ε – molar absorption coefficient [$dm^3\ mol^{-1}\ cm^{-1}$]; f – oscillator strength; H – highest occupied molecular orbital; and L – lowest unoccupied molecular orbital.

UV–vis spectrum was calculated to ~270 nm. Thus the shortest wavelength experimental band of **2** is not assigned to the calculated transitions; some intraligand and interligand transitions are expected to be found at higher energies in the calculations for **2**.

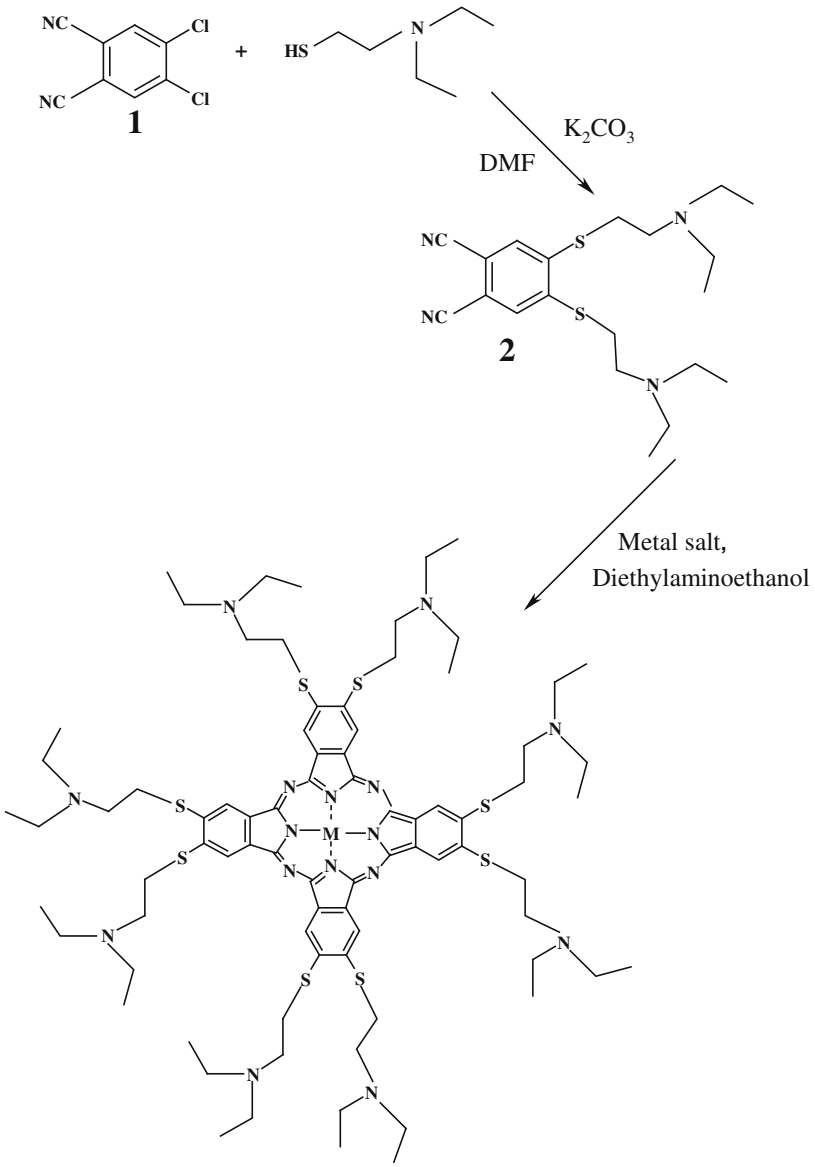
3.9. [$ReOBr_3$(dpk-OH)]

The two longest wavelength experimental bands of **3** originate in the HOMO−LUMO and HOMO−LUMO+1 transitions, respectively. As can be seen from the Fig. 7, the LUMO and LUMO+1 orbitals are mainly formed from rhenium *d* atomic orbitals, the HOMO orbital is delocalized among rhenium ion and bromide orbitals. Accordingly, the transitions assigned to the experimental bands at 794.1 and 623.6 nm can be seen as mixed bromide → Re (*Ligand-Metal Charge Transfer*; *LMCT*) and d → d (*Ligand Field; LF*) transitions.

The experimental absorption band at 367.4 nm can be assigned to *Ligand-Metal Charge Transfer* transitions occurring from the bromide, oxo, and dpk-OH ligands to *d* rhenium orbitals.

The absorption bands at 278.1 and 204.0 nm result mainly from *Ligand-Ligand Charge Transfer* and interligand (*IL*) transitions, but participation of *Ligand-Metal Charge Transfer* into this band is also confirmed by the calculations.

Supplementary data



CCDC 731661, 731662 and 731663 contain the supplementary crystallographic data for $C_{29}H_{23}Cl_3N_2OPRe$, $C_{29}H_{23}Cl_3N_2O_2PRe$ and $C_{33}H_{27}Br_4N_6O_5Re$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Center, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Synthetic pathway for octakis-(2-diethylaminoethanethiol)-phthalocyanine. **M** = MnAc (**3**), Ni (**4**), Fe (**5**) and Co (**6**) [4].

The synthesis of cobalt octakis-(2-diethylaminoethanethiol)-phthalocyanine (**6**) has been reported before [4].

2.2. Electrochemical studies

All electrochemical experiments were performed using Autolab potentiostat PGSTAT 302 (Eco Chemie, Utrecht, The Netherlands) driven by the general purpose Electrochemical System data processing software (GPES, software version 4.9). Square wave voltammetric analysis was carried out at a frequency of 10 Hz, amplitude; 50 mV and step potential; 5 mV. A conventional three-electrode system was used. The working electrode was a bare glassy carbon electrode (GCE), Ag|AgCl wire and platinum wire were used as the pseudo reference and auxiliary electrodes respectively. The potential response of the Ag|AgCl pseudo-reference electrode was less than the Ag|AgCl (3 M KCl) by 0.015 ± 0.003 V. Prior to use, the working electrode surface was polished with alumina on a Buehler felt pad and rinsed with excess millipore water. All electrochemical experiments were performed in freshly distilled dry DMF or DCM containing $TBABF_4$ as supporting electrolyte.

Spectroelectrochemical data were obtained using a home-made optically transparent thin-layer electrochemical (OTTLE) cell which was connected to a Bioanalytical Systems (BAS) CV 27 voltammograph.

2.3. Equipment

UV/Vis spectra were recorded on Cary 500 UV/Vis/NIR spectrophotometer. IR (KBr disks) was recorded on Bruker Vertex 70-Ram II spectrophotometer. Elemental analysis was performed using Vario Elementar Microcube EL111. ^{1}H nuclear magnetic resonance (^{1}H NMR, 400 MHz) was obtained in $CDCl_3$ using Bruker EMX 400 NMR spectrometer.

2.4. Synthesis

2.4.1. 1,2-Bis-(diethylaminoethanethiol)-4, 5-dicyanobenzene (*2*)

1,2-Dichloro-4,5-dicyanobenzene (**1**) was synthesised according to reported procedures [17]. 1,2-Bis-(2-diethylaminoethanethiol)-4,5-dicyanobenzene (**2**) was also synthesised according to literature procedure [4], with slight modification as follows:

compound **1** (2.32 g, 11.75 mmol) was dissolved in anhydrous DMF (100 ml) under nitrogen and 2-diethylaminoethanethiol hydrochloride (6 g, 35.34 mmol) was added. After stirring for 10 min, finely ground anhydrous K_2CO_3 (19.5 g, 141.36 mmol) was added in portions over 2 h with stirring. The reaction mixture was stirred at room temperature for 48 h under nitrogen. Then the solution was poured into ice water (600 g). The precipitate was filtered off, washed with water, until the filtrate was neutral. The product was then dried in air. Yield: 3.61 g (80%). IR (KBr) υ_{max}/cm^{-1}: 3075, 2970–2812, 2229, 1562, 1459, 1382, 1343, 1275, 1200, 1113, 1066, 991, 733, 529. ^1H NMR ($CDCl_3$) δ = 7.54 (s, 2H,Ar–H), 3.12–3.08 (t, 4H, SCH_2), 2.80–2.77 (t, 4H, NCH_2), 2.61–2.55 (qnt, 8H, CH_2C), 1.05–1.01 (t, 12H, CH_3) ppm.

*2.4.2. Manganese(III)acetate (**3**), nickel (**4**) and iron (**5**) octakis-(2-diethylaminoethanethiol)-phthalocyanine*

Manganese(III)acetate (**3**), nickel (**4**) and iron (**5**) octakis-(2-diethylaminoethanethiol)-phthalocyanine were synthesised according to the procedure recently reported [3,4] with some modifications. A mixture of compound **2** (0.6 g, 1.54 mmol), manganese acetate (0.066 g, 0.38 mmol) or nickel(II) chloride (0.049 g, 0.38 mmol) or iron(II) chloride (0.049 g, 0.38 mmol) and 2-(dimethylaminoethanol) (1.2 ml) was refluxed for 12 h under nitrogen. After cooling to room temperature, the mixture was treated with excess MeOH: H_2O (1:1 ml) in order to precipitate the products. The products were filtered and dried in air. The products were then purified using column chromatography with neutral alumina as column material and DCM/methanol (20:1) as eluent.

*2.4.2.1. Complex **3**.* Yield: 0.54 g (86.72%) (*Anal.* Calc. for $C_{80}H_{120}N_{16}S_8MnOAc{\cdot}CH_2Cl_2$: C, 58.51; H, 7.34; N, 13.16. Found: C, 57.11; H, 6.72; N, 12.63%); UV–Vis (THF): λ_{max} (nm) (log ε): 353(4.6), 423(4.5), 465(4.5), 503(4.4), 676(4.3), 750(5.0); IR (KBr) υ_{max}/cm^{-1}; 2966–2805 (CH_2), 1413, 1377, 1327, 1070, 781, 744, 705, 606.

3. Results and discussion

3.1. Synthesis and characterization

3.1.1. Synthesis

Scheme 1 shows the synthetic route involved in the formation of complexes **3**, **4** and **5**. The phthalonitrile, compound **2**, was obtained via a based-catalyzed (K_2CO_3) nucleophilic aromatic substitution reaction, with the 2-diethylaminoethanethiol acting as the nucleophile. Cyclotetramerization of compound **2** to form the corresponding MPc occurred in the presence of the desired metal salt; $Mn(CH_3COO)_2$, $NiCl_2$ and $FeCl_2$ for complexes **3**, **4** and **5**, respectively. Purification of these complexes was achieved by column chromatography on alumina. Complex **3** was soluble in solvents such as THF, DCM and DMF while complex **4** dissolved in THF and DCM. Complex **5** was soluble in DMF and DCM but insoluble in THF.

These complexes were characterized by IR and UV–Vis spectroscopies as well as elemental analysis. The results obtained were consistent with the predicted structures shown in Scheme 1. The formation of complexes **3**, **4** and **5** was confirmed by the disappearance of the sharp C≡N vibration at 2229 cm^{-1} of **2**.

3.1.2. Spectroscopic characterization

All the complexes exhibited spectral properties characteristic of metallophthalocyanine (MPc). Complex **3** showed characteristic Q-band absorption, in THF, at 750 nm, Fig. 1. The absorption in the 450 nm region is usually associated with charge transfer in MnPc [10]. Complex **4** showed considerable aggregation in THF, with the peak at 694 nm attributed to the monomer while that at 633 nm is due to the aggregate, Fig. 1. Extensive aggregation of NiPc derivatives has been observed before [18]. Fig. 1 shows that the Q-band due to complex **3** is appreciably red-shifted compared to complex **4**. This observation is characteristic of MnPc complexes [10].

Fig. 2a shows the effect of increasing concentration (3.3×10^{-6}–8.8×10^{-6} M) on the spectra of complex **3**. Inset in Fig. 2a is a linear plot of absorbance, due to the Q-band (750 nm), against concentration of complex **3**. There was no evidence of aggregation in Fig. 2a and Beer's law was obeyed for concentrations less than 1×10^{-5}. Fig. 2b shows the effect of changing concentration (1.7×10^{-6}–1.02×10^{-5}M) on the spectra of complex **4**. The intensities of both the monomeric (694 nm) and dimeric peaks (633 nm) decreased with decreasing concentration. The Q-band due to the aggregate became less pronounced, compared to that due to the monomer, as concentration decreased, thus confirming the aggregated nature of the complex. Inset in Fig. 2b is the plot of absorbance, due to the Q-band at 694 nm, versus concentration. Even though the plot is almost linear at these concentrations, the UV–Vis spectra do give evidence of aggregation.

Complex **5** (not soluble in THF) exhibited spectra (Fig. 2c) characteristic of stacked monomer in FePc complexes, which is normally observed at about 630 nm in DMF [19]. The UV/visible spectral analysis of FePc complexes has been a subject of extensive research due to the complexity and the wide variety of species that may be formed in solution. For example, perchlorinated iron(II) phthalocyanine dissolved in DMF is known [20] to react with oxygen, resulting in oxidation and formation of a μ-oxo species, $Pc^{-2}Fe^{III}–O–Fe^{III}Pc^{-2}$, which changes back to the original monomeric species upon reduction. In the present study, Fig. 2c, the spectra were obtained in freshly prepared DMF solutions which had been de-aerated, suggesting that the peak near 630 nm is

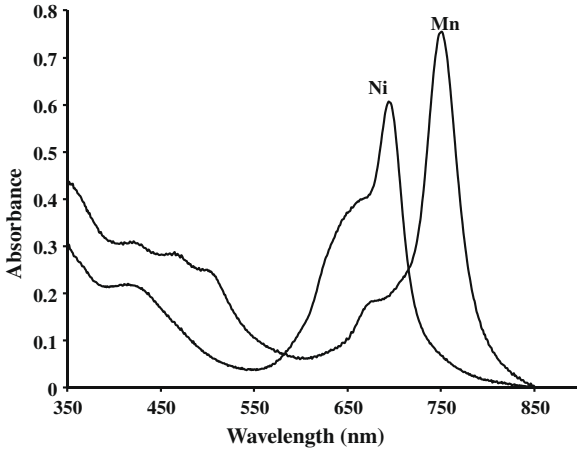

Fig. 1. UV–Vis spectra of 6.7×10^{-6} M of complex **3** (Mn) and complex **4** (Ni) in THF.

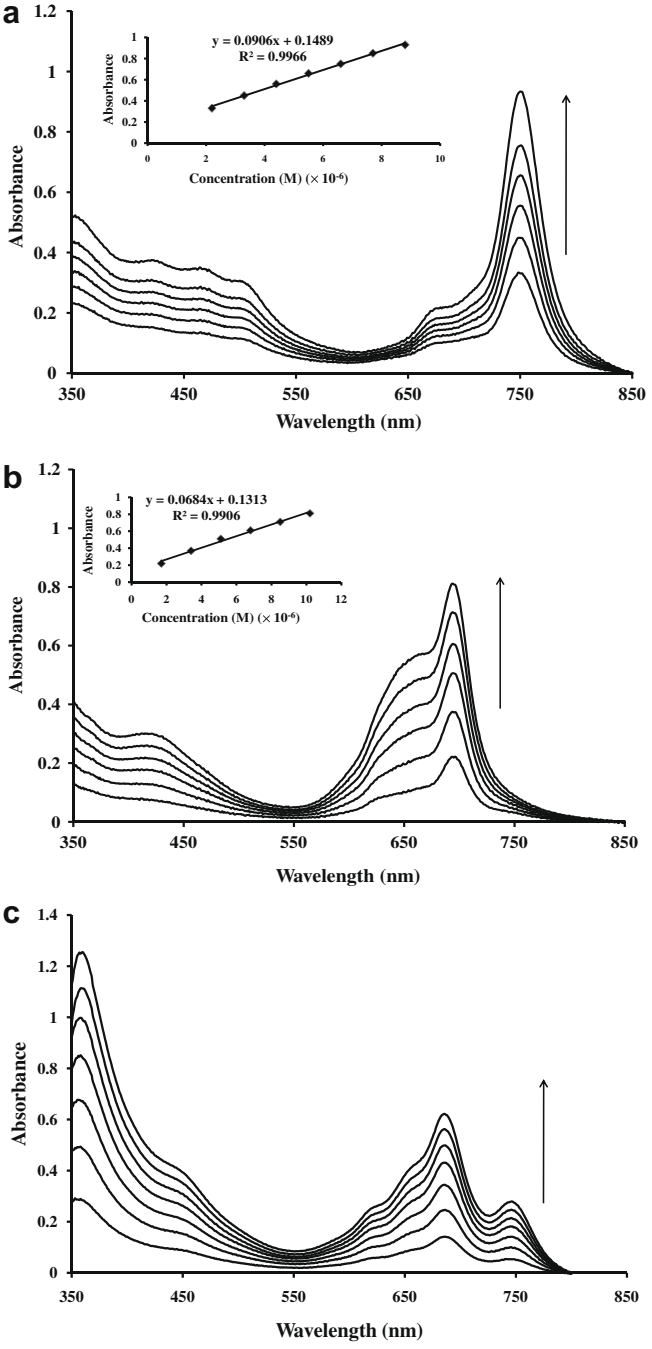

Fig. 2. Effect of changing concentration on the UV–Vis spectra of (a) complex **3** (3.3–8.8 × 10^{-6} M) in THF; (b) complex **4** (1.7 × 10^{-6}–1.02 × 10^{-5} M) in THF and (c) complex **5** (7.42 × 10^{-6}–5.2 × 10^{-5} M) in DMF.

not related to the μ-oxo species, but only to the presence of monomeric species as well as cofacially aggregated one. On dilution (5.2 × 10^{-5} M–7.42 × 10^{-6}), the peak near 630 nm decreased faster than the main peak at 686 nm. Aggregation (the presence of the band near 630 nm) was evident, even at concentration as low as 7.42 × 10^{-6} M, Fig. 2c. The split in the main Q-band suggests the presence of $Fe^{III}Pc$ species [10].

3.1.3. Voltammetric and spectroelectrochemical characterization

Voltammetric properties of complexes **3**, **4**, **5** and **6** are reported in this work. The peak potentials for the complexes are summarized in Table 1. In the current work, clearly defined reversible ring reductions were observed for all the complexes, but the reduction products get easily adsorbed on the electrode and the complexes degrade fast upon oxidation, especially the FePc derivative.

3.1.3.1. Complex **3**. Fig. 3 shows the cyclic and square wave (inset) voltammetry profiles of ~1 × 10^{-3} M of complex **3** in freshly distilled dimethyl formamide (DMF) containing 0.1 M $TBABF_4$ as supporting electrolyte. Three distinct processes, labeled **I**, **II** and **III**, can be identified. Redox couples **II** ($E_{1/2}$ = −0.12 V) and **III** ($E_{1/2}$ = −0.82 V) versus Ag|AgCl, have both anodic and cathodic components but with larger peak separation, ΔE (120 mV), than the expected 60 mV, thus suggesting slow electron transfer. These processes were quasi-reversible since ΔE value for ferrocene, at the same scan rate (100 mV versus Ag|AgCl), was 91 mV versus Ag|AgCl. The cathodic to anodic peak current ratio were near unity for both processes. Plots of peak current (I_p) versus square root of scan rate ($v^{1/2}$) (not shown) were linear for both processes, thus suggesting diffusion control. Redox couple **II** is assigned to $Mn^{III}Pc^{-2}/Mn^{II}Pc^{-2}$ while couple **III** is assigned to $Mn^{II}Pc^{-2}/Mn^{II}Pc^{-3}$ in comparison with literature [21], Table 1. Process **I** is irreversible (E_p = +0.78 V versus Ag|AgCl), it is assigned to ring oxidation, $Mn^{III}Pc^{-1}/Mn^{III}Pc^{-2}$ in comparison with literature, Table 1, [21]. The lack of reversibility of the oxidation processes is typical of thio substituted MPc complexes [14]. The redox processes and the number of electron transferred in each case were confirmed using spectroelectrochemical studies.

Spectroelectrochemical studies were carried out using optically transparent thin-layer electrode (OTTLE) cell. Fig. 4a shows the spectral changes observed on the application of potential of couple **II** (−0.12 V versus Ag|AgCl). The initial spectrum showed very pronounced peak at 653 nm with the main Q-band at 757 nm. The slight shift in the Q-band from 750 nm (Fig. 1) to 757 nm (Fig. 4a) is due to differences in solvents and the presence of electrolyte. The peak at 653 nm is characteristic of MnPc μ-oxo complexes [22]. This species is observed in DMF (Fig. 4a) but was not observed in THF (Fig. 1). The peak at 757 nm is due to $Mn^{III}Pc$ species. There is no $Mn^{II}Pc$ species before reduction. We used DMF for electrochemistry of complex **3** for comparative purposes with the other complexes under discussion in this work.

The presence of the μ-oxo MnPc species was confirmed by monitoring the spectral transformations of complex **3** in DMF solution when not de-aerated and when de-aerated with dry N_2 gas. This was evident by the decrease of the peak at 653 nm on bubbling nitrogen. However attempts to exclude oxygen completely during spectroelectrochemical studies were unsuccessful. The cyclic and square wave voltammograms reported above (Fig. 3) were reported under an atmosphere of nitrogen hence are due to mainly the $Mn^{III}Pc$ species.

Upon reduction at potentials of processes **II**, there was a blue shift in the Q-band from 757 to 705 nm and the color of the complex changed from purple to green, a gradual disappearance of the charge transfer bands in the 500 nm region was also noticed, with an isobestic point at 736 nm. The isobestic point observed was not so clear, which suggests the presence of more than two species, thus confirming the presence of the μ-oxo complex with the starting $Mn^{III}Pc^{-2}$ species and the electro-generated species, $Mn^{II}Pc^{-2}$. The formation of the latter was accompanied by the formation of more μ-oxo MnPc species. The persistence of μ-oxo MnPc species has been observed for some MnPc complexes [23].

A shift in the position of the Q-band without a decrease in intensity is typical of metal-based electro reduction process, and a blue shift in the Q-band is usually associated with the reduction of $Mn^{III}Pc^{-2}$ to $Mn^{II}Pc^{-2}$ [10]. These spectra changes thus confirmed that redox couple **II** in Fig. 3 is due to the reduction of $Mn^{III}Pc^{-2}$ to $Mn^{II}Pc^{-2}$ (n was calculated to be approximately 1 using the Eq. (1),

$$Q = nFVC \quad (1)$$

where n, F, V and C are the number of electrons transferred, Faraday's constant, volume and concentration of the electroactive species, respectively.

Increase in intensity of the band at 653 nm confirmed the presence of the μ-oxo complex, as earlier discussed, together with the electro-generated $Mn^{II}Pc^{-2}$ species. This observation has been reported before [5,22,23]. It was suggested that a form of equilibrium, as shown below, exists between MnPc species in DMF and in the presence of oxygen.

$$PcMn^{II} + O_2 \rightleftarrows PcMn^{III}(O_2) \quad (2)$$

$$PcMn^{III}(O_2) + PcMn^{II} \rightleftarrows PcMn^{III}{-}O_2{-}Mn^{III}Pc \quad (3)$$

$$PcMn^{III}{-}O_2{-}Mn^{III}Pc \rightleftarrows 2PcMn^{IV}O \quad (4)$$

$$2PcMn^{IV}O + 2PcMn^{II} \rightleftarrows 2PcMn^{III}{-}O{-}Mn^{III}Pc \quad (5)$$

$$4PcMn^{II} + O_2 \rightarrow 2PcMn^{III}{-}O{-}Mn^{III}Pc \text{ (Net equation)} \quad (6)$$

Further reduction of complex **3**, at the potentials of couple **III**, resulted in the spectral changes shown in Fig. 4b. A decrease in intensity of the new Q-band (705 nm) and emergence of new bands, with decreased intensities, at 543 and 590 nm are characteristic of ring-based redox process [24]. This observation confirmed that process **III** is a ring-based reduction, thus justifying the assignment of the couple to $Mn^{II}Pc^{-2}/Mn^{II}Pc^{-3}$ redox process. This supports the claim that first reduction in $Mn^{II}Pc^{-2}$ occur at the ring [25], although, other authors have reported metal reduction to the $Mn^{I}Pc^{-2}$ species [5,10]. Ring versus metal reduction in

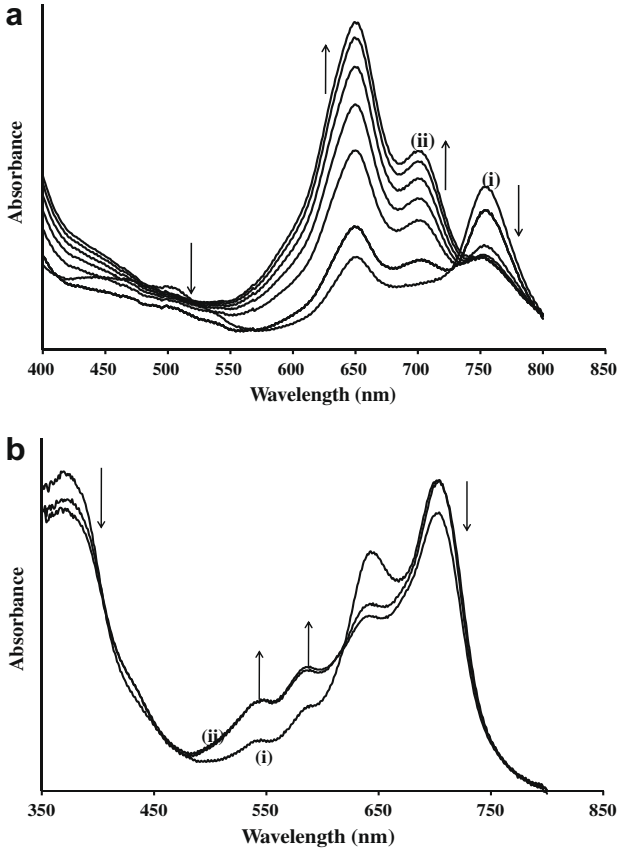

Fig. 4. UV–Vis spectral changes observed for complex **3** during controlled potential electrolysis at (a) −0.12 V (process **II**) and (b) −0.82 V (process **III**). (i) Spectra before electrolysis and (ii) spectra after electrolysis. The first spectrum in (b) is the same as the last spectrum in (b). Electrolyte = DMF containing 0.1 M $TBABF_4$.

$Mn^{II}Pc$ complexes is highly dependent on the nature of substituents [5]. A decrease in intensity was also observed for the band (653 nm) associated with the μ-oxo complex.

Application of potential of process **I** resulted in the formation of a new less intense band at 509 nm, typical of ring oxidation in MPc [24], complicated by redox processes based on the ring substituents. Process **I** is thus assigned to ring oxidation, $Mn^{III}Pc^{-1}$/$Mn^{III}Pc^{-2}$.

*3.1.3.2. Complex **4**.* Fig. 5 shows the cyclic and square wave (inset) voltammograms of 10^{-3} M complex **4** in a mixture of freshly distilled DCM and DMF (2:1) containing 0.1 M $TBABF_4$ as supporting electrolyte. This mixture was used because of the difficulty of obtaining a clearly defined cyclic voltammogram of the complex in DCM and the insoluble nature of the complex in DMF alone. Three processes can be observed: processes **I** (E_p = +0.92 V), **II** ($E_{1/2}$ = −0.02 V) and **III** ($E_{1/2}$ = −0.69 V). All redox processes are assigned to the ring since only ring reduction or oxidation has been documented for NiPc complexes in solution [10]. The first reduction process is observed at less negative potentials than has been reported [18] for NiPc complexes, probably due to the presence of sulfur and nitrogen in the ring substituents which will make the ring easier to oxidize. Couple **II** and **III** were reversible, while process **I** was irreversible. Due to the aggregated nature of the complex, it was not possible to do reliable spectroelectrochemical studies, however only ring-based redox processes occur for NiPc derivatives.

*3.1.3.3. Complex **5**.* The cyclic and square wave (inset) voltammetry profiles of ~1 × 10^{-3} M of complex **5**, in freshly distilled DMF containing 0.1 M $TBABF_4$ as supporting electrolyte, are shown in Fig. 6. Wider potential window (−1.3–+1.3 V versus Ag|AgCl) was used compared to that used for complexes **3** and **4** (−1–+1 V versus Ag|AgCl), because ring-based processes were not observed for complex **5** within the latter potential window. Even though the UV–Vis spectra showed complex behavior, the cyclic voltammetry peaks were well resolved in Fig. 6. The cyclic voltammetry will be dominated by $Fe^{II}Pc$ derivatives since the spectrum of the complex showed this species to be dominant. Four distinct processes were observed. Process **I** (E_p = +0.87 V versus Ag|AgCl) was assigned to ring oxidation, $Fe^{III}Pc^{-1}/Fe^{III}Pc^{-2}$. This process is irreversible as was the case for complexes **3** and **4**. Process **II** ($E_{1/2}$ = +0.26 V versus Ag|AgCl) was assigned to metal oxidation, $Fe^{III}Pc^{-2}/Fe^{II}Pc^{-2}$, in comparison with other alkyl or aryl thio substituted FePc complexes [26], Table 1. Process **II**, with a weak cathodic component compared to the anodic component, was quasi-reversible. Process

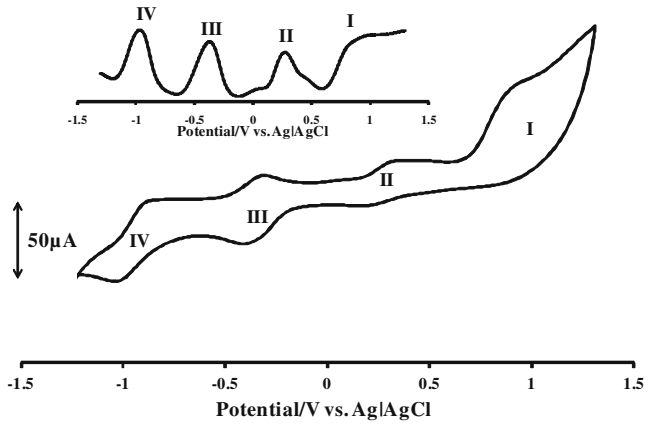

Fig. 6. Cyclic and square wave (inset) voltammograms of 10^{-3} M of complex **5** in freshly distilled DMF containing 0.1 M $TBABF_4$. Scan rate: 100 mVs^{-1}.

III ($E_{1/2}$ = −0.35 V versus Ag|AgCl) was assigned to metal reduction, $Fe^{II}Pc^{-2}/Fe^{I}Pc^{-2}$. This process was reversible, with peak separation, ΔE, of 60 mV versus Ag|AgCl, and cathodic to anodic current ratio of near unity. Process **IV** ($E_{1/2}$ = −0.96 V versus Ag|AgCl) was assigned to ring reduction, $Fe^{I}Pc^{-2}/Fe^{I}Pc^{-3}$.This process was quasi-reversible, with cathodic to anodic current ratio of near unity and peak separation, ΔE, of 120 mV versus Ag|AgCl compared to 91 mV for ferrocene at the same scan rate, 100 mV versus Ag|AgCl.

Due to the presence of more than one species in solution, spectroelectrochemical studies were not successful in the assignment of the cyclic voltammetry peaks. However, the assignments were based on the well known electrochemistry of FePc complexes in comparison with FePc complexes substituted with alkylthio groups, Table 1.

*3.1.3.4. Complex **6**.* The synthesis of the cobalt analogue of complexes **3**, **4** and **5** has been reported before [4], but it's electrochemical and spectroelectrochemical properties were not reported, hence they are reported in the current work, for the purpose of comparison with that of the new complexes. Fig. 7 shows both the cyclic and square wave (inset) voltammograms of ~1 × 10^{-3}M of complex **6** in freshly distilled DMF containing 0.1 M $TBABF_4$. A wider potential range (−2.0–+1.0 V) was used, compared to the other complexes, in order to observe the ring reduction processes. In coordinating solvents such as DMF, Co^{III}/Co^{II} couple occurs before the ring oxidation in CoPc complexes [27], thus process I (at 0.8 V) may be assigned to this process,

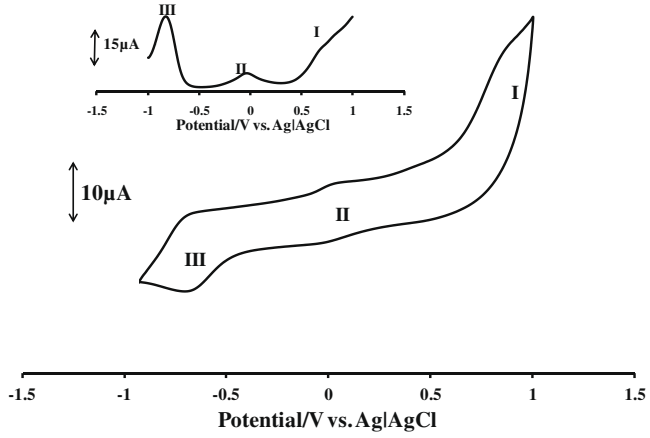

Fig. 5. Cyclic and square wave (inset) voltammograms of 10^{-3} M of complex **4** in distilled mixture of DCM and DMF containing 0.1 M $TBABF_4$. Scan rate: 100 mVs^{-1}.

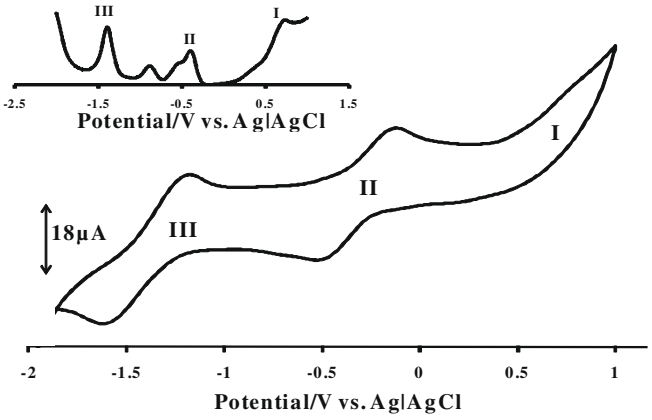

Fig. 7. Cyclic and square wave (inset) voltammograms of 10^{-3} M of complex **6** in freshly distilled DMF containing 0.1 M $TBABF_4$. Scan rate: 100 mVs^{-1}.

but complicated by contribution from the oxidation of ring substituent as was the case for the rest of the complexes. The process occurs at more positive potential values compared to CoPc complexes in general, but is within the range of some arylthio substituted CoPc derivatives [28,29], Table 1.

Processes **II** ($E_{1/2}$ = −0.32 V versus Ag|AgCl) and **III** ($E_{1/2}$ = −1.4 V versus Ag|AgCl) were quasi-reversible. Process **II** is in the potential range for $Co^{II}Pc^{2-}/Co^{I}Pc^{2-}$ species, while process **III** is typical of $Co^{I}Pc^{2-}/Co^{I}Pc^{3-}$ [27], Table 1. The more sensitive square wave voltammogram showed the presence of another process (−0.9 V). This was not observed on the cyclic voltammogram. The origin of the peak is not clear at the moment.

Spectroelectrochemical studies were used to confirm some of the assigned processes. The spectral changes in Fig. 8a were observed on the application of the potential of process **II**. The starting spectrum (curve i) shows considerable aggregation as a result of the high concentration used for the OTTLE cell. The peaks at 692 and 655 nm are associated with monomer and dimer respectively. A red-shift in the position of the Q-band, from 692 to 726 nm, was observed on the application of the potential of process **II**. There was an emergence of a new peak at 492 nm with increased intensity. New intense peak between 400 to 500 nm are characteristic of $Co^{I}Pc$ species [10]. The shift in Q-band without decrease in intensity is characteristic of metal-based reduction in MPc complexes. Thus spectral changes shown in Fig. 8a confirmed that couple **II** was as a result of the reduction of $Co^{II}Pc$ to $Co^{I}Pc$ (the number of moles of electrons transferred, n, was calculated to be approximately 1, using Eq. (1)). Also, distinct isobestic points at 580 and 710 nm showed that the process is a clear reduction involving two species. Application of the potential of process **III** resulted in the spectral changes shown in Fig. 8b. The starting spectrum (curve i), which is the last spectrum in Fig. 8a, has peaks at 726, 663, 492 and 604 nm. The peaks at 726 and 663 nm decrease in intensity without change in positions, while that at 492 nm shifted to 496 nm. The decrease in the intensity of Q-band is typical of ring-based process in MPcs. Bands in the 500 to 600 nm region are characteristic of ring-based reduction and the formation of a Pc^{3-} species [24]. Hence, reduction at potential of couple **III** resulted in the formation of $Co^{I}Pc^{3-}$ species.

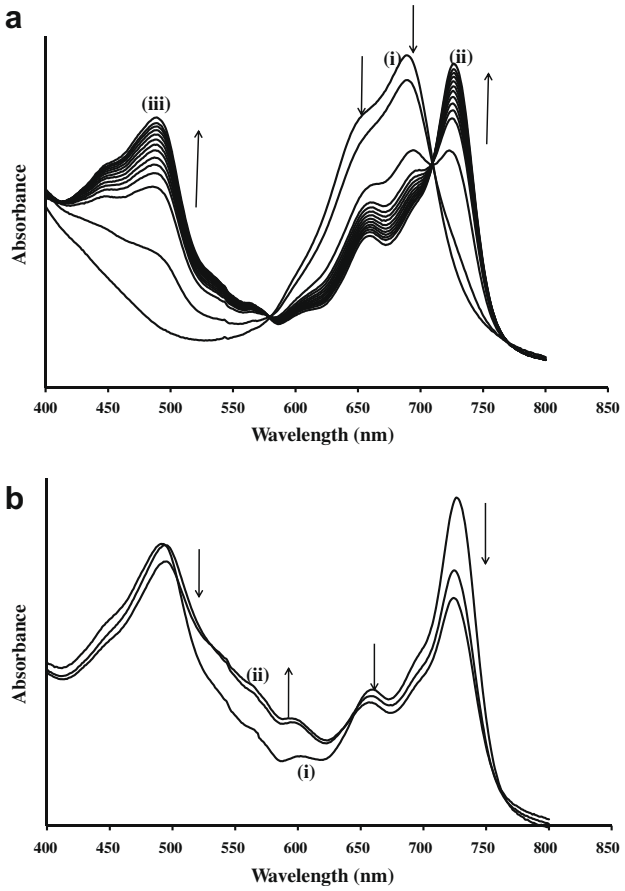

Fig. 8. UV–Vis spectral changes observed for complex **6** during controlled potential electrolysis at (**a**) −0.32 V (process **II**), (**b**) −1.40 V (process **III**). (i) Spectrum before electrolysis and (ii) spectrum after electrolysis. Electrolyte = DMF containing 0.1 M $TBABF_4$. The final spectrum in (**a**) is the starting spectrum in (**b**).

4. Conclusions

The syntheses, spectroscopic and electrochemical properties of the new complexes: manganese (**3**), nickel (**4**) and iron (**5**) octakis-(2-diethylaminoethanethiol) phthalocyanines are reported. The observed spectroscopic and electrochemical properties of the complexes were distinctly defined by the nature of the central metals. During spectroelectrochemical studies, the UV–Vis spectra of complex **3** in DMF showed bands characteristic of μ-oxo complex in MnPc complexes and that associated with the monomeric species. Well defined redox processes, assigned to $Mn^{III}Pc^{-2}/M^{II}Pc^{-2}$ and $Mn^{II}Pc^{-2}/M^{II}Pc^{-3}$ species, were observed and confirmed using spectroelectrochemical studies. Complex **4** showed aggregation behavior, characteristic of NiPc complexes, in THF. Complex **5** showed spectral property characteristic of stacked monomer in FePc. Solution electrochemistry of complex **5** showed four distinct redox processes, assigned to $Fe^{III}Pc^{-2}/Fe^{II}Pc^{-2}$, $Fe^{III}Pc^{-1}/Fe^{III}Pc^{-2}$, $Fe^{II}Pc^{-2}/Fe^{I}Pc^{-2}$ and $Fe^{I}Pc^{-2}/Fe^{I}Pc^{-3}$. Solution electrochemistry of the cobalt derivative (6) showed redox processes characteristic of $Co^{II}Pc^{-2}/Co^{I}Pc^{-2}$ and $Co^{I}Pc^{-2}/Co^{I}Pc^{-3}$ species.

dithiosemicarbazone

bis(thiosemicarbazone)

Fig. 1. Example of a dithiosemicarbazone and a bis(thiosemicarbazone) (X = aliphatic or aromatic spacer).

Palladium dichloride was received as a donation from Anglo Platinum. Ethane-1,2-dithiosemicarbazide [26], benzene-1,4-dithiosemicarbazide [23], and $Pd(PPh_3)_2Cl_2$ [27] were prepared following reported literature procedures. Solvents were freshly distilled and dried over the appropriate drying agents.

2.2. Instrumentation

Nuclear magnetic resonance (NMR) spectra were recorded on either a Varian Mercury XR300 MHz spectrometer (^{1}H at 300.08 MHz, ^{13}C at 75.46 MHz, ^{31}P at 121.47 MHz) or a Varian Unity XR400 MHz spectrometer (^{1}H at 399.95 MHz, ^{13}C at 100.58 MHz, ^{31}P at 161.90 MHz). ^{1}H and $^{13}C\{^1H\}$ NMR chemical shifts are reported using tetramethylsilane (TMS) as the internal standard and $^{31}P\{^1H\}$ spectra were measured relative to H_3PO_4 as the external standard. Infrared (IR) spectra were determined using a Perkin–Elmer Spectrum One FT-IR spectrometer and were recorded using KBr pellets. Elemental analyses (C, H and N) were recorded on a Thermo Flash 1112 Series CHNS-O Analyser. Mass spectrometry was carried out at the University of Stellenbosch on a Waters API Quattro Micro triple quadrupole mass spectrometer. Data were recorded using Electrospray Ionisation (ESI) mass spectrometry in the negative or positive modes. Melting points are corrected and were determined on a Reichert Thermovar hot stage microscope.

2.3. Synthesis of ethylene- (**1**–**3**) and phenylene-bridged (**4**–**6**) dithiosemicarbazone ligands

General procedure: Either ethane-1,2-dithiosemicarbazide or benzene-1,4-dithiosemicarbazide (1 equiv.) was dissolved in *N,N*-dimethylformamide (20 mL) at 120 °C. Upon complete dissolution, the appropriate salicylaldehyde (2 equiv.), dissolved in DMF (5 mL), was then added dropwise to the solution. The mixture was stirred at 120 °C for 5 h. Cold water was added to induce precipitation of the product in all cases. The resulting precipitate was collected by filtration and washed with cold water. The products were dried in the oven at 110 °C.

Compound **1** was prepared from ethane-1,2-dithiosemicarbazide (0.205 g, 0.985 mmol) and salicylaldehyde (0.210 mL, 1.97 mmol). Compound **1** was isolated as a light yellow powder. Yield 0.307 g (74.7%). M.p. 223–227 °C. *Anal.* Calc. for $C_{18}H_{20}N_6S_2O_2$: C, 51.90; H, 4.84; N, 20.17; S, 15.40. Found: C, 51.58; H, 5.11; N, 20.30; S, 16.06%. ν_{max}/cm^{-1} 1618 (C=N). ^{1}H NMR (400 MHz, DMSO-d_6, 25 °C): δ = 3.83 (4H, s, CH_2), 6.77 (2H, t, J = 7.72, Ar), 6.85 (2H, d, J = 8.17, Ar), 7.19 (2H, t, J = 7.53, Ar), 7.96 (2H, d, J = 7.73, Ar), 8.39 (2H, s, CH=N), 8.57 (2H, s, $NHCH_2$), 9.86 (2H, s, OH), 11.47 (2H, s, C=NNH) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6, 25 °C): δ = 43.32, 115.85, 118.99, 120.22, 126.61, 130.78, 139.64, 156.22, 177.23 ppm. MS ESI: m/z 415 (100%, $[M-H]^+$).

Compound **2** was prepared from ethane-1,2-dithiosemicarbazide (0.205 g, 0.986 mmol) and 2-hydroxy-3-methoxy-benzaldehyde (0.300 g, 1.97 mmol). The product was isolated as a pale yellow powder. Yield 0.441 g (93.7%). M.p. 245–249 °C. *Anal.* Calc. for $C_{20}H_{24}N_6S_2O_4$: C, 50.40; H, 5.08; N, 17.63; S, 13.46. Found: C, 49.99; H, 5.34; N, 17.36; S, 12.92%. ν_{max}/cm^{-1} 1671 (CN). ^{1}H NMR (400 MHz, DMSO-d_6, 25 °C): δ = 3.80 (6H, s, OMe), 3.83 (4H, s, CH_2), 6.73 (2H, t, J = 7.98, Ar), 6.94 (2H, d, J = 7.03, Ar), 7.58 (2H, d, J = 7.86, Ar), 8.41 (2H, s, CH=N), 8.56 (2H, s, $NHCH_2$), 9.12 (2H, s, OH), 11.5 (2H, s, CH=NNH) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6, 25 °C): δ = 43.32, 55.79, 112.84, 118.14, 118.74, 120.68, 139.44, 145.8, 147.78, 177.23 ppm. MS ESI: m/z 475 (100%, $[M-H]^+$).

Compound **3** was prepared from ethane-1,2-dithiosemicarbazide (0.204 g, 0.979 mmol) and 3-*tert*-butyl-salicylaldehyde (0.340 mL 1.96 mmol). Compound **3** was isolated as a pale yellow powder. Yield 0.365 g (73.9%). M.p. 226–230 °C. *Anal.* Calc. for $C_{24}H_{36}N_6S_2O_2$: C, 57.11; H, 7.19; N, 16.65; S, 12.71. Found: C, 57.55; H, 6.88; N, 16.44; S, 12.80%. ν_{max}/cm^{-1} 1599 (C=N). ^{1}H NMR (400 MHz, DMSO-d_6, 25 °C): δ = 1.39 (18H, s, ^{t}Bu), 3.84 (4H, s, CH_2), 6.84 (2H, t, J = 7.67, Ar), 7.24 (4H, m, Ar), 8.29 (2H, s, CH=N), 8.60 (2H, s, $NHCH_2$), 9.96 (2H, s, OH), 11.41 (2H, s, CH=N–NH) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, DMSO-d_6, 25 °C): δ = 30.06, 35.15, 44.33, 119.52, 120.02, 129.14, 129.99, 137.49, 147.66, 156.00, 177.88 ppm. MS ESI: m/z 529 (100%, $[M+Na]^+$).

Compound **4** was synthesized from benzene-1,4-dithiosemicarbazide (0.205 g, 0.800 mmol) and salicylaldehyde (0.171 mL, 1.60 mmol). The precipitate was isolated as a pale yellow powder. Yield 0.323 g (86.9%). M.p. 233–241 °C. *Anal.* Calc. for $C_{22}H_{20}N_6S_2O_2$: C, 56.88; H, 4.34; N, 18.09; S, 13.80. Found: C, 56.32; H, 4.36; N, 17.63; S, 13.41%. ν_{max}/cm^{-1} 1622 (C=N). ^{1}H NMR (300 MHz, DMSO-d_6, 25 °C): δ = 6.85 (4H, m, Ar), 7.23 (2H, t, J = 8.46, Ar), 7.55 (4H, s, Ph), 8.02 (2H, d, J = 7.78, Ar), 8.49 (2H, s, CH=N), 9.89 (2H, s, OH), 9.93 (2H, s, S=CNHPh), 11.64 (2H, s, CH=NNH) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6, 25 °C): δ = 116.03, 119.16, 120.15, 124.88, 127.15, 131.16, 136.02, 140.45, 156.47, 175.72 ppm. MS ESI: m/z 465 (100%, $[M+H]^+$).

Compound **5** was prepared using benzene-1,4-dithiosemicarbazide (0.206 g, 0.800 mmol) and 2-hydroxy-3-methoxy-benzaldehyde (0.245 g, 1.60 mmol). Compound **5** was isolated as a pale yellow powder. Yield 0.273 g (65.1%). M.p. 233–236 °C. *Anal.* Calc. for $C_{24}H_{24}N_6S_2O_4$: C, 54.95; H, 4.61; N, 16.02; S, 12.22. Found: C, 54.10; H, 4.65; N, 16.84; S, 12.94%. ν_{max}/cm^{-1} 1659 (CN). ^{1}H NMR (300 MHz, DMSO-d_6, 25 °C): δ = 3.83 (6H, s, OMe), 6.81 (2H, t, J = 7.96, Ar), 6.99 (2H, d, J = 8.06, Ar), 7.48–7.66 (2H, m, Ar), 7.57 (4H, s, Ph), 8.52 (2H, s, CH=N), 9.82 (2H, m, OH), 9.93 (2H, m, S=CNHPh), 11.66 (2H, s, CH=NNH) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6, 25 °C): δ = 55.89, 113.16, 118.58, 118.86, 120.58, 124.99, 135.99, 140.18, 146.15, 147.88, 175.70 ppm. MS ESI: m/z 525 (10%, $[M+H]^+$); 391 (100%, $[M-C_8H_6O_2]^+$).

Compound **6** was prepared using benzene-1,4-dithiosemicarbazide (0.153 g, 0.596 mmol) and 3-*tert*-butyl-salicylaldehyde (0.204 mL, 1.19 mmol) in a DMF/EtOH solution. Compound **6** was isolated as a pale yellow powder. Yield 0.098 g (28.5%). M.p. 288–292 °C. *Anal.* Calc. for $C_{30}H_{36}N_6S_2O_2$: C, 62.47; H, 6.29; N, 14.57; S, 11.12. Found: C, 62.19; H, 6.57; N, 14.55; S, 11.05%. ν_{max}/cm^{-1} 1667 (CN). ^{1}H NMR (300 MHz, DMSO-d_6; 25 °C): δ = 1.33 (18H, m, ^{t}Bu), 6.95 (2H, m, Ar), 7.75–7.21 (8H, m, Ar/Ph), 8.39 (2H, s, CH=N), 10.07 (4H, m, OH/NHPh), 11.58 (2H, m, CH=NNH) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6; 25 °C): δ = 29.17, 34.42, 118.75, 119.24, 121.09, 125.10, 128.50, 129.43, 136.857, 147.47, 155.42, 176.40 ppm. MS ESI: m/z 577 (100%, $[M+H]^+$).

2.4. Synthesis of binuclear palladium complexes (**7**–**12**)

2.4.1. General procedure

A heated solution (50 °C) of either ethane-1,2-dithiosemicarbazone or benzene-1,4-dithiosemicarbazone (1 equiv.) in ethanol (50 mL) was stirred under nitrogen. To the mixture was added, 1 equiv. of triethylamine. Upon dissolution of the dithiosemicarbazone, $Pd(PPh_3)_2Cl_2$ (2 equiv.) was added resulting in an orange reaction mixture. The reaction mixture was refluxed for 6 h and then cooled to room temperature. The resulting orange precipitate was filtered, washed with ethanol and dried *in vacuo*.

2.4.2. Compound **7**

Compound **1** (0.103 g, 0.247 mmol), triethylamine (0.035 mL) and $Pd(PPh_3)_2Cl_2$ (0.347 g, 0.494 mmol) were refluxed in ethanol. The product was obtained as a light orange powder. Yield 0.213 g (74.9%). M.p. 274–283 °C (with decomposition). *Anal.* Calc. for $C_{54}H_{46}N_6S_2P_2O_2Pd_2$: C, 56.40; H, 4.03; N, 7.31; S, 5.58. Found: C, 56.08; H, 4.04; N, 7.02; S, 5.09%. ν_{max}/cm^{-1} 1599 (C=N). ^1H NMR (300 MHz, DMSO-d_6, 25 °C): δ = 3.36 (4H, s, CH_2), 6.55 (4H, m, Ar), 6.98 (2H, s, N*H*CH_2), 7.18 (2H, t, J = 8.78, Ar), 7.38 (2H, d, J = 7.80, Ar), 7.39–7.68 (30H, m, PPh_3), 8.33 (2H, d, J = 13.98, CH=N) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6, 25 °C): δ = 44.99, 114.31, 117.77, 119.81, 128.38–134.02, 148.82, 161.47, 169.16 ppm. ^{31}P NMR (120 MHz, DMSO-d_6, 25 °C): δ = 25.58 (2P, s, PPh_3) ppm. MS ESI: m/z 1151 (100%, $[M+H]^+$).

2.4.3. Compound **8**

Compound **2** (0.119 g, 0.249 mmol), triethylamine (0.035 mL) and $Pd(PPh_3)_2Cl_2$ (0.350 g, 0.498 mmol) were refluxed in ethanol. The product was isolated as an orange powder. Yield 0.286 g (94.9%). M.p. 264–271 °C (with decomposition). *Anal.* Calc. for $C_{56}H_{50}N_6S_2P_2O_4Pd_2$: C, 55.58; H, 4.17; N, 6.90; S, 5.30. Found: C, 56.00; H, 4.49; N, 6.36; S, 5.30%. ν_{max}/cm^{-1} 1598 (C=N). ^1H NMR (300 MHz, DMSO-d_6, 25 °C): δ = (OMe signal suppressed by H_2O), 3.59 (4H, s, CH_2), 5.72 (2H, s, N*H*CH_2), 6.52 (2H, t, J = 7.41, Ar), 6.86 (2H, m, Ar), 7.10 (2H, d, J = 7.41, Ar), 7.20–7.88 (30H, m, PPh_3), 8.27 (2H, d, J = 14.01, CH=N) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6, 25 °C): δ = 44.97, 55.87, 113.52, 114.24, 117.42, 125.85, 128.13–134.14, 149.04, 150.68 152.87, 168.83 ppm. ^{31}P NMR (120 MHz, DMSO-d_6, 25 °C): δ = 19.61 (2P, s, PPh_3) ppm. MS ESI: m/z 1210 (20%, $[M+H]^+$); 279 (100%, $[M-C_8H_6N_2SO_2Pd(PPh_3)_2]^+$).

2.4.4. Compound **9**

Compound **3** (0.122 g, 0.243 mmol), triethylamine (0.034 mL) and $Pd(PPh_3)_2Cl_2$ (0.341 g, 0.485 mmol) were refluxed in ethanol. This yielded the product **9** as an orange powder. Yield 0.221 g (72.1%). M.p. 258–262 °C (with decomposition). *Anal.* Calc. for $C_{62}H_{62}N_6S_2P_2O_2Pd_2$: C, 59.00; H, 4.95; N, 6.66; S, 5.08. Found: C, 60.21; H, 5.32; N, 5.89; S, 4.94%. ν_{max}/cm^{-1} 1593 (C=N). ^1H NMR (300 MHz, $CDCl_3$, 25 °C): δ = 0.75 (18H, s, ^{t}Bu), 3.38 (2H, s, CH_2), 5.08 (2H, s, N*H*CH_2), 6.56 (2H, t, J = 7.57, Ar), 7.19–7.79 (34H, m, PPh_3, Ar), 8.28 (2H, d, J = 14.19, CH=N) ppm. $^{13}C\{^1H\}$ NMR (75 MHz, DMSO-d_6, 25 °C): δ = 30.08, 34.95, 45.91, 114.39, 118.88, 128–135, 139.92, 151.07, 161.95 ppm. ^{31}P NMR (120 MHz, $CDCl_3$, 25 °C): δ = 24.35 (2P, s, PPh_3) ppm. MS ESI: m/z 1263 (50%, $[M+H]^+$); 675 (100%, $[M-C_{11}H_{13}N_2SOPdPPh_3]^+$).

2.4.5. Compound **10**

Compound **4** (0.100 g, 0.210 mmol), triethylamine (0.031 mL) and $Pd(PPh_3)_2Cl_2$ (0.312 g, 0.430 mmol) were refluxed in dry ethanol. Compound **10** was isolated as an orange powder. Yield 0.239 g (95.1%). M.p.: does not melt below 300 °C. *Anal.* Calc. for $C_{58}H_{46}N_6S_2P_2O_2Pd_2$: C, 58.15; H, 3.87; N, 7.02; S, 5.35. Found: C, 57.45; H, 3.83; N, 6.96; S, 5.50%. ν_{max}/cm^{-1} 1598 (CN). ^1H NMR (300 MHz, DMSO-d_6, 25 °C): δ = 6.60 (4H, m, Ar), 7.21 (4H, m, Ar), 7.57–7.71 (34H, m, PPh_3, Ph), 8.63 (2H, d, J = 13.78, CH=N), 9.26 (2H, s, N*H*Ph) ppm. ^{31}P NMR (120 MHz, DMSO-d_6, 25 °C): δ = 25.61 (2P, s, PPh_3) ppm.

2.4.6. Compound **11**

Compound **5** 0.113 g, 0.210 mmol), triethylamine (0.030 mL) and $Pd(PPh_3)_2Cl_2$ (0.301 g, 0.430 mmol) were refluxed in ethanol. A dark orange powder (**11**) was isolated. Yield 0.241 g (91.3%). M.p.: does not melt below 300 °C. *Anal.* Calc. for $C_{60}H_{50}N_6S_2P_2O_4Pd_2$: C, 57.28; H, 4.01; N, 6.68; S, 5.10. Found: C, 57.62; H, 3.84; N, 6.84; S, 5.21%. ν_{max}/cm^{-1} 1589 (C=N). ^1H NMR (300 MHz, DMSO-d_6, 25 °C): δ = 3.63 (6H, s, OMe), 6.56 (2H, t, J = 7.81, Ar), 6.91 (2H, d, J = 7.70, Ar), 7.16 (2H, d, J = 8.24, Ar), 7.76–7.49 (34H, m, PPh_3, Ar), 8.61 (2H, d, J = 13.85, CH=N), 9.23 (2H, s, N*H*Ph) ppm. ^{31}P NMR (120 MHz, DMSO-d_6, 25 °C): δ = 19.73 (2P, s, PPh_3) ppm.

2.4.7. Compound **12**

Compound **6** (0.126 g, 0.219 mmol), triethylamine (0.031 mL) and $Pd(PPh_3)_2Cl_2$ (0.307 g, 0.438 mmol) were refluxed in ethanol. A dark orange powder was isolated. Yield 0.227 g (79.12%). M.p.: does not melt below 300 °C. *Anal.* Calc. for $C_{66}H_{62}N_6S_2P_2O_2Pd_2$: C, 60.50; H, 4.77; N, 6.42; S, 4.89. Found: C, 60.45; H, 4.91; N, 6.88; S, 4.95%. ν_{max}/cm^{-1} 1593 (C=N). ^1H NMR (300 MHz, DMSO-d_6, 25 °C): δ = 0.69 (18H, s, ^{t}Bu), 6.53 (2H, t, J = 7.56, Ar), 7.08–7.86 (38H, m, Ar/Ph), 8.59 (2H, d, J = 14.05, CH=N), 9.12 (2H, s, N*H*Ph) ppm. $^{13}C\{^1H\}$ NMR (100 MHz, $CDCl_3$-*d*, 25 C): δ = 29.4, 34.8, 114.1, 118.1, 119.4, 128.4–134.8, 140.3, 153.2, 162.4, 164.8 ppm. ^{31}P NMR (120 MHz, DMSO-d_6, 25 °C): δ = 25.67 (2P, s, PPh_3) ppm. MS ESI: m/z 1311 (10%, $[M+H]^+$).

2.5. X-ray crystallography

Crystals suitable for X-ray diffraction study for **7**·2 DMSO and **11**·4 DMSO were grown from concentrated DMSO solutions of complexes **7** and **11**, respectively. An orange crystal of **7**·2 DMSO was mounted on a Stoe Image Plate Diffraction system equipped with a ϕ circle goniometer, using Mo Kα graphite monochromated radiation (λ = 0.71073 Å) with ϕ range 0–200°, increment of 1.2°, $D_{max} - D_{min}$ = 12.45–0.81 Å. Whereas a yellow crystal of **11**·4 DMSO was mounted on a Nonius Kappa-CCD diffractometer using graphite monochromated Mo Kα radiation (λ = 0.71073 Å), equipped with an Oxford Cryostream cooling system. Data were evaluated using the Bruker Nonius "Collect" program and was scaled and reduced using DENZO-SMN software. Both structures were solved by direct methods using the program SHELXS-97 [28]. The refinement and all further calculations were carried out using SHELXL-97 (see Table 1) [29]. The hydrogen atoms were included in calculated positions and treated as riding atoms using the SHELXL default parameters. All non-H atoms were refined anisotropically, using weighted full-matrix least-square on F^2. Figs. 2 and 3 were drawn with ORTEP [30]. Packing diagram (Fig. 4) was produced using the program PovRay [31] and the graphic interface X-seed [32].

2.6. Cytotoxic assay

The dithiosemicarbazone ligands were evaluated for their *in vitro* anticancer activity against three oesophageal cancer cell lines, WHCO1, WHCO5 and WHCO6, derived from biopsies of primary oesophageal squamous cell carcinomas [33] and kindly provided by Professor Rob Veale (University of Witwatersrand, South Africa). IC_{50} determinations were carried out using the MTT assay. Briefly, 3000 cells were seeded per well in 96-well plates. Cells were incubated at 37 °C under 5% CO_2 (24 h), after which aqueous DMSO solu-

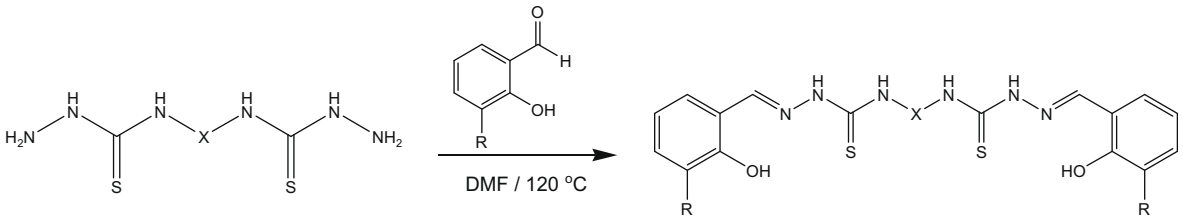
tions of each compound (10 μL, with a constant final concentration of DMSO = 0.2%) were plated at various concentrations. After 48 h incubation, observations were made, and MTT (10 μL) solution added to each well. After a further 4 h incubation, solubilization solution (100 μL) was added to each well, and plates were incubated overnight. Plates were read at 595 nm on a BioTek microplate reader.



3. Results and discussion

3.1. Synthesis and characterization of dithiosemicarbazone ligands (*1*–*6*)

A series of ethylene- and phenylene-bridged salicylaldimine dithiosemicarbazones were synthesized using a procedure similar to that previously reported by Scovill [26] and Dilworth et al. [23]. Our initial attempts at preparing dithiosemicarbazones via amination reactions of the appropriate aryl thiosemicarbazide with either ethylenediamine or phenylenediamine proved to be unsuccessful, despite refluxing for extended periods or using microwave-assisted techniques.

Two different routes were followed to prepare the bridged dithiosemicarbazone ligands. The synthesis of the ethylene-bridged dithiosemicarbazone ligands via the known reaction of hydrazine with a diacid precursor produced ethane-1,2-dithiosemicarbazide [26]. Benzene-1,4-dithiosemicarbazide was obtained using a simple one-step procedure via the reaction of hydrazine with phenylene diisothiocyanate as the starting precursor [23]. Subsequent Schiff-base condensation of either ethane-1,2-dithiosemicarbazide or benzene-1,4-dithiosemicarbazide with salicylaldehyde, 2-hydroxy-3-methoxy benzaldehyde or 3-*tert*-butyl salicylaldehyde afforded the ethylene-bridged (**1–3**) and phenylene-bridged (**4–6**) dithiosemicarbazones (Scheme 1).

The ethylene- and phenylene-linked dithiosemicarbazone ligands (**1–6**) were isolated by precipitation in water, as pale yellow

X = C_2H_4 (**1-3**) ; C_6H_4 (**4-6**)

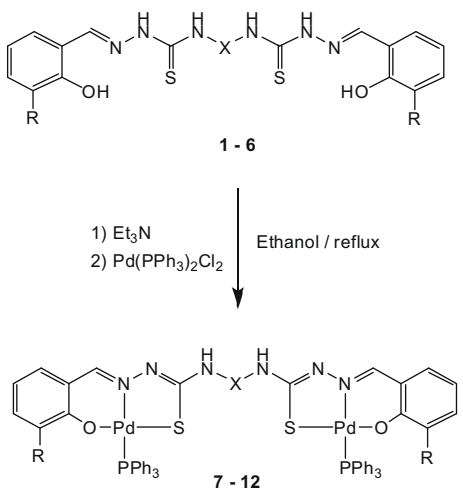
Scheme 1. Synthetic route to dithiosemicarbazones **1–6**.

powders in varying yields (65–94%) and the proposed structures are supported by analytical and spectroscopic data.

The structures of dithiosemicarbazone ligands **1–6** were confirmed by ^{1}H, ^{13}C, COSY and HSQC NMR spectroscopy. The ^{1}H NMR spectra of the products show a singlet in the range δ 8.3–8.5 ppm, assigned to the imine protons. A characteristic singlet is observed for the ethylene (**1–3**) and phenylene protons (**4–6**) at about δ 3.83 ppm and δ 7.55 ppm respectively, due to the symmetrical nature of the dithiosemicarbazone compounds. Generally, the phenylene-bridged thiosemicarbazone ligands (**4–6**) show similar trends in the NMR spectra to those of the ethylene-bridged ligands (**1–3**). ^{13}C{^{1}H} NMR spectral assignments were made with the aid of 2D Heteronuclear Single Quantum Coherence (HSQC) spectroscopy. Peaks assigned to the carbons of the aromatic groups are observed in the region of δ 115–156 ppm. A peak assigned to the imine carbon is observed around δ 140 ppm.



Further information on the integrity of the ligands was gleaned from infrared spectroscopic techniques. The IR spectra of the Schiff base dithiosemicarbazone ligands showed a strong absorption band for the imine functionality at around 1622–1598 cm^{-1}. The absorption band at 850–820 cm^{-1} in the free ligand may be assigned to the thioamide vibration $\nu_{(C=S)}$, indicating that the ligands exist in the thione form.

The ESI mass spectra for compounds **1–2**, **4–6** recorded in the negative mode generally showed a 100% relative intensity peak (base peak) due to the $[M-H]^+$ ion. For compound **3**, however, a base peak at m/z 527 is observed in the ESI spectrum, attributed to the presence of a sodium adduct, $[M+Na]^+$.

3.2. Binuclear dithiosemicarbazone salicylaldiminato palladium(II) complexes (*7–12*)

For polydentate ligands such as compounds **1–6**, various bonding modes are possible depending on the ligand to metal ratio. In an attempt to prepare binuclear palladium dithiosemicarbazones, the palladium(II) complexes (**7–12**) were selectively prepared by reacting the corresponding dithiosemicarbazone ligands (**1–6**) with $Pd(PPh_3)_2Cl_2$ in a 1:2 stoichiometric ratio (ligand:metal), giving rise to binuclear palladium complexes (Scheme 2). The synthesis of the complexes was performed using methodologies similar to those reported previously by Halder et al. [34].

The palladium complexes (**7–12**) are isolated as orange powders in high yields (75–95%). They are air-stable as solids and in solution. The ethylene-bridged palladium(II) complexes (**7–9**) are readily soluble in polar solvents such as DMSO, chlorinated solvents (CH_2Cl_2), and are sparingly soluble in alcoholic solvents. The phenylene-bridged palladium(II) complexes (**10, 11**), however, are found to be far less soluble than their ethylene-bridged counterparts. Surprisingly, complex **12** shows greater solubility than the analogous phenylene-bridged palladium complexes. The bimetallic complexes (**7–12**) have been characterized by elemental analyses, ^{1}H, ^{13}C, ^{31}P NMR and IR spectroscopies, and ESI-MS.

3.2.1. NMR spectroscopy

The ethylene- and phenylene-bridged palladium complexes display in the ^{1}H NMR spectra the expected singlet for the ethylene and phenylene protons at around δ 3.38 ppm and δ 7.47–7.71 ppm, respectively, due to the symmetrical nature of the compounds. Evidence for the formation of palladium complexes is seen by the notable shift of the signal for the imine proton, suggesting coordination of palladium to the imine nitrogen. Splitting of the imine signal into a doublet in the region at around δ 8.33 ppm is observed and is attributed to coupling of the imine proton to the nucleus of the phosphorus atom ($^4J_{P-H}$ = 13.98 Hz). The disappearance of the signal for the hydroxyl proton, together with the observed shift of the imine proton observed in the ^{1}H NMR spectrum, provides good evidence of coordination of palladium, resulting in a six-membered ring with N,O donor atoms. In addition to this, the disappearance of the signal assigned to the hydrazinic proton adjacent to the imine group, confirms the formation of a second imine bond upon coordination of palladium, suggesting that the sulfur atom coordinates in the thiolate form rather than the thione form, thus forming a five-membered chelate ring (N, S donor atoms). The phenylene-bridged complexes (**10, 11**) were difficult to characterize using NMR spectroscopic techniques due to their low solubility in most deuterated solvents, including DMSO-d_6. The ^{1}H NMR spectrum of compound **10**, specifically, was not well-resolved, but a trend similar to that of the ethylene-bridged complex **7** was discernible and assignments made on that basis.

All the expected peaks are observed in the $^{13}C\{^1H\}$ NMR spectra for compounds **7–12**. It was not possible to obtain ^{13}C NMR spectral data for the phenylene-bridged complexes (**10, 11**), even at elevated temperatures, due to the poor solubility of these complexes. A sharp singlet is observed in the $^{31}P\{^1H\}$ NMR spectra for each palladium-PPh_3 complex in the region around δ 25.6 ppm.

3.2.2. Infrared spectroscopy

Infrared spectroscopy is a useful diagnostic tool to confirm coordination of palladium. The IR spectra of the palladium complexes **7–12** show a band of medium to strong intensity within 1599–1589 cm^{-1}, attributed to the C=N–N=C fragment of the coordinated dithiosemicarbazone ligand. The shift of the imine absorption band (ν_{C-N}) in the free ligand (1600–1671 cm^{-1}) to lower wavenumbers in the metal complexes, is indicative of the coordination of palladium to the imine nitrogen. The IR spectra of the [Pd(L)(PPh_3)] (L = dithiosemicarbazone) complexes (**7**–**12**) generally show many vibrations of different intensities in the 1600–400 cm^{-1} region and are qualitatively very similar. Three diagnostic bands for the PPh_3 ligands near 533, 694 and 743 cm^{-1} are observed for all the complexes. The characteristic bands due to the $\nu_{(P-C)}$ vibration are also observed in the region 1098–1095 cm^{-1}, indicative of the presence of coordinated PPh_3 in the complexes [35–37]. Bands involving the C=S functional group are often difficult to assign. Coordination by sulfur induces changes in position and intensity of the bands and the proximity of the phenyl ring bands (triphenylphosphine ligand) makes it difficult to clearly assign the vibration modes. The disappearance of the C=S band observed in the free ligand, correlates with the loss of double-bond character upon deprotonation of the NH group. This supports the lengthening of the C–S bond which we observe in representative molecular structures. For thiosemicarbazones bonding in the thiolate form, the C=S band generally shifts to lower energy in the region 820–790 cm^{-1}. However, no definite assignment of each individual band to a specific vibration could be made.

3.2.3. Mass spectrometry

ESI-mass spectrometry further confirmed the integrity of the binuclear complexes. The ESI spectrum of compound **7** displays a base peak for the complex in its protonated form $[M+H]^+$ at *m*/*z* 1151. The spectrum of compound **8** reveals a peak at *m*/*z* 1210 for the $[M+H]^+$ ion of 20% intensity. A base peak at *m*/*z* 279, accounts for the fragment, $[M-C_8H_6N_2SO_2Pd(PPh_3)_2]^+$. The spectrum of compound **9** displays a peak of 50% intensity for the protonated complex at *m*/*z* 1263. In addition to this, a base peak at *m*/*z* 675, corresponds to the fragment, $[M-C_{11}H_{13}N_2SOPdPPh_3]^+$. The poor solubility of complexes **10** and **11** precluded an accurate determination by ESI-mass spectrometry.

3.3. Solid-state structures of complexes 7 and 11

To further confirm the mode of coordination of these palladium dithiosemicarbazone complexes, molecular structures of one member of each group (ethylene- and phenylene-bridged) have been determined using single-crystal X-ray crystallography. Single crystals of compounds **7** and **11** were obtained from concentrated dimethyl sulfoxide solutions. Figs. 2 and 3 show the molecular structures of **7** and **11**, respectively, while Table 2 gives selected bond lengths and angles.

The crystal structures show that the dithiosemicarbazone ligands coordinate to each palladium center *via* the phenolic oxygen, imine nitrogen and sulfur atoms in a square-planar geometry, as the spectroscopic data suggests. These two structures confirm that the fourth coordination site is occupied by a triphenylphosphine ligand. Both complexes show that the dithiosemicarbazone ligands (**1** and **5**) are coordinated to palladium in the expected tridentate (O–N–S) fashion on either side of the dithiosemicarbazone. The structures show the formation of six- and five-membered chelate rings upon coordination, thus imposing distortion around the square-planar metal centers. Indeed, the structures display O(1)–Pd(1)–N(1) and N(1)–Pd(1)–S(1) bite angles of 93.1(2)° and 84.55(17)° in **7** and of 92.15(12)° and 84.03(10)° in **11**. In both, a triphenylphosphine ligand is found trans to the nitrogen atom with Pd–P distances of 2.273(2) and 2.284(1) Å, respectively and with O(1)–Pd(1)–P(1) and S(1)–Pd(1)–P(1) bite angles of 88.53(14) and 93.91(7)° in **7** and of 91.28(8) and 92.44(4)° in **11**. These parameters are comparable to those in other trans P–N, S–O square-planar palladium complexes [16]. In addition to this, it can be seen that coordination of the dithiosemicarbazone sulfur atoms occur *via* the thiolate form, rather than the thione form (Figs. 2 and 3) due to the formation of a second imine bond

Table 3
IC_{50} values (μM) of dithiosemicarbazone ligands (**1**–**3**, **5**, **6**) in various oesophageal cancer cells.

Compound	IC_{50} values in μM (95% CI)		
	WHCO1	WHCO5	WHCO6
1	8.62 (7.06–10.54)	5.63 (4.72–6.72)	10.36 (9.34–11.49)
2	2.53 (1.78–3.58)	5.88 (5.57–6.21)	3.56 (2.92–4.36)
3	6.38 (5.42–7.52)	3.26 (2.39–4.45)	11.70 (10.62–12.89)
5	2.67 (2.08–3.43)	1.64 (1.14–2.35)	12.37 (9.59–15.94)
6	1.28 (0.97–1.69)	1.24 (0.93–1.66)	30.97 (12.81–74.91)

between C(2) and N(2) in **7** and between C(9) and N(2) in **11**: Values of 1.311(7) and 1.300(5) Å being found for these bonds. This further supports that these C–N bonds tend towards double-bond character upon coordination. Comparison of these distances to the C(2)–N(3) and C(9)–N(3) bond lengths, shows that the latter are slightly longer (1.354(7) and 1.352(5) Å) and therefore tend towards single-bond character. The C–S bond lengths are also found to be consistent with coordination of sulfur in the thiolate form, with values of 1.781(6) and 1.769(4) Å, respectively. A previous study by Halder et al. [34] based on similar monomeric complexes, reported C–S values of approximately 1.75 Å. In simple systems it would be expected that a single C–S bond length would be approximately 1.82 Å and a double C=S bond would exhibit a length of 1.56 Å. The length obtained in this study, therefore appears to be close to the nature of a single C–S bond.

Further analysis of compound **11** reveals that the packing arrangement displays four solvent molecules (DMSO) of crystallisation per complex. This can be seen in the crystal lattice (Fig. 4). Closer inspection of the packing arrangement of compound **11** reveals hydrogen bonding of two oxygen atoms of two of the DMSO molecules to the secondary amine groups on either side of the complex. This bonding is depicted by N(3)–H(3)N···O(1X) on the right-hand side of the molecule. The same phenomenon is observed on the adjacent end of the complex. In **7**, in which two symmetry related molecules of DMSO crystallized per complex, the oxygen atom of the solvent interacts with two adjacent hydrogen atoms of the dithiosemicarbazone phenyl groups. The H···O distances are 2.686 and 2.691 Å and the C–H···O angles 122.9° and 124.4°, respectively.

The information obtained herein therefore allowed us to further confirm the integrity of these molecules, in addition to their spectral properties. We were therefore able to rationalize the modes of coordination upon complexation of the metals.

3.4. Preliminary biological evaluation

The dithiosemicarbazone ligands were evaluated for their *in vitro* anticancer activity against three oesophageal cancer cell lines (WHCO1, WHCO5, WHCO6). All the dithiosemicarbazone ligands, with the exception of ligand **4**, were cytotoxic in the cell lines evaluated, showing IC_{50} values in the range 1.2–35 μM. The fact that ligand **4** did not show any biological activity is ascribed to the poor solubility of the ligand. The IC_{50} values calculated from the dose-survival curves obtained after 48 h drug treatment from the MTT assay, are shown in Table 3. Unfortunately, the cytotoxicity of the palladium complexes could not be determined due to the poor solubility of these complexes. Detailed studies are currently underway to prepare more soluble palladium(II) salicylaldiminato dithiosemicarbazone complexes.

4. Conclusions

In summary, we have shown that palladium(II) complexes of salicylaldimine dithiosemicarbazones containing ethylene or phenylene spacers may be prepared by the reaction of the new salicylaldehyde-derived dithiosemicarbazone ligands (**1–6**) with $Pd(PPh_3)_2Cl_2$. This involved the preparation of ethylene- and phenylene-bridged dithiosemicarbazides, that were condensed with the appropriate salicylaldehydes, and thereafter metallated to give rise to the new binuclear palladium complexes (**7–12**). For each binuclear complex, it was found that in their solid-state structures, both palladium centers coordinate in a tridentate (O–N–S) manner. The expected square-planar geometry of the metal was also observed. Preliminary *in vitro* antitumour activity of the dithiosemicarbazone ligands showed a moderate to good cytotoxicity for the indicated cell lines. Biological activity of the palladium(II) complexes of the dithiosemicarbazones could not be determined due to poor solubility. Further investigations are underway to increase the solubility of the palladium complexes and to explore their anticancer activity.

Supplementary data

CCDC 723512 and 719351 contain the supplementary crystallographic data for **7**·2 DMSO and **11**·4 DMSO. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

2.1. NMR and FT-IR spectra

In the ^{1}H NMR spectra ($CDCl_3$) of ligands (**1a**–**g**), the NH protons appear at 8.60–7.85 ppm as broad singlets. This signal is absent in the ^{1}HNMR spectra of the corresponding nickel, palladium and copper complexes as a consequence of the deprotonation that occurs upon coordination. Similarly in the IR spectra, all ligands (**1a**–**g**) show NH stretching vibrations in the range 3375–3260 cm^{-1} but these signals are absent in the spectra of the corresponding metal complexes. In the ^{13}C NMR spectra, the carbon atom of the thiocarbonyl group appears at 177.5–189.9 ppm for (**1a**–**g**) and this shifts to 173.4–174.5 ppm in the respective metal complexes as a consequence of complex formation.

The IR bands at 1731–1752 cm^{-1} and 1237–1285 cm^{-1} in the spectra of the metal complexes are assigned to the ester ν(C=O) and ν(C–O), respectively. All the compounds show ν(C=O) amide vibration band in the 1681–1640 cm^{-1} range owing to conjugation with the aromatic ring [21,25,26]. These appear at almost the same wavenumber in their metal complexes indicating that the ester carbonyl group is not involved in coordination. The thionyl ν(C–S) vibration bands appears at 1210–1187 cm^{-1} for the ligands and shifts to lower values, 1209–1169 cm^{-1}, in their corresponding metal complexes as a result of the coordination the sulfur atom [19,24,27] to the metal. In all the metal complexes a strong peak appears in the 1358–1419 cm^{-1} range corresponding to the coordinated oxygen of the delocalised amide coordinated to the metal cations [6–8].

2.2. Crystal structures of *2a* and *8*

A view of crystal structure of compound **2a**, $[C_{29}H_{27}N_2O_5S]_2Ni$, and **8** $[C_{30}H_{29}N_2O_6S]_2Ni$ are depicted in Figs. 1 and 3, and selected atomic distances and bond angles are listed in Table 2. The structure of **2a**, red prisms, and **8**, pale violet plates, solved in the triclinic space group $P\bar{1}$ and the asymmetric unit contains one molecule of the complex and in the case of **2a** contains dichloromethane (occupancy 0.4) both in general positions (Table 1). Many hydrogen atoms could be located in the Fourier difference map but, in the final stages of refinement, all were placed geometrically and refined using a riding model. C–H distances: CH_3, 0.98 Å; CH_2, 0.99 Å; CH, 1.00 Å; aromatic, 0.95 Å. The square planar Ni(II) ion is coordinated by two thiocarbonyl S atoms and two carbonyl O atoms.

The ligands of compound **2a** are coordinated in a relatively undistorted manner and the angles between O(7b)–Ni(1)–S(8a) and O(7a)–Ni(1)–S(8b) are 174.84(6)° and 174.48(5)°, respectively. The bond lengths for Ni(1)–O(7a) = 1.8602(15) Å, Ni(1)–O(7b) = 1.8670(15) Å, Ni(1)–S(8a) = 2.1201(6) Å and Ni(1)–S(8b) = 2.1495(6) Å are well within the range expected [4,6,23]. The bond lengths of carbonyl moieties O(7a)–C(7a) = 1.272(2) Å, O(7b)–C(7b) = 1.270(3) Å and thiocarbonyl moieties S(8a)–C(8a) = 1.724(2) Å and S(8b)–C(8b) Å = 1.727(2) Å are longer than the average C=O and C=S [8,23,51]. The C–N bonds for N(7a)–C(8a) = 1.339(3) Å, N(7a)–C(7a) = 1.333(3) Å and N(7b)–C(7b) = 1.333(3) Å, N(7b)–C(8b) = 1.345(3) Å in the complex ring are shorter than the average C–N single bonds but within the range of C=N double bond distances [8,23,28]. The crystal structure of the ligand **1a** has been derived from the crystal structure of **2a** (Fig. 2).

The ligands of compound **8** are coordinated in a relatively undistorted manner and the angles between O(5a)–Ni(1)–S(1b) and O(5b)–Ni(1)–S(1a) are 176.25(6)° and 175.16(6)°, respectively. The bond lengths for Ni(1)–O(5b) = 1.8725(14) Å, Ni(1)–O(5a)) = 1.8965(15) Å, Ni(1)–S(1b) = 2.1543(6) Å and Ni(1)–O(5a) = 2.1794(6) Å, are well within the range expected [4,6,23]. The bond lengths of carbonyl moieties C(4a)–O(5a) = 1.276(2) Å, C(4b)–O(5b) = 1.282(2) Å and thiocarbonyl moieties S(1a)–C(2a) = 1.748(2) Å and S(1b)–C(2b) = 1.748(2) Å are longer than the average C=O and C=S [8,23,51]. The C–N bonds for C(2a)–N(3a) = 1.349(3) Å, N(3a)–C(4a) = 1.348(3) Å and N(3b)–C(4b) = 1.345(3) Å, C(2b)–N(3b) = 1.354(3) Å in the complex ring are shorter than the average C–N single bonds but within the range of C=N double bond distances [23,28]. These bond angles and atomic distances for **2a** and **8** are similar to those observed for related compounds [4,6,23,28].

Inspection of the crystallographic data of **2a** and **8** show them to be *meso* compounds and there is no evidence of either inter- or intramolecular π–π stacking.

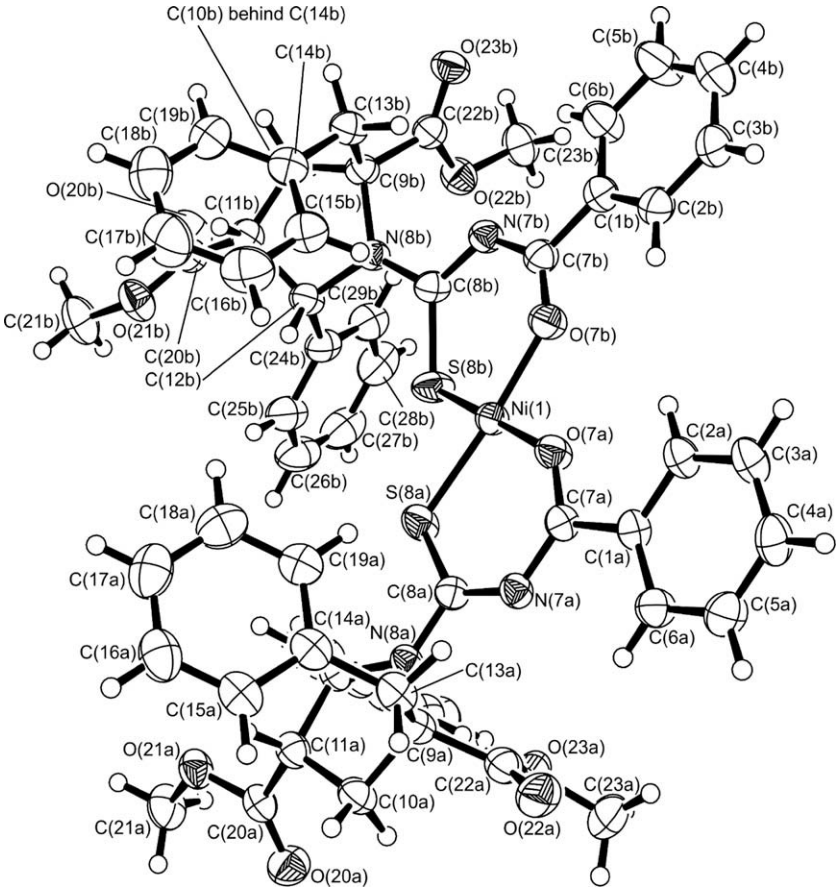

Fig. 1. Crystal structure of compound **2a**.

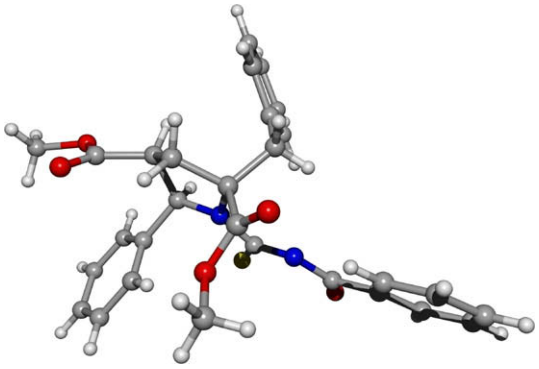

Fig. 2. Crystal structure of ligand **1a**.

3. Antifungal activity against yeast *Saccharomyces cerevisae* and fungus *Penicillium* digitatum

Antifungal susceptibility testing was performed by modification of literature methods [6–8,52–57]. The yeast cell inoculum was prepared from the stock culture of *S. cerevisae* grown in Tryptic Soy Broth (TSB) at room temperature (25 °C) for 24 h. The yeast concentration was adjusted according to Mcfarland 0.5 turbidity tubes ($\sim 10^5$ cells per ml) using sterilized TSB. Stock solutions of chemical derivatives were prepared in DMSO at 1000 μg/ml. A modified macrodilution test was applied for antimicrobial activity. One millilitre TSB was added to each of ten sterilized tubes. One millilitre of chemical derivative solution was added to the first tube and 2-fold dilutions of the stock solution were prepared (1/2–1/1024) of yeast cell (McFarland 0.5; 20 μl) was added to each tube except the last control tube. Only 2 ml of yeast cell was added in to control tube without chemical and used as control for growing. All tubes were incubated at 25 °C for 24 h. After the incubation, the minimal inhibitor concentrations (MIC) concentrations were noted by controlling the growth inhibition. For confirmation and determination the minimal fungicidal concentrations (MFC), subcultivations were done from four dilutions (two dilutions from preinhibition, two dilutions from postinhibition) by inoculation of 20 μl samples from the tubes to Sabaroud Dextrose Agar (SDA). All agar plates were incubated at 25 °C for 24 h. The same procedures were performed for filamentous fungus *Penicillium* spp. except the incubation time was 4 days at 25 °C.

The benzoylaminocarbothioyl pyrrolidines (**1a**–**e**) and metal complexes (**2a**, **3c**, **4a** and **6**), were tested against the yeast *S. cerevisae and* the fungus *P. digitatum.* Activities (Table 3) were disappointingly low. Sensitivity of the compounds tested was found to be different between both microorganisms. In general, filamentous fungal growth inhibition was higher than yeast growth inhibition for the ligand and nickel complexes. The ligands (**1b** and **d**) and metal complexes (**3c** and **4a**) were found to be most active when tested against *P. digitatum* giving MIC values of 31.25 μg/ml. No detectable correlation was found between ligands and their metal complexes. However, some correlation as seen between the ligand (**1b**) and its metal complex (**3c**) and similarly between the ligand (**1e**) and its metal complex (**6**). The metal complex (**3c**), MIC value of 62.5 was twice as active as the ligand (**1b**), MIC value of 125 μg/ml and an identical trend was found for metal complex (**6**) and ligand (**1e**) against *S. cerevisae*. A similar trend of the metal complex displaying greater activity than the ligand is seen for

metal complex (**4a**) and ligand (**1e**) against the fungus *P. digitatum* (Table 3).

In summary, technically simple metal catalysed imine-azomethine ylides-1,3-dipolar cycloaddition cascades [40] provide access to novel highly functionalized aroylaminocarbothioyl pyrrolidines and their metal complexes. The antifungal effect of these against pathogenic fungi and yeast was found to be disappointing low.

4. Experimental

4.1. General technical data

IR spectra were recorded on a Shimadzu 435 spectrophotometer, using KBr pellets or on a Varian Scimitar Series 1000 FT-IR spectrophotometer, using horizontal ATR. Nuclear magnetic resonance spectra and decoupling experiments were determined at 400 MHz on a Varian instrument, at 500 MHz on a Bruker AM500 and at 300 MHz on a Bruker Ultrashield TM spectrometer as specified. Chemical shifts are given in parts per million (δ) downfield from tetramethylsilane as internal standard. Spectra were determined in deuteriochloroform except where otherwise stated. The following abbreviations are used; s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br = broad and brs = broad singlet. Flash column chromatography was performed using silica gel 60 (230–400 mesh). Kieselgel columns were packed with silica gel GF254 (Merck 7730). Petroleum ether refers the fraction with b.p. 40–60 °C unless otherwise specified. Melting points were determined on a digital electrothermal model 9200 or Stuart SMP3 hot stage apparatus and are uncorrected. Microanalyses were obtained using a Carlo-Erba Model 1106 instrument or Varian Liberty Series II ICP-AES Axial CHNS-932(LECO). Magnetic susceptibilities were determined on a Sherwood scientific magnetic susceptibility balance (Model K1) at 20 °C using $Hg[Co(SCN)_4]$ as a calibrant; diamagnetic corrections were calculated from Pascal's constants [58]. Mass spectra were recorded at 70 eV on a VG Autospec or Agilent LC/MSD mass spectrometer for the ligands. Accurate molecular masses were recorded on a Bruker micrOTOF instrument employing electrospray ionisation techniques. The X-ray crystal structure data were collected on a Stadi 4-circle diffractometer. All solvents were purified according to procedures given in the literature [59]. The ligands (**1a**–**e**) were prepared as reported previously [50,51] and the ligands (**1f** and **g**) were prepared as indicated below.

Table 2
Selected bond angles (°) and interatomic distances (Å) with s.u.s. in parentheses for compound **2a** and **8**.

[b] Activity of each compound after 4 days at 25 °C.

4.2. General procedure for the synthesis of aroylaminocarbo-N-thioyl pyrrolidines (**1f**, **g**)

To a stirred solution of aroylisothiocyanate (1.22 mmol) in freshly distilled, dry, degassed acetonitrile (20 mL) was added a stirred solution of pyrrolidine cycloadduct (1.22 mmol) in acetonitrile (10 mL) over 15 min and the mixture stirred at ambient temperature under a nitrogen atmosphere for 5–6 h. The solvent was evaporated under reduced pressure (bath temperature not higher than 30 °C) and the residue purified by column chromatography eluting with 1:2 v/v ether–petroleum ether afforded the product.

4.2.1. 1-(3-Chlorobenzoylaminocarbothioyl)-2,5-diphenyl-pyrrolidine-2,4-dicarboxylicacid dimethyl ester (**1f**)

After a reaction time of 5 h and work up the product (88%) crystalised from ether as a pale yellow prisms, as a 1:3 rotamer mixture, m.p. 110–112 °C. (*Anal.* Calc. $C_{28}H_{25}ClN_2O_5S$ requires: C, 62.60; H, 4.70; N, 5.20; S, 5.95. Found: C, 62.75; H, 4.80; N, 5.55; S, 5.65%.) *vmax* (KBr): 3260, 3063, 2950, 1740, 1676, 1598, 1496, 1433, 1402, 1229 and 1203 cm^{-1}. δ_H(300 MHz): 7.87(brs, 1H, NH), 7.77–7.06(m, 14H, Ar–H), 5.88(d, 1H, 5-H, minor rotamer), 5.81(d, 1H, 5-H, major rotamer), 3.92(s, 3H, OCH_3, major rotamer), 3.74(s, 3H, OCH_3, minor rotamer), 3.40(m, 1H, 4-H), 3.34(s, 3H, OCH_3, minor ratomer), 3.26(s, 3H, OCH_3, major rotamer), 2.57–2.47(m, 2H, 3-H). δ_C(75 MHz): 187.21 and 179.16 (C=S, rotamers), 171.50 and 170.72 (C=O, rotamers), 170.15 and 169.13 (C=O, rotamers), 168.74 and 163.41 (C=O, rotamers). *m/z* (%) (ES): 537.2 (MH^+, 100), 539.2 (MH^+, 35).

4.2.2. 1-Benzoylaminocarbothioyl-2-benzyl-5-(4-methoxyphenyl)-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**1g**)

After a reaction time of 6 h and work up the product (91%) crystalised from ether as pale yellow prisms as a 1:3 rotamer mixture, m.p. 161–163 °C. (*Anal.* Calc. $C_{30}H_{30}N_2O_6S$ requires: C, 65.90; H, 5.55; N, 5.15; S, 5.85. Found: C, 66.10; H, 5.70; N, 5.25; S, 5.55%.) *vmax* (KBr): 3279, 3034, 2950, 1736, 1681, 1612, 1516, 1454, 1405, 1233, 1187 cm^{-1}. δ_H(300 MHz): 8.15 (brs, 1H, NH), 7.59–6.78(m, 14H, Ar-H), 5.23(d, 1H, 5-H, minor rotamer), 5.09(d, 1H, 5-H, major rotamer), 4.68(d, 1H, 4-H, major rotamer), 4.21(d, 1H, 4-H, minor ratomer), 3.94(s, 3H, OCH_3), 3.81(s, 3H, OCH_3, major rotamer), 3.77(s, 3H, OCH_3, minor rotamer), 3.51–3.01(m, 2H, –CH_2Ph), 3.17(s, 3H, OCH_3, minor ratomer), 3.12(s, 3H, OCH_3, major rotamer), 2.41–2.17(m, 2H, 3-H). δ_C(75 MHz): 186.43 and 177.58 (C=S, rotamers), 173.47 and 172.18 (C=O, rotamers), 172.02 and 169.85(C=O, rotamers), 169.39 and 163.96(C=O, rotamers). *m/z* (%) (ES): 547.1 (MH^+, 100).

4.3. General procedure for complex formation

The Ni(II), Pd(II) and Cu(II) complexes of (**1a**–**g**) were prepared by modification of a literature method [4,5,20]. A solution of ligand (1.0 mmol) in methanol was mixed with a solution of metal acetate (0.5 mmol) in methanol and the reaction mixture stirred at ambient temperature for 2–3 h. during which time the product precipitated. The product was filtered off and crystallized from dichloromethane–methanol.

4.3.1. Ni complex of 1-benzoylaminocarbothioyl-2-benzyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**2a**)

After a reaction time of 2 h and work up the product (86%) as crystallised from dichloromethane–methanol as red prisms, m.p. 198–200 °C. (*Anal.* Calc. $C_{58}H_{54}N_4O_{10}S_2Ni$ requires: C, 63.75; H, 5.10; N, 5.10. Found: C, 63.70; H, 5.00; N, 5.00%.) *vmax* (KBr): 3028, 2949, 1742, 1600, 1502, 1409, 1367, 1251, 1202, 1025 and 703 cm^{-1}. δ_H(500 MHz): 8.06 (m, 4H, Ar-H), 7.58–6.99(m, 26H, ArH), 5.0 and 4.94(2 × d, 2H, 5-H), 4.23 and 4.20(2 × d, 2H, CH_2Ph), 3.78 and 3.74(2 × s, 6H, OMe), 3.35(m, 2H, CH_2Ph), 3.10 and 3.09(2 × s, 6H, OMe), 2.91(m, 2H, 3-H), 2.24–2.17(m, 4H, 4-H and 3′-H). δ_C(125 MHz): 174.00 and 173.59 (C=S), 173.30 and 173.27 (C=O), 173.15 and 173.05 (C=O), 169.67 (2C=O).

4.3.2. Pd complex of 1-benzoylaminocarbothioyl-2-benzyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (2b)

After a reaction time of 2 h and work up the product (82%) crystallised from dichloromethane–methanol as a yellow prisms, m.p. 272–274 °C. ν_{max} (KBr): 3060, 2949, 1743, 1598, 1497, 1402, 1367, 1245, 1173, 1024 and 699 cm^{-1}. δ_H(400 MHz): 8.17–8.15(m, 4H, Ar-H), 7.52–7.14(m, 26H, ArH), 5.10 and 5.04(2 × d, 2H, 5-H), 4.32 and 4.25(2 × d, 2H, CH_2Ph), 3.82 and 3.76(2 × s, 6H, OMe), 3.45 and 3.37(2 × d, 2H, CH_2Ph), 3.13 and 3.11(2 × s, 6H, OMe), 2.98(m, 2H, 3-H), 2.32–2.24(m, 4H, 4-H and 3′-H). δ_C(100 MHz): 173.40 (2C=S), 172.89 and 172.48 (C=O), 172.09 and 171.97 (C=O), 169.80 (2C=O).

4.3.3. Cu complex of 1-benzoylaminocarbothioyl-2-benzyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**2c**)

After a reaction time of 2 h and work up the product (90%) crystallised from dichloromethane–methanol as green prism, m.p.

257–259 °C (decomp.). (*Anal.* Calc. for $C_{58}H_{54}N_4O_{10}S_2Cu$ requires: C, 63.60; H, 4.95; N, 5.10; S, 5.85. Found: C, 63.15; H, 4.85; N, 4.95; S, 5.45%.) *vmax* (ATR): 3060, 2946, 1733, 1597, 1494, 1451, 1400, 1363, 1252, 1204, 1022, 699 cm^{-1}. Gouy Balance μ_{eff} [B.M.], Found: 1.92, requires: 1.73.

4.3.4. Ni complex of 1-benzoylaminocarbothioyl-2-sec-butyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**3a**)

After a reaction time of 2 h and work up the product (78%) crystallised from dichloromethane–methanol as a red prisms, m.p. 285–287 °C. (Anal. Calc. for $C_{52}H_{58}N_4O_{10}S_2Ni$ requires: C, 61.10; H, 5.70; N, 5.50; S, 6.30. Found: C, 60.95; H, 5.50; N, 5.40; S, 5.85%.) *vmax* (KBr): 3000, 2965, 1741, 1506, 1409, 1364, 1245, 1204, 1025 and 720 cm^{-1}. δ_H(400 MHz): 7.92(m, 2H, ArH), 7.41–7.15(m, 18H, Ar-H), 5.41(m, 2H, 5-H), 3.60(m, 2H, 4-H), 360 and 3.58(2 × s, 6H, OMe), 3.20(brs, 6H, OMe), 2.94(m, 2H, 3-H), 2.75(m, 2H, 3′-H), 2.37(m, 2H, CH), 1.92–0.80(m, 16H, $CH_3CHCH_2CH_3$). δ_C(100 MHz): 174.10 (C=S), 173.68 (C=S), 173.58 (C=O), 173.29 (2C=O), 169.93 (C=O), 169.87 (2C=O). *m/z* (%) (ES+): 1021.3(MH^+). HRMS (ES+) found MH^+ 1021.3021, $C_{52}H_{59}N_4O_{10}S_2Ni$ requires MH^+ 1021.3065.

4.3.5. Pd complex of 1-benzoylaminocarbothioyl-2-sec-butyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**3b**)

After a reaction time of 2 h and work up the product (72%) crystallised from dichloromethane–methanol as a yellow prism, m.p. 231–233 °C (decomp.). ν_{max} (ATR): 3059, 2963, 1736, 1586, 1497, 1389, 1364, 1258, 1171, 1021, 697 cm^{-1}. δ_H(500 MHz): 8.08(m, 6H, ArH), 7.83–7.17(m, 14H, Ar-H), 5.51 and 5.47(2 × d, 2H, 5-H), 3.72 and 3.71(2 × s, 6H, OMe), 3.67(m, 2H, 4-H), 3.31 and 3.30(2 × s, 6H, OMe), 3.01(m, 2H, 3-H), 2.84(m, 2H, 3′-H), 2.48(m, 2H, CH), 1.29–0.82(m, 16H, $CH_3CHCH_2CH_3$). δ_C(125 MHz): 173.46 (C=S), 173.36 (C=S), 172.59 and 172.53 (C=O) 171.86 and 171.84 (C=O), 169.69 (C=O) and169.62 (C=O). *m/z* (%) (ES+): 1069.3(MH^+). HRMS (ES+) found 1069.2702, $C_{52}H_{59}N_4O_{10}S_2Pd$ requires MH^+ 1069.2714.

4.3.6. Cu complex of 1-benzoylaminocarbothioyl-2-sec-butyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**3c**)

After a reaction time of 2 h and work up the product (90%) separated from dichloromethane–methanol as a green amorphous, m.p. 194–196 °C. (*Anal.* Calc. for $C_{52}H_{58}N_4O_{10}S_2Cu$ requires: C, 60.85; H, 5.70; N, 5.45; S, 6.25. Found: C, 60.50; H, 5.55; N, 5.45; S, 5.70%.) *vmax* (KBr): 3000, 2967, 1740, 1507, 1406, 1362, 1243, 1202, 1025 and 703 cm^{-1}. *m/z* (%) (ES+): 1026.3(MH^+). HRMS (ES+) found 1026.2963, $C_{52}H_{59}N_4O_{10}S_2Cu$ requires MH^+ 1026.2926. Gouy Balance μ_{eff} [B.M.], Found: 1.92, requires: 1.73.

4.3.7. Ni complex of 1-benzoylaminocarbothioyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**4a**)

After a reaction time of 2 h and work up the product (86%) crystallised from dichloromethane–methanol as red prisms, m.p. 287–289 °C. (Anal. Calc. for $C_{44}H_{42}N_4O_{10}S_2Ni$ requires: C, 58.10; H, 4.65; N, 6.15; S, 7.05. Found: C, 57.85; H, 4.55; N, 6.15; S, 6.70%.) *vmax* (ATR): 3061, 2947, 1752, 1586, 1497, 1409, 1362, 1275, 1169, 1031, 713 cm^{-1}. δ_H(400 MHz): 8.01–7.22(m, 20H, ArH), 5.80 and 5.45(2 × m, 2xH, 5-H), 4.78(m, 2H, 2-H), 3.78 and 3.75(2 × s, 6H, OMe), 3.55–3.40(m, 2H, 3-H), 3.48 and 3.46(2 × s, 6H, OMe), 2.62–2.44(m, 4H, 4-H and 3′-H). δ_C(100 MHz): 174.47 and 174.42 (C=S), 173.80 and 173.62 (C=O), 171.82 and 171.72 (C=O) 169.23 (2C=O).

4.3.8. Pd complex of 1-benzoylaminocarbothioyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**4b**)

After a reaction time of 2 h and work up the product (72%) crystallised from dichloromethane–methanol as pale yellow prisms, m.p. 252–254 °C. (*Anal.* Calc. for $C_{44}H_{42}N_4O_{10}S_2Pd$ requires: C, 55.20; H, 4.40; N, 5.85; S, 6.70. Found: C, 54.95; H, 4.40; N, 5.95; S, 6.30%.) *vmax* (ATR): 3038, 2943, 1749, 1588, 1499, 1427, 1405, 1363, 1265, 1171, 1025, 713 cm^{-1}. δ_H(400 MHz): 8.14–7.24(m, 20H, ArH), 5.65(m, 2H, 5-H), 4.84(m, 2H, 2-H), 3.74 and 3.72(2 × s, 6H, OMe), 3.53–3.35(2 × m, 2H, 3-H), 3.42(s, 6H, OMe), 2.65–2.40(m, 4H, 4-H and 3′-H).

4.3.9. Cu complex of 1-benzoylaminocarbothioyl-5-phenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**4c**)

After a reaction time of 2 h and work up the product (88%) crystallised from dichloromethane–methanol as green prisms, m.p. 211–213 °C (decomp.). ν_{max} (ATR): 3052, 2945, 1743, 1585, 1510, 1404, 1358, 1238, 1169, 1021, 712 cm^{-1}. *m/z* (%) (ES+): 914.2(MH^+) and 936.2 (MNa^+). HRMS (ES+) found 914.1711, $C_{44}H_{43}N_4O_{10}S_2Cu$ requires MH^+ 914.1725. Gouy Balance μ_{eff} [B.M.], Found: 1.95, requires: 1.73.

4.3.10. Ni complex of 1-benzoylaminocarbothioyl-2,5-diphenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**5a**)

After a reaction time of 2 h and work up the product (86%) crystallised from dichloromethane–methanol as red prisms, m.p. 198–200 °C. (*Anal.* Calc. for $C_{56}H_{50}N_4O_{10}S_2Ni$ requires: C, 63.25; H, 4.90; N, 5.25. Found: C, 63.00; H, 4.60; N, 5.20%.) *vmax* (ATR): 3062, 2947, 1742, 1584, 1497, 1397, 1361, 1242, 1179, 1021 and 716 cm^{-1}. δ_H(500 MHz): 7.59–7.13(m, 30H, ArH), 5.63–5.59(m, 2H, 5-H), 3.65 and 3.63(2 × s, 6H, OMe), 3.30 and 3.25(2 × s, 6H, OMe), 3.28–3.12(m, 4H, 3-H and 4-H), 2.33(m, 2H, 3′-H). δ_C(125 MHz): 174.31 and 173.94 (C=S), 173.50(2C =O), 171.26 and 171.20 (C=O), 169.18 (2C=O).

4.3.11. Pd complex of 1-benzoylaminocarbothioyl-2,5-diphenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**5b**)

After a reaction time of 2 h and work up the product (82%) crystallised from dichloromethane–methanol as yellow amorphous. m.p. 272–274 °C. *vmax* (ATR): 3060, 2949, 1739, 1586, 1495, 1360, 1242, 1224, 1170, 1023, 698 cm^{-1}. δ_H(500 MHz): 7.65–7.53(m, 8H, ArH), 7.42–7.11(m, 22H, ArH), 5.70 and 5.68(2 × d, 2H, 5-H), 3.61 and 3.59(2 × s, 6H, OMe), 3.32 and 3.31(2 × s, 6H, OMe), 3.30–3.25(m, 4H, 3-H and 4-H), 2.45–2.37(m, 2H, 3′-H). δ_C(125 MHz): 172.62 and 172.27 (C=S), 172.11 and 171.93 (C=O), 171.17 and 171.11 (C=O), 169.11 (2C=O). *m/z* (%) (ES+): 1109.2(MH^+). HRMS (ES+) found 1109.2076, $C_{56}H_{51}N_4O_{10}S_2Pd$ requires MH^+ 1109.2091.

4.3.12. Cu complex of 1-benzoylaminocarbothioyl-2,5-diphenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**5c**)

After a reaction time of 2 h and work up the product (92%) crystallised from dichloromethane–methanol as green prisms, m.p. 248–250 °C. (*Anal.* Calc. for $C_{56}H_{50}N_4O_{10}S_2Cu$ requires: C, 63.05; H, 4.70; N, 5.25; S, 5.50. Found: C, 62.85; H, 4.60; N, 5.30; S, 5.70%.) *vmax* (ATR): 3058, 2948, 1740, 1585, 1494, 1397, 1360, 1241, 1174, 1022, 697 cm^{-1}. Gouy Balance μ_{eff} [B.M.], Found: 1.88, requires: 1.73.

4.3.13. Ni complex of 1-benzoylaminocarbothioyl-5-(naphthalen-3-yl)-pyrrolidine-2,3,4-tricarboxylic acid trimethyl (**6a**)

After a reaction time of 2 h and work up the product (76%) crystallised from dichloromethane–methanol as red prisms, m.p. 213–215 °C. ν_{max} (KBr):3056, 2950, 1743, 1502, 1419, 1360, 1237, 1170, 1054 and 712 cm^{-1}. δ_H(400 MHz): 8.20–7.10(m, 24H, ArH), 5.70–5.60(m, 2H, 5-H), 3.70(s, 6H, OMe), 3.65(m, 2H, 2-H), 3.25(brs, 12H, OMe), 3.18(m, 2H, 4-H), 2.38(m, 2H, 3-H). δ_C(100 MHz): 174.56 and 174.14 (C=S), 173.78 and 173.72 (C=O), 171.47 and 171.39 (C=O) 169.29 and 169.27(2C =O) *m/z* (%) (ES+):

1125.2(MH^+). HRMS (ES+) found 1125.2191, $C_{56}H_{51}N_4O_{10}S_2Ni$ requires MH^+ 1125.2393.

*4.3.14. Cu complex of 1-benzoylaminocarbothioyl-5-(naphthalen-3-yl)-pyrrolidine-2,3,4-tricarboxylic acid trimethyl (**6b**)*

After a reaction time of 2 h and work up the product (92%) crystallised from dichloromethane–methanol as green prisms, m.p. 248–250 °C. ν_{max} (ATR): 3055, 2948, 1736, 1598, 1497, 1402, 1358, 1283, 1204, 1166, 1052, 710 cm^{-1}. Gouy Balance μ_{eff} [B.M.], Found: 1.88, requires: 1.73. *m/z* (%) (ES+): 1130.2(MH^+), 1153.2 (MNa^+). HRMS (ES+) found 1130.2134, $C_{56}H_{51}N_4O_{10}S_2Cu$ requires MH^+ 1130.2163.

*4.3.15. Ni complex of 1-benzoylaminocarbothioyl-2,5-diphenyl-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**7**)*

After a reaction time of 3 h and work up the product (89%) crystallised from dichloromethane–methanol as red prisms in yield, m.p. 295–297 °C. (*Anal.* Calc. for $C_{56}H_{48}$ $Cl_2N_4O_{10}S_2Ni$ requires: C, 59.50; H, 4.25; N, 4.95. Found: C, 59.05; H, 4.35; N, 4.65%.) *vmax* (ATR): 3065, 2988, 1740, 1512, 1394, 1243, 1198, 1028, 746 and 703 cm^{-1}. δ_H(500 MHz): 7.70–7.50(m, 6H, ArH), 7.40–7.07(m, 22H, ArH), 5.58(m, 2H, 5-H), 3.68 and 3.66(2 × s, 6H, OMe), 3.30 and 3.29(2 × s, 6H, OMe), 3.32–3.22(m, 4H, 3-H and 4-H), 2.40(m, 2H, 3′-H). δ_C(125 MHz): 174.57 and 174.24 (C=S), 171.95 (2C=O) 171.23 and 171.16 (C=O) 169.06 (2C=O) *m/z* (%) (ES+): 1129.1(MH^+), 1131.1(MH^+). HRMS (ES+) found 1129.1615, $C_{56}H_{49}Cl_2N_4O_{10}S_2Ni$ requires MH^+ 1129.1663.

*4.3.16. Ni complex of 1-benzoylaminocarbothioyl-2-benzyl-5-(4-methoxyphenyl)-pyrrolidine-2,4-dicarboxylic acid dimethyl ester (**8**)*

After a reaction time of 3 h and work up the product (87%) crystallised from dichloromethane–methanol as pale violet plate, m.p. 255–257 °C. (*Anal.* Calc. for $C_{60}H_{58}N_4NiO_{12}S_2{\cdot}0.5H_2O$ requires: C, 62.25; H, 5.10; N, 4.85; S, 5.30. Found: C, 62.00; H, 5.10; N, 4.90; S, 5.20%.) *vmax* (ATR): 3062, 2949, 1731, 1610, 1508, 1402, 1245, 1201, 1025, 749 and 704 cm^{-1}. δ_H(300 MHz) ($CDCl_3$): 8.08(m, 4H, Ar-H), 7.52–7.19(m, 20H, Ar-H), 6.86 and 6.75(2 × d, 4H, Ar-H), 5.01 and 4.95(2 × d, 2H, 5-H), 4.24(m, 2H, CH_2Ph), 3.85, 3.80, 3.79 and 3.77(4 × s, 12H, OMe), 3.40–3.33(m, 2H, 4-H), 3.17 and 3.15(2 × s, 6H, OMe), 2.97(m, 2H, CH_2Ph), 2.31–2.13(m, 4H, 3-H and 3′-H). δ_C($CDCl_3$): 173.88 and 173.42 (C=S), 173.35 (2C=O), 173.03 (C=O), 172.94 (C=O) and 169.82 (2C=O). *m/z* (%) (ES+): 1149.3(MH^+). HRMS (ES+) found 1149.2919, $C_{60}H_{59}N_4O_{12}S_2Ni$ requires MH^+ 1149.2866.

Supplementary data

CCDC 721640 and 721641 contain the supplementary crystallographic data for **2a** and **8**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Synthetic route of three phthalonitriles (**1**, **2** and **3**), and their zinc phthalocyanines derivatives (i) anhydrous $Zn(Ac)_2$, 1-pentanol, 15 h, argon atm.

diazabicyclo[5.4.0] undec-7-ene (DBU), potassium carbonate, and zinc acetate were purchased from Aldrich.

FT-IR spectra (KBr pellets) were recorded on a Perkin–Elmer spectrum 2000 FT-IR spectrometer. UV–Vis spectra were recorded on a Cary 500 UV–Vis/NIR spectrophotometer. ^1H and ^{13}C NMR spectra were obtained in $CDCl_3$ using a Bruker EMX 400 NMR spectrometer. Elemental analyses were done on Vario Elementar EL III. Fluorescence spectra were recorded on the Varian Eclipse spectrofluoremeter. Triplet absorption and decay kinetics were recorded on a laser flash photolysis system, the excitation pulses were produced by a Nd: YAG laser (Quanta-Ray, 1.5 J/90 ns) pumping a dye laser (Lambda Physic FL 3002, Pyridin 1 in methanol). The analyzing beam source was from a Thermo Oriel xenon arc lamp, and a photomultiplier tube was used as detector. Signals were recorded with a two-channel digital real-time oscilloscope (Tektronix TDS 360); the kinetic curves were averaged over 256 laser pulses. Photo-irradiations were done using a General Electric Quartz line lamp (300 W). A 600 nm glass cut off filter (Schott) and a water filter were used to filter off ultraviolet and infrared radiations, respectively. An interference filter (Intor, 670 nm with a band width of 20 nm) was additionally placed in the light path before the sample. Light intensities were measured with a POWER MAX 5100 (Molelectron detector incorporated) power meter. Mass spectras were obtained using a ABI Voyager DE-STR Maldi TOF instrument at University of Stellenbosch.

2.2. Synthesis

2.2.1. 4-[3,4-(Methylendioxy)-phenoxy]-phthalonitrile (*1*)

The 4-nitrophthalonitrile (4.40 g, 25.35 mmol) was dissolved in DMF (35 ml) under argon and 3,4-(methylendioxy)-phenol (3.50 g, 25.35 mmol) was added. After stirring for 30 min at room temperature, finely ground anhydrous potassium carbonate (8.65 g, 63.40 mmol) was added in portions during 4 h with efficient stirring. The reaction mixture was stirred under argon atmosphere at room temperature for 24 h. Then the mixture was poured into 400 ml ice water, and the precipitate was filtered off, washed with water and methanol and then dried. The crude product was recrystallized from methanol. Finally the pure product was dried in vacuum. Thin layer chromatography with silica gel was employed to confirm the absence of the starting phthalonitrile.

Yield: 4.50 g (67%). IR spectrum (cm^{-1}): 3084 (Ar–CH), 2226 (C≡N), 1599 (C=C), 1564, 1486, 1417, 1306, 1249, 1096 (C–O–C), 1037, 966, 778, 664. ^1H NMR ($CDCl_3$): δ = 7.75 (d, J = 8.41 Hz, 1H, Ar–H), 7.32 (2H, broad s, Ar–H), 6.89 (d, J = 8.16 Hz, 1H, Ar–H), 6.59 (2H, s, Ar–H), 6.08 (2H, s, CH_2). ^{13}C NMR ($CDCl_3$): δ = 162.69 (Ar–CO), 149.55 (Ar–CO), 148.19 (Ar–CO), 146.31 (Ar–CH), 135.75 (Ar–C), 121.46 (Ar–CH), 118.46 (Ar–CH), 115.76 (Ar–CN), 113.74 (Ar–CH), 109.30 (Ar–CH), 109.21 (Ar–CH), 102.54 (O–CH). *Anal.* Calc. for $C_{15}H_8N_2O_3$: C, 68.18; H, 3.05; N, 10.06. Found: C, 68.23; H, 3.01; N, 10.01%.

*2.2.2. 3-[3,4-(Methylendioxy)-phenoxy]-phthalonitrile (**2**)*

The synthesis of **2** was similar to that of **1**, except 3-nitrophthalonitrile (1.25 g, 7.25 mmol) instead of 4-nitrophthalonitrile was employed. The amounts of the other reagents were: 3,4-(methylendioxy)-phenol, 1.00 g (7.25 mmol) and anhydrous potassium carbonate, 2.50 g (18.12 mmol).

Yield: 1.34 g (70%). IR spectrum (cm^{-1}): 3087, 3073 (Ar–CH), 2228 (C≡N), 1576 (C=C), 1438, 1389, 1243, 1097 (C–O–C), 1034, 990, 866, 799, 719. ^1H NMR ($CDCl_3$): δ = 7.58 (d, J = 8.42 Hz, 1H, Ar–H), 7.47 (d, J = 7.53 Hz, 1H, Ar–H), 7.13 (d, J = 8.46 Hz, 1H, Ar–H), 6.87 (d, J = 8.33 Hz, 1H, Ar–H), 6.65 (2H, s, Ar–H), 6.07 (2H, s, CH_2). ($CDCl_3$): δ = 161.83 (Ar–CO), 150.03 (Ar–CO), 148.45 (Ar–CO), 146.30 (Ar–CH), 134.71 (Ar–C), 120.37 (Ar–CH), 117.72 (Ar–CH), 115.49 (Ar–CN), 113.01 (Ar–CH), 109.15 (Ar–CH), 106.16 (Ar–CH), 102.50 (O–CH). *Anal.* Calc. for $C_{15}H_8N_2O_3$: C, 68.18; H, 3.05; N, 10.06. Found: C, 68.15; H, 3.08; N, 10.11%.

*2.2.3. 4,5-[3,4-(Methylendioxy)-phenoxy-phthalonitrile (**3**)*

The synthesis of **3** was similar to that of **1**, except 4,5-dichlorophthalonitrile (0.71 g, 3.62 mmol) instead of 4-nitrophthalonitrile was employed. The amounts of the other reagents were: 3,4-(methylendioxy)-phenol, 1.02 g (7.25 mmol) and anhydrous potassium carbonate, 2.50 g (18.12 mmol).

Yield: 1.00 g (69%). IR spectrum (cm^{-1}): 3084, 3050 (Ar–CH), 2230 (C≡N), 1599 (C=C), 1486, 1444, 1249, 1096 (C–O–C), 1037, 966, 884, 778, 664. ^1H NMR ($CDCl_3$): δ = 7.16 (2H, s, Ar–H), 6.88 (d, J = 8.35 Hz, 2H, Ar–H), 6.65 (d, J = 2.38 Hz, 2H, s, Ar–H), 6.59 (dd, J = 8.36, 2.42 Hz, 2H, Ar–H), 6.08 (4H, s, CH_2). ^{13}C NMR ($CDCl_3$): δ = 152.72 (Ar–CO), 149.50 (Ar–CO), 148.37 (Ar–CO), 135.46 (Ar–C), 121.40 (Ar–CH), 115.55 (Ar–CN), 113.23 (Ar–CH), 110.52 (Ar–CH), 109.21 (Ar–CH), 102.91 (O–CH). *Anal.* Calc. for $C_{22}H_{12}N_2O_6$: C, 66.00; H, 3.02; N, 7.00. Found: C, 65.94; H, 2.99; N, 7.05%.

*2.2.4. (4)-Tetra[3,4-(methylendioxy)-phenoxy]phthalocyaninato zinc(II) (**4**)*

Compound **1** (0.50 g, 1.89 mmol), anhydrous zinc acetate (0.41 g, 1.89 mmol) and 3 ml of dry 1-pentanol were placed in a standard Schlenk tube in the presence of 1,8-diazabicyclo[5.4.0] undec-7-ene (DBU) (0.45 ml, 0.29 mmol) under a nitrogen atmosphere and held at reflux temperature for 15 h. After cooling to room temperature, the reaction mixture was precipitated by adding it drop-wise into *n*-hexane. The crude product was precipitated, collected by filtration and washed with hot hexane, ethanol and methanol. The crude green product was further purified by chromatography over a silica gel column using THF, $CHCl_3$ and a mixture of THF and CH_2Cl_2 (1:15 by volume), as eluents, respectively.

Yield: 0.25 g (47%). UV–Vis (DMSO): λ_{max} nm (log ε) 358 (4.95), 613 (4.74), 680 (5.43), (toluene): λ_{max} nm (log ε) 351 (4.84), 612 (4.70), 680 (5.40), (DCM): λ_{max} nm (log ε) 357 (4.97), 612 (4.72), 681 (5.45). IR spectrum (cm^{-1}): 3073 (Ar–CH), 2945, 2892 (CH), 1608 (C=C), 1482, 1396, 1335, 1218, 1093 (C–O–C), 952, 815, 745, 731 (Pc skeletal). ^1H NMR ($CDCl_3$): δ = 8.11–6.43 (24H, m, Ar–H), 5.99 (8H, s, CH_2). *Anal.* Calc. for $C_{60}H_{32}N_8O_{12}Zn$: C, 64.21; H, 2.87; N, 9.98. Found: C, 64.35; H, 3.03; N, 9.73%. MS (ES^+), (m/z): Calc. 1122.4. Found: 1123.6 [M^+].

*2.2.5. (3)-Tetra[3,4-(methylendioxy)-phenoxy]phthalocyaninato zinc(II) (**5**)*

The synthesis and purification of **5** was as outlined for **4**, except compound **2** (0.50 g, 1.89 mmol) instead of complex **1** was employed. The amounts of the other reagents were anhydrous zinc acetate (0.41 g, 1.89 mmol), dry 1-pentanol (3 ml) and DBU (0.45 ml, 0.29 mmol).

Yield: 0.20 g (38%). UV–Vis (DMSO): λ_{max} nm (log ε) 365 (4.75), 626 (4.72), 697 (5.40), (Toluene): λ_{max} nm (log ε) 352 (4.82), 626 (4.83), 696 (5.53), (DCM): λ_{max} nm (log ε) 358 (4.70), 627 (4.61), 694 (5.39). IR spectrum (cm^{-1}): 3077 (Ar–CH), 2955, 2885 (–CH), 1607 (C=C), 1477, 1395, 1333, 1236, 1090 (C–O–C), 1038, 968, 928, 878, 815, 744 (Pc skeletal). ^1H NMR ($CDCl_3$): δ = 8.43–6.49 (24H, m, Ar–H), 5.98 (8H, s, CH_2). *Anal.* Calc. for $C_{60}H_{32}N_8O_{12}Zn$: C, 64.21; H, 2.87; N, 9.98. Found: C, 64.15; H, 3.01; N, 9.77%. MS (ES^+), (m/z): Calc. 1122.4. Found: 1123.6 [M^+].

*2.2.6. 2,3-Octakis-[3,4-(methylendioxy)-phenol]phthalocyaninato zinc(II) (**6**)*

The synthesis and purification of **6** was as outlined for **4**, except compound **3** (0.50 g, 1.25 mmol) instead of complex **1** was employed. The amounts of the other reagents were anhydrous zinc acetate (0.27 g, 1.25 mmol), dry 1-pentanol (3 ml) and DBU (0.45 ml, 0.29 mmol).

Yield: 0.13 g (25%). UV–Vis (DMSO): λ_{max} nm (log ε) 359 (5.01), 629 (4.78), 679 (5.24), (Toluene): λ_{max} nm (log ε) 363 (4.63), 614 (4.49), 680 (5.11), (DCM): λ_{max} nm (log ε) 359 (4.99), 612 (4.74), 680 (5.350). IR spectrum (cm^{-1}): 3074 (Ar–CH), 2957, 2890 (–CH), 1605 (C=C), 1482, 1391, 1334, 1237, 1097 (C–O–C), 1038, 993, 930, 865, 814, 744 (Pc skeletal). ^1H NMR ($CDCl_3$): δ = 7.16–6.39 (32H, m, Ar–H), 5.56 (16H, s, CH_2). *Anal.* Calc. for $C_{88}H_8N_8O_{24}Zn$: C, 63.41; H, 2.90; N, 6.72. Found: C, 63.01; H, 3.12; N, 6.97%. MS (ES^+), (m/z): Calc. 1666.7; Found: 1667.6 [M^+].

2.3. Photophysical studies

2.3.1. Fluorescence quantum yields

Fluorescence quantum yields (Φ_F) were determined by the comparative method) [24,25], (Eq. (1)):

$$\Phi_F = \Phi_{F(Std)} \frac{F \cdot A_{Std} \cdot n^2}{F_{Std} \cdot A \cdot n_{Std}^2} \quad (1)$$

where F and F_{Std} are the areas under the fluorescence curves of **4**–**6** and the standard, respectively. A and A_{Std} are the respective absorbances of the sample and standard at the excitation wavelengths (which was ~0.05 in all solvents used), and n and n_{Std} are the refractive indices of solvents used for the sample and standard, respectively. ZnPc in DMSO (Φ_F = 0.20) [26], was employed as the standard.

2.3.2. Triplet quantum yields and lifetimes

The solutions for triplet quantum yields and lifetimes were introduced into a 1.0 mm pathlength UV–Vis spectrophotometric cell, deaerated using nitrogen and irradiated at the Q-band maxima. Triplet state quantum yields (Φ_T) of **4**–**6** were determined by the triplet absorption method [27], using zinc phthalocyanine (ZnPc) as a standard; Eq. (2):

$$\Phi_T = \Phi_T^{Std} \cdot \frac{\Delta A_T \cdot \varepsilon_T^{Std}}{\Delta A_T^{Std} \cdot \varepsilon_T} \quad (2)$$

where ΔA_T and ΔA_T^{Std} are the changes in the triplet state absorbances of **4**–**6** and the standard, respectively. ε_T and ε_T^{Std} are the triplet state molar exctinction coefficients for **4**–**6** and the standard, respectively. Φ_T^{Std} is the triplet quantum yield for the standard, ZnPc (Φ_T = 0.65 in DMSO [28] and 0.65 in toluene [29]). ε_T and ε_T^{Std} were determined from the molar extinction coefficients of their respective ground singlet state (ε_s and ε_S^{Std}) and the changes in absorbances of the ground singlet states (ΔA_S and ΔA_S^{Std}), according to Eq. (3):

$$\varepsilon_T = \varepsilon_S \cdot \frac{\Delta A_T}{\Delta A_S} \quad (3)$$

Quantum yields of internal conversion (Φ_{IC}) were obtained from Eq. (4), which assumes that only three processes (fluorescence, intersystem crossing and internal conversion), jointly deactivate the excited singlet state of the **4**–**6** molecules.

$$\Phi_{IC} = 1 - (\Phi_F + \Phi_T) \quad (4)$$

2.4. Photochemical studies

2.4.1. Singlet oxygen quantum yields

Quantum yields of singlet oxygen photogeneration were determined as previously explained in detail [30–32] in air (no oxygen bubbled) using the relative method with ZnPc as reference and DPBF as chemical quencher for singlet oxygen, using Eq. (5):

$$\Phi_{\Delta} = \Phi_{\Delta}^{\mathrm{Std}} \cdot \frac{R_{\mathrm{DPBF}} I_{\mathrm{abs}}^{\mathrm{Std}}}{R_{\mathrm{DPBF}}^{\mathrm{Std}} I_{\mathrm{abs}}} \tag{5}$$

where $\Phi_{\Delta}^{\mathrm{Std}}$ is the singlet oxygen quantum yield for the standard, ZnPc (Φ_{Δ} = 0.67 in DMSO [33] and 0.58 in toluene [32]). R_{DPBF} and $R_{\mathrm{DPBF}}^{\mathrm{Std}}$ are the DPBF photobleaching rates in the presence of **4–6** and the standard, respectively. I_{abs} and $I_{\mathrm{abs}}^{\mathrm{Std}}$ are the rates of light absorption by **4–6** and the standard, respectively. To avoid chain reactions induced by DPBF in the presence of singlet oxygen [34], the concentration of DPBF was $\sim 3 \times 10^{-5}$ mol l^{-1}. Solutions of sensitizer (absorbance = 0.2 at the irradiation wavelength) containing DPBF were prepared in the dark and irradiated in the Q-band region using the setup described above. DPBF degradation at 417 nm was monitored. The light intensity for singlet oxygen studies was 2×10^{15} photons s^{-1} cm^{-2}. The error in the determination of Φ_{Δ} was ~10% (determined from several Φ_{Δ} values).

2.4.2. Photodegradation quantum yields

For determination of photodegradation quantum yields, the usual Eq. (6) was employed [30–32]:

$$\Phi_{\mathrm{Pd}} = \frac{(C_0 - C_t) V N_A}{I_{\mathrm{abs}} S t} \tag{6}$$

where C_0 and C_t in mol dm^{-3} are the concentrations of **4–6** before and after irradiation, respectively; V is the reaction volume; S is the irradiated cell area (2.0 cm^2); t is the irradiation time; N_A is the Avogadro's number and I_{abs} is the overlap integral of the radiation source intensity and the absorption of **4–6** (the action spectrum) in the region of the interference filter transmittance. The light intensity for photodegradation studies was 5×10^{16} photons s^{-1} cm^{-2}.

3. Results and discussion

3.1. Syntheses and characterization

The synthetic routes to novel phthalocyanines (**4–6**) are shown in Scheme 1. These complexes were prepared by the template cyclotetramerization of 4-[3,4-(methylendioxy)-phenoxy]-phthalonitrile (**1**), 3-[3,4-(methylendioxy)-phenol]-phthalonitrile (**2**), 4,5-[3,4-(methylendioxy)-phenol]-phthalonitrile (**3**) and anhydrous $Zn(OAc)_2$ in the presence of 1-pentanol at reflux temperature under argon atmosphere and in the presence of 1,8-diazabicyclo[5.4.0] undec-7-ene (DBU) as a strong base. All of these new zinc phthalocyanines were purified by column chromatography and were obtained in a moderate yield (47% for **4**, 38% for **5**, and 25% for **6**) and were also characterized by elemental analysis together with the spectral data (^{1}H NMR, FT-IR, mass and UV–Vis spectra).

The characterization data of the new compounds are consistent with the assigned formula. The tetra-substituted complexes (**4** and **5**) were isolated as a mixture of isomers, as expected. The presence of isomers might be verified by the slight broadening encountered in the UV–Vis absorption bands and broadening in the ^{1}H NMR spectra as compared with the spectra of octa-substituted phthalocyanines which are composed of a single isomer [35–38]. No attempt was made to separate the isomers of **4** and **5**.

The characteristic vibrations corresponding to CN and ethers groups (C–O–C) at 2226, 2228 and 2230 cm^{-1} and 1096, 1097, 1096 cm^{-1} were observed for **1**, **2** and **3** in the FT-IR spectra, respectively. Aromatic C–H peaks occurred above 3050 cm^{-1} for all the phthalonitriles. The ^{1}H NMR spectrum of the compounds **1**, **2** and **3** showed signals with δ ranging from 7.75 to 6.59, belonging to aromatic protons and 6.07 and 6.08 ppm belonging to aliphatic H integrating for a total of 8 protons for **1** and **2**, and 12 protons for **3** as expected. ^{13}C NMR spectral data were in good agreement with the proposed structure. The characteristic signals related to aromatic carbon atoms and dicyano carbon atoms about δ = 135 and 115 ppm, respectively for **1–3** supported the structures.

After conversion into zinc phthalocyanine derivations, the characteristic CN stretch at ~2230 cm^{-1} of phthalonitriles **1**, **2** and **3** disappeared in the FT-IR spectra, indicative of metallophthalocyanine formation. The characteristic vibrations corresponding to ether groups (C–O–C) were observed at 1093 (for **4**), 1090 cm^{-1} (for **5**) and 1097 cm^{-1} (for **6**) and aromatic C–H peaks were above 3000 cm^{-1} for the complexes.

The compounds were found to be pure by ^{1}H NMR with both the substituents and ring protons observed in their respective regions. The ^{1}H NMR spectra of tetra-substituted phthalocyanine derivatives (**4** and **5**) and octa-substituted derivative (**6**) were almost identical with that of the starting compounds **1**, **2** and **3** except for broadening and small shift. Complexes **4** and **5** showed complex patterns due to the mixed isomer character of these compounds. In the ^{1}H NMR spectrum of **4** and **5** the aromatic and Pc protons appear between 6.43 and 8.11 ppm (for **4**, integrating for 24H), 6.49 and 8.43 ppm (for **5**, integrating for 24H), and 6.39 and 7.16 ppm (for **6**, integrating for 32H). For all complexes aliphatic protons, were observed at about at 6 ppm, integrating for a total of 8 protons for **4** and **5** and 16 protons for complex **6**. In the mass spectrum of Zn phthalocyanines (**4–6**), the presence of molecular ion peaks at m/z 1123.6 $[M]^+$, 1123.6 $[M]^+$ and 1667.6 $[M]^+$, respectively, confirmed the proposed structures. Elemental analysis results also were consistent with the proposed structures of all compounds **1–6**.

3.2. Ground state electronic absorption spectra

The UV–Vis spectra of the phthalocyanine complexes exhibit characteristic Q- and B-bands. Two principle π–π^* transitions are seen for phthalocyanines: a Q-band (~700 nm, a π–π^* transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the complexes) and a B-band (~300–350 nm, a deeper π–π^* transition from the HOMO's (a_{1u} and a_{2u}) to the LUMO (e_g)) [39,40]. The Q-band absorptions in the UV–Vis absorption spectra of the phthalocyanines (**4**, **5** and **6**) were observed as a single high intensity band due to a π–π^* transition at 681, 697 and 680 nm in DMSO, 681, 694 and 680 nm in DCM and 677, 693 and 679 nm in toluene, respectively, Table 1 and Fig. 1.

In DMSO, toluene and DCM, the Q-band positions of **5** are red-shifted relative to those of **4** and **6**, with the greatest red-shifting being observed in DMSO. Non-peripheral substitution greatly influences the energy levels of molecular orbitals and hence the absorption spectrum, whereas peripheral substitution has a smaller effect on the Q-band position. In **5**, the (methylendioxy)-phenoxy substituents are closer to the ring, hence they bring about greater destabilization of the a_{1u} orbital (HOMO), and result in larger bathochromic shifts.

The consequence of the substitution with four [3,4-(methylendioxy)-phenoxy] is clearly observed by the high solubility of the Pcs **4**, **5** and **6** in organic solvents such as DCM, $CHCl_3$, THF, DMF, DMSO, toluene and acetone. Aggregation behavior of Pc is depicted

Table 1
Spectral parameters of **4**, **5** and **6** in DMSO and toluene.

Compound	Solvent	Q-band, λ_{max} (nm)	(log ε)	Excitation, λ_{Ex} (nm)	Emission, λ_{Em} (nm)	Stokes shift, Δ_{Stokes} (nm)
4	DMSO	681	5.43	682	693	12
	toluene	677	5.40	679	689	12
5	DMSO	697	5.40	699	712	15
	toluene	693	5.53	695	705	10
6	DMSO	680	5.24	682	692	12
	toluene	679	5.11	681	689	10

as a coplanar association of rings progressing from monomer to dimer and higher order complexes and it is dependent on concentration, nature of solvent and substituents, metal ions and temperature [41]. In this study, the aggregation behavior of the Pcs derivatives (**4**, **5** and **6**) were investigated in DMSO, DCM and toluene at different concentrations. As the concentration was increased, the intensity of absorption of the Q-band also increased and there was no new bands due to the aggregated species [42], Fig. 2. Complexes **4**, **5** and **6** did not show aggregation in these solvents. Though complex **6** did not show aggregation in toluene, chloroform, THF and DCM, it showed broad band around 627 nm because of aggregation just in DMSO (Fig 1). DMSO is known to prevent aggregation since it is strong coordinating solvent. However, it has been observed [43] before that aggregation occurs in DMSO and in less coordinating solvents for some MPc derivatives. Except for **6** in DMSO, Lambert–Beer law was obeyed for these compounds in the concentrations ranging from 2.0×10^{-6} to 1.0×10^{-5} mol dm^{-3} as given an example for **5** in toluene in Fig. 2.

3.3. Fluorescence spectra, and quantum yields

Fig. 3 shows the absorption, fluorescence excitation and emission spectra of **4**, **5** and **6** in DMSO. The excitation spectra were similar to absorption spectra and both were mirror images of the fluorescent spectra for **4** and **5**. For complex **6** the emission spectrum shows little less broadening when compared to excitation and absorption spectra, confirming that the aggregates do not fluoresce. The proximity of the wavelength of each component of the Q-band absorption to the Q-band maxima of the excitation spectra for both complexes suggest that the nuclear configurations of the ground and excited states are similar and not affected by excitation [44]. Fluorescence emission peaks were observed at: 693 nm for **4**, 712 nm for **5**, 692 nm for **6** in DMSO (Table 1). The Stokes' shifts range from 10 to 15 nm, which is usual for ZnPc derivatives [45].

The fluorescence quantum yield (Φ_F) values are different for **4**, **5** and **6** in DMSO, but the values are similar for the three complexes in toluene, with **4** showing larger values in both solvents, Table 2. Φ_F values in the two solvents demonstrate that fluorescence is influenced by the environment of the fluorescing molecule, e.g., solvent parameters. Solvent effects on Φ_F are usually interpreted in terms of the Förster–Hoffman equation [46] (Eq. (7)), which predicts a direct dependence of Φ_F on solvent viscosity.

$$\log \Phi_F = C + x \log \eta \quad (7)$$

The values of Φ_F in the two solvents are in conformity with the Förster–Hoffman equation for the complexes. The viscosities of DMSO and toluene are 1.99 and 0.59 cP, respectively.

Peripherally tetra-substituted complex (**4**) shows the largest (Φ_F) value in DMSO compared to the other complexes. The octa-substituted complex (**6**) shows lowest Φ_F value in DMSO. The very low Φ_F value for **6** in DMSO can be explained by the aggregation tendencies of the molecules in this solvent. Aggregation reduces the likelihood of radiative deactivation (fluorescence) through dissipation of energy by the aggregates. Complex **6** showed larger quantum yield for internal conversion (Φ_{IC}, Table 2) in DMSO when compared to complexes **4** and **5**, most likely due to aggregation.

3.4. Triplet quantum, yields and lifetimes

Triplet quantum yield (Φ_T) represents the fraction of absorbing molecules that undergo intersystem crossing to the metastable triplet excited state. Therefore, factors which induce spin–orbit coupling will certainly populate the triplet excited state. Transient spectrum for complex **4** in DMSO as shown in Fig. 4, and shows a maximum at 490 nm, hence triplet lifetimes and yields were determined at this wavelength. Fig. 5 displays the triplet decay curves of the complexes (using complex **6** in toluene as an example). The triplet life time for **4** (210 μs), **5** (210 μs) and **6** (190 μs) in DMSO and of 150 (**4**), 140 (**5**) and 180 μs (**6**) in toluene are lower than for unsubstituted ZnPc (350 μs) in DMSO and (330 μs) in toluene [47] respectively. This suggests that the [3,4-(methylendioxy)-phenoxy] substituents quench the triplet state. The τ_T values are higher in DMSO for all complexes. The reason for the large difference in value (going from DMSO to toluene) is not clear, but could partly be ascribed to the higher viscosity of DMSO (1.99 cP) than toluene (0.58 cP). In high viscocity solvents, translational and rotational motions are reduced, thereby reducing the likelihood of non-radiative deactivation of the excited singlet state via internal conversion.

The triplet quantum yields (Φ_T) for substituted complexes (**4**, **5** and **6**) in toluene are high compared to ZnPc standard in toluene (Φ_T = 0.65 for ZnPc). The high values of Φ_T in toluene suggest efficient intersystem crossing (ISC) in the presence of the substituents for substituted complexes (**4**, **5** and **6**). Complex **6** showed low Φ_T value in DMSO due to the aggregation in this solvent.

3.5. Photochemical properties

3.5.1. Singlet oxygen quantum yields

Singlet oxygen quantum yield Φ_Δ is a measure of singlet oxygen generation and the Φ_Δ values were obtained using Eq. (5). Singlet oxygen quantum yields were studied in DMSO and toluene using a chemical method (1,3-diphenylisobenzofuran, DPBF). Fig. 6 shows spectral changes observed during photolysis of complex **4** in toluene in the presence of DPBF. The disappearance of DPBF was monitored using UV–Vis spectroscopy. There were no changes in the Q-band intensities during the Φ_Δ determinations, confirming that complexes are not degraded during singlet oxygen studies [48]. The Φ_Δ values of three complexes were higher in toluene than in DMSO, corresponding to high Φ_T values in this solvent. The Φ_Δ values for **4**, **5** and **6** (0.80, 0.74 and 0.65 in toluene and 0.48, 0.43 and 0.22 in DMSO, respectively) are lower when compared to unsubtituted ZnPc in DMSO (0.67 [33]) and higher in toluene (0.58 [32]). Complex **6** has the lowest the value of Φ_Δ in DMSO (0.22) due to aggregation.

The magnitude of the S_Δ (=Φ_Δ/Φ_T) represents the efficiency of quenching of the triplet excited state by singlet oxygen. Compound

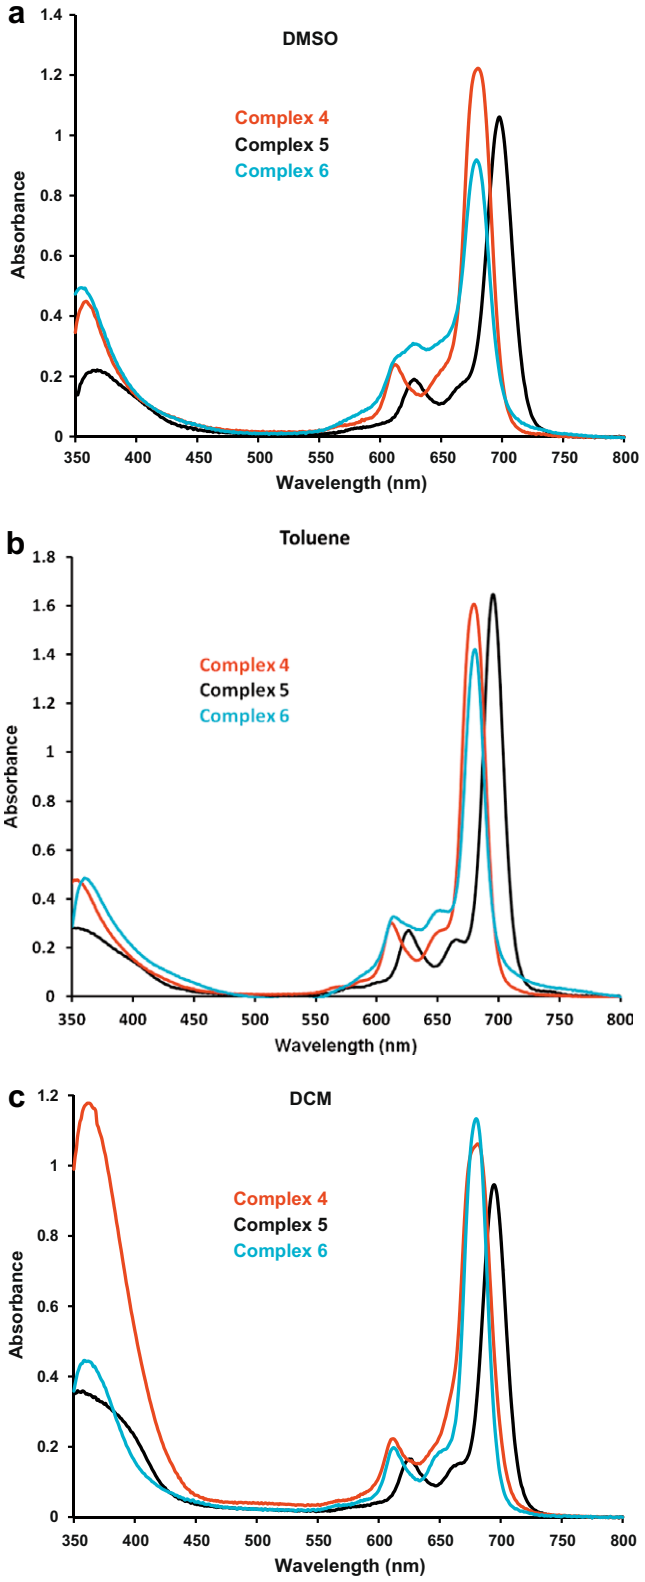

Fig. 1. UV–Vis absorption spectra of **4**, **5** and **6** in DMSO (a), concentration = 4×10^{-6} mol dm^{-3}; toluene (b), concentration = 4×10^{-6} mol dm^{-3} for **4** and **5**, 10×10^{-6} mol dm^{-3} for **6**; DCM (c), concentration = 4×10^{-6} mol dm^{-3}.

4, **5** and **6** displayed S_Δ of near unity in toluene and DMSO. However, complex **6** showed very low value in DMSO due to aggregation.

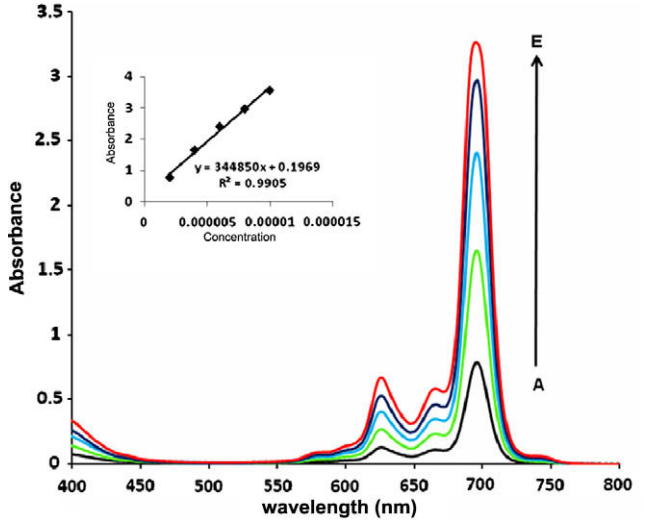

Fig. 2. Absorption spectra of **5** in toluene at different concentration: (A) 2×10^{-6}, (B) 4×10^{-6}, (C) 6×10^{-6}, (D) 8×10^{-6}, (E) 10×10^{-6} mol dm^{-3}.

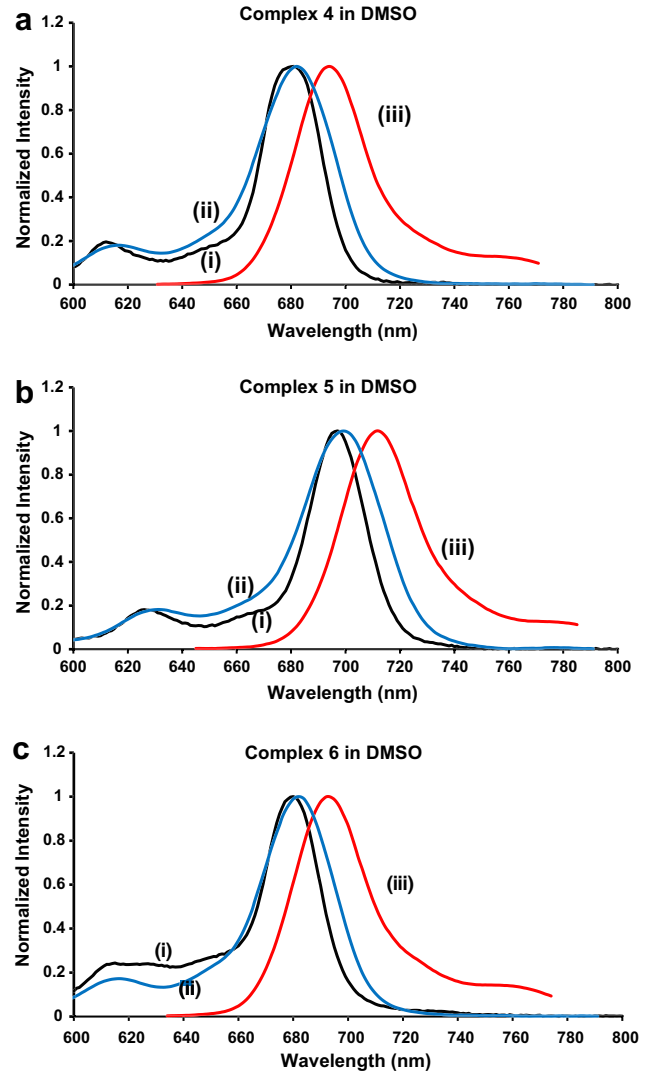

Fig. 3. Absorption (i), excitation (ii) and emission (iii) spectra of the compounds **4** (a), **5** (b), and **6** (c) in DMSO. Excitation wavelength = 682 nm for (**4**) 699 nm for (**5**) and 682 nm for (**6**) in DMSO.

Table 2
Photophysical and photochemical properties of **4**, **5** and **6** in DMSO and toluene.

Compound	Solvent	Φ_F	τ_T	Φ_T	Φ_{IC}	Φ_d (10^6)	Φ_Δ	S_Δ
4	DMSO	0.18	210	0.66	0.16	1.20	0.48	0.80
	toluene	0.06	150	0.85	0.09	0.83	0.80	0.94
5	DMSO	0.13	210	0.59	0.28	2.00	0.43	0.73
	toluene	0.05	140	0.79	0.16	0.72	0.74	0.89
6	DMSO	0.10	190	0.55	0.35	8.53	0.22	0.26
	toluene	0.05	180	0.73	0.22	0.98	0.65	0.78

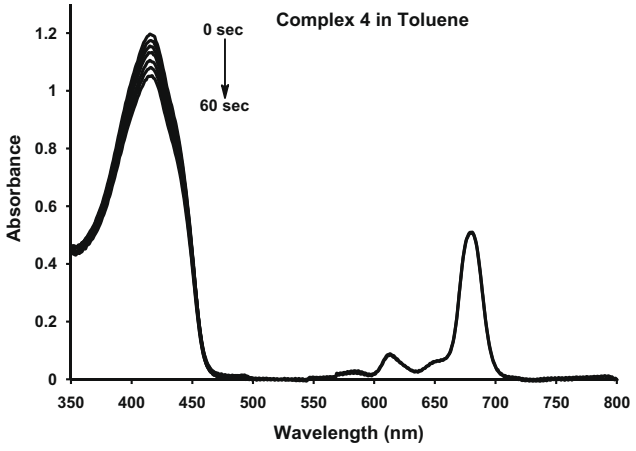

Fig. 6. A typical spectrum for the determination of singlet oxygen quantum yield. This figure was for complex **4** in toluene at a concentration 4×10^{-6} mol dm^{-3}.

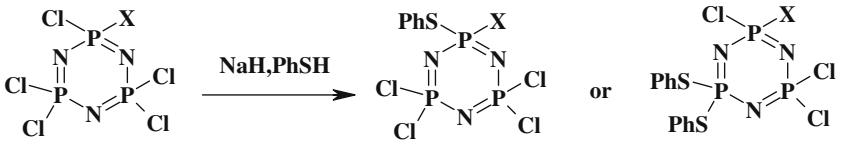
3.5.2. Photodegradation quantum yields

Photodegradation is a process where a phthalocyanine is degraded under light irradiation. It can be used to determinate MPcs stability and this is especially important for those molecules intented for use as photocatalysts. The photobleaching stabilities of complexes **4**, **5** and **6** were determined in DMSO and toluene by monitoring the decrease in the intensity of the Q-band under irradiation with increasing time. The photodegradation quantum yield (Φ_d) values for the complexes are listed in Table 2 and are of the order of 10^{-6}. These values show that the molecules are of high stability in two solvents used. Stable ZnPc molecules show values as low as 10^{-6} and for unstable molecules, values of the order 10^{-3} have been reported [49]. Photobleaching quantum yields for the complexes were smaller in toluene than in DMSO, indicating that they are more stable in toluene than in DMSO. This could be due to the high singlet oxygen quantum yields in toluene. Since photobleaching is initiated by singlet oxygen attack. The order of stability among the substituted complexes was **4** > **5** > **6** in DMSO and **5** > **4** > **6** in toluene.

4. Conclusion



In this study, the syntheses, spectral and photophysicochemical properties of soluble peripheral and non-peripheral tetrakis- and octakis [3,4-(methylendioxy)-phenoxy]-substituted zinc phthalocyanines (**4**, **5** and **6**), respectively are discussed. The complexes have good solubility and are mainly monomeric in solution. The introduction of [3,4-(methylendioxy)-phenoxy on the ring results in high triplet quantum yields (ranging from 0.55 to 0.85 in DMSO and toluene). All complexes showed similar and typical fluorescence quantum yields for MPcs in DMSO. Complex **6** has a low triplet quantum yield (0.65) and singlet quantum yield values (0.22) in DMSO due to aggregation. Triplet lifetimes are higher in DMSO than in toluene for substituted complexes (**4**, **5** and **6**). The tetra-substituted complexes (**4** and **5**) have good singlet oxygen quantum yields especially complex **4** which has the highest value in both solvents. The Pcs reported in this study can be applied as efficient candidates for solution studies requiring monomeric form of this material. The singlet oxygen quantum yields, which give indication of the potential of the complexes as photosensitizers in applications where singlet oxygen is required (Type II mechanism) ranged from 0.22 to 0.80. Thus, these complexes show potential as Type II photosensitizers and can be used in photodynamic therapy.

2. Result and discussion

*2.1. Syntheses and characterisations of cyclotriphosphazatrienes **3**, **5**, **7**, **9**, **11**, and **13***

It is investigated firstly the reactions of primary amino-substituted cyclotriphosphazenes **(2**, **4**, **6)** with thiophenol in the presence of NaH in THF at room temperature for 24 h and obtained novel cyclotriphosphazene derivatives **(3**, **5**, **7)** in this work. The chloro atom in P–Cl bond (designated as *a* in Fig. 1) has replaced with a thiolate group probably by a proton abstraction-chloride ion elimination reaction mechanism at these reactions according to ^{31}P NMR (Scheme 2). A dissociative route, the conjugate base mechanism, S_N1 (CB), shown in Scheme 2, is believed to be operative in the formation of geminal isomers [1]. In this process, a base abstracts a proton from the mono primary aminophosphazene. This is followed by loss of chloride ion leading to a coordinatively unsaturated transition state. Attack by thiophenol on the phosphoranimine leads to the observed geminally substituted product [1,22].

Furthermore, an understanding of why the reaction of cyclotriphosphazenes with thiophenol resulted in substitution at the P–Cl bond (*a* in Fig. 1) rather than geminal substitution at PCl_2 group is provided from the crystal structures of **1**, **2, 6** [23–25]. Table 1 shows that the P–Cl bond in the PNHCl group is longer than the PCl_2 bonds owing to the electron-releasing capacity of the –NHR group. Therefore, P–Cl bond (*a*) is more reactive to nucleophilic substitution with thiophenol than those of the PCl_2 groups [1,18a,20].

Secondly, it is investigated the reactions of secondary amino-substituted cyclotriphosphazenes **(8**, **10**, **12)** with thiophenol at the same conditions of **2**, **4**, **6** and obtained new cyclotriphosphazene derivatives **(9**,**11**, **13)** in present work. It is shown that electron-releasing groups have a greater effect on the lengthening of PNCl bonds (e.g. P–Cl: 2.041 Å for **10** in Table 1). However, steric effects are shown to dominant in the reaction of thiophenol with **10**. For sterically crowded amines (dibenzylamine, dimethylamine) and strongly electron donating amine (pyrrolidine), the pathway lead to nongeminal product [1]. The thiophenol substitution of untouched PCl_2 group may be performed via an S_N2 mechanism (Scheme 3). This pathway is similar in the reactions of secondary

amines with $N_3P_3Cl_6$ [19]. The nucleophilic attack of thiophenol seems to proceed via the S_N1 type [1,15]. These pathways are seen that the respective sulfur bases, like sodium thiophenol and dimercaptoethylene, prefer geminal substitution of two chlorine atoms at non macrocyclic phosphorus atom (in PCl_2 group) of cyclotriphosphazene containing 16-membered crown ether ring [26].

The structures of **3**, **5**, **7**, **9**, **11**, **13** are defined by MS, elemental analysis, ^{1}H and ^{31}P NMR spectroscopies. All the results are consistent with the proposed structures as shown in Scheme 1. The ^{31}P{^{1}H} NMR data for **2–13** are given Table 2.

The ^{31}P{^{1}H} NMR spectra of **3**, **5**, **7** show that the two different phosphorus nuclei are non-equivalent (analysed as AX_2 or AB_2, as appropriate) with characteristic chemical shifts for the >PCl_2 of 20.4–21.0 ppm and >P–(NHR)SPh of 24.3–29.1 ppm moieties in these compounds (Table 2). ^{31}P NMR spectra of **9**, **11**, **13** analysed as AMX or AXX′ spin systems due to three different phosphorus environment within the molecules. It is investigated in detail the ^{31}P NMR spectra of some compounds (e.g. **5**, **11**, **13**) in this work.

The ^{31}P {^{1}H} NMR spectrum (AX_2 spin system) of **5** consisting of one triplet of >P(NHPh)(SPh)(δ = 24.3 ppm) and one doublet of >PCl_2 (δ = 21.4 ppm) groups is shown in Fig. 2a. The expanded proton coupled ^{31}P NMR signals as doublets of triplet of >P(NHPh)(SPh) group are seen at ca. 24.0–24.5 ppm in Fig. 2b, and this signals are emerged from coupling by other phosphorus atoms and proton of NH group.

The ^{31}P {^{1}H} NMR spectrum (AXX′ spin system) of **11** consisting of one doublet of >P[$(CH_2)_2Ph_2$] at ca. 22.3 ppm, one doublet of >PCl_2 at ca. 20.6 ppm and >$P(SPh)_2$ at ca. 47.6 is shown in Fig. 3a. The proton coupled ^{31}P NMR signals as multiplet of >P[$(CH_2)_2Ph_2$] are observed at ca. 22.3 ppm which are coupling from other phosphorus atoms and CH_2 groups, the signals of >PCl_2 (δ = 20.6 ppm) and >$P(SPh)_2$ (δ = 47.6 ppm) groups remain unchanged in Fig. 3b.

The ^{31}P {^{1}H} NMR spectrum (AXX′ spin system) of **13** is shown in $CDCl_3$ in Fig. 4a. The chemical shifts(δ) and $^{2}J_{(PP)}$(Hz) of signals of >PCl_2 and >P(NR)Cl groups could not be analysed using this solvent. Therefore, ^{31}P{^{1}H} NMR spectrum is taken in toluene-d_8 (Fig. 4b). The doublet of >P[(NC_4H_8)Cl] group at ca. 26.8 ppm, one doublet of >PCl_2 at ca. 26.0 ppm, one doublet of >$P(SPh)_2$ at ca. 51.6 ppm, and multiplet of >P[(NC_4H_8)Cl] at ca. 26.5–26.9 ppm are presented in Fig. 4b and c, respectively.

^{1}H NMR spectrum (δ = 1.2 ppm (s, 9H, CH_3), δ = 2.9 ppm (d, H, NH), δ = 7.60–7.62 ppm (*m*-, *p*-, 3H, Ar–CH), δ = 7.4 ppm (*o*-, 2H, Ar–CH) of compound **7** is shown in Fig. 5a as an example of the proton spectroscopy. The ^{1}H NMR spectrum of **7** has been treated with D_2O to eliminate the N–H coupling (Fig. 5b).

Table 5
Hydrogen-bond geometries (Å, °) for **5** and **13**.

	D–H···A	D–H	H···A	D···A	D–H···A
5	C12–H12···N3	0.93	2.36	3.071(2)	133
	C4–H4···Cg3^{i}	0.93	2.89	3.698(2)	147
13	C9–H9···N2^{ii}	0.93	2.57	3.443(2)	156
	C4–H4···Cg4^{iii}	0.93	2.73	3.638(2)	165

Symmetry codes: (i) $x-½, ½-y, z-½$, (ii) $x+½, ½-y, z+½$, (iii) $x-1, y, z-1$, where Cg3 and Cg4 are centroids of rings (C7–C12) in compounds **5** and **13**.

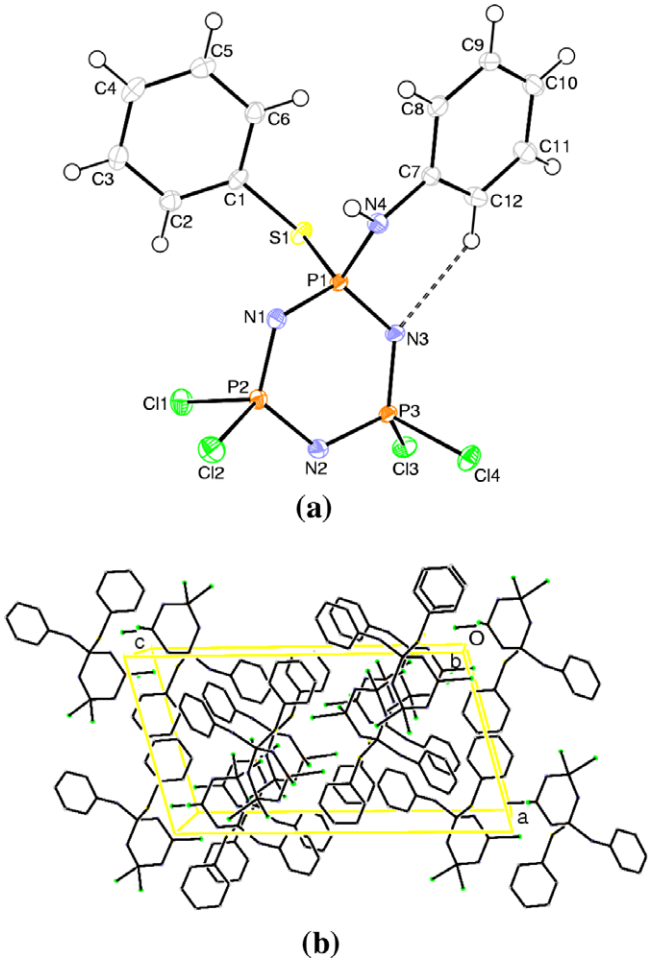

Fig. 6. (a) An ORTEP-3 [28] drawing of **5** with the atom-numbering scheme. Displacement ellipsoids are drawn at the 50% probability level, hydrogen bond is shown as dashed line, (b) a partial packing diagram of **5**, respectively.

2.2. X-ray crystallographic characterisation of *5* and *13*

The x-ray structural determinations of compounds **5** and **13** confirm the assignments of their structures from spectroscopic data. Crystallographic data are listed in Table 3. Selected bond lengths and angles are given in Table 4, and hydrogen bonds data are given in Table 5, respectively. The molecular structures and the packing diagrams of **5** and **13** along with the atom-numbering schemes are depicted in Figs. 6a and 7a, respectively. The phosphazene rings of **5** and **13** are not planar and are in flattened-boat forms [$\varphi_2 = -165.8(1)°$, $\theta_2 = 125.2(1)°$ and $\varphi_2 = -163.3(4)°$, $\theta_2 = 83.7(4)°$] having total puckering amplitudes Q_T of 0.706(1) (for **5**) and 0.149(1) (for **13**) [27].

In **5**, the six-membered aromatic rings (C1–C6) and (C7–C12) are oriented at a dihedral angle of 27.09(4)°. Intramolecular C–H···N hydrogen bond (Table 5) results in the formation of a six-membered ring (P1/N3/N4/C7/C12/H12) having twisted conformation. In the crystal structure, the molecules are elongated along the c axis and stacked along the b axis (Fig. 6b). There exists a C–H···π interaction (Table 5).

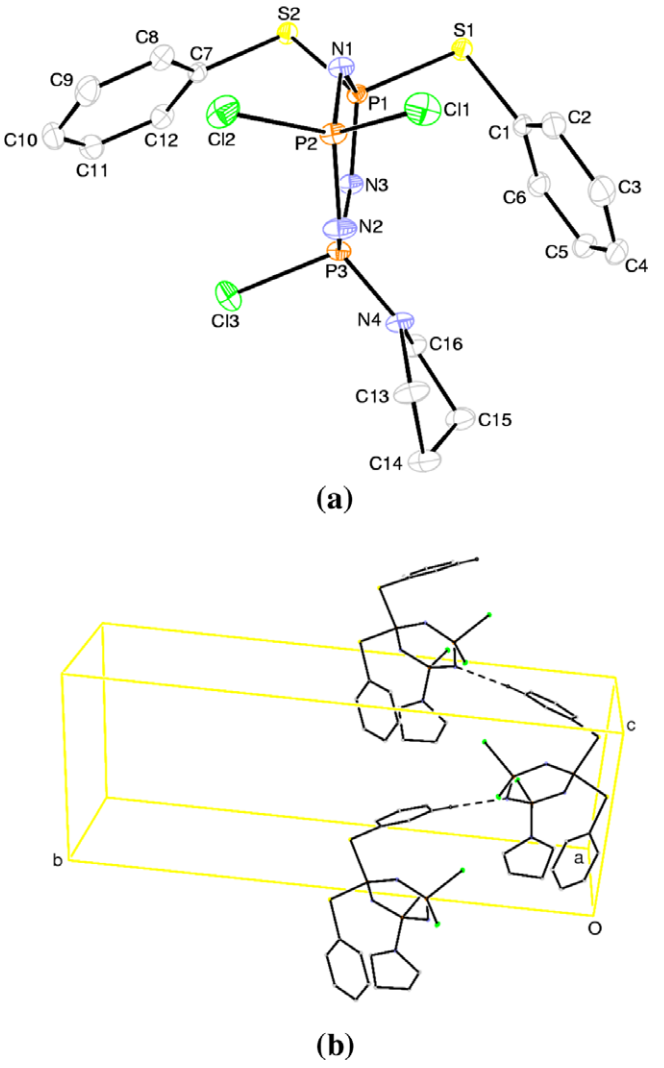

Fig. 7. (a) An ORTEP-3 [28] drawing of **13** with the atom-numbering scheme. Displacement ellipsoids are drawn at the 50% probability level, (b) a partial packing diagram of **13**, hydrogen bonds are shown as dashed lines, respectively.

In **13**, the six-membered aromatic rings (C1–C6) and (C7–C12) are oriented at a dihedral angle of 85.66(5)°, while the five-membered ring (N4/C13–C16) adopts envelope conformation with atom C15 displaced by 0.613(2) Å from the plane of the other ring atoms. In the crystal structure, intermolecular C–H···N hydrogen bonds (Table 5) link the molecules into chains along the *c* axis (Fig. 7b), in which they may be effective in the stabilisation of the structure. There also exists a C–H···π interaction (Table 5). In the phosphazene rings, the P–N bond lengths are in the ranges 1.5647(12)–1.6037(12) Å (for **5**) and 1.5690(13)–1.6136(12) Å (for **13**). The phosphazene rings P–N bonds generally show double-bond character (Table 4).

3. Conclusion

In this paper, six novel cyclotriphosphazatrienes **(3**, **5**, **7**, **9**, **11**, **13)** are synthesised and characterised. Mechanisms of **3**, **5**, **7** can be formed via a proton abstraction-chloride elimination and **9**, **11**, **13** may be constituted both the S_N2 and S_N1 reaction, respec-

tively with respect to our results and previous works e.g. [1,14,18,26]. These compounds can be also a promising candidate as a building block for optical materials [14b]. This original work is potentially very useful addition to the literature and may guide to some high-polymer works.

4. Experimental

4.1. General remarks

Hexachlorocyclotriphosphazene (a gift from the Shin Nisso Kako Co. Ltd.) was purified by fractional crystallisation from *n*-hexane. The following chemicals were obtained from Merck; THF (⩾99.0%), *n*-hexane (>96%), NaH (60% dispersion in mineral oil), dichloromethane (⩾99.0%), dimethylamine (40% aqueous solution), tert-butylamine (>99%), thiophenol (>98.0%), dibenzylamine (>95%), aniline (>95%), diethylether (>99.5%), petroleum ether (40–60 °C), acetonitrile (99%), C_4H_8NH (⩾99.0%), triethylamine (>98.0%), Na_2SO_4 (⩾99.0%). All solvents used in this work were purified by conventional methods. THF was distilled over a sodium–potassium alloy under an atmosphere of dry argon. Solvents ($CDCl_3$ and toluene-d_8) for NMR spectroscopy are obtained from Merck.

Elemental analyses were obtained using a Carlo Erba 1106 Instrument. Mass spectra were obtained by Bruker MicrOTOF LC/MS spectrometer using electrospray ionisation (ESI); ^{35}Cl values were used for calculated masses. Analytical Thin Layer Chromatography (TLC) was performed on silica gel (Merck, Kieselgel 60, 0.25 mm thickness) with F_{254} indicator. Column chromatography is performed on silica gel (Merck, Kieselgel 60, 70–230 mesh; for 3 g crude mixture, 100 g silica gel was used in a column of 3 cm in diameter and 60 cm in length). ^1H and ^{31}P NMR spectra were recorded in $CDCl_3$ solutions on a Varian INOVA 500 MHz spectrometer using TMS as an internal reference for ^1H NMR and 85% H_3PO_4 as an external reference for ^{31}P.

4.2. X-ray crystallography

Colourless crystals of **5** and **13** were re-crystallised from dichloromethane–petroleum ether (1:1) and dichloromethane-*n*-hexane (1:1) at room temperature, respectively. Crystallographic data were recorded on a Bruker Kappa APEXII CCD area-detector diffractometer using Mo Kα radiation (λ = 0.71073 Å) at T = 100(2) K. Absorption corrections by multi-scan have been applied [29]. Structures were solved by direct methods and refined by full-matrix least squares against F^2 using all data [30]. All non-H atoms were refined anisotropically. In compound **5**, only the H atom of NH group was located in a difference synthesis and refined isotropically [N–H = 0.861(15) Å, U_{iso}(H) = 0.026(5) Å^2]. The remaining H atom positions were calculated geometrically at distances of 0.93 Å (CH) and 0.97 Å (CH_2) from the parent C atoms; a riding model was used during the refinement process and the U_{iso}(H) values are constrained to be $1.2U_{eq}$(carrier atom).

4.3. Synthesis and reactions

2-Isopropilamino-2,4,4,6,6-pentachlorocyclotriphosphazatriene **(2)** was prepared as described by Das et al. [31]. Compound **6** was prepared as described by Bartlett et al. [25]. Compounds **4**, **8**, **10** and **12** were prepared as in the literatures [32–35], respectively.

4.3.1. Synthesis of compound *3*

A solution of NaH (60% oil suspension, 0.02 g, 1.35 mmol) in 10 mL dry THF was added dropwise to a stirred solution of thiophenol (0.15 g, 1.35 mmol) in 5 mL dry THF under atmosphere of argon in a 100 mL three-necked round bottomed flask. Then, **2** (0.35 g, 1.35 mmol) in 20 mL dry THF was added. The reaction mixture was stirred under an atmosphere of argon at room temperature for 24 h. Sodium chloride was filtered off and the solvent removed under reduced pressure at 30 °C. The crude product was subjected to column chromatography using *n*-hexane–CH_2Cl_2 (3:2) as eluent. 2-isopropilamino-2-thiophenoxy-4,4,6,6-tetrachlorocyclotriphosphazatriene **(3)** was isolated as an oil (Rf: 0.57, 0.15 g, 20%). *Anal.* Calc. for $C_9H_{13}Cl_4N_4P_3S$: C, 24.35; H, 2.95; N, 12.62; M, 444. Found: C, 24.34; H, 2.94; N, 12.60; ($M+Na^+$), 467%. ^1H NMR, δ = 1.21 ppm (d, 6H, CH_3), δ = 3.65 ppm (m, H, CH), δ = 2.93 ppm (H, NH), δ = 7.6 ppm (*m*-, *p*-, 3H, Ar–CH), δ = 7.4 ppm (*o*-, 2H, Ar–CH).

4.3.2. Synthesis of compound *5*

A solution of NaH (60% oil suspension, 0.1 g, 2.5 mmol) in 10 mL dry THF was added dropwise to a stirred solution of thiophenol (0.27 g, 2.5 mmol) in 5 mL dry THF under an atmosphere of argon in a 100 mL three-necked round bottomed flask. Then, **4** (1 g, 2.5 mmol) in 10 mL dry THF was added. The reaction mixture was stirred under an atmosphere of argon at room temperature for 24 h. Sodium chloride was filtered off and the solvent removed under reduced pressure at 30 °C. The crude product was subjected to column chromatography using *n*-hexane–CH_2Cl_2 (1:1) as eluent. 2-anilino-2-thiophenoxy-4,4,6,6-tetrachlorocyclotriphosphazatriene **(5)** was isolated as a white powder and re-crystallised from dichloromethane–petroleum ether (1:1) (m.p.:132 °C, Rf: 0.49, 0.33 g, 28%). *Anal.* Calc. for $C_{12}H_{11}Cl_4N_4P_3S$: C, 30.15; H, 2.32; N, 11.72; M, 475. Found: C, 30.16; H, 2.33; N, 11.74; (MH^+): 476%. ^1H NMR, δ = 2.93 ppm (H, NH), δ = 7.10–7.75 ppm (*m*-, *p*-, 3H, NH–Ar–CH), δ = 6.99 ppm (*o*-, 2H, NHAr–CH), δ = 7.63–7.66 ppm (*m*-, *p*-, 3H, S–Ar–CH), δ = 7.54 ppm (*o*-, 2H, S–Ar–CH).

4.3.3. Synthesis of compound *7*

A solution of NaH (60% oil suspension, 0.014 g, 0.98 mmol) in 10 mL dry THF was added dropwise to a stirred solution of thiophenol (0.108 g, 0.98 mmol) in 10 mL dry THF under an atmosphere of argon in a 100 mL three-necked round bottomed flask. Then, **6** (0.5 g, 0.98 mmol) in 10 mL dry THF was added. The reaction mixture was stirred under an atmosphere of argon at room temperature for 24 h. Sodium chloride was filtered off and the solvent removed under reduced pressure at 30 °C. The crude product was subjected to column chromatography using *n*-hexane–THF (7:1) as eluent. 2-tert-butylamino-2-thiophenoxy-4,4,6,6-tetrachlorocyclotriphosphazatriene **(7)** was isolated as an oil (Rf: 0.65, 0.018 g, 4%). *Anal.* Calc. for $C_{10}H_{15}Cl_4N_4P_3S$: C, 26.22; H, 3.30; N, 12.23; M, 456. Found: C, 26.21; H, 3.28; N, 12.22; (MH^+), 457%.

4.3.4. Synthesis of compound *9*

A solution of NaH (60% oil suspension, 0.56 g, 1.4 mmol) in 10 mL dry THF was added dropwise to a stirred solution of thiophenol (0.15 g, 1.4 mmol) in 5 mL dry THF under an atmosphere of argon in a 100 mL three-necked round bottomed flask. Then, **8** (0.5 g, 1.4 mmol) in 10 mL dry THF was added. The reaction mixture was stirred under an atmosphere of argon at room temperature for 24 h. Sodium chloride was filtered off and the solvent removed under reduced pressure at 30 °C. The crude product was subjected to column chromatography using *n*-hexane–CH_2Cl_2 (1:1) as eluent. 2-dimethylamino-4,4-thiophenoxy-2,6,6-trichlorocyclotriphosphazatriene **(9)** was isolated as an oil (Rf: 0.49, 0.33 g, 28%). *Anal.* Calc. for $C_{14}H_{16}Cl_3N_4P_3S_2$: C, 33.38; H, 3.20; N, 11.12; M, 503. Found: C, 33.40; H, 3.21; N, 11.13; ($M+Na^+$), 527%. ^1H NMR, δ = 5.5 ppm (s, 6H, CH_3), δ = 7.42–7.93 ppm (10H, Ar–CH).

4.3.5. Synthesis of compound *11*

A solution of NaH (60% oil suspension, 0.02 g, 1.3 mmol) in 10 mL dry THF was added dropwise to a stirred solution of

thiophenol (0.143 g, 1.3 mmol) in 5 mL dry THF under an atmosphere of argon in a 100 mL three-necked round bottomed flask. Then, **10** (0.5 g, 1.3 mmol) in 10 mL dry THF was added. The reaction mixture was stirred under an atmosphere of argon at room temperature for 24 h. Sodium chloride was filtered off and the solvent removed under reduced pressure at 30 °C. The crude product was subjected to column chromatography using *n*-hexane–THF (6:1) as eluent. 2-dibenzylamino-4,4-thiophenoxy-2,6,6-trichlorocyclotriphosphazatriene **(11)** was isolated as an oil (Rf: 0.80, 0.1 g, 20%). *Anal.* Calc. for $C_{26}H_{24}Cl_3N_4P_3S_2$: C, 47.61; H, 3.69; N, 8.54; M, 656. Found: C, 47.62; H, 3.70; N, 8.55; ($M+Na^+$), 679%. ^1H NMR, δ = 4.2 ppm (d, 4H, CH_2), δ = 7.34–7.49 ppm (*m*-, *p*-, 6H, N–CH_2Ar–CH), δ = 7.68 ppm (*o*-, 4H, NCH_2Ar–CH), δ = 7.61–7.93 ppm (*m*-, *p*-, 6H, S–Ar–CH), δ = 7.42 ppm (*o*-, 4H, S–Ar–CH).

*4.3.6. Synthesis of compound **13***

A solution of NaH (60% oil suspension, 0.15 g, 1.9 mmol) in 10 mL dry THF was added dropwise to a stirred solution of thiophenol (0.2 g, 1.9 mmol) in 5 mL dry THF under argon pressure in a 100 mL three-necked round bottomed flask. Then, **12** (0.72 g, 1.9 mmol) in 10 mL dry THF was added. The reaction mixture was stirred under an atmosphere of argon at room temperature for 24 h. Sodium chloride was filtered off and the solvent removed under reduced pressure at 30 °C. The crude product was subjected to column chromatography using *n*-hexane–THF (8:1) as eluent. 2-pyrrolidino-4,4-thiophenoxy-2,6,6-trichlorocyclotriphosphazatriene **(13)** was isolated as a white powder and re-crystallised from dichloromethane-*n*-hexane (1:1) (m.p.: 88 °C, Rf: 0.45, 0.33 g, 28%). *Anal.* Calc. for $C_{16}H_{18}Cl_3N_4P_3S_2$: C, 36.28; H, 3.42; N, 10.58; M, 528. Found: C, 36.26; H, 3.41; N, 10.56; (MH^+), 529%. ^1H NMR, δ = 2.64 ppm (4H, CH_2), δ = 2.77–3.15 ppm (4H, NCH_2), δ = 7.42–7.93 ppm (10H, Ar–CH).

Supplementary data

CCDC 731622 and 731623 contain the supplementary crystallographic data for **5** and **13**. These data can be obtained free of charge http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033, or e-mail: deposit@ccdc.cam.ac.uk.

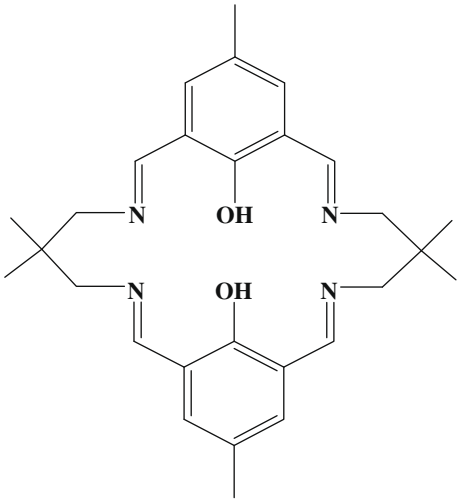

Chart 1. Chemical structure of H_2L.

a Perkin–Elmer LS-50B spectrofluorometer was utilized to study emission spectra.

2.2. Syntheses

2.2.1. $[H_4L](ClO_4)_2$ (**1**)

The diprotonated perchlorate salt, $[H_4L](ClO_4)_2$, of the macrocyclic Schiff base ligand H_2L has been synthesized by the condensation of 4-methyl-2,6-diformylphenol with 2,2′-dimethyl-1,3-diaminopropane following the procedure of Nag et al. to prepare the related other macrocyclic ligand [2]. To a boiling methanol solution (30 mL) containing 2,6-diformyl-4-methylphenol (0.33 g, 2 mmol), $NaClO_4$ (1 g, 8 mmol) and acetic acid (0.25 ml, 4 mmol) was added a methanol solution of 2,2′-dimethyl-1,3-propanediamine (0.208 g, 2 mmol). The solution was removed from the source of heating and kept at room temperature overnight. The product separated as orange crystals that were collected by filtration and washed with methanol and diethyl ether. Yield 0.60 g (90%). *Anal.* Calc. for $C_{28}H_{38}N_4O_{10}Cl_2$: C, 50.83; H, 5.74; N, 8.47. Found: C, 50.75; H, 5.63; N, 8.51%. Selected IR data on KBr (cm^{-1}): ν(C=N), 1655s; ν(perchlorate), 1145s, 1117s, 626 m. ^1H NMR (300 MHz, CD_3CN) δ values (ppm): 13.92 (s, 4H, N–H···O); 8.47, 8.43 (dd, 4H, CH=N); 7.36 (s, 4H, 4-ArH); 3.89, 3.87 (dd, 8H, α-CH_2); 2.17–1.93 (m, 6H, H_3C–Ar); 1.37 (s, 12H, H_3C–amine).

2.2.2. $[Pb^{II}_2L(NO_3)_2]$ (**2**)

This dinuclear complex of Pb(II) was synthesized according to the procedure reported by Nag et al. for the synthesis of related other Pb^{II}_2 complexes [16]. To a boiling methanol solution (100 ml) of 2,6-diformyl-4-methylphenol (1.64 g, 10 mmol) was added a DMF solution (15 ml) of $Pb(NO_3)_2$ (1.61 g, 5 mmol) and $Pb(OAc)_2$ (1.9 g, 5 mmol). After one hour reflux, a methanol solution (20 ml) of 2,2′-dimethyl-1,3-propanediamine (1.040 g, 10 mmol) was added to the boiling solution. Reflux was continued for another 4 h to get yellow crystalline compound which was collected by filtration and washed with methanol. Yield 3.89 g (78%). *Anal.* Calc. for $C_{28}H_{34}N_6O_8Pb_2$: C, 33.73; H, 3.44; N, 8.43. Found: C, 33.85; H, 3.55; N, 8.51%. Selected IR data on KBr (cm^{-1}): ν(C=N), 1633s; ν(nitrate), 1384s, 1305s, 995w.

2.2.3. $[Zn^{II}L(NO_3)(H_2O)](ClO_4)$ (**3**)

To a stirred methanolic suspension (20 ml) of **2** (1 g, 1 mmol) a methanol solution (10 ml) of $ZnCl_2$ (0.273 g, 2 mmol) was added dropwise. With the addition of $ZnCl_2$ solution, the suspension slowly converted into solution. After two hours stirring, a white precipitate of $PbCl_2$ was separated and removed by filtration. To the filtrate, $NaClO_4$ (0,5 g, 4 mmol) in methanol was added slowly and solution was kept for slow evaporation. After two days later a yellowish crystalline compound containing diffractable single crystals was collected. Yield 0.585 g (76%). *Anal.* Calc. for $C_{28}H_{36}N_5O_{10}ClZn_2$: C, 43.74; H, 4.72; N, 9.10. Found: C, 43.95; H, 4.63; N, 9.25%. Selected IR data on KBr (cm^{-1}): ν(water), 3382br; ν(C=N), 1637s; ν(nitrate), 1438s, 1300s, 1006 m; ν(perchlorate), 1095s, 623 m. ^1H NMR (300 MHz, CD_3CN) δ values (ppm): 8.26 (s, 4H, CH=N); 7.39 (s, 4H, 4-ArH); 3.80 (s, 8H, α-CH_2); 2.29 (s, 6H, H_3C–Ar); 1.02 (s, 12H, H_3C–amine).

2.2.4. $[Zn^{II}_2L(H_2O)_2](ClO_4)_2.(H_2O)_2$ (**4**)

An acetonitrile solution (10 ml) of zinc(II) acetate dihydrate (0.440 g, 2 mmol) was added to a CH_3CN solution (10 ml) of **1** (0.661 g, 1 mmol) with stirring. After two hours stirring, the volume of the yellow solution obtained was reduced to 10 ml. From the concentrated solution a yellow compound was separated out which was collected in suction and washed with ether. Recrystallization from acetonitrile–ethanol (1:1) yielded yellow crystalline compound. Yield 0.731 g (85%). *Anal.* Calc. for $C_{28}H_{42}N_4O_{14}Cl_2Zn_2$: C, 39.09; H, 4.92; N, 6.51. Found: C, 39.35; H, 4.81; N, 6.42%. Selected IR data on KBr (cm^{-1}): ν(water), 3417br; ν(C=N), 1639s; ν(perchlorate), 1092s, 625 m. ^1H NMR (300 MHz, CD_3CN) δ values (ppm): 8.29 (s, 4H, CH=N); 7.44 (s, 4H, 4-ArH); 3.82 (s, 8H, α-CH_2); 2.31 (s, 6H, H_3C–Ar); 1.03 (s, 12H, H_3C–amine).

2.3. Crystal structure determination of **1** and **3**

The crystallographic data of these two compounds (**1** and **3**) are summarized in Table 1. Diffraction data for both **1** and **3** were collected on a Nonius APEX-II diffractometer at 293 K with data collection and reduction using the Nonius program suite DENZO-SMN

package [40,41]. All data for the compound **1** and **3** were corrected for Lorentz, polarisation, background and absorption effects. For both the compounds, crystal structures were determined by Direct methods and subsequent Fourier and difference Fourier syntheses, followed by full-matrix least-squares refinements on F^2 using SHELXL-97 [42]. Only water and methyl hydrogen atoms of **3** were refined using restraints. All other hydrogen atoms of **3** and all hydrogen atoms of **1** were refined freely. Using anisotropic treatment of the non-hydrogen atoms and isotropic treatment of the hydrogen atoms of these two compounds, the final refinements converged at the R_1 values ($I > 2\sigma(I)$) 0.0519 and 0.0481 for **1** and **3**, respectively.

3. Results and discussion

3.1. Syntheses and characterization

The template condensation of 2,6-diformyl-4-methylphenol and 2,2′-dimethyl-1,3-diaminopropane in the presence of lead(II) nitrate and lead(II) acetate results in the formation of the dinuclear Pb(II) complex $[Pb^{II}_2L(NO_3)_2]$ (**2**). When complex **2** is treated with $ZnCl_2$, metal substitution reaction takes place and the dinuclear zinc(II) complex $[Zn^{II}_2L(NO_3)(H_2O)](ClO_4)$ (**3**) is formed in good yield and in single crystalline form, suitable for single crystal analysis. On the other hand, the condensation of 2,6-diformyl-4-methylphenol and 2,2′-dimethyl-1,3-diaminopropane in presence of acetic acid and sodium perchlorate produces the diprotonated free macrocyclic salt $[H_4L](ClO_4)_2$ (**1**). The treatment of **1** with zinc(II) acetate in acetonitrile, deprotonation of $[H_4L]^{2+}$ and incorporation of the metal ion in the ligand compartment takes place resulting in the formation of the dinuclear zinc(II) complex (**4**). Although microcrystals of **4** can be isolated from acetonitrile–ethanol, it has not been possible to prepare diffraction quality crystals of this compound. Similarly, it has not been possible to get diffraction quality crystals of the dinuclear Pb(II) complex **2**. Attempts to prepare single crystals of **2** and **4** in several ways were not successful.

The IR spectrum (in the range of 500–1800 cm^{-1}) of **2**–**4** is compared. The IR spectrum of **1** exhibits one strong signal at 1655 cm^{-1}

Table 3
Geometries (distances in (Å) and angles in (°)) of the hydrogen bonds in $[H_4L](ClO_4)_2$ (**1**) and $[Zn^{II}_2L(NO_3)(H_2O)](ClO_4)$ (**3**). Symmetry codes as in the figures.

Compound	D–H···A	D···A	H···A	D–H···A
1	C(7)–H(7A)···O(5)	3.426	2.516	158.26
	C(8)–H(8B)···O(2)	3.228	2.446	141.26
	C(12J)–H(12CJ)···O(3)	3.445	2.524	160.84
3	O(6)–H(6A)···O(7)	2.732	1.869	148.04
	O(6)–H(6B)···O(3E)	3.054	2.184	148.58
	O(6)–H(6B)···O(5E)	2.770	1.922	144.52
	C(27)–H(27A)···O(8)	3.498	2.552	164.92
	C(28)–H(28)···O(10B)	3.138	2.451	132.58

due to $\nu_{C=N}$ vibration. In comparison, the characteristics C=N stretching for metal complexes **2**, **3** and **4** is observed as a single strong signal at slightly lower energy (1633, 1637 and 1639 cm^{-1}, respectively). The strong absorption due to ionic perchlorate of **1** is observed at 1117 cm^{-1} [43]. The lower energy signal of ionic perchlorate of **1** appears as a medium intensity band at 626 cm^{-1} [44]. The appearance of a strong intensity band (1095 cm^{-1} for **3** and 1092 cm^{-1} for **4**) and one medium intensity band (623 cm^{-1} for **3** and 625 cm^{-1} for **4**) are indicative of the presence of ionic perchlorate(s) in **3** and **4** [43,44]. Although the region of nitrate vibration is crowded by several absorptions due to the macrocyclic ligand, two strong intensity bands (1384 and 1305 cm^{-1} for **2**; 1384 and 1300 cm^{-1} for **3**) and one medium intensity band (994 cm^{-1} for **2** and 1006 cm^{-1} for **3**) may be assigned to the absorption due to nitrates. The observation of these three bands indicates unidentate nitrates in both the complexes **2** and **3** [43]. It may be noted that single X-ray structure of **3** confirms the unidentate coordinating mode of nitrate in this complex.

3.2. Description of the structure of $[H_4L](ClO_4)_2$ (**1**)

The crystal structure of $[H_4L](ClO_4)_2$ (**1**) is shown in Fig. 1, while the selected bond lengths and angles including the geometries of the hydrogen bonds are listed in Table 2. The compound has a centrosymmetric structure with the center of inversion at the geometric center of the cation $[H_4L]^{2+}$. The conformation of $[H_4L]^{2+}$ is reminiscent of calixarenes [45] and of related Schiff-base macrocycles [2], with the phenyl ring folded downwards to leave the N and O donor atoms on an exposed face. The azomethine linkages are evident from the N(1)–C(8) and N(2)–C(13) bond lengths (1.280(5) and 1.268(6) Å, respectively), N(1)–C(8)–C(2) and N(2)-C(13)–C(6) angles (122.0(3) and 125.0(4)°, respectively), and the C(9)–N(1)–C(8)–C(2) and C(14)–N(2)–C(13)–C(6) torsion angles (177.64 and 174.35°, respectively). These bond length involving the phenyl carbon and the phenoxo oxygen, C(1)–O(1), is 1.281(4) Å. The values of these structural parameters are in the range as observed in the previously reported related macrocyclic cations [2,5].

The macrocyclic cation in **1** is stabilized by four intramolecular hydrogen bonds involving the phenolic oxygens and the imino nitrogen (Fig. 1). Between two possibilities regarding the type of the hydrogen bonds, N–H···O and O–H···N, the former is the reasonable choice because the range of N···H distances (0.66(4) and 0.97(3) Å) is much smaller than the O···H distances (1.773 and 2.163 Å). The donor···acceptor contacts of the four N–H···O inter-

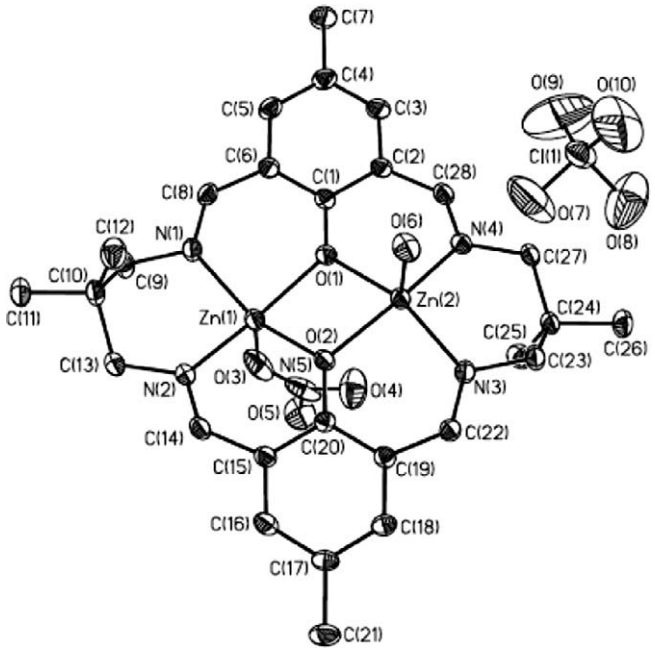

Fig. 5. ORTEP representation (30% thermal ellipsoids) of **3** with atom-labeling schemes. Hydrogen atoms are omitted for clarity.

Zn(1)–O(2)–Zn(2)	101.85(10)

actions lie in the range 2.573–2.636 Å, while the N–H···O angles vary between 129.7° and 138°, which indicate that the intramolecular hydrogen bonds are quite strong. Similarly strong hydrogen bonds are also observed in the previously reported compounds. It may be mentioned that four six-membered rings are formed due to the four N–H···O hydrogen bonds in **1** and in analogous salts resulting in extra stabilization. The dihedral angle (20°) between the two symmetry related phenyl rings in $[H_4L]^{2+}$ is larger than the range of the dihedral angles (0–14°) observed in previously reported analogous systems, indicating that the macrocyclic moiety in **1** is most twisted [2–5].

Weak C–H···O hydrogen bonds involving three perchlorate oxygen atoms (O(2), O(3) and O(4)) and three C–H moieties (C(7)–H(7A)···O(5), C(8)–H(8B)···O(2) and C(12J)–H(12CJ)···O(3)) (Fig. S1) result in the formation of three-dimensional self-assembly in $[H_4L](ClO_4)_2$ (**1**). As shown in Fig. 2, a two-dimensional network (in *ac*-plane) is generated due to two hydrogen bonds, C(7)–H(7A)···O(5) and C(8)–H(8B)···O(2). A perspective view along the *c*-axis of the 2-D sheet is shown in Fig. 3. These two-dimensional sheets are further interlinked by C(12J)–H(12CJ)···O(3) interactions to generate overall three-dimensional topology in **1** (Fig. 4). The geometries of these weak interactions are listed in Table 3.

3.3. Description of the structure of $[Zn^{II}_2L(NO_3)(H_2O)](ClO_4)$ (**3**)

The crystal structure of this compound is shown in Fig. 5, while the selected bond lengths and angles are listed in Table 4. The structure shows that compound $[Zn^{II}_2L(NO_3)(H_2O)](ClO_4)$ (**3**) is a diphenoxo-bridged dinuclear zinc(II) complex consisting of $[Zn^{II}_2L(NO_3)(H_2O)]^+$ cation and one perchlorate anion. Each zinc(II) ion is five coordinated, bonded to two imine nitrogen atoms and two endogenous bridging phenolate oxygen atoms in the basal plane, with nitrate oxygen (O(3)) and water oxygen (O(6)) satisfying the apical position of Zn(1) and Zn(2) centers, respectively, and the apical oxygens for the two zinc(II) ions coordinate in a *trans* arrangement. The Addison distortion index [46] (τ = 0.015 and 0.05 for Zn(1) and Zn(2), respectively) for the two zinc(II) centers is close to 0 indicating that the coordination geometry of the both the metal ions is slightly distorted square pyramidal. Deviation of the NO basal donor sets from the N_2O_2 mean planes lie in the ranges −0.009 to +0.010 Å for Zn(1) and −0.031 to +0.031 Å for Zn(2). The metal centers, Zn(1) and Zn(2), are displaced towards the axial coordinated oxygen by 0.459 and 0.371 Å, respectively, from the corresponding least-squares N_2O_2 planes. The dihedral angle (5.4°) between the two basal N_2O_2 planes and the average deviation (0.058 Å) from the nitrogen and oxygen atoms from the least-squares N(1)N(2)N(3)N(4)O(1)O(2) planes may apparently indicate that the bridging moiety is almost planar. However, Zn(1) and Zn(2) are displaced from the least-squares N(1)N(2)N(3)N(4)O(1)O(2) plane towards the opposite directions by 0.441 and 0.387 Å, respectively, which indicate the deviation of the bridging core from planarity. All the five bond lengths (2.047(2)–2.067(3) Å for Zn(1); 2.036(3)–2.059(3) Å for Zn(2)) for the coordination environment of both the metal ions are very close. However, the distortion of the coordination environment can be evidenced from the significant deviation, in comparison to the ideal values, of the *transoid* angles (152.34(13)° and 153.24(13)° for Zn(1); 155.37(12)° and 158.63(11)° for Zn(2)) in the basal plane and the *cisoid* angles (77.31(9)–106.74(15)° for Zn(1); 77.60(10)–102.47(11)° for Zn(2)). It may be mentioned that the displacement of the metal ions from the basal plane is the reason of the smaller values of the *transoid* angles and the wide range of the *cisoid* angles resulting in the distortion of the coordination environment. In this compound the planarity of the macrocyclic ligand is evident from the 0.9° dihedral angle between the two phenyl rings. The two metal centers are separated to each other by 3.186 Å. The two bridge angles, Zn(1)–O(1)–Zn(2) and Zn(1)–O(2)–Zn(2) are 102.47(11) and 101.85(10)°, respectively.

Five hydrogen bonds, three O–H···O type and two C–H···O type, link the individual component in $[Zn^{II}_2L(NO_3)(H_2O)](ClO_4)$ (**3**) into a two-dimensional network (Fig. 6). One hydrogen (H(6B)) of the coordinated water $H_2O(6)$ forms bifurcated hydrogen bonds with two nitrate oxygen (O(3E) and O(5E)) of the nitrate ion of a

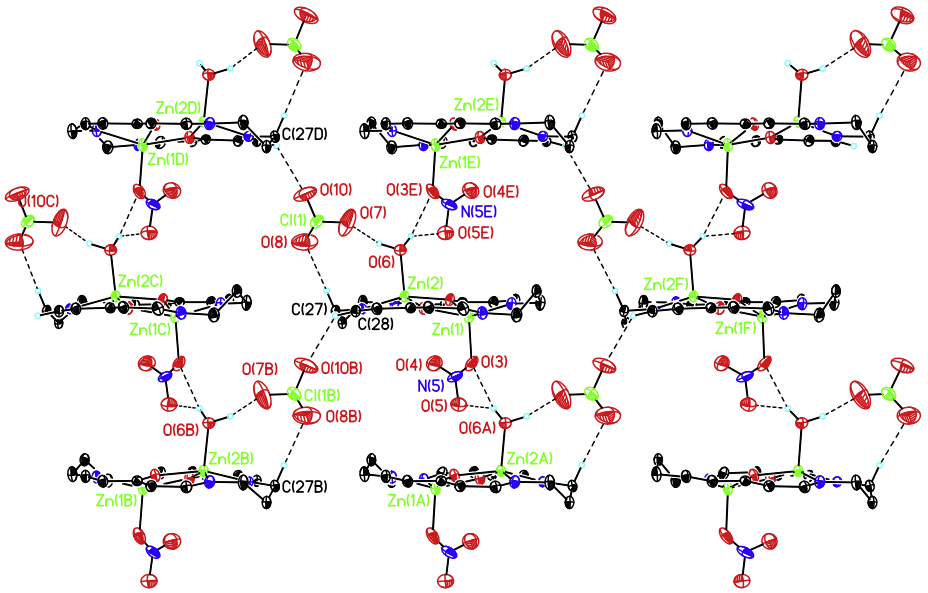

Fig. 6. View down the *b*-axis of the two-dimensional sheet of the compound **3**. Symmetry code; A, $x-0.5, 0.5-y, 0.5-z$; B, $x-0.5, 0.5-y, -z$; C, $x, y, z-1$; D, $0.5+x, 0.5-y, -z$; E, $0.5+x, 0.5-y, -z$; F, $x, y, 1+z$.

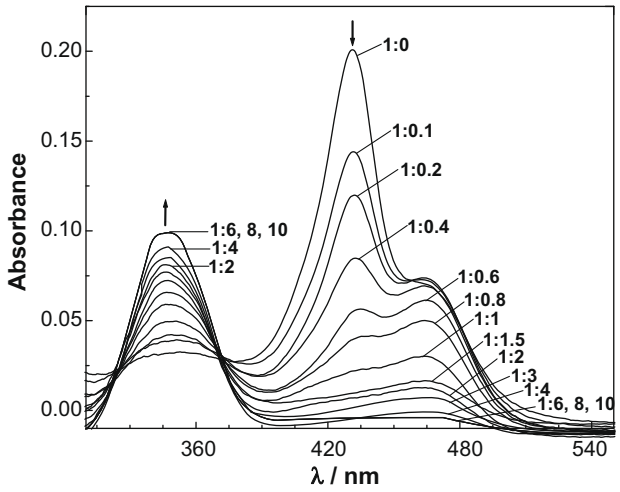

Fig. 7. Spectrophotometric titration of the macrocycle $[H_4L](ClO_4)_2$ (0.5×10^{-5}) with triethylamine (0.5×10^{-5}) in acetonitrile. Equivalent ratio of the macrocycle and triethylamine has been indicated in the figure.

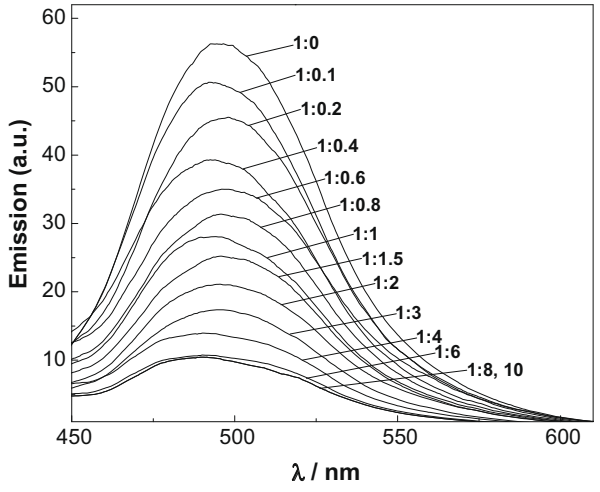

Fig. 8. Changes in emission intensity of the macrocycle $[H_4L](ClO_4)_2$ (0.5×10^{-5}) in acetonitrile upon addition of triethylamine (0.5×10^{-5}). $\lambda_{ex} = 431$ nm.

neighbouring molecule. Another hydrogen atom (H(6A)) of $H_2O(6)$ acts as a single donor to a perchlorate oxygen O(7) of another neighbouring molecule. As shown in Fig. 6, the two-dimensional topology may be considered to generate as a result of these three O–H···O bonds. However, two more hydrogen bonds (C(27)–H(27A)···O(8) and C(28)–H(28)···O(10B); Fig. 6) also participate in developing the 2-D self-assembly.

3.4. Absorption and emission spectroscopy

The UV–Vis spectrum (Fig. 7) of $[H_4L](ClO_4)_2$ in acetonitrile in the wave length range 300–900 nm shows one band at 430 nm, one shoulder at 465 nm and a weak and broad envelop at 350 nm, all of which arise due to internal $\pi \rightarrow \pi^*$ transitions. $[H_4L](ClO_4)_2$ exhibits fluorescence behavior on irradiation at 430 nm and the peak of the luminescence spectrum lies at 495 nm (Fig. 8).

Both spectrophotometric and spectrofluorimetric titrations have been carried out to understand the effect of a base such as triethylamine on $[H_4L](ClO_4)_2$. The absorption and emission profiles are represented in Figs. 7 and 8, respectively. The intensity of the band at 430 nm and the shoulder at 465 nm is continuously diminished, while the broad envelop at 350 nm becomes more intense as the saturation of the spectral profiles takes place at $[H_4L](ClO_4)_2$:Et_3N ratio of 1:6. All the absorption curves pass through an isosbestic point at 372 nm which indicates that the deprotonation process takes place smoothly. Again, as shown in Fig. 8, the fluorescence intensity gradually decreases with the increasing amount of base added and the saturation in this case also takes place at 1:6 ratio, indicating that the spectrophotometric and spectrofluorimetric titrations are consistent to each other. It may be mentioned that similar spectral changes are observed for a number of similar compounds reported by Nag et al. However, in contrast to 1:6 ratio in the case of $[H_4L](ClO_4)_2$, the saturation reaches in the reported related compounds when 25 times base is added [2].

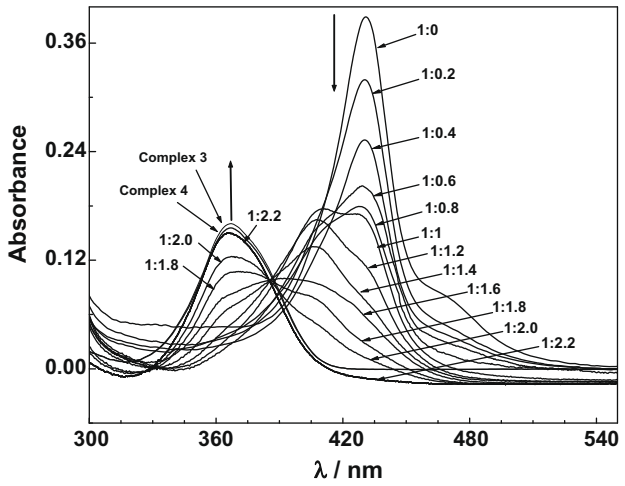

Fig. 9. Spectrophotometric titration of the macrocycle $[H_4L](ClO_4)_2$ (1×10^{-5}) with various numbers of equivalents of $Zn(OAc)_2{\cdot}2H_2O$ in acetonitrile.

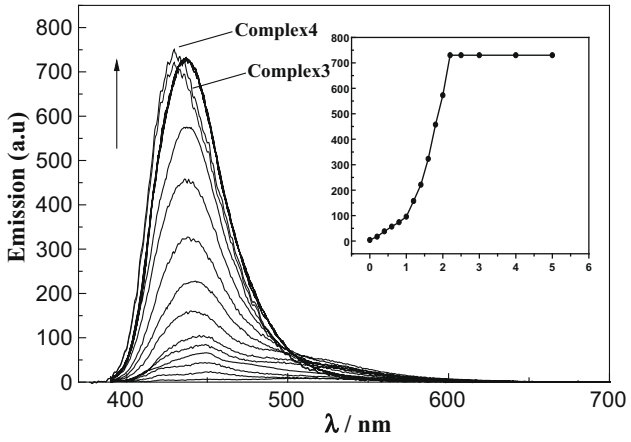

Fig. 10. Spectrofluorimetric titration of the macrocycle $[H_4L](ClO_4)_2$ (1×10^{-5}) with various numbers of equivalents of $Zn(OAc)_2{\cdot}2H_2O$ in acetonitrile. The arrow indicates the increasing concentration of $Zn(OAc)_2{\cdot}2H_2O$ added. The inset shows the variation of emission intensity with number of equivalents of $Zn(OAc)_2{\cdot}2H_2O$ added. λ_{ex} = 367.5 nm.

Absorption spectra of both of **3** and **4** show only one band at 367 nm with almost identical extinction coefficient (Fig. 9). Again, with 367 nm as the excitation wavelength, both of the complexes exhibit fluorescence with almost equal intensity and the emission peak is observed at 435 nm (Fig. 10).

To understand the reaction equilibria for the reaction of the macrocycle and zinc(II) ion, both the spectrophotometric and spectrofluorimetric titrations of $[H_4L](ClO_4)_2$ with $Zn(OAc)_2{\cdot}2H_2O$ have been carried out in acetonitrile. In these titrations (Figs. 9 and 10), ligand–metal ratio has been increased gradually until no further spectral change is taking place.

During the interval of addition of 0–1 equivalent of metal acetate, a new band at 410 nm is generated with the gradual loss intensity of the ligand band at 430 nm and the shoulder at 465 nm. On further addition of zinc acetate, the intensity of the band at 410 nm is diminished, while another new band at 367 nm is gradually generated. Saturation of this spectrophotometric titration takes place at 1:2.2 ligand–metal ratio. As compared in Fig. 9, the saturated spectrum is almost identical with the spectra of both the dinuclear complexes $[Zn^{II}_2L(NO_3)(H_2O)](ClO_4)$ (**3**) and $[Zn^{II}_2L(H_2O)_2](ClO_4)_2.(H_2O)_2$ (**4**). The generation of the two bands at 410 and 367 nm at the two stages of the spectrophotometric titration indicates that the complex formation takes place in stepwise manner (Eqs. (1) and (2)). However, while during the interval of addition of 1–2.2 equivalent of the metal ion, the absorption curves pass through an isosbestic point at 385 nm, the spectral profiles in the initial stages are not defined by an isosbestic point.

$$[H_4L]^{2+} + Zn(OAc)_2 \overset{K_1}{\rightleftharpoons} [Zn(H_2L)]^{2+} + 2HOAc \quad (1)$$

$$[Zn(H_2L)]^{2+} + Zn(OAc)_2 \overset{K_2}{\rightleftharpoons} [ZnL]^{2+} + 2HOAc \quad (2)$$

Inspite of the stepwise formation of the complex species, as already mentioned, it has not been possible to isolate the mononuclear zinc(II) complex. Evidently, two equilibrium constants are overlapped. It may be mentioned at this point that although both the mononuclear and dinuclear zinc(II) complexes can be isolated in some cases of the related ligands, attempts to synthesize the mononuclear complexes have been failed in some other cases due to more overlapping of the two equilibrium constants [37].

The spectrofluorometric titration is shown in Fig. 9. On exciting at 367 nm ($\lambda_{max.}$ of the dinuclear zinc(II) complexes), the emission intensity gradually increases with the addition of zinc(II) to $[H_4L]^{2+}$. The shapes of the luminescence profiles are indicative of the overlapping of the two steps of the complex formation.

4. Conclusions

A little investigated tetraiminodiphenolate ligand obtained on condensation of 2,6-diformyl-4-methylphenol and 2,2′-dimethyl-1,3-diaminopropane is addressed in the present study. In this investigation, this ligand is synthesized in its free diprotonated form. Template synthesis of a dinuclear lead(II) complex $[Pb^{II}_2L(NO_3)_2]$ (**2**), synthesis of a dinuclear zinc(II) complex $[Zn^{II}_2L(NO_3)(H_2O)](ClO_4)$ (**3**) through metal substitution reaction and synthesis of another dinuclear zinc(II) complex $[Zn^{II}_2L(H_2O)_2](ClO_4)_2.(H_2O)_2$ (**4**), structures of **1** and **3**, spectrophotometric and spectrofluorometric titrations of **1** with triethylamine as well as with zinc(II) acetate are described in the present study. The free ligand **1**, complexes **2**–**4** and their structural and spectroscopic studies are additions in the important family of Robson type macrocycles. The significant aspect of the present study is the zinc-induced fluorescence enhancement of an organic fluorophore $[H_4L](ClO_4)_2$ (**1**). These types of studies are important to develop zinc fluorophore and metal ion sensor.

investigate the chemistry of Ca with the other isomeric nitrobenzoic acids to understand the role of the nitro substituent in the structural chemistry of calcium-nitrobenzoates. The disposition of the $-NO_2$ substituent, ortho to the –COOH group in 2-nitrobenzoic acid (2-nbaH), results in the formation of a coordination polymer, with the carboxylate moiety of 2-nba (2-nitrobenzoate) functioning as a bridging ligand.

2. Experimental

2.1. Materials and methods

All the chemicals used in this study were of reagent grade and were used as received. The starting materials and reaction products are air stable and hence were prepared under normal laboratory conditions. Infrared (IR) spectra were recorded on a Shimadzu (IR prestige -21) FT-IR spectrometer in the range 4000–400 cm^{-1}. Samples for IR spectra were diluted with solid KBr and the signals referenced to polystyrene bands. UV–Vis diffuse-reflectance spectra were obtained using a Shimadzu UV-2450 double beam spectrophotometer. $BaSO_4$ powder was used as a reference (100% reflectance). Absorption data were calculated from the reflectance data using the Kubelka–Munk function $(a/S = (1-R)^2/2R$ where a is the absorption coefficient, R the reflectance and S the scattering coefficient). TG-DSC measurements were performed in Al_2O_3 crucibles on a STA-409PC simultaneous thermal analyzer from Netzsch in flowing air. A heating rate of 10 K min^{-1} was employed for all measurements. Acidification of **1** and **2** with a slight excess of dilute HCl resulted in the quantitative formation of the free carboxylic acid (2-nbaH), which was extracted with ether. Evaporation of the ether, followed by drying and weighing, afforded the 2-nbaH content as described earlier [50]. Pyrolysis of **1** and **2** at 800 °C resulted in the quantitative formation of CaO. Isothermal weight loss studies were performed in an electric furnace fitted with a temperature controller. Metal analysis was performed as described earlier [49,51].

2.2. Preparation of $[Ca(H_2O)_2(2\text{-}nba)_2]$, **1**

A mixture of calcium carbonate (1.0 g, 10 mmol) and 2-nitrobenzoic acid (2-nbaH) (3.34 g, 20 mmol) was taken in water (50 ml) and heated on a steam bath. The insoluble $CaCO_3$ slowly started dissolving, accompanied by brisk effervescence. The heating of the reaction mixture was stopped when there was no more evolution of CO_2. At this stage, the reaction mixture was almost clear. The hot pale yellow solution was filtered and left undisturbed for 9–10 days. The colorless crystalline blocks that separated were filtered, washed thoroughly with ether and dried. Yield: 3.42 g (84%). The crystals obtained in this method were suitable for X-ray studies. **1** can also be prepared starting from $CaCl_2$ as the Ca source. The sodium salt of 2-nba was first generated *in situ* by reacting 2-nbaH (1.67 g, 10 mmol) with $NaHCO_3$ (0.84 g, 10 mmol) in water. Into this, an aqueous solution of $CaCl_2$ (0.555 g, 5 mmol) was added and the reaction mixture was filtered and left aside for crystallization. The crystals that separated after a few days were isolated in 71% yield. The IR spectrum and the DSC thermogram of the product obtained by this method were identical to that of the product obtained using $CaCO_3$ as the Ca source.

Anal. Calc. for $C_{14}H_{12}CaN_2O_{10}$ (408.34): C, 41.18; H, 2.96; N 6.86; Ca, 9.82; 2-nbaH, 81.86; CaO, 13.73. Found: C, 41.10; H, 2.98; N, 6.58; Ca, 9.80; 2-nbaH, 80.35; CaO, 13.70%.

IR (in cm^{-1}): 3649, 3591, 3350, 3078, 2864, 2425, 2000, 1967, 1859, 1626, 1568, 1526, 1485, 1423, 1350, 1306, 1265, 1144, 1076, 968, 870, 851, 795, 789, 746, 702, 650, 430.

UV–Vis (in nm): 250, 350.

DSC (°C): 144 (Endo), 322 (Exo), 354 (Exo), 544 (Exo); residual mass 14.3%.

2.3. Preparation of anhydrous bis(2-nitrobenzoato)calcium(II) **2**

A powdered sample of **1** (0.325 g) was heated at 150 °C for 15 min. This resulted in the formation of the anhydrous compound **2**. The observed mass loss of 8.80% is in agreement with the expected value (8.81%) for the loss of two moles of water.

Anal. Calc. for $C_{14}H_8CaN_2O_8$ (372.34): C, 45.17; H, 2.17; N 7.52; Ca, 10.76; 2-nbaH, 89.78; CaO, 15.06. Found: C, 44.53; H, 2.1; N, 7.40; Ca, 10.5; 2-nbaH, 88.15; CaO, 14.80%.

IR (in cm^{-1}): 3074, 2866, 1585, 1566, 1524, 1517, 1485, 1415, 1350, 1308, 1265, 1153, 1078, 961, 864, 847, 785, 737, 700, 648, 432.

DSC (°C): 322 (Exo), 354 (Exo), 544 (Exo); residual mass 14.3%.

2.4. Rehydration studies

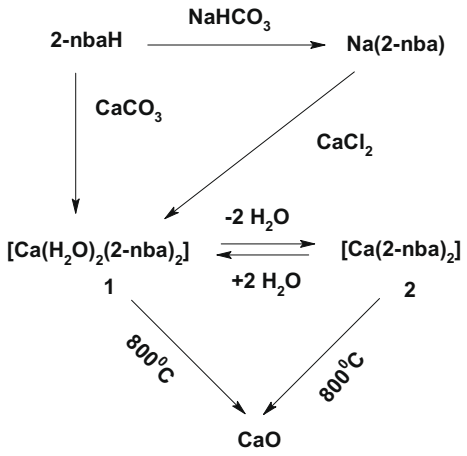
The anhydrous compound **2** was prepared from **1** as mentioned above. Equilibration of a powdered sample of **2** over water vapor resulted in the formation of the starting material 1 in near quantitative yield in about a day. The IR spectrum and the DSC thermogram of the rehydrated compound are identical to that of **1**.

2.5. X-ray crystallography

Intensity data for 1 were collected on a Bruker (SMART APEX) CCD diffractometer using graphite-monochromated Mo Kα radiation. The data integration and reduction were carried out using SAINT-PLUS [52] software. An empirical absorption correction was applied to the collected reflections with SADABS [52]. The structure was solved with direct methods using SHELXS-97 [53] and refinement was done against F^2 using SHELXL-97 [53]. All non-hydrogen atoms were refined anisotropically. Aromatic hydrogens were introduced in calculated positions and included in the refinement riding on their respective parent atoms. The hydrogen atoms of the coordinated water molecules were located in the difference map but were not stable on subsequent refinements and hence were fixed at calculated positions by using the DFIX command and later refined isotropically using a riding model. The technical details of data acquisition and selected crystal refinement results for **1** are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and spectroscopy



During the course of our studies on metal-carboxylates [50,54], we have shown that crystalline hydrates of metal-nitrobenzoates can be conveniently prepared in good yields under ambient conditions by an aqueous reaction of an alkali-metal carbonate with 4-nbaH or by the reaction of the *in situ* generated sodium salt of 4-nbaH with a metal halide. The generality of these reactions for the synthesis of hydrated metal-carboxylates can be evidenced by the synthesis of 4-nba compounds of alkaline-earths [49,50,55–57] as well as transition metals [58–60], the synthesis of a polymeric Ba compound [61] containing 2-nba as well as the Ca compound described herein. In the present work, the direct reaction of $CaCO_3$ with 2-nbaH in water resulted in the formation of a crystalline hydrate **1** containing Ca:2-nba:H_2O in a 1:2:2 mole ratio. Compound **1** could also be prepared by reacting an aqueous solution of $CaCl_2$ with *in situ* generated sodium salt of 2-nbaH. The composition of **1** was arrived at based on elemental analysis, 2-nbaH content

Table 1
Technical details of data acquisition and selected refinement results for **1**.

Empirical formula	$C_{14}H_{12}CaN_2O_{10}$
Formula weight	408.34
T (K)	293(2)
λ (Å)	0.71073
Crystal system	triclinic
Space group	$P\bar{1}$

Z, D_{calc} (Mg/m^3)	2, 1.556
Absorption coefficient (mm^{-1})	0.418
F (0 0 0)	420
Crystal size (mm^3)	0.38 × 0.32 × 0.20
θ range for data collection (°)	1.85–25.93
Index ranges	$-9 \leqslant h \leqslant 9$, $-11 \leqslant k \leqslant 12$, $-13 \leqslant l \leqslant 13$
Reflections collected/unique	6780/3753 (R_{int} = 0.0204)
Completeness to θ = 25.93°	98.4%
Refinement method	full-matrix least-squares on F^2
Data/restraints/parameters	3353/4/260
Goodness-of-fit (GOF) on F^2	1.077
Final R indices [$I > 2\sigma(I)$]	R_1 = 0.0395, wR_2 = 0.0863
R indices (all data)	R_1 = 0.0461, wR_2 = 0.0896
Extinction coefficient	0.0040(2)
Largest difference peak and hole (e Å^{-3})	0.215 and −0.202

obtained by acidification and CaO formed on pyrolysis and weight loss studies. Compound **1** can be dehydrated to the anhydrous bis(2-nitrobenzoato)calcium(II) **2** by heating at 150 °C (Scheme 1). The temperature for the dehydration reaction was chosen based on the thermal property (*vide infra*) of **1**. Equilibration of the anhydrous compound **2** in an atmosphere of water vapor resulted in the regeneration of compound **1**. This was confirmed by a comparison of the IR spectrum and the TG-DSC thermogram of the rehydrated product with that of **1**. Both **1** and **2** are decomposed to CaO by heating in a furnace at 800 °C.

The diffuse reflectance spectrum of compound **1**, which absorbs strongly at around 350 nm, is very similar to that of the free acid (Supplementary Fig. 1) and this can be assigned to the intramolecular charge transfer transition of the aromatic 2-nitrobenzoate. In addition **1** also exhibits a signal at around 250 nm, unlike the free acid, and the diffused reflectance spectrum of the anhydrous compound **2** is very similar to that of **1**. The IR spectra of **1** and **2** exhibit

Scheme 1. Synthesis of **1** and **2**.

several sharp bands in the mid-infrared region, clearly indicating the presence of the organic moiety. The strong signals at 3649 and 3591 cm^{-1} in **1** indicate the presence of water and can be assigned to the O–H stretching vibration. The IR spectrum of **2** is devoid of bands above 3074 cm^{-1}, which is indicative of the anhydrous nature of **2**. Below 3074 cm^{-1}, the IR spectrum is very similar to that of **1**. Although the IR spectra **1** and **2** exhibit absorptions due to the vibrations of the carboxylate and nitro groups, no definite conclusions can be drawn on the exact nature of the binding of the 2-nba ligand based only on infrared data.

3.2. Thermal studies

Compound **1** exhibits an endothermic event in its TG-DSC thermogram (Fig. 1) at 144 °C, accompanied by a mass loss of 8.5%. This value is in good agreement with that expected (8.83%) for the loss of two molecules of water. Above this temperature, the thermogram shows only exothermic processes with signals at 322, 354 and 544 °C. The first two closely related exotherms can be attributed to the decomposition of 2-nitrobenzoate. In view of the absence of mass spectral data of the emitted fragments, we do not wish to comment on the exact nature of the decomposition processes at these high temperatures. However it should be noted that the observed residual mass of 14.3% is in good agreement for the formation of CaO. The formation of the oxide phase can also be evidenced by the featureless infrared spectrum of the residue as well as its powder pattern. The residue on exposure to atmosphere shows an increase in weight corresponding to the formation of calcium carbonate. The results of the isothermal weight loss studies at 150 °C and at 800 °C in a furnace add more credence to the TG-DSC data. The TG-DSC thermogram of the anhydrous compound **2** is devoid of the first endothermic signal observed for the dehydration of **1**. A comparison of the TG-DSC thermograms of **1** and **2** (Fig. 1) shows the identical nature of the TG-DSC curve of **2** to that of **1** above 150 °C. The observed residual mass of 13.7% can be accounted for by the formation of CaO.

3.3. Description of the crystal structure of *1*

Compound **1** crystallizes in the centrosymmetric triclinic space group $P\bar{1}$ with all atoms situated in general positions. The central metal is eight coordinated and is bonded to two oxygen atoms of

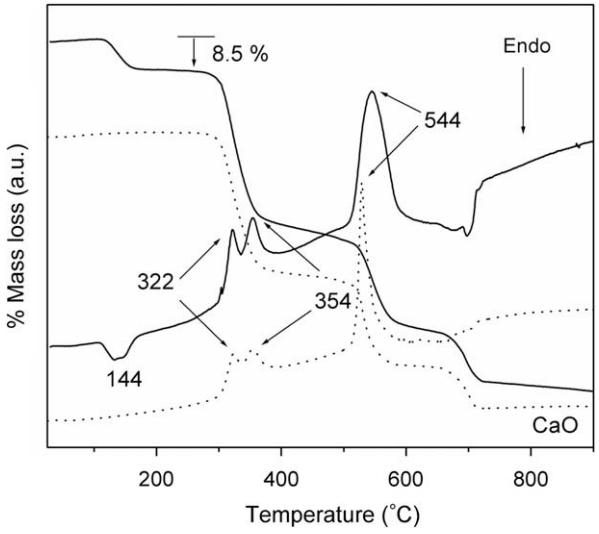

Fig. 1. TG-DSC thermograms of $[Ca(2\text{-nba})_2(H_2O)_2]_n$ **1** (solid line) and $[Ca(2\text{-nba})_2]_n$ **2** (dotted lines). (Heating rate 5 K min^{-1}; air atmosphere.)

two terminal aqua ligands and six oxygen atoms from four symmetry related 2-nba anions, resulting in a distorted triangular dodecahedral $\{CaO_8\}$ coordination polyhedron (Fig. 2). The geometric parameters of the 2-nba ligand are in the normal range and are in agreement with reported values [61]. The observed Ca–O bond distances vary between 2.3442(13) and 2.6539(15) Å (Table 2), while the O–Ca–O angles range from 77.32(6)° to 153.76(6)°. These values are comparable with those reported for other Ca(II)-carboxylates [7–12]. The Ca(II) center is linked to the O9 and O10 atoms of the water molecules by bonds of lengths 2.3918(18) and 2.4121(17) Å, respectively.

The structure of compound **1** is a one-dimensional (1-D) polymer and hence it is formulated as $[Ca(2\text{-nba})_2(H_2O)_2]_n$. Each formula unit of **1** contains Ca(II) coordinated to two aqua ligands and two unique 2-nitrobenzoate ligands, both of which function as bridging ligands. The first unique μ_2–η^2:η^1 2-nba ligand (O1, O2) binds to Ca(II) in a bidentate fashion with Ca1–O1 and Ca1–O2 distances of 2.4548(15) and 2.6313(15) Å, respectively. The O2 oxygen is further linked to a symmetry related Ca(II) center at a distance of 2.3498(14) Å, resulting in a Ca···Ca separation of 3.9865(8) Å. A pair of such μ_2–η^2:η^1 2-nba ligands are linked to two Ca(II) ions resulting in the formation of a tricyclic dicalcium-dicarboxylate unit (Fig. 3) which constitutes the basic building block of the coordination polymer. This tricyclic unit differs from the well-known eight membered cyclic dimetal-dicarboxylate unit in several dinuclear carboxylates where $(-COO)^-$ functions as a μ_2–η^1:η^1 bidentate bridging ligand. The second independent 2-nba ligand (O5, O6) binds to two symmetry related Ca(II) ions in an identical fashion resulting in a tricyclic dicalcium-dicarboxylate unit with a Ca···Ca separation of 3.9967(9) Å (Supplementary Fig. 2). The Ca–O bond lengths formed by this ligand are different. With this ligand, a Ca(II) ion is linked to the O5 and O6 oxygen atoms in a bidentate manner (Ca1–O5 2.4213(14); Ca1–O6 2.3442(13) Å) and the O6 atom is further linked to a second Ca(II) ion at 2.6539(15) Å. In the crystal structure of **1** alternating pairs of the two crystallographically independent μ_2–η^2:η^1 2-nba ligands link pairs of $\{Ca(H_2O)_2\}^{2+}$ units into a 1-D polymeric chain extending along the *a*-axis (Fig. 4). As a result, alternating Ca···Ca separations of 3.9865(8) and 3.9967(9) Å are observed in the infinite chain (Fig. 4). These values are in very good agreement with the Ca···Ca separations of 3.8585(7) and 3.8432(3) Å reported for the coordination polymers $[Ca(L^1)(4\text{-nba})_2]_n$ (L^1 = N-methylimidazole)

Color code: C, black; H, medium gray; N, blue; O, red; Ca, orange. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

[47] and $[Ca(L^2)(H_2O)(4\text{-nba})_2]_n$ (L^2 is 2-methylimidazole), respectively [48].

A scrutiny of the crystal structure of **1** reveals that each eight coordinated Ca(II) complex in the polymeric chain is H-bonded to six neighboring complexes with the aid of two varieties of H-bonding interactions comprising of three O–H···O hydrogen bonds and three C–H···O interactions (Supplementary Fig. 3). All these O···H contacts are shorter than the sum of their van der Waals radii and their geometric parameters are listed in Table 3. The O9–H9···O1^{i} and O10–H10B···O5^{ii} (for symmetry code see Table 3) interactions between the coordinated water molecules and the carboxylate oxygen atoms O1 and O5 occur within the 1-D polymeric chain (Fig. 4) and thus are intrachain interactions. The oxygen atoms of the nitro group function as H-acceptors and this behavior has been observed in several nitrobenzoates [47–49,55–61]. The nitro oxygen atoms O4 and O7 in one polymeric chain are hydrogen bonded to the H11 and H10A atoms in an adjacent chain via C11–H11···O4^{v} and O10–H10A···O7^{iii}, and these can be termed as interchain interactions. Likewise the H-bonding between O9 (water) and O1 (carboxylate) with the H atoms of the aromatic ring serve to link parallel chains (Supplementary Fig. 3).

Abbreviations used: C.N. = coordination number; D = dimensionality of polymer; N-MeIm = N-methylimidazole; 4-nba = 4-nitrobenzoate; Phen = 1,10-phenanthroline; Sa = salicylato; BDC – benzene-1,4-dicarboxylate, DEF = N,N-diethylformamide; 2-MeIm = 2-methylimidazole; gly = glycinate; dnSa = 3,5 dinitrosalicylato; DMF = N,N-dimethylformamide; benz = benzoate; val = rac-valinate; 4-aba = 4-aminobenzoate; 2-nba = 2-nitrobenzoate; OAc = acetate; 3-aba = 3-aminobenzoate; 4-CNbenz = 4-cyanobenzoate; Nic = nicotinate; OPA = 2-oxo-1,2-dihydropyridine-1-acetate; $C_4H_4O_5$ = malate; leu = rac-leucinate; bpdc = 4,4′-biphenyldicarboxylic acid; 2-aba = 2-aminobenzoate; 4-fba = 4-fluorobenzoate; $C_8H_5O_3$ = 2-formylbenzoate;PY-Thr = N-(6-amino-3,4-dihydro-3-methyl-5-nitroso-4-oxopyrimidin-2-yl) thronato; $C_9H_{11}N_6O_5$ = bis[N-(6-amino-3,4-dihydro-3-methyl-5-nitroso-4-oxopyrimidine-2-yl) glycylglycinate; 1,4-bdc = 1,4-benzenedicarboxylate; 1,3-bdc = 1,3-benzenedicarboxylate; L = 4-(2-nitrophenyl)-3,6-dioxaoctane dioate; NDC – naphthalene 2,6-dicarboxylate; TPDC – 4,5,9,10-tetrahydropyrene-2,7-dicarboxylate; DADC – 5,10-dihydroanthracene-2,7-dicarboxylate; H_3BTC = benzene-1,3,5-tricarboxylic acid; tda = $S(CH_2COO)_2^{2-}$; BTA = 1,3,5-benzenetriacetate; $(O_2C)_2C_6H_3CO_2H$ = trimellitate; DTBB = 2,2′-dithiobis(benzoate); Hpdc = 3,5-pyrazoledicarboxylate; A_3Br = 1,3-biscarboxyethylimidazolium bromide; $C_{10}H_8O_6$ = benzene 1,4-dioxylacetate; 5-OH-BDC = 5-hydroxy isophthalate; $C_3H_3O_4$ = malonate; AIP = 5-aminoisopthalate.

several differences. Both compounds contain alkaline-earth:2-nba in a 1:2 ratio and are 1-D polymers based on dinuclear units. The alkalnei-earth metals in both compounds are linked to four different carboxylate ligands. However the compounds are differently hydrated and Ba adopts a 9 coordination. Of the two crystallographically independent 2-nba ligands in the Ba compound, one ligand binds in a μ_2–η^2:η^1 manner, as observed in the Ca compound, while the other 2-nba ligand functions as a monoatomic bridge between two adjacent Ba ions in the chain with one of the nitro oxygen atoms bonded to one Ba, resulting in a denticity of three for this second 2-nba ligand. This binding mode of the carboxylate moiety in $[Ba(H_2O)_3(2\text{-}nba)_2]_n$ can be designated as μ_2–η^1:η^1. In the 1-D polymeric chain alternating pairs of bivalent metals are bridged by a pair of 2-nba ligands.

