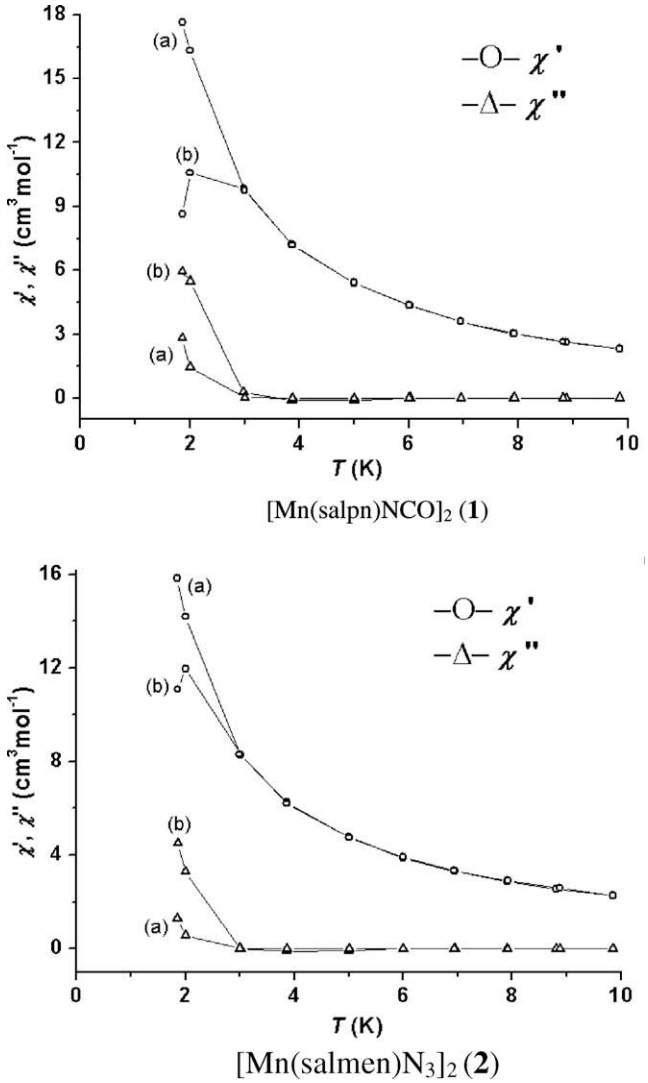

Fig. 5. Temperature variation of the in-phase χ' and out-of-phase χ'' components of the *ac*-magnetic susceptibility in zero static field for complexes **1** and **2** at, (a) 100 Hz and (b) 1000 Hz. Solid lines between the experimental data points are shown as a guide to the eye, they do not result from fitting.

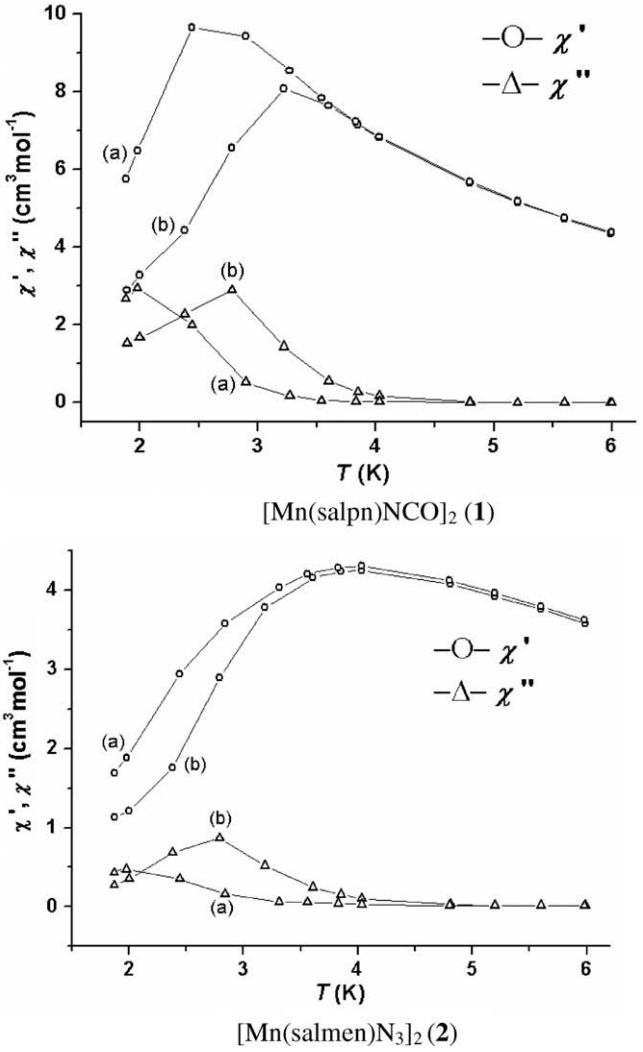

Fig. 6. Temperature variation of the in-phase χ' and out-of-phase χ'' components of the *ac*-magnetic susceptibility for complex **1** at a *dc* field of 0.1 T and for complex **2** at a *dc* field of 0.5 T. The *ac* field fluctuates at a frequency of (a) 100 Hz and (b) 1000 Hz. Solid lines between the experimental data points are shown as a guide to the eye, they do not result from fitting.

following respective values: −0.4, 101.2 in **3**; 0.84, 100.6 in **1**; 1.16, 98.5 in **2**.

In order to check whether compounds **1** and **2** behave as single molecule magnets (SMMs), their *ac* susceptibility was measured in the temperature range 2–10 K at two different frequencies (100 and 1000 Hz). The observation of frequency dependent in-phase χ' and out-of-phase χ'' magnetic susceptibilities (Fig. 5) suggests an SMM behavior for both compounds. Even though no maxima were seen in the above data obtained with zero *dc* field, clear maxima appeared when a *dc* field (0.1 and 0.5 T for complexes **1** and **2**, respectively) was applied (Fig. 6). While the above results are in agreement with observation of an SMM behavior for other phenoxo-bridged Mn^{III} dimers [4,6], further detailed *ac* susceptibility measurements needed for evaluating the relaxation parameters of complexes **1** and **2** is not attempted in the present study.

4. Conclusions

The present results further demonstrate, in line with previous studies [5,6], that a precise correlation of the magnetic exchange parameter with bridge geometry is difficult in the case of phenoxo-bridged dimers due to the weakness of the magnetic coupling and the involvement of several magnetic orbitals in the interaction. An important finding from the present study is that weak inter-dimer interactions like stacking or C–H···π can cause dramatic changes in the overall temperature dependence of the magnetic susceptibility as seen in the case of compounds **1** and **2**, both of which are ferromagnetically coupled dimers. Alkyl substituents on the Schiff base are effective in modulating the inter-dimer interactions causing differences in behavior at lower temperatures. The ferromagnetically coupled dimers, in spite of their very small magnitude of the zero-field splitting do show evidence for single molecule magnetism.

concentration of $\sim 10^{-3}$ mol L^{-1}. The redox behaviors of the complexes were examined on a computer controlled EG&G PAR model 270 VERSTAT electrochemical instrument using a Ag/AgCl electrode with TBAP as the supporting electrolyte. All the measurements were made at 298 K in dimethylformamide solution for a complex concentration range of 10^{-3}–10^{-4} mol L^{-1} using dry dinitrogen for 3–4 min in order to remove dissolved oxygen.

2.2. Preparation of the complexes

The complexes were synthesized following a common procedure, as described below, using the respective metal(II) chloride salts and 1,3-bis(2-pyridylmethylthio)propane (L) in a 1:1 mole ratio. To a methanolic solution (15 mL) of L (276.0 mg, 1.0 mmol), iron(II) chloride tetrahydrate (1.0 mmol) (for **1**), cobalt(II) chloride hexahydrate (1.0 mmol) (for **2**) or nickel(II) chloride hexahydrate (for **3**) was added dropwise, stirring the mixture for an hour. The reaction mixture was refluxed for 3 h and then kept at room temperature. The pure crystallized product was obtained from this solution by allowing slow evaporation of the solvent. The product was collected by filtration followed by washing with water and methanol, and dried in *vacuo*.

2.3. X-ray crystal structure analysis

Single crystals of complexes **1** and **3** suitable for X-ray diffraction analysis were grown by slow evaporation of methanolic solutions at ambient temperature. Crystallographic data and details of the refinements are provided in Table 1. Diffraction data for **1** were collected at 150(2) K using the Oxford Diffraction X-Calibur CCD System (321 frames, counting time of 2 s, the crystal positioned at 50 mm from the CCD). The experiment for **2** was carried out at room temperature on a Nonius DIP-1030H system (45 frames, the crystal positioned at 90 mm from the image plate). Mo Kα radiation (λ = 0.71073 Å) was used for both data collections. Cell refinement, indexing and scaling of the data sets were carried out using programs CRYSALIS [22], DENZO and SCALEPACK [23]. An absorption correction was applied to **1** by the ABSPACK program [24]. Both structures were solved using direct methods with the SHELXS97 program and refined by the full-matrix least-squares method based on F^2 with all observed reflections [25]. Hydrogen atoms were fixed at geometrical positions. As the complexes were located on a crystallographic twofold axis, the central methylene C(8) atom results was disordered over two sites (0.5 occupancy each). All the calculations were performed using the WINGX System, Version 1.70.01 [26].

Table 1
Crystallographic data for **1** and **3**.

	1	**3**

3. Results and discussion

3.1. Synthesis and characterization

The organic ligand 1,3-bis(2-pyridylmethylthio)propane (L) was synthesized by the reaction of the respective alkyl dithiol compound with 2-picolyl chloride in the presence of sodium ethoxide. The complexes were obtained in good yields from the reaction of the corresponding metal salt with an equimolar amount of the respective organic moiety in methanol medium. All the complexes are monomeric in nature and are sparingly soluble in common organic solvents. The complex conductivity measurements in dimethylformamide show conductance values in range 42–52 Λ_o mol^{-1} cm^{-1}, which suggest that the complexes exist in solution as non-electrolytes. The magnetic moment (μ) at room temperature of iron(II) in (**1**) is 5.45 B.M., which indicates a high-spin octahedral iron(II) complex; the values of μ for the cobalt(II) and nickel(II) complexes are 4.91 and 3.08 B.M., respectively.

3.2. Structures of complexes *1* and *3*

The X-ray structural analyses evidence that the crystals of **1** and **3** are isomorphous, and an ORTEP view of complex **1** is shown in Fig. 1, together with the atom numbering scheme. The metal resides on a crystallographic twofold axis bisecting the Cl–M–Cl and S–M–S angles. Thus the methylene C(8) atom of the organic moiety is disordered over two positions (each of occupancy 0.5), and only one orientation is displayed in Fig. 1. The tetradentate NSSN ligand is wrapped around the metal in such a way that the pyridine rings are in *trans* positions and the metal ion completes the highly distorted octahedral coordination sphere with two chlorides located in *cis* positions. The present coordination pattern of L

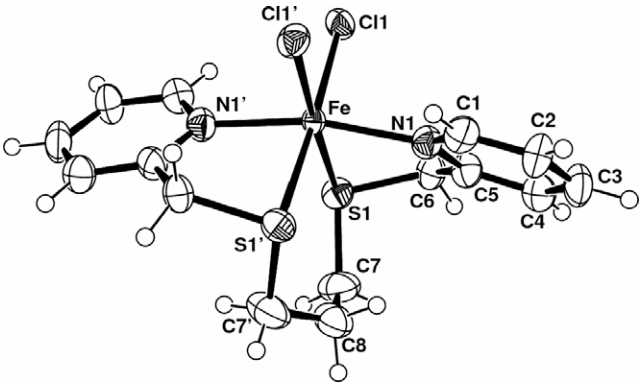

Fig. 1. ORTEP drawing (ellipsoids at 50% probability) of complex [Fe(L)Cl_2] (**1**). The molecule is located on a twofold axis and only one position for the disordered C(8) methylene is shown. The same atom numbering is applied to the isomorphous complex [Ni(L)Cl_2] (**3**), substituting Fe with Ni.

Table 2
Coordination bond distances (Å) and angles (°) for **1** and **3**.

