A dark green crystal of **1** (0.15 × 0.20 × 0.30 mm) was mounted in air, and a yellow–brown crystal of **2** (0.07 × 0.36 × 0.48 mm) was taken directly from the mother liquor and immediately cooled to −93 °C. Diffraction measurements for **1** were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11 < 2\theta < 23°$. Intensity data were recorded using a $\theta\text{–}2\theta$ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using CRYSTAL LOGIC software. Diffraction measurements for **2** were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Mo Kα radiation. Data collection (ω-scans) and processing (cell refinement, data reduction and empirical absorption correction) were performed using the CRYSTALCLEAR program package [32]. Important crystallographic and refinement data are listed in Table 1. The structures were solved by direct methods using SHELXS-97 [33] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [34]. Further crystallographic details for **1**: $2\theta_{max} = 50°$; reflections collected/unique/used, 3904/3664 [$R_{int} = 0.0190$]/3664; 340 parameters refined; $(\Delta/\sigma)_{max} = 0.001$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.664/-0.306$ e/Å^3; R/R_w (for all data), 0.0471/0.0841. Hydrogen atoms were located by difference maps and were refined isotropically. All non-H atoms were refined anisotropically. Further crystallographic details for **2**: $2\theta_{max} = 52°$; reflections collected/unique/used, 93095/9494 [$R_{int} = 0.0426$]/9494; 723 parameters refined; $(\Delta/\sigma)_{max} = 0.002$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.922/-0.705$ e/Å^3; R/R_w (for all data), 0.0331/0.0841. Hydrogen atoms were located by difference maps and were refined isotropically. All non-H atoms were refined anisotropically.

2.3. Synthesis

All manipulations were carried out under a pure Ar atmosphere. All chemical reagents used were purchased from Aldrich. The ligands $Ph_2P(Se)NHPPh_2$ [23] and $Ph_2P(Se)N\{(S)\text{-}CH(CH_3)Ph\}PPh_2$ [31] were prepared according to published procedures.

2.3.1. trans-[Ni{$Ph_2P(Se)NPPh_2$-*Se*,*P*}$_2$] (**1**)

^{t}BuOK (0.0591 g, 0.5 mmol) was added to a solution of $Ph_2P(Se)NHPPh_2$ (0.2322 g, 0.5 mmol) in methanol (20 mL) and the mixture was stirred at room temperature for 30 min. $NiCl_2\cdot 6H_2O$ (0.0594 g, 0.25 mmol) was subsequently added to the mixture, which was stirred for additional 2 h. The resulting dark green precipitate was removed by filtration, washed with methanol (2 × 10 mL) and dried *in vacuo*. Yield: 0.1841 g, 0.1868 mmol, 75%. *Anal.* Calc. for $C_{48}H_{40}N_2NiP_4Se_2$: C, 58.51; H, 4.09; N, 2.84. Found: C, 57.54; H, 4.34; N, 2.79%. IR (cm^{-1}) ν(P–N–P) 1127, ν(P–Se) 541. $^{31}P\text{–}\{^1H\}$ NMR ($CDCl_3$): $\delta = 89.5$ [t, P(Ni), N 167.2 Hz], $\delta = 57.9$ [t, P(Se), N 166.9 Hz].

2.3.2. trans-[Ni{$Ph_2P(Se)NPPh_2$-*Se*,*P*}{$Ph_2P(Se)N(H)PPh_2$-*Se*,*P*}]$Cl\cdot CH_2Cl_2\cdot H_2O$ (**2**)

An appropriate amount of the ligand $Ph_2P(Se)N\{(S)\text{-}CH(CH_3)Ph\}PPh_2$ (0.1000 g, 0176 mmol) was added to a solution of $NiCl_2\cdot 6H_2O$ (0.0418 g, 0.176 mmol) in THF (10 mL). The mixture was stirred for 8 h. During the first hour, the colour of the mixture was dark red and finally changed to brown. The brown precipitate, obtained by addition of 15 mL of Et_2O, was then removed by filtration and dried *in vacuo*. Crystals were obtained from a 1:3 mixture of CH_2Cl_2/*n*-hexane.

3. Results and discussion

3.1. Synthesis and spectroscopic study

The reaction of $Ph_2P(Se)NHPPh_2$ with $NiCl_2\cdot 6H_2O$, in the presence of ^{t}BuOK for the *in situ* deprotonation of the ligand, gave **1** in satisfactory yield, according to the metathesis reaction:

$$2[K\{Ph_2P(Se)NPPh_2\}] + NiCl_2\cdot 6H_2O \rightarrow [Ni\{Ph_2P(Se)NPPh_2\}_2] + 2KCl + 6H_2O$$

Single crystals of **1** were obtained by adding *n*-hexane into a CH_2Cl_2 solution of **1**. It is of interest to note that an attempt, in a different experiment, to synthesize [Ni{$Ph_2P(Se)NHPPh_2$-*Se*,*P*}Cl_2] by mixing equivalent amounts of [Ni$(PPh_3)_2Cl_2$] and $Ph_2P(Se)NHPPh_2$, in the absence of ^{t}BuOK, afforded crystals, the analysis of which revealed the formation of **1**.

On the other hand, crystals of **2** were isolated while studying the reaction between $NiCl_2\cdot 6H_2O$ and the ligand $Ph_2P(Se)N\{(S)\text{-}CH(CH_3)Ph\}PPh_2$ [31]. The IR spectrum of these crystals showed

the presence of N–H bond [3042 cm^{-1}, ν(N–H)], while the ^{31}P NMR showed additional peaks compared to the triplets of **1** (*vide infra*). Therefore, the crystals were studied by X-ray crystallography but no attempt was made to analyse their IR and NMR spectra. The structure of **2** contains one Ni–Se–P–N(H)–P and one Ni–Se–P–N–P five-membered ring (*vide infra*). Therefore, cleavage of the N–C bond and removal of the –C{CH(CH_3)Ph} moiety is responsible for the formation of **2**. A similar observation was previously reported concerning the interaction of M(III) precursors, M = Rh, Ir, with the same ligand $Ph_2P(Se)N\{(S)$-CH(CH_3)Ph$\}PPh_2$, in acetone, which resulted in the formation of the $[(Cp^*)MCl\{Ph_2P(S)NHPPh_2$-*S*,*P*$\}]BF_4$ complexes [19]. The correlation between this type of cleavage reactions and the nature of the solvent in which the reaction takes place will be further investigated.

Fig. S1 shows the electronic spectrum of **1** in CH_2Cl_2. A band at 378 nm is well defined (ε = 5860 M^{-1} cm^{-1}), whereas there are two shoulders at 270 and 307 nm (ε = 27 660 and 19 190 M^{-1} cm^{-1}). Owing to the rather large extinction coefficients determined, most likely these bands correspond to charge transfer transitions [35]. From the spectrum of **1**, it was not possible to clearly identify any bands due to d–d transitions, although a very broad and not well defined feature is observed at about 490 nm, in agreement with the spectra of typical square–planar complexes of Ni(II) [35].

One of the most characteristic IR peaks of chalcogenated imidodiphosphinate systems is due to ν(P–E), which in the case of **1** is observed at 541 cm^{-1} [ν(P–Se)]. Since the free ligand $Ph_2P(Se)NHPPh_2$ exhibits the corresponding IR peak at 551 cm^{-1} [23], it is concluded that the P–Se bond in **1** is slightly weakened compared to the free ligand. This is a typical observation concerning the coordination chemistry of either bis-chalcogenated or monooxidised imidodiphosphinate ligands [2–5].

The assignments in the ^{31}P NMR spectrum of the two different P atoms of **1**, namely the metal bound, P(Ni), and Se-bound, P(Se), are based on the fact that the former is less shielded than the latter. This is borne out by the fact that the P(Se)–N bond is stronger compared to the corresponding P(Ni)–N bond (*vide infra*). The ^{31}P NMR spectrum of **1** (Fig. 1), shows a pair of mutually coupled triplets, consisting of an AA′XX′ type pattern. These triplets are "deceptive" since, based on the structure of **1**, a pair of mutually coupled doublets would have been expected instead. Similar patterns were previously observed in analogous complexes, like *trans*-$[M\{Ph_2P(Se)CH_2PPh_2$-*Se*,*P*$\}_2]^{2+}$, M = Pt [36], Pd [37], *trans*-$[M\{Ph_2P(Se)N(H)PPh_2$-*Se*,*P*$\}_2]^{2+}$, M = Pd [23], Pt [23] and *trans*-$[Ni\{^iPr_2P(Se)NP^iPr_2$-*Se*,*P*$\}_2]$ [38]. In all these cases, the separation of the outermost lines of each triplet, N [= J(A–X) + J(A–X′)], is reported [23]. In the case of **1**, the values of N are 167.2 and 166.9 Hz. The above pattern in the ^{31}P NMR spectrum of **1** shows that the *trans*-Ni(*Se*,*P*)$_2$ arrangement, observed in the solid state, is maintained in solution. Moreover, the ^{31}P chemical shifts in **1** are in the diamagnetic part of the spectrum, which provides evidence that the geometry of the $NiSe_2P_2$ core of the complex remains square–planar in solution. This is in contrast to the analogous square–planar $NiSe_4$-containing complexes, in which the corresponding ^{31}P NMR peaks are in the paramagnetic part of the spectrum, most likely due to the formation of tetrahedral $NiSe_4$ centers, as was shown in the case of $[Ni\{^iPr_2P(Se)NP(Se)^iPr_2$-*Se*,*Se*$\}_2]$ [8]. The above difference shows that in the latter case the coordination sphere, which contains six-membered chelating rings, is more flexible in solution compared to complex **1** with five-membered rings.

3.2. Molecular structures

The structures of **1** and **2** were determined by single crystal X-ray diffraction. The crystal data and refinement characteristics are shown in Table 1. Selected bond lengths and angles are listed in Table 2. In the case of **2**, data are shown separately for its two five-membered rings. The only available crystallographic structures for monooxidised imidodiphosphinate ligands are for $Ph_2P(O)NHPPh_2$ [10] and $^iPr_2P(Se)NHP^iPr_2$ [39]. Therefore, it is not possible to make direct comparisons with the structures of **1** and **2**. However, from the data of Table 2, we can draw the conclusions described in the following paragraphs.

3.2.1. *trans*-[Ni{$Ph_2P(Se)NPPh_2$-*Se*,*P*}$_2$] (**1**)

The ORTEP representation of the crystal structure is shown in Fig. 2. The crystals of **1** contain discrete monomeric molecules, exhibiting square–planar $NiSe_2P_2$ cores, in which Ni(II) ions are coordinated by two (*Se*,*P*) chelates in *trans* arrangement. Overall, the structure contains a center of symmetry, and therefore the two five-membered Ni–Se–P–N–P rings are identical. The equivalent equatorial Ni–Se and N–P bond lengths are 2.296 and 2.239 Å, respectively, and very similar to the corresponding bond

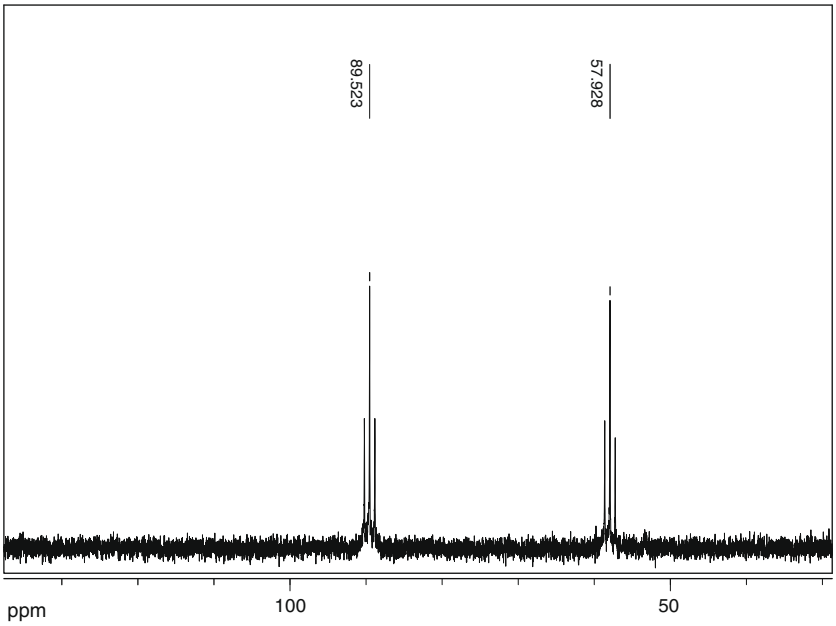

Fig. 1. ^{31}P NMR spectrum of **1** in $CDCl_3$.

P1–Ni–Se′	88.84(3)	(P2–Ni–Se2) 87.98(2), (P4–Ni–Se1) 90.18(2)	

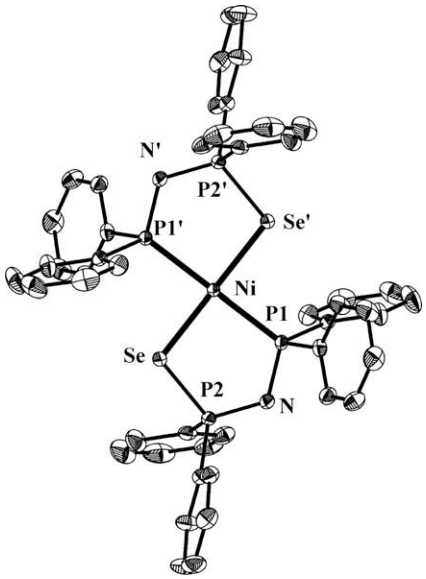

Fig. 2. Partially labelled ORTEP plot of **1** with ellipsoids drawn at the 30% probability level. Primed atoms are generated by symmetry (′ = −*x*, 1−*y*, −*z*).

lengths (2.305 and 2.239 Å, respectively) in the recently characterized *trans*-[Ni{^{i}Pr$_2$P(Se)NP^{i}Pr$_2$-*Se*,*P*}$_2$] complex [38]. The Se–Ni–P and P–N–P angles in **1** (91.16 and 118.42°) and the latter complex (91.33 and 119.03°) are also very similar. Therefore, the difference of the R peripheral groups in the two complexes (Ph or ^{i}Pr) has no effect in their structural characteristics. This observation is in contrast to the marked difference between the corresponding [Ni{Ph$_2$P(Se)NP(Se)Ph$_2$-*Se*,*Se*}$_2$] and [Ni{^{i}Pr$_2$P(Se)NP(Se)^{i}Pr$_2$-*Se*,*Se*}$_2$] complexes, since the former crystallizes in square–planar [30] and the latter in a mixture of tetrahedral and square–planar NiSe$_4$ polymorphs [8]. It is concluded that the six-membered Ni–Se–P–N–P–Se rings in these complexes provide structural flexibility to the NiSe$_4$ core, the geometry of which is affected by the nature of the R groups, not only in solution (*vide supra*) but also in the solid state. This is in contrast to the corresponding five-membered Ni–Se–P–N–P rings of **1** and *trans*-[Ni{^{i}Pr$_2$P(Se)NP^{i}Pr$_2$-*Se*,*P*}$_2$] [38], which maintain a rather rigid square–planar NiSe$_2$P$_2$ coordination sphere, irrespective of the nature of the R groups.

The P–N bond lengths in Ni{Ph$_2$P(Se)NP(Se)Ph$_2$-*Se*,*Se*}$_2$] are almost identical (1.600 and 1.602 Å) [30]. On the other hand, in the case of **1**, these bond lengths are not equal (P2–N, 1.586 and P1–N, 1.639 Å). Therefore, the P–N bond adjacent to the Se atom is strengthened, whereas the other P–N bond is weakened, compared to the P–N bonds in Ni{Ph$_2$P(Se)NP(Se)Ph$_2$-*Se*,*Se*}$_2$]. Related to the above effects, it should be noted that the Ni–Se bond length in **1** (2.296 Å) is smaller by 0.054 Å compared to the Ni–Se bond lengths (average 2.350 Å) in [Ni{Ph$_2$P(Se)NP(Se)Ph$_2$-*Se*,*Se*}$_2$] [30]. For comparison, the Ni–P bond lengths of **1** (2.239 Å) and [Ni{Ph$_2$PNPPh$_2$-*P*,*P*}$_2$] (2.222 Å) [29] differ only by 0.02 Å. These differences might be justified by the higher electronegativity of Se compared to P, which, in complex **1**, would result in electron density flow from N to P2 to Se. A similar trend is also observed in the case of *trans*-[Ni{^{i}Pr$_2$P(Se)NP^{i}Pr$_2$-*Se*,*P*}$_2$] [38], which should be extended in other systems containing five-membered M–E–P–N–P rings by the coordination of monooxidised imidodiphosphinate ligands [10–26].

By comparing the endocyclic angles X–Ni–Y, X, Y = P, P or Se, P or Se, Se, in [Ni{Ph$_2$PNPPh$_2$-*P*,*P*}$_2$] (67.43°) [29], complex **1** (91.16°) and [Ni{Ph$_2$P(Se)NP(Se)Ph$_2$-*Se*,*Se*}$_2$] (99.41°) [30], it is obvious that only **1** exhibits an angle very close to the value of the ideal square–planar geometry, a fact that should be critical in conserving its square–planar NiSe$_2$P$_2$ core geometry in solution (*vide supra*).

3.2.2. *trans*-[Ni{Ph$_2$P(Se)NPPh$_2$-*Se*,*P*}{Ph$_2$P(Se)N(H)PPh$_2$-*Se*,*P*}]Cl·CH$_2$Cl$_2$·H$_2$O (**2**)

The ORTEP representation of the crystal structure is shown in Fig. 3. The crystal was shown to contain the [Ni{Ph$_2$P(Se)NPPh$_2$-*Se*,*P*}{Ph$_2$P(Se)N(H)PPh$_2$-*Se*,*P*}]$^{+}$ ion, along with a Cl^{-} as a counter ion, one solvent molecule (CH$_2$Cl$_2$) and a H$_2$O molecule. As in the case of **1**, the system contains square–planar NiSe$_2$P$_2$ cores, in which Ni(II) ions are coordinated by two (*Se*,*P*) chelates in *trans* arrangement. However, unlike **1**, complex **2** contains two different rings, one protonated at the N atom, Ni–Se–P–N(H)–P, and one unprotonated, Ni–Se–P–N–P, a fact that introduces asymmetry to the system, and affects the bond lengths and angles (Table 2). The Ni–Se bond lengths in **2** are rather similar to those in **1**. On the other hand, a notable difference is the *ca.* 0.03 Å decrease in the Ni–P2 bond length, in the Ni–Se–P–N(H)–P ring, compared to both the Ni–Se–P–N–P ring of **2**, as well as of **1**.

The trend in the P–N bond lengths described above for **1** is conserved in **2** (Table 2). Moreover, the presence of the N–H bond in the Ni–Se–P–N(H)–P ring of **2** weakens the P–N bonds compared to both the Ni–Se–P–N–P ring of **2**, as well as of **1**, since part of the electronic density of N is devoted to the N–H bond formation.

With respect to the angles in **1** and **2**, Table 2 shows that these are rather similar between **1** and the Ni–Se–P–N–P ring of **2**, but

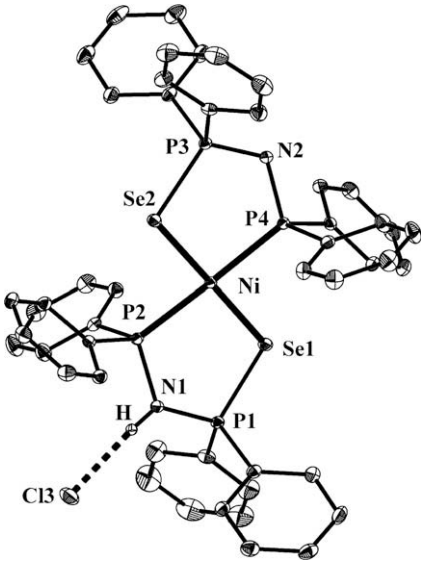

Fig. 3. Partially labelled ORTEP plot of **2** with ellipsoids drawn at the 30% probability level.

there are notable differences in the angles of the Ni–Se–P–N(H)–P ring of **2**. For instance, the P–N–P angle in the latter is increased by 2.7°, whereas the N–P–Se angle is decreased by 3.9°, compared to the Ni–Se–P–N–P ring of **2**. Moreover, the P–N–P angle in the Ni–Se–P–N(H)–P ring of **2** is larger by 1.7° compared to the equivalent P–N–P angles of **1**. Also, the P–Se–Ni angle in the Ni–Se–P–N(H)–P ring of **2** is larger by 3.3°, whereas the N–P–Se is smaller by 3.8° and the N–P–Ni smaller by 3.3° compared to the corresponding angles of **1**. The P–N–P angles in other complexes containing M–Se–P–N(H)–P rings are close to 120° [21,23], indicating an sp^2 hybridization of the N atom [40].

It is of interest that in the case of [Pd{$Ph_2P(S)NP(S)Ph_2$-*S*,*S*}{$Ph_2P(S)N(H)P(S)Ph_2$-*S*,*S*}]Cl [41], which contains one Ni–S–P–N(H)–P–S and one Ni–S–P–N–P–S six-membered ring, the latter contains longer P–S bonds and shorter P–N bonds compared to the former [41]. However, the angles in the two rings are rather similar [41], unlike what has been described above for **1** and **2**.

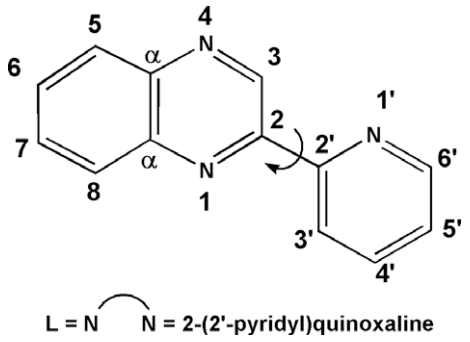
In [Pd{$Ph_2P(S)NP(S)Ph_2$-*S*,*S*}{$Ph_2P(S)N(H)P(S)Ph_2$-*S*,*S*}]Cl [41], the counter ion Cl^- is hydrogen bonded to the Ni–S–P–N(H)–P–S ring (distances H···Cl 2.20 Å, N···Cl 2.93 Å and angle N–H···Cl 134°) [41]. In the case of the Ni–Se–P–N(H)–P ring of **2**, the analogous distances and angle are H···Cl, 2.19 Å, N···Cl, 3.01 Å and N–H···Cl, 175.2°. The situation is analogous to other systems which contain M–Se–P–N(H)–P five-membered rings, like *trans*-[Pt{$Ph_2P(Se)N(H)PPh_2$-*Se*,*P*}$_2$]Cl_2 [23] and [Ag{$Ph_2P(Se)N(H)PPh_2$-*Se*,*P*}$_2$]Br [21].

The atoms that are coordinated to the Ni(II) ions in **1** and **2** are in the same plane. The five-membered rings exhibit a pseudo-boat conformation. The protonation at the N atom of one ring in **2** does not seem to cause major changes to the ring conformation.

4. Conclusions

The work described here adds more information on the structural and spectroscopic properties of coordination compounds containing monooxidised imidodiphosphinate ligands. The main conclusions drawn from the analysis of spectroscopic and structural data, are the following: (i) The square–planar *trans*-Ni(*Se*,*P*)$_2$ arrangement in **1,** established in the solid state by X-ray crystallography, is maintained in solution and justifies the "deceptive" triplets in the diamagnetic part of its ^{31}P NMR spectrum. (ii) Availability of the structures of **1** and **2** makes possible to establish structural effects due to the higher electronegativity of Se compared to P, as well as to the protonation/deprotonation at the N atom of the five-membered rings. These effects will be further probed by appropriate theoretical calculations, as in the case of the analogous bis-chalcogenated imidodiphosphinate ligands and their complexes [40]. In addition, the NMR properties of **1** will be further investigated by studies in the solid state [42].

Acknowledgements



We would like to thank the Special Account of the University of Athens (Grant 70/4/7575), as well as the Empirikion Foundation, for funding. Eleftherios Ferentinos is thanked for technical assistance and helpful discussions. This article is dedicated with gratitude to Dr. Aris Terzis, whose contribution, over the years, to the advancement of our projects, has been invaluable.

Appendix A. Supplementary data

CCDC 721470 and 721471 contains the supplementary crystallographic data for **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk. Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.poly.2009.05.006.

Scheme 1. Structural formula of the 2-(2′-pyridyl)quinoxaline ligand.

source of rhodium(III), along with conducting preliminary biological tests.

In this paper we report on the synthesis and complete characterization of a new rhodium(III) complex, namely *cis*-$[Rh(pqo)_2Cl_2]Cl$ (**1**) together with early results on the inhibitory effect of this compound on PAF-induced rabbit platelet aggregation.

Platelet Activating Factor (PAF), characterized mainly as 1-*O*-alkyl-2-acetyl-sn-glycero-3-phosphochloline [13], is a potent lipid mediator expressed upon inflammation, oxidation or thrombosis [14] (Scheme 2). PAF exhibits its effects at exceptionally low concentrations (10^{-12}–10^{-9} M) through the specific PAF receptor (PAF-R), a transmembrane receptor located in the cell membrane of its target-cells, such as platelets, neutrophils, macrophages, leukocytes and endothelial cells [15].

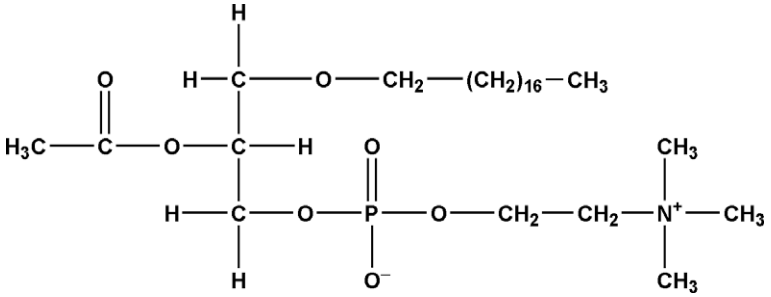
This mediator participates in both physiological processes (reproduction, haemostasis, neurotransmission, gastrointestinal, vascular homeostasis and kidney function) and in pathological conditions (inflammation, allergy asthma, acute pancreatitis, bowel disease, pulmonary disease, diabetes, cancer, renal damages, pulmonary tissue injury, organ transplantation rejection, and septic shock). Given the spectrum of target cells and tissues, it seems likely that PAF may play an integral role in both pathological and physiological aspects of inflammation throughout the body [16].

Due to the involvement of the Platelet Activating Factor in cancer disease [15] as a next step we are interested to examine the cytotoxicity of this and other rhodium(III) species prepared in our laboratory. Preliminary results towards this goal will be presented in due course.

2. Experimental

2.1. Reagents and materials

All manipulations were performed under aerobic conditions and all chemicals and solvents used in this study were of analytical grade and used as received without further purification. $RhCl_3{\cdot}3H_2O$ was purchased from Johnson Matthey Co. The ligand 2-(2′-pyridyl)quinoxaline (L = pqo) was synthesized according to already published procedures [9].



2.2. Physical measurements

Infrared spectra were measured with Perkin–Elmer 883 spectrometer and a Nicolet 550 Magna-IR™ spectrometer as potassium bromide pellets in the spectral range of 4000–400 cm^{-1}. The far-IR measurements were recorded on a Bruker Optics IFS-55 spectrometer as polyethylene plates in the range of 480–100 cm^{-1} with a 4 cm^{-1} spectral resolution. Micro-Raman spectra were measured in backscattering configuration using a Renishaw inVia Reflex microscope with an Ar^+ ion laser (λ = 514.5 nm) and a high power near infrared (NIR) diode laser (λ = 785 nm) as excitation sources. The C, H, N analyses were carried out on a Perkin Elmer 2400 CHN elemental analyzer. Melting or decomposition points were determined using an Electrothermal 9100 (IA9000 series) Digital melting point apparatus and are uncorrected. Absorption spectra were recorded using a CARY 3E UV–Vis spectrometer. ^1H and $^{13}C\{^1H\}$ NMR spectra were measured with a Bruker Avance 500 MHz and a Varian 300 MHz spectrometers in $(CD_3)_2SO$. The ^1H NMR signals of the 2-(2′-pyridyl)quinoxaline ligand in complex **1** were assigned by two dimentional ^1H–^1H, ^1H–^{13}C COSY experiments. Electrospray ionization mass spectra (ESI-MS) were performed using a TSQ 7000 Finnigan Mat spectrometer.

2.3. Synthesis

2.3.1. Synthesis of *cis*-$[RhL_2Cl_2]Cl$ (**1**)

In a two-necked round-bottomed flask 0.105 g (0.385 mmol) of $RhCl_3{\cdot}3H_2O$ was suspended in 5 ml of MeOH. 0.222 g (1.07 mmol) of the ligand pqo dissolved in MeOH (20 ml) was added slowly under stirring to the suspension above. Upon addition, the color of the suspension changed from violet to orange–yellow with the precipitation of an orange solid. The mixture was then heated to a gentle reflux for about 45 min. After 10 min of heating the orange solid was dissolved giving an orange–yellow solution. The slightly cloudy solution was filtered and the clear filtrate was concentrated to the third of the volume and stored in a −20 °C refrigerator overnight. The yellow solid precipitated was washed with small amounts of cold MeOH (4 ml), cold Et_2O (2 × 10 ml) and dried *in vacuo*. The microcrystalline product (0.2 g) was redissolved in hot MeOH (10 ml) filtered off and the clear solution was cooled at ambient temperature. The methanol solution was then placed in the refrigerator for crystallization via slow diffusion of diethyl ether. Some crystals were used for X-ray diffraction measurement and the bulk material was washed with small amounts of Et_2O and dried in vacuo at 50 °C for about 5 h. Yield: 0.12 g (50%). M.p: 190 °C (dec). *Anal.* Calc. for **1** × **1.5**(**H_2O**) $C_{26}H_{21}Cl_3N_6O_{1.5}Rh$ (650.75 g mol^{-1}): C, 47.99; H, 3.25; N, 12.91; Cl, 16.34. Found: C, 48.11; H, 3.05; N, 13.09; Cl, 16.25%. IR (KBr, $\tilde{\nu}$ in cm^{-1}): 3022(w,

ESI (*m/z*, QMS, MeOH): 587 (M^+, 100%), 551 (M^+-Cl, 90%), 515 (M^+-2Cl, 25%), 208 ($L+1^+$, 0.5%).

2.3.2. Crystal structure determination

Yellow needles and yellow prismatic single crystals of **1**·2CH_3OH were obtained upon slow diffusion of diethylether into a methanolic solution of the complex at +6 °C. Diffraction measurements were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo radiation. Important crystal data and parameters for data collection are reported in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11° < 2\theta < 23°$. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization corrections were applied using Crystal Logic software. The structure was solved by direct methods using SHELXS-97 [17] and refined by least-squares techniques on F^2 with SHELXL-97 [18]. Intensity data were recorded using a θ–2θ scan. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. The methanol solvate molecules in the prismatic polymorph were found disordered and were refined over two positions with occupation factors fixed to 0.50; no-H atoms for these molecules were included in the refinement.

2.4. Biological assay

2.4.1. PAF-induced aggregation

Washed rabbit platelets were prepared as previously described [13b]. The biological activity of complex **1** against PAF-induced aggregation on washed rabbit platelets was tested. The experiments were performed using two different batches of platelets. The solutions of PAF and of the examined samples, after having being dried under nitrogen stream, were dissolved in 2.5 mg of bovine serum albumin (BSA)/ml of saline. In order to determine the inhibitory effect of each sample, the platelet aggregation induced by PAF (2×10^{-11} M, final concentration in the cuvette) was measured in the absence (0% inhibition) and in the presence of various concentrations of each sample. Consequently, the plot of percent inhibition (ranging from 20% to 80%) versus different sample concentrations is linear. From this curve, the concentration of the sample that inhibited 50% PAF-induced aggregation was calculated, and this value was defined as IC_{50} [13b]. Desensitization experiments were performed using PAF and samples, as previously described [19]. PAF-induced aggregation was measured in a Chrono-Log (Havertown, PA) aggregometer coupled to a Chrono-Log recorder (Havertown, PA). All reagents and chemicals were of analytical grade supplied from Merck (Darmstadt, Germany). PAF standard and BSA were obtained from Sigma (St. Louis, MO).

2.4.2. [^{3}H]-PAF binding to washed rabbit platelets

The experiments involving the specific binding of [^{3}H]-PAF to washed rabbit platelets and its inhibition by complex **1**, were performed as previously described with some modifications [20].

R_1/wR_2 (for data with $I > 2(\sigma)I$)	R_1 = 0.0420, wR_2 = 0.1225	R_1 = 0.0385, wR_2 = 0.1015

Briefly, [^{3}H]-PAF (1 nM), PAF (1 μM), and *cis*-[RhL_2Cl_2]Cl were diluted in BSA 2.5 mg/ml saline. [^{3}H]-PAF (1 nM) was mixed in the presence or absence of either PAF (1 μM) or *cis*-[RhL_2Cl_2]Cl in various quantities and the volume was adjusted in 100 μl with BSA 2.5 mg/ml saline. The mixture was placed in 360 μl of Tg–Ca^{2+} buffer pH 7.2 (tyrode's buffer pH 7.2 containing $CaCl_2$ 1.72 mM) and the incubation started by adding 40 μl of the washed rabbit platelet suspension (1×10^8 platelets in Tg buffer pH 6.2) at 22 °C for 4 min. Each sample concentration was tested twice and incubation was terminated by adding 0.7 ml ice cold Tg–Ca^{2+} buffer pH 7.2, followed by rapid centrifugation at 11500*g* for 2 min at 4 °C on a Heraeus Labofuge 400R (Hanau, Germany). The specific PAF antagonist, BN 52021, was used as a reference compound [21]. The radioactivity was measured by scintillation counting on a 1209 Rackbeta liquid scintillation counter from Pharmacia (Wallac, Finland). Nonspecific binding was defined as the total binding measured in the presence of excess unlabelled PAF (1 μM) and specific binding was defined as the difference between total binding and nonspecific binding. The percent inhibition was expressed as $\%I = [(\text{total binding} - \text{total binding with tested compound})/\text{specific binding}] \times 100$. The IC_{50} value was defined as the concentration of inhibitor required to obtain 50% inhibition of the PAF specific binding. Scatchard analysis was performed with GRAPHPAD PRISM software (San Diego, Calif, USA). All reagents were purchased by Sigma (St. Louis, MO) unless otherwise stated.

3. Results and discussion

The mononuclear rhodium(III) complex of the formula *cis*-[Rh(pqo)$_2$Cl$_2$]Cl (**1**) was synthesized by a one-pot procedure from the direct reaction of the pqo ligand with $RhCl_3 \cdot 3H_2O$ in a 1:2 molar ratio (Scheme 3). Under the same conditions the reaction of the metal salt with the ligand in the 1:3 (M:L) molar ratio yields complex **1** [22].

After work up of the reaction mixture, the cationic rhodium(III) complex **1** was obtained analytically pure as an orange–yellow solid in 50% yield. This was possible by following a simple crystallization method, i.e. crystallization of the crude product, avoiding therefore the use of time consuming column chromatography. It is an air stable solid that shows remarkable thermal stability and decomposes upon heating at 190 °C. It dissolves well in methanol, ethanol, H_2O, DMF and DMSO, while is less soluble in $CHCl_3$ and insoluble in Et_2O and pentane. The composition of **1** was confirmed by elemental analyses and the spectroscopic properties was examined by FT-IR, FT-Raman, UV–Vis, ^{1}H, ^{13}C NMR spectroscopy and by two-dimensional ^{1}H–^{1}H, ^{1}H–^{13}C COSY experiments. The molecular composition of the rhodium(III) complex was further confirmed by mass spectrometric data (electrospray). All analytical data are in accord with the proposed formulation. The molecular structure of **1**·2CH_3OH was determined by single-crystal X-ray diffraction (vide infra).

Scheme 3. Synthesis of complex **1**.

3.1. IR and Raman spectroscopic data

In the FT-IR spectrum of complex **1** the characteristic in-plane and out-of-plane pyridyl ring deformation bands at 620 and 401 cm^{-1} in free ligand L [9], are shifted to higher frequencies at 669 and 444 cm^{-1}, respectively indicating coordination through the pyridyl nitrogen atom N(1) [23] (see Scheme 1). Also the appearance of a sharp single band at 972 cm^{-1} characterizes the monodentate quinoxaline coordination [24]. The far-IR spectrum of complex **1** in polyethylene exhibits medium intensity bands at 334 and 343 cm^{-1} due to terminal Rh–Cl stretching vibrations [25] in the typical region observed for similar compounds supporting a *cis*-arrangement of the Cl atoms [26]. The Rh–Cl stretching mode of **1** has a slightly lower frequency than those of *cis*-[$Rh(bpy)_2Cl_2$]Cl·2H_2O (350 and 355 cm^{-1}), *cis*-[$Rh(phen)_2Cl_2$]Cl·3H_2O (348 and 353 cm^{-1}) [27] and the related *cis*-[$Rh(pq)_2Cl_2$]Cl complex (pq = 2-(2′-pyridyl)quinoline; 350 and 365 cm^{-1}) [28] reflecting the weaker bonding of Cl to the rhodium center in complex **1**. The low frequency region of the spectrum exhibits weak vibration bands at 269 and 211 cm^{-1}, assignable to ν(Rh–N) vibrations (vide infra).

Fig. 1 compares the solid state Raman spectra of the pqo ligand (L) at 785 nm and the complex **1** at both 514.5 and 785 nm. The luminescence background has been subtracted from the Raman spectra by polynomial fitting and/or cubic spline interpolation routines. However, in the case of the pqo ligand, the strong luminescence precluded detection of the Raman spectrum at 514.5 nm. The NIR Raman spectrum of L (upper trace in Fig. 1) shows distinct vibrational bands at 535, 772, 1369 and 1408 cm^{-1} that lie close to the skeletal bending (536 and 759 cm^{-1}) and ring stretching (1370 and 1416 cm^{-1}) modes of quinoxaline [29]. In addition, several intense bands of the pqo ligand can be identified with those of bipyridine [30] and terpyridine [31] ligands, namely the characteristic ring deformation mode at 997 cm^{-1}, the pyridine ring stretching modes at 1550–1595 cm^{-1} and the strong band at 1321 cm^{-1} arising from the inter-ring C–C vibrations of terpyridine. Significant differences are detected in the corresponding NIR Raman spectrum of complex **1** (middle trace in Fig. 1). Strong Raman bands are observed at 1613, 1603, 1575, 1542, 1485, 1369, 1360, 1348, 1042, 785, 343, 152, 140 and 111 cm^{-1}. The modes at wave numbers above 700 cm^{-1}, comply favorably with previous non-resonant Raman data on coordination compounds containing the 2-(2′-pyridyl)quinoxaline ligand as a bidentate chelate with the pyridine nitrogen and the nearest quinoxaline nitrogen acting as donor atoms to Pd [11h], Cu [32] and Re [33] metal atoms. According to

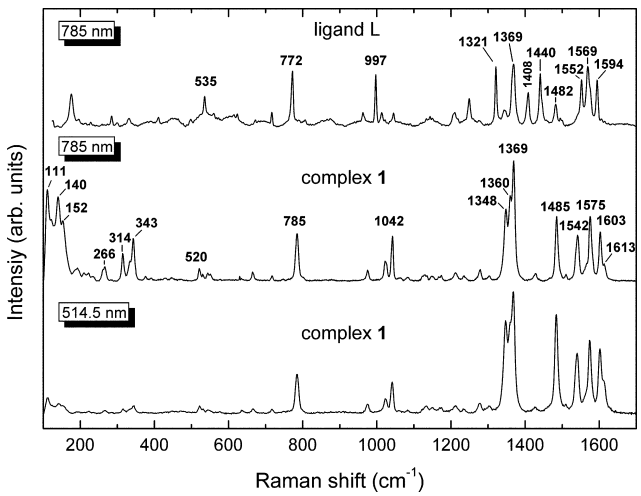

Fig. 1. Micro-Raman spectrum of the ligand (L) and complex **1** in powder form.

density functional theoretical calculations of the normal vibrational modes of these complexes [32,33], the high frequency modes at 1500–1600 cm^{-1} are mostly pyridine based vibrations, while the intense mode at 1485 cm^{-1}, is largely localized on the quinoxaline ligand. A similar but weaker band is also observed in the free 2-(2′-pyridyl)quinoxaline ligand (upper trace in Fig. 1).

At lower frequency, the Raman spectrum of **1** reveals one strong and a medium intensity band for the ν_s(Rh–Cl) stretching mode at 314 and 343 cm^{-1}, respectively. The latter appears as a shoulder with an extra band at 334 cm^{-1}. The band at 266 cm^{-1}, are probably due to the ν(Rh–N) vibrations [25].

Excitation with the green laser line at 514.5 nm results in a significant variation of the relative intensity distribution of most vibrational bands compared to the NIR Raman spectra, as shown in the lower trace of Fig. 1. The intensity of the Raman bands at wave numbers above 700 cm^{-1} becomes considerably enhanced with respect to the lower frequency bands, especially for the higher frequency modes (1300–1650 cm^{-1}), which are mostly localized on the pqo ligand. This is particularly prominent for the quinoxaline based mode at 1485 cm^{-1}. This behavior is consistent with previous resonance Raman studies on 2-(2-pyridyl)quinoxaline metal complexes, where laser excitation with energies around the metal-to-ligand charge transfer (MLCT) transition at 420–450 nm, cause the enhancement of the resonating vibrational modes [32,33]. In the present case, the laser excitation at 514.5 nm approaches the weak MLCT band in the visible range of complex **1**, causing the enhancement of the high frequency modes that involve mostly the vibration of the pyridyl-quinoxaline ligand. This would further indicate that the corresponding MLCT transition is mainly associated with the redistribution of the electron density in the ligand system, in agreement with the resonance Raman study of [Re(pqo)$(CO)_3$Cl] [33].

3.2. Absorption spectra

The absorption spectrum of complex **1** was recorded in methanol and is shown in Fig. 2. The electronic spectrum of the complex cannot be compared with this of the free ligand, due to different conformation in both cases (see NMR discussion as well). The UV–Vis spectrum of the ligand, in methanol, exhibits π–π^* transitions at 275 and 332 nm, respectively.

The electronic spectrum of the cation *cis*-$[RhL_2Cl_2]^+$ displays two ligand centered (LC) bands at 238 and 280 nm and the metal–ligand charge transfer bands (MLCT) as shoulder at 363 and 376 nm, respectively. In this region, MLCT and d–d transitions are present, hindering a complete assignment of the bands. In concentrated solutions, a weak band centered at approximately 540 nm (not seen in the spectrum of Fig. 2) could be responsible for the characteristic yellow color of the complex. These values are in good agreement with the reported data for the *cis*-[Rh$(phen)_2Cl_2$]Cl system [34]. The latter, presents the characteristic π–π^* transitions at 223 and 274 nm and the MLCT bands at 354 and about 380 nm, respectively. Other two bands at 300 nm (sh) and at 337 have also been reported in methanol as a solvent as well.

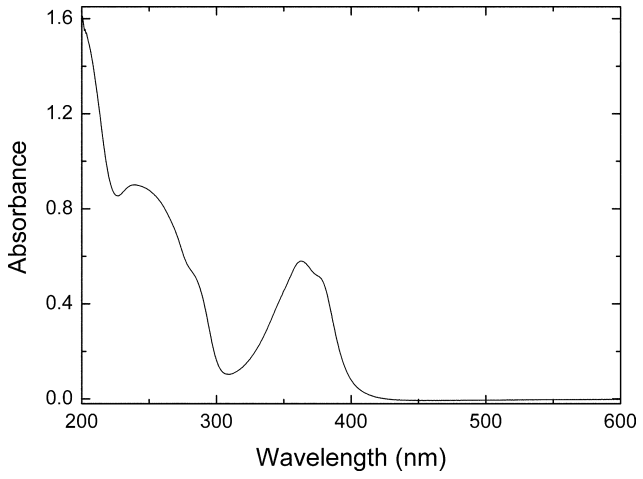

Fig. 2. UV–Vis absorption spectrum of **1** in methanol (2×10^{-4} M) at 298 K.

3.3. NMR spectra

The ^{1}H NMR spectrum of complex **1** was recorded in $(CD_3)_2SO$ at ambient temperature. Signal assignment is based on integration, splitting pattern, chemical shifts, ^{1}H–^{1}H and ^{1}H–^{13}C COSY experiments and literature values concerning similar systems [27].

The aromatic region of the spectrum of **1** displays well resolved narrow resonance signals for all the protons of the ligand as expected for diamagnetic Rh(III) complexes. Each signal corresponds to 2H as is indicated by integration. Upon chelation, the $H_{6'}$ proton is downfield shifted by 0.47 ppm compared to the free ligand [35] due to a decrease in the electron density of the pyridine ligand. Moreover, the chemical shifts of the $H_{6'}$ and $H_{3'}$ protons on going from the 2-(2′-pyridyl)quinoxaline ligand to complex **1** are downfield shifted by 0.73 and 0.88 ppm, respectively. An important feature of the spectrum of **1**, is the presence of a single resonance at δ = 10.34 ppm characteristic of the H_3 proton of the ligand. This pronounced downfield shift ($\Delta\delta$ = 0.46 ppm compared to the free ligand [35]) may be an indication that the N(4) atom of the quinoxaline ligand is coordinated to the meal center [10 m]. This further implies that the structure of **1** in solution is rather different from that in the crystal.

Finally, the ^{13}C{^{1}H} NMR spectrum of **1** reveals twenty six resonance signals in the aromatic region (δ = 120–160 ppm) corresponding to the pyridyl ring carbons. The downfield resonances at 156.5 and 154.3 ppm are assigned to $C_{2'}$, C_2 carbons that are near to the electron withdrawing nitrogen of the coordinated pyridine ring. The remaining carbon atoms were assigned on the basis of the ^{1}H NMR data and by ^{1}H–^{13}C COSY experiments.

3.4. X-ray crystallography

The solid-state structure of complex **1** was determined by single-crystal X-ray diffraction. During crystallization two polymorphs, yellow needles and yellow prismatic crystals, were obtained. The asymmetric unit of the crystal structure of **1** contains two molecules of methanol. The molecular structure of complex **1** crystallizing in the orthorhombic and triclinic crystallographic system is depicted in Figs. 3 and 4, respectively. Selected bond lengths and angles are given in Table 2. All data described below refer to needle like crystals.

In the molecular structure of **1**·$2CH_3OH$ the rhodium environment adopts a distorted octahedral geometry with the chlorine atoms *cis* to each other. This agrees with the results of the NMR studies in solution (vide supra). The 2-(2′-pyridyl)quinoxaline ligand acts in a bidentate manner through N(1), N(2) and N(11), N(12) adopting a *syn* conformation, where the pyridyl and quinoxaline nitrogen atoms are located on the same side of the C(5)–C(6) [C(25)–C(26)] bond. The deviation from the ideal octahedral geometry is shown by the angles N(1)–Rh–N(11) (175.3°(2)), N(1)–Rh–N(2) (80.1°(2)), N(1)–Rh–N(12) (103.2°(2)) and N(2)–Rh–N(12) (94.0°(2)), respectively. The bond lenghts within the coordinated ligand in **1** are in good agreement with the corresponding ones in the free ligand [9] and other pyridyl-quinoxaline complexes with different metal ions [11]. There are two sets of Rh–N

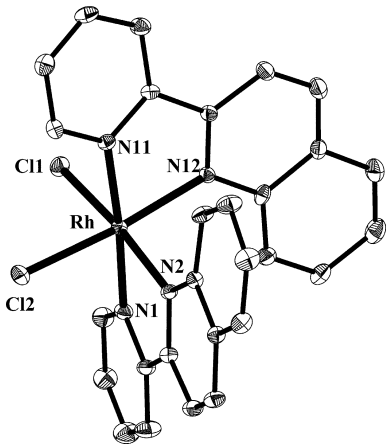

Fig. 3. A perspective view of the cation **1**·2(CH_3OH) in the solid state (needle like polymorph). Thermal ellipsoids are set at the 50% probability. Hydrogen atoms and solvate methanol molecules have been omitted for clarity.

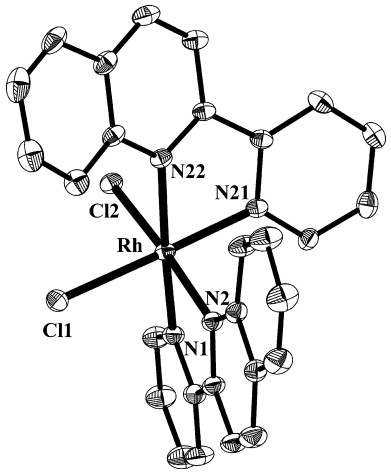

Fig. 4. A perspective view of the cation **1**·2(CH_3OH) in the solid state (prismatic polymorphs). Thermal ellipsoids are set at the 50% probability. Hydrogen atoms and solvate methanol molecules have been omitted for clarity.

distances. An average of 2.031 Å for the pyridyl moiety and 2.096 Å for the quinoxaline moiety, something that implies a stronger bonding of rhodium to the pyridyl nitrogen atoms (N(11) and N(1)). The Rh–Cl bond lengths of 2.318(2) Å (Rh–Cl(1)) and 2.308(2) Å (Rh–Cl(2)) are slightly shorter than those found in *cis*-$[Rh(bpy)_2Cl_2]Cl_2{\cdot}2H_2O$ [36] (Rh–Cl(1) = 2.341(2), Rh–Cl(2) = 2.328(2)) and in *cis*-$[Rh(phen)_2Cl_2]Cl_2{\cdot}H_2O$ [37] (Rh–Cl(1) = 2.329(2), Rh–Cl(2) = 2.320(2)). The atoms N(1), N(2) and C(1)–C(12) defining the (pyridyl)quinoxaline ligand, are planar and the rhodium atom lies 0.43 Å from the mean plane. The second 2-(2′-pyridyl)quinoxaline ligand defined by the N(11), N(12) and C(21)–C(32) atoms is also planar with the Rh atom almost lying on this plane (deviation 0.09 Å).

3.5. Biological activity

The IC_{50} value of **1** was measured as described in the experimental section and calculated to be 210 nM (towards 0.02 nM PAF). IC_{50} value represents the inhibitory potency of this compound against PAF-induced aggregation, thus the smaller the IC_{50} value is, the greater the inhibitory effect. The investigated compound inhibits PAF-induced platelet aggregation in a non-cytotoxic way, even at high concentrations. The respective BN 52021 IC_{50} value, is 24 600 nM (2.5 nM PAF) [21], meaning that the inhibitory effect of **1** is of the same order of magnitude. At 210 nM (IC_{50} value) the *cis*-$[RhL_2Cl_2]Cl$, induced 18% inhibition of PAF binding onto platelet PAF-R, whereas the highest *%I* was observed at 50 nM (34% inhibition). These data indicate that **1** inhibits PAF action on platelets and this effect is attributed only in part to the inhibition of PAF binding onto PAF-R. It seems that at low concentrations, **1** affects PAF-R much more effectively and inhibits PAF action in another pathway.

PAF has been implicated in carcinogenesis and cancer metastasis, whereas BN 52021 has antitumor effects [38]. Perhaps *cis*-$[RhL_2Cl_2]Cl$, that inhibits PAF action, may also be used as a potential anticancer agent.

Table 2
Selected bond lengths (Å) and angles (°) of **1**·2(CH_3OH). Data of both polymorphs are given.

Needles		Prisms

4. Conclusions

In summary, a new Rh(III) complex with the 2-(2′-pyridyl)quinoxaline ligand, synthesized in a one pot process, was fully characterized. The new complex crystallizes out from the mother liquor in two polymorphs, with two solvate methanol molecules. The molecular structures in the crystal of both polymorphs have been elucidated by X-ray crystallography. For the first time, an X-ray crystallographic analysis of the Rh(III) complex with the pqo ligand is described. The biological activity of *cis*-$[RhL_2Cl_2]Cl$ on PAF-induced rabbit platelet aggregation showed that this compound is a potent inhibitor with an IC_{50} value of 210 nM. In this study, compound **1** inhibited PAF action partly through PAF-R dependent way.

Our further efforts will be devoted to evaluating the anticancer activity of the new complex **1** and other similar complexes that are under investigation.

Acknowledgments

The authors express their gratitude to Prof. Dr. A.C. Filippou for access to the Central Analytical Group of the Chemistry Department of the University of Bonn. We also thank Dr. N. Weidemann of the same University for his help with the far-IR measurements.

Appendix A. Supplementary data

CCDC 720833 and 720834 contains the supplementary crystallographic data for the two polymorphs of **1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

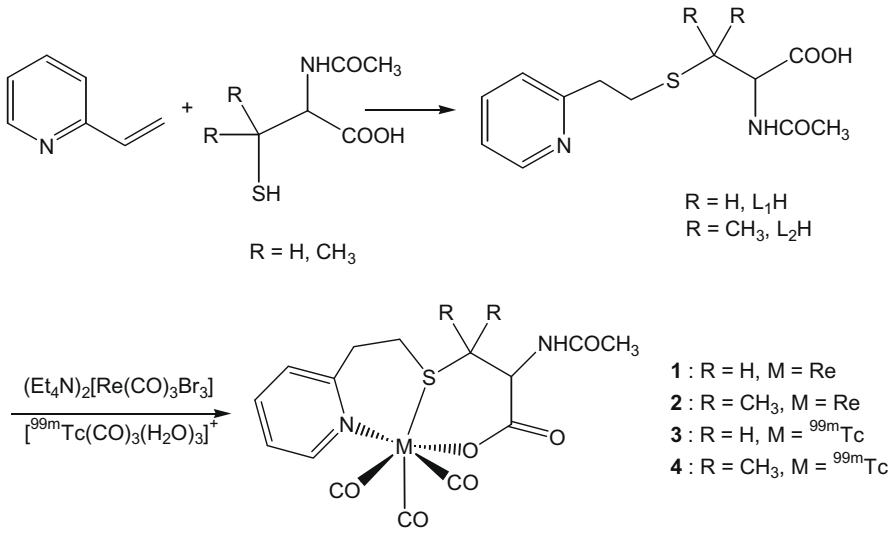

Fig. 1. Synthetic scheme of the ligands and complexes studied.

a novel bifunctional chelating system in the development of target-specific radiopharmaceuticals [12–14].

In this work, we present the synthesis of two *N*-acetylcysteine derivatized ligands, S-(2-(2-pyridyl)ethyl)-*N*-acetyl-L-cysteine, L_1H and S-(2-(2-pyridyl)ethyl)-*N*-acetyl-D-penicillamine, L_2H, as shown in Fig. 1, as well as the synthesis of their corresponding rhenium(I) and technetium(I) complexes. In these ligands the primary amine of the cysteine moiety is acetylated to allow coordination to the $[M(CO)_3]^+$ core through the pyridine nitrogen, the thioether sulfur and the carboxylate oxygen.

2. Experimental

2.1. Materials and methods

All reagents and organic solvents used in this study were purchased from Aldrich and used without further purification. Solvents for high-performance liquid chromatography (HPLC) were HPLC-grade. They were filtered through membrane filters (0.22 μm, Millipore, Milford, MA) and degassed by a helium flux before and during use. Ligand L_1H was prepared by a slightly modified method described elsewhere [15,16]. $[NEt_4]_2[Re(CO)_3Br_3]$ was prepared according to published procedure [17]. For ^{99m}Tc labelling, a kit containing 5.5 mg $NaBH_4$, 4 mg Na_2CO_3 and 10 mg Na–K tartarate, was purged with CO gas prior to addition of $Na^{99m}TcO_4$, as described in literature [6].

IR spectra were recorded as KBr pellets on a Perkin–Elmer 1600 FT-IR spectrophotometer in the region 4000–500 cm^{-1}. NMR spectra were recorded on a Bruker 500-MHz Avance DRX spectrometer using $(CH_3)_4Si$ as the internal reference. Elemental analyses for C, H and N were conducted on a Perkin–Elmer 2400 automatic elemental analyzer. HPLC analysis was performed on a Waters 600 chromatography system coupled to both a Waters 2487 Dual λ Absorbance detector and a Gabi gamma detector from Raytest. Separations were achieved on a Nucleosil C18 (10 μm, 250 × 4 mm) column eluted with a binary gradient system at 1 mL min^{-1} flow rate. Mobile phase A was methanol containing 0.1% trifluoroacetic acid and mobile phase B was water containing 0.1% trifluoroacetic acid. The elution profile was 0–1 min 100% B followed by a linear gradient to 30% B in 10 min; this composition was held for another 10 min. After a column wash with 95% A for 5 min, the column was re-equilibrated by applying the initial conditions (100% B) for 15 min prior to the next injection.

2.2. Synthesis of ligands, S-(2-(2-pyridyl)ethyl)-N-acetyl-L-cysteine, L_1H, and S-(2-(2-pyridyl)ethyl)-N-acetyl-D-penicillamine, L_2H

31 mmol of *N*-acetyl-L-cysteine or *N*-acetyl-D-penicillamine were dissolved in 100 ml methanol and 31 mmol of freshly distilled under vacuum 2-vinylpyridine were added dropwise. The reaction mixture was heated under reflux for 6 h. Methanol was then removed on a rotary evaporator and the remaining thick oil was recrystallized from ethanol.

L_1H: White needles, yield 92%. I.R. (KBr, cm^{-1}): 1720, 1646, 1606, 1534, 1487, 1445. *Anal. Calc.* for $C_{12}H_{16}N_2SO_3$: C, 53.71; H, 6.01; N, 10.44. Found: C, 52.75; H, 6.11; N, 10.65%. NMR (DMSO-d_6, ppm): 8.60, 8.40, 7.90, 7.80, 4.27, 3.26, 2.95, 2.78, 1.93.

L_2H: White needles, yield 90%. I.R. (KBr, cm^{-1}): 1705, 1662, 1603, 1539, 1442, 1371. *Anal. Calc.* for $C_{14}H_{20}N_2SO_3$: C, 56.73; H, 6.80; N, 9.45. Found: C, 56.45; H, 6.91; N, 9.19%. NMR (DMSO-d_6, ppm): 8.40, 8.20, 7.70, 7.50, 3.90, 3.05, 1.93, 1.05, 1.10.

2.3. Synthesis of rhenium complexes, $[Re(CO)_3(L_1)]$, **1** and $[Re(CO)_3(L_2)]$, **2**

Both complexes, **1** and **2**, were prepared according to the following procedure: A solution of L_1H or L_2H (0.2 mmol) in methanol (5 ml) and 0.2 ml NaOH 1 N were added under stirring to a solution of $[NEt_4]_2[Re(CO)_3Br_3]$ (0.154 g, 0.2 mmol) in methanol (10 ml). The mixture was heated under reflux for 2 h. The solution was then cooled at room temperature yielding white crystals which were filtered. The product was washed with CH_2Cl_2 and CH_3CN and characterized by spectroscopic methods and elemental analysis.

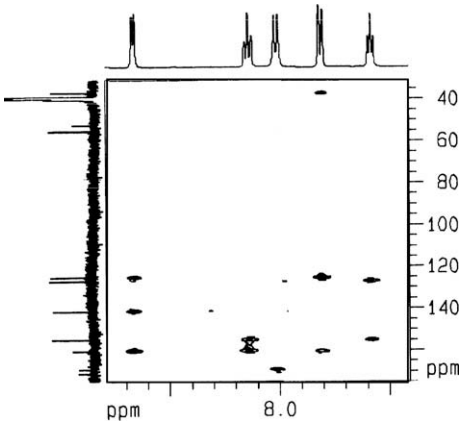

Fig. 2. ^{1}H–^{13}C long range correlation (HMBC) spectrum for complex **2** in DMSO-d_6 at 25 °C (range δH 8.79–7.41, range δC 175.0–30.9).

Goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined by using the angular settings of 25 automatically centered reflections in the range $11 < 2\theta < 23°$ and they are presented in Table 2. Intensity data were recorded using a θ–2θ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarization and psi-scan absorption corrections were applied using Crystal Logic software. The structure was solved by direct methods using SHELXS-97 [18] and refined by full-matrix least squares techniques on F^2 using SHELXL-97 [19]. Further crystallographic details for **2**: $2\theta_{max} = 50°$, scan speed 5.5°/min, scan range 1.6 + $\alpha_1\alpha_2$ separation, reflections collected/unique/used 3798/3496 [$R_{int} = 0.1400$]/3496, 275 parameters refined, $[\Delta\rho]_{max}/[\Delta\rho]_{min} = 0.538/-1.216$ e/Å^3, $[\Delta/\sigma]_{max} = 0.012$, R_1/wR_2 (for all data) = 0.0523/0.1214. Hydrogen atoms were located by difference maps and were refined isotropically, or introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. Plots of the structure were drawn using the DIAMOND 3 program package [20].

2.5. Synthesis of technetium complexes, [^{99m}Tc(CO)$_3$(L$_1$)], **3** and [^{99m}Tc(CO)$_3$(L$_2$)], **4** and challenge experiments

Synthesis: Technetium-99m complexes, **3** and **4**, were prepared according to the general procedure: 400 μL of a freshly prepared solution of the *fac*-[^{99m}Tc(CO)$_3$(H$_2$O)$_3$]$^+$ precursor (pH 6) were added to a vial containing a 100 μL solution of L$_1$H or L$_2$H (10^{-3} M) in methanol. The vial was sealed, flushed with N_2 and heated for 30 min at 70 °C. The complexes **3, 4** were analyzed by HPLC: **3:** t_R = 17.1 min, **4:** t_R = 18.2 min.

Challenge experiments against L-histidine and L-cysteine: Aliquots of 100 μl of complex **3** or **4** were added to 900 μl of a 10^{-2} M L-histidine and 10^{-2} M L-cysteine solutions in saline. The samples were incubated at room temperature for 24 h. At the 1, 6, and 24 h time points, 100 μl of each sample were removed and analyzed by gradient HPLC under the same solvent system used for the characterization of the complexes.

3. Results and discussion

3.1. Synthesis and characterization of rhenium complexes

Ligands L$_1$H and L$_2$H react readily with the [NEt$_4$]$_2$[Re(CO)$_3$Br$_3$] precursor in methanol to generate the corresponding neutral Re(CO)$_3$(NSO) complexes **1** and **2** (Fig. 1). HPLC analysis of the reaction mixture showed the formation of a single product. Both compounds were collected as white solids and were characterized by elemental analysis and spectroscopic methods. Complex **1** is insoluble in all common solvents while complex **2** is slightly soluble in methanol and DMSO. Crystals suitable for X-ray crystallography were obtained for **2** by recrystallization from a methanolic solution. Both complexes are stable in the solid state while complex

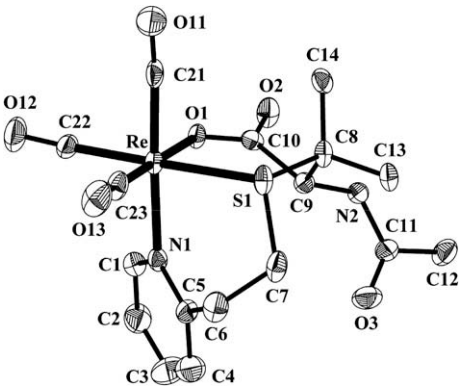

Fig. 3. Labelled plot of **2** with ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity.

Table 3
Selected bond distances (Å) and angles (°) for **2**.

Distances

C(22)–Re–N(1)	93.3(4)		

2 is stable in methanol for a period of months as shown by both HPLC and NMR.

The infrared spectra of complexes **1** and **2** demonstrate strong bands in the 2029–1875 cm^{-1} range, attributed to the C≡O stretch of the *fac*-$[Re(CO)_3]^+$ unit [21,22]. In addition, both complexes exhibit strong broad absorptions in the 1686–1650 cm^{-1} region which correspond to the asymmetrical C=O stretching vibration of the coordinated carboxylate and the amide groups.

The NMR assignments for complex **2** in DMSO-d_6 were based on the combined analysis of a series of ^1H–^1H and ^1H–^{13}C correlation spectra and are presented in Table 1. The numbering of the atoms is according to the crystallographic structure and is shown in Fig. 3. Upon complexation of the L_2H ligand, a characteristic chemical shift differentiation of the gemical protons on C-6 (by 0.7 ppm) and C-7 (by 0.9 ppm) takes place. The H-6 protons are distinguished from the H-7 protons based on the presence of a NOESY peak with the neighboring pyridinyl H-4 proton. The assignment is further confirmed through the observation of the long range heteronuclear coupling of H-4 and C-6 (Fig. 2).

3.2. Description of the structure

The molecular structure of **2** is given in Fig. 3 and selected bond distances and angles are listed in Table 3. The distorted octahedral environment of the Re atom in the structure of **1** is defined by the three facially bound CO groups and the NSO donor atom set of the tridentate ligand. The Re-carbonyl bond distances, 1.893(10)–1.941(13) Å, are consistent with those found in other Re-tricarbonyl complexes [23]. The Re–S, Re–N and Re–O bond distances fall well in the ranges observed in the analogous complexes. The Re–N1–C5–C6–C7–S1 six-membered ring in the coordination sphere adopts the boat conformation with C6 and Re displaced by 0.74 and 0.70 Å on the same side of the mean plane defined by the remaining four atoms. The Re–S1–C8–C9–C10–O1 six-membered ring in the coordination sphere adopts a distorted envelope conformation with C9 displaced by 0.81 Å out of the mean plane of the remaining five atoms (the largest deviation for the atoms on the plane is 0.12 Å for C10).

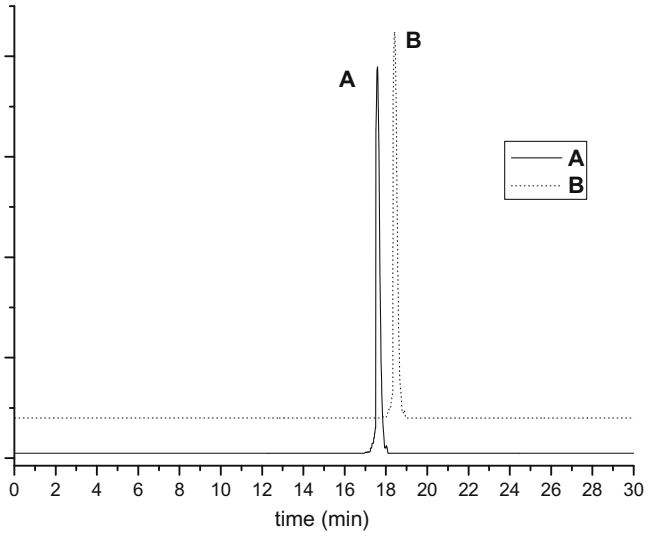

Fig. 4. Comparative reverse-phase HPLC chromatograms: (A) UV recording at 254 nm, complex **2,** retention time: 17.60 min and (B) radiometric detection, complex **4,** retention time: 18.2 min.

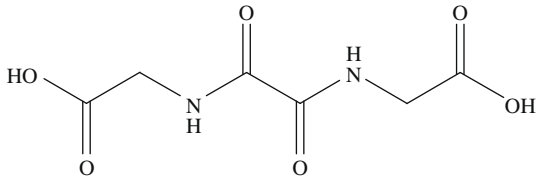
3.3. Synthesis of technetium-99m complexes

At technetium-99m level, the complexes *fac*-$^{99m}Tc(CO)_3(NSO)$, **3** and **4**, were obtained almost quantitatively (>90%) by heating the *fac*-$[^{99m}Tc(CO)_3(H_2O)_3]^+$ precursor at 70 °C in water (pH 6) in the presence of a 2×10^{-4} M concentration of the corresponding ligand. The reaction mixture was analyzed by HPLC and the analysis demonstrated that in both cases the reaction produces a single complex. The radioactivity recovery from the HPLC column after the injection of the reaction mixture was monitored and found to be quantitative. The identity of complexes **3** and **4** was established by HPLC comparison of their retention times to those of the analogous well-characterized rhenium complexes, **1** and **2**, respectively, by applying parallel radiometric and photometric detection (Fig. 4).

Both complexes were stable against high concentrations of L-histidine and L-cysteine. The HPLC analysis showed that at 24 h no trans-chelation product is formed and no decomposition of the complexes **3** and **4** occurs.

4. Conclusions

The two *N*-acetylcysteine derivative ligands L_1H and L_2H, synthesized by pyridinethylation (S-alkylation of the *N*-acetyl-L-cysteine and *N*-acetyl-D-penicillamine), react quantitatively with the $[NEt_4]_2[Re(CO)_3Br_3]$ and *fac*-$[^{99m}Tc(CO_3)(H_2O)_3]^+$ precursors and lead to the formation of a single, neutral $[M(CO)_3(NSO)]$ (M = Re, ^{99m}Tc) complex in high yield. The complexes were found to be stable at high concentrations of L-histidine and L-cysteine, a prerequisite for their further exploitation in the development of potential radiopharmaceuticals. The *N*-acetyl group present in cysteine may in principle be replaced by a great variety of pharmacophore groups through the formation of an amide bond. A major advantage of the presented work is that the pharmacophore-coupled cysteine can easily generate – in a single and high yield pyridinethylation step – tridentate SNO ligands suitable for coordination to the $[M(CO)_3]^+$ core.



Supplementary data

CCDC 721589 contains the supplementary crystallographic data for complex **2**. These data can be obtained free of charge via <http://www.ccdc.cam.ac.uk/conts/retrieving.html>, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. The ligand oxamide-*N*,*N*′-diacetic acid (H_4L).

in 3D supramolecular architectures by hydrogen bonding and stacking interactions [22].

Utilization of oxamide-*N*,*N*′-diacetic acid (H_4L) (Scheme 1) represents a sequential step in our systematic study carried out on the assembly of flexible ligands under mild conditions. The flexibility of this ligand is based firstly on different donor atoms that can offer different chelate rings, secondly on the *trans* configuration of amide groups and the antiparallel orientation of the C=O groups of oxalyl moiety. Furthermore, the amide groups of the ligand can be a source of hydrogen bonds leading to the formation of supramolecular architectures. Solution studies which carried out in the absence of metal ions, suggest a total deprotonation of the ligand around pH ~13 [23]. Solid state studies of the ligand regarding Cu(II) suggest that its deprotonation is taking place only at the terminal carboxylic groups, acting as bis-monodentate (H_2L^{2-}), resulting in the configuration of 1D-polymeric chain [23]. According to further solid state studies, the ligand (L^{4-}) is totally deprotonated, acting as bis-tridentate, leading to the formulation of centrosymmetric binuclear molecules either with Ni(II) [23] or Cu(II) [24]. We initiated our synthetic efforts with transition metals (namely Co(II), Ni(II), Zn(II) and Cd(II)) and in all cases we isolated 1D polymers with the diprotonated ligand (H_2L^{-2}) utilizing only the carboxylate groups for coordination. Bearing in mind the spherical charge distribution of Ca^{2+} ions, and believing that it could force a different coordination of the ligand, we decided to include it in our synthetic attempts. This way, we have successfully isolated a novel two-dimensional polymeric structure containing the diprotonated ligand (H_2L^{2-}).

Herein, we report the synthesis and the structural, spectroscopic, and physicochemical characterization of five new oxamide-*N*,*N*′-diacetate complexes with the general formula $\{[M(H_2L)(H_2O)_x]\cdot 2(H_2O)\}_n$ where M = Co(II), $x = 4$ **(1)**; Ni(II), $x = 4$ **(2)**; Zn(II), $x = 3$ **(3)**; Cd(II), $x = 3$ **(4)**; Ca(II), $x = 2$ **(5)**. Compounds **1**–**4** are 1D polymers with the ligand being doubly deprotonated and coordinated through the carboxylic edges. **5** is a 2D polymer with the ligand utilizing all of the available oxygen atoms for coordination. Extended H-bonded networks are present in all of the above coordination polymers leading to interesting supramolecular architectures.

2. Experimental

2.1. General

All reagents and solvents were of commercially available reagent quality unless otherwise stated. All the reactions were performed at room temperature and no special conditions were demanded.

2.2. Instrumentation

IR spectra were recorded on a Perkin–Elmer Spectrum GX FT-IR spectrophotometer with samples as KBr pellets. UV–Vis spectra on solid state (Diffuse Reflectance Spectra) were recorded on a Shimadzu UVPC 2401 spectrophotometer; the samples were prepared as 1:2 solid mixtures in $BaSO_4$, which was also used as reference. TG-DTA analysis was carried out under nitrogen, at a scan speed of 5 °C/min, on a Shimadzu DTG 60 apparatus with the sample size being *ca.* 5 mg. X-ray powder diffraction patterns were recorded on a Siemens (now Bruker) D8 ADVANCE diffractometer. C, H and N analyses were conducted by the University of Ioannina, Greece, Microanalytical Service.

2.3. Preparation of the compounds

The ligand was synthesized by following the procedure reported [23]. All the products are air stable and insoluble in all common organic solvents such as MeOH, EtOH, THF, CH_3CN and DMSO.

H_4L (20.4 mg, 0.1 mmol) was dissolved in H_2O (5 ml) and then a solution of NaOH 0.5 M was added until pH ~5. After that a solution of $Co(NO_3)_2\cdot 6(H_2O)$ in H_2O (5 ml) in a 1:1 molar ratio was added. Suitable crystals for X-ray analysis were obtained by slow evaporation

2.4. X-ray crystallography

X-ray diffraction intensities were collected at 120 K on a Nonius Kappa CCD diffractometer with φ and ω scans with κ offsets and Mo Kα radiation, $\lambda = 0.71073$ Å. The Denzo-Scalepack [25] or EVALCCD [26] program packages were used for cell refinements and data reductions. A semi-empirical absorption correction (SADABS) [27] was applied to all data. SHELX-97 [28] was used for structure solution (SHELXS) and refinement (SHELXL). The structures were solved by direct methods and all non-hydrogen atoms were refined anisotropically. Some of the methylene H atoms were located from different Fourier maps, but finally all of them were introduced in idealized positions and treated as riding on the parent non-hydrogen atoms. The amide and water protons were located from Fourier maps and refined smoothly isotropically, without any SHELX

restrains. A summary of crystal data and structure refinement for the compounds are provided in Table 1. Figures were drawn with X-Seed [29].

3. Results and discussion

3.1. Synthetic comments

The reaction of $M(NO_3)_2{\cdot}yH_2O$ (M = Co, Ni, Zn, $y = 6$; M = Cd, Ca, $y = 4$) with one equivalent of oxamide-*N*,*N*′-diacetic acid (H_4L) in aqueous media and conventional workup leads to the isolation of the polymeric complexes $\{[M(H_2L)(H_2O)_x]\cdot 2(H_2O)\}_n$ where M = Co(II), $x = 4$ **(1)**; Ni(II), $x = 4$ **(2)**; Zn(II), $x = 3$ **(3)**; Cd(II), $x = 3$ **(4)**; Ca(II), $x = 2$ **(5)** according to the balance Eq. (1):

$$n\mathrm{M(NO_3)_2}\cdot y\mathrm{H_2O} + n\mathrm{H_4L} \xrightarrow{\mathrm{H_2O}} \{[\mathrm{M(H_2L)(H_2O)}_x]\cdot 2(\mathrm{H_2O})\}_n + 2n\mathrm{H^+} + 2n\mathrm{NO_3^-} + (y-x-2)n\mathrm{H_2O} \quad (1)$$

1–5

In all complexes the ligand is in its doubly deprotonated form as it is expected from the low pK_a of the carboxylic group. The solid products are pure and homogeneous as derived from comparisons of the X-ray powder patterns (XRPD's) of the bulk samples with the corresponding patterns simulated from the crystal structures.

Few features of the reaction represented by chemical Eq. (1) deserve comments: First, the appearance of HNO_3 in the products might imply that complexes **1**–**5** (which contain deprotonated organic ligands) decompose under "acidic" conditions, i.e. excess of protons could move the reaction to the left. We did not have such evidence probably due to high dilution. A second point of synthetic interest is the absence of a base from the reaction mixtures that lead to **1**–**5**. The employment of base in the $M(NO_3)_2{\cdot}yH_2O/H_4L$ reaction system in H_2O leads to the precipitation of solids which produce XRPD's with strong background indicating amorphous phases. On the other hand, microanalytical results on the above solids suggest formulations that are not reasonable. When the metal to ligand ratio was changed to 2:1 and in the absence of base the same products were isolated but in smaller yields. Maintaining the metal to ligand ratio to 2:1 and adding small amounts of base (i.e. up to pH = 6.5) insoluble precipitates were isolated which are formulated as $M_2L{\cdot}xH_2O$. Our efforts towards the structural characterization of those products are in progress.

From the use of H_2O viewpoint, the preparation of the five polymeric complexes may be considered as a "green" procedure [30]. The use of environmentally benign solvents (and solventless systems) has been one of the most active areas of green chemistry over the past 10 years [26].

3.2. Description of the crystal structures

Compounds **1** and **2** are isomorphous and only the structure of **2** will be described in detail. Selected inter-atomic bond distances and angles and additionally H-bond's geometrical characteristics, for both compounds are presented in Table 2. The crystal structure of compound **2** consists of linear chains (Fig. 1) running parallel to the $[0\ \bar{1}\ 1]$ crystallographic direction of the unit cell, and two lattice water molecules per metal ion held together with hydrogen bonds.

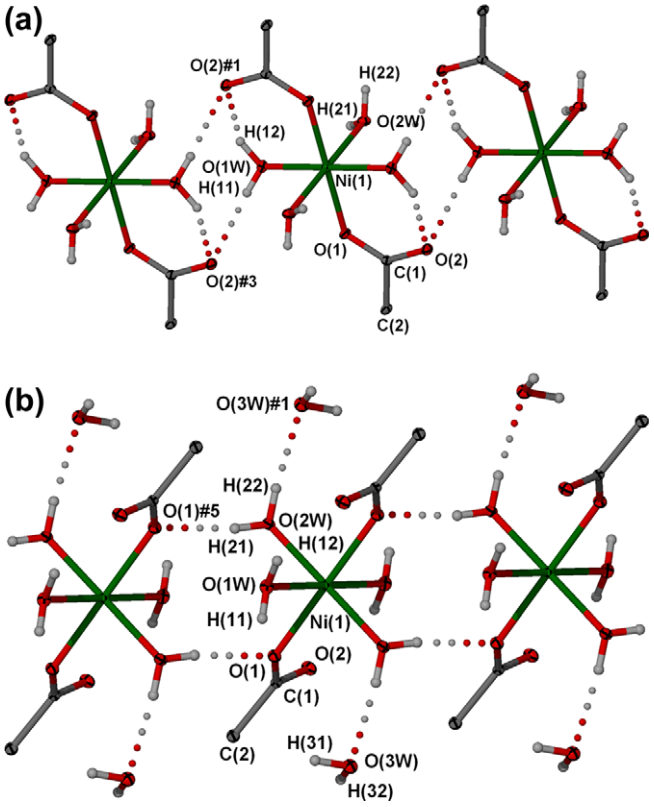

Fig. 2. Parts of the 1D H-bonded chains present in the crystal structure of **2**. (a) H-bonds through water O(1W) parallel to *c*. (b) H-bonds through water O(2W) parallel to *a*. The oxamide part of the ligand has been omitted for clarity. Symmetry transformations to generate equivalent atoms: #1 $-x, -y+1, -z+2$; #3 $x, y-1, z$; #5 $-x-1, -y+1, -z+2$.

Each metal ion is coordinated in a rather regular octahedron to two oxygen atoms belonging to two monodentate carboxylates of two symmetry related H_2L^{2-} ligands and four terminal water molecules (Fig. 1). The oxamide ligand is deprotonated only at the terminal carboxylate groups and acts as a μ_2-bridge.

There is an extended array of H-bonds that stabilize the overall crystal structure and leads to a 3D supramolecular architecture. Practically, each 1D chain is connected to four surrounding chains through H-bonds. The first coordinated water molecule acts as a donor to one intra-chain $\{O(1W)–H(12)\cdots O(2)\#1, (-x, -y+1, -z+2)\}$ H-bond to the uncoordinated oxygen atom of the symmetry related carboxylate in the same metal coordination sphere, and to one inter-chain $\{O(1W)–H(11)\cdots O(2)\#3, (x, y-1, z)\}$ H-bond to the uncoordinated oxygen atom of the symmetry related carboxylate in a different metal coordination sphere. This way, a 1D H-bonded chain is formed that runs parallel to *c* (Fig. 2a). The second water molecule

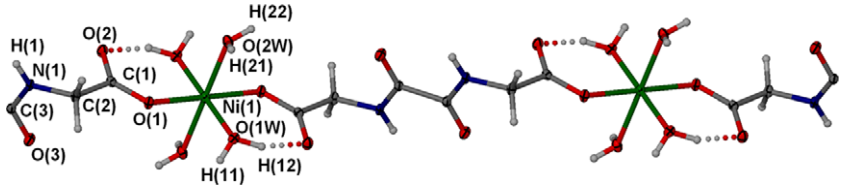

Fig. 1. A part of the linear chains in **2** showing the labeling scheme, the coordination of the ligand, the coordination sphere of the metal ion, and the intra-chain H-bonds with 40% probability thermal ellipsoids. The lattice water molecules have been omitted for clarity. Compound **2** has a very similar structure.

participates in two H-bonds as a donor. The first is to an adjacent coordinated carboxylate oxygen {O(2W)–H(21)···O(1)#5, $(-x-1, -y+1, -z+2)$}, and leads to the formation of H-bonded 1D chains parallel to *a*. The second is to the lattice water molecule {O(2W)–H(22)···O(3W)#1, $(-x, -y+1, -z+2)$} (Fig. 2b).

Apart from the previously described, the lattice water molecule participates in three additional H-bonds, reinforcing this way the overall 3D supramolecular architecture. As an acceptor it interacts with the amide bond {N(1)–H(1)···O(3W)#4, $(x-1, y+1, z)$} of the ligand, and as a donor interacts with a different amide bond {O(3W)–H(32)···O(3)} and an uncoordinated carboxylate oxygen atom {O(3W)–H(31)···O(2)#3, $(x, y-1, z)$}. A packing diagram, including all the previously described interactions is shown in Fig. 3.

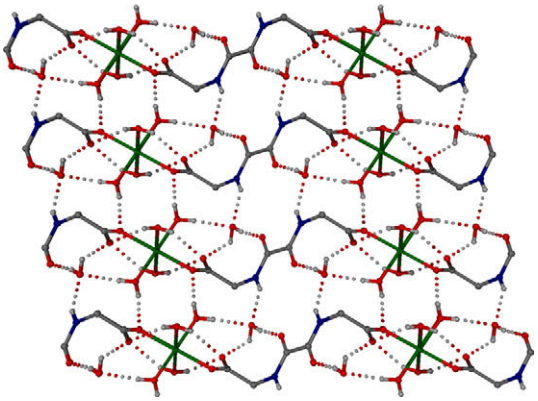

Fig. 3. A packing diagram of **2**, shown down to *b* axis. Methylene hydrogen atoms have been omitted for clarity.

The simplest way to describe the topology of the 3D supramolecular structure [31] is to ignore the lattice water molecule and check the connectivity of the obvious node (either the metal ion or the asymmetric unit). This way, a uninodal 6-connected net is formed with $4^{12}.6^3$-**pcu** topology [32,33]. When the lattice water is taken into account two extra links between the nodes are formed. The new net is a uninodal 8-connected hexagonal primitive net with $3^6.4^{18}.5^3.6$-**hex** topology [32,33].

Compounds **3** and **4** are isomorphous with substantial structural differences due to the larger ionic radius of Cd^{2+}. Again only the structure of **3** will be described in detail and additionally the minor differences between the two structures. Selected interatomic bond distances and angles and H-bond's geometrical characteristics, for both compounds are presented in Table 3.

The crystal structure of compounds **3** and **4** consist of zig-zag chains (Fig. 4) running parallel to the $[\bar{1}\ 0\ 1]$ crystallographic direction of the unit cell, and two lattice water molecules per metal ion held together with hydrogen bonds. In **3**, Zn(II), being bonded to two carboxylate oxygen atoms belonging to two different H_2L^{2-} ligands, and three water molecules, is five coordinated in a trigonal

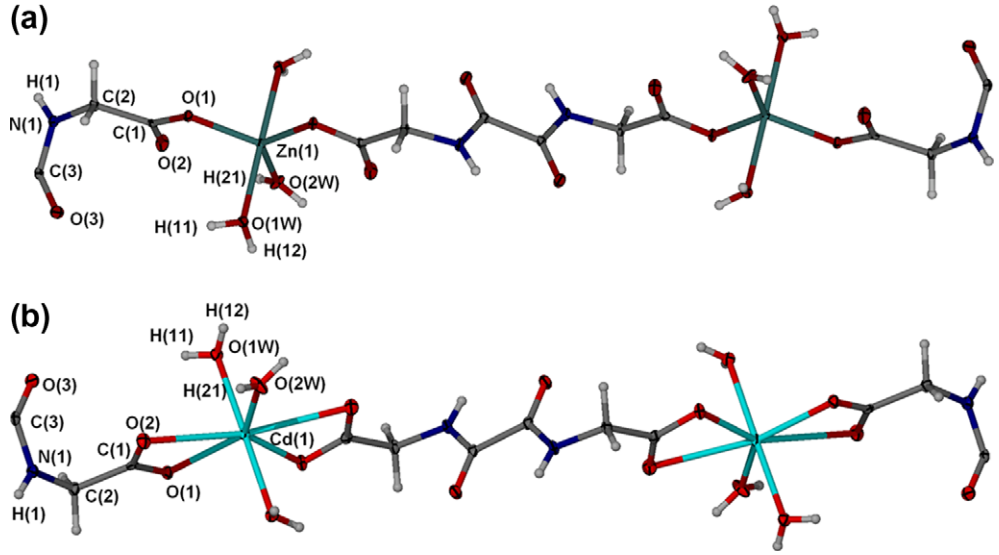

Fig. 4. Parts of the zig-zag chains in **3** (a) and **4** (b) showing the labeling scheme, the coordination of the ligand, the coordination sphere of the metal ion, and the intra-chain H-bonds with 40% probability thermal ellipsoids. The lattice water molecules have been omitted for clarity.

bipyramidal environment. In **4**, Cd(II) can be considered as seven coordinated in a pentagonal bipyramidal environment and it is bonded to asymmetrically chelated carboxylates belonging to two different H_2L^{2-} ligands, and three water molecules. The oxamide ligand is deprotonated only at the terminal carboxylate groups and acts as a bridge between two metal ions in both structures. There are not any more important differences between the crystals structures and we continue describing polymer **3**.

There is an extended array of H-bonds that stabilize both crystal structures and lead to 3D supramolecular architectures. Instead of an inversion center that exists on the metal atoms in **1** and **2**, in **3** and **4** there is a C_2 axis which coincides with the M–O(2W) bond (M = Zn(1) and Cd(1) in **3** and **4**, respectively). Due to this difference, the H-bonded array that formed in the later compounds is different from the array already described for compounds **1** and **2**. As in **1** and **2** each chain is connected via H-bonds to four adjacent chains, but the presence of only three water molecules in the coordination sphere of the metal ions forms a different motif of H-bonds. The water molecule O(2W) acts as a donor to a symmetry related O(1W) {O(2W)–H(21)···O(1W)#5, $(x + 1/2, y - 1/2, z)$} forming, this way, 1D H-bonded chains parallel to *b*. Those chains are connected to each other with another H-bond {O(1W)–H(12)···O(1)#4, $(x - 1/2, y - 1/2, z)$} leading to the formation of 2D layers parallel to *ab* plane (Fig. 5).

The lattice water molecule participates in four H-bonds, as in **1** and **2**, reinforcing this way the overall 3D supramolecular architecture. As an acceptor it interacts with the amide bond {N(1)–H(1)···O(3W)#3, $(x + 1, y, z)$} of the ligand, and one of the coordinated water molecules {O(1W)–H(11)···O(3W)}, and as a donor interacts with a different amide bond {O(3W)–H(32)···O(3)} and

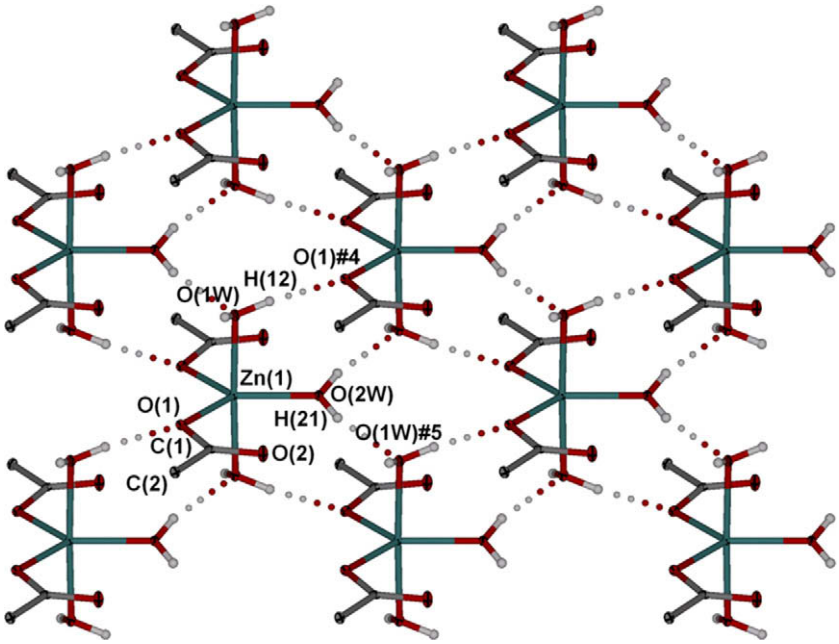

Fig. 5. Part of the 2D H-bonded layers present in the crystal structure of **3** down to *c* axis. The oxamide part of the ligand has been omitted for clarity. Symmetry transformations to generate equivalent atoms: #4 $x - 1/2, y - 1/2, z$; #5 $x + 1/2, y - 1/2, z$.

an uncoordinated carboxylate oxygen atom {O(3W)–H(31)···O(2)#6, $(x-1/2, y+1/2, z)$}. A packing diagram, including all the previously described interactions is shown in Fig. 6.

The same two scenarios used for the description of the topology of the supramolecular structures of **1** and **2**, can be applied here for **3** and **4**, as well; they lead to 6- and 8-connected nets with the same topology.

The crystal structure of **5** consists of 2D layers parallel to the *bc* plane of the cell, and two lattice water molecules per calcium atom held together with H-bonds. Selected inter-atomic bond distances and angles and H-bond's geometrical characteristics, are presented in Table 4.

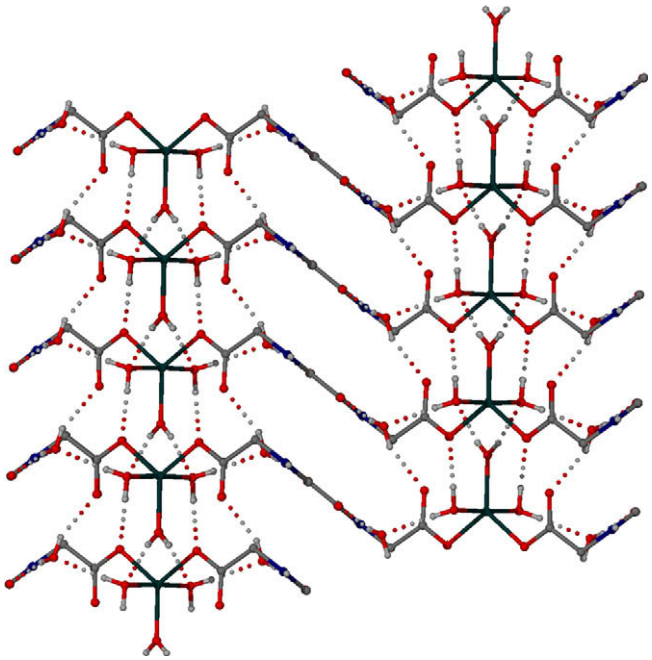

Fig. 6. A packing diagram of **3**, shown down to *a* axis. Methylene hydrogen atoms have been omitted for clarity.

The ligand is doubly deprotonated, but this time utilizes all oxygen atoms for coordination, bridging this way four Ca(II) atoms (Fig. 7a). Each Ca(II) atom is eight coordinated in a distorted square antiprismatic environment [34]. The calcium atom is coordinated to four different ligands via two symmetrically chelated carboxylate groups, and two amide oxygens; its coordination sphere is saturated with two water molecules (Fig. 7b). In this way, a 2D layer is formulated possessing 4^4-**sql** topology [32] (Fig. 8).

Hydrogen bonding interactions are a dominant feature of the crystal structure of **5**, as in the structures of **1**–**4**. Eventually, a 3D supramolecular architecture is formed. There is one intra-layer H-bond generated from the amide N–H, which interacts with a symmetry related coordinated carboxylate oxygen {N(1)–H(1)···O(2)#6, $(-x, -y+1, -z+2)$}. The 2D layers interact directly through H-bonds and indirectly, through the lattice water molecule. The coordinated water molecule O(1W) acts as a donor to a symmetry related coordinated carboxylate oxygen belonging to a different layer {O(1W)–H(11)···O(1)#7, $(-x+1/2, y-1/2, z)$}. The lattice water molecule participates in three hydrogen bonds and acts as a bridge between two different 2D layers. As an acceptor it is connected to the coordinated water molecule {O(1W)–H(12)···O(2W)#2, $(-x, y-1, -z+3/2)$}. As a donor it is connected to a coordinated carboxylate oxygen belonging to the original layer {O(2W)–H(22)···O(2)} and to a coordinated water molecule of an adjacent layer {O(2W)–H(21)···O(1W)#8, $(x-1/2, y+1/2, -z+3/2)$.

An interesting feature of the structure is revealed when we see the crystal down to *b* axis (Fig. 9). An H-bonded water chain is formed by alternating connection of coordinated and lattice water molecules. The water chain can be calcified according to Mascal et al. [35] as C_2. The H-bonds involved in the formation of the chain are: O(1W)–H(12)···O(2W)#2 $(-x, y-1, -z+3/2)$ and O(2W)–H(21)···O(1W)#8 $(x-1/2, y+1/2, -z+3/2)$.

A search in CSD [36] reveals a compound (VUHWEA) with the same chemical formula and lattice geometrical characteristics [37]. The structure of that compound is different from the structure of **5**. The ligand is utilizing all O atoms for coordination to Ca, but it bridges only two metal ions in a much distorted manner.

3.3. Spectroscopy

The IR spectra of all compounds display a broad strong band centered at 3400 cm^{-1}, which reveals the presence of water in all cases.

Table 4
Selected bond distances (Å) and angles (°) for complex **5**.

Bond distances			
Ca(1)–O(1)	2 × 2.4918(13)	Ca(1)–O(2)	2 × 2.5158(14)
Ca(1)–O(3)#2	2 × 2.4342(13)	Ca(1)–O(1W)	2 × 2.3968(14)
Bond angles

Symmetry transformations to generate equivalent atoms: #1 $-x, y, -z+3/2$; #2 $-x, y-1, -z+3/2$; #3 $x, y-1, z$; #4 $x, y+1, z$; #5 $-x, -y+2, -z+2$; #6 $-x, -y+1, -z+2$; #7 $-x+1/2, y-1/2, z$; #8 $x-1/2, y+1/2, -z+3/2$.

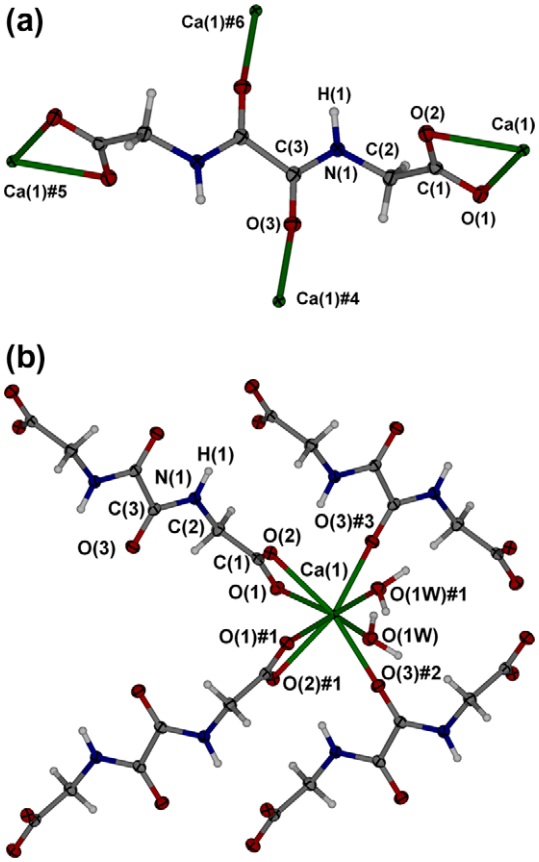

Fig. 7. The coordination of the ligand (a) and the coordination sphere of the metal (b) in **5** with 40% probability ellipsoids and the labeling scheme. Symmetry transformations: #1 $-x, y, -z+3/2$; #2 $-x, y-1, -z+3/2$; #3 $x, y-1, z$; #4 $x, y+1, z$; #5 $-x, -y+2, -z+2$; #6 $-x, -y+1, -z+2$; #7 $-x+1/2, y-1/2, z$; #8 $x-1/2, y+1/2, -z+3/2$.

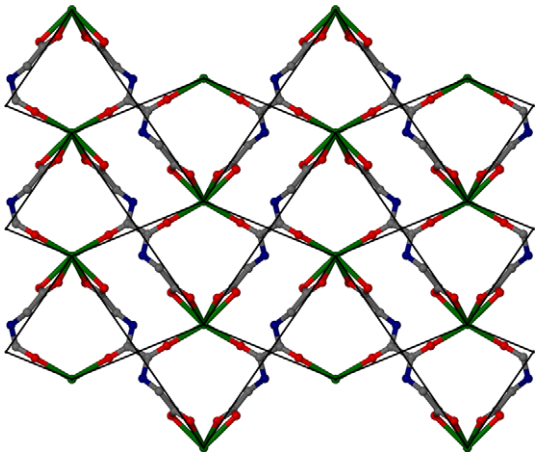

Fig. 8. A part of the 2D layer formed in **5**, shown down to *a*. Hydrogen atoms and coordinated water molecules have been omitted for clarity. The topological net formed is embedded in black.