In order to understand the role of the nitro group in the structural chemistry of Ca-nitrobenzoates, a comparison of the structural features of the title Ca compound **1** with the related monomeric Ca compound [49] of 4-nba namely $[Ca(H_2O)_4(\eta^1\text{-}4\text{-}nba)(\eta^2\text{-}4\text{-}nba)]$ is made. In the 4-nba compound, containing the nitro group para to the carboxylate functionality, the heptacoordinated Ca(II) is linked to two crystallographically independent 4-nba ligands which coordinate in a monodentate (η^1) and bidentate

(η^2) manner, respectively. In our original report [49] on the structural aspects of [Ca(H_2O)$_4$(η^1-4-nba)(η^2-4-nba)] only the O–H···O interactions were described, and the weak C–H···O interactions were not mentioned. A reinvestigation of the structure data reveals that one nitro oxygen atom on each unique 4-nba is involved in a C–H···O interaction at distances of 2.61 and 2.45 Å, accompanied by CHO angles of 158–166°, respectively. Hence the –NO_2 group in the 4-nba and 2-nba compounds of Ca, which are differently disposed with respect to the carboxylate in the benzene ring, are very similar in terms of their secondary interactions. However there is a noticeable difference between 1 and [Ca(H_2O)$_4$(η^1-4-nba)(η^2-4-nba)] in terms of the number of coordinated waters, which can account for the observed structural variation in these two compounds.

3.4. Comparative study of Ca(II) coordination polymers

In the 4-nba compound [Ca(H_2O)$_4$(η^1-4-nba)(η^2-4-nba)], each Ca(II) ion is linked to four oxygen atoms from water, and the monodentate and bidentate coordination of 4-nba results in hepta-coordination around Ca. In contrast, the tridenticity of the two crystallographically independent bridging 2-nba ligands in **1** leads to an eight coordination around Ca in the diaqua compound [Ca(2-nba)$_2$(H_2O)$_2$]$_n$ **1**, a feature observed in several calcium-carboxylates [19]. The attainment of a higher coordination number appears to be a key feature in Ca structural chemistry. It is noted that when there are a lesser number of coordinated water molecules in a calcium-carboxylate, the carboxylate ligand prefers to adopt a bridging mode of ligation. The importance of the number of coordinated waters can be evidenced by a comparative study of calcium-carboxylates, several of which are listed in Table 4.

Polymeric Ca-carboxylates of varying dimensionalities, derived from different carboxylic acids, are listed in Table 4. The coordination number of Ca(II) varies from 6 to 10, with eight coordination being observed in the majority of the compounds. It is interesting to note that in all the coordination polymers, excepting the three Ca compounds (entry numbers 45–47) derived from the dicarboxylic acids Hpdc (3,5-pyrazoledicarboxylate) and AIP (5-aminoisophthalate), the number of coordinated water molecules is three or less and in all such compounds the carboxylate ligand exhibits a bridging coordination mode leading to a polymeric chain. In the helical chain compound [[Ca(H_2O)$_4$(AIP)$_2$](H_2O)]$_n$, which has four water molecules, the entire AIP ligand acts as a bridge between two symmetry related Ca(II) ions, with each carboxylate showing a bidentate coordination to one Ca(II). In this case, octacoordination around Ca can be achieved without a bridging carboxylate mode of binding. Likewise in [[Ca(H_2O)$_4$(Hpdc)]·2H_2O]$_n$, the Hpdc ligand functions as a bridge between two Ca(II) ions with each carboxylate group binding in a monodentate fashion to one Ca. Additionally one of the pyrazole N atoms is also ligated in one of the ligands. It is to be noted that both AIP and Hpdc are ditopic ligands as they contain two carboxylate groups anchored onto a ring, and the ditopicity is responsible for the polymeric structure, without making use of a bridging carboxylate mode in these compounds. It is interesting to note that in the 1-D polymer [[Ca(H_2O)$_4$(Hpdc)].H_2O]$_n$, synthesized at a more acidic pH, a bridging carboxylate ligation is observed even though the Ca is coordinated to four water molecules. In this case pyrazole N ligation is not observed. From Table 4 it is very clear that when the number of coordinated water molecules is three or less, a bridging carboxylate binding mode is always observed. In Ca(II) compounds derived from mono carboxylic acids like 4-nbaH, for example [Ca(H_2O)$_4$(η^1-4-nba)(η^2-4-nba)] (entry number 48 in Table 4) seven coordination around Ca is observed due to the mono and chelating binding modes of the crystallographically independent 4-nba ligands, and this compound exhibits a zero-dimensional structure. When the number of water ligands in this compound is reduced by heating, the 4-nba adopts a bridging binding mode leading to a polymeric structure, as reported by us recently [47,48]. Another noteworthy feature is the tendency for the majority of the compounds to crystallize in centrosymmetric space groups.

4. Conclusions

In the present work we have described the synthesis, spectral and thermal properties and structural characterization of a new Ca(II) coordination polymer based on a tricyclic dicalcium-dicarboxylate building block. A comparative study of several Ca polymers shows that when the number of coordinated water molecules is three or less, in a Ca-carboxylate, the carboxylate ligand adopts a bridging mode of ligation.

FTIR transmission spectra were taken on Perkin Elmer Spectrum BX model Infrared Spectrophotometer from 4000 to 400 cm^{-1}.

Scanning Electron Microscopy (SEM) analysis was performed on a FEI XL40 Sirion FEG Digital Scanning Microscope. Samples were coated with gold at 10 mA for 2 min prior to SEM analysis.

Magnetic measurements were carried out with the Quantum Design Model 6000 Vibrating Sample Magnetometer (VSM) and parameters like specific saturation magnetization (Ms), coercive force (Hc) and remanence (Mr) were evaluated.

2.2. Procedure

In an appropriate ratio, analytical grade of cobalt nitrate ($Co(NO_3)_2{\cdot}6H_2O$), zinc nitrate ($Zn(NO_3)_2{\cdot}6H_2O$), ferric nitrate ($Fe(NO_3)_3{\cdot}9H_2O$) and constant amount of urea (1 g) were mixed to obtain precursor solutions. The crucibles containing the precursor solution was introduce into a microwave oven one by one. Initially, the solution boils and undergoes dehydration followed by decomposition with the evolution of large amount of gases (N_2O and CO_2). After the solution reaches to the point of spontaneous combustion, it begins to burn and releases lots of heat, vaporizes all the solution instantly and becomes solid burning at high temperature. The entire combustion process takes only 5 min to produce ferrite powders in a microwave oven.

3. Results and discussion

3.1. XRD analysis

The X-ray diffraction patterns (Fig. 1) of the prepared samples, $Co_xZn_{1-x}Fe_2O_4$ ($x = 0.2, 0.4, 0.8$) exhibited the 11 reflection planes (1 1 1), (2 2 0), (3 1 1), (2 2 2), (4 0 0), (4 2 2), (5 1 1), (4 4 0), (6 2 0), (5 3 3) and (6 2 2) that indicate the presence of the spinel cubic structure [26]. All XRD peaks are correspondent with the JCPDS card no. 89-1012 ($ZnFe_2O_4$) and 22-1086 ($CoFe_2O_4$).

The reaction can be described as follows:

$$(1-x)Zn(NO_3)_2(s) + xCo(NO_3)_2(s) + 2Fe(NO_3)_3(s) + 7CO(NH_2)_2(s) + 13O_2(g) \rightarrow Co_xZn_{(1-x)}Fe_2O_4(s) + 11N_2O(g) + 14H_2O(g) + 14CO_2(g)$$

To determine the crystallite size distribution of the samples, the diffraction profiles (11 reflection planes) were fitted according to the Eq. (1) in Wejrzanowski et al. [27] which allows the estimation of average crystallite size and its standard deviation from XRD profile fitting. The calculated average crystallite sizes, D, and their standard deviations, σ, were presented in Table 1.

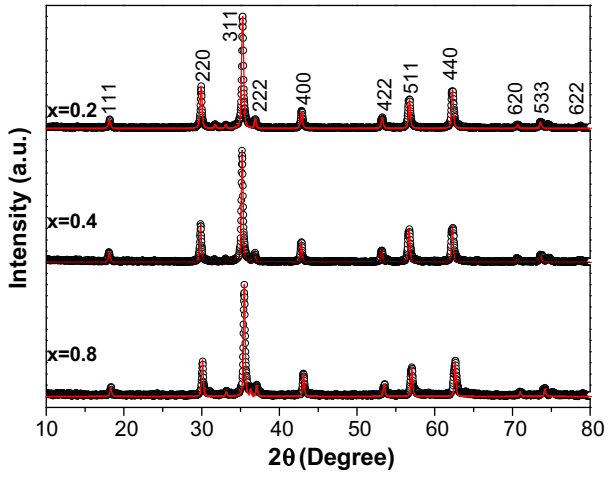

Fig. 1. XRD powder patterns of $Co_xZn_{1-x}Fe_2O_4$ ($x = 0.2, 0.4, 0.8$) nanoparticles.

The lattice constant for each peak of each sample was calculated by using the formula:

$a = d\,(h^2 + k^2 + l^2)^{1/2}$, where h, k, and l are miller indices of the crystal planes. To determine the exact lattice parameter for each composition (sample), Nelson–Riley method was used. The Nelson–Riley function $F(\theta)$ is given as $F(\theta) = 1/2[(\cos^2\theta/\sin\theta) + \cos^2\theta/\theta]$. The values of lattice constant a_o of all the peaks for a sample was plotted against $F(\theta)$ (not given). Then using a least square fit method exact lattice constant a_o was determined (Table 1). The point where the least square fit straight line cut the y-axis (where $F(\theta) = 0$) is the actual lattice parameter of the composition.

It was observed that the lattice constant for each composition decreases with increasing Co substitution and follows Vegard's law (Table 1). This probably due to variation of ionic sizes of the Zn^{2+} and Co^{2+} cations since ionic size of Co^{2+} (0.72 Å) is lower than that of Zn^{2+} (0.82 Å) [28,29]. A similar behavior was also observed by Hossain et al. [30]. Because the lattice constants (a_o) were found to be within the range of the lattice constants of $ZnFe_2O_4$ and $CoFe_2O_4$.

3.2. FTIR analysis

FTIR spectrum of as-made ferrite nanocrystals is presented in Fig. 2. Two main broad metal-oxygen bands are seen in the FTIR spectra of all spinels, and ferrites in particular. The highest one, ν_1, is generally observed in the range 600–500 cm^{-1}, and it corresponds to intrinsic stretching vibrations of the metal at the tetrahedral site (T_d), $M_{tetra} \leftrightarrow O$, whereas the ν_2 lowest band is usually observed in the range 430–385 cm^{-1}, is assigned to octahedral-metal stretching (O_h), $M_{octa} \leftrightarrow O$ [3–9,31–34]. In the FTIR spectrum of the products, we also observed the band at 600 cm^{-1} is assigned as ν_1 ($M_{tetra} \leftrightarrow O$). Due to the limitation of our FTIR instrument near 400 cm^{-1}, ν_2 (430–385 cm^{-1}), and below 400 cm^{-1}, ν_3 (328 cm^{-1}) and ν_4 (below 300 cm^{-1}) were not detected clearly. The absorption bands observed at ~3450 and ~1630 cm^{-1} prove the presence of adsorbed water on the surface of the ferrite nanocrystals. The small absorption band at around 1380 and 1720 cm^{-1} in the as-prepared material may be assigned to the unreacted metallic salts and carbonyl (from urea), respectively. In the $Co_xZn_{1-x}Fe_2O_4$ nanocrystals, Zinc ion occupies the tetrahedral (T_d) site while cobalt and iron have two valences, therefore partially occupy both the tetrahedral and octahedral sites [35]. Consequently, the ν_1 band, observed at 561 cm^{-1} for $ZnFe_2O_4$ can be assigned to tetrahedral Zn^{2+} stretching and the ν_2 band, observed at 425 cm^{-1}, involves the Fe^{3+} vibration at the octahedral site. In the $Co_xZn_{1-x}Fe_2O_4$ sample, when Zn^{2+} are replaced by smaller Co^{2+} ions with lower atomic weight, the ν_1 vibration shifts to higher wavenumber.

3.3. SEM analysis

The scanning electron micrographs of $Co_xZn_{1-x}Fe_2O_4$ nanocrystals (Fig. 3) shows that the sample has a large grain structure. Heating has resulted in sintering of the well-faceted grains to form solid bodies. It is a very porous network of sintered bodies. The scanning

Table 1
Calculated crystallite sizes (nm) with standard deviations of $Co_xZn_{1-x}Fe_2O_4$ ($x = 0.2$, 0.4, 0.6) nanoparticles from XRD and their lattice constants (a_o).

Nanoparticles	D (nm)	Sigma	Lattice constant (Å)
$Co_{0.2}Zn_{0.8}Fe_2O_4$	39.1	9.8	8.426(±1)
$Co_{0.4}Zn_{0.6}Fe_2O_4$	35.1	11.2	8.412(±3)
$Co_{0.8}Zn_{0.2}Fe_2O_4$	37.5	12	8.396(±2)

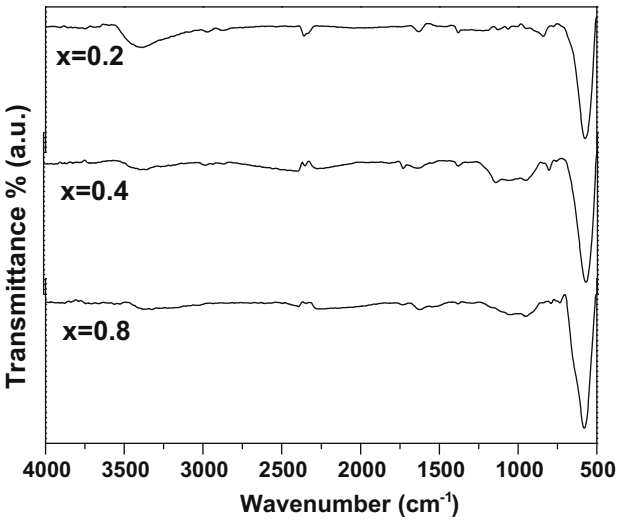

Fig. 2. FTIR spectrum of $Co_xZn_{1-x}Fe_2O_4$ ($x = 0.2, 0.4, 0.8$) nanoparticles.

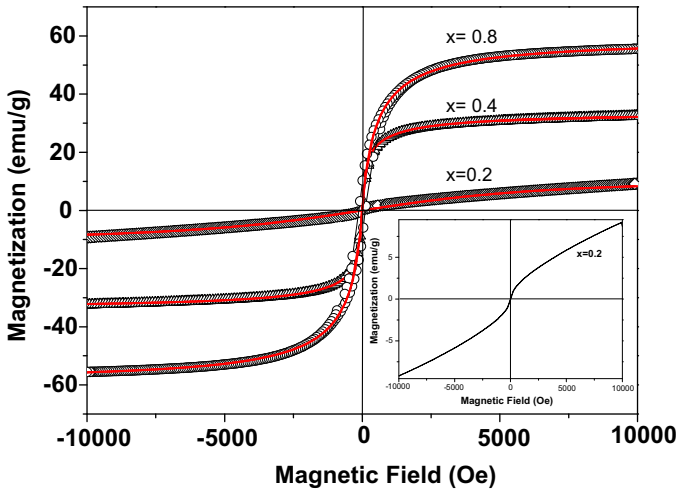

Fig. 4. Magnetic hysteresis loops of $Co_xZn_{1-x}Fe_2O_4$ nanoparticles at room temperature The solid lines represents the best fits for the Langevin function (The inset shows the M–H curve of $Co_xZn_{1-x}Fe_2O_4$ ($x = 0.2$) nanoparticles).

electron micrograph reveals a porous network, more like a foam. The surface of the powders shows pores formed by the escaping gases during the combustion reaction. These particles exhibit a network with voids and pores typical of combustion – synthesized powders [3,8,36]. The porous powders are highly friable, which facilitate easy grinding to obtain finer particles [37].

3.4. VSM analysis

All magnetic measurements have been carried out by using Quantum Design Vibrating Sample Magnetometer (QD-VSM). The samples were cooled either in the presence of an external magnetic field (Field cooling case-FC) or in zero field (Zero field cooling case-ZFC) and, the magnetic hysteresis curves were recorded by sweeping the external field between ±10 kOe at different temperatures.

We have taken $Co_xZn_{1-x}Fe_2O_4$ ($x = 0.2, 0.4, 0.8$) as a basic system for the following reasons. This sample is a mixture of $CoFe_2O_4$ with long range ferrimagnetic transition temperature at 790 K and $ZnFe_2O_4$ with antiferromagnetic Neel temperature at 9 K. It has been reported that $CoFe_2O_4$ has the highest anisotropy constant K_1 among the ferrite spinels due to the presence of Co^{2+} ions on B sites. $CoFe_2O_4$ is a good candidate for magnetic recording media and magnetic fluids whereas, $ZnFe_2O_4$ is used as a catalyst [38–40].

Fig. 4 represents the room temperature magnetic hysteresis of the $Co_xZn_{1-x}Fe_2O_4$ nanocrystals over the field range −10 kOe to 10 kOe. The value of magnetization sharply increases with the external magnetic field strength at low field region. However, it can not reach a saturation state yet in the presence of a relatively strong magnetic field of even 10 kOe. Similar reports about room temperature magnetization have been coated by others [41,42].

For all samples, a typical superparamagnetic 'S'-like shape of hysteresis curves (without open loops- coercive fields are zero) were observed at room temperature. Those 'S'-like shape loops can be divided into two parts: linear parts and curvature parts. While the M–H curve shows no hysteresis and no saturation for $x = 0.2$ and $x = 0.4$ samples, it shows a small hysteretic behavior with a coercivity of 117 Oe for $x = 0.8$ sample. The saturation magnetization of the samples were found (obtained by extrapolating M vs. 1/H plot to 1/H = 0) for $x = 0.2$, 0.4, 0.8 compositions as 11.5 emu/g, 34.1 emu/g and 59.0 emu/g, respectively.

The increase in the saturation magnetization and the coercivity of the nanocrystals by increasing the Co content can be attributed to the magnetic character and the anisotropic nature of cobalt. Since more Co ions replace with Zn ions by increasing the "x", the saturation magnetization and the coercivity increases and the sample with $x = 0.8$, $Co_{0.8}Zn_{0.2}Fe_2O_4$, shows ferromagnetic behavior at room temperature.

At room temperature, the absence of saturation, remanent magnetization and coercivity in M–H curves indicates the superparamagnetic nature of the particles ($x = 0.0$ and $x = 0.4$), $ZnFe_2O_4$ and $Co_{0.4}Zn_{0.6}Fe_2O_4$, which relax back their spins by rotation on removal of applied magnetic field so as to give a zero net magnetic moment [4,43–47]. The absence of coercivity at room temperature could also be attributed to the presence of more Zn concentration in the otherwise ferromagnetic cobalt ferrite phase, for the presented composition [48,49].

Fig. 5 shows M–H loops at 10 K for $Co_xZn_{1-x}Fe_2O_4$ samples with different Co content. $Co_xZn_{1-x}Fe_2O_4$ nanocrystals show a considerable saturation magnetization, the coercivity and remanence at lowest temperature and they increase with the increase of Co content. The samples does not show saturation even at 10 kOe. The saturation magnetization is found to increase from 64.32 emu/g for the $x = 0.2$ to 106 emu/g for the $x = 0.8$ at the temperature of 10 K.

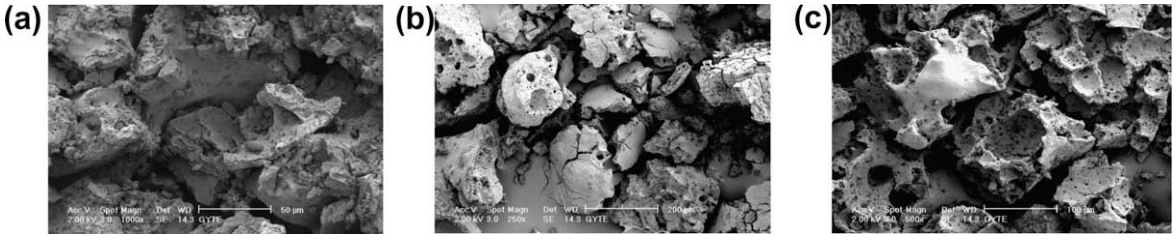

Fig. 3. SEM micrographs of $Ni_xCo_{1-x}Fe_2O_4$ nanoparticles; (a) $x = 0.2$, (b) $x = 0.4$, (c) $x = 0.8$.

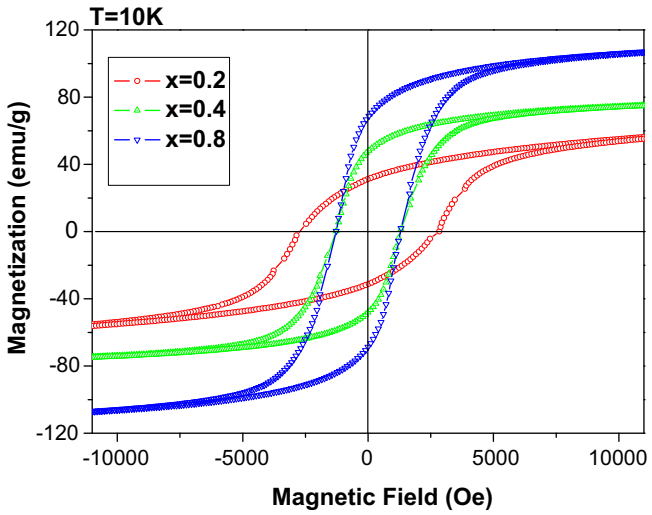

Fig. 5. Magnetic hysteresis loops of $Co_xZn_{1-x}Fe_2O_4$ nanoparticles at 10 K.

The wide hysteresis loop for $x = 0.2$ at 10 K with a coercive field (H_c) of 2.8 kOe and remanent magnetization (M_r) of 32 emu/g confirm the presence of large ferromagnetic order at low temperatures. The large values of coercive field (H_c) and irreversibility field (H_{irr}) below the blocking temperature is associated with the increase of effective anisotropy field (K_{eff}), where $K_{eff} = 4\pi M_s H_{irr}$. This can be attributed to the random freezing of clusters in locally canted states, for which the random anisotropy energy will act as pinning potential. The decrease of remanent magnetization (M_r) and saturation magnetization (M_s) suggest the decrease of strongly interacted magnetic state towards a paramagnetic state [42,44,50].

For $x = 0.4$ and $x = 0.8$ remanent magnetizations of 46 emu/g and 67 emu/g, a coercivity of 1280 Oe and 1282 Oe, the saturation magnetization of 78.6 emu/g and 106 emu/g are observed at 10 K.

The changes in magnetic properties such as M_s, H_c, and M_r are due to the influence of the cationic stoichiometry and their occupancy in the specific sites. The magnetic order in the cubic system of ferromagnetic spinels is due to super-exchange interaction mechanism occurring between the metal ions in the tetrahedral A-sites and octahedral B-sites. The substitution of Zn^{2+} ion (with zero magnetic moment), which has a preferential A site occupancy results in the reduction of super-exchange interaction between A and B sites. Hence, it is possible to vary the magnetic properties by varying the degree of Zn substitution [29]. Additionally, the changes can also be attributed to the formation of dead layer on the surface, existence of random canting of particle surface spins, non-saturation effects due to random distribution of particle size, deviation from the normal cation distribution, presence of adsorbed water, etc. [8,42,51–54].

Zero field cooled (ZFC) and field cooled (FC) temperature dependent magnetizations performed on a VSM device for $Co_xZn_{1-x}Fe_2O_4$ nanocrystals are presented in Fig. 6. In ZFC measurements, the samples are cooled from room temperature to 5 K without applying an external magnetic field. After reaching 5 K, a 100 Oe magnetic field is applied (FC) and the magnetization is recorded as the temperature is increased. As seen in Fig. 6a, for $x = 0.2$ the ZFC case upon increasing the measurement temperature, the magnetization of $Co_{0.2}Zn_{0.8}Fe_2O_4$ nanoparticle increases and reaches a maximum value of 8.5 emu/g at the blocking temperature (127 K), T_B. Above the blocking temperature, the magnetization

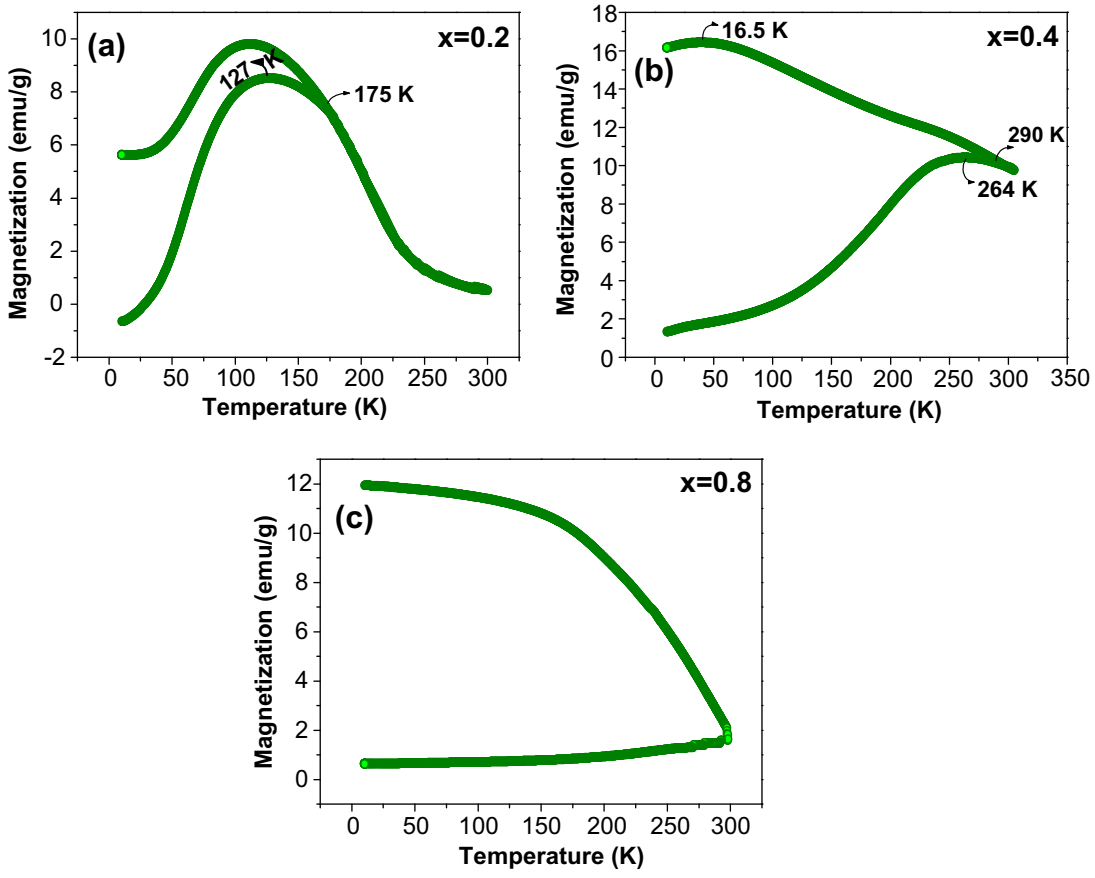

Fig. 6. M–T curve of $Co_xZn_{1-x}Fe_2O_4$ nanoparticles with applied field of 100 Oe.

starts to decrease and displays a typical paramagnetic behavior. FC magnetization curve of $Co_{0.2}Zn_{0.8}Fe_2O_4$ nanocrystals follows the same path as ZFC curve, but it unstucks from ZFC curve at 175 K. The separation between the ZFC and the FC curves gives an indication that there is a non-equilibrium magnetization and represents the irreversibility temperature, T_{irr} [55]. And the FC magnetization curve reaches to a maximum magnetization of 9.8 emu/g at 110 K then starts to decrease by decreasing temperature.

Fig. 6b displays the M–T curves of the $Co_{0.4}Zn_{0.6}Fe_2O_4$ nanoparticle at the applied magnetic field of 100 Oe. In the case of the FC curve, the magnetization increases to a value of 16.5 emu/g down to 50 K, which is due to the decrease of the interactions among the particles with decreasing applied field [56]. Below this temperature, it slightly decreases.

For the ZFC curve, the magnetization slowly increases down to 270 K. At around 264 K it exhibits typical features of an assembly of magnetic particles with a distribution of blocking temperatures and the particles indicate the spin-glass behavior [57]. This is compatible with the heat capacity results obtained by Hamdeh et al. [58]. In detail, the magnetization increases slowly with the rise of the temperature up to 100 K. While the temperature exceeds 100 K, as a result of the uncompensated spins in the two sublattices, magnetization increases rapidly with the rise of the temperature, and reaches a peak at about 264 K. At this temperature, the relaxation time of spins are equal to the measurement time of VSM, the magnetization decreases, indicating the spins become disordered, namely superparamagnetic.

The magnetic properties of $Co_{0.8}Zn_{0.2}Fe_2O_4$ nanocrystals have been studied by measuring the magnetization as a function of temperature; ZFC and FC (with field of 200 Oe) M–T curves are shown in Fig. 6c. While the ZFC curve slightly increasing with the temperature, FC curve slightly decreases up to 150 K and rapidly above 150 K. Both curves do not come together up to room temperature. This means that the blocking temperature of the sample is higher than the room temperature.

4. Conclusion

Using nitrates of nickel, cobalt, and iron in combination with urea, fine cobalt doped zinc ferrite powders have been successfully synthesized by microwave-induced combustion method. XRD and FT-IR analysis confirm the composition and structure as spinel ferrite. Average crystallite sizes obtained by XRD line-profile fitting were between 35 and 39 nm. The novel combustion method provides a rapid and reproducible route for the preparation of crystalline spinel ferrite. The scanning electron micrograph revealed that products were porous network powders with a substantial surface area. Magnetization measurements have revealed that the samples having less Co content shows superparamagnetic behavior at room temperature. Temperature dependent magnetization measurements presented the spin-glass like nature of the samples. The blocking temperature of the sample has also increased by increasing the cobalt content, which indicates that the samples show a magnetic phase transition from superparamagnetic to ferromagnetic phase.

2.3. Physical methods

Elemental analyses were performed on a Perkin–Elmer CHN 2400 Elemental Analyzer (CHN) and AAS (Varian Spectra AA 240 FS) instrument (Ni) after mineralization of the sample in aqua regia. The IR spectra were recorded on a Nicolet-Avatar 330 FT-IR spectrometer using the KBr pellets technique (concentration 2:200). Thermal stability was checked on a Netzsch Sta 409 PC/PG instrument.

2.4. X-ray structure analysis

X-ray experiments for **1** were carried out on an imaging plate area detector system [18] equipped with graphite-monochromatized Mo Kα radiation (λ = 0.71073 Å) at 193(2) K. Rotation method data acquisition using ω scans was used. Accurate cell parameters and an orientation matrix were determined by the least-squares fit of 7998 reflections. The structure was solved by direct methods using the SHELXS97 program [19]. All non-hydrogen atoms were refined anisotropically using the SHELXL-97 program [19]. Hydrogen atoms were put in calculated positions and refined using the "riding" model with tied isotropic thermal parameters. Crystal data and structure refinement parameters are gathered in Table 1, while selected geometric parameters are summarized in Table 2. The figures were drawn using the DIAMOND program [20].

2.5. Magnetic and thermodynamic measurements

Magnetic susceptibility measurements of a powdered sample with a mass of 122.1 mg have been performed in a commercial Quantum Design SQUID magnetometer. The specific heat of a powdered sample pressed into a thin pellet with a mass of 4.2 mg was experimentally studied in a commercial, Quantum Design PPMS device. Both susceptibility and specific heat data were corrected for the contribution of the sample holder, which was determined in separate runs.

3. Results and discussion

3.1. Synthesis

Previously, several fumarato complexes of Ni(II) with various N-donor ligands were prepared using solution techniques. As examples we can mention two structurally characterized complexes containing the *phen* ligand, ionic [Ni(*phen*)$_3$]*fum*·2H$_2$*fum*·4H$_2$O and dinuclear [Ni$_2$(*phen*)$_4$(*fum*)(H$_2$O)$_2$]*fum*·16H$_2$O [21,22]. On the other hand, hydrothermal conditions have been used for the preparation of some carboxylato complexes of Co(II), e.g. {Co$_2$(*suc*)$_2$(*phen*)$_2$}$_n$ (*suc* = succinato anion) [23]. The use of solvothermal conditions in the case of the Ni-*phen*-*fum* system led, in our case, to the formation of single crystals of the title compound **1**. It is interesting to note that single crystals were formed only in the case of a Ni:*phen* ratio of 1:2, however, this preparation method was reproducible. Other Ni:*phen* ratios after solvothermal treatment led to the formation of green solutions, which upon standing did not yield single crystals but only badly defined solid residues. Our attempts to prepare the title compound using simple solution techniques were unsuccessful. The formed crystals of **1** were characterized by chemical analyses, which gave satisfactory agreement with the assumed composition (see Section 2). The formed crystals are thermally rather stable, as checked by TG measurements; no mass loss was observed up to 350 °C.

3.2. IR spectroscopy

The IR spectrum of **1** is displayed in Fig. 1. In the spectrum two absorption bands positioned at 3066 and 3017 cm^{-1} can easily be identified; these bands, according to the literature data [24], can be attributed to the ν(C$_{ar}$–H) stretching vibrations of the *phen* ligand. In the spectrum of solid *phen* the corresponding bands were found at 3056 and 3025 cm^{-1}. Several very strong absorption bands (see Section 2) are observed in the IR spectrum between 1600 and

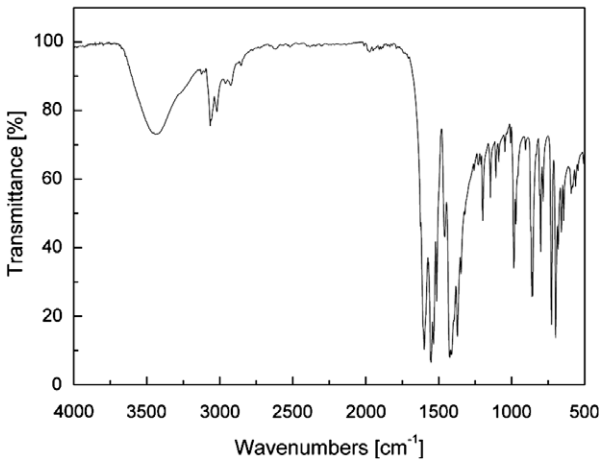

Fig. 1. FT-IR spectrum of **1**.

1340 cm^{-1}; the absorption bands at 1599 and 1553 cm^{-1} can be attributed to the asymmetric vibrations of the carboxylate groups, ν_{as}(OCO), and the absorption bands positioned at 1424, 1413 and 1372 cm^{-1} can be attributed to the symmetric vibration of the carboxylate group, ν_s(OCO). The corresponding absorption bands in Mn(*fum*) were observed at 1575 and 1387 cm^{-1} [25]. Moreover, in this region a medium to strong very sharp absorption band can be observed at 1514 cm^{-1}; we suggest that this band arises from the ν(ring) vibration of the *phen* ligand. In the spectrum of solid *phen* the corresponding absorption band is present at 1503 cm^{-1}.

3.3. Crystal and molecular structure

Crystal structure of **1** exhibits 2D character and is built of $\{Ni_2(fum)_2\}_n$ layers which are perpendicular to the [0 1 0] direction (Fig. 2). A similar 2D crystal structure is formed by a Co(II) central atom and an another dicarboxylato anion, succinato anion(2−) (*suc*), resulting in $\{Co_2(suc)_2(phen)_2\}_n$ [23].

Both crystallographically independent Ni(II) atoms, Ni1 and Ni2, are hexa-coordinated in the form of deformed octahedra *cis*-$NiO_2O_2N_2$; two coordination sites are occupied by one chelate bonded *phen* ligand and four by *fum* ligands (Fig. 3). It is interesting to note that both *cis*-$NiO_2O_2N_2$ octahedra are chiral but the structure is not optically active as the structure is centrosymmetric. Such a type of Ni(II) atom coordination by a combination of aromatic amine (*phen* or *bipy*) and carboxylate groups is, to our knowledge, unique, and has not been observed to date. A somewhat similar type of coordination was found in the polymeric $[Ni(H_2O)(phen)(ter)]_n$ (*ter* = terephatlato) complex in which hexacoordinated Ni(II) atoms contain in the coordination sphere one chelate bonded *phen* ligand, one chelate bonded *ter* ligand, one monodentate *ter* ligand and an aqua ligand [26].

There are two crystallographically different *fum* ligands which also differ by their coordination modes. The first type of *fum* ligand coordinates to four Ni(II) atoms (μ_4-ligand) and the coordination fashion of both carboxylato groups is of the *syn-anti* type. As a consequence a dimeric arrangement of Ni atoms is formed (Fig. 2). The distance between the nickel atoms within the $\{Ni_2\}$ dimer is 4.4905(9) Å. A similar pairing of Ni(II) atoms, but with a substantially shorter Ni···Ni distance (2.9772(13) Å) due to the *syn–syn* type of coordination of the carboxylato groups was observed in $[(F_3CCOO)_2(tmsa)_2Ni]$ (*tmsa* = η^3-2-trimethylsilylallyl) [27]. A somewhat longer distance between the Ni(II) atoms (3.058 Å) was found in dinuclear $[(MeOH)(L)Ni(\mu_2\text{-}CCl_3CO_2)Ni(L)(CCl_3CO_2)]$ where L is a phenolate like anion $\{(O^-)(C_6H_4CH{=}NCH_2\text{-}CH_2N(CH_3)_3)\}$ [28]. The second type of *fum* ligand in **1** coordinates as a bis(chelate) ligand, bridging two Ni(II) atoms and leading to a 1D arrangement of Ni atoms in the [0 0 1] direction (Figs. 2 and 3).

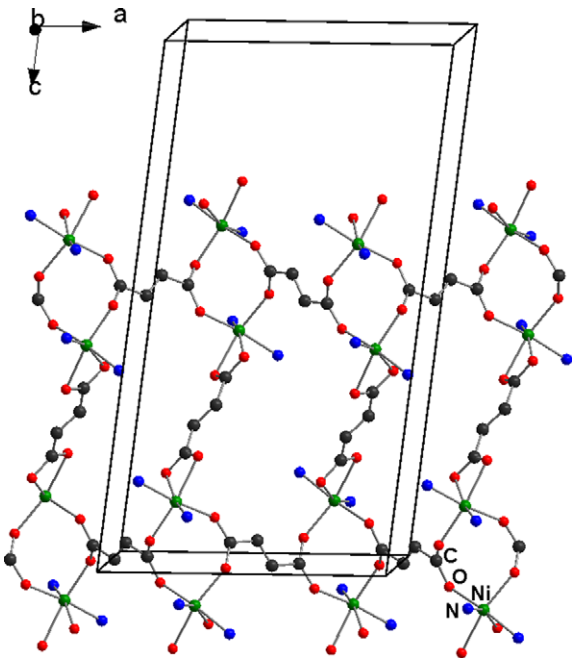

Fig. 2. View of the 2D crystal structure of **1**. The hydrogen atoms as well as the carbon atoms of the *phen* ligand are omitted for the sake of clarity.

As a consequence of the chelate bonding of the carboxylato groups, the O–Ni–O angles within the nickel central atoms coordination spheres (62.44(6)° for O5–Ni1–O6 and 62.00(6)° for O7–Ni2a–O8) are very deformed (Table 2). Similar values of O–Ni–O angles (61.1(2) and 61.2(2)°) for the same type of four-membered metallocycle were observed in $[Ni_2(py)_6(fum)_2]\cdot 2py$ (*py* = pyridine), which exhibits a 1D crystal structure [16]. The Ni–O distances in **1** vary from 2.0210(16) to 2.1469(17) Å; the Ni–O bonds to oxygen atoms from the chelate bonded carboxylate group (mean value is 2.1469(17) Å) are longer than the Ni–O ones formed by oxygen atoms from *syn-anti* bridging carboxylate group (mean value is 2.0210(16) Å). Similar differences in Ni–O distances were observed in $[Ni_2(py)_6(fum)_2]\cdot 2py$ in which the mean Ni–O bond lengths are 2.165 and 2.015 Å for the chelate bonded carboxylate and the *syn–syn* type bridging carboxylate group, respectively [16]. The Ni–N distances in the title compound **1** are almost the same (Table 2); slightly shorter values (range from 2.064(2) to 2.0921(19) Å) were observed in $[Ni_2(phen)_2(adip)_2(H_2O)_2]$ (*adip* = adipato) [29]. The geometric parameters within the respective N- and O-donor ligands (*fum*, *phen*) in **1** exhibit their usual values [16,26].

The aromatic ring of the *phen* ligands from neighbouring layers interact via π–π interactions (Fig. 4). The distances between aromatic rings, defined as distances between the centroid of one aromatic ring and the nearest carbon atom in the second one, vary between 3.296 and 3.530 Å; these values are as expected [30]. These interactions contribute to the packing forces of the crystal structure.

3.4. Magnetic and thermodynamic properties

The crystal structure of **1** contains two sets of crystallographically non-equivalent Ni(II) positions (Fig. 3). The geometry of the corresponding local octahedra mildly differ in bond lengths and angles (Table 2) and the determination of the character of distortion which gives rise to magnetic anisotropy is non-trivial. Following the approach developed in Ref. [31] for heteroleptic Ni(II)

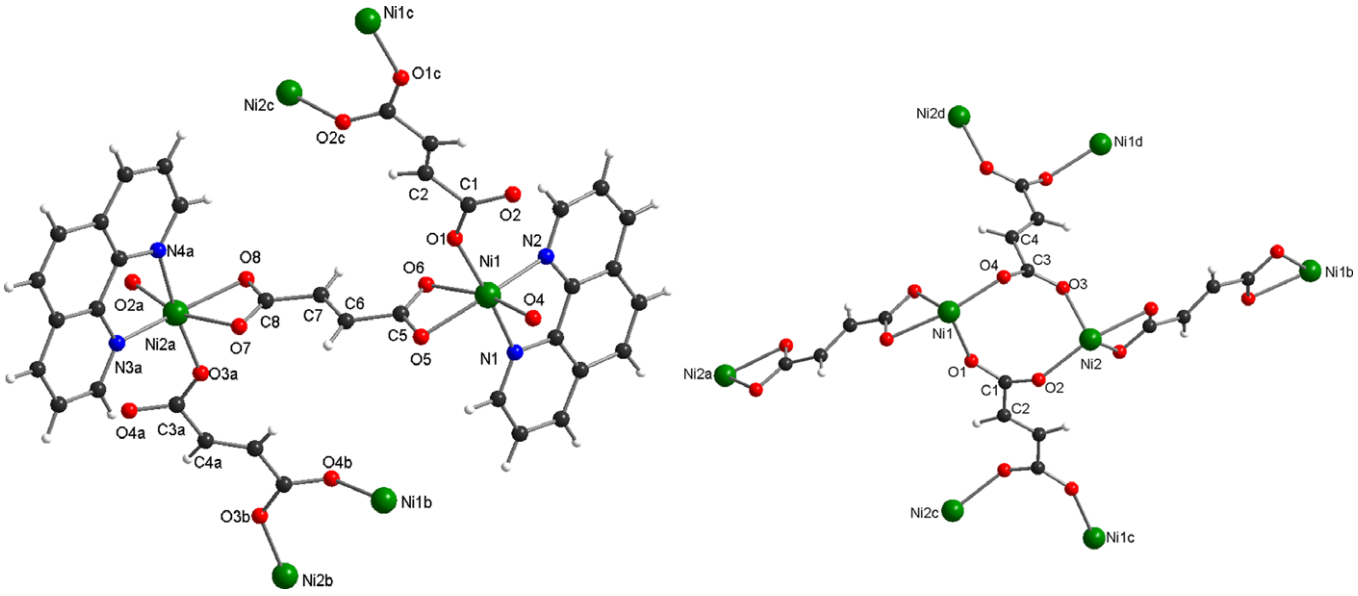

Fig. 3. Partial views of the crystal structure of **1** displaying the bis(chelate) type bridging ability of the *fum* ligand (symmetry codes: (a): x, $1-y$, $-0.5+z$; (b): $1-x$, y, $0.5-z$; (c): $2-x$, $1-y$, $1-z$) (left), and μ_4-bridging *fum* ligand along with formation of nickel dimers (symmetry codes: (a): x, $1-y$, $-0.5+z$; (b): x,$1-y$, $0.5+z$; (c): $2-x$, $1-y$, $1-z$; (d): $1-x$, $1-y$, $1-z$) (right). The *phen* ligands coordinated to the Ni atoms are partially omitted for the sake of clarity. Thermal ellipsoids are drawn at the 50% probability level.

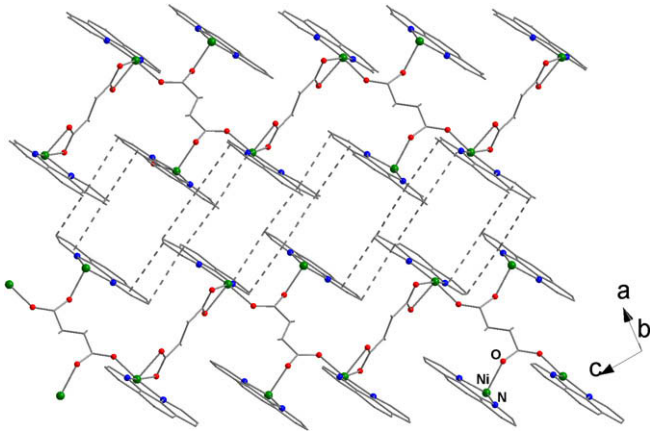

Fig. 4. View on the π–π interactions between the *phen* ligands from the neighbouring layers.

complexes, the effective axial distortion D_{str} was calculated using the bond lengths within the chromophore. The calculations for each octahedron yielded $D_{str}(1) = -4.65$ pm and $D_{str}(2) = -4.86$ pm and according to the semi empirical relation between structural distortion and magnetic anisotropy D derived in Ref. [31], such distortion should induce easy-axis magnetic anisotropy $D/k_B = -7 \pm 3$ K. Significant rhombic distortion of the octahedra implies the presence of a rather strong rhombic anisotropy characterized by a parameter E in the spin Hamiltonian $H = DS_z^2 + E(S_x^2 - S_y^2)$. Thus, in the first approximation, both sets of octahedral surroundings can be treated as a suppressed octahedron with a significant rhombic distortion.

Concerning the magnetic correlations between Ni(II) ions, magnetic orbitals d_{z^2} and $d_{x^2-y^2}$ support the formation of exchange pathways potentially along all three directions. The most significant exchange coupling J_1 can be expected between the Ni1 and Ni2 ions within the pairs, mediated by a double *syn-anti* type carboxylate exchange bridge –O–C–O–. Much weaker couplings J_2 and J_3 can be expected along the c and a axes mediated by *fum* ligands. Consequently, a [Ni(*phen*)(*fum*)] magnetic subsystem might represent a 2D array of magnetic dimers (J_1 interaction within the dimer) coupled via J_2 and J_3 interactions within a structural layer identical to the *ac* plane.

The magnetic susceptibility was experimentally studied in a field of 10 mT and in the temperature range from 2 to 300 K. A rather significant difference between the data obtained in field cooling (FC) and zero field cooling (ZFC) regimes appears below 10 K and might indicate a magnetic anisotropy effect or the presence of a phase transition. In the quantitative analysis, only the data above 10 K were taken into account. The data were corrected for the contribution of core diamagnetism which was estimated using Pascal constants, $\chi^{cor} = -153.10^{-6}$ emu/mol. In this region, the susceptibility is characterized by a typical monotonic decrease (Fig. 5) and the effective magnetic moment reaches a value of 3.4 μ_B at room temperature, which is close to the value expected for a $S = 1$ system. The temperature dependence of the effective magnetic moment is characterized by a sharp peak below 10 K, which may be ascribed to the aforementioned FC–ZFC differences (Fig. 6). The temperature dependence of the inverse susceptibility shows above 100 K a slight deviation from linearity, probably resulting from an inaccurate estimation of the diamagnetic contribution, which becomes crucial at high temperatures. To avoid the inaccuracy, the temperature range from 15 to 100 K was chosen for fitting the data by the Curie-Weiss law (Fig. 6). The fitting procedure provided an estimation of the g-factor and the Curie temperature Θ, $g = 2.2 \pm 0.1$ and $\Theta = -1.5 \pm 0.5$ K, respectively. The obtained value for the g-factor is typical for Ni(II) compounds while a non-zero value of the Curie temperature indicates the combined influence of magnetic (single-ion) anisotropy and magnetic correlations between Ni(II) ions. To estimate the importance of individual mechanisms, the susceptibility data were compared with the theoretical predictions for an $S = 1$ paramagnet with single-ion anisotropy $D/k_B = -7$ K, as derived from structural analysis (Fig. 5). The logarithmic scale enables the detection of deviations between the data and theory which appear below 10 K. A satisfactory agreement observed at higher temperatures may indicate suppression of magnetic correlations by thermal fluctuations and, correspondingly, the dominant influence of single-ion anisotropy.

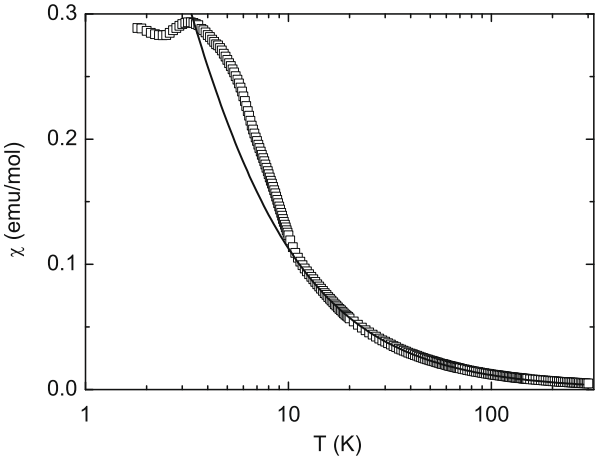

Fig. 5. Temperature dependence of the magnetic susceptibility of a powdered sample of **1** obtained in the ZFC regime. The solid line represents the theoretical prediction for a $S = 1$ paramagnet with single-ion anisotropy $D/k_B = -7$ K and $g = 2.15$.

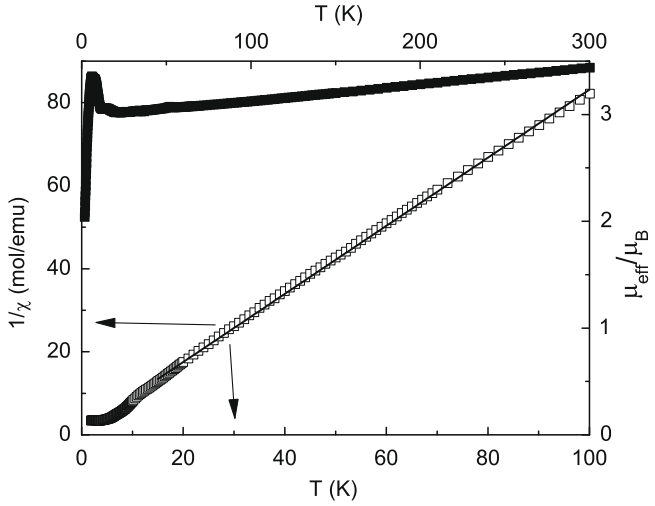

Fig. 6. Temperature dependence of the effective magnetic moment of a powdered sample of **1** derived from ZFC susceptibility data (full squares). Temperature dependence of inverse ZFC susceptibility (empty squares). The solid line represents the fit by the Curie Weiss law.

Since the monotonic behaviour of susceptibility data above 10 K allows uncritical application of other models, such analysis cannot provide reliable results and in a further step the specific heat was studied to refine the physical model of magnetic subsystem.

The specific heat was experimentally studied in a zero magnetic field in the temperature range from 2 K to 30 K. The behaviour of the data is dominated by a round anomaly at 4.2 K and a monotonic increase is observed at higher temperatures (Fig. 7). No phase transition is observed down to 2 K. Since **1** represents a magnetic insulator, the total specific heat, C_{tot}, is determined by the contribution of lattice vibrations, C_{latt}, and the magnetic subsystem, C_{mag}. The individual contributions were determined in the temperature interval from 12 to 26 K by a fitting procedure using a high temperature approximation for the magnetic specific heat, $C_{mag} = a/T^2$ and a low temperature approximation for the lattice specific heat [32], $C_{latt} = bT^3 + cT^5 + dT^7$. Corresponding coefficients have been found, $a = 293$ JK/mol, $b = 0.0041$ J/K^4 mol), $c = -8.1 \times 10^{-6}$ J/K^6 mol), $d = 6.1 \times 10^{-9}$J/K^8 mol) and the magnetic specific heat was obtained by subtracting the lattice contribution from the total specific heat (Fig. 8).

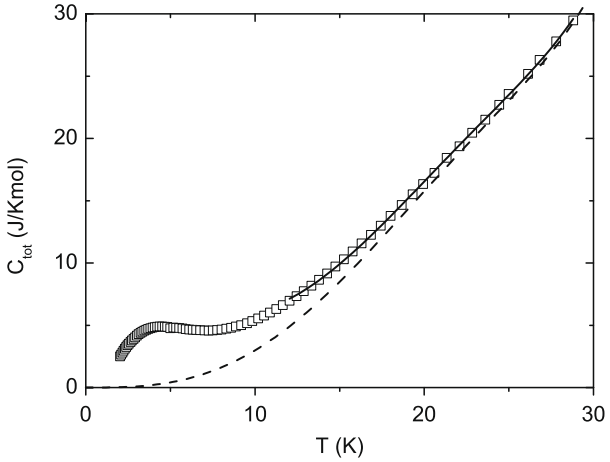

Fig. 7. Temperature dependence of the total specific heat of a powdered sample of **1** in a zero magnetic field (empty squares). The dashed line represents the lattice contribution, $C_{latt} = bT^3 + cT^5 + dT^7$.

Like the magnetic susceptibility, the present magnetic specific heat data were compared with the theoretical prediction for the $S = 1$ paramagnet with single ion anisotropy $D/k_B = -7$ K (Fig. 8). It is evident, that the model is far from reality (at least with respect to the specific heat maximum height) and it is necessary to include other mechanisms. As was mentioned above, the crystal structure analysis indicates a rather strong rhombic distortion of a local octahedron, thus the experimental data were compared with the model of the $S = 1$ paramagnet with single ion anisotropy and rhombic anisotropy. The best agreement was found for the parameters $E/D = 0.27$, $D/k_B = -13.5$ K and $E/k_B = -3.6$ K (Fig. 8). Rather large values of the parameters indicate the need to incorporate other mechanism to obtain more realistic estimates. Assuming the aforementioned interaction J_1 is much stronger than the others, a model of an antiferromagnetic dimer with single ion anisotropy [33] was applied (Fig. 8). A comparison of the dimer model with selected parameters $D/J = 1$, $D/k_B = J/k_B = -6$ K indicates that the introduction of exchange coupling leads to a more realistic estimate of the single ion anisotropy parameter. Thus, for refining all the D, J, E parameters, a more sophisticated analysis is required to incorporate all mechanisms at the same time. For the sake of comparison it is interesting to note that in the above mentioned nickel dinuclear

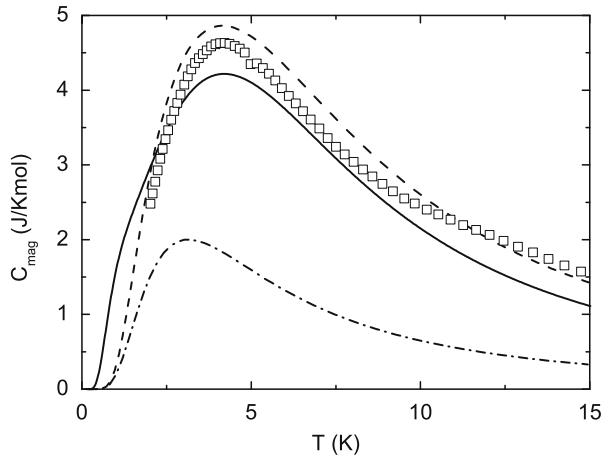

Fig. 8. Temperature dependence of the magnetic specific heat of **1** (open square). The dashed-dotted line represents the theoretical prediction for an $S = 1$ paramagnet with $D/k_B = -7$ K, the dashed line corresponds to the $S = 1$ paramagnet with $E/D = 0.27$, $D/k_B = -13.4$ K and $E/k_B = -3.6$ K. The solid line represents a theoretical prediction for the $S = 1$ dimer with $D/J = 1$, $D/k_B = J/k_B = -6$ K.

[(MeOH)(L)Ni(μ_2-CCl_3CO_2)Ni(L)(CCl_3CO_2)] complex with a substantially shorter Ni···Ni distance of 3.058 Å, a higher value of the antiferromagnetic intra-dimer interaction $J_1/k_B = -17.2$ K was found [28].

4. Conclusions

Based on the presented experimental data and discussion it can be concluded that under solvothermal conditions a new low-dimensional Ni(II) complex [Ni(*phen*)(*fum*)] (**1**) has been prepared and characterised. Its crystal structure is 2D and is based on hexa-coordinated Ni(II) atoms linked by bridging *fum* ligands; the *phen* molecules act as blocking ligands. Within the formed layers, pairs of nickel atoms linked by two *syn-anti* fashioned carboxylate bridges can be distinguished. The layers are held by π−π interactions. The results of susceptibility and heat capacity studies down to 2 K allow the conclusion that **1** can be approximated by a system of $S = 1$ dimers with single ion and rhombic anisotropy, comparable to intra-dimer exchange coupling. Further experiments are necessary at lower temperatures to refine the magnetic model.

5. Supplementary data

CCDC 721837 contains the supplementary crystallographic data for [Ni(*fum*)(*phen*)]. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

this system. The purpose of this study is, on one hand, to obtain additional experimental data on the magnetic anisotropy in this molecular antiferromagnet, and on the other hand, to summarize all experimental data obtained through various physical techniques on this material by us to look into the origin of the uncompensated magnetization below T_N in $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$. In this paper we concentrate mainly on the results of these studies obtained at low temperatures.

2. Experimental

The polycrystalline material of $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(C_2O_4)_3]\}_\infty$ (Mn–Fe in short) was synthesised according to Ref. [3] and its X-ray diffraction pattern was consistent with the literature data [11]. AC susceptibility data were collected for a polycrystalline sample of ≈100 mg by means of a 7225 Lake Shore instrument. Both real (χ') and imaginary (χ'') components of $\chi_{AC} = \chi' - i\chi''$ were registered as a function of increasing temperature. The frequency f of the driving field was changed in the range 40–4000 Hz, the dependence of the output signal on the amplitude H_{AC} of the driving field was tested for H_{AC} = 1–15 Oe. Isothermal magnetization curves at T = 4.2, 10, 20, 30, 40, 48, 64 and 92 K and isofield temperature dependences of magnetization in the ZFC and FC modes were measured with the DC option of the same set-up using the extraction method.

Magnetization measurements were carried out with a SQUID MPMS XL magnetometer at 5 K with 10 mg of a powder sample, whereas the heat capacity measurements were done with a PPMS 6000 calorimeter. For heat capacity measurements, the polycrystalline material was pressed into a pellet and a small part (mass 1.4377 mg) was used for the heat capacity measurements. Heat capacities were measured in the 2–50 K range. The temperature jump adopted for the relaxation was 1% of the absolute temperature for all measurements. Mössbauer spectra were recorded using a conventional constant-acceleration spectrometer with a liquid helium bath cryostat and a superconducting magnet to produce a magnetic field parallel to the γ-ray propagation. The hyperfine parameters were obtained by least squares fitting to Lorentzian lines using the Recoil (1.03a) Mössbauer software analysis program.

3. Results and discussion

3.1. Magnetic measurements

AC magnetic susceptibility data of $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$, measured with various amplitudes H_{AC} of the driving field, are given in Fig. 1a. The χ' value, which at T = 4.2 K is ~0.35 emu/mol, increases slowly with increasing temperature. The Néel temperature T_N is marked with a weak narrow spike at 28.8 K. The χ'' component, equal to about 1% of χ', points to the presence of the uncompensated moment in the system. The χ'' peak is located also at 28.8 K. As expected for an antiferromagnet, there is no susceptibility dependence on H_{AC}. Above T_N the χ' component does not decrease but shows a wide hump at around 54 K. Fig. 1b presents the temperature dependence of χ' for f = 40, 625 and 4000 Hz. It appears that with higher frequencies the peak at T_N becomes invisible; at the present stage it is difficult to say whether for higher f the low temperature side of the hump gets enhanced and shifts to lower temperatures or a peak at T_N which gets wider (see Fig. 1b insert). In spite of the poor accuracy of the data, conditioned by the low magnetic response of the sample, we can state that there is no frequency dependence of χ' detected for T < 20 K. Also no effect of frequency is seen at the high-temperature side of the bump for T above ≈ 120 K. The overall χ' vs. T dependence with the weak peak at T_N and a hump above T_N is typical for two-dimensional Heisenberg antiferromagnets, showing strong short-range correlations above the transition temperature. The temperature T_{max} of the susceptibility hump maximum is a measure of the intraplanar exchange coupling J. Using the relation $\frac{k_B T_{max}}{abs(J)S(S+1)} \approx 2$ (Ref. [10], p. 64) one gets $J/k_B \approx -3.1$ K, close to the value obtained from the heat capacity data (see below) [14]. The χ_{AC} vs. T dependence observed by us is similar to that reported for a novel layered magnet $[Fe(C_2O_4)(CH_3OH)]_n$ which exhibits magnetic ordering at $T_N \approx 23$ K [17]. The crystal structure of the latter does not possess a honeycomb lattice and spin canting originates from the non-centered structural features of the compound. The χ_{AC} of $[Fe(C_2O_4)(CH_3OH)]_n$ is ca. 3 times stronger, yet did not show dependence on frequency as checked for 10, 100 and 1000 Hz ([13], ESI).

In order to learn more about the low- and high-temperature behavior of the $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ compound,

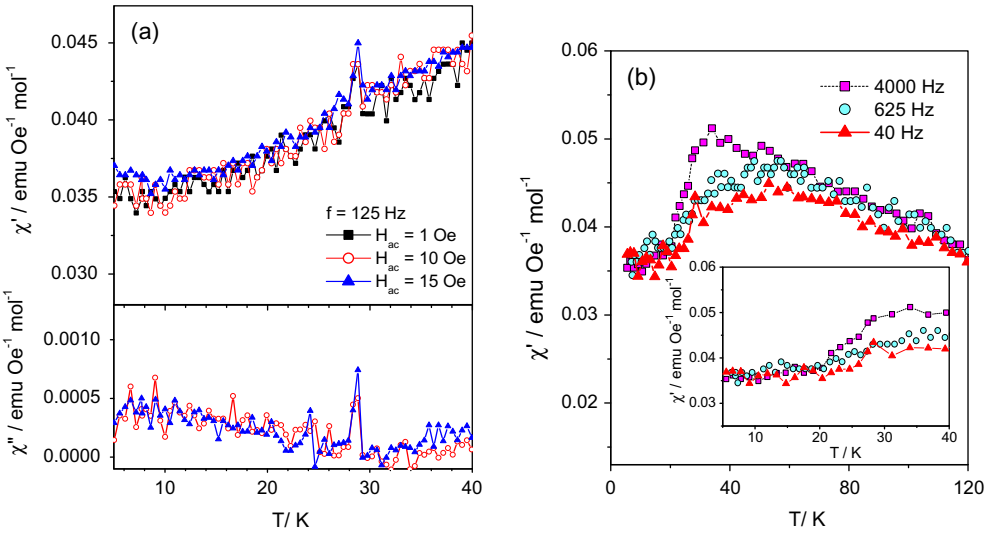

Fig. 1. (a) AC magnetic susceptibility (χ' and χ'') at frequency f = 125 Hz measured with varied amplitudes of the oscillating field; (b) temperature dependence of χ' for f = 40, 625 and 4000 Hz, insert: same data in a smaller temperature range.

magnetization curves at $T = 4.2$, 10, 20, 30, 40, 48, 64 and 92 K, and isofield temperature dependences of magnetization in the ZFC and FC modes have been measured by means of the Lake Shore instrument. The obtained results are in accordance with the adequate $M(H)$ data recorded with the SQUID magnetometer and reported in [13]. Fig. 2a shows the magnetization curve at $T = 4.2$ K and the corresponding susceptibility $\chi_{DC} = M/H$ for increasing and decreasing magnetic field. At the highest field the magnetization is 2635 emu/mol (0.47 μ_B), which is less than 5% of the expected saturation value. The irreversible χ_{DC} vs. H dependence is the result of the weak ferromagnetic moment coming from small canting of the antiferromagnetically coupled moments. The $M(H)$ dependence is not linear, but weakly concave and may be fitted to a Boltzmann sigmoidal function $y + \frac{A_1 - A_2}{1 + e^{x - x_0}/dx} + A_2$, where A_1 and A_2 are left and right horizontal asymptotes and x_0 refers to the curve inflection point. The fitted $A_2 - A_1$ value equals 49700 emu/mol (8.9 μ_B), close to the expected saturation value of 10 μ_B, while x_0 is equal to 219 kOe. The last value should be understood as the critical field for the reorientation of the spin axis from the direction of the easy axis to that perpendicular to it, i.e. the spin flop transition. Spin flop occurs in "metamagnetic-like" antiferromagnets showing an anisotropy, where the anisotropy energy H_A is smaller than the exchange energy H_E [18,19]. The poorly pronounced sigmoidal shape of the $M(H)$ curve in Fig. 2a suggests that in our system $H_A << H_E$. Fig. 2b gives χ_{DC} in fields of 5, 10, 15, 20, 30, 40, 50 and 56 kOe, obtained from the $M(H)$ curves taken at various temperatures, together with $M_{ZFC}(T)$ and $M_{FC}(T)$ in 20 kOe. The insert gives the difference in χ_{DC} when determined at 56 kOe and at 5 kOe,

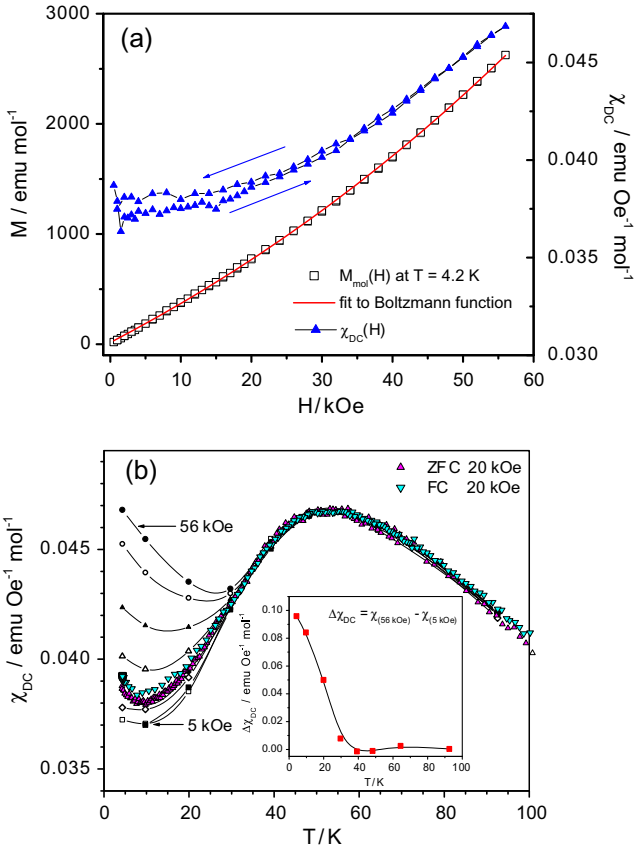

Fig. 2. (a) $M(H)$ magnetization curve at $T = 4.2$ K fitted to Boltzmann sigmoidal function (left scale) and DC susceptibility obtained from $M(H)$ (right scale); the increasing and decreasing field is marked with arrows; (b) black empty and solid symbols – χ_{DC} in the fields of 5, 10, 15, 20, 30, 40, 50 and 56 kOe obtained from the $M(H)$ curves; up- and down-triangles $M_{ZFC}(T)$ and $M_{FC}(T)$ in 20 kOe; insert: $\Delta\chi_{DC} = \chi_{(56\ kOe)} - \chi_{(5\ kOe)}$.

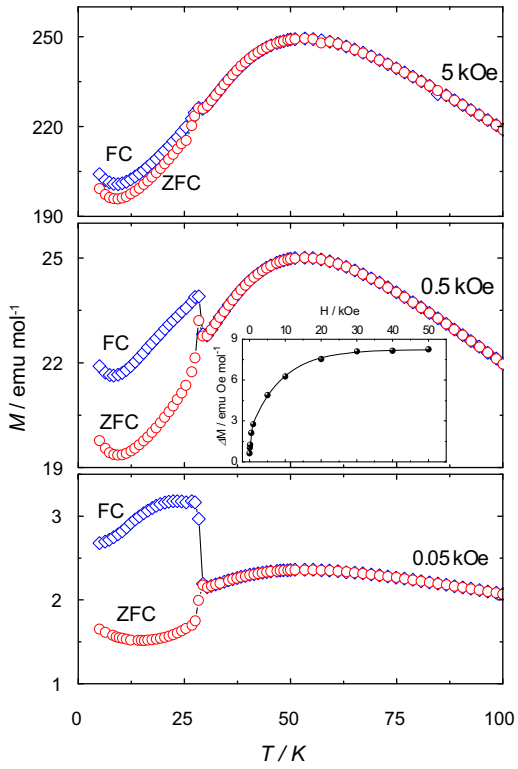

Fig. 3. Temperature variation of magnetization for $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ in ZFC and FC protocols under different applied magnetic fields. Insert shows the variation of the estimated ΔM values with applied magnetic field, where the solid curve is a fit to Eq. (1).

$\Delta\chi_{DC} = \chi_{(56\ kOe)} - \chi_{(5\ kOe)}$, as a function of temperature. $\Delta\chi_{DC}$ is positive because of the sigmoidal shape of the $M(H)$ curves, while the sigmoidal character originates from the anisotropy of the system. Therefore, the $\Delta\chi_{DC}$ vs. T curve shown in the insert in Fig. 2b reflects the decrease of anisotropy with temperature. $\Delta\chi_{DC}$ becomes zero at $T \geqslant T_N$, and so obviously does the weak ferromagnetic moment. The vanishing of $\Delta\chi_{DC}$ coincides with the bifurcation point of the ZFC-FC $M(T)$ curves (see Fig. 3 below). One should also note that the M(H) curves measured at temperatures above T_N up to $T = 92$ K showed strong short-range antiferromagnetic correlations. One can estimate that the spin system becomes uncorrelated only for $T > 150$ K.

In Fig. 3 we show some selected plots of temperature dependence of M of Mn–Fe under ZFC and FC measurement protocols in the 5–100 K range studied in a SQUID magnetometer under various magnetic fields (H) ranging between 0.01 and 50 kOe in FC and ZFC modes. The differences in the magnetization values ($\Delta M = M_{FC} - M_{ZFC}$), which is a measure of anisotropy, have been estimated for the 5 K values of M under each applied magnetic field. The insert of Fig. 3 shows the variation of ΔM values with applied magnetic field. The ΔM values are found to fit with the following relation:

$$\Delta M = \Delta M_{H=0} + A_1(1 - e^{-H/t_1}) + A_2(1 - e^{-H/t_2}) \quad (1)$$

This is a reflection of two different types of responses of the spins to the applied magnetic field, indicating the existence of at least two magnetically different spin sites or magnetic sub-lattices.

3.2. Heat capacity studies

The observed calorimetric results for Mn–Fe in the 2–50 K temperature range under 0 and 90 kOe magnetic fields, evaluated in

terms of molar heat capacity under constant pressure C_p, are shown in Fig. 4. Apparently the $C_p(T)$ plots show no thermal anomaly around T_N, expected from magnetic studies, as well as any significant magnetic field dependence. The excess heat capacity due to magnetic phase transition (C_{mag}) have been estimated by considering the lattice heat capacities as the following polynomial function of temperature,

$$C_p = C_p(\text{lattice}) + C_{mag}(\text{short -range order}) = \sum_{i=3}^{n} a_i T^i + bT^{-2} \quad (2)$$

and then subtracting those from the observed C_p values. The observed C_p data were well fitted to Eq. (2) in the 32–50 K range for $n = 5$ with parameters $a_3 = 8.579 \times 10^{-3}$ J K^{-4}, $a_4 = -2.297 \times 10^{-4}$ J K^{-5} mol^{-1}, $a_5 = 1.754 \times 10^{-6}$ J K^{-6} mol^{-1} for $H = 0$ and 90 kOe, whereas $b = 2.175 \times 10^4$ J K mol^{-1} and 2.013×10^4 J K mol^{-1} for $H = 0$ and 90 kOe, respectively. Estimated C_{mag} values thus calculated from the observed C_p values for both magnetic field conditions are shown in Fig. 5. A heat capacity anomaly due to magnetic phase transition can now easily be seen in this plot at 27.1 K for $H = 0$ and at 28.2 K for $H = 90$ kOe. The fact that the magnetic phase transition temperature shifts to higher temperature with increasing H seems to indicate that the observed magnetic phase transition is ferromagnetic. In general, however, ferromagnets and ferrimagnets show the tendency that the heat capacity peak due to magnetic phase transition shifts to higher temperature and simultaneously broadens with increasing H. Therefore, such a slight shift and non-broadening of the magnetic phase transition by applying the strong magnetic field of 90 kOe rather suggests that this magnetic phase transition is antiferromagnetic.

A remarkable feature of the plots in Fig. 4 is the existence of a dominant short-range order manifested by the large tail of the magnetic heat capacity. A heat capacity anomaly above the magnetic transition temperature due to the short-range ordering in the present case can be well represented by a $S = 5/2$ 2D antiferromagnetic Heisenberg model for a honeycomb lattice with $J/k_B = -3.29$ K [14]. The solid curve in Fig. 5 indicates the theoretical heat capacity following such a model. Although the present complex has a 2D magnetic structure of the Heisenberg type, the occurrence of the magnetic phase transition does not conflict with the existence of dominant 2D interactions. When a 3D interaction, even though weak, exists at low temperatures, dimensional crossover between 2D and 3D may happen and bring about a phase transition. In fact, the heat capacities in the spin wave excitation region are well-reproduced with $C_{SW} \propto T^{d/n}$ (d: dimensionality, n: exponent of dispersion relation), where the exponent is approximated by $d/n \approx 3$, implying that the ordered state at low temperatures is actually a 3D antiferromagnet [14] [at $T < T_N$: for $H = 0$: $C_{mag} = 1.314 \times 10^{-2} T^{2.819} \approx 1.057 \times 10^{-2} T^{3/1}$; for $H = 90$ kOe: $C_{mag} = 1.755 \times 10^{-2} T^{2.669} = 1.165 \times 10^{-2} T^{3/1}$]. The magnetic entropy gain is obtainable by integration of C_{mag} with respect to ln$T$: $\Delta S = \int C_{mag} d\ln T$. The estimated entropy gain for the magnetic phase transition is 33.22 J K^{-1} mol^{-1} and 31.99 J K^{-1} mol^{-1} for $H = 0$ and 90 kOe, respectively, which are slightly higher than the expected magnetic entropy [$R\ln\{(2S + 1) \times (2S + 1)\} = 29.80$ J K^{-1} mol^{-1} for $S = 5/2$]. Application of spin wave theory [14] for C_{mag} values at $T/T_N < 0.5$ led to an interlayer exchange interaction $J'/k_B = \pm 0.014$ K, but was unable to predict the nature of the interlayer interaction in the present material. The dashed curve shows the heat capacity in accordance with the spin wave theory for 3D antiferromagnets.

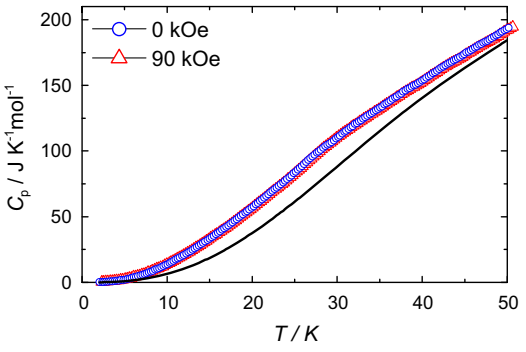

Fig. 4. Temperature variation of molar heat capacity C_p of $\{N(nC_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ in the 2–50 K range under two applied magnetic field conditions. The solid curve indicates the lattice heat capacity.

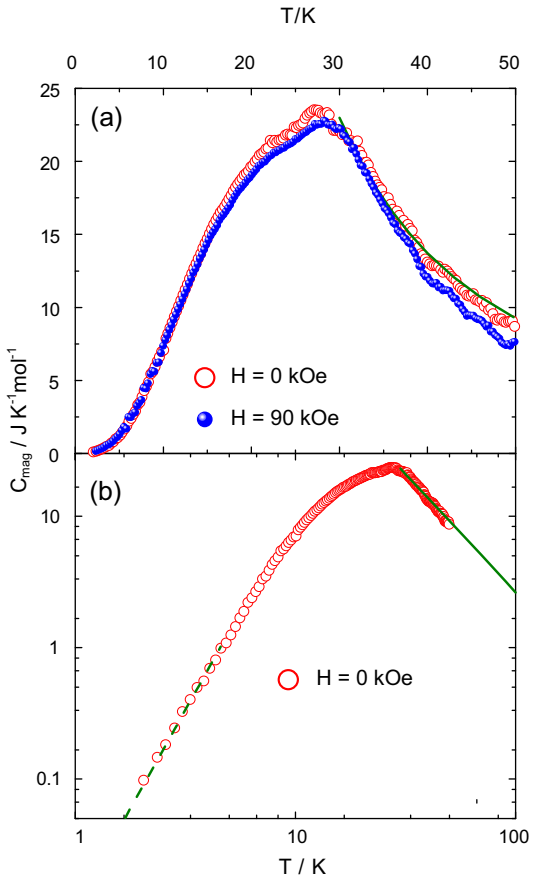

Fig. 5. (a) Temperature variation of magnetic heat capacity of $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ under zero and 90 kOe magnetic fields; (b) Temperature variation of the magnetic heat capacity of $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ under a zero magnetic field in logarithmic scale. The solid curve indicates the theoretical heat capacity for an $S = 5/2$ two-dimensional antiferromagnetic Heisenberg model of a honeycomb lattice with $J/k_B = -3.29$ K. The dashed curve shows the heat capacity in accordance with the spin wave theory for three-dimensional antiferromagnets.

3.3. Mössbauer study

The Mössbauer spectra of Mn–Fe obtained at 4.2 K under zero and 50 kOe magnetic fields are shown in Fig. 6. At 4.2 K, well below T_N, the zero-field spectrum appears as sextets. These sextets indicate the presence of long range magnetic order in the complex at this temperature. The spectra could be fitted to two sextets, say Fe_A^{III} (light gray) and Fe_B^{III} (gray). At 4.2 K and under zero magnetic field, the estimated values of the isomer shift δ (with respect to α-iron), quadrupole splitting ΔE_Q, hyperfine field H_n and areal intensity for Fe_A^{III} are 0.46, 0.30 mm s^{-1}, 500 kOe and 75%, respectively, whereas those for Fe_B^{III} ions are 0.47,

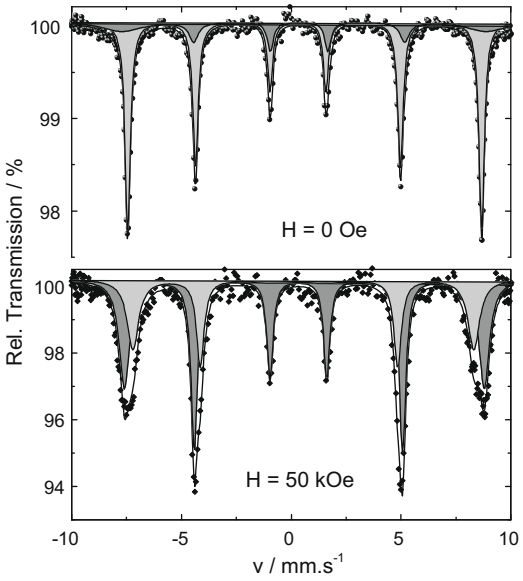

Fig. 6. Mössbauer spectra of $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ at 4.2 K under zero and 50 kOe magnetic field.

0.22 mm s^{-1}, 515 kOe and 25%, respectively. The estimated isomer shift, quadrupole splitting and hyperfine field values are in general agreement with those observed for high spin Fe^{III} ions in this type of molecular system [15] under zero applied magnetic field. Under zero applied magnetic field the areal intensity ratio of $Fe^{III}{}_A$- and $Fe^{III}{}_B$-sextets is 3:1, which on application of an external magnetic field of 50 kOe becomes 36:64 ≈ 3:5. It is understood that the present compound has two Fe^{III} spin sites and the responses of these spin sites towards the external magnetic field are of dissimilar nature, which has been observed in the *M* vs. *T* plots. From Fig. 6, it is also clear that there is significant variation of the intensity among the border-line sextets under application of a magnetic field, which are the usual signatures of a canted spin structure [16].

The H_n values determined at 4.2 K under 50 kOe magnetic field for $Fe^{III}{}_A$- and $Fe^{III}{}_B$-sextets are 508 and 481 kOe, respectively, which are quite a lot lower than the saturation value of the hyperfine field expected for high spin Fe^{III} under zero applied magnetic field (550 kOe). The magnetic interaction between the high spin Mn^{II} and Fe^{III} in the present compound is already established to be antiferromagnetic [2,11]. Under the applied magnetic field of 50 kOe, the Mössbauer spectrum of a single crystal having two Fe^{III} ions coupled antiferromagnetically, may exhibit two sextets, giving rise to H_n values close to (550 ± 50) kOe for the high spin Fe^{III} ions parallel and antiparallel to the applied magnetic field direction, respectively [16]. Thus, the presently observed Mössbauer spectra under 50 kOe magnetic field and the H_n values (508 and 481 kOe), certainly indicate that $Fe^{III}{}_A$- and $Fe^{III}{}_B$-spins are antiparallel to the applied magnetic field direction, but are mutually parallel to each other. Presuming a single type of Mn^{II} site in the present compound and considering the intralayer antiferromagnetic interaction between two neighboring Mn^{II} and Fe^{III} sites [2], it may be conjectured that the Mn–Fe compound has two sub-lattices as (Mn^{II}–ox–$Fe^{III}{}_A$–ox–Mn^{II}–ox–$Fe^{III}{}_A$–...) and (Mn^{II}–ox–$Fe^{III}{}_B$–ox–Mn^{II}–ox–$Fe^{III}{}_B$–...). As the $Fe^{III}{}_A$ and $Fe^{III}{}_B$-spins are parallelly aligned with each other between the adjacent layers, they should be interlayer nearest neighbors. This will make [Mn^{II} and $Fe^{III}{}_A$] and [Mn^{II} and $Fe^{III}{}_B$] interlayer nearest neighbors, giving rise to an interlayer ferromagnetic interaction in accordance with the polarized neutron diffraction study of the related $\{P(C_6D_5)_4[Mn^{II}Fe^{III}(ox)_3]\}_n$ compound [20] and as evidenced by heat capacity and Mössbauer studies of this material.

The estimated magnetic hyperfine field is a powerful parameter of the magnetic properties of the atoms and their immediate environment [21]. The hyperfine field H_n at any spin site may be correlated with the net atomic magnetic moment as proportional to the sum of the magnetic moment of that site and the contribution due to magnetic interactions with the nearest neighbors. This can be written as $H^{\beta}_{n_\alpha} = a\mu^{\beta}_{\alpha} + b\mu' f(z,\theta)$, where μ' = contribution due to magnetic interactions with the nearest neighbors; α = ionic site Mn or Fe; β = spin site of Fe; μ = magnetic moment of metal atoms; z = number of nearest neighbors; θ = spin canting angle; *a*, *b* = proportionality constants. Thus, the $H_{n^{\beta}_{\alpha}}$ value for any particular spin site will reflect the change in its magnetic environment, as μ' is a function of the number of nearest neighbors and their respective spin canting angle with the spin at the site under consideration. The presence of local spin configurations with a different magnetic environment leading to a varying amount of μ' may lead to the hyperfine field distribution in the lattice. Now, from the description of the magnetic lattice structure of the present compound, and the analogy between the hyperfine field and atomic magnetic moments of the different Mn^{II} and Fe^{III} sites, it is evident that the hyperfine field distribution in the (Mn^{II}–ox–$Fe^{III}{}_A$–ox–Mn^{II}–ox–$Fe^{III}{}_A$–...) and (Mn^{II}–ox–$Fe^{III}{}_B$–ox–Mn^{II}–ox–$Fe^{III}{}_B$–...) layers will create a frustration in the magnetic interactions between different Mn^{II} and Fe^{III} spin pairs. Moreover, in these compounds, the metal centers show alternating chirality. The net effect due to frustration on the near-neighbor magnetic interactions will be more prominent in the intralayer than in the interlayer interactions as the intralayer magnetic interaction will dominate the overall magnetic property of this compound. This situation can easily be held responsible for resulting into various competing magnetic interactions leading to net uncompensated magnetization seen in the present compound at temperatures below the transition temperature.

4. Discussion and conclusions

Magnetic measurements, both AC and DC, of antiferromagnetic $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(C_2O_4)_3]\}_\infty$ under different measuring protocols have revealed the existence of a substantial uncompensated magnetic moment in this compound at temperatures below T_N of 27 K. It has also been found that the antiferromagnetic short-range coupling through the oxalate bridges of iron and manganese moments influences the magnetization of the system well above T_N and the spins become uncorrelated only for $T > 150$ K.

The estimated magnetic entropy from heat capacity studies established the high spin species of Mn and Fe ions. Application of a magnetic field shifts the transition temperature towards higher temperatures. The present magnetic system is an $S = 5/2$ 2-D Heisenberg antiferromagnet system with the intralayer exchange parameter $J/k_B = -3.29$ K. Application of spin wave theory to the magnetic heat capacity below $0.5T_N$ revealed the existence of a very weak interlayer exchange interaction, but could not assign its nature.

Mössbauer spectroscopy complemented the results obtained from heat capacity studies and highlighted the nature of the interlayer interaction. The Mössbauer study resolved the co-existence of different Fe^{III} spin sites in the lattice at low temperatures and has portrayed the interlayer ferromagnetic arrangement of different Fe^{III} spins. The honeycomb layered structure of the compound contains non-equivalent magnetic sub-lattices, (Mn^{II}–ox–$Fe^{III}{}_A$–...) and (Mn^{II}–ox–$Fe^{III}{}_B$–...), with different responses of the $Fe^{III}{}_A$ and $Fe^{III}{}_B$ spin sites towards the external magnetic field. It is concluded

that the different behavior of the Fe^{III} spin sites might be responsible for the uncompensated magnetization in this compound observed below the Néel temperature.

The reason for two non-equivalent Fe^{III}_A and Fe^{III}_B spin sites within the iron sub-lattice of $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ is not straightforward to explain. It is known that in the $A[M(II)M'(III)(ox)_3]$ structure, where bimetallic layers are separated by the organic cation A, the different metal centers show alternating chirality. As recently discussed by Fishman et al. [22], the mutual alignment of the chiral axes, collinear in two-dimensional (2D) and non-collinear in three-dimensional (3D) oxalates, gives rise to the quite different magnetic properties, in spite of the almost identical exchange coupling and local crystal-field environment in both systems. The spin–orbit coupling with the non-collinear orbital moments causes the spins to cant in 3D compounds. In our case the $S = 5/2$ Mn(II) and Fe(III) $3d^5$ multiplets are orbital singlets, but a possible small difference in the g-factors for the Mn^{II} and Fe^{III} ions has been mentioned in [11] along with a relatively large zero-field splitting for Mn^{II}. Additionally, the $N(n\text{-}C_5H_{11})_4$ cation may play a role in breaking the local symmetry of the Fe^{III} spin sites, like in the case of $N(n\text{-}C_4H_9)_4[Fe^{II}Fe^{III}(ox)_3]$, discussed in [23]. The presence of two Fe^{III} sites with subtly different behavior is also consistent with the lower symmetry group of $\{N(n\text{-}C_5H_{11})_4[Mn^{II}Fe^{III}(ox)_3]\}_\infty$ as compared to other $\{A[Mn^{II}Fe^{III}(C_2O_4)_3]\}_\infty$ compounds [11]. Therefore, in spite of the same electronic ground states of Mn^{II} and Fe^{III}, the system under study is not a simple layered antiferromagnet and the net effect of anisotropy and frustration on the near-neighbor magnetic interactions will be more prominent in the intralayer than in the interlayer interactions, as the former dominates the overall magnetic properties of the system under study. This situation can easily be held responsible for resulting into various competing magnetic interactions leading to net uncompensated magnetization seen in the present compound at temperatures below the transition temperature.

able for the analysis of biomolecules, for instance, phospholipids [15,16] and proteins/peptides [9].

This study was undertaken to investigate the MALDI-TOF mass spectrometric behaviour of Pt(II) and Pd(II) complexes under the typical experimental conditions (i.e. the addition of trifluoroacetic acid and/or high salt content) applied for MALDI-TOF MS analysis. The obtained results demonstrate differences in the MALDI-TOF mass spectra of Pt(II) and Pd(II) complexes in dependence on the combination of the metal complex and matrix and, additionally, point to the optimal conditions for MALDI-TOF mass spectrometric analysis of Pt(II) and Pd(II) complexes.

2. Materials and methods

2.1. Chemicals

Platinum(II) and palladium(II) complexes: [$PtCl_2$(*en*)] (ethylenediamine Pt(II) chloride;), [$PtCl_2$(*dach*)] (diaminocyclohexane Pt(II) chloride), and [PdCl(*dien*)]Cl (diethylenetriamine Pd(II) chloride) were synthesised as described in the literature [17,18]. Chemical analysis, UV–Vis and ^{1}H NMR spectral data of these complexes were in good agreement with those obtained in previous preparations. Trifluoroacetic acid solution, matrices for MALDI-TOF MS – 2,3-DHB and α-CHCA were also purchased from Sigma Aldrich Chemie Gmbh (München, Germany) and they were applied without further purification.

2.2. Preparation of samples for MALDI-TOF mass spectrometry

Pt(II) complexes were resuspended in distilled water and kept refrigerated (+4 °C) prior to applying onto the sample plate. The following concentrations of the suspensions were prepared: 0.08 and 0.1 M for [$PtCl_2$(*en*)] and [$PtCl_2$(*dach*)], respectively. The water solution of [PdCl(*dien*)]Cl was of 0.02 M concentration. Matrices – 2,5-DHB and α-CHCA were prepared fresh prior to use. The following solutions of the matrices were used: 0.5 M 2,5-DHB in methanol and 5 mM α-CHCA in acetonitrile/water (1:1, v/v). For some experiments, solutions of NaCl or KCl (final concentration 0.4%) were added to the matrix solutions.

The suspensions of the complexes were vigorously vortexed prior to applying onto the MALDI-TOF sample plate made of stainless steel; the same volume of the matrix solution (1.2 μL) was subsequently applied onto the sample plate. The matrix/analyte mixture was then left to co-crystallise at room temperature. This approach was shown to yield co-crystals with the best homogeneity.

2.3. MALDI-TOF mass spectrometry

MALDI-TOF mass spectra were acquired on a Bruker Daltonics workstation (Bruker Daltonik GmbH, Germany) with a 50 Hz pulsed nitrogen laser emitting at λ = 337 nm. The extraction voltage was 20 kV and all spectra were recorded under delayed extraction conditions and in the reflector mode, thus improving mass accuracy and resolution. Spectra were acquired without low mass gate and each spectrum represents an average of at least 100 single laser shots.

3. Results and discussion

3.1. MALDI-TOF mass spectrometry of Pt(II) complexes

The MALDI-TOF mass spectra of Pt(II) and Pd(II) complexes were acquired with 2,5-DHB or with CHCA as matrices. The positive ion mode MALDI-TOF mass spectra of [Pt(*en*)Cl_2] are shown in Fig. 1: the spectra given in (a) and (b) are acquired with DHB, whereas CHCA was used for the spectra presented in (c) and (d). TFA was added to the matrix solutions applied for the spectra given in (b) and (d). All peaks arising from Pt-complexes are listed in Table 1 and their *m*/*z* ratios are also indicated in the figure.

It should be pointed out that the individual peaks arising from Pt-complexes are complicated due to a great number of naturally occurring isotopes of Pt, which has six isotopes. Therefore, a great number of combinations with isotopes of other atoms composing the complex are possible. In certain cases, as it will be demonstrated further in the text, the overlapping with the peaks arising from polymerisation products of the matrix itself additionally complicates the spectra. An inset in Fig. 1a is given to illustrate the complexity of individual peaks that arise from Pt-complexes. However, this characteristic pattern of the MALDI-TOF mass spectra of Pt(II) and Pd(II) complexes can make the monitoring of their interaction with biomolecules much easier.

[Pt(*en*)Cl_2] yields two peaks with the DHB matrix (Fig. 1a): at *m*/*z* = 409.2 and at *m*/*z* = 446.2. These peaks are generated by the addition of one ligand (*ethylenediamine*) to the complex, followed by cationisation with sodium (at *m*/*z* = 409.2), and by the addition of two ligands (*en*) and further ionisation with proton (*m*/*z* = 446.2). This behaviour is different from the spectra obtained with other matrices, such as flavonoids [14]. When flavonoids were used as matrices for MALDI-TOF MS of Pt(II) and Pd(II) complexes, undetectable loss of ligands and no fragmentation of complexes were noticed. On the other hand, under conditions more suitable for a MS analysis of biomolecules, certain peaks recognised as peaks arising from Pt(II) or Pd(II) can be explained only by the addition of ligands previously eliminated from Pt-complexes. This is not necessarily surprising, since higher laser intensities are required for the spectra acquisition with DHB or CHCA, in comparison to flavonoids, and with higher laser intensity the elimination of ligands occurs to a higher extent. In addition, this might explain why it is also possible to detect other unusual peaks arising from the complexes in MALDI-TOF mass spectra when "traditional" matrices, such as DHB and CHCA, are used.

In the next experiments we added a small amount of TFA to the matrix solution, since this approach had been shown to increase the signal-to-noise ratio in the analysis of biomolecules [9,19]. We wanted to test whether the peak pattern arising from Pt(II) complexes would change in the presence of this proton source and whether the TFA addition would result in increased fragmentation of the complexes.

Upon addition of TFA (Fig. 1b) the spectra of [Pt(*en*)Cl_2] looks much simpler than the spectra recorded without TFA. In this case, the number of peaks decreased and the signals arising from the analyte were more intense. In the spectra of [Pt(*en*)Cl_2], there are almost no peaks arising from the DHB matrix. Only the peaks at *m*/*z* = 409.2 and at *m*/*z* = 446.2 generated by adding the ligand, *ethylenediamine*, to the Pt(II) complex and further cationisation, are detectable in the spectra of this Pt(II) complex acquired with DHB containing small amounts of TFA.

The spectra of the same complex acquired with CHCA are much more complicated (Fig. 1c). Apart from the already described peak at *m*/*z* = 446.2 (*cf.* Table 1), there are peaks generated by the addition of matrix molecule and the further incorporation of a proton (the peak at *m*/*z* = 478.3), as well as the peak corresponding to the product of hydrolysis (i.e. replacement of one Cl^- ion with the OH^-) of the complex (peak at *m*/*z* = 330.6, *cf.* Table 1 for peak assignment). The hydrolysis of the complexes is favoured by the low concentration of chloride ions in the solution. Since distilled water has been used for the suspension of the complexes, it is possible to detect the products of hydrolysis. On the other hand, these hydrolysis products were not detectable in the spectra acquired with DHB. This has to be

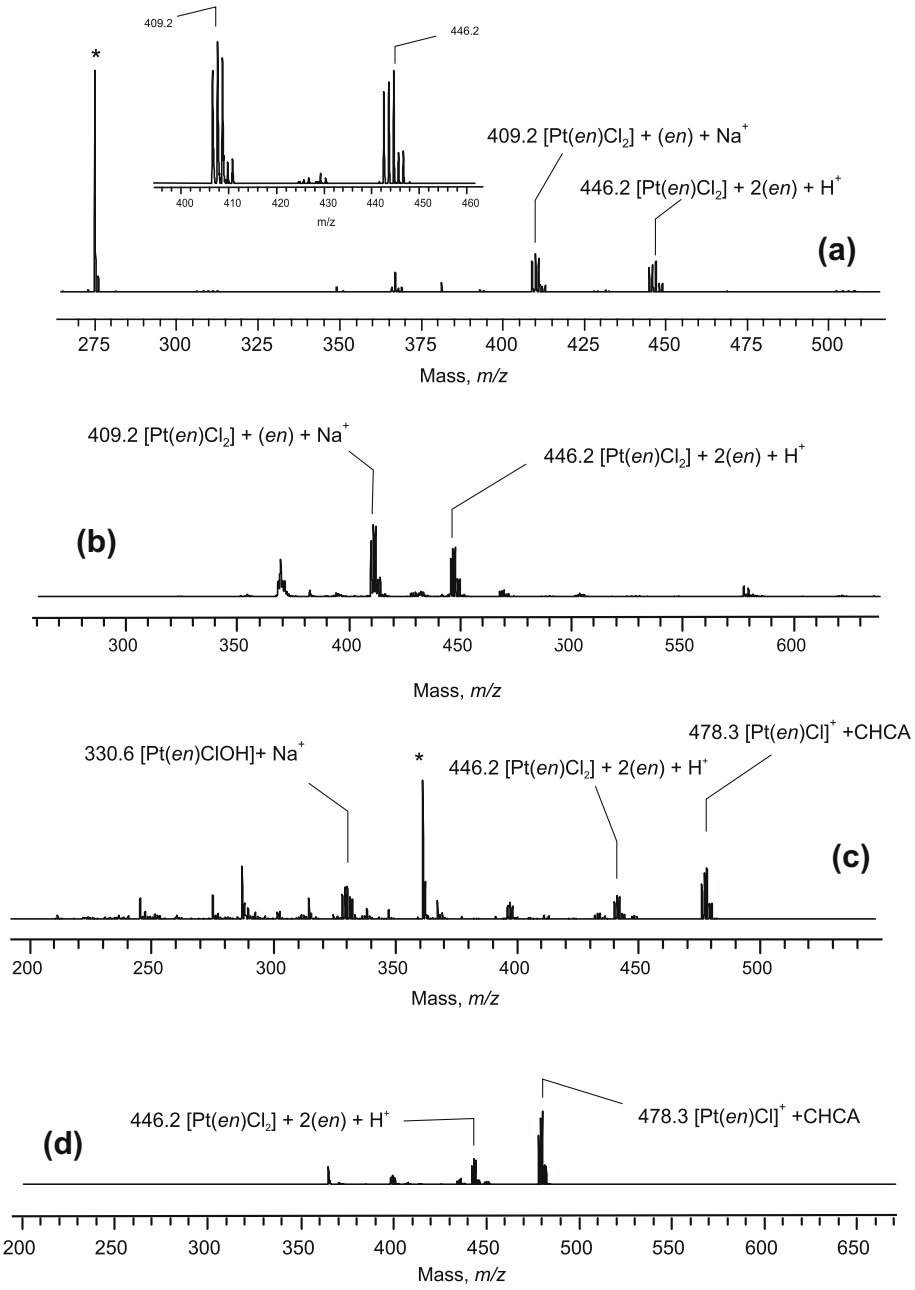

Fig. 1. Positive ion MALDI-TOF mass spectra of [Pt(*en*)Cl_2] acquired with DHB (a and b) and with CHCA (c and d) matrices. In the spectra given in (b) and (d) TFA was added to the matrix solution (0.1% final concentration). The identity of peaks and their position (*m*/*z* ratios) are indicated in the figure. Peaks arising from matrix are labelled with an asterisk.

related to the nature of the matrix itself: since higher laser intensities are required for DHB compared to CHCA, it is possible that this peak is beyond the detection limit for the applied experimental conditions.

In a similar manner to the spectra acquired with DHB containing TFA, the spectra of [Pt(*en*)Cl_2] acquired with CHCA containing small amounts of TFA (Fig. 1d) are simpler compared to the spectra without TFA. There are two peaks: at *m*/*z* = 446.2 and at *m*/*z* = 478.3 that arise from the complex, whereas the peaks arising from the applied matrix were of much low intensity in the presence of TFA. The former peak was detected also in the spectra recorded with DHB, whereas the latter, at a higher *m*/*z* ratio, is related to the CHCA matrix since it has been generated by eliminating Cl^- from the Pt(II) complex investigated and subsequent addition of CHCA to the generated cation (*cf.* Table 1). Interestingly, under these conditions, the formation of clusters with two ligands is favoured when the spectra are recorded with CHCA matrices, and these ions seem to be more stable than those obtained with the DHB matrix.

Positive ion mode MALDI-TOF mass spectrum of [Pt(*dach*)Cl_2] shows a somewhat different spectral pattern. MALDI-TOF mass spectra of this complex acquired with DHB matrix are presented in Fig. 2a and b, whereas CHCA was used as matrix for the spectra given in 2c and d. Small amounts of TFA were added to the spectra given in Fig. 2b and d.

Two peaks that correspond to the sodium (*m*/*z* = 403.2) and to the potassium (*m*/*z* = 419.2) adducts of the molecule dominate the spectrum recorded with the DHB matrix (Fig. 2a). There are also some additional peaks that arise from the ion generated by adding one ligand, *dach* (peak at *m*/*z* = 498.4) to the molecule and

cationising with sodium. There are also some peaks (*cf.* Table 1) which could not be identified, but which most probably contain Pt (judging according to the peak pattern).

When the TFA was added to the matrix solution, a more pronounced loss of ligand occurs and the clusters between the Pt(II) complex and the ligand become detectable (Fig. 2b). This can be observed as a peak at $m/z = 498.4$. The peak at $m/z = 419.2$ arises from the potassium adduct of the complex, whereas the identity of the peak at 452.4 is so far unknown. It might be a result of adding already fragmented ligand (*dach*) to the complex, but this assumption has to wait for its final confirmation.

In the spectra of the same complex, recorded with the CHCA matrix (Fig. 2c), the distribution of peaks is similar to the spectrum recorded with the assistance of the DHB matrix. There is also an additional peak at $m/z = 534.2$ generated from the complex by eliminating a Cl^- ion and adding neutral CHCA.

The spectra of $[Pt(dach)Cl_2]$ acquired with CHCA in the presence of TFA (Fig. 2d) are simple, since they contain only one peak corresponding to the potassium adduct of the complex. Other adducts are not detectable under these experimental conditions.

In summary to this part of the work, we may say that the addition of TFA to the matrices that can be used for the analysis of Pt(II) complexes, but also for the analysis of biomolecules, does not lead to the increased fragmentation of complexes, but results in increased signal intensity corresponding to the complex. Although there are some unidentified peaks in these spectra, it is clear that they arise from Pt.

3.2. MALDI-TOF mass spectrometry of [Pd(dien)Cl]Cl

In the next part of our work, we analysed the spectra of the cationic complex, $[Pd(dien)Cl]^+Cl^-$. The positive ion mode MALDI-TOF mass spectra of the complex acquired with DHB and CHCA matrices are given in Fig. 3: in (a) and (c) the spectra with DHB are given and in (b) and (d) the spectra recorded with CHCA are presented. TFA was added to the matrices used for the spectra given in (c) and (d).

In accordance with the spectra acquired with flavonoids, [14] two peaks at $m/z = 209.1$ and at $m/z = 245.1$ are generated by the loss of Cl^- ion and subsequent elimination of HCl, whereas the loss of the easy-leaving Cl^- ion leaves the complex detectable at $m/z = 245.1$. In addition to these peaks there are two peaks in the spectra of Pd(II) complex acquired with the assistance of DHB: the peak at $m/z = 318.3$, corresponding to the addition of potassium to the complex, and the peak at $m/z = 364.2$ generated by adding DHB molecule to the fragment generated by the loss of Cl^- ion and elimination of HCl (*cf.* Table 1 for peak identity).

When the spectra of [Pd(*dien*)Cl]Cl were recorded with the CHCA matrix (Fig. 3b), only two peaks were detectable: at $m/z = 245.1$ and at $m/z = 209.1$. Neither matrix adducts nor peaks corresponding to the addition of any cation to the complex could be detected. The reason for this might be the lower content of inorganic ions in CHCA, and the complex's weaker tendency to generate clusters with the matrix when CHCA was used for the analysis. One can easily observe differences in the intensity of individual peaks that correspond to the complex in the spectra acquired with the two matrices, while the intensity of the peaks at $m/z = 209.1$ and at $m/z = 245.1$ is rather low with DHB (Fig. 3a), the intensity of their counterparts in the spectra acquired with CHCA (Fig. 3b) is higher. Since higher laser intensities must be applied for the spectra acquisition with DHB, in comparison to CHCA, it is possible that these clusters at higher m/z are generated only at higher laser intensities, which has already been observed for other molecules analysed with the DHB matrix [16].

After adding TFA to the matrix solution, Pd(II) complex was barely detectable, as only one peak could be observed. This peak was, according to the above described peaks, most probably overlapping with the matrix peak (peak at $m/z = 361.2$), preventing its reliable identification. These results are in contrast to those obtained with flavonoids. Namely, when the spectra were acquired with flavonoids, the Pd(II) complex was stable even after the addition of TFA.

3.3. MALDI-TOF mass spectrometry of Pt(II) and Pd(II) complexes in the presence of high salt content

A higher salt content is characteristic for samples of biological origin. This fact might affect the choice of the method to be used for the analysis of some important biological processes and elucidation of the interactions of e.g. drugs with biomolecules. Most commonly, MS methods are sensitive to salt content. On the other hand, MALDI-TOF MS, which is still primarily used for the analysis of biomolecules, appears to tolerate somewhat higher content of salts and, up to a certain concentration, there is no need to remove salts from the solution prior to analysis. To test the possibility for the application of MALDI-TOF MS for monitoring the interactions between metallo-drugs and biomolecules under more physiologically relevant conditions (i.e. in the presence of physiological solutions and a high content of inorganic ions), we analysed Pt(II) and Pd(II) complexes with DHB and CHCA in the presence of 0.4% NaCl or KCl.

The spectra of $[Pt(en)Cl_2]$ and $[Pt(dach)Cl_2]$ acquired with DHB and 0.4% NaCl are given in Fig. 4a and b, respectively. Interestingly, signals were suppressed when the same spectra were recorded with the assistance of CHCA (data not shown). This might also be related to better ionisation properties of CHCA, in comparison to DHB: a higher content of salt demanded a higher laser intensity, which in turn most probably resulted in the saturation of the detector with inorganic salts.

In the spectra of $[Pt(en)Cl_2]$, two peaks are detectable: at $m/z = 409.2$ and at $m/z = 446.2$. They are also detectable in the spectra of the same complex acquired under somewhat different conditions and their identity is given in Table 1. Although expected, no higher adducts with sodium could be detected, but the quality of the spectra was better compared to the same spectra recorded without the addition of salt.

The spectra of $[Pt(dach)Cl_2]$ in the presence of NaCl (Fig. 4b) have the same pattern as the spectra recorded in the absence of salt. There are three peaks: at $m/z = 403.2$, 419.2 and 460.9 arising from the complex (*cf.* Table 1 for peak identity), whereas the peak

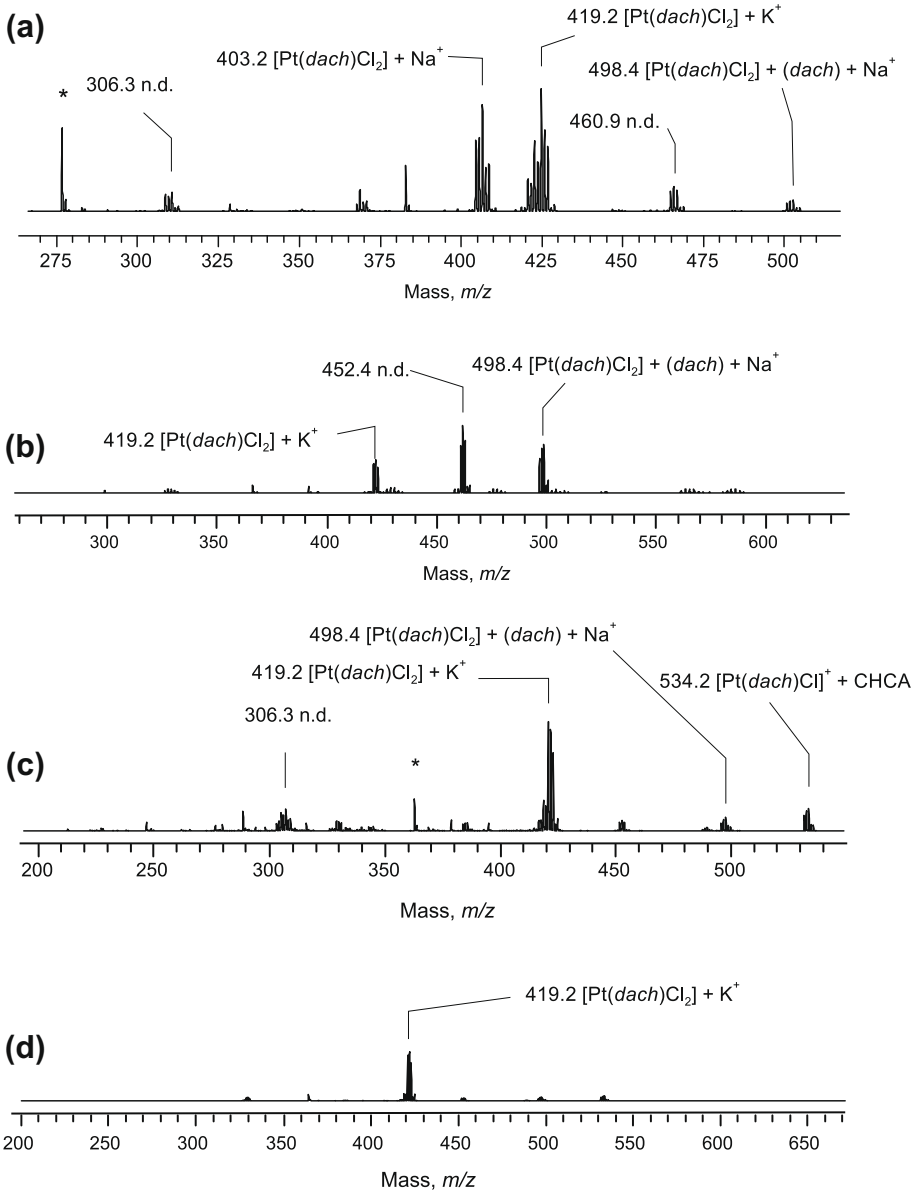

Fig. 2. Positive ion MALDI-TOF mass spectra of [Pt(*dach*)Cl_2] acquired with DHB (a and b) and with CHCA (c and d) matrices. In the spectra given in (b) and (d) TFA was added to the matrix solution (0.1% final concentration). The identity of peaks and their position (*m*/*z* ratios) are indicated in the figure. Peaks arising from matrix are labelled with an asterisk; n.d. is "not determined".

at *m*/*z* = 724.2 most probably represents the cluster generated from the complex and the same complex that has previously lost Cl^-. Obviously, a higher content of sodium could not suppress the peak arising from the potassium adduct of [Pt(*dach*)Cl_2] (peak at *m*/*z* = 419.2). However, the quality of the spectra was much worse in the presence of higher sodium content.

The presence of a higher potassium content (also 0.4%) in the solution of matrix resulted in a different spectra pattern, but also in a reduced number of detectable peaks in the spectra of Pt(II) complexes. The spectra of [Pt(*en*)Cl_2] are given in Fig. 5a and c, whereas the positive ion mode MALDI-TOF mass spectra of [Pt(*dach*)Cl_2] are presented in Fig. 5b and d. The spectra presented in 5a and b are acquired with DHB as matrix, whereas for the spectra in 5c and d CHCA was used. Both matrix solutions contained 0.4% KCl and 0.1% TFA.

The peak at *m*/*z* = 362.2 was detectable in the spectra of [Pt(*en*)Cl_2] acquired with both matrices and in the presence of high K^+ ion content (Fig. 5a and c). The identity of this peak could not be determined, but it seems that it is overlapping with the signal arising from the matrix. In the spectrum 5a, there is an additional peak at *m*/*z* = 446.2 that can be assigned to the Pt-complex to which two ligands were added and which was further ionised by proton.

The positive ion MALDI-TOF mass spectra of [Pt(*dach*)Cl_2] in the presence of KCl are much simpler compared to the above described spectra of [Pt(*en*)Cl_2]. Only one peak at *m*/*z* = 419.2 was detectable. This peak corresponds to the potassium adduct of [Pt(*dach*)Cl_2] (*cf.* Table 1), whereas other peaks are suppressed. This difference observed in the spectra pattern between these complexes can be attributed to the different nature of the ligand coordinatively bound to Pt and the differences in their affinity towards different inorganic ions, as observed for other molecules.

In Fig. 6a and b, the spectra of [Pd(*dien*)Cl]Cl acquired with DHB and with CHCA matrices, respectively, containing 0.4% of KCl are shown. Obviously, in this case, the presence of high potassium content led to barely detectable signals. Although, according to the peak pattern, certain peaks could be attributed to species that con-

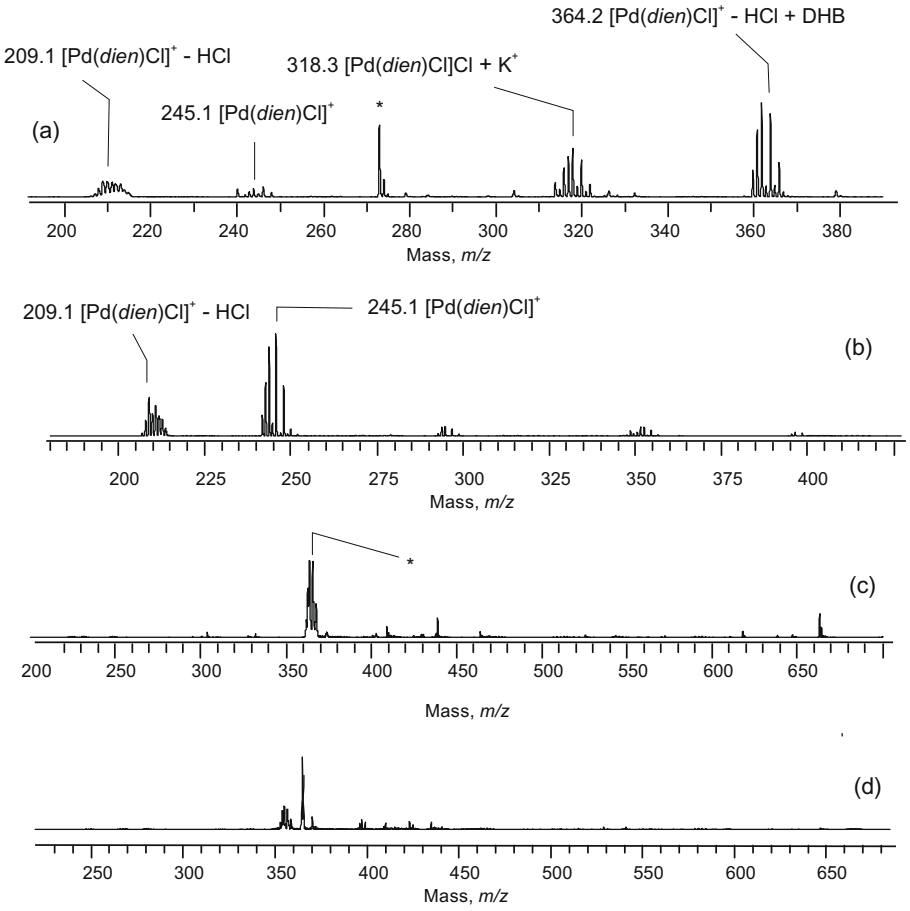

Fig. 3. Positive ion MALDI-TOF mass spectra of [Pd(*dien*)Cl]Cl acquired with DHB (a and c) and with CHCA (b and d). For the spectra presented in (c) and (d) 0.1%, TFA was added to the matrix solution. The identity of peaks and their position (*m*/*z* ratios) are indicated in the figure. Peaks arising from matrix are labelled with an asterisk.

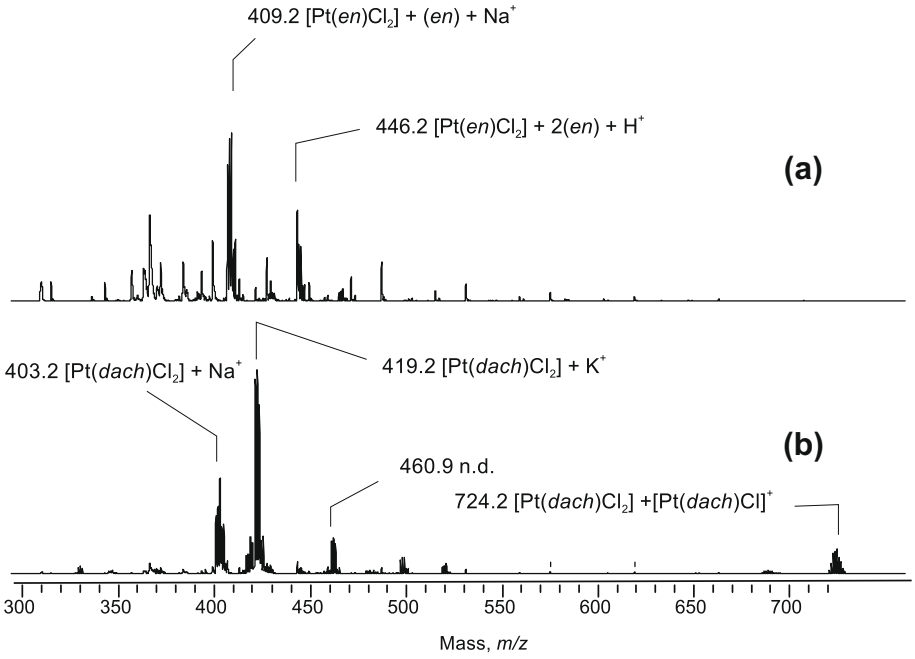

Fig. 4. Positive ion mode MALDI-TOF mass spectra of [Pt(*en*)Cl_2] (a) and [Pt(*dach*)Cl_2] (b) acquired with the DHB matrix in the presence of 0.4% NaCl. The identity of peaks and their position (*m*/*z* ratios) are indicated in the figure.

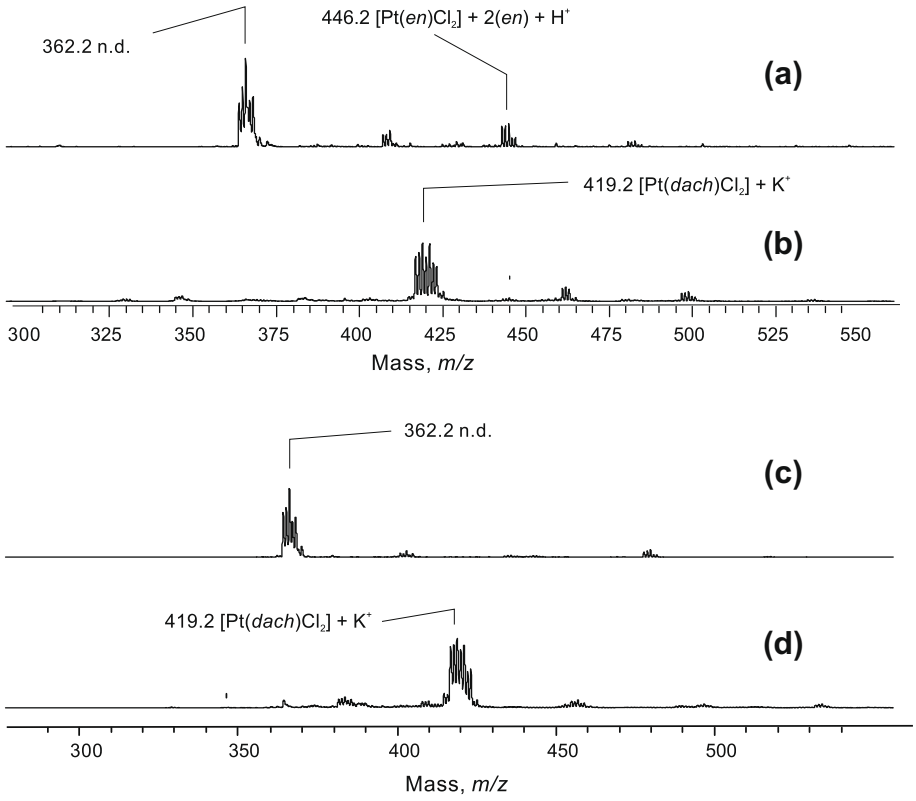

Fig. 5. Positive ion mode MALDI-TOF mass spectra of [Pt(*en*)Cl_2] (a and c) and [Pt(*dach*)Cl_2] (b and d) acquired in the presence of 0.4% KCl and 0.1% TFA. The spectra in (a) and (b) were acquired with DHB, whereas for the spectra given in (c) and (d) CHCA was used as a matrix. The identity of peaks and their position (*m*/*z* ratios) are indicated in the figure.

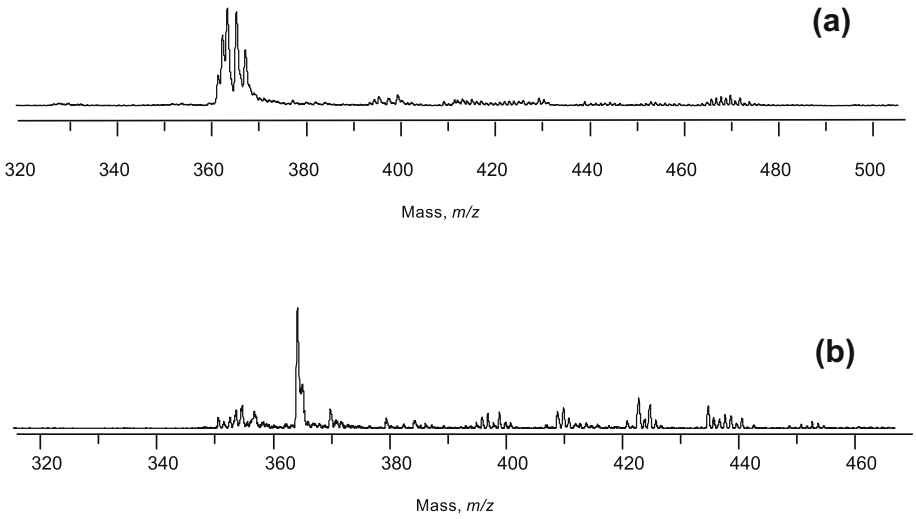

Fig. 6. Positive ion mode MALDI-TOF mass spectra of [Pd(*dien*)Cl]Cl acquired with the DHB (a) and CHCA (b) matrices. In both spectra, a high content of KCl (0.4% in the matrix solution) was present.

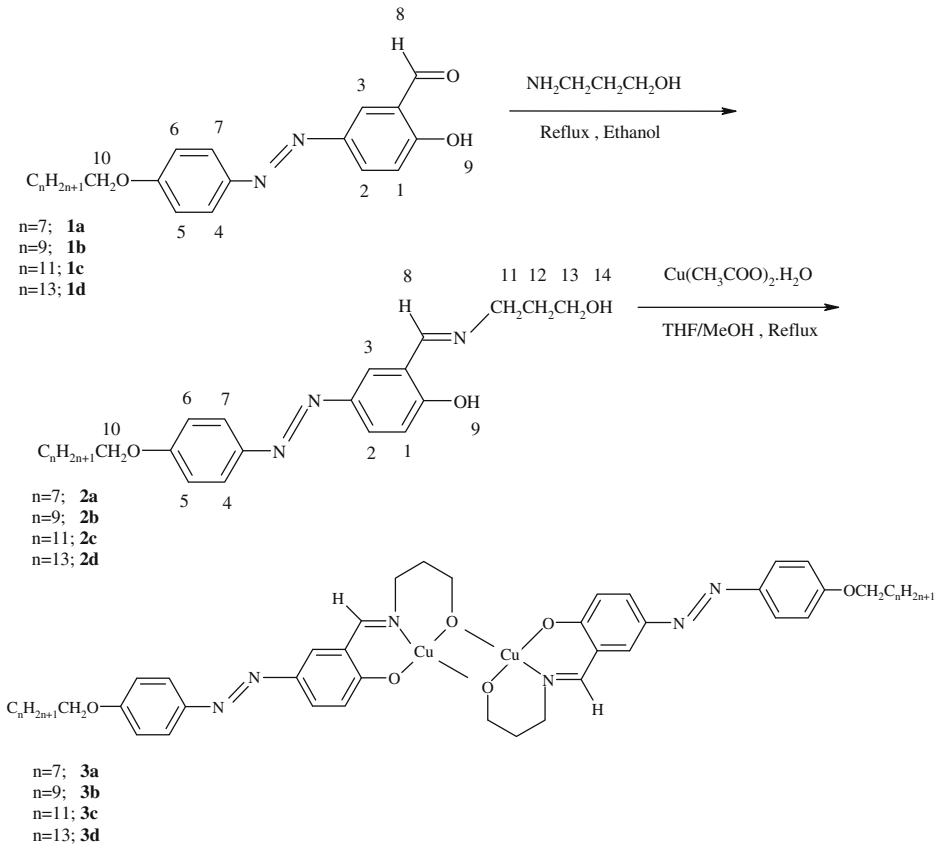
tain Pd, their intensity is by far too low for any reliable peak identification.

4. Summary

The analysis of the MALDI-TOF mass spectra of transition metals (Pt(II), Pd(II)) and their complexes acquired with the DHB and CHCA matrices, with the addition of TFA and with a high inorganic salt content, demonstrated differences in their behaviour depending on the metal/ligand combination and on the matrix used for the analysis. While Pt(II) complexes could be easily and reliably analysed with the DHB matrix, it seems that CHCA is better suitable for MALDI-TOF MS of Pd(II) complex used in this study. On the other hand, the spectra obtained under experimental conditions usually applied in the MALDI-TOF mass spectrometric analysis of biomolecules (which might contain a higher content of inorganic salts in the sample) and with the addition of small



amounts of TFA have to be subjected to careful analysis. It is possible that certain complexes, such as cationic Pd(II) complex, do not tolerate acidic conditions for the analysis and the absence of the corresponding peak might be misinterpreted.

then the crude 4-^{n}alkoxynitrobenzene homologous were purified by recrystallization from ethanol. The 4-^{n}alkoxyaniline homologous prepared by reducing the corresponding 4-^{n}alkoxynitrobenzenes as described in the literature [29].

2.2. Physical measurements

Elemental (C, H and N) analyzes were carried out on a Perkin–Elmer automatic equipment model 240B. Electron impact (70 eV) mass spectra were recorded on a Finnegan-mat GC–MS–DS spectrometer model 8430. Infrared spectra were taken with a FT-IR Bruker, vector 22 spectrometer using KBr pellets in the 400–4000 cm^{-1} range. The DSC thermograms of the compounds were obtained on a Mettler–Toledo DSC 822e module, which was calibrated with indium metal (T = 156.6 ± 0.3, ΔH = 28.45 ± 0.6 J g^{-1}). Samples of 2–5 mg in the solid form were placed in aluminum pans (40 μl) with a pierced lid, and heated or cooled at a scan rate of 10 °C min^{-1} under a nitrogen flow. TGA thermograms were carried out on a Mettler–Toledo TGA 851e at a heating rate of 10 °C min^{-1} under a nitrogen atmosphere. The optical observations were made with a Zeiss polarizing microscope equipped with a Linkam THMSG 600 heating and cooling stage and Linkam THMS 93 programmable temperature-controller. ^{1}H NMR spectra were obtained in deuterated chloroform as the solvent on a Bruker FT-NMR AC-400 (400 MHz) spectrometer. All chemical shifts are reported in δ(ppm) relative to tetramethylsilane as an internal standard.

2.3. Materials

All homologous materials were prepared similarly as described in the literature [30].

2.3.1. 5-(4-Octyloxyphenylazo)salicylaldehyde (**1a**)

Yellow, yield 80%, mp 126 °C. MS m/z (relative intensity): 355.4 (M+1, 15), 354.3 (M, 40). *Anal.* Calc. for $C_{21}H_{26}N_2O_3$: C, 71.16; H, 7.39; N, 7.90. Found: C, 70.8; H, 7.1; N, 7.5%. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 11.27 (s, H-8), 10.02 (s, H-9), 8.18 (d, J 3.2 Hz, H-3), 8.14 (dd, J 3.1, 8.4 Hz, H-2), 7.91 (dd, J 3.1, 8.2 Hz, H-4, H-7), 7.10 (d, J 8.7 Hz, H-1), 7.01 (dd, J 3.6, 8.3 Hz, H-5,H-6), 4.05 (t, J 7.1 Hz, H-10), 1.81–1.00 (15H, alkyl chain). IR (KBr, cm^{-1}) ν: 3416 (O–H), 3069 (C–H, aromatic), 2921, 2959 (C–H, aliphatic), 1661 (C=O), 1600 (C=C, aromatic), 1500 (N=N), 1245 (C–O, ether), 1150 (C–O, phenolic).

2.3.2. 5-(4-Decyloxyphenylazo)salicylaldehyde (**1b**)

Yellow, yield 80%, mp 124 °C. MS m/z (relative intensity): 383.4 (M+1, 15), 382.3 (M, 40). *Anal.* Calc. for $C_{23}H_{30}N_2O_3$: C, 72.19; H, 7.84; N, 7.32. Found: C, 71.8; H, 7.5; N, 7.0%. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 11.27 (s, H-8), 10.02 (s, H-9), 8.18 (d, J 3.2 Hz, H-3), 8.14 (dd, J 3.1, 8.4 Hz, H-2), 7.91 (dd, J 3.1, 8.2 Hz, H-4, H-7), 7.10 (d, J 8.7 Hz, H-1), 7.01 (dd, J 3.6, 8.3 Hz, H-5,H-6), 4.05 (t, J 7.1 Hz, H-10), 1.81–1.00 (19H, alkyl chain). IR (KBr, cm^{-1}) ν: 3417 (O–H), 3065 (C–H, aromatic), 2923, 2957 (C–H, aliphatic), 1661 (C=O), 1599 (C=C, aromatic), 1501 (N=N), 1245 (C–O, ether), 1149 (C–O, phenolic).

2.3.3. 5-(4-Dodecyloxyphenylazo)salicylaldehyde (**1c**)

Yellow, yield 80%, mp 123 °C. MS m/z (relative intensity): 411.6 (M+1,14), 410.6 (M, 45). *Anal.* Calc. for $C_{25}H_{34}N_2O_3$: C, 73.15; H, 8.35; N, 6.83. Found: C, 72.8; H, 8.2; N, 6.5%. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 11.26 (s, H-9), 10.02 (s, H-8), 8.15 (d, J 2.8 Hz, H-3), 8.13 (dd, J 2.9, 8.2 Hz, H-2), 7.89 (dd, J 3.0, 7.9 Hz, H-4, H-7), 7.11 (d, J 8.1 Hz, H-1), 7.01 (dd, J 3.2, 7.9 Hz, H-5, H-6), 4.04 (t, J

6.7 Hz, H-10), 1.84-0.87 (23H, alkyl chain). IR (KBr, cm^{-1}) *v*: 3416 (O–H), 3065 (C–H, aromatic), 2921, 2851 (C–H, aliphatic), 1661 (C=O), 1600 (C=C, aromatic), 1500 (N=N), 1245 (C–O, ether), 1148 (C–O, phenolic).

*2.3.4. 5-(4-Tetradecyloxyphenylazo)salicylaldehyde (**1d**)*

Yellow, yield 76%, mp 122 °C. MS *m*/*z* (relative intensity): 439.6 (M+1, 13), 438.6 (M, 42). *Anal.* Calc. for $C_{27}H_{38}N_2O_3$: C, 73.97; H, 8.68; N, 6.39. Found: C, 73.6; H, 8.3; N, 6.0. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 11.26 (s, H-9), 10.02 (s, H-8), 8.15 (d, *J* 2.8 Hz, H-3), 8.13 (dd, *J* 2.9, 8.2 Hz, H-2), 7.89 (dd, *J* 3.0, 7.9 Hz, H-4, H-7), 7.11 (d, *J* 8.1 Hz, H-1), 7.01 (dd, *J* 3.2, 7.9 Hz, H-5, H-6), 4.03 (t, *J* 6.7 Hz, H-10), 1.83–0.88 (27H, alkyl chain). IR (KBr, cm^{-1}) *v*: 3418 (O–H), 3065 (C–H, aromatic), 2919, 2850 (C–H, aliphatic), 1660 (C=O), 1600 (C=C, aromatic), 1500 (N=N), 1244 (C–O, ether), 1149 (C–O, phenolic).

2.4. Syntheses of the ligands

All the homologous materials were prepared in similar manners. Thus, 0.02 mol of 3-amino-1-propanol and 0.02 mol of the related 5-(4-^{n}dodecyloxyphenylazo)salicylaldehyde were dissolved in 100 ml absolute ethanol with a few drops of glacial acetic acid as a catalyst. The solution was refluxed for 1 h and then left at room temperature. After cooling, the ligands were obtained as yellow micro crystals. The micro crystals were filtered off, washed with 15 ml of cold absolute ethanol and then recrystallized several times in ethanol–chloroform (1:3, v/v).

*2.4.1. 5-(4-Octyloxyphenylazo)salicylaldimine-N-(3-hydroxypropyl) (**2a**)*

Yellow, yield 80%, mp 107.4 °C. MS *m*/*z* (relative intensity): 412.4 (M+1, 13), 411.3 (M, 42). *Anal.* Calc. for $C_{24}H_{33}N_3O_3$: C, 70.07; H, 8.03; N, 10.22. Found: C, 69.7; H, 7.8; N, 9.9%. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 14.21 (s, H-9), 10.12 (s,H-14), 8.45 (s, H-8), 7.93 (dd, *J* 8.2, 2.8, Hz, H-2), 7.83–7.89 (H-3, H-4, H-7),7.03 (d, *J* 8.3 Hz, H-1), 6.97 (d, *J* 8.3 Hz, H-5, H-6), 4.03 (t, J 6.8 Hz, H-10), 3.75–3.81 (4H, H-11, H-13), 1.99 (p, *J* 4.2 Hz, H-12), 0.86–1.84 (15H, alkyl chain). IR (KBr, cm^{-1}) *v*: 3390 (O–H, alcoholic), 3220 (OH, phenolic), 3069 (C–H, aromatic), 2921, 2851 (C–H, aliphatic), 1640 (C=N), 1601 (C=C, aromatic), 1503 (N=N), 1254 (C–O, ether), 1149 (C–O, phenolic).

*2.4.2. 5-(4-Decyloxyphenylazo)salicylaldimine-N-(3-hydroxypropyl) (**2b**)*

Yellow, yield 90%, mp 112.2 °C. MS *m*/*z* (relative intensity): 440.4 (M+1, 12), 439.3 (M, 60). *Anal.* Calc. for $C_{26}H_{37}N_3O_3$: C, 71.07; H, 8.43; N, 9.57%. Found: C, 70.7; H, 8.1; N, 9.2%. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 14.22 (s, H-9), 10.14 (s, H-14), 8.45 (s, H-8), 7.93 (dd, *J* 2.8, 8.2 Hz, H-2), 7.82–7.89 (H-3, H-4, H-7), 7.03 (d, *J* 8.3 Hz, H-1), 6.97 (d, *J* 8.3 Hz, H-5, H-6), 4.04 (t, *J* 6.8 Hz, H-10), 3.76–3.83 (4H, H-11, H-13), 1.99 (p, J 4.2 Hz, H-12), 0.86–1.85 (19H, alkyl chain). IR (KBr, cm^{-1}) *v*: 3415 (O–H, alcoholic), 3223 (OH, phenolic), 3065 (C–H, aromatic), 2919, 2851 (C–H, aliphatic), 1638 (C=N), 1603 (C=C, aromatic), 1502 (N=N), 1254 (C–O, ether), 1152 (C–O, phenolic).

*2.4.3. 5-(4-Dodecloxyphenylazo)salicylaldimine-N-(3-hydroxypropyl) (**2c**)*

2.5. Syntheses of the copper complexes

The copper complexes were prepared in similar manners with slight modifications, using the method described elsewhere [31]. Thus, an alcoholic solution containing 10 mmol of 3-amino-1-propanol was added to a solution of 5-alkoxyphenylazosalicylaldehyde (10 mmol) in 50 ml of boiling methanol. Then 10 mmol sodium acetate in 10 ml water was added to the above reaction system. Finally 50 ml boiling methanol solution containing 10 mmol $Cu(CH_3COO)_2{\cdot}H_2O$ was added. The reaction mixture was kept boiling for 30 min. The crystals precipitated from the solution and recrystallization was performed from the methanol/THF (2:1 v/v) solution. The copper complexes were obtained as dark green crystals. The micro crystals were filtered off, washed with absolute ethanol and then recrystallized from methanol/THF (2:1 v/v).

3. Results and discussion

3.1. Synthesis

The Schiff base ligands were synthesised in a four-step process, in which the hydroxyl group in 4-nitrophenol is first replaced by an alkoxy chain, followed by reduction of the nitro group to an amine. In the third step, salicylaldehyde is coupled with the diazonium chloride obtained from the 4-alkoxyaniline. As a final step, the Schiff base ligands were obtained by the reaction of 5-(4-^{n}alkoxyphenylazo)salicylaldehyde with 3-amino-1-propanol (Scheme 1) by refluxing in absolute ethanol, using a few drops of acetic acid as a catalyst. The 5-(4-^{n}alkoxyphenylazo)salicylaldehyde homologous (**1a–d**) and the Schiff base ligands (**2a–2c)** were purified by repeated crystallization from ethanol to give a single spot on thin layer chromatography and characterized by IR, ^{1}H NMR, mass spectroscopy and elemental analyzes. The dicopper complexes were characterized by C, H, N elemental analyzes and IR spectroscopy. Physical and characterization data for the ligands and the complexes are given in the Section 2.

A comparison of the IR spectra of the metal complexes with those of the free ligands shows that the stretching frequency of the C=N bond is shifted to lower wavenumbers (ca. 15 cm^{-1}) after coordination. This shift is due to reduction of the double-bond character of the C=N bond as a result of coordination of the nitrogen to the metal center, and is in agreement with the results obtained for other similar complexes described previously [10,19,20]. On the other hand, the disappearance of the OH bands of the free ligands in the spectra of the metal complexes indicates that the OH groups have been deprotonated and coordinate to the metal ion as –O. Based on these observations and elemental analyzes results, we concluded that the Schiff base ligands are coordinated to the metal center as tridentate (NOO) ligands in a 1:1 ratio (see scheme 1).

3.2. Mesomorphism

The mesomorphic properties of the 5-(4-^{n}alkoxyphenylazo)salicylaldehyde homologous (**1a–d**), the Schiff ligands (**2a–d**) and related dicopper complexes (**3a–d**) have been studied by polarizing optical microscopy observations using a heating- cooling stage and the phase transition temperatures and enthalpies were obtained by differential scanning calorimetry (DSC).

All the 5-(4-^{n}alkoxyphenylazo)salicylaldehyde homologous (**1a–d**) and the Schiff base ligands (**2a–d**) were not mesomorphic. The absence of liquid crystalline behavior in the free ligands can be attributed to the strong intermolecular hydrogen bonding brought about by the presence of the two hydroxyl groups (phenolic and alcoholic OH) in the ligand molecular structure.

All the dicopper complexes (**3a–d**) exhibit liquid crystalline character as revealed by polarizing optical microscopy. Phase transition temperatures along with the corresponding enthalpy values for the Schiff base ligands (**2a–d**) and the dicopper complexes (**3a–d**) are summarized in Table 1. Fig. 1 shows the DSC curves of the dicopper complexes in the heating process. A complete set of DSC curves for **3a** in the heating and cooling processes is illustrated as a representative example.

The thermal behaviors of the complexes are similar as it is apparent from the DSC curves. Compounds **3a** and **3d** show one solid–solid transition at 176.1 and 173.8 °C with ΔH values of 1.7 and 4.7 kJ mol^{-1}, respectively. Compound **3b** exhibits two solid–solid transitions at 69.8 and 154.5 °C with ΔH values of 6.8 and 3.7 kJ mol^{-1}, respectively. The dicopper complexes (**3a–3d**) display endothermic transitions at 225.9, 205.8, 195.4 and 192.5 °C with ΔH values of 51.4, 54.4, 40.5 and 43.6 kJ mol^{-1}, respectively. Such a high value of the enthalpy of fusion is in agreement with the presence of a crystal phase to a mesophase transition. However, the melting temperatures of the dicopper compounds decrease slightly by increasing the alkyl chain length. The texture of the mesophase was investigated by polarizing optical microscopy (POM). For all the complexes, a viscous mesophase organized as a focal conic texture after the melting process, which indicates the formation of an SmA mesophase. Continued heating of the complexes **3a–3d** mesophases causes a considerable amount of decomposition at 278.9, 281.1, 282.0 and 282.2 °C respectively which has been detected by exothermic peaks in the DSC trace, TGA thermograms and optical observations. A microscopic picture from the SmA mesophase for complex **3b** is illustrated in Fig. 2 as a representative example. To understand the thermal decomposition process, the dicopper compounds were examined by thermo gravimetric analysis (TGA). The TGA thermograms of the dicopper compounds at a heating rate of 10 °C/min show that decomposition begins at around 280 °C, as is seen optically, which is near the temperature of clearing to the isotropic liquid. All the dicopper compounds have similar TGA thermograms. Fig. 3 gives the TGA thermogram of **3a** as a representative example. Thermodynamic data for the Schiff base ligands and dicopper complexes are tabulated in Table 1.

Table 1
Transition temperatures, enthalpy changes, mesophase type and temperature range of the mesophase for the dicopper complexes.

Compound	Transition [a]	T[b]/°C	ΔH[b]/kJ mol^{-1}	Temperature range, ΔT (°C)
2a	Cr–I	107.4	85.9	
2b	Cr–I	112.2	91.3	
2c	Cr–I	116.6	87.5	
2d	Cr–I	110.5	91.7	
3a	Cr_1–Cr_2	176.1	1.7	53.0

[c] Decomposition occurred immediately at clearing point.

These complexes represent a further example of a mesomorphic complex derived from a non-mesogenic ligand. Based on our knowledge, only a few dicopper compounds based on salicylaldimine ligands have been reported as liquid crystalline materials. Similar mesomorphic properties were previously reported by Lai et al. for dicopper complexes with a similar coordination environment based on salicylaldimine Schiff bases ligands, but without a 4-alkoxyphenyazo linkage [31]. In the case of the dicopper complexes reported in Ref. [31], the temperature range of the mesophase was narrow (from 18.6 to 25.1 °C) and varied slightly with alkyl chain length, but the complexes reported in this research work have fairly wide temperature range of mesophase. From Table 1, it can be seen clearly that the mesophase of complexes **3a–3d** is stable in for temperature ranges (ΔT) of 53.0, 75.3, 86.5 and 88.7 °C, respectively. This fact may be related to the presence of the alkoxyphenylazo moiety in the structure of the complexes. The mesophase range increases with increasing alkyl chain length, and is in agreement with results obtained from other complexes, described previously by our research group [26,27].Furthermore, Lai et al. [32] reported a new type of dicopper(II) complex derived

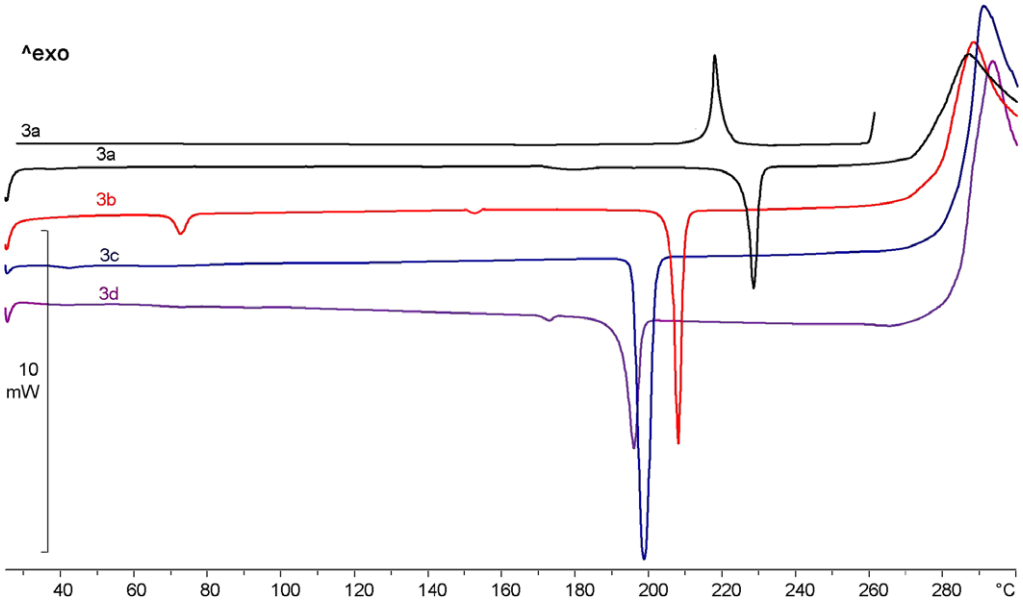

Fig. 1. DSC thermograms of the dicopper complexes.

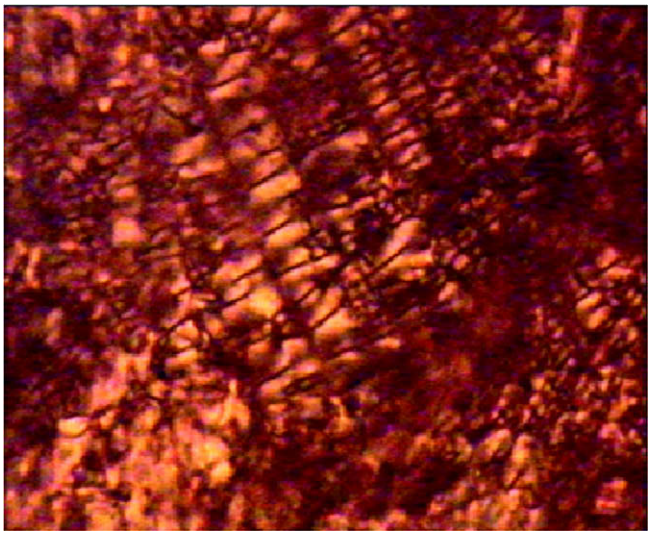

Fig. 2. Optical texture observed for the copper complex **3b** through crossed polarizers at 212 °C.

from μ-exogenous 3,4,5-trialkoxybenzoate- or acetate-bridged *N*,*N*′-(propane-2-ol)-bis(4-alkoxysalicylal-dimines), prepared by the condensation of 2-hydroxy-4-alkoxybenzaldehydes with 1,3-diaminopropane-2-ol. The formation of mesomorphic phases was found to be dependent upon the bridging groups used, acetate-bridged compounds formed a smectic A (SmA) phase and benzoate-bridged compounds formed a hexagonal columnar (Col_h) phase. The temperature range of mesophases was very narrow (from 5.8 to 12.9 °C) and varied slightly with alkyl chain length.

The induction and formation of mesophases are mainly controlled and/or determined by attractive interactions between neighboring molecules. These weak interactions are of various types, for example dipole–dipole, dispersion, hydrogen bonding, charge transfer and dative coordination. Transition metal ions can induce mesomorphism in non-mesogenic ligands. The coordination geometry of the metal center in this type of material greatly influences the molecular packing in the formation of the mesophase. While in classic organic structures, the intention is, frequently, to increase intermolecular contacts to induce mesomorphism, in coordination compounds the objective is to avoid intermolecular contacts and strong dipolar interactions that are sufficiently strong to cause three-dimensional order. Hence, it

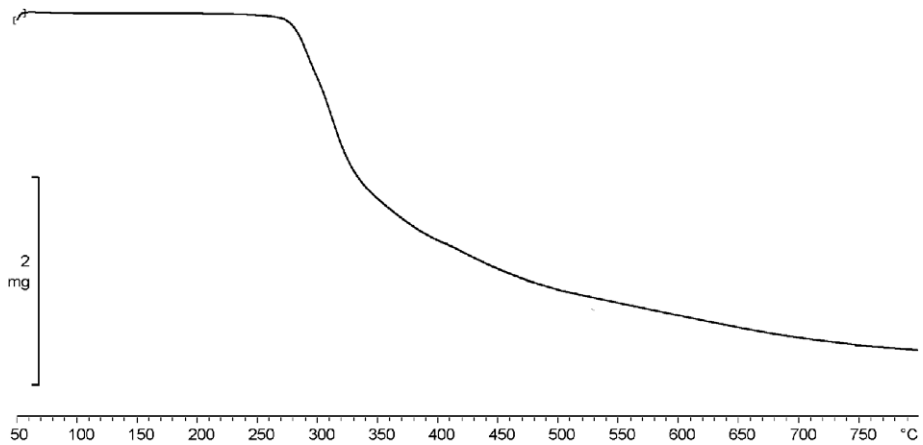

Fig. 3. TGA thermogram of **3a**.

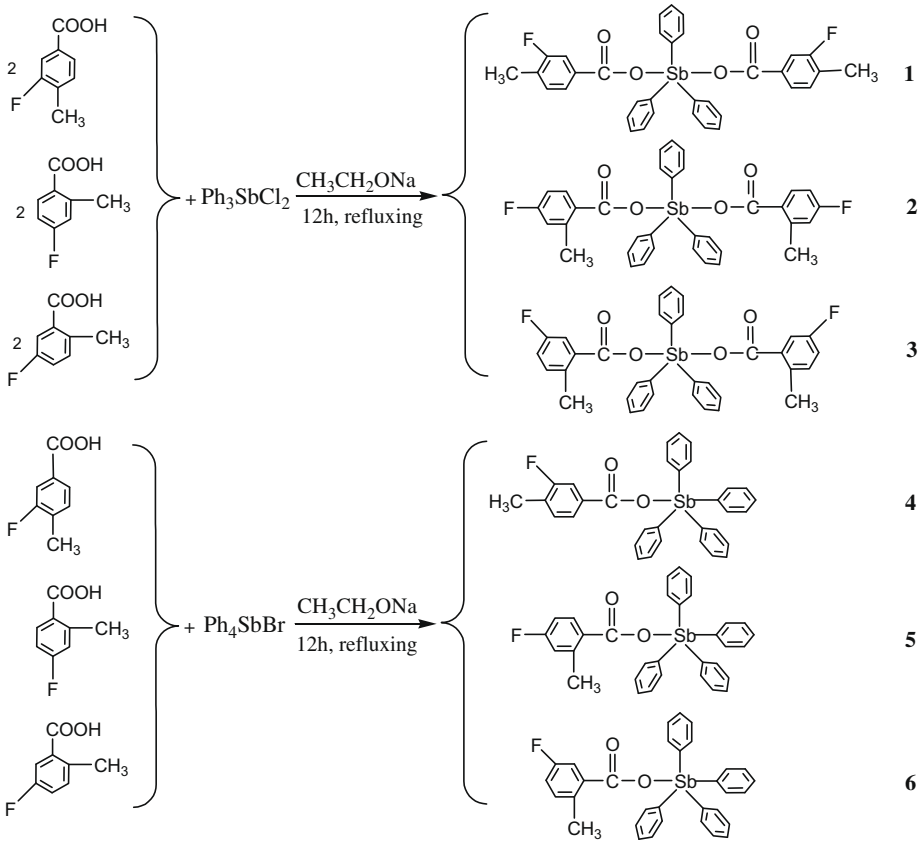
is fundamentally important to achieve a delicate balance in the magnitude of molecular interactions by tuning the molecular geometries in order to optimize the liquid crystalline behavior. The addition of a long aliphatic chain to the rigid nucleus furnishes both the anisotropy and irregular packing needed to promote mesomorphism [33,34].

4. Conclusion



In this work we have prepared dicopper complex homologous derived from tridentate 5-(4-^{n}alkoxyphenylazo)salicylaldimine-N-(3-hydroxypropyl) ligands. While the Schiff base ligands do not show any liquid crystalline character, the dicopper complexes have mesomorphic properties and form a smectic A mesophase as confirmed by their typical texture. For all the dicopper complexes, the mesophase was decomposed immediately at the clearing point. The mesophases have a wide temperature range which increased with increasing alkyl chain length.

2.2. Syntheses of complexes **1–6**

2.2.1. Synthesis of [3-F-4-(CH_3)C_6H_3COO]$_2$SbPh$_3$ (**1**)

The reaction was carried out under nitrogen atmosphere. 3-Fluoro-4-methyl-benzoic acid (0.077 g, 0.5 mmol) and sodium ethoxide (0.6 mmol) were added to a stirred solution of methanol (30 ml) in a Schlenk flask and stirred for 0.5 h. Triphenylantimony dichloride (0.106 g, 0.25 mmol) was then added to the reactor and the reaction mixture was stirred for 12 h at room temperature. The resulting clear solution was evaporated under vacuum. The product was crystallized from a mixed of dichloromethane/ether (1:1) to yield colourless blocks of crystals, yield: 82%, m.p. 210–212 °C. *Anal.* Calc. for $C_{34}H_{27}F_2O_4Sb$ (Mw = 659.31): C, 61.93; H, 4.13; F, 5.76. Found: C, 61.77; H, 4.24; F, 5.87%. 2.2.3. Synthesis of [5-F-2-(CH_3)C_6H_3COO]$_2$SbPh$_3$ (**3**)

Complex **3** was prepared in the same way as **1**. The colourless solid was recrystallized from a mixed of dichloromethane/ether (1:1) to give colourless crystals, yield: 80%, m.p. 183–185 °C. *Anal.* Calc. for $C_{34}H_{27}F_2O_4Sb$ (Mw = 659.31): C, 61.93; H, 4.13; F, 5.76. Found: C, 61.73; H, 4.26; F, 5.89%. IR (KBr) ν(cm^{-1}): 3061 (m, Ar–H), 1632 (s, C=O), 557 (s, Sb–C), 449 (s, Sb–O). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C) δ: 8.10 (m, 6H, Sb–PhH: H-3, H-5), 7.50 (m, 9H, Sb–PhH: H-2, H-4, H-6), 7.40 (d, J = 9.2 Hz, 2H, PhH: H-6), 6.94–7.05 (m, 4H, PhH: H-3, H-4), 2.29 (s, 6H, CH_3). ^{13}C NMR (100 MHz, $CDCl_3$, 25 °C) δ: 171.10 (COO), 138.59, 132.45, 131.16, 129.37 (Sb–PhC), 159.24, 134.83, 132.52, 129.37, 117.79, 116.81 (PhC), 20.65 (CH_3–Ph). ^{19}F NMR (376 MHz, $CDCl_3$, 25 °C) δ: −118.24.

2.2.4. Synthesis of [3-F-4-(CH_3)C_6H_3COO]SbPh$_4$ (**4**)

The reaction was carried out under nitrogen atmosphere. 3-Fluoro-4-methyl-benzoic acid (0.0385 g, 0.25 mmol) and sodium ethoxide (0.3 mmol) were added to a stirred solution of methanol (30 ml) in a Schlenk flask and stirred for 0.5 h. Tetraphenylantimony bromide (0.128 g, 0.25 mmol) was then added to the reactor and the reaction mixture was stirred for 12 h at room temperature. The colourless solid was recrystallized from a mixed of dichloromethane/petroleum ether (1:1) to give colourless crystals, yield: 76%, m.p. 156–158 °C. *Anal.* Calc. for $C_{32}H_{26}FO_2Sb$ (Mw = 583.28): C, 65.89; H, 4.49; F, 14.48. Found: C, 65.83; H, 4.51; F, 14.50%. IR (KBr) ν(cm^{-1}): 3066 (m, Ar–H), 1631 (s, C=O), 562 (s, Sb–C), 458 (s, Sb–O). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C) δ: 7.70 (m, 8H,

Sb–PhH: H-3, H-5), 7.47–7.50 (m, 14H, Sb–PhH: H-2, H-4, H-6 and PhH: H-2, H-6), 7.04 (t, J = 7.6 Hz, 1H, PhH: H-5), 2.22 (s, 3H, CH_3). ^{13}C NMR (100 MHz, $CDCl_3$, 25 °C) δ: 168.57 (COO), 137.71, 130.29, 127.25, 127.07 (Sb–PhC), 161.89, 135.17, 130.38, 128.96, 124.71, 115.61 (PhC), 14.60 (CH_3–Ph). ^{19}F NMR (376 MHz, $CDCl_3$, 25 °C) δ: −119.10.

2.2.5. Synthesis of [4-F-2-(CH_3)C_6H_3COO]$SbPh_4$ (**5**)

Complex **5** was prepared in the same way as **4**. The colourless solid was recrystallized from a mixed of dichloromethane/petroleum ether (1:1) to give colourless crystals, yield: 74%, m.p. 132–134 °C. *Anal.* Calc. for $C_{32}H_{26}FO_2Sb$ (Mw = 583.28): C, 65.89; H, 4.49; F, 14.48. Found: C, 65.81; H, 4.53; F, 14.57%. IR (KBr) ν(cm^{-1}): 3063 (m, Ar–H), 1627 (s, C=O), 560 (s, Sb–C), 461 (s, Sb–O). ^{1}H NMR (400 MHz, $CDCl_3$, 25 °C) δ: 7.68 (m, 8H, Sb–PhH: H-3, H-5), 7.25–7.51 (m, 14H, Sb–PhH: H-2, H-4, H-6 and PhH: H-5, H-6), 6.72 (t, J = 2.8 Hz, 1H, PhH: H-3), 2.18 (s, 3H, CH_3). ^{13}C NMR (100 MHz, $CDCl_3$, 25 °C) δ: 170.37 (COO), 135.23, 130.09, 128.79, 128.15 (Sb–PhC), 171.35, 140.47, 131.66, 126.30, 116.09, 111.56 (PhC), 21.09 (CH_3–Ph). ^{19}F NMR (376 MHz, $CDCl_3$, 25 °C) δ: −113.46.

2.2.6. Synthesis of [5-F-2-(CH_3)C_6H_3COO]$SbPh_4$ (**6**)

Complex **6** was prepared in the same way as **4**. The colourless solid was recrystallized from a mixed of dichloromethane/petroleum ether (1:1) to give colourless crystals, yield: 80%, m.p. 151–153 °C. *Anal.* Calc. for $C_{32}H_{26}FO_2Sb$ (Mw = 583.28): C, 65.89; H, 4.49; F, 14.48. Found: C, 65.81; H, 4.53; F, 14.51. 2.3. X-ray crystallography

Single crystals suitable for X-ray analysis were mounted on a fiber. All measurements were made on a Bruker Smart-1000 CCD diffractometer with graphite monochromated Mo Kα (λ = 0.71073 Å) radiation at 298(2) K using the ω and φ scans technique. The structures were solved by the direct method and different Fourier syntheses using the SHELXL-97 program, and refined by full-matrix least squares on F^2. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed at calculated positions with methyl C–H distances of 0.96 Å and aromatic C–H distances of 0.93 Å and riding on carrier atoms. Crystallographic data and experimental details of the structure determinations are listed in Table 1.

3. Results and discussion

3.1. IR spectra

The infrared spectroscopic data provide further support for the molecular constitution of the complexes. In the IR spectra of ligands, the stretching vibration bands of O–H appear at 3300–3500 cm^{-1}, which disappear from the spectra of the complexes

Symmetry code: (a) $-x, y, -z+3/2$.

1–**6**. The disappearance of ν(OH) indicates that deprotonation and subsequent coordination of the carboxylate group with antimony metal have occurred as expected. In addition, the frequencies of Sb–C deformations appear between 550 and 570 cm^{-1}, which are consistent with the literature [22]. The formation of Sb–O bond is further supported by the appearance to a weak to medium intensity band in the region 420–460 cm^{-1} and is assigned to νSb–O [23].

The IR stretching vibration frequencies of carbonyl groups in organoantimony carboxylates are very important for determining their structure: When there are interactions between the antimony atom and the carbonyl oxygen atoms of the carboxylate groups, the asymmetric absorption vibration frequencies [ν_{masy} (CO_2)] of carboxylate groups decrease, while the symmetric absorption vibration frequencies [ν_{msym} (CO_2)] increase [24]. Therefore, their differences [$\Delta\nu$ (CO_2)] decrease [25,26]. In the IR spectra of the complexes, the carboxylate bands are observed in the characteristic regions: ν_{masy} (CO_2) between 1606 and 1650 cm^{-1} and ν_{msym} (CO_2) between 1318 and 1384 cm^{-1}. On the basis of the difference in $\Delta\nu$ (CO_2), we can assume that there has been weak interaction or no interaction between the antimony atom and the carbonyl oxygen atoms of the carboxylate groups.

3.2. NMR spectra

In the ^{1}H NMR spectra of the free ligands, the single resonance of the –COOH group is observed at δ 10.85 ppm and is absent in the spectra of the complexes, thus indicating the deprotonation of the –COOH group and confirming that the carboxylate ligand coordinate to the antimony atom. The signals for CH_3 protons in the complexes appeared at δ 2.18–2.30 ppm as singlet. And the aryl protons of the complexes appeared at δ 6.72–8.10 ppm as multiplet and do not allow any clear interpretation. They shift downfields 0.1–0.4 ppm as compared with free ligands, as the electron density reduced when they coordinated with Sb atom.

The ^{13}C NMR spectra of all complexes show a significant downfield shift of all carbon resonances compared with the free ligand because of an electron density transfer from the ligand to the metal. In complexes **1**–**6**, ^{13}C signals for CH_3 appeared at δ 14.60–22.88 ppm. The ^{13}C signals due to aryl group were assigned which appeared at δ 111.56–171.35 ppm. And the signals for carbonyl appeared at δ 168.57–171.10 ppm.

In complexes **1** and **4**, 2 and **5**, 3 and **6**, the ^{19}F signals appeared at δ −118.08 to −119.10 ppm, −113.16 to −113.46 ppm, −118.24 to −119.38 ppm, respectively. The F signal appeared as singlet in all these derivatives. The F_3 signals appeared at higher field as compared to the F_4 chemical shift, indicating that the electron density

has been withdrawn due to the carboxylate group coordinated with the antimony atom. This observation is in accordance to previous studies that the carbon atoms of perfluorinated benzene ring feel high electron density due to diminished inductive effect of

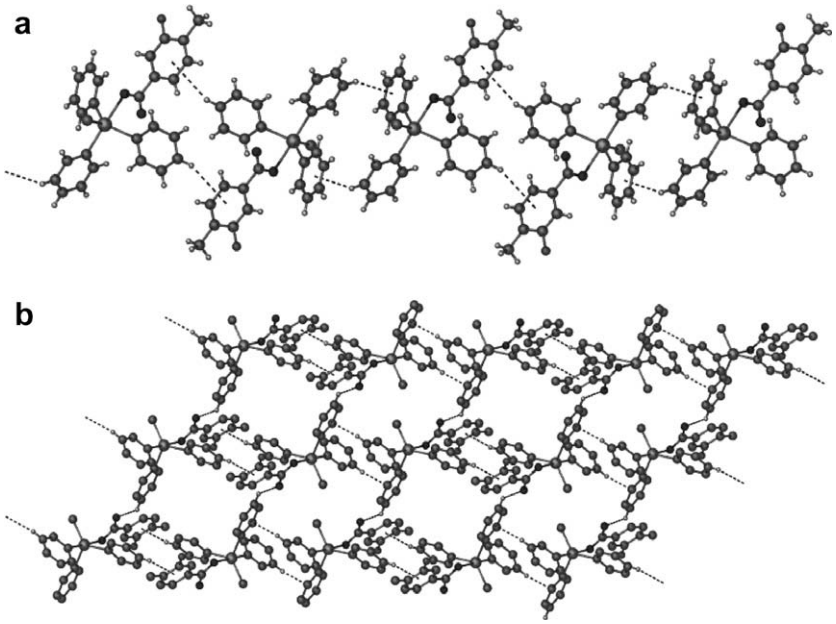

Fig. 5. The supramolecular structure of complex **4**, (a) showing C–H···π stacking interactions and (b) showing 2D framework via C–H···pi stacking interactions and C–H···O hydrogen bonds, for clarity, the carbon atoms which contact to the central Sb atoms stand for the phenyl groups.

fluorine atom and donation of electron density from the unshared p electron of fluorine to the π system of the ring [27,28].

3.3. Crystal structure of [3-F-4-(CH_3)C_6H_3COO]$_2$$SbPh_3$ (**1**)

Selected bond distances and angles of complex **1** are given in Table 2 and the molecular structure is shown in Fig. 1.

As is shown in Fig. 1, the central antimony atom is five-coordinated with a slightly distorted trigonal bipyramidal geometry. Around the central Sb(1) atom, C(17), C(23) and C(29) occupy the equatorial plane, while O(1) and O(3) lie in axial sites. The sum of the equatorial angles is 360.07° [C(23)–Sb(1)–C(17) 106.7(2)°, C(23)–Sb(1)–C(29) 143.6(2)°, C(17)–Sb(1)–C(29) 109.8(2)°] and the corresponding axial–Sb–axial angle is 174.5(1)°, which suggests that it has slightly deviated from an ideal trigonal bipyramidal geometry. The Sb–O bond lengths in organoantimony compounds are extremely variable, ranging from 1.935 Å in triphenylstibine oxide [29] to 2.506 Å in tetraphenylstibonium benzenesulphonate hydrate [30]. The Sb–O distances [Sb(1)–O(1) 2.122(3) Å and Sb(1)–O(3) 2.127(3) Å] in complex **1** lie within this range. The Sb–C bond distances [Sb(1)–C(17) 2.107(5) Å, Sb(1)–C(23) 2.102(5) Å, Sb(1)–C(29) 2.112(5) Å] fall in the normal range for Sb–C(phenyl) bonds (2.10–2.13 Å).

3.4. Crystal structure of [5-F-2-(CH_3)C_6H_3COO]$_2$$SbPh_3$ (**3**)

Selected bond distances and angles of complex **3** are given in Table 2. The molecular structure and 1D extended chain structure are shown in Figs. 2 and 3, respectively.

As is shown in Fig. 2, the structure consists of discrete monomeric units with both carboxylate bound to the antimony atom through oxygen [Sb(1)–O(1) 2.136(2) Å]. The coordination environment around the antimony can be described as slightly distorted trigonal bipyramidal with equatorial Sb–C bonds and axial oxygen atoms [O(1)–Sb(1)–O(1)a angles of 175.8(1)°]. The SbC_3 unit is planar (the sum of the C–Sb–C angle is 359.99°) and C–Sb–O angles lie in the range of 87.9(6)–91.4(1)°. The average Sb–O bond of 2.136(2) Å is approximately equal to the sum of the covalent radii of Sb and O (2.07 Å), while the average Sb–C bond of 2.122 Å is slightly shorter than the sum of the covalent radii of Sb and C (2.18 Å) [31], as expected for the axial and equatorial positions of a trigonal bipyramid.

In the crystal structure, which is shown in Fig. 3, molecules are connected by intermolecular C–H···O hydrogen-bonding interactions forming a 1D extended chain structure. It can be seen that each discrete molecule link with other monomers through two intermolecular C(18)–H(18)···O(2) hydrogen bonds and a 8-membered heart-shaped ring is formed by the two such hydrogen bonds. The H(18)···O(2), C(18)···O(2) distance and the C(18)–H(18)···O(2) angle are 2.52 Å, 3.246 Å, 135.1°, respectively.

3.5. Crystal structure of [3-F-4-(CH_3)C_6H_3COO]$SbPh_4$ (**4**)

Selected bond distances and angles of complex **4** are given in Table 2. The molecular structure and 2D network structure are depicted in Figs. 4 and 5, respectively.

As is shown in Fig. 4, there are four planar phenyl rings and one carboxylate ligand in the inner coordination sphere of complex **4**.

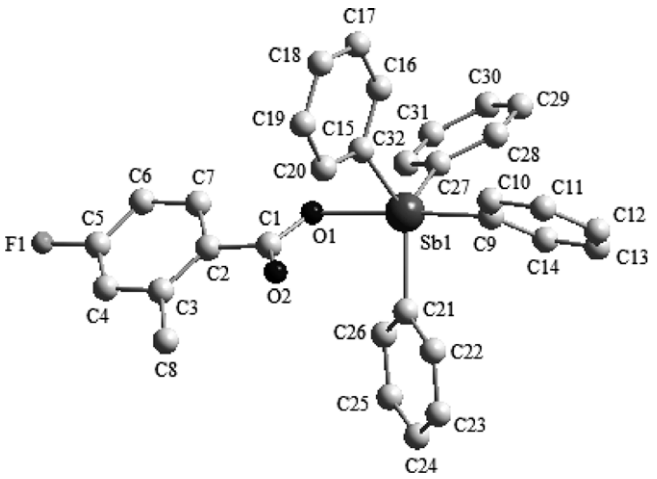

Fig. 6. The molecular structure of complex **5**.

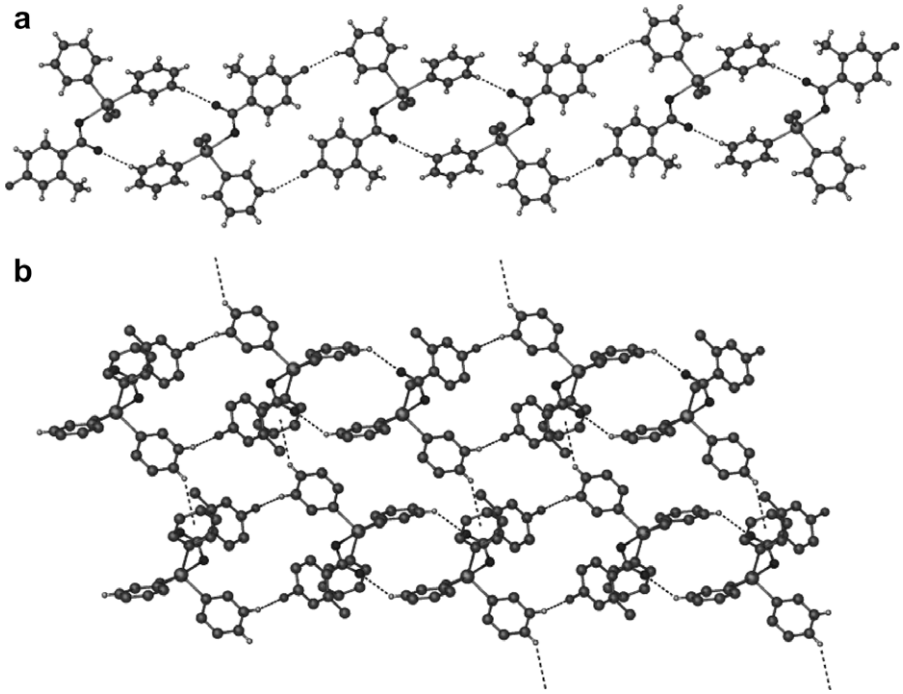

Fig. 7. The supramolecular structure of complex **5**, (a) showing C–H···O and C–H···F hydrogen bonds and (b) showing 2D framework via C–H···π stacking interactions and C–H···O, C–H···F hydrogen bonds, for clarity, the carbon atoms which contact to the central Sb atoms stand for the phenyl groups.

These exhibit a distorted trigonal bipyramidal neighbouring environment of the antimony atom (with the coordination number equal to 5). Three phenyl rings forming the short chemical bonds Sb(1)–C(15), Sb(1)–C(21), Sb(1)–C(27) (2.117(3), 2.127(3), 2.116(3) Å) are in the equatorial plane of the discussed trigonal bipyramid, while the fourth, less strongly bound, phenyl ring: Sb(1)–C(9) 2.173(3) Å and the carboxylate group: Sb(1)–O(1) 2.275(2) Å define two axial positions. The C(9)–Sb(1)–O(1) angle is equal to 178.0(8)° that is close to the corresponding value in the ideal trigonal bipyramid (TBP) – 180°.

The salient feature of the supramolecular structure of complex **4** is dominated by intramolecular C–H···O hydrogen-bonding interactions and C–H···π stacking interactions. The intermolecular edge-to-face C–H···π stacking interactions has been identified between the C(11), C(18) and the phenyl ring, showing in Fig. 5a. C(11)–H(11)···Cg(1) [Cg(1) center of the C(21) to C(26), C(11)···Cg(1) = 3.533 Å, H(11)···Cg(1) = 2.716 Å, C(11)–H(11)···Cg(1) = 147.18°] and C(18)–H(18)···Cg(2) [(Cg(2) center of the C(2) to C(7), C(18)···Cg(2) = 4.410 Å, H(18)···Cg(2) = 3.534 Å, C(18)–H(18)···Cg(2) = 157.93°] and C(24)–H(24)···O(2) [C(24)···O(2) = 3.309(5) Å, H(24)···O(2) = 2.55 Å, C(24)–H(24)···O(2) = 138.5°)] forming a 2D network structure (Fig. 5b). Interestingly, as shown in Fig. 5, the 14-membered cycle and 20-membered macrocycle are formed by the two intermolecular C–H···π stacking interactions between discrete molecules. To our knowledge, this similar structure has not been reported so far.

3.6. Crystal structure of [4-F-2-(CH_3)C_6H_3COO]$SbPh_4$ (**5**)

Selected bond distances and angles of complex **5** are given in Table 2. The molecular structure and 2D network structure are depicted in Figs. 6 and 7, respectively.

The molecular structure of complex **5** is illustrated in Fig. 6. The coordination about the antimony atom is only slightly distorted from a regular trigonal bipyramidal geometry. The angle C(9)–Sb(1)–O(1) 175.3(2)° is close to a linear arrangement. The sum of the angles subtended at the antimony atom in the trigonal plane is 358.0°, so that the atoms Sb(1), C(15), C(21), and C(27) are almost in the same plane. The Sb–C distances [2.106(8)–2.179(7) Å] are equal within experimental error and close to the single-bond value for trigonal bipyramidal antimony [32]. And the Sb–O distance in complex **5** [2.261(5) Å] lies within the range from 1.935 to 2.506 Å [29,30], showing that the oxygen atom is strongly bound to the central Sb atom.

It is worthwhile to note that the supramolecular structure of the complex **5** is linked into a 2D network structure through intramolecular C–H···O, C–H···F hydrogen-bonding interactions and C–H···π stacking interactions. The intermolecular edge-to-face C–H···π stacking interactions have been identified between the C(30) and the phenyl ring, showing in Fig. 7b. As shown in Fig. 7a, 1D infinite chain structure is linked by intermolecular C–H···O and C–H···F hydrogen-bonding interactions. It is noteworthy that complex **5** contains two types of macrocycles: one is 16-membered macrocycle which is formed by two intermolecular C–H···O [C(11)···O(2) = 3.212 Å, H(11)···O(2) = 2.59 Å, C(11)–H(11)···O(2) =

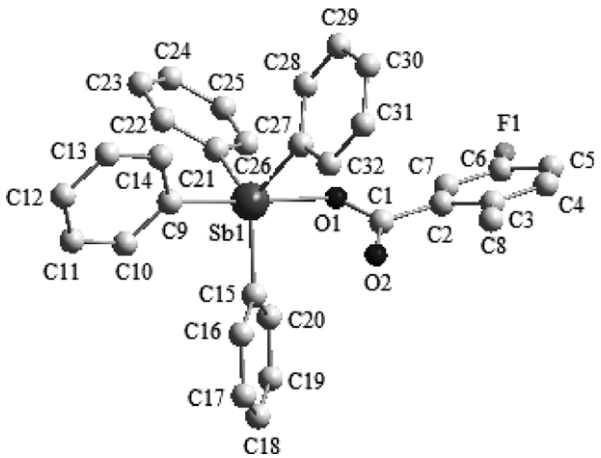

Fig. 8. The molecular structure of complex **6**.

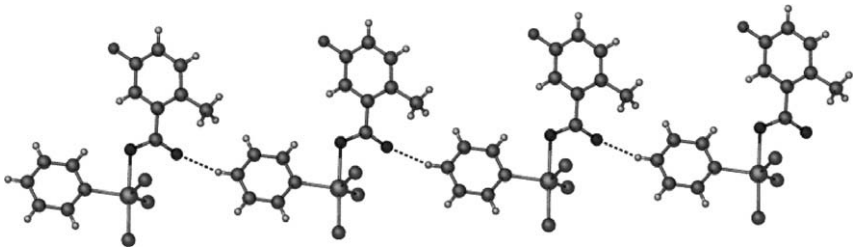

Fig. 9. The supramolecular structure of complex **6**, showing a 1D extended chain structure linked by intermolecular C–H···O contacts, for clarity, the carbon atoms which contact to the central Sb atoms stand for the phenyl groups.

125.0°)] hydrogen bonds between two discrete molecules, the other is 24-membered macrocycle which is formed by two intermolecular C–H···F [C(31)···F(1) = 3.245 Å, H(31)···F(1) = 2.40 Å, C(31)–H(31)···F(1) = 151.7°)] hydrogen bonds between two discrete molecules. Furthermore, as shown in Fig. 7b, C(30)–H(30)···Cg(1) [Cg(1) center of the C(21) to C(26), C(30)···Cg(1) = 4.012 Å, H(15)···Cg(1) = 3.202 Å, C(15)–H(15)···Cg(1) = 146.59°] forming a head-to-tail 2D network.

3.7. Crystal structure of [5-F-2-(CH_3)C_6H_3COO]$SbPh_4$ (**6**)

Selected bond distances and angles of complex **6** are given in Table 2. The molecular structure and 1D extended chain structure are depicted in Figs. 8 and 9, respectively.

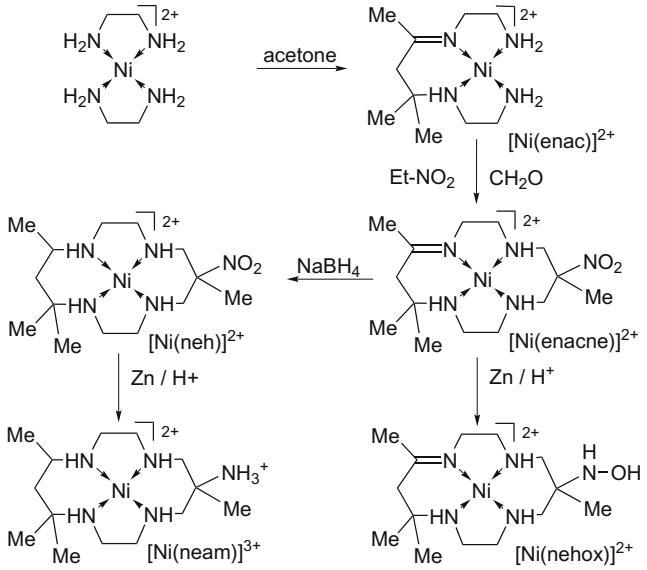
In the crystal structure of complex **6**, which is shown in Fig. 8, the coordination geometry around the antimony center is best described as a distorted trigonal bipyramid, in which one carboxylate group and one phenyl ring occupy the apical sites. The C(9)–Sb(1)–O(1) angle is 176.4(1)°. In the equatorial plane of the structure, the C(15)–Sb(1)–C(21), C(21)–Sb(1)–C(27) and C(27)–Sb(1)–C(15) angles are 115.9(1)°, 108.7(1)° and 131.3(1)°, respectively, which are close to the normal 120°. The Sb(1)–C(15), Sb(1)–C(21), Sb(1)–C(27) bond distances [2.120(3), 2.122(3), 2.126(3) Å] are similar to the corresponding distances in $[SbPh_3(O_2CCF_3)]_2O$ [2.100(6)–2.112(6) Å] [33]. The Sb–O distance [2.2556(19) Å] does not lie within the range from 1.935 to 2.506 Å, but shorter than the sum (3.6 Å) of the van der Waals radii of antimony and oxygen atoms (2.2 and 1.4 Å, respectively) [34], showing that the oxygen atom is weakly bound to the central Sb atom.

In Fig. 9 the supramolecular structure exhibits a zigzag 1D infinite chain structure via intermolecular C–H···O hydrogen-bonding interactions. It can be seen that each discrete molecule link with other monomers through one intermolecular C(24)–H(24)···O(2) hydrogen bonds. The H(24)···O(2), C(24)···O(2) distance and the C(24)–H(24)···O(2) angle are 2.34 Å, 3.209 Å, 154.7°, respectively.

4. Conclusions

The molecular structures of six new organoantimony(V) complexes have been reported. Although the various isomers of fluoromethylbenzoate ligands have the same coordination capacity function as a rigid bridging carboxylate binding the antimony atoms through oxygen atoms, and antimony atoms are in a trigonal bipyramidal environment, different intermolecular interactions which lead to aggregation and assembly of these complexes into 1D or 2D supramolecular frameworks are observed in the solid state.

Supplementary data



CCDC 713406, 713405, 715112, 720255 and 715111 contain the supplementary crystallographic data for complexes **1**, **3**, **4**, 5 and **6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Showing preparations of $[Ni(enac)]^{2+}$, $[Ni(enacne)]^{2+}$, $[Ni(neh)]^{2+}$, $[Ni(nehox)]^{2+}$ and $[Ni(neamH)]^{3+}$.

been reported for compounds of Co(III) [26] and Ni(II) [27] which have ligands with hydroxylamino-nitrogen atoms coordinated.

The nitro function of the cyclic tetraamine cation $[Ni(neh)]^{2+}$ is reduced by zinc/acid under similar conditions to form the 13-amine-substituted cyclic amine cation (13-amine-5,5,7,13-tetramethyl-1,4,8,11-tetraazacyclotetradecane-κ^4)nickel(II), $[Ni(neam)]^{2+}$. This was isolated from acid solution as the tetrachlorozincate chloride salt, with the 13-amino-substituent protonated, $[NineamH)][ZnCl_4]Cl{\cdot}2.25H_2O$, for which the structure is reported.

Structures have been determined for the related compounds $[Ni(enacne)][ZnCl_4]$* [9], $[Cu(enacnp)(OH_2)](ClO_4)_2$* [10], $[Cu(enacne)(NCS)]ClO_4$* [28] and $[Cu(enacnp)][Ni(CN_4)]{\cdot}H_2O$* [11] and β-$[Ni(neh)](ClO_4)_2{\cdot}H_2O$*, β-$[Ni(neh)](ClO_4)_2$, α-$[Ni(neh)](ClO_4)_2$, β-$[Ni(neh)]_2[ZnCl_4][ZnCl_3(OH_2)]_2{\cdot}H_2O$*, *catena-trans*-β-$[Ni(neh)(\mu\text{-}C_2O_4)]_n{\cdot}3nH_2O$* and β-$[Cu(nph)Cl]ClO_4$* (where enacnp and nph are the 13-ethyl homologues and α indicates the 1*R*,4*R*,8*R*,11*R* nitrogen configuration (V) and β the 1*R*,4*R*,8*S*,11*S* configuration (III) [12]. The structures marked * have disorder arising from co-crystallisation of enantiomers, manifest as superimposed 5,7,7-trimethyl and 5,5,7-trimethyl configurations (or 5,7,7-trimethyl–5-ene and 5,5,7-trimethyl-7-ene configurations), which results in disorder in the location of the axial component of the gem-dimethyl function, with the axially oriented methyl group is distributed over partially occupied sites on ring atoms C5 and C7.

The preparation of 6-amino-1,4,8,11-tetraazacyclotetradecane (L) has been reported and its coordination properties with nickel(II) described [29]. The structure of $[Ni(L)](ClO_4)_2$ shows nickel(II) in square-pyramidal coordination, with the four N–H groups of the cyclic tetraamine all oriented to the same side of the N_4 plane (configuration I of the nitrogen centres) with the amino-substituent group coordinated axially on the opposite side. The amines 6-amino-6-methyl-1,4,8,11-tetraazacyclotetradecane [17–21] and 6-amino-6-methyl-13-hydroxyl-1,4,8,11-tetraazacyclotetradecane [22] have been prepared by zinc/acid reduction of the nitro function of the 6-nitro substituted copper(II) compounds and structures reported for copper(II), cobalt(III) and chromium(III) compounds. The M(III) compounds commonly have the amine substituent coordinated.

2. Results

2.1. The preparation and structure of (13-hydroxylamino-5,5,7,13-tetramethyl-1,4,8,11-tetraazacyclotetradec-4-ene-κ^4)nickel(II) tetrachlorozincate(II), [Ni(nehox)][$ZnCl_4$]

The cation $[Ni(enacne)]^{2+}$ is readily reduced by zinc in dilute acid to form $[Ni(nehox)]^{2+}$, isolated as the orange coloured singlet ground state tetrachlorozincate salt. The structure of [Ni(nehox)][$ZnCl_4$] has been determined by X-ray diffractometry, see Section 4.2 for details.

The asymmetric unit of [Ni(nehox)][$ZnCl_4$] contains one square-planar (13-hydroxylamino-5,7,7,13-tetramethyl-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II) cation (see Fig. 1) and one tetrahedral tetrachlorozincate anion. The dimensions about the nickel(II) ion are normal for singlet ground state square-planar nickel(II), see Table 1. The hydroxylamino group is axially oriented on the chair conformation six-membered chelate ring, with the N–OH group oriented away from the nickel(II) ion, in projection lying approximately midway between C14 and C13.

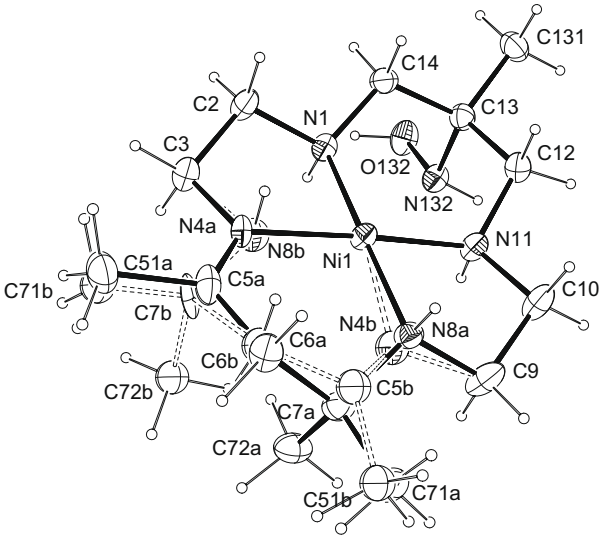

Fig. 1. The cation of [Ni(nehox)][$ZnCl_4$], drawn [31] with displacement ellipsoids at the 50% confidence level. Hydrogen atoms are shown as circles of arbitrary radii. Bonds to the minor disorder components are shown as dashed lines.

Table 1
Selected dimensions (Å/°) for [Ni(nehox)][$ZnCl_4$].

Atoms	Distance/angle	Atoms	Distance/angle
Ni1–N1	1.936(1)	N4A–C5A	1.501(3)
Ni1–N4A	1.937(2)	N4B–C5B	1.501(3)
Ni1–N4B	1.937(3)	C7A–N8A	1.263(3)
Ni1–N8A	1.917(2)	C7B–N8B	1.263(4)
Ni1–N8B	1.95(1)	O132–N132	1.449(2)
Ni1–Cl4[a]	2.9058(4)	C13–N132	1.479(2)
Ni1–Cl2	3.7118(4)		
N1–Ni1–N4A	85.45(7)	N4B–Ni1–N8B	89.9(6)
N1–Ni1–N4B	173.3(8)	N4B–Ni1–N11	87.4(6)
N1–Ni1–N8A	174.9(2)	N8A–Ni1–N11	86.5(1)

N4A–Ni1–N11	176.83(8)	Ni1–Cl2–Zn1	120.98(1)
Cl2–Ni1–Cl4[a]	151.25(1)	Ni1–Cl4[a]–Zn1[a]	117.96(1)

Symmetry operation $A = x + ½, -y + ½, z + ½$.
[a] Zn1–Cl: 2.2478(4)–2.3082(4) Å; Cl–Zn1–Cl: 103.90(2)–113.17(2)°.

The cation shows disorder arising from co-crystallisation of enantiomers of the chiral centre at C13 (chiral because of the different substitutions at C5 and C7). This leads to disorder in location of the axial component of the gem-dimethyl group, with partial occupancy of sites axial with respect to C5 and C7. The disorder components have the N4···N8 trimethyl substituted amine-imine chelate ring reversed, with atoms labelled N4A–C5A(C51A)–C6A–C7A(C71A, C72A)–N8A for the major component and N4B–C5B(C51B)–C6B–C7B(C71B, C72B)–N8B for the minor component. All the atoms of the two disorder components were resolved and refined with common s.o.f. of 0.766(3) for the 1*S*,8*R*,11*R*,13*S*-configuration and 0.234(3) for the 1*R*,8*S*,11S,13*R*-configuration. Two sites were resolved for nitrogen atoms N4 and N8, with N–C distances and associated bond angles corresponding with the imine character of the N4–C5 and N4A–C5A bonds and the amine character of the C7–N8 and C7A–N8A bonds, see Table 1. The r.m.s. displacements from the best N_4 donor atom plane N1,N4A,N8A,N11 are ±0.024(2) Å with Ni1 0.060(2) Å from the plane and for the plane N1,N4B,N8B,N11 are ±0.038(7) Å with Ni1 0.145(6) Å from the plane. Displacements of other atoms from the planes defined by Ni,N4A,N8A,N11 and N1,N4B,N8B,N11 are listed in Table S1 of the Supplementary data.

The cation has approximate mirror symmetry through C13, N131, C131, Ni1 and C6/C6A, as is usual for square-planar cyclam-like azamacrocycle compounds, with N1–H1 and N11–H11 oriented to the same side of the NiN_4 'plane' as the hydroxylamine group and the partial occupancy axial methyl groups C72A and C72B, with the partial occupancy N4A–H4A and N4B–H4B groups oriented to the other side of the coordination 'plane'.

The $[Ni(nehox)]^{2+}$ cations and $[ZnCl_4]^{2-}$ anions are linked into chains, with N–H···Cl and O–H···Cl hydrogen bonds (see Table S2 of the Supplementary data) and with weak approximately axial interactions, Ni···Cl4 ($-x+½, -y+½, -z-½$) = 2.9058(4) Å, on the less crowded side of the NiN_4 'plane' and Ni···Cl2 = 3.7118(4) Å) on the other side.

2.2. The preparation and structure of (5,5,7,13-tetramethyl-13-azonium-1,4,8,11-tetraazacyclotetradecane)nickel(II) chloride tetrachlorozincate 2.25 hydrate, [Ni(neamH)][ZnCl$_4$]Cl·2.25H$_2$O

The cation $[Ni(neh)]^{2+}$ is readily reduced by zinc in dilute acid to form (13-azonium-5,5,7,13-1,4,8,11-tetraazacyclotetradecane) nickel(II), $[Ni(neam)]^{2+}$, isolated from acid solution as the orange coloured singlet ground state tetrachlorozincate chloride salt with the 13-amino-substituent protonated, [Ni(neamH)][$ZnCl_4$]Cl·2.25H_2O, for which the structure has been determined by X-ray diffractometry, see Section 4.2 for details.

The asymmetric unit contains two (tetraazamacrocycle)nickel(II) cations (cation 1 with ring atoms N1–C14 and cation 2 with ring atoms N21–C34, two tetrachlorozincate anions, (anion 1 with Zn1 and Cl1–Cl4 and anion 2 with Zn2 and Cl5–Cl8) and two independent chloride anions (Cl9 and Cl0), see Fig. 2 and Table 2 for dimensions.

The triply charged cations have 13-azonium-5,5,7,13-tetramethyl-1,4,8,11-tetraazacyclotetradecane macrocycles in square-planar coordination to singlet ground state nickel(II). The N_4 donor atom groups are tetrahedrally twisted, (r.m.s. displacements from best N_4 planes N1,N4,N8,N11 and N21,N24,N28,N31 are ±0.068(1) Å and ±0.031(1) Å, respectively, with Ni1 and Ni2 displaced from these planes by 0.031(1) Å and 0.013(1) Å, respectively). See Fig. 3 for a representation of the cation 1. Both macrocycles have the 1*R*,4*R*,8*S*,11*S* configuration III of the coordinated nitrogen centres which is usual for planar coordination of cyclam-like macrocycles, with the six-membered chelate rings in chair and the five-membered chelate rings in gauche conformations (see Table S3 of Supplementary data for displacements of atoms from NiN_2 chelate planes). The 13-azonium substituents of both cations are axially oriented, on the same side of the N_4 plane as the axial methyl substituent. The closest axial interactions for the nickel(II) ions are with tetrachlorozincate(II) chloride ions

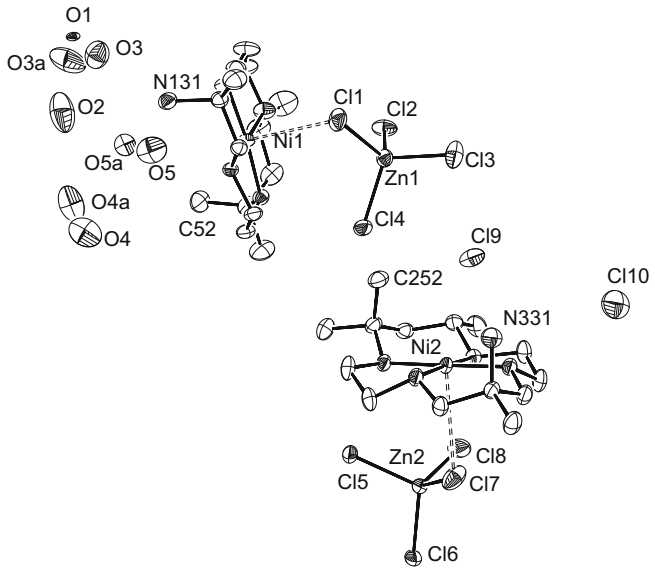

Fig. 2. The asymmetric unit of [Ni(neamH)][ZnCl4]Cl·2.25H_2O, drawn as for Fig. 1. Hydrogen atoms and minor disorder components are omitted for clarity.

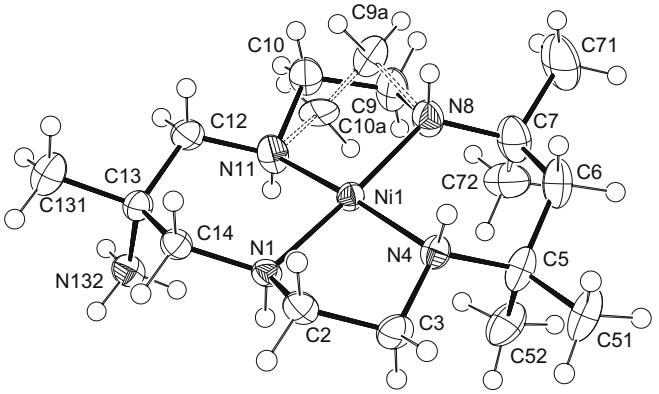

Fig. 3. The cation including Ni1 of [Ni(neamH)][$ZnCl_4$]Cl·2.25H_2O, drawn as for Fig. 1. Bonds to the minor disorder components C9a, C10a and C72 are shown as dashed lines. The cation including Ni2 is similar, but without the disorder of C9 and C10.

Table 2
Selected dimensions (Å, °) for [Ni(neamH)][$ZnCl_4$]Cl·2.25H_2O.

Atoms, cation 1	Dimension	Atoms, cation 2	Dimension
Ni1–N1	1.923(2)	Ni2–N21	1.926(2)

Symmetry operation $A = x-1, y+1, z$.

{Ni1···Cl2 = 3.059 Å and Ni2···Cl7 = 3.234 Å}, both on the side of the N_4 planes remote from the axial substituents. There are longer 'off axis" interactions with free chloride ions on the other side, with Ni1···Cl10 = 3.561 and Ni2···Cl9 = 3.442 Å.

The cations show disorder arising from co-crystallisation of enantiomers, similar to that shown by the previous compound. This is manifest as disorder in the location of the axial component of the gem-dimethyl group, with significant electron density in the axial substitution sites near C5 and C7, modelled as partial occupancy methyl groups. For the cation 1 the methyl group in the axial site near C5, $(C52)H_3$ has s.o.f. = 0.87(1) and that in the site near C7, $(C272)H_3$ has s.o.f. = 0.13(1) and for the cation 2 the methyl group $(C252)H_3$ has s.o.f. = 0.72(1) and the group $(C252)H_3$ has s.o.f. = 0.28(1). The major component for both cations has the configuration, 1*R*,4*R*,7*S*,8*S*,11*S*,13*R*.

The cation 1 also has disorder of one of the five-membered chelate rings, modelled with alternative gauche conformations {s.o.f. for sites $(C9)H_2$ and $(C10)H_2$ = 0.78(2) and s.o.f. for $(C9A)H_2$ and $(C10A)H_2$ = 0.22(2)}. The conformation usually observed for planar cyclam complexes, with approximate mirror symmetry through C6, Ni1 and C13, would have sites C9 and C10 occupied. The similarity of the s.o.f. for $(C52)H_3$ (0.87(1) and $(C9)H_2$ (0.78(2) suggests that these site occupancies are probably correlated.

Several residual electron density peaks were assigned as oxygen of water molecules. Refinement of the s.o.f. indicated that site O1, which lies on a centre of symmetry has s.o.f. = 0.5 whilst site O2 has s.o.f. = 1, within the uncertainties, so the s.o.f. of these atoms were fixed at these values for final refinement. Six other isolated sites occurred as pairs which had s.o.f. which were complementary within the uncertainties, and were assigned as water molecules O3, O4 and O5 with disordered sites. Sites O3 (s.o.f = 0.78(1) and O3A have separation 1.81(2) Å; O4 (s.o.f. = 0.72(1) and O4A, have separation 0.94(2) Å and O5 (s.o.f. = 0.80(1) and O5A have separation 0.69(3) Å. The C72 site is 2.76(1) Å from the O4A site and 3.67(1) Å from the O4B site, whilst the C272 site is 2.39(1) Å from the O3A site and 3.93(1) Å from the O3B site. Steric repulsion arising from occupancy of the C72 site would give preference to the more remote O4A site, and that of the C272 site to the more remote O3A site. The O5 sites are close to the O4 sites and presumably linked to them by hydrogen bonding so that occupation of the O4B site would give preference to the closer O5B site {O4B···O5B = 2.264 Å}.

The asymmetric unit thus has 4.5 water molecules for 2 cations (assuming that the half-occupancy water molecule on the inversion centre is not an artifact), making the compound a 2.25 hydrate. Not all the water hydrogen atoms were located.

Hydrogen bonds link the cations, anions and water molecules. The azonium ions are each hydrogen bonded to the water molecule including O2 ($-x, -y, -z$) and a free chloride ion. Hydrogen bonds are listed in Table S4 of the Supplementary data.

3. Discussion

The reduction of the nitro-function of $[Ni(enacne)]^{2+}$ to form the hydroxylamino function by zinc/acid is somewhat surprising, as the nitro-functions of a variety of related cations are reduced to amine functions by zinc/acid [1,3–6,13–22]. The related di-nitro-substituted cation 6,13-dimethyl-6,13-dinitro-1,4,8,11-tetraazacyclotetradecane)nickel(II) [1,30], which is reduced by catalytic hydrogenation to form the 6,13-diamine cation [30], is also readily reduced to the diamine-substituted cyclic tetramine by zinc/acid.

The hydroxylamine function is relatively uncommon and few structures of compounds with the function have been reported, see the Supplementary data for a listing of structures reported in the Cambridge Crystallographic Data Base.

The hydroxylamine group for $[Ni(nehox)][ZnCl_4]$ is not coordinated and attempts to prepare compounds with the group coordinated were unsuccessful, although similarly structurally situated amino groups readily coordinate to nickel(II) [30].

The nitro group of the nitro-substituted cyclic tetraamine cation $[Ni(neh)]^{2+}$ is reduced by zinc/acid to form the amine-substituted tetraamine cation $[Ni(neam)^{2+}$, isolated as $[Ni(neamH)][ZnCl_4]Cl{\cdot}2.25H_2O$. The non-protonated cation $[Ni(neam)]^{2+}$ was formed in solution by adding 3 mol proportions of $NaHCO_3$ and filtering off the $ZnCO_3$. The solution was yellow, indicating that the primary amino group was not coordinated. Attempts to isolate this cation as a crystalline product were unsuccessful. This behaviour is in contrast to that reported for 6-amino-1,4,8,11-tetraazacyclotetradecane (L) [29]. This amine reacted with $[Ni(H_2O)_6](ClO_4)_2$ in water at pH 8.5 and the isolated salt $[Ni(L)](ClO_4)_2$ had a cation with the amine substituent group coordinated axially, with the nitrogen configuration I (1*R*,4*S*,8*R*,11*S*) with all four N–H groups on the same side of the N_4 plane. In acid this formed a metastable square-planar cation with the amine group protonated, which slowly isomerized to the stable configuration III cation with a configuration and conformation analogous to $[Ni(neamH)]^{3+}$. This process was reversed in base. The related amine-substituted cyclic amines 6-amine-6-methyl- [13–21] and 6-amine-6-methyl-13-hydroxy-1,4,8,11-tetraazacyclotetradecane [22] form compounds with the amine substituent coordinated, though no compounds of nickel(II) have been described.

Both the $[Ni(nehox)]^{2+}$ and $[Ni(neamH)]^{3+}$ structures reported show disorder arising from reversal of the trimethyl-substituted 1,3-amine-imine or 1,3-diamine chelate ring, as also observed for a number of related compounds (above). The main structural difference between the disorder components is in the location of the axial methyl substituent, and this apparently has only a small effect on the packing of the cell components, with the s.o.f. ratio of the components typically about 0.7:0.3. For $[Ni(nehox)]^{2+}$, as for $[Ni(enacne]^{2+}$, the reversed 1,3-amine-imine chelate ring of the disorder components would have conformational asymmetries arising from the differences between the trigonal imine and tetrahedral amine donor groups, which would extend to the linking chelate rings. For most of the compounds showing this disorder only the axial methyl substituents of the disorder components were resolved, but for $[Ni(nehox)][ZnCl_4]$ all the atoms of the disorder components of the 1,3-amine-imine chelate ring were resolved. For the $[Ni(neamH)]^{3+}$ cation, as for $[Ni(neh)]^{2+}$, the reversed1,3-diamine chelate ring components would have smaller differences in conformation, so the disorder components were not resolved for $[Ni(neamH)][ZnCl_4]Cl{\cdot}2.25H_2O$ (though some atoms were resolved for $[Ni(neh)(\mu\text{-}C_2O_4)]_n{\cdot}3nH_2O$ [12]). For one cation present for $[Ni(neamH)][ZnCl_4]Cl{\cdot}2.25H_2O$ the disorder extends to an adjacent chelate ring and apparently also determines the location of water molecules.

The nitro-methyl substituted C13 atom of $[Ni(enacne)]^{2+}$ is a chiral centre, and reductions of the nitro-function to hydroxylamino or amine functions generate no new chirality. Reduction of the C7–N8 imine function of $[Ni(enacne)]^{2+}$ generates a new chiral centre at C7, and in principle a pair of diastereoisomerides (discounting the labile chiral coordinated secondary amine centres). Only one reduction product, $[Ni(neh)]^{2+}$, was isolated, in high yield [12], and the chirality of this is retained when the nitro-function of $[Ni(neh)]^{2+}$is reduced to form $[Ni(neam)]^{2+}$.

4. Experimental

The compounds $[Ni(enacne)](ClO_4)_2$ [11] and $[Ni(neh)](ClO_4)_2$ [12] were prepared as previously reported.

4.1. Synthesis

4.1.1. (13-Hydroxylamino-5,7,7,13-tetramethyl-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II) tetrachlorozincate, [Ni(nehox)][ZnCl$_4$]

(5,7,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradec-4-ene)nickel(II) perchlorate (2 g) was dissolved in 1 mol dm^{-1} hydrochloric acid (50 cm^3). Mercuric chloride (5 mg) was added, followed by zinc wool (2 g). The mixture was stirred for 1 d, then filtered and rotary-evaporated. The orange product sometimes crystallised, though crystallisation was usually slow unless the solution was seeded with the product. More usually the solution evaporated to leave an orange gum. This was heated with methanol, when the orange coloured *product* crystallised. This was filtered off and recrystallised by evaporation from water. *Anal. calc.* for $C_{14}H_{32}Cl_4N_5NiOZn$: C, 30.4; H, 6.0; N, 12.7. Found: C, 30.5; H, 5.6; N, 12.6%. IR spectrum (band maxima/cm^{-1}) ν(OH), 3384, ν(NH), 3243, 3204, 3153; ν(C=N), 1647.

4.1.2. (13-Azonium-5,5,7,13-tetramethyl-1,4,8,11-tetraazacyclotetradecane)nickel(II) tetrachlorozincate chloride 2.25 hydrate, [Ni(neamH)][ZnCl$_4$]Cl·2.25H$_2$O

This orange compound was prepared by reducing (5,5,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradecane)nickel(II) perchlorate, as for the previous compound. The orange *product* was recrystallised by evaporation from water. Nucleation was generally very slow unless the solution was seeded. *Anal. Calc.* for $C_{14}H_{38.5}Cl_5N_5NiO_{2.25}Zn$: C, 27.4; H, 6.3; N, 11.4 Found: C, 27.4; H, 6.2; N, 11.3%. IR spectrum (band maxima/cm^{-1}) ν(OH), 3370s, ν(NH), 3243, 3189, 3209, 3165; 3155; δ(HOH), 1646w.

4.2. Crystallography

Diffraction data was collected by using a Bruker CCD diffractometer with Mo Kα radiation (0.71073 Å) from a fine-focus sealed tube with graphite monochromator, using phi and omega scans, and absorption corrections applied [32,33]. The structure was solved by direct methods and full-matrix refined [34], with anisotropic parameters for all non-H atoms. The components of the disordered chelate ring were located from difference maps and refined as separate parts with common s.o.f. Hydrogen atoms are in calculated positions (except for H132 which was located from difference syntheses) and refined using a riding model. See Table 3 for details. SADI restraints were applied to N4A–C5A, N4B–C5B and C7A–N8A, C7b–N8B for [Ni(nehox)][ZnCl$_4$].

Appendix A. Supplementary data

CCDC 711582 and 711583 contain the supplementary crystallographic data for [Ni(nehox)][ZnCl$_4$] and [Ni(neamH)][ZnCl$_4$]Cl·2.25H$_2$O. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.06.084.

2. Experimental

2.1. Materials and instrumentations

All reagents were obtained from Sigma Aldrich and were used without purification. 4′-(6-Hydroxyhexylthio)-1,2-dicyanobenzene and 3′-(6-hydroxy hexylthio)-1,2-dicyanobenzene were prepared according to literature procedures [15,16]. FTIR (KBr) were recorded on a Shimatzu IR-prestige-2 spectrophotometer. Elemental analysis (C, H, N and S) was performed at the instrumental Analysis Laboratory of Marmara University. Routine UV–Vis spectra were recorded on an Agillent Model 8453 diode array spectrophotometer. Matrix-assisted laser desorption/ionisation time-of-flight (MALDI-TOF) mass spectra (MS) were measured using a Bruker Autoflex III mass spectrometer equipped with a nitrogen UV-Laser operating at 337 nm. The cyclic voltammetry (CV) and differential pulse voltammetry (DPV) measurements were carried out with a Gamry Reference 600 potentiostat/galvanostat. UV–vis absorption spectra and chromaticity diagrams were measured by an OceanOptics QE65000 diode array spectrophotometer.

2.2. Synthesis

2.2.1. 1(4),8(11),15(18),22(25)-(6-Hydroxyhexylthio)-phthalocyaninato manganese (III) chloride (**2**) and 2(3),9(10),16(17),23(24)-tetrakis – {β-6-hydroxyhexylthio}-phthalocyaninato manganese (III) chloride (**3**)

A mixture of 3′-(6-hydroxyhexylthio)-1,2-dicyanobenzene (**1**) or 4′-(6-hydroxyhexylthio)-1,2-di cyanobenzene (**1′**) (∼0.15 g, 0.58 mmol), and anhydrous $MnCl_2$ (∼0.02 g, 0.170 mmol) in *n*-hexanol (∼1.00 mL) was heated to reflux in a sealed tube under N_2 atmosphere for 6 h. The color of the mixture turned brown during the course of time. The brown product was cooled to room temperature after additional heating for about 3 h. Then the mixture was diluted with petroleum ether. The crude product was washed several times, first with cold *i*-PrOH, and then with cold CH_3CN successively to remove impurities. Finally, the product was further purified by silica gel chromatography (with chloroform ($CHCl_3$) and then with $CHCl_3$/MeOH (20:1 v/v) and sephadex with tetrahydrofuran (THF)/$CHCl_3$). The final product is soluble in MeOH, THF, dimethylformamide (DMF), dimethylsulfoxide (DMSO) and insoluble in diethylether.

Yield of **2**: 0.030 g (13.58 %). *Anal.* Calc. for $C_{56}H_{64}N_8O_4S_4Mn$ (1095 g/mol): C, 61.37; H, 5.84; N, 10.23; S, 11.69. Found: C, 60.88; H, 5.92; N, 9.88; S, 11.33%. 2.3. Electrode preparation

For electrocoating measurements, the CV technique was employed with a glassy carbon electrode (GCE) as the working electrode with a surface area of 0.071 cm^2. A Pt wire as the counter electrode and a saturated calomel electrode (SCE) as the reference electrode were employed. Electrochemical grade tetrabutylamonium perchlorate (TBAP) in spectroscopic grade dimethyl sulfoxide (DMSO) (0.10 mol dm^{-3}) was employed as the supporting electrolyte. 50 successive CV cycles between the potential windows of TBAP/DMSO electrolyte system were employed to follow coating of **2** and **3** on the working electrode. Coating of the complexes on the working electrode was followed by a increase of the present peaks or by formation of new peaks whose currents increased with the repetitive CV cycles. The modified electrodes were abbreviated as GCE/**2** and GCE/**3**.

2.4. Electrochemical measurements

The CV and DPV measurements were carried out utilizing a three-electrode configuration at 25 °C. The working electrode was a Pt disc with a surface area of 0.071 cm^2. A Pt wire served as the counter electrode. A saturated calomel electrode (SCE) was employed as the reference electrode and separated from the bulk of the solution by a double bridge. Electrochemical grade TBAP in extra pure DMSO was employed as the supporting electrolyte at a concentration of 0.10 mol dm^{-3}.

2.5. In situ spectroelectrochemical and in situ electrocolorimetric measurements

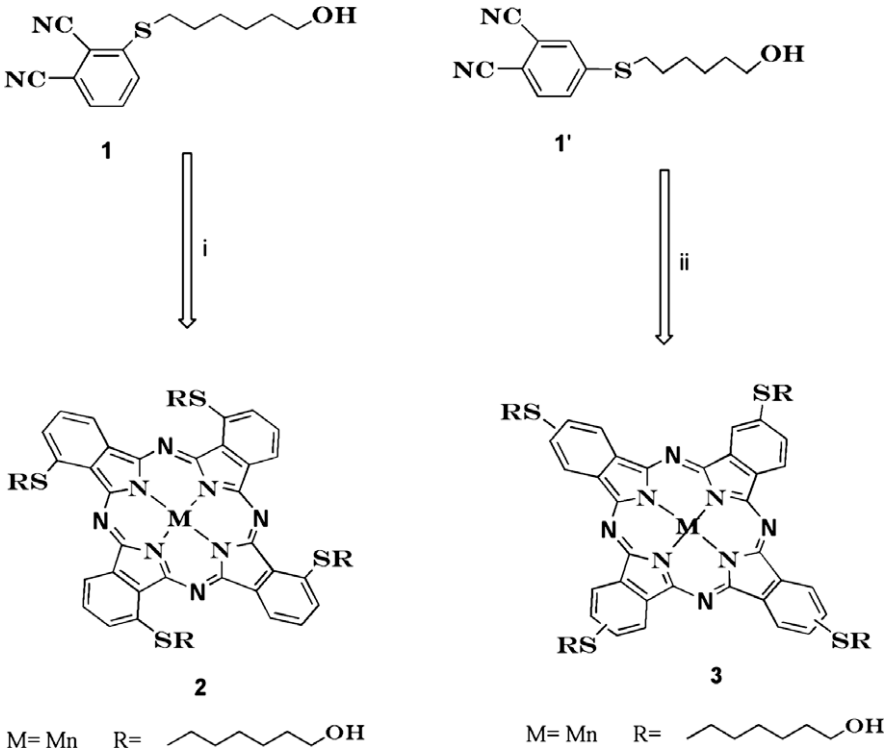
In situ spectroelectrochemical measurements were carried out by utilizing a three-electrode configuration of thin-layer quartz thin-layer spectroelectrochemical cell at 25 °C. The working electrode was Pt tulle. A Pt wire counter electrode separated by a glass bridge and a SCE reference electrode separated from the bulk of the solution by a double bridge were used. *In situ* electrocolorimetric measurements, under potentiostatic control, were obtained using an OceanOptics QE65000 diode array spectrophotometer in the color measurement mode by utilizing a three-electrode configuration of a thin-layer quartz spectroelectrochemical cell. The standard illuminant A with a 2-degree observer at constant temperature in a light booth designed to exclude external light was used. Prior to each set of measurements, background color coordinates (*x*,*y* and *z* values) were taken at open-circuit, using the electrolyte solution without the complexes under study. During the measurements, readings were taken as a function of time under kinetic control, however only the color coordinates at the beginning and end of each redox processes were reported.

2.6. Electrocatalytic measurements

Electrocatalytic measurements were performed by using CV, chronoamperometry (CA) and chronocoulometry (CC) techniques in aqueous solution. The working electrodes were modified GCE/**2**, GCE/**3** and bare GCE electrodes. A spiral Pt wire as the counter electrode and SCE as the reference electrode were used. Aqueous phosphate buffer solution containing 0.1 mol dm^{-3} NaCl as an electrolyte in triple distilled water was employed as the supporting electrolyte. The pH was adjusted by addition of 0.2 mol dm^{-3} NaOH or conjugated acid solutions.

3. Results and discussions

3.1. Synthesis and characterization



3′-(6-Hydroxyhexylthio)-phthalonitrile and 4′-(6-hydroxyhexylthio)-phthalonitrile can be obtained by nucleophilic aromatic substitution reactions of 6-mercapto-1-hexanol on 3- or 4-nitrophthalonitrile [15,16]. Manganese phthalocyanines, {Mn[Pc(α-S(CH$_2$)$_6$-OH)$_4$]Cl} (**2**) and {Mn[Pc(β-S(CH$_2$)$_6$OH)$_4$]Cl} (**3**) were accomplished by heating a pulverized mixture of 3′- or 4′-(6-hydroxyhexylthio)-phthalonitrile with anhydrous $MnCl_2$ salts at ca. 170 °C under N_2 atmosphere in the presence of 1,8-diazabicyclo [5.4.0] undec–7-ene (DBU) (Scheme 1). Synthesis and purification of MnPcs are, generally, more difficult than those of other MPcs due to the three forms of MnPcs: Mn(II)Pc, Mn(III)PcX (where X is an axial ligand coordinated on the metal center such as Cl^-, OAc^- or OH^-), and μ-oxo manganese(III) phthalocyanines (Mn(III)Pc–O–PcMn(III)) [20]. In all cases, a mixture of four possible structural isomers are obtained. The presence of the isomers could be verified by a slight broadening encountered in the UV–Vis absorption spectrum as compared with those of octa-substituted phthalocyanines composed of a single isomer [16,21,22].

The structures of the phthalocyanines (**2** and **3**) were verified by FTIR, elemental analysis, UV–vis and MALDI-TOF-MS spectroscopic methods. UV–Vis spectra of the MnPcs exhibit characteristic Q- and B-bands, at ca. 700–800 nm (Q-band) attributed to the π–π^* transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the Pc^{2-} ring, and the other in the UV region at ca. 340–370 nm (B-band) arising from deeper π–π^* transitions [23]. Both **2** and **3**, gave a single Q-band with high intensity at 769 and 747 nm due to a π–π^* transition, as expected as a result of their D_{4h} symmetry, with shoulders at the slightly higher energy side of the Q-band (691 and 667 nm) in addition to B-bands in UV region. The broad bands between 450 and 550 nm may be due to charge transfer from the electron-rich ring to the electron-poor metal center [21,25]. The B-bands are very clear due to the unsuperimposition of the B1 and B2 bands in the 340–370 nm region [21].

Fig. 1 shows the change of the UV–vis spectra of **2** upon titration with water. The Q band of **2** shifted to longer wavelength in water (789 nm) due to the higher polarization effect of water exchanged with the Cl^- counter anion. Quantitative analysis of the titration indicates 1:1 coordination of water exchanged with the Cl^- anion on the axial position of the Mn(III) center of the MnPc. Fig. 1 also shows that the complexes do not aggregate in THF and water, although it is known that phthalocyanine molecules tend to aggregate especially in polar media [20]. The non-aggregating behaviors of complexes **2** and **3** may due to the existence of polar peripheral functional end groups and the axial ligand, Cl^-, which reduce the π–π^* interaction between two macrocycle units [20]. A MALDI-MS spectrum (2,5-dihydroxybenzoic acid (DHB)) of **2** is given in Fig. 2 [16,21]. The protonated molecular ion peak was observed at 1095 Da with the other isotopic peaks.

3.2. Voltammetric and spectroelectrochemical characterization

The CV and DPVs (Figs. 3 and 4) of **2** and **3** were obtained in a deaerated DMSO/TBAP electrolyte system on a Pt working electrode. Table 1 lists the assignments of the redox couples and estimated electrochemical parameters, including the half-wave peak potentials ($E_{1/2}$), ratio of anodic to cathodic peak currents ($I_{p,a}/I_{p,c}$), peak to peak potential separations (ΔE_p) and difference between the first oxidation and reduction processes ($\Delta E_{1/2}$). As shown in Fig. 3, within the potential window of the DMSO/TBAP electrolyte system, three reduction processes (labeled $\mathbf{R_1}$–$\mathbf{R_3}$) and one oxidation process (labeled $\mathbf{O_1}$) are recorded for the complexes. Both complexes have redox processes approximately at the same potentials, indicating a similar effect of the substituents at the α and β positions to the electronic nature of the Pc ring. Couples $\mathbf{R_1}$ and $\mathbf{R_2}$ are well resolved and reversible with anodic to cathodic

Scheme 1. Synthetic route of 1(4),8(11),15(18),22(25)-tetrakis(6-hydroxyhexylthio)-manganese (III) phthalocyanine (**2**) and 2(3),9(10),16(17),23(24)-tetrakis(6-hydroxyhexylthio)-manganese (III) phthalocyanine (**3**) i and ii: anhydrous $MnCl_2$, quinoline, dbu.

peak separations (ΔE) ranging from 60 to 130 mV with increasing scan rates from 10 to 500 mVs^{-1} (ΔE_ps of 60–110 mV were obtained for a ferrocene reference). Unity of the $I_{p,a}/I_{p,c}$ ratio at all scan rates and linear variation of the peak currents with the square root of the scan rates indicated the purely diffusion controlled mass transfer of the complexes. Reversibility of the redox processes shows that axial ligand Cl^- may present as being bonded to the metal center after the redox processes or the axial ligand exchange reactions are very fast. Therefore, these chemical reactions did not disrupt the reversibility of the processes.

In comparison with the MnPcs in the literature [20–26], the first two reduction processes are assigned to metal-based processes, $Mn^{III}Pc^{-2}/Mn^{II}Pc^{-2}$ and $Mn^{II}Pc^{-2}/Mn^{I}Pc^{-2}$, and the third one is assigned to a ligand-based process, $Mn^{I}Pc^{-2}/Mn^{I}Pc^{-3}$. The oxidation process of the complexes is also a metal-based process, $Mn^{III}Pc^{-2}/Mn^{IV}Pc^{-2}$. *In situ* spectroelectrochemical experiments were employed to confirm the identities of these redox processes. In situ UV–Vis spectral changes and a chromaticity diagram of **2** are given in Fig. 5. Fig. 5A shows the *in situ* UV–Vis spectral changes observed upon controlled potential reduction of **2** at −0.40 V, corresponding to couple $\mathbf{R_1}$. The band at 517 nm and red shifted Q band at 781 nm are characteristic of $Mn^{III}Pc^{-2}$ species. Upon reduction, the Q band at 781 nm shifts to 716 nm, and new bands are formed at 582 and 918 nm. The formation of $Mn^{II}Pc^{-2}$ is characterized by shifting of the Q band to shorter wavelength values (~70 nm) and the formation of new bands at the charge transfer region [20–25]. Clear isosbestic points at 350, 396, 456, 537, 739 and 872 nm in the spectra are recorded. These spectral changes

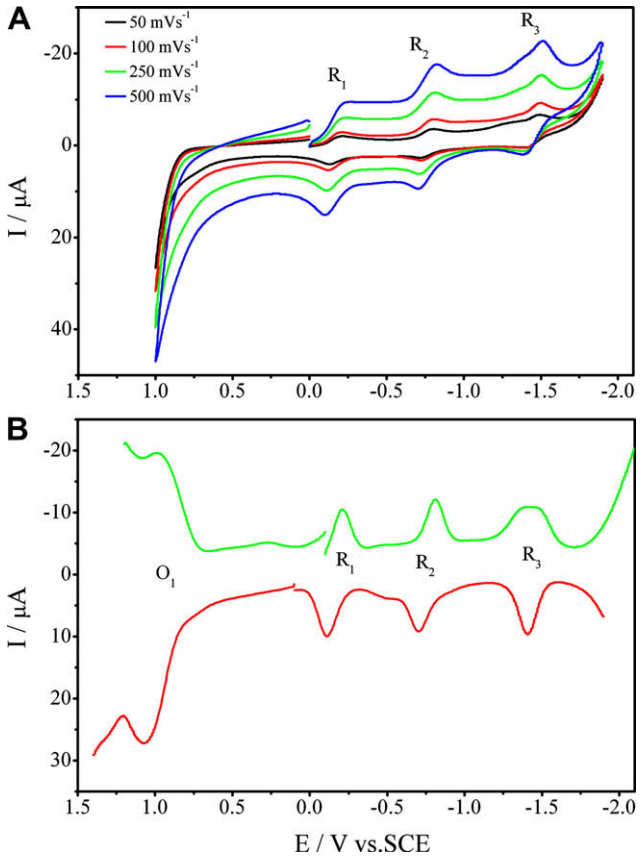

Fig. 3. CV (A) and DPV (B) of **2** at various scan rates on Pt in DMSO/TBAP.

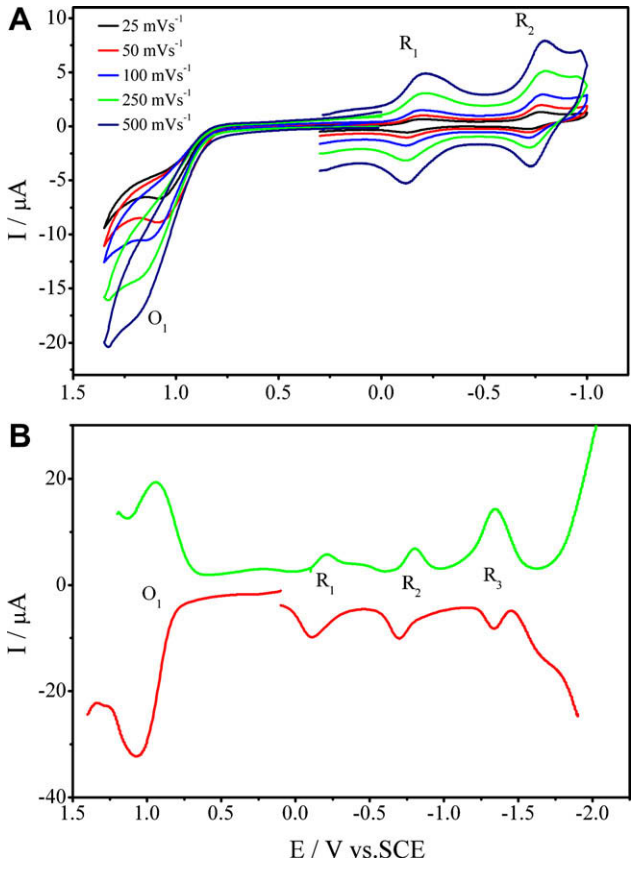

Fig. 4. CV (A) and DPV (B) of **3** at various scan rates on Pt in DMSO/TBAP.

suggest that the $\mathbf{R_1}$ couple observed at −0.16 V is a metal-based reduction process, $Mn^{III}Pc^{-2}/Mn^{II}Pc^{-2}$. Color changes of the complex in solution during the redox processes were recorded by *in situ* electrocolorimetric measurements. Fig. 5D gives the chromaticity diagrams of **2** recorded simultaneously during the spectroelectrochemical measurements. Without any potential application, the solution of **2** is light brown ($x = 0.372$ and $y = 0.352$) (point □ in Fig. 5D). As the potential is stepped from 0 to −0.40 V, the color of neutral **2**, $Mn^{III}Pc^{-2}$, starts to changes and the light green color ($x = 0.325$ and $y = 0.349$) (point ○ in Fig. 5D) of the monoanionic form of **2**, $Mn^{II}Pc^{-2}$, was obtained at the end of the first reduction.

The reduction of the $Mn^{II}Pc^{-2}$ species has been a subject of some controversy, with some reports proposing ring-reduction to the $Mn^{II}Pc^{-3}$ species and others suggesting metal reduction to the $Mn^{I}Pc^{-2}$ species [20]. Fig. 5B shows further spectral changes observed during the $\mathbf{R_2}$ process. The spectral changes are typical of a metal-based reduction with the formation of a broad band at 533 nm, because the band at 533 nm characterizes $Mn^{I}Pc^{-2}$ species [26]. At the same time while the Q band decreases in intensity, a new band is observed at 873 nm instead of the band at 918 nm. Clear isosbestic points at 385, 466, 667, 827 and 904 nm in the spectra are recorded. Similarly the color of the dianionic species, $Mn^{I}Pc^{-2}$ was recorded as light purple ($x = 0.311$ and $y = 0.246$) with in situ colorimetric measurements (point △ in Fig. 5D). The ring-reduction process, upon further reduction of the $Mn^{I}Pc^{-2}$ species, is represented in inset of Fig. 5B. Formation of a new broad band at 570 nm and a decrease of the Q band in intensity are characteristics of the process, $Mn^{I}Pc^{-2}/Mn^{I}Pc^{-3}$. During this process, the band at 533 nm, characterizing $Mn^{I}Pc$ species, is still present. The color of the $Mn^{I}Pc^{-3}$ species was recorded as light blue ($x = 0.275$ and $y = 0.226$) (point ◇ in Fig. 5D). The original spectra (in Fig. 5A) could be regenerated (to >90%) by application of a positive potential (0.50 V), after the formation of the $Mn^{I}Pc^{-3}$ species. To confirm origin of the oxidation process, $\mathbf{O_1}$, *in situ* UV–Vis changes were recorded under controlled potential application at 1.20 V (Fig. 5C). During this process, the Q band increases in intensity with a red shift from 781 to 788 nm, while the bands at 441 and 500 nm increases in intensity. These spectral changes are characteristics of a metal-based oxidation process in MnPcs, thus the couple of $\mathbf{O_1}$ is easily assigned to the $Mn^{III}Pc^{-2}/Mn^{IV}Pc^{-2}$ redox process [20–26]. Similarly the color of the monocationic species, $Mn^{IV}Pc^{-2}$ was recorded as light red ($x = 0.402$ and $y = 0.293$) with *in situ* colorimetric measurements (point ☆ in Fig. 5D).

To determine formation of μ-oxo MnPc species and its effects on the spectral changes, *in situ* UV–Vis changes were also recorded without purging with N_2 gas. Fig. 6 represents the *in situ* UV–Vis spectral changes with (Fig. 6A and B; case 1) and without (Fig. 6C and D; case 2) dissolved O_2 during controlled potential reduction processes. When we compare the spectral changes in Fig. 6A with those in Fig. 6C, it is shown that while complex **2** gives two new bands at 582 and 917 nm in case 1, these bands are not recorded in case 2 under controlled potential application at −0.40 V. The charge transfer band of the neutral $Mn^{III}Pc^{2-}$ species recorded at 514 nm disappears in case 2 while it is not changed in case 1. There are also considerable spectral change differences between case 1 and case 2 during the second reduction process. While the spectral changes indicate a metal-based reduction in case 1 (Fig. 6B), it is a ligand-based reduction in case 2 (Fig. 6D), because in case 2, the new band at 590 nm and the decrease of the Q band at 716 nm without shift are characteristics of a ligand-based reduction. However, two new bands at 533 and 873 nm are recorded in case 1 during the second reduction process, which are characteristics of a metal-based reduction process. All of these

(D) Chromaticity diagram of **2** (each symbol represents the color of electro-generated species; □: neutral **2**, $Mn^{III}Pc^{-2}$, ○: $Mn^{II}Pc^{-2}$, △: $Mn^{I}Pc^{-2}$, ◇: $Mn^{I}Pc^{-3}$, ☆: $Mn^{IV}Pc^{-2}$.

spectral changes indicate the reaction of $Mn^{III}Pc^{2-}$ species with O_2 dissolved in the solution and the formation of μ-oxo MnPc species. Formation of μ-oxo MnPc species was also stated by Nyokong et al. [26]. She stated that during the reduction processes of MnPc, new bands were recorded indicating the presence of μ-oxo MnPc species in solution.

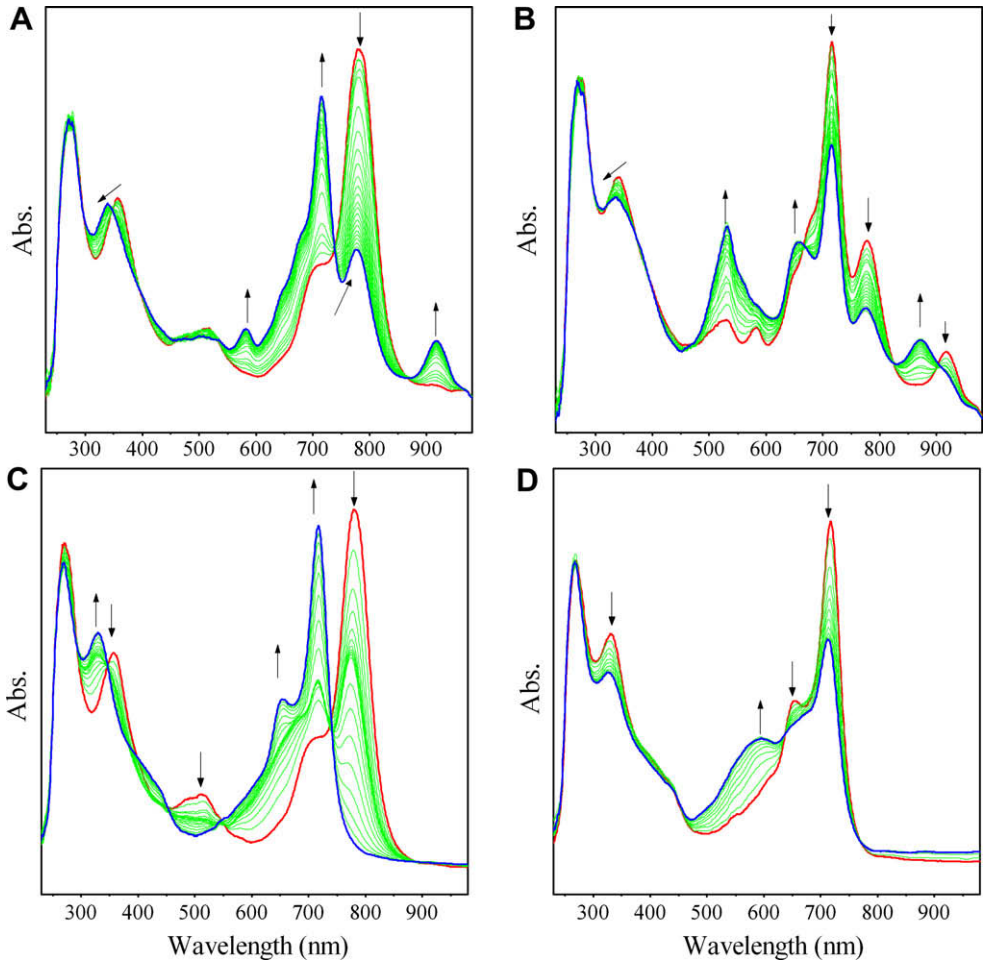

Fig. 6. *In situ* UV–Vis spectral changes of **2**. (A) E_{app} = −0.40 V without O_2 (case 1, purged with N_2 gently). (B) E_{app} = −1.00 V without O_2 (case 1, purged with N_2 gently). (C) E_{app} = −0.40 V with O_2 (case 2, not purged with N_2). (B) E_{app} = −1.00 V with O_2 (case 2, not purged with N_2).