	1, M = Fe	**3**, M = Ni
Bond distance (Å)		
M–N(1)	2.099(5)	2.104(2)
M–S(1)	2.440(2)	2.451(1)
M–Cl(1)	2.384(2)	2.392(1)
Bond angles (°)		
N(1)–M–N(1′)	167.4(3)	166.48(9)
N(1)–M–Cl(1′)	95.35(15)	95.50(5)
N(1)–M–Cl(1)	93.16(15)	93.63(5)
N(1)–M–S(1)	82.40(15)	82.22(5)
N(1)–M–S(1′)	89.23(15)	88.77(5)
Cl(1)–M–Cl(1′)	94.90(9)	94.88(4)
Cl(1)–M–S(1)	84.20(6)	84.38(3)
Cl(1)–M–S(1′)	177.51(5)	177.54(2)
S(1)–M–S(1′)	96.80(9)	96.45(3)

Primed atoms at $-x,y,-z+1/2$.

was also detected in the neutral $[Ni(L)(ONO_2)_2]$ derivative [27], but it is noteworthy that in the trigonal bipyramidal copper(II) complex $[Cu(L)Cl]^+$ [21] a pyridine-N and a thioether-S reside at the axial positions whereas the equatorial sites were occupied by the other N and S donors and by the chloride ligand. The coordination bond lengths and angles of **1** and **3**, listed in Table 2, show only minor differences related to the metal ionic radii. The M–N bond lengths are comparable within their e.s.d.'s (2.099(5) and 2.104(2) Å in **1** and **3**, respectively), while the values of the M–S and M–Cl distances differ by *ca.* 0.01 Å, being of 2.440(1), 2.451(1) Å and 2.384(2), 2.392(1) Å in **1** and **3**, respectively. The bond angles subtended at the metal differ by less than 1° in the two structures, but they deviate considerably from the ideal octahedral values and the N–M–N angle of 167° (mean value for the two structures) shows the highest deviation. In fact the pyridine rings of the ligand are bent with respect to the S_2Cl_2 plane, forming a dihedral angle of 80.57° (mean value), likely induced by ligand constraints upon coordination, while the dihedral angle made by the trans located pyridine planes is 55.3(2)° and 54.9(1)° in **1** and **3**, respectively. The bond distances and geometrical distortions of **3** agree with those found in [Ni(2,2′-(2,5-dithiahexamethylene) dipyridine)Cl_2] [28] while small differences are evidenced when compared with the disordered crystal structure of $[Ni(L)(ONO_2)_2]$ [7].

3.3. Spectroscopic properties

The infrared spectra of all the complexes exhibit characteristic strong to medium intensity bands in the regions 1468–1472 and 758–761 cm^{-1}, which are assignable to $\nu_{C=N}$ and ν_{C-S}, respectively, in addition to the other characteristic bands of the organic moieties. This observation supports the presence of the ligand frame containing the pyridine ring and the C–S bond, and ν_{C-S} is generally observed in the free ligand in the range of 780–790 cm^{-1} [21].

The electronic absorption spectra of complexes **1**–**3** were recorded at room temperature using dimethylformamide as the solvent and the data tabulated in Table 3. All the spectra in the high energy region (below 400 nm) exhibit bands corresponding to intramolecular $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions. In addition, characteristic bands for the complexes were detected as follows.

In the electronic spectrum of $[Fe(L)Cl_2]$, a prominent peak around 475 nm with a shoulder at about 752 nm was observed, corresponding to MLCT and d–d transitions, respectively. The electronic spectrum of **2** shows bands at 425, 560 and 967 nm, assignable to the transitions $^4T_{1g} \rightarrow {}^4T_{1g}(P)$, $^4T_{1g} \rightarrow {}^4A_{2g}(F)$ and $^4T_{1g} \rightarrow {}^4T_{2g}(F)$, respectively. The position of these bands indicates an octahedral geometry about the Co^{II} ion [29]. The spectrum of **3** exhibits bands at 475, 685 and 873 nm, which may be assigned to $^3A_{2g}(F) \rightarrow {}^3T_{1g}(P)$, $^3A_{2g}(F) \rightarrow {}^3T_{1g}(F)$ and $^3A_{2g}(F) \rightarrow {}^3T_{2g}(F)$ transitions, respectively. These observations suggest an octahedral geometry of the Ni^{II} ion [30].

3.4. Electrochemistry

The redox properties of the complexes were examined by cyclic voltammetry using a Pt-disk working electrode and a Pt-wire auxiliary electrode in dry dimethylformamide using $[n\text{-}Bu_4N]ClO_4$ as the supporting electrolyte. Voltammetric data are set out in Table 3.

The voltammetric response for $[Fe(L)Cl_2]$ (**1**) exhibits an oxidative couple at the $E_{1/2}$ value of +0.295 V, assigned to the Fe^{II}/Fe^{III} pair, [29] with a peak potential separation (ΔE_p) of 120 mV and cathodic to anodic current intensity ratio of 0.97. The cyclic voltammogram of $[Co(L)Cl_2]$ (**2**) shows a quasi-reversible peak for the Co^{II}/Co^{III} redox couple at $E_{1/2}$ of 0.795 V with ΔE_p of 195 mV. The cyclic voltammogram of $[Ni(L)Cl_2]$ (**3**) exhibits a quasi-reversible Ni^{II}/Ni^{III} redox couple centered at 0.745 V versus Ag/AgCl. Here, the $E_{1/2}$ value for complex **3** lies at the higher side of the range generally measured, 0.3–0.8 V, for the Ni^{III}/Ni^{III} oxidation potential data for thioether containing nickel(II) complexes, [31] indicating that Ni^{II} is fairly stabilised in **3**. No cathodic response, recommended for $Ni^{II} \rightarrow Ni^{I}$ reduction, was observed for **3** up to −1.51 V. The voltammetric parameters were studied in the scan rate interval 50–400 mV s^{-1}. The ratio between the cathodic peak current and the square root of the scan rate ($I_{pc}/v^{1/2}$) is approximately constant. The peak potential shows a small dependence on the scan rate. The ratio I_{pc} to I_{pa} is close to unity. From these data, it can be deduced that the redox couple is related to a quasi-reversible one-electron transfer process controlled by diffusion.

Table 3
UV–Vis spectral and electrochemical data.[a]

Compound	UV–Vis data[a]	Electrochemical data[b]			
	λ (nm) (ε, $dm^3\ mol^{-1}\ cm^{-1}$)	E_{pc}[a] (V)	E_{pa}[a] (V)	$E_{1/2}$ (V)	Reversibility (I_{pc}/I_{pa})
1	212(9530), 261(8310), 332(3010), 475(975), 752(108)	+0.235	+0.355	+0.295	0.97
2	210(9000), 257(6300), 337(2820), 425(89), 560(186), 967(22)	+0.600	+0.990	+0.795	1.03
3	210(10230), 258(7430), 328(2915), 475(221), 685(520), 873(31)	+0.665	+0.825	+0.745	0.93

[a] In DMF.
[b] Data recorded in mV, at 298 K and scan rate 100 mV s^{-1}; $E_{1/2} = (E_{pc} + E_{pa})/2$; I_{pc}/I_{pa} is constant for scans in the range of 50–400 mV s^{-1}.

4. Conclusion

The synthesis and characterization of three new mononuclear complexes of iron(II), cobalt(II) and nickel(II) with a N_2S_2 donor set have been performed. No inert atmosphere (i.e. dinitrogen) is required for the synthesis of the iron(II) and cobalt(II) complexes, but these are prone to aerial oxidation. Structural characterization of **1** and **3** by X-ray diffraction indicates isomorphous crystals with the metal ion in an octahedral geometry with the chloride and py ligands occupying *cis* and *trans* positions, respectively. All the complexes manifest very similar redox behavior in dimethylformamide solution, showing M^{II}/M^{III} redox couples in the cyclic voltammograms, but no cathodic response for the M^{II}/M^{I} redox process.

Supplementary data

CCDC 697636 and 697637 contain the supplementary crystallographic data for compounds **1** and **3**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. General

All chemicals were of reagent grade purity and were used without further purification. All experiments were carried out in air. Elemental analyses were performed by atomic absorption spectroscopy for copper and spectrophotometrically for chromium (as chromate at λ = 370 nm) at the Department of Chemistry, National Taras Shevchenko University of Kyiv and with a vario EL III Universal CHNOS Elemental Analyzer (for C, H, N, S) at the Faculty of Chemistry, University of Wroclaw.

2.2. Preparation

Copper powder (1.26 mmol for **1**–**3**; 2.5 mmol for **4**), $NH_4[Cr(NCS)_4(NH_3)_2]\cdot H_2O$ (2.52 mmol for **1**, **3**; 1.26 mmol for **2**; 0.625 mmol for **4**), NH_4NCS (1.26 mmol for **2**; 4.375 mmol for **4**), non-aqueous solvent (20 mL, dmf for **1**, CH_3CN for **2**, CH_3OH for **3**, dmso for **4**), acetone (5 mL, for **3** and **4**) and *N*,*N*-dimethylethylenediamine (2.25 mmol for **1**–**3**; 5.0 mmol for **4**) were placed in a flask in the above order, heated to 50–60 °C and magnetically stirred until total dissolution of the copper powder was observed (10–15 min). Crystals suitable for X-ray crystallography were formed after several days (**2**), separated after several days following the successive addition of 5 ml of Pr^iOH (**1** and **4**), deposited after slowly evaporation of the solvent at room temperature (**3**). The crystals were filtered off and dried in vacuo at room temperature. The compounds are soluble in CH_3CN, dmso and dmf.

2.2.1. $[Cu(dmen)_2(dmf)_2][Cr(NCS)_4(NH_3)_2]_2 \cdot 6dmf$ (**1**)

Yield: 1.24 g, 67% (per copper). *Anal. Calc.* for $C_{40}H_{92}N_{24}S_8O_8Cr_2Cu$: C, 32.88; H, 6.34; N, 23.00; S, 17.55; Cr, 7.12; Cu, 4.35. Found: C, 32.7; H, 6.5; N, 22.8; S, 17.7; Cr, 7.3; Cu, 4.4%. 2.3. Physical measurements

Infrared spectra were recorded as KBr discs on a UR-10 spectrophotometer in the 4000–400 cm^{-1} region using conventional techniques. UV/Vis spectra were recorded on a Perkin–Elmer Lambda 900 spectrophotometer using the diffuse-reflectance technique.

The EPR spectra were recorded on a Bruker ESP 300E (Bruker, Germany) spectrometer operating at X-band and equipped with a Bruker NMR gaussmeter ER 035 M and a Hewlett–Packard microwave frequency counter HP 5350B. The spectra were measured using typical instrument parameters: microwave frequency, from about 9.5 GHz at 77 K to about 9.7 GHz at 295 K.; microwave power, 20 milliwatts; modulation frequency, 100 kHz; modulation amplitude not greater than 0.5 mT. The EPR parameters were calculated by computer simulation of the experimental spectra using Bruker's WIN-EPR SIMFONIA Software Version 1.25. Magnetic susceptibility data of powdered samples were measured with a SQUID magnetometer (Quantum Design MPMSXL-5) over the temperature range 1.8–300 K at a magnetic induction of 0.5 T. Corrections for diamagnetism of the constituted atoms were calculated from Pascal's constants [15].

2.4. Crystal structure determination

Details of the structure determination and crystallographic data for compounds **1**–**4** are summarized in Table 1. X-ray diffraction data were collected on an XCalibur 3 diffractometer equipped with graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) and a CCD detector using ω- and ϕ-scans. The structures were solved by direct methods and refined by full-matrix least-squares methods using the SHELXTL package [16]. All non-hydrogen atoms were refined within anisotropic approximation except for the disordered atoms of one of the dmso molecules in **4** [O(6) and O(6A) atoms], which were refined isotropically. In the structure of **2** one of the methylene groups of the dmen ligand was disordered over two positions with populations 40:60%. In **4**, six dmso molecules were found, two of them were disordered over two positions with populations 37:63% and 50:50%. The H atoms were located from the difference maps of electron density and refined by the "riding" model with $U_{iso} = nU_{eq}$ of the carrier non-hydrogen atom ($n = 1.5$ for methyl and 1.2 for other H-atoms).