In addition, a single absorption of medium intensity centered at 3330 cm^{-1} ν(N–H) (stretching band), reveal the existence of N–H amide groups. A strong band centered at 1638 cm^{-1} for compounds **1**–**4** corresponds to the carbonyl group of the amide bond, while for **5** this absorption shifts to lower value (1629 cm^{-1}), indicating also the coordination of the oxalyl moiety. The ν_a(COO) and ν_{as},(COO)

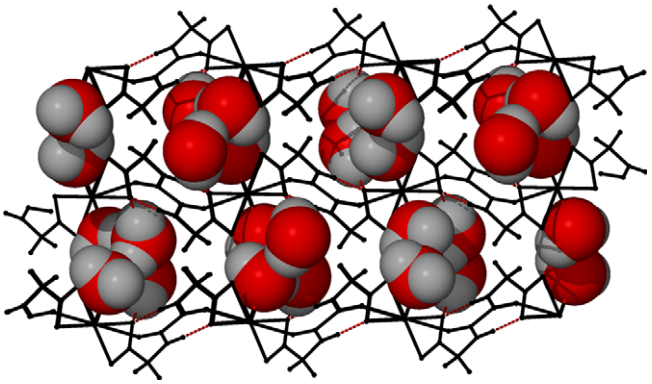

Fig. 9. A packing diagram of **5** shown down to *b*. The water molecules are in space filling mode; the rest of the atoms are drawn black to emphasize the position of the chains between the layers parallel to *bc* plane.

stretching vibrations of carboxylate groups appear as strong absorptions centered at 1663 and 1390 cm^{-1} for **1**–**3**, 1655 and 1402 cm^{-1} for **4** and **5**, respectively. These values are consistent with bis-monodentate carboxylate coordination for **1**–**3** and bis-chelate carboxylate coordination for **4** and **5** [38]. The diffuse reflectance spectra (DRS) of all compounds reveals two absorption bands at 205 and 258 nm which can be assigned to $\pi \rightarrow \pi^*$ transfer transition of the ligand. Furthermore, the DRS of **1** shows subtly distinguishable shoulders around 457 and 488 nm which are attributed to spin–orbit coupling effects or to transitions to doublet states, a shoulder around 619 nm can be attributed to the $^4T_{1g}(F) \rightarrow {}^4A_{2g}$ transition and the major peak at 507 nm can be assigned to the $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transition. As regard to the diffuse reflectance spectra of compound **2**, this is typical to an octahedral Ni(II) complex, exhibiting two peaks at 364 and 661 nm corresponding to $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ and $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ transitions, respectively [39].

3.4. Thermal analysis

In a typical measurement, TG curve of the cobalt polymer **1** can be divided into two areas corresponding to two different weight losses. When **1** is heated under nitrogen, an endothermic dehydration starts at 79 °C which is completed at 180 °C. The observed weight loss of 28.2% is in agreement with the calculated value of 29.3% of the four coordinated and two lattice water molecules. The anhydrous intermediate is stable up to 248 °C; and at this point the second decomposition process begins (weight loss 46.6%), as shown by the DTA curve. The decomposition proceeds up to 700 °C, where the purple final residue corresponds to Co_2O_3 (found 23.1%, calculated 22.2%). Compounds **2**–**4** show similar TG DTA curves, where the final residues are in good agreement with the calculated values.

The TG curve of the calcium polymer **5** can be divided into three areas corresponding to three different weight losses. When the calcium compound **5** is heated under nitrogen, a two stepped endothermic dehydration occurs; the first step starts at 79 °C and is completed at 123 °C. A curve inflection at 125 °C suggests the initiation of the second step which is completed at 197 °C. The observed weight losses of 11.77% and 11.23%, respectively are in good agreement with the total calculated value of 23.18% of the two lattice and the two coordinated water molecules. The anhydrous intermediate $[Ca(C_6H_6N_2O_6)]$ is stable up to 294 °C; and at this point the second decomposition process begins (weight loss 45.23%), as shown by the DTA curve, and the anhydrous intermediate is converted to $CaCO_3$ (calculated value 45.23%). Further heating up to 700 °C, results in to the final residue which corresponds to CaO (found 14.73%, calculated 14.01%).

4. Concluding remarks

In this work, five new complexes of the oxamidic ligand oxamide-bis-*N*,*N*′-acetate (H_4L) have been synthesized; their structures have been elucidated and their spectroscopic and thermal properties were studied. The selection of mild conditions for the preparation of the complexes allows isolation of pure crystalline products with the ligand being doubly deprotonated.

With transition metals, H_2L^{2-} utilizes only the carboxylates for coordination. In complexes **1** and **2** the carboxylates are monodentate while in **4** and **5** asymmetrically and symmetrically bidentate, respectively. In **3** there is certainly an attractive interaction between zinc and the non-bonded carboxylate oxygen, but their distance could not easily characterize that interaction as a bond (Table 3).

The presence of water in all structures is very important for their stabilization. All water molecules (coordinated and lattice) in all compounds are involved in strong hydrogen bonding, leading to supramolecular architectures. The compounds are reasonably stable, but they can not regain their structures after a dehydration–rehydration procedure, and behave similarly with other hydrated compounds [21].

Attempts to synthesize coordination polymers with oxamide-bis-*N*,*N*′-acetate (H_4L) in the presence of Lewis bases and/or the oxamide in its fully deprotonated form are in progress.

Supplementary data

CCDC 724713–724717 contain the supplementary crystallographic data. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336 033; or e-mail: deposit@ccdc.cam.ac.uk.

organophosphonate substrates and especially bis(phosphonate) substrates that represent a useful class of drugs, have been employed in the treatment of bone diseases (Paget's disease of bone, myeloma) [16,17]. The biological benefit of organophosphonate moieties has emerged primarily because of their influence on calcium metabolism and its availability.

On the basis of the above views, interactions arising between organophosphonate binders and metal ions such as Ni(II), are expected to promote metal ion solubilization and influence metallo(bio)chemical processes. Two representative low molecular mass organophosphonic acids are: (a) imino bis(methylenephosphonic acid) (H_4IDA2P), and (b) *N*-(phosphonomethyl) glycine (glyphosate, H_3IDAP). The first organophosphonate substrate H_4IDA2P acts as a binder with two very important features: (a) it contains two phosphonate moieties, known to promote metal ion binding, and (b) it contains one imino group. Glyphosate, on the other hand, is a well-known herbicide first introduced in 1974 under the trade name "Roundup". It is one of the very few biodegradable commercial herbicides used to kill weeds. It is degraded in the soil to the non-toxic products CO_2, NH_3 and PO_4^{3-} within a few days. As in the case of H_4IDA2P, glyphosate (H_3IDAP) exists in a zwitterionic form. Glyphosate possesses three binding sites capable of coordinating metal ions such as Ni(II): (a) a carboxylate moiety, (b) a phosphonate moiety, and (c) an imino moiety. Complexes arising from interactions of glyphosate with metal ions are expected to exhibit a variety of structural attributes including five-membered rings, bestowing stability to the isolated species. The use of a diphosphonate and a (carboxy)phosphonate ligand respectively, exemplifies structural attributes of various phosphorylated analogs of amino acids and organophosphonate-containing drugs. In both cases, it is important to point out the paucity of structurally characterized complexes of organophosphonates with Ni(II) in aqueous media.

Poised to understand the underlying principles of the aqueous chemical reactivity of Ni(II) toward organophosphonate ligands, variably mimicking phosphorylated and phosphonate species in cellular media, the binary systems of Ni(II) with the aforementioned substrates were investigated. Herein, we report on the pH-specific synthesis, isolation and characterization of two new binary Ni(II)–organophosphonate complexes with distinct properties (a) reflecting the nature of interactions involved in binary species of the corresponding aqueous speciation schemes, (b) exemplifying the solid state and solution features potentially relating to the aqueous speciation of Ni(II) with phospho-substituted ligands of biological relevance, seeking to contribute to physiology and/or toxicity, and (c) projecting physicochemical properties akin to Ni(II)–phosphonate materials.

2. Experimental

2.1. Materials and methods

All experiments were carried out in aqueous media under aerobic conditions. Nanopure quality water was used for all reactions. $Ni(NO_3)_2{\cdot}6H_2O$ was purchased from Carlo Erba, and imino bis(methylphosphonic acid), (H_4IDA2P) from Fluka. Ammonia, KOH and NaOH were also supplied by Fluka. Glyphosate (H_3IDAP) was purchased from Aldrich.

2.2. Physical measurements

FT-IR spectra were recorded on a Perkin Elmer 1760X FT-infrared spectrometer. UV–Vis measurements were carried out on a Hitachi U2001 spectrophotometer in the range from 190 to 1000 nm. A ThermoFinnigan Flash EA 1112 CHNS elemental analyzer was used for the simultaneous determination of carbon, hydrogen and nitrogen (%). The analyzer is based on the dynamic flash combustion of the sample (at 1800 °C) followed by reduction, trapping, complete GC separation and detection of the products. The instrument is (a) fully automated and controlled by PC via the Eager 300 dedicated software, and (b) capable of handling solid, liquid or gaseous substances.

A TA Instruments, model Q 600, system was used to run the simultaneous TGA-DTG experiments. The employed heating rate was 10 °C/min. The instrument mass precision is 0.1 μg. About 20 mg of sample was placed in an open alumina sample pan for each experiment. High purity air (80/20 in N_2/O_2) was used at a constant flow rate of 100 mL/min, depending on the conditions required for running the experiment(s). During the experiments, the sample weight loss and rate of weight loss were recorded continuously under dynamic conditions, as a function of time or temperature, in the range 30–1010 °C. Prior to activating the heating routine program, the entire system was purged with the appropriate inert gas for 10 min, at a rate of 400 mL/min, to ensure that the desired environment had been established.

Magnetic susceptibility data were collected on powdered samples of **1** with a Quantum Design SQUID susceptometer in the 2–300 K temperature range, under various applied magnetic fields. Magnetization measurements were carried out at three different temperatures in the field range 0–5 T.

Electrochemical measurements were carried out with a model PGSTAT30 potensiostat-galvanostat from Autolab Electrochemical Instruments. The entire system was under computer control and supported by the appropriate computer software GPES, running on Windows XP. The employed electrochemical cell had platinum (disk) working and auxiliary (wire) electrodes. An Ag/AgCl electrode was used as reference electrode. Thus, the derived potentials in the cyclic voltammetric measurements are referenced to that electrode. The water used in the electrochemical measurements was of nano-pure quality. KNO_3 was used as a supporting electrolyte. Normal concentrations used were 1–6 mM in electroanalyte and 0.1 M in supporting electrolyte. Purified argon was used to purge the solutions prior to the electrochemical measurements. Derived $E_{1/2}$ values are reported versus Ag/AgCl electrode.

2.3. Synthesis of complex $[Ni(C_2H_8O_6NP_2)_2(H_2O)_2]$ (**1**)

(a) A sample of 0.50 g of $Ni(NO_3)_2{\cdot}6H_2O$, (1.7 mmol) and 0.35 g (1.7 mmol) of imino-bis(methylenephosphonic acid) were dissolved in nano-pure water. The pH of the resulting solution was raised to 3 with 0.1 M aqueous ammonia. The derived reaction mixture was stirred at room temperature overnight. On the following morning, the solution was clear and its color was green. Subsequently, the reaction solution was filtered and allowed to stand at room temperature. After a period of several weeks green needle-like crystals grew out of the solution by slow evaporation. The crystalline material was collected by filtration and dried in vacuo. Yield: 0.56 g (~66%). *Anal.* Calc. for **1**, $[Ni(C_2H_8O_6NP_2)_2(H_2O)_2]$ ($C_4H_{20}O_{14}N_2P_4Ni$, MW = 502.81): C, 9.54; H, 3.98; N, 5.57. Found: C, 9.68; H, 4.03; N, 5.64%.

(b) The same reaction was run in the presence of NaOH or KOH, affording morphologically identical green needle-like crystals. The FT-IR spectrum of the crystals and the X-ray unit cell determination of one of the isolated single crystals identified the material as complex **1**.

(c) The same reaction as in (a) was also run with a metal to ligand stoichiometry of 1:2. In this case, green crystalline material was also isolated. FT-IR spectroscopy in combination with X-ray crystallography identified the isolated material as complex **1**.

2.4. Synthesis of complex [Ni(OOC–CH2–NH–CH2–PO3H)2]·[Ni(H2O)6]·3.3H2O (2)

(a) A sample of 0.23 g of $Ni(NO_3)_2{\cdot}6H_2O$ (0.79 mmol) and 0.26 g (1.5 mmol) of *N*-(phosphonomethyl) glycine (glyphosate) were dissolved in nano-pure water. The pH of the resulting solution was raised to 4 with 0.1 M NaOH. The derived reaction mixture was stirred at room temperature. On the following morning, the solution was clear and its color was blue. Subsequently, ethanol was added and the reaction mixture was placed at 4 °C. A few weeks later, bluish crystals appeared at the bottom of the flask. The crystals were isolated by filtration and dried in vacuo. The yield was 0.75 g (~77%). *Anal.* Calc. for **2**, $[Ni(OOC{-}CH_2{-}NH{-}CH_2{-}PO_3H)_2]{\cdot}[Ni(H_2O)_6]{\cdot}3.3H_2O$ ($C_6H_{30.6}O_{19.3}N_2P_2Ni_2$, MW = 619.08): C, 11.63; H, 4.94; N, 4.52. Found: C, 11.89; H, 5.25; N, 4.34%.

(b) A similar reaction as in (a) was carried out using aqueous ammonia to raise the pH. Blue crystalline material appeared at the bottom of the reaction flask. FT-IR spectroscopy in combination with the X-ray determination of the unit cell of a single crystal identified the isolated crystals as complex **2**.

2.5. X-ray crystal structure determination

X-ray quality crystals of compound **1** were grown from aqueous reaction mixtures upon slow evaporation. A single crystal with dimensions 0.15 × 0.09 × 0.05 mm was mounted on the tip of a glass fiber with epoxy glue. The crystal was mounted on an Xcalibur Oxford Diffractometer equipped with a Sapphire 3 CCD detector and a 4-cycle Kappa geometry goniometer, using an enhanced Mo X-ray source and graphite radiation monochromator. Unit cell dimensions for **1** were determined and refined by using the angular settings of all the reflection frames in the range $6.30 < 2\theta < 60.50°$. Relevant crystallographic data appear in Table 1. An analytical absorption correction was applied using CrysAlis RED software. CrysAlis CCD and CrysAlis RED software were used for monitoring data collection and computing data reduction/cell refinement, respectively [18,19]. The structure was solved by direct methods and refined by full-matrix least-squares techniques on F^2 by using SHELXS-97 [20,21]. Special computing molecular graphics incorporated in the WinGX 3.2 interface were used [22]. Further crystallographic details for **1**: $2\theta_{max} = 62.44°$; reflections collected/unique/used, 11 076/2263 [$R_{int} = 0.0669$]/2263; parameters refined, 136; $[\Delta\rho]_{max}/[\Delta\rho]_{min}$ = 0.895/−0.686 e/Å^3; R/R_w (for all data), 0.0291/0.0720. All of the non-H atoms were refined anisotropically. The methylene hydrogen atoms of the phosphonate ligand were introduced at calculated positions as riding on bonded atoms. The remainder of the hydrogen atoms were located by difference Fourier maps and were refined isotropically. Further details on the crystallographic studies as well as atomic displacement parameters are given as Supporting Information in the form of cif files.

X-ray quality crystals of compound **2** were grown from water–ethanol mixtures. A single crystal, with dimensions 0.06 × 0.20 × 0.28 mm was mounted on a Crystal Logic dual-goniometer diffractometer, using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Unit cell dimensions for **2** were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11.00 < 2\theta < 23.00°$. Crystallographic details are given in Table 1. Intensity data were measured by using θ–2θ scans. Three standard reflections were monitored every 97 reflections, over the course of data collection at 298 K. They showed less than 3% variation and no decay. Lorentz, polarization and psi-scan absorption corrections were applied by using Crystal Logic software. The structure of complex **2** was solved by direct methods using SHELXS-97 [20]. Refinement was achieved by full-matrix least-squares techniques on F^2 with SHELXL-97 [21]. Further crystallographic details for **2**: $2\theta_{max} = 50.00°$; reflections collected/unique/used, 4042/3915 [$R_{int} = 0.0249$]/3915; parameters refined, 381; $[\Delta\rho]_{max}/[\Delta\rho]_{min}$ = 2.023/−0.861 e/Å^3; R/R_w (for all data), 0.0697/0.1645. All hydrogen atoms were located in difference maps and were refined isotropically; no H-atoms for the partially occupied water solvate molecules were included in the refinement. All non-H atoms were refined anisotropically.

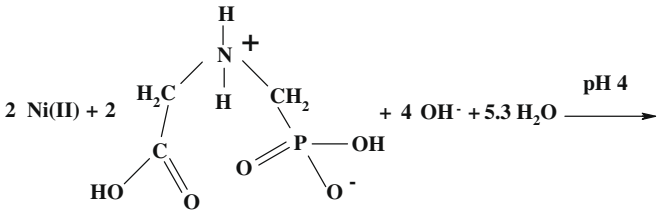
2.6. Synthesis

The synthesis of compound **1** was pursued through a pH-specific reaction between Ni(II) and imino-bis(methylenephosphonic acid) (H_4IDA2P) in aqueous media. The pH, at which the reaction was developed, was 3. The adjustment of pH was achieved by adding aqueous ammonia (NaOH or KOH). The stoichiometric reaction leading to the isolation of compound **1** is shown below (Reaction 1):



$[Ni(C_2H_8O_6NP_2)_2(H_2O)_2]$

(Reaction1)

Compound **1** was easily isolated in pure crystalline form after several weeks of having the reaction flask stand in the air. Elemental analysis of the isolated green crystalline material suggested the molecular formulation $[Ni(C_2H_8O_6NP_2)_2(H_2O)_2]$ for **1**. It appears that the sole purpose of the employed aqueous base solutions was to adjust the pH of the reaction mixture. No cations arising from the use of such bases were found to be incorporated into the arising lattice of **1**. Further examination of **1** by FT-IR spectroscopy confirmed the presence of the phosphonate moieties bound to Ni(II), thus lending credence to the proposed formulation. Compound **1** is sparingly soluble in water, but it is insoluble in organic solvents, such as acetonitrile, chlorinated solvents ($CHCl_3$, CH_2Cl_2), toluene and DMF.

The pH-specific synthesis of compound **2** was achieved through a similar reaction to that of compound **1**. In the synthesis of **2**, employing the carboxy-phosphonate ligand *N*-(phosphonomethyl) glycine in aqueous media, the pH of the reaction mixture was 4. The adjustment of pH was achieved by adding aqueous NaOH (or ammonia). The stoichiometric reaction leading to the isolation of **2** is shown below (Reaction 2):

(Reaction2)

Elemental analysis of the isolated blue crystalline material suggested the molecular formulation $[Ni(OOC–CH_2–NH–CH_2–PO_3H)_2]·[Ni(H_2O)_6]·3.3H_2O$. It appears that employment of the two separate base solutions used in the synthesis contributed solely to the adjustment of the reaction mixture pH, in view of the fact that Na^+ and NH_4^+ ions were not incorporated in the ultimate lattice of **2**. Further examination of **2** by FT-IR spectroscopy confirmed the presence of phosphonate and carboxylate moieties bound to Ni(II), thus supporting the proposed formulation. Compound **2** is insoluble in water as well as in organic solvents, such as acetonitrile, chlorinated solvents ($CHCl_3$, CH_2Cl_2), toluene and DMF.

2.7. Description of the structures

2.7.1. Compound $[Ni(C_2H_8O_6NP_2)_2(H_2O)_2]$ (1)

The X-ray crystal structure of **1** reveals the presence of discrete species in a molecular type of lattice. The crystal structure diagram of **1** is shown in Fig. 1A, while a packing view of the same complex is provided in Fig. 2A. A list of selected bond distances and angles for **1** is given in Table 2. Complex **1** crystallizes in the monoclinic space group $P2_1/n$ with two molecules per unit cell. The structure shows a mononuclear assembly of Ni(II) bound to two H_3IDA2P^- ligands. In particular, there are two different ligands bound to Ni(II), namely imino bis(methylenephosphonate) ($^-HO_3P–CH_2–NH_2^+–CH_2–PO_3H^-$ = H_3IDA2P^-) and water. The two H_3IDA2P^- ligands in the coordination sphere of Ni(II) are singly deprotonated with the deprotonation site being the hydroxide group of the phosphonate moiety. The second hydroxide group of each phosphonate moiety remains in the protonated form. In this respect, each phosphonate group acts as a monodentate ligand. Finally, two water molecules lie in the equatorial plane of the octahedral metal ion Ni(II).

Analogous cases of bound bis(phosphonate) metal complexes had been previously observed in the case of Co(II) and Mn(II). Specifically, the characterized complexes $[Co(C_2H_8O_6NP_2)_2(H_2O)_2]$ (**3**) [23] and $[Mn(C_2H_8O_6NP_2)_2(H_2O)_2]$ (**4**) [24] exhibit a coordination environment similar to that of Ni(II) generated by two H_3IDA2P^- ligands and two water molecules. A different coordination environment, however, is present in the case of other metal complexes with H_4IDA2P: $Cu[NH(CH_2PO_3H)_2]$ (**5**) [25], $Pb_2[NH(CH_2PO_3)_2]·2H_2O$ (**6**) [26], $Mn[NH_2(CH_2PO_3H)(CH_2PO_3)]·H_2O$ (**7**) [25], $Cu_3[NH_2(CH_2PO_3)_2]_2$ (**8**) [24], $Co_3[NH_2(CH_2PO_3)_2]_2$ (**9**) [24], and $\{Mn[NH(CH_2PO_3H)_2](H_2O)_2\}_2·\{Mn(C_4O_4)(H_2O)_4\}·(C_4H_2O_4)$ (**10**) [27].

The Ni–O bond distances (2.037(1)–2.093(1) Å) in **1** compare favorably with those observed in the crystal structure of complexes $(NH_3CH_2CH_2NH_3)·\{Ni(O_2CCH_2N(CH_2PO_3H)_2](H_2O)_2\}_2$ (2.028(6)–2.097(6) Å) (**11**) [28], $Ni[HO_3PCH_2N(CH_3)CH_2CH_2N(CH_3)CH_2PO_3H](H_2O)_2$ (2.052(4)–2.074(4) Å) (**12**) [29], $[C_{30}H_{50}N_8Ni_2O_2(H_2O)_2]·(ClO_4)_2·CH_3OH·3H_2O$ (2.041(2)–2.141(2) Å) (**13**) [30], and $[Ni(pyr)(H_2O)_4]·[Ni(C_5H_7NO_7P)_2(pyr)(H_2O)_2]·2H_2O$ (2.038(2)–2.110(2) Å) (**14**) [31].

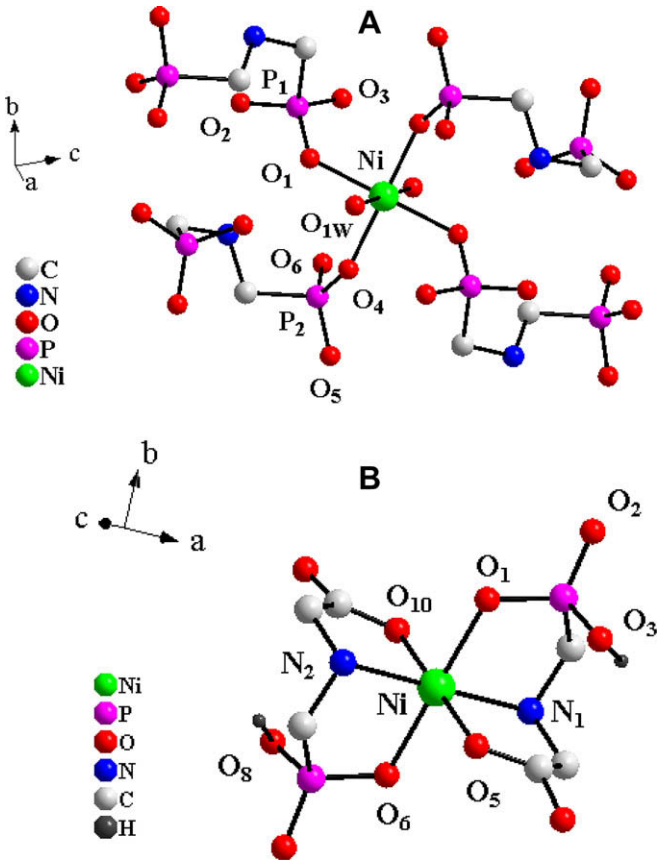


Fig. 1. (A) Crystal structure of $[Ni(C_2H_8O_6NP_2)_2(H_2O)_2]$ (**1**). (B) Partially labeled plot of the anion in **2** with thermal ellipsoids at the 30% probability level.

The angles within the equatorial plane defined by O(4), O(4)′, O(1w) and O(1w)′ are in the range 87.11(5)–92.89(5)°, and hence fairly close to the ideal octahedral angle of 90°. A similar angle variation is observed between the axial donor atoms O(1) and O(1)′ and those in the equatorial plane (range: 86.46(4)–93.54(4)°). The aforementioned angle values are similar to those observed in (**3**)–(**10**) as well as in complexes arisen through interactions of other divalent metals with a diphosphonate ligand similar to H_4IDA2P, i.e. $[Cu(HO_3PC(CH_3)(OH)PO_3H)_2]^{2-}$ (84.7–95.3° and 87.8–92.2°, respectively) [32] and $[Zn(HO_3PC(CH_3)(OH)PO_3H)_2]^{2-}$ (85.0–95.0° and 88.6–91.4°, respectively) [33].

The mode of coordination of the H_3IDA2P^- ligand to Ni(II) in **1** is monodentate. The exact same behavior is observed in the case of the divalent metal ions Co(II) and Mn(II). In the free form, H_4IDA2P consists of two terminal phosphonate groups, both of them capable of binding to Ni(II). However, in the work presented here, the terminal phosphonate group is coordinated to an adjacent Ni(II) ion, which in turn is surrounded by the same type of ligands in an octahedral environment. Finally, the four H_3IDA2P^- binders surrounding the central metal ion Ni(II), are also bound to four other Ni(II) ions due to the presence of the second phosphonate group in each H_4IDA2P molecule. In this sense, saturation of the coordination sites in contiguous octahedral Ni(II) ions extends to infinity, thereby giving rise to the molecular lattice in **1**.

An interesting attribute of the iminodiphosphonate ligand is the presence of a protonated central imino group, reflecting the zwitterionic form of the ligand. Hence, the interaction of the H_3IDA2P^-

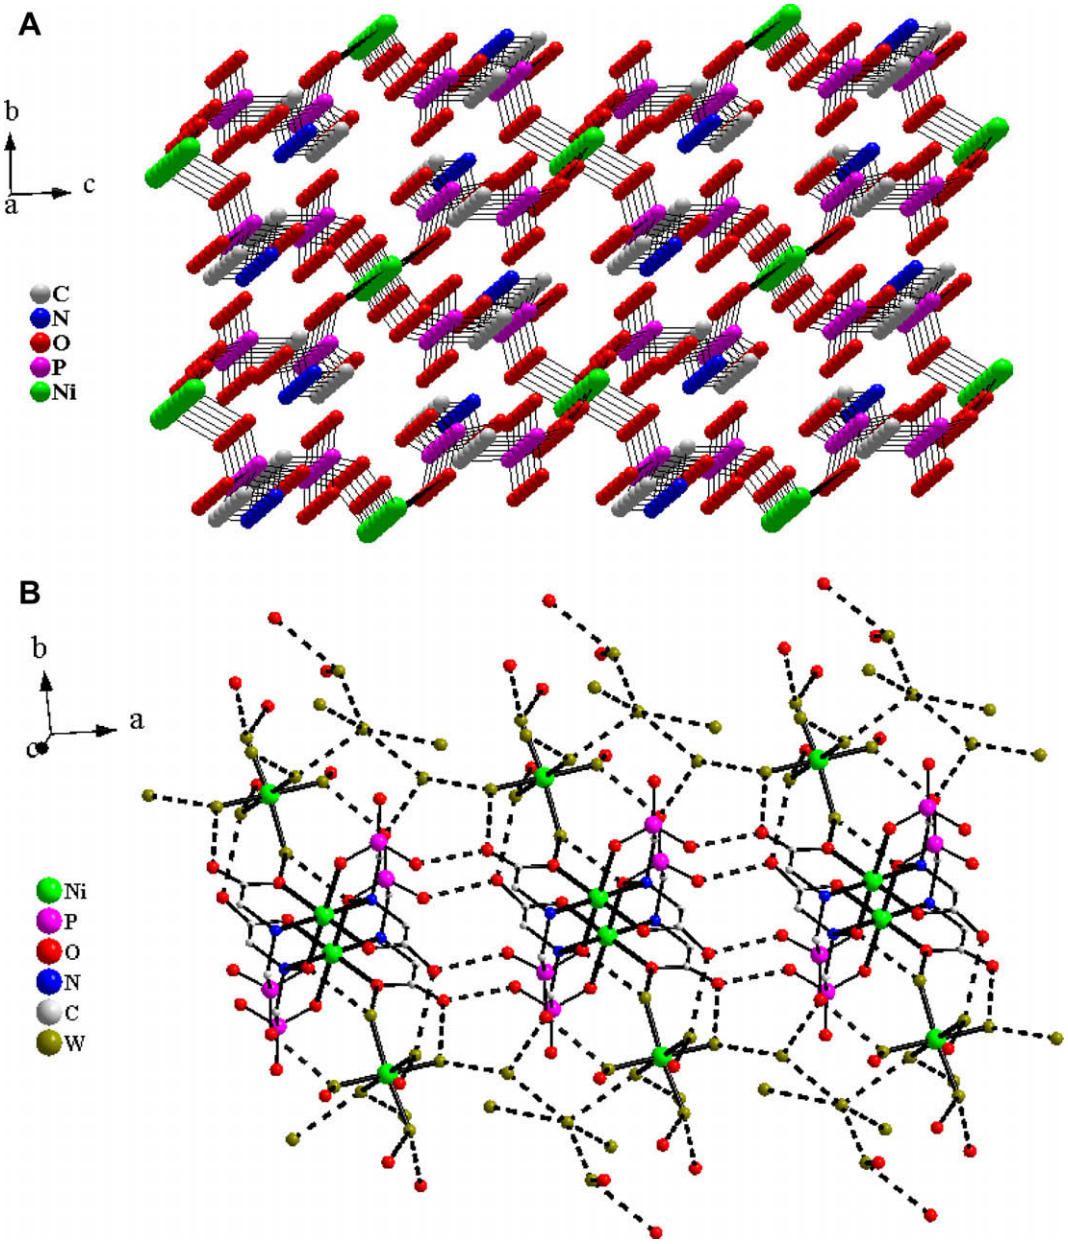

Fig. 2. (A) Packing view of complex **1** in the *bc* plane. (B) Section of the 3D structure of **2** reflecting hydrogen bonding interactions. Water molecules (Ni-bound and free) in the figure are represented as W.

ligand with Ni(II), affording complex **1**, denotes the presence of two singly deprotonated phosphonate groups and a singly protonated imino group. As a result, the overall charge of the iminodiphosphonate ligand coordinated to Ni(II) ion is 1−. Two of these ligands need to balance the overall zero charge of the isolated species. The two additional H_3IDA2P^- ligands coordinated to Ni(II) do not contribute to the overall charge, as they originate in an adjacent mononuclear Ni(II) site and complete the octahedral coordination sphere of Ni(II). The remaining two coordination sites of Ni(II) ion are occupied by two water molecules.

2.7.2. Compound $[Ni(OOC–CH_2–NH–CH_2–PO_3H)_2]·[Ni(H_2O)_6]·3.3H_2O$ (**2**)

Complex **2** crystallizes in the monoclinic space group $P2_1/n$ with four molecules per unit cell. The lattice of **2** consists of discrete mononuclear cations and anions. A list of selected bond distances and angles for **2** is given in Table 2. In the first mononuclear unit, the six coordination sites of Ni(II) (Ni(1)) are occupied by two glyphosate ligands (Fig. 1B). Each glyphosate ligand bound to Ni(II) ion acts as a chelator with a 2− charge ($HIDAP^{2-}$), since the two terminal sites of the glyphosate ligand are deprotonated, i.e. the carboxylate and phosphonate moieties. The second hydroxide moiety of the phosphonate group remains protonated. The imino nitrogen of the bound glyphosate ligand is not protonated as in the case of the H_3IDA2P^- ligand in **1**. As a result, it actively participates in the coordination of the $HIDAP^{2-}$ ligand to the central Ni(II) ion. To this end, in each bound glyphosate two five-membered chelate rings form, defined by Ni–N–C–P–O and Ni–N–C–C–O, respectively, which provide stability to the isolated complex **2**. The two five-membered rings defined by Ni–N–C–P–O adopt the stable envelope configuration with atoms C(4) and C(1) displaced ~0.60 Å out of the best mean plane of the remaining four atoms. In the case of the five-membered rings defined by Ni–N–C–C–O, the out-of-plane atoms are C(2) and C(5), displaced at 0.31 and 0.25 Å, respectively, out of the best mean plane of the remaining four atoms. The negative charge of the first mononuclear unit is counterbalanced

Symmetry operations for **1** and **2**: (i) x, y, z; (ii) $-x+1/2,\ y+1/2,\ -z+½$; (iii) $-x, -y, -z$ and (iv) $x-1/2, -y-1/2, z-1/2$.

by the positive charge of the second mononuclear unit, which is the well-known hexa-aqua Ni(II) ion $[Ni(H_2O)_6]^{2+}$ (Ni(2)). Ni(2) is coordinated to six water molecules in an octahedral fashion, displaying a 2+ charge.

Finally, it is worth re-emphasizing the presence of the hexa-aqua Ni(II) ion, $[Ni(H_2O)_6]^{2+}$, in the lattice of complex **2**. This mononuclear dicationic unit is not unlikely to appear in a crystal lattice. It was observed in the lattice of other Ni(II)-complexes displaying similar ligand coordination modes, including: $[Ni(H_2O)_6][Ni(H_2O)_2(C_4H_2O_4)]\cdot 4H_2O$ (**20**) [34], $[Ni(H_2O)_6][Ni_2(C_{10}H_4O_4N_2)_3]\cdot 5H_2O$ (**21**) [35], $[Ni(H_2O)_6][Ni(C_4H_4O_4S)_2]\cdot 4H_2O$ (**22**) [36] and $[Ni(H_2O)_6][Ni(C_7H_3O_4N)_2(H_2O)_2]$ (**23**) [37].

The Ni(1)–O distances (2.049(4)–2.132(4) Å) in complex **2** are similar to those observed in other Ni(II)–O, N compounds (**11**–**14**). The glyphosate ligand, on the other hand, is coordinated in a variety of coordination modes exemplified in the following complexes reported in the literature: $[Cd(C_3H_6NO_5P)(H_2O)_2]_n$ (**15**) [38], $NaCu[O_2CCH_2NHCH_2PO_3]\cdot 3.5H_2O$ (**16**) [6], $Pb[O_3PCH_2NH_2CH_2COO]$ (**17**) [39] and the trivalent metal ion complexes $Na_3[Co(C_3H_5PNO_5)_2]\cdot 11H_2O$ (**18**) [40] and $[Eu_2(HO_3PCH_2NH_2CH_2CO_2)_2(H_2O)_7(ClO_4)]\cdot 3ClO_4\cdot H_2O$ (**19**) [41]. The lattice structure of **2** is stabilized by an extensive hydrogen bonding pattern (Fig. 2B, Table 3) in a 3D network.

2.8. UV–Vis spectroscopy

The UV–Vis spectrum of **1** was recorded in water (Fig. 3). The spectrum exhibits a major absorption at $\lambda_{max} = 395$ nm ($\varepsilon \sim 2.5\ M^{-1}\ cm^{-1}$) and a distant band around 208 nm ($\varepsilon \sim 25\ M^{-1}\ cm^{-1}$). The remaining absorption features are most likely due to d–d transitions typical for a Ni(II) d^8 octahedral species [42]. The absorption feature around 395 nm ($\varepsilon \sim 2.5\ M^{-1}\ cm^{-1}$) could be tentatively attributed to the $^3A_{2g} \rightarrow {}^3T_{1g}(P)$ transition. The observed multiple structure containing the 656 and 730 nm features, a region normally corresponding to the $^3A_{2g} \rightarrow {}^3T_{1g}(F)$ transition, is in line with literature reports invoking the presence of an ^1E_g state lying so close to $^3T_{1g}$ that extensive mixing takes place. That mixing leads to the observation of a doublet band, where the spin forbidden transition picks up intensity from the spin-allowed transition, thus accounting for the complexity of the spectrum [43]. In the absence of detailed studies no further assignments could be proposed.

Table 3
Hydrogen bonds in **2**.

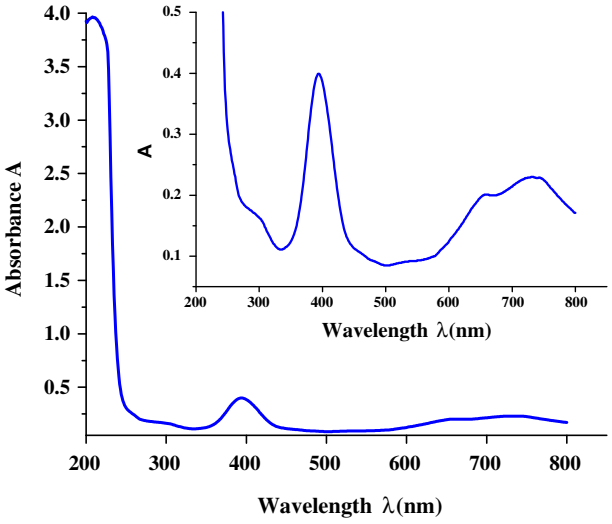

Fig. 3. UV–Vis spectrum of **1** in water.

2.9. FT-IR spectroscopy

The FT-IR spectrum of **1** was recorded in KBr. The spectrum exhibits strong absorptions for the PO_3 groups observed in both the antisymmetric $\nu_{as}(PO_3)$ and symmetric $\nu_s(PO_3)$ vibration regions. Specifically, the antisymmetric stretching vibrations appear in the range between 1090 and 980 cm^{-1}, whereas the symmetric stretching vibrations appear in the range 970–920 cm^{-1}. The frequencies for the aforementioned stretches appear to be shifted to lower values compared to those of free H_4IDA2P acid, indicating changes in the vibrational status of the ligand due to coordination to the Ni(II) ion [23,24].

The FT-IR spectrum for complex **2** in KBr exhibits strong absorptions for the vibrationally active carbonyl moiety of the

carboxylate and PO_3 groups of the glyphosate ligand in both the antisymmetric and symmetric vibration regions. The antisymmetric stretching vibrations $\nu_{as}(COO^-)$ appear in the range from 1600 to 1550 cm^{-1}, whereas the corresponding symmetric stretches $\nu_s(COO^-)$ appear in the range from 1475 to 1385 cm^{-1}. In the same respect, the antisymmetric stretching vibrations $\nu_{as}(PO_3)$ appear in the range from 1209 to 1140 cm^{-1}, whereas the symmetric stretching vibration $\nu_s(PO_3)$ appear in the range from 1074 to 993 cm^{-1}. The frequencies of the various stretches are shifted to lower values compared to those of the free glyphosate binder, due to the coordination of the ligand to the Ni(II) ion [44].

2.10. Thermogravimetric studies

The thermal decomposition of both **1** and **2** was studied by TGA-DTG under an atmosphere of oxygen (see Supplementary data). The TGA diagram shows that an initial process involves the loss of water molecules per formula unit of **1**. The release of Ni(II)-coordinated water molecules until 285 °C, signifies an exothermic process associated with the specific part of the diagram. The observed weight loss amounts to 9.2%, a value very close to the calculated value of 7.2% based on the molecular formula of **1**. Two additional steps are observed in the thermal decomposition of **1**: (a) the release of water molecules due to condensation of the hydrogen phosphonate groups, and (b) the decomposition of the organic moiety. The total weight loss of complex **1** is close to 60.0% and is reached at approximately 1000 °C.

In much the same fashion, the TGA diagram of **2** shows an initial process reflecting the loss of water molecules. The release of all water molecules up until ~300 °C, signifies an exothermic process associated with the specific part of the diagram. The observed weight loss amounts to 28.2%, a value very close to the calculated value of 27.0% based on the molecular formula of the title complex. Two additional steps are observed owing to (a) the carboxylate and phosphonate moieties, and (b) the decomposition of the organic moiety in **2**. The total weight loss due to the decomposition of all the organic composition of **2** is 45.7% and is reached at approximately 935 °C, signifying an endothermic process. The small number of observed TGA peaks reflects simple mechanisms of decomposition for complex **2**.

2.11. Cyclic voltammetry

The cyclic voltammetry of complex **1** was studied in aqueous solutions, in the presence of KNO_3 as a supporting electrolyte (Fig. 4). The cyclic voltammogram projects a well-defined electrochemical behavior, with a pronounced chemically reversible process reflecting: (a) a reduction wave at E_{pc} 0.436 V, and (b) an oxidation wave at E_{pa} 0.616 V, and $E_{1/2}$ 526 mV ($i_{pc}/\{(v)^{1/2}C\}$ constant and $i_{pa}/i_{pc} = 1$). This behavior reflects a process involving the Ni(II)/Ni(III) redox couple. Attempts to pursue the redox chemistry of complex **1** at such high redox potentials are currently ongoing.

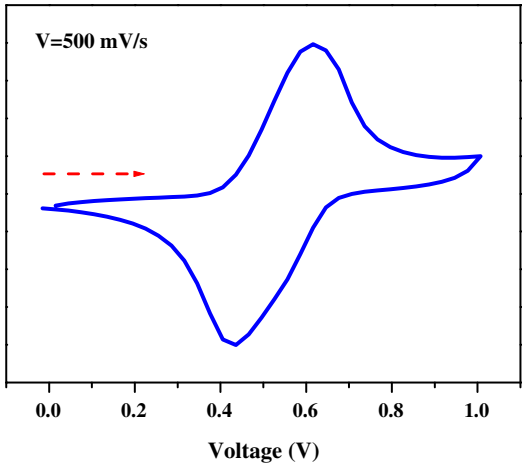

Fig. 4. Cyclic voltammetry of complex **1** in aqueous solutions (scan rate 500 mV/s).

2.12. Magnetic susceptibility studies

Magnetic susceptibility measurements were carried out at different magnetic fields in the temperature range 2–300 K. The temperature dependence of $\chi_M T$ (χ_M being the magnetic susceptibility for one Ni(II) ion) for complex **1** is shown in Fig. 5 (open stars). The $\chi_M T$ value is 1.42 emu mol^{-1} K at 300 K and until 10 K there is a smooth linear decrease. Below that temperature and down to 2 K, a more pronounced decrease occurs reaching the value of 0.8 emu mol^{-1} K. The shape of this curve is characteristic of the occurrence of large zero field effects along with the temperature independent paramagnetism (TIP) effect. The latter effect leads to a linear temperature dependence of the susceptibility data. The susceptibility data were fitted by the following equation:

$$H = D\left[S_z^2 - \frac{1}{3}S(S+1)\right] + E(S_x^2 - S_y^2) + g_z\mu_B H_z S_z + g_x\mu_B H_x S_x + g_y\mu_B H_y S_y \quad (1)$$

where an isotropic g-value was used. The best fit (solid line in Fig. 5) is given by the parameters $D = 4.3(2)$ cm^{-1} and $g = 2.3(1)$, TIP = 9.8×10^{-4}. In the inset of the figure, simulations of the susceptibility function are shown for different values of the D parameter, where the g and TIP values were those obtained from the fitting procedure.

2.13. Magnetization studies

The isothermal magnetization curve at $T = 1.8$ K, in the applied field 0–5 T, is shown in Fig. 6. The curves for the increasing and decreasing fields are identical. The data were fitted using (Eq. (1)) and the best fit (solid line in Fig. 6) is given by the parameters of $D = 3.8(1)$ cm^{-1}, $g = 2.3(1)$. The latter are very close to the values

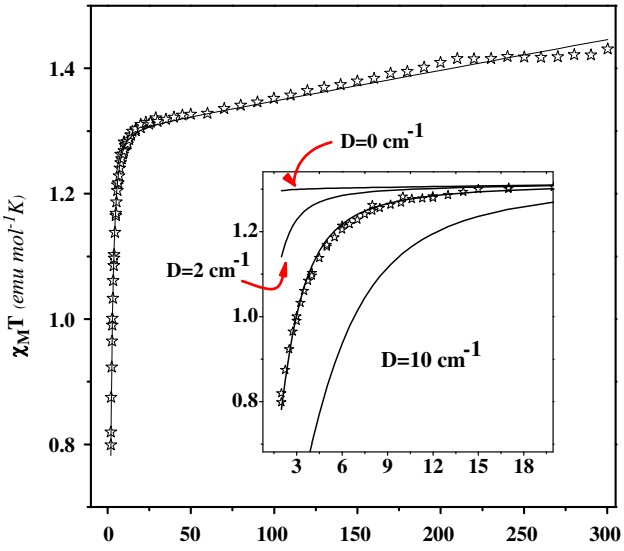

Fig. 5. Temperature dependence of the susceptibility data in the form of $\chi_M T$ vs. T (solid stars) and the fitting results using the theoretical formula discussed in the text (solid line). In the inset simulations of the susceptibility function are shown, in the form of $\chi_M T$ vs. T, for different values of the D parameter.

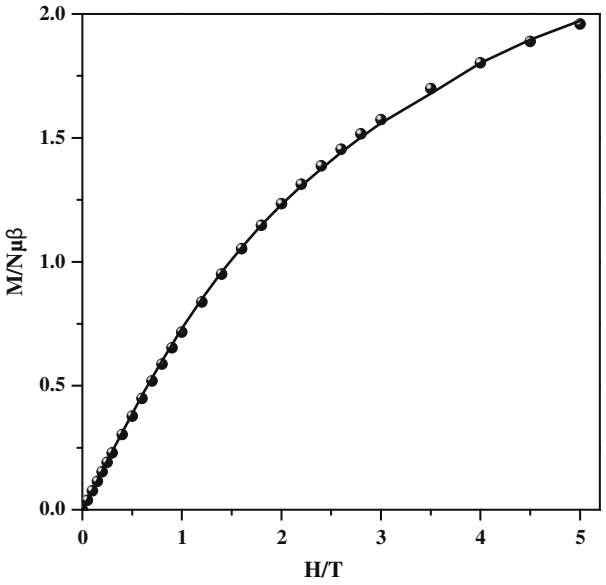

Fig. 6. Magnetization measurements, in the form of $M/N_{\mu\beta}$ vs. H/T, in the field range 0–5 T and at temperature $T = 2$ K, and fitting results using the theoretical formula discussed in the text (solid line).

obtained from the susceptibility study, thus verifying the large zero-field character of the system.

3. Discussion

3.1. The aqueous binary Ni(II)–organophosphonate chemistry

The interaction of two organophosphonate ligands with the divalent metal ion Ni(II), at specific pH values in aqueous media, led to the isolation of two compounds (**1** and **2**). The two ligands employed in these interactions exhibit a zwitterionic form in the free state, i.e. $H_2O_3P–CH_2–NH_2^+–CH_2–PO_3H^-$ and $HOOC–CH_2–NH_2^+–CH_2–PO_3H^-$. This zwitterionic form is essential to the developing synthetic chemistry with Ni(II). In both binary Ni(II)–phosphonate systems, a number of factors appeared to play a role in the isolation of **1** and **2**: (a) the pH of the employed reaction mixture. The acidic reaction conditions in both cases facilitated the formation of the crystalline compounds. Raising the pH of the reaction mixture resulted in the formation of a precipitate of non-crystalline nature in both systems. In the case of the binary Ni(II)–H_4IDA2P system, formation of insoluble precipitate occurred at pH 4, with no dissolution of the precipitate observed at higher pH values. In contrast to that behavior, formation of a precipitate in the second binary system occurred at pH 7. In view of the ostensible pH-dependent behavior of the two binary Ni(II)–organophosphonate systems, it would not be unlikely to consider the existence of the carboxylic moiety in the glyphosate molecule as one of the key factors providing increased solubility to the Ni(II)–glyphosate system compared to the diphosphonate counterpart and (b) the involvement of the alkali solutions in the adjustment of the reaction mixture pH of each binary system investigated. Despite the use of different bases (NaOH, KOH, ammonia) in the binary reaction mixtures, the molecular formulation of the isolated products, as proven by elemental analysis and X-ray crystallography, did not include counter ions originating in those bases. Therefore, the sole use of bases was to adjust the pH and facilitate isolation of the crystalline products **1** and **2**. Moreover, in the case of complex **1**, different molar ratios in the Ni(II)–H_4IDA2P system were employed affording the isolation of **1**. It appears, therefore, that complexes **1** and **2** are stable enough to be isolated under variable reaction conditions. Even though, **1** and **2** are the first isolated products resulting from the interaction of Ni(II) with the two aforementioned phosphonate ligands, the possibility of other Ni(II)-(carboxy)phosphonate species (arising from such specific interactions) being present in solution and currently eluding isolation and characterization, cannot be discounted.

Undoubtedly, the herein described species **1** and **2** project chemical and structural features that emphasize (a) the unique chemistry of phosphonate and mixed carboxy-phosphonate substrates toward Ni(II), and (b) the differentiation of the composition and structure of the derived and ultimately isolated species brought about by the distinct nature of the phosphonate substrates reacting with Ni(II) under the employed conditions. Collectively, therefore, the observed physicochemical behavior of the substrates H_4IDA2P and H_3IDAP influences quite elegantly the nature of binary interactions developing between them and Ni(II). To this end, it would not be unreasonable to envision analogous interactions emerging between that metal ion and corresponding phosphorylated substrates (amino acids, peptides, proteins) and organophosphonate drug substrates in the requisite aqueous speciation of a biological setting. Delving into the exploration of such interactions (a) with low and high molecular mass phospho-derivative biotargets, and (b) at the binary and ternary level, is a challenge of multidisplinary approaches, currently under investigation in the lab.

3.2. Relevance to Ni(II)–organophosphonate materials

Over the last decades, special attention has focused on delineating the reactivity of organophosphonate ligands toward metal ions, such as Ni(II), Co(II), Mn(II), etc. Materials arising from such interactions are employed in a plethora of applications, including catalysis and intercalation chemistry. In this regard, the nature of the organophosphonate binders is crucial in the isolation of metal–ligand frameworks with well-defined properties. Substrates containing one phosphonate group [45,46], such as glyphosate, or various diphosphonic acids [47,48], such as $H_2O_3P–R–PO_3H_2$ (R=alkyl, phenyl, alkylimino, benzylimino, etc.) under diverse reaction conditions are likely to afford new interesting materials with variable physicochemical properties reflected into the size of the employed binder, the shape, the complexity, the nature of the terminal groups, and their chemical reactivity. Under the influence of these factors, various metal frames may emerge, differing in the size of the final metal frame, the inter-layer distance, the lattice, the coordination shape, etc. To date, a limited number of Ni(II)–phosphonate materials have been synthesised either through interactions at room temperature or chemical reactivity at high temperatures (hydrothermal and/or solvothermal conditions) [49].

The organophosphonate ligands presented in this work, are multifunctional binders that bind metalloelements in a variety of ways. The iminodiphosphonate and imino-carboxy-phosphonate ligand bind Ni(II) ions in an octahedral fashion, with each phosphonate group in compounds **1** and **2** being singly deprotonated. The variety of lattices achieved through the interaction of metal ions with such binders is exemplified in both **1** and **2**, given that the iminodiphosphonate ligand is coordinated to Ni(II) ion in a monodentate fashion **1**, whereas the imino-carboxy-phosphonate ligand acts as a chelator in **2**. A reflection of the distinct nature of the arising binary Ni(II)–L interactions due to the nature of the ligand L, is the extended structure of **1**, which is composed of a repeat unit configured by four mononuclear Ni(II) octahedral sites. Therefore, the iminodiphosphonate groups of the H_4IDA2P binders exhibit the role of a linker, bringing four Ni(II) ions in each arising unit. Each such unit is basically a 32-membered ring. Each ring defines the periphery of a large elliptical cavity, with the calculated

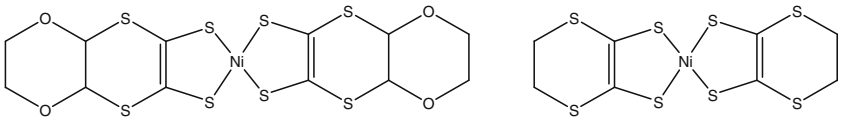
dimensions being 8.094 Å (*b* axis) and 13.897 Å (*c* axis). The formulated area of each cavity approaches 88.4 $Å^2$. Furthermore, the height of the void space between contiguous elliptical cavities in the lattice is 7.33 Å (*a* axis), thus leading to a volume of ~648 $Å^3$ for each cavity. Complex **1** is X-ray isomorphous to the already characterized species between Co(II) and H_4IDA2P [23]. In conclusion, the nature of the phosphonate substrate does influence the nature of interactions and the ultimately isolated binary Ni(II)–phosphonate compound.

On the basis of the aforementioned grounds, compounds **1** and **2** exhibit composition (exchangeable water ligands, carboxy-phosphonates, phosphonates) and structural properties that could support chemical reactivity toward other metal ionic species (complexes or clusters) under appropriately configured reaction conditions. To this end, **1** and **2** could serve as viable candidate precursor species that can be used in the synthesis of homometallic or heterometallic Ni(II)-(M)-phosphonate advanced materials of variable nuclearity and physicochemical properties (e.g. magnetic). Research in this direction is currently ongoing in our lab.

4. Conclusions

The pH-specific synthetic chemistry presented in this work led to well-defined binary Ni(II)–organophosphonate species of distinct physical, chemical and structural properties. The collective physicochemical properties of **1** and **2** define the characteristics for which such species could be useful in the synthesis of advanced Ni(II)–(carboxy)phosphonate materials. Moreover, in both complexes, the retention of the octahedral environment around Ni(II), suggests that the particular metal ion could interact aptly, in a unique fashion, with imino-phosphonate ligands, such as imino bis(methylenephosphonic acid) and *N*-(phosphonomethyl) glycine, or similar substrates, such as aminoalkylphosphonate and IDA derivative phosphonate substrates. Given the essentiality of Ni(II) in the biological systems as well as its toxicity potential, the herein presented species reflect the nature of the arising binary interactions in potential participants of variably formulated aqueous Ni(II)–phosphoderivative binary systems. It remains to be seen whether species such as those encountered in **1** and **2** reflect corresponding binary forms of Ni(II) with actual phosphorylated cellular targets (amino acids, peptides, etc.) or organophosphonate drug molecules, further influencing the physiology or toxicity at the cellular level.

Supplementary data



CCDC 722262 and 722263 contain the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgments

This work was supported by a "PENED" grant co-financed by the EU – European Social Fund (75%) and the Greek Ministry of Development – GSRT (25%).

Scheme 1. Structural formulas of $Ni(edodddt)_2$ and $Ni(dddt)_2$.

In this paper the synthesis of a new metal 1,2-dithiolene similar to $Ni(dddt)_2$ is described. It contains an ethylene-dioxo group extension, as an additional heteroatom group and the transition metal Ni (Scheme 1). Electrochemical measurements, X-ray measurements and spectral investigations have been made. DFT studies are also included.

2. Experimental

2.1. Materials and methods

All starting materials of analytical grade were obtained commercially and used as received, except the methanol that was dehydrated according to the literature [12].

2.2. Synthesis of 2,3-dichloro-1,4-dioxane (**2**)

The starting material 2,3-dichloro-1,4-dioxane (**2**) was prepared according to the literature by chlorination of 1,4-dioxane. The product was a mixture of *cis* and *trans* isomers [13].

2.3. 4,5-(1,4-Dioxane-2,3-diyldithio)-1,3-dithiole-2-thione (**3**)

2,3-Dichloro-1,4-dioxane (**2**) (1.65 g, 10 mmol) was dissolved in 200 ml acetone and 5 g (5 mmol) of $(Bu_4N)_2Zn(dmit)_2$ were added. The solution was refluxed for 20 h and the color changed from bright red to yellow-brown. The solvent was evaporated and the resulting dark-brown sticky residue was washed with 200 ml of water and extracted with 200 ml of dichloromethane. The organic layer dried with magnesium sulfate and filtered. Purification of the final product was made by column chromatography in silica gel using CH_2Cl_2 as eluent. Yellow-brown crystals were produced.

Yield: 1.7 g, (60%); mp: 187 °C; UV–Vis (CH_3CN, nm): 238, 268, 395, nm; ^1H NMR (300 MHz, $CDCl_3$) δ(ppm): 5.52 (s, 2H), 4.07 (m, 2H), 3.76 (m, 2H); IR data (ν, cm^{-1}): 2967, 2936, 2906, 2860, 1490, 1442, 1366, 1322, 1274, 1241, 1118, 1091, 1037, 1014, 989, 935, 879, 853, 813, 748, 588, 565.

2.4. 4,5-(1,4-Dioxane-2,3-diyldithio)-1,3-dithiol-2-one (**4**)

Oxidation of thione (**3**) with mercuric acetate in acetic acid affords the 4,5-(1,4-dioxane-2,3-diyldithio)-1,3-dithiol-2-one (**4**) as white-yellow crystals [14].

Yield: (77%); mp: 144–146 °C, UV–Vis (CH_3CN, nm): 286, nm; ^1H NMR (300 MHz, $CDCl_3$) δ(ppm): 5.50 (s, 2H), 4.07 (m, 2H), 3.76 (m, 2H); IR data (ν, cm^{-1}): 2980, 2932, 2915, 2865, 1771, 1674, 1644, 1615, 1513, 1445, 1365, 1323, 1273, 1241, 1120, 1095, 1043, 1015, 992, 938, 901, 878, 852, 765, 745, 587, 565, 537.

2.5. Bis[4,5-(1,4-dioxane-2,3-diyldithio)-1,3-dithiole] Nickel tetrabutylammonium [$(Bu_4N)Ni(edodddt)_2$] (**5**)

Ketone (**4**) (100 mg, 0.38 mmol) was added to sodium metal (20 mg, 0.87 mmol) dissolved in 15 ml methanol. The mixture was stirred for an hour, under nitrogen atmosphere. Addition of a solution of Nickel chloride hexahydrate (45 mg, 0.19 mmol) in 5ml methanol was made and has been stirred for 30 min. An addition of a solution of tetrabutyl ammonium bromide (122 mg, 0.38 mmol) in 5 ml methanol followed, resulting to the precipitation of a dark green solid. The solid was removed by filtration in vaccuo and washed repeatedly with methanol to give **5** as a dark powder.

Yield: 108 mg, (76%), of pure product. mp: 156 °C; UV–Vis (CH_2Cl_2, nm): 1089 (ε = 17 385), 581(ε = 2338), 380 (ε = 10 469), 305 (ε = 39 815); IR data (ν, cm^{-1}): 2958, 2926, 2866, 1442, 1388, 1334, 1271, 1232, 1118, 1090, 1066, 1047, 932, 889, 747, 733, 663, 597, 561; Raman Shifts (cm^{-1}): 141, 245, 356, 417, 456, 487, 526, 565, 594, 895, 995, 1138, 1439, 1490, 2863, 2936, 2975; Elemental *Anal. Calc.* for $C_{28}H_{48}NNiO_4S_8$: C, 43.23; H, 6.22. Found: C, 42.95; H, 6.35%.

2.6. Bis[4,5-(1,4-dioxane-2,3-diyldithio)-1,3-dithiole] Nickel [$Ni(edodddt)_2$] (**6**)

The compound **5** (50 mg 0.065 mmol) was dissolved in PhCN (5 ml), heated and filtered. TCNQ (13 mg 0.065 mmol) was dissolved in ACN (5 ml) heated and filtered. The two filtrates ware united and refluxed for 40 min. The solution left to stand at room temperature for 24 h. The dark solid was filtered and washed with ACN.

Yield: 29 mg, (57%); mp: >290 °C; UV–Vis (CH_2Cl_2, nm): 944 (ε = 43 431), 648 (ε = 56992), 374 (ε = 12777); ^1H NMR (300 MHz, $CDCl_3$) δ(ppm): 5.45 (s, 4H), 4.11 (m, 4H), 3.74 (m, 4H); IR data (ν, cm^{-1}): 2975, 2930, 2897, 2845, 1444, 1381, 1368, 1328, 1283, 1263, 1235, 1112, 1085, 1062, 1042, 1022, 981, 935, 894, 880, 851, 756, 610, 564; Raman Shifts (cm^{-1}): 125, 162, 250, 278, 297, 317, 355, 371, 392, 413, 460, 498, 533, 832, 880, 912, 1368, 2668, 2855, 2976; Elemental *Anal. Calc.* for $C_{12}H_{12}NiO_4S_8$: C, 26.92; H, 2.26. Found: C, 26.50; H, 2.35%.

3. Analysis and physical measurements

Elemental analyses were obtained on a Perkin–Elmer 2400 Series II elemental analyser. Melting points were determined in open-end capillaries using a Buchi melting point apparatus (pat. 320–388) at a ramp rate 120 (a.u.) without calibration. Solution 1H NMR spectra were recorded on Varian 300 MHz. Chemical shifts are reported in ppm downfield of TMS. UV–Vis spectra were obtained by the Perkin–Elmer, UV/Vis/Nir Lambda 19 spectrometer FTIR spectra were obtained by a Bruker equinox 55 and. Raman spectra were recorded on a Renishaw inVia Reflex Raman microscope system using the 514 and 785 nm laser lines.

4. Single crystal X-ray crystallography

Data were collected on an Oxford Diffraction Xcalibur-3 diffractometer (equipped with a Sapphire CCD area detector) using a graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). A crystal of compound $[Ni(edodddt)_2]\cdot 1.88H_2O$ (black needle, size 0.1 × 0.04 × 0.03 mm) was attached to a glass fiber using silicone grease and transferred to a goniostat where it was cooled to 100 K for data collection. Data were collected using the ω-scan

method (0.75° frame width). Empirical absorption corrections (multiscan based on symmetry-related measurements) were applied using the CRYSALIS RED software.[15] The structure was solved by direct methods using SHELXS-97, and refined on F^2 using full-matrix least-squares with SHELXL-97 [16]. The non-H atoms were treated anisotropically, whereas the H atoms were placed in calculated, ideal positions and refined as riding on their respective C atoms. The programs used were CRYSALIS CCD [15] for data collection, CRYSALIS RED 15 for cell refinement and data refinement and WINGX [17] for crystallographic calculations. Unit cell parameters and structure solution and refinement data are listed in Table 1.

5. Results and discussion

5.1. Synthesis

The thione **3** was first synthesized by Kotov in 25% yield by [2 + 4] cycloaddition of 1,3-dithiole-2,4,5-trithione oligomer to 1,4-dioxene [18]. We used a new improved method for its preparation with a yield of 60% (Scheme 2). The starting material 1,2-dichlorodioxane **2** was prepared by chlorination of dioxane. The nucleophilic displacement reaction of $(Bu_4N)_2Zn(dmit)_2$ with **1** in one step gave thione **3**. The thione **3** was converted to ketone **4** by treatment with $Hg(CH_3COO)_2$ in CH_2Cl_2/CH_3COOH [14]. Deprotection of ketone **4** with a base (MeONa) in MeOH leads to the formation in situ of the corresponding dithiolene salt **5**. The neutral complex **6** can be obtained by oxidation with TCNQ. The **6** was obtained as a dark powder.

In an attempt to obtain crystals, an acetone–isopropanol (1/1) solution of **5** was left to evaporate. During this open to the air procedure the salt **5** oxidizes to neutral **6** and water condensed in the solution to give crystals of $[Ni(edodddt)_2]\cdot 1.88H_2O$ suitable for crystallographic studies.

5.2. Crystal structure of bis[4,5-(1,4-dioxane-2,3-diyldithio)-1,3-dithiole] Nickel

Compound $[Ni(edodddt)_2]\cdot 1.88H_2O$ crystallizes in the monoclinic space group $P2_1/n$. A labeled ball and stick representation of the compound is given in Fig. 1 and selected bond lengths and angles from the crystal structure determination and calculated values from DFT studies are shown in Tables 2 and 3.

The crystal structure consists of compound $[Ni(edodddt)_2]$ and also 1.88 water molecules of crystallization. The water molecules occupy two sites. Compound $[Ni(edodddt)_2]\cdot 1.88H_2O$ contains one Ni^{2+} ion linked with the two vicinal exocyclic sulfur atoms of the two chelating ligands. The Ni atom is thus tetra-coordinate and has a square planar geometry. The dioxo outer rings adopt a chair conformation preventing the formation of stacks with short intermolecular contacts. The packing motive of the crystal along the α-axis, shown in Fig. 2, reveal a parallel alignment of the $[Ni(edodddt)_2]$ molecules.

A close examination of the packing revealed the existence of intermolecular hydrogen-bonding interactions involving the crystallization H_2O molecules (O···O separations = 2.769 Å) and also the C, O, S atoms of the ligands (C···O, C···S separations = 3.285-3.426 Å). The closest Ni···Ni distance is 4.5870(1) Å which is the length of the b-axis. The Ni–S bond lengths are 2.123(2) [Ni–S1] and 2.132(2) [Ni–S2] Å, whereas the S–C, C = C and C–O bond distances are 1.700(6)–1.751(6) Å, 1.378(8) and 1.415(7)–1.449(7) Å, respectively. These bond distances of the $[Ni(edodddt)_2]\cdot 1.88H_2O$

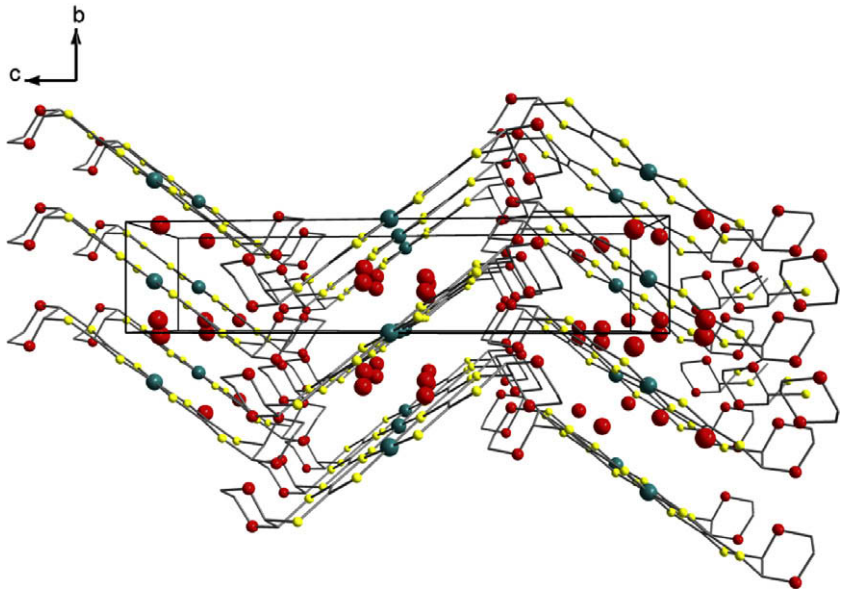

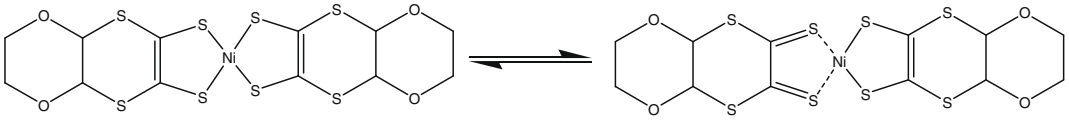

Fig. 2. Packing of [Ni(C_6H_6 O_2 S_4)$_2$] ·1.88H_2O molecules, viewed down the *a*-axis. Color code: Ni, green; O, red; S, yellow; C, gray. H atoms were omitted for clarity. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

compound lie within the range observed for other neutral dithiolenes [5,9,19–22]. Finally, it can be seen that the C2–S2 and C1–S1 distances are shorter than the C2–S4 and Cl–S3 distances, respectively. This is not surprising since resonance structures with the ligand in the radical form allow for a partial C1–S1 and C2–S2 double bond (Scheme 3).

5.3. IR, Raman

The Raman spectra of **6** were acquired using the 514 and 785 nm (Fig. 8a) laser lines. It showed in both frequencies the characteristic vibrations of S–Ni–S and Ni–S at 125, 371, 413 and 498 cm^{-1} (125, 417 and 487 cm^{-1} for **5**) and the characteristic vibrations of O–C–C, C–O–C and C–O at 355 cm^{-1}, 392 and 460 cm^{-1} (356 and 456 cm^{-1} for **5**). There are also intensities at 533, 832, 880 and 912 cm^{-1} (526, 565 and 895 cm^{-1} for **5**) which are corresponding to the S–C–S and S–C vibrations. The C=C appears at 1368 cm^{-1} (1439 cm^{-1} for **5**). The intensities at 2668, 2855 and 2976 cm^{-1} correspond to the C–H vibrations and appear only by excitation with the 514 nm and not with the 785 nm laser lines, (in the compound **5** these intensities appear at 2863, 2936 and 2975 cm^{-1} and are enhance due to the existence of the tetrabutyl moiety). This is probably a result of the different Raman crosssection between the two excitation lines.

[b] vs. SCE as reference electrode in CH_2Cl_2..
[c] Ag/AgCl as reference electrode in CH_2Cl_2.

$[NBu_4][Ni(edodddt)_2]$ displays a very rich IR spectra with characteristic peaks. The stretching vibrations of O–C bonds are observed at 932, 1047, 1066 and 1090 cm^{-1}. The S–C stretching vibrations are also present in the IR spectra at 747 and 889 cm^{-1}. Furthermore there are also the characteristic bands in the region between 2800 and 3000 cm^{-1} related to the C–H stretching vibrations.

The neutral complex **6** shows the same peaks at 935, 981, 1042, 1085 cm^{-1} for the O–C stretching. The S–C stretching appears at 756, 851, 880 and 894 cm^{-1}. There are also the characteristic bands between 2800 and 3000 cm^{-1} related to the C–H stretching vibrations.

In this paper also the theoretical IR and Raman spectra of the neutral complex **6** were calculated (Figs. 8 and 9). The comparison between them and the experimental ones is discussed later.

5.4. UV–Vis–NIR spectra

The UV–Vis–NIR spectra of complexes **5** and **6** are shown in Fig. 3.

The complex **5** in dichloromethane shows a strong broad absorption at 1089 nm (ε = 17385 dm^3 mol^{-1} cm^{-1}) which is assigned to a $\pi \rightarrow \pi^*$ transition ($2b_{1u} \rightarrow 3b_{2g}$) [19]. The characteristic long wave transition is also found in the **6** complex at 944 nm (ε = 43 431 dm^3 mol^{-1} cm^{-1}).

There are also bands at 581 and 380 nm which are assigned to a $\pi \rightarrow$ Ni and Ni $\rightarrow \pi$ transitions, respectively [19]. These bands are also observed in the neutral complex **6** at 648 and 374 nm.

5.5. Cyclic voltammetry

The electrochemistry of the complex **6** was investigated using cyclic voltammetry in CH_2Cl_2 (versus Ferocene with $Ag/AgNO_3$ as reference electrode and Pt as working electrode, Fig. 4). As

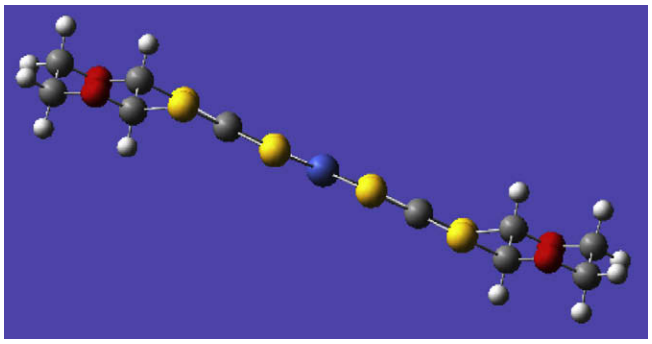

Fig. 6. Calculated geometrical position of the $Ni(edodddt)_2$.

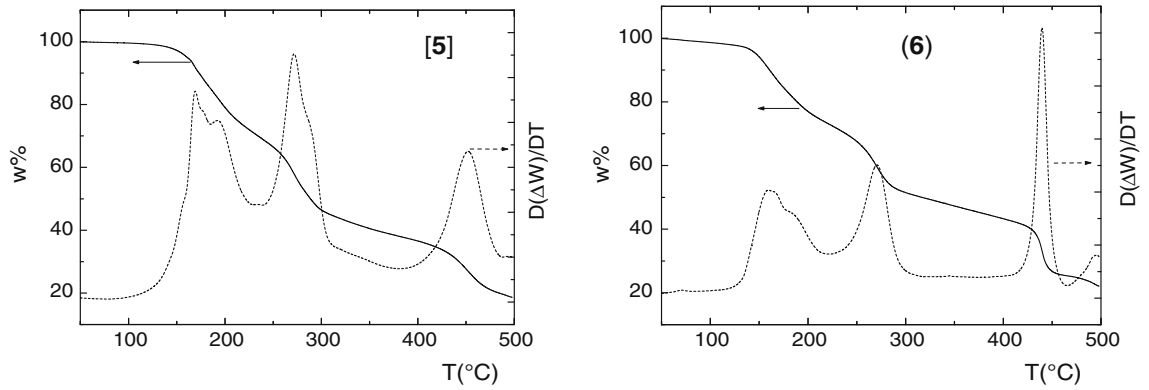

Fig. 5. TGA spectra of **5** and **6**.

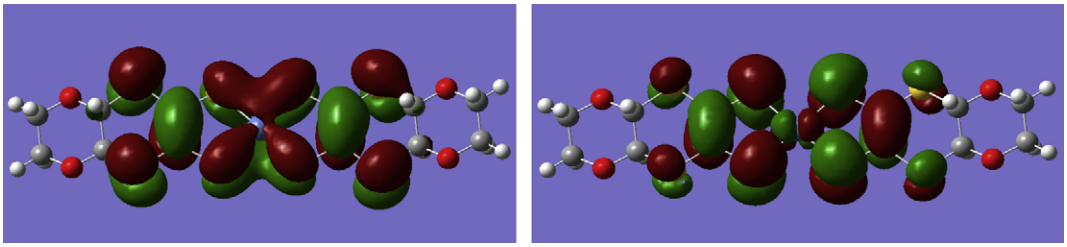

Fig. 7. The HOMO (left) and LUMO (right) molecular orbital of Ni(edodddt)$_2$.

expected, the cyclovoltammogram exhibit three 1e$^-$ reversible redox waves at $E_{1/2}$ = −0.951V versus Ag/AgNO$_3$ (−1.071 V versus Ferocene), −0.250V versus Ag/AgNO$_3$ (−0.370 V versus Ferocene) and 0.763 V versus Ag/AgNO$_3$ (0.640 V versus Ferocene). These oxidations correspond to the equilibrium [Ni(edodddt)$_2$]$^{-2}$ ↔ [Ni(edodddt)$_2$]$^{-1}$ ↔ [Ni(edodddt)$_2$] ↔ [Ni(edodddt)$_2$]$^{+1}$. As it can be seen from Table 4 the potentials of Ni(edodddt)$_2$ are negatively shifted than other molecules with extended outer rings like Ni(bddt)$_2^{-1}$ [20] or Ni(cddt$_2^{-1}$ [21] (the outer ring consist of six or five carbon atoms) indicating that the molecule has stronger donor ability than the other two. On the other hand this expansion did not improve this ability compared with "shorter" molecules like Ni(edo)$_2$ and Ni(dddt)$_2$ [9,23].

5.6. TGA thermal analysis

From the thermal stability spectra (Fig. 5) it seems that this compound either as a salt or as neutral is stable for temperatures till 150 °C. In higher temperatures it decomposes in three stages.

5.7. DFT studies

In the case of Ni(edodddt)$_2$ we additionally performed a theoretical study. For the optimization of molecular geometries as well as the calculation of the vibrational frequencies we used the DFT formalism combined with the B3-LYP [24,25] hybrid functional. The 6-311G(d,p) [26–28] basis set was used for all elements except Nickel for which we used the 6-311++G(d,p) basis set, resulting in 626 basis functions on total. All calculations were done with the GAUSSIAN 03 [29] set of programs.

Selected observed and calculated distances as well as bond angles in the molecule are shown in Tables 2 and 3. In Table 3 the experimental bond angle S3–C3–O1 (110.9°) differs from the calculated one (103.95°). As it has already be mentioned earlier, there is a relatively strong intermolecular (hydrogen-bonding) interaction between O1 and C4 atoms of adjacent molecules (O1···C4 = 3.285 Å). Such intermolecular interactions are not considered in the theoretical calculations and presumably contribute to the observed deviation between the experimental and calculated values for this angle. However there is a good agreement between the experimental and calculated data.

A comparison between the calculated Ni–S and C–S bond length with the Ni(dddt)$_2$ [10] analogous was made. The Ni–S and C–S bonds in the new molecule proved to be shorter than in the case of Ni(dddt)$_2$ [10]. The theoretical calculations show that the most stable position of the molecule is the geometry with the outer rings

[a] Visible only with the 514 nm excitation line.

adopting a chair conformation (Fig. 6). This is also supported by the X-ray measurements.

The HOMO molecular orbital is of b_{1u} symmetry and as it can be seen from Fig. 7 it is mainly constructed from the p_z atomic orbitals of the sulfur donor atoms and the p_z orbitals of the carbons. The LUMO molecular orbital is of b_{3g} symmetry and shows some contribution from the d_{xz} atomic orbital of Ni. In both MOs we can notice some contribution from atomic orbitals of the sulfurs of the outer rings while there is no contribution from the atomic orbitals of the oxygens partially because they are out of plane. So the main core of the molecule is similar to the core of the $M(dmit)_2$ [30]. The calculated energy in Hartrees of the molecule was $E = -5459.62151$. Addition of the zero point energy gave $E + E_o = -5450.38291$.

The theoretical and experimental Raman spectra of **6** are displayed in Fig. 8. The experimental Raman spectra showed the characteristic vibrations of S–Ni–S and Ni–S at 125, 371, 413 and 498 cm^{-1}. In the theoretical spectra the S–Ni–S vibration peaks appeared at 113, 361, 405 and 483 cm^{-1}. Generally there are several strong lines in the region between 125 and 498 cm^{-1} in the experimental spectra representing not only S–Ni–S bending vibrations but also some C–O–C bending vibrations. The intensity of these peaks seems to be underestimated in our calculations. The C–H stretching vibrations in the experimental spectrum with the 785 nm excitation line did not appear. These vibrations appear at 2668, 2855 and 2976 cm^{-1} in the experimental spectra with the 514 nm excitation line. In the calculated spectrum these peaks were shifted, as expected.

The experimental and the calculated infrared spectra of **6** are displayed in Fig. 9. The Ni–S symmetric and asymmetric stretching appears in the theoretically calculated spectrum at 411 and 483 nm with very low intensities, this area is out of our instrument detection limit. Both infrared spectra of the neutral complex showed absorptions at the region between 890 and 1130 cm^{-1} for the C–O vibrations but with different intensities.

The region from 1130 to 1500 cm^{-1} consists mainly of strechings, S–C, C–C and C–O. The characteristic peaks at 2800–3000 cm^{-1} related to the C–H stretching vibrations in the experimental spectrum are shifted in the theoretical one to higher wavenumbers. Overall it seems that there is a good agreement between the theoretically calculated and the experimentally recorded spectra of the investigated complex. It was very important to propose both Raman and IR band assignments for the investigated donor. These data (Table 5) should be useful for the design of new dithiolene complexes of desired physical properties.

6. Conclusion

The synthesis of the new metal donor $Ni(edodddt)_2$ was made. Its crystal structure was resolved with X-ray crystallography. Structure and spectral investigation was made both experimentally and theoretically. A comparison of the results in both cases showed a very good agreement helping us to understand this new complex.

Supplementary data

CCDC 721320 contains the supplementary crystallographic data for **6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

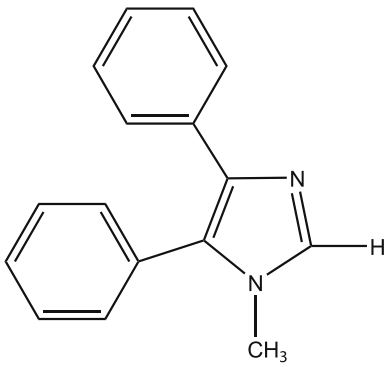
help in the design and synthesis of metal complexes with *desired* supramolecular structures. Hydrogen bonds with carbon donor atoms that may probably develop are very weak and are not expected to affect the tenability of the conclusions. The ligands that will be used in this investigation are various heavily substituted imidazole derivatives of the two types described above. In particular, 1-methyl-4,5-diphenylimidazole (L) (Scheme 1), a monodentate ligand of the first type, has been selected to initiate our studies. So far, there have been only few studies on the coordination chemistry of L [10,11].

An investigation of the $M^{II}/X^-/L$ [M^{II} = Co, Ni, Cu, Zn; X^- = Cl^-, Br^-, I^-, NCS^-, NO_3^-, N_3^-, CH_3COO^-] general reaction system in various solvents is currently under way. We report here on the first Co(II) and Zn(II) complexes based on the neutral monodentate ligand L that have been synthesized, and characterized by spectroscopic methods and single-crystal X-ray diffraction techniques. Their formulae are $[Co(NO_3)_2(L)_2]$ (**1**), $[Zn(NO_3)_2(L)_2]$ (**2**) and $[Co(NCS)_2(L)_2]\cdot EtOH$ (**3**·EtOH). Compounds **1** and **2** are isomorphous. These complexes have proven to be useful starting material for the entry to our supramolecular programme.

2. Experimental



2.1. General remarks

Starting materials were purchased from Merck. All manipulations were performed using materials as received. The ligand 1-methyl-4,5-diphenylimidazole (L) was synthesized according to the literature [12]. Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer.

2.2. Compound preparation

2.2.1. Preparation of $[Co(NO_3)_2(L)_2]$ (**1**)

A pale yellow solution of L (0.30 g, 1.25 mmol) in EtOH (25 ml) and triethylorthoformate, TEOF (3 ml) was treated with solid $Co(NO_3)_2\cdot 6H_2O$ (0.15 g, 0.50 mmol). The resulting pink suspension was refluxed for 1 h and a pink solution was obtained. The solution was left undisturbed at room temperature for 20 min, during which time a pink microcrystalline solid rapidly precipitated. The solution was filtered, and the filtrate left undisturbed at room temperature to slowly concentrate by evaporation. After 2 days, mauve-violet crystals of **1** were collected by filtration, washed with cold EtOH (2 × 2 ml) and Et_2O (2 × 5 ml), and dried in air. Yield 60% (based on the metal). *Anal.* Calc. for $C_{32}H_{28}CoN_6O_6$: C, 58.98; H, 4.34; N, 12.91. Found: C, 58.71; H, 4.32; N, 13.02%. IR data (KBr, cm^{-1}): 3129w, 3118w, 3049w, 2950w, 1762w, 1720w, 1602m, 1573w, 1506s, 1472s, 1443w, 1420w, 1305s, 1274s, 1255sh, 1193m, 1127w, 1073w, 1028m, 1018w, 1001m, 978m, 916m, 858w, 850sh, 810w, 787m, 774m, 744m, 726m, 700s, 654m, 616w, 582m, 518w, 490w. Selected far-IR data (polyethylene, cm^{-1}): 330s, 302s, 284m, 271w, 255m, 235m. Diffuse reflectance spectral data (kK): 18.3, 19.0sh, 8.9, 7.7. Room-temperature effective magnetic moment, μ_{eff} (BM): 4.55.

L

Scheme 1. The ligand 1-methyl-4,5-diphenylimidazole (L) used in this work.

2.2.2. Preparation of $[Zn(NO_3)_2(L)_2]$ (**2**)

A pale yellow solution of L (0.48 g, 2.00 mmol) in EtOH (25 ml) and triethylorthoformate, TEOF (3 ml) was treated with solid $Zn(NO_3)_2\cdot 4H_2O$ (0.27 g, 1.00 mmol). The resulting pale yellow suspension was refluxed for 1 h and soon a homogeneous, yellow solution was obtained. The solution was left undisturbed at room temperature for 20 min, during which time large pale yellow crystals of **2** began precipitating. Once the precipitation of the crystals of **2** was completed, at ~2 days, the solid product was collected by filtration, washed with cold EtOH (2 × 2 ml) and Et_2O (2 × 5 ml), and dried in air. Yield 80% (based on the metal). *Anal.* Calc. for $C_{32}H_{28}ZnN_6O_6$: C, 58.40; H, 4.29; N, 12.77. Found: C, 58.36; H, 4.31; N, 12.73%. IR data (KBr, cm^{-1}): 3120m, 3048m, 1761w, 1719m, 1602m, 1575w, 1522sh, 1500s, 1470s, 1442m, 1420w, 1384m, 1310s, 1286s, 1256sh, 1192m, 1128m, 1074m, 1032m, 1019w, 998m, 978m, 918m, 858w, 812w, 788s, 774s, 744m, 726m, 700s, 654m, 617w, 582m, 516w, 490w. Selected far-IR data (polyethylene, cm^{-1}): 325s, 303s, 279m, 265w, 248m, 219m.

2.2.3. Preparation of $[Co(NCS)_2(L)_2]\cdot EtOH$ (**3**·EtOH)

A pale yellow solution of L (0.15 g, 0.63 mmol) in EtOH (30 ml) and triethylorthoformate, TEOF (2 ml) was treated with solid $Co(NCS)_2$ (0.04 g, 0.25 mmol). The resulting blue suspension was refluxed for 1 h and a homogeneous, blue solution was obtained. The solution was left undisturbed at room temperature for 20 min, during which time a blue microcrystalline solid rapidly precipitated. The solution was filtered, and the filtrate was layered with Et_2O (60 ml). After 2 days, blue crystals of **3**·EtOH were collected by filtration, washed with cold EtOH (2 × 2 ml) and Et_2O (2 × 5 ml), and dried in vacuo over silica gel. The vacuum-dried solid was analyzed as solvent-free (**3**). Yield 65% (based on the metal). *Anal.* Calc. for $C_{34}H_{28}CoN_6S_2$: C, 63.43; H, 4.39; N, 13.06. Found: C, 63.39; H, 4.41; N, 13.10%. IR data (KBr, cm^{-1}): 3130w, 3057w, 3040w, 2962w, 2058vs, 1601m, 1582w, 1522s, 1484m, 1444m, 1422w, 1290w, 1225w, 1192m, 1128m, 1074m, 1048w, 1018m, 1001w, 982m, 910m, 816w, 790s, 774s, 746m, 724m, 700s, 648m, 580m, 505w, 482w. Selected far-IR data (polyethylene, cm^{-1}): 306s, 294s, 250m, 231m. Diffuse reflectance spectral data (kK): 16.0, 8.5, 7.1, 5.9. Room-temperature effective magnetic moment, μ_{eff} (BM): 4.70.

2.3. X-ray crystallographic analysis

Suitable single crystals of **1**, **2** and **3**·EtOH were covered with Paraton N oil and mounted on the tip of a glass capillary. X-ray data for all three compounds were collected (ω-scans) on an Oxford Diffraction Xcalibur diffractometer under a flow of nitrogen gas at 100(2) K using Mo Kα radiation (λ = 0.71073 Å, graphite monochromator). Data collection and reduction was performed with CRYSALIS CCD and RED software [13], respectively. The reflection intensities were corrected for absorption by the multi-scan method. All three structures were solved by direct methods with SIR92 [14] and refined by full-matrix least-squares on F^2 with SHELXL-97 [15]. All non-H atoms were refined anisotropically. Carbon-attached H-atoms were introduced at calculated positions applying the riding model [C(sp^2)–H and C(sp^3)–H 0.93 and 0.96 Å, respectively; $U_{iso}(H) = 1.2U_{eq}(C)$ (1.5 for Csp^3 methyl

groups) of their parent C atom]. The hydroxyl H-atom of the solvent molecule in **3**·EtOH was found in a difference Fourier map and refined isotropically [U_{iso}(H) = 1.5U_{eq}(O)] applying a soft distance restraint. Geometric calculations were carried out using WINGX [16] and PLATON [17] packages; molecular graphics were prepared with DIAMOND [18] and MERCURY [19]. Crystallographic data and details of the structural analyses are summarized in Table 1.

2.4. Spectroscopic and physical measurements

Room-temperature magnetic susceptibility measurements were carried out by Faraday's method using a Cahn-Ventron RM-2 balance standardized with $HgCo(NCS)_4$; diamagnetic corrections were applied using Pascal's constants. IR spectra were recorded on a Perkin–Elmer PC 16 FT-IR spectrometer with samples prepared as KBr pellets, and as nujol and hexachlorobutadiene mulls between CsI discs. Far-IR spectra were recorded on a Bruker IFS 113v FT spectrometer with samples prepared as polyethylene pellets. Solid-state, diffuse reflectance electronic spectra in the 2000–300 nm range were recorded on a Perkin–Elmer 330 spectrophotometer using spectroscopic grade MgO as reference.

3. Results and discussion

3.1. Brief synthetic comments

Reactions of the metal salts $Co(NO_3)_2{\cdot}6H_2O$, $Zn(NO_3)_2{\cdot}4H_2O$ and $Co(SCN)_2$, and a slight excess of L in EtOH/TEOF under reflux leads to the isolation of the compounds $[Co(NO_3)_2(L)_2]$ (**1**), $[Zn(NO_3)_2(L)_2]$ (**2**) and $[Co(SCN)_2(L)_2]\cdot$EtOH (**3**·EtOH), respectively, according to the balanced Eqs. (1)–(3).

$$Co(NO_3)_2\cdot 6H_2O + 2L \xrightarrow[T]{EtOH/TEOF} \underset{\mathbf{1}}{[Co(NO_3)_2(L)_2]} + 6H_2O \quad (1)$$

$$Zn(NO_3)_2\cdot 4H_2O + 2L \xrightarrow[T]{EtOH/TEOF} \underset{\mathbf{2}}{[Zn(NO_3)_2(L)_2]} + 4H_2O \quad (2)$$

$$Co(SCN)_2 + 2L + EtOH \xrightarrow[T]{EtOH/TEOF} \underset{\mathbf{3}\cdot EtOH}{[Co(SCN)_2(L)_2]\cdot EtOH} \quad (3)$$

Two features of the reactions represented by Eqs. (1)–(3) deserve brief comments. First, the metal to ligand reaction ratio, the nature of the solvents (MeOH and MeCN were also used) and the precipitation/crystallization method have no influence on the identity of the products. Second, it is not possible to isolate completely pure samples of complexes **1**–**3** without use of the dehydrating agent triethylorthoformate (TEOF). Working without TEOF, the isolated products contained 2–3% H_2O, as indicated by analytical data.

3.2. Description of structures of the isomorphous compounds *1* and *2*

To facilitate comparison, all three compounds **1**, **2** and **3** have the same (where applicable) atom, ring and ligand numbering [ligand L_A (rings A1, A2 and A3), ligand L_B (rings B1, B2 and B3)] (see Fig. 1). The X-ray structural analysis reveals that **1** and **2** are not just isostructural but are actually isomorphous since (a) both have the same space group ($I4_1cd$) and quite similar unit cell dimensions and (b) the types and the positions of atoms in both are the same except for a replacement of the Co(II) atom in **1** with a Zn(II) atom in **2**. Therefore, detailed information will be presented mostly for complex **1**. The molecular structure of complex **1** is depicted in Fig. 1. Table 2 contains selected interatomic distances, angles and torsion angles for the three complexes.

Compound **1** consists of discrete neutral mononuclear molecules in which the Co^{II} ion is surrounded by two monodentate 1-

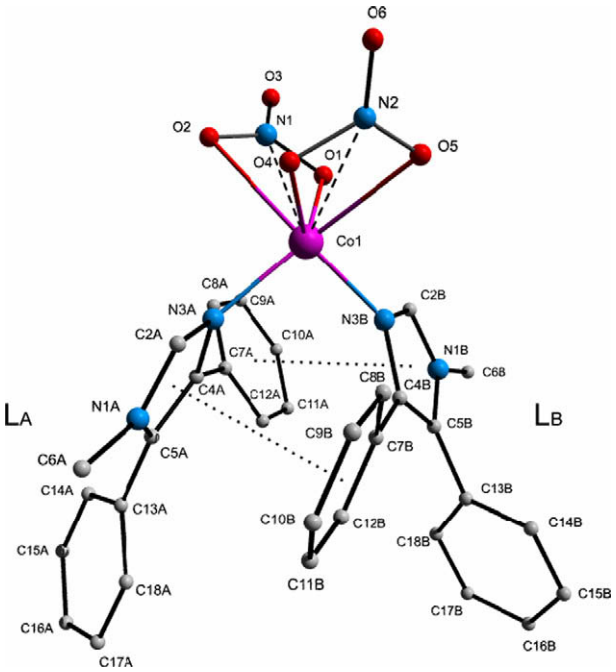

Fig. 1. View of the molecular structure of **1** showing the intramolecular $\pi-\pi$ interactions (dotted lines) between the two ligands L_A and L_B. The dashed lines do not represent bonding interactions (see text). Hydrogen atoms have been omitted for clarity. Ring numeration: A1 (N1A–C2A–N3A–C4A–C5A), A2 (C7A to C12A), A3 (C13A to C18A), B1 (N1B–C2B–N3B–C4B–C5B), B2 (C7B to C12B), B3 (C13B to C18B).

methyl-4,5-diphenylimidazole ligands and two chelating nitrates. The ligands L are *cis* to each other. Both nitrate species (with N1 and N2 nitrogen atoms) are planar, the sum of the three O–N–O angles being 360.0° and 361.0°, respectively. According to the criteria suggested by Reedijk and co-workers [20] concerning the nitrate coordination modes (monodentate, anisobidentate and bidentate), the nitrate bearing N1 is at the borderline of anisobidentate/monodentate and the nitrate bearing N2 can be classified as anisobidentate. The Co^{II} ion is therefore in a highly distorted octahedral environment, comprising the two imidazole nitrogen donor atoms and the four nitrate oxygen atoms. The Co–O bonds *trans* to the nitrogen atoms are longer than the other two, as expected for this type of complexes [21]. The severe distortion of the octahedron is due to the acute O–Co–O bite angles [51.7(1)° and 56.5(1)°] of the two chelating nitrato ligands. Alternatively, the six-coordinate Co^{II} center can be regarded as having a distorted quasi-tetrahedral structure with bonds directed towards the centers of the bidentate nitrato groups instead of towards the oxygen atoms (Fig. 1); however, this approach is not without criticism [22]. The situation is similar for complex **2**, with the exception that both nitrates are at the borderline of anisobidentate/monodentate (see Table 2 for comparison).

Table 3
Intramolecular $\pi-\pi$ stacking distances (Å) and angles (°) for **1**, **2** and **3**·EtOH.

Distance/angle	Rings	**1**	**2**	**3**·EtOH
Distance between ring centroids	A1–B2	3.501(1)	3.496(1)	3.724(1)
	B1–A2	3.654(1)	3.649(1)	3.560(1)
Perpendicular distance between ring planes	A1–B2	3.324(1)	3.336(1)	3.660(1)
	B1–A2	3.476(1)	3.472(1)	3.521(1)
Centroid offset	A1–B2	1.102(1)	1.047(1)	0.692(1)
	B1–A2	1.146(1)	1.137(1)	0.525(1)
Dihedral angle between ring mean-planes	A1–B2	6.9(1)	7.0(1)	18.7(1)
	B1–A2	9.0(1)	8.5(1)	13.0(1)

The two 1-methyl-4,5-diphenylimidazole ligands (L_A and L_B) are 'antiparallel' with their methyl groups pointing at opposite directions. The overall conformation of L_A and L_B is similar. The angle between the mean-plane of the phenyl rings A2 and A3 is 64.4(1)° and that between B2 and B3 is 75.1(1)°. The imidazole ring A1 is facing the phenyl ring B2 [angle: 6.9(1)°] and the imidazole ring B1 is equally facing the phenyl ring A2 [angle: 9.0(1)°]; this is most likely attributed to steric effects and the weak $\pi-\pi$ stacking interactions among those pairs of rings. Similar conformations and $\pi-\pi$ interactions among ligands L_A and L_B have also been encountered in a previously characterized Pd^{II} complex with L [11], in a series of analogues complexes of other divalent metals with L [23], as well as in Cu^{II} and Zn^{II} complexes of 2-[2′-(4′,6′-di-*tert*-butylhydroxyphenyl)]-4,5-diphenylimidazole [24,25]. This information brings out a characteristic structural pattern of the complexes and reveals a preferred mode of packing between neighbouring ligands bearing the 4,5-diphenylimidazole moiety.

Table 4
Hydrogen-bond geometries for **1**, **2** and **3**·EtOH (Å, °).

D–H···A	D–H	H···A	D···A	D–H···A
Complex ***1***				
C17A–H17A···O1^{i}	0.93	2.59	3.513(2)	171
C2A–H2A···O3^{ii}	0.93	2.55	3.328(2)	141
C6A–H6A3···O3^{ii}	0.96	2.47	3.267(2)	141
C15A–H15A···O3^{iii}	0.93	2.54	3.423(2)	160

C6B–H6B1···O1^{v}	0.96	2.52	3.470(2)	171

Symmetry codes: (i) 1/2 + *y*, 1 − *x*, −1/4 + *z*; (ii) 1 − *x*, *y*, −1/2 + *z*; (iii) 1 − *x*, 1 − *y*, *z*; (iv) −1 + *x*, *y*, *z*; (v) 1 + *x*, ½−*y*, −1/2 + *z*.

Geometrical details of the π–π interactions between L_A and L_B, providing additional stabilization within the complexes, are presented in Table 3. These results confirm the initial considerations with regard to the fitness of ligand L to form such π–π interactions. Dance and Aakeröy have studied aromatic interactions as a crystal engineering tool and have suggested that they can play a role in the assembly and orientation of complexes in inorganic supramolecular chemistry [26,27].

The length of the C–C and C–N bonds of the imidazole groups agree very well for all three structures and are as expected [28]. The Co–N bond lengths are normal for this kind of compound [29–31]. Corresponding information for the isomorphous compound **2** is given in Tables 2 and 3.

The packing of the molecules in the crystal lattice of **1** proceeds through normal van der Waals contacts and weak C–H···O(nitrate) interactions which contribute to the supramolecular aggregation of the mononuclear species (Table 4). In general, it is assumed that C–H···O bonds could play a role in the determination of crystal packing, especially when stronger (classic) hydrogen bonding is absent [32,33]. The geometry of the present C–H···O interactions fulfills the criteria for such bonds as proposed by Jeffrey [34] and other researchers [35].

A least-squares fit of **1** and **2** (Fig. 2) clearly shows that the two compounds are almost superimposable, the most apparent deviation being in the nitrate ligands moiety. As can be seen from Table 4, both **1** and **2** contain the same number and type of C–H···O interactions, a consequence of their isomorphism. The closest Co···Co and Zn···Zn distances in their crystals are 7.289(5) and 7.276(5) Å, respectively.