Complex **3** has very similar electrocolorimetric and spectroelectrochemical responses with **2**. *In situ* UV–Vis spectral changes and a chromaticity diagram of **3** are given in Fig. 7. During reduction under a controlled potential at −0.40 V, corresponding to the couple $\mathbf{R_1}$, the Q band at 750 nm shifts to 698 nm and new bands are formed at 587, 647 and 902 nm (Fig. 7A). The formation of $Mn^{II}Pc^{-2}$ is characterized by the shift of the Q band to shorter wavelength values and formation of new bands at the charge transfer region. Differently, a band at 647 nm is also recorded, while this was not the case with the complex **2**. This may be the result of the μ-oxo MnPc species due to the reaction of the reduced species with oxygen, which may have entered the cell during the reduction process. It was stated in the literature that a band at around 640 nm indicates the existence of μ-oxo MnPc species [26]. Clear isosbestic points at 320, 404, 542, 716 and 846 nm in the spectra are recorded. These spectral changes suggest the formation of $Mn^{II}Pc^{-2}$. Thus, couple $\mathbf{R_1}$ observed at −0.16 V is assigned to $Mn^{III}Pc^{-2}/Mn^{II}Pc^{-2}$. Fig. 7D gives the chromaticity diagrams of complex **3** recorded simultaneously during the spectroelectrochemical measurements. Without any potential application, the solution of **3** is light brown (x = 0.375 and y = 0.374) (point □ in Fig. 7D). As the potential is stepped from 0 to −0.40 V, the light green color (x = 0.320 and y = 0.360) (point ○ in Fig. 7D) of the monoanionic form of **3**, $Mn^{II}Pc^{-2}$, was obtained at the end of the first reduction. Fig. 7B shows further spectral changes observed during further reduction processes. The spectral changes during the second reduction process are typical of a metal-based reduction, with the formation of split bands at 533 and 563 nm. At the same time, while the Q band decreases in intensity, the band at 902 nm shifts to 863 nm. Clear isosbestic points at 397, 488, 624, and 798 nm in the spectra are recorded. The color of the dianionic species, $Mn^{I}Pc^{-2}$, was recorded as light purple (x = 0.301 and y = 0.288) with *in situ* colorimetric measurement (point △ in Fig. 7D). The ring-reduction process upon further reduction of the $Mn^{I}Pc^{-2}$ species is represented in the inset of Fig. 7B. The formation of a new broad band in the charge transfer region, leaving the bands at 533 and 563 nm without change, and a decrease of the Q band in intensity are characteristics of the process, $Mn^{I}Pc^{-2}/Mn^{I}Pc^{-3}$. The color of the $Mn^{I}Pc^{-3}$ species was recorded as light blue (x = 0.301 and y = 0.259) (point ♢ in Fig. 5D). During the controlled potential application at 1.20 V, The Q band increases in intensity with a red shift from 750 to 758 nm, while the bands at 535 and 563 nm increase in intensity. These spectral changes are characteristics of a metal-based oxidation process in MnPc complexes, thus the couple of $\mathbf{O_1}$ is easily assigned to the $Mn^{III}Pc^{-2}/Mn^{IV}Pc^{-2}$ redox process. Similarly, the color of the monocationic species, $Mn^{IV}Pc^{-2}$ was recorded as light red (x = 0.404 and y = 0.266) with *in situ* colorimetric measurements (point ☆ in Fig. 7D).

3.3. Electrocatalytic measurements

Solution electrochemistry shows that the MnPc complexes have multi electron metal-based reduction couples having diffusion

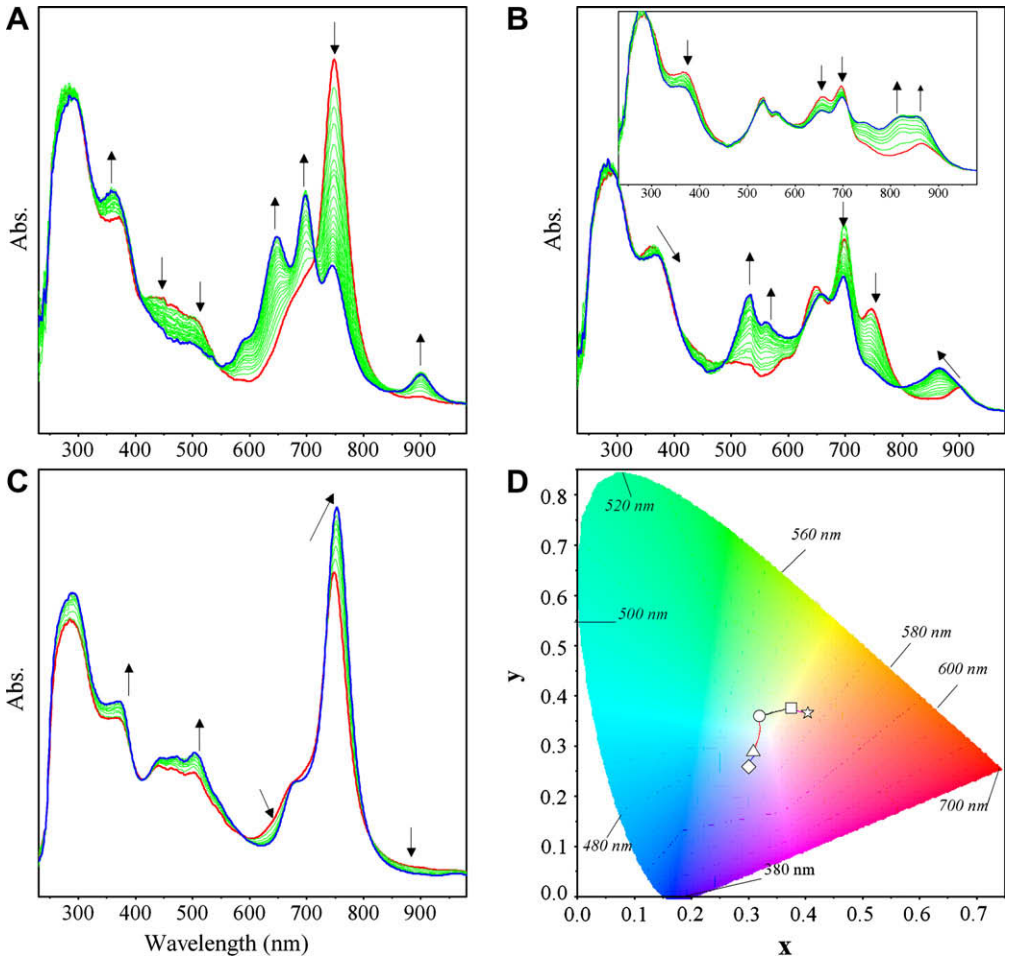

Fig. 7. *In situ* UV–Vis spectral changes of **3**. (A) $E_{app} = -0.40$ V. (B) $E_{app} = -1.00$ V (Inset: $E_{app} = -1.70$ V). (C) $E_{app} = 1.10$ V. (D) Chromaticity diagram of **3** (each symbol represents the color of electro-generated species; □: neutral **3**, $Mn^{III}Pc^{-2}$, ○: $Mn^{II}Pc^{-2}$, △: $Mn^{I}Pc^{-2}$, ◇: $Mn^{I}Pc^{-3}$, ☆: $Mn^{IV}Pc^{-2}$.

controlled reversible and/or *quasi*-reversible characters between 0.0 and −1.50 V versus SCE. These distinctive properties of the complexes indicate their possible electrocatalystic application. Therefore, electrocatalytic activities of the complexes were investigated for hydrogen evolution reaction in aqueous solution. The complexes were potentiostatically coated on a GCE for electrocatalytic applications. Electrocoating of the complexes was studied using CV performed in the TBAP/DMSO electrolyte system on a GCE working electrode. Repetitive scanning (50 scans) between the negative and positive potential windows of the electrolyte systems shows the appearance and gradual increase of new redox waves and the changing of the properties of the existence waves. During the repetitive scanning, while the redox waves of **2**, recorded at −0.22, −0.82, −1.46, and 0.45 V, disappeared gradually, new enhanced waves were recorded at −0.52, −0.68, −1.66 and −1.87 V (Fig. 8). These CV responses are easily attributed to the polymerization of **2** on the working electrode [20,27,28].

The electrocatalytic activities of the complexes for the hydrogen evolution reaction (*her*) in aqueous solution were studied using CV and CA performed in the presence of 0.1 mol dm^{-3} NaCl in phosphate buffer aqueous solution at different pHs with manganese phthalocyanine modified working electrodes (GCE/**2** and GCE/**3**). We compared the proton reduction potentials (from CV graphs) and charges passed during the proton reduction at constant reduction potentials (from CA and CC graphs). Electrocatalytic measurements show that both complexes catalyze the *her* reaction in a similar manner and degree. While the complexes are almost inactive at acidic and neutral media, their activities increase in basic media. As shown in Fig. 9, while the proton reduction reaction starts at −1.65 V on a bare GCE electrode (CV, CA and CC are represented with label "*i*") at pH 10.20, it starts at −1.50 V on modified electrodes, having higher hydrogen discharge currents (CV, CA and CC are represented with label "*ii* and *iii*"). During the CA and CC measurements (Fig. 9B), higher currents and charges recorded on the modified electrodes with respect to the bare GCE electrode support the catalytic activity of the complexes. The aim of the electrocatalytic reactions for hydrogen production is to reduce the reduction potential by decreasing the over potential of the working electrode and to gain a higher current at the same potential [29–31]. Therefore, accomplishing the proton reduction on modified electrodes at approximately 0.160 V lesser potential with a higher current than those on the bare electrode displays the catalytic activity of the MnPcs for the *her*.

The redox reaction of the MnPc derivatives is a very significant factor to their electrocatalytic activities towards the *her*. Due to the high hydrogen discharge currents, the redox waves of the complexes are invisible in Fig. 9A. Thus, expanded forms of the CV recorded on GCE/**2** with different switching potentials are given as an inset in Fig. 9A. Two cathodic waves are recorded on the GCE/**2** electrode at ca. −0.30 V corresponding to $Mn^{III}Pc^{2-}/Mn^{II}Pc^{2-}$ and at ca. −0.90 V corresponding to $Mn^{II}Pc^{2-}/Mn^{I}Pc^{2-}$ processes (CV "c"). These waves were then followed by a very sharp increase in current due to the *her*. Disappearance of the anodic couples of the peaks during the reverse scan indicates the regeneration of

the original species after the *her*. When the potential was reversed before the *her*, the anodic couples of these peaks are still present (CV "b"). These results clearly affirm the electrocatalytic contribution of the complexes to the *her*. According to the literature on transition metal complexes which catalyzed H_2 production, stable or transient hydride complexes can be generated via either a chemical route (C mechanism) or an electrochemical route (E mechanism) [32–35]. For example, Savèant and coworkers demonstrated that hydrogen evolution by iron porphyrins begins with reduction of the catalyst followed by its protonation to a transient $Fe^{II}H$ species. H_2 production proceeds subsequently through proton/hydride coupling [32]. Kaneko and coworkers reported that porphyrin and phthalocyanine derivatives could catalyze proton reduction to generate hydrogen. They proposed that there exist at least two steps for hydrogen evolution; one-step is reduction of the complex, and the second one is the proton reduction by the protonated-reduced complex [35]. In summary, it is well documented in the literature that first, second and/or third reduced transition metal complexes may catalyze the proton reduction process depending on the substituent environment of the complex. In this study, increasing of the activity of the complexes in basic media shows that the second reduced MnPc species may catalyze the proton reduction process depending on the pH of the media.

4. Conclusion

α- and β-substituted tetrakis{6-hydroxy-hexylthiol)-phthalocyaninato manganese (III) chloride complexes have been prepared and characterized by elemental analysis, FTIR, MS and UV–Vis spectral data. A Q-band maximum in the near-IR region of the electronic spectra was due to the Mn (III) metal center of the complexes. UV–Vis spectral changes of $\{Mn[Pc(\alpha\text{-}S(CH_2)_6OH)_4]Cl\}$ upon titration with water show exchange of the axial chloride ion with water. The voltammetric and spectroelectrochemical studies of the complexes show that the complexes exhibit three reversible one-electron reduction processes, assigned to $Mn^{III}Pc^{2-}/Mn^{II}Pc^{2-}$, $Mn^{II}Pc^{2-}/Mn^{I}Pc^{2-}$ and $Mn^{I}Pc^{2-}/Mn^{I}Pc^{3-}$ and an oxidation assigned to $Mn^{III}Pc^{2-}/Mn^{IV}Pc^{2-}$, respectively. These solution properties of the complexes are in harmony with similar MnPcs with small potential shifts due to the different substituents. Orientation of the 6-hydroxyhexylthiol substituents at α and β does not affect the solution properties of the complexes. Measurement of the xyz coordinates allows quantification of the color of each electro-generated anionic and cationic redox species which is very important in deciding their possible electrochromic application. Presence of O_2

in the reaction medium during the reduction of the complexes causes the formation of μ-oxo MnPc species, which affect the spectral changes and redox states of the species. Decreasing of the over potential and increasing the hydrogen discharge current indicate electrocatalytic activity of the complexes coated on GCE potentiostatically.

powder was recrystallised in ethanol. Yield for the complex 90%, m.p. 249–251 °C. Elemental analysis, *Anal.* Calc. for $C_{16}H_{18}O_8Cu$: C, 47.82; H, 4.51. Found: C, 47.35; H, 4.78%.

2.1.2. Synthesis of (**1**) and (**2**)

Trans-bisaquabis(*o*-vanillinato)copper(II) (1 mmol, 0.4 g), dissolved in methanol (100 ml), was added dropwise with stirring at 50 °C to a suspension of 1,8-diamino-3,6-dioxaoctane (1 mmol, 0.15 g) or (R)-(−)-2-amino-1-butanol (2 mmol, 0.09 g) in methanol. The reaction mixture was then cooled to room temperature. The dark green crystals formed were filtered and washed with 10 ml of acetone. Yield: 68%, m.p. 184 °C for (**1**) and yield: 77%; m.p. 163 °C for (**2**).

2.2. Materials and measurements

Elemental analyses were performed by standard methods at TÜBİTAK (The Turkish Scientific Research Centre). The UV–Vis spectra were obtained for the methanol solution of the title complexes with a Unicam UV2 spectrometer in the range 900–200 nm. The IR spectra were recorded on a Jasco 430 FT/IR spectrophotometer using KBr pellets and operating at 4000–200 cm^{-1}. Magnetic susceptibility measurements at room temperature were performed using a Sherwood Scientific MXI model Gouy magnetic balance. A TG8110 thermal analyzer was used to record simultaneous TG and DTA curves in static air atmosphere at a heating rate of 10 K min^{-1} in the temperature range 20–1000 °C using platinum crucibles. Highly sintered α-Al_2O_3 was used as a reference and the DTG sensitivity was 0.05 mg s^{-1}.

2.3. Crystallographic analyses

For (**1**) and (**2**), all H atoms were refined using a riding model for C–H bonds with d(C–H) = 0.93–0.97 Å. The U_{iso} values for these H atoms were assigned to $1.2U_{eq}$(C) [$1.5U_{eq}$(methyl C)]. A summary of the crystallographic data, experimental details and refinement results for (**1**) and (**2**) are given in Table 1.

Data collection: Stoe X-AREA [24]; cell refinement: Stoe X-AREA [24]; data reduction: Stoe X-RED [24]; program used to solve structures: SHELXS-97 [25]; program used to refine structures: SHELXL97 [25]; molecular graphics: ORTEP-3 for Windows [26]; software used to prepare material for publication: WINGX [27].

3. Results and discussion

3.1. UV–Vis spectra and magnetic properties

The electronic spectrum was measured at room temperature in methanol (10^{-4} M) for the dark green complex bis(*o*-vanillinato)-triethylenglycoldiiminecopper(II) (**1**), and it exhibited two absorption bands. The bands at 370 nm (ε = 9101 L mol^{-1} cm^{-1}) and 472 nm (ε = 1556 L mol^{-1} cm^{-1}) have been assigned to $\pi \rightarrow \pi^*$

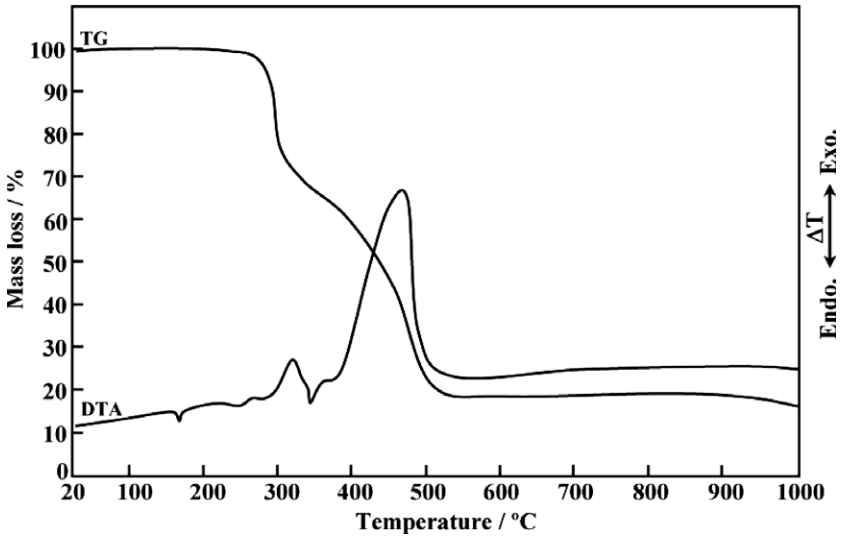

Fig. 1. TG and DTA curves of (**1**).

and $n \rightarrow \pi^*$ transitions of the bis(*o*-vanillinato)-triethylenglycoldiimine ligand, respectively. d–d transitions were not observed in the spectrum. This band may be remain under the $n \rightarrow \pi^*$ transition.

The electronic spectrum was measured at room temperature in methanol (10^{-3} M) for the dark green complex (**2**), and it exhibited a broad d–d absorption transition centered at 646 nm (ε = 115.15 L mol^{-1} cm^{-1}). This value was assigned to the $b_{2g} \rightarrow b_{1g}$ transition, thereby suggesting a square planar geometry around the Cu(II) center.

The complexes exhibit experimental magnetic moment values of 1.89 BM for (**1**) and 1.82 BM for (**2**), which correspond to one unpaired electron.

3.2. IR spectra

The IR spectrum of (**1**) displays a strong absorption at 1636 cm^{-1} which is assigned to a C=N stretching mode in the Schiff base. A band observed at 1450 cm^{-1} is due to υ(C–O) of the phenolic group of the title complex. The coordination of the azomethine nitrogen and phenolic oxygen to Cu(II) is observed at 513 cm^{-1} and 420 cm^{-1}, respectively. Similar M–O and M–N stretching bands are reported in the previous work on N-(*o*-vanillinidene)-*p*-anisidine and N,N′-bis(*o*-vanillinidene)-ethylenediamine complexes [28].

The IR spectrum of (**2**) displays a strong absorption bands at 3515 cm^{-1} and 2950 cm^{-1} which are attributed to the stretching bands of the free hydroxyl and methylene groups of (R)-(−)-2-amino-1-butanol, respectively. The strong absorption band at 1616 cm^{-1} is assigned to a C=N stretching mode in the Schiff base and a band at 1444 cm^{-1} due to υ(C–O) of the phenolic group is observed.

3.3. Thermal analyses

The thermal analysis curves of the studied complexes are shown in Figs. 1 and 2. The complexes decompose in a similar

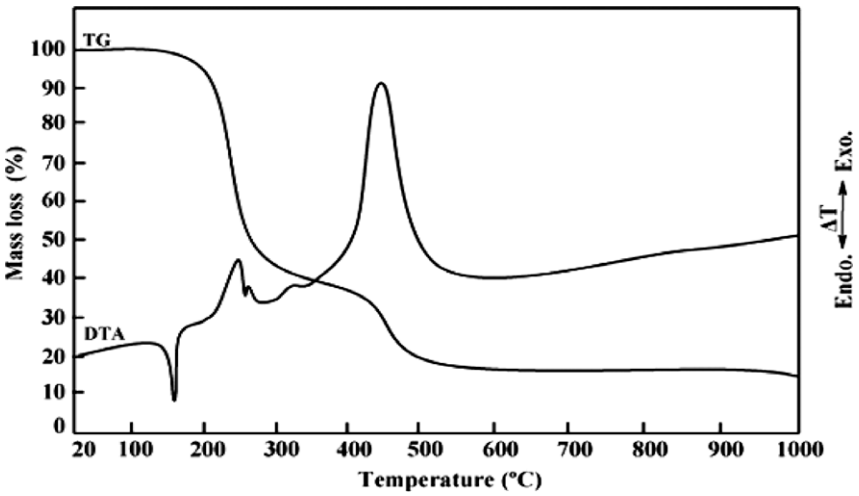

Fig. 2. TG and DTA curves of (**2**).

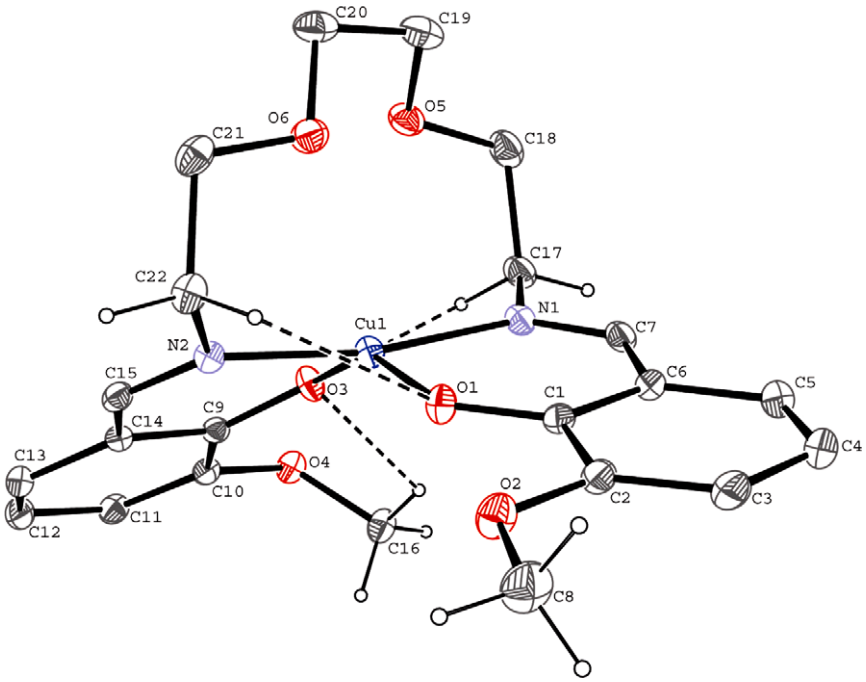

Fig. 3. Molecular structure and atom-labeling scheme of (**1**).

manner. Complex (**1**) melts at 184 °C and is thermally stable up to 245 °C. Complex (**2**) is thermally stable up to 146 °C and begins to decompose with melting (endothermic $DTA_{max.}$: 163 °C). Thermal decomposition of complexes proceeds in two exothermic stages. The first mass loss stage of these complexes was observed in the range 290–550 °C for (**1**) and 146–550 °C for (**2**). This first stage of each complex is related to the partial decomposition of the Schiff base ligands. The second stage of decomposition is associated with a strong exothermic oxidation process (DTA curves: 476 and 444 °C for the complexes (**1**) and (**2**), respectively). During this stage, the remaining organic part is abruptly burnt in these complexes. The total weight losses are 82.61% for (**1**) and 83.98% for (**2**), suggesting that the final decomposition product is CuO (calcd. 83.35%). The final decomposition products were identified by IR spectroscopy and also confirmed by mass loss calculations. On the basis of the first decomposition temperature, the thermal stability of the complexes follows the order: (**1**) (245 °C) > (**2**) (146 °C) in static air atmosphere.

3.4. Crystal structures

3.4.1. Bis(o-vanillinato)-triethylenglycoldiiminecopper(II) (1)

The molecular structure and packing diagrams of (**1**) are illustrated in Figs. 3 and 4, respectively, and selected bond distances and angles are listed in Table 2. Tetra-coordinated Schiff base metal complexes may form *trans* or *cis* planar or tetrahedral structures. A strictly planar or slightly distorted coordination is characteristic for transition metal complexes of copper(II) with a CuN_2O_2 coordination sphere [28]. In (**1**), bis(*o*-vanillinato)-triethylenglycoldiiminecopper(II), the *o*-vanillinato ligands moieties of the molecule are in a *trans* configuration and the Cu atom is coordinated by two imine N atoms and two phenol O atoms from the Schiff base ligand in a slightly distorted square planar coordination (Fig. 3). The N1–Cu1–O1, N1–Cu1–O3, N2–Cu1–O1 and N2–Cu1–O3 bond angles are 92.41(13)°, 90.78(12)°, 90.27(11)° and 91.29(11)°, respectively. The Cu–N distances [1.953(3) and 1.965(3) Å] are longer than the Cu–O distances [1.891(2) and

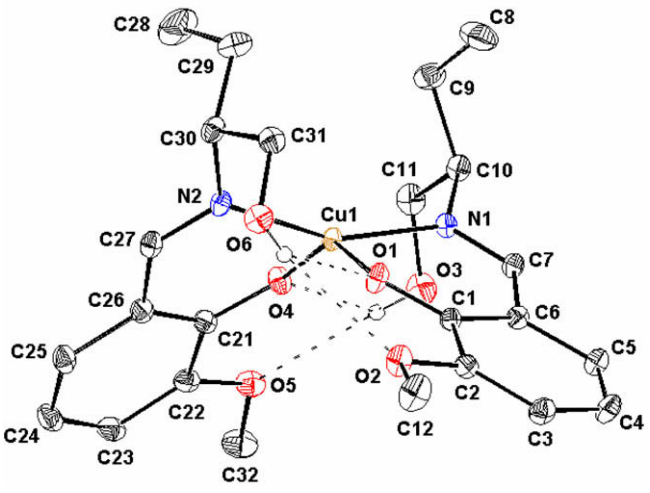

Fig. 5. Molecular structure and atom-labeling scheme of (**2**).

1.912(2) Å]. The bond lengths and angles around the Cu(II) ion in the title complex are in good agreement with the values found in similar copper complexes [22,23,28].

Complex (**1**) contains rings A (Cu1/N1/C7/C6/C1/O1), B (C1/C2/C3/C4/C5/C6), C (Cu1/N2/C15/C14/C9/O3) and D (C9/C10/C11/C12/C13/C14), and the dihedral angles between A/B, A/C, A/D, B/C, B/D and C/D are 2.19(12)°, 34.76(9)°, 41.84(11)°, 36.93(12)°, 43.97(14)° and 7.69(11)°, respectively. In our previous work, the *o*-vanillinato ligands were in a *cis* configuration and the dihedral angles were 3.45(11)°, 6.53(10)°, 6.47(11)°, 3.20(11)°, 4.21(12)°, 2.91(13)° and 20.47° (10)°, respectively, in the *cis*-aquabis(*o*-vanillinato)copper(II) compound [28].

The title compound does not display classical hydrogen bonds, π–π or π-ring interactions, but there are three intra- and seven inter-molecular C–H···O hydrogen bonds (Table 3, Fig. 4). These C–H···O interactions employ most of the available topological features to stabilize the crystal structure.

3.4.2. Bis[(R)-(−)-hydroxymethylpropylimine o-vanillinato]copper(II) (**2**)

The molecular structure and packing diagrams of (**2**) are illustrated in Figs. 5 and 6, respectively. A summary of the crystallographic data, experimental details, and refinement results for (**2**) are given in Table 1. The crystal structure determination of (**2**) reveals that the local coordination geometry around the Cu(II) center is tetrahedrally distorted square planar. In the *trans*-[CuN_2O_2] coordination, the bond angels of N(1)–Cu(1)–N(2), O(4)–Cu(1)–O(3), O(4)–Cu(1)–N(1) and O(4)–Cu(1)–N(2) are 157.35(11)°, 141.83(10)°, 93.66(8)° and 92.85(8)°, respectively. Selected bond distances are listed in Table 2. The Cu(1)–O(3) and Cu(1)–O(4) distances of 1.9074(19) and 1.9032(19) Å, respectively, are similar to the corresponding values in bis(*o*-vanillinato)-triethylenglycoldiiminecopper(II) [Cu–O = 1.912(2) and 1.891(2) Å]. The Cu(1)–N(1) and Cu(1)–N(2) bond distances of 1.953(2) and 1.955(3) Å, respectively are also similar to the corresponding values of similar complexes (1.949(7)–1.962(7) Å) [2]. The Schiff base acts as a bidentate ligand and chelates to Cu(II) through the O atom and N atom. The bond angles are 94.35(8)° for O(3)–Cu(1)–N(1) and 92.85(8)° for O(4)–Cu(1)–N(2), which are reasonable near the ideal angle of 90° in a regular square planar. The dihedral angels between the Cg1 and Cg2 (Cg1 = C1/C2/C3/C4/C5/C6, Cg2 = C21/C22/C23/C24/C25/C26), Cg1 and the Cu1/N1/C7/C10 plane, Cg2 and the Cu1/N2/C27/C30 plane are 79.15(9)°, 15.36(9)°, 22.65(1)°, respectively.

Complex **(2)** has four classical intramolecular-hydrogen bonds, four intermolecular-hydrogen C–H···O bonds and four C–H···π interactions (Table 3, Fig. 6). Both hydrogen-bonding and C–H···π

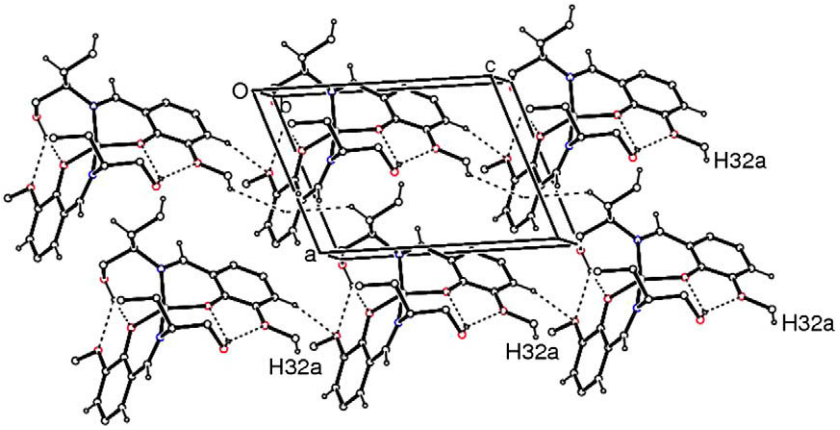

Fig. 6. An ORTEP ([27]) view of the packing diagram of (**2**) along the *c*-axis [hydrogen-bonding and π–π stacking (dashed lines). H atoms not involved in hydrogen-bonding have been omitted].

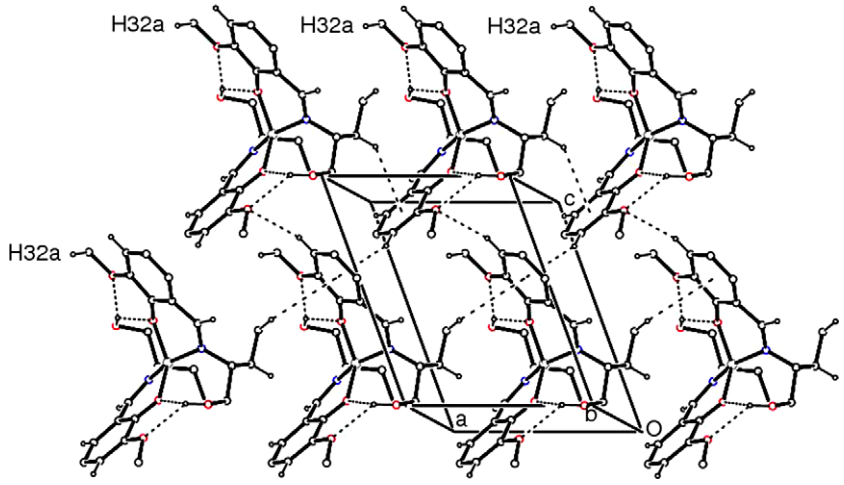

Fig. 7. An ORTEP ([27]) view of the packing diagram of (**2**) along the *a*-axis [hydrogen-bonding and π–π stacking (dashed lines). H atoms not involved in hydrogen-bonding have been omitted].

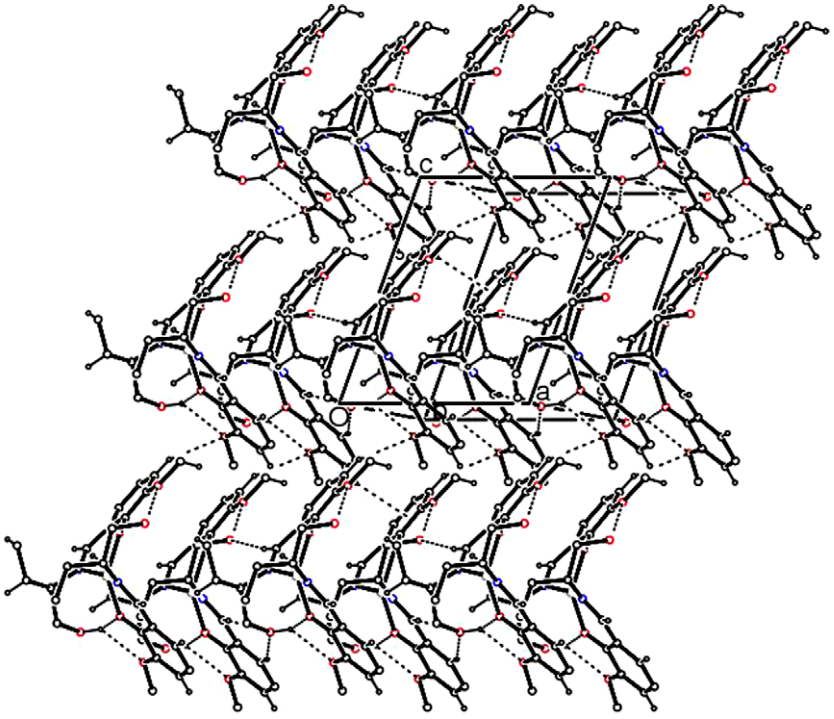

Fig. 8. An ORTEP ([27]) view of the packing diagram of (**2**) [hydrogen-bonding and π–π stacking (dashed lines). H atoms not involved in hydrogen-bonding have been omitted].

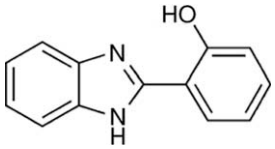

interactions combine to stabilize the extended structure (Figs. 7 and 8). The C3–H3···Cg2$^{(viii)}$ [(viii): $1+x$, y, $-1+z$; 145.70°], C28–H28···Cg2$^{(viii)}$ [132.50°], C29–H29···Cg1$^{(ix)}$ [(ix): $-1+x$, y, z; 133.26°] C32–H32···Cg1$^{(ix)}$ [124.65°] are 2.6816(4), 3.3316(5), 3.2024(4), 2.7181(4) Å, respectively.

Supplementary data

CCDC 719334 and 719335 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Structure of Hhpb ligand.

As an extension of this work, we decided to examine the reactivity of $[ReOX_3(EPh_3)_2]$ (X = Cl, Br; E = As, P) towards 2-(2-hydroxyphenyl)-1H-benzimidazole (Hhpb, Scheme 1).

Imidazole and its derivatives are an important class of heterocycle with N-donor atoms, which can be excellent organic ligands to generate various complexes upon ligation. Recently some new cobalt(II), copper(II) and zinc(II) coordination compounds with 2-(benzimidazol-2-yl)phenolato ligand have been synthesized and characterized [16–20]. As far as rhenium compounds are concerned, only one complex with the relative ligand 2-(1-methyl-1H-benzimidazol-2-yl)phenolato has been obtained so far [21].

Here, we present the synthesis, structural and spectroscopic characterization of *trans*-$[ReOCl_2(hpb)(PPh_3)]$ (**1a**), *cis*-$[ReOCl_2(hpb)(PPh_3)]$ (**1b**), *trans*-$[ReOBr_2(hpb)(PPh_3)]$ (**2a**), *cis*-$[ReOBr_2(hpb)(PPh_3)]$ (**2b**), *cis*-$[ReOCl_2(hpb)(AsPh_3)]$ (**3**), *cis*-$[ReOBr_2(hpb)(AsPh_3)]$ (**4**) and $[ReO(OMe)(hpb)_2]\cdot MeCN$ (**5**) complexes. The experimental studies have been accompanied computationally by the density functional theory (DFT) and time-dependent DFT calculations. Currently density functional theory (DFT) is commonly used to examine the electronic structure of transition metal complexes. It meets with the requirements of being accurate, easy to use and fast enough to allow the study of relatively large molecules of transition metal complexes [22,23].

2. Experimental

2.1. General procedure

All the reagents used to the synthesis were commercially available and were used without further purification. The $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)_2]$ complexes were prepared according to the literature methods [24].

IR spectra were recorded on a Nicolet Magna 560 spectrophotometer in the spectral range 4000–400 cm^{-1} with the samples

in the form of KBr pellets. Electronic spectra were measured on a spectrophotometer Lab Alliance UV–VIS 8500 in the range 1100–180 nm. Elemental analyses (C, H, N) were performed on a Perkin–Elmer CHN-2400 analyzer. ^{1}H NMR spectrum was obtained in $CDCl_3$ using Bruker Avance 400 spectrometer.

2.2. Preparation of [$ReOCl_2$(hpb)(PPh_3)] (**1a** and **1b**)

[$ReOCl_3(PPh_3)_2$] (0.50 g, 0.6 mmol) was added to 2-(2-hydroxyphenyl)-1H-benzimidazole (0.13 g, 0.62 mmol) in acetonitrile (50 ml) and the reaction mixture was refluxed for 2 h. The resulting solution was reduced in volume to ~10 ml and allowed to cool to room temperature. A green crystalline precipitate of [$ReOCl_2$(hpb)(PPh_3)] was filtered off and dried in the air. Yield 80%.

Single crystals of *trans*-[$ReOCl_2$(hpb)(PPh_3)] (**1a**) and *cis*-[$ReOCl_2$(hpb)(PPh_3)] (**1b**) were obtained by recrystallization from acetonitrile, and they were collected in 10% and 70% yield, respectively. Crystals of **1a** and **1b** were separated using microscope.

Anal. Calc. for $C_{31}H_{24}PCl_2N_2O_2Re$: C, 50.00; H, 3.25; N, 3.76. Found: C, 50.45; H, 3.45; N, 3.59%.

2.6. Preparation of [ReO(OMe)(hpb)$_2$]·MeCN (**5**)

[$ReOBr_3(AsPh_3)_2$] (0.50 g, 0.47 mmol) was added to 2-(2-hydroxyphenyl)-1H-benzimidazole (0.23 g, 1.10 mmol) in a mixture of acetonitrile (50 ml) and methanol (50 ml), and the reaction mixture was refluxed for 6 h. The resulting solution was allowed to cool to room temperature and reduced in volume to ~10 ml. A blue crystalline precipitate of [ReO(OMe)(hpb)$_2$]·MeCN was filtered off and dried in the air. Yield 75%.

Anal. Calc. for $C_{29}H_{24}N_5O_4Re$: C, 50.28; H, 3.49; N, 10.11. Found: C, 50.97; H, 3.63; N, 10.47%

IR (KBr; ν/cm^{-1}): 3228 (m) ν_{NH}, 1624 (m), 1603 (s), 1564 (s) and 1541 (s) ν_{CN} and $\nu_{C=C}$; 955 (s) $\nu_{Re=O}$.

^{1}H NMR (400 MHz; CD_3OD) δ = 8.06 (d, 1H), 7.91 (dd, 1H), 7.68 (d, 1H), 7.55–7.45 (m, 3H), 7.39 (dd, 1H), 7.22 (d, 1H), 7.19 (dd, 1H,), 7.02 (dt, 1H), 6.95 (dt, 1H), 6.83 (dt, 1H), 6.76 (dt, 1H), 6.47 (dt, 1H), 6.41 (d, 1H), 6.04 (d, 1H), 3.34 (s, 3H).

2.7. Crystal structures determination and refinement

The X-ray intensity data of **1a**, **1b**, **2a**, **3, 4** and **5** were collected on a KM-4-CCD automatic diffractometer equipped with CCD detector and graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. Details concerning crystal data and refinement are given in Table 1. Lorentz, polarization and empirical absorption correction using spherical harmonics implemented in SCALE3 ABSPACK scaling algorithm [25] were applied. The structures were solved by the Patterson method and subsequently completed by the difference Fourier recycling. All the non-hydrogen atoms were refined anisotropically using full-matrix, least-squares technique. The hydrogen atoms were treated as "riding" on their parent carbon atoms and assigned isotropic temperature factors equal 1.2 (non-methyl) and 1.5 (methyl) times the value of equivalent temperature factor of the parent atom. The methyl groups were allowed to rotate about their local threefold axis. SHELXS97 [26], SHELXL97 [27] and SHELXTL [28] programs were used for all the calculations. Atomic scattering factors were those incorporated in the computer programs.

2.8. Computational details

The gas phase ground state geometries of **2a**, **4** and **5** were optimized without any symmetry restrictions with the DFT method using the hybrid B3LYP functional of GAUSSIAN-03 [29–31]. The calculations were performed using ECP LANL2DZ basis set [32] with an additional *d* and *f* function with the exponent α = 0.3811 and 2.033 [33] for rhenium and the standard 6-31G basis set for other atoms. For bromine, oxygen, nitrogen and phosphorous atoms, diffuse and polarization functions were added [34–39]. All vibrations in the calculated vibrational spectra of **2a**, **4** and **5** were real thus the geometries correspond to true energy minimum.

The electronic spectra of **2a**, **4** and **5** were calculated with the TDDFT method [40], and the solvent effect (acetonitrile for **2a** and **4**, and methanol for **5**) was simulated using the polarizable continuum model with the integral equation formalism (IEF-PCM) [41–44].

Natural bond orbital (NBO) calculations were performed with the NBO code [45] included in GAUSSIAN03.

3. Results and discussion

3.1. Preparation and infrared data

The [$ReOX_2$(hpb)(EPh_3)] (X = Cl, Br; E = As, P) complexes were prepared in good yield by ligand exchange reactions starting from [$ReOX_3(EPh_3)_2$] complexes and 2-(2-hydroxyphenyl)-1H-benzimidazole (Hhpb) in acetonitrile:

$$[ReOX_3(EPh_3)_2] + Hhpb \rightarrow [ReOX_2(hpb)(EPh_3)] + HX + EPh_3$$
$$X = Cl,\ Br;\ E = As,\ P$$

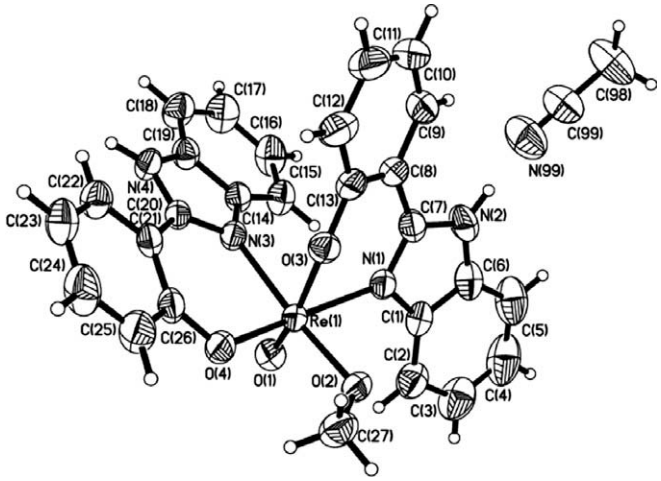

Fig. 4. The molecular structure of **5**. Displacement ellipsoids are drawn at 50% probability.

The starting arsine oxocompounds react with Hhpb to give only *cis*-[$ReOX_2(hpb)(AsPh_3)$] (**3** and **4**), whereas the reactions of [$ReOX_3(PPh_3)_2$] with 2-(2-hydroxyphenyl)-1H-benzimidazole lead to a mixture of *cis* and *trans* stereoisomers of [$ReOX_2(hpb)(PPh_3)$] (**1a**, **1b**, **2a** and **2b**). The majority of the known [$ReOX_2$(O–N)(PPh_3)] structures has halide ligands in *cis* arrangement. The *trans-Cl,Cl* conformation is far more rarely in this type of complex, and it has been previously confirmed for [$ReCl_2(APO)(PPh_3)$] and [$ReOCl_2(DPO)(PPh_3)$] (APOH = 4-anilino-3-penten-2-one; DPOH = 4-[2,6-dimethylanilino]-3-penten-2-one) [46]. It is interesting to note that mixture of *cis* and *trans* stereoisomers were also isolated from the analogous reactions of [$ReOX_3(PPh_3)_2$] with 2-(2′-hydroxyphenyl)-2-benzothiazole, whereas reactions of [$ReOX_3(EPh_3)_2$] (E = P, As) with related 2-(2′-hydroxyphenyl)-2-benzoxazoline have resulted in the isolation only [$ReOX_2$(N–O)(EPh_3)] with *cis*-halide arrangement [9–14]. It confirms that even small changes of the electronic properties in the ligand have significant impact on the reactivity towards [$ReOX_3(EPh_3)_2$].

The disubstituted [$ReO(OMe)(hpb)_2$]·MeCN chelate (**5**) has been isolated from the reaction of [$ReOX_3(EPh_3)_2$] with ligand excess in a mixture of acetonitrile and methanol (Scheme 2).

All the isolated complexes are air stable and slightly soluble in acetonitrile, dichloromethane, chloroform, sparingly soluble in benzene and toluene. The solubility of the *cis* stereoisomers in acetonitrile is better than the *trans* ones, thus the stereoisomers of [$ReOX_2(hpb)(PPh_3)$] can be separated by fractional crystallization. Furthermore, due to the difference in crystal shape of [$ReOX_2(hpb)(PPh_3)$] stereoisomers, they can be easily separated by hand (using microscope).

The IR spectroscopic measurements outlined in the Section 2 are not distinctive for molecular structure determination. The IR spectra of the *cis* and *trans* stereoisomers are very similar in terms of the position, intensity and shape of the bands in the whole region 4000–400 cm^{-1}. The strong ν(Re=O) stretching bands of both *cis* and *trans* stereoisomers of [$ReOX_2(hpb)(EPh_3)$] are found in the narrow range 960–970 cm^{-1}, similar to those observed for the other [$ReOX_2$(O–N)(EPh_3)] chelates [9–14]. Relatively high wavenumbers of the ν(Re=O) absorption bands suggest that the Re–hydroxy bond *trans* to the oxo ligand does not compete effectively for the Re_d orbitals and indicate the presence of very stable {O≡Re–O} structural moiety in the examined structures. Characteristic bands corresponding to the ν(CN), ν(C=C) modes of the hpb^- ligand appear in the range 1650–1500 cm^{-1}, and strong band in the range 3300–3200 cm^{-1} confirms the presence N–H group in the coordinated hpb^- ligand of the examined complexes.

^{1}H NMR spectra (summarized in Section 2 and presented in Fig. 1) make it possible to distinguish between *cis and trans* sterei-

somers of $[ReOX_2(hpb)(PPh_3)]$ chelates. However, molecular configuration can not be predicted on this basis.

3.2. Crystal structures

A definite proof for the structures of $[ReOX_2(hpb)(EPh_3)]$ and $[ReO(OMe)(hpb)_2]\cdot MeCN$ is provided by the X-ray diffraction results. The crystallographic data of **1a**, **1b**, **2a**, **3, 4** and **5** are summarized in Table 1. The *cis*-halide complexes $[ReOX_2(hpb)(EPh_3)]$ (**1b**, **3** and **4**) are isostructural and crystallise in the triclinic $P\bar{1}$ space group with two crystallographically independent molecules of $[ReOX_2(hpb)(EPh_3)]$ in the asymmetric unit. Because these molecules are connected by center of pseudo-symmetry the asymmetric unit contains one pair of enantiomers of two pairs occupying unit cell. Due to small gap between lengths of *a* and *b* unit cell edges, and small changes of unit cell dimensions (originating from differences in compounds composition), the *a* and *b* axes are interchanged in compound **4** in comparison to compounds **1b** and **3** (the unit cell edge of compound **4** corresponding

to *a* axis of compounds **1b** and **3** is not shortest unit cell edge). The *trans* stereoisomers (**1a** and **2a)** are also isostructural but consist of discrete and well-separated [$ReOX_2(O–N)(EPh_3)$] monomers and crystallise in the orthorhombic Pbca space group. The disubstituted chelate crystallises as acetonitrile solvate in the monoclinic $P2_1/n$ space group. The short intra- and intermolecular contacts [47,48] detected in the **1a**, **1b**, **2a**, **3, 4** and **5** are gathered in Table 2. In general hydrogen bonding schemes in isostructural compounds are similar and small observed changes originate mainly from minor differences in packing. The medium strength N–H···X hydogen bonds of **1b**, **3** and **4** create cyclic tetramer described by $N_2R_2^2(24)$ motif. In **1a** and **2a** medium strength N–H···X hydrogen bonds forms zig-zag chain along crystallographic *a* axis and it is described by $N_1C(6)$ graph. In **5** the N–H···O hydrogen bonds links complex molecules to $N_1C(6)$ chain extending along crystallographic [1 0 1] direction. Additionally, in all the structures exist short C–H···O, C–H···N and C–H···X intermolecular interactions, which can be considered as weak or very weak hydrogen bonds. In the structures of **1b**, **3** and **4** exists solvent accessible voids (SOVs), however close inspection of residual electron density show no obvious maxima in SOVs regions, thus it can be supposed that SOVs contains no solvent and they existence originate from crystal packing.

The perspective drawing of *trans*-[$ReOBr_2(hpb)(PPh_3)$] (**2a)** is presented in Fig. 2, and the selected bond distances and angles of **2a** are collected in Table 3. Fig. 3 presents the molecular structure of *cis*-[$ReOBr_2(hpb)(AsPh_3)$] (**4**), and selected bond distances and angles of **4** are gathered in Table 4. The molecular structure of the disubstituted [$ReO(OMe)(hpb)_2$]·MeCN chelate (**5**) is shown in Fig. 4, and Table 5 presents its selected bond distances and

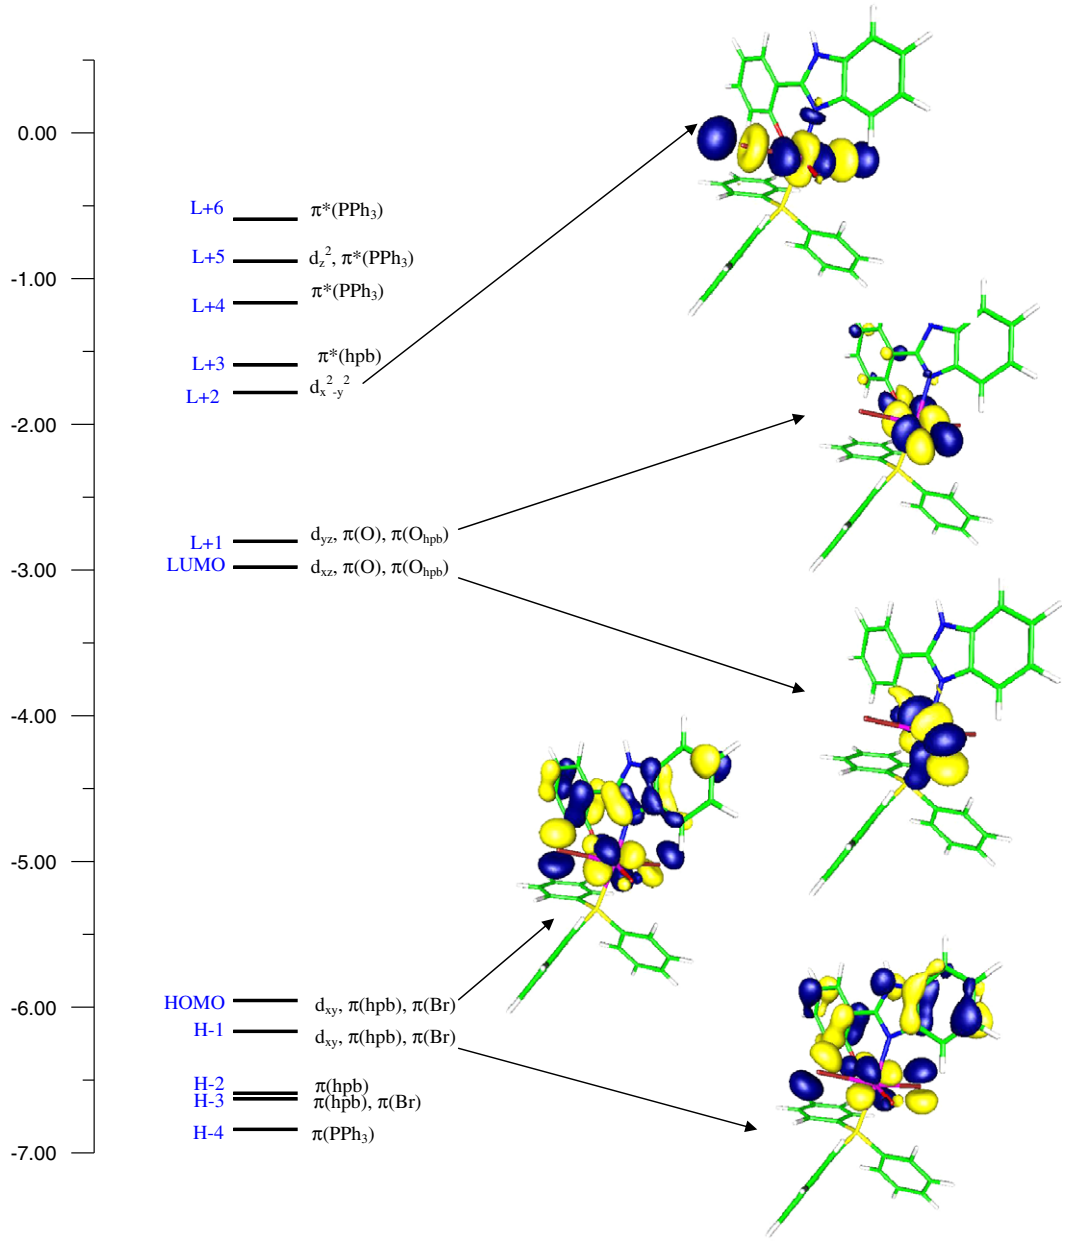

Fig. 5. The energy (eV), character and some contours of the unoccupied molecular orbitals of **2a**. Positive values of the orbital contour are represented in blue (0.04 au) and negative values in yellow (−0.04 au). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

angles. The selected bond distances and angles of the other complexes are gathered in Table 6.

3.3. $[ReOX_2(hpb)(EPh_3)]$ complexes

All the complexes $[ReOX_2(hpb)(EPh_3)]$ show octahedral geometry about the central rhenium atom defined by the terminal oxo-group, two halide ions, the phosphorus or arsine atom of EPh_3 molecule, and the bidentate N,O donors of the hpb^- ligand. The halide ions of **1b**, **3** and **4** are arranged in *cis* geometry, whereas the halide ligands of **1a** and **2a** occupy *trans* positions to each other. In all the complexes triphenylphosphine or triphenylarsine molecule with their π-acidity adopts *cis* position with respect to the linear O≡Re–O unit. Consequently, the O≡Re–O core with multiply bonded oxo ligand is stabilized to some extent due to accessible π-donation from rhenium to triphenylphosphine or triphenylarsine molecule. The multiple bonding ligand (terminal oxo) and narrow bite angle of the chelating ligand contribute to clear distortions of the pseudooctahedral environment of Re center in both *cis*- and *trans*-halide complexes.

In complexes **1a** and **2a**, the rhenium atom is displaced, respectively 0.1795(16) and0.1862(13) Å from the plane formed by the two halogen, one nitrogen and one phosphorous (or arsine) atoms (plane A), 0.0516(17) and 0.0617(13) Å from the plane formed by the two oxygen and two halogen atoms (plane B), 0.0920(20) and 0.0793(18) Å from the plane formed by two oxygen, one phosphorous and one nitrogen atoms (plane C). Least squares plane A is inclined at 87.40(8)°, 87.26(7)°, to plane B and at 89.37(9)°, 89.45(7)°, to plane C; planes B and C are inclined at 89.51(8)°, 89.84(18)°, respectively as above.

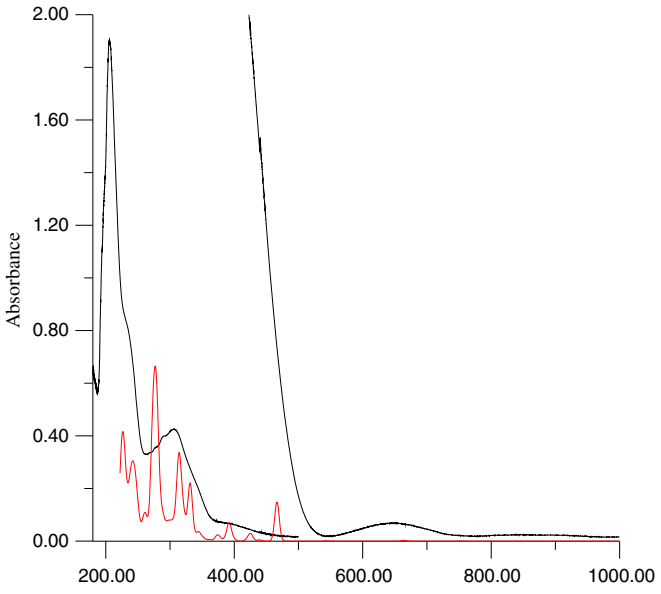

Fig. 8. The experimental (black) and calculated (red) electronic absorption spectra of **2a**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

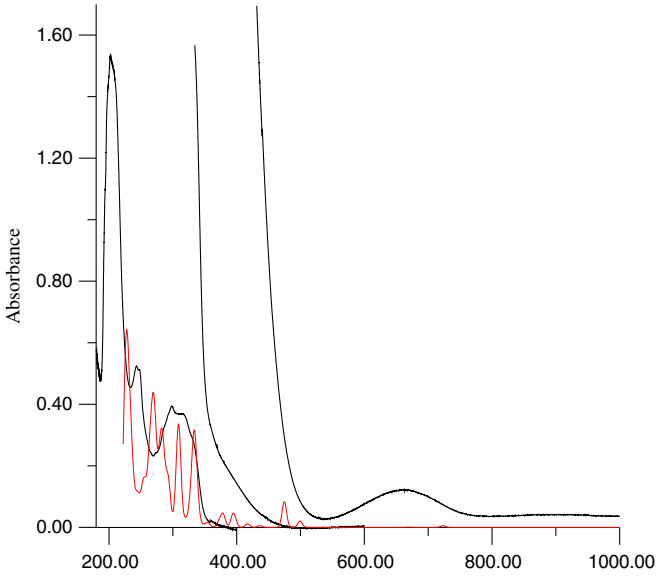

Fig. 9. The experimental (black) and calculated (red) electronic absorption spectra of **4**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

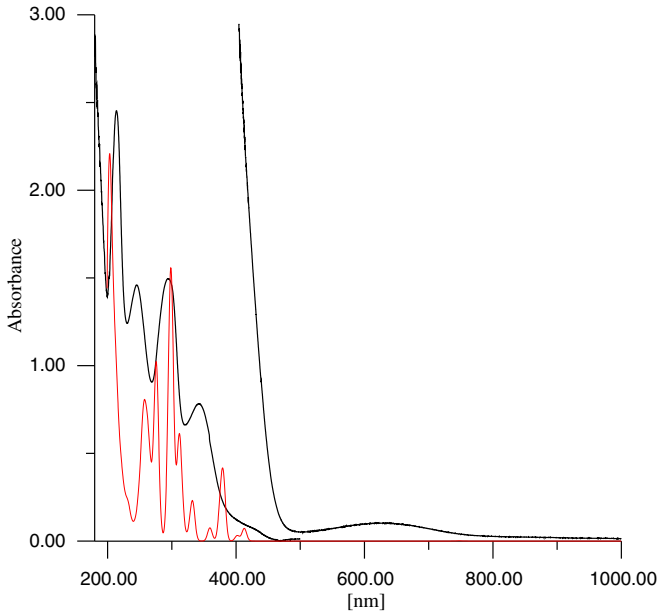

Fig. 10. The experimental (black) and calculated (red) electronic absorption spectra of **5**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

In complexes **1b**, **3** and **4** the Re(1) atom is displaced respectively 0.1166(9), 0.124(3), 0.112(3) Å from the plane formed by the two halogen, one nitrogen and one phosphorous (or arsine) atoms (plane A), 0.0648(8), 0.062(3), 0.063(3) Å from the plane formed by the two oxygen, one halogen and phosphorous (or arsine) atoms (plane B) and 0.0255(11), 0.044(4), 0.050(4) Å from the plane formed by two oxygen, one nitrogen and one halogen atoms (plane C). Least squares plane A is inclined at 89.83(4)°, 89.77(17)°, 89.54(15)° to plane B and at 88.44(5)°, 88.17(20)°, 88.32(15),° to plane C; planes B and C are inclined at 88.76(5)°, 89.11(18)°, 89.0(3)°, respectively as above.

No extraordinary features in terms of bond lengths and angles can be noticed between *cis*- and *trans*-halide $[ReOX_2(hpb)(PPh_3)]$ complexes. The Re–O_t (O_t = terminal oxygen) bond lengths fall in the range 1.639–1.76°Å, typical of mononuclear complexes of rhenium(V) having $[ReO]^{3+}$ core, and indicate the presence of a triple bond Re≡O [49].

The interatomic distances between the rhenium atom and the oxygen atom of hpb^- ligand are somewhat shorter than an ideal single Re–O bond length (*ca.* 2.04 Å) [50], indicating only small delocalization in the O(2)–Re(1)–O(1) moiety.

For *cis*-halide $[ReOX_2(hbt)(PPh_3)]$ complexes the Re–X distances *trans* to the phosphorus or arsine atom of EPh_3 molecule are slightly longer than the Re–X bonds *trans* to the nitrogen atom of the hpb^- ligand. It indicates *structural trans* effect of the EPh_3 ligands. A similar trend was observed in the other $[ReOCl_2(O–N)(PPh_3)]$ chelates [9–15].

3.4. [ReO(OMe)(hpb)$_2$]·MeCN complex

The geometry of $[ReO(OMe)(hpb)_2]$ compound also reveals typical features of quasi-octahedral oxorhenium(V)complexes with oxygenated bidentate ligands. For complex $[ReO(OMe)(hpb)_2]$ the rhenium atom is displaced 0.2252(10) Å from the equatorial plane formed by the two nitrogen and two oxygen atoms (plane A) and 0.0437(9) and 0.0325(8) Å from the axial planes formed, respectively by O(1), O(2), O(3) and N(3) atoms (plane B) and O(1), O(3), O(4) and N(1) atoms (plane C). Least squares plane A is in-

clined at 88.91(5)° to the plane B and at 88.40(5)° to the plane C. The planes B and C are inclined at 87.18(5)°. Clear distortions of the pseudooctahedral environment of Re center in [ReO(OMe)(hpb)$_2$] is induced by the multiple bonding ligand (terminal oxo ligand –O$_t$) and narrow bite angle of the chelating ligands.

Similar to the [ReOX$_2$(hpb)(PPh$_3$)] complexes, the Re–O$_t$ bond length of [ReO(OMe)(hpb)$_2$] falls in the range typical of a triple bond Re≡O [47]. The interatomic distance between the rhenium atom and the oxygen atom of hpb$^-$ in *trans* position to the terminal oxo ion is somewhat longer than the corresponding Re–O bond in the equatorial plane (in *trans* position to the nitrogen atom). This structural *trans* influence of O$_t$ ligand is common in mononuclear six-coordinate oxoRe(V) complexes with an monoanionic oxygen *trans* to the oxo-group [51].

3.5. Geometry optimisations, charge distributions, electronic structures and NBO analyses

The geometries of **2a**, **4** and **5** were optimized in singlet states by the DFT method with the B3LYP functional. The optimized geometric parameters of **2a**, **4** and **5** are gathered in Tables 3–5, respectively. In general, the predicted bond lengths and angles are in agreement with the values based upon the X-ray crystal structure data, and the general trends observed in the experimental data are well reproduced in the calculations. The largest differences are found for the Re–Br and Re–E (E = P, As) bond distances. It may come from the basis sets which are approximated to a certain extent or may indicate the influence of the crystal packing on the values of the experimental bond lengths. The theoretical calculations do not consider the effects of chemical environment.

Table 7 presents the atomic charges from the Natural Population Analysis (NPA) for **2a**, **4** and **5**. The calculated charges on the rhenium atoms in **2a** and **4** are almost the same, whereas the calculated charge on the Re atom in complex **5** is considerably larger in comparison with the monosubstituted compounds. However, all the values are lower than the formal charge +5 as a result of significant charge donation from the donor atoms of the ligands. For all the complexes considerable differences in values of charges are observed for the terminal oxo ligand and the oxygen atom of hpb$^-$ ligand – less negative are the terminal oxo ligands, which indicate the higher electron density delocalization from the terminal ligands towards the rhenium centers and correspond to differences in the Re–O$_t$ and Re–O$_{hpb}$ bonds lengths. As far as the charge on the terminal oxo ligand is concerned, some difference between the monosubstituted and disubstituted complexes is visible. The higher charge donation from the terminal oxo ligand is observed for **2a** than **4**. For *cis* and *trans* isomers are also observed some differences in values of charges on the bromide ions. The higher charge donation from the bromide ions is noticed for the *cis*-[ReOBr$_2$(hpb)(PPh$_3$)] complex.

The **2a**, **4** and **5** are closed-shell structures. Their partial molecular orbital diagrams with the several highest occupied and lowest unoccupied molecular orbital contours are presented in Figs. 5–7, respectively.

Two highest occupied MOs of **2a**, are of d$_{xy}$ type with some contributions from p$_\pi$ bromide and hpb$^-$ orbitals. The LUMO and LUMO+1 are predominately localized on the rhenium atom (d$_{xz}$ and d$_{yz}$ orbitals) with some contribution of p$_\pi$ oxygen orbitals. The LUMO+2 is of d$_{x^2-y^2}$ character, and d$_z^2$ rhenium orbital contributes mainly to the LUMO+15. The value of the energy separation

between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) equals to 2.98 eV.

The qualitative molecular orbitals scheme of **2a** is almost the same as for **4**. HOMO and HOMO−1 of **2a** and **4** are of d_{xy} type with some contributions from p_π bromide and hpb^- orbitals. The LUMO and LUMO+1 are predominately localized on the rhenium atom (d_{xz} and d_{yz} orbitals) with significant contribution of p_π oxygen orbitals. The LUMO+2 is of $d_{x^2-y^2}$ character, and d_z^2 rhenium orbital contributes to the higher unoccupied MO. The HOMO−LUMO gap of **4** is equal to 3.01 eV, and is almost the same as for **2a**.

The HOMO−LUMO gap of **5** is equal to 3.16 eV. The HOMO of **5** is comprised of rhenium d_{xy} and π orbitals of $O_{(OMe)}$ and hpb^-. The LUMO and LUMO+1 are predominately localized on the rhenium atom (d_{xz} and d_{yz} orbitals) with significant contribution of the p_π oxygen orbitals. However, in comparison with corresponding orbitals of **2a** and **4** they are more delocalized, with higher contribution of the π-anti-bonding orbitals of hpb^- ligands. The $d_{x^2-y^2}$ character, and d_z^2 rhenium orbital contributes to the higher unoccupied MO.

The nature of rhenium–terminal oxygen (O_t) interaction in **2a**, **4** and **5** has been studied by NBO analysis. The occupancy and composition of the calculated Re–O_t natural bond orbitals (NBOs) are given in Table 8.

Each natural bond orbital (NBO) σ_{AB} can be written in terms of two directed valence hybrids (NHOs) h_A and h_B on atoms A and B:

$$\sigma_{AB} = c_A h_A + c_B h_B$$

where c_A and c_B are polarization coefficients. Each valence bonding NBO must in turn be paired with a corresponding valence *anti*-bonding NBO:

$$\sigma^*_{AB} = c_B h_A - c_A h_B$$

to complete the span of the valence space. The Lewis-type (donor) NBOs are thereby complemented by the non-Lewis-type (acceptor) NBOs that are formally empty in an idealized Lewis picture. The interactions between 'filled' Lewis-type NBOs and 'empty' non-Lewis NBOs lead to loss of occupancy from the localized NBOs of the idealized Lewis structure into the empty non-Lewis orbitals, and they are referred to as 'delocalization' corrections to the zeroth-order natural Lewis structure [52].

Similar to the previously described [$ReOX_2(O–N)(PPh_3)$] and [$ReOX(O–N)_2$] chelates [9–14], two strongly polarized to the oxygen atom natural Re–O_t bond orbitals were detected for **2a**, **4** and **5**. For each complex the both detected natural Re–O_t bond

orbitals are similar in energy and they are composed of the p oxygen and d rhenium orbitals. The terminal oxo ligand of **2a**, **4** and **5** has two lone pair orbitals, and electron density from one of them is strongly delocalized into non-Lewis rhenium orbital (see Table 9). It can be assumed that the detected natural Re–O_t bond orbitals are of π character and not detected σ_{Re-Ot} bond has ionic character, similar as Re–N bond orbital in $[ReCl_4(MeCN)_2]$ [53].

Accordingly, NBO analysis confirms a triple bond between the rhenium and the terminal oxygen ligand in **2a**, **4** and **5**.

3.6. Electronic spectra

The experimental and calculated electronic spectra of **2a**, **4** and **5** are presented in Figs. 8–10, respectively. The positions of absorption bands for the other $[ReOX_2(hbo)(EPh_3)]$ complexes are given in the experimental part. Each calculated transition for **2a**, **4** and **5** complexes is represented by a gaussian function $y = ce^{-bx^2}$ with the height (c) equal to the oscillator strength and b equal to 0.04 nm^{-2}.

Tables 10–12 present the most important electronic transitions calculated with the TDDFT method assigned to the observed absorption bands of **2a**, **4** and **5**, respectively. For the high energy part of the spectrum, only transitions with oscillator strengths larger than 0.020 are listed in Tables 10–12. The assignment of the calculated orbital excitations to the experimental bands was based on an overview of the contour plots and relative energy to the occupied and unoccupied orbitals involved in the electronic transitions.

3.7. Electronic spectrum of *2a*

The longest wavelength experimental band of **2a** at 649.8 nm originates in the HOMO → LUMO, HOMO−1 → LUMO and HOMO → LUMO+1 transitions. As can be seen from Fig. 4, the LUMO orbital is mainly formed from rhenium d atomic orbital, the HOMO−1 and HOMO orbitals are delocalized among rhenium ion, bromide and hpb^- ligands. Accordingly, the transitions assigned to the longest wavelength experimental band can be seen as mixed bromide/hpb → Re (*Ligand–Metal Charge Transfer*; *LMCT*) and d → d (*Ligand Field; LF*) transitions.

The experimental absorption band at 407.6 nm can be assigned to *Ligand–Metal Charge Transfer* transitions occurring from the bromide, triphenylphosphine and hpb^- ligands to d rhenium orbitals.

The absorption bands at 308.5 and 209.3 nm result mainly from *Ligand–Ligand Charge Transfer* and interligand (*IL*) transitions. However, some contribution of the *Ligand–Metal Charge Transfer* from

the bromide, triphenylphosphine and hpb$^-$ orbitals to the d rhenium orbitals in these bands is also confirmed by the calculations.

3.8. Electronic spectrum of **4**

As can be seen from Figs. 8 and 9, the UV/Vis spectra of the *cis* and *trans* stereoisomers are very similar in terms of the position, intensity and shape of the bands, as well as character of the assigned transitions (see Tables 10 and 11). The longest wavelength experimental band of **2** at 665.9 nm can be seen as mixed bromide/hpb → Re (*Ligand–Metal Charge Transfer*; *LMCT*) and d → d (*Ligand Field; LF*) transitions. The experimental absorption band at 398.8 nm is attributed to *Ligand–Metal Charge Transfer* transitions occurring from the bromide, triphenylarsine and hpb$^-$ ligands to *d* rhenium orbitals.

The absorption bands at 306.6, 245.2 and 202.1 nm result mainly from *Ligand–Ligand Charge Transfer* and interligand (*IL*) transitions. However, some contribution of the *Ligand–Metal Charge Transfer* from the bromide, triphenylphosphine and hpb$^-$ orbitals to the d rhenium orbitals in these bands is also confirmed by the calculations.

3.9. Electronic spectrum of **5**

The longest wavelength experimental band of **5** at 639.9 originates in the HOMO → LUMO transition. The HOMO and LUMO orbitals are delocalized among rhenium ion, bromide, oxo and hpb ligands, so a delocalized *MLLCT* (metal–ligand-to-ligand CT) description can be used. However, considering that HOMO and LUMO comprise mainly rhenium 5d atomic orbitals (Fig. 5), the HOMO → LUMO may be also ascribed as transition of d → d character.

The experimental bands at 413.0 and 342.7 nm can be assigned to *Ligand–Metal Charge Transfer* transitions occurring from the bromide, oxo and hpb$^-$ ligands to d rhenium orbitals.

The experimental bands below 300 nm result mainly from *Ligand–Ligand Charge Transfer* and interligand (*IL*) transitions.

Supplementary data

2.2. Synthesis of the complex $\{[Fe^{II}(phen)_3]_2[Fe^{III}ox_5]\}\cdot 11H_2O$ (**1**)

Complex **1**, as red plates, can be prepared (yield about 75%) by slow evaporation of aqueous solutions (30 mL) containing iron(III) chloride (0.5 mmol), oxalic acid (1 mmol), and the phenantroline ligand (1.0 mmol) previously solubilized in the minimum amount of ethanol. The crystals were filtered off and dried on filter paper at air. *Anal.* Calc. for $C_{82}H_{70}Fe_4N_{12}O_{31}$ (**1**): C, 50.99; H, 3.63; N, 8.65. Found: C, 50.92; H; 3.68; N, 8.71%. Water content was confirmed by thermogravimetric analysis (TGA).

2.3. Crystallographic data collection and structure determinations

X-ray diffraction data were collected using a Bruker–Nonius X8APEX CCD area detector diffractometer. Graphite-monochromated Mo Kα radiation (α = 0.71073 Å) was used. The theta range for data collection is 1.63–32.09°, the index ranges are $-18 \leqslant h \leqslant 18$, $-19 \leqslant k \leqslant 19$, $-20 \leqslant l \leqslant 19$.

The data were processed through the SAINT [11] reduction and SADABS [12] absorption software. The structures were solved by direct methods and subsequently completed by Fourier recycling using the SHELXTL software package. [13] Non-hydrogen atoms were refined anisotropically, with the exception of the O(6w) atom. This latter has been located on the Δ*F* map, with an occupancy factor of 0.5, and shows a very large thermal motion. The hydrogen atoms of the O(6w) water molecule were not defined, while those of the other water molecules were located on the Δ*F* map and refined with restrains. The short O(6 W)···O(5Wb) contact [2.392(8) Å, (b) $-x+1, -y+2, -z$] is most likely a consequence of the high thermal disorder of O(6w).

The final formulation of the compound is in agreement with the residual electron density and elemental analysis.

3. Results and discussion

The structure of compound **1** consists of centrosymmetric dinuclear $[Fe_2(ox)_5]^{4-}$ anions, mononuclear $[Fe(phen)_3]^{2+}$ cations (Fig. 1) and crystallization water molecules linked together by means of electrostatic interactions and hydrogen bonds. The resulting structure is similar to that found in the parent compound of formula $[Fe(bpm)_3]_2[Fe_2(ox)_5]\cdot 8H_2O$ (**2**) that we have previously reported [10].

The anionic unit contains two Fe(III) atoms, four terminal and one bridging oxalato ligands. Each iron(III) ion has a distorted octahedral environment. The iron-bridging-oxalato bond lengths are significantly longer than those involving the terminal oxalato ligands, as already observed in complex **2**. The bridging oxalato is planar because of the inversion center located at the midpoint of the C–C bond. The $[Fe(phen)_3]^{2+}$ cation consists of iron(II) ion coordinated to three phenantroline molecules in a distorted octahedral geometry.

The average Fe(1)–N bond length is in the range of the observed bond lengths for low-spin tris-chelated iron(II) complexes [14]. The iron(III) and iron(II) bond length are reported in Table 2. The phenantroline ligands are planar, as expected.

Non-covalent interactions are expected to occur in compounds containing π systems. In the case of compound **1**, the tris-chelated cations are connected by π–π interactions in such a way as to form a supramolecular bi-dimensional motif. All the three phen ligands are involved in these stacking interactions, the mean distance between the phenantroline planes being 3.48(1) Å. A similar supramolecular arrangement is not found in compound **2**, where only two of the bpm molecules of the $[Fe(bpm)_3]^{2+}$ cation are involved in stacking interactions, leading to a chain motif along the *b* crystallographic axis. The anionic dimers in **1** alternate with the cations

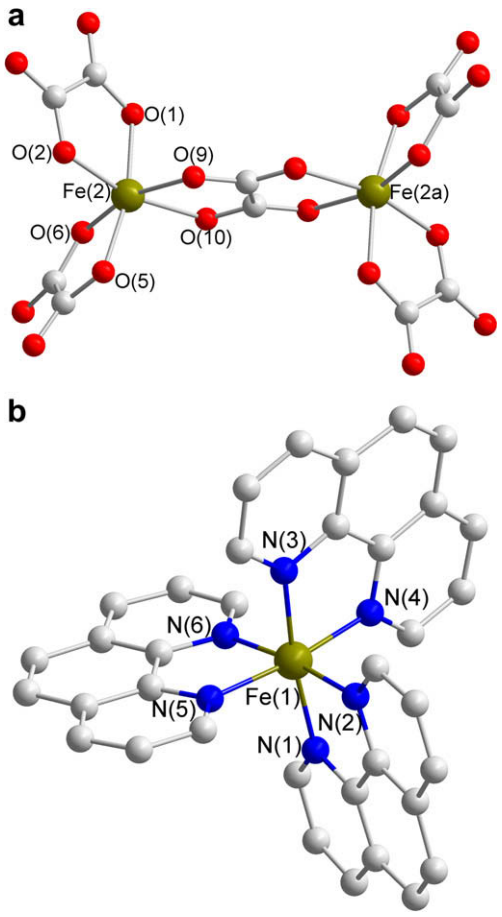

Fig. 1. A view of the anionic dimeric unit (a) and the monomeric cation (b) with the atomic labeling scheme. Hydrogen atoms have been omitted for clarity.

within the supramolecular planes. Water molecules are located among the anionic dimers, filling the gaps between these planes.

The most interesting feature of the solid state structure of **1** is the formation of decanuclear water clusters (Fig. 2) self-assembled by means of hydrogen bonding interactions between water molecules. The classification of the decamer in the Infantes and Motherwell nomenclature is not obvious to us [2a]. Each decanuclear water cluster consists of a cyclic hexanuclear water cluster hydrogen bonded to an unclosed trinucler cluster and an additional water molecule. The $(H_2O)_{10}$ clusters display extensive multiple interactions with the dimeric units, by means of hydrogen bonds with the terminal oxalate ligands. These multiple interactions play a key role in the structural stabilization and formation of an extended 3D supramolecular assembly, wherein extended tapes of hexameric water clusters interconnected with dodecameric hybrid water–$O_{oxalate}$ clusters can be recognized (Figs. 3 and 4) when the equally strong H-bonding interactions of water molecules with the inorganic host are included.

The geometrical parameters of the decameric water clusters and their interactions with the bimetallic host are collected in Table 3.

Symmetry-generated water molecules [O(1 W)···O(2Wd)···O(3Wa)···O(1Wb)···O(2Wc)···O(3We), where (a) $-x, -y+1, -z+1$; (b) $-x, -y+1, -z+2$; (c) $-x+1, y, z+1$; (d) $-x+1, -y+1, -z+1$; (e) $x, y, z+1$] are interconnected to assemble the $(H_2O)_6$ cluster with a slightly puckered conformation (mean deviation from the ideal plane of 0.14(1) Å). Cyclic planar water hexamer is the basic structural motif found in ice II structure under high pressure [15] and a computational simulation determinated that it is a predominant structural unit [16] in liquid water, too. A quasi-planar hexamer was also detected within a helium droplet [17]. The planar water hexamers can be regarded as the simplest supramolecular analogues of benzene.

Each water molecules within the hexanuclear cluster act at once as donor and acceptor of two hydrogen bonds. Within the hexameric water clusters the average O···O contact is of ca. 2.816(3) Å, comparable to that observed in other discrete $(H_2O)_6$ clusters [7–9,18] which are trapped by various metal–organic matrixes. This distance in regular ice, in liquid water, and in the vapor phase is, respectively, 2.74, 2.85, and 2.98 Å [19]. The average O···O distances reported for the Ice II phase are 2.77–2.84 [20]. The nonbonding O···Ô···O angles (Table 1) in **1** span a wide range [108.9(3)–132.1(3)°] deviating considerably from an ideal benzene-like structure.

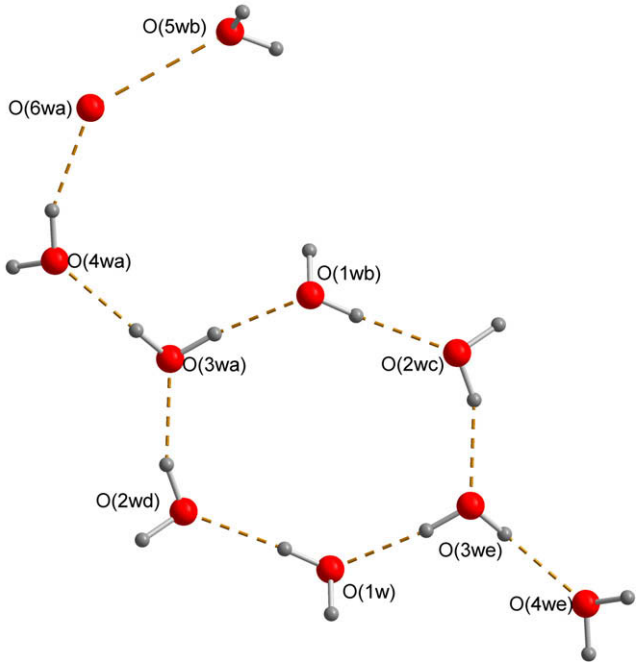

Fig. 2. A view of the decanuclear water cluster showing the atomic labeling scheme. (Symmetry transformations used to generate equivalent atoms: (a) $-x, -y+1, -z+1$; (b) $-x, -y+1, -z+2$; (c) $-x+1, y, z+1$; (d) $-x+1, -y+1, -z+1$; (e) $x, y, z+1$.)

The unclosed trinuclear cluster is defined by the O(4wa), O(5wb) and O(6wa) set of atoms, hydrogen bonded *via* O(4wa) to the O(3wa) water molecule of the exanuclear cluster, the mean O···O distance being 2.859(6) Å.

The decanuclear clusters are connected to the anionic dimers, by means of hydrogen bonding interactions with the oxygen atoms of the oxalate ligands [O(1wb)···O(3b), O(2wd)···O(6), O(4wa)···O(7f), O(4wa)···O(8f), O(5wb)···O(3b), O(5wb)···O(4b) and O(5wb)···O(7 g), where (f) $-x, -y+2, -z+1$; (g) $x-1, y, z+1$], the mean O···O distance being 2.988(4) Å, generating a 3D supramolecular network as showed in Fig. 3b. The atomic labeling scheme is reported in Fig. 4a. Taking into account these water–oxalate interactions, the total H-bond pattern can be alternatively described as extended tapes of fused water hexamers and hybrid dodecameric water–$O_{oxalate}$ clusters (Fig. 4b). This latter accommodate in its cavity a dangling water molecule [O(6wa)] which interact by means of hydrogen bonds with two water molecules of the cluster [O(6wa)···O(4wa), O(6wa)···O(5wb) and O(6wa)···O(5wh), where (h) $x-1, y+1, z$]. Other hybrid water clusters containing water molecules hydrogen bonded with other solvents, counterions, or small molecules have been reported [21].

For comparing compound **1** with the previously reported compound **2**, we performed a careful analysis of the crystal structure that reveals the presence of isolated hexameric water clusters with a chair-like conformation in compound **2**.

Within the hexameric water clusters the average O···O contact is of ca. 2.925(3) Å, and the nonbonding O···Ô···O angles span a wide range [70.3(2)–125.3(2)°]. These values are essentially in agreements with those reported for other water cluster with a chair conformation [7]. The presence of a longer interaction [O(14)···O(13b) 3.136(2) Å, (b) $1-x, -y, -z$], if compared with the other O···O contacts within the cluster, and of a small nonbonding O···Ô···O angle [O(11)···Ô(13b)···O(14) 70.3(2)°] let suppose a very strained hexamerix water cluster conformation, that tends towards the limit of two isolated trimers.

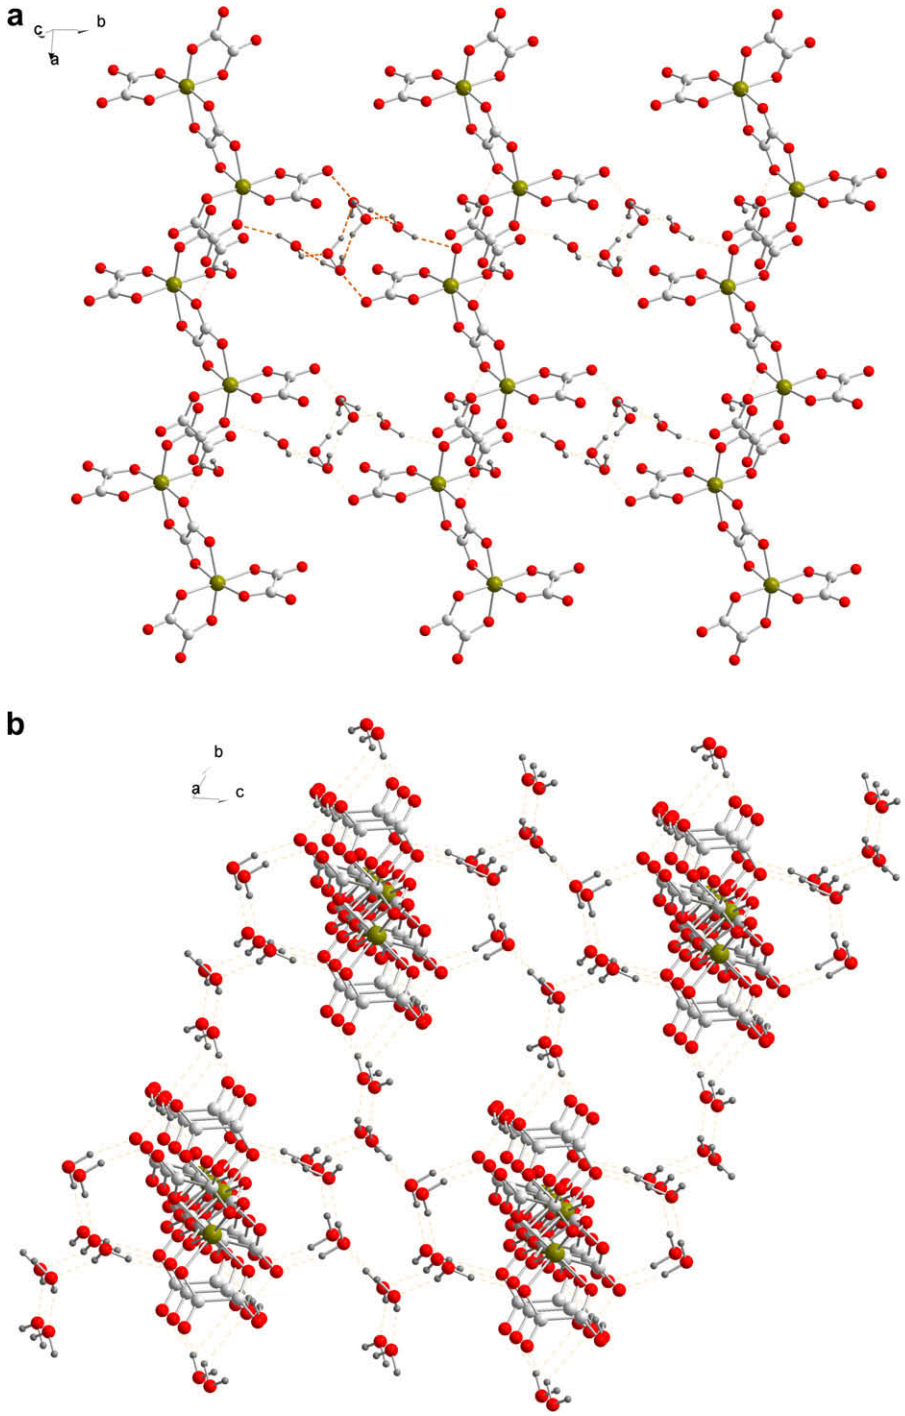

Fig. 3. A view of the 2D (a) and 3D (b) supramolecular motif in compounds **2** and **1**, respectively. The O(6w) water molecule has been omitted for clarity in this picture.

In this case the clusters are directly hydrogen bonded to the oxygen atoms of the oxalate ligands of two dimeric units [O(11)···O(5) 2.879 Å, O(13)···O(4a) 2.942(2) Å, (a) $3-x$, $1-y$, $-z$]. The anionic dimers are also involved in H-bonding interactions with additional water molecules [O(12)···O(8) 2.879(2) Å, O(12)···O(9b) 3.049(2) Å, (b) $1-x$, $-y$, $-z$], these latter interactions producing a supramolecular chain motif along the *a* crystallographic axes. The atomic labeling scheme is shown in Fig. 5. The sum of both interactions leads to a supramolecular bi-dimensional motif in the *xy* plane (see Fig. 6a). The $[Fe(bpm)_3]^{2+}$ cations are sandwiched between these planes. On the contrary in compound **1** the resulting supramolecular structure provided by the H-bonding interactions is trhee-dimensional and cations and anions nearly lie within a same plane.

We want to conclude this work with some considerations on the different nuclearity of water aggregates in compounds **1** and **2** and the changed conformation of the water hexamer moiety in both compounds.

The $[Fe(phen)_3]^{2+}$ cations result to be more effective in the construction of extended water clusters, if compared with the $[Fe(bpm)_3]^{2+}$ cation, since acting like a bulkier spacer it's able to create larger voids between the anions which are filled by a major

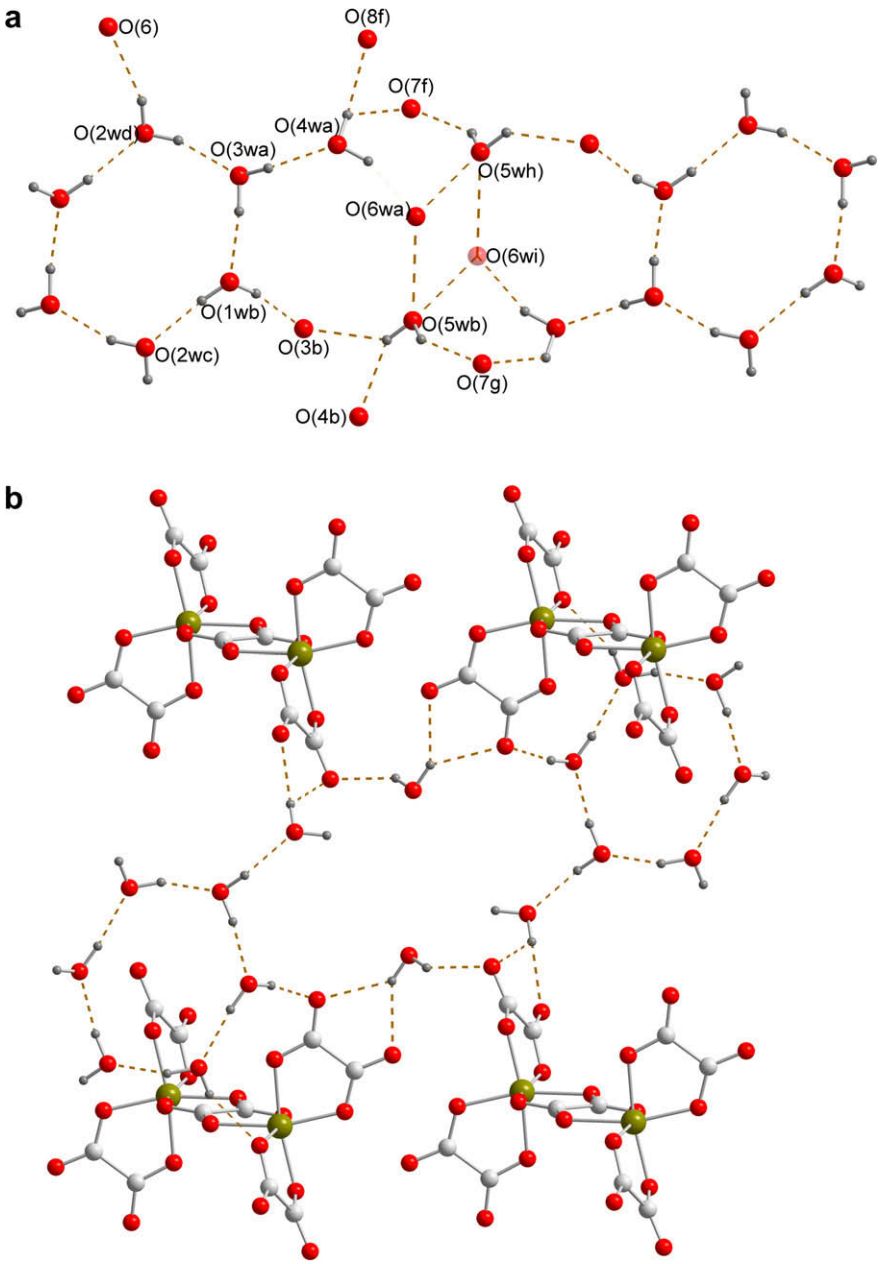

Fig. 4. A view of the interaction of the decanuclear water clusters with the oxalate dimers showing the atomic labeling scheme (a). The two equivalent positions of the O(6w) water molecule are showed in the picture. Fragment of the crystal packing diagram showing the hexameric water clusters interconnected with the dodecameric hybrid water···$O_{oxalate}$ cluster . The O(6w) water molecule has been omitted for clarity. (b) Symmetry transformations used to generate equivalent atoms: (f) $-x$, $-y+2$, $-z+1$; (g) $x-1$, y, $z+1$; (h) $x-1$, $y+1$, z; (i) $x-1$, $y+1$, $z+1$.

number of water molecules. These hipotesys are also supported by the comparison of both structures with those of the other dinuclear penta-oxalate compounds reported in the crystallographic database. To the best of our knowledge, only the compound of formula $\{(NH_2CH_2CH_2)_2[Zn_2ox_5]\}\cdot 8H_2O$ containing the piperazinium cation show the presence of a tetranuclear water cluster [22]. The smaller or linear-shaped cations of the other compounds [23] seems not allowing the formation of similar water clusters.

Both compounds shows the presence of cyclic hexanuclear motifs with different conformations. As stated before, theoretical calculations for the hexameric conformation have revealed the existence of several almost isoenergetic conformations, suggesting that the conformation that will be detected for a cluster strongly depends on its chemical environment. On this subject it has been recently reported that a gradual tuning of the chemical environment is a general strategy to promote the inclusion of relatively large water clusters in certain crystalline salts and to control their size and shape [3].

In our case, the occurrence of hydrogen bonding interactions with the anionic dimers and the presence of two bulky and globular-shaped cations are responsible of the formation of the hexameric water clusters in both compounds. The conformation of such water molecules arrays, on the contrary, seems be most likely affected by the size of the templating cation and the resulting supramolecular arrangement. While the $[Fe(phen)_3]^{2+}$ cation stabilize an higher nuclearity clusters and the almost planar form of the hexameric cluster in **1,** the $[Fe(bpm)_3]^{2+}$ cation support the chair conformation. The Fe···Fe distances between the two $[Fe_2(ox)_5]^{4-}$

Symmetry transformations used to generate equivalent atoms: (d) $-x+1, -y+1, -z+1$, (l) $x+1, y, z$, (m) $x, y, z-1$, (n) $x, y-1, z$.

anions supporting the hexameric cluster increases from 11.51(1) Å in **2** to 12.86(1) Å in **1** (Fig. 6), as a result of the altered supramolecular arrangements caused by the presence of a different cations, namely $[Fe(phen)_3]^{2+}$ in **1**. The passage from the chair conformation to a quasi-planar one seems to represent the attempt of the water molecules to fit into a larger void and optimize the hydrogen bonding interactions with the anionic dimers.

4. Conclusions

In summary, we reported on the self-assembly of an extended 3D array comprising interconnected water hexamers and hybrid water–$O_{oxalate}$ clusters, originated in the compound of formula $[Fe^{II}(phen)_3]_2[Fe^{III}ox_5]\cdot 11H_2O$ (**1**). A comparative study was possible between the supramolecular structure of **1** and that found in the parent compound formula $[Fe(bpm)_3]_2[Fe_2(ox)_5]\cdot 8H_2O$ (**2**). The presence of different cations seem to influence the water cluster nuclearity, that increase from hexa- (**2**) to decanuclear (**1**), and the hexanuclear cluster conformation, passing from a chair (**2**) to a quasi-planar form (**1**). They are also responsible of the two different supramolecular organizations, namely the bi- and three-dimensional ones. We want finally to remark that the comparative studies on water clusters in crystalline materials are not banal, since they are in general hindered by the serendipitous nature of their occurrence and the unpredictability of their structures.

Supplementary data

CCCDC 710269 contains the supplementary crystallographic data for compounds **1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

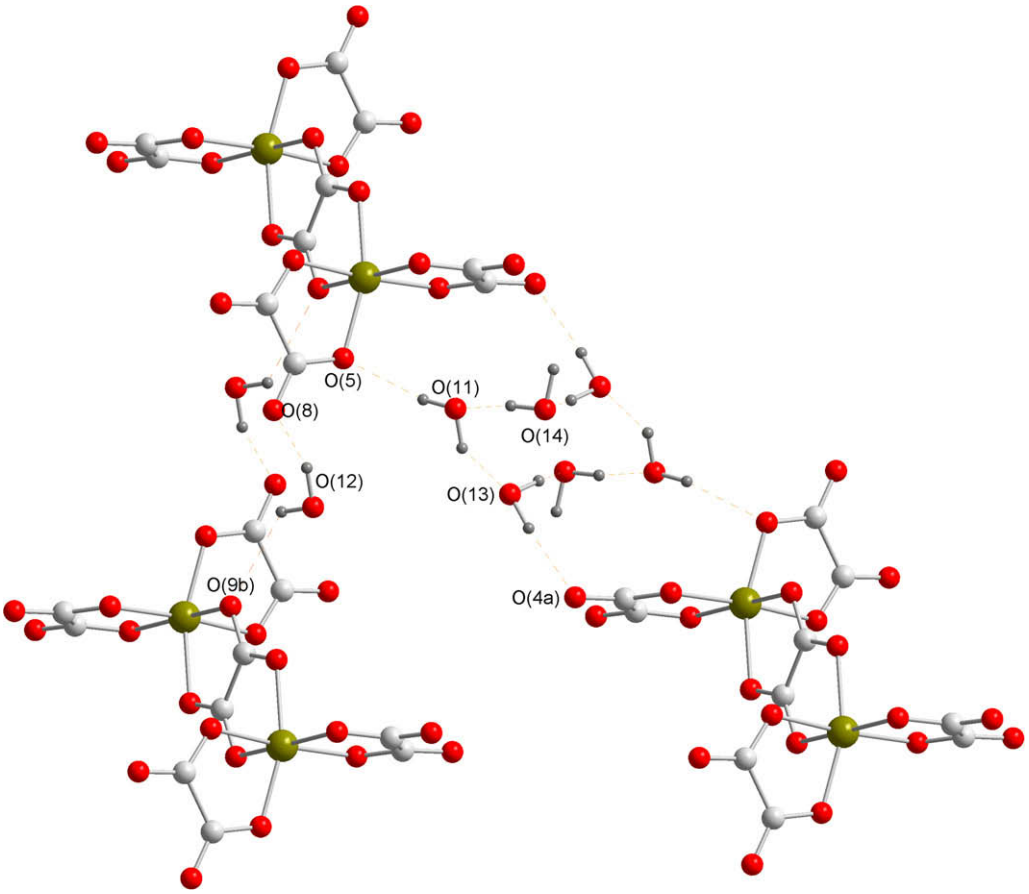

Fig. 5. Fragment of the supramolecular motif found in compound **2** showing the atomic labeling scheme.

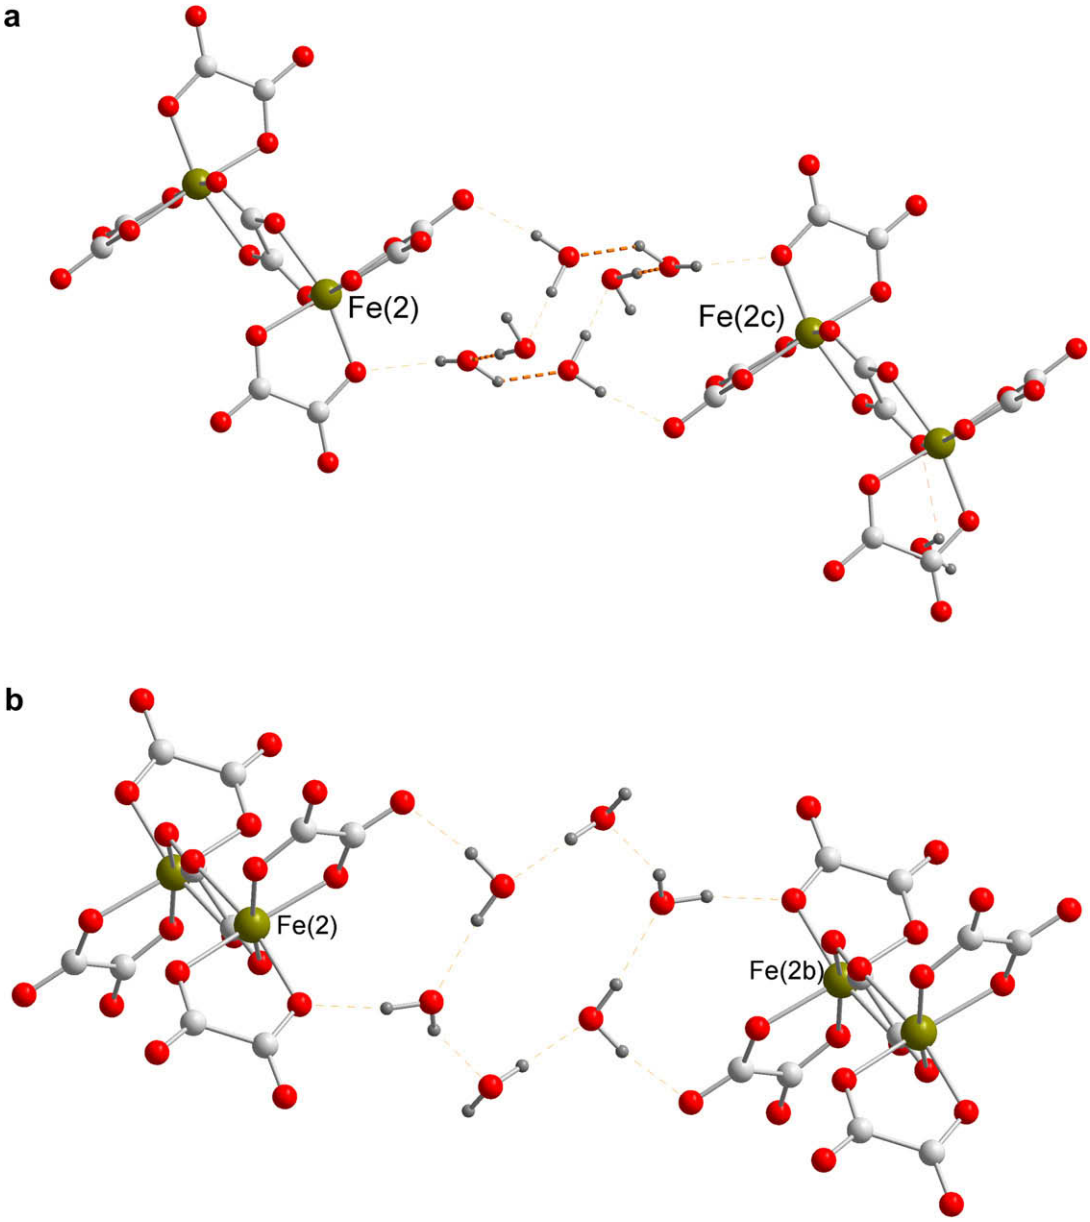

Fig. 6. A view of the two anionic dimers supporting the hexameric water clusters in compounds **2** and **1** respectively. The shorter Fe···Fe distances are 11.508(8) and 12.836(1) Å [Fe(2)···Fe(2c), where (c) $1-x$, $1-y$, $-z$ (**2**) or Fe(2)···Fe(2b), where (b) $-x$, $-y+1$, $-z+2$; (**1**)] in compounds **2** and **1**, respectively.

observed X-ray powder diffraction pattern with a calculated pattern generated from the single crystal X-Ray analysis results.

X-ray powder diffraction data were collected on a Philips APD 1700 instrument. Infrared spectra were measured on KBr pellets with a Scimitar FTS 2000c spectrometer in the range 4000–400 cm^{-1}. Elemental analyses: Vario EL of Elementar Analysensysteme GmbH; NMR: Bruker CXP-300.

2.2. General procedure for the syntheses of compounds 1–3

Seventy milligram of the appropriate Re_4 cluster compound, namely $[Re_4Se_4(TeBr_2)_4Br_8]$ for compound **1**, $[Re_4Te_4(TeBr_2)_4Br_8]$ for compound **2** and $[Re_4Te_4(TeCl_2)_4Cl_8]$ for compound **3**, and an excess of PMe_2Ph (0.06 ml) were dissolved in 10 mL of CH_2Cl_2 and stirred at room temperature for 24 h. The resulting dark brown solutions were filtered and diethyl ether was layered. After 1 week, the black crystalline products obtained were decanted and washed with small amounts of diethyl ether and acetone. Yields: 38 mg (65%) (**1**), 43 mg (74%) (**2**), 45 mg (67%) (**3**). Single crystals for X-Ray study were separated from obtained crystalline products.

$[Re_4Se_4(PMe_2Ph)_4Br_8]\cdot 1.5CH_2Cl_2$ (**1**): *Anal.* Calc. for $C_{33.5}H_{47}Br_8Cl_3P_4Re_4Se_4$ (**1**) 2379.86: C, 16.9; H, 1.99. Found: C, 17.2; H, 2.10%. ^{31}P NMR (CD_2Cl_2): δ −41.1, −41.8, −42.9, −44.1. IR (cm^{-1}): ν(P–C(C_6H_5)) 1098, ν(P–C(CH_3)) 704.

$[Re_4Te_4(PMe_2Ph)_4Br_8]\cdot CH_2Cl_2$ (**2**): *Anal.* Calc. for $C_{33}H_{46}Br_8Cl_2P_4Re_4Te_4$ (**2**) 2531.96: C, 15.7; H, 1.83. Found: C, 15.8; H, 2.21%. ^{31}P NMR (CD_2Cl_2): δ −50.5, −51.0. IR (cm^{-1}): ν(P–C(C_6H_5)) 1100, ν(P–C(CH_3)) 708.

$[Re_4Te_4(PMe_2Ph)_4Cl_8]\cdot CH_2Cl_2$ (**3**): *Anal.* Calc. for $C_{33}H_{46}Cl_{10}P_4Re_4Te_4$ (**3**) 2176.28: C, 18.2; H, 2.13. Found: C, 18.3; H, 2.21%. ^{31}P NMR (CD_2Cl_2): δ −33.0, −34.3, −35.5, −36.4. ν(P–C(C_6H_5)) 1097, ν(P–C(CH_3)) 704.

2.3. X-ray crystal structure analysis

The single crystals of **1**–**3** were selected directly from the reaction mixtures and attached to glass fibers using epoxy resin. At room temperature, the crystals lost their crystallinity within several minutes after their removal from the mother liquor. Thus, X-ray experiments were carried at low temperature. Single-crystal X-ray diffraction data were collected with the use of graphite monochromatized Mo Kα radiation (λ = 0.71073 Å) at 100 K on a Bruker Nonius X8Apex diffractometer equipped with a 4 K CCD area detector. The φ-scan technique was employed to measure intensities. Decomposition of the crystals did not occur during data collection. Corrections were applied for Lorentz and polarization effects and for absorption [26]. The structures were solved by direct methods by employing difference Fourier syntheses and refined anisotropically by full-matrix least-squares techniques on F^2 using the SHELXL-97 RELEASE 97-2 software package [27]. All nonhydrogen atoms were refined anisotropically. The positions of hydrogen atoms of PMe_2Ph ligands and solvate CH_2Cl_2 molecules were calculated corresponding to their geometrical conditions and refined using the rigid model. Crystallographic data as well as details of data collection and refinement for complexes **1**–**3** are given in Table 1.

3. Result and discussion

3.1. Synthesis

Three new molecular tetrahedral rhenium cluster complexes, namely, $[Re_4Se_4(PMe_2Ph)_4Br_8]\cdot 1.5CH_2Cl_2$ (**1**), $[Re_4Te_4(PMe_2Ph)_4Br_8]\cdot CH_2Cl_2$ (**2**), and $[Re_4Te_4(PMe_2Ph)_4Cl_8]\cdot CH_2Cl_2$ (**3**) have been prepared by the reactions of corresponding chalcohalides $[Re_4Q_4(TeX_2)_4X_8]$ (X = Br, Q = Se (for **1**), Te (for **2**); X = Cl, Q = Te (for **3**)) with dimethylphenylphosphine in CH_2Cl_2, stirring for 24 h at room temperature. The products were isolated as black crystalline precipitates by layering of diethyl ether on the resulting CH_2Cl_2 solutions. The compounds lose easily their crystallinity under contact with air at room temperature. However, they are highly soluble in CH_2Cl_2 and can be recrystallized using the same technique.

During the reactions, the $\{Re_4Q_4\}$ cluster core remains as an unalterable unit, while the four outer sphere neutral TeX_2 ligands can be easily replaced by the neutral PMe_2Ph ligands, forming the appropriated compounds. The analogous substitution was observed in the reaction of $[Re_4Te_4(TeCl_2)_4Cl_8]$ with DMF, which resulted in the molecular complex $[Re_4Te_4(DMF)_4Cl_8]$ [19]. In the

case of compounds **1** and **3**, a set of signals in the ^{31}P NMR spectra indicate to the formation of either isomeric cluster complexes with a different arrangement of the terminal ligands or complexes containing different number of the PMe_2Ph ligands in solution. Whereas the data of chemical analyses are in a good agreement with the reported formulas, the first assumption is more plausible. Therefore, we have studied a number of crystals for these two samples. For compound **1,** all the crystals checked had similar unit cell parameters. However, in the case of compound **3** we were able to find and characterize single crystals with two different unit cell parameters, revealing two isomers of the cluster compound $[Re_4Te_4(PMe_2Ph)_4Cl_8]$. Most likely, compound **1** also forms isomers, but our efforts to confirm this assumption by X-ray diffraction were unsuccessful.

3.2. Crystal structures

All three compounds obtained were characterized by single-crystal X-ray diffraction analysis. Their structures are based on a $\{Re_4Q_4\}^{8+}$ (Q = Se in **1** or Te in **2** and **3**) cluster core in which the Re_4 tetrahedron is coordinated by four μ_3-Q atoms (Figs. 1 and 2). The Re–Re and Re–Q interatomic distances in compounds **1**–**3** are assembled in Table 2, and do not appreciably differ from those in the starting materials and other related compounds. Each Re atom is ligated by two halide atoms (bromide in **1** and **2** or chloride in **3a** and **3b**) as well as one dimethylphenylphosphine ligand, resulting in neutral charged cluster units. It is worth noting that the molecular cluster complexes $[Re_4Q_4(PMe_2Ph)_4X_8]$ **1**–**3** also contain CH_2Cl_2 as solvate molecules.

Compounds **1** and **2** represent one isomeric type; while for compound **3** two isomers (**3a** and **3b**) were isolated. The isomerism in this system is due to the different orientation of outer ligands around the cluster core. When the $\{Re_4Q_4\}$ cluster core is considered as a cube and the coordination number of Re atoms being equal to 6 (including outer and μ_3-ligands), these two isomeric forms could be represented by Scheme 1. Isomeric form A corresponds to the compounds **1**, **2** and **3a**, while isomeric form B describes the compound **3b**. As can be seen in Scheme 1, ligand arrangements in $\{ReQ_3(PMe_2Ph)Cl_2\}$ units numbered 1, 2, and 3 are identical in both isomeric forms, while those in the units numbered 4 are different in A and B isomeric forms.

The hetero-nuclear cluster compound $[Re_3CoS_4Cl_6(PMe_2Ph)_4]$ [28] described recently exists also in two isomeric forms, deriving from the different orientation of terminal ligands Cl^- and dimethylphenylphosphine connected with Re atoms. The coordination environment of Co atom is not taken into account, because it has only one terminal ligand. Analogically to Re_4

Isomeric form A

Isomeric form B

Scheme 1.

cluster compounds, the Re_3Co cluster forms isomers at which two of three Re atoms have a similar coordination environment, while the coordination environment of the third Re atom is different in both isomers. Moreover, the three dimethylphenylphosphine ligands connected with Re1, Re3, Re4 atoms to occur in the isomeric forms A and B of **3a** and **3b** are oriented in the same way as it was found in the corresponding $[Re_3CoS_4Cl_6(PMe_2Ph)_4]$ isomers, respectively.

It can also be stated that the above mentioned complex $[Re_4Te_4(DMF)_4Cl_8]$ and the starting materials possess the same symmetrical orientation of DMF or TeX_2 ligands, respectively, as the compound **3b** (isomeric form B). This means that during the reaction the ligand arrangement around the Re atoms in the complexes have to be changed. Thus, it can be concluded that we do not have a simple ligand exchange reaction between TeX_2 and PMe_2Ph. Rather, most likely, a reaction occurs at which an intermediate product that contains Re atoms with four terminal ligands (2X, TeX_2 and PMe_2Ph) releases TeX_2 fragments. Thus, taking into account both of the above mentioned assumptions, the observed isomeric structures are formed in accordance with the recently reported heterometallic cluster compound $[Re_3CoS_4Cl_6(PMe_2Ph)_4]$ [28]. Derived from that, it can be concluded that the isomeric form A of Re_4 and Re_3Co cluster compounds is the thermodynamically controlled product.

Supplementary data

CCDC 721592, 721593, 721592 and 721595 contains the supplementary crystallographic data for **1**, **2**, **3a** and **3b**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. Materials and methods

Tetrahydroisoquinoline, piperidine, carbon disulfide, sodium hydroxide, cadmium chloride, hexadecylamine (HDA) (98%) and tri-octylphosphine (TOP) (90%) were purchased from Aldrich and were used as purchased. Toluene (BDH, 99%), methanol (BDH, 99.8%) and dichloromethane (BDH, >99%) were used as solvents without further purification.

2.2. Physical measurements

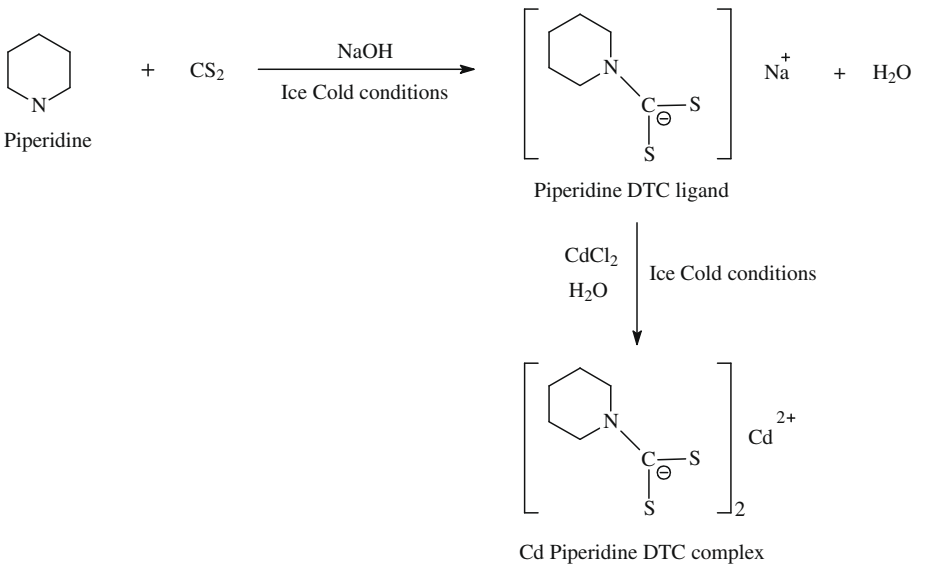
The C, H, N, S elemental analysis was carried out with Leco-CHNS 932 analyzer. Roughly 2.0 mg of sample was introduced into Ag capsule and was placed in a furnace, which was maintained at 800 °C. The products of combustion in the CHNS analysis (CO_2, H_2O and SO_x gases) were carried through the system by the He carrier. Adjustments for blank, calibration and weights were applied to the final integrated signal and the results were displayed as weight percentage of carbon, hydrogen, nitrogen and sulfur.

FT-IR spectra of various powder samples of ligands and complexes were recorded on a Bruker Tensor 27 spectrometer with a 4 cm^{-1} resolution and 32 scans in the mid IR (200–4000 cm^{-1}) region. PL and UV–Vis absorption spectra were measured at room temperature with a Perkin Elmer LS 55 luminescence spectrometer and a Varian Cary 50 Conc UV–Vis spectrophotometer, respectively. Photoluminescence spectra were recorded by placing the sample in a quartz cuvette of 1 cm path length. The excitation wavelength for PL measurement was 400 nm. The samples were analyzed at a scan speed of 500 nm min^{-1} within a scan range of 200–800 nm. UV–Vis spectra were recorded by placing the samples in a quartz cuvette of 1 cm path length at an absorption range of 200–800 nm with the scan rate of 600 nm min^{-1}. Toluene was used as a solvent (as reference in UV) in the measurements. Powder XRD patterns were recorded for all the samples in order to verify the formation and structure of materials. The dry samples were ground with the help of a mortar and pestle and the fine powder of nanoparticles was packed on the surface of a sample holder. The diffraction patterns were recorded in the high angle 2θ range of 10–80° using a Bruker AXS D8 Advance X-ray diffractometer, equipped with nickel filtered Co Kα radiation (λ = 1.5418 Å) at 40 kV, 40 mA and at room temperature. The scan speed and step size were 0.05° min^{-1} and 0.00657, respectively. For the transmission electron microscopy (TEM and HRTEM) measurements, samples were prepared by placing a drop of dilute solution of nanoparticles on Formvar-coated grids (150 mesh). The samples were allowed to dry completely at room temperature and viewed using a JEOL 1010 TEM and JEOL 2100 HRTEM. Viewing was done at an accelerating voltage of 100 kV (TEM) and 200 kV (HRTEM), and the images were captured digitally using a Megaview III camera; stored and measured using Soft Imaging Systems iTEM software.

2.3. Preparation of ligands

A standard solution of NaOH 4 M (25.0 mL) was cooled in an ice bath and the corresponding secondary amine, piperidine or tetrahydroisoquinoline (25.0 mL) was added. To this suspended mixture in ice, CS_2 (7.0 mL) was added dropwise while stirring. The solution was allowed to stand for 1 h and the solidified mixture was dried in air. The solid was re-crystallised using 100.0 mL of dichloromethane and methanol (50:50 – v:v) mixture and was maintained at ice cold conditions overnight. The resultant precipitate was filtered and washed with excess dichloromethane.

$C_{10}H_{10}NS_2Na$: CHNS analysis: Calc.: C, 51.93; H, 4.36; N, 6.06; S, 27.72. Found: C, 51.58; H, 4.07; N, 5.85; S, 27.47%; Percentage yield: 54%; melting point: 137.8–138.2 °C. Significant IR bands: $\nu_{(C-N)}$: 1473 cm^{-1}; $\nu_{(C-S)}$: 949 cm^{-1}.



$C_6H_{10}NS_2Na$: CHNS analysis: Calc.: C, 39.32; H, 5.50; N, 7.64; S, 34.99. Found: C, 38.47; H, 5.98; N, 7.43; S, 34.51. Percentage yield: 58%; melting point: 133.2–135.4 °C. Significant IR bands: $\nu_{(C-N)}$: 1435 cm^{-1}; $\nu_{(C-S)}$: 958 cm^{-1}.

2.4. Preparation of complexes

2.4.1. Synthesis of [Cd ($S_2CNC_5H_{10}$)$_2$] (**I**)

A $CdCl_2$ solution, 10.0 mmol (25.0 mL) was added dropwise to the 25.0 mL solution of piperidine DTC ligand (5.0 mmol) at ice cold temperature (Scheme 1). The reaction was stirred for 1 h and the white precipitate formed was filtered, washed with distilled water and vacuum dried.

CHNS analysis: Calc.: C, 33.29; H, 4.66; N, 6.47; S, 29.62. Found: C 34.29; H, 4.56; N, 6.18; S, 29.47%. Percentage yield: 46%, melting

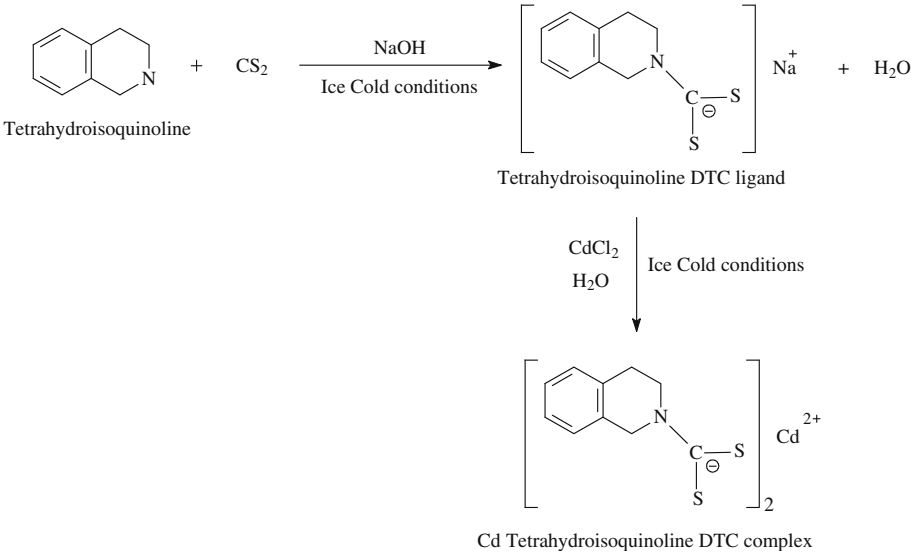
point: 258–269 °C. Significant IR bands: $\nu_{(C-N)}$: 1482 cm^{-1}; $\nu_{(C-S)}$: 976 cm^{-1}; $\nu_{(Cd-S)}$: 227 cm^{1}.



2.4.2. Synthesis of [Cd ($S_2CNC_9H_{10})_2$] (**II**)

A $CdCl_2$ solution, 10.0 mmol (25.0 mL) was added dropwise to the 25.0 mL solution of tetrahydroisoquinoline (5.0 mmol) DTC ligand at ice cold temperature (Scheme 2). The mixture was then stirred for 1 h and the pale yellow precipitate was filtered. The product was washed with distilled water and vacuum dried.

CHNS analysis: Calc.: C, 45.41; H, 3.81; N, 5.30; S, 24.24. Found: C, 45.09; H, 3.662; N, 5.05; S, 24.18%. Percentage yield: 39%, melting point: 269.3–270.1 °C. Significant IR bands: $\nu_{(C-N)}$: 1438 cm^{-1}, $\nu_{(C-S)}$: 965 cm^{-1}, $\nu_{(Cd-S)}$: 262 cm^{-1}.

2.5. Synthesis of HDA capped CdS nanoparticles

Cadmium sulfide nanoparticles were prepared from the single source precursors **I** and **II**. The thermolysis was carried out by varying the amount of the capping agent hexadecylamine (HDA) at a constant temperature (140 or 180 °C). In each thermolysis reaction 0.5 g of the complex was used, with 3.0 and 6.0 g of HDA. The complexes were dissolved in tri-octylphosphine (TOP) and injected into a three-necked flask containing hot HDA at 140 °C. The solution

Scheme 2. Reaction scheme for the synthesis of Cd tetrahydroisoquinoline DTC complex.

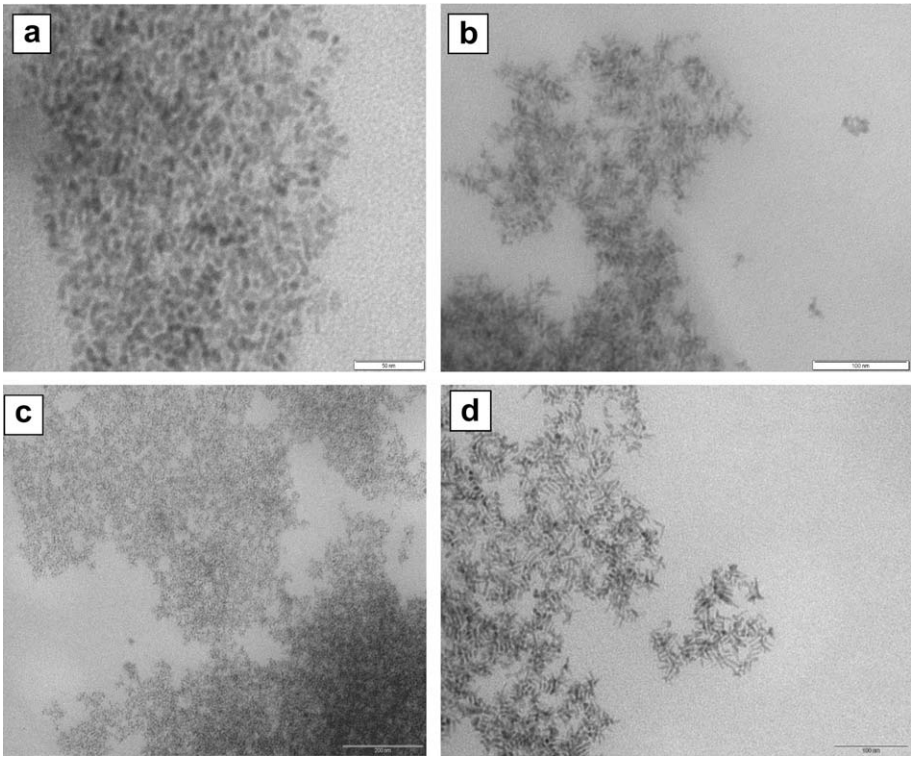


Fig. 1. TEM images of CdS nanoparticles prepared with 0.5 g of complex **I** with (a) 3.0 g, (b) 6.0 g of HDA and complex **II** with (c) 3.0 g, (d) 6.0 g of HDA at 140 °C (1 h).

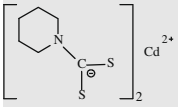

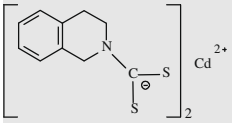

turned bright yellow instantaneously after injection. The reaction was allowed to proceed for 1 h. Excess methanol was added to the cooled solution to flocculate the particles. The resultant precipitate (CdS nanoparticles) was separated by centrifugation. The yellow CdS nanoparticles were then dispersed in toluene for optical studies. The procedure was repeated at 180 °C to study the effect of temperature.

3. Results and discussion

The final morphology of nanoparticles in any solution is governed by the preferred growth regime of the reaction. The reaction can proceed in either a kinetic or a thermodynamic growth regime [2,15]. Parameters such as monomer concentration, reaction temperature, and capping group influence the type of growth regime. The thermodynamic growth regime is favored by high temperatures and low monomer concentration yielding stable isotropic particles. In contrast non-equilibrium kinetic conditions are favoured by low reaction temperatures and high monomer concentration yielding selective anisotropic particles (i.e. rods, tetrapods) [2,15,16].

Fig. 1 shows the TEM images for CdS nanoparticles synthesized from complexes **I** and **II** at different concentrations (3.0 and 6.0 g HDA) at 140 °C. The results of the TEM studies are summarized in Table 1. At the highest concentration (0.5 precursor in 3.0 g HDA) the CdS nanoparticles synthesized from **I** were predominantly oblate in shape with an average diameter size of 7.9 ± 0.9 nm. At a lower concentration under similar reaction conditions the shape of the particles changes to rods. For complex **II** at both concentrations the particles are rod shaped with bipods and tripods also present at the lower concentration.

Table 1
CdS nanocrystals synthesized with 0.5 g of complexes **I** and **II** with 3.0 and 6.0 g of HDA at 140 and 180 °C (reactions 1, 2, 4, 5, 7, 8, 10, and 11).

Cd complex	Mass of HDA (g)	Reaction temp. (°C)	Particle shape	Particle size (nm)
	3.0	140	oblate	diameter = 7.9 ± 0.9
	6.0	140	rods	length = 14.1 ± 2.1
				breadth = 4.1 ± 0.65
	3.0	180	dots	19.71 ± 3.24
	6.0	180	rods	length = 19.35 ± 2.98
			bipods tripods	breadth = 5.80 ± 0.78
	3.0	140	rods	length = 9.99 ± 1.38
				breadth = 5.31 ± 0.9
	6.0	140	rods	length = 18.18 ± 2.10
			bipods tripods	breadth = 4.82 ± 0.77
	3.0	180	dots	diameter = 20.61 ± 4.72
	6.0	180	rods	length = 20.91 ± 2.96
			bipods tripods	breadth = 6.13 ± 1.02

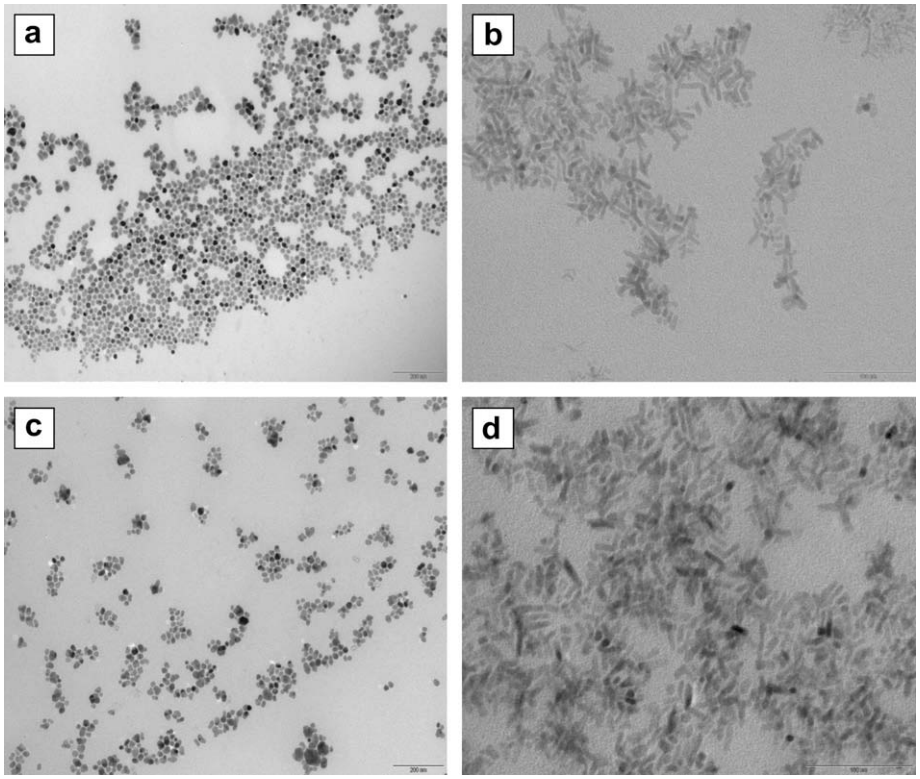

Fig. 2. TEM images of CdS nanoparticles prepared with 0.5 g of complex **I** with (a) 3.0 g, (b) 6.0 g of HDA and complex **II** with (c) 3.0 g, (d) 6.0 g of HDA at 180 °C.

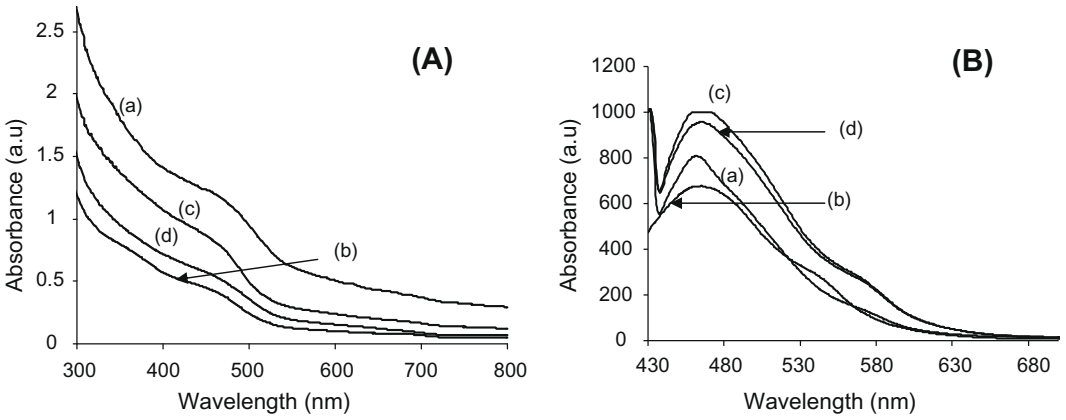

Fig. 3. Optical absorption (A) and corresponding photoluminescence (B) spectra of CdS nanoparticles synthesized with 0.5 g of complex **I** and (a) 3.0 g, (b) 6.0 g of HDA; and with 0.5 g of complex **II** and (c) 3.0 g, (d) 6.0 g of HDA at 180 °C.

When the temperature is increased to 180 °C similar trends are observed for the particles synthesized from both complexes at varying concentrations. For complex **I**, at high concentration, very well defined close to spherical particles (dots) with an average diameter of 19.71 ± 3.24, are observed (Fig. 2a). A reduction of the precursor concentration results in an evolution of shape, with rods, bipods and tripods observed (Fig. 2b). For complex **II** a similar trend is observed (Fig. 2c and d), with shape transformation from isotropic to anisotropic shaped particles clearly evident. The evolution of shape from close to spherical particles to distinct rod shaped particles with decrease in concentration of the precursor is in contrast to previous reports [2,15,16]. Nair and Scholes [17] reported that anisotropic particle growth could be due to oriented attachment. Recently it has been reported that low reaction temperatures can slow down the rate of decomposition of the single source precursor [18]. At this condition nanorods are produced through a mechanism of self assembly. We can conclude from our results that other factors such as the nature of precursor in addition to temperature and concentration can also influence the mechanism of formation of the final particle morphology.

The absorption spectra for the CdS nanoparticles synthesized at 180 °C from both complexes at the two concentrations are shown in Fig. 3A. The absorption band edges (ca. 500 nm) [Fig. 3(A) a and c] for the particles synthesized at higher concentrations for both complexes are distinctly sharper and more pronounced than the band edges [Fig. 3(A) b and d] of the particles synthesized at lower concentrations. The broadening of the band edges at the lower concentrations is an indication of a broader size distribution or the presence of larger elongated particles. This observation is confirmed by the TEM measurements which show the presence of rod shaped particles at lower concentrations (Fig. 2d). The photoluminescence (PL) spectra (Fig. 3B) of all the samples show broad emission peaks with an absorption maximum at 465 nm. The broad emission peaks are indicative of particles with large size distributions and/or the presence of anisotropic particles. A secondary emission shoulder is observed at 575 nm for all samples except for complex I at high concentration. This secondary peak maybe attributed to emission from a subset of larger particles and/or aggregation of particles. Emission due to recombination of charge carriers from surface defects could also account for the emission shoulder [19].

The powder X-ray diffraction patterns for the CdS nanoparticles prepared from complexes **I** and **II** (6.0 g HDA, 180 °C) are shown in Fig. 4. The presence of the (1 1 0), (1 0 3) and (1 1 2) planes in the diffraction patterns is characteristic of the hexagonal phase of CdS. The observed narrow peaks at (1 0 0), (0 0 2) and (1 0 1) show that the nanoparticles are elongated towards the *c*-axis which is the characteristic of rod shaped particles.

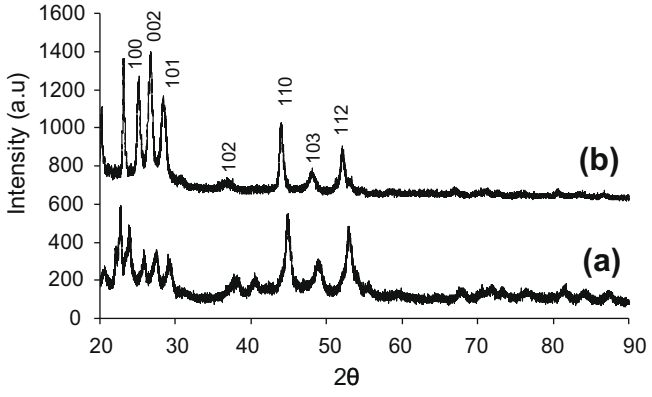

Fig. 4. XRD patterns of CdS nanocrystals synthesized with 0.5 g of complexes **I** and **II** with 6.0 g of HDA at 180 °C.

4. Conclusions

Heterocyclic cadmium dithiocarbamate complexes were successfully used as single source precursors in the synthesis of CdS nanoparticles. At high temperature, 180 °C, and high concentrations very distinct, close to spherical particles were observed. An evolution of rods and bipods and tripods shape was observed with the decrease in concentration of the precursor. The optical measurements also support the presence of anisotropic particles at lower precursor concentrations. The XRD patterns confirm the hexagonal phase of CdS. The inherent nature of the precursor has an influence on the shape of the particles.

L2 = oxalate anion, L3 = glutarate anion and L4 = 1,4-naphthalenedicarboxylate anion). Our study shows that the structures of dicarboxylate anions play important role in the formation of these silver(I) complexes.

2. Experimental

2.1. Materials and Instrumentation

All reagents and solvents in the syntheses were of reagent grade, and they were used without further purification. Infrared spectra were recorded on a Nicolet AVATAT FT-IR360 spectrometer as KBr pellets in the frequency range 4000–400 cm^{-1}. The elemental analyses (C, H, N contents) were determined on a CE instruments EA 1110 analyzer. Photoluminescence measurements were performed on a Hitachi F-4500 fluorescence spectrophotometer with solid powder on a 1 cm quartz round plate.

2.2. Synthesis of complex $[Ag_2(L1)_2(L2)]\cdot 2H_2O$ (**1**)

A mixture of $AgNO_3$ (170 mg, 1 mmol), 2-aminopyrimidine (94 mg, 1 mmol) and oxalate (90 mg, 1 mmol) were stirred in CH_3OH–H_2O mixed solvent (10 mL, v/v: 1/1). Then aqueous NH_3 solution (25%) was dropped into the mixture to give a clear solution. The resultant solution was allowed slowly to evaporate in darkness at room temperature for several days to give colorless crystals of **1** (Yield, 50%). They were washed with a small volume of cold CH_3OH and diethyl ether. *Anal.* Calc. for $Ag_2C_{10}H_{14}N_6O_6$: C, 22.66; H, 2.66; N, 15.85. Found: C, 22.61; H, 2.71; N, 15.76%. IR (KBr): $\nu(cm^{-1})$ = 3398 (m), 3296 (m), 2962 (m), 2925 (m), 1625 (s), 1600 (s), 1569 (s), 1478 (s), 1351 (m), 1313 (m), 1223 (m), 788 (m), 660 (w), 520 (w), 462 (m).

2.3. Synthesis of complex $[Ag_2(L1)_2(L3)]\cdot H_2O$ (**2**)

The synthesis of **2** was similar to that of **1**, but with glutarate (132 mg, 1 mmol) in place of oxalate. Colorless crystals of **2** were obtained in 62% yield. *Anal.* Calc. for $Ag_2C_{13}H_{17}N_6O_5$: C, 28.23; H, 3.09; N, 15.19. Found: C, 28.31; H, 3.14; N, 15.25%. IR (KBr): $\nu(cm^{-1})$ = 3400 (m), 3300 (m), 2958 (m), 2924 (m), 1630 (s), 1567 (s), 1472 (s), 1396 (m), 1349 (m), 1219 (m), 1185 (m), 1056(w), 790 (m), 660 (w), 517 (w), 462 (m).

2.4. Synthesis of complex $[Ag_2(L1)_2(L4)]\cdot 2H_2O$ (**3**)

The synthesis of **3** was similar to that of **1**, but with 1,4-naphthalenedicarboxylate (216 mg, 1 mmol) in place of oxalate. Colorless crystals of **3** were obtained in 55% yield. *Anal.* Calc. for $Ag_2C_{20}H_{20}N_6O_6$: C, 36.61; H, 3.07; N, 12.81. Found: C, 36.70; H, 3.12; N, 12.88%. IR (KBr): $\nu(cm^{-1})$ = 3393 (m), 3301 (m), 1626 (s), 1570 (s), 1479 (s), 1410(m), 1364 (m), 1223 (m), 789 (m), 660 (w), 512 (w), 468 (m).

2.5. X-ray crystallography

Single crystals of the complexes **1–3** with appropriate dimensions were mounted on a glass fiber and used for data collection. Data was collected on a Bruker-AXS CCD diffractometer equipped with a graphite-monochromated Mo Kα radiation source (λ = 0.71073 Å) for **1–3**. All absorption corrections were performed with the SADABS program [46]. All the structures were solved by direct methods using SHELXS-97 [47] and refined by full-matrix least-squares techniques using SHELXL-97 [48]. All the non-hydrogen atoms were treated anisotropically. The positions of hydrogen atoms were generated geometrically. The crystallographic details of **1–3** are summarized in Table 1. Selected bond lengths and bond angles of **1–3** are displayed in Table 2. The hydrogen bond geometries are shown in Table S1 (in the Supplementary data).

3. Results and discussion

3.1. Syntheses and IR spectra

The syntheses of complexes **1–3** are carried out in the darkness to avoid photodecomposition and summarized in Scheme S1, in the Supplementary data. The formation of the products is not significantly affected by changes of the reaction mole ratio of organic ligands to metal ions, and the resultant crystals are insoluble in water and common organic solvents. The infrared

the protonated carboxylic groups, indicating that the complete deprotonation of all carboxylate groups in **1**-**3** upon reaction with Ag ions [49].

3.2. Crystal structure of $[Ag_2(L1)_2(L2)]\cdot 2H_2O$ (**1**)

The present X-ray crystal structure analysis suggests that complex **1** crystallizes in the monoclinic space group $C2/c$. The C_2 axis lies in the midpoint of C–C single bond of L2 anion, hence, each asymmetric unit contains one Ag(I) ion, one L1 ligand, a half L2 anion and one uncoordinated water. As shown in Fig. 1a, each four-coordinate Ag, which adopts a distorted tetrahedral geometry, is coordinated by two bridging L1 nitrogen atoms, one amino nitrogen atom and one deprotonated oxalic acid oxygen atom. The largest N(2)–Ag(1)–O(2) angle opened up to 132.69(8)° from the ideal tetrahedral angle while the remaining angles are in the range from 104.81(8) to 123.33(9)°. It is noteworthy that the Ag–N distances to amino nitrogen atoms [Ag(1)–N(3A) = 2.540(3) Å] are significantly longer than those to the pyrimidyl nitrogen atoms [Ag(1)–N(1) = 2.313(2) and Ag(1)–N(2B) = 2.312(2) Å]. This difference may partially be due to the electronic effect between amino nitrogen and pyrimidyl nitrogen atoms. Interestingly, As far as we know, most of aminopyrimidine derivatives often adopt *N*-monodentate and *N*,*N*′-bidentate coordination modes with silver atoms *via* pyrimidyl nitrogen atoms, and the only example with tridentate fashion was ever reported by Wang [40]. Here, L1 ligands are coordinated to the Ag(I) metal centers by taking this rare *N*,*N*′,*N*″-tridentate modes to form 1-D ladder structures (Fig. 1b), which were interlinked by L2 anions [Ag(1)–O(2) = 2.630(4) Å] to generate 2-D pleated molecular sheets (Fig. 1c). Each L2 anion is coordinated to the metal centers in a bidentate μ_1-O, μ_1-O′-bonding mode.

In addition, as shown in Fig. 1c, in each molecular sheet, the Ag(I) ions, L1 ligands and L2 anions are interlinked to form chair-like eight-membered binuclear ring and 18-membered metallocycles in each molecular sheet. Two kinds of intermolecular hydrogen bonds are observed in the 18-membered metallocycles, including N–H···O hydrogen bonds where the amino group of L1 ligands serve as donors while the uncoordinated oxygen atoms on the L2 anions act as acceptors [N(3)–H(3C)···O(1)^{i}, 2.843(4) Å, ∠N–H···O, 141.7°; symmetry code: (i), x, $y-1$, z], and O–H···O hydrogen bonds where oxygen atoms of L2 anions serve as acceptors while hydrogen atoms of uncoordinated water act as donors [O(1W)–H(1WB)···O(2)^{ii}, 2.957(6) Å, ∠O–H···O, 157.0°; symmetry code: (ii), $-x+1$, $y+1$, $-z+1/2$].

3.3. Crystal structure of $[Ag_2(L1)_2(L3)]\cdot H_2O$ (**2**)

When oxalate is replaced by more flexible glutarate and reacted with $AgNO_3$ and L1 ligand under the similar synthetic conditions, a fascinating 3-D structure of **2** is produced. The molecular ORTEP drawing of **2** together with the atom-numbering scheme is depicted in Fig. 2a. X-ray crystal structure determination displays that **2** consists of molecular bilayers with T-shaped blocks as the fundamental building units, in which each central Ag(I) cation adopts a T-shaped coordination configuration with two pyrimidyl nitrogen donors [Ag(1)–N(1A) = 2.317(5) and Ag(1)–N(2) = 2.219(5) Å] of L1 ligand in the horizontal direction. The coordination sphere is completed by one oxygen donor [Ag(1)–O(2) = 2.290(5) Å] of one deprotonated glutarate (L3) in the axial

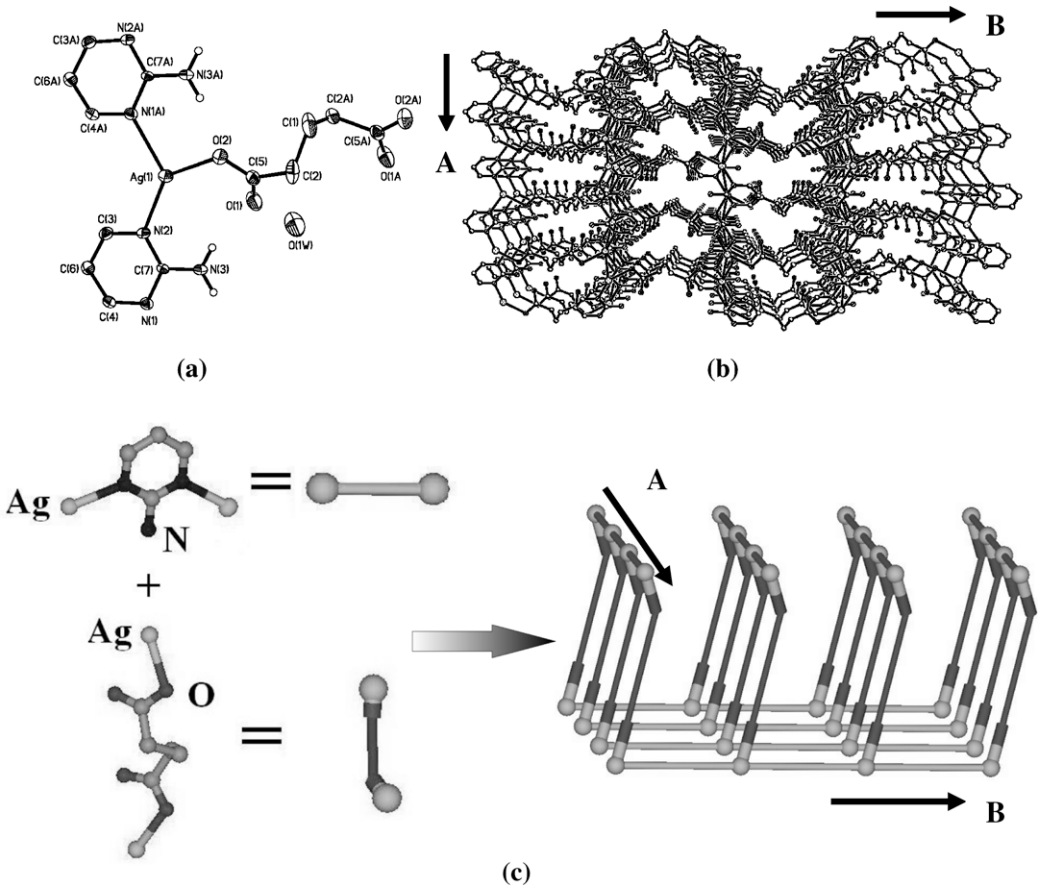

Fig. 2. (a) ORTEP drawing of **2** showing the coordination environment around Ag(I) centers at 40% probability level. (b) Packing diagram of **2** showing microporous tongue-and-groove structure along the *c* axis. All hydrogen atoms and solvent molecules have been omitted for clarity. (c) Schematic representation of molecular bilayer motif of **2**.

direction, forming a new type of T-shaped unit. Fig. 2b shows that **2** contains molecular bilayer motifs, and Fig. 2c gives the schematic representation of corresponding bilayer motif. Each L1 as a bidentate ligand links Ag(I) centers to form infinite 1-D chains in the *ab* plane, and intramolecular N–H···O hydrogen bonds occur in the 1-D chains where oxygen atoms of L3 anions serve as acceptors while the uncoordinated amino groups of L1 ligands act as donors [H···O, 2.02–2.06 Å, N···O, 2.863(6)–2.897(7) Å, ∠N–H···O, 163.7–167.5°]. Interestingly, two kinds of extended modes are observed for these 1-D chains (herein designated as A and B). When viewed from above the *ab* plane, Fig. 2b shows that two related $[Ag(L1)]_{\infty}$ chains are interlaced. The complete deprotonated L3 anions, acting as pillars, interlink the upper and lower chains to generate bilayer galleries. The width of the galleries is determined by the length of L1 ligand (6.448 Å), and their height is fixed by the length of L3 anion (9.847 Å).

To the best of our knowledge, most of the reported silver(I) metal–organic frameworks containing such bilayer motifs have focused on the structures based on single ligand 4,4′-bipy or other mixed ligands with 4,4′-bipy bridges. However, there are no such a distinctive tongue-and-groove structure of 3-D frameworks of coordination polymers with aminopyrimidine bridges reported in the literature. Furthermore, a remarkable feature of the structure of **2** is that the bilayer is sustained by the long L3 anion and short L1 ligand and displays an unusual entanglement (see Fig. S1, in the Supplementary data). Its structure belongs to a kind of 2-D to 3-D parallel interpenetration of "thick" layers: the 2-D layers interpenetrate each other in quintuple mode and the 5-fold interpenetrating results in Ag···Ag interactions. The separations between silvers are alternatively 3.269 and 3.241 Å, which are slightly shorter than the summed van der Waal radius of two silver atoms (3.44 Å) [50,51], indicating the existence of weak Ag···Ag interactions. In the molecular bilayer, the lattice water molecule is enclathrated in the cavity of the bilayer and it forms a hydrogen bond with the O1 atom of L3 anion [$O(1w)\cdots O(1)^{i}$ = 2.809(7) Å, symmetry code: (i), $-x-1/2$, $y+1/2$, $-z-1/2$].

Obvious changes are observed from the structures and dimensions (2-D(**1**) to 3-D(**2**)) of **1** and **2**. The striking structural difference between **1** and **2** is simply caused by different $-CH_2-$ spacers in the dicarboxylate anions, *i.e.*, L3 anion with longer spacers than L2 anion shows more flexible in nature, which allows the anion to bend and rotate freely when coordinating to metal centers.

3.4. Crystal structure of $[Ag_2(L1)_2(L4)]\cdot 2H_2O$ (**3**)

When using rigid aromatic 1,4-naphthalenedicarboxylate instead of oxalate to react with $AgNO_3$ and L1 under the similar synthetic conditions, complex **3** with a different structural type from others has been obtained. Single crystal X-ray analysis reveals that complex **3** crystallizes in the orthorhombic space group *Pnna*. The asymmetric unit consists of two Ag(I) ions, two L1 ligands, one L4 anion, and two uncoordinated water molecules. The charge neutrality is achieved by the fully deprotonated carboxylate groups

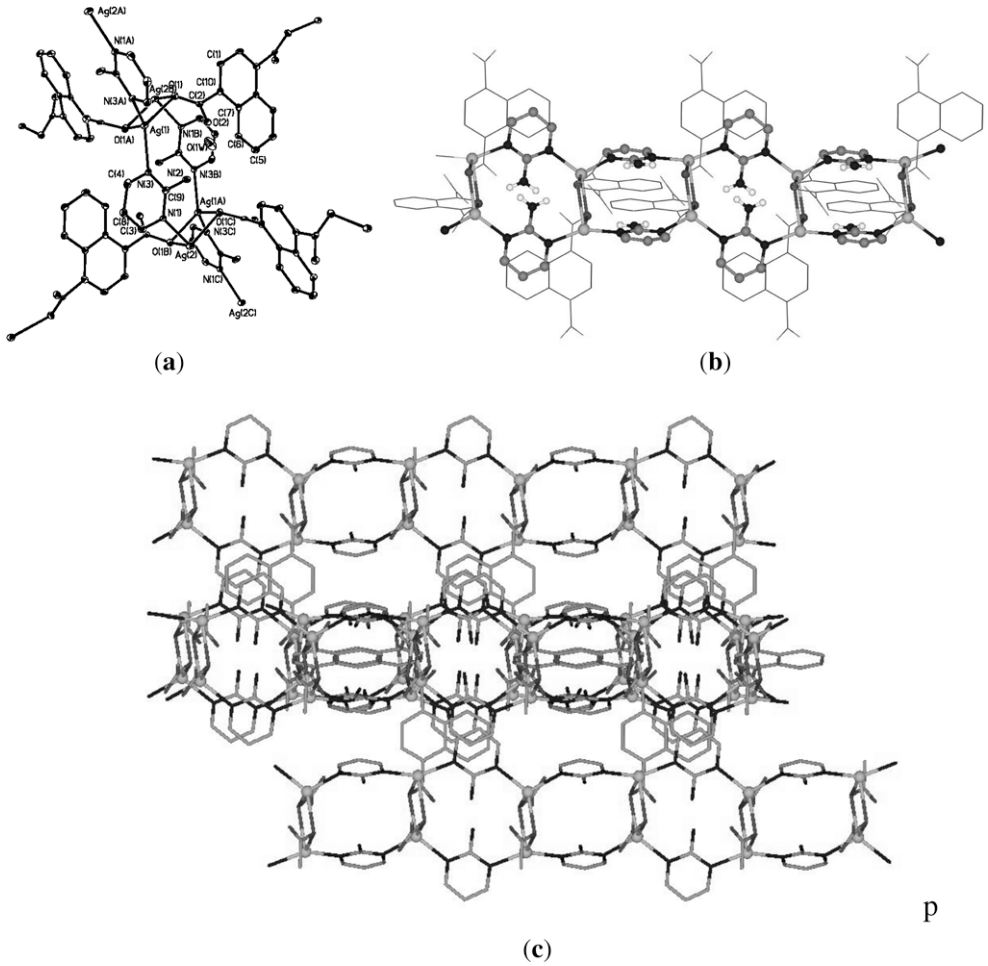

Fig. 3. (a) ORTEP drawing of **3** showing the coordination environment around Ag(I) centers at 40% probability level. (b) A packing diagram showing the 1-D ladder structure in **3**. (c) The 3-D supramolecular structure of **3**. All hydrogen atoms and solvent molecules have been omitted for clarity.

of 1,4-naphthalenedicarboxylate. As shown in Fig. 3a, two independent Ag(I) ions have similar coordination environments, and each central Ag(I) ion is coordinated by two nitrogen atoms [Ag(1)–N(3) = 2.322(4), Ag(1)–N(3A) = 2.322(4) Å; Ag(2)–N(1) = 2.180(4), Ag(2)–N(1A) = 2.180(4) Å] from two L1 ligands and two oxygen atoms [Ag(1)–O(1) = 2.406(3), Ag(1)–O(1A) = 2.406(3) Å; Ag(2)–O(1B) = 2.579(3), Ag(2)–O(1C) = 2.579(3) Å] from different L4 anions in a tetrahedral geometry. All the Ag–N and Ag–O bond distances are within the normal range [35,52,53]. Two such asymmetric units are connected to form a centrosymmetrically tetranuclear 12-membered metallocycle $[Ag_4(L1)_2(L4)_2]$. There is a quadrangle core in the discrete tetranuclear unit. The interatomic distances of Ag–Ag are 6.287 Å on the long sides of the quadrangle and 3.925 Å on the short sides of the quadrangle, excluding any direct metal–metal interaction. The 12-membered rings are interconnected each other through L1 ligands to generate 1-D double polymeric chains (Fig. 3b). Each L1 ligand has similar *N*,*N*′-bidentate coordination mode. Moreover, acting as bridging linkers through corresponding μ^2-carboxylates, L4 anions connect a pair of adjacent Ag(I) atoms to yield 3-D supramolecular networks (Fig. 3c). It is noteworthy that L4 anions hold the same coordination mode with different naphthyl orientation. In addition, lattice water molecules occupy the residual space and are hydrogen bonded to the carboxylate groups from L4 anions [O(1w)···O(2) = 2.941(6) and O(1w)···O(2)^{i} = 2.944(5) Å, symmetry code: (i) x, $-y + 3/2$, $-z + 5/2$].

4. Conclusions

With the principal aim of obtaining new high-dimensional coordination polymers with interesting photoluminescence, we try to introduce dicarboxylates into previous silver/aminopyrimidine system, and get three new silver(I) coordination polymers spanning from 2-D to 3-D frameworks. The analysis of the crystallographic data of **1–3** clearly shows that the structures of dicarboxylate anions are the key factors in directing self-assembly such diverse structures of these silver(I) complexes.

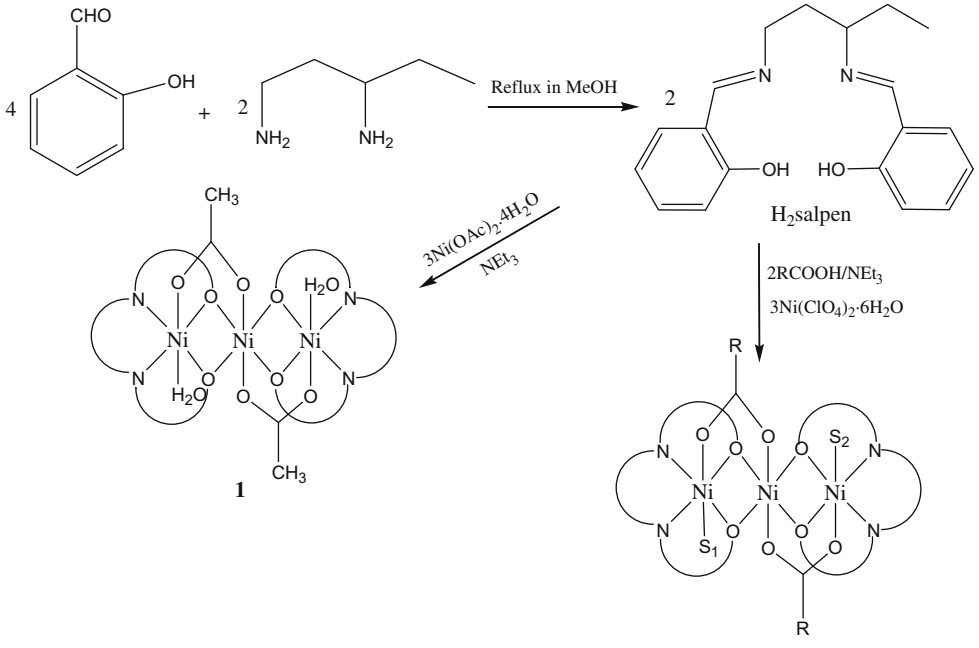
Scheme 1.



bridges yielded quite a few linear trinuclear complexes with hexacoordinated Ni(II) centres [20–23]. However, the potential for utilizing the bridging properties of carboxylate groups other than acetate has not been investigated apart from one example with formate [24]. One benzoate bridged trinuclear Ni(II) compound is also reported [25] but this is with the reduced di-Schiff base ligand. It is also to be noted that although several papers have reported the synthesis and X-ray structural analyses of such kind of linear trinuclear complexes [20–25], detailed magnetic characterizations are seldom forthcoming.

We, therefore, intend to investigate the variation in the structure and magnetic properties by systematically varying the carboxylate bridge. For this purpose, we have taken acetate, benzoate, phenylacetate and cinnamate ion along with the di-Schiff base H_2salpen (*N*,*N*′-bis(salicylidene)-1,3-pentanediamine) and have produced successfully the linear trinuclear Ni(II) complexes ($[Ni_3(salpen)_2(OAc)_2(H_2O)_2]\cdot 4H_2O$ (**1**), $[Ni_3(salpen)_2(OBz)_2]$ (**2**), $[Ni_3(salpen)_2(OPh)_2(EtOH)]$ (**3**) and $[Ni_3(salpen)_2(OCn)_2(CH_3CN)_2]$ (**4**), where OAc = acetate, CH_3COO^-; OBz = benzoate, $PhCOO^-$; OPh = phenyl acetate, $PhCH_2COO^-$; OCn = cinnamate, PhCH CHCOO$^-$) (Scheme 2). The structure of the complexes reveal for the first time that the coordination geometry around Ni(II) can be tuned i.e. it may be hexacoordinated or pentacoordinated depending upon the bridging carboxylate group. Variable-temperature magnetic measurements show antiferromagnetic couplings within the trinuclear units of Ni(II) in all four compounds. The variations in the structures and geometry around Ni(II) in the present complexes afford better insight into the key structural parameters that control the strength and sign of the magnetic interactions as well as zero-field splitting (ZFS) parameters *D*, both factors which are extremely important in the rational design of new complexes which contain the desired properties of a molecular based magnet.

Moreover, the morphology of complexes **1**–**4** has been examined by scanning electron microscopy (SEM) experiments. Among these complexes, the compound with phenylacetate, $[Ni_3(salpen)_2(OPh)_2(EtOH)]$ (**3**) shows a very interesting dye absorption property by forming vesicles and fused vesicles depending upon the concentration of the solution. Its structure and solution state property has been reported by us recently [26]. The SEM experiments have also been performed for the rest of the complexes. They show porous architecture when samples are prepared from CH_2Cl_2 and show microcrystalline nature when samples are prepared from CH_2Cl_2/EtOH solvent mixture. Observation of such morphology of the solids obtained from the different solvent systems proved to be immensely helpful in choosing the appropriate solvent for growing X-ray quality single crystals.

2. Experimental

Salicylaldehyde, 1,3-pentanediamine, N-methyl-1,3-propanediamine, $Ni(OAc)_2\cdot 4H_2O$ (OAc = acetate), benzoic acid (HOBz), phenyl acetic acid (HOPh) and cinnamic acid (HOCn) were purchased from commercial sources and used as received. All other solvents were of reagent grade and were used without further purification.

In **2**, $S_1 = S_2$ = none, R = Ph
In **3**, S_1 = none, $S_2 = CH_3CH_2OH$, $R = PhCH_2$
In **4**, $S_1 = S_2 = CH_3CN$, R = PhCH=CH

Scheme 2.

2.1. Synthesis of the Schiff base ligands N,N′-bis(salicylidene)-1,3-pentanediamine (H_2salpen)

The tetradentate Schiff base ligand was prepared by the condensation of salicylaldehyde (1.05 cm^3, 10 mmol) and 1,3-pentanediamine (0.596 cm^3, 5 mmol) in methanol (10 cm^3) as reported earlier [27].

2.2. Synthesis of $[Ni_3(salpen)_2(OAc)_2(H_2O)_2]\cdot 4H_2O$ (**1**)

A suspension of $Ni(OAc)_2\cdot 4H_2O$ (1.86 g, 7.5 mmol), in methanol (10 cm^3) was added to a methanolic solution (10 cm^3) of the ligand (Hsalpen) (5 mmol) and stirred for ca. 10 min. Triethylamine (1.4 cm^3, 10 mmol) was added dropwise with constant stirring. A green precipitate separated out within an hour. The green solid was then filtered and washed with diethyl ether and then redissolved in CH_2Cl_2. Layering of the green solution with ethanol gave well formed X-ray diffraction quality green single crystals of **1**.

Complex **1**: (Yield: 1.96 g; 80%). *Anal.* Calc. for $C_{44}H_{62}N_4Ni_3O_{14}$: C, 53.98; H, 5.34; N, 5.71. Found: C, 53.48; H, 5.29; N, 5.75%. IR (KBr pellet, cm^{-1}): 1627 ν(C=N), 1584 ν_{as}(C=O), 1415 ν_s(C=O), λ_{max}/nm (ε_{max}/dm^3 mol^{-1} cm^{-1}) (CH_2Cl_2), 826, 617 (663).

2.3. Synthesis of $[Ni_3(salpen)_2(OBz)_2]$ (**2**) and $[Ni_3(salpen)_2(OCn)_2(CH_3CN)_2]$ (**4**)

A 10 cm^3 methanolic solution of the ligand H_2salpen (5 mmol) was added to a methanolic solution of $Ni(ClO_4)_2\cdot 6H_2O$ (2.74 g, 7.5 mmol). Methanolic solutions of either benzoic acid, PhCOOH (for **2**) (0.61 g, 5 mmol) or cinnamic acid, PhCH=CHCOOH (for **4**) (0.74 g, 5 mmol) were then added to (10 cm^3) of this solution. Triethylamine (2.2 cm^3, 15 mmol) was added drop wise to each of the solution with constant stirring. In both cases green precipitate appeared immediately. The green solids (for **2** and **4**) were then filtered and washed with diethyl ether and then redissolved in CH_2Cl_2. Layering of the green solution of **2** and **4** with ethanol and acetonitrile, respectively, gave well formed X-ray diffraction quality green single crystals.

Complex **2**: (Yield: 1.76 g; 82%). *Anal.* Calc. for $C_{52}H_{50}N_4Ni_3O_8$: C, 60.34; H, 4.87; N, 5.41. Found: C, 60.12; H, 4.79; N, 5.56%. IR (KBr pellet, cm^{-1}): 1617 ν(C=N), 1558 ν_{as}(C=O), 1401 ν_s(C=O), λ_{max}/nm (ε_{max}/dm^3 mol^{-1} cm^{-1}) (CH_2Cl_2), 833, 621 (568).

Complex **4**: (Yield: 1.76 g; 78%). *Anal.* Calc. for $C_{54}H_{61}N_6Ni_3O_8$: C, 59.06; H, 5.60; N, 7.65. Found: C, 59.12; H, 5.19; N, 7.36%. IR (KBr pellet, cm^{-1}): 1631 ν(C=N), 1559 ν_{as}(C=O), 1395 ν_s(C=O), λ_{max}/nm (ε_{max}/dm^3 mol^{-1} cm^{-1}) (CH_2Cl_2), 830, 617 (590).

2.4. Physical measurements

Elemental analyses (C, H and N) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra in KBr (4500–500 cm^{-1}) were recorded using a Perkin–Elmer RXI FT-IR spectrophotometer. The electronic absorption spectra (1200–350 nm) of the complexes were recorded in CH_2Cl_2 with a Hitachi U-3501 spectrophotometer, SEM (Scanning Electron Microscopy) experiments were performed using VEGA II LSU electron microscope. Magnetic measurements were carried out in the "Unitat de Mesures Magnètiques (Universitat de Barcelona)" on polycrystalline samples (20 mg) with a Quantum Design SQUID MPMS-XL magnetometer working in the 2–300 K range. The magnetic field was 5000 G. The field-dependent magnetization was measured in the applied magnetic field range 0–5 T at 2 K. The diamagnetic corrections were evaluated from Pascal's constants.

2.5. Crystal data collection and refinement

Crystal data for the three crystals are given in Table 1. Intensity data were measured via the Oxford X-Calibur CCD System using Mo Kα radiation. The crystals were positioned at 50 mm from the CCD. 321 frames were measured with a counting time of 10 s. Data analyses were carried out with the CRYSALIS program [28]. The structures were solved using direct methods with the SHELXS97 program [29]. The non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms bonded to carbon were included in geometric positions and given thermal parameters equivalent to 1.2 times those of the atom to which they were attached. The hydrogen atoms of the water molecules in **1** could not be located. Empirical absorption corrections were carried out using the ABSPACK program [30]. The structures were refined on F^2 using SHELXL97 [29] to give R_1 0.1028, 0.0838 and 0.0900; wR_2 0.2432, 0.1611 and 0.1441 for 7867, 2893 and 5776 independent reflections with $I > 2\sigma(I)$ for **1**, **2** and **4**, respectively.

3. Results and discussion

3.1. Synthesis of the complexes and electronic microscopic study in search of crystallinity

We have synthesized four trinuclear Ni(II) complexes with a tetradentate di-Schiff base ligand (H_2salpen). Complexes **1**, **2** and **4** have been synthesized varying only the bridging carboxylate moiety. For **1**, a methanol solution of nickel acetate and H_2salpen (*N*,*N*′-bis(salicylidene)-1,3-pentanediamine) were reacted in 3:2 molar ratio. Complexes **2** and **4** were synthesized in similar ways – by addition a methanol solution of $Ni(ClO_4)_2\cdot 6H_2O$, to a methanol solution containing, benzoic acid (for **2**), or cinnamic acid (for **4**) and the Schiff base ligand H_2salpen followed by triethylamine. In all the four complexes, we have utilized the bridging properties of the phenoxo as well as carboxylate groups to obtain the trinuclear complexes by maintaining the metal:ligand ratio 3:2. The formation of the complexes **1**, **2** and **4** and their crystallization deserve some comments. Literature data shows that the di-Schiff base, salpn (the 2:1 condensate of salicyldehyde and 1,3-propanediamine) and its derivative yielded quite a few such linear trinuclear complexes [5–7] but interestingly none is reported with the well-studied analogue salen (the 2:1 condensate of salicyldehyde and 1,2-ethanediamine); the only trinuclear complex reported with salen is not linear [31]. The difference in crystal field stabiliza-

tion energies of the Schiff base ligands seems to play an important role in the formation of these complexes. The greater steric hindrance due to the bulkier trimethylene group in salpn compared to the dimethylene group in salen between the N atoms causes a weaker ligand field for the Schiff bases derived from 1,3-propanediamine and its derivative and consequently facilitates the formation of a linear trinuclear structure, bridged either by acetate and phenoxo- by increasing the coordination number of Ni(II) beyond four. Hence, we choose the di-Schiff base H_2salpen for the synthesis of such linear trinuclear Ni(II) complexes. The presence of the ethyl group in the diamine chelate ring of the ligand provides an advantage over its 1,3-propanediamine analogue by making the complexes more soluble in organic solvents e.g. dichloromethane. However, slow evaporation of the solvent or slow diffusion of diethylether or *n*-hexane which are common practice to obtain single crystals proved to be unsuccessful for these compounds. As the compounds were sparingly soluble in many other common organic solvents (methanol, ethanol, acetonitrile), we decided to investigate the microcrystalline nature of the product which was obtained initially just after the addition of the solvents to the dichloromethane solution with the help of scanning electron microscopy (SEM). We found that the solid obtained by simple evaporation of the dichloromethane solution does not show any crystalline nature and the compound remains as a porous amorphous material as evidenced by SEM experiments (Fig. 1, and Figs. S1 and S2 for compounds **1**, **2** and **4**, respectively). The crystalline nature of the product was also not visible when diethylether or *n*-hexane was added to separate the solid compound from dichloromethane solution. On the other hand, addition of methanol, ethanol and acetonitrile to the dichloromethane solution produced a good microcrystalline product and among them the best formed crystallite is formed by ethanol (for **1** and **2**) and acetonotrile (for **4**). Therefore we chose the slow diffusion of ethanol (for **1** and **2**) or acetonitrile (for **4**) to the dichloromethane solution of the respective compounds to obtain the X-ray quality single crystals. During these studies we observed the formation of vesicles and dye absorption properties of compound **3** in dichloromethane solution, which has been reported recently [26].

3.2. IR and UV–Vis spectra of complexes

In the IR spectra of complex **1**, the appearance of a broad band near 3400 cm^{-1} indicates the presence of water molecule. The attributions of the IR spectra in the 1300–1650 cm^{-1} region are difficult due to the appearance of several absorption bands from both, the Schiff base and the carboxylate ligands. However, by comparing the IR spectra of the Ni(II) complexes of the same ligand but with other anion (NO_3^-, and halides), the moderately strong and sharp band at 1627, 1617 and 1631 cm^{-1}, respectively for **1**, **2** and **4** are assigned to the azomethine ν(C=N) group. The strong bands at 1584, 1558 and 1559 cm^{-1} are likely to be due to the antisymmetric stretching mode of the carboxylate group and the bands

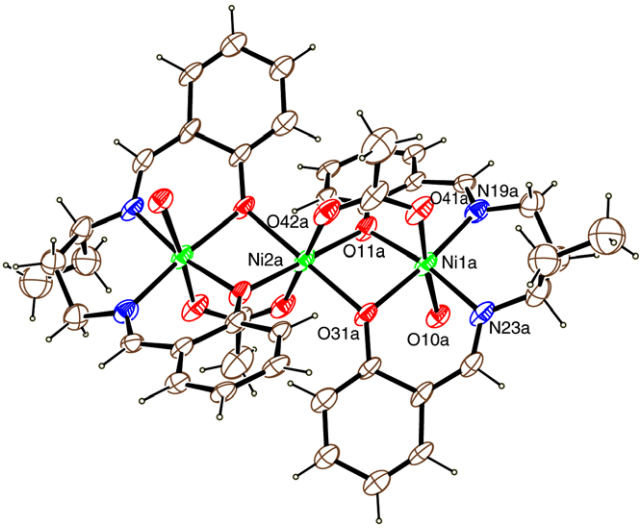

Fig. 2. ORTEP-3 view of the asymmetric unit of **1-A** with ellipsoids at 30% probability (the hydrogen atoms on the coordinated water molecules O(10) could not be located, solvent water molecules are omitted for clarity).

at 1415, 1401 and 1395 cm^{-1} for the symmetric stretching modes for the carboxylates [32,33].

The electronic absorption spectra of complexes **1**, **2** and **4** were studied in CH_2Cl_2 solutions. The absorption spectra of all these complexes show a broad band at ca. 830 nm, well separated from the second transition at ca 617 nm, as is usual for octahedral and pentacoordinated Ni(II) complexes [34–36]. The higher energy d–d bands are obscured by strong charge-transfer transitions.

3.3. Description of the structure of $[Ni_3(salpen)_2(OAc)_2(H_2O)_2]\cdot 4H_2O$ (**1**), $[Ni_3(salpen)_2(OBz)_2]$ (**2**) and $[Ni_3(salpen)_2(OCn)_2(CH_3CN)_2]$ (**4**)

Complexes **1**, **2** and **4** consist of similar trinuclear structures showing three nickel atoms in an approximately linear disposition. The ethyl group introduces a chiral atom, C3 on 1,3-pentanediamine. For the synthesis of the complexes we used racemic (D,L) source of diamine. The X-ray analysis shows that all three structures crystallize in centrosymmetric space groups, therefore contain both enantiomers i.e. there is no spontaneous resolution at the crystal level. The crystal structure of **1** contains two trinuclear units with similar structures – A, containing a crystallographic centre of symmetry and B in a general position. In addition there are four solvent water molecules, two of which were refined with 50% occupancy. A labeled diagram of the centrosymmetric trinuclear molecule **1-A** of complex **1** is shown in Fig. 2 while the trinuclear molecule **1-B** in a general position is shown in Fig. S3. Complexes **2** and **4** comprise of discrete centrosymmetric trinuclear units of the neutral compound $[Ni_3(salpen)_2(OBz)_2]$ and

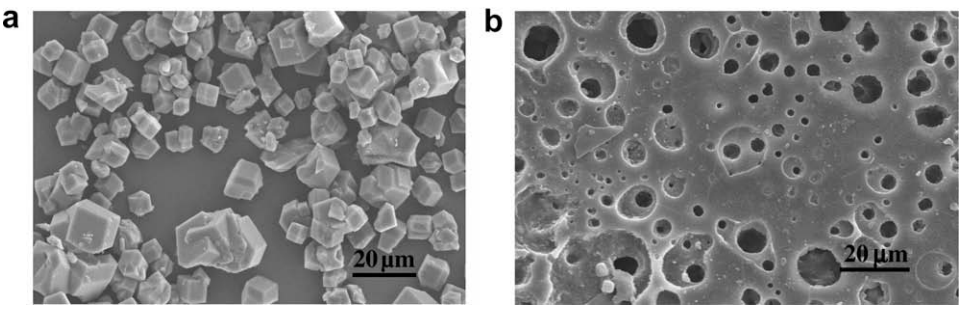

Fig. 1. SEM images of complex **1**; (a) crystalline state (obtained from CH_2Cl_2/CH_3CH_2OH, 1:1 v/v) and (b) amorphous state (obtained from CH_2Cl_2).

$[Ni_3(salpen)_2(OCn)_2(CH_3CN)_2]$ and are shown in Figs. 3 and 4, respectively. The selected bond lengths and angles of the complexes are summarized in Table 2. For all three complexes, the two tetradentate ligands are bound to the two terminal nickel atoms and also bridged through their two phenoxo-oxygen atoms to the central nickel atom. There are two carboxylates, RCO_2^- where R = CH_3, C_6H_5 and $C_6H_5CH{=}CH$ in **1**, **2** and **4**, respectively, bridging from the central nickel atom to the two outer nickel atoms.

In all three complexes the central nickel atom, Ni(2) has a coordination number of six being bonded to the four oxygen atoms of the two outer Ni(salpen) moieties, at distances ranging 2.046(5)–2.088(4) Å in both molecules of **1** and 2.063(4)–2.064(4) Å in **2** and 2.056(3)–2.066(4) Å in **4**, that form the square plane of the Ni(II) while the trans axial positions are occupied by the bridging oxygen atom O(42) of the carboxylates; acetate in **1-A** and **1-B**, benzoate in **2** and cinnamate in **3** at distances of 2.098(8) Å in **1-A**, 2.011(4) and 2.037(4) Å in **1-B**, 2.051(4) Å in **2** and 2.049(4) Å in **4**.

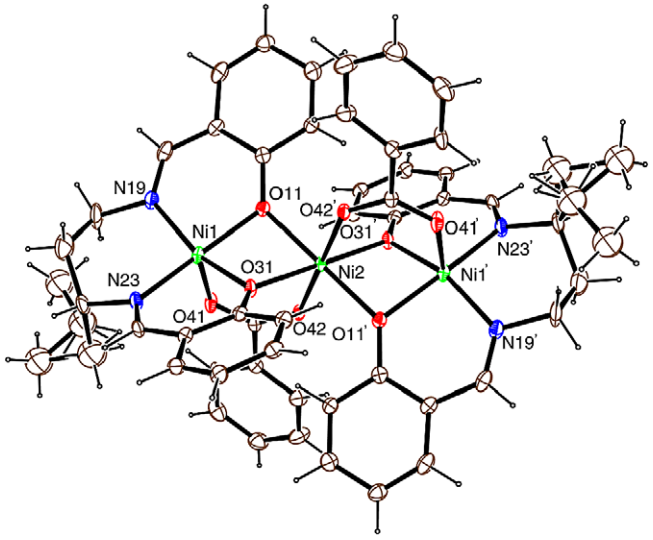

Fig. 3. ORTEP-3 view of the asymmetric unit of **2** with ellipsoids at 30% probability.

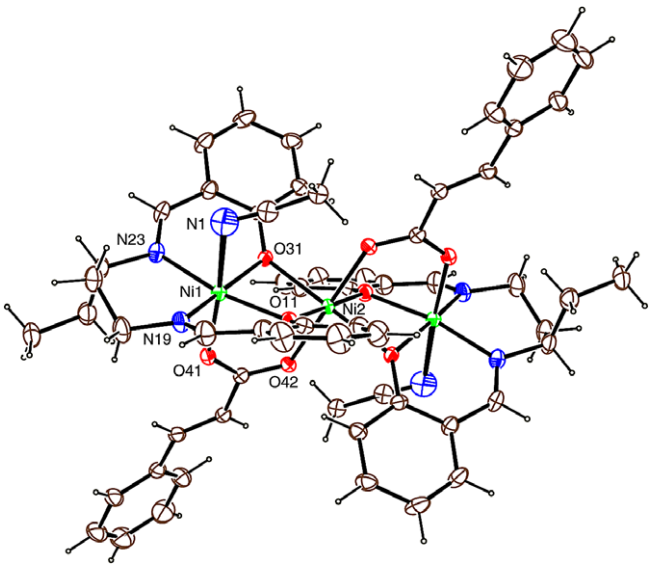

Fig. 4. ORTEP-3 view of the asymmetric unit of **4** with ellipsoids at 30% probability.

The bond distances involving the central nickel atom, Ni(2) are longer than those to the terminal nickel atoms, Ni(1) in all three complexes. The two outer nickel atoms in **1**, **2** and **4** are bonded to four atoms from ligand salpen making up the equatorial plane, with two oxygen atoms O(11), O(31) and two imine nitrogen atoms N(19) and N(23) with Ni(1)–O distances of 1.994(5), 2.015(6) Å in **1-A**, and in the range of 1.960(5)–2.018(4) Å in **1-B** and Ni–N distances of 2.017(8), 2.047(7) Å in **1-A**, and in the range of 2.004(6)–2.105(19) Å in **1-B**. Ni(1)–O and Ni(1)–N distances are,1.995(4), 2.000(4) and 1.995(4), 2.029(5) Å in **2** and 2.005(3), 2.007(3) and 2.004(5)–2.032(4) Å in **4**. In both molecules of **1**, the outer nickel atoms Ni(1) have six-coordinate distorted octahedral environments being bonded to the oxygen atom of the solvent water molecule Ni(1)–O(10) at 2.260(6) Å in **1-A** and 2.344(5), 2.247(5) Å in **1-B**. In **2**, the terminal nickel atoms are five-coordinate while in **4**, there is significant electron density in the other axial position trans to O(41) which is refined as an acetonitrile solvent molecule with 50% occupancy but this identification is not definitive. In all the three complexes, the dimensions involving the other five atoms in the coordination sphere are similar although in **1** and **4**, the Ni(1)–O(41) bond trans to the respective solvent molecules (water for **1** and CH_3CN for **4**) is somewhat lengthened being 2.049(7) Å in **1-A**, 2.050(5), 2.098(8) Å in **1-B**, and 2.027(4) Å in **4** compared to 1.999(4) Å in **2** where there is no trans atom. Among the three complexes the coordination sphere in **2** is mostly distorted from octahedral with a maximum deviation of 22° of the ideal 90° or 180°. The coordination spheres in **1** are least distorted from octahedral with all angles within 8° of the ideal 90° or 180° while complex **4** shows intermediate deviation. Moreover in **1**, the dimensions in **1-B** symmetry are similar although atoms at one end have high thermal motion as is apparent in Fig. S5 and as a result standard deviations are high. The mean deviation of four donor atoms from their respective mean plane are 0.0265 Å in **1-A**, 0.021 and 0.013 Å in **1-B**, 0.08 Å in **2** and 0.017 Å in **4** while the metal atom Ni(1) is deviated by 0.059 Å in **1-A**, 0.101 and 0.120 Å in **1-B**, 0.262 Å in 2 and 0.164 Å in **4** in the direction of the axial O(41). The nickel atoms are separated at the average Ni···Ni distances 3.013 Å in **1-A**, 3.030 and 2.975 Å in **1-B**, 3.027 Å in **2** and 3.010 Å in **4**.

A comparison of the structure of the complexes shows an interesting variation in the geometry of the terminal nickel atoms. In compound **1** where the bridging carboxylate is an acetate group, the water molecule coordinates to one of the axial positions of both the terminal Ni(II) atoms. However, this water molecule is loosely bound as is evident from the comparatively long bond distance Ni(1)–O(10) 2.260(6) Å in **1-A** and 2.344(5) and 2.247(5) Å in **1-B**. In complex **2** where the benzoate ion bridges the nickel atom, no solvent molecule coordinates to the axial position of the terminal Ni(II) leaving the metals in pentacoordinated square pyramidal geometry. The greater steric demand of the bulkier phenyl group of the benzoate ion seems to prevent any solvent molecule from being coordinated. In complex **4**, the phenyl group of the bridging cinnamate is not in close proximity to the terminal Ni(II) and therefore allows a solvent acetonitrile molecule to coordinate in its axial position. It can be noted that a water molecule which is smaller in size than ethanol or acetonitrile could have been coordinated to the terminal Ni(II) to complete a six-coordinate co-ordination sphere in complexes **2–4**, but the hydrophobic nature of the aromatic ring seems to exclude that possibility. In this context it is worth mentioning that in all the reported trinuclear complexes of tetradentate di-Schiff base ligand, the bridging carboxylate is acetate except in one compound where it is formate and in all of them the terminal Ni(II) atoms are hexacoordinated being bonded by a solvent molecule. Thus by introducing a phenyl ring in the bridging carboxylate with varying distances the geometry of the terminal Ni(II) atom could be monitored.

The centrosymmetric trinuclear complex **1-A** forms a two-dimensional porous architecture through intermolecular hydrogen bonds with water molecules (Fig. S4). Complexes **2** and **4** have no significant hydrogen bonding interactions.

3.4. Magnetic properties

Temperature-dependence molar susceptibility measurements of powdered samples of **1–4** were carried out in an applied field of 5000 G in the temperature range of 2–300 K. The magnetic properties of complexes **1–4** under the form of $\chi_M T$ versus T plots are shown, together with χ_M versus T plot (χ_M is the molar susceptibility per Ni_3 unit), in Figs. 5 and Figs. S5–S7, respectively**.** The $\chi_M T$ value at 300 K is 3.86 $cm^3\ mol^{-1}\ K$ (for **1**), 3.45 $cm^3\ mol^{-1}\ K$ (for **2**), 4.03 $cm^3\ mol^{-1}\ K$ (for **3**) and 3.63 $cm^3\ mol^{-1}\ K$ (for **4**) which are closely the spin-only value of 3.00 $cm^3\ mol^{-1}\ K$ ($g = 2.00$), for a non-interacting Ni_3 unit. On lowering the temperature, the $\chi_M T$ values for complexes **1**, **2**, **3** and **4**, decrease slowly until 60–70 K, then decrease dramatically to 0.49, 0.26, 0.45 and 0.44 $cm^3\ mol^{-1}\ K$ at 2 K for **1–4**, respectively. The profile of the curves suggests weak antiferromagnetic coupling between the Ni(II) ions and an active D parameter at low temperatures.

According to the structural data, for complex **1** there are two crystallographically independent trinuclear units, **1-A** with a crystallographic centre of symmetry and **1-B** in a general position but with a similar geometry with all nickel atoms six-coordinate. For complex **2**, the trinuclear entity also centrosymmetric with the central Ni(II) ion hexa-coordinate while the terminal Ni(II) ions

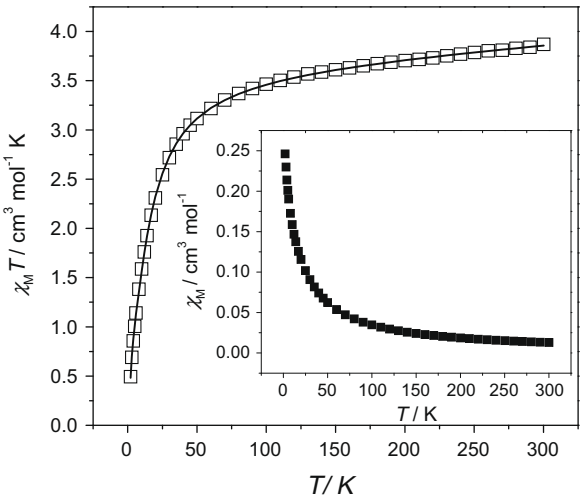

Fig. 5. Thermal dependence of $\chi_M T$ at 5000 G for **1**. The solid line represents the best-fit curve. Inset: thermal dependence of χ_M at 5000 G for **1**.

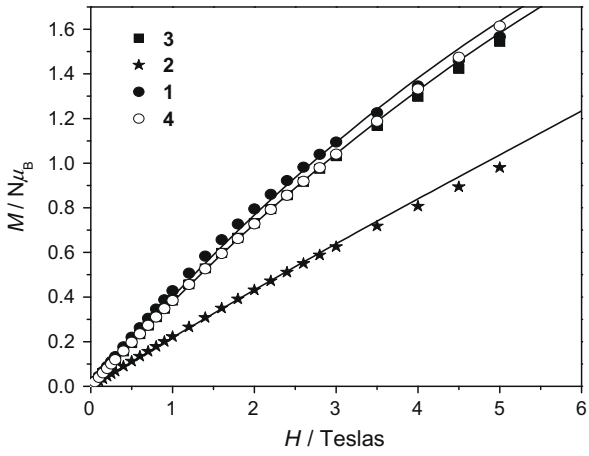

Fig. 6. Magnetization versus H at 2 K for **1–4.** The solid line represents the best-fit curve.

are five-coordinate. For complex **3**, the trinuclear unit contains no imposed symmetry, with the central and one of the terminal Ni(II) ion hexa-coordinate and the other terminal Ni(II) ion is five-coordinate. For complex **4**, the trinuclear unit is centrosymmetric and all the Ni(II) ions are hexa-coordinate. Taking into account these features, the magnetic interactions, between the Ni(II) ions for complexes **1**, **2**, **3** and **4**, could be evaluated.

The experimental data of complexes **1–4** can be fitted using the following Hamiltonian equation:

$$H = -2J(S_1S_2 + S_2S_3) + \sum_{i=1-3}(g_{Ni}\beta S_i \cdot H_i + S_i \cdot D_i \cdot S_i)$$

according to which the single-ion anisotropy D is assumed to be the same for the three Ni(II) ions $D_1 = D_2 = D_3 = D$ while only one exchange constant, J. The reason for using single-ion anisotropy in the Hamiltonian formalism is the drastic decrease of the susceptibility data at low temperatures. The best-fits with the above equation to the magnetic data were found with $J = -3.2(1)$ cm^{-1}, $g = 2.25$ and $D = +9.1(2)$ cm^{-1} for **1**, $J = -4.6(1)$ cm^{-1}, $g = 2.10$, $D = +14.2(2)$ cm^{-1} for **2**, $J = -3.2(1)$ cm^{-1}, $g = 2.20$, $D = +9.8(2)$ cm^{-1} for **3**, and $J = -2.8(1)$ cm^{-1}, $g = 2.10$ and $D = +8.6(1)$ cm^{-1} for **4** (Table 3). The magnetization measurements at 2 K corroborate the effect of the D parameter, i.e. the reduced magnetization ($M/N\beta$ at 5 T are only consistent with 1.6 electrons for **1**, 0.98 electrons for **2**, 1.5 electrons for **3** and 1.6 electrons for **4**, instead of six electrons which should be the theoretical value for three isolated Ni(II) ions with $g = 2.00$ (Fig. 6)**.** The same model is used for the simulation of the magnetization data using the parameters obtained from the fit of the susceptibility data, the results are shown in Fig. 6 as solid lines and reproduces the behaviour of the magnetization versus field quite well. Both data sets confirm the large values of the single-ion anisotropy of the Ni(II) ions.

The magnetic susceptibilities and magnetization data treatment of compounds **1–4** were made using the MAGPACK program [37] employed with a nonlinear least-squares curve-fitting program, DSTEPIT [38].

4. Discussion

Considering the absence of magnetic interaction between the terminal Ni(II) ions in the trinuclear compounds, the Ni···Ni interactions between the spin $S = 1$ are transmitted, between each pair of Ni(II) ions, through two oxo groups of the tetradentate ligand and one carboxylate in bis-monodentate *syn–syn* mode in **1–4.** Magneto-structural correlations for a series of octahedral and square pyramidal dinuclear Ni(II) complexes with the oxo group of phenoxy-ligand, acting as a bridge in dinickel(II) complexes, show a linear relationship between the J values and the Ni–O–Ni bridge angle [39] and inversion from antiferromagnetic to ferromagnetic coupling is anticipated at a bridge angle of 97°. The effect of the acetate bridge in *syn–syn* configuration is weak antiferromagnetic [40]. The values of the calculated average J parameters, for complexes **1–4**, seem to be logical, taking into account the symmetry and geometry of the Ni(II) ions. The Ni–O–Ni angles in complexes **1–4** are in the range of 92–97°. These values are very near the crossover point between ferromagnetic and antiferromagnetic behaviour, therefore, the type of interaction mediated by this pathway may not be anticipated, and will be weak in any case. The additional exchange pathway occurs *via* a carboxylate ligand in a *syn–syn* configuration that facilitates moderate antiferromagnetic couplings. The latter will, thus, dominate the exchange in the **1–4** system, which will consequently be of antiferromagnetic nature.

The data, compiled for mononuclear hexacoordinate Ni(II) compounds, show that the D parameters adopt values between −22 and +12 cm^{-1} [41]. The D parameter has been evaluated only for a few Ni(II) compounds with chain structures and they show moderate D values between −7 and 7 cm^{-1}[42–45]. Among the 30 similar trinuclear Ni(II) complexes which are reported to date, D parameter has been calculated from the magnetic data of only one complex [46] The difficulties for calculating the D values lies in the strong correlations between the intermolecular coupling with the zero-field splitting parameter at low temperature and such calculations usually led to unrealistic values. Hence evalua-

Table 3
Comparison of magnetic data along with bond angles within the bridges for complexes **1–4**.

Complex		J (cm^{-1})	g	Ni–O–Ni (°)
1	$D = +9.1(2)$ cm^{-1}	−3.2(1)	2.25	96.4(2), 95.2(2)[a] 98.3(2), 92.8(2)[b] 94.8(2), 96.7(2)[c]
2	$D = +14.2(2)$ cm^{-1}	−4.6(1)	2.10	96.3(2), 96.5(2)
3	$D = +9.8(2)$ cm^{-1}	−3.2(1)	2.20	95.2(4), 96.7(4)
4	$D = +8.6(1)$ cm^{-1}	−2.8(1)	2.10	95.3(1), 95.6(1)

[a] Centrosymmetric part of complex **1**.
[b,c] Non-centrosymmetric part of complex **1**.

tion of realistic D value from magnetic data is a difficult task for this kind of systems. For complexes **1–4**, we have succeeded in calculating D values which are well related to the geometry around the Ni(II) ion as indicated by some systematic investigations of the zero-field splitting correlated with the degree of distortion in the coordination polyhedra in octahedral Ni(II) mononuclear complexes which appeared recently [47–50]. Pentacoordinated mononuclear Ni(II) complexes show higher anisotropy than hexacoordinate ones, and this feature implies high D values (around 15 cm^{-1}) as is found in the few examples studied in the literature [51].

The values of D for complexes **1–4** are in the high range of those already reported in the literature. The highest D value of +14.2(2) and +9.8(2) cm^{-1} for complexes **2** and **3**, respectively, agree with the pentacoordinated geometry of the two terminal nickel(II) ions in **2** and one terminal nickel(II) ion in **3**.

5. Conclusions

We have succeeded in synthesizing trinuclear Ni(II) complexes with the monocarboxylate anions: acetate, benzoate, phenylavetate and cinnamate as bridging ligands. The systematic variation of the carboxylate ligand nicely illustrates how a slight change in the steric properties of the bridging carboxylate can influence the coordination geometry of the terminal nickel atom in such complexes. The variable-temperature magnetic measurements reveal the antiferromagnetic couplings within the trinuclear Ni(II) units in all four complexes **1**–**4** containing tetradentate ligand (H_2salpen). The tuning of pentacoordination and hexacoordination in the terminal Ni(II) allow us to calculate the D parameters in the polynuclear Ni(II) compounds with different degree of distortion in the coordination polyhedra. Expectedly, the compounds (**2** and **3**) containing pentacoordinated terminal Ni(II) possess high D values. Growing suitable single crystals for X-ray diffraction is one of the most challenging parts of research in chemical, physical or biological sciences and in most cases "trial-and-error" methods are applied to select the proper solvent systems to obtain the crystal. We have shown here that observation of the morphology of the initially separated solid by an SEM study can help one to move quickly in the right direction for choosing the proper solvents for successful crystallization.

Acknowledgments

We thank CSIR, Government of India [Senior Research Fellowship to P.M., Sanction No. 09/028 (0663)/2006-EMR-I] and EPSRC and the University of Reading for funds for the the X-Calibur system. We also thank Spanish Government (Grant CTQ2006-03949) for their financial support.

Appendix A. Supplementary data

CCDC 723299, 723300 and 723301 contain the supplementary crystallographic data for **1**, **2** and **4**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.07.014.

were performed on a Perkin–Elmer TGA7 instrument in flowing N_2 with a heating rate of 10 °C min^{-1}. Variable temperature magnetic susceptibility was measured at 1000 Oe from 1.99 to 300 K (SQUID Quantum Design).

2.2. Synthesis of the complexes

2.2.1. Synthesis of *1*

A mixture of $FeCl_2{\cdot}4H_2O$ (0.080 g, 0.40 mmol), dpa (0.192 g, 0.80 mmol), 4,4′-bipy (0.125 g, 0.80 mmol) and 8 ml H_2O was stir-

red for 30 min, and then the pH value was adjusted to 5 with 1 M NaOH. After stirring for another 30 min, the mixture was transferred to a 23 ml Teflon-lined stainless steel bomb and kept at 170 °C under autogenously pressure for 4 days. The reaction system was cooled to room temperature over 24 h. A large amount of green block crystals of **1** were obtained. Yield: 63% (based on Fe). *Anal.* Calc. for $C_{24}H_{16}N_2O_4Fe$: C, 63.74; H, 3.57; N, 6.19. Found: C, 63.69; H, 3.41; N, 6.33%. IR (cm^{-1}): 1582 (m), 1556 (w), 1520 (s), 1451 (w), 1378 (s), 1269 (w), 1068 (w), 1008 (w), 965 (m), 849 (w), 748 (m), 721 (m), 624 (w), 556 (m).

2.2.2. Synthesis of *2* and *3*

Complexes **2** and **3** were prepared from a mixture of $Co(OAc)_2{\cdot}4H_2O$ (0.099 g, 0.40 mmol), dpa (0.192 g, 0.80 mmol) and 4,4′-bipy (0.125 g, 0.80 mmol) in 8 ml H_2O. The mixture was stirred for 25 min, and the pH value was then adjusted to 5 with 1 M NaOH. After this, the mixture was transferred to a 23 mL Teflon-lined stainless steel bomb and it was kept at 165 °C under autogenously pressure for 4 days. Red crystals of **2** and purple crystals of **3** were obtained. For complex **2**: Yield: 41% (based on Co). *Anal.* Calc. for $C_{24}H_{16}N_2O_4Co$: C, 63.25; H, 3.54; N, 6.15. Found: C, 63.36; H, 3.68; N, 6.27%. IR (cm^{-1}): 3441 (w), 1586 (m), 1558 (w), 1527 (s), 1371 (s), 1129 (m), 1076 (w), 1014 (w), 958 (m), 761 (m), 717 (m), 642 (w). For complex **3**: Yield: 18% (based on Co). *Anal.* Calc. for $C_{34}H_{36}O_{20}Co_4$: C, 40.79; H, 3.63. Found: C, 40.66; H, 3.49%. 2.2.4. Synthesis of **6**

Complex **6** was prepared from a mixture of $Cd(OAc)_2{\cdot}2H_2O$ (0.107 g, 0.40 mmol), dpa (0.192 g, 0.80 mmol) and 2,2′-bipy (0.125 g, 0.80 mmol) in 8 ml H_2O. The mixture was stirred for 15 min and sealed in a 23 mL Teflon-lined stainless steel bomb. The bomb was kept at 170 °C under autogenously pressure for 5 days. The reaction system was then cooled to room temperature over 24 h, and yellow block crystals of **6** were obtained. Yield: 71% (based on Cd). *Anal.* Calc. for $C_{48}H_{36}N_4O_{10}Cd_2$: C, 54.67; H, 3.44; N, 5.32. Found: C, 54.81; H, 3.51; N, 5.27%. 2.3. X-ray crystallography study

Crystallographic data for **1** to **6** were all collected at 298 K with a Bruker AXS SMART APEX II CCD diffractometer. The structures were solved by the direct method and refined by the full-matrix least-squares method on F^2 using the SHELXTL 97 crystallographic software package [34,35]. Carbon-bound hydrogen atoms were placed in calculated positions, with C–H = 0.93 Å, and treated as riding atoms in the final cycles of refinement. Oxygen-bound hydrogen atoms were located in the difference Fourier maps, refined with isotropic temperature factors and kept in that position. Further details of the X-ray structural analysis are given in Table 1. Selected bond lengths are listed in Table 2.

3. Result and discussion

3.1. Structural description

3.1.1. $[Fe(dpa)(4,4'\text{-bipy})]_n$ (**1**) and $[Co(dpa)(4,4'\text{-bipy})]_n$ (**2**)

Complex **1** is composed of a two-dimensional layer of Fe(dpa)(4,4′-bipy). The asymmetric unit of complex **1** consists of one crystallographic independent Fe atom, as shown in Fig. 1a. Fe(1) adopts a distorted octahedral coordination mode and connects with four oxygen atoms from three dpa ligands and two

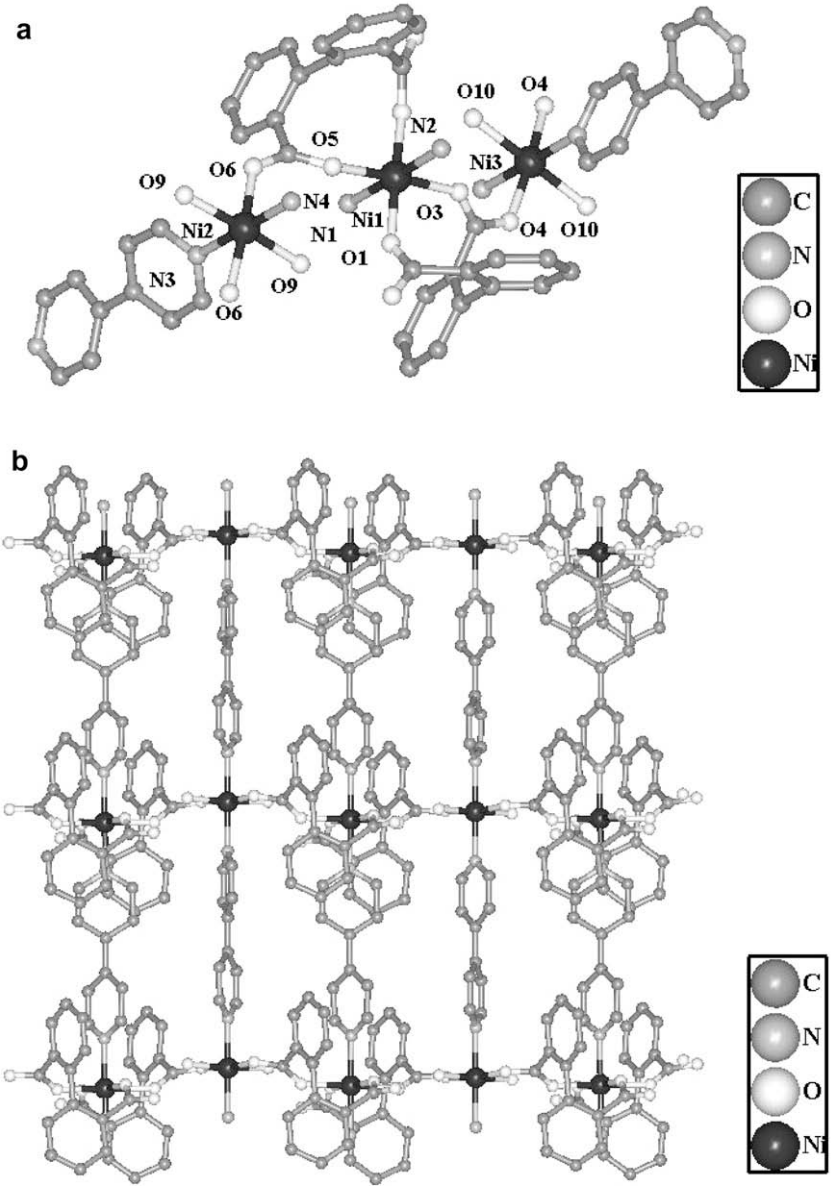

Fig. 3. (a) The fundamental unit of complex **4**. (b) The two-dimensional layer structure of complex **4**.

nitrogen atoms from two 4,4′-bipy ligands. The Fe–O distances range from 2.094–2.129 Å, the O–Fe–O bond angles are in the range 87.09 to 176.58°, and the average Fe–N bond distance is 2.260 Å. In this complex, the dpa ligand adopts only one kind of coordination mode, two carboxylate groups of the dpa ligand are deprotonated and both adopt bridging coordination modes as shown in Fig. S1. The carboxylate oxygen atoms of the dpa ligands connect the adjacent Fe atoms and form a one-dimensional chain-like structure. Furthermore, the 4,4′-bipy ligands link such neighboring chains and form a two-dimensional layer structure, as shown in Fig. 1b.

When $FeCl_2{\cdot}4H_2O$ is replaced by $Co(OAc)_2{\cdot}4H_2O$, complex **2** is successfully synthesized. The crystal structure of complex **2** is isomorphic to complex **1**, with little difference.

3.1.2. $\{[Co_4(dpa)_2(CH_3COO)_3(OH)(H_2O)_2]\cdot 3H_2O\}_n$ (**3**)

To our interest, during the synthesis of complex **2**, we obtained complex **3** accidentally. The single crystallographic analysis reveals that complex **3** shows a one-dimensional chain-like structure. There exist five crystallographic independent Co atoms in the fundamental unit, as shown in Fig. 2a. Co1 connects with six oxygen atoms, three from dpa ligands, two from OAc^- ligands, and one from an OH^- group. The Co–O bond distances range from 2.012 to 2.214 Å and the O–Co–O bond angles are in the range 79.00 to 171.05°. This results in distorted octahedral coordination geometry. Similar to Co1, Co3, Co4, and Co5 also adopt the same coordination manners, but with different bond lengths and bond angles. Different to the above four Co atoms, Co2 adopts a square pyramidal coordination mode and connects with five oxygen atoms. The two carboxylate groups in the dpa ligand both adopt bridging coordination modes, as shown in Fig. S2, the OAc^- ligand adopts two kinds of coordination modes, as shown in Fig. S3, and with such connection modes, five crystallographic independent Co atoms are connected together and form an interesting pentanuclear Co building unit. To our knowledge, such a kind of building unit has seldom been synthesized in previous works. Adjacent pentanuclear Co clusters are further connected by dpa ligands and OAc^- to form a one-dimensional chain-like structure, as shown in Fig. 2b.

3.1.3. $[Ni_2(dpa)_2(4,4'\text{-bipy})_2(H_2O)]_n$ (**4**)

Single crystal X-ray diffraction analysis reveals that complex **4** is also a two-dimensional covalent network, derived from $Ni_2(dpa)_2(4,4'\text{-bipy})_2(H_2O)$. There exist three crystallographic independent Ni atoms in the fundamental unit, as shown in Fig. 3a. Ni(1) adopts an octahedral coordination mode and connects with four oxygen atoms from two different dpa ligands and two nitrogen atoms from two different 4,4′-bipy ligands. The Ni(1)–O bond distances are in the range 2.051–2.152 Å, and the O–Ni–O bond angles range from 78.28 to 176.33°. The average Ni–N bond distance is 2.105 Å. Ni(2) also adopts an octahedral coordination mode and connects with two oxygen atoms from dpa ligands, two nitrogen atoms from 4,4′-bipy ligands and the other two coordination sites are occupied by two water molecules. The Ni–O distances are in the range 2.040–2.076 Å, and the bond angles range from 88.42 to 175.18°. The average Ni–N distance is 2.099 Å. Ni(3) adopts the same coordination mode as Ni(2), but with different bond lengths and angles. In this complex, two carboxylate groups in dpa ligand adopt two kinds of coordination modes. One is bridging, and the other is monodentate, as shown in Fig. S4. The adjacent Ni

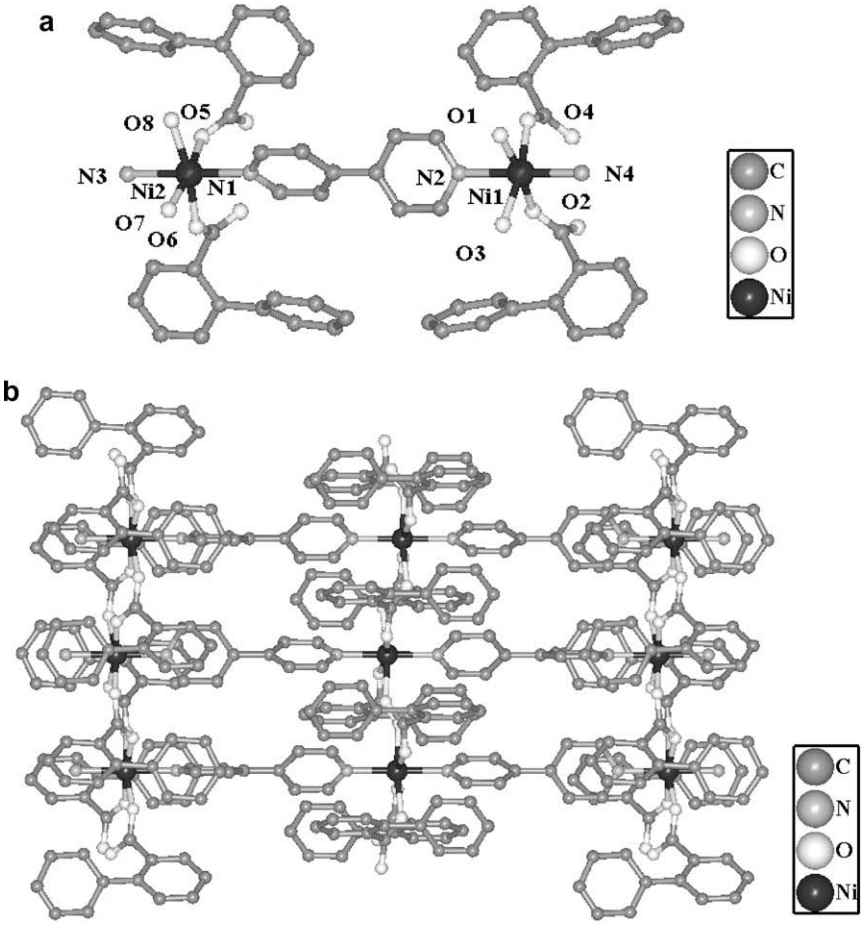

Fig. 4. (a) The fundamental unit of complex **5**. (b) The two-dimensional layer structure of complex **5**.

atoms are linked by dpa ligands to form a one-dimensional chain-like structure. The 4,4′-bipy ligands link neighboring chains and form a two-dimensional layer structure, as shown in Fig. 3b.

To our interest, complex **4** crystallizes in a chiral space group. Although some complexes with helical structures have been synthesized from dpa ligands, to date homochiral complexes have never been synthesized from the dpa ligand.

3.1.4. $[Ni_2(2\text{-bpa})_4(4,4'\text{-bipy})_2]_n$ (**5**)

During the synthesis of complex **4**, we obtained complex **5**. Like complex **4**, complex **5** is also a two-dimensional layer network. There exist two crystallographic independent Ni atoms in this complex, as shown in Fig. 4a. Ni(1) adopts an octahedral coordination mode, connected with four oxygen atoms from four different carboxylate groups and two nitrogen atoms from different 4,4′-bipy ligands. The Ni(1)–O bond distances range from 2.063 to 2.086 Å and the O–Ni–O bond angles are in the range 88.35–172.67°. Ni(2) adopts the same coordination mode, but with different bond angles and bond lengths. The carboxylate group adopts a bridging coordination mode, as shown in Fig. S5, and connects the above two kinds of Ni atoms to form a one-dimensional chain-like structure. Such chains are further connected by 4,4′-bipy ligands and form a two-dimensional layer structure, as shown in Fig. 4b.

It is surprising that one of the two carboxylate groups of the dpa ligand decomposes during the reaction process and the dpa ligand turns into 1,1′-biphenyl-2-carboxylate acid (2-bpa). To our knowledge, this phenomenon has been reported in previous studies [36].

3.1.5. $[Cd_2(dpa)_2(2,2'\text{-bipy})_2(H_2O)_2]_n$ (**6**)

Single crystal X-ray diffraction study reveals that there exists only one crystallographic independent Cd atom in complex **6**, which adopts an octahedral coordination mode. It connects with

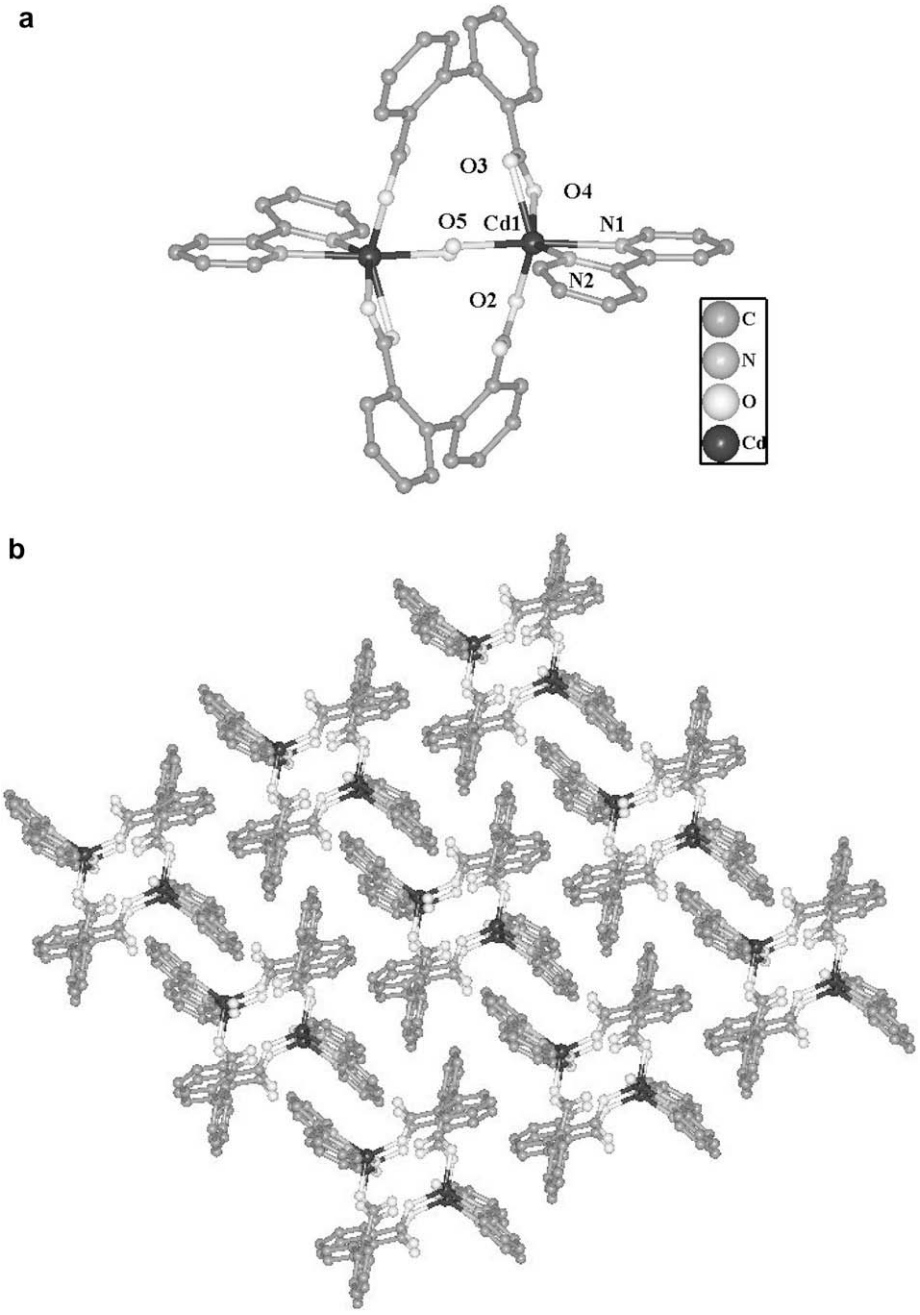

Fig. 5. (a) The fundamental unit of complex **6**. (b) The three-dimensional supramolecular network of complex **6**.

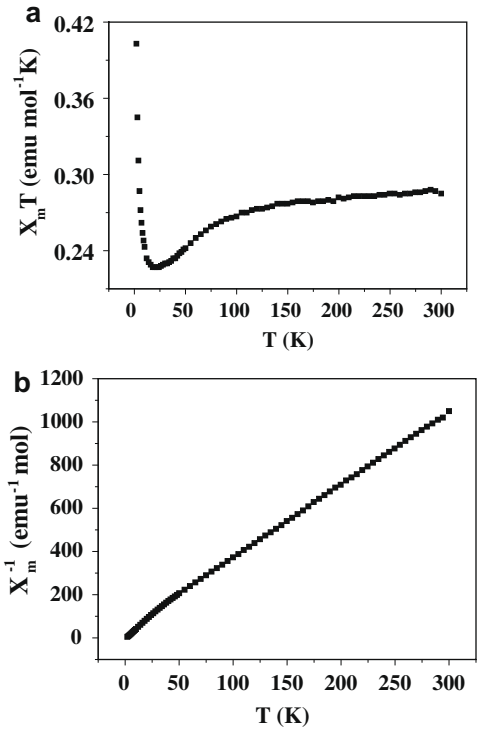

Fig. 6. Thermal variation of $\chi_m T$, $1/\chi_m T$ for complex **2**.

three oxygen atoms from two dpa ligands, two nitrogen atoms from 2,2′-bipy ligands, and the other coordination mode is occupied by a water molecule, as shown in Fig. 5a. The Cd(1)–O bond distances range from 2.192 to 2.583 Å and the O–Cd–O bond angles are in the range 53.38–123.79°. The carboxylate groups in the dpa ligand adopt two kinds of coordination modes, one is chelating and the other is monochelating, as shown in Fig. S6. Based on these two modes, an 18-membered ring is formed. Furthermore, the rings are extended to form an interesting three-dimensional supramolecular network through π–π interactions between the phenyl rings from the dpa ligands and 2,2′-bipy ligands. The distances of the adjacent phenyl rings range from 3.50 to 3.57 Å, as shown in Fig. 5b.

3.2. Thermal properties

The thermal stability properties have been determined on single crystalline samples in a nitrogen atmosphere by thermo gravimetric analysis (TGA). For complex **1**, the TG curve shows that chemical decomposition starts at 369 °C and ends at 458 °C, with a weight loss of 87.69% (Calculated: 87.74%), which is equivalent to the loss of the dpa and 4,4′-bipy ligands. For complex **3**, the TG curve exhibits two weight losses: the first (10.56%), from 90 to 170 °C, represents the loss of water molecules (Calculated: 10.70%), the second (65.82%), from 360 to 481 °C, represents the loss of organic ligands (Calculated: 65.68%). For complex **4**, a weight loss of 1.82% is observed from 167 to 198 °C, equivalent to the loss of coordinated water molecules (Calculated: 1.90%). The second weight loss of 83.60%, from 408 to 506 °C, corresponds to the loss of the dpa and 4,4′-bipy ligands (Calculated: 83.70%). For complex **5**, the weight loss of 90.38%, from 391 to 474 °C, corresponds to the loss of organic ligands (Calculated: 90.27%). For complex **6**, the first weight loss (3.51%), from 134 to 166 °C, corresponds to the loss of water (Calculated: 3.42%); the second (75.29%), from 376 to 457 °C, represents the loss of organic ligands (Calculated: 75.17%).

3.3. Magnetic properties

For complex **2**, the magnetic susceptibility data was studied in the temperature range 1.99 to 300 K, as shown in Fig. 6. The inverse susceptibility plot as a function of temperature is linear in the temperature range 50 to 300 K, closely following the Curie–Weiss law with $C = 0.2904$ emu K mol^{-1} and $\Theta = -6.30$ K. This suggests typical antiferromagnetic interactions in above 50 K. The $\chi_m T$ versus T plot shows a value of 0.28 emu mol^{-1} K at 300 K, and continuously decreases on cooling to a value of 0.22 emu mol^{-1} K at 15 K. However, an abruptly increase at around 13 K was observed and $\chi_m T$ reaches 0.40 emu mol^{-1} K at 1.99 K. This indicates the occurrence of ferromagnetic behavior [37].

4. Conclusions

In this work, a series of coordination polymers generated from mixed-ligand systems of dpa and isomeric bipyridine mixed ligands have been successfully synthesized under hydrothermal conditions. It is anticipated that more coordination polymers containing the flexible dpa ligand with interesting structures as well as physical properties will be synthesized.

2.2. Characterization

XRD patterns were recorded by a Rigaku D-max C III, X-ray diffractometer using Ni-filtered Cu Kα radiation. Elemental analyses were obtained from Carlo ERBA Model EA 1108 analyzer. Scanning electron microscopy (SEM) images were obtained on Philips XL-30ESEM equipped with an energy dispersive X-ray spectroscope. Transmission electron microscopy (TEM) images were obtained on a Philips EM208 transmission electron microscope with an accelerating voltage of 100 kV. X-ray photoelectron spectroscopy (XPS) of the as-prepared products was measured on an ESCA-3000 electron spectrometer with non-monochromatized Mg Kα X-ray radiation as the excitation source. Room temperature photoluminescence (PL) was studied on an F-4500 fluorescence spectrophotometer. Fourier transform infrared (FT-IR) spectra were recorded on Shimadzu Varian 4300 spectrophotometer in KBr pellets. The electronic spectra of the complexes were taken on a Shimadzu UV–Vis scanning spectrometer (Model 2101 PC).

2.3. Synthesis of ZrO_2 nanoparticles

The current synthetic procedure is a modified version of the method developed by the Hyeon group for the synthesis of various nanoparticles of metals and oxides, which employs the thermal decomposition of metal–surfactant complexes in hot surfactant solution [26]. A stock solution of $[Zr(HAP)_3]$–surfactant complex, prepared by reacting 0.6 g of bis-aqua, tris-2-hydroxyacetophenato zirconium (IV) nitrate, $[Zr(HAP)_3(H_2O)_2](NO_3)$, with 5 ml of oleylamine at 150 °C, was slowly injected into 5 g of triphenylphosphine (TPP) under vigorous stirring at 250 °C. The mixture was heated at 250 °C and the resulting solution was stirred at this temperature for 90 min. The initial white color of the solution slowly turned yellow, indicating that nanoparticles were generated. The reaction mixture was then cooled to room temperature and the white nanoparticles were retrieved by adding 30 ml of ethanol, followed by centrifugation. The final products were washed with ethanol at least three times to remove impurities, if any, and dried at 100 °C. The retrieved powder form of the nanoparticles could be easily redispersed in non-polar organic solvents such as hexane or toluene (Scheme 1).

3. Results and discussion

3.1. Thermogravimetric analysis of the $[Zr(HAP)_3(H_2O)_2](NO_3)$ precursor

The TGA curve for the decomposition of $[Zr(HAP)_3(H_2O)_2](NO_3)$ was recorded in air atmosphere and is shown in Fig. 1. As shown in Fig. 1, a total of two weight losses were observed. A weight loss of 9% occurred between 100 and 180 °C, and this weight loss is indicative of the loss of one coordinated H_2O molecule. The TG curve of the complex shows a gradual loss of weight of about 70% around 460 °C to give a residual mass consisting of about 30%, close to that expected for a complete conversion to ZrO_2. The weight loss from 250 to 460 °C is linked with burning of 2-hydroxyacetophenato (exothermic) to acetone, CO_2 and H_2O [27]. There was no organic residue left after 450 °C, as confirmed by the FT-IR spectrum of the residual mass.

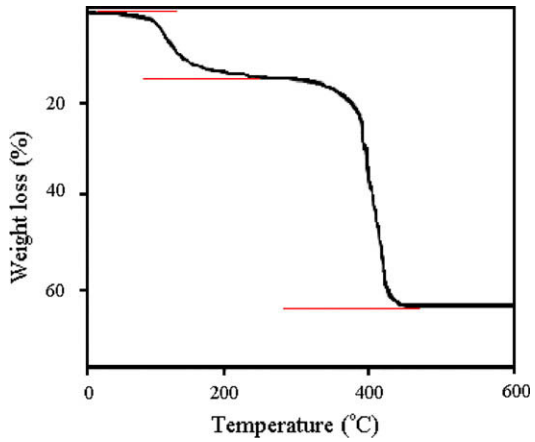

Fig. 1. TG curve of the $[Zr(HAP)_3(H_2O)_2](NO_3)$ precursor in air.

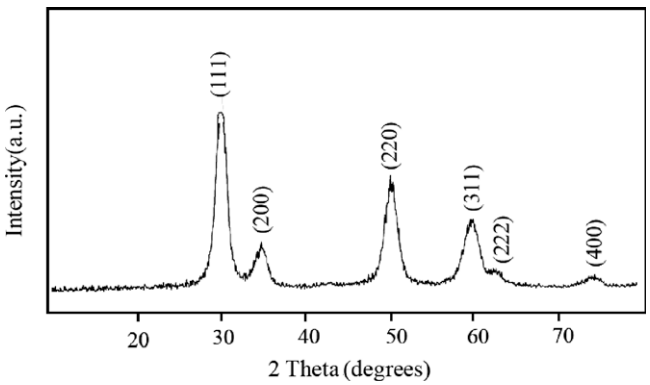
3.2. XRD analysis of the products

The XRD diffraction pattern of the ZrO_2 was recorded for the identification of the product (Fig. 2). From the XRD data, the crystallite size (D_c) of the as-prepared ZrO_2 particles was calculated to be 40 nm using the Debey–Scherrer equation [28],



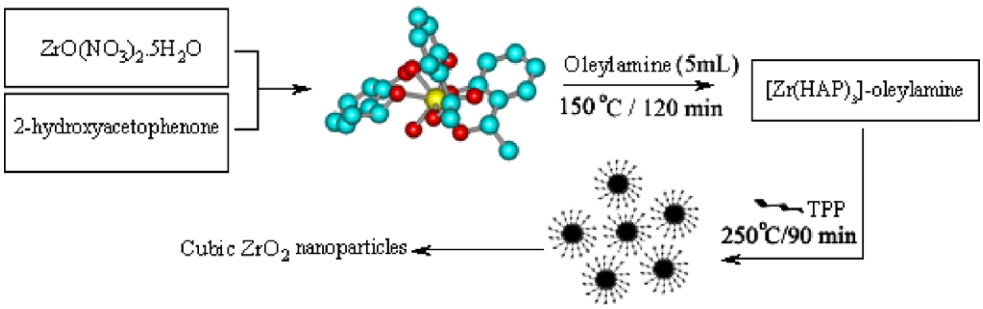


Fig. 2. XRD patterns of ZrO_2 nanoparticles.

Scheme 1. Synthetic procedure for ZrO_2 nanoparticles.

$$D_c = \frac{K\lambda}{\beta \cos\theta}$$

where β is the breadth of the observed diffraction line at its half-intensity maximum, K is the so-called shape factor, which usually takes a value of about 0.9, and λ is the wavelength of X-ray source used in the XRD. All of the reflections of the XRD pattern in Fig. 2 can be indexed to the standard pattern of the pure cubic phase of ZrO_2, which is in good agreement with the reported data (JCPDS No. 27–0997). This revealed that the ZrO_2 sample produced a single-phase cubic structure. Three observed peaks with 2θ values of 30.46°, 50.45° and 60.37° correspond to the (1 1 1), (2 2 0) and (3 1 1) diffraction peaks of crystalline zirconia, respectively. Zirconia nanocrystallite with an average size of 35 nm was estimated by using the Debye–Scherrer formula.

3.3. TEM studies

The TEM image of the sample is shown in Fig. 3, from which it can be seen that the ZrO_2 is composed of some agglomerated particles with an average size of about 30–40 nm. The TEM image shows quasi-spherical nanoparticles. The size of the nanoparticles obtained from the XRD diffraction patterns are in close agreement with the TEM studies, which show sizes of 30–40 nm (Fig. 3).

3.4. Photoluminescence study

Fluorescence spectra were measured with several excitation wavelengths between 230 and 290 nm. While the fluorescence intensity changes to some extent with the excitation wavelength, the fluorescence band position and the band shape remained about the same for excitation wavelengths below 290 nm. This indicates that the fluorescence involves the same initial and final states even when the excitation wavelength is varied between 230 and 290 nm. This result can be explained by fast relaxation from the final state reached by photo-excitation to those states from which the fluorescence originates. Fig. 4 shows one representative fluorescence spectrum with an excitation wavelength of 265 nm. The spectrum features a broad fluorescence band centered at 371 nm [29,30]. The broad band and the substantial red shift of the band maximum compared to the band gap (5.6 eV) of the bulk material [31,32] strongly indicate that the fluorescence involves extrinsic states. Because the particle size distribution is very narrow, the broad fluorescence band seems to be mostly caused by the small particle size leading to an inhomogeneous broadening from a distribution of surface or defect states [33].

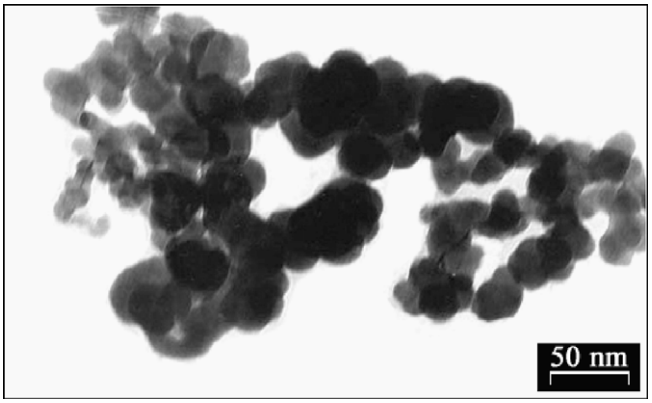

Fig. 3. TEM image of ZrO_2 nanoparticles.

3.5. FT-IR spectra of the products

The FT-IR spectra for the free TPP, oleylamine, $[Zr(HAP)_3(H_2O)_2](NO_3)$ and the as-prepared ZrO_2 nanoparticles are shown in Fig. 5a–d. As shown in Fig. 5a and b, peaks corresponding to P–Ph stretching at 1710 cm^{-1}, rocking and bending mode of the methylene group $\omega(CH_2)$ at 1270 cm^{-1}, the bending mode of the phenyl group $\gamma(=CH)$ at 742 $cm^{-1}$and ν (benzene ring) at 697 cm^{-1}can be seen. The only difference among these characteristic peaks is either the peak intensity or a slight shift in the peak position. For example, the peak position of the longitudinal modes of oleylamine and TPP shifts to lower wavenumbers after TPP and oleylamine are adsorbed on the surface of the ZrO_2 nanocrystals. In the case of $[Zr(HAP)_3(H_2O)_2](NO_3)$ (see Fig. 5c), the presence of bands at 1526 cm^{-1} and 1590 cm^{-1} are due to metal bonded C–O and bands at 1451 cm^{-1} and 1382 cm^{-1} are due to the C–C bond of the 2-hydroxyacetophenone group [34,35]. In free 2-hydroxyacetophenone two C–O bonds give a band pattern at 1600 cm^{-1} and 1500 cm^{-1} whereas two C–C bonds give a band pattern at 1450 cm^{-1} and 1260 cm^{-1}. The lowering of the absorption frequency of these two bonds indicates chelation of the 2-hydroxyacetophenone group to the metal center. A very broad peak at 3440–3100 cm^{-1} is assigned to a water molecule present in the complex. Absorption peaks at 500–650 cm^{-1} are due to a M–O bond. However, there are no absorption bands around this range in 2-hydroxyacetophenone. Therefore, the added 2-hydroxyacetophenone was thought to be fully chelated to the zirconium ion, and no free 2-hydroxyacetophenone exists in the solution. It is well known that FT-IR spectra are very useful for the determination of the crystal phase for ZrO_2 [36]. The extended spectrum in the 400–4000 cm^{-1} region signified a structure with the surface of the sample having chemisorbed H_2O molecules. The spectra of ZrO_2, (Fig. 5d), shows two very weak stretch vibrations at 2925 and 2865 cm^{-1}, attributed to the C–H stretching models of the car-

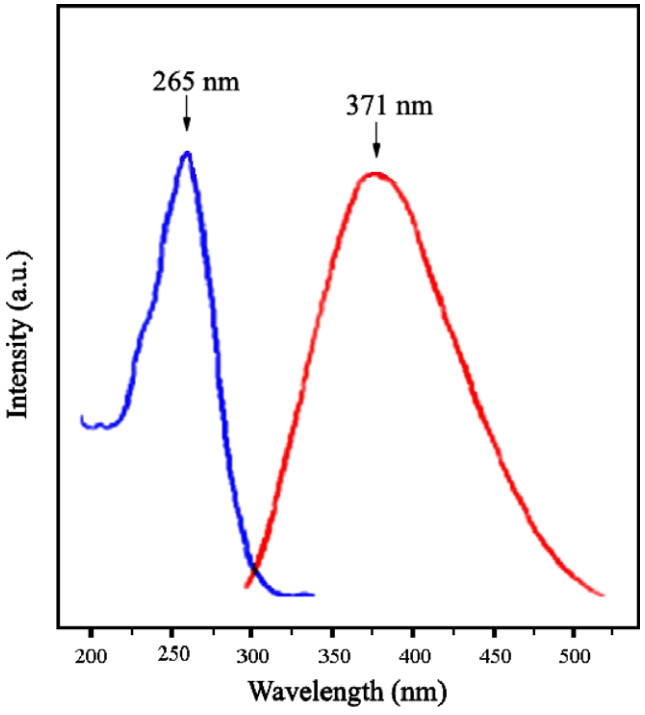

Fig. 4. Photoluminescence spectra of ZrO_2 nanocrystals (excited at 265 nm (blue color), the excitation spectrum of the emission recorded at 371 nm (red color)). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

bon chain of oleylamine that were adsorbed on the surface of the ZrO_2 nanocrystals. The spectrum in Fig. 5d showed broad bands at 451, 540 and 705 cm^{-1} related to the c-ZrO_2 phase (Fig. 5) [37]. The trend is consistent with the fact that for cubic ZrO_2 only one fundamental mode is IR active and the active modes increase markedly upon lowering the symmetry of the structure by going from cubic to tetragonal and then to monoclinic ZrO_2. Two bands of c-ZrO_2 nanocrystallites were obtained at 865 and 1500 cm^{-1}. By comparing the infrared spectra of the nanoparticles with free surfactants we can see that the organic molecules have indeed become a small part of the nanoparticles.