3. Results and discussion

3.1. Synthesis and spectroscopic characterization

The reaction of copper powder, Reinecke's salt, NH_4NCS (in the case of **2**) with *N*,*N*-dimethylethylenediamine (dmen) in dmf (**1**) or CH_3CN (**2**) in open air, using a Cu:$NH_4[Cr(NCS)_4(NH_3)_2]$:dmen molar ratio of 1:2:2 (for **1**) and 1:1:2 (for **2**), affords heterometallic compounds with a Cu(II):Cr(III) ratios of 1:2 (**1**) and 1:1 (**2**). The reactions proceed by the following pathways:

$$Cu^0 + 2NH_4[Cr(NCS)_4(NH_3)_2] + 2dmen + 1/2O_2 + 8dmf \rightarrow \rightarrow [Cu(dmen)_2(dmf)_2][Cr(NCS)_4(NH_3)_2]_2 \cdot 6dmf + 2NH_3 + H_2O \quad (1)$$

$$Cu^0 + NH_4[Cr(NCS)_4(NH_3)_2] + 2dmen + NH_4NCS + 1/2O_2 \rightarrow \rightarrow [Cu(dmen)_2(NCS)][Cr(NCS)_4(NH_3)_2] + 2NH_3 + H_2O \quad (2)$$

In our previous work, we have shown that the Reinecke's salt could act as a source of ammonia molecules and thiocyanato groups as well as creating favorable conditions for the formation of 2-methyl-2-amino-4-imino-pentan derivatives in the presence of acetone molecules [14]. The one-step reaction of copper powder, Reinecke's salt in acetone/CH_3OH (1:4) (for **3**) or acetone/dmso (1:4) (for **4**) solution of *N*,*N*-dimethylethylenediamine (dmen) with a molar ratio of Cu:$NH_4[Cr(NCS)_4(NH_3)_2]$:dmen of 1:2:1 and 4:1:8, respectively, gave two different compounds with two novel open-chain aliphatic Schiff-base ligands, dmenac and $dmen_2ac$. Their formation can be understood if one considers the following reaction schemes (it should be noted that the molar ratios of the starting reagents in the syntheses differ from those in the reaction schemes):

$$Cu^0 + NH_4[Cr(NCS)_4(NH_3)_2] + dmen + NH_4SCN + 2(CH_3)_2CO + + 1/2O_2 \rightarrow [Cu(dmenac)(NCS)(\mu\text{-}SCN)Cr(NCS)_3(NH_3)_2] + + NH_3 + 3H_2O \quad (3)$$

$$Cu^0 + NH_4[Cr(NCS)_4(NH_3)_2] + 2dmen + + NH_4SCN + 2(CH_3)_2CO + 6dmso + 1/2O_2 \rightarrow \rightarrow [Cu(dmen_2ac)(NCS)][Cr(NCS)_4(NH_3)_2] \cdot 6dmso + + 2NH_3 + 3H_2O \quad (4)$$

The infrared spectra for complexes **1**–**4** show all the characteristic ligands frequencies: $\nu_{as}(NH_2)$, $\nu_s(NH_2)$, ν(N–H), ν(C–H), $\delta(NH_2)$, ν(C–N) and ν(C–C) in the ranges 3330–3300, 3250–3230, 3180–3150, 2980–2950, 1600–1590, 1060–1030 and 980–950 cm^{-1}, respectively, and ν(C=N) for **3** and **4** at 1660 and 1650 cm^{-1}, respectively. The presence of the last two bands in the spectra of **3** and **4** confirms that the condensation process has taken place. The IR spectra show very strong absorption bands in the spectral region characteristic of the NCS ligand (Table 2), suggesting the presence of terminal N-bonded thiocyanate groups in **1**–**4** and bridging thiocyanate groups in **3** [17]. The observed value of ν(CN) at 2100 cm^{-1} for **2**–**4** and the Reinecke's salt, as well as the presence of two bands attributable to ν(CN) in **2** and a very strong and broad band in the region 2120–2070 cm^{-1} in **3** could be a result of the participation of some of NCS groups in hydrogen bonding, which is confirmed by the X-ray analyses of **1**–**4**. The presence of solvent molecules in **1** and **4** can be identified by peaks at 1665 cm^{-1} (dmf, **1**) and 1020 cm^{-1} (dmso, **4**), typical for coordinated dmf and dmso [18]. In our case the shift of ν(CO) and ν(SO) to lower values can be explained by the involvement of the solvate molecules in hydrogen bonding.

The solid-state diffuse-reflectance spectra of **1**–**4** show broad asymmetric bands with maxima in the region 525–545 nm, which probably result from overlapping d–d transitions for the distorted Cu(II) and Cr(III) centers [19–21]. Additionally, the spectra display ligand-to-metal charge transfer bands at *ca.* 300 nm.

3.2. Description of the crystal structures

3.2.1. $[Cu(dmen)_2(dmf)_2][Cr(NCS)_4(NH_3)_2]_2 \cdot 6dmf$ (**1**)

Crystalline samples of **1** represent small grown together crystals with mane defects. All attempts to obtain well defined crystals with bigger size were unsuccessful. This property of **1** results in a relatively low precision of the crystal structure determination. Therefore, we cannot discuss in detail the geometrical parameters of **1**. However, the structural data reflects the coordination pattern of the metals and general organization of the crystals.

The crystal structure of **1** consists of discrete $[Cu(dmen)_2(dmf)_2]^{2+}$ cations, anions of the Reinecke's salt $[Cr(NCS)_4(NH_3)_2]^-$ as counterions and dmf molecules, that are hydrogen bonded into supramolecular sheets. The $[Cr(NCS)_4(NH_3)_2]^-$ anion is structurally similar to previously reported compounds (Table S1) [12–14,22–25]. The copper(II) ions in **1** are in an elongated octahedral (4 + 2) coordination environment with four nitrogen atoms of two dmen bidentate ligands in the equatorial plane and two oxygen atoms of dmf molecules in the axial positions (Fig. 1).

The compound **1** contains six solvate dmf molecules, and hence the crystal architecture is assisted by numerous N–H···O hydrogen

2	2100 and 2070	860 and 840
3	2140 and 2120–2070	790 and 775
4	2100	790

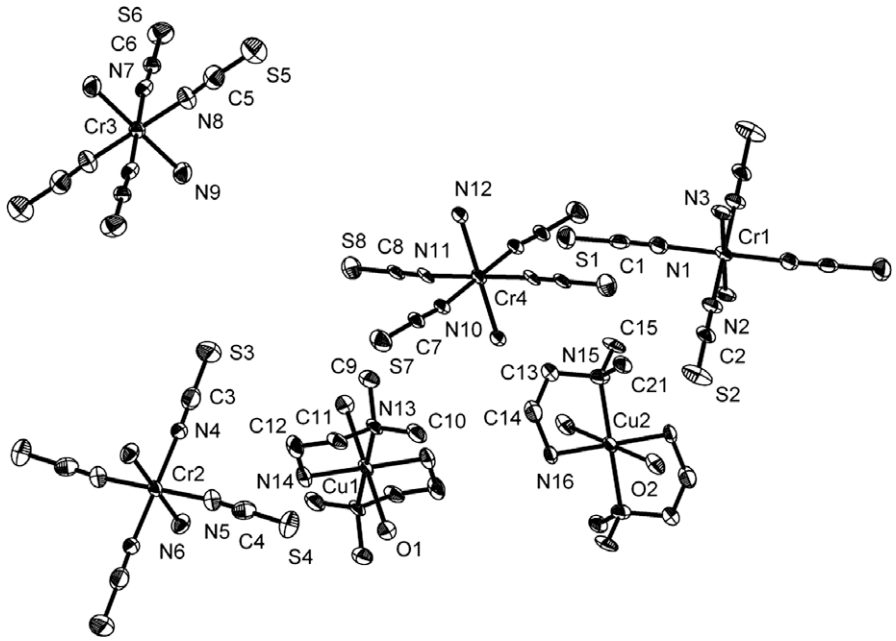

Fig. 1. Fragment of the structure of **1** with 50% probability thermal ellipsoids, showing the atom numbering scheme (H atoms and dmf molecules are omitted for clarity).

bonds (Table S2). The oxygen atoms of dmf molecules are H-bonded by hydrogen atoms of NH_3 molecules of $[Cr(NCS)_4(NH_3)_2]^-$ anions and by hydrogen atoms of primary amine groups of dmen ligands of $[Cu(dmen)_2(dmf)_2]^{2+}$ cations, forming supramolecular sheets. The sheets can be considered as being built up of two types of hydrogen bonded chains, as can be visualized in Fig. 2. It is noteworthy, that there are two types of supramolecular sheets, based on two sets of crystallographically independent atoms [sheet 1, formed by Cu(1), O(4), Cr(4), Cr(2), O(7) and O(9) atoms, and sheet 2, formed by Cu(2), O(3), Cr(1), Cr(3), O(45) and O(5) atoms] (Table S2). The sheets are well separated from each other and finally form the 2D layered supramolecular architecture.

3.2.2. $[Cu(dmen)_2(NCS)][Cr(NCS)_4(NH_3)_2]$ (**2**)

The structure of **2** includes $[Cu(dmen)_2(NCS)]^+$ cations and anions of the Reinecke's salt $[Cr(NCS)_4(NH_3)_2]^-$, that are hydrogen bonded into cationic and anionic chains. These are linked together into 2D supramolecular sheets, which are further stacked by hydrogen bonding to form a three-dimensional supramolecular architecture. In **2**, the chromium(III) ion has the same coordination environment and geometrical parameters as in **1** (Table S1). The coordination geometry of the copper(II) ion in **2** is a slightly distorted square-based pyramid (trigonality index $\tau = 0.054$ [26]); the four N atoms of two dmen ligands form the base and the fifth N atom, from the thiocyanate anion, occupies the apex position (Fig. S1). The $Cu–N_{dmen}$ distances are in the range 1.986(3)–2.104(3) Å, with slightly shorter bond lengths to the primary amine nitrogen atoms than those to the tertiary ones (Table S1), which is usually observed for complexes with the dmen ligand [27–30].

In the crystal lattice of **2**, $[Cu(dmen)_2(NCS)]^+$ cations form cationic chains through N–H···S hydrogen bonds between H(N) atoms of primary amine groups of dmen ligands and S atoms of terminal NCS groups of adjacent cations, while $[Cr(NCS)_4(NH_3)_2]^-$ anions are joined into anionic chains by means of N–H···S bonds between NH_3

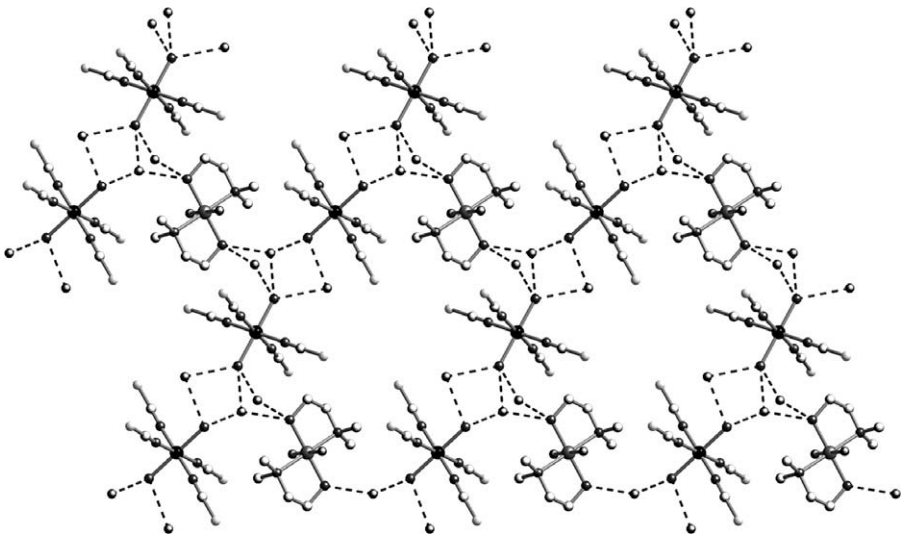

Fig. 2. Fragment of the supramolecular sheet of **1** (hydrogen atoms are omitted for clarity and only oxygen atoms of dmf molecules are shown).

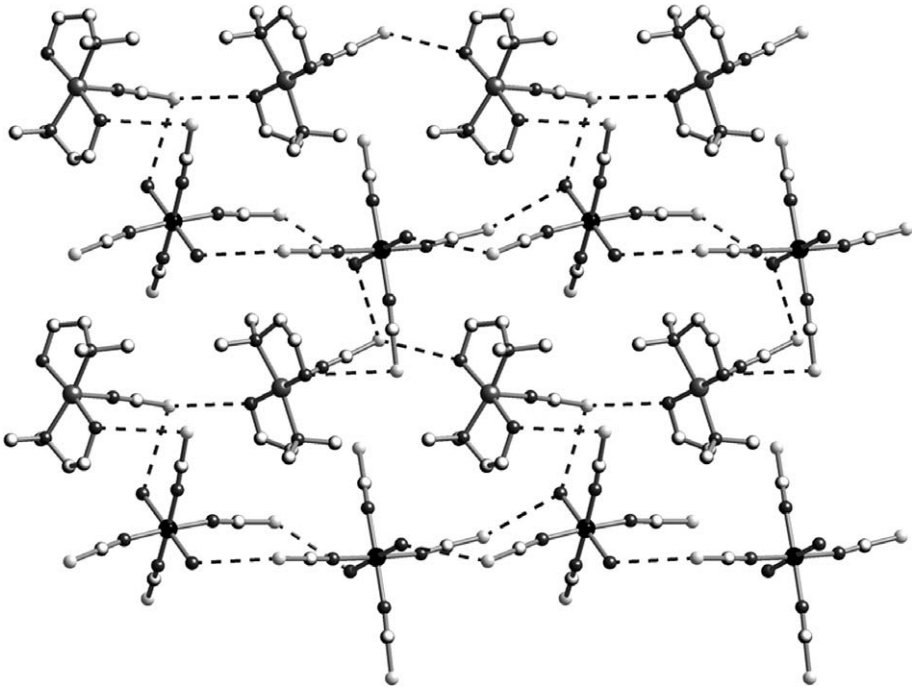

Fig. 3. Fragment of the H-bonded sheet of **2** (H atoms are removed for clarity).

molecules and the S atoms of thiocyanate groups (Fig. 3). The alternating cationic and anionic chains are inter-connected by N–H···S hydrogen bonds (Table S2) to create a three-dimensional supramolecular network.