3.3. Description of structure of compound **3**·EtOH

The structure of **3**·EtOH consists of $[Co(NCS)_2(L)_2]$ and solvate ethanol molecules. It crystallizes in the monoclinic space group $P2_1/c$. The complex molecule has a tetrahedral $Co^{II}N_4$ coordination, involving the pyridine-type nitrogen donor atoms from the L_A and L_B ligands and the two terminal isothiocyanato groups (Fig. 3). The angles around the Co^{II} atom (Table 2) show the tetrahedral environment to be slightly distorted. The two SCN^- ions are almost linear [N1–C1–S1 = 179.3(2)° and N2–C2–S2 = 178.5(2)°] and are coordinated (especially the second one) in a bent fashion, as indicated by the Co–N–CS angles of 173.8(2)° and 160.8(2)°, respectively. The bent coordination at the nitrogen atoms may be caused by intermolecular hydrogen bonding (atom S1 participates in intermolecular hydrogen bonding, see below) and crystal packing [29]. Similar bent geometries have also been observed in a series of six-coordinate Ni(II) and Co(II) complexes [30,36]. An investigation by Noh et al. [37] on the bonding fashion of the SCN^- ion did not reveal any systematic correlation between the C–N bond distance and the Co–N–CS angle, suggesting, in their turn, that the bent angle is determined by steric/packing effects rather than electronic effects of the metal ion.

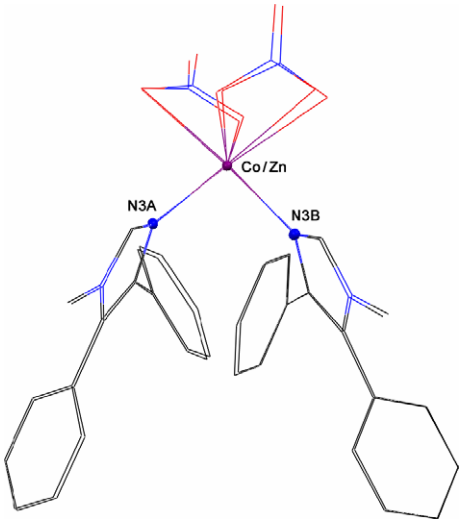

Fig. 2. A least-squares fit of **1** and **2**. The fitting fragment N3A–Co/Zn–N3B of the two complexes has been drawn in ball-and-stick (r.m.s. deviation for fitted atoms: 0.029). Hydrogen atoms have been omitted for clarity.

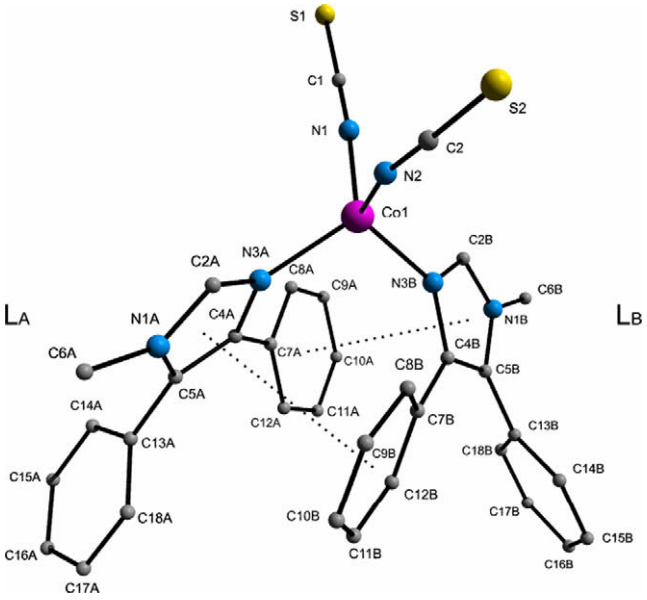

Fig. 3. View of the molecular structure of **3**·EtOH showing the intramolecular π–π interactions (dotted lines) between the two ligands L_A and L_B. The non-coordinated ethanol molecule and hydrogen atoms have been omitted for clarity. The numeration of the rings is identical to that of Fig. 1.

The two ligands L_A and L_B of complex **3** maintain (as in **1** and **2**) the 'antiparallel' orientation of their methyl groups and their conformation is similar. The overall conformation of the complex resembles that of complex **1** (or **2**) preserving the structural pattern of the π–π intramolecular interactions between L_A and L_B (Tables 2 and 3). However, the differences between **3** and **1** (or **2**) are more striking that those between the isomorphous complexes **1** and **2**. The EtOH molecule assists to the stabilization of the crystal structure by forming, through its hydroxyl group, a medium-strength hydrogen bond to the S1 atom of a isothiocyanato ligand, as well as a weak C–H···O interaction (Table 4). The closest Co···Co spacing in the crystal is 5.026(1) Å, significantly different from those of 7.289(5) and 7.276(5) Å for **1** and **2**, respectively.

3.4. IR, magnetochemical and ligand-field studies

The IR bands of L [10] do not shift significantly in the spectra of **1**–**3**. In the spectrum of **3**, the bands at 2058, 816 and 482 cm^{-1} are assigned [38] to the ν(CN), ν(CS) and δ(NCS) modes of the SCN^- ion; the frequencies of these modes are characteristic of terminal isothiocyanato (i.e., *N*-bonded) isothiocyanato groups [38]. The far-IR spectrum of **3** exhibits the two ν(Co–NCS) [306 and 294 cm^{-1}] and the two ν(Co–N_L) bands in the regions expected for pseudotetrahedral C_{2v} stereochemistry [38].

In the spectrum of **1**, the bands at 1472 and 1274 cm^{-1} are assigned to the $\nu_L(A_1)[\nu(N=O)]$ and $\nu_5(B_2)[\nu_{as}(NO_2)]$ modes of the chelating bidentate (C_{2v}) nitrato groups, respectively. The corresponding bands for **2** appear at 1470 and 1286 cm^{-1}. The separation of these two bands is large (198 cm^{-1} for **1**, 184 cm^{-1} for **2**),

in accordance with the bidentate character of the nitrato ligands. The 1700–1800 cm^{-1} region is viewed as the key to differentiate between monodentate and bidentate coordination of nitrato groups [38,39]. The separation of the combination bands $\nu_2 + \nu_3$ and $\nu_2 + \nu_5$ in the spectra of **1** and **2**, appearing around 1760 and 1720 cm^{-1} is about 40 cm^{-1} and this fact is consistent [38,39] with the crystallographically established bidentate character of the nitrato ligands. The great number of the $\nu(M–O_{nitrato})$ [325, 303, 279, 265 cm^{-1} for **2**; 330, 302, 284, 271 cm^{-1} for **1**) and $\nu(M–N_L)$ [248, 219 cm^{-1} for **2**; 255 235 cm^{-1} for **1**) reflects the *cis* stereochemistry of the Co^{II} and Zn^{II} nitrato complexes [38].

The KBr IR spectrum of **2** exhibits a medium intensity band at 1384 cm^{-1}, assigned to the $\nu_3(E')[\nu_d(NO)]$ mode of the D_{3h} ionic nitrate, suggesting [20] that a certain amount of nitrato ligands are replaced by bromides (thus generating ionic nitrates) in the KBr matrix; this spectral phenomenon has been discussed in detail [20,40]. In accordance with this conclusion, the 1384 cm^{-1} band is absent from the mull spectra of **2**.

The room-temperature effective magnetic moment (μ_{eff}) value (4.70 BM) and the electronic spectrum of **3** in the solid state indicate pseudotetrahedral stereochemistry around Co^{II}, the band at 16.0 kK being assigned to the $^4A_2 \rightarrow {}^4T_1(P)$ transition and with the band assigned to the $^4A_2 \rightarrow {}^4T_1(F)$ transition at ~7 kK being split (by virtue of the reduction of symmetry from T_d to C_{2v}) into bands (8.5, 7.1 and 5.9 kK) representing the transitions to the $^4B_1$, $^4A_2$ and $^4B_2$ states [41,42]. These assignments give rise to the parameters 10Dq = 4575 cm^{-1}, B = 672 cm^{-1} and β = 0.69, typical for Co^{II} tetrahedrally surrounded by four nitrogen atoms [30,42].

While the μ_{eff} value of **1** at room-temperature (4.55 BM) is in the region expected for tetrahedral complexes [41], the electronic spectrum of this compound in the solid state differs from spectra of typical tetrahedral Co^{II} complexes. The absorption band at 18.3 kK, although similar in general contour to the visible band of other tetrahedral Co^{II} complexes, is at rather higher energy than would have been expected [42]. Moreover, the color of **1** is abnormally intense for an octahedral complex; octahedral Co^{II} complexes have pink colors. This peculiar magnetochemical and spectral behavior has been found for some other $[Co(NO_3)_2(L')_2]$ complexes, where L′ is a phosphine or arsine oxide [43], a hindered monodentate amine [44] and 1-methylbenzotriazole [30]. The behavior has been explained [43] by postulating that the six-coordinated complex can be regarded as having a rather distorted quasi-tetrahedral structure with bonds directed toward the centers of the bidentate nitrato groups instead of toward the oxygen atoms. In accordance with a quasi-tetrahedral formulation of **1**: (1) The Co–N3(A,B) bond distances (Fig. 1, Table 2) are very similar to those observed in the tetrahedral complex **3**·EtOH (Fig. 3, Table 2); (2) the Co···N(1,2) distances [2.615(1), 2.749(1) Å] may be regarded as *very weakly* bonding; and (3) the N–Co–N angles lie in the 91.6–128.1° range, which is typical for distorted tetrahedral complexes [30]. Lever has suggested that the assumption of a quasi-tetrahedral coordination is perhaps unnecessary [44]. Such molecules have a distorted six-coordinated structure of C_2 symmetry; the degeneracy of the ground state of the Co^{II} ion is lifted [$T_{1g}(O_h) \rightarrow {}^4A$, 2 ^4B in C_2]. The new ground state being an orbital singlet gives rise to a μ_{eff} value closer to the spin-only value than that observed in an octahedral complex (~5 BM). This was observed in **1**. The absence of a center of symmetry could produce a fairly high intensity *d–d* spectrum (since both p and d orbitals span common representations in C_2); this is also observed in **1**.

4. Conclusions and perspectives

This work comprises the initial results of our investigation on a series of divalent, 3d-metal complexes using the 1-methyl-4,5-diphenylimidazole ligand in order to explore the structural consequences of intermolecular forces and the way in which such interactions cooperate, compete and eventually control the supramolecular assembly and architecture of such compounds. Three representative complexes, namely $[Co(NO_3)_2(L)_2]$ (**1**), $[Zn(NO_3)_2(L)_2]$ (**2**) and $[Co(NCS)_2(L)_2]$·EtOH (**3**·EtOH), have been synthesized and subsequent crystallographic analysis showed **1** and **2** to be isostructural and isomorphous. A characteristic structural feature, evidenced in all three compounds, and enhancing the stability and rigidity of the complexes, involves the formation of intramolecular π–π interactions between aromatic rings of adjacent 4,5-diphenylimidazole moieties of the two ligands of the complexes. On the other hand, the observed bent coordination of the isothiocyanate ions in complex **3** seems to be due to intermolecular hydrogen bonding and crystal packing effects.

Further synthetic and structural work (including examples of isomorphism and polymorphism) is in progress; it includes complexes with various imidazole derivatives as ligands (as described in the Introduction) towards a better understanding of their supramolecular organization.

bdmpp

Scheme 1. The ligand 2,6-bis(3,5-dimethylpyrazol-1-yl)pyridine (bdmpp) used in this work.

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. The starting materials $[Ti(Cp)_2Cl_2]$ [11] and bdmpp [12] were synthesized by literature methods, the former under an argon atmosphere using dried THF.

Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer. IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT-spectrometer with samples prepared as KBr pellets. The FT-Raman spectrum was recorded on a Bruker IFS 66v spectrometer equipped with an FT-Raman FRA 106 module. The compound was excited by the 1064 nm line of a Nd:YAG laser operating at 200 mW. For the spectrum, 1000 scans were recorded and averaged. The ^1H NMR spectrum of the complex in $CDCl_3$ was recorded with a JEOL FX90Q FT-spectrometer; chemical shifts are reported relative to tetramethylsilane. The solid-state (diffuse reflectance) spectrum in the 300–800 nm range was recorded on a Varian Cary 3 spectrometer equipped with an integration sphere; the sample was diluted with spectroscopic grade MgO.

2.2. Compound preparation

2.2.1. $[TiCl_2(O_2)(bdmpp)]$ (**1**)

A colourless solution of bdmpp (0.08 g, 0.4 mmol) in Me_2CO (10 ml) was added to a red solution of $[Ti(Cp)_2Cl_2]$ (0.09 g, 0.4 mmol) in the same solvent to give an orange–red solution. The reaction solution was stirred overnight. Upon storage of the closed reaction flask at room temperature for few days, orange–red, X-ray quality crystals formed. The crystals were collected by filtration, washed with ice-cooled Me_2CO (1 ml) and Et_2O (2x2 ml), and dried in vacuo over silica gel. Typical yields were in the 55–60% range. *Anal.* Calc. for $C_{15}H_{17}N_5O_2Cl_2Ti$ (418.14): C, 43.08; H, 4.11; N, 16.75. Found: C, 42.88; H, 3.99; N, 16.62%. Selected IR bands (KBr, cm^{-1}) : 2926w, 1600m, 1586m, 1484sh, 1450s, 1378m, 1360m, 1158w, 1060w, 1048w, 990w, 905w, 800m, 720w, 660w, 614w, 551w. ^1H NMR (90 MHz, $CDCl_3$): δ 2.40 (6H, s, pyrazolyl Me), 3.01 (6H, s, pyrazolyl Me), 6.43 (2H, s, pyrazolyl H), 8.22 (3H, m, NC_5H_3). Solid-state (diffuse reflectance) spectrum (MgO, nm): 425.

2.3. Single-crystal X-ray crystallography

A red–orange crystal of **1** with approximate dimensions $0.20 \times 0.30 \times 0.50$ mm was mounted in air and covered with epoxy glue. Diffraction measurements were made on a CRYSTAL LOGIC dual goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $11 < 2\theta < 23°$. Intensity data were recorded using a $\theta-2\theta$ scan. Three standard reflections monitored every 97 reflections showed less that 3% intensity fluctuation and no decay. Lorentz, polarization corrections were applied using Crystal Logic software. Important crystal data and parameters for data collection and processing are listed in Table 1.

Table 1
Crystallographic data for complex **1**.

Parameter	**1**
Formula	$C_{15}H_{17}TiN_5O_2Cl_2$
Formula weight	418.14

[b] $wR_2 = \left\{\sum\left[w(F_o^2-F_c^2)^2\right]/\sum[w(F_o^2)^2]\right\}^{1/2}$.

The structures were solved by direct methods using SHELXS-86 [13] and refined by full-matrix least squares techniques on F^2 with SHELXL-97 [14]. All H atoms were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. Further crystallographic details for **1**: $2\theta_{max} = 50.0°$, scan speed = 4.0° min^{-1}, scan range = 1.8° + $\alpha_1\alpha_2$ separation, 473 parameters refined, $(\Delta/\sigma)_{max} = 0.012$, $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.474/-0.414$ e/Å^3, R_1/wR_2 (for all data) = 0.0808/0.1617, GOF (on F^2) = 1.077.

3. Results and discussion

The 1:1 reaction between $[Ti(Cp)_2Cl_2]$ and bdmpp in Me_2CO is accompanied by a colour change from red to orange–red; storage of the resulting solution at room temperature gives prismatic, X-ray quality crystals of **1**. We were surprised to see that the product is an η^2-peroxo Ti^{IV} complex also bearing one bdmpp and two chloro ligands (vide infra). This reaction is unusual. Peroxo metal complexes are obtained either by oxidative addition of dioxygen to a low-valent metal complex or by ligand exchange on a high-valent metal complex upon reaction with H_2O_2 [5,15]. These are not the cases here. The Ti^{IV} center in the starting material is d^0 and cannot be oxidized; moreover, there was no peroxide source in the reaction mixture. It should be mentioned at this point that the reaction does not take place in absolute Me_2CO. Although we are far from understanding the reaction mechanism, our first impression is that the reducing equivalents for the dioxygen reduction come from solvent impurities and the whole process is facilitated by $[Ti(Cp)_2Cl_2]$.

With the identity of **1** established by single-crystal, X-ray crystallography (vide infra), the complex could be prepared in excellent yields by the addition of a slight excess of an aqueous H_2O_2 10% solution in the 1:1 $[Ti(Cp)_2Cl_2]$/bdmpp reaction mixture in alcohols or Me_2CO, see Eq. (1).

$$[Ti(Cp)_2Cl_2] + \text{bdmpp} + H_2O_2 \rightarrow \underset{\mathbf{1}}{[TiCl_2(O_2)(\text{bdmpp})]} + 2HCp \qquad (1)$$

Complex **1** crystallizes in the monoclinic space group $P2_1/c$. There are two, crystallographically independent molecules in the asymmetric unit (molecule A and molecule B). Since the two molecules have very similar structures, only the structure of the representative molecule A will be discussed in detail. The structure of A is shown in Fig. 1, while selected bond lengths and angles are listed in Table 2.

The coordination polyhedron of Ti^{IV} is a distorted pentagonal bipyramid. The equatorial positions are occupied by the three nitrogen atoms [N(1), N(3), N(5)] of the chelating bdmpp ligand and the oxygen atoms of the peroxo group. The axial positions are occupied by the two chloro ligands; the Cl(1)–Ti(1)–Cl(2) angle is 163.9(1)°. The distances of O(1), O(2), N(1), N(2) and N(3) from their mean equatorial plane are 0.028, 0.019, −0.058, 0.074 and −0.062 Å, respectively. The distances of the axial ligands Cl(1) and Cl(2) from the mean equatorial plane are −2.363 and 2.366 Å, respectively.

The peroxide group O_2^{2-} binds to Ti^{IV} in a side-on η^2-fashion, occupying two coordination sites in the equatorial plane. The peroxo groups can be (i) part of a three-membered ring, (ii) bridging staggered, (iii) bridging symmetrical, or (iv) bridging through a single oxygen atom [5], see Scheme 2. The two Ti(1)–O(1) and Ti(1)–O(2) bonds are equivalent in **1**. The O–O bond lengths are 1.455(5) and 1.446(5) Å in molecules A and B, respectively. It appears that similar Ti–O, O–O, O–Ti-O and Ti–O–O lengths and angles are observed in **1** and a number of $Ti^{IV}(O_2^{2-})$ complexes exhibiting pentagonal bipyramidal geometry around the Ti^{IV} ion(s) [1,2,16]. Due to the geometric constraints of the η^2-O_2^{2-} group, some coordination angles in the equatorial plane, e.g. O(1)–Ti(1)–O(2) [46.5(2)°], O(1)–Ti(1)–N(5) [85.0(2)°] and O(2)–Ti(1)–N(1) [85.2(2)°] deviate significantly from the ideal value of 72°.

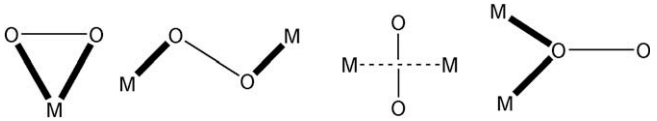
N(1)–Ti(1)–N(3)	72.1(2)		

[a] See Fig. 1.



Although the bonding in the three-membered ring (Scheme 2, left) is most easily described by localized bonding, it can also be described by a MO treatment similar to that for the bonding of olefins or acetylenes [5]. Crudely, a σ bond is formed by filled Opπ → Mdσ bonding and back-bonding is due to Mdπ → Opπ* [5]; the latter is not feasible in **1** due to its d^0 nature.

In the crystal structure of the free ligand bdmpp [17], the pyrazolyl rings are oriented away from the pyridine nitrogen atom in order to minimize the electronic repulsion between the nitrogen lone pairs (Scheme 1), in spite of the fact that some steric congestion is thus created by the methyl substituents. A major reorientation of the pyrazolyl rings occurs upon coordination in **1**, thus allowing the molecule to act as a tridentate *N*,*N*′,*N*″-chelate. The interelectronic repulsion of the nitrogen lone pairs is dissipated upon complexation due to the interaction with Ti^{IV} [17]. In addition to this conformational change, the angles N(3)–C(4)–N(2) [113.3(4)°] and N(3)–C(8)–N(4) [113.7(4)°] in the complex are smaller than the corresponding angles in the uncoordinated molecule [average: 117.3(2)°], reasonably due to the formation of the "pocket" for the metal cation [17]. The Ti–N bond lengths are in the range 2.198(4)–2.212(4) Å, very close to the Ti–N(terpy) bond lengths [2.171(4)–2.216(4) Å] in the structurally characterized complex [Ti(Cp^*)($NNC_5H_3Me_2$-2,6)(terpy)](OTf)$_2$ [18], where $^-NNC_5H_3Me_2$-2,6 is the 2,6-dimethyl(1-pyridinio)imido(-1) ligand and OTf^- the triflate ion.

The three bdmpp rings in the molecule A (Fig. 1) of **1** are not coplanar, the dihedral angles between the central pyridine ring and the peripheral pyrazolyl rings being 13.3° [N(3)C(4)C(5)C(6)C(7)C(8)/N(1)N(2)C(3)C(2)C(1)] and 9.12° [N(3)C(4)C(5)C(6)C(7)C(8)/N(4)N(5)C(11)C(10)C(9)]. In molecule B, the three rings are almost coplanar, the corresponding dihedral angles being 0.9 and 7.0°.

Somewhat to our surprise, there are no intermolecular stacking interactions in the crystal lattice. The crystal structure of **1** is stabilized by a series of weak, intermolecular C–H···Cl interactions. In the structure of the complex there are intra- and intermolecular C–H···O (peroxide) H-bonding interactions which stabilize the lattice structure (Fig. 2). Their dimensions are: C(12)···O(2) = 2.913(1) Å, O(2)···H(12A) = 2.261(9) Å, C(12)–H(12A)···O(2) = 124.4(5)°; C(35)···O(22) = 2.829(1) Å, O(22)···H(35A) = 2.256(6) Å, C(35)–H(35A)···O(22) = 117.3(4)°; C(14)···O(22)[x, $-y+1/2$, $z+1/2$] = 3.415(2) Å, H(14A)···O(22)[x, $-y+1/2$, $z+1/2$] = 2.489(1) Å, C(14)–H(14A)···O(22)[x, $-y+1/2$, $z+1/2$] = 162.1(4)°.

Complex **1** is the first, structurally characterized Ti^{IV} complex of bdmpp and it joins a small family of structurally characterized metal complexes of this ligand [9,17,19]. Complex **1** is only the

Scheme 2. The up-to-date crystallographically confirmed coordination modes of the O_2^{2-} ligand.

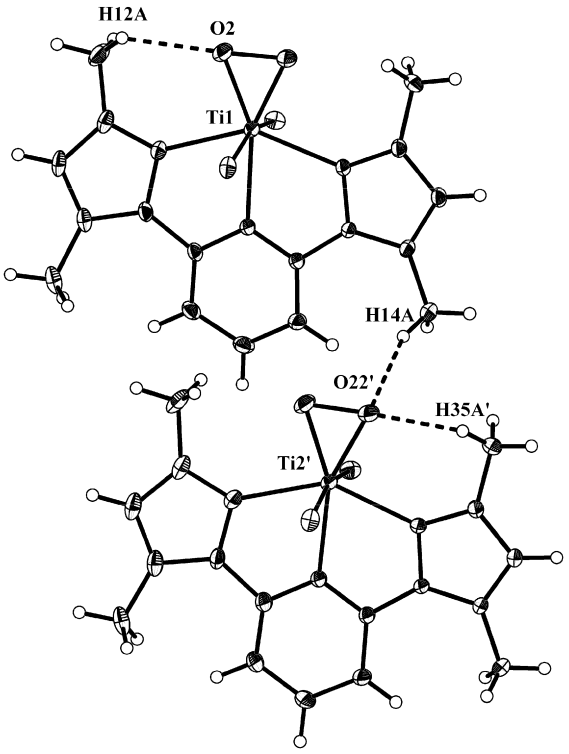


Fig. 2. Partially labeled plot of **1**, with thermal ellipsoids drawn at the 30% probability level, showing the intra- and intermolecular C–H···O (peroxide) H-bonding interactions (dashed lines). Primed atoms are generated by the symmetry operation: (′) = x, $-y + 1/2$, $z + 1/2$.

second, structurally characterized complex of the general type $[Ti^{IV}Cl_2(\eta^2\text{-}O_2)(L\text{–}L\text{–}L)]$, where L–L–L is a neutral, tridentate chelate. The first such complex was $[TiCl_2(O_2)(Me_3tacn)]$ [16b], where Me_3tacn is 1,4,7-trimethyl-1,4,7-triazacyclononane; however, there is strong evidence that there is compositional disorder in the structure and the compound contains an appreciable amount of $[TiCl_2O(Me_3tacn)]$.

The solid-state electronic spectrum of **1** is featureless beyond 500 nm, due to the fact that Ti^{IV} has no d electrons. Attention was focused on the band at ~425 nm. This can be reasonably be attributed to a $\pi_v^* \rightarrow$ d O^{2-} to Ti^{IV} charge-transfer (LMCT) vibration [2,16b].

The IR and Raman spectra of **1** display the expected bands due to the presence of the side-on $\eta^2\text{-}O_2^{2-}$ group [1,2,16b–d]. The ν(O–O), $\nu_s[Ti(O_2)]$ and $\nu_{as}[Ti(O_2)]$ vibrations appear at 905, 614 and 551 cm^{-1}, respectively, in the IR spectrum. The most intense Raman peaks in the 1000–500 cm^{-1} region are located at 908 and 624 cm^{-1}. These spectral features are attributed [1,2,16b] to the O–O and Ti–O_2 symmetric stretching vibrations, respectively, in accordance with the peaks reported in the literature for a peroxide group bound to the Ti^{IV} center in the side-on fashion. The $\nu_{as}[Ti(O_2)]$ mode does not appear in the Raman spectrum, as expected.

The IR bands of **1** at 1600, 1586, 1484 and 1450 cm^{-1} are assigned to carbon–nitrogen ring stretching vibrations of the coordinated bdmpp ligand, while the 800 and 720 cm^{-1} features are typical for out-of-plane C–H bending vibrations [17]. The in-plane deformation band of the pyridine ring of free bdmpp at ~630 cm^{-1} shifts upwards (660 cm^{-1}), confirming the involvement of the pyridine ring N-atom in coordination [20].

The ^{1}H NMR spectrum of **1** in $CDCl_3$ is very similar to that reported for complex *trans*-$[Ru(NO_2)(bdmpp)(PMe_3)_2](ClO_4)$ [9] and is consistent with the tridentate coordination of bdmpp.

4. Concluding comments and perspectives

The main aspect of this work is the discovery that a cyclopentadienyl-free, titanium peroxo complex is synthetically available from the reaction of $[Ti(Cp)_2Cl_2]$ with a *N*,*N*′,*N*″-chelate in acetone under aerobic conditions. The reaction that initially led to complex **1** is neither an oxidative addition of O_2 to low-valent Ti, nor a simple ligand exchange on a Ti^{IV} species by added peroxide sources. It is obvious that the reactivity chemistry of $[Ti(Cp)_2X_2]$ warrants further expansion to other tridentate aromatic *N*-heterocycles (including terpy) to investigate the substitution degree of the Cp^- ligands and the possibility of obtaining other peroxo complexes. Reactions of zircocene and hafnocene derivatives with bdmpp have not been studied to date, and it is currently not evident whether the identity of the products is dependent on the particular nature of the metal ion. Experiments on these projects, as well as on the use of $[Ti(Cp)_2X_2]$ compounds as precursors for the synthesis of heterometallic Ti/3d-metal clusters are currently in progress in our laboratories.

5. Supplementary data

CCDC 727374 contains the supplementary crystallographic data for **1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgement

We thank Prof. H.O. Desseyn (Chemistry Department, University of Antwerp, Belgium) for providing us with the Raman and ^{1}H NMR spectra of **1**.

three phosphonate ligands containing four phosphonate moieties have been studied for their ability to form ionic compounds with non-metal cations, ethylenediammonium (en^{2+}), ammonium (NH_4^+, and the $Zn(H_2O)_6^{2+}$ ion that forms *in situ*. Schematic structures are shown in Fig. 2. These three tetraphosphonate ligands all have the same coordinating moieties (two amino-*bis*(methylenephosphonate) groups), but they are linked by two (EDTMP), four (TDTMP) and six (HDTMP) methylene chains. All three phosphonates are zwitter-ionic (each phosphonate group is monodeprotonated and the N atoms are protonated). The ligand charge is "2−", therefore it requires a "2+" charge balancing cation(s) for electroneutrality.

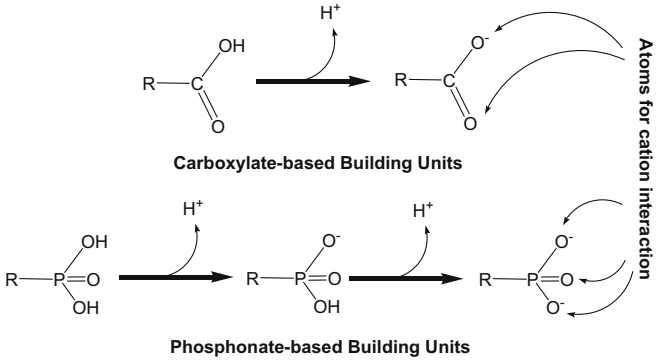

Fig. 1. Structural and functional differences between carboxylic and phosphonic acids.

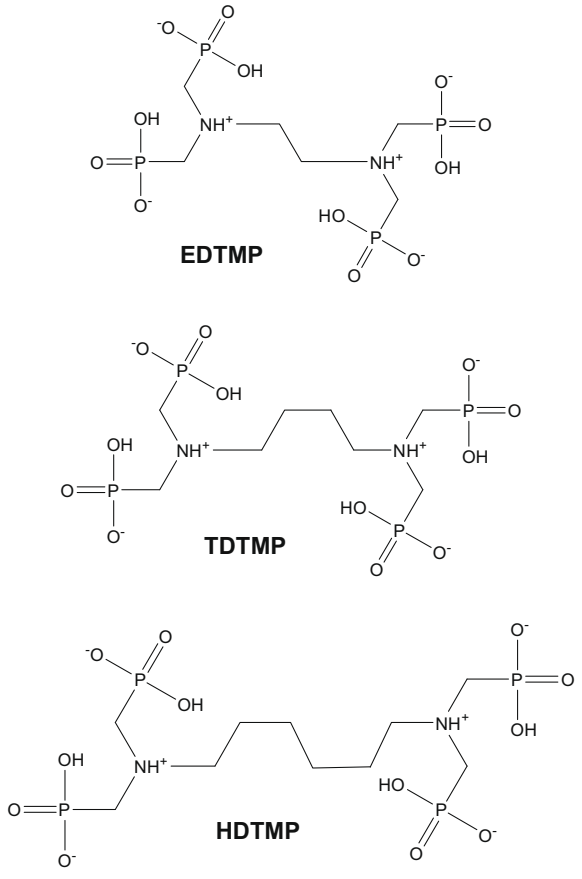

Fig. 2. The three tetraphosphonates (EDTMP, TDTMP and HDTMP) used in this paper in their zwitter-ionic form and an overall ligand charge "2−".

2. Experimental

2.1. Materials

All water-soluble metal salts were commercial samples and were used without further purification. Ethylenediamine was from Fluka. Phosphonic acids (EDTMP, TDTMP and HDTMP) were from Solutia Inc. Stock solutions of HCl and NaOH were used for pH adjustments. In-house, deionized (DI) water was used for all syntheses.

2.2. Syntheses

2.2.1. (en)(HDTMP)·2H$_2$O

The material (en)(HDTMP)·2H_2O was obtained from our attempts to synthesize Zn-HDTMP materials. The Zn^{2+} ion was not incorporated into the final product. (en)(HDTMP)·2H_2O can be synthesized according to the procedure below, without the Zn salt. A quantity of acid HDTMP (1.230 g, 2.5 mmol) is suspended in 40 mL DI water and mixed with 1.2 mL ethylenediamine (neat). The pH is adjusted to 2.0 by addition of HCl stock solution. Then a quantity of $ZnCl_2$·6H_2O is added (0.204 g, 1.5 mmol) under rigorous stirring. Final pH adjustment was done to 2.5. At this point a clear colorless solution forms. This solution is left under quiescent conditions at room temperature. After 2 days colorless crystals appear. They are isolated by filtration, washed with DI water and air-dried. Yield ~40%. Yields can be increased by prolonged crystallization times.

2.2.2. (NH_4)$_2$(EDTMP)

The material (NH_4)$_2$(EDTMP) was obtained from our attempts to synthesize Zn-EDTMP materials. The Zn^{2+} ion was not incorporated into the final product. (NH_4)$_2$(EDTMP) can be synthesized according to the procedure below, without the Zn salt. A quantity of acid EDTMP (0.947 g, 2.00 mmol) is suspended in 40 mL DI water. Sufficient quantity of a stock solution of NH_4OH is added until the solid dissolved. The pH is adjusted to 2.0 by addition of a stock solution of HCl. Then $ZnCl_2$·6H_2O is added (0.270 g, 2.00 mmol) under vigorous stirring and the final pH is adjusted to 1.8. The clear colorless solution is left undisturbed for 3 days, during which a white crystalline precipitate appears. It is filtered, washed with DI water and left to dry at room temperature. Yield ~60%.

2.2.3. Zn(H_2O)$_6$·(TDTMP)

A mixture of TDTMP and $ZnCl_2$ with a molar ratio of 1:1 was prepared in water at room temperature, as follows: 1 mmol (0.450 g) of solid TDTMP was dissolved in water (25 mL) with addition of NaOH until it completely dissolved. The pH was then adjusted to 2.0 by addition of HCl. Then, 1 mmol (0.136 g) of $ZnCl_2$ was gradually added under constant stirring. The pH of the final solution was adjusted to 2.2. After several days single crystals of the final compound appeared. The crystals were collected by filtration and dried in air. Yield ~70%.

2.3. Single crystal determinations

X-ray diffraction data were collected on a SMART 1K CCD diffractometer at 298(2) K with Mo Kα (λ = 0.71073 Å). Data were corrected for absorption using the empirical method employed in Sortav [15]. All structures were subsequently refined by full-matrix least squares refinement on F2 (SHELXL97) [16]. Non-hydrogen atoms were refined anisotropically. Hydrogen atoms were either located in the difference Fourier map or placed geometrically. Subsequent refinement of the thermal parameters was carried out isotropically in all cases. CCDC reference numbers: (en)(HDTMP)·2H_2O CCDC-651135; (NH_4)$_2$-(EDTMP) CCDC-625197; Zn(H_2O)$_6$·(TDTMP) CCDC-287045. Copies of the data may be obtained free of charge from the CCDC, e-mail: deposit@ccdc.cam.ac.uk or www: http://www/ccdc/cam/ac/uk).

Crystallographic details and selected bond distances and angles are given in Tables 1–4.

2.4. Sample characterization

FT-IR spectra were recorded on a FT-IR Perkin–Elmer FT 1760. ATR-IR spectra were collected on a Thermo-Electron NICOLET 6700 FTIR optical spectrometer.

3. Results and discussion

All three crystalline materials described herein share a common structural feature. They are layered compounds. The layered structure is composed of anionic phosphonate layers and charge-balancing cations, see Fig. 3. These layers are held together by complicated networks of hydrogen bonds. Waters of crystallization are found only in the structure of (en)(HDTMP)·$2H_2O$.

Metric features within the tetraphosphonate backbone are trivial and close to values reported in the literature [17]. The P—O bond distances are in the range 1.444–1.591 Å, typical for organophosphonates [18]. However, upon closer examination of the P—O bond lengths it becomes evident that they are separated into two categories, the "short" and the "long" bonds. All "long" bonds are associated with the protonated —P—OH moiety, whereas the "short bonds" are from the non-protonated portion of the —PO_3 moiety. Distinction between the P=O and the P—O— bond lengths is not possible because these are of equivalent length, based on the crystallography results. Therefore, this leads to the conclusion that the negative charge is delocalized over the O=P—O— moiety. Similar observations have been noted for metal-coordinated (and mono-deprotonated) phosphonates [19].

3.1. Crystal structure of (en)(HDTMP)·$2H_2O$

There are discrete $HDTMP^{2-}$ dianions and en^{2+} dications in the structure of (en)(HDTMP)·$2H_2O$, see Fig. 4 (upper). The presence of waters of crystallization, $HDTMP^{2-}$ dianions and en^{2+} dications leads to a complicated network of hydrogen bonds, finally yielding a 2D layered structure, see Fig. 4 (lower). They are described in detail below. The —NH_3^+ portion of the en molecule is hydrogen-bonded with one of the two water molecules of crystallization O(8) (2.974 Å), and with three O—P moieties (all from different phosphonate groups) (2.708, 2.804 and 2.984 Å).

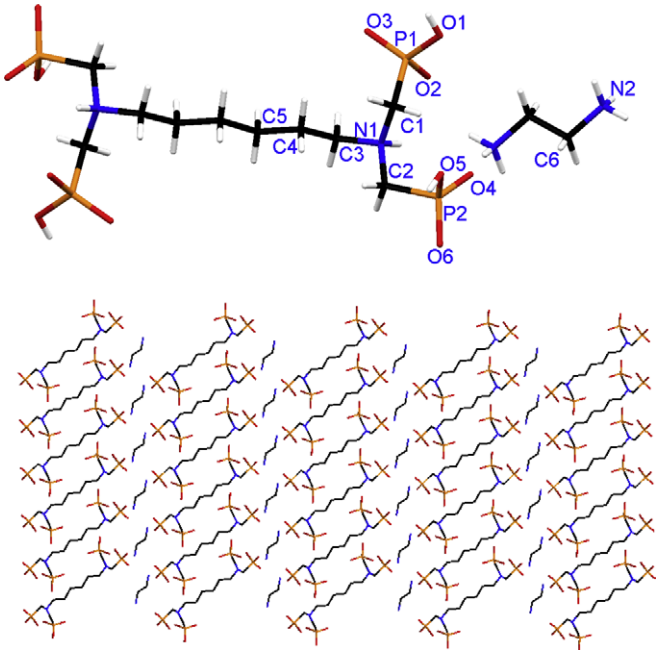

Fig. 4. Structure of $HDTMP^{2-}$ with the en^{2+} dications (upper, the water molecules are ommited for clarity). Layers of $HDTMP^{2-}$ and en^{2+} dications (lower) down the *b*-axis.

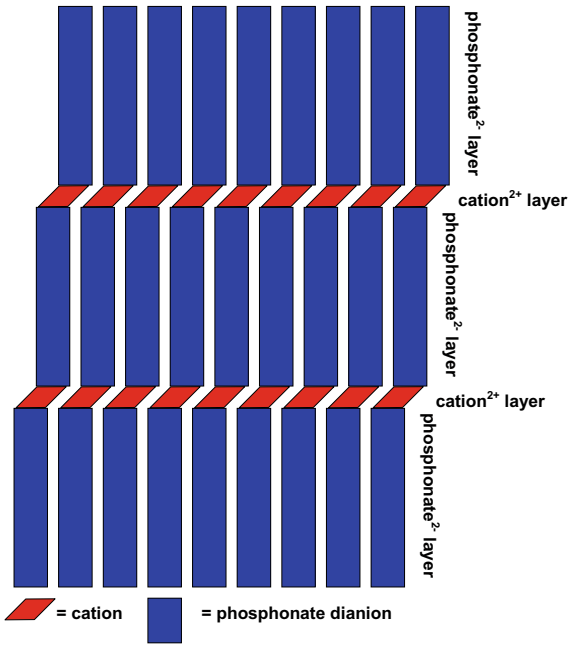

Fig. 3. The common structural feature in the three materials described herein. The cation and anion layers are assembled by hydrogen bonds.

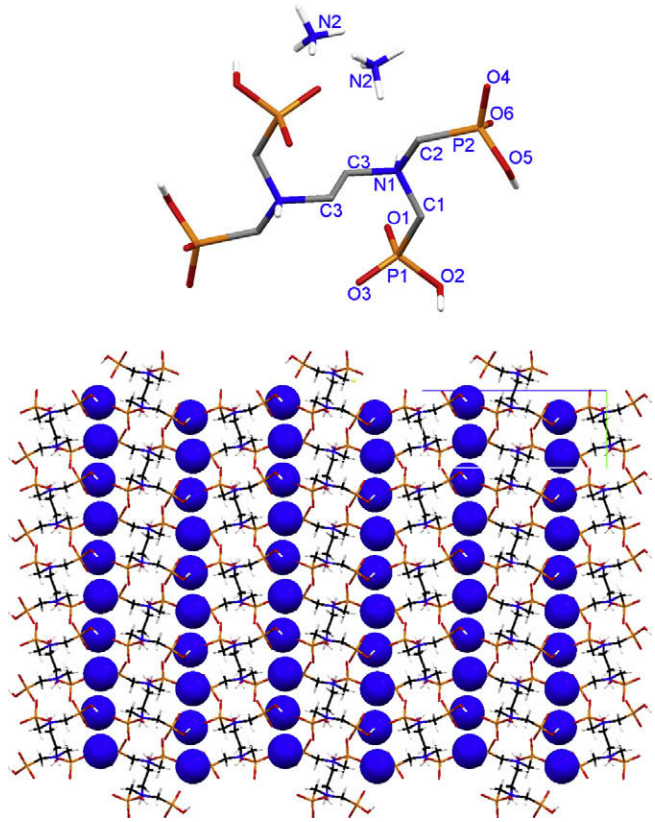

Fig. 5. Structure of $EDTMP^{2-}$ with the two NH_4^+ cations (upper). Layers of $EDTMP^{2-}$ and NH_4^+ cations, shown as blue spheres (lower) down the *a*-axis.

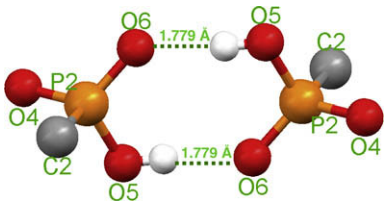

Fig. 6. Structure of the hydrogen-bonded dimer in the structure of $(NH_4)_2$(EDTMP).

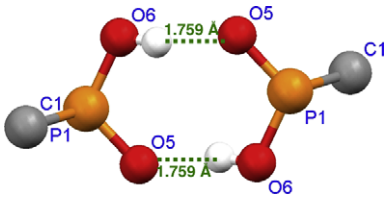

Fig. 9. Structure of the hydrogen-bonded dimer in the structure of $Zn(H_2O)_6$·(TDTMP).

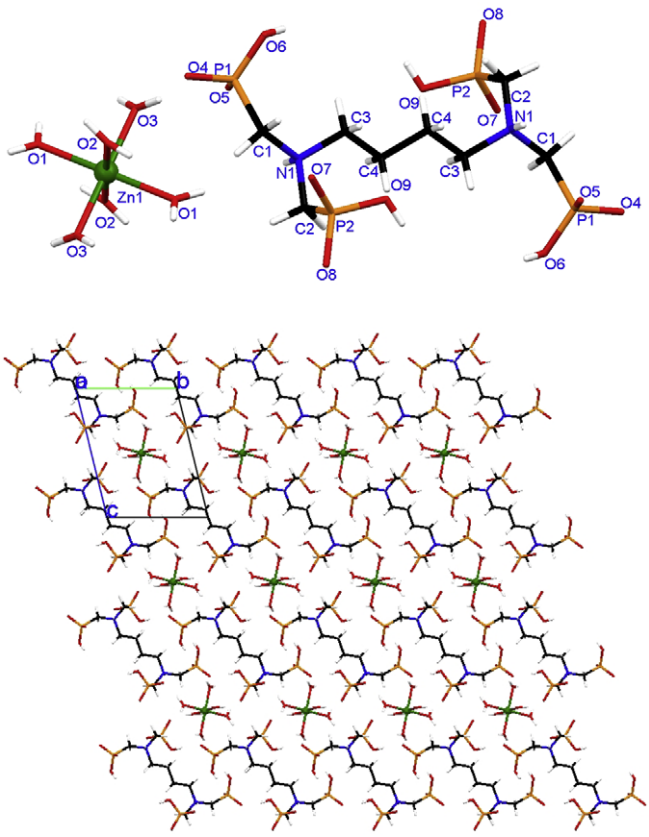

Fig. 7. Structure of $TDTMP^{2-}$ dianion with the $Zn(H_2O)_6^{2+}$ dication (upper). Layers of $TDTMP^{2-}$ and $Zn(H_2O)_6^{2+}$ dications down the *a*-axis (lower).

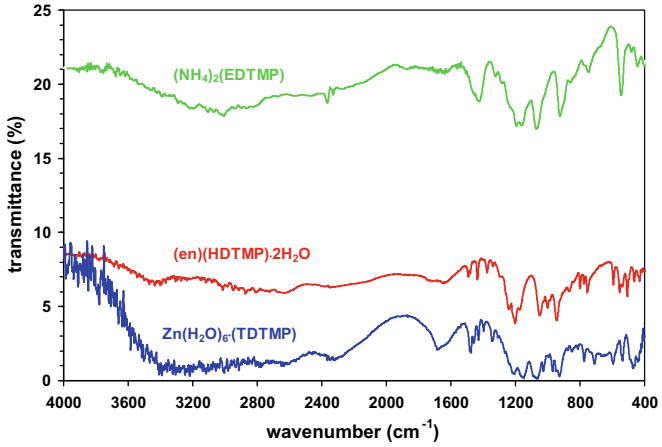

Fig. 10. FT-IR spectra of compounds (en)(HDTMP)·$2H_2O$, $(NH_4)_2$(EDTMP), and $Zn(H_2O)_6$·(TDTMP).

The two waters of crystallization are located in the vicinity of the en^{2+} dication. One water molecule (O(8)) forms hydrogen bonds with the N(1)–H^+ moiety (2.963 Å), with the $^+H_3N(2)$ group of the en^{2+} cation (2.974 Å), and with and the O(4) from a deprotonated phosphonate ligand, ^-O—P (2.999 Å). The second water molecule (O(7)) participates in three hydrogen bonds, one with a —P—O(1)H group (2.553 Å), and two hydrogen bonds with two deprotonated P—$O(3)^-$ moieties (2.729 and 2.743 Å) from neighboring phosphonate ligands.

The $P(1)O_3H^-$ phosphonate participates in four hydrogen bonds. P—O(1) connects to a water molecule O(7) (2.553 Å). P—O(3) forms two hydrogen bonds with two symmetry-related water molecules O(7) (2.743 and 2.729 Å). Finally, P—O(2) is only hydrogen bonded to protonated H—O(5)P(2) (2.533 Å).

The $P(2)O_3H^-$ phosphonate group takes part in five hydrogen bonds. Protonated P—O(5) connects to a P—O(6) group from a neighboring phosphonate (2.533 Å). P—O(4) H-bonds to a water molecule O(8) (2.999 Å) and to a protonated N(2) from en (2.804 Å). Finally, P—O(6) interacts with two protonated N(2) groups from two different en molecules (2.708 and 2.984 Å).

3.2. Crystal structure of $(NH_4)_2$(EDTMP)

There are discrete $EDTMP^{2-}$ dianions and NH_4^+ cations in the structure of $(NH_4)_2$(EDTMP), see Fig. 5 (upper). The presence of $EDTMP^{2-}$ dianions and NH_4^+ cations leads to a complicated network of hydrogen bonds, finally yielding a 2D layered structure, see Fig. 5 (lower). They are described in detail below.

Each of the ammonium cations participates in five hydrogen bonds, all with non-protonated P—O groups from different phosphonate ligands: with O(3)—P(1) (2.895 Å), with O(2)—P(1) (2.929 Å), with O(4)—P(2) (2.949 Å), with O(3)—P(1) (2.799 Å) and with O(6)—P(1) (2.820 Å).

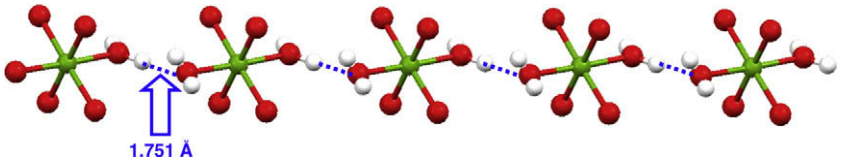

Fig. 8. $Zn(H_2O)_6^{2+}$ dications (part of the "inorganic layer") linked by hydrogen bonds.

The $P(1)O_3H^-$ phosphonate group participates in five hydrogen bonds. Protonated P—O(2)H participates in a hydrogen bond with the ammonium N(2) group of the NH_4^+ cation (2.929 Å) and the non-protonated group O(4)—P(2) from a neighboring phosphonate (2.559 Å). The group P–O(1) forms only one H-bond with the protonated $N(1)H^+$ group belonging to another EDTMP molecule (2.648 Å). Finally, P–O(3) forms two H-bonds with two symmetry-related N(2) groups from two different en molecules (2.799 and 2.895 Å).

The $P(2)O_3H^-$ phosphonate group also participates in five hydrogen bonds. Protonated P–O(5)H participates in a hydrogen bond with the non-protonated P(2)–O(6) group from a neighboring phosphonate. At the same time non-protonated P(2)–O(6) hydrogen bonds with the protonated P(2)–O(5)–H moiety with the same phosphonate group. This creates a hydrogen-bonded dimer, the structure of which is shown in Fig. 6. A similar phosphonate hydrogen-bonded dimmer has been observed in the structure of 2-phosphonobutane-1,2,4-tricarboxylic acid monohydrate ($PBTC{\cdot}H_2O$) [20].

3.3. Crystal structure of $Zn(H_2O)_6{\cdot}(TDTMP)$

There are discrete $TDTMP^{2-}$ dianions and $Zn(H_2O)_6^{2+}$ dications in the structure of $Zn(H_2O)_6{\cdot}(TDTMP)$, see Fig. 7 (upper). This result is somewhat surprising because reaction of Zn^{2+} with HDTMP in similar conditions yields a Zn-HDTMP inorganic organic hybrid [17a]. At present we have no satisfactory explanation for this. One can link this absence of TDTMP coordination to Zn^{2+} to a reduced basicity of the phosphonate oxygens. The metric features of the $Zn(H_2O)_6^{2+}$ octahedron are expected and comparable to those of $[Zn(H_2O)_6](triflate)_2$ [21] and a Zn6 cluster with the ligand N-(phosphonomethyl)-N-methylglycine containing non-coordinated $Zn(H_2O)_6^{2+}$ dications in the lattice [22]. Also, an Mg ionic material containing non-coordinating aminoethylphosphonate has been reported that contains $Mg(H_2O)_6^{2+}$ dications in the lattice [23]. The presence of $TDTMP^{2-}$ dianions and $Zn(H_2O)_6^{2+}$ dications (there are no waters of crystallization in the structure) leads to an intricate network of hydrogen bonds, finally yielding a 2D layered structure, see Fig. 7 (lower). They are described in detail below.

The $Zn(H_2O)_6^{2+}$ dication participates in a total of fourteen hydrogen bonds. Two of them (O···O 2.733 Å) are with neighboring $Zn(H_2O)_6^{2+}$ dication, thus creating a one-dimensional 'wire', as part

				O(4)–P(1)–O(6)	108.12(14)

of the $[Zn(H_2O)_6^{2+}]_n$ layer, see Fig. 8. The remaining twelve H-bonds are exclusively with phosphonate oxygens from layers below and above. Bond distances are in the range 2.618–2.972 Å.

The $P(1)O_3H^-$ phosphonate group takes part in six hydrogen bonds. Three of them are with Zn-bound water molecules (2.797, 2.972 and 2.809 Å). It is interesting to note that the protonated P(1)–O(6)–H moiety along with a non-protonated group P(1)–O(5) create a hydrogen bonded dimer with the corresponding P–O groups of a neighboring P(1) phosphonate. The structure of this dimer (analogous to that formed in the structure of $(NH_4)_2$(EDTMP) is shown in Fig. 9.

The $P(2)O_3H^-$ phosphonate group takes part in five hydrogen bonds. Three of them are with Zn-bound waters (2.718, 2.737 and 2.621 Å). The protonated P(2)–O(9)–H group hydrogen bonds to a non-protonated P(1)–O(4) moiety (2.569 Å). Finally, there is a hydrogen bond between non-protonated P(2)–O(7) and the —NH^+ amine moiety of a neighboring phosphonate (2.854 Å).

The $P(1)O_3H^-$ phosphonate group takes part in five hydrogen bonds. Two of them participate in the hydrogen-bonded dimer mentioned above. Two of them are with Zn-bound waters (2.752 and 2.949 Å). Finally, there is a hydrogen bond between non-protonated P(1)–O(4) and a protonated P(2)–O(9)–H moiety of a neighboring phosphonate (2.569 Å).

3.4. Vibrational spectroscopy

Vibrational spectroscopy was employed as well to further characterize these compounds. FT-IR spectra are shown in Fig. 10. Mid IR spectra (400–4000 cm^{-1} region) of the tetraphosponate products display a multitude of bands in the region 1100–1270 cm^{-1} assigned to the P=O stretch. A doublet in the region 920–970 cm^{-1} is assigned to the —P—OH antisymmetric and symmetric stretching vibrations. The strong band in the region 1045–1055 cm^{-1} is tentatively assigned to an antisymmetric vibration mode of the —CPO_3 group. Bands in the spectra for all compounds are also observed in the 400–550 cm^{-1} region. These are assigned to the —PO_3 symmetric and —PO_3 antisymmetric bending modes. Broad bands in the region 1640–1670 cm^{-1} in the spectra of (en)(HDTMP)·$2H_2O$ and $Zn(H_2O)_6$·(TDTMP) are due to lattice water and Zn-bound water, respectively. Such bands are absent in the spectrum of $(NH_4)_2$(EDTMP), which is anhydrous.

4. Conclusions

The three ionic materials reported herein share a 2D structural motif. They are layered compounds with anionic tetraphosphonate layers separated with cationic layers. These structures are held together by an intricate network of hydrogen bonds, which act as the driving for the self assembly process. The field of metal phosphonate chemistry is growing rapidly. The area of frameworks composed of organic ionic components is also expected to grow in parallel and act in a supporting fashion. A viable goal is the designed synthesis of supramolecular arrays in a predictable fashion by use of appropriate reactants.

Supplementary data

CCDC 651135, 625197 and 287045 contain the supplementary crystallographic data for compounds (en)(HDTMP)·$2H_2O$, $(NH_4)_2$(EDTMP), and $Zn(H_2O)_6$·(TDTMP). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

i = 1) MeONa in MeOH; 2) $NaAuCl_4$ in MeOH/H_2O;
ii = *n*-Bu_4NBr_3 in MeOH; n = 2- and/or 1-

Scheme 1. Route used for the synthesis of Au(dpedt)$_2$.

on a Bruker IFS-113 V, FT-IR spectrometer, in the range 4000–500 cm^{-1}. Cyclic voltammetry measurements were carried out with a Bipotentiostat AFCBP1 from Pine Instrument Company and controlled with the PINECHEM 2.7.9 software, using a glassy carbon disk working electrode (1.6 mm diameter) and a Ag/Ag$^+$ (0.01 M $AgNO_3$ and 0.5 M *n*-Bu_4NPF_6 in acetonitrile) non-aqueous reference electrode (Bioanalytical Systems, Inc.) with a prolonged bridge (0.5 M *n*-Bu_4NPF_6 in acetonitrile). A Pt foil or gauge (8 cm^2, Sigma–Aldrich) was employed as counter electrode. The working electrode was polished using successively 6, 3, 1 mm diamond paste on a DP-Nap polishing cloth (Struerg, Westlake, OH), washed with water, acetone and air dried. The Pt foil and gauge electrodes were cleaned in a H_2O_2/H_2SO_4 (conc.) solution (1:4 v:v) and oven-dried. The concentration of the sample was 3 mM and that of supporting electrolyte (*n*-Bu_4NPF_6) was 0.5 M. The potential sweep rate varied between 10 and 1000 mV/s. All potentials were reported *versus* the ferrocenium/ferrocene (F_c^+/F_c) couple.

2.2. Synthesis of Au(dpedt)$_2$

In a two-necked 250 mL flask, a solution-suspension of 4,5-diphenyl-1,3-dithiol-2-one (dpdto) (500 mg, 2 mmol) in dry MeOH (40 mL) was prepared with stirring under nitrogen atmosphere. Then, a solution of NaOMe, freshly prepared from Na (115 mg, 5 mmol) and MeOH (20 mL), was added and the mixture stirred at r.t. for 30 min. To the yellow solution obtained, a solution of $NaAuCl_4{\cdot}2H_2O$ (398 mg, 1 mmol in deoxygenated MeOH/H_2O) (5/0.5 mL) was added slowly within 10 min. The resulting brown solution was stirred under nitrogen atmosphere for 1 h at r.t., whereupon the color turned brown–red. Then, a solution of *n*-Bu_4NBr_3 (482 mg, 1 mmol) in MeOH (25 mL) was added, and the mixture stirred for 2 h. Then, it was transferred to a beaker and stirred in air overnight. The precipitate was filtered, washed with water and MeOH and dried in air. The greenish-brown solid was extracted with CS_2 and chromatographed on a short silica-gel column, using CS_2 as eluent. The first greenish-brown fraction contained Au(dpedt)$_2$. Slow evaporation of the solvent gave gray-bronze crystals (190.9 mg, 28%). This compound was obtained in a lower yield as a byproduct of the preparation of Au(dpedt)(dddt) [4b]. M.p.: 234 °C. *Anal.* Calc. for $C_{28}H_{20}S_4Au$ (MW 681.695): C, 49.33; H, 2.96. 2.3. X-ray crystallography

A prismatic single crystal of Au(dpedt)$_2$ (0.18 × 0.36 × 0.70 mm^3) was mounted in capillary. Diffraction measurements were performed on a CRYSTAL LOGIC dual Goniometer diffractometer using graphite-monochromated Mo Kα radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range 11° < 2θ < 23°. Three standard reflections monitored every 97 reflections showed less than 3% intensity fluctuation and no decay. Lorentz, polarization corrections were applied using CRYSTAL LOGIC software. Important crystal data and refinement parameters for data collections are given in Table 1. The structure was solved by direct methods using SHELXS-97 [15] and refined by full matrix least-squares techniques on F^2 with SHELXL-97 [16]. Hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. Selected bond lengths and bond angles within the AuC_4S_4 chelate are given in Table 2.

3. Results and discussion

3.1. Formation of Au(dpedt)$_2$

The reaction of dpdto with MeONa, followed by treatment with $NaAuCl_4$ (Scheme 1) afforded the species [Au(dpedt)$_2$]^n (n = 2− and/or 1−). These species cannot be completely oxidized in air, under conditions reported in [4–6]. The oxidation stops when the species [Au(dpedt)$_2$]$^{1-}$ is formed. Further oxidation was performed with *n*-Bu_4NBr_3 to give the required neutral Au(dpedt)$_2$. The preparation of this material under strong oxidation conditions (*n*-Bu_4NBr_3) indicates its stability in air. The complex is soluble in CS_2 (10 mg/mL) and other organic solvents.

3.2. Structural information

Single crystals of the complex $Au(dpedt)_2$ crystallize in the triclinic system, space group $P\bar{1}$ (see Table 1). It is isostructural with β-$Ni(dpedt)_2$ [17a], but not isostructural with α-$Ni(dpedt)_2$ [17b,c], $Pt(dpedt)_2$ [17d] and $Pd(dpedt)_2$·0.5toluene [9a]. Fig. 1 shows the molecular structure of $Au(dpedt)_2$. From this figure and the data, of Table 2, one can see that in the AuC_4S_4 chelate of $Au(dpedt)_2$ molecule the Au–S, C–S and the olefinic C–C bond lengths are 2.288–2.295, 1.723–1.744 and 1.367–1.370 Å, respectively. The theoretically calculated values for $Au(dpedt)_2$ are 2.360, 1.756 and 1.383 Å, respectively [9a]. The experimentally obtained values could be comparable with those reported for $[Au(^2L)_2]\cdot CH_2Cl_2$ [9a], *i.e.*, the Au–S, C–S and olefinic C–C average bond lengths are 2.291(5), 1.749(20) and 1.36(2) Å, respectively. Selected bond lengths for several complexes are listed in Table 3. One can see that the bond length M–S increases with the order Au–S > Pd–S > Pt–S > Ni–S. In $Au(dpedt)_2$ molecule, as in the case of β-$Ni(dpedt)_2$, the conformation of phenyl groups (Fig. 1) is such that the molecule totally lacks reflection and inversion symmetry [17a]. The molecule $Au(dpedt)_2$ is also a dissymmetric molecule and is expected to exhibit optical activity. Fig. 2 shows the packing diagram of $Au(dpedt)_2$ molecules, which are stacked along the *b* crystallographic axis. Both intrastacking and interstacking S···S intermolecular distances are longer than 4.5 Å. These distances are much larger than the sum of the van der Waals radii (3.70 Å). It was found that the long axis of the crystal is almost parallel to the *a*-axis.

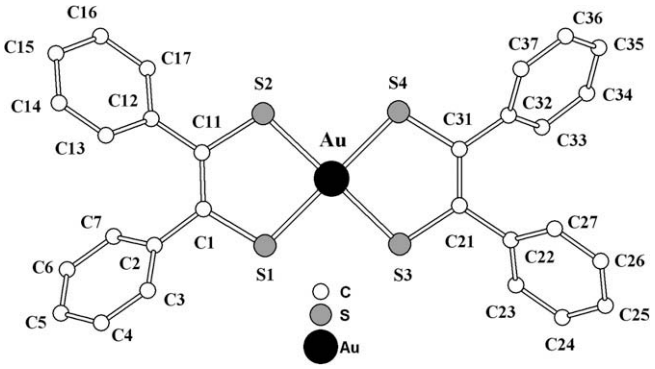

Fig. 1. Molecular structure of $Au(dpedt)_2$ in the crystal.

Table 3
Selected bond lengths (Å) for several complexes.

Complex	M–S	C–S	C=C	Ref.
$Au(dpedt)_2$	2.288–2.295	1.723–1.744	1.367–1.370	this work
$Au(^2L)_2$	2.291(5)	1.749(20)	1.36(2)	[9a]
$Pd(dpedt)_2$	2.251(1)	1.708(4)	1.399(5)	[9a]
$Pt(dpedt)_2$	2.244–2.246	1.699–1.716	1.395	[17d]
β-$Ni(dpedt)_2$	2.120–2.127	1.695–1.701	1.404–1.424	[17a]
α-$Ni(dpedt)_2$	2.101 ± 0.002	1.71 ± 0.01	1.37 ± 0.01	[17b]
α-$Nidpedt)_2$	2.1220(4)–2.1195(6)	1.698(1)–1.712(2)	1.396(2)	[17c]

3.3. EPR spectrum

Fig. 3 shows the EPR spectrum (X-band) of the complex $Au(dpedt)_2$ in frozen CH_2Cl_2 solution (0.1 M n-Bu_4NPF_6). The estimated from this spectrum g_x, g_y and g_z values are 2.064, 2.029 and 1.936, respectively. These values are close to the theoretically calculated ones (2.028, 2.023 and 1.962, respectively) and almost the same as those obtained experimentally from $Au(^2L)_2$ (2.065, 2.030 and 1.944, respective) [9a].

3.4. The electronic optical absorption spectra

Fig. 4 shows the UV–Vis–NIR optical absorption (OA) spectra of $Au(dpedt)_2$ solutions in CH_2Cl_2 and CS_2. One can see that there is an

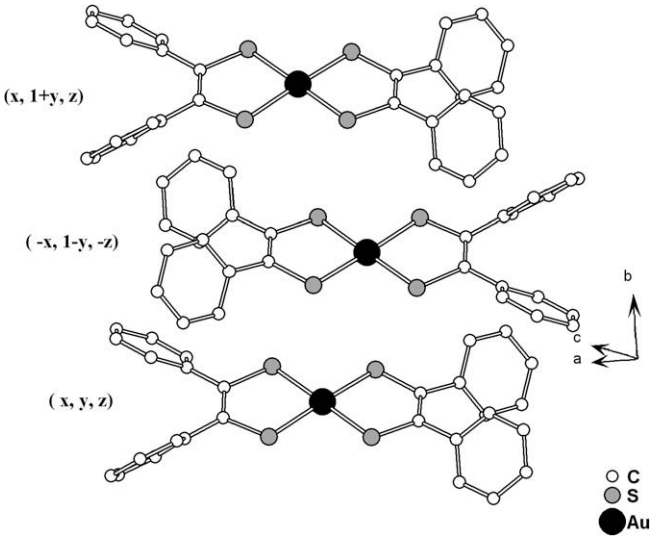

Fig. 2. Packing diagram of $Au(dpedt)_2$.

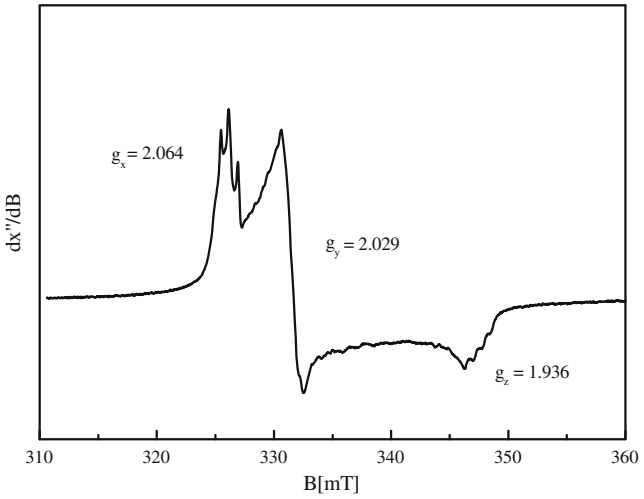

Fig. 3. EPR spectrum of $Au(dpedt)_2$ in frozen CH_2Cl_2 and 90 K. Experimental conditions: microwave frequency 9.41602 GHz, microwave power 3.2 mW, modulation amplitude 0.2 mT, modulation frequency 100 kHz.

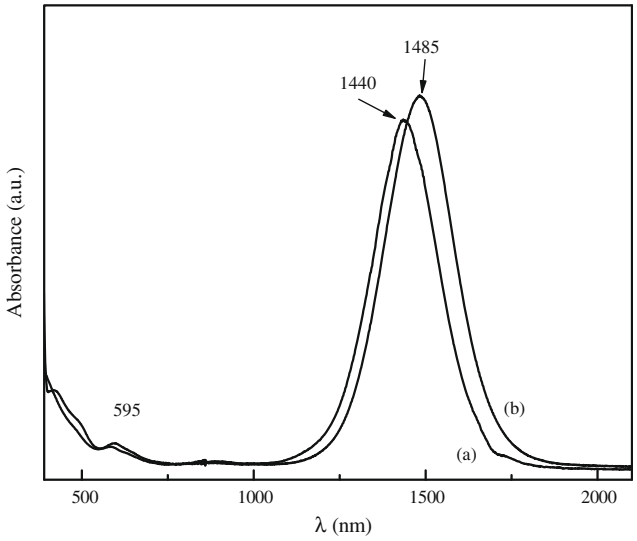

Fig. 4. UV–Vis–NIR optical absorption spectra of Au(dpedt)$_2$ in CH_2Cl_2 (a) and CS_2(b).

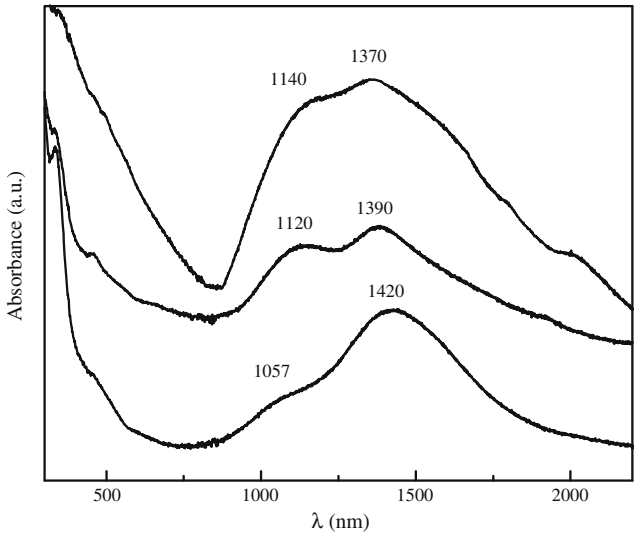

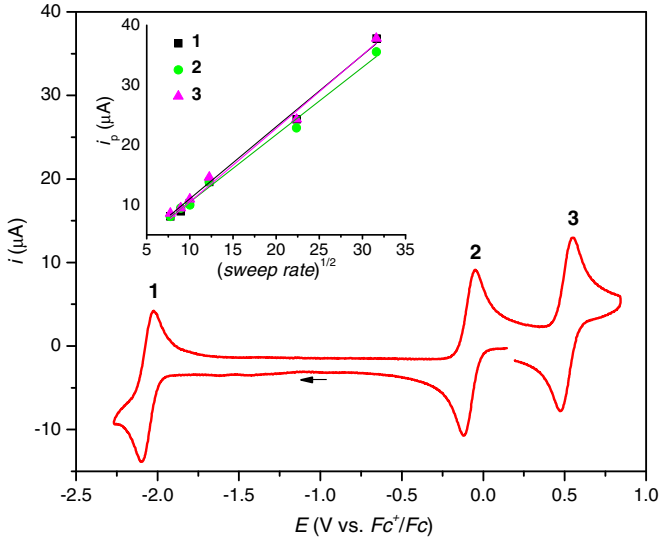

Fig. 5. UV–Vis–NIR optical absorption spectra of Au(dpedt)$_2$ deposited on quartz plates (three samples).

optical absorption onset (E^{opt}_{onset}) at ca. 1750 nm (0.7 eV), and a very strong absorption band at 1440 (CH_2Cl_2) or at 1485 (CS_2) nm. As in the case of Au(^{2}L)$_2$ [9a,10], this band is assigned to the intervalence charge transfer $1b_{1u} \rightarrow 2b_{2g}$ (*x*-polarized $^2B_{1u}$ state) transition. Another weak band at ca. 1180 nm, observed in the spectrum of Au(^{2}L)$_2$ solution in CH_2Cl_2 and assigned to the intervalence charge transfer $1a_u \rightarrow 2b_{2g}$ (*y*-polarized ^2A_u state) transition [9a,10], was not observed in the spectra of Au(dpedt)$_2$ solutions. The low frequency bands are discrete in the solid state spectra of Au(dpedt)$_2$. Fig. 5 shows the spectra of three samples of Au(dpedt)$_2$ deposited on quartz plates from solutions in CH_2Cl_2 or CS_2 by the spin coating technique. One can see that the position, intensity and shape of the low frequency bands vary from sample to sample. This behavior is attributed to the several different kinds of orientation and interaction of crystallites in the deposits. In the spectra of thin deposits the (E^{opt}_{onset}) occurs at ca. 2000 nm (0.61 eV). More discrete bands are expected in the single crystal polarized reflectance spectra, as in the case of Au(bdt)$_2$ (where bdt is benzene-1,2-dithiolate) [11]. The theoretically calculated optical absorption spectrum of Au(dpedt)$_2$ shows the low frequency bands at ca. 1420 and 1370 nm [9a,10].

The low frequency OA band and (E^{opt}_{onset}) of Au(dpedt)$_2$ in solution occur close to those of Au(^{2}L)$_2$ [9a], but at lower frequencies than those of M(dpedt)$_2$ (M = Ni, Pt, Pd) [9,17,18]. The position, intensity and shape of the low frequency the OA band of thin deposits of Au(dpedt)$_2$ remain unchanged for long time. This means that, in the solid state, the complex is stable in air.

3.5. Redox behavior

The key features of the cyclic voltammograms of Au(dpedt)$_2$ in CH_2Cl_2 at r.t. are three chemically and kinetically reversible waves: two reduction waves at $E_{1/2}(1) = -2.061$ V ($\Delta E = 69$ mV, $i_{p,c}/i_{p,a} = 1.07$) and $E_{1/2}(2) = -0.085$ V ($\Delta E = 66$ mV, $i_{p,c}/i_{p,a} = 0.97$) and one oxidation wave at $E_{1/2}(3) = +0.510$ V ($\Delta E = 70$ mV, $i_{p,a}/i_{p,c} = 1.07$). All potential values are given *versus* the ferrocenium/ferrocene (F_c^+/F_c) couple. This behavior was maintained for scan rates ranging from 80 to 1000 mV/s (the ΔE values and the faradaic

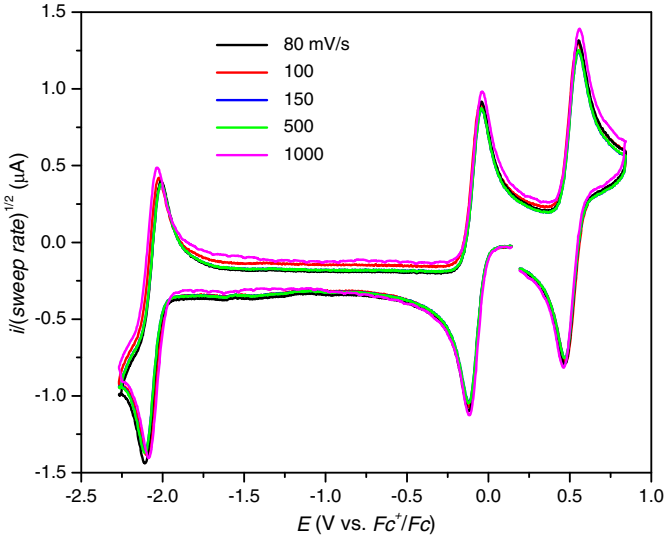

Fig. 6. Left: cyclic voltammetry of Au(dpedt)$_2$ in CH_2Cl_2/0.5 M *n*-Bu_4NPF_6 with a glassy carbon disk electrode (3 mm in diameter); scan rate 100 mV/s. Arrow indicates direction of scan. Inset: Randles–Sevcik plots for the anodic part of the oxidation wave and the cathodic parts of the reduction waves. Right: plots of i/(sweep rate)$^{1/2}$ vs. E for various sweep rates, as indicated.

current ratios given above are taken from the voltammogram recorded at 100 mV/s, Fig. 6, left). At lower scan rates (70–20 mV/s) a small wave appears at ca. −1.36 V, which also affects the reversibility of wave 1. Randles–Sevcik plots yielded straight lines, indicating diffusion controlled processes (Fig. 6, left, inset). Voltammograms normalized by dividing the faradaic current by the square root of the potential sweep rate are superimposable over a wide range of sweep rates, confirming its full chemical and kinetic reversibility (Fig. 6, right).

The electrochemical data exhibit pronounced similarities with data reported previously for analogous compounds [9a]. Thus, the three reversible redox waves can be tentatively assigned to the following transformations:

$$[Au(dpedt)_2]^{2-} \underset{E_{1/2}(1)}{\rightleftharpoons} [Au(dpedt)_2]^{-} \underset{E_{1/2}(2)}{\rightleftharpoons} [Au(dpedt)_2]^{0} \underset{E_{1/2}(3)}{\rightleftharpoons} [Au(dpedt)_2]^{+}$$

At higher potentials (1–2.5 V) further multi-electron oxidation of the complex occurs, as evidenced by the presence of irreversible waves at ca. 1.26, 1.48, 1.79 and 2.18 V. These oxidations have not been further investigated.

The reduction onset (E^{rd}_{onset}) for the neutral complex occurs at ca 0.03 V and the oxidation onset (E^{ox}_{onset}) occurs at ca. 0.42 V. The potential values are very close to those obtained for $Au(^2L)_2$ and similar complexes of Au [9,10], but the $E_{1/2}(2)$ value is larger than the values observed for other $M(dpedt)_2$ compounds (M = Ni, Pt, Pd; [1,4,6,9,10,18] and references therein).

3.6. Calculation of the LUMO and HOMO levels

The LUMO energy level (E_{LUMO}) value was calculated from the reduction onset (E^{rd}_{onset}) value for the 1e process *via* the equation $-E_{LUMO} = 4.8 + (E^{rd}_{onset})$ [19]. This is $E_{LUMO} = -4.83$ eV and is more negative than that obtained from $Ni(dpedt)_2$ [9c,18]. The HOMO energy level (E_{HOMO}) value was calculated from the oxidation onset (E^{ox}_{onset}) value for the 1e process *via* the equation $-E_{HOMO} = 4.8 + (E^{ox}_{onset})$ [19]. This is $E_{HOMO} = -5.22$ eV. The difference $E_{LUMO} - E_{HOMO}$ gives the energy gap of the semiconducting material, $E_g = 0.39$ eV, a value which is little smaller than that obtained from the optical absorption spectra of thin deposits of material on quartz plates (Fig. 4), $(E^{opt}_{onset}) = 0.61\ eV$ [19g]. The $E_{LUMO} = -4.83$ and $E_{HOMO} = -5.22$ eV values of $Au(dpedt)_2$ indicate that the material is stable in air [2]. The complex can be a candidate material for fabrication of n-type or ambipolar FETs in thin film or single crystal form, more stable in air than those based on Ni 1,2-DTs [1–3].

Supplementary data

CCDC 721849 contains the supplementary crystallographic data for $Au(dpedt)_2$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

of magnetoanisotropy, as measured by the axial, zero-field splitting parameter *D*. An entirely different family of molecular nanomagnets has been recently unearthed with the discovery of single-ion (mononuclear) lanthanide(III) SMM complexes [6]. This innovation represents a crucial step in the miniaturization of nanomagnets [1a].

From the above brief discussion, it is becoming clear that there continues to be a need for new synthetic methods [7] to metal clusters and SMMs. Ligands used in synthesizing 3d-metal clusters are however comparatively restricted and thus discovery of new combinations ("blends") of ligands remains important in the field. With this in mind, we have been exploring "ligand blend" reactions involving carboxylates (RCO_2^-) *and* anioning bridging-chelating ligands (viz., bridging ligands that simultaneously form chelating rings), *with* or *without* additional inorganic annions, e.g., Cl^-, Br^-, NO_3^-, N_3^-, SCN^- and SO_4^{2-}. Besides their deprotonating ability, the RCO_2^- ions are flexible ligands, a consequence of their ability to adopt a number of different ligation modes, both terminal and bridging as well as both monodentate and bidentate. Results with the anionic *gem*-diol derivatives of di-2-pyridyl ketone [5a,b,8], various 2-pyridyloximates [9], a plethora of derivatized salicylaldoximates [5d,10] and the anionic forms of pyridine-2,6-dimethanol [8b,11] have been very encouraging, and a series of Mn, Fe, Co, Ni and Cu carboxylate clusters with nuclearities up to 20 and with interesting properties (including SMM behaviour [5b,c,d,10]) have been prepared.

As part of our continuing search for new ligand combinations in 3d-metal cluster chemistry, we have recently turned our attention to simple 2-pyridyl alcohols that present a kind of structural similarity to 2-pyridyl oximes. Our goals are to investigate to what extent the use of such ligands might affect the identity of the obtained products compared with 2-pyridyl oximes and to what extent this might thus prove to be a route to new cluster types. For example, we have reported [12] that aerobic reactions of $Co(O_2CR)_2$ (R = Me,Ph) with 2-(hydroxymethyl)pyridine (hmpH; for the coordination modes of the neutral ligand and its anion, see Scheme 1), in the presence of ClO_4^- counterions give the hexanuclear, mixed-valence clusters $[Co^{II}_4Co^{III}_2(O_2CR)_4(hmp)_8](ClO_4)_2$ which possess the novel $\{Co^{II}_4Co^{III}_2(\mu_2\text{-}O\acute{R})_4(\mu_3\text{-}O\acute{R})_4\}^{6+}$core [$\acute{R}$ = (2-pyridyl)CH_2–]. In the present work, we report two complexes (one mononuclear, one tetranuclear) resulting from the initial use of hmpH in Ni^{II} acetate chemistry. Ni^{II} with a large single-ion anisotropy and a moderate spin (*S* = 1), may be a good candidate for making SMMs [3b], and there are some reports in the literature of Ni^{II}-based SMMs [13]. The ligand hmpH has been rather extensively used in the synthesis of Mn [14], Fe [15], Co [12] and Cu [16] *carboxylate* clusters, but has been sparingly used with Ni^{II} carboxylates, the only exception being complex $[Ni_4(OH)_2(pypentO)(hmp)(O_2CMe)_2(NCS)_2(H_2O)]$ [17] which contains four (!) bridging ligands [pypentO is the monoanion of 1,5-bis [(2-pyridymethyl)amino] pentane-3-ol]. The deprotonated hmp^- group has been used previously in Ni^{II} *non-carboxlate* chemistry by the groups of Vicente and co-workers [18], Christou/Hendrickson [19] and Hendrickson [20], who reported ferromagnetic cubane clusters (*S* = 4) of the general formula $[Ni_4X_4(hmp)_4(ROH)_4]$ (X = N_3, Cl, Br; R = various), most of which are SMMs. We suspected that there might be a number of Ni^{II}/RCO_2^-/hmp^- cluster species accessible and have therefore been investigating the reactions of hmpH with Ni^{II} carboxylate sources under a variety of conditions; our *initial* investigations on the $Ni(O_2CMe)_2\cdot 4H_2O$/hmpH reaction system are described herein.

Scheme 1. The up-to-now crystallographically confirmed coordination modes of hmpH and hmp^-.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions using materials (reagent grade) and solvents as received. Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical Laboratory using an EA 1108 Carlo Erba analyzer.

IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT-spectrometer with samples prepared as KBr pellets. Magnetic susceptibility measurements in the 1.9–300 K range under a field of 0.5 T were performed with a Quantum Design SQUID-based MPMSXL-5-type magnetometer. The magnetometer was calibrated with a palladium rod sample (Materials Research Corporation, measured purity 99.9985%). The measurements were carried out on polycrystalline samples. Data were corrected for diamagnetic contributions using Pascal's constants; the temperature-independent paramagnetism of the Ni^{II} ion was considered to be $Na = 2.5 \times 10^{-9}$ m^3 mol^{-1} (SI units).

2.2. Compound preparation

2.2.1. $[Ni(O_2CMe)_2(hmpH)_2]$ (**1**)

The ligand hmpH (0.114 ml, 1.20 mmol) was added to an aqueous solution (10 ml) of $Ni(O_2CMe)_2\cdot 4H_2O$ (0.158 g, 0.60 mmol). The resulting blue solution was stirred for about 10 min and was then allowed to slowly concentrate by solvent evaporation at room temperature for a period of 10 d. Well-formed, blue prismatic crystals of the product appeared, which were collected by filtration, washed with Me_2CO (2 × 3 ml) and dried in air; yield 80% (based on the metal). IR (KBr pellet): *v* = 3386 mb, 2838 m, 1600 s, 1568 s, 1480 m, 1416 s, 1358 m, 1286 m, 1236 w, 1154 w, 1082 s, 1048 m, 1024 m, 932 w, 762 m, 730 m, 674 m, 646 m, 492 w cm^{-1}. *Anal.* Calc. for $C_{16}H_{20}NiN_2O_6$: C, 48.65; H, 5.10; N, 7.09. Found: C, 48.69 H, 5.08; N, 7.11%.

2.2.2. $[Ni_4(O_2CMe)_4(hmp)_4(H_2O)_2]\cdot 2.25H_2O\cdot 0.5$(1,4-dioxane) [**2**·2.25H_2O·0.5(1,4-dioxane)]

The ligand hmpH (0.057 ml, 0.60 mmol) was added to an aqueous solution (15 ml) of $Ni(O_2CMe)_2\cdot 4H_2O$ (0.158 g, 0.60 mmol). The resulting deep green solution was stirred for about 15 min, mixed with 1,4-dioxane (10 ml) and left undisturbed in a closed flask at room temperature for about 4 d. Green prismatic crystals of the product formed, which were collected by filtration, washed with Me_2CO (2 × 3 mL) and dried in air; yield 65% (based on the metal). IR (KBr pellet): *v* = 3474 mb, 3356 mb, 2902 m, 2836 m, 1590 s, 1562 s, 1482 m, 1418 s, 1358 m, 1288 m, 1234 w, 1216 w, 1156 w, 1082 s, 1048 m, 1024 m, 818 s, 760 m, 728 m, 672 m, 646 m, 620 w, 498 w, 472 w cm^{-1}. *Anal.* Calc. for $C_{34}H_{48.50}Ni_4N_4O_{17.25}$: C, 39.88; H, 4.77; N, 5.47. Found: C, 39.85; H, 4.78; N, 5.43%.

2.3. Single-crystal X-ray crystallography

A blue prismatic crystal of **1** (0.20 × 0.30 × 0.40 mm) was mounted in air, while a green prismatic crystal of **2**·2.25H_2O·0.5(1,4-dioxane) (0.10 × 0.20 × 0.50 mm) was mounted in capillary. Diffraction measurements for **1** were made on a Nicolet $P2_1$ diffractometer upgraded by Crystal Logic using graphite mono-

chromated Cu radiation. Diffraction measurements for **2**·2.25 H_2O·0.5(1,4-dioxane) were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo radiation. Crystal data and details of the data collection and data processing are listed in Table 1. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $22 < 2\theta < 54°$ for **1** and in the range $11 < 2\theta < 23°$ for **2**·2.25H_2O·0.5(1,4-dioxane). Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay for both complexes. Lorentz, polarization and psi-scan absorption corrections were applied using Crystal Logic software.

The structures were solved by direct methods using SHELXS-86 [21] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [22]. All hydrogen atoms were located by difference maps and were refined isotropically, except those of the methyl group for structure **2**·2.25H_2O·0.5(1,4-dioxane), which were introduced at calculated positions as riding on their respective bonded atoms. For **1,** all non-hydrogen atoms were refined using anisotropic displacement parameters. All non-hydrogen atoms for **2**·2.25H_2O·0.5(1,4-dioxane) were refined anisotropically, except of the 1,4-dioxane and a water solvate molecule which were refined isotropically with fixed occupation factors. No hydrogen atoms for the solvate molecules were included in the refinement of the structure of **2**·2.25H_2O·0.5(1,4-dioxane).

3. Results and discussion

3.1. Synthetic comments and IR spectra

The chemical and structural identity of the products from the $Ni(O_2CMe)_2$·4H_2O/hmpH reaction system *in H_2O in the absence of counterions*, e.g. ClO_4^-, PF_6^-, Me_4N^+ etc., depends on the Ni^{II}: hmpH reaction ratio. Treatment of $Ni(O_2CMe)_2$·4H_2O with 2 equiv. of hmpH in H_2O leads to the isolation of complex **1**, while the 1:1 reaction gives complex **2**. The preparation of the two compounds is summarized in the balanced Eqs. (1) and (2).

$$Ni(O_2CMe)_2 \cdot 4H_2O + 2hmpH \xrightarrow{H_2O} \underset{\mathbf{1}}{[Ni(O_2CMe)_2(hmpH)_2]} + 4H_2O \quad (1)$$

$$4Ni(O_2CMe)_2 \cdot 4H_2O + 4hmpH \xrightarrow{H_2O} \underset{\mathbf{2}}{[Ni_4(O_2CMe)_4(hmp)_4(H_2O)_2]} + 4MeCO_2H + 14H_2O \quad (2)$$

Few features of the reactions represented by Eqs. (1) and (2) deserve comments. First, the use of different solvents, e.g. MeCN and EtOH, does not affect the identity of the mononuclear product from the 1:2 reaction, but only the quality of the crystals obtained (better crystals were obtained in H_2O); the yields were comparable (70–80%). Second, there is an excess of acetates in the 1:1 reaction (the $MeCO_2^-$: hmpH ratio is 2:1 versus 1:1 in the preparation of **1**). The $MeCO_2^-$ ions play a double role; a quantity of them act as base deprotonating the hmpH ligand, while the remaining acetates behave as ligands. Third, a larger excess of acetates does not lead to another product; the 2:1 $Ni(O_2CMe)_2$·4H_2O/hmpH reaction mixture in H_2O gives again complex **2** (analytical and IR evidences), emphasizing the thermodynamic stability of this neutral tetranuclear cluster. Fourth, compound **2** can be obtained in the form of X-ray quality crystals *only* in the presence of 1,4-dioxane (see Section 2). 1,4-dioxane is a highly non-polar solvent due to its symmetric structure, but it is miscible in all proportions with H_2O [23]. The

fact that complexes **1** and **2** both contain $MeCO_2^-$ groups and neutral (**1**) or anionic (**2**) 2-(hydroxymethyl)pyridine ligands (the difference being in the number of ligands per Ni^{II} ion) led us suspect that **1** could be transformed into **2** by reacting with an excess of a base; this has indeed turned out to be the case. Treatment of a blue aqueous solution of **1** with 2 equiv. of NaOH led to a green solution and subsequent precipitation of **2** in low yields (<20%) upon slow evaporation of H_2O at room temperature over a period of several days, see Eq. (3); due to the low yield, the preparation of **2** using this method is not given in Section 2. Addition of 1,4-dioxane or Me_2CO in the reaction solution increases the yield, but the product is contaminated with NaO_2CMe and Na(hmp) [IR evidence, presence of colourless microcrystals on the surface of the blue precipitate].

$$4\underset{\mathbf{1}}{[Ni(O_2CMe)_2(hmpH)_2]} + 8NaOH \xrightarrow{H_2O} \underset{\mathbf{4}}{[Ni_4(O_2CMe)_4(hmp)_4(H_2O)_2]} + 4NaO_2CMe + 4Na(hmp) + 6H_2O \quad (3)$$

The IR spectra of **1** and **2**·2.25H_2O·0.5(1,4-dioxane) exhibit medium intesity broad bands in the region 3500–3350 cm^{-1} assignable to the ν(OH) vibration of hmpH [24] and coordinated/lattice H_2O, respectively. The broadness and relatively low frequency of these bonds are both indicative of hydrogen bonding. The in-plane deformation band of the 2-pyridyl ring appears at 674 and 672 cm^{-1} for **1** and **2**, respectively; the high wavenumber for this vibration confirms the involvement of the ring-N atom in coordination [24]. The strong bands at 1600 and 1416 cm^{-1} in the spectrum of **1** are assigned [12,25] to the $\nu_{as}(CO_2)$ and $\nu_s(CO_2)$ vibrations, respectively, of the acetato ligands, both having also a ring stretching character. The difference Δ, where $\Delta = \nu_{as}(CO_2) - \nu_s(CO_2)$, is 184 cm^{-1}, more than that for NaO_2CMe (164 cm^{-1}), as expected for the monodentate mode of the carboxylate ligation [25]. Owing to the presence of two different types of carboxylate ligation (monodentate, bidentate bridging; vide infra) in **2**, two $\nu_{as}(CO_2)$ and two $\nu_s(CO_2)$ bands appear in its spectrum; the modes are strongly coupled with ring stretching vibrations and the proposed assignments should be regarded as approximate descriptions of the vibrations. The 1590, 1418 cm^{-1} pair (Δ = 172 cm^{-1}) are assigned to the monodentate acetates, while the 1562, 1435 cm^{-1} pair (Δ = 127 cm^{-1}) to the bidentate bridging carboxylate groups [25].

3.2. Description of structures

Partially labeled plots of the mononuclear molecule present in complex **1** and the tetranuclear cluster present in complex **2**·2.25H_2O·0.5(1,4-dioxane) are shown in Figs. 1 and 2, respectively. Selected interatomic distances and angles for the two complexes and hydrogen bonding details for **2**·2.25H_2O·0.5(1,4-dioxane) are listed in Tables 2–4.

Complex **1** crystallizes in the triclinic space group $P\bar{1}$. Its structure consists of well-separated $[Ni(O_2CMe)_2(hmpH)_2]$ molecules, with the metal ion lying on an inversion center. The Ni^{II} center is coordinated by two monodentate $MeCO_2^-$ groups (1.10 adopting the Harris notation [26]) and two *N*,*O*-chelating (1.11, Scheme 1) hmpH ligands. The hmpH donor atoms are the oxygen atom of the –OH group and the nitrogen atom of the 2-pyridyl group. The coordination sphere of the Ni^{II} ion exhibits a distorted octahedral geometry; the distortion is a consequence of the relatively small bite angle of the chelating ligand [O(1)–Ni–N(1) = 80.9(1)°]. The Ni–(N,O) bond lengths agree well with values observed for bonds of the some nature in octahedral complexes [24a,27]. There is a very strong intramolecular H-bond between the –OH group and the unbound acetate oxygen [O(3)]. The dimensions are: O(1)–HO(1)···O(3) 2.493 Å, HO(1)···O(3) 1.480 Å, O(1)–HO(1)···O(3) 167.9°. There are neither intermolecular H-bonds nor π–π stacking interactions. Complex **1** joins a very small family of $[NiX_2(hmpH)_2]$ [24a,28] and $[Ni(H_2O)_2(hmpH)_2]^{2+}$ [29] complexes, where X is a

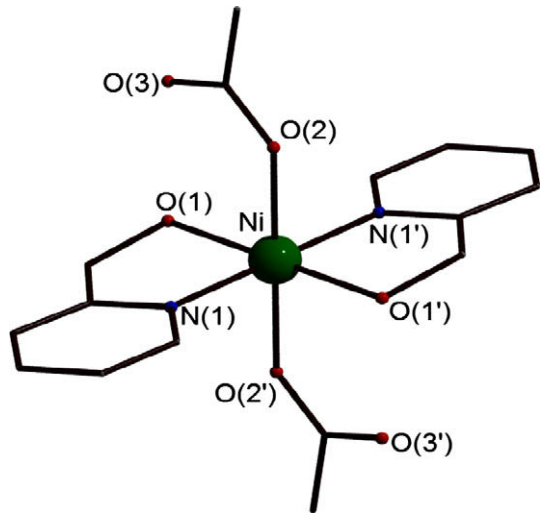

Fig. 1. Partially labeled plot of the molecule present in complex **1**. H atoms have been omitted for clarity. Primes are used for the symmetry-related atoms.

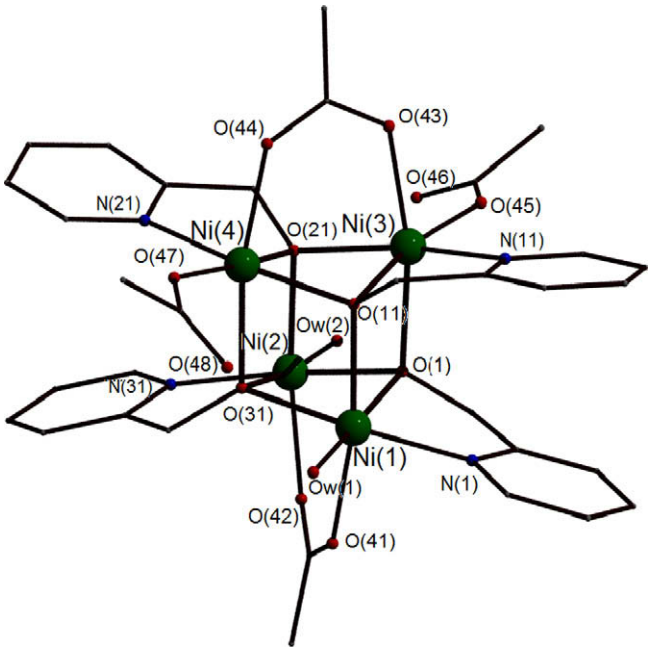

Fig. 2. Partially labeled plot of the tetranuclear cluster molecule present in complex **2**·2.25H_2O·0.5(1,4-dioxane). H atoms have been omitted for clarity.

monodentate anionic ligand; the structure of the 1:3 complex *mer*-[Ni(hmpH)$_3$]Cl_2 has also been recently reported [30].

Complex **2**·2.25H_2O·0.5(1,4-dioxane) crystallizes in monoclinic space group $P2_1/n$. Its structure consists of tetranuclear [$Ni_4(O_2CMe)_4(hmpH)_4(H_2O)_2$] molecules (Fig. 2), and solvate H_2O and 1,4-dioxane molecules; the latter two will not be further discussed. The tetranuclear cluster molecule has a distorted cubane {$Ni_4(\mu_3\text{-}OR')_4$}$^{4+}$ core with Ni^{II} and oxygen atoms occupying alternate vertices of the cube [R′ = (2-pyridyl)CH_2–]. Thus, the molecule consists of two interpenetrating tetrahedra: one of four Ni^{II} ions and one of four μ_3 oxygen atoms originating from the hmp$^-$ ligands. In addition to three μ_3-oxygen atoms, each Ni^{II} center is coordinated to one 2-pyridyl nitrogen atom. For Ni(3) and Ni(4), the remaining two coordination sites per metal ion are occupied by two oxygen atoms coming from one 2.11 and one 1.10 $MeCO_2^-$ groups. The Ni(1) and Ni(2) ions are each coordinated by one aqua ligand and one oxygen atom from the second 2.11 $MeCO_2^-$ ligand. Thus, an octahedral coordination environment is created about each metal center, all chromophores being of the $Ni^{II}O_5N$ type. One octahedral face of each Ni^{II} ion is occupied by the three alkoxide-type oxygen atoms and another contains the remaining donor atoms.

Each hmp$^-$ ion functions as a 3.31 ligand (Scheme 1) forming a five-membered NiNCCO chelating ring with a metal ion and two alkoxide-type bonds to two other Ni^{II} ions. This ligation mode is common for hmp$^-$ [19,20]. Two $MeCO_2^-$ groups are monodentate, while the remaining two behave as 2.11 ligands capping two opposite faces of the cube diagonally. The metal centers that are bridged by the $MeCO_2^-$ ions have the shortest metal–metal distances [Ni(1)···Ni(2) 2.889, Ni(3)···Ni(4) 2.956 Å].

There are two types of Ni–O (alkoxide-type) bonds for each metal ion: one bond is rather short at an average distance of 2.056 Å, whereas the two other bonds are slightly longer (average distance 2.082 Å). The cube deviates from the ideal geometry. The internal cube angles (R′O–Ni–OR′) at the metal vertices average 81.9°, whereas the corresponding angles at the alkoxide corners are much larger averaging 97.0°. The Ni···Ni vectors in the cluster reflect the different Ni–O (alkoxide-type) bond lengths, with the Ni(1)···Ni(3) distance (3.220 Å) being the longest. The shortest Ni(1)···Ni(2) distance (2.889 Å) corresponds to the smaller Ni–O–Ni angles [Ni(1)–O(1)–Ni(2) 89.4, Ni(1)–O(31)–Ni(2) 88.9°], whereas the longest Ni(1)···Ni(3) distance involves the larger Ni–O–Ni angle [Ni(1)–O(1)–Ni(3) 102.0°]. The average Ni–N and Ni–O (alkoxide-type) bond lengths of 2.070 and 2.073 Å, respectively, lie well within the range of reported values for the corresponding bond lengths of other cubane Ni^{II} clusters involving the hmp$^-$ ligand [18–20].

There is an amount of H-bonding in **2**·2.25H_2O·0.5(1,4-dioxane), see Table 4. Each coordinated H_2O molecule is strongly intramolecularly H-bonded to an unbound $MeCO_2^-$ oxygen atom [O(46), O(48)]. One of the aqua ligands [OW(2)] forms an intercubane H-bond with a coordinated $MeCO_2^-$ O atom [O(42)] of a neighbouring tetranuclear molecule. There is also an indication of the presence of H-bonds involving the lattice H_2O molecules; however, due to the fact that their hydrogen atoms were not located, those H-bonds can not be considered in detail. The intermolecular H-bonding interactions form a 2D network which extends parallel to the *ab* crystallographic plane (Fig. S1).