3.6. X-ray photoelectron spectroscopy (XPS) analysis

The chemical state of the zirconia nanoparticles was analyzed by XPS measurements. In an X-ray photoelectron spectroscopy (XPS) experiment, the samples are exposed to monochromic X-radiation and the properties of the inner-shell electrons are probed. Fig. 6 displays the XPS spectra of the Zr 3d and O 1s core levels. The peaks located at 181.3 and 183.8 eV are attributed to the spin–orbit splitting of the Zr 3d components, Zr $3d_{5/2}$, Zr $3d_{3/2}$. The binding energy of O 1s in zirconia is located at 530.1 eV. The peak positions and their relative intensities are basically consistent with those of a standard cubic structure of zirconia [31]. It is noted in Fig. 6 that the peaks of Zr 3d and O 1s shift to higher binding energies with increasing particle diameter. The result is in good agreement with the results obtained by XRD.

3.7. Synthesis of ZrO_2 under different condition

In addition, the ZrO_2 nanoparticles have been prepared under different conditions (Table 1). By controlling the quality of the nanoparticles, ZrO_2 with various sizes can be formed. $[Zr(HAP)_3(H_2O)_2](NO_3)$ calcined at 600 °C for 4 h (sample 1) resulted in ZrO_2 spherical shapes with sizes of 40–50 nm (Fig. 7), 0.6 g of $[Zr(HAP)_3(H_2O)_2](NO_3)$ and 5 ml of oleylamine mixed and heated

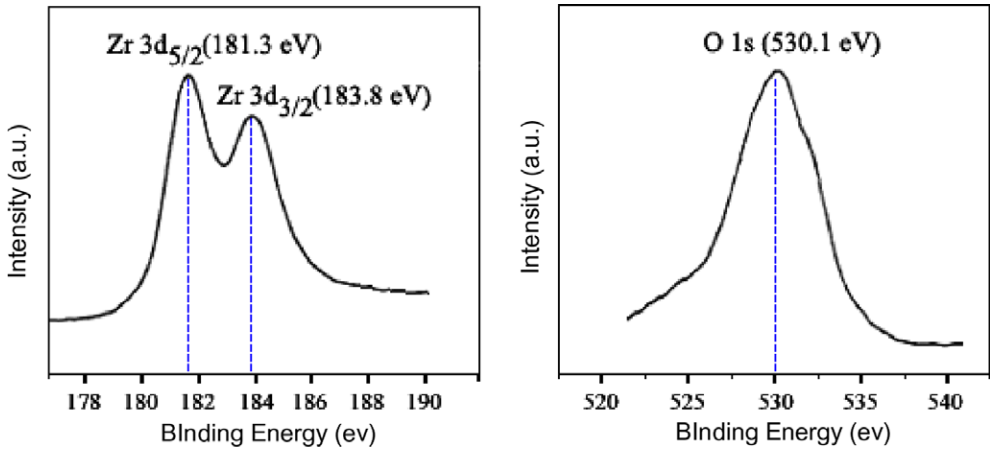

Fig. 6. XPS spectra of ZrO_2 nanoparticles, Zr 3d and O 1s.

Table 1
Preparation of ZrO_2 under different conditions.

Sample	Capping agent	Temperature (°C)	Time	Particles size
1		600	4 h	40–50 nm
2	oleylamine	250	90 min	30 nm (according to XRD)
3	TPP	250	90 min	no product
4	oleylamine + TPP	250	90 min	30–40 nm

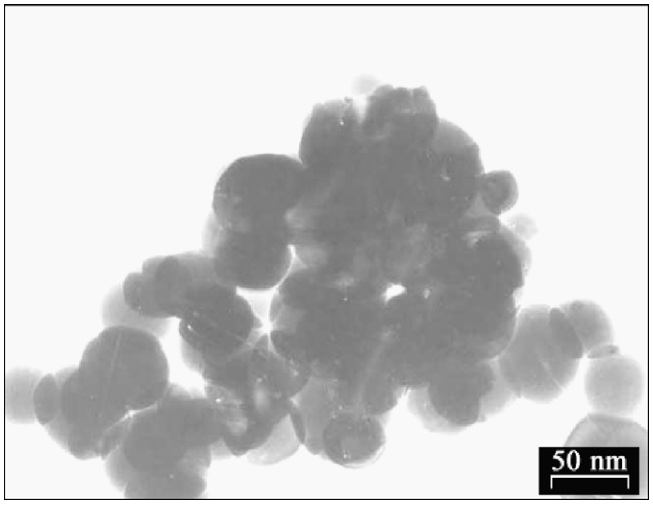

Fig. 7. TEM image of ZrO_2 nanoparticles ((sample 1); $[Zr(HAP)_3(H_2O)_2](NO_3)$ was calcined at 600 °C for 4 h).

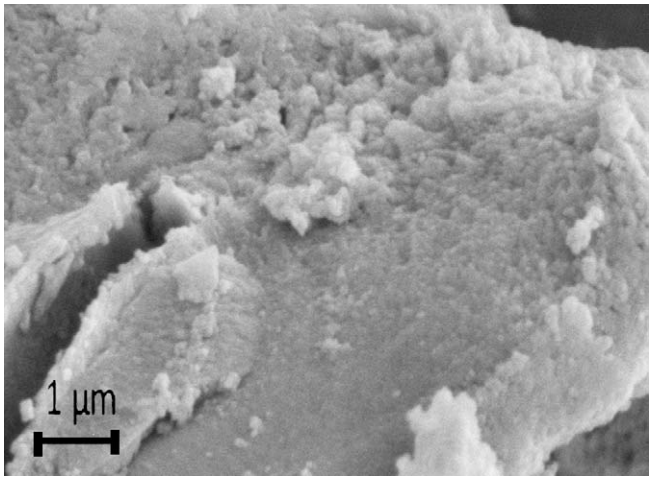

Fig. 8. SEM image of the ZrO_2 nanoparticles (sample 2).

to 245 °C for 90 min led to ZrO_2 nanoparticles with a quasi-spherical shape and an average size of about 30 nm, but the products are agglomerated (sample 2) (Fig. 8). Also 0.6 g $[Zr(HAP)_3(H_2O)_2](NO_3)$ and 5 g of TPP (sample 3) were heated together at 250 °C for 90 min, but after washing with ethanol no precipitation was obtained. To prepare ZrO_2 spherical nanocrystals (sample 4), the procedure mentioned in Section 2, including $C_{18}H_{37}N$ and TPP, was carried out. Considering the different conditions employed to prepare these samples, it is obvious that using both $C_{18}H_{37}N$ and TPP as capping agents are preferred in ZrO_2 nanoparticle synthesis.

In summary, pure zirconium oxide nanoparticles arrays were successfully prepared by the thermolysis method. We have used SEM, TEM, XRD, XPS, FT-IR and PL techniques to characterize the structure of the zirconia nanoparticles. XRD analysis indicated that the nanoparticles closely resembled cubic zirconia nanoparticles. ZrO_2 was also prepared by heat-treatment of bis-aqua, tris-2-hydroxyacetophenato zirconium (IV) nitrate, $[Zr(HAP)_3(H_2O)_2](NO_3)$. The morphology and particle size of the obtained products were compared with each other. Considering the different conditions employed in the synthesis of nanoparticles, it is obvious that using both oleylamine and triphenylphosphine as capping agents are preferred for the synthesis of small size, pure ZrO_2 nanoparticles.

4. Conclusion

ZrO_2 nanoparticles powders were prepared via thermolysis of a new precursor, $[Zr(HAP)_3(H_2O)_2](NO_3)$. ZrO_2 nanoparticles were synthesized under different conditions. The TEM image shows that the size of the quasi-spherical nanoparticles synthesized in the presence of oleylamine and TPP are about 30–40 nm. According to the XRD pattern, to prepare cubic ZrO_2 nanospherical particles, oleylamine and TPP must be used together. Thermolysis is a simple method to prepare ZrO_2 nanoparticles and is one that can be used for large-scale syntheses.

2. Experimental

2.1. Materials and physical measurements

All chemicals and solvents were purchased from commercial sources and were used without further purification. Elemental analyses for C, H, N and S were carried by an Elementar Vario El III. IR spectra of the complexes were determined as KBr discs using a Perkin Elmer 100 FT-IR spectrometer within the 4000–400 cm^{-1} frequency range. Magnetic susceptibility measurements were performed using a Sherwood Scientific MXI model Gouy magnetic balance at room temperature. The UV–Vis spectra were obtained for aqueous solutions of the complexes (10^{-3} M) with a Shimadzu UV-3150 spectrometer in the range 900–190 nm. Thermal analyses were performed with a Diamond TG/DTA thermal analyzer in static air atmosphere from 30 to 550 °C at heating rate of 10 °C/min using platinum crucibles.

2.2. Preparation of the complexes

2.2.1. $\{[Cu_2(\mu\text{-}tdc)_2(ampy)]\cdot 2DMF\}_n$

A solution of $Cu(CH_3COO)_2\cdot H_2O$ (0.23 g, 1.15 mmol) in water (10 mL) was added slowly to a solution of DMF containing ampy (0.13 g, 1.15 mmol) and thiophene-2,5-dicarboxylic acid (0.2 g, 1.16 mmol). The mixture solution was stirred for about 4 h at 55 °C and then cooled to room temperature. Several days later navy blue crystals were formed and collected. *Anal.* Calc. for $C_{30}H_{34}Cu_2N_6O_{10}S_2$: C, 43.42; H, 4.13; N, 10.13; S, 7.73. Found: C, 43.38; H, 4.11; N, 10.21; S, 7.68%.

2.2.2. $[Cu(H_2O)_2(en)_2](tdc)$

A solution of $Cu(CH_3COO)_2\cdot H_2O$ (0.58 g, 2.90 mmol) in water (10 mL) was added to a solution of thiophene-2,5-dicarboxylic acid (0.5 g, 2.90 mmol) in water (20 mL). After 10 min, a blue precipitate was formed and the mixture was stirred for about 4 h at 50 °C. After that, an aqueous solution of an ethylenediamine (0.35 g, 5.8 mmol) aqueous solution was added. A clear solution was observed, stirred for 4 h at 60 °C and then cooled to room temperature. Several days later, glossy dark blue crystals were formed and collected. *Anal.* Calc. for $C_{10}H_{22}CuN_4O_6S$: C, 30.80; H, 5.69; N, 14.37; S, 8.22. Found: C, 30.72; H, 5.58; N, 14.33; S, 8.19%.

2.2.3. $[Cu(H_2O)_2(4\text{-}meim)_4](tdc)\cdot 4H_2O$

The same synthetic method was applied for the second and third complexes, but using 4-methylimidazole (0.95 g, 0.012 mol) in place of ethylenediamine. Again glossy dark blue crystals were formed and collected. *Anal.* Calc. For $C_{22}H_{38}CuN_8O_{10}S$: C, 39.43; H, 5.72; N, 16.72; S, 4.78. Found: C, 39.38; H, 5.64; N, 16.74; S, 4.67%.

2.3. Crystallographic analyzes

Diffraction experiments were carried out at 293 (2) K on a Stoe IPDS diffractometer. The structures were solved by direct methods and refined using the programs SHELXS97 and SHELXL97 [22]. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares methods [22]. The hydrogen atoms were placed in geometrically idealized positions and refined as riding atoms. Data collection: X-AREA, cell refinement: X-AREA, data reduction: X-RED [23]; program(s) used for molecular graphics: ORTEP-3 for Windows [24]; software used to prepare material for publication: WINGX [25].

3. Results and discussion

3.1. Synthesis

The aim of this work was to study the effects of diverse N-ligands containing two nitrogen atoms as a co-ligand on the coordination mode of tdc in mixed-ligand complexes. The reaction of aqueous solutions of different N-donor ligands yielded compounds of the formulas $\{[Cu_2(\mu\text{-}tdc)_2(ampy)_2]\cdot 2DMF\}_n$ (**1**), *trans*-$[Cu(H_2O)_2(en)_2](tdc)$ (**2**) and *trans*-$[Cu(H_2O)_2(4\text{-}meim)_4](tdc)\cdot 4H_2O$ (**3**). The composition of the complexes was determined by IR and thermal analysis in detail. In addition, their structures were determined by the single crystal X-ray diffraction technique.

3.2. UV–Vis spectra and magnetic properties

The electronic spectra of aqueous solutions of the complexes display broad absorption bands at 683 (ε = 25 L mol^{-1} cm^{-1}), 564 (ε = 52 L mol^{-1} cm^{-1}) and 352 (ε = 17 L mol^{-1} cm^{-1}), respectively, which are assigned to the $E_g \rightarrow T_{2g}$ transition. The strong absorption bands below 300 nm are due to intraligand transitions.

The magnetic behaviors of the three Cu(II) complexes have been investigated at room temperature. The complexes exhibit a magnetic moment value of 1.86 for **1**, 1.65 for **2** and 1.55 for **3**, which corresponds to one unpaired electron.

3.3. IR spectra

The IR spectrum of thiophene-2,5-dicarboxylic acid exhibits broad absorption bands in the region 2850–2500 cm^{-1}, characteristic of associated acids, and at 1662, 1415 and 930 cm^{-1}.

In the IR spectra of complexes **1**, **2** and **3**, an insignificant shift in the frequency of vibrations of the thiophene ring is revealed. Bands characteristic of H_2tdc are retained. In the IR spectrum of **1**, characteristic bands of carboxylic groups occur at 1531 cm^{-1} for asymmetric stretching and at 1448 cm^{-1} for the symmetric stretching. These values are shown in Table 1. The comparatively low Δ value (83 cm^{-1}, $\Delta = \nu_{as}COO^- - \nu_sCOO^-$) possibly indicates [26] that tdc is bidentate in **1**. The NH_2 stretching bands of the ampy ligand occur at 3158 cm^{-1}.

For complex **2**, intense bands appear at 1560 cm^{-1} for asymmetric stretching and 1350 cm^{-1} for symmetric stretching. The corresponding absorption bands for **3** are observed nearly at the same frequencies, being at 1559 and 1352 cm^{-1}. The comparatively low Δ values (210 and 207 cm^{-1}, respectively) possibly indicate [26] that tdc is in an ionic form in **2** and **3**. The NH_2 stretching band of ethylenediamine for **2** was at 3294 cm^{-1} and for complex **3** the NH stretching band of 4-methylimidazole was at 3159 cm^{-1}. A broad feature is observed in the 3450 cm^{-1} region and is attributed to the stretching modes of the coordinated water molecules for **2** and **3**. These bands are also significantly different due to the existence of various hydrogen bonds in **2** and **3**.

Table 1
IR data of **1**, **2** and **3**.

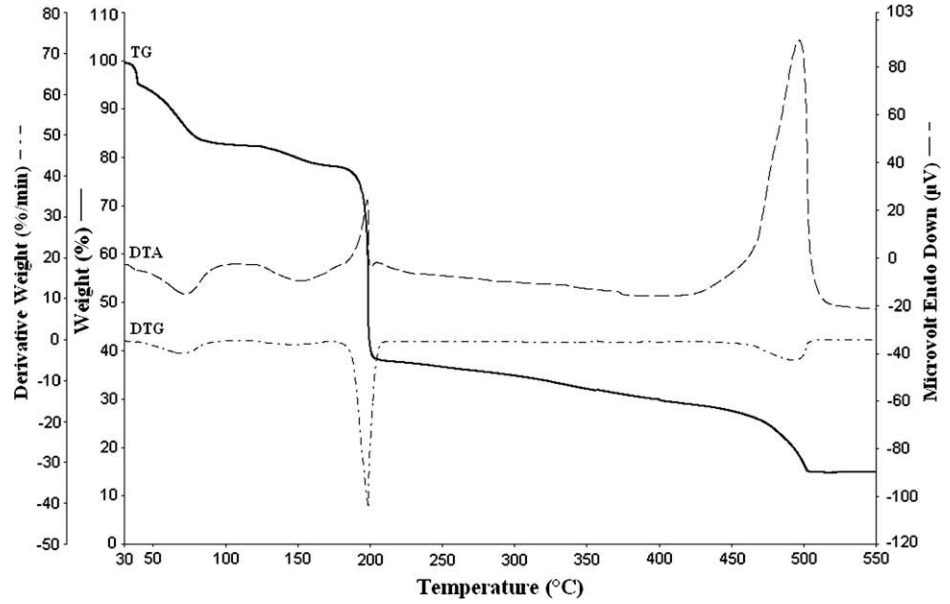

Fig. 1. TG, DTG and DTA curves of **1**.

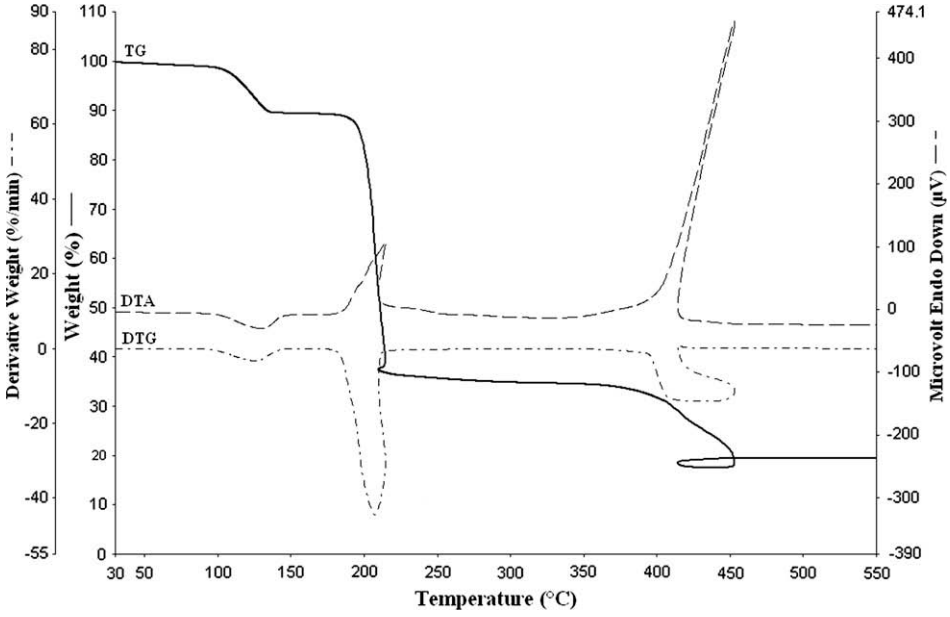

Fig. 2. TG, DTG and DTA curves of **2**.

3.4. Thermal analyzes

Thermal analyzes (TG/DTG and DTA) were carried out to examine the thermal stabilities and to make sure about the proposed formulas and structures of the Cu(II) complexes. Thermograms are shown in Figs. 1–3, respectively for complexes **1**–**3**.

For the complex **1**, the TG shows a three component weight loss. The first step occurs at a maximum temperature of 68 °C. The weight loss of two DMF molecules was 15.20%, with a calculated value is 17.6%. The second step, occurring between 150 and 216 °C, corresponds to the loss of two ampy ligands and two CO_2 molecules, representing a weight loss of 36.70%, with a calculated value of 42.00%. The third step occurring between 216 and 525 °C corresponds to the loss of $-C_4H_4S$, representing a weight loss of 19.80%, with a calculated value of 22.94%. The final thermal product obtained at 550 °C was CuO.

The thermal decomposition of the complex **2** occurs in three steps. The first step falls in the range 25–148 °C, and is assigned to the loss of two water molecules with a weight loss of 10.56% and a calculated value of 9.24%. The second step occurring between 148 and 218 °C corresponds to the loss of the two en ligands and two CO_2 molecules, representing a weight loss of 52.9% with a calculated value of 53.38%. The third step occurs at 218–502 °C, corresponding to the loss of C_4H_4S (organic moiety) and representing a weight loss of 21.00% with a calculated value of 17%. The final thermal product obtained at 550 °C was CuO.

The thermal decomposition of the complex **3** proceeds approximately with main three degradation steps. The first stage occurs at a maximum temperature of 86 °C. The weight loss associated with this stage is 15.10%, which is very close to the theoretical value of 16.13% corresponding to the loss of six water molecules, as is described in Table 2. The second step, occurring at 114–252 °C,

corresponds to the loss of 4-meim and represents a weight loss of 50.08%, with a calculated value of 48.97%. The third step occurring at 252–470 °C corresponds to the loss of tdc, representing a weight loss of 21.4%, with a calculated value of 23%. The final thermal product obtained at 550 °C was CuO.

In the present investigation the general thermal behavior of the complexes in terms of stability ranges and peak temperatures are shown in Table 2.

3.5. Structure of the complexes

3.5.1. $\{[Cu_2(\mu\text{-tdc})_2(ampy)_2]?2DMF\}_n$ (**1**)

The relevant crystal data and experimental conditions, along with the final parameters, are summarized in Table 3. Selected bond lengths and angles are given in Table 4. The crystal structure with the atom labeling for the structure of **1** is shown in Fig. 4. An X-ray analysis reveals that complex **1** exhibits a one-dimensional zig-zag polymeric chain. Each Cu(II) ion is coordinated by two N atoms of ampy and four O atoms from two carboxylate groups of tdc ligands, acting in a bis(bidentate) fashion in a distorted octahedral geometry (Fig. 4.). The Cu1–N bond lengths (1.982 (4) and 1.980 (3) Å) are similar to those of $[Cu(ampy)_2(CF_3SO_3)_2]$ [27], but shorter than those of $[Cu(sac)_2(ampy)_2]$ [28]. The Cu1–O1/O7 [average length = 1.960 Å] and Cu2–O3/O5 bond distances [average length = 1.957 Å] are in agreement with those observed in $[Cu(tdc)(phen)(H_2O)]_n$ (Cu–O 1.932(2) and 1.971(2) [14]). The axial Cu1–O2 (2.596 Å) and Cu2–O4 (2.578 Å) bond distances are longer than those in the related complex $\{[Cd(tdc)(H_2O)_3]\cdot 4H_2O\}_n$ Cd–O = 2.365(3) and 2.454(3) Å [16] and the equatorial bond distances due to the Jahn–Teller effect. The tdc ligand behaves as a bis(bidentate) ligand bridging two adjacent Cu(II) atoms through four oxygen atoms from both carboxylate groups. The C7–O2, C12–O4, C19–O6 and C24–O7 bond distances of the carboxylate groups are significantly shorter (1.230(5), 1.249(5), 1.228(4) and 1.226(5) Å, respectively) than the C7–O1, C12–O3, C19–O5 and C24–O7 distances of 1.273(5), 1.260(5), 1.280(4) and 1.289(5) Å, respectively, which are considered to be due to the weaker coordination with an ionic bond contribution. The dihedral angles formed between the carboxylate plane and the aromatic ring in the tdc anion is 7.55 Å for O5–C19–O6. The intra-chain Cu···Cu distance is 9.767(3) Å, which is comparable to the intra-helix Cd···Cd distance (10.577 Å) [18]. Between adjacent chains, the shortest Cu···Cu distance is 4.767 Å.

The crystal packing in **1** displays strong hydrogen bond interactions. The strong N–H···O hydrogen bonds between the nitrogen atoms of the amine group of the ampy ligand (N2 and N4) and the oxygen atoms of carboxylate groups (O4, O6 and O8) (O4···N2 = 2.887(5), O6···N2 = 2.951(4) and O8···N4 = 2.905(4) Å) and an oxygen atom of a DMF molecule (O10) (O10···N4 = 3.003(9) Å) were found within the chains (Table 5). These intermolecular interactions give rise to a three-dimensional framework.

3.5.2. Trans-$[Cu(H_2O)_2(en)_2](tdc)$ (**2**)

X-ray analysis indicates that the asymmetric unit of **2** contains a $[Cu(H_2O)_2(en)_2]^{2+}$ cation and a tdc^{2-} anion (Fig. 5.). Each Cu(II) ion in **2** is coordinated by four nitrogen atoms of two chelating en ligands and two oxygen atoms of the trans aqua ligands, and thus adopts a distorted octahedral N_4O_2 environment. The basal plane is defined by N1, $N1^{i}$, N2 and $N2^{i}$ from the two en ligands, the apical position is occupied by O1 and $O1^{i}$ of the aqua ligands. The Cu1–N1 and Cu1–N2 distances are 2.012(1) and 2.020(1) Å, respectively, while the Cu(1)–O1 bond distance of 2.556(1) Å is strongly elongated due to Jahn–Teller distortion. Similar geometrical parameters for the coordination sphere have been reported for other diaquabis(ethylenediamine) copper(II) salts [29,30].

The tdc dianion acts as a fully deprotonated counterion. The dihedral angle between the thiophen plane and the carboxylate group is 8.06°. The O–C bond lengths (1.251(2) and 1.252(2) Å) in

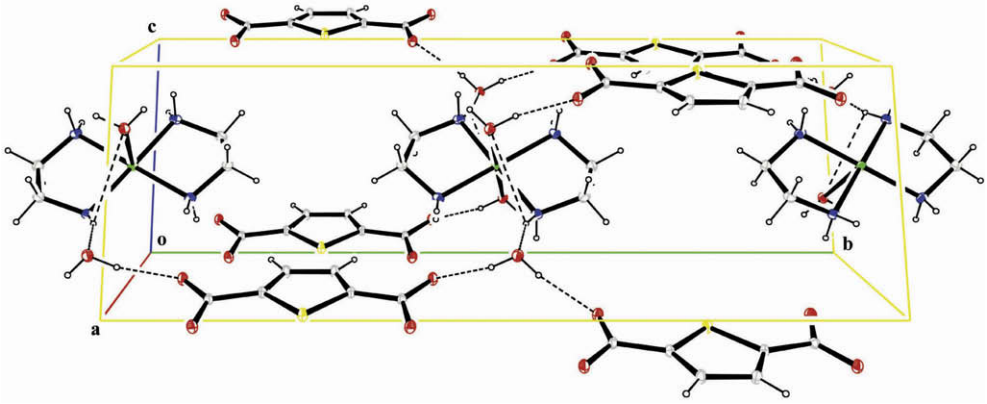

Fig. 5. Packing diagram of a unit cell of **2**.

the tdc anion are in agreement with related structures [31]. The crystal packing is mainly stabilized by intra and inter-molecular hydrogen bonding between the oxygen atoms of the tdc anion and aqua ligand and nitrogen atoms of the en ligands [N2···O2 = 3.025(2), N···O (average) = 3.008 and O···O (average) = 2.778(2) Å] (Fig. 5.).

3.5.3. Trans-[Cu(H$_2$O)$_2$(4-meim)$_4$](tdc)·4H$_2$O (**3**)

The molecular structure of **3** is illustrated in Fig. 6. Table 4 lists selected bond distances and angles. The molecule consists of a complex cation, $[Cu(H_2O)_2(4\text{-meim})_4]^{2+}$, one tdc ion and four lattice water molecules. In the complex cation, the Cu(II) is coordinated by four 4-meim ligands and two water molecules. The coordination geometry around the Cu(II) centre is a distorted octahedral. Both 4-meim ligands are essentially planar and are almost perpendicular to each other. The angle between the corresponding planes is 90.12(7)°, 90.61(7)°, 89.97(7)° and 89.48(7)°. The Cu-N distances range from 1.984(2) to 2.015(2) Å, while the average distance of the Cu–O bonds is 2.623 (2) Å due to the Jahn–Teller effect. Bond angles and distances are similar to the previously observed values for Cu(II) complexes containing 4-meim ligands [32–34].

The crystal structure is stabilized through strong intra- and inter-molecular hydrogen bonding and weak C–H···π interactions (Fig. 6.). Details of hydrogen bonding geometries are given in Table 5. These interactions give rise to a three-dimensional framework.

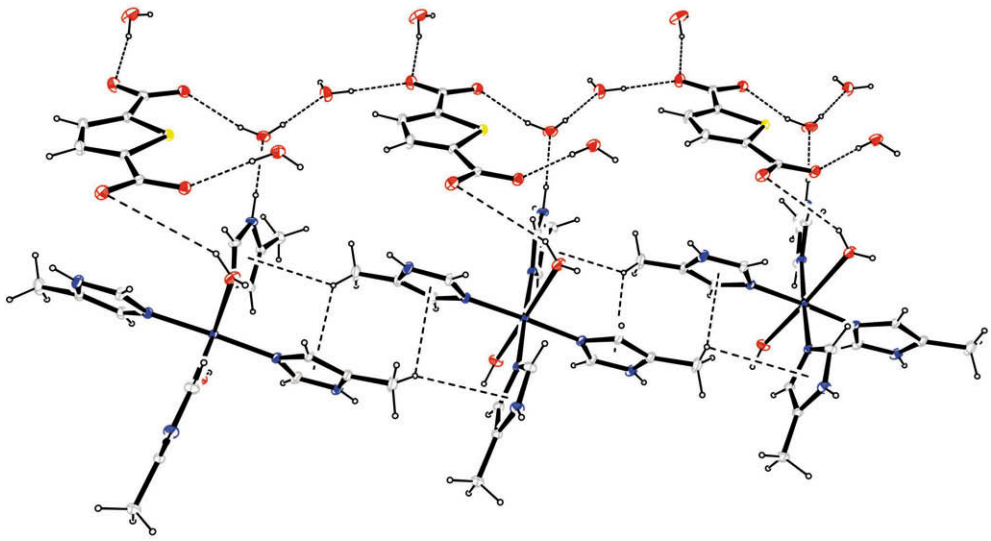

Fig. 6. The C–H···π and π···π interactions of **3**.

4. Conclusion

In summary, we have synthesized and structurally characterized three 3D Cu(II) complexes which are derived from 2,5-thiophenedicarboxylate with dissimilar ligands. One of the complexes has a 1-D zigzag polymeric structure and tdc behaves as a bidentate ligand. In the other complexes, the tdc dianion acts as a counter ion. In all these complexes the Cu(II) atom has a distorted octahedral coordination geometry. Three-dimensional frameworks are constructed though hydrogen bonding and/or C–H···π interactions in all the synthesized complexes.

Supplementary data

CCDC 716509, 716508 and 716507 contain the supplementary crystallographic data for **1**, **2** and **3**. Given this, it is perhaps unfortunate that many reports of 3d/4f systems only describe a small number of aggregates, rather than presenting a systematic study of a range of what might be termed "lanthanologues".

The present work describes the synthesis, structures, magnetochemistry and ^{57}Fe Mössbauer spectroscopy of a series of isostructural tetranuclear complexes $[Fe_3Ln(\mu_3\text{-}O)_2(CCl_3COO)_8(H_2O)(THF)_3]\cdot THF$ (Ln = Ce^{III} (**1**), Pr^{III} (**2**), Nd^{III} (**3**)) and $[Fe_3Ln(\mu_3\text{-}O)_2(CCl_3COO)_8(H_2O)(THF)_3]\cdot THF\cdot C_7H_{16}$ (Ln = Sm^{III} (**4**), Eu^{III} (**5**), Gd^{III} (**6**), Tb^{III} (**7**), Dy^{III} (**8**), Ho^{III} (**9**), Lu^{III} (**10**) and Y^{III} (**11**)). All compounds were prepared by the reaction between $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ [14] and the corresponding Ln^{III} nitrate salt. We have previously reported the crystal structure of the europium compound **5** [12]. Its cell determination in the present paper is given for comparison only.

2. Experimental

2.1. General

All chemicals and solvents used for synthesis were purchased from Aldrich and were of reagent grade and used without further purification. The precursor trichloroacetate $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ was prepared as described elsewhere [14].

2.2. Preparations

2.2.1. $[Fe_3LnO_2(CCl_3COO)_8H_2O(THF)_3]THF$

All compounds were synthesised by the reaction between $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ (1.50 g, 0.90 mmol) and $Ln(NO_3)_3\cdot 6H_2O$ (0.23–0.28 g, 0.60 mmol) in acetone (30 ml) at 50 °C with stirring for 30 min. After filtration, the solution was evaporated and the solid product was dissolved in THF (30 ml) followed by addition of heptane (6 ml). A brown, microcrystalline material precipitated from this solution after 7 days and was isolated by filtration, washed with benzene and air dried. Yield: 54–66%, except 42% for the Y^{III} complex. Compound **1**: Yield 750 mg (63%). Elemental *Anal.* Calc. for $C_{32}H_{34}Cl_{24}CeFe_3O_{23}$: C, 19.76; H, 1.76. Found: C, 19.94; H, 1.92%. IR (KBr, cm^{-1}): 3450 (w), 2958 (w), 1706 (m), 1680 (vs), 1628 (w), 1371 (vs), 1023 (w), 968 (w), 918 (w), 850 (s), 836 (s), 742 (s), 686 (vs), 543 (w), 512 (w), 457 (w). Compounds **1**–**11** give rise to very similar infrared spectra over the range 4000–400 cm^{-1} as Ln–O bond vibrations are not found in this range. The IR spectrum of the Fe_3Ce compound, together with a list of main peaks, is available in the Supporting Information. The luminescence spectra for compounds **3**–**5**, measured both in the solid state and in aqueous solutions, together with analysis of the influence of Fe^{3+} on the luminescence intensities of the lanthanides ions have already been reported [15].

Compound **2**: Yield 690 mg (60%). Elemental *Anal.* Calc. for $C_{32}H_{34}Cl_{24}Fe_3O_{23}Pr$: C, 19.75; H, 1.76. Found: C, 19.65; H, 2.00%. Compound **3**: Yield 695 mg (60%). 2.3. Physical measurements

The FTIR spectra were measured using KBr discs on a Perkin–Elmer Spectrum One Spectrometer. Elemental analyses for C and H were carried out at the Institute for Inorganic Chemistry at the University of Karlsruhe. The ^{57}Fe Mössbauer spectra were acquired using a conventional spectrometer in the constant-acceleration mode equipped with a ^{57}Co source (3.7 GBq) in a rhodium matrix. Isomer shifts are given relative to α-Fe at room temperature. The sample was cooled inside an Oxford Instruments Mössbauer-Spectromag 4000 Cryostat, in which the sample temperature can be varied between 3.0 and 300 K. The spectra were fitted using the NORMOS Mössbauer Fitting Program. The magnetic susceptibility measurements were carried out on polycrystalline samples using a Quantum Design SQUID magnetometer MPMS-XL, with the ac option using an exciting field of 4 Oe, or in the magnetization measurement mode with an applied field of 1000 Oe. They coincided in all instances. The T = 1.8 K magnetization measurements were performed up to a field of 9 T using a Quantum Design PPMS magnetometer. Data were corrected for the sample holder and the diamagnetic contribution estimated from Pascal's constants.

2.4. Crystal structure determination

Crystals suitable for crystallography were grown from THF:heptane (5:1) mixture. Data were measured on a Bruker SMART Apex CCD diffractometer using graphite-monochromated Mo $K\alpha$ radiation and corrected for absorption using SADABS [16]. Structure solution by direct methods and full-matrix least-squares refinement against F^2 (all data) was carried out using SHELXTL [17]. All ordered non-H atoms were refined anisotropically. Trichloroacetate and THF ligands are often found to show disorder, and the structures here were no exception. A combination of geometrical (SAME and SADI in SHELXTL) and similarity (DELU, SIMU) restraints were often necessary for successful refinement, particularly when threefold disorder of trichloroacetates was involved. Crystallographic data and details of structure refinements are summarized in Table 1 for complexes **1**–**4**, **8** and **9**. The geometries of the $\{Fe_3Ln(\mu_3\text{-}O)_2\}$ cores are summarized in Table S2. The unit cells of **6**, **7**, **10** and **11** (for which the ligand disorder precluded satisfactory refinement) are compared with those of **8** and **9** in Table 2.

3. Results and discussion

3.1. Synthesis

All eleven tetranuclear trichloroacetates have been obtained by the reaction of the iron–barium μ_3-oxotrinuclear compound $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ [14] with the corresponding Ln^{III} nitrates in acetone. After removal of barium nitrate and evaporation of acetone, crystals were obtained in a reproducible manner from a THF:heptane (5:1) mixture in good yield (54–66%, except for the Y^{III} complex, which was obtained in 42% yield). The complexes are brown crystalline substances insoluble in water but readily soluble in a variety of polar organic solvents, and can be recrystallized from THF–heptane mixture without change of composition. They are stable to storage in air under ambient conditions. We used $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ and lanthanide nitrates because Ba^{II} has an ionic radius only a little larger than those of the lanthanides, and $Ba(NO_3)_2$ has a low solubility in the usual organic solvents, so that

exchange of barium by lanthanides should be favorable. Several solvents were investigated, but the heterometallic clusters were obtained only using acetone as solvent. Although $BaSO_4$ is also insoluble in organic solvents, reactions of lanthanide sulfates in presence of small quantity of water (due to the insolubility of $Ln_2(SO_4)_3$ in acetone) only gave rise to a homometallic tetranuclear Fe_4 compound. Probably, the presence of water redirects the reaction to homometallic product. The original intention was to use $[Fe_2BaO(CCl_3COO)_6(THF)_6]$ to obtain isostructural compounds with a $\{Fe_2LnO\}$ core. However, it appears that during the synthesis a rearrangement of the presumed initial $\{Fe_2LnO\}$ cluster takes place, leading to the isolated tetranuclear $\{Fe_3LnO_2\}$ products. Attempts to obtain the same products using either simple iron salts or trinuclear clusters such as $[Fe_3O(CCl_3COO)_6(L)_3]^+A^-$ as starting material were unsuccessful.

3.2. Structural analysis

The complexes are generally isostructural, and only small changes in Ln–O bond lengths, resulting from the lanthanide contraction, are observed. The structure of the Pr^{III} analogue **2** will be described as an example; the bond lengths and angles for the six complexes which were fully crystallographically characterized are compared in Table S2.

The $[Fe_3Pr(\mu_3\text{-}O)_2(CCl_3COO)_8(H_2O)(THF)_3]$ molecule in **2** (Fig. 1) is of the well-known tetranuclear "butterfly" type, with two $Fe_2Pr(\mu_3\text{-}O)$ triangles sharing the Pr(1)···Fe(2) edge. The two triangles are close to coplanar, with the two (μ_3-O) ligands O(1) and O(2) lying respectively 0.132(3) and 0.011(3) Å out of the plane of their respective Fe_2Pr triangles. The $Fe_2Pr(\mu_3\text{-}O)$ triangles are markedly non-equilateral. The two Fe(2)–O–Ln(1) angles are in the range 99–101°, while the remaining angles are much larger, 124–134°. Three of the four outer M···M edges are bridged by two trichloroacetate ligands; Fe(2)···Fe(3) is bridged by just one trichloroacetate, as is Pr(1)···Fe(2). All trichloroacetate ligands have the same *syn, syn*-μ:η^1:η^1-bridging mode which is common in lanthanide [18] and iron [14] trichloroacetates; the latter bridge has the effect of making the two triangles non-coplanar, the dihedral angle between the two Fe_2Pr triangles is 147.32(2)°. Three THF ligands coordinate to Fe(1), Fe(3) and Pr(1), and the coordination sphere of Fe(3) is completed by an aqua ligand. This latter, O(22), forms two hydrogen bonds, one intramolecular to the carboxylate oxygen O(16), and one to the lattice THF molecule, O(31).

All three Fe centers have distorted octahedral coordination geometries. That of Fe(2) consists of the two (μ_3-O) ligands mutually *cis*, and four chloroacetate oxygens. Those of Fe(1) and Fe(3) consist of a (μ_3-O) ligand and a THF oxygen *trans* to each other, and either four chloroacetate oxygens Fe(1) or three chloroacetate oxygens and an aqua oxygen Fe(3) forming an equatorial plane. Thus the coordination environment of Fe(2) is significantly different from the other two. The environment of Pr(1) is eight-coordinate, with a rather irregular coordination polyhedron that may best be described as a distorted bicapped trigonal prism. The Ce^{III} used in the synthesis of **1** could oxidize to Ce^{IV} during the reaction,

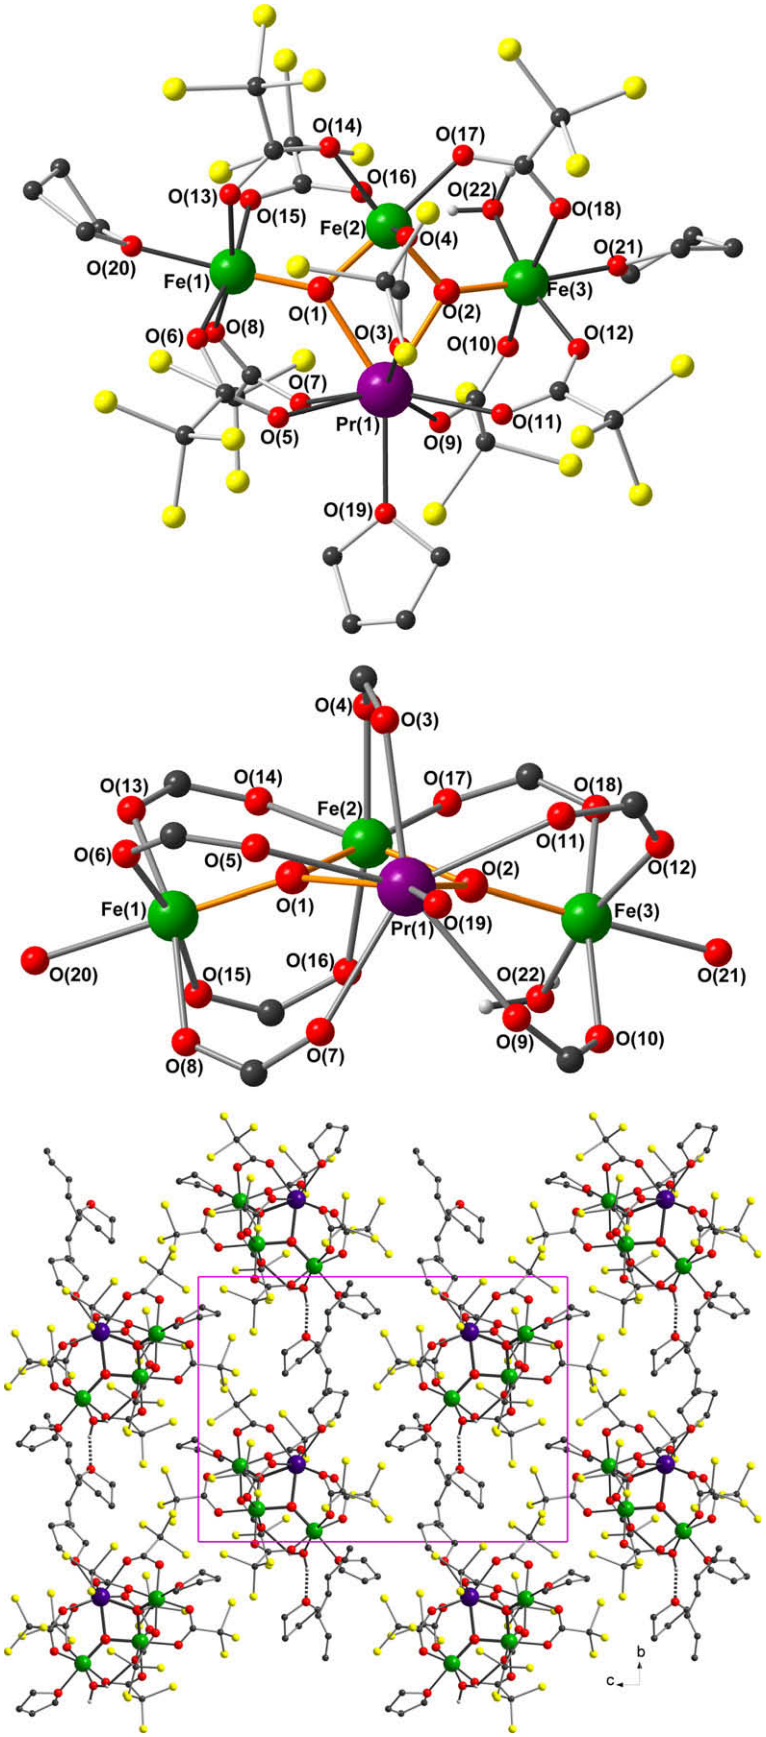

Fig. 1. Molecular structure of complex **2** (organic H-atoms and minor disorder components omitted for clarity) (top); core of complex **2** showing just bridging groups and coordinated oxygens of terminal ligands (middle); packing diagram for 8 viewed along the *a*-axis, with H-bonds to lattice THF molecules shown dotted (bottom).

and there is also the possibility of intramolecular electron transfer from Ce^{III} onto one of the Fe^{III} centers, although the latter possibility is less likely since the Fe–O bond lengths in **1** are in line with the other compounds in the series. The oxidation state of Ce(1) in **1** was checked by Bond Valence Sum Analysis [19], and the calculated value was 2.81.

Although the tetranuclear complex molecules in **1**–**11** are essentially isostructural, they crystallize in three different structural types, which appear to depend on the ionic radius of the lanthanide. Complexes **1**–**3** crystallise in the orthorhombic space group $P2_12_12_1$ with $Z = 4$. The asymmetric unit contains one tetranuclear complex and one lattice THF molecule. The Fe_3Sm complex **4** crystallizes, unusually for a molecular metallo–organic complex, in the acentric triclinic space group $P1$. The metal centers correspond closely to the more usual $P\bar{1}$, but refinement in this space group resulted in severe and mostly unresolvable disorder of the ligands and unacceptably high R-factors ($R_1 = 0.1343$). Refinement in $P1$, on the other hand, gave mostly ordered ligands and $R_1 = 0.0385$, and it is considered that intermolecular ligand–ligand interactions are such as to result in ordering of the trichloroacetate groups to give the acentric structure. In contrast to the orthorhombic structure type of **1**–**3**, complex **4** crystallizes with one molecule of THF and one of n-heptane in the crystal lattice. Compounds **5**–**11** crystallize isomorphously in the monoclinic space group $P2_1$ with $Z = 2$; as for the structure of **4**, the asymmetric unit also contains one THF and one heptane molecule. The structures of **8** and **9**, although showing some ligand disorder, could be refined without particular problems, but for **6**, **10** and **11** the disorder was such that even with application of extensive restraints the structures could not be refined satisfactorily. The unit cells of the six compounds are compared in Table 2. It may be that within the series **5**–**11**, the molecules of **8** and **9** are an ideal size for this crystal packing, whereas those at either end of the series, for which the lanthanide ionic radius is either larger or smaller, the slight differences in molecular size are sufficient for the packing to be less efficient, leading to the extensive ligand disorder. In none of the structures reported here were there any unusually short intermolecular contacts, apart from the hydrogen bond from the aqua ligand to the lattice THF molecule already mentioned.

3.3. Magnetic properties

The magnetic behavior of all the compounds was investigated in the temperature range 1.8–300 K and the obtained data are presented as χT vs T plots shown in Fig. 2. The Fe_3Lu (**10**) and Fe_3Y (**11**) compounds, with their diamagnetic Lu(III) and Y(III) metal ions, show similar behavior to compounds **1**–**5**, with χT in the range of 4–5.5 $cm^3\ K\ mol^{-1}$ at 300 K, and showing only a very slow decrease as the temperature is reduced, with a final sharper decrease at very low temperatures. By contrast, compounds **6**–**9** show much higher values of χT at 300 K, with a slow decrease as T decreases, followed by a faster decrease below *ca.* 50 K. This effect is related to the antiferromagnetic coupling between the Fe_3 trinuclear unit and the magnetic Ln^{III} cations. As seen in Table 3, the χT products at room temperature for the Y and Lu compounds are very close to those expected for an asymmetric Fe_3 unit with strong antiferromagnetic coupling ($J/k_B \approx -50$ K) between each of the outer, or "wingtip" Fe(1) and Fe(3) and the central Fe(2), and negligible coupling between Fe(1) and Fe(3). This result suggests that the Fe_3 unit has a robust $S = 5/2$ ground state, with two spins parallel (Fe(1) and Fe(3)) and one antiparallel (Fe(2)). In Fig. 4, left panel, the χT data at 300 K (taken from Table 3) are shown as squares, together with calculated values (the sum of the Fe_3 contribution and the Ln contribution, calculated as $\chi_{Ln}T = \mu^2_{eff,Ln}/8$, where $\mu_{eff,Ln}$ is taken from external Tables [20]) shown as the solid line; the value for the Fe_3Lu is shown with a dotted line as a reference point. The calculated values are followed reasonably well by the experimental results, indicating that the Ln metals are weakly coupled to the Fe_3 core.

The experimental data fit well to the Curie–Weiss law $\chi = C/(T - \theta)$, where $C = C_{Fe_3} + C_{Ln}$. The fit parameters C and θ for the [Fe_3Ln] samples are given in Table 3. C_{Fe_3} are taken as those of the Ln = Y and Lu entries in column 5. The Weiss constant θ pro-

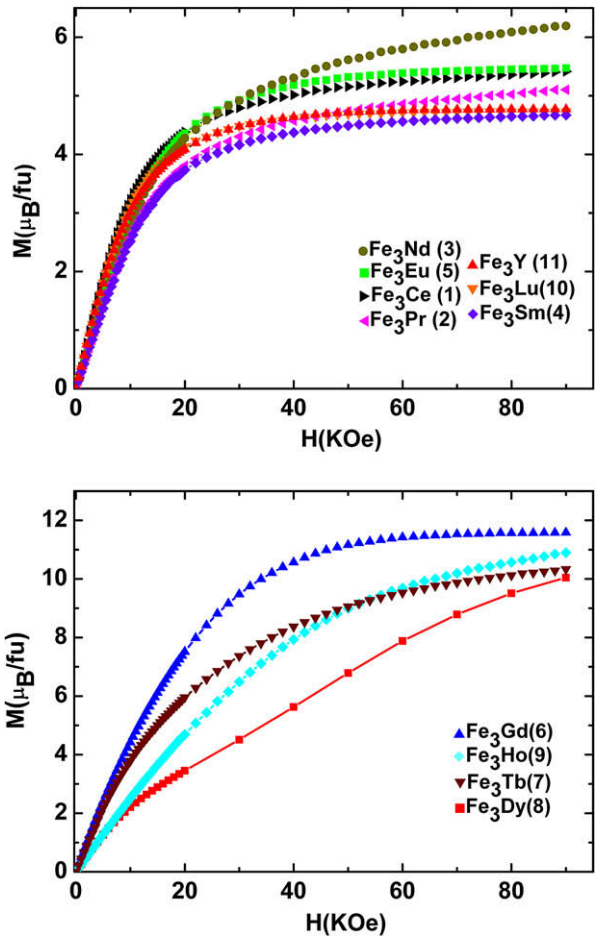

Fig. 3. Field dependence of the magnetization for compounds **1**–**5, 10, 11** (top) and **6**–**9** (bottom) at 1.8 K. Lines are guides to the eyes.

vides a measure of the intercomplex interactions, probably of dipolar character. They are weak as may be expected for well separated complexes.

The field dependences of the magnetization measured at 1.8 K for the complexes are shown in Fig. 3. As may be expected, the complexes containing diamagnetic (Lu^{III} **10**, Y^{III} **11**) or isotropic (Gd^{III} **6**) lanthanides show clear saturation above *ca.* 60 kOe. The saturation values for **10** and **11** are *ca.* 4.7 μ_B, in good agreement with the expected value for three strongly antiferromagnetically-coupled Fe^{III} centers with an overall $S = 5/2$ ground state. The magnetization for **6** saturates at *ca.* 11.8 μ_B at 90 kOe, close to the sum of the values for $S = 7/2$ Gd^{III} and an $S = 5/2$ Fe_3 unit. Moreover, fitting of the curve using Brillouin functions has shown that the Gd–Fe_3 interactions were negligible at 1.8 K [22].

In Fig. 4, right panel, the measured M values at $H = 90$ kOe (squares) are compared to the expected values (the sum of the Ln^{III} free ion value and the $S = 5/2$ Fe_3 contribution, shown as the solid line). Except for **6** with Ln = Gd^{III}, the experimental values are lower than the respective calculated values due to the effects of Ln^{III} crystal field splitting, spin–orbit coupling or exchange with the Fe_3 entity. For the complexes containing anisotropic lanthanide cations, there is a clear distinction between the lighter and heavier lanthanides. Compounds **1**–**5** ($4f^1$–$4f^6$) show either near or complete saturation behavior. By contrast, compounds **7**–**9** ($4f^8$–$4f^{10}$) show no saturation of their magnetization as expected in the presence of low lying excited states and/or magnetic anisotropy. The Fe_3Eu compound **5** has a magnetization of 6.2 μ_B at 9 kOe without complete saturation. Since Eu^{III} should have an $S = 0$ ground state, this higher value compared to those for the Fe_3Lu and Fe_3Y complexes (both *ca* 4.7 μ_B) must result from the incompletely quenched orbital moment of the Eu^{III} ground state.

In order to assess whether these molecules exhibit a slow relaxation of their magnetisation, ac magnetic susceptibility measurements were performed. The measurements were carried out over the 1.8–30 K range under 3.5 G ac field oscillating in 1–1420 Hz range. As an example, complex **7** showed a weak signal with a low ratio χ''/χ' frequency-dependent out-of-phase signal (Fig. 5), which could be the tail of a maximum lying at a temperature below 1.8 K. The fact that the out-of-phase component of the ac susceptibility signal is rather small, is not unprecedented as many molecules exhibiting claimed SMM behavior have a similarly weak χ''/χ' ratio [23]. The analysis of the magnetic properties of the compounds **1**–**11** with fitting of the data (magnetization and χT for Fe_3Y, Fe_3Lu and Fe_3Gd) will be presented in more detail elsewhere [22].

3.4. Mössbauer spectra

The Mössbauer spectra of complexes **1**–**4** were investigated by ^{57}Fe Mössbauer spectroscopy at 300 and 15 K. As already discussed, all complexes have a butterfly structure in which the three Fe^{III} centers all have FeO_6 coordination environments. However, these environments are made up of different combinations of types of oxygens, either oxo ligands or oxygens from carboxylate, aquo or

THF ligands, as follows: Fe(1): $(\mu_3\text{-O})(O_{carb})_4(O_{THF})$; Fe(2): $(\mu_3\text{-O})_2(O_{carb})_4$, Fe(3): $(\mu_3\text{-O})(O_{carb})_3(O_{aq})(O_{THF})$. The ^{57}Fe Mössbauer spectra of the complexes **1**–**4** (Fig. 6), both at room temperature and 15 K, each consist of two asymmetrical and rather broad peaks, which were fitted with two doublets, with relative areas in a 2:1 ratio, in each case. The Mössbauer parameters (Table 4) of the two doublets, with isomer shift (δ_{Fe}) and quadrupole splitting (ΔE_q) ranging between 0.22 and 0.52 mm s^{-1} and between 0.94 and 1.72 mm s^{-1} respectively, indicate that all the Fe^{III} ions are in a high-spin state ($S = 5/2$) and that the electronic structures and related interactions around two of the distinct Fe^{III} centers, probably Fe(1) and Fe(3), are similar although probably not identical.

According to ΔE_q values at 15 K, the symmetry of the electronic environment around the Fe(2) nucleus is higher than around the other two iron nuclei, Fe(1) and Fe(3). An increase in the isomer shift at cryogenic temperatures is the result of the second-order Doppler effect [24]. The nature of lanthanide ion in the complex has little effect on the electronic interaction of the Fe^{III} ions, and

the Mössbauer spectra for compound **1** support the conclusion that the Ce is in the +3 oxidation state, since the values from the spectrum of **1** are in line with those for the other complexes.

The Mössbauer spectra down to 15 K do not show evidence for any magnetic ordering around the iron nuclei for the compounds studied. As discussed above, ac susceptibility measurements showed no evidence for slow relaxation of magnetisation for the complexes involving the lighter lanthanides, but the measurements on complex **7** did indicate such slow relaxation. Therefore, Mössbauer measurements at lower temperatures than 15 K were carried out for compound **7**. The spectra measured at 3 K could be fitted with three sextets (resulting from antiferromagnetically-coupled high-spin Fe^{III}, according to the isomer shift values) with the area ratio 1:1:1. But at this temperature, the electron spins are not completely blocked or frozen on the Mössbauer time scale (*ca.* 10^{-7} s), being still in a rather slow relaxation regime as derived from the line-width values of the sextets (Table 5). In other words, we see evidence of blocking of the magnetization below 3 K for compound **7**.

Under an applied field of 6.5 T, one sextet showed an increased splitting while the other two showed smaller splittings, relative to the 3 K spectrum without applied field, as can be seen from the values in Table 5. The "in field" data suggest that one sub-lattice, in this case that of Fe(2), is antiferromagnetically-coupled to the other two belonging to Fe(1) and Fe(3). The doublets seen in the spectra measured at 77, 150 and 300 K showed a decrease of the quadrupole interactions with increasing temperature. The more pronounced asymmetric shape of the peaks in the Mössbauer spectra at higher temperatures, is the result of a smaller degree of overlap between the doublets, caused by a reduced interaction (see Table 5) for the inner doublet, assigned to Fe(2), derived from a careful evaluation of the data [22] dealing with electronic mechanisms.

The compounds with Ln^{III} ions located in the first half of the lanthanide series showed no spin blocking at very low temperatures, but a much stronger temperature-dependence of the quadrupole interaction was observed, as clearly seen in the spectra shown in Fig. 6. Their quadrupole splittings are larger than that observed (Fig. 7) for compound **7**, with its higher number of 4f electrons.

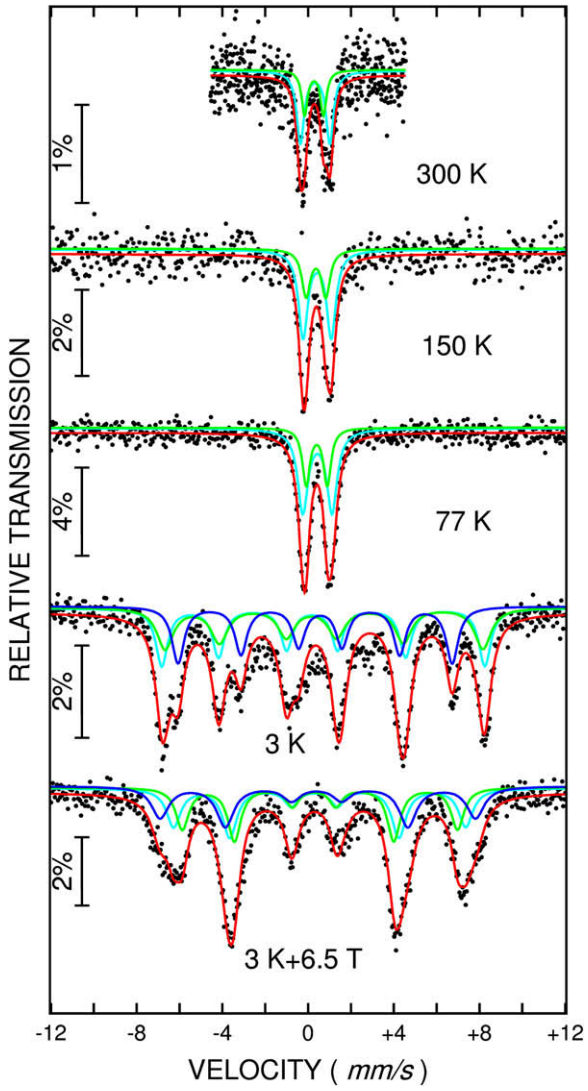

Fig. 7. The ^{57}Fe Mössbauer spectra for **7** at 300, 150, 77 and 3 K in zero-applied magnetic field and at 3 K in applied magnetic field of 6.5 T. See Table 5 for the fitting parameters.

4. Conclusions

A series of new heterotetranuclear trichloroacetate complexes $[Fe^{III}_3Ln^{III}(\mu_3\text{-}O)_2(CCl_3COO)_8(H_2O)(THF)_3]$ (Ln = Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Lu, Y) has been prepared and structurally characterized. Magnetochemical and Mössbauer studies were interpreted in terms of the tetranuclear structure of the compounds. The complexes exhibit strong intramolecular antiferromagnetic exchange between the Fe^{III} metal ions. The temperature-dependence of the χT products showed two different patterns, with one type of behavior for complexes containing lighter or diamagnetic lanthanides, and another for the complexes containing the heavier lanthanides Gd^{III}–Ho^{III}. The Mössbauer investigation showed that all the Fe^{III} centers are high-spin ($S = 5/2$), and also showed the existence of two different type of Fe sites, with distinct interactions, in the molecule, which were assigned to the two "wingtip" Fe(1) and Fe(3) and to the central Fe(2). At low temperatures, evidence for magnetic blocking, i.e. slow relaxation of the spins, was observed in the Mössbauer spectra for compound **7**, confirming the results of ac magnetic susceptibility measurements.

Shimadzu-470 spectrometer. UV–Vis spectra were obtained on a Shimadzu 2100 spectrometer using a 1 cm path length cell. The melting point is uncorrected and was obtained by a Kofler Heizbank Rechart type 7841 melting point apparatus. Elemental analysis was performed using a Heraeus CHN–O Rapid analyzer.

2.2. X-ray data collection and structure refinement

The X-ray diffraction measurements were made on a STOE IPDS-II diffractometer with graphite monochromated Mo Kα radiation. For [Pt(5,5′-dmbipy)Cl_4] (**1**) and [Pt(6-mbipy)Cl_4] (**2**), yellow prismatic crystals with dimensions of $0.21 \times 0.18 \times 0.11$ and $0.27 \times 0.23 \times 0.21$ mm, respectively, were mounted on a glass fiber and used for data collection. Cell constants and an orientation matrix for data collection were obtained by least-squares refinement of the diffraction data from 3963 for **1** and 3691 for **2** unique reflections. Data were collected at a temperature of 298(2) and 120(2) K to a maximum 2θ value of 58.36° for **1** and 53.26° for **2** and in a series of ω scans in 1° oscillations and integrated using the Stoe X-AREA [27] software package. The numerical absorption coefficient, μ, for the Mo Kα radiation are 10.217 mm^{-1} for **1** and 10.909 mm^{-1} for **2**. A numerical absorption correction was applied using X-RED and X-SHAPE [28] software. The data were corrected for Lorentz and Polarizing effects. The structures were solved by direct methods [29] and subsequent difference Fourier map and then refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters [29]. All of the hydrogen atoms were located in a difference Fourier map and then after refined isotropically. Subsequent refinement then converged with R factors and parameter errors significantly better than for all attempts to model the solvent disorder. All refinements were performed using the X-STEP32 crystallographic software package [30]. A summary of the crystal data, experimental details and refinement results is given in Table 1.

Table 1
Crystallographic and structure refinement data for complexes **1** and **2**.

	Complex **1**	Complex **2**
Formula	$C_{12}H_{12}Cl_4N_2Pt$	$C_{11}H_{10}Cl_4N_2Pt$

[a] $R_1 = \sum||F_o|-|F_c||/\sum|F_o|$, $wR_2 = [\sum(w(F_o^2 - F_c^2)^2)/\sum w(F_o^2)^2]^{1/2}$.

2.3. Synthesis of [Pt(5,5′-dmbipy)Cl_4] (**1**)

5,5′-Dimethyl-2,2′-bipyridine (0.15 g, 0.79 mmol) in 5 ml methanol was added to a solution of $H_2PtCl_6{\cdot}6H_2O$ (0.41 g, 0.79 mmol) in methanol (10 ml) and the resulting yellow solution was stirred at 40–45 °C for 15 min. Suitable crystals for X-ray diffraction measurement were obtained by methanol diffusion to a yellow solution of **1** in DMSO over one week (yield 0.32 g, 77.7%, decompose <298 °C). ^{1}H NMR (DMSO-d_6): 2.61 (s, 3 H), 8.42 (d, 1 H), 8.81 (d, 1 H), 9.26 (satellite, 1 H, $^4J_{HPt}$ = 26 Hz) ppm.

^{13}C NMR (DMSO-d_6): 19.1, 126.2, 141.1, 144.6, 147.1, 152.4 ppm. ^{195}Pt NMR (DMSO-d_6): 1724.6(s) ppm. UV–Vis (DMSO) λ (cm^{-1}): 3.8×10^4, 3.1×10^4, 2.97×10^4. IR (KBr, cm^{-1}): 3106w, 3042m (νCH), 1482s, 1473s, 1454w, 1393m, 1374m, 1338w, 1320m, 1311s, 1292w, 1247m, 1229s, 1153m, 1137w, 1076w, 1056m, 1035w, 994w, 919w, 857m, 839s, 712m, 667w, 519m, 509m, 429m, 387m, 348s (νPt–Cl), 280m (νPt–N). *Anal.* Calc.: C, 27.64; H, 2.30; N, 5.37. Found: C, 27.51; H, 2.26; N, 5.26%.

2.4. Synthesis of [Pt(6-mbipy)Cl$_4$] (**2**)

6-Methyl-2,2′-bipyridine (0.14 g, 0.79 mmol, 0.13 ml) in 5 ml methanol was added to a solution of $H_2PtCl_6{\cdot}6H_2O$ (0.41 g, 0.79 mmol) in methanol (10 ml) and the resulting yellow solution was stirred at 313–318 K for 15 min. Suitable crystals for X-ray diffraction measurement were obtained by methanol diffusion to the yellow solution in DMSO over one week (yield 0.31 g, 77.4%, M.p 285–286 °C). ^{1}H NMR (DMSO-d$_6$): 3.29 (s, 3 H), 7.86 (d, 1 H), 8.07 (s, 1 H), 8.41 (t, 1 H), 8.55 (t, 1 H), 8.75 (d, 1 H), 8.84 (d, 1 H), 9.48 (d, 1 H, $^4J_{HPt}$ = 26 Hz) ppm. ^{13}C NMR (DMSO-d$_6$): 26.5(s), 124.5(t), 126.7(t), 129.3(t), 132.8(t), 143.1(s), 144.3(s), 148.1(s), 156.1(s), 156.5(s), 165.7(s) ppm. ^{195}Pt NMR (DMSO-d$_6$): 2012.9(s) ppm. UV–Vis (DMSO) λ (cm^{-1}): 3.78×10^4 and 3.11×10^4. IR (KBr, cm^{-1}): 3082m, 2919w, 2844w (νCH), 1599m, 1565m,1493m, 1456s,1379w, 1329w, 1292m, 1269w, 1235m, 1174m, 1128w, 1092m, 1040w, 1016m, 894w, 805m, 778s, 723w, 660w, 584w, 345s (νPt–Cl), 254m (νPt–N). *Anal.* Calc.: C, 26.03; H, 1.97; N, 5.52. Found: C, 25.87; H, 1.89; N, 5.42%.

3. Results and discussion

Compounds **1** and **2** were obtained from the reaction of 1 equivalent of $H_2PtCl_6{\cdot}6H_2O$ with 1 equivalent of the appropriate bipyridine ligand in a methanol solution around 40 °C over 15 min. The products were isolated in about 77% yield. These compounds were recrystallized in a DMSO/methanol solution to obtain suitable crystals for X-ray studies. Table 1 shows details of the data collection and refinement of the X-ray crystal structure determinations for **1** and **2**. Selected bond lengths and bond angles are presented in Table 2. The ORTEP view with the numbering schemes for compounds **1** and **2** are shown in Figs. 1 and 2, respectively. In the title complexes, the Pt(IV) atom has a distorted octahedral coordination by two N atoms from two 3-methylpyridine and four terminal Cl atoms in **1** and by two N atoms from one 2-methylpyridine and one pyridine, and four terminal Cl atoms in **2**. The Pt–Cl bonds are in the range 2.299–2.323 Å in complexes **1** and **2**. In both complexes, the shorter Pt–Cl bond lengths are for the bond *trans* to the N and reveal the significance of *trans* effects. The Pt–N bond distances are between 2.018 and 2.037 Å in **1** and **2**, with the exception of one Pt–N bond, equal to 2.076 Å in **2**, that is adjacent to the 2-methyl pyridine. This bond is a little larger due to steric hindrance of the methyl group. The Pt–Cl and Pt–N bond lengths are in good agreement with the corresponding values in [PtCl$_4$(bpym)]·MeOH [15], [PtCl$_4$(bipy)] [16], [PtCl$_4${pz(py)$_2$}] [18]

C11–H11···Cl4	0.93	2.65	3.197(8)	119

Symmetry codes: (i) 1 + *x*, *y*, *z*; (ii) 3/2−*x*, −1/2 + *y*, 1/2−*z*.

and [$PtCl_4$(4,4′-dmbipy)] [19]. The pyridine ring is slightly distorted from planarity with a maximum deviation of 0.119(6) Å for atom N1 in **1** and 0.207(5) Å for atom C3 in **2**. The mean planes of rings A (Pt1/N1/N2/C6/C7), B (N1/C1/C2/C4/C5/C6) and C (N2/C7/C8/C9/C10/C12) in **1** make the following dihedral angles with each other: A/B = 4.39(10), A/C = 4.54(9) and B/C = 7.78(13)°. In **2**, the mean planes of rings A (Pt1/N1/N2/C6/C7), B (N1/C2/C3/C4/C5/C6) and C (N2/C7/C8/C9/C10/C11) make the following dihedral angles with each other: A/B = 14.87(13), A/C = 9.48(13) and B/C = 16.75(14)°. It appears that deviation from planarity is larger in **2** than **1** due to steric hindrance of the methyl groups in **2** and also due to unsymmetrical substitution in the pyridine rings in compound **2**. The packing diagrams for compounds **1** and **2** are shown in Figs. 3 and 4, respectively. In these compounds, there are some weak intermolecular C–H···Cl hydrogen contacts (Tables 3 and 4) that seem to be effective in the stabilization of the crystal structures. The highest peaks and deepest holes for compounds **1** and **2** are around the Pt atoms (a distance of 0.85 and 0.82 Å for highest peaks and 0.78 and 0.73 Å for deepest holes for **1** and **2**, respectively).

NMR spectroscopy reveals that the structures of compound **1** and **2** are held in solution. In compound **1**, the ^{1}H NMR spectrum shows three signals at around 8–9 ppm for aromatic protons and a signal at 2.61 ppm for the methyl protons. H_2 and H_3 are split and show a doublet pattern as expected. Only H_1, which is close to the platinum centre, shows a 1:4:1 satellite pattern due to coupling with the ^{195}Pt atom, trace A of Fig. 5. In the ^{13}C NMR spectrum, five distinct signals are seen for the aromatic carbon around 126–153 ppm. Both ^{1}H and ^{13}C spectra confirm the symmetry of the compounds seen in the solid state by X-ray diffraction. However in compound **2** the ^{13}C signals are increased to 10 in 124–166 ppm region due to chemically different carbons in the aromatic region. The ^{1}H NMR signals show that only H_1 is seen with satellites of the platinum nucleus. Other protons are split by neighboring hydrogen atoms as expected. Full assignments of the protons are shown in Fig. 5. The ^{195}Pt NMR spectrum shows a signal for **1** at 1724.6 ppm and one for **2** at 2012.9 ppm, relative to the Na_2PtCl_4 reference to an external sample of Na_2PtCl_4 at −1642 ppm relative to H_2PtCl_6 at 0 ppm. Similar positions are reported for Pt^{IV} bearing chloride and nitrogen ligands [14]. The ^{195}Pt signals are relatively broad due to coordination of the quadruple nitrogen nucleus, especially in compound **2**.

The vibrational bands present around 3000 cm^{-1} in complexes **1** and **2** are assigned as ν(C–H). The bands observed in the range 1600–1400 cm^{-1} are assigned to ν(C=N) and ν(C=C) vibrations. The medium to strong vibrations in the region 960–550 cm^{-1} are assigned to the deformation vibrations of δ(C=C=N) and δ(C=C=C) in the pyridine rings [31,32]. Far infrared spectra of complexes **1** and **2** were recorded between 500 and 250 cm^{-1}. Pt–N stretching

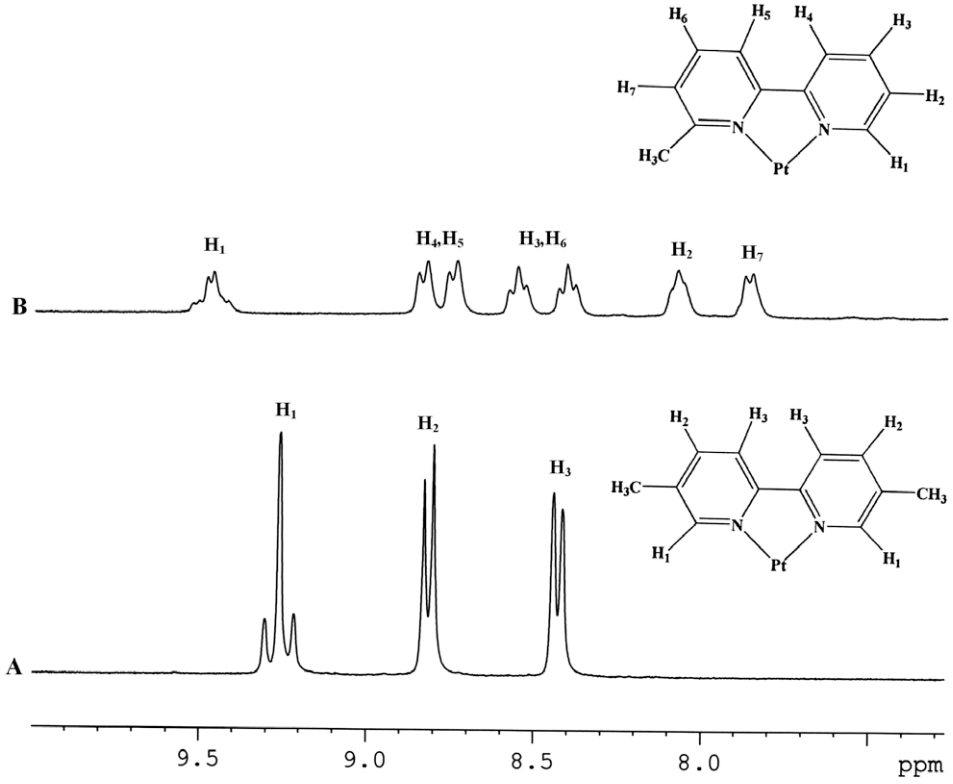

Fig. 5. Aromatic region of ^{1}H NMR spectra of compounds **1** and **2** in DMSO-d_6.

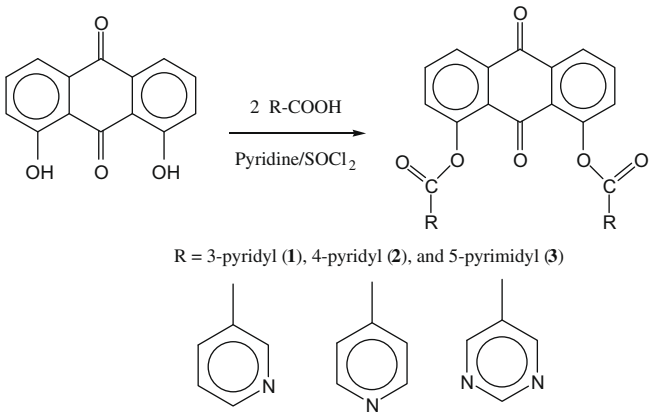
vibrations for complexes **1** and **2** are seen at 280 and 254 cm^{-1}, respectively. Pt–Cl frequencies appear at 348 and 345 cm^{-1}, as expected [12,21,33,34].

Supplementary data



CCDC 699392 and 699393 contain the supplementary crystallographic data for **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgment

We would like to thank the Graduate Study Councils of Shahid Beheshti University for financial support (Project 600/2441).

Crystallographic data were collected at low temperature using Mo Kα radiation on Bruker CCD APEXII diffractometers. Cell constants were determined after integration from typically more than 6,000 reflections [12]. Structures were solved by direct methods using SIR97 [13] and refined using SHELXL-97 [14]. Data reduction and refinement were completed using the WINGX suite of crystallographic software [15]. All hydrogen atoms were placed in ideal positions and refined as riding atoms with relative isotropic displacement parameters. Table 1 lists additional crystallographic and refinement information.

Compound **5** has a spherically disordered hexafluorophosphate anion in ~50:50 relative occupancies. Compound **6** has a hexafluorophosphate anion with similar disorder in a ~90:10 relative ratio with the smaller occupancy refined isotropically. One of the nicotinyl ligands is disordered in Compound **8** in a 50:50 ratio. There is also an acetonitrile solvate group that is present in 50% occupancy when the disordered nicotinyl does not occupy that position. In addition both tetrafluoroborate anions were modeled as rotationally disordered in ~50:50 ratios and left isotropic. Compound **9** has the entire anthraquinone moiety disordered over two positions in a ~50:50 ratio, and both components were refined isotropically.

3. Results

A new disubstituted anthraquinone ligand that contains pyrimidine groups, compound **3**, was synthesized in the same manner as that reported for the dinicotinyl (**1**) and diisonicotinyl (**2**) anthraquinone ligands (Scheme 1) [9,10]. The structure of the dipyrimidine adduct has also been determined (Table 1), which confirms the structure of the compound and a thermal ellipsoid diagram has been placed in supporting information only (Fig. S1).

Reaction of ligands **1–3** with $[M(CH_3CN)_4]X$ (M = Ag(I),Cu(I) and X = BF_4^-, PF_6^-) produce a variety of different chelating and bridging motifs and a variety of different coordination geometries. Reaction of one equivalent of the nicotinyl-containing ligand, **1**, with one equivalent of $[Ag(CH_3CN)_4](BF_4)$ results in the formation of a new dimer where the nicotinyl groups bridge two silver atoms, $[Ag_2(\mathbf{1})_2](BF_4)_2.2CH_3CN$ (**4**) (Fig. 1). This is a different binding mode than that previously observed where **1** has been shown to chelate a metal center [9]. In this complex, the Ag···Ag distance is greater than 5.1 Å, indicating no metal–metal bond is formed, and the acetonitrile solvate present in the crystal also has large interatomic Ag–$NCCH_3$ distances, producing a near linear two-coordinate silver(I) coordination geometry. Reaction of two equivalents of **1** with one equivalent of $[Ag(CH_3CN)_4](PF_6)$ however, produces an entirely

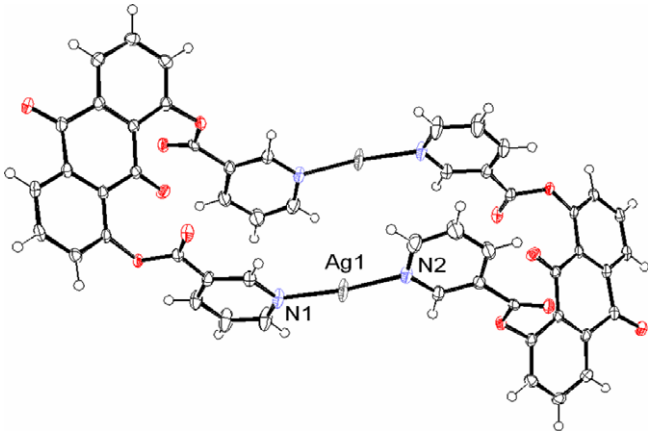

Fig. 1. Thermal ellipsoid diagram (50%) of $[Ag_2(1,8\text{-}bis(\text{nicotinyloxy})\text{anthracene-9,10-dione})_2](BF_4)_2{\cdot}2CH_3CN$ (**4**). The non-coordinating acetonitrile and tetrafluoroborate anions have been omitted for clarity. Ag1–N1 = 2.158(3), Ag1–N2 = 2.153(3), Ag–N3 (CH_3CN, not shown) = 2.86 and 3.73, Ag1–Ag1 = 5.168(5) Å.

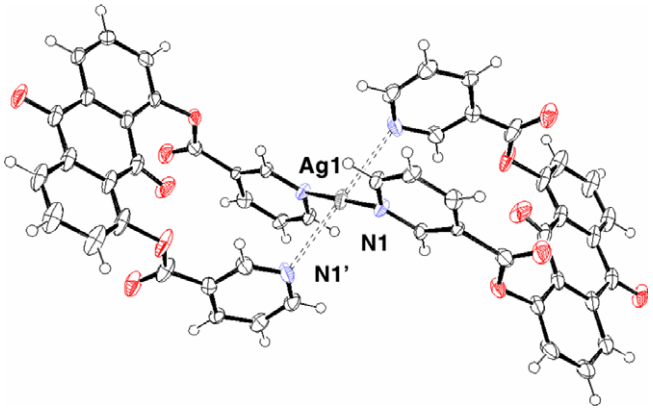

Fig. 2. Thermal ellipsoid diagram (50%) of $[Ag(1,8\text{-}bis(\text{nicotinyloxy})\text{anthracene-9,10-dione})_2](PF_6)$ (**5**). The hexafluorophosphate anion has been omitted for clarity. Ag1–N1 = 2.226(5), Ag1–N1′ = 2.763(6) Å.

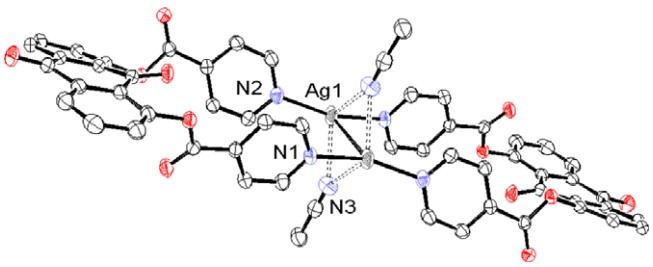

Fig. 3. Thermal ellipsoid diagram (50%) of $[Ag_2(1,8\text{-}bis(\text{isonicotinyloxy})\text{anthracene-9,10-dione})_2(CH_3CN)_2](PF_6)_2$ (**6**). The hexafluorophosphate anions and hydrogen atoms have been omitted for clarity. Ag1–N1 = 2.179(2), Ag1–N2 = 2.163(2), Ag1–N3 = 2.555(3), Ag1′–N3 = 2.817(3), Ag–Ag = 3.266(4) Å.

different complex, $[Ag(\mathbf{1})_2](PF_6)$ (**5**), where the nicotinyl groups are now found chelating the silver(I) center (Fig. 2). The chelating ability of **1** has previously been demonstrated [9]. In complex **5**, two short and two long Ag–N bonds are observed as related by symmetry, adopting a pseudo linear Ag(I) geometry, but more accurately described as square planar in geometry when including the longer Ag–N bonds.

Reaction of one equivalent of the isonicotinyl-anthraquinone ligand **2** with both Ag(I) and Cu(I) produce similar structures where the anthraquinone ligands bridge two metal centers: $[Ag_2(\mathbf{2})_2(CH_3CN)_2](PF_6)$ – Fig. 3 and $([Cu_2(\mathbf{2})_2(CH_3CN)_2](BF_4)$ – Fig. 4. One acetonitrile from the crystallization solvent is found bridging the metal atoms on each face of the dimer. In complex **6**, the Ag–N bond distances for the acetonitrile are significantly longer than the Ag–pyridyl bond distances and are unequal in length, Ag1–N3 = 2.555(3), Ag1′–N3 = 2.817(3). For the copper adduct, **7**, the acetonitrile group is localized on only one Cu(I) atom almost equal to the pyridyl Cu–N bonds, rather than bridging two metal atoms as is the case with **6**; Cu1–N3 = 2.050(4), Cu1'–N3 = 3.40 Å. We have been unable to isolate other caged structures by the addition of excess amounts of **2**, ie. $[Ag_2(\mathbf{2})_4]^{2+}$.

We have also isolated a catenated structure of ligand **1** when reacted with Ag(I), *catena*-$[Ag_2(\mathbf{1})_3](BF_4)_2.0.5CH_3CN$ (**8**, Fig. 5). Combining ligand **1** and Ag(I) in a 3:2 ratio, a unique ladder structure results. Here two anthraquinone ligands bridge two silver atoms to yield the sides of the ladder, where the pyridyl groups on each anthraquinone ligand face in opposite directions. The rungs of the ladder are formed by the third anthraquinone ligand that bridges the silver atoms on each side. The pyridyl groups in this third ligand are also pointed in opposite directions. The silver centers are distinctly trigonal planar in geometry with a Ag···Ag internuclear distance, representing the distance between sides of the

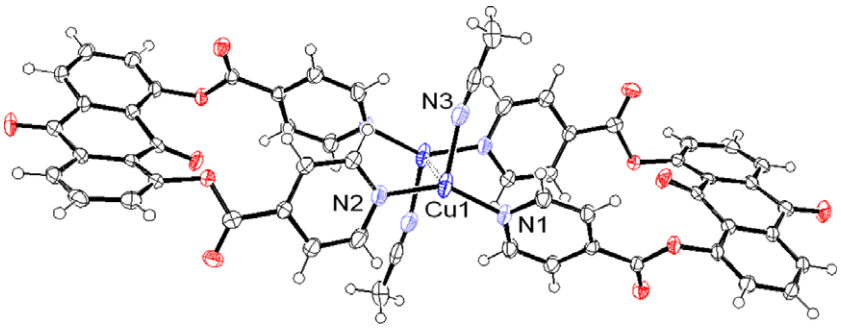

Fig. 4. Thermal ellipsoid diagram (50%) of $[Cu_2(1,8\text{-}bis(isonicotinyloxy)anthracene\text{-}9,10\text{-}dione)_2(CH_3CN)_2](BF_4)_2$ (**7**). The tetrafluoroborate anions have been omitted for clarity. Cu1–N1 = 1.946(3), Cu1–N2 = 1.949(3), Cu1–N3 = 2.050(4), Cu1′–N3 = 3.40, Cu–Cu = 3.141(5) Å.

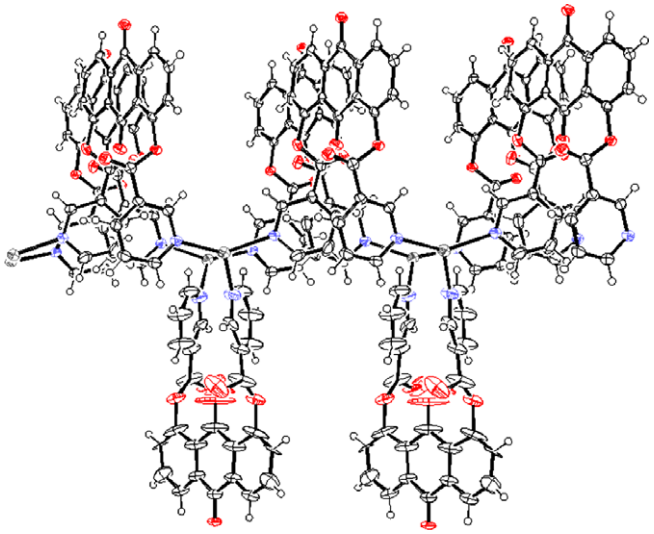

Fig. 5. Thermal ellipsoid diagram (50%) of the *catenate* structure of $[Ag_2(1,8\text{-}bis(nicotinyloxy)anthracene\text{-}9,10\text{-}dione)_3](BF_4)_2.0.5CH_3CN$ (**8**). The solvates and tetrafluoroborate anions have been omitted for clarity. Ag1–N1 = 2.284(5), Ag1–N2 = 2.222(9), Ag1–N3 = 2.212(5), Ag1···g1′ = 6.50 Å. A figure of the metal coordination environment is provided in the supporting information.

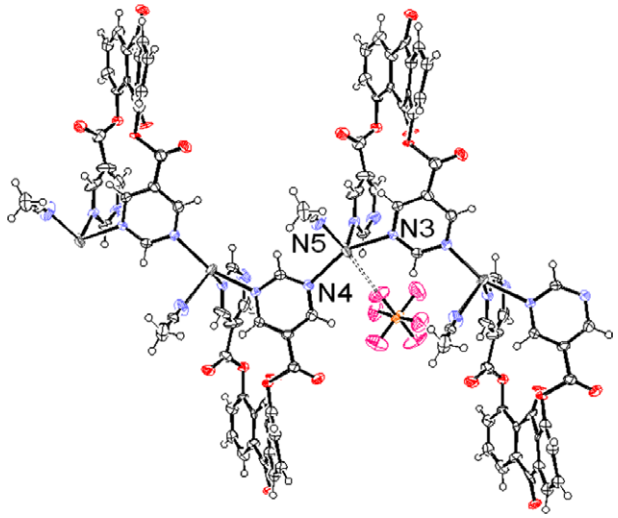

Fig. 6. Thermal ellipsoid diagram (50%) of the *catenate* structure of $[Ag(1,8\text{-}bis(pyrimidine\text{-}5\text{-}carboxyloxy)anthracene\text{-}9,10\text{-}dione)\text{-}(CH_3CN)](PF_6)$ (**9**). Ag1–N1 = 2.284(5), Ag1–N3 = 2.222(9), Ag1–N4 = 2.212(5), Ag1–N5 = 2.222(x), Ag1···F4 = 2.812 Å. A figure of the metal coordination environment is provided in the supporting information.

ladder, equal to 6.51 Å. Within the crystal, layers of anthraquinone units between separate one-dimension chains form infinite pi-stacks (not shown).

The multidentate pyrimidine-containing ligand, **3**, has been reacted with one equivalent of Ag(I) to yield another catenated, one-dimensional coordination polymer of composition *catena*-$[Ag(\mathbf{3})(CH_3CN)](PF_6)$ (**9**, Fig. 6). Two pyrimidines on the same anthraquinone scaffold act together as a chelating ligand, similar to that observed previously for **1**, and at the same time as a μ^2 ligand, one of the pyrimidine groups bridging two silver atoms. An additional acetonitrile complexes to the silver metal center and a semi-short metal–anion interaction (Ag1–F4 = 2.82 Å) yields a trigonal bipyrimidal coordination geometry. At this time, we have been unable to synthesize additional complexes containing higher ligand **3** to M(I) ratios.

4. Discussion

The most notable observation is that the coordination of dinicotinyl and diisonicotinyl anthraquinone ligands have been expanded to include bridging motifs, and these have been observed for both Ag(I) and Cu(I). As opposed to previous work [10], where coordination of water competes with dimer formation, the judicious choice of acetonitrile-solvated starting complexes that promote low coordination number and linear coordination geometries has produced new bridged, dimeric products. The nicotinyl-anthraquinone (**1**) complexes, in fact, show three widely different binding motifs: chelating as in **5** (Fig. 3), bridging-*syn* as in **6** (Fig. 2), and bridging-*anti* as in **8** (Fig. 6) that results in an unusual ladder structure. Pyrimidine-5-carboxylate has been previously investigated for formation of solid network structures coordinated to first row transition metals [16]; however only monomeric complexes were formed that did not involve coordination of both pyrimidine nitrogens. The introduction of ligand **3** and complexation with Ag(I) ion shows that coordination of both pyrimidine nitrogens is possible under the right conditions (Fig. 6), producing a linear one-dimensional coordination polymer in this case.

For the bridging isonicotinic complexes (Figs. 3 and 4), the Ag–Ag bond distance in **6** equals 3.27 Å and the Cu–Cu bond distance in **7** equals 3.14 Å. A recent revisit of covalent radii from data retrieved from the *Cambridge Structural Database* shows the covalent radius for Cu and Ag equal 1.32(4) and 1.45(5) Å, respectively [17]. Doubling these values and taking into consideration the uncertainties, ballpark figures for homonuclear metal–metal bond distances may be estimated, i.e. 2.56–2.72 Å for Cu–Cu and 2.80–3.00 Å for Ag–Ag. Although there is controversy regarding what exactly constitutes a metal–metal bond, the small difference between the largest CSD metal–metal covalent bond distance and the experimental bond distance observed in **6** shows a credibly strong argentophillic interaction between the two silver metal

atoms, and a bond has been drawn between Ag atoms in Fig. 3. The fact that the isonicotinic groups are also "bowed in" provides some support for the presence of a metal–metal interaction. The silver–silver bond distance in compound **6** also matches other silver–silver internuclear distances found in the literature [18]. The nicotinyl dimer, **4** (Fig. 1), on the other hand, has a Ag–Ag internuclear distance of 5.12 Å, no metal–metal bond, and an internuclear distance that ideally matches the distance between the 1,8-positions of substitution on the anthraquinone backbone of 5.04 Å. Although the difference between the CSD value and the Cu–Cu bond distance determined for in **7** is larger, the "bowing in" effect of the isonicotinic ligands again infers a metal–metal interaction, although presumably weaker. Additionally, the coordination of the acetonitrile ligands correlates with the metal–metal bond order. The acetonitrile ligands in complex **6** are attached by longer Ag–N bonds and are shared between the silver atoms. Complex **7**, with a weaker metal–metal interaction, has short and non-bridging Cu–acetonitrile bonds. The Cu–Cu internuclear distance here is longer than previously found in other Cu(I) dimer complexes [19].

Finally, coordination geometries for these silver complexes vary greatly. With the exception of compound **9**, most complexes exhibit coordination numbers of three or less, which likely limits the formation of caged complexes with higher coordination numbers, i.e. $[Ag_2(\mathbf{2})_4]^{2+}$, and unfortunately does little to limit coordination to exclusively linear geometries desired for the controlled synthesis of building blocks in supramolecular applications.

Acknowledgments

The authors thank NSF-EPSCOR (EPS-0554609) and the South Dakota Governor's 2010 Initiative for financial support and the purchase of a Bruker SMART APEX II CCD diffractometer. The elemental analyzer was provided by funding from NSF-URC (CHE-0532242). S.P. was supported by NSF-REU (CHE-0532242), and A.G.S is also grateful for a grant from the ACS-PRF-UFS program and additional support from the Truman and Beverley Schwartz Fund, University of South Dakota, College of Arts and Science.

spheres. Since, a higher solution pH (pH > 9) is required to produce Hap particles, $Ca(OH)_2$ is suitable for the reaction instead of $CaCl_2$. Therefore, the authors have investigated in the present study the formation of Hap particles by using a $Ca(OH)_2$–tpp mixed solution instead of the $CaCl_2$–tpp one employed in the previous study [21]. The formation of transparent balloon-like hollow sphere was also attempted.

2. Experimental

2.1. Materials

Following the method reported by the authors in the previous paper [21], we produced calcium phosphate particles by aging a solution of $Ca(OH)_2$ [1.0×10^{-3}–1.0×10^{-2} mol/dm^3] and Natpp [1.0×10^{-3}–$.0 \times 10^{-1}$ mol/dm^3] in a 20-cm^3 Teflon-lined screw-capped Pyrex test tube. In this study, $Ca(OH)_2$ was used instead of $CaCl_2$. To facilitate the aging, the test tubes were allowed to stand for 18 h at various temperatures (100–150 °C) in an air turbulent oven. The standard aging temperature examined was 100 °C. The resulting particles were thoroughly washed by filtration with deionized and distilled water and finally dried in an air-oven at 70 °C for 18 h. The solution pH, before and after aging, was monitored at room temperature. Guaranteed reagent grade chemicals from Wako Pure Chemical Co. Inc. (Osaka, Japan) were used without further purification.

2.2. Characterization

The resulting particles were characterized by transmission electron microscope (TEM), thermogravimetry and differential thermal analysis (TG-DTA), Fourier transform infrared spectrophotometry embedded in KBr pellets (0.2 wt.%) (FTIR), powder X-ray diffraction measurement (XRD) and adsorption experiments of N_2 [8–13]. The adsorption isotherms of N_2 were measured at liquid N_2 temperature with an ordinary house built automatic volumetric flow method using a Baratron diaphragm-type manometer with a mass flow meter attached. The degree of confidence on the specific surface area measured by this apparatus was within 2%. Prior to these N_2 adsorption measurements, the samples were evacuated at 100 °C for 2 h. The chemical composition of the precipitated particles (concentration of calcium and phosphorus) was determined by dissolving a few milligrams in concentrated nitric acid. The solutions were diluted and the calcium and phosphorus concentrations were determined by inductively coupled plasma atomic emission spectroscopy (ICP-AES).

3. Results and discussion

3.1. Particle morphology and crystal form

Fig. 1 displays (a) the solution pH and (b) the morphology of the particles precipitated after aging the solution for 18 h at 100 °C. The grey circles suggest the solution produced precipitates before aging. The solution pH of 9.69–13.27 was dropped 0.4–5.2 units by the reaction. It has reported that the hydrolysis of tpp ions is expressed as the following two reactions (1) and (2) [22]

$$P_3O_{10}^{5-} + 2H_2O \rightarrow 3PO_4^{3-} + 4H^+ \quad (1)$$

$$2P_3O_{10}^{5-} + H_2O \rightarrow 3P_2O_7^{4-} + 2H^+ \quad (2)$$

Reaction (1) shows that the tpp ions are completely hydrolyzed to orthophosphate ions, though the tpp ions are not completely hydrolyzed and still remain as pp ions in reaction (2). Since the solutions are almost neutral to alkaline after the reaction (7.43 < pH < 12.89), the protonated states of the orthophosphate (HPO_4^{2-}) and pyrophosphate ($HP_2O_7^{3-}$) ions were ignored in reactions (1) and (2). Both the reactions generate protons in any event. Therefore, the pH drop watched in this experiment proves that the tpp ions are hydrolyzed. Figs. 2 and 3 show the TEM pictures and XRD patterns of the typical particle precipitates at the points A–G in Fig. 1. The assayed results and properties of these particles are listed in Table 1. Clearly, calcium pyrophosphates (α-$CaNa_2P_2O_7{\cdot}4H_2O$; JCPDS 97-002-0572) with small aggregates are produced at a higher concentration of tpp ions (sample A). On the other hand, amorphous and spherical or small spherical aggregated particles are produced at other concentration domains (samples B and D). It should be emphasized that Hap particles with lower (sample C) and higher crystallinity (samples E–G) are precipitated in the present study. Especially, highly crystallized Hap particles are formed in the lower concentration region of tpp (samples E–G) where the precipitates are produced before aging the solution (grey circles). Sample A contains pp ions, suggesting that the hydrolysis reaction of tpp ions was incomplete and is following reaction (1). The Ca/P molar ratio of the sample A is 1.38, suggesting that the composition of sample A can be described as α-$CaNa_2(P_2O_7)_{0.36}(OH)_{2.56}{\cdot}2.5H_2O$ by assuming that a part of the $P_2O_7^{4-}$ ions are exchanged to OH^- ions (see in Table 1). The Ca/P molar ratios of amorphous samples B and D are 0.93 and 1.08,

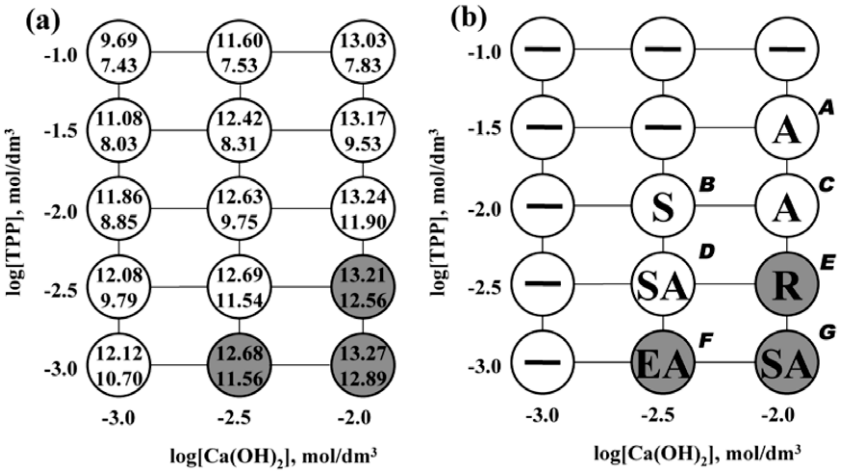

Fig. 1. (a) The pH and states of mixed solutions of $Ca(OH)_2$ and Natpp for aging at 100 °C. Upper and lower numbers are solution pH before and after aging, respectively. Grey circles indicate the solution produced precipitates before aging. (b) Particle shape of precipitates after aging. R: rod-like, S: spheres, A: aggregates, E: ellipsoidal. Bar in the circle indicates no precipitate after aging.

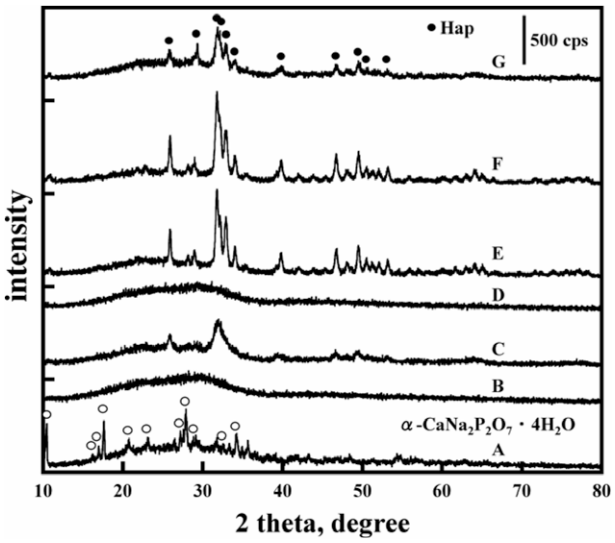

Fig. 3. XRD patterns of samples A–G in Fig. 1.

respectively. The Ca/P molar ratios of the low crystallized Hap Sample C is 1.26, though the highly crystallized samples E and F are 1.63 and 1.62, respectively. These latter values are slightly lower than the stoichiometric one of Hap (1.67), indicating that these particles are calcium-deficient. From these Ca/P molar ratios, the chemical compositions of these particles can be calculated as $Ca_{9.78}(HPO_4)_{0.22}(PO_4)_{5.78}(OH)_{1.78}\cdot 0.22H_2O$ and $Ca_{9.72}(HPO_4)_{0.28}(PO_4)_{5.72}(OH)_{1.72}\cdot 0.28H_2O$ (Table 1). Here, we assumed that the weight loss from 25 to 500 °C, shown in Fig. 4, is due to elimination of water of crystallization. Unfortunately, sample G could not be dissolved in nitric acid solution, thus the Ca/P molar ratio and chemical composition could not be determined. The crystal phase of the samples formed after heated the samples in an oven at 800 °C for 2 h is also listed in Table 1. Sample A, α-$CaNa_2P_2O_7\cdot 4H_2O$, was crystallized to α-$CaNa_2P_2O_7$ by dehydration, though samples B–D were crystallized to β-$Ca_2P_2O_7$ or α- and β-$Ca_3(PO_4)_2$.

The crystallization of sample A to α-$CaNa_2P_2O_7$ was further confirmed by TG-DTA measurement, as is shown in Fig. 4. A small exothermic peak can be recognized at 570 °C in the DTA curves on sample A. In addition, a large endothermic peak appears at ca. 25–140 °C together with a large weight loss (ca. 8 wt.) in the TG curves. This endothermic peak and weight loss are due to dehydration of water molecules that remained in the poorly ordered amorphous particles and water of crystallization. On samples B and D, a similar exothermic peak can be seen at 540 and 650 °C, respectively. These peaks can be also naturally identified as crystallization to β-$Ca_2P_2O_7$.

3.2. Formation mechanism of Hap particles

To disclose the formation mechanism of Hap, a time resolved TEM experiment was done on the formation of sample E. As has been described before, this system produced small precipitates before aging (0 h). The time resolved TEM pictures are displayed in Fig. 5 together with their Ca/P molar ratios. The XRD patterns of these precipitates are also shown in Fig. 6. Clearly, very small amorphous particles precipitated before aging are grown to ellipsoidal particles with aging the solution at 100 °C. After aging for 6 h, highly crystallized Hap particles are formed. This result strongly indicates that the crystallization of the Hap particles takes place on the surface of tiny amorphous particles precipitated before aging. These tiny particles would play the role as nuclei for Hap crystallization. The domain for producing samples E–G is located in the lower tpp concentration. The lower tpp concentration is adequate for fully hydrolyze tpp to produce orthophosphate ions together with the high pH values in this domain after the reaction (11.56–12.89).

3.3. Effects of forced hydrolysis temperature

In the previous paper [21], the authors attempted to raise the aging temperature from 100 to 150 °C in order to increase the degree of hydrolysis of tpp ions under the conditions for producing monodisperse spherical particles. The authors incidentally found that an aging temperature of 125 °C supplies transparent balloon-like hollow spheres. Therefore, we investigated again in the present study, using the $Ca(OH)_2$–tpp system, whether or not balloon-like hollow spheres could be attained under the conditions for producing spherical particles (sample B). Fig. 7 shows the TEM pictures of sample B formed at various aging temperatures together with their Ca/P molar ratios. Clearly, solid spherical particles are produced up to 120 °C. However, hollow spheres can be seen at 125 °C and finally transparent balloon-like hollow spheres can be recognized at 127 °C. The wall thickness of the balloon-like hollow spheres is approximately 10 nm (measured from TEM micrographs). Small needle-like particles are produced together with balloon-like ones at 127 °C. However, above 130 °C, no balloon-like hollow spheres are recognized, but small rod-like ones are mainly detected. The XRD patterns of those particles are shown in Fig. 8.

Table 1
Results and properties of samples A–G.

	Ca/P molar ratio	XRD (as precipitated)	Chemical composition	After heating at 800 °C for 2 h	Specific surface area (m^2/g)[a]
A	1.38	α-$CaNa_2P_2O_7{\cdot}4H_2O$	α-$CaNa_2(P_2O_7)_{0.36}(OH)_{2.56}{\cdot}2.5H_2O$	α-$CaNa_2P_2O_7$	18
B	0.93	amorphous	amorphous	β-$Ca_2P_2O_7$	2
C	1.26	low crystallized Hap	–	α-$Ca_3(PO_4)_2$, β-$Ca_3(PO_4)_2$	168
D	1.08	amorphous	amorphous	β-$Ca_2P_2O_7$	66
E	1.63	Hap	$Ca_{9.78}(HPO_4)_{0.22}(PO_4)_{5.78}(OH)_{1.78}{\cdot}0.22H_2O$	Hap	65
F	1.62	Hap	$Ca_{9.72}(HPO_4)_{0.28}(PO_4)_{5.72}(OH)_{1.72}{\cdot}0.28H_2O$	Hap	86
G	–	Hap		Hap	122

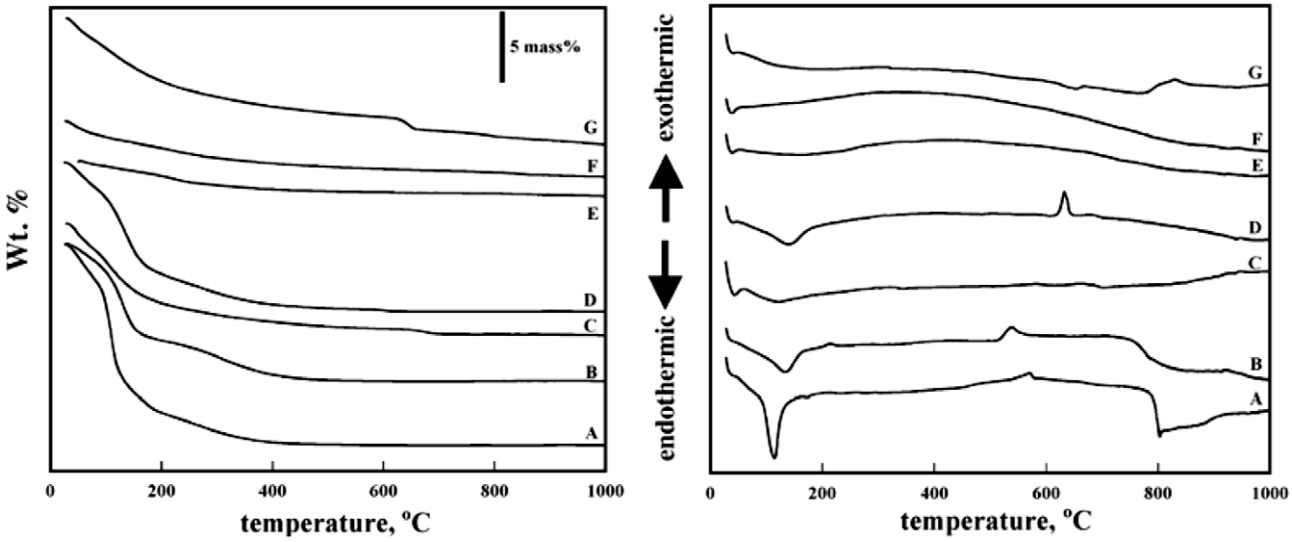

Fig. 4. TG and DTA curves of samples A–G in Fig. 1.

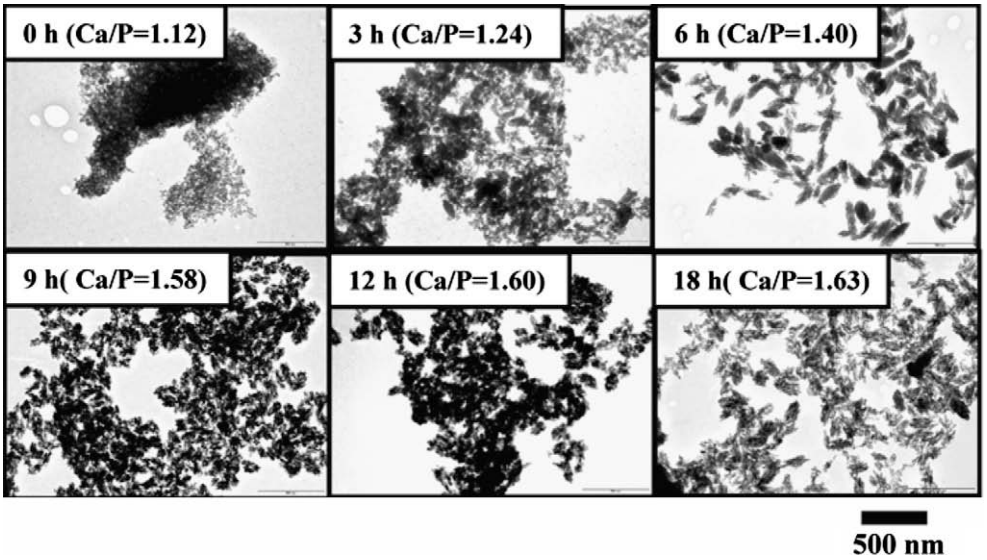

Fig. 5. Time resolved TEM pictures of precipitates for producing Hap particles at 100 °C (sample E in Fig. 1).

The spherical particles and/or balloon-like hollow spheres are amorphous, but the characteristic peaks of Hap (JCPDS 9-432) appear for the samples produced above 127 °C though their crystallinity is low, with a small *S*/*N* ratio. The Ca/P molar ratios of the amorphous particles are 0.89–0.91, though these values increased to 1.30–1.50 by raising the aging temperature. Even though the XRD patterns suggest a Hap crystal form, the Ca/P molar ratios of these particles are less than the expected stoichiometric value of 1.67. This fact indicates that the Hap particles are Ca-deficient with a low crystallinity. The formation of the Hap crystal form of the particles is also identified by FTIR measurement (data not shown). These results indicate that the transparent balloon-like hollow spheres can be produced not only by the $CaCl_2$–tpp system, but also by the $Ca(OH)_2$–tpp one. The specific surface area (abbreviated

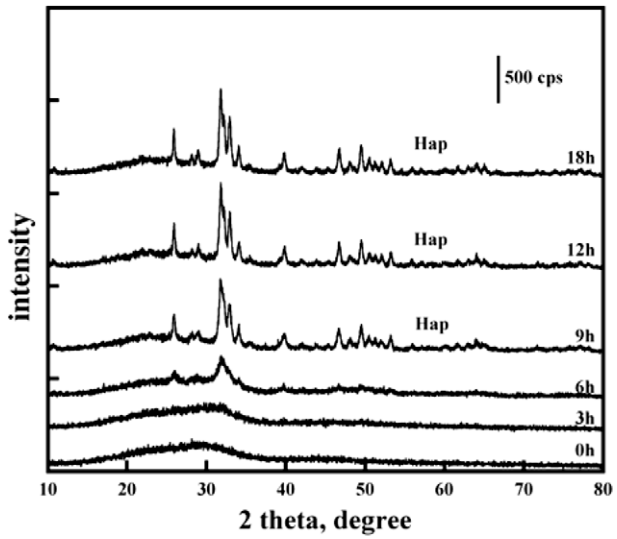

Fig. 6. Time resolved XRD patterns of precipitates for producing Hap particles at 100 °C as shown in Fig. 5.

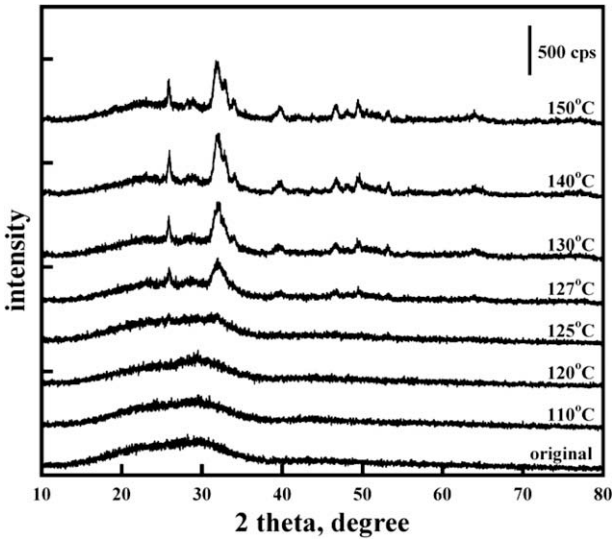

Fig. 8. XRD patterns of precipitates as shown in Fig. 7.

as S_n) of the hollow-like particles produced at 127 °C measured by the N_2 adsorption measurement was about 56 m^2/g, coinciding with a calculated S_n value of ca. 63 m^2/g in the hollow spheres with an outer diameter (φ_1) of 790 nm and an inside diameter (φ_2) of 770 nm (the theoretical density ρ of Hap is 3.16 g/cm^3, $S_n = \frac{6(\phi_1^2+\phi_2^2)}{(\phi_1^3+\phi_2^3)\rho}$) [23]. The coincidence of the S_n value strongly supports the fact the balloon-like particles have a hollow structure.

In Fig. 7, we successfully prepared calcium phosphate particles with a fairly uniform and transparent balloon-like structure. Recently, various efforts have been made to prepare inorganic hollow spheres by using different templates, including polyelectrolyte nano-particles [24], emulsion droplets [25,26], polymer micelles [27], or simply a sacrificial metastable precursor phase [28]. Recently, a double hydrophilic block copolymer (DHBC) and mixed solvents of surfactants and DHBC have also been used as templates for preparing $CaCO_3$ hollow spheres by Cölfen [29]. They explained that the hollow spheres develop from spheres by a dissolution process staring at the center of the sphere. Qi et al. reported the synthesis of micrometer sized calcite hollow spheres by the cooperative effect of DHBC-surfactant complex micelles as the templates [30]. Furthermore, many methods have already been reported on the synthesis of calcium phosphate particles, including microemulsion templating [31], ultrasonic spray pyrolysis [32], emulsion templating [33], block copolymer templating [34], polyelectrolyte mediated crystallization [35] and high temperature ceramic methods [36]. However, the sizes of the hollow particles reported in these literature articles were large and they possess a poor quality surface with a porous shell. Even though they produce nano-particles [33,34], the preparation methods include complicated procedures such as calcinations for removing the templates. Comparing to these particles, the present work is a simple single pot method and the balloon-like hollow spheres produced in this experiment have a unique structure, *i.e.*, fairly uniform, transparent and a smooth surface. Therefore, it is worthwhile to elucidate the formation mechanism of this unique structure. Thus, a detailed time-dependent experiment was conducted at 127 °C to track the formation of the balloon-like particles in the next section.

Fig. 9 illustrates time resolved TEM pictures of precipitates for producing the balloon-like particles at 127 °C in Fig. 7. When the hydrolysis reaction was conducted for 10 h, many solid spherical particles ca. 500–800 nm in diameter were produced. The reaction was further continued to 12.5 h, however, some of the spherical solid spheres changed into transparent balloon-like hollow spheres.

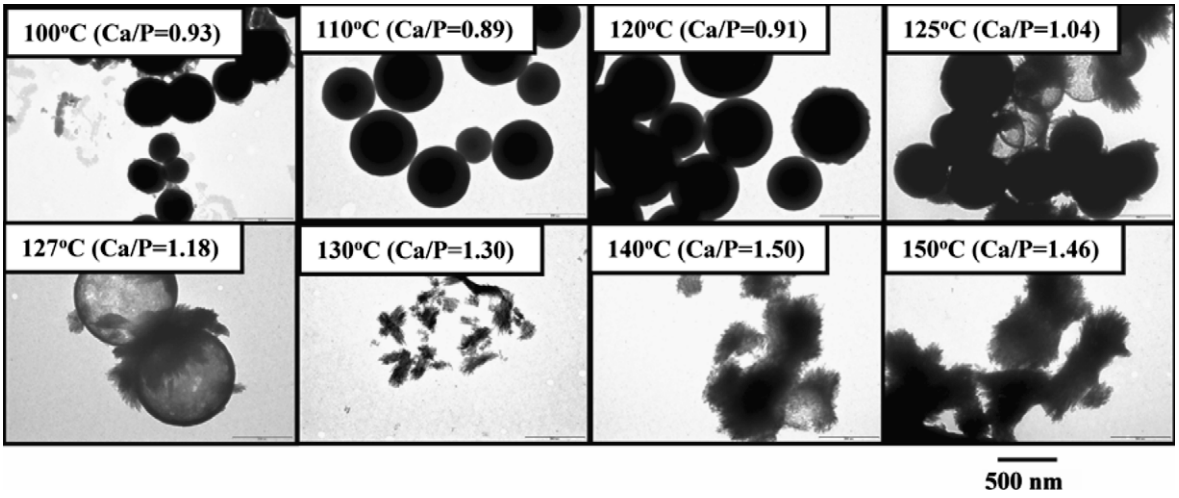

Fig. 7. TEM pictures of precipitates for producing spherical solid particles at various aging temperatures.

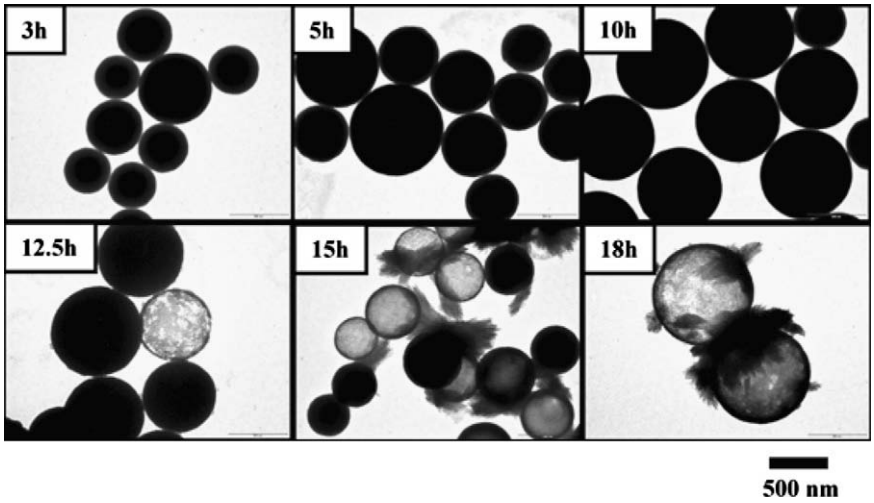

Fig. 9. Time resolved TEM pictures of precipitates for producing balloon-like particles at 127 °C in Fig. 7.

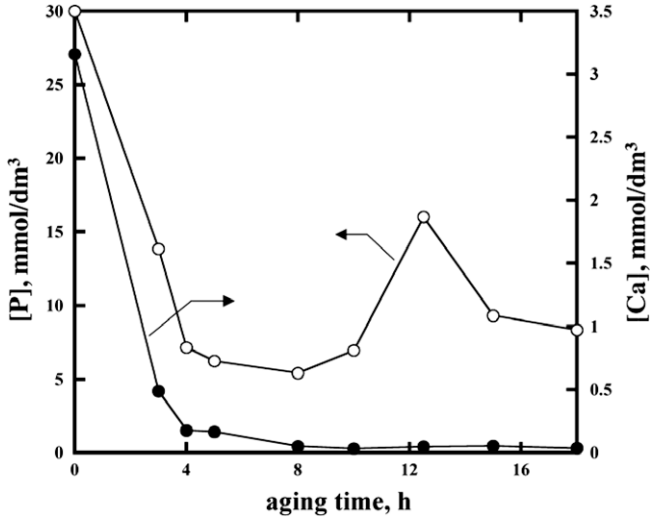

Fig. 10. Changes of concentrations of phosphate and calcium ions in the aging solution for producing balloon-like particles at 127 °C.

After aging for 15 h, many transparent balloon-like hollow spheres can be seen together with rod- or needle-like small particles. To follow this structural change of the solid spherical particles, we further investigated the change of concentrations of phosphate ([P]) and calcium ([Ca]) ions by ICP-AES measurement. The result is displayed in Fig. 10. Clearly, the [Ca] value decreases steeply until 8 h, but the [P] one reduces by 80%. Since the reduction of [P] was only 20% in the previous study using $CaCl_2$, this promotion of [P] reduction in the present study could be due to the $Ca(OH)_2$ used as a starting material. $Ca(OH)_2$ raised the solution pH and increased the hydrolysis of tpp. Another finding in Fig. 10 is the [P] value is at a maximum at an aging time of 12.5 h. This increase of [P] strongly supports that the inside of the solid spherical particles is dissolved as well, as was discussed in our previous paper [21]. However, this value decreases quickly again on further aging. This decrease is probably due to the production of small rod-like calcium phosphate particles (probably Hap), as can be seen in the TEM pictures produced after 15–18 h in Fig. 9. Since tpp and pp ions have a very strong adsorption ability to the Hap surface, as the authors already revealed before [37], the unhydrolyzed tpp and also the pp ions of the hydrolysis product of tpp ions would be adsorbed on the solid spherical particles initially produced. The adsorption of tpp and pp ions may protect the dissolution of the particles' shell and turns out the balloon-like structure. The explanation of this formation mechanism will be the subject of further work. Hollow spheres of calcium phosphate hold potential as drug delivery vehicles, for example, and have biocompatibility advantages over other materials.

4. Conclusions

The preparation procedure employed in this work precipitated large spherical and/or small aggregated spherical particles with an extremely fast rate of reaction under 100 °C. The large spherical particles were amorphous but the small aggregated ones were α-$CaNa_2P_2O_7{\cdot}4H_2O$, and the former ones crystallized to β-$Ca_2P_2O_7$ after being calcined above 600 °C.

Calcium hydroxyapatite with rod-like and ellipsoidal or spherical aggregates was successfully produced using polyphosphates as a source of orthophosphate ions.

The aging temperature drastically varied the particle shape under conditions for producing uniform amorphous spherical particles. Fully transparent balloon-like hollow spheres were produced with mere trace amounts of small rod-like particles after aging the solution above 127 °C.

TEM observation and ICP-AES measurements revealed that the particles with unique structures such as the balloon-like hollow spheres were produced by dissolving the interior of solid spherical particles after reinforced their shell by the adsorption of unhydrolyzed ttp and/or pp ions hydrolyzed from tpp ones.

2. Experimental

2.1. Materials

$Mn_2(CO)_{10}$ (Alfa), $RuCl_3{\cdot}xH_2O$ (Aldrich), 2,2′-bipyridine (Merck), 4,4′-bipyridine (Fluka), $AgCF_3SO_3$ (Alfa), and NH_4PF_6 (Alfa) were used as received. All solvents used for the synthesis were of reagent grade and for spectral measurements spectral grade was used.

2.2. Physical measurements

UV–Vis spectra were recorded on Analtikjena Specord S100 spectrophotometer and emission spectra were measured in JASCO FP6300 spectrofluorimeter. All the samples used for emission were purged with dry nitrogen gas for about 20 min. IR spectra were measured using JASCO FT-IR spectrophotometer. The samples were recorded in the form of KBr pellets. All the mass spectra were recorded using a Quattro LC triple-quadrupole mass spectrometer (Micromass, Manchester, UK) interfaced to an (Electro Spray ionization) ESI source; data acquisition was done under the control of Masslynx software (version 3.2). The ESI capillary voltage was maintained between 4.0 and 4.2 kV and the cone voltage kept at 25 V. Nitrogen was used as desolvation and nebulization gas. The source and desolvation temperatures were 100 °C.

2.3. Electrochemistry

The redox potentials of the complexes were determined by cyclic voltammetric and differential pulse voltammetric techniques using EG & G Princeton Applied Research Potentiostat/Galvanostat Model 273 A. Measurements were performed by purging the solution in acetonitrile (spectroscopic grade) by dry nitrogen gas for 30 min. The supporting electrolyte was 0.1 M TBAP, Pt was the working electrode, and Ag/AgCl was the reference electrode.

2.4. Lifetime and transient measurements

The excited state lifetime measurements for all the complexes were made, after degassing the solutions with argon for 30 min, and the details are given in previous reports [32]. Transient absorption measurements were made with laser flash photolysis technique as described elsewhere [32].

2.5. Syntheses

The complexes **bRu** [33], **bRuRub** [33], **pRub** [34], **pRuRup** [34] and [$Mn(CO)_3(NN)(CF_3SO_3)$] [35] were synthesized by reported procedures.

2.6. [$Mn(CO)_3(bpy)(4,4'\text{-bpy})](PF_6$) (bMn)

To a degassed solution of [$Mn(CO)_3(bpy)(CF_3SO_3)$] (0.2 g, 0.45 mmol) in CH_3CN (25 mL), 4,4′-bipyridine (0.7 g, 4.5 mmol) was added. It was constantly protected from light and stirred for 45 min at RT. The completion of the reaction was monitored by TLC. The solvent was evaporated under reduced pressure. The residue was dissolved in minimum of acetone and excess ether was added. The product precipitated was filtered and dried. This was repeated for 2–3 times to remove the excess 4,4′-bipyridine. Finally the product was metathesized to PF_6^- salt by dissolving in minimum amount of acetone and adding an aqueous solution of NH_4PF_6. The yellow precipitate formed was washed with water and ether, dried *in vacuo* for overnight. Yield = 74%. IR (KBr, cm^{-1}): 2041, 1949; ESI-MS (*m/z*): 451.

2.7. [$(CO)_3(bpy)Mn(4,4'\text{-bpy})Mn(bpy)(CO)_3](PF_6)_2$ (bMnMnb)

$Mn(CO)_3(bpy)(CF_3SO_3)$ (0.2 g, 0.45 mmol) was dissolved in degassed CH_3CN and protected from light. 4,4′-Bipyridine (0.036 g, 0.23 mmol) was added and the solution was stirred for 18 h at RT. The solvent was evaporated under reduced pressure and the contents were dried. The product was purified by column chromatography by using pet.ether/CH_2Cl_2. The column was constantly protected from light. Finally, the product was metathesized to PF_6^- salt by dissolving in minimum amount of acetone and adding an aqueous solution of NH_4PF_6. The yellow precipitate formed was washed with water and ether, dried *in vacuo* for overnight. Yield 72%. IR (KBr, cm^{-1}): 2043, 1933; ESI-MS (*m/z*): 839.

2.8. [$Mn(CO)_3(phen)(4,4'\text{-bpy})](PF_6$) (pMn)

$Mn(CO)_3(phen)(CF_3SO_3)$ (0.2 g, 0.43 mmol) was dissolved in degassed CH_3CN (25 mL), and 4,4′-bipyridine (0.67 g, 4.3 mmol) was added. It was stirred under dark for 45 min at RT. The completion of the reaction was monitored by TLC. At the end of the reaction the solvent was evaporated under reduced pressure. The residue was dissolved in minimum of acetone and excess ether was added. The product precipitated was filtered and dried. This was repeated for 2–3 times to remove the excess 4,4′-bipyridine. Finally, the product was metathesized to PF_6^- salt by dissolving in minimum amount of acetone and adding an aqueous solution of NH_4PF_6. The yellow precipitate formed was washed with water and ether, dried *in vacuo* for overnight. Yield = 77%. IR (KBr, cm^{-1}): 2041, 1941; ESI-MS (*m/z*): 474.

2.9. [$(CO)_3(phen)Mn(4,4'\text{-bpy})\ Mn(phen)(CO)_3](PF_6)_2$ (pMnMnp)

$Mn(CO)_3(phen)(CF_3SO_3)$ (0.2 g, 0.43 mmol) was dissolved in degassed CH_3CN and protected from light. 4,4′-bipyridine (0.034 g, 0.22 mmol) was added and the solution was stirred for 20 h at RT. The solvent was evaporated under reduced pressure and the contents were dried. The product was purified by column chromatography by using pet.ether/CH_2Cl_2. Finally, the product was metathesized to PF_6^- salt by dissolving in minimum amount of acetone and adding an aqueous solution of NH_4PF_6. The yellow precipitate formed was washed with water and ether, dried *in vacuo* for overnight. Yield = 76%. IR (KBr, cm^{-1}): 2043, 1933; ESI-MS (*m/z*): 939.

2.10. [$(CO)_3(bpy)Mn(4,4'\text{-bpy})Ru(bpy)_2Cl](PF_6)_2$ (bMnRub)

The complex **bRu** (0.186 g, 0.25 mmol) was dissolved in degassed EtOH and protected from light. To this solution was added $Mn(CO)_3(bpy)(CF_3SO_3)$ (0.11 g, 0.25 mmol) and stirred for 8 h under nitrogen at RT and constantly protected from light. The solvent was evaporated under reduced pressure and the contents were dried. The complex was purified by column chromatography by packing the column with alumina and eluting with pet. ether/ethanol mixture. During the purification, the column was protected from light. A yellow band of unreacted Mn(I) complex eluted first. Upon increasing the composition of ethanol a brown band of the product got eluted. The product was dried under reduced pressure and metathesized to PF_6^- salt by dissolving in minimum amount of acetone and adding an aqueous solution of NH_4PF_6. The precipitate formed was washed with water and ether, dried *in vacuo* for overnight. Yield: 72% IR (KBr, cm^{-1}): 2038, 1935; ESI-MS (*m/z*): 1045.

2.11. [$(CO)_3(phen)Mn(4,4'\text{-bpy})Ru(phen)_2Cl](PF_6)_2$ (pMnRup)

To a degassed solution of **pRu** (0.140 g, 0.175 mmol) in EtOH was added $Mn(CO)_3(phen)(CF_3SO_3)$ (0.082 g, 0.175 mmol). The contents were stirred for 10 h under nitrogen at RT and constantly

protected from light. The solvent was evaporated under reduced pressure and the contents were dried. The complex was purified by column chromatography by using alumina as the solid support and eluting with pet. ether/ethanol mixture. The column was protected from light during the purification. A yellow band of unreacted Mn(I) complex eluted first. Upon increasing the composition of ethanol a brown band of the product got eluted. The product was dried under reduced pressure and metathesized to PF_6 salt by dissolving in minimum amount of acetone and adding an aqueous solution of NH_4PF_6. The precipitate formed was washed with water and ether, dried *in vacuo* for overnight. Yield: 70%. IR (KBr, cm^{-1}): 2038, 1934; ESI-MS (*m/z*): 1116.

3. Results and discussion

3.1. Synthesis

The manganese(I) and ruthenium(II) complexes used in the present work are shown in Chart 1. The ruthenium(II) complexes **bRu**, **pRu**, **bRuRub** and **pRuRup** were prepared by literature procedures [33,34]. The Mn(I) carbonyl complexes were prepared by treating the precursor complex $[Mn(CO)_3(NN)(CF_3SO_3)]$ [35] with the ligand 4,4′-bpy. The reactions were carried out under inert atmosphere and protected from light. The Mn–Ru heterobimetallic complexes were prepared by complex as metal/complex as ligand strategy [36]. The Mn(I) precursor complex was treated with the corresponding Ru(II) monometallic complex. The complexes were characterized by ESI-MS, IR, cyclic voltammetry, absorption and emission spectral techniques.

3.2. ESI-MS

The Mn(I) monometallic and bimetallic complexes were characterized by ESI-MS spectral technique. These complexes show a peak corresponding to the loss of PF_6^- ion. The *m/z* values corresponding to the loss of a PF_6^- ion for the complexes **bMn**, **pMn**, **bMnMnb**, **pMnMnp** and **bMnRub** are 451, 474, 891, 939 and 1045 respectively. The other peaks are assigned to loss of 4,4′-bipyridine, followed by a carbonyl moiety and then two carbonyl groups. This trend is followed in all the complexes. The ESI-MS spectra of the complexes **bMn**, **bMnMnb** and **bMnRub** are given in Figs. S1–S3.

Table 1
IR spectral and Electrochemical data[a] of monometallic and bimetallic complexes containing 2,2′-bipyridine.

Complex	$E_{1/2}$ (V) $Ru^{3+/2+}$	E_P (V) $Mn^{2+/+}$	$E_{1/2}$ (V)		ν(CO) cm^{-1}
			$bpy^{0/-}$	4,4′-$bpy^{0/-}$	
bRu	0.75		−1.59	−0.96	
bRuRub	0.89	1.9	−1.61	−0.97	2041, 1949
bMn	1.01	1.71	−1.6	−0.93	2043, 1933

bMnRub			−1.49	−0.9	

[a] Ag/AgCl reference electrode; 0.1 M TBAP supporting electrolyte.

3.3. IR spectra

The IR spectra for all the complexes were recorded in KBr pellets. The presence of two strong ν(CO) stretching frequencies indicate the *fac.* configuration for these complexes. When the halide (X = Br^-) is replaced with 4,4′-bipyridine, the carbonyl stretching frequency is increased. This is due to the decrease in electron density at the metal center (Mn^I) when 4,4′-bipyridine is coordinated to Mn^I, because 4,4′-bpy is a strong π-accepting ligand. The IR spectral data are collected in Tables 1 and 2.

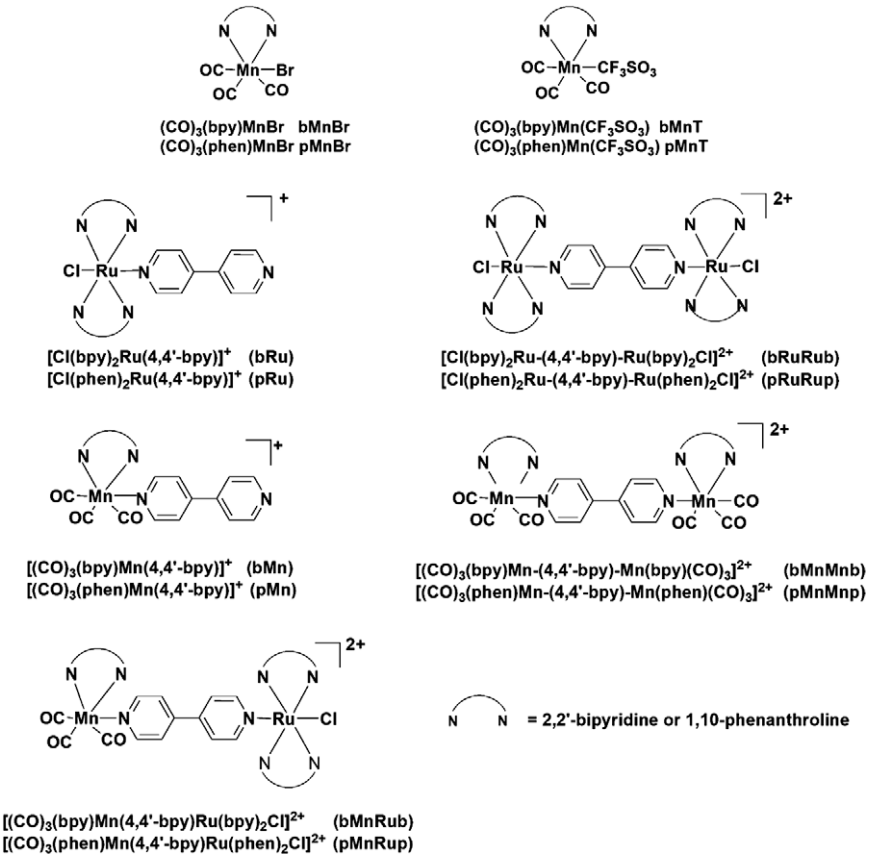

Chart 1. Structure of complexes.

Table 2
IR spectral and Electrochemical data[a] of monometallic and bimetallic complexes containing 1,10-phenanthroline.

Complex	$E_{1/2}$ (V) $Ru^{3+/2+}$	E_P (V) $Mn^{2+/+}$	$E_{1/2}$ (V)		ν(CO) cm^{-1}
			phen$^{0/-}$	4,4′-bpy$^{0/-}$	
pRu	0.81		−1.61	−0.97	
pRuRup	0.85	1.53	−1.63	−0.99	2041, 1941
pMn	1.01	1.54	−1.49	−1.03	2043, 1933
pMnMnp		1.53	−1.6	−1.09	2038, 1934
pMnRup			−1.49	−1.06	

[a] Ag/AgCl reference electrode; 0.1 M TBAP supporting electrolyte.

In the case of Ru–Mn heterobimetallic complexes the ν(CO) stretching frequency is slightly decreased compared to monometallic and homobimetallic Mn^{I} complexes. This indicates the attachment of $Mn(CO)_3$ unit into the Ru^{II} complex and the decrease in the ν(CO) stretching frequency is due to electron donation from Ru^{II} unit.

3.4. Electrochemistry

The electrochemical properties of all the complexes were studied in CH_3CN using Ag/AgCl as the reference electrode. The manganese complexes show poor reversibility on applying the potential. In the anodic scan, the complexes **bMn** and **bMnMnb** undergo oxidation at the manganese site ($Mn^{I/II}$). In the cathodic scan, the complexes undergo reduction occurring at the ligands. The reduction at less negative potential can be attributed to the reduction of bridging ligand (4,4′-bpy$^{0/-}$) and the one at large potential is due to ancillary ligand (bpy$^{0/-}$) [37]. The electrochemical data of all the complexes are given in Tables 1 and 2. The DPV of **bMn** is shown in Fig. S4. For the manganese complexes with phenanthroline ligands **pMn** and **pMnMnp**, oxidation occurs at *ca* 1.54 V. In the negative region reduction occurs at −1.09 and −1.60 V due to the bridging ligand and phen ligand. The ruthenium complexes **bRu** and **bRuRub** show oxidation with the $E_{1/2}$ value of 0.75 and 0.89 V, respectively due to $Ru^{II/III}$ [34]. In the cathodic region reduction occurs at considerably lower potential (−0.99 V) which can be assigned to the reduction of bridging ligand and other two reductions at large negative potentials can be assigned to the reduction of ancillary bipyridine ligands. Similar assignments can be made for ruthenium complexes with phenanthroline ligand [34]. The anodic part of the cyclic voltammogram of **pRuRup** is shown in Fig. S5.

The Mn–Ru heterobimetallic complexes **bMnRub** and **pMnRup** show two oxidation peaks. The differential pulse voltammogram of **pMnRup** is shown in Fig. 1.

From the comparison of ruthenium(II) monometallic and homobimetallic complexes, the peak at 1.01 V is assigned to $Ru^{II/III}$. Another peak at +1.54 V is due to $Mn^{I/II}$ oxidation and this is assigned based on the observed redox potentials for Mn^{I} monometallic and bimetallic complexes. The attachment of Mn^{I} unit into Ru^{II} monometallic complexes **bRu** and **pRu** can be seen in the shift in the oxidation potential values. In the heterobimetallic complexes the oxidation potential of the ruthenium(II) unit is shifted towards more positive value, indicating it is difficult to get oxidized upon coordination of $Mn(CO)_3$ unit, and the oxidation potential of the manganese(I) unit is shifted towards less positive value due to electron donation from Ru(II) unit. This result is in agreement with what we observe in IR spectra.

3.5. Absorption spectra

The absorption spectra for all the complexes were recorded in CH_3CN at room temperature. The absorption spectra of complexes **bMnBr**, **bMnT**, **pMnBr** and **pMnT** are shown in Figs. S6 and 2. From the absorption spectra it is evident that on replacing Br^- with $CF_3SO_3^-$, a blue shift to a tune of 53 nm is observed because of poor π-accepting ligand [35]. The absorption spectral data of the complexes with 2,2′-bipyridine ancillary ligand are given in Table 3.

The manganese complexes with 2,2′-bpy ancillary ligands **bMn** and **bMnMnb**, have a peak at 290 nm due to ligand centered $\pi \rightarrow \pi^*$ transition. These complexes show a broad absorption in the region 320–400 nm because of ^{1}MLCT transition arising out of transfer of an electron from Mn(dπ) → (π*) [35]. The absorption spectrum of **bMnMnb** is shown in Fig. S7. Similarly manganese complexes with 1,10-phenanthroline ligand **pMn** and **pMnMnp** have $\pi \rightarrow \pi^*$ transition at 265 nm and a broad absorption in the region 320–400 nm due to ^{1}MLCT transition. The absorption spectrum of **pMnMnp** is shown in Fig. 3. The absorption spectral data of the complexes with phenanthroline ancillary ligand are given in Table 4.

Ruthenium(II) complexes **bRu** and **bRuRub** display ligand centered transition at 290 nm and MLCT transitions in the region 325–375 nm and 470–500 nm with maximum absorption occurring at 487 and 489 nm, respectively. The absorption spectrum of the complex **bRuRub** is shown in Fig. S7. For the known complexes the absorption spectral data observed here are very similar to the reported values [33,34]. Similarly the ruthenium(II) complex with phenanthroline ancillary ligand **pRuRup** show intense transitions in the UV region due to ligand centered $\pi \rightarrow \pi^*$ transition and low energy ^{1}MLCT transition in the region 450–475 nm (Fig. 3). In the case of Mn^{I}–Ru^{II} heterobimetallic complexes **bMnRub** and **pMnRup** intense peaks in the UV region at 290 and 264 nm are assigned to ligand centered $\pi \rightarrow \pi^*$ transition. In the visible region ^{1}MLCT transition is seen at 447 and 448 nm, respectively, for the complexes **bMnRub** and **pMnRup**. When we compare the absorption spectrum of the complex **bMnRub** with that of monometallic and homobimetallic ruthenium(II) complexes **bRu** and **bRuRub**, a blue shift to a tune of 40 and 42 nm, respectively is observed. Similarly for the complex **pMnRup** a blue shift to a magnitude of 15 nm is observed when compared to **pRuRup**. The blue shift can be attributed to the attachment of strong π-accepting $Mn(CO)_3$ core. This observation is supported by IR and cyclic voltammetry results. This kind of blue shift is seen in related ruthenium(II) and osmium(II) complexes when more π-accepting ligands like triphenyl phosphine and carbonyl are attached [38].

3.6. Emission spectra

The emission spectra of all the complexes were recorded in CH_3CN at room temperature and spectral data are collected in

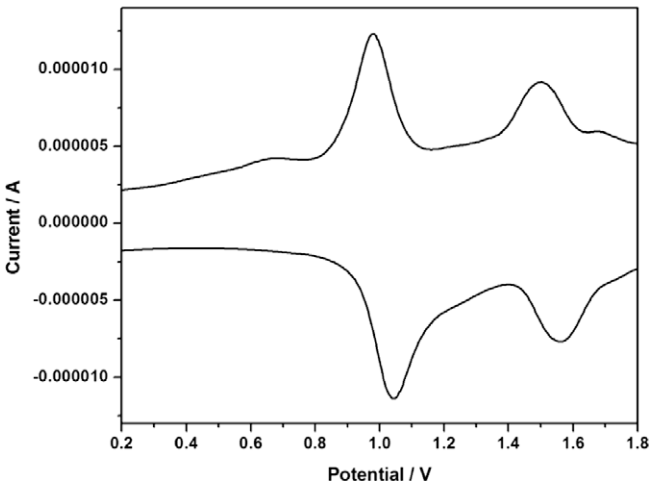

Fig. 1. Differential Pulse Voltammogram of **pMnRup** in CH_3CN.

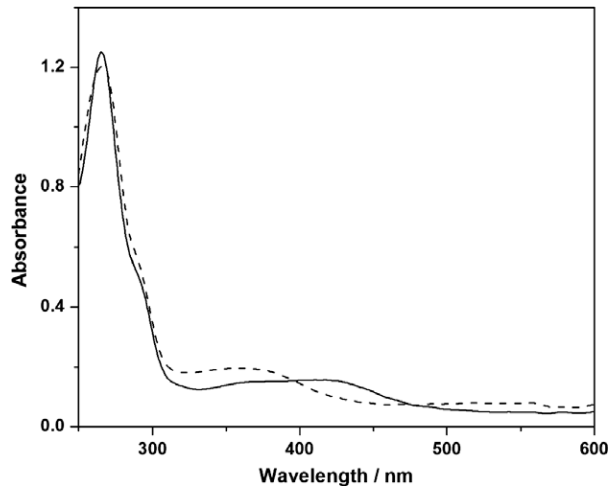

Fig. 2. Absorption spectra of complexes **pMnBr** (solid line) and **pMnT** (dotted line) in CH_3CN at RT.

Table 3
Photophysical properties of monometallic and bimetallic complexes with 2,2′-bipyridine ligand in CH_3CN at 298 K.

Complex	$\lambda_{\xi\alpha\mu}$	$\lambda_{\xi\alpha\mu,\mu\varepsilon}$	τ (ns)	$\varphi_{\mu\varepsilon}$	$k_{r\ 10}{}^{4}$	$k_{nr\ 10}{}^{6}$

Tables 3 and 4. The manganese complexes **bMn**, **pMn**, **bMnMnb** and **pMnMnp** have no detectable emission. The ruthenium(II) complexes **bRu** and **bRuRub** display emission at 722 and 726 nm, respectively, from ^{3}MLCT state upon excitation at 489 nm and the emission maximum is independent of excitation wavelength. The emission spectrum of **bRuRub** is shown in Fig. S8. Similarly ruthenium complexes with phenanthroline ligand **pRu** and **pRuRup** emit from ^{3}MLCT state at 680 and 684 nm, respectively, upon excitation at the wavelength corresponding to ^{1}MLCT absorption. The emission spectrum of **pRuRup** is shown in Fig. 4.

a = No detectable emission.

The emission spectrum of the heterobimetallic complex **bMnRub** is shown in Fig. S8. The complex displays emission at 613 nm from ^{3}MLCT state and it has the same emission maximum irrespective of excitation wavelength. On comparing the emission maximum of heterobimetallic complex **bMnRub** with the corresponding monometallic and homobimetallic complexes **bRu** and **bRuRub**, a blue shift to a tune of 109 and 113 nm, respectively, has been observed. Also the emission intensity of the heterobimetallic complex is increased compared to the ruthenium(II) homobimetallic complex **bRuRub**. The emission spectrum of **pMnRup** is shown in Fig. 4 and it displays emission maximum at 599 nm, which is independent of excitation wavelength. A blue shift to a magnitude of 81 and 85 nm is observed compared to **pRu** and **pRuRup**, respectively. As seen in **bMnRub**, the emission intensity of **pMnRup** is also increased compared to **pRuRup**. These results are in line with what we observe in absorption spectra, in which also a blue shift occurs in heterobimetallic complexes. Hence emission spectra also confirm the attachment of more π-accepting $Mn(CO)_3$ core into ruthenium(II) monometallic complex leading to increased energy gap between ground state and excited state. The increase in the emission intensity of heterobimetallic Mn–Ru complexes can be explained by energy gap law [6], which states that the non-radiative decay rate increases exponentially with decrease in the energy gap between ground and excited states. Hence in Mn–Ru heterobimetallic complexes, the increase in energy difference between ground and excited state decreases the rate of non-radiative decay. When we look into the absorption spectra of manganese(I) complexes, the ^{1}MLCT transition appears in the high energy region compared to ruthenium(II) complexes. So in the manganese(I)–ruthenium(II) heterobimetallic complexes, the emission intensity of ruthenium is not quenched. Since Mn(I) complexes have no detectable emission, the intrinsic non-radiative

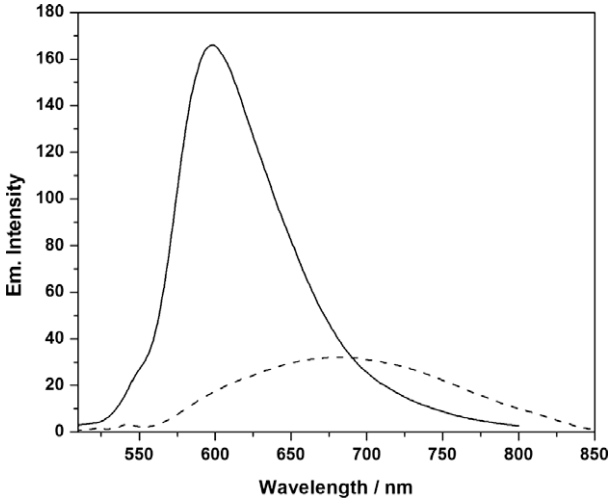

Fig. 4. Emission spectra of **pRuRup** and **pMnRup** in CH_3CN at RT.

decay may compete with energy transfer from *Mn(I) to Ru(II). Since there is no luminescence quenching of Ru(II), electron transfer from or to Mn(I) can be excluded. The uncorrected excitation spectrum of **pMnRup**, shown in Fig. 5, was recorded by using the emission wavelength of 599 nm, which is the emission maximum of this complex. The excitation spectrum of **pMnRup** is similar to the absorption spectrum, which shows that the complex is stable under irradiation of UV–Vis light.

3.7. Excited state lifetime and quantum yield

The excited state lifetime and quantum yield of all the complexes **bRu**, **bRuRub, pRu** and **pRuRup** are given in Tables 3 and 4. The ruthenium(II) complexes **bRu** and **bRuRub** have excited state lifetime of 28 ns each. The lifetime decreased substantially for complex **bRu** when compared to $[Ru(bpy)_3]^{2+}$ which has an excited state lifetime of 1100 ns in CH_3CN [6]. These values indicate that the lowest excited level is bridge localized ^{3}MLCT state and this interpretation is supported by the observation of long wavelength emission at 722 nm for **bRu**. Similarly the lifetime of complexes **pRu** and **pRuRup** decreased tremendously compared to $[Ru(phen)_3]^{2+}$ which has an excited state lifetime of 460 ns and quantum yield of 0.028 [7]. The decrease in the lifetime and quantum yield values of **bRu**, **bRuRub**, **pRu**, and **pRuRup** can be explained in terms of energy gap law [6]. Since the energy gap between ground and excited state is less for these complexes, it facilitates faster non-radiative relaxation which leads to low excited state lifetime. Also, thermal deactivation through ligand-field state is possible, since Cl^- is a weak field ligand it may keep the ligand-field state close to ^{3}MLCT state. Interestingly the lifetime and quantum yield of heterobimetallic complexes **bMnRub** and **pMnRup** are enhanced when compared to ruthenium(II) monometallic and homobimetallic complexes (Tables 3 and 4). The increase in lifetime of heterobimetallic complexes can also be explained by energy gap law [6]. The attachment of electron withdrawing $Mn(CO)_3$ unit in heterobimetallic complex increases the energy gap between the ground and excited state of ruthenium(II), and decreases the non-radiative decay (*vide supra*).

3.8. Transient spectra

The transient absorption spectra of the complexes were recorded in acetonitrile solution at room temperature following excitation at 355 nm. The transient spectrum of ruthenium(II) complex **bRuRub**, (Fig. S9), shows a bleach around 490 nm due to the decay of the ground state ^{1}MLCT absorption. The transient spectrum of parent complex $[Ru(bpy)_3]^{2+}$ shows bleaching around 450 nm due to the decay of ground state ^{1}MLCT absorption and formation in the region 370–390 nm due to bpy$^{\cdot}$ radical anion absorption. Similar decay around 490 nm observed for **bRu** and **bRuRub** indicates the decay of ground state ^{1}MLCT, and a broad absorption seen at 590 nm is due to 4,4′-bipyridine radical absorption [37] which indicates that ^{1}MLCT state is bridge localized. This happens because the π^* level of 4,4′-bpy is lower than that of 2,2′-bpy. The transient absorption spectrum of manganese(I)–ruthenium(II) heterobimetallic complex, **bMnRub**, recorded at various time intervals, is shown in Fig. 6.

The transient absorption spectrum shows bleach in the region 400–470 nm with maximum at 450 nm and absorption at 370 nm. The bleach is due to disappearance of ^{1}MLCT state of ruthenium(II) [10] and the absorption is due to the formation of 4,4′-bpy$^{\cdot}$ radical anion. The transient absorption spectrum of **pMnRup** is shown in Fig. S10. The bleach observed around 450 nm for **pMnRup** is due to the decay of ground state ^{1}MLCT of ruthenium(II). When we look into the results of transient spectra of rhenium(I)–ruthenium(II) heterobimetallic complexes [39], obtained by placing Re(I) instead of Mn(I), similar bleach is observed in the region 450–490 nm, due to decay of ^{1}MLCT state of ruthenium(II). In the transient absorption spectra of heterobimetallic complexes, the bleach observed at the time scale is very short (Figs. 6 and S10) compared to ruthenium(II) complex. Hence in **bMnRub** and **pMnRup** the bleach, observed due to the disappearance of ruthenium(II), may be partly due to energy transfer from *Mn(I) to Ru(II). After the formation of excited MLCT state, in the absence of detectable emission, there are two ways for its deactivation. Either the MLCT state of the Mn(I) component may come directly to the ground state via non-radiative decay or it may undergo energy transfer process. When we look into the absorption spectra shown in Fig. 3 and Fig. S7, at 355 nm, which is the wavelength used for excitation, Mn(I) and Ru(II) have almost similar absorption. So it is not possible to selectively generate ^{1}MLCT state of Mn(I), though Ru(II) ^{1}MLCT state is also formed. Although the intrinsic non-radiative decay of *Mn(I) will be fast, a small portion of the energy may be transferred to Ru(II) since the ^{1}MLCT state of Mn(I) is lying higher than that of Ru(II). However at this stage we are not able to provide a clear evidence to prove the energy transfer. The occurrence of non-radiative energy transfer process is a well established phenomenon in recent years [40]. Since Mn(I) complexes are non-luminescent, it is not possible to follow the

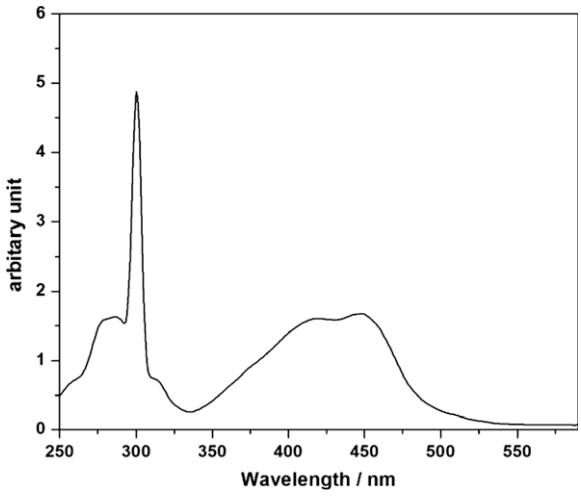

Fig. 5. Excitation spectrum of **pMnRup** in CH_3CN.

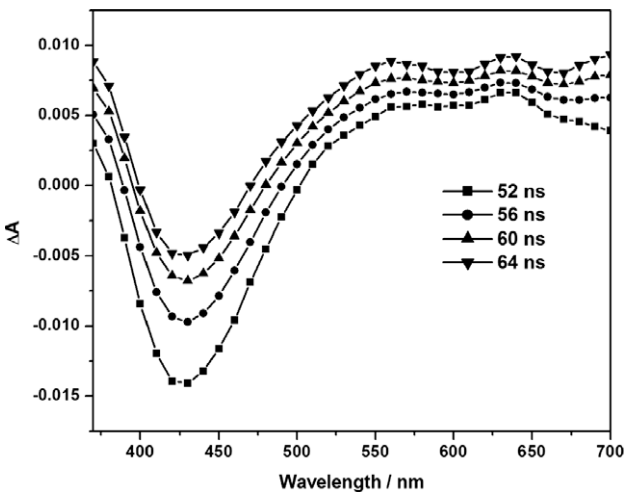

Fig. 6. Transient absorption spectra of **bMnRub** recorded at various time intervals in degassed CH_3CN upon excitation at 355 nm at RT.

emission intensity of Mn(I) complexes. However the time resolved infrared (TRIR) spectroscopy, which measures the change in the stretching vibration frequency of IR active groups (here CO stretching frequency can be followed) when the excited state is formed, can be used. Also this technique can operate on very short time scales (picoseconds) so that the processes that are so fast can be detected. In order to get the rate of intramolecular process, TRIR studies will be carried out.

4. Conclusions

In this work, six new complexes, (two monometallic manganese(I) complexes, two homobimetallic manganese(I) complexes and two heterobimetallic manganese(I)–ruthenium(II) complexes) were synthesized and characterized by various spectral techniques. Upon attaching $Mn(CO)_3$ unit, the absorption and emission maxima are blue-shifted in heterobimetallic complexes compared to ruthenium(II) monometallic and homobimetallic complexes. Also the heterobimetallic complexes show enhanced lifetime and quantum yield compared to ruthenium(II) monometallic and homobimetallic complexes. In order to corroborate intramolecular energy transfer, TRIR studies will be attempted.

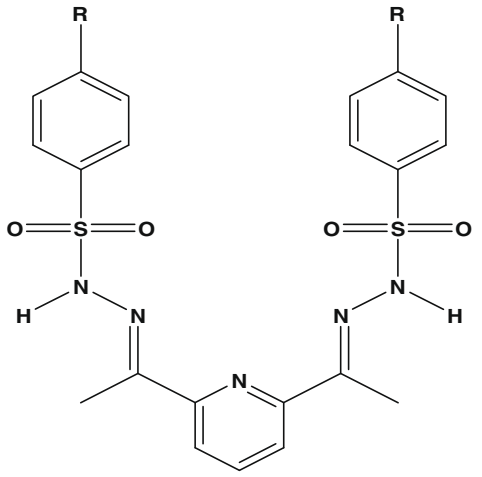

Fig. 1. Chemical diagram of the Schiff bases [R = H (L^1), CH_3 (L^2) and OCH_3 (L^3)].

2.2. Preparation of the Schiff bases

2.2.1. General method for the preparation of the Schiff bases

L^1 was obtained by adding benzenesulfonohydrazine (0.516 g, 0.20 mmol) dropwise into an acidified ethanolic solution of 2,6-diacetylpyridine (0.245 g, 0.10 mmol). The mixture was refluxed for about 3 h. On cooling to room temperature, the resulting white precipitate was filtered off, washed with cold ethanol and dried over silica gel. L^2 and L^3 were obtained following the same procedure as for L^1, by adding the relevant benzenesulfonohydrazine compounds, 4-methylbenzenesulfonohydrazine and 4-methoxybenzenesulfonohydrazine, respectively.

2.2.2. L^1

2.3. Preparation of the copper(II) complexes

2.3.1. General method for the preparation of the copper(II) complexes

Each Schiff base (0.30 mmol) was dissolved in ethanol (50 mL) and three drops of triethylamine were added, followed by an ethanolic solution containing a stoichiometric amount of hydrated copper(II) acetate. The mixture was refluxed for 5 h. The resultant dark brown solids were filtered and dried over silica gel.

The most suitable solvents used for all the complexes were dimethylsulfoxide and pyridine, and the crystals of [CuL^3·py]·py for single crystal X-ray diffraction analysis were successfully recrystallized from the latter solvent.

2.3.2. [$CuL^1 \cdot H_2O$]

Yield: 63%. Melting point: 225–228 °C. *Anal.* Calc. for $C_{21}H_{21}N_5O_5S_2Cu$: C, 45.75; H, 3.84; N, 12.71. Found: C, 45.69; H, 3.49; N, 12.40%. IR [ν_{max} (cm^{-1}) (KBr)]: ν_{OH} 3449; $\nu_{C=N}$ 1597; $\nu_{as}(SO_2)$ 1334; $\nu_s(SO_2)$ 1162; $\nu_{dis}(SO_2)$ 1080; UV–Vis [λ_{max} (nm) (DMSO)]: 270 ($\pi \rightarrow \pi^*$); 335 ($n \rightarrow \pi^*$), 440 (LMCT), 765(d–d transition). μ_{eff} = 1.84 BM.

2.3.3. [$CuL^2 \cdot H_2O$]

Yield: 67%. Melting point: 227–230 °C. *Anal.* Calc. for $C_{23}H_{25}N_5O_5S_2Cu$: C, 47.54; H, 4.36; N, 12.09. Found: C, 47.34; H, 4.39; N, 12.16%. IR [ν_{max} (cm^{-1}) (KBr)]: ν_{OH} 3488, $\nu_{C=N}$ 1593; $\nu_{as}(SO_2)$ 1316; $\nu_s(SO_2)$ 1151; $\nu_{dis}(SO_2)$ 1077; UV–Vis [λ_{max} (nm) (DMSO)]: 265 ($\pi \rightarrow \pi^*$); 330 ($n \rightarrow \pi^*$), 412 (LMCT), 770(d–d transition). μ_{eff} = 1.87 BM.

2.3.4. [$CuL^3 \cdot H_2O$]

Yield: 65%. Melting point: 231–234 °C. *Anal.* Calc. for $C_{23}H_{25}N_5O_5S_2Cu$: C, 45.19; H, 4.38; N, 11.46. Found: C, 45.47; H, 4.38; N, 11.31%. IR [ν_{max} (cm^{-1}) (KBr)]: ν_{OH} 3448, $\nu_{C=N}$ 1592; $\nu_{as}(SO_2)$ 1332; $\nu_s(SO_2)$ 1162; $\nu_{dis}(SO_2)$ 1081; UV–Vis [λ_{max} (nm) (DMSO)]: 240 ($\pi \rightarrow \pi^*$); 330 ($n \rightarrow \pi^*$), 410 (LMCT), 770(d–d transition). μ_{eff} = 1.94 BM.

2.4. X-ray structure analyses

A single crystal of [CuL^3·py]·py suitable for X-ray diffraction was mounted on a glass fibre using perfluoropolyether oil and cooled rapidly to 100 K in a stream of cold N_2. Diffraction data were measured using a Bruker APEX II CCD area-detector diffractometer (graphite-monochromated Mo Kα radiation, λ = 0.71073 Å). The orientation matrix, unit cell refinement and data reduction were all handled by the APEX II software (SAINT integration, SADABS absorption correction) [8]. The structure was solved using direct methods and vectors in the program SHELXS-97 [9] and was refined by the full matrix least-squares method on F^2 with SHELXL-97 [9]. All the non-hydrogen atoms were refined anisotropically and all the hydrogen atoms were placed at calculated positions and refined isotropically. Drawings of the molecules were produced with XSEED [10].

2.5. Antimicrobial activity

2.5.1. Microorganisms

Bacteria strains: Methicillin-resistant *S. aureus:* MRSA 0701-4, MRSA 1, MRSA 0307-28, MRSA 0302-4, MRSA 0704-3 and MDR-*Salmonella typhi* TP MDR 160/99 were isolated from the Labour Ward, Hospital Kuala Kubu, Selangor, Malaysia. MDR-*Escherichia coli* EC 187 and MDR-*Pseudomonas aeruginosa* PA 339 were obtained from the Institute of Medical Research, Kuala Lumpur, Malaysia. MDR-*Acinetobacter baumannii* AC/01601-10 was supplied by the University of Malaya Medical Center, Kuala Lumpur, Malaysia.

2.5.2. Antibacterial screening

The antibacterial activity of the Schiff bases and their copper(II) complexes was determined by the disc diffusion method [11]. Muller-Hinton agar was employed as the bacteria growth medium. A suspension of tested microorganism (10^8 CFU/mL) was spread on the solid media plates. Filter paper discs (6 mm in diameter) were soaked with 10 μl of the solutions and placed on the inoculated plates. After keeping the plates at 2 °C for 2 h, they were incubated at 37 °C for 24 h for bacteria. The tested compounds were prepared in dimethyl sulfoxide with a concentration of 10 mg mL^{-1}. The inhibition zones were measured in millimeters and the assays were performed in duplicate.

2.5.3. Determination of minimum inhibitory concentration (MIC)

The minimal inhibitory concentration of each of the tested compounds was defined as the lowest concentration exhibiting no visible growth compared with the drug-free control wells. Muller-Hinton Broth was employed as the bacteria growth medium. Serial concentrations of each of the tested compounds in the range 0.156–10.0 mg/mL were prepared for the determination of MICs and inoculated with different strain Methicillin-resistant *S. aureus* bacteria. After incubation at 37 °C for 24 h, the first well without turbidity was determined as the minimal inhibitory concentration.

3. Results and discussion

3.1. General characterizations

3.1.1. Infrared spectra

The IR spectra of the copper(II) complexes show strong typical absorptions in the region 1592–1597 cm^{-1} related to the C=N stretching vibration of the Schiff base imino group. The strong band at 1595–1618 cm^{-1} attributed to the C=N stretching vibration in the ligands is shifted to lower energy in the complexes, indicating coordination of the azomethine nitrogen [12]. The IR spectra of the complexes also do not contain the ν(N–H) absorption band of the free ligand, suggesting the proton on the imine nitrogen atom of the ligand is lost upon complexation [13]. In the complexes, the remaining band of $\nu_s(SO_2)$ at 1151–1162 cm^{-1} and the weaker intensity of $\nu_{as}(SO_2)$ at 1316–1334 cm^{-1} together with the appearance of a new band at 1077–1081 cm^{-1}, assigned to the bending SO_2 group, suggest the distortion of one of the SO_2 groups from its structure [3]. The broad band in the region 3448–3488 cm^{-1} and two weaker bands in the regions 803–809 and 597–600 cm^{-1} are assigned to the coordinated water molecule, and are due to ν(–OH) rocking and wagging mode vibrations [5,14].

3.1.2. Absorption spectra and magnetic studies

An intense band centered at 303–315 nm is attributable to $n \rightarrow \pi^*$ transitions associated with the azomethine chromophore [15]. There is another intense band in the high-energy region (250–290 nm) of the spectra of the free ligands which is related to $\pi \rightarrow \pi^*$ transitions of aromatic rings [16]. These transitions are also found in the spectra of the complexes, but they undergo hypsochromic or bathochromic shifts, confirming the coordination of the ligands to the metallic ions [17,18]. In the spectra of the copper(II) complexes, the intense and broad bands in the 410–440 nm region are attributable to the $O \rightarrow Cu^{II}$ (LMCT) transition, which further supports coordination of the ligands to the copper(II) ion via one of the oxygen atoms. The absorption bands in the range 765–770 nm in the spectra of the copper(II) complexes correspond to d–d transitions, and this is consistent with a square pyramidal geometry of the copper(II) complexes [19]. The magnetic moment of the copper(II) complexes (1.84–1.94 BM) is normal for a $3d^9$ metal ion in a magnetically dilute environment [20] and in the range approximately similar to other square pyramidal copper(II) complexes [19,21].

3.2. Crystal and molecular structure of [CuL^3·py]·py

The structure of the complex [CuL^3·(py)]·py is depicted in Fig. 2. Crystal data and structure refinement details are compiled in Table 1. Some bond lengths and bond angles are listed in Table 2. The

$[CuL^3{\cdot}(py)]{\cdot}py$ complex crystallizes in the triclinic space group $P\bar{1}$, and the copper ion has a penta-coordinate environment.

The structure shows that the complex is a monomer in which the copper(II) ion has a five-coordinate geometry with the Schiff base being asymmetrically coordinated to it as a binegatively charged tetradentate chelating agent containing three N atoms and one oxygen atom in an almost planar arrangement around the copper ion. The other chain in the ligand includes only the deprotonated hydrazine N atom with the rest of the chain remaining pendant. A nitrogen atom of the pyridine molecule occupies the fifth apical site.

While coordinating with the copper(II) ion, deprotonation of the ligands generates a negative charge on the sulfonyl oxygen atom on one of the five-membered chelate rings N(2)–N(1)–S(1)–O(1). This is delocalized over the O(1)–S(1)–N(2) group [O(1)–S(1) 1.452(5) Å and S(1)–N(2) 1.623(7) Å]. The corresponding O(1)–S(1) and S(1)–N(2) bonds of the free ligands of related compounds are 1.423(4)–1.436(4) Å and 1.626(2)–1.645(2) Å, respectively [22,23].

The index τ is used to define the five coordination shape in terms of the two largest bond angles (α and β) around the central atom as [$\tau = (\beta-\alpha)/60$]. If $\tau = 0$, the coordination is an ideal square pyramid and if $\tau = 1$, the coordination is an ideal trigonal bipyramid [24]. The geometrical parameter τ has a value of 0.01, indicating the coordinated $(L^3)^{2-}$ ligand presents a geometry much closer to square pyramidal ($\tau = 0$). The distortion is also shown by the angles between the pyridine nitrogen atom at the apical position, the metal atom and donor set of the basal plane, which is larger than 90° [91.5(2)–100.7(3)°]. In the equatorial plane, the ideal square pyramidal geometry is distorted by the steric requirements imposed by the chelate rings, N(2)–Cu–N(3), 79.5(3)° and O(1)–Cu–N(5), 108.0(3)°, as compared to the ideal value of 90°.

The distance of $Cu–N_{pyridine}$ [1.971(6) Å] is significantly longer than $Cu–N_{amine}$ [1.912(7) Å] in a similar study on the square pyramidal structure of $[Cu(Hdapsox)H_2O]^+$ [21].

3.3. Biological activity

The ligands and their copper(II) complexes were investigated for antibacterial activity against gram-positive and gram-negative bacteria. None of the Schiff bases showed antibacterial activity against all the gram-positive and gram-negative bacteria. However, significant inhibition was displayed by all the copper(II) complexes against all strains of gram-positive bacteria, Methicillin-resistant *S. aureus* (Table 3). The MIC values of the copper(II) complexes that showed positive results in the screening process were determined as a quantitative measurement of antibacterial activity (Table 4). The results revealed that $[CuL^1{\cdot}H_2O]$ is most effective against *S. aureus* MRSA 1 with a MIC value of 1250 μg/mL, while $[CuL^2{\cdot}H_2O]$ proved to be the best against *S. aureus* MRSA 0701-4 and *S. aureus* MRSA 1 with a MIC value of 2500 μg/mL. $[CuL^3{\cdot}H_2O]$ was found to be most effective against *S. aureus* MRSA 0307-28, *S. aureus* MRSA 0302-4 and *S. aureus MRSA 0704-3* (2500 μg/mL). Also, $[CuL^1{\cdot}H_2O]$ is effective against *S. aureus* MRSA 0701-4, *S. aureus* MRSA 0307-28, *S. aureus* MRSA 0302-4 and *S. aureus* MRSA 0704-3 (2500 μg/mL). From a comparative study of the results in Tables 3 and 4, it was concluded that the antibacterial activities of the ligands are enhanced when they are chelated with copper(II) ions and the activity of the copper(II) complexes decreases when there are substituents in the ligands.

It is important to note that previous studies on other compounds have shown that the antibacterial activity of copper(II) complexes is generally better than their parent ligands [25]. There is also a report on the antibacterial activities for copper(II) complexes of valine-Schiff bases which have shown good inhibition against clinically isolated gram-positive Methicillin-resistant *S. aureus*. Chelation of

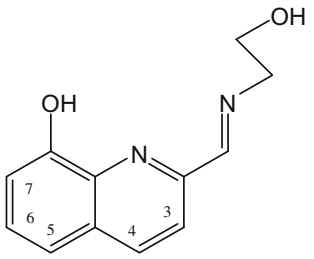
the copper(II) ion to a heterocyclic ligand containing a nitrogen atom such as pyridine is believed to increase the activity of the compounds against the microorganism [4]. It may be suggested that these copper complexes deactivate various cellular enzymes, which play role in various metabolic pathways of gram-positive bacteria, Methicillin-resistant *S. aureus* [26]. It has also been proposed that the ultimate action of the toxicant, i.e. the copper complex, is the denaturation of one or more proteins of the cell, which as a result, impairs normal cellular processes [25].

Generally, it was observed that the gram-negative bacteria were resistant to all the synthesized compounds. The extra outer layer on the cell wall of the gram-negative bacteria acts as a barrier and needs high penetration of the compounds to reach the cell [27]. The bacteria cell may also change the structure of its cell membrane and prevent the compound from entering the cell [28]. However, it is not yet possible to correlate the bioactivity of these compounds to any of their structural features due to the limited data. To the best of our knowledge, there is no report on the antibacterial activity of 2,6-diacetylpyridine bis(benzenesulfonohydrazide) Schiff bases and their copper(II) complexes and our present findings show that it is worth exploring more in this area in the future.

4. Conclusion

The 2,6-diacetylpyridine bis(benzenesulfonohydrazide) Schiff bases behave as binegatively charged tetradentate O, N, N, N chelates with copper(II), forming five-coordinate copper(II) complexes with a water molecule apically coordinated to the copper(II) ion. The crystal structure of $[CuL^3 \cdot (py)] \cdot py$ shows that the Cu(II) cation has a penta-coordinate and near square pyramidal geometry within the asymmetric unit, with a pyridine molecule replacing the water molecule at the apical position. Antibacterial tests for all the compounds reveal that the antibacterial activity of the Schiff bases against Methicillin-resistant *S. aureus* (MRSA) is enhanced when they are chelated with a copper(II) ion.

Supplementary data



CCDC 730751 contains the supplementary crystallographic data for $[CuL3 \cdot (py)] \cdot py$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

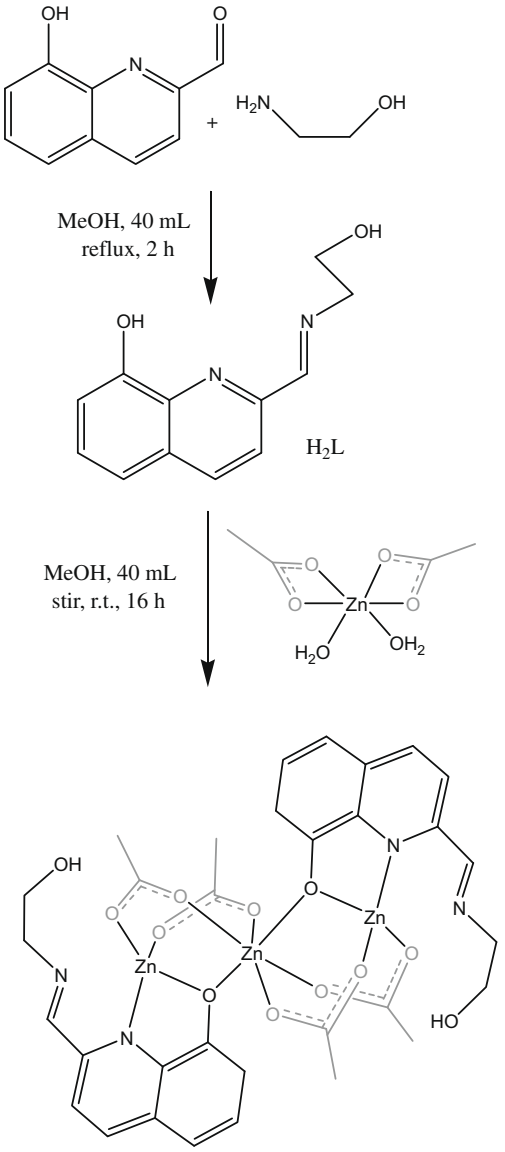
Scheme 1. Chemical structure of the 8-hydroxyquinoline derivative, 2-[(2-hydroxyethylimino)methyl]quinolin-8-ol (H_2L).

collected at 100 K on a Bruker CCD SMART1000 diffractometer, using graphite-monochromated Mo Kα radiation ($\lambda = 0.71073$ Å) from a fine focus sealed tube. Data were processed and corrected for Lorentz, polarisation and absorption effects. The structure was solved by standard direct methods, and refined by full matrix least squares on F^2 using the SHELX-97 program package [10]. Non-hydrogen atoms were anisotropically refined, while H atoms of HL^- were found in the Fourier maps, and then isotropically treated. Methyl H atoms of the acetate groups were included in the structure factor calculation in geometrically idealised positions, with thermal parameters depending of the parent atom, although their orientations were also refined.

2.3. Ligand synthesis



2-((2-Hydroxyethylimino)methyl)quinolin-8-ol (H_2L in Scheme 2) was obtained by refluxing a methanol solution (40 mL) containing 8-hydroxyquinoline-2-carboxaldehyde (0.352 g, 2 mmol) and 2-aminoethanol (0.12 mL, 2 mmol) for about 2 h. Vacuum concentration of the resulting yellow solution yielded a yellow solid that was filtered, washed with diethyl ether, and recrystallised in MeOH.

Scheme 2. Synthetic route used to obtain H_2L and $Zn_3(HL)_2(OAc)_4$.

2.4. Complex synthesis

$Zn_3(HL)_2(OAc)_4$ was obtained when 8-hydroxyquinoline-2-carboxaldehyde (0.176 g, 1 mmol) and 2-aminoethanol (0.06 mL, 1 mmol) were firstly refluxed in methanol (*ca.* 40 mL), and $Zn(OAc)_2{\cdot}2H_2O$ (0.329 g, 1.5 mmol) subsequently added to the resulting solution, which was stirred for about 16 h at room temperature. The same result was also obtained when using a 4:2 molar ratio. Vacuum concentration of the resulting solution yielded a solid that was filtered, washed with diethyl ether, and then dried in vacuum.

Single crystals suitable for X-ray diffraction studies were obtained from the mother liquor by simple evaporation at room temperature. Likewise, recrystallisation in acetone of the crude solid isolated from the mentioned reaction also resulted in the same. The same result was obtained by *r*.

2.4.1. $Zn_3(HL)_2(OAc)_4$

Orangish powder (0.240 g, 56%); Anal. Calc. for $C_{32}H_{34}N_4O_{12}Zn_3$ (M, 862, 8 g mol^{-1}) requires: C, 44.6; H, 4.0; N, 6.5. Found: C, 44.3; H, 4.0; N, 6.4%. FTIR (KBr, cm^{-1}): ν(C=N) 1620(vs), ν_a(COO)

1575(vs), ν_s(COO) 1405(s); ^{1}H NMR (500 MHz, Cl_3CD, ppm) 8.58 (s, 2H, *H*CN), 8.42(d, 2H, *H*C3), 7.65 (d, 2H, *H*C4), 7.30 (d, 2H, *H*C5), 7.12 (t, 2H, *H*C6), 7.02 (d, 2H, *H*C7), 4.08 (m, 4H, H_2C–OH), 4.05 (m, 4H, H_2C–N), 2.07 (s, 12H, H_3C); ^{1}H NMR (500 MHz, DMSO-d_6, ppm) 8.68 (2H, *H*CN), 8.59 (2H, *H*C3), 7.93 (2H, *H*C4), 7.45 (2H, *H*C5), 7.04 (2H, *H*C6), 6.82 (2H, *H*C7), 4.71 (2H, *H*O–CH_2), 3.79 (8H, H_2C–H_2C–N), 1.81 (12H, H_3C).

3. Results and discussion

3.1. Ligand characterisation

Although $Zn_3(HL)_2(OAc)_4$ has been prepared from a methanol solution of the non isolated H_2L, this was additionally isolated as a solid, with the aim of showing some characterisation data that proved its previous formation. Elemental analysis, IR, mass and ^{1}H NMR spectroscopies evidence the identity of the ligand.

The IR spectrum of H_2L exhibits an intense band assignable to ν(C=N) that clearly indicates the aldehyde–amine condensation. The observation of a high intensity peak attributable to the molecular ion M^+ at 217.1 *m/z* in the ESI$^+$-TOF spectrum of free H_2L supports this previous statement. The presence of the expected signals for azomethine, aromatic and methylene protons [5,6b] in the spectrum of H_2L evidence the formation of the Schiff base ligand.

3.2. Molecular structure of $Zn_3(HL)_2(OAc)_4$

The asymmetric unit of $Zn_3(HL)_2(OAc)_4$ only contains a half molecule of the complex, since the other half is generated by means of an inversion around the centre located on the origin of the cell unit, and on which the central atom of the complex (Zn2) is located. This symmetry operation ($-x$, $-y$, $-z$) is indicated in the labelling scheme of Fig. 1 by $^{\#1}$, on the atoms generated by this inversion. The symmetry of the linear trinuclear complex is also shown by the coplanarity of each pair of equivalent ligands around the metal centres. Some significant bond distances and angles have been listed in Table 2.

Observation of the Zn–N bond distances shows that Zn1–N2 is sensibly longer than Zn1–N1. Since the first one exceeds the sum of the covalent radii of Zn and N atoms (1.330 and 0.700 Å, respectively) in more than 0.4 Å, the interactions between the imine N atoms and the two terminal zinc ions have been considered as secondary rather than proper coordination interactions. This is also supported by the slight differences observed for angles and bond distances affecting the azomethine group, when they are compared with those reported for some free Schiff base ligands [11]. For that reason, the terminal metal ions, Zn1 and Zn1$^{\#1}$, display O_3N coordinative environments can be considered in a distorted tetrahedral fashion. Each one involves the bidentate *O,N* site of the monodeprotonated hydroxyquinoline residue present in HL^-, and one of the O atoms of each pair of μ_2–η^1:η^1 bridging acetate ligands that connect both Zn1 and Zn1$^{\#1}$ with Zn2. The distortion of these tetrahedral coordination polyhedrons is intimately related with the secondary Zn–N_{imine} interaction mentioned.

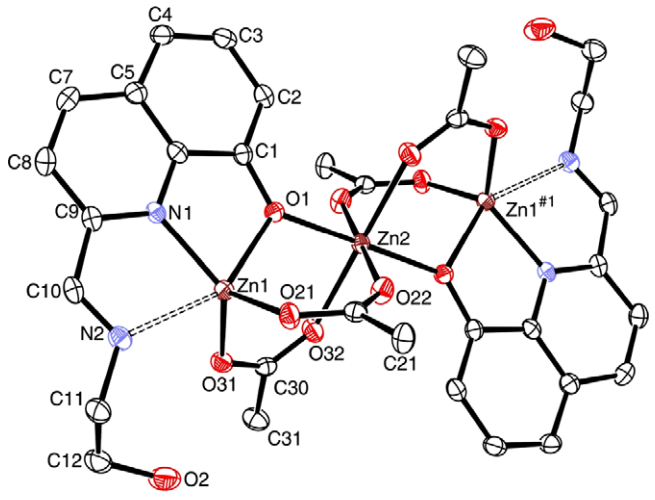

Fig. 1. An ORTEP view of the molecular structure of $Zn_3(HL)_2(OAc)_4$. Ellipsoids are drawn at 50% probability. Secondary interactions are represented as dotted lines. Hydrogen atoms were omitted for clarity.

Table 2
Selected geometric parameters for $Zn_3(HL)_2(OAc)_4$.

Atoms	Distance (Å)	Atoms	Distance (Å)
Zn1–O21	1.9354(15)	Zn2–O1	2.0160(14)
Zn1–O31	1.9655(15)	Zn2–O22	2.1343(15)

O1–Zn1–N1	78.15(6)	O22–Zn2–O32$^{\#1}$	90.86(6)
N1–Zn1–N2	72.90(6)		

$^{\#1}$Atoms generated by the symmetry operation $-x$, $-y$, $-z$.

Respect to the central zinc(II) ion, this is in an O_6 coordinative environment that comprises four oxygen atoms (one from each bridging acetate group) and two phenoxo bridges (one from each Schiff base ligand) with a quasi-octahedral disposition. This could be understood as the four O atoms of the acetate bridges forming the equatorial plane, while the two capping phenoxo bridges show a *trans*-configuration, with a slight elongation.

Comparison of $Zn_3(HL)_2(OAc)_4$ with other linear trinuclear zinc complexes bridged by carboxylate (and phenolate) oxygen atoms, allows observing some trends in the formation of this type of trinuclear assembly. Thus, their central Zn^{II} ion displays quasi-octahedral O_6 coordination polyhedra related with the carboxylate (and phenolate) groups. Likewise, on one hand, the obtaining of bis(carboxylate) complexes of the type $Zn_3(L)_2(carboxylate)_2$ has been reported with several dianionic tetradentate ligands containing phenolate groups [12]. On the other hand, examples of linear trinuclear zinc complexes containing endogenous ligands with a lower denticity are much less common. In this latter case, either neutral monodentate ligands as quinoline, or bidentate ligands as bipy or phen, yielded *hexakis*(carboxylate) complexes of the type $Zn_3(L)_2(carboxylate)_6$ [13]. To the best of our knowledge, one complex of the type $Zn_3(L)_2(carboxylate)_4$ has been reported for a monoanionic tridentate Schiff base [14], which in that case shows a real coordination through the imine N atom. Therefore, the coordinative behaviour of HL^- in $Zn_3(HL)_2(OAc)_4$ means a novelty. Regarding to the values of Zn–O and Zn···Zn distances; they do not seem to merit further comment, since they appear in normal ranges.

Apart from the clear intramolecular interactions between the two hydroxyl groups of the 2-aminoethanol residues and one of the O atoms of the acetate ligands (O2–H2···O31, Fig. 1), no intermolecular hydrogen bonds were detected. In view of this, the significant π–π interactions, with inter-planar distances of about 3.3 Å (Fig. 2) appear to play a crucial role in the crystal packing scheme. This is facilitated by the extended planarity resulting of the conjugation of the imine groups with the 8-hydroxyquinoline residues, being both π systems coplanar in the molecule. Likewise,

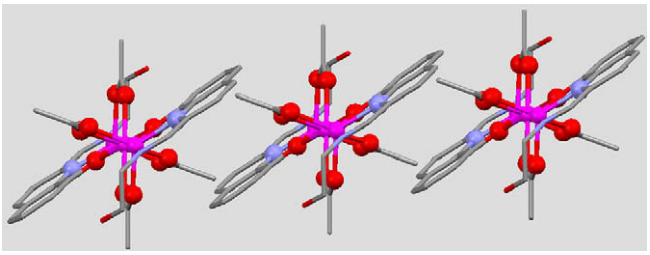

Fig. 2. Balls and sticks diagram showing the π–π stacking of neighbouring $Zn_3(HL)_2(OAc)_4$ molecules, and the coplanarity of the ligands (grey: C; red: O; blue: N, and fuchsia: Zn). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

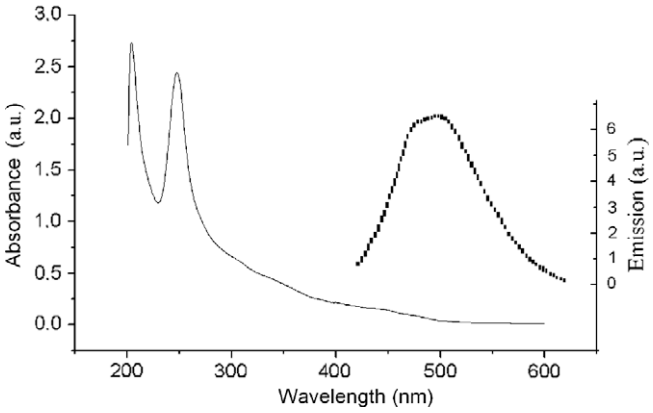

Fig. 3. UV–Vis absorption (left) and emission (right) spectra of H_2L in MeOH solution (10^{-3} M).

significant C–H···O interactions between methyl and carboxylic groups of neighbouring acetate ligands contribute to the crystal packing.

3.3. Physicochemical characterisation of the compounds

The presence of two intense absorption bands at 202 and 248 nm (Fig. 3), and which are also present in the spectrum of 8-hydroxyquinoline-2-carboxaldehyde, is a characteristic spectral feature of free H_2L.

The photoluminescence spectrum of H_2L (Fig. 3) displays a low intensity band at about 500 nm, by excitation of the solution at 398 nm. The formation of the Schiff base ligand results in a red-shift of the fluorescence wavelength, when this is compared with that of 8-hydroxyquinoline-2-carboxaldehyde (see below). This fact may be related to the increase of the conjugation that provides the imine bond to the ligand arm [15].

The IR spectrum of $Zn_3(HL)_2(OAc)_4$ exhibits two intense bands assignable to $\nu_a(COO)$ and $\nu_s(COO)$ that support the presence of coordinated acetate groups. The Δ value $[\nu_a(COO) - \nu_s(COO)]$ of about 170 cm^{-1}, which is close to those reported for other acetate bridged zinc complexes [16], indicates a bidentate bridging behaviour of the acetate ligand.

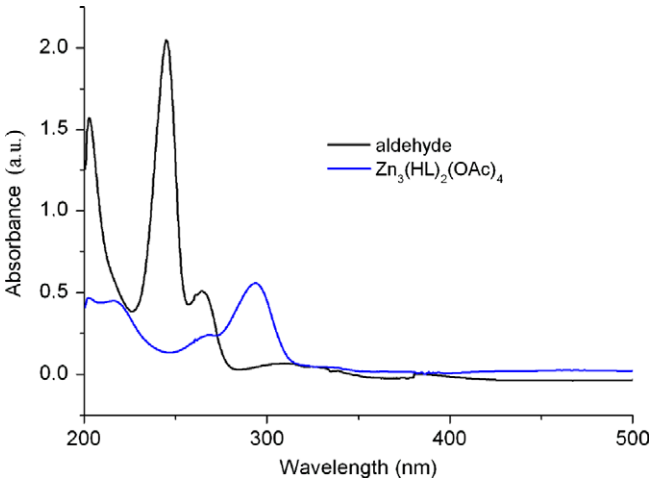

Fig. 4. UV–Vis absorption spectra (in MeOH, 10^{-5} M) of 8-hydroxyquinoline-2-carboxaldehyde and $Zn_3(HL)_2(OAc)_4$.

$Zn_3(HL)_2(OAc)_4$ presents a signal near to 1.8 ppm in its ^1H NMR spectrum, in agreement with the coordination of the acetate ligand to the metal centres. The presence of a signal near to 8.7 ppm, which is attributable to the azomethine proton *H*CN, indicates the coordination of the Schiff base ligand.

3.4. Photophysical study of $Zn_3(HL)_2(OAc)_4$

The UV–Vis absorption spectra, and the photoluminescence spectra of $Zn_3(HL)_2(OAc)_4$, as well of 8-hydroxyquinoline-2-carboxaldehyde were measured at room temperature in dilute methanol solutions. Table 3 summarises the main data obtained from these studies.

The absorption bands of $Zn_3(HL)_2(OAc)_4$ (in the range 200–350 nm) may be attributed to n–π^* and π–π^* intraligand transitions, involving the π-system of the quinoline residue, in addition to MLCT transitions [17–22]. The pronounced changes in the absorption spectrum of the aldehyde as result of the formation of the Schiff base ligand H_2L and its metal complexation are shown in Fig. 4. The presence of two new intense absorption bands at 216 and 294 nm, which have been related to the metal–ligand interaction, is a characteristic spectral feature of $Zn_3(HL)_2(OAc)_4$.

The photoluminescence emission maxima of the aldehyde and the zinc complex, which emit at the same wavelength (402 nm) are shown in Fig. 5. The quantum yield of $Zn_3(HL)_2(OAc)_4$ ($\Phi_F = 0.07$) is slightly higher than that of 8-hydroxyquinoline-2-carboxaldehyde ($\Phi_F = 0.06$). Since d^{10} metal ions are unable to participate in low energy charge transfer, or in metal-centred transitions, the excited states resulting from $Zn_3(HL)_2(OAc)_4$ is typically ligand-centred in nature [23]. Hence, the emission is believed to arise from an excited state centred on the ligand.

Emission from a predominantly ligand-based excited state should give a large Stokes shift between the MLCT absorption and the emission band [24]. $Zn_3(HL)_2(OAc)_4$ exhibits not very large Stokes shift (70 nm), while the 8-hydroxyquinoline-2-carboxaldehyde shows a larger shift (92 nm). This seems to indicate that the emission observed for $Zn_3(HL)_2(OAc)_4$ could be predominately caused by a ligand-based excited state, rather than by a MLCT state.

Table 3
Photophysical data for 8-hydroxyquinoline-2-carboxaldehyde and $Zn_3(HL)_2(OAc)_4$.

Compound	Absorption (λ_{max}/nm) (ε/mmol^{-1} cm^2)	Excitation (λ_{exc}/nm)	Emission (λ_{max}/nm)
Aldehyde	203(157200), 245(204900), 265(50900), 310(6500)	310	402
$Zn_3(HL)_2(AcO)_4$	202(46700), 216(45000), 268(24000), 294(55800), 332(4600), 472(2400)	332	402

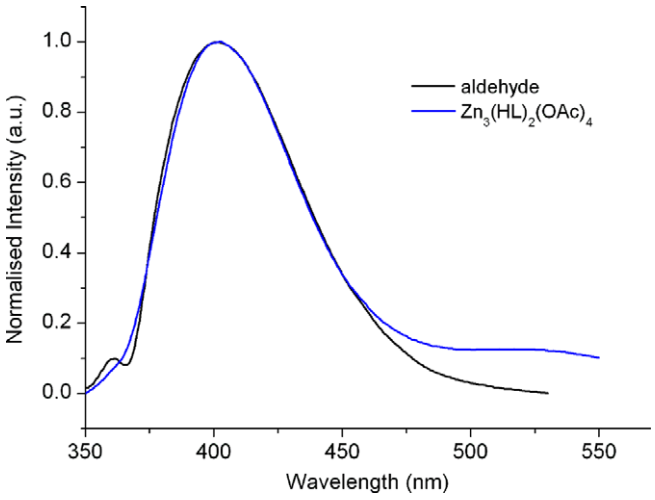

Fig. 5. Emission spectra (in MeOH, 10^{-4} M) of 8-hydroxyquinoline-2-carboxaldehyde (λ_{exc} = 310 nm) and $Zn_3(HL)_2(OAc)_4$ (λ_{exc} = 332 nm).

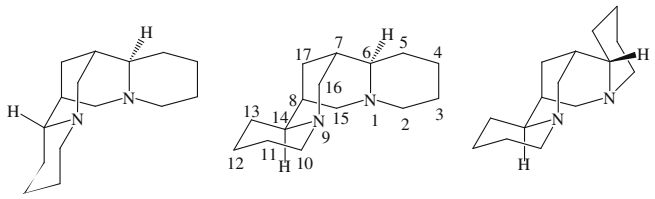
4. Conclusions

H_2L offers an *N,O* chelating site related to the 8-hydroxyquinoline residue, to which the conjugated imine *N* atom can join to act as a planar tridentate unit. Even in very mild reaction conditions, the acidity of the phenoxyl H atom leads to H_2L to act as monoanionic. Its interaction with zinc(II) acetate leads to the obtaining of $Zn_3(HL)_2(OAc)_4$ using both 3:2 and 4:2 $Zn(AcO)_2$:H_2L molar ratios.

The presence of the uncoordinated hydroxyl groups corresponding to the 2-aminoethanol residues allows the formation of hydrogen bonds that participate in the packing scheme of $Zn_3(HL)_2(OAc)_4$, via intra- or intermolecular interactions. The conjugation of the imine group with the 8-hydroxyquinoline residue facilitates an extended planarity that is responsible for some significant π–π interactions in the crystal packing.

The quantum yield of $Zn_3(HL)_2(OAc)_4$ (Φ_F = 0.07) is slightly higher than that of 8-hydroxyquinoline-2-carboxaldehyde (Φ_F = 0.06). The fluorescent emission of $Zn_3(HL)_2(OAc)_4$ is predominately caused by a ligand-based state rather than a MLCT state.

Supplementary data



CCDC 710289 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Three diastereomers of (−)-sparteine.

2. Experimental

2.1. Materials and preparation

All reagents and solvents were obtained commercially either from Fisher Scientific Co. or Aldrich Chemical Co. and were used without further purification, except where noted. Anhydrous ethanol was distilled from calcium hydride and stored under argon. (−)-Sparteine (Sp; $C_{15}H_{26}N_2$) was purchased from Sigma Chemical Company. The (−)-α-isosparteine (α-Sp; α-$C_{15}H_{26}N_2$) was derived from commercially available (−)-sparteine by a method in the literature [25].

2.1.1. Cu(Sp)(NCS)$_2$ (**1**) and Cu(Sp)(N$_3$)$_2$ (**2**)

The precursor copper(II) complex, [Cu(Sp)$(NO_3)_2$], was prepared by mixing an ethanol-triethylorthoformate (5:1 v/v) solution of copper(II) nitrate hemipentahydrate (3.00 g, 12.42 mmol) with a stoichiometric amount of (−)-sparteine at room temperature for 2 h. The resulting blue precipitate was filtered off, washed with triethylorthoformate, and then dried in a vacuum. Complex **1**, [Cu(Sp)$(NCS)_2$], was prepared from the substitution reaction of [Cu(Sp)$(NO_3)_2$] (1.00 g, 2.37 mmol) with a stoichiometric amount of NaNCS in 50 ml ethanol-triethylorthoformate (5:1 v/v) solution. The reddish brown precipitate was filtered off, washed with cold absolute ethanol, and then dried in a vacuum. The yield of the product was 78.5%. Dark reddish brown single crystals were obtained by recrystallization at about 278 K from a dichloromethane–triethylorthoformate (5:1 v/v) solution under carbon tetrachloride vapor. *Anal.* Calc. for $CuC_{17}H_{26}N_4S_2$: C, 49.31; H, 6.33; N, 13.53. Found: C, 49.08; H, 6.35; N, 13.63%. IR (in cm^{-1}, KBr): 2934 (s, ν_s(C–H)), 2856 (s, ν_s(C–H)), 2077 (vs, ν_a(NCS)), 2058 (vs, ν_a(NCS)), 1467 (m, ν_a(C–H)), 1434 (s, ν_a(C–H)), 1304 (s, ν_s(NCS)), 1292 (m, ν_s(NCS)), 432 (w, ν(Cu–N_{Sp})). Complex **2**, [Cu(Sp)$(N_3)_2$], was prepared from the substitution reaction of [Cu(Sp)$(NO_3)_2$] (1.00 g, 2.37 mmol) with a stoichiometric amount of NaN_3 in 50 ml ethanol-triethylorthoformate (5:1 v/v) solution as reported [21]. The yield of the dark yellowish brown precipitate obtained was 85.3%. *Anal.* Calc. for $CuC_{15}H_{26}N_8$: C, 47.17; H, 6.86; N, 29.34. Found: C, 47.83; H, 6.91; N, 29.59%. IR (in cm^{-1}, KBr): 2929 (s, ν_s(C–H)), 2861 (s, ν_s(C–H)), 2048 (vs, $\nu_a(N_3)$), 2058 (vs, $\nu_a(N_3)$), 1466 (m, ν_a(C–H)), 1447 (s, ν_a(C–H)), 1283 (s, $\nu_s(N_3)$), 468 (w, ν(Cu–N_{Sp})).

2.1.2. Cu(α-Sp)(NCS)$_2$ (**3**) and Cu(α-Sp)(N$_3$)$_2$ (**4**)

The precursor copper(II) complex, [Cu(α-Sp)$(NO_3)_2$], was prepared in a glove box by mixing an ethanol-triethylorthoformate (5:1 v/v) solution of copper(II) nitrate hemipentahydrate (1.20 g, 5.16 mmol) with a stoichiometric amount of (−)-α-isosparteine. The resulting blue precipitate was filtered off, washed with triethylorthoformate, and then dried in a vacuum. Complex **3**, [Cu(α-Sp)$(NCS)_2$], was prepared from the substitution reaction of [Cu(α-Sp)$(NO_3)_2$] (1.00 g, 2.37 mmol) with a stoichiometric amount of NaNCS in 60 ml ethanol-triethylorthoformate (5:1 v/v) solution. The reddish brown precipitate was filtered off, washed with cold absolute ethanol, and then dried in a vacuum. The yield of the product was 79.6%. Dark reddish brown single crystals were obtained by recrystallization at about 278 K from a dichloromethane–triethylorthoformate (5:1 v/v) solution under carbon tetrachloride vapor. *Anal.* Calc. for $CuC_{17}H_{26}N_4S_2$: C, 49.31; H, 6.33; N, 13.53. Found: C, 49.01; H, 6.42; N, 13.39%. Complex **4**, [Cu(α-Sp)$(N_3)_2$], was prepared from the substitution reaction of [Cu(α-Sp)$(NO_3)_2$] (1.00 g, 2.37 mmol) with a stoichiometric amount of NaN_3 in 50 ml ethanol-triethylorthoformate (5:1 v/v) solution as reported [22]. The yield of the dark yellowish brown precipitate obtained was 77.4%. *Anal.* Calc. for $CuC_{15}H_{26}N_8$: C, 47.17; H, 6.86; N, 29.34. Found: C, 47.47; H, 6.89; N, 29.67%.

2.2. Physical measurements

Elemental analyses were carried out using a Profile HV-3 Elemental Analyzer System (Germany) at the Korean Basic Science Institute (Busan Branch). Infrared spectra were obtained using standard KBr pellet techniques with a Mattson Polaris FT-IR spectrometer. The resolution was 4 cm^{-1}. X-band (9.44 GHz) ESR spectra were acquired at room temperature and 77 K using a Bruker Instruments ESP-300S ESR spectrometer at the Korean Basic Science Institute (Seoul Branch).

2.3. X-ray crystal structure determination

Crystals of complexes **1** and **3** for X-ray analysis were obtained by slow evaporation from dichloromethane–triethylorthoformate solutions. The dark reddish brown crystals of **1** and **3** were mounted and aligned on a CAD-4 diffractometer [26]. Accurate cell parameters were refined from setting angles of 40 reflections with $4.87^\circ \leqslant \theta \leqslant 12.54^\circ$ for **1** and 51 reflections with $5.20^\circ \leqslant \theta \leqslant 11.99^\circ$ for **3**. 2508 independent reflections for **1** in an asymmetric unit in range $-11 \leqslant h \leqslant 1$, $-1 \leqslant k \leqslant 17$, $-11 \leqslant l \leqslant 11$ and 2717 independent reflections for **3** in an asymmetric unit in range $-1 \leqslant h \leqslant 10$, $-15 \leqslant k \leqslant 1$, $-1 \leqslant l \leqslant 20$ were collected using graphite-monochromated Mo Kα radiation and the $2\theta/\omega$ scan mode.

All non-H atoms were found by direct methods and their parameters were refined successfully with a full matrix least-squares procedure. The function minimized during least-squares refinement was $\omega^{-1} = [\sigma^2(F_o)^2 + (0.0467P)^2 + 1.7583P]$ for **1** and $\omega^{-1} = [\sigma^2(F_o)^2 + (0.0237P)^2]$ for **3**. H atoms were geometrically positioned and fixed. Empirical absorption corrections by using psi-scan for crystals **1** and **3** were applied to the intensity data (T_{max} and T_{min} are 0.9814 and 0.8493 for **1**, and 0.2699 and 0.2370 for **3**, respectively). Data collection and cell refinement: Bruker XSCANS [27]. Data reduction: SHELXTL [28]. Program used to solve and refine the structures: SHELXS97 and SHELXL97 [29]. Molecular graphics: ORTEP-3 for windows [30].

3. Results and discussion

3.1. Characterization of the compounds

Among the three diastereomers of sparteine, (−)-sparteine was commercially available and (−)-α-isosparteine was derived from (−)-sparteine according to the literature method [25]. The copper(II) sparteine pseudohalide complexes, Cu(Sp)$(NCS)_2$ **1**, Cu(Sp)$(N_3)_2$ **2**, Cu(α-Sp)$(NCS)_2$ **3** and Cu(α-Sp)$(N_3)_2$ **4**, were prepared from the substitution reaction of copper(II) sparteine dinitrate complexes with stoichiometric amounts of the corresponding sodium salts (NaNCS and NaN_3) in ethanol solution. Characterization of these complexes and the precursor complexes, Cu(Sp)$(NO_3)_2$ and Cu(α-Sp)$(NO_3)_2$, was conducted by IR spectros-

copy and elemental analyses (see Section 2). Single crystals of the complexes **1** and **3** were obtained by recrystallization at 278 K from dichloromethane solutions. Although complexes **2** and **4** have already been reported [21,22], these complexes were also prepared in order to compare them with the other CuN_4 type complexes.

3.2. X-ray crystal structure

The pseudo-tetrahedral geometry around the Cu^{II} center of the copper(II) sparteine complexes in the ultimate molecular structure is due to the steric requirements imposed by the bulky sparteine ligand and the influence of the anionic ligand. In order to evaluate the extent of the distortion imposed by the conformation of the sparteine diastereomers and/or by the different anionic ligands, we determined the crystal structures of complexes **1** and **3**. Crystallographic data and structural refinements are summarized in Table 1 and selected bond distances and bond angles are listed in Table 2.

As shown in Figs. 1 and 2, both complexes **1** and **3** contain a copper(II) atom ligated by sparteine (Sp or α-Sp) with two isothiocyanate ligands in the remaining coordination sites, forming a distorted CuN_4 chromophore. The conformation of the coordinated (−)-sparteine in **1** consists of one terminal ring folded down over the copper(II) atom (endo) and the other terminal ring folded back away from the copper(II) atom (exo), whereas that of the coordinated (−)-α-isosparteine in **3** consists of both two terminal rings folded down over the copper(II) atom (endo). These conformations of the sparteine ligands are identical to those of the free ligands, Sp and α-Sp, as already shown in the crystal structures of **2** and **4** [21,22].

The dihedral angles between N_{Sp}–Cu–N_{Sp} and N_{NCS}–Cu–N_{NCS} in **1** and **3** are 58.2(6)° and 52.2(9)°, respectively, which are comparable with those between N_{Sp}–Cu–N_{Sp} and N_{N3}–Cu–N_{N3} [55.3(2)° and 50.2°, respectively] in **2** and **4** [21,22]. These values of the dihedral angles indicate that the steric effect of Sp is larger than that of α-Sp and the dihedral angle of the copper(II) complex with the NCS ligand is larger than that with the N_3 ligand. Therefore, the dihedral angle can be estimated by the steric effect of the sparteine diastereomers together with the crystal field stabilization effect caused by the influence of the anionic ligands (NCS^- and N_3^-) bound terminally to the copper(II) center.

The 'tilt' of the bidentate sparteine ligand with respect to the N_{NCS}–Cu–N_{NCS} plane is another parameter to evaluate the extent of the distortion of the tetrahedron. In **1**, the mid-point of the N1···N9 line does not lie exactly in the N3–Cu–N4 plane, but is tilted towards atom N9 by 0.045 Å (3.2% of half of the N1···N9 distance). Similarly, the mid-point of the N3···N4 line also does not lie exactly in the N1–Cu–N9 plane, but is tilted towards atom N3 by 0.132 Å (8.9% of half of the N3···N4 distance). In the case of **3**, the mid-points are tilted towards atom N9 by 0.086 Å (6.1%) and atom N3 by 0.046 Å (3.2%). On the other hand, in **1** and **3**, the N1–Cu–N3 and N9–Cu–N4 angles differ by only 0.5° and 0.9°, whereas the N1–Cu–N4 and N9–Cu–N3 angles differ by 2.8° and 2.9°, respectively (see Table 2). Therefore, the distortion towards

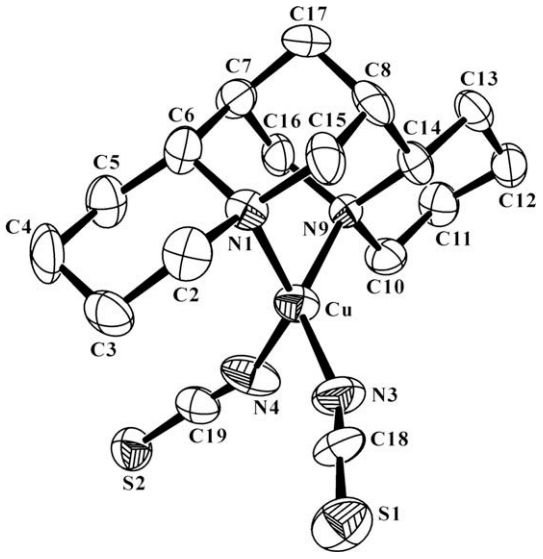

Fig. 1. ORTEP-3 diagram of complex **1** showing the atom numbering scheme and 30% probability ellipsoids. H atoms have been omitted for clarity.

The 'tilt' of the bidentate sparteine ligand with respect to the N_{NCS}–Cu–N_{NCS} plane is another parameter to evaluate the extent of the distortion of the tetrahedron. In **1**, the mid-point of the N1···N9 line does not lie exactly in the N3–Cu–N4 plane, but is tilted towards atom N9 by 0.045 Å (3.2% of half of the N1···N9 distance). Similarly, the mid-point of the N3···N4 line also does not lie exactly in the N1–Cu–N9 plane, but is tilted towards atom N3 by 0.132 Å (8.9% of half of the N3···N4 distance). In the case of **3**, the mid-points are tilted towards atom N9 by 0.086 Å (6.1%) and atom N3 by 0.046 Å (3.2%). On the other hand, in **1** and **3**, the N1–Cu–N3 and N9–Cu–N4 angles differ by only 0.5° and 0.9°, whereas the N1–Cu–N4 and N9–Cu–N3 angles differ by 2.8° and 2.9°, respectively (see Table 2). Therefore, the distortion towards

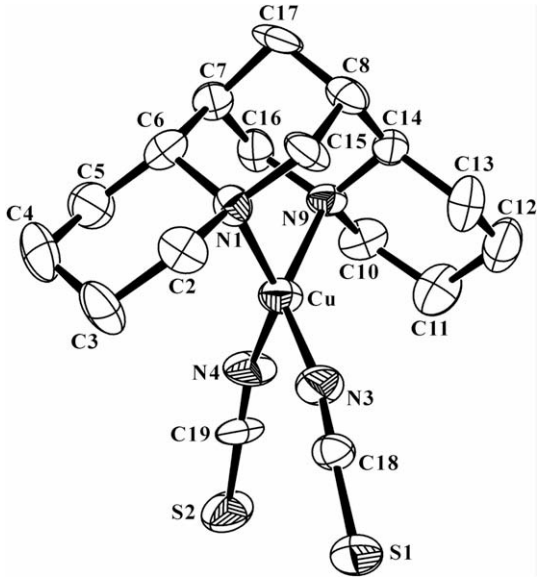

Fig. 2. ORTEP-3 diagram of complex **3** showing the atom numbering scheme and 30% probability ellipsoids. H atoms have been omitted for clarity.

a tetrahedron for both **1** and **3** is quite symmetrically twisted and similar to that for both **2** and **4** [21,22]. The Cu–N_{Sp} distances in **1** are slightly smaller than those in **3**, whereas the Cu–N_{NCS} distances in **1** are similar to those in **3** (see Table 2). This result is in a good agreement with that obtained from copper(II) diazide complexes with Sp and α-Sp, **2** and **4** [21,22].

3.3. Electron spin resonance spectra

X-band electron spin resonance (ESR) spectra of the complexes **1–4** have been recorded in CH_2Cl_2/DMF (1:1 v/v) at 77 K and the electron spin Hamiltonian parameters are summarized in Table 3. As shown in Fig. 3, all ESR spectra exhibit axial symmetry with $g_{||} > g_{\perp} > 2.0023$, indicating that the geometry around the copper(II) center of complexes **1–4** is tetrahedrally distorted and the copper(II) center has a $d_{x^2-y^2}$ ground state. The ESR spectra of **1–4**, which have a $Cu^{II}N_4$ chromophore, showed a relatively small $A_{||}$ value in the range 130–141 $\times 10^{-4}$ cm^{-1}. It is well known that the parallel hyperfine coupling $A_{||}$ value for $CuCl_4^{2-}$ decreases by over 100×10^{-4} cm^{-1} upon distortion from D_{4h} to D_{2d}-distorted tetrahedral [7] and the $A_{||}$ value for square–planar copper(II) complexes having a $Cu^{II}N_4$ chromophore is always greater than 140×10^{-4} cm^{-1} [31,32]. Therefore, the low $A_{||}$ values displayed by complexes **1–4** are caused by the reduction of the site symmetry from D_{4h} to D_{2d} and the ESR spectral results indicate that the coordination geometry and covalency of the metal–ligand binding interaction co-determine the $A_{||}$ values.

A plot of the dihedral angle between the N_{Sp}–Cu–N_{Sp} and N_L–Cu–N_L (L = NCS^- and N_3^-) planes versus the parallel hyperfine coupling $A_{||}$ value for **1–4** is shown in Fig. 4. A good correlation between the dihedral angle in the X-ray structure and the $A_{||}$ value in the ESR spectra was observed. As the dihedral angle between N_{Sp}–Cu–N_{Sp} and N_L–Cu–N_L increases, the parallel hyperfine coupling $A_{||}$ value decreases because of the lower coupling between the electron spin and the orbital. The results of X-ray crystallography and ESR spectroscopy are in a good agreement with the assumption that the degree of distortion from planarity to tetrahedron will reduce the $A_{||}$ value of four-coordinate copper(II) complexes if the set of donor atoms are maintained.

Table 3
Spin Hamiltonian parameters for the complexes **1–4** in CH_2Cl_2/DMF (1:1 v/v) at 77 K.

Compound	$g_{||}$	$g_{\perp}$	$A_{||}$ ($\times 10^4$ cm^{-1})
Cu(Sp)$(NCS)_2$ **1**	2.255	2.042	130.3
Cu(Sp)$(N_3)_2$ **2**	2.230	2.027	135.1
Cu(α-Sp)$(NCS)_2$ **3**	2.283	2.061	139.2
Cu(α-Sp)$(N_3)_2$ **4**	2.267	2.075	141.3

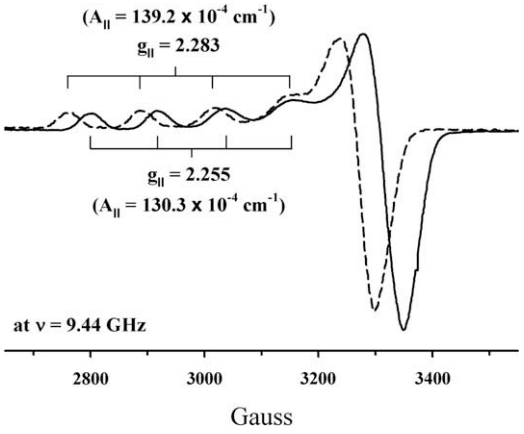

Fig. 3. X-band ESR spectra of the complexes **1** (solid line) and **3** (dashed line) in CH_2Cl_2/DMF (1:1 v/v) at 77 K.

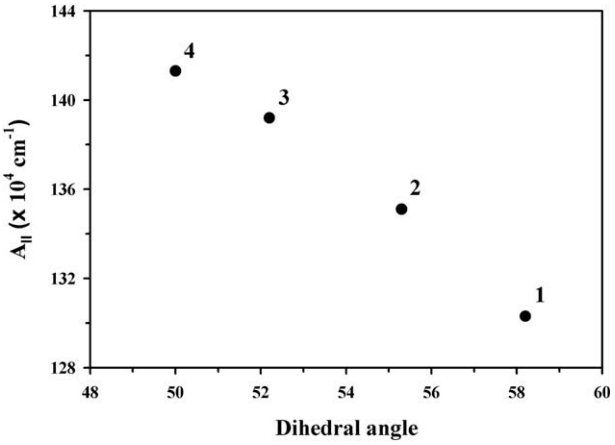

Fig. 4. Plot of the dihedral angle between the N_{Sp}–Cu–N_{Sp} and N_L–Cu–N_L (L = NCS^- and N_3^-) planes vs. the parallel hyperfine coupling $A_{||}$ value for complexes **1–4**.

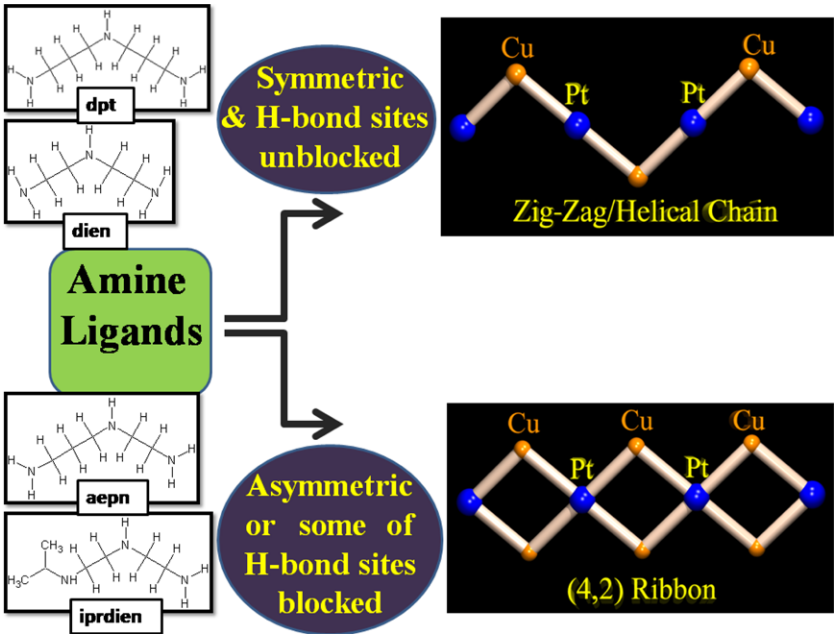
4. Conclusion

The crystal structures of copper(II) isothiocyanate complexes with two sparteine epimers, Sp and α-Sp, were determined and compared with copper(II) azide complexes previously reported [21,22]. The dihedral angle between the N_{Sp}–Cu–N_{Sp} and N_L–Cu–N_L (L = NCS^- and N_3^-) planes increased in the order **1** > **2** > **3** > **4**. As a result, the ESR parallel hyperfine coupling $A_{||}$ value decreased in the order **1** < **2** < **3** < **4** because the electron spin and orbital coupling reduced according to the increase of the degree of distortion from planar to tetrahedral. These results indicate that the steric effect imposed by Sp and NCS^- ligands is larger than that imposed by α-Sp and N_3^- ligands.

Supplementary data

CCDC 726870 and 726871 contain the supplementary crystallographic data for **1** and **3**, respectively. These data can be obtained



free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1.

2. Experimental

2.1. Materials

High purity (98%) *N*-(2-aminoethyl)-1,3-propanediamine (aepn), diethylenetriamine (dien), 3,3′-imino bispropylamine (dpt), N′-isopropyldiethylenetriamine (iprdien) and potassium tetracyanoplatinate(II) were purchased from the Aldrich Chemical Co. Inc. and were used as received. All others chemicals were of AR grade.

2.2. Physical measurements

Elemental analyses (carbon, hydrogen and nitrogen) were performed using a Perkin–Elmer 240C elemental analyzer. IR spectra were measured from KBr pellets on a Nicolet 520 FTIR spectrometer. The magnetic measurements were carried out on polycrystalline samples using a Quantum Design MPMS SQUID magnetometer working in the temperature region 300–2 K. Diamagnetic corrections were estimated from Pascal's table [47].

2.3. Synthesis

2.3.1. $[\{Cu_2(aepn)_2Pt(CN)_42H_2O\}\cdot 2(H_2O)\cdot\{Pt(CN)_4\}]_n$ (**1**)

N-(2-aminoethyl)-1,3-propanediamine (aepn) (2 mmol, 0.234 g) was added dropwise to an aqueous solution (10 cm^3) of $Cu(ClO_4)_2\cdot 6H_2O$ (2 mmol, 0.741 g) with constant stirring for a few minutes. To the resulting deep blue solution, an aqueous solution (10 cm^3) of $K_2[Pt(CN)_4]\cdot 2H_2O$ (2 mmol, 0.754 g) was added slowly and the reaction mixture was stirred for 1 h and then filtered and the filtrate was kept in a $CaCl_2$ desiccator. Shiny deep blue single crystals suitable for X-ray analysis were obtained after a few days. Yield 65%. *Anal.* Calc. for $C_{18}H_{38}Cu_2N_{14}O_4Pt_2$ (**1**): C, 20.95; H, 3.71; N, 19.00. Found: C, 20.75; H, 3.64; N, 19.16%. IR spectra (KBr disk; cm^{-1}) 3300–3500 [ν(O–H)]; 3200–3400 [ν(N–H)]; 2141 [ν(C–N)].

2.3.2. $[\{Cu(dpt)Pt(CN)_4\}]_n$ (**2**)

Complex **2** was synthesized by the same procedure adopted for **1** using 3,3′-imino bispropylamine (dpt), (2 mmol, 0.262 g) instead of aepn. Yield 70%. *Anal.* Calc. for $C_{10}H_{17}CuN_7Pt$ (**2**): C, 24.29; H, 3.44; N, 19.84. Found: C, 24.25; H, 3.41; N, 19.82%. IR (KBr disk; cm^{-1}) 3200–3400 [ν(N–H)]; 2138 [ν(C–N)].

2.3.3. $[\{Cu(dien)Pt(CN)_4\}]_n$ (**3**)

Complex **3** was synthesized by the same procedure adopted for **1** using diethylenetriamine (dien) (2 mmol, 0.206 g) instead of aepn. Yield 70%. *Anal.* Calc. for $C_8H_{13}CuN_7Pt$ (**3**): C, 20.61; H, 2.79; N, 21.04. Found: C, 20.59; H, 2.76; N, 21.01%. IR (KBr disk; cm^{-1}) 3200–3400 [ν(N–H)]; 2155 [ν(C–N)].

2.3.4. $[\{Cu_2(iprdien)_2Pt(CN)_4\}\cdot 2(ClO_4)\cdot 2(H_2O)]_n$ (**4**)

Complex **4** was synthesized by the same procedure adopted for **1** using N′-isopropyldiethylenetriamine (iprdien) (2 mmol, 0.284 g) instead of aepn. Yield 70%. *Anal.* Calc. for $C_{18}H_{32}Cu_2N_{10}PtCl_2O_8$ (**4**) C, 23.65; H, 3.82; N, 15.14. Found: C, 23.75; H, 3.52; N, 15.39%. IR (KBr disk; cm^{-1}) 3200–3400 [ν(N–H)]; 2190, 2181, 2140 [ν(C–N)].

2.4. Crystallographic data collection and refinement

Diffraction data collection of all four complexes was carried out on a Bruker SMART diffractometer, equipped with a graphite monochromator and Mo Kα radiation (λ = 0.71073 Å). The data integration and reduction were processed with SAINT [48] software. An empirical absorption correction was applied to the collected reflections with SADABS [49] using XPREP [50]. The structures were solved by the Patterson method. Metal atoms in all four complexes were located from the *E*-maps. Other non-hydrogen atoms were located in successive difference Fourier syntheses and refined with anisotropic thermal parameters on F^2. The water hydrogen atoms in **1** were located from the difference Fourier map and refined isotropically but the positions of the hydrogen atoms attached to the carbon atoms were calculated geometrically with a fixed thermal parameter 1.2 times that of their parent atoms. Water hydrogen atoms in **4** could not be located from the difference Fourier map. Crystallographic data and experimental details for the structural analyses are listed in Table 1. Large residual electron densities in **1** and **3** are within 1 Å of the heavy metals (Pt) and are due to a series truncation error having no chemical significance. All calcula-

2.5. Crystal structure descriptions

2.5.1. Crystal structure description of complex *1*

The X-ray crystal structure determination of complex **1** reveals that the Cu(II) centers are bridged by tetracyanoplatinate anions to form a cationic 1D coordination polymer having a (4,2) ribbon-like topology (Scheme 1), with the formula $[Cu_2(aepn)_2Pt(CN)_4 2H_2O]_n^{-}$. The ORTEP diagram showing the (4,2) ribbon of the complex has been depicted in Fig. 1. The polymeric ribbons run along the crystallographic *b*-axis. Charge neutrality of the complex has been satisfied through the incorporation of free tetracyanoplatinate units. These also play vital role in the determination of the supramolecular architecture of the complex by acting as a strong hydrogen bond acceptor. In the formation of the cationic (4,2) ribbon, all CN groups of a $Pt(CN)_4^{2-}$ unit take part in bridging four Cu(II) centers. The coordination bond lengths and angles are given in Table S1. The octahedral environment comprises of three N atoms (N1, N2, N3) of aepn and a cyanide N atom (N4), which form the equatorial plane, and the apical positions are occupied by a N atom (N5) of another cyanide ligand and an O atom (O2w) of a water molecule. The Cu–N(amine) bond distances are in the range 2.009(7)–2.044(8) Å, and match well with this type of Cu(II) complex and are almost comparable to the basal Cu–N4(cyano) bond length of 2.026(8) Å. On the other hand, the apical Cu–N5 distance is 2.288(9) Å. In the bridging $[Pt(CN)_4]^{2-}$ anions, the Pt–C bond distances are 1.983(9) and 2.020(10) Å. In the free $Pt(CN)_4^{2-}$ anions, the Pt–C bond distances are 1.985(9) and 2.009(11) Å.

The assembly created through the hydrogen bonding interaction (Table 2) between the CN groups of free $[Pt(CN)_4]^{2-}$ and the coordinated water/amine is shown in Fig. 2. Each free $[Pt(CN)_4]^{2-}$ interacts with four adjacent Cu(II) centers from each (4,2) ribbon. This leads to a 3D hydrogen bonded supramolecular assembly with

two types of channels along the *b*-axis, where lattice water molecules reside inside a wider rectangular channel (7.2 × 4.3 Å) (Fig. 3). The $R_2^4(16)$ hydrogen bonded motif between free $[Pt(CN)_4]^{2-}$ units and coordinated water molecules lead to the generation of narrower channels (Fig. 3). Within the rectangular channels lattice water molecules stay nearly in the middle and establish

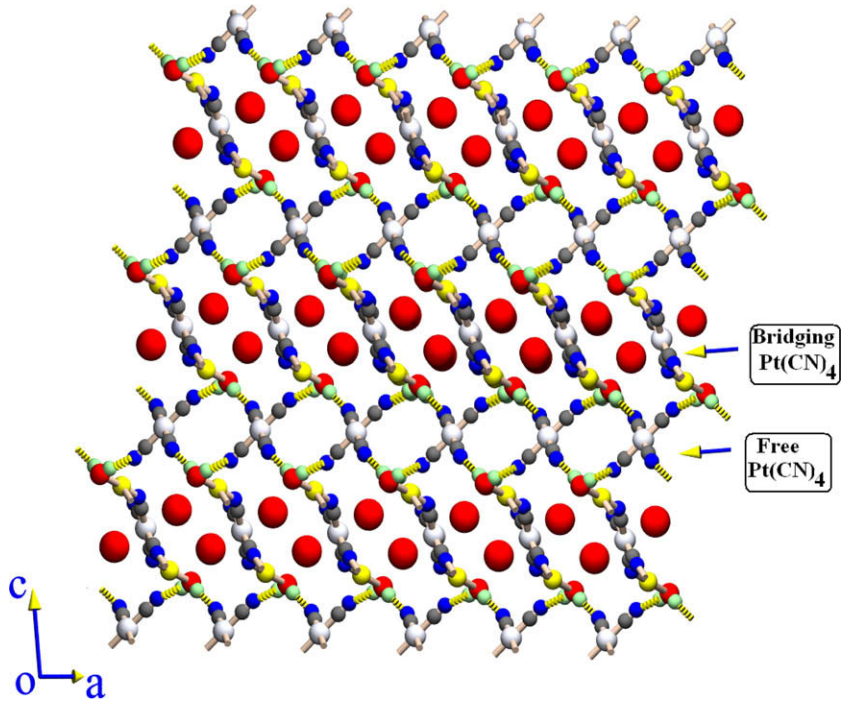

Fig. 3. The supramolecular assembly in complex **1** viewed along the *b*-axis.

contact with the channel wall through the formation of hydrogen bonds with one of the amine terminals (N3) of the chelated triamine. It is of note that the plane of the free $[Pt(CN)_4]^{2-}$ units makes an angle of ~59.4° with the corresponding plane of $[Pt(CN)_4]^{2-}$ units in the ribbon and optimally positions itself to maximize hydrogen bonding interactions.

2.5.2. Crystal structure description of complex ***2***

X-ray crystal structure analysis reveals a neutral helical polymeric chain (formula $[Cu(dpt)Pt(CN)_4]_n$) to be the basic unit of the complex. The ORTEP diagram of the polymeric chain has been depicted in Fig. 4. The coordination bond lengths and angles of the complex are given in Table S2. Three N atoms of the triamine (N2, N3, N4) and one cyanide nitrogen (N1) of a $[Pt(CN)_4]^{2-}$ unit form the basal plane of distorted square pyramidal Cu(II) coordination environment ($\tau = 0.13$). The apical position is occupied by the N6* (* = 1/2−*x*,−1/2 + *y*,1/2−*z*) cyanide nitrogen from an adjacent symmetry related $[Pt(CN)_4]^{2-}$ unit. The Cu atom is located 0.267(1) Å towards the apical N6* above the mean plane formed by basal N1, N2, N3 and N4 atoms, which reflects the degree of distortion of the metal coordination environment. The Cu–N(amine) bond distances in the present complex fall in the range 2.013(6)–2.023(4) Å, and are typical of Cu(II) complexes. The apical Cu–N6* distance is 2.200(5) Å. In the bridging $[Pt(CN)_4]^{2-}$ anions, the Pt–C bond distances are 1.982(5) and 1.992(6) Å. Two nitrogen atoms of $[Pt(CN)_4]^{2-}$, which are *cis* to each other, bridge two Cu(II) centers, one forms the apex of one Cu(II) square pyramid but the other one, together with three amine nitrogens, constitute the

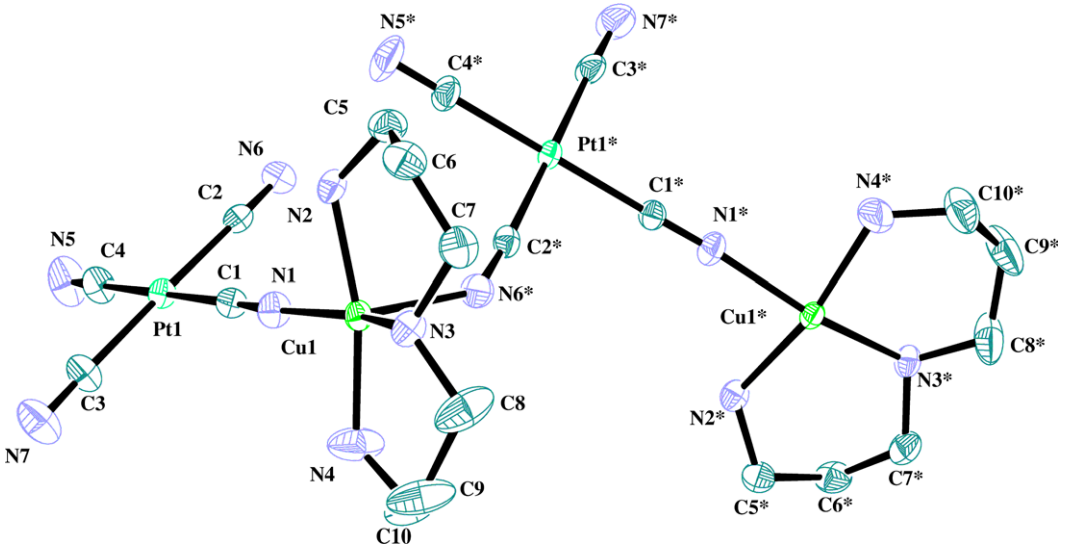

Fig. 4. The ORTEP diagram with 30% ellipsoidal probability of complex **2**.

basal plane of the adjacent Cu(II) square pyramid. This axial to basal bridging by $[Pt(CN)_4]^{2-}$ enforces the rotation of successive Cu(II) square pyramids. The polymeric assembly thus results in a helical 1D chain along the crystallographic *b*-axis (2_1) (Fig. 5). The screw pitch of the helix is equal to the length of the *b*-axis, which is 10.29 Å.

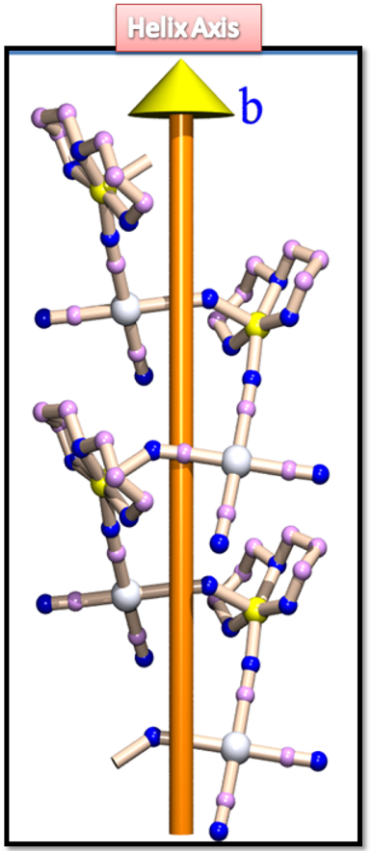

Fig. 5. Helical 1D chain along the crystallographic *b*-axis in complex **2**.