3.2.3. *[Cu(dmenac)(NCS)(μ-SCN)Cr(NCS)$_3$(NH$_3$)$_2$] (**3**) and [Cu(dmen$_2$ac)(NCS)][Cr(NCS)$_4$(NH$_3$)$_2$] · 6dmso (**4**)*

Fragments of the crystal structures of binuclear complex **3** and solvated ionic complex **4**, with their labelling schemes, are shown in Fig. 4 and Fig. S2, respectively. The crystal structure of **3** is made up of Cu(dmenac)(NCS)$^+$ and Cr(NCS)$_4$(NH$_3$)$_2^-$ moieties, connected by a thiocyanate bridge. The crystal structure of **4** consists of [Cr(NCS)$_4$(NH$_3$)$_2$]$^-$ anions, [Cu(dmen$_2$ac)(NCS)]$^+$ cations and six dmso molecules of crystallization. Three of dmso molecules participate in hydrogen bonds with anions of the Reinecke's salt, forming supramolecular chains, while the cations with the rest of solvate molecules are accommodated in the interchain space.

In the compounds **3** and **4**, all the chromium(III) atoms have the same coordination environment and geometrical parameters as in **1** and **2** (Table S1). The coordination geometries of the five-coordinated copper(II) atoms in **3** and **4** are closely related to a distorted square-based pyramid (τ = 0.243 for **3**, τ = 0.112 for **4**) with the sulfur atom of the bridging thiocyanate group and nitrogen atom of a terminal thiocyanate group at the axial sites in **3** and **4**, respectively. The apical Cu–S distance in **3** has a value of 2.694(4) Å, which is close to those found in other pentacoordinated copper(II) complexes with the sulfur atom at an apical position [31–34]. The basal sites of the copper pyramids are occupied by three nitrogen atoms of the dmenac ligand and one nitrogen atom of a terminal NCS group (**3**), and by four nitrogen atoms of the dmen$_2$ac ligand (**4**). Usually, complexes with Curtis-type ligands have slightly shorter bond lengths to the imine nitrogen than those to the secondary amine nitrogen [35–38], this is the case in **4**, while **3** exhibits a slightly shorter bond to the primary amine nitrogen of the dmenac ligand (Table S1).

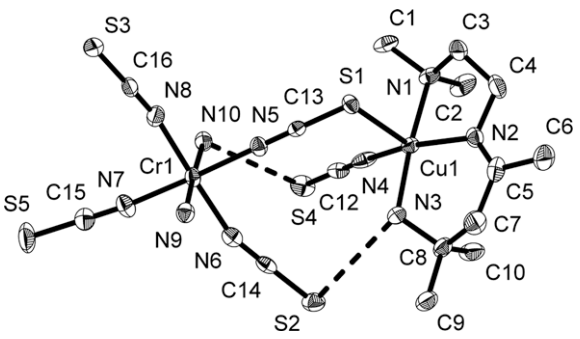

Fig. 4. View of the molecular structure of **3** with the atom numbering scheme showing intramolecular hydrogen bonds. Atom displacement ellipsoids are shown at the 50% probability level (H atoms are omitted for clarity).

The molecular structure of **3** is strengthened by two intramolecular N–H···S bonds (Fig. 4), while adjacent binuclear complexes are connected into two-dimensional sheets by intermolecular hydrogen bonds between thiocyanate ligands and NH$_3$ molecules of [Cr(NCS)$_4$(NH$_3$)$_2$]$^-$ anions (Table S2, Fig. 5).

An interesting feature of the crystal structure of **4**, revealed by analysis of the packing diagram, is the presence of anionic supramolecular chains, built from H-bonded solvate molecules and [Cr(NCS)$_4$(NH$_3$)$_2$]$^-$ anions. The interchain space is filled with [Cu(dmen$_2$ac)(NCS)]$^+$ cations, each of which is bound to the oxygen atom of a dmso molecule through the H(N) atom of the secondary amine group of the dmen$_2$ac ligand, forming a cationic agregate, and two uncoordinated solvate molecules (Fig. 6).

3.3. EPR and magnetic properties

The EPR spectra of polycrystalline samples of compounds **1**, [Cu(dmen)$_2$(dmf)$_2$]$^{2+}$, **3** and **4** at 295 and 77 K are very similar (Fig. 7): they exhibit an almost isotropic and very broad line around g = 2, which seems to be caused by resonance transitions between the electronic levels split by a small zero-field splitting parameter D (according to Spin Hamiltonian due to at least S = 3/2). It is in agreement with the rather high symmetry of the Cr(III) coordination. The parameters of the spectra remain practically

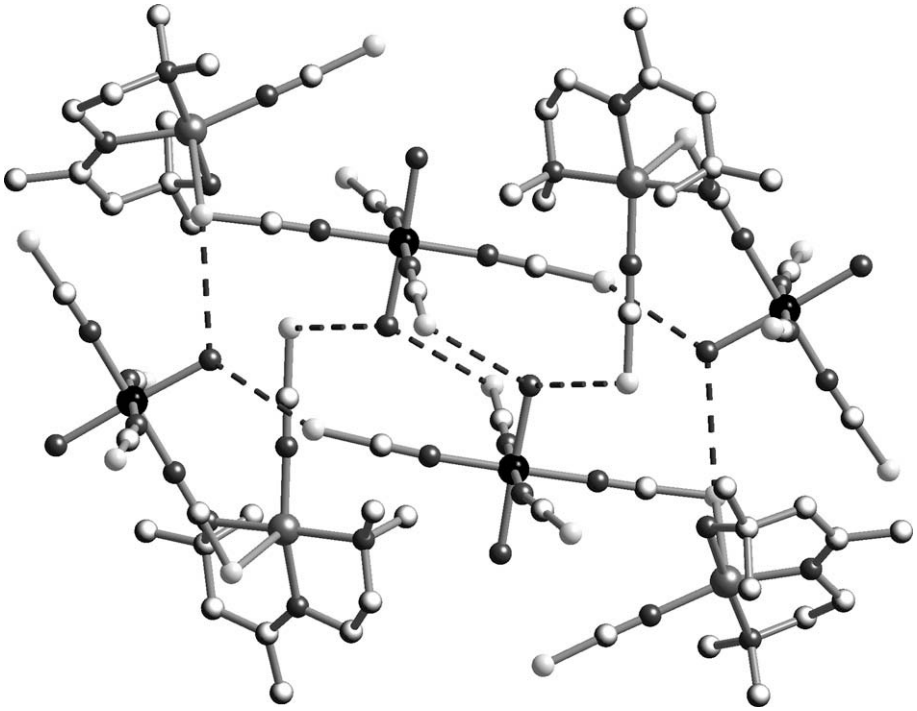

Fig. 5. Fragment of the supramolecular sheets of **3** showing intermolecular hydrogen bonds (H atoms are omitted for clarity).

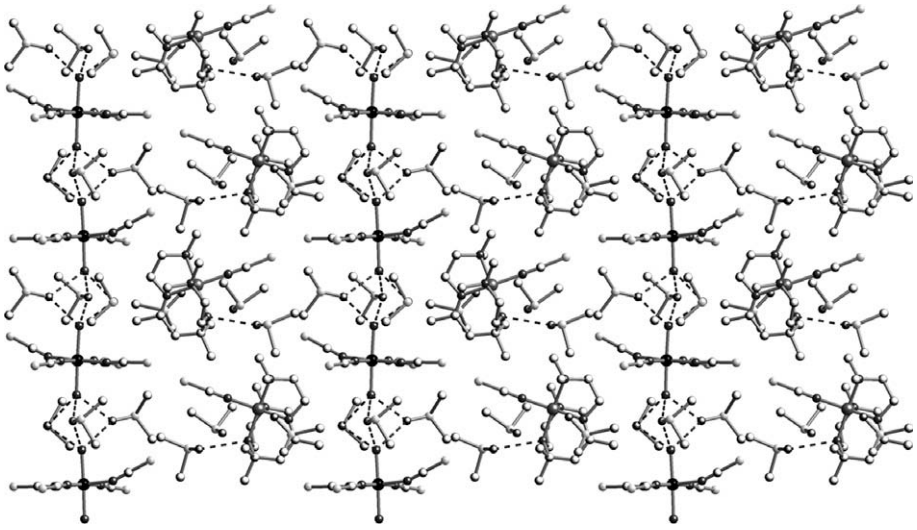

Fig. 6. The arrangement of anionic supramolecular chains, copper(II) cations and solvate molecules of **4** (the hydrogen atoms are omitted for clarity).

unchanged on lowering the temperature down to 77 K. The lack of anisotropy, typical for Cu(II) complexes, and g about 2 indicates that the EPR signal due to copper(II) is overlapped by that from the Cr(III) complex. The spectrum of **2** (295 K) also displays a broad line due to Cr(III), but a strong narrow line of rhombic type is distinctly seen; its simulation gave $g_1 = 2.164$, $g_2 = 2.109$ and $g_3 = 2.055$ which correspond to the Cu(II) complex, but are effective, not molecular.

A comparison of the EPR frozen solution spectra for the compounds dissolved in dmf (Fig. 8) reveals that the spectra of **1** and **2** are the same, but are different from those for **3** and **4**, which in turn are also very close. The following spin Hamiltonian parameters were obtained by computer simulation of the experimental spectra for compounds **1** and **2**: $g_{II} = 2.214$, $g_{\perp} = 2.048$, $A_{II} = 189 \times 10^{-4}\,cm^{-1}$, $A_{\perp} = 22 \times 10^{-4}\,cm^{-1}$ (which are typical for a 4 N donor set around the Cu(II) plane) and for compounds **3** and **4**: $g_z = 2.218$, $g_x = 2.064$, $g_y = 2.040$, $A_z = 178 \times 10^{-4}\,cm^{-1}$, $A_x = 45 \times 10^{-4}\,cm^{-1}$, $A_y = 15 \times 10^{-4}\,cm^{-1}$ (suggesting deviation from the in-plane coordination of the ligands). The tendency of the g and A tensors to change from axial to rhombic may be assign to an increase of axial symmetry distortion of the coordination geometry, indicated by crystal structure studies; for **1** this distortion is absent, for **2** it is very small, and for **3** and **4** it is apparently greater according to the trigonality index τ (see Section 3.2). The second-derivative spectrum for **3** shows in the high field region of the spectrum the resolution of ^{14}N hyperfine splitting of ~12 Gs due to the nitrogen nuclei of the ligands.

A careful inspection of the low field region (Fig. 9) of the frozen solution spectra, measured over a wide range of the magnetic field allows the detection, for all compounds, of a broad slightly resolved line with a dominant signal at $g = 3.86$ and with a relatively weaker signal at about 5.6. The computer simulation of this line,

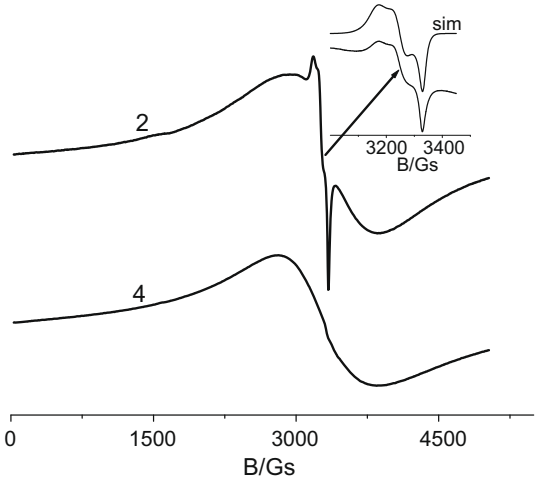

Fig. 7. The EPR spectra of polycrystalline compounds **2** and **4** at 77 K, with a magnified signal due to the Cu(II) centers simulated using the parameters giving in the text.

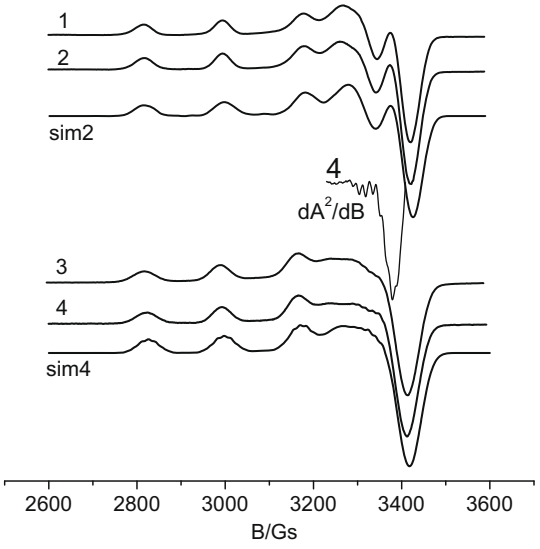

Fig. 8. The EPR spectra of frozen DMF solutions of Cu(II) complexes **1**–**4**, together with the corresponding spectra simulated (sim) for complexes **2** and **4** using the parameters given in the text, at 77 K. In the middle, the fragment of compound **4** spectrum as a second-derivative (in the same magnetic field scale) shows the hyperfine splitting (about 12 G) due to interaction with ^{14}N nuclei of the ligands.