Complex **2** joins a rather large family of Ni_4^{II} cubanes with a {$Ni_4(\mu_3\text{-}OR)_4$}$^{+4}$ core [13c,17–20,27b,31–33]. Williams, Decurtins and co-workers have recently reported [31] a critical survey of the crystal structures containing {$Ni_4(OR)_4$} cubane units. They

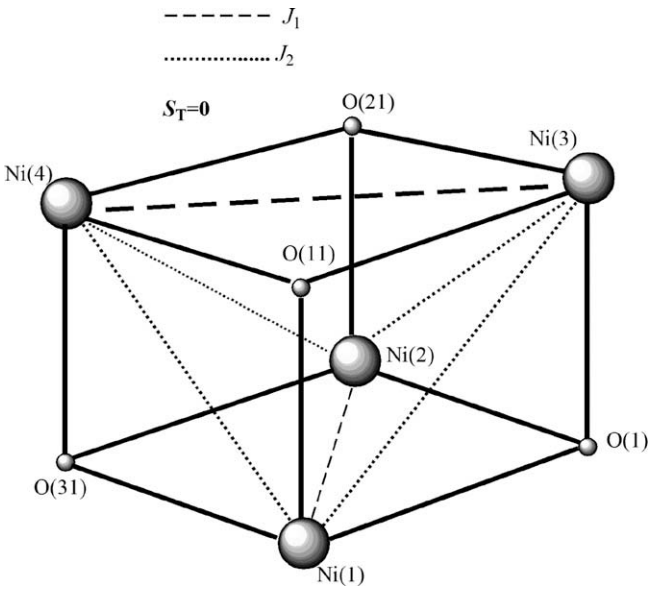
showed that the average Ni···Ni distances in such complexes is relatively constant. The structures are all distorted from the idealized cube to a T_d symmetry, and most show a further distortion which, however, usually maintains some elements of symmetry. The Ni···Ni distances afford a simple method of analyzing the distortion of the Ni_4 tetrahedron. If the tetrahedron is distorted by extension along a S_4 axis, four Ni···Ni distances will be increased, and two others will remain the same (S_4+ distortion); an S_4+ distortion will increase eight of the Ni–O–Ni angles, and decrease four. Perusal of the Ni···Ni distances and Ni–O–Ni angles for **2** (Table 3) reveals that the distortion mode of the Ni_4 tetrahedron is S_4+.

Complex **2** is a new, welcome addition in the subfamily of the Ni^{II}/hmp$^-$ cubanes. All [18–20], but one [17], contain four 3.31 hmp$^-$ groups. This coordination mode for the four ligands leaves totally eight unoccupied coordination sites, two for each metal center. In the cubanes prepared by the group of Escuer et al. [18], the peripheral ligation is provided by Cl^- or N_3^- groups and MeOH ligands. In the cubanes prepared and studied by the groups of Christou/Hendrickson [19,20], the peripheral ligation is provided by Cl^- or Br^- ligands and a variety of primary alcohols. In the Winter's cubane [34], the coordination number six for each Ni^{II} center is completed by one chelating *O*-ethylxanthate-*S*,*S*′ ligand. In all the just mentioned $4Ni^{II}$/4hmp$^-$ cubanes, the only bridging groups are the μ_3 oxygen atoms of the 3.31 hmp$^-$ ligands. Thus, complex **2** is a unique example amongst these complexes where two opposite faces of the cube are each capped by an additional bridging ligand, i.e., the $MeCO_2^-$ group. *This seems to have an influence on the magnetic properties of cluster* **2**.

3.3. Magnetic study of complex *2*

Solid-state dc magnetic susceptibility measurements were performed on polycrystalline sample of complex **2**, under a constant field of 0.1 T in the temperature range 1.9–300 K.



The exchange coupling of four $S = 1$ centers results in $n = 3^4 = 81$ molecular magnetic states which are split into 3 singlets ($S = 0$), 6 triplets ($S = 1$), 6 quintets ($S = 2$), 3 septets ($S = 3$) and 1 nonet ($S = 4$). Depending upon the actual topology, these states can be degenerate (the case of a perfect tetrahedron with a single exchange coupling constant) or the degeneracy can be partially removed.

The structural parameters of **2** suggest a lower symmetry than T_d. The magnetic analysis was carried out using a 2-*J* model and assuming that the tetranuclear structure results from the association of two doubly-bridged dimeric units, see Scheme 2. The intradimer interaction (denoted J_1) is between Ni(1) and Ni(2) on the one hand and between Ni(3) and Ni(4), on the other hand (the numbering scheme used for the magnetic analysis is the same with that employed in the real structure; see Fig. 2), while the interdimer one is denoted J_2. The spin Hamiltonian for such a model, reflecting the S_4 symmetry, is given by Eq. (4).

$$\hat{H}(\mathbf{S}_4) = -J_1(\vec{S}_1\cdot\vec{S}_2+\vec{S}_3\cdot\vec{S}_4) - J_2(\vec{S}_1\cdot\vec{S}_3+\vec{S}_1\cdot\vec{S}_4+\vec{S}_2\cdot\vec{S}_3+\vec{S}_2\cdot\vec{S}_4) + \mu_B Bg(\vec{S}_1+\vec{S}_2+\vec{S}_3+\vec{S}_4) \quad (4)$$

The Hamiltonian matrix in the basis set of coupled kets $|S_1S_2S_{12}S_3S_4S_{34}SM\rangle$ is already diagonal, so that the energy levels are given by a simple formula (Eq. (5)),

$$\begin{aligned}\varepsilon_{B=0}(S) &= \langle S_{12}S_{34}SM|\hat{H}(\mathbf{S}_4)|S_{12}S_{34}SM\rangle \\ &= -(J_2/2)[S(S+1)-S_{12}(S_{12}+1)-S_{34}(S_{34}+1)] \\ &\quad -(J_1/2)[S_{12}(S_{12}+1)+S_{34}(S_{34}+1)] \\ &\quad +(J_1/2)[S_1(S_1+1)+S_2(S_2+1)+S_3(S_3+1)+S_4(S_4+1)]\end{aligned} \quad (5)$$

Scheme 2. Core representation of the tetranuclear molecule of **2** showing the coupling scheme used in the magnetic model. The numbering scheme from Fig. 4 has been used.

where the last, constant term can be omitted. The addition of the Zeeman term results in the formula given by Eq. (6), where a single, isotropic g_{iso}-factor common to all magnetic centers occurs. The identification of the van Vleck coefficients is now an easy task, so that one can apply the van Vleck equation (with a vanishing second-order term) to end up with an analytical formula (Eq. (7)) for the mean magnetic susceptibility, i.e.

$$\varepsilon_B(S,M) = \varepsilon_{B=0}(S) + \mu_B g_{iso} MB \quad (6)$$

$$\tilde{\chi}_{mol} = C_0\frac{g_{iso}^2}{T}\frac{\sum_S\sum_{M=-S}^{+S}M^2\exp[-\varepsilon_{B=0}(S)/kT]}{\sum_S\exp[-\varepsilon_{B=0}(S)/kT]} \quad (7)$$

where the physical constants in the reduced Curie constant $C_0 = N_A\mu_0\mu_B^2/k$ adopt their usual meaning.

There is an evidence for a paramagnetic impurity, in the complex. This admixture has been involved by assuming

$$\chi = (1-x_{PI})\chi^{tetramer} + 4x_{PI}\chi^{monomer} \quad (8)$$

where the Curie law was assumed for the monomer

$$\chi^{monomer} = C_0(g_{PI}^2/T)[S_{PI}(S_{PI}+1)/3] \quad (9)$$

with $S_{PI} = 1$, $g_{PI} = 2.0$.

Fig. 3 shows plots of the experimental data for **2** in the forms of μ_{eff} (effective magnetic moment) per complex, χ_{mol} and χ_{mol}^{-1} versus *T*. The value of μ_{eff} at 300 K is 6.13 μ_B. As the temperature is lowered, μ_{eff} experiences a slight decrease, reaching a value of 5.82 μ_B at 50 K, followed by a much sharper decline at lower temperatures, 1.48 μ_B at 1.9 K. The best fit parameters ($R = 0.057$) are found to be $J_1 = -10.1$ cm^{-1}, $J_2 = -3.14$ cm^{-1} and $g_{iso} = 2.28$.

The zero-field energy levels of **2** are shown in Fig. 4. At temperatures above 100 K, all the levels are almost equally populated, so that the Curie law is obeyed. On cooling, the highest-spin states are consecutively depopulated and thus the magnetic productivity of the populated states gradually decreases to zero at zero temperature (the ground state is a singlet); under the term "magnetic productivity" we mean the contribution of the state $g^2M^2\exp[\varepsilon_{B=0}(S)/kT]$ to the susceptibility function and/or the effective magnetic moment. The low-temperature data for **2** are modulated by the Curie-type susceptibility for the paramagnetic impurity which superimposes the susceptibility curve of the tetranuclear molecule.

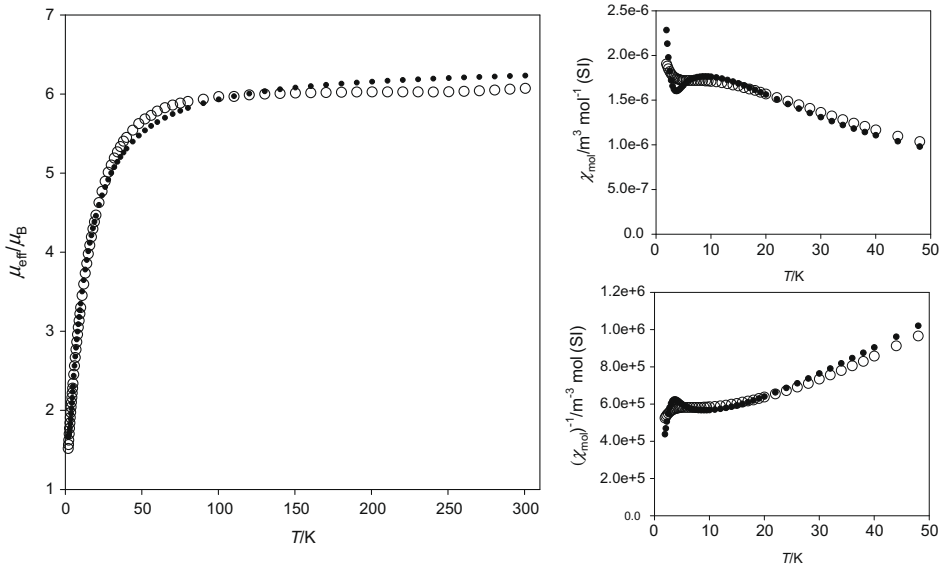


Fig. 3. Plots of experimental (open circles) μ_{eff} (left), χ_{mol} (right up) and χ_{mol}^{-1} (right bottom) vs. T per molecule of **2**. The filled circles are the fits to the experimental data (see text for details).

The magnetic susceptibility of cubane complexes has been studied extensively in recent years. Their high nuclearity and the magnetic exchange pathways offered by the triply bridging oxygen atoms make them particularly interesting, and several complexes have shown potential as SMMs [13c,19,20,35]. The effective magnetic moments of the Ni^{II} cubanes fall into two classes [31]. Type A is generally the most common and shows a rise in μ_{eff} per molecule at low temperatures, until a sharp drop is observed below ~10 K. Type B shows a steady drop in μ_{eff} in the range 100–50 K tending towards zero at very low temperatures. The S_4+ distortion mode of the Ni_4^{II} tetrahedron favours type B behaviour [31]. It is clear from Fig. 3 (left) that compound **2** follows a type B behaviour.

It should be mentioned at this point that the most important parameter in the magnetostructural correlation of tetranuclear clusters possessing the $\{Ni_4(\mu_3\text{-}OR)_4\}^{4+}$ cubane core has been reported [17,27b,31–33,36] to be the average Ni–O–Ni angle of a cubane face. A ferromagnetic exchange interaction is observed for Ni–O–Ni angles lower than 99° and the J value increases as the angle decreases. On the other hand, Ni–O–Ni angles in the vicinity of, and larger than, 99° lead to an antiferromagnetic interaction and the $|J_1|$ value increases as the angle increases. A second, less-significant parameter has been proposed to be the Ni–O–O–Ni torsion angle. The value and the sign ($-3.14\ cm^{-1}$) of the interdimer J_2 parameter (see also Scheme 2) are in line with the previous studies mentioned above. The mean Ni–O–Ni angle for the four Ni_2^{II} pairs (faces of the cube) described by J_2 is 100.6 (1)°; the coupling is thus predicted to be weakly antiferromagnetic, and, indeed, it is. The value of $-3.14\ cm^{-1}$ matches fairly well the linear J versus Ni–O–Ni bridging angle curve established by Christou and co-workers [36] for complexes containing the $\{Ni_4(\mu_3\text{-}OR)_4\}^{4+}$ cubane core. *What was unexpected is the antiferromagnetic value for* J_1 (*$-10.1\ cm^{-1}$*). The opposite faces of the cube including both μ_3-OR'^{-} and $MeCO_2^-$ bridges [Ni(1)O(1)Ni(2)O(31) and Ni(3)O(11)Ni(4)O(21), Fig. 2] have all Ni–O–Ni angles (Table 3) close to orthogonality, the average value being 89.8°. The J_1 coupling parameter that characterizes the Ni(1)···Ni(2) and Ni(3)···Ni(4) exchange interactions was thus expected to be ferromagnetic [17,27b,31–33,36], in agreement with the expectation that the Ni^{II} e_g electrons will couple ferromagnetically through oxygen p orbitals for Ni–O–Ni angles of ~90°. The only *tentative* explanation we can offer for the moment for this discrepancy is the presence of the additional syn, syn bridging $MeCO_2^-$ ligand which caps each of the above mentioned faces. The acetate bridge can provide an additional pathway for antiferromagnetic coupling [17,36], which seems to be strong enough in the case of **2** overcoming the ferromagnetic exchange arising from the triply bridging oxygen atoms of the hmp^- ligands. An analogous effect has been reported previously for complexes $[Ni_4(OH)_2(pypentO)(hmp)(O_2CMe)_2(NCS)_2(H_2O)]$ [17] and $[Ni_4(OMe)_4(O_2CMe)_2(TMB)_4](BPh_4)_2$ [37] which both have two syn, syn bridging (2.11) $MeCO_2^-$ ligands on opposite faces of the cube (TMB is 2,5-dimethyl-2,5-diisocyanohexane); however, in these two complexes the exchange interaction was ferromagnetic, but in both cases the J value was much lower than the predicted on the basis of the correlation established by Christou and co-workers [36]. In complete agreement with this explanation, the cubane complexes $[Ni_4X_4(hmp)_4(ROH)_4]$ [19,20], which do *not* contain additional bridging ligands, are all characterized by ferromagnetic exchange interactions and an $S = 4$ ground state. It should be mentioned at this point that a similar explanation was used by Winpenny to explain the magnetic properties of the $[Ni_4(Piv)_4(Mq)_4]$ cubane [32f], where Piv^- is the pivalate group and Mq^- the anion of 8-hydroxyquinaldine. The mean Ni–O–Ni angle for four Ni_2 pairs is 93.9° in this complex, thus, according to the established magnetostructural

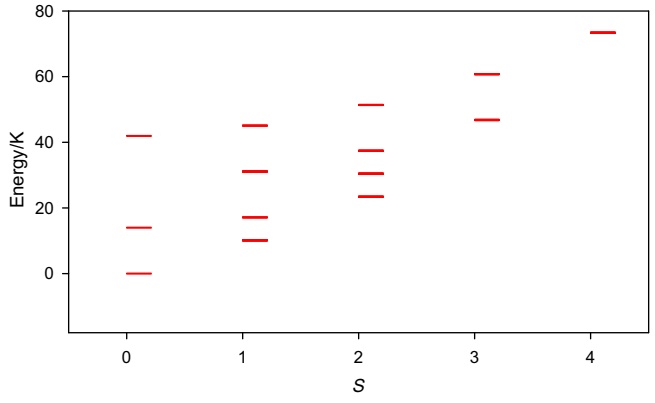

Fig. 4. Calculated spin energy levels for individual total spins in complex **2**.

criteria the coupling is predicted to be ferromagnetic. The fact that the coupling within the four pairs is antiferromagnetic was explained by the presence of an additional carboxylate bridge from the Piv^- ligands in a syn, syn fashion, which favours the antiferromagnetic contribution to the coupling. We refrain from discussing more the unusual J_1 because work is in progress in our laboratories to prepare $[Ni_4(O_2CR)_4(hmp)_4S_2]$, $[Ni_4(O_2CR)_4(hmp)_4]$ and $[Ni_4(O_2CR)_2(hmp)_4S_4]^{2+}$ cubanes (R = various, S = solvent) containing two or four bridging carboxylate groups; their magnetic study will hopefully help us to clarify the presence of ferromagnetic or antiferromagnetic exchange interactions within Ni_2 pairs characterized by low Ni–O–Ni angles and involving carboxylate bridging [38].

4. Concluding comments and perspectives

The present extension of the use of the hmpH ligand in Ni^{II} chemistry is a further demonstration of the ability of this group to yield products with interesting structures and properties. In addition to the Ni^{II}/hmpH and Ni^{II}/hmp^- complexes reported previously and prepared from non-carboxylate Ni^{II} sources, the $Ni^{II}/MeCO_2^-$/hmpH reaction system has provided access to the mononuclear compound **1** and to the antiferromagnetically-coupled, cubane cluster **2**. The latter is a new, welcome addition to the small subfamily of cubane Ni^{II} clusters containing 3.31 hmp^- ligands. Of particular magnetochemical interest is the antiferromagnetic coupling between the Ni^{II} centers that are additionally bridged by $MeCO_2^-$ ligands despite the small (~90°) Ni^{II}–$(\mu_3\text{-}O)_{hmp}^-$–Ni^{II} angles. This matter warrants further investigation and we currently try to prepare a family of structurally similar Ni^{II}/hmp^- cubanes with a variety of carboxylate groups ($Me_3CCO_2^-$, $PhCO_2^-$, $ClCH_2CO_2^-$, etc.).

Both **1** and **2** have been prepared from aqueous media in the absence of counterions. Of particular interest would be the synthetic investigation of the Ni^{II}/RCO_2^-/hmpH and the Ni^{II}/RCO_2^-/hmpH/ClO_4^- or PF_6^- reaction systems in organic solvents. The latter system would hopefully give cubanes with non-bridging RCO_2^- groups, which might introduce ferromagnetic components in the superexchange scheme leading to Ni_4^{II} clusters with an $S = 4$ ground state. The analogue of **2** with 2-(hydroxyethyl)pyridine, hepH, is not known to date, and it is currently not evident whether the preparation and stability of such neutral cubanes are dependent on the nature of the aliphatic chain that connects the 2-pyridyl ring with the hydroxyl oxygen. Work along these lines is currently in progress in our groups.

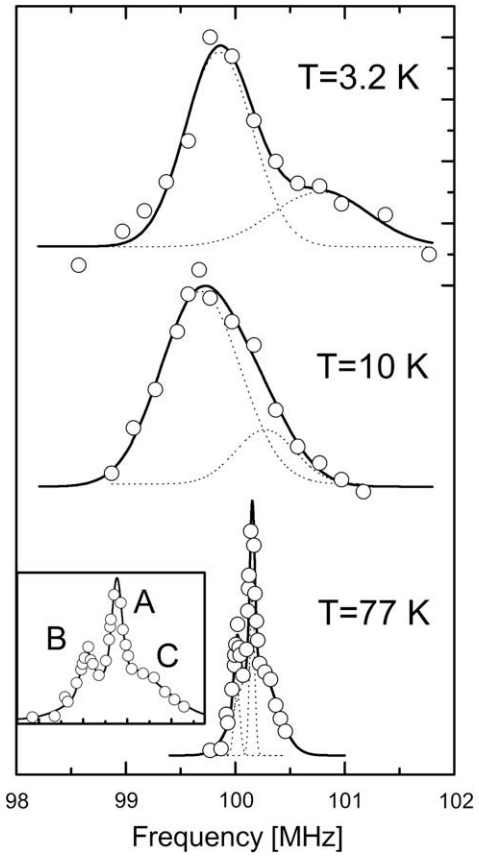

Fig. 1. ^{1}H NMR spectra at $H_0 = 2.35$ T for selected temperatures for $[FeCp_2^*][TCNE]$. The open circles are the experimental data acquired by the point-by-point spin–echo method. The solid lines are fits to the spectra using Gaussian functions. The inset shows the expanded NMR lineshape at 77 K, where three peaks A, B, and C are clearly identified.

magnetic field $H_0 = 2.35$ T. Fig. 1 shows typical ^{1}H NMR spectra for selected low temperatures. Similar results were obtained at $H_0 = 4.7$ T applied magnetic field. The high temperature spectra (not shown) are narrow with a width in the kilohertz range, whereas the low temperature spectra are broadened with a width in the megahertz range.

Fig. 1 clearly shows that the NMR resonance lines exhibit a structure at low temperatures, due to the large number of protons in the system situated at magnetically inequivalent crystallographic sites. At 77 K three peaks (A, B, and C) could be resolved whereas at liquid helium temperatures the line is further broadened and shifted to lower frequencies and could be decomposed into two Gaussian line profiles. The protons are coupled to the electronic spin system through the hyperfine electron–nucleus dipolar interaction. The different hyperfine couplings lead to a distribution of paramagnetic shifts and result in an inhomogeneous broadening of the NMR line. It is also evident from Fig. 1 that the linewidth of the spectra increases substantially below liquid nitrogen temperatures signifying the onset of strong magnetic interactions in the low temperature regime, since the overall width of the inhomogeneous broadened NMR line is proportional to the magnitude of the local magnetic moment.

In order to study the low-energy spin dynamics of $[FeCp_2^*][TCNE]$ we performed ^{1}H T_1 spin–lattice and T_2 spin–spin relaxation time measurements, shown in Fig. 2 as a function of temperature at $H_0 = 2.35$ and 4.7 T.

Both T_1 and T_2 relaxation times at the two applied fields decrease on cooling and exhibit minima at around 15–20 K. Before analyzing the temperature dependence of the relaxation times,

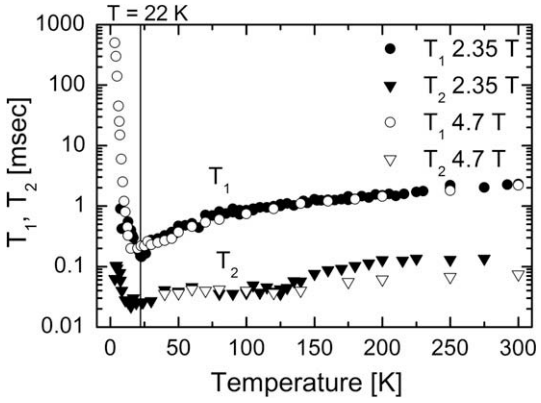

Fig. 2. Temperature dependence of ^{1}H NMR T_1 and T_2 relaxation times for $[FeCp_2^*][TCNE]$ at two applied magnetic fields $H_0 = 2.35$ and 4.7 T.

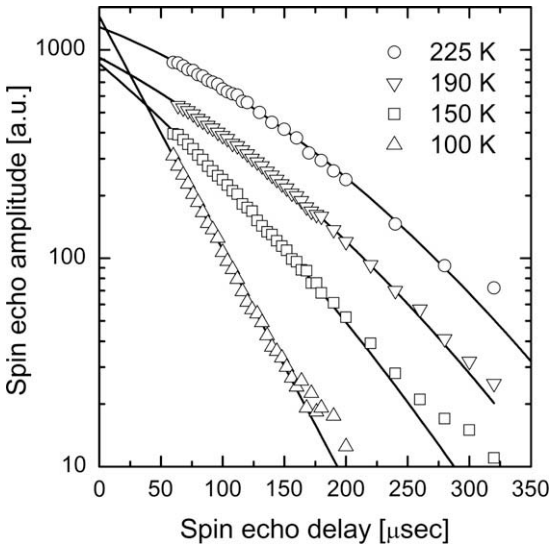

Fig. 3. Spin–echo decays of $[FeCp_2^*][TCNE]$ at $H_0 = 2.35$ T for selected temperatures. The data have been shifted for clarity. The solid lines are fits using a product of a Gaussian and an exponential function (see text). For temperatures between 50 and 100 K, the decays are double exponentials. For the decay at 100 K, only the fast component of the double exponential relaxation (solid line) is shown.

we first consider the analysis of the relaxation decays which determine the values of T_1 and T_2. The longitudinal relaxation decays were single exponentials thus providing a unique value of T_1, whereas the transverse relaxation decays were in general non-exponential functions. The T_2 spin–echo decays for selected temperatures in the high temperature regime at $H_0 = 2.35$ T are shown in Fig. 3.

The spin–echo decays between 100 and 300 K could be analyzed using a function that is a product of a Gaussian and an exponential function shown as solid lines in Fig. 3. Below 100 K we observe a distinct crossover from the Gaussian-exponential to double exponential decay. The Gaussian-exponential function has been frequently encountered in the NMR literature (e.g. high temperature cuprate superconductors), and in general signifies the coupling of the nuclei through the electron spins (Gaussian contribution, T_{2G}) weighted by the T_1 relaxation (Redfield contribution, T_{2R}) [10,11]. The temperature behavior of echo decay can be understood if the measured ^{1}H nuclei are coupled to neighboring spins that experience a fast relaxation time. For very long T_1 the echo decay is Gaussian. As T_1 decreases, the echo decay becomes exponential. However, in our present system, although T_1 decreases

with decreasing temperature and the Gaussian-exponential function seems to adequately describe the relaxation decay data, the fitted parameters are found to be interdependent, and in general, T_{2G} – the Gaussian part was larger than T_{2R} – the exponential part contrary to observation. Therefore, for the present system the exact origin of the observed non-exponential decay at high temperatures is not yet known and further experiments in lower applied magnetic fields are required. For this reason we calculated the $T_2(1/e)$ parameter, which is the time corresponding to the $1/e$ value of the spin–echo decay measured from the origin. The relaxation time $T_2(1/e)$ is plotted in Fig. 2. It can be seen that T_2 decreases on cooling up to 100 K in a manner similar to the T_1 decrease with temperature.

To further investigate the temperature dependence of the relaxation time T_2, we plot T_2 and $\Delta\omega$ (the linewidth of the NMR spectra) as a function of temperature for the data taken at magnetic field $H_0 = 2.35$ T (Fig. 4).

The dotted lines in Fig. 4 indicate the temperature crossovers of the shape of the spin–echo decay. The high temperature crossover at $T = 140$ K marks also the temperature where the linewidth $\Delta\omega$ substantially increases. As a measure of linewidth, the frequency difference $\Delta\omega$ between the A and B peaks (inset in Fig. 1) is plotted in Fig. 4. In the high temperature regime T_2 starts to decrease below 200 K, the shape of the spin–echo decay is non-exponential with a Gaussian short time profile, and the width $\Delta\omega$ of the lineshape is small being approximately independent with temperature. In the same temperature range, T_1 decreases in a continuing fashion (Fig. 2). In this regime, we consider that the spins are in the fast fluctuation limit in a probably magnetically inhomogeneous medium. Between 50 and 140 K, T_2 exhibits a shallow minimum with temperature, while the width $\Delta\omega$ increases by an order of magnitude. It is also observed that at the temperature of the T_2 minimum, the linewidth is comparable to the T_2^{-1} relaxation rate, that is the product $\Delta\omega T_2 \approx 2$.

A minimum at T_2 is not easily explained in NMR experiments when there is no phase transition in the system. Nevertheless, there is a theoretical model, originally proposed by Hu and Hartmann [12], which predicts such a T_2 minimum when $\Delta\omega$ and T_2^{-1} are of comparable order. This model is based on spectral diffusion caused by the fluctuation of the local field at the site of the resonance ions (system of A spins whose resonance is being observed) because of the uncorrelated flipping of a system of B spins at an average flipping rate w. The A and B spins resonate at different Larmor frequencies as for example in our case where the A spins, whose signal are observed, belong to the peak A, (inset of Fig. 1) and the B spins belong to the peak B. The pertinent parameter in the model is the ratio $2w/\Delta\omega_{1/2}$, where w is the B spins flipping rate and $\Delta\omega_{1/2}$ is the half-width at half height of the width of the lineshape in the notation of Hu and Hartmann. The model demonstrates that the product $\Delta\omega_{1/2}T_2$ exhibits a minimum as a function of $2w/\Delta\omega_{1/2}$ (Fig. 5 of Ref. [12]) as observed in our measurements. Further experiments are needed to clarify the applicability of Hu and Hartmann's model in our system.

In the following we consider the low temperature minima ($T \sim 22$ K) in the T_1 and T_2 relaxation times (Fig. 2). In particular, T_1 spin–lattice measurements probe directly the low-frequency spin dynamics of the electronic system through the time dependence of the fluctuating local magnetic fields which in the system examined originates from the fluctuation of the Fe^{3+} electron moment.

Firstly, we consider the high temperature side of the T_1 minimum which is into the paramagnetic regime. To facilitate analysis of the experimental data we plot the relaxation rates T_1^{-1} and T_2^{-1} at both magnetic fields as a function of the inverse temperature T^{-1}, as shown in Fig. 5. No appreciable field dependence was observed for the T_1^{-1} relaxation rates at high temperatures. The T_2^{-1} relaxation data have been multiplied by a factor (4/30) in order to demonstrate the similar temperature dependence of T_1^{-1} and T_2^{-1} in the high temperature side of the relaxation rates maximum.

The relaxation data in the temperature range 20–100 K (Fig. 5) may well be fitted with an Arhenius type relation:

$$T_{1,2}^{-1} = A\exp(E_a/k_BT) \quad (1)$$

indicating that the electron–nucleus interaction is modulated by an thermally activated mechanism. We can safely assume that electronic magnetic fluctuations are expected to dominate in this high temperature regime.

The experimental T_1^{-1} and T_2^{-1} data may well be described by an activation energy $E_a/k_B = 57.8$ K determined from the muon experiments [9] to show the consistency between the different techniques. This activation energy, according to Eq. (1), is shown as solid line in Fig. 5 and fits reasonably well both the T_1^{-1} and T_2^{-1} data in the high temperature side of the maximum. The spin–spin relaxation T_2^{-1} follows the temperature behavior of the spin–lattice relaxation rate T_1^{-1} presumably due to the lifetime broadening factor in the T_2 relaxation. The activation energy $E_a/k_B = 57.8$ K is consistent with a thermal activation process in a ferromagnetic Ising chain, where the basic excitations are the domain walls. In particular, the elementary excitations of such a chain are spin clusters, where an n-fold spin cluster is defined as

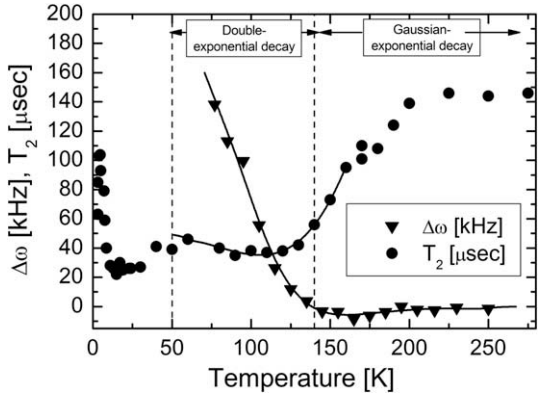

Fig. 4. T_2 relaxation time and $\Delta\omega$ frequency difference between the A and B peaks (inset Fig. 1) as a function of temperature for $[FeCp_2^*][TCNE]$ at magnetic filed $H_0 = 2.35$ T. The solid lines are guides to the eye. The dotted lines mark the crossover temperatures for the shape of the spin–echo decay.

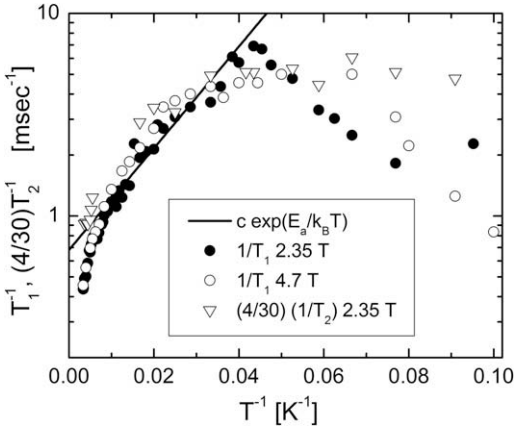

Fig. 5. T_1^{-1} and T_2^{-1} relaxation rates as a function of T^{-1} for $[FeCp_2^*][TCNE]$ at 2.35 and 4.7 T. The solid line is an activated behavior in the high temperature side of the maximum, with an activation energy of $E_a/k_B = 57.8$ K.

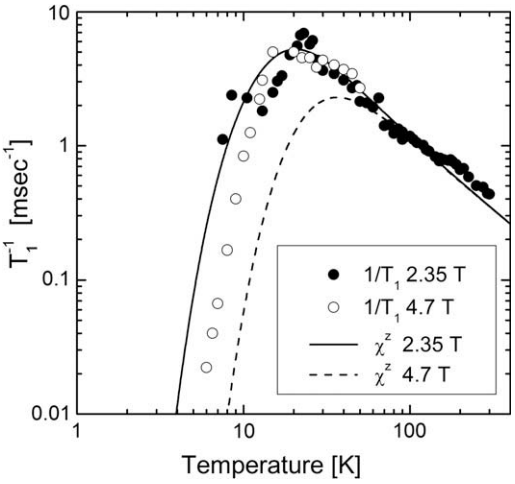

Fig. 6. Temperature dependence of T_1^{-1} for [FeCp$_2^*$][TCNE] at 2.35 and 4.7 T. The curves denote the static longitudinal susceptibility χ^z (normalized to fit the NMR data at 20 K) for 1D ferromagnetic Ising chain (Eq. (3)) at magnetic fields of 2.35 (solid line) and 4.7 T (dashed line).

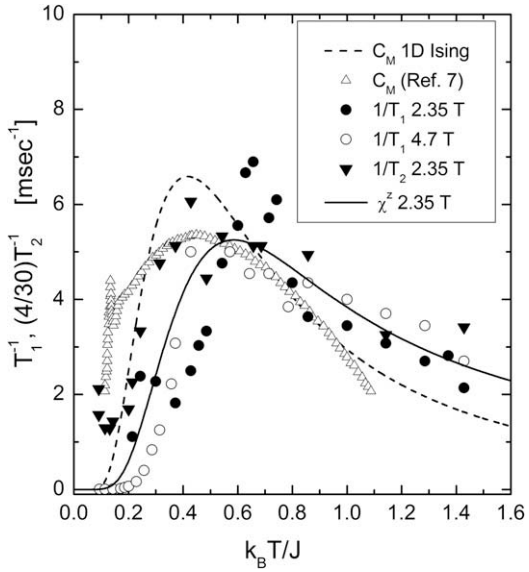

Fig. 7. T_1^{-1} (open and filled circles) and T_2^{-1} (filled inverted triangles) relaxation rates as a function of k_BT/J for [FeCp$_2^*$][TCNE] at 2.35 and 4.7 T. The experimental data are plotted using $J/k_B = 35$ K [7]. The open triangles are experimental specific heat data (C_M) at zero magnetic field, adapted from Ref. [7]. The dashed line is the specific heat for the 1D Ising model. The specific heat data are scaled in order to be compared with the NMR measurements. The solid line is the uniform susceptibility χ^z for 1D ferromagnetic Ising chain at 2.35 T.

n adjacent spins which are reversed with respect to the majority of the spins in the chain [13,14]. In this model, the activation energy is the one required to flip spins within a pair of wall and is equal to 2 J, the intrachain exchange constant, since the energy associated with creating an n-fold spin cluster is localized at the ends of the cluster and is, therefore independent of length [9,13]. Using $E_a = 2$ J, we obtain $J/k_B = 29$ K, consistent with $J_{||} = 27.4$ K as determined from susceptibility measurements [8].

The temperature dependence of the relaxation rates at their maximum values is now considered. This is shown in Fig. 6 where the T_1^{-1} relaxation rates at both magnetic fields show pronounced temperature dependences.

Generally, in the high temperature approximation, the nuclear T_1^{-1} relaxation rate due to fluctuating dipole fields from the electronic spins can be expressed as [15–17]:

$$T_1^{-1} = (g\mu_B\gamma_N)^2/4\pi \int dq A^z(q)(g_z\mu_B)^{-2}\chi^z(q)\cdot 2k_BT/\Gamma_q^z \qquad (2)$$

where $A^\alpha(q)$ are the Fourier transforms of the components of the product of the two dipole-interaction tensors, $\chi^\alpha(q)$ is the static q-dependent susceptibility and Γ_q^α is a damping factor characteristic of the normalized relaxation function. Assuming that Γ_q^α has a weak temperature and field dependence and considering only the $q = 0$ fluctuations because of the ferromagnetic character of the system, one obtains that the part of the relaxation rate T_1^{-1} arising from the longitudinal fluctuation contribution ($\alpha = z$) is simply proportional to the product of the static susceptibility χ^z and the temperature T, that is $T_1^{-1} \sim \chi^z T$ [16,17].

The uniform susceptibility for an Ising linear chain in the presence of a non-zero longitudinal magnetic field is given by [17]:

$$\chi^z = \frac{(g_z\mu_B)^2}{2k_BT}\frac{\mathrm{sech}^2 h\cdot(1+j\tanh^2 h)}{(1+j\mathrm{sech}^2 h)^{1/2}} \qquad (3)$$

where $j = \exp(-2J/k_BT) - 1$ and $h = g_z\mu_B H_z/k_BT$

The temperature dependences of χ^z for $H_0 = 2.35$ and 4.7 T, according to Eq. (3), are shown as solid lines in Fig. 6 (solid and dashed lines respectively), normalized in the y-axis in order to fit the NMR data at the peak temperature. It is observed that the T_1^{-1} relaxation data are represented fairly well by χ^z except from the higher magnetic field at low temperatures. It is to be noted that apart from the normalization constant, no other adjustable parameter has been used to fit the data. In the fitting of the NMR data with χ^z, the value of the exchange constant J/k_B, had little effect on the position of the χ^z maximum, being primarily sensitive to the large values of the external magnetic fields. The result of the analysis of the NMR relaxation data using only the static uniform susceptibility, implies – according to Eq. (2) – that the damping rate Γ_q is more or less proportional to the temperature T, since $T_1^{-1} \sim \chi^z T$. The damping constant of a linear magnetic chain with various degrees of anisotropy has been calculated for low-dimensional spin systems [18]. In the Ising limit, a weak temperature dependence of the damping constant $\Gamma_{q=0}^\alpha$ has been obtained [18], in disagreement with the results of the analysis of the NMR relaxation data. This might be due to the effect of the large applied magnetic field used in the NMR experiments on the temperature dependence of the damping constant.

Another point to be considered is the short range order that is developed in the region above the critical temperature. The NMR relaxation maximum is exactly at the temperature range where short range order is building up. This is shown in Fig. 7, where the T_1^{-1} and T_2^{-1} relaxation rates are plotted as a function of k_BT/J in order to be compared with specific heat measurements.

In Fig. 7, the experimental data of the magnetic specific heat C_M, adapted from Ref. [7] and the theoretical specific heat for the 1D Ising model, are also plotted. For reasons of comparison all the data are plotted using the value of the exchange constant derived from the specific heat measurements of Ref. [7], $J/k_B = 35$ K. These specific heat data show a cusp in C_M at the zero-field magnetic ordering temperature $T_c = 4.82$ K from a 3D ferromagnetic state at low temperatures to a 1D Ising-like behavior at higher temperatures. The broad maximum in C_M at $T \approx 15$ K, is associated with the development of strong short range order characteristic of the 1D structure. This short range order originates from the strong magnetic anisotropy of Ising character present in the compound [7]. It is clearly seen from Fig. 7 that the low temperature NMR data are clearly affected by the development of short range order above the critical temperature.

Therefore, the nuclear relaxation of this ferromagnetic Ising-like magnetic chain is attributed to the temperature dependence of the static uniform susceptibility and it is also affected by the develop-

ment of short range order before the magnetic ordering transition. In the case of 1D magnetic chains this build-up of short range order can lead to maxima or minima of T_1^{-1} as for example in the quasi-1D exchange-coupled paramagnet TMMC [16] and in 1D ferro and antiferro Ising chains [17].

4. Conclusion

The low-frequency electron spin dynamics of $[FeCp_2^*][TCNE]$ has been studied by applying T_1 spin–lattice and T_2 spin–spin ^1H NMR relaxation measurements. In the high temperature paramagnetic phase, the NMR linewidths and T_2 relaxation measurements revealed a magnetically inhomogeneous medium with fast fluctuations of the electronic spins. The T_1 relaxation data were successfully analyzed in the temperature range $13 < T < 110$ K and yielded an Arrhenius activation law for the correlation time of the electron spin fluctuations in very good agreement with previous μSR measurements. The activation energy obtained is consistent with elementary magnetic excitations of 1D ferromagnetic Ising chains. The temperature dependences of T_1^{-1} and T_2^{-1} show significant maxima at temperatures around 22 K, above the paramagnetic–ferromagnetic critical temperature $T_c = 4.8$ K. This behavior has been associated with the temperature dependence of the static uniform susceptibility of 1D ferromagnetic Ising chain and also with the development of significant short range order at temperatures above the magnetic ordering transition. This short range order indicates the presence of strong anisotropic interactions of Ising character in agreement with previous magnetization studies. Further NMR experiments at lower fields are needed to fully investigate the region near the critical temperature.

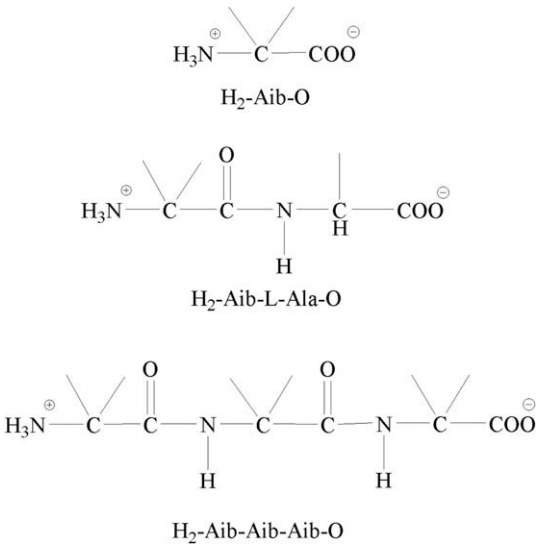
contrast, the structures of metal–oligopeptide complexes are till now scarce, due to the reluctance of the peptide molecules to form crystalline solids. This is specifically valid for the Zn(II)-aminoacid/peptide coordination chemistry. From a careful search in the CCDC base it is evident that crystal structures of Zn(II) complexes with almost all naturally occurring α-aminoacids have been reported. However, there are less than fifteen structure determinations of Zn(II)/dipeptide complexes, including those containing peptide derivatives or –N and –C protected aminoacid constituents. Among them, only three *binary* Zn(II)/*free-peptide* compounds have been structurally characterized: $\{[Zn(H\text{-}Gly\text{-}Gly\text{-}O)_2]\cdot 2H_2O\}_n$ [11a], $\{[Zn(H\text{-}Gly\text{-}L\text{-}Thr\text{-}O)_2]\cdot 2H_2O\}_n$ [11b] and $\{[Zn(H\text{-}Gly\text{-}His\text{-}O)_2]\cdot 7H_2O\}_n$ [11c]; the *ternary* complex $[Zn_2(H\text{-}Gly\text{-}Gly\text{-}O)_2(LH^+)_2](ClO_4)_4\cdot 2H_2O$ (L = 1-methyl-4(6-amino-2-pyridylmethyl) piperazine) is also known [11d]. Furthermore, in the whole Zn(II)/oligopeptide chemistry, only the crystal structure of the coordination polymer $\{[Zn(H\text{-}Gly\text{-}Gly\text{-}Gly\text{-}O)(H_2O)](SO_4)_{0.5}\cdot 2H_2O\}_n$ has been reported so far [11e].

We have initiated a systematic study of the coordination chemistry of α-aminoisobutyric acid (H-Aib-OH), and dipeptides and tripeptides containing the α-aminoisobutyryl residue [–HNC(CH$_3$)$_2$CO–, Aib]. The α-aminoisobutyric acid (also called α-methyl-alanine or α,α-dimethylglycine) is an uncommon natural aminoacid which is commonly found in a family of natural antibiotics produced by microbial sources. As shown by early studies, the replacement of the hydrogen atoms of the C_α carbon of glycine with methyl groups produces severe restrictions on the conformational freedom of the molecule and, consequently, -Aib- is a strong promoter and stabilizer of folded (β-bends) and 3_{10} or α-helical structures [12]. Our interest in this chemistry is mainly to investigate how the inductive and steric properties of the α-carbon methyl groups affect the structures of the complexes in the solid state, to test the possibility of creating helical complexes (helicates) or/and one-dimensional (1D), two-dimensional (2D) and three-dimensional (3D) coordination polymers or polynuclear aggregates (clusters) and to study the supramolecular assemblies of these species through their hydrogen bonding interactions.



Concerning the coordination chemistry of the free aminoacid (H-Aib-OH), 15 structurally characterized H-Aib-OH/metal ion complexes have been reported. It is impressive that the aminoacid employed in these structures adopts *eight* different coordination modes in its anionic, neutral or zwitterionic forms, as these are illustrated in Scheme 1. The reported metal complexes are listed in Table 1, with the corresponding coordination modes being described using Harris notation [13].

The coordination chemistry of Aib-based *dipeptides* is poorly explored. In our previous work, the crystal structures of Cu(II) complexes with the dianionic forms of dipeptides H-Aib-Aib-OH [27a], H-Aib-Gly-OH, H-Aib-L-Leu-OH H-Aib-L-Phe-OH [27b], and with the monoanionic and dianionic forms of H-Aib-L-Ala-OH [27c] have been reported. Also, the diorganotin complexes [(*n*-Bu)$_2$Sn(H$_{-1}$L) where LH = H-Aib-L-Leu-OH and H-Aib-L-Ala-OH, have been structurally characterized and their antibacterial and antiproliferative acitivities investigated [27d]. Finally, in the coordination chemistry of Aib-based *tripeptides,* the X-ray crystal structure of the remarkable copper(III) complex $[Cu^{III}(H_{-2}Aib_3)].2H_2O.1.5NaClO_4$, containing the trianion of tri-α-amino-isobutyric acid as ligand, has been determined [28a]. Reduction of this complex by 2,4-di-*tert*-butylphenol gave the dinuclear complex $[Cu_2(H_{-1}Aib_3)_2]$ [28b].

We wish to report here the results of our studies concerning the interaction of Zn(II) and the aminoacid H-Aib-OH, the dipeptide H-Aib-L-Ala-OH and the tripeptide H-Aib-Aib-Aib-OH (Scheme 2). Emphasis is given on the characterization of the products in the solid state.

Scheme 1. The crystallographically established coordination modes of H-Aib-OH using Harris notation [13].

Scheme 2. The ligands used in the present work.

2. Experimental

2.1. General procedures and physical measurements

All manipulations were performed under aerobic conditions. All chemicals and solvents were purchased from commercial sources and used without further purification. Microanalyses (C, H, N) were performed by the University of Ioannina (Greece) Microanalytical

Service using an EA 1108 Carlo Erba analyzer. Melting points were taken on a Electrothermal 9200 apparatus and are uncorrected. IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer 16 PC FT spectrometer with samples prepared as KBr pellets.

2.2. Synthesis of the ligands

2.2.1. H-Aib-L-Ala-OH

The dipeptide was prepared in the liquid phase, as described earlier [27c].

2.2.2. H-Aib-Aib-Aib-OH

The protected aminoacids Z-Aib-OH and p-TsA-Aib-OBzl were prepared according to the literature [29]. Coupling of Z-Aib-OH with *p*-TsA-Aib-Obzl *via* the PyBOP procedure [30], provided Z-Aib-Aib-OBzl [27a]. The dipeptide Z-Aib-Aib-OBzl (0.97 g, 2.5 mmol) was deprotected upon treatment with 2.5 N HBr/CH_3COOH (25 ml) for 1.5 h at room temperature and the HBr salt was precipitated by trituration with dry ether, washed with dry ether repeatedly and dried over P_2O_5/KOH (yield 80%). This salt was dissolved in DMF (4 ml), neutralized with Et_3N and allowed to react with Z-Aib-OH (0.45 g, 2 mmol) dissolved in DMF (4 ml) and preactivated at 0 °C for 30 min with HOBt (0.45 g, 3.0 mmol) and DCC (0.83 g, 4 mmol). The reaction mixture was stirred for 2 h at 0 °C and overnight at room temperature. The precipitated DCU was filtered and the solvent was removed *in vacuo*. The residue was partitioned in AcOEt-H_2O. The organic layer was washed alternatively with 5% $NaHCO_3$ and dried over Na_2SO_4. Evaporation of the solvent and recrystallization of the product from AcOEt/petroleum ether yielded 0.75 g (75%); mp 138-139 °C; TLC: R_f 0.65 (single spot) ($CHCl_3$/MeOH/AcOEt, 85:10:5), R_f 0.87 (single spot) (n-BuOH:MeCOOH-H_2O 3:1:1). The protecting groups were removed by catalytic hydrogenolysis (10% Pd on charcoal) in DMF and the free tripeptide crystallized upon addition of AcOEt-petroleum ether. It was further purified by column chromatography on Sephadex G-10 using AcOH (5%) as the eluent. Yield: 0.33 g (80%); mp 186–187 °C; TLC: 0.40 (single spot) ($CHCl_3$/MeOH/AcOEt, 85:10:5), R_f 0.60 (single spot) (*n*-BuOH:MeCOOH–H_2O 3:1:1).

2.3. Synthesis of zinc(II) complexes

2.3.1. $[Zn_3(H\text{-}Aib\text{-}O)_6]\cdot MeCOOH\cdot H_2O$ (**1**·MeCOOH·H_2O)

H-Aib-OH (0.004 g, 0.04 mmol) was added to a stirred solution of $Zn(O_2CMe)_2\cdot 2H_2O$ (0.011 g, 0.05 mmol) in MeOH (5 ml). After the addition of 4–5 drops of H_2O, the solid soon dissolved. The "pH" of the solution was ~5.5 and adjusted to ~8 with saturated LiOH·H_2O in MeOH. Colourless crystals of the product (suitable for crystallographic studies) were obtained from the solution by vapour diffusion with Et_2O. The crystals were collected by filtration and dried in air. Yield: 57%. The dried solid was analysed as H_2O-free (**1**·MeCOOH). *Anal.* Calc. for $C_{26}H_{52}N_6O_{14}Zn_3$: C, 35.9; H, 6.0; N, 9.7. Found: C, 35.8; H, 6.3; N, 9.6%. Selected IR data (KBr, cm^{-1}): 3430mb [$\nu_{as}(NH_2)$], 3294mb [$\nu_s(NH_2)$], ~3150wb [$\nu(OH)_{acetic\ acid}$], 1655s [$\nu(C{=}O)_{acetic\ acid}$], 1586s [$\nu_{as}(CO_2)$], 1472m [$\delta_d(CH_3)$], 1414mb [$\nu_s(CO_2)$], 1385sh [$\nu_s(CO_2)$], 1216m, 1098m, 902w, 814m, 692m, 624m.

2.3.2. $\{[Zn(H\text{-}Aib\text{-}L\text{-}Ala\text{-}O)_2]\cdot H_2O\}_n$ (**2**·H_2O)

To a stirred solution of $Zn(O_2CMe)_2\cdot 2H_2O$ (0.013 g, 0.06 mmol) in MeOH (6 ml), the dipeptide H-Aib-L-Ala-OH was added (0.016 g, 0.09 mmol). H_2O (1 ml) was added and the solid soon dissolved. The "pH" of the solution was ~6. Colourless X-ray quality crystals of the product were obtained from the solution by vapour diffusion with Et_2O. The crystals were collected by filtration and dried in air. Yield: 60%. The dried solid was analyzed as H_2O-free (**2**). *Anal.* Calc. for $C_{14}H_{26}N_4O_6Zn$: C, 40.8; H, 6.4; N, 13.6. Found: C, 41.1; H, 6.3; N, 13.5%. Selected IR data (KBr, cm^{-1}): 3400mb [$\nu_{as}(NH_2)$], 3265m [$\nu_s(NH)_{peptide}$], 3236m [$\nu_s(NH_2)$], 1646m [$\nu(C{=}O)_{peptide}$ or amide I], 1593sb [$\nu_{as}(CO_2)$], 1559m [$\nu(CN)+\delta(NH)$ or amide II], 1416m [$\nu_s(CO_2)$], 1260m [$\delta(NH+\nu(CN)$ or amide III].

2.3.3. $[Zn(H_2\text{-}Aib\text{-}Aib\text{-}Aib\text{-}O)_4](ClO_4)_2\cdot 5.8H_2O$ (**3**·5.8H_2O)

To a stirred solution of $Zn(ClO_4)_2\cdot 6H_2O$ (0.011 g, 0.03 mmol) in MeOH (6 ml), the tripeptide H-Aib-Aib-Aib-OH was added (0.016 g, 0.06 mmol). The "pH" of the solution was ~4 and no adjustment was made. Colourless crystals of the product (suitable for crystallographic studies) were obtained from the solution by vapour diffusion with Et_2O. The crystals were collected by filtration and dried in air. Yield: 55%. The dried solid was analyzed as H_2O-free (**3**). *Anal.* Calc. for $C_{48}H_{102}N_{12}O_{24}Cl_2Zn$: C, 42.2; H, 7.5; N, 12.3. Found: C, 42.3; H, 7.2; N, 12.4%. Selected IR data (KBr, cm^{-1}): ~3390sb [$\nu(OH)_{water}$], 3254mb [$\nu(NH)_{peptide}$], ~3100m [$\nu(NH_3^+)$], 1654s [$\nu(C{=}O)_{peptide}$ or amide I], 1620s [$\nu_{as}(CO_2)$], 1524s [$\nu(CN)+\delta(NH)$ or amide II], 14 586m [$\delta_d(CH_3)$], 1430m [$\nu_s(CO_2)$], 1284w [$\delta(NH+\nu(CN)$ or amide III], 1094sb [$\nu_d(ClO)$], 624m [$\delta_d(OClO)$].

2.4. X-ray crystallographic studies

Crystals of complexes **1**·MeCOOH·H_2O, **2**·H_2O and **3**·5.8H_2O were mounted in air and covered with epoxy glue. Diffraction measurements were made on a $P2_1$ Nicolet diffractometer upgraded by Crystal Logic using monochromated Cu radiation. Complete crystal data and parameters for data collection and processing are

reported in Table 2. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the range $22° < 2\theta < 54°$. Intensity data were recorded using a $\theta - 2\theta$ scan. Three standard reflections, monitored every 97 reflections, showed less than 3% variation and no decay. Lorenz, polarization and Ψ-scan absorption corrections were applied using Crystal Logic software. The structures were solved by direct methods using SHELXS-86 [31] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [32]. Further experimental crystallographic details for **1**·MeCOOH·H_2O: $2\theta_{max} = 118°$; 472 parameters refined; $(\Delta/\sigma)_{max} = 0.052$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 2.353/-0.772$ e Å^3; R_1/wR_2 (for all data), 0.0777/0.2052. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms, except those of water solvate which were located by difference maps and were refined isotropically. All non-hydrogen atoms were refined anisotropically. Further experimental crystallographic details for **2**·H_2O: $2\theta_{max} = 125°$; 279 parameters refined; $(\Delta/\sigma)_{max} = 0.003$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.450/-0.339$ e Å^3; R_1/wR_2 (for all data), 0.0307/0.0832. Hydrogen atoms were either located by difference maps and refined isotropically or were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically. Further experimental crystallographic details for **3**·5.8H_2O: $2\theta_{max} = 109.4°$; 453 parameters refined; $(\Delta/\sigma)_{max} = 0.010$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.722/-0.527$ e Å^3; R_1/wR_2 (for all data), 0.1127/0.2549. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically, except of water solvate molecules which were refined isotropically.

3. Results and discussion

3.1. Brief synthetic comments

Complexes **1**·MeCOOH·H_2O, **2**·H_2O and **3**·5.8H_2O were prepared according to Eqs. (1)–(3), respectively:

$$3\ Zn(O_2CMe)_2{\cdot}2H_2O + 6\ (H_2\text{-Aib-O}) + 5\ LiOH{\cdot}H_2O \xrightarrow{MeOH} [Zn_3(H\text{-Aib-O})_6]{\cdot}MeCOOH{\cdot}H_2O + 5\ LiO_2CMe + 15\ H_2O$$

1·MeCOOH·H_2O (1)

$$n\ Zn(O_2CMe)_2{\cdot}2H_2O + 2n\ (H_2\text{-Aib-L-Ala-O}) \xrightarrow{MeOH/H_2O} [Zn(H\text{-Aib-L-Ala-O})_2]_n{\cdot}nH_2O + 2n\ MeCOOH + n\ H_2O$$

2·H_2O (2)

$$Zn(ClO_4)_2{\cdot}6H_2O + 4\ (H_2\text{-Aib-Aib-Aib-O}) \xrightarrow{MeOH} [Zn(H_2\text{-Aib-Aib-Aib-O})_4]\ (ClO_4)_2{\cdot}5.8\ H_2O + 0.2\ H_2O$$

3·5.8H_2O (3)

The use of metal-carboxylates is a common practice in our synthetic procedures in metal–peptide chemistry. The reasons are: (i) carboxylate anions can act as strong bases with consequent deprotonation of the ligands, (ii) the by-products (i.e. $MeCO_2H$, $PhCO_2H$) can be easily removed from the reaction mixture without contamination of the product, and (iii) a portion of the anions RCO_2^- can act as ligands with a variety of coordination modes, resulting in the isolation of ternary complexes with interesting and aesthetically pleasant structures.

In fact, the trinuclear complex **1**·MeCOOH·H_2O was isolated from reaction mixture $Zn(O_2CMe)_2{\cdot}2H_2O$/H_2-Aib-O/LiOH·H_2O containing a small excess of Zn(II). The stoichiometric metal/ligand molar ratio of 1:2 was avoided in order to prevent the isolation of the known complex $[Zn(H\text{-Aib-O})_2(H_2O)_2][Zn(H\text{-Aib-O})_2(H_2O)]_2$ [17]. On the other hand, the addition of a strong base (LiOH) seems to be necessary for the deprotonation of the aminoacid (for H_2-Aib-O: $pK_1 = 2.36$, $pK_2 = 10.21$) and its consequent coordination.

The isolation of complex **2**·H_2O was initially succeeded by using the 1:1.5 metal:ligand stoichiometry. With the identity of **2**·H_2O crystallographically established (vide infra), the "correct" stoichiometric ratio, i.e. Zn(II): dipeptide = 1:2, was employed and led to the pure compound in very good yield (60–65%). The same product was also isolated by employing several metal sources (i.e. $Zn(ClO_4)_2.6H_2O$, $ZnCl_2$, $Zn(NO_3)_2{\cdot}4H_2O$) in metal:ligand proportions 1:1or 1:2 and in the presence of LiOH·H_2O. The fact that all the above synthetic procedures had as a result the isolation of the

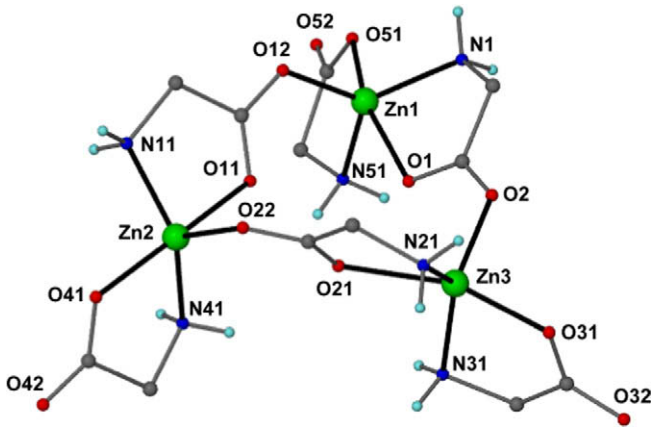

Fig. 1. The molecular structure of **1**·MeCOOH·H_2O. The lattice MeCOOH and H_2O molecules have not been drawn. All methyl groups of the H-Aib-O^- ligands have been omitted for clarity. Color code: Zn = green, O = red, N = blue, C = grey, H = cyan. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

same product demonstrates the high stability of the isolated Zn(II)/dipeptide complex **2**·H_2O.

Our first attempts for the isolation of a Zn(II)/H_2-Aib-Aib-Aib-O complex were made once more by employing $Zn(O_2CMe)_2{\cdot}2H_2O$ as the metal source. Indeed, from the 1:2 (metal:ligand) reaction, a crystalline product was isolated, whose solution of the structure revealed the cationic complex $[Zn(H_2\text{-Aib-Aib-Aib-O})_4]$ $(O_2CMe)_2$. Unfortunately, the full crystallographic analysis of this complex proved impossible. With the aim to stabilize and isolate the above cationic species, where the tripeptide was in its zwitterionic form (a fact scarce in metal/peptide chemistry), the use of $Zn(ClO_4)_2{\cdot}6H_2O$ as starting material was the next step. Complex **3**·5.8H_2O was then isolated employing the "wrong" (1:2) or the "correct"(1:4) metal:ligand ratio.

3.2. Description of structures

The molecular structures of complexes **1**·MeCOOH·H_2O, **2**·H_2O, and **3**·5.8H_2O are shown in Figs. 1, 5 and 9, respectively. Aspects of the crystal structures are shown in Figs. 2–4 (**1**·MeCOOH·H_2O), 6–8 (**2**·H_2O), and 10 and 11 (**3**·5.8H_2O). Selected interatomic distances and angles are listed in Tables 3, 5 and 6 for **1**·MeCOOH·H_2O, **2**·H_2O, and **3**·5.8H_2O, respectively, while important hydrogen bonding interactions are presented in Tables 4 (for **1**·MeCOOH·H_2O), and 7 (for **3**·5.8H_2O).

Complex **1**·MeCOOH·H_2O crystallizes in the monoclinic space group *An*. Its crystal structure consists of trinuclear $[Zn_3(H\text{-Aib-O})_6]$ units and of lattice MeCOOH and H_2O molecules. One H-Aib-O^- ligand chelates to each of the three Zn^{II} atoms through its amino nitrogen atom and one of the carboxylate oxygen atoms, while each of the remaining three anions chelates to each Zn^{II} atom and bridges a neighboring metal ion through the second carboxylate oxygen atom. The carboxylate bridging interaction is of the *syn*, *anti* type (Fig. 1).

Thus, three of the six H-Aib-O^- anions behave as η^1: η^1 ligands or in a 1.101 mode [13], while the other three α-aminoisobutyrate anions behave as $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ ligand or in a 2.111 mode (Scheme 1). Each metal center is five-coordinate with an O_3N_2 environment. On the basis of the angular criterion τ, as defined by Addison et al. (τ = 1.00 for an ideal trigonal bipyramid and τ = 0.00 for an ideal square pyramid) [33], the coordination polyhedra around all three Zn atoms lie almost between the two geometrical shapes, with a slight inclination towards the trigonal bipyramidal (τ = 0.55, 0.56 and 0.54 for Zn(1), Zn(2) and Zn(3), respectively). The principal axes and angles for the three trigonal bipyramidal Zn^{II} atoms are O(1)–Zn(1)–O(51) 160.3(3)°, O(11)–Zn(2)–O(41) 164.1(3)° and

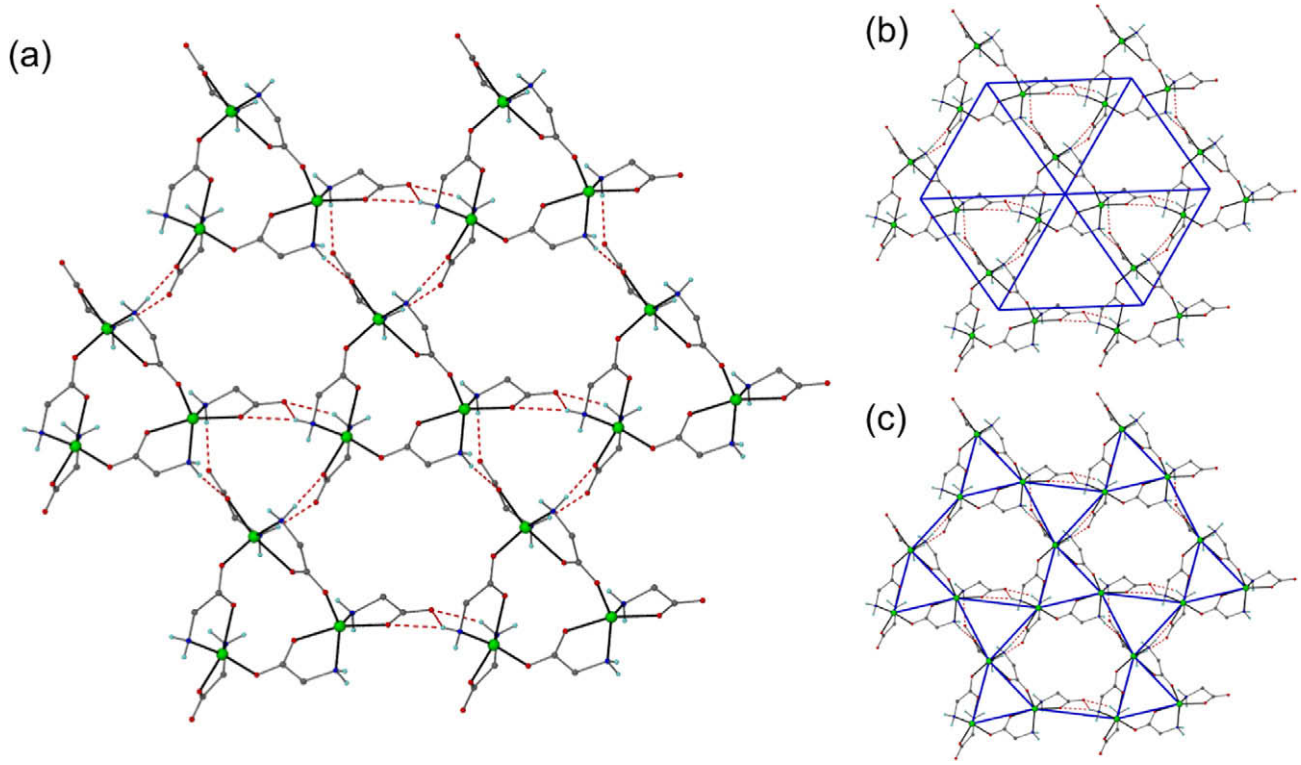

Fig. 2. The 2D hydrogen bonded framework of **1**·MeCOOH·H_2O (a) that conforms to a (3,6)-net (b) or to a (3.6.3.6)-net (c). All methyl groups of the H-Aib-O^- ligands have been omitted for clarity. Color code: Zn = green, O = red, N = blue, C = grey, H = cyan. The blue lines in (b) and (c) are guides for the eye and draw the underline nets. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

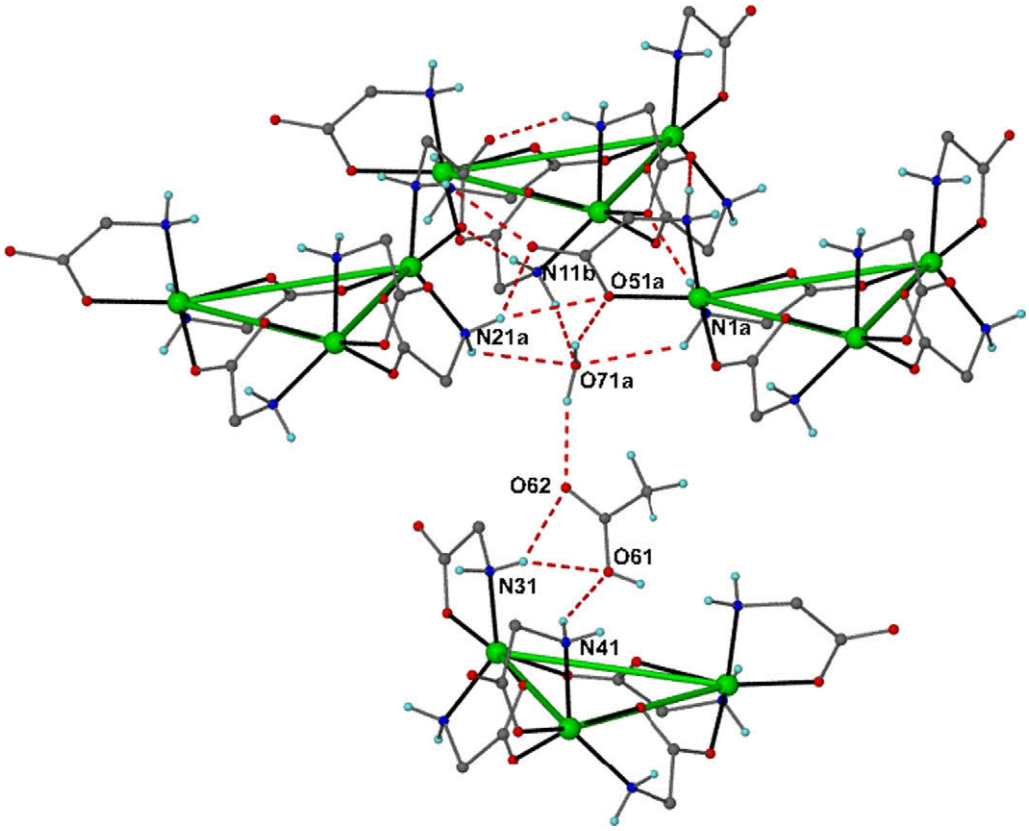

Fig. 3. The hydrogen bonding interactions between the layers in $[Zn_3(\text{-H-Aib-O})_6]\cdot MeCOOH\cdot H_2O$. All methyl groups of the H-Aib-O$^-$ ligands have been omitted for clarity. Color code: Zn = green, O = red, N = blue, C = grey, H = cyan. The green lines are guides for the eye and draw the trinuclear units. Symmetry codes: a 0.5 + *x*, 1.5 − *y*, *z*; b 05 + *x*, 1 − *y*, 0.5 + *z*. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

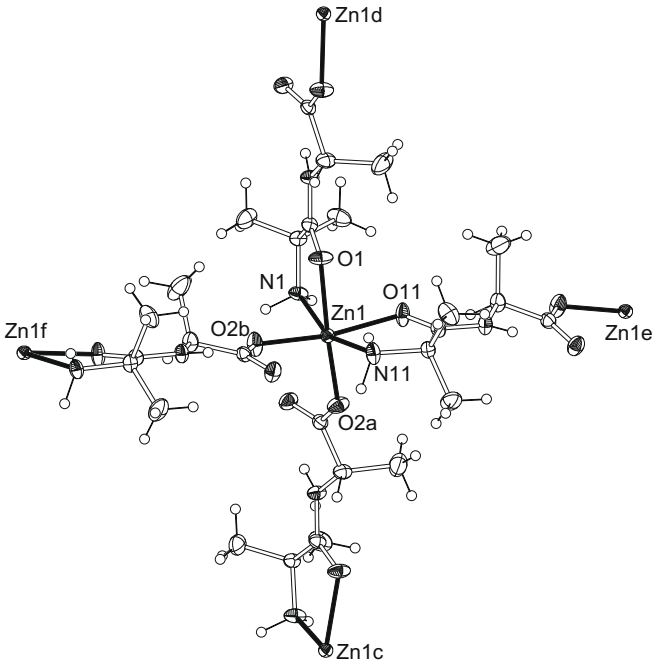

Fig. 5. ORTEP plot (30% probability) of the coordination environment around the central atom in $\mathbf{2}\cdot H_2O$ and the connectivity of the 2D polymer. Symmetry codes: a 2 − *x*, 0.5 + *y*, −*z*; b 1 − *x*, 0.5 + *y*, 1 − *z*; c 2 − *x*, 0.5 + *y*, −*z*; d 1 − *x*, −0.5 + *y*, 1 − *z*; e 2 − *x*, −0.5 + *y*, −*z*; f 1 − *x*, 0.5 + *y*, 1 − *z*.

O(21)–Zn(3)–O(31) 159.2(3)° (Table 3). The Zn(1)···Zn(2) and Zn(1)···Zn(3) and Zn(2)···Zn(3) separations are 5.335, 5.351, and 5.317 Å, respectively.

All twelve values of the C–O carboxylate bonds of the organic ligands lie in the range 1.219–1.292 Å (mean value 1.26 Å), which is referred as the range (1.20–1.33 Å, mean value 1.245 Å) of C–O bond lengths of α-aminoacids in all metal complexes [34].

In complex $\mathbf{1}\cdot\mathbf{MeCOOH}\cdot H_2O$, the aminoacid moiety obviously presents quite different conformation (which is defined by the ϕ = Zn–N–C^a–C' and ψ = N–C^a–C'–O dihedral angles) from the minimum energy conformation, as calculated theoretically, which is

[b] A, acceptor atom.

also that commonly observed for α-aminoisobutyric acid residues in peptide crystal structures [12,18]. This conformation, characterized by ϕ and ψ values of about −60°, −30° (or the centrosymmetric 60°, 30°) falls in the helical region of the ϕ–ψ map [35]. In the parent complex, in which the aminoacid anion coordinates in a chelate mode, the observed conformation is folded with values for the ϕ and ψ dihedral angles in the region of 26.58° to 33.77° and −11.37° to −27.36°, respectively.

The trinuclear units assemble through seven hydrogen bonds (and their symmetry related) that involve the $-NH_2$ groups and some of both the coordinated and uncoordinated carboxylate O atoms (Table 4) to form a 2D hydrogen bonded framework (Fig. 2) that conforms to a regular net of a (3,6) topology running parallel to the *bc* plane (Fig. 2a). Due to the size and the shape of the trinuclear complexes which serve as 6-connected nodes within the 2D (3,6) framework, half of the triangular cavities around a trinuclear node are bigger than the others and look like hexagons. The hexagonal cavities could also be envisaged by considering each metal as a 4-connected node. In this perspective, the resulting network is a semi-regular net with (3.6.3.6) topology (kagome net) (Fig. 2c) [36].

The lattice acetic acid and water molecules sit within the layers and connect them to create a 3D hydrogen bonded framework with a $3^{24}.4^{36}.5^6$ topology (**fcu**) [37,38]. The acetic acid molecule sits above the trinuclear unit and is hydrogen bonded to it through three hydrogen bonds [N31–H31B···O61, N31–H31B···O62 and O71–H71B···O62] (Fig. 3). The water molecule sits above a small trigonal cavity and is hydrogen bonded to the three trinuclear units [N1–H1B···O71, N11–H11B···O71, N21–H21B···O71 and O71–H71A···O51] that form the trigonal cavity, while it is also hydrogen bonded to the acetic acid molecule [O71–H71B···O62] (Fig. 3). In this arrangement each trinuclear unit is connected *via* the MeCOOH and the H_2O molecules to six trinuclear units belonging to two neighboring layers above and below the main layer's plane. In this arrangement each trinuclear unit connects to six other trinuclear units that belong to the same (3,6)-layer and to six trinuclear units that belong to neighboring layers, giving rise to a 12-connected 3D network with **fcu** topology (Fig. 4).

Complex **1**·MeCOOH·H_2O is the ninth member of crystallographically established *binary* H-Aib-OH/metal ion complexes (Table 1), and three of its ligands adopt the new coordination mode [2.111], as is seen in Scheme 1.

Concerning the structurally characterized Zn(II)/α-aminoacid *binary* complexes we have to mention the following: (a) The crystal structures of binary complexes of Zn(II) with almost all the natural

α-aminoacids have been reported. (b) The majority of these compounds are monomeric or coordination polymers with only few exceptions, where the Zn(II)/aminoacid coordination results in a cluster formation. These are: $[Zn(Iva)_2]\cdot 2H_2O$ (Iva = isovaline), which is described as a 1D coordination polymer or as a cyclic trimer [39], $[Zn(Iva)_2]\cdot 3.25H_2O$ in which six $[Zn(Iva)_2]$ moieties form the discrete cyclic complex $[Zn_6(Iva)_{12}]$ [39], and the organometallic tetranuclear cluster $[EtZn(\alpha,\alpha\text{-}Ph_2Gly)]_4\cdot CH_3CN$ (α,α-Ph_2Gly = α,α-diphenylglycine) [40]. At this point, a remarkable feature has to be noted: All three aminoacids, i.e. H-Aib-OH, H-Iva-OH and H-Ph_2Gly-OH, are closely related to each other. So, -Iva- is formally derived from -Aib- by replacing a methyl group by an ethyl group, and -Ph_2Gly- by replacing the two methyl groups by two phenyl groups. The dialkylation of the α-carbon, which sterically restricts the conformational freedom of the aminoacid and causes a bent around C[a] atom, seems to favor cluster formation.

Complex **2**·H_2O crystallizes in the monoclinic space group $P2_1$.The Zn^{II} atom and the anionic peptide H-Aib-L-Ala-O^- ligands have assembled to create a two-dimensional (2D) square grid framework laying parallel to the 1 0 1 plane (Figs. 5 and 6). The Zn^{II}

[a] Symmetry transformations used to generate equivalent atoms: a = −*x*, −*y*, *z*.

atom is in a distorted octahedral N_2O_4 environment. Two dipeptide monoanions bind one Zn^{II} atom *via* their amino nitrogens [N(1), N(11)] and peptide oxygens [O(1), O(11)], with the oxygen atoms in a *cis* orientation and the nitrogen atoms in a *trans* orientation, and two adjacent Zn^{II} atoms each through one of their carboxylate oxygens, adopting the $\eta^1{:}\eta^1{:}\eta^1{:}\mu_2$ or 2.11010 [13] coordination mode. Two monodentate carboxylate oxygen atoms from the C-terminal group of two other H-Aib-L-Ala-O^- ligands in *cis* orientation complete the octahedral environment around the Zn^{II} atom.

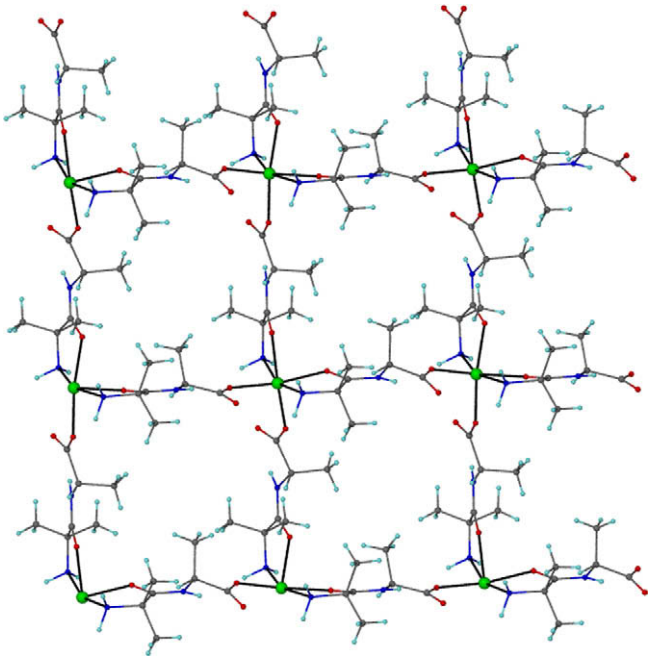

Fig. 6. Perspective view of the 2D layer in **2**·H_2O. Color code: Zn = green, O = red, N = blue, C = grey, H = cyan. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

The 2D layers are parallel and stacked off set in such a way that the Zn^{II} atoms of one layer are placed above the square cavities of the next layer. The layers are connected in the third dimension through two complementary hydrogen bonds (and their symmetry related) that involve the amidic N-H group and the uncoordinated carboxylate O atom [N2–Hn2···O13 and N12–Hn12···O3] (Fig. 7). In this arrangement, each Zn^{II} atom serves as a 4-connected node, by being the vertice of the square grid [(4,4)-net], while each dipeptide ligand might be regarded as a 3-connected node by bridging two Zn^{II} atoms within the same layer and connecting an H-Aib-L-Ala-O^- ligand of a neighbouring net through the two complementary hydrogen bonds. The resulting framework conforms to a **tfa** net (Fig. 8) [38,41]. The solvate H_2O molecules complement this hydrogen bonding pattern by forming a bifurcated hydrogen bond with the two carboxylate O atoms [Ow1–Hw1A···O3 and Ow1–Hw1A···O13] that form the double hydrogen bond bridge between the layers, connecting a neighbouring coordinated carbonyl O atom [Ow1–Hw1B···O1], while accepting a hydrogen bond from a N-H group of the N terminal side [N1–Hn1A···Ow1] (Fig. 7).

Complex **2**·H_2O is the fourth member of a small family of structurally characterized *binary* Zn^{II}/free dipeptide complexes (see Section 1 [11a–c], in all of which the dipeptide anions adopt the same N_{amine}, $O_{peptide}$, $O_{carboxylate}$ coordination mode.

Complex **3**·5.8 H_2O crystallizes in the orthorhombic space group $P2_12_12_1$. Its molecular structure consists of mononuclear complex cations $[Zn(H_2Aib\text{-}Aib\text{-}Aib\text{-}O)_4]^{2+}$, CLO_4^- anions and lattice water molecules. The Zn^{II} atom lies in a distorted tetrahedral environment surrounded by four (two crystallographically independent) tripeptide ligands. Each tripeptide is in its zwitterionic form and coordinated to the metal ion through one of its carboxylate oxygen atoms, while the protonated NH_3^+ group forms an intramolecular hydrogen bond [N3–Hn3A···O12 and N13–Hn13A···O2] with the uncoordinated carboxylate oxygen atom of a neighbouring ligand (Fig. 9).

This "head-to tail" sequence, in which the terminal amine and carboxylate groups are brought in proximity, is also observed in the crystal structure of the free tripeptide (H_2-Aib-Aib-Aib-O)·2H_2O [42]. A comparison of the values of important parameters

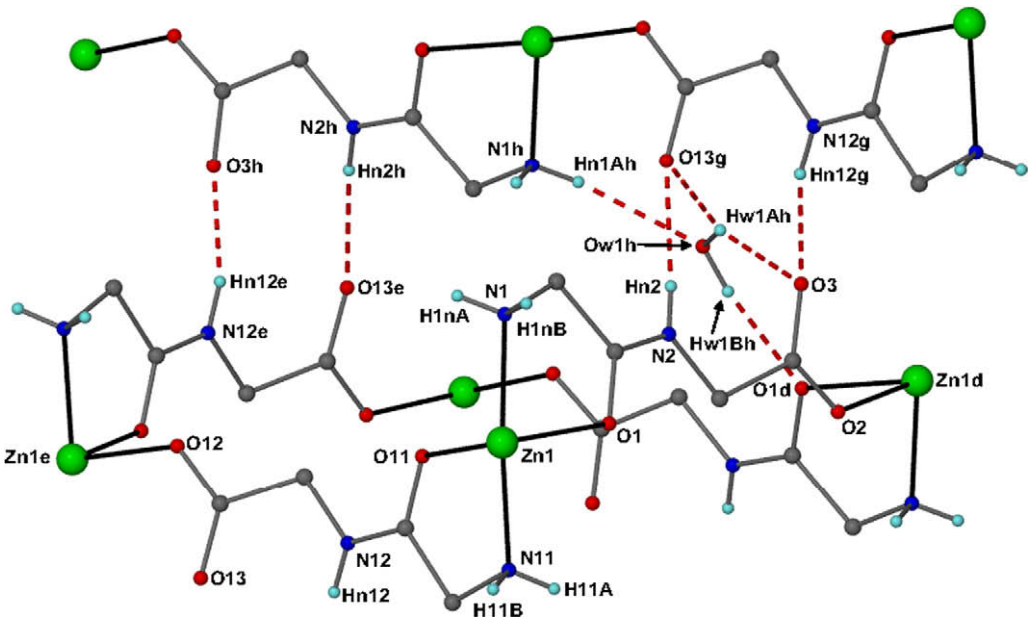

Fig. 7. The hydrogen bonding between the square grid layers and the solvate H_2O molecule in **2**·H_2O. Color code as in Fig. 6. Many H and C atoms have been omitted for clarity. Symmetry codes same as in Fig. 5 and h $2-x, -0.5+y, 1-z$; g $x, y, 1+z$. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

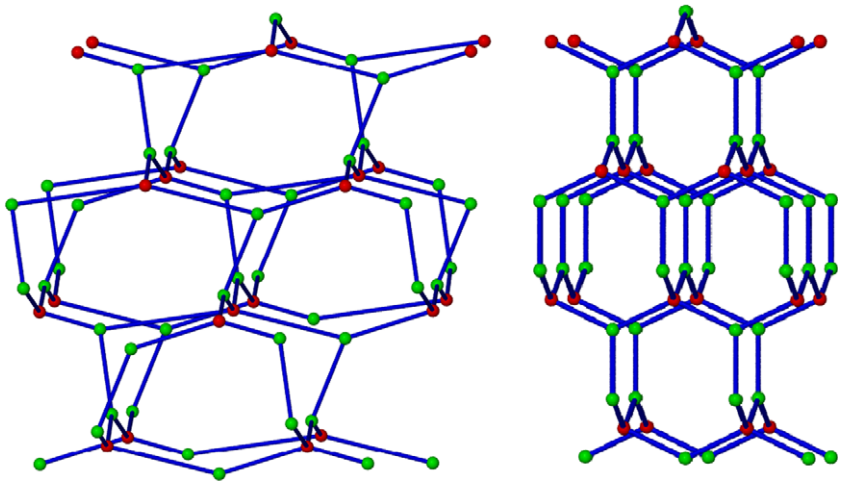

Fig. 8. The real (left) and ideal (right) **tfa** network that **2**·H_2O adopts (see text for details). Color code: Zn = red, H-Aib-Ala-O^- = green. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

of the coordinated and free peptide skeleton can give us a measure of the difference in conformation upon complexation of the ligand. The values of N–C[a]–C' angles are not significantly affected by metal ion coordination, the major difference being the value of the second -Aib- residue [N(2)–C(6)–C(5) = 110.6°/N(12)–C(26)–C(25) = 112.3°], which is larger in the complex than the corresponding value of free peptide (107.1°). Also, small to negligible deviations of the values of C–O and C–N peptide bonds are observed for the free and coordinated tripeptide. The two carboxylate C–O bonds in the free peptide (both of which are involved in hydrogen bonds) (C–O1 = 1.248(3) Å, C–O2 = 1.256(3) Å), are elongated (C(1)–O(1) = 1.284(12) Å, C(21)–O(11) = 1.262(12) Å) and shortened (C(1)–O(2) = 1.236(11) Å, C(21)–O(12) = 1.231(12) Å) after complexation. The planarity of the peptide bonds is retained in the free and complexed tripeptide, as it results from the sum of the angles around the peptide carbon atom (359.5–360.0°). A better description of the peptide backbone conformation is possible by comparing the values of the dihedral angles, (ϕ, ψ) for each residue in the structures of the free and complexed tripeptide. For the first and the third residues these values do not differ essentially for the two forms (ψ_1 = 180°, ϕ_3 = 178.4°, ψ_3 = 4.6° for the free peptide [42], ψ_1 = −172.76° and −174.51, ϕ_3 = −172.02° and −175.20°, ψ_3 = 6.83° and −3.53° for the complex) and these residues are in an extended conformation. A significant difference appears in the values of the second residue (ϕ_2 = 52.9°, ψ_2 = −141.5° for the free ligand, ϕ_2 = −56.89° and −62.64°, ψ_2 = −32.82° and −22.67° for the complexed peptide). The above values indicate a more folded conformation which lies in the limits of the helical region (ϕ = ±60, ψ = ±30) of the ϕ–ψ map [35].

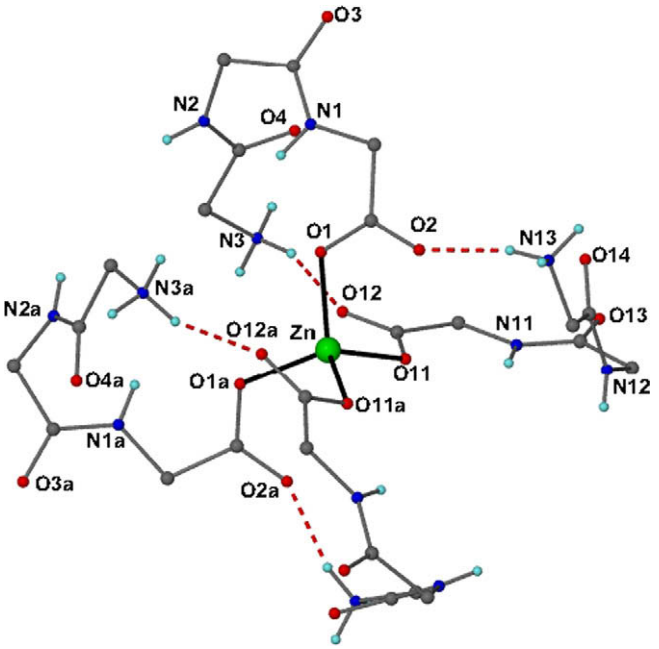

Fig. 9. The coordination environment around the central atom in **3**·5.8H_2O and the intramolecular hydrogen bonding. All methyl groups of the side chains of the tripeptide ligands and the H_2O solvate molecules have been omitted for clarity. Color code: Zn = green, O = red, N = blue, C = grey, H = cyan. Symmetry code: a −*x*, −*y*, *z*. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Each tripeptide ligand is connected to two other tripeptide ligands belonging to two neighboring $[Zn(H_2\text{-Aib-Aib-Aib-O})_4]^{2+}$ complexes through two hydrogen bonds [N3–Hn3B···O3b and N13–Hn13B···O13c; b −0.5 + *x*, 0.5 − *y*, 1 − *z*; c 05 + *x*, 0.5 − *y*, −*z*] that involve the protonated $-NH_3^+$ group and one of the carbonyl O atoms (Table 7). In this arrangement each $[Zn(H_2\text{-Aib-Aib-Aib-O})_4]^{2+}$ cation is connected to eight neighbouring complexes forming a 3D hydrogen-bonded framework (Fig. 10) that adopts the **bcu** network [38] (Fig. 11) with the Zn^{II} atoms being the nodes of the 8-connected net.

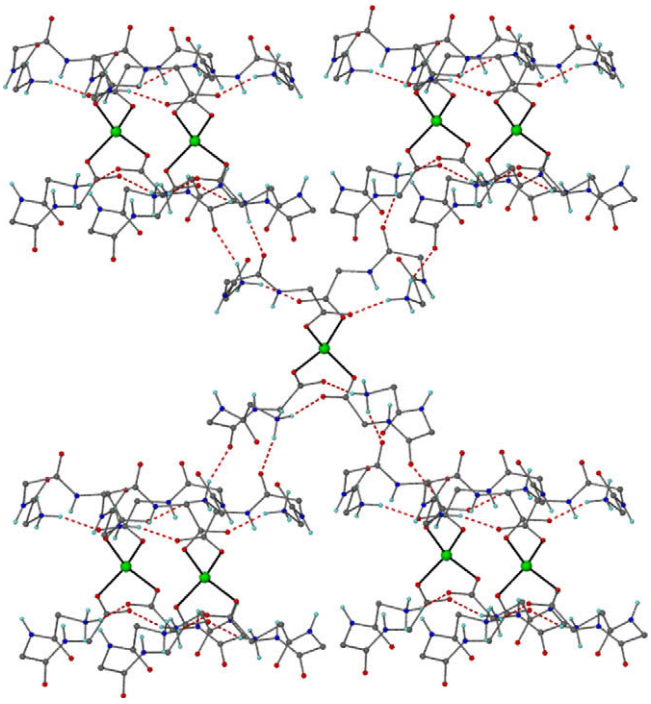

Fig. 10. The hydrogen bonding between the $[Zn(H_2\text{-Aib-Aib-Aib-O})_4]^{2+}$ cations in **3**·5.8H_2O. All methyl groups of the side chains of the tripeptide ligands have been omitted for clarity. Color code: Zn = green, O = red, N = blue, C = grey, H = cyan. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

Alternatively, if we regard each tripeptide ligand as a 3-connected node due to its hydrogen bonding to two other tripeptide ligands and the coordination to the Zn^{II} atom, which can now be regarded as a 4-connected node, the resulting network is a 3,4-connected net with a Schäfli symbol $(8^3)_4{\cdot}8^6$ (topological type: **sqc185**) [43] (Fig. 11).

The above topological analysis is rather oversimplified, giving the connectivity of the $[Zn(H_2\text{-Aib-Aib-Aib-O})_4]^{2+}$ cation in the lattice through the intermolecular hydrogen bonds that form between the coordinated tripeptide ligands, but ignoring the ClO_4^- and the lattice water molecules. The presence of the ClO_4^- (one of which is disordered) ions and the lattice water molecules (also disordered) which participate in the formation of several hydrogen bonds with the tripeptide ligands and with each other, complicate the resulting three-dimensional framework making the topological analysis difficult, if not impossible.

Table 8
The crystallographically established coordination modes of tripeptides in the *binary* M^{n+}/free-tripeptide complexes, in their zwitterionic, mono-, di- and trianionic forms.

Compound	Coordination mode[a]	Ref.

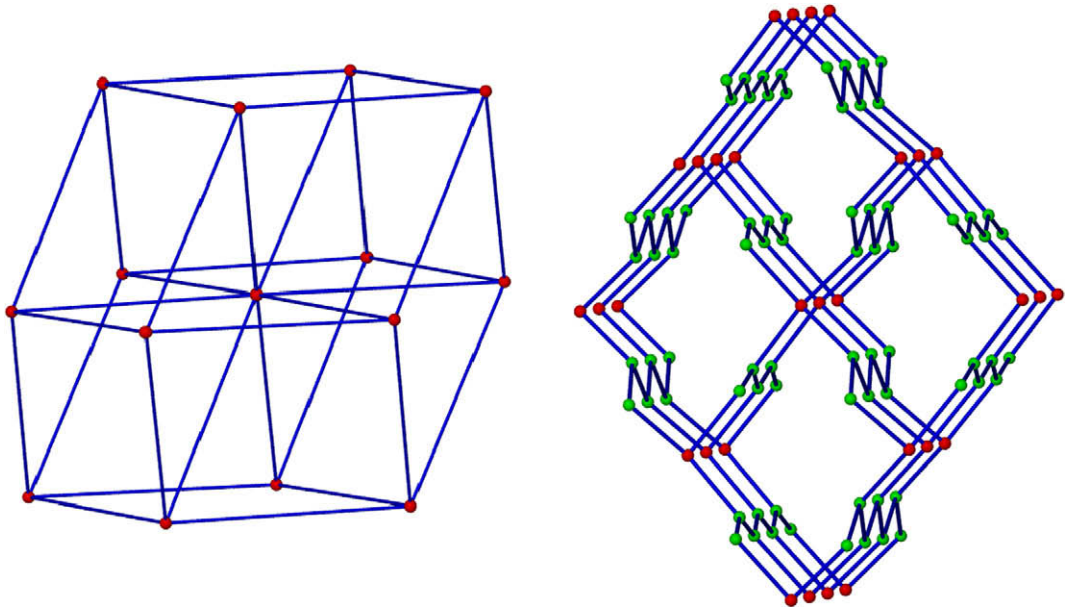
[a] The coordination modes of the ligands are given using Harris notation [13].

The monodentate carboxylate coordination of the zwitterionic form of the peptide ligand, as it is observed in complex **3**·5.8H_2O, is very scarce in the metal/peptide coordination chemistry. In fact, there are 16 crystal structures of binary M^{n+}/free tripeptide complexes deposited at CCDC (May 2009). We note a very interesting feature: In the 10 structures (after the exclusion of the tripeptides with coordinated side chains), the tripeptide ligands adopt *eight* different coordination modes (Table 8, Scheme 3); the coordination mode of the tripeptide ligand in **3**·5.8 H_2O is novel. In the remarkable complexes $[Fe_3(\mu_3\text{-O})(H_2\text{-Gly-Gly-Gly-O})_6(H_2O)_3]^{7+}$ [44] and $\{[Mo_4O_{12}(H_2\text{-Gly-Gly-Gly-O})_2]{\cdot}9H_2O\}_n$ [45], the tripeptide is in its zwitterionic form and bridges two metal ions through the bidentate bridging carboxylate group.



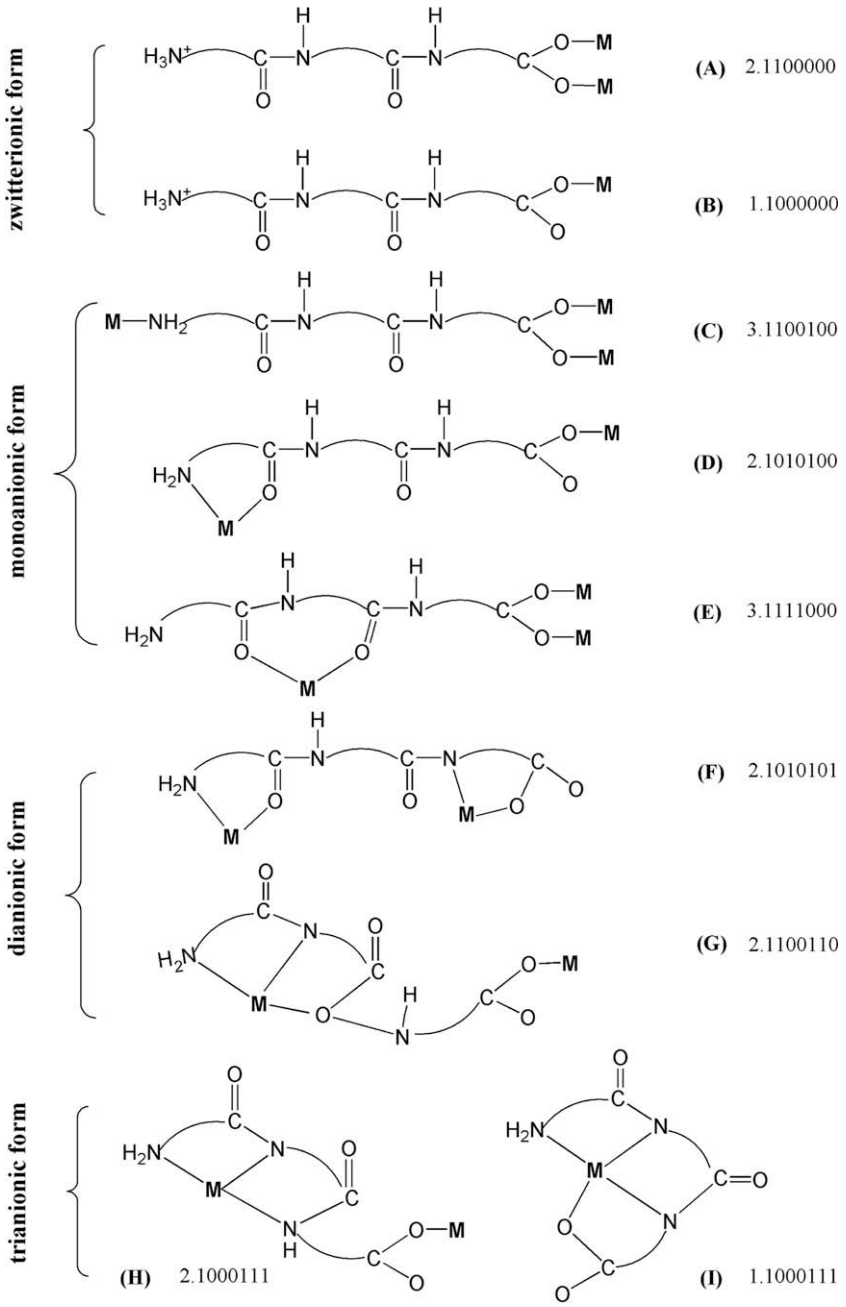


Fig. 11. The 8-connected **bcu** net (left) and the 3,4-connected **sqc185** net (right) in the crystal structure of **3**·5.8H_2O.