A view of the crystal packing of these helical chains down the helix axis (*b*) is portrayed in Fig. 6. The cross-section of the helix is a parallelogram with Cu(II) square pyramids and square–planar $[Pt(CN)_4]^{2-}$ units occupying diagonally opposite corners of the parallelogram. It is interesting to note that the free CN^- terminals of the $[Pt(CN)_4]^{2-}$ units and amine terminals of the chelated triamine at the Cu(II) centers are all directed away from the central region of the helix and facilitate the maximum number of hydrogen bonding contacts with the adjacent helices. In the hydrogen bonding contacts, the NH terminals of the chelated triamine act as a donor and the free CN^- terminals act as an acceptor. One of the free CN^- groups takes part in bifurcated hydrogen bonding (N3–H3···N7 and N4–H4A···N7) to establish contact with two nearby helices (Table 2).

Interestingly, the N3–H3···N7 interactions leads to a supramolecular sheet in the *ab* plane (Fig. 7), whereas N4–H4A···N7 interactions generates a sheet in the $(1\,0\,\bar{1})$ plane (Fig. 8). Through the other free CN^- terminal, a single N2–H2A···N5 contact is established with another adjacent helix in the $(1\,0\,\bar{1})$ plane (Fig. 9). Considering the existence of four free CN^- terminals at the two diagonally opposite corners of the helix, a total of six hydrogen bonding contacts are established from any helix to six other helices surrounding it. So from a packing viewpoint, hexagonal packing that has maximum packing efficiency is achieved. The maximum packing efficiency is the result of the maximization of the hydrogen bonding using all the available amine donors.

2.5.3. Crystal structure description of complex 3

The ORTEP drawing of the polymeric chain of this complex is shown in Fig. 10. The coordination bond lengths and angles of the complex are given in Table S3. Three N atoms of the triamine (N5, N6, N7) and one cyanide nitrogen (N4) of a $[Pt(CN)_4]^{2-}$ unit form the basal plane of the distorted square pyramidal ($\tau = 0.21$) coordination environment at the Cu(II) centers. The apical position of the square pyramid is occupied by the N1 cyanide nitrogen from an adjacent symmetry related $[Pt(CN)_4]^{2-}$ unit. The Cu atom resides 0.242(1) Å towards the apical N1 above the mean plane formed by the basal N4, N5, N6 and N7 atoms, which reflects the degree of distortion of the metal coordination environment. The Cu–N(amine) bond

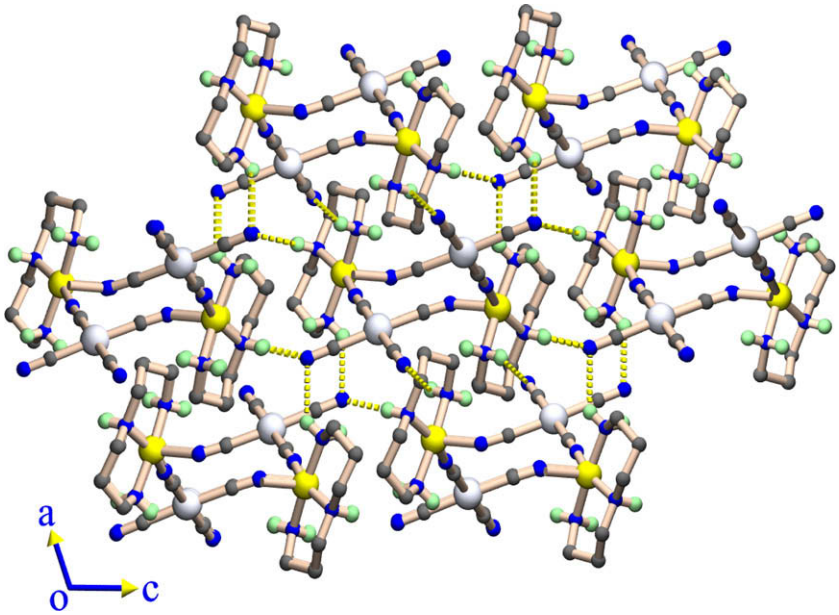

Fig. 6. Crystal packing of the helical chains down the *b*-axis for complex **2**.

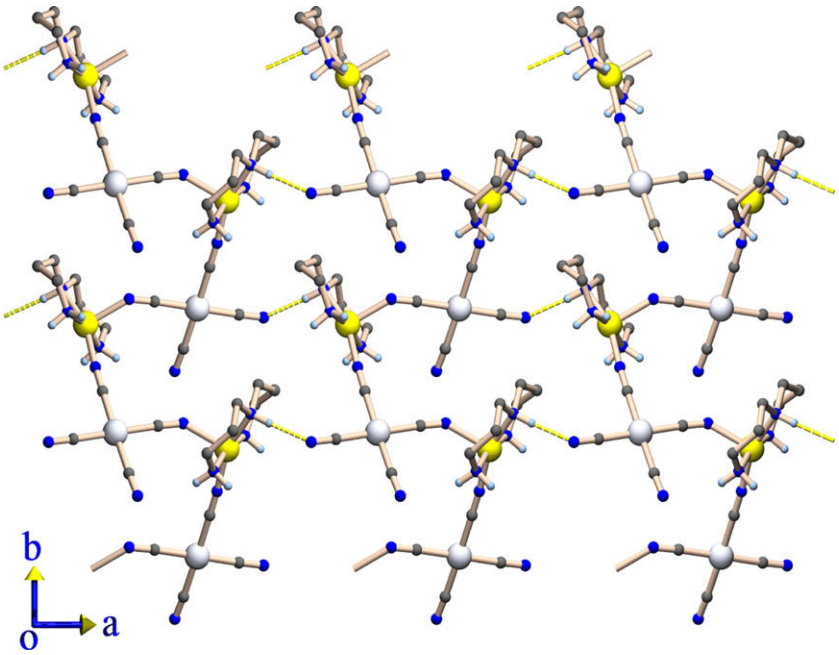

Fig. 7. Arrangement of helices in the *ab* plane through N3–H3···N7 hydrogen bonding in complex **2**.

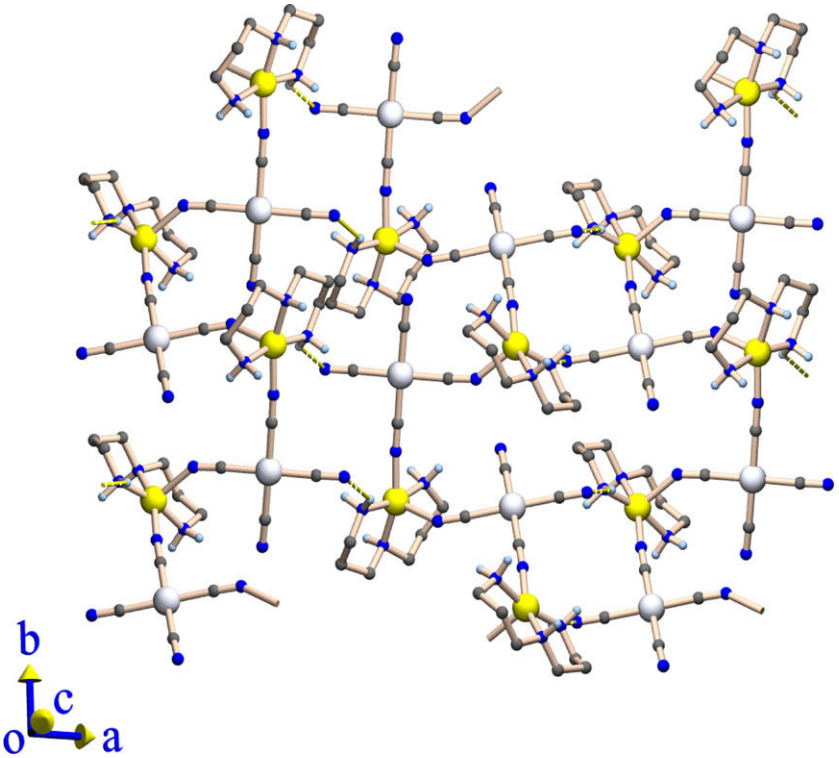

Fig. 8. Arrangement of helices in the $(10\bar{1})$ plane through N4–H4A···N7 hydrogen bonding in complex **2**.

distances in the basal plane vary in the range 1.985(5)–2.025(5) Å, as is usually found in this type of Cu(II) complex. On the other hand, the apical Cu–N5 distance is 2.160(5) Å. In the bridging $[Pt(CN)_4]^{2-}$ anions, the Pt1–C1 bond distance is 1.987(6) Å and Pt2–C4 is 1.995(6) Å.

In contrast to complex **2**, in the present case the *trans* binding mode of the $[Pt(CN)_4]^{2-}$ units enforces a zig-zag arrangement of Cu and Pt centers leading to 1D polymeric chains. Successive apical to apical and basal to basal bridging of Cu(II) square pyramids by $[Pt(CN)_4]^{2-}$ enforces rotation of successive Cu and Pt centers by ~90° and renders a saw-tooth nature of the polymeric chain. Successive Cu(II) and Pt(II) centers are separated by 10.179 and 7.725 Å, respectively.

A 3D supramolecular hydrogen bonded assembly of these zig-zag chains can be easily understood in terms of the formation of two 2D supramolecular sheets. The free ends (N2 and N3) of

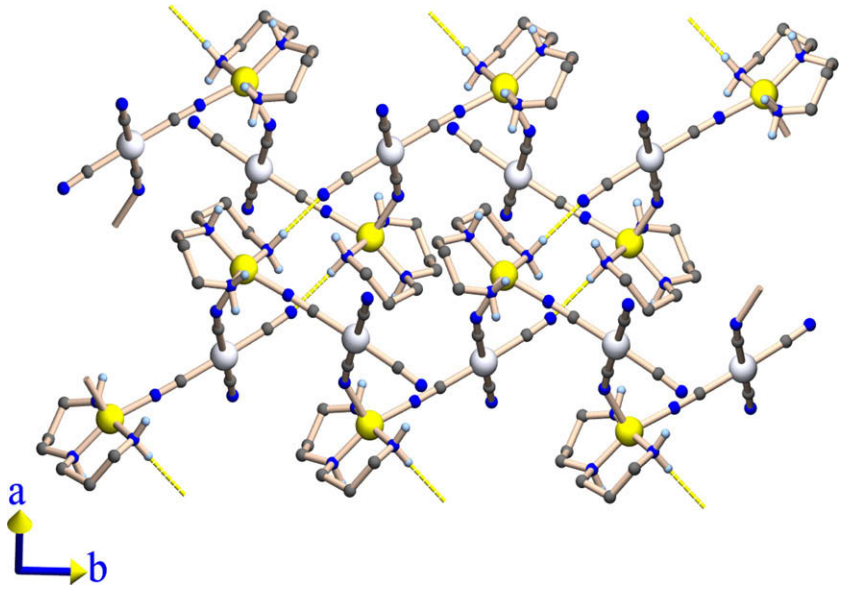

Fig. 9. Arrangement of helices in the $(10\bar{1})$ plane through N2–H2A···N5 hydrogen bonding in complex **2**.

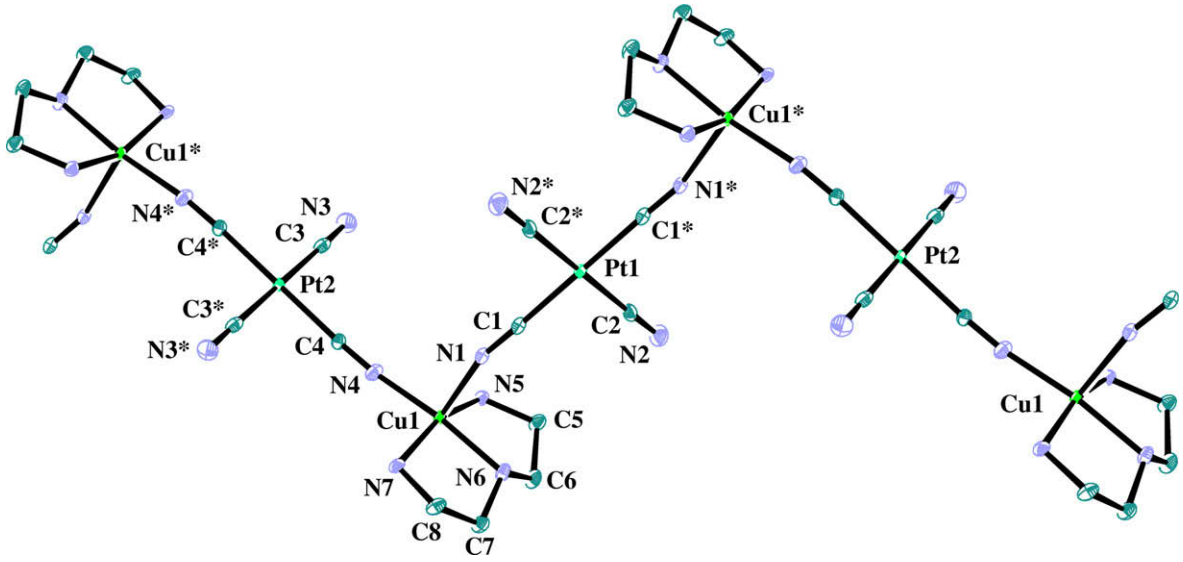

Fig. 10. ORTEP diagram (30% ellipsoidal probability) with the atomic labelling scheme of complex **3**.

$[Pt(CN)_4]^{2-}$ assemble the chains in the bc plane through hydrogen bonding (N7–H7C···N2 and N5–H5C···N3) interactions and in the $(10\bar{1})$ planes through (N6–H6···N2 and N5–H5D···N3) interactions (Fig. 11 and Table 2). Thus arrangement of the sheets to form a 3D supramolecular assembly is through two bifurcated hydrogen bonding interactions of N2 and N3 (Fig. 12). In so doing, the free ends of $[Pt(CN)_4]^{2-}$ prefer a trans mode coordination so that it can exhaust all the amine donors for maximal hydrogen bonding interactions.

*2.5.4. Crystal structure description of complex **4***

An ORTEP drawing showing the (4,2) ribbon of complex **4** is given in Fig. 13. The coordination bond lengths and angles of the complex are given in Table S4. The structure consists of two independent polymeric chains with a (4,2) ribbon-like topology (Fig. 13). These chains are inclined with respect to each other by approximately 46°. In one of the chains (type A), Pt1 through its four CN terminals (N1, N2, N6, N7) bridges successive Cu1 and Cu2 centers whereas in the other chain (type B), Pt2 through its four CN terminals (N11, N12, N16, N17) doubly bridges successive Cu3 and Cu4 centers. Like the previous complexes, the triamine nitrogen atoms and one of the bridging CN nitrogen atoms form the basal plane of the square pyramid ($\tau = 0.18$) and its apical position is occupied by one of the cyanide nitrogen atoms. In the basal plane the Cu–N(amine) bond distances fall in the range 1.941(4)–2.079(5) Å, as is usually found in this type of Cu(II) complex. On the other hand, the apical Cu–N1 distances vary in the range 2.220(3)–2.197(4) Å. The Cu1, Cu2, Cu3 and Cu4 atoms are located 0.311(1), 0.328(1), 0.239(1) and 0.333(1) Å, respectively towards their individual apical N6* ($* = 2-x,-1/2+y,1/2-z$), N1*, N12 and N17 atoms above the mean planes. In the bridging $[Pt(CN)_4]^{2-}$ anions, the Pt–C bond distances vary in the range 1.949(5)–1.987(5) Å.

Two types of (4,2) ribbons are arranged in a herringbone pattern (Fig. 14). Two perchlorate counter-ions play the charge-balancing role and maintain overall neutrality of the complex (Fig. 15 and Table 2). The perchlorates act as hydrogen bonded bridges between successive (4,2) ribbons by acting as acceptors for the amine

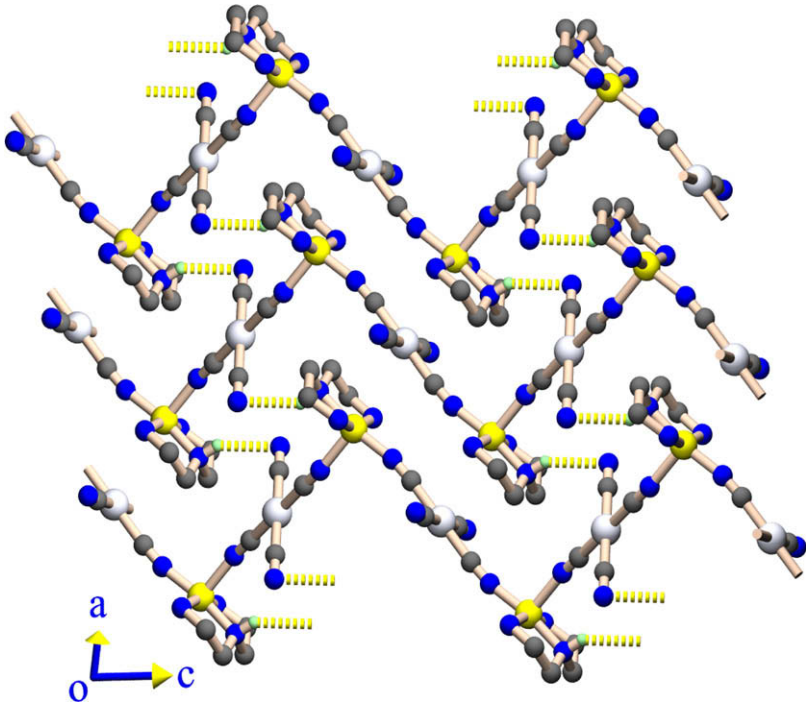

Fig. 11. 2D supramolecular hydrogen bonded sheet of complex **3**.

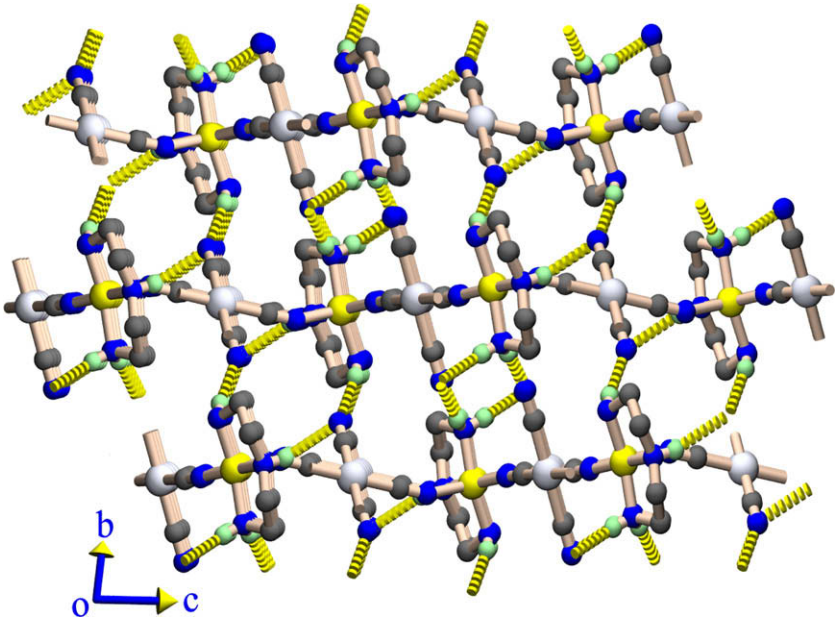

Fig. 12. 3D packing of layers in complex **3**.

hydrogens (Table 2). Lattice water molecules also form hydrogen bonds with the amine groups. It is to be noted that unlike the previous complexes, no hydrogen bonding acceptors from $[Pt(CN)_4]^{2-}$ units are available, instead perchlorate anions take part in the hydrogen bonding.

2.6. Comparative discussion of the structural features

From the above structural discussion, it is interesting to note that we have diverse structural topologies for the same synthetic procedure of $Cu(ClO_4)_2{\cdot}6H_2O$ with aepn/dpt/dien/iprdien. In complex **1**, the Cu(II) centers are chelated by an asymmetric triamine with two carbon atoms and three carbon atoms respectively on either side of the central nitrogen atom. The Cu(II) coordination environment in this case is an octahedral one with a coordinated water molecule forming the apex of the octahedron with a Jahn–Teller elongated $Cu–O_w$ bond. This water molecule plays a vital role in the supramolecular assembly of the complex by acting as a strong hydrogen bond donor.

A closer look into the structure of complex **1** reveals that all the amine terminals of the chelated triamine also act as hydrogen bond donors. To utilize all the hydrogen bonding sites, interestingly free

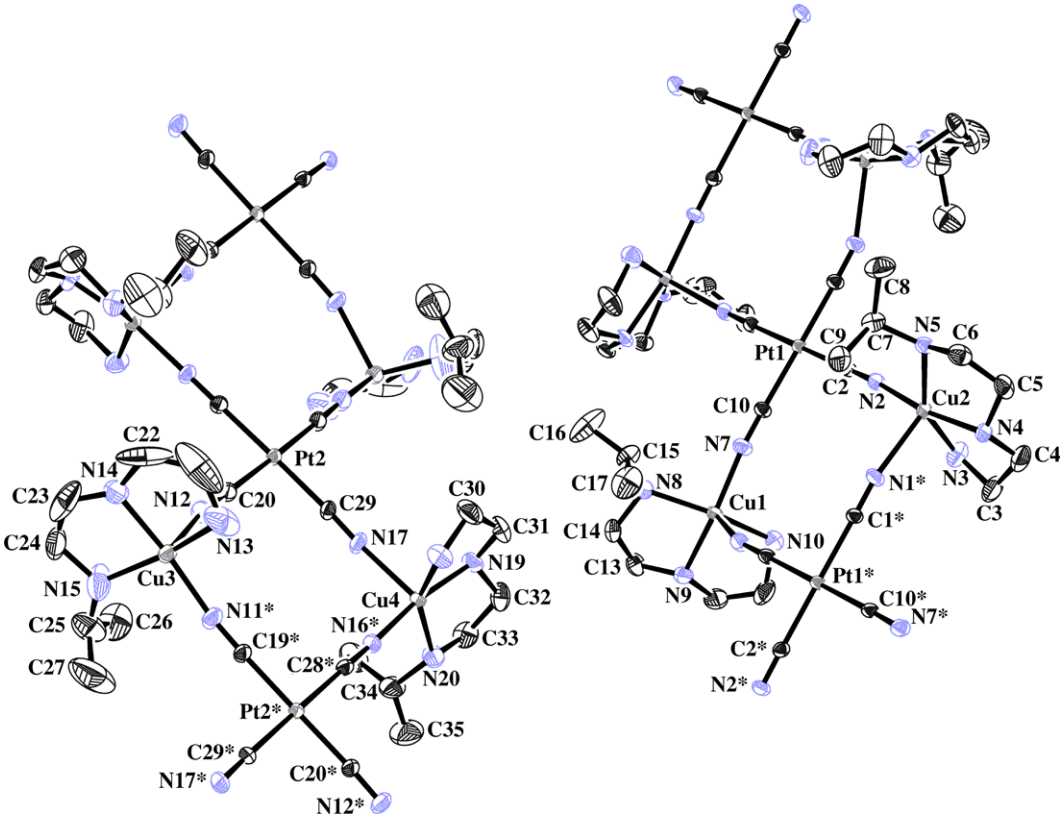

Fig. 13. The ORTEP diagram with 30% ellipsoidal probability of complex **4**.

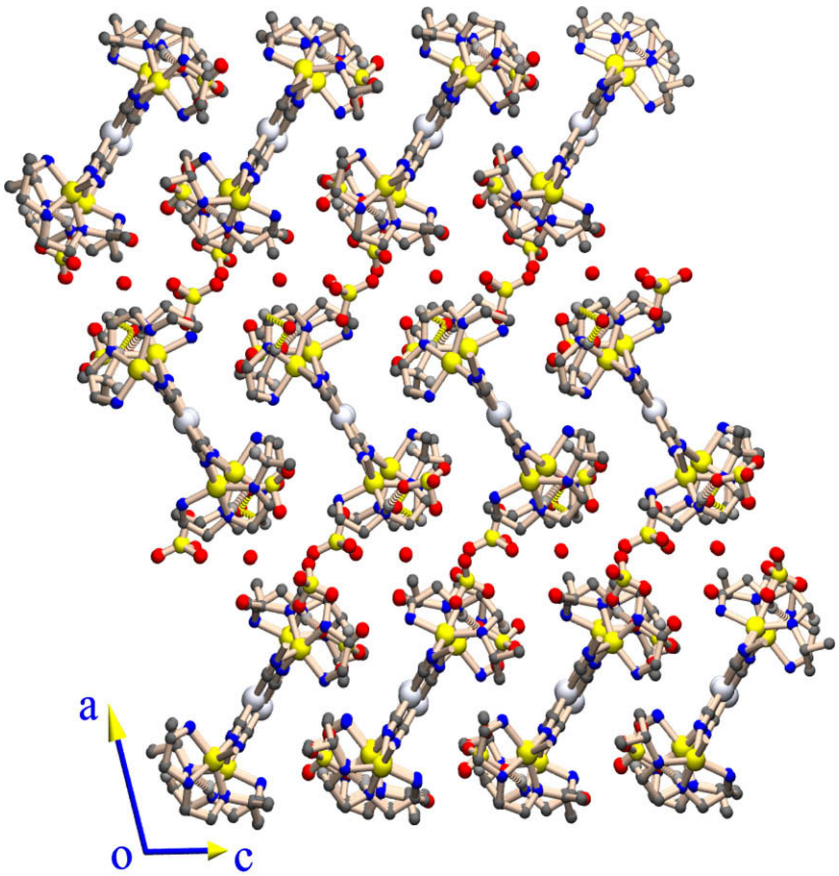

Fig. 14. Herringbone packing of (4,2) ribbons in complex **4**.

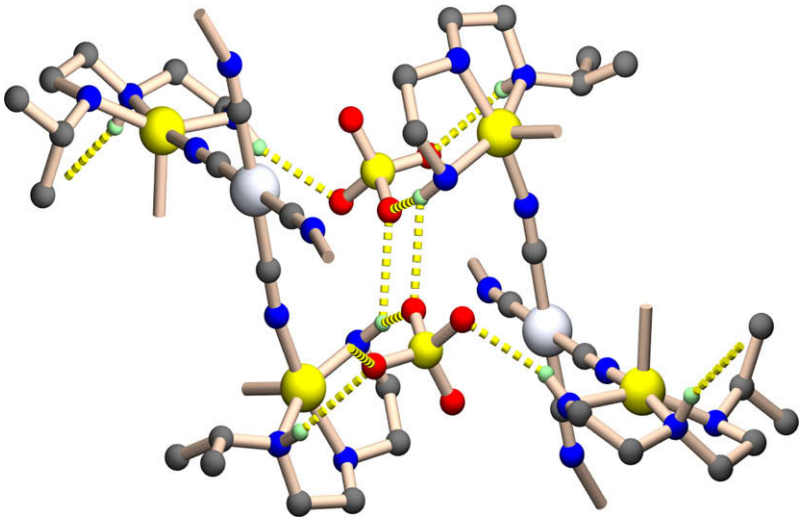

Fig. 15. Hydrogen bonding arrangement of perchlorate anions with the amine groups in complex **4**.

$[Pt(CN)_4]^{2-}$ units take part in the complexation instead of the perchlorate counter-ions, though they are available in solution as a possible charge-balancing and hydrogen bonding agent. This should be due to the preference of strong hydrogen bond donors (coordinated water) for strong hydrogen bond acceptors {$[Pt(CN)_4]^{2-}$ units in this case} instead of perchlorate counter-ions which are relatively weak hydrogen bond acceptors. In the supramolecular network of the complex all the amine sites are maximally utilized in hydrogen bonding. Lattice water molecules participate in hydrogen bonding to stabilize the structure.

In complex **2**, a symmetric triamine with three carbon atoms on both side of the central nitrogen of the triamine chelates the Cu(II) centers. $[Pt(CN)_4]^{2-}$ units in this case bridge in a cis mode and establish apical to basal contacts between successive Cu(II) square pyramidal coordination units, leading to a helical 1D neutral polymeric chain.

In complex **3**, a symmetric triamine has also been used but it forms a smaller chelate ring around the Cu(II) centers with two carbon atoms on either side of the middle nitrogen. In this case $[Pt(CN)_4]^{2-}$ units bridge in a trans mode and establish successive apical to apical and basal to basal contacts between successive Cu(II) square pyramidal coordination units, leading to a symmetric zig-zag 1D neutral polymeric chain.

A careful look into the supramolecular assembly in these two complexes (**2** and **3**) reveals that in both cases all three amine terminals of the triamines have been used to establish hydrogen bonding contacts with the free CN terminals of the bridging $[Pt(CN)_4]^{2-}$ units. In the case of complex **3**, due to the small size of the chelate ring both intra-chain and inter-chain hydrogen bonding has become possible, leading to the establishment of maximum number of hydrogen bonding contacts. On the other hand in the case of complex **2**, the larger chelate ring size due to the presence of six carbon atoms on the triamine would have prohibited intra-chain hydrogen bonding if the assembly of the chains was in a similar trans bridging mode as that of complex **3**, and so to maximize the utilization of all the amine terminals for hydrogen bonding the *cis* mode bridging into helical turning of the chains is preferred so that hydrogen bonding contacts with the maximum number of adjacent chains could be established.

In summary, the supramolecular structures of the complexes reveal the following features: (a) Asymmetric ligand; complex **1** possesses four donor sites. $[Pt(CN)_4]^{2-}$ plays a dual role, a linker forming a (4,2) ribbon and a free anion forming a supramolecular network. (b) Symmetric ligand; complex **2** possesses three donor sites. $[Pt(CN)_4]^{2-}$ prefers only two coordinations. (c) Symmetric ligand; complex **3** possesses the same number of donor sites. $[Pt(CN)_4]^{2-}$ prefers only two coordinations, keeping two ends free. (d) Thus decrease in the number of donor sites increases the possibility of coordination and vice versa. (e) The chain length determines a *cis* or *trans* mode.

These observations have led us to carry out further experimentation by blocking one of the possible hydrogen bonding sites of the triamine with a substitution made on that site and with this we make the ligand asymmetric. So a triamine with one of the amine terminals bearing a bulky isopropyl group is used in case of complex **4**. A bi-bridged (4,2) ribbon-like polymeric chain appeared. A perchlorate counter-ion balances the charge. In this case the unavailability of the amine terminals for supramolecular assembly is the driving force behind the appearance of bi-bridged chains so that all the nitrogen atoms of $[Pt(CN)_4]^{2-}$ prefer coordinative bonding to the Cu(II) center. Due to the lack of strong donors, the weak ClO_4^- acceptor appears to play a role in the structure. From complexes **1** and **4**, we observe again the old rule that strong donors prefer strong acceptors while weak donors prefer weak acceptors.

The observations motivated us to propose an empirical rule: (a) if the maximum hydrogen bonding sites are available for symmetric amine ligands through the use of all the amine terminals, one gets a singly bridged chain, (b) if hydrogen bonding sites are blocked for asymmetric amine ligands, one gets a doubly bridged (4,2) ribbon.

2.7. Magnetic properties of the complexes

The magnetic properties of complexes **1–4** as $\chi_M T$ versus T plots (χ_M is the molar magnetic susceptibility for one or two Cu(II) ions) are shown in Fig. 16 [for **1**] and Figs. S1–S3 [for **2**–**4**]. As expected, the magnetic overlap is negligibly small through the diamagnetic $[Pt(CN)_4]^{2-}$ pathway. Table S5 gives the main important crystallographic data from a magnetic point of view, together to the best-fit J and g values. In all cases, the short–short magnetic pathway for distorted square pyramidal Cu (II) ions has only been considered for doing the fit. For this reason compounds **1**, **2**, **3** and **4** were fit as dinuclear applying the typical Bleaney–Bower formula. Starting from room temperature, the $\chi_M T$ values are practically constant to 50 K, below this temperature to 2 K, they quickly decrease. This feature is characteristic of a very weak antiferromagnetic interaction.

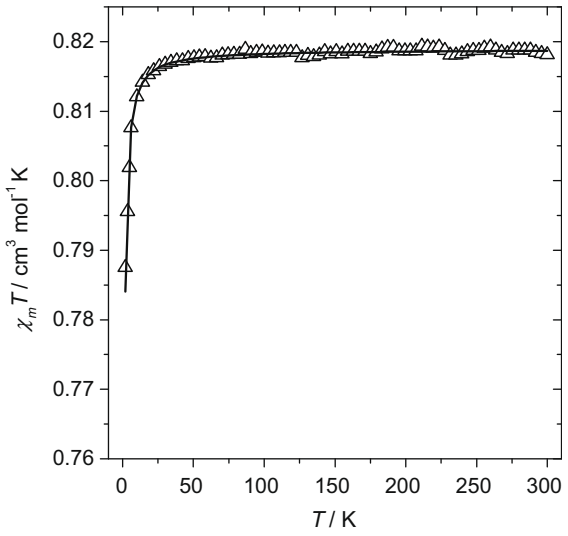

Fig. 16. Plot of $\chi_M T$ vs. T in the temperature range 2–300 K for complex **1**. Solid line represents the curve obtained with the best-fit parameters.

The calculated J and g values are given in Table S5. The small (almost negligible) J values for the four complexes can be interpreted as a consequence of the almost nil overlap between the Cu(II) ions through the long diamagnetic $[Pt(CN)_4]^{2-}$ bridge. These very small J values hamper any attempt to draw magneto-structural correlations, because in all cases intermolecular interactions have not been taken into account in the formulae used. These interactions can have the same order of magnitude of the main J values. Looking at the literature, we note several Cu(II) systems with diamagnetic $[M(CN)_4]^{2-}$ bridging ligands (M = Ni, Pd, Pt), but without magnetic studies [55–57]. However, the limited number of studies [58–60] with 1D zig-zag chains or bridging Cu–Pt complexes showed antiferromagnetic interactions of a similar order of magnitude as the present bridged structures (**1–4**).

The number of analogous complexes with magnetic studies is scarce [61,62] but the results are similar to those previously reported for the $[Ni(CN)_4]^{2-}$ analogue derivatives [35]. Considering the small values of J in both series (Cu–Pt and Ni–Pt) it is impossible to draw any conclusion, because together to the intra-chain coupling there are inter-chain magnetic pathways that, due to the diamagnetic character of the cyanide bridge, can be of a similar order. The conclusion is thus that these diamagnetic ligands do not allow a strong (or medium) transmission of magnetic coupling, as expected.

3. Conclusion

Four coordination complexes of $[Pt(CN)_4]^{2-}$ bridged Cu(II) complexes have been synthesized and crystallographically characterized. The 1D polymeric complexes have two types of topology, zig-zag/helical chains are obtained when $[Pt(CN)_4]^{2-}$ bridges in a bi-coordination mode, and on the other hand tetra-coordinated bridging by $[Pt(CN)_4]^{2-}$ lead to a (4,2) ribbon topology. A careful investigation of the packing of these complexes reveal that zig-zag/helical chains or (4,2) ribbons is the result of competition between hydrogen bonding and coordinative forces. A zig-zag/helical 1D chain appears when the chelating amine at the Cu(II) center is capable of forming the maximum number of hydrogen bonds, but when one or more amine sites are blocked or due to asymmetry steric hindrance prevents maximization of the hydrogen bonds in the usual way, (4,2) ribbons appear. These finding may act as a guiding principle for the designed construction of cyano bridged transition metal 1D polymers that should find important applications in the promising field of singe chain magnets.

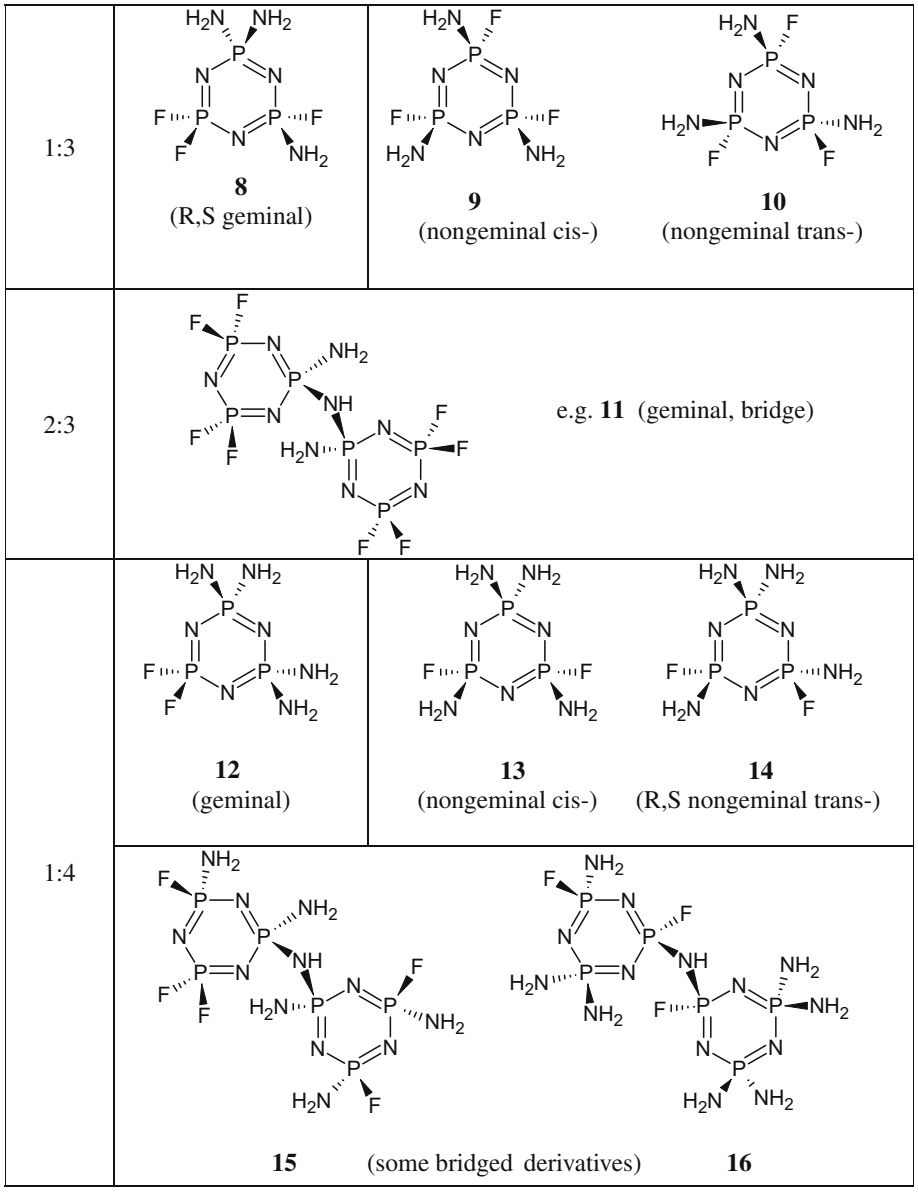
	 **6**  **7** (some bridged derivatives)	



Scheme 1. Possible products in the reaction of $P_3N_3F_6$ with ammonia (1:8).

derivatives were isolated from a direct reaction of $P_3N_3F_6$ with various amines [30–33]. Geminal disubstituted $P_3N_3F_4(NMe_2)_2$ was described by Chivers et al. [32]. Nevertheless, the authors elucidated its formation from geminal $P_3N_3F_4Cl_2$ whose residues were found in the starting $P_3N_3F_6$. Fluorination of aminochlorophosphazenes by SbF_3 or KSO_2F [34–36] is the most common way used for the preparation of multiple-substituted aminoderivatives of hexafluoro-*cyclo*-triphosphazene.

It is known that the reaction of $P_3N_3Cl_6$ with gaseous ammonia in diethylether leads to the formation of disubstituted derivative $P_3N_3Cl_4(NH_2)_2$ [37–39]. Monosubstituted aminoderivative $P_3N_3Cl_5NH_2$ can be prepared by adding dry gaseous HCl to the solution of $P_3N_3Cl_4(NH_2)_2$ in acetonitrile [40] or in dioxane [41]. On the contrary, ammonolysis of $P_3N_3F_6$ carried out in diethylether at −25 °C yielded monosubstituted $P_3N_3F_5NH_2$ as the main product [42]. Geminal disubstituted derivative $P_3N_3F_4(NH_2)_2$ was prepared by fluorination of the corresponding chlorophosphazene $P_3N_3Cl_4(NH_2)_2$ by CsF in acetonitrile [43]. Structure of $P_3N_3F_4(NH_2)_2$ was determined by X-ray analysis [44], elemental analysis, melting point and mass spectrum can be found in [43].

Direct syntheses of higher-substituted amino fluorophosphazenes from $P_3N_3F_6$ and ammonia, have not been described yet. The only information available can be found in [45] where the behavior of $P_3N_3F_6$ and ammonia in various solvents at increasing molar ratio of starting compounds up to 1:24 was studied. The reaction mixtures, even after long reaction times, were found to be very complex and no effective way to separate individual reaction products was found. Mass spectrometry proved the presence of at most trisubstituted aminoderivatives of $P_3N_3F_6$ and dimer compounds while in the case of reaction between hexachloro-*cyclo*-triphosphazene with excess ammonia it was possible to prepare fully substituted aminoderivative [46,47].

Therefore our effort to elucidate the reaction system $P_3N_3F_6$ and ammonia was concentrated on finding such reaction conditions (molar ratio of starting compounds, solvent, reaction time) that would enable to prepare also higher-substituted aminoderivatives of $P_3N_3F_6$. Molar ratio of starting compounds of 1:8 was chosen for our studies. In this case at most tetrasubstituted aminoderivatives of $P_3N_3F_6$ can be expected (4 NH_3 molecules are used for substitution, 4 NH_3 molecules serve as acceptor of released HF). There are

* number of phosphazene rings : number of amino (imino, respectively) groups

Scheme 1. *(continued)*

many possibilities how to combine reaction products, some of them are summarized in Scheme 1.

Results of our investigations of the reaction system $P_3N_3F_6$/ammonia/solvent are summarized in this article.

2. Experimental

2.1. Reagents and general procedures

$P_3N_3F_6$ was prepared by fluorination of $P_3N_3Cl_6$ with NaF in acetonitrile [48]. The solvent was distilled off and a crude semi-solid product was obtained. Anhydrous $MgSO_4$ was added with the aim to remove last traces of water. Then, $P_3N_3F_6$, due to its volatility, was distilled off in vacuum from this mixture.

Liquid ammonia (Chemopetrol Litvínov a.s., CZ) was prepared by condensation from gaseous ammonia that was dried by passing it through a column filled with KOH (Lachema Brno, CZ) and metallic sodium wire (Ferak Berlin, BRD).

All operations were performed under dry gaseous nitrogen using conventional Schlenk techniques and vacuum lines.

Solvents – 1,1,2,2-tetrachlorethane, diethylether (Penta Chrudim, CZ), and acetonitrile (Lach-Ner s. r. o. Neratovice, CZ) were of reagent grade purity and dried by methods described in Perrin and Armarego [49].

2.2. Instrumentation

Elemental analysis was performed after mineralization of a sample with sodium peroxide in Parr bomb. The content of phosphorus was determined gravimetrically by precipitation with quinoline [50]. The content of fluorine was obtained from the difference between masses of the sample before and after fuming off SiF_4 (in the presence of sulfuric acid and silica sand). The content of nitrogen was determined by Kjeldahl method.

The IR spectra were recorded in nujol and Kel-F mulls using a FTIR Bruker 28 spectrometer (measuring range 4000–400 cm^{-1}, resolution 2 cm^{-1}). Measurements were performed in demountable KBr cell. Raman spectra of solid samples in original Raman capillaries were measured on Bruker IFS55 Equinox apparatus, with Raman adapter FRA106/S (laser λ = 1064 nm, W = 150–400 mW) equipped.

Table 1
The compounds and their content determined by GC (in %).[a]

Retention time (min)	M^+ (found/calculated)	Compound	Filtrate	**S1** 160 °C + 6 h	**S2** 65 °C + 6 h	**S3** 80°C + 6 h
5.8	246/245.965	$P_3N_3F_5NH_2$ (**1**)	1	0	0	0
9.4	243/242.962	*gem*$P_3N_3F_4(NH_2)_2$ (**3**)	20	20	0	0
10.5	243/242.962	new *cis* and *trans non-gem* $P_3N_3F_4(NH_2)_2$ (**4**, **5**)	20	5	10	5
10.9	243/242.962		20	5	10	5
12.3	472/471.896	new compound (**2**)	39	0	4	35

[a] The content of components is related to their content in filtrate.

The ^{31}P NMR spectra were measured using FT NMR spectrometer Bruker Avance DRX 500 (frequency 202.404 MHz). Spectra were referred to 85% H_3PO_4. The samples were filled in the Simax® tubes (external diameter 4 mm). These tubes were inserted into original cuvettes Wilmad® (external diameter 5 mm) filled by D_2O that was used as the deuterium lock.

Mass spectra (EI) were measured by a spectrometer Finnigan MAT Trio 1000, series II, connected to a gas chromatograph GC 8000 and column DB-5. Excitation energy was 70 eV and 1–2 μl of liquid samples were sprayed into the column. The temperature of the heating zone was 50–280 °C and the rate of temperature rise was 10 or 15 °C min^{-1}. Nitrogen was used as carrier gas (flow 1.8 cm^3 min^{-1}).

The melting points were determined using electric Boethius apparatus Nagema PHMK 05. The samples were sealed in a glass capillary.

The structures of the compounds were determined using a KUMA KM-4 CCD κ-axis diffractometer with a graphite monochromatized Mo Kα radiation (λ = 0.71069 Å). The structure was solved through direct methods. Non-hydrogen atoms were refined anisotropically while hydrogen atoms were inserted in calculated positions and isotropically refined assuming a "ride-on" model. SHELX-97 program package [51] was used for the structure determinations; the drawings were made by XP program of Bruker SHELXTL V5.1 program package [52].

2.3. Quantum chemical calculations

The quantum chemical calculations were carried out with the molecular ADF program, version 2007.01 [53–55].

In the ADF calculation of the two-dimensional conformational PES two dihedral angles were changed in steps of 20°, all other nuclear coordinates being optimized, and DZP basis set, middle frozen core, integration accuracy to 4 digits, and LDA (VWN) functional was used. Molecular geometries for the two local minima closest to the by X-ray diffraction determined conformers were optimized with QZ4P basis set, no frozen core, integration accuracy to 6 digits, and OPBE [56] functional that combines OPTX (exchange) [57] and PBEc (correlation) [58]. The calculations of the IR spectra were carried out at the same level with no scaling factor.

2.4. Synthesis of $P_3N_3F_5$–NH–$P_3N_3F_4NH_2$ (**2**)

Ammonolysis of $P_3N_3F_6$ with liquid ammonia was carried out at a molar ratio of 1:8. Amount 2.489 g (10 mmol) of $P_3N_3F_6$ was placed into 30 cm^3 of acetonitrile in a sealed Schlenk tube connected to a vacuum line and 1.32 g (80 mmol) of ammonia was added by condensation of gaseous ammonia. The mixture was kept at 20 °C for 24 h. Precipitated NH_4F was filtered off by a Schlenk frit (porosity S4).

The solvent was removed from the filtrate by means of vacuum distillation (oil pump). A white solid, crude **2,** was obtained and purified by vacuum sublimation (2 Pa, 80 °C, 6 h).

This sublimation product was recrystallized from 1,1,2,2-tetrachloroethane. The substance **2** was isolated in the form of two polymorphs **2A** or **2B**.

The yield of the compound **2** was 35%, as related to $P_3N_3F_6$. Its melting point was determined from microcrystalline material to be 186 °C. The crystals of **2** for X-ray diffraction were grown from 1,1,2,2-tetrachloroethane.

Elemental analysis of **2**: found/calc. (%): P – 38.13/39.37, F – 35.78/36.23, N – 23.51/23.75.

Mass spectrum of **2**: M^+ = 472 ($P_6N_6F_9N_2H_3^+$), 457 ($P_6N_6F_9NH_2^+$), 456 ($P_6N_6F_9NH^+$), 453 ($P_6N_6F_8N_2H_3^+$), 438 ($P_6N_6F_8NH_2^+$), 436 ($P_6N_6F_8N^+$), 433 ($P_6N_6F_7N_2H_2^+$), 423 ($P_6N_6F_8H^+$), 397 ($P_6N_6F_6N^+$), 353 ($P_5N_5F_6N^+$), 245 ($P_3N_3F_5NH^+$), 230 ($P_3N_3F_5^+$), 227 ($P_3N_3F_4NH_2^+$), 212 ($P_3N_3F_4H^+$), 211 ($P_3N_3F_4^+$), 209 ($P_3N_3F_3NH_2^+$), 197 ($P_3N_2F_4^+$), 166 ($P_2N_2F_4^+$), 152 ($P_2NF_4^+$), 148 ($P_2N_2F_3H^+$), 129 ($P_2N_2F_2H^+$), 128 ($P_2N_2F_2^+$), 114 ($P_2NF_2^+$), 107 (PF_4^+), 88 (PF_3^+), 69 (PF_2^+), 50 (PF^+), 46 (PNH^+).

Raman spectrum of **2A**: 211 vw, 259 vw, 289 w, 292 w, 297 w, 300 vw, 317 vw, 355 vw, 399 vw, 407 vw, 463 vw, 474 vw, 526 vw, 538 vw, 550 sh, 554 w, 600 vw, 736 vs, 782 vw, 948 vw, 1545 vw, 2712 vw, 3043 bvw, 3273 vw.

Raman spectrum of **2B**: 211 vw, 260 vw, 288 w, 293 w, 295 w, 302 vw, 317 vw, 335 vw, 368 vw, 445 vw, 463 vw, 474 vw, 526 vw, 537 w, 550 w, 555 vw, 601 vw, 737 vs, 792 vw, 854 vw, 945 vw, 1546 vw, 2714 vw, 2992 bvw, 3270 vw.

Infrared spectrum of **2A**: 409 vw, 430 vw, 445 w, 463 m, 446 s, 485 m, 505 s, 509 sh, 527 vw, 537 vw, 560 vw, 569 vw, 596 vw, 723 vw, 738 vw, 792 w, 809 s, 817 s, 826 vs, 842 vs, 861 sh, 888 m, 898 sh, 937 sh, 949 vs, 962 sh, 1009 m, 1040 m, 1180 vw, 1196 vw, 1252 sh, 1279 vs, 1371 m, 1544 vw, 1559 vw, 2714 vw, 3080 bvw, 3282 vw, 3302 vw, 3423 w, 3444 vw.

3. Results and discussion

Ammonolysis of $P_3N_3F_6$ was studied by simple mixing of the substrate ($P_3N_3F_6$) with liquid ammonia in a Schlenk tube in acetonitrile. The molar ratio of reactants was kept at 1:8, the reaction was carried out at 20 °C for 24 h. Solid NH_4F was formed in the course of the reaction and was filtered off. The solvent, together with volatile $P_3N_3F_5NH_2$ (**1**), were evaporated from the filtrate and **1** was identified by MS spectrometry. The residue in the form of a white powder was obtained. Its purification was carried out by vacuum sublimation at 2 Pa. Several fractions of a solid (**S1**, **S2**, **S3**) were isolated in the course of vacuum sublimation. Fraction **S1** was obtained at 60 °C after 6 h, fraction **S2** at 65 °C after another 6 h of sublimation. Thus more volatile products **3**, **4, 5** were removed from the crude product. The sublimation at 80 °C for additional 6 h led to the isolation of an unknown compound **2**.

The composition of the filtrate and sublimation fractions was studied by NMR spectrometry and GC/MS (see Table 1).

It follows from Table 1 that the first sublimation fraction **S1** contains mostly geminal $P_3N_3F_4(NH_2)_2$ (**3**), fraction **S2** has majority of nongeminal *cis* or *trans*-$P_3N_3F_4(NH_2)_2$ (**4**, **5**) that have not been described so far. The signals of **4**, **5** were identified in ^{31}P NMR spectrum of the sublimation fraction **S3** dissolved in acetonitrile. Diamines $P_3N_3F_4(NH_2)_2$, (**3, 4**, **5**) were also identified by GC/MS.

The third sublimation fraction **S3** contains mainly the substance **2**. Recrystalization of **2** from 1,1,2,2-tetrachloromethane yielded pure crystals suitable for X-ray analysis. X-ray diffraction experiments showed that the substance **2** is the hitherto not described dimeric phosphazene aminoderivative in which two phosphazene cycles are connected via a NH-bridge.

2

Two kinds of monoclinic crystals (polymorphs **2A**, **2B**) were obtained by crystallization of the sublimation fraction **S3** from 1,1,2,2-tetrachloroethane (see below).

If the ammonolysis of $P_3N_3F_6$ was performed in diethylether the NMR analysis of the reaction mixture showed that monoamine $P_3N_3F_5NH_2$ (**1**) was present as the main product in the reaction mixture (>95% yield). Other substitution products, geminal (**3**) and *cis* and *trans* nongeminal isomers $P_3N_3F_4(NH_2)_2$ (**4**, **5**), and new derivative (**2**) were present only in negligible amounts as indentified by GC/MS.

3.1. X-ray structure analysis of **2**

The crystals of polymorph **2A** are monoclinic, space group $P2_1/n$. The asymmetric unit contains one molecule of **2A** in a general position (Fig. 1). The angle between the best planes through both P–N rings is 123.7(1)° with P1–N4–P4 bridging angle 128.6(1)°. The P1–F1 bond of P1–N1–P2–N2–P3–N3 (ring **R1**) is fairly parallel to the P4–N6–N7–P6–N8 ring (ring **R2**) and thus F1 and N5 are mutually in *trans* position. Both P–N rings are slightly twisted and thus deviating from exact planarity. The largest deviations of N atoms from the planes defined by P atoms are 0.058(3) Å (**R1**, N3) and 0.121(2) Å (**R2**, N8).

There are three possible hydrogen bond systems involving all three hydrogen atoms which bind the molecules into parallel columns: N4(H1)···N8 (2.19 Å), N5(H2)···N1 (2.67 Å), and N5(H3)···N6 (2.34 Å) (Fig. 2 and Table 5 upper part).

The structure of polymorph **2B** is also monoclinic, space group *C2/c*. The asymmetric unit contains two molecules ($\mathbf{2B_a}$ and $\mathbf{2B_b}$) in general positions. However, contrary to the structure of **2A**, the molecules are two different conformers (Fig. 3).

3.1.1. $2B_a$ molecule

The molecule $\mathbf{2B_a}$ is the same conformer as that in the polymorph **2A** (Fig. 4).

Thus the angle between the best planes drawn through P11–N11–P21–N21–P31–N31 (ring **R11**) and P41–N61–P51–N71–P61–N81 (ring **R21**) is 132.5(1)° (123.7° in **1A**) with P11–N41–P41 bridging angle 129.4(1)° (128.6° in **2A**). Deviation of both rings from planarity is practically the same both in **2A** and $\mathbf{2B_a}$. The largest deviations of N atoms from the best planes defined by P atoms are 0.048(3) Å (**R11**, N21) and 0.148(3) Å (**R21**, N81).

3.1.2. $2B_b$ molecule

$\mathbf{2B_b}$ can be derived from $\mathbf{2B_a}$ (or **2A**) by rotating one P–N ring by approx. 180° around the P–N(H) bond. As a result, F11 and N51(H) are mutually in a *cis* position.

Thus the angle between the best planes drawn through P12–N12–P22–N22–P32–N32 (ring **R12**) and P42–N62–P52–N72–P62–N82 (ring **R22**) is 30.9(1)° and P12–N42–P42 bridging angle 124.2(2)° (128.6° in **1A**, 129.4° in $\mathbf{2B_a}$. The largest deviations of N atoms from the best planes defined by P atoms are 0.126(3) Å (**R12**, N12) and 0.133(3) Å (**R22**, N82).

The crystal structure of **2B** is built from alternating columns of molecules propagating along the axis *b*, each column being composed of the same conformer only (Fig. 5). Within each column the molecules are connected by hydrogen bonds (Table 5, lower part).

Crystal data and structure refinement for **2A** and **2B** are given in Table 2, selected bond lengths in Table 3 and selected bond angles in Table 4.

The comparison between bond parameters of **2A**, **2B** with analogical data, e.g. for compounds **1**, **3,** shows that bond P–N and P–F lengths are similar. However, P–N bonds in the P–N ring, which are in the vicinity of P1, P4, or P7, P10 atoms, respectively, are somewhat longer (1.601–1.617 Å) as compared to published data (1.582–1.597 Å) [44,59,60].

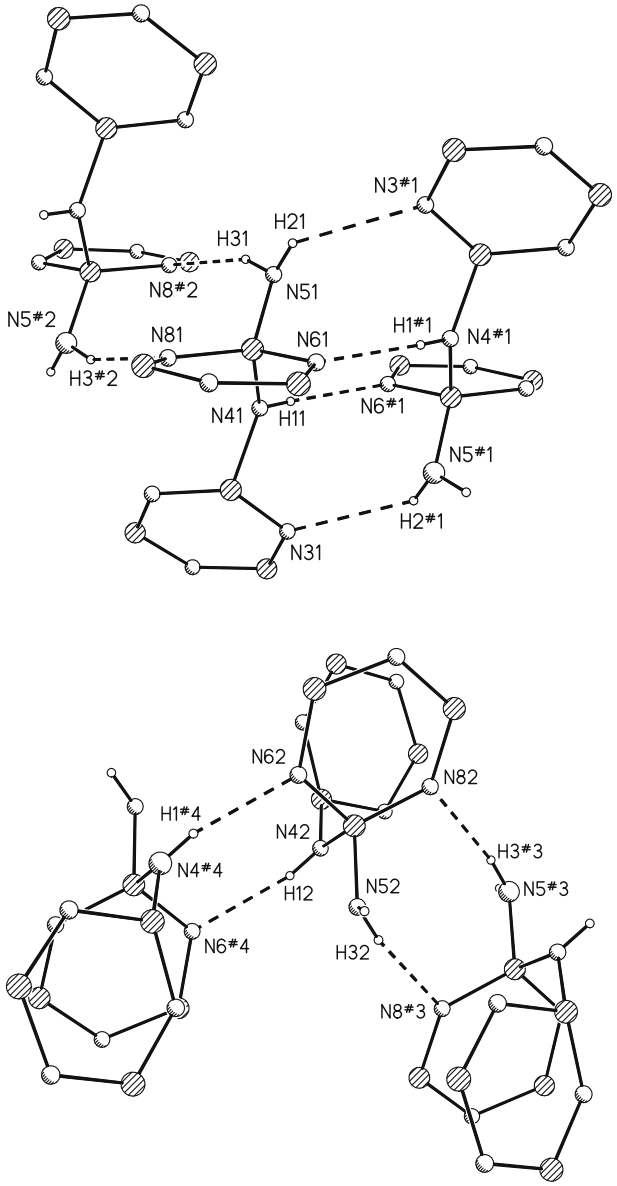

Fig. 5. Parts of $\mathbf{2B_a}$ (upper) and $\mathbf{2B_b}$ (lower) molecular columns showing hydrogen bonds in the structure of **2B**. Fluorine atoms are omitted for clarity. Symmetry code: #1 1 − *x* + 1/2, −*y* + 1/2, −*z* + 1; #2 −*x* + 1/2, −*y* + 3/2, −*z* + 1; #3 −*x*, −*y* + 1, −*z*, #4 −*x*, −*y* + 2, −*z*.

3.2. Quantum chemical calculations for **2**

The agreement between the metrical parameters from X-ray and from ADF calculation is very good except for the two sloppy torsions around P–N bonds in the P–NH–P bridge. Selected metrical parameters are shown in Table 6. The two-dimensional potential energy surface (PES) is in Fig. 6. It shows 8 minima with the torsion angles given in Table 7. The calculated minima for the gas phase molecules with the labels **a** and **b** in Fig. 6 and Table 7 differ in those dihedral angles by 6–12° from X-ray data. The conformational PES extends within 30 kJ/mol including apparent local maxima, in fact saddle points of second order. All the 8 local

minima and the first order saddle points are thermally accessible. So, the molecule is stereochemically nonrigid which is connected not only to the P–NH–P bridge but also to the easy distortions of the P_3N_3 ring that is planar and comparably rigid, perhaps, only in $P_3N_3F_6$ [21,22]. The Fig. 6 suggests that all barriers to internal rotation around exocyclic P–N bonds in **2** are very low, less than 15 kJ/mol, in the gas phase. This is in the agreement with the special bonding pattern of the phosphazene rings (e.g. [22]) that leaves those bonds with no π-contribution.

The numerical labels of local minima correspond to the Table 7; **a** corresponds to **2B$_a$** (or **2A**, respectively), **b** corresponds to **2B$_b$**.

Energy is expressed in kJ/mol relative to the lowest local minimum labeled **e**; the step for isolines amounts to 2 kJ/mol; α is the torsion angle N(7)–P(4)–N(4)–P(1) in Fig. 1; β is the torsion angle P(4)–N(4)–P(1)–F(1) in Fig. 1.

3.3. IR and raman spectra of *2A*

The calculated IR spectra have been useful in the assigning experimental bands to a mode of vibrational motion in most cases. Fig. 7 compares calculated and experimental IR spectra of **2A**.

The bands near 3444, 3423, 3302, 3282 cm^{-1} in the experimental IR spectrum of **2A** are in agreement with ADF calculations and were assigned to valence vibrations ν of NH_2 and NH group. The broad band extending from 3150 cm^{-1} to 2850 cm^{-1} belongs to the system of hydrogen bridges. There are two types of H-bridges that are identical in both types of the molecules **2A** and **2B** (Figs. 2 and 5). The low intensity band at 2714 cm^{-1} can be probably assigned to the combination vibration (overtone) of NH group (2 × δ NH). The double band of low intensity at 1559 and 1544 cm^{-1} belongs unambiguously to the deformation vibration δ of NH_2 group (ADF calculations 1540 cm^{-1}). The group of absorption bands in the region from 1279 sh, 1252 vs, 1196 s to 1180 sh cm^{-1}, can by ascribed, with agreement with ADF calculations (1282 s, 1278 vs, 1247 m, 1217 w) to several types of vibrations: deformation vibration δ of NH group, valence vibrations ν of both phosphazene

Scheme 1. Structures of the ligands: H_3Or = orotic acid; 2-meim = 2-methylimidazole.

activities and crystal structures of the orotate complexes of Co(II), Ni(II), Cu(II) and Zn(II) with 2-methylimidazole ligand (Scheme 1).

2. Experimental

2.1. Preparation of the complexes

A solution of orotic acid monohydrate (0.871 g, 5 mmol) in water (50 mL) was added dropwise with stirring at 80 °C to a solution of $Co(CH_3COO)_2{\cdot}4H_2O$ (1.25 g, 5 mmol) (**1**) or $Ni(CH_3COO)_2{\cdot}4H_2O$ (1.24 g, 5 mmol) (**2**) or $Cu(CH_3COO)_2{\cdot}H_2O$ (1.00 g, 5 mmol) (**3**) or $Zn(CH_3COO)_2{\cdot}2H_2O$ (1.09 g, 5 mmol) (**4**) in distilled water (25 mL). The solutions immediately became suspensions and were stirred for 4 h at 60 °C. Then 2-methylimidazole (1.65 g, 20 mmol) for all in water (10 mL) was added dropwise to these suspensions. The clear solutions that formed were stirred for 2 h at 60 °C and then cooled to room temperature. The reddish for (**1**), green for (**2**), light blue for (**3**), colorless for (**4**) crystals that formed were filtered and washed with 10 mL of water and dried in air.

2.2. Materials and measurements

All chemicals used were analytical reagents and were commercially purchased. IR spectra were obtained with a Perkin Elmer 100 FT-IR spectrometer using KBr pellets in the 4000–400 cm^{-1} range. The UV–Vis spectra were obtained for an aqueous solution of the complex (10^{-3} M) with a Shimadzu UV-3150 spectrometer in the range 900–190 nm. Magnetic susceptibility measurements at room temperature were performed using a Sherwood Scientific MXI model Gouy magnetic balance. A Perkin Elmer Diamond TG/DTA Thermal Analyzer was used to record simultaneous TG, DTG and DTA curves in static air atmosphere at a heating rate of 10 °C min^{-1} in the temperature range of 30–1000 °C for **1** and 30–700 °C for **2**–**4** using platinum crucibles.

2.3. Crystallographic analyses

Data collection was performed on a STOE IPDS II image plate detector using Mo Kα radiation (λ = 0.71073 Å). Data collections: Stoe X-AREA [46]. Cell refinement: Stoe X-AREA [46]. Data reduction: Stoe X-RED [46]. The structure was solved by direct-methods using SIR97 [47] and anisotropic displacement parameters were applied to non-hydrogen atoms in a full-matrix least-squares refinement based on F^2 using SHELXL-97 [48]. Molecular drawings were obtained using ORTEP-III [49].

2.4. Antimicrobial activity studies

Escherichia coli W3110, *Pseudomonas aeruginosa* ATCC 27853, *Staphylococcus aureus* ATCC 6535, *Bacillus cereus* ATCC 7064, *Candida albicans* ATCC 10231 and clinical isolate (Methicillin Resistant *S. aureus* (MRSA) – Orthopedy Exuda, *Pseudomonas aeruginosa* – urology–urine isolates, from Ondokuz Mayıs University, Faculty of Medicine) were used for the antimicrobial assays. Antimicrobial activity tests were carried out using the broth dilution method as described by the NCCSL standards [50]. All stock solutions of the orotic acid and the complexes were prepared in dimethylsulfoxide (DMSO, Merck) according to the needed concentrations for experiments.

For the broth dilution method, cultures were grown in 5 mL nutrient broth (Merck) at 37 °C for 18 h in an orbital shaker incubator shaking at 175 rpm. These cultures were used as starter cultures. Initial bacterial concentrations (approximately 5×10^5 cfu/mL) were estimated for the cultures at 600 nm by matching with 0.5 McFarland turbidity standards. Nutrient broth containing microorganisms were transferred 1 mL in test tubes and made twofold serial dilution in nutrient broth from 3000 to 23.4 μg/mL. The compounds were tested in twofold serial dilution; eventually the ranges were narrowed to define more exact values. Growth inhibition was determined by measuring MICs, defined as the lowest concentration in which microbial growth was prevented. As indicated by the lack of turbidity or colour change after 24 h of incubation at 37 °C, represents the mean of at least three determinations. The solvents were also tested for antimicrobial activity. Standard antibiotics (chloramphenicol, oflaxacin, rifampicin, cefuroxime, tetracycline, nystatin) were also tested by disc diffusion method for the cultures at an optical density at 600 nm by matching with 0.5 McFarland turbidity standards (approximately 10^6 cfu/mL). Test strains were spread on solid nutrient agar surfaces using a sterile glass rod. Standard antibiotic discs were placed on the agar surface and were incubated 37 °C for 24 h.

3. Results and discussion

The Co(II), Ni(II) and Cu(II) complexes exhibit magnetic moment values of 4.66, 2.54 and 1.26 BM which corresponds to three, two and one unpaired electrons, respectively, which are consistent with a weak field octahedral geometry as expected. The Zn(II) complex is diamagnetic. All the complexes comprise broad composite bands in the UV region, being due to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ intraligand transitions of HOr and 2-meim ligands. The λ_{max} value of the absorption band in the spectrum of **1** is 499 nm. This value was assigned to the following d–d transitions, $^4T_{1g} \rightarrow {}^4T_{2g}$. The $^4T_1g \rightarrow {}^4A_{2g}$ and $^4T_{1g} \rightarrow {}^4T_{1g}(P)$ transitions were not observed which are shift to the UV and IR regions, respectively. The UV–Vis spectrum for **2** exhibits three d–d absorption transitions at 888, 638 and 390 nm which support the octahedral geometry. These values were assigned to $^3A_{2g} \rightarrow {}^3T_{2g}$, $^3A_{2g} \rightarrow {}^3T_{1g}$, $^3A_{2g} \rightarrow {}^3T_{1g}$ (P), respectively. The UV–Vis spectrum for **3** exhibits a broad d–d absorption transition centered at 707 nm. This value was assigned to a1 → b1 transition. The colourless Zn(II) complex does not show d–d bands as expected.

The strong and broad absorption bands of ν(OH) vibrations of H_2O in complexes are observed between 3402 and 3361 cm^{-1}. IR spectra of the complexes exhibit a medium intensity and broad band in the 3272–3178 cm^{-1} region which can be attributed to the N–H stretching vibration. The relatively weak two close bands at 2752–2964 cm^{-1} are due to the ν(CH) vibrations. The strong and broad bands appeared in the 1653–1623 and 1488–1382 cm^{-1} regions in all complexes are ascribed to the asymmetric and symmetric stretching vibrations of the coordinated carboxylate groups of the orotate ligand, respectively. Similar absorption values have already been reported earlier for Ni(II) and Co(II)-orotate complexes with imidazole and its derivatives [16,19,33,51] and the positions of these bands have been well described in recently reports [52]. Separation between asymmetric and symmetric stretching frequencies for complexes range from 167 to 141 cm^{-1} is in agreement with monodentate coordination mode for the

[b] $[Co(HOr)(H_2O)(4\text{-meim})_3]$ [19].

carboxylate group. In IR spectra of the complexes, $\nu(OH_{acid})$ band at 2500 cm^{-1} in the orotic acid completely disappeared and a new carboxylate band ν(COO) appeared between 1488 and 1382 cm^{-1}, respectively, indicating that the carboxylate group participates in the coordination with the metal ions by deprotonation (Table 1).

3.1. Thermal analyses

3.1.1. $[Co(HOr)(H_2O)_2(2\text{-meim})_2]$ (**1**) and $[Zn(HOr)(H_2O)_2(2\text{-meim})]$ (**4**)

The thermal behaviour of **1** and **4** are quite similar and they show a three stage mass loss (Supplementary Figs. S1 and S2). The first stage between 37 and 199 °C for **1**, 33 and 212 °C for **4** corresponds to the endothermic elimination of two aqua ligands with an experimental mass loss of 9.06% and 11.19% (calc. mass loss 8.71% and 10.66%). The removal of 2-meim ligands occurs in the second stage between 199 and 391 °C for **1**, 212 and 373 °C for **4** with an experimental mass loss of 40.54% and 23.49% respectively (calc. mass loss 39.73% and 24.32%). In the last stage, a strong exothermic peak on the DTA curve (DTA_{max} = 423 and 529 °C, respectively) is associated with decomposition and burning of the orotate ligands. The overall experimental mass losses, 82.92% for **1** and 75.18% for **4**, are in agreement with this stoichiometry. The thermal decomposition products were identified as CoO or ZnO (calc. 81.85% and 75.88%).

3.1.2. $[Ni(HOr)(H_2O)_2(2\text{-meim})_2]$ (**2**)

The complex **2** shows three stages decomposition process (Supplementary Fig. S3). Although the complex is containing aqua ligands, it is stable up to 151 °C. In the first stage, complex **2** starts to lose aqua ligands between 151 and 225 °C with an experimental mass loss of 8.71% (calc. mass loss 9.73%). The second stage is related to the release of two imidazole ligands by giving endothermic effect (found = 41.11, calc. = 39.74%). This type of behaviour of methylimidazole ligands in the *mer*-$[Mn(\mu\text{-}HOr)(H_2O)(2\text{-meim})_2]_n$ [16] and $[Ni(HOr)(H_2O)(4\text{-meim})_3]$ [19] complexes have been reported earlier. In the last extremely exothermic stage between 398 and 474 °C orotate ligand is abruptly burnt (DTA = 454 °C). The total mass loss of all decomposition process is 82.82% (calc. 81.88%) suggest that NiO is the end product.

3.1.3. $[Cu(HOr)(H_2O)_2(2\text{-meim})]$ (**3**)

The complex **3** shows four stages decomposition process (Supplementary Fig. S4). In the first stage, the complex starts to lose one aqua ligand between 37 and 160 °C with an experimental mass loss of 5.65% (calc. 5.36%). The second stage is related to the release of other aqua ligand by giving endothermic effect (found = 6.22, calc. = 5.36 %). The third stage in the temperature range of 246–288 °C related to release of 2-meim ligand (found 23.42, calc. 24.45%, DTA_{max} = 267 °C). In the last extremely exothermic stage between 288 and 458 °C orotate ligand is abruptly burnt (DTA = 423 °C). The total mass loss of all decomposition process is 77.61% (calc. 76.29%) suggest that CuO is the end product.

3.2. Crystal structures

Details of crystal data, data collection, structure solution and refinement are given in Table 2. The molecular structures of **1** and **2** with the atom-numbering scheme are shown in Fig. 1. Selected bond lengths and angles together with the hydrogen bonding geometry are collected in Table 3. The structures of **1** and **2** consist of the *mer*-$[M(HOr)_2(H_2O)_2(2\text{-meim})_2]$ (M = Co(II) and Ni(II)) molecules. Both metal ions are coordinated bidentate orotate ligand thought oxygen atom of carboxylate group and nitrogen atom of pyrimidine ring, two aqua ligands and two 2-methylimidazole ligands. The basal plane of the distorted octahedral is formed by N1, O4, O5 and O6 atoms. The Co–O (average 2.108 (1) Å), Ni–O (average 2.071 (1) Å) and Co–N1 (2.138 (1) Å), Ni–N1 (2.087 (1) Å) bond distances are longer than previously reported values ($[Co(HOr)(H_2O)_4]\cdot 2.5H_2O$ [47], $[Co(HOr)(en)_2](H_2Or)\cdot 5H_2O$ [18] and *mer*-$[Ni(HOr)(H_2O)_2(ata)_2]$ [43]). However these bond distances are similar to the corresponding values found in reported $[Co(HOr)(H_2O)_3]_n$, $[Ni(HOr)(H_2O)_3]_n$ [23] and [Ni(HOr)(bipy)] [53]. Distorted octahedral geometry is completed with two nitrogen atoms by monodentate coordination of two 2-meim ligands (Co1–N3/N5 = 2.164(2)/2.158(2) and Ni1–N3/N5 = 2.127 (2)/2.123 (2) Å).

The crystal packing of **1** and **2** are stabilized through strong intra- and intermolecular hydrogen bonding interactions (Fig. 2a). Each HOr ligand is doubly hydrogen bonded forming DA:AD dimer between the O1, N2 of HOr and the O4 atom of carboxylate group and aqua ligand (O5) [N2···O4 = 2.896 (2) for **1**, 2.882 (2) for **2** and O5···O1 = 2.757 (2) for **1**, 2.736 (2) for **2**] with a pattern $R_2^2(8)$ in Etter's notation [54]. There are also $\pi\cdots\pi$ interaction between the symmetry related 2-meim rings [Cg*A* = N(3)–C(6)–C(7)–N(4)–C(8) and Cg*B* = N(5)–C(10)–C(11)–N(6)–C(12), Cg*A*–CgA^i = 3.8251 (i = $-x$, $-y$, $-z$) and Cg*B*–CgB^i = 3.9814 Å, i = $1-x$, $1-y$, $-z$) (Fig. 2b).

In pentacoordinated systems, the actual geometry of the complex can be described by a structural index parameter τ such that $\tau = \alpha - \beta/60°$, where α and β are the two largest angles ($\alpha > \beta$). Thus, the geometric parameter τ is applicable to pentacoordinated structures as an index of the degree of trigonality, within the structural continuum between trigonal bipyramidal (τ = 1) and square pyramidal (τ = 0). The complex **3** and **4** have τ values of 0.20 for **3** [$\tau = (169.81 - 158.00)/60 = 0.20$] and 0.60 for **4** [$\tau = (164.91 - 128.77)/60 = 0.60$], indicating a distorted square bipyramidal and trigonal bipyramidal geometries, respectively (Fig. 3). The M ion in $[M(HOr)(H_2O)_2(2\text{-meim})]$ (M = Cu(II) and Zn(II)) is coordinated by a bidentate HOr ligand, two coordinated water molecules and one 2-meim ligand [Cu1–N1 = 1.992(2), Cu1–O4 = 2.073(1), Zn1–O4 = 2.083 (2) and Zn1–N1 = 2.066 (2) Å]

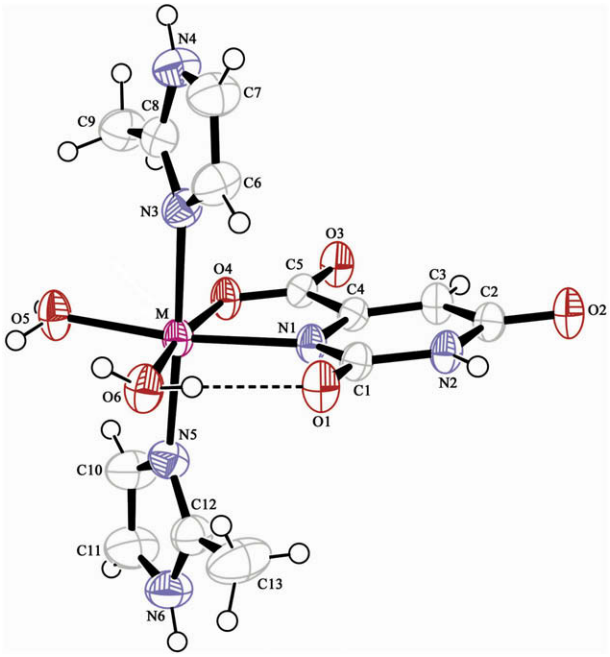

Fig. 1. Ortep III view of **1** and **2** with the atom-numbering scheme (M = Co1 and Ni1).

(Table 4). These distances are found to be similar to those of previously reported complexes [7,18,41,55]. The dihedral angle between the pyrimidine and imidazole rings is 67.65 Å for **3** and 66.79 for **4**. The C5–O4 bond distance (1.260 Å for **3** and 1.251 Å for **4**) is longer than C5–O3 bond distance (1.240 Å for **3** and 1.241 Å for **4**) in HOr ligand due to the coordination of M(II) ion.

The presence of aqua ligands and carboxyl or carbonyl groups make extensive hydrogen bonding interactions in complexes **3** and **4**, which are listed in Table 4. Each of the HOr ligand is doubly hydrogen bonded to corresponding ligands of a neighbouring HOr ligand, forming DA:AD dimer [N2···O2^{i} = 2.830 (**2**) for **3** and 2.897 (**3**) Å for **4**, N2–H2···O2^{i} = 172 for **3** and 170° for **4**, (i) $-x+2$, $-y$, $z+1$ for **3** and $x+2$, $-y$, $-z+1$ for **4**]. These arrangement gives rise

to eight membered rings that can be described as $R_2^2(8)$ [54] (Fig. 4). These intermolecular hydrogen bonding interactions are very important in the construction of the crystal edifice of complexes **3** and **4**. Similar orotate complexes containing double hydrogen bonding interactions were reported [41–45]. In addition, the layers are interlinked together into a network by π···π interactions between both pyrimidine rings of orotate ligand [Cg*A* = N(1)–C(1)–N(2)–C(2)–C(3)–C(4)] (CgA···CgA^{i}) is 3.863 Å for **3** (i = $1-x$, $1-y$, z) and 4.011 Å for **4** (i = $1-x$, $-y$, $1-z$) and imidazole rings [Cg*B* = N(3)–C(6)–C(7)–N(4)–C(8)], the contact distance of two adjacent aromatic rings (CgB···CgB^{i}) is 3.763 for 3 ($-x$, $2-y$, $-z$) and 3.895 Å for **4** (i = $-x$, $2-y$, $-z$). All of these intermolecular interactions give three-dimensional framework results (Fig. 5).

3.3. Antimicrobial activities

The complexes were tested for their in vitro antimicrobial activities against two Gram-positive bacteria (*S. aureus* and *B. cereus*), two Gram-negative bacteria (*E. coli* and *P. aeruginosa*), one fungi *C. albicans* and two clinical isolate (MRSA and *P. aeruginosa*). For

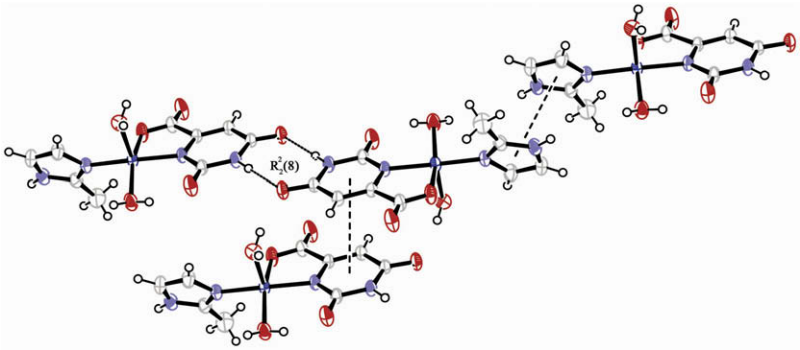

Fig. 4. The π···π and hydrogen bonding interactions of **3** and **4**.

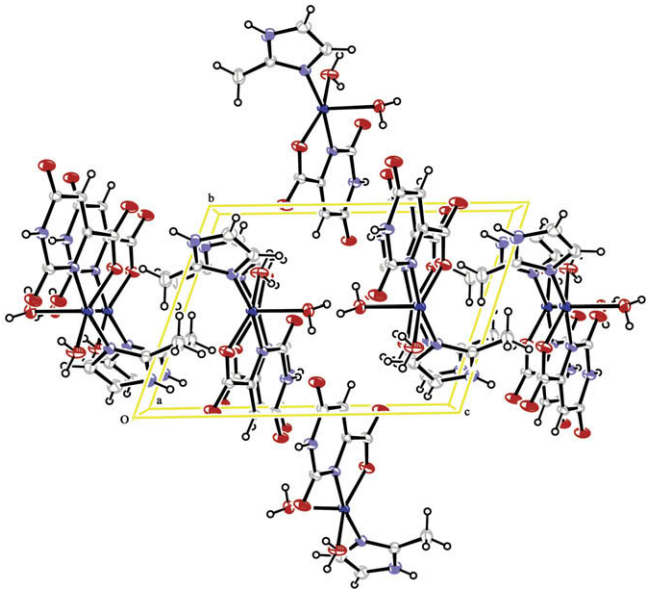

Fig. 5. Packing diagram of **3**.

comparison, the orotic acid and its metal complexes ([Co(HOr)-$(H_2O)_4]\cdot H_2O$ (**5**) [18], $[Ni(HOr)(H_2O)_4]\cdot H_2O$ (**6**) [7], [Cu(HOr)-$(H_2O)_4]\cdot H_2O$ (**7**) [22] and $[Zn(HOr)(H_2O)_4]\cdot H_2O$ (**8**) [7]) were tested for MIC values. The results are presented in Table 5 as minimum inhibitor concentration (MIC) values (μg/mL) which is the minimum concentration to inhibit the growth of bacteria or fungi.

While orotic acid showed activity at higher concentrations on *C. albicans* (2000 μg/mL) and *E. coli* (1375 μg/mL), MICs of other studied microorganism were approximately 1000 μg/mL exception *B. cereus* (750 μg/mL). The antimicrobial activities of **5** and **8** are higher than the orotic acid, **6** and **7** on the all tested microorganisms. While MIC values of **6** according to orotic acid was decreased at *E. coli* (from 1375 to 750 μg/mL), *S. aureus* (from 1000 to 750 μg/mL), *C. albicans* (from 2000 to 750 μg/mL), its activity was increased *P. aeruginosa* (from 1000 to 1500 μg/mL), *B. cereus* (from 750 to 1000 μg/mL), MRSA (from 1000 to 1800 μg/mL) clinical isolate *P. aeruginosa* (from 1000 to 1250 μg/mL). Compared to the orotic acid, the MICs of **7** did not approximately change effective dose on microorganism. Complex **8** had the highest activity on wild type microorganisms between complexes.

The MICs of new complex **1** for strains, gram (−) wild type *E. coli*, *P. aeruginosa*, and clinic isolate *P. aeruginosa* were 800, 700 and 1000 μg/mL respectively, while the growth of *S. aureus*, *B. cereus* and clinic strain MRSA were inhibited more effectively at 400, 400, 250 μg/mL. For **2**, the growth of all the strains with exception MRSA were inhibited at approximately concentration of 1100–1300 μg/mL of the complex, while the MICs for MRSA was 900 μg/mL. **3** had much the same MIC values for all the strains. As can clearly be seen from Table 5, the effective dose of **1**–**4** were, almost without exception, superior to that of metal orotic acid ligands **5**–**8** across all of the bacterial and the fungal strains studied, except for **4** at *S. aureus* and MRSA. As a result, antimicrobial activities were decreased with to be synthesized from **5**–**8** ligands to **1**–**4**. Complex **4** is more effective at both wild type and clinic strain *S. aureus* in comparison to **8** and orotic acids.

1, **4** and **5** have higher activity against Gram-positive than Gram-negative bacteria. In classifying the antibacterial activity as Gram-positive or Gram-negative, it would generally be expected that to be more active against Gram-positive than Gram-negative bacteria because of outer membrane [55]. The **8** has activity on both Gram-positive and Gram-negative bacteria at wild type. The

C. albicans	–	–	–	–	–	24
Clinic isolates						
MRSA	22	–	–	–	13	–
P. aeroginosa	–	21	–	–	18	–

C: chloramphenicol, OFX: oflaxacin, RD: rifampicin, CXM: cefuroxime, TE: tetracycline, N: nystatin.

presence of metal ions plays an important role at antimicrobial activity. We think that the disparity at antimicrobial activities between complexes on the microorganisms is change bond characteristics on target area of metal ions because of identical molecular structures of **1**–**8**. Orotic acid and metal complexes have been demonstrated to possess antibacterial and antifungal properties [43,56].

The results of our study indicate that clinic isolates are more resistant than wild type microorganism at standard antibiotics (Table 6). It is a well-known fact that hospital infections are quite important for the public healthy and quite resistant against standard antibiotics. Therefore, there is an urgent demand for new antibiotics and new classes of chemical formula that will efficiently inhibit the growth of pathogenic microorganism. In this study, as part of our efforts into the development of new metal based antimicrobial complexes, new complex **4** could be a new candidate for therapy of *S. aureus* infections and **5** could be candidate for therapy of candidal infection diseases.

Scheme 1. Thione–thiol tautomerism.

In course of this investigation, we further observed that the reaction of diacetylmonoxime with morpholine N-thiohydrazide in ethanol under reflux in absence of any metal ion for a longer period of time (16 h) afforded a zwitterionic nitrogen–sulfur heterocyclic compound, N-(3,4-dimethyl-1,2,5-thiadiazol-2-ium-2-yl)morpholine-4-carbothioate. This paper also records the results of this investigation (Scheme 2).

2. Experimental

2.1. Materials and physical measurements

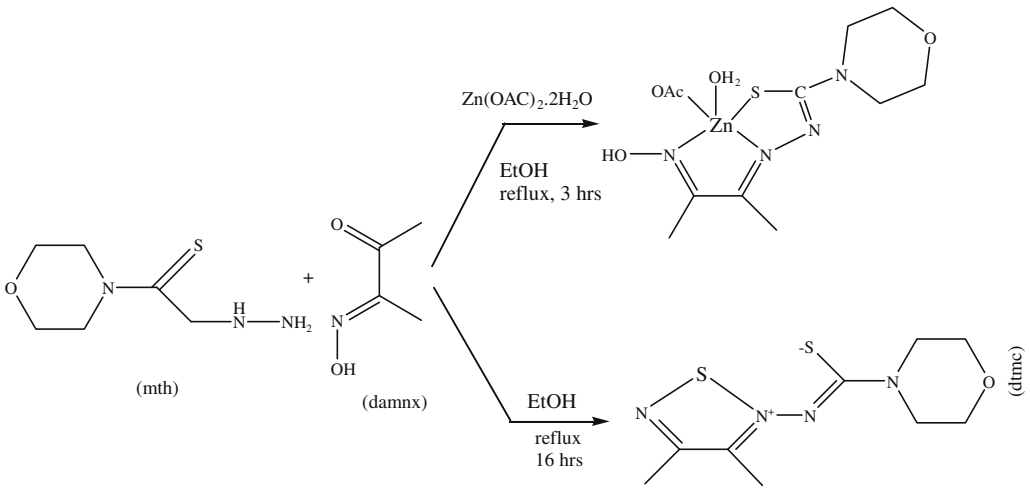
The solvents and chemicals were purified and dried before use by standard procedures. Diacetylmonoxime (damnx) was purchased from Aldrich and used as received and morpholine N-thiohydrazide (mth) was prepared by literature method [36,37]. $[Zn(OAc)_2]\cdot 2H_2O$ was purchased from SRL Mumbai, India and used as received. The elemental analyses were carried out at the Regional Sophisticated Instrumentation Center, Central Drug Research Institute, Lucknow, India. The electronic spectrum was recorded on a Simadzu UV-1601 spectrophotometer and infrared spectral data were collected (KBr disc) on a Perkin–Elmer L120-000A spectrophotometer and NMR spectra were recoded at Indian Institute of Chemical Biology, Kolkata, India. The molar conductance was measured using an Elico CM-180 conductivity bridge in double distilled water (10^{-3} M).

2.2. Synthesis

2.2.1. Nitrogen–sulfur heterocyclic (dtmc) (**5**)

Diacetylmonoxime (0.5 g, 0.005 mol) was treated with an ethanolic solution (50 ml) of morpholine N-thiohydrazide (0.8 g, 0.005 mol) containing few drops of water under reflux for 16 h. The light yellow colored solution on slow evaporation gave a light yellow compound, which was filtered off, washed with cold chloroform and dried in *vacuo*. Finally the compound was re-crystallized from chloroform. Light-yellow crystals suitable for single crystal X-ray diffraction were obtained.

M.p 254 °C Yield, 0.58 g, (45%). ^{1}H NMR ($CDCl_3$, 300 MHz, δ ppm): CH_3(singlet) (2.51, 2.28 ppm), N–CH_2 (singlet) 3.17 ppm, O–CH_2 (singlet) 3.60 ppm. ^{13}C NMR ($CDCl_3$, 300 MHz, δ ppm) 152.82 (C_7), 147.90 (C_6), 47.57 (C_1), 66.82 (C_2), 15.48 (C_8), 12.40 (C_9), 179.11 (C_5). IR (KBr pellet) ν_{max} (cm^{-1}) 1589 (C_7=N_4), 1569 (C_6=N_3), 772 (C_5–S_1), 1035 (N_3–N_2). λ_{max}/nm(ε/M^{-1} cm^{-1}) ($CHCl_3$) 238 (5970), 260 (4555). *Anal.* Calc. for $C_9H_{14}N_4OS_2$: C, 41.84; H, 5.46; N, 21.69. Found C, 41.71; H, 5.42; N, 21.49%.



2.2.2. $[Zn(Hdammthiol)(OAc)(H_2O)]\cdot H_2O$

The mixture of diacetylmonoxime (0.5 g, 0.005 mol) and morpholine N-thiohydrazide (0.8 g, 0.005 mol) was heated under gentle reflux in the presence of $[Zn(OAc)_2]\cdot 2H_2O$ (1.095 g, 0.005 mol) in ethanol (50 ml) for 3 h. The yellow colored compound thus formed, was re-crystallized from chloroform. Crystals suitable for single crystal X-ray diffraction were obtained.

Yield 1.58 g (75%). M.p. 285 °C ^{1}H NMR ($CDCl_3$, 300 MHz, δ ppm) CH_3 [2.33 (singlet), 2.04 ppm(singlet)], N–CH_2 (singlet) 3.47 ppm, O–CH_2 (singlet) 3.89 ppm, OH_2 (co-ordinated) 7.27 ppm (singlet), OH_2 (lattice) 2.2 ppm (singlet). ^{13}C NMR ($CDCl_3$, 300 MHz, δ ppm) 151.47 (C_7), 147.73 (C_6), 47.5 (C_1), 66.46 (C_2), 15.03 (C_8), 11.99 (C_9), 180.53 (C_5). IR (KBr pellet) ν_{max} (cm^{-1}) 1608 (C_7=N_4), 1570 (C_6=N_3), 756 (C_5–S_1), 1027 (N_3–N_2), 948 (N_4–O_5) and 2990–3264 (O_5–H_3, oxime). λ_{max}/nm(ε/M^{-1} cm^{-1}) ($CHCl_3$) 242 (6490), 322 (5930), 392 (1280) and 480 (720) (shoulder). *Anal.* Calc. for $C_{11}H_{20}O_5N_4SZn$: C, 32.72; H, 5.49; N, 13.88; Zn, 16.20. Found: C, 32.31; H, 5.19; N, 14.46; Zn, 16.91%. Λ_M = 14.9 Ω^{-1} cm^2 mol^{-1}.

2.3. X-ray crystal structure and refinement

Single crystal X-ray diffraction measurement of the Zn-complex and the S–N heterocyclic compound was carried out on a Brüker-AXS APEX CCD diffractometer by ω-scan method with a graphite-monochromated Mo Kα radiation (k = 0.71073 Å) at 295(2) K. The structure was solved by direct methods with SHELXS97 [38]

Scheme 2. Synthetic pathway for the preparation of the compounds.

and refined by full matrix least-square procedure based on F^2 using SHELXL97 program [38]. Crystal data and structure refinement parameters are summarized in Table 1. The data-set was treated with SADABS absorption corrections based on redundant multi-scan data [38]. All hydrogen atoms were treated as idealized contributions. Structure factors are contained in the SHELXTL 6.12 program library [38]. Graphics were obtained with ORTEP 3 for Windows at the 50% probability level [39,40]. Additional figures were drawn with PLATON for Windows [41,42].

3. Results and discussion

The reaction of morpholine N-thiohydrazide with diacetylmonoxime under reflux (16 h) afforded a light yellow crystalline compound. Single crystal X-ray diffraction and other analytical data show that the product is a zwitterionic nitrogen–sulfur heterocyclic compound, N-(3,4-dimethyl-1,2,5-thiadiazole-2-ium-2-yl)morpholine-4-carbothioate (dtmc). Although *in situ* reaction of the above components in the presence of $[Zn(OAc)_2]\cdot 2H_2O$ in stoichiometric ratios in ethanol under gentle reflux yielded a light yellow compound, $[Zn(Hdammthiol)(OAc)(H_2O)]\cdot H_2O$, where Hdammthiol is the mono anion of the thiol form H_2dammthiol (Scheme 1). The schematic representation of the formation of nitrogen–sulfur heterocyclic compound is shown below in Scheme 3.

The probable mechanism for the formation of the zwitterionic nitrogen–sulfur heterocyclic compound is given in Scheme 3. The acid hydrolysis of morpholine N-thiohydrazide produces hydrazide and H_2S which protonates the morpholine N-thiohydrazide to form the imminium salt (**1a**). The Schiff base (**2**) (formed by the reaction of diacetylmonoxime and morpholine N-thiohydrazide) in presence of H_2S is converted to 3,4-dimethyl-1,2,5-thiadiazole (**3**) and morpholine-4-carbothioamide (**4**) [43,44]. The thiadiazole in turn reacts with the imminium salt (**1a**) to yield finally zwitterionic nitrogen–sulfur heterocyclic compound, N-(3,4-dimethyl-1,2,5-thiadiazol-2-ium-2-yl)morpholine-4-carbothioate(**5**)

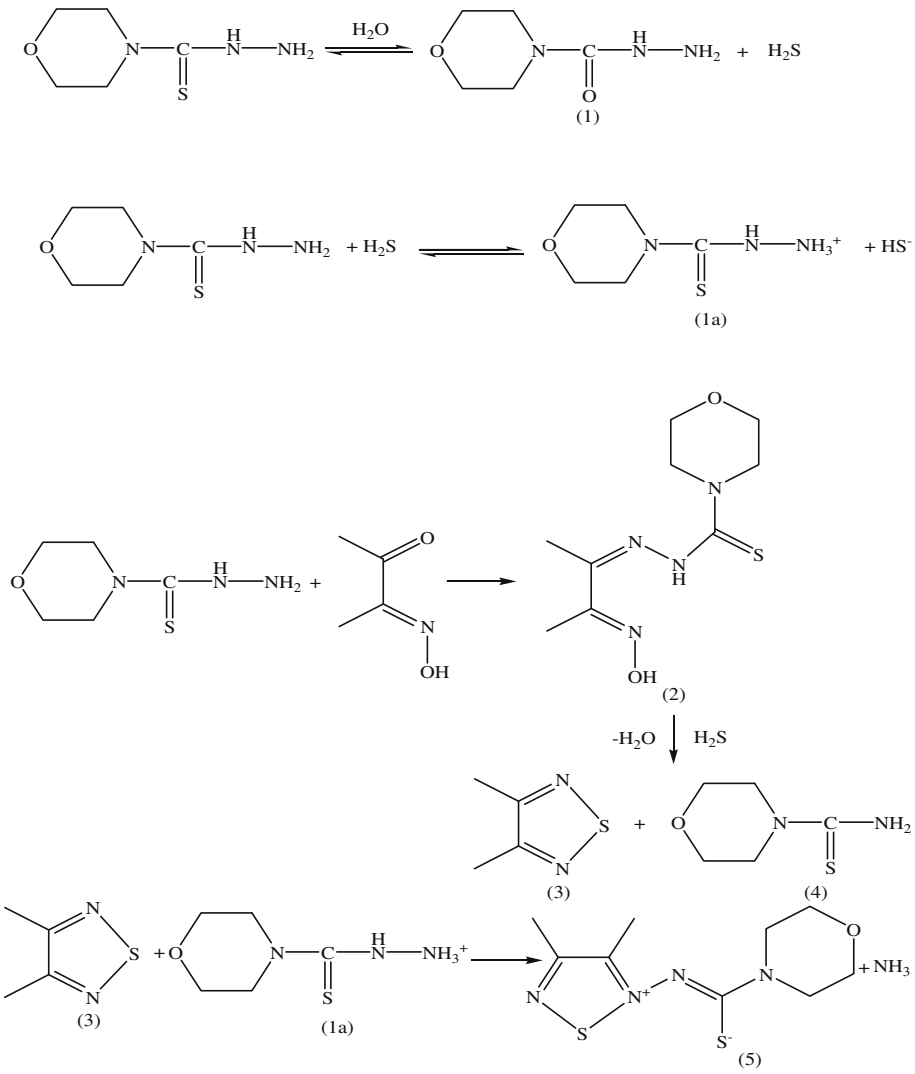
3.1. Structure of the nitrogen–sulfur heterocyclic compound (*5*)

The perspective view of the nitrogen–sulfur heterocyclic compound together with atom-numbering scheme is shown in Fig. 1 and the geometric parameters are given in Table 2. The structure shows that the nitrogen–sulfur heterocyclic compound is in zwitterionic form. The bond lengths of N(2)–C(5) [1.336(2) Å] and N(3)–C(6) [1.337(2) Å] are little larger than N(4)-C(7) [1.319(2) Å] bond. This lengthening of N-C bond lengths may be due to delocalization of π-bonded electron. All other inter atomic distances are normal. The morpholine ring exists in a chair conformation.

The C(5)–S(1) bond distance of the heterocyclic compound is 1.7033 (19) Å. This bond distance is shorter than a C–S single bond (1.81 Å) but longer than a C–S double bond (1.62 Å), suggesting partial double bond character in the compound [46,47]. This lengthening of bond distance is possibly due to resonance stabilization.

The heterocyclic compound possesses a short non-bonded $S^-\cdots S$ contact with the distance of 2.738 Å. This contact may arise due to nucleophilic approaching of S^- in the N(3)–S(2)–N(4) plane along posterior extension of N(4) → S(2) or N(3) → S(2) bond, which is interpreted as an interaction of S^- with σ^* orbital of N(4) → S(2) or N(3) → S(2) bonds [45].

In the nitrogen–sulfur heterocyclic compound, the adjacent mononuclear units are locked by C(9)–H(9B)···O(1) hydrogen bonding along a axis by the formation of 1D supramolecular chain. The H(9B)···O(1)[a] ($a = 1 + x, y, z$) distance is 3.456(3) Å and C(9)–H(9B)···O(1) angle is 174°. This 1D chain is further extended to two dimensional supramolecular sheet by face-to-face π–π interactions along b axis. The Cg···Cg distance (Cg is the centroids of the interacting rings) is 4.260(3)[b] Å and the dihedral angle is 1° ($b = 1 - X, -1/2 + Y, 1/2 - Z$). The molecules are arranged in an offset manner to maximize such interactions and generate a 2D supramolecular sheet along *ab* plane (Fig. 2). The disposition of the adjacent sheets is shown in Fig. 3.



3.2. Structure of the zinc complex

Representations of the X-ray crystal structure of the $[Zn(Hdammthiol)(OAc)(H_2O)]\cdot H_2O$ complex is shown in Fig. 4 and a selection of bond lengths are given in Table 2. The metal ion is contained in geometrically similar distorted square pyramidal environment ($\tau = 0.05$) [48]. The distortion of the complex from idealized geometry is most likely caused by ligand constraints. The O(2)–Zn–N(3) (152.96(8)°) angle would remain approximately linear for both idealized sq pyr geometry, lying in the basal plane of the square pyramid.

The oxime nitrogen, azomethine nitrogen, deprotonated thiol sulfur of Hdammthiol and acetato oxygen defines the equatorial plane of the square pyramid while the axial position is occupied by oxygen (O4) of coordinated water molecule. The zinc ion is 0.3766 (8) Å off the basal plane towards the O(4). The two Zn–O distances of the $[Zn(Hdammthiol)(OAc)(H_2O)]\cdot H_2O$ which are

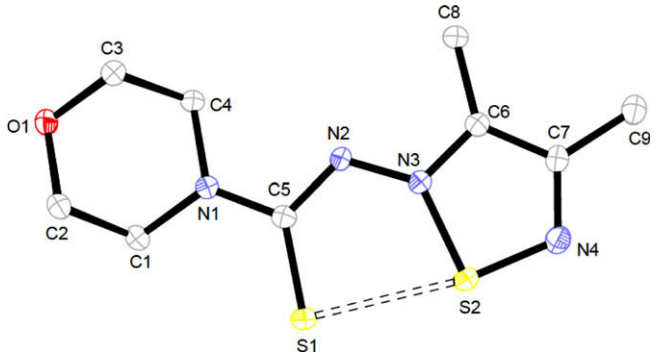

Fig. 1. ORTEP drawing of the nitrogen–sulfur heterocyclic compound with the $S^{-}\cdots S$ contact and the atom labeling scheme, and with 50% probability.

slightly different, are the shortest of the five coordinating bond lengths. Significantly shorter bond lengths show that axial ligation is stronger to the softer water O-donor than acetate-O. The deprotonation of the ligands results in extensive delocalisation of charge and as a consequence the C–S bond length (1.7459(18) Å) are much closer in length to a C–S single bond (1.82 Å), which has partial double bond character [46,47]. The Zn–N(3) (azomethine) distance [2.0985(16) Å] is slightly shorter than Zn–N(4) (oxime) distance [2.1901(16) Å]. This shortening of C=N distance may be due to intramolecular hydrogen bonding.

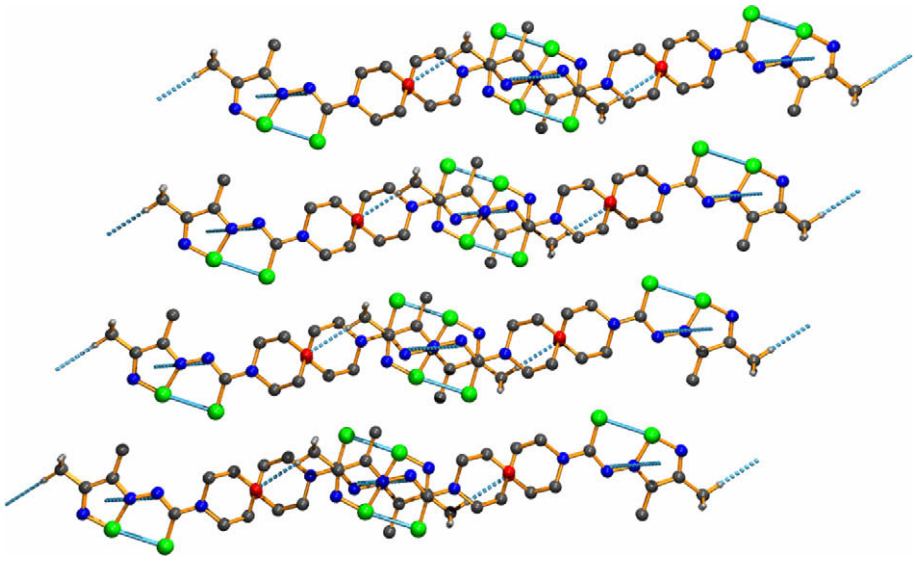

Fig. 3. A perspective view of the disposition of adjacent sheets of the nitrogen–sulfur heterocycle compound (**5**).

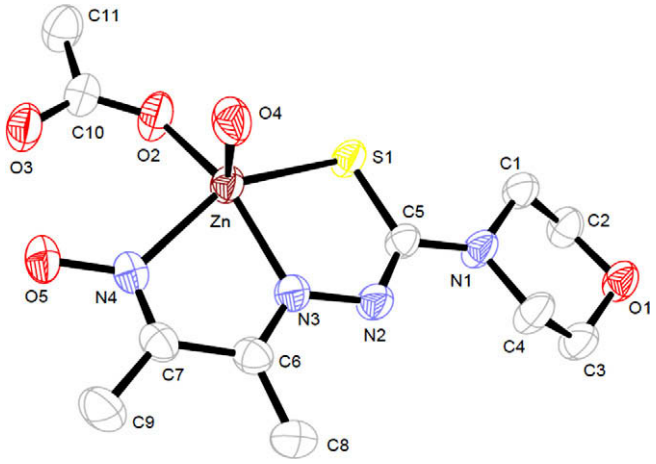

Fig. 4. Molecular drawing of [Zn(Hdammthiol)(OAc)(H_2O)] with atom labeling scheme and anisotropic displacement ellipsoid depicted at 50% probability.

Structure of zinc complex displays some interesting hydrogen bonding network. The two hydrogen atoms of coordinated water molecule form one dimensional hydrogen bonding network diagonally to *ab* plane (Fig. 5). The H(1) of coordinated water molecule is hydrogen bonded to morpholinic oxygen O(1) while H(2) is hydrogen bonded to acetate oxygen O(3). The H(2)···O(3)^{c} (1.87(3) Å, $c = 2 - x,\ 2 - y,\ 2 - z$) distance is slightly shorter than the H(1)···O(1)^{d} (2.18(3) Å, $d = 1 - x,\ 1 - y,\ 1 - z$) distance.

3.3. ^{1}H NMR, ^{13}C NMR and IR spectra

The following differences can be drawn from the comparison between the nitrogen–sulfur heterocyclic compound and the Zn-complex based on their spectroscopic characterization data: (a) the small differences in the carbon resonance in the ^{13}C NMR spectrum between the heterocycle and the zinc complex may be due to some conformational change of the morpholine ring [49], (b) the lowering in the δ values of C6 and C7 in the Zn-complex compared to that of heterocycle suggest the bonding to the Zn atom through N(4) and N(3) attached with C6 and C7, (c) the ν(C=S) of the thioketo form of the ligand (HL^{1}) generally absorbs at around 800 cm^{-1} in the infrared spectrum [50], which in the Zn-complex is absent, instead a new band around 756 cm^{-1} was observed, assignable to ν(C–S), suggesting thereby the coordination of Zn(II) ion through

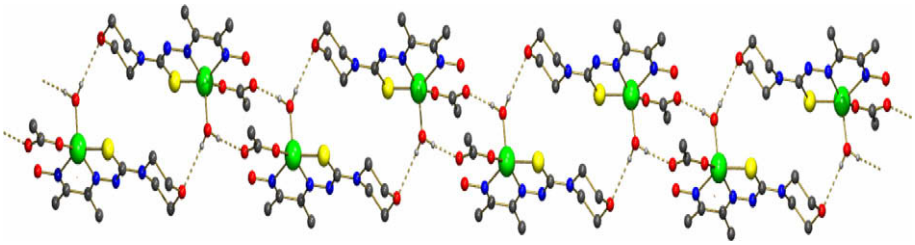

Fig. 5. 1D hydrogen bonding chain of [Zn(Hdammthiol)(OAc)(H_2O)] diagonal to the *ab* plane.

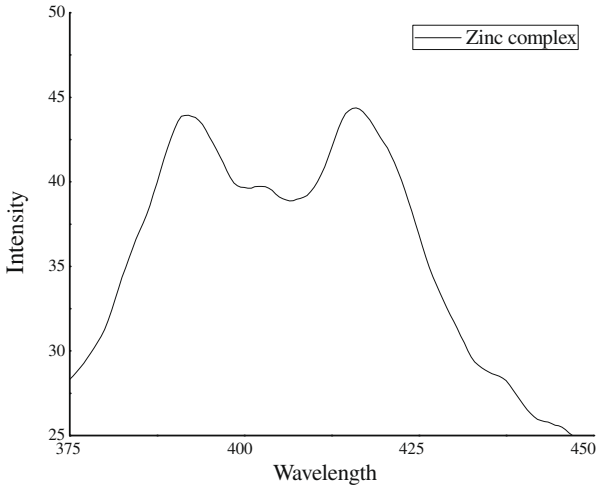

Fig. 6. Emission spectra of a 10^{-6}M solution of [Zn(Hdmmthiol)(H_2O)(OAc)]·H_2O in $CHCl_3$, λ_{ex} = 322 nm.

thiol sulfur *via* deprotonation [51]. The *ν*(C=S) band of heterocyclic compound is observed at 772 cm^{-1}.

The ^1H NMR spectra for the nitrogen–sulfur heterocyclic compound (**5**) does not show any chemical shift due to oxime –OH and –SH proton in $CDCl_3$. Two singlets one at *δ* 2.50 ppm and another at 2.28 ppm may tentatively be assigned to the two sets of methyl protons of (**5**) [52]. The chemical shifts of N–CH_2 (4H) and O–CH_2 (4H) of the morpholine ring are observed at *δ* 3.17 ppm (singlet) and *δ* 3.60 ppm (singlet), respectively [53].

The methyl protons of the Zn(II) complex are observed at *δ* = 2.33 ppm (singlet) and 2.04 ppm (singlet) [54] while for the methylene protons {N–CH_2 (4H) and O–CH_2 (4H)} of the morpholine ring at *δ* = 3.47 ppm (singlet) and 3.89 ppm (singlet), respectively [53]. The zinc complex also exhibits peaks at 7.27 ppm (broad singlet) and 2.2 ppm (singlet) for coordinated and lattice water, respectively [54,55].

The ^{13}C NMR spectrum of (**5**) shows seven signals due to the presence of nine carbon atoms. Two signals at 152.82 ppm and 147.90 ppm are due to carbon atom of –C=N–S and –C=N–N group of the five member ring. The signal at 179.11 ppm may be due to carbon atom of N=C–S^-. The other signals of the heterocyclic compound at 47.57, 66.82, 15.48 and 12.40 are due to C(1), C(2), C(8) and C(9), respectively [49,56].

The zinc(II) complex shows nine signals in ^{13}C NMR spectra. The extra two signals are due to the presence of acetate group in the complex. The signals at 151 ppm and 147.73 ppm are due to carbon atom of –C=N–O and –C=N–N groups. The signal at 180.53 ppm may be due carbon atom of N=C–S–Zn. The other signals of the zinc complex are at 47.5, 66.46, 15.03 and 11.99 are due to C(1), C(2), C(8) and C(9), respectively [49,56]. The small differences in the carbon resonances in the heterocyclic and the zinc complex may due to conformational change of morpholine ring [57].

3.4. Luminescence spectrum of zinc complex

In the electronic spectra of the zinc complex, recorded in chloroform solution, an absorption band in the range 320–392 nm was observed, which may be associated with a $\pi \rightarrow \pi^*$ transition originating mainly in the azomethine chromophore (imine $\pi \rightarrow \pi^*$ transition). Since Zn^{2+} ion has no unoccupied valence electron orbitals, therefore does not exhibit fluorescent characteristics. The zinc complex, [Zn(Hdammthiol)(OAc)(H_2O)]·H_2O shows two intense peaks at about 392 and 416 nm in the chloroform solution at room temperature when excited at 322 nm (Fig. 6) which may be interpreted as the intraligand fluorescence and (π–π^*) phosphorescence [58]. The ligand under influence of Zn^{2+} ion forms a rigid chelate ring (Fig. 4). When irradiated under an ultraviolet light, the ligand absorbs the light energy and transition occurs. So, the emission of complex in $CHCl_3$ at 298 K (λ_{max} = 322 nm) is dominated by the intraligand fluorescence of the thiohydrazone ligand.

4. Conclusion

Heterocycles containing sulfur and/or nitrogen atoms are useful as components of functional materials since heteroatoms in their rings are helpful to stabilize ions or ion-radical species, and extended π-conjugation decreases Coulombic repulsion. In addition, intermolecular interactions caused by heteroatom contacts can be expected to form novel molecular assemblies. Here in this paper we focused on reaction of diacetylmonoxime with morpholine N-thiohydrazide in absence and in presence of metal ion. The reaction of diacetylmonoxime with morpholine N-thiohydrazide under refluxing (16 h) condition in ethanol afforded zwitterionic nitrogen–sulfur heterocyclic compound, N-(3,4-dimethyl-1,2,5-thiadiazole-2-ium-2-yl)morpholine-4-carbothioate (dtmc) with non-bonded S···S interaction. This heterocyclic compound forms 2D supramolecular sheet *via* C–H···O and π···π interactions. A suitable mechanism has been proposed for the formation of heterocyclic compound. However, reaction of this two components in presence of [$Zn(OAc)_2$]·$2H_2O$ in ethanol yielded a zinc complex, [Zn(Hdammthiol)(H_2O)(OAc)]·H_2O. The 1D supramolecular chain diagonally to *ab* plane has been formed in this molecule also by O–H···O hydrogen bonding. The zinc complex shows both intraligand fluorescence and π–π^* phosphorescence in chloroform solution at room temperature.

Supplementary data

CCDC 721752 and 721753 contain the supplementary crystallographic data for nitrogen–sulfur heterocyclic compound (dtmc) and [Zn(Hdammthiol)(H_2O)(OAc)]·H_2O. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12

Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

One of us (K.D.) is thankful to the U.G.C. (New Delhi) for Emeritus Fellowship and financial grant. We are also thankful to The Regional Sophisticated Instrumentation Center, Central Drug Research Institute, Lucknow for elemental analysis and Indian Institute of Chemical Biology, Kolkata for NMR data, respectively. We are indebted to the Department of Science and Technology, Govt. of India for donation of Spectrophotometers (UV–Vis and IR) in a Scheme of Funding for Improvement under Science and Technology. We are also thankful to Dr. K. Ghosh and Prof. S.C. Chattopadhyay, Department of Chemistry, University of Kalyani, India for useful discussions.

and with cone and desolvation gas flows of 5–10 and 500 L/h, respectively (details and spectra Figs. S2–S12 in Supplementary material).

2.2. Preparation of the ligands

A mixture of cytosine (1 mmol) and *N,O*-bis(trimethylsilyl)acetamide (BSA) (3 mmol) was heated under reflux in dry acetonitrile (3.3 mL) for 1 h. The solution was cooled to 0 °C and sulfonyl chloride (1.2 mmol) was added. The reaction mixture was heated for 16 h at 80 °C, cooled and treated with a small amount of methanol. The resulting solid was filtered off and recrystallized.

2.2.1. 1-(p-Toluenesulfonyl)cytosine (**1**)

Synthesis of ligand **1** was performed according to the procedure reported by Kašnar-Šamprec et al. [7]. [^{1}H NMR (DMSO-d_6) δ/ppm: 8.14 (d, 1H, $J_{6,5}$ = 7.8 Hz, H-6), 7.95 (brd, 2H, NH_2), 7.87 (d, 2H, $J_{b,c}$ = 8.1 Hz, Ph-b), 7.46 (d, 2H, $J_{c,b}$ = 8.1 Hz, Ph-c), 5.98 (d, 1H, $J_{5,6}$ = 7.8 Hz, H-5), 2.42 (s, 3H, CH_3); ^{13}C NMR (DMSO-d_6) δ/ppm: 166.27 (s, C-4), 151.22 (s, C-2), 145.61 (s, Ph-d), 139.73 (d, C-6), 134.47 (s, Ph-a), 129.80 (d, Ph-c), 129.02 (d, Ph-b), 97.50 (d, C-5), 21.20 (q, CH_3)]. *Anal.* Calc. for $C_{11}H_{11}N_3O_3S$ (M_r = 265.30): C, 49.80; H, 4.18; N, 15.84. Found: C, 50.09; H, 4.02; N, 15.89%.

Additional data for 1-(*p*-toluenesulfonyl)cytosine (**1**): ^{1}H NMR (CD_3CN) δ/ppm: 8.13 (d, 1H, $J_{6,5}$ = 7.9 Hz, H-6), 7.92 (brd, 2H, $J_{b,c}$ = 8.4 Hz, Ph-b), 7.46 (d, 2H, $J_{c,b}$ = 8.0 Hz, Ph-c), 6.42 (brd 2H, NH_2), 5.98 (d, 1H, $J_{5,6}$ = 7.8 Hz, H-5), 2.49 (s, 3H, CH_3).

2.2.2. 1-Methanesulfonylcytosine (**6**)

1-Methanesulfonylcytosine (**6**) was prepared according to the literature method [8]. [^{1}H NMR (DMSO-d_6) δ/ppm: 8.21 (brs, 1H, NH), 8.05 (brs, 1H, NH), 7.87 (d, 1H, $J_{6,5}$ = 7.8 Hz, H-6), 5.96 (d, 1H, $J_{5,6}$ = 7.9 Hz, H-5), 3.63 (s, 3H, CH_3); ^{13}C NMR (DMSO-d_6) δ/ppm: 165.44 (s, C-4), 151.42 (s, C-2), 139.45 (d, C-6), 96.64 (d, C-5), 41.13 (q, CH_3)]. *Anal.* Calc. for $C_5H_7N_3O_3S$ (M_r = 189.20): C, 31.74; H, 3.73; N, 22.21. Found: C, 31.92; H, 4.01; N, 22.02%.

2.3. Preparation of the complexes

To a water or methanol solution of $MCl_2 \times nH_2O$ (1 equiv.), the 1-sulfonylcytosine ligand (2 equiv.) in methanol was added and the reaction mixture was left stirring. The solid product obtained by evaporation was filtered off, washed with methanol and dried.

2.3.1. Cu(1-TsC-N3)$_2$Cl$_2$ (**2**)

Starting materials: solutions of 1-(*p*-toluenesulfonyl)cytosine (**1**) (133 mg, 0.5 mmol) in methanol (23 mL), $CuCl_2 \times 2H_2O$ (43 mg, 0.25 mmol) in methanol (5 mL). The resulting dark green solution was left to slowly evaporate at room temperature in order to obtain high quality single crystals. After 7 days, two types of single crystals were present in the crystallization vessel – deep blue prisms (X-ray structure **2**) and turquoise plates [methanol solvate of **2**, X-ray structure **3** (**2** × $2CH_3OH$)]. After selection of single crystals suitable for X-ray diffraction experiments, the remaining crystals were filtered off and dried in vacuum to remove the methanol yielding 110 mg (66%) of the blue-green complex **2**: ^{1}H NMR (DMSO-d_6) δ/ppm: 8.25 (brs, 1H, H-6), 7.89 (brs, 2.5H, Ph-b + part of NH_2), 7.42 (brs, 3.5H, Ph-c + part of NH_2), 2.34 (brs, 3H, CH_3); ^{1}H NMR (CD_3CN) δ/ppm: 9.48 (brs, 1H), 8.71 (brs, 2H), 7.79 (brs, 2H), 2.59 (brs, 3H, CH_3); ^{13}C NMR (DMSO-d_6) δ/ppm: 143.22 (s, Ph-d), 132.13 (s, Ph-a), 127.58 (d, Ph-c), 126.75 (d, Ph-b), 19.27 (q, CH_3). *Anal.* Calc. for $C_{22}H_{22}Cl_2CuN_6O_6S_2 \times 2H_2O$ (M_r = 701.06): C, 37.69; H, 3.74; N, 11.99. Found: C, 37.29; H, 4.10; N, 11.74%. ESI-HRMS (*m*/*z*): $[M-TsC-Cl]^+$ ($C_{11}H_{11}N_3O_3SCuCl$): calc. 362.9506, found: 362.9494 (3.3 ppm); $[M-Cl]^+$ ($C_{22}H_{22}N_6O_6S_2CuCl$): calc. 628.0027, found: 627.9995 (5.1 ppm); $[M+TsC-Cl]^+$ ($C_{33}H_{33}N_9O_9S_3CuCl$): calc. 893.0548, found: 893.0547 (0.1 ppm).

2.3.2. Cd(1-TsC-N3)$_2$Cl$_2$ (**4**)

Starting materials: solutions of 1-(*p*-toluenesulfonyl)cytosine (**1**) (133 mg, 0.5 mmol) in methanol (23 mL), 2 M aqueous solution of $CdCl_2$ (0.125 mL, 0.25 mmol). The colorless solution was stirred overnight and was then left to evaporate at room temperature. After 4 days, colorless prisms were obtained. One transparent colorless crystal was picked for the X-ray diffraction study, and the remaining crystals were filtered off and dried in vacuum to give 131 mg (77%) of white powder **4**: ^{1}H NMR (DMSO-d_6) δ/ppm: 8.75 (brs, 1H, NH), 8.26 (brs, 1H, NH), 8.22 (d, 1H, $J_{6,5}$ = 8.0 Hz, H-6), 7.88 (d, 2H, $J_{b,c}$ = 8.3 Hz, Ph-b), 7.48 (d, 2H, $J_{c,b}$ = 8.1 Hz, Ph-c), 6.06 (d, 1H, $J_{5,6}$ = 8.0 Hz, H-5), 2.41 (s, 3H, CH_3); ^{1}H NMR (CD_3CN) δ/ppm: 8.19 (brd, 1H, H-6), 8.08 (brs, 1H, NH), 7.90 (brd, 2H, Ph-b), 7.43 (brd, 2H, Ph-c), 7.39 (brs, 1H, NH), 6.10 (brd, 1H, H-5), 2.45 (brs, 3H, CH_3); ^{13}C NMR (DMSO-d_6) δ/ppm: 163.35 (s, C-4), 148.38 (s, C-2), 146.02 (s, Ph-d), 140.38 (d, C-6), 133.29 (s, Ph-a), 129.71 (d, Ph-c), 129.01 (d, Ph-b), 97.13 (d, C-5), 21.17 (q, CH_3). ESI-HRMS (*m*/*z*): $[M-TsC-Cl]^+$ ($C_{11}H_{11}N_3O_3SCdCl$): calc. 413.9243, found: 413.9225 (4.3 ppm); $[M-Cl]^+$ ($C_{22}H_{22}N_6O_6S_2CdCl$): calc. 678.9764, found: 678.9730 (5.0 ppm); $[M+TsC-Cl]^+$ ($C_{33}H_{33}N_9O_9S_3CdCl$): calc. 944.0286, found: 944.0291 (0.5 ppm).

2.3.3. Co(1-TsC-N3)$_2$Cl$_2$ (**5**)

Starting materials: solutions of 1-(*p*-toluenesulfonyl)cytosine (**1**) (130 mg, 0.5 mmol) in methanol (40 mL), $CoCl_2 \times 6H_2O$ (60 mg, 0.25 mmol) in methanol (4 mL). The resulting dark violet solution was left to slowly evaporate at room temperature yielding 112 mg of blue powder **5**: ^{1}H NMR (DMSO-d_6) δ/ppm: 8.10 (d, 1H, $J_{6,5}$ = 8 Hz, H-6), 7.90 (brd, 2H, NH_2), 7.84 (d, 2H, $J_{b,c}$ = 8.4 Hz, Ph-b), 7.44 (d, 2H, $J_{c,b}$ = 8.4 Hz, Ph-c), 5.93 (d, 1H, $J_{5,6}$ = 7.9 Hz, H-5), 2.40 (s, 3H, CH_3); ^{1}H NMR (CD_3CN) δ/ppm: 8.05 (brd, 1H, H-6), 7.85 (brd, 2H, Ph-b), 7.40 (brd, 2H, Ph-c), 6.33 (brs, 2H, NH_2), 2.42 (brs, 3H, CH_3). ESI-HRMS (*m*/*z*): $[M-Cl]^+$ ($C_{22}H_{22}N_6O_6S_2CoCl$): calc. 624.0063, found: 624.0041 (3.5 ppm); $[M+TsC-Cl]^+$ ($C_{33}H_{33}N_9O_9S_3CoCl$): calc. 889.0584, found: 889.0582 (0.2 ppm).

2.3.4. Cu(1-MsC-N3)$_2$Cl$_2$ (**7**)

Starting materials: solutions of 1-methanesulfonylcytosine (**6**) (113 mg, 0.6 mmol) in methanol (40 mL), $CuCl_2 \times 2H_2O$ (51 mg, 0.3 mmol) in methanol (2 mL). The resulting turquoise solution was left to slowly evaporate at room temperature in order to obtain high quality single crystals. After 5 days, dark green prisms were obtained, one of which was picked for X-ray diffraction measurements, while the others were filtered off, yielding 137 mg (89%) of dark green powder **7**: ^{1}H NMR (DMSO-d_6) δ/ppm: 7.97 (brs, 2H, NH_2), 7.32 (brs, 1H, H-6), 3.67 (s, 3H, CH_3); ^{13}C NMR (DMSO-d_6) δ/ppm: 136.06 (d, C-6), 39.01 (q, CH_3). ESI-HRMS (*m*/*z*): $[M-Cl]^+$ ($C_{10}H_{14}N_6O_6S_2CuCl$): calc. 475.9401, found: 475.9388 (2.7 ppm).

2.3.5. Cd(1-MsC-N3)$_2$Cl$_2$ (**8**)

Starting materials: solutions of 1-methanesulfonylcytosine (**6**) (113 mg, 0.6 mmol) in methanol (40 mL), 2 M aqueous solution of $CdCl_2$ (0.15 mL, 0.3 mmol). After 1 h, a white precipitate was formed. It was filtered off and dried in vacuum to give 131 mg (77%) of snow-white powder **8**. The mother liquor was left to crystallize, but the colorless prisms formed after four days turned out to be single crystals of ligand **6**. Complex **8**: ^{1}H NMR (DMSO-d_6) δ/ppm: 7.92 (brs, 1H, NH), 7.89 (brs, 1H, NH), 7.84 (d, 1H, $J_{6,5}$ = 7.8 Hz, H-6), 5.90 (d, 1H, $J_{5,6}$ = 7.8 Hz, H-5), 3.62 (s, 3H, CH_3); ^{13}C NMR (DMSO-d_6) δ/ppm: 166.06 (s, C-4), 152.08 (s, C-2), 139.08 (d, C-6), 96.68 (d, C-5), 41.05 (q, CH_3). ESI-HRMS (*m*/*z*): $[M-Cl-HCl]^+$ ($C_{10}H_{13}N_6O_6S_2Cd$): calc. 490.9372, found: 490.9345

(5.5 ppm); $[M-Cl-HCl+TsC]^+$ ($C_{15}H_{20}N_9O_9S_3Cd$): calc. 679.9580, found: 679.9556 (3.5 ppm).

2.4. X-ray structural analysis

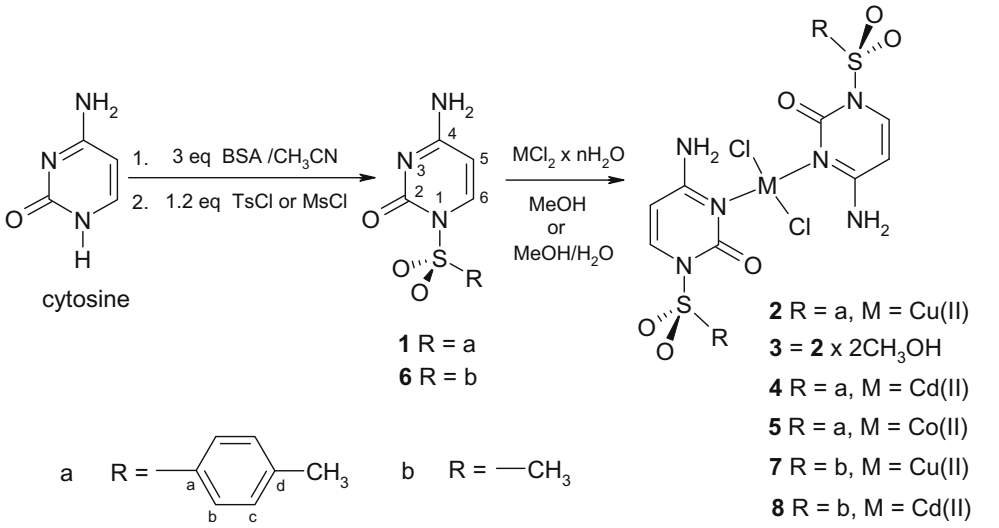
Crystal data, data collection and refinement parameters are summarized in Table 1. Data collections were performed on an Enraf Nonius CAD4 diffractometer using graphite monochromated Cu Kα radiation (λ = 1.54179 Å) (structures **2**, **3** and **4**) and on an Oxford Diffraction Xcalibur Nova R diffractometer with a microfocusing Cu tube (structures **6** and **7**). The X-ray structure of ligand **1** was reported in our previous paper [6]. Data reduction and cell refinement were carried out using the procedures incorporated into the WINGX package [9] for structures **2**, **3** and **4**, while, CRYSALIS software [10] was used for the structures **6** and **7**. Intensities were measured at room temperature. All structures were solved using direct methods with SIR2002 [11] and refined using full matrix least-squares refinement based on F^2, with SHELX97 [12]. Molecular illustrations were prepared with ORTEP-3 [13] and PLATON [14]. All non-hydrogen atoms in the structures were refined anisotropically and hydrogen atoms were included in their geometrically calculated positions (except for some hydrogen atoms included in hydrogen bonding), and refined according to the riding model.

3. Results and discussion

3.1. Synthesis

The organic ligands were synthesized by procedures described in the literature [7,8]. Condensation of silylated cytosine with *p*-toluenesulfonyl chloride (TsCl) or methanesulfonyl chloride (MsCl) gave the corresponding ligands 1-tosylcytosine, **1** (1-TsC), and 1-mesylcytosine, **6** (1-MsC). The mononuclear complexes described in this paper were prepared by the reaction of Cu(II), Cd(II) and Co(II) chlorides with the corresponding ligands in a 1:2 molar ratio of reactants in methanol and led to complexes of the $M(L)_2Cl_2$ type (Scheme 1).

Two forms of copper complexes with the 1-tosylcytosine ligand **1** were isolated in the process of crystal growth from a diluted methanolic solution: Cu(1-TsC-*N*3)$_2$Cl$_2$ (**2**) and its solvated pseudopolymorph Cu(1-TsC-*N*3)$_2$Cl$_2$ × 2CH$_3$OH (**3**), with suitable monocrystals for X-ray diffraction studies. Crystals suitable for X-ray crystallography were also obtained in the reaction of copper(II) chloride with 1-mesylcytosine **6**, yielding the complex Cu(1-MsC-*N*3)$_2$Cl$_2$ (**7**), and yielding the complex Cd(1-TsC-*N*3)$_2$Cl$_2$ (**4**) in the reaction of cadmium(II) chloride with 1-tosylcytosine **1**. On the other hand, the IR and NMR studies suggested the existence of the Co(II) complex with ligand **1** and the Cd(II) complex with ligand **2**, for which we assume them to be the N3 coordinated species Co(1-TsC-*N*3)$_2$Cl$_2$ (**5**) and Cd(1-MsC-*N*3)$_2$Cl$_2$ (**8**); their molecular formulas were confirmed by HRMS spectrometry.



3.2. NMR Spectroscopy

In the ^{1}H NMR spectrum (measured in DMSO-d_6), complex Cd(1-TsC-*N*3)$_2$Cl$_2$ (**4**) displays a slight downfield shift of the signals for two sets of doublets in the aromatic region corresponding to the H-6 and H-5 protons (δ 8.22 and 6.06 ppm) and phenyl Ph-b and Ph-c protons (δ 7.88 and 7.48 ppm) relative to the free ligand **1**. The H-6 ($\Delta\delta$ 0.03 ppm), H-5 ($\Delta\delta$ 0.06 ppm) and NH ($\Delta\delta$ 0.28 and 0.16 ppm) signals in the Cd(1-MsC-*N*3)$_2$Cl$_2$ (**8**) complex are slightly shifted to higher frequencies compared to those of the free cytosine ligand **6**, which is in accord with coordination *via* N3. These very small changes are in agreement with other cytosine complexes [15].

NMR peak positions are particularly sensitive to the presence of paramagnetic species and "diamagnetic" ^{1}H NMR spectroscopy has not been applied extensively to Cu(II) and Co(II) coordination complexes because of their paramagnetism, which complicates the spectra acquisition and interpretation. On the other hand, almost all signals for complexes Cu(1-TsC-*N*3)$_2$Cl$_2$ (**2**), Co(1-TsC-*N*3)$_2$Cl$_2$ (**5**) and Cu(1-MsC-*N*3)$_2$Cl$_2$ (**7**) were registered in the "diamagnetic" (in the range δ = 0–14 ppm) part of the ^{1}H NMR spectra, showing broad resonances (doublets collapsed into broad singlets). The

signal of H-5, a proton of the cytosine moiety, which is not in the nearest neighborhood to the coordination center, disappeared from the range of "diamagnetic" spectra for complexes **2**, **5** and **7** (*Figs.* S13 and S14 Supplementary material).

The spectrum of complex Co(1-TsC-*N*3)$_2$Cl$_2$ (**5**) exhibits signals of the free ligand **1** in DMSO-d_6 solution (*Figs.* S13), indicating low stability of the complex in polar coordinative solvent. However, the ^{1}H NMR spectrum of **5** measured in CD_3CN shows the disappearance of the H-5 signal, as can be seen for the paramagnetic Cu(II) complex **2**; all other broad resonances are slightly shifted to higher field compared to the spectrum of the free ligand **1** (*Figs.* S14). Due to the lack of an X-ray structure for the Co(II) complex **5**, we can only suggest that the binding probably takes place at the N-3 atom of the cytosine moiety.

3.3. Infrared spectroscopy

The infrared spectra of the free ligands, 1-tosylcytosine **1** and 1-mesylcytosine **6**, together with their complexes with copper, cadmium and cobalt, are shown in Figs. 1 and 2, while the band assignments are given in Table 2. Direct evidence of complexation is the presence of absorption bands due to the metal–chlorine stretching vibration in the spectral region below 500 cm^{-1}. In the region corresponding to ν(NH) vibrations, the spectra of 1-tosylcytosine **1** and 1-mesylcytosine **6** undergo prominent changes due to complexation, both in the band positions and intensities.

3.4. The molecular and crystal structures of 1-tosylcytosine complexes *2*, *3* and *4*

The molecular structures of the Cu(II) complexes, pseudopolymorphs **2** and **3**, as well as of the Cd(II) complex **4** are given in Figs. 3–5, respectively. The geometries of the pyrimidine rings in complexes **2**, **3** and **4** are given in Table 3. As the Cu(II) ion in complex **2** lies on an inversion center, and consequently the molecule possesses C_i symmetry, the two cytosine rings have identical geometries. This is, however, not the case of complexes **3** and **4**. Moreover, in the cytosine ring 1 (cy1) of complex **3**, the values of bond lengths N3–C4 and C4–N4 suggest an increase of the single bond character of the former, and an increase of the double bond character of the latter, compared to complexes **2** and **4** as well as to the other cytosine ring (cy2) of the same complex (Table 3). They

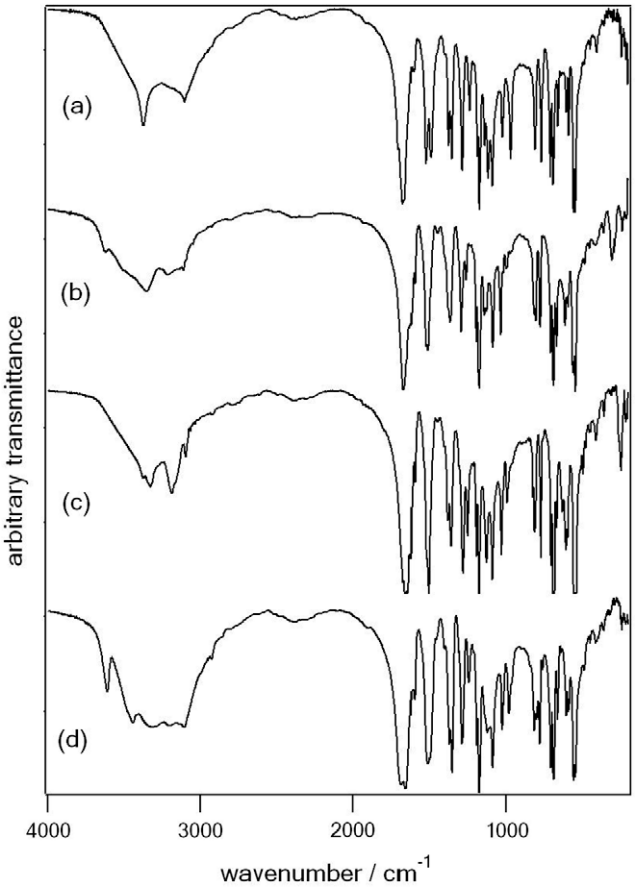

Fig. 1. Infrared spectra of (a) 1-tosylcytosine **1**, (b) Cu(1-TsC-*N*3)$_2$Cl$_2$ x 2CH$_3$OH (**3**), (c) Cd(1-TsC-*N*3)$_2$Cl$_2$ (**4**) and (d) Co(1-TsC-*N*3)$_2$Cl$_2$ (**5**).

are, in fact, in very good accord with the analogous average values extracted from the current version of *CSD* [16] for a set of 14 structures containing the iminooxo form of *N*-1-substituted cytosine [N3–C4, 1.359(5) Å; C4–N4, 1.300(4) Å]. This is due to charge delocalization over the bonds N3–C4 and C4–N4, caused by the copper coordination. Search of the same version of the *CSD* has revealed

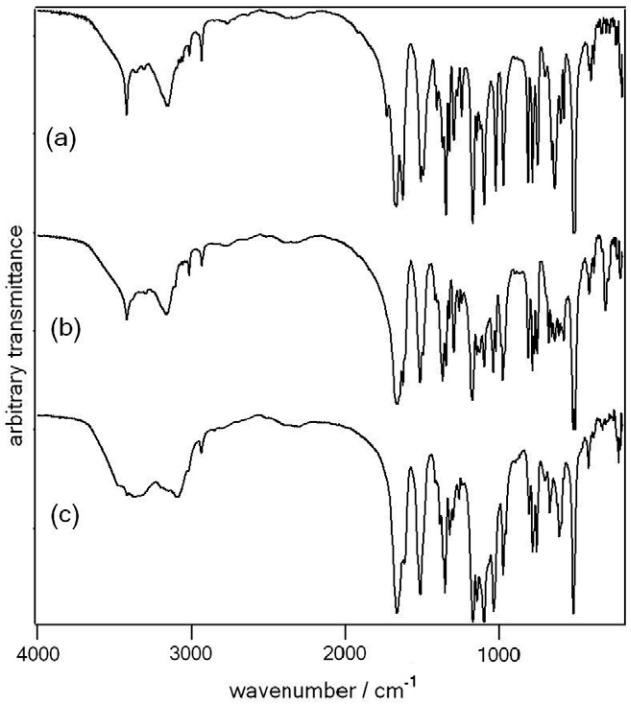

Fig. 2. Infrared spectra of (a) 1-mesylcytosine **6**, (b) Cu(1-MsC-*N*3)$_2$Cl$_2$ (**7**) and (c) Cd(1-MsC-*N*3)$_2$Cl$_2$ (**8**).

291 structures containing the preferred amino-oxo form of *N*-1-substituted cytosine. In this set, the average values for these bond lengths are: N3–C4, 1.346(1) Å, and C4–N4, 1.323(1) Å, which correspond to the analogous values in complexes **2** and **4**, and also, approximately, to the bond lengths revealed by the cytosine ring 2 (cy2) of complex **3**.

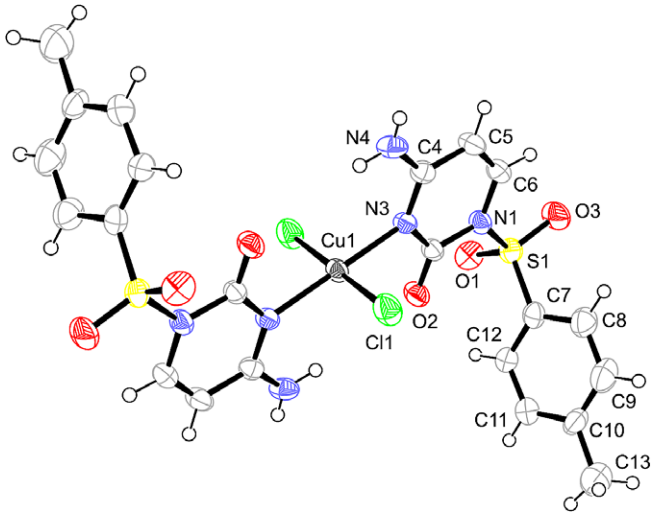

Fig. 3. ORTEP drawing of **2**. Thermal ellipsoids are scaled at the 50% probability level.

In both copper complexes **2** and **3**, the central ion forms a square-planar coordination sphere, almost ideal in the case of **2**, and considerably distorted in the case of **3** (Table 4). On the other hand, while the two coordinated pyrimidine rings are in a *trans*-arrangement with respect to the central Cu(II) ion [N3–Cu1–N3*i*, 180(11)°, see Table 4] and are virtually coplanar (head-to-tail oriented), they are mutually *cis*-oriented in complex **3** [N3–Cu1–N23, 90.88(14)°, see Table 4], and their corresponding *ls* planes

[a] Thermogravimetry of **3** shows a continuous mass loss of 6.45%. This, together with the IR band position, shows that methanol is only weakly adsorbed to the crystal of **3** (Figs. S1a).

[b] The thermogram of the complex **5** reveals a continuous mass loss of 2.66%, which corresponds to one water molecule per formula unit. This, together with the IR band position, indicates that water is only weakly adsorbed to the crystal of **5** (Figs. S1b).

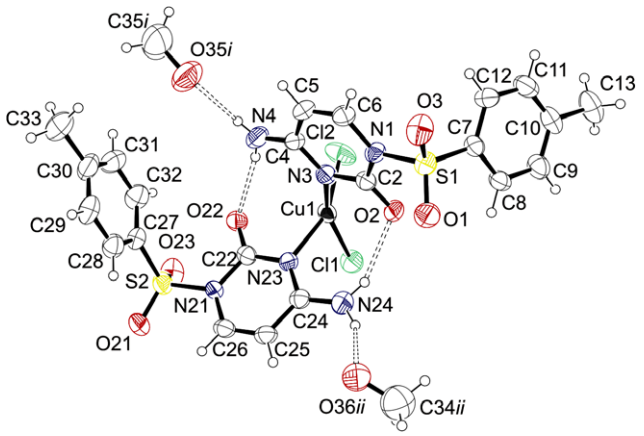

Fig. 4. ORTEP drawing of **3**. Thermal ellipsoids are scaled at the 40% probability level Hydrogen bonds are given by dashed lines.

form an angle of 72.5(2)°. The crystal structure of **2** is characterized by a complex three-dimensional hydrogen bonded molecular network where each complex molecule is connected to two others through amino-group protons forming hydrogen bonds towards O2*i* and O3*i* of the neighboring molecule (Table 5a and Fig. 6). The crystal packing is less complicated by far in the structure of complex **3**, where a single complex molecule is connected through intermolecular hydrogen bonds to only two neighboring solvent molecules, forming with them discrete hydrogen bonded units (Table 5a and Fig. 4). The refinement of the OH group hydrogens of both solvent molecules does not converge, and consequently they are not included in the model. They might however extend the hydrogen bonding network in this structure.

Complex **4** is a neutral complex where the positive charge of the central Cd(II) ion is compensated by two chlorine anions, forming together with two endocyclic N3 atoms that belong to cytosine rings of the two ligand molecules a slightly distorted tetrahedral coordination sphere (Table 4 and Fig. 5). Its crystal structure is characterized by a complex hydrogen bonded three-dimensional molecular network. Two ligand molecules coordinated to the central Cd(II) ion form different hydrogen bonds *via* their amino groups, thus creating an asymmetric environment around the Cd(II) cation (Table 5a). While cytosine 1 of complex **4** forms one intramolecular H-bond *via* N4-H4A, and one intermolecular hydrogen bond with the chlorine from the neighboring molecule *via* N4-H4B, cytosine 2 forms, besides these two hydrogen bonds, an

additional hydrogen bond N24–H24A···O21*ii*, thus creating a bifurcated hydrogen bond *via* the H24A proton.

*3.5. The molecular and crystal structures of 1-mesylcytosine **6** and its Cu(II) complex **7***

The hydrogen bonding pattern of ligand **6** is given in Fig. 7. The molecular structure of this ligand reveals no unexpected features. The geometry of the pyrimidine ring is typical of an N1-substituted cytosine in the preferred aminooxo form [6]. The hydrogen bonding pattern (Table 5b) reveals centrosymmetric dimers formed by the H-bond N4–H4A···N3*i*. These dimers are further connected into endless chains *via* the N4–H4B···O2*ii* hydrogen bond. The ORTEP drawing of complex **7** is given in Fig. 8 and its crystal packing is displayed in Fig. 9. In complex **7**, the Cu(II) ion resides in the center of a rather unusual, severely distorted coordination sphere that could be described as a transition state between a square planar and a tetrahedral arrangement, and strongly resembles the coordination sphere of Cu(II) in complex **3**. Relevant geometry parameters are given in Table 4. Both of these complexes lack molecular C_i symmetry, unlike complex **2** where the central Cu(II) ion lies on an inversion center and reveals a square-planar coordination sphere. Four ligand atoms (N3, N23, Cl1 and Cl2) reveal strong deviations from the *ls* plane calculated through them and the central Cu(II) ion, with the average absolute value of 0.38(2) Å. The angle between the planes defined by Cl1, Cu1 and Cl2 and by N3, Cu1 and N23 is 28.97(4)°. These values describe the coordination sphere of complex **7** as a severely distorted square plane, rather than as a severely distorted tetrahedron. Angles N3–Cu1–N23 and Cl1–Cu1–Cl2 [91.21(8)° and 96.26(4)°, see Table 4] further support this conclusion and, moreover, suggest a *cis*-arrangement. An obvious result is the angle of 73.56(6)° formed by the *ls* planes of two pyrimidine rings, which are, hence, close to a mutual perpendicular arrangement, similarly as in complex **3**, and unlike in complex **2**, where the two pyrimidine rings are coplanar and *trans* oriented with respect to the central Cu(II) ion (*vide supra*). The crystal structure of **7** is characterized by endless hydrogen bonded molecular chains along the crystallographic *b* axis (Fig. 9). These chains are formed by the N4–H4A···O2*i* hydrogen bond (Table 5b). Through its remaining hydrogen, H4B, N4 forms an intramolecular hydrogen bond, N4–H4B···O22, symmetrical (with respect to Cu(II)) with the hydrogen bond N24–H24B···O2 (Fig. 8). Hence, O2 acts as a double acceptor, taking part in one intramolecular and one intermolecular hydrogen bond. Nevertheless, two exocyclic nitrogen atoms from two cytosine rings, N4 and N24, reveal an asymmetrical hydrogen bonding pattern. N4 forms an intermolecular bond to O2*i* and an intramolecular one to O22 (*vide supra*), while N24 forms an intramolecular hydrogen bond to O2, and an

intermolecular bond N24–H24a···Cl*ii* through which the above described molecular chains along the crystallographic *b* axis are interconnected, forming a two-dimensional molecular grid which propagates parallel to the *bc* plane. A narrow *zig-zag* channel separates two neighboring grids.

4. Conclusions

The mononuclear complexes of the type M(L$_2$)Cl$_2$ described in this paper were prepared by the reaction of Cu(II), Cd(II) and Co(II) chlorides with the 1-tosylcytosine **1** or 1-mesylcytosine **6** ligands. NMR and IR spectra show clear evidence of the complexation of ligands **1** and **6** with Cu(II) [complexes **3** and **7**], Cd(II) [complexes **4** and **8**] and Co(II) [complex **5**].

Two forms of copper complexes with 1-tosylcytosine ligand **1** were isolated in the process of crystal growth from a diluted methanolic solution: Cu(1-TsC-*N*3)$_2$Cl$_2$ (**2**) and its solvated pseudopolymorph Cu(1-TsC-*N*3)$_2$Cl$_2$ × 2CH$_3$OH (**3**). The X-ray structure of the complex **3** revealed charge delocalization inside the cytosine ring, prompted by metal coordination, which is the first step towards tautomerization. This, to the best of our knowledge, has not been observed previously with the copper complexes of *N*-1 substituted cytosine.

Acknowledgments

We appreciate the financial support of the Ministry of Science, Education and Sports of the Republic of Croatia through Grant Nos. 098-0982914-2935, 098-1191344-2943 and 098-0982904-2927. We also thank Renata Kobetić and Dubravka Gembarovski for HRMS, Ernest Sanders for TG measurements, and Krešimir Molčanov for X-ray data collection for compounds **6** and **7**.

Appendix A. Supplementary data

CCDC 729010, 729011, 729012, 729013 and 729014 contains the supplementary crystallographic data for **2**, **3**, **4**, **6** and **7**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.06.088.

NMR and ^{13}C NMR spectra were recorded on a Bruker 300 spectrometer instruments. Multiplities are given as s (singlet), d (dublet), t (triplet). FT-IR was recorded on SHIMADZU IR-PRESTIGE-2 Spectrophotometer. Elemental analysis (C, H and N) was performed at the instrumental Analysis Laboratory. Routine UV–Vis spectra were obtained in a quartz cuvette on an Agilelt 8453 UV–Vis spectrophotometer. Mass spectra were performed on a Bruker Autoflex III mass spectrometer. Spectra were recorded both in linear and reflectron modes with average of 50 and 100 shots for linear and reflectron modes. 2,5-Dihydroxy benzoic acid (DHB) MALDI matrix for **3** was prepared. MALDI samples were prepared by mixing complexes (2 mg/mL in acetonitrile) with the matrix solution (1:10 v/v) in a 0.5 mL eppendorf® micro tube. Finally 1 μL of this mixture was deposited on the sample plate, dried at room temperature and then analyzed. Fluorescence spectra were measured by a JASCO FP-777 W spectrophotometer (Japan Spectroscopic Co. Ltd.) at 25 °C; the slits for the excitation and emission monochrometers were 5 nm; and the spectral scan rate was 50.0 nm/min. The concentration of compound **3** was 5 μM and that of **2** was 20 μM since four derivative of benzofuran groups were bounded to one ZnPc core.

2.1. Synthesis

2.1.1. 6-(3,4-Dicyanophenylthio)-hexyl–2-chloroacetate (**1**)

About 1.0 g (3.84 mmol) of 4′-(1-hydroxyhexylthio)-1,2-dicyanobenzene (**1**) and ca. 0.32 mL (excess) of triethylamine were dissolved in 20 mL of THF at room temperature. The mixture was placed in an ice-bath. About 0.45 mL (4.2 mmol, excess 10%) of 2-chloroethylchloride was added dropwise to a stirred solution at −5 °C. The mixture was stirred at 0 °C for 3 h and at room temperature for 12 h and finally was heated for 1 h at 30 °C. The reaction mixture was poured into water and the resulting precipitates was filtered and washed with lots of water. It was dried under vacuum for 12 h at room temperature. It was chromatographed over silica gel column using a mixture of $CHCl_3$:MeOH 100/5 as eluent, giving yellow 6-(3,4-dicyanophenylthio)-hexyl-2-chloroacetate finally pure powder was dried in vacuum.

MS (ESI-MS): *m/z* (%): 370, 0 $[M]^+$.

2.1.2. 6-(3,4-Dicyanophenylthio)-hexyl–2-benzofuranate, BzF (**2**)

About 0.49 g (3.56 mmol) of K_2CO_3 in 50 mL of CH_3CN (Acetonitrile) was added to 0.38 mL (3.56 mmol) of salicylaldehyde. The mixture was stirred at room temperature for 1 h and heated at 40 °C for 1 h. About 1.00 g (2.96 mmol) of 6-(3,4-dicyanophenylthio)-hexyl-2-chloroacetate was added to this mixture at room temperature. The reaction was continued at room temperature for 1 h and refluxed for 6 h. The product formed was poured into water (100 mL). The precipitated product was filtered and washed with excess of water and was dried at 40 °C under vacuum. The product was crystallized from EtOH.

Yield: 1.04 g (86.96%) m.p.: 80 °C, *Anal.* Calc. for $C_{23}H_{20}N_2O_3S$ (404 g/mol): C, 68.32; H, 4.95; N, 6.93; S, 7.92. Found: C, 67.89; H, 4.90; N, 6.48; S, 7.46%. 2.1.3. 2,9,16,23-Tetrakis-{6-(-benzofuran-2-carboxylate)-hexylthio}-phthalocyaninato zinc (II) ZnPcBzF (**3**)

A mixture of **2** (0.150 g, 0.405 mmol), anhydrous Zn $(O_2CMe)_2$ (0.019 g, 0.107 mmol), DBU (one drop) and hexan-1-ol (∼0,2 mL) in a sealed tube was heated 6 h with efficient stirring at 150–160 °C under N_2 atmosphere. After cooling to room temperature, resulting solid was washed successively with MeOH, MeCN, and *i*-PrOH (2-propanol) and filtered to remove impurities until the filtrate was clear. The green–blue product was isolated by silica gel column chromatography with $CHCl_3$/MeOH (9,1 v/v) as eluent. Pure **3** was obtained as viscous green oil after column chromatography over sephadex (THF/$CHCl_3$, 1:2 v/v eluent) and then dried in vacuum. This product exhibited moderate solubility in $CHCl_3$ and excellent solubility in THF, DMF, DMSO and pyridine.

Yield: 0.036 g (23.0%). *Anal.* Calc. for $C_{92}H_{80}N_8O_{12}S_4Zn$ (1681 g/mol): C, 67.68; H, 4.76; N, 6.66; S, 7.61. Found: C, 67.14; H, 4.80; N, 6.45; S, 7.37%. 3. Results and discussion

Benzofuran attached zinc phthalocyanine, ZnPcBzF, (**3**), was synthesized by heating pulverized compound **2** with anhydrous

$Zn(O_2CMe)_2$ salt at ca. 150–160 °C under N_2 atmosphere in the presence of 1,8-diazabicyclo [5.4.0] undec-7-ene (DBU) as a strong base (Scheme 1). The yield of ZnPcBzF (**3**) was low (23.0%). Final product was obtained as pure sample after purifications via column chromatography over silica gel. Purification steps were tedious because of peripheral reactive end-group. The blue–green ZnPcBzF (**3**) was isolated as a mixture of isomers as expected. The structures of newly synthesized compounds were verified by FT-IR, ^{1}H NMR, UV–Vis and MALDI-TOF MS spectroscopic methods, as well as by elemental analysis. All the analytical and spectral data are consistent with the predicted structures. While the major strong –CN band appeared at 2231 in the IR spectrum of BzF (**2**) disappeared after conversion to ZnPcBzF (**3**), the strong COOR band in the compound ZnPcBzF (**3**), at around 1700 cm^{-1} came out with small shift. The aliphatic and aromatic peaks at above and below 3000 cm^{-1} and the rest of the spectra is closely similar to that of compound **2** and diagnosed easily. The ^{1}H NMR spectra of ZnPcBzF (**3**), was almost identical with starting compound **1** and BzF (**2**) except small shifts and broadening. The aromatic, aliphatic protons in the lower and higher field region of the ^{1}H NMR spectrum on the periphery and sixteen different aromatic carbon atoms between 110 and 170 ppm in addition to the aliphatic ones (30–65 ppm) in ^{13}C APT spectrum are the most instinctive indicator signals for (**1**), BzF (**2**) and ZnPcBzF (**3**). UV–Vis spectra of the ZnPcBzF (**3**), exhibit characteristic Q and B bands, one in the visible region at *ca*. 600–700 nm (Q-band) attributed to the π–π^* transition from HOMO (Highest occupied molecular orbital) to the LUMO (Lowest unoccupied molecular orbital) of the Pc^{2-} ring, and the other in the UV region at *ca*. 300–400 nm (B-band) arising from the deeper π–π^* transitions [21]. The Q-band absorptions in the UV–Vis absorption spectra of ZnPcBzF (**3**), was observed as a single band with high intensity due to a single π–π^* transition at 688, with shoulder at slightly higher energy side of the Q-band of ZnPcBzF (**3**). The absorption positions of spectrum are dependent on the ionic radii of the metal center and peripheral substitutions. The effect of S-substitution on the periphery for the ZnPcBzF (**3**) was a shift in these intense Q-bands to longer wavelengths as a result of the electron-donating thioether substituents when compared with those of unsubstituted and alkyl or O-substituted derivatives[19,20,22,23]. Maldi-MS spectroscopy has been extensively used to characterize metal-base phthalocyaninates. Therefore, the mass spectra of **1**, BzF (**2**) and ZnPcBzF (**3**), confirmed the proposed structures. The protonated mono isotopic molecular ion peaks were easily identified at *m/z*: 1682 $[M+H]^+$ for ZnPcBzF (**3**). Protonated molecular ion peak was observed at 1682 Da that was exactly overlapped with the mass of the lowest mass of the isotopic mass distribution of complex ZnPcBzF (**3**), calculated theoretically from the elemental composition of the zinc complex. Isotopic peaks resulted from isotopic distribution of the protonated molecular ion of the ZnPcBzF (**3**) was observed in between 1682 and 1690 Da with 1 Da increment in the high mass range. Following the protonated molecular ion peak, a peak group was observed at 38 Da mass higher than the protonated molecular ion peak group resulting almost same pattern. This peak is resulted from the potassium adduct of the neutral ZnPcBzF (**3**).

3.1. Peripheral silver ion binding

3.1.1. UV-measurement

Sulfur donor atoms on the periphery of the tetra or octa substituted phthalocyanines act as heavy metal ionophore and impart a preference for coordination with soft heavy metal ions with different size [3,17,18,23]. Soft-acid and soft-base coordination on peripheral side of ZnPcBzF (**3**) was carried out with Ag^+ ion as acceptor and readily monitored by UV–Vis spectroscopy. Addition of Ag^+ ion to the solution of ZnPcBzF (**3**) caused a gradual color change, from blue–green to intractable black–darkgreen, suggesting the complex formation of ZnPcBzF (**3**), with Ag^+ (Fig. 1). As seen from Fig. 1, binding of Ag^+ to the donor atoms of ZnPcBzF (**3**) resulted in pronounced effects in the Q and B bands, and in the n–π^* transitions. As shown in the Fig. 1, while addition of small increment of Ag^+ to ZnPcBzF (**3**) leads to gradual disappearance of monomeric species at which show absorption at 688, simultaneously enhancing the intensity of the oligomeric aggregated species around 642 nm (inset figure in Fig. 1). B-band of the ZnPcBzF (**3**) shifts to higher energy sides about 10 nm, such as from 362 to 352 nm together with change in intensity. These spectroscopic changes indicate the coordination of Ag^+ by the donor atoms of the phthalocyanines to form less soluble oligomeric aggregated species [3,18,23].

3.1.2. Fluorescence measurements

Excitation spectra of BzF (**2**) and ZnPcBzF (**3**) in THF were obtained upon titration with Ag^+ ion (Fig. 2). As seen from Fig. 2, BzF (**2**) displays three distinct peaks centered near 252 nm, 298 nm and 336 nm. When substituted on Pc ring, the peaks of benzofuran derivative at shorter and longer wavelengths regions are 9 nm red shifted. Both of the excitation intensities of BzF (**2**) and ZnPcBzF (**3**) were diminished by addition of silver ion and there was no spectral shift in maxima of the peaks. When excited at 345 nm of wavelength, BzF (**2**) and ZnPcBzF (**3**) exhibit maximum emission at 402 and 425 nm, respectively (Fig. 3). The maximum fluorescence emission of ZnPcBzF (**3**) gradually reduced and shifted to red region upon addition of Ag^+ ion. Silver ion titration also influenced the emission spectra of BzF (**2**) causing to quenching of fluorescence intensity but spectral shift in maximum was not observed (Fig. 3, inset). Two possibilities must be considered for the reason of the fluorescence quenching effect: The first is attributed to electron density variations on benzofuran moiety, caused by introducing positively charged ions. The second is that the decreased fluorescence is the result of benzofuran substituted Pc aggregations [24].

A bathochromic shift was observed from $\lambda = 425$ nm to $\lambda = 470$ nm along with a steady quenching of the fluorescence intensity on addition of silver ion (Fig. 4). Red shifts in spectra can be explained by a lowering of the LUMO energy level upon binding of benzofuran moiety to Pc core because formation of dimmer spicies

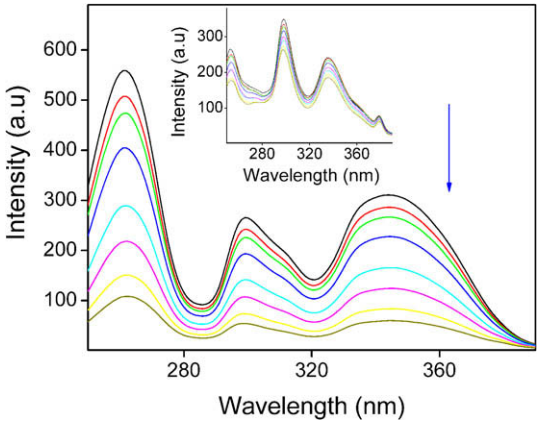

Fig. 2. Excitation spectra of 5 μM **3** in THF as function of Ag^+ ion titration. *Inset*: excitation spectra of 20 μM **2** upon titration with Ag^+ ion. Arrow shows the increase in Ag^+ ion concentration. ($\lambda_{em} = 425$ nm).

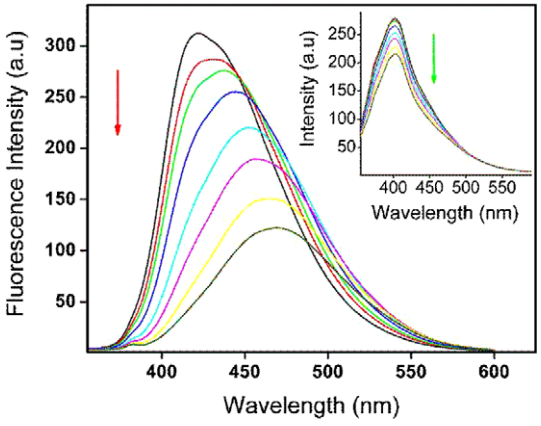

Fig. 3. Emission intensity responses of 5 μM **3** and 20 μM **2** (inset figure) in THF upon addition of 1.0, 2.5, 5.0, 7.5, 10, 25 and 50 μM Ag^+ ion. Arrow shows the increase in Ag^+ ion concentration. ($\lambda_{ex} = 345$ nm).

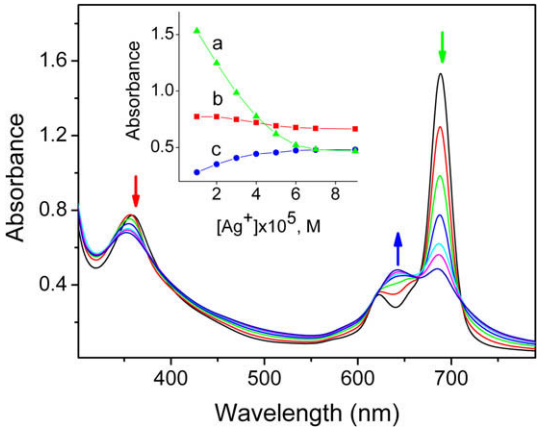

Fig. 1. UV–Visible spectra of 10 μM **3** in THF upon addition of 10, 20, 30, 40, 50, 60, 70, 90 μM Ag^+ ion. *Inset:* spectroscopic changes in Q-band (a), B-band (b) and non-bonding band (c) of **3** during Ag^+ ion titration.

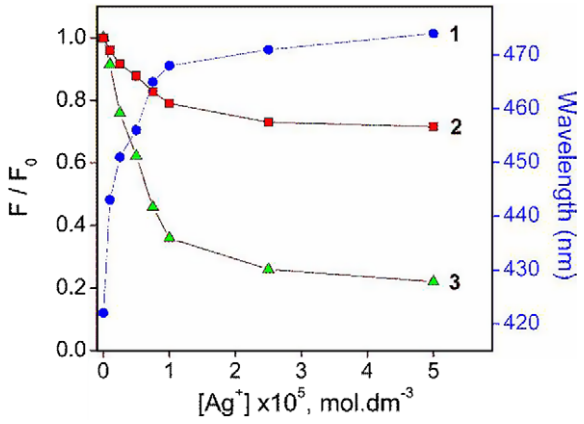

Fig. 4. Change in the maximum emission wavelength of **3** (1) and F/Fo values for **2** (2) and **3** (3) in THF with regard to Ag^+ concentration. ($\lambda_{ex} = 345$ nm).

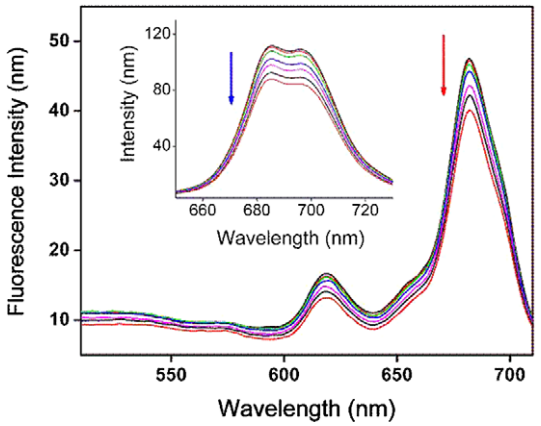

Fig. 5. Excitation spectra of **3** recorded for emission at 730 nm as a function of Ag^+ concentration. *Inset:* emission obtained for excitation at 616 nm. Arrow indicates decrease in intensity.

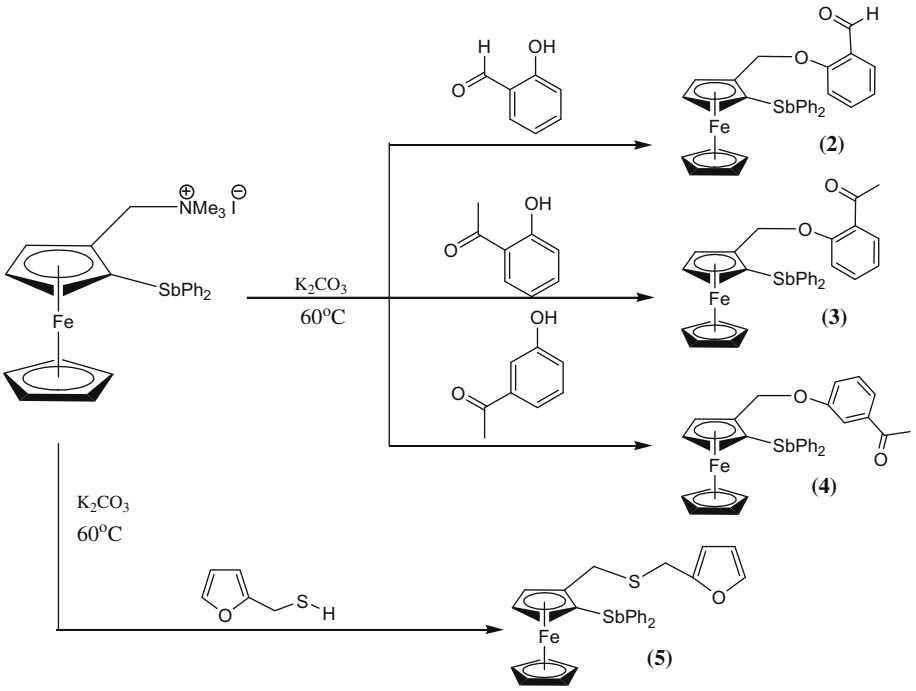
of ZnPcBzF (**3**) in solution effects π-electron conjugation on molecule causing to lowered LUMO energy level [25,26].

The variation of the electron density of the benzofuran backbone caused by Ag^+ ion plays a minor role both in the quenching of fluorescence and bathochromic effect on the emission spectra of ZnPcBzF (**3**). From the above analysis, it is reasonably deduced that the amplified fluorescence quenching effect of benzofuran moiety results mainly from the Ag^+-induced Pc core aggregation. These facts allow us to conclude that the emission band shift of BzF (**2**) on silver-cation addition is due to cation-π electron interactions [27]. The fluorescence intensity of BzF (**2**) is solely quenched without an accompanying band shift showing that the association between the sulfur atom on BzF (**2**) molecule and the silver-cation is rather weak (Fig. 4). This observation indicates that the electron transfer from the sulfur atom to the photoexcited Pc unit should be weakly depressed by the complexation of sulfur with silver ion.

Fig. 5 depicts the plots of excitation spectra belonging to Pc core [28] of ZnPcBzF (**3**) in long wavelength region with regard to titration with Ag^+ ion. As seen from Fig. 5, the excitation intensity of ZnPcBzF (**3**) was decreased by the addition of silver ion. When excited at wavelength of 616 nm, which is the isobestic point of Pc core, the fluorescence emission of ZnPcBzF (**3**) was also decreased with the increase in the silver ion concentration. This demonstrates that formation of the silver ion complex via sulfur atom on BzF (**2**) influences the fluorescence emission of Pc core. This effect is probably due to the intermolecular aggregation induced by silver ion, which brings Pc unit close each other and interacts with the π-electrons of the Pc core, causes to quenching of fluorescence emission.

4. Conclusion



In conclusion, we described the complete synthesis and characterization of a new family of peripherally functionalized zinc phthalocyanine bearing benzofuran derivative which can be used as a new fluorescent chemosensor for Ag(I). Fluoroprobe bounded Pc; ZnPcBzF (**3**), exhibits distinct changes in both spectra of absorbance and fluorescence upon titration with Ag^+ ion where as derivative of benzofuran, BzF (**2**), does not exhibit a definite affinity for Ag^+ ion. Q-band absorption peak of ZnPcBzF (**3**) gradually disappeared and dimeric peak increased in response to treatment with Ag^+ in solution. Fluorescence emission intensities at shorter and longer wavelength regions were quenched but there was only spectral shift at shorter wavelength region which belongs to BzF (**2**). This indicates the complex formation between Ag^+ and ZnPcBzF (**3**), and also shows that Ag^+-induced Pc aggregation plays a major role in the amplified fluorescence quenching.

Scheme 1.

The methylene protons of the $FcCH_2O$–/$FcCH_2S$– moiety are not magnetically equivalent. This phenomenon has been observed in the ^1H NMR spectra of complexes containing both monodentate and bidentate 1,2-disubstituted ferrocenyl ligands [19,20]. This is also a consequence of the asymmetry of the disubstituted Cp ring.

As expected a higher chemical shift for both aromatic and ferrocenyl protons adjacent to Sb–C bond, as a consequence of the dπ–pπ bond between the metal and the carbon atoms in comparison to those of similar ferrocenyl phosphines [21]. This higher chemical shift is also observed in ^{13}C NMR spectrum of these compounds with respect to phosphines.

The molecular structures of (**2**–**5**) have been confirmed by X-ray crystallography and are shown in Figs. 1–4. Crystal data for all structural analyses are given in Table 1. Selected bond lengths and angles for all compounds are listed in Table 2. All these compounds are monomeric in nature and no significant inter or intramolecular interactions were observed. All these compounds possess planar chirality. Single crystals of (**2**–**5**) were obtained by slow diffusion of hexane in dichloromethane solution. Few other ferrocenyl stibines have previously been characterized by X-ray diffraction. All compounds adopt a mononuclear distorted trigonal pyramid structure considering the lone pair of the antimony atom.

The average $Sb–C_{ferrocenyl}$ bond length found in these ferrocenylstibines is 2.126 Å, which is slightly shorter than that $Sb–C_{phenyl}$ bond length presented by other tertiary stibine, a similar observation was reported earlier also [22,8]. This shortening $Sb–C_{ferrocenyl}$ bond length is ascribed to the effect of bidentate and electron

donating. This may be due to the pπ–dπ bonding to a greater extent and thus shortening of Sb–$C_{ferrocenyl}$ bond length in all the compounds [12].

The unit cell of compound (**4**) contains two independent molecules per asymmetric unit. The *m*-acetylphenoxy portion is disordered and it was modeled in two major contributions. The average Sb–C bond length value is 2. 142 Å, with a Sb–$C_{ferrocenyl}$ bond length of 2.135 Å, which is slightly larger than those found in compounds (**2**) and (**3**).

The Sb–$C_{ferrocenyl}$ bond distances found in compounds (**2**–**5**) are slightly larger than Sb–$C_{ferrocenyl}$ bond lengths found in previously reported stibine (2.124 Å) [12,13], which may be due to the electron withdrawing capabilities of the organic moiety. In these stibines, similar bond distances and bond angles of the ferrocenyl –CH_2OR/–CH_2SR groups have been observed without any significant changes.

In compounds (**2**), (**3**), (**4**) and (**5**) geometry around antimony is pyramidal, showing average C–Sb–C angles of 95.91, 95.82, 96.74 and 96.37 respectively which are not very similar to the bond angles found in other tertiary stibines [23–25]. It is worthy to note that there is no evidence of Sb–O or Sb–S intramolecular interactions, which is probably caused by stereoelectronic factors in compounds (**2**–**5**). This type of interaction was found in similar compounds with CH_2NR_2 pendant arm.

3. General synthesis

All the solvents were distilled immediately prior to use. All the reactions were performed under an atmosphere of oxygen-free dry nitrogen. Melting points were obtained on a MEL-TEMP II Fisher and are uncorrected. FAB^+ mass spectra were recorded on a JEOL SX102 double-focusing mass spectrometer with reverse geometry using a 6-kV Xenon beam (10 am); nitrobenzyl alcohol was used as matrix for recording the mass spectra. ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ or CD_3OD on JEOL ECLIPSE 300 (^1H: 300.5311 MHz; ^{13}C: 75.5757) spectrometer.

3.1. Diphenyl [2-(2-hydroxy-benzaldehyde) methylferrocen-1-yl]stibine (*2*)

In a Schlenk tube, under N_2, 0.14 mL (1 mmol) of salicyladehyde were added to a mixture of 0.645 g (1 mmol) of *Rac*-diphenyl[(*N,N*-trimethylaminomethylferrocenyl)iodide]stibine (**1**) [12] and 1.38 g (10 mmol) of K_2CO_3 in acetonitrile. After stirring for 8 h at 80 °C the solvent was evaporated and the mixture was extracted with a water/chloroform mixture and dried with Na_2SO_4 anhydrous. Compound (**2**) was obtained as red crystals after recrystallization from a chloroform/hexane mixture. Yield : 75%, IR (ν cm^{-1}): 3041.46 (C–H aromatic), 11681.38 (C=O), 484.90 (Sb–C) ^1H NMR ($CDCl_3$, 300 MHz; δ: ppm): 4.55 (1H, s, C*H*, C_3H_5), 4.91,5.05 (2H, d^2, J = 10 Hz, CH_2), 7.25–7.36 (14H, m, Ph), 4.13 (5H, s, C_5H_5); 10.02 (1H, s, C*H*O), ^{13}C NMR ($CDCl_3$, 75 MHz; ppm): 75.45(C_{FC}–Sb), 138.16(C_{Ph}–Sb), 52.85 (CH_2), 189.6(CHO), 69.28(C_5H_5), MS-FAB^+ *m/z* (%): 595 (90%) $[M]^+$, 473 (100%) $[M-C_7H_5O_2]^+$, 275 (15%) $[M-C_{17}H_{17}FeO_2]^+$, 199 (18%) $[C_{11}H_{10}Fe]^+$.

3.2. Diphenyl [2-(2-acetyl-hydroxiphenyl) methylferrocen-1-yl]stibine (*3*)

By following the same procedure used for the preparation of (**2**), the red–orange product (**3**) was obtained after 8 h stirring from *Rac*-diphenyl[(*N,N*-trimethylaminomethyl ferrocenyl)iodide]stibine (**1**) (0.645 g, 1 mmol) and 1-(2-hydroxyphenyl)-ethanone (0.13 mL, 1 mmol). Yield: 80%, IR (ν cm^{-1}): 3060.33 (C–H aromatic), 1661.13 (C=O), 487.02 (Sb–C) ^1H NMR ($CDCl_3$, 300 MHz; δ: ppm): 4.55 (1H, s, C*H*, C_3H_5), 6.97–7.22 (14H, m, Ph), 4.09, 5.25 (2H, d^2, J = 8 Hz CH_2), 4.09 (5H, s, C_5H_5), 2.28 (3H, s, CH_3), ^{13}C NMR ($CDCl_3$, 75 MHz; ppm): 87.30(C_{FC}–Sb), 138.63(C_{Ph}–Sb),

31.02 (CH_3), 158(C=O), 69.25 (C_5H_5), MS-FAB$^+$ *m/z* (%):608 (34%) $[M]^+$, 473 (75%) $[M-C_8H_7O_2]^+$, 275 (46%) $[M-C_{19}H_{17}FeO_2]^+$, 199 (100%) $[C_{11}H_{10}Fe]^+$.

3.3. Diphenyl [2-(3-acetil-hydroxyphenyl) methylferrocen-1-yl]stibine (*4*)

By following the same procedure used for the preparation of (**2**), the red–orange product (**4**) was obtained after 8 h stirring from *Rac*-diphenyl [(*N*,*N*-trimethylaminomethylferrocenyl) iodide]stibine (**1**) (0.645 g, 1 mmol) and 1-(3-hydroxiphenyl)-etanone (0.12 mL, 1 mmol). Yield: 79%, IR (ν cm^{-1}): 3047.11 (C–H aromatic), 1683.25 (C=O), 484.90 (Sb–C), ^{1}H NMR ($CDCl_3$, 300 MHz; δ: ppm): 4.53 (1H, s, C_3H_5), 7.24–7.36 (14H, m, Ph), 4.84, 4.98 (2H, d^2, J = 7 Hz CH_2), 4.12 (5H, s, C_5H_5), 2.52 (3H, s, CH_3), ^{13}C NMR ($CDCl_3$, 75 MHz; ppm): 75.28 (C_{FC}–Sb), 139.38 (C_{Ph}–Sb), 30.41 (CH_2), 69.28 (C_5H_5), 198.17 (C=O), MS-FAB$^+$ *m/z* (%): 608 (100%) $[M]^+$, 473 (84%) $[M-C_8H_7O_2]^+$, 275 (33%) $[M-C_{19}H_{17}FeO_2]^+$, 199 (74%) $[C_{11}H_{10}Fe]^+$.

3.4. Diphenyl [2-(furan-2-ylmethylthio) methylferrocen-1-yl]stibine (*5*)

By following the same procedure used for the preparation of (**2**), the red–orange product (**5**) was obtained after 8 h stirring from *Rac*-diphenyl[(*N*,*N*-trimethylaminomethylferrocenyl) iodide]stibine (**1**) (0.645 g, 1 mmol) and 2-furyl-mercaptane (0.1 mL, 1 mmol). Yield: 74%, IR (ν cm^{-1}): 3476 (O–H), 3057 (C–H aromatic), 1063 (C–S), 452 (Sb–C) ^{1}H NMR ($CDCl_3$, 300 MHz; δ: ppm): 3.80 (1H, s, C_3H_5), 7.22–7.58 (10H, m, Ph), 4.25, 4.37 (2H, d^2, J = 10 Hz CH_2), 6.27 (2H, d, J = 15 Hz, C_4H_3O), 3.99 (5H, s, C_5H_5) 6.05 (1H, d, J = 15 Hz, C_4H_3O), ^{13}C NMR ($CDCl_3$, 75 MHz; ppm): 89.98 (C_{FC}–Sb), 32.6(CH_2), 136.9 (C_{Ph}–Sb), 69.37(C_5H_5) MS-FAB$^+$ *m/z* (%):586 (100%) $[M]^+$, 473 (84%) $[M-C_5H_5SO]^+$, 397 (7%) $[M-C_{10}H_{10}SO]^+$, 275 (10%) $[M-C_{17}H_{15}FeSO]^+$, 199 (74%) $[C_{11}H_{10}Fe]^+$.

4. X-ray crystallography

The X-ray intensity data were measured at 293°K on a Bruker SMART APEX CCD-based X-ray diffractometer by using monochromated Mo Kα radiation (λ = 0.71073 Å). The detector was placed at a distance of 4.837 cm from the crystals in all cases. Empirical absorption correction's and SHELXTL V 6.12 (Sheldrick, 2000) program were used for compounds **2** and **3**. For compounds **4** and **5** the absorption correction method was multi-scans and the program used was SADABS, Bruker (2004). SADABS and SAINT-PLUS. Bruker AXS Inc., Madison, Wisconsin, USA.

Supplementary data

CCDC 719548, 719549, 719550 and 719551 contain the supplementary crystallographic data for compounds **2**, **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk

(Θ_{zz}) or the sum of the Hammett constants σ_p and σ_m ($\sum\sigma_p$ and $\sum\sigma_m$) of the substituted Cp rings are explored.

2. Computational methods

All substituted Cp anions were optimized and characterized via frequency calculations at the RHF/6-311++G** level of theory for the purpose of determining the quadrupole moments, Θ_{zz}. The RHF/6-311G** level of theory was chosen because it gives excellent agreement between the calculated and experimental Θ_{zz} values of benzene (calculated: −8.76 DÅ [19,20]; experimental: −8.7 ± 0.5 DÅ [21]) and hexafluorobenzene (calculated: +10.06 DÅ [19,20]; experimental: +9.5 ± 0.5 DÅ [21]). We employed the 6-311++G** basis set for this work because a proper description of the electron density of anions requires diffuse functions. Of course, the molecular quadrupole moment is a 3 X 3 tensor and the calculations gave the diagonal quadrupole moment tensor components Θ_{ii} ($i = x, y$ or z) and the off-diagonal tensor components Θ_{ij} ($i = x, y$ or z; $j = x, y, z$; $i \neq j$). The Θ_{zz} values were determined from the equation $\Theta_{zz} = \Theta_{zz} - 0.5(\Theta_{xx} + \Theta_{yy})$. For the planar Cp rings the off-diagonal tensor components are all zero and the equation requires no approximations. For the Cp anions with substituents that extend above and below the plane of the ring the off-diagonal tensor components are non-zero, however, their magnitudes range from 0.1% to 10% of the value of the diagonal tensor components and therefore the equation is an excellent approximation of the Θ_{zz} value.

The Cp–Li and Cp–Na complexes were optimized, characterized and binding energies were calculated at the MP2(full)/6-311++G** level of theory, and the counterpoise method was subsequently employed to account for basis set superposition error (BSSE) [22]. This level of theory was chosen for binding energy calculations because the MP2(full)/6-311G** calculated Na^+-benzene binding energy gives excellent agreement with experiment; the calculated ΔH_{298} is −24.51 kcal/mol and the gas-phase experimental value is −22.13 ± 1.39 kcal/mol [23]. As was the case with the Θ_{zz} calculations, we incorporated diffuse functions to describe the anionic character of Cp. Metal charges were determined using the NBO method [24]. Hammett σ_m and σ_p constants were taken from standard references [25].

The Cp and Cp-cation geometries conformed to the highest level of symmetry, however, at the MP2(full)/6-311++G** level of theory the frequency calculation for certain Cp anions had one or more imaginary frequencies, indicating the optimized structure was not a minimum (details can be found in Supplementary material). These curious imaginary frequencies disappeared for methods other than MP2, and they were also absent when diffuse functions were omitted from the basis set. Similar results have been recently documented for aromatic compounds optimized at the MP2, MP3, CISD, and CCSD levels of theory, and explained as arising from a two-electron basis set incompleteness error (BSIE) where distortion from planarity improves the ability of the basis sets to recover σ–π electron correlation to which correlated wave functions such as MP2 are susceptible [26]. To account for the anionic nature of the Cp ring, all binding energies are reported at the MP2(full)/6-311++G** level of theory. For the Cp rings that were not minima at the MP2(full)/6-311++G** level of theory, the minimum character was assured by the absence of imaginary frequencies when the optimizations were done at the RHF/6-311++G** theoretical level. For the Cp-cation complexes that were not minima at the MP2(full)/6-311++G** level of theory, the minimum character was assured by the absence of imaginary frequencies when the optimizations were done at the MP2(full)/6-311G** theoretical level. All calculations were performed using the GAUSSIAN03 suite of programs [27].

3. Results and discussion

The quadrupole moments of the parent and substituted Cp anions, calculated at the RHF/6-311++G** level of theory, are shown in Table 1. The MP2(full)/6-311++G** Cp–Li and Cp–Na ring centroid-metal distances (dCp–Li, dCp–Na), binding energies ($E_{bind,Li}$, $E_{bind,Na}$), and the NBO calculated metal charges (q_{Li}, q_{Na}) are also collected in Table 1. The general structure of the complexes is shown in Fig. 1.

3.1. Effects of substitution on Cp-metal distance

The values calculated for the Cp–Li and Cp–Na ring centroid-metal distances are in agreement with results obtained by previous computational work [15]. The calculated distances of 1.72 Å for Cp–Li and 2.22 Å for Cp–Na are significantly shorter than the Cp–Li and Cp–Na distances found in the solid-state. The solid-state literature is rich with examples of Cp–Li and Cp–Na complexes with differently substituted Cp rings and/or different solvent conditions [6] and these complexes have ring centroid-metal distances about 0.2–0.3 Å longer than the calculated values presented here. For instance, the crystal structure of a Cp–Li complex where the Li^+ metal is solvated by TMEDA has a ring centroid-metal distance of 1.92 Å and a Cp–Na complex where the Na^+ metal is solvated by three pyridine molecules has a solid-state Cp–Na distance of 2.40 Å [6]. As has previously been discussed, the primary reason for the discrepancy between the calculated values and the solid-state values is due to solvent coordination in the latter [15]. As shown in Fig. 2, the correlation between Cp–Li bond distances and the Cp Θ_{zz} values for the entire set of 30 substituted Cp rings is bad ($R^2 = 0.24$). The greatest outlier from the line of best fit is the amide (–NHC-OCH_3) substituted Cp (**27**) with a Cp–Li distance of 1.83 Å. This is the only substituted Cp where the substituent chelates to the metal and the calculated structure is shown in Fig. 3. This essentially mimics what is observed in the solid-state; chelation of Li^+ either by solvent or other complexing agents results in a longer Cp–Li ring centroid-metal distance. Removing the chelating Cp (**27**) from the analysis substantially improves the correlation with the Cp Θ_{zz} values, however, the R^2 of 0.55 is still not very good (Fig. 2). Although none of the other substituents chelate to the Li^+, the other major deviations from the line of best fit generally belong to Cp rings with substitution patterns that are likely to cause steric interactions between the Cp substituents and the lithium cation. Thus, if we omit the Cp rings with substituents that contain three or more linearly bonded atoms (**15**, **16**, **21**, **22**, **24**, **25** and **27**), along with those containing four or more methyl groups (**17**, **18** and **20**) we see a marked improvement for the correlation between the Cp–Li distance and the Cp Θ_{zz} values ($R^2 = 0.93$, Fig. 2).

Extending this analysis to the correlation between the Cp–Li distance and the $\sum\sigma_p$ values of the Cp rings shows slightly different results (Fig. 2). For all Cp rings, the correlation is significantly better ($R^2 = 0.45$) than it was with the Θ_{zz} values, and when Cp (**27**) is omitted the correlation is decent ($R^2 = 0.74$). However, for the Cp rings with the 20 sterically least hindering substitution patterns the correlation with the Cp $\sum\sigma_p$ values is much worse ($R^2 = 0.68$) than it was for Θ_{zz} values (Fig. 2). We next looked at the correlation between the Cp–Li distance and the Cp $\sum\sigma_m$ values and found significant improvement. For all 30 substituted Cp rings the line of best fit has an R^2 value of 0.53, and when Cp (**27**) is omitted the correlation improves to near-unity ($R^2 = 0.95$, Fig. 2). Omitting the Cp rings with sterically hindering substitution patterns does not improve the correlation ($R^2 = 0.95$, Fig. 2). Thus, the $\sum\sigma_m$ values of the substituted Cp rings allow us to discuss trends in Cp–Li ring centroid-metal distances without discarding certain substituents or substitution patterns based on the somewhat arbitrary definitions of steric hindrance we introduced above.

Table 1
The RHF/6-311++G** calculated quadrupole moments, Θ_{zz} (DÅ), for the substituted the cyclopentadienyl anions (Cp), and the MP2(full)/6-311++G** calculated Cp-metal distances (d_{Cp-Li}, d_{Cp-Na} (Å)), binding energies ($E_{bind,Li}$, $E_{bind,Na}$ (kcal/mol)), and NBO metal charges (q_{Li}, q_{Na}) for the Cp–Li (normal font) and Cp–Na (italicized font) complexes.

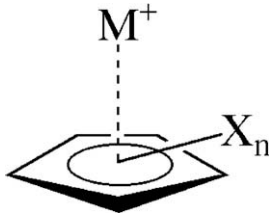

Fig. 1. General structure for the Cp-cation complexes.

Similar results are obtained for the Cp–Na complexes. The correlation between the Cp–Na ring centroid-metal distance and either the Θ_{zz} or $\sum\sigma_p$ values is poor to decent depending on whether all substituted rings are included in the analysis, Cp (**27**) with the metal chelating amide group is discarded, or the sterically hindering substitution patterns are discarded, and they can be found in Supplementary material. However, the correlation between the Cp–Na distance and the Cp $\sum\sigma_m$ values is excellent so long as Cp (**27**) is omitted (R^2 = 0.91, Fig. 4). Discarding the Cp rings with the sterically hindering substitution patterns doesn't improve the correlation. The $\sum\sigma_m$ graphs for all Cp–Na complexes and for

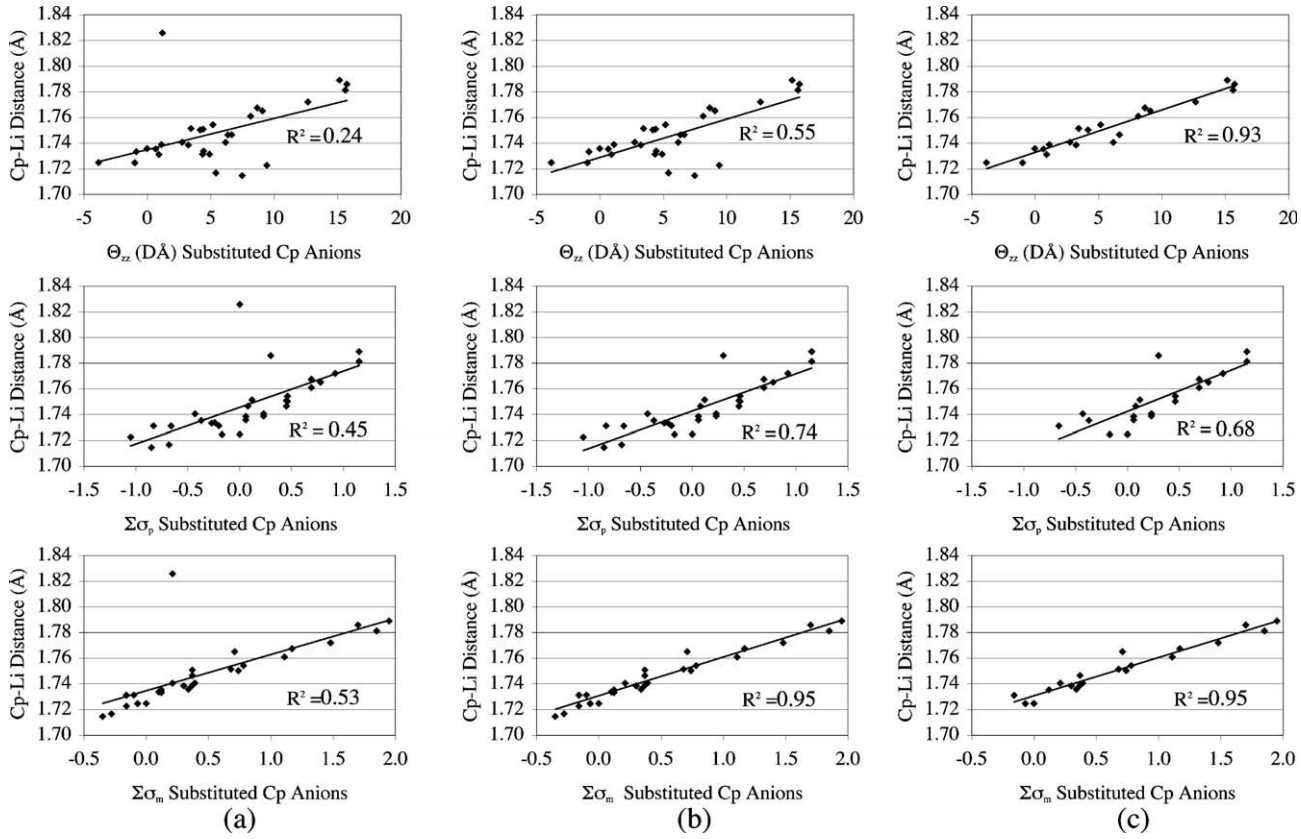

Fig. 2. Cp–Li distances plotted against Cp Θ_{zz}, $\sum\sigma_p$ and $\sum\sigma_m$ values for (a) all Cp rings; (b) all Cp rings except the metal coordinating amide-substituted Cp (**27**); (c) the 20 sterically least hindering groups.

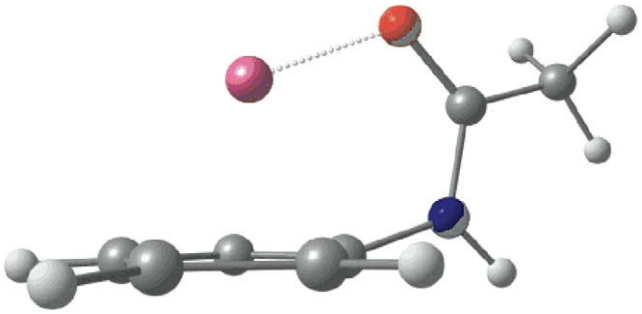

Fig. 3. Structure of Li^+ bound to methylamide substituted Cp anion (**27**). The amide oxygen chelates the lithium.

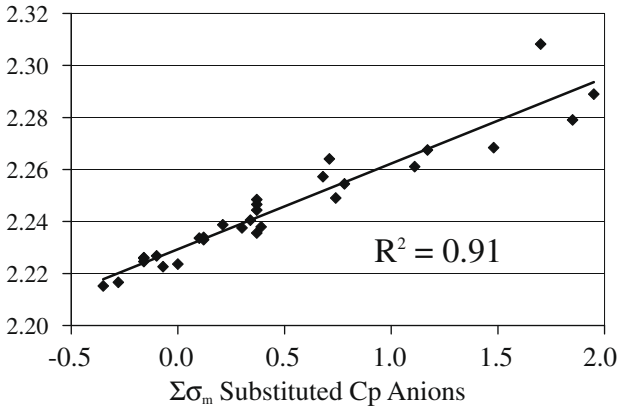

Fig. 4. Cp–Na distances plotted against Cp $\sum\sigma_m$ values for all Cp rings except the metal coordinating amide-substituted Cp (**27**).

the Cp–Na complexes without sterically hindering groups are in Supplementary material. It is worth noting at this point that the Hammett constants σ_p and σ_m were not developed for the purpose of predicting the properties of Cp-metal complexes. They were derived from the ionization of *para*- and *meta*-substituted benzoic acids, respectively, and have traditionally been employed to understand the reactivity of an atom or group directly attached to an aromatic [28]. More specifically, they are commonly used to probe how the reactivity of the atom or group attached to an aromatic ring changes upon *para*- or *meta*-substitution [28]. Recently, however, Hammett constants have been investigated for how well they correlate with arene–arene binding energies [29–31] and the work presented here extends their use along a similar vein.

The best predictor of Cp–Li and Cp–Na ring centroid-metal distances is the Cp $\sum\sigma_m$ value. The more inductively electron-donating the substituent (negative σ_m), the shorter the distance and, as shown in Figs. 2b and 4, the correlation is exceptional. This is by no means a surprising result. The more electron donating groups attached to the Cp ring, the more electron-rich the anion and thus the more the anionic ring is attracted to the cation. Of course this analysis is predicated on the binding force for the Cp–Li and Cp–Na complexes being electrostatic, and this has been illustrated in previous theoretical work [15]. The explanation for the correlation with the Cp $\sum\sigma_p$ values uses the exact same rationale, although the line of best fit has a significantly poorer R^2 value (Fig. 2). The correlation with the Cp Θ_{zz} values is also readily explained; the more electron-rich the substituted Cp, the more negative (or less

positive) the Θ_{zz} value and the shorter the ionic Cp-metal distance. Again, this explanation carries the caveat that the R^2 values are significantly decreased except when the smallest subset of Cp rings is included in the analysis for Cp–Li (Fig. 2).

The more interesting aspect of these results is that the Cp $\sum\sigma_m$ values correlates so well with the Cp-metal distances while the correlation with the Cp Θ_{zz} and $\sum\sigma_p$ values is relatively poor. The poor correlation with the Cp Θ_{zz} values is likely due to this property being a descriptor for the electron density of the entire molecule. Thus, when all Cp rings except the chelating Cp (**27**) are included in the correlation graph (Fig. 2b) there are many instances where the molecular electron density involves much more than just the π-density. It is in just these cases where the deviation from the line of best fit is greatest. For instance, in the graph correlating Cp–Li distances with Cp Θ_{zz} values in Fig. 2b the three greatest outliers with Θ_{zz} values of 5.40, 7.47 and 9.41 DÅ belong to the tetramethyl-, pentamethyl-, and hydroxytetramethyl-substituted Cp rings. Of course, these are among the group of Cp rings with sterically hindering substitution patterns that were omitted in the Fig. 2c graphs, and thus the significant improvement in the correlation between the Cp–Li distance and the Cp Θ_{zz} values. It is worth noting this result is highly fortuitous and the Θ_{zz} values of the Cp rings with sterically non-hindering substitution patterns do not correlate with the Cp–Na distances (graph shown in Supplementary material). The poor correlation with the $\sum\sigma_p$ values is more difficult to explain. The binding in Cp–Li and Cp–Na complexes is certainly a result of the attraction between the cation and the Cp π-electron density. For substituted benzenes the Hammett σ_p constant describes both the resonance and inductive effects of the substituent, whereas the σ_m constant describes only the inductive effects. Thus, it would seem most reasonable for the Cp $\sum\sigma_p$ values to correlate best with the Cp-metal distances. Yet, our results suggest the opposite and including the resonance contributions of the substituents to the Cp π-density is not only unnecessary, which would be surprising in itself, yet it decreases the correlation with the Cp-metal distances. Put another way, the substituent constant that provides the more complete description of the Cp π-density does a poorer job of predicting Cp–Li and Cp–Na distances. One explanation for why the Cp $\sum\sigma_m$ values better predict the Cp-metal distances may be that the interaction between the cation and the Cp substituents is important, and the inductive effects of the substituents captured in the σ_m values is a good descriptor of the electron density at the substituent. We have previously shown the importance of anion-substituent interactions in anion-π complexes of substituted benzenes [32] and Houk has shown the importance of substituent–substituent interactions in arene–arene interactions [29], and thus it is reasonable to suppose such interactions are important in complexes like Cp–Li and Cp–Na where a cationic Li^+ or Na^+ is interacting with the anionic π-cloud of a Cp ring. In Houk's work it was suggested substituent–substituent interactions would best be described by σ_m values, and thus it is not wholly unexpected to find the excellent correlation with the $\sum\sigma_m$ values. Still, the idea that the attraction between Cp and either Li^+ or Na^+ is guided by Cp substituent–metal interactions, and why this interaction is so well described by $\sum\sigma_m$ values (and not $\sum\sigma_p$ values) is not completely understood and current work in our group is exploring this issue.

3.2. Effects of substitution on Cp-metal binding energies

The calculated binding energies (E_{bind}) of Cp–Li and Cp–Na are −166.3 and −138.0 kcal/mol (Table 1) and these are very similar to those reported in previous computational studies [15]. Previous theoretical investigations have also shown the Cp–Li and Cp–Na binding energies are almost entirely electrostatic in nature [15] and the highly ionic Cp-metal bond weakens according to Coulomb's law with increasing Cp–M distance for M = Li^+, Na^+, K^+ [16,17]. The correlations between either the Cp–Li or Cp–Na E_{bind} values and the Cp Θ_{zz}, $\sum\sigma_p$ or $\sum\sigma_m$ values follows the same general trends shown for the Cp-metal distances (Fig. 2). For the Cp Θ_{zz} values the correlation with Cp–Li and Cp–Na binding energies is relatively poor until the Cp rings with sterically hindering substitution patterns are omitted. For the $\sum\sigma_p$ values the correlation is never above $R^2 = 0.80$. The correlation between the Cp $\sum\sigma_m$ values and either the Cp–Li and Cp–Na binding energies is excellent when Cp (**27**) with the metal chelating group is omitted, as shown in Fig. 5. Paring the Cp rings to those with sterically non-hindering substitution patterns does not improve the correlation. The other $\sum\sigma_m$ graphs, along with all Θ_{zz} and $\sum\sigma_p$ graphs are in Supplementary material. All discussion on Cp–Li and Cp–Na binding energies mirrors what was stated above for the Cp-metal distances. The same reasoning that was employed to explain the Cp-metal distance correlations with Cp Θ_{zz}, $\sum\sigma_p$ and $\sum\sigma_m$ values extends to Cp–Li and Cp–Na binding energies, and the same questions concerning why the Cp $\sum\sigma_m$ values correlate so well with the Cp-metal distances, while the $\sum\sigma_p$ values do not, remain for the binding energies.

3.3. Effects of substitution on the metal charge in Cp-metal complexes

Finally, we also investigated the correlation between the metal NBO charge in Cp–Li or Cp–Na complexes and the Cp Θ_{zz}, $\sum\sigma_p$ and $\sum\sigma_m$ values. Fig. 6 shows the graphs correlating the Cp–Li NBO lithium charges with the Θ_{zz} and $\sum\sigma_m$ values of the Cp anions for all substituted Cp rings (Fig. 6a), omitting Cp (**27**) with the amide-chelating group (Fig. 6b), and omitting the Cp rings with sterically hindering substitution patterns (Fig. 6c). The corresponding Cp–Na graphs are shown in Fig. 7. The $\sum\sigma_p$ graphs are not included because the correlations are so poor. The graphs can be

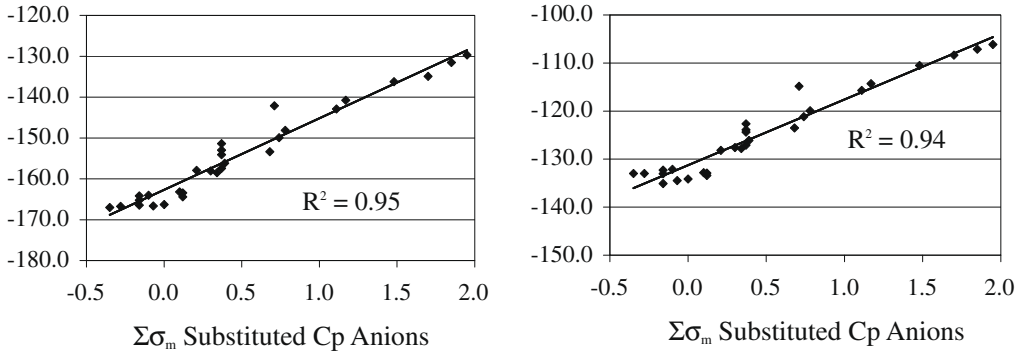

Fig. 5. Cp–Li (left graph) and Cp–Na binding energies plotted against Cp $\sum\sigma_m$ values for all Cp rings except the metal coordinating amide-substituted Cp (**27**).

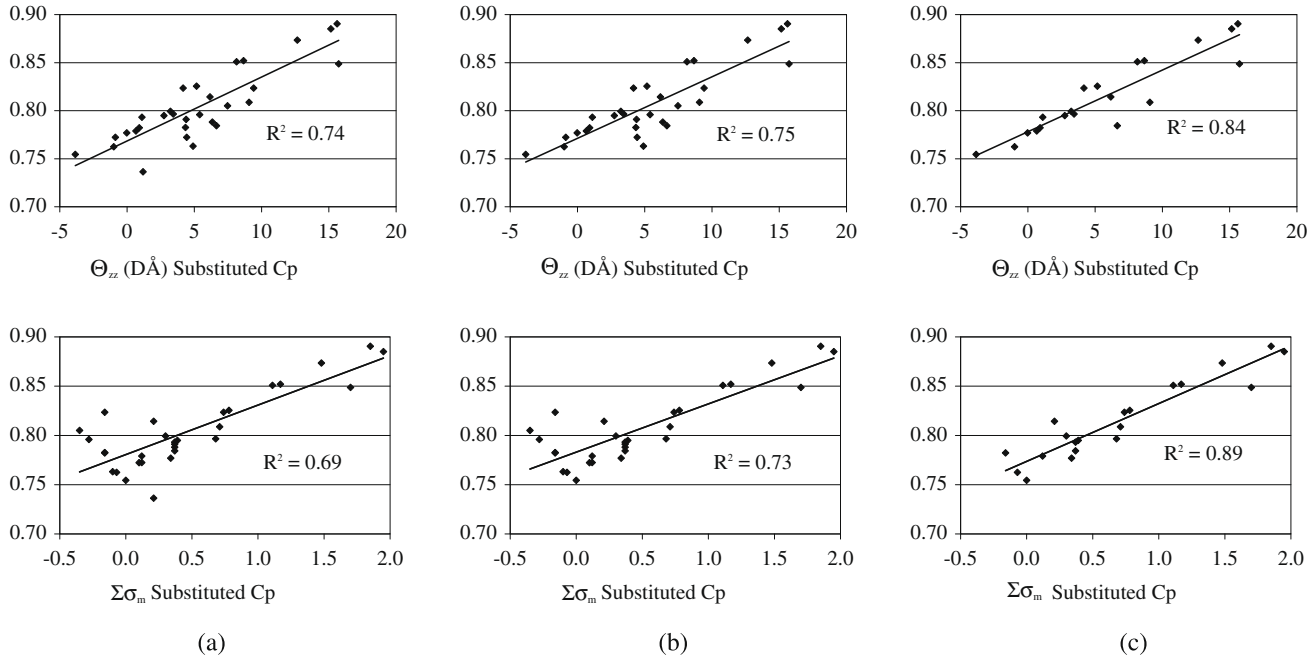

Fig. 6. Lithium NBO charge in Cp–Li complexes plotted against Cp Θ_{zz} and $\sum\sigma_m$ values for (a) all Cp rings; (b) all Cp rings except the metal coordinating amide-substituted Cp (**27**); (c) the 20 sterically least hindering groups.

found in Supplementary material. The relative performance of the Cp Θ_{zz}, $\sum\sigma_p$ and $\sum\sigma_m$ values in predicting the metal NBO charges does not mirror what was found for the Cp-metal distances and binding energies. The correlation between the metal NBO charge and either the Θ_{zz} or $\sum\sigma_m$ values for all substituted Cp rings is decent (Figs. 6a and 7a), compared to the Cp-metal distance and binding energy graphs. However, omission of Cp (**27**) does not improve the correlation as it did with the Cp-metal distance and binding energy graphs. Thus, whereas almost perfect correlation was found between the Cp-metal distances or binding energies and the Cp $\sum\sigma_m$ values, the correlation for the metal NBO charge is only decent for the Cp–Li complexes (Fig. 6b, Θ_{zz}: $R^2 = 0.75$; $\sum\sigma_m$: $R^2 = 0.73$) and it is worse for the Cp–Na complexes (Fig. 7b, Θ_{zz}: $R^2 = 0.61$; $\sum\sigma_m$: $R^2 = 0.48$). When only the Cp rings with sterically non-hindering substitution patterns are considered, the correlation between Cp–Li lithium charges is quite good with both the Cp Θ_{zz} ($R^2 = 0.84$) and $\sum\sigma_m$ ($R^2 = 0.89$) values (Fig. 6c), however, only decent correlation is found for the Cp–Na complexes (Fig. 7c, Θ_{zz}: $R^2 = 0.70$; $\sum\sigma_m$: $R^2 = 0.66$).

Explaining the correlation between the metal NBO charges in the Cp-metal complexes and the Cp Θ_{zz}, $\sum\sigma_p$ or $\sum\sigma_m$ values is also quite different than it was for the Cp-metal distances and binding

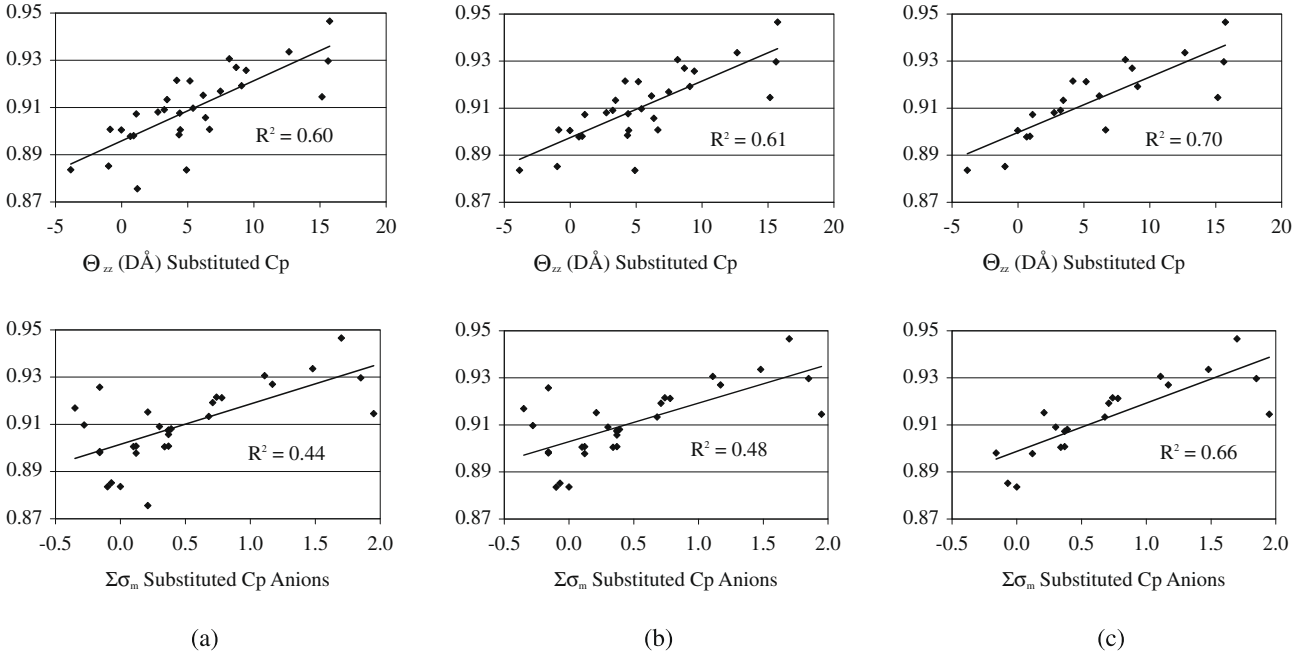

Fig. 7. Sodium NBO charge in Cp–Na complexes plotted against Cp Θ_{zz} and $\sum\sigma_m$ values for (a) all Cp rings; (b) all Cp rings except the metal coordinating amide-substituted Cp (**27**); (c) the 20 sterically least hindering groups.

energies, however, the exercise leads to some interesting insights. The one similarity is that the correlation with the Cp $\sum\sigma_m$ values is far better than with the $\sum\sigma_p$ values and thus including substituent resonance effects significantly decreases the ability to predict the metal charge. As is shown by the graphs in Supplementary material, the correlations with the $\sum\sigma_p$ values is very poor, to the point of precluding an explanation of the observed trend. The correlation between the metal NBO charge in the Cp-metal complexes and either the Cp Θ_{zz} or $\sum\sigma_m$ values seems counterintuitive. The more electron-rich the Cp ring, as dictated either by a less positive/negative Θ_{zz} value or a less positive/negative $\sum\sigma_m$ value, the less positive the Li^+ or Na^+. This is, of course, the opposite of what would be expected. Regardless of how much ionic or covalent character one assigns to the Cp-metal bond, increasing the electron density of the Cp π-cloud should give a more positive metal charge. Looking at how the charge on the substituted Cp atoms change upon Li^+ complexation (Table 2) provides an explanation for this curious trend. Upon Li^+ complexation for the parent (**1**) and perfluorinated (**2**) Cp rings, the charge on the ring carbon atoms remain largely unchanged and the H and F atoms become more positive by 0.048 and 0.044 charge units, respectively. When the perchloro- and perbromo-substituted Cp rings, **5** and **10**, are complexed with Li^+ the Cp carbon atoms become significantly more negative, by 0.069 and 0.073 charge units, and the Cl and Br atoms become substantially more positive, by 0.091 and 0.096 charge units. Thus, when the Cp ring is substituted with the large, polarizable Cl and Br substituents, Li^+ complexation causes electron density to be transferred from the halogens to the metal, which explains the increased positive charge at the halogen atoms (Table 2). However, this electron density does not stay at the metal, but instead it is transferred to the Cp ring carbon atoms, which explains the increased negative charge at the Cp carbon atoms (Table 2). The effect of electron density being transferred from the electron-withdrawing substituent to the metal cation and onto the Cp ring carbon (Fig. 8) is most likely to occur with large, polarizable groups, and this is what the changes in Cp atomic charges upon metal complexation show in Table 2. It so happens that the trend in inductive electron-withdrawing ability, using σ_m values as the measure, is the same as the trend for substituent polarizability. The bromine and chlorine atoms have the largest σ_m, and thus are classified as being the most inductively electron withdrawing, and they are also the most polarizable. This analysis offers a valuable insight. If electron density is flowing as shown in Fig. 8, and σ_m is a measure of substituent polarizability, then for the purpose of predicting the charge on the metal cation the sign of the σ_m value is irrelevant. For instance, for OH σ_m = +0.12 while for NH_2 σ_m = −0.16. By any definition an amino group is more polarizable than a hydroxyl group, the sign of the σ_m values simply inform us that the NH_2 is inductively electron donating while the OH group is inductively electron withdrawing. Thus, the correlations for $\sum\sigma_m$ in Figs. 6 and 7 are not quite right. Instead the important correlation would be between the metal NBO charges and the $\sum|\sigma_m|$ values since it is the absolute σ_m values that inform us about the relative polarizability and how well the substituents will donate electron density to the metal cation, as illustrated in Fig. 8. The graphs showing these correlations are given in Figs. 9 and 10 for Cp–Li and Cp–Na, respectively, and the improvements in the R^2 values are striking. For all substituted Cp rings the correlation between the Li^+ NBO charge in Cp–Li complexes and the $\sum|\sigma_m|$ values is R^2 = 0.87 (Fig. 9a) compared to 0.69 when the $\sum\sigma_m$ values are used (Fig. 6a). When the metal chelating Cp (**27**) is omitted the correlation with $\sum|\sigma_m|$ values is R^2 = 0.90 (Fig. 9b) compared to 0.73 for $\sum\sigma_m$ values (Fig. 6b). Only for the subset of twenty substituted Cp rings with sterically non-hindering substituent patterns are the R^2 values comparable: R^2 = 0.93 for $\sum|\sigma_m|$ values (Fig. 9c) and 0.89 for $\sum\sigma_m$ values (Fig. 6c). Of course, the more points are omitted, the more correlation one will generally find. That the correlation with the Cp $\sum|\sigma_m|$ values is very good for all points shows its value over the $\sum\sigma_m$ values for predicting Li^+ charges in Cp–Li complexes. Unfortunately, the charge on Na^+ in the Cp–Na complex does not have a very good correlation with the Cp $\sum|\sigma_m|$ values, as shown in Fig. 10. However, the correlation for all substituted Cp rings has an R^2 value of 0.59 and this is considerably better than the R^2 value of 0.44 with Cp $\sum\sigma_m$ values. Still, the fact that the metal charges in Cp–Li and Cp–Na significantly improve when Cp $\sum|\sigma_m|$ values are considered instead of $\sum\sigma_m$ values supports the view of electron density redistribution upon metal complexation shown in Fig. 8. Ultimately, the correlation trend when $\sum\sigma_m$ values are employed is a red herring because besides measuring inductive electron withdrawing ability, the Hammett σ_m constants also contain information about substituent polarizabilities. When considering the effect Cp substitution has on the metal charge in Cp-metal complexes it is the latter property of σ_m constants that is important. Of course, our explanation for the correlation between the metal charges and Cp $\sum|\sigma_m|$ values stems from the charge-transfer model proposed in Fig. 8, and this was derived from looking at the change in charge values Δq(C) and Δq(X) calculated using the NBO method. As further support for this model we also considered the Δq(C) and Δq(X) values calculated using the Mulliken method and the same relative trends were observed. The Mulliken charge data is given in Supplemental material.

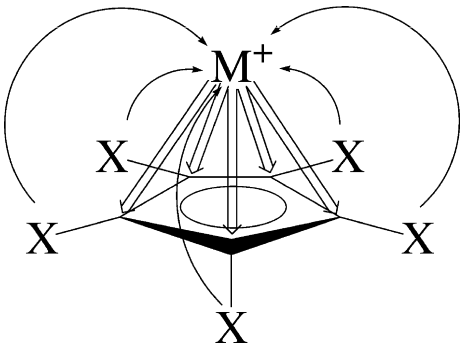

Fig. 8. Cp complexation of Li^+ or Na^+ causes electron density to flow from the polarizable X groups, to the metal, and ultimately to the Cp carbon atoms.

Table 2
The MP2(full)/6-311++G** calculated NBO Cp atomic charges (q(C) and q(X)) for the non-complexed and Li^+-complexed ring, and the change in atomic charge upon Li^+ complexation (Δq(C) and Δq(X)).

C_5X_5	Cp charges		Cp charges in lithium complex		Change in Cp charges	
X=	q(C)	q(X)	q(C)	q(X)	Δq(C)	Δq(X)
H (**1**)	−0.355	+0.156	−0.355	+0.204	+0.000	+0.048
F (**2**)	+0.214	−0.414	+0.200	−0.370	−0.014	+0.044
Cl (**5**)	−0.155	−0.045	−0.224	+0.046	−0.069	+0.091
Br (**10**)	−0.236	+0.036	−0.309	+0.132	−0.073	+0.096

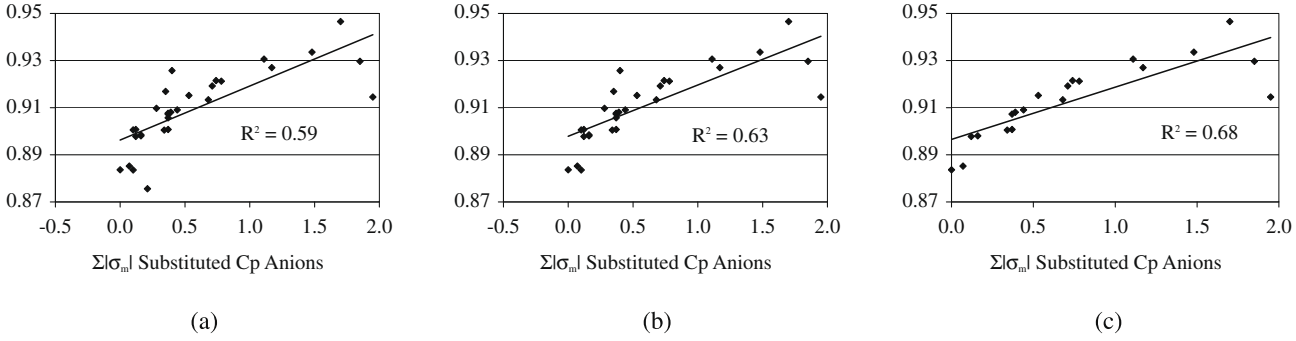

Fig. 10. Sodium NBO charge in Cp–Na complexes plotted against Cp Θ_{zz} and $\sum|\sigma_m|$ values for (a) all Cp rings; (b) all Cp rings except the metal coordinating amide-substituted Cp (**27**); (c) the 20 sterically least hindering groups.

4. Conclusion

Cp–Li and Cp–Na ring centroid-metal distances and binding energies correlate exceptionally well with the $\sum\sigma_m$ values of the substituted Cp rings so long as the substituents do not chelate with the metal. If only Cp rings with sterically non-hindering substitution patterns are considered, these values also correlate very well with the Θ_{zz} values of the Cp rings. Still, the prediction of the Cp-metal distance and binding energy for a complex between a substituted Cp and either Li^+ or Na^+ is best done using the $\sum\sigma_m$ value of the Cp. The Cp-metal bond will be shorter and the binding energy will be stronger when inductively electron-donating substituents are present on the Cp (negative $\sum\sigma_m$ values). Surprisingly, the correlation between Cp-metal distances and binding energies and the Cp $\sum\sigma_p$ values is significantly worse than for the $\sum\sigma_m$ values. Thus, including the resonance effects of the Cp substituents gives a poorer correlation and current work in our group is aimed at understanding this result. The metal charge in the Cp–Li and Cp–Na complexes correlates about equally with the Cp $\sum\sigma_m$ or Θ_{zz} values, and once again the correlation with the Cp $\sum\sigma_p$ values is poor. The correlation trend with either the Cp $\sum\sigma_m$ or Θ_{zz} values is not immediately intuitive. The more electron-rich the Cp (negative $\sum\sigma_m$ and Θ_{zz} values), the less positive the metal cation. Thus, the shorter and stronger the Cp-metal bond, the less positive the Li^+ or Na^+. Regardless of how much ionic or covalent character one assigns to the Cp-metal bond, this trend defies a simple explanation. The explanation we offer involves the Cp substituents donating electron density back to the metal, and the metal donating this electron density onto the Cp carbon atoms. The more polarizable the substituents, as defined by the $|\sigma_m|$ values, the more likely this electron flow. The fact that substituent $|\sigma_m|$ values contain information about the substituent polarizability is important to recognize. Instead of the confusing view that Cp rings with electron-withdrawing substituents (electron-poor Cp rings) have Cp-metal complexes with the most positive metals, we end up with the more consistent view that Cp rings with polarizable substituents have Cp-metal complexes with the most positive metals. The charge-transfer model we present here is related to recent work by Houk and co-worker [33] and Frontera et al. [34] where they illustrate the importance of through-space interactions in cation-substituted benzene complexes [33] and cation-substituted paracyclophane complexes [34].

metal cation on the spectroscopic and aggregation properties of Pcs in different solvents, tetrahydrofuran (THF) and dimethylformamide (DMF) are investigated.

2. Experimental

Routine IR-spectra were recorded on a Shimadzu Fourier Transform FTIR-8300 Infrared Spectrophotometer using KBr pellets, electronic spectra on a Shimadzu UV-1601 UV–Visible Spectrophotometer. ^{1}H and ^{13}C NMR spectra on a Varian Unity Inova 500 MHz NMR Spectrophotometer using TMS as internal reference. Elemental analysis was performed by the Instrumental Analysis Laboratory of TUBITAK Ankara Test and Analysis Laboratory. Mass spectra were performed on a Bruker Daltonic Autoflex III MALDI-TOF spectrometer at Marmara University. 2,5-Dihydroxybenzoic acid (DHB) (20 mg/mL in THF) matrix for compounds (**1**–**4**) was used. MALDI samples were prepared by mixing the complex [2 mg/mL in tetrahydrofuran (THF)] with the matrix solution (1:10 v/v) in a 0.5 mL Eppendorf micro tube. Finally, 1 μL of this

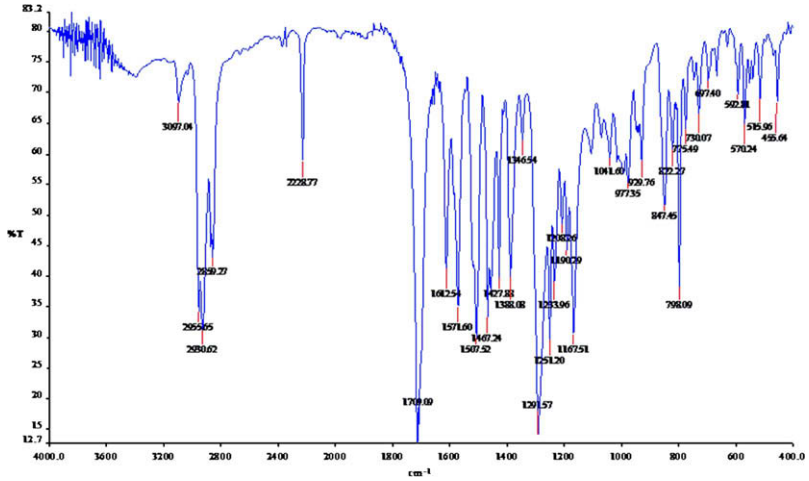
Scheme 1. The synthesis of coumarin (**2**–**5**) and phthalocyanines (**3a**–**3d** and **5a**–**5d**).

mixture was deposited on the sample plate, dried at room temperature and then analyzed. Fluorescence excitation and emission spectra were recorded on a HITACHI F-7000 Fluorescence spectrophotometer using 1 cm pathlength cuvettes at room temperatures.

4-Nitrophthalonitrile, 3-nitrophthalonitrile and *p*-(3,4-dicyanophenoxy)phenylacetic acid were synthesized according to the reported procedures [22–24]. All reagents and solvents were of reagent-grade quality obtained from commercial suppliers. All solvents were dried and purified. The solvents were stored over molecular sieves (4 Å). The homogeneity of the products was tested in each step by TLC (SiO_2).

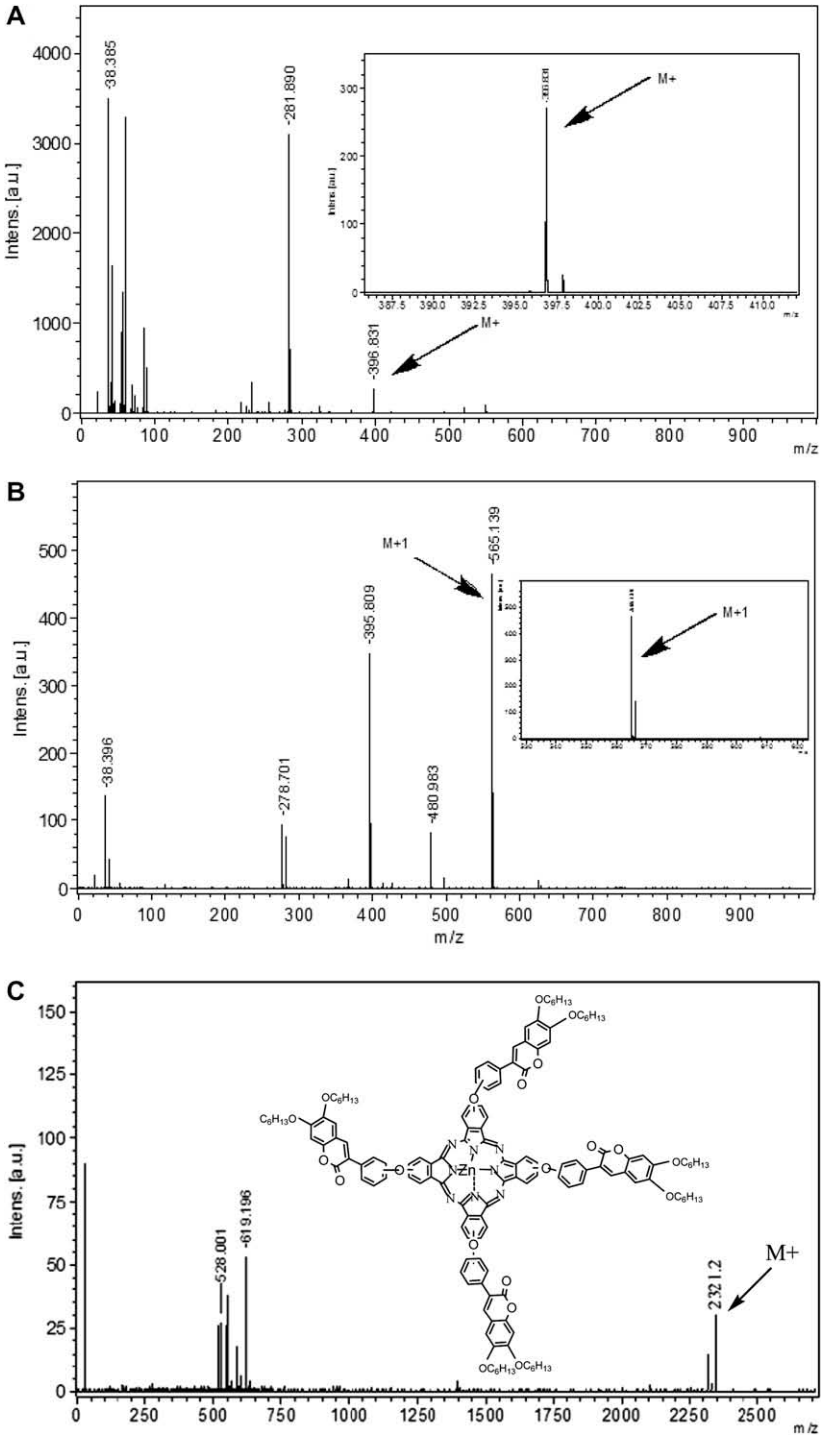
2.1. General procedure for the synthesis of p-(2,3-dicyanophenoxy)phenylacetic acid (**1**)

4-Hydroxyphenylacetic acid (1.75 g, 11.56 mmol) and 3-nitrophthalonitrile (2.0 g, 11.56 mmol) were dissolved in dry DMF (20 ml) under nitrogen and anhydrous K_2CO_3 (3.19 g, 23.12 mmol) was added. After stirring for 5 days at 50–60 °C, the reaction mixture was treated with diluted HCl under ice cooling. The pure precipitate was filtered, washed with water to neutralize, and dried. Yield: 1.8 g (56%). m.p.: 178–183 °C. IR ν(cm^{-1}): 3510 (carboxylic acid OH), 3083–3062 (Ar–CH), 2970–2932 (aliphatic CH), 2230 (C≡N), 1705 (C=O), 1600–1548 (Ar C=C), 1250 (Ar–O–Ar), 1210, 1164, 1081, 945, 842, 810, 670 and 530. ^{1}H NMR (d-DMSO 500 MHz, δ ppm): 12.21 (s, 1H, COOH), 8.11 (d, 1H, Ar–H), 7.74 (d, 1H, Ar–H), 7.41 (d, 1H, Ar–H), 7.38 (dd, 2H, Ar–H), 7.21 (dd, 2H, Ar–H), 3.77 (s, 2H, CH_2). ^{13}C NMR (d-DMSO 500 MHz, δ ppm): 175,1 (acid C=O, C_a), 164.8 (Ar, C_g), 155.1 (Ar, C_f), 138.0 (Ar, C_l), 134.3 (Ar, $2C_d$), 133.2 (Ar, C_c), 124.3 (Ar, C_j), 123.4 (Ar, C_h), 122.6, (Ar, $2C_e$), 119.4 (Ar, C_k), 117.6 (C≡N, C_n), 117.0 (C≡N, C_o), 106.8 (Ar, C_m), 41.2 (CH_2, C_b). MS (MALDI-TOF): *m/z* 278 $[M]^+$. UV–Vis λ_{max} (nm) (log ε) (THF) (1.10^{-5} M): 310 (3.78).



2.2. General procedure for the synthesis of 6,7-dihydroxy-3-[p-(2′,3′-dicyanophenoxy)phenyl]coumarin (**2**) and 6,7-dihydroxy-3-[p-(3′,4′-dicyanophenoxy)phenyl]coumarin (**4**)

A mixture of *p*-(2,3-dicyanophenoxy)phenylacetic acid (**1**) (1.8 g, 6.48 mmol) or *p*-(3,4-dicyanophenoxy)phenylacetic acid (2.0 g, 7.19 mmol), 2,4,5-trihydroxybenzaldehyde (1.10 g, 7.19 mmol)/(0.99 g, 6.48 mmol), sodium acetate (2.94 g, 35.90 mmol)/(2.65 g, 32.3 mmol) and anhydrous acetic anhydrite (15 ml) was heated and stirred at 160–170 °C in a sealed glass tube for 8 h under nitrogen. After cooling to room temperature, water was added and the mixture was stirred for overnight.



The resulting solid (6,7-diacetoxy-3-[*p*-(2′,3′-dicyanophenoxy)phenyl]coumarin)/(6,7-diacetoxy-3-[*p*-(3′,4′-dicyanophenoxy)-phenyl]coumarin) was filtered, washed with water and dried. The crude product was suspended in methanol. About 10% HCl was added to adjust pH to 3 and the ensuing mixture was heated and stirred at 60 °C for 5 days under nitrogen. The resulting solid (6,7-dihydroxy-3-[*p*-(2′,3′-dicyanophenoxy)phenyl]coumarin)/(6,7-dihydroxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin) was filtered, washed with water and dried. The slightly brown products were purified by silica gel column chromatography using $CHCl_3$ as eluent.