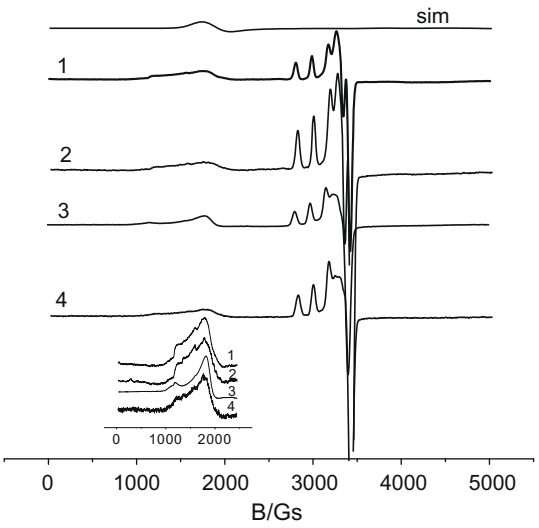

Fig. 9. The EPR spectra of DMF frozen solutions of compounds **1**–**4**, recorded in the magnetic field range of 5000 Gs, with magnified low field lines and with the spectrum simulated (sim) using $S = 3/2$, $D \sim 0.5$ cm^{-1}, $g_x = g_y = g_z = 1.97$.

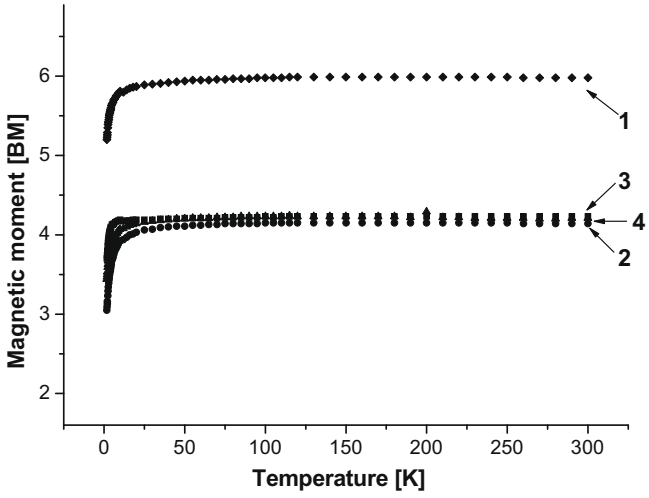

Fig. 10. Temperature dependences of the experimental effective magnetic moments for **1**–**4**.

performed using $S = 3/2$, gives D (the zero-field splitting parameter) of about 0.4 cm^{-1} and $g_x = g_y = g_z = 1.97$. The parameters are similar to those detected for other Cr(III) complexes with $D > h\nu$ [39,40] and suggest that the low field line corresponds to resonance transitions between the spin levels (split in zero magnetic field) of the Cr(III) center.

The results of the magnetic susceptibility measurements for **1**–**4** are plotted as the effective magnetic moment (μ_{eff}) versus temperature in Fig. 10. Compound **1** shows a room temperature magnetic moment of 5.9 μ_B, which is close to the expected one for the non-interaction of the Cu(II) ion and two Cr(III) ions, where the constituent metals have typical μ_{eff} spin-only values of 1.8 and 3.8 μ_B, respectively. Compounds **2**–**4**, with the same formula unit "CuCr", reveal room temperature magnetic moments of 4.14 (**2**), 4.23 (**3**) and 4.21 μ_B (**4**), respectively, in agreement with the expected value for non-interacting Cu(II) and Cr(III) ions. On lowering the temperature, the effective magnetic moments for **1**–**4** remain constant down to *ca.* 20 K and then decrease progressively to 5.26 (**1**), 3.13 (**2**), 3.78 (**3**) and 3.5 μ_B (**4**), respectively, at 2 K. These data indicate the paramagnetic behavior with the Curie–Weiss constants $\Theta = -0.64$ and $C = 4.49$ (**1**), $\Theta = -1.19$ and $C = 2.16$ (**2**), $\Theta = -0.49$ and $C = 2.24$ (**3**), $\Theta = -0.53$ K and $C = 2.23$ cm^3 mol^{-1} K (**4**).

4. Conclusion

Mild direct synthesis conditions, as well as commercially available and relatively simple precursors provide an easy and promising way of synthesizing new heterometallic complexes with primary amines and their Schiff-base derivatives. This research describes the synthesis and structural as well as magnetic characterization of four novel Cu(II)/Cr(III) complexes using a one-pot self-assembly from zerovalent copper, Reinecke's salt, NH_4NCS (in the case of **2** and **4**), acetone (in the case of **3** and **4**) and *N*,*N*-dimethylethylenediamine (dmen) in non-aqueous solvents in the

open air. It has been shown that the presence of acetone in the reaction mixture provides favorable conditions for metal-directed self-assembly condensation, yielding two novel open-chain Schiff-base ligands, dmenac and $dmen_2ac$.

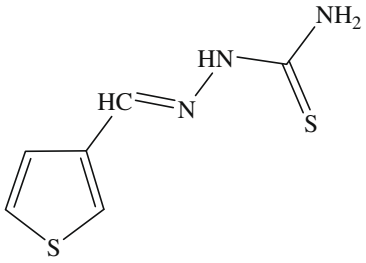

Fig. 1. Chemical structure of the ligand.

tions were estimated from Pascal's constants and magnetic data were corrected for diamagnetic contributions of the sample holder.

2.3. Crystal data collection and processing

Crystals of the ligand 3TTSCH and [Ni(3TTSC)$_2$] are monoclinic with the space group $P2_1/c$. The crystal and instrumental parameters used in the unit-cell determination and data collection are summarized in Table 1. X-ray single-crystal diffraction data were collected at 293 K on a STOE-IPDS diffractometer, equipped with a graphite monochromator using Mo Kα radiation (λ = 0.71073 Å) (CIMA, UMR CNRS 6200, Université d'Angers). The structures were solved by full-matrix least-squares techniques using the SHELX-97 package [15]. Positions of H-atoms were calculated geometrically and the distances N1–H1A and N1–H1B for [Ni(3TTSC)$_2$] were refined. Gaussian absorption corrections were applied.

2.4. Synthesis of the ligand 3TTSCH

The ligand was obtained from thiophene-3-carboxaldehyde and thiosemicarbazide (1:1 molar ratio) in absolute ethanol with the addition of two drops of sulfuric acid [16]. The mixture was refluxed for 1 h and then cooled, filtered and recrystallized from ethanol. Yellow single crystals suitable for X-ray analysis were grown at room temperature by slow evaporation of solution of the ligand in a mixture of ethanol (75%) and water (25%).

$w = 1/[\sigma^2(F_o^2) + (0.1414P)^2 + 0.00000P]$ where $P = (F_o^2 + 2F_c^2)/3$ for 3TTSCH.
$w = 1/[\sigma^2(F_o^2) + (0.0440P)^2 + 0.22020P]$ where $P = (F_o^2 + 2F_c^2)/3$ for [Ni(3TTSC)$_2$].

2.5. Preparation of the complexes

All the complexes were prepared starting from 5 mmol (1 g) of 3TTSCH dissolved in EtOH. An ethanolic solution of the metal halide was added slowly while stirring. The complexes were removed by filtration, washed with MeOH and finally dried in vacuum over silica gel.

2.5.1. Bis(3-thiophenaldehyde thiosemicarbazone) cobalt(II) [Co(3TTSC)$_2$]

$CoCl_2 \cdot 6H_2O$ (0.64 g; 2.5 mmol, 10 cm^3) or $CoBr_2$ (0.59 g; 2.5 mmol, 10 cm^3) was added to the 3TTSCH ethanolic solution (20 cm^3) under refluxing conditions. The reflux was maintained for 24 h. The resulting solution was concentrated and a dark-brown precipitate was filtered off.

2.5.2. Bis(3-thiophenaldehyde thiosemicarbazone) nickel(II) [Ni(3TTSC)$_2$]

$NiCl_2 \cdot 6H_2O$ (0.64 g; 2.5 mmol, 10 cm^3) or $NiBr_2 \cdot xH_2O$ (0.59 g; 2.5 mmol, 10 cm^3) was added to the ethanolic solution of 3TTSCH (20 cm^3) under refluxing conditions. An aqueous solution of sodium hydroxide was added dropwise to reach a pH value in the range 6–7 [17]. The reflux was maintained for 3 h.

2.5.3. Bis[chloro (3-thiophenaldehyde thiosemicarbazone) copper(II)] [CuCl(3TTSC)]$_2$

$CuCl_2 \cdot 2H_2O$ (0.91 g; 5 mmol, 10 cm^3) was added to 3TTSCH in EtOH (15 cm^3). Although the complex appeared instantaneously, the reflux was maintained for 1 h in order to complete the reaction. The same compound was obtained when operating at room temperature.

2.5.4. Dibromo (3-thiophenaldehyde thiosemicarbazone) copper(II) [CuBr$_2$(3TTSC)]

$CuBr_2$ (1.2 g; 5 mmol, 10 cm^3) was added to 3TTSCH in EtOH (15 cm^3) at room temperature. The complex appeared instantaneously, however, the reaction was maintained for 3 h.

2.5.5. Bis(bromo (3-thiophenaldehyde thiosemicarbazone) copper(II)) [CuBr(3TTSCH)]$_2$

$CuBr_2$ (1.2 g; 5 mmol, 10 cm^3) was added to 3TTSCH in EtOH (15 cm^3). Although the complex appeared instantaneously, the reflux was maintained for 2 h.

3. Results and discussion

3.1. Crystal structure of the ligand 3TTSCH

The main crystal parameters are reported in Table 1. The monoclinic unit cell (space group $P2_1/c$) contains twelve molecules in four groups of three independent molecules. The three independent molecules, with the numbering scheme, are given in Fig. 2. Each of the three independent molecules is quite planar and the most important deviations are observed for the thiosemicarbazone sulfur atoms as follows: S(1): 0.1838 Å, S(3): 0.1867 Å and S(5): 0.7895 Å. The first and the second molecules lie in quite parallel planes, while the third one is located in a plane forming angles of 54.17(6)° with the first molecule and 53.69(6) with the second one. The sulfur atom S(1) and the hydrazone nitrogen N(3) are in the E position with respect to the C(1)–N(2) bond, the same configuration is observed for S(3) and S(5) with respect to the C(7)–N(5) and C(13)–N(8) bonds, respectively. This configuration is often ob-

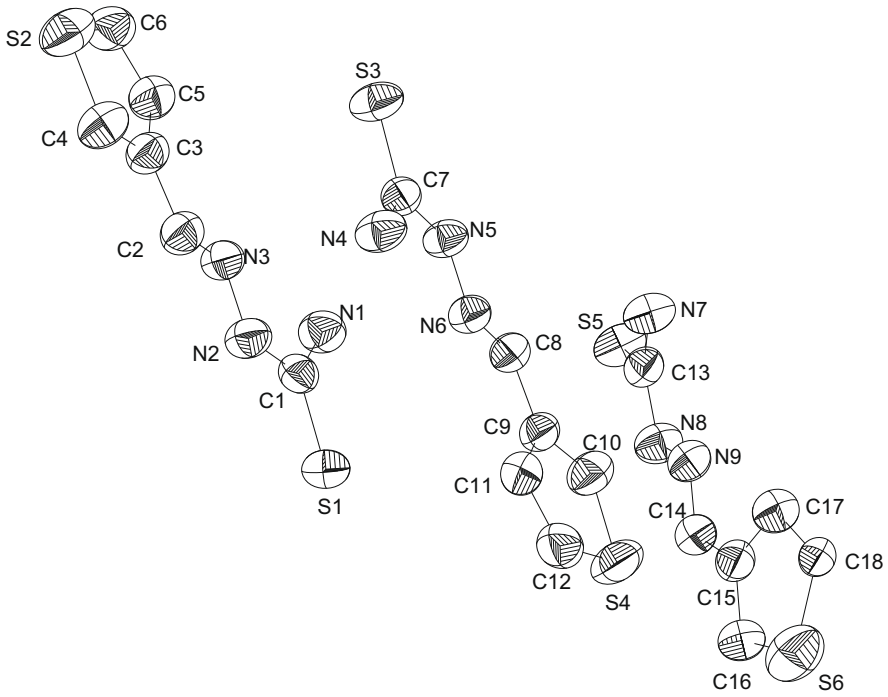

Fig. 2. ORTEP view (50% displacement ellipsoids) of the three independent molecules of the ligand with the numbering scheme.

served in thiosemicarbazones and its stability is due to the presence of an intramolecular hydrogen bond between the N-imino atom and H from NH_2 [5]. In the case of 3TTSCH, the distances N(3)–H, N(6)–H and N(9)–H are 2.358(2), 2.248(2) and 2.290(3) Å, respectively, and consequently these interactions are weak, but sufficient to stabilise the *E* configuration.

There are no significant differences for bond distances and angles in the thiosemicarbazone moiety between the three independent molecules. Representative bond distances and angles for the three independent molecules are shown in Table 2. The C–S bond lengths (1.683(3)–1.691(3) Å) and the dihedral angles around C(1), C(7) and C(13) are typical of a delocalised π electron system [10,18]. The bond length of the C(2)–N(3) bond is 1.268(4) Å, that of N(2)–N(3) is 1.389(4) Å, and these distances are typical of a C=N double bond and an N–N single bond, respectively, and similar values are observed for the two other independent molecules.

The packing arrangement in the unit cell is given in Fig. 3. The third independent molecules in parallel planes are located along the *c* edges and are common to two unit cells. The first and the second independent molecules are grouped in two rows between the planes of the third molecule. The packing of a group of independent molecules is governed by hydrogen bonds (Table 4). Their lengths are consistent with those observed in the case of the furanic analogue thiosemicarbazone [9,19].