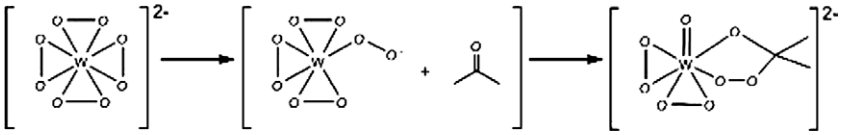
Scheme 3. The coordination modes of tripeptides in the *binary* M^{n+}/free-tripeptide complexes (without coordination of their side chains), in their zwitterionic, mono-, di- and trianionic forms. The coordination modes are given using Harris notation [13].

4. Concluding comments and perspectives

The present work extends the body of results that emphasize the ability of α-aminoisobutyric acid and α-aminoisobutyric acid-based peptides to form new structural types in 3d-metal chemistry. The use of H-Aib-OH, H-Aib-L-Ala-OH and H-Aib-Aib-Aib-OH in reactions with Zn^{II} sources has provided access to complexes **1**, **2** and **3**, respectively. Complex **1** is the second, structurally characterized Zn^{II} complex containing any form of H-Aib-OH and proves the ability of the monoanionic ligand to give non-hydroxo/oxo triangular clusters; the 2.111 ligation mode is observed for the first time in the coordination chemistry of this aminoacid. Complex **2** is the first structurally characterized Zn^{II} complex of any form of H-Aib-L-Ala-OH and constitutes a welcome new addition to the family of complexes that adopt the **tfa** network. Compound **3** is a novel example of a complex containing a monodentate tripeptide ligand; of structural interest is also the **bcu** network observed as a result of hydrogen bonding.



Clearly, Zn^{II}/α-aminoisobutyric acid-based peptide chemistry warrants further expansion to other di- and tripeptides. With complexes **2** and **3** as stimuli, we are also exploring synthetic methods for isolating Zn^{II} complexes involving the dianionic form of H-Aib-L-Ala-OH and the various anionic forms of H-Aib-Aib-Aib-OH as ligands. Finally, analogues of **1**–**3** with the other Group 12 metals, i.e. Cd^{II} and Hg^{II}, are not known to date, and it is currently not evident whether the preparation and stability of such mononuclear, trinuclear and polymeric complexes are dependent on the nature of the metal ion; work along this line is in progress in our group.

Supplementary data

CCDC 738622, 738623 and 738624 contains the supplementary crystallographic data for **1**·MeCOOH·H_2O, **2**·H_2O and **3**·5.8H_2O. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. The proposed mechanism for the formation reaction of the acetone peroxide complex.

2. Experimental

2.1. Materials and methods

Sodium tungstate, and guanidinium carbonate obtained from Aldrich were used without further purification. Hydrogen peroxide (30%) obtained from Merck was used as received and de-ionized and distilled water was used throughout this study. Deuterated solvents for use in the NMR, D_2O, and DCl were purchased from Merck. IR spectra were recorded using a KBr pellet on a Perkin Elmer 880 IR spectrophotometer. High-frequency Raman spectra were recorded with a Perkin–Elmer GX Fourier 514.5 nm using an Ar+ laser with a Jobin–Yvon (T64000) triple spectrometer as the excitation source. The UV–Vis absorption spectra in the range 900–200 nm were recorded using a Cary 3E spectrophotometer. NMR spectra were recorded with a Bruker Avance 500 MHz instrument and were processed by X-WIN MR 2.6 (Bruker Analytik GmbH).

2.2. Preparation of $(gu)_2[WO(O_2)_2CO(O)_2(CH_3)_2](CH_3)_2CO$

A solution of sodium tungstate (1.08 g, 3.3 mmol) in 30% H_2O_2 (20 mL) was treated with $(gu)_2CO_3$ (1.35 g, 7.5 mmol) in 20 mL distilled water. The clear yellow solution was stirred for a few minutes and the pH solution was recorded to be 8.7. 120 ml of acetone were slowly added and a white precipitate was formed immediately after the addition of acetone. The solid was filtered off. The filtered solution was cooled at 4 °C and colourless crystals suitable for X-ray diffraction were obtained after 7 days. *Anal.* Calc. for: C. 18.06; H, 4.55; N, 15.79. Found: C, 18.26; H, 4.49; N, 15.85%.

2.3. X-Ray diffraction

Slow crystallization from acetone yielded colourless prismatic crystals. A crystal with approximate dimensions $0.29 \times 0.42 \times 0.56$ mm was taken from the mother liquor and immediately cooled to −10 °C. Diffraction measurements were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Cu Kα radiation. Data collection (ω-scans) and processing (cell refinement, data reduction, Numerical and Empirical absorption correction) were performed using the CRYSTALCLEAR program package [19]. The structure was solved by direct methods using SHELXS-97 [20] and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [21]. Further experimental crystallographic details for the complex: $2\theta_{max} = 130°$; reflections collected/unique/used, 10 537/2843 [$R_{int} = 0.0539$]/2843; 223 parameters refined; $(\Delta/\sigma)_{max} = 0.007$; $(\Delta\rho)_{max}/(\Delta\rho)_{min} = 0.689/-0.588$ e/Å^3; R_1/wR_2 (for all data), 0.0281/0.0644. All hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-hydrogen atoms were refined anisotropically.

3. Results and discussion

3.1. Crystal structure

The crystal data for the complex are given in Table 1 and selected bond lengths and angles in Table 2. The structure of the monomeric oxo diperoxo complex is depicted in Fig. 1.

The coordination sphere about the tungsten atom consists of seven oxygen atoms arranged in a pseudotrigonal bipyramid geometry with the oxo ligand O(5) and an oxygen atom of the ligand O(6), in the axial positions. The two peroxo groups and the oxygen O(7) of the ligand lie in the equatorial plane. Similar structural data for peroxo complexes of tungsten W(VI) are reported in a more recent review published in 2008 by Sergienko [18]. The complex compound has a similar structure with the heteroleptic tungsten complex with the quinaldinic ligand reported in our work as it can be seen by the bond angles [9]. The oxo atom, the bond (C–O–W) and the peroxo group of the acetone peroxide ligand are almost copla-

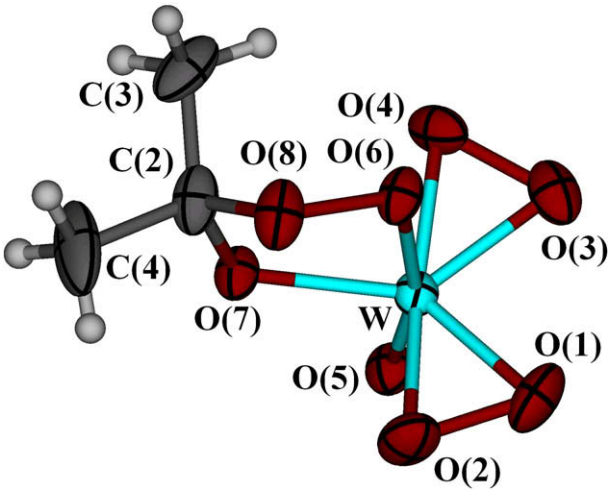

Fig. 1. Structure and atom numbering of $(gu)_2[WO(O_2)_2CO(O)_2(CH_3)_2](CH_3)_2CO$ (where gu^+ = guanidinium ion, $CN_3H_6^+$ ion). Thermal ellipsoids are drawn at the 50% probability level.

nar and perpendicular to the plane of the peroxo oxygen atoms. The acetone peroxide bidentate chelating ligand is coordinated to the metal atom by the oxygen atoms of the oxygen–carbon–tungsten bond (C–O–W) and by two peroxo oxygen atoms and closes the five membered metallocycle $WOCO_2$. The angle between them (O5–W–O7) is 88.7(15) which is close to the angle between the oxo atom the tungsten ion and the oxygen of the quinolinium ring of the quinaldinic tungsten complex [9]. The distance of the W=O double bond is 1.733 (4), whereas the W=O distance is 1.698 Å respectively in the quinaldinic complex. The O–O bond lengths (1.509(7)–1.505(7) Å). The W–O(peroxo) bond lengths are in the range 1.943(4)–1.994(5) Å, which suggests that they are bonded asymmetrically. These data are also in accordance with those reported in our previews work except that the lengths of the O–O (1.509(7)–1.505(7)) bonds are noticeably longer comparing to the quinaldinic complex reported previously [9]. The crystal packing of the complex is dominated by intermolecular O–H···O hydrogen bonds. The co crystallized acetone molecule and the guanidinium N atoms participate in 8 hydrogen bonds of each molecule (Fig. 2) (in) the same way (as) the peroxo tungstate complex with

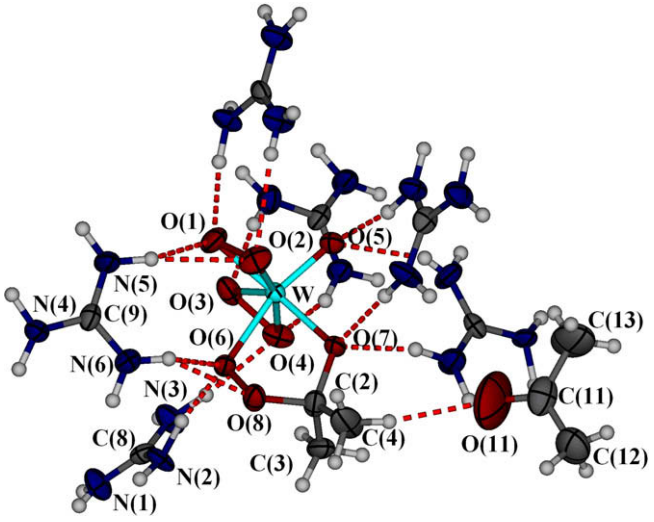

Fig. 2. Crystal packing of $(gu)_2[WO(O_2)_2CO(O)_2(CH_3)_2](CH_3)_2CO$. Hydrogen bonds are represented by dotted lines, and selected donor and acceptor atoms are labelled.

the quinaldinic ligand does [9]. Raczynska et al. reported the richness of intermolecular interactions in guanidinium salts. These are hydrogen bonds, Coulomb and Van der Waals interactions. In particular, the highly symmetric and planar guanidinium ion with six equivalent protons, is a hydrogen bond donor. Since the H-bond donor and acceptor are charged species, the electrostatic interactions in the crystal lattice may additionally modify the hydrogen bond network [15]. The selected hydrogen bond lengths are reported in Table 3.

3.2. Infrared and Raman data

The infrared spectrum of the complex revealed the characteristic spectral pattern main vibrations of which are summarized in Table 4. The spectrum of the complex illustrated in Fig. 3 exhibits a strong sharp band at 929 cm^{-1} consistent with the presence of the W=O bond vibration Two strong and sharp bands packing at 869 and 828 cm^{-1} are ascribed to the O–O vibration [14]. The occurrence of two bands indicates the presence of different peroxo groups side-on bound to the metal. Additional bands in the range of 690–540 cm^{-1} belong to $\nu_{as}(W–O_2)$ and $\nu_s(W–O_2)$ [10]. The bands at 1551 and 1363 are assigned to the methyl group bending motion, and the band at 1227 corresponds to the C–O stretch [16]. The peaks at 3417 and 3182 cm^{-1} are attributed to the asymmetric $\nu_{as}(NH_2)$ and symmetric $\nu_s(NH_2)$vibrations. Drozd et al. in a theoretical vibrational spectra study of guanidine selenate (GUSE) and guanidinium sulphate (GUS), reported that the bands at 3574–3511 cm^{-1} and at 3575–3502 cm^{-1} are assigned in $\nu_{as}(NH_2)$vibrations in (GUS) and (GUSE), respectively, and the symmetric vibrations $\nu_s(NH_2)$ at 3103 and 3315 for (GUS) and (GUSE). In the IR

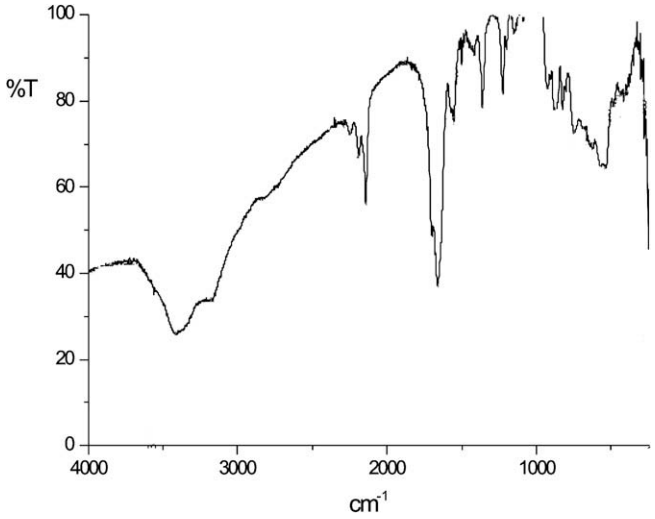

Fig. 3. IR spectra of the acetone peroxide tungsten complex.

spectra reported here the corresponding peaks are shifted due to the hydrogen bonding of the guanidinium cation. Also the band at 3417 cm^{-1} is characterized by higher intensity comparing to the band at 3182 cm^{-1}. This finding is in contrast to Drozd et al. who supported that the ν_s(NH2) is the strongest band in the spectra. The distinct peak at 1661 cm^{-1} has been assigned to the ν_{as}(CN) of the counter ion but also can be attributed to the NH_2 in-plane bending vibrations which are mixed with the ν_{as}(C–N) vibrations. The band at 1089 cm^{-1} with a low-intensity corresponds to the symmetric ν_s(CN) vibration and to the ρNH_2 rocking vibrations. Finally, the bands at 574 and 481 cm^{-1} are also assigned to the in-plane vibrations of CN_3 and are characterized by their low intensities in accordance with Drozd [11].

The wave numbers of the characteristic infrared bands described previously fit those obtained from the Raman spectra (Table 4 and Fig. 4) of the complex. The peaks at 1011, 896, 839, 823, and 645 cm^{-1} correspond to the ν_sC–N, W=O, O–O and ν_{as}(W–O_2) bond vibrations of the complex, respectively. Additionally, the peaks at 526 and 496 cm^{-1} are attributed to the ν_s(W–O_2) and ν_s(W–O–O–C) bond vibrations. The low-intensity, high-frequency peaks at 1668 and 1580 cm^{-1} can be assigned to the bond vibrations of the methyl protons in the acetone peroxide ligand [16].

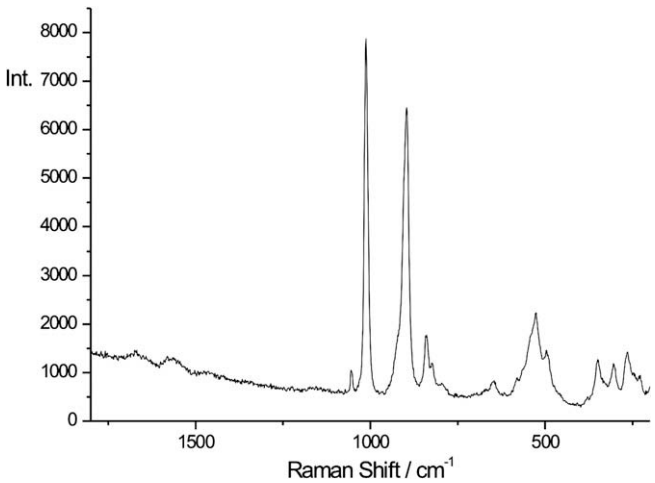

Fig. 4. Raman spectra of the acetone peroxide tungsten complex solution.

3.3. Raman in solution

The Raman spectra of the complex in aqueous solution both in absence and presence of hydrogen peroxide at different pH values, is extremely useful for the identification of the different peroxo species formed and the data are summarized in Table 5. In order to obtain valuable conclusions a strictly specific procedure was followed. Firstly, a spectrum, obtained 20 min after the dissolution of the complex in water, exhibits two main bands at 1013 and 932 cm^{-1} corresponding to the C–N and W=O vibrations, respectively.

After the addition of an appropriate quantity of H_2O_2, capable to prepare a solution with an excess of H_2O_2, a second spectrum obtained which is depicted in Fig. 5. In that spectrum the appearance of four new bands at 876 main, 858 shoulders, 795 broad band, and 573 cm^{-1}, not present before indicates the interaction of H_2O_2 with the complex compound. The band at 876 corresponds to the O–O vibration of the free H_2O_2 and the two bands at 858 and 795 cm^{-1} to the coordinated H_2O_2. The band at 573 cm^{-1} is attributed to the W–O–C vibration [16]. Another interesting difference between the two spectra is the absence of the band at 932 cm^{-1} in the second spectrum. All the peaks mentioned above except for the peak at 573 cm^{-1} appeared in the solid state. The above findings are in accordance with those reported in our work with peroxo tungsten complexes [9]. The disappearance of the band at 932 cm^{-1} indicates the absence of the W=O bond to the compound in the presence of an excess of H_2O_2. Under these conditions a triperoxo form of the complex is dominant. This assertion becomes stronger due to the appearance of the bands at 858 and 795 cm^{-1}. On the contrary, the mono or diperoxo form is present in aqueous solution in the absence of H_2O_2. The Raman spectrum of the complex in aqueous solution also indicated that the complex is rather photosensitive even in the presence of excess hydrogen peroxide.

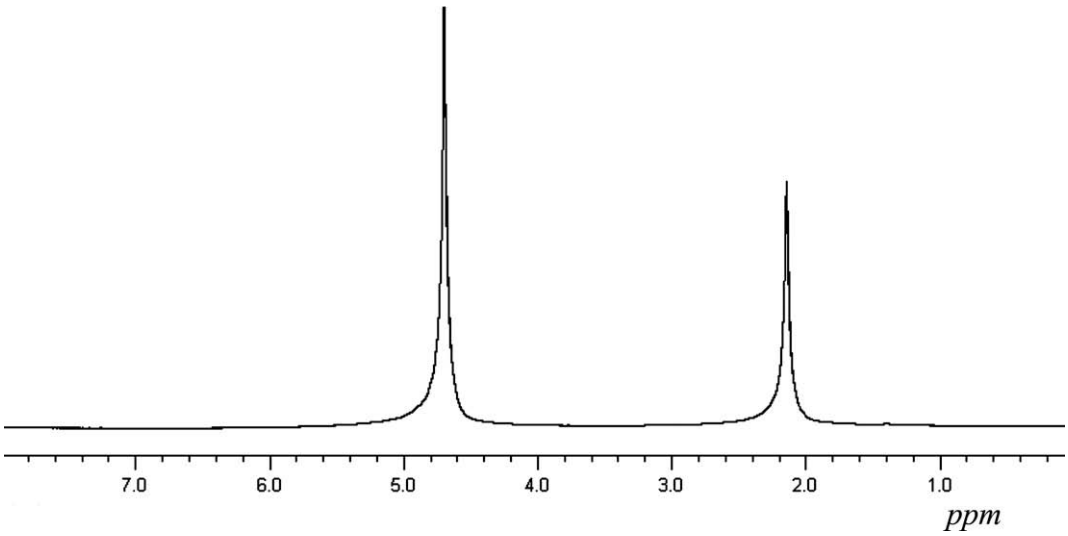

Fig. 6. ^{1}H NMR spectra of the acetone peroxide tungsten complex $(gu)_2[WO(O_2)_2CO(O)_2(CH_3)_2](CH_3)_2CO$ in D_2O solution 10 min after dissolution.

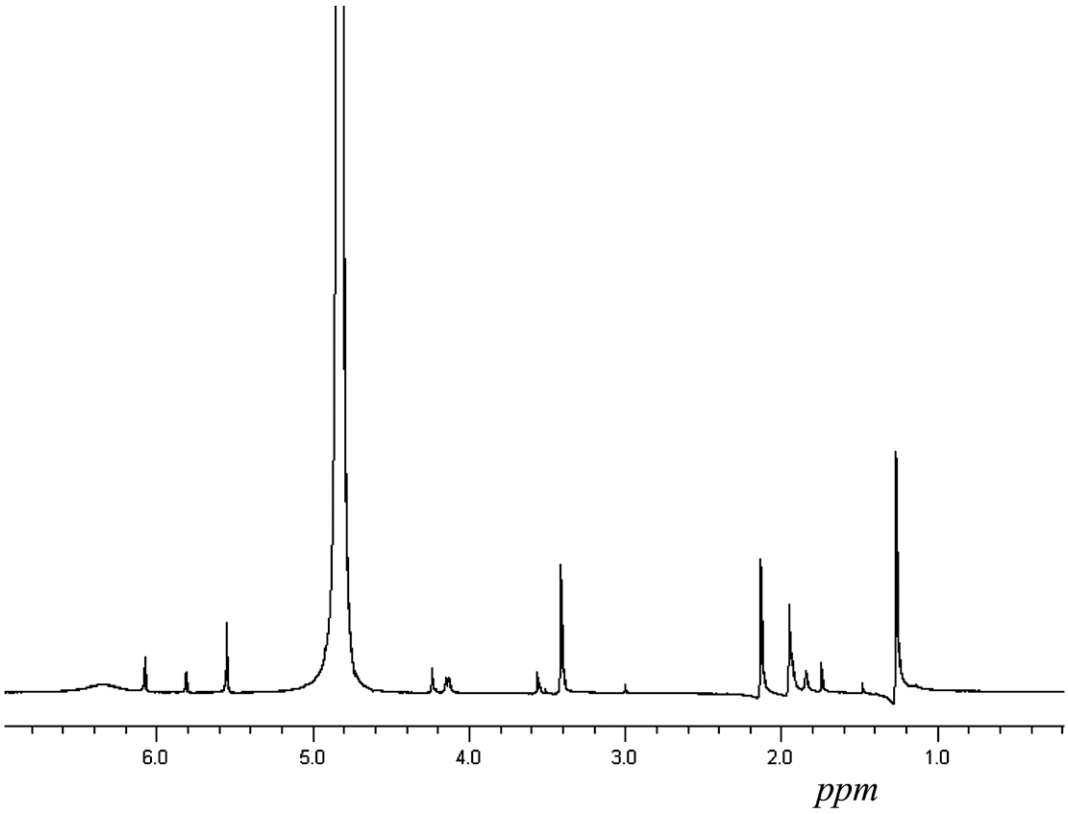
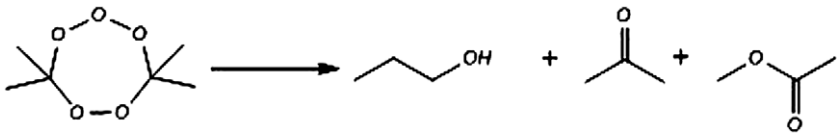
3.4. NMR spectroscopy

The ^{1}H NMR spectrum of the peroxo tungstate complex with the acetonato ligand in D_2O obtained 10 mins after dissolution in D_2O, is illustrated in Fig. 6. The above spectrum exhibits a peak at 2.15 ppm which is the peak of the free non coordinated acetone methyl protons. The source of the free acetone is attributed to the release of the crystal lattice acetone liberated by the dissolution of the complex and also to the acetone from the dissociation of the compound. The rapid dissociation of the complex immediately after the dissolution in water is proved by the fact that the peak which corresponds to the methyl protons of the acetone peroxide ligand at 1.4 ppm [12] is not detected in any spectra. The spectra obtained 7 days later were of no significant difference.

The second sample for NMR spectrum was prepared by the dissolution of the complex in D_2O, and the addition of an appropriate quantity of DCl in order to create acidic environment. In the first spectra obtained 10 mins after the preparation of the sample,





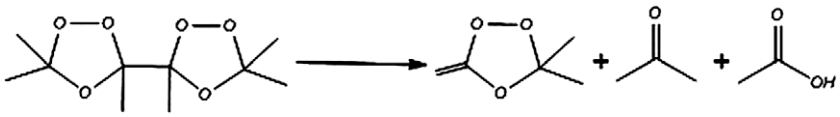


Fig. 7. ^{1}H NMR spectra of the acetone peroxide tungsten complex $(gu)_2[WO(O_2)_2CO(O)_2(CH_3)_2](CH_3)_2CO$ in D_2O solution with DCl 7 days after dissolution.

Scheme 2. Dissociation reaction mechanism of the triacetone triperoxide to acetone and the main intermediate products.

Scheme 3. Decomposition reaction mechanism of a diozonide and the main products.

two new peaks exhibited, at 4.1 ppm (single), and a small peak at 1–1.1 ppm (double), whereas the peak obtained in the previous sample at 2.15 ppm disappeared and a new intense and multiple (triple) peak appeared around 1.8 ppm. The second spectrum obtained 7 days after, exhibited a new range of peaks and is illustrated in Fig. 7.

The peaks at 1.25, 3.4, and 4.15 ppm are attributed to the protons of 2-propanol produced by the reduction of acetone, which is a possible reaction to happen. Dupnicova et al. proposed a mechanism (Scheme 2) of the decomposition reaction of triacetone triperoxide to acetone and ozone and presented the main intermediate products. The above compound has a similar structure with the peroxide complex presented in this paper. The peaks at 3.67 ppm and 2.01 ascribed to CH3–O–C(O)–CH3 are present in this spectrum and the appearance of the peaks at 3.65 and 1.2 indicates the existence of ethanol. The peak at 2.1 is also attributed to the presence of acetone [16]. Griesbaum et al. presented the decomposition reaction (Scheme 3) of a diozonide which gave also an intermediate with analogous structure to the peroxo tungsten complex with the acetone peroxide ligand. This diozonide decomposes to a mixture of an unsaturated form of this compound and acetic acid. The peaks at 5.55, 5.8 and 6.1 ppm indicate the presence of similar unsaturated components, and the peak at 2.15 can be ascribed to acetic acid [17]. Another interesting fact that indicates the decomposition of the compound is the explicit lowering of the peak 1.8 ppm, which was dominant in the spectra obtained immediately after dissolution of the complex.

3.5. Structure and stability towards decomposition

In our previous studies we demonstrated that peroxoniobate and peroxotungstates exhibit low stability toward decomposition in aqueous solution [8,9]. In these studies we also came to the conclusion that the bond length of the O–O bonds influences the chemical reactivity of the complexes. The peroxo O–O bonds of the acetone peroxide complex are noticeably longer than those of the peroxotungsten and peroxoniobate complexes with the quinaldinium ligand [8,9]. The Raman spectra of the complex in aqueous solution indicate that the peroxo groups of the complex are transformed to oxo groups immediately after the dissolution of the complex in water, and that, when H_2O_2 is added, the peroxo groups regenerate; this fact is in accordance with our previous works [8,9]. The NMR spectra in D_2O in both in absence or presence of DCl, indicate that the chelating ligand decomposes immediately after the dissolution of the complex in D_2O releasing acetone, and significantly faster in the presence of DCl; thus a group of products is formed due to various decomposition reactions occurring in acidic environment. The correlation of the above facts indicates that the complex compound is extremely unstable in besides the existence of a chelating ligand which according to the literature induces stability to the complexes in solution. The elucidation of the decomposition reaction mechanism of the complex in aqueous solution and the determination of the intermediate and final products is currently under research.

Supplementary data

CCDC 728377 contains the supplementary crystallographic data for $(gu)_2[WO(O_2)_2CO(O)_2(CH_3)_2](CH_3)_2CO$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgments

The authors are grateful to Dr. Polycarpos Falaras (Institute of Physical Chemistry NCSR 'Demokritos') for collecting the Raman data and to Dr. Eleni K. Efthimiadou for her assistance. The present work was supported by the Special Research Account of Athens University (E.L.K.E. 70/4/6495) and by the Postgraduate Studies Programme on "Catalysis an Integrated Approach" of Epeaek II Programme of Greek Ministry of Education, and the European Union (75/25).

using spin-coating techniques [17]. The photoluminescence (PL) of the thin film fabricated by vacuum deposition was measured from cast film of the Al-complex of 8-hydroxyquinoline and a-pyridoin on quartz substrate [18]. Electroluminescence (EL) mechanism of dye-doped vacuum thin film deposition of organic light-emitting diodes (OLEDs) was investigated by using three familiar fluorescent dyes, i.e. (DMQA), (DCJTB) and (Rubrene) [19]. On the other hand, several other techniques are widely used for thin film formation of organic or inorganic deposited materials [20]. These include chemical bath deposition (CBD) [21], electrochemical deposition [22], e-beam evaporation technique [23] Magnetron sputtering technique [24,25] and Langmuir–Blodgett (LB) [26–29].

In our previous report [30], we have presented a simple and direct chemical deposition method for synthesis of nano-sized metal-8-hydroxyquinolate complexes based on layer-by-layer surface deposition of the metal ion followed by 8-hydroxyquinole as the ligating environment for the formation of thin films. In the present work, a comprehensive study is devoted to explore, evaluate and optimize the various affecting and controlling factors in the process of thin film formation of nano-sized Co(II)-8-hydroxyquinalate complex, as a selected example, by surface layer-by-layer chemical deposition technique. In addition, the optical properties of nano-sized Co(II)-8-hydroxyquinolate complex thin film were also aimed to study and explore.

2. Experimental

2.1. Instrumentation

The metal analysis of cobalt contents after acid digestion and suitable dilution of all synthesized Co(II)-8-hydroxyquinolate complexes were determined by flame atomic absorption spectrophotometric measurements by using a Shimadzu model AA-6650 atomic absorption spectrophotometer at the appropriate wavelength. Scanning electron microscope (JSM-6360LA, JEOL Ltd.), (JSM-5300, JEOL Ltd.) and an ion sputtering coating device (JEOL-JFC-1100E) were used to examine the deposited thin film of metal quinolate complexes. SEM specimens were coated with gold to increase the conductivity. The FT-IR spectrum of Co(II)-8-hydroxyquinalate complexes were measured by a Shimadzu Fourier Transform infrared (FT-IR-8400S) spectrophotometer in the range 4000–200 cm^{-1}. Thermal gravimetric analysis (TGA) and thermoanalytical curves of Co(II)-8-hydroxyquinolate complexes were obtained by using a Perkin–Elmer TGA7 Thermobalance at Mubarak City, Egypt. The operating conditions include a temperature heating range is 20–1000 °C with a heating rate 10 °C min^{-1}, a flow rate of 20 ml min^{-1} pure nitrogen atmosphere and the sample mass in the range of 5–12 mg.

Shimadzu gas chromatography-mass spectrometer (GCMS-QP2010 plus) interfaced with a direct insertion probe (DIP), Micro-analytical Laboratory-Cairo University, was used to acquire the electron impact mass spectra (EI-MS) of Co(II)-8-hydroxyquinolate complexes by 70-eV as the ionization energy. Heating temperature programming of the DIP was performed based on 50 °C min^{-1}. The maximum temperature was adjusted to 350 ^{0}C and the run time was completed in 8.0 min.

2.2. Chemical and materials

Cobalt chloride hexahydrate, $CoCl_2{\cdot}6H_2O$, of analytical grade was purchased from Aldrich Chemical Company, USA. 8-Hydroxyquinoline (8-HQ), ethanol and methanol were obtained from BDH limited, Poole, England and used as received. The metal ion solution (0.1 M) was prepared from doubly distilled water by dissolving the appropriate mass of metal salt in a 500 ml flask. Methanolic and ethanolic solutions of 8-HQ (0.1, 0.2 or 0.3 M) were also prepared and used. The micro-slide glass substrates 76.2 mm, 25.4 mm and 1.0 mm were cleaned as previously reported [31].

2.3. Thin film formation of Co(II)-8-hydroxyquinolate complexes via layer-by-layer chemical deposition method

2.3.1. General procedure

The formation of Co(II)-8-hydroxyquinolate complex thin films were carried out according to previously reported procedure [30]. In this method, a clean glass micro-slide of the size 76.2 mm, 25.4 mm and 1 mm was used as the solid substrate. Solutions of $CoCl_2.6H_2O$ and 8-HQ were prepared in the selected solvents. The clean substrate was vertically immersed into the metal ion solution to deposit the Co(II) ion on the substrate surface. The substrate was then immersed in the ligand solution whereas the pre-adsorbed metal ion on the glass substrate was allowed to react with the ligand. A colored and uniform thin film of the Co(II)-8-hydroxyquinolate complex was formed after few dipping cycles. The reaction substrate was rinsed with distilled water after each reaction cycle. This procedure was repeated to increase the film thickness and homogeneity.

2.3.2. Studied and optimized factors

The effect of molar concentration on thin film formation of Co(II)-8-hydroxyquinolate complex was studied by keeping the cobalt ion concentration constant at 0.1 M, while the concentration of 8-HQ was varied to cover three different values of 0.1, 0.2 and 0.3 M. The selected and evaluated number of dipping cycle were kept constant at 2 and 20 cycles while the immersion time values were kept constant at 2 and 20 s.

The effect of number of dipping cycles on Co(II)-8-hydroxyquinolate complex thin films formation was studied at constant immersion time (2-s) and The selected number of dipping cycles is 2, 5, 10, 30, 40 and 50. The (1:1), (1:2) and (1:3) molar stoichiometric ratios of metal to ligand and the immersion time were kept constant.

The effect of immersion time on Co(II)-8-hydroxyquinolate complex thin films formation was also studied. The time of immersion were adjusted to 2, 5, 10, 20, 30, 40 and 50 s. The (1:1), (1:2) and (1:3) are the selected molar stoichiometric ratios of metal to ligand and the number of dipping cycles (five cycles) were kept constant during the course of this evaluation study.

The effect of pH value of metal ion and ligand solution on the Co(II)-8-hydroxyquinolate complex thin film formation was also studied by adjusting the pH value of metal ion solutions to pH 1, 3, 5 and 7. The stoichiometric ratio (1:2) of metal to ligand, the time of immersion (5 s) and the number of dipping cycles (5) were kept constant during the course of this study.

Two different solvents were selected to conduct the study of the effect of solvent and these are ethanol and methanol. The ligand solutions were prepared in ethanol and methanol and the $CoCl_2{\cdot}6H_2O$ solution was prepared in DW. The selected molar stoichiometric ratio was (1:2) of metal to ligand, the time of immersion (5 s) and the number of dipping cycles were (2, 5 and 10 cycles).

2.4. Optical properties

2.4.1. Thin film deposition and optical measurements

Deposited Co(II)-8-hydroxyquinolate complex on solid substrate was re-dissolved in 50 ml absolute methanol at room temperature. Pre-cleaned glass micro slides were used as substrates. Deposited film on glass by dip coating is characterized by high transparency and good quality while its thickness is too small to be measured by optical transmittance. Another technique of thin

film formation was prepared by evaporation of the solvent in air from a Petri dish containing the prepared solution and glass slide. After 24 h the solvent was evaporated and Co(II)-8-hydroxyquinolate thin film with good quality and higher thickness ~0.5 micron was deposited. The optical transmittance was measured by using double beams UV–Vis spectrophotometer type LABOMED of spectral range 190–1100 nm, scan step 2 nm. A reference glass substrate was used.

3. Results and discussion

Layer-by-layer technique for thin film formation is recently used for synthesis of several important classes of nano-compounds and nano-materials. This process is mainly based on deposition of the first target species either ionic or molecular one already dissolved in a solution on the surface of a solid support followed by deposition of the second interacting species from its solution on the same solid support. This initial step is directly leading to the formation of first layer of the aimed compounds. Successive deposition of multilayer thin film is then formed upon repeating the layer-by-layer deposition steps to produce the required thickness and homogeneity of thin film. Several factors are of significant importance on controlling the thin film formation by layer-by-layer technique. These are mainly summarized as (i) the molar concentration of the two interacting species and their effect on the final molar stoichiometric ratio of the produced thin film compound. (ii) The dipping time of the solid substrate in the two interacting solutions and its effect on thickness and homogeneity of the synthesized thin film. (iii) The number of successive dipping cycles and its effect on the thin film thickness. (iv) The effect of pH values of both interacting species on the process of thin film formation, especially if the required deposited compound is a metal complex. (v) The effect of solvent on the possibility and kinetics of the direct thin film formation. Therefore, these factors are extensively studied, evaluated and optimized for thin film formation of Co(II)-8-hydroxyquinolate complex. Table 1 summarizes and compiles all studied factors.

Various spectroscopic methods of detection and analysis were used and applied to follow-up the thin film formation including metal analysis by atomic absorption (AA), scanning electron microscope (SEM), electron impact mass spectrometry (EI-MS), Fourier transform-infrared spectra (FT-IR) and thermal gravimetric analysis (TGA).

3.1. Effect of molar concentration on stoichiometric ratio of Co(II)-8-hydroxyquinolate complexes

The effect of molar concentration of metal ion and ligand solutions was studied based on the selection of a 0.1 M Co(II) solution as a single metal ion concentration, while the molar concentration of 8-HQ was selected and varied as 0.1, 0.2 and 0.3 M. The percentage of the Co(II) in the produced thin film of nano-sized Co(II)-8-hydroxyquinolate complex under these stoichiometric conditions ion was determined by atomic absorption spectrophotometry after dissolution of the deposited thin film in a concentrated nitric acid solution, digestion and dilution in distilled water in order to identify the final stoichiometric ratio of the formed complex in each case. The determined percentage of Co(II) in the three synthesized thin films (1:1, 1:2 and 1:3) were found 17.0 ± 0.3% in all tested nano-sized Co(II)-8-hydroxyquinolate complexes suggesting a unique (1:2) stoichiometric ratio of Co(II) to 8-HQ. This percentage values of Co(II) indicates that the molar concentration values of either Co(II) solution or 8-hydroxyquinoline solution are less important and insignificant in the final stoichiometric ratio of the produced nano-sized metal complexes. In addition, all synthesized thin films of nano-sized Co(II)-8-hydroxyquinolate complex under any examined factors were characterized by the formation of a (1:2) stoichiometric ratio based on the elemental analysis determination of Co(II) constituent.

Table 1
Studied and optimized factors.

Factor	Specifications
Molar stoichiometry	(1:1), (1:2) and (1:3) based on 0.1 M-metal ion solution and 0.1, 0.2 and 0.3-ligand solutions
Dipping cycles	2, 5, 10, 20, 30, 40 and 50 cycles
Dipping time	2, 5, 10, 20, 30, 40 and 50 s
pH-Effect	Buffered metal solution in pH 1, 3, 5 and 7
Solvent effect	Methanol and ethanol for ligand dissolution and DW for metal ion dissolution

The similarities in chemical structure and composition of the three synthesized nano-sized Co(II)-8-hydroxyquinolate complexes by the selected (1:1), (1:2) and (1:3) molar stoichiometric ratios was also confirmed from the study of EI-MS, FT-IR and TGA analysis. The electron impact mass spectra of these three complexes were found to exhibit identical profiles of mass fragmentation patterns confirming similar chemical structures. The molecular ion peaks of the three Co(II)-8-hydroxyquinolate complexes were characterized at *m/z* 347 (Rel. Int. = 100%) assuming that ^{59}Co as the most abundant isotopes of cobalt. These molecular ions were found to exhibit identical losses of 144 amu as the deprotonated 8HQ ligand to form $[Co(II)–8HQ]^+$ fragment ions producing a mass spectral fragment ion peak at *m/z* 203 (Rel. Int. = 28 ± 2%). In addition, characteristic fragment ion peaks that are derived from 8-HQ at *m/z* 145, 117, 89 and 63 are evident in the EI-MS of these three metal complexes. The complete EI-MS data of all ion peaks of the three studied complexes are compiled in Table 2.

The thermal gravimetric analysis of the three nano-sized Co(II)-8-hydroxyquinolate complexes were characterized by producing three identical thermograms revealing another evidence for the similarities of these metal complexes. Two characteristic degradation steps were identified with percentage losses of 9.69–10.21% and 66.01–67.57% at temperature ranges of 371–464 and 646–974 K, respectively. The first degradation steps were suggested to produce from partial decomposition of one of the coordinated 8-HQ ligand and the second degradation steps were identified for the complete decomposition of the two coordinating 8-HQ ligands and producing cobalt oxide as the final fragments in all studied Co(II)-8-hydroxyquinolate complexes. The complete thermal data of the three studied complexes are compiled in Table 2.

The FT-IR spectral analysis was also used to further confirm the similarities outlined for chemical structure and composition of the same three thin film Co(II)-8-hydroxyquinolate. The FT-IR spectra were characterized by the disappearance of the absorption peak υ(OH) due to the deprotonation of H-atom of C_{8-OH} of the ligand moiety, while the υ(C=N) was shifted indicating that coordination of 8-HQ to Co(II) ion in all metal complexes via the C_{8-O} bond as well as nitrogen atom of imin [30]. The FT-IR data and peak assignments of the three studied complexes are compiled in Table 2.

SEM-images of the synthesized thin films of Co(II)-complexes based on the three studied stoichiometric ratios are shown in Fig. 1. The image shown in Fig. 1i represents an identical distribution of deposited thin film of Co(II)-8-hydroxyquinolate complex. The same image was obtained and repeated either the complex was formed by (1:1), (1:2) or (1:3) stoichiometric ratio indicating that the complex is directly formed regardless of the concentration values of the metal ion and the ligand solutions. It is also evident from these image that a uniform and homogeneous film is formed upon layer-by-layer deposition of Co(II) ion followed by the ligand via chemical deposition method. Fig. 1iii represents the SEM-image

of Co(II)-8-hydroxyquinolate synthesized based on experimental stoichiometric ratio of (1:1). A quick and uniform film was obtained after only 2 s dipping time and 10 dipping cycles. The quick and homogeneous complex particles distribution are formed as shown by Fig. 1iv and v in which SEM-images of Co(II)-8-hydroxyquinolate were synthesized on the basis of stoichiometric ratios of (1:2) and (1:3), respectively.

The determined particle size of all synthesized Co(II)-8-hydroxyquinolate complexes based on SEM studies were characterized in the range of 50–150 nm as shown in Fig. 2 as a representative image of similar nano-sized Co(II)-8-hydroxyquinolate complexes.

3.2. Effect of number of dipping cycle

The effect of dipping cycles on the thin film formation was extensively studied for the three selected stoichiometric ratios of metal to ligand, 1:1, 1:2 and 1:3. The dipping time was taken as 2-s for all thin film formation and the selected number of cycles are 2, 5, 10, 20, 30, 40 and 50. Fig. 3 clearly shows that a gradual increase in the masses of deposited thin films upon increasing the number of dipping cycles. The mass of deposited thin film was determined by weight difference of glass substrate before and after deposition of the thin film. The maximum masses were identified at 50 dipping cycles as 4.0, 4.8 and 5.2 mg for the three stoichiometric ratios 1:1, 1:2 and 1:3, respectively. In all studies, the highest masses of deposited thin films of Co(II)-complexes were identified in the case of 1:3 stoichiometric ratio while the lowest ones were detected in the case of 1:1. However, the collected data from the mass spectrometric analysis and atomic absorption of cobalt analysis of some selected samples of these synthesized thin film were found to give a 1:2 stoichiometric ratio as described in Section 3.1. In addition, the particle size of Co(II)-complexes synthesized by any selected dipping cycles were found in the range 50–150 nm as determined by the SEM analysis referring to the suitability of the layer-by-layer deposition method for obtaining the desired nano-sized thin films.

3.3. Effect of number of dipping time

The effect of dipping time on layer-by-layer thin film formation of nano-sized Co(II)-8-hydroxyquinolate was also studied as one of the important factors. The time of immersion was varied to cover 2, 5, 10, 20, 30, 40 and 50 s. The selected molar stoichiometric ratios of metal to ligand are (1:1), (1:2) and (1:3) and the number of dipping cycles is five cycles. These factors were kept constant during the course of this evaluation study. The general trend observed from this study can be outlined as the gradual increase in the thin film formation upon increasing the dipping time of substrate in the metal ion and ligand solutions. In the case of (1:2) stoichiometric ratio, the determined masses were found as 0.3, 0.6, 0.9, 1.0, 1.1, 1.1 and 1.1 mg for 2, 5, 10, 20, 30, 40 and 50 dipping time in second, respectively. It evident from these data that very close nano-sized Co(II)-8-hydroxyquinolate complex thin films were formed after 20 s as a dipping time with respect to the deposited masses. Thus, one can easily conclude that the 20 s dipping time is the optimum one for forcing a complete reaction between the deposited metal ion and ligand molecules for the formation of the aimed thin film. This behavior can be interpreted on the basis of mass deposited of initial layer of Co(II) ion on the surface of glass substrate which in this case require at least 20 s to completely react with suitable number of 8-hydroxyquinoline molecules and form the aimed stoichiometric complex species. Moreover, the identified optimum time (20 s) can directly refer to the rapid interaction processes of nano-sized Co(II)-8-hydroxyquinolate complex thin film formation. On the other hand, increasing the contact time to 30, 40 or 50 s was not practically important due to the less pronounced deposition of metal complex than those detected by 20 s dipping time. It is also important to report here that the particle size of Co(II)-complexes synthesized under any selected dipping time as determined by the SEM analysis were found in the range 50–150 nm. This also refers to the suitability of the layer-by-layer deposition method for obtaining good nano-sized thin films.

3.4. Effect of pH and solvent

The effect of pH of metal ion and ligand solutions is also considered of great importance on the process of layer-by-layer deposition of nano-sized thin film formation of Co(II)-8-hydroxyquinolate complex. Four selected buffer solutions of pH 1, 3, 5 and 7 were used to evaluate the process of thin film formation. This study was completed at constant dipping time (5-s) and dipping cycle (5-cycles). The stoichiometric ratio of metal to ligand was taken as 1:2. It was found and identified that a gradual increase in the pH value of deposited metal ion has led to a gradual increase in the mass of deposited thin film. The optimum pH value for thin film formation of Co(II)-8-hydroxyquinolate complex was characterized in pH 5 judging from the 4.8 mg deposited mass of thin

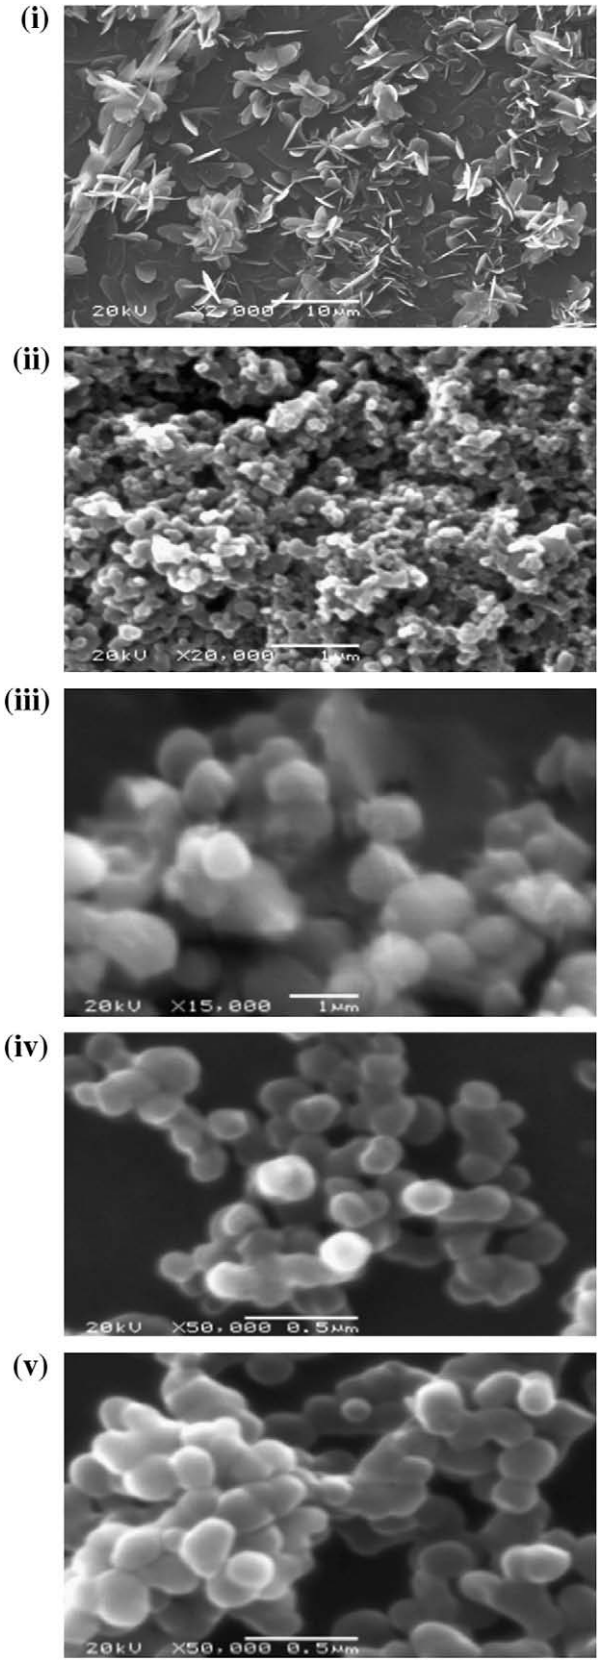

Fig. 1. SEM-images of Co(II)-8-hydroxyquinolate complexes. (i) Thin film image of Co(II)-8-hydroxyquinolate at 2000 magnification times. (ii) General thin film image of Co(II)-8-hydroxyquinolate at 20,000 magnification times. (iii) Co(II)-8-hydroxyquinolate synthesized based on (1:1) ratio at 2 s dipping time and 10 dipping cycles. (iv) Co(II)-8-hydroxyquinolate synthesized based on (1:2) ratio at 2 s dipping time and 10 dipping cycles. (v) Co(II)-8-hydroxyquinolate synthesized based on (1:3) ratio at 2 s dipping time and 10 dipping cycles.

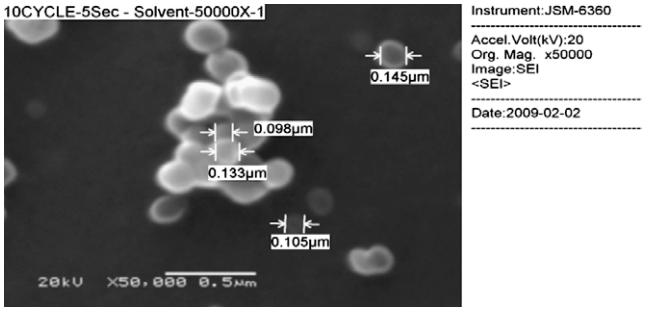

Fig. 2. Representative SEM-image of Co(II)-8-hydroxyquinolate complex for particle size determination.

film. The buffer solution with pH value 7 was also found to produce a thin film of Co(II)-8-hydroxyquinolate complex with a mass equal 3.9 mg. The buffered Co(II) solutions in pH values 1 and 3 were found to produce thin films of Co(II)-8-hydroxyquinolate with low mass values of 0.4 and 0.6 mg, respectively. This indicates that the mass deposited of the initial layer of Co(II) ion was low compared to that at pH 5 and 7 and this behavior may be due to the strong preference of Co(II) ion to exist as dissolved species rather than being deposited on the glass substrate. The results of this study refer to the possibility of thin film formation under any pH values of both contacting metal and ligand solutions. However, the maximum deposited mass and thickness of the required thin film is only obtained when the optimum pH condition is reached. Moreover, the range 50–150 nm as determined by the SEM analysis was also identified as the particle size of Co(II)-8-hydroxyquinolate synthesized under any selected and studied pH value.

Finally, the effect of solvent on nano-sized thin film formation of Co(II)-8-hydroxyquinolate complex was studied and evaluated by using only two solvents, ethanol and methanol, for ligand dissolution and water for Co(II) dissolution. These two solutions were selected on the basis of solubility factor of 8-hydroxyquinoline. The experimental results collected from this study indicated that no pronounced difference in thin film formation between dissolution of 8-hydroxyquinoline in either ethanol or methanol owing to the close polarity of these two solvents. However, other less polar solvents may facilitate the reaction of thin film formation due to rapid deposition of the ligand molecules on the glass substrate. This factor will be comprehensively studied and evaluated in our new thin film works.

3.5. Optical properties of Co(II)-8-hydroxyquinolate complex

The optical transmittance and absorbance of thin films of Co(II)-8-hydroxyquinolate complex is represented in Fig. 4. The average film transmittance in the long wavelength region was >85%. Three absorption bands or edges are evident and referred namely by 1, 2 and 3. The first edge was identified in the UV region with a wavelength range 300–400 nm and the second is located in the wavelength range 400–500 nm. The third is a very weak absorption band and located in the wavelength range 500–700 nm. These absorption edges correspond to optical transitions between occupied and unoccupied energy levels and are commonly referred in organic semiconductors as high occupied molecular orbital "HOMO" and low unoccupied molecular orbital "LUMO" levels. The optical transition between HOMO and LUMO energy levels can be described by the optical absorption coefficient, α, which is given by Eq. (1) [32].

$$\alpha = \left(\frac{A}{h\upsilon}\right)(h\upsilon - E_g)^2 \quad (1)$$

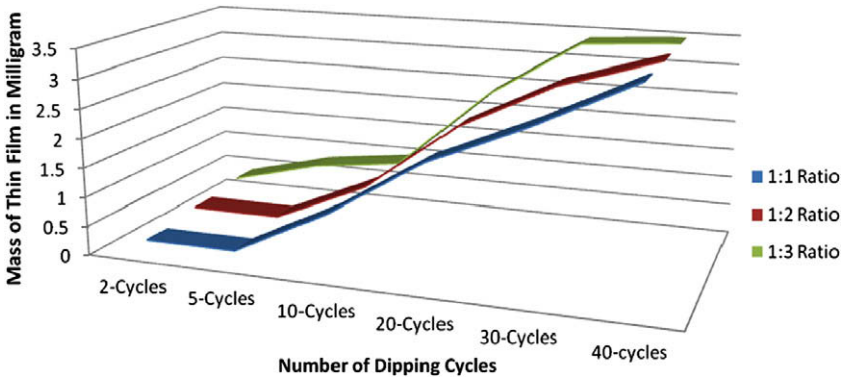

Fig. 3. Effect of dipping cycles on thin film formation at 2-s dipping time.

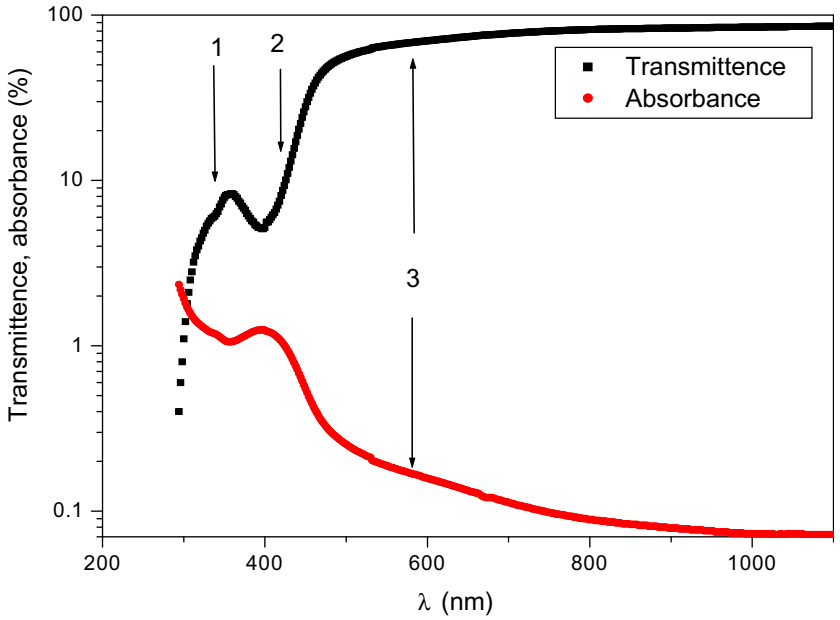

Fig. 4. Optical transmittance of Co(II)-8-hydroxyquinolate complex thin film.

where A is a constant, $h\nu$ is the incident photon energy and E_g is the band gap known as the energy difference between HOMO and LUMO. The exponent m is governed by the type of transition.

In order to obtain information about these transitions, the absorption coefficient α can be calculated according to Eq. (2) [33].

$$\alpha = \frac{1}{d}\ln\left[\frac{\left(1-R^2\right)}{2T}) + \sqrt{\frac{(1-R)^4}{4T^2}+R^2}\right] \tag{2}$$

where T is the transmittance, R is the reflectance and d is the thickness of the film. The value of the reflectance was noticed to be very small compared to the total transmittance and Eq. (2) can be converted to Eq. (3).

$$\alpha = \frac{1}{d}\ln\left(\frac{1}{T}\right) \tag{3}$$

Fig. 5 shows the absorption coefficient dependence upon wavelength in the case of the absorption edge denoted as number 2. It seems that this curve is similar to the absorbance and consists of the pre-mentioned three absorption edges.

The energy band gaps in this case are defined as the difference between the LUMO's and HOMO's levels determined on the basis of spectral absorption edges within the framework of band-to-band transition theory [33]. This theory can be used to analyze the absorption edge data of many organic semiconductors [32–35]. First, the constant m is determined by writing Eq. (1) in natural logarithm form as represented by Eq. (4) and the first derivative with respect to photon energy is given by Eq. (5).

$$\ln(\alpha h\nu) = \ln A + m\ln(h\nu - E_g) \tag{4}$$

$$\frac{d[\ln(\alpha h\nu)]}{d(h\nu)} = \frac{m}{h\nu - E_b} \tag{5}$$

The type of optical transition is based on the determination of m-value. By plotting the data of Eq. (3) by using originlab 6.1 software and differentiating the curve, we can obtain $d\{\ln(\alpha h\nu)\}/d(h\nu)$ versus $h\nu$. This plot shows a peak at 2.5 eV which determines the first estimation of the band gap. Substitution of the obtained value in Eq. (1) to plot the curve $\ln(\alpha h\nu)$ vs $\ln(h\nu - E_g)$ to determine m-value which was then found as 1.89. The nearest optical transition process is found at the $m = 2$ and this represents an indirect allowed transition. Then re-plotting $(\alpha h\nu)^{1/2}$ as a function of photon energy, $h\nu$ gave a straight line as shown in Fig. 6. The optical band gap was determined by extrapolating the linear portion of the plot to $(\alpha h\nu)^{1/2} = 0$. This suggests that the absorption edge is formed by an indirect allowed transition from HOMO to LUMO levels with

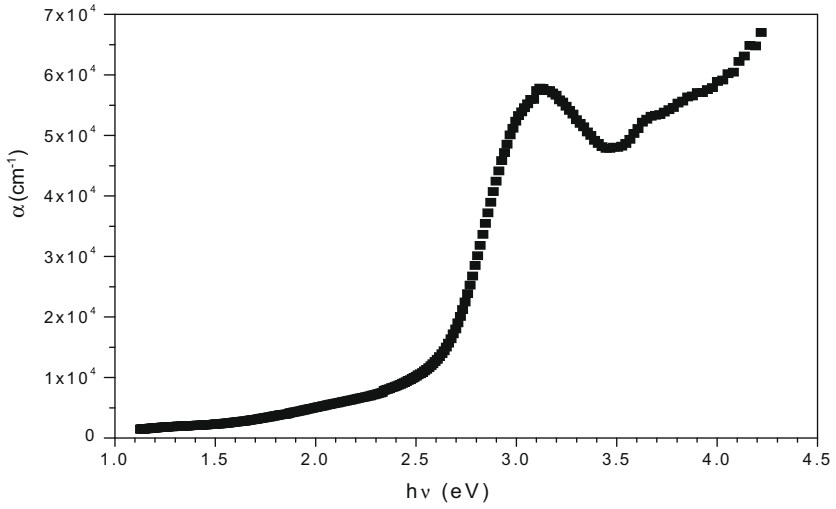

Fig. 5. Absorption coefficient vs. photon energy of Co(II)-8-hydroxyquinolate complex thin film.

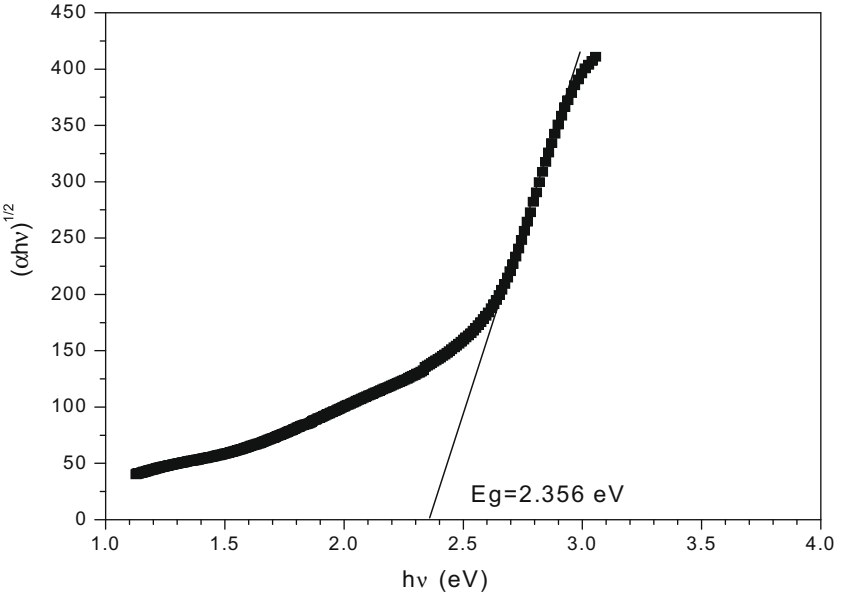

Fig. 6. $(\alpha h\nu)^{1/2}$ vs. hν for indirect transition Co(II)-8-hydroxyquinolate complex thin film.

energy difference of 2.356 eV as shown in Fig. 6. Similar mathematical treatments were also applied for the higher and the lower identified absorption peaks number 1 and 3 (Fig. 4), respectively. It was found that these two edges possess a constant $m = 0.5$ corresponding to the direct allowed transitions. Plotting $(\alpha h\nu)^2$ vs $h\nu$ produces a straight line with an intercept representing the difference between HOMO's and LUMO's in UV and equal 3.13 eV as given in Fig. 7. The lower absorption edge number 3 (Fig. 4) was determined by similar approach to give 1.5 eV. Optical transitions in Co(II)-8-hydroxyquinolate complex can be understood on the basis of two small direct optical transitions from high occupied molecular orbitals (HOMO) to low unoccupied molecular orbitals (LUMO) with transition energy values 1.5 and 3.13 eV. In addition, high indirect optical transition from HOMO to LUMO with transition energy value 2.356 eV is evident. Thus, four main types of electronic transition states are expected and can be outlined in transition metal complexes as discussed by Evans et al. [36].

1. *d–d* States [metal-centered (MC)] transition: When the ligand is coordinated to the metal, the d orbitals are split. Excited d–d states arise from promotion of an electron within d orbital which are essentially confined to the metal center.
2. d–π^* states (metal-to-ligand-charge-transfer (MLCT)): These involve the excitation of a metal centered electron to an anti-bonding orbital located on the ligand system.
3. $\pi-\pi^*$ or $n-\pi^*$ states [intra ligand (IL) transition]: Promotion of an electron from a π-bonding or non-bonding orbital to a higher energy anti-bonding orbital giving rise to these states.
4. π–d states [ligand-to-metal-charge-transfer (LMCT)]: These states arise from the transfer of electronic charge from the ligand π-system to a metal centered orbital.

In Co(II)-8-hydroxyquinolate complex, the highest optical transition is resulting from $\pi-\pi^*$ or n, π^* states with energy gap located in the UV at 3.13 eV. The lowest optical transition results

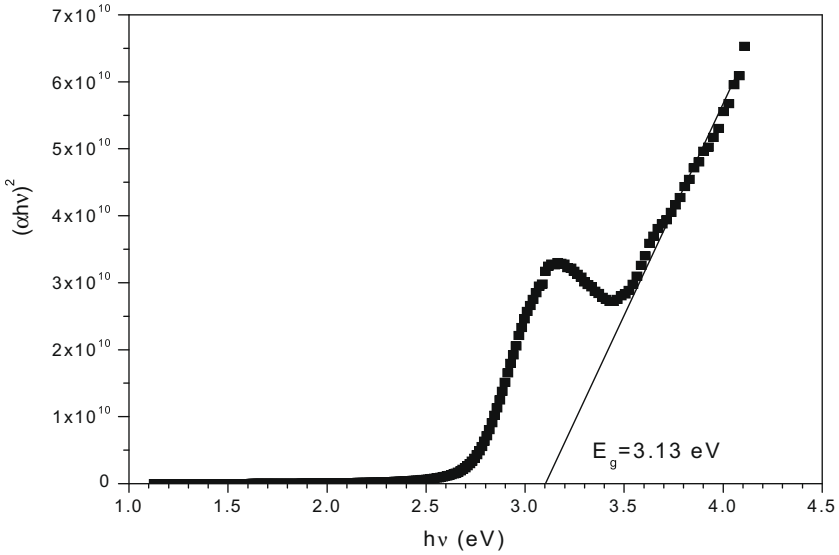

Fig. 7. $(\alpha h\nu)^2$ vs. $h\nu$ for indirect transition Co(II)-8-hydroxyquinolate complex thin film.

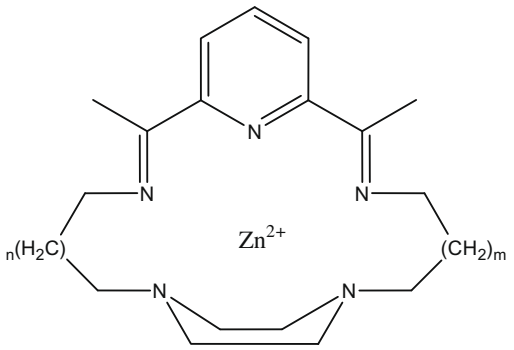

from d–d transition or metal centered transition with energy of 1.5 eV. The optical transition at 2.356 eV corresponds to the contribution of metal–ligand or ligand–metal transition.

4. Conclusion

In the present study, five different controlling factors were studied and explored for layer-by-layer chemical deposition of nano-sized Co(II)-8-hydroxyquinolate complex thin films. First, The molar stoichiometric of metal to ligand was found to be insignificant as the Co(II)-8-hydroxyquinolate complex was identified as 1:2 under any stoichiometric condition. Second, the role of dipping cycles was identified by its strong contribution to thin film formation as the maximum thin film masses were characterized at maximum dipping cycles (50 cycles in this study). Third, evaluation of the optimum dipping time factor was characterized as 20 s with respect to the deposited masses. Fourth, the effect of pH on thin film formation of nano-sized Co(II)-8-hydroxyquinolate complex was found to play a significant role judging from the maximum deposited mass at buffer solution with pH 5 as the identified optimum value. Fifth, the studied solvent effect on thin film formation was proved to exhibit no contribution owing to the similar polarity of the evaluated solvents. Finally, the optical properties of Co(II)-8-hydroxyquinolate complex was studied and confirmed that the highest optical transition from HOMO to LUMO energy levels are located in the visible region at 2.356 eV with indirect transition, while other direct optical transitions at energy values 1.5 and 3.13 eV were observed. Upon these results, Co(II)-8-hydroxyquinolate complex can be accepted as an organic semiconductor with the potential application as a component layer in organic light-emitting diodes (OLEDs).

Fig. 1. The template condensation between 2,6-diacetylpyridine and two different amines with piperazine moiety, in the presence of zinc(II) ion.

Safety note: Perchlorate complexes are potentially explosive. While we have not experienced any problems with the compounds described, they should be treated with caution and handled in small quantities.

2.2. Synthesis of metal complexes

2.2.1. Synthesis of $[ZnL^1Br]ClO_4{\cdot}H_2O$ (**1**)

A solution of NaOH (2 mmol) in absolute EtOH (10 cm^3) was added to a suspension of N,N′(2-aminoethyl)(3-aminopropyl)piperazine (0.5 mmol) in absolute EtOH (10 ml). The mixture was stirred at room temperature for a few minutes then filtered, and the precipitate was washed well with absolute EtOH (10 ml). The washings and the filtrate were combined and this solution was added dropwise to a hot solution of $ZnBr_2$ (0.5 mmol) and DAP (0.5 mmol) in absolute EtOH (20 ml) over a period of 2 h. After refluxing the solution for 18 h, then $NaClO_4$ (1 mmol) was added. The solution was filtered and the filtrate was reduced to ca. 10 ml. A crystalline compound was obtained by slow diffusion of Et_2O vapor into this solution. Yield of the complex $[ZnL^1Br]ClO_4{\cdot}H_2O$ **(1)**, 0.27 g, 47%. *Anal.* Calc. for $C_{18}H_{29}BrClN_5O_5Zn$ (MW: 576.2): C, 37.7; H, 5.2; N, 12.1. Found: C, 37.4; H, 5.4; N, 12.0%. IR (KBr, cm^{-1}): 3443, 1644 (νC=N Schiff-base), 1591, 1455 [ν(C=C) and ν(C=N)py], 1092, 623 cm^{-1} ν(ClO_4^-). FAB-MS (*m*/*z*, %): $[ZnL^1Cl]^+$, 412 (85.7%); $[ZnL^1Br]^+$, 458 (100%). Λ_M/Ω^{-1} cm^2 mol^{-1} (in DMF): 120 (2:1).

2.2.2. Synthesis of $[ZnL^2](ClO_4)_2{\cdot}H_2O$ (**2**)

A solution of N,N′-bis(3-aminopropyl)piperazine (0.5 mmol) in absolute methanol (10 ml) was added dropwise to a hot solution of $Zn(ClO_4)_2{\cdot}xH_2O$ (0.5 mmol) and 2,6-diacetylpyridine (0.5 mmol) in absolute methanol (20 ml), over a period of 2 h. After refluxing the solution for 24 h, the resulted solution was reduced to ca. 2–3 ml. The precipitated was filtered off and dried in vacuum. Yield of the complex $[ZnL^2](ClO_4)_2{\cdot}H_2O$ (**2**), 0.24 g, 40%. *Anal.* Calc. for $C_{19}H_{31}Cl_2N_5O_9Zn$ (MW: 607.1): C, 37.4; H, 5.1; N, 11.5. Found: C, 37.0; H, 5.3; N, 11.3%. IR (KBr, cm^{-1}): 3442, 1642, (νC=N Schiff-base), 1591, 1457 1455 [ν(C=C) and ν(C=N)py], 1085, 624 cm^{-1} ν(ClO_4^-). FAB-MS (*m*/*z*, %): $[ZnL^2]ClO_4^+$, 492 (32%). Λ_M/Ω^{-1} cm^2 mol^{-1} (in DMF): 140 (2:1).

2.3. Physical measurements

Elemental analyzes were performed in a Carlo-Erba EA microanalyser. FT-IR spectra in the 4000–400 cm^{-1} region were recorded from KBr pellets on a Bruker VECTOR 22 spectrophotometer. FAB mass spectra were recorded using a Kratos-MS-50T spectrometer connected to a DS90 data system using 3-nitrobenzyl alcohol as the matrix. Conductivity measurements were carried out in 10^{-3} mol dm^{-3} dimethylformamide solutions at 20 °C using a CARISON GLP32 conductivimeter.

2.4. X-ray crystal structure determination

Vapor diffusion of diethyl ether into a solution of $[ZnL^1Br]$ ClO_4 in the mixture of acetonitrile and methanol provided crystals suitable for study by X-ray diffraction. Data were collected on a Bruker SMART CCD area diffractometer operating at room temperature. Data were empirically corrected for absorption and other effects [15]. The structure was solved by direct methods and refined by the full matrix least-squares method on F^2 data using SHELXTL [16]. All non-H atoms were refined anisotropically, except oxygen atoms of the perchlorate ion, which were found to be disordered over two positions with site occupancy factors of 0.40 and 0.60. They were refined isotropically with the restrain bond distances of 1.42 Å. The H atoms were constrained to idealized geometries and refined isotropically. The crystallographic and refinement data are summarized in Table 1.

3. Results and discussion

3.1. Synthesis and characterization

The Schiff-base macrocyclic complexes $[ZnL^n]^{2+}$ (n = 1 and 2) were prepared from [1 + 1] cyclocondensation of 2,6-diacetypyridine and N,N′-bis(3-aminopropyl)piperazine or N,N′(2-amino-

ethyl)(3-aminopropyl)piperazine, respectively. The complexes were characterized by elemental analysis, IR, FAB mass spectrometry and conductivity measurements. The compounds were air stable solids and had elemental analyzes consistent with the formulations given in Section 2. The infrared spectra of the complexes are all very similar and confirm the formation of the macrocyclic compounds by the absence of bands characteristic of carbonyl and amine groups of the starting materials. An important feature is the occurrence of a strong band at approximately 1642–1644 cm^{-1} attributable to C=N stretching modes, indicating the Schiff-base condensation and also bands at ca. 1591 and 1456 cm^{-1} associated with $\nu(C{=}N)_{py}$ and $\nu(C{=}C)$ vibrations from the pyridine and phenyl rings [17]. The absorptions attributable to ionic perchlorate were found at approximately 1090 and 624 cm^{-1} [18]. The lack of splitting these bands suggests that the perchlorate anions are not coordinated. The FAB mass spectra also provide strong evidence for the formation of the macrocyclic ligand systems L^1 and L^2. The FAB mass spectra give the parent peak at *m/z* 458 and 490 corresponding to $[ZnL^1Br]^+$ and $[ZnL^2]ClO_4^+$, respectively. The spectrum in **1** also exhibits a peak due to the $[ZnL^1Cl]^+$ at *m/z* 412. The molar conductance values of the complexes measured in dimethylformamide lie in the range reported for 2:1 electrolytes in this solvent [19]. Due to the dynamic character and low solubility of two complexes (1 and 2), we were unable to obtain suitable NMR spectra of sufficient quality to allow unambiguous assignment of the ^1H and ^{13}C NMR.

3.2. X-ray crystal structure analysis

The structure of the $[ZnL^1Br]^+$ cation, determined by single-crystal X-ray diffraction. Selected bond lengths and angles are given in Table 2. Perchlorate ion was found to be highly disordered resulting in rapid fall-off the intensities and relatively poor statistical parameters for room temperature diffraction data. The $[ZnL^1Br]ClO_4$ complex crystallizes in the triclinic system with space group P-1 (No. 2). Crystal structure of the complex as shown in Fig. 2 represents the Zn(II) ion with a N5Br coordination environment. The geometry around the metal can be better described as in a slightly distorted pentagonal-pyramidal. The pentagonal plane is conformed by the five nitrogen atoms from the ligand (rms 0.4077) with the Zn(II) ion 0.554 Å out of this plane, while the apex of the pyramid is occupied by the bromide ion. The sum of the five

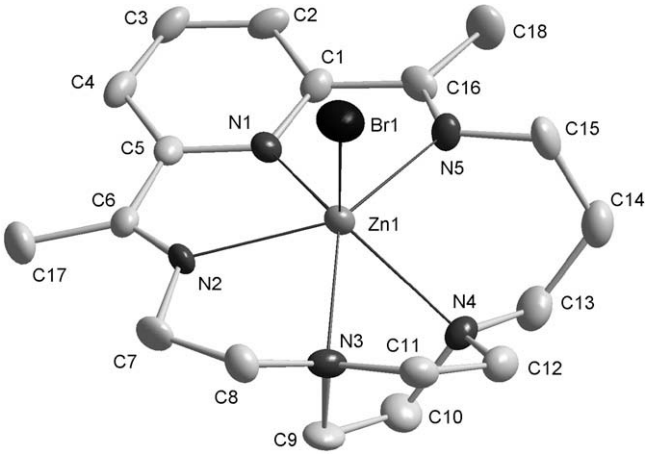

Fig. 2. Crystal structure of the cation $[ZnL1Br]^+$ with atom-numbering scheme. All H atoms are omitted for clarity. Displacement ellipsoids are shown at 30% probability level.

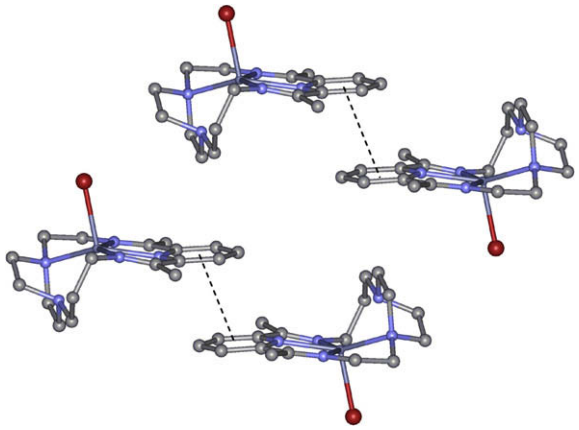

Fig. 3. π,π-Stacking interaction between the pyridine units of adjacent ligand.

N–Zn–N chelate angles (358.6°) is near 360° for an ideal planar structure.

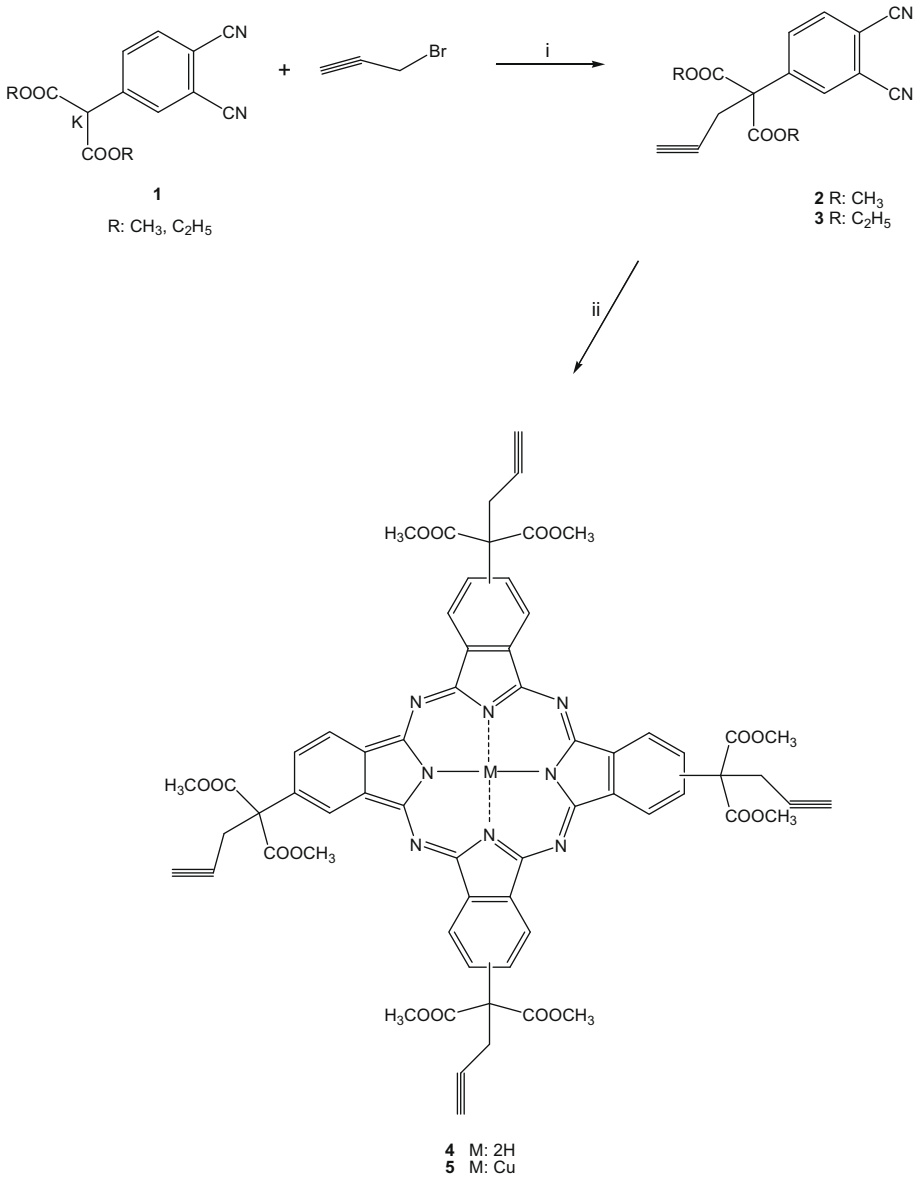
The pyridine group provides the shortest bond to the metal, Zn(1)–N(1) 2.157(8) Å, while the longest belongs to the piperazine nitrogen atoms, Zn(1)–N(3) 2.230(8) and Zn(1)–N(4) 2.379(9) Å. The Zn–N_{imine} bond lengths, Zn(1)–N(2) 2.261(8) and Zn(1)–N(5) 2.183(8) Å show intermediate values. The Zn(1)–Br(1) bond distance of 2.381 Å, is longer than the distance found for this sort of bond in similar complexes [20,21]. The perchlorate ion giving typical bond distances and angles, and the structure shows that it is not coordinated to the Zn(II) ion reflecting the low coordination ability of this anion. Some intermolecular π,π-stacking interactions have been observed between the pyridine rings of adjacent ligands (See Fig. 3). In the net, the pyridine rings lie parallel by pairs, being the distance between the planes containing the rings of 3.33 Å. The distance between centroids (d_{c-c}) is 3.51 Å gives rise to a slipped angle of 18.4°.

4. Conclusion

The template Zn(II) synthesis of the Schiff-base macrocyclic complexes $[ZnL^n]^{2+}$ (n = 1 and 2) prepared from [1 + 1] cyclocondensation of 2,6-diacetylpyridine and N,N′-bis(3-aminopropyl)piperazine or N,N′(2-aminoethyl)(3-aminopropyl)piperazine have been investigated. The crystal structure of $[ZnL^1Br]ClO_4$

shows the metal ion hexacoordinated in a N5Br distorted pentagonal-pyramidal geometry, with the nitrogen atoms from the macrocycle in the pentagonal plane and the bromide ion occupying the axial position.

5. Supplementary data



CCDC 699403 contains the supplementary crystallographic data for $[ZnL^1Br]ClO_4$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

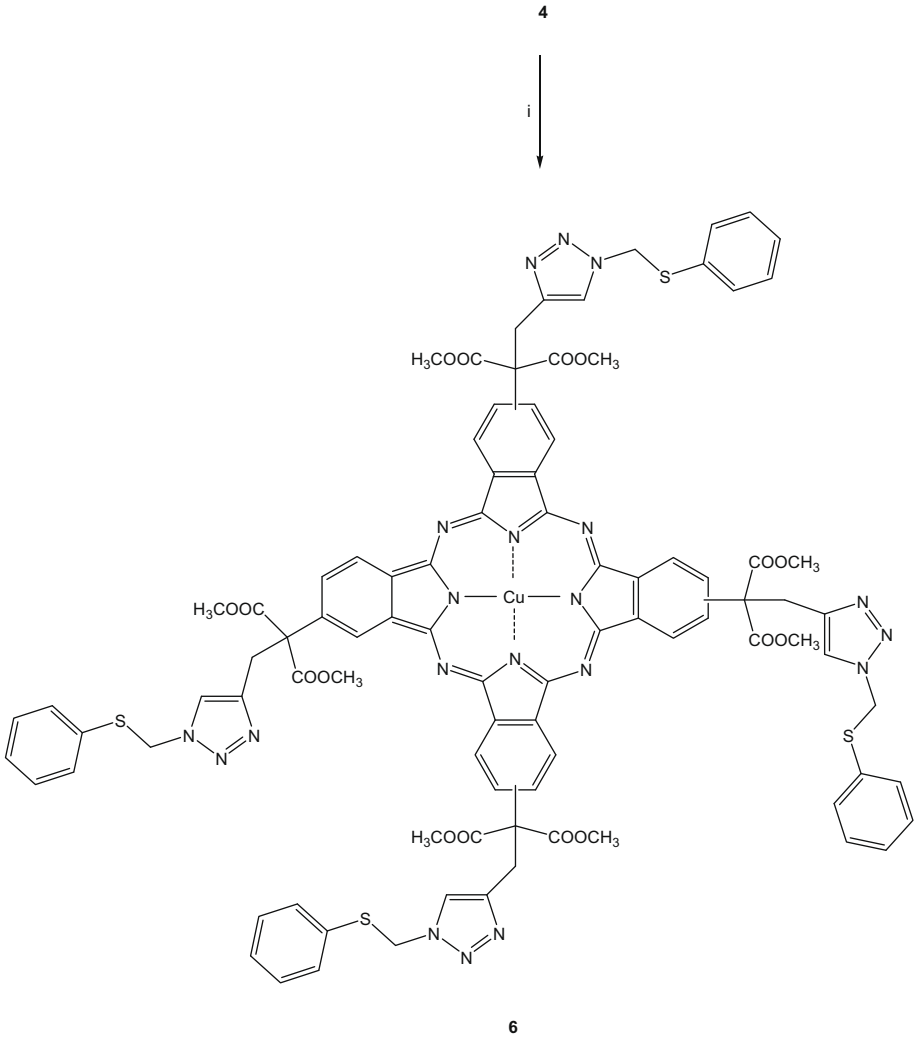
Scheme 1. Reagents and conditions: (i) acetone/acetonitrile, reflux; (ii) *n*-pentanol, DBU, reflux, $CuCl_2$ for **5**.

was also synthesized according to the literature procedure, with some minor modifications [31].

2.1. General procedures for the preparation of dialkyl (3,4-dicyanophenyl)propargylmalonates (**2**, **3**)

To the potassium salt of dialkyl-3,4-dicyanophenylmalonate (3.0 mmol, 0.9 g dimethyl-3,4-dicyanophenylmalonate, 0.97 g diethyl-3,4-dicyanophenylmalonate) in 2:1 acetone/acetonitrile (150 mL) was added propargyl bromide (3.6 mmol, 80% in toluene, 0.54 g). The mixture was boiled for 20 h under Ar and then filtered. The solvent was evaporated under reduced pressure to give an oily residue, which was washed with water until the product was free of KBr and finally crystallized from dichloromethane. These compounds were soluble in acetone, chloroform and THF. **2**. Yield: 0.75 g, 84%. Mp: 90–91 °C. FT-IR ν (cm^{-1}): 3288 (H–C≡C–), 3103–3049 (CH, aromatic), 2957 (CH, aliphatic), 2237 (C≡N), 1753, 1731 (C=O). **3**. Yield: 0.79 g, 81%. Mp: 47 °C. FT-IR ν (cm^{-1}): 3278 (H–C≡C–), 3085 (CH, aromatic), 2979–2940 (CH, aliphatic), 2241 (C≡N), 1753, 1724 (C=O); ^{1}H NMR (DMSO-d_6) δ: 8.19–8.16 (aromatic H), 7.96–7.94 (aromatic H), 4.25–4.19 (OCH_2), 3.26 (CH_2), 2.95–2.94 (H–C≡), 1.19–1.16 (CH_3); ^{13}C NMR ($CDCl_3$) δ: 168.1, 142.2, 134.8, 134.4, 134.3, 116.3, 116.2, 115.1, 114.9, 79.4, 75.7, 63.2, 62.2, 25.5, 14.3; GC–MS *m/z*: 324 $[M]^+$, 252 $[M-COOC_2H_5]^+$, 223 $[M-(C_2H_5+COOC_2H_5)]^+$, 205 $[M-(OC_2H_5+COOC_2H_5)]^+$, 179 $[M-2(COOC_2H_5)]^+$, 152 $[M-(2(COOC_2H_5)+HCN)]^+$, 125 $[M-(2(COOC_2H_5)+2(HCN))]^+$.



2.2. 2,9,17,23-(1,1-(Dimethoxycarbonyl)-2-(ethynyl)ethyl)phthalocyanine (**4**)

A mixture of dinitrile **2** (0.1 g, 0.33 mmol) and a catalytic amount of DBU in *n*-pentanol (1 mL) was heated at 140 °C with stirring for 20 h. After evaporation of the solvent, the residue was purified by column chromatography (SiO_2, chloroform/methanol 100:1). Yield: 0.075 g, 20%. FT-IR ν (cm^{-1}): 3311 (N–H), 3291 (H–C≡C–), 2956–2856 (CH, aliphatic), 2114 (–C≡C–), 1726 (C=O); UV–Vis λ_{max} (nm) in chloroform: 698, 661, 342; MALDI-TOF MS (2,5-dihydroxybenzoic acid or sinapic acid) *m/z*: 1179.6

$[M-6H]^{6-}$, 2358 $2 \times [M-6H]^{6-}$. *Anal.* Calc. for $C_{64}H_{50}N_8O_{16}$: C, 64.75; H, 4.25; N, 9.44. Found: C, 64.63; H, 4.22; N, 9.41%.

2.3. 2,9,17,23-(1,1-(Dimethoxycarbonyl)-2-(ethynyl)ethyl)phthalocyaninatocopper (**5**)

A mixture of dinitrile **2** (0.1 g, 0.33 mmol), $CuCl_2$ (0.011 g, 0.08 mmol) and a catalytic amount of DBU in *n*-pentanol (1 mL) was heated at 140 °C with stirring for 20 h. The reaction mixture was cooled to room temperature. The precipitate was filtered off and washed with methanol. After extraction of the crude product with chloroform, the purification was carried out by column chromatography on silica gel using chloroform/methanol (100:1) as the eluent to afford **5** as a blue solid. Yield: 0.010 g, 10%. FT-IR ν (cm^{-1}): 3285 (H–C≡C–), 2955–2854 (CH, aliphatic), 2121 (–C≡C–), 1726 (C=O); UV–Vis λ_{max} (nm) in chloroform: 677,

Scheme 2. Reagents and conditions: (i) $CuSO_4 \cdot 5H_2O$, NaAsc., THF/H_2O, rt.

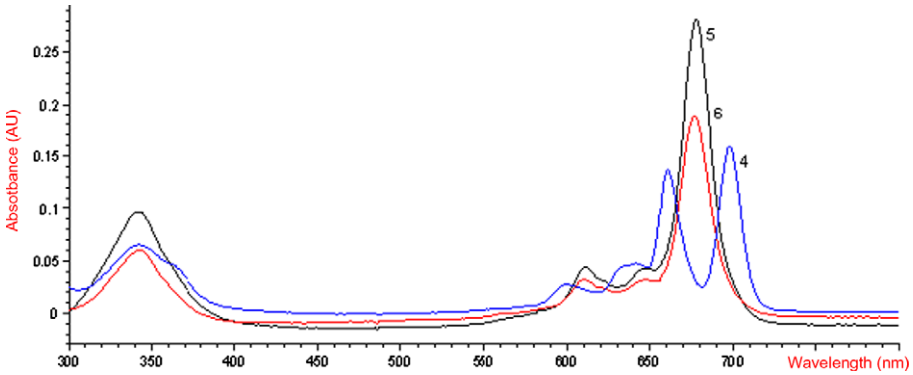


Fig. 1. UV–Vis spectra of **4** (blue line), **5** (black line) and **6** (red line) in chloroform. Concentration: $\sim 10^{-6}$ mol l^{-1}. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

342. *Anal.* Calc. for $C_{64}H_{48}N_8O_{16}Cu$: C, 61.56; H, 3.87; N, 8.97. Found: C, 61.62; H, 3.85; N, 8.93%.

2.4. Preparation of **6** using click chemistry

A mixture of **4** (0.025 g, 0.015 mmol), azidomethyl phenyl sulfide (0.0084 mL, 0.06 mmol), $CuSO_4.5H_2O$ (0.015 g, 0.06 mmol) and sodium ascorbate (0.012 g, 0.06 mmol) were dissolved in 4 mL of THF/H_2O (1:1). The mixture was stirred at room temperature for 24 h under Ar. The solvent was removed under reduced pressure, and the residue was taken up in dichloromethane, washed with water and dried over Na_2SO_4. After the filtration and evaporation of the solvent, the product was washed with methanol to remove unreacted azidomethyl phenyl sulfide. Yield: 0.022 g, 51%. FT-IR ν (cm^{-1}): 3137–3055 (CH, aromatic), 2954–2858 (CH, aliphatic), 1724 (C=O); UV–Vis λ_{max} (nm) in chloroform: 678, 342; MALDI-TOF MS (2,5-dihydroxybenzoic acid) *m/z*: 1901.8 $[M-6H]^{6-}$. *Anal.* Calc. for $C_{92}H_{76}N_{20}O_{16}S_4Cu$: C, 57.87; H, 4.01; N, 14.67. Found: C, 57.93; H, 3.99; N, 14.68%.

3. Results and discussion

The novel phthalocyanines bearing a terminal alkyne moiety were prepared in two steps. First the dialkyl (3,4-dicyano-

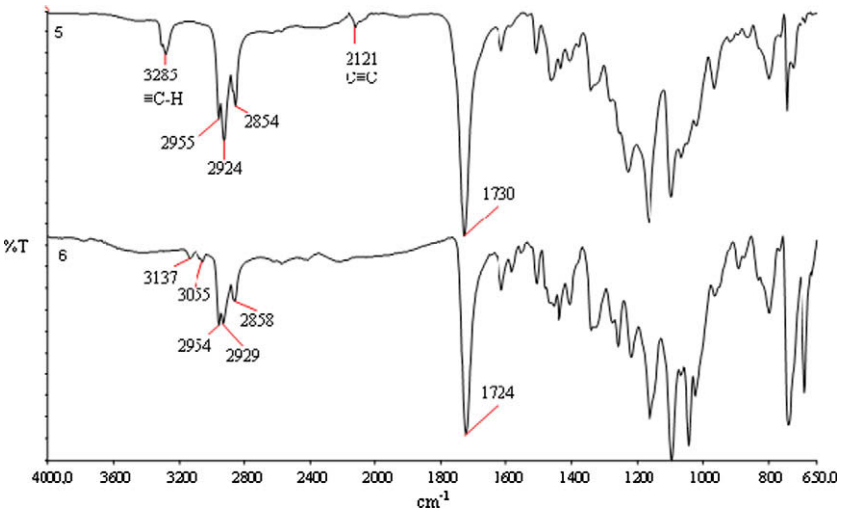

Fig. 2. FT-IR spectra of **5** and **6**.

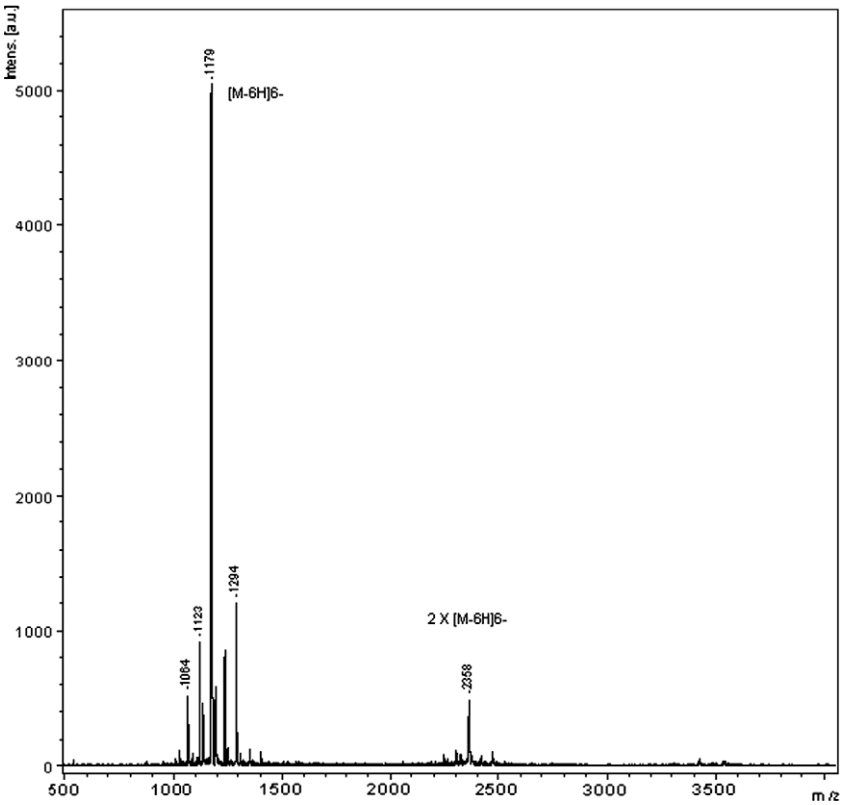

Fig. 3. MALDI-TOF MS spectrum of **4**.

phenyl)propargylmalonates **2**, **3** were synthesized by coupling the potassium salts of dialkyl-3,4-dicyanophenylmalonates **1** with propargyl bromide in acetone/acetonitrile (2:1) at reflux temperature. Then, phthalocyanines **4** and **5** were prepared by the standard method of cyclotetramerization of dialkyl (3,4-dicyanophenyl) propargylmalonates in the presence of DBU in pentanol for 20 h; anhydrous $CuCl_2$ was added when a copper phthalocyanine was desired (Scheme 1). Some difficulties were encountered in trying to obtain copper phthalocyanine (**5**). When the cyclotetramerization reaction was carried out in the presence of anhydrous $CuCl_2$, insoluble polymeric species were obtained with the metallophthalocyanine. The desired product **5** was separated from insoluble polymeric material by extraction with chloroform. The products **4** and **5** were purified by column chromatography using silica gel as the stationary phase and chloroform–methanol (100:1) mixtures as the eluent. The 1,3-dipolar cycloaddition of compound **4** with azidomethyl phenyl sulfide was carried out in THF/H_2O at room temperature using $CuSO_4{\cdot}5H_2O$ as a catalyst and sodium ascorbate as the reducing agent (Scheme 2). Under these reaction conditions, metallation of **4** was also observed (Fig. 1). As a natural consequence of the single substituent on each benzo group, the phthalocyanines (**4**–**6**) are all a mixture of constitutional isomers. Attempts were made to separate each of them by HPLC, but the isomers did not separate [18]. The blue products are easily soluble in a number of solvents, such as chloroform, dichloromethane, THF, acetone, CCl_4. In addition, 1,2,3-triazole-substituted phthalocyanine (**6**) is soluble in DMF as a different solvent.