The compound **2** is soluble in ethanol, methanol, tetrahydrofuran (THF), dimethylsulfoxide (DMSO) and dimethylformamide (DMF). Yield: 1.73 g (60%), m.p.: >300 °C. IR ν(cm^{-1}): 3461–3398 (OH), 3098 (Ar–H), 2923–2898 (alkyl–CH), 2240 (C≡N), 1707 (C=O lactone), 1632 (C=C), 1586–1492 (Ar C=C), 1244 (Ar–O–Ar). UV–Vis λ_{max} (nm) (log ε) (THF) ($1.01.10^{-5}$ M): 360 (4.30), 305 (4.13). ^{1}H NMR (500 MHz; DMSO): δ_H, ppm 9.28 (s, 1H, OH), 8.25 (s, 1H, OH), 8.08 (s, 1H, lactone 4-H), 7.87 (dd, *J* = 8 Hz, 1H, Ar–H), 7.60 (dd, *J* = 8 Hz, 1H, Ar–H), 7.54 (dd, *J* = 8 Hz, 1H, Ar–H), 7.42 (dd, *J* = 8 Hz, 2H, Ar–H), 7.04 (dd, *J* = 8 Hz, 2H, Ar–H), 6.76 (s, 1H, Ar–H), 6.66 (s, 1H, Ar–H). ^{13}C NMR (d-DMSO 500 MHz, δ ppm): 160.5 (lactone C=O, C_a), 160.3 (Ar, C_o), 156.2 (Ar, C_n), 149.9 (Ar, C_j), 145.4 (Ar, C_g), 142.7 (Ar, C_f), 141.1 (Ar, C_c), 133.4 (Ar, C_r), 128.8 (Ar, $2C_l$), 128.0 (Ar, C_k), 126.0 (Ar, C_s), 124.7 (Ar, C_b), 122.5 (Ar, C_p), 117.4 (Ar, $2C_m$), 116.2 (Ar, C_d), 115.5 (Ar, C_t), 115.8 (C≡N, C_y), 113.5 (C≡N, C_w), 113.9 (Ar, C_e), 103.8 (Ar, C_h), 103.5 (Ar, C_u). *Anal.* Calc. for $C_{23}H_{12}N_2O_5$: C, 69.69; H, 3.03; N, 7.07. Found: C, 69.56; H, 3.12; N, 6.48%. Fluorescence data: (EM) $1.01.10^{-5}$ M, λ_{em}: 458 nm and (EX) $1.01.10^{-6}$ M, λ_{ex}: 364 nm (20 slitt) (THF). MS (MALDI-TOF): *m/z* 396 $[M]^+$, 397 $[M+1]^+$.

The compound **4** is soluble in ethanol, methanol, THF, DMSO and DMF. Yield: 1.73 g (60%), m.p.: >300 °C. IR ν(cm^{-1}): 3400–3396 (OH), 3100 (Ar–H), 2950–2890 (alkyl–CH), 2200 (C≡N), 1703 (C=O lactone), 1600 (C=C), 1566–1488 (Ar C=C), 1245 (Ar–O–Ar). UV–Vis λ_{max} (nm) (log ε) (THF) ($1.01.10^{-5}$ M): 357 (4.25). ^{1}H NMR (500 MHz; DMSO): δ_H, ppm 9.31 (s, 1H, OH), 8.28 (s, 1H, OH), 8. 12 (d, *J* = 8 Hz, 1H, Ar–H), 8.08 (s, 1H, lactone 4-H), 7.82 (d, *J* = 3 Hz, 1H, Ar–H), 7.42 (dd, *J* = 8 Hz, 2H, Ar–H), 7.24 (dd, *J* = 8 Hz, 1H, Ar–H), 7.04 (dd, *J* = 8 Hz, 2H, Ar–H), 6.76 (s, 1H, Ar–H), 6.66 (s, 1H, Ar–H). ^{13}C NMR (d-DMSO 500 MHz, δ ppm): 162.0 (Ar, C_p), 160.5 (lactone C=O, C_a), 156.2 (Ar, C_n), 149.9 (Ar, C_j), 145.4 (Ar, C_g), 142.7 (Ar, C_f), 141.1 (Ar, C_c), 134.4 (Ar, C_s),

Scheme 2. The IR-spectra of **3**.

Scheme 3. The positive ion and linear mode MALDI-TOF spectrum of **2 (A)**, **5 (B)** and **5b (C)** (in the presence of 2,5-dihydroxybenzoic acid (DHB) (20 mg/mL in THF) as a matrix) were obtained using nitrogen laser accumulating 50 laser shots. Inset spectrum shows expanded molecular mass region of the complex.

128.8, (Ar, $2C_i$), 128.0 (Ar, C_k), 124.7 (Ar, C_b), 122.5 (Ar, C_r), 121.8 (Ar, C_o), 117.4 (Ar, $2C_m$), 116.2, (Ar, C_d) 115.5 (Ar, C_u), 115.8 (C≡N, C_y), 115.6 (C≡N, C_w), 113.9 (Ar, C_e), 108.9 (Ar, C_t), 103.8 (Ar, C_h). *Anal.* Calc. for $C_{23}H_{12}N_2O_5$: C, 69.69; H, 3.03; N, 7.07. MS (MALDI-TOF), (2,5-dihydroxybenzoic acid as matrix): *m/z* 2316 $[M]^+$.

The compound **3d** is soluble in THF, DMF and DMSO. Yield: 0.041 g (43%), m.p.: >300 °C. IR $\nu(cm^{-1})$: 3112–3094 (Ar–H), 2985–2898 (alkyl–CH), 1726 (C=O lactone), 1620 (C=C), 1250 (Ar–O–Ar). UV–Vis λ_{max} (nm) (log ε) (THF) ($1.293.10^{-5}$ M): 351 (4.87), 690 (4.75). *Anal.* Calc. for $C_{140}H_{144}N_8O_{20}Cu$: C, 72.38; H, 6.20; N, 4.83. Found: C, 71.44; H, 6.38; N, 5.01%. MS (MALDI-TOF), (2,5-dihydroxybenzoic acid as matrix): *m/z* 2321 $[M+1]^+$.

The compound **5d** is soluble in DMF and DMSO. Yield: 0.056 g (55%), m.p.: >300 °C. IR $\nu(cm^{-1})$: 3059–3027 (Ar–H), 2925–2890 (alkyl–CH), 1721 (C=O lactone), 1615 (C=C), 1248 (Ar–O–Ar).

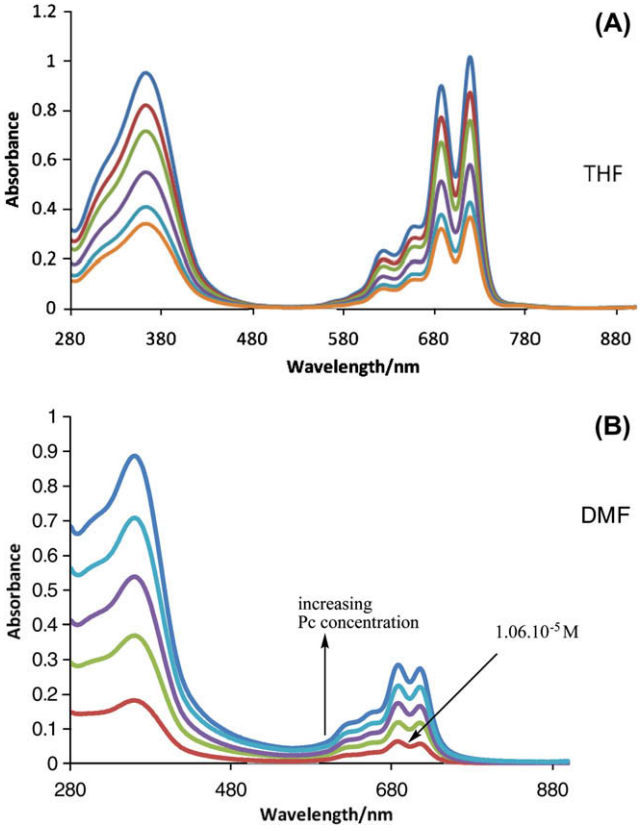

Fig. 4. The aggregation behaviour of the H_2Pc complex (**3a**) was monitored at several concentrations in THF (A) and DMF (B).

UV–Vis λ_{max} (nm) (log ε) (DMF) ($1.293.10^{-5}$ M): 351 (4.70), 694 (4.50). *Anal.* Calc. for $C_{140}H_{144}N_8O_{20}Cu$: C, 72.38; H, 6.20; N, 4.83. Found: C, 70.59; H, 6.24; N, 4.96%. MS (MALDI-TOF), (2,5-dihydroxybenzoic acid as matrix): *m/z* 2320 $[M]^+$.

3. Result and discussion

6,7-Dihydroxy-3-[*p*-(2′,3′-dicyanophenoxy)phenyl]coumarin (**2**) and 6,7-dihydroxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin (**4**) were prepared according to the literature [24,25], which involve the condensation of 2,4,5-trihydroxybenzaldehyde with *p*-(2,3-dicyanophenoxy)phenylacetic acid (**1**) or *p*-(3,4-dicyanophenoxy)phenylacetic acid in the presence of sodium acetate and acetic anhydride at 160 °C. The formed diacetoxy derivatives (not isolated) of compounds **2** and **4** were then deacetylated in 10% HCl/CH_3OH solution. The crude products were purified by silica gel column chromatography using $CHCl_3$ as eluent. Compounds **2** and **4** were reacted with 1-bromohexane in the presence of K_2CO_3 in DMF to obtain 6,7-dihexyloxy-3-[*p*-(2′,3′-dicyanophenoxy)phenyl]coumarin (**3**) and 6,7-dihexyloxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin (**5**). Cyclotetramerization of the phthalonitrile derivative **3** and **5** to the metal-free Pcs (**3a** and **5a**) were accomplished in DMAE at 145 °C in a sealed glass tube. The MPcs (**3b**–**3d** and **5b**–**5d**) were obtained from the reaction of dicyano derivatives **3**, **5** and the corresponding metal salts [$Zn(AcO)_2{\cdot}2H_2O$, $Co(AcO)_2{\cdot}4H_2O$ or $Cu(AcO)_2{\cdot}4H_2O$] in DMAE at reflux temperature (Scheme 1). The novel Pcs (**3a**–**3d** and **5a**–**5d**) were reasonably soluble in DMF, $CHCl_3$ and THF due to the long alkyl substituents; consequently easily purified with silica gel chromatography. The spectroscopic characterization of the newly synthesized intermediates and Pcs included elemental analysis, ^1H NMR, IR, fluorescence spectra, MALDI-TOF mass and UV–Vis spectral investigations. These results were in accordance with the proposed

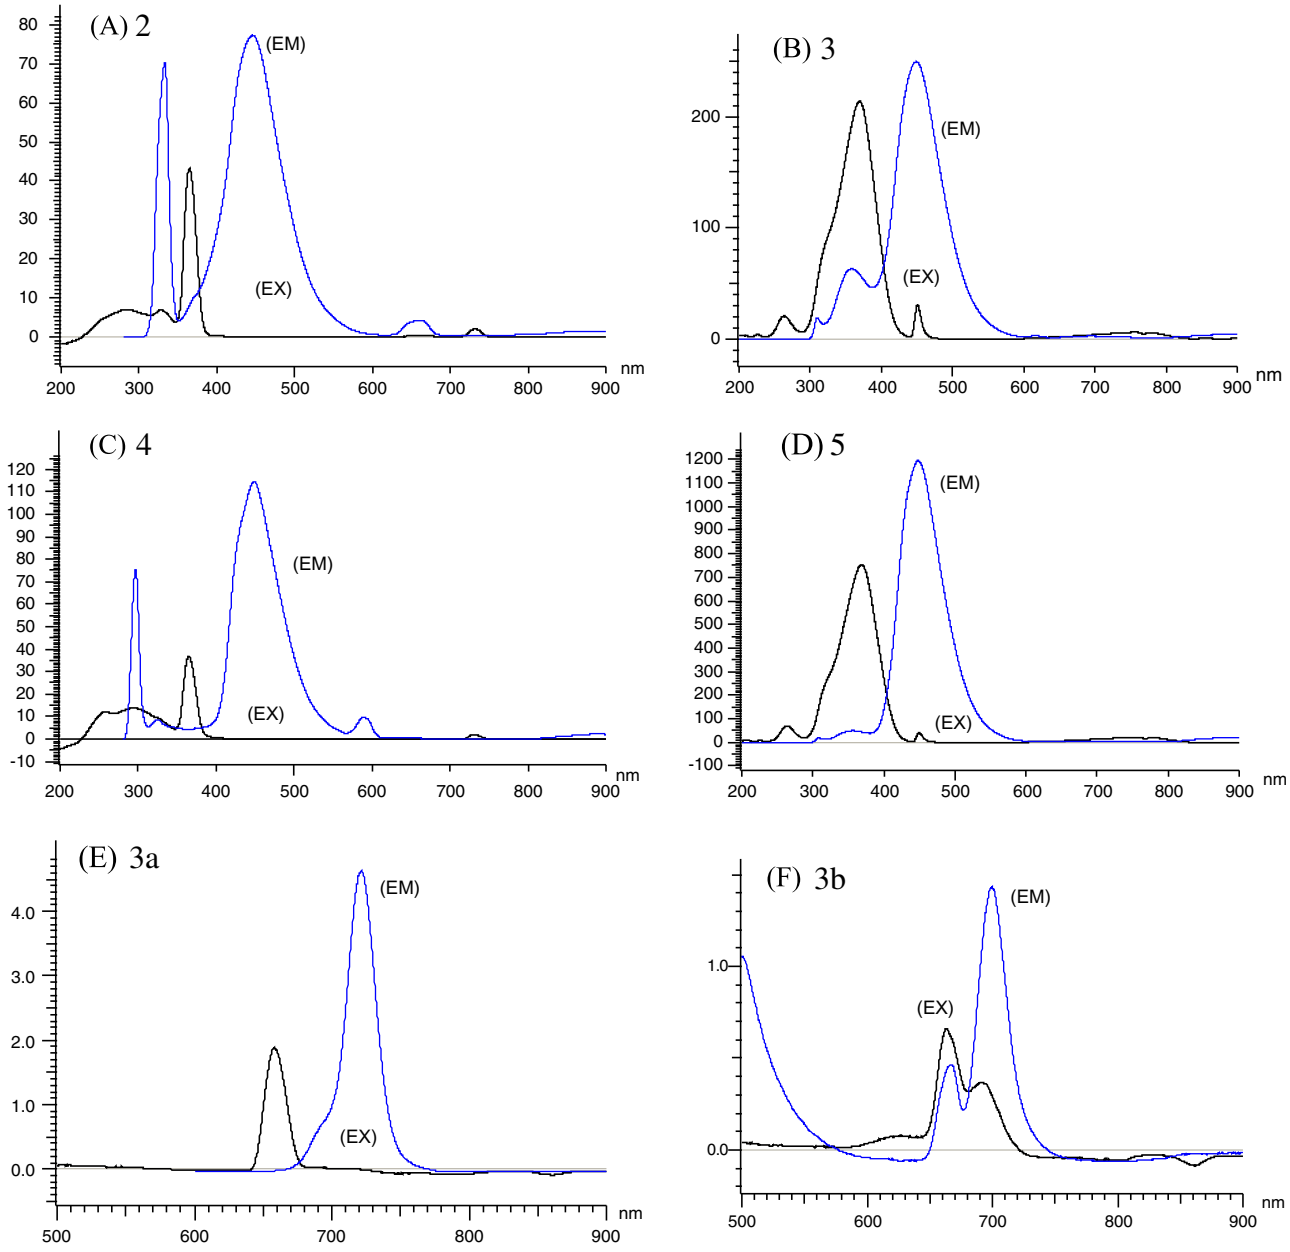

Fig. 5. Fluorescence emission and excitation spectra of **2**–**5** and **3a**, **3b** in THF. Excitation wavelength = 364 nm for **2 (A)**, 364 nm for **3 (B)**, 369 nm for **4 (C)**; 368 nm for **5 (D)**, 657 nm for **3a (E)** and 655 nm for **3b (F)**.

structures. The yields were satisfactory and depended upon the metal cation.

The IR-spectra of **2/4** exhibit the intense absorption band at 2240/2200 cm^{-1} corresponding to the C≡N stretching, and characteristic frequencies at 3461–3398/3400–3396 (–OH), 3098/3100 (Ar–H) and 1707/1703 (lactone C=O) cm^{-1}. The broad absorption band at 3461–3398/3400–3396 cm^{-1} corresponding to –OH stretching, disappeared after conversion to **3/5** (Scheme 2). The ^1H NMR spectra of **2/4** indicated the –OH protons at 9.28 and 9.31 ppm as singlets, the aromatic protons at 6.66–8.25/6.66–8.28 ppm as doublets and the proton of coumarin at position 4 at 8.08 ppm as a singlet. In the IR-spectra of **2/4**, alkyl groups ($–CH_2–$ and $–CH_3$) gave intense absorptions at 2923–2898/2950–2890 cm^{-1}. The C≡N band appeared at 2240/2220 cm^{-1} and the lactone –C=O group stretched around 1707/1703 cm^{-1}. In the ^1H NMR analysis of **3/5** in DMSO, the proton of coumarin at position 4 appeared at 8.09 ppm as a singlet, the aromatic protons at 7.05–8.09/7.05–8.20 ppm as doublets and the $–CCH_2C–$ protons in the long chains at the range of 1.32–1.78/1.29–1.76 ppm as multiplets. The CH_3 protons at the end of the chains were observed as two triplets at 0.98/0.92 ppm and 0.92/0.88 ppm. The triplets at 4.12/4.09 ppm and 4.06/4.01 ppm indicated the presence of two $–OCH_2–$ groups adjacent to an aromatic ring.

Cyclotetramerization of the dinitriles (**3** and **5**) to the Pcs (**3a–3d** and **5a–5d**) were confirmed by the disappearance of the sharp C≡N vibration at 2228/2220 cm^{-1}. The IR-spectra of metal-free (**3a**/**5a**) and metallo Pcs (**3b–3d** and **5b–5d**) are very similar, except ν(NH) vibrations of the inner Pc core in the metal-free molecule at 3250/3268 cm^{-1}. In addition to the elemental analysis results, mass spectra were definitive. The mass spectra of **2/4** and **3/5** confirmed the proposed structures. The mass spectral studies by the MALDI-TOF technique on the newly synthesized compounds identified at m/z: 396 $[M]^+$ for **2/4** and m/z: 564 $[M]^+$ for **3/5** (Scheme 3A and B). Values of the molecular ions show good agreement with the calculated values for metal-free Pc **3a/5a** (m/z 2258), ZnPc **3b/5b** (m/z 2321) (Scheme 3C), CoPc **3c/5c** (m/z 2316) and CuPc **3d/5d** (m/z 2320) in the presence of 2,5-dihydroxybenzoic acid (DHB) (20 mg/mL in THF) as a matrix.

The ground state electronic spectra of the compounds showed characteristic absorptions in the Q band region at 685/663 and 717/696 nm for **3a**/**5a**, 690/671 nm for **3b**/**5b**, 680/653 nm for **3c**/**5c** and 690/694 nm for **3d**/**5d** in THF and DMF (Figs. 1 and 2). The B band region was observed around 338–350 nm in THF and DMF. The 3-phenylcoumarins show high absorption in the near UV range around 340–346 nm [26]. After Pc formation, four 6,7-dihexyloxy-3-[*p*-(2′,3′-dicyanophenoxy)phenyl]coumarin (**3**) and 6,7-dihexyloxy-3-[*p*-(3′,4′-dicyanophenoxy)phenyl]coumarin (**5**) groups are present in each Pc molecule, so the B band absorption intensity can probably be multified as that of Pc core alone. The absorption of **3a–3d** and **5a–5d** can be carelessly named as only B band of Pc core around 350 nm; this covers also the absorption of coumarin units. There were also characteristic shoulders at slightly higher energy side of the Q band for each Pc. The spectra of **3b–3d** and **5b–5d** in THF/DMF showed monomeric behaviour evidenced by a narrow Q band, typical of metallo Pc complexes. The metal-free Pc complexes **3a/5a** gives a doublet Q band as a result of the D_{2h} symmetry. It was found that the Q bands of H_2Pc and ZnPc are red shifted 20 nm for **3a** and 5 nm for **3b** as compared with that of **5a** and **5b** in THF (Fig. 3).

Aggregation is usually depicted as a coplanar association and strongly dependent on the concentration and nature of the solvent. For Pcs, the aggregation behaviour in solution is a good indication of interaction between the aromatic macrocycles. Upon formation of higher order complexes, the coupling between the electronic states of individual monomeric Pc units causes significant spectral perturbations. Thus, aggregation is easily detected from optical absorption studies. The UV–Vis spectra of the Pc compound (**3a**) in THF are relatively narrow as compared with those in DMF. It is clear that while **3a** is in the form of monomeric species in THF, it is aggregated in DMF. THF seems to be able to disrupts π–π stacking by coordination to the metal center. Thus, the aggregation of the Pc compounds can be inhibited by using THF as the solvent. In the case of aggregation, any increase in concentration generally results in the broadening of the Q band absorption and insignificant peak around 620 nm Pc molecules, which accompanied by a blue shift of the Q band with some decrease in intensity [27]. For this reason, in this study, the aggregation behaviour of the Pc complex **3a** was monitored at several concentrations in THF and DMF (Fig. 4). Fig. 4 indicates the effect of increasing concentration on the UV–Vis spectra of $1.06 \cdot 10^{-6}$ mol dm^{-3} **3a** in DMF. At the beginning (for $1.06 \cdot 10^{-6}$ mol dm^{-3} **3a**), the intensities of two bands are approximately equal to each other. As the concentration of **3a** is increased, the band with the lower wavelength becomes higher in intensity as compared with the higher one. The changes in the Q band absorption with increasing concentration in the spectra of **3a** provide additional support for the presence of aggregation in DMF and the absence of aggregation in THF.

Fluorescence emission spectra for ligands (**2–5**) and Pcs (**3a** and **3b**) in THF were shown in Fig. 5. While the Pcs **3a** and **3b** showed similar fluorescence behaviour, the Pc **3c**/5c and **3d**/**5d** does not show fluorescence at excitation wavelength. The emission peaks for **2–5** and **3a**/**5a**, **3b**/**5b** were observed at 458, 454, 440, 439 nm and 721/720, 700/694 nm, respectively. The excitation spectra of the compounds are similar to that of absorption spectra, and are mirror images of the fluorescence spectra (Table 1).

Table 1
Absorption, excitation and emission spectral data for ligands and phthalocyanines **2–5**, **3a**, **3b** and **5a**, **5b** in THF.

Compound	Q band λ_{max} (nm)	log ε	Excitation λ_{Ex} (nm)	Emission λ_{Em} (nm)	Stokes shift Δ_{stokes} (nm)
2	360/305	4.30/4.13	364	458	98/153
3	360/323	4.32/4.06	364	454	94

1-Ethyl-, 1-tert-butyl- and 1-(1-adamantyl)-5-thiotetrazoles were prepared by the reaction of commercial alkyl isothiocyanates with sodium azide in refluxing aqueous 2-propanol [16]. Potassium tetrachloroaurate and sodium borohydride were of analytical reagent grade and were used without further purification.

2.2. Characterization

2.2.1. Transmission electron microscopy (TEM)

The particle size and morphology of the NPs were examined on a JEOL JEM 1010 transmission electron microscope operating at 200 kV. Samples were prepared by drop-casting of a dilute solution of the NPs in toluene on 400-mesh carbon-coated copper grids and quickly removing of the excess of solution.

2.2.2. UV–Vis spectroscopy

UV–Vis absorption spectra of toluene solutions of the NPs were recorded on a Cary 500 Scan UV–Vis–NIR (Varian Ltd.) spectrophotometer over the range 300–900 nm. The liquid samples were placed in a quartz cell with a 1 mm path length.

2.2.3. X-ray diffraction

XRD patterns were recorded on a DRON-2 X-ray diffractometer using a focused monochromatic Co Kα source. The registered coverage was contained in the range $2\theta = 40-100^\circ$. Solutions of the NPs were placed on Si support and evaporated.

2.2.4. Fourier transform infrared (FTIR) spectroscopy

FTIR spectra were acquired on a Thermo Nicolet AVATAR-300 FTIR spectrometer over the range 400–4000 cm^{-1}. Solutions of the gold NPs or thiotetrazoles were placed on a NaCl plate and the spectra were collected after evaporation of solvent at room temperature.

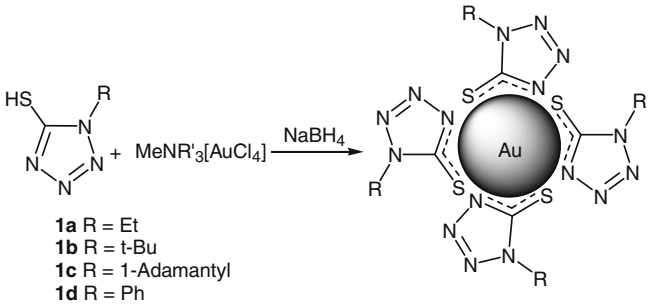
2.2.5. Thermogravimetric analysis (TGA)

TGA was carried out on a NETZSCH STA429 thermoanalyzer in a nitrogen atmosphere over a temperature range 30–600 °C at a heating rate of 10 °C/min.

2.3. Synthesis of the gold nanoparticles

The current synthetic procedure is a modified version of the method developed by the Brust group based on reduction of the tetrachloroaurate anion with sodium borohydride in the presence of a phase transfer catalyst and a stabilizing agent in a two-phase system [5]. In a typical procedure, 10 ml of an aqueous solution of potassium tetrachloroaurate (0.04 M) was mixed with 30 ml of a toluene solution of Aliquat 336 (0.05 M). The mixture was vigorously stirred for 30 min until the gold solution was extracted into the organic layer almost completely. The top toluene layer was separated from the aqueous layer, and washed with water. 1-R-5-thiotetrazole (0.0025 mmol) was added to the toluene solution with stirring. A freshly prepared aqueous solution of sodium borohydride (12 ml, 0.2 M) was added slowly. Stirring of the resulting mixture was continued for 3 h at room temperature. The organic and aqueous phases were separated upon completion of the reaction. The toluene layer was concentrated with a rotary evaporator under reduced pressure. The obtained residue was washed with hexane (R = Et) or ethanol (R = t-Bu, 1-adamantyl). The final product could easily be redispersed in organic solvents, such as chloroform or toluene.

3. Results and discussion



We found that reduction of the tetrachloroaurate anion with sodium borohydride in the presence of the phase transfer catalyst Aliquat 336 and 1-substututed 5-thiotetrazoles, **1**, in a water–toluene biphasic solution yielded spherical gold NPs with a relatively narrow size distribution (Scheme 1).

Fig. 1 shows TEM images of the obtained NPs. The sizes of the obtained NPs are strongly dependant on the hydrocarbon substituent R. The largest NPs (4.7 nm, $\sigma = 0.09$) were obtained using tetrazole **1a**, with relatively small ethyl substituent. The presence of bigger tert-butyl and 1-adamantyl substituents in the molecule of stabilizing agent, **1b** and **1c**, leads to the formation of smaller NPs with sizes 2.8 nm ($\sigma = 0.42$) and 3.2 nm ($\sigma = 0.36$), correspondingly. The influence of the substituent in the capping agent on the size of gold NPs obtained by two-phase reduction is not very clear. We can assume that tetrazoles **1b** and **1c** are stronger stabilizers of NPs in comparison with **1a** due to the bulky structure of the tert-butyl and 1-adamantyl substituents, while the linear ethyl substituent prevents growth and aggregation of NPs to a lesser extent. This dependence is consistent with one for alkanethiol capped gold NPs. In the latter case the increase of a methylene unit in the alkanethiol decreases the NP core size [17]. However, this dependence can be non-monotonic [18]. Fig. 2 shows the UV–Vis spectra of the as synthesized gold NPs. They displayed a broad peak around 510 nm, which is a peculiar characteristic of the gold surface plasmon band [19].

The NPs capped with thiotetrazoles **1a–c** are readily redispersed in non-polar solvents such as toluene and chloroform, showing no color changes and precipitation after 3 months storage under ambient conditions. An example photo of a toluene solution of gold NPs capped with tetrazole **1a** after 3 months storage at ambient conditions is presented in the inset of Fig. 2. It should be noted that 1-phenyl-5-thiotetrazole **1d** was also investigated as a capping agent in the synthesis of gold NPs. However, NPs capped with this ligand have tendency to coagulate and their solutions are stable for less than 1 week. Such behavior of NPs capped with **1d** was observed also during the synthesis of CdS NPs [12] and can be explained by π–π interactions between the phenyl rings of single NPs, leading to their agglomeration.

The XRD pattern of the gold NPs capped with thiotetrazole **1b** is shown in Fig. 3. Bragg's reflections for the above mentioned NPs are observed in the XRD pattern at 2θ values of 44.7, 52.1, 76.7 and 93.5°, representing the [1 1 1], [2 0 0], [2 2 0] and [3 1 1] planes of a face centered cubic lattice of gold (JCPDS File No. 4-0784). Gold NPs capped with tetrazoles **1a** and **1c** showed similar reflections.

Comparative analysis of the IR spectra of synthesized NPs and the corresponding free ligands confirmed the presence of thiotetrazoles at the surface of the NPs. As an example, the IR spectra of **1b** and gold NPs capped with this ligand are presented in Fig. 4. The IR spectra clearly indicate that the surface of the NPs is covered with 1-R-5-thiotetrazolate anions, SCN_4R^-, which form under

Scheme 1. Synthesis of gold NPs capped with thiotetrazoles.

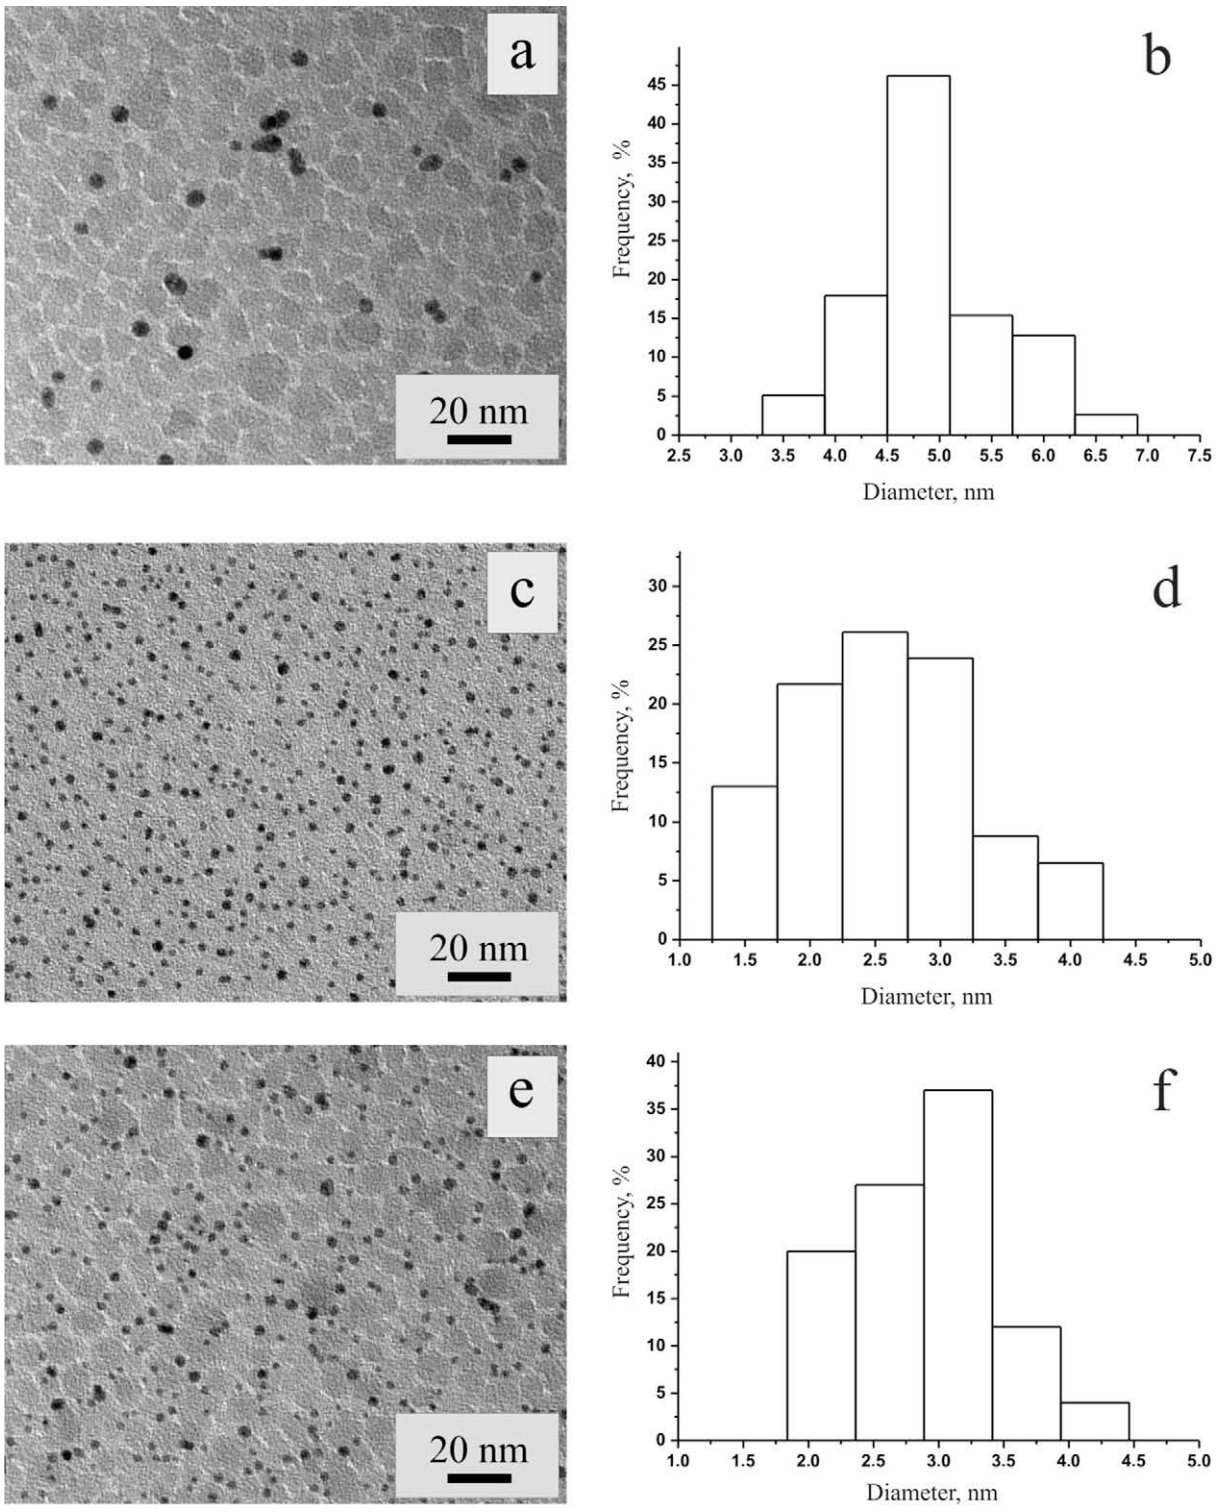


Fig. 1. TEM images and histograms of gold NPs capped with thiotetrazoles **1a** (a and b), **1b** (c and d), **1c** (e and f).

deprotonation of tetrazoles **1** and present a stable 6π-electron ring system. Disappearance of the duplet band of the S–H bond at 2540 and 2575 cm^{-1} and the appearance of a new duplet at 1733 and 1621 cm^{-1} in the spectra of NPs is typical for thiotetrazolate anions [20].

Fig. 5 shows TGA curves of thiotetrazole **1b** and the corresponding NPs. It indicates that thermolysis of the ligand bonded with NPs is characterized with a more fluent lost of weight and proceeds in a wider temperature range in comparison with the free ligand molecule. Since it is well-known [12] that thiotetrazolate salts are characterized with higher thermal stability in comparison with the corresponding thiotetrazoles, the observed differences in thermal behavior can be explained by the presence of the thiotetrazolate anion on NPs surface.

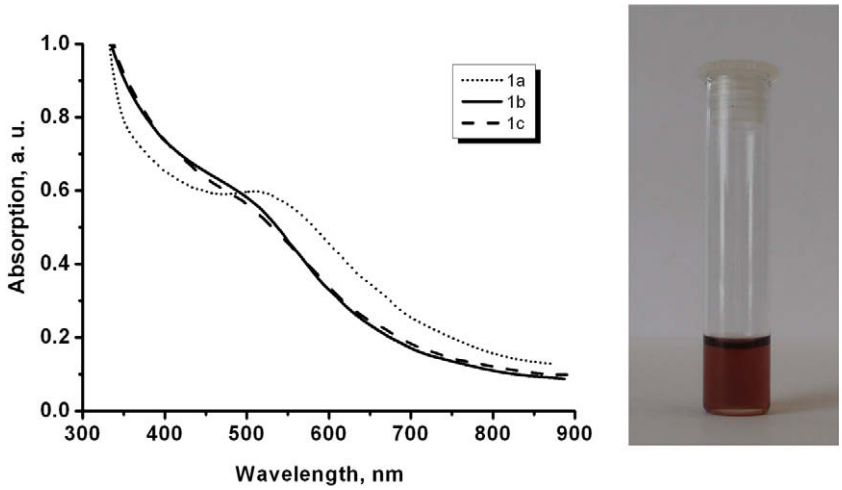

Fig. 2. UV–Vis spectra of gold NPs capped with tetrazoles **1** and a photograph of the solution of gold NPs capped with tetrazole **1a** after 3 months storage under ambient conditions.

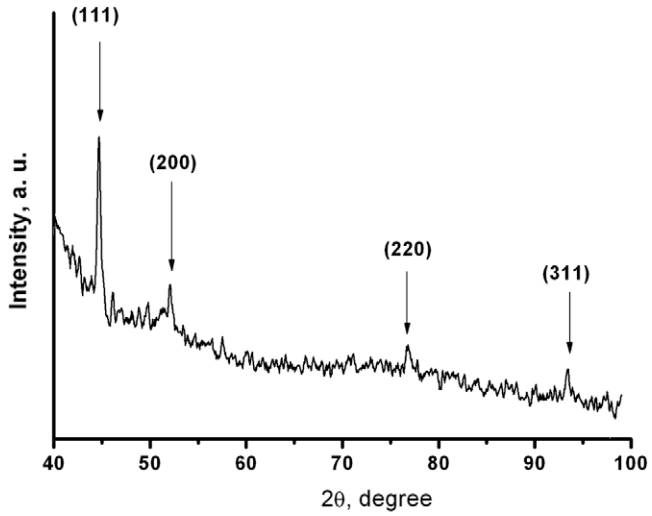

Fig. 3. X-ray power diffraction of gold NPs capped with **1b**.

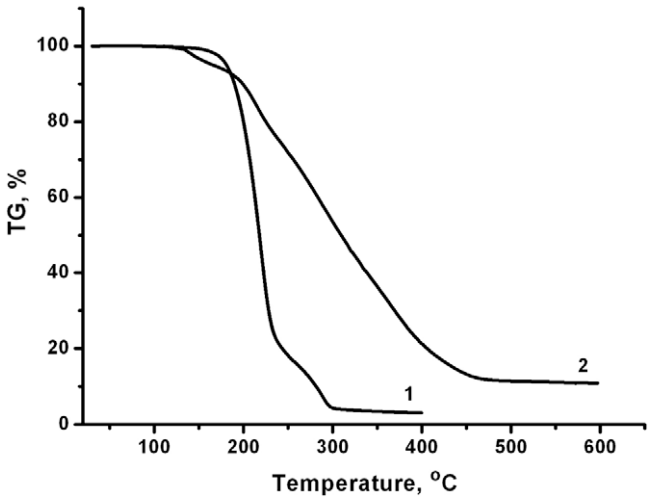

Fig. 5. TGA curves of pure tetrazole **1b** (1) and gold NPs, capped with **1b** (2).

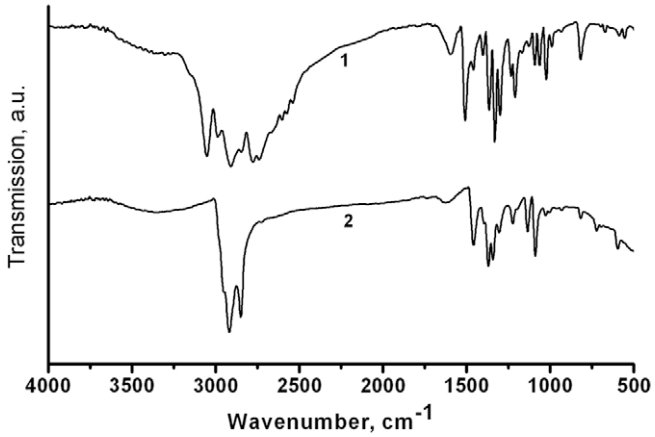

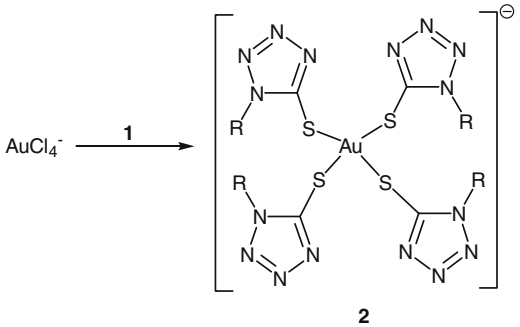

Fig. 4. FT-IR spectra of pure **1b** (1) and gold NPs capped with **1b** (2).

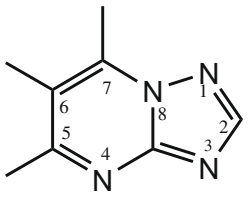
It should be noted that during addition of tetrazoles **1** to a toluene solution of the aurate salt, the color changes from yellow to orange or red-orange. Probably, this change is due to the formation of tetrakis(1-R-5-mercaptotetrazolato)-gold(III) complexes, **2**, which form by the replacement of the chloride ligands by thiotetrazolate in $AuCl_4^-$ [21]. According to X-ray analysis in such complexes, the tetrazole moiety is coordinated through sulfur atoms. However, in the formed NPs, binding of the thiotetrazolate anion with NPs can occur not only via sulfur atom, but also *via* nitrogen, and for the above mentioned ligands S-monodentate and N(4),S-bridging modes are favoured [14].



2

4. Conclusion

In summary, 1-R-5-thiotetrazoles were investigated as a novel ligands for stabilization of gold NPs. NPs capped with these easily available ligands were obtained by reduction of the tetrachloroaurate anion with sodium borohydride in the presence of the phase transfer catalyst Aliquat 336 and thiotetrazoles in a water – toluene two-phase system. These NPs are attractive for making efficient catalysts and electronic materials based on "naked" nanostructures.

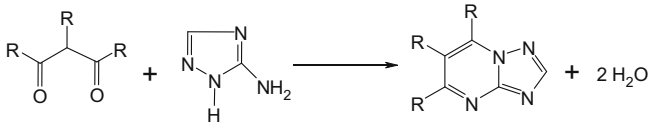
Scheme 1. The ligand tmtp (5,6,7-trimethyl[1,2,4]triazolo[1,5-*a*]pyrimidine) and its IUPAC recommended ring-atom numbering system.

2.2. Synthesis of the ligand

The synthesis of the ligand tmtp was carried out by a known condensation procedure [2,22] at 160 °C, from a diketone and 3-amino-1,2,4-triazole schematically as summarized in Scheme 2, followed by recrystallization using ethanol. Observed yields were 60–70% depending on small variations in the conditions. Characterisation of the free ligand was done by elemental analysis, IR and NMR spectroscopy.

2.3. Synthesis of the coordination compounds

The coordination compounds were prepared by the following general recipes:



A solution of 1–2 mmol of the metal salt in 10–20 mL water was added to a warm aqueous solution of the ligand (1–5 mmol). Upon standing at room temperature crystals appeared, which were collected by filtration. In some cases, MeOH/water or pure MeOH were used as a solvent. To prepare the thiocyanate compounds a metathesis reaction was used, starting from the aqueous metal nitrate and ammonium thiocyanate (1:2). Yields were found to be between 30% and 60% depending on the metal and anion. Satisfactory elemental analysis was obtained for all compounds.

2.4. Physical and analytical methods

C, H, N determinations were performed on a PerkinElmer 2400 Series II analyzer. Ligand field spectra in the 300–2000 nm range were obtained on a PerkinElmer Lambda 900 spectrophotometer using the diffuse reflectance technique, using MgO as a reference. Infrared spectra of all compounds were recorded on a PerkinElmer Paragon 1000 FTIR spectrophotometer equipped with a Golden Gate ATR device, using the reflectance technique (4000–300 cm^{-1}, res. 4 cm^{-1}). (Far-)FTIR spectra were obtained on a Bruker IFS 113v infrared spectrophotometer as polyethylene mulls (600–100 cm^{-1}, Mylar 6 μ, res. 2 cm^{-1}). X-band powder EPR spectra were obtained on a Bruker EMX*plus* electron spin resonance spectrometer (field calibrated with DPPH (g = 2.0036)).

2.5. X-ray diffraction studies

For each coordination compound a suitable crystal was selected from the mother liquid and mounted to a glass fiber using the oil-drop method. Diffraction data were collected on a Nonius KappaCCD diffractometer (graphite-monochromated Mo Kα radiation).

Scheme 2. Synthesis scheme of substituted triazolopyrimidines; for tmtp: R = Me.

The structures were solved by direct methods. The programs COLLECT [23], SHELXS-97 [24], SHELXL-97 [25] were used for data reduction, structure solution and structure refinement, respectively. Refinement of F^2 was performed against all reflections. All non-hydrogen atoms were refined anisotropically. The water Hydrogen atoms of compounds **6**, **9** and **10** were picked from difference maps and refined isotropically. All other H-atoms were introduced in calculated positions and refined with fixed geometry with respect to their carrier atoms. Details of compound **5**: one of the two methanol molecules and the water molecule were found to be severely disordered. The methanol C7 and the water O9 were each refined with an occupancy factor of 0.5, while the methanol O8 atom was refined in three positions with site occupancy factors of 1/3. The H-atoms of these water and disordered methanol molecules could neither be determined, nor fixed.

Crystallographic data of the compounds are summarized in Table 1. Compound **11**, was found to be isomorphous with compounds **9** and **10**, as deduced from infrared and X-ray powder diffraction.

3. Results and discussion

3.1. General observations and spectral analyses

A variety of metal salts has been reacted in alcoholic or aqueous solution with the ligand, and a (micro)crystalline, reproducible product was formed, irrespective of the used metal to ligand ratio. The so-obtained products are listed in Table 2 with their composition and with some spectral characteristics. All compounds have been characterized by common physical methods, i.e. infrared, ligand field, and C, H, N analysis. The Cu compounds were also characterized by EPR, and the Zn compound also by NMR. In 10 cases an X-ray structure determination was carried out to obtain molecular structure details (*vide infra*). These compounds are numbered **1–10**.

3.2. Description of the X-ray structures

The compound $[CuCl_2(tmtp)_2]$ (**1**) crystallizes in the monoclinic space group $P2_1/c$. An ortep perspective view of **1** is shown in Fig. 1. Selected bond lengths and angles are given in Table 3. The Cu(II) ion is in a distorted tetrahedral environment formed by two tmtp ligands and two chlorides. Such tetrahedrally distorted geometries are not uncommon for Cu(II) with N donor ligands [26]; a packing diagram is given in Fig. S1. The degree of distortion of the Cu(II) ion can be expressed by the parameter τ_4 (τ_4 = 0.46 for Cu; τ_4 = 0 for a square planar geometry and τ_4 = 1 for a tetrahedral geometry) [27]. The Cu–N and Cu–Cl bond distances are in typical ranges for this type of $[CuN_2Cl_2]$ tetrahedron, see Table 3 [28,29].

The corresponding bromide $[CuBr_2(tmtp)_2]$ (**2**). crystallizes in the orthorhombic space group $Pca2_1$. The unit cells contains two slightly different chromophores, but both very similar to the chloride in Fig. 1. An ortep perspective view of **2** is shown in Fig. S2 and a packing figure in Fig. S3. Both Cu ions are in quite distorted tetrahedral environment (τ_4 = 0.54 for Cu; τ_4 = 0 for a square planar geometry and τ_4 = 1 for a tetrahedral geometry) [27], formed by two bromido ligands and to monodentate tmtp ligands. The Cu–N and Cu–Br bond distances are in typical ranges for this type of $[CuN_2Br_2]$ tetrahedron [28,29].

The compound $[ZnBr_2(tmtp)_2]$ **3** crystallizes in the monoclinic space group $P2_1/c$. An ortep perspective view of compound **3** is depicted in Fig. S4 and a packing diagram is given in Fig. S5. In this case the distortion from tetrahedral is much smaller, as commonly seen for Zn(II) d^{10} ions. The Zn(II) ions are in an almost perfect tetrahedral environment (τ_4 = 0.89 for Zn; τ_4 = 0 for a square planar

sh = shoulder, (v)br = (very)broad, w = weak, CT = charge transfer band.

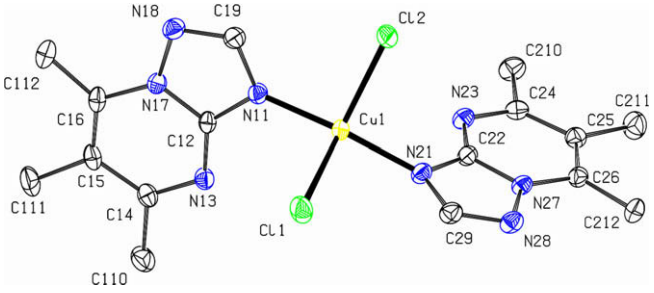

Fig. 1. ORTEP drawing (30% probability level) of [CuCl2(tmtp)2] (**1**). Hydrogen atoms are omitted for clarity.

geometry and $\tau_4 = 1$ for a tetrahedral geometry) [27], formed by two bromido ligands and to monodentate tmtp ligands. Selected bond lengths and angles are given in Table 3. The dihedral angles of the two largest angles from which τ_4 is calculated are 116.05(8) and 118.70(2)°. The Zn–N and Zn–Br bond distances are in typical ranges for this type of $[ZnN_2Br_2]$ tetrahedron [28,29].

The compound $[Cu(NO_3)_2(tmtp)_2]$ (**4**) crystallizes in the triclinic space group $P\bar{1}$. An ortep perspective view of **4** is shown in Fig. 2. Selected bond lengths and angles are given in Table 3. The geometry is distorted octahedral with chelating nitrates, having one long band (Cu–O3 = 2.529(2) Å) and one short bond (Cu–O1 = 1.964(1) Å) to the Cu(II) ion. The crystal packing is depicted in Fig. S6 and is uneventful.

The compound $[Cu(SO_4)_2(tmtp)_2]_2(CH_3OH)_{2⅓}(H_2O)_{1/6}$ (**5**) crystallizes in the trigonal space group $R\bar{3}$. An ortep perspective view of the dinuclear sulfate-bridged unit of **5** is presented in Fig. 3. Selected bond lengths and angles are given in Table 3. The compound has a quite unique bis(sulfato)-bridged dinuclear structure, where each Cu(II) ion is 5-coordinated in a geometry close to tetragonal pyramidal ($\tau_5 = 0.10$; $\tau_5 = 0$ for a square pyramidal geometry and $\tau_5 = 1$ for a trigonal bipyramidal geometry; [30]). The sulfate is chelating to one Cu, with Cu–O distances of 1.97–1.99 Å, and providing a third O atom to the other Cu(II) ion, with Cu–O = 2.216(2) Å. The chelating O–Cu–O angle is 71.6(1)°. The crystal lattice of **5** contains water and MeOH molecules (of which one MeOH molecule and the water molecule are disordered); hydrogen bonds exist between the MeOH molecule and the sulfate oxygen atom and between the water and the MeOH molecules. Details are given in Table S1. A packing diagram is depicted in Fig. S7.

Compound **6**, $[Cu(H_2O)(NCS)_2(tmtp)_2]$, crystallizes in the monoclinic space group $P2_1/c$ and has the Cu^{II} ion is in a coordination environment which is intermediate between trigonal bipyramidal and square-pyramidal ($\tau_5 = 0.49$; $\tau_5 = 0$ for a square pyramidal geometry and $\tau_5 = 1$ for a trigonal bipyramidal geometry; [30]), formed by two crystallographically equivalent thiocyanate anions (nitrogen atoms N1 and N1a) and one water molecule (oxygen atom O1) in the trigonal plane, and by two symmetry-related tmtp ligands (nitrogen atoms N11 and N11a) at the apical positions. Intramolecular hydrogen bonding between the coordinated water and the non-coordinating N23 (N···O = 2.77(1) Å is observed. The structure is depicted in Fig. 4, and the packing diagram is shown in Fig. S8.

The structure of $[Zn(NCS)_2(tmtp)_2]$, **7**, is uneventful; it crystallizes in the in the monoclinic space group $P2_1/c$ and resembles somewhat compound **3** with the bromide. The molecular structure is depicted in Fig. S9, with the packing diagram given in Fig. S10.

The compound $[Cd(NCS)_2(tmtp)_2]$, **8**, is quite different from that of **7**; it crystallizes in the in the triclinic space group $P\bar{1}$. The difference with Zn is ascribed to the much larger ionic radius of Cd(II), compared to Zn(II), allowing now an octahedral coordination. The octahedral geometry is reached by bridging (thiocyanato-N,S) ligands, as depicted in Fig. 5. A packing diagram is depicted in Fig. S11.

Changing the anion to the non-coordinating tetrafluoridoborate, it appeared possible to coordinate as much as four tmtp ligands to the metal; crystals for X-ray diffraction were obtained for Co and Zn, resulting in the compounds: $[Co(tmtp)_4(H_2O)_2](BF_4)_2$, **9**, and $[Zn(H_2O)_2(tmtp)_4](BF_4)_2$, **10**. They crystallize in the in the triclinic space group $P\bar{1}$. In addition a similar Ni(II) compound was obtained, found to be isomorphous as a powder. The structure of **9** is depicted in Fig. 6, and its packing is shown in Fig. S12. The Zn compound is isomorphous and its structure and packing is shown in figures S13 and S14. The octahedrally-based geometry is reached by two additional water ligands, which at the same time provide medium-strong hydrogen bonds to the lone pairs of the ligand N3 atoms (N···O = 2.75–2.85 Å).

4. IR, Ligand field and EPR spectroscopy

In Table 2 selected infrared vibrations are presented. In all compounds vibrations of the ligand are easily recognized, and for the polyatomic anions also the anions are visible. The mid-IR spectra of compounds **1, 2** and **3** are identical. In the far-IR the Cu–N vibrations are observed at 284, 246 and 248 cm^{-1} for 1, 2 and 3, respec-

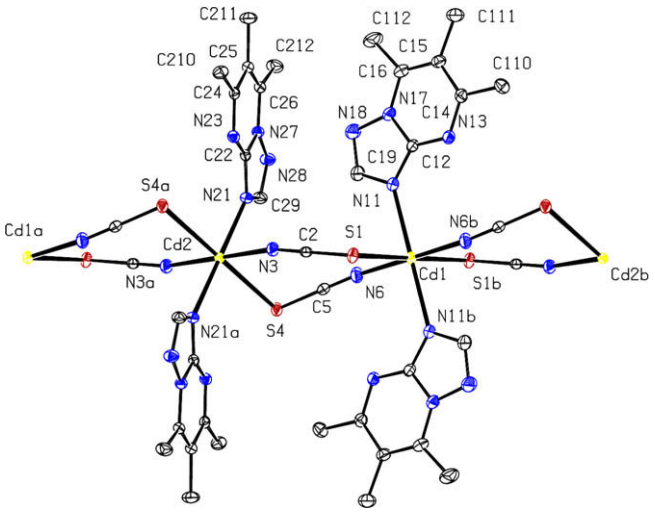

Fig. 5. ORTEP drawing (30% probability level) of a few units in the chain of [Cd(NCS)2(tmtp)2] (**8**). Hydrogen atoms are omitted for clarity.

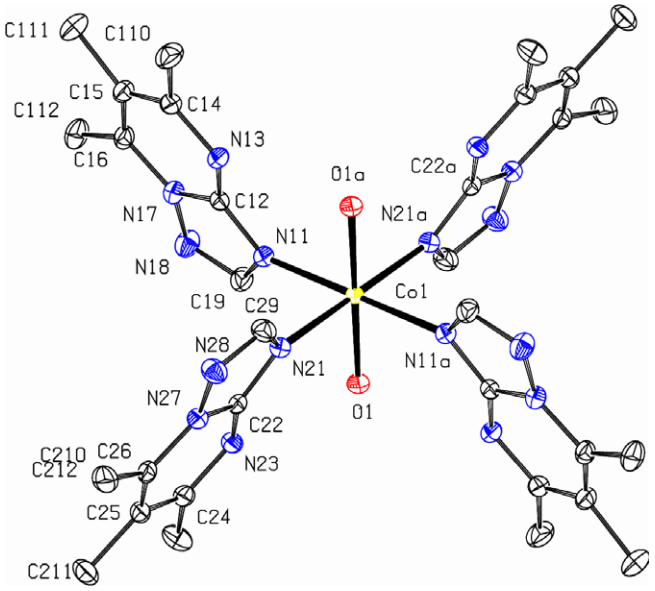

Fig. 6. ORTEP drawing (30% probability level) of a few units in the chain of [Co(tmtp)4(H2O)2](BF4)2 (**9**). Hydrogen atoms are omitted for clarity.

tively. The Cu–Cl vibration in 1 is observed at 309 cm^{-1}, while the Cu–Br vibration is observed at 160 cm^{-1}. For compound **3** the Zn–Br vibration is observed as a strong split band at 213–200 cm^{-1}. These vibrations are consistent with the literature [31–33]. For the other compounds the anion vibrations are listed, i.e. for compound **4** the nitrate vibrations at 1270 and 798 cm^{-1}, other nitrate vibrations which should be visible for bonded nitrate [34] are obscured by ligand vibrations. The NC vibrations of NCS compounds **6, 7** and **8** are observed at around 2051–2097 cm^{-1}. The highest vibration is from the bidentate coordinating NCS. The IR spectra of compounds **9, 10** and **11** are virtually identical, suggesting the same structure, the BF_4 vibrations of these three compounds are observed at around 1050 cm^{-1}. All these values are in agreement with the literature [34] for non-coordinated tetrafluoridoborate. The bridging sulfate anion in compound **5** gives four peaks at 1205, 1145, 1121 and 994 cm^{-1}, which is according to the literature for bridging sulfate [34].

Compounds containing water and/or MeOH show vibrations around 3400 cm^{-1} in compounds, i.e. for **5, 6, 9, 10** and **11** a broad band (sometimes a small splitting is observed) is observed, which are attributed to the OH vibration of methanol and/or water. For coordinated water the wagging en rocking vibrations can be observed in the 700–600 cm^{-1} and the M–O vibrations around 450 cm^{-1} [35]. Indeed for compounds **9**, **10** and **11** in compound **9** two very broad vibrations are observed at ca. 660, 600 and 450 cm^{-1}, for compound **10** at around 630 and 450 cm^{-1} and for compound **11** at around 680, 620 and 480 cm^{-1}, which is confirming the observations in the literature [35].

The powder EPR spectra of compounds **2** and **5** reveal at RT a broad isotropic band due to $S = ½$ (around $g = 2.10$); for compounds **1** and **4** an axial signal with $g_\perp$ of 2.07–2.08 and a $g_{||}$ of 2.24–2.26. These signals are in agreement with a $d_{x^2-y^2}$ configuration for the ground state [36]. For compound **6** a rhombic signal ($g_1 = 2.28$, $g_2 = 2.11$ and $g_3 = 2.05$) is observed, which is in consistence with the five coordinated geometry of the Cu(II) ion [36].The ligand field transitions measured as a solid with the diffuse reflectance technique for the Cu(II) compounds (**1, 2, 4, 5, 6**) are observed in general as broad bands with a maximum which vary from 16.1 to 11.6 $\times 10^3$ cm^{-1} with a shoulder, which vary from 13.1 to 9.1 $\times 10^3$ cm^{-1}. These bands are in agreement with common ligand field transitions for square-planar based geometries with a variety of distortions [36,37]. Also the ligand field transitions of the Co(II) compound (**9**) and the Ni(II) compound (**11**) are in agreement with the literature for octahedral Co(II) and Ni(II) [37,38].

5. Concluding remarks

The study described above on the coordination behavior of the ligand tmtp, an example of one of the several easily accessible triazolopyridimidine ligands, has shown that such ligands are versatile in their behavior. The resulting coordination compound display interesting structural and electronic properties, and in some cases interference with hydrogen bonding from solvent and to anions is seen. Fine-tuning of the formed structure appears possible by proper choice of counterions and solvents in the synthesis. Which compounds are formed as described above is difficult to determine a priori, and depends strongly on the used metal and the selected anion.

Acknowledgements

This work was performed in the framework of freshmen students research project "Leren Onderzoeken 1" (Learning Research 1) in the BSc programme "Molecular Science and Technology" a recently started concept in the joint programme of Delft University of Technology and Leiden University. The present student co-authors, *Huub Adriaanse, Sven Askes, Yorrick van Bree, Stefan van Oudheusden, Eelke van den Bos, Esref Günay,* have performed this project in a team of six freshmen students.

electronic (diffuse and absorbance) spectra, 5000–50 000 cm^{-1}, were collected using a Cary 500 Scan NIR–Vis–UV Spectrophotometer (Varian). The analysis of the spectra was based on a variable digital method and the deconvolution of the spectral contour into Gaussian components [23–28]. Thermal analysis: TGA and DTA were performed on Setsys TG-DTA 16 Setaram equipment at a heating rate 2 °C/min under N_2.

2.2. Synthesis of the complex

A solution of benzoylglycine (1.50 mmol, 0.269 g) and benzimidazole (3.76 mmol, 0.444 g) in 20 cm^3 of 1-propanol was added dropwise to a solution of $Cu(CH_3COO)_2{\cdot}2H_2O$ in 1-propanol (0.75 mmol, 0.150 g), 10 cm^3. The mixture was kept at room temperature. After several days, blue needle-like crystals were obtained (yield 71%). *Anal.* Calc. for $C_{140}H_{146}Cu_4N_{24}O_9$: C, 58.33; H, 5.10; N, 11.66. Found: C, 58.40; H, 4.80; N, 12.05%. IR spectrum, cm^{-1}: 3460(m), 3316(s), 3137(m), 3064(s), 2999(s), 2843(s), 1606(vs), 1542(vs), 1497(s), 1420(vs), 1297(vs) 1253(s), 1161(w), 1055(w), 1005(w), 977(w), 932(w), 859(m), 747(s), 695(m), 614(m), 559(m), 444(m), 426(m), 388(w), 339(w), 310(w), 294(w), 264(w), 239(w), 245(w), 204(vw), 182(w).

2.3. X-ray structure determination

Diffraction measurements were made on an Xcalibur PX kappa-geometry diffractometer with a CCD Onyx camera (graphite monochromatized Cu Kα radiation). Intensities were recorded at 100(2) K. Data collection and processing parameters are summarized in Table 1. The structure was solved by direct methods using SHELXS-97 [29]. The *n*-propanol molecule was found to be disordered and was refined in two positions with the occupancy factors fixed at 0.5. The C–C and C–O distances for both propanol molecules were restrained. Furthermore in the crystal, the water molecule was found; the occupancy factor was initially refined and finally fixed at 0.25. The hydrogen atoms were generated geometrically (except for those of the water molecule) and were allowed to ride on their carrier atoms. The Flack parameter refined to a value close to 0.45(5), indicating twinning by inversion.

Table 1
Crystal data and structure refinement for $[Cu(hipp)_2(bim)_2]{\cdot}PrOH{\cdot}0.25H_2O$.

Crystal shape	needle

Goodness-of-fit	1.012

2.4. Computational details

The optimized geometry of $[Cu(hipp)_2(bim)_2]$, harmonic frequencies, IR intensities and Raman scattering activities were calculated with the density functional theory DFT at the UB3LYP level [30,31]. The effective core potential (ECP) of Hay and Wadt and the concomitant LanL2DZ basis set has been used [32]. Since our model complex contains the Cu(II) ion, which is an open-shell system (d^9), we have performed unrestricted UB3LYP calculations. The details concerning the IR and Raman spectra will be published elsewhere. The disadvantage of unrestricted hybrid DFT functionals, incorporating the Hartree-Fock exchange, is that unrestricted wave functions are not eigenfunctions of the spin-squared operator $\hat{S}^2$ e.g. they are contaminated by states of higher spin multiplicity [33]. The final $\langle\hat{S}^2\rangle$ value was adjusted at the end of the complex geometry optimization to exactly 0.7500, which corresponds to a doublet ground state wave-function with no spin contamination, and confirm the validity of used method [34,35]. To obtain the natural charges, Natural Bond Orbital (NBO) analysis has been performed [36]. All calculations were carried out with the GAUSSIAN 03 package [37].

3. Results and discussion

3.1. Crystal structure

A perspective view of the molecule of the complex together with the atom numbering scheme is shown in Fig. 1, where the displacement ellipsoids are plotted with 50% probability. The solvent

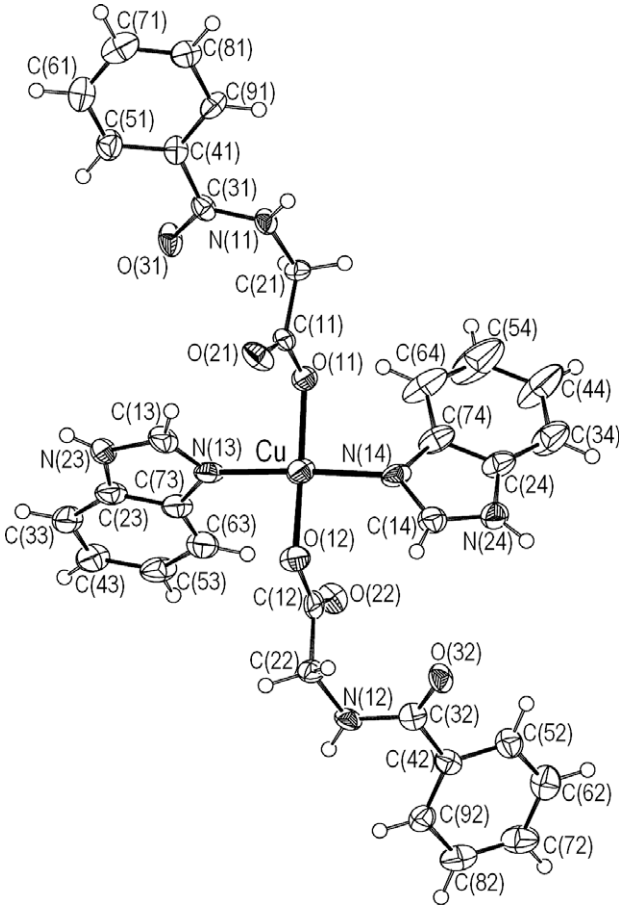

Fig. 1. The molecular structure of $[Cu(hipp)_2(bim)_2]$ with the atom numbering scheme, plotted with 50% probability of displacement ellipsoids.

C(32)–C(42)	1.495(7)	1.503			

molecules are omitted for clarity. Selected structural data for **1**, derived from the X-ray study and calculated by theoretical methods are listed in Table 2. The asymmetric unit of the crystal is built of a copper(II) ion, two hippurate ions, two benzimidazole molecules, one propanol molecule and one quarter of a water molecule. The TGA experiment has been performed to justify the results of the crystallographic study concerning the solvent molecules. During the thermal decomposition of the title complex, two endothermic events occur at 159 and 164 °C (Fig. S1. Suppl. Mat.). This observation confirms that molecules of different solvents are present in the crystal, however the partial overlap of the decomposition processes make the precise estimation of the weight loss impossible.

The coordination polyhedron of the copper ion can be described as tetrahedrally distorted square, the symmetry of the CuN_2O_2 moiety is very close to C_{2v}. The carboxylate *trans*-O(11)–Cu–O(12) and imidazole *trans*-N(13)–Cu–N(14) bond angles are 163.42(17)° and 161.56(18)°, respectively, showing a marked tetrahedral distortion from the square planar geometry [38–43]. The *cis*-N–Cu–O bond angles fall into the range from 90.0(2)° to 92.4(2)°. A degree of the tetrahedral distortion can be also expressed by the dihedral angle between two opposite CuNO planes [44–51]. The (Cu–N(13)–O(12))–(Cu–N(14)–O(11)) angle of 24.80° (24.41° between the second pair of planes) corresponds to a significant tetrahedral deformation of the $[CuN_2O_2]$ core.

The copper ion is four coordinated by two oxygen atoms from non-equivalent hippurate ions and by two nitrogen atoms from non-equivalent benzimidazole molecules. The copper-oxygen distances, (O(11) and O(12) equal to 1.932(4) and 1.954(4) Å, respectively), are shorter than those found in the $[Cu(hipp)_2(im)_2]$ complex (1.976(3) Å) [14] and in $[Cu(hipp)(phen)]ClO_4{\cdot}2H_2O$ (2.0195(16) Å) [17], whereas the Cu–N distances are very similar to the bond lengths observed for copper-benzimidazole nitrogen bonds [19,52]. The water molecule occupies statistically one quarter of the apical positions at a distance of 2.68(2) Å from the central Cu(II) ion. Moreover, two non-bonding contacts with uncoordinated carboxylate oxygens are observed (2.999 and 3.142 Å).

The molecules of the studied compound, connected by a system of intermolecular N–H···O hydrogen bonds (Table 3), form a 2D infinite network parallel to the *ab* plane of the unit cell (Fig. 2). Only one of the disordered propanol molecules is attached to the complex via hydrogen bonds (Table 3), although both are located within the layers. One set of propanol molecules acts as a donor in a weak hydrogen bond (O(16)–H(16)···O(12)), the distance of the oxygen atom O(15) from the second set of propanol molecules to the closest acceptor atom (O12) is considerably large (3.584 Å) and cannot be regarded as a hydrogen bond. The presence of the non-hydrogen bonded hydroxyl group is confirmed by the medium intensity sharp band found in the IR spectrum of the complex at 3460 cm^{-1} [53].

Table 3
Hydrogen-bond geometry for $[Cu(hipp)_2(bim)_2]{\cdot}PrOH{\cdot}0.25H_2O$ (Å, °).

3.2. Theoretical study

The structure of $[Cu(hipp)_2(bim)_2]$ has been fully optimized at the UB3LYP/LanL2dz level [30,31]. The molecular parameters predicted for $[Cu(hipp)_2(bim)_2]$ are in good agreement with the X-ray diffraction results. The metal–ligand distances are equal to 1.980 and 2.012 Å for the Cu–O bonds and 2.008 Å for the copper-nitrogen bonds. A comparison of atomic distances and intramolecular angles is presented in Table 2. Some discrepancies between the theoretical and experimental bond lengths should be attributed to intermolecular hydrogen bonding in the crystal, since the theoretical study has been done for an isolated molecule.

Natural Bond Orbital (NBO) analysis has provided detailed insight into the nature of electronic conjugations between bonds in the molecule. According to the NBO results, the electronic configuration of Cu is $[core]4s^{0.30}3d^{9.34}4p^{0.01}$: 18 core electrons, 9.64 valence electrons (on 4s and 3d atomic orbitals) and 0.01 Rydberg electrons, mainly on the 4p orbital. This gives the total of 27.65 electrons, which is consistent with the calculated natural charge (+1.35) on the Cu atom in $[Cu(hipp)_2(Hbim)_2]$. Table 4 collects the calculated natural charges on the atoms. The largest negative charges are located on the carboxylate oxygen atoms O11 and O12 coordinated to copper (−0.824 and −0.844 e, respectively).

The NBO analysis can be used to estimate delocalization of electron density between occupied Lewis-type orbitals and formally unoccupied non-Lewis NBOs (antibonding or Rydberg), which corresponds to a stabilizing donor-acceptor interaction [36]. Second order perturbation theory allows to make conclusions about the strength of these interactions. According to the calculations, four bonds between the copper atom and the donor atoms of the organic ligands can be described as donation of electron density from lone pair orbitals of the oxygen and nitrogen atoms to unoccupied copper atom orbitals. The calculated values of the second-order interaction energy (E^2) between the donor–acceptor orbitals are equal to 11.51, 12.10, 17.79 and 17.75 kcal/mol for LP(2)O11 → LP*(6)Cu, LP(2)O12 → LP*(6)Cu, LP(1)N13 → LP*(6)Cu and LP(1)N14 → LP*(6)Cu, respectively. These values suggest similar strength metal-ligand bonds in complex **1**. The donations of electron density from the donor atoms of the organic ligands to the antibonding orbitals of copper can be described as ligand to metal coordination bonds.

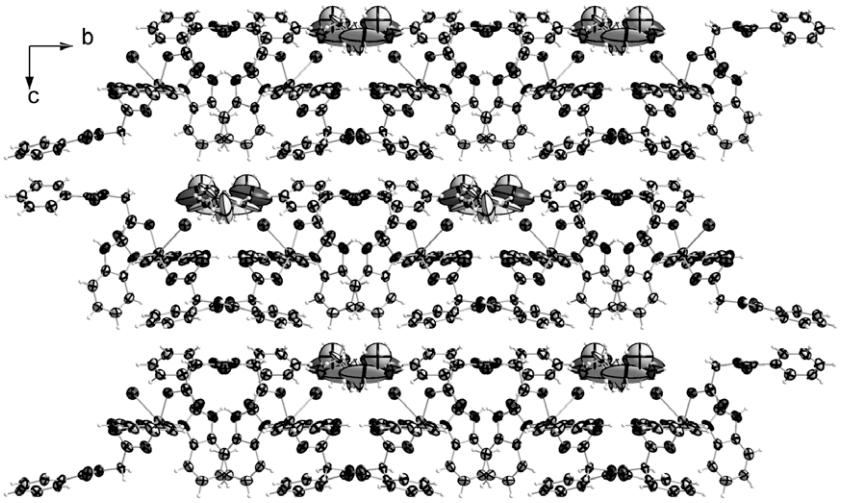

Fig. 2. 2D layers parallel to the *ab* plane of the crystal.

Table 4
Natural charge (e) on selected atoms of $[Cu(hipp)_2(Hbim)_2]$ calculated at the DFT/B3LYP/LanL2DZ level.

Atom	Charge	Atom	Charge
Cu1	1.346	N11	−0.652

N14	−0.662	C41	−0.124
C11	0.803	C13	0.340
O21	−0.714	N23	−0.594

3.3. Spectroscopic and magnetic study

The EPR spectrum of polycrystalline complex **1** exhibits parallel components of copper hyperfine splitting, suggesting that the Cu(II) centers are efficiently isolated by the diamagnetic ligands (Fig. S2. Suppl. Mat.). It unambiguously indicated that the symmetry of the coordination polyhedron is axial, in agreement with the tetrahedrally distorted square geometry shown by the crystal structure studies. The spectrum observed for the similar complex $Cu(hipp)_2im_2$ was not resolved due to a hyperfine interaction and its form was much more complicated and g parameters debatable [14]. The simulation of the experimental EPR spectra of $Cu(hipp)_2(bim)_2$ gave the spin Hamiltonian parameters $g_{II} = 2.27$, $g_{\perp} \sim 2.07$ and $A_{II} = 190 \times 10^{-4}\ cm^{-1}$. These values are usually observed for complexes with two chelating ON ligands (Table S1) or for N4 coordination of four monodentate nitrogen donors coplanar with Cu(II) [54]. It is probable that the relatively small distance of one of copper–oxygen bond, with the length of 1.932 Å as compared to the distance of 1.976 Å for $Cu(hipp)_2(Im)_2$ [14], may be responsible for the stronger ligand field, leading to the observed spin Hamiltonian parameters. The splitting due to the copper hyperfine interaction was also previously observed for the polycrystalline sample of $[Cu(1\text{-benzyl-2-hydroxymethylimidazole})_4](NO_3)_2$ [54], with a Cu–Cu distance of 9.6 Å, close to the distance in **1**, which equals 9.437(4) Å.

The reflectance spectrum of **1** exhibits a characteristic broad asymmetric *d–d* band with a maximum at 16100 cm^{-1} and a poorly marked shoulder at *ca* 11500 cm^{-1} (Fig. 3S, Suppl. Mat.). The absorbance spectrum in propanol (Fig. 3) shows a slight blue shift in energy. The bands in the higher energy region over 25000 cm^{-1} are assigned as carboxylate-to-copper ligand-to-metal charge transfer bands (LMCT) and to $\pi \rightarrow \pi^*$ intraligands transitions.

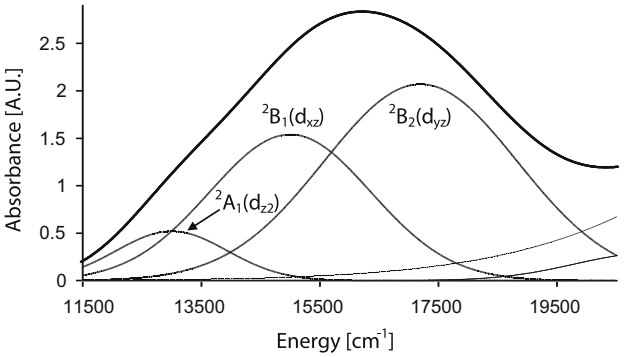

Fig. 3. The NIR–Vis–UV electronic absorption spectrum (in propanol) of $[Cu(hipp)_2(bim)_2]\cdot PrOH\cdot 0.25H_2O$ and Gaussian deconvolution.

For a tetrahedrally distorted square planar CuX_4 configuration, the unpaired electron occupies the $d_{x^2-y^2}$ orbital (a_1 representation of C_{2v} point group), whereas d_{xz} (b_1) and d_{yz} (b_2) are lowest in energy. Three electric dipole transitions, d_{z^2} (a_1) → $d_{x^2-y^2}$, d_{xz} (b_1) → $d_{x^2-y^2}$ and d_{yz} (b_2) → $d_{x^2-y^2}$, are spin-allowed while the d_{xy} (a_2) → $d_{x^2-y^2}$ transition is forbidden.

Analysis of polarized crystal spectra and angular overlap model calculations gave the orbital energy order: $d_{x^2-y^2} > d_{xy} > d_{z^2} > d_{yz} > d_{xz}$, according to [55,56]. Thus, the asymmetric absorption band in solution was considered as the envelope of three spin-allowed transitions. The individual transfers were distinguished from the absorption shape using Gaussian analysis, assuming a maximum of three components. The bands obtained from the curve fitting at 13000, 15000 and 17200 cm^{-1} (Fig. S4, Supplementary material) were assigned to the three spin-allowed transitions, $^2A_1(d_{x^2-y^2}) \rightarrow {}^2A_1(d_{z^2})$, $^2B_1(d_{xz})$ and $^2B_2(d_{yz})$, respectively.

The ligand field energy levels scheme derived from the NIR–Vis–UV spectra are consistent with EPR results. In C_{2v} rhombic symmetry, the *g*-values for the copper(II) ion with the $^2A_1(d_{x^2-y^2})$ ground level are given by [57,58]:

$$g_x - 2.0023 = -2k_x^2\lambda/E_{yz}, \quad (1)$$

$$g_y - 2.0023 = -2k_y^2\lambda/E_{xz}, \quad (2)$$

$$g_z - 2.0023 = -2k_z^2\lambda/E_{xy}, \quad (3)$$

where k_x, k_y, k_z are the orbital reduction coefficients, λ is the spin-orbit constant ($-830\ cm^{-1}$ for the copper(II) free ion), and $E_{yz} = E(^2A_1 \leftarrow {}^2B_2)$, $E_{xz} = E(^2A_1 \leftarrow {}^2B_1)$ and $E_{xy} = E(^2A_1 \leftarrow {}^2A_2$, spin-forbidden). With the above-quoted transition energies and $k_x \approx k_y \approx k_z \approx 0.72$ [59] the values of $g_x = 2.052$ and $g_y = 2.060$ are obtained. After inserting the experimental value of $g_z = 2.27$ into Eq. (3), the forbidden $^2A_1 \leftarrow {}^2A_2$ transition may be estimated. The value of $12860\ cm^{-1}$ situates the d_{xy} orbital below the d_z^2 orbital.

The magnetic susceptibility of **1** shows Curie-Weiss behavior in the entire temperature range, with a magnetic moment $\mu = 1.91\ \mu_B$ and Weiss constant $\theta = -0.1$ K, both values being characteristic of mononuclear Cu(II) compounds with extremely weak magnetic exchange interactions. The same conclusion may be inferred from the field dependence of the magnetization (Fig. S4. Suppl. Mat). The experimental data are perfectly simulated with the Brillouin function for $S = 1/2$. The best fit g value, equal to 2.126, is almost identical to the average EPR value $g_{av} = 2.13$ [$g_{av}^2 = (g_x^2 + g_y^2 + g_z^2)/3$].

spectrofluorometer (Varian) equipped with a xenon lamp and quartz carrier at room temperature. Thermogravimetric (TG) analysis was performed on a Perkin–Elmer TG-7 analyzer heated from 40 to 700 °C under nitrogen.

2.2. Syntheses of the compounds

2.2.1. Synthesis of $[Cd(L3)_2]\cdot H_2O$ (**1**)

A mixture of $Cd(OOCCH_3)_2\cdot 2H_2O$ (0.30 mmol, 0.080 g), L3 (0.20 mmol, 0.036 g) and NaOH (0.60 mmol, 0.024 g) in H_2O (14 ml) was sealed in a 25 ml Teflon-lined stainless steel container, which was heated at 150 °C for 72 h and then cooled down to room temperature at a rate of 5 °C h^{-1}. Colorless crystals of **1** were collected and washed with distilled water and dried in air to give the product; yield, 35 mg (44% based on Cd(II) salts). Elemental *Anal.* Calc. for $C_{38}H_{32}N_4O_9Cd$ (801.08): C, 56.98; H, 4.03; N, 6.99. Found C, 56.96; H, 4.01; N, 6.97%. IR (KBr pellet, cm^{-1}): 3493 (w), 3072 (w), 1607 (m), 1557 (s), 1474 (w), 1435 (m), 1403 (m), 1371 (s), 1327 (m), 1154 (s), 1043 (m), 851 (w), 783 (s), 704 (m), 642 (w).

2.2.2. Synthesis of $[Zn(L3)_2]$ (**2**)

Similar procedures were performed to obtain colorless crystals of compound **2**, except that $Zn(OOCCH_3)_2\cdot 2H_2O$ (0.30 mmol, 0.066 g) was used instead of $Cd(OOCCH_3)_2\cdot 2H_2O$. Yield, 25 mg (38% based on Zn(II) salts). Elemental *Anal.* Calc. for $C_{38}H_{30}N_4O_8Zn$ (736.03): C, 62.01; H, 4.11; N, 7.61. Found C, 62.04; H, 4.12; N, 7.64%. IR (KBr pellet, cm^{-1}): 3432 (w), 3041 (w), 1605 (m), 1553 (s), 1474 (m), 1440 (m), 1410 (s), 1374 (s), 1319 (m), 1143 (s), 1053 (m), 782 (m), 706 (m), 649 (w).

2.2.3. Synthesis of $[Co(L3)_2]$ (**3**)

Similar procedures were performed to obtain purple crystals of compound **3**, except that $Co(OOCCH_3)_2\cdot 4H_2O$ (0.30 mmol, 0.075 g) was used instead of $Cd(OOCCH_3)_2\cdot 2H_2O$. Yield, 31 mg (41% based on Co(II) salts). Elemental *Anal.* Calc. for $C_{38}H_{30}N_4O_8Co$ (729.59): C, 62.56; H, 4.14; N, 7.68. Found C, 62.53; H, 4.14; N, 7.65%. IR (KBr pellet, cm^{-1}): 3432 (m), 3042 (w), 1609 (m), 1542 (s), 1474 (m), 1415 (s), 1376 (s), 1319 (m), 1293 (w), 1143 (s), 1052 (s), 781 (m), 706 (w).

Scheme 1. Coordination modes of the L3 ligand in compounds **1**–**5**.

*2.2.4. Synthesis of [Ni(L3)$_2$] (**4**)*

Similar procedures were performed to obtain green crystals of compound **4**, except that $NiCl_2{\cdot}6H_2O$ (0.30 mmol, 0.072 g) was used instead of $Cd(OOCCH_3)_2{\cdot}2H_2O$. Yield, 25 mg (35% based on Ni(II) salts). Elemental *Anal.* Calc. for $C_{38}H_{30}N_4O_8Ni$ (729.37): C, 62.58; H, 4.15; N, 7.68. Found C, 62.56; H, 4.16; N, 7.66%. IR (KBr pellet, cm^{-1}): 3432 (m), 3041 (w), 1610 (m), 1535 (s), 1475 (m), 1419 (s), 1376 (s), 1319 (m), 1292 (w), 1143 (s), 1051 (m), 783 (s), 705 (w).

*2.2.5. Synthesis of [Cu$_2$(L3)$_2$]·3H$_2$O (**5**)*

Similar procedures were performed to obtain brown crystals of compound **5**, except that CuI (0.30 mmol, 0.057 g) was used instead of $Cd(OOCCH_3)_2{\cdot}2H_2O$. Yield, 16 mg (28% based on Cu(I) salts). Elemental *Anal.* Calc. (%) for $C_{38}H_{36}N_4O_{11}Cu_2$ (851.79): C, 53.58; H, 4.26; N, 6.58. Found C, 53.55; H, 4.29; N, 6.57%. IR (KBr pellet, cm^{-1}): 3394 (s), 1603 (m), 1540 (s), 1371 (m), 1276 (s), 1115 (w), 1023 (m), 782 (m), 705 (w).

2.3. X-ray crystallography analysis

Data collection of compounds **1**–**5** were performed on a Bruker SMART APEX II CCD diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. All absorption corrections were performed by using the SADABS program. The crystal structure was solved by direct methods and refined with full-matrix least-squares (SHELXTL-97) with atomic coordinates and anisotropic thermal parameters for all nonhydrogen atoms. The hydrogen atoms of aromatic rings were included in the structure factor calculation at idealized positions by using a riding model. The hydrogen atoms from water molecules were directly located from successive Fourier differences syntheses. In compound **5**, the hydrogen atoms of one lattice-water molecules have not been found from Fourier maps due to the high disorder of water molecules. The detailed crystallographic data and structure refinement parameters for compounds **1**–**5** are summarized in Table 1. Selected bond lengths and angles are given in Table 2.

3. Results and discussion

3.1. Description of the structures

*3.1.1. [Cd(L3)$_2$]·H$_2$O (**1**)*

The single-crystal X-ray diffraction analysis reveals that the structure of **1** contains one kind of Cd^{II} atom, two kinds of L3 ligands and one lattice-water molecule in an asymmetric unit. Each Cd^{II} atom is coordinated by four carboxylate oxygen atoms (Cd–O 2.334(2)–2.514(2) Å) of two L3 ligands and three nitrogen atoms (Cd–N 2.354(2)–2.389(2) Å) of three L3 ligands to furnish a pentag-

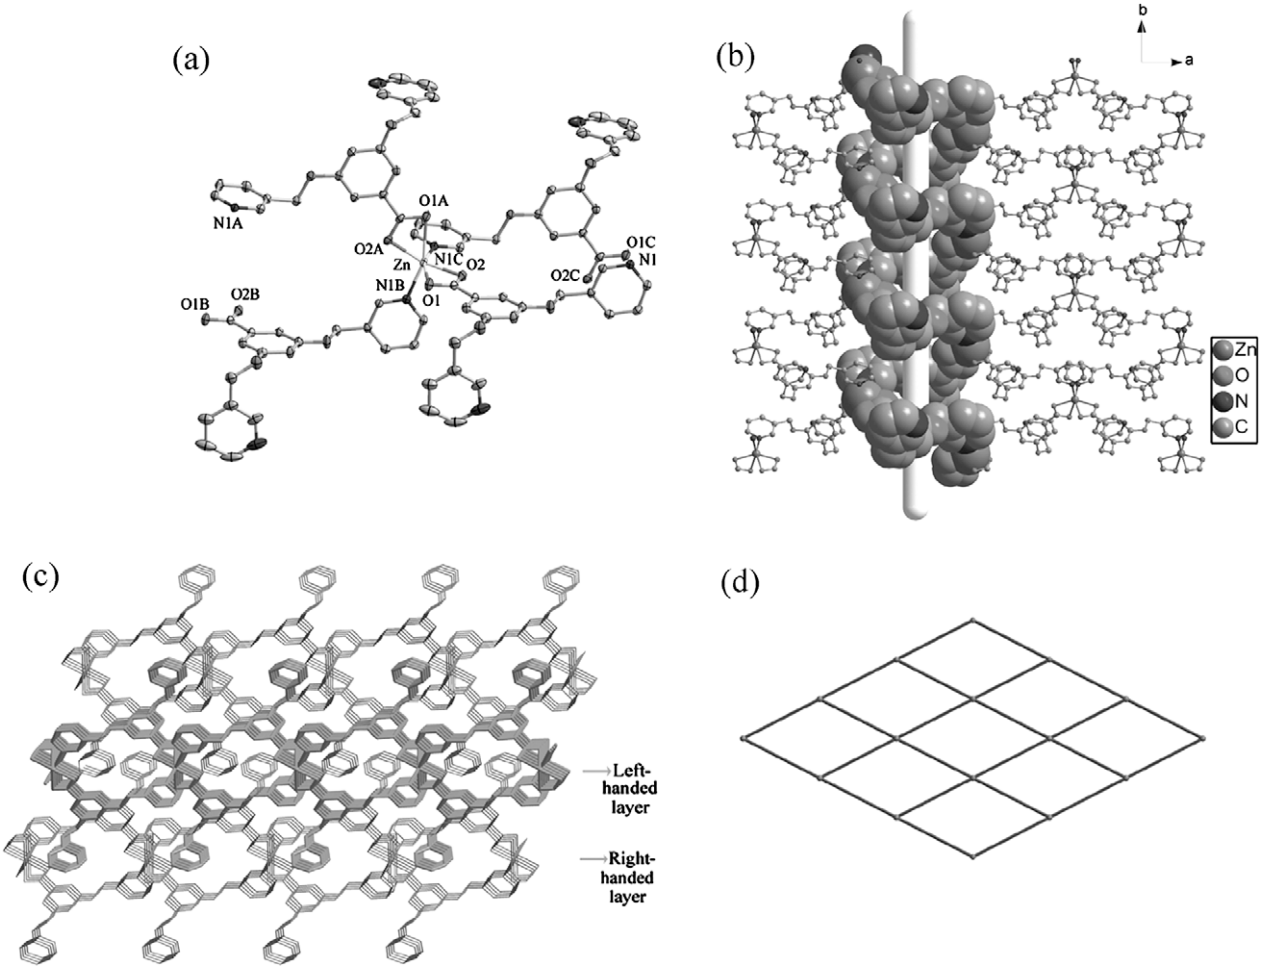

Fig. 2. (a) The coordination environment of Zn^{II} atom in compound **2**. All of the hydrogen atoms were omitted for clarity. (b) Left-handed layer formed by L3 ligands and Zn^{II} atoms in **2** along the *b*-axis. (c) The packing diagram of the 2D polymeric layers in **2**. (d) Schematic view of the uninodal (4,4)-connected net with ($4^4 \cdot 6^2$) Schläfli symbol. (Symmetry transformations used to generate equivalent atoms: A, $-x$, y, $0.5 - z$; B, $-0.5 + x$, $-0.5 + y$, z; C, $0.5 - x$, $-0.5 + y$, $0.5 - z$.)

onal bipyramidal coordination geometry (Fig. 1a). The Cd–O and Cd–N bond distances are all in the normal ranges [44–49].

The coordination modes of L3 ligand in this work are summarized in Scheme 1. In compound **1**, L3 ligands adopt two coordination modes: one bridges two Cd^{II} atoms through one carboxylate group and one pyridyl-N atom, containing an uncoordinated pyridyl-N atom; and the other connects three Cd^{II} atoms through one carboxylate group and two pyridyl-N atoms (Schemes 1a and 1b). As depicted in Fig. 1b, each tri-connected L3 ligand connects with three metal centers to form (6,3)-connected net, which is further linked by bridged L3 ligands to form the final 2D bilayer structure. If the two bridged L3 ligands between two Cd^{II} atoms can be considered as one linker, each Cd^{II} atom can be treated a 4-neccted node, the structure of **1** is a binodal (3,4)-connected network with $(6^3)(6^6)$ topology (Fig. 1c). Moreover, the lattice-water molecules form hydrogen-bonding interactions with carboxylate group and uncoordinated pyridyl-N atom of L3 ligands in the adjacent layers (dOw···O5*i* = 2.951 Å, *i*: $1-x$, $1-y$, $1-z$; dOw-N4*ii* = 2.884 Å, *ii*: x, y, $-1+z$) to extend the 2D layer into a 3D supramolecular net.

3.1.2. $[M(L3)_2]$ (M = Zn, **2**; Co, **3**; Ni, **4**)

Single-crystal X-ray diffraction analyses reveal that compounds **2**–**4** are isostructural, and crystallize in the monoclinic space group *C*2/*c*; thus, only the structure of **2** is representatively described in detail here. The crystal structure of **2** contains one kind of Zn^{II} atom and one kind of L3 ligand in an asymmetric unit. As shown in Fig. 2a, each Zn^{II} atom is coordinated by four carboxylate oxygen atoms (Zn–O 2.053(6)–2.333(2) Å) of two L3 ligands and two nitrogen atoms (Zn–N 2.090(7) Å) of two L3 ligands, showing a distorted octahedral coordination geometry. The Zn–O and Zn–N bond distances are all in the normal ranges [50–53]. It should be noteworthy that the adjacent Zn^{II} atoms are linked to each other through pyridyl-N atom and carboxylate group of L3 ligands (Scheme 1a) to form helical chains running along *b*-axis (Fig. 2b). The adjacent helical chains are also linked by L3 ligands to generate a 2D rhombic structure (9.95×20.54 Å^2) involving 44-membered rings. With in the layer, all Zn–L3 helical chains display the same chirality, while those in adjacent layers display opposite chirality (Fig. 2c). So the overall structure of **2** is a racemic structure. If L3 ligands are considered as linear linkers, Zn^{II} atoms are considered as 4-connected nodes, the structure of **2** can be symbolized as a uninodal (4,4)-connected net with $(4^4 \cdot 6^2)$ Schläfli symbol (Fig. 2d).

3.1.3. $[Cu_2(L3)_2]\cdot 3H_2O$ (**5**)

Single-crystal X-ray diffraction analysis reveals that compound **5** crystallizes in the triclinic space group $P\bar{1}$ and there are one crystallographic independent Cu^{I} atom, one L3 ligand and one and a half lattice-water molecules in an asymmetrical unit. As shown in Fig. 3a, the Cu^{I} atom is in a trigonal coordination geometry with one carboxylate oxygen atom (Cu–O 2.097(2) Å) of one L3 ligand and two nitrogen atoms (Cu–N 1.946(2)–1.954(3) Å) of two L3 ligands. The Cu–O and Cu–N bond distances are all in the normal ranges [54–57].

Different from that of compounds **1** and **2**, each L3 ligand acts as a tri-connector linking three Cu^{I} atoms in compound **5** (Scheme 1c), the carboxylate group connects one Cu^{I} atom through a mono-dentate oxygen atom, two pyridyl-N atoms bind to two Cu^{I} atoms, consequently resulting in the formation of a 2D layer. By treating the Cu^{I} atom as a single node and connecting the nodes according to the connectivity defined by the geometrical centers of the L3 ligand, a distorted 2D bimodal (6,3) network sustained by 3-connected nodes is then yielded, as illustrated in Fig. 3b. Two types of supramolecular interactions, $\pi\cdots\pi$ stacking interactions between phenyl rings of adjacent layer (3.490 Å) and hydrogen-bonding interactions between lattice-water molecules and uncoor-

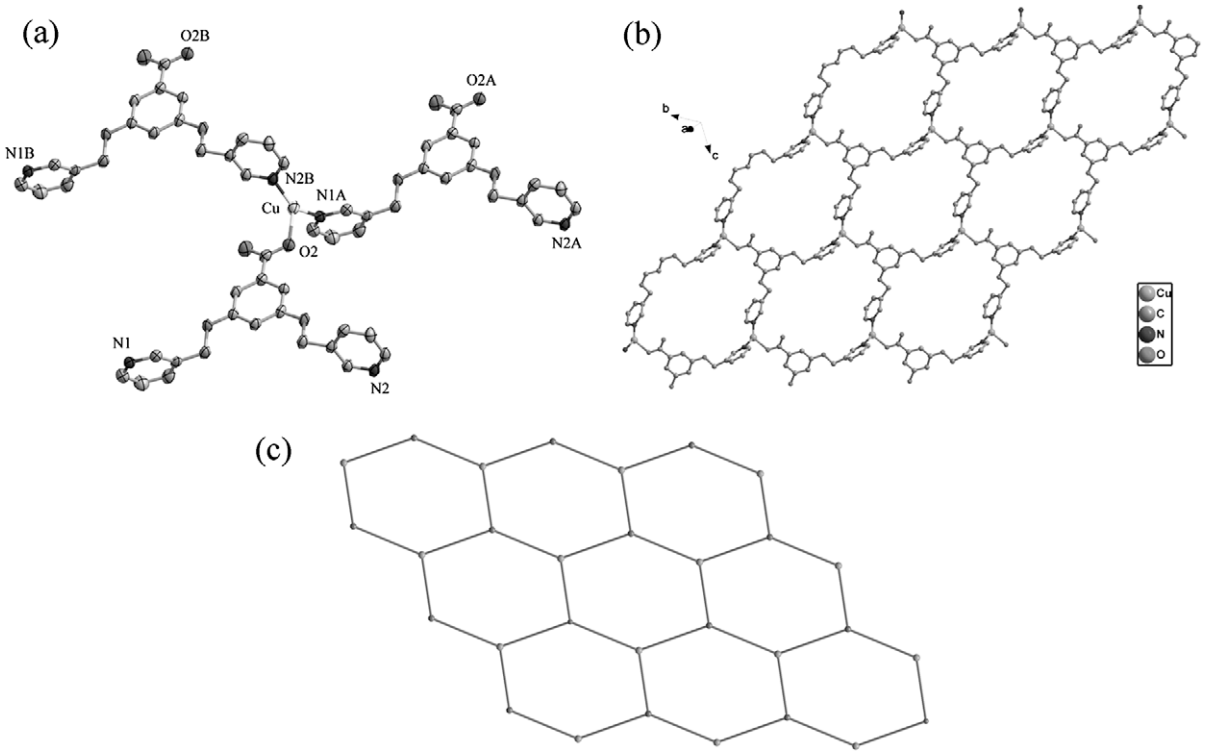

Fig. 3. (a) The coordination environment of Cu^{I} atom in compound **5**. All of the hydrogen atoms and lattice-water molecules were omitted for clarity. (b) 2D layer structure of **5**. (c) Topology of **5** showing the binodal (6,3)-net based on the Cu^{I} atoms and L3 ligands. (Symmetry transformations used to generate equivalent atoms: A, 1+x, 1+y, z; B, x, y, -1+z.)

dinated carboxylate oxygen atoms, contribute to the formation of the 3D supramolecular architecture.

As to the syntheses of compounds **1**–**5**, all the reaction conditions are the same except for the difference of metal ions. From the structural analyses of **1**–**5**, we can see that the increase in coordination number (from 3 to 7) of metal ions induces the progressive increase in complexity of the ultimate net (from (6,3)-net to bilayer (3,4)-net); in other words, the coordination number of metal ions plays a significant role in tuning the connectivity of a specific network [58,59]. On the other hand, flexible L3 ligand has the advantages in that its flexibility and conformational freedom allow it to conform to the coordination environment of transition-metal ions. This is further evidence that the selection of suitable metal ions and organic ligands is a major strategy to synthesize functional materials with useful properties.

3.2. Properties

3.2.1. Luminescent properties

Taking into account of the excellent luminescent properties of Cd(II) and Zn(II), the solid-state luminescent spectra of **1** and **2** have been studied at room temperature. As shown in Fig. 4, compound **1** shows the emission maxima at 453 nm (λ_{ex} = 340 nm), compound **2** shows the emission maxima at 464 nm (λ_{ex} = 349 nm). In order to understand the nature of the emission, we analyzed the photoluminescent property of L3 ligand and found that the strongest emission peak at 392 nm (λ_{ex} = 246 nm). The emission of the ligand may be assigned to $\pi^* \rightarrow n$ and $\pi^* \rightarrow \pi$ transitions of the intraligands. In comparison with the free ligand, the emission of compounds **1** and **2** may be attributed to ligand to metal charge transfer (LMCT) [60–63]. These observations indicate that these condensed polymeric compounds could be potentially used as photoactive materials, since they are thermally stable and insoluble in common polar and nonpolar solvents.

3.2.2. Thermal properties

To study the thermal stability of compounds **1**–**5**, thermogravimetric (TG) analyses were performed on polycrystalline samples under a nitrogen atmosphere with a heating rate of 10 °C min^{-1} (Fig. 5). The TG curve of **1** shows that the first weight loss of 2.46% between 46 and 120 °C corresponding to the loss of the lattice-water molecules (calcd. 2.25%). A total weight loss of 81.39% occurred in the temperature range of 240–560 °C, mainly corresponding to the removal of the L3 ligands (calcd. 81.72%), no weight loss were observed up to 700 °C indicating the complete deposition of the compound with the formation of CdO as the final product. The TG curves of **2**–**4** all show one main weight loss. No weight losses were observed for the compounds up to 280 °C; above 280 °C, significant weight losses occurred and ended at 610 °C, 660 °C, 560 °C, respectively, indicating the removal of the corresponding organic components. The remaining weight may correspond to the final products of ZnO in **2** (obsd. 11.23%, calcd. 11.06%), CoO in **3** (obsd. 11.46%, calcd. 10.27%) and NiO in **4** (obsd. 10.42%, calcd. 10.24%). The TG curve of **5** shows that the first weight loss of 6.08% between 70 °C and 130 °C, corresponding to the loss of the lattice-water molecules (calcd. 6.35%). The framework collapsed in the temperature range of 220–450 °C before the final formation of a metal oxide.

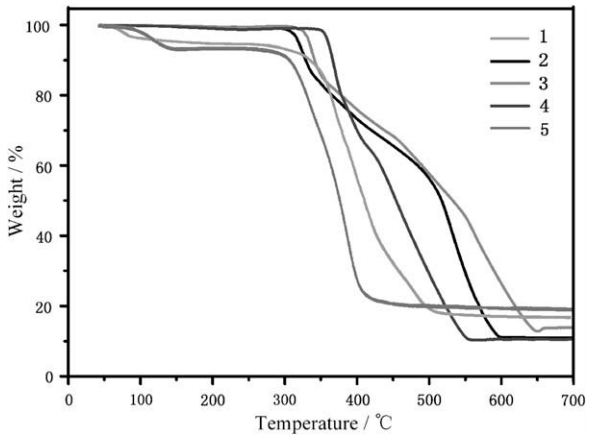

Fig. 5. TG curves of **1**–**5**.

4. Conclusion

In summary, we have synthesized five new coordination polymers based on 3,5-bis(pyridin-3-ylmethoxy)benzoic acid ligand under hydrothermal conditions. The successful syntheses of the five compounds indicate that it is promising to build up unusual architectures via combining transition metals and L3 ligands. Further work on the properties of this new flexible organic ligand and its metal compounds are still explored in our laboratory.

Supplementary data

CCDC 722283, 722284, 722285, 722286, and 722287 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

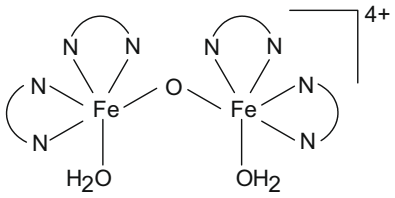

Fig. 1. Schematic drawing of $[Fe_2(\mu\text{-}O)(phen)_4(H_2O)_2]^{4+}$. $\widehat{NN}$ is 1,10-phenanthroline.

of pyruvic acid oxidation by higher valent metal oxidants are rather limited in the literature [40–46].

The title complex is not a powerful oxidant (E^0_{red} for $Fe^{III}{}_2/Fe^{III}Fe^{II}$ = −0.18 V *versus* NHE [33]). An estimated value for the one-electron oxidation potential for pyruvic acid is about −0.10 V *versus* NHE [40]. In spite of the unfavorable potentials, redox between these species occurs at a moderate rate. Thus, among the goals of this study is to examine the factors, including increased basicity of the μ-oxo bridge of the reduced **1**, that could reduce the activation barriers for the overall two electron redox leading to thermodynamically stable products.

2. Experimental

2.1. Materials

The complex salt $[Fe_2O(phen)_4(H_2O)_2](NO_3)_4{\cdot}5H_2O$, (**1**), was prepared from stoichiometric proportions of $Fe(NO_3)_3{\cdot}9H_2O$ and phen in water [21] and identified by elemental (CHN) analysis and optical spectroscopy [21]. The preparation, standardization and storage of pyruvic acid [44] and sodium nitrate [47] have been described previously. 1,10-Phenanthroline (G.R., E. Merck) and D_2O (Aldrich, 99.9 atom% D) were used as received. All other chemicals were of reagent grade. Chromium(II)-scrubbed nitrogen gas was used for deoxygenating the reacting solutions to study the effect of dissolved oxygen on the reaction rate. Freshly boiled doubly distilled water was used throughout. All the reported kinetic and equilibrium data are at (25.0 ± 0.1) °C and at I = 1.0 M maintained by $NaNO_3$ unless mentioned otherwise.

2.2. Physical measurements and kinetics

All absorbances and electronic spectra were recorded with a Shimadzu (1601 PC) spectrophotometer using 1.00 cm quartz cells in the electrically controlled thermostated (25.0 ± 0.1 °C) cell housing (CPS – 240 A). The kinetics was monitored *in situ* in the 'kinetic mode' of the instrument at 510 nm, the visible absorption maximum of the product iron species, $[Fe(phen)_3]^{2+}$ [48,49]. All kinetic runs included excess 1,10-phenanthroline concentration, C_{phen} (=$[Hphen^+]$ + [phen]), in the range of 3–10 mM. Solution pH values (2.58–5.50) were measured with an Orion pH-meter (model 710 A) electrode, the electrode calibration was described earlier [50,51]. For reactions in D_2O, pD was calculated as pD = $(pH)_{measured}$ + 0.40 [52,53] where $(pH)_{measured}$ is the pH-meter reading in D_2O. Total pyruvate concentration, T_R (= [Hpy] + $[Py^-]$), was at least 10 times that of the oxidant. The observed rate constants (first-order) were determined from the least squares fit of absorbance *versus* time data (*vide infra*).

2.3. Stoichiometry and reaction products

The stoichiometry was determined under kinetic conditions ($T_R > [Fe^{III}{}_2]$) by measuring the absorbance of the reduction product, $[Fe(phen)_3]^{2+}$ at 510 nm ($\varepsilon = 1.11 \times 10^4\ M^{-1}\ cm^{-1}$) [48,49] and by detecting CO_2 and acetic acid. The UV–Vis spectra of product solutions indicate quantitative formation (98 ± 3%) of $[Fe(phen)_3]^{2+}$ as the sole iron product. The generation of gaseous CO_2 as oxidation product of pyruvic acids was qualitatively detected by GC analysis as follows [54]. The gaseous product formed during the reaction was collected over a saturated sodium chloride solution and analysed by gas chromatography using a Chemito (India) GCHT 8610 equipped with TCD, a Porapack Q and molecular sieve 13X column. Splitless mode injection of 500 μL of sample was used. The oven temperature, injector and detector temperature were kept at 50 °C, 100 °C and 150 °C, respectively. The carrier hydrogen gas flow was adjusted to 30 mL min^{-1}. Formation of acetic acid from oxidation of pyruvic acid was ensured with the aid of $La(NO_3)_3/I_2$ test [55]. For this purpose, the red coloured $[Fe(phen)_3]^{2+}$ was precipitated from the product mixture as the perchlorate salt by addition of excess $NaClO_4$. $NaNO_3$, phen or $NaClO_4$ did not interfere in the detection of acetic acid as described.

2.4. Equilibrium measurements

The acid dissociation constant, K_a of pyruvic acid was measured using a Titrino Autotitrator (Metrohm, 736 GP) at (25.0 ± 0.1) °C by pH-metric titration of 15.0 mL of 1.0 mM solution of the acid with standard carbonate free NaOH at 1.0 M $NaNO_3$ solution both in H_2O and in 95% D_2O media.

3. Results and discussion

3.1. Stoichiometry and reaction products

Absorbance measurements at 510 nm established the quantitative (twice that of $[Fe^{III}{}_2]$) formation of ferroin, $[Fe(phen)_3]^{2+}$. The presence of acetic acid in the product solution was confirmed by the $La(NO_3)_3/I_2$ test [55]. These observations lead to the stoichiometric relation shown in Eq. (1):

$$\left[Fe^{III}_2(\mu-O)(phen)_4(H_2O)_4\right]^{4+} + CH_3COCO_2H + 2phen \rightarrow 2[Fe(phen)_3]^{2+} + CO_2 + CH_3CO_2H + 2H_2O \quad (1)$$

3.2. Equilibrium measurements

Results of at least 10 independent determinations of pK_a of pyruvic acid yielded values of 2.50 in H_2O and 2.75 in 95% D_2O, respectively, at 25.0 °C and at I = 1.0 M ($NaNO_3$). The associated experimental uncertainty is well within 0.1 pK_a units. These acidity values are in good agreement with literature values [40,45].

3.3. Kinetics

No immediate spectral change was observed on mixing pyruvic acid with **1** over the entire range of experimental pH and T_R. Because of slow self-decomposition of **1** in the presence of excess phen, parallel blanks were performed for each set of conditions and the absorbance (at 510 nm) *versus* time data were adjusted accordingly. After adjustment, plots of $\log_{10}(A_\mu - A_t)$ *versus* time proved to be linear through at least four half-lives ($r^2 \geqslant 0.98$) in both H_2O and in D_2O media and the *pseudo*-first-order rate constants, k_0, were evaluated from the slopes of these linear plots. Averages of k_0 values from at least three independent runs were taken and the average coefficient of variation (CV) for these measurements were well within 3%. Some representative k_0 values are displayed in Table 1.

Table 1
Some representative first-order rate constants for the oxidation of pyruvic acid by the dinuclear iron(III,III) complex[a], T = 25.0 °C, I = 1.0 M ($NaNO_3$).

pH	T_R (M)	C_{phen}, (mM)	10^5 k_0 (s^{-1})	CV in %[b]
2.58	0.02	3	46	2.5
3.05	0.02	3	62	2.6
3.45	0.02	3	53	2.8
3.93	0.02	3	38	2.8
4.42	0.02	3	15	2.7
4.96	0.02	3	4.2	2.9
5.5	0.02	3	0.9	2.6
4.49	0.005	3	3.2	2.8
4.52	0.01	3	5.9	2.5
4.52	0.04	3	24	2.6
4.94	0.02	3	6.5[c]	2.9
4.98	0.02	3	9.0[d]	2.7
3.95	0.02	3	38[e]	2.6
4.01	0.02	6	37	2.6
2.98	0.02	5	62[f]	2.9
4.53	0.01	3	4.6[g]	2.9
4.51	0.02	3	12[h]	2.8

[a] $[Fe^{III}{}_2]$ = 0.05 mM unless otherwise stated.
[b] CV was measured using the relation: CV = sd × 100/x, where sd = standard deviation of the measurements of k_0 and x = average k_0.
[c] At I = 0.50 M ($NaNO_3$).
[d] At I = 0.10 M ($NaNO_3$).
[e] 0.20 mM $[Fe(phen)_3]^{2+}$ added.
[f] $[Fe^{III}{}_2]$ = 0.025 mM.
[g] At I = 1.0 M (0.50 M ($NaNO_3$) + 0.50 M (NaCl)).
[h] At I = 1.0 M (0.50 M ($NaNO_3$) + 0.50 M (NaBr)).

The k_0 values remain unchanged when the reactions were carried out with varied complex concentration (0.025–0.1 mM), in presence of added phen (3.0–10.0 mM) and at different monitoring wavelengths in the region 440–530 nm. The presence of excess phen (pK_a of $Hphen^+$ = 5.12 and of H_2phen^{2+} = 1.9 [56]) and pyruvic acid (pK_a = 2.5) controls any pH drift during the reactions well within 0.05 units. Use of excess phen also ensured quantitative formation of the tris(phenanthroline) product $[Fe(phen)_3]^{3+}$ and $[Fe(phen)_3]^{2+}$ from any transient bis intermediate. The presence or absence of dissolved oxygen did not alter the observed rate significantly (within 5%).

The variation of k_0 with pH in the range 2.58 < pH < 5.50, is shown in Fig. 2. The rate increases at first as pyruvic acid is deprotonated above its pK_a. This substantiates a common observation that deprotonated reductants react faster than their protonated forms [33–37,57]. The reduction in rate beyond pH 3 can be attributed to the conversion of the fully protonated complex, **1** to the less reactive deprotonated **2** and **3** (pK_{a1} and pK_{a2} of **1** are 3.71 ± 0.05 and 5.28 ± 0.10, respectively under our conditions [33]) and this more than compensates for the higher reactivity of Py^-, which is already over 75% of T_R at pH 3. Deprotonated metal

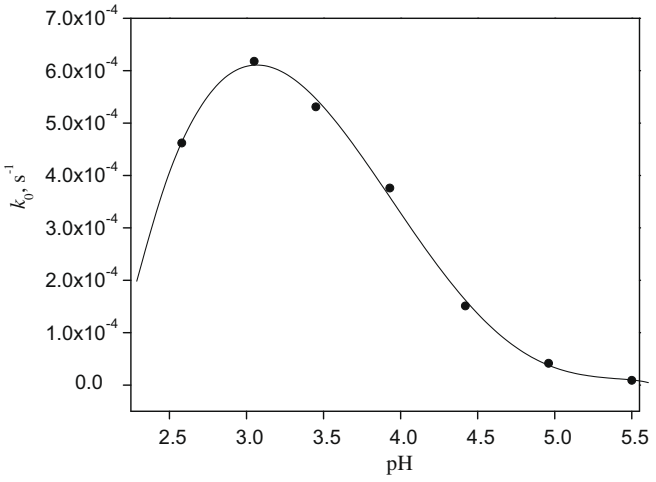

Fig. 2. Plot of k_0 (s^{-1}) *vs.* pH at $[Fe^{III}{}_2]$ = 0.05 mM, T_R = 0.02 M, C_{phen} = 3.0 mM, T = 25.0 °C, I = 1.0 M ($NaNO_3$). The solid line represents the fit of Eq. (9).

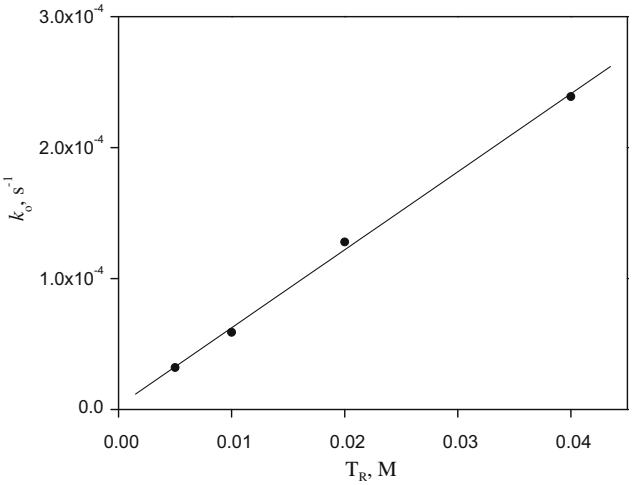

Fig. 3. Plot of k_0 (s^{-1}) *vs.* T_R at $[Fe^{III}{}_2]$ = 0.05 mM, pH 4.5, C_{phen} = 3.0 mM, T = 25.0 °C, I = 1.0 M ($NaNO_3$).

complexes are generally less reactive than their conjugate acids [33,35,37,38,45]. Ionic strength had a noticeable effect on the observed rate – the k_0 values increase at lower ionic strength. This is as expected for reaction between the positively charged metal complex and negatively charged pyruvate ion. [58,59]. The k_0 values were found to increase linearly with T_R at a particular acidity

$$[Fe^{III}{}_2(\mu\text{-}O)(phen)_4(H_2O)_2]^{4+} \underset{pK_{a1} = 3.71}{\overset{K_{a1}}{\rightleftharpoons}} [Fe^{III}{}_2(\mu\text{-}O)(phen)_4(H_2O)(OH)]^{3+} + H^+ \quad (2)$$
(**1**) (**2**)

$$[Fe^{III}{}_2(\mu\text{-}O)(phen)_4(H_2O)(OH)]^{3+} \underset{pK_{a2} = 5.28}{\overset{K_{a2}}{\rightleftharpoons}} [Fe^{III}{}_2(\mu\text{-}O)(phen)_4(OH)_2]^{2+} + H^+ \quad (3)$$
(**2**) (**3**)

$$HPy \overset{K_a}{\rightleftharpoons} H^+ + Py^- \qquad pK_a = 2.5 \quad (4)$$

$$\mathbf{1} + Py^- \xrightarrow{k_1} \text{Products} \quad (5)$$

$$\mathbf{2} + Py^- \xrightarrow{k_2} \text{Products} \quad (6)$$

$$\mathbf{3} + Py^- \xrightarrow{k_3} \text{Products} \quad (7)$$

Scheme 1.

(Fig. 3) suggesting the absence of stoichiometrically significant amounts of adduct formation between the Fe^{III}_2 dimer and Py^- (*vide infra*).

Scheme 1 (Eqs. (2)–(7)) defines a general sequence for the redox reaction where HPy has not been included owing to its low pK_a and (expected) non-reactivity.

Defining the rate as in Eq. (8), Scheme 1 leads to the relation given in Eq. (9):

$$\text{Rate} = -\mathrm{d}[Fe_2^{III,III}]/\mathrm{dt} = k_d[Fe_2^{III,III}] = +1/2\,\mathrm{d}[Fe(phen)_3]/\mathrm{dt} \quad (8)$$

$$k_d[H^+]^2/(T_R\alpha_1\alpha_2) = k_1[H^+]^2 + k_2K_{a1}[H^+] + k_3K_{a1}K_{a2} \quad (9)$$

where k_d is the derived *pseudo*-first-order rate constant, α_1 is the fraction of the total iron complex present as **1** and α_2 is the fraction of total pyruvic acid present as Py^-.

A fit of the observed first-order rate data to Eq. (9) indicates that the third term is negligible; *i.e.* the deprotonated complex, **3**, does not contribute to the reaction under our conditions. The excellent fit (solid line in Fig. 2) also justifies the assumption that HPy is not involved in the redox. Noting that the observed rate is twice that defined by Eq. (8), we may now reformulate the reaction in terms of the formation of the iron(II) product (Scheme 2).

Eq. (9) now reduces to Eq. (12), written in terms of the *pseudo*-first-order observed rate constant, k_0 and the two constants represented in Scheme 2.

$$k_0[H^+]/(T_R\alpha_1\alpha_2) = k_1'[H^+] + k_2'/K_{a1} \quad (12)$$

The best fit of the experimental k_0 values leads to k_1' and k_2' (in $M^{-1}\,s^{-1}$) of 4.7 (±0.2) × 10^{-2} and 3.5 (±0.1) × 10^{-4}, respectively. Since the rate of $[Fe(phen)_3]^{2+}$ formation is twice that of dimer disappearance, these values are twice those of the corresponding parameters of Eq. (9). They are listed in Table 2 for both H_2O and 95% D_2O solutions.

It is well-established that hydration of α-oxo acids and their anions form the respective gem diols [60–69], and the extent of hydration is higher for the free acid forms than their respective anions, the pyruvate anion being the least hydrated. However potential influences that could affect the rate like keto-enol tautomeric equilibria [70,71], dimerisation equilibria [72,73] and polymerization of pyruvate [74,75] are negligible at the low concentrations of pyruvic acid used in this study [60–71].

4. Mechanism

The observed order for the second order rate constants, $k_1 > k_2 \gg k_3$ clearly demonstrates the increased reactivity of protonated oxidants over their conjugate bases. This trend is common for reactions of the title complex, **1**, [31–38] as well as other metal ion complexes [76–80]. While there are examples of hydrated α-oxo-acids with higher reactivity than their (hydrated) conjugate bases [41,42,45,46], a greater reducing power of deprotonated reductants is a common phenomenon [33–37,57] including in pyruvate chemistry [45,81]. Although we were unable to work below the pK_a of pyruvic acid, our observation that pyruvate anion is the more reactive species is consistent with other studies [45,81].

Table 2
Second order rate constants[a] (in $M^{-1}\,s^{-1}$) for the oxidation of pyruvic acid by the dinuclear iron(III,III) complex at T = 25.0 °C, I = 1.0 M ($NaNO_3$), C_{phen} = 3.0 mM.

Reaction path	Rate constant (in H_2O)	Rate constant (in 95% D_2O)
k_1'	(4.7 ± 0.2) × 10^{-2}	(1.8 ± 0.1) × 10^{-2}
k_2'	(3.5 ± 0.1) × 10^{-4}	(1.7 ± 0.1) × 10^{-5}

[a] These values are for Fe(II) formation and are therefore equal to twice the rate constants for dimer disappearance as shown in Eq. (9).

An inner-sphere binding of pyruvic acid with trivalent [82,83] as well as with divalent [84,85] metal centers has been reported to occur with formation constants lying in the range 10^1–10^2. The absence of a more complex [Py^-] term leads to the conclusion that there is no significant pre-equilibrium between the reactants in our system. Hence, we estimate a maximum value for the pre-equilibrium constant (K_i) around 1 M^{-1} holding the inequality $K_i[Py^-] \ll 1$ with no obvious lower limit. Inner-sphere replacement of iron(III)-bound H_2O by Py^-, while weak at best still appears to be involved in the initial process leading to overall redox. The rate retardation in the presence of Cl^- (Table 1) is likely due to a competitive process where non-reducing chloride, present in heavy excess, competes with Py^- for adduct formation. It is well-documented that solutions of $[L_4Cl_2(\mu\text{-}O)Fe^{III}_2]^{4+}$ [85] rapidly aquate to generate $[L_4(H_2O)_2(\mu\text{-}O)Fe^{III}_2]^{4+}$ and also instantaneously produce $[L_4(SCN)_2(\mu\text{-}O)Fe^{III}_2]^{2+}$ upon addition of KSCN (L = 2,2′-bipyridine or phen) [86,87]. These observations clearly demonstrate the labile nature of the monodentate ligands, *viz.* Cl^- and H_2O bound to each d^5 high-spin Fe^{III} center. Although substitution at low-spin d^5 iron(III) is slow, d^5 high-spin species are labile to substitution [88]. Thus the formation of a weak oxidant–pyruvate complex by the substitution of labile H_2O molecules prior to electron transfer is a distinct possibility.

The much lower reactivity of the deprotonated complexes **2** and (apparently non-reactive) **3** seems justified for several reasons. Inner-sphere adduct formation, prior to electron transfer, is less favorable for **2** than that for **1** due to decreased number of water molecules present (one *versus* two). Not only should **1** form an adduct more easily, but it should also dominate kinetically since the iron centers in **1** are the most electron deficient due to the charge effects and back-donation from the π electrons of the hydroxide ligands in **2**. It has been noted that in most redox systems involving cationic complexes protonation of the oxidant increases the reactivity [31–38,76–80]. The presence of $Fe^{III} \leftarrow OH$ π-bonding also reduces lability, thus inhibiting metal–pyruvate interaction. Although π interactions cause an increase in water exchange rate for the high-spin d^5 Fe(III) center of $[Fe(H_2O)_5(OH)]^{2+}$ ($1.2 \times 10^5\ s^{-1}$) over $[Fe(H_2O)_6]^{3+}$ ($1.6 \times 10^2\ s^{-1}$) [88], this is a *trans*-effect and cannot apply to the first step of the present system since there are no labile ligands *trans* to the hydroxide. The absence of any labile water in **3** would further inhibit ligand replacement, thus adding credence to the postulation of an inner-sphere mechanism with pre-equilibrium adduct formation between the diiron(III,III) complex and pyruvate.

The overall two electron redox is expected to occur in steps where the initial one-electron transfer (Eq. (12)) is proposed to be the rate-determining step and the subsequent steps are kinetically silent.

$$1/2\ \mathbf{1} + 1/2\ Py^- \xrightarrow{k_1'} [Fe(phen)_3]^{2+} + \text{oxidation products} \quad (10)$$

$$1/2\ \mathbf{2} + 1/2\ Py^- \xrightarrow{k_2'} [Fe(phen)_3]^{2+} + \text{oxidation products} \quad (11)$$

Scheme 2.

$$Fe^{III}—O—Fe^{III} + Py^{-} \underset{slow}{\overset{k}{\rightarrow}} Fe^{III}—O—Fe^{II} + Py^{\cdot} \quad (13)$$

Generation of pyruvate radical during oxidation of pyruvic acid has been reported elsewhere [40,44,45].

The Fe^{III}–O–Fe^{III} linkage in the title oxidant is stable. The $\{Fe_2O\}^{4+}$ core unit gains stability from the super-exchange of the two high-spin d^5 metal centers linked by an oxo-bridge [89,90]. However, after redox, the $\{Fe_2O\}^{3+}$ product would be less strongly bound to the oxygen since antibonding electrons in both oxidation states are directed towards the formal bond axes. This would impart weaker Fe^{III}–O–Fe^{II} and Fe^{II}–O–Fe^{II} bonds, both of which should be rapidly broken by aquation or further (rapid) reaction with the pyruvate radical produced in (13). In fact, the oxo-bridge in the mixed-valent system is persistent only with a limited number of stabilizing ligands [2,91–93]. Thus, we propose that the Fe^{III}–O–Fe^{II} dimer formed in the rate-determining step instantaneously collapses either by aquation to Fe(II) and Fe(III) monomers or by further reduction to Fe(II) monomers. If formed, the iron(III) monomer, $[Fe(phen)_2(H_2O)_2]^{3+}$ is further reduced to iron(II) monomer with complexation by a third phen ligand either before or after reduction [94,95]. The pyruvate radical formed in the rate-determining step (Eq. (13)) could reduce Fe(III) monomers rapidly, or this reduction could involve Py^{-}. In separate experiments, we have verified that $[Fe(phen)_3]^{3+}$ is almost instantaneously reduced to ferroin by pyruvic acid, used in concentrations comparable to that in our study. $[Fe(phen)_2(H_2O)_2]^{3+}$ is expected to react even faster. Moreover, we observed that the reaction studied in 6% (*v*/*v*) acrylonitrile showed polymerization confirming the involvement of radicals in the reaction.

There are reports in the literature where the intermediate mixed valence $Fe^{III,II}{}_2$ form generated by one-electron reduction of $[(trispicMeen)ClFe^{III}OFe^{III}Cl(trispicMeen)]^{2+}$ (trispicMeen = N,N,N′-tris(2-pyridylmethyl)-N′-methylethane-1,2-diamine) and in $[(MeTACN)_2Fe_2(OH)(RCO_2)_2]^{2+}$ (TACN = 1,4,7-triazacyclononane) slowly (within one hour) disproportionate to a mixture of $Fe^{III}{}_2$ and $Fe^{II}{}_2$ forms [96,97]. Also, it was nicely demonstrated that the mixed-valent $Fe^{III,II}{}_2$ (semi-met) produced at the first phase of the overall three-phase reduction of the binuclear iron(III,III) active sites in the octameric metHr from *Themiste zostericola* by several one-equivalent cobalt(II) and chromium(II) reagents disproportionates to $Fe^{III,III}{}_2$ and $Fe^{II,II}{}_2$ within minutes by intramolecular electron transfer [98]. Although we did not observe any deviations from first-order behavior in our experiments, which had half-lives from about 20 min to several hours, we cannot rule out disproportionation of mixed-valent $Fe^{II}Fe^{III}$ intermediates which could be occurring without affecting the kinetic determinations.

The basicity of the oxo-bridge is expected to increase tremendously in the one-electron reduced iron dimer, $\{Fe^{II}–O–Fe^{III}\}^{3+}$, in comparison to the oxo-bridge in $\{Fe^{III}–O–Fe^{III}\}^{4+}$ as the one-unit positive charge reduction favors immediate uptake of a proton from the solvent. Such differences in basicities of the oxo-bridges in di- or multinuclear higher valent Mn complexes are well-established [99,100] and are key feature in redox steps of the Kok cycle in Photosystem II [101,102]. The possibility of protonation of the oxo-bridge in **1** is ruled out under our kinetic conditions as during its synthesis (*vide supra*), pH as low as ~1.9 is inherently maintained. We find that the available evidence on hemerythrin [103,104] argue against protonation of the oxo-bridge in the one-electron reduction of the diferric site in methemerytrin. Protonation of the oxo-bridge after one-electron reduction could reduce thermodynamic and/or kinetic barriers to further reduction [105]. Proton coupled electron transfer is the basic mechanism for the bioenergetic redox conversions in proteins [106–111]. Protonation of $\{Fe_2O\}^{3+}$ (Eq. (13)) thus remains an essential step in the overall reaction; reactions shown in Eqs. (14)–(16) are fast and kinetically silent

$$\{Fe^{II}—O—Fe^{III}\}^{3+} + H^{+} \rightleftharpoons \{Fe^{II}—\underset{H}{O}—Fe^{III}\}^{4+} \quad (14)$$

$$\{Fe^{II}—\underset{H}{O}—Fe^{III}\}^{4+} \overset{red}{\rightarrow} 2Fe^{II} \quad (15)$$

$$Fe^{II} \overset{phen}{\rightarrow} [Fe(phen)_3]^{2+} \quad (16)$$

In order to collect further information on the proposed mechanism involving the possible involvement of proton coupled electron transfer as described in steps (13) and (14), we performed several kinetic runs in aqueous media partially substituted with D_2O and found a detectable lowering in rate. All the calculations in D_2O media were done using $pK_{a1} = 3.92 \pm 0.10$, $pK_{a2} = 5.36 \pm 0.10$, for complex **1** measured in D_2O [33]. Variations in rate resulting from substitution of D_2O for solvent H_2O are expected to be slight for simple electron transfer reactions but substantial rate retardation is expected when such transfer is coupled with the movement of protons that are in equilibrium with solvent protons [77,112]. A plot of k_0 *versus* mole fraction of D_2O for these experiments is linear (Fig. 4, $r > 0.98$). The linearity of the plot is indicative of the transfer of a single proton in the rate-determining step of the redox process [113]. This relationship is mechanistically reminiscent of the results for the deoxygenation process of the oxygen binding to hemerythrin [114]. We are thus able to state that simultaneous electron/proton transfer is a thermodynamic driving force for the title redox. Additionally, exceptional stability of low-spin $[Fe(phen)_3]^{2+}$ formed as the sole iron product in presence of excess phen also encourages the reaction to completion.

The second order rate constants were also determined in 95% D_2O media and compared with those in H_2O (Table 2). The observed difference in kinetic isotope effect is seen to be prominent at higher pH (k_2 path is much more affected than k_1). The hydroxo ligand is much more basic than H_2O and makes the iron centers less electron accepting thus increasing the basicity of the oxo-bridges in the order **3** > **2** > **1**. A similar trend in isotope effect was also observed in the reduction of $[Mn^{IV}_2(\mu\text{-}O)_2(\mu\text{-}MeCO_2)(bipy)_2(H_2O)_2]^{3+}$ ($MeCO_2H$ = acetic acid, bipy = 2,2′-bipyridine) and its hydrolytic derivatives with hydroxylamine [47].

In conclusion, we find substantial differences in the reactivities of **1**, **2** and **3** towards pyruvate. There is no evidence for involvement of fully deprotonated complex, **3**, in the pH range studied.

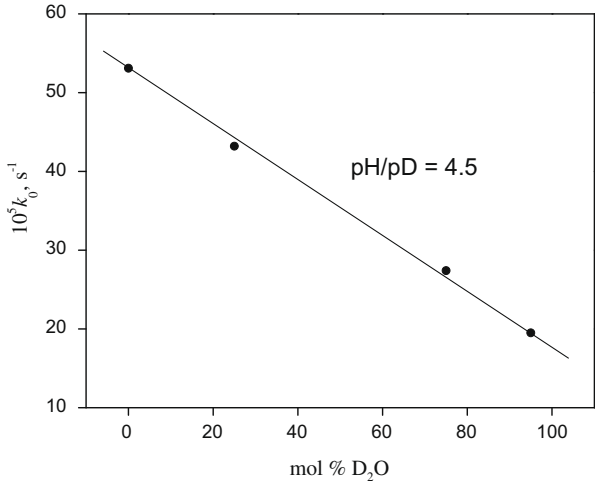

Fig. 4. Effect of mole% D_2O on k_0 (s^{-1}) at [complex] = 0.05 mM, T_R = 0.02 M, C_{phen} = 3.0 mM, T = 25.0 °C, I = 1.0 M ($NaNO_3$).

The kinetic isotope effect is particularly prominent in the k_2 path where the basicity of the oxo-bridge of the one-electron reduced dimer, *viz.* $[(phen)_2(H_2O)Fe^{III}OFe^{II}(phen)_2(OH)]^{2+}$ is higher than that of $[(phen)_2(H_2O)Fe^{III}OFe^{II}(phen)_2(H_2O)]^{3+}$. This clearly demonstrates that oxo-bridge protonation is important in the proposed mechanism.

Only acetic acid and CO_2 were found as oxidation products. Initial decarboxylation to acetaldehyde can be ruled out here because further oxidation would be expected to produce a mixture of formic and acetic acids [115,116]. Furthermore, separate experiments have shown that acetaldehyde reacts too slowly with the title diiron complex to account for the production of acetic acid.

Preface

Dr. Aris Terzis

It is a great pleasure for us to see the completion of this special issue of *Polyhedron* entitled "The Impact of Crystallography on Inorganic Chemistry in Greece". The idea for this issue came from the recognition that inorganic chemistry research in our country has undergone a renaissance over the last three decades or so, for the obvious reason, of course, that this period has seen significant changes to the Greek chemistry community. Three new Chemistry Departments were founded or developed during this period (at the Universities of Patras, Ioannina and Crete), and all three created strong research programs in inorganic chemistry. Inorganic chemistry was also developed in a brilliant way at several institutes in the National Center of Scientific Research (NCSR) 'Demokritos' and the Hellenic Research Foundation, both located in Athens. Many appointments by the Universities of Athens and Thessaloniki in the 1950's resulted in the partial or full retirement of a large number of academics 20–30 years ago. As a result, new generations of people with their own new research ideas and directions were appointed, and they are currently helping to shape the future of inorganic chemistry in Greece. Another important reason for the progress of inorganic chemistry in Greece has been the access of researchers to the X-ray crystallographic facilities of the NCSR 'Demokritos'. We do believe that the heart and soul of inorganic chemistry is making new molecules, new substances. There is no doubt that when a solid compound has to be identified, there is nothing to beat a single-crystal, X-ray crystal structure determination.

The scientist who undoubtedly pioneered single-crystal X-ray crystallography of small molecules in Greece, and subsequently made available to outside groups the crystallographic facilities of his laboratory at the Institute of Materials Chemistry, NCSR 'Demokritos', is Dr. Aris Terzis, who holds a Ph.D. from Princeton, USA, and who has just retired. He has worked in many aspects of X-ray crystallography his whole professional career, which has been characterized by outstanding levels of creativity, enthusiasm, innovation and sheer quality. His impact on the scientific community goes far beyond just his tremendous publication list in top quality, peer-reviewed journals and the fact that his work supported more than 100 PhD theses in the five Greek Chemistry Departments. Aris had the ability to inspire most Greek synthetic inorganic chemists to greater efforts and patience, often giving smart ideas and suggesting new projects to us. In addition to being a brilliant scientist, Aris is also a most friendly and generous spirited person (but very strict with us when he found himself solving structures of starting materials) with whom it was a privilege for us to be associated closely for the last 25 exciting years. His extremely broad education and sound political ideas also make him a fantastic speaker on topics outside science.

One issue of a journal is a rather limited forum, but nevertheless we have attempted as far as possible to have this special issue of *Polyhedron* reflect the great development of crystallography-based inorganic chemistry in Greece and the great respect that Aris commands throughout the scientific community in our country and internationally. This issue certainly contains contributions from many of the scientists with whom Aris has been collaborating, but there are also a few others who gladly and indeed eagerly

doi:10.1016/j.poly.2009.09.013

accepted our invitation to participate as a means to show their respect for the man and his scientific impact. There is no unifying scientific theme to the issue, other than that the papers contain crystallography and are all dedicated to Aris Terzis. On behalf of all the authors, and indeed the Greek scientific community as a whole, we wish him a happy retirement (he currently works as before!), and many more years of success in his future scientific endeavors.

Last, but not least, we would like to express our gratitude to the Americas Editor of *Polyhedron*, Professor George Christou, for encouraging us to realize this idea and for his great help during the organization of the special issue.

2. Experimental

2.1. Materials and instrumentation

All laboratory chemicals were reagent grade and were used without further purification. Solvents for high-performance liquid chromatography (HPLC) were HPLC-grade. They were filtered through membrane filters (0.22 μm, Millipore, Milford, MA) and degassed by a helium flux before and during use.

IR spectra were recorded as KBr pellets on a Perkin–Elmer 1600 FT-IR spectrophotometer in the region 4000–500 cm^{-1}. The NMR spectra were recorded in D_2O and DMSO-d_6, at 25 °C on a Bruker 500 MHz Avance DRX spectrometer using DSS and $(CH_3)_4Si$ as internal references, respectively. Elemental analyses for C, H and N were conducted on a Perkin–Elmer 2400 automatic elemental analyzer. HPLC analysis was performed on a Waters 600 chromatography system coupled to both a Waters 2487 Dual λ Absorbance detector and a Gabi gamma detector from Raytest. Separations were achieved on a Nucleosil C18 (10 μm, 250 mm × 4 mm) column eluted with a binary gradient system at a 1 mL min^{-1} flow rate. Mobile phase A was methanol containing 0.1% trifluoroacetic acid, while mobile phase B was water containing 0.1% trifluoroacetic acid. The elution gradient was 0 to 1 min 100% B (0% A), followed by a linear gradient to 75% A (25% B) in 9 min; this composition was held for another 10 min. After a column wash with 95% A for 5 min, the column was re-equilibrated by applying the initial conditions (100% B) for 15 min prior to the next injection.

*Chloroacetiminoethylether hydrochloride (**1**), 2-(chloromethyl)-imidazoline hydrochloride (**2**)* and the precursor $[Et_4N][ReBr_3(CO)_3]$ were synthesized according to literature methods [8–10]. $Na^{99m}TcO_4$ was obtained in physiological saline as a commercial $^{99}Mo/^{99m}Tc$ generator eluate (Mallinckrodt Medical B.V., The Netherlands). The radioactive precursor *fac*-$[^{99m}Tc(OH_2)_3(CO)_3]^+$ was prepared using a commercially available IsoLink kit (Malinckrodt), according to the manufacturers.

2.2. Synthesis of the ligands

2.2.1. Synthesis of N1-ethyl-2-(chloromethyl)imidazoline hydrochloride (**3**)

Chloroacetiminoethylether hydrochloride (15.8 g, 0.1 mol) is added slowly at 0 °C to *N*-ethyl-ethylenediamine (8.8 g, 0.1 mol) in absolute ethanol (80 mL). After 1 h, abs ethanol saturated with HCl (50 mL, 3.6 g HCl) is added and the mixture is slowly warmed to room temperature. The NH_4Cl is removed by filtration and the filtrate is concentrated to dryness at reduced pressure. Recrystallization of the residue from hot abs ethanol affords **3**, as colorless crystals. Yield 13.4 g (73%). M.p.: 100 °C. *Anal.* Calc. for $C_6H_{11}N_2Cl.HCl$: C, 39.36; H, 6.61; N, 15.30. Found: C, 39.03; H, 6.95; N, 15.04%. ^1H NMR (D_2O, δ): 4.50 (s, 2H, CH_2Cl), 3.95–3.85 (m, 4H, im), 3.45 (q, 2H, CH_2CH_3), 1.15 (t, 3H, CH_2CH_3). ^{13}C NMR (D_2O, δ): 167.15, 51.89, 45.42, 43.82, 35.54, 14.34.

2.2.2. Synthesis of the ligand 4-(imidazolin-2-yl)-3-thiabutanoic acid (4)

2-(Chloromethyl)imidazoline hydrochloride (3.1 g, 0.02 mol) and sodium hydroxide (powder, 4.05 g, 0.04 mol) are added to thioglycolic acid (1.84 g, 0.02 mol) in 30 mL abs ethanol. This suspension is refluxed for 3 h. The mixture is cooled and the precipitated NaCl is removed by filtration. The ligand precipitated as colourless crystals after concentration of the filtrate. Crystals suitable for X-ray were isolated by re-crystallization from ethanol. Yield 1.20 g (28.6%). M.p.: 135–140 °C. *Anal.* Calc. for $C_6H_{10}N_2O_2S.H_2O$: C, 37.49; H, 6.29; N, 14.57. Found: C, 37.18; H, 6.43; N, 14.29%. IR (KBr, cm^{-1}): 3482, 3385, 3115, 2979, 2907, 2705, 1625, 1556, 1386, 1283, 1231. ^1H NMR (D_2O, δ): 3.60 (s, 6H, im, im-CH_2S–), 3.20 (s, 2H, SCH_2COO).

2.2.3. Synthesis of the ligand 4-(N-ethylimidazolin-2-yl)-3-thiabutanoic acid (**5**)

The compound is prepared in a similar procedure to the one described above for **4**, using *N*1-ethyl-2-(chloromethyl)imidazoline hydrochloride (2.76 g, 0.015 mol), thioglycolic acid (1.38 g, 0.015 mol) and sodium hydroxide (powder, 1.2 g, 0.03 mol) in 30 mL abs ethanol. The mixture is filtered and the filtrate is concentrated to dryness to give yellow oil (2.7 g). The oil is dissolved in ethanol, diethylether is added and the flask is placed in the freezer (−22 °C). The white solid formed is collected by filtration. Yield 1.30 g (36.4%). M.p.: 133.6–135 °C. *Anal.* Calc. for $C_8H_{14}N_2O_2S$: C, 47.50; H, 6.98; N, 13.85. Found: C, 47.16; H, 7.15; N, 13.64%. IR (KBr, cm^{-1}): 2986, 2914, 1661(sh), 1600(br), 1381, 1296, 1233. ^1H NMR (D_2O, δ): 3.95–3.85 (m, 4H, im), 3.65 (s, 2H, im-CH_2S–) 3.50 (q, 2H, CH_2CH_3), 3.28 (s, 2H, SCH_2COO), 1.22 (t, 3H, CH_2CH_3). ^{13}C NMR (D_2O, δ): 178.97 (COO), 168.99, 51.51, 44.96, 43.65, 27.88, 14.31.

2.3. Synthesis of the rhenium complexes 6 and 7

2.3.1. General method

A mixture of the ligand **4** or **5** (0.1 mmol), $[NEt_4]_2[ReBr_3(CO)_3]$ (0.077 g, 0.1 mmol) in acetonitrile (5 mL) and 1 mL 0.1 N NaOH (0.1 mmol) is refluxed for 2 h. Upon standing at room temperature a pale yellowish crystalline product precipitates and is collected by filtration. The product can be re-crystallized from methanol, ethanol and acetonitrile. Crystals suitable for X-ray were isolated by re-crystallization from ethanol.

*Re-Complex **6***: Yield 0.032 g (72.2%). *Anal.* Calc. for $C_9H_9N_2O_5ReS$: C, 24.38; H, 2.05; N, 6.32. Found: C, 24.18; H, 2.25; N, 6.48%. IR (KBr, cm^{-1}): 3218, 3057, 2991, 2023 (s), 1920 (sh, s) and 1903 (br, s), 1634, 1598. ^1H and ^{13}C NMR in Table 1. t_R: 14.9 min.

*Re-Complex **7**:* Yield 0.031 g (65.7%). *Anal.* Calc. for $C_{11}H_{13}N_2O_5ReS$: C, 28.02; H, 2.78; N, 5.94. Found: C, 27.81; H, 2.95; N, 5.68%. IR (KBr, cm^{-1}): 2988, 2916, 2021(s), 1911(s), 1865 (s), 1641, 1626, 1578. ^1H and ^{13}C NMR in Table 1. t_R: 15.8 min.

2.4. Synthesis of ^{99m}Tc-complexes 8 and 9

[^{99m}Tc]-sodium pertechnetate (370–740 MBq, 1 mL) is added to the Isolink kit formulation (Mallinckrodt Medical B.V.) containing sodium tetraborate (2.85 mg), sodium carbonate (7.15 mg), sodium boranocarbonate decahydrate (2.85 mg) and sodium tartrate dihydrate (8.5 mg) and the mixture was incubated at 95 °C for 20 min. After cooling, the pH was adjusted to 8 by addition of 0.1 N HCl and formation of *fac*-$[^{99m}Tc(OH_2)_3(CO)_3]^+$ was checked by HPLC,

Table 1
^1H and ^{13}C NMR chemical shifts for complexes **6** and **7** in DMSO-d_6 at 25 °C. The numbering of the atoms is shown in Figs. 3 and 4.

	6	**7**		**6**	**7**
H-2	3.56, 3.50	3.53	C-1	177.62	177.39
H-3	4.13, 3.99	4.30, 4.19	C-2	35.81	35.95
H-5	3.84, 3.63	3.78, 3.65	C-3	35.11	34.36
H-6	3.87, 3.64	3.85, 3.68	C-4	175.15	174.08
H-7		3.28	C-5	45.85	49.62
H-8		1.09	C-6	56.24	54.47
NH	8.42		C-7		42.00
			C-8		12.82
			CO	196.12	196.13
				195.43	195.41
				194.65	194.68

t_R = 5.5 min. An amount of the *fac*-[^{99m}Tc(OH$_2$)$_3$(CO)$_3$]$^+$ precursor (450 μL) is added to a vial containing an aqueous solution of **4** or **5** (5 μg, 50 μL). The vial is sealed with a rubber stopper and aluminium crimp cap and the solution is incubated at 70 °C for 20 min. After cooling, a sample is analyzed by HPLC and in each case the formation of a single radioactive complex, in more than 95% yield is observed. The retention time of **8** and **9** is 15.3 and 16.2 min, respectively. The identity of the Tc-99m complexes **8** and **9** is established by comparative HPLC studies using as references the well characterized analogous rhenium complexes **6** and **7**, respectively. In order to evaluate the stability of the ^{99m}Tc complexes samples are periodically analyzed by HPLC for a period up to 6 h.

2.5. Single-crystal X-ray crystallography

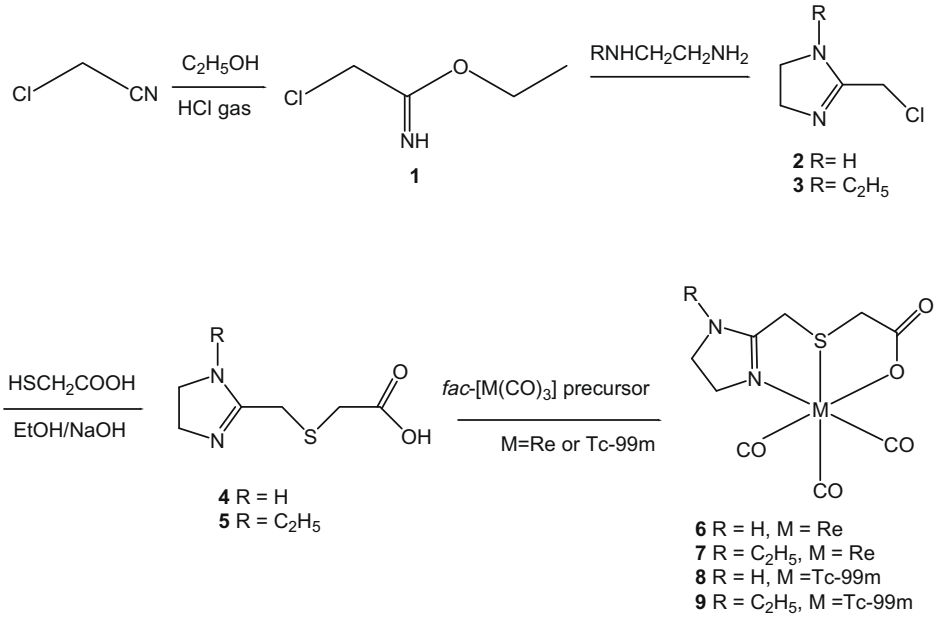
Colorless crystals of **4**·H$_2$O (0.30 × 0.40 × 0.50 mm), **6** (0.20 × 0.20 × 0.40 mm) and **7** (0.10 × 0.20 × 0.60 mm) suitable for X-ray analysis were mounted in air and covered with epoxy glue. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined by using the angular settings of 25 automatically centered reflections in the range 11 < 2θ < 23° and they appear in Table 2. Intensity data were recorded using a θ–2θ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and psi-scan absorption corrections were applied using Crystal Logic software. The structure was solved by direct methods using SHELXS-97 [11] and refined by full-matrix least squares techniques on F^2 using SHELXL-97 [12]. Further crystallographic details for **4**·H$_2$O: 2θ_{max} = 50°, scan speed 4.5°/min, scan range 2.3 + $\alpha_1\alpha_2$ separation, reflections collected/unique/used 1590/1522 [R_{int} = 0.0244]/1522, 157 parameters refined, $[\Delta\rho]_{max}/[\Delta\rho]_{min}$ = 0.262/−0.209 e/Å^3, $[\Delta/\sigma]_{max}$ = 0.000, R_1/wR_2 (for all data) = 0.0334/0.0872. Hydrogen atoms were located by difference maps and were refined isotropically. All non-H atoms were refined anisotropically. Further crystallographic details for **6**: 2θ_{max} = 45.5°, scan speed 2.3°/min, scan range 2.3 + $\alpha_1\alpha_2$ separation, reflections collected/unique/used 3051/2993 [R_{int} = 0.0452]/2993, 325 parameters refined, $[\Delta\rho]_{max}/[\Delta\rho]_{min}$ = 2.649/−3.723 e/Å^3, $[\Delta/\sigma]_{max}$ = 0.000, R_1/wR_2 (for all data) = 0.0620/0.1493. Hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. Further crystallographic details for **7**: 2θ_{max} = 50°, scan speed 3.0°/min, scan range 1.7 + $\alpha_1\alpha_2$ separation, reflections collected/unique/used 2806/2581 [R_{int} = 0.0086]/2581, 222 parameters refined, $[\Delta\rho]_{max}/[\Delta\rho]_{min}$ = 1.249/−0.747 e/Å^3, $[\Delta/\sigma]_{max}$ = 0.001, R_1/wR_2 (for all data) = 0.0277/0.0674. Hydrogen atoms were located by difference maps and were refined isotropically or were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. Plots of the structure were drawn using the Diamond 3 program package [13].

3. Results and discussion

3.1. Synthesis and characterization

The organic compounds **4** and **5** were synthesized by reacting 2-mercaptoacetic acid with the corresponding 2-chloromethylimidazoline **2** or **3** (Scheme 1) and were characterized by elemental analysis, NMR spectroscopy. Ligand **4** was further characterized by X-ray crystallography. These compounds were designed to act as monoanionic tridentate ligands (NSO) with the *fac*-[M(CO)$_3$]$^+$ core (M = Re and Tc).

The synthesis of non-radioactive Re(I)-complexes, **6** and **7**, (Scheme 1) was effected by ligand exchange reaction using the organometallic Re tricarbonyl precursor [NEt$_4$]$_2$[ReBr$_3$(CO)$_3$] and equimolar quantities of **4** and **5**, respectively. HPLC analysis of the reaction mixture showed that in each case only one product is formed with a retention time 14.9 and 15.8 min, respectively. The complexes were isolated as colourless crystals in high yield (70%) and were fully characterized by IR and NMR spectroscopies, elemental analysis and X-ray crystallography. The rhenium complexes are stable in the solid state as well as in solution as shown by HPLC and NMR.



3.2. Description of the structures

The molecular structure of **4** is given in Fig. 1. The compound is present in the crystal in the zwitterionic form with essentially symmetric ionized carboxylate groups and with both nitrogens of the imidazoline bearing protons. In the lattice structure of **4**·H$_2$O there are intermolecular hydrogen bonding interactions which form a 2D network extending parallel to the *bc* plane [N1···O2 (0.5 − *x*, −0.5 − *y*, 1 − *z*) = 2.734 Å, HN1···O2 = 1.899 Å, N1–HN1···O2 = 170.5°; N2···O1 (0.5 − *x*, 0.5 + *y*, 0.5 − *z*) = 2.795 Å, HN2···O1 = 1.956 Å, N2–HN2···O1 = 172.8°; Ow1···O1 (*x*, −*y*, 0.5 + *z*) = 2.854 Å, Hw1A···O1 = 2.131 Å, Ow1–Hw1A···O1 = 151.9°; Ow1···O2 (0.5 − *x*, −0.5 − *y*, 1 − *z*) = 2.841 Å, Hw1B···O2 = 1.992 Å, Ow1-Hw1B···O2 = 162.7°] (Fig. 2).

Scheme 1. Synthetic pathway of **4–9**.

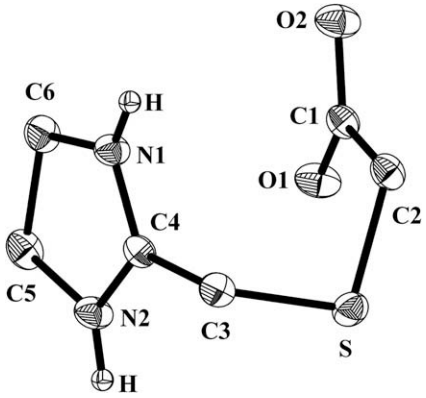

Fig. 1. Labeled plot of **4** with ellipsoids drawn at the 30% probability level. Only the imine hydrogen atoms are shown for clarity purposes.

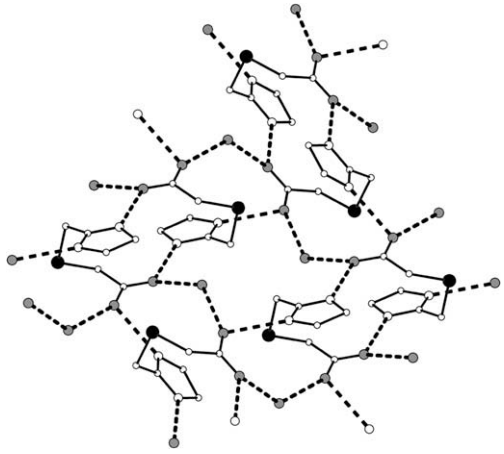

Fig. 2. A part of the 2D structure of **4**·H_2O due to hydrogen bonding interactions.

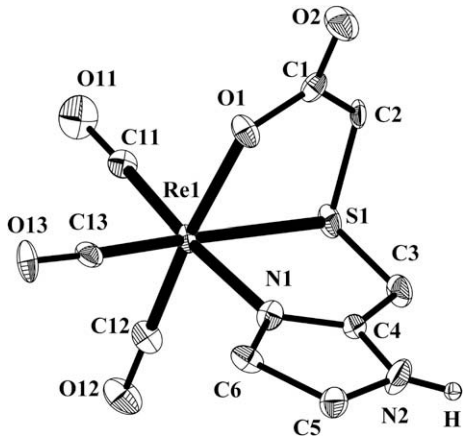

Fig. 3. Labeled plot of **6** with ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity.

The molecular structures of **6** and **7** are given in Figs. 3 and 4, selected bond distances and angles are listed in Tables 3 and 4, respectively. The asymmetric unit of **6** contains two crystallographically independent molecules, thereafter denoted as A and B. The distorted octahedral environment of the Re atom in the structures of **6** and **7** is defined by the three facially bound CO groups and the NSO donor atom set of the tridentate ligand. The Re-carbonyl bond distances (**6A**: 1.865–1.910 Å, **6B**: 1.890–1.911 Å, **7**: 1.903–1.925 Å) are consistent which those found in other Re-tricarbonyl complexes [14–18]. The Re–S, Re–N and Re–O bond distances fall well in the ranges observed in analogous complexes. In the coordination sphere of **6**, the Re–N–C–C–S five-membered ring is planar (largest deviation ~0.08 and ~0.05 Å for **6A** and **6B**, respectively), while the Re–S–C–C–O five-membered ring adopts the envelope configuration with the sulfur atom being out of the best mean plane defined by the remaining four atoms (0.49 and 0.52 Å for **6A** and **6B**, respectively). In the coordination sphere of **7**, the two five-membered rings defined by Re–N–C–C–S and Re–S–C–C–O adopt the envelope configuration with C3 and C2 being 0.37 and 0.30 Å, respectively, out of the best mean plane of their respective four atoms. In the lattice structure of **6**, there are intermolecular hydrogen bonding interactions which form double chains extending parallel to the *a* axis [N2···O22 (−1 + *x*, −1 + *y*, *z*) = 2.781 Å, HN2···O22 = 1.943 Å,

3.3. Synthesis of the ^{99m}Tc complexes

The synthesis of the ^{99m}Tc-complexes **8** and **9** was carried out by ligand substitution reaction employing the tricarbonyl *fac*-$[^{99m}Tc(OH_2)_3(CO)_3]^+$ as precursor. The precursor was prepared by the addition of pertechnetate to a commercially available IsoLink kit that contains sodium boranocarbonate, which acts simultaneously as reductant and "in situ" source of CO [6]. The reaction was monitored by HPLC (Rt of pertechnetate 3.0 min, t_P of precursor 5.5 min under the employed conditions) and was quantitative (>95%).

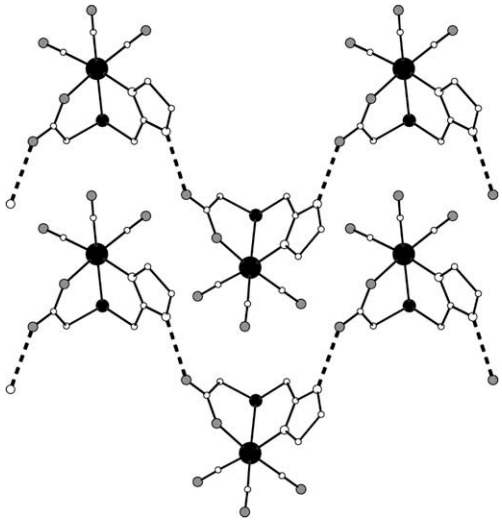

Fig. 5. A part of the 1D structure of **6** due to hydrogen bonding interactions.

Reaction of the ligands **4** and **5** with the precursor *fac*-$[^{99m}Tc(OH_2)_3(CO)_3]^+$ for 20 min at 70 °C resulted in the formation of **8** and **9**, respectively. In each case, the HPLC analysis demonstrated the formation of a single complex with yields greater than 95%, eluting at 15.3 and 16.2 min, respectively. Corroboration of the structure of the Tc-99m complex was effected by comparative HPLC analysis using the analogous non radioactive rhenium complexes **6** and **7,** eluting at 14.9 and 15.8 min, respectively, as references.

Stability studies performed by HPLC, demonstrate that the ^{99m}Tc complexes remained stable for a period of at least 6 h (max time tested). Their stability in the presence of histidine and cysteine at a molar ratio of 1/1000 was also monitored by HPLC and only minor changes were observed in the radiochromatogram indicating the stability of the Tc complexes.

3.4. Spectral properties

The characteristic finding in the infrared spectra of the rhenium complexes **6** and **7** is the presence of three very strong bands in the 2023–1865 cm^{-1} region. These bands are attributed to the symmetric and asymmetric stretching vibration of the C≡O bond and they are characteristic for the *fac*-$[Re(CO)_3]^+$ core [14–18]. In addition, **6** and **7** exhibit two strong broad absorptions at 1634, 1598 cm^{-1} and at 1641, 1578 cm^{-1}, respectively, which correspond to the asymmetrical C═O stretching vibration to the coordinated carboxylate and to the C═N bond.

^{1}H and ^{13}C chemical shift assignments for complexes **6** and **7** were based on the combined analysis of a series of ^{1}H–^{1}H and ^{1}H–^{13}C correlation spectra (Fig. 6) and are reported in Table 1. The numbering of the atoms is according to the crystallographic structures shown in Figs. 3 and 4. As is typically observed with asymmetric complexes, after coordination, the geminal protons on C-2 and C-3, as well as on C-5 and C-6 of the imidazolinyl ring, become diastereotopic, appearing at different chemical shifts in the ^{1}H spectrum (a rare exception is noted in the case of the H-2 protons of complex **7** that coincide and appear as a singlet peak). H-3 protons were distinguished from H-2 based on their NOE

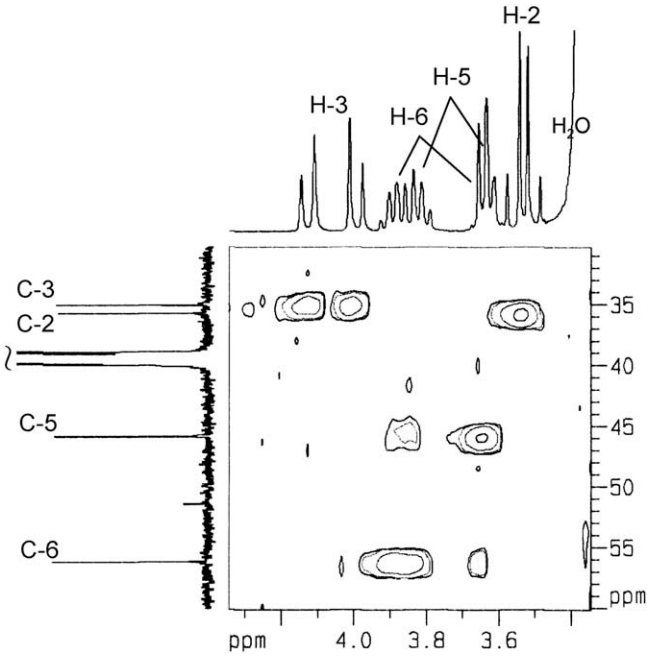

Fig. 6. ^{1}H–^{13}C correlation spectrum for complex **6** in DMSO-d_6 at 25 °C (range δ_H 4.35–3.34, range δ_C 60.1–30.3).

correlation with the imidazolinyl NH proton in **6,** and the *N*-ethyl group protons in **7**. H-5 protons were distinguished from H-6 based on the chemical shift differentiation of their corresponding carbons; specifically, C-6 is shifted downfield compared to C-5 – by appr. 10 ppm in **6** and 5 ppm in **7 –** due to its proximity to the coordinated imidazolinyl nitrogen. In complex **7**, the distinction of H-5 from H-6 is further confirmed by the existence of a long range coupling between C-5 and the H-7 protons of the *N*-ethyl group.

4. Conclusions

In conclusion, two new NSO ligands and their *fac*-$[Re(CO)_3]^+$ complexes have been synthesized and characterized. The ligands, 4-(imidazolin-2-yl)-3-thiabutanoic acid and its *N*-ethyl derivative, bind to the rhenium *fac*-$[M(CO)_3]^+$ core with the imidazolinyl nitrogen, the thioether and the carboxylate oxygen through the resulting in a single stable and neutral complex. The analogous complexes were also prepared at tracer level with the gamma emitting radionuclide ^{99m}Tc. The high affinity of these ligands for the *fac*-$[M(CO)_3]^+$ metal core coupled with their capacity for easy derivatization at the N1-imidazolyl position, indicate that exploitation of this ligand system for development of ^{99m}Tc-radiopharmaceuticals is promising.

Supplementary data

CCDC 721586, 721587 and 721588 contain the supplementary crystallographic data for compound **4** and complexes **6** and **7**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

considerable forethought in the ligands, metals and conditions (reaction ratio, 'pH', solvent, etc.) used for any significant progress to be made. As the field develops, the boundary between "designed" and "serendipitous" assembly is becoming blurred [4].

In the context of the several variations of "serendipitous assembly", we have been exploring "ligand blend" reactions involving carboxylates ($R'CO_2^-$) *and* various 2-pyridyloximates [10] (Scheme 1) *with* or *without* additional inorganic monoanions (Cl^-, Br^-, NO_3^-, N_3^-, SCN^-) as a means to high-nuclearity species. The presence of a deprotonated oxime group leads to a great coordinative flexibility due to the well known ability of the oximate group to bridge two or three metal ions. On the other hand, carboxylates are able to deprotonate the oxime group of (py)C(R)NOH under mild conditions (the use of external hydroxides often perplexes the reactions). Besides their deprotonating ability, the $R'CO_2^-$ ions are flexible ligands, a consequence of their ability to adopt a number of different ligation modes, both terminal and bridging as well as both bidentate and tridentate. Thus, the $(py)C(R)NO^-/R'CO_2^-$ (R = H, Me, Ph, py; R′ = H, Me, Et, Ph) "blends", without (*binary* "blends") or with (ternary "blends") additional inorganic anions have led to a variety of Cr, Mn, Fe, Co, Ni and Cu clusters [10–12] with nuclearities ranging from 3 to 12 and with interesting magnetic properties, including SMM behavior [11h,n].

Scheme 1. General structural formula and abbreviations of simple 2-pyridyl oximes, including phenyl(2-pyridyl)ketone oxime [(py)C(ph)NOH].

Three years ago we decided to begin a program which can be considered as a modification of the above mentioned *binary* "ligand blend" approach. We have been exploring the use of the sulfato ligand, SO_4^{2-}, instead of the carboxylato ligand, $R'CO_2^-$, in the 3d-metal cluster chemistry with 2-pyridyloximate ligands. The sulfate ion [13] is currently a ligand of limited interest. However, metal-sulfato complexes have been studied for their roles in the

Scheme 2. The up to now crystallographically established coordination modes of the sulfato ligand and the Harris notation [20] which describes these modes.

field of porous-framework materials [14], in catalysis [15], in the construction of luminescent molecular materials [16], and in medicinal [17], environmental [18] and bioinorganic [19] chemistry. The great coordinative flexibility of the (py)C(R)NO$^-$ family of ligands, as well as the μ_2, μ_3, μ_4, μ_5, μ_6, μ_8 or μ_{10} potential of SO_4^{2-} (Scheme 2), prompted us to combine the two ligand types to aim for new types of clusters. Our belief was that the simultaneous employment of the two ligand types would give tremendous structurally flexibility in these "blends". The possible advantages of using SO_4^{2-} instead of $R'CO_2^-$ include (i) the possibility of triggering aggregation of preformed smaller cationic species into new, higher-nuclearity products, and (ii) the possible diversion of known reaction systems developed using *mono*anionic carboxylates to new species as a result of the higher charge and higher density/bridging capability of sulfates.

In this work, we report the synthesis and the X-ray structural characterization of the hexanuclear sulfato Ni(II) complex $[Ni_6(SO_4)_2\{(py)C(ph)NO\}_8]\cdot 6DMF$ (**1**·6DMF) which contain the anion of phenyl(2-pyridyl)ketone oxime as an organic ligand. Complex **1**·6DMF has also been studied by variable-temperature dc magnetic susceptibility techniques and IR spectroscopy.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer.

IR spectra (4000–400 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT-spectrometer with samples prepared as KBr pellets. Magnetic susceptibility measurements in the 2–300 K range under a field of 0.3 *T* were performed using a Quantum Design SQUID magnetometer at the Magnetochemistry Service of the University of Barcelona. All measurements were carried out on polycrystalline samples. Data were corrected for diamagnetic contributions calculated from Pascal's constants.

2.2. Compound preparation

2.2.1. $[Ni_6(SO_4)_2\{(py)C(ph)NO\}_8]\cdot 6DMF$ (**1**·6DMF)

DMF (25 mL) was added to a solid mixture containing $NiSO_4\cdot 6H_2O$ (0.158 g, 0.60 mmol), (py)C(ph)NOH (0.119 g, 0.60 mmol) and NaOMe (0.033 g, 0.60 mmol). The mixture was refluxed for 2 h. The resulting red solution was filtered and layered with Et_2O (50 mL). Slow mixing gave X-ray quality, red prismatic crystals of the product. The crystals were collected by filtration, washed with Et_2O (2 × 3 mL) and dried in air; yield 53% (based on the metal). IR (KBr pellet): ν = 3394m, 3060w, 2926w, 1658m, 1594m, 1462s, 1438m, 1384w, 1340w, 1210m, 1124s, 1072m, 1012m, 974w, 786 m, 746m, 704m, 642m, 616m, 474w, 452w. *Anal.* Calc. for $C_{114}H_{114}N_{22}Ni_6O_{22}S_2$ (2560.66): C, 53.47; H, 4.49; N, 12.03. Found: C, 53.61; H, 4.35; N, 11.98%.

2.3. Single-crystal X-ray crystallography

A crystal of **1**·6DMF with approximate dimensions 0.05 × 0.10 × 0.30 mm was mounted in capillary. Diffraction measurements were made on a $P2_1$ Nicolet diffractometer upgraded by CRYSTAL LOGIC using graphite monochromated Cu Kα radiation. Complete crystal data and parameters for data collection and processing are listed in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $22 < 2\theta < 54°$. Intensity data were recorded using the θ–2θ scan method. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and Ψ-scan absorption were applied using the CRYSTAL LOGIC software package.

[a] $R_1 = \Sigma(|F_o| - |F_c|)/\Sigma(|F_o|)$.
[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

The structure was solved by direct methods using SHELXS-86 [21] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [22]. The crystals were of poor quality showing large ω-widths with shoulders on one side, a fact that is also reflected in the quality of the crystallographic data (Table 1), while our repeating efforts to improve the quality of the crystals were unsuccessful. The data were collected in increasing 2θ shells and the data collection was terminated when about half of the collected shell data were unobserved. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms; no H-atoms for the solvent molecules (DMF) were included in the refinement. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Brief synthetic comments

Our general synthetic approach for the isolation of heteroleptic Ni(II) clusters was to treat the metal sulfate with (py)C(ph)NOH and a base in a variety of solvents. The addition of base is necessary for the deprotonation of the organic ligand. Note that reactions in the absence of base lead to complexes $[Ni_2(SO_4)_2\{(py)C(ph)NOH\}_4]$ and $[Ni\{(py)C(ph)NOH\}_3](SO_4)$ [23] that contain the neutral ligands.

Treatment of $NiSO_4\cdot 6H_2O$ with 1 equiv. of (py)C(ph)NOH and 1 equiv. of NaOMe in DMF under reflux gave a red solution from

which the new hexanuclear cluster $[Ni_6(SO_4)_2\{(py)C(ph)NO\}_8]\cdot 6DMF$ (**1**·6DMF) has been isolated. Its formation can be summarized in Eq. (1). The methoxide ions act as proton acceptors to facilitate formation of the $(py)C(ph)NO^-$ ligands. As expected, the nature of the base is not crucial for the identity of the product; we were able to isolate **1** by using plethora of bases such as NEt_3, NMe_4OH, NEt_4OH and $LiOH\cdot H_2O$.

$$6NiSO_4\cdot 6H_2O + 8(py)C(ph)NOH + 8NaOMe + 6DMF \xrightarrow[T]{DMF} \underset{\mathbf{1}\cdot 6DMF}{[Ni_6(SO_4)_2\{(py)C(ph)NO\}_8]\cdot 6DMF} + 4Na_2SO_4 + 8MeOH + 36H_2O \quad (1)$$

It should be mentioned at this point that the chemical and structural identity of the products from the $NiSO_4\cdot 6H_2O/(py)C(ph)NOH/OH^-$ general reaction system depends on the solvent used and the oxime to OH^- ratio. For example, the employment of MeOH leads to the *hydroxo* hexanuclear Ni(II) sulfato clusters $Ni_6(SO_4)_4(OH)\{(py)C(ph)NO\}_3\{(py)C(ph)NOH\}_3(MeOH)_3]$ (**2**) and $[Ni_6(SO_4)_4(OH)\{(py)C(ph)NO\}_3\{(py)C(ph)NOH\}_3(H_2O)_3]$ (**3**) [24], whereas employment of an excess of base in MeOH yields the sulfate-free trinuclear complex $[Ni_3\{(py)C(ph)NO\}_6]$ (**4**) [25]. Complexes **2** and **3** have similar structures which contain the $[Ni_6(\mu_3\text{-}OH)(\mu_3\text{-}SO_4)_3(\mu_3\text{-}ONPh)_3]^{2+}$ core. The core consists of six Ni^{II} ions arranged as two parallel equilateral triangular subunits, one small (Ni···Ni = ~3.3 Å) and the other larger (Ni···Ni = ~6.0 Å).

3.2. Description of structure

A partially labelled plot of the hexanuclear molecule present in **1**·6DMF is shown in Fig. 1. Selected interatomic distances and angles are listed in Table 2.

The structure of **1**·6DMF consists of hexanuclear molecules $[Ni_6(SO_4)_2\{(py)C(ph)NO\}_8]$ (Fig. 1) and solvate DMF molecules; the latter will not be further discussed. The hexanuclear molecule lies on a crystallographic inversion center. The metal ions are held together by two 3.211 (using Harris notation, [20]) and six 2.111 $(py)C(ph)NO^-$ ligands, as well as two 5.2210 SO_4^{2-} ions.

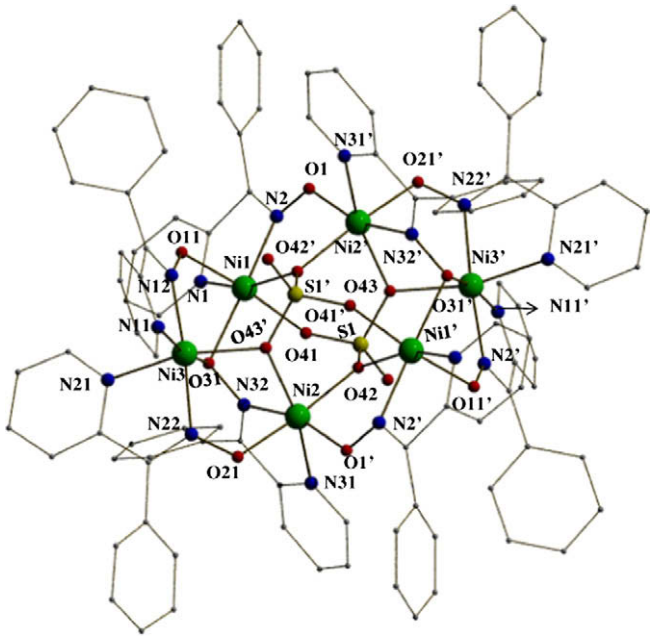

Fig. 1. The structure of **1** in the crystal. Primed and unprimed atoms are related by the crystallographic inversion center.

Symmetry operation used to generate equivalent atoms: $-x, -y, 1-z$.

A distorted octahedral environment is created about each metal center; the chromophores are $Ni(1,2,1',2')(N_{py})(N_{ox})(O_{ox})_2(O_{sulf})_2$ and $Ni(3,3')(N_{py})_2(N_{ox})_2(O_{ox})(O_{sulf})$, where the abbreviations "py", "ox" and "sulf" are for the 2-pyridyl, oximate and sulfato donor atoms, respectively. The average Ni–O_{ox}, Ni–N_{ox} and Ni–N_{py} bond lengths of 2.035(7), 2.048(7) and 2.069(10) Å, respectively, agree well with values expected for high-spin Ni^{II} ions in octahedral environment [11o,p,26,27]. The Ni–O_{sulf} bond lengths are typical [13,24,26,28]. The Ni–O bond distances for the bridging sulfate oxygen atoms are longer than the Ni–O distance exhibited by the terminal oxygen atom from the same sulfato ligand. For example, the Ni(2)–O(43′) and Ni(3)–O(43′) bond distances are 2.119(5) and 2.086(5) Å, respectively, while the Ni(1′)–O(41′) distance is 2.037(6) Å. The bridging Ni–O_{sulf} distances are asymmetric, e.g., the Ni(2)–O(43′) bond length is longer than the Ni(3)–O(43′) distance.

The molecule of **1** contains the $[Ni_6(\mu_5\text{-}SO_4)_2(\mu_2\text{-}ONR)_6(\mu_3\text{-}ONR)_2]$ core, where R^- = –C(py)(ph) (Fig. 2, left). An alternative description of the core (using only the sulfate oxygen atoms) is $[Ni_6(\mu_5\text{-}SO_4)_2]^{8+}$ (Fig. 2, right). The six Ni^{II} atoms have a chair-like conformation (Fig. 2) which is a common topology in organometallic Ni(II) compounds [29], but it is observed only for the second time in non-organometallic Ni(II) clusters [30a]. The most common topologies of the metal ions in Ni_6^{II} complexes are the hexagons, the Chinese-lantern-like objects and the face-shared distorted dicubanes in which one of the corners of each cubane is missing [24,30].

The 5.2210 [20] coordination mode of the SO_4^{2-} (Scheme 2) is very rare in coordination chemistry and novel in Ni(II) chemistry. Hitherto, it has been observed in two polyoxomolybdenate clusters

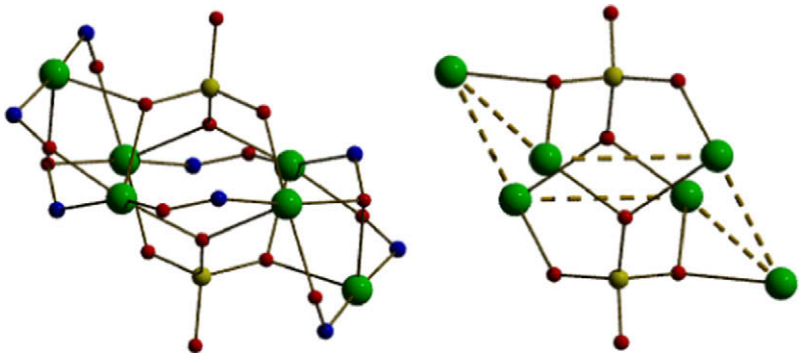

Fig. 2. Left: the $[Ni_6(\mu_5\text{-}SO_4)_2(\mu_2\text{-}ONR)_6(\mu_3\text{-}ONR)_2]$ core of complex **1**, where R^- = −C(py)(ph). Right: the core of **1** using only the sulfate oxygen atoms; the chair-like topology of the Ni^{II} atoms is emphasized with dashed lines.

[31], and in the coordination polymers $[Ag_2(SO_4)(L)]_n$ [32] and $[Zn_2(SO_4)(OH)(L')]_n$ [33], where L = 4,4′-bipyrazine and L' = 1,2,4-triazolato anion. Complex **1** is the third highest-nuclearity nickel(II) sulfato cluster which has been structurally characterized. The other three are the compounds $[Ni_6(SO_4)_4(OH)\{(py)C(Me)NO\}_3\{(py)C(Me)NOH\}_3(MeOH)_2(H_2O)]$, $[Ni_6(SO_4)_4(OH)\{(py)C(ph)NO\}_3\{(py)C(ph)NOH\}_3(MeOH)_3]$ and $[Ni_6(SO_4)_4(OH)\{(py)C(ph)NO\}_3\{(py)C(ph)NOH\}_3(H_2O)_3]$ [24].

Complex **1** joins a small but growing family of structurally characterized metal complexes containing the neutral or anionic forms of phenyl(2-pyridyl)ketone oxime as ligands. Since most of these complexes have been reported only recently, we felt it timely to collect the crystallographically characterized, non-organometallic metal complexes of (py)C(ph)NOH and/or $(py)C(ph)NO^-$ in Table 3, together with the ligands' coordination modes and the cores of the polynuclear complexes for convenient comparison. It should be mentioned at this point that the first structurally characterized complexes of phenyl(2-pyridyl)ketone oxime were the carbonyl compounds $[Os_3(CO)_8\{(py)C(ph)NO\}_2]$, $[Os_3(CO)_8\{(py)C(ph)NO\}\{(py)C(ph)HNH\}]$, $[Os_3H(CO)_9\{(py)C(ph)NO\}]$ and $[Os_3H(CO)_{11}\{(py)C(ph)NO\}]$ which exhibit interesting structural features [34]; these complexes have not been incorporated in Table 3. Inspection of Table 3 clearly shows that: (i) complex **1** is amongst the highest-nuclearity clusters of any metal identified with the $(py)C(ph)NO^-$ ligand; (ii) the 2.111 coordination mode is the most common for the bridging $(py)C(ph)NO^-$ ligands; and (iii) the 3.211 mode of $(py)C(ph)NO^-$ observed in **1** is rare in the complexes containing bridging $(py)C(ph)NO^-$ ligands.

3.3. IR spectra

The medium intensity bands at 1568 and 1094 cm^{-1} in the spectrum of the free ligand (py)C(ph)NOH are assigned to $\nu(C{=}N)_{oxime}$ and $\nu(N{-}O)_{oxime}$, respectively [24,37]. The 1094 cm^{-1} band is shifted to a lower wavenumber (1072 cm^{-1}) in **1**. This shift is attributed to the coordination of the neutral oxime nitrogen [38]. Somewhat to our surprise, the 1568 cm^{-1} band is shifted to a higher wavenumber in the complex (1594 cm^{-1}), overlapping with an aromatic stretch. This shift may be indicative of the oxime nitrogen coordination [38]. Extensive studies on Schiff-base complexes (which also contain a C=N bond) have shown [39] that a change in the s character of the nitrogen lone pair occurs upon coordination such that the s character of nitrogen orbital involved in the C=N bond increases; this change in hybridization produces a greater C=N stretching force constant relative to the free neutral ligand.

The in-plane deformation band of the 2-pyridyl ring of free (py)C(ph)NOH at 622 cm^{-1} shifts upwards (642 cm^{-1}), confirming the involvement of the ring-N atom in coordination [40].

The IR spectrum of the free, *i.e.*, ionic, sulfate (the ion belongs to the T_d point group) consists of two bands at ~1105 and ~615 cm^{-1}, assigned to the $\nu_3(F_2)$ stretching $[\nu_d(SO)]$ and $\nu_4(F_2)$ bending $[\delta_d(O\text{-}SO)]$ modes, respectively [13,41]. The $\nu_1(A_1)$ stretching $[\nu_s(SO)]$ and $\nu_2(E)$ bending $[\delta_d(OSO)]$ fundamentals are not IR-active. The coordination of SO_4^{2-} to metal ions decreases the symmetry of the group and the ν_3 and ν_4 modes are split [13,41]. In the case the SO_4^{2-}-site symmetry is lowered from T_d to C_{3v} (monodentate coor-

[d] Using Harris notation [20].

dination), both ν_1 and ν_2 appear in the IR spectrum with weak to medium intensity, while ν_3 and ν_4 each splits into two bands. In the case the SO_4^{2-}-site symmetry is lowered from T_d to C_{2v} (bidentate chelating or bridging coordination), again both ν_1 and ν_2 appear in the IR spectrum, while ν_3 and ν_4 each splits into three IR-active vibrations [41]. In the case the SO_4^{2-}-site symmetry is lowered to C_1, ν_3 and ν_4 each splits into three IR-active vibrations, ν_1 appears in the IR spectrum, while ν_2 splits into two IR modes [41]. The symmetry of the sulfato groups in **1** is lower than C_i. The bands at 1210, 1124 and 1072 (overlapping with the $N–O_{oxime}$ stretch) cm^{-1} are attributed to the ν_3 modes [41], while the bands at 616, 642 and 704 cm^{-1} are assigned to the ν_4 modes [13,41] with the intermediate wavenumber band being superimposed by a ligand's vibration. The band at 974 cm^{-1} and the two weak features at 474 and 452 cm^{-1} are assigned [13,41] can be assigned to the ν_1 and ν_2 modes, respectively. These spectral features suggest a low symmetry for the sulfato ligand in the complex.

The ν(C=O) vibrational mode of the lattice DMF molecules appears at 1658 cm^{-1} [42].

3.4. Magnetic properties

Variable-temperature dc magnetic susceptibility studies were performed on a polycrystalline sample of compound **1** in an applied magnetic field of 0.3 *T* (3.0 KG) and in the 2.0–300 K range. The data are plotted as $\chi_M T$ versus *T* in Fig. 3. The $\chi_M T$ value at 300 K is 7.19 $cm^3\,mol^{-1}\,K$, close to the expected value of 7.26 $cm^3\,mol^{-1}\,K$ for six non-interacting $S = 1$ centers assuming $g = 2.20$. As *T* is lowered, the $\chi_M T$ product decreases to reach a final value of 1.02 $cm^3\,K\,mol^{-1}$ at 2 K; the decline is sharper below ~100 K. The data indicate an overall antiferromagnetic behavior. The χ_M versus *T* plot does not exhibit a maximum in the temperature range studied. Magnetization experiments performed at 2.0 K show a continuous increase of *M* as the field increases, reaching a non-saturated value equivalent to two electrons with a non-Brillouin shape, suggesting the population of various spin levels close to the ground state spin.

To fit and interpret the magnetic susceptibility data of **1**, it is first necessary to find all possible magnetic pathways in the complicated structural type. Close inspection of the molecular structure reveals that there are five different superexchange pathways and thus five different kinds of *J* values: J_1 is associated (from now onwards the numbering scheme that will be used is the same with that used in the real structure of **1**, see Fig. 1) with the Ni(1)···Ni(3) and Ni(1′)···Ni(3′) interactions, each through one monoatomic bridge from a 3.211 (py)C(ph)NO^- ligand, a triatomic part of one sulfato ligand and one diatomic oximate group from a 2.111 (py)C(ph)NO^- ligand; J_2 is associated with the Ni(2)···Ni(3) and Ni(2′)···Ni(3′) interactions, each through one monoatomic bridge from a sulfate ion and two diatomic oximate bridges coming from a 2.111 and a 3.211 organic ligands; J_3 is associated with the Ni(1)···Ni(2′) and Ni(1′)···Ni(2) interactions, each through one diatomic oximate group from a 2.111 (py)C(ph)NO^- ligand, one monoatomic bridge from a sulfate ion and one triatomic part of the second (symmetry-related) sulfato ligand; J_4 is associated with the Ni(1)···Ni(2) and Ni(1′)···Ni(2′) interactions, each through two triatomic parts of the two sulfato ligands and one diatomic oximate group from a 3.211 (py)C(ph)NO^- ligand; and finally J_5 is associated with the Ni(1)···Ni(3′) and Ni(2)···Ni(3′) (and their symmetry equivalents) interactions, each through the triatomic part of a sulfato ligand. The spin Hamiltonian for such a system is given by Eq. (2).

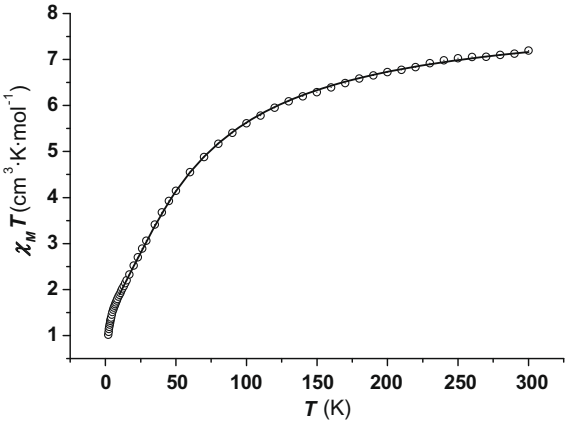
$$\begin{aligned} H = &-J_1(S_1\cdot S_3 + S_{1'}\cdot S_{3'}) - J_2(S_2\cdot S_3 + S_{2'}\cdot S_{3'}) \\ &- J_3(S_1\cdot S_{2'} + S_{1'}\cdot S_2) - J_4(S_1\cdot S_2 + S_{1'}\cdot S_{2'}) \\ &- J_5(S_2\cdot S_{3'} + S_{2'}\cdot S_3 + S_{1'}\cdot S_3 + S_1\cdot S_{3'}) \end{aligned} \quad (2)$$

To avoid a vast parameterization, we decided to attempt to fit the susceptibility data using a simpler 3-*J* model. It is known that the superexchange Ni–O–X–O–Ni interactions mediated by tetrahedral anions with electronegative central atoms, e.g. SO_4^-, ClO_4^-, PO_3^{3-}, are negligible [26]. Another simplification can be made according to the kind and the number of the bridges between the Ni^{II} ions; Ni1 and Ni3 (and their symmetry equivalents) are interacting through three pathways involving one monoatomic, one diatomic and one triatomic bridge. The same number and kind of bridges (with similar Ni–N–O–Ni torsion and Ni–O–Ni bond angles) comprise the interaction pathways between Ni1 and Ni2′ (and their symmetry equivalents). Thus, assuming that $J_5 = 0$ and $J_1 = J_3$, the spin Hamiltonian can be expressed in the form of Eq. (3) and the resulting new, simpler interaction scheme is shown in Scheme 3.

$$\begin{aligned} H = &-J_1(S_1\cdot S_3 + S_1\cdot S_{2'} + S_{1'}\cdot S_{3'} + S_{1'}\cdot S_2) - J_2(S_2\cdot S_3 + S_{2'}\cdot S_{3'}) \\ &- J_3(S_1\cdot S_2 + S_{1'}\cdot S_{2'}) \end{aligned} \quad (3)$$

The fit on the interaction pattern of Scheme 3 was performed by means of the computer program CLUMAG [43]. The best fit parameters were $J_1 = -12.7\ cm^{-1}$, $J_2 = -12.9\ cm^{-1}$, $J_3 = -21.0\ cm^{-1}$, $g = 2.32$ and $R = 1.2\cdot10^{-2}$ [$R = \Sigma((\chi_M)^{calc} - (\chi_M)^{obs})^2/\Sigma((\chi_M)^{obs})^2$].

The fitting results are in accordance with the behavior of the system at low temperatures (Fig. 4). A low *T*, simulation of the $\chi_M T$ response of a hexagonal arrangement of six $S = 1$ metal centers results in a well isolated $S = 0$ ground state ($J_1 = J_2$ and $J_3 = 0$). In contrast, increasing the antiferromagnetic interaction J_3 within the hexagonal array of the spin carriers, the ground state remains



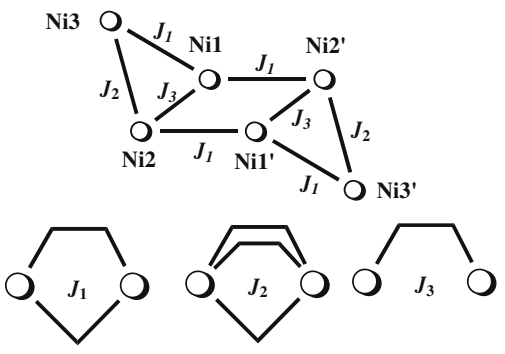


Fig. 3. $\chi_M T$ vs. *T* plot for complex **1**. The solid line represents the best fit to the data as described in the text.

Scheme 3. Top: a 3-*J* exchange-interaction pattern corresponding to the Hamiltonian of Eq. (3) for **1**. Bottom: schematic representation of the bridges involved in each pathway; the monoatomic bridges derive from oximato or sulfato groups.

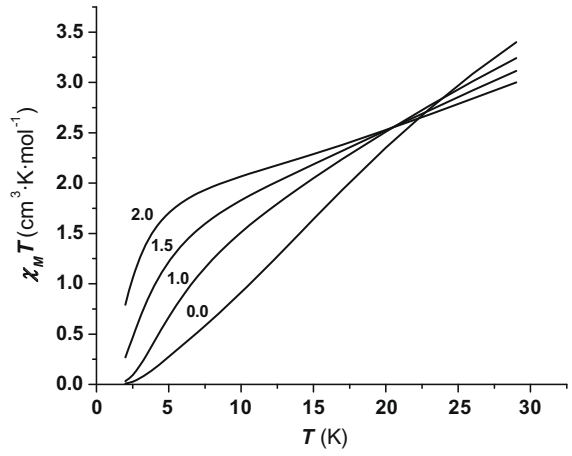

Fig. 4. Low temperature simulation of the response of six $S = 1$ centers arranged in the manner shown in Scheme 3 and assuming $J_1 = J_2$. The four plots correspond to the indicated ratios $J_3/J_{1,2}$.

$S = 0$, but the slope of $\chi_M T$ plot changes and for high $J_3/J_{1,2}$ ratios it tends to values close to 1 $cm^3\,K\,mol^{-1}$ as a result of competitive interactions in the magnetically isosceles triangle Ni1–Ni2–Ni3 (and its equivalent) (Fig. 4), which reduces the gap between the $S = 0$ ground state and the first excited states $S = 1$ and $S = 2$. The vicinity of these S levels leads to the characteristic non-saturated magnetization plot.

The J values are reasonable for $Ni^{II}\cdots Ni^{II}$ magnetic exchange interactions through di-/monoatomic oximato and monoatomic sulfato bridges [24].

4. Conclusions

The present work extends the body of results that emphasize the ability of the sulfate ion to create interesting structural types in 3d-metal chemistry. The study of the coordination chemistry of the *binary* SO_4^{2-}/(py)C(ph)NOH ligand system in the presence of base in DMF has provided access to the novel hexanuclear Ni(II) cluster $[Ni_6(SO_4)_2\{(py)C(ph)NO\}_8]\cdot 6DMF$ (**1**·6DMF). Complex **1** contains the $[Ni_6(\mu_5\text{-}SO_4)_2(\mu_2\text{-}ONR)_6(\mu_3\text{-}ONR)_2]$ core, where $R^- = -C(py)(ph)$, with a chair-like topology of the Ni^{II} ions; it is a valuable addition to the family of hexanuclear Ni^{II} clusters. In compound **1**, the SO_4^{2-} adopts the rare 5.2210 coordination mode. The magnetic properties of **1** have been interpreted using three exchange interactions in a simplified model.

Analogues of **1** with 2-pyridinealdoxime [(py)C(H)NOH], methyl(2-pyridyl)ketone oxime [(py)C(Me)NOH] or di-2-pyridyl ketone oxime [$(py)_2$CNOH] (Scheme 1) are not known, until to date, and it is currently not evident whether the preparation and stability of such hexanuclear complexes are dependent on the particular nature of the R substituent on the oximate carbon.

Scheme 1. Some of the ligands discussed in the text and their coordination modes. The ligand used in this work is the maleamate(−1) ion (HL^-).

Safety note. Perchlorate salts are potentially explosive; such compounds should be synthesized and used in small quantities, and treated with utmost care at all times.

2.2. Compound preparation

2.2.1. $[Cu_2(HL)_2(bppy)_2](ClO_4)_2{\cdot}H_2O$ (**1**·H_2O)

A colorless aqueous solution (1.5 ml) of $LiOH{\cdot}H_2O$ (0.018 g, 0.43 mmol) was added to a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeCN (20 ml) to give a white suspension which was stirred for 10 min to afford a colorless solution. Solid bppy (0.061 g, 0.29 mmol) was then added to give a colorless solution. A blue solution of $Cu(ClO_4)_2{\cdot}6H_2O$ (0.107 g, 0.29 mmol) in MeCN (10 ml) was finally added to obtain a dark green solution. Layering of the final solution with a mixture of Et_2O/*n*-hexane (10 ml, 1:1 v/v) afforded X-ray quality, dark blue prismatic crystals of **1**·H_2O, which were collected by filtration under vacuum, washed with cold MeCN (3 ml) and Et_2O (5 ml), and dried in air. Typical yields were in the 45–50% range. FT-IR for **1**·H_2O (KBr pellet, cm^{-1}): 3420mb, 3100m, 3078m, 3040w, 1688s, 1624vs, 1592s, 1530s, 1500m, 1482vs, 1438w, 1404vs, 1350s, 1314w, 1304sh, 1222vw, 1210vw, 1172m, 1130sh, 1112sh, 1094vs, 1074sh, 1048sh, 1036sh, 974s, 910vw, 806s, 774s, 680vw, 656vw, 636sh, 626s, 598m, 484w. *Anal.* Calc. for $C_{30}H_{28}N_{12}O_{15}Cl_2Cu_2$ (994.62): C, 36.23; H, 2.84; N, 16.90. Found: C, 36.28; H, 2.80; N, 16.78%.

2.2.2. $[Cu(HL)(bppy)(ClO_4)]$ (**2**)

Solid $LiOH{\cdot}H_2O$ (0.018 g, 0.43 mmol) was added to a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeOH (20 ml) to give a white suspension which was stirred for 20 min to finally afford a colorless solution. Solid $Cu(ClO_4)_2{\cdot}6H_2O$ (0.107 g, 0.29 mmol) was added to give a light blue solution. A colorless solution of bppy (0.061 g, 0.29 mmol) in MeOH (10 ml) was then added to obtain a final blue solution. Vapor diffusion of Et_2O into the final solution afforded X-ray quality, light blue needle-like crystals of **2** after 15 days. The crystals were collected by filtration under vacuum, washed with cold MeOH (3 ml) and Et_2O (5 ml), and dried in air. Typical yields were in the 60–65% range. FT-IR for **2** (KBr pellet, cm^{-1}): 3408mb, 3194w, 3156w, 3117m, 2923w, 2854vw, 2736vw, 2313vw, 2021vw, 1806w, 1813vw, 1775w, 1685vs, 1644ssh, 1629vs, 1597vs, 1525vs, 1503s, 1485vs, 1435s, 1405vs, 1355vs, 1321s, 1301vs, 1237m, 1216m, 1177m, 1077vsb, 1053vs, 1035sh, 980s, 934w, 911m, 889w, 875w, 865vw, 817sh, 802s, 782vs, 717w, 684m, 662m, 624s, 599m, 591sh, 554mb, 490w, 471w, 459vw. *Anal.* Calc. for $C_{15}H_{13}N_6O_7ClCu$ (488.30): C, 36.90; H, 2.68; N, 17.21. Found: C, 37.02; H, 2.47; N, 16.99%.

2.2.3. $[Cu_2(L')_2(bppy)_2](ClO_4)_2$ (**3**)

Solid bppy (0.061 g, 0.29 mmol) was dissolved in a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeOH (20 ml). A light blue solution of $Cu(ClO_4)_2{\cdot}6H_2O$ (0.107 g, 0.29 mmol) in the same solvent (10 ml) was then added to obtain a green-turquoise solution. X-ray quality, blue prismatic crystals of **3** were formed in a closed vial after 7 days. The crystals were collected by filtration under vacuum, washed with Et_2O (2 × 2 ml) and dried in air. Typical yields were in the 50–55% range. FT-IR for **3** (KBr pellet, cm^{-1}): 3510w, 3424wb, 3150sh, 3116m, 1720vs, 1660s, 1624vs, 1594s, 1532s, 1502m, 1488vs, 1438m, 1404vs, 1354s, 1320m, 1298m, 1222m, 1178m, 1136sh, 1090vs, 1060sh, 1036w, 988w, 974s, 892w, 820w, 792m, 782sh, 772m, 686m, 644sh, 636sh, 624m, 598m, 588w, 488vw, 456vw. *Anal.* Calc. for $C_{32}H_{28}N_{10}O_{16}Cl_2Cu_2$ (1006.32): C, 38.18; H, 2.80; N, 13.91. Found: C, 38.32; H, 2.77; N, 13.76%.

2.2.4. $[Cu(HL)(terpy)(H_2O)](ClO_4)$ (**4**)

A colorless aqueous solution (1.5 ml) of $LiOH{\cdot}H_2O$ (0.018 g, 0.43 mmol) was added to a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeCN (20 ml) to give a white suspension which was stirred for 10 min to afford a colorless solution. Solid terpy (0.068 g, 0.29 mmol) was added to afford a pale yellow, almost colorless, solution. A light blue solution of $Cu(ClO_4)_2{\cdot}6H_2O$ (0.063 g, 0.17 mmol) in MeCN (5 ml) was then added to obtain a dark green solution. Vapor diffusion of Et_2O into the final solution afforded X-ray quality, blue-marine prismatic crystals of **4** after 2 days. The crystals were collected by filtration under vacuum, washed with cold MeCN (3 ml) and Et_2O (5 ml), and dried in air. Typical yields

were in the 60–65% range. FT-IR for **4** (KBr pellet, cm^{-1}): 3538m, 3453m, 3343m, 3204w, 3100vw, 3070vw, 2924vw, 1732vw, 1674s, 1638s, 1598vs, 1573sh, 1499w, 1478m, 1445s, 1406w, 1370m, 1328sh, 1313m, 1300m, 1257w, 1212w, 1183w, 1167w, 1104vs, 1091vs, 1064vs, 1038sh, 1022m, 1009sh, 976m, 932w, 872vw, 834w, 821w, 811w, 779s, 743vw, 733w, 674w, 652m, 621s, 540wb, 509sh, 483w. *Anal.* Calc. for $C_{19}H_{17}N_4O_8ClCu$ (528.37): C, 43.19; H, 3.24; N, 10.60. Found: C, 43.31; H, 3.17; N, 10.29%.

*2.2.5. $[Cu(L1)_2(NO_3)_2]$ (**5**)*

2.2.5.1. Method A. Solid $Cu(NO_3)_2{\cdot}2.5H_2O$ (0.067 g, 0.29 mmol) was dissolved in a colorless solution of H_2L (0.049 g, 0.43 mmol) in MeOH (20 ml) to afford a light blue solution. A pale yellow solution of tptz (0.047 g, 0.15 mmol) in MeOH (8.5 ml) was then added to obtain a final light green solution. X-ray quality light blue plate-needle-like crystals of **5** were formed by layering of the final solution with Et_2O (10 ml). The crystals were collected by filtration under vacuum, washed with MeOH (3 ml) and Et_2O (5 ml), and dried in air. Typical yields were in the 50–55% range. FT-IR for **5** (KBr pellet, cm^{-1}): 3273mb, 3079sb, 2782vw, 2445vw, 2353w, 2033w, 1995vw, 1750vw, 1681s, 1585m, 1566s, 1499m, 1445s, 1408s, 1384vs, 1324vs, 1310sh, 1280m, 1184m, 1172w, 1129m, 1105w, 1055w, 1045vw, 1033m, 908w, 831m, 808m, 793sh, 757m, 707vw, 679w, 660m, 524w, 458sh, 446w. *Anal.* Calc. for $C_{12}H_{12}N_6O_8Cu$ (431.81): C, 33.38; H, 2.80; N, 19.46. Found: C, 33.51; H, 2.69; N, 19.32%.

2.2.5.2. Method B. Solid $Cu(NO_3)_2{\cdot}2.5H_2O$ (0.067 g, 0.29 mmol) was dissolved in a pale yellow solution of tptz (0.091 g, 0.29 mmol) in MeOH (20 ml) to afford a green solution. X-ray quality light blue plate-needle-like crystals of the product were formed by layering of the final solution with Et_2O (10 ml). The crystals were collected by filtration under vacuum, washed with MeOH (3 ml) and Et_2O (5 ml), and dried in air. Typical yields were in the 60–65% range. The identity of the crystals was confirmed by unit cell determination (a = 7.463(9), b = 13.67(2), c = 8.83(1) Å, β = 104.24(3)°, see Table 1).

2.3. Single-crystal X-ray crystallography

Important crystallographic data for the structures of **1**·H_2O and **3** have been previously reported [4b]. Crystals of **2** (0.08 × 0.18 × 0.48 mm), **4** (0.10 × 0.25 × 0.70 mm) and **5** (0.10 × 0.10 × 0.80 mm) were mounted in capillaries. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined by using the angular settings of 25 automatically centered reflections in the range $11 < 2\theta < 23°$. Intensity data were recorded using a θ–2θ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and ψ-scan absorption corrections (for **4**) were applied using CRYSTAL LOGIC software. Important crystallographic and refinement data are listed in Table 1.

The structures were solved by direct methods using SHELXS-97 [7] and refined by full-matrix least-squares techniques on F^2 with SHELXS-97 [8]. Further crystallographic details for **2**: $2\theta_{max}$ = 50°; reflections collected/unique/used, 3528/3256 [R_{int} = 0.0090]/3256; 323 parameters refined; $(\Delta/\sigma)_{max}$ = 0.008; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 1.030/−0.804 e/Å^3; R/R_w (for all data), 0.0624/0.1470. Hydrogen atoms were located by difference maps and refined isotropically. All non-H atoms were refined anisotropically. Further crystallographic details for **4**: $2\theta_{max}$ = 50°; reflections collected/unique/used, 3812/3583 [R_{int} = 0.0072]/3583; 366 parameters refined; $(\Delta/\sigma)_{max}$ = 0.001; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.562/−0.324 e/Å^3; R/R_w (for all data), 0.0335/0.0855. Hydrogen atoms were located by difference maps and refined isotropically. All non-H atoms were refined anisotropically. Further crystallographic details for **5**: $2\theta_{max}$ = 50°; reflections collected/unique/used, 1649/1527 [R_{int} = 0.0311]/1527; 148 parameters refined; $(\Delta/\sigma)_{max}$ = 0.000; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.777/−0.517 e/Å^3; R/R_w (for all data), 0.0497/0.1323. Hydrogen atoms were located by difference maps and refined isotropically. All non-H atoms were refined anisotropically. Plots of all structures were drawn using the DIAMOND 3 program package [9].

Table 1
Crystallographic data for complexes **2**, **4** and **5**.

	2	**4**	**5**
Formula	$C_{15}H_{13}ClCuN_6O_7$	$C_{19}H_{17}ClCuN_4O_8$	$C_{12}H_{12}CuN_6O_8$

wR_2[a]	0.1384	0.0832	0.1273

[a] $w = 1/[\sigma^2(F_o^2) + (\alpha P)^2 + bP]$ and $P = (\max\ F_o^2, 0) + 2F_c^2)/3$, $R_1 = \Sigma(|F_o| - |F_c|)/\Sigma(|F_o|)$ and $wR_2 = \{\Sigma[w(F_o^2F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$.

3. Results and discussion

3.1. Syntheses

Our previous investigation of the tertiary $Cu^{II}/H_2L/N,N'$-chelates reaction system (N,N'-chelates used were 1,10-phenanthroline [4] and 2,2′-bipyridine [5]) led to interesting results concerning the chemical and structural properties of the compounds isolated. From the chemical point of view, interesting Cu^{II}-assisted/promoted transformations of the H_2L ligand to the maleate(−2) and monomethyl maleate(−1) (Scheme 1) ligands were observed, as a result of the hydrolysis and methanolysis of the primary amide group of H_2L to a carboxylate function and an ester group, respectively. From the structural point of view, five different coordination modes of the HL^- ligand were observed, leading to mononuclear, dinuclear and polymeric complexes; the latter formed via the rarely observed coordination of the amide oxygen. Our efforts involved the investigation of various synthetic parameters that might affect the identity of the products, i.e. the reaction solvent, the presence or absence of externally added hydroxides, the inorganic anion in the copper(II) salts, the stoichiometry of the reactants, the crystallization method, and the nature of the aromatic N,N'-chelating ligands.

We have expanded our research to the tertiary $Cu^{II}/H_2L/N,N',N''$-chelate reaction system, in order to examine to what extent the binding of three coordination sites per Cu^{II} center by the tridentate aromatic heterocycle might affect the identity of the products. We have explored the influence of the reaction solvent, the presence or absence of external OH^-s and the inorganic anion in the copper(II) salt, on the products of the above general reaction system.

Our initial efforts involved the reaction of $Cu(ClO_4)_2{\cdot}6H_2O$ with 1.5 equiv. of H_2L and 1 equiv. of bppy in the presence of 1.5 equiv.

of $LiOH\cdot H_2O$ in $MeCN/H_2O$ (10:1 v/v). Layering of the resultant dark green solution with a mixture of Et_2O/*n*-hexane afforded complex **1**·H_2O. The preparation of **1**·H_2O can be summarized in the balanced equation:

$$2Cu(ClO_4)_2\cdot 6H_2O + 2H_2L + 2bppy + 2LiOH\cdot H_2O \xrightarrow{MeCN/H_2O} \underset{\mathbf{1}\cdot H_2O}{[Cu_2(HL)_2(bppy)_2](ClO_4)_2\cdot H_2O} + 2LiClO_4 + 15H_2O \quad (1)$$

In order to examine the influence of the reaction solvent, we have performed the above reaction in MeOH and isolated complex [Cu(HL)(bppy)(ClO_4)] (**2**) by vapor diffusion of Et_2O into the reaction solution. The preparation of **2** can be summarized in the balanced equation:

$$Cu(ClO_4)_2\cdot 6H_2O + H_2L + bppy + LiOH\cdot H_2O \xrightarrow{MeOH} \underset{\mathbf{2}}{[Cu(HL)(bppy)(ClO_4)]} + LiClO_4 + 8H_2O \quad (2)$$

In a next step, we wondered whether the absence of external OH^-s in MeOH, might lead to interesting maleamate(−1) to monomethyl maleate(−1) ligand transformation, as we have previously observed with *N*,*N*′-chelates [4,5]. Thus, we have performed the reaction of $Cu(ClO_4)_2\cdot 6H_2O$ with 1.5 equiv. of H_2L and 1 equiv. of bppy in MeOH. Upon storage of the reaction mixture at room temperature for *ca.* 7 days, complex $[Cu_2L'_2(bppy)_2](ClO_4)_2$ (**3**) was formed; L'^- is the monomethyl maleate(−1) ligand, see Scheme 1. Without any mechanistic implications, we believe that L'^- was formed in situ via the Cu^{II}-assisted/promoted $HL^- \rightarrow L'^-$ transformation, as we have previously observed in the case of bpy- and phen-containing reaction systems [4,5]. The preparation of **3** can be summarized in the balanced equation:

$$2Cu(ClO_4)_2\cdot 6H_2O + 2H_2L + 2bppy + 2MeOH \xrightarrow{MeOH} \underset{\mathbf{3}}{[Cu_2(L')_2(bppy)_2](ClO_4)_2} + 2NH_4ClO_4 + 12H_2O \quad (3)$$

In a subsequent step, we extended our research to the study of the influence of the aromatic *N*,*N*′,*N*″-chelate by introducing 2,2′;6′,2″-terpyridine (terpy) and 2,4,6-tris(2-pyridyl)-1,3,5-triazine (tptz) in the reaction systems.

The reaction of $Cu(ClO_4)_2\cdot 6H_2O$ with 2.5 equiv. of H_2L and 1 equiv. of terpy in the presence of 2.5 equiv. of $LiOH\cdot H_2O$ in $MeCN/H_2O$ afforded complex [Cu(HL)(terpy)(H_2O)](ClO_4) (**4**) by vapor diffusion of Et_2O into the reaction solution. The preparation of **4** can be summarized in the balanced equation:

$$Cu(ClO_4)_2\cdot 6H_2O + H_2L + terpy + LiOH\cdot H_2O \xrightarrow{MeCN/H_2O} \underset{\mathbf{4}}{[Cu(HL)(terpy)H_2O](ClO_4)} + LiClO_4 + 7H_2O \quad (4)$$

The reaction of $Cu(ClO_4)_2\cdot 6H_2O$ with 1.5 equiv. of H_2L and 1 equiv. of tptz in the presence of 1.5 equiv. of $LiOH\cdot H_2O$ in $MeCN/H_2O$ afforded green microcrystalline solids by layering the dark green reaction solution with Et_2O. Repeating efforts to obtain crystals, suitable for X-ray structure analysis, by varying the reaction solvent (MeOH, MeCN/MeOH), the stoichiometry of the reactants, and the crystallization methods, proved unsuccessful.

In order to isolate a complex analogous to **3** from the Cu^{II}/H_2L/tptz reaction system, we performed the 1:1.5:1 CuX_2/H_2L/tptz ($X = ClO_4^-, NO_3^-$) reactions in MeOH and we isolated green microcrystalline solids. The infrared spectra of all products showed peaks at ~1720 cm^{-1}, which are attributed to the carbonyl stretching vibration of the ester group [10] of the monomethyl maleate(−1), L'^-, ligand. The reaction of 2 equiv. of $Cu(NO_3)_2\cdot 2.5H_2O$ with 1.5 equiv. of H_2L and 1 equiv. of tptz in MeOH afforded complex $[Cu(L1)_2(NO_3)_2]$ (**5**) (L1 = pyridine-2-carboxamide); thus the excess of $Cu(NO_3)_2\cdot 2.5H_2O$ in the reaction mixture has dramatically affected the identity of the product. L1 is formed in situ via the Cu^{II}-assisted hydrolysis [11] of 2,4,6-tris(2-pyridyl)-1,3,5-triazine. Lerner and Lippard reported an analogous hydrolytic reaction which occurs with tptz and the chemically similar 2,4,6-tris(2-pyrimidyl)-1,3,5-triazine (tpmtz) in aqueous solutions of copper(II), which promotes the hydrolysis of these triazines yielding the [bis(arylcarbonyl)amido]copper(II) complexes and free pyridine-2-carboxamide [11b,c]. It has also been pointed out that other metal ions promote the hydrolysis of these 2,4,6-trisubstituted triazines [11b]. It is interesting to note that although simple triazines are known to hydrolyze under mild conditions, 2,4,6-triaryltriazines such as tptz and tpmtz are usually stable towards hydrolysis; concentrated mineral acid and temperatures above 150 °C are required to achieve it. Kinetic and thermodynamic data [11d,e] suggest that the hydrolytic reaction of 2,4,6-triaryltriazines that yields the carboximidate ligand may take place via the nucleophilic attack of OH^- or H_2O to the triazine ring; steric considerations have been also suggested to play a significant role [11c]. Julve and coworkers [11a] have proved that the two main products of the hydrolysis of tptz in aqueous solutions of copper(II) are the bis(pyridylcarbonyl)amido anion [$(NC_5H_4CO)_2N$] and pyridine-2-carboxamide ($NC_5H_4CONH_2$); both present in the crystal structure of complex $[Cu\{(NC_5H_4CO)_2N\}(NC_5H_4CONH_2)]ClO_4\cdot H_2O$. In order to examine to what extent the presence of H_2L might be involved to the tptz → L1 transformation mechanism, we have performed the 1:1 reaction between $Cu(NO_3)_2\cdot 2.5H_2O$ and tptz in MeOH and isolated blue-ocean crystals of **5** by layering the reaction solution with Et_2O/*n*-hexane. The identity of the crystals was confirmed by unit cell determination.

3.2. Description of structures

The molecular structures of the dinuclear complexes **1**·H_2O and **3** have been previously communicated [4b] and will not be discussed in detail. The crystallographically established coordination modes of HL^-, L'^- and L1 in complexes **1**–**5** are shown in Scheme 1. Selected interatomic distances and angles for complexes **2**, **4** and **5** are listed in Tables 2 and 3. The molecular structure of the

cation **1**·H_2O consists of a [Cu_2] unit bridged by two η^2 carboxylato oxygen atoms of HL^- (Fig. 1). Three nitrogen atoms of the bppy and the second carboxylato oxygen atom of HL^- (Cu(1)···O(12) = 2.861(2) Å, shown as dashed line in Fig. 1) complete distorted octahedral coordination geometry around each metal ion. Intermolecular hydrogen bonding interactions between the cations of **1**, the perchlorate anions and the solvate water molecules form chains. Further π–π stacking interactions between the aromatic rings of the bppy belonging to neighboring chains form a 2D structure parallel to the (1 1 1) plane (Fig. 2, Table 4).

The structure of **2** consists of [Cu(HL)(bppy)(ClO_4)] molecules. The Cu^{II} atom is in a distorted octahedral geometry (Fig. 3). The equatorial coordination sites are occupied by the three nitrogen atoms of the bppy ligand and a carboxylate oxygen atom of the HL^- ion. The second carboxylate oxygen atom and a monodentate perchlorate anion occupy the axial, Jahn–Teller distorted coordination sites (Table 2). The molecules of **2** form dimers through two N(6)···O(3) hydrogen bonding interactions; the dimers are further connected to 1D chains extending parallel to the *a*-axis (Fig. 4, Table 4).

The molecular structure of the cation of **3** (Fig. 5) is quite similar to the structure of the cation of **1**·H_2O, the only difference being that **3** contains the monomethyl maleate(−1) ligand, L'^-, instead of HL^-. The coordination modes of HL^- and L'^- in **1**·H_2O and **3**, respectively, are the same, see Scheme 1. The crystal structure of **3** is stabilized by π–π stacking interactions between the aromatic rings of bppy belonging to neighboring cations, thus 1D chains are formed along the *a*-axis (Fig. 6).

The structure of **4** consists of [Cu(HL)(terpy)(H_2O)]$^+$ cations and perchlorate counterions (Fig. 7). The structure of the cation of **4** is similar to the structure of the molecule that is present in **2**. The coordination geometry of the Cu^{II} atom in the cation of **4** is distorted octahedral. The three nitrogen atoms of terpy and a carboxylate oxygen atom of HL^- define the equatorial plane; the second carboxylate oxygen atom of HL^- and an aquo ligand occupy the axial, Jahn–Teller coordination sites. The cations of **4** are held together through intermolecular hydrogen bonding interactions involving the perchlorate anions and form 1D chains (Fig. 8, Table 4).

The structure of **5** (Fig. 9) consists of centrosymmetric mononuclear [$Cu(L1)_2(NO_3)_2$] molecules. Two oxygen atoms from the two terminal monodentate nitrate ions, two pyridine N atoms and two amide oxygen atoms from the two L1 ligands create the coordination environment around the Cu^{II} atom. The metal coordination geometry is described as octahedral. The Jahn–Teller sites are occupied by the oxygen atoms of the nitrate atoms. The mononuclear molecules are hydrogen bonded through the amide group of L1 and the nitrate anions and form a 3D network (Fig. 10, Table 4).

3.3. IR spectra

Dried samples of complexes **1**·H_2O, **2**, **3**, **4** and **5** were characterized by IR spectroscopy. Complexes **1**·H_2O and **4** exhibit a very broad band covering the whole 3450–3150 cm^{-1} range, assignable to ν(OH) vibrations of lattice (**1**·H_2O) or/and coordinated (**4**) H_2O [12]. The broadness and relatively low frequency of this band are both indicative of H-bonding.

In the spectra of **1**·H_2O, **3** and **4** the strong band at 1077–1112 cm^{-1} and the medium-intensity band at ~625 cm^{-1} are attributed to the $\nu_3(F_2)$ [ν_d(ClO)] and $\nu_4(F_2)$ [δ_d(OClO)] modes, respectively, of the uncoordinated T_d ionic perchlorates [13]. The large number of ClO_4^- bands at around 1070 and 640 cm^{-1} in the spectrum of **2** are consistent with the presence of coordinated ClO_4^- groups in this compound [13]. In the spectrum of **5**, the bands at 1445 and 1324 cm^{-1} are assigned [13] to the

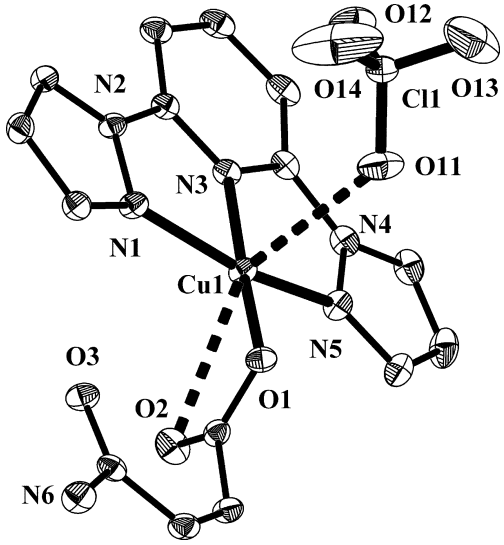

Fig. 3. Partially labelled plot of **2** with ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity.

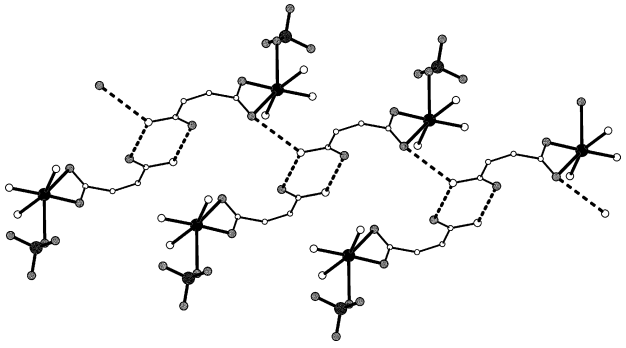

Fig. 4. A part of the 1D structure of **2**. Colour code: Cu, black; O, moderate grey; N, large white; C, small white; Cl, dark grey. H bonds are shown as dashed lines. Only the N atoms of the bppy ligands are shown.

$\nu_5(B_2)[\nu_{as}(NO_2)]$ and $\nu_1(A_1)[\nu_s(NO_2)]$ stretching modes (under C_{2v} symmetry), respectively, of the nitrato ligand; their separation is small ($\sim$120 cm^{-1}) in accordance with the monodentate coordination of the nitrato groups [13].

The very strong band at 1720 cm^{-1} in the spectrum of **3** is assigned to the carbonyl stretching vibration of the ester group [10].

The IR spectra of **1**·H_2O, **2**, **4** and **5** exhibit the typical bands of the primary amide and carboxylate groups [13]. Tentative assignments of few diagnostic bands attributed to these groups are given in Table 5. The assignments have been given in comparison with the data obtained for sodium maleamate, Na(HL), assumed to contain a "free" carboxylate group [14], oxamato(−1) (**II** in Scheme 1) [15], malonamato(−1) (**I** in Scheme 1; $n = 1$) [16] and succinamato(−1) (**I** in Scheme 1; $n = 2$) [17] metal complexes. As a general remark, we must emphasize that some of the vibrational modes shown in Table 5 are strongly coupled and thus the proposed assignments must be regarded as approximate descriptions of

the vibrations [10]. The typical bands of the neutral amide group, i.e., $\nu_{as}(NH_2)$, $\nu_s(NH_2)$, ν(C=O) and ν(CN), in the spectra of **1**·H_2O, **2** and **4** are observed at approximately the same wavenumbers as those of Na(HL), confirming the crystallographically established non-participation of the amide group in coordination. The difference Δ, where $\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)$, for **1**·$H_2O$ (242 cm^{-1}) and **3** (276 cm^{-1}) is large, as expected for the crystallographically confirmed, essentially monoatomic bridging mode of the carboxylate ligation [18]. The difference Δ for **2** (192 cm^{-1}) and **4** (192 cm^{-1}) is more than that of the "free" maleamate(−1) ion (169 cm^{-1})

[d] Overlapping bands.

[19], as expected for the essentially monodentate mode of the carboxylate ligation [14].

4. Concluding comments and perspectives

The use of the HL^-/bppy "ligand blend" in reactions with $Cu(ClO_4)_2{\cdot}6H_2O$ has yielded the new dinuclear and mononuclear complexes **1**·H_2O, **2** and **3**. The chemistry of the $Cu(ClO_4)_2{\cdot}6H_2O$/HL^-/bppy system shows more differences than similarities to that of the corresponding $Cu(ClO_4)_2{\cdot}6H_2O/HL^-$/phen [4a] and $Cu(ClO_4)_2{\cdot}6H_2O/HL^-$/bpy [5a] systems. The binding of an extra Cu^{II} coordination site from bppy, with respect to phen and bpy, did not prove detrimental to the isolation of dinuclear complexes. The Cu^{II}-assisted methanolysis of the primary amide group of HL^- to L'^- has been observed in phen/bpy reaction systems as well as in the bppy-containing systems yielding complex **3**. The main difference is that, in the present case, the isolation of **3** takes place without the formation of an intermediate compound as in the phen/bpy systems. Worth mentioning is also the fact that the Cu^{II}-assisted hydrolysis of the primary amide group of HL^- to a carboxylate, yielding the maleate(−2) ligand, was not observed in the case of the bppy-containing systems. Bppy proved to be a hydrophobic ligand in contrast to bpy. This feature can be justified from the presence of coordinated aquo ligands in the complexes of bpy. On the other hand, terpy which is structurally similar to bppy and not to bpy, afforded complex **4** which contains a coordinated aquo ligand. Complex **4** is similar to complex [19] [Cu(Hsucm)(terpy)(MeOH)](ClO_4) ($Hsucm^-$ is the succinamate ligand, $^-OOC–CH_2CH_2–CONH_2$). The main difference between the two complexes is the terminal monodentate ligand (H_2O versus MeOH) coordinated to the Cu^{II} ion.

The use of HL^-/tptz "ligand blend" in reactions with Cu^{II} salts led to a completely different chemistry. Only one mononuclear complex (**5**) was structurally characterized which does not contain HL^- or L'^-. The impressive feature of this reaction system was the Cu^{II}-assisted hydrolysis [11] of tptz to pyridine-2-carboxamide, L1 (Scheme 1). Our current efforts are oriented on the isolation of X-ray quality crystals from the spectroscopically characterized Cu^{II} complexes of tptz with HL^- or L'^-, as well as the in depth investigation of the synthetic parameters that might affect the products from the terpy and tptz reaction systems.

Appendix A. Supplementary data

CCDC 723352, 723353, and 723354 contain the supplementary crystallographic data for **2**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Chadjistamatis, Ph.D. Thesis, University of Patras, Greece, 2005 (The coordination geometry about the Cu^{II} ion in [Cu(Hsucm)(terpy)(MeOH)](ClO_4) is distorted octahedral comprised of the three nitrogen atoms of the terpy (Cu–N = 1.945(2) – 2.026(3) Å) and the carboxylato oxygen atom of $Hsucm^-$ (Cu–O1 = 1.963(2) Å) in the equatorial positions, whereas the second carboxylato oxygen atom of $Hsucm^-$ and the coordinated MeOH are directed in the Jahn–Teller positions of the distorted octahedron (Cu–Om = 2.274(2), Cu–O2 = 2.581(2) Å)).

$_2NH_2)(HNCH_2\ CH_2NH_2)_3Zn_2Ge_2Se_8$ (**3**). To the best of our knowledge, the 1D chains $[Zn_2Ge_2Se_8]^{4-}$ in **3** are observed for the first time and also **3** is a rare templated semiconductor that contains two different charge balancing organic cations. We report here the synthesis and structural characterization of **3** as well as its optical and thermal properties.

2. Experimental

2.1. Reagents

N-(2-aminoethyl)piperazine (98%) and zinc powder (99.9%) were purchased from Alfa Aesar. Germanium (99.99%) and selenium (99.5%) were purchased from Aldrich. All chemicals were used as received.

2.2. Synthesis of $(H_2NC_4H_8NCH_2CH_2NH_2)(HNCH_2CH_2NH_2)_3Zn_2Ge_2Se_8$ (3)

In a typical synthesis, an amount of Zn (0.052 g, 0.795 mmol), Ge (0.029 g, 0.399 mmol), Se (0.219 g, 2.774 mmol) and 6 ml of *N*-(2-aminoethyl)piperazine were placed in a 45 ml Teflon-lined stainless steel autoclave (Parr Instruments) and heated at 200 °C for 62 h. The product, in the form of transparent, yellow–orange rod like crystals, was isolated by suction filtration and washed with copious amount of CH_3OH. Yield 0.210 g based on Ge.

2.3. Single crystal X-ray crystallography

A STOE IPDS II diffractometer was used to collect intensity data at room temperature, operated at 2000 W power (50 kV, 40 mA) with graphite monochromatized Mo Kα (λ = 0.71073 Å) radiation. An analytical absorption correction was applied using the program X-RED (routine within the X-AREA software package). The structure was solved with SHELXL software (Sheldrick, SHELXL, University of Göttingen, 2002). All non-hydrogen atoms were refined anisotropically expect the carbon atom C9 (–CH_2– group in a piperazinium cation) which was refined using the isor command (six restrains) because the ADPs were found physically not very sensible. The hydrogen atoms were generated with idealized geometries.

2.4. Physical measurements

Powder X-ray diffraction patterns were collected on a Rigaku D/MAX-2000H rotating anode diffractometer (Cu Kα radiation) equipped with a secondary pyrolytic graphite monochromator operated at 40 kV and 178 mA. The scan rate was 0.15°/min with a step size of 0.01°. Simulated PXRD patterns were calculated from the corresponding single crystal data using the program POWDER CELL 2.3. Thermogravimetric analyses (TGA) were performed using a TA SDT Q 600 analysis system. An amount of 20 mg of sample was placed inside an alumina cup and heated up to 600 °C under Argon flow with a heating rate of 5 °C/min. ATR-IR spectra were recorded on a Thermo-Electron Nicolet 6700 FT-IR optical spectrometer with a DTGS KBr. Raman spectrum was recorded at room temperature on a single crystal using a Nicolet Almega XR Raman spectrometer with a 473 nm blue laser (25% of the 15 mW laser power). The beam was focused on the sample through a confocal microscope using a 10× objective lens. Solid state UV–Vis/near IR electronic absorption spectrum was obtained at room temperature on a Perkin Elmer LAMBDA 950 UV/Vis/NIR spectrophotometer in the wavelength range of 200–2500 nm. $BaSO_4$ powder was used as a reference (100% reflectance) and base material on which the powder sample was coated. Reflectance data were converted to absorbance data as described elsewhere [27].

3. Results and discussion

3.1. Synthesis

In templated solvothermal syntheses of metal chalcogenides usually a common solvent such as water, methanol, ethylenediamine, pyridine or acetonitrile is required in addition to the templating molecules. That was the case in the successful synthesis of **1** in which a mixture of CH_3OH and **2** was used under solvothermal reaction conditions. Interestingly, when germanium was used instead of tin, under otherwise the same reaction conditions, we did not observed the isostructural phase of **1** or any other ternary Zn/Ge/Se crystalline phase. In contrast, when only **2** was used as solvent and template we obtained the ternary phase **3** in pure form (see below the powder X-ray data) and high yield (>80%). As we report below, the crystal structure of **3** consists of 1D $[Zn_2Ge_2Se_8]^{4-}$ chains made of edge sharing $[ZnSe_4]$ and $[GeSe_4]$ tetrahedra. Alternatively, the chains can be viewed as made of $[GeSe_4]^{4-}$ anions bridged by Zn^{2+} cations. These results could be explained based on solvent effects as follows: the highly basic nature of the $[GeSe_4]^{4-}$ anions requires a relatively strong basic environment in order to be stabilized and therefore, the fact that the synthesis of **3** requires only the amine **2** as a solvent (basic environment) and not a mixture of **2**/CH_3OH could be explained in terms of the relative basicity of the reaction medium. In fact, the effect of basicity in the stabilization of different germanium chalcogenide species, for example in aqueous solutions, has been document [28]. Accordingly, in highly basic solutions the anions $[GeQ_4]^{4-}$ (Q = S, Se) are stable, while at lower pH, condensation reactions occur leading to the formation of dimeric $[Ge_2Q_6]^{4-}$ and tetrameric, adamantine type $[Ge_4Q_{10}]^{4-}$ species. We note that the pH dependence of metal chalcogenide clusters has also been used as a tool for the controlled formation of ordered mesostructured metal chalcogenides [29].

3.2. X-ray diffraction characterization

The powder X-ray diffraction pattern of **3** is in full agreement with that calculated from the corresponding crystal structure (see Fig. 1) and confirms that the as-made, bulk material is a pure phase.

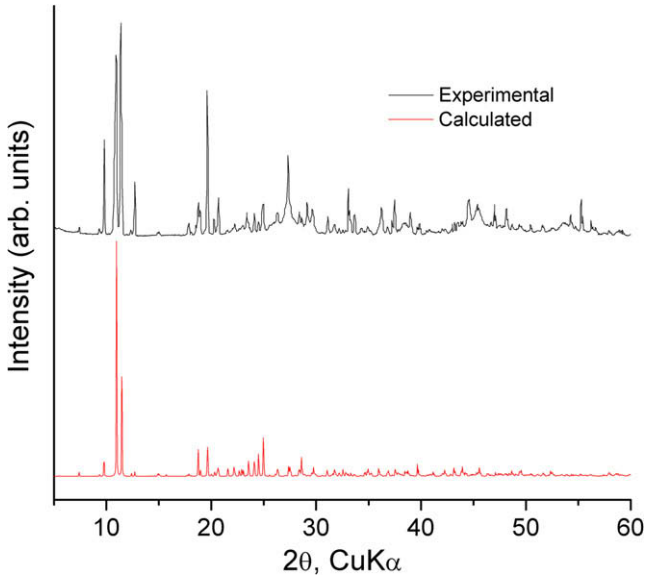

Fig. 1. Experimental (black line) and calculated (red line) powder X-ray diffraction pattern of **3**. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Compound **3** crystallize in the orthorhombic non-centrosymmetric space group $P2_12_12$ (see Table 1). The unit cell is shown in Fig. 2. The inorganic network consists of 1D $[Zn_2Ge_2Se_8]^{4-}$ chains made of edge sharing $[ZnSe_4]$ and $[GeSe_4]$ tetrahedral, running down the *c*-axis (see Fig. 3). Selected bond distances and bond angles are shown in Tables 2 and 3, respectively. The Zn–Se and Ge–Se bond distances lie between 2.4700(15)–2.5171(16) and 2.3416(15)–2.3580(16) Å, respectively, in the same range to those reported in some crystalline metal chalcogenides, as for example in ZnSe and $GeSe_2$.

R indices (all data)	R_{all} = 0.1052, wR_{all} = 0.1224
Largest differences in peak and hole (e Å^{-3})	1.017 and −1.762

$R = \sum||F_o|-|F_c||/\sum|F_o|$, $wR = \{\sum[w(|F_o|^2-|F_c|^2)^2]/\sum[w(|F_o|^4)]\}^{1/2}$ and calc. $w = 1/[\sigma^2(F_o^2) + (0.0448P)^2 + 0.0000P]$ where $P = (F_o^2 + 2F_c^2)/3$.