Table 2
Selected bond lengths (Å) and angles (°) of the three independent molecules for the ligand 3TTSCH.

Bond lengths		Bond angles

C(13)–S(5)	1.691(3)	N(8)–C(13)–S(5)	119.1(2)
C(14)–N(9)	1.270(4)	N(9)–C(14)–C(15)	120.8(3)
N(8)–N(9)	1.371(4)	C(13)–N(8)–N(9)	119.9(3)

3.2. Crystal structure of the nickel complex [Ni(3TTSC)$_2$]

The main crystal parameters are reported in Table 1. The bond distances and angles for the thiosemicarbazone moiety are listed in Table 3 and the structure and the numbering scheme are given in Fig. 4. The centrosymmetric structure consists in the neutral complex species [Ni(3TTSC)$_2$], with the nickel at the centre of symmetry. The coordination results in a square-planar geometry involving the thiolato sulfur atoms and the N(3) nitrogen atoms in a *Z* configuration around the C(1)–N(2) bond (Fig. 4). As the ligand is deprotonated, the resulting negative charge is delocalized along the thiosemicarbazone moiety. Due to the free rotation around the C(2)–C(3) bond there are two possible configurations for the thiophene ring, with an almost 50% probability for each one. This phenomenon was not observed in the case of the furan analogue [10]. The complex molecule is quite planar, the highest deviations are due to the S(1) and N(2) atoms, with 0.5477 and −0.2654 Å deviations, respectively (Fig. 5).

The molecular arrangement inside the unit cell is given in Fig. 6. All the nickel ions are located at the midpoint of the *b* and *c* edges (Fig. 6a). The neutral molecules Ni(3TTSC)$_2$ lie in two sets of parallel planes (Fig. 6b) with a 60° angle between them. The packing is governed by hydrogen bonds between S(1) and H(1A), and N(2) and H(1B) (Table 4). Though these interactions are weak, they have already been observed and described for similar compounds [5].

3.3. Structures of the cobalt and copper complexes

3.3.1. Analytical data

The elemental analysis of the ligand and its complexes is summarized in Table 5. A good harmony between the experimental and

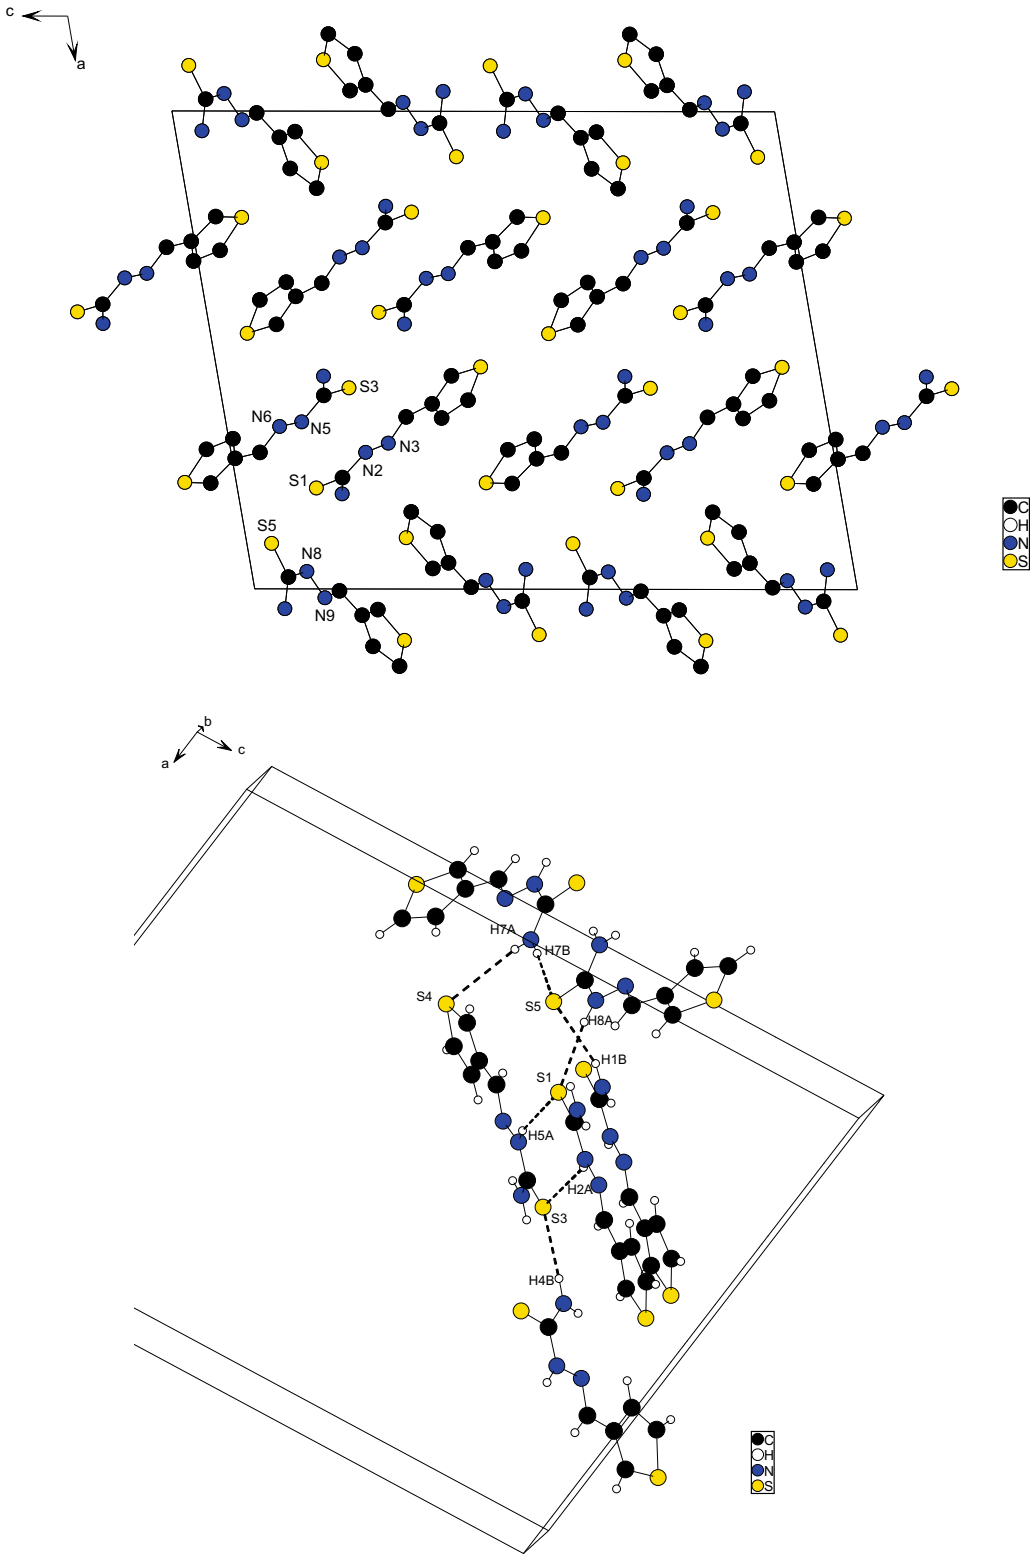

Fig. 3. Packing arrangement and intermolecular hydrogen bonds for the ligand.

calculated values is observed and the formulae of the complexes are $[Co(3TTSC)_2]$, $[Ni(3TTSC)_2]$, $[CuCl(3TTSC)]_2$, $[CuBr(3TTSC)]_2$ and $[CuBr_2(3TTSCH)]$.

The melting points were determined using DSC. In all complexes, decomposition follows the beginning of the melting process.

3.3.2. Infrared spectra

The main infrared vibration bands are reported in Table 6. In principle, since the ligand contains a thioamide –NH–C═S functional group, it can exhibit thione–thiol tautomerism [20]. The ν(S–H) band around 2570 cm^{-1} [21] is absent from IR spectra of the ligand but the ν(N–H) band at 3149 cm^{-1} is present, indicating

Table 3
Bond lengths (Å) and angles (°) for the nickel complex.

Table 4
Bond lengths (Å), angles (°) and positions of intermolecular hydrogen bonds for the ligand and the Ni(II) complex.

Compound	Hydrogen bonds	Distance (Å)	Angle (°)
3TTSCH	S(1)···H(5A)	2.63	160.2(2)
	S(1)···H(8A)	2.53	162.4(2)
	S(3)···H(2A)	2.55	145.5(2)
	S(3)···H(4B)	2.48	173.7(2)
	S(4)···H(7A)	3.00	144.1(2)
	S(5)···H(1B)	2.61	162.5(2)
	S(5)···H(7B)	2.53	172.5(2)
$[Ni(3TTSC)_2]$	S(1)···H(1A)	2.69	162(1)
	N(2)···H(1B)	2.64	127(1)

that in the solid state the ligand remains as the thione tautomer. The spectrum of the ligand exhibits a strong band at 1603 cm^{-1} due to the C=N stretching vibration.

In the case of the nickel complex, the $\nu(NH_2)$ vibration band is slightly shifted to lower wavenumbers, whereas ν(N–H) is shifted to higher values. The ring breathing remains quite unchanged when passing from ligands to complexes at *ca.* 830 cm^{-1} [22] and ν(C=N) is not significantly modified. There is no significant influence of complexation upon the two bands corresponding to ν(CS), situated at 1165 and 786 cm^{-1} in the ligand spectrum.

In addition, the spectrum of the nickel complex shows the two vibration bands, ν(M–S) and ν(M–N), at 519 and 420 cm^{-1}, respectively, which correspond to coordination bonds [23]. In the spectra of the other complexes, we find the same bands shifts as in the case of the nickel complex. The respiration band of the cycle at *c.a.* 830 cm^{-1} remained unchanged.

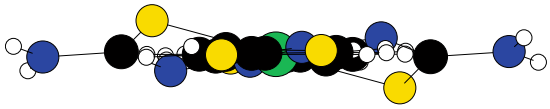

Fig. 5. Atoms deviation with respect to the plane of the molecule of $[Ni(3TTSC)_2]$.

The spectra of all the complexes show the presence of ν(M–S) and ν(M–N) bands, again like in the case of the nickel complex. Thus, in all the complexes the coordination occurs through the sulfur and the nitrogen atom of the imino moiety of the molecule. According to these results, the proposed structures for these new complexes are given in Fig. 6.

3.3.3. Structures of the complexes

The structures of the cobalt(II) and copper(II) complexes are given in Fig. 7. They were determined on the basis of the crystal structure of $[Ni(3FTSC)_2]$ and from their spectroscopic data. In all the species, the coordination occurs through the sulfur (thiosemicarbazone) atom and the N (imino) atom, as in all cases the vibration bands relative to these atoms are identically shifted (Table 5). In addition, the nickel complex was found to be a diamagnetic species.

The elemental analysis for the cobalt(II) complex shows unambiguously that the ligand acts as the deprotonated thiol tautomer. The χT value at 300 K is 0.5 $cm^3\ mol^{-1}$, corresponding to a low spin Co(II) complex and the magnetic moment is 2.13 B.M. This value, much lower than expected for Co(II) tetrahedral complexes, is typical of Co^{II} in a strongly distorted tetrahedral geometry, almost square-planar [24,25]. In addition, there no signal in the EPR spectrum, which is typical of low spin cobalt(II) species.

The two binuclear complexes $[CuX(3TTSC)]_2$ (X = Cl or Br) exhibit the same binuclear structure in which the copper(II) shows a square-planar geometry and bridging halogenides, as has already been reported for 3-furaldehyde thiosemicarbazone [10]. These complexes revealed antiferromagnteic coupling, as is usually observed in binuclear copper(II) complexes with bridging halides [26].

The mononuclear $[CuBr_2(3TTSC)]$ complex is a square-planar species and the copper is coordinated through the sulfur thione atom and the N-imino atom. In this case, the ligand remains protonated and remains as the thione tautomer, like in Ref. [10]. The

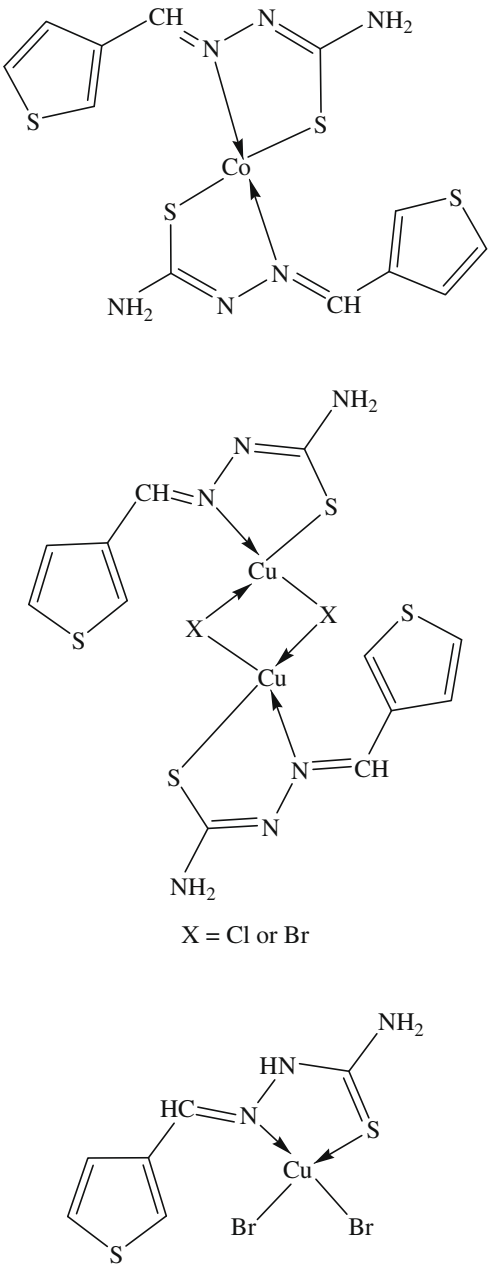

Fig. 7. Chemical structures of the cobalt(II) and copper(II) complexes.