The structures of the novel compounds were confirmed by elemental analysis together with FT-IR, ^{1}H NMR, ^{13}C NMR, UV–Vis and MS spectroscopic techniques. In the FT-IR spectra of the alkynyl-substituted phthalocyanines, the click functionality propargyl group was evidenced by characteristic bands of H–C≡C– and –C≡C– appearing at 3285 cm^{-1} and 2121 cm^{-1}, respectively. After the click reaction, the characteristic bands of the propargyl group disappeared completely and also the aromatic CH stretchings from the triazole and benzene rings appeared at 3137 and 3055 cm^{-1}, respectively (Fig. 2). The MALDI-TOF MS spectrum of the free-base Pc is especially interesting. The MALDI-TOF mass spectrometry (MS) experiment showed a main peak at *m/z* 1179 which was attributed $[M-6H]^{6-}$. This experiment also showed a peak at *m/z* 2358 which was due to supramolecular association of two molecules of the metal-free phthalocyanine **4** (Fig. 3). In the MALDI-TOF MS spectrum, we observed the $[M-6H]^{6-}$ peak at *m/z* 1901.8 for **6** (Fig. 4). In the ^{1}H NMR spectrum of compound **4**, as a consequence of the presence of four constitutional isomers and supramolecular association, the signals are broad and uninformative. Nevertheless, the integration values of the various assignable signals are consistent with the expected values. The paramagnetic nature of copper(II) phthalocyanines (**5** and **6**) precluded NMR measurements on these compounds [32].

The phthalocyanines display typical electronic spectra with two strong absorption regions, one of them in the UV region at about 300–350 nm (B band) and the other one in the visible region at 600–700 nm (Q band). All the metallophthalocyanines (**4**–**6**) exhi-

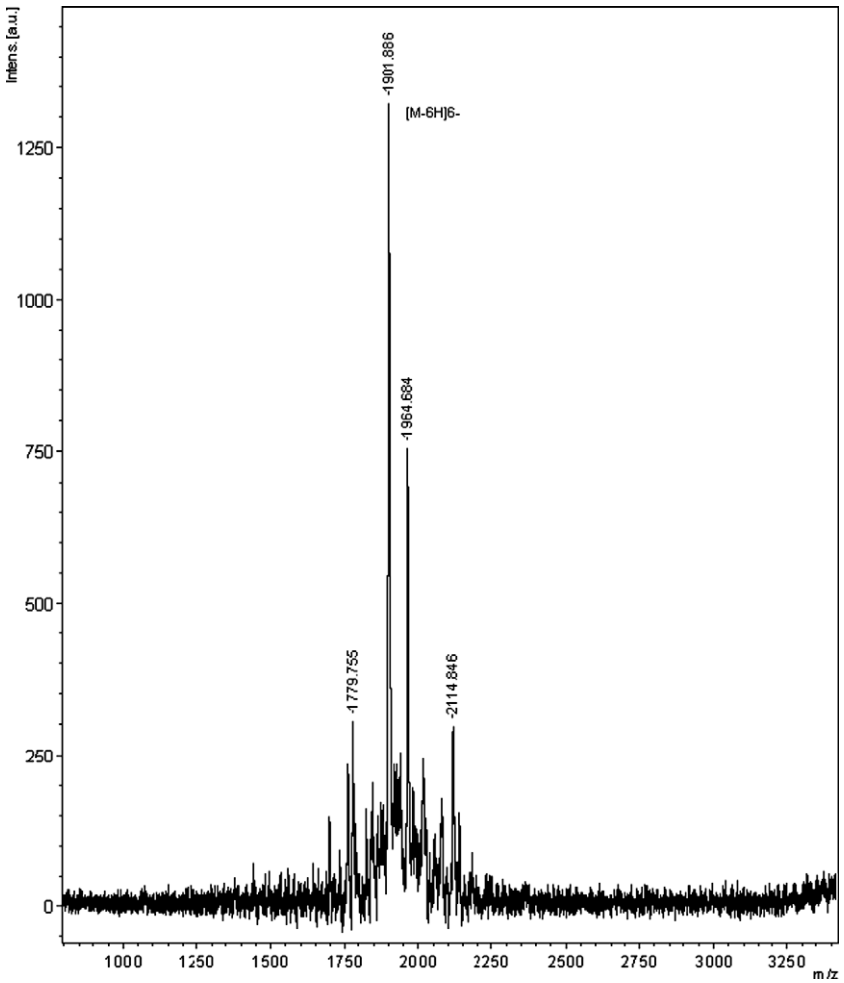

Fig. 4. MALDI-TOF MS spectrum of **6**.

bit intense Q bands around 675–680 nm with a relatively sharp absorption peak and almost no shoulder on the higher energy side, which would correspond to aggregated species [16]. The spectrum of compound **4**, is somewhat different from those of **5** and **6**, with a split Q band (661 and 698 nm) indicating lower symmetry (D_{2h}) of the metal-free derivative (Fig. 1).

In summary, we have synthesized alkynyl-substituted phthalocyanines without protective/deprotective chemistry. In addition, we have applied click chemistry to the synthesis of soluble tetratriazole-functionalized phthalocyanines. Further studies on the click reaction of **4** with functional azides are currently in progress.

pyrazine, 4,4′-bipyridine, 1,2-bis(4-pyridyl)ethane and 1,2-bis(4-pyridyl)- ethelene. We report the synthesis, structural and spectroscopic studies of the pentanuclear complexes $[Zn_5(bta)_6(acac)_4(dmf)]\cdot dmf$ (**1**·dmf) and $[Zn_5(bta)_6(acac)_4(dmf)]\cdot 3.7dmf$ (**2**·3.7dmf), the enneanuclear complex $[Zn_9(bta)_{12}(acac)_6]\cdot 6dmf$ (**3**·6dmf), and the 1D coordination polymer $[Zn(acac)_2(4,4'\text{-bpy})]_n$ (**4**).

2. Experimental

2.1. General and spectroscopic measurements

All manipulations were performed under aerobic conditions using materials as received (Aldrich Co). All chemicals and solvents were of reagent grade. Elemental analyses for C, H and N were performed on a Perkin Elmer 2400/*II* automatic analyzer. IR spectra were recorded from KBr pellets in the range 4000–400 cm^{-1} on a Bruker Equinox 55/S FT-IR spectrometer.

2.2. Compound preparation

2.2.1. $[Zn_5(bta)_6(acac)_4(dmf)]\cdot dmf$ (**1**·dmf)

A colourless solution of btaH (0.467 g, 4.00 mmol) in dmf (25 mL) was stirred under heating at ~100 °C until solid $Zn(acac)_2$ (0.527 g, 2.00 mmol) was added. The heating immediately turned off and the stirring continued for 10 min. The final colourless solution left for slow evaporation at room temperature and afforded colourless X-ray quality crystals of **1**·dmf after 4 days (Yield: 0.50 g, 80%). The crystals were collected by filtration and dried in air. *Anal.* Calc. for (**1**·dmf) ($C_{62}H_{66}N_{20}O_{10}Zn_5$, fw = 1578.20): C, 47.18; H, 4.22; N, 17.75. Found: C, 47.03; H, 4.24; N, 17.69%. FT-IR (cm^{-1}, KBr pellets): 3432br, 3073m, 3055m, 3025w, 2992w, 2955w, 2922m, 2849m, 1679vs, 1600vs, 1515vs, 1494m, 1451s, 1442s, 1393vs, 1363sh, 1296w, 1275sh, 1260s, 1226m, 1193vs, 1172sh, 1159m, 1147sh, 1129m, 1086m, 1062w, 1013m, 995m, 922s, 846m, 786vs, 752vs, 695m, 640s, 555vs, 430m, 406m.

2.2.2. $[Zn_5(bta)_6(acac)_4(dmf)]\cdot 3.7dmf$ (**2**·3.7dmf)

Solid **1**·dmf (0.158 g, 0.10 mmol) was added to a colourless solution of pyrazin (0.024 g, 0.30 mmol) in dmf (12 mL) and the resultant suspension was refluxed for 30 min. The final colourless solution was filtered and left for slow evaporation at −4 °C. Colourless X-ray quality crystals of **2**·3.7dmf were obtained after 4 days (Yield: 0.10 g, ~60%). The crystals were collected by filtration and dried in air. The resulting powder was analysed as **2**·3dmf. *Anal.* Calc. for (**2**·3dmf) ($C_{68}H_{80}N_{22}O_{12}Zn_5$, fw = 1724.43): C, 47.36; H, 4.68; N, 17.87. Found: C, 47.22; H, 4.70; N, 17.81%. FT-IR (cm^{-1}, KBr pellets): 3438br, 3071m, 3053m, 3020w, 2995w, 2953w, 2920m, 2845m, 1678vs, 1600vs, 1516vs, 1493m, 1449s, 1440s, 1394vs, 1361sh, 1297w, 1277sh, 1259s, 1224m, 1192vs, 1174sh, 1160m, 1148sh, 1130m, 1085m, 1060w, 1012m, 997m, 923s, 845m, 784vs, 752vs, 693m, 641s, 555vs, 432m, 408m.

2.2.3. $[Zn_9(bta)_{12}(acac)_6]\cdot 6dmf$ (**3**·6dmf)

2.2.3.1. Method A. A colourless solution of btaH (0.260 g, 2.18 mmol) and pyrazine (0.052 g, 0.65 mmol) in dmf (25 mL) was stirred under heating at ~100 °C until solid $Zn(acac)_2$ (0.287 g, 1.09 mmol) was added. The heating immediately turned off and the stirring continued for 10 min. The final colourless solution left for slow evaporation at room temperature and afforded colourless X-ray quality crystals of **3**·6dmf after 4 days (Yield: 0.22 g, ~60%). The crystals were collected by filtration and dried in air. *Anal.* Calc. for (**3**·6dmf) ($C_{120}H_{132}N_{42}O_{18}Zn_9$, fw = 3039.06): C, 47.43; H, 4.38; N, 19.36. Found: C, 47.29; H, 4.40; N, 19.30%. FT-IR (cm^{-1}, KBr pellets): 3435br, 3073m, 3055m, 3025w, 2992w, 2958w, 2919m, 2849m, 1679vs, 1600vs, 1515vs, 1494m, 1448s, 1393vs, 1363sh, 1299w, 1260s, 1223m, 1193vs, 1163sh, 1150sh, 1129m, 1089m, 1019s, 995s, 922s, 846m, 786vs, 749vs, 695m, 640s, 555vs, 430m, 409m

2.2.3.2. Method B. Solid **1**·dmf (0.158 g, 0.10 mmol) was dissolved under reflux in dmf (15 mL). The resultant colourless solution was filtered off and left for slow evaporation at room temperature. Colourless X-ray quality crystals of **3**·6dmf were obtained after 10 days. The identity of the crystals was confirmed by unit cell determination (a = 26.40(3), b = 15.89(1), c = 32.41(3) Å, β = 91.22(3) o, see Table 1).

2.2.4. $[Zn(acac)_2(4,4'\text{-bpy})]_n$ (**4**)

A colourless solution of btaH (0.260 g, 2.18 mmol) in dmf (5 mL) was added to a colourless solution of $Zn(acac)_2$ (0.287 g, 1.09 mmol) in dmf (15 mL). A colourless solution of 4,4′-bpy (0.102 g, 0.65 mmol) in dmf (5 mL) was finally added. The final colourless solution was stirred for 10 min and filtered off. X-ray quality crystals of **4** were formed in closed vials at −4 °C after 8 days (Yield: 0.30 g, ~65%). The crystals were collected by filtration and dried in air. *Anal.* Calc. for (**4**) ($C_{20}H_{22}N_2O_4Zn$, fw = 419.77): C, 57.22; H, 5.28; N, 6.67. Found: C, 57.02; H, 5.32; N, 6.63%. FT-IR (cm^{-1}, KBr pellets): 3423br, 3052m, 3003w, 2958w, 2909w, 1597vs, 1536s, 1512vs, 1460s, 1402vs, 1256s, 1220s, 1193m, 1080m, 1044w, 1005s, 919s, 865m, 825s, 761s, 737w, 667w, 652m, 625s, 573m, 552s, 509s, 412s.

Slow evaporation of the final reaction solution at room temperature afforded plate-like crystals of **3**·6dmf and needle-like crystals of **4** after 10 days. The identity of the plate-like crystals was confirmed by unit cell determination (a = 26.43(2), b = 15.93(1), c = 32.52(2) Å, β = 91.36(4)°, see Table 1), and those of the needle-like crystals by infrared spectroscopy.

2.3. Single-crystal X-ray crystallography

Colourless prismatic crystals of **1**·dmf, **2**·3.7dmf, **3**·6dmf and **4** were mounted in capillaries. Diffraction measurements were made on a Rigaku R-AXIS SPIDER Image Plate diffractometer using graphite monochromated Cu Kα (for **1**·dmf and **2**·3.7dmf) and Mo Kα (for **3**·6dmf) radiation. Data collection (ω-scans) and processing (cell refinement, data reduction and Empirical absorption correction) were performed using the CRYSTALCLEAR program package [8]. Diffraction measurements for **4** were made on a Crystal Logic Dual Goniometer diffractometer using graphite monochromated Mo Kα radiation. Unit cell dimensions were determined and refined by using the angular settings of 25 automatically centred reflections in the range $11 < 2\theta < 23°$. Intensity data were recorded using a θ–2θ scan. Three standard reflections monitored every 97 reflections showed less than 3% variation and no decay. Lorentz, polarisation corrections were applied using Crystal Logic software. Important crystal data and parameters for data collection are reported in Table 1. The structures were solved by direct methods using SHELXS-97 [9] and refined by full matrix least-squares techniques on F^2 with SHELXL-97 [10]. Further experimental crystallographic details for **1**·dmf: 2θmax = 130°; reflections collected/unique/used, 48 898/11 716 [R_{int} = 0.0273]/11 716; 1007 parameters refined; $(\Delta/\sigma)_{max}$ = 0.003; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 0.365/−0.366 e/Å^3; R/R_w (for all data), 0.0386/0.0895. Hydrogen atoms of the methyl groups were introduced at calculated positions as riding on bonded atoms, the rest H-atoms were located by difference maps and were refined isotropically. All non-H atoms were refined anisotropically. Further experimental crystallographic details for **2**·3.7dmf: 2θmax = 130°; reflections collected/unique/used, 78 273/14 898 [R_{int} = 0.0333]/14 898; 1027 parameters refined; $(\Delta/\sigma)_{max}$ = 0.004; $(\Delta\rho)_{max}/(\Delta\rho)_{min}$ = 1.214/−0.928 e/Å^3; R/R_w (for

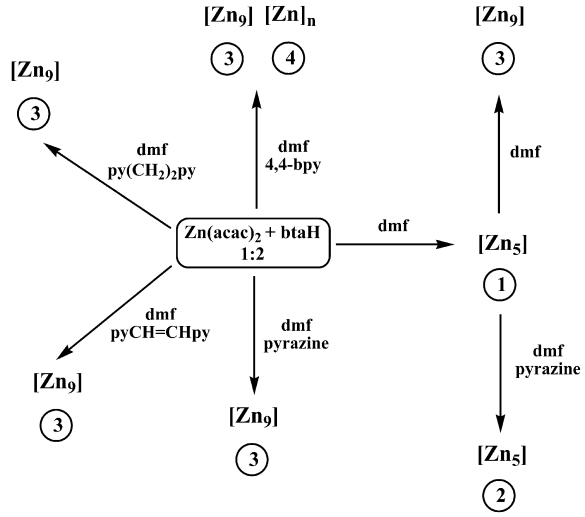
Hydrogen atoms were introduced at calculated positions as riding on bonded atoms. All non-H atoms were refined anisotropically. Plots of all structures were drawn using the Diamond 3.1 application [11].



3. Results and discussion

3.1. Syntheses

The reaction of one equivalent of $Zn(acac)_2$ with two equivalents of btaH in dmf afforded a colourless solution which left for slow evaporation. X-ray quality colourless crystals of **1**·dmf were formed after *ca* 4 days (Scheme 1). The chemically balanced equation for the synthesis of **1**·dmf is given below:

$$5Zn(acac)_2 + 6btaH + 2dmf \xrightarrow{dmf} [Zn_5(bta)_6(acac)_4(dmf)] \cdot dmf + 6acacH \quad (1)$$

The molecular structure of **1**·dmf (vide infra), shows that the four peripheral Zn^{II} ions have vacant coordination sites or contain coordinatively labile dmf molecules, which could be completed and/or replaced by neutral ligands. In the particular case of neutral bridging ligands, this approach could be applied for the synthesis of coordination polymers based on $[Zn_5]$ clusters. With this consideration in mind, we have performed the reaction of one equivalent of **1**·dmf with three equivalents of pyrazine in dmf. The colourless solution was refluxed for 30 min, filtered off and left for slow evaporation to yield X-ray quality crystals of **2**·3.7dmf after *ca* 4 days

Scheme 1. The reaction pathways discussed in the text.

(Scheme 1). The molecular structure of **2**·3.7dmf (vide infra) shows that it consists of a $[Zn_5]$ cluster analogous to **1**·dmf; the only difference is the crystallization solvent molecules.

In a subsequent step, we applied a different synthetic approach in order to obtain coordination polymers based on zinc clusters. According to this approach, it was attempted the in situ synthesis of the $[Zn_5]$ clusters in the presence of pyrazine. The reaction of one equivalent of $Zn(acac)_2$ with two equivalents of btaH and 0.6 equivalents of pyrazine in dmf gave a colourless solution. Slow evaporation of the final colourless solution afforded X-ray quality crystals of **3**·6dmf after *ca* 4 days (see Method A in the Experimental Section; Scheme 1). The chemically balanced equation for the synthesis of **3**·6dmf is given below:

$$9Zn(acac)_2 + 12btaH + 6dmf \xrightarrow{dmf} [Zn_9(bta)_{12}(acac)_6] \cdot 6dmf + 12acacH \quad (2)$$

The molecular structure of **3**·6dmf (vide infra) shows that: (i) it does not contain pyrazine and (ii) it consists of $[Zn_9]$ clusters which can be derived from the association of two $[Zn_5]$ clusters followed by abstraction of $Zn(acac)_2$. This alternative was realised by recrys-

tallization of **1**·dmf from dmf. The resultant colourless solution was filtered off and left for slow evaporation. X-ray quality crystals of **3**·6dmf were formed after *ca* 10 days (see Method B in the Experimental Section; Scheme 1). The identity of the crystals was confirmed by unit cell determination. The chemically balanced equation for the synthesis of **3**·6dmf is given below:

$$2[Zn_5(bta)_6(acac)_4(dmf)] \overset{dmf}{\rightarrow} [Zn_9(bta)_{12}(acac)_6] + Zn(acac)_2 + 2dmf \quad (3)$$

In order to explore to what extend the nature of the neutral bridging ligand might affect the preparation of coordination polymers based on $[Zn_5]$ clusters, we performed the reaction of one equivalent of $Zn(acac)_2$ with two equivalents of btaH and 0.6 equivalents of 4,4′-bpy in dmf (Scheme 1). The colourless reaction solution was stirred for 10 min and filtered off. Slow evaporation at room temperature afforded a mixture of plate-like crystals of **3**·6dmf and needle-like crystals of **4**, whereas in closed vials at −4 °C only crystals of **4** were formed. The simultaneous isolation of **3**·6dmf and **4** is indicative of the chemical equilibria in solution and is usually observed in metal ions/ligands reaction mixtures, from which a multitude of products can be isolated due to the labile nature of the coordination bonds and the presence of weak bonding interactions (H-bonds, π–π stacking, etc.). Moreover, the isolation of **3**·6dmf and **4** in mixture, and pure **4**, is indicative of the influence of crystallization methods to the chemical and structural identity of the products from a given reaction system. The chemically balanced equation for the synthesis of **4** is given below:

$$nZn(acac)_2 + n4,4'\text{-bpy} \overset{dmf}{\rightarrow} [Zn(acac)_2(4,4'\text{-bpy})]_n \quad (4)$$

Analogous reactions as the above introducing 1,2-bis(4-pyridyl)ethane and 1,2-bis(4-pyridyl)ethelene also afforded **3**·6dmf from slow evaporation at room temperature (these procedures are not described in the experimental section; Scheme 1).

3.2. Description of structures

The molecular structures of **1**·dmf and **2**·3.7dmf are similar; they differ only in the crystallization dmf molecules, thus only one structure will be described. The structure of **1**·dmf is given in Fig. 1, selected bond distances and angles are listed in Table S1. The complex consists of five Zn^{II} ions, four of which span the corners of a tetrahedron and the fifth lies at its centre. The edges of the tetrahedron fall in the range 5.923–6.064 Å, and the central Zn^{II} lies at 3.616–3.752 Å from the peripheral ones. The central Zn^{II} ion is octahedrally coordinated to six nitrogen atoms from six different bta^- ligands. One of the peripheral Zn^{II} ions possesses distorted octahedral coordination environment comprised by three nitrogen atoms from three different bta^- ligands, and three oxygen atoms, two from a chelating $acac^-$ ligand and one from a coordinated dmf molecule. The rest peripheral Zn^{II} ions adopt a square pyramidal coordination geometry comprised by three nitrogen atoms from three different bta^- ligands and two oxygen atoms from a chelating $acac^-$ ligand. Each μ_3-κ*N*:κN′κN″ bta^- ligand bridges three Zn^{II} ions; two peripheral ones and the central metal ion. The Zn–N and Zn–O bond distances range from 2.018(2)–2.248(2) Å to 1.946(2)–2.243(2) Å, respectively. Compound **1**·dmf is analogous to $[Cu_5(bta)_6(acac)_4]$ [12], $[Cu_5(bta)_6L_4]$ (L = β-diketonates) [13], $[M^{II}Zn_4(L)_6(L')_4]$ (M^{II} = Co, Zn; L = 1,2,3-benzotriazolate derivatives; L′ = Cl^-, $acac^-$) [14] and $[Ni_5(5Mebta)_6(dbm)_4(Me_2CO)_4]$ (5MebtaH = 5-methyl-1,2,3-benzotriazole, dbmH = dibenzoylmethane) [15].

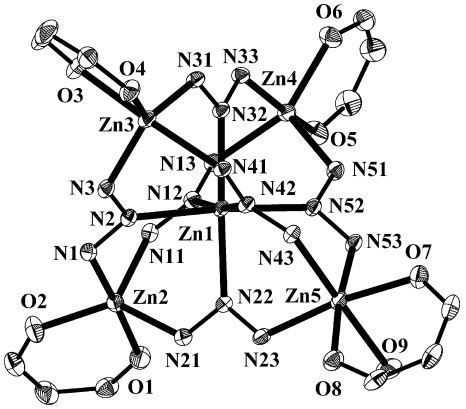


Fig. 1. Partially labelled plot of **1** at 30% thermal probability ellipsoids. The benzene ring of the bta^- ligands, the methyl groups of the $acac^-$ ligands and all hydrogen atoms have been omitted for clarity.

The molecular structure of **3**·6dmf is given in Fig. 2, selected bond distances and angles are listed in Table S2. The complex consists of nine Zn^{II} ions, seven of which reside at the corners of two corner sharing tetrahedra and each of the remaining two lies at the centre of each tetrahedron. The common Zn^{II} ion of the two tetrahedra resides on an inversion centre. The edges of the two tetrahedra fall in the range 5.978–6.066 Å, whereas each of the central Zn^{II} lies at 3.614–3.819 Å from the peripheral ones. The seven peripheral Zn^{II} ions are coordinated to three nitrogen atoms from three different bta^- ligands and two oxygen atoms from a chelating $acac^-$ ligand, thus describing a square pyramidal coordination geometry. The central Zn^{II} ions are coordinated to six nitrogen atoms form six different bta^- ligands thus adopting a distorted octahedral coordination environment. Each μ_3-κ*N*:κN′:κN″ bta^- ligand bridges three Zn^{II} ions; two peripheral ones and the central Zn^{II} of each tetrahedron. The structure of each of the two tetrahedra is similar to the structure of the tetrahedra in **1**·dmf; the structure of **3**·6dmf can be described as derived from the addition of two tetrahedra of **1**·dmf followed by the simultaneous abstraction of two $acac^-$ ligands, two dmf molecules and a Zn^{II} ion. The Zn–N and Zn–O bond distances range from 1.998(4)–2.224(4) Å to 1.943(3)–2.104(4) Å, respectively. Compound **3**·6dmf is analogous to $[Ni_9(5,6Mebta)_{12}(bzac)_6(MeOH)_6]$ (5,6MebtaH = 5,6-dimethyl-1,2,3-benzotriazole, bzacH = benzoylacetone) [15].

A small fragment of the molecular structure of **4** is shown in Fig. 3, selected bond distances and angles are listed in Table S3. The structure consists of $[Zn(acac)_2]$ mononuclear units assembled

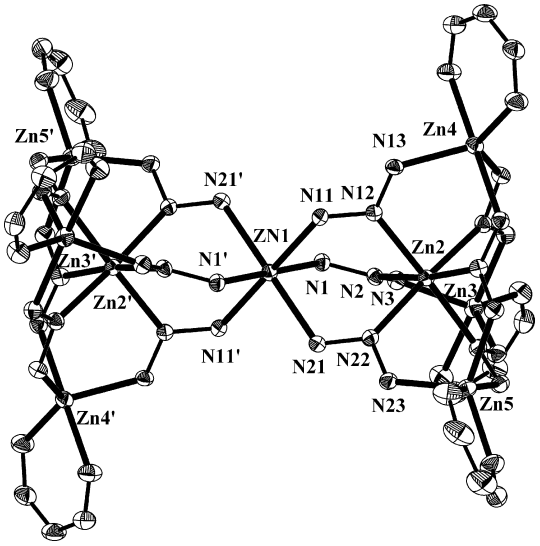

Fig. 2. Partially labelled plot of **3** at 30% thermal probability ellipsoids. The benzene ring of the bta^- ligands, the methyl groups of the $acac^-$ ligands and all hydrogen atoms have been omitted for clarity. Symmetry operations to generate equivalent atoms: (′) = 0.5−*x*, 0.5−*y*, −*z*.

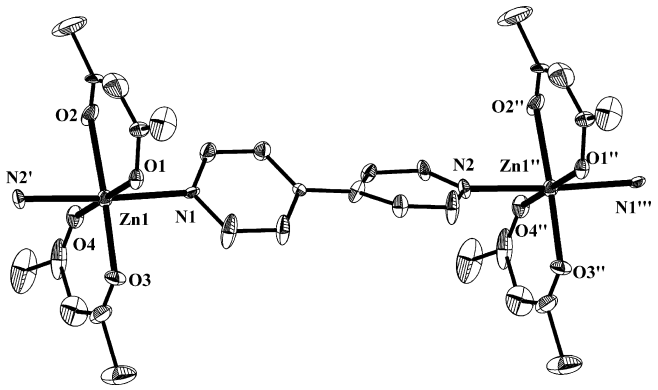

Fig. 3. Partially labelled plot of a small fragment of **4** at 30% thermal probability ellipsoids. Symmetry operations to generate equivalent atoms: (') = $-1 + x, y, 1 + z$; ('') = $1 + x, y, -1 + z$; (''') = $1 + x, y, -1 + z$.

via bridges of 4,4′-bpy in one dimensional polymer. The aromatic rings of the bridging 4,4′-bpy are twisted to each other forming an angle of 32.5° between the respective mean planes. The coordination geometry of the Zn^{II} ions is distorted octahedral with the oxygen atoms of the two $acac^-$ ligands defining the equatorial plane and the nitrogen atoms of two 4,4′-bpy ligands in the apical positions. The Zn–O and Zn–N bond distances range from 1.987(10)–2.122(13) Å to 2.245(11)–2.272(12) Å, respectively. The structure of **4** has been previously described in different space group [16]. The molecular structure of **4** is analogous to the structure of $[Zn(hfac)(4,4'\text{-bpy})]_n$ (hfacH = hexafluoroacetylacetone) [17] and to the various solvate forms of $[Zn(dbm)(4,4'\text{-bpy})]_n$ (dbmH = dibenzoylmethane) [18].

3.3. IR spectra

In the spectra of solid btaH the medium intensity bands in the region 3090–3040 cm^{-1} are attributed to ν(CH) stretching vibrations, and the strong bands in the region 1620–1380 cm^{-1} are attributed to benzene (ν(C=C), ν(N=N), ν(C=N)) and triazole ring stretching vibrations [19]. The bending and breathing vibrations of the benzene and triazole rings are observed as weak and medium intensity bands in the region 1380–1090 cm^{-1} [19]. In the spectra of **1**–**3** the ν(CH) stretching vibrations of the benzotriazolato ligands are observed in the region 3073–3020 cm^{-1}. A series of strong bands in the region 1600–1400 cm^{-1} is found in the spectra of **1**–**3**. Contributions from benzotriazolate ν(C⋯C), ν(N⋯N) and ν(C⋯N) vibrations would be expected in this region [20], but overlap with the $\nu(C\cdots C)_{acac}$ and $\nu(C\cdots O)_{acac}$ bands renders assignments difficult [21]. The presence of coordinated and/or solvate dmf molecules in **1**–**3** is manifested by a strong band at ~1680 cm^{-1} and a medium intensity band at 1494 cm^{-1}, assigned to ν(C=O) and ν(C–N), respectively [22]. In the spectra of **4**, in the region 1600–1400 cm^{-1}, a set of strong bands is attributed to the ν(C⋯C) and ν(C⋯N) bands of the 4,4′-bpy. These bands, also observed in the spectra of free 4,4′-bpy, are sensitive to chelation [23], but overlap with the $\nu(C\cdots C)_{acac}$ and $\nu(C\cdots O)_{acac}$ bands renders assignments difficult. The characteristic bands of the C–H out-of-plane deformations, which appear as a strong band at 757 cm^{-1} and a weak satellite at 735 cm^{-1} in the spectra of free 4,4′-bpy, upon chelation appear as a strong band at 761 cm^{-1} and a weak band at 737 cm^{-1}.

4. Concluding comments and perspectives

Pentanuclear and enneanuclear Zn^{II} clusters, i.e. $[Zn_5(bta)_6(acac)_4(dmf)]\cdot dmf$ (**1**·dmf), $[Zn_5(bta)_6(acac)_4(dmf)]\cdot 3.7dmf$ (**2**·3.7dmf) and $[Zn_9(bta)_{12}(acac)_6]\cdot 6dmf$ (**3**·6dmf), as well as the 1D coordination polymer $[Zn(acac)_2(4,4'\text{-bpy})]_n$ (**4**) were prepared from the $Zn(acac)_2$/btaH reaction system in dmf in the presence or absence of neutral bridging *N*,*N*′-ligands. Recrystallization of **1**·dmf from dmf yielded **3**·6dmf, which can be prepared also from the $Zn(acac)_2$/btaH reaction system in dmf in the presence of pyrazine, 4,4′-bpy, 1,2-bis(4-pyridyl)ethane, and 1,2-bis(4-pyridyl)ethelene. The isolation of **3**·6dmf from various reaction mixtures is indicative of the thermodynamic and/or kinetic stability of the complex. In the case of 4,4′-bpy containing reaction mixtures, the 1D coordination polymer **4** is also formed, either in mixture with **3**·6dmf or in pure form.

Concerning the anticorrosion action of benzotriazole and its derivatives towards certain metals, there are still open matters that need to be elucidated. Coordination chemistry can be used to probe several aspects of corrosion inhibitors such as the bonding of inhibitor molecules on the metal surfaces, the structure of the surface polymeric complexes, the orientation of inhibitors with different functional groups, intramolecular rearrangements, etc. Chemical, physical and structural studies on realistic model complexes, such as **1**·dmf, **2**·3.7dmf and **3**·6dmf, are needed to understand the complex surface chemistry that leads to corrosion inhibition and to create new inhibitors even more efficient than benzotriazole. Studies of the inhibition of zinc corrosion by various triazole derivatives, including benzotriazole, with respect to dependence on pH, potential and other factors, have shown the presence of zinc triazole complex on the zinc surface by XPS spectroscopy [24]. Electrochemical studies of the corrosion inhibition of benzotriazole on brass have shown that the addition of the latter enhances ZnO film formation and insoluble Cu^I/bta film complex on the surface of Cu^I/oxides and Cu^{II}/hydroxides film [25].

From the chemical and structural point of view, compounds **1**·dmf, **2**·3.7dmf and **3**·6dmf represent new members of the family of 3D clusters bearing benzotriazole and its substituted derivatives as ligand. The molecular structures of **1**·dmf, **2**·3.7dmf and **3**·6dmf reveal that the peripheral Zn^{II} ions have vacant coordination sites or contain labile solvate molecules. These sites can be easily modified by the coordination of bridging ligands (spacers); partial or total occupation of these (in)complete sites would increase the nuclearity and/or dimensionality of the complexes. The tetrahedral topology of the Zn^{II} ions in the present complexes, along with coordination completeness is beneficial for the synthesis of porous three dimensional materials (metal–organic frameworks) based on $[Zn_5]$ and $[Zn_9]$ clusters (nodes). On the other hand, the modification of **1**·dmf, **2**·3.7dmf and **3**·6dmf by other β-diketonates and/or benzotriazole derivatives would lead to families of $[Zn_5]$ and $[Zn_9]$ clusters-nodes for the development of polymeric materials with different internal surface environments. These matters are currently under investigation in our lab.

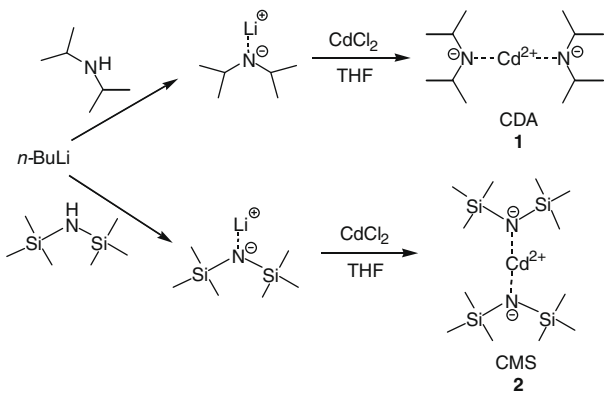
For primary aliphatic amines as nucleophiles and hexachlorine-containing clathrochelate iron and ruthenium(II) precursors only partially substituted complexes (mainly tetrasubstituted products) have been isolated [13,16]. The reactions with low-nucleophilic unsubstituted aromatic amines and the amines with electron-withdrawing substituents gave the mixtures of partially substituted clathrochelate products without a stereoselectivity of the substitution. We tried to use silver(I), copper(I,II), mercury(II) and thalium (I,III) derivatives for the activation of the C–Hal bond as well as the deprotonation of the amino- and oxygen-containing nucleophiles with alkaline and alkaline-earth metal amides and alcoholates [13,15,16]. However, in most cases the nucleophilic substitution in such hard conditions leads to the destruction of the clathrochelate framework. On the other hand, we used successfully the imidazol magnesium derivative for synthesis of the bis-imidazolyl iron(II) clathrochelate [26].

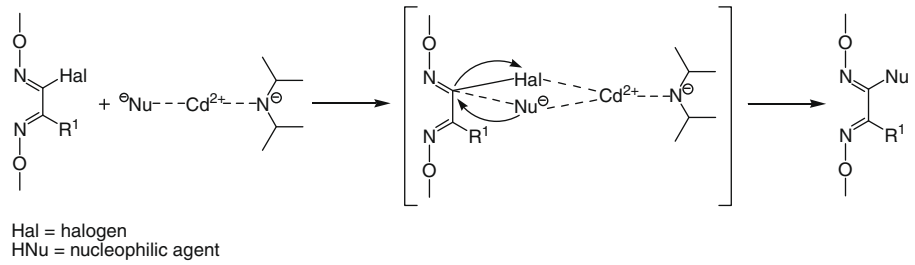


In general, the substitution with soft nucleophilic agents requires an activation of the leaving halogen substituents and an increase of the nucleophilicity of these agents without the use of the strong bases. In this paper, the convenient pathways for ribbed functionalization of the tris-dioximate clathrochelates based on the nucleophilic substitution of the halogen-containing clathrochelate precursors with soft *N*- and *O*-nucleophiles in the presence of cadmium diamides as the promotors are described.

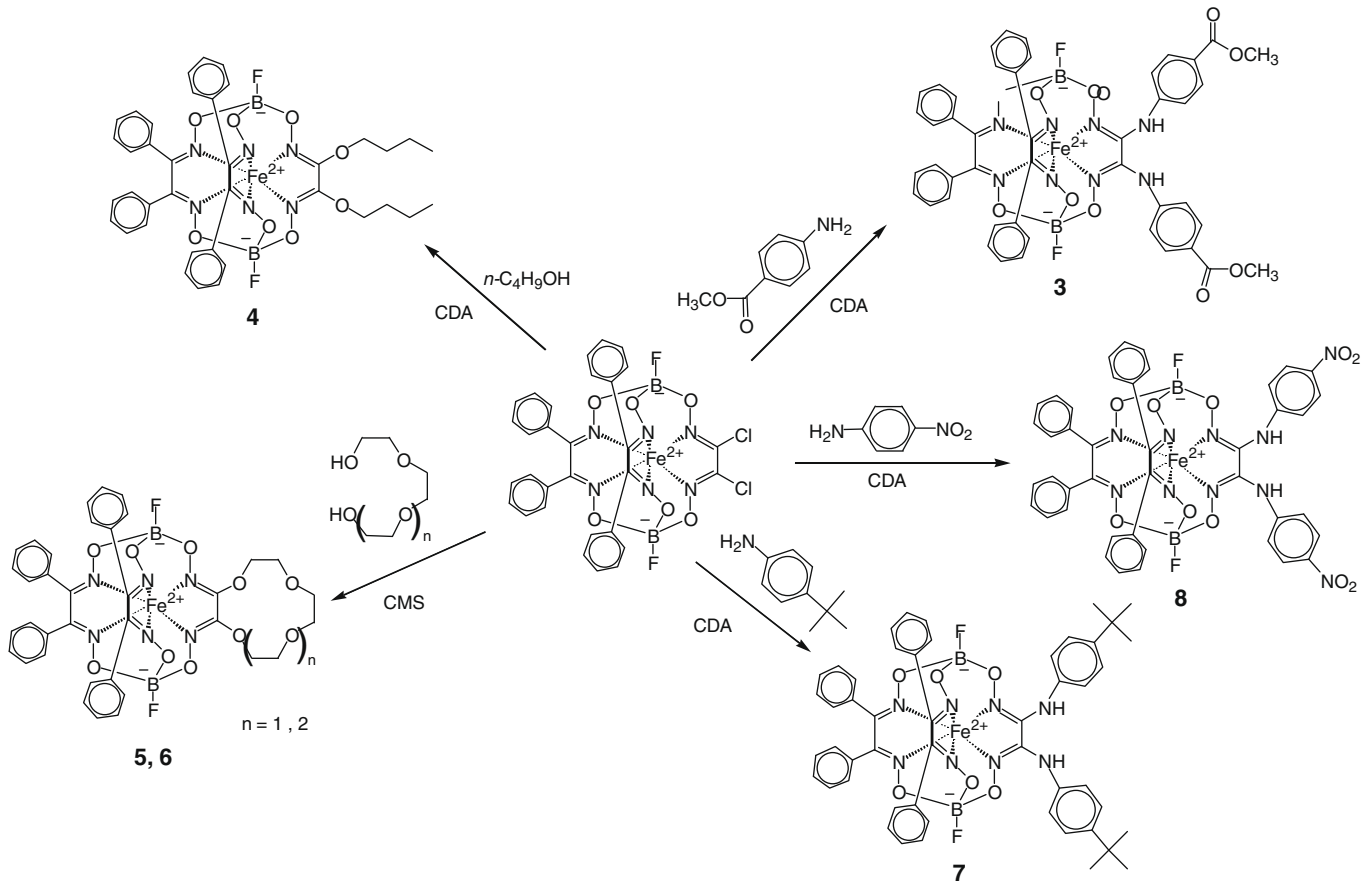
2. Results and discussion

Two cadmium(II) diamides **1** and **2** were used for the activation of the nucleophilic substitution of the ribbed chlorine substituents in the clathrochelate precursors. The THF – hexane solutions of these diamides were obtained *one-pot* by treatment of diisopropylamine and hexamethyldisilazane with *n*-butyl lithium followed by the reactions of the lithium derivatives with $CdCl_2$ (Scheme 1).

The diamide CMS is stable in wide temperature range, whereas the compound CDA is stable only below −20 °C and decomposes at room temperature in few hours with the formation of fine metallic cadmium. The reactivity of these cadmium(II) compounds in the reactions studied is similar. Cadmium(II) derivatives activate the C–Hal bond in the clathrochelate precursors both by the coordination of halogen ribbed substituents to metal ion (Scheme 2) and the formation of anionic forms of a nucleophilic agent due to interaction with cadmium amides, that increases the electron density on a reactive site of this agent. Moreover, the cadmium amides and alcoholates, in the contrast to their lithium-containing analogs, are low-basic reagents.

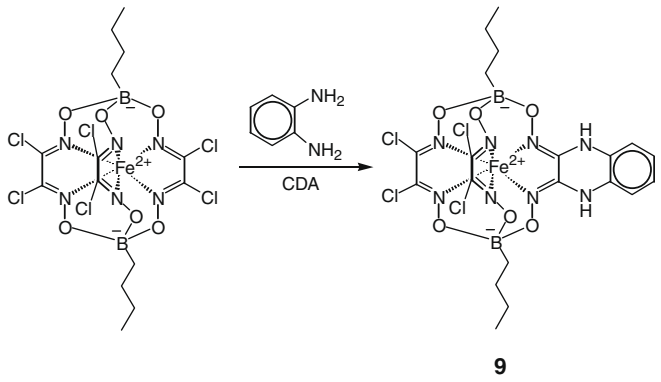


The generation *in situ* low-basic cadmium(II) alcoholates and amides in these nucleophilic substitution reactions allowed us to obtain the derivatives of soft nucleophilic agents [alcohols (including the fluorinated ones) and aromatic amines (including the nucleophiles with electron-withdrawing substituents)] by efficient one-pot procedures in relatively high yields (40%–70%) under mild conditions. The reactions performed for the di- and hexachlorine-containing clathrochelate iron(II) precursors in the presence of cadmium-containing compounds are summarized in Schemes 3–5. The proposed approach allowed to obtain selectively previously unavailable functionalized compounds, in particular, the hexafunctionalized ribbed-substituted clathrochelates with fluorinated alkoxyl groups and monoribbed-functionalized complexes with *n*-butoxyl, crown ether and aromatic amine-, carboxymethyl- and nitro-containing functionalizing fragments.



Scheme 1. Synthesis of cadmium(II) amides.

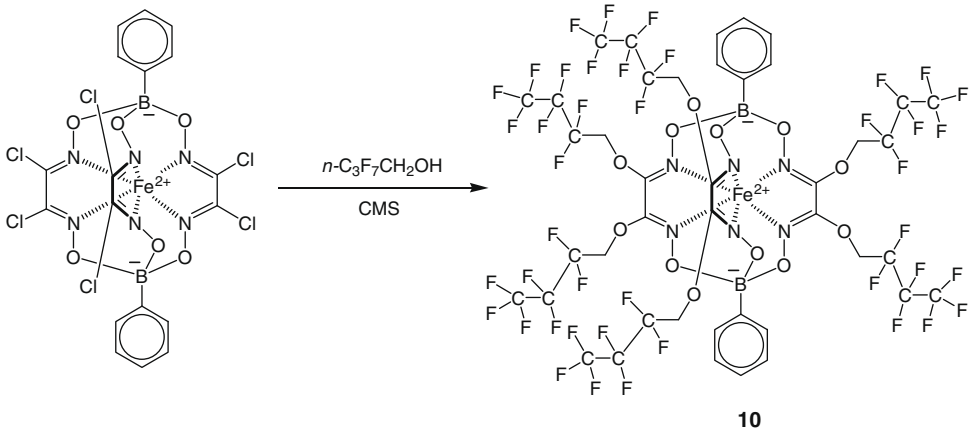
The clathrochelates **3**–**5** were characterized by X-ray crystallography; their molecular structures are shown in Figs. 1–3 and the main geometrical parameters of these molecules are listed in Table 1. The main bond lengths in macrobicyclic frameworks **3**–**5** are almost equal and characteristic of the boron-capped iron(II) clathrochelates [1]. Coordination polyhedra of the encapsulated iron(II) ions are intermediate between a trigonal prism (TP, the distortion angle $\varphi = 0°$) and a trigonal antiprism (TAP, $\varphi = 60°$), which is also characteristic of the hexadentate macrobicyclic ligands [1]. As seen from Table 1, the distortion angle φ values for molecules **3–5** are very close (from 25.3° to 26.9°) as well as the heights *h* of the coordination polyhedra (2.31 Å) and the bite angles α (half the chelate N–Fe–N angles, 39.1°–39.5°). In the earlier-studied mono- and dinitroxide ribbed-functionalized $FeBd_2((TempoNH)GmCl)(BF)_2$ and $FeBd_2((TempoNH)_2Gm)(BF)_2$ clathrochelates (where Bd^{2-} is α-benzyldioxime dianion, Tempo is 2,2,6,6-tetra-methylpyperidinyl-1-oxyl) these values are equal to 2.32 and 2.31 Å, 25.8° and 27.5°, 39.2° and 39.2°, respectively [18]. Thus, the nature of the ribbed substituents in chelate α-dioximate fragments affects the angle φ values only, whereas the height *h* and the α angles remain practically constants.



Nevertheless, the nonbonding interactions of the functionalizing ribbed substituents at the C(1) and C(2) atoms affect a molecular geometry of the complexes obtained. The steric hindrances of bulky *n*-butyl and crown ether substituents at α-carbon atoms in the crystals **4** and **5** resulted in *anti*-conformation of these functionalizing groups, whereas in the crystal **3** neighboring *p*-$Ph(COOCH_3)$ aromatic rings are almost parallel (the angle between their planes is equal to 20°) and situated rather close to each other (the minimal distances between the C(31)···C(44) and C(32)···C(39) atoms are equal to 3.34 Å). The functionalized NH-containing dioximate fragment of the molecule **3** has a *syn*-conformation because of the π-staking interactions between its aromatic moieties and is similar to that of the $Fe((n\text{-}C_4H_9NH)_2Gm)_2(Cl_2Gm)(BC_6H_5)_2$ complex [13], whereas in the $FeBd_2((TempoNH)_2Gm)(BF)_2$ [18] and $FeBd_2((tert\text{-}C_4H_9NH)_2Gm)(BF)_2$ [33] molecules these fragments have an *anti*-conformation. These interactions also cause the high distortion of the N–C(1)–N–N–C(2)–N moiety (the dihedral angle is equal to 21.1°), whereas in the molecules **4** and **5** (as well as in the $Fe((n\text{-}C_4H_9NH)_2Gm)_2(Cl_2Gm)(BC_6H_5)_2$, $FeBd_2((TempoNH)_2Gm)(BF)_2$ and $FeBd_2((tert\text{-}C_4H_9NH)_2Gm)(BF)_2$ macrobicycles [13,18,33]) the corresponding dihedral angles are from 8.5° to 18.8°. Nevertheless, the iron(II) coordination polyhedron in the molecule **3** is most regular with all Fe–N distances equal to 1.90(1) Å (Table 1), whereas in the $Fe((n\text{-}C_4H_9NH)_2Gm)_2(Cl_2Gm)(BC_6H_5)_2$, $FeBd_2((TempoNH)_2Gm)(BF)_2$ and $FeBd_2((tert\text{-}C_4H_9NH)_2Gm)(BF)_2$ molecules one of the Fe–N bonds is significantly longer (1.956 1.942 and 1.937 Å, respectively) then the other bonds of this type (the average value is 1.90(1) Å). The elongation of one of the six Fe–N bonds seems to be caused by the steric hindrances between the bulky $n\text{-}C_4H_9$, $tert\text{-}C_4H_9$ and *Tempo* groups [13,18,33]. Other bond lengths and angles in the molecules **3**–**5** are characteristic of the clathrochelate iron(II) tris-dioximates; the dihedral angles between the planes of

Scheme 2. The activation of the C–Hal bond by the coordination to the cadmium(II) ion.

Scheme 3. Synthesis of the monoribbed-functionalized iron(II) clathrochelates.



Scheme 4. Reaction of the hexachloride clathrochelate precursor with *o*-phenylenediamine.

neighboring phenyl substituents in the α-benzyldioximate chelate fragments are from 53° to 68°.

Packing diagram for the crystal **3** is shown in Fig. 4. In this crystal the strong intermolecular contacts were found: the dimers are formed by the N(7)–H(7)···O(9) hydrogen bonds with N(7)···O(9) distances equal to 2.924(6) Å and the N–H–O angles *ca* 164°. The crystal packings **4** and **5** (see Supplementary data) are formed by weak intermolecular contacts only.

The isomeric shift (IS) values (0.33–0.44 mm s^{-1}) in the ^{57}Fe Mössbauer spectra of the clathrochelates **3**–**10** allow one to characterize them as the low-spin iron(II) complexes, whereas the quadrupole splitting (QS) values (0.43–1.20 mm s^{-1}) are an evidence of essential trigonal-prismatic distortion of the TP–TAP coordination polyhedra of the encapsulated iron(II) ions. The QS values (Table 1) were deduced for the X-ray crystallography characterized complexes using the partial QS concept from the following equa-

Scheme 5. Reaction of the hexachlorine-containing clathrochelate precursor with fluorinated alcohol.

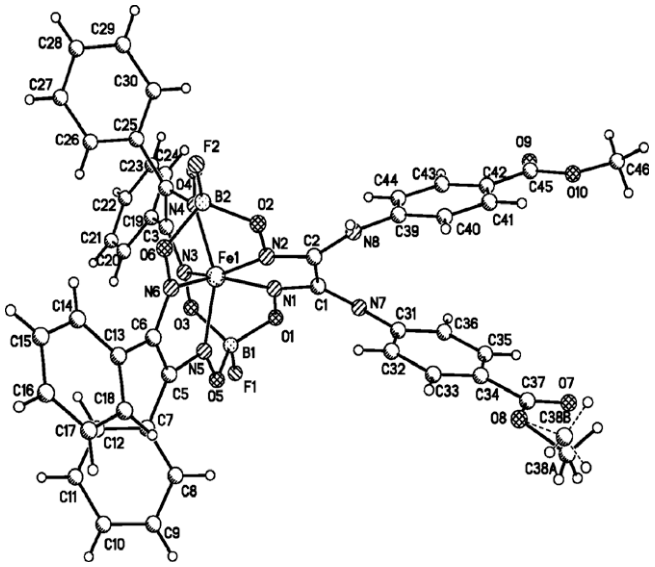


Fig. 1. Molecular structure of **3**. One of the methyl groups is equiprobably disordered (shown with the solid and dashed lines).

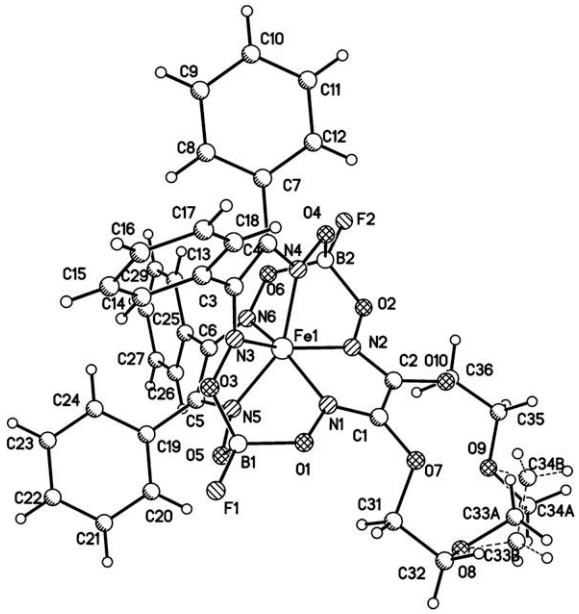

Fig. 3. Molecular structure of **5**. Ethylene moiety is disordered by two positions with occupancies 0.7:0.3 (shown with the solid and dashed lines, respectively).

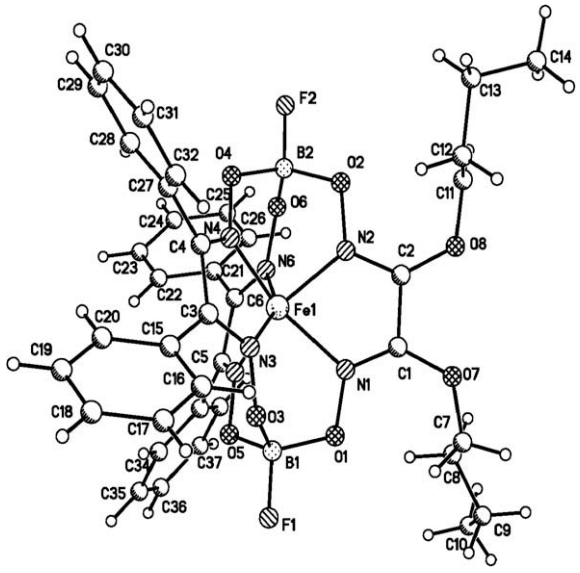

Fig. 2. Molecular structure of **4**.

tion: $QS = 6–9(cos^2\alpha/cos^2(\varphi/2))$ [34]. The essential differences between the experimental and calculated QS values are caused by the absence of symmetry C_3 axis in the molecules studied because of non-equivalence of their ribbed fragments.

In our opinion, the cadmium-promoted reactions have a great potential for synthesis of both the novel heterocyclic systems starting from various halogen-containing heterocyclic precursors and new ribbed-functionalized cage complexes. These previously unavailable compounds with improved properties and functionality might be used for the design of new efficient polyfunctional electro- and photocatalytic systems, biomimetics and pharmaceutical candidates for diagnostics and therapy.

An undoubted interest in cadmium(II) derivatives is caused also by a possible activation of the inert coordination compounds with these reagents. In our opinion, the halogen ligands in the platinum group metal complexes may be activated by the coordination to the Cd^{2+} ion that will allow one to obtain new types of previously unavailable metal complexes starting from precursors with inert metal–halogen bonds.

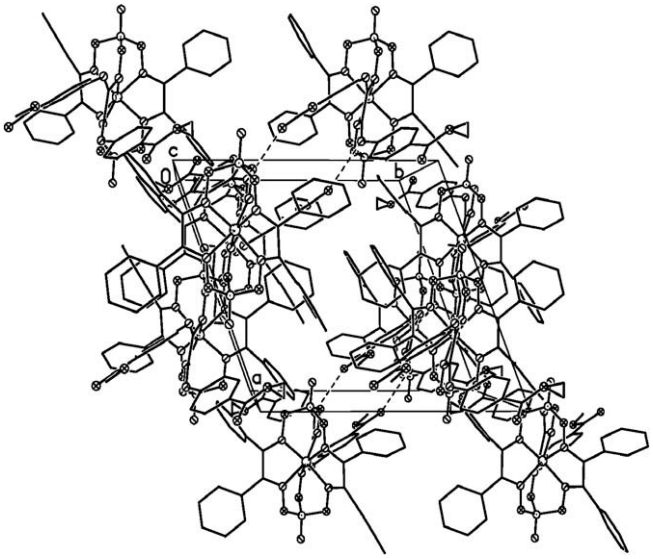

Fig. 4. Packing diagram of **3** along the crystal axis *c*. Solvent molecules and hydrogen atoms are omitted for clarity. The N(7)–H(7)···O(9) hydrogen bonds are shown with a dashed line.

3. Experimental

3.1. General procedures

The reagents used, $CdCl_2{\cdot}2.5H_2O$, n-$C_3F_7CH_2OH$, triethyleneglycol, tetraethyleneglycol, hexamethyldisilazane, n-C_4H_9Li (1.6 M solution in hexane), sorbents, aromatic amines and their derivatives, organic bases and organic solvents were obtained commercially (Fluka). The $Fe(Cl_2Gm)_3(Bn\text{-}C_4H_9)_2$ and $Fe(Cl_2Gm)_3(BC_6H_5)_2$ complexes were prepared as described elsewhere [12,13]. The $FeBd_2(Cl_2Gm)(BF)_2$ complex was prepared as described earlier [15].

Analytical data (C, H, N contents) were obtained with a Carlo Erba model 1106 microanalyzer. Iron content was determined spectrophotometrically.

The MALDI-TOF mass spectra were recorded using a MALDI-TOF-MS Bruker Autoflex mass spectrometer in reflecto-mol mode. The ionization was induced by UV-laser with wavelength 336 nm. The samples were applied to a nickel plate, 2,5-dihydroxybenzoic acid was used as a matrix. The accuracy of measurements was 0.1%.

The IR spectra of solid samples (KBr tablets) in the range of 400–4000 cm^{-1} were recorded with a IR200 Thermo Nicolet FT-spectrophotometer.

The UV–Vis spectra of solutions in dichloromethane were recorded in the range of 230–900 nm with a Lambda 9 Perkin Elmer spectrophotometer. The individual Gaussian components of these spectra were calculated using the SPECTRA program.

The ^{1}H and ^{13}C NMR spectra were recorded from CD_2Cl_2 and $CDCl_3$ solutions with a Bruker AC-200 and AMX-400 FT-spectrometers.

The ^{57}Fe Mössbauer spectra were obtained with a NP-255 (Hungary) spectrometer with a constant acceleration mode. The spectra were collected with a 256-multichannel amplitude analyzer. The isomer shift was measured relative to sodium nitroprusside, and an α-Fe foil was used for the velocity scale calibration. The ^{57}Co in a rhodium matrix was used as the source, which was always kept at room temperature. The minimal absorption line-width in the spectrum of a standard sample of sodium nitroprusside was 0.24 mm s^{-1}.

3.2. Synthesis

3.2.1. Li[N(iso-$C_3H_7)_2$] (LDA)

Diisopropylamine (13.93 g, 138 mmol) was dissolved in THF (62.5 ml) under argon, the solution was cooled to −20 °C and 1.6 M solution of n-BuLi in hexane (87.5 ml, 140 mmol) was added dropwise to the stirring reaction mixture. The resulted 0.92 M solution of LDA in THF–hexane mixture was used for preparation of CDA (**1**).

3.2.2. Cd[N(iso-$C_3H_7)_2]_2$ (CDA, **1**)

0.92 M solution of LDA in THF–hexane mixture (20 ml, 18.4 mmol) was cooled to −20 °C under argon and dry $CdCl_2$ (1.68 g, 9.2 mmol) was added. The reaction mixture was stirred for 2 h at −20 °C. The obtained 0.46 M solution of CDA was used for synthesis of the clathrochelate complexes.

3.2.3. Cd[N(Si($CH_3)_3)_2$] (CMS, **2**)

Hexamethyldisilazane (32.2 g, 200 mmol) was dissolved in THF (183 ml) at −40 °C and 1.6 M solution of n-BuLi in hexane (125 ml, 200 mmol) was added dropwise for 30 min to the stirring reaction mixture under argon. Then $CdCl_2$ (18.3 g, 100 mmol) was added and the reaction mixture was stirred for 1 h. The obtained 0.325 M solution of CMS was used for synthesis of the clathrochelate complexes.

3.2.4. $FeBd_2$((p-$CH_3OOCC_6H_4NH)_2Gm)(BF)_2$. (**3**)

Complex $FeBd_2(Cl_2Gm)(BF)_2$ (0.2 g, 0.27 mmol) and p-carboxymethylaniline (0.163 g, 1.08 mmol) were dissolved/suspended in THF (5 ml) under argon. The reaction mixture was cooled to

−20 °C and 0.46 M solution of CDA (2.32 ml, 1.07 mmol) was added. The reaction mixture was stirred for 1 h at −20 °C and heated to room temperature. Then 0.5% aqueous acetic acid (100 ml) was added and the mixture obtained was extracted with chloroform (30 ml, in 3 portions). The extract was washed with Na_2CO_3 saturated aqueous solution, dried with Na_2SO_4, rotary evaporated to ~5 ml and precipitated with heptane. The precipitate was washed with heptane and dried *in vacuo*. Yield: 0.16 g (62%). *Anal.* Calc. for $C_{46}H_{36}N_8O_{10}B_2F_2Fe$: C, 55.52; H, 3.79; N, 11.78; Fe, 5.78. 3.2.5. $FeBd_2((n\text{-}C_4H_9O)_2Gm)(BF)_2$ (**4**)

Complex $FeBd_2(Cl_2Gm)(BF)_2$ (0.18 g, 0.24 mmol) and *n*-butanol (0.076 ml, 1.07 mmol) was dissolved/suspended in THF (5 ml) under argon. The reaction mixture was cooled to −20 °C and 0.46 M solution of CDA (1.09 ml, 0.5 mmol) was added. The reaction mixture was stirred for 1 h at −20 °C and heated to room temperature. The product was isolated as described above for complex **3**. Yield: 0.11 g (55%). *Anal.* Calc. for $C_{38}H_{38}N_6O_8B_2F_2Fe$: C, 55.54; H, 4.63; N, 10.23; Fe, 6.70. 3.2.6. $FeBd_2(12cw4Gm)(BF)_2$ (**5**)

Complex $FeBd_2(Cl_2Gm)(BF)_2$ (0.4 g, 0.54 mmol) and triethyleneglycol (0.077 ml, 0.55 mmol) were dissolved/suspended in THF (40 ml) at −20 °C under argon and 0.325 M solution of CMS (2.3 ml, 0.75 mmol) was added. The reaction mixture was stirred for 4 h and 0.5% aqueous acetic acid (100 ml) was added. The mixture obtained was extracted with chloroform (30 ml in 3 portions). The extract was washed with Na_2CO_3 saturated aqueous solution, evaporated to dryness and the solid residue was separated by column chromatography on silica gel (0.035–0.070 mm, eluent: chloroform). The major dark-orange elute was evaporated to dryness, washed with hexane and dried in vacuo. Yield: 0.19 g (42%). *Anal.* Calc. for $C_{36}H_{32}N_6O_{10}B_2F_2Fe$: C, 52.49; H, 3.89; N, 10.10; Fe, 6.68. Found: C, 52.60; H, 4.00; N, 10.08; Fe, 6.60%. MS (MALDI-TOF): *m/z*: (positive region) 824 $[M]^{+\cdot}$, 847 $[M+Na^+]^+$, 863 $[M+K^+]^+$, (negative region) – 824 $[M]^{-\cdot}$. ^1H NMR (400.13 MHz, CD_2Cl_2): δ = 3.54 (m, 4H, $CltOCH_2CH_2OCH_2$), 3.68 (m, 4H, $ClTOCH_2CH_2OCH_2CH_2$), 4.74 (m, 4H, $ClTOCH_2CH_2OCH_2$), 7.25 (m, 20H, Ph) ppm. $^{13}C\{^1H\}$ NMR (100.61 MHz, CD_2Cl_2): δ = 71.56 (s, $ClTOCH_2CH_2OCH_2$), 72.3 (s, $ClTOCH_2CH_2OCH_2$), 76.2 (s, $ClTOCH_2CH_2OCH_2CH_2$), 130.0, 131.4, 132.0, 132.5 (four s, Ph), 149.1 (s, OC=N), 158.7 (s, PhC=N) ppm. UV–Vis (CH_2Cl_2): λ_{max} ($\varepsilon \times 10^{-3}$, $mol^{-1}\,l\,cm^{-1}$): 251 (36), 300 (9.3), 321 (5.7), 382 (5.6), 433 (5.6), 503 (15), 516 (3.8) nm. ^{57}Fe Mössbauer (mm s^{-1}): IS = 0.33, QS = 0.43.

3.2.9. $FeBd_2((p\text{-}NO_2C_6H_4NH)_2Gm)(BF)_2$ (**8**)

This complex was obtained like the clathrochelate **3** except that *p*-nitroaniline (0.15 g, 1.07 mmol) was used instead of *p*-carboxymethylaniline. Yield: 0.16 g (65%). *Anal.* Calc. for $C_{42}H_{30}N_{10}O_{10}B_2F_2Fe$: C, 53.11; H, 3.16; N, 14.75; Fe, 5.80. Found: C, 53.05; H, 3.18; N, 14.66; Fe, 5.74%. MS (MALDI-TOF): *m/z*: −950 $[M]^{-\cdot}$. ^1H NMR (400.13 MHz, CD_2Cl_2): δ = 6.52, 6.65 (two d, 4H, *o*-Ar), 7.25 (m, 20H, Ph), 7.83, 7.91 (two d, 4H, *m*-Ar) ppm. $^{13}C\{^1H\}$ NMR (100.61 MHz, CD_2Cl_2): δ = 120.3 (s, *o*-Ar), 125.0 (s, *m*-Ar), 128.4, 129.7, 130.5, 131.0 (four s, Ph), 142.0, 142.7, 144.2 (three s, *p*-Ar+NC=N), 158.0 (PhC=N) ppm. IR (KBr): 1549, 1577, 1596 ν(C=N), 1185m ν(B–O) + ν(B–F), 914, 1003, 1057, 1109 ν(N–O), 1628 δ(N–H) cm^{-1}. UV–Vis (CH_2Cl_2): λ_{max} ($\varepsilon \times 10^{-3}$, $mol^{-1}\,l\,cm^{-1}$): 237 (32), 291 (3.9), 309 (11), 50 (6.4), 363 (11), 443 (7.8), 484 (17), 521 (11) nm. ^{57}Fe Mössbauer (mm s^{-1}): IS = 0.33, QS = 0.47.

3.2.10. $Fe((HNC_6H_4NH)Gm)(Cl_2Gm)_2(Bn\text{-}C_4H_9)_2$ (**9**)

Complex $Fe(Cl_2Gm)_3(Bn\text{-}C_4H_9)_2$ (0.2 g, 0.3 mmol) and *o*-phenylenediamine (0.043 g, 0.4 mmol) were dissolved/suspended in THF (5 ml) at −20 °C under argon and cooled to −20 °C 0.46 M solution of CDA (0.87 ml, 0.4 mmol) was added. The reaction mixture was stirred for 1 h at −20 °C, heated to room temperature and then the product was isolated as described above for complex **3**. Yield: 0.10g (48%). *Anal.* Calc. for $C_{20}H_{24}N_8O_6B_2Cl4Fe$: C, 34.73; H, 3.47; N, 16.21; Fe, 7.96. Found: C, 34.71; H, 3.45; N, 16.12; Fe, 7.84%. MS (MALDI-TOF): *m/z*: −691 $[M]^{-\cdot}$. ^1H NMR (400.13 MHz, CD_2Cl_2):

δ = 0.47 (s, 4H, BCH_2), 0.80 (s, 6H, CH_3), 1.27 (m, 8H, CH_2CH_2), 6.80 (m, 4H, Ph), 7.94 (br s, 2H, NH) ppm. $^{13}C\{^1H\}$ NMR (100.61 MHz, CD_2Cl_2): δ = 14.2 (s, CH_3), 17.1 (br s, BCH_2), 26.2, 26.6 (two s, CH_2), 115.5, 124.2, 125.3 (three s, Ph), 127.9 (s, ClC=N), 136.8 (s, NC=N) ppm. IR (KBr): 1601m ν(C=N), 1099m ν(B–O) + ν(N–O), 917, 1001, 1046 ν(N–O), 1649 δ(N–H) cm^{-1}. UV–Vis (CH_2Cl_2): λ_{max} ($\varepsilon \times 10^{-3}$, $mol^{-1}\,l\,cm^{-1}$): 250 (23), 287 (4.8), 312 (5.8), 346 (4.7), 384 (7.3), 430 (7.2), 473 (8.7), 570 (1.4) nm. ^{57}Fe Mössbauer spectrum (mm s^{-1}): IS = 0.39, QS = 1.20.

3.2.11. $Fe((n\text{-}C_3F_7CH_2O)_2Gm)_3(BC_6H_5)_2$ (**10**)

Complex $Fe(Cl_2Gm)_3(BC_6H_5)_2$ (0.5 g, 0.72 mmol) and *n*-$C_3F_7CH_2OH$ (1.15 g, 5.76 mmol) were dissolved/suspended in THF (50 ml) at −10 °C under argon and 0.325 M solution of CMS (13.3 ml, 4.32 mmol) was added dropwise to the stirring reaction mixture. The reaction mixture was stirred overnight and 0.5% aqueous acetic acid (100 ml) was added. The mixture obtained was extracted with chloroform (30 ml in 3 portions). The extract was washed with Na_2CO_3 saturated aqueous solution, dried with $CaCl_2$ and filtered through the Silasorb SPH-300 layer (30 mm). The filtrate was evaporated to a small volume and the oily residue was dissolved in hexane. The solution was filtered, evaporated to dryness and the solid product was dried *in vacuo*. Yield: 0.83 g (69%). *Anal.* Calc. for $C_{42}H_{22}N_6O_{12}B_2F_{42}Fe$: C, 30.04; H, 1.31; N, 5.01; Fe, 3.28. Found: C, 30.14; H, 1.35; N, 5.00; Fe, 3.34%. MS (MALDI-TOF): *m/z:* 1678 $[M]^+$, 1701 $[M+Na^+]^+$, 1717 $[M+K^+]^+$). ^1H NMR (200.13 MHz, $CDCl_3$): δ = 5.27 (m, 12H, CH_2), 7.50 (m, 10H, Ph) ppm. $^{13}C\{^1H\}$ NMR (50.32 MHz, $CDCl_3$): δ = 68.8 (t, CH_2), 108.5 (m, CF_3), 114.0, 120.2 (two m, CF_2), 127.8, 128.6, 130.9 (three s, Ph), 144.3 (s, C=N) ppm. ^{19}F NMR (188.31 MHz, $CDCl_3$): δ = −80.6 (m, CF_3), −121.4 (m, β-CF_2), −127.1 (m, α-CF_2) ppm. IR (KBr): 1571 ν(C=N), 1230m ν(B–O), 972, 1018, 1084, 1124 ν(N–O) cm^{-1}. UV–Vis (CH_2Cl_2): λ_{max} ($\varepsilon \times 10^{-3}$, $mol^{-1}\,l\,cm^{-1}$): 238 (8.9), 266 (11), 300 (2.5), 331 (1.6), 426 (2.0), 452 (3.4), 459 (3.6) nm. ^{57}Fe Mössbauer spectrum (mm s^{-1}): IS = 0.44, QS = 0.65.

3.3. X-ray crystallography

Details of the crystal data collection and refinement parameters for the crystals **3–5** are listed in Table 2. Single crystals of these complexes were grown from benzene–isooctane (**4**) and chloroform–heptane (**3** and **5**) mixtures at room temperature.

The single-crystal X-ray diffraction experiments for the complexes **3–5** were carried out with a Bruker SMART APEX II CCD diffractometers at 110 K, using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Reflection intensities were integrated using SAINT software and corrected for absorption by semi-empirical method (SADABS program) [35,36].

The structures were solved by the direct method and refined by full-matrix least squares method against F^2 of all data, using SHELXTL PLUS software [37]. Non-hydrogen atoms were found on difference Fourier maps and refined with anisotropic displacement parameters except for disordered ones. One methyl group in the crystal **3** is disordered with equal occupancies (C(38A) and C(38B) atoms). One ethylene moiety (atoms C(33A), C(34A) and C(33B), C(34B)) and one solvate chloroform molecule (C(2SA), Cl(4A), Cl(5A), Cl(6A) and C(2SB), Cl(4B), Cl(5B), Cl(6B)) in the crystal **5** are disordered by two positions with occupations 7:3. The positions of hydrogen atoms were calculated and included in refinement in isotropic approximation by the riding model with the U_{iso}(H) = 1.5U_{eq}(C_i) for methyl groups and 1.2 for other groups. All calculations were made with SHELXTL, ver. 5.0 software [36]. The crystal **3** includes unidentified disordered solvate molecules, which have been treated as a diffuse contribution to the overall scattering without specific atom positions by SQUEEZE/PLATON [38]. The best

Scheme 1. Resonant forms of the $-NCSS^-$ moiety.

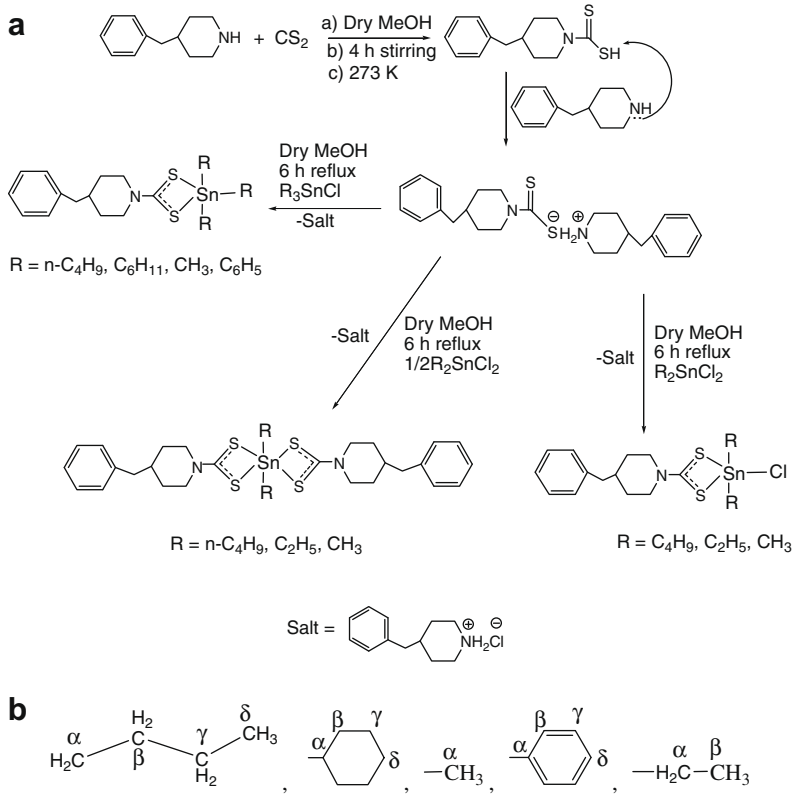
using a Bio-Rad Excaliber FT-IR, model FTS 300 MX spectrometer (USA). Raman spectra (±1 cm^{-1}) were measured with an InVia Renishaw spectrometer, using argon-ion (514.5 nm) and near-infrared diode (785 nm) lasers. WIRE 2.0 software was used for the data acquisition and spectra manipulations. The ^1H and ^{13}C NMR spectra were obtained by a Hg-300 MHz spectrometer and the ^{119}Sn NMR spectra were recorded on a Varian Unity 500-MHz instrument using Me_4Sn as external reference.

2.2. Syntheses

2.2.1. Synthesis of 4-benzylpiperidinium 4-benzylpiperidine-1-carbodithioate (L-salt)

Carbon disulfide (in excess) in methanol (50 mL) was added dropwise to 4-benzylpiperidine (5 g, 28.57 mmol) in methanol (50 mL) and the mixture was stirred for 4 h at 273 K. The solvent was evaporated under reduce pressure to yield a white product, which was recrystallized from methanol. (Yield: 4.68 g, 77%). M.p. 132–134 °C. *Anal.* Calc. for $C_{25}H_{34}N_2S_2$ (426.7): C, 70.37; H, 8.03; N, 6.57; S, 15.03. Found: C, 70.22; H, 7.97; N, 6.61; S, 14.91%. Raman (cm^{-1}): 644 ν(C–S), 1075 ν(C=S), 1455 ν(C–N). IR (cm^{-1}): 1017 ν(C–S), 1453 ν(C–N). ^1H NMR (ppm): 3.04–2.96, 2.60–2.58, 2.82–2.67, 2.60–2.58, 1.84–1.64, 1.35–1.27 (m, 18H, piperidine-H), 5.77, 3.79 (d, 4H, CH_2), 7.34–7.14 (m, 10H, Ar–H), 8.3 (s, 2H, NH_2). ^{13}C NMR (ppm): 208.8 (C-1), 51.2, 44.7, 38.2, 36.5, 32.4, 29.7, (piperidine-C), 42.9, 42.8 (CH_2), 140.1, 139.4, 129.1, 129.0, 128.4, 128.3, 126.3, 126.0 (Ar–C).

2.2.2. General procedure for synthesis of complexes



Triorganotin(IV) chloride and diorganotin(IV) dichloride in methanol (30 mL) was added dropwise to the ligand-salt in methanol (50 mL) in the appropriate molar ratio and the mixture was refluxed for 6 h with constant stirring. The salt was allowed to settle and was removed by filtration. The filtrate was rotary evaporated and the product thus obtained was recrystallized from chloroform–ethanol (4:1) mixture (Scheme 2a).

2.2.3. Tributyltin(IV) 4-benzylpiperidine-1-carbodithioate **(1)**

(Yield: 0.46 g, 74%). Sticky material. *Anal.* Calc. for $C_{25}H_{43}NS_2Sn$ (540.5): C, 55.56; H, 8.02; N, 2.59; S, 11.87. Found: C, 55.49; H, 7.93; N, 2.56; S, 11.81%. Raman (cm^{-1}): 587 ν(C–S), 1030 ν(C=S), 1440 ν(C–N), 504 ν(Sn–C), 380 ν(Sn–S). IR (cm^{-1}): 965 ν(C–S), 1467 ν(C–N). ^1H NMR (ppm): 1.38–1.28, 3.08–3.04, 1.85–1.78 (m, 9H, piperidine-H) 5.19 (d, $^3J_{H-H}$ = 12.9 Hz, 2H, CH_2), 7.33–7.12 (m, 5H, Ar–H), 1.65–1.20 (m, 18H, $H_{\alpha,\beta,\gamma}$, SnBu), 0.93 (t, $^3J_{H-H}$ = 7.3 Hz, 9H, H_δ, SnBu). ^{13}C NMR (ppm), [^nJ(^{119}Sn, ^{13}C), Hz]: 197.2 (CS), 36.5, 42.6, 52.4 (piperidine-C), 31.9 (CH_2), 139.8, 129.1, 128.5, 126.3 (Ar–C), 17.5 {(C-α, SnBu), [341]}, 29.1 {(C-β, SnBu), [18]} 27.8 {(C-γ, SnBu), [68]}, 13.7 (C-δ, SnBu). ^{119}Sn NMR: δ −129.6.

2.2.4. Tricyclohexyltin(IV) 4-benzylpiperidine-1-carbodithioate **(2)**

(Yield: 0.51 g, 70%). M.p. 122–124 °C. *Anal.* Calc. for $C_{31}H_{49}NS_2Sn$ (618.6): C, 60.19; H, 7.98; N, 2.26; S, 10.37. Found: C, 60.07; H, 7.90; N, 2.23; S, 10.30%. 2.3. X-ray crystallographic studies

A crystal fragment, cut to size to fit in the homogeneous part of the X-ray beam, was mounted on top of a glass fiber and aligned on a Bruker SMART APEX CCD diffractometer (platform with full three-circle goniometer). The crystal was cooled to 100(1) K using the Bruker KRYOFLEX low-temperature device. Intensity measurements were performed using graphite monochromatized Mo Kα radiation from a sealed ceramic diffraction tube (SIEMENS). X-ray diffraction data were collected on a Bruker SMART APEX CCD diffractometer which was equipped with a 4 K CCD detector set 60.0 mm from the crystal. Data integration and global cell refinement was performed with the program SAINT. The program suite SAINTPLUS was used for space group determination (XPREP). The structure was solved by Patterson method; extension of the model was accomplished by direct methods and applied to different structure factors using the program DIRDIF. All refinement calculations and graphics were performed with the program PLUTO and PLATON package.

3. Results and discussion

3.1. Syntheses of ligand-salt and complexes 1–10

The new organotin(IV) 4-benzylpiperidine-1-carbodithioate complexes were prepared by the reaction of the ligand-salt (L-salt)

with the selected triorganotin(IV) chlorides and diorganotin(IV) dichlorides in the appropriate mole ratio in dry methanol (Scheme 2a). The numbering system for the organic groups attached to Sn is given in scheme 2b. The compounds **1**–**10** are quite stable in moist-air and are soluble in common organic solvents.

3.2. Vibrational spectra

The assignment of the Raman bands of the complexes has been made by comparison with the Raman spectra of their related precursors. In the complexes, the appearance of a new peak in the region 334–380 cm^{-1} owing to a Sn–S vibration indicated the formation of complexes. In addition, all the complexes displayed a sharp Sn–C peak in the range 476–645 cm^{-1}, except for the triphenyltin(IV) derivative where a weak vibration appeared at 263 cm^{-1} due to Sn–C stretching. A peak associated with ν(Sn–Cl) was observed in the chlorodiorganotin(IV) derivatives only, which indicates the substitution of one chloride in the diorganotin salt during the reaction.

With respect to the dithiocarboxylate moiety, two main regions of the IR are of particular interest. First, the 1450–1580 cm^{-1} region, which is primarily associated with the 'thioureide' band due to the ν(N–CSS) vibration; second, the 940–1060 cm^{-1} region, which is associated with ν(C–S) stretching. The stretching vibration peak due to ν(N–CSS), in the complexes studied here were located in the range 1457–1475 cm^{-1}. These values lie between the range reported for C–N single bond (1250–1360 cm^{-1}) and C=N double bond (1640–1690 cm^{-1}), and is an indication of partial double bond character in C–N bond [13]. The presence of a band in the above-mentioned range for ν(N–CSS) is due to the four possible resonance structures (Scheme 1). On passing from the ligand-salt to the complexes, the ν(N–CSS) mode is shifted to higher energies, showing an increase of C–N double bond character [14]. Regarding the chlorodiorganotin(IV) derivatives, the ν(N–CSS) band is shifted to higher energy as compared to diorganotin(IV) complexes owing to the presence of electron-withdrawing effect of chloride in the complexes, thus promoting a higher positive charge on nitrogen atom. A single band for C–S in the region of 900–1060 cm^{-1}, in complexes, is in accord with bidentate bonding of 1,1-dithiolate moiety with Sn [15].

3.3. NMR spectra

The ^{1}H NMR spectra were recorded for the compounds **1**–**10** in DMSO-d_6. The characteristic chemical shifts were identified by their intensity and multiplicity patterns. The total number of protons, calculated from the integration curves, is in agreement with the expected molecular composition of the compounds. For the ligand, the piperidine protons demonstrate three triplets (1.78–1.85, 1.27–1.39 and 3.04–3.08 ppm) in the aliphatic region as expected for the structure. The protons of the benzyl part resonate in two regions; a doublet (~5.07 ppm) due to CH_2 protons and a multiplet (7.12–7.33 ppm) because of phenyl moiety. The proton chemical shifts assignment of the organic groups attached to Sn exhibited a singlet at ~1.53 ppm for compounds **3**, **9** and **10** and appeared as multiplets in the aliphatic region in case of compounds **1**, **2**, **5** and **6**. The protons of the ethyltin(IV) derivatives appeared as a quartet and a triplet as expected, while the aromatic protons of the triphenyltin(IV) complex resonate as multiplets in the range 7.42–7.71 ppm. The ^2J [^{119}Sn, ^{1}H] coupling constant value for complex **3** was 57 Hz, in the range normally expected for four-coordinate Sn and consistent with CSnC angle of 110.9° while the angle calculated (Table 1) from ^2J [^{119}Sn, ^{1}H] coupling constant certify the 5- and six-coordinate environment around Sn for compounds **9** and **10**, respectively [16]. However, the coupling constants, ^2J [^{119}Sn, ^{1}H] for *n*-butyl-, cyclohexyl-, ethyl- and triphenyltin(IV) derivatives could not be calculated due to their complex peak pattern. In case of compound **4**, the difference in chemical shift resonances of *ortho* to *meta* and *para* protons (0.3 ppm) is an indication of anisobidentate bonding of 1,1-dithiolate moiety in solution [17].

The ^{13}C NMR chemical shifts due to organic groups, attached to Sn atom, were observed at positions comparable to the other similar compounds [18]. The disappearance of duplicate peak pattern and a small shift in the position of CS carbon confirmed the coordination of ligand to the Sn center via CSS moiety. In organotin compounds, the ^1J(^{119}Sn, ^{13}C) coupling constant can be used to assess the coordination number of the Sn atom. The coupling constants were calculated and found to be in the order of 341 Hz for tributhyltin **1**, 334 Hz for tricyclohexyltin **2** and 391 Hz for trimethyltin **3** compounds which are the typical values for tetrahedral compounds [19] as given in Table 1. A characteristic feature for triphenyltin derivative is the observance of ^{13}C chemical shift of the *ipso*-carbon at about 142.9 ppm which is attributed to a five-coordinated Sn atom [20]. The calculated value of the ^1J(^{119}Sn, ^{13}C) coupling constant for **5**, **6**, **7**, **8** and **9** are 590, 601, 534, 578 and 571 Hz, respectively which described the penta-coordinated environment about the Sn atom in these compounds.

The ^{119}Sn chemical shift values obtained for triorganotin(IV) complexes lie in the range expected for tetrahedral geometry, except for the Ph_3Sn(IV) complex which gave a ^{119}Sn peak corresponding to a five-coordinated Sn atom. The ^{119}Sn NMR data for the chlorodi- and diorganotin(IV) compounds are in conformity with five coordination around the Sn atom. Among the diorganotin(IV) derivatives, only complex **10** furnished a ^{119}Sn peak associated with the octahedral geometry in solution [21].

3.4. X-ray structures

3.4.1. Crystal structures of compound *2*, *4*, *6* and *9*

An ORTEP view of compound **2** together with atomic numbering scheme is depicted in Fig. 1. Pertinent crystallographic parameters, relevant bond lengths and bond angles are given in Tables 2 and 3. The Sn atom is five-coordinate, being chelated by asymmetrically coordinating 4-benzylpiperidine-1-carbodithioate ligand and three cyclohexyl substituents. The Sn–S1 [3.160 Å] bond distance approximately *trans*- to the C26 is longer than the other Sn–S2 [2.4756(9) Å] bond distance. According to Addison et al., the geometry around the Sn atom can be characterized by the value of $\tau = (\beta - \alpha)/60$ [22], where β is the largest of the basal angles around the Sn atom. The angle $\alpha = \beta = 180°$ correspond to a square-pyramidal geometry, and the value of $\alpha = 120°$ corresponds to perfectly trigonal-bipyramidal geometry. Thus, the τ value is equal to zero for a perfect square-pyramidal and unity for a perfect trigonal-bipyramidal. For compound **2**, β is S1–Sn–C26 = 157.39°. The second largest of the basal angles around the Sn atom, α for compound **2** is S2–Sn–C20 = 116.84(8)°. The calculated τ value for the **2** is 0.67, and is an indicative of highly distorted trigonal-bipyramidal

geometry. The C26 atom occupies one of the apical positions of the trigonal-bipyramid with the C26–Sn–S2 angle of 95.35(8)°. The quasi-axial S1 atom cannot occupy exactly the position *trans* to C26 and C26–Sn–S1 angle is 157.39°. Thus, ligand chelates the Sn atom via its two sulfur atoms in anisobidentate fashion, forming a four-membered ring with S1–Sn–S2 bond angle of 62.80°. The S–C bond lengths [S1–C13 = 1.691(3) Å and S2–C13 = 1.768(3) Å] also demonstrate the asymmetric nature of the ligand. The packing diagram confirmed trimeric structure for compound **2**, formed as the result of intermolecular H···H interactions (Fig. 2).

The molecular structure of compound **4** is shown in Fig. 3, while crystal data and selected bond lengths and bond angles are given in Tables 2 and 4, respectively. The geometry around Sn is almost a midway between square-pyramidal and trigonal-bipyramidal as evident from the τ value (0.66). The value indicates a highly

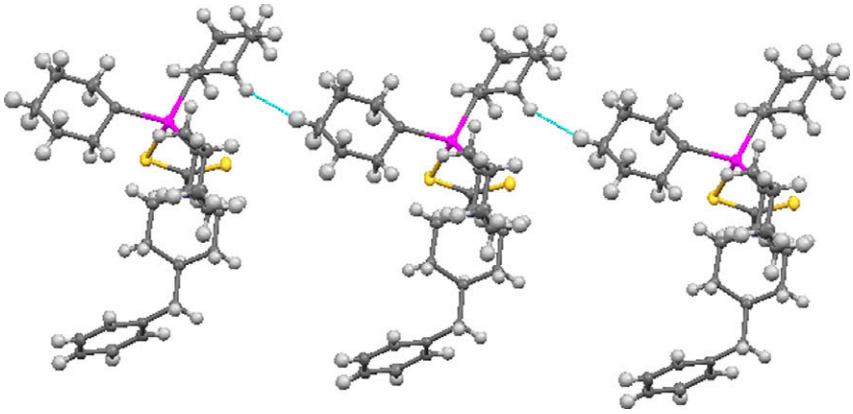

Fig. 2. Loosely associated trimer in compound **2**, connected through weak intermolecular cyclohexyl H···H interactions.

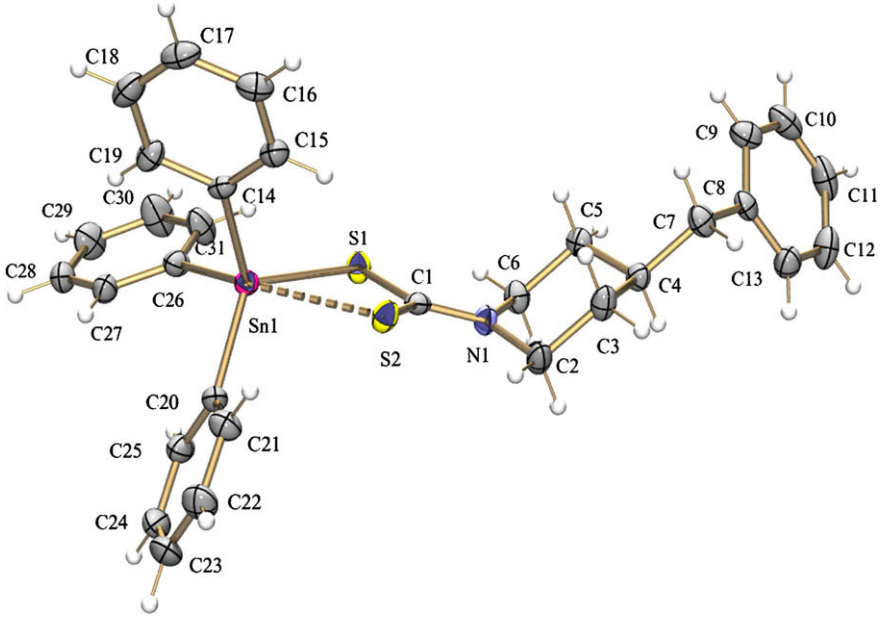

Fig. 3. ORTEP drawing of compound **4** with atomic numbering scheme.

distorted trigonal-bipyramidal arrangement around the Sn1 atom with C26 from a phenyl group and the S2 from the dithiocarboxylate ligand at the axial positions while C14 and C20 from two phenyl groups and S1 in the plane positions. The sum of the equatorial angles is 350° instead of the ideal value of 360°. Being a part of chelate, the angle S2–Sn1–S1 is not 90° but only 65.70°, so the S2 cannot occupy exactly the corresponding *trans* apical position of C26 and the angle between the apical groups is 158.88°. Finally, the C–S bond lengths are characteristic of the 1,1-dithiolate moiety and are intermediate between the values expected for single and double bonds [23]. The packing diagram indicated π···H interactions that gave rise to a dimeric structure (Fig. 4).

Crystal data and selected interatomic parameters for compound **6** are collected in Tables 2 and 5, respectively. An ORTEP view of the molecule including numbering scheme is shown in Fig. 5. The Sn atom in **6** is coordinated by two butyl groups and two 4-benzylpiperidine-1-carbodithioate ligands, with the latter adopting different asymmetric coordination modes. The first dithiocarboxylate ligand is chelating but forms asymmetric Sn–S bond distances of 2.5315(14) Å and 2.9574(15) Å, respectively, while for the second ligand, Sn–S bond lengths are 2.5470(14) Å and 2.8970 (16) Å. The weaker Sn–S distances are well within the sum of the van der Waals radii for the Sn and S atoms (4.0 Å). The overall geometry at Sn is, however, highly distorted from the *trans* octahedral: the C27–Sn–C31 angle is only 137.3(2)° which is intermediate between *cis* and *trans*, the Sn and the four S atoms of the ligands are nearly coplanar but distorted from square-planar geometry, so that the *cis* S2-Sn–S4 angle is only 83.89(4)° and the *cis* S1-

S3–C26–S4	120.5(3)		

Sn–S3 angle is 145.29(4)°. In both anisobidentate ligands, each shorter Sn–S bond is associated with a longer C–S bond and vice versa; this is in consonance with the bonding asymmetry of the ligands. The bond angles subtended at the Sn atom by the methylene carbons and S2 and S4 atoms range from 104.45(14)° to 107.05(18)° demonstrating that the Sn–C bonds are bent toward the longer Sn–S bonds. This situation must be a consequence of repulsion between the bonding electron pairs around the central Sn atom. Electronic and steric arguments have also been invoked to account the distortion of the similar structures from the regular octahedral geometry. Thus, the coordination geometry about the Sn atom in compound **6** is best described as being distorted skew trapezoidal-bipyramidal. Secondary π···H and H···H interactions, in compound **6**, result in a supramolecular cyclic structure as shown in Fig. 6.

The asymmetric unit of complex **9** contains two different molecules. An ORTEP diagram for one of the two independent molecules, together with an example of the atom numbering scheme used here is shown in Fig. 7. Crystal data and selected interatomic parameters are collected in Tables 2 and 6, respectively. The configuration about the tin atom is five-coordinate. The sum of the equatorial angles involving the two α-carbons of the methyl groups and a S atom [S11, S22]: 358.7°, show little deviation from the ideal angle of 360°. The coordination geometry, for both molecules, is almost intermediate between square-pyramidal and trigonal-bipyramidal with a slight bias towards the former, based on the τ value (0.40 and 0.44). A concrete explanation is available for the deviation of the coordination geometries towards square-pyramidal. In complex **9**, a secondary Sn···S interaction is responsible for lowering the τ value, which leads to the formation of a supramolecular zig–zag chain structure (Fig 8). For each molecule, the Cl atom occupies one of the apical positions of the highly distorted trigonal-bipyramid with the Cl1–Sn1–S11 and Cl2–Sn2–S22 angles of 86.57(3)° and 86.49(3)°, respectively. The quasi-axial S12 and S21 atoms cannot occupy exactly the position *trans* to Cl and Cl1–Sn1–S12 and Cl2–Sn2–S21 angles are 155.58(3)° and 155.38(3)°. Thus, the dithiocarboxylate group in both molecules is asymmetrically coordinated, and in each molecule Sn–S [Sn1–S12 = 2.6765(11) Å, Sn2–S21 = 2.6961(11) Å] bond length approximately *trans* to the chloride is longer than the other Sn–S [Sn1–S11 = 2.4908(9) Å and Sn2–S22 = 2.4866(9) Å] bond distance. The S–C bond lengths [(Sx1–Cx13 = 1.745(5) Å and 1.706(3) Å) and (Sx2–Cx13 = 1.711(3) Å and 1.763(5) Å)] also illustrate the asymmetric nature of the dithiocarboxylate group in each molecule.

By comparing the Sn–S bond lengths, the shorter Sn–S bond distance decreases in the following order: **6** > **4** > **2** > **9** and the longer Sn···S bond value decreases in the sequence: **2** > **6** > **4** > **9**. The smallest Sn–S bond distances for compound **9** in the series is presumably due to two reasons: firstly the less steric hindering methyl groups and secondly electron-withdrawing effect of the chloride group that increases electron accepting capability of the Sn atom. For Sn–$S_{shorter}$, the high value for compound **4** might be due to the back-donation capability of the phenyl groups, thus stabilizing Sn atom d-orbitals and reducing their interactions with S-orbitals of the ligand. For complex **6** the highest value can be explained on the basis of electron-donating effect of the butyl groups which increase the electron density on Sn atom as a consequence repulsion between Sn and S atoms increase. In the case of Sn–S_{longer}, the order for complexes **2**, **4** and **6** can be explained on the basis of steric reasons. The high value for complex **2** is due to high steric hindrance of the cyclohexyl groups as compared to the phenyl and butyl groups.

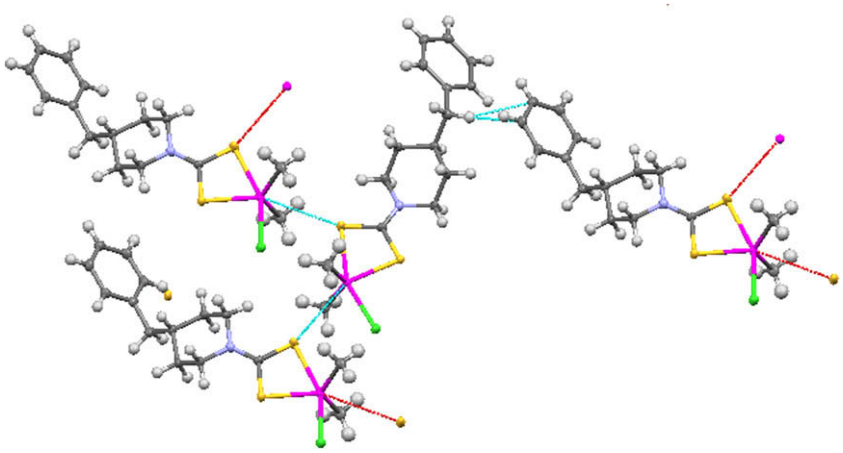

Fig. 8. Supramolecular zig–zag chain in the structure of compound **9** mediated by secondary Sn···S and benzyl-C···H interactions.

A comparison of the τ values for the five-coordinate complexes **2**, **4** and **9** reveals the smallest value for complex **9** because of secondary Sn···S intermolecular interactions. The presence of such kinds of interaction in compound **9** only, is due to the presence of small methyl groups on one end, that allow the molecules to approach one another closely. Secondly the presence of electronegative chloride group makes the Sn atom electron deficient and thus facilitates its interaction with S atom of the adjacent molecule.

3.5. Biocidal activities

3.5.1. Antifungal activity

The agar tube dilution protocol method was employed to test the antifungal activities of the synthesized compounds against the five different strains of fungi *Aspergillus nigar, A. flavus, Helminthosporium solani, Alternia solani, Fusarium* sp. and the results are shown in Table 7. The activity of compounds is highly strain dependent. Triorganotin(IV) derivatives are more active than are the chlorodi- and diorganotin(IV) complexes against the *A. nigar* and *A. flavus*. However, for the other three species, the order is reversed which is an indication of different mode of interaction of these compounds with the strains studied. The different mechanism of these compounds may be due to their ability to form secondary intermolecular interactions (as can be seen in crystal packing diagram) with bioreceptors in the cells of the microorganisms, which in turn block the synthesis of protein by inhibiting the movement of ribosome along with RNA. This situation would inhibit synthesis of DNA in the cell nucleus [10]. The higher activity of complex **1** may be due to highest lipophilic character of tributyltin(IV) derivatives [24]. The ligand and tributyltin(IV) complex are more active than is the standard drug against *A. nigar* and these compounds have potential to be used as fungicides in future.