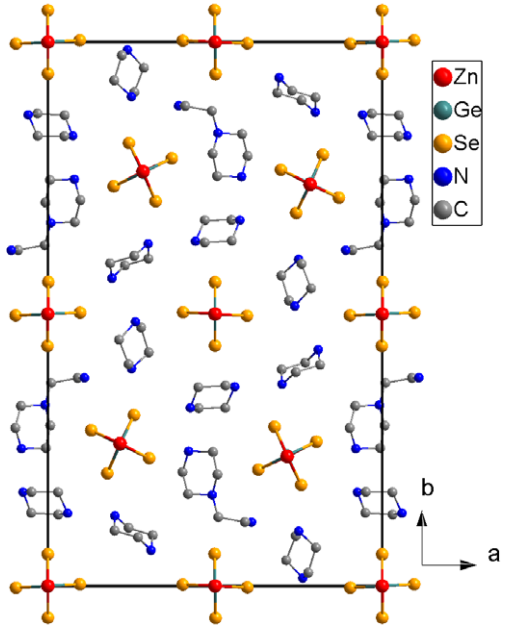

Fig. 2. The unit cell of **3** looking down the *c*-axis. Hydrogen atoms are omitted for clarity.

Notably, although in the system Zn/Sn/Se a number of crystalline ternary and quaternary compounds have been discovered and structurally characterized [30–33], in the system Zn/Ge/Se only the synthesis of Zn_2GeSe_4 and Zn_2GeSe_3 has been reported. The $[ZnSe_4]$ tetrahedra in **3** are highly distorted and the Se–Zn–Se bond angles lie in the range 93.09(7)–119.92(4)° (see Table 3). This large distortion from the ideal T_d symmetry of the zinc cations have been observed in other tetrahedral, transition metal containing metal chalcogenides including the isostructural series $(Me_4N)_2M[Ge_4S_{10}]$ (M = Mn^{2+}, Fe^{2+}, Co^{2+}, Zn^{2+}, Cd^{2+}) [34–37], $(Me_4N)_2M[Ge_4Se_{10}]$ (M = Fe^{2+}, Cd^{2+}) [38], $(Me_4N)_2M[Sn_4Se_{10}]$ (M = Mn^{2+}, Fe^{2+}, Co^{2+}, Zn^{2+}) [39,40] and $(Me_4N)_2Mn[Ge_4Te_{10}]$ [39]. The Se–Ge–Se bond angles lie in the range 100.34(7)–116.21(5)° which is typical for main-group metal chalcogenides [10].

A unique feature in **3** is that the anionic chains $[Zn_2Ge_2Se_8]^{4-}$ are charged balanced by two different organic cations. The asymmetric unit of **3** contains one templating molecule **2** and three piperazine molecules (**4**). Because compound **4** was not included in the starting reaction mixture, their formation indicates that **2** are partially decomposed during the reaction forming **4** and presumably ethylamine. In compound **3**, looking down the *c*-axis, the chain $[Zn_2Ge_2Se_8]^{4-}$ located at the center of the unit cell (Zn^{2+} and Ge^{4+} atoms at +1/2, +1/2, *z*), is surrounded by six molecules **4**, while all the other are surrounded by four molecules **4** and two molecules **2** (see Fig. 2). Taking into account charge balancing considerations, the observed packing indicates that the molecule **2** and the three molecules **4** of the asymmetric unit are monoprotonated forming *N*-(2-aminoethyl)piperazinium and piperazinium cations, respectively that compensate the anionic charge of the chains. Accordingly, the overall charged balanced formula of **3** is $(H_2NC_4H_8NCH_2CH_2NH_2)(HNCH_2CH_2NH_2)_3Zn_2Ge_2Se_8$.

3.3. Infrared and Raman spectroscopy

Infrared spectroscopy confirmed the presence of $-NH_2^+-$, –NH– and $-NH_2$, groups [41] in **3** (see Fig. 4).

Raman spectroscopy was used to further characterize the inorganic part in **3**. The Raman spectrum of **3** in the range 0–500 cm^{-1}, recorded at room temperature on a single crystal, is shown in Fig. 5. At least five vibrational modes were observed and provide information about the local environment of the germanium atoms in the structure. Normally, an ideal $[GeSe_4]^{4-}$ tetrahedron should show only a single Raman peak due to the symmetric (A_g) mode of vibration. The observation of multiple peaks suggests a local symmetry lowering of the tetrahedron, in full agreement with the crystallographic data of **3**. A comparison with the Raman spectra of $ASmGeSe_4$ (A = K^+, Rb^+, Cs^+) [42], $KCeGeSe_4$ [43], $M_{0.5}Pb_{1.75}GeSe_4$ (M = Ag^+, Na^+) [44] and $GeSe_2$ [45] all of which contain linked $[GeSe_4]^{4-}$ distorted tetrahedra, allows for a qualitative assignment of the observed bands. Accordingly, the sharp, intense peak centered at 213 cm^{-1} can be assigned to the primary symmetric Ge–Se stretching modes (A_1 mode, ν_1) of $[GeSe_4]$ tetrahedra. The peaks at 300 and 284 cm^{-1} can be assigned to the asymmetric Ge–Se stretching modes (F) while those at 166 and 101 cm^{-1} to the partially overlapping antisymmetric Se–Ge–Se bends (E).

3.4. Thermal analysis

The thermal stability of **3** was studied by thermogravimetric analysis (TGA). As shown in Fig. 6, the material is stable up to ~105 °C. Between 105 and 450 °C weight loss occur in two steps,

corresponding to the removal of the organic molecules, with a total weight loss of 22.5%. This value is close to that calculated from the chemical formula of **3** (30 wt%), assuming completely removal of the organic part. The difference between the observed and the calculated weight loss could be explained by remaining carbon in the form of coke, due the calcination of **3** under inert (flow of argon) conditions.

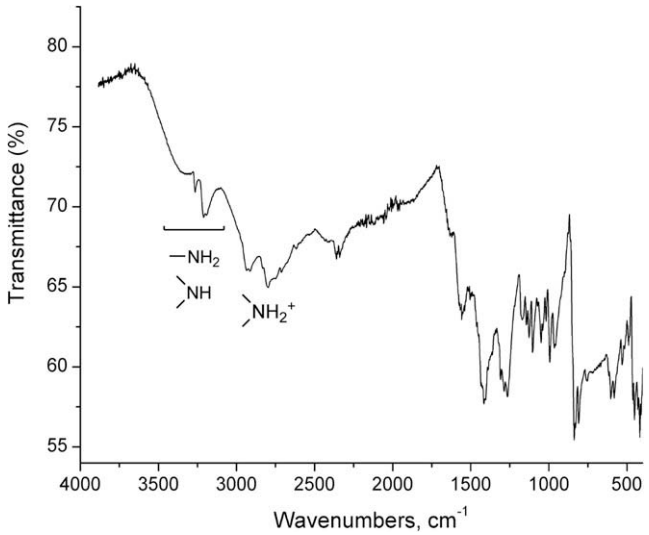

Fig. 4. ATR-IR spectrum of **3**.

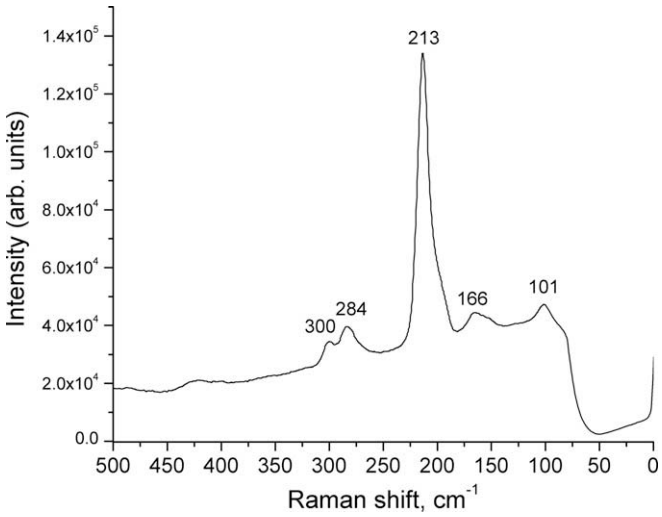

Fig. 5. Raman spectrum for compound **3** recorded at room temperature on a single crystal.

3.5. Solid-state diffuse reflectance spectroscopy

Diffuse reflectance UV–Vis/near IR spectroscopy was used to investigate the optical properties of **3**. As shown in Fig. 7, a well

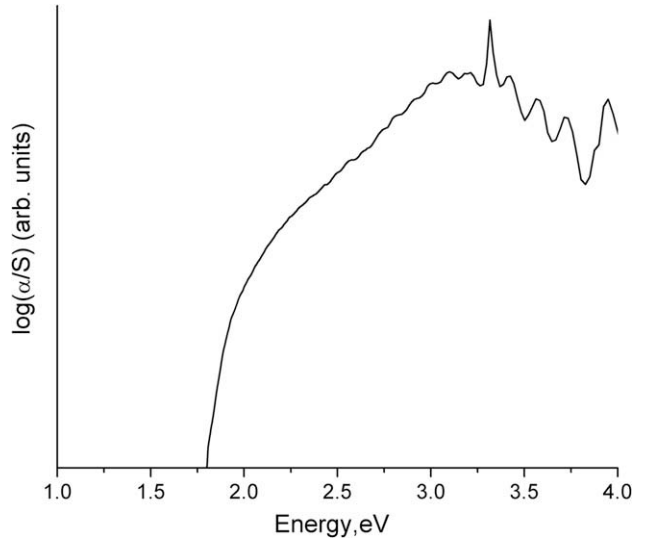

Fig. 7. Solid state UV–Vis/near IR electronic absorption spectrum for compound **3**.

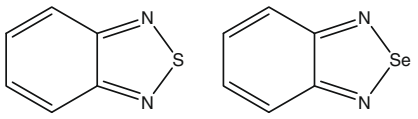
defined optical absorption associated with a band-gap transition at 1.8 eV is observed, indicating that this is a medium gap semiconductor, in the same range of some important chalcogenides such as GaAs (1.43 eV) and CdSe (1.70 eV). Interestingly, the observed band-gap is lower to that found in **1** (2.3 eV). One would expect a higher band-gap in **3** in comparison to **1**, because **1** is a two-dimensional (2D) solid and also contains a heavier main-group metal (Sn instead of Ge). These results indicated that the chemical composition of the inorganic part in **3** is not the decisive factor that controls the optical properties of the material and structural parameters should also be considered. Band structure calculations may seed light into the optical properties of **3** and currently are performed. It is important to note here that similar surprising observations have been reported in other low-dimensional semiconductors such as in the case of the 2D compound $Ga_4Se_7(en)_2(enH)_2$ [46].

4. Conclusions

In conclusion, we have synthesized and characterized the first organically templated semiconductor in the system Zn/Ge/Se. The compound features 1D anionic chains made of alternating edge-shared [$ZnSe_4$] and [$GeSe_4$] tetrahedra that charged balanced by two different organic cations. The material is a medium gap semiconductor with an absorption edge at 1.8 eV. Currently, we are exploring other amine-based organic molecules as templating agents for the development of novel transition metal containing group 14 (Ge and Sn) chalcogenides.

5. Supplementary data

CCDC 721564 contains the supplementary crystallographic data for **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.



Acknowledgments

Financial support from the European Union (75%) and the Greek Government (25%) through the program PENED-2003 code number 03ED450, from INTERREG IIIA Greece-Cyprus (K2301.004) and from BIOSOLENUTI (REGPOT-2008-1) grant number 229927, is gratefully acknowledged.

btd bsd

Fig. 1. The structures of 2,1,3-benzothiadiazole (btd) and 2,1,3-benzoselenadiazole (bsd).

temperature. Colorless crystals of **1** were formed over a period of three days. The crystals were isolated by vacuum filtration, washed with Et_2O (2 × 5 mL) and dried in air. Yield ~40%. *Anal.* Calc. for $C_{12}H_8HgCl_2N_4Se_2$: C, 22.60; H, 1.26; N, 8.79. Found: C, 22.51; H, 1.15; N, 8.87%. Selected IR data (cm^{-1}): 3040 (w), 1602 (m), 1530 (s), 1485 (s), 1460 (s), 1350 (m), 1280 (m), 1130 (m), 924 (s), 870 (vs), 848 (s), 709 (vs), 592 (m), 475 (s).

2.2.2. Synthesis of $[HgCl_2(bsd)]_n$ (**2**)

$HgCl_2$ (271 mg, 1.0 mmol) and bsd (183 mg, 1.0 mmol) were dissolved in MeOH (25 mL). The resulting pale yellow solution was allowed to stir for 20 min and left undisturbed to evaporate at room temperature. Pale yellow crystals of **2** were formed over a period of two days. The crystals were isolated by vacuum filtration, washed with Et_2O (2 × 5 mL) and dried in air. Yield ~30%. *Anal.* Calc. for $C_6H_4HgCl_2N_2Se$: C, 15.85; H, 0.89; N, 6.16. Found: C, 15.82; H, 0.76; N, 6.18%. Selected IR data (cm^{-1}): 3038 (w), 1598 (m), 1520 (s), 1479 (s), 1465 (s), 1340 (m), 1276 (m), 1128 (m), 930 (s), 878 (vs), 840 (s), 712 (vs), 588 (m), 468 (s).

2.3. Single-crystal X-ray crystallography

2.3.1. Complex **1**

Slow crystallization from MeOH yielded colorless prismatic crystals. A crystal with approximate dimensions 0.05 × 0.14 × 0.50 mm was mounted in a capillary. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range 11<2θ<23° and they appear in Table 1. Intensity data were recorded using a θ–2θ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and psi-scan absorption corrections were applied using Crystal Logic software. The structure was solved by direct methods using SHELXS-97 [20] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [21]. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically.

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum(|F_o|)$.
[b] $wR_2 = \left\{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\right\}^{\frac{1}{2}}$.
[c] For 1198 reflections with $I > 2\sigma(I)$.
[d] For 1543 reflections with $I > 2\sigma(I)$.

2.3.2. Complex **2**

Slow crystallization from MeOH yielded yellow prismatic crystals. A crystal with approximate dimensions 0.05 × 0.05 × 0.50 mm was mounted in air and covered with epoxy glue. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$ and they appear in Table 1. Intensity data were recorded using a θ–2θ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and psi-scan absorption corrections were applied using Crystal Logic software. The structure was solved by direct methods using SHELXS-97 [20] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [21]. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Brief synthetic comments

Reaction of one mol of $HgCl_2$ with one and two mol of bsd in MeOH results in yellow crystals of $[HgCl_2(bsd)]_n$ (**2**) and colorless crystals of $[HgCl_2(bsd)_2]_n$ (**1**), respectively and therefore, the identity of the products is ratio depended. Higher $HgCl_2$/bsd mole ratios than 1:2 (i.e. 1:3, 1:4) always result in the formation of **1**, while mole ratios of 1:1 or 2:1 result in **2**. The $HgCl_2$/bsd reaction system is not temperature depended since refluxing the reaction mixtures always resulted in the formation of **1** or **2** according to the $HgCl_2$/bsd molar ratio.

3.2. Description of structures

Selected bond distances and angles for compound **1** are listed in Table 2. The structure of **1** consists of 1D $\{Hg(\mu\text{-}Cl)_2\}_n$ linear chains running along the *c*-axis (Fig. 2), with *intra*chain Hg···Hg separations of 3.857(3) (*c*-axis). The shortest *inter*chain Hg···Hg separation is 9.746(6) Å (*a*-axis). The Hg^{II} atom sits on an inversion

Table 2

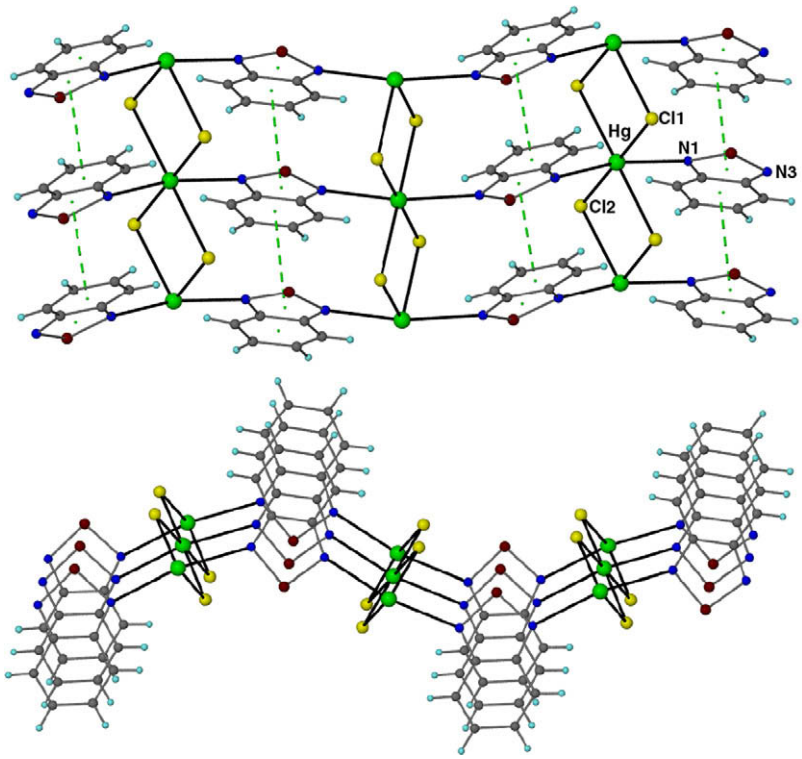

Fig. 4. Ball and stick representation of **2** showing the top and side view of the undulated layer and the π···π interactions (green dashed lines) between the bsd molecules. Color code: Hg green, Cl yellow, N blue, Se dark-red, C grey, H cyan, centroids small green spheres. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

center. Each Hg^{II} atom is octahedrally coordinated to four Cl^- ligands and two terminal bsd molecules. The Hg–Cl distances are 2.427(7) and 3.100(7) Å and the Hg–N bond length is 2.627(1) Å, in good agreement with those of other similar Hg(II) complexes [1].

A characteristic structural feature common to free bsd and **1** is the existence of strong face-to-face stacking interactions between the bsd ligands. The bsd molecules form columns within the crystal lattice, with the *inter*planar distances being 3.576 and 3.474 Å for free bsd [13] and **1**, respectively. In **1** the columns of the bsd molecules are orientated on alternating sides of each $\{Hg(\mu\text{-}Cl)_2\}_n$ chain. The bsd molecules within a column in **1** stack off set such that the five-membered ring (C_2N_2Se) of one molecule forms a π···π stacking interaction with the phenyl ring of a neighboring molecule [centroid···centroid 3.622 Å] (Fig. 2). The centroid···centroid distance between the five-membered ring of one molecule and the phenyl ring of a neighboring molecule in the structure of the free ligand is 3.621 Å. This structural feature has also been observed in the crystal structures of btd [22] and its complexes [10,11].

Neighboring layers of **1** are further bridged in the second dimension via N···Se interactions (Fig. 3). Each bsd molecule forms two complementary N···Se interactions [N···Se 2.876(1) Å] with a bsd molecule belonging to a neighboring chain giving rise to an undulated layer running parallel to the *bc* plane. Similar N···Se conducts are observed in the crystal structure of the free ligand with the N···Se distance being 3.155(6) Å [13].

Selected bond distances and angles for complex **2** are listed in Table 3. Complex **2** consists of 1D $\{Hg(\mu\text{-}Cl)_2\}_n$ linear chains running along the *a*-axis and linked via μ-bsd ligands along the *b*-axis to afford an extended undulated (4,4) 2D layered network (Fig. 4), with *intra*layer Hg···Hg separations of 3.923 Å (via chlorides) and 7.480 Å (via bsd). The shortest *inter*layer Hg···Hg separation is 7.773 Å. The Hg^{II} atom is octahedrally coordinated to four Cl^- ligands and two bsd molecules. There are two kinds of Hg–Cl bonds, short and long. The short Hg–Cl distances are 2.352(3) and 2.348(3) Å, while the long Hg–Cl distances are 3.050(3) and 3.059(3) Å. The Hg–N bond lengths are 2.666(9) and 2.718(9) Å. Complex **2** has a similar structure with $[CuCl_2(btd)]_n$ [10], $[CoCl_2(btd)]_n$ and $[CoBr_2(btd)]_n$ [11].

Complex **2** is dominated by the existence of strong face-to-face *intra*layer stacking interactions between the bsd ligands along the *c*-axis (Fig. 4). Like in **1**, the bsd molecules in **2** form columns within the crystal lattice, with the *inter*planar distances being 3.516 Å. The columns of the bsd molecules in **2** are orientated on alternating sides of each sheet. The bsd molecules within each column in **2** stack off set such that the five-membered ring (C_2N_2Se) of one molecule forms a π···π stacking interaction with the phenyl ring of a neighboring molecule [centroid···centroid 3.624 Å] (Fig. 4).

3.3. Spectroscopic characterization

3.3.1. IR Spectroscopy

The IR spectra of both complexes are similar and exhibit the typical bands of the disubstituted benzene ring and bands assignable to vibrations of the selenadiazole ring. The bands in the 1600–1520 cm^{-1} region are associated with the ν(C=N) and ν(C=C) of the phenyl ring while the bands at *ca.* 1480 and 470 cm^{-1} are associated with the ν(CN) and ν(SeN) vibrational modes of the selenadiazole ring, respectively. Due to coordination these bands are shifted compared to those in free bsd.

4. Conclusions and perspectives

The employment of 2,1,3-benzoselenadiazole in the coordination chemistry of mercury(II) chloride afforded two coordination polymers. Both polymers feature 1D $\{Hg(\mu\text{-}Cl)_2\}_n$ linear chains, while bsd molecules act as terminal ligands in **1** and as bridging ligands in **2** to create a 2D layer in the latter case. The linear chains in **1** are further bridged via N···Se interactions to create a 2D layer. A structural feature observed in the crystal structures of the free ligand and of both complexes is the present of π···π stacking interactions between the bsd molecules. The same feature has been observed in the crystal structures of the similar ligand btd and its complexes [10,11] and seems to be persistent regardless of the different heteroatom in the five-membered ring. Efforts to employ other mercury salts and bsd are continuing.

Supplementary data

CCDC 723314 and 723315 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

which have produced a new family of octanuclear complexes $[Mn_8(N_3)_4(O_2CR)_6(L)_4(py)_6]$ (L = pd^{2-}, R = Et **1**; L = mpd^{2-}, R = Et **2**; L = pd^{2-}, R = Ph **3**) with a near-planar, rod-like topology. The magnetic properties of compounds **1** and **2** were studied by dc and ac magnetic susceptibility measurements, which revealed that both compounds have a diamagnetic spin ground state.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received; water was distilled in-house. *Warning: Although no such behavior was observed during the present work, azide salts are potentially explosive; such compounds should be used in small quantities, and treated with utmost care at all times.* $Mn(O_2CEt)_2{\cdot}2H_2O$ [13], $Mn(O_2CPh)_2{\cdot}2H_2O$ [14] were synthesized according to published methods. Elemental analyses (C, H, N) were performed by the in-house facilities of the University of Florida, Chemistry Department.

2.2. Compound preparation

2.2.1. $[Mn_8(N_3)_4(O_2CEt)_6(pd)_4(py)_6]$ (**1**)

To a solution of $[Mn(O_2CEt)_2]{\cdot}2H_2O$ (0.131 g, 0.553 mmol) in a 10:2 ml mixture of MeCN/py was added pdH_2 (0.20 ml, 2.77 mmol) and NaN_3 (0.036 g, 0.55 mmol). The resulting yellowish-brown slurry was then left under magnetic stirring for 10 min. Then, it was filtered off, and the filtrate was left undisturbed at room temperature. After a few days X-ray quality crystals appeared and were collected by filtration, washed with MeCN and dried in vacuum. The yield was 36%. Elemental analysis: *Anal.* calc. for $C_{60}H_{84}O_{20}N_{18}Mn_8$ (**1**): C 39.66, H 4.66, N 13.88. Found: C 39.82, H 4.64, N 13.78%. Selected IR data (KBr): ν~ = 3441s, br, 2980w, 2937w, 2856w, 2073s, 1566s, 1427s, 1300w, 1087s, 1051s, 941w, 817w, 596w, 523w.

2.2.2. $[Mn_8(N_3)_4(O_2CEt)_6(mpd)_4(py)_6]$ (**2**)

To a solution of $[Mn(O_2CEt)_2]{\cdot}2H_2O$ (0.107 g, 0.450 mmol) in a 10:2 ml mixture of MeCN/py was added $mpdH_2$ (0.20 mL, 2.25 mmol) and NaN_3 (0.029 g, 0.45 mmol). The resulting yellowish - brown slurry was left under magnetic stirring for 15 min. Then, it was filtered off, and the filtrate was left undisturbed at room temperature. After a few days, X-ray quality crystals appeared and were collected by filtration, washed with MeCN and dried in vacuum. The yield was 34%. Elemental analysis: *Anal.* calc. for $C_{64}H_{92}O_{20}N_{18}Mn_8$ (**2**): C 41.04, H 4.95, N 13.46. Found: C 41.27, H 5.03, N 13.31%. Selected IR data (KBr): ν~ = 3412s, br, 2979w, 2937w, 2877w, 2862w, 2077s, 1570s, 1429s, 1300w, 1110m, 1042m, 1042m, 951w, 817w, 590m, 537w.

2.2.3. $[Mn_8(N_3)_4(O_2CPh)_6(pd)_4(py)_6]$ (**3**)

To a solution of $[Mn(O_2CPh)_2]{\cdot}2H_2O$ (0.184 g, 0.552 mmol) in a 10:2 ml mixture of Me_2CO/py was added pdH_2 (0.20 mL, 2.77 mmol) and NaN_3 (0.036 g, 0.55 mmol). The resulting yellowish-brown slurry was left under magnetic stirring for 15 min. Then, it was filtered off, and the filtrate was left undisturbed at room temperature. After a few weeks X-ray quality crystals appeared and were collected by filtration, washed with Me_2CO and dried in vacuum. The yield was 23%. Elemental analysis: *Anal.* calc. for $C_{84}H_{84}O_{20}N_{18}Mn_8$ (**3**): C 47.93, H 4.02, N 11.98. Found: C 47.78, H 4.12, N 12.06%. Selected IR data (KBr): ν~ = 3453s, br, 2942w, 2856w, 2070s, 1601s, 1558s, 1445w, 1399s, 1088m, 1052m, 944w, 817w, 723w, 593w.

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum(|F_o|)$.
[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

2.3. Single-crystal X-ray crystallography

Crystals of **1**, **2** and **3** in Paratone-N oil were mounted on glass fibers. Diffraction measurements were made on an Oxford Diffraction CCD instrument using graphite-monochromated Mo radiation. Complete crystal data and parameters for data collection and processing are reported in Table 1. Unit cell dimensions were determined and refined by using 12620 ($3.1 \leqslant \theta \leqslant 30.6°$) and 15442 ($3.1 \leqslant \theta \leqslant 30.4°$) reflections for **1** and **2,** respectively. Empirical absorption corrections (multi-scan based on symmetry-related measurements) were applied using CRYSALIS RED software [15]. Data for **3** were of insufficient quality to allow full structure analysis but were suitable for the atom connectivity, and chemical formula to be confirmed; crystal data of **3** thus are not included in Table 1.

The structures were solved by direct methods using SIR92 [16a] and refined by full-matrix least-squares techniques on F^2 using SHELXL97 [16b]. Programs used: CRYSALIS CCD [15] for data collection, CRYSALIS RED [15] for cell refinement and data reduction, and DIAMOND [17a] and MERCURY [17b] for molecular graphics. All non-hydrogen atoms of the two structures were refined anisotropically. The hydrogen atoms attached to carbon atoms of the ligands of compounds **1** and **2** were positioned geometrically (riding model).

2.4. Other measurements

IR spectra (4000–400 cm^{-1}) were recorded at the University of Cyprus, using a Shimadzu Prestige – 21 spectrometer with samples prepared as KBr pellets. Variable-temperature dc and ac magnetic susceptibility data were collected at the University of Florida using a Quantum Design MPMS-XL SQUID susceptometer equipped with a 7 T magnet. The sample was embedded in solid eicosane to prevent torquing. Diamagnetic corrections to the observed susceptibilities were applied using Pascal's constants.

3. Results and discussion

3.1. Synthesis

Recently, we have been exploring the use of a combination of N_3^- and (m)pdH_2 ligands in Mn carboxylate chemistry. The initial

results of this investigation were the 1-D coordination polymers $[Mn_{17}(\mu_4\text{-}O)_8(N_3)_5(O_2CMe)_4(L)_{10}(py)_6]_\infty$ (L = pd^{2-}, **4** or mpd^{2-}, **5**), consisting of Mn_{17} octahedral units [9,10]. These compounds were isolated from the reaction of $[Mn(O_2CMe)_2]\cdot 4H_2O$, pdH_2 (or $mpdH_2$) and NaN_3 in a 1:5:1 ratio in MeCN/py (py = pyridine). A number of modifications were performed to this reaction system, some of which resulted in a discrete Mn_{17} cluster and also in a 2-D coordination polymer consisting of the same Mn_{17} octahedral unit discussed above [9] and some others resulted in microcrystalline precipitates that we were unable to further characterize. However, the reactions which involved the use of different $[Mn(O_2CR)_2]$ starting materials resulted in the isolation of three new octanuclear compounds with a rod-like topology (**1**–**3**). Thus, the reaction of $[Mn(O_2CEt)_2]\cdot 2H_2O$ with pdH_2 and NaN_3 in a 1:5:1 ratio in MeCN/py (10/2 ml) resulted in the formation of yellowish-brown crystals of **1** in 36% yield. Analogous reactions, using $mpdH_2$ instead of pdH_2, and $[Mn(O_2CPh)_2]\cdot 2H_2O$ as a starting material instead of $[Mn(O_2CEt)_2]\cdot 2H_2O$ were also performed, resulting in the formation of yellowish-brown crystals of complexes **2** and **3** in 34 and 23% yields, respectively. Note that crystals of **3** were isolated only when the reaction took place in an Me_2CO/py solvent system. Although all the reactions took place in organic solvents (MeCN/py, Me_2CO/py) where NaN_3 is nearly insoluble, we should not forget that the solvents, which were used as received, contain small amounts of water and thus NaN_3 is slightly soluble in these solvent systems. The NaN_3 that comes in the solution reacts rapidly, more NaN_3 is then dissolved and the color of the reaction mixture changes to darker yellowish-brown as the reaction proceeds.

Compounds **2** and **3** are similar to **1** since they all possess the same structural core and differ from **1** mainly in the propanediol (mpd^{2-} instead of pd^{2-} in **2**) or the carboxylate (^-O_2CPh instead of ^-O_2CEt in **3**) ligand they contain. In all those reactions, the oxidation state of the starting material is 2+, whereas the average oxidation state of the final products is higher, i.e. 2.25+ although no oxidant was added in the reaction mixture; we believe that the atmospheric O_2 is responsible for this oxidation which is facilitated

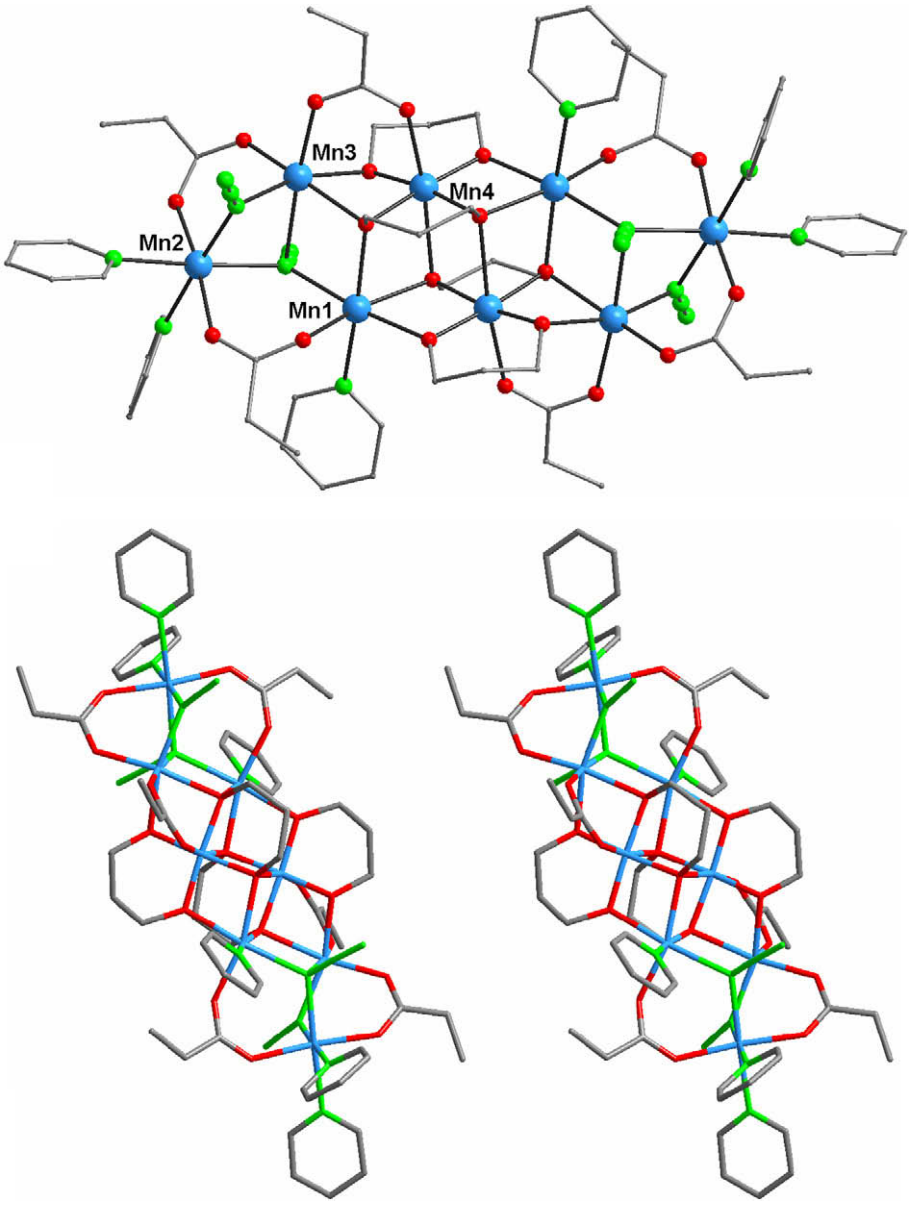

Fig. 1. Molecular structure (top) and stereoview (bottom) of complex **1**. Color code: Mn, blue; O, red; N, green; C, grey. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

by the existence of a large excess of a base (pyridine) as it has also been observed in the past [18]. The formation of compounds **1**–**3** is summarized in Eq. (1).

$$8Mn(O_2CR)_2 \cdot 2H_2O + 4H_2(m)pd + 4NaN_3 + 6py \rightarrow [Mn_8(N_3)_4(O_2CR)_6((m)pd)_4(py)_6] + 6RCO_2H + 4RCOO^-Na^+ + 8xH_2O + 2H^+ + 2e^- (R = C_2H_5, C_6H_5) \quad (1)$$

The isolation of compounds **1**–**3** when $[Mn(O_2CR)_2]\cdot 2H_2O$ (R = Et, or Ph) are used as starting materials does not imply that analogues of **4** and **5** with propionate and benzoate ligands respectively, are not formed as reaction co-products and vise versa. It is possible that the reaction solution in each case consists of a mixture of various species in equilibrium, which could include the analogues of **4** and **5**. However, since the identity of the product that is isolated from such reactions is determined by a number of factors such as relative solubility, lattice energies, crystallization kinetics, etc, it is reasonable that the use of different carboxylate ligands will result in the precipitation of different products.

3.2. Description of the structures

A partially labelled plot and a stereoview of **1** are shown in Fig. 1. A view of the structural core of **1**–**3** emphasizing its two butterfly units is shown in Fig. 2. Selected interatomic distances and BVS calculations data for compound **1** are listed in Tables 2 and 3, respectively. Since, the crystal structures of compounds **1**–**3** are strikingly similar, only the structure of **1** will be described in detail, and the other two structures will be compared to that of **1**. Complex **1** crystallizes in the triclinic space group $P\bar{1}$, with the asymmetric unit consisting of two halves of two octanuclear units of **1**. Bond-valence sum calculations (Table 3), charge considerations, and inspection of metric parameters revealed a mixed-valent complex containing six Mn^{II} and two Mn^{III} ions. The eight Mn ions of **1** are held together by bridging N_3^- and 1,3-propanediol ligands, resulting in a $[Mn^{II}_6Mn^{III}_2(\mu_3\text{-}N_3)_2(\mu\text{-}N_3)_2(\mu_3\text{-}OR)_4(\mu\text{-}OR)_4]^{6+}$ core (Fig. 2) with a near-planar, rod-like topology.

All eight Mn ions are in distorted octahedral geometries with the two Mn^{3+} ions displaying the expected Jahn-Teller elongations. The structure of **1** consists of two symmetry-related butterfly units, which are connected through RO^- groups of pd^{2-} ligands (Fig. 2). The four pd^{2-} ligands are fully deprotonated and two of them sit above and the other two below the plane of the core. Two of the pd^{2-} ligands bridge three Mn ions in a $\eta^2{:}\eta^2{:}\mu_3$ fashion, whereas the other two bridge five Mn ions in a $\eta^3{:}\eta^3{:}\mu_5$ fashion. The Mn^{2+} ions of each butterfly unit are held together by two end-on N_3^- ligands. One of the N_3^- group bridges three Mn^{2+} in a μ_3-1,1,1 fashion, whereas the second N_3^- group bridges two Mn^{2+} ions in a μ_2-1,1 fashion. The peripheral ligation of the compound is completed by six $CH_3CH_2COO^-$ ligands, and six terminal pyridine groups. The six $CH_3CH_2COO^-$ ligands coordinate in their usual *syn*, *syn* μ_2 fashion. A close examination of the packing revealed that there are no intermolecular interactions between neighbouring Mn_8 units which are well separated since the shortest Mn···Mn distance between different Mn_8 units is relatively large (7.958 Å).

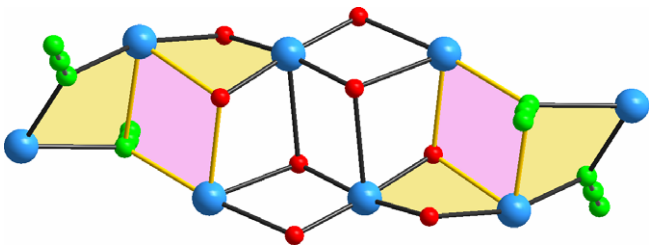

Fig. 2. The metal – oxygen–nitrogen core of **1**; the yellow lines connecting the Mn ions and the yellow and pink planes emphasise the two butterfly units. The color code is as in Fig. 1. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Table 3
Bond-valence sums for the Mn atoms of **1**.[a]

Atom	Complex **1**		
	Mn^{II}	Mn^{III}	Mn^{IV}
Mn1	*1.79*	1.66	1.70
Mn2	*1.88*	1.78	1.76
Mn3	*1.95*	1.81	1.85
Mn4	3.04	*2.78*	2.92
Mn5	*1.88*	1.75	1.78
Mn6	*1.93*	1.83	1.81
Mn7	*1.93*	1.79	1.83
Mn8	3.07	*2.81*	2.95

[a] The italicized value is the one closest to the charge for which it was calculated. The oxidation state of a particular atom can be taken as the nearest whole number to the italicized value.

As it was mentioned above, the structures of compounds **2** and **3** are strikingly similar to this of **1** with the main differences between them being the diolate (mpd^{2-} in **2** instead of pd^{2-}) or carboxylate (benzoate in **3** instead of propionate) ligands included in the compounds.

To our knowledge, the $[Mn^{II}_3Mn^{III}(\mu_3\text{-}N_3)(\mu\text{-}N_3)(\mu_3\text{-}OR)(\mu\text{-}OR)_2]^{4+}$ that is present in **1**–**3** is unknown in discrete form but would be particularly attractive since it is expected to have a large spin ground state because of the presence of the end - on N_3^- ligands. Complexes **1**–**3** are related to compounds $[Mn^{III}_8O_4(O_2CCMe_3)_{10}(thme)_2(py)_2]$ (**6**) [19] (H_3thme = 1,1,1-tris(hydroxymethyl)ethane) and $[Mn^{III}_4Mn^{II}_4(O_2CCMe_3)_2(tmp)_2(Htmp)_4Br_4(H_2O)_2]$ (**7**) (H_3tmp = 1,1,1-tris(hydroxymethyl)propane) reported by Brechin and coworkers [18c] since they are all octanuclear Mn clusters with rod-like topologies. However, there are a number of significant differences between **1**–**3** and **6**, **7** including: (i) the presence in **1**–**3** of end-on N_3^- ligands which lead in very different structural cores, (ii) the existence in **1**–**3** of fully deprotonated diols instead of triols, (iii) different oxidation states of the Mn ions, etc.

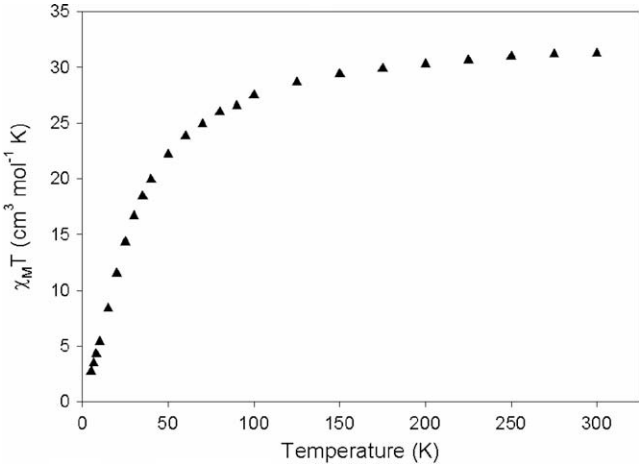

Fig. 3. Magnetic susceptibility data for **1**, shown as $\chi_M T$ vs T curves.

3.3. Magnetism

Variable-temperature, solid-state magnetic susceptibility measurements were performed on powdered polycrystalline samples of **1** and **2** in a 1kG (0.1T) field in the 5.0–300 K range. The obtained data for **1** and **2** are almost identical and thus only those for compound **1** are shown as a $\chi_M T$ vs T plot in Fig. 3. The $\chi_M T$ values at 300 K are 31.26 and 30.96 cm^3 mol^{-1} K for **1** and **2** respectively. These values are slightly smaller than that expected for a cluster comprising six Mn^{II} and two Mn^{III} non-interacting ions (32.25 cm^3 mol^{-1} K with $g = 2$). The $\chi_M T$ values gradually decrease with decreasing temperature to 22.15 cm^3 mol^{-1} K and 22.34 at 50 K before dropping to 2.68 and 2.52 cm^3 mol^{-1} K at 5.0 K. This behavior is indicative of the existence of dominant antiferromagnetic interactions between the metal centers, with the low temperature values suggesting a very small or zero ground spin state. In order to determine the ground state, magnetization data were collected in the temperature and magnetic field ranges 1.8–10.00 K and 0.1–7 T. Attempts were made to fit the resulting data using the program MAGNET [20], which assumes that only the ground state is populated at these temperatures and includes axial zero-field-spliting ($D\hat{S}_z^2$) and Zeeman interactions. However, it was not possible to obtain a satisfactory fit.

Reliable conclusions about the ground state S value, can nevertheless, be reached by using alternating current (ac) magnetic susceptibility measurements [5b,8,11]. The in-phase $\chi_M'T$ vs. T data for compound **1** are shown in Fig. 4. The $\chi_M'T$ signal for both compounds decreases linearly with decreasing temperature in the whole temperature range, and is clearly heading to $\chi_M'T$ values close to 0 at 0 K. This is consistent with the existence of antiferromagnetic interactions within the Mn ions of **1** and **2** and a diamagnetic ground spin state as was suggested on the basis of the dc magnetic susceptibility data. As expected for compounds with diamagnetic ground spin states, there are no out-of-phase ac signals down to 1.8 K.

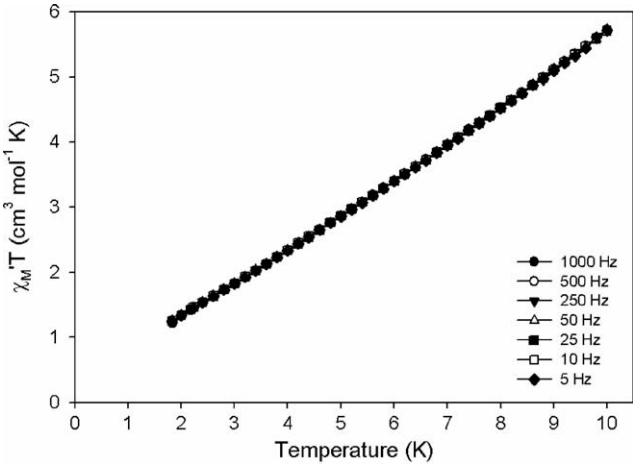

Fig. 4. Plot of the in-phase (χ_M') ac magnetic susceptibility as $\chi_M'T$ vs T for complex **1**, in a 3.5 Oe field oscillating at the indicated frequencies.

An $S = 0$ ground state for compounds such as **1** and **2** with end - on N_3^- ligands, which are expected to mediate ferromagnetic interactions, is somewhat surprising. Since, the $[Mn_3^{II}Mn^{III}(\mu_3\text{-}N_3)(\mu\text{-}N_3)(\mu_3\text{-}OR)(\mu\text{-}OR)_2]^{4+}$ sub-unit does not exist in a discrete form in order to make relatively safe predictions about the sign and the magnitude of the various exchange interactions within **1** and **2**, it is quite difficult to rationalize the diamagnetic spin ground state. However, a rather simple and also reasonable rationalization of the $S = 0$ ground states of **1** and **2** is that whatever the ground state S of each of the two $[Mn_3^{II}Mn^{III}(\mu_3\text{-}N_3)(\mu\text{-}N_3)(\mu_3\text{-}OR)(\mu\text{-}OR)_2]^{4+}$ sub-units of the Mn_8 cluster might be, they are overall interacting antiferromagnetically with each other, and thus yield an $S = 0$ ground state for the complete molecule. Note, that compound **7,** which is the only other Mn_8 cluster with a planar rod-like topology, also has an $S = 0$ ground state [18c].

4. Conclusions

The present work is an extension of our investigations on the use of a combination of pdH_2 or $mpdH_2$ and N_3^- ligands in Mn carboxylate chemistry [9,10]. This study has produced a new family of octanuclear manganese complexes with a near-planar, rod-like topology which appears for first time in Mn–(m)pdH_2 chemistry. In addition, compounds **1**–**3** are the first that combine the rod-like topology with the presence of end – on N_3^- ligands and thus their $[Mn_6^{II}Mn_2^{III}(\mu_3\text{-}N_3)_2(\mu\text{-}N_3)_2(\mu_3\text{-}OR)_4(\mu\text{-}OR)_4]^{6+}$ structural core is unprecedented in Mn cluster chemistry. Magnetic susceptibility studies revealed the existence of antiferromagnetic exchange interactions within the Mn_8 unit that result in a diamagnetic ground state. Finally, it is clear that the Mn-(m)pdH_2 chemistry is proving a rich source of new polynuclear compounds. Further studies are thus in progress, which are expected to result in a number of new Mn clusters with a variety of structural topologies in the near future.

Supplementary data

CCDC 724079 and 724080 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

[19,20]. In such systems, Cr(III) is able to react due to its solubility maintained by weaker organic and inorganic ligands.

Undoubtedly, therefore, soluble Cr(III) presents a metal ion linked to a number of abiotic and biological species for which specific knowledge of chemistry and biology are needed. Poised to understand the binary interactions of Cr(III) with low molecular mass substrates in cellular processes, we have launched research efforts targeting the pH-specific reactivity of Cr(III) toward metal-complexing hydroxycarboxylate-containing physiological ligands. In this respect, we herein report the pH-specific synthesis and physicochemical characterization of two new binary pH-structural variants of the Cr(III)–citrate system emerging from the requisite aqueous speciation.

2. Experimental

2.1. Materials and methods

All experiments were carried out in air. Nanopure quality water was used for all reactions. $Cr(NO_3)_3{\cdot}9H_2O$ and citric acid monohydrate, were purchased from Aldrich. Sodium hydroxide was supplied by Fluka and 2,9-dimethylphenanthroline (dmphen) ($C_{14}H_{12}N_2$) by Aldrich.

2.2. Physical measurements

FT-Infrared spectra were recorded on a Thermo, Nicolet IR 200 FT-infrared spectrometer. UV–Vis measurements were carried out on a Hitachi U2001 spectrophotometer in the range from 190 to 1000 nm. A ThermoFinnigan Flash EA 1112 CHNS elemental analyzer was used for the simultaneous determination of carbon, hydrogen, and nitrogen (%). The analyzer is based on the dynamic flash combustion of the sample (at 1800 °C) followed by reduction, trapping, complete GC separation and detection of the products. The instrument is fully automated and controlled by PC via the Eager 300 dedicated software and is capable of handling solid, liquid or gaseous substances.

A TA Instruments thermal analyzer, model Q 600, system was used to run the simultaneous TGA–DTG experiments. The employed heating rate was 5 °C/min. The instrument mass precision is 0.1 μg. About 15.9 mg of sample was placed in an open alumina sample pan for the experiment. High purity air (80/20 in N_2/O_2) was used at a constant flow rate of 100 mL/min. During the experiments, the sample weight loss and rate of weight loss were recorded continuously under dynamic conditions, as a function of time or temperature, in the range 30–1000 °C. Prior to activating the heating routine program, the entire system was purged with the appropriate inert gas for 10 min, at a rate 400 mL/min, to ensure that the desired environment had been established.

The EPR spectra in the solid state and frozen aqueous solutions were recorded on a Bruker ER 200D-SRC X-band spectrometer, equipped with an Oxford ESR 9 cryostat at 9.43 GHz, 10 dB, and in the range 4–150 K. Magnetic susceptibility data were collected on powdered samples of the title complexes with a Quantum Design SQUID susceptometer in the 2–300 K range, under various applied magnetic fields. Magnetization measurements were carried out at three different temperatures in the field range 0–5 T.

Electrochemical measurements were carried out with an Autolab model PGSTAT100 potensiostat–galvanostat. The entire system was under computer control and supported by the appropriate computer Autolab software GPES, running on Windows. The employed electrochemical cell had platinum (disk) working and auxiliary (wire) electrodes. As reference electrode, a saturated Ag/AgCl electrode was used. The water used in the electrochemical measurements was of nano-pure quality. KNO_3 was used as a supporting electrolyte. Normal concentrations used, were 1–6 mM in electroanalyte and 0.1 M in supporting electrolyte. Purified argon was used to purge the solutions prior to the electrochemical measurements. Derived $E_{1/2}$ values are reported versus Ag/AgCl electrode.

2.3. Preparation of complex $Na_3[Cr(C_6H_5O_7)_2]{\cdot}8.5H_2O$ (**1**)

A quantity of $Cr(NO_3)_3{\cdot}9H_2O$ (0.80 g, 2.0 mmol) was placed in a flask and dissolved in 3 mL of H_2O. Subsequently, citric acid (1.3 g, 6.0 mmol) was added slowly and under continuous stirring. Sodium hydroxide was then added slowly to adjust the pH to a final value of ~5.5. The resulting solution was left to stir overnight. Addition of cold ethanol at 4 °C resulted, after a couple of months, in the deposition of a pink-like crystalline material. The crystals were isolated by filtration and dried in vacuo. The yield of the reaction was 0.64 g (~49%). *Anal.* Calc. for **1**, $Na_3[Cr(C_6H_5O_7)_2]{\cdot}8.5H_2O$ (**1**), ($C_{12}H_{27}O_{22.5}Na_3Cr$, M.W. 652.31): C, 22.0; H, 4.1. Found: C, 22.2; H, 4.2%.

2.4. Preparation of complex $(Hdmphen)_6[Cr(C_6H_5O_7)_2]{\cdot}(NO_3)_3{\cdot}14H_2O$ (**2**)

A quantity of $Cr(NO_3)_3{\cdot}9H_2O$ (0.20 g, 0.50 mmol) was placed in a flask and dissolved in 3 mL of H_2O. Subsequently, citric acid (0.42 g, 2.0 mmol) was added slowly and under continuous stirring. 2,9-dimethylphenanthroline ($C_{14}H_{12}N_2$) (0.40 g, 4.0 mmol) was then added slowly to adjust the pH to a final value of ~3.5. The resulting solution was left to stir overnight. Addition of cold ethanol at 4 °C resulted, after a few days, in the deposition of a purple-like crystalline material. The crystals were isolated by filtration and dried in vacuo. The yield of the reaction was 0.30 g (~30%). *Anal.* Calc. for **2**, $(Hdmphen)_6[Cr(C_6H_5O_7)_2]{\cdot}(NO_3)_3{\cdot}14H_2O$ (**2**), ($C_{96}H_{116}CrN_{15}O_{37}$, M.W. 2124.04): C, 54.2; H, 5.5; N, 9.9. Found: C, 54.4; H, 5.5; N, 9.4%.

2.5. X-ray crystal structure determination

2.5.1. $Na_3[Cr(C_6H_5O_7)_2]{\cdot}8.5H_2O$ (**1**)

X-ray quality crystals of compound **1** were grown from mixtures of water–ethanol solutions. A single crystal of **1** with dimensions 0.15 × 0.09 × 0.06 mm was mounted on an Xcalibur Oxford Diffractometer equipped with a Sapphire 3 CCD detector and a 4-cycle Kappa geometry goniometer, using an enhanced Mo X-ray source and a graphite radiation monochromator. Unit cell dimensions for **1** were determined and refined by using the angular settings of all the reflection frames in the range $6.30° < 2\theta < 60.50°$. Relevant crystallographic data appear in Table 1. Intensity data were measured by using a θ–2θ scan. Three standard frames were monitored every 35 reflections, over the course of data collection, to ensure the stability of the sample. Further experimental crystallographic details: for **1**, $2\theta_{max} = 60.64°$; 427 parameters refined; $(\Delta/\sigma)_{max} = 0.001$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.685/-0.576$ e/Å^3; R/R_w (for all data) = 0.0683/0.1051. CrysAlis CCD and CrysAlis RED software were used for monitoring data collection and carrying out data reduction/cell refinement, respectively [21,22]. The structure was solved by direct methods and refined by full-matrix least-squares techniques on F^2, by using SHELXS-97 [23,24]. Special computer molecular graphics incorporated in the WINGX 3.2 interface were used [25]. All of the non-H atoms were refined anisotropically. The methylene hydrogen atoms of the citrate ligands were introduced at calculated positions as riding on bonded atoms. The remainder of the hydrogen atoms were located by difference Fourier maps and were refined isotropically.

Table 1
Summary of crystal, intensity collection and refinement data for $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ (**1**) and $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ (**2**).

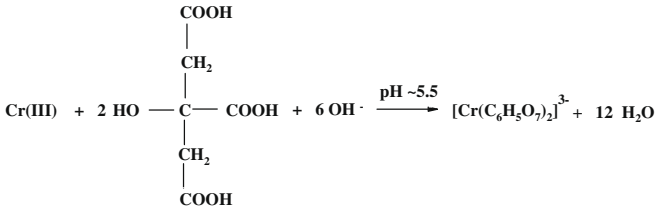
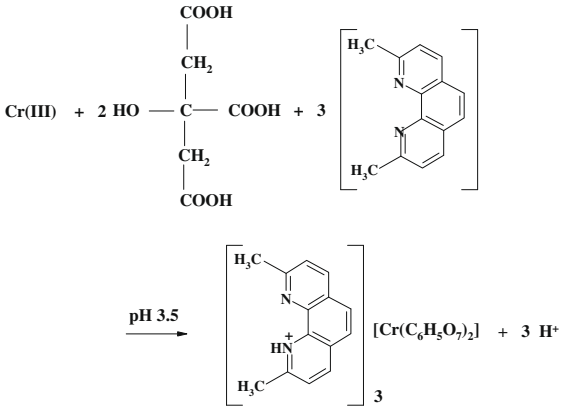
[a] R values are based on F values, R_w values are based on F^2. $R = \frac{\sum||F_o|-|F_c||}{\sum(|F_o|)}$, $R_w = \sqrt{\frac{\sum[w(F_o^2-F_c^2)^2]}{\sum[w(F_o^2)^2]}}$.
[b] For **1**: 3820, for **2**: 5180, refs. $I > 2\sigma(I)$.



2.5.2. $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ (**2**)

X-ray quality crystals of compound **2** were grown from mixtures of water–ethanol solutions. A single crystal, with dimensions 0.15 × 0.25 × 0.40 mm was mounted on a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic, using graphite monochromated Cu Kα radiation. Unit cell dimensions for **2** were determined and refined by using the angular settings of 25 automatically centered reflections in the range 22.00° < 2θ < 54.00°. Crystallographic details are given in Table 1. Intensity data were measured by using θ–2θ scans. Throughout data collection, three standard reflections were monitored every 97 reflections, and showed less than 3% variation and no decay. Lorentz, polarization, and ψ-scan absorption corrections were applied by using Crystal Logic software. Further experimental crystallographic details for **2**: $2\theta_{max}$ = 105.22°; 714 parameters refined; $(\Delta/\sigma)_{max}$ = 0.007; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.578/−0.347 e/Å^3; R/R_w (for all data), 0.0629/0.1771. The structure of complex **2** was solved by direct methods using SHELXS-97 [26], and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [23,24]. All non-H atoms in the structure of **2** were refined anisotropically. Hydrogen atoms were either located by difference maps and were refined isotropically or introduced at calculated positions as riding on bonded atoms; no H atoms for the solvate water molecules were included in the refinement. The third nitrate counterion was found disordered around an inversion center and was refined over two positions.

3. Results



3.1. Synthesis

The synthesis of compound **1** was expediently pursued through a facile reaction between Cr(III) and citric acid (molar ratio 1:3) in aqueous solutions at pH ∼ 5.5. Product **1** was also obtained in the pH-range 5–8.5. The adjustment of pH was achieved by addition of aqueous NaOH solution. NaOH served as a base for the adjustment of the pH of the reaction mixture and the concurrent generation of the counter ion for the assembled anionic complex. This behavior had been previously observed on a number of occasions in metal-citrate chemistry. The stoichiometric reaction leading to the synthesis and isolation of **1** is shown below:

The compound was isolated in pure crystalline form upon addition of ethanol to the reaction mixture at 4 °C. Elemental analysis of the isolated pink crystalline material suggested the molecular formulation $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ for **1**. Further spectroscopic inspection of **1** by FT-IR revealed the presence of citrate bound to Cr(III), thus affirming the proposed formulation. Remarkably, when the same reaction was run with a molar ratio of Cr(III):citrate 1:2, under identical reaction conditions as above, the same product was obtained at comparable yields, albeit of lower bulk crystallinity.

The synthesis of compound **2** was expediently pursued through a facile reaction between Cr(III) and citric acid (molar ratio 1:4) in aqueous solution at pH 3.5. The adjustment of pH was achieved by addition of 2,9-dimethylphenanthroline (dmphen). 2,9-Dimethylphenanthroline was also used for the concurrent generation of the counter ion for the assembled anionic complex. It is worth noting, that **2** was isolated only at this specific pH and only under the conditions specified. The stoichiometric reaction leading to the formation and isolation of **2** is shown below:

Compound **2** was isolated in pure crystalline form upon addition of ethanol to the reaction mixture at 4 °C. Elemental analysis of the isolated purple crystalline material suggested the molecular formulation $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ for **2**. Further spectroscopic inspection of **2** by FT-IR revealed the presence of citrate bound to Cr(III), thus supporting the proposed formulation.

Compounds **1** and **2** are soluble in water. There are insoluble in organic solvents, such as methanol, acetonitrile, chlorinated solvents ($CHCl_3$, CH_2Cl_2), toluene and DMF. The materials are stable in the air at room temperature for a long period of time.

3.1.1. Description of the structure: $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ (**1**)

The X-ray crystal structure of **1** reveals the presence of discrete cations and anions in the lattice. The compound crystallizes in the monoclinic space group $C2/c$. The structural diagram of **1** is shown

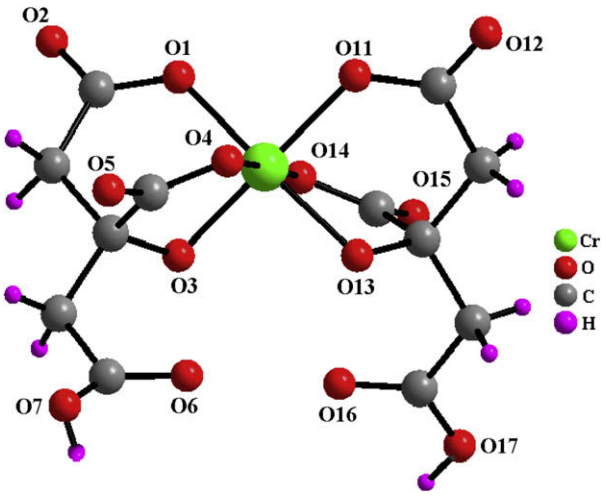


Fig. 1. Labeled plot of the structure of the $[Cr(C_6H_5O_7)_2]^{3-}$ anion in **1**.

in Fig. 1. Selected interatomic distances and bond angles for **1** are listed in Table 2. The structure of **1** consists of a mononuclear core unit composed of a central Cr(III) ion, surrounded by two citrate ligands. The latter ligands bind to Cr(III) through the central carboxylate and alkoxide oxygens, promoting the formation of a stable five-membered ring. An additional carboxylate oxygen from one of the terminal carboxylates of each citrate ligand coordinates to the central metal ion, thus occupying a third coordination site around Cr(III). The second terminal carboxylate group of each citrate does not bind Cr(III). Therefore, the six coordination sites around Cr(III) are taken up by the two citrate ligands bound in the same fashion. The arising geometry from the described citrate coordination is distorted octahedral.

The negative charge of 3- in complex **1** is counterbalanced by three sodium ions. These counter ions likely contribute to the stability of the crystal lattice through interactions with oxygen anchors from the citrate ligands and lattice water molecules. In this respect, Na(1) exhibits a coordination number 6 formulated by oxygen atoms from four different citrate ligands. Na(2) displays a coordination number 5 and binds to oxygen atoms from two different citrate ligands as well as oxygens from three water molecules. Na(3) exhibits a coordination number 6 and is bound to oxygen atoms from one citrate ligand and five water molecules. Overall, sodium ions are diversely coordinated to O-bearing anchors, contributing to the establishment of the crystal lattice (Fig. 2A and B).

Table 2
Bond lengths (Å) and angles (°) in $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ **(1)** and in $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ **(2)**.

3.1.2. $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ (**2**)

Compound **2** crystallizes in the triclinic space group $P\bar{1}$. The structural diagram of **2** is shown in Fig. 3. Selected interatomic distances and bond angles for **2** are listed in Table 2. The structure consists of a mononuclear core unit composed of a central Cr(III) ion, surrounded by two citrate ligands in the same fashion as in compound **1**. The latter ligands each bind to the metal ion through the central carboxylate and alkoxide oxygens, promoting the formation of a stable five-membered ring. An additional carboxylate oxygen from one of the terminal carboxylates of each citrate ligand binds the central metal ion, thus occupying a third coordination site around Cr(III). The second terminal carboxylate group of each citrate does not bind Cr(III). Therefore, the six coordination sites around Cr(III) are taken up by the two citrate ligands bound in the same fashion. The arising geometry from the described citrate coordination is distorted octahedral.

The deprotonation state of the citrate ligand in both complexes **1** and **2** is 3-. A triple (3-) deprotonation state for the citrate ligand had been previously observed in the case of $(NH_4)_3[Ga^{III}(C_6H_5O_7)_2]\cdot 4H_2O$ [27]. The two complexes **1** and **2**, however, are not identical. There is a distinct difference between them. Specifically, the two citrate ligands in **1** are bound to Cr(III) in such a way that (a) the five-membered cyclic rings lie above and below the planes formulated by the six membered rings [O(1),C(1),C(2),C(3),O(3),Cr] and [O(11),C(11), C(12),C(13),O(13),Cr], respectively, and (b) the non-coordinated protonated terminal carboxylates are in the syn-orientation with respect to Cr(III). In **2**, the disposition of the two ligands is dictated by the presence of a center of inversion.

The Cr–O bond distances in $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ (**1**) (1.906(2)—2.005(2) Å) and $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ (**2**) (1.956(2)–1.972(2) Å) are in line with those in other O-containing Cr(III) complexes such as $(NH_4)_4[Cr(C_6H_4O_7)(C_6H_5O_7)]\cdot 3H_2O$ (1.933(2)–1.973(2) Å) [28], $(C_5H_6N)_2[Cr(C_6H_{5.5}O_7)_2]\cdot 4H_2O$ (1.965(2)–1.987(2) Å) [29], $Na_2[Cr(C_5H_7NO_4)_2]$ (1.963(2)–1.948(2) Å) [30], $K_3[Cr(C_2O_4)_3]\cdot 3H_2O$ (1.955(2)–1.985(2) Å) [31], $K_2[Cr_2(C_6H_6NO_6)_2(OH)_2]\cdot 6H_2O$ (1.937(4)–1.983(3) Å) [32], *trans*(O_5)–Na[Cr(ed3ap)]$\cdot 3H_2O$ (ed3ap = ethylenediamine-*N*,*N*,*N*′-triacetate-*N*′-3-propionate) (1.945(6)–1.974(5) Å) [33]. Furthermore, the Cr–O bond distances in **1** and **2** are in line with corresponding bonds in other trivalent metal-citrate complexes such as $(NH_4)_3[Ga^{III}(C_6H_5O_7)_2]\cdot 4H_2O$ [27] (1.890(2)–1.900(2) Å).

It appears that angles similar to those in $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ (**1**) (82.35(6)—96.66(6)°) and $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ (**2**) (82.4(1)–97.6(1)°) are observed in a number of Cr(III)–O_6 core-containing complexes, exhibiting octahedral geometry around the Cr(III) ion. Among such complexes are $K_3[Cr(C_2O_4)_3]\cdot 3H_2O$ (81.5(1)–88.7(1)°) [31], *trans*(O_5)–Na[Cr(ed3ap)]$\cdot 3H_2O$ (ed3ap = ethylenediamine-*N*,*N*,*N*′-triacetate-*N*′-3-propionate) (81.8(1)–98.9(1)°) [33] and $[Cr(C_9H_{12}N_2O_6COOH)(H_2O)]$ (89.43(8)–97.10(10)°) [34].

In the lattice of **2**, there exist intermolecular hydrogen-bonding interactions involving the $[Cr(C_6H_5O_7)_2]^{3-}$ anion, the NO_3^- and $Hdmphen^+$ ions, and the solvate water molecules, which result in the formation of a 2D network extending parallel to the (1 0 1) plane (Fig. 4, Table 3).

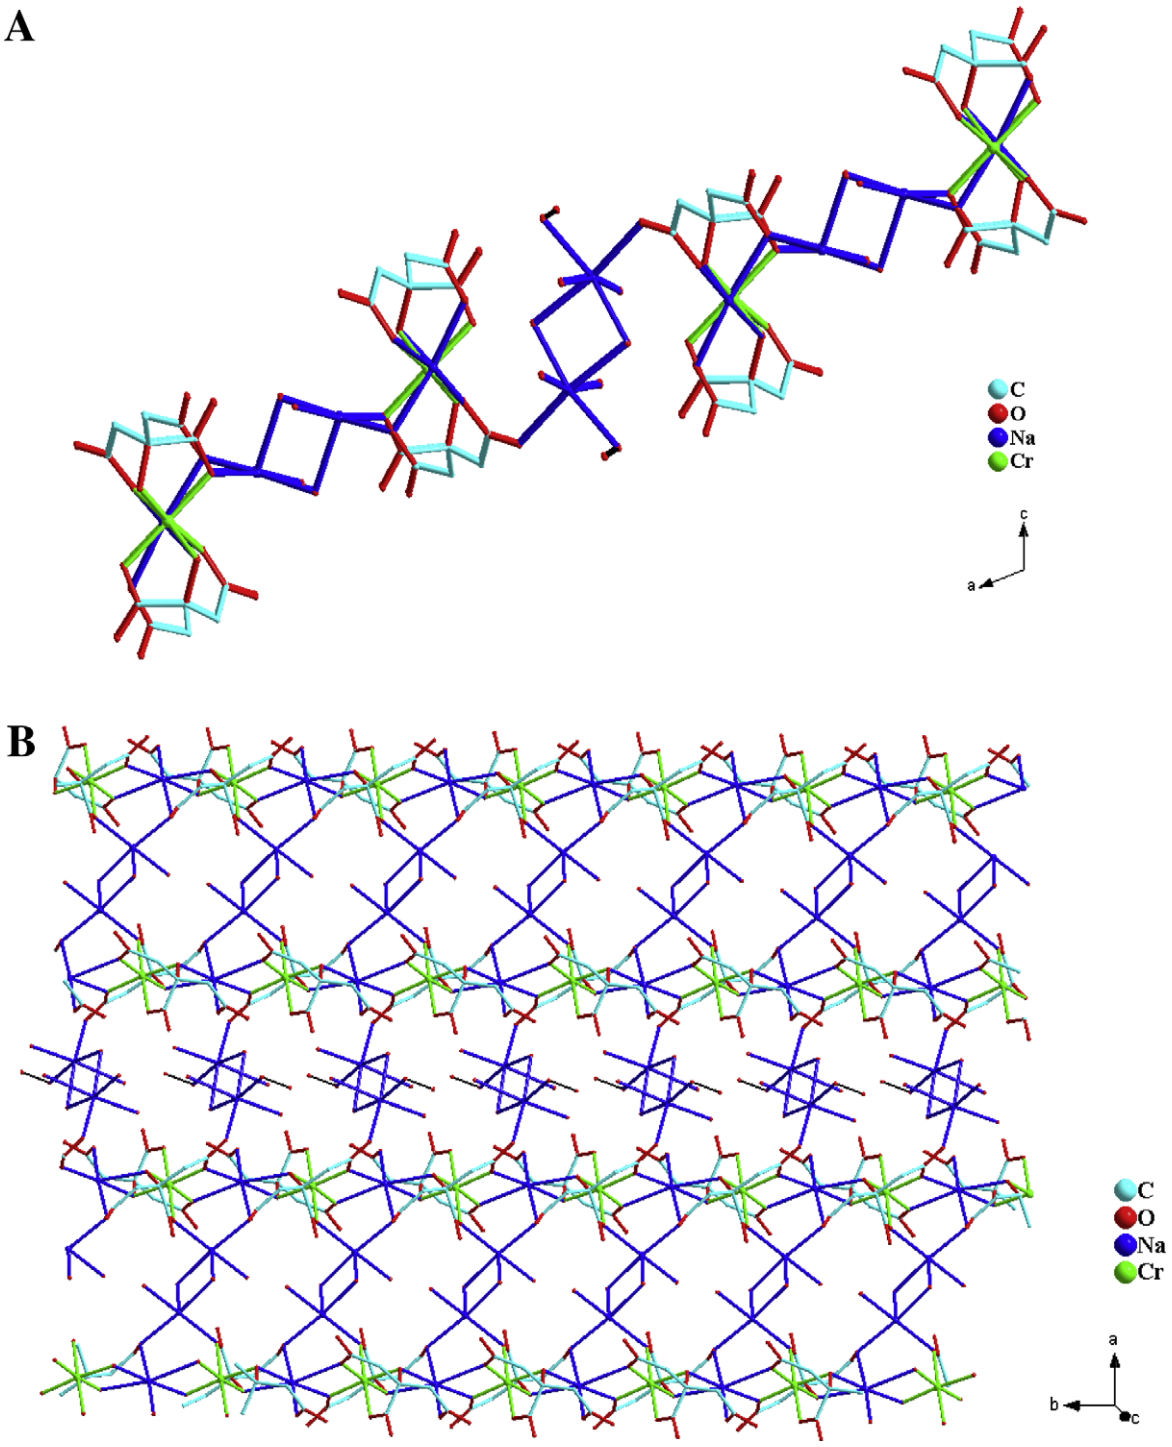

Fig. 2. Packing diagram of **1** along the *ac* (A) and off the *ab* (B) plane.

4. Electronic spectroscopy

The UV–Vis spectra of **1** and **2** were taken in water and are the same. The spectrum of **1** shows a band at $\lambda_{max} = 564$ nm (ε 48 M^{-1} cm^{-1}). At higher energies, a shoulder-like band appears at 443 nm ($\varepsilon \sim 19$ M^{-1} cm^{-1}), ultimately reaching a well-formed major peak at $\lambda_{max} = 395$ nm (ε 51 M^{-1} cm^{-1}). The absorption features are likely due to d–d transitions, which are typical of a Cr(III) d^3 (^4F) octahedral species [35]. The band at 564 nm could be tentatively attributed to the $^4A_{2g} \rightarrow {}^4T_{2g}$ transition. In an analogous fashion, the band at 395 nm could be assigned to the $^4A_{2g} \rightarrow {}^4T_{1g}(F)$ transition. No further definitive assignments could be made in the absence of detailed specific studies.

5. FT-IR spectroscopy

The FT-Infrared spectra of **1** and **2** in KBr revealed the presence of vibrationally active carboxylate groups. Antisymmetric as well as symmetric vibrations for the carboxylate groups of the coordinated citrate ligands were present. Specifically, antisymmetric

Ow7···Ow3	2.840			x, y, z

stretching vibrations $\nu_{as}(COO^-)$ for the carboxylate carbonyls appeared in the range 1616–1579 cm^{-1} for **1** and in the range 1641–1603 cm^{-1} for **2**, respectively. Symmetric vibrations $\nu_s(COO^-)$ for the same groups were present around 1384 cm^{-1} for both **1** and **2**.

The frequencies of the observed carbonyl vibrations were shifted to lower values in comparison to the corresponding vibrations in free citric acid, indicating changes in the vibrational status of the citrate ligand upon binding to Cr(III) [36]. The difference between the symmetric and antisymmetric stretches, $\Delta(\nu_{as}(COO^-) - \nu_s(COO^-))$, was greater than 200 cm^{-1}, indicating that the carboxylate groups of the citrate ligand were either free or coordinated to Cr(III) in a monodentate fashion [37]. This contention was subsequently confirmed by the X-ray crystal structure of **1** and **2**. All of the above assignments were in agreement with past assignments in mononuclear Cr(III)–O_6 complexes [38], and in line with previous reports on carboxylate-containing substrates bound to variable nature metal ions [39–46].

6. Magnetic susceptibility studies

Magnetic susceptibility studies were carried out on both **1** and **2**. It appears that the two species exhibit the same behavior over the temperature range 2–300 K. Consequently, only the data for **1** are presented here. The temperature dependence $\chi_M T$ (χ_M being the magnetic susceptibility for one Cr(III) ion) for complex **1** is shown in Fig. 5A (solid stars). The $\chi_M T$ value is 1.94 emu mol^{-1} K at 300 K, higher than the value expected for an isolated ion of Cr(III), which is 1.87 emu mol^{-1} K. In the range from 300 to 10 K, there is a smooth linear decrease, while after that temperature and down to 2 K a more pronounced decrease occurs reaching the value of 1.64 emu mol^{-1} K. The shape of this curve is characteristic of the occurrence of large zero field effects along with a temperature independent paramagnetism (TIP) effect. The large zero effects are responsible for the drastic decrease of the susceptibility data in the low temperature range, while the latter effect leads to a

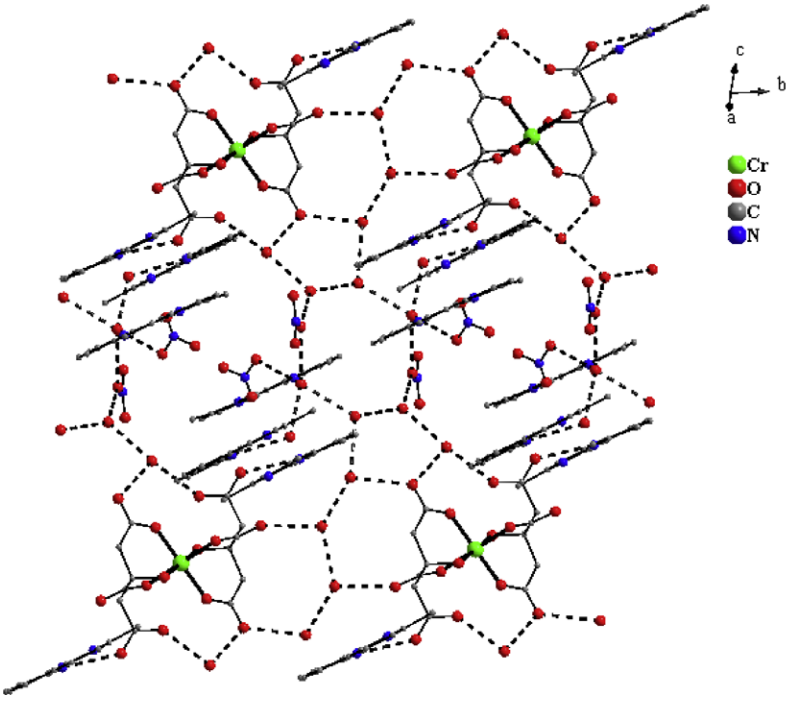

Fig. 4. Part of the 2D network in the lattice structure of **2** due to intermolecular hydrogen-bonding interactions. H bonds are shown as dashed lines.

linear temperature dependence of the susceptibility data in the high temperature range. The susceptibility data were fitted by the following equation:

$$H = D\left[S_z^2 - \frac{1}{3}S(S+1)\right] + E(S_x^2 - S_y^2) + g_z\mu_B H_z S_z + g_x\mu_B H_x S_x + g_y\mu_B H_y S_y \quad (1)$$

where an isotropic g-value was used. The best fit (solid line in Fig. 5A) is given by the parameters $D = 0.78(1)\,cm^{-1}$ and $g = 1.97(1)$, TIP = 800×10^{-6}.

Isothermal magnetization curves at $T = 1.8$–2.5–5 K in an applied field 0–5 T are shown in Fig. 5B. The data were fitted using (Eq. (1)) and the best fit (solid line in Fig. 5B) is given by the parameters of $D = 0.80(1)\,cm^{-1}$, $g = 1.97(1)$ for all temperatures, very close to the values obtained from the susceptibility study, thus verifying the large zero field character of the system.

7. EPR studies

7.1. Solid-state powder spectrum

X-band EPR measurements were carried out on powder samples of **1** and are shown in Fig. 6 (Top). An isotropic magnetic-field domain line width was used for the powder spectrum ($lw = 35$ G), while the broadness of the spectrum reveals the presence of g-strain effects. Gaussian distributions of the g-principal values were used and the results are ($\sigma g_x = \sigma g_y = 0.1$, $\sigma g_z = 0.2$). The principal g-values for the powder spectrum are $g_{xy} = 1.96(1)$, $g_z = 1.98(1)$. The values for the crystal field terms are: $D = 0.45(2)$ cm^{-1} and $\lambda = E/D = 0.30(2)$, revealing the rhombic character of the system. Gaussian distributions of the D and E parameters were also used ($\sigma(D) = 0.3$, $\sigma(E) = 0.03$). The simulation of the powder EPR spectrum of complex **1** verifies the large value of the D parameter, calculated from the simulation of the magnetization curve. The spectrum of **2** was not taken in the solid state.

7.2. Solution spectrum

The EPR spectra of **1** and **2** in aqueous frozen solution are the same. Therefore, only the spectrum of **1** is discussed here (Fig. 6 – Bottom). The effective g-value $g \approx 4$ of the complex is typical of an electronic spin $S = 3/2$, with moderately large zero field splitting (ZFS) and small rhombicity ($D > h\nu \approx 0.3$ cm^{-1} at X-band; $E/D \approx 0$) parameters. In this regime of ZFS, the spin quartet is split into two Kramers doublets, |3/2, ±1/2> and |3/2, ±3/2>, for virtually all fields applied in the EPR spectrometer, with EPR transitions occurring only within these doublets. For $E/D = 0$, only the $m_s = \pm 1/2$ doublet is EPR detectable, whereas the $m_s = \pm 3/2$ doublet is EPR silent. In this limiting case of a large axial ZFS ($D \gg h\nu$, $E/D = 0$), the effective g-values for |3/2, ±1/2> would be expected at (a) $g_{perpendicular} = 2S + 1$ for fields applied in the x/y directions, and (b) $g_{parallel} = 2$ along z, which is in close agreement with the experimental findings. The simulations showed that the experimental line shape can not be reproduced by a single $S = 3/2$ species with a well defined value for E/D, even if one employs angular dependent line

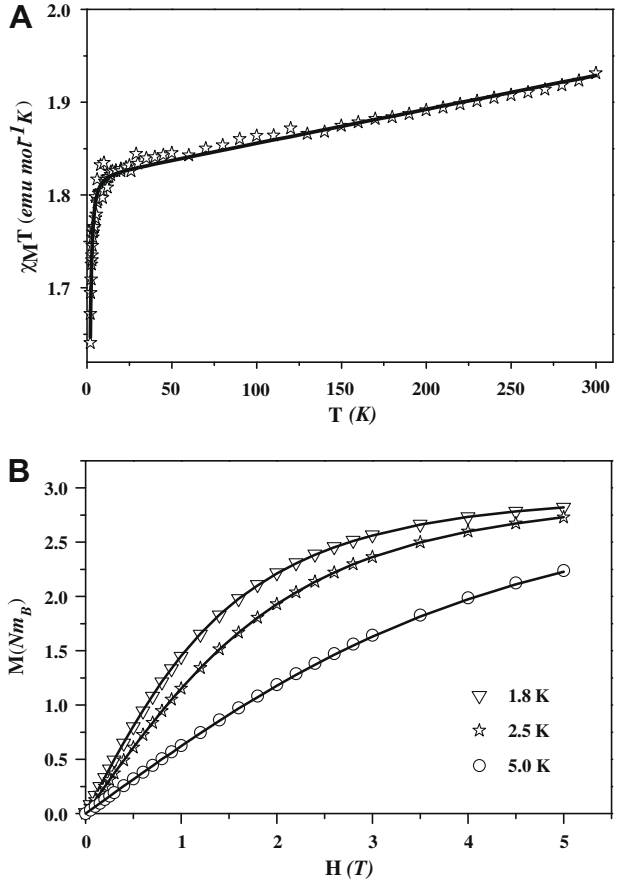

Fig. 5. A. Temperature dependence of the susceptibility data in the form of $\chi_M T$ vs. T (solid stars) and fitting results using the theoretical formula discussed in the text (solid line). B. Magnetization measurements in the field range 0–5 T and at temperatures (1.8, 2.5, 5.0 K), and fitting results using the theoretical formula discussed in the text (solid line).

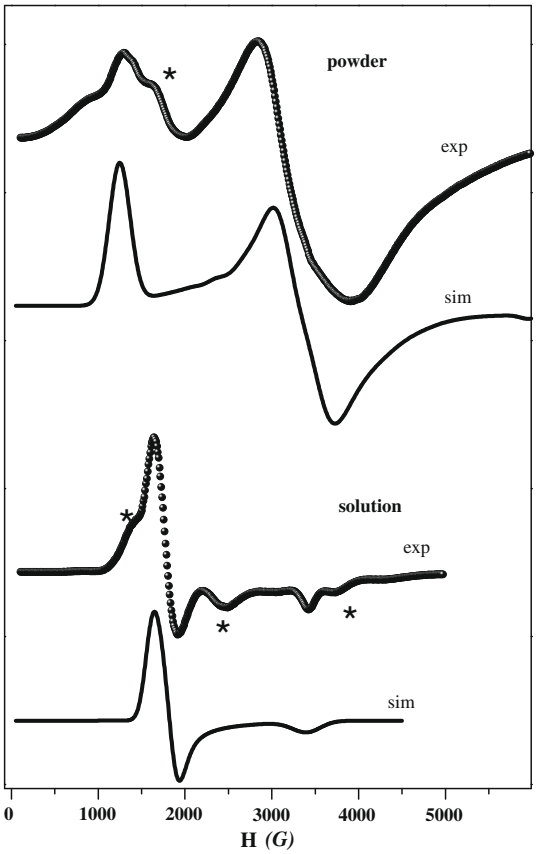

Fig. 6. (Top) Experimental X-Band EPR powder spectra of complex **1** at 4 K along with the simulated spectrum. (Bottom) Experimental X-Band EPR frozen solution spectra of complex **1** at 4 K along with the simulated spectrum. The microwave resonance is 9.43 GHz.

shape distributions of the type $W^2 = \sqrt{\sum W_i^2 l_i^2}$, where l_i denotes the direction cosines of the applied field. An isotropic magnetic-field domain line width was used for the powder spectrum (lw = 25 G), while the broadness of the spectrum reveals the presence of g-strain effects. Gaussian distributions of the isotropic g-value were used ($\sigma g = 0.1$) and the isotropic g-value for the solution spectrum was $g = 1.96(1)$. The values of the crystal filed terms are $D = 1.6(2)\,cm^{-1}$ and $\lambda = E/D = 0.06(2)$ and the Gaussian distributions of the D and E parameters were ($\sigma(D) = 0.3$, $\sigma(E) = 0.03$).

Both simulation procedures were unable to reproduce all the features of the experimental spectra (see asterisks in Fig. 6). Very likely, the population of excited states as well as the inclusion of other terms in the Hamiltonian formalism such as antisymmetric or intermolecular interactions must be taken into consideration. However, such an overparameterization of the final Hamiltonian could lead to parameters with no physical meaning. To this end, no further attempt was made to improve our simulations.

8. Thermal studies

The thermal decomposition of complex **1** was studied by TGA–DTG under an atmosphere of oxygen. Compound **1** is thermally stable up to 65 °C. From that point on, an initial process points to dehydration, with the release of lattice water between 65 and 296 °C, signifying an endothermic process. The observed weight loss amounts to 24.6%, a value close to the calculated value of 24.5% based on the molecular formula of the title complex. Beyond this point, there are multiple steps between 296 and 504 °C involving the decomposition of the organic part of the molecule. No clear plateaus are reached in these stages, suggesting that the derived products are unstable and decompose further. The total weight loss of 55.3% due to the decomposition of the title complex is reached at 504.7 °C with no further loss up to 1000 °C. The DTG profile of the complexes exhibits clear features that depict the aforementioned TGA process.

9. Cyclic voltammetry

Electrochemical measurements for **1** were taken in water, in the presence of KNO_3 as a supporting electrolyte (Fig. 7). A Pt electrode was used as a working electrode and an Ag/AgCl electrode served as a reference electrode. The cyclic voltammogram of **1** reflects a one electron chemically reversible process ($ip_a/ip_c = 1$, $ip_c/\{(v)^{1/2}C\}$ constant) with a value of $E_{1/2} = -615$ mV that corresponds to the Cr(III)/Cr(II) redox couple. Attempts to pursue the isolation of the one electron reduced product of the title complex **1** are currently ongoing.

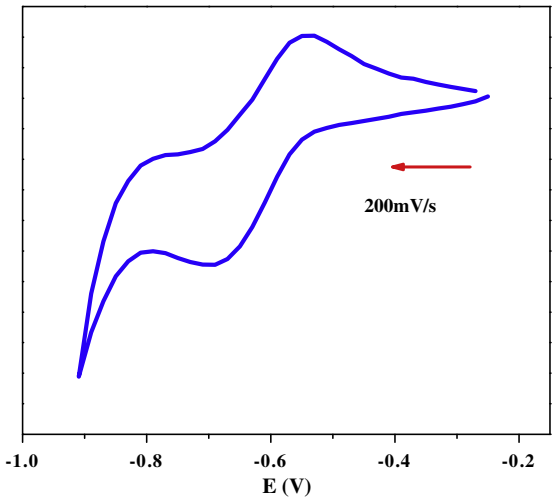

Fig. 7. Cyclic voltammetry of **1** in water (scan rate 200 mV/s).

10. Discussion

The current investigation of the binary Cr(III)–citrate system has led to the emergence of two new mononuclear Cr(III)–citrate species $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ (**1**) and $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ (**2**), with specific properties (analytical, spectroscopic, electrochemical, thermal, magnetic and structural). The following major points are worth pointing out in this work:

(a) The species were synthesized and isolated at specific yet distinct pH values i.e. 5.5 and 3.5, with the use of two different cations arising from the associated bases sodium hydroxide and 2,9-dimethylphenanthroline, respectively. Nevertheless, the isolated complexes contain the same type of anion $[Cr(C_6H_5O_7)_2]^{3-}$, with the two citrate ligands bound to Cr(III) being triply deprotonated, thus leading to the overall charge of 3- for both anionic species.

The structural characterization of **1** and **2** showed that Cr(III), a rather kinetically inert metal ion, follows a similar reactivity with other trivalent metal ions in its aqueous chemistry toward α-hydroxycarboxylic acids, such as citric acid. In fact, the nature of the isolated complexes **1** and **2** is similar to that of the Al(III) and Ga(III) congener species already studied synthetically and structurally. Characteristic examples of relevant anionic M(II,III) complexes include $[Cr(C_6H_4O_7)(C_6H_5O_7)]^{4-}$ [28], $[Al(C_6H_4O_7)_2]^{5-}$ [39], $[Al(C_6H_4O_7)(C_6H_5O_7)]^{4-}$ [47], $[Ga^{III}(C_6H_5O_7)_2]^{3-}$ [27], $[Fe(C_6H_4O_7)_2]^{5-}$ [40], $[Mn(C_6H_4O_7)_2]^{5-}$ [42], $[Mn(C_6H_5O_7)_2]^{4-}$ [42], $[Co_2(C_6H_5O_7)_2(H_2O)_4]^{2-}$ [48], $[Co_2(C_6H_5O_7)_2]^{2-}$ [41] and $[Ni(C_6H_5O_7)(H_2O)_2]_2^{2-}$ [49]. A worth noting remark in the aforementioned series of studied M(III) and M(II)–citrate complexes is that they exhibit variable deprotonation states for the bound citrate ions i.e. 3- and 4-. In the case of **1** and **2**, the deprotonation state of citrate is 3-. A binary species of Cr(III), $(NH_4)_4[Cr(C_6H_4O_7)(C_6H_5O_7)]\cdot 3H_2O$, bearing both triply and fully deprotonated citrate ligands has been synthesized and characterized [28].

The importance of the degree of deprotonation of the Cr(III)-bound citrates is linked to an important observation on the structural identity of **1** and **2**. Specifically, the hydrogen of the non-coordinated terminal carboxylate group of citrate in **2** forms a hydrogen bond with the alkoxide oxygen of the same ligand. This property is specific to the structure of the anion in **2**. No such hydrogen bond exists in the case of the anion in **1**. Therefore, the ability of the triply deprotonated citrate ligand bound to Cr(III) to form an intramolecular hydrogen bond provides an imprint of the conformational identity of compound **2** in comparison to that of compound **1**. That H bond formation in concert with the presence of an appropriately large counter ion (such as $Hdmphen^+$) and nitrate ions may contribute to favorable lattice dynamics necessary to differentiate the solid state structure of **2** relative to that in **1**.

Furthermore, an equally remarkable characteristic of the two compounds **1** and **2** is their distinct structural conformation in the solid state (vide supra). That is reflected into the disposition of the two citrates bound to the Cr(III) ion and suggests that pH-structural variants exist in the requisite binary system. In solution, spectroscopic data (UV–Vis, EPR) support the same identity for both **1** and **2**, with the solid state conformers very likely interconverting rapidly so that it is not easy to discern them as discrete species. Their solid state identity is exemplified through the use of appropriate counter ions giving rise to discrete lattice dynamics and favoring their isolation. It appears, therefore, that under carefully screened and tuned reaction conditions, favorable lattice

dynamics may lead to the capture of conformational structural variants of binary Cr(III)–citrate species that otherwise would not have been able to distinguish easily in solution. That contention may also apply to other binary metal–hydroxycarboxylate systems containing hitherto unknown compounds. To this end, the employment of the Na^+ and $Hdmphen^+$ counter ions (vide infra) facilitates "trapping" of the two conformers in the solid state. Interestingly, the magnetic susceptibility profiles of the two species are the same over the temperature range studied. Ostensibly, the conformational signature of the two species in the solid state does not influence the magnetic susceptibility behavior of Cr(III). It may very well be that the immediate Cr(III)–O_6 coordination sphere in **1** and **2** is rather insensitive to magnetic susceptibility differentiation despite the existing distinctly variable conformational status of the two species.

(b) The importance of cations in the synthetic process leading to the isolation of variable nature binary Cr(III)–citrate complexes from aqueous media is amply exemplified in **1** and **2**. The cations employed in this and previous work [28] on the specific Cr(III)–citric acid binary system derive from the use of inorganic (NaOH, KOH, etc.) and organic bases (dmphen), both acting as essential pH-adjustment agents while concurrently providing the necessary counter ions to balance the arisen charge on the assembled metal ionic complex in solution. Albeit of both inorganic (K^+, Na^+, etc.) and organic ($Hdmphen^+$) nature, these cations affect the solubility of species arising at the specific pH at which the reaction mixture is adjusted, thus influencing (1) the lattice dynamics of the species synthesized and ultimately isolated, and (2) the isolation of variable nature metal ionic complexes at the same or different pH of the aqueous synthesis medium. To this end, the nature of bases from which the cations emerge, the cations themselves, the bulkiness of the cations, the ability of counter ions to (1) interact with solvent molecules and the assembled metal ionic complex, and (2) influence packing forces involved in crystal lattice dynamics, all project the importance of cations in the synthesis of metal ionic complexes, not unlike those in the Cr(III)–citrate system. Undoubtedly, cation significance in delineating the structural speciation of the herein investigated binary system has been high, in view of the fact that (1) pH-structural Cr(III)–citrate variants bearing citrate at different deprotonation states, and (2) pH-structural conformers of the same binary variant Cr(III)–citrate complex (**1** and **2**) could be isolated from the requisite speciation scheme. It is worth pointing out that in other metal–hydroxycarboxylate systems, the employment of cations, originating in the use of bases for the mere adjustment of the pH of the reaction mixture, has not resulted in their participation in the isolated respective lattice, thus influencing again the nature of the isolated metal–ligand assembly (charged or uncharged) [50,51]. Hence, the use of variable nature cations appears to play an important role in the synthetic and structural delineation of binary M(II,III)–ligand aqueous speciation distributions.

(c) The alcoholic moiety of the citrate ligand is deprotonated upon binding to Cr(III). The derived alkoxide group participates in the formation of the five-membered cyclic ring, which further stabilizes the entire mononuclear complex. A similar behavior was observed in the case of other trivalent metal ions such as Al(III), Ga(III), Mn(III) and Fe(III) in aqueous binary systems with citric acid. This is in contrast to the congener complexes of citrate with divalent metal ions, in which the alcoholic moiety in the five member metallacyclic ring remains protonated. The structural features in **1** and **2** seem to be in line with the previously reported $(NH_4)_4[Cr(C_6H_4O_7)(C_6H_5O_7)]\cdot 3H_2O$ [28] and in contrast to the reported complex $(C_5H_6N)_2[Cr(C_6H_{5.5}O_7)_2]\cdot 4H_2O$ [29]. In the latter case, it appears that the alkoxide groups of the two citrate ligands share a proton (half occupancy), thus reflecting partial deprotonation of the alcoholic moiety bound to Cr(III). Undoubtedly, more Cr(III)–citrate pH-structural variants need to be synthesized, isolated and characterized crystallographically in order to settle the issue of deprotonation state of the citrate alcoholic moiety. Such work is currently under way.

(d) In previous work, solution speciation studies were reported on the binary Cr(III)–citric acid system [28]. An important species arising into that speciation scheme was the mononuclear complex $[CrL_2H_{-1}]^{4-}$, reflected into the known $(NH_4)_4[Cr(C_6H_4O_7)(C_6H_5O_7)]\cdot 3H_2O$ [28] complex synthesized and isolated in the solid state. By analogy to the behavior of $(NH_4)_4[Cr(C_6H_4O_7)(C_6H_5O_7)]\cdot 3H_2O$ in the solid state and in solution, the collective spectroscopic and structural data for complexes **1** and **2** suggest that they (a) not retain their crystal structure in solution, and (b) dissociate in solution. In light of the above information, knowledge of (a) the nature of the binary Cr(III)–citrate and by extension other Cr(III)–hydroxycarboxylate species present at pH-specific values in solution, and (b) the physical and chemical properties of the potential speciation participants across the physiological pH-range, will undoubtedly contribute to the understanding of the bioavailability of soluble Cr(III) forms as a prerequisite to (i) its biochemical interactions with low and high molecular mass cellular targets, and (ii) any potential influence of Cr(III) binary and ternary species on toxicity effects or support of cellular physiology.

11. Cr(III) solubility and potential toxicity

Chromium is encountered in forest soils, sediments [52], leather tanning industries and laboratories, and surface and atmospheric waters. Two thermodynamically stable states of chromium exist in that variety of environments, namely Cr(III) and Cr(VI). In biological systems, chromium activities include well-established genotoxic, mutagenic, and carcinogenic actions of Cr(VI) compounds and a more controversial role of Cr(III) as an insulin potentiator in glucose and fat metabolism [53]. A generally accepted mechanism of Cr(VI)-induced genotoxicity [54] involves the following main steps: (i) active transport of Cr(VI) into cells (through anion channels for soluble chromates or through phagocytosis for insoluble compounds such as $PbCrO_4$), (ii) reduction of Cr(VI) within the cells or at the cell surface linked to the formation of potentially DNA damaging Cr(V)/Cr(IV) intermediates (which can be stabilized by intracellular ligands) and organic radicals, (iii) formation of kinetically inert Cr(III) complexes, including highly genotoxic ternary DNA–Cr(III)–protein and DNA–Cr(III)–DNA cross linked species, as a result of such reduction. X-ray absorption spectroscopic (XAS) studies on single cells [54] have confirmed the predominance of the Cr(III) oxidation state in Cr(VI)-treated mammalian cells. In contrast to Cr(VI), most Cr(III) complexes to which cells are exposed, are non-cytotoxic and non-mutagenic even at mM concentrations [55], presumably due to the low cellular permeability related to their octahedral geometry and kinetic inertness [56]. On the other hand, one of the less-studied aspects of Cr(VI)-induced genotoxicity is the possibility of intracellular re-oxidation of Cr(III) complexes accumulated in Cr(VI)-treated cells [54,57–59]. Re-oxidation, involving reactive oxygen species (ROS) arising through the action of cellular redox enzymes, could potentially lead to genotoxic Cr(V)/Cr(IV) complexes and be blamed for the long-term toxicity and carcinogenicity of Cr(VI), when the latter metal ion finds its way into the cellular environment [54,58–60]. Furthermore, a recent thesis [60] has related the reported antidiabetic activities of some Cr(III) complexes [60] to their intra- or extra-cellular oxidation to Cr(VI)/Cr(V) species, which can act as phosphatase inhibitors by mechanisms not unlike those of well-known insulin-mimetic V(V) species [61,62] (its worth pointing out that Cr(VI) is isoelectronic to V(V)). In this regard, it has been shown that Cr(III) dietary supplements could be

oxidized to Cr(VI) by a) biological inorganic oxidants (H_2O_2, OCl^-), or b) enzymatic oxidation, with the emerging Cr(VI) (and Cr(V)) being very efficient inhibitors of phosphatase enzymes in much the same way as V(V) [60]. Enzyme inhibition is one of the postulated mechanisms of the antidiabetic activity of V(IV)/V(V) complexes [62,63].

In view of the above information, it appears that knowledge of well-characterized soluble forms of Cr(III) is important in understanding (a) its aqueous chemistry at the molecular level, and (b) any subsequent toxic repercussions that it potentially gives rise to in the cellular environment. Given that solubility is a prerequisite for bioavailability, with the latter being strongly linked to toxic effects, the presence of well-characterized species of Cr(III) could contribute to (a) comprehending early steps of toxicologically significant chemical processes, and (b) associating initial forms of chromium with cellular damage.

In the present case, the pH-specific chemistry of the binary system Cr(III)–citric acid afforded two species, which can be isolated in a pure crystalline form, studied and characterized. In this effort, the spectroscopic and structural characterization of **1** and **2** in the solid state and in solution projects their distinct fingerprint signature in the progressively growing family of binary Cr(III)–citrate species. Therefore, key physicochemical properties of new Cr(III)–hydroxycarboxylate species have become known and could be used in: (a) the design and development of methodologies for the sensitive and selective detection [63] of that metal ion in a variety of aqueous media (environment, bacteria, plants, humans), and (b) the assessment of the potential of Cr(III) to influence cellular physiology and/or inflict toxic damage to cellular structures.

12. Cr(III) precursors to new materials

Chromium has been known to be a component of multifunctional materials. To this end, chromium is an essential component, among others, of (a) binary Cr/W oxide thin film materials destined for gas sensing [64], (b) Cr-substituted hematites and magnetite materials relevant to the removal of corrosion products-deposits on iron-based alloys in Pressurized Water Reactors [65,66], and (c) mixed oxides of the type $La_{0.9}Sr_{0.1}Ni_{1-x}Cr_xO_3$ exhibiting a perovskite structure [67]. Materials with a perovskite phase are prepared by the citrate method and used as catalysts involving H_2O_2 decomposition. To this end, structurally, spectroscopically and magnetically well-characterized Cr(III) precursor species (vide supra) are needed for the expedient synthesis of new materials leading to the preparation of mixed metal perovskite phases such as the ones mentioned above. Furthermore, synthetic binary and/or ternary Cr(III)–L complexes could facilitate processes leading to the synthesis of new materials destined for an array of technological applications. In this regard, well-characterized Cr(III) complexes with (hydroxy)carboxylate-containing substrates could be competent starting materials for the preparation of variable temperature solid-state phases. Hence, compounds **1** and **2** could serve as promising starting agents in the synthesis of advanced materials.

In line with the aforementioned, a significant area of technology where (a) the nature of the hydroxycarboxylate ligand is important in promoting reactivity toward metal-based (e.g. Cr(III)) starting reagents, and (b) binary Cr(III)–hydroxycarboxylate species could be competent starting agents influencing novel synthetic materials processes, is that of molecule-based magnets. In such materials, the metal ionic binder oxalate (ox) has been demonstrated to be one of the most versatile ligands used in relevant synthetic investigations. As a bidentate chelate linker, it can assist in the tuning of the magnetic properties of materials. To this end, the topology, dimensionality and sign of magnetic exchange can be tuned in emerging systems, thus allowing for the preparation of novel magnetic materials (hybrid magnets [68,69], chiral magnets [70,71], conducting magnets [72] or photoactive magnets) [73,74]. Such versatility is extensively reflected into the employment of dinuclear metal–oxalate complexes. These compounds are obtained by using a $[M^{III}(ox)_3]^{3-}$ octahedral species as a ligand toward paramagnetic divalent ions. Initially, the chemical reactivity affords anionic oligomeric species in solution. Subsequently, employment of bulky cations in the media leads to the self-assembly of these molecular species and formation of insoluble coordination polymers. The first successful example of such an approach was reported by Okawa et al. in the early 1990s. It was then reported that addition of a bulky monovalent cation, such as alkylammonium, affords layered 2D compounds bearing the general formula $[A][M^{II}M^{III}(C_2O_4)_3]$ ($M^{(II)}$ = Mn, Fe, Co, Ni, Cu, Zn; $M^{(III)}$ = Cr, Fe, V, Ru, Mn; A = counter ion). Depending on the identity of the divalent and trivalent metal ions, these compounds behave as ferromagnets, ferrimagnets or weak ferromagnets with critical temperatures between 6 and 45 K [75–83]. Substitution of the bulky monocation by tris(bipyridyl) metal complexes $[M_1^{II}(bpy)_3]^{2+}$ (M_1 = Fe, Co, Ni, Ru; bpy = $C_{10}H_8N_2$) facilitates formation of extended bimetallic oxalate-based 3D networks: $[M_1^{II}(bpy)_3][ClO_4][M^{II}M^{III}(C_2O_4)_3]$ (where M_1(II) and M(III) may or may not be the same). These compounds exhibit ferro- and ferrimagnetic behavior, with lower ordering temperatures than their 2D counterparts. Contrary to the previous cations, the flat $[K(18\text{-crown-}6)]^+$ cation induces reduction of the dimensionality, yielding other less connected 2D anionic layers and even 1D chains [84,85]. These systems, too, reach magnetic ordering at lower temperatures than their 2D counterparts. Other cations, with the help of capping ligands, allow for even further decrease in the dimensionality, thus yielding discrete polynuclear compounds, such as dimers [86–89], trimers [90–92], or tetramers [93–97]. In the framework of such an approach, Cr(III)–citrate complexes could be viable starting materials (synthons) providing soluble metal ionic centers (a) accessible to reactive hetero- or homo-metal ionic complex or cluster species, and (b) eliciting the promotion of interactions toward divalent metal ions, potentially giving rise to novel magnetic materials. This work is currently in progress in our lab.

13. Conclusions

One of the two predominant ionic forms of chromium in nature, Cr(III), was found to (a) react with citric acid, a low molecular mass physiological agent of many structural and chemical attributes, under pH-specific conditions, and (b) afford two new binary Cr(III)–citrate complexes $Na_3[Cr(C_6H_5O_7)_2]\cdot 8.5H_2O$ (**1**) and $(Hdmphen)_6[Cr(C_6H_5O_7)_2]\cdot(NO_3)_3\cdot 14H_2O$ (**2**). The two conformationally discrete pH-structural variants complement the already known Cr(III)–citrate species, justifying the focused effort to delineate the structural speciation of the binary Cr(III)–citrate system. Both **1** and **2** were characterized spectroscopically, structurally and magnetically, thus providing essential information on the relevant binary interactions under pH-variable conditions and molecular stoichiometries dictated by a plethora of factors in abiotic or biological settings. Given that well-characterized forms of Cr(III) in the presence of citrate are likely involved in (bio)chemical processes, underlying physiological and/or toxic manifestations linked with that metal ion's involvement in biological media, further studies targeting (a) the synthesis and characterization of binary and ternary Cr(III)-hydroxycarboxylate-L (L = O-, N-containing substrate) species, and (b) the investigation of the solution chemistry of such species toward variable molecular mass substrates, are needed. Collectively, such studies are expected to provide good understanding of the chemical reactivity of Cr(III) in binary and ternary systems, under variable conditions, leading to species (a)

of specific structural, spectroscopic and magnetic properties, and (b) useful in the development of technologically apt materials. Studies along these lines are currently in progress in our lab.

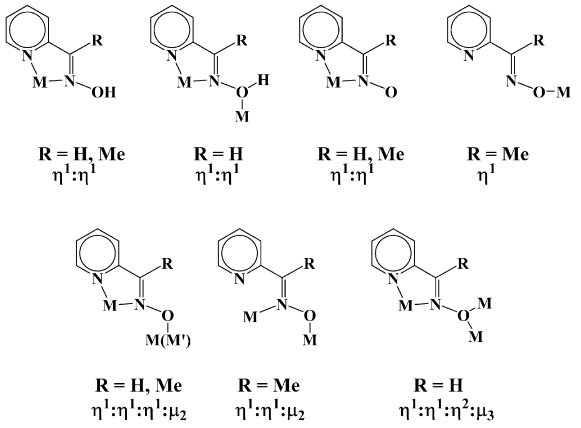

Scheme 1. The 2-pyridyl ketone oxime ligands discussed in the text.

characterized Fe^{III} carboxylato complex of pyC(Me)NOH; its molecular structure contains the $[Fe_4(\mu_3\text{-}O)_2]^{8+}$ 'butterfly' core, and the pyC(Me)NO$^-$ adopts the $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ coordination mode (Scheme 2).

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials as received (Aldrich Co). All chemicals and solvents were reagent grade. The basic iron(III) benzoate $[Fe_3O(O_2CPh)_6(H_2O)_3]Cl$ was synthesised by addition of 2.2 equivalents of NaO_2CPh in an aqueous solution of $FeCl_3{\cdot}6H_2O$. The immediately formed orange precipitate was filtered, washed with Et_2O and dried in vacuo. Methyl 2-pyridyl ketone oxime, pyC(Me)NOH, was synthesised by the reaction of equimolar quantities of 1-pyridin-2-ylethanone (2-acetyl-pyridine). pyC(Me)O, $H_2NOH{\cdot}HCl$ and NaOEt in EtOH [12]. Elemental analyses for carbon, hydrogen, and nitrogen were performed using a Perkin–Elmer 2400/II automatic analyzer. Infrared spectra were recorded as KBr pellets in the range 4000–400 cm^{-1} on a Bruker Equinox 55/S FT-IR spectrometer. Mössbauer spectra for **2** was taken with a constant acceleration spectrometer using a ^{57}Co (Rh matrix) source at RT and a variable temperature Oxford cryostat. Variable-temperature magnetic susceptibility measurements for **2** were carried out on polycrystalline samples in the 2.0–300 K temperature range using a Quantum Design MPMS SQUID susceptometer under a magnetic field of 0.5 T. Data were corrected with standard procedures for the contribution of the sample holder and diamagnetism of the sample. The calculation of the magnetic susceptibility was accomplished by analytical calculation

Scheme 2. The crystallographically established coordination modes of pyC(R)NOH and pyC(R)NO$^-$ (R = H, Me).

of the energy levels associated with the spin Hamiltonian. Minimization was carried out with an adapted version of MINUIT [13]. The error factor R is defined as $R = \sum \frac{x_{exp}-x_{calc}}{Nx^2_{exp}}$, where N is the number of experimental points.

2.2. Compound preparation

2.2.1. $[Fe_4O_2Cl_2(O_2CPh)_2\{pyC(H)NO\}_4]$ (**1**)

2.2.1.1. Method A. A colorless solution of pyC(H)NOH (0.061 g, 0.50 mmol) in dmf (10 mL) was added to a stirred suspension of NaO_2CPh (0.144 g, 1.00 mmol) in dmf (20 mL). The stirring continued for 5 min until an orange solution of $FeCl_3{\cdot}6H_2O$ (0.135 g, 0.50 mmol) in EtOH (10 mL) was added. After 5 min of stirring, the clear brown solution was layered with Et_2O (1:2 v/v) to afford a microcrystalline brown product after ~1 month, which was filtered off and dried *in vacuo*. Yield: 0.055 g, 42%. The resulting powder was analyzed as solvent free. *Anal.* Calc. for $C_{38}H_{30}Fe_4N_8O_{10}Cl_2$: C, 43.35; H, 2.87; N, 10.64; Found: C, 42.48; H, 2.81; N, 10.34%. Main IR data (KBr pellet): ν~ = 3062(w), 1603(s), 1544(s), 1539(s), 1475(m), 1405(vs), 1344(w), 1309(w), 1294(w), 1252(w), 1218(m), 1178(w), 1156(w), 1116(s), 1090(vs), 1015(m), 891(m), 774(m), 720(m), 689(s), 643(m), 604(m), 552(m), 519(m), 470(m), 422(m).

2.2.1.2. Method B. An orange solution of $[Fe_3O(O_2CPh)_6(H_2O)_3]Cl$ (0.170 g, 0.17 mmol) in EtOH (10 mL) was added to a stirred solution of pyC(H)NOH (0.061 g, 0.50 mmol) in dmf (30 mL). The resulting brown solution was stirred for 5 min and layered with Et_2O (1:2 v/v) yielding brown microcrystalline precipitate after 15 days, which was filtered off and dried *in vacuo*. Yield: 0.052 g, 40%. The resulting powder was analyzed as solvent free. *Anal.* Calc. for $C_{38}H_{30}Fe_4N_8O_{10}Cl_2$: C, 43.35; H, 2.87; N, 10.64; Found: C, 42.45; H, 2.79; N, 10.29%. Main IR data (KBr pellet): ν~ = 3064(w), 1604(s), 1544(s), 1529(s), 1475(m), 1406(vs), 1344(w), 1309(w), 1296(w), 1252(w), 1218(m), 1178(w), 1156(w), 1116(s), 1090(vs), 1013(w), 893(w), 774(m), 720(m), 689(s), 642(m), 604(m), 552(m), 518(m), 470(m), 420(m).

2.2.2. $[Fe_4O_2Cl_2(O_2CPh)_2\{pyC(Me)NO\}_4]{\cdot}EtOH{\cdot}Et_2O$ (**2**$\cdot EtOH\cdot Et_2O$)

2.2.2.1. Method A. A colorless solution of pyC(Me)NOH (0.068 g, 0.50 mmol) in dmf (10 mL) was added to a stirred suspension of NaO_2CPh (0.144 g, 1.00 mmol) in dmf (20 mL). The stirring continued for 5 min until an orange solution of $FeCl_3{\cdot}6H_2O$ (0.135 g, 0.50 mmol) in EtOH (10 mL) added. After 5 min of stirring, the clear brown solution was layered with Et_2O (1:2 v/v) yielding microcrystalline brown precipitate after ~1 month, which was filtered off and dried *in vacuo*. Yield: 0.058 g, 42%. The resulting powder was analyzed as solvent free. *Anal.* Calc. for $C_{42}H_{38}Fe_4N_8O_{10}Cl_2$: C, 45.48; H, 3.45; N, 10.10; Found: C, 44.61; H, 3.35; N, 9.88%. Main IR data (KBr pellet): ν~ = 3411(br), 3063(w), 1600(s), 1551(s), 1534(s), 1473(m), 1406(vs), 1374(m), 1293(w), 1256(w), 1151(s), 1100(m), 1074(s), 1051(m), 779(m), 750(w), 727(m), 705(s), 672(m), 642(m), 599(m), 562(w), 504(m), 484(m), 420(m).

2.2.2.2. Method B. To a refluxed orange suspension of $[Fe_3O(O_2CPh)_6(H_2O)_3]Cl$ (0.170 g, 0.17 mmol) in EtOH (10 mL) was added a solution of pyC(Me)NOH (0.068 g, 0.50 mmol) in dmf (30 mL). The color of the solution immediately turned to brown and the reflux stopped. X-ray quality red crystals of **2** were obtained by vapor diffusion or layering of Et_2O (1:2 v/v) to the brown solution after two weeks. Yield: 0.058 g, 42%. The crystals were collected by filtration and were dried *in vacuo*. The resulting powder was analyzed as solvent free. *Anal.* Calc. for $C_{42}H_{38}Fe_4N_8O_{10}Cl_2$: C, 45.48; H, 3.45; N, 10.10; Found: C, 44.57; H, 3.38; N, 9.90%. Main IR data (KBr pellet): ν~ = 3439(br), 3064(vw), 1600(s), 1551(s), 1534(s), 1478(m), 1407(vs), 1375(m), 1294(w), 1258(w), 1151(s), 1100(m), 1075(s),

2.3. Single-crystal X-ray crystallography

A red prismatic crystal of **2**·EtOH·Et_2O (0.10 × 0.20 × 0.50 mm) was taken directly from the mother liquor and immediately cooled to −93 °C. Diffraction measurements were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Mo Kα radiation. Data collection (ω-scans) and processing (cell refinement, data reduction and Empirical absorption correction) were performed using the CRYSTALCLEAR program package [14]. Important crystal data and parameters for data collection are reported in Table 1. The structure was solved by direct methods using SHELXLS-97 [15] and refined by full matrix least-squares techniques on F^2 with SHELXLS-97 [16]. Further experimental crystallographic details for **2**·EtOH·Et_2O: $2\theta_{max} = 51°$; reflections collected/unique/used, 39051/10042 [$R_{int} = 0.0651$]/10042; 704 parameters refined; $(\Delta/\sigma)_{max} = 0.006$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.534/-0.481$ e/Å3; $R1/wR2$ (for all data), 0.0745/0.1510. Hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. The ethanol solvate was found disordered and it was refined over two positions with occupation factors summing one. Plots of all structures were drawn using the DIAMOND 3 program package [17].

3. Results and discussion

3.1. Syntheses

Complexes **1** and **2** can be obtained either from the 1:2:1 Fe^{III}/$PhCO^-$/pyC(R)NOH molar ratio reaction in EtOH/dmf, or by the 1:3 $[Fe_3O(O_2CPh)_6(H_2O)_3]Cl$/pyC(R)NOH molar ratio reaction in EtOH/dmf. The large excess of NaO_2CPh used (Fe^{III}/pyC(R)NOH/NaO_2CPh = 1:1:2 or 4:4:8) is beneficial to the preparation of **1** and **2**. The excess of $PhCO_2^-$ helps the deprotonation of the neutral ligand pyC(R)NOH and the so-formed weak acid ($PhCO_2H$) does not decompose the oxide-bridged cluster. The balanced chemical equations describing the synthesis of **1** and **2** may be written in the form of Eqs. (1) and (2):

$$4FeCl_3\cdot 6H_2O + 4pyC(R)NOH + 8NaO_2CPh \xrightarrow{EtOh/dmf} \underset{\mathbf{1,2}}{[Fe_4O_2Cl_2(O_2CPh)_2\{pyC(R)NO\}_4]} + 8NaCl + 2HCl + 6PhCO_2H + 22H_2O \quad (1)$$

In this case, it is assumed that the H_2O from the solvents and/or the starting materials is the source of the O^{2-} ions.

$$6[Fe_3O(O_2CPh)_6(H_2O)_3]Cl + 12pyC(R)NOH + 6NaCl \xrightarrow{EtOH/dmf} 3\,\underset{\mathbf{1,2}}{[Fe_4O_2Cl_2(O_2CPh)_2\{pyC(R)NO\}_4]} + 2''[Fe_3O(O_2CPh)_6(H_2O)_2(OH)]'' + 18PhCO_2H + 10H_2O \quad (2)$$

The 1:1 Fe^{III}/pyC(R)NOH molar ratio reaction is reflected to the stoichiometry of the final product. An excess of the metal ion in the reaction mixture may favor the synthesis of even higher nuclearity metal clusters, a possibility that is currently under investigation in our laboratory.

In an attempt to explore to what extend the presence of counterions might affect the identity of the products isolated, we have performed the 1:3:3 $[Fe_3O(O_2CPh)_6(H_2O)_3]Cl$/pyC(Me)NOH/$NaClO_4$ or Bu_4NBF_4 molar ratio reactions in EtOH and/or EtOH/dmf mixtures. In every case the red precipitate formed was identified as compound **2** by infrared spectroscopy.

The IR spectrum of complexes **1** and **2** exhibit strong absorptions at 1544 and 1406 cm^{-1} (for **1**) and 1551 and 1407 cm^{-1} (for **2**) which are assigned to the $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ modes of the benzoate ligands, respectively. The difference Δ [$\Delta = \nu_{as}(CO_2)-\nu_s(CO_2)$] is 138 and 144 cm^{-1} for **1** and **2**, respectively, less than that for NaO_2CPh (184 cm^{-1}), as expected for a bidentate bridging mode of the carboxylate ligation [18]. A strong absorption band at ~1600 cm^{-1} and a weak absorption band at ~1294 cm^{-1} are assigned to the (C–N) and (N-Ooximate) stretching vibrations, respectively, of the pyC(R)NO$^-$ ligands [11].

3.2. Description of the structure

The molecular structure of **2** is depicted in Fig. 1 and selected bond distances and angles are listed in Table 2. The tetranuclear complex contains the $[Fe_4(\mu_3\text{-}O)_2]^{8+}$ core comprising four Fe^{III} ions in a "butterfly" disposition and two μ_3-O^{2-} ions, each bridging three Fe^{III} ions forming the 'wings' of the 'butterfly'. Atoms Fe(1) and Fe(2) occupy the 'hinge' or 'body' sites and Fe(3) and Fe(4) occupy the 'wingtip' positions. The topology of the central $[Fe_4(\mu_3\text{-}O)_2]^{8+}$ core can be also described as two edge-sharing $[Fe_3(\mu_3\text{-}O)]^{7+}$ triangular subunits. The dihedral angle between the

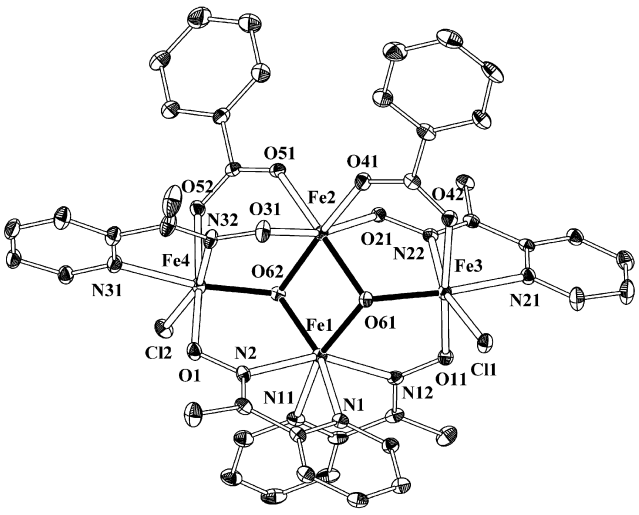

Fig. 1. Partially labeled plot of **2** with ellipsoids drawn at the 30% probability level. Hydrogen atoms have been omitted for clarity. Black bonds describe the $[Fe_4(\mu_3\text{-}O)_2]^{8+}$ core.

planes defined by Fe(1)/Fe(2)/Fe(3) and Fe(1)/Fe(2)/Fe(4) is 176.3(3)°; thus, the four Fe^{III} ions are essentially coplanar. As a result, the two μ_3-O^{2-} ions are forced to leave out of their respective [Fe_3(μ_3-O)] triangle and are displaced above and below the [Fe_4] best mean plane (0.53(1) and 0.55(1) Å for O(61) and O(62)). This is also reflected to the sums of the Fe–O–Fe angles around the μ_3-O^{2-} ions, which severely deviate from 360° (337.7°/334.9° for O(61)/O(62), respectively) and are close to the ideal value of 328.4° expected for pure sp^3 hybridization. A literature survey of tetranuclear complexes presenting the [Fe_4(μ_3-O)$_2$]$^{8+}$ core showed a number of different configurations regarding the position of the 'wing' metal ions and the displacement of the μ_3-O^{2-} ions with respect to their respective [Fe_3] planes. The most common include a) the trans arrangement of the 'wing' metal ions with respect to the central [Fe_2O_2] core and the displacement of the μ_3-O^{2-} ions above and below their respective [Fe_3] planes (type A) [19], (b) the cis arrangement of the 'wing' metal ions with respect to the central [Fe_2O_2] core and the displacement of the μ_3-O^{2-} ions below their respective [Fe_3] planes (type B) [20], and (c) an intermediate configuration between those two (type C) [21]. However, in all cases the sum of the Fe–O–Fe angles around the μ_3-O^{2-} ion falls in the range 350°–359°. Only in the case of K_2[Fe_4(OH)$_2$(PO_4)$_4$(H_2O)$_2$] [22] the sum of the Fe–O–Fe angles around the μ_3-OH group is 339.8°. In the case of **2**, which belong to the first type of configuration described above, the two μ_3-O^{2-} ions show a more pyramidal character than in analogous complexes. Each μ_3-O^{2-} ion presents two short (~1.9 Å) and one longer (~2.0 Å) Fe–O distance, unlike the case of the more symmetrical [Fe_3(μ_3-O)] triangular units found in various 'basic iron(III) carboxylates' [23] where the μ_3-O^{2-} ion is symmetrically coordinated to the iron(III) ions at ~1.9 Å. The two short Fe–O bond distances exert a *trans* influence on the Fe–N bond (Fe–N ~ 2.2 Å).

The two 'body' iron(III) ions [Fe(1) and Fe(2)] are bridged by two μ_3-oxides, while a single μ_3-oxide ion participates in the coordination sphere of the 'wingtip' iron(III) ions. As a result, the central Fe(1)···Fe(2) separation is much shorter (2.910(1) Å) than the body-to-wing separations which fall in the range 3.266(7)–3.390(6) Å. The wing-to-wing separation is the largest one as expected (5.969(6) Å).

The four methyl 2-pyridyl ketone oxime ligands are anionic presenting the η^1:η^1:η^1:μ_2 coordination mode (Scheme 2) around the Fe^{III} ions. Two of the pyC(Me)NO^- ligands are coordinated to the 'body' Fe(1) through their pyridine and oximato nitrogen atoms, and they use their oximato oxygen atom to bridge one of the 'wingtip' ions, Fe(3) and Fe(4). In this way, Fe(1) presents an

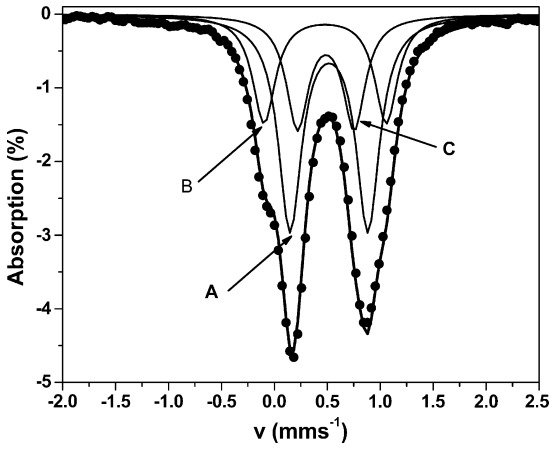

Fig. 2. Zero field Mössbauer spectrum from **2** recorded at 90 K. The solid lines are theoretical spectra assuming three sites as explained in the text.

O_2N_4 distorted octahedral coordination. The remaining two pyC(Me)NO^- ligands are coordinated through their pyridine and oximato nitrogen atoms to the 'wingtip' ions Fe(3) and Fe(4) respectively, and their oximato oxygen atom is bridging the 'body' ion Fe(2). The 'body' Fe(2) ion is also bridged to each of the 'wingtip' ions Fe(3) and Fe(4) through a syn,syn $\eta^1{:}\eta^1{:}\mu_2$ benzoato group. The octahedral coordination around each of the 'wingtip' iron(III) ions is completed by a chloride ion. In this manner, Fe(2) presents an oxygen-rich octahedral coordination environment, while Fe(3) and Fe(4) present an O_3N_2Cl octahedral coordination.

Complex **2** is the forth member of a small family of structurally characterized iron(III) carboxylate complexes with pyC(R)NOH type ligands (R = H, Me, Ph, py); the rest being the analogous tetranuclear compounds $[Fe_4O_2(O_2CMe)_2\{(py)_2CNO\}_4X_2]$ ($X = Cl^-$, N_3^-) featuring 'butterfly' cores [11], and the dodecanuclear compound $[Fe_{12}O_8(OMe)_2(O_2CPh)_{12}(pyCHNO)_6]$ [8b].

3.3. Mössbauer spectroscopy

A Mössbauer spectrum from a powdered sample of **2** recorded in zero field at 90 K is shown in Fig. 2. The spectrum consists of overlapping quadruple doublets. The crystal structure of **2** indicates the presence of at least three different, six coordinated ferric sites, FeO_3N_2Cl, FeO_6, FeO_2N_4 with a ratio 2:1:1. In order to reproduce the spectrum we take into account this information allowing for three different sites **A**, **B**, **C** at a ratio 2:1:1 and assuming close lying values for the isomer shifts. The results are quoted in Table 3.

The values listed in Table 3 are only indicative and by no means unique. The average value of the isomer shift is in the range expected for six-coordinated high-spin ferric ions and consistent with the type of ligands for the iron sites. Moreover, the heterogeneity in the coordination of the iron sites of the complex is depicted in the different values of the quadruple splitting.

3.4. Magnetic susceptibility studies

The $\chi_M T$ value of **2** is 2.50 $cm^3\ mol^{-1}\ K$ at 300 K, significantly below the theoretically expected value for four non-interacting spins (17.51 $cm^3\ mol^{-1}\ K$, $g = 2$), suggesting the interplay of strong antiferromagnetic interactions. This was corroborated by the continuous decrease of the $\chi_M T$ value, down to a plateau of 0.015 $cm^3\ mol^{-1}$ below 20 K (Fig. 3). This plateau is characteristic of a small fraction of high-spin ferric paramagnetic impurity. This impurity is manifested as an abrupt increase of χ_M below 15 K.

For the interpretation of the magnetic susceptibility data, we initially considered two types of interactions, usually considered for butterfly-type complexes, i.e. wingtip-body (J_{wb}) and body–body (J_{bb}) interactions. However, several attempts to fit our data yielded very poor results. After examination of the structural parameters of **2**, we considered that this model should be refined. In particular we note that the Fe(1)/Fe(3) and Fe(1)/Fe(4) pairs are each bridged by one N–O moiety from the pyC (Me)NO^- ligand (excluding the μ_3-O^{2-} bridges) and that the Fe(2)/Fe(3) and Fe(2)/Fe(4) are additionally bridged by one benzoate bridge each. This fact affects the respective Fe–O–Fe angles formed by the μ_3-oxide bridges, which are 126.4(2) and 124.8(2)° for the Fe(1)/Fe(3) and Fe(1)/Fe(4) pairs, respectively, and 115.5(2) and 114.3(2)° for the Fe(2)/Fe(3) and Fe(2)/Fe(4) pairs, respectively. The oxide bridge being considered to provide the main superexchange pathway, we assumed that these differentiations in the Fe–O–Fe angles might affect the exchange couplings. We therefore decided to account for these interactions with two different exchange coupling parameters (Fig. 4). Thus the Hamiltonian used was:

$$\hat{H} = -2[J_1(\hat{\mathbf{S}}_1\hat{\mathbf{S}}_3 + \hat{\mathbf{S}}_1\hat{\mathbf{S}}_4) + J_2(\hat{\mathbf{S}}_2\hat{\mathbf{S}}_3 + \hat{\mathbf{S}}_2\hat{\mathbf{S}}_4) + J_{bb}\hat{\mathbf{S}}_1\hat{\mathbf{S}}_2] \quad (3)$$

It should be noted that the assignment of J_1 and J_2 is arbitrary, since the symmetry of the problem does not allow us to readily distinguish between the two types of interaction, which are topologically equivalent. Adoption of this model yielded significant improvements to the fits. Best-fit parameters were $J_1 = -85\ cm^{-1}$, $J_2 = -27\ cm^{-1}$, $J_{bb} = +25\ cm^{-1}$, $g = 2$ (fixed), $\rho = 0.36\%$, with $R = 4.3 \times 10^{-3}$, where ρ is a small fraction of high-spin ferric paramagnetic impurity. Although the values for J_1 and J_2 are well determined, that of J_{bb} is not. It was found within a wide range of values (e.g. from -25 to $+25\ cm^{-1}$); this parameter did not influence the agreement factor significantly. This is a known issue for this parameter in Fe^{III} butterfly complexes with $S = 0$ ground states, resulting to an indeterminate ground state [11]. Therefore, we present here the best-fit value of this parameter, although it should not be considered as reliable.

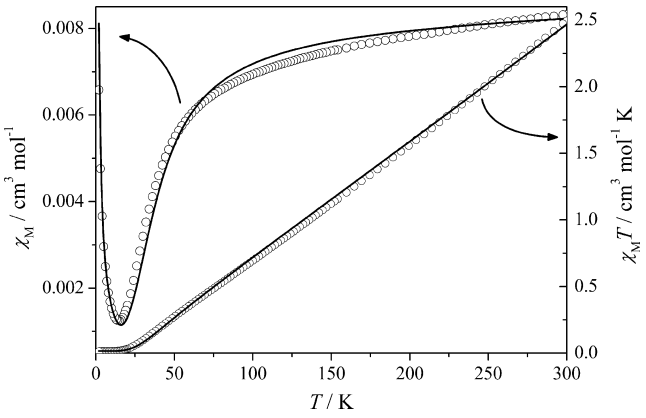

Fig. 3. χ_M vs T and $\chi_M T$ vs T data and best-fit curved according to the model described in the text.

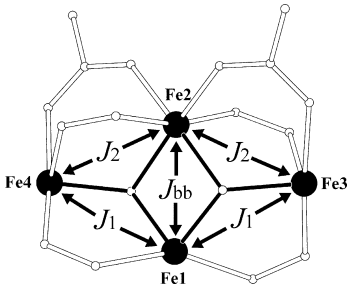

Fig. 4. Spin-coupling scheme used for the interpretation of the magnetic susceptibility data of **2**.

4. Conclusions

The use of 2-pyridyl oximes, pyC(R)NOH (R = H, Me), in Fe^{III}-carboxylate chemistry has yielded tetranuclear clusters that contain the $[Fe_4(\mu_3\text{-}O)_2]^{8+}$ 'butterfly' core, compounds $[Fe_4O_2Cl_2(O_2CPh)_2\{pyC(R)NO\}_4]$ (R = H, **1**; R = Me, **2**). Complex **2** is the first crystallographically characterized Fe^{III} carboxylato complex of

Table 3
Mössbauer parameters of the three different sites A, B, C.

Doublet	δ[a] (mm/s)	ΔE_Q[a] (mm/s)	Area[b] (%)
A	0.52	0.74	50
B	0.48	1.15	25
C	0.49	0.54	25

[a] ±0.01 mm/s.
[b] Fixed.

pyC(Me)NOH. The use of different Fe^{III} sources and the presence of counterions in the reaction mixtures have not affected the isolation of **1** and **2**, thus suggesting that they represent the more thermodynamically stable products of the reactions. From the structural point of view, complex **2** is analogous to the previously reported tetranuclear 'butterfly' complexes of Fe^{III} with di-2-pyridyl ketone oxime, $(py)_2CNOH$, i.e. R = py, $[Fe_4O_2(O_2CMe)_2\{(py)_2CNO\}_4X_2]$ ($X = Cl^-$, N_3^-). From the magnetic point of view, the latter complexes of $(py)_2CNOH$ and **2** present striking differences. Complexes $[Fe_4O_2(O_2CMe)_2\{(py)_2CNO\}_4X_2]$ ($X = Cl^-$, N_3^-) present a $S = 1$ ground state because of the particular value of the J_{bb}/J_{wb} ratio [11], whereas complex **2** presents a diamagnetic ground state as is the case for the majority of the $[Fe_4]$ 'butterfly' complexes. In order to draw safe conclusions regarding the origin of the different magnetic behavior and the possible influence of the R-substituent of the 2-pyridyl oximes we are currently investigating the Fe^{III}-carboxylate chemistry of ligands containing various R groups (Et, Ph, etc).

Supplementary data

CCDC 723976 contains the supplementary crystallographic data for **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

present work is an extension of our research efforts on coordination polymers [12,14–20] and hydrogen-bonded frameworks [21,22].

2. Experimental

2.1. General

All reagents and solvents were of commercially available reagent quality unless otherwise stated. All reactions were performed at room temperature and no special conditions were required.

2.2. Instrumentation

^{13}C and ^{113}Cd NMR spectra were recorded on a Bruker AMX 400 MHz spectrometer. For ^{113}Cd NMR spectra a 0.1 M $Cd(NO_3)_2{\cdot}4H_2O$ solution was used as an external standard. The samples for solution NMR studies were prepared by dissolving $Cd(NO_3)_2{\cdot}4H_2O$ and *trans*-aconitic acid in D_2O; the pH of the D_2O solutions was adjusted with NaOD. Mass spectra were measured on an Agilent 1100 series LC-MSD-TRAP-SL-Spectrometer. The samples for ESI-MS spectra were prepared by dissolving $Cd(NO_3)_2{\cdot}4H_2O$ and *trans*-aconitic acid in a solvent mixture (H_2O/CH_3CN: 90/10) and the pH of the solutions was adjusted using NaOH. The FT-IR spectra were recorded on a Perkin–Elmer Spectrum GX FT-IR spectrophotometer with the samples as KBr pellets. The TG-DTA analysis was carried out under nitrogen, at a scan speed of 5 °C/min, on a Shimadzu DTG 60 apparatus. The weight of the samples was about 5 mg. C, H and N analyses were conducted by Microanalytical Service at the University of Ioannina, Greece.

2.3. Potentiometry

Potentiometric titrations of free ligand (H_3L) and its complexes with Cd(II) ions were carried out at 25 °C, using a total volume of 10.0 mL. The titrations were performed in the presence of 0.1 M KNO_3 over the pH range 2–8 on a Mettler Toledo DL50 automatic titrator and a combined glass-silver chloride electrode calibrated in hydrogen concentrations using HNO_3 [23]. About 0.1 M KOH was used as titrant. The concentrations of *trans*-aconitic acid and the metal ion was 4 mM at a1:1 metal:ligand molar ratio. The experimental data were analyzed using the HYPERQUAD program [24]. Standard deviations computed by HYPERQUAD refer to random errors.

2.4. Preparation of the compounds

2.4.1. Synthesis of $[Cd_3L_2(H_2O)_6]_n$ (**1**)

$Cd(NO_3)_2{\cdot}4H_2O$ (46.4 mg, 0.15 mmol) was dissolved in H_2O (4 mL). To this, an aqueous solution of *trans*-aconitic acid (17.4 mg, 0.1 mmol), was added. The pH of the resulting solution was adjusted to 6.2. This molecular ratio affords the optimum yield for compound **1**. A microcrystalline powder was formed after 1 h, it was collected and washed with ethanol and diethyl ether, and dried in vacuum. Yield 80% (31.4 mg based on L). For the preparation of a suitable sample for crystallographic analysis 1.7 mg of *trans*-aconitic acid were dissolved in 6 mL H_2O. To this solution, 4.64 mg of $Cd(NO_3)_2{\cdot}4\ H_2O$ (dissolved in 4 mL H_2O) was added. The resulting solution was left undisturbed for slow evaporation. The first crop of colourless crystals was isolated after 5 days; a second crop of crystals isolated after 3 weeks. *Anal.* Calc. for $C_{12}H_{18}O_{18}Cd_3$, (**1**): C, 18.30; H, 2.30. Found: C, 17.96; H, 2.22%. IR (KBr, cm^{-1}) = 3448 (s), 2965 (w), 2925 (w), 1638 (m), 1564 (s), 1400 (s), 1307 (w), 1264 (m), 1222 (w), 1106 (w), 964 (w), 941 (m), 887 (m), 791 (m), 700 (m).

2.4.2. Synthesis of $\{[Cd(HL)(1,10\text{-phen})(H_2O)]_n{\cdot}n(H_2O)\}$ (**2**)

$Cd(NO_3)_2{\cdot}3H_2O$ (46.4 mg, 0.15 mmol) was dissolved in H_2O (4 mL). To this, a solution of 1,10-phenanthroline (15 mg, 0.075 mmol) in hot H_2O (1 mL), was added. Separately, *trans*-aconitic acid, (17.4 mg, 0.1 mmol) was dissolved in water (5 mL) and was added to the metal solution. The resulting solution was left undisturbed for slow evaporation. The first crop of colorless crystals was isolated after 5 days; a second crop of colorless crystals was isolated after 1 week. Yield 75% (28.1 mg based on phen). *Anal.* Calc. for $C_{18}H_{16}N_2O_8Cd$, (**2**): C, 43.03; H, 3.21; N, 5.58. Found: C, 42.96; H, 3.18; N, 5.45%. IR (KBr, cm^{-1}) = 3448 (s), 3071 (m), 2992 (w), 2607 (w) (–OH), 1700 (m) (–COOH), 1649 (m), 1567 (s), 1517 (m), 1411 (s), 1332 (m) [phen], 1294 (w), 1273 (w), 1210 (m) [phen], 1103 (m), 924 (w), 848 (m) [phen], 801 (w), 727 (m) [phen].

2.4.3. Synthesis of $\{[Cd(HL)(2,2'\text{-bipy})(H_2O)]_n{\cdot}n(H_2O)\}$ (**3**)

The synthesis of **3** was carried out as for **2** but using 2,2′-bipy instead of 1,10-phenanthroline. The formation of the colorless crystals was slower and the last crop of crystals was collected after almost 8 weeks. Overall yield: 72% (23 mg based on 2,2′-bipy). *Anal.* Calc. for $C_{16}H_{16}N_2O_8Cd$, (**3**): C, 40.17; H, 3.37; N, 5.86. Found: C, 40.06; H, 3.33; N, 5.78%. IR (KBr, cm^{-1}) = 3425 (s), 3296 (m), 3072 (w), 2983 (w), 2951 (w), 2604 (w) (–OH), 1703 (m) (–COOH), 1639 (m), 1576 (s), 1475 (m), 1438 (m), 1377 (s), 1317 (w), 1210 (m), 1171 (m), 1077 (w), 1016 (m), 851 (w), 770 (m).

2.5. X-ray crystallography

The crystals of **1–3** were immersed in cryo-oil, mounted in a Nylon loop, and measured at a temperature of 120 K. The X-ray diffraction data were collected on a Nonius KappaCCD diffractometer using Mo Kα radiation (λ = 0.71073 Å). The EVALCCD [25] program package was used for cell refinements and data reductions. The structures were solved by direct methods using the SIR92 [26] or SIR97 [27] programs with the WINGX [28] graphical user interface. A semi-empirical absorption correction (SADABS) [29] was applied to all data. Structures were refined using the SHELXL-97 program [30]. The H_2O and OH hydrogen atoms were located from the difference Fourier map but constrained to ride on their parent atom, with U_{iso} = 1.5. Other hydrogens were positioned geometrically and constrained to ride on their parent atoms, with C–H = 0.95–0.99 Å and $U_{iso} = 1.2U_{eq}$ (parent atom). The crystallographic details are summarized in Table 1 and selected bond lengths and angles in Tables 2 and 3.

3. Results and discussion

3.1. Description of the structures

The molecular structure of **1** is depicted in Fig. 1 and bond distances and angles are listed in Table 2. The crystal structure of **1** reveals the formation of a neutral 3D metal-organic framework $[Cd_3L_2(H_2O)_6]_n$. [31]. The formation of **1** has been reported under hydrothermal conditions [11]. There are two independent Cd(II) atoms in the asymmetric unit (Table 2). Cd(2) is coordinated to three oxygen atoms belonging to water molecules and three oxygen atoms of three different *trans*-aconitates, forming a distorted octahedral geometry. The three water molecules are placed around the centre in a meridional plane. Cd(1) is coordinated to eight oxygen atoms, which belong to two chelating and two chelating-bridging carboxylates with two elongated Cd(1)–O(6) distances of 2.671(2) Å. In the reported compound, the authors considered that Cd(1) is six coordinate and adopts a distorted octahedral geometry [11]. A detailed analysis of the molecular geometry reveals that

Cd(1) is represented by sky blue nodes while Cd(2), which acts as a linker between the two ligands, is green. Protons and water molecules have been omitted for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Cd(1) has a dodecahedral (*mmmm* Dod) coordination environment [32]. Each *trans*-aconitate bridges four cadmium centers through the six carboxylic oxygen atoms. Three different coordination modes of the ligand carboxylate moieties can be assigned in **1**: a bidentate in a *syn-anti* configuration (η^1:η^2:μ_2) for the C3A carboxylate group, a chelating (η^1:η^1:μ_1) for the carboxylate based on C2A and a chelating - bridging mode (η^1:η^2:μ_2) for the C1A carboxylate (Scheme 1). The water molecules form hydrogen bonds which amplify the construction of the 3D structure (Table 2).

The structure of compound **1** propagates in three directions through the bridging ligand and the metal center Cd(1) (Fig. 1). Topologically, Cd(1) has been replaced by node B and the geometric centroid of the tritopic carboxylate ligand has been substituted by node A. The Cd(2) metal center is not concerned to the *decorated* compound. In this way, a neutral 3D network is formed, formulated as A_2B. Node B is connected through four short pillars to four A nodes possessing a square tetrahedral geometry, whereas node A is bridged to two B and two A nodes through two short and two elongated pillars adopting a tetrahedral configuration. The *decorated* compound that is formed is a four-connected *non-homogeneous binodal* network, possessing a moganite (**mog**) topological structure (Fig. 2). The Schläfli symbol for a **mog** network is $(4.6^4.8)_2(4^2.6^2.8^2)$, while the elongated symbol for each node is $(4.4.6_2.6_2.8_2.8_2)$ and $(4.8_6.6.6.6.6)$ for nodes A and B, respectively.

To our knowledge, few examples of metal-organic frameworks having a **mog** topology have been reported [33–34]. Usually, a typical **mog** network possesses tetrahedral and tetragonal nodes, while there are a few exceptions in which both nodes adopt a tetrahedral configuration. To conclude, the *decorated* compound **1** is a distorted **mog** net with tetrahedral nodes and represent the first example of this topology that originates from this carboxylate ligand.

Both compounds **2** and **3** were characterized crystallographically and they were found to belong to the triclinic $P\bar{1}$ space group. Selected distances (Å) and angles (°) for both compounds are presented in Table 3. The compounds are similar; therefore, only interactions for compound **2** will be further discussed. The crystal structure of **2** consists of linear [Cd(HL)(N–N)] 1D chains (Fig. 3) (for **3**, see Fig. S1), running parallel to the *a*-axis and a lattice water molecule held with H-bonds. The coordination number of each Cd(II) center is six, forming an octahedral coordination polyhedron. Each metal is coordinated by two nitrogen atoms belonging to the chelated Lewis base, three oxygen atoms belonging to two different aconitate anions, and a water molecule [CdN_2O_4]. The equatorial positions are occupied by one nitrogen atom (N(1) for **2** and N(2) for **3**) and three oxygen atoms, two belonging to a chelate carboxylate and one to a terminal water molecule. The second nitrogen atom and one oxygen atom of a monodentate carboxylate

Scheme 1. Coordination mode of L^{3-} and HL^{2-} organic ligand found in **1** (left) and **2**, **3** (right).

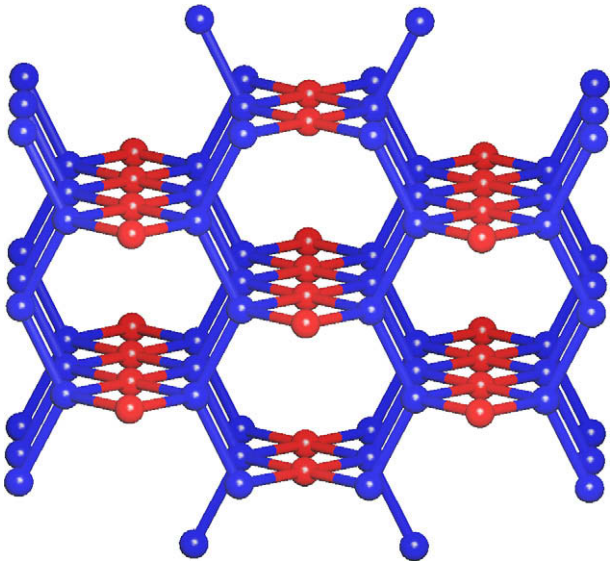

Fig. 2. Topological presentation of the four-connected non-homogeneous binodal network with **mog** topology of compound **1**. (node A; blue, node B; red). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

are placed in the axial positions. The axial angle N–Cd–O displays a significant deviation from linearity (160.04(11)° for **2** and 160.51(6)° for **3**), and the equatorial angles vary from 55.19(10)° to 141.09(11)° for **2** and 54.48(5)° to 136.54(7)° for **3**.

The three carboxylate groups in the doubly deprotonated ligand behave differently (Scheme 1). The carboxylate group of C1A is chelated, carboxylate of C3A is monodentate, while the carboxylate group based on C2A remains protonated. In this way, the ligand bridges two Cd(II) ions leading to the formation of linear chains. To the best of our knowledge, this coordination mode has not been observed previously for this tricarboxylic acid [9–12]. Compared to our recent work, the present coordination mode of the HL^{2-} ligand is completely different from that observed in the one-dimensional 1D [Zn(HL)(N–N), where N–N = Lewis base] linear chains [12]. In both compounds **2** and **3** there are two different kinds of interactions that lead to the formation of 3D metal-supramolecular architectures; hydrogen bonding and stacking interactions. In **2**, the terminal water molecule forms two hydrogen bonds (Table 4) and acts as a bridge between two different 1D chains (Fig. 4). The first hydrogen bond involves hydrogen atom H(71) and a carboxylate oxygen from the chelated carboxylate group O(5) and the second involves the other hydrogen atom of lattice water H(72) and the non-coordinated carboxylate oxygen from the monodentate carboxylate group, O(2), of a different chain. Finally, the lattice water molecule acts as donor and acceptor forming three hydrogen bonds. The former involve hydrogen atoms H(81) and H(82) and oxygen atoms O(4) of the protonated carboxylate group and O(1) of the monodentate carboxylate, respectively, while the latter involves oxygen atom O(8) and forms the third hydrogen bond with the hydrogen atom H(3) of the protonated carboxylate group of a third chain, belonging to a third different chain resulting in the formation of thick layers (Fig. 3, middle–lower). The angle between the planes defined by the Cd(II) atoms in the double chains and the ribbons connected by the lattice water molecules is 80.01° (76.52° for **3**).

The 2D H-bonded undulating layers interact via stacking interactions through symmetry-related phenanthroline moieties that occupy the space between the previously described layers. There is a combination of strong and medium π–π stacking interactions between the aryl moieties resulting in the formation of a 3D

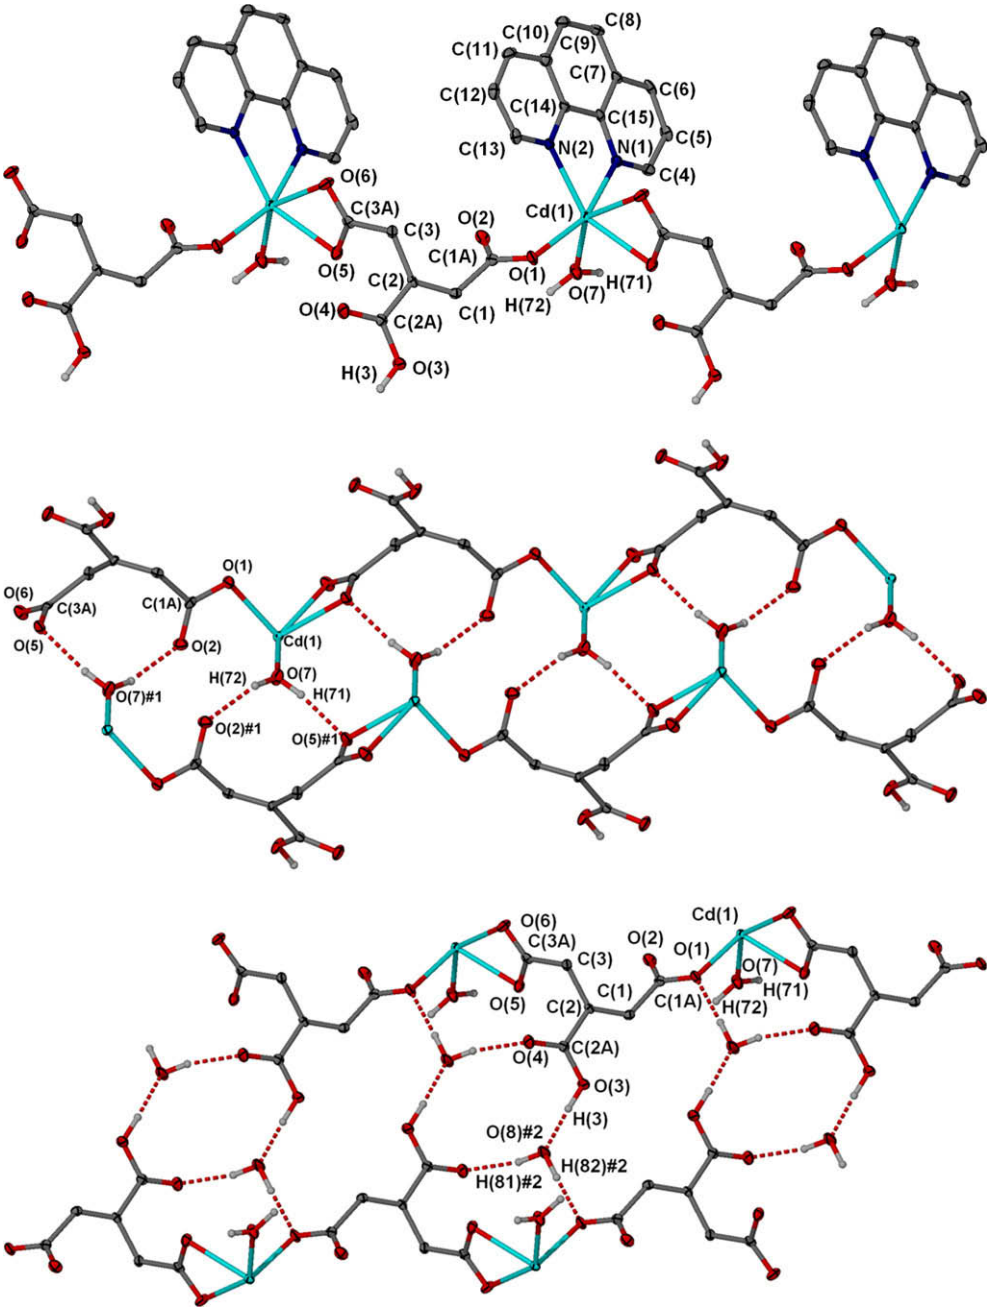

Fig. 3. Part of the 1D polymeric chains of **2** showing the coordination of the ligand (50% probability ellipsoids). Lattice water molecules and organic protons have been omitted for clarity (top). metal-supramolecular structure (Fig. 4). In **2**, the aromatic ligand utilizes all aromatic rings (a–c, Scheme 2, Table 4) for the stacking interaction. In a similar way, in **3** (Table 5) both aromatic rings participate in the stacking interactions (see Fig. S2) [35,36].

3.2. Solution study

3.2.1. Free ligand protonation constants

Overall protonation and ionization constants (pK_a) derived by the potentiometric measurements on the free ligand are collected in Table 6 while ^{13}C NMR data are presented in Table 7 [5].

Three ionization constants are expected for *trans*-aconitic acid (H_3L) due to the presence of three carboxylate groups (Table 6). The first two pK_α values 2.72 and 3.95 should be assigned to carboxylate groups attached in C=C bond in *trans* position (C2A and C3A), presenting almost the same pK_α difference as the corresponding values of fumaric acid [37], and the last one (5.61) is assigned to C1A. All observed pK_α values are in agreement with similar data already published [38,39].

3.2.2. Cd–ligand interaction

The interaction of Cd(II) and *trans*-aconitic acid was studied in aqueous solutions in 1:1 molar ratios. The titration curves were best fitted assuming the formation of four species over the pH range 2–8, namely CdH_4L_2, $Cd_3L_2H_2$, Cd_3L_2H and Cd_3L_2. The stability constants of the above Cd(II) complexes with the ligand *trans*-

aconitic acid have already been presented in Table 7 and the species distribution diagram of Cd(II) complexes, is presented in Fig. 5.

For the assignment of the species, ESI-MS and ^{113}Cd NMR spectra were also recorded over the pH range 2–5 and in a Cd(II): ligand molar ratio 1:1. It is evident from the speciation diagram that Cd(II)–ligand interaction begins above pH 2 and CdH_4L_2 species are formed. Complexes with stoichiometry 1:2 are not expected in the studied 1:1 system. Nevertheless, the ESI-MS spectra (Fig. 6) recorded in the positive ion mode provides a strong indication for the existence of bis complexes. The spectra recorded at pH 2.5 comprise two peak clusters (marked a and b in Fig. 6) presenting the typical isotopic distribution of Cd(II) ions. The first one can

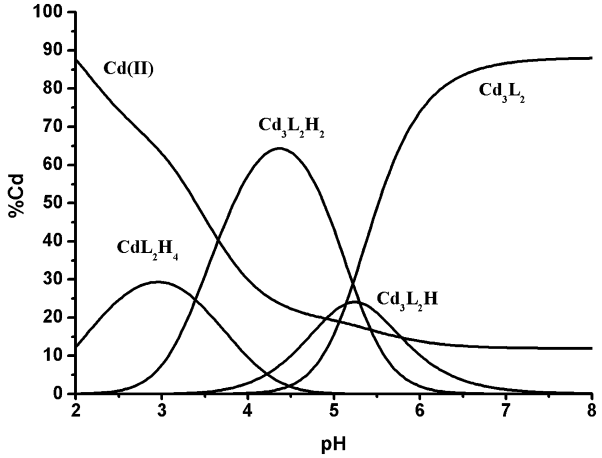

Fig. 5. Speciation curves for the complexes formed in the Cd(II)–*trans*-aconitic acid system at 1:1 metal ion to ligand molar ratio and c_{ligand} = 0.004 M.

be assigned to formula $[CdH_4L_2 + 2Na^+ + 2CH_3CN]$ (m/z = 295) while the second to formula $[CdH_4L_2 + 2Na^+ + 4CH_3CN + H_2O]$ (m/z = 324). The next three species detected were $Cd_3L_2H_2$, Cd_3L_2H and Cd_3L_2 presenting the same stoichiometry as the isolated and

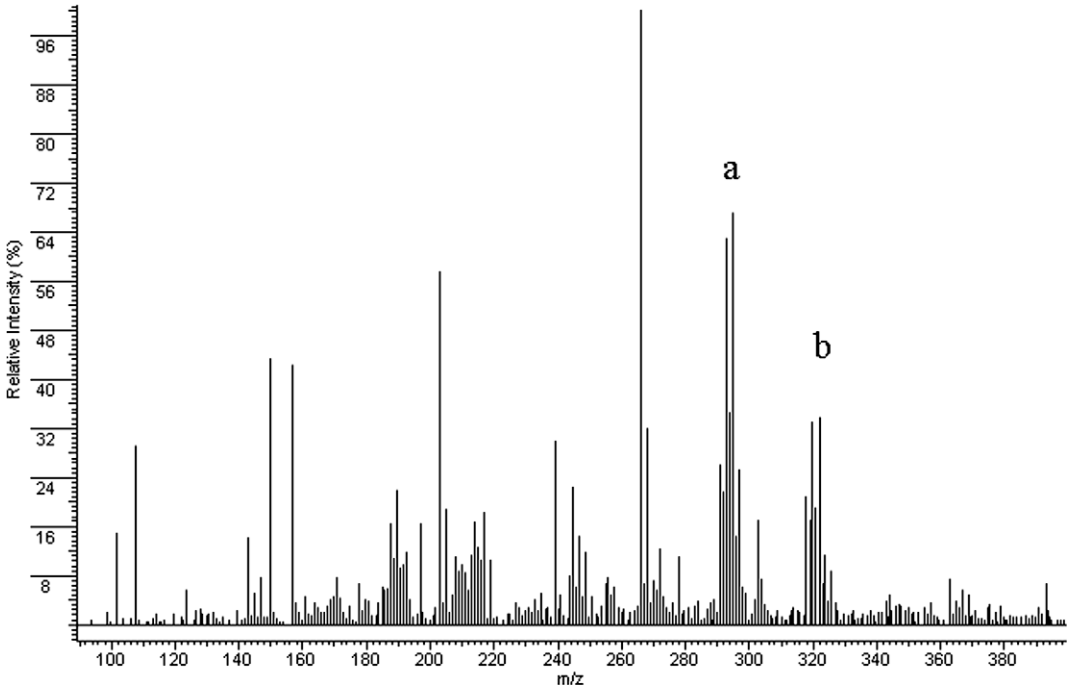

Fig. 6. ESI-MS spectrum recorded in the positive ion mode in the binary Cd(II)–*trans*-aconitic acid system at 1:1 metal ion to ligand molar ratio and c_{ligand} = 0.004 M.

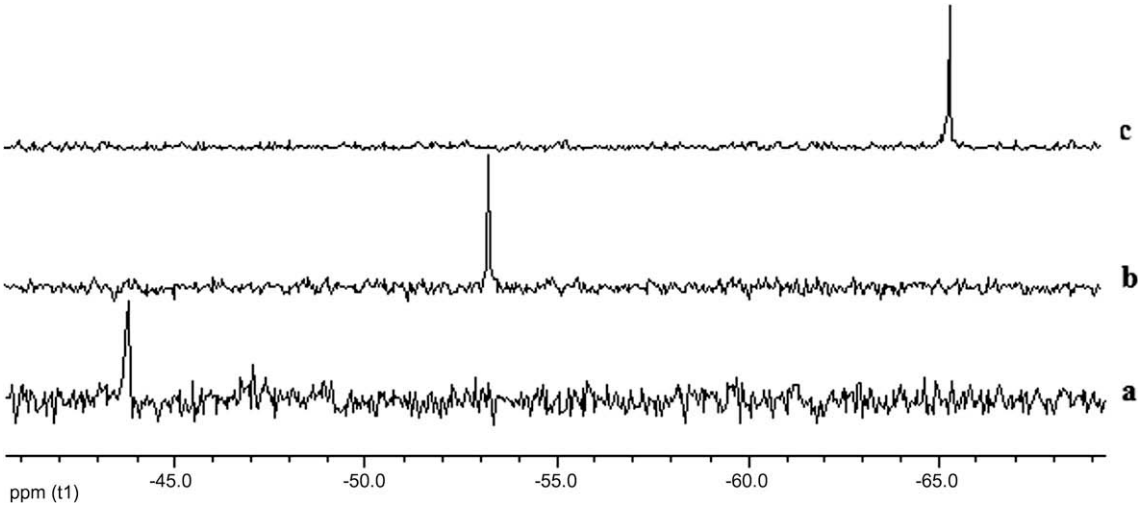

Fig. 7. ^{113}Cd NMR spectra were recorded at pH values 1.8(a), 3.2(b) and 5.8(c).

crystallized compound. Unfortunately, no information regarding the existence of these species can be extracted from ESI-MS spectra recorded at higher pH values in either positive or negative modes, possibly indicating decomposition in the gas phase under ESI-MS conditions. To substantiate the presence of Cd(II)–ligand interaction in solution at higher pH values, ^{113}Cd NMR spectra were recorded at pH values 1.8, 3.2 and 5.8 (Fig. 7a–c, respectively). At 298 K the spectral data clearly suggest metal ion–carboxylate interaction. It is generally known that 6–8 coordinate Cd complexes with oxo ligands give shifts in the range 150 to −100 ppm [40]. In the present case, chemical shifts of −43.77, −53.22 and −65.80 ppm, respectively were observed, corroborating our assumption and suggesting a possible increase of metal coordination number from 6 to 7 or 8 in higher pH values. It should also be mentioned here that a crystalline solid precipitated from the solution at pH 3.2 upon 4 h standing. This solid was identified as compound **1** on the basis of X-ray and Powder XRD measurements, suggesting the existence of species of the above stoichiometry in solution.

3.3. FT-IR spectroscopy

The multiple coordination modes of the ligand L^{3-} in **1** and HL^{2-} in **2** and **3** make it difficult to unambiguously assign the IR spectra; however, some bands can be explained. The IR spectrum of compound **1** displays a broad band centered at 3448 cm^{-1} in agreement with the presence of water molecules, and characteristic asymmetric and symmetric stretching vibrations of carboxylate groups at 1564 and 1400 cm^{-1}. The IR spectra display broad bands centered at 3448 and 3425 cm^{-1} for **2** and **3**, respectively, in agreement with the presence of H-bonded water molecules. The multiple coordination of the ligand HL^{2-} makes the distinct assignment

of the IR bands difficult; however, some bands can be explained. The bands at 1700 cm^{-1} for **2** and 1703 cm^{-1} for **3** can be attributed to the ν(C=O) of the free carboxyl at position 3A (Scheme 1), while the pairs of bands at 1567 and 1411, and 1576 and 1438 cm^{-1} are characteristic for the symmetric and asymmetric COO stretching vibrations for **2** and **3**, respectively [41].

3.4. TG-DTA studies

The TG-DTA spectra of **1** show that there is a loss in the range 116.5–230.0 °C which is possibly due to the loss of six terminal water molecules of two cadmium centers (calc. 13.71%; found 13.23%). The dehydrated product of **1** is stable up to 313 °C, whereupon a simple decomposition process begins which proceeds up to 492 °C, where the white final residue corresponds to CdO (calc. 48.79%; found 48.16%). When the 1D coordination polymer **3** is heated under nitrogen atmosphere, an endothermic dehydration starts at 36 °C which is completed at 187 °C. The observed weight loss of 7.60% corresponds well to the calculated values of 7.56% of two lattice water molecules. The dehydrated product of **3** is stable up to 205 °C and after that temperature a rather complicated decomposition process begins which involves at least three continuous steps as shown by the DTA curve. The decomposition proceeds up to 555 °C, where the white final residue corresponds to CdO (calc. 26.85%; found 25.75%). Similar TG-DTA curves were recorded also for compound **2**.

4. Conclusion

The complexing ability of the binary system *trans*-aconitic acid (H_3L) with regard to Cd(II) is presented. The crystal structures of the species $Cd_3L_2(H_2O)_6$ (**1**) and the ternary system of Cd(II)–(H_3L)–Lewis base [Lewis base = 1,10-phenanthroline (**2**) and 2,2′-bipyridine (**3**)] have been determined. Topological representation of compound **1** reveals a rare binodal four-connected 3D metal-organic framework possessing a **mog** topology, in which both four-connected nodes adopt distorted configurations. Compounds **2** and **3** represent 1D-infinite chains forming 3D metal-supramolecular architectures through H-bond and π–π^* stacking interactions. The coordination mode of HL^{2-} differs from those reported previously. The solution studies support the existence and the formation of compound **1** upon increasing the pH of the solution.

In the binary system, correlation between its behavior in the solid state and in solution with that of species arising from solution speciation studies can be accomplished. We believe that this study can contribute to the elucidation of the mechanism of the action of H_3L and comprise a fundamental research towards the exploration of the substitute action mechanism against other metal ions. The present findings provide new structural data, which could enhance the understanding of the exact mechanism by which Cd(II) toxicity arises. It is worth mentioning that small flexible biological organic ligands are a fruitful source for the construction of coordination polymers.

pdmH$_2$

Scheme 1. Structural formula and abbreviation of pyridine-2,6-dimethanol.

with suitable chelates (generally denoted as "L") [14]. Thus, we and others have been exploring various such binary (L/RCO_2^- or L/N_3^-) and ternary ($L/RCO_2^-/N_3^-$) reaction schemes as potentially new routes to high-nuclearity molecular species with unprecedented structural motifs.

In particular, some of our current efforts are focused on copper(II) chemistry and, for example, we have recently reported Cu^{II}_6, and 1D $(Cu^{II}_4)_n$ and 2D $(Cu^{II}_2)_n$ cluster and coordination polymers, respectively, by using the di-2-pyridyl ketone $[(py)_2CO]/PhCO_2^-/N_3^-$ 'ligand blend' [15]. Across this line, the initial employment of the pyridyl alkoxide ligand pyridine-2,6-dimethanol ($pdmH_2$, Scheme 1) in $Cu^{II}/MeCO_2^-$ chemistry has provided access to a compound consisting of cocrystallized Cu^{II}_3 and Cu^{II}_4 clusters, the individual Cu^{II}_4 component of the latter "mixed"-species through a designed synthesis, and a unique 1D $(Cu^{II}_5)_n$ coordination polymer [16]. Despite its rather extensive use in *trivalent* 3d-metal cluster chemistry [8a,b,17], there has been only very limited use of $pdmH_2$ in Cu^{II} chemistry (and generally in the *divalent* 3d-metal chemistry), and only one dinuclear [18] and few mononuclear [18] complexes were further reported.

As an extension of the work with $pdmH_2$, we have now asked what kind of products might result from the use of this ligand in Cu^{II} *non*-carboxylate chemistry. Since the RCO_2^- ions are structure-determining components in the $[Cu_3]\cdot[Cu_4]$, Cu_4 and $(Cu^{II}_5)_n$ complexes [16], we anticipated that the absence of RCO_2^- from the reactions would give distinctly different products, and we have therefore explored this possibility. In the present work, we have explored the reactions between $pdmH_2$ and a Cu^{II} non-carboxylate starting material, namely copper(II) nitrate, under basic conditions. This has successfully led to the known [18] mononuclear Cu^{II} compound with a Jahn–Teller distorted octahedral geometry and a new Cu^{II}_4 cluster possessing a distorted tetrahedral metal arrangement; the latter was prepared by using both the "metal complexes as ligands" strategy [19] and "one-pot" procedures. The synthesis, structure and magnetochemical characterization of the tetranuclear compound are described in this paper.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received.

Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyser. IR spectra (4000–450 cm^{-1}) were recorded on Perkin–Elmer 16 PC and Nicolet 520 FTIR spectrometers with samples prepared as KBr pellets, and as Nujol and hexachlorobutadiene mulls between CsI discs. Variable-temperature magnetic studies for complex **2** were performed using a Quantum Design SQUID magnetometer at the Magnetochemistry Service of the University of Barcelona. Diamagnetic corrections were applied to the observed paramagnetic susceptibilities using Pascal's constants.

2.2. Compound preparation

2.2.1. $[Cu(pdmH_2)_2](NO_3)_2$ (**1**)

Solid $pdmH_2$ (0.28 g, 2.00 mmol) was added to a pale blue solution of $Cu(NO_3)_2\cdot 3H_2O$ (0.48 g, 2.00 mmol) in MeCN (30 mL). The solid soon dissolved to give a blue solution. The solution was stirred for 30 min, filtered and the filtrate was layered with Et_2O (60 mL). After 6 days, X-ray quality, blue prismatic crystals of **1** were collected by filtration, washed with MeCN (2×5 mL) and Et_2O (2×5 mL), and dried in air. Yield: 80% (based on the ligand). *Anal.* Calc. for $C_{14}H_{18}CuN_4O_{10}$: C, 36.10; H, 3.89; N, 12.03. Found: C, 36.21; H, 3.94; N, 11.95%. Selected IR data (KBr pellet, cm^{-1}): 3220mb, 2820m, 1612s, 1580m, 1476m, 1380vs, 1292s, 1232m, 1164m, 1102w, 1024vs, 828m, 798s, 660m, 622m.

2.2.2. $[Cu_4(NO_3)_2(pdmH)_4(H_2O)(MeOH)](NO_3)_2\cdot H_2O\cdot MeOH$ (**2**$\cdot H_2O\cdot MeOH$)

Method A. To a pale blue solution of **1** (0.47 g, 1.00 mmol) in MeOH (30 mL) was added solid NaOMe (0.05 g, 1.00 mmol). The solid soon dissolved to give a pale green solution. The solution was stirred for 40 min, during which time no further colour change occurred. The resulting solution was filtered and the filtrate was layered with Et_2O/*n*-hexane (1:1 v/v, 60 mL). After 10 days, pale green prismatic crystals of **2**$\cdot H_2O\cdot$MeOH were collected by filtration, washed with cold MeOH (2×2 mL) and Et_2O (2×5 mL), and dried in air. Yield: 40%. The air-dried sample analyzed as **2**$\cdot H_2O$. *Anal.* Calc. for $C_{29}H_{40}Cu_4N_8O_{23}$: C, 31.02; H, 3.59; N, 9.98. Found: C, 31.13; H, 3.62; N, 9.85%. Selected IR data (KBr pellet, cm^{-1}): 3428mb, 3074sb, 2836m, 2360m, 1610s, 1586m, 1452vs, 1383vsb, 1317s, 1224m, 1162m, 1040vs, 826m, 790m, 696m, 634w, 574m, 432w.

Method B. To a stirred, colourless solution of $pdmH_2$ (0.28 g, 2.00 mmol) and NaOMe (0.11 g, 2.00 mmol) in MeOH (30 mL) was added solid $Cu(NO_3)_2\cdot 3H_2O$ (0.48 g, 2.00 mmol). The resulting pale green solution was stirred for 40 min, filtered and the filtrate was layered with Et_2O/*n*-hexane (1:1 v/v, 60 mL). After 7 days, pale green prismatic crystals of **2**$\cdot H_2O\cdot$MeOH were collected by filtration, washed with cold MeOH (2×2 mL) and Et_2O (2×5 mL), and dried in air. Yield: 70%. The IR spectrum of the product was identical with that of the authentic material prepared by Method A. The purity of the sample prepared from this method was also confirmed by microanalytical data.

2.3. Single-crystal X-ray crystallography

The crystallographic data and structure refinement details for the two complexes are summarized in Table 1. It should be mentioned at this point that the crystal structure of **1** was reported five years ago [18]. Since the X-ray analysis by our group has led to a better quality structure due to the better quality of crystals [e.g., the reported R_1 ($I > 2\sigma(I)$) is 0.0564 [18], while our solution leads to 0.0286], we have included data for this mononuclear compound in Tables 1 and 2, and we briefly discuss its structure in the text of the present paper (vide infra). A selected crystal of **1** ($0.50 \times 0.40 \times 0.35$ mm) was mounted in air, whereas a selected crystal of **2**$\cdot H_2O\cdot$MeOH ($0.30 \times 0.20 \times 0.15$ mm) was mounted in capillary filled with drops of mother liquor. Diffraction measurements for **1** and **2**$\cdot H_2O\cdot$MeOH were made on a Crystal Logic Dual Goniometer diffractometer using graphite-monochromated Mo radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$. Intensity data were recorded using a θ–2θ scan to a maximum 2θ value of 50°. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using Crystal Logic software. Both structures were solved by direct

methods using SHELXS-97 [20a] and refined on F^2 by full-matrix least-squares techniques with SHELXL-97 [20b]. All H atoms were located by Fourier difference maps and refined isotropically. All non-H atoms were refined anisotropically.

3. Results and discussion

3.1. Brief synthetic comments and IR spectra

Many synthetic procedures [5,10,14a] to polynuclear 3d-metal clusters rely on the reactions of carboxylate starting materials such as $M(O_2CR)_2$ (R = various) with a potentially chelating/bridging ligand. This route was also known from our previous work to yield magnetically and structurally interesting Cu^{II} complexes upon reaction with $pdmH_2$ [16]. In the present study we have investigated the reactions with a simple Cu^{II} source, i.e. $Cu(NO_3)_2{\cdot}3H_2O$, *in the absence of carboxylate groups*.

Various reactions have been systematically explored with differing reagent ratios, reaction solvents, and other conditions. The reaction of $Cu(NO_3)_2{\cdot}3H_2O$ with $pdmH_2$ in a 1:1 molar ratio in MeCN gave a blue solution and the subsequent isolation of well-formed blue crystals of the known complex [18] $[Cu(pdmH_2)_2](NO_3)_2$ (**1**) in excellent yield (~80%). The formation of **1** is summarized in Eq. (1). The "wrong" reaction ratio employed for the preparation of the complex, compared to the stoichiometric ratio (1:2) required by Eq. (1), obviously did not prove detrimental to the formation of the product. The "correct" stoichiometric ratio, i.e. Cu^{II}:$pdmH_2$ = 1:2, was also employed and led to the pure compound in an excellent yield (>80%). Complex **1** was isolated from Weber's group [18] in EtOH/H_2O. Since (i) we have prepared this complex in MeCN and (ii) we have used it as starting material, we give its detailed preparation in Section 2 (Experimental) of this paper.

$$Cu(NO_3)_2 \cdot 3H_2O + 2pdmH_2 \xrightarrow{MeCN} \underset{\mathbf{1}}{Cu(pdmH_2)_2](NO_3)_2} + 3H_2O \quad (1)$$

In an attempt to obtain higher nuclearity Cu^{II} products, several reactions were performed with higher Cu^{II}:$pdmH_2$ ratios, up to 4:1. However, complex **1** was still the only isolable product, in comparable (1.5:1 ratio) or lower (3–4:1 ratio) yields. Complex **1** was also obtained when the reaction was performed in MeOH, EtOH [18] or $MeNO_2$, but in much lower yields (~20–35%), whereas no significant reaction was observed when the solvent was CH_2Cl_2 or $CHCl_3$.

Since we could not easily divert the Cu^{II}/$pdmH_2$ reaction system to higher nuclearity products, we instead decided to investigate reactions of pre-isolated **1**, i.e., we suspected that this mononuclear Cu^{II} compound could act as "ligand" (the so-named "metal complexes as ligands strategy" [19,21]). Its insolubility in many common solvents limited our choices, and we thus employed MeOH in which **1** is very soluble. Given the neutral form of $pdmH_2$ in **1**, we targeted its deprotonation by reaction of **1** with 1–3 equiv. of base, either NEt_3 or NaOMe. Such reactions with NEt_3 gave insoluble amorphous powders that perhaps were polymeric; these products were not further characterized. However, when NaOMe was reacted with one equivalent of **1** in MeOH (Method A of Section 2) a pale green solution was obtained which led to subsequent isolation of well-formed pale green crystals of $[Cu_4(NO_3)_2(pdmH)_4(H_2O)(MeOH)](NO_3)_2 \cdot H_2O \cdot MeOH$ (**2** · H_2O · MeOH) in good yield (~40%) upon layering of the reaction solution with Et_2O. Its formation is summarized in Eq. (2).

$$\begin{aligned} 4\underset{\mathbf{1}}{[Cu(pdmH_2)_2](NO_3)_2} + 4NaOMe + H_2O &\xrightarrow{MeOH} \\ &\times \underset{\mathbf{2}}{[Cu_4(NO_3)_2(pdmH)_4(H_2O)(MeOH)](NO_3)_2} \\ &+ 4NaNO_3 + 4pdmH_2 + 3MeOH \end{aligned} \quad (2)$$

Once the identity of **2** had been established, we also sought and devised a convenient preparation of **2** in MeOH involving the *in situ* deprotonation of $pdmH_2$ (Method B of Section 2). This was the reaction between $Cu(NO_3)_2 \cdot 3H_2O$, $pdmH_2$ and NaOMe in a 1:1:1 ratio in MeOH, which gave **2** in high-yield (~70%) upon layering of the reaction solution with precipitation solvents; the reaction is summarized in Eq. (3).

$$\begin{aligned} 4Cu(NO_3)_2 \cdot 3H_2O + 4pdmH_2 + 4NaOMe &\xrightarrow{MeOH} \\ &\times \underset{\mathbf{2}}{[Cu_4(NO_3)_2(pdmH)_4(H_2O)(MeOH)](NO_3)_2} + 4NaNO_3 \\ &+ 3MeOH + 11H_2O \end{aligned} \quad (3)$$

Note that prolonged solvent evaporation should be avoided because the crystals of the product are contaminated with $NaNO_3$, requiring copious washing with MeOH to obtain an analytically pure sample. An increase in the NaOMe:$pdmH_2$ ratio up to 3:1 gave comparable (or slightly decreased) yields of complex **2** rather than a higher nuclearity product resulting from complete deprotonation of $pdmH_2$ groups. Further increases in the amount of NaOMe led to insoluble amorphous precipitates that may be polymers formed from this further deprotonation.

The IR spectrum of a vacuum-dried sample of complex **1**, arising from a KBr pellet, exhibits a medium intensity band at 3220 cm^{-1}, assignable to $\nu(OH)_{pdmH_2}$ [22]. The broadness and relatively low frequency of this band are both indicative of strong hydrogen-bonding. Several bands appear in the 1610–1383 cm^{-1} range in

the spectra of both **1** and **2**. These are assigned to contributions from the stretching vibrations of the aromatic ring, which overlap with stretches of the nitrate bands; they, thus, do not represent pure vibrations and render exact assignments difficult. The presence of ionic NO_3^- in **1** (established by crystallography) follows from the spectrum of this compound through the appearance of the $\nu_3(E')[\nu_d(NO)]$ mode of the D_{3h} ionic nitrate at $\sim$1380 cm^{-1} [23]. The nitrate vibrations in the mull and KBr spectra of **2** are indicative of the simultaneous presence of coordinated and ionic nitrates (also established by crystallography). The bands at $\sim$1452 and $\sim$1317 cm^{-1} may assigned to the $\nu_5(B_2)$ and $\nu_1(A_1)$ stretching modes (under C_{2v} symmetry), respectively, of the nitrato ligands [23]; their separation is small ($\sim$135 cm^{-1}) in accordance with the monodentate character of two nitrate groups [23]. It should be mentioned at this point that the highest-frequency NO stretching mode belongs to the A_1 species in complexes containing bidentate and to the B_2 species in complexes containing monodentate nitrato ligands [23]. As expected, the strong and broad band at $\sim$1383 cm^{-1} is present in both the KBr and mull spectra of **2**; this band is assigned (as in **1**) to the $\nu_3(E')$ mode of the ionic nitrate [23].

3.2. Description of structures

The molecular structures of the cations of complexes **1** and **2** are depicted in Figs. 1 and 2, respectively. Selected interatomic distances and angles are listed in Tables 2 and 3.

Complex **1** crystallizes in the monoclinic space group *C*2/*c*. Its asymmetric unit contains half of the mononuclear $[Cu(pdmH_2)_2]^{2+}$ cation in a general position (Fig. 1) and one NO_3^- anion. The Cu^{II} center is coordinated by two *N*,*O*,*O*′-tridentate chelating (η^3) $pdmH_2$ ligands. The $pdmH_2$ donor atoms are the nitrogen atom of the pyridyl group and the two oxygen atoms of the neutral alcohol arms. Thus, the Cu^{II} atom is six-coordinate with a compressed, *trans*-octahedral N_2O_4 environment [24]. The pyridyl nitrogen atoms can be viewed as strongly coordinating to the metal [Cu(1)–N(1) = 1.936(2) Å)] in the axial direction (N(1)–Cu(1)–N(1′) = 174.3(1)°), while the four alcohol-type oxygen atoms of the equatorial plane form weaker bonds to Cu^{II} [Cu(1)–O(1) = 2.163(2)/Cu(1)–O(2) = 2.192(2) Å].

The pyridyl rings of the two $pdmH_2$ ligands are planar and almost perpendicular to each other, forming an angle of 71.4° [N(1)C(2)C(3)C(4)C(5)C(6)/N(1′)C(2′)C(3′)C(4′)C(5′)C(6′)]. The two five-membered chelating rings, Cu(1)–N(1)–C(6)–C(7)–O(2) and Cu(1)–N(1)–C(2)–C(1)–O(1), share the common Cu(1)–N(1) edge. The dihedral angle formed between the mean planes Cu(1)–C(6)–C(7)–O(2) and Cu(1)–C(2)–C(1)–O(1) is 7.9°. There are four symmetry-equivalent, interionic OH···O hydrogen bonds involving the protonated $pdmH_2$ O atoms as donors and NO_3^- counterion O atoms as the acceptors. Their dimensions are: O(1)···O(4) 2.639(4) Å, HO(1)···O(4) 1.948(4) Å, O(1)–HO(1)···O(4) 156.3(1)° and O(2)···O(3) 2.739(4) Å, HO(2)···O(3) 2.063(4) Å, O(2)–HO(2)···O(3) 158.5(1)°. These H bonds serve to link neighbouring Cu^{II} monomers into one-dimensional, linear chains along the *b*-axis (Fig. S1) and their existence rationalizes the high thermodynamic stability of **1**.

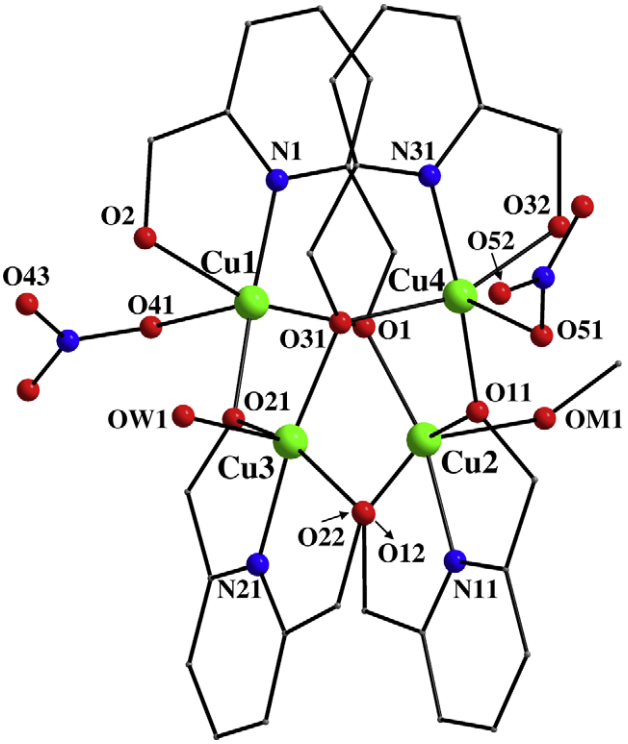

Fig. 2. Partially labelled plot of the cation of complex **2**. H atoms have been omitted for clarity. Colour scheme: Cu^{II}, green; O, red; N, blue; C, gray. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Complex **2** · H_2O · MeOH crystallizes in the monoclinic space group $P2_1/n$. Its structure consists of $[Cu_4(NO_3)_2(pdmH)_4(H_2O)(MeOH)]^{2+}$ cations (Fig. 2), NO_3^- anions, and solvate H_2O and MeOH molecules; the latter two will not be further discussed.

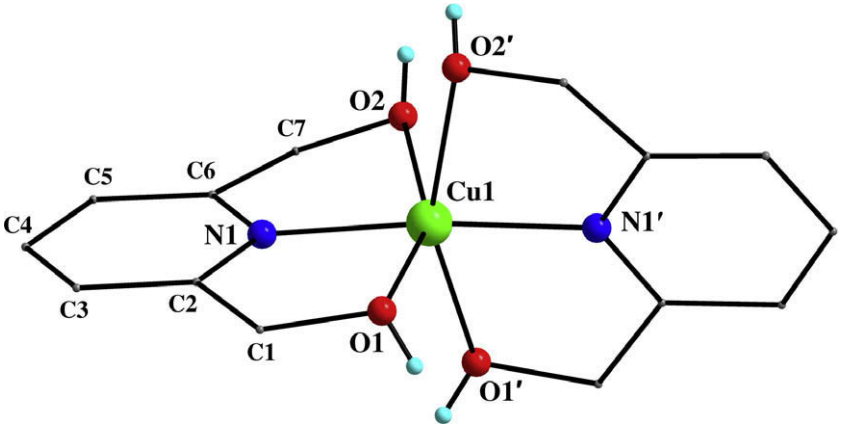

Fig. 1. Partially labelled PovRay representation of the cation of **1**, with some H atoms omitted for clarity. Colour scheme: Cu^{II}, green; O, red; N, blue; C, gray; H, sky blue. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

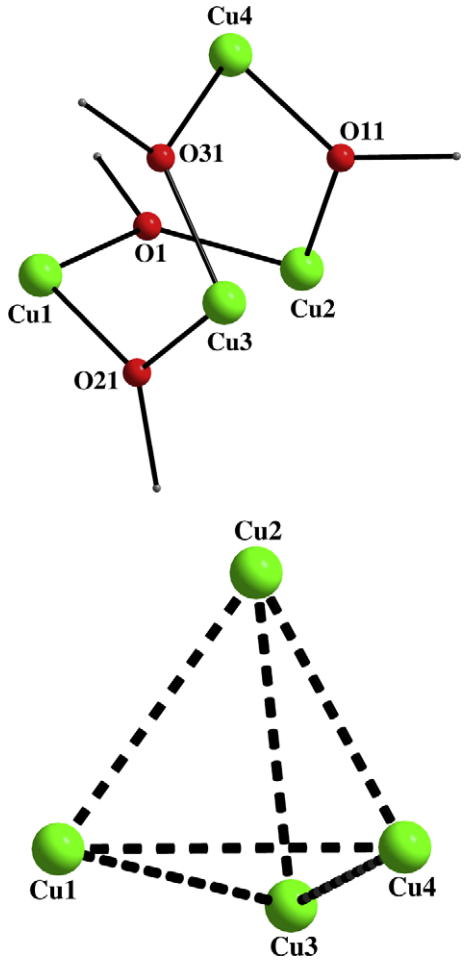

Fig. 3. (top) PovRay representation of the $[Cu_4(\mu_2\text{-}OR)_4]^{4+}$ core of complex **2**. (bottom) The Cu_4 skeleton of **2**, emphasizing its slightly distorted tetrahedral metal topology. Colour scheme: Cu^{II}, green; O, red; C, gray. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The core of the cation of **2** (Fig. 3, top) consists of four Cu^{II} ions arranged at the vertices of a *slightly* distorted tetrahedron. The Cu_4 topology of **2** is shown in the bottom of Fig. 3. It can be alternatively described as a *very* distorted, non-planar "ring", at the "corners" of which are lying the four Cu^{II} centers (Fig. S2); the deviation of the metal ions from their best least-squares plane ranges from 0.92 to 1.15 Å.

The Cu^{II} ions are held together by four monoatomic RO^- bridges [O(1), O(11), O(21), O(31)] of four pdmH$^-$ groups to give a $[Cu_4(\mu_2\text{-}OR)_4]^{4+}$ core (Fig. 3, top). Each O atom of the μ_2-OR bridges spans an edge of the tetrahedron. The Cu^{II}_4 tetrahedron is only slightly distorted; the bridged Cu···Cu distances are within the 3.223(1)–3.373(3) Å range, while the unbridged Cu···Cu separations are 3.505(3) and 3.762(1) Å for Cu(1)···Cu(4) and Cu(2)···Cu(3), respectively. The Cu···Cu···Cu and Cu–OR–Cu angles are all acute and obtuse, respectively, varying from 53.6(1) to 68.6(1)° and 115.5(1) to 121.3(1)°. The alkoxide bridges involving O(1), O(11), O(21) and O(31) are slightly asymmetrical, with Cu–O distances ranging from 1.874(3) to 1.965(3) Å.

All Cu^{II} ions are five-coordinate with almost ideal [Cu(2) and Cu(3); τ = 0.07 and 0.02, respectively] or slightly distorted [Cu(1)

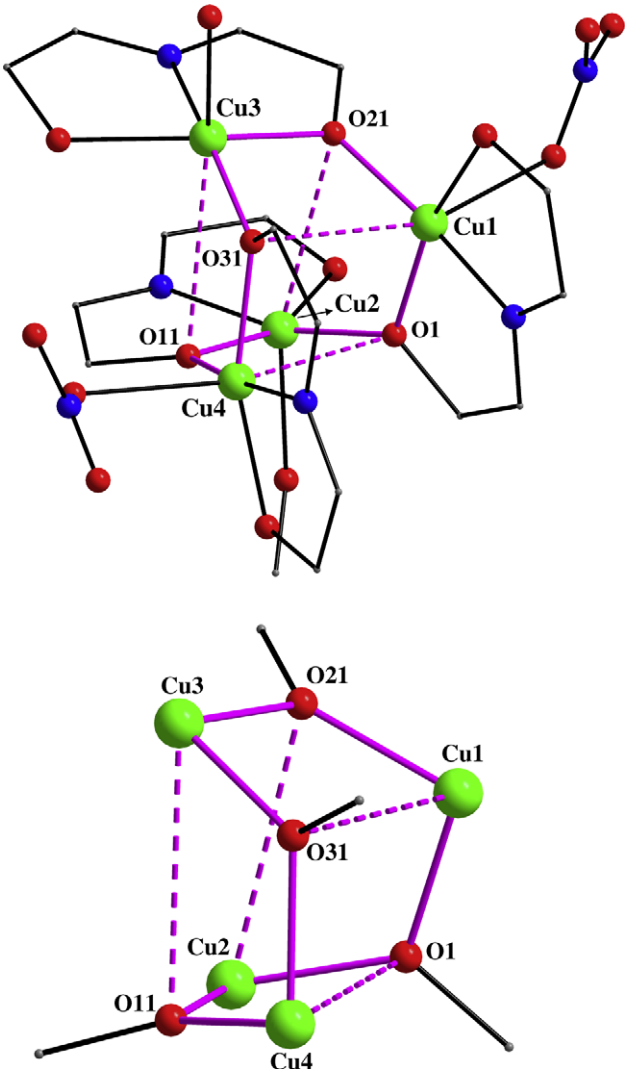

Fig. 4. (top) Molecular structure of the cation of **2**, and (bottom) its $[Cu_4(\mu_3\text{-}OR)_4]^{4+}$ core, emphasizing the very distorted cubane description (purple thick lines). The purple dashed lines represent the four long distances (edges) of the cubane unit. Colour scheme: Cu^{II}, green; O, red; N, blue; C, gray. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

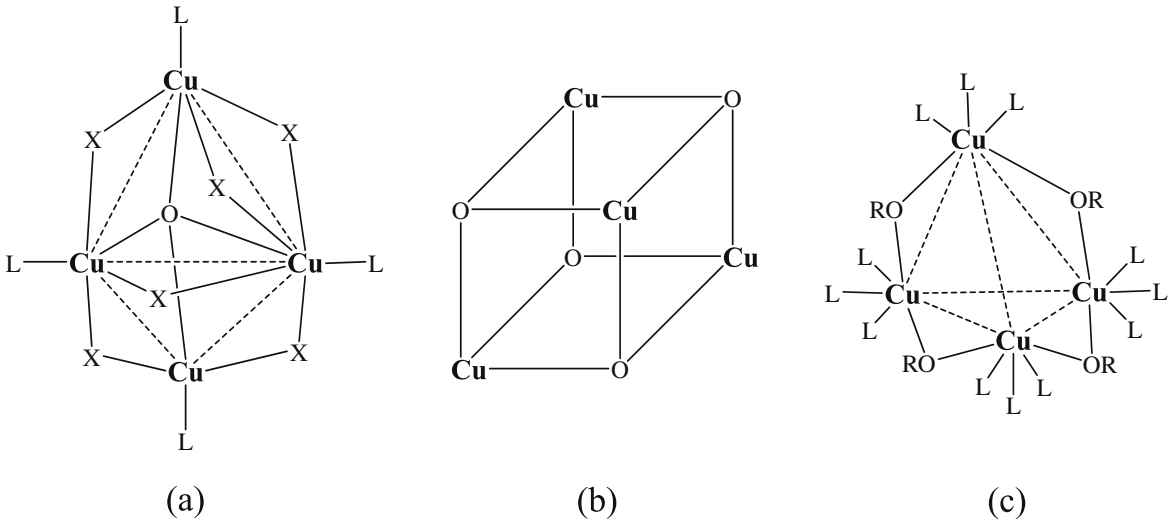
and Cu(4); τ = 0.15 and 0.19, respectively] square pyramidal geometry, where τ is 0 and 1 for perfect square pyramidal and trigonal bipyramidal geometries [25], respectively. The basal planes of the square pyramidal Cu^{II} ions are of the same type, and consist of one N and two O atoms belonging to the 'chelate' part of one $pdmH^-$ ligand and one bridging O atom from an adjacent $pdmH^-$ ligand; these groups are thus $\eta^1{:}\eta^1{:}\eta^2{:}\mu_2$. The two coordinated monodentate NO_3^- ions, as well as the H_2O and MeOH molecules, are each terminally bound to Cu(1)/Cu(4), Cu(3) and Cu(2), respectively, occupying the apical positions of the square pyramids; the Cu^{II} ions lie 0.111 [Cu(1)], 0.230 [Cu(2)], 0.236 [Cu(3)] and 0.177 Å [Cu(4)] Å above the O_3N least-squares basal planes, towards the apical donor atom.



In addition to the tetrahedral or non-planar, ring-like description of **2**, an alternative way of describing it can be presented *if* we consider as bonding the four, abnormally long Cu(1)–O(31) [2.812(1) Å], Cu(2)–O(21) [3.191(4) Å], Cu(3)–O(11) [3.158(6) Å] and Cu(4)–O(1) [3.047(7) Å] distances that involve the RO^- bridges, which thus become μ_3 (Fig. 4, top). Thus, the resulting $[Cu_4(\mu_3\text{-}OR)_4]^{4+}$ core (Fig. 4, bottom) can be described as a very distorted cubane with the four, distorted octahedral Cu^{II} atoms (now six- instead of five-coordinate) and the deprotonated μ_3-O atoms from the four $\eta^1{:}\eta^1{:}\eta^3{:}\mu_3$ (instead of $\eta^1{:}\eta^1{:}\eta^2{:}\mu_2$) $pdmH^-$ ligands occupying alternate vertices.

The structure of complex **2** is stabilized by two strong hydrogen bonds between the protonated, bound OH groups of two $pdmH^-$ ligands and the O atoms of a monodentate or ionic NO_3^- group. The dimensions are: O(2)···O(43) 2.606(4) Å, HO(2)···O(43) 1.768(4) Å, O(2)–HO(2)···O(43) 170.6(1)° and O(32)···O(72) 2.705(3) Å, HO(32)···O(72) 1.918(3) Å, O(32)–HO(32)···O(72) 160.7(1)°. There are also many weak hydrogen bonds involving the remaining protonated OH groups of $pdmH^-$ ligands and the terminal H_2O and MeOH molecules as donors and the monodentate/ionic NO_3^- groups as acceptors, with O···O distances in the 2.9–3.1 Å range, or slightly greater. These serve to link neighbouring Cu_4 cations and NO_3^- anions in the crystal into a 3D H-bonded network. The tetrahedral arrangement of the four Cu^{II} in the 'folded' crystal structure of complex **2** is further stabilized by two intramolecular π–π stacking interactions [26] on the two sides of the molecule that involve the pyridyl groups of two sets of $pdmH^-$ ligands, i.e., those containing N(1)/N(31) and N(11)/N(21). In both sets, the aromatic rings of the $pdmH^-$ ligands are nearly parallel, the angle between their mean planes being 10.3 and 3.9°, respectively. Moreover, the distances between the centroids of rings containing N(1)/N(31) and N(11)/N(21) are 3.805 and 3.755 Å, respectively.

Tetranuclear copper(II) coordination complexes with *N*- and/or *O*-based ligands show a variety of structural types [24,27]. Well known examples are the clusters having the metal ions in a tetrahedral arrangement bridged over the edges by μ_2-halide ions and by a μ_4-O^{2-} in the center of the tetrahedron (Scheme 2a) [28]. More recently tetranuclear compounds of the cubane type have been studied extensively, structurally as well as with respect to their magnetic properties, by Haase, Ruiz and Alvarez, among others (Scheme 2b) [16,29]. The common feature characterizing the tetranuclear compounds studied so far is the fact that monoatomic bridges interconnect the metal ions. Tetranuclear Cu^{II} complexes containing diatomic bridges are also known [30]. Complex **2** joins a handful of structurally characterized Cu_4^{II} complexes with a tetrahedral metal topology that contain *solely* monoatomic bridges (Scheme 2c) [31].

3.3. Magnetochemistry

Variable-temperature dc magnetic susceptibility data in a 0.1 T field and in the 2.0–300 K range were collected on a powdered microcrystalline sample of $\mathbf{2}\cdot H_2O$ restrained in eicosane to prevent torquing. The obtained data are plotted as $\chi_M T$ and χ_M vs. T in Fig. 5. The $\chi_M T$ value at 300 K is 1.23 $cm^3\ mol^{-1}$ K. This value is slightly less than that expected for a cluster comprising four Cu^{II} non-interacting ions (1.50 $cm^3\ mol^{-1}$ K with g = 2). The $\chi_M T$ product continuously decreases with decreasing temperature and gradually tends to 0 $cm^3\ mol^{-1}$ K at the very low temperature range (<20 K). This behaviour is indicative of predominant antiferromagnetic interactions between the metal centers with the low temperature value suggesting a ground state spin of S = 0. The shape of the $\chi_M T$ vs. T plot indicates an overall, moderate antiferromagnetic coupling between the four metal centers. On the other hand, the molar magnetic susceptibility χ_M shows a continuous increase upon cooling, but below ~110 K it exhibits a sudden drop, thus revealing a well-defined maximum. This further supports antiferromagnetic interactions, which are expected to be of moderate strength considering the position of the maximum, and an S = 0 ground state. The Curie tail in the low temperature susceptibility data reveals the existence of a paramagnetic, possibly monomeric, impurity.

Scheme 2. Common structural types in Cu_4^{II} clusters: (a) halide- and oxo-bridged, tetrahedral clusters; (b) cubanes; (c) alkoxide-bridged, tetrahedral clusters (X = halide ion, L = monodentate ligand).

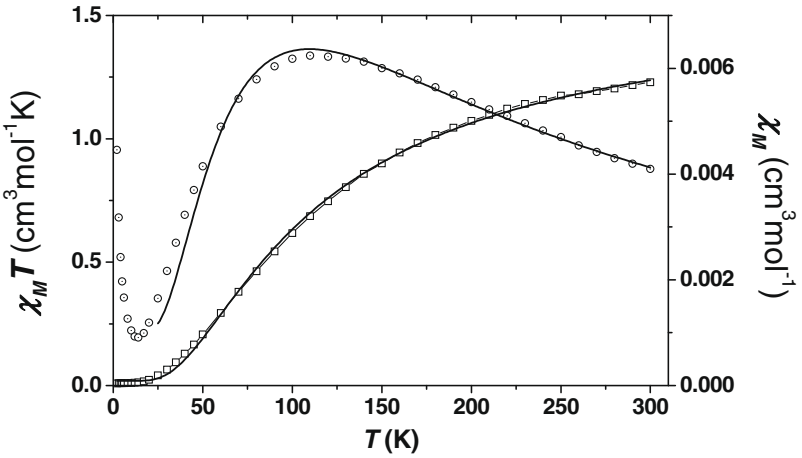


Fig. 5. χ_M vs. T (open cycles) and $\chi_M T$ vs. T (open squares) plots for **2**·H_2O in a 1 kG field. The solid lines are the fit of the data; see the text for the fit parameters.

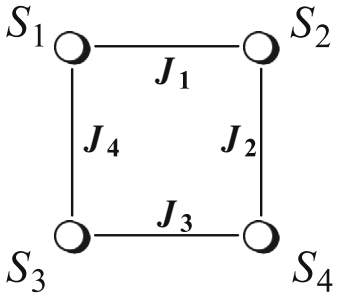
As we mentioned before, from a structural viewpoint, complex **2** adopts a slightly distorted tetrahedral metal topology; however, magnetically, the system behaves as a ring (vide infra). Considering as bonding the four long Cu(1)–O(31), Cu(2)–O(21), Cu(3)–O(11), and Cu(4)–O(1) distances the system could potentially behave magnetically as a cube; however, given the real rigid shape of the structure, this is clearly not the case and thus there are no superexchange pathways that involve these axial Cu–O–Cu interactions. Nevertheless, from the magnetic point of view, the exact geometric arrangement of the spin carriers in a molecule is of less importance compared with the actual number of interactions through the exchange pathways. In the case of **2**, the system is magnetically defined by four exchange interactions, J_{ij} (Scheme 3).



From examination of the structural data of **2**, there are strictly four different Cu–O–Cu bond angles, thus four different superexchange pathways from which derives the spin Hamiltonian (using the atomic numbering in Scheme 3) shown in Eq. (4).

$$H = -J_1(S_1 \cdot S_2) - J_2(S_2 \cdot S_4) - J_3(S_3 \cdot S_4) - J_4(S_1 \cdot S_3) \quad (4)$$

However, the Cu–O–Cu bond angles have similar values (120.3, 119.7, 121.3 and 115.5°); thus, assuming that the four J coupling constants are not identical, an attempt to differentiate J_1, J_2, J_3 and J_4 is not reliable because three of them should be extremely similar to each other, and only the coupling constant related to the smaller angle can be slightly different. Then, the only possibility to simplify the system is to assume a mean value defined by the spin Hamiltonian:

$$H = -J_1(S_1 \cdot S_2 + S_2 \cdot S_4 + S_3 \cdot S_4 + S_1 \cdot S_3) \quad (5)$$

A fit of the experimental data of **2** · H_2O to the expression derived from the simplified spin Hamiltonian shown in Eq. (5), i.e. assuming that all the coupling constants are equal, gives the parameters $J_1 = -99.5$ cm^{-1} and $g = 2.11(4)$, which lead to an overall $S = 0$ ground state. The large, obtuse Cu–O–Cu angles are considered responsible for the moderately strong antiferromagnetic J_1 coupling [15,16,22,29c,32].

Scheme 3. The magnetic coupling scheme of **2** involving four J parameters.

4. Conclusions

The present work extends the body of results that emphasize the ability of $pdmH_2$ to form interesting structural types in copper(II) cluster chemistry. In addition to the $\{[Cu_3(O_2CMe)_2(pdm)_2(MeOH)_2][Cu_4(O_2CMe)_2(pdmH)_4]\}(ClO_4)_2$, $[Cu_4(O_2CMe)_2(pdmH)_4](O_2CMe)_2$ and $[Cu_5(O_2CMe)_6(pdm)_2]_n$ carboxylate-based complexes reported previously [16], the $Cu/NO_3^-/pdmH_2$ reaction system has provided access to the tetranuclear cluster **2** and the known [18] mononuclear compound **1**. Complex **2** is a new addition to the small Cu_4 family of clusters with a tetrahedral metal arrangement bridged solely by monoatomic alkoxide bridges. This compound has been found to possess a $S = 0$ spin ground state and its magnetic behaviour can be interpreted considering a simplified $1-J$ model as a result of its folded ring-like $[Cu_4(\mu_2\text{-}OR)_4]^{4+}$ core. The monomeric complex **1** has been also used as a "ligand" for the construction of the larger, tetranuclear cluster **2** under basic conditions. Thus, from the synthetic inorganic chemistry viewpoint, this work further demonstrates the utility of the "metal complexes as ligands" approach in transition metal cluster chemistry. Preliminary experiments show that the reactions of **1** with sources of other divalent 3d or 4f metals under strong basic conditions lead to a variety of mixed-metal Cu^{II}/M complexes (M = Fe, Mn, Ni, Co, Ln). Finally, an important chemical message from this and our previous [16] work is that the $pdmH_2/X^-$ (X^- = RCO_2^-, NO_3^-) ligand combination looks like a promising candidate system for the generation of interesting new 3d-metal (other than Cu^{II}) clusters and coordination polymers, whose structure may be dependent on the nature of X^-.

Scheme 1. Paddle wheel (left), trinuclear basis carboxylate (middle) and tetranuclear "butterfly" carboxylate (right) complexes. Curved lines represent bidentate bridging carboxylate groups. The paddle wheel structural type is associated with a variety of metal–metal interactions ranging from no interaction, weak spin-pairing, various orders of metal–metal bonding, to the "super-short" metal–metal bonds. The L groups are often monodentate ligands, but they may represent intercluster association into polymeric structures or (only in the case of the "butterfly" complexes) one donor atom of a bidentate chelate.

Scheme 2. General structural formula and abbreviation of the 2-pyridyl oximes that are used in our laboratories (left); the ligands pyridine-3-carbaldehyde oxime [3-pyridinealdoxime, (3-py)C(H)NOH] and pyridine-4-carbaldehyde oxime [4-pyridinealdoxime, (4-py)C(H)NOH] employed in this work are shown in the middle and right part, respectively, of the scheme.

(the term "simple" means here ligands with only one pyridyl and one oxime group as donors). Our goals are to investigate if clusters and coordination polymers can be prepared from the Zn^{II}/RCO_2^-/(py)C(R′)NOH reaction systems (R′=H, Me, Ph) and to isolate, if possible, photoluminescent complexes. Reactions of $Zn(O_2CR)_2{\cdot}2H_2O$ (R = Me, Ph) with the more complex ligand di-2-pyridyl ketone oxime, (2-py)C(2-py)NOH, have led to compounds $[Zn_4(OH)_2(O_2CR)_2\{(2\text{-py})C(2\text{-py})NO\}_4]$ [11] with the extremely rare inverse 12-metallacrown-4 structural motif. We report here the preparation and characterization of two complexes derived from the reactions of $Zn(O_2CPh)_2{\cdot}2H_2O$ with (3-py)C(H)NOH and (4-py)C(H)NOH (see Scheme 2). Efforts to date with the isomeric pyridine-*x*-carbaldehyde oximes [*x* = 2, (2-py)C(H)NOH, R′ = H in Scheme 2; *x* = 3, (3-py)C(H)NOH; *x* = 4, (4-py)C(H)NOH] have almost completely neglected Zn chemistry; no Zn^{II} complexes of (3-py)C(H)NOH and (4-py)C(H)NOH have been reported, while the only structurally characterized Zn^{II}/(2-py)C(H)NOH or (2-py)C(H)NO^- compound is $[Zn_4(OH)_2Cl_2\{(2\text{-py})C(H)NO\}_4]$ [12].

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. $Zn(O_2CPh)_2{\cdot}2H_2O$ was prepared by the reaction of $Zn(O_2CMe)_2{\cdot}2H_2O$ with and excess of $PhCO_2H$ in $CHCl_3$ under reflux. Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer.

IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT-spectrometer with samples prepared as KBr pellets.

2.2. Compound preparation

2.2.1. $[Zn_3(O_2CPh)_6\{(3\text{-py})C(H)NOH\}_2]$ (**1**)

A solution of $Zn(O_2CPh)_2{\cdot}2H_2O$ (0.346 g, 1.00 mmol) in MeCN (10 ml) was added gradually to a stirred solution of (3-py)C(H)NOH (0.122 g, 1.00 mmol) in MeCN (10 ml). Slow evaporation of the resulting solution at room temperature yielded colourless prismatic crystals of **1** after three days. The crystals were collected by filtration under vacuum, washed with MeCN (2 × 5 ml) and Et_2O (5 ml), and dried in air. Typical yields were in the 50–55% range (based on the metal). FT-IR (KBr pellet, cm^{-1}): 3354mb, 3064w, 1622sh, 1612vs, 1602m, 1570s, 1540m, 1490m, 1448w, 1400vs, 1304m, 1192w, 1130w, 1058w, 1026w, 978m, 890w, 874w, 838w, 814w, 720s, 700m, 670m, 654w, 586w, 528w, 446w. *Anal.* Calc. for $C_{54}H_{42}N_4O_{14}Zn_3$ (1167.03): C, 55.57; H, 3.63; N, 4.80. Found: C, 55.29; H, 3.37; N, 4.82%.

2.2.2. $[Zn_2(O_2CPh)_4\{(4\text{-py})C(H)NOH\}_2]$ (**2**)

To a stirred solution of $Zn(O_2CPh)_2{\cdot}2H_2O$ (0.138 g, 0.40 mmol) in MeCN (10 ml) was added a solution of (4-py)C(H)NOH (0.049 g, 0.40 mmol) in the same solvent (10 ml). The reaction solution was stirred for 15 min during which time a white solid precipitated. The precipitate was collected by filtration and the filtrate was allowed to slowly evaporate at room temperature. After

[b] $wR_2 = \{\sum[w(F_o^2 - F_c^2)^2]/\sum[w(F_o^2)^2]\}^{1/2}$.

three days, X-ray quality colourless crystals of **2** were collected by filtration under vacuum, washed with MeCN (2 × 5 ml) and Et_2O (5 ml), and dried in air. Typical yields (including the white solid) were in the 50–55% range. FT-IR (KBr pellet, cm^{-1}): 3221mb, 3066w, 1634vs, 1573s, 1409vs, 1301m, 1225w, 1175vw, 1067vw, 1030w, 990m, 932w, 832m, 714s, 673m, 560w, 536m, 472w, 460w. The IR spectra of the white powder and the colourless crystals (in the form of a powder) are identical. *Anal.* Calc. for $C_{40}H_{32}N_4O_{10}Zn_2$ (859.44): C, 55.90; H, 3.76; N, 6.52. Found: C, 55.62; H, 3.78; N, 6.55%.

2.3. Single-crystal X-ray crystallography

A colourless crystal of **1** (0.10 × 0.20 × 0.60 mm) and a colourless crystal of **2** (0.20 × 0.30 × 0.50 mm) were mounted in air and covered with epoxy glue. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Details for data collection and processing are listed in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11 < 2\theta < 23°$. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using Crystal Logic software. Ψ-scan data were collected for both structures. The intensity of a certain reflection remains invariant during 360° rotation around the Φ axis, thus absorption correction is not required.

The structures were solved by direct methods using SHELXS-86 [13] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [14]. Further experimental crystallographic details for **1**: $2\theta_{max} = 50°$; 424 parameters refined; $(\Delta/\sigma)_{max} = 0.000$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.557/-0.712$ e/Å^3; R_1 (for all data), 0.0581. All hydrogen atoms were located by difference maps and refined isotropically. All non-hydrogen atoms were refined anisotropically. Further experimental crystallographic details for **2**: $2\theta_{max} = 47.2°$; 633 parameters refined; $(\Delta/\sigma)_{max} = 0.002$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.292/-0.354$ e/Å^3; R_1 (for all data), 0.1075. All hydrogen atoms were located by difference maps and were refined isotropically. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Brief synthetic comments and IR spectra

The chemical and structural identities of the products from the $Zn(O_2CPh)_2{\cdot}2H_2O$/LH reaction systems in MeCN, where LH is (3-py)C(H)NOH or (4-py)C(H)NOH, depends on the pyridyl oxime ligand. Use of (3-py)C(H)NOH gives the trinuclear cluster **1**, whereas employment of (4-py)C(H)NOH led to the dinuclear compound **2**.

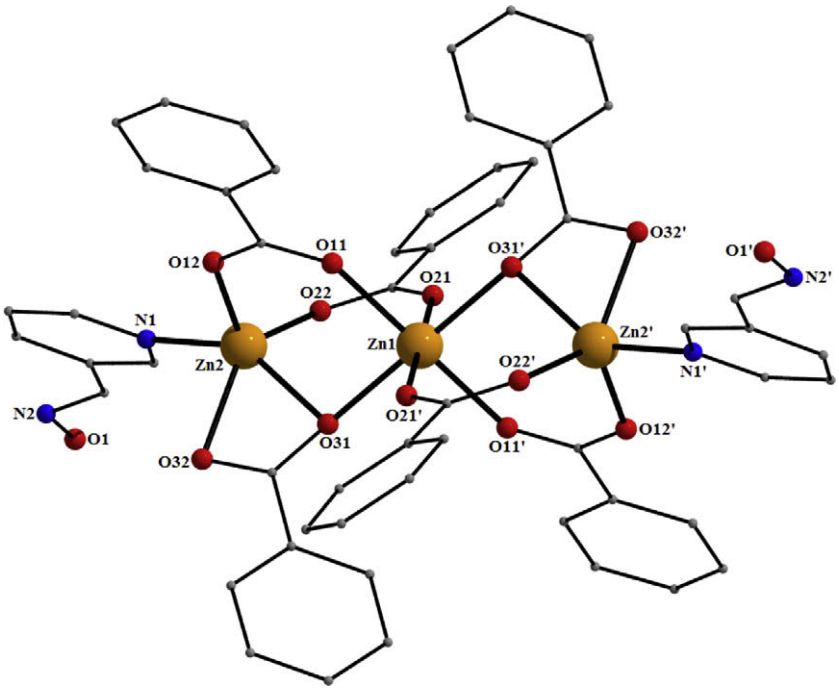

Fig. 1. Partially labeled plot of the molecular structure of **1**. H atoms have been omitted for clarity. Colour code: Zn, orange; O, red; N, blue; C, gray. Primes are used for symmetry related (−*x*, 1 − *y*, −*z*) atoms. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

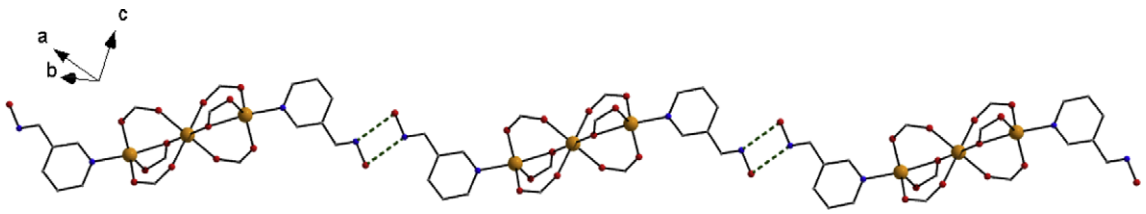

Fig. 2. A part of the 1D structure of **1** due to H-bonding interactions (green dashed lines); colour code as in Fig. 1. H atoms and the phenyl rings of the benzoates have been omitted for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

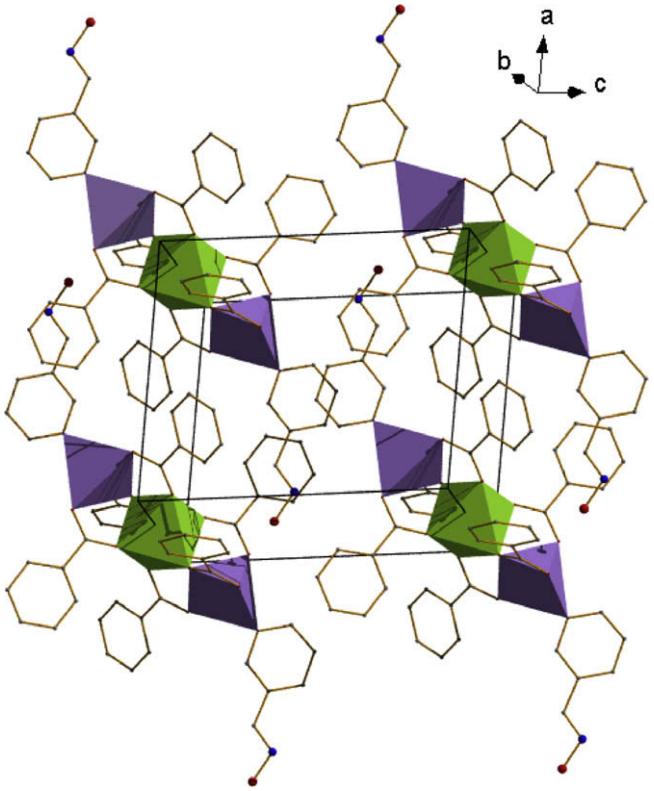

Fig. 3. Crystal packing diagram of complex **1**. The metal coordination spheres are represented as polyhedra [Zn(1), green; Zn(2), purple]. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The preparation of the two complexes is summarized in the balanced Eqs. (1) and (2):

$$3Zn(O_2CPh)_2 \cdot 2H_2O + 2(3\text{-py})C(H)NOH \xrightarrow{MeCN} [Zn_3(O_2CPh)_6\{(3\text{-py})C(H)NOH\}_2] + 6H_2O \quad (1)$$

$$2Zn(O_2CPh)_2 \cdot 2H_2O + 2(4\text{-py})C(H)NOH \xrightarrow{MeCN} [Zn_2(O_2CPh)_4\{(4\text{-py})C(H)NOH\}_2] + 4H_2O \quad (2)$$

Two features of the reactions represented by the chemical (1) and (2) deserve comments. First, the "wrong" reaction ratio (1:1) employed for the preparation of **1**, compared to the stoichiometric ratio (1.5:1) required by Eq. (1), obviously did not prove detrimental to the formation of the complex. With the identity of **1** crystallographically established (vide infra), the "correct" stoichiometric ratio, i.e. Zn^{II}:(3-py)C(H)NOH = 1.5:1, was employed and led to the pure compound in very good yield (60–65%). Second, complexes **1** and **2** seem to be the only isolable products from the $Zn(O_2CPh)_2{\cdot}2H_2O$/LH reaction systems. The Zn^{II} to ligand reaction ratio (we used 1:2 and 1:3 ratios to "force" the formation of mononuclear complexes, e.g. $[Zn(O_2CPh)_2(LH)_x]$ with $x = 2$ or 3), the presence of counteranions (we added ClO_4^- or PF_6^- in some reaction mixtures to "force" the isolation of cationic complexes), the nature of the solvent (use of alcohols gives the same products) and the precipitation/crystallization method have no influence on the identity of the products.

The IR spectra of **1** and **2** exhibit medium intensity bands at ~3350 and 3320 cm^{-1}, respectively, assignable to the ν(OH) vibration of the coordinated pyridyl oxime ligands [6a,15]. The broadness and low frequency of these bands are both indicative of hydrogen bonding. The medium intensity bands at 1636 and 1124 cm^{-1} in the spectrum of the free ligand (3-py)C(H)NOH are assigned to $\nu(C{=}N)_{oxime}$ and $\nu(N{-}O)_{oxime}$, respectively [6a,16]. The corresponding vibrations in the spectrum of free (4-py)C(H)NOH appear at 1566 and 1096 cm^{-1}. In the spectra of the complexes, these typical bands of the neutral oxime group are situated at approximately the same wavenumbers to those in the spectra of the corresponding free ligands, confirming the crystallographically established (vide infra) non-participation of the oxime group in coordination. For example, the $\nu(C{=}N)_{oxime}$ and $\nu(N{-}O)_{oxime}$ vibrations appear at 1622 and 1130 cm^{-1}, respectively, in the spectrum of **1**. The in-plane deformation band of the pyridyl ring of the free ligands [638 cm^{-1} in (3-py)C(H)NOH, 646 cm^{-1} in (4-py)C(H)NOH] shifts upwards in the complexes (654 cm^{-1} in **1**, 673 cm^{-1} in **2**), confirming the involvement of the ring-N atom in coordination [17]. The strong bands at 1573 and 1409 cm^{-1} in

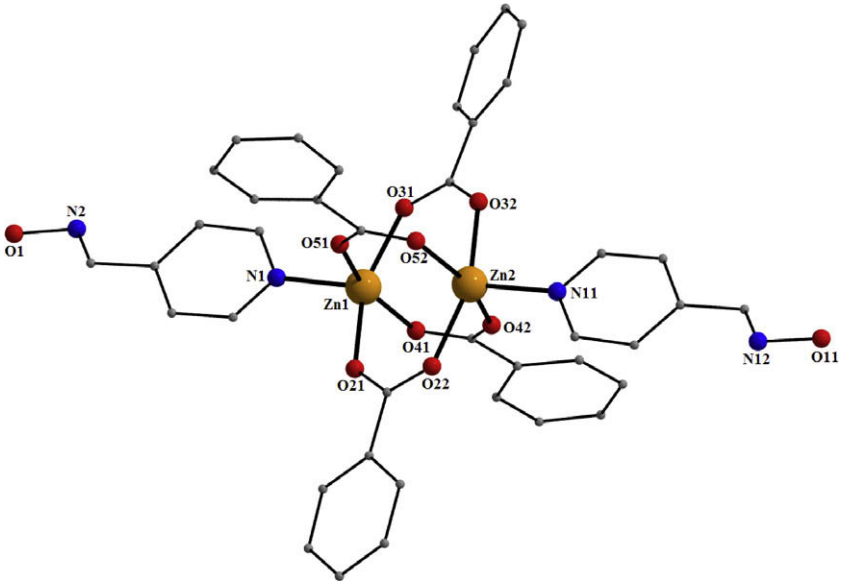

Fig. 4. Partially labeled plot of the molecular structure of **2**. Colour code as in Fig. 1. H atoms have been omitted for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

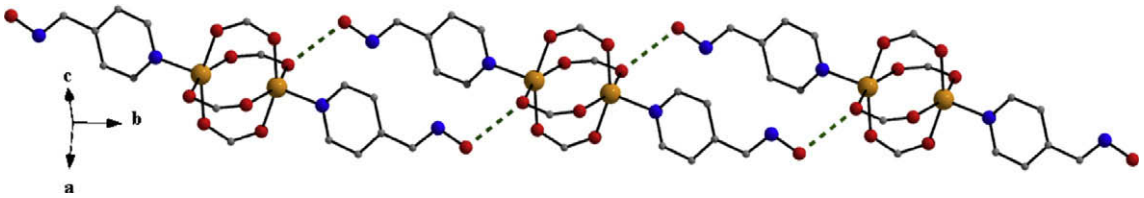

Fig. 5. A small portion of the ladder-like 1D architectures of **2** due to H-bonding interactions (green dashed lines). Colour code as in Fig. 1. The H atoms and the phenyl rings of the benzoates have been omitted for clarity. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

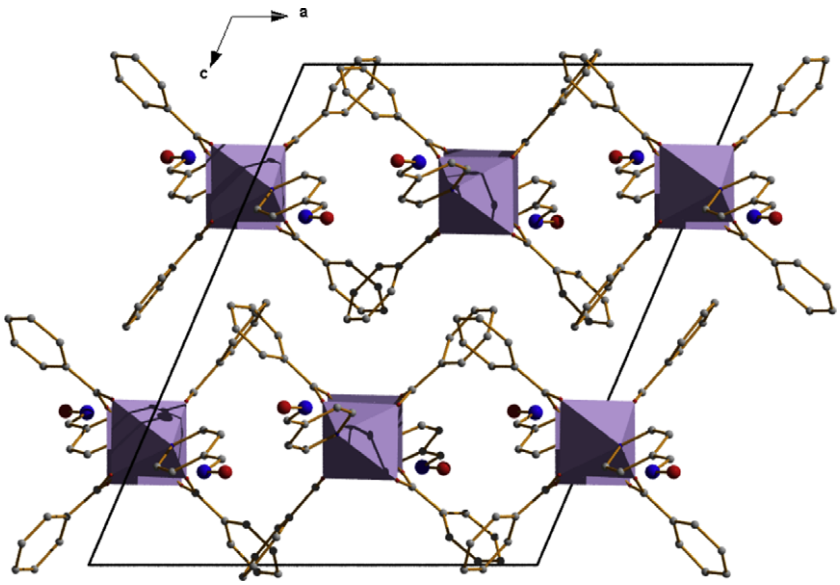

Fig. 6. Crystal packing diagram of complex **2**. The metal coordination spheres are represented as polyhedra (purple colour). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Symmetry operations used to generate equivalent atoms: (′) $-x, 1-y, -z$.

the spectrum of **2** are assigned to the $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ modes of the benzoato ligands, respectively [18]; the former may also involve a pyridyl stretching character. The difference Δ, where $\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)$, is 164 cm^{-1}, less than that for NaO_2CPh (184 cm^{-1}), as expected for bidentate bridging ligation [18]. In the IR spectrum of **1**, the bands at 1570 and 1612 cm^{-1} are assigned to $\nu_{as}(CO_2)$; both may also involve a pyridyl stretching character. The $\nu_s(CO_2)$ modes appear at 1400 and 1448 cm^{-1}. The appearance of two distinct bands for each mode reflects the presence of two different types of $PhCOO^-$ groups in the complex (vide infra) [19]. The 1612, 1400 cm^{-1} pair ($\Delta = 212$ cm^{-1}) are assigned [18–20] to the $\eta^1{:}\eta^2{:}\mu_2$ benzoate, while the 1570, 1448 cm^{-1} pair ($\Delta = 122$ cm^{-1}) to the bidentate bridging ($\eta^1{:}\eta^1{:}\mu_2$) benzoates.

3.2. Description of structures

Aspects of the molecular and crystal structures of complexes **1** and **2** are shown in Figs. 1–6. Selected interatomic distances and angles are listed in Tables 2 and 4, while important hydrogen bonding interactions are presented in Table 5.

Complex **1** crystallizes in the triclinic space group $P\bar{1}$. Its crystal structure consists of trinuclear $[Zn_3(O_2CPh)_6\{(3\text{-py})C(H)NOH\}_2]$ molecules. The central metal center [Zn(1)] is located on a crystallographic inversion center and thus the trinuclear molecule adopts a strictly linear structure. Zn(1) is coordinated by six oxygen atoms belonging to six $PhCO_2^-$ groups. One $\eta^1{:}\eta^2{:}\mu$ and two *syn*, *syn*-$\eta^1{:}\eta^1{:}\mu$ carboxylate groups span each pair of neighbouring Zn^{II} ions. The terminal metal ions [Zn(2), Zn(2′)] are each capped by one monodentate (3-py)C(H)NOH ligand; the donor atom of (3-py)C(H)NOH is the pyridyl nitrogen. The ZnO_6 octahedron is almost perfect with the Zn(1)–O bond lengths and the cis O–Zn(1)–O bond angles being in the ranges 2.069(3)–2.144(3) Å and 86.4(1)–93.6(1)°, respectively. The coordination geometry about the terminal Zn^{II} ions is described as distorted square pyramidal with the carboxylate oxygen atoms O(12) and O(12′) occupying the apical positions for Zn(2) and Zn(2′), respectively. Analysis of the shape-

determining angles using the approach of Reedijk and co-workers [21] yields a trigonality index, τ, value of 0.12 (τ = 0 and 1 for perfect *sp* and *tbp* geometries, respectively). The coordination of the bridging benzoate oxygen [O(31), O(31′)] is slightly pyramidal [$\sum$O(31) = 341.4(1)°]. The Zn(1)–O(31)–Zn(2) angle is 104.5(1)°.

In the crystal lattice of **1**, the molecules interact through hydrogen bonds building 1D chains parallel to the [2 0 −1] vector.

Complex **1** is the third structurally characterized Zn^{II}_3 complex containing the $[Zn^{II}_3(\eta^1{:}\eta^1{:}\mu_2\text{-}O_2CPh)_4(\eta^1{:}\eta^2{:}\mu_2\text{-}O_2CPh)_2]^0$ unit. The other two complexes are $[Zn_3(O_2CPh)_6(2,3\text{-}Me_2pyz)_2]$ [22a] and the trinuclear part of complex $[Zn_3(O_2CPh)_6(py)_2]\cdot[Zn_2(O_2CPh)_4(py)_2]$ [22b], where 2,3-Me_2pyz and py are 2,3-dimethylpyrazine and pyridine, respectively. Such complexes have been important in the establishment of the "carboxylate shift" concept [23]. Of the various types of metal-carboxylate binding modes, monoatomic bridging between metal ions offers great flexibility. Analysis [23] of the structural characteristics of dinuclear and trinuclear complexes containing monoatomically bridging carboxylate groups reveals that they can be grouped into three classes, depending upon the strength of the interaction of the non-bridging, or dangling (O_d), oxygen atom [O(32) in compound **1**] with one of the bridged metal centers [Zn(2) in **1**]. The application of this analysis to trinuclear Zn^{II} benzoate complexes is demonstrated in Scheme 3 and Table 3. The monoatomic bridging mode is postulated to be an important intermediate between the other, more common carboxylate binding modes, based on observed variation of the geometry for monoatomic bridges in structurally characterized metal complexes. The "movement" from monoatomic bridging to the other binding modes has been termed "carboxylate shift" [23]; such a shift is considered to be kinetically important in carboxylate-containing metalloproteins. Complex **1** is characterized by a moderate *D* value, *D* > *B*, *A*, a rather long Zn···Zn distance, a difference between C–O_d and C–O_b and a distinct tilt (α–β) of the $\eta^1{:}\eta^2{:}\mu$ carboxylate group towards Zn(2); thus, this compound can be placed in class II in Lippard's "carboxylate shift" classification scheme [23].

Compound **1** joins only a handful of structurally characterized metal complexes of (3-py)C(H)NOH [24]; in all the previously reported complexes the 3-pyridinealdoxime ligand is attached to the metal ions through the pyridine nitrogen atom (like in **1**) with

Scheme 3. Schematic structure of complex **1** showing the dangling (O_d) and bridging (O_b) oxygen atoms of the $\eta^1{:}\eta^2{:}\mu_2$ carboxylate groups, and defining the geometry of monoatomic carboxylate-bridged polymetallic centers in relation to the "carboxylate shift" mechanism proposed by Lippard and co-workers [23]; the values of the relevant structural parameters for **1** and the other two, structurally characterized complexes containing the $[Zn^{II}_3(\eta^1{:}\eta^1{:}\mu\text{-}O_2CPh)_4(\eta^1{:}\eta^2{:}\mu\text{-}O_2CPh)_2]^0$ unit are listed in Table 3.

Table 5
Hydrogen bonding interactions in **1** and **2**.

Interaction D–H···A	D···A (Å)	H···A (Å)	D–H···A (°)	Symmetry operation of A
1				
O1–HO1···N2	2.894(6)	1.94(8)	159(7)	2 − *x*, 1 − *y*, −1 − *z*
2				
O1–HO1···O52	2.727(7)	1.92(8)	169(8)	*x*, −1 + *y*, *z*
O11–HO11···O41	2.781(7)	2.05(11)	157(11)	*x*, 1 + *y*, *z*

the free oxime group participating in hydrogen bonding interactions. Complex **1** is the first Zn^{II} complex of (3-py)C(H)NOH.

Complex **2** crystallizes in the monoclinic space group $P2_1/n$. The four *syn*, *syn*-η^1:η^1:μ $PhCO_2^-$ ligands display a paddle wheel arrangement about the Zn···Zn axis. Each Zn^{II} center has a square pyramidal coordination geometry [τ = 0.04 for Zn(1) and 0.02 for Zn(2)], with the apex provided by coordination of the pyridyl nitrogen atom of a monodentate (4-py)C(H)NOH ligand. The metal to apical atom distances are the same, i.e., 2.028(4) Å. The mean Zn–O(carboxylate) bond lengths are 2.054(5) Å for Zn(1) and 2.053(5) Å for Zn(2). These distances are typical and unremarkable [25]. Zn(1) lies 0.386 Å and Zn(2) lies 0.387 Å out of their respective least-squares basal planes towards N(1) and N(11), respectively. The Zn(1)···Zn(2)–N(11) and Zn(2)···Zn(1)–N(1) angles are the same, i.e. 160.8°. Dinuclear $[Zn_2(O_2CR)_4L_2]$ complexes (L = monodentate ligand) have previously been observed to be either collinear [26] or similarly offset [25]. The tetracarboxylate bridging framework can accommodate metal–metal separations of up to ~3.5 Å [25]. The Zn···Zn separation in **1** [2.990(2) Å] is shorter than this maximum, but longer than the Cu···Cu distances in structurally similar Cu_2^{II} complexes [27].

In the crystal lattice of **2**, the dinuclear molecules interact through hydrogen bonds forming double, ladder-like chains along the *b* axis (Table 5, Fig. 5). Both oxime groups act as donors to carboxylate oxygen atoms.

Complex **2** is a new member of a small family of paddle wheel $[Zn_2(O_2CPh)_4L_2]$ complexes [22,28]. It is the sixth structurally characterized metal complex of (4-py)C(H)NOH. The previously reported complexes $[UO_2(acac)_2\{(4\text{-py})C(H)NOH\}]$ [29a], $[Cu(ClO_4)_2(phen)\{(4\text{-py})C(H)NOH\}_2]\cdot(4\text{-py})C(H)NOH$ [29b], $[Ni\{(4\text{-py})C(H)NOH\}_4(H_2O)_2]Br_2\cdot 2(4\text{-py})C(H)NOH$ [29c], $[Ag_4Mn_2(CN)_8\{(4\text{-py})C(H)NOH\}_4(H_2O)_2]_n$ [29d] and $[Cu(dipic)\{(4\text{-py})C(H)NOH\}(H_2O)]$ [29e], where $acac^-$ is the pentane-2,4-dionato (−1) ion and $dipic^{2-}$ is the pyridine-2,6-dicarboxylato (−2) ligand, all involve monodentate (4-py)C(H)NOH ligands with the pyridine nitrogen as the donor atom.