EPR spectrum at room temperature showed typical signals corresponding to the Cu^{2+} ion.

These various structures for complex species have already been observed for other thiosemicarbazones [19,27].

Supplementary data

CCDC 710981 and 710982 contains the supplementary crystallographic data for this article. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgement

The authors wish to thank Eric Rivière, Research Engineer (Equipe Chimie Inorganique, ICMMO, Université Paris-Sud, Orsay, France), for SQUID measurements, EPR spectra recording and useful discussions about the structures of the complexes.

confirmed that $[UO_2Cl_4]^{2-}$ is the most stable chloro complex in [Bmim][Tf_2N] and [$MeBu_3N$][Tf_2N] [26]. The authors have also defined the coordination spheres of the different uranyl-chloro complexes in both ionic liquids and they have studied the influence of the ionic liquid cation on the uranyl solvation. Spectroscopic analysis by Nockemann et al. have also revealed a D_{4h} symmetry for $[UO_2Cl_4]^{2-}$ [27] in Tf_2N-based ionic liquids. Gaillard et al. have confirmed by EXAFS and molecular dynamics simulation that this tetrachloro complex of uranium is the most stable form in various ionic liquids, and they measured a U–Cl distance of 2.69 Å [28]. Few works are also reported on the electrochemical behaviour of uranyl-chloro complexes in both chloro [12] and non-chloroaluminate-based ILs [29,30].

Concerning the complexation of uranyl(VI) by bromide ions in ionic liquids, the electrochemical behaviour is described in a bromoaluminate-based solvent [31] and the luminescence of the tetrabromouranyl complex was recently reported in a pyrrolidinium ionic liquid [32]. However, the coordination of uranyl bromide complexes in ionic liquids has not been investigated so far. UV–Vis absorption spectra of uranyl tetrabromo complexes are only reported in solid state [33] and in anhydrous organic solvents [34], and several crystal structures of uranyl tetrabromo complexes are described [27,34,35].

Within the frame of our work on the fundamental data on uranium in the presence of halide ions in ionic liquids, it is essential to determine which species are present in solution. For that purpose, solid state structural techniques can be coupled with solution spectroscopies. X-ray diffraction allows obtaining information on the structure of crystallized products. However, the collected data do not systematically reflect the coordination environment of the complex in solution [36–38]. To circumvent this problem, UV–Vis and X-ray absorption spectroscopies appear as powerful complementary techniques, allowing to gain further insight into the coordination of the involved species and to determine whether the ligand arrangement of the solution species is preserved or not in the solid state. This is the motivation to study UO_2^{2+} with bromide anions by comparing the crystal structure and the coordination in solution.

In the present work, the coordination of the UO_2^{2+} ion by bromide ions in the ionic liquids [Bmim][Tf_2N] and [$MeBu_3N$][Tf_2N] has been studied by UV–Vis and EXAFS spectroscopies and compared to the crystal structure of $[Bmim]_2[UO_2Br_4]$.

2. Experimental

Yellow single crystals of $[Bmim]_2[UO_2Br_4]$ are obtained by slow evaporation, at room temperature, of an aqueous solution of [Bmim]Br and UO_2Br_2 in the stoechiometry 2:1. One drop of HBr is added to the solution to avoid hydrolysis of the uranyl compounds. X-ray intensity data were collected on a SMART 6000 diffractometer, equipped with a CCD detector, using Cu Kα radiation (λ = 1.54178 Å). The images were interpreted and integrated with the program SAINT from Bruker [39]. Both structures were solved by direct methods and refined by full-matrix least-squares on F^2 using the SHELXTL program package [40]. Non-hydrogen atoms were anisotropically refined and the hydrogen atoms in the riding mode with isotropic temperature factors were fixed at 1.2 times U_{eq} of the parent atoms (1.5 times for methyl groups).

The ionic liquids ([Bmim][Tf_2N] 99.9% and [$MeBu_3N$][Tf_2N] 99.9%) and the bromide salts ([Bmim]Br 98% and [$MeBu_3N$]Br 98%) were commercially available (Solvionic) and used without further purification. The uranyl salt $UO_2(OTf)_2$ (where OTf^- is the triflate anion $CF_3SO_3^-$) was synthesized according to the procedure described in Ref. [41]. Bromide stock solutions (0.3 M) were prepared in both ionic liquids and dried under reduced pressure (~5 mbar) at 70–80 °C during at least 24 h. Prior to addition of bromide salt, the bromide content in the ionic liquids is lower than 8×10^{-5} M. Uranyl stock solutions (0.02 M) were prepared by dissolving $UO_2(OTf)_2$ in both ionic liquids. The water concentration, measured by coulometric Karl–Fisher titration, was found equal to 125 ± 20 ppm in all solutions. The ionic liquids, the bromide salts and the uranyl salt were stocked in an argon-filled dry box and all the samples were prepared in this dry box at least 24 h before analysis.

The samples for UV–Vis absorption spectroscopy (1.2 mL) were either prepared from the above mother solutions or by dissolving a sample of $[Bmim]_2[UO_2Br_4]$ in the ionic liquid [Bmim][Tf_2N]. In all cases the uranyl concentration in the samples is 0.01 M. The absorption spectra were recorded with a Shimadzu UV-2501 PC spectrophotometer using 1 cm path length quartz cells sealed airtight by Teflon stoppers, at 25 °C in [Bmim][Tf_2N] and at 60 °C in [$MeBu_3N$][Tf_2N].

The EXAFS measurements were performed on 200 μL solutions of $UO_2(OTf)_2$ (0.02 M) in presence of four equivalents of [Bmim]Br and [$MeBu_3N$]Br in [Bmim][Tf_2N] and [$MeBu_3N$][Tf_2N], respectively. Uranium L_{III}-edge EXAFS spectra were collected at the Rossendorf Beamline [42] at the ESRF. The measurements were performed using a double crystal Si(1 1 1) monochromator in equidistant k-steps of 0.05 $Å^{-1}$ across the EXAFS region. Higher harmonics were rejected by two platinum-coated mirrors. The measurements were carried out at ambient temperature in transmission mode using argon-filled ionization chambers. For the energy calibration the first inflection point of an yttrium metal foil at 17038 eV was used. The uranium L_{III} threshold energy, $E_{k=0}$, was arbitrarily defined at 17185 eV. EXAFS data extraction and data fit were performed with the program EXAFSPAK [43]. Theoretical phase and amplitude functions were calculated with FEFF 8.2 [44] using the crystal structure of $[NH_4]_2[UO_2Br_4] \cdot 2H_2O$ [35]. The amplitude reduction factor, s_0^2, was defined as 0.9. The multiple scattering paths in the uranyl unit were included in the curve fit by constraining its Debye–Waller factor and its effective path length to twice the values of the corresponding $U–O_{ax}$ single-scattering path. The overall goodness of the fits, F, is given by χ^2 weighted by the magnitude of data.

3. Results and discussion

3.1. Crystal structure

The structure of $[Bmim]_2[UO_2Br_4]$ was determined by single crystal X-ray diffraction (Table 1). The crystal structure of $[Bmim]_2[UO_2Br_4]$ consists of $[Bmim]^+$ cations and $[UO_2Br_4]^{2-}$ anions (Fig. 1). The uranium atom is located on an inversion centre. The geometry of the uranium anion is a tetragonal bipyramid, with four Br^- anions in the equatorial plane perpendicular to the uranyl moiety.

The average U–Br and U–O distances are 2.823(3) and 1.765(6) Å, respectively (Table 2). The U–Br bond lengths are in good agreement with those previously reported [34,35]. In the packing of the crystal structure, which is displayed in Fig. 2, the butyl-methyl-imidazolium cations are arranged into layers parallel to (1 0 0), and the $[UO_2Br_4]^{2-}$ anions into rows along the [0 1 0] direction. Each $[UO_2Br_4]^{2-}$ anion is surrounded by four $[Bmim]^+$ cations, which form weak C–H···Br2 hydrogen bonds with distances ranging from 2.83 to 2.86 Å (C–Br distances range from 3.695(9) to 3.704(9) Å). The formation of such hydrogen bonding between anionic uranium species and $[Bmim]^+$ cations was already described in $[UCl_6]^{2-}$ and $[UO_2Cl_4]^{2-}$ [23,31].

3.2. UV–Vis absorption spectroscopy

The absorption spectrum of $[Bmim]_2[UO_2Br_4]$ dissolved in $[Bmim][Tf_2N]$, reported on Fig. 3, shows four main bands at 449.6, 464.2, 480.1 and 497.2 nm. This spectrum displays similarities with that of $[N(C_{10}H_{21})_4]_2[UO_2Br_4]$ measured in anhydrous benzene [34] and of $Cs_2[UO_2Br_4]$ in the solid state [33]. This observation suggests that $[UO_2Br_4]^{2-}$ would present the same symmetry in the ionic liquid as in organic solvents and in the solid state. The tetrabromo complex would thus present a D_{4h} symmetry, like the chloro analogue. Moreover, this spectrum also coincides with those obtained when four equivalents of [Bmim]Br are added to $UO_2(OTf)_2$ in $[Bmim][Tf_2N]$ (Fig. 3). This latter observation indicates that the triflate and Tf_2N^- ligands are easily displaced by bromide ions. An increase in bromide amount (up to 10 equivalents) does not lead to any change in the absorption spectra pattern, neither in the position of the peaks nor in their relative intensities, indicating that the $[UO_2Br_4]^{2-}$ entity is the most stable species in solution.

Similar results are observed in $[MeBu_3N][Tf_2N]$. An increase in $[MeBu_3N]Br$ concentration does not modify the absorption spectrum obtained when four equivalents of $[MeBu_3N]Br$ ions are added to $UO_2(OTf)_2$ in $[MeBu_3N][Tf_2N]$ (Fig. 4). In this ionic liquid the positions of the four characteristic bands are 449.8, 464.3, 479.9 and 497.1 nm. These results tend to demonstrate that, in both ionic liquids, the tetrabromo uranyl complex is the predominant species as soon as a stoichiometric quantity of bromide ions is added to $UO_2(OTf)_2$. Moreover, this complex would present the same D_{4h} symmetry in these media as in organic solvents and in the solid state. UV–Vis absorption spectra do not allow to observe any significant effect of the IL cation, neither on the formation nor on the structure of the tetrabromo uranyl complex. This was already observed in the case of the tetrachloro uranyl complex [25].

The absorption spectrum of $[UO_2Cl_4]^{2-}$ in $[Bmim][Tf_2N]$, described in Ref. [25], is also reported on Fig. 3. Compared to $[UO_2Cl_4]^{2-}$ in the same ionic liquid, the absorption bands of the tetrabromo uranium complex are shifted to longer wavelengths and the intense charge-transfer band due to the bromide ions is observed at higher wavelength than in the case of chloride ions. Moreover, the discrete transitions in the spectrum of the uranyl bromide solution show a larger peak width and a higher molar extinction coefficient (ε) compared with the spectrum of $[UO_2Cl_4]^{2-}$. Due to the interference with the intense charge-transfer band, the UV–Vis absorption spectra of uranyl bromide are difficult to analyze and only a conclusion based on comparison has been drawn. In the uranyl chloride system, it has been observed that the intermediate species show higher extinction coefficients than the limiting species $[UO_2Cl_4]^{2-}$, which is related with a lower complex symmetry [38,45]. To this point of discussion, the possibility of a contribution of lower symmetry uranyl bromide complexes cannot be totally excluded. Furthermore, the remaining water molecules present in the ionic liquids, which are known to be hygroscopic, may coordinate to the UO_2^{2+} ions. Indeed, in the present work, the water concentration in $[Bmim][Tf_2N]$ and in $[MeBu_3N][Tf_2N]$ is 10^{-2} M, which is the same as the concentration of uranium in the samples. The coordinative interaction between uranyl and water may result in an increasing acidity of the water protons, which may lead subsequently to a deprotonation and to the formation of hydrolysis products. The hydrolysis products of UO_2^{2+} show broad featureless absorption bands with high extinc-

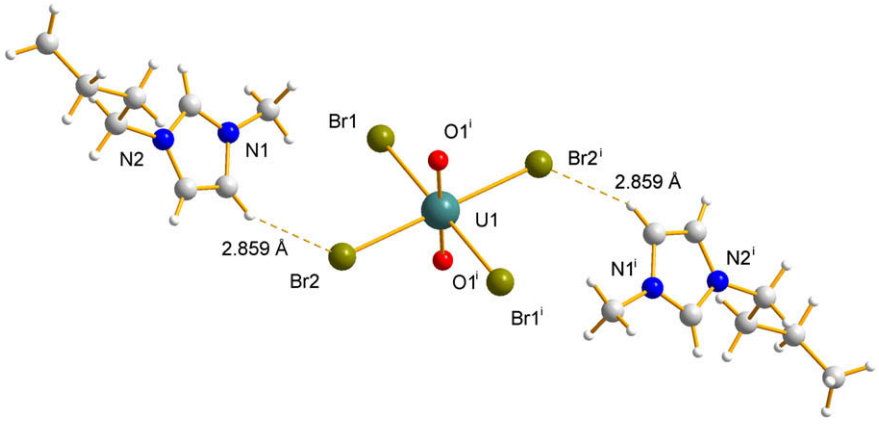

Fig. 1. Part of the crystal structure of $[Bmim]_2[UO_2Br_4]$, showing the $[UO_2Br_4]^{2-}$ anion forming weak hydrogen bonds with the surrounding $[Bmim]^+$ cations (symmetry codes: (i) $1-x,2-y,-z$).