3.5.2. Antibacterial activity

The compounds **1–10** were tested by agar well diffusion method against five different types of bacteria, namely, *Escherichia coli, Salmonella typhi, Pseudomonas aeroginosa, Staphylococcus auerus* and *Streptococcus, Streptomycin* was used as the reference drug and the results are presented in Table 8. Almost all the compounds were more toxic than was their parent ligand but slightly less so than the standard drug. Among the triorganotin(IV) derivatives, the bactericidal activity of **1** and **4** are fairly good; however, neither of these complexes (**1–4**) demonstrated any activity against *Staphlococcus aureus*. The chlorodiorganotin(IV) complexes were found to be more active than their counterparts without chloride substituents. The most probable reason is the ease of hydrolysis of the former [25]. The enhanced bactericidal activity of the ligand on complexation with organotin moiety may be explained by chelation theory [26], according to which chelation reduces the polarity of the central Sn atom because of the partial sharing of its positive charge with donor groups and possible π-electrons delocalization within the whole chelating ring. As a result, the lipophilic nature

of the central Sn atom increases, which favors the permeation of the complexes through the lipid layer of the cell membrane.

4. Conclusions

The presence of intermolecular interactions in packing diagrams can be exploited to conclude that these compounds exert their toxic actions on microorganisms by making similar contacts with the cells constituents. The influence of the metal is clearly visible in the antibacterial activity. This study provides a further step in designing novel antifungal metal-based drugs.

Supplementary data

CCDC 717026, 717715, 717024, and 717025 contain the supplementary crystallographic data for **2, 4**, **6** and **9**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

coordination chemistry, in the present report we describe the formation of sodium and potassium complexes by the solid-state microwave reaction of alkali salts of ethyl [α-(4-benzeneazoanilino)-*N*-benzyl]phosphonic acid (Na/KA_1) and ethyl [α-(4-benzeneazoanilino)-*N*-4-methoxybenzyl]phosphonic acid (Na/KA_2) with crown ethers containing 18-, 24- and 30-membered macrocyclic rings. As a preliminary screening for their biological activity, the complexes were evaluated for their cytostatic activity *in vitro* against murine leukemia L1210, murine mammary carcinoma FM3A and human T-lymphocyte CEM and MT-4 cell lines, and the results thus obtained were compared with those of the free crown ethers and discussed in terms of their binding behaviour and structure–activity relationships. The antiviral activity of the compounds was evaluated against a number of DNA and RNA viruses.

Similarly to natural cationic ionophores, crown ether compounds were also found to be toxic in prokaryotic and eukaryotic cellular systems. Toxicological research was done in various microorganisms and higher organisms such as mice, rats and dogs, and the results obtained in this field, along with biomedical potentials of crown ethers, have been summarized in our recently published review [17]. In most cases the proposed mechanism for the toxicity of crown ethers is connected with their ability to transport ions, most probably by inserting and integrating into membrane bilayers and conducting cations, as expected for carriers [18,19]. In addition, we reported the antiproliferative activity of several crown ethers and their derivatives *in vitro* against several tumor cell lines and compared their activity to that of valinomycin, an antibiotic known as a selective potassium ionophore [20]. This was the first systematic study of the cytostatic activity of non-functionalized crown compounds. Some crown ethers showed marked tumor cell growth inhibitory activity, presumably as the result of their activity as membrane-active potassium ion transporters, which may promote K^+ efflux. No interaction with double-stranded DNA was detected. There are substantial differences between normal and tumor cells with respect to the membrane potentials of K^+ transport regulation [21,22]. It is worth noting that some functionalized crown ethers, such as acridine, antraquinone, bis(propargilic)sulfone and cisplatin derivatives, were designated to act either as DNA intercalators or DNA metal chelators [17,23–26].

2. Experimental

2.1. Materials and methods

Crown ethers dibenzo-18-crown-6 (DB18C6), bis(4′-di-*tert*-butylbenzo)-18-crown-6 (mtbDB18C6), dibenzo-24-crown-8 (DB24C8) and dibenzo-30-crown-10 (DB30C10), obtained commercially or prepared according to published methods [2], were purified by repeated recrystallizations from the appropriate solvents: acetone (DB18C6), methanol (mtbDB18C6, DB24C8), and *n*-hexane (DB30C10), respectively. Sodium and potassium salts of monoethyl [α-(4-benzeneazoanilino)-*N*-benzyl]phosphonic acid (NaA_1, KA_1) and [α-(4-benzeneazoanilino)-*N*-4-methoxybenzyl]phosphonic acid (NaA_2, KA_2) were prepared and purified following previously described procedures [27,28]. All compounds were dried on P_2O_5 in a vacuum at room temperature and stored in a dry-box before use. The solvents used (AR grade) were purified and dried by standard procedures. Microwave experiments were performed in a microwave oven in an open porcelain vessel at 700 W. Melting points were determined on a hot stage microscope and are uncorrected. FTIR spectra were recorded on an ABB Bomen MB102 spectrometer using KBr pellets. LDI mass spectra were performed on a Finnigan FT/MS 2001 DD instrument (Finnigan, Madison, WI) operating in the linear positive ion mode. The one- and two-dimensional ^1H and ^{13}C NMR spectra (in $CDCl_3$) including ^1H, ^{13}C. APT, ^1H–^1H COSY, ^1H–^{13}C COSY, HMQC and HMBC experiments, were recorded with a Bruker XWIN-600 Fourier-transform spectrometer at ambient temperature. The ^1H and ^{13}C chemical shifts (δ) were referred to $SiMe_4$. All two-dimensional experiments were performed by standard pulse sequences, using Bruker XWIN-NMR software Version 3.5. Elemental analyses (CHN) were performed on a Perkin–Elmer Analyser PE 2400 Series 2. The phosphorus content was determined by the vanadomolybdatophosphoric acid spectrophotometric method, and water by thermogravimetric analysis carried out on a Cahn RG electromicrobalance in an air atmosphere applying a heating rate of 4 °C min^{-1}.

2.2. Preparations of the complexes

The crown ether complexes were prepared by a conventional thermal method in solution and by microwave-promoted solid-state synthesis. Preparation of complexes of DB18C6 (**1**–**4**) and DB24C8 (**7**–**10**) by heating in solution was described earlier [29–31].

2.2.1. Conventional thermal method in solution

The reactions were in general carried out by dissolving an equimolar amount of the crown ether and sodium (NaA_1, NaA_2) and potassium (KA_1, KA_2) salt, respectively, of the corresponding monoethyl ester of benzeneazophosphonic acid in acetonitrile, then refluxing for 2–6 h with vigorous stirring. Only for complex **7** was dry ethanol used as the solvent. The clear hot solution was filtered and allowed to stand at room temperature. Most of the complexes were gradually formed by removal of solvent. The precipitate was filtered off, washed with a small amount of cold reaction solvent, and dried. Complexes of mtbDB18C6 (**5** and **6**) and DB30C10 (**11**) were obtained as a syrup after all the solvent was removed, which solidified slowly on standing, and were washed with cold CH_2Cl_2. All the complexes obtained were hygroscopic compounds, as were the free sodium and potassium phosphonate salts, and were dried under high vacuum at ambient temperature without decomposition, giving stable anhydrous complexes. Only complex **1** was obtained as a monohydrated complex, which was confirmed by thermogravimetric analysis. The purity of the complexes was checked by elemental, thermogravimetric and spectral analyses. Only elemental data for the newly synthesized complexes of mtbDB18C6 and DB30C10 are given.

Na(mtbDB18C6)A_1 (**5**): M.p. 104–106 °C. *Anal.* Calc. for $C_{49}H_{61}N_3O_9PNa$: C, 66.13; H, 6.91; N, 4.72; P, 3.49. Found: C, 66.313; H, 6.78; N, 4.51; P, 3.27%.

K(mtbDB18C6)A_1 (**6**): M.p. 96–98 °C. *Anal.* Calc. for $C_{49}H_{61}N_3O_9PK$: C, 64.95; H, 6.79; N, 4.64; P, 3.42. Found: C, 64.78; H, 6.99; N, 4.54; P, 3.21%.

K(DB30C10)A_1 (**11**): M.p. 93–95 °C. *Anal.* Calc. for $C_{49}H_{61}N_3O_{13}PK$: C, 60.67; H, 6.34; N, 4.33; P, 3.19. Found: C, 60.47; H, 6.59; N, 4.21; P, 3.09%.

2.2.2. Focused solid-state microwave irradiation

Equimolar amounts of the crown ether and the appropriate alkali salt (ca. 0.5 mmol) in a porcelain mortar were ground together until a fine homogenous powder was obtained. This mixture was then irradiated either for 6 min (3 × 2) in the case of complexes **1**–**6** or 4 min (2 × 2) for complexes **7**–**11**, using a 700 W microwave. After the reaction was completed, the liquefied product was allowed to cool down, washed with small amount of cold CH_2Cl_2 and dried *in vacuum* for 24 h giving an orange solid (Yield 92–95%).

2.3. In vitro cytostatic assays

The cytostatic activity of the complexes, uncomplexed crown ethers and alkali benzeneazophosphonate salts NaA_1 and KA_2 was assayed *in vitro* against the murine leukemia L1210 cell line, the murine mammary carcinoma FM3A cells and the human T-lymphocyte CEM and MT-4 cell lines, according to previously described methods [32]. Briefly, the cells were suspended in growth medium and added to 200 μl-microplate wells in the presence of varying concentrations of the test compounds. The cells were then allowed to proliferate in a humidified CO_2-controlled atmosphere for 2 (L1210, FM3A), 3 (CEM) and 5 (MT-4) days, and at the end of the incubation period the number of viable cells was determined by a Coulter counter (L1210, FM3A, CEM) or by the MTT dye exclusion method (MT-4). The activity was expressed as the concentration (in μM) of the compound at which tumor cell growth was inhibited by 50% (IC_{50}).

2.4. In vitro antiviral assays

The assay procedures for measuring the antiviral activity of the compounds against a wide variety of DNA and RNA viruses were based on the inhibition of the virus-induced cytopathic effect in either human lung embryonic HEL, human cervix carcinoma HeLa, African green monkey Vero or human lymphocyte MT-4 cell cultures, as previously described [33,34]. The 50% effective concentration (EC_{50}) was defined as the compound concentration required to confer 50% protection of virus-infected cells against viral destruction. The cytostatic activity of the compounds was assessed in parallel with the antiviral activity, and the cytostatic concentration (CC_{50}) was determined as the concentration of compound to inhibit the number of viable cells in mock-infected cells by 50%.

3. Results and discussion

3.1. Synthesis and properties

Investigations of the reactions of crown ethers containing 18-membered (DB18C6 and mtbDB18C6), 24-membered (DB24C8) and 30-membered (DB30C10) macrocyclic rings with sodium (NaA_1 and NaA_2) and potassium (KA_1 and KA_2) benzeneazophosphonate salts (Fig. 1) in the solid state under microwave irradiation have shown that 1:1 (crown–cation) ion-pair salt complexes are formed, similarly as in conventional thermal reactions in solution. The factors that influence the formation of metal ion complexes with crown ethers are well known [5,35]. The metal–ligand interactions in general depend on the size and charge density of the cation, the size and flexibility of the crown ether, the number and the nature of substituted groups on the macrocyclic ring, the nucleophilicity of the counterion, and the nature of the solvent. In our earlier papers we studied, by electrochemical and UV–Vis spectroscopic methods, the complex formation, solvation and ion-pairing of a number of sodium and potassium salt complexes (picrate, perchlorate, tetraphenylborate, hexafluorophosphate, tetrafluoroborate, anilinobenzylphosphonate) with various crown ethers in organic solutions [29,30,36,37]. Generally, the relative dimensions of the crown ether cavity and the linked cation is the most significant factor for crowns up to 18-membered rings with a planar conformation and limited flexibility. Sodium and potassium ions with cationic diameters of 1.94 and 2.66 Å, respectively, fit well into the 18-membered polyether cavity of 2.6–3.2 Å with anion and solvent molecules having the possibility of interacting with the alkali cation in axial positions. On the other hand, the cavity size effects are not of crucial importance for the larger crown ethers with 24- and 30-membered polyether rings and high conformation mobility which provides a complexation profile of high

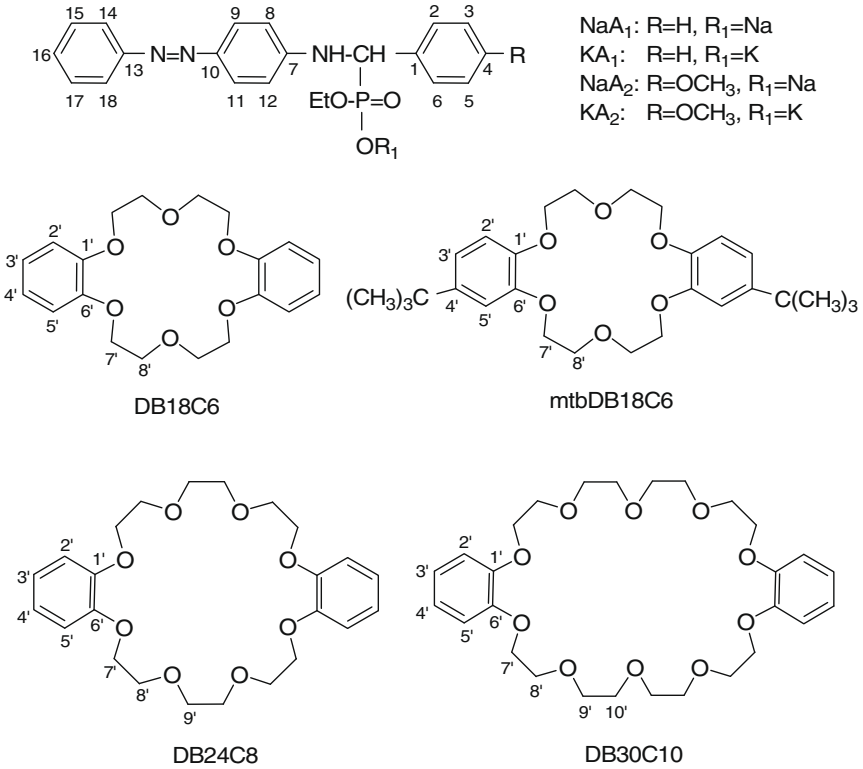

Fig. 1. Sodium and potassium benzeneazophosphonates and crown ethers.

coordination metal geometry, similarly to naturally occurring cyclic ionophores [9,38]. They may form complexes by wrapping around the alkali cation either by expelling the conjugate anion and solvent molecules from the cation coordination sphere or leaving space for bonding with the anion. Thus DB24C8, with a hole diameter of about 4.7 Å, formed sodium and potassium complexes with benzeneazophosphonate salts, while in the case of larger DB30C10 only the potassium complex was obtained. All complexes formed by conventional heating in solution were also obtained by microwave heating in the solid state. A comparative study has shown up to 10% higher yields in the case of DB18C8 (**1**–**4**) and mtbDB18C6 (**5**,**6**) complexes and between 20% and 30% for the DB24C8 (**7**–**10**) and DB30C10 (**11**) complexes. The complexation time is much shorter for the reaction run under microwave irradiation (4–6 min) compared to that with classical heating (2–6 h). In addition, it is twice shorter with respect to the microwave synthesis of the complex of the dioxa-diaza 15-membered macrocycle with NaA_1 (12 min) [11], which confirms the greater affinity towards alkali cations of pure oxa-crown than aza-crown ligands.

It may be presumed that the alkali ion in all the complexes is involved in bonding interactions with all the oxygen atoms of the crown ether and to the phosphonate anion. The low melting points of the complexes (90–140 °C) with respect to the high melting point of the free sodium salts (above 220 °C) [15], indicate that the charge of the alkali ion in the complex is extremely delocalized. Some degree of charge transfer between the metal ion and the anion can take place, increasing the stability of the complex. The X-ray structure determination of complex **1**, obtained in the crystalline form as acetonitrile solvate, shows a strong bonding between the crown ether complexed cation and the phosphonate anion [39]. Sodium is coordinated to all six crown oxygens at distances from 2.601 to 2.769 Å in the base of a hexagonal pyramid and to one of the phosphonate oxygen atoms in the apical position at a distance of 2.183 Å. Therefore, it could be concluded that a stronger interaction exists between the sodium ion and the phosphonate oxygen than with the oxygens in the crown ring, which was supported also by the mass spectra. The low symmetry of the monoalkyl benzeneazophosphonate anions with sites of charge localization may account for the strong cation–anion electrostatic interaction. It is worth noting that the conductometric and UV–Vis spectroscopic studies of sodium and potassium complexes of DB18C6 and DB24C8 reveal also a strong cation–anion interaction in acetonitrile [36,37,40]. A larger ion-pair association was found for DB24C8 complexes, which can be attributed to the lack of solvation of these complex ions compared to those of DB18C6. Furthermore, the potassium complexes are more dissociated than the corresponding sodium analogues, which is in agreement with the assumption that complexes of potassium should be more acceptable to a lipid phase compared to the sodium products. Such effects can be generalized for natural systems and should significantly account for a greater resistance of sodium against complexation with natural carriers and its accumulation outside the cell membrane.

In the present work results of infrared, LDI mass and ^1H and ^{13}C NMR spectroscopic studies as well as the cytostatic and antiviral activity of the benzeneazophosphonate crown ether complexes **1**–**11** are presented.

3.2. Infrared spectra

IR spectra of the crown ether complexes are too complex to allow a complete assignment of the absorption bands. In every case, however, the spectrum of the complex is distinctively different

from that of the physical mixture of the constituents, and shows the absence of the uncomplexed constituents [28]. Upon complexation marked changes may be noticed in the 1270–900 cm^{-1} region where bands arising from various modes of vibrations of ether and methylene groups along with the benzeneazoanilinophosphonate ester group are present (Table 1, Fig. 2). Generally, compared with the spectra of the free crown ethers, most of the ligand bands in the complexes are slightly shifted to lower energies, presumably due to less restriction on the coupling of some vibrational modes caused by bonding between the oxygen atoms of the crown ether ring and the sodium and potassium ion, respectively. The greatest changes could be observed in the 1000–900 cm^{-1} region, which contains bands attributed to wagging, twisting and rocking modes of vibration of the methylene groups [29,31,41]. Thus, while free DB18C6 has two strong bands at 997 and 932 cm^{-1} associated with these vibrations, its complexes are characterized by a medium to strong band around 947 cm^{-1} (Fig. 2a–c). In complexes **1** and **2** this band shows a shoulder on the lower frequency side. Complexes of mtbDB18C6 and DB24C8 exhibit either two (**5**, **6**, **7** and **9**) or three bands (**8** and **10**) between 965 and 928 cm^{-1}, while in complex **11** deformation modes of methylene vibrations give a multiple absorption with considerable differences in band intensities compared to those in the free crown ether DB30C10 (Fig. 2d and e).

3.3. Mass spectra

The structures of the complexes were also supported by the LDI mass spectra, and the major structurally informative fragment ions are given in Table 1. All complexes show a weak protonated molecular ion $[M+H]^+$ with a relative abundance of 4–8%. The more abundant ions are those of the sodium $[L+Na]^+$ and potassium $[L+K]^+$ cationic crown ether complexes (20–35%) as well as of the sodium $[NaA+Na]^+$ and potassium $[KA+K]^+$ adduct ions of the corresponding alkali benzeneazophosphonate salts (50–60%). The results obtained are in accordance with the structural data, which indicate strong bonding between the alkali ion and the phosphonate anion.

3.4. NMR spectra

While all the potassium complexes are sufficiently soluble in $CDCl_3$ for NMR spectral analysis, among the sodium complexes only for that of mtbDB18C6 could a satisfactory spectrum be obtained. The complete ^1H and ^{13}C NMR resonance assignments of the complexes and free potassium ethyl benzeneazophosphonate salts KA_1 and KA_2 are summarized in Tables 2 and 3, according to the numbering scheme shown in Fig. 1.

The ^1H NMR spectra of the free non-substituted crown ethers show two separated closely spaced multiplets in the aromatic region characteristic for a four-spin AA′BB′ coupled system, typical of the spectra found for 1,2-disubstituted benzenes. Due to the loss of symmetry in mtbDB18C6, all the aromatic crown ether resonances are separated. In the ether region, are present either two (DB18C6, mtbDB18C6), three (DB24C24) or four (DB30C10) sets of resonant signals for the methylene protons of the chemically non-equivalent ether fragments (Fig. 1). As expected, in mtbDB18C6 these sets of signals are split, as are the corresponding carbon resonances. The assignments were carried out on the basis of the ring current effect of the benzo group for the ether methylenic protons and the inductive effect due to the oxygen for the benzo group protons. Upon complex formation some changes could be observed both in the aromatic and methylene crown ether absorptions. Generally, all the aromatic protons in the complexes show an upfield shift, which varied slightly depending on the crown ether used. The protons 2′,5 in the complexes of non-substituted crown ethers show only a negligible shift of ca. 0.01 ppm,

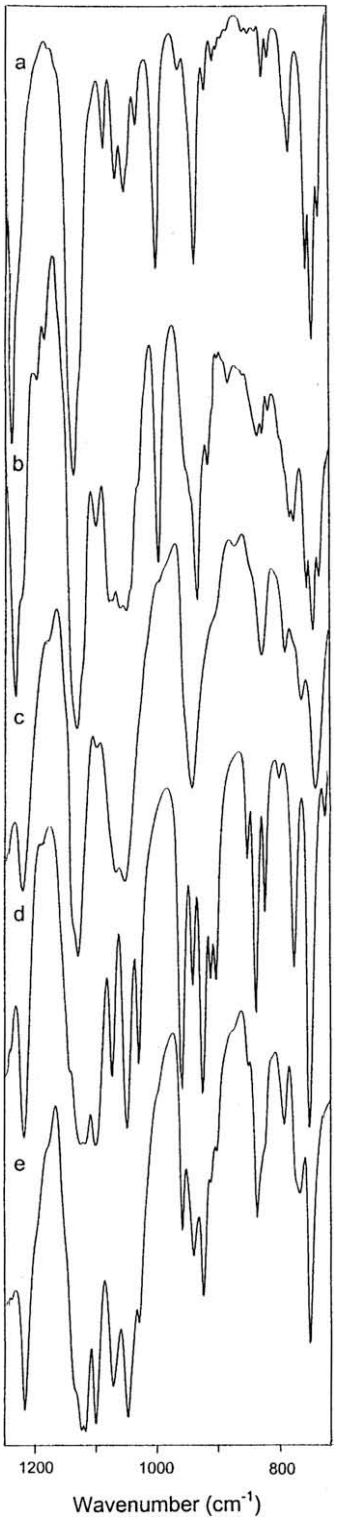

Fig. 2. A part of the infrared spectra of (a) DB18C6; (b) NaA_1; (c) $Na(DB18C6)A_1$; (d) DB30C10; (e) $K(DB30C10)A_1$.

while protons 3′,4′ are shifted by ca. 0.1 ppm in complexes of DB18C6 (**2** and **4**) and DB30C10 (**11**) and ca. 0.02 ppm in complexes of DB24C8 (**8** and **10**). In the complexes of mtbDB18C6 (**5** and **6**) with a weakly electron-releasing *tert*-butyl substituent at the 4′ position, protons 2′ and 5′ show an upfield shift of 0.05–0.1 ppm, while proton 3′ is shifted only by 0.01 ppm. Greater chemical shift differences between complexes could be observed

[g] Partly overlapped with $POCH_2$.

in the methylene absorptions, arising from different skeletal structural and conformational changes and charge density variations within the macrocyclic ring during alkali complexation. In complexes of the 18-membered ring crown ethers, the $ArOCH_2$ protons (7′) exhibit an upfield shift of about 0.15 ppm. The $OCH_2CH_2O–CH_2$ protons (8′) are shifted upfield by 0.03 ppm in complexes of DB18C6, while in complexes of mtbDB18C6 this absorption overlaps with that of 7′ giving a broad singlet. The binding of sodium induces the same general spectral pattern observed for potassium complexation. In complexes of DB24C8 protons 7′ show a smaller upfield shift of only 0.03 ppm, while those of 8′ and 9′ are shifted by 0.06 and 0.11 ppm, respectively. Complexation of DB30C10 induces an upfield shift for protons 7′, 8′, 9′ and 10′ of 0.14, 0.16, 0.14 and 0.05 ppm, respectively (Fig. 3). It is worth noting that in spite of the complexation with the alkali cation, which by itself would induce a downfield shift due to the increased electronegativity of the oxygen ether atoms [42,43], in all the complexes the methylene resonances move to a higher field. This may be explained by a change in the position of the ether protons relative to that of the benzo groups, especially in the case of the larger crown ethers DB24C8 and DB30C10, as well as by the proximity of the crown ether molecule to the benzeneazophosphonate aromatic rings. No dissociation of salt complexes could be expected in the examined solvent and no spectral differences were observed as a function of concentration. It should be pointed out that a comparison of the literature spectral data of complexes of various crown ethers as well as those of various alkali metal salts indicates that not only the type of crown ether and cation, but also the anion and solvent could have an important role in the resulting chemical shift of the crown ether ring protons due to different solubilization and charge separation of the complexes in solution [38,44,45].

In the ^{13}C NMR spectra, differences between complexes of crown ethers with different cavity size could also be observed both for the aromatic and methylene carbon absorptions. In the complexes of DB18C6 and mtbDB18C6, all the carbon resonances show a certain upfield shift, which is more pronounced for the aromatic 1′,2′, 5′ and 6′ carbons and both methylene 7′ and 8′ carbons. It varies from 2.0 to 2.4 ppm in complexes **2** and **4**, and between 1.5 and 3.2 ppm in complexes **5** and **6**. While the aromatic protons 1′ and 6′ in the complexes of DB24C8 and DB30C10 show an upfield shift of 1.3–1.5 ppm (complexes **8** and **10**) and 0.6 ppm (complex **11**), the other aromatic carbons 2′–5′ are shifted to towards lower field by

[a] Spectra recorded in $CDCl_3$ at room temperature.
[b] Data for free crown ethers are given for comparative purposes. DB18C6: 148.92 (1′,6′); 113.28 (2′,5′); 121.13 (3′,4′), 69.05 (7′), 69.71 (8′); mtbDB18C6: 146.71 (1′), 113.64, 113.61 (2′), 117.91, 117.89 (3′), 144.57 (4′), 112.54, 112.50 (5′), 148.28 (6′), 70.08, 70.06, 69.97, 69.96 (7′), 69.48, 69.36, 69.24, 69.11 (8′), 34.20 ($\mathbf{C}(CH_3)_3$), 31.36 ($C(\mathbf{C}H_3)_3$); DB24C8: 148.82 (1′,6′), 113.97 (2′,5′), 121.28 (3′,4′), 69.27 (7′), 69.79 (8′), 71.13 (9′); DB30C10: 149.06 (1′,6′), 114.58 (2′,5′), 121.54 (3′,4′), 69.16 (7′), 69.82 (8′), 70.92 (9′), 70.74 (10′).

0.25–0.4 ppm and about 1.3 ppm, respectively. All the methylene carbons in these complexes are shifted upfield, but to various extents. Thus, in complexes of DB24C8 this shift is about 1.2 ppm for 7′ and 1.0 ppm for 8′ and 9′ carbons, while in the complex of DB30C10 the upfield shift for 7′ is only 0.4 ppm, that for 8′ is 1.2 ppm, while 9′ and 10′ are shifted by about 2 ppm.

The spectral pattern of the benzeneazophosphonate anion in all the complexes examined exhibited similar basic spectral characteristics. In comparison to the free alkali phosphonates some changes could be observed for resonances of the aminophosphonate group and those aromatic protons and carbons in the vicinity of this group. Thus, there is a downfield shift of 0.04–0.09 ppm for the $POCH_2$ protons, and an upfield shift of 0.1–0.2 ppm for the NH resonance and 0.07–0.24 ppm for the aromatic 3,5; 4; 8,12 and 9,11 protons. Small changes could also be observed for the corresponding carbon resonances (0.6–1.8 ppm).

3.5. In vitro cytostatic activity

The cytostatic activity of the crown ether complexes was assayed *in vitro* against the murine leukemia L1210, the murine mammary carcinoma FM3A and the human T-lymphocyte CEM and MT-4 cell lines. The results of the crown ether complexes **1–11**, expressed as the micromolar concentration of the compound required to inhibit tumor cell growth by 50% (IC_{50}), are listed in Table 4, together with those of the free crown ethers as well as the sodium (NaA_1) and potassium (KA_2) salt of the monoethyl benzeneazophosphonic acids. These compounds were assayed in order to evaluate the effect of the constitutional parts of the complex molecules on tumor cell growth and to assess their individual activity.

All the tested compounds showed antiproliferative activity against the examined cell lines. The IC_{50} concentrations of the complexes varied from 2 to 70 μM, while those of the crown ethers and alkali benzeneazophosphonate salts were within 1.4–160 and 300–500 μM, respectively. In general, most of the complexes are slightly more cytostatic to L1210 and FM3A cells than to the CEM and MT-4 cells. Except for DB18C6, this difference is not pronounced in the free crown ethers or in the benzeneazophosphonate salts NaA_1 and KA_2. Very weak, if any, growth-inhibitory effects of the phosphonate salts (IC_{50} > 300 μM) indicate that this part of the complex molecule does not influence the cytostatic ability of the complex. Both the free crown ethers and their complexes have much stronger antiproliferative effects and the results obtained clearly demonstrate that the crown ether part of the complex is responsible for its cytostatic activity. When comparing the activity between

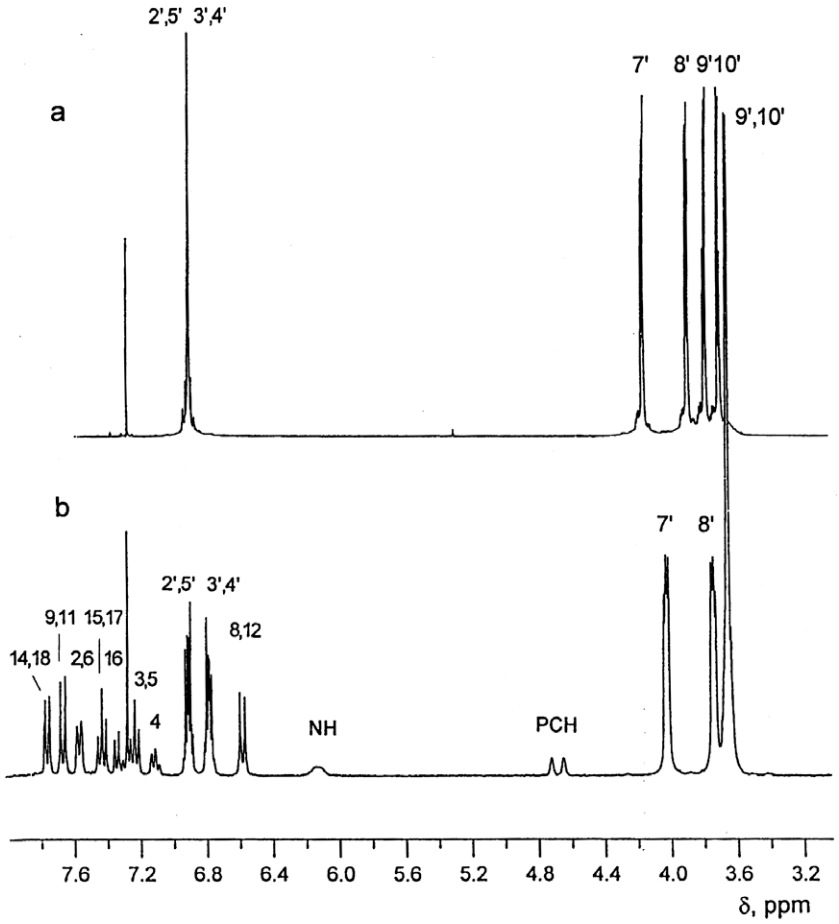

Fig. 3. ^{1}H NMR spectra of (a) DB30C10 and (b) K(DB30C10)A_1.

Table 4
In vitro cytostatic activity of the crown and benzeneazophosphonate compounds.

Compound	IC_{50} (μM)[a]

EtA_2[g]	25 ± 1		17 ± 3	

[a] 50% Inhibitory concentration.
[b] L1210 – murine leukemia cells.
[c] FM3A – murine mammary carcinoma cells.
[d] CEM – human T-lymphocyte cells.
[e] MT-4 – human T-lymphocyte cells.
[f] Monoethyl ester of [α-(benzeneazoanilino)-*N*-4-methoxybenzyl]phosphonic acid (R = OCH_3, R_1 = H in Fig. 1).
[g] Diethyl ester of [α-(benzeneazoanilino)-*N*-4-methoxybenzyl]phosphonic acid (R = OCH_3, R_1 = Et in Fig. 1).

the crown ethers and their metal complexes, it could be seen that only complexes of DB18C6 are more active than the free parent crown ether, while complexes of the other crown ethers were slightly less active. In general, the tested compounds show a growth-inhibitory effect of the following order:

Crown ethers: mtbDB18C6 >> DB30C10 > DB24C8 ~ DB18C6

Crown ether complexes: mtbDB18C6 (**5**,**6**) >> DB30C10 (**11**) ⩾ DB18C6 (**1**–**4**) > DB24C8 (**7**–**10**).

There is, in general, a good correlation for the IC_{50} values against the different tumor cell lines (Table 4). The greatest activity demonstrated that mtbDB18C6 and its complexes (IC_{50} values of 1.4–2.5 μM) have ca. 10–30 times higher cell growth-inhibitory effects with respect to the other crown ether compounds. These findings may arise from the higher solubility and lipophilicity of these compounds caused by the presence of the bulky *tert*-butyl groups in the crown ether molecule, and this may facilitate their transport through the cellular membranes. The potassium complexes of DB18C6 and mtbDB18C6 are slightly more active than their sodium analogues, while there are no substantial differences in inhibitory activity between the corresponding sodium and potassium complexes of DB24C8. Furthermore, complexes derived from the non-substituted benzeneazophosphonates (Na/KA_1) are slightly less active than those of the methoxy-substituted phosphonates (Na/KA_2), which could be ascribed to lower solubility and lipophilicity of the former complexes. Generally, a fairly good relationship could be seen between the activity and solubility of the complexes and the free crown ethers.

It is interesting to note that comparing the activity of the potassium salt KA_2 with those of the corresponding diester and

monoester phosphonate derivatives EtA_2 and HA_2 (see Table 4), it could be seen that the monoester is ca. twice more active than its alkali salt, while the diester shows about twenty times higher activity. The greater activity of the diester may be ascribed to higher lypophilicity of this compound, which increases with increasing bulkiness from the monoester to the diester derivatives. On the other hand, the presence of the acidic phosphonate group in the monoester may cause the opposite effect. It is important to point out that all phosphonate derivatives, i.e. the ethyl phosphonates, the corresponding sodium salts and their crown ether complexes, were prepared and investigated in the racemic form. These compounds contain an asymmetric PCH carbon atom (diester) or both the carbon and phosphorus atoms (monoester derivatives). The cytotoxicity of the aniline-based ethyl phosphonates (EtA_2 and HA_2) is similar to that of the quinoline-based ethyl phosphonates without a chiral center in their molecules [46] and some palladium(II) and platinum(II) complexes of both types of alkyl phosphonates have shown pronounced antiproliferative effects [47].

3.6. In vitro antiviral activity

The compounds listed in Table 4 were also evaluated for their antiviral activity. The antiviral assays were based on the inhibition of virus-induced cytopathogenicity. Following viruses were investigated: herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2), vaccinia virus (VV) and vesicular stomatitis virus (VSV) in human lung embryonic HEL cell cultures; Coxsackie B4 virus, vesicular stomatitis virus (VSV) and respiratory syncytial virus (RSV) in human cervix carcinoma HeLa cell cultures; parainfluenza-3 virus, reovirus-1, Sindbis virus, Coxsackie B4 virus and Punta Toro virus in African green monkey Vero cell cultures; human immunodeficiency virus type 1 [HIV-1(III_B)] and type 2 HIV-2(ROD) in human lymphocyte MT-4 cell cultures. The results obtained are given as Supplementary material. The antiviral activity of the evaluated compounds, expressed as the concentration of the compound required to reduce virus-induced cytopathogenicity by 50%, as well as their cytotoxicity expressed as the concentration of the compound required to destroy 50% of mock-infected cells, have shown that all compounds exhibited no antiviral activity at subtoxic concentrations to the host cells. For a specific antiviral effect the compound needs to block the virus at a concentration that is $\geqslant$5 fold lower than the cytotoxic concentration.

4. Conclusion

Sodium and potassium benzeneazophosphonate complexes of crown ethers with 18-, 24- and 30-membered macrocyclic rings have been prepared by reactions in the solid state under microwave irradiation, as a first example of microwave-supported synthesis of pure oxa-crown ether complexes. The simple work-up, eco-friendly solvent free reactions resulted in complex formation in a shorter reaction time and with excellent yields, compared to conventional thermal reactions in solution. Investigation of the cytostatic activity *in vitro* of the free crown ethers, their alkali metal complexes and the free benzeneazophosphonate salts in murine leukemia L1210, murine mammary carcinoma FM3A and human T-lymphocyte CEM and MT-4 cell lines have shown that only the crown ethers and their complexes exhibit tumor cell growth-inhibitory effects. The greatest activity with IC_{50} values in the lower micromolar range was observed for *tert*-butyl-substituted dibenzo-18-crown-6 and its complexes, most probably due to a higher lipophilicity and better cellular uptake. Since, in general, there are no substantial differences in activity between the free crown ethers and their complexes, it could be presumed that alkali benzeneazophosphonate complexation does not facilitate or enhance the inherent mode of action of the crown ether. The only exception is a greater activity of complexes of DB18C6 against CEM cells. All investigated compounds had no specific antiviral activity.

Acknowledgements

Financial support granted by the Croatian Ministry of Science, Education and Sports (Grant No. 098-0982915-2950) and the "Geconcerteerde Onderzoeksacties" (No. GOA-05/19) of the K.U.Leuven is gratefully acknowledged. The authors would like to thank Mr. Ž. Marinić for recording the NMR spectra, and Lizette van Berckelaer, Frieda De Meyer, Anita Van Lierde, Kris Uyttersprot and Kristien Erven for excellent technical assistance.

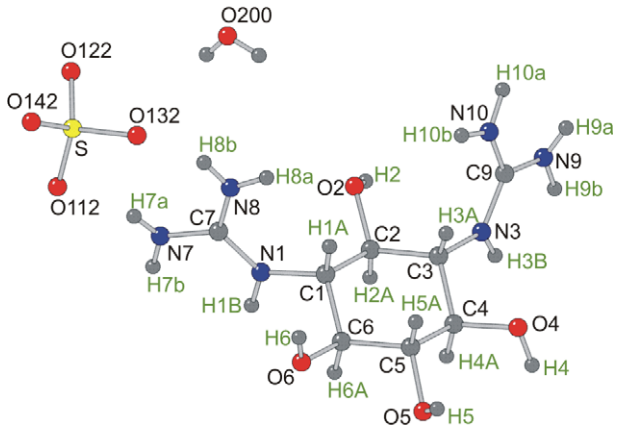

Fig. 1. Atomic numbering and ball and stick representation of the structure $(H_2Std)(SO_4)(H_2O)$, as taken from its crystal structure (*vide infra*). Hydrogen atoms are labeled in green for the sake of clarity. Nitrogen atoms are in dark blue, oxygen in red, sulfur in yellow and carbon and hydrogen in grey colours. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

defined parts, both of them with expected bioactivity: (i) as a platinum drug, the anticancer properties of the final complex would be tested; (ii) by utilizing the activity and fluorescence properties of the ligand (H_2Std), *in vitro* studies using digital fluorescence microscopy could be performed and additional antibacterial studies can also be carried.

This paper describes the synthesis and detailed characterization (including Pt L_3- and Cl K-edge XAS) of the first solid platinum–streptidine compound (**1**, $(H_2Std)PtCl_4$). An accurate X-ray diffraction study of the hydrated H_2Std sulfate was performed at room temperature, to assist in the characterization of compound **1**. However, during the preparation for publication of this work, a structural report of H_2Std sulfate at low *T* was published [34], so in this manuscript we will only elude to some of the most relevant features of the former to assist the structural refinement of $(H_2Std)PtCl_4$.

Finally, in this manuscript the results of biological *in vitro* studies of compound **1** (cytotoxicity, UV–Vis titration, fluorescence and antibacterial experiments) will be discussed.

2. Experimental

2.1. Chemistry

K_2PtCl_4 was obtained from Johnson and Matthey and 3-acetylpyridine was used without further purification as purchased from Aldrich. Synthesis was performed in the absence of light, and the final product was kept away from light to avoid any photochemical decomposition.

Infrared spectra were recorded from 4000 to 300 cm^{-1} on Perkin–Elmer Paragon 1000 FTIR spectrometer equipped with a Golden Gate ATR device, using the reflectance technique. ^1H, ^{13}C and ^{195}Pt NMR experiments were performed on a Bruker DPX 300 spectrometer, with measurements carried out at room temperature in dmso-d_6. Elemental analysis of C, H, N were carried out on a Perkin–Elmer 2400 series II analyzer. Pt analysis was carried out by AAS and ICP. Electrospray ionization-mass spectra (ESI-MS) were achieved from dmso (dimethyl sulfoxide) and recorded on a Thermo Finnigan AQA apparatus. XAS and EXAFS experiments were performed at the Stanford Synchrotron Radiation Lightsource (SSRL), as described below.

2.2. X-ray measurements

Diffraction data for the H_2Std sulfate monohydrate were collected at room temperature on a Siemens P4 diffractometer using standard procedures [35] (see Table S1 and the deposited CIF file for details). Handedness of the enantiomorphic space group was arbitrarily chosen and the structure refined in $P3_1$ on the basis of non-corrected data. The relative stereochemistry of chiral centers was assigned after refining a Flack parameter, which corresponds to that expected for a Std derivative. The high resolution of the diffraction data allowed for accurate determination of the H atom positions [36]. The sulfate ion appeared to be disordered over two positions. Sulfate O atoms were found distributed over two sites, and their respective occupancies refined with their sum constrained to 1. Site occupation factors converged to 0.775(7) and 0.225(7). Final least-squares cycles were performed without restraints or constraints for the geometry.

2.3. Cytotoxicity studies

The A2780 and A2780R cells were generously provided by Dr. J.M. Perez (Universidad Autónoma de Madrid, Spain). The cells were grown as monolayers in Dulbecco's modified Eagle's Medium supplemented with 10% fetal calf serum (Gibco, Paisley, Scotland), penicillin (100 units/mL: Dufecha, the Netherlands) and streptomycin (100 μg/mL: Dufecha, the Netherlands). The L1210 and L1210R cell lines were cultured in McCoy's 5a medium supplemented with 10% fetal calf serum (Gibco, Paisley, Scotland), penicillin (100 units/mL: Dufecha, the Netherlands) and streptomycin (100 μg/mL: Dufecha, the Netherlands).

For the cell growth assay, cells were pre-cultured in 96 multiwell plates for 48 h at 37 °C in a 5% CO_2 containing incubator and subsequently treated with 45 μL of compound in triplicate. After 48 h incubation, 50 μL of a 5 mg/mL MTT solution in PBS was added to each well, and allowed to develop at 37 °C for 2 h. After this, the medium was removed carefully and 100 μL of dmso was added to each well. The absorbance of the resulting purple solutions were measured at 590 nm using a Biorad 550 microplate reader. The cytotoxicity is determined by the IC_{50} values of each compound. The IC_{50} values are drug concentrations that inhibit cell growth for 50% with respect to control. The lower the IC_{50} value the better anti-tumor activity can be expected. The numbers were determined graphically using Graphpad Prism analysis software.

2.4. UV–Vis titration

UV–Vis titration experiments were performed in order to clearly discern the behavior of the Pt complex and CT-DNA at different ratios and also to support previous CD analysis. Tris buffer pH 7.2 was used in all the solutions and variations on the amount of platinum compound versus a constant concentration of DNA were accomplished (*R* ratio from 5 to 0.3). Data were collected on Varian Cary 50 UV–Vis Spectrophotometer with new Fiber Optic Dip Probe accessory. The Cary 50 utilizes a very long-life Xenon source lamp with wavelength range between 190 and 1100 nm as well as photometric range of +/−3.3 Å.

2.5. XAS

All data were measured at the Stanford Synchrotron Radiation Lightsource (SSRL) under ring conditions of 3.0 GeV and 60–100 mA.

Pt L_3-edge XAS data were measured on focused 16-pole wiggler beam line 9-3. A Si(2 2 0) monochromator was utilized for energy selection. A harmonic rejection mirror was (set to a 15 keV cutoff) was used to minimize higher harmonic components in the X-ray

beam. Solid samples were prepared in a matrix with boron nitride, pressed into a pellet and sealed between 38 μm Kapton tape windows in a 1 mm aluminum spacer. Solution samples (3.8 mM) were dissolved in dmso. The samples were maintained at 10 K during data collection using an Oxford Instruments CF1208 continuous flow liquid helium cryostat. Data were measured in transmission mode or fluorescence mode, for solid and solution samples, respectively. Internal energy calibrations were performed by simultaneous measurement of a Pt reference foil placed between a second and third ionization chamber. The first inflection point of the Pt L_3-edge was assigned to 11563.0 eV. Data represent three to six scan averages and were processed by fitting a second order polynomial to the pre-edge region and subtracting this background from the entire spectrum. A three-region cubic spline was used to model the smooth background above the edge. The data were normalized by subtracting the spline and normalizing the post-edge 1.0.

All Cl K-edge data were measured using the 54-pole wiggler beam line 6-2 in high magnetic field mode of 10 kG with a Ni-coated harmonic rejection mirror and a fully tuned Si(1 1 1) double crystal monochromator. Data were measured at room temperature by fluorescence, using a Lytle detector. To check for reproducibility, 2–3 scans were measured for each sample. The energy was calibrated from Cl K-edge spectra of Cs_2CuCl_4, run at intervals between sample scans. The maximum of the first pre-edge feature in the spectrum was fixed at 2820.20 eV. Data were averaged, and a smooth background was removed from all spectra by fitting a polynomial to the pre-edge region and subtracting this polynomial from the entire spectrum. Normalization of the data was accomplished by fitting a flattened polynomial or straight line to the post-edge region and normalizing the post-edge to 1.0.

3. Results and discussion

3.1. Synthesis of H_2Std sulfate

Although we have previously reported the preparation of streptidine [21], here we present a more detailed description of the crystalline preparation. Streptomycin (5.38 g, 14.23 mmol) was dissolved in H_2O (420 mL), acetone (350 mL) and concentrated H_2SO_4 (10 mL). After two days refluxing the solution turned orange and a white precipitate gradually appeared, corresponding to the solid streptidine sulfate. The solution was filtered and stored at 4 °C. After few days crystals of $(H_2Std)SO_4(H_2O)$ were formed. The crystals were filtered and washed with acetone and cold water.

3.2. Crystallographic structures of H_2Std sulfate monohydrate

Preliminary crystallographic studies have been reported for this salt, using powdered samples [37] and single crystals [21] very recently Leśniewska et al. [34] reported a low-temperature diffraction study of the streptidine sulfate monohydrate. The Supplementary data of this manuscript shows the high resolution structural analysis that we performed at room temperature, to provide a more precise picture of the free ligand and a better understanding of the final platinum compound.

The refinement of both structures is rather similar, corroborating that the H_2Std sulfate monohydrate conserves at RT the same structural features observed at 100 K. For the following discussion, the projection of the asymmetric unit and a view of the crystal structure are given in Figs. 1 and 2, respectively. Tables with structural parameters, selected bond lengths and angles as well as a more accurate description of the structure are given in the Supplementary data (Tables S1–S3) and in the deposited CIF file.

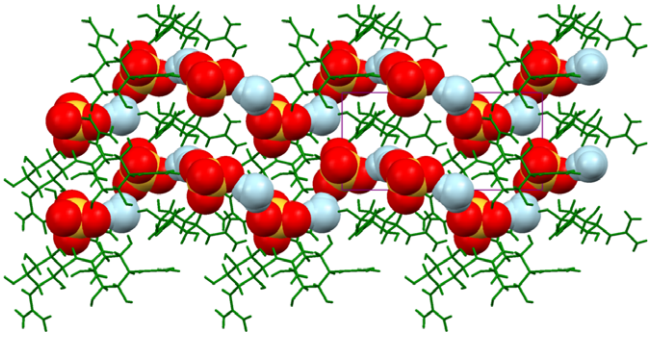

Fig. 2. A part of the crystal structure of $H_2Std^{2+}SO_4^{2-}\cdot H_2O$ viewed along the *b* axis of the trigonal cell. Sulfate (red and yellow) and water molecules (light blue) are displayed using a spacefill style. The 3_1 screw axes are in the plane of projection, generating 1D anionic chains. H_2Std^{2+} cations (green) are represented with capped sticks. For clarity, a single orientation is shown for sulfate, corresponding to the highest site-occupation factor. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

A quite original feature of the crystal structure (Fig. 2) is the remarkably complex network of hydrogen bonds, involving all available donor and acceptor groups, i.e. amine and guanidine N–H, hydroxyl O–H, lattice water molecule, and sulfate O atoms (see Supplementary data, Table S3).

In relation to the general goal of our work, the role of the water molecules (light blue, Fig. 2) in the crystal structure deserves a special comment. Lattice solvent does not merely fill the voids in the crystal. It has an essential function as a building block of the anionic matrix, which accommodates cations. On the other hand, because of the limited dimensionality of that matrix, 1D, and the fact that hydrogen bonds are not too strong, we can assume that anionic chains dissociate easily in aqueous media. The salt $H_2Std^{2+}SO_4^{2-}\cdot H_2O$ is therefore a good starting material for our purpose: the H_2Std^{2+} cation, once available in-solution, should work as an efficient shuttle for any anionic Pt-containing moiety, providing that both moieties form a bond, for instance a classic coordination of Std to the metal.

3.3. Synthesis of the platinum–streptidine compound (**1**)

Streptidine (0.025 g, 0.07 mmol), $(H_2Std)(SO_4)(H_2O)$, was dissolved in H_2O (2.5 mL) and added to a 2.5 mL of an aqueous solution of 0.086 mg (0.21 mmol) of K_2PtCl_4. The reaction was protected from the light and stirred at room temperature. After two days, a dark green precipitate ($(H_2Std)PtCl_4$) was isolated by filtration, washed with H_2O and dried with diethyl ether. The observed yield was 20%. IR (KBr), ν (cm^{-1}): 3312, 1634, 1597, 1406, 1392, 1366, 1216, 1084, 1033, 993, 953 and 466; EA: for $Pt(H_2Std)Cl_4\cdot 2H_2O$, *Anal.* Calc. for $C_8H_{24}N_6O_6Cl_4Pt$: C, 15.08; H, 3.80; N, 13.19. Found: C, 14.81; H, 3.16; N, 12.88%. A fit on a second sample also agreed with formula $Pt(H_2Std)(OH)_{0.5}Cl_{3.5}(H_2O)_{2.5}$, *Anal.* Calc. for $C_8H_{25.5}N_6O_7Cl_{3.5}Pt$: C, 15.08; H, 4.04; N, 13.19; Cl, 19.48. Found: C, 14.87; H, 3.42; N, 12.84; Cl, 19.48%.

3.4. Spectroscopic characterization of $(H_2Std)PtCl_4$ (**1**)

After mixing H_2Std sulfate (white solid) with K_2PtCl_4, a dark green precipitate, corresponding to $(H_2Std)PtCl_4$ resulted. The final, colored compound was soluble in dimethyl sulfoxide and dimethyl formamide. However, we were unable to obtain suitable crystals and in the absence of crystallographic information, XAS and EXAFS experiments were thus utilized to characterize the structures (see Section 3.6).

In the solid state, the IR spectrum of the $(H_2Std)PtCl_4$ complex shows shifted and attenuated bands compared with free streptidine, all over the range between 300 and 4000 cm^{-1}; however, one of the most significant changes in the infrared spectrum of **1** is the absence of two intense bands at approximately 1100 and 1068 cm^{-1}, associated to the SO_4^{2-} counterion, suggesting either a neutral species, or an exchange of the counterion from sulfate to Cl^- anions. These observations were reinforced by elemental analysis in which the green precipitate fitted well with a $(H_2Std)PtCl_4(H_2O)_x$ formula ($x = 1–4$ depending on the sample). This formulation involves a streptidine molecule in its protonated form, implying weak interactions between the Pt moiety and the streptidine instead of the formation of a coordination bond. On the other hand, the Pt–ICP results agreed with the theoretical value of 32.67% of Pt, expected for a $(H_2Std)PtCl_4$ molecule.

Several experiments in solution corroborated these results: the molecular ion peaks M^+ (ESI^+-MS in dmso) for $(H_2Std)PtCl_4$ species included Pt and H_2Std in a 1:1 ratio, (see *Fig.* S1). Some of these arrays can only be achieved by varying the charge of H_2Std from +2 to 0, i.e. implying total or partial deprotonation of the streptidine under these conditions. The presence of dmso in the sample as a part of the ionic units shows the replacement of one or more Cl^- ions by dmso molecules. Such a feature is not at all surprising and has been reported before in the literature taking into account the greater affinity that this metal has for S ions [38].

The electronic spectra of $(H_2Std)PtCl_4$ was recorded in dimethyl sulfoxide between 250 and 500 nm. Comparison with the free ligand sulfate was not possible due to the limited solubility of the streptidine in organic solvent. The absorbance of $(H_2Std)PtCl_4$ with time is shown in *Fig.* S2. In dmso, compound **1** resulted in a transparent, yellow solution after continued stirring for several minutes. This change is consistent with the replacement of at least one coordinated Cl^- ion for a dmso molecule. Compound **1** showed a broad and intense band at approximately 290 nm, which can be assigned to a combination of metal–ligand charge transfer and d–d bands [39], and in general, intense bands around 300 nm which may also be indicative of interactions between adjacent platinum atoms, related in this case with the intensity of the color of $(H_2Std)PtCl_4$.

3.5. NMR studies

As mentioned above, detailed comparison of the ^1H NMR of free streptidine and $(H_2Std)PtCl_4$ in dmso was not suitable and did not yield useful information. Nevertheless, the ^1H NMR spectrum of **1** in dmso-d_6 (Fig. 3) presented clean sets of peaks that could be divided in three series depending on their chemical shifts: from 3.11 to 3.30 ppm (broad peaks, partly overlapped with the water from the solvent), from 5.14 to 5.67 ppm (three sets of doublets) and from 7.00 to 7.57 ppm (a broad band and a sharp doublet), respectively. Taking into account the nature of the H_2Std protons, the peaks at ~3.11 ppm were associated to the –CH of the cycle and the rest of signals, to the H atoms from the –OH, –NH and $–NH_2$ groups.

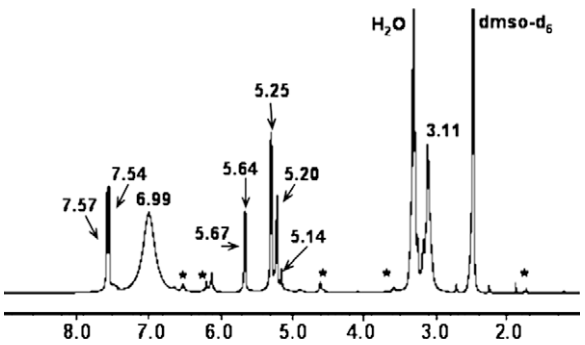

Fig. 3. ^1H NMR of $(H_2Std)PtCl_4$ recorded in dmso-d_6.

The ^{13}C NMR spectrum of the $(H_2Std)PtCl_4$ in dmso-d_6 (Fig. 4) provided even more valuable information: it showed five different chemical shifts at 58.9, 70.9, 71.7, 75.9 and 158.1 ppm. The assignment of the peaks was performed by comparison with the free ligand (in D_2O), their intensity and additional ^{13}C NMR where the quaternary character of the single peak (involving to 2C atoms) at 158.1 ppm and the *tertiary* nature of the rest of the peaks were identified. The spectrum in D_2O of the free-H_2Std showed the same number of peaks with chemical shifts at 59.3, 71.7, 72.4, 75.6 and 159.1, respectively. The intensities for both were 2:1:2:1:2. The number of peaks revealed to basic two aspects: (i) that in solution the final Pt complex exhibited high symmetry, almost identical to the free streptidine and (ii) that the chemical shifts differ slightly from the free ligand (<1 ppm, Table 1) providing some insight on the strength of the interaction between the Pt and the H_2Std.

Altogether, this result was found compatible with our previous work, using additional 3d metals (Ni, Co and Cu) [21], and strongly pointed to the ionic nature of the interactions in complex **1,** where $PtCl_4^{2-}$ would function as a counterion stabilizing the charge of the streptidine ligand. Thus, the putative structure of this compound could be also related to that established for the free streptidine (see Section 3.2), where instead of SO_4^{2-} anions in a pseudo-tetrahedral geometry among the H_2Std^{2+} species, we now would find tetrachloridoplatinate(2−) ions in a square-planar arrangement.

2D NMR correlation experiments with ^{13}C–^1H were performed to assign the H atoms in **1** (Fig. 5). As expected, the peaks observed between 3.11 and 3.30 ppm were clearly related to all *tertiary* C atoms from the ring (–CH type). Following the numbering given in Fig. 1, the chemical shifts of H_{2A}, H_{4A}, H_{5A} and H_{6A}, were found

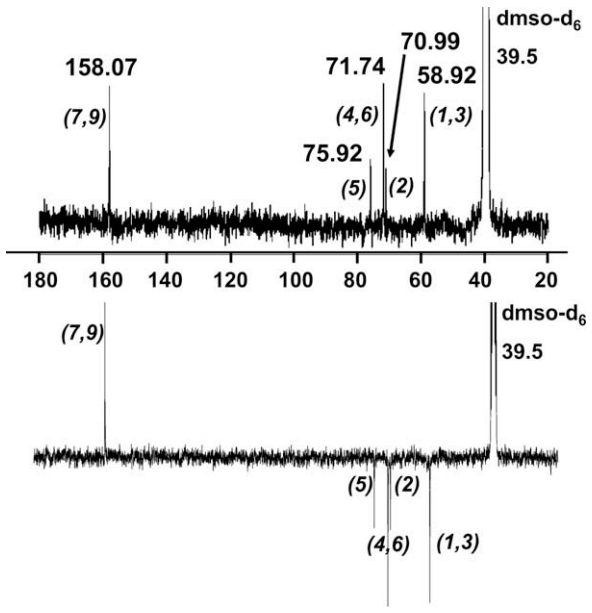

Fig. 4. ^{13}C NMR of $(H_2Std)PtCl_4$ recorded in dmso-d_6. Atom numbering as used in Fig. 1.

Table 1
^{13}C chemical shifts. Comparison between free streptidine and $(H_2Std)PtCl_4$.

Species	C_1/C_3	C_2	C_4/C_6	C_5	C_7/C_9
$(H_2Std)PtCl_4$	58.9	70.9	71.7	75.9	158.1
Free-H_2Std	59.3	71.7	72.4	75.6	159.1

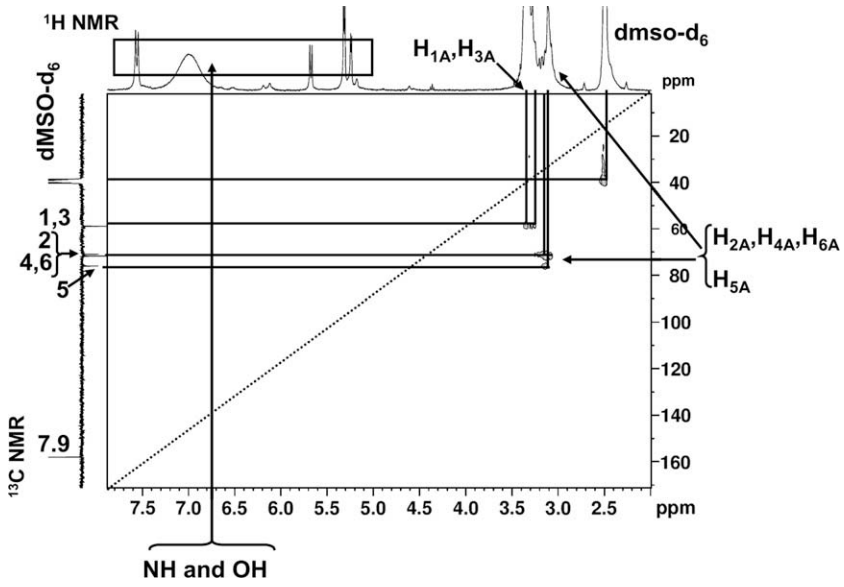

Fig. 5. 2D NMR experiments correlating ^{13}C–^{1}H of $(H_2Std)PtCl_4$ as recorded in dmso-d_6. Atom numbering as in Fig. 1.

at high fields (3.11 ppm) than those for H_{1A} and H_{3A}, shifted downfield and overlapped by an intense peak from the water molecules contained in the solvent (at approximately 3.3 ppm). No further correlation was observed from the other sets of peaks, as was also anticipated by consideration of their possible coordination to O and N atoms (H_2–H_{10}, H_{1B} and H_{3B}).

Furthermore, COSY experiments were performed with the aim of correlating the H atoms previously specified (H_{1A}–H_{6A}) with the adjacent protons from the –OH and –NH groups. Thus it was possible to link the high field chemical shifts corresponding to H_{4A}–H_{6A} and H_{2A} at 3.1 ppm with the three doublets from 5.14 to 5.67 ppm. These peaks were assigned as the protons from hydroxide groups. Similarly, H_{1A} and H_{3A} were related to the singlet at 7.59 ppm corresponding to the H atoms from NH groups. Integrations agreed with the interpretation of the data in all of the peaks. By elimination, the broad band at 7.00 ppm was assigned to the –NH_2 protons from the guanidine (Fig. 6).

At the same time, ^{195}Pt NMR in dmso-d_6 displayed a single peak at −2951 ppm indicative of only one type of Pt species in the sample (Fig. S3). This shift agrees with a platinum center coordinated to one S and three Cl atoms, compatible with other spectroscopic characterization in solution. The substitution of two or more Cl ions by two dmso molecules was discarded, because the resulting peak/s should have appeared at higher fields.

Therefore an additional approach, applying Pt L_3- and Cl K-edge XAS, was employed to compare the results from **1** in the solid and in solution, with the aim of obtaining more insight of the coordination sphere of the Pt ion and the exchange of ligands.

3.6. XAS

Fig. 7 shows a comparison of the Pt L_3-edge spectra of solid and solution $(H_2Std)PtCl_4$ (Fig. 7). The corresponding EXAFS and the fits to the data are shown in (Fig. 8). The Pt L_3-edge data of the solid

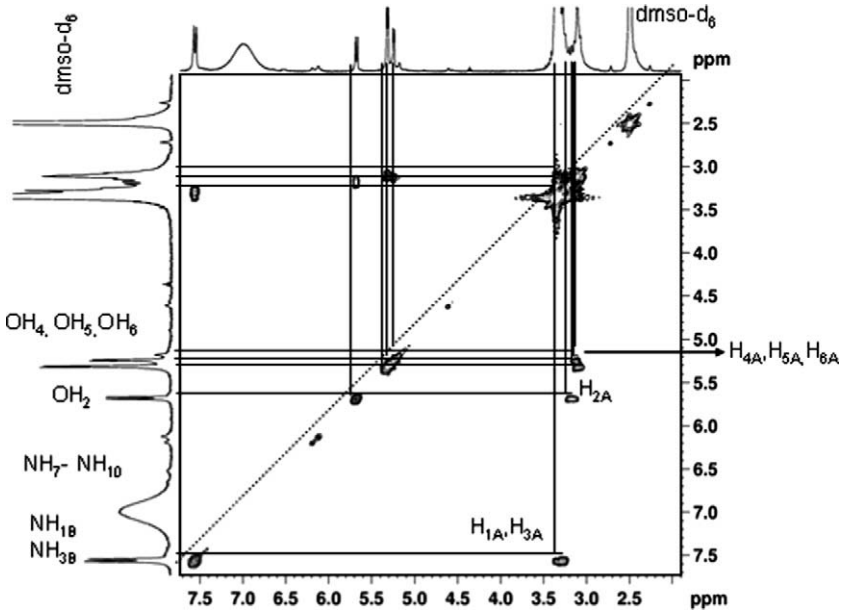

Fig. 6. COSY NMR experiment of $(H_2Std)PtCl_4$ as recorded in dmso-d_6. For the used numbering, see Fig. 1.

complex are shifted to lower energy, indicating a more reduced Pt site or a change in the local coordination environment upon solvation.

The EXAFS data also indicate a change in the local Pt coordination upon solvation of $(H_2Std)PtCl_4$ in dmso. The decrease in amplitude may be attributed to greater disorder in solution and/or a change in local coordination environment (as indicated by the edge data). A good fit to the solid $(H_2Std)PtCl_4$ is obtained by including four Pt–Cl interactions at 2.30 Å (Table 2, fit 1). A slight improvement in the fit is obtained by including an additional Pt–N/O vector at 2.02 Å; however, the improvement in the error value is not statistically significant (Table 2, fit 2). The fit clearly becomes worse if only three Pt–Cl interactions are included (Table 2, fit 3), indicating that the solid $(H_2Std)PtCl_4$ data require four Pt–Cl interactions.

In contrast, the solution $(H_2Std)PtCl_4$ data are best fit by three Pt–Cl at 2.30 Å and one Pt–N/O at 2.04 Å (Table 2, fit 4). The absence of the Pt–N/O vector results in increase in the error to 1.04 (Table 2, fit 5). Thus, these data suggest that oxygen (from dmso) or a N (from Std^{2+}) may be replacing a chloride in solution. However, this is in contradiction with the ^{195}Pt NMR, which should appear at higher fields if the Pt were coordinated to the dmso through the oxygen instead of the sulfur atom. In addition, the strong affinity of Pt for S is well-known.

Table 2
Representative EXAFS fits to solid and solution samples of $(H_2Std)PtCl_4$.

Complex	Fit number	Vector	Length (Å)		σ^2 (Å^2)	ΔE_0	Error[a]
Solid	1	4	Pt–Cl	2.30	0.0024	−4.20	0.594
	2	4	Pt–Cl	2.30	0.0023	−2.19	0.569
		1	Pt–N	2.02	0.0068		
	3	3	Pt–Cl	2.31	0.0013	−4.33	0.671
		1	Pt–N	2.14	0.0005		
Solution	4	3	Pt–Cl	2.30	0.0031	−4.80	0.688
		1	Pt–N	2.04	0.0017		
	5	4	Pt–Cl	2.31	0.0052	−2.10	1.040

[a] Error is given by $\sum[(\chi_{obsd}-\chi_{calcd})^2k^6]/\sum[(\chi_{obsd}{}^2k^6]$.

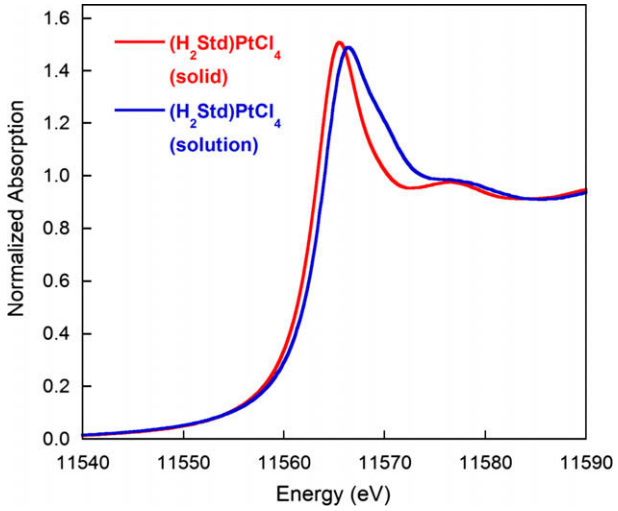

Fig. 7. Comparison of the normalized Pt L_3-edges for $(H_2Std)PtCl_4$ as a solid and as a solution in dmso.

In order to further understand the differences between solid and solution XAS data of $(H_2Std)PtCl_4$, Pt L3-edge data of $(^nBu_4)PtCl_3(NH_3)$, $(^nBu_4)_2[PtCl_4]$ were obtained as both solids and solutions (in CH_2Cl_2). Comparison of the Pt L_3-edge of solid and solution $(^nBu_4)_2[PtCl_4]$ show clear changes in the Pt L_3-edges, while the EXAFS data are identical (Figs. S4–S7). The differences in the edges may be attributed to longer-range order in the solid (perhaps due to the NBu_4 interaction), which are absent in solution. Similarly for $(^nBu_4)PtCl_3(NH_3)$, differences are observed in the edges upon solvation, whereas no changes in the EXAFS data occur. The solution data of all these compounds suggest that caution must be exercised in the interpretation of the Pt L_3-edges. A full XANES analysis of the edge data, however, is beyond the scope of this study.

Cl K-edge XAS data were also obtained for $(^nBu_4)PtCl_3(NH_3)$, $(^nBu_4)_2[PtCl_4]$ and $(H_2Std)PtCl_4$ in the solid state. The presence of a Cl K-pre-edge feature confirms the presence of coordinated Cl in $(H_2Std)PtCl_4$. Interestingly, the Cl K-edge data show a pre-edge energy and intensity for $(H_2Std)PtCl_4$, which is closer to that of $(^nBu_4)PtCl_3(NH_3)$ (Fig. 9). Due to the absorbing nature of dmso at these energies, measurements of $(H_2Std)PtCl_4$ in solution were not possible.

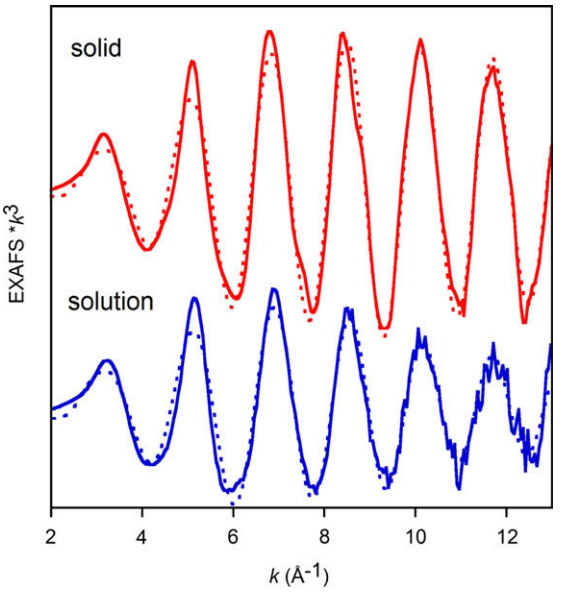

Fig. 8. The k^3-weighted EXAFS data (solid lines) and the fits to the data (dashed lines) $(H_2Std)PtCl_4$ as a solid (top) and as a solution in dmso (bottom).

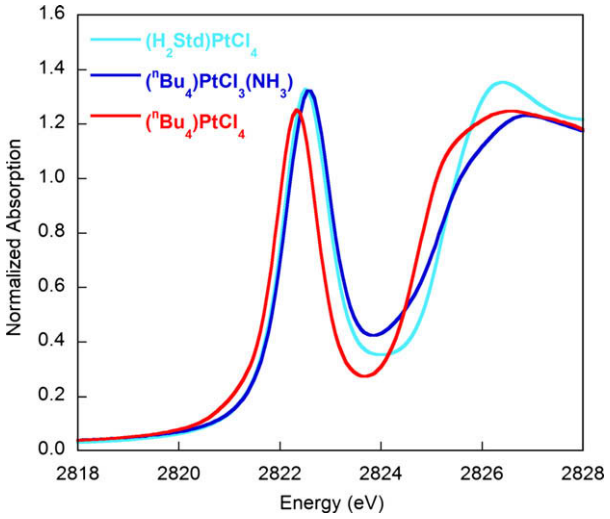

Fig. 9. Comparison of the normalized Cl K-edges of solid $(H_2Std)PtCl_4$, $(^nBu_4)PtCl_3(NH_3)$, and $(^nBu_4)PtCl_4$.

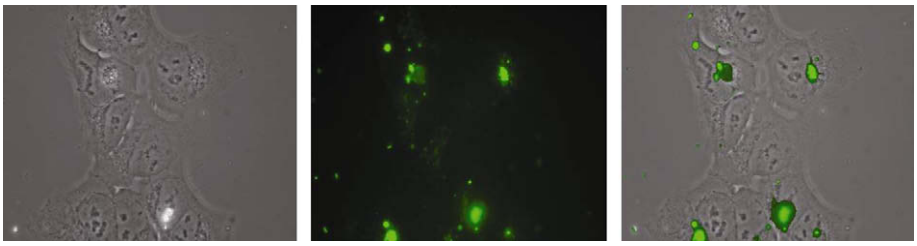

Fig. 10. Pictures with visible and green light (left, center) and overlapped (right) of $(H_2Std)PtCl_4$ in ostereosarcoma cells after 3 h or incubation. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

4. Biological assays and biophysical studies

4.1. Growth inhibition assay

Four types of cell lines were used to study the growth inhibition: A2780, L1210 and their respective resistant analogs. The cells were prepared in a complete medium and added to duplicate wells of a 96-well culture plate. They were treated with $(H_2Std)PtCl_4$ that had been previously dissolved in dmso (2% diluted in complete medium) at a 40 μg/mL and incubated for 48 h at 37 °C in a CO_2 incubator. The control set contained tumor cells without test compounds. MTT was added to each well and incubated for 2 h more and later dmso was added to each well. Absorbance values were measured with a microplate reader at 560 nm. The $(H_2Std)PtCl_4$ does not have any apparent activity against the four used cell lines and similar results were found for $(H_2Std)SO_4(H_2O)$, which was found also not toxic in our *in vitro* experiments. Moreover, an additional sample of the platinum complex was checked in the laboratories of Tevapharmachemie, to study a wider range of tumor cancer cells, with analogous results compared with the above cell lines.

4.2. Fluorescence studies

Given the fact that the streptidine sulfate has fluorescent properties [23] it was decided to study the fluorescent activity of $(H_2Std)PtCl_4$ in cells with the aim of having a better understanding on the actions that cancer cells have to shield themselves against the putative anti-tumor actions of this Pt complex. The questions we tried to answer are basically: (i) could the $(H_2Std)PtCl_4$ complex enter into the cells? (ii) once inside: would it be possible to enter the cellular nucleus?

Preliminary studies were performed on free-H_2Std sulfate in H_2O and on the $(H_2Std)PtCl_4$ in dmso, respectively, and their emission spectra at different wavelengths were compared and followed in time. Similarities between the two samples were observed when both solutions were excited at 240 and 410 nm, respectively. The emission spectra at such wavelengths of the final $(H_2Std)PtCl_4$ complex exhibited attenuated bands at 402 and also at 423 and 450 nm, respectively, as well as the free-H_2Std. The rest of the emission bands observed for the free ligand were found to be quenched in **1**.

Fluorescence experiments were performed using ostereosarcoma cells. Fig. 10 shows a picture of the cells after 3 h of being incubated with compound **1**. The overlap of the pictures clearly shows fluorescence inside the cells, although, it appears that this phenomena takes place outside the nuclei, suggesting that to protect themselves, the cells may store the compound in vacuoles and later they disposed them.

The results from these preliminary fluorescence data provide visual explanations on the non-toxicity effects of the $(H_2Std)PtCl_4$. In order to check the activity of the complex with the DNA preliminary binding studies were performed.

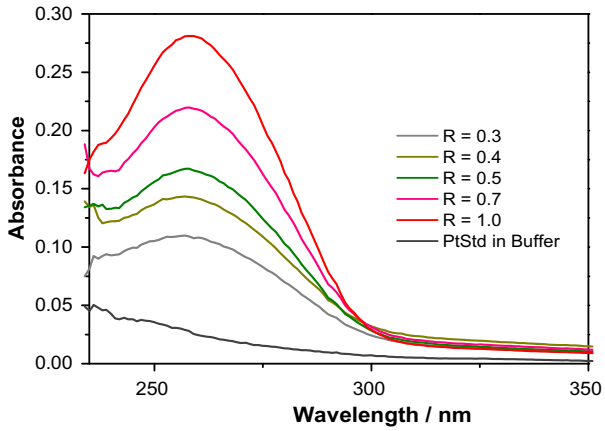

Fig. 11. Titration experiments at different *R* values of DNA and $(H_2Std)PtCl_4$ complex. *R* is defined as the ratio Pt:DNA base pair.

4.3. UV–Vis titration with DNA

Finally, and parallel to the studies of the fluorescence measurements above UV–Vis titrations with DNA were achieved with different ratios Pt/DNA. The *R* values (defined as the ratio Pt:DNA base pair) varied from 0.3 to 1.0 (Fig. 11). The graph of all the *R* values shows the increase of the band of the absorbance of the DNA while increasing the *R* value. At the same time the comparison between *R* = 1, free DNA at this concentration and $(H_2Std)PtCl_4$ shows that the absorbance of the free DNA is lower than the absorbance of the one containing DNA/$(H_2Std)PtCl_4$ at a ratio equal to 1.0. (Fig. S8) This experiment shows that the DNA can indeed be affected upon interaction with **1**, however, the absence of cytotoxic activity in cells could be related to the impossibility of reach the nuclei of the cells.

5. Conclusions

The synthesis of a unique Pt–streptidine compound (**1**) has been achieved and the characterization of this final compound, $(H_2Std)PtCl_4$, was possible based on current spectroscopic techniques. In the absence of crystallographic data, structural characterization was performed using NMR, MS, XAS and EXAFS in the solid state as well as in solution. It was found that compound **1** has anionic nature, where the streptidine acts as cation and the platinum remains present as the $PtCl_4^{2-}$ counterion. In the solution the final arrangement of cations and anions was studied by the XAS edge measurements, suggesting a loss of at least one chloride and perhaps N or O of the Std bonding to the Pt. The substitution of a Cl

ion is in concordance with what was observed by a number of spectroscopic techniques including ^{195}Pt NMR; however, the later suggested coordination with a molecule of solvent (dmso) through a S atoms instead of an O. These results, which initially appear to be contradictory, could be interpreted taking into account that the loss of a Cl will create negative charged, platinum species that may interact electrostatically with Std^{2+} ions and also could be related to the complex network of hydrogen bonds that it was already observed in the crystal structure of H_2Std sulfate.

In addition, biological studies have shown that $(H_2Std)PtCl_4$ does not affect drastically cancer cells or bacteria. Using the fluorescence properties of the compounds it was possible to show that accumulation of **1** occurs in the cells but outside the nuclei of the studied cells. DNA-binding studies have showed the interaction of the complex with the CT-DNA. Although further biological studies would be required with this system, the present results suggest that the lack of anticancer activity may originate from the inability of the compound of passing the nuclear membrane.

Acknowledgments

The authors wish to thank Johnson and Matthey (Reading, UK) for their generous loan of K_2PtCl_4. Continuous support from the Netherlands Research Organisation (NWO) and its Chemical Council (CW) is also gratefully acknowledged for the TOP grant with number 700.53.310. The authors gratefully acknowledge Dr. J.M. Perez (Universidad Autónoma de Madrid, Spain) for providing A2780 and A2780R cell lines.

Scheme 1. Synthesis of complexes **2**–**5**.

metal-coordinated phosphinous acid, $R_2P(OH)$, the free form of which is usually unstable and tautomerizes to give the phosphine oxide $R_2P(O)H$. Complexes containing such type of ligands are rare, and only a limited number of Pt and Ni complexes with phosphinous acid as ligand ($PhP(OH)(CH_2)_2P(OH)Ph$) is described in the literature [30]. Usually, hydrolysis of chlorophosphine complexes is achieved with acids or bases [31,32]. Here, we observed that UV irradiation of **1** with $[Cr(CO)_6]$ in moist THF results in hydrolysis of both P–Cl bonds and formation of $[Cr(CO)_4\{1,2\text{-}(P(OH)^tBu)_2C_2B_{10}H_{10}\}]$ (**5**). The reaction was followed by $^{31}P\{^1H\}$ NMR spectroscopy. After 33 h, only minor amounts of **1** are present. Alternatively, **5** is formed on irradiation of a *rac*/*meso* mixture of **2** in moist THF in 2.5 h according to $^{31}P\{^1H\}$ NMR spectroscopy.

3. Molecular structures of 2, 3a,b, 4 and 5

X-ray structure determinations of **2**–**5** (Figs. 1–3) show that the bis(phosphino)carbaborane coordinates in a chelating fashion. The structural parameters of **1a,b** [21] remain nearly unchanged on coordination to the group 6 metal atom (Table 1).

For the M–CO groups *trans* to the coordinated P atoms, the M–C distances are longer and the C–O bond lengths shorter. Similar trends, that is, lengthening of the Mo–P and C–O bonds and shortening of the Mo–C bonds, are observed for the complexes $[Mo(CO)_4\{1,2\text{-}(PPh_2)_2C_2H_4\}]$ [33] and $[Mo(CO)_4\{1,2\text{-}(PPh_2)_2C_2H_2\}]$ [34]. This suggests increased π-acceptor properties of the P atoms in **1a**,**b** in comparison with other bisphosphines [2,35], due to the presence of the electron-deficient carbaboranyl ligand in **1a** [2].

The compounds *rac*-$[M(CO)_4\{1,2\text{-}(P^tBuCl)_2C_2B_{10}H_{10}\}]$ (M = Cr (**2**), Mo (**3a**), W (**4**)) are isotypic and crystallize in the monoclinic space group $P2_1/n$ with comparable lattice parameters.

4. Spectroscopic properties of 2, 3a,b, 4 and 5

The coordination of the bisphosphine **1a**,**b** leads to a remarkable low-field shift in the $^{31}P\{^1H\}$ NMR spectra (see Table 2) in compounds **2**–**4** (from ca. 160 ppm for **4** to 186 ppm for **3a/b** and to ca. 215 ppm for **2**) in comparison with the starting material (*rac* 116.7 and *meso* 116.4 ppm) [21]. Substitution of the Cl atoms in **2** by OH groups results in a high-field shift (215 ppm in **2**,

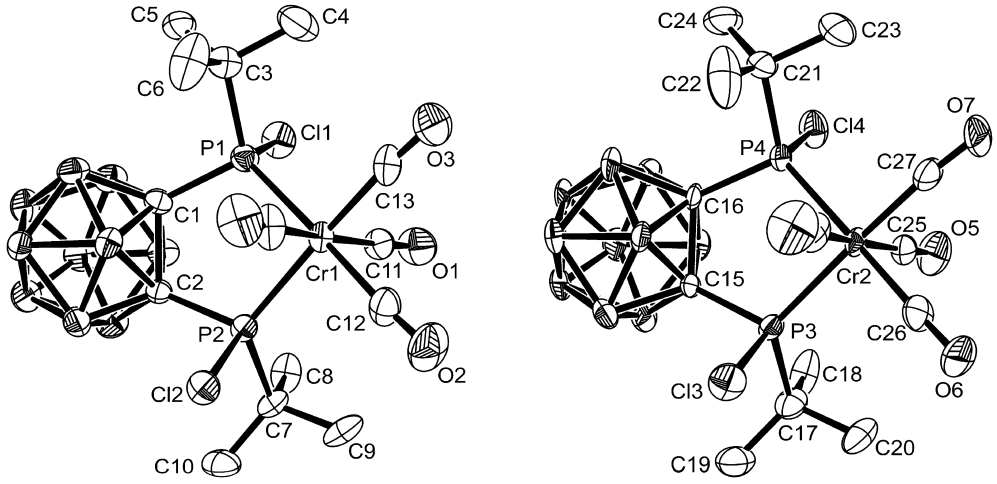

Fig. 1. Molecular structure of *cis-rac*-[Cr(CO)$_4${1,2-(P^{t}BuCl)$_2$C$_2$B$_{10}$H$_{10}$}] (**2**) showing the atom numbering scheme employed (ORTEP) [44]. The two independent molecules in the asymmetric unit are shown. The complexes *cis-rac*-[Mo(CO)$_4${1,2-(P^{t}BuCl)$_2$C$_2$B$_{10}$H$_{10}$}] (**3a**) and *cis-rac*-[W(CO)$_4${1,2-(P^{t}BuCl)$_2$C$_2$B$_{10}$H$_{10}$}] (**4**) are isotypic.

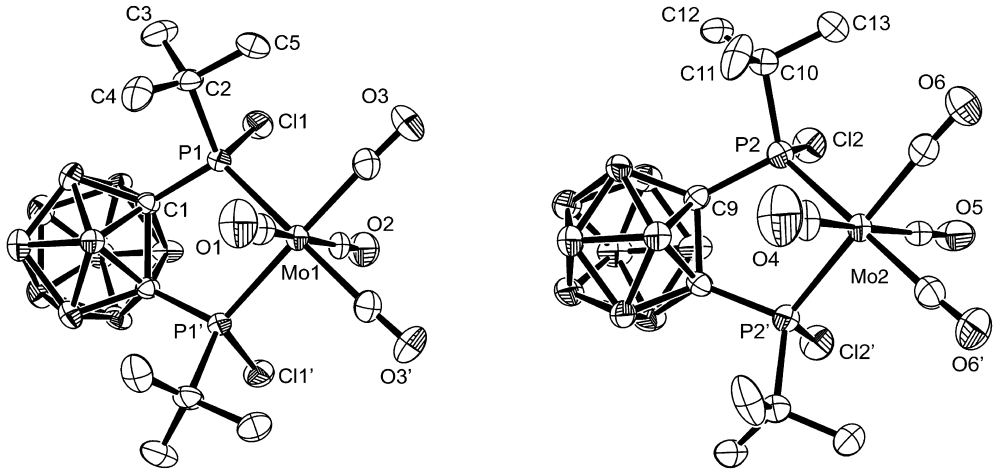

Fig. 2. Molecular structure of *cis-meso*-[Mo(CO)$_4${1,2-(P^{t}BuCl)$_2$C$_2$B$_{10}$H$_{10}$}] (**3b**) showing the atom numbering scheme employed (ORTEP) [44]. The two independent molecules in the asymmetric unit are shown.

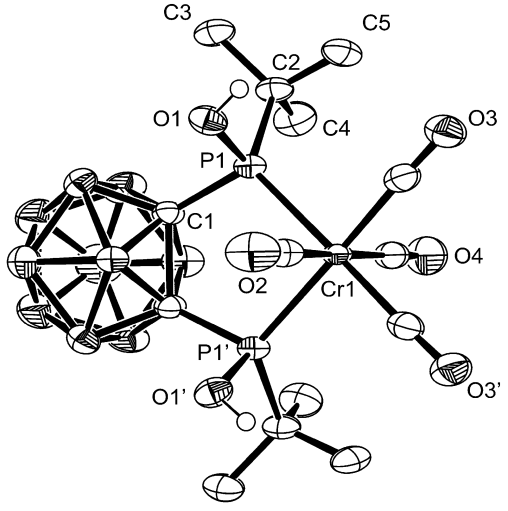

Fig. 3. Molecular structure of *cis-meso*-[Cr(CO)$_4${1,2-(P(OH)^{t}Bu)$_2$C$_2$B$_{10}$H$_{10}$}] (**5**) showing the atom numbering scheme employed (ORTEP) [44].

208 ppm in **5**). Additionally for the tungsten complex **4**, ^{183}W satellites with a $^1J_{PW}$ coupling constant of 289.3 Hz were observed.

The proton NMR spectra show the typical broad multiplets for the cluster protons (2.0–4.0 ppm) and a doublet for the *tert*-butyl protons at ca. 1.15 ppm ($^3J_{HP}$ range from 16.0 to 20.0 Hz).

In the ^{13}C{^{1}H} NMR spectra, all compounds show two signal groups for the four CO ligands. The CO groups *trans* to phosphorus are observed as multiplets due to an ABX spin system for all compounds at 202–223 ppm. For the CO groups *cis* to phosphorus a triplet is observed at 198–216 ppm due to an AA′X spin system in the case of the *rac* isomers **2**, **3a**, and **4** and an A$_2$X spin system for the *meso* isomer in **3b** and **5**. Accordingly, the carbon atoms of the carbaborane cluster also exhibit multiplets due to an ABX spin system. The methyl groups of the *tert*-butyl group show a very broad singlet at ca. 25 ppm, due to hindered rotation at room temperature. A low temperature ^{13}C{^{1}H} NMR spectrum at 213 K revealed a doublet according to C–P coupling. The ^{11}B{^{1}H} NMR spectra of **2**, **3a**, **4** and **5** show four signals in a 2:2:4:2 ratio, whereas compound **3b** shows seven signals in a 2:1:1:2:1:2:1 ratio. The signals can be assigned according to the literature, where boron atoms closest to carbon atoms are observed at the lowest chemical shift and boron atoms furthest from carbon atoms are observed at highest chemical shift [36].

[a] *cis* = CO *cis* to P; *trans* = CO *trans* to P; in the $^{13}C\{^1H,^{31}P\}$ NMR spectra singlets were observed for the CO and carbaborane carbon atoms (see Supplementary data).

5. Experimental

All experiments were carried out under purified dry nitrogen. For the irradiation experiment, a diving torch with water cooling and polychromatic light was employed. Solvents were dried and freshly distilled under argon. The NMR spectra were recorded with an AVANCE DRX 400 spectrometer (Bruker), ^{1}H NMR: internal standard solvent (benzene), external standard TMS; ^{13}C NMR: external standard TMS, internal standard solvent; ^{31}P NMR: external standard 85% H_3PO_4; ^{11}B NMR: external standard $BF_3(Et_2O)$. The melting points were determined in sealed capillaries under argon and are uncorrected. $[Mo(CO)_4(NBD)]$ [37], $[Mo(CO)_4(EtCN)_2]$ [38], and $[Cr(CO)_4(NBD)]$ [39] were prepared by literature procedures. 1,2-Bis(*tert*-butylchlorophosphino)-1,2-dicarba-*closo*-dodecaborane(12) (**1a,b**) was prepared and the diastereomers separated as described earlier [21]. $[M(CO)_6]$ (M = Cr, Mo, W) are commercially available.

5.1. cis-rac-[1,2-Bis(tert-butylchlorophosphino)-1,2-dicarba-closo-dodecaborane(12)]-tetracarbonylchromium(0) (*2*)

A solution of 0.1 g (0.25 mmol) **1a** and 0.07 g (0.27 mmol) $[Cr(CO)_4(NBD)]$ was stirred at 70 °C in toluene for 35 h. The solution was then cooled to rt, and the solvent evaporated. The residue was washed with *n*-hexane (3 ml) and recrystallized from toluene. At 4 °C pale yellow crystals of **2** were obtained. Yield: 0.06 g (43%), m.p. 230–5 °C (decomp.). *Anal.* Calc. for $C_{14}H_{28}B_{10}Cl_2CrO_4P_2$ (553.30): C, 30.32; H, 5.09. Found: C, 30.10; H, 4.73%. MS (ESI^-, MeOH) *m/z*: 542.1 $(M-B)^-$.

5.2. cis-rac- and cis-meso-[1,2-Bis(tert-butylchlorophosphino)-1,2-dicarba-closo-dodecaborane(12)]-tetracarbonylmolybdenum(0) (*3a,b*)

A mixture of 0.16 g (0.6 mmol) $[Mo(CO)_6]$ and 0.2 g (0.51 mmol) **1** in 5 ml toluene was refluxed for 3 h. Then the solvent was evaporated and the residue kept at rt in vacuum for 30 min to remove $[Mo(CO)_6]$. The residue was suspended in 3 ml *n*-hexane and filtered giving the product as a *rac/meso* mixture of **3a:3b** = 5:1 (0.26 g, 86%). The solid was recrystallized twice from toluene, but the isomers could not be separated. M.p. >210 °C (decomp.). *Anal.* Calc. for $C_{14}H_{28}B_{10}Cl_2MoO_4P_2$ (597.24): C, 28.20; H, 4.70; Cl, 11.89. Found: C, 28.20; H, 4.86; Cl, 11.90%. MS (FAB^+, 3-nitrobenzyl alcohol) *m/z*: 597.0 (28.4%, M^+), 486.1 (68.8%, M^+–4CO), 428.9 (25.2%, M^+–4CO–^{t}Bu).

5.3. cis-rac-[1,2-Bis(tert-butylchlorophosphino)-1,2-dicarba-closo-dodecaborane(12)]-tetracarbonylmolybdenum(0) (*3a*)

A mixture of **1a** (0.1 g, 0.25 mmol) and $[Mo(CO)_4(NBD)]$ (0.08 g, 0.27 mmol) in toluene (5 ml) was stirred at 65–70 °C for 15 h. The mixture was then filtered through 2 cm SiO_2 and washed twice

with 5 ml toluene. The solvent was removed in vacuo, and the resulting solid was recrystallized from toluene. At 4 °C pale yellow crystals of **3a** were obtained. Yield: 0.07 g (47%), m.p. >210 °C (decomp.). *Anal.* Calc. for $C_{14}H_{28}B_{10}Cl_2MoO_4P_2$ (597.24): C, 28.20; H, 4.70. Found: C, 28.54; H, 4.80%.

5.4. cis-meso-[1,2-Bis(tert-butylchlorophosphino)-1,2-dicarba-closo-dodecaborane(12)]-tetracarbonylmolybdenum(0) (**3b**)

A solution of 0.07 g (0.18 mmol) **1b** in CH_2Cl_2 (5 ml) was added to a solution of 0.06 g (0.19 mmol) [$Mo(CO)_4(EtCN)_2$] in CH_2Cl_2 (5 ml) and then stirred for 48 h. The solvent was removed in vacuo, and the resulting solid was suspended in *n*-hexane (5 ml) and filtered. The solid was recrystallized from toluene. At 4 °C pale yellow crystals of **3b** were obtained. Yield: 0.05 g (47%), m.p. >210 °C (decomp.). *Anal.* Calc. for $C_{14}H_{28}B_{10}Cl_2MoO_4P_2$ (597.24): C, 28.20; H, 4.70. Found: C, 28.36; H, 4.98%.

5.5. cis-rac-[1,2-Bis(tert-butylchlorophosphino)-1,2-dicarba-closo-dodecaborane(12)]-tetracarbonyltungsten(0) (**4**)

A solution of 0.39 g (1 mmol) **1a** and 0.35 g (1 mmol) [$W(CO)_6$] in THF (15 ml) was irradiated at rt for 42 h. Then the solvent was evaporated and unreacted [$W(CO)_6$] sublimed off. The residue was washed with *n*-hexane (2 × 5 ml) and purified by chromatography (toluene solution, SiO_2 column, eluated with *n*-hexane, then toluene). The product **4** was obtained as pale yellow crystals from toluene at −18 °C. The starting material **1a** was obtained from the *n*-hexane fraction (0.17 g, 49%). Yield: 0.19 g (47% based on reacted **1a**), m.p. 238–42 °C (decomp.). *Anal.* Calc. for $C_{14}H_{28}B_{10}Cl_2O_4P_2W$ (685.15): C, 24.48; H, 4.11. Found: C, 24.80: H, 4.29%. MS (FAB, 3-nitrobenzyl alcohol) *m*/*z*: 685.1 (100%, M^+), 573.1 (69.0%, M^+–4CO), 517.0 (36.8%, M^+–4CO–^{t}Bu).

5.6. cis-meso-[1,2-Bis(tert-butylhydroxophosphino)-1,2-dicarba-closo-dodecaborane(12)]-tetracarbonylchromium(0) (**5**)

A solution of 0.2 g (0.51 mmol) **1** and 0.13 g (0.6 mmol) [$Cr(CO)_6$] in moist THF (10 ml THF and 0.018 g (1 mmol) H_2O) was irradiated at rt for 33 h. The THF was evaporated and the oily residue was washed with *n*-hexane (3 ml) and then passed through SiO_2 (eluated first with *n*-hexane, then with toluene). At room temperature pale yellow crystals of **5** were obtained from toluene. Yield: 0.10 g (38%), m.p. 228–30 °C (decomp.). *Anal.* Calc. for $C_{14}H_{30}B_{10}CrO_6P_2$ (516.42): C, 32.42; H, 5.83. Found: C, 33.10; H, 6.13%. MS (FAB, 3-nitrobenzyl alcohol) *m*/*z*: 516.2 (17.3%, M^+), 432.2 (61.7%, M^+–3CO), 404.2 (100%, M^+–4CO), 387.1 (13.1%, M^+–4CO–OH).

6. Data collection and structural refinement of 2–5

The data were collected on an Siemens CCD diffractometer (SMART [40]) using Mo Kα radiation (λ = 71.073 pm) and ω-scan rotation. Data reduction was performed with SAINT [41] including the program SADABS [42] for empirical absorption correction. All structures were solved by direct methods and the refinement of

all non-hydrogen atoms was performed with SHELX97 [43]. H atoms are calculated on idealized positions with the exception of all boron protons in **3a**. Structure figures were generated with ORTEP [44] Crystal data and structure refinement for complexes **2**–**5** are given in Table 3.

phen = 1,10-phenantroline, were prepared according to literature methods [9].

2.2. Apparatus

$^{31}P\{^{1}H\}$ NMR experiments were recorded on a BRUKER equipment 9.4 T (400 MHz for hydrogen frequency) in CH_2Cl_2, using a capillary containing D_2O. The microanalyses were performed in the Microanalytical Laboratory, Department of Chemistry at Universidade Federal de São Carlos, São Carlos (SP), using a FISIONS CHNS, mod. EA 1108 micro analyser.

2.3. X-ray crystallography

Crystals of the isolated complexes were grown by slow evaporation of dichloromethane/diethyl ether solution. These crystals were mounted on an Enraf-Nonius Kappa-CCD diffractometer with graphite monochromated Mo Kα (λ = 0.71073 Å) radiation. The final unit cell parameters were based on all reflections. Data collections were made using the COLLECT program [10]. Integration and scaling of the reflections were performed with the HKL Denzo-Scalepack system of programs [11]. Gaussian absorption corrections were carried out [12]. The structures were solved by direct methods with SHELXS-97 [13]. All hydrogen atoms were stereochemically positioned and refined with the riding model. The ORTEPs shown in Fig. 1 were prepared using ORTEP-3 for windows [14]. Hydrogen atoms of the aromatic rings were set isotropic with a thermal parameter 20% greater than the equivalent isotropic displacement parameter of the atom to which each one is bonded. The data collections and some experimental details are summarized in Table 1.

2.4. Synthesis

cis-[RuCl(L)(P–P)(N–N)](PF_6) type complexes, where N–N = 2,2′-bipyridine (bipy) or 1,10-phenantroline (phen), P–P = 1,4-bis-(diphenylphosphino)butane (dppb) or 1,1′-bis(diphenylphosphino)-ferrocene (dppf), and L = 4-methylpyridine (4-Mepy), benzonitrile (bzCN), and 4-phenylpyridine (4-Phpy), were prepared by reacting the *cis*-[$RuCl_2$(P–P)(N–N)] complex (0.128 mmol) dissolved in CH_2Cl_2 with three times of excess of the L ligands and 0.256 mmol of NH_4PF_6 in methanol (ca. 5 mL) under argon atmosphere for 3 h.