4. Concluding comments and perspectives

The initial use of (3-py)C(H)NOH and (4-py)C(H)NOH in reactions with $Zn(O_2CPh)_2\cdot 2H_2O$ has yielded the first Zn^{II} complexes of these ligands; the complexes have interesting molecular and crystal structures. The nuclearity of the product depends on the isomeric ligand form used. This work demonstrates the synthetic potential of combining 3- or 4-pyridinealdoxime with carboxylate ligands. Complexes **1** and **2** augur well that they are merely the first members of a new family of 3d-metal carboxylate clusters with (*x*-py)C(H)NOH-based ligands (*x* = 2, 3, 4). We currently investigate several M^{II}/RCO_2^-/(3-py)C(H)NOH or (4-py)C(H)NOH reaction systems (M^{II} = Mn^{II}, Co^{II}, Ni^{II}, Cu^{II}, Cd^{II}; R = Me, CMe_3, Ph) as an entry point to clusters with various nuclearities and structural types.

Metal complexes with *N*, *O*- or *N*,*N*′-bidentate bridging behaviours of the two ligands or complexes in which the oxime functionality is deprotonated are not known to date, and it is currently not evident if such species could be capable of existence; such complexes could be high nuclearity clusters or coordination polymers. We are studying these matters. It is also clear that the M^{II}/(3-py)C(H)NOH or (4-py)C(H)NOH chemistry warrants expansion to anionic ligands other than carboxylates, e.g. NO_3^-, SO_4^{2-}, etc.

5. Supplementary data

CCDC 727528 and 727529 contains the supplementary crystallographic data for complexes **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. The dpk and dpcp ligands.

2. Experimental

2.1. Materials

All materials were commercially available and used as received expect dpcp, which was synthesized according to a literature procedure [6]. *Caution!* Although no such tendency was observed during the present work, perchlorate salts are potentially explosive and should be handled with care and in small quantities.

2.2. Synthesis

Solid dpcp (15.0 mg, 0.052 mmol) was added to a light orange solution of $Fe(ClO_4)_3$?$9H_2O$ (107.0 mg, 0.208 mmol) in MeOH (45 mL). After cooling, the solution was left for slow evaporation. Yellow crystals of $[Fe_2\{pyCO(OMe)pyCO(OMe)py\}_2(MeO)_2](ClO_4)_2$·MeOH (**1**·MeOH) formed after 3 days, which were filtered off and dried in vacuo. The yield was ~9 mg (~16% with respect to dpcp). The dried complex was analyzed as solvent-free. *Anal.* Calc. for $C_{40}H_{42}Cl_2Fe_2N_6O_{18}$: C, 44.59; H, 3.93; N, 7.80. Found: C, 44.32; H, 3.80; N, 7.72%.

2.3. X-ray crystallography

A crystal with approximate dimensions 0.07 × 0.18 × 0.47 mm was taken from the mother liquor and immediately cooled to −93 °C. Diffraction measurements were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Cu Kα radiation. Data collection (ω-scans) and processing (cell refinement, data reduction and Empirical absorption correction) were performed using the CrystalClear program package [13]. The structure was solved by direct methods using SHELXS-97 [14] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [15]. Important crystallographic data are listed in Table 1. Further experimental crystallographic details for **1**·MeOH: $2\theta_{max}$ = 130°; reflections collected/unique/used, 28 753/7696 [R_{int} = 0.0521]/7696; 728 parameters refined; $(\Delta/\sigma)_{max}$ = 0.019; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.922/−0.758 e/Å^3; R_1/wR_2 (for all data), 0.0583/0.1417. Hydrogen atoms were either located by difference maps and were refined isotropically or were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically.

2.4. Physical measurements

Elemental analysis for carbon, hydrogen, and nitrogen was performed on a PerkinElmer 2400/*II* automatic analyzer. Infrared spectra were recorded as KBr pellets in the range 4000–400 cm^{-1} on a Bruker Equinox 55/S FT-IR spectrophotometer. Mössbauer spectra were taken with a constant acceleration spectrometer using a ^{57}Co (Rh) source at RT and a variable temperature Oxford cryostat. Variable-temperature magnetic susceptibility measurements were carried out on a powdered sample of **1** in the 2–300 K temperature range using a Quantum Design MPMS SQUID susceptometer operating under a magnetic field of 1 T for **1**. Magnetization isotherms between 0 and 5.5 T were collected at 2 and 5 K for **1** and at 2 K for **2** and **3**. Diamagnetic corrections for the complexes were estimated from Pascal's constants. The magnetic susceptibility for **1** has been computed by exact calculation of the energy levels associated with the spin Hamiltonian through diagonalization of the full matrix with the enhanced version of a general program for axial symmetry [16]. Least-squares fittings were accomplished with an adapted version of the function-minimization program MINUIT [17]. The error-factor R is defined as $R = \sum \frac{(\chi_{exp}-\chi_{calc})^2}{N\chi^2_{exp}}$, where N is the number of experimental points. X-band EPR spectra at liquid helium temperatures were recorded on a Bruker ER 200D-SRC X-band spectrometer equipped with an Oxford ESR 9 cryostat, an NMR-Gaussmeter, and an Anritsu microwave frequency counter.

3. Results and discussion

3.1. Synthesis of $[Fe_2\{pyCO(OMe)pyCO(OMe)py\}_2(MeO)_2](ClO_4)_2$ (**1**)

For the preparation of **1** a simple reaction between iron(III) perchlorate and dpcp in MeOH was employed. The synthesis reaction of **1** can be summarized in the following equation:

$$2(FeClO_4)_3 \cdot 9H_2O + 2pyCOpyCOpy + 4MeOH \xrightarrow{MeOH} [Fe_2\{pyC(O)(OMe)py(H)C(O)(OMe)py\}_2(OMe)_2](ClO_4)_2 + 18H_2O + 4HClO_4 \quad (1)$$

The molecule of dpcp in **1** is present in its monoanionic $\{pyC(O)(OMe)py(H)C(O)(OMe)py\}^-$ form, observed here for the first time. In this form, the two hemiacetal functions are both deprotonated, while the central pyridine is protonated. The reasons for this behavior are currently unclear to us.

The forms of dpcp observed in other iron(III) complexes are $L^{2-} = \{pyC(O)(OMe)pyC(O)(OMe)py\}^{2-}$ in the trinuclear complex $[Fe_3(L)_2Cl_2(OMe)_2][FeCl_4]$ and $L'^- = \{pyCOpyC(O)(OR)py\}^-$ (R = H, Me) in a series of mononuclear complexes of the general formula $[Fe(L')_2Cl_2]$ [12]. Although in the case of the trinuclear complex

hot methanolic solutions were employed, in our work, heating was not required for full methanolysis. This point might be of chemical significance in the understanding of the solvolysis chemistry of dpcp and the synthetic parameters that govern it. However, given the small number of reported ferric complexes, this is not yet an easy task. In the absence of such examples, we believe that useful conclusions are to be drawn from the preparations of ferric complexes of dpk. Three such complexes have been structurally characterized, namely the mononuclear complex $[Fe\{(py)_2C(O)(OH)\}_2](NO_3)$ [18] and the clusters $[Fe_4\{(py)_2C(OMe)O\}_2\{(Hpy)(py)C(OMe)O\}_2(dbcat)_4](ClO_4)_2$ and $(HNEt_3)[Fe_3\{(py)_2C(OH)O\}_2(dbcat)_4]$ ($dbcat^{2-}$ = the dianion of 3,5-di-*tert*-butylcatechol) [19], all of which were prepared at ambient temperatures.

In light of these results, we might say that iron(III) exhibits a higher potential to assist the solvolysis of the C=O bond in dpk and dpcp, even at ambient temperatures. In the case of dpcp, full solvolysis may be expected, provided there is a sufficient quantity of nucleophile (e.g. H_2O and ROH). Thus, in the case of the mononuclear iron(III) complexes of L'^{-}, prepared by Mak and coworkers [12], the use of dry solvents with only small amounts of nucleophile (namely H_2O and MeOH) may be the cause for the partial solvolysis of dpcp.

3.2. Description of the structure

A partially labeled POV-Ray plot of complex **1** is shown in Fig. 1. Important structural parameters are shown in Table 2. Complex **1** crystallizes in the triclinic $P\bar{1}$ space group and consists of two independent dinuclear cationic complexes, each sitting on an inversion centre. The asymmetric unit contains the two half molecules, which generate the two cations through inversion. Due to the similarity of the cations, we will only describe the cation containing Fe(1), shown in Fig. 1. Due to symmetry, we will only describe Fe(1), unless otherwise required.

Fe(1) is hexacoordinate, exhibiting a distorted octahedral coordination sphere with a N_2O_4 chromophore. The Fe–L bond lengths range between 1.94 and 2.16 Å. The longest bonds are formed with the dpcp pyridine donors N(1) and N(3′) (2.158(3) and 2.159(3) Å, respectively), while the shortest ones are formed with the dpcp alkoxo oxygen atoms O(1) and O(3′) (1.946(2) and 1.951(2) Å, respectively).

Bridging within **1** is accomplished through two monatomic $\mu:\eta^2$ methoxo bridges, which form a Fe–O–Fe angle of 105.2(1)°. Additional bridging is provided by the dpcp ligand, present in its *bis*-hemiacetal form. In particular, the ligand is bis-chelating to each Fe atom, adopting a $\mu:\eta^1:\eta^1:\eta^1:\eta^1$ bridging mode, observed for the first time in the structurally characterized complexes of dpcp (Scheme 2). The cause for this coordination mode is the protonation of the central pyridine, which renders it coordinatively inactive.

Scheme 2. Bridging mode of dpcp in **1**.

3.3. Ir spectroscopy

A strong band at 3138 and a weaker one at 3110 cm^{-1} are assigned to the υ[C–H(py)] stretching vibrations of the pyridyl moieties of dpcp. A medium-intensity band at 2970 cm^{-1} is assigned to the asymmetric υ_{as}[C–H(CH_3)] stretching vibration of the methyl functions of the dpcp ligands and the bridging methoxides. The symmetric υ_s[C–H(CH_3)] vibration is more sensitive to the adjacent groups [20]. For these two types of methyls, these bands are found at 2931 and 2825 cm^{-1}, respectively.

The bands at 1603, 1491, 1471 and 1444 are attributed to the stretching υ(C···C) and υ(C···N) vibrations of the pyridyl rings of dpcp. A series of bands between 1300 and 1100 cm^{-1} (1320, 1299, 1269, 1245, 1222, 1186, 1133 cm^{-1}) are assigned to the in-plane δ[C–H(py)] deformations of the pyridyl groups of dpcp.

A strong and broad band around 1100 cm^{-1} and the medium band at 624 cm^{-1} are attributed to the $\nu_3(F_2)$ and $\nu_4(F_2)$ modes, respectively, of the uncoordinated T_d perchlorate anions [21].

The band at 1051 cm^{-1} is assigned to the υ[C–O(OCH_3)$_{dpcp}$] stretching vibration of the –OCH_3 function of dpcp, while the 1023 cm^{-1} band is assigned to the υ[C–O(OCH_3)] stretching vibration of the methoxo bridges [22].

The out-of-pane π[C–H(py)] vibrations for the pyridyl rings appear split to two bands at 789 and 767 cm^{-1}, assigned to the two

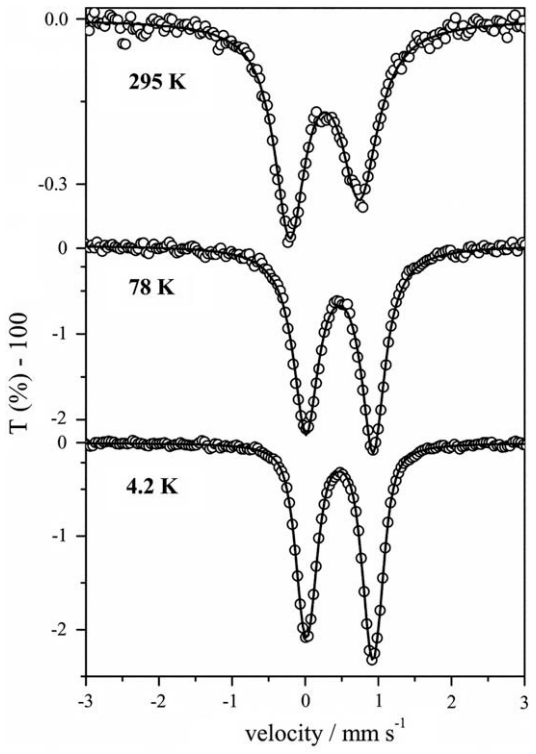

Fig. 2. Mössbauer spectra of 1 at various temperatures.

types of pyridyl functions of dpcp, i.e. external (mono-substituted) and internal (disubstituted).

3.4. Mössbauer spectroscopy

Mössbauer spectra of complex **1** are shown in Fig. 2. Due to the crystallographically imposed symmetry for each cation in **1** and due to the structural resemblance of the two cations, a single quadrupole-split doublet is expected for its Mössbauer spectrum. The 295 K spectrum of **1** consists of an asymmetric quadrupole-split doublet, whose isomer shift is indicative of high-spin ferric ions in octahedral N/O environments.

Initial fitting attempts were carried out using asymmetric Lorentzians. These afforded mediocre fits. High-quality fits were obtained only when Voigt lines were considered; these are the ones presented here. For the fits, the linewidths and areas of the two peaks of each doublet were fitted separately. The results of the fits are shown in Table 3. An increase in the isomer shift upon cooling is attributed to a second-order Doppler effect [23].

From these results it is seen that there are important asymmetries of the quadrupole-split doublets. Such asymmetries have been attributed to several phenomena and can be divided to area asymmetry and linewidth asymmetry.

Area asymmetry ($A_-/A_+ \neq 1$) is attributed to the anisotropy of the recoil-free fraction (Goldanskii–Karyagin effect) [24]. This effect is associated with anisotropic vibrations in the crystal lattice, of sites with lower than cubic symmetry. These anisotropic vibrations produce an anisotropic Debye–Weller factor, which is the source for the anisotropic recoil-free fraction. The result is an asymmetry of the relative intensities of the two Mössbauer lines. Since the area of a line is the measure of its intensity, the Goldanskii–Karyagin effect is perceived as an area asymmetry. Upon heating, the accelerated vibrations cause an increase of the recoil-free fraction anisotropy, and hence of the asymmetry. In our case, however, the area asymmetry being only marginal at high temperatures ($A_-/A_+ = 1.04$), this possibility is discarded.

Another source of area asymmetry are texture effects due to crystallite orientation in the packed sample. However, this should not give rise to a temperature-dependent asymmetry as is the case here, so this possibility is also discarded.

Linewidth asymmetry ($\Gamma_-/\Gamma_+ \neq 1$) has been attributed to the thermal population of the excited $S_T = 1, 2, 3, 4, 5$ states [25], which are expected to exhibit a zero-field splitting (zfs). It has been proposed by Reiff and coworkers, that this zfs of the excited states leads to slow *inter*molecular spin–spin relaxation, due to the poor exchange pathway between neighboring molecules (*intra*molecular spin–spin relaxation is expected to be fast due to the small intermetallic separations). At low temperatures, only the ground $S_T = 0$ state will be populated, which is free of hyperfine splitting or paramagnetic relaxation due to zfs. Therefore, symmetric doublets are expected at those temperatures. Upon heating, thermal population of the anisotropic excited states will cause a decrease of the intermolecular spin–spin relaxation rate and consequently to doublet asymmetries.

Given the fact that our spectra were area symmetric at room temperature and linewidth asymmetric ($\Gamma_-/\Gamma_+ = 0.844$), we conclude that the source of the asymmetry is the thermal population of higher spin multiplicity anisotropic states. The large intermolecular separation (9.47 Å) in **1** is also in agreement with the mechanism of slow *inter*molecular spin–spin relaxation. The same source of asymmetry has been found in other diferric complexes exhibiting weak antiferromagnetic couplings through hydroxo- [25,26] or alkoxo-[27] bridges. In one case [28], a similar behavior was observed for a diferric complex with a postulated benzoquinone bridge and a very weak ($J = -2.0\ \mathrm{cm}^{-1}$) antiferromagnetic coupling.

Table 3
Mössbauer parameters for **1** at various temperatures.

3.5. Magnetic properties

Magnetic susceptibility data for complex **1** are shown in Fig. 3. The $\chi_M T$ value of **1** at 300 K is 5.34 cm^3 mol^{-1} K, lower than theoretically expected for two non-interacting $S = 5/2$ spins (8.76 cm^3 mol^{-1} K, $g = 2$). This indicates the interplay of antiferro-

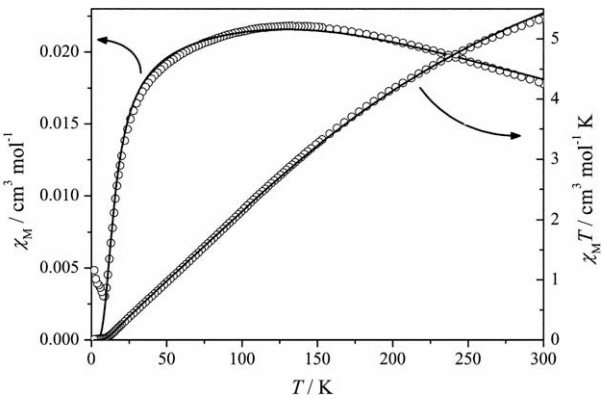

Fig. 3. χ_M and $\chi_M T$ vs T data for complex **1** and calculated curves according to the model described in the text.

magnetic interactions. This is corroborated by the constant drop of the $\chi_M T$ product upon cooling (9.4×10^{-3} cm^3 mol^{-1} K at 2 K), and by a broad maximum of the χ_M versus T curve around 130 K. A small rise of χ_M below 8 K is attributed to a small fraction of high-spin ferric paramagnetic impurity.

For the interpretation of the data, a simple model consisting of two $S = 5/2$ spins was considered. The observation of increased asymmetries in the linewidths of the Mössbauer spectra at high temperatures, prompted us to include a single-ion zfs parameter, common for the two sites. The Hamiltonian used was:

$$\hat{H} = -2J\hat{\mathbf{S}}_1\hat{\mathbf{S}}_2 + D(\hat{S}_{z1}^2 + \hat{S}_{z2}^2) \quad (2)$$

To avoid contributions from the paramagnetic impurity, fits were carried out over the 20–300 K region. Initial fitting attempts were carried out considering $D = 0$. These yielded satisfactory fits with best-fit parameters $J = -15.6$ cm^{-1}, $g = 2.04$ with $R = 9.9 \times 10^{-5}$. This J value is consistent with values derived for other bis-methoxo-bridged diferric complexes, which were found to vary between -5.7 and -28.6 cm^{-1} [29] and implies an $S = 1$ first excited state at 31.2 cm^{-1}.

Additional fitting attempts were made, releasing the D parameter. However, it was found that this parameter did not sufficiently influence the calculated curve for its value to be reliably determined by magnetic susceptibility data.

3.6. Epr spectroscopy

In order to study further the magnetic properties of complex **1** we carried out EPR spectroscopic studies at the X-band. Measurements from powdered samples were carried out over the 4.2–200 K temperature range and indicative spectra are shown in Fig. 4.

At 4.2 K the spectrum consists of relatively weak signals: an absorption peak at g ~ 6.00 and a sharp derivative at $g \sim 4.3$. Both signals are attributed to two different monomeric high-spin ferric species representing a small amount of impurities in agreement with the magnetic susceptibility measurements. As the temperature increases new signals emerge in a wide field range. The temperature dependence of these signals strongly suggests that they arise from excited states ($S > 0$) of the dimer and is consistent with the analysis of the magnetic susceptibility measurements. Similar EPR signals at X-band have been observed from other antiferromagnetically coupled ferric dimers and were attributed to the excited states of the system [30]. Such signals are affected by the combination of single-ion anisotropy and non-Heisenberg exchange interactions. A comparison with the signals observed in other diferric systems [30] suggests that these interactions are also present in the case of **1**.

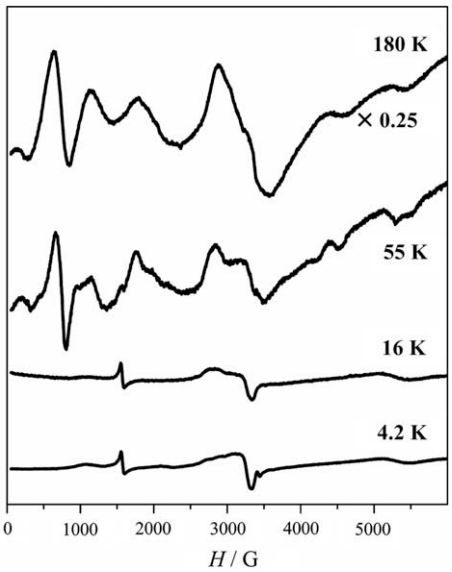

Fig. 4. Temperature dependence of X-band EPR spectra from powdered samples of **1**. The spectra are normalized according to Intensity × Temperature. Other EPR conditions. Modulation amplitude: 25 Gpp, microwave power: 2.2 mW, microwave frequency: 9.43 GHz.

4. Conclusions

Our research on the cluster chemistry of dpcp, continues to reveal new capabilities of this ligand in adopting different forms (of varying degrees of solvolysis or protonation) and coordination modes. Clearly, this chemistry has still a lot of promising results to afford.

In particular, its use in combination with iron(III) gave access to a dinuclear complex bridged by two alkoxo ligands. Complex **1** was found to contain dpcp in a *bis*-hemiacetal, monoanionic form, observed here for the first time. In this form, the two hydroxyl functions were deprotonated, whereas the central pyridine was protonated and coordinatively inactive. This was an interesting finding from a Chemical perspective.

The physical properties for complex **1** were in agreement with its structure. The *bis*-methoxo-bridged core exhibited a weak antiferromagnetic coupling as expected, which gives rise to several phenomena associated with the thermal population of the excited states. On one hand, this thermal population of the anisotropic $S = 1, 2, 3, 4, 5$ states was manifested as a linewidth asymmetry of the Mössbauer spectra at high temperatures. This asymmetry was associated with spin–spin intermolecular relaxation, which is decelerated by the population of these anisotropic states. On the other hand, thermal population of these states gave rise to EPR signals, of increasing intensity upon heating. Thus, from a Physical perspective, complex **1** was found to be interesting, for allowing us to directly monitor the thermal population of its excited magnetic states by different spectroscopic techniques (Mössbauer, EPR), instead of deriving them indirectly from magnetic susceptibility data.

Supplementary data

CCDC 721737. contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

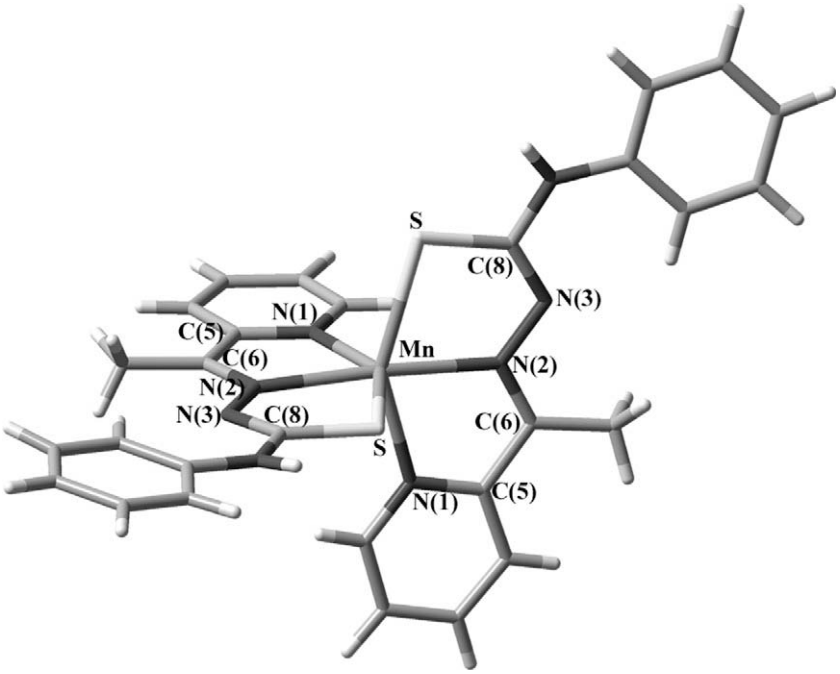
(**1**) (HAc4Ph denotes the 4-phenyl-2-acetylpyridine thiosemicarbazone molecule) [17]. The anionic $Ac4Ph^-$ acts as a tridentate ligand which coordinates to manganese(II) through the pyridyl nitrogen, N(1), the azomethine nitrogen, N(2), and the thiolato sulfur atom (Scheme 1). The tridentate ligand has a ZEZ configuration based on the C(5)–C(6), N(2)–C(6) and N(3)–C(8) bonds for the donor centres nitrogen, nitrogen and sulfur, respectively. The manganese atom is coordinated in a distorted octahedral configuration in a *trans*-N(2)–*cis*-N(1)–*cis*-S configuration. Complex **1** belongs to a relatively rare class of octahedral Mn(II) complexes exhibiting sulfur coordination.

Among the few octahedral Mn(II) complexes with sulfur coordination two have been studied by EPR spectroscopy [18,19]. In both cases non negligible ZFS was observed. For the complex $[Mn([9]aneN_2S)_2](ClO4)_2$ ([9]aneN$_2$S: 1-thia-4,7-diazacyclononane) [18], simulations of the powder X- and Q-band EPR spectra allowed the determination of the absolute value of the axial Zero Field Splitting term (0.19 cm^{-1}). In the complexes described in Ref. [19] the value of the ZFS terms was not reported. However, the X-band EPR spectrum of frozen solution at 77 K from Mn(Me2L) complex [19] indicates ZFS smaller than 0.3 cm^{-1}.



The purpose of the present work is to study the electronic properties of **1** by EPR spectroscopy. In solid state, **1** gives rise to a broad derivative feature at X-band. Such a behavior is indicative of intermolecular interactions. This is consistent with the molecular packing revealed in the crystal structure of **1**, which indicates extended network of hydrogen bonds and π–π stacking interactions. In a frozen DMSO solution, dual mode X-band EPR spectra exhibit signals, that agree with mononuclear Mn(II) species [17]. The spectra, however, are rather complicated spanning several hundred mT at X-band and quantitative information cannot be easily derived without tedious simulation efforts. Therefore we present here a HF EPR investigation for determining the ZFS parameters of **1** in DMF solution. Moreover, the electronic properties of **1** are studied by means of theoretical calculations. A good agreement between theoretical and experimental values is found. In many cases the experimental spectra are characterized by line-broadening. This line-broadening is usually attributed to distributions of the parameters pertinent to the system. For instance, in the present case the line-broadening is correlated with distribution of the D and E parameters. Apparently, distribution on such parameters reflects distribution on the electronic parameters of the system which in turn may originate from geometrical distortions. In the present work, we attempt to correlate the experimentally derived distributions on D and E with distribution on the geometry of the complex. It is found that reasonable structural distortions can account for such distributions.

2. Experimental

2.1. EPR spectroscopy

The synthesis and the crystal structure of **1** have been reported elsewhere [17]. The EPR studies were carried out in frozen solutions of **1** in dimethyl formamide, DMF, or dimethyl sulfoxide, DMSO (∼4 mM). Dual mode X-band EPR measurements were carried out with an upgraded Bruker ER-200D spectrometer equipped with a Bruker Dual Mode cavity, an Anritsu frequency counter, an NMR Gaussmeter and an Oxford ESR-9 cryostat. The spectra were found to be independent on the concentration of the solutions in the 0.4–5.0 mM range. HF-EPR spectra were recorded on a laboratory made spectrometer [20]. Gunn diodes operating at 95 and 115 GHz have been used as the radiation source. The frequency is calibrated via the Gunn diode. The magnetic field was produced by a superconducting magnet (0–12 T). Simulations of the spectra were carried out with SpinCount software kindly provided to us by Prof. M. Hendrich, Department of Chemistry, Carnegie Mellon University, Pittsburgh, PA, USA.

The spectral lineshapes are determined by assuming a distribution on the ZFS parameters D and E/D of Eq. (1). We assume that the variation of these parameters follows a Gaussian distribution specified as one standard deviation, σ_D, $\sigma_{E/D}$. A residual linewidth of σ_B in the magnetic field is also specified to account for other unspecified line-shape determinants, such as unresolved hyperfine from coordinated nitrogen to Mn(II). Gaussian spin-packets with linewidths determined in relation to these linewidth parameters

Scheme 1. The crystal structure of **1**.

(σ_D, $\sigma_{E/D}$ and σ_B) and properly normalized for field-swept experimental spectra are folded into the spectrum at each resonance position.

2.2. Computational

Geometry optimizations were conducted with the GAUSSIAN 03 suite of programs [21] by using DFT methods [22]. The model chemistry used in this particular case was the BP86 [23] functional, along with the TZVP [24] basis set of Ahlrichs, i.e. BP86/TZVP optimizations were performed under C_2 point group symmetry, where the C_2 axis traverses the Mn(II) ion. Harmonic frequencies calculations were also performed at the BP86/TZVP level of theory and produced no imaginary frequencies, which signifies that the optimized structure pertains to an equilibrium point. Tight self consistent field, SCF, and geometry optimization criteria were used throughout the calculations. Due to the $S = 5/2$ ground state, unrestricted, *U*, open shell wavefunctions were used, i.e. different spatial functions were used to describe α and β electrons.

Theoretical calculations of the ZFS parameters were carried out with the ORCA program package [25]. Unrestricted Kohn–Sham formalism was applied for the solution of the SCF equations at the BP86/TZVP level of theory. Tight SCF convergence criteria were applied during the single-point calculations, and for the Mn(II) cation, the integration grid accuracy was increased compared to the atoms remainder. The centre of electric charge is the choice of the gauge origin in our calculations.

In the ZFS tensor calculation, two kinds of contributions have to be considered: (i) the first order terms, i.e. the spin–spin, SS, interactions, and (ii) the second order terms, i.e. the spin–orbit coupling, SOC [26]. SS interactions are a two-electron effect and very difficult to calculate accurately [26]. However, it was included in the $\tilde{D}$ tensor calculation [27a], by using the direct spin density, obtained from the single-point calculation. In the Breit–Pauli approximation, the SOC operator is [27]:

$$\hat{H}_{SOC} = \hat{H}^{(1)}_{SOC} + \hat{H}^{(2)}_{SSOC} + \hat{H}^{(2)}_{SOOC}, \quad (2)$$

which contains one-electron, $\hat{H}^{(1)}_{SOC}$, and two-electron, $\hat{H}^{(2)}_{SSOC}$ and $\hat{H}^{(2)}_{SOOC}$, terms, where SSOC and SOOC stand for spin-same orbit and spin-other orbit coupling, respectively. The SOC operator is also difficult to handle computationally, so the spin–orbit mean-field, SOMF, [28] approximation to the full Breit–Pauli operator, and in particular the variation of the SOMF operator implemented in ORCA, is employed in our study [29]. The second order contribution to $\tilde{D}$ has three components, as was derived elsewhere [30]. If the ground state has a total spin number *S*, then the excited states interacting with the ground state, via SOC, acquire a total spin number of either *S*, $S + 1$ or $S - 1$ [30]. In a more compact form, the ZFS is equal to:

$$D = D_{SS} + D^{S,S}_{SOC} + D^{S,S+1}_{SOC} + D^{S,S-1}_{SOC}. \quad (3)$$

In order to calculate the SOC contribution to ZFS, four types of excitations must be considered [30]:

(i) DOMO → SOMO ($\beta \rightarrow \beta$), which couples excited states with the same multiplicity as the ground state,
(ii) SOMO → VMO ($\alpha \rightarrow \alpha$), which also couples excited states with the same multiplicity as the ground state,
(iii) SOMO → SOMO ($\alpha \rightarrow \beta$), which couples excited states of an $S - 1$ total multiplicity to the ground state, and
(iv) DOMO → VMO ($\beta \rightarrow \alpha$), which couple excited states of an $S + 1$ total multiplicity to the ground state.

DOMO, SOMO and VMO stand for doubly occupied, singly occupied and virtual molecular orbital, respectively. The exact equations used to calculate D_{SS} and D_{SOC} tensor matrix elements can be found in the article by Neese [31]. The SOC contribution to *D* was calculated using the coupled-perturbed method, which uses revised prefactors for the spin-flip terms and solves a set of coupled-perturbed SCF, equations for the SOC perturbation [31].

3. Results and discussion

Preliminary dual mode X-band EPR spectroscopic studies from **1** in DMSO gave rise to complicated spectra spanning several hundred mT, which were consistent with a $|D|$ value of the order of 0.1 cm^{-1} [17]. For this order of magnitude, the EPR spectra recorded at high frequencies (>95 GHz) and high magnetic fields (>2.0 T) are expected to be less complicated and their interpretation almost straightforward. Therefore, we first present the results from HF-EPR studies.

3.1. High frequency/high field EPR studies

In Fig. 1, we show the 5 K EPR spectrum from **1** in a DMF solution recorded at 115 GHz. The part of the spectrum centred at $g = 2.0$ is characterized by a sharp strong feature which has attributed to the transitions occurring between the states $M_s = -1/2$ and $M_s = +1/2$. This part of the spectrum has been removed for clarity purposes from Fig. 1. It is shown in more detail in Fig. 2 and will be discussed separately. Despite the poor S/N the interpretation of the spectrum is quite straightforward [11]. It is consistent with a negative *D* term with moderate rhombicity. Under these conditions, the two peaks at the lower field part of the spectrum arise from the $-\frac{5}{2} \leftrightarrow -\frac{3}{2}$ and $-\frac{3}{2} \leftrightarrow -\frac{1}{2}$ transitions for molecules lying with the *z*-axis of the ZFS tensor parallel to the external magnetic field. First order perturbation treatment [11] of the spin Hamiltonian of Eq. (1) is considered a good approximation for those transitions in high field limit conditions and the separation of these two peaks is given by $\frac{2D}{g\beta}$, independently on the parameter *E*. The separation of the peaks from the spectrum is roughly 20 mT, from which the value of *D* is restricted between −0.1 and −0.09 cm^{-1}. The high magnetic field part of the spectrum arises from molecules lying with their *z*-axis perpendicular to the external magnetic field. The signals from the $-\frac{5}{2} \leftrightarrow -\frac{3}{2}$ and $-\frac{3}{2} \leftrightarrow -\frac{1}{2}$ transitions do not exhibit hyperfine features, whereas the former are broader than the

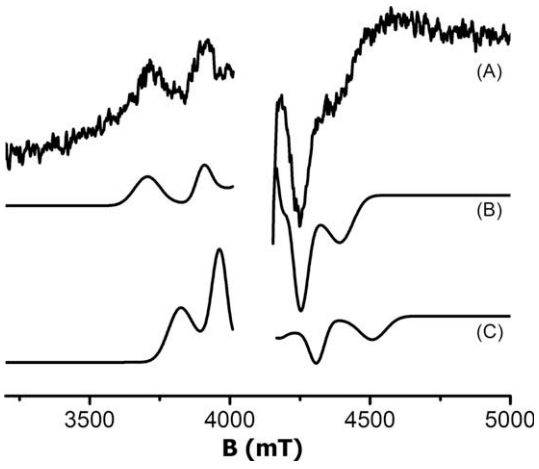


Fig. 1. Experimental (A) and simulated (B and C) 115 GHz EPR spectra from a frozen DMF solution of **1**. Simulated spectra are calculated from Eq. (1) with $D = -0.095$ cm^{-1} (B) or +0.095 cm^{-1} (C), $E/D = 0.15$, $A = 7.8 \times 10^{-4}$ cm^{-1}, $g = 1.999$, $\sigma_D = 0.01$ cm^{-1}, $\sigma_{E/D} = 0.04$, $\sigma_B = 2.0$ mT.

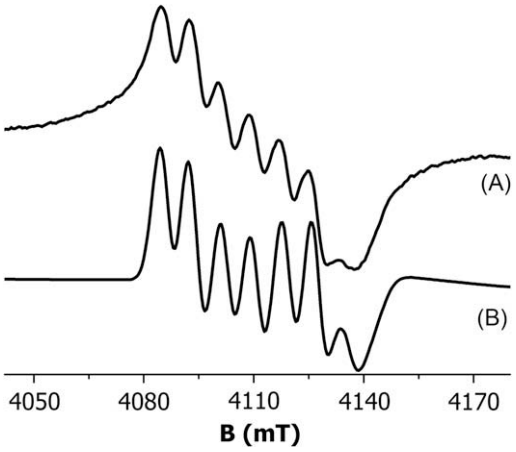

Fig. 2. Experimental (A) and simulated (B) 115 GHz EPR spectra from a frozen DMF solution of **1**. The simulated spectrum is obtained from Eq. (1) with $D = -0.095\ cm^{-1}$, $E/D = 0.15$, $A = 7.8 \times 10^{-3}\ cm^{-1}$, $g = 1.999$ and $\sigma_D = 0.01\ cm^{-1}$, $\sigma_{E/D} = 0.04$, $\sigma_B = 2.0$ mT.

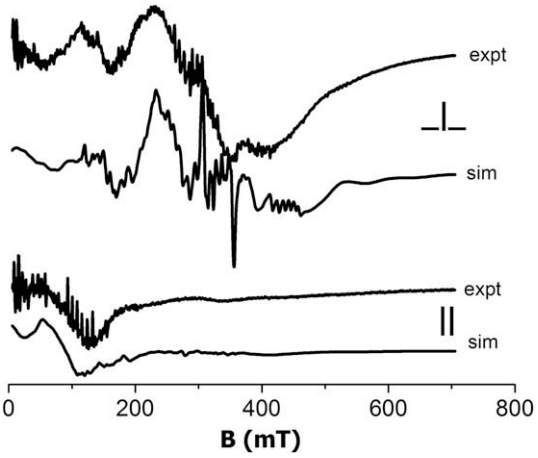

Fig. 3. Dual mode X-band EPR spectra from a frozen solution of **1** in DMF. The simulated spectra are obtained as described in the text. EPR conditions: *T*, 10 K; modulation amplitude, 1.0 mT; microwave power, 2.2 mW; perpendicular mode: 9.59 GHz, parallel mode: 9.31 GHz.

latter. Both observations may be rationalized by the presence of distributions on the ZFS parameters, σ_D and $\sigma_{E/D}$.

In high field limit conditions [16], the signal originating from the transitions $-\frac{1}{2} \leftrightarrow +\frac{1}{2}$ is less sensitive on the parameters *D* and *E*, and therefore, from this transition hyperfine features may be resolved. This is demonstrated in Fig. 2, where we display the magnetic field region corresponding to these transitions. Well resolved hyperfine features are observed and the hyperfine interaction may be determined. The hyperfine lines are superimposed on a broad background which is attributed to the mixing of the in-phase and out-of-phase signals. Finally, no signals are observed from the other transitions $+\frac{1}{2} \leftrightarrow +\frac{3}{2}$ and $+\frac{3}{2} \leftrightarrow +\frac{5}{2}$ along the three magnetic axes. This is due to the fact that at 5 K the corresponding energy levels have considerably lower thermal occupation in comparison with the levels corresponding to the $-\frac{5}{2} \leftrightarrow -\frac{3}{2}$ and $-\frac{3}{2} \leftrightarrow -\frac{1}{2}$ transitions.

More accurate determination of the parameters is obtained by simulating the experimental spectra within the framework of the Hamiltonian of Eq. (1). The obtained parameters are quoted in Table 1. Simulated spectra are included in Figs. 1 and 2. In Fig. 1, we include also a simulated spectrum assuming a positive value for *D*. Clearly a positive value for *D* cannot account for the spectral behavior. The 115 GHz data and analysis presented above are in agreement with similar studies carried out in 95 GHz (not shown).

3.2. Dual mode X-band EPR studies

In Fig. 3 we show the X-band EPR spectra from a DMF frozen solution of **1** recorded either in perpendicular or parallel mode and under non saturating conditions. In perpendicular mode, the spectrum is characterized by signals expanding in a large magnetic field range. The complexity of the X-band EPR spectrum is due to the value of ZFS terms and such spectra have been observed in many mononuclear Mn(II) complexes. Because the ZFS of the energy levels of the $S = 5/2$ manifold is small in comparison with the microwave energy, many transitions are induced at X-band. Hyperfine interactions complicate further the spectrum.

For a Mn(II) system with an approximate $|D|$ value of 0.1 cm^{-1}, transitions are expected when the microwave field oscillates parallel to the external magnetic field. Indeed such signals are observed as it is shown in Fig. 3. Since the transitions which have appreciable transition probability in parallel mode are rather few, the parallel mode spectrum is less complicated than the perpendicular mode one. Still, the interpretation of this spectrum is not straightforward. However, such transitions arise from states which are separated at zero magnetic field. For an $S = 5/2$ system as in the present case such transitions are induced between the $|\pm 1/2\rangle$, $|\pm 3/2\rangle$, and $|\pm 5/2\rangle$ Kramer's doublets. The separation of these doublets depends on *D*. In the axial case, the energy difference between $|\pm 1/2\rangle$ and $|\pm 3/2\rangle$ doublets is $2|D|$ and between $|\pm 1/2\rangle$ and $|\pm 5/2\rangle$ is $6|D|$. Therefore, the position of the signals in the parallel mode spectrum may be used as a rough estimate of *D*.

Superimposed to the experimental spectra are simulated ones obtained using the parameters deduced from the HF-EPR spectra. Even if the simulated spectra do not accurately reproduce the experimental ones, they reproduce the main features with the same set of parameters. At X-band, the EPR spectra are more sensitive for distribution on the ZFS parameters. Because such distributions may not have an ordinary behavior (for instance Gaussian) the exact line-shape of the spectra cannot be accurately reproduced by simulations and probably more sophisticated models for line broadening are required. Although the interpretation of X-band EPR spectra from such species is not straightforward they may be used in order to estimate the magnitude of $|D|$ and this is achieved by simulation. Still, however, the determination of the sign of *D* can be determined only with HF-EPR spectra measurements.

Noteworthy, in the X-band spectra (either in perpendicular or parallel mode) from the DMF frozen solution, characteristic multiline features (with irregular spacing) are present at certain parts of the spectra. These multiline features arise from hyperfine interactions with the ^{55}Mn nucleus. The simulations do not account for these features. In Fig. 4, we compare the X-band dual mode EPR spectra from **1** dissolved in DMSO and DMF. The spectra in both solvents are almost identical suggesting that the ZFS parameters do not depend upon the solvent. The main difference is the lack of hyperfine patterns in the case of DMSO. In order to simulate

Table 1
EPR parameters for **1** determined by simulations of the 115 GHz spectra (Figs. 1 and 2).

$D\ (cm^{-1})$	−0.095

$A\ (cm^{-1})$	7.8×10^{-3}

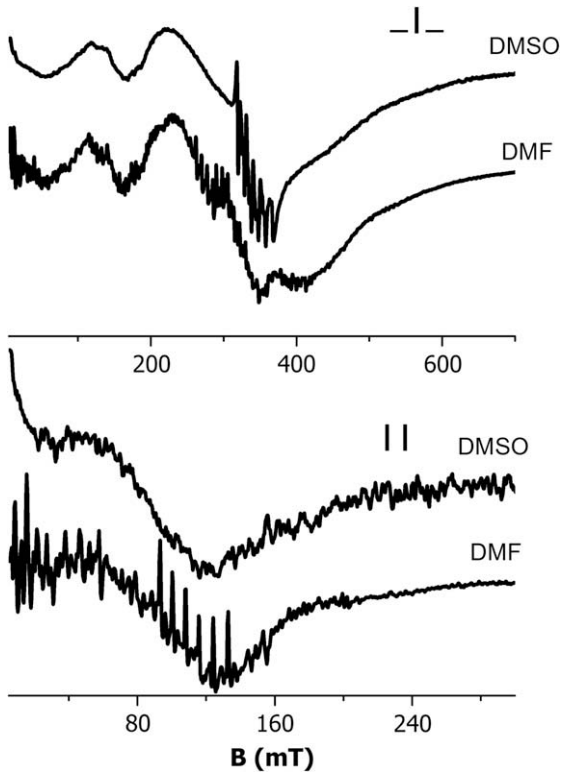

Fig. 4. Dual mode X-band EPR spectra from a frozen solution of **1** in DMSO and DMF. EPR conditions: *T*, 10 K; modulation amplitude. 1 mT, microwave power, 2.2 mW, DMF, perpendicular mode: 9.59 GHz, parallel mode: 9.31 GHz; DMSO, perpendicular mode: 9.60 GHz, parallel mode: 9.32 GHz.

the X-band EPR spectra in the case of DMF, we adopted a simple model assuming Gaussian distributions for the parameters *D* and *E*/*D*. As it was noted earlier it appears that the assumption of a Gaussian distribution is not strictly correct. We suggest that a minority fraction of the molecules are characterized by a rather homogeneous environment, which allows resolved hyperfine features at X-band. However, for the majority of the molecules, a Gaussian distribution of their parameters appears to be a good approximation for the spectral line-shape. It also works better for the X-band EPR spectra in the case of DMSO. Apparently the nature of homogeneity depends upon the solvent. Similar solvent effects were also observed in X- and Q-band EPR studies of some Mn(II) dimers [32] and *trans*-bis(oxalato) Cr(III) complexes [33].

3.3. Theoretical investigations

In the previous sections, we have experimentally determined the ZFS parameters of **1** by means of EPR spectroscopy at high frequency (115 GHz) and X-band. Apart from the determination of these parameters, our studies indicate that in solution distributions are affecting the spectra. In order to rationalize this behavior we have performed DFT calculations.

3.3.1. Geometry optimizations

The optimized structure at the BP86/TZVP level of theory, denoted as **A**, is depicted in Fig. 5 and selected geometric parameters are presented in Table 2. The obtained geometry is a distorted octahedron and well agrees with the experimentally derived crystal structure (Scheme 1). Bond lengths are quite accurately reproduced and certain bond angles deviate by no more than 12° to the crystal structure values. Furthermore, in our calculations, the phenolic ring of the 4-phenyl-2-acetylpyridine thiosemicarbazone is slightly out of plane, compared to the remainder of the anion, i.e. the C(19)–N(21)–C(23)–C(24) and C(51)–N(53)–C(55)–C(56) dihedral angles are equal to −174.6° (due to the C_2 symmetry), whereas in the crystal structure the value is equal to −180.0°. This can be attributed to the internal rotation around the N(21)–C(23) and N(53)–C(55) bond axis, respectively. Finally, the C(19)–N(18)–N(17)–C(12) and C(51)–N(50)–N(49)–C(44) dihedral angles have a value of −172.3° in the optimized structure, **A**, as opposed to the −176.3° value of the crystal structure data, due to the rotation around the N(17)–N(18) and N(50)–N(51) single bonds. All deviations from the crystal structure could be attributed to the fact that π–π interactions and intermolecular hydrogen bonds are present in the crystalline structure but not accounted in the gas phase calculations.

The experimentally obtained EPR spectra were simulated introducing distributions on the parameters *D* and *E*. These distributions may correlate with the electronic properties of the system which in turn may correlate with distributions in specific geometrical elements. Upon closer inspection of **A**, it became evident that the C(19)–N(18)–N(17)–C(12) and C(51)–N(50)–N(49)–C(44) dihedral angles (denoted as δ further on) could vary, as it has been previously mentioned. In the solid state, this motion is restricted by intermolecular hydrogen bonding and π–π stacking. However, in solution such interactions are lost and multiple conformers may be present. While freezing, it is reasonable to assume that a number of conformations in relation with this geometrical element are trapped.

For this reason we have considered four additional conformations by varying the value of the dihedral angle δ around the global minimum of −172.3°. The δ value was held frozen at −174.0°, −176.0°, −170.0° and −168.0° and geometry optimizations were performed, resulting in the structures denoted as **B**, **C**, **D** and **E**, respectively. Selected geometric parameters of all conformers are included in Table 2, along with the corresponding experimental ones. As was the case with the minimum, conformers' structure agrees quite well with the crystal structure, although differences can be located particularly at dihedral angle values, due to the aforementioned lack of effects present in the solid state.

Before proceeding further, it is important to check whether any of these conformations is characterized by significantly larger energy in comparison to the optimized local minimum. The electronic energies of the various conformers with respect to the corresponding one of minimum **A** are given in Table 3. We observe that the energy values of **B**, **C**, **D** and **E** differ only by few cm^{-1} to the corresponding value for **A** suggesting that inter-conversion between different configurations is feasible, since there is no significant rotational energy barrier. Therefore, at room temperature a multitude of configurations in solution are thermally accessible. Such configurations are assumed to be trapped upon freezing rapidly to cryogenic temperatures.

3.3.2. Zero field splitting calculations

The calculation of ZFS parameters was carried out as described previously and the results are given in Table 4. For the local minimum and the four conformers, the mean *D* value is $-0.106\ cm^{-1}$ with standard deviation of $0.014\ cm^{-1}$. The theoretically derived mean value of *D* is very close to the experimentally determined one ($-0.095\ cm^{-1}$). For all conformers the theoretically calculated *E* and |*E*/*D*| values are lower compared to the experimental ones. The good agreement between theoretical and experimental values in the case of *D* is not unprecedented. Similar studies have been carried out for several mononuclear Mn(II) compounds [6,7,14,34] and it was found that the methodology concerning the theoretical calculations followed in the present work leads to reliable results.

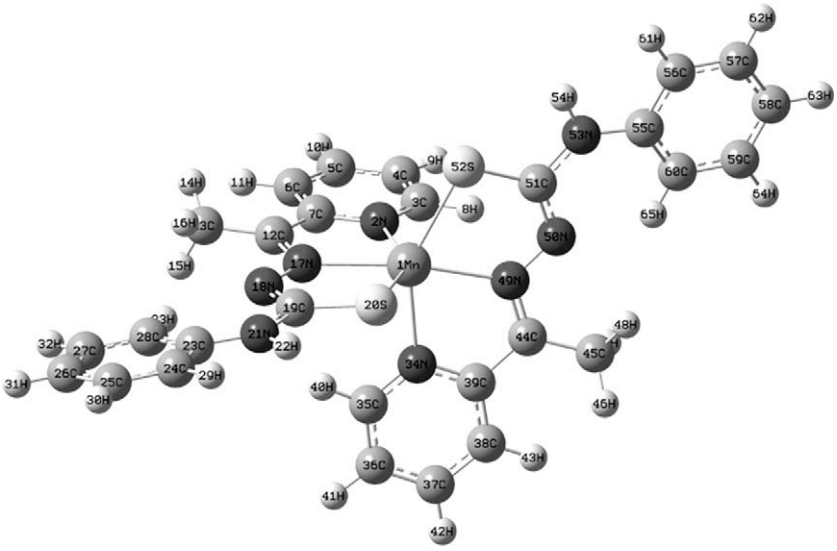

Fig. 5. Optimized structure of **1**, denoted as **A**, at the BP86/TZVP level of theory.

Table 2
Selected optimized structural parameters (bond lengths in Å, and bond angles in °) for the global minimum and the rotational conformers at the BP86/TZVP level of theory, along with the available experimental values.

Table 3
Differences in electronic energy between **A** and its conformers **B**, **C**, **D** and **E**, as were calculated with the GAUSSIAN 03 program [21].

Structure	Energy difference (cm^{-1})
C	25.4
B	3.3
A	0.0
D	10.2
E	37.0

We also calculated the ZFS on the crystal structure of **1**, and the results are included in Table 4. The sign of *D* is correctly reproduced but the absolute magnitude is somehow larger than the configurations **A**–**E** and the experimentally derived values. Theoretical calculations carried out in the geometry dictated by the crystal structure have been successful in reproducing the ZFS parameters derived from powdered samples of Mn(II) complexes [7,14,34,35]. In the present case we observe that the ZFS parameters are better reproduced assuming geometrically optimized structures. This is probably due to the fact that the experimental values are derived

Table 4
Experimental and theoretically calculated ZFS parameters for complex **A**, its conformers **B**, **C**, **D** and **E** and the crystal structure **1**.

from frozen solutions. In the present work we did not study powder samples of **1** so we have not determined the ZFS in the solid state. Differences in ZFS between the solid state and in frozen solutions have been observed [7].

For the **A–E** structures, SS interactions have the major contribution to the ZFS. The major contribution to the spin-spin coupling comes mostly from one centre terms and in the case of **A**, it is the main contribution. The SOC contribution to the overall D value is quite important, but is not the dominant factor for the **A–E** conformers ($|D_{SOC}| < |D_{SS}|$). An inspection of Table 4 indicates that this is due to the cancelling signs of the terms contributing to D_{SOC}. The relative contributions of SOC and SS are reversed when the calculations are carried out in the geometry of the crystal structure and in this case $|D_{SOC}| > |D_{SS}|$. This is mainly due to the fact that the spin flip term $D_{SOC}^{\alpha \rightarrow \beta}$ has a relatively large negative value whereas $|D_{SS}|$ is almost half the value of those obtained for the optimized structures.

The analysis of the EPR spectra indicates that $|D|$ has a spread of the order of 0.01 cm^{-1} around an average value of the order of 0.1 cm^{-1}. The theoretical calculations indicate that such a spread may be reproduced if we assume different structures of the molecule which do not differ for more than a few tenths of cm^{-1} from the energy of the configuration exhibiting local minimum. Similar correlations were recently made in the case of a high spin, four-coordinate Fe(II) diketiminate complex [36] where the distribution on the hyperfine tensor of the ^{57}Fe, studied by Mössbauer spectroscopy were correlated with narrow distributions ($\sim 0.5^{\circ}$) in a torsion angle φ of the complex.

4. Summary and conclusions

In the present work we determine the ZFS terms of a mononuclear Mn(II) complex in frozen solutions by multifrequency EPR spectroscopy. The absolute value of D lies in the range found for six coordinated Mn(II) ($S = 5/2$) complexes. The experimental values were compared to the theoretical ones on the basis of DFT calculations and a very good agreement was found. The EPR spectra indicate the presence of distributions. The present work shows that theoretical calculations may also be used in order to rationalize these distributions, which can be correlated with structural variations of the complex. Distributions on ZFS parameters have been observed even in the case of paramagnetic ions in single crystals [37]. Other mechanisms, which may lead to broadening of EPR lines, are intermolecular magnetic interactions [32]. More systematic studies are required in order to quantitatively distinguish the contributions of each mechanism in the line-shape of the EPR signals.

Acknowledgements

Dr. Dimitrios A. Pantazis, University of Bonn, is gratefully acknowledged for providing helpful assistance, regarding the EPR parameters calculations. T. D. Tzima has been the recipient of a graduate fellowship from N.C.R.P.S. Demokritos. The electronic structure calculations were supported by the Computer Centre, University of Ioannina.

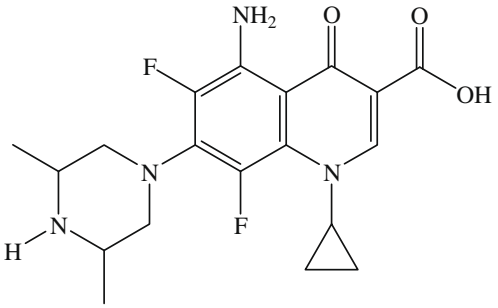

Fig. 1. Sparfloxacin (Hsf = 5-amino-1-cyclopropyl-7-(*cis*-3,5-dimethyl-1-piperazinyl)-6,8-difluoro-1,4-dihydro-4-oxo-3-quinolinecarboxylic acid).

2. Experimental

2.1. Materials

Sparfloxacin, CT DNA and EB were purchased from Sigma, NaCl and all solvents were purchased from Merck, trisodium citrate was purchased from Riedel-de Haen and $NiCl_2 \cdot 6H_2O$, pyridine and KOH were purchased from Aldrich Co. All the chemicals and solvents were reagent grade and were used as purchased.

DNA stock solution was prepared by dilution of CT DNA to buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) followed by exhaustive stirring at 4 °C for 3 days, and kept at 4 °C for no longer than a week. The stock solution of CT DNA gave a ratio of UV absorbance at 260 and 280 nm (A_{260}/A_{280}) of 1.89, indicating that the DNA was sufficiently free of protein contamination [34]. The DNA concentration was determined by the UV absorbance at 260 nm after 1:20 dilution using $\varepsilon = 6600\ M^{-1}\ cm^{-1}$ [35].

2.2. Synthesis of complex $Ni(sf)_2(py)_2 \cdot 6.4H_2O$, **1** $\cdot 6.4H_2O$

Sparfloxacin (0.4 mmol, 157 mg) was dissolved in methanol (15 mL), was deprotonated with KOH (0.4 mmol, 22 mg) and was added to a methanolic solution (10 mL) of $NiCl_2 \cdot 6H_2O$ (0.2 mmol, 48 mg) followed by the addition of 3 mL of pyridine. The solution was left for slow evaporation. Green crystals of $Ni(sf)_2(py)_2 \cdot 6.4H_2O$, **1** $\cdot 6.4H_2O$, suitable for X-ray structure determination, were deposited after a few days. Yield: 280 mg, 70%. *Anal.* Calc. for $Ni(sf)_2(py)_2 \cdot 6.4H_2O$ ($C_{48}H_{64.8}F_4N_{10}O_{12.4}Ni$) (MW = 1115.01): C, 51.71; H, 5.86; N, 12.56. Found: C, 51.40; H, 5.83; N, 12.73%. IR: ν_{max}/cm^{-1}; $\nu(C{=}O)_{ket}$: 1643(vs); $\nu_{as}(CO_2)$: 1600(vs); $\nu_{sym}(CO_2)$: 1380(vs); $\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$: 220 cm^{-1} (KBr pellet); UV–Vis: λ_{max}/nm ($\varepsilon/M^{-1}\ cm^{-1}$) as nujol mull: 615, 415(sh), 385, 313, 291; in dmso: 620 (12), 412(sh) (220), 380 (6500), 312 (6800), 286 (13 500). The complex is soluble in dmso and dmf and is non-electrolyte.

2.3. Instrumentation – physical measurements

Infrared (IR) spectra (400–4000 cm^{-1}) were recorded with a Nicolet FT-IR 6700 spectrometer with samples prepared as KBr pellets. UV–Visible (UV–Vis) spectra were recorded as nujol mulls and in solution at concentrations in the range 5×10^{-6}–10^{-3} M with a Hitachi U-2001 dual beam spectrophotometer. C, H and N elemental analysis were performed with a Perkin–Elmer 240B elemental analyzer. Molecular conductivity measurements were carried out with a Crison Basic 30 conductometer. Fluorescence spectra were recorded in solution with a Hitachi F-7000 fluorescence spectrophotometer.

Cyclic voltammetry (CV) studies were performed with an Eco chemie Autolab Electrochemical analyzer. CV experiments were carried out in a 30 mL three-electrode electrolytic cell. The working electrode was platinum disk, a separate Pt single-sheet electrode was used as the counter electrode and a Ag/AgCl electrode saturated with KCl was used as the reference electrode. The cyclic voltammograms of the complexes were recorded in 0.4 mM dmso solutions and in 0.4 mM 1/2 dmso/buffer solutions at ν = 100 mV s^{-1} where teap (=tetraethylammonium perchlorate) and the buffer solution were the supporting electrolytes, respectively. Oxygen was removed by purging the solutions with pure nitrogen which had been previously saturated with solvent vapors. All electrochemical measurements were performed at 25.0 ± 0.2 °C.

2.4. X-ray crystal structure determination

Slow crystallization from methanol yielded green prismatic crystals of **1**. A crystal with approximate dimensions 0.24 × 0.49 × 0.59 mm was taken directly from the mother liquor and immediately cooled to −93 °C. Diffraction measurements were made with Rigaku R-AXIS SPIDER Image Plate using graphite monochromated Cu radiation. Data collection (ω-scans) and processing (cell refinement, data reduction and Empirical absorption correction) were performed using the CrystalClear program package [36].The structure was solved by direct methods using SHELXS-86 and refined by full-matrix least-squares techniques on F^2 with SHELXL-93 using 8326 reflections and refining 921 parameters [37,38]. The final values for R_1, wR_2 and GOF for all data are 0.0481, 0.1242 and 1.045, respectively. The maximum and minimum residual peaks in the final difference map were 1.022 and −0.354 e/Å and the largest shift/esd in the final cycle was 0.001. All non-H atoms were refined anisotropically. There are six water solvate molecules in the structure, which were refined with full occupation factor, and one water solvate molecule which was refined with occupation factor fixed to 0.40. Hydrogen atoms were located by difference maps and were refined isotropically, except those of the partially occupied water solvate molecule which were not included in the refinement. The H-atoms of one of the fully occupied water solvates were not found in the difference maps and were not included in the refinement (Table 1).

2.5. DNA binding studies

The interaction of **1** with CT DNA has been studied with UV spectroscopy and CV in order to investigate the possible binding

mode to CT DNA and to calculate the binding constants to CT DNA (K_b).

In UV titration experiments, the spectra of CT DNA in the presence of **1** have been recorded for a constant CT DNA concentration in diverse [complex]/[CT DNA] mixing ratios (r). The intrinsic binding constants, K_b, of the complex with CT DNA have been determined using the UV spectra of **1** recorded for a constant concentration in the absence or presence of CT DNA for diverse r values.

The interaction of **1** with CT DNA has been also investigated by monitoring the changes observed in the cyclic voltammogram of a 0.40 mM 1/2 dmso/buffer solution of **1** upon addition of CT DNA at diverse r values. The buffer solution was also used as the supporting electrolyte and the cyclic voltammograms were recorded at $v = 100$ mV s^{-1}.

The competitive studies of complex **1** with EB have been investigated with fluorescence spectroscopy in order to examine whether it is able to displace EB from its CT DNA–EB complex. The CT DNA–EB complex was prepared by adding 20 μM EB and 25 μM CT DNA in buffer (150 mM NaCl and 15 mM trisodium citrate at pH 7.0). The intercalating effect of **1** with the DNA–EB complex was studied by adding a certain amount of a solution of **1** step by step into the solution of the DNA–EB complex. The influence of the addition of complex **1** to the DNA–EB complex solution has been obtained by recording the variation of fluorescence emission spectra.

3. Results and discussion

3.1. Synthesis and spectroscopic study of complex *1*

The synthesis of $Ni(sf)_2(py)_2$ **1** was achieved via the reaction of sparfloxacin, deprotonated with KOH, with $NiCl_2 \cdot 6H_2O$ in the presence of pyridine under air, according to the equation:

$$NiCl_2 \cdot 6H_2O + 2C_{18}H_{21}F_2N_4O - COOH + 2KOH + 2C_5H_5N \rightarrow Ni(C_{18}H_{21}F_2N_4O - COO)_2(C_5H_5N)_2 + 2KCl \quad (1)$$

In the IR spectrum of **1**, the observed absorption bands at 3462(br,m) cm^{-1}, 1716(s) cm^{-1} and 1292(s) cm^{-1} attributed to the stretching vibrations ν(H–O), ν(C=O)$_{carboxyl}$, ν(C–O)$_{carboxyl}$, respectively, of the carboxylic group (–COOH) of the sparfloxacin molecule, have been replaced by two very strong characteristic bands at 1600 cm^{-1} and 1380 cm^{-1} assigned as antisymmetric, ν_{asym}(C=O), and symmetric, ν_{sym}(C=O), stretching vibrations, respectively. The difference Δ [=ν_{asym}(C=O) − ν_{sym}(C=O)], a useful characteristic tool for determining the coordination mode of carboxylato ligands, with a value of 220 cm^{-1} is indicative of a monodentate coordination mode [39]. The vibration ν(C=O)$_{ket}$ is slightly shifted from 1640 cm^{-1} to 1643 cm^{-1} upon bonding. The overall changes of the IR spectrum suggest that the sparfloxacinato ligand is coordinated to Ni(II) via the ketone oxygen and a carboxylate oxygen [1,19].

The UV–Vis spectra of the complex have been recorded as nujol mull and in dmso solution and they are similar, with the exception, in some cases, of a few nm shifts suggesting that the complex retains its structure in solution. The UV spectrum of the complex is practically identical with that of sparfloxacin but slightly shifted, indicative of the coordination of sparfloxacin to Ni(II) through the ketone oxygen and a carboxylate oxygen [11]. In the visible region spectra, there is a characteristic band at 620 nm (ε = 12 M^{-1} cm^{-1}) attributed to d–d transitions as expected for distorted octahedral high-spin Ni(II) [21] complexes. Similar behavior has been observed for the distorted octahedral Ni(II) [40] cinoxacin complex as well as for other Ni(II) quinolone complexes [12,41,42]. Additionally, a band assigned to the ligand-to-metal charge transfer transition for the quinolone ligand [41–43] exists at 412 nm (ε = 220 M^{-1} cm^{-1}) as a shoulder.

3.2. Description of the structure of $Ni(sf)_2(py)_2 \cdot 6.4H_2O$, ***1*** $\cdot$ $6.4H_2O$

An ORTEP diagram of **1** is shown in Fig. 2, and selected bond distances and angles are listed in Table 2. The complex is monomeric, the sparfloxacinato ligand behaves as a bidentate deprotonated ligand and is coordinated to nickel ion via the ketone oxygen and a carboxylate oxygen.

The nickel atom is six-coordinate and is in an octahedral environment formed by nitrogen atoms from the two pyridine ligands and four oxygen atoms from the two sparfloxacinato ligands.

Two sets of Ni–O distances are observed: the Ni–O$_{carb}$ [Ni(1)–O(1) = 2.012(2) Å, Ni(1)–O(22) = 2.015(2) Å] are shorter than the Ni–O$_{ket}$ [Ni(1)–O(2) = 2.072(2) Å, Ni(1)–O(21) = 2.059(1) Å]. The arrangement of the two sparfloxacinato ligands is such that the two ketone oxygen atoms [O(2)–Ni(1)–O(21) = 89.05(6)°] are in a *cis* arrangement and the two carboxylato oxygen atoms [O(1)–Ni(1)–O(22) = 174.54(6)°] are *trans* to each other.

The Ni–N bond distances [Ni(1)–N(51) = 2.073(2) Å, Ni(1)–N(61) = 2.088(2) Å] are similar to the values reported for other Ni(II) complexes with N-donor heterocyclic ligands [44,45]. The N$_{pyr}$–Ni–N$_{pyr}$ angle [N(51)–Ni(1)–N(61) = 91.88(7)°] shows a *cis* arrangement of the two pyridine ligands.

The lattice structure of **1** is stabilized by an extensive network of hydrogen bonding interactions (Table 3) leading to the overall stability of the structure.

3.3. Cyclic voltammetry for $Ni(sf)_2(py)_2$

The complete scan in the range +1.5 V to −1.0 V of **1** in 0.4 mM dmso solution shows one cathodic wave at −775 mV and one anodic wave at −615 mV (Fig. 3A). This quasi-reversible wave can be assigned to the couple Ni(II)/Ni(I) [8,46,47].

Table 3
Hydrogen bonding interactions in the structure of **1**.

Interaction	D···A (Å)	H···A (Å)	D–H···A (°)	Symmetry operation
N2–H1N2···Ow5	2.936	2.171	147.4	$1+x, y, z$
N4–HN4···Ow7	3.042	2.278	169.3	$-x, 1-y, -1-z$

Ow2···Ow3	2.862			$-1-x, -y, -z$

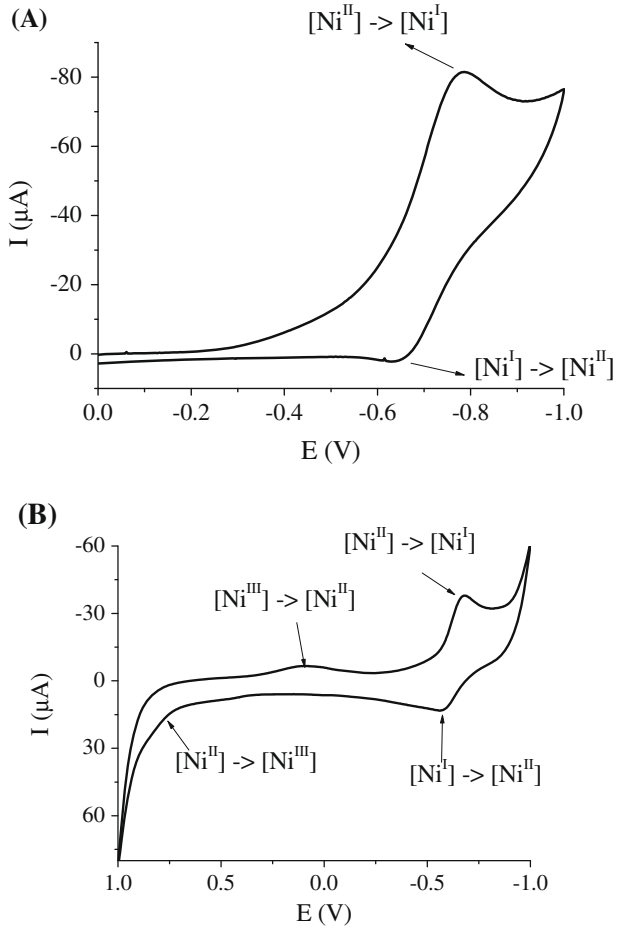

Fig. 3. Cyclic voltammograms of $Ni(sf)_2(py)_2$ **1** in (A) 0.4 mM dmso solution in the range +1.5 V to −1.0 V (supporting electrolyte = teap, 0.1 M); (B) in 0.4 mM 1/2 dmso/buffer (150 mM NaCl and 15 mM trisodium citrate at pH 7.0) solution (supporting electrolyte = buffer solution). Scan rate = 100 mV s^{-1}.

The cyclic voltammogram of complex **1** in 0.4 mM 1/2 dmso/buffer solution shows the existence of one cathodic wave at −686 mV ($[Ni^{II}] \rightarrow [Ni^{I}]$) and two anodic waves at −567 mV and +530 mV ($[Ni^{II}] \rightarrow [Ni^{III}]$), while a second cathodic wave attributed to $[Ni^{III}] \rightarrow [Ni^{II}]$ process appears at +95 mV in the reverse scan [8,47]. The current intensities attributed to the couple Ni(II)/Ni(I) are much higher than the others which are sometimes difficult to distinguish (Fig. 3B).

3.4. Interaction with DNA

Titration with UV absorption spectroscopy is an effective method to examine the binding mode of DNA with metal complexes [48]. The transition metal complexes can bind to DNA via covalent mode (a labile ligand of the complexes is replaced by a nitrogen atom of DNA bases) and/or noncovalent interactions (intercalative, electrostatic and groove binding of metal complexes along outside of DNA helix, along major or minor groove) [49]. It has been reported that the quinolone metal complexes can interact with DNA only via noncovalent interactions comprising groove binding, electrostatic binding to phosphate group or intercalation [50].

The UV spectra of the interaction of CT DNA with **1** have been recorded for a constant CT DNA concentration in different [complex]/[DNA] mixing ratios (r) and are shown in Fig. 4. The changes observed in the absorption spectra of CT DNA in the presence of **1**, i.e. the decrease of the intensity at λ_{max} = 258 nm, which is accompanied by a red-shift of the λ_{max} up to 266 nm, indicate that the interaction of **1** with CT DNA results in the direct formation of a new complex with double-helical CT DNA [51]. The observed

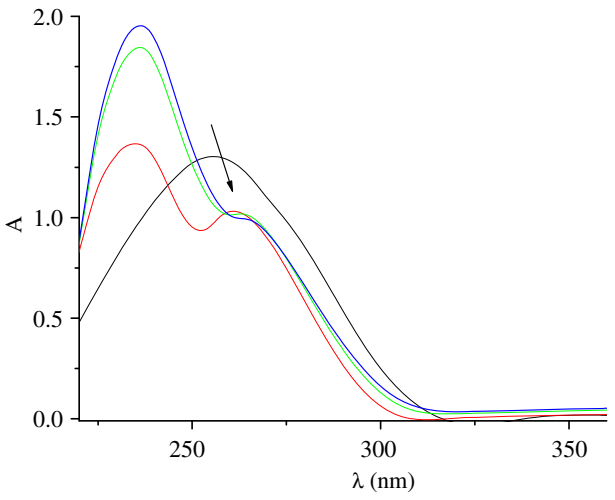

Fig. 4. UV spectra of CT DNA ([DNA] = 2×10^{-4} M) in buffer solution (150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of $Ni(sf)_2(py)_2$, **1** at diverse r values (r = [**1**]/[DNA]). The arrow shows the changes upon increasing amounts of complex **1** (r = 0–0.08).

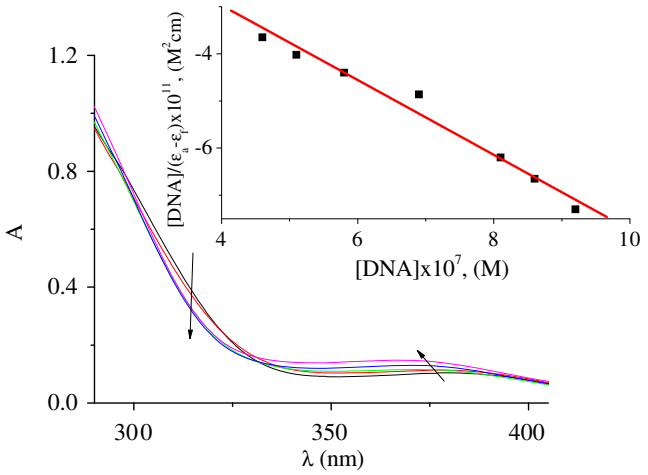

Fig. 5. UV spectra of Ni(sf)$_2$(py)$_2$ ([**1**] = 5 μM) in dmso solution in the absence and presence of CT DNA ([CT DNA] = 0–5 μM) at increasing amounts. The arrows show the changes upon increasing amounts of CT DNA. Inset: plot of $\frac{[DNA]}{(\varepsilon_a-\varepsilon_f)}$ vs. [DNA].

hypochromism is due to stacking interaction between the aromatic chromophore (either from sparfloxacinato and/or pyridine ligands) of **1** and DNA base pairs consistent with the intercalative binding mode [48,52]. Additionally, the observed bathochromism of 8 nm is an evidence of the stabilization of the CT DNA duplex [53].

In Fig. 5, the changes occurred in the spectrum of a 5×10^{-6} M solution of **1** during the titration upon addition of CT DNA in diverse r values can be observed. In the UV region, the intense absorption bands observed in the spectrum are attributed to the intraligand $\pi \rightarrow \pi^*$ transition of the coordinated groups of sparfloxacinato and pyridine ligands. Any interaction between a compound and CT DNA could perturb the intra-ligand centred spectral transitions of the compound [54]. There are not observed any significant changes in the position of the $\pi \rightarrow \pi^*$ transition bands of sparfloxacinato ligand upon addition of CT DNA. On the other hand, the intensity of the band (observed as a shoulder) centred at 315 nm is decreased in the presence of increasing amounts of CT DNA. The observed hypochromic effect suggests tight binding to CT DNA probably due to intercalation induced through the sparfloxacinato ligands [55]. Additionally, the intensity of the band centred at 380 nm is increased in the presence of increasing amounts of CT DNA, while a blue-shift of 10 nm (up to 370 nm) can be observed. The observed hyperchromic effect suggests binding to CT DNA ascribed either to external contact (electrostatic binding) [56] or to the fact that complex could uncoil the helix structure of DNA and make more bases embedding in DNA exposed [57]. One distinct isosbestic point at 320 nm appears upon addition of CT DNA.

The intrinsic binding constant K_b is determined in order to estimate the magnitude of the binding strength of **1** with CT DNA, represents the binding constant per DNA base pair, can be obtained by monitoring the changes in the absorbance at λ_{max} = 315 nm with increasing concentrations of CT DNA and is given by the ratio of the slope to the y intercept in plots $\frac{[DNA]}{(\varepsilon_a-\varepsilon_f)}$ versus [DNA] (inset in Fig. 5), according to the following equation [52]:

$$\frac{[DNA]}{(\varepsilon_a-\varepsilon_f)} = \frac{[DNA]}{(\varepsilon_b-\varepsilon_f)} + \frac{1}{K_b(\varepsilon_b-\varepsilon_f)} \quad (2)$$

where [DNA] is the concentration of DNA in base pairs, $\varepsilon_a = A_{obsd}/[\mathbf{1}]$, ε_f = the extinction coefficient for free complex **1** and ε_b = the extinction coefficient for the compound in the fully DNA-bound form.

The obtained K_b value [=3.87(±0.14) × 10^7 M^{-1}] suggests very strong binding of **1** to CT DNA and it is much higher than that of Hsf (=1.71(±0.02) × 10^5 M^{-1}) [58], indicating that the coordination of sparfloxacinato ligand to Ni(II) ion, in combination with the existence of the N-donor aromatic ligand pyridine, enhances significantly its ability to bind to CT DNA. The K_b for **1** is higher than the binding affinity for CT DNA of EB, a classical intercalator, (K_b = 1.23(±0.07) × 10^5 M^{-1}) [59], suggesting that intercalative interaction may affect EB displacement from the EB–DNA complex [59].

The changes observed in the cyclic voltammogram of a small molecule upon addition CT DNA can provide a useful complement to spectroscopic methods for the molecule–DNA interaction [60] since the electrochemical potential of the molecule will shift positively when the molecule intercalates into DNA double helix, and it will shift into a negative direction, if the molecule is bound to DNA by an electrostatic interaction [61,62].

In Fig. 6, the cyclic voltammograms of **1** in the absence or presence of CT DNA are shown. No new redox peaks appeared after the addition of CT DNA to the complex, but the current intensity of all the peaks decreased significantly, suggesting the existence of an interaction between complex **1** and CT DNA, and can be explained in terms of an equilibrium mixture of free and DNA-bound complex to the electrode surface [63]. It can be observed (Fig. 6) that for increasing amounts of CT DNA, the cathodic potential E_{pc} shows a positive shift up to −672 mV (ΔE_{pc} = +14 mV) and the anodic potential E_{pa} presents a lower positive shift up to −560 mV (ΔE_{pa} = +5 mV). These positive shifts of the potentials may suggest the existence of intercalation between **1** and CT DNA as the most possible interaction mode [8,53,62].

3.5. Competitive studies with ethidium bromide

Complex **1** does not show any fluorescence at room temperature in solution or in the presence of CT DNA, so that the binding to DNA cannot be directly predicted through the emission spectra. Hence, a competitive EB (=3,8-diamino-5-ethyl-6-phenyl-phenanthridinium bromide) binding study will give support for the binding of **1** with DNA. EB, a phenenthridine fluorescence dye and a typical indicator of intercalation [64], does not show any appreciable emission in buffer solution due to fluorescence quenching of the free EB by the solvent molecules [65], while the fluorescence intensity is highly enhanced upon addition of CT DNA, due to its strong intercalation through the planar phenenthridinium ring between the adjacent DNA base pairs [66,67].

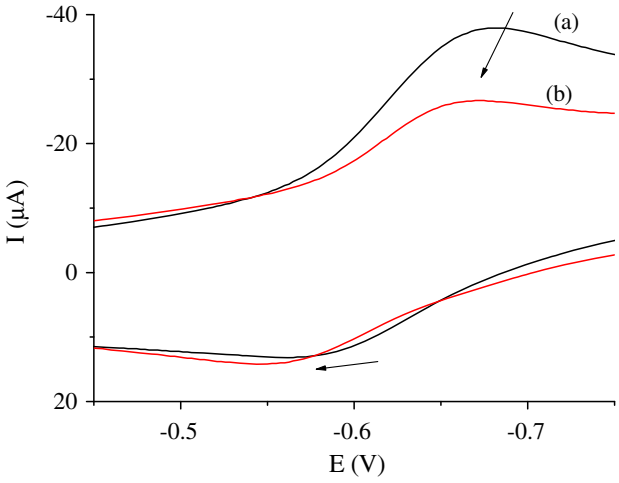

Fig. 6. Cyclic voltammograms of Ni(sf)$_2$(py)$_2$ **1** in 0.4 mM 1/2 dmso/buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) solution (supporting electrolyte = buffer solution) in (a) the absence and (b) presence of CT DNA for r = 2. The arrows show the changes upon addition of CT DNA. Scan rate = 100 mV s^{-1}.

Addition of a second molecule, which can bind to DNA more strongly than EB, would result to a decrease the DNA-induced EB emission [68]. Two mechanisms have been proposed to account for this reduction in the emission intensity: the replacement of EB, and/or electron transfer [69].

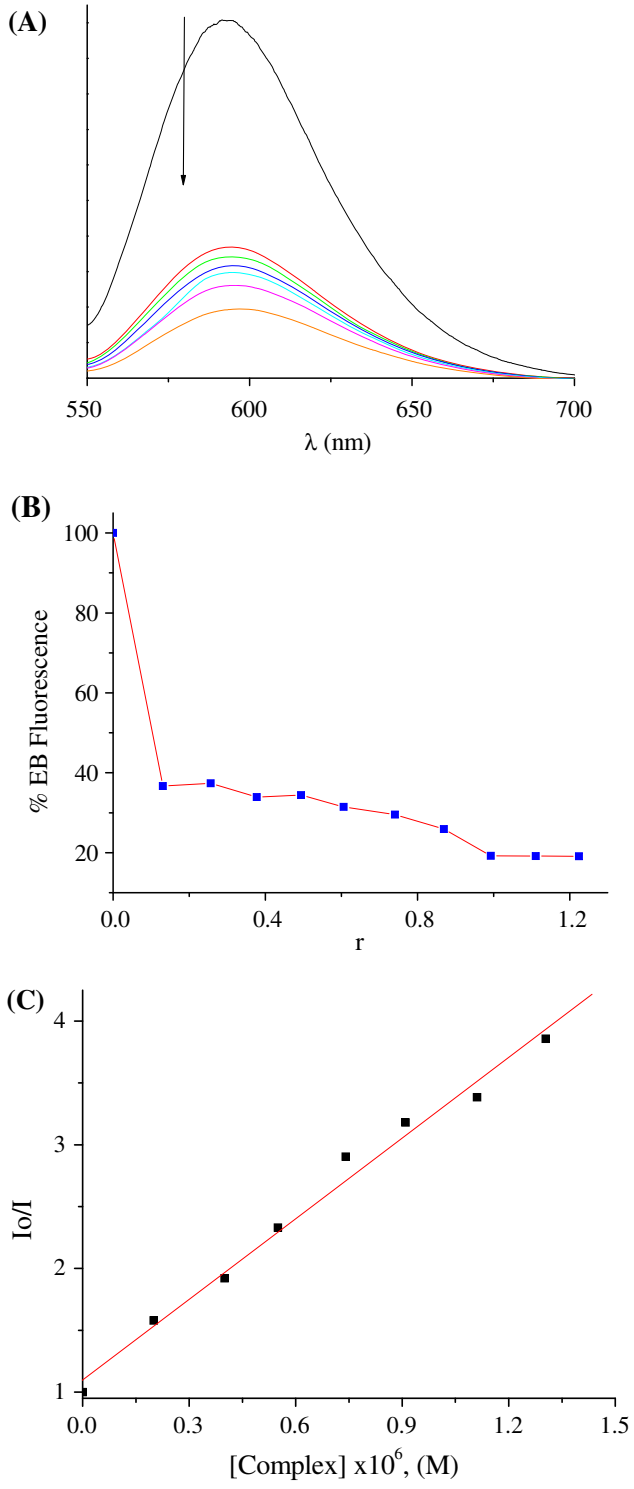

Fig. 7. (A) Emission spectra (λ_{exit} = 540 nm) for EB–DNA in buffer solution (150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the absence and presence of increasing amounts of complex **1** (r = [**1**] / [DNA] = 0–1.2). The arrow shows the changes of intensity upon increasing amounts of **1**. (B) Plot of EB relative fluorescence intensity (%) vs. r (=[**1**]/[DNA]) for **1** in buffer solution (150 mM NaCl and 15 mM trisodium citrate at pH 7.0). (C) Stern–Volmer quenching plot of EB bound to CT DNA by complex **1**. [EB] = 20 μM, [DNA] = 25 μM, λ_{em} = 592 nm.

The emission spectra of EB bound to CT DNA in the absence and presence of **1** have been recorded for [EB] = 2×10^{-5} M, [DNA] = 2.5×10^{-5} M for increasing amounts of complex **1** (Fig. 7A). The intensity of the emission band at 592 nm of the DNA–EB system decreased in intensity (up to 19% of the initial EB–DNA fluorescence intensity) upon addition of **1** at diverse r values (Fig. 7B) indicating the competition of complex **1** with EB in binding to DNA. The observed quenching of DNA–EB fluorescence for complex **1** suggests that it can displace EB from the DNA–EB complex and it can interact with CT DNA probably by the intercalative mode [8,70].

The Stern–Volmer constant K_{SV} is often used to evaluate the quenching efficiency for a compound, it varies with the experimental conditions and is given by the equation:

$$\frac{I_o}{I} = 1 + K_{SV}[\text{complex}] \quad (3)$$

where I_o and I are the emission intensities in the absence and the presence of the complex, respectively. The Stern–Volmer plot of DNA–EB for **1** (Fig. 7C) illustrates that the quenching of EB bound to DNA by the complex is in good agreement (R = 0.99) with the linear Stern–Volmer equation (Eq. (3)), which proves that the partial replacement of EB bound to DNA by **1** results in a decrease in the fluorescence intensity [71]. The high K_{SV} value of the complex ($K_{SV} = 2.17 \pm 0.16 \times 10^6$ M^{-1}) shows that **1** can be bound tightly to the DNA [55].

4. Conclusions

The synthesis and characterization of the neutral mononuclear nickel(II) complex with the third-generation quinolone antibacterial drug sparfloxacin in the presence of the N-donor heterocyclic ligand pyridine has been realized. The crystal structure of complex $Ni(sf)_2(py)_2$ has been determined with X-ray crystallography revealing a distorted octahedral environment around Ni(II). The interaction of **1** with CT DNA has been studied with UV spectroscopy revealing its ability to bind to DNA. UV spectroscopic titrations have been used in order to calculate the intrinsic binding constant K_b [=3.87(±0.14) × 10^7 M^{-1}], which suggests very strong binding of **1** to CT DNA. Cyclic voltammetric titration has shown that **1** can bind to CT DNA by the intercalative mode. Competitive binding study with EB, performed with fluorescence spectroscopy, has shown that the interaction between DNA–EB complex and **1** releases EB from its DNA complex, indicating that complex **1** can bind to DNA probably via the intercalative mode

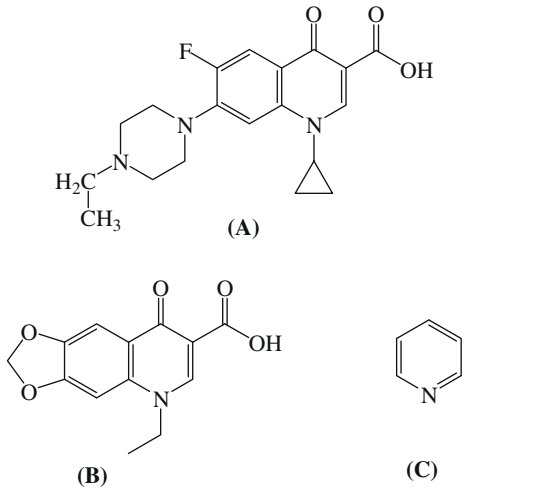

Fig. 1. (A) Enrofloxacin (Herx = 1-cyclopropyl-7-(4-ethyl-piperazin-1-yl)-6-fluoro-4-oxo-1,4-dihydro-quinoline-3-carboxylic acid). (B) oxolinic acid (Hoxo = 5,8-dihydro-5-ethyl-8-oxo-1,3-dioxolo[4,5-g]quinoline-7-carboxylic acid), (C) pyridine (= py).

Cu(oxo)(phen)Cl has been reported in the literature [29]. We have also initiated studies on the co-ordination chemistry of carboxylate-containing herbicides or anti-inflammatory agents with metal ions in an attempt to examine their mode of binding and possible biological relevance. In addition, we have reported studies on the effect of polynuclear metal complexes on the integrity and electrophoretic mobility of nucleic acids [30–39].

The role of zinc in various biological systems is important [40], since zinc is critical for numerous cell processes and is a major regulatory ion in the metabolism of cells [41]. In the literature, diverse zinc complexes with biological activity are reported, but only zinc complexes with drugs used for the treatment of Alzheimer's disease [42] and others showing antibacterial [43], anticonvulsant [44], antidiabetic [45], anti-inflammatory [46], antimicrobial [47] and antiproliferative – antitumor [48–50] activity are structurally characterized.

The synthesis, the characterization and the DNA-binding properties of two novel neutral mononuclear zinc complexes with enrofloxacin, $Zn(erx)_2(py)_2$ **1,** and oxolinic acid, $Zn(oxo)_2(py)_2$ **2**, in the presence the N-donor heterocyclic ligand pyridine (=py) (Fig. 1C) are presented. The ability of these complexes to bind to CT (calf-thymus) DNA has been investigated with UV spectroscopic titration and their intrinsic binding constants, K_b, with CT-DNA have been determined. Competitive binding studies with ethidium bromide (EB), one of the most widely used intercalative agents and fluorescence probes for DNA structure, have been employed in the study of the interaction of the complexes with CT-DNA in order to investigate a potential intercalative binding mode.

2. Experimental

2.1. Materials

Enrofloxacin, oxolinic acid, CT-DNA and EB were purchased from Sigma, NaCl and all solvents were purchased from Merck, trisodium citrate was purchased from Riedel-de Haen and $ZnCl_2$, pyridine and KOH were purchased from Aldrich Co. All the chemicals and solvents were reagent grade and were used as purchased.

DNA stock solution was prepared by dilution of CT-DNA to buffer (containing 150 mM NaCl and 15 mM trisodium citrate at pH 7.0) followed by exhaustive stirring at 4 °C for 3 days, and kept at 4 °C for no longer than a week. The stock solution of CT-DNA gave a ratio of UV absorbance at 260 and 280 nm (A_{260}/A_{280}) of 1.89, indicating that the DNA was sufficiently free of protein contamination [51]. The DNA concentration was determined by the UV absorbance at 260 nm after 1:20 dilution using $\varepsilon = 6600\ M^{-1}\ cm^{-1}$ [52].

2.2. Synthesis of the complexes

2.2.1. Synthesis of $Zn(erx)_2(py)_2 \cdot 6H_2O \cdot MeOH$ ($1 \cdot 6H_2O \cdot MeOH$)

A methanolic solution (15 mL) of enrofloxacin (0.4 mmol, 144 mg), deprotonated with KOH (0.4 mmol, 22 mg), was added to a methanolic solution (10 mL) of $ZnCl_2$ (0.2 mmol, 28 mg) followed by the addition of 3 mL of pyridine. The solution was left for slow evaporation. Colorless crystals of $Zn(erx)_2(py)_2 \cdot 6H_2O \cdot MeOH$, $\mathbf{1} \cdot 6H_2O \cdot MeOH$, suitable for X-ray structure determination, were deposited after ten days. Yield: 260 mg, 70%. *Anal.* Calc. for $Zn(erx)_2(py)_2 \cdot 6H_2O \cdot MeOH$ ($C_{49}H_{58}F_2N_8O_{13}Zn$) (MW = 1080.48): C, 54.47; H, 6.34; N, 10.37. Found: C, 54.92; H, 6.38; N, 10.23%. IR: ν_{max}/cm^{-1}; $\nu(C{=}O)_{ket}$: 1631(vs); $\nu_{as}(CO_2)$: 1611(vs); $\nu_{sym}(CO_2)$: 1384(vs); $\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$: 227 cm^{-1} (KBr pellet). The complex is soluble in dmso and dmf and is non-electrolyte.

2.2.2. Synthesis of $Zn(oxo)_2(py)_2 \cdot 6H_2O$, $2 \cdot 6H_2O$

Complex **2** was prepared in a similar way. Oxolinic acid (0.4 mmol, 105 mg) was used instead. Yield: 190 mg, 65%. *Anal.* Calc. for $Zn(oxo)_2(py)_2 \cdot 6H_2O$ ($C_{36}H_{42}N_4O_{16}Zn$) (MW = 852.13): C, 50.74; H, 4.97; N, 6.58. Found: C, 50.40; H, 4.83; N, 6.30%. IR: ν_{max}/cm^{-1}; $\nu(C{=}O)_{ket}$: 1642(vs); $\nu_{as}(CO_2)$: 1596(vs); $\nu_{sym}(CO_2)$: 1388(vs); $\Delta = \nu_{asym}(CO_2) - \nu_{sym}(CO_2)$: 208 cm^{-1} (KBr pellet). The complex is soluble in dmso and dmf and is non-electrolyte.

2.3. Instrumentation – physical measurements

Infrared (IR) spectra (400–4000 cm^{-1}) were recorded on a Nicolet FT-IR 6700 spectrometer with samples prepared as KBr pellets. UV–Visible (UV–Vis) spectra were recorded as nujol mulls and in solution at concentrations in the range 10^{-5}–10^{-3} M on a Hitachi U-2001 dual beam spectrophotometer. C, H and N elemental analysis were performed on a Perkin–Elmer 240B elemental analyzer. Molecular conductivity measurements were carried out with a Crison Basic 30 conductometer. Fluorescence spectra were recorded in solution on a Hitachi F-7000 fluorescence spectrophotometer.

2.4. X-ray crystal structure determination

Slow crystallization from methanol yielded colorless prismatic crystals of $\mathbf{1} \cdot 6H_2O \cdot MeOH$. A crystal with approximate dimensions 0.43 × 0.44 × 0.69 mm was taken directly from the mother liquor and immediately cooled to −93 °C. Diffraction measurements were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Cu radiation. Data collection (ω-scans) and processing (cell refinement, data reduction and Empirical absorption correction) were performed using the CRYSTALCLEAR program package [53]. The structure was solved by direct methods using SHELXS-97 and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 using 4034 reflections and refining 356 parameters for **1** [54,55]. The final values for R_1, wR_2 and GOF for all data for **1** are 0.0463, 0.1264 and 1.075, respectively, and are given in Table 1. The maximum and minimum residual peaks in the final difference map were 0.820 e/Å and −0.440 e/Å and the largest shift/esd in the final cycle was 0.001. Hydrogen atoms were introduced at calculated positions as riding on bonded atoms, except those of the water solvate molecules which were located by difference maps and were refined isotropically. All non-H atoms were refined anisotropically.

2.5. DNA binding studies

The interaction of the ligands and the complexes with CT-DNA has been studied with UV spectroscopy in order to investigate the possible binding modes to CT-DNA and to calculate the binding constants to CT-DNA (K_b).

In UV titration experiments, the spectra of CT-DNA in the presence of each compound have been recorded for a constant CT-DNA concentration in diverse [compound]/[CT-DNA] mixing ratios (r). The intrinsic binding constants, K_b, of the compounds with CT-DNA have been determined using the UV spectra of the compounds recorded for a constant concentration in the absence or presence of CT-DNA for diverse r values.

The competitive studies of each compound with EB have been investigated with fluorescence spectroscopy in order to examine whether the quinolone or the complex is able to displace EB from its CT-DNA–EB complex. The CT-DNA–EB complex was prepared by adding 20 μM EB and 30 μM CT-DNA in buffer (150 mM NaCl and 15 mM trisodium citrate at pH 7.0). The intercalating effect of the free quinolones and complexes **1**and **2** with the DNA–EB complex was studied by adding a certain amount of a solution of the compound step by step into the solution of the DNA–EB complex. The influence of the addition of each compound to the DNA–EB complex solution has been obtained by recording the variation of the fluorescence emission spectra.

3. Results and discussion

3.1. Synthesis and spectroscopic study of the complexes

The synthesis of the complexes Zn(erx)$_2$(py)$_2$ **1** and Zn(oxo)$_2$-(py)$_2$ **2** was achieved via the reaction of the corresponding quinolone ligand, deprotonated with KOH, in the presence of pyridine with $ZnCl_2$ under air, according to the equations:

$$ZnCl_2 + 2C_{18}H_{21}FN_3O{-}COOH + 2KOH + 2C_5H_5N \rightarrow Zn(C_{18}H_{21}FN_3O{-}COO)_2(C_5H_5N)_2 + 2KCl + 2H_2O$$

$$ZnCl_2 + 2C_{12}H_{10}NO_3{-}COOH + 2KOH + 2C_5H_5N \rightarrow Zn(C_{12}H_{10}NO_3{-}COO)_2(C_5H_5N)_2 + 2KCl + 2H_2O$$

In the IR spectra of the complexes, the observed absorption bands at 3442(br,m) cm^{-1}, 1736(s) cm^{-1} and 1254(s) cm^{-1} and at 3443(br,m) cm^{-1}, 1712(s) cm^{-1} and 1260(s) cm^{-1} attributed to the stretching vibrations ν(H–O), ν(C=O)$_{carboxyl}$, ν(C–O)$_{carboxyl}$, respectively, of the carboxylic group (–COOH) of the Herx and Hoxo molecule, have been replaced by two very strong characteristic bands at 1611 and 1384 cm^{-1} for **1** and at 1596 and 1388 cm^{-1} for **2,** assigned as antisymmetric, ν_{asym}(C=O), and symmetric, ν_{sym}(C=O), stretching vibrations, respectively. The difference Δ [= ν_{asym}(C=O) − ν_{sym}(C=O)] is a useful characteristic tool for determining the coordination mode of the carboxylato ligands and has a value of 227 cm^{-1} for **1** and 208 cm^{-1} for **2** indicating a monodentate coordination mode [56]. The vibration ν(C=O)$_{ketone}$ is slightly shifted from 1627 cm^{-1} in Herx to 1631 cm^{-1} for **1** from 1633 cm^{-1} in Hoxo to 1642 cm^{-1} for **2** upon bonding. The overall changes of the IR spectra suggest that enrofloxacinato and oxolinato ligands are coordinated to the zinc via the ketone oxygen and a carboxylate oxygen [1,22,29].

3.2. Description of the structure of Zn(erx)$_2$(py)$_2$ · $6H_2O$ · MeOH (1 · $6H_2O$ · MeOH)

An ORTEP diagram of **1** is shown in Fig. 2, and selected bond distances and angles are given in Table 2. There are six water and a methanol solvate molecules. The complex is monomeric and the enrofloxacinato ligands behave as bidentate deprotonated ligands and are coordinated to zinc ion via the ketone oxygen and a carboxylate oxygen.

The structure of the complex is centrosymmetric, the Zn(II) ion is sitting on a center of symmetry and it is coordinated to two pyridine and two bidentate enrofloxacinato ligands related by the inversion center. Thus, the zinc ion is six-coordinate and, as a result of the inversion center, it displays a distorted octahedral geometry.

The quinolone ligands in the reported structurally characterized zinc–quinolone complexes may be found in different coordination modes. More specifically, the quinolone is (a) in neutral bidentate mode coordinated through the ketone oxygen and a carboxylate oxygen as in complexes Zn(Hnorf)$_2$(NO$_3$)$_2$ · $2H_2O$ [57], [Zn(Hcf)(1,3-bdc)] (1,3-bdc = 1,3-benzenedicarboxylate) [58] and [Zn$_2$(Hcf)$_4$(1,4-bdc)](1,4-bdc) · $13H_2O$ (1,4-bdc = 1,4-benzenedicarboxylate) [58], (b) in deprotonated bidentate mode coordinated

O1–Zn–O2′	91.76(6)	N4–Zn–O2′	88.87(7)
N4–Zn–N4′	180.00(12)	O1–Zn–O1′	180.00(8)
O2–Zn–O2′	180.00(13)		

Primed atoms are generated by symmetry operation: (′) = –x, –y, –z.

through the ketone oxygen and a carboxylate oxygen atom as in complexes $[Zn(cx)_2(dmso)_2]\cdot 4H_2O$ [59], $[Zn(cf)_2(H_2O)_2]\cdot 8H_2O$ [60], $[Zn(cf)_2]\cdot 2.5H_2O$ [48,58] and $Zn(gatx)_2(H_2O)_2\cdot 4H_2O$ [33,43], (c) in protonated counter cation mode as in the complex $(H_2norf)(Hnorf)[ZnCl_4]C1\cdot H_2O$ [61], and (d) in deprotonated tridentate mode bound to zinc through the ketone oxygen, a carboxylate oxygen and piperazine nitrogen atom as in the polymeric complex $Zn(norf)_2\cdot 4H_2O$ [57], where Hnorf = norfloxacin, Hcx = cinoxacin, Hcf = ciprofloxacin and Hgatx = gatifloxacin are quinolones.

The Zn–O distances observed, $Zn–O_{carb}$ [Zn–O(2) = 2.059(2) Å] and $Zn–O_{ket}$ [Zn–O(1) = 2.082(2) Å], are quite shorter than the $Zn–N_{pyr}$ [Zn–N(4) = 2.178(2) Å]. The Zn–O distances are longer than those observed in $Zn(Hnorf)_2(NO_3)_2\cdot 2H_2O$ [$Zn–O_{carb}$ = 2.028(3) Å, $Zn–O_{ket}$ = 2.057(3) Å] [57], $[Zn_2(Hcf)_4(1,4–bdc)](1,4–bdc)\cdot 13H_2O$ [$Zn–O_{carb}$ = 2.014(4) Å, $Zn–O_{ket}$ = 2.047(3) Å] [58], $[Zn(cx)_2(dmso)_2]\cdot 4H_2O$ [$Zn–O_{carb}$ = 2.019(2) Å, $Zn–O_{ket}$ = 2.058(2) Å] [59], $[Zn(cf)_2(H_2O)_2]\cdot 8H_2O$ [$Zn–O_{carb}$ = 2.013(17) and 2.030(16) Å, $Zn–O_{ket}$ = 1.983(16) and 2.023(13) Å] [60] and shorter than those in $[Zn(cf)_2]\cdot 2.5H_2O$ [$Zn–O_{carb}$ = 2.0779(19) Å, $Zn–O_{ket}$ = 2.0873(17) Å] [58], $Zn(norf)_2\cdot 4H_2O$ [$Zn–O_{carb}$ = 2.070(3) Å, $Zn–O_{ket}$ = 2.095(3) Å] [47]. In $Zn(gatx)_2(H_2O)_2\cdot 4H_2O$ [43] the $Zn–O_{carb}$ (=1.992(5) Å) is shorter and the $Zn–O_{ket}$ (=2.108(5) Å) is longer than those found in **1**, while in [Zn(Hcf)(1,3-bdc)] [58] the $Zn–O_{carb}$ (=2.085(3) Å) is longer and the $Zn–O_{ket}$ [=2.037(2) Å] is shorter than those found in **1**. In all these complexes, the $Zn–O_{carb}$ is shorter than the $Zn–O_{ket}$ distance as observed in **1**, except those in $[Zn(cf)_2(H_2O)_2]\cdot 8H_2O$ [60] and [Zn(Hcf)(1,3-bdc)] [58] where the $Zn–O_{carb}$ distance is longer than the $Zn–O_{ket}$ one.

The Zn–N distances, [Zn–N(4) = 2.178(2) Å] are longer than those found in $[Zn(S_2CNMe_2)_2(py)]$ (2.079(6) Å) [62], $[Zn(bipy)_2(pybet)](ClO_4)$ (2.081(5)–2.140(6) Å, bipy = 2,2′-bipyridine, $pybet^-$ = pyridinioacetate) [63], $[Zn(bipy)(CC1_3CO_2)_2(H_2O)]$ (2.086(2) and 2.151(2) Å) [64], $[Zn(bipy)_2(ONO)](NO_2)$ (2.122(9)Å) [65] and $[Zn(phen)_2(MeCO_2)](ClO_4)$ (2.100(5)–2.160(5) Å, phen = 1,10-phenanthroline) [63] and shorter than those in $[Zn(pipdtc)_2(bipy)]$ (2.196(3) Å, $pipdtc^-$ = piperidine–carbodithioato anion) [66], $[Zn(cf)_2]\cdot 2.5H_2O$ (2.245(2) Å) [58] and $Zn(norf)_2\cdot 4H_2O$ (2.253(3) Å) [57].

The two pyridine rings are vertical to the mean plane defined by the Zn(II) and the four enrofloxacinato coordinated oxygens. The uncoordinated carboxylato oxygen atoms O(3) [Zn···O(3) = 4.098 Å] lie out the ZnO_4 plane and are displaced at 1.004 Å above and below the mean plane.

3.3. Interaction with DNA

Transition metal complexes can bind to DNA via covalent interactions, where a labile ligand of the complexes is replaced by a nitrogen base of DNA such as guanine N7, and/or noncovalent interactions which include intercalative, electrostatic and groove (surface) binding of metal complexes along outside of DNA helix, along major or minor groove [67]. Quinolone metal complexes can interact with CT-DNA via noncovalent interactions; groove binding, electrostatic binding to phosphate group and intercalation [68].

The UV spectra of CT-DNA in the presence of the quinolones Herx and Hoxo as well as complexes **1** and **2** have been recorded for diverse [compound]/[DNA] mixing ratios (r) and are shown in Fig. 3. The changes observed in the absorption spectra of CT-DNA in the presence of these compounds, i.e. the increase of the intensity at λ_{max} = 258 nm which is accompanied with a red-shift of the λ_{max} up to 267 nm, after mixing with each compound, indicate that the interaction with CT-DNA results in the direct formation of a new complex with double–helical CT-DNA [69]. The absorption intensity at 258 nm is increased due to the fact that the purine and pyrimidine DNA–bases are exposed because of the binding of the compounds to DNA. These characteristics can be attributed to an interaction [70] having caused the changes of the conformation of DNA [71]. Additionally, the observed bathochromism is an evidence of the stabilization of the CT-DNA duplex [72], while the existence of the intercalative binding mode may not be ruled out [15].

In Fig. 4, the changes occurred in the spectrum of a 4×10^{-5} M solution of free quinolones and complexes **1 and 2** during the titra-

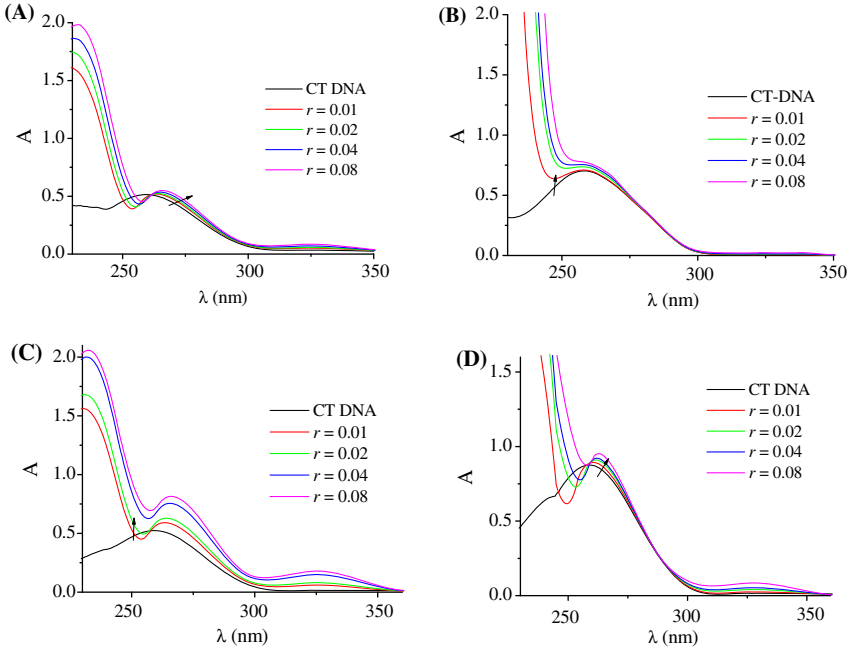

Fig. 3. UV spectra of CT-DNA in buffer solution (150 mM NaCl and 15 mM trisodium citrate at pH 7.0) in the presence of (A) Herx ([DNA] = 0.78×10^{-4} M), (B) Hoxo ([DNA] = 1.10×10^{-4} M), (C) $Zn(erx)_2(py)_2$, **1** ([DNA] = 0.79×10^{-4} M) and (D) $Zn(oxo)_2(py)_2$, **2** ([DNA] = 1.38×10^{-4} M) at diverse r values (r = [complex]/[DNA]) (r = 0–0.08). The arrows show the changes upon increasing amounts of compound.

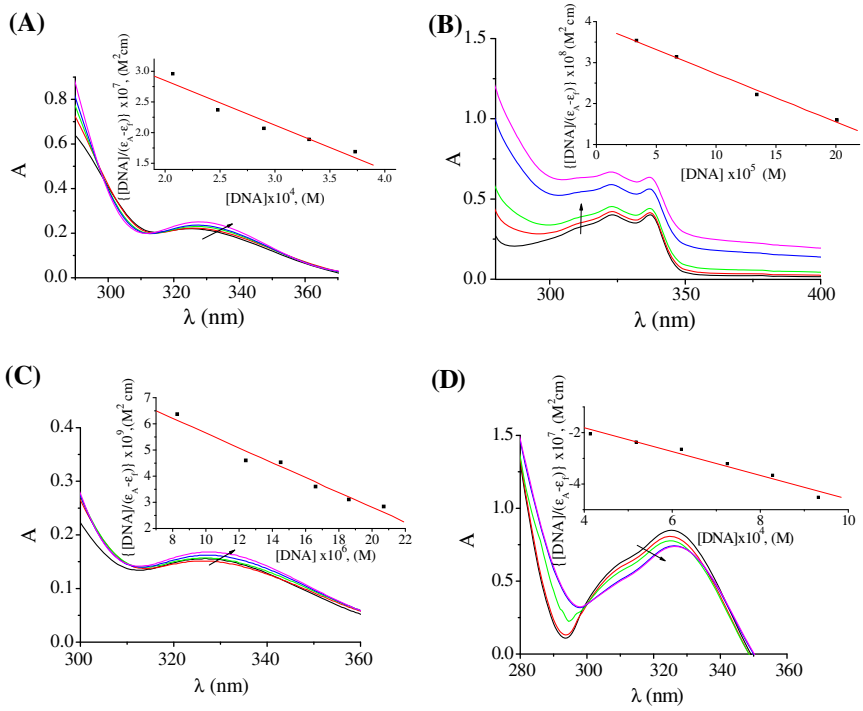

Fig. 4. UV spectra of dmso solution of (A) Herx (2×10^{-5} M), (B) Hoxo (4×10^{-5} M), (C) $Zn(erx)_2(py)_2$, **1** (2.5×10^{-6} M) and (D) $Zn(oxo)_2(py)_2$, **2** (5×10^{-5} M), in the presence of CT-DNA at increasing amounts. The arrows show the changes upon increasing amounts of CT-DNA. Insets: plots of $\frac{[DNA]}{(\varepsilon_a-\varepsilon_f)}$ vs [DNA].

tion upon addition of CT-DNA in diverse *r* values are presented. In the UV region, the intense absorption bands observed in the spectra of the quinolones and the complexes are attributed to the intraligand $\pi \rightarrow \pi^*$ transition of the coordinated groups. Any interaction between each compound and CT-DNA could perturb the intra-ligand centred spectral transition bands of the compound [73].

No significant changes are observed in the position of the $\pi \rightarrow \pi^*$ transition bands of the quinolones upon addition of CT-DNA. For Herx, the band centred at 325 nm shows a hyperchromism in the presence of increasing amounts of CT-DNA (Fig. 4A), which is accompanied with a red–shift of 3 nm (up to 328 nm). For Hoxo, the intensity of the bands centred at 324 nm and 334 nm is increased in the presence of increasing amounts of CT-DNA (Fig. 4B), while a blue-shift of 3 nm (up to 321 nm) and a red-shift of 4 nm (up to 338 nm), respectively, has been observed. The observed hyperchromic effect for Herx and Hoxo suggests binding to CT-DNA ascribed either to external contact (electrostatic binding) [72,74] or to the fact that the quinolones could uncoil the helix structure of DNA and make more bases embedding in DNA exposed [75].

For **1**, the intraligand band of enrofloxacinato ligand at 325 nm presents a red-shift of 3 nm (up to 328 nm), accompanied with a hyperchromism (Fig. 4C), suggesting tight binding to CT-DNA, maybe by electrostatic mode [76], and stabilization. One distinct isosbestic point at 311 nm appears upon addition of CT-DNA.

For **2**, the intensity of the band of oxolinato ligand centred at 325 nm is decreased upon addition of increasing amounts of CT-DNA (Fig. 4D), while a red-shift of 2 nm (up to 327 nm) is observed. The resultant hypochromism suggests tight binding of complex **2** to CT-DNA, probably by the intercalative mode and stabilization [72].

The results derived from the UV titration experiments suggest that all compounds can bind to CT-DNA, resulting in the stabilization of DNA duplex [72]. Nevertheless, the oxolinato ligands provide to **2** a more extended aromatic/planar moiety than the enrofloxacinato ligands in **1,** so that the binding of **2** involving intercalation of such an aromatic/planar ring between the base pairs of CT-DNA cannot be ruled out.

The intrinsic binding constant K_b, a tool to investigate the magnitude of the binding strength of a compound with CT-DNA, which represents the binding constant per DNA base pair, can be obtained by monitoring the changes in the absorbance at the corresponding λ_{max} with increasing concentrations of CT-DNA and is given by the ratio of slope to the *y* intercept in plots $\frac{[DNA]}{(\varepsilon_a-\varepsilon_f)}$ versus [DNA] (Insets in Fig. 4), according to the following equation [70]:

$$\frac{[DNA]}{(\varepsilon_a-\varepsilon_f)} = \frac{[DNA]}{(\varepsilon_b-\varepsilon_f)} + \frac{1}{K_b(\varepsilon_b-\varepsilon_f)} \quad (1)$$

where [DNA] is the concentration of DNA in base pairs, $\varepsilon_a = A_{obsd}/[compound]$, ε_f is the extinction coefficient for the free compound and ε_b is the extinction coefficient for the compound in the fully DNA-bound form. The calculated K_b values for the quinolones and the complexes are given in Table 3.

The K_b values suggest a relatively strong binding of the quinolones and complexes to CT-DNA. Especially, the K_b value obtained for complex **2** ($=1.16(\pm0.14) \times 10^5\ M^{-1}$) is much higher than the other compounds. This can be attributed to the existence of the oxolinato ligands containing a more extended aromatic/planar moiety than the enrofloxacinato ligands.

The K_b for the quinolone ligands and complex **1** are much lower than that of the classical intercalator EB, while the K_b value of **2** is

Table 3
The DNA binding constants (K_b) and the Stern–Volmer constants (K_{SV}) of the quinolones Herx, Hoxo and complexes **1** and **2**.

Complex	K_b (M^{-1})	K_{SV} (M^{-1})

Hoxo	$3.02(\pm0.10) \times 10^3$	nd [a]
$Zn(erx)_2(py)_2$, **1**	$3.35(\pm0.05) \times 10^4$	$3.40(\pm0.25) \times 10^5$
$Zn(oxo)_2(py)_2$, **2**	$1.16(\pm0.14) \times 10^5$	$3.68(\pm0.21) \times 10^5$

[a] n.d., not determined.

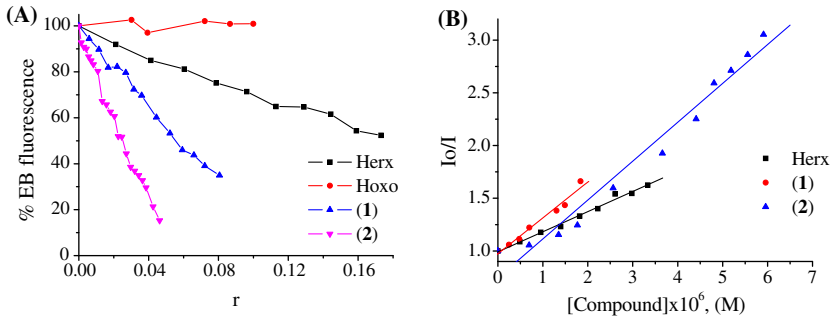

Fig. 5. (A) Plot of EB relative fluorescence intensity (%) vs r (=[complex]/[DNA]) for (■) Herx, (●) Hoxo, (▲) $Zn(erx)_2(py)_2$, **1** and (▼) $Zn(oxo)_2(py)_2$, **2** in buffer solution (150 mM NaCl and 15 mM trisodium citrate at pH 7.0). (B) Stern–Volmer quenching plot of EB bound to CT-DNA by (●) Herx, (▲) $Zn(erx)_2(py)_2$, **1** and (▼) $Zn(oxo)_2(py)_2$, **2**. [EB] = 20 μM, [DNA] = 30 μM, λ_{em} = 592 nm.

comparable to the EB binding affinity for CT-DNA, ($K_b = 1.23(\pm 0.07) \times 10^5\ M^{-1}$) [77], suggesting that electrostatic and/or intercalative interaction could affect EB displacement from the EB–DNA complex [77].

The quinolones and the complexes do not show any fluorescence at room temperature in solution or in the presence of CT-DNA, and their binding to DNA cannot be directly predicted through the emission spectra, so that competitive EB binding studies have been performed to gain support for the binding of each compound with DNA. EB (=3,8-diamino-5-ethyl-6-phenyl-phenanthridinium bromide), a phenenthridine fluorescence dye and a typical indicator of intercalation [78], does not show any appreciable emission in buffer solution due to fluorescence quenching of the free EB by the solvent molecules [79]. It can form soluble complexes with nucleic acids and emitting enhanced fluorescence in the presence of CT-DNA due to the intercalation of the planar phenenthridinium ring between adjacent base pairs on the double DNA-helix [80,81]. Addition of a second molecule, which can bind to DNA more strongly than EB results to a decrease the DNA-induced EB emission [82]. Two mechanisms have been proposed to account for this reduction in the emission intensity: the replacement of EB, and/or electron transfer [83].

The emission spectra of EB bound to CT-DNA in the absence and presence of each compound have been recorded for [EB] = 2×10^{-5} M, [DNA] = 3×10^{-5} M for increasing amounts of each compound. Free oxolinic acid does not provoke any significant changes of the intensity of the emission band at 592 nm of the DNA–EB system indicating that Hoxo cannot displace EB from the DNA–EB complex. On the other hand, the intensity of the emission band at 592 nm of the DNA–EB system decreased in intensity (up to 15% of the initial EB–DNA fluorescence for **2**) upon addition of enrofloxacin and complexes **1** and **2** at diverse r values (Fig. 5A) indicating the competition of the compounds with EB in binding to DNA. The observed quenching of DNA–EB fluorescence for Herx and complexes **1** and **2** may suggest that they can displace EB from the DNA–EB complex interacting with CT-DNA probably by the intercalative mode [15,84].

The Stern–Volmer constant K_{SV} is often used to evaluate the quenching efficiency for a compound and varies with the experimental conditions:

$$\frac{Io}{I} = 1 + K_{SV}\,[\text{compound}] \qquad (2)$$

where Io and I are the emission intensities in the absence and the presence of the compound, respectively. Fig. 5B shows the Stern–Volmer plots for Herx and **1** and **2** and the corresponding K_{SV} values calculated are shown in Table 3. The Stern–Volmer plot of DNA–EB illustrates that the quenching of EB bound to DNA by Herx and complexes **1 and 2** is in good agreement ($R = 0.99$) with the linear Stern–Volmer equation (Eq. 2), which proves that the partial replacement of EB bound to DNA by each compound results in a decrease in the fluorescence intensity [85]. Especially, the high K_{SV} values of the complexes show that they can be bound tightly to the DNA [86]. More specifically, complex **2** presents a higher value for K_{SV} than complex **1**, which is in accordance to the magnitude order observed for the K_b values, indicating its higher affinity to CT-DNA.

4. Conclusions

The synthesis and characterization of two novel neutral mononuclear zinc complexes with the quinolone antibacterial drugs enrofloxacin (second-generation) and oxolinic acid (first-generation) in the presence of the N-donor heterocyclic ligand pyridine has been realized. In these complexes, the quinolone ligands are bound to zinc(II) via the ketone oxygen and a carboxylato oxygen. The crystal structure of the complex $Zn(erx)_2(py)_2$ has been determined with X-ray crystallography revealing a distorted octahedral geometry for Zn(II).

The interaction of the quinolones and the complexes with CT-DNA has been studied with UV spectroscopy revealing their ability to bind to DNA. UV spectroscopic titrations have been used in order to calculate their binding strength with CT-DNA. $Zn(oxo)_2(py)_2$ exhibits the highest K_b value among all the compounds examined, which is comparable to that of EB.

Competitive binding studies with EB have been performed with fluorescence spectroscopy and have shown that the interaction between DNA–EB complex and the complexes release EB from its DNA complex, indicating that the complexes can bind to DNA probably via the intercalative mode.

5. Supplementary data

CCDC 716239 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions. Gallium (III) acetylacetonate, [Ga(acac)$_3$], 2-aminophenol and 5-methylsalicylaldehyde (2-hydroxy-5-methyl-benzaldehyde) were obtained from Aldrich. 5-Bromosalicylaldehyde was from Fluka, while salicylaldehyde and the rest of the reagents were from Merck. All chemicals were of the best quality available and were used as received. Microanalyses (C, H and N) were performed by the University of Ioannina (Ioannina, Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyser. IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT spectrometer with samples prepared as KBr pellets.

2.2. Compound preparation

2.2.1. Synthesis of N-salicylidene-o-aminophenol (saphH$_2$) and derivatives

Synthesis of saphH$_2$ was achieved by the condensation in absolute ethanol of 2-aminophenol with salicylaldehyde in the case of the unsubstituted Schiff base, with 2-hydroxy-5-methyl-benzaldehyde in the case of methyl substituted Schiff base or with 5-bromosalicylaldehyde in the case of bromo-substituted Schiff base, in accordance with literature methods [20]. The chemical structures of the free and substituted Schiff bases are shown in Fig. 1.

2.2.2. [Ga(acac)(saph)(EtOH)] (**1**)

A yellow solution of H$_2$saph (0.021 g, 0.10 mmol) in EtOH (10 mL) was added to a colorless solution of [Ga(acac)$_3$] (0.037 g, 0.10 mmol) in the same solvent (10 mL). The clear yellow solution, obtained was allowed to stand undisturbed for one day at room temperature. Well-formed X-ray quality single crystals of **1** slowly appeared. The yellow crystals were isolated by vacuum filtration, washed with cold EtOH (2 × 3 mL) and dried in air. The yield was 80% based on Ga. *Anal.* Calc. for $C_{20}H_{22}GaNO_5$: C, 56.37; H, 5.21; N, 3.29. Found: C, 55.78; H, 5.12; N, 3.24%. IR (KBr pellets, cm^{-1}): 3440br, 3048w, 2968w, 2790w, 1620s, 1586s, 1546m, 1526s, 1474s, 1446w, 1386s, 1342w, 1308m, 1270m, 1222w, 1176m, 1154m, 1128w, 1090w, 1042m, 928m, 876w, 836m, 774w, 742m, 678w, 626w, 610w, 526w, 538m, 490w.

2.2.3. [Ga(acac)(5Mesaph)(MeOH)] (**2**)

Solid [Ga(acac)$_3$] (0.037 g, 0.10 mmol) was added to a yellow–orange solution of H$_2$5Mesaph (0.023 g, 0.10 mmol) in MeOH/EtOH (1:1 v/v, 20 mL). The yellow solution obtained was filtered and layered with Et$_2$O/hexane (1:1 v/v, 40 mL). Slow mixing yielded well-formed, X-ray quality yellow crystals of **2**. The crystals were isolated by vacuum filtration, washed with Et$_2$O (2 × 3 mL) and dried in air. The yield was 78% based on Ga. *Anal.* Calc. for $C_{20}H_{22}GaNO_5$: C, 56.37; H, 5.21; N, 3.29. Found: C, 57.10; H, 5.75; N, 3.47%. IR (KBr pellets, cm^{-1}): 3450wbr, 3003w, 2760w, 2552w, 1621m, 1588s, 1537s, 1478s, 1433w, 1393m, 1378s, 1315m, 1282m, 1270m, 1252w, 1214w, 1200w, 1161m, 1147w, 1134m, 1028m, 961w, 933w, 891w, 830m, 814w, 785w, 740m, 684w, 652w, 616w, 584w, 564w, 532w, 491w, 478w, 451w.

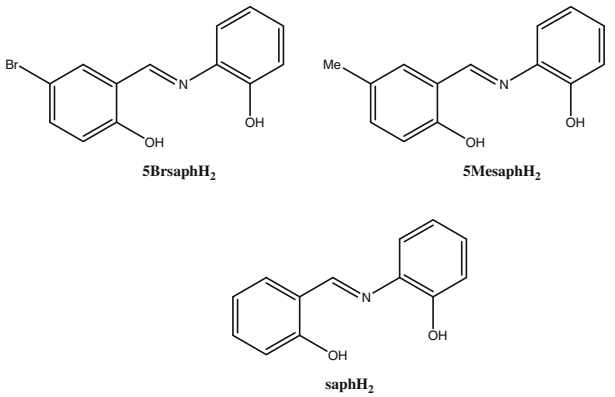

Fig. 1. The chemical structures of the ligands discussed in the text.

2.2.4. [Ga(acac)(5Brsaph)(EtOH)] (**3**)

A colorless solution of [Ga(acac)$_3$] (0.037 g, 0.10 mmol) in EtOH (10 mL) was added to a yellow solution of H$_2$5Brsaph (0.058 g, 0.20 mmol) in the same solvent (10 mL). The yellow solution obtained was filtered and allowed to stand undisturbed in the refrigerator for thirteen days. Well-formed X-ray quality single crystals of **3** slowly appeared. The yellow crystals were isolated by vacuum filtration, washed with Et$_2$O (2 × 3 mL) and dried in air. The yield was 60% based on Ga. *Anal.* Calc. for $C_{20}H_{21}GaNO_5Br$: C, 47.56; H, 4.20; N, 2.77. Found: C, 48.79; H, 5.94; N, 2.84%. IR (KBr pellets, cm^{-1}): 3460br, 2348w, 2284br, 1658w, 1619s, 1589m, 1524s, 1475s, 1458s, 1377s, 1307m, 1261m, 1248m, 1209w, 1169s, 1137w, 1114w, 1087w, 1045w, 875w, 826m, 744s, 678m, 648m, 620w, 580w, 544w, 518w, 493w.

2.3. Single-crystal X-ray crystallography

Crystals of **1** and **2** were mounted in capillary. Diffraction measurements were made on a Nicolet diffractometer upgraded by Crystal Logic using graphite-monochromated Cu radiation. Complete crystal data and parameters for data collection and processing are reported in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $22 < 2\theta < 54°$ for **1** and

Table 1
Crystallographic data for complexes **1** and **2**.

Parameter	**1**	**2**

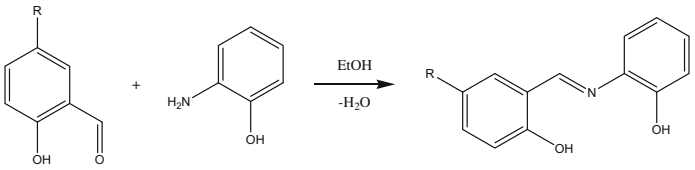
R_1[a], wR_2[b] ($I>2\sigma(I)$)	0.0486, 0.1186[c]	0.0361, 0.0991[d]

[a] $R_1 = \sum(|F_o| - |F_c|)/\sum(|F_o|)$.

[b] $wR_2 = \left\{\sum\left[w(F_o^2 - F_c^2)^2\right]/\sum\left[w(F_o^2)^2\right]\right\}^{1/2}$.

[c] For 3579 reflections with $I > 2\sigma(I)$.

[d] For 2674 reflections with $I > 2\sigma(I)$.



2. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using Crystal Logic software.

The structures were solved by direct methods using SHELXS-86 [21] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [22]. For **1**, all hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically. For **2**, the hydrogen atoms were either located by difference maps and were refined isotropically or were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Brief synthetic comments

Eq. (1) summarizes the synthesis of the ligands. Complexes **1**–**3** were obtained by ligand substitution reactions between $Ga(acac)_3$ (acacH = 2,4,-pentanedione) and $5XsaphH_2$ (X = H, $saphH_2$; X = Me, $5MesaphH_2$ and X = Br, $5BrsaphH_2$) in alcoholic solutions as yellow crystals. Eq. (1) summarizes the preparation of the representative complex **1**. The ligand substitution reactions can be realized on the basis of the different coordination strength of the acacH and the $5XsaphH_2$ ligands.

R = H : $saphH_2$
R = Br : $5BrsaphH_2$
R = Me : $5MesaphH_2$ (1)

$$Ga(acac)_3 + saphH_2 + EtOH \xrightarrow{EtOH} [Ga(acac)(saph)(EtOH)] + 2acacH \quad (2)$$

3.2. Description of structures

Complexes **1** and **2** were characterized by X-ray crystallography, while preliminary X-ray characterization of complex **3** revealed that it is isostructural to **1** and therefore we did not performed full X-ray characterization.

Complex **1** crystallizes in the monoclinic space group $P2_1/n$, while there are two crystallographically independent mononuclear complexes in the unit cell. Fig. 2 shows the molecular structure of one monomer of **1**, while selected bond distances and angles are listed in Table 2. The Ga^{III} ion adopts a six-coordinate distorted octahedral geometry. The $saph^{2-}$ ligand chelates the Ga^{III} ion through the imine nitrogen atom and the deprotonated hydroxyl oxygen atoms all on the equatorial plane of the octahedron. The $acac^-$ ligand also chelates the Ga^{III} atom with one O atom completing the equatorial plane of the octahedron and the other on one of the axial positions. The ethanol O atom occupies the second axial position. Although the EtOH hydroxyl hydrogen atom was not located, it appears that each [Ga(acac)(saph)(EtOH)] is hydrogen

bonded to the other crystallographically indepedented monomer (Fig. 3) through two hydrogen bonds that involve the EtOH oxygen [O5 and O15] and the depropotonated hydroxyl oxygen [O12 and O2] atoms of the saph^{2-} ligand with the O···O distances equal to 2.618 and 2.650 Å for O5···O12a and O2···O15a (a: $x-1/2$, $3/2-y$, $1/2+z$), respectively. A π–π stacking interaction (centroid···centroid distance: 3.638 Å) between the aminophenolate rings of the two monomers assists the hydrogen bonding in forming the dimer (Fig. 3).

Complex **2** crystallizes in the triclinic space group $P\bar{1}$. The molecular structure of **2** is shown in Fig. 4, while selected bond distances and angles are listed in Table 3. The mononuclear complex **2** is very similar to **1**, with the Ga^{III} ion adopting a distorted octahedral environment. A tridentate 5Mesaph^{2-} ligand chelates to the Ga^{III} ion through the imine nitrogen atom and the deprotonated hydroxyl oxygen atoms. A bidentate chelating acac$^-$ ligand and a MeOH molecule complete the octahedron around the metal centre. The NO_2 donor set from the 5Mesaph^{2-} ligand and one oxygen atom from the acac$^-$ ligand are situated on the equatorial plane, while the other acac$^-$ oxygen atom and the methanolic oxygen atom occupy the axial positions of the octahedron. Two

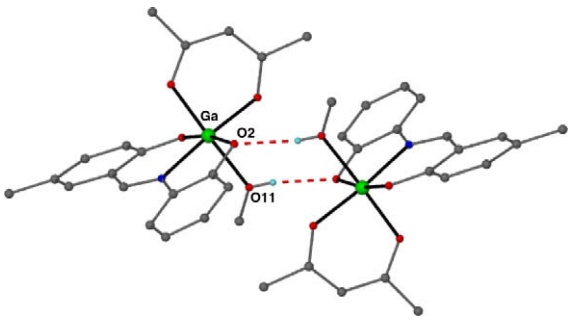

Fig. 5. The hydrogen bonding that form the dimer in **2**. All hydrogen atoms have been omitted for clarity.

[Ga(acac)(5Mesaph)(MeOH)] complexes assemble to form a hydrogen bonded dimer (Fig. 5) through the O11–HO11···O2a [O11···O2a 2.627 Å, a: $1-x,-y,1-z$] hydrogen bond (and its symmetry related) which involves the methanolic oxygen atom O11 and one of the deprotonated hydroxyl oxygen atoms O2 of the 5Mesaph^{2-} ligand.

3.3. Spectroscopic characterization

The IR spectra of all complexes are similar. In the ν(O–H) region, the IR spectra of the complexes exhibit medium-intensity bands at 3440 (**1**), 3450 (**2**) and 3460 (**3**) cm^{-1}, assignable to $\nu(O-H)_{alcohol}$ [23]. The broadness and the relatively low frequency of these bands are both indicative of hydrogen bonding. The ν(C=N) in spectra free ligands appears at 1632, 1628 and 1630 cm^{-1} for saphH$_2$, 5MesaphH$_2$ and 5BrsaphH$_2$, respectively [24]. These bands are shifted to lower wavenumbers in the spectra of **1** (1620 cm^{-1}), **2** (1621 cm^{-1}) and **3** (1619 cm^{-1}) due to complexation. The ν(C=C) and ν(C=O) modes [25] of the acetylacetonate ligand at 1586 and 1532 cm^{-1} in the spectrum of Ga(acac)$_3$ have not shifted significantly in the spectra of **1** (1586 and 1526 cm^{-1}), **2** (1588 and 1537 cm^{-1}) and **3** (1589 and 1524 cm^{-1}), respectively.

4. Conclusions and perspectives

In this manuscript, we presented the chemical aspects of our first results from the exploitation of the Ga(III)/5XsaphH$_2$ reaction system. The Ga(acac)$_3$/saphH$_2$, 5MesaphH$_2$ and 5BrsaphH$_2$ reaction systems provided access to three mononuclear Ga(III) complexes. Two of the complexes were characterized by single-crystal X-ray crystallography, while the identity of the third was confirmed by crystal cell determination and IR data. All three complexes are surrounded by a tridentate-chelate 5Xsaph^{-2} ligand, a chelate acac$^-$ ligand and a terminal alcohol molecule. The optical properties of this series indicated [19] that all three complexes emitted light upon photo- or electro-excitation. Efforts are being devoted to change the acac$^-$ and alcohol molecules with other electron rich molecules.

5. Supplementary data

CCDC 725905 and 725906 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk

the compositionally ordered $L1_2$ phase before studying the magnetic properties of the products.

2. Experimental

Mn–Pt nanoparticles were synthesized by thermolytic reduction of platinum acetylacetonate ($Pt(acac)_2$, Aldrich) with either 1,2-hexadecanediol (Aldrich) or long-chain amines, in the presence of various manganese precursors, as described below. Several synthesis protocols were employed, based on modifications of literature procedures for the preparation of other nanoparticle systems. Table 1 provides an overview of the prepared samples, classified according to the starting reagents of choice.

Concerning synthesis via the decomposition of manganese(II) acetylacetonate, in a typical procedure (e.g. sample 1 in Table 1), 197 mg $Pt(acac)_2$ (0.5 mmol) and 127 mg (0.5 mmol) of $Mn(acac)_2$ were diluted in 15 mL of oleylamine in a three-neck vessel. The mixture was degassed under stirring at room temperature, with the use of a vacuum pump for 10 min. After heating up to 100 °C, degassing was continued for 1 h. Flow of Ar was applied and the temperature was then raised up to 300 °C with an average rate of 5 °C min^{-1} and kept stable for 1 h. The mixture was allowed to cool at room temperature, the particles were precipitated by ethanol and the solid product was subsequently washed twice with a mixture of *n*-hexane and excess ethanol. Eventually, the particles were dispersed into *n*-hexane.

Regarding decomposition of dimanganese decacarbonyl (e.g. sample 6 of Table 1), 50 mg $Pt(acac)_2$ (0.125 mmol) and 135 mg (0.75 mmol) of 1-adamantanecarboxylic acid (ACA) were introduced in a three-neck vessel containing 3 g hexadecylamine, 10 mL phenyl ether and 162 mg 1,2-hexadecanediol. The mixture was degassed under stirring at room temperature, with the use of a vacuum pump for 10 min. After heating up to 120 °C, degassing was continued for 1 h. Flow of Ar was applied through the reacting solution and 3 mL DMF, containing 147 mg (0.375 mmol) of $Mn_2(CO)_{10}$, were injected. The temperature was then increased up to 196 °C at a rate of 4 °C min^{-1} and maintained constant for 1 h. Natural cooling was followed by precipitation of the formed particles with iso-propanol and the solid product was subsequently washed repeated times with a mixture of hexane and excess iso-propanol. Finally, the particles were stored in *n*-hexane.

In the case of decomposition of manganese acetates (e.g. sample 10 of Table 1), in a three-neck vessel containing 9 mL phenyl ether and 15 mL oleylamine, 5.4 g hexadecylamine, 160 mg $Mn(ac)_3{\cdot}2H_2O$, 100 mg $Pt(acac)_2$, 323 mg 1,2-hexadecanediol and 245 mg 1-adamantanecarboxylic acid were introduced. The mixture was flushed with Ar for 20 min and then heated up to 255 °C at an average rate of 5 °C min^{-1}. The black color at the solution had already appeared at ~205 °C, implying the formation of nanoparticles. After cooling, the particles were isolated by centrifuging with acetone. Repeated washes with hexane and excesses of acetone or ethanol yielded a well purified solid product which was afterwards dispersed into *n*-hexane.

Certain samples were annealed by depositing a few drops of the nanoparticle solutions onto Si wafers, which were inserted in a tube furnace, flashed with argon during 30 min, and then the temperature raised to 600 °C and maintained for 1 h. The crystalline structure of the particles was analyzed using X-ray powder diffraction (XRD) with a Philips PW 1820 diffractometer, using Cu Kα radiation. X-ray photoelectron spectroscopy (VG EscaLab 250-IXL XPS system) provided additional information concerning the elemental composition and chemical state of manganese in the particles. To investigate the size and arrangement of the nanoparticles, samples for transmission electron microscopy (TEM) were prepared by drop-casting from the colloidal dispersions onto carbon-coated copper grids. TEM images were acquired on a Philips CM20 and JEOL JEM 2010F microscopes, both operating at an acceleration voltage of 200 kV and equipped with EDX analyzers. Magnetic properties were measured using a vibrating sample magnetometer (1.2H/CF/HT Oxford Instruments VSM) and a superconducting quantum interference device (SQUID, Quantum Design MPMS-5), between 10 and 300 K.

3. Results and discussion

3.1. Morphology and composition

We have explored the synthesis of Mn–Pt alloy nanoparticles by thermal decomposition of platinum and manganese precursors in high-boiling-point organic solvents in the presence of suitable surfactants. Reaction conditions and particle sizes are summarized in Table 1. Several manganese precursors [$Mn_2(CO)_{10}$, $Mn(acac)_2$, $Mn(ac)_2{\cdot}4H_2O$ and $Mn(ac)_3{\cdot}2H_2O$], possessing different decomposition temperatures and decomposition rates, were employed as Mn sources. Additionally the variety of the applied surfactants, reductants and solvents is also depicted. The analysis of the results is presented by grouping the samples according to the used Mn precursor, as referred in Table 1.

Decomposition of manganese(II) acetylacetonate led to small particle sizes (2.5–4.4 nm), no matter which was the type and ratio of surfactants. The Mn:Pt initial ratio was kept constant at 1:1. The obtained results for the particles size are in agreement with the previously published data for $MnPt_3$ nanoparticles obtained by metal-acetylacetonate decomposition. In particular, $MnPt_3$ particles have been synthesized from decomposition of $Mn(acac)_2$ and $Pt(acac)_2$ and yielded a size of 2 nm [7]. Smaller particle sizes were also

Table 1
Starting reagents and particle sizes for the synthesis procedures applied to prepare Mn–Pt nanoparticles.*

Sample	Mn precursor	Pt precursor	Surfactants	Solvent	Reducing agent	Size (nm)
S1	$Mn(acac)_2$ (0.5 mmol)	$Pt(acac)_2$ (0.5 mmol)		OAm (15 mL)		4.4 ± 0.7
S2	$Mn(acac)_2$ (0.5 mmol)	$Pt(acac)_2$ (0.5 mmol)		TOAm (15 mL)		3.5 ± 0.4
S3	$Mn(acac)_2$ (0.5 mmol)	$Pt(acac)_2$ (0.5 mmol)	TOPO, OA, OAm (0.2, 0.5, 0.5 mmol)	TOAm (15 mL)		3.1 ± 0.3
S4	$Mn(acac)_2$ (0.5 mmol)	$Pt(acac)_2$ (0.5 mmol)	ACA (2.25 mmol)	ODE (15 mL)	HDOL (0.6 mmol)	2.5 ± 0.3
S5	$Mn_2(CO)_{10}$ (0.125 mmol)	$Pt(acac)_2$ (0.125 mmol)	ACA (0.75 mmol)	HDA, DPE (3 g, 5 mL)	HDOL (0.6 mmol)	9.1 ± 1.3
S6	$Mn_2(CO)_{10}$ (0.375 mmol)	$Pt(acac)_2$ (0.125 mmol)	ACA (0.75 mmol)	HDA, DPE (3 g, 10 mL)	HDOL (0.6 mmol)	3.1 ± 0.3
S7	$Mn_2(CO)_{10}$ (0.375 mmol)	$Pt(acac)_2$ (0.125 mmol)	ACA (1.25 mmol)	HDA, DPE (3 g, 10 mL)	HDOL (0.6 mmol)	6.1 ± 0.7
S8	$Mn_2(CO)_{10}$ (0.375 mmol)	$Pt(acac)_2$ (0.125 mmol)	Decanoic acid (0.125 mmol)	ODE (15 mL)	HDOL (0.6 mmol)	2.5 ± 0.3
S9	$Mn(ac)_2{\cdot}4H_2O$ (1.17 mmol)	$Pt(acac)_2$ (0.5 mmol)		OAm (30 mL)		7.1 ± 1.3
S10	$Mn(ac)_3{\cdot}2H_2O$ (0.6 mmol)	$Pt(acac)_2$ (0.25 mmol)	ACA (1.36 mmol)	HDA, OAm, DPE (5.4 g, 15 mL, 9 mL)	HDOL (1.2 mmol)	6.7 ± 0.5

* OAm = oleylamine, OA = oleic acid, TOAm = trioctylamine, TOPO = trioctylphosphine oxide, ACA = 1-adamantanecarboxylic acid, ODE = 1-octadecene, HDOL = 1,2-hexadecanediol, HDA = hexadecylamine, DPE = diphenyl ether. HDA, OAm and TOAm are in some samples listed as solvents, but they act simultaneously as surfactants. In the absence of 1,2-hexadecanediol, the amines are supposed to act also as reducing agents.

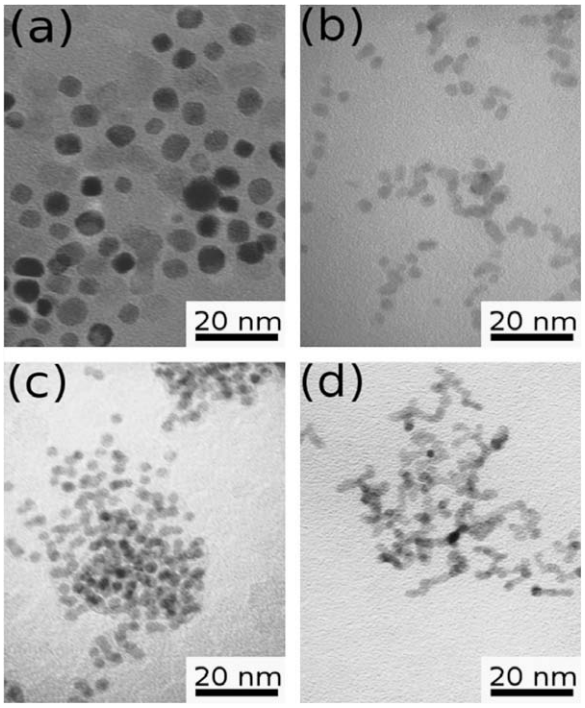

Fig. 1. TEM images of the nanoparticles prepared using manganese acetylacetonate as a precursor (from A–D, images correspond to samples S1–S4 in Table 1).

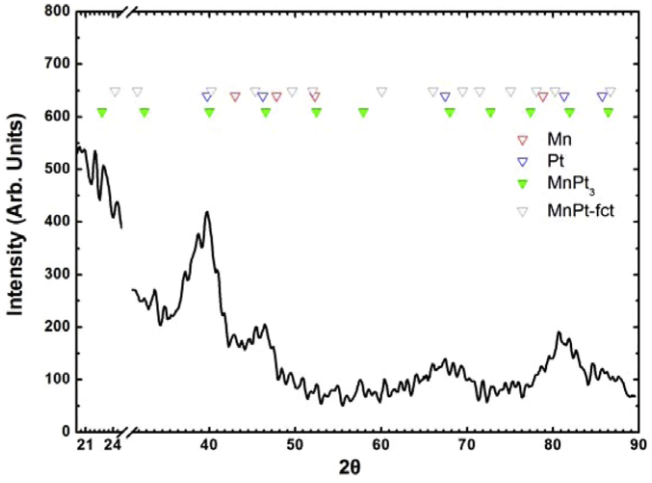

Fig. 2. X-ray diffraction pattern for the sample S2.

reported for FePt nanostructures that were produced from the thermal decomposition of $Fe(acac)_3$ in comparison with other precursors and for a diversity of surfactant/precursor starting ratios [18,19].

Keeping constant the nature and the ratio of the precursors we tried to correlate the role of several surfactants. We started our investigation without the use of any other reagent, except for oleylamine (sample S1) and trioctylamine (sample S2) that are targeted to act in a triple role as high-boiling-point solvents, mild reducing agents and weak-bonding surfactants at the same time. The particles were well separated and the average particle size in sample S1 was 4.4 nm (Fig. 1a), while for S2 an average size of 3.5 nm (Fig. 1b) was measured. Despite the high temperatures used, 303 and 332 °C, respectively, the average particle size did not show any further increase. Aiming to study the effect of other capping ligands on the obtained morphology, the addition of bulky or strongly binding surfactants such as TOPO and oleic acid (S3, Fig. 1c) and ACA (S4, Fig. 1d) was found to lead to a small decrease in particle size, up to 3.1 and 2.5 nm, correspondingly. It is worth mentioning that a slight improvement in monodispersity was obtained in these samples, as compared with S1 and S2. The use of ACA as the only surfactant led to the formation of particles which had some tendency to coalesce (Fig. 1d).

Regarding the composition of these samples, it is interesting to notice the appearance of some faint-colored particles in Fig. 1a, which are most likely Mn-rich particles. Such a difference in contrast has been attributed to the co-existence of separate Mn particles during the preparation of $MnPt_3$ nanocrystals [7]. Moreover, XPS measurements revealed considerable oxidation of manganese for samples S1 and S2. In the XRD pattern of S2 sample (Fig. 2), the main peak at ~39.8° indicates the existence of Pt or Pt-rich particles, supporting the claim for a rather inefficient alloying between the two metals in this sample.

Dimanganese decacarbonyl has been used for the syntheses of the samples S5, S6 and S7. TEM images are displayed in Fig. 3a, b and c, respectively. The first noticeable observation is that the particles from S5 are faceted, with an average particle size of ~9.1 nm, indicating that the use of manganese carbonyl, rather than acetylacetonate, resulted in a significant size increase. Concerning the composition of S5, EDX measurements yielded a Mn/Pt ratio lower than 1/9. This might be related to the high tendency of $Mn_2(CO)_{10}$ to sublime [20], even upon careful handling. In an attempt to obtain nanocrystals with a higher Mn content, we changed the injection temperature of manganese carbonyl from 80 to 120 °C in sample S6, so as to minimize the time interval between injection and decomposition, along with a higher Mn/Pt starting ratio. The increased injection temperature promoted the formation of particles with a significantly smaller average size (~3.1 nm), which is in agreement with literature data for $CoPt_3$ nanocrystals [21].

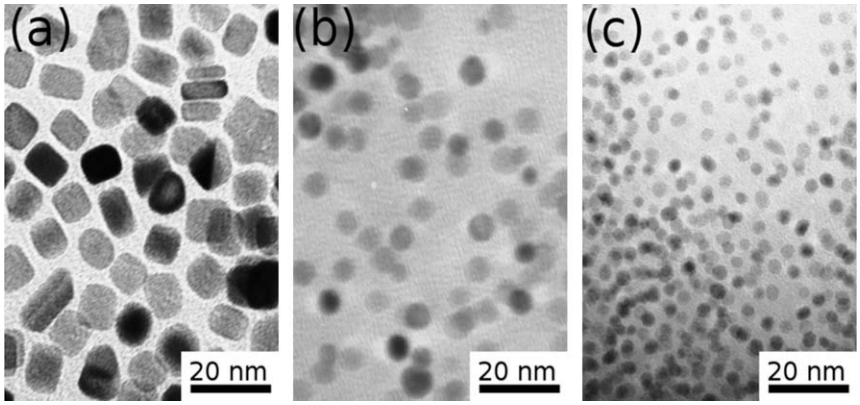

Fig. 3. TEM images of the nanoparticles prepared using manganese carbonyl as a precursor. The injection temperature was 80 °C (S5), 100 °C (S7) and 120 °C (S6) for A, B and C, respectively. (Refer to Table 1 for synthesis details.)

Fig. 4 shows a high resolution image of the particles in sample S6, together with the corresponding EDX microanalysis spectrum. S6 particles show a Mn/Pt ratio of 23/77 when a relatively large area (more than 100 nanoparticles) was sampled, which is close to the theoretical value 1/3 for $MnPt_3$. For the same sample, XRD diffraction data (Fig. 5) revealed the absence of MnPt and manganese oxide phases, as analyzed below. Consequently, we assigned the composition of the material as a $MnPt_3$ alloy.

Chemically synthesized M–Pt (M = Fe, Co or Mn) alloy nanostructures usually possess a disordered face-centered-cubic A1 phase [22], where M and Pt atoms occupy random positions in the crystal lattice and for this reason they do not show so significant magnetic properties. Therefore, annealing was necessary also in our case to transform the disordered phase into the ordered $L1_2$ cubic phase of the $MnPt_3$ alloy, where both elements retain specific positions within the crystal. The X-ray powder diffraction patterns of S6 before and after annealing in Ar atmosphere (Fig. 5) show some characteristic peaks of the $MnPt_3$ alloy, while no Mn-oxide or MnPt peaks were recorded. It is difficult to distinguish the ordered and disordered $MnPt_3$ alloys from the XRD analysis due to the small difference in the position of the main peaks of both alloys. However, magnetic measurements allowed us to perform a more clear assignment of the annealed alloy to the ordered phase (see below). An increment in particle size, explained by sintering phenomena as a result of the annealing treatment, was identified through the sharpness of the XRD peaks. The average crystalline grain size in the sintered material was estimated to be ~18.2 nm from Scherrer's equation.

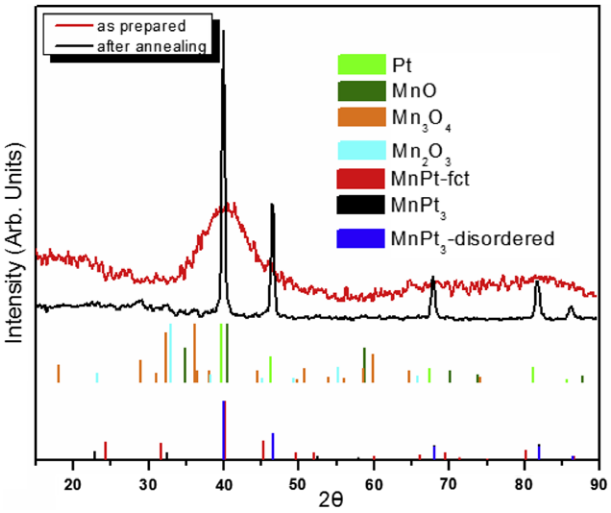

Fig. 5. X-ray powder diffraction pattern from sample S6 before and after annealing.

Increase of the final particle size of the $MnPt_3$ nanoparticles was achieved by injecting the manganese precursor at an intermediate temperature (100 °C) and raising the ACA/Pt ratio from 6/1 up to 10/1. The average particle size in sample S7 was ~6.1 nm, as measured from TEM. The role of ACA toward the size increment of bimetallic nanoparticles has also been observed in the case of $CoPt_3$ particles prepared by Shevchenko et al. [21]. In our case, the larger concentration of ACA in S7 possibly led to the formation of a complex between ACA with either Mn or Pt, which could complicate the nucleation stage, resulting in a bigger size compared to sample S6. From elemental analysis carried out by XPS, a Mn/Pt ratio of 29/71 was derived. The corresponding XRD spectrum indicates the existence of the $MnPt_3$ $L1_2$-phase after annealing (Fig. 6). The average crystalline grain size for the annealed S7 sample, estimated from Scherrer's equation, was only ~12.3 nm, which means that grain growth during annealing was much smaller than that observed for S6, revealing a better surface stabilization of the particles within S7 sample. We believe that the higher concentration of the bulky organic ligand ACA in S7 somehow hindered the coalescing process. Though, it has to be noted that the nanoparticles probably lose their solubility after annealing, due to the

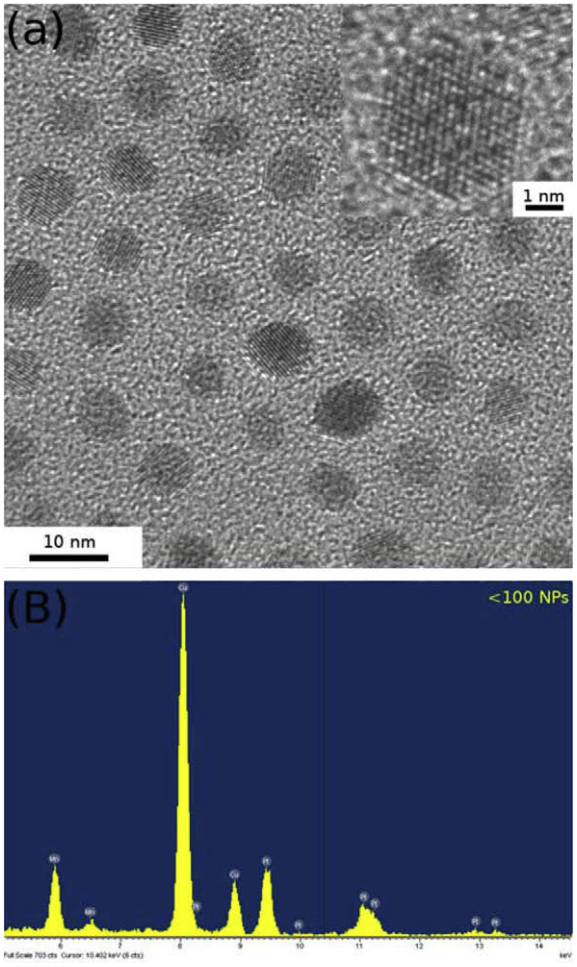

Fig. 4. Representative HRTEM image (a) from sample S6 (the atomic lattice is clearly seen in the inset) and EDX spectrum (b) from an area containing more than 100 nanocrystals.

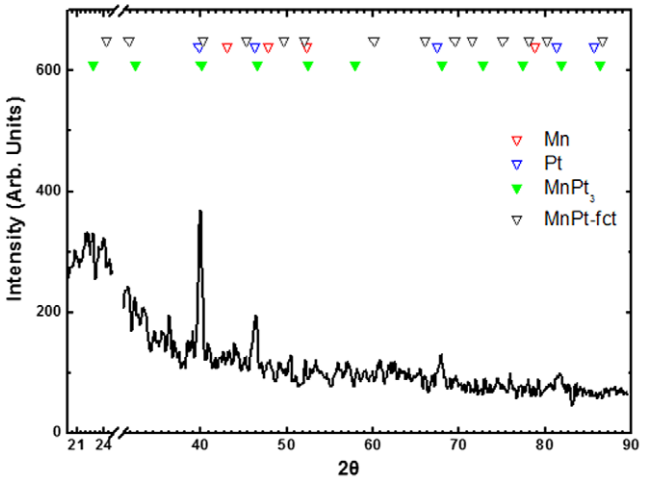

Fig. 6. X-ray diffraction pattern for the annealed S7 sample.

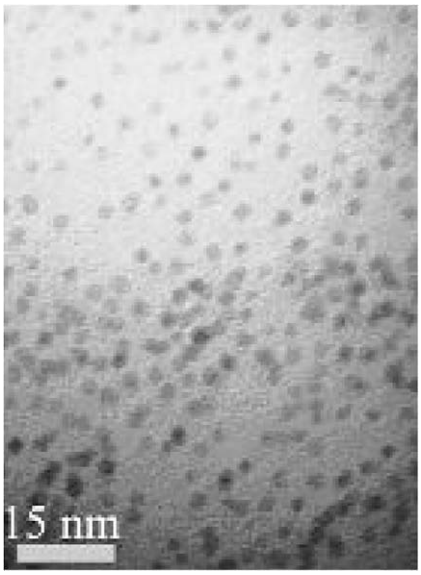

Fig. 7. TEM image of S8 sample.

decomposition of the protective organic layer surrounding the surface of each particle and the unavoidable aggregation and sintering [22].

Synthesis in the presence of a single and relatively short chain surfactant (decanoic acid) leads to rather monodisperse nanoparticles with an average diameter of ~2.5 nm (Fig. 7). In this case (sample S8), only an acid (decanoic) was used as surfactant, and the obtained product was difficult to precipitate and purify, just as in the case of the ACA-capped nanoparticles (S4). It has been observed that occasionally, if the acid surfactants are not combined with surfactants with milder bonding behavior (e.g. amines), the obtained nanoparticle colloids either tend to aggregate or prove difficult to purify and characterize [21,23]. However, after repeated washing cycles with a mixture of hexane/acetone, the S8 particles appeared well separated. The small size obtained in this case can be explained by the molecular structure and low concentration of decanoic acid. For example, in maghemite nanocrystals, decreasing the chain length or reducing the amount of the carboxylic acid ligand has been shown to lead to a decrease in the resulting nanoparticle size [24].

Mn(II) acetate and Mn(III) acetate have been used, respectively for the production of the samples S9 and S10. In the case of S9, the use of Mn(II) acetate in oleylamine yielded ~7.1 nm particles (Fig. 8a) with a polydispersity of 18%. The particles were not well separated as shown by TEM imaging, which might be due to the sole use of oleylamine as solvent, surfactant and reductant simultaneously. Occasionally, amines are weakly binding ligands, and therefore cannot totally prevent the aggregation of the formed particles. In certain areas of the TEM grid, the particles were assembled into big circular structures ($d \sim 400$–450 nm) during the evaporation of the carrier solvent on the grid.

In the case of sample S10, we noticed a remarkable self-assembly, occasionally even forming multilayers, as shown in Fig. 8b. The particles in this sample were highly monodisperse (~6.7 nm), with sufficient interparticle distances. Thus, one can see that by using both Mn(II) and Mn(III) acetates, particle size can be slightly increased as compared to particles obtained from $Mn(acac)_2$, while having similar values to particles made from $Mn_2(CO)_{10}$. It seems that manganese acetylacetonate feeds the solution with atoms in a fast rate, when it starts to decompose, and a rapid nucleation of Mn–Pt clusters takes place followed by a slow growth, leading to a relatively smaller particle size compared to the synthesis using carbonyl or acetate Mn-precursors. An appropriate combination of different types of surfactants (ACA, amines) in sample S10, together with the use of a moderate reaction temperature (255 °C) allow the particles to grow further and then assemble in a controlled way. The Mn/Pt ratio determined for these particles from elemental analysis was 31/69.

3.2. Magnetic characterization

We discuss in what follows the magnetic behavior of two types of samples: (i) a sample with a considerable degree of oxidation

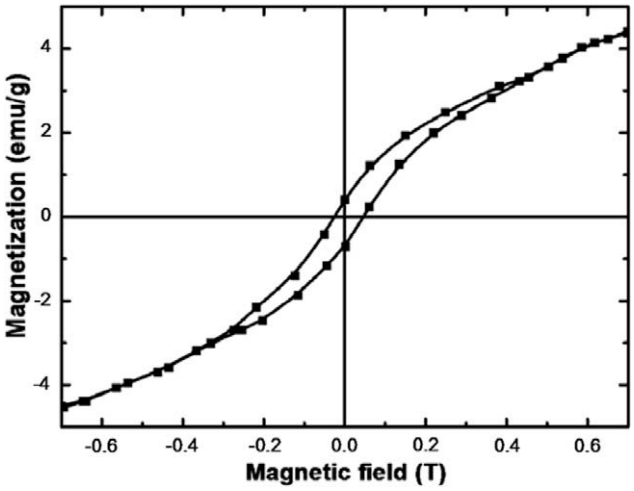

Fig. 9. *M–H* plot for sample S2 obtained by VSM measurement at 77 K.

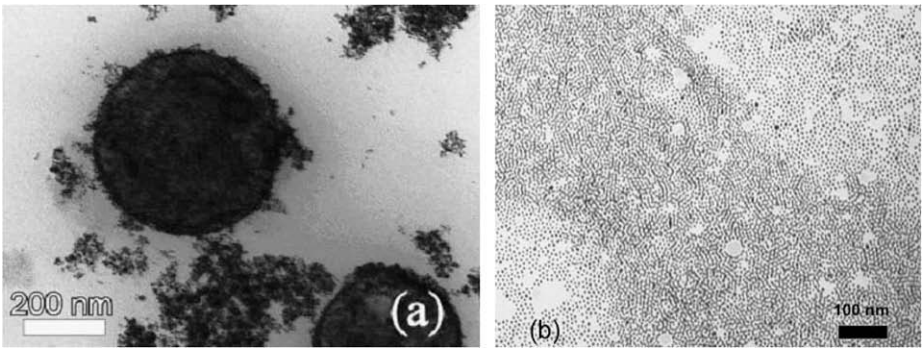

Fig. 8. TEM images of S9 and S10 samples [(a) and (b) images, respectively].

and poor alloying between Mn and Pt (S2) and (ii) two samples which showed an effective formation of the $MnPt_3$ alloy (S6 and S7).

(i) Sample S2: We have plotted in Fig. 9 the hysteresis loop of sample S2, measured at 77 K by vibrating sample magnetometry (VSM). As mentioned above, manganese was oxidized in a significant percentage in this sample. VSM results reveal the presence of a small exchange bias field of ~0.01 T, as derived by

$$H_{ex} = \frac{H_{c(pos)} + H_{c(neg)}}{2}. \quad (1)$$

This result indicates the possible co-existence of antiferromagnetic and ferromagnetic components in this sample. In our case, MnO is the obvious antiferromagnetic component, while Mn_3O_4 is ferrimagnetic. Exchange bias values up to ~0.18 T were recently reported for the case of MnO–Mn_3O_4 core shell nanoparticles [25]. In sample S2, the appearance of H_{ex} above the T_C of Mn_3O_4 is an indication of irreversible switching of antiferromagnetic (MnO) spin lattices by exchanged-coupled uncompensated spins, with the assistance of thermal activation [25]. In Fig. 9, the shift of the hysteresis loop along the horizontal axis of the *M–H* plot is not itself a proof for the co-existence of two magnetically different phases, but it is a strong indication for such consideration. The loop was shifted to the positive-field side of the axis. No magnetic field was applied during the cooling process from room temperature to 77 K. A low value for magnetization remanence is observed (~0.4 emu/g) and no saturation for this system was achieved for fields up to 1 T, as expected from the large amount of antiferromagnetic and paramagnetic materials (MnO and Pt, respectively).

(ii) S6 and S7 alloy samples: The magnetic properties of samples S6 and S7 after annealing have been examined. These specific samples were chosen to be annealed and further investigated because they possessed the optimum composition, close to $MnPt_3$ alloy, as shown above by XRD and elemental analysis measurements among the as-prepared samples. In Fig. 10a, temperature-dependent zero-field-cooled (ZFC) and field-cooled (FC) magnetization scans under an applied field of 0.01 T for the annealed S6 sample are shown. These $L1_2$-phase $MnPt_3$ nanocrystals display a blocking temperature at approximately 50 K. The observed split between the curves happens at much higher temperature than the maximum of the ZFC curve, possibly due to the sintering effect and the consequent breakdown of the size monodispersity caused by the annealing. The decay of the magnetization versus temperature after the maximum of the ZFC deviates from a Curie law behavior, where the magnetization would vary in proportion to the reciprocal of the temperature ($1/T$), probably due to the presence of some interactions among the particles. The presence of dipolar couplings between the nanoparticles is more specifically implied by the shape of the plateau of the FC curve at low temperatures. Regarding the deviation from a Curie law behavior in the superparamagnetic regime, it can also be attributed to the fact that the saturation magnetization varies with temperature. In general, a nanoscale size provides a much lower T_C for a material, compared to the T_c of its corresponding bulk counterpart. Such phenomenon results in the significant variation of M_S with temperature in nanoparticles. The field sweep at 10 K shows hysteresis with a coercivity of ~0.075 T (Fig. 10b).

The magnetic behavior of the annealed sample S7 is shown in Fig. 11. The blocking temperature T_b is similar to that for S6 (~50 K) and the ZFC peak (Fig. 11a) is indicative of superparamagnetic single domain particles. However, also in this case, as in the annealed S6, the shape of the curves implies the existence of some interactions among particles. The coercivity at 10 K reaches 1.1 T (Fig. 11b), which is one of the highest values of coercivity ever reported for Mn–Pt nanocrystals. For instance, Lee et al. have prepared $MnPt_3$ nanoparticles with various sizes, which displayed coercivity values in the range of 0.05–0.22 T at 5 K after annealing [7]. The respective value for the Mn–Pt nanoparticles of Ono et al.

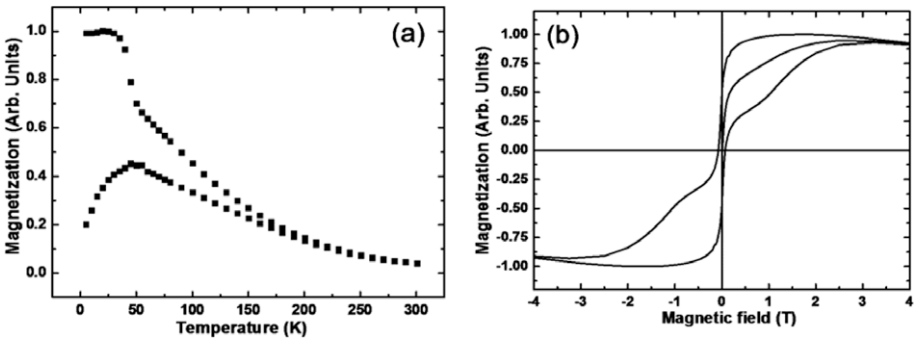

Fig. 10. Magnetic properties for the annealed sample S6: (a) ZFC–FC curves under an applied field of 0.01 T. (b) Field-sweep of the magnetization at 10 K (SQUID).

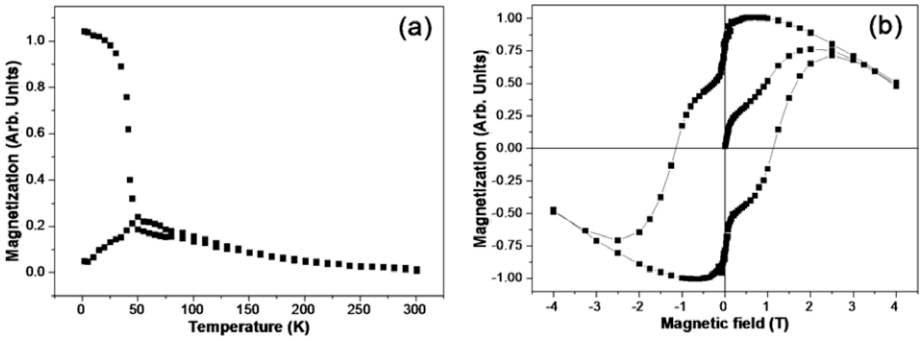

Fig. 11. Magnetic properties for the annealed S7 sample: (a) ZFC–FC curves under an applied field of 0.01 T. (b) Field-sweep of the magnetization at 10 K (SQUID).

was 0.95 T at 5 K [12]. In addition, Ho et al. reported a maximum value for $H_C \sim 0.48$ T at 5 K for their MnPt nanoparticles, having tried several different annealing conditions [13]. Concerning our samples, we notice a big difference in the coercivity values between S6 and S7: 0.075 T for S6 versus 1.1 T for S7, both at 10 K. From the morphological and structural characterization of these samples, some differences were found in particle size and composition. The difference in particle size (18.2 nm of annealed S6 versus 12.3 nm of annealed S7) is not expected to promote such large deviation among the measured coercivity values. Taking into account that the magnetic properties of the $MnPt_3$ alloy are very sensitive to Mn–Pt composition and atomic ordering in the lattice [7], we assume that a small difference in the Mn:Pt ratio recorded by elemental analysis (23/77 for S6 versus 29/71 for S7) and a somewhat better ordering in the $MnPt_3$ lattice of S7 due to the higher reaction temperature (257 °C in S7 versus 196 °C in S6) are responsible for the observed difference in the magnetic properties.

The 'constricted' shape of the hysteresis loops, as depicted in Figs. 10b and 11b, might be attributed to the presence of two magnetically different phases in the product. The peculiar bendings observed at both curves probably imply the co-existence of a 'hard' magnetic phase with a 'soft' one. For instance, it is reasonable to assume that most of the particles of the annealed S7 sample show 'hard' magnetic features (Fig. 11b), thus resulting in the observed large coercivity, but there is also a minority of particles that despite the annealing maintain 'soft' magnetic behavior which however cannot seriously affect the total magnetic behavior of this sample. Since the XRD measurements for S7 (Fig. 6) do not show any sign of oxidation, we speculate that some of the annealed particles transformed into the $L1_2$ (ordered) $MnPt_3$ phase, which is responsible for the 'hard' magnetic contribution, while the rest of the particles maintained the A1 (disordered) $MnPt_3$ phase, with much 'softer' magnetic features.

4. Conclusions

Mn–Pt nanoparticles were synthesized by thermal decomposition/reduction method with variation of metal precursors, organic solvents and capping ligands. Depending on the type and concentration of the starting reagents, monodisperse $MnPt_3$ nanoparticles could be obtained, while in some cases significant oxidation of manganese was observed, together with the formation of Pt-rich or single Pt particles. The size, shape and arrangement of the particles could be tuned by careful choice of proper surfactants. Regarding the magnetic properties, exchange bias phenomena were assumed in the oxidized samples, while $MnPt_3$ particles showed also a two-phase behavior after annealing, displaying high coercivity at 10 K. Further experiments are underway including annealing in reducing atmosphere (93% Ar/7% H_2) instead of simply inert (Ar) so as to facilitate the conversion of the alloy into the compositionally ordered $L1_2$ phase of $MnPt_3$, even via the additional incorporation of oxidized Mn in the alloy.

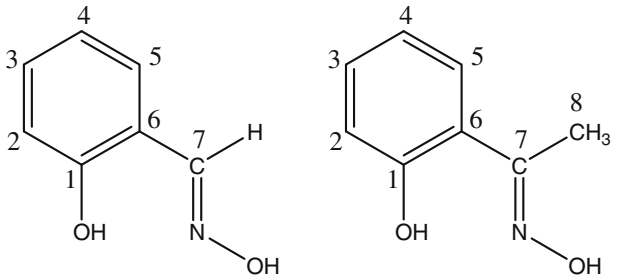

Fig. 1. The structures of the ligands discussed in the text.

^1H and ^{13}C NMR spectra were recorded on a Varian UNITY Plus spectrometer operating at 300 MHz. Samples were run in a 5 mm probe with $CDCl_3$ as internal lock and reference.

2.2. Compound preparation

2.2.1. Synthesis of $Ga(NO_3)_3{\cdot}9H_2O$ and $Ga(acac)_3$

A drop of gallium metal (5.808 g, 83.3 mmol) was weighed in a 100 mL flat bottom flask. Concentrated HNO_3 (65%, 50 mL) was added and the mixture was stirred overnight at room temperature to produce a clear colorless solution. The solution was cooled at 5 °C and seeded with a small crystal of $Ga(NO_3)_3{\cdot}9H_2O$. Almost immediately the whole mass of the solution transformed to a white crystalline solid. The solid was crashed with a glass rod and $Ga(NO_3)_3{\cdot}9H_2O$ isolated by vacuum filtration, washed two times with ice-cold water (2 × 3 mL) and dried over $CaCl_2$. Yield: 25.8 g, 74% based on Ga. The filtrate, including the washing liquids, was transferred to a 250 mL flat bottom flask and diluted with water to a final volume of 100 mL. The pH of the solution was adjusted to ~2–3 with concentrated NH_3 (25%) and then acacH (26.7 mL, 25.9 mmol) was added. The mixture was heated to reflux while concentrated NH_3 was added in drops until no obvious turbidity was observed by adding. $Ga(acac)_3$ was separated as a pale white crystalline solid. The pH of the final solution was ~7–8. The mixture was left to cool at room temperature and then $Ga(acac)_3$ was isolated by vacuum filtration, washed several times with water and dried over $CaCl_2$. Yield: 6.7 g. IR (KBr pellets, cm^{-1}): 2998w, 2966w, 2922w, 1586s, 1532s, 1382sbr, 1278m, 1194w, 1018m, 934m, 795wsh, 776w, 682w, 654w, 582w. The total yield for both $Ga(NO_3)_3{\cdot}9H_2O$ and $Ga(acac)_3$ was 96% based on Ga. Both compounds gave satisfactory analytical data. $Ga(acac)_3$ can be also synthesized by the reaction of an aqua solution of $Ga(NO_3)_3{\cdot}9H_2O$ and 12-fold excess of acacH in the presence of concentrated NH_3 as described above in yields of 80–85%.

2.2.2. Synthesis of $saoH_2$ and Me-$saoH_2$

A water solution (20 mL) containing hydroxylamine hydrochloride (1.40 g, 20.0 mmol) and Na_2CO_3 (1.06 g, 10 mmol) was added to a 100 mL flat bottom flask containing salicylaldehyde (2.46 g, 20 mmol). The resulting mixture was stirred for three days. Salicylaldoxime was separated as a white solid. The solid was isolated by vacuum filtration, washed several times with water and dried over $CaCl_2$. Yield: 1.84 g, 67%. IR (KBr pellets, cm^{-1}): 3371mbr, 1623msh, 1614s, 1573s, 1492s, 1472m, 1408m, 1396msh, 1390m, 1295msh, 1285s, 1258s, 1120m, 1192m, 1152m, 1113w, 1037w, 989s, 957m, 899s, 856w, 786m, 753m, 739msh, 720m, 696m, 648s, 561m, 470m. Me-$saoH_2$ was prepared in a similar manner by replacing salicylaldehyde by 2′-hydroxyacetophenone (2.4 mL, 20 mmol). Yield: 2.65 g, 88%. IR (KBr pellets, cm^{-1}): 3343mbr, 1628s, 1610s, 1584s, 1553w, 1539w, 1505s, 1500s, 1465m, 1403sbr, 1367s, 1310m, 1286s, 1250sbr, 1157m, 1124w, 1070w, 1044s, 1015s, 986w, 942s, 848s, 834s, 781sbr, 748sbr, 652sbr, 561m, 510m.

2.2.3. $[Ga(acac)(saoH)_2]$ (**1**)

$Ga(acac)_3$ (0.13 g, 0.35 mmol) and $saoH_2$ (0.10 g, 0.73 mmol) were dissolved in CH_2Cl_2 (5 mL). The solution was heated gently and hexane (25 mL) was added. The resulting colorless solution was refluxed for 30 min and left undisturbed to cool to room temperature. Colorless crystals of **1** were formed over a period of one day. The crystals were isolated by vacuum filtration, washed with hexane (2 × 5 mL) and dried in air. Yield: 0.12 g, 77%. *Anal.* Calc. for $C_{19}H_{19}GaN_2O_6$: C, 51.74; H, 4.34; N, 6.35. Found: C, 51.78; H, 4.29; N, 6.37%. IR (KBr pellets, cm^{-1}): 3064mbr, 3004w, 1647m, 1595s, 1586ssh, 1552s, 1530s, 1517s, 1465s, 1440s, 1375s, 1350m, 1328m, 1278s, 1195m, 1150m, 1120w, 1013s, 963w, 953w, 930m, 907m, 859w, 806m, 786w, 757s, 740w, 687w, 642m, 599m, 586w, 570w, 548w, 491w, 453m.

2.2.4. $[Ga(acac)_3][Ga(acac)(Me\text{-}saoH)_2]$ (**2**)

$Ga(acac)_3$ (0.12 g, 0.32 mmol) and Me-$saoH_2$ (0.05 g, 0.33 mmol) were dissolved in CH_2Cl_2 (4 mL). The solution was heated gently and hexane (30 mL) was added. The resulting colorless solution was refluxed for 30 min and left undisturbed to cool to room temperature. Light yellow crystals of **1** were formed over a period of two days. The crystals were isolated by vacuum filtration, washed with hexane (2 × 5 mL) and dried in air. Yield: 0.09 g, 65%. *Anal.* Calc. for $C_{36}H_{44}Ga_2N_2O_{12}$: C, 51.71; H, 5.30; N, 3.35. Found: C, 51.76; H, 5.27; N, 3.38%. 2.3. Single-crystal X-ray crystallography

The data collection for the single crystals of compounds **1** and **2** was carried out at 22 °C on a SMART CCD 1k diffractometer with graphite monochromated Mo Kα radiation. Complete crystal data and parameters for data collection and processing are reported in Table 1.

The structures were solved by direct methods using SHELXS-86 [36] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [37]. The coordinates of the metal atoms were obtained from the initial solutions and for all other non-hydrogen atoms found in subsequent difference Fourier syntheses. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Brief synthetic comments

Complexes **1** and **2**, were obtained by the ligand substitution reactions between $Ga(acac)_3$ (acacH = 2,4,-pentanedione) and R-$saoH_2$ (R = H $saoH_2$, R = Me Me-$saoH_2$) in CH_2Cl_2/hexane solutions as crystalline solids. Eq. (1) summarizes the preparation of the representative complex **1**. Altering the $Ga(acac)_3/saoH_2$ ratio in the same solvent mixture did not affect the identity of the product but the yield of the reaction. The use of more polar solvents such as alcohols, acetone or acetonitrile resulted in oily products that could not turn to solids by adding hexane or diethylether. In the case of Me-$saoH_2$, we were not able to isolate the $[Ga(acac)(Me\text{-}saoH)_2]$ without the presence of $Ga(acac)_3$. The use of polar solvents had the same effect as in the case of **1**.

3.2. Description of structures

Complex **1** crystallizes in the monoclinic space group $P2/c$. The molecular structure of **1** is shown in Fig. 2 while selected bond distances and angles are listed in Table 2. The Ga^{III} ion is in a distorted octahedral geometry. Two saoH$^-$ ligands chelate the Ga^{III} ion through the deprotonated phenoxy oxygen atom and the oximic nitrogen atom with the oxygen atoms in *trans* and the nitrogen atoms in *cis* orientation. A bidentate chelate acac$^-$ ligand completes the octahedron with both oxygen atoms in *trans* orientation with respect to the oximic nitrogen atoms of the saoH$^-$ ligands. The Ga–O_{acac} and Ga–O_{saoH} are very similar ranging from 1.928 to 1.934 Å while the two Ga–N distances are 2.067 and 2.069 Å for Ga1–N1 and Ga1–N2, respectively and compare favorably with those of other octahedral Ga(III) complexes [38]. Each of the two oximic OH groups forms an intramolecular hydrogen bond with the phenoxy oxygen atom of a neighboring saoH$^-$ [O2–H2A···O3, O···O 2.643(9) Å and O4–H4A···O1, O···O 2.621(7) Å].

Complex **2** crystallizes in the monoclinic space group $P2_1/n$, with two mononuclear complexes in the unit cell, namely [Ga(acac)$_3$] and [Ga(acac)(Me-saoH)$_2$]. Fig. 3 shows the asymmetric unit of **2**, while selected bond distances and angles are listed in Table 3. The structure of [Ga(acac)$_3$] within **2** compares well with the structures of [Ga(acac)$_3$] [39] and [Ga(acac)$_3$]·*trans*-CHCl=CHCl [40]. The structure of [Ga(acac)(Me-saoH)$_2$] is very similar to that of **1**. The Ga^{III} ion is in a distorted octahedral geometry with two bidentate chelate Me-saoH$^-$ ligands to coordinate through the deprotonated phenoxy oxygen atom and the oximic nitrogen atom around the Ga^{III} ion with the oxygen atoms in *trans* and the nitrogen atoms in *cis* orientation. The acac$^-$ ligand chelates the central atom with

both oxygen atoms in *trans* orientation with respect to the oximic nitrogen atoms of the Me-saoH$^-$ ligands. The oximic OH groups form two intramolecular hydrogen bonds with the phenoxy oxygen atoms of the neighboring Me-saoH$^-$ ligands [O2–H2A···O3, O···O 2.609(8) Å and O4–H4A···O1, O···O 2.589(8) Å].

3.3. Spectroscopic characterization

3.3.1. IR spectroscopy

In the ν(O–H) region, the IR spectra of the complexes exhibit medium-intensity broad bands at 3064 (**1**) and 3050 (**2**) cm^{-1}, assignable to $\nu(O–H)_{oxime}$. The broadness and the relatively low frequency of these bands are both indicative of hydrogen bonding. The ν(C=N) in spectra free ligands appear at 1623 and 1628 cm^{-1} for saoH$_2$ and Me-saoH$_2$, respectively. These bands are shifted to lower wavenumbers in the spectra of **1** (1595 cm^{-1}) and **2** (1593 cm^{-1}) due to complexation. The ν(C=C) and ν(C=O) modes of the acetylacetonate ligand at 1586 and1532 cm^{-1} in the spectrum of Ga(acac)$_3$ have not shifted significantly in the spectra of **1** (1586 and 1530 cm^{-1}) and **2** (1579 and 1528 cm^{-1}), respectively.

3.3.2. ^{1}H and ^{13}C NMR spectroscopy

^{1}H and ^{13}C NMR spectra of **1**, **2**, Ga(acac)$_3$, saoH$_2$ and Me-saoH$_2$ were recorded in CDCl$_3$ solution at ambient temperature. Figs. 4, 5 and 7, 8 show the ^{1}H and ^{13}C NMR spectra of **1** and **2**, respectively. The signal assignment is based on chemical shifts and comparison between the spectra of the complexes and the spectra of the starting materials. The ^{1}H and ^{13}C NMR spectra of Ga(acac)$_3$, saoH$_2$ and Me-saoH$_2$ are shown in Figs. S1–S6. The methyl (CH$_3$) and methinic (CH) protons of the acac$^-$ ligands in spectrum of Ga(acac)$_3$ appear as two singlets at 2.01 and 5.44 ppm, respectively (Fig. S1). The spectrum of **1** (Fig. 4) is more complex in these two regions exhibiting three distinct signals (singlets) and a shoulder for each of the methyl and methinic protons of the acac$^-$ ligand. The oximic (NOH) and the methinic (C–H) protons in the spectrum of saoH$_2$ appear as two singlets at 10.03 and 8.24 ppm, respectively (Fig. S2). Those signals have shifted downfield in the spectrum of **1** due to the deprotonation and coordination of the saoH$^-$ ligands and split in sets of two peaks at 9.96 and 9.75 for the oximic and 8.22 and 8.20 for the methinic protons. The phenolic proton (OH) appears as a singlet at 7.86 in the spectrum of saoH$_2$ and it is absent in the spectrum of **1**. The aromatic protons in the spectrum of saoH$_2$ appear as two triplets for the C3 and C4 protons and two doublets for C2 and C5 protons (for numbering pattern see Fig. 1). The spectrum of **1** is more complex in the region of the aromatic protons exhibiting not only overlapping signals of triplets and doublets but overlapping of lower integration peaks which indicate the presence of isomers in the CDCl$_3$ solution.

The ^{13}C NMR spectrum of **1** corroborates with the presence of isomers in the CDCl$_3$ solution (Fig. 5). The methyl (CH$_3$), methinic (CH) and carbonyl (CO) carbon atoms of the acac$^-$ ligands appear at 27.36, 100.36 and 192.96 ppm in the spectrum of Ga(acac)$_3$ (Fig. S3). Those signals have not shifted significantly in the spectrum of **1**, but the signals of the methyl and methinic carbon atoms have split in sets of two signals (Fig. 5). The seven carbon atoms of saoH$_2$ appear as seven distinct peaks in the ^{13}C NMR spectrum of

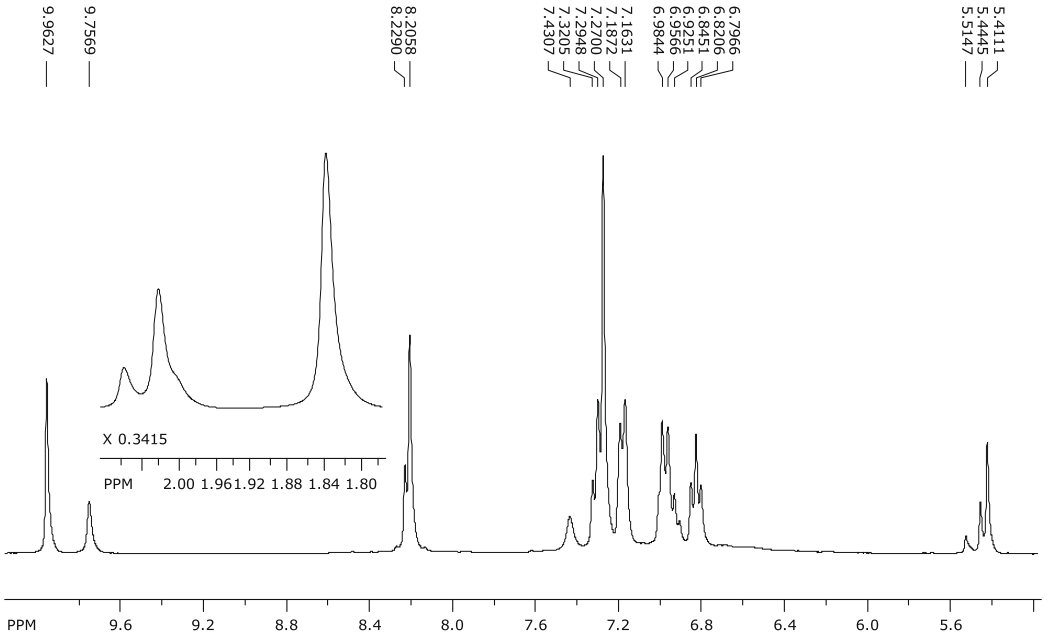

Fig. 4. The ^{1}H NMR spectrum of **1** in CDCl$_3$.

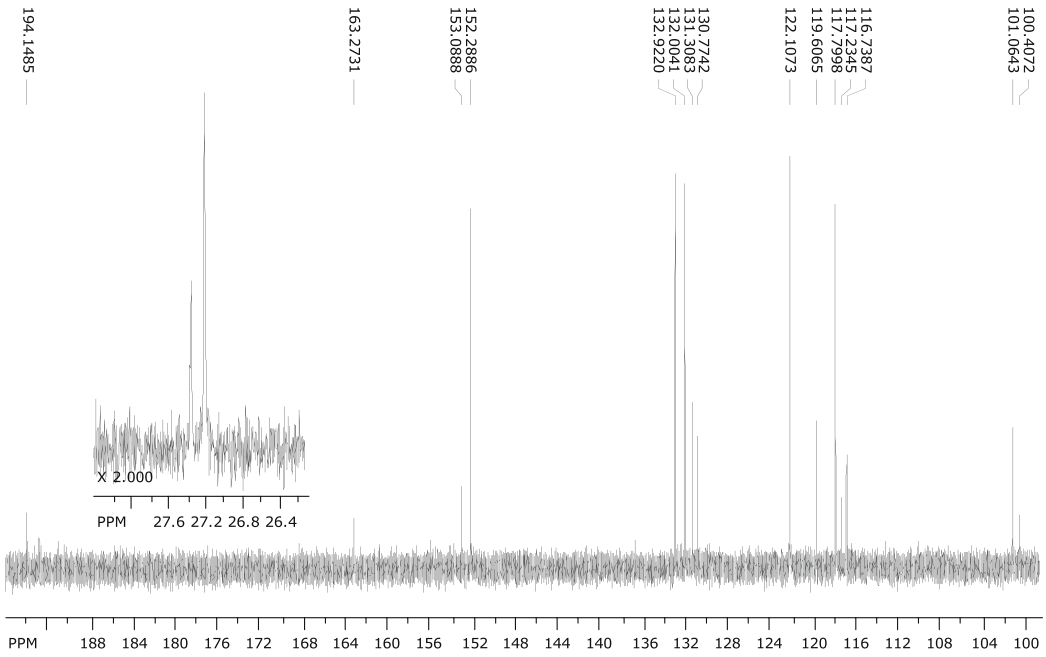

Fig. 5. The ^{13}C NMR spectrum of **1** in $CDCl_3$.

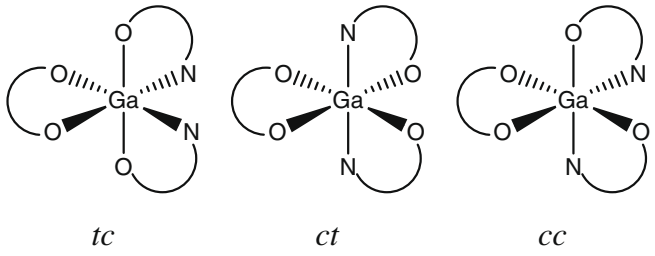

Fig. 6. The structures of the three geometric isomers of the Tris–chelate $[Ga(O,O)(O,N)_2]$ complexes.

the ligand (Fig. S4). Those peaks have shifted and split in sets of two peaks for all carbon atoms of saoH$^-$ except for the C1 and C6 which appear as two single peaks at 194.14 and 117.23 ppm in the ^{13}C NMR spectrum of **1**, respectively (Fig. 5). The fact that those two carbon atoms as well as the carbonyl carbon atoms of the acac$^-$ ligand give very weak signals in the ^{13}C NMR spectra of saoH$_2$ and Ga(acac)$_3$ and given that the minor species of **1** give a small percent signals compared with the signals of the majors species in solution, suggest that the signals of the minor species for those three carbon atoms are within the noise in the spectrum of **1**.

Tris–chelate complexes of the general formula $[Ga(O,O)(O,N)_2]$ such as **1** and the $[Ga(acac)(Me\text{-}saoH)_2]$ in **2** may exist in three iso-

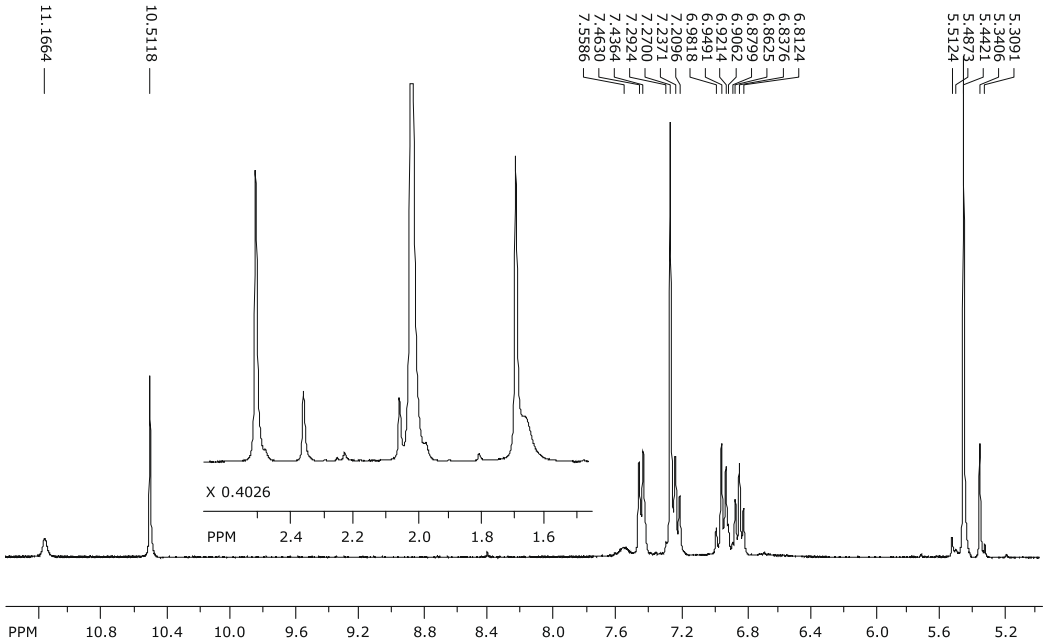

Fig. 7. The ^1H NMR spectrum of **2** in $CDCl_3$.

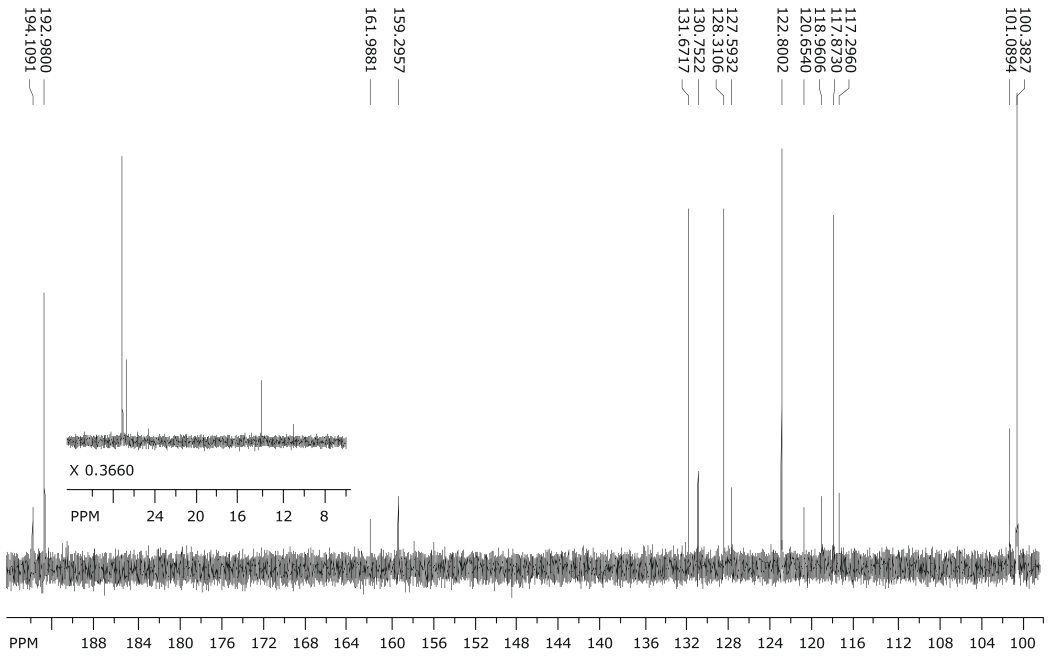

Fig. 8. The ^{13}C NMR spectrum of **2** in $CDCl_3$.

meric forms [41–43]. Those three geometric isomers are shown in Fig. 6 and with respect of the orientation of the N and O atoms of the two (O,N)-ligands are the *cis–cis* (*cc*), the *cis–trans* (*ct*) and the *trans–cis* (*tc*) with the latter being the one isolated in the solid-state in **1** and **2**. The *ct* and *tc* isomers have a C_2-symmetry where as *cc* has a C_1-symmetry. The ^1H and ^{13}C solution NMR spectra support at least the presence of two isomers in different proportion. The overlapping of the signals in the ^1H NMR spectrum of **1** makes the evaluation of the proportion difficult. A rough estimation of the proportion of the two isomers made on the integration of the oximic (NOH) protons, suggests that the two isomers are present in the $CDCl_3$ solution in 72:28% ratio.

The ^1H NMR spectrum of **2** indicates the presence of at least two isomers in $CDCl_3$ solution (Fig. 7). The aliphatic region is more complicated than that in the spectrum of **1** due to the presence of the methyl groups of the $Ga(acac)_3$ and the Me-saoH$^-$. The region where the methinic protons of the acac$^-$ ligands appear exhibits five signals, four of which are attributed to the two isomers and one to the methinic proton of the $Ga(acac)_3$. The aromatic region contains overlapping signals of triplets and doublets as well as lower integration peaks which indicate the presence of the other isomer. A rough estimation of the proportion of the two isomers made again on the oximic protons which appear as two peaks at 10.51 and 11.16 ppm in the spectrum of **2** suggests that the two isomers are present in the $CDCl_3$ solution in 74:26% ratio, which is similar to that observed in **1**. The ^{13}C NMR spectrum of **2** exhibits two peaks for the Me-saoH$^-$ methyl carbon atoms at 10.76 and 13.81 ppm (Fig. 8). The remaining Me-saoH$^-$ carbon atoms except C1, C6 and C7 (for numbering pattern see Fig. 1) appear as two sets of peaks in the ^{13}C spectrum of **2**, while there are eight distinct signals for the carbon atoms in the ^{13}C NMR spectrum of Me-saoH$_2$ (Fig. S6). As in the case of **1**, the C1, C6 and C7 atoms give very weak signals in the ^{13}C NMR spectrum of Me-saoH$_2$ and therefore the signals of the minor species of **2** for those three carbon atoms are not observed. The ^{13}C NMR spectrum of **2** exhibits two peaks for the acac$^-$ methyl carbon atoms around 27 ppm, two peaks for the methinic carbon atom at 100.38 and 101.08 ppm and two peaks for the carbonyl carbon atoms at 194.10 and 192.98 ppm. A closer look at the spectrum of **2** and the spectrum of $Ga(acac)_3$ indicates that the higher intensity signals at 27.36, 101.38 and 192.98 ppm are due to the $Ga(acac)_3$ within **2**. Concentrating our attention at the methinic carbon signals at around 100 ppm in the spectra of **1** and **2**, we can observe that the intense and the weak signals in the spectrum of **1** have been reversed in the spectrum of **2** and that the signals of the minor species in **2** overlap with the signals of the $Ga(acac)_3$ in **2**.

4. Conclusions and perspectives

Our first attempt to employ salicylaldoximes in the coordination chemistry of Ga(III) afforded two mononuclear Ga(III) complexes. Both complexes were characterized by single-crystal X-ray crystallography, IR, ^1H and ^{13}C NMR spectroscopy. Complex **1** is an octahedral Ga(III) complex surrounded by a bidentate-chelate saoH$^-$ ligand and a bidentate chelate acac$^-$ ligand, while complex **2** contains the same core with Me-saoH$^-$ instead of saoH$^-$ and has co-crystallized with one $Ga(acac)_3$ molecule. Both ^1H and ^{13}C NMR spectra of the compounds suggest the presence of at least two geometrical isomers in the $CDCl_3$ solution. Detailed preparations of the starting materials $Ga(acac)_3$, saoH$_2$ and Me-saoH$_2$ as well as $Ga(NO_3)_3{\cdot}9H_2O$ are given along with their IR and ^1H and ^{13}C NMR data. Although we did not manage to isolate higher nuclearity Ga(III) complexes in our first attempt, we continue working toward the synthesis of polynuclear Ga(III) complexes with salicyladoximes.

Appendix A. Supplementary data

CCDC 729176 and 729177 contain the supplementary crystallographic data for (**1**) and (**2**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.04.039.

to standard procedures. Melting points (m.p.) were determined in open capillaries and are uncorrected. IR and far-IR spectra were recorded on a Perkin–Elmer Spectrum GX Fourier transform spectrophotometer using KBr pellets (4000–400 cm^{-1}) and nujol mulls dispersed between polyethylene disks (400–40 cm^{-1}). NMR spectra were recorded on a Bruker AV-400 spectrometer operating at 400 and 100 MHz for ^1H and ^{13}C acquisition, respectively, or on a Bruker AV-250 spectrometer operating at 250.13 and 62.90 MHz for ^1H and ^{13}C acquisition, respectively. The spectra were acquired at room temperature (298 K). The chemical shifts are reported in ppm for ^1H and ^{13}C NMR). Samples were dissolved in dimethylsulfoxide-d6 and spectra were obtained at room temperature with the signal of free dimethylsulfoxide-d6 (at 2.50 ppm ^1H NMR, 39.5 ppm ^{13}C NMR) as a reference. Elemental analyses were carried out by the microanalytical service of the University of Ioannina, Greece.

*2.1.1. Preparation of pyruvic acid thiosemicarbazone hemihydrate ($H_2pt·1/2H_2O$) (**1**)*

The ligand was synthesized according to a published procedure [6d]. The white powder was recrystallized from diethyl ether and was dried *in vacuo* over silica gel. Yield: 85%. M.p. 188–190 °C. IR (cm^{-1}) [6d]: 3431 m, $\nu(H_2O)$; 3294 m, $\nu(NH_2)$; 1626s, υ(C=N); 1733s, 1702 m, υ(C=O), 1046 m, υ(N—N); 859 m, υ(C=S). ^1H NMR (DMSO): δ 12.10 (s, 1H, OH); 10.74 (s, 1H, NH); 8.67 (d, 2H, NH_2, J_{H-H} = 16.8); 2.11 (s, 3H, Me); ^{13}C NMR: δ 180.3 (C=S); 165.3 (C=O); 139.1 (C—CH_3); 12.6 (Me). *Anal.* Calc. for $C_4H_7N_3O_2S.1/2H_2O$ (Mw: 170.2): C, 28.2; H, 4.7; N, 24.7, S, 18.8. Found: C, 28.0; H, 4.8; N, 24.5; S, 18.9%.

*2.1.2. Preparation of [$Ph_2Sn(pt)$] (**2**)*

Diphenyltin(IV) oxide (0.0867 g, 0.3 mmole) and pyruvic acid thiosemicarbazone hemihydrate (H_2pt) (0.0511 g, 0.3 mmole) in benzene (20 ml) were refluxed overnight under azeotropic removal of water (*Dean-Stark* trap). The resulting clear solution was rotary evaporated under vacuum to a small volume (2 ml), chilled and triturated with diethyl ether to give a white solid. The white powder was recrystallized from diethyl ether and dried *in vacuo* over silica gel. Yield: 15%. M.p. 196–198 °C. IR (cm^{-1}): 3285s, $\nu(NH_2)$; 1610, 1593 m, υ(C=N); 1667s, ν_{as}(COO); 1431s, ν_{sym}(COO); 1070 m, υ(N–N); 766 ms, υ(C=S); 333 m, υ(Sn–C); 310 m, υ(Sn–O); 396 m, ν(Sn–S); 278 m, υ(Sn–N). ^1H NMR (DMSO): δ 8.28 (s, 2H, NH_2); 7.67 (H*o*-Ph); 7.45–7.40 (m, H*m*, *p*-Ph); 2.30 (s, 3H, Me); ^{13}C NMR: δ 175.2 (C=S); 164.6 (C=O); 148.9 (Co-Ph); 146.0 (Cm-Ph); 135.9 (Cp-Ph); 129.5 (C–CH_3); 15.2 (CH_3). *Anal.* Calc. for $C_{16}H_{15}N_3O_2SSn$ (Mw: 432.1): C, 44.5; H, 3.5; N, 9.7; S, 7.4. Found: C, 44.2; H, 3.7; N, 9.4, S, 7.5%.

*2.1.3. Preparation of [$SnMe_2(Hpt)(H_2O)$]Cl (**3**)*

Pyruvic thiosemicarbazone hemihydrate (0.04 g, 0.24 mmole) and equimolar quantity of KOH in methanol (10 ml) were mixed and dimethyltin(IV) dichloride (0.053 g, 0.24 mmole) was added. The reaction mixture was stirred for 2 h. The resulting clear solution evaporated and triturated with distilled diethyl ether to give a pale white solid. The pale white powder was recrystallized from distilled diethyl ether and dried *in vacuo* over silica gel. Yield: 61%. M.p. 157–159 °C. IR (cm^{-1}): 3420 m, $\nu(H_2O)$; 3244s, $\nu(NH_2)$; 1560 m, υ(C=N); 1625s, ν_{as}(COO); 1393s, ν_{sym}(COO); 1062 m, υ(N–N); 768 m, υ(C=S); 517 m, 493 υ(Sn–C); 331sh, 311 m υ(Sn–O); 403 m, ν(Sn–S); 277 m, υ(Sn–N). ^1H NMR (DMSO): δ 12.12 (s, 1H, H_2O); 10.70 (s, 1H, NH); 8.75 (d, 2H, NH_2, $J_{(H)-(H)}$ = 21.5); 2.28 (s, 3H, Me); 1.06/0.81 (s, Sn–Me, $J_{(Sn)-(Me)}$ = 63.6); ^{13}C NMR: δ 185.5; 180.9(C=S); 170.5, 169.4, 156.2 (C=O); 121.3 (C–CH_3); 14.4 (Me); 9. (Me–Sn). *Anal.* Calc. for $C_6H_{14}N_3O_3SSnCl$ (Mw: 362.37): C, 19.9; H, 3.9; N, 11.6, S, 8.8. Found: C, 19.4; H, 3.8; N, 12.0, S, 9.1%.

*2.1.4. Preparation of [$Ph_2Sn(Hpt)(H_2O)$]Cl (**4**)*

Pyruvic thiosemicarbazone hemihydrate (0.04 g, 0.24 mmole) and equimolar quantity of KOH in methanol (10 ml) were mixed and diphenyltin(IV) dichloride (0.0825 g, 0.24 mmole) was added. The reaction mixture was stirred for 2 h. The resulting clear solution evaporated and triturated with distilled diethyl ether to give a pale white solid. The pale white powder was recrystallized from distilled diethyl ether and dried *in vacuo* over silica gel. Yield: 46%. M.p. 124–126 °C. IR (cm^{-1}): 3409 m, $\nu(H_2O$; 3299s, $\nu(NH_2)$; 1597 m, υ(C=N); 1618s, ν_{as}(COO); 1391, ν_{sym}(COO); 1066s, υ(N–N); 766 m, υ(C=S); 340 m, υ(Sn–C); 329 m, 315sh, υ(Sn–O); 397 m, ν(Sn–S); 279 m,, υ(Sn–N). ^1H NMR (DMSO): δ 12.03 (s, 1H, H_2O); 10.65 (s, 1H, NH); 8.68 (d, 2H, NH_2, $J_{(H)-(H)}$ = 20.9); 8.18 (m, H*o*-Ph); 7.87 (m, H*p*-Ph); 7.61 (m, H*m*-Ph); 2.22 (s, 3H, Me); ^{13}C NMR: δ 207.4, 180.7, 175.2 (C=S); 165.7, 164.6 (C=O); 148.9 (Co-Ph); 146.2 (C*m*-Ph); 139.5 (C*p*-Ph); 129.5 (C–CH_3); 15.2 (Me). *Anal.* Calc. for $C_{16}H_{18}N_3O_3SSnCl$ (Mw: 486.5): C, 39.5; H, 3.7; N, 8.6; S, 6.6. Found: C, 39.1; H, 3.5; N, 8.4; S, 6.4%.

2.2. X-ray crystallography

X-ray data for **2** and **3** were collected at low temperature using an Oxford Cryosystem device on a Kuma KM4CCD κ-axis diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). Crystals were positioned at 65 mm from the CCD camera. Six hundred and twelve frames were measured at 0.75° intervals with a counting time of 10–20 s. Accurate cell parameters were determined and refined by least-squares fit of 11 200 and 12 000 the strongest reflections for **1** and **2**, respectively. The data were corrected for Lorentz and polarization effects. Analytical absorption correction was applied for both crystals. Data reduction and analysis were carried out with the Oxford Diffraction (Poland) Sp. z o.o programs [9]. Crystal structures were solved by direct methods (program SHELXS97 [9a]) and refined by the full-matrix least-squares method on all F^2 data using the SHELXL97 [9b] programs. Non-hydrogen atoms were refined with anisotropic displacement parameters; hydrogen atoms were included from geometry of molecules and $\Delta\rho$ maps. During the refinement process they treated as riding atoms [9a–d]. Crystal data are given in Table 1, together with refinement details.

2.3. Antiproliferative assay in vitro

2.3.1. Compounds

Test solutions of the compounds tested (1 mg/ml) were prepared by dissolving the substance in 100 µl of DMSO completed with 900 µl of tissue culture medium. Afterwards, the tested compounds were diluted in culture medium to reach the final concentrations of 100, 50, 10, 1 and 0.1 ng/µl. The solvent (DMSO) in the highest concentration used in test did not reveal any cytotoxic activity.

2.3.2. Cells

The cell lines are maintained in the Cell Culture Collection of the University of Ioannina. Twenty-four hours before addition of the tested agents, the cells were plated in 96-well plates at a density of 10^4 cells per well. The MCF-7 cells were cultured in the D-MEM (Modified Eagle's Medium) medium supplemented with 1% antibiotic and 10% fetal calf serum. L-929 cells were grown in Hepes-buffered RPMI 1640 medium supplemented with 10% fetal calf serum, penicillin (50 U/ml) and streptomycin (50 mg/ml). A-549 cells were grown in F-12 K Ham's medium supplemented with 1% glutamine, 1% antibiotic/antimycotic, 2% $NaHCO_3$ and 10% fetal calf serum. The cell cultures were maintained at 37 °C in a humid atmosphere saturated with 5% CO_2. Cell number was counted by the Trypan blue dye exclusion method. MCF-7, L-929 and A-549

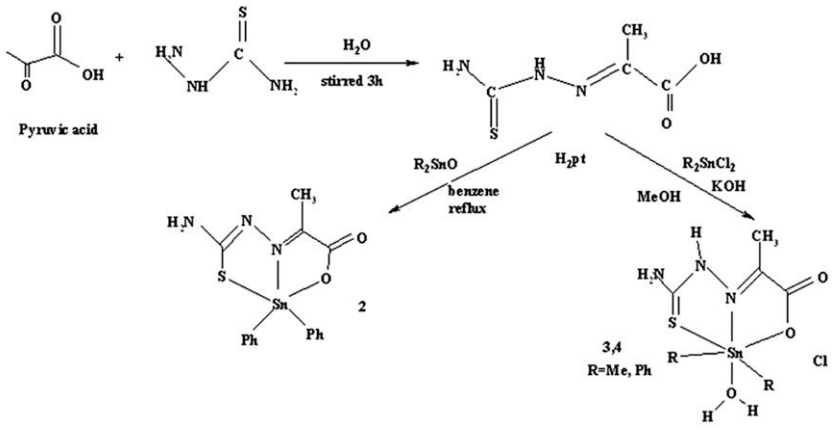
cells were determined by the sulforhodamine B assay [10a], while T-24 cells by the MTT assay [10b]. The in vitro tests were performed as described previously [10c].

3. Results and discussion

3.1. Synthetic aspects

Pyruvic acid thiosemicarbazone hemihydrate (H_2pt·1/2H_2O) was prepared by the condensation of pyruvic acid and thiosemicarbazide hydrochloride [6d]. The reaction of dimethyltin(IV)oxide with pyruvic acid thiosemicarbazone (H_2pt) and subsequent recrystallization from THF leads to the formation two *pseudo*-polymorfs based on triangular $[(CH_3)_2Sn(pt)]_3$ units; one of them $[(CH_3)_2Sn(pt)]_3$·3THF with tubular cavities while the other $[(CH_3)_2Sn(pt)]_3$·1.5THF is a H-bonded 3D network with truncated tetrahedral cavities [6e]. When diphenyltin(IV) oxide was reacted with H_2pt the monomer [*Sn*Ph_2(pt)] (**2**) was formed. Probably, the steric hindrance effect of phenyl groups prevent the formation of a trimer. The stoichiometry of the complex indicates that SnR_2(IV) is coordinated by the doubly charged anion pt^{2-} formed on the loss of the two protons from the carboxylato oxygen and thioamide nitrogen, N. The doubly deprotonated ligand, pt^{2-}, is coordinated as a tridentate ligand *via* the carboxylato oxygen O, the azomethine nitrogen N and the thiolato sulfur S atoms. In the trimer the carboxylato group OCO bridge two tin centers. Reaction of potassium pyruvic thiosemicarbazone with SnR_2Cl_2 (where R = Me or Ph) gives the cationic complexes [$SnMe_2$(Hpt)(H_2O)]Cl (**3**) and [$SnPh_2$(Hpt)(H_2O)]Cl (**4**). The stoichiometries of the cationic complexes indicate that SnR_2(IV) is coordinated by the singly charged anion Hpt^- and one molecule of water. The formula of these diorganotin(IV) complexes were confirmed by elemental analysis, spectroscopic studies and by X-ray analysis, Scheme 1.



3.2. Structural characterization

Complexes **2** and **3** were recrystallized from C_6H_6/toluene/DMSO/CH_3CN and distilled diethyl ether respectively, to furnish white prisms suitable for single-crystal X-ray analysis. Selected interatomic distances and bond angles are collected in Table 2.

3.2.1. Crystal structure of [$SnPh_2$(pt)] (**2**)

The crystal structure of compound **2** is shown in Fig. 1. The dianionic, tridentate ligand has a ZEZ configuration based on the C(1)–C(2), C(2)–N(1) and N(2)–C(4) bonds. The double deprotonated ligand is coordinated as tridentate ligand *via* the carboxylato oxygen O(1), the azomethine nitrogen N(1) and thiolato sulfur S(1) atoms. The penta-coordination number is completed by two carbon atoms of phenyl groups. The coordinated part of the ligand is made of two chelate rings Sn(1)S(1)N(1)N(2)C(4) and Sn(1)O(1)N(1)C(1)C(2) (I and II). The dihedral angles between the planes of the rings I and II is 4.60(6)°, indicating that the ligand is nearly planar.

Analysis of the shape determining angles using the approach of Reedijk and coworkers [11] yields τ ($(\alpha - \beta)/60$) value of 0.44 for Sn(1) (τ = 0.0 and 1.0 for *SPY* and *TBPY* geometries, respectively). The metal coordination geometry is therefore described as distorted *SPY* with the C(11) occupying the apical position for Sn(1). The donor C(11) is chosen as apex by the simple criterion that neither should be any of the four donor atoms which define the two largest angles, a and b [11]. The angles S(1)–Sn(1)–C(11) and O(1)–Sn(1)–C(11), are 101.16(4)° and 93.46(6)° respectively, and

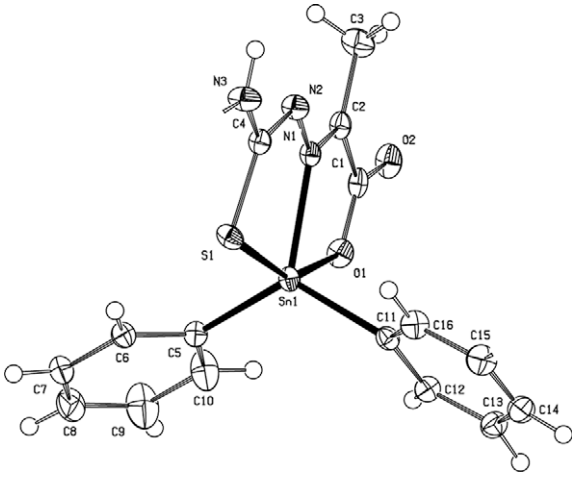

Fig. 1. Molecular structure of the neutral diorganotin complex **2**.

the angles C(5)–Sn(1)–C(11) and N(1)–Sn(1)–C(11) are 123.26(7)° and 110.47(6)° respectively, and deviate by ~20–33° from the 90° expected for a square-base pyramid, so the polyhedron formed is far from being a square pyramid.

The C(3)–N(1) bond length is 1.299(3) Å and is close to a double bond (1.28 Å). The deprotonation of N(2)H produces a negative charge, which is delocalized in the C(3)–N(1)–N(2)–C(4) group. All the metal-donor bond distances, Sn–O and Sn–N were similar to other organotin complexes presented in literature [8c,d]. $\pi \rightarrow \pi$ intermolecular interactions and intra- and intermolecular hydrogen bonds stabilize this structure. The polar hydrogen atom on N(3) participates in intermolecular hydrogen bond. For **2** the monomers of Sn(1) are linked through intermolecular hydrogen bonds of N(3)–H(3A)–O(2) type. A strong π–π interaction is that between the rings Sn(1)–N(1)–N(2)–C(4)–S {Cg(1)–Cg(1); symmetry operation; $1-x, 1-y, 1-z$} at a center to center separation of 4.0360(9) Å, Fig. 2.

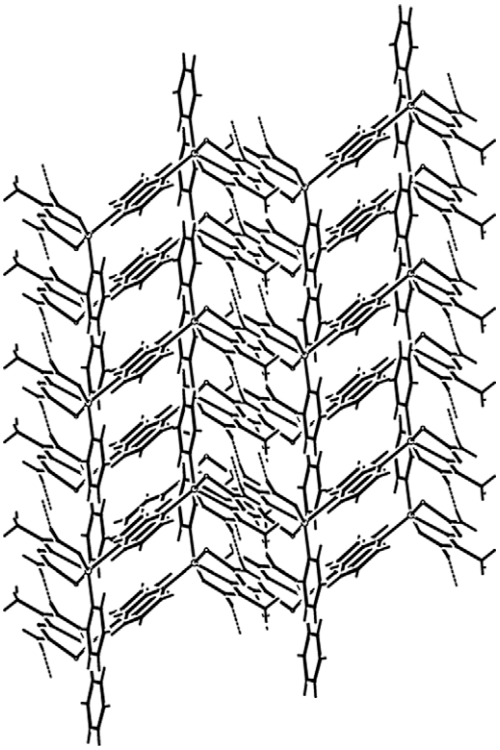

Fig. 2. A view of the extended network of **2** along the *b* axis.

*3.2.2. Crystal structure of [SnMe$_2$(Hpt)(H$_2$O)]Cl (**3**)*

A perspective view of **3** is shown in Fig. 3. The mono deprotonated ligand is coordinated as tridentate ligand *via* the carboxylato oxygen O(1), the azomethine nitrogen N(1) and thiolato sulfur S(1) atoms. The molecule of H_2O is coordinated to the tin through oxygen O(1W) atom. The six coordination number is completed by two carbon atoms of methyl groups. Two axial places are occupied by the two carbon atoms and the basal plane by the three donor atoms of ligand and the O(1W) donor atom. The charge of the organotin fragment is balanced by an ionic chloride anion. The

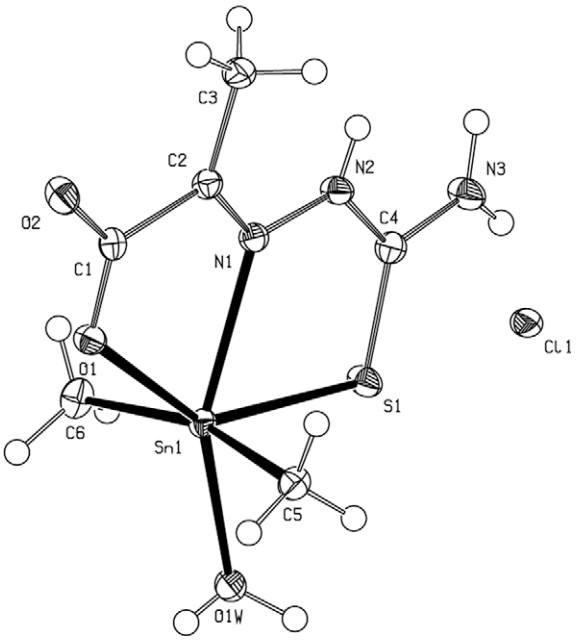

Fig. 3. Molecular structure of the cationic diorganotin complex **3**.

structure is distorted octahedral. The distortion from the ideal octahedral configuration is shown by the C(5)–Sn(1)–C(6) angle of 162.50(7). Also, the angles S(1)–Sn(1)–O(1) and O(1W)–Sn(1)–N(1) in the basal plane are 141.39(3) and 149.41(5) respectively, which deviates from the ideal value of 180°, probably due to the ligand constraint. The organic molecule acts as anionic tridentate with the ONS donors placed in the same side. The tridentate ligand has a ZEZ configuration. The coordinated ligand consists of two chelate rings, SnSNNC and SnONCC, I and II, respectively. The dihedral angle between the planes of the rings I and II is 3.17(6) indicating that the ligand does not deviate appreciably from planarity. The distance between the metal centers is 4.2960(3) Å.

The counter anion participates in five hydrogen bonds. The Cl(1) anion participates in three hydrogen bonds of N(2)–H(2N)···Cl(1), N(3)–H(31N)···Cl(1) and O(1W)–H(2W)···Cl(1) with one monomer of **3**. The polar hydrogen atoms on N(3) partcipate in two intermolecular hydrogen bonds [12]. The monomers of **3** form hydrogen-bonded dimers linked by two N(3)–H(32N)···Cl(1) hydrogen bonds involving the amino N(3)–H(32N) hydrogen atom and the adjacent Cl(1) chloride and *vice versa* of centrocymetrically related pairs of molecules. The observed hydrogen-bonding pattern is of the DA = AD type. Another centrosymmetric pair of hydrogen bonds of the DA = AD type involving the methyl carbon C(3)–H(3) and the same chloride Cl(1) atom connects the dimers and results in the formation of infinite layers, Fig. 4 [12]. Intra and inter molecular hydrogen bonds stabilize this structure and leads to a supramolecular assembly, Table 3.

Table 3
π–π, inter- and intramolecular hydrogen bonds for **2**, inter and intra-molecular hydrogen bonds for **3**[a].

*π–π, intra- and intermolecular hydrogen bonds for **2***					
		Cg–Cg[b]	β[c]	CgI-Perp[d]	CgJ-Perp[e]

[a] Cg(1) refer to the centroid Sn(1)–N(1)–N(2)–C(4)–S for **2**, (i) $1-x, 1-y, 1-z$; (ii) $x, 1+y, z$; (iii) $-x, -y, 2-z$; (iv) $1-x, 1/2+y, 3/2-z$;v,$1-x, -1/2+y, 3/2-z$; (vi) $x, 1/2-y, 1/2+z$.
[b] Cg–Cg is the distance between ring centroids.
[c] Where β is the angle Cg(I) → Cg(J).
[d] CgI-Perp is the perpendicular distance of Cg(I) on ring J.
[e] CgJ-Perp is the perpendicular distance of Cg(J) on ring I.

3.3. Spectroscopy

3.3.1. Infrared spectroscopy

The three medium-strong intensity bands at around 3294, 3210 and 3120 sh cm^{-1} in the spectra of $H_2tpt{\cdot}1/2H_2O$, are assigned to $\upsilon_{as}NH_2$, υ_sNH_2 and υNH, respectively, while the bands at 3430 and 3407 are assigned to υOH mode. These bands are superimposed upon the broader more intense O–H stretching absorption typical of the carboxylic acid functions. The broad band at 3000–2980 cm^{-1} is taken to represent the υ(NH···O) mode, due to intra- or intermolecular hydrogen bonding [8c,d,13,14]. In the NH stretching frequency region the spectral band υ(NH) disappears in the complex **2**, indicating the deprotonation of the NH group. The difference, $\Delta[\upsilon_{as}(COO)-\upsilon_{sym}(COO)]$ between these frequencies for **2**–**4** is close to that found for monodentate carboxylato group (230–240 cm^{-1}). The significant changes in the ligand bands upon complexing are the decrease in υ(C=N) and increase in υ(N–N) and the absence of the large systematic shifts of $\upsilon_{as}(NH_2)$ to lower frequencies. These data indicate coordination through the nitrogen of the azomethine group and no interaction between the terminal amino nitrogen and the metal ion. The υ(CS) bands at 859 cm^{-1} are less intense in the complexes **2**–**4** and are shifted to a lower frequency, suggesting coordination of the metal through sulfur after deprotonation. From the metal–ligand stretching vibrations, which are below 600 cm^{-1}, it is possible to assign the bands characteristic for υ(SnC). Also, υ(SnS) at 403–395 cm^{-1}, υ(SnN) at 270–250 cm^{-1} and υ(SnO) at 330–310 cm^{-1} [8c,d,13,14].

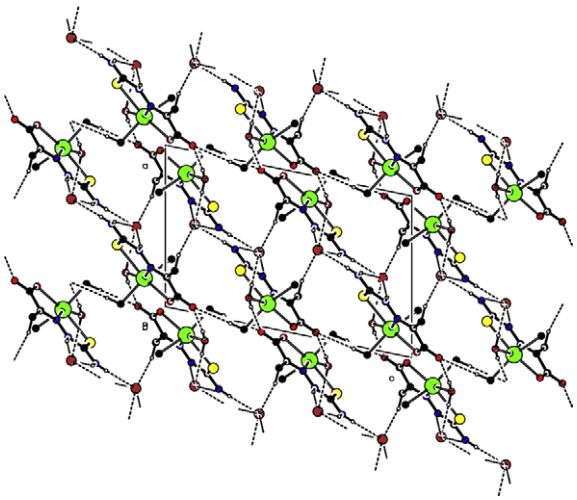

Fig. 4. Arrangement of the intermolecular hydrogen bonds in **3**.

3.3.2. NMR spectra

In the ^{1}H NMR spectra of (H_2pt) (**1**) the appearance of the signal ^{2}NH at δ 10.74 ppm, indicates that this proton is involved in hydrogen bonding [13]. The absence of peak corresponding to the imino proton in the spectrum of **2** indicates that this nitrogen is present in the deprotonated form. The existence of the ^{2}NH resonance in the ^{1}H NMR spectra of the complexes **3** and **4** indicates that the nitrogen atoms remain protonated. The signals corresponding to the hydroxyl groups for **2**–**4** disappear upon interaction with the metal, indicating deprotonation of these atoms and possible coordination to the tin atom. The C=S resonances of the thiosemicarbazone moieties in the free ligand resonated at 180.3 ppm. In the complex **2** an upfield shift was observed, indicating increased electron density at this site on complexation, due probably to π-back bonding for thiolato sulfur [8c,d,14]. ^{13}C NMR spectra for **3** and **4** clearly show the existence of two-three signals for most of the ligand's atoms. For this case, the contemporary presence of two structural isomers or two different complexes could be concluded [14c].

3.4. Pharmacology: Antiproliferative activity in vitro

Platinum(II) complexes of *N*4-ethyl 2-formyl and 2-acetylpyridine thiosemicarbazones showed cytotoxicity and were found to be able to overcome the *cisplatin* resistance of A2780/Cp8 cells [3a]. Pt(II) or Pd(II) complexes with 2-acetyl pyridine N(4)-ethyl-thiosemicarbazone, HAc4Et were tested in a panel of human tumor

Table 4
The antiproliferative activity *in vitro* of **1**–**4** (expressed as as $IC_{50} \pm SD$ (μM)) against MCF-7, T-24, A-549 and L-929 cancer cell lines.

	L-929	A-549	T-24	MCF-7
H_2pt	34.7 ± 1.5	n.a.	18.2 ± 0.5	160.4 ± 5.1
2	0.88 ± 0.04	7.2 ± 0.18	0.43 ± 0.03[a]	0.69 ± 0.03
3	1.02 ± 0.03	0.91 ± 0.05	19.73 ± 0.9	1.24 ± 0.30
4	0.95 ± 0.02	4.83 ± 0.31	4.52 ± 0.14	0.62 ± 0.03
Me_2SnCl_2	20.5 ± 1.0	12.7 ± 0.9	n.a.	8.5 ± 0.05
Ph_2SnCl_2	1.45 ± 0.08	9.89 ± 0.14	n.a.	0.84 ± 0.02
Cisplatin	0.69 ± 0.03	1.53 ± 0.10	41.66 ± 2.2	7.99±0.31

[a] In this case the IC_{50} is $\times 10^{-10}$.

cell lines of different origins (breast, colon, and ovary cancers), and *cisplatin*-refractory/resistant cell lines and were found to exhibit very remarkable growth inhibitory activities with mean IC_{50} values of 0.9–0.5 nM and support the hypothesis that both $[Pt(Ac4Et)_2]$ and $[Pd(Ac4Et)_2]$ complexes can be characterized by cellular pharmacological properties distinctly different from those of *cisplatin* [4d].

The compounds **1**–**4** were tested for their antiproliferative activity *in vitro* against the cells of three human cancer cell lines: MCF-7 (human breast cancer cell line), T-24 (bladder cancer cell line), A-549 (non-small cell lung carcinoma) and a mouse fibroblast L-929 cell line. The results of cytotoxic activity *in vitro* are expressed as IC_{50} – the concentration of compound (in μM) that inhibits a proliferation rate of the tumor cells by 50% as compared to control untreated cells, Table 4.

The ligand **1** is less cytotoxic compared to *cisplatin* against the L929, MCF7, non-toxic against A549 cell lines and more cytotoxic against T-24 cancer cell line. The diorganotin complexes **2**–**4** are in the same μM range compared to *cisplatin* against L929 cancer cell line. The diorganotin complexes **2**–**4** and Ph_2SnCl_2 are more cytotoxic compared to *cisplatin* against MCF-7 and T-24 cancer cell lines.

The IC_{50} values for **2** against MCF-7 and T-24 cell lines are 0.69 μM and 0.43×10^{-10} M, respectively and against A-549 and L-929 cell lines are 7.2 and 0.88 μM, respectively. Complex **2** is 11.6 and 10^6 times more active than *cisplatin* against MCF-7 and T-24 cell lines, respectively. The IC_{50} values for **3** against MCF-7 and T-24 cell lines are 1.24 and 19.73 μM, respectively and against A-549 and L-929 cell lines are 0.91 and 1.02 μM, respectively. Complex **3** is 6.4 times more active than *cisplatin* against MCF-7 cell line and 2.7 times more active than *cisplatin* against T-24 cell line. The IC_{50} values for **4** against MCF-7 and T-24 cell lines are 0.62 and 4.52 μM, respectively and against A-549 and L-929 cell lines are 4.83 and 0.95 μM, respectively. Complex **4** is 12.9 times more active than *cisplatin* against MCF-7 cell line and 9.2 times more active than *cisplatin* against T-24 cell line.

Selectivity was observed for complexes **2**–**4**, which were found especially active against MCF-7 and T-24 cancer cell lines. The most active of all was found the diorganotin complex **2**. The cytotoxic activity shown by these compounds against all these cancer cell lines indicates that coupling of **1** with $R_2Sn(IV)$ metal center result in metallic complexes with important biological properties and remarkable cytotoxic activity, since they display IC_{50} values in a μM range better to that of the antitumor drug *cisplatin*. Compound **2** is considered as agent with potential antitumor activity, and can therefore be candidate for further stages of screening *in vitro* and/or *in vivo*.

4. Conclusions

The reaction of dimethyltin(IV)oxide with pyruvic acid thiosemicarbazone (H_2pt) leads to the formation two *pseudo*-polymorfs based on triangular $[(CH_3)_2Sn(pt)]_3$ units [6e]. When diphenyltin(IV) oxide was reacted with H_2pt the monomer $[SnPh_2(pt)]$ (**2**) was formed. The stoichiometry of the complex indicates that $SnR_2(IV)$ is coordinated by the doubly charged anion pt^{2-} formed on the loss of the two protons from the carboxylato oxygen and thioamide nitrogen, N. Reaction of potassium pyruvic thiosemicarbazone with SnR_2Cl_2 (where R = Me or Ph) gives the cationic complexes $[SnMe_2(Hpt)(H_2O)]Cl$ (**3**) and $[SnPh_2(Hpt)(H_2O)]Cl$ (**4**). The stoichiometries of the cationic complexes indicate that $SnR_2(IV)$ is coordinated by the singly charged anion Hpt^- and one molecule of water. The formula of these diorganotin(IV) complexes were confirmed by elemental analysis, spectroscopic studies and by X-ray analysis.

The *in vitro* cytotoxic activity has been evaluated against the cells of three human cancer cell lines: MCF-7 (human breast cancer cell line), T-24 (bladder cancer cell line), A-549 (non-small cell lung carcinoma) and a mouse L-929 (a fibroblast-like cell line cloned from strain L). Selectivity was observed for complexes **2**–**4**, which were found especially active against MCF-7 and T-24 cancer cell lines. The most active of all was found the diorganotin complex **2**. Compound **2** is considered as agent with potential antitumor activity, and can therefore be candidates for further stages of screening *in vitro* and/or *in vivo*.

Supplementary data

CCDC 721898 and 721899 contain the supplementary crystallographic data for **2** and **3**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

was characterized by UV–Vis, IR and NMR spectroscopy, as well as by X-ray crystallography. The structure of this complex enables comparisons with the previously characterized [Ni{Ph_2PNPPh_2-*P*,*P*}$_2$] [29] and [Ni{$Ph_2P(Se)NP(Se)Ph_2$-*Se*,*Se*}$_2$] [30] complexes, in which there are four- and six-membered rings, respectively. Furthermore, while investigating the coordination between $Ph_2P(Se)N\{(S)\text{-}CH(CH_3)Ph\}PPh_2$ [31] and Ni(II), single crystals were isolated, the analysis of which revealed the *trans*-[Ni{$Ph_2P(Se)$-$NPPh_2$-*Se*,*P*}{$Ph_2P(Se)N(H)PPh_2$-*Se*,*P*}]$Cl\cdot CH_2Cl_2\cdot H_2O$ (**2**) structure, which contains one Ni–Se–P–N(H)–P and one Ni–Se–P–N–P ring, in the same molecule. This unprecedented structure makes possible to compare the structural characteristics of such rings in the same molecule, as well as in the structure of **1**.

2. Experimental

2.1. UV–Vis, IR and NMR spectroscopy

Electronic spectra were recorded in a Carry 300 Varian spectrophotometer. IR spectra were run in the range 4000–200 cm^{-1} on a Perkin–Elmer 883 IR spectrophotometer, as KBR discs. $^{31}P\text{–}\{^1H\}$ NMR spectra were recorded in a Varian Unity Plus 300 MHz instrument, operating at 121 MHz, using $CDCl_3$ solutions. The ^{31}P chemical shifts are relative to 85% H_3PO_4.

2.2. X-ray crystal structure determination