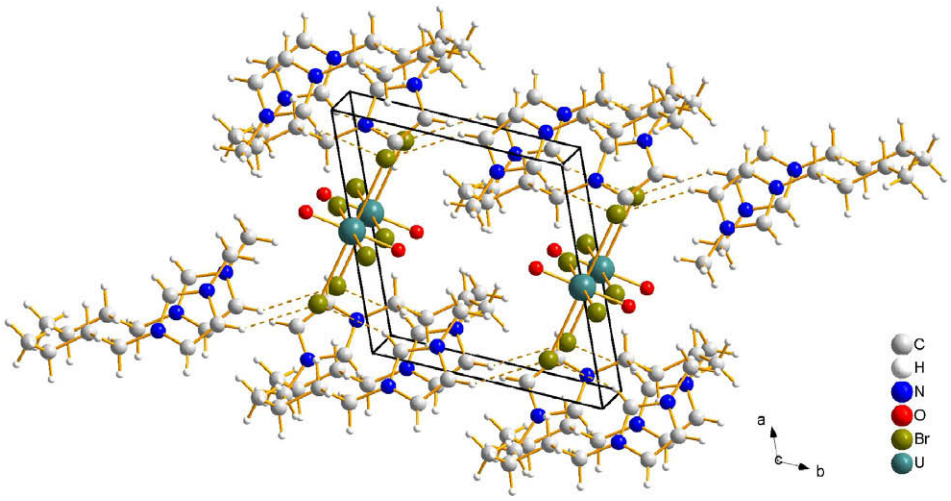

Fig. 2. Packing diagram of the crystal structure of $[Bmim]_2[UO_2Br_4]$, viewed along the *c*-axis.

tion coefficients [27,46]. Contribution of such species may interfere with the charge-transfer band from bromide ligands, and may contribute to explain the enhanced ε coefficient. The UV–Vis spectra do not allow to exclude this possibility. In order to clarify the UO_2^{2+} coordinating environment in more detail EXAFS measurements were performed.

3.3. EXAFS spectroscopy

EXAFS is used to investigate the first coordination sphere of the uranyl(VI) complex and to measure the uranium interatomic distances. Bromide ions are the main coordinating ligands, but beside the solvent, the residual water contained in the ionic liquid may also act as a ligand. Therefore, as discussed previously, the possibility of a participation of oxygen from water in the coordination of U(VI) bromide complex has to be considered. EXAFS spectroscopy suffers from the relative large error for the determination of the coordination number *N*, which is in the range of 15% of the estimated value. A better indicator is therefore often provided by the bond lengths in the first coordination shell, which can be determined within a confidence range of ±0.01 Å, and which are strongly correlated with the coordination number by the bond valence relationship [47].

The crystal structure data show the formation of the tetracoordinate uranyl dianion $[UO_2Br_4]^{2-}$, with the four bromide ions lying in the equatorial plane (equatorial coordination number *N* of 4). In this arrangement, the U–Br distances are usually in the range of 2.80–2.83 Å [48]. Pentacoordinate uranyl complexes are well known; compounds with five identical equatorial ligands are much more scarce but have been reported in $[UO_2(CN)_5]^{3-}$ [49] and $[UO_2(NCS)_5]^{3-}$ [50] for example. The derivative $[UO_2Br_5]^{3-}$ has not been observed up to now in crystal structures, but bromo uranyl complexes with a mixed coordination number $N_{Oeq} + N_{Br}$ of 5 have been reported such as $[UO_2Br_2(OH_2)_3]$ (see Scheme 1) [51].

With the exception of $[UO_2Br_2(THF)_3]$, where the mean U–Br distance is close to 2.85 Å [52], the U–Br distances in pentacoordinate uranyl compounds are notably longer, and are in the range of 2.90–2.91 Å in $[UO_2Br_2(OH_2)_3]$ [51]. The increasing of the U–Cl

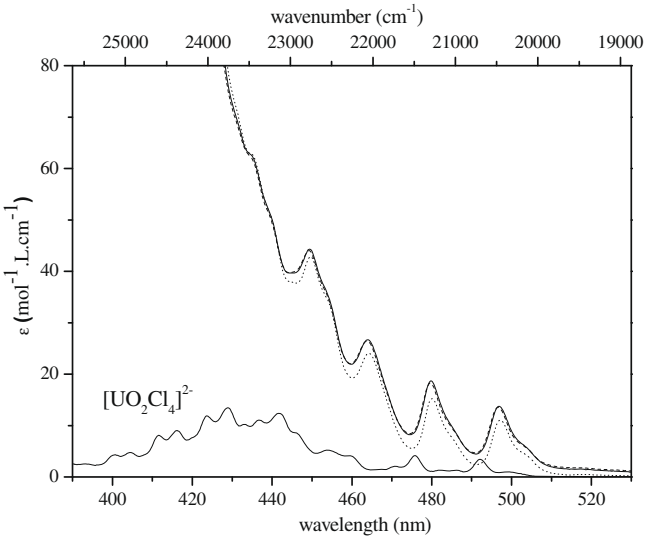

Fig. 3. Absorption spectra of 0.01 M $[Bmim]_2[UO_2Br_4]$ (dotted line) and 0.01 M $UO_2(OTf)_2$ with four (solid line) and seven (dashed line) equivalents of [Bmim]Br in $[Bmim][Tf_2N]$ at 25 °C. The absorption spectra of $UO_2(OTf)_2$ (0.01 M) with four equivalents of [Bmim]Cl in $[Bmim][Tf_2N]$ at 25 °C is added for comparison (Ref. [25]).

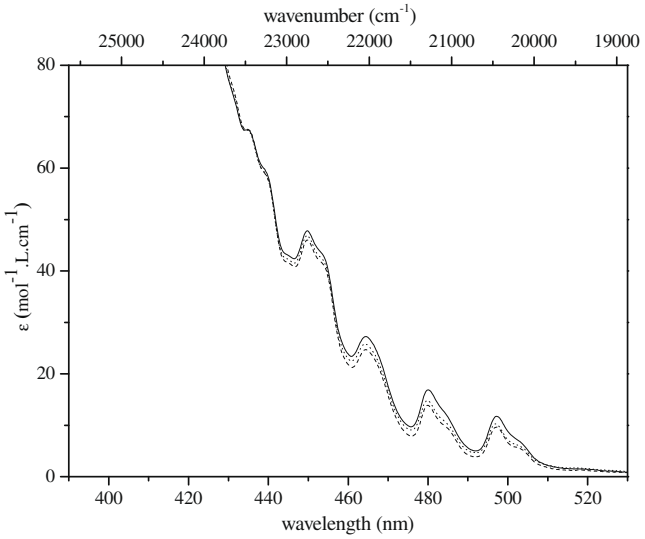

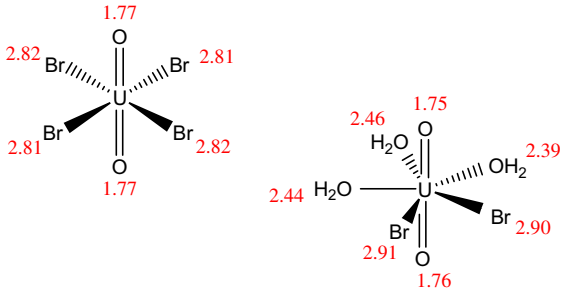

Fig. 4. Absorption spectra of 0.01 M $UO_2(OTf)_2$ with four (solid line), six (dotted line) and 15 (dashed line) equivalents of $[MeBu_3N]Br$ in $[MeBu_3N][Tf_2N]$ at 60 °C.

Scheme 1. References of cluster $[UO_2Br_4]^{2-}$ taken from Ref. [35] and $[UO_2Br_2(OH_2)_3]$ taken from Ref. [51]. The numbers indicate the bond lengths to uranium.

bond length with increasing of the equatorial coordination number can also be illustrated in some aquo-chloro uranyl(VI) compounds. Indeed, the tetracoordinate complex $[UO_2Cl_4]^{2-}$ shows a U–Cl distance of 2.68 Å [53], whereas the U–Cl bond length of several intermediate pentacoordinate species with a mixed equatorial coordination (e.g. $UO_2(H_2O)_4Cl^+$, $UO_2(H_2O)_3Cl_2^0$ and $UO_2(H_2O)_2Cl_3^-$) reaches 2.71–2.74 Å [54]. The lengthening of the U–Br bonds in U(VI) aquo-bromo complexes is in the order of ~0.05–0.1 Å, which is greater than the lengthening occurring in uranyl chloride compounds. This may result from the larger size of the bromide ion. These distance differences are beyond the error limit for distance determination in EXAFS, which is a prerequisite to extract the coordination of U(VI) bromide in [Bmim][Tf_2N] and [$MeBu_3N$][Tf_2N]. The k^3-weighted U L_{III}-edge EXAFS spectra obtained for the 0.02 M $[UO_2Br_4]^{2-}$ solutions in [Bmim][Tf_2N] and [$MeBu_3N$][Tf_2N] at room temperature are shown in Fig. 5.

In both ionic liquids, the first peak of the Fourier transform, also displayed on Fig. 5 in the k range of 4.2–16.2 $Å^{-1}$, corresponds with the two axial oxygen atoms in a U–O distance of 1.77 Å. The second shell indicates bromine atoms in a U–Br distance of 2.82 Å in [Bmim][Tf_2N] and 2.83 Å in [$MeBu_3N$][Tf_2N] (Table 3). These distances are in a good agreement with a fourfold Br coordination, although the determined equatorial coordination numbers are slightly higher than 4. An inclusion of solvent or water molecules does not improve the fit procedure. Therefore, we can conclude from EXAFS spectroscopy that the $[UO_2Br_4]^{2-}$ coordination polyhedron is maintained in [Bmim][Tf_2N] and [$MeBu_3N$][Tf_2N] without any other ligand in the coordination shell. From these results, the ionic liquid cation seems to have no influence on the coordination sphere of the tetrabromo uranyl complex and on the U–Br and U–O distances. Moreover, we can conclude that the crystal structure of $[Bmim]_2[UO_2Br_4]$ can serve in the presented case as a good model for the uranyl bromide coordination in the ionic liquid. Because the hydrogen bonds between Br and $[Bmim]^+$ have only a weak influence on the U–Br distance in the crystal structure, we are not able to draw a conclusion whether they also exist in the liquid sample.

Table 3
EXAFS fit parameters of $[UO_2Br_4]^{2-}$ (0.02 M) in [Bmim][Tf_2N] and [$MeBu_3N$][Tf_2N].

Sample	Scattering path	R (Å)	N	σ^2 (Å^2)	$\Delta E_{k=0}$	F
$[UO_2Br_4]^{2-}$ in [Bmim][Tf_2N]	U–O_{ax}	1.766(2)	2.0(1)	0.0015(3)	−2.6	0.24
	U–Br	2.821(2)	4.4(2)	0.0051(2)		
$[UO_2Br_4]^{2-}$ in [$MeBu_3N$][Tf_2N]	U–O_{ax}	1.768(2)	1.9(1)	0.0013(3)	−1.8	0.24
	U–Br	2.827(2)	4.2(2)	0.0047(2)		

Standard deviations are given in bracket. The threshold energy, $E_{k=0}$, was arbitrarily defined at 17185 eV and varied as a global fit parameter resulting in the energy shift $\Delta E_{k=0}$.

4. Concluding remarks

In the solid state, the $[Bmim]_2[UO_2Br_4]$ complex consists of a tetragonal bipyramid. The average U–Br and U–O distances are 2.823(3) and 1.765(6) Å, respectively. Single crystal XRD also reveals the presence of H-bonding between $[UO_2Br_4]^{2-}$ anions and $[Bmim]^+$ cations.