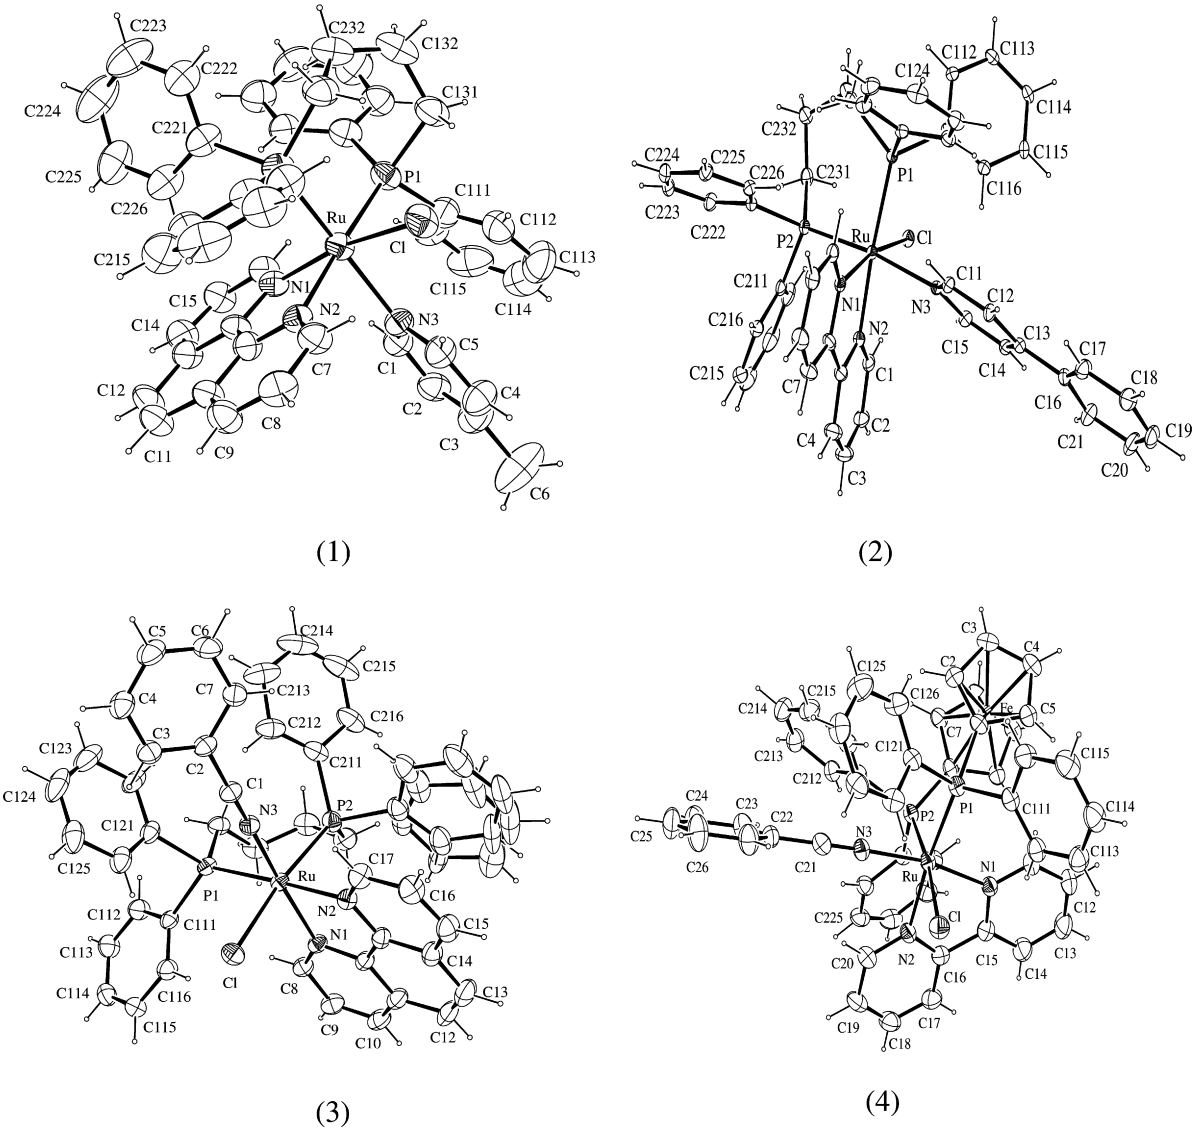

Fig. 1. *ORTEP* [15] view of the [RuCl(4-Mepy)(dppb)(phen)](PF_6)·0.5H_2O **(1)**, [RuCl(4-Phpy)(dppb)(bipy)](PF_6)·CH_2Cl_2 **(2),** [RuCl(bzCN)(dppb)(phen)](PF_6)·0.5H_2O **(3)** and [RuCl(bzCN)(dppf)(bipy)]Cl·H_2O·3/2(C_7H_5N) **(4)** complexes, showing the atoms labeling and the 30% probability ellipsoids.

The solution was then filtered, concentrated to ca. 2 mL and hexane was added to precipitate the products. The solids were filtered off, rinsed with water (3 × 5 mL) and diethyl ether (3 × 5 mL) and dried under vacuum. The complex **(4)** was also synthesized in the same way, but without adding the NH_4PF_6.

3. Results and discussion

The X-ray structures of the complexes **(1–4)** are shown in Fig. 1.

In all cases, the isolated complexes were formed by the displacement of one chloride atom from the respective precursor *cis*-[$RuCl_2$(dppb)(bipy)], *cis*-[$RuCl_2$(dppb)(phen)] or *cis*-[$RuCl_2$-(dppf)(bipy)]. As depicted in Fig. 1, the 4-Mepy and 4-Phpy ligands are coordinated *trans* to phosphorus atoms in complexes **(1)** and **(2)**, respectively, while in complexes **(3)** and **(4)** the benzonitrile ligand occupy the position *trans* to nitrogen atoms of the N–N ligands. Recently the [RuCl(dppb)(bipy)(4-Mepy)]PF_6 complex was synthesized by us showing the same structure of **(1)** and **(2)** [17].

Some selected bond lengths of complexes **(1–4)** are in Table 2.

The bond lengths in Table 2 are in the range found for similar ruthenium phosphine complexes, but the distances Ru–N of the bzCN ligand in complexes **(3)** and **(4)** [Ru–N(3)] are shorter than the other Ru–N bond lengths (involving the nitrogen atoms of the 2,2′-bipyridine or of the 1,10-phenantroline) since the cyano-group is a stronger π acceptor than the nitrogen atoms in the rings of the aromatic amino ligands [9,18–23]. The distances Ru–N(2), which are *trans* to phosphorus atoms in the four complexes, are longer than the distances of Ru–N(1), as a consequence of the strong *trans* influence of the phosphorus atoms of the diphosphine

Table 2
Selected bond lengths (Å) for complexes **(1–4)**, with estimated standard deviations in parentheses.

Complex	Ru–N(1)	Ru–N(2)[a]	Ru–N(3)[b]	Ru–P(1)	Ru–P(2)	Ru–Cl
(**1**) $0.5H_2O$	2.074(5)	2.130(5)	2.190(5)	2.3428(18)	2.3259(19)	2.4352(16)
(**2**) CH_2Cl_2	2.099(3)	2.122(3)	2.170(3)	2.3582(9)	2.3317(9)	2.4168(9)
(**3**) $0.5H_2O$	2.0919(19)	2.111(2)	2.011(2)	2.3434(7)	2.3166(7)	2.4555(7)
(**4**) $H_2O{\cdot}3/2$ (C_7H_5N)	2.089(3)	2.106(3)	2.002(3)	2.3749(10)	2.3163(10)	2.4687(10)

[a] Nitrogen *trans* P(1).
[b] Nitrogen from the entering ligand (L).

ligands. The Ru–P(1) bond lengths of complexes (**1–4)** are longer than the distances Ru–P(2). This observation suggests that the *trans* influence of the bidentate N–N ligands is stronger than the same effect of the monodentates ligands (4-Mepy, 4-Phpy and chloride).

In order to elucidate the mechanism of formation of the $[RuCl(bzCN)(dppb)(phen)]PF_6$ complex with the bzCN ligand coordinated *trans* to the nitrogen atom of the 1,10-phenantroline, the reaction of the benzonitrile ligand with the precursor *cis*-$[RuCl_2(dppb)(phen)]$ was followed by the NMR technique [$^{31}P(^1H)$]. Thus, as can be seen in Fig. 2 initially three complexes are present in the solution: the precursor (δ 42.8 and 31.3); the final product $[RuCl(bzCN)(dppb)(phen)]PF_6$ with the bzCN *trans* to a nitrogen (δ 40.9 and 32.4) and an intermediate complex (δ 40.4 and 37.6). Since in the end of the reaction only the complex $[RuCl(bzCN)(dppb)(phen)]PF_6$ (δ 40.9 and 32.4) with the entering ligand positioned *trans* to the nitrogen atom of the 2,2′-bipyridine molecule is present in solution, according to its X-ray structure (Fig. 1), the intermediate very probably consists of a complex with the same composition as the final product but with the bzCN ligand coordinated *trans* to a phosphorus atom of the diphosphine. The fact that the two doublets for this intermediate are very close from each other reinforce our suggestion that in this case both phosphorus atoms are *trans* to nitrogen atoms (one of the 1,10-phenantroline and the other one of the bzCN ligand).

An interesting point that must be addressed to explain the position of the bzCN ligand in the $[RuCl(bzCN)(dppb)(phen)](PF_6)$ **(3)** and in the [RuCl(bzCN)(dppf)(bipy)]Cl **(4)** complexes is the fact that the phosphorus atom is a strong π acceptor as well as is the cyano-group of the benzonitrile ligand. Thus, when two good π acceptor ligands are mutually *trans*, they compete for electron density residing in the same metal d orbital and the amount of M → C back-bonding is reduced by trying to labilize each other. Consequently, by the competition for the metal center electrons between the diphosphine phosphorus atom and the cyano-group of the bzCN, the bond Ru–NCbz results thermodynamically less stable. Therefore, this ligand is easily dissociated and then located in the position *trans* to one of the nitrogen atoms of the N–N ligands where the competitive effect is less accentuated, since the pyridine rings from the 1,10-phenantroline or from the 2,2′-bipyridine ligand are not strong π electron acceptors. The differential pulse voltammetry experiment supports this suggestion. As shown in Fig. 3, the intermediate complex with the bzCN ligand positioned *trans* to the phosphorus atom (δ 40.4 and 37.6 in the $^{31}P\{^1H\}$ spectra)

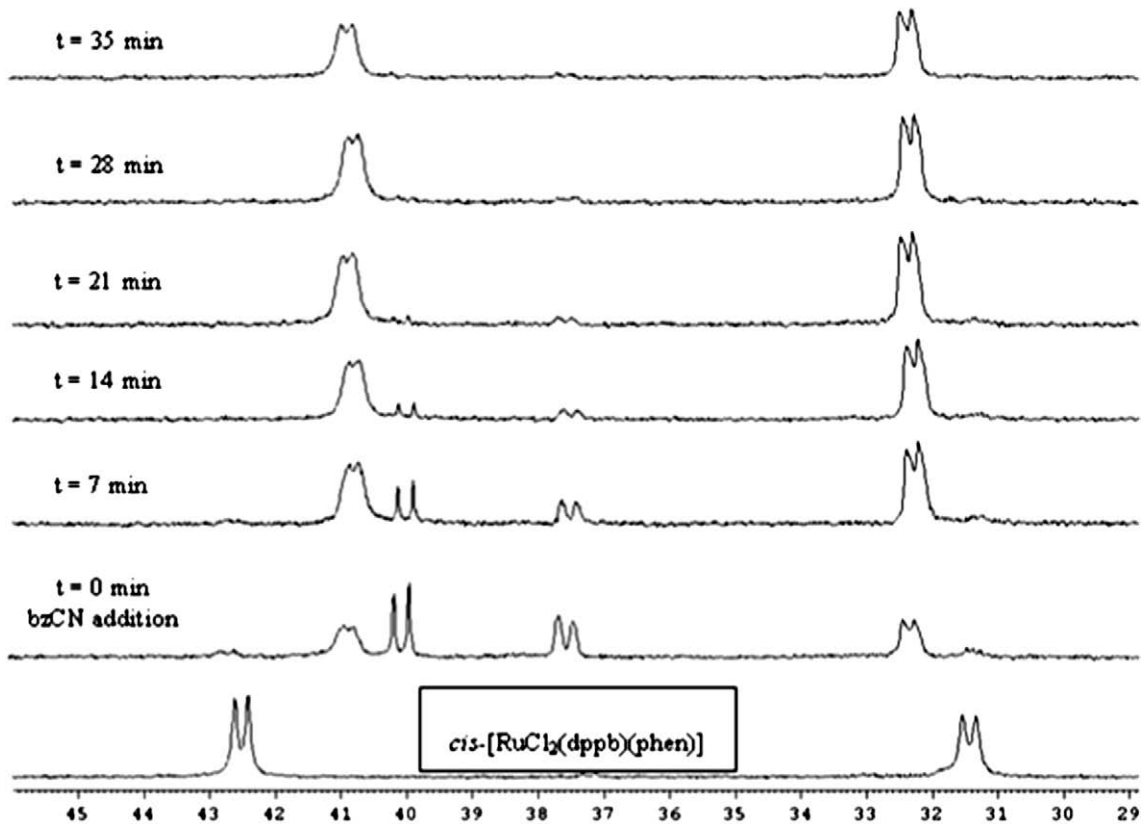

Fig. 2. The $^{31}P\{^1H\}$ NMR spectra, in CH_2Cl_2, following the reaction of the precursor *cis*-$[RuCl_2(dppb)(phen)]$ (bottom) with the bzCN ligand (20 times excess).

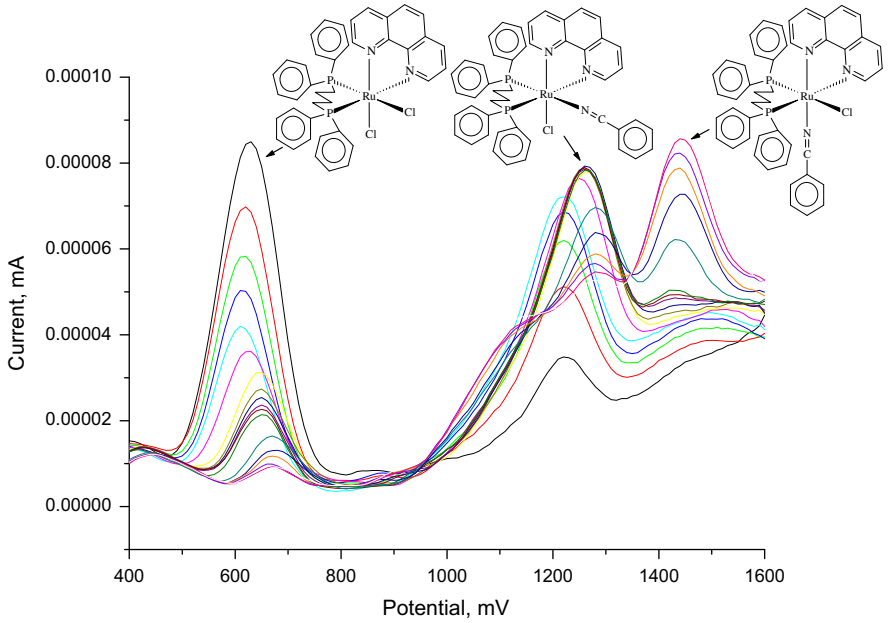

Fig. 3. The differential pulse voltammograms, in CH_2Cl_2, following the reaction of the precursor *cis*-[$RuCl_2$(dppb)(phen)] with the bzCN ligand (20 times excess) (Pt vs. AgCl, 0.1 M PTBA; [Ru] = 1.0×10^{-3} mol L^{-1}; [bzCN] = 20×10^{-3} mol L^{-1}; T = 293 K). Interval of each measurement 7 min.

shows a lower oxidation potential than the other isomer, the final product of the reaction (δ 40.9 and 32.4), with the bzCN ligand sited *trans* to the nitrogen atom. This behavior, provoked by competitive effect, has previously observed by us and by others [24–26].

The same phenomenon observed for the benzonitrile ligand in its reaction with the *cis*-[$RuCl_2$(dppb)(bipy)], *cis*-[$RuCl_2$(dppf)(bipy)] complexes was also observed when acetonitrile (δ 42 e 34 ppm, when acetonitrile is coordinated *trans* to P atom, and δ 43 e 34.5 ppm, when acetonitrile is coordinated *trans* to N atom), a small molecule, was used as entering ligand, suggesting that in these reactions the steric effect does not play a decisive role for the stereochemistry of the final products. Here we would like to point out that in this work "*trans* effect" is used to define the competition for the electron density of the metal that occurs between one strong and one weak π acceptor ligand, while "competitive effect" is used in the case when this competition occurs between two good π acceptor ligands mutually *trans*. These two phenomena are indeed the driving forces in the octahedral complexes studied in this work, leading to thermodynamically stable products, depending of the characteristics of the entering ligand.

The kinetic study of the dissociation of a coordinated chloride, using differential pulse voltammetry for the benzonitrile complex, yielded a rate saturation which is typical of a dissociative mechanism. The limiting first order specific rate of dissociation of the chloride was found to be about $1.0 \pm 0.1 \times 10^{-2}$ s^{-1} and the isomerization rate for the [RuCl(bzCN)(dppb)(phen)]PF_6 (bzCN *trans* to phosphorus to the species *trans* to the nitrogen) was found to be $5.0 \pm 0.1 \times 10^{-4}$ mol L^{-1} s^{-1}. These values are consistent with the data observed in the $^{31}P\{^1H\}$ spectra, in Fig. 2, where the dissociation of the chloride is much faster than the isomerization process. This observed isomerization rate is in the same order as those found for the isomerization of the *trans*-[$RuCl_2$(dppb)(X-bipy)] to the correspondents *cis*-[$RuCl_2$(dppb)(X-bipy)] complexes (X-bipy = 2,2′-bipyridine derivatives) [27].

4. Conclusions

In complexes with general formula *cis*-[$RuCl_2$(P–P)(N–N)] (P–P – diphosphine and N–N = 2,2′-bipyridine or 1,10-phenantroline) the chloride *trans* to the phosphorus atoms is more labile than that one *trans* to the nitrogen atoms, but the final position of an entering good π acceptor ligand is better defined by the competitive effect, which plays a crucial role in the process. The dissociation of the chloride from the *cis*-[$RuCl_2$(dppb)(phen)], *trans* to a phosphorus atoms, follows a dissociative mechanism and its constant rate is $1.0 \pm 0.1 \times 10^{-2}$ s^{-1} while the isomerization rate for the [RuCl(bzCN)(dppb)(phen)]PF_6 (bzCN *trans* to phosphorus to the species *trans* to the nitrogen) is $5.0 \pm 0.1 \times 10^{-4}$ mol L^{-1} s^{-1}.

5. Supplementary data

CCDC 707431, 707432, 707433 and 707434 contain the supplementary crystallographic data for (**1**), (**2**), (**3**) and (**4**), respectively.. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

$[W_3Te_7(dtp)_3]Br$ was prepared according to Ref. [11] by mechanochemical treatment of solid $W_3Te_7Br_4$ and Kdtp. Mechanochemical syntheses were done in a vibration mill, described in Ref. [12] In all cases a cylindrical titanium reactor was used (volume 100 ml, height 50 mm). The reactor was filled with tungsten carbide balls (diameter 10 mm, total mass 320 g), and with a mixture of solid reagents. The reactions were run under the following conditions: frequency of reactor vibrations 25 Hz, amplitude of vertical movement 1 cm, duration – 10 h. IR spectra (4000–400 cm^{-1}) were recorded with an IFS-85 Bruker spectrometer in KBr pellets, Raman spectra were obtained on a Triplimate 21 spectrometer. The elemental analysis was done in the Laboratory of Microanalysis, Institute of Organic Chemistry, Novosibirsk, Russia.

2.2. Electrospray ionization mass spectrometry

A Q-TOF Premier mass spectrometer with an orthogonal Z-spray electrospray source (Waters, Manchester, UK) was used. The temperature of the source block was set to 120 °C and the desolvation temperature to 150 °C. A capillary voltage of 3.5 kV was used in the positive scan mode, and the cone voltage was set to 10 V to control the extent of fragmentation. ESI(+) mass spectra were acquired in the W-scan mode operating at a resolution of ca. 17500 (FWHM). About 2×10^{-5} M CH_3OH:$CHCl_3$ sample solutions were infused via a syringe pump directly connected to the ESI-MS source at a flow rate of 10 μL/min. The observed isotopic pattern of each compound perfectly matched the theoretical isotopic pattern calculated from their elemental composition using the MASSLYNX 4.1 program [13].

2.3. Synthesis of $[Mo_3(_3\text{-}Te)(_2\text{-}Te_2)_3(dtp)_3]I$ (**1**)

About 2.0 g (1.1 mmol) of solid $Mo_3Te_7I_4$ and 0.90 g $(EtO)_2PS_2K$ (4.0 mmol) were treated in a vibration mill. The reaction mixture was extracted with 30 ml of $CHCl_3$, mixed with 60 ml of ethanol and left at 5 °C for two days. A black crystalline solid was filtered off, washed with ethanol and ether and dried in air. Yield 0.37 g (17%). *Anal.* Calc. for $C_{12}H_{30}IMo_3O_6P_3S_6Te_7$: C, 7.73; H, 1.62. Found: C, 7.84; H, 1.37%. IR (cm^{-1}): 3445 w, 2974 w, 2891 w, 1469 w, 1436 w, 1384 w, 1288 w, 1157 m, 1098 w, 1028 s, 1010 s, 959 s, 811 m, 775 s, 635 s, 546 m, 445 w. Raman (cm^{-1}): 278 w, 265 w, 230 w, 213 m, 194 m, 141 w, 123 m, 90 w, 65 s. Electronic spectrum (in $CHCl_3$): λ_{max}/nm (ε_M) = 354 (14500), 391 (9700). ESI(+)-MS: $[Mo_3Te_7((EtO)_2PS_2)_3]^+$ (*m/z* = 1738.2).

2.4. Synthesis of $[W_3Te_{4.25}S_{2.75}((EtO)_2PS_2)_3]Br$ (**2**)

To a solution of $[W_3(\mu_3\text{-}Te)(\mu_2\text{-}Te_2)_3((EtO)_2PS_2)_3]Br$[14] (0.07 g, 0.03 mmol) in 4 ml of $CHCl_3$, bromine (0.02 g, 0.13 mmol) was added. The solution was refluxed for 2 h, a black precipitate was filtered off, and a double volume of ethanol was added to the solution which then was left at −5 °C for 2 days. Red crystals of X-ray quality were separated by decantation, washed with ethanol and ether, and dried in air. Yield 0.010 g (18%). IR (cm^{-1}): 3437 m, 2976 w, 2931 w, 2895 w, 1637 w, 1471 w, 1439 w, 1388 w, 1290 w, 1161 m, 1101 w, 1052 m, 1004 s, 968 s, 816 m, 791 m, 638 m, 531 w. Raman (cm^{-1}): 634 w, 524 w, 399 m, 389 m, 352 w, 281 w, 254 w, 219 w, 203 w, 160 w, 123 w, 100 m, 87 w, 47 s, 29 m. ESI(+)-MS: see Fig. 1.

2.5. Synthesis of $[W_3Te_{4.30}S_{2.70}((EtO)_2PS_2)_3]Br_{0.62}Cl_{0.38}$ (**3**)

To a solution of 0.11 g of $[W_3(\mu_3\text{-}Te)(\mu_2\text{-}Te_2)_3((EtO)_2PS_2)_3]Br$ (0.053 mmol) in 7 ml of $CHCl_3$, a solution of 0.025 g of S_2Cl_2 in 1 ml of $CHCl_3$ (0.19 mmol) was added. The reaction mixture was left stirring for 20 h. A black precipitate was filtered off, and a double volume of ethanol was added to the solution, which then was left at −5 °C for 2 days. Red crystals of X-ray quality were separated by decantation, washed with ethanol and ether, and air-dried. Yield 0.03 g (31%). ESI(+)-MS: see Fig. 1. Recrystallization of the solid, kept for 2 months, from a $CHCl_3$/EtOH mixture at −5 °C gave single crystals of $[W_3Te_{3.91}S_{3.10}((EtO)_2PS_2)_3]Br_{0.64}Cl_{0.36}$ (**4**).

2.6. Synthesis of $[Mo_3Te_{4.74}S_{2.26}((EtO)_2PS_2)_3]I_{0.72}Cl_{0.28}$ (**5**)

To a solution of 0.060 g $[Mo_3(\mu_3\text{-}Te)(\mu_2\text{-}Te_2)_3((EtO)_2PS_2)_3]I$ (0.03 mmol) in 2 ml of $CHCl_3$, a solution of 0.020 g S_2Cl_2 (0.15 mmol) in 2 ml of $CHCl_3$ was added, followed by 7 drops of DMF. The reaction mixture was left stirring for 5 h. A black precipitate of Te was filtered off, and a double volume of CH_3OH was added to the filtrate, and the solution was left at 7 °C overnight. The crystals (suitable for X-ray structural analysis) of $[Mo_3Te_{4.74}S_{2.26}((EtO)_2PS_2)_3]I_{0.72}Cl_{0.28}$ were removed by decantation, washed with methanol and ether, and dried in vacuum. Yield 0.030 g (62%). ESI(+)-MS: see Fig. 2.

2.7. Reaction of **5** with excess of S_2Cl_2

To a solution of 0.022 g of **5** (0.01 mmol) in 2 ml of $CHCl_3$, a solution of S_2Cl_2 (0.020 g, 0.15 mmol) in 2 ml of $CHCl_3$ was added.

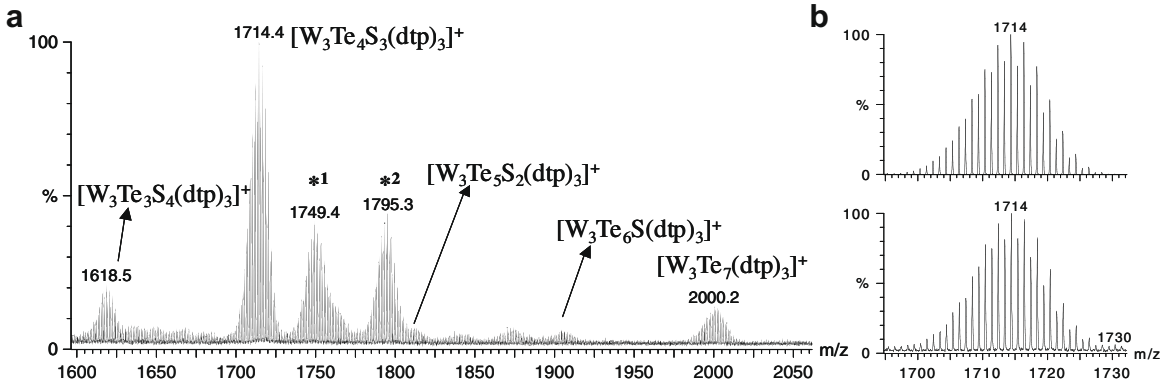

Fig. 1. Electrospray ionization mass spectrum of $[W_3Te_{4.30}S_{2.70}((EtO)_2PS_2)_3]Br_{0.62}Cl_{0.38}$ (**3**) in $CHCl_3$/CH_3OH mixtures (U_c = 10 V) (a) and simulated (top) and experimental (bottom) spectra for $[W_3Te_4S_3((EtO)_2PS_2)_3]^+$ centered at *m/z* = 1714.4 (b). Species marked with ^{*1} and ^{*2} formally correspond to HCl and HBr adducts of the cation $[W_3Te_4S_3(dtp)_3]^+$.

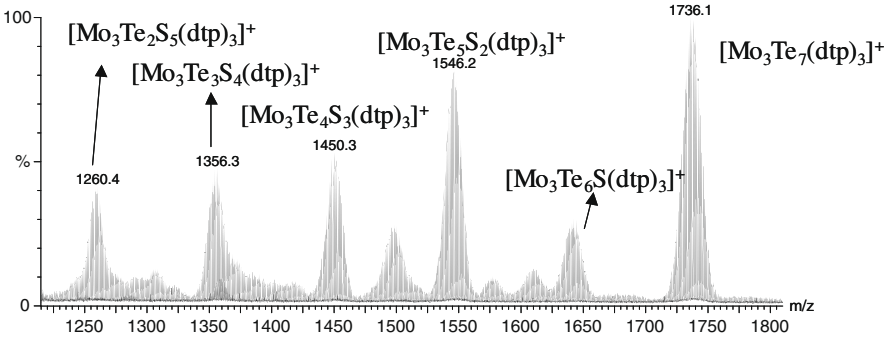

Fig. 2. Electrospray ionization mass spectrum of $[Mo_3Te_{4.74}S_{2.26}((EtO)_2PS_2)_3]I_{0.72}Cl_{0.28}$ (**5**) in $CHCl_3/CH_3OH$ mixtures (U_c = 10 V).

Further treatment was as above. Red crystals of $[Mo_3Te_4S_3((EtO)_2PS_2)_3]I$ (**6**) were obtained. Yield 0.007 g (44%). IR (cm^{-1}): 3437 m, 2974 w, 2927 w, 2864 w, 1468 w, 1438 w, 1384 w, 1287 w, 1159 m, 1099 w, 1053 w, 1005 s, 965 s, 814 m, 788 s, 633 m, 528 w, 459 m. ESI(+)-MS: $[Mo_3Te_2S_5((EtO)_2PS_2)_3]^+$ (m/z = 1259), $[Mo_3Te_3S_4((EtO)_2PS_2)_3]^+$ (m/z = 1357), $[Mo_3Te_4S_3((EtO)_2PS_2)_3]^+$ (m/z = 1447), $[Mo_3Te_5S_2((EtO)_2PS_2)_3]^+$ (m/z = 1547).

2.8. X-ray structure determinations

The diffraction data for **2**–**6** were collected on a Bruker *X8APEX* CCD diffractometer with Mo Kα radiation (λ = 0.71073 Å) using φ- and ω-scans of narrow (0.5°) frames. The structure of **3** was solved by direct methods and refined by full-matrix least-squares method against $|F|^2$ in anisotropic approximation using the SHELXTL programs set [14]. The data for the isostructural analogs **2**, **4**, **5** and **6** were refined with the model for **3**. Absorption corrections were applied empirically using the SADABS program [15]. In all cases the statistical occupancies of the sulfur and tellurium atoms in the cluster cores as well as the halogenide counter ions were refined with fixed isotropic atomic displacement parameters, and then with fixed occupancy factors, while the coordinates and anisotropic atomic displacement parameters are equal. The positions of statistically disordered atoms cannot be distinguished except the positions of the chlorine and iodine atoms in the crystal structure of **5**. The Cl and I atoms in **5** were refined anisotropically with equal atomic displacement parameters. Detailed crystallographic data and atomic distances are collected in Tables 1 and 2, respectively. Intermolecular interactions in the crystal and the packing types were analyzed with the program set for multi-purpose crystallochemical analysis TOPOS 4.0 Professional [16].

3. Result and discussion

3.1. Syntheses and electrospray ionization mass spectrometry (ESI-MS)

The starting materials $[M_3Te_7(dtp)_3]X$ (M = Mo, W; X = Br, I; dtp = $(EtO)_2PS_2$) were synthesized from polymeric tellurohalides

Table 2

$M_3Te_7X_4$ by mechanochemical treatment in 15–20% yields [11]. The yields are modest, but higher than in the reactions between the solids in the absence of mechanical activation, originally proposed for the synthesis of $[M_3Te_7(dtp)_3]I$ (M = Mo, W) [9].

Initially we turned to the idea of finding a way of converting the M_3Te_7 clusters into Mo_3Te_4 clusters by tellurium abstraction with mild electrophilic reagents, e.g., Ph_3PX_2 (X = Cl, Br). No reaction was found to take place, however, between $[W_3Te_7(dtp)_3]Br$ and either of the phosphine dihalides. A reaction between $[W_3Te_7(dtp)_3]Br$ with free Br_2 did take place, but surprisingly the product was found to be $[W_3Te_{4.25}S_{2.75}(dtp)_3]Br$ (**2**, yield 18%) – the first complex with a new TeS^{2-} ligand. Its formation can be tentatively explained by the following reaction sequence (**1**–**3**):

$$W_3Te_7^{4+} + 3Br_2 \rightarrow W_3Te_4^{4+} + 3\text{“}TeBr_2\text{“} \quad (1)$$

$$2(EtO)_2PS_2^- + Br_2 \rightarrow (EtO)_2P(S)\text{-}S\text{-}S\text{-}P(S)(OEt)_2 + 2Br^- \quad (2)$$

$$W_3Te_4^{4+} + 3(EtO)_2P(S)\text{-}S\text{-}S\text{-}P(S)(OEt)_2 \rightarrow W_3Te_4S_3^{4+} + 3(EtO)_2P(S)\text{-}S\text{-}P(S)(OEt)_2 \quad (3)$$

Uncomplexed $TeBr_2$ is unstable and disproportionates into $TeBr_4$ and Te. It is known that treatment of $M_3Se_4^{4+}$ clusters with alcoholic solutions of P_4S_{10}, which are known to contain both $(RO)_2PS_2H$ and a mixture of polysulfides $(RO)_2P(S)S_xP(S)(OR)_2$ (x = 2, 3, 4), [17] gives $[M_3(\mu_3\text{-}Se)(\mu\text{-}SeS)_3(dtp)_3]^+$ in good yields [18]. It has to be pointed out that this reaction limits the overall reaction yield since the only source of sulfur is provided by the dtp^- ligands, a fact that inherently implies cluster degradation. In order to prevent this undesirable process, we used S_2Cl_2 which can simultaneously chlorinate Te and deliver S to the *in situ* forming $W_3Te_4^{4+}$ core. In this way, $[W_3Te_{4.30}S_{2.70}((EtO)_2PS_2)_3]Br_{0.62}Cl_{0.38}$ (**3**) was obtained in 31% yield, which is higher than in the reaction with Br_2. The formation of $[W_3Te_4S_3((EtO)_2PS_2)_3]^+$ can be explained by the following reactions:

$$[W_3Te_7((EtO)_2PS_2)_3]^+ + 3S_2Cl_2 \rightarrow [W_3Te_4((EtO)_2PS_2)_3] + 3\text{“}TeCl_2\text{”} + 6S$$

$$[W_3Te_4((EtO)_2PS_2)_3]^+ + 3S \rightarrow [W_3Te_4S_3((EtO)_2PS_2)_3]^+$$

As judged by X-ray analysis, there is high degree of regioselectivity in these reactions (irrespective of the use of Br_2 or S_2Cl_2), Te by S replacement being first observed at the equatorial positions (see Table 3), thus leading to μ-TeS ligands. As can be seen in Table 3, Q_{ax} is predominantly Te whereas Q_{eq} is a mixture S/Te. The variable occupation of the Q_{eq} positions disorder is reflected in the bond distances Q_{ax}–Q_{eq} (Table 2). This characteristic regioselectivity is similar to that well-established for M_3Q_7 (Q = S, Se) cluster complexes, where chalcogen abstraction and exchange reactions (by phosphines, KSeCN, polysulfides) take place preferentially at the equatorial positions, probably due to a weaker bonding of the chalcogen atom there [19].

Electrospray ionization mass spectra of $CHCl_3$:CH_3OH solutions of the product formulated as $[W_3Te_{4.30}S_{2.70}((EtO)_2PS_2)_3]Br_{0.62}Cl_{0.38}$ (**3**) and the product obtained by recrystallization of **3** from $CHCl_3$/EtOH after 2 months, $[W_3Te_{4.25}S_{2.75}((EtO)_2PS_2)_3]Br$ (**4**), further confirms the degree of substitution as well as the regioselectivity. Fig. 1 illustrates the ESI mass spectrum of **3** recorded at low cone voltages (typically U_c = 10 V).

Three dominant signals corresponding to the incomplete cuboidal cluster $[W_3Te_4S_3((EtO)_2PS_2)_3]^+$ (m/z = 1713.4) and its HCl and HBr adducts (m/z = 1749.4 and m/z = 1795.4, respectively) are observed, thus indicating a high degree of regioselectivity for the Te by S replacement at the Q_{eq} position. Middle intensity signals attributed to different W/S/Te based species are also detected, namely $[W_3Te_3S_4((EtO)_2PS_2)_3]^+$ (m/z = 1618.4) and the starting material $[W_3Te_7((EtO)_2PS_2)_3]^+$ (m/z = 2000.2), whereas the homologous W/Te/S cations with only one and two incorporated sulfur atoms were observed as minor signals, namely $[W_3Te_5S_2((EtO)_2PS_2)_3]^+$ (m/z = 1810.3) and $[W_3Te_6S((EtO)_2PS_2)_3]^+$ (m/z = 1904.2). The electrospray mass spectrum of **4** revealed a similar speciation to that observed for sample **3**, where the presence of the cluster cation $[W_3Te_4S_3((EtO)_2PS_2)_3]^+$ peak was dominant.

The reactivity described above for W was extended to molybdenum chemistry. The reaction of $[Mo_3Te_7((EtO)_2PS_2)_3]I$ with S_2Cl_2 in a 1:5 molar ratio in a $CHCl_3$/DMF mixture leads to Te by S replacement, yielding a mixture of complexes formulated as $[Mo_3Te_{4.74}S_{2.26}((EtO)_2PS_2)_3]I_{0.72}Cl_{0.28}$ (**5**) on the basis of X-ray analysis. Despite the fact that both W and Mo complexes display roughly an identical degree of Te by S replacement as judged by the overall stoichiometries (for example, $W_3Te_{4.30}S_{2.7}^{4+}$ in **3** and $Mo_3Te_{4.74}S_{2.26}^{4+}$ in **5**), a detailed inspection of the X-ray data reveal some important differences, specifically related to the observed occupation disorder at the Q_{ax} and Q_{eq} sites. While the Q_{ax} and Q_{eq} positions are close to 100% (Te) and 0% (Te), respectively, for the tungsten derivatives **2**–**4** (see Table 3), in the case of Mo these occupancy factors are approximately 90% (Te) and 50% (Te) for Q_{ax} and Q_{eq}, respectively. Such distinctive replacement patterns mean that the degree of regioselectivity at the Q_{eq} sites is higher for the $W_3Te_7^{4+}$ core. This is also very well evident in the ESI(+) mass spectrum of $[Mo_3Te_{4.74}S_{2.26}((EtO)_2PS_2)_3]I_{0.72}Cl_{0.28}$ (**5**) (Fig. 2) where the distribution of species featuring $Mo_3Te_{7-x}S_x^{4+}$ cluster cores ranges from x = 0 to 5.

In order to obtain additional insights on the Te by S replacement, we tried to change the reaction conditions. On one hand, we believe that it is illustrative to investigate the reactivity trends of bridging Te ligands with a large excess of S_2Cl_2, aimed at proving whether further substitution in the axial position or even the inert μ_3-Te ligand takes place. The reaction of **5** with S_2Cl_2 in a 1:15 molar ratio gives a product with the composition $[Mo_3Te_4S_3((EtO)_2$

[a] Distances are given to the Cl position.

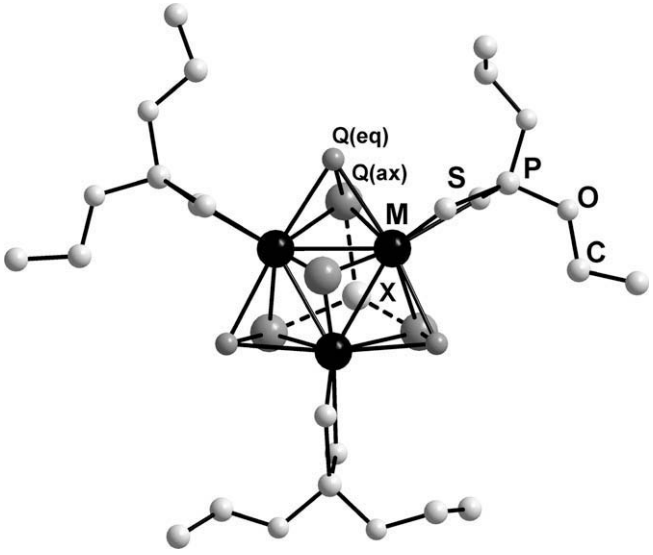

Fig. 3. The ionic pair $[M_3Q_7(dtp)_3]X$ (M = Mo, W; X = Br, I) in **2**–**6**. The Q(ax) and Q(eq) designate axial and equatorial positions statistically occupied by sulfur and tellurium atoms.

$PS_2)_3]I$ (**6**), which really turned out to be a mixture of $[Mo_3Te_2S_5((EtO)_2PS_2)_3]^+$, $[Mo_3Te_3S_4((EtO)_2PS_2)_3]^+$, $[Mo_3Te_4S_3((EtO)_2PS_2)_3]^+$ and $[Mo_3Te_5S_2((EtO)_2PS_2)_3]^+$ with S_2^{2-}, TeS^{2-} and Te_2^{2-} dichalcogenide ligands according to its mass spectrum and occupancy of the Q_{ax} and Q_{eq} positions, in concordance with the following row of decreasing reactivity: $Te_{eq} > Te_{ax} > \mu_3$-Te.

On the other hand, since coordinatively unsaturated species $[W_3Te_4(dtp)_3]^+$ are supposedly involved as a key intermediate during the Te by S replacement process, we attempted to intercept them by doing the reaction of $[W_3Te_7(dtp)_3]^+$ with S_2Cl_2 in the presence of pyridine or DMF, aiming to stabilize the transient coordinatively unsaturated $[M_3Te_4(dtp)_3]^+$ species as the more stable $[M_3Te_4(dtp)_3L_3]^+$ (L = py, DMF) complexes. However, the reaction did not take place at all in the presence of pyridine, while with DMF a product of the composition $[Mo_3Te_{4.74}S_{2.26}((EtO)_2PS_2)_3]I_{0.72}Cl_{0.28}$ (**5**) was obtained, as described above.

3.2. Crystal structures

Crystal structures were determined for all the newly synthesized compounds, **2**–**6**. They are isostructural and crystallize in the monoclinic unit cell ($P2_1/c$ space group). The cluster cation displays an identical geometry to that observed for the closely related $Mo_3Q_7^{4+}$ clusters bearing dithiophosphate ligands (see Fig. 3); the geometrical parameters are summarized in Table 2. The equatorial (Q_{eq}) and axial (Q_{ax}) atoms of the μ_2-Q_2 ligands are mixed-sorted in the most cases, containing both sulfur and tellurium in different ratios. The S/Te composition (see Table 3) determined by X-ray diffraction is in satisfactory agreement with ESI mass spectra and chemical data. From the comparison of interchalcogen bond distances in the coordinated Q_2 ligands, the S–Te bond length was expected to be about 2.35–2.4 Å, as indeed found in **2** and **5** (for comparison: S–S, 2.03–2.04 Å in $[Mo_3S_7(dtp)_3]Cl$ [24], S–Se; 2.20 Å in $[W_3(\mu_3\text{-}Se)(\mu_2\text{-}SSe)_3(dtp)_3]Cl$ [22]; Se–Se, 2.32–2.34 Å in $[W_3Se_7(dtp)_3]Br$ [18]; Se–Te, 2.50–2.52 Å in $K_3\{[W_3Te(SeTe)_3(CN)_6]Br\}$ [8]; Te–Te, 2.68–2.69 Å in $[W_3Te_7(dtp)_3]Br$ [11]).

The crystal packing in **2**–**6** is strongly influenced by specific non-bonding interactions involving the halogen anion (X^-) and

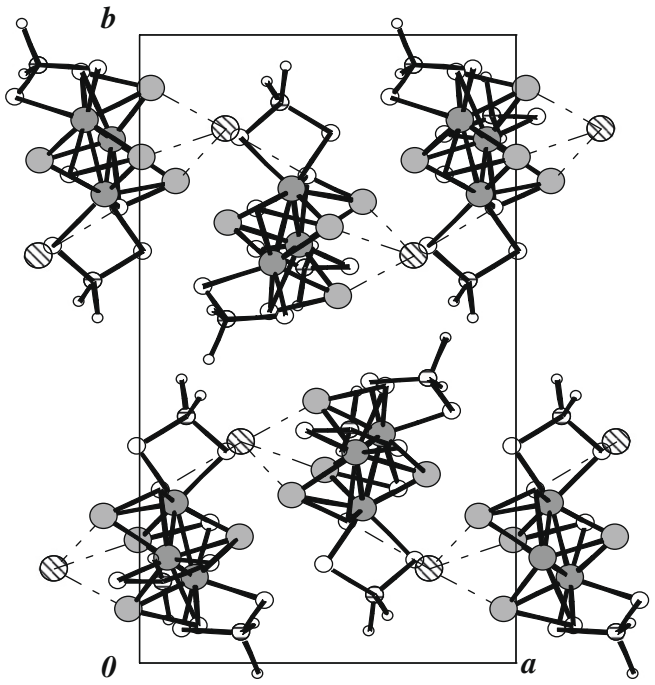

Fig. 4. Crystal packing in **2**–**6**. Shortened halogen···chalcogen contacts are shown by dashed lines. Carbon and oxygen atoms of ethyl groups are omitted for clarity.

both equatorial (Q_{ex}) and axial (Q_{ax}) atoms of the μ_2-Q_2 ligands of the cluster core. These interactions result in two types of shortened halogen···chalcogen contacts, namely, *axial* $3Q_{ax}$···X and *equatorial* Q_{eq}···X [11,20] (Table 3). Cluster anions are joined to halogen anions into ionic pairs *via* axial contacts (Fig. 3). The ionic pairs in turn are joined to each other by means of equatorial contacts into infinite chains running along the crystallographic *a* axis (Fig. 4). According to the crystal packing analysis [16] the cluster cations, as well as cation–anion ionic pairs, form distorted primitive cubic packing. In agreement with this, the cationic–anionic chains form rectangular rod packing.

The compounds **2**–**6** have various isostructural analogs among cluster complexes with the general formula $[M_3Q_7(dtp)_3]X$. In all the structures, similar chains of alternating cluster cations and halogenide anions are found (Table 3). As expected, the Q_{ax}···X and Q_{eq}···X distances demonstrate a tendency to increase along the ranges S–Se–Te and Cl–Br–I.

4. Conclusion

We have found that in the clusters $M_3(\mu_3\text{-Te})(\mu_2\text{-Te}_2)_3^{4+}$ the Te atoms can undergo electrophilic substitution by S (directly or via elimination–addition). The most reactive position was found to be Te_{eq} which makes possible the preparation of complexes with a $Te_{ax}S_{eq}$ bridging ligand.

Supplementary data

CCDC 691116 and 691120 contain the supplementary crystallographic data for **2**–**6**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk

polymers containing 4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene.

2. Experimental

Resorcinarene, 4,5-dichloro-1,2-dicyanobenzene and 4-nitro-1,2-dicyanobenzene were prepared by previously reported procedure [35–37]. FTIR spectra were recorded on a Perkin–Elmer Spectrum 100 Fourier Transform Infrared Spectrometer as KBr pellets. UV–Vis spectra were recorded on a Shimadzu UV–Vis spectrometer. ^{1}H NMR and ^{13}C NMR studies were done on a Varian UNITY INOVA 500 MHz spectrometer. Elemental analyses were performed by the Instrumental Analyses Laboratory of the TÜBİTAK Gebze Research Center. Microwave-assisted syntheses were carried out using a modified BEKO MD domestic microwave oven.

2.1. Microwave-assisted synthesis of 4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**)

Resorcinarene (5.44 g, 10 mmol), 2-chloroethanol (5.64 g, 80 mmol) and K_2CO_3 (11.04 g, 80 mmol) were added into *N*,*N*-dimethyl formamide (DMF) (20 mL). This mixture was heated by microwaves for 20 min with a fixed power of 360 W [19,35]. The reaction mixture was poured in an ice bath, added HCl solution to eliminate base trace and the formed solid material was filtered off and washed with water until the filtrate became neutral. The crude product was purified by two successive column chromatographic separations (silica gel, DMF/methanol = 40:1). This compound was soluble in alcohol, DMF and DMSO. Yield: 6.52 g (72%), mp: 213 °C. *Anal.* Calc. for $C_{48}H_{64}O_{16}$: C, 64.20; H, 7.19. Found: C, 63.93; H, 7.19%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3229 (OH), 2963 (CH), 1620, 1611, 1502, 1431, 1287, 1217, 1100, 895. ^{1}H NMR ($(CD_3)_2SO$), (δ:ppm): 7.40–6.80 (br, 8H, ArCH), 5.20 (br, 4H, CH), 4.23 (s, 8H, OH), 3.42 (t, 16H, CH_2), 3.28 (t, 16H, CH_2), 1.87 (d, 12H, CH_3). ^{13}C NMR ($(CD_3)_2SO$), (δ:ppm): 155.20, 129.89, 105.45, 95.60, 71.26 ($ArOCH_2$), 60.60 (CH_2OH), 31.51, 20.71 (CH_3).

2.2. Microwave-assisted synthesis of tetrakis(4,5-bis(2-hydroxyethoxy))phthalonitrile substituted resorcinarene compound (**2**)

4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**) (2.0 g, 2.22 mmol), 4,5-dichloro phthalonitrile (1.75 g, 8.88 mmol) and K_2CO_3 (2.70 g, 19.56 mmol) were added into *N*,*N*-dimethyl formamide (DMF) (20 mL). This mixture was heated by microwaves for 20 min with a fixed power of 360 W [35]. The reaction mixture was poured in an ice bath, added HCl solution to eliminate base trace and the formed solid material was filtered off and washed with water until the filtrate became neutral. The crude product was purified by washing with hot ethanol (5 × 50 mL). This compound was soluble in DMF and DMSO. Yield: 2.72 g (88%), mp > 300 °C. *Anal.* Calc. for $C_{80}H_{64}O_{16}N_8$: C, 68.40; H, 4.63; N, 8.04. Found: C, 67.93; H, 4.25; N, 8.12%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3076 (=CH), 2969 (CH), 2236 (C≡N), 1583, 1480, 1379, 1273, 1189, 1097, 895. ^{1}H NMR ($(CD_3)_2SO$), (δ:ppm): 8.39 (s, 8H, ArCH), 8.01 (s, 4H, ArCH), 7.10 (s, 4H, ArCH), 4.70–4.20 (m, 4H, CH), 2.82 (t, 16H, CH_2), 2.70 (t, 16H, CH_2), 1.74 (d, 12H, CH_3). ^{13}C NMR ($(CD_3)_2SO$), (δ:ppm): 157.40, 151.20, 136.35, 128.85, 115.10 (CN), 71.26 ($ArOCH_2$), 59.62 (CH_2OAr), 29.51, 20.71.

2.3. Microwave-assisted synthesis of octakis(4-(2-hydroxyethoxy)) phthalonitrile substituted resorcinarene (**3**)

4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**) (2.0 g, 2.22 mmol), 4-nitro-1,2-dicyanobenzene (3.08 g, 17.83 mmol) and K_2CO_3 (2.70 g, 19.56 mmol) were added into *N*,*N*-dimethyl formamide (DMF) (20 mL). This mixture was heated by microwaves for 20 min with a fixed power of 360 W [35]. The reaction mixture was poured in an ice bath, added HCl solution to eliminate base trace and the formed solid material was filtered off and washed with water until the filtrate became neutral. The crude product was purified by washing with hot ethanol (5 × 50 mL). This compound was soluble in DMF and DMSO. Yield: 2.64 g (62%), mp > 300 °C. *Anal.* Calc. for $C_{112}H_{80}O_{16}N_{16}$: C, 70.58; H, 4.23; N, 11.76. Found: C, 69.93; H, 4.25; N, 11.69%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3076 (=CH), 2967 (CH), 2233 (C≡N), 1589, 1568, 1485, 1310, 1279, 1189, 1093, 851. ^{1}H NMR ($(CD_3)_2SO$), (δ:ppm): 7.96 (s, 16H, ArCH), 7.42 (s, 8H, ArCH), 7.21 (s, 4H, ArCH), 7.11 (s, 4H, ArCH) 4.70–4.40 (m, 4H, CH), 2.82 (t, 16H, CH_2), 2.70 (t, 16H, CH_2), 1.12 (d, 12H, CH_3). ^{13}C NMR ($(CD_3)_2SO$), (δ:ppm): 162.40, 156.50, 151.20, 137.45, 124.85, 116.10 (CN), 109.80, 70.26 ($ArOCH_2$), 60.02 (CH_2OR), 31.51, 21.71 (CH_3).

2.4. Microwave-assisted synthesis of octakis(2-hydroxyethoxy)-resorcinarene bridged polymeric phthalocyanines (**2a**–**d**)

The general procedure, employed for synthesis of various metallophthalocyanine (Zn, Cu, Ni, Co) polymers was described as; compound (**2**) (0.5 g, 0.35 mmol), metal salts ($Zn(CH_3COO)_2$, $CuCl_2$, $NiCl_2$, $CoCl_2$) (0.08 mmol), DMAE (*N*,*N*-dimethylaminoethanol) (5 mL) and 2–3 drops DBU (1,8-diazabicyclo [5.4.0]undec-7-ene) were charged together into round bottomed flask. The reaction flask was irradiated by a microwave oven at 360 W for 20 min [19,35]. After cooling to room temperature, the reaction mixture treated with water to precipitate the product which was filtered off. The green product was washed with DMF, hot alcohol and hot chloroform (4 × 50 mL). Yield, melting point, elemental analysis, FTIR and UV–Vis spectra of the products were as following:

Zn-containing polymer (**2a**): Yield: 0.40 g (80%), mp > 300 °C. *Anal.* Calc. for $C_{320}H_{256}O_{64}N_{32}Zn$: C, 68.16; H, 4.58; N, 7.95. Found: C, 67.93; H, 4.90; N, 7.89%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3060 (=CH), 2931 (CH), 2234 (C≡N), 1774 (C=N), 1724 (C=N), 1587, 1490, 1352, 1276, 1187, 1090, 894. UV–Vis (DMF): λ_{max}/nm: 245, 638, 688.

Cu-containing polymer (**2b**): Yield: 0.43 g (81%), mp > 300 °C. *Anal.* Calc. for $C_{320}H_{256}O_{64}N_{32}Cu$: C, 68.18; H, 4.58; N, 7.95. Found: C, 67.95; H, 4.87; N, 7.90%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3060 (=CH), 2931 (CH), 2232 (C≡N), 1774 (C=N), 1715 (C=N), 1660, 1489, 1393, 1256, 1160 1093, 896. UV–Vis (DMF): λ_{max}/nm: 289, 298, 748, 762.

Ni-containing polymer (**2c**): Yield: 0.40 g (80%), mp > 300 °C. *Anal.* Calc. for $C_{320}H_{256}O_{64}N_{32}Ni$: C, 68.24; H, 4.58; N, 7.96. Found: C, 67.98; H, 4.87; N, 7.87%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3060 (=CH), 2931 (CH), 2227 (C≡N), 1770 (C=N), 1719 (C=N), 1692, 1492, 1386, 1253, 1092, 896. UV–Vis (DMF): λ_{max}/nm: 271, 299, 609, 685.

Co-containing polymer (**2d**): Yield: 0.40 g (80%), mp > 300 °C. *Anal.* Calc. for $C_{320}H_{256}O_{64}N_{32}Co$: C, 68.24; H, 4.58; N, 7.96. Found: C, 67.97; H, 4.89; N, 7.87%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3060 (=CH), 2930 (CH), 2232 (C≡N), 1726 (C=N), 1690 (C=N), 1491, 1385, 1254, 1091, 895. UV–Vis (DMF): λ_{max}/nm: 248, 271, 610, 683.

2.5. Microwave-assisted synthesis of octakis(2-hydroxyethoxy)-resorcinarene bridged polymeric phthalocyanines (**3a**–**d**)

The general procedure, employed for synthesis of various metal phthalocyanine (Zn, Cu, Ni, Co) polymers was described as; compound (**3**) (0.5 g, 0.26 mmol), metal salts ($Zn(CH_3COO)_2$, $CuCl_2$, $NiCl_2$, $CoCl_2$) (0.08 mmol), DMAE (*N*,*N*-dimethylaminoethanol) (5 mL) and 2–3 drops DBU (1,8-diazabicyclo [5.4.0]undec-7-ene)

were charged together into round bottomed flask. The reaction flask was irradiated by a microwave oven at 360 W for 20 min [19,35]. After cooling to room temperature, the reaction mixture treated with water to precipitate the product which was filtered off. The green product was washed with DMF, hot alcohol and hot chloroform (4 × 50 mL). Yield, melting point, elemental analysis, FTIR and UV–Vis spectra of the products were as following:

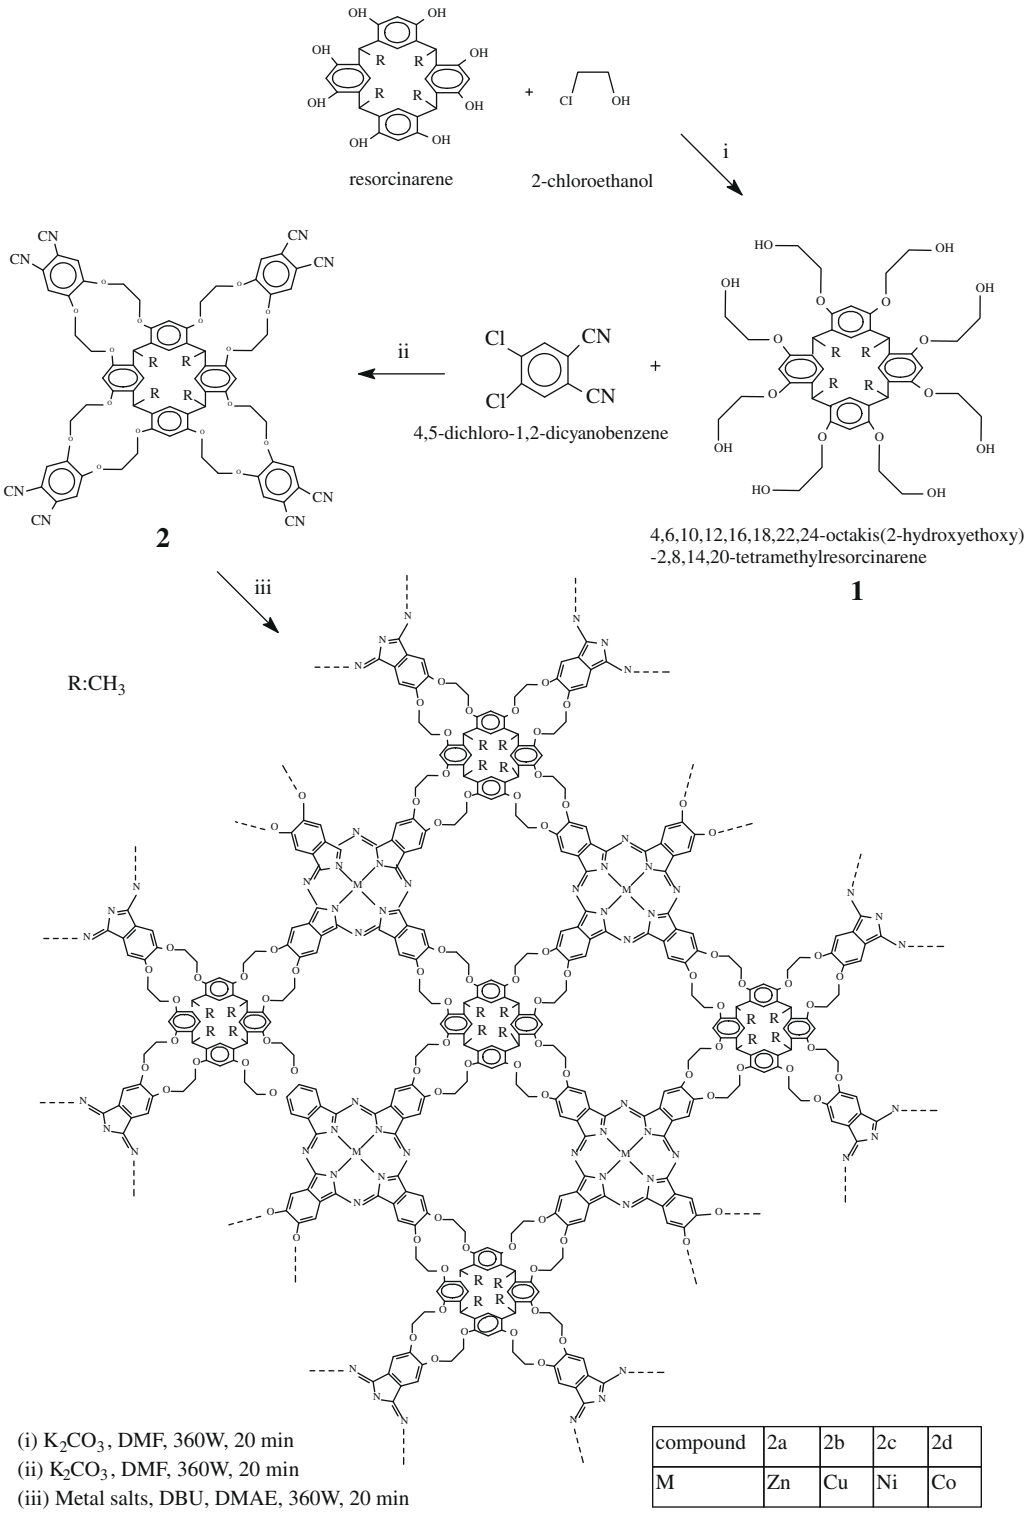
Zn-containing polymer (**3a**): Yield: 0.40 g (80%), mp > 300 °C. *Anal.* Calc. for $C_{224}H_{160}O_{32}N_{32}Zn$: C, 69.39; H, 4.16; N, 11.56. Found: C, 68.93; H, 4.90; N, 11.52%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3063 (=CH), 2930 (CH), 2232 (C≡N), 1769 (C=N), 1715 (C=N), 1600, 1474, 1276, 1085, 837. UV–Vis (DMF): λ_{max}/nm: 288, 306, 616, 683.

Cu-containing polymer (**3b**): Yield: 0.27 g (75%), mp > 300 °C. *Anal.* Calc. for $C_{224}H_{160}O_{32}N_{32}Cu$: C, 69.42; H, 4.16; N, 11.57. Found: C, 68.95; H, 4.78; N, 11.50%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3071 (=CH), 2924 (CH), 2232 (C≡N), 1714 (C=N), 1592, 1434, 1247, 1091, 837. UV–Vis (DMF): λ_{max}/nm: 275, 609, 681.

Ni-containing polymer (**3c**): Yield: 0.40 g (80%), mp > 300 °C. *Anal.* Calc. for $C_{224}H_{160}O_{32}N_{32}Ni$: C, 69.51; H, 4.17; N, 11.58. Found: C, 68.96; H, 4.69; N, 11.52%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3063 (=CH), 2930 (CH), 2232 (C≡N), 1718 (C=N), 1653, 1595, 1477, 1244, 1085, 836. UV–Vis (DMF): λ_{max}/nm: 270, 289, 674.

Co-containing polymer (**3d**): Yield: 0.41 g (82%), mp > 300 °C. *Anal.* Calc. for $C_{224}H_{160}O_{32}N_{32}Co$: C, 69.51; H, 4.17; N, 11.58. Found: C, 68.91; H, 4.66; N, 11.54%. FTIR (KBr tablet) ν_{max}/cm^{-1}: 3063 (=CH), 2922 (CH), 2225 (C≡N), 1714 (C=N), 1674, 1649, 1465, 1276, 1056, 834. UV–Vis (DMF): λ_{max}/nm: 289, 298, 694.

3. Results and discussion



Resorcinarene, 4,5-dichloro-1,2-dicyanobenzene and 4-nitro-1,2-dicyanobenzene were synthesized in according to previously reported literature [35–37]. In order to obtain polymeric phthalocyanines containing octakis(2-hydroxyethoxy)resorcinarene, firstly, 4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**) was synthesized by treating resorcinarene with 2-chloroethanol in DMF using K_2CO_3 as the base for nucleophilic substitution, under microwave irradiation 360 W for 20 min [19,35]. All spectroscopic data of 4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**) show good agreement with the values reported in literature [38].

The synthesis of phthalonitrile compounds was the most important step in these reaction sequences. For this purpose, tetrakis(4,5-bis(2-hydroxyethoxy))phthalonitrile substituted resorcinarene compound (**2**) and octakis(4-(2-hydroxyethoxy))phthalonitrile substituted resorcinarene compound (**3**) were synthesized by treating compound (**1**) with 4,5-dichloro-1,2-dicyanobenzene and 4-nitro-1,2-dicyanobenzene, respectively, in DMF using K_2CO_3 as the base for nucleophilic substitution under microwave irradiation 360 W for 20 min [35]. The chemical structures of compound (**2**) and (**3**) were determined in according to previously reported paper by Cram et al. [39–41]. At the last step, metallophthalocyanine (Zn, Cu, Ni, Co) polymers were synthesized using microwave irradiation from the corresponding phthalonitrile derivatives and metal salts in DMAE for 20 min [35]. Both microwave irradiation and also conventional methods for the preparation of metal-free phthalocyanine polymer containing octakis(2-hydroxyethoxy)resorcinarene were not successful. Phthalocyanines can be obtained by the metal-template effect [42], however, metal-free phthalocyanine polymers containing octakis(2-hydroxyethoxy)resorcinarene could not be obtained due to absence of metal-template effect. The solubility of metal phthalocyanine polymers containing octakis(2-hydroxyethoxy)resorcinarene was moderate in common organic solvent such as DMF and DMSO. The solubility of the newly synthesized metal phthalocyanine polymers containing octakis(2-hydroxyethoxy)resorcinarene is more than previously synthesized metal phthalocyanine polymers containing resorcinarene by our group [35] in common organic solvents such as DMF and DMSO. The reason for this increase in solubility might be a consequence of the increased intermolecular interactions between solvent and polymeric phthalocyanines containing octakis(2-hydroxyethoxy)resorcinarene groups which have 16 oxygen atoms.

The purification of metallophthalocyanine polymers was carried out by the successive washings with various solvents. Characterization of the products involved a combination of methods including elemental analyses, FTIR, UV–Vis, ^1H NMR and ^{13}C NMR spectroscopy. ^1H NMR and ^{13}C NMR data could not be obtained for metal phthalocyanine polymers due to its insufficient solubility in polar solvents such as $CHCl_3$, DMF and DMSO. Elemental analyses of the phthalonitrile derivatives and the phthalocyanines show good agreement with the calculated values. Phthalonitrile compounds (**2**) and (**3**) are the repeated units in the structures of the newly synthesized metal phthalocyanine (Zn, Cu, Ni, Co) polymers containing octakis(2-hydroxyethoxy)resorcinarene. Microwave-assisted synthesis route of octakis(2-hydroxyethoxy)resorcinarene and new metal phthalocyanine (Zn, Cu, Ni, Co) polymers can be seen in Figs. 1 and 2.

FTIR spectrum of 4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**) shows good agreement with the values reported in literature [38]. The formation of compound (**2**) was clearly indicated by the disappearance of the OH band at 3229 cm^{-1} and appearance of the C≡N band at 2236 cm^{-1} in its FTIR spectrum. The FTIR spectra of the polymeric phthalocyanines (**2a–d**) clearly indicate the cyclotetramerization of the phthalonitrile derivatives with the disappearance of the C≡N peak at 2236 cm^{-1}. The formation of compound (**3**) was clearly indicated by the disappearance of the OH band at 3229 cm^{-1} and appearance of the C≡N band at 2233 cm^{-1} in its FTIR spectrum. The FTIR spectra of the polymeric phthalocyanines (**3a–d**) clearly indicate the cyclotetramerization of the phthalonitrile derivatives with the disappearance of the C≡N peak at 2233 cm^{-1}. But, the polymeric phthalocyanines (**2a–d** and **3a–d**) have cyano end groups together with imide functions [11–13], as indicated by the weak absorbtions C≡N at 2234, 2232, 2234, 2232 cm^{-1}, imide at 1774, 1774, 1770 and 1724, 1715, 1719, 1726 cm^{-1}.

^1H NMR and ^{13}C NMR spectra of 4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**) show good agreement with the values reported in literature [38]. The formation of compound (**2**) was clearly indicated by the disappearance of the OH peak at 4.23 ppm in its ^1H NMR spectrum. In the ^1H NMR spectrum of compound (**2**) the aromatic protons appear as three singlets at 8.39, 8.01 and 7.10 ppm and aliphatic protons appear as a multiplet at 4.70–4.20 ppm, as two triplet 2.82 and 2.70 and as a doublet at 1.74 ppm. The ^{13}C NMR spectrum of compound (**2**) indicated the presence of nitrile carbon atoms at 115.10 ppm, methyl carbon atoms at 20.71 ppm. The formation of compound (**3**) was clearly indicated by the disappearance of the OH peak at 4.23 ppm in its ^1H NMR spectrum. In the ^1H NMR spectrum of compound (**3**) the aromatic protons appear as four singlets at 7.96, 7.42, 7.21 and 7.11 ppm and aliphatic protons appear as a multiplet at 4.70–4.40 ppm, as two triplet 2.82 and 2.70 and as a doublet at 1.12 ppm. The ^{13}C NMR spectrum of compound (**3**) indicated the presence of nitrile carbon atoms at 116.10 ppm, methyl carbon atoms at 21.71 ppm. ^1H NMR and ^{13}C NMR measurements of the metal phthalocyanine (Cu, Co, Ni) polymers were precluded due to its paramagnetic nature. ^1H NMR and ^{13}C NMR spectra could not be obtained for polymeric phthalocyanines (**2a**) and (**3a**) due to its insufficient solubility in polar solvents such as $CHCl_3$, DMF and DMSO.

compound	2a	2b	2c	2d
M	Zn	Cu	Ni	Co

Fig. 1. Microwave-assisted synthesis of 4,6,10,12,16,18,22,24-octakis(2-hydroxyethoxy)-2,8,14,20-tetramethylresorcinarene (**1**), compound (**2**) and metallophthalocyanine polymers (**2a–d**).

The best indication for the phthalocyanine systems is their UV–Vis spectra in solutions. The newly synthesized metallophthalocyanine polymers (**2a–d** and **3a–d**) showed typical electronic spectra with two strong absorption regions, one of them is in UV region at about 245–289 nm for the compounds (**2a–d**), 270–289 nm for the compounds (**3a–d**) (B band) and the other one is in the visible region at about 683–762 nm for the compounds (**2a–d**), 674–694 nm for the compounds (**3a–d**) (Q band) in DMF. The Q band was attributed to $\pi \rightarrow \pi^*$ transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) of the Pc ring. The other bands (B) in the UV region are observed due to the transitions from the deeper π levels to the LUMO [3,20]. Q bands shifted to above values due to polymerization of phthalonitrile derivatives [43].

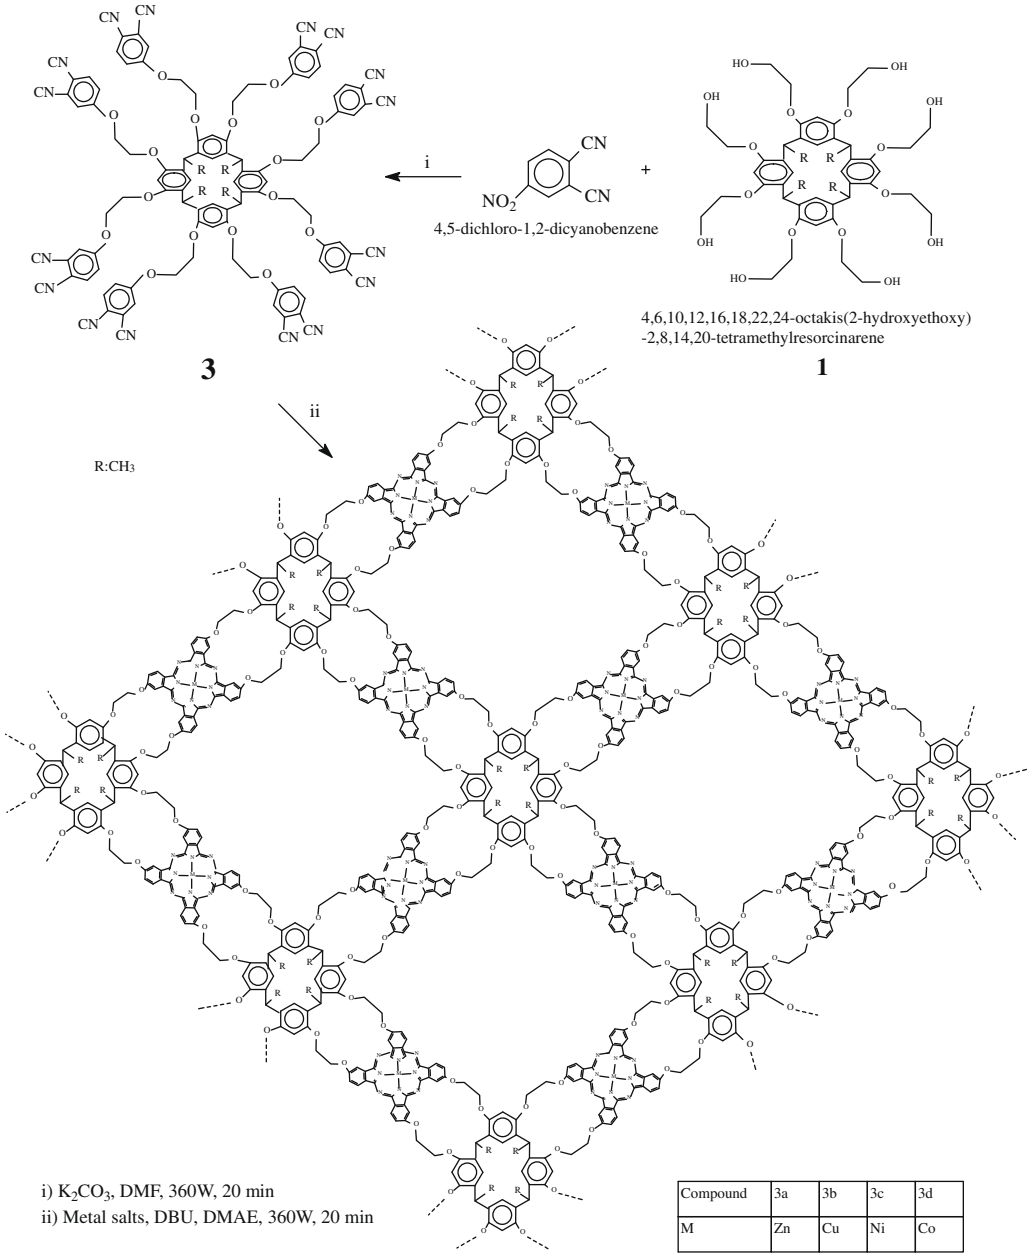


Fig. 2. Microwave-assisted synthesis of compound (**3**) and metallophthalocyanine polymers (**3a–d**).

4. Conclusion

It is the first time, the preparation of metal phthalocyanine (Zn, Cu, Ni, Co) polymers containing octakis(2-hydroxyethoxy)resorcinarene has been achieved by using as starting materials tetrakis(4,5-bis(2-hydroxyethoxy))phthalonitrile substituted resorcinarene and octakis(4-(2-hydroxyethoxy)phthalonitrile substituted resorcinarene under microwave irradiation. The solubility of the newly synthesized metal phthalocyanine polymers is more than previously reported (resorcinarene [35]) metal phthalocyanines polymers in common organic solvents such as DMF and DMSO. Microwave-assisted synthesis technique reduces reaction time and enhances yield in all of carried out reactions.

standard methods prior to use. Elemental analyses were performed in a PE240C elemental analyzer. IR spectra were recorded on a BRUKER VECTOR 22 FT-IR spectrometer with KBr pellets. ESI-MS spectra were carried out with a TRACE DSQ instrument.

2.2. Syntheses of complexes **1–5**

2.2.1. [Cu(DMPzA)(2,2′-bipy)]·$(ClO_4)_2$ (**1**)

A solution of $Cu(ClO_4)_2·6H_2O$ (37.1 mg, 0.1 mmol) in acetonitrile (5 ml) was added dropwise to a solution of TMPzA (34.1 mg, 0.1 mmol) in acetonitrile (5 ml) with stirring. To the reaction mixture, a solution of 2,2-bipy (15.6 mg, 0.1 mmol) in acetonitrile (3 ml) was added; the resulting mixture was stirred for 1 h at room temperature. The final mixture was filtered and the filtrate was left to stand for over two weeks. Dark blue single crystals of **1** were obtained. Yield: 52% based on Cu. *Anal.* Calc. for $C_{22}H_{29}Cl_2CuN_7O_9$ (**1**): C, 39.40; H, 4.33; N, 14.63. Found: C, 38.50; H, 5.10; N, 14.20%. IR data (KBr, cm^{-1}): 3553 w, 3308 m, 3140 w, 2924 w, 2022 w, 1613 m, 1616 m, 1555 m, 1500 m, 1476 m, 1447 s, 1426 m, 1391 m, 1314 m, 1251 w, 1237 w, 1097 vs, 883 w, 774 m, 730 w, 663w, 623 s, 557 w.

2.2.2. [(DMPzA)Cu(μ-4,4′-bipy)Cu(DMPzA)]·$(ClO_4)_4$ (**2**)

Complex **2** was prepared by a similar procedure to that of **1** in a CH_3OH/H_2O co-solvent, except using 4,4-bipyridine as the auxiliary ligand instead of 2,2-bipyridine. Yield: 61% based on Cu. *Anal.* Calc. for $C_{34}H_{42}Cl_4Cu_2N_{12}O_{16}$ (**2**): C, 35.67; H, 3.67; N, 14.69. Found: C, 35.38; H, 3.89; N, 14.34%. IR (KBr, cm^{-1}): 3424 br, 3225 w, 3138 w, 3115 m, 3002 w, 1615 s, 1555 s, 1496 m, 1461 s, 1421 s, 1389 s, 1337 w, 1309 w, 1270 m, 1228 m, 1120 vs, 1100 vs, 1071 vs, 1051 vs, 978 m, 928 m, 826 m, 808 m, 728 w, 649 m, 623 vs, 563 w, 511 w.

2.2.3. [(TMPzA)Cu(μ-H_2DPC)Cu(DMPzA)]·$(ClO_4)_2$ (**3**)

A solution of $Cu(ClO_4)_2·6H_2O$ (0.1 mmol, 37.1 mg) in MeOH (10 ml) was added to a solution of TMPzA (0.1 mmol, 34.1 mg) in MeOH (10 ml) with stirring. To the reaction mixture, a solution of H_2DPC (0.05 mmol, 8.4 mg, deprotoned by reacting with NaOH) in water (5 ml) was added, and the resulting mixture was stirred for 1 h at room temperature. The final mixture was filtered, and the filtrate was left to stand for one month. Dark blue single crystals of **3** were isolated (yield: 53% based on Cu). *Anal.* Calc for $C_{37}H_{49}Cl_2Cu_2N_{13}O_{12}$ (**3**): C, 41.66; H, 4.60; N, 17.08. Found: C, 41.34; H, 4.82; N, 17.20%. IR (KBr, cm^{-1}): 3447 br, 3198 w, 2920 w, 2850 w, 2018 w, 1630 s, 1610 vs, 1582 m, 1552 m, 1507 w, 1472 m, 1436 m, 1375 vs, 1281 m, 1243 w, 1120 vs, 1096 vs, 1060 vs, 924 w, 910 w, 823 w, 731 m, 625 m, 597 w, 559 w.

2.2.4. [(DMPzA)Co(μ-H_2DPC)Co(TMPzA)]·$(ClO_4)_2$ (**4**)

Complex **4** was prepared in a way similar to the procedure of **3** except using $Co(ClO_4)_2·6H_2O$ instead of $Cu(ClO_4)_2·6H_2O$. Yield: 60% based on Co. *Anal.* Calc. for $C_{37}H_{51}Cl_2Co_2N_{13}O_{13}$ (**4**): C, 41.32; H, 4.75; N, 16.94. Found: C, 40.88; H, 4.80; N, 17.20%. IR (KBr, cm^{-1}): 3593 w, 3470 br, 2925 m, 2066 m, 1639 s, 1609 s, 1568 s, 1554 s, 1468 s, 1439 m, 1387 m, 1281 m, 1247 m, 1146 s, 1092 vs, 1053 s, 997 w, 738 m, 693w, 625 s, 595 w.

2.2.5. [(TMPzA)Co(μ-HZPC)Co(TMPzA)(H_2O)$_2$]·$(ClO_4)_3$ (**5**)

Complex **5** was prepared in a way similar to the procedure of **4** except using 5-methyl-3-pyrazol-carboxylic acid instead of 2,6-pyridine-dicarboxylic acid as the auxiliary donor. Yield: *ca.* 25% based on Co. *Anal.* Calc. for $C_{41}H_{62}Cl_3Co_2N_{16}O_{16}$ (**5**): C, 39.07; H, 4.92; N, 17.79. Found: C, 38.87; H, 5.10; N, 17.81%. IR (KBr, cm^{-1}): 3852 w, 3746 w, 3647 w, 2926 m, 2018 w, 1733 w, 1649 s, 1576 m, 1555 s, 1468 s, 1425 m, 1386 m, 1277 m, 1247 m, 1093 vs, 1054 s, 984 w, 928 w, 835 m, 794 m, 625 s, 549 w.

Caution! Although we have not met any problems in handling perchlorate salts during this work, these should be treated cautiously because of their potential explosive nature.

2.3. X-ray crystallography

Details of the crystallographic parameters, data collection and refinements are summarized in Table 1. Structure measurements

of these complexes were performed on a Bruker SMART 1000 CCD area detector equipped with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) by the ω-scan mode. The structures were solved by direct methods and refined with the full-matrix least-squares technique using the SHELXS-97 and SHELXL-97 programs [12,13]. The non-hydrogen atoms were refined anisotropically, whereas non-water hydrogen atoms were included in calculated positions and refined with isotropic thermal parameters riding on the parent atoms. The H atoms of water molecules were fixed by difference Fourier E-maps.

3. Results and discussion

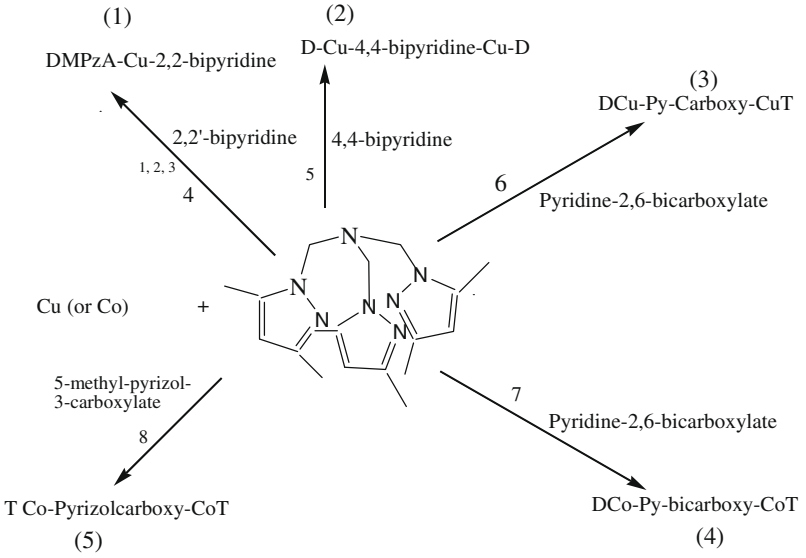
3.1. Syntheses

The synthetic methods for complexes **1**–**5** are given in Scheme 1. In the initial stage, the mononuclear complex **1** with TMPzA losing one arm, has been obtained. Then various metal salts have been employed to prepare metal complexes, with pyridyl derivatives as auxiliary ligands also being involved in the system to survey the effect of the metal atom on the structures of the complexes, and complexes **2**, **3** and **4** have been isolated. The same result to that of **1**, namely one pendant arm of the TMPzA ligand is removed in these complexes with various metal atoms, has been observed. In these complexes, the tripodal ligand TMPzA loses a pendant arm and coordinates with the metal center, meanwhile the pyridyl ring also coordinates with the metal center. In order to confirm further the effect of the pyridyl compounds on the cleavage reaction of the tripodal ligand, 5-methyl-3-pyrazolyl-carboxylate as the auxiliary ligand has been employed instead of the pyridyl compounds, and in this case complex **5** has been prepared. It has been found that two TMPzA ligands have coordinated with the metal center and no pendant arm is removed in complex **5**. This result proves further that the metal complexes of TMPzA have the ability to recognize pyridine compounds.

3.2. Descriptions of crystal structures

3.2.1. [Cu(DMPzA)(2,2′-bipy)]·(ClO_4)$_2$ (**1**)

The structure of **1** consists of a mononuclear [Cu(DMPzA)(2,2-bipy)]$^{2+}$ unit and two uncoordinated ClO_4^- anions (Fig. 1). In this complex, TMPzA loses an uncoordinated arm and turns into DMPzA, The Cu(II) atom has a five-coordinated distorted square pyramidal coordination, including two $N_{pyrazole}$ atoms of TMPzA and two $N_{pyridyl}$ of 2,2-bipyridine as well as a N_{amine} atom of TMPzA. The N_{amine} is in an axial site, and the bottom plane is defined by two $N_{pyrazole}$ atoms and two N_{pyrine} atoms. The Cu–$N_{pyrazole}$ and Cu–$N_{pyridine}$ bonds are normal coordinated bonds. The Cu–N_{amine} bond [2.342(4) Å] in the axial site is somewhat longer than a normal bond due to the Jahn–Teller effect from the copper atom and the strain action from the ligand, and the coordination configuration of **1** is best described as a square based pyramid. Selected bond lengths and angles for **1** are listed in Table 2.



3.2.2. [(DMPzA)Cu(μ-4,4′-bipy)Cu(DMPzA)]·(ClO_4)$_4$ (**2**)

The molecular structure of **2** consists of discrete [Cu_2(DMPzA)$_2$-(4,4-bipy)]$^{2+}$ cations and two perchlorates (Fig. 2a). Both TMPzA molecules lose an arm and become DMPzA. The cation, [Cu_2(DMPzA)$_2$(4,4-bipy)]$^{2+}$, has C_2 symmetry with two-fold axis passing through the center of 4,4-bipyridine. The 4,4-bipyridine molecule bridge links two Cu(II) centers in a bidentate mode, and the two Cu(II) atoms are in square-planar environments involving two $N_{pyrazol}$ atoms, two N_{amine} atoms and two $N_{pyridine}$ atoms. The molecular structure of **2** is quite similar to that of the complex Cu($C_{14}H_9NO_3$)($C_3H_4N_2$) reported by Gao et al. [14]. The Cu–N bond lengths fall in the range 1.9762(12)–2.036(15) Å and they are normal coordination bonds. The Cu–N_{amine} bond is somewhat longer than the Cu–$N_{pyrazol}$ bond, and they can be regarded as normal for this class of complexes [15]. The Cu atoms protrude out from the mean plane by 0.0195 Å. Selected bond lengths and angles for **2** are listed in Table 3.

The symmetry units are developed into a 1D chain through an intermolecular hydrogen bond at the uncoordinated perchlorate groups with O···H–CH_2 = 2.413 Å, shown in Fig. 2b.

3.2.3. Descriptions of the crystal structures of complexes *3* and *4*

The coordinated configurations of complexes **3** and **4** are quite similar, as shown in Figs. 3 and 4, respectively. In these complexes, one carboxyl group of H_2DPC coordinates with the metal center in a monodentate fashion, and the other carboxyl group coordinates with two metal ions in bidentate mode. In **3** and **4**, one metal atom, M(1), coordinated by the four N atoms of TMPzA and one O atom of

Scheme 1. The synthesis methods of the complexes **1**–**5**. (D = bis(3,5-bimethyl-pyrazolmethyl)amine. T = tris(3,5-bimethyl-pyrazolmethyl)amine; bipy = 4,4′-bipyridine; pda = pyridine-2,6-dicarboxylate; pzoa = 5-methyl-3-pyrazole-carboxylate). (1) L:Cu(ClO_4)$_2$ = 1:1; (2) in CH_3OH/H_2O; (3) stirring for 30 min; (4) L:Cu(ClO_4)$_2$:bipy = 1:1:1; (5) L:Cu(ClO_4)$_2$:bipy = 1:1:0.5; (6) L:Cu(ClO_4)$_2$:pda = 1:1:0.5; (7) L:Co(ClO_4)$_2$:pda = 1:1:0.5; (8) L:Co(ClO_4)$_2$:pzoa = 1:1:0.5.

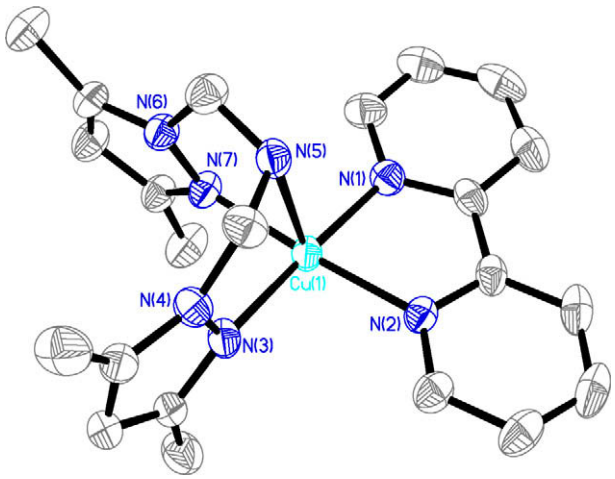


Fig. 1. ORTEP view of complex **1**. Hydrogen atoms are omitted for clarity.

Table 2
Selected bond distances (Å) and angles (°) for **1**.

a carboxyl group, has a distorted trigonal bipyramidal configuration with the axial O–M–N bond angles 176.9(3)° and 177.85(10)°, respectively. The coordination configuration of the other metal atom, M(2), which is different from that of the M(1) atom, is a six-coordinated octahedron with two $O_{carboxyl}$ atoms and one $N_{pyridyl}$ atoms of H_2DPC and two $N_{pyrizale}$ and one N_{amine} of the TMPzA ligand. TMPzA has lost a pendant arm and turns into DMPzA, and coordinates with the metal atoms through the N_{amine} and two $N_{pyrazol}$ atoms. Selected bond lengths and angles for **3** and **4** are listed in Table 4.

3.2.4. Descriptions of crystal structure of complex *5*

Complex **5** also consists of two asymmetric units, and HZPC is employed in the system as an auxiliary ligand (Fig. 5). The configuration of **5** is different from those of the previous four complexes. In complex **5**, two TMPzA molecules are retained and no pendant arm is removed. The carboxyl group of HZPC coordinates with two Co atoms in a bidentate mode, bridging the two metal centers. The Co(1) atom is penta-coordinated trigonal bipyramidal with three $N_{pyrazol}$ atoms, one N_{amine} atom and one $O_{carboxyl}$ atom, which is quite similar to that of the metal(1) atoms in **3** and **4**. Three $N_{pyrazol}$ atoms define the mean plane and the N_{amine} and $O_{carboxyl}$ atoms are in axial sites with the $O_{carboxyl}$–Co–N_{amine} angle being 178.36(4)°. The N(7)–Co(1)–N(3) angle [128.28(5)°] is larger than the angles N(3)–Co(1)–N(5) [106.786(6)°] and N(5)–Co(1)–N(7) [109.70(6)°], which might be due to the strain of the coordinated carboxyl groups.

Table 3
Selected bond distances (Å) and angles (°) for **2**.

The Co(2) atom is in an octahedral coordinated environment involving two $N_{pyrazol}$ atoms and one N_{amine} atom of TMPzA, one $N_{pyrazol}$ and one $O_{carboxyl}$ atom of the bridging ligand and one O_{water}. One uncoordinated pendant arm still links with the skeleton of TMPzA. The $O_{carboxyl}$–Co(2)–O_{H2O} defines the in the axial sites, and the mean plane is defined by three $N_{pyrazol}$ atoms and one N_{amine} atom. There are three disordered perchlorate ions and two uncoordinated water molecules, O(16) and O(17), in which one water molecule, O(17), is disordered. Selected bond lengths and angles for **5** are listed in Table 5.

3.3. Study on the cleavage mechanism of the pendant arm on the tripodal ligand

3.3.1. Quantum chemistry calculation

Full geometry optimizations were performed at the DFT/B3LYP levels with the 6-31G(d) basis sets. The vibration analysis was performed on the B3LYP/6-31G(d) geometries to verify the structures of minimum energy and to provide zero-point vibration energies (ZPVEs, scaled by the recommended factor of 0.980619). The C–N bond dissociation enthalpies (BDEs) of model derivatives were corrected for ZPVEs and thermal effects due to transitional, rotational

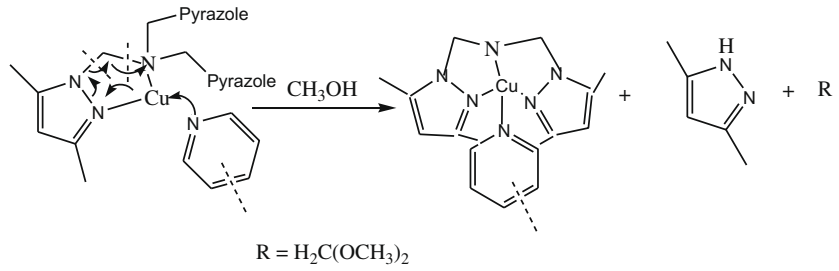
and vibration motions of the related non-linear molecules/radicals. All calculations were carried out with the GAUSSIAN 03 program package [16]. The calculated results by the computation method are collected in Table 6.

From Table 6, it can be seen that the breaking energy of H_2N┼CH_2–pyrazole is lower than that of H_2N–CH_2┼pyrazole, which leads to the methyl–pyrazole group dissociating from N_{amine} of TMPzA, and both bonds are more easily broken than H_2N┼CH_2–pyridine because the energies to break those bonds mentioned above are lower than that of H_2N┼CH_2–pyridine. Thus, the pendant arm of tripodal ligands involving pyrazole arms is more easily broken than that of tripodal ligands involving pyridyl pendant arms, such as TPA, TLA and TEPA, which do not display the cleavage of a pendant arm of the ligand. The cleavage mechanism of the pendant arm on TMPzA might be also illustrated by the special molecular structure of the pyrazole.

3.3.2. The molecular structure of pyrazole

It has been known that the pyrazole molecule has two tautomeric isomers [17–19], as shown in Chart 1.



The proton on the nitrogen atom of the pyrazole ring could migrate between both nitrogen atoms, leading to the methyl–pyrazole bond linking with the amine nitrogen of TMPzA being unstable in certain conditions [20]. The mechanism details have been studied and confirmed further by ESI-MS spectra.

3.3.3. ESI-MS spectra and cleavage mechanism studies

After the complex was separated from the reaction system of TMPzA with the metal salt, the mother solution was taken to carry out ESI-MS in order to detect other product molecules. Taking complex **1** as the example, there is a moderate intensity peak of m/z + H at 97.20 (intensity: 4×10^5) assigned to the 3,5-bimethylpyrazole and a peak of m/z – H at 74.2 (intensity: 3.5×10^5) assigned to $CH_2(OCH_3)_2$ in the ESI-MS spectra. A stronger peak of m/z + H at 266.4 (intensity: 12×10^5) assigned to NH(–CH_2–3,5-bimethylpyrazole)$_2$·CH_3OH was also observed.

These results indicate that the complexes with TMPzA have a strong ability of selected recognition of pyridine compounds. The pendant arm on TMPzA can be removed by pyridine derivatives, two C–N bonds of the $N_{pyrazole}$–C–N_{amine} are broken and the pyridyl group coordinates with the metal center on attacking by pyridine compounds. Meanwhile, the complexes with DMPzA give a pyri-

dine-coordinated complex, generated *via* a S_N2-like mechanism. The $-OCH_3$ groups from methanol react with $-CH_2-$ groups to generate $CH_2(OCH_3)_2$ molecules. The reaction can be described as follows:

use the UV–Vis spectral titration method to track the reaction process, but changes of absorptions have not been observed because the rate of the reaction is very slow. A study on the influencing factors for the reaction is under way in our group now.

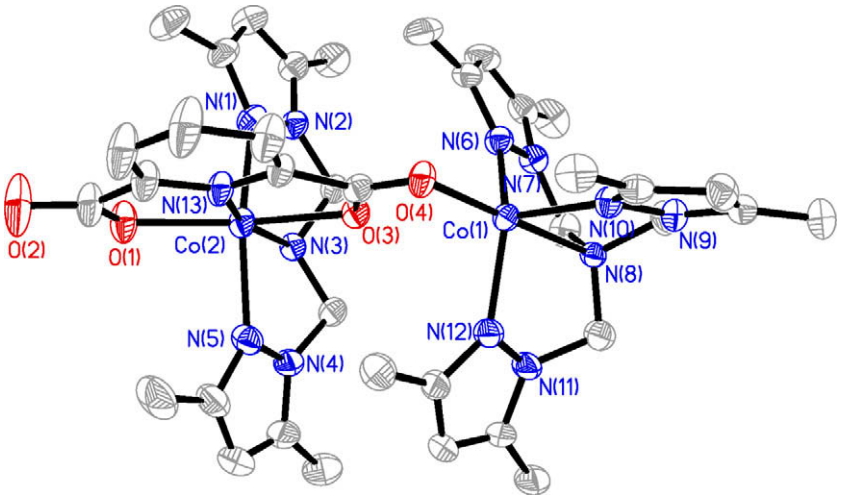


Fig. 4. ORTEP view of complex **4**. Hydrogen atoms are omitted for clarity.

Only pyridine and its derivatives promote the reaction of the pendant arms being broken in the metal complexes, because the pyridine species catalyze the aldol condensation-like reaction in methanol solvent with active hydrogen atoms [21]. Other solvents, such as acetonitrile, chloroform have been employed in these reactions, and the results above have not been obtained. We tried to

4. Conclusion

In summary, it is possible to draw the following conclusions. Firstly, when pyridine and its derivatives coordinate with metal centers, one arm on the metal complexes of TMPzA is removed, which bears no relationship to the various metal atoms used. Thus,

we speculate that these complexes have the ability to recognize pyridine compounds, and the complexes might be constructed as a molecular knife in the future. In these complexes, the bond lengths order of M–N (the metal atom with the nitrogen atoms) is: M–$N_{amine(TMPzA)}$ > M–$N_{amine(DMPzA)}$ > M–N_{pyrazo}, which arises from the steric effect of the tripodal ligand; secondly, by comparing the complexes **1**, **2** and **3**, it has been found that when the auxiliary ligands are changed from 2,2-bipy to 4,4-bipy to H_2DPC, the coordinated number changes from 4 to 5 to 6, and their coordination geometries are also changed from square-planar to trigonal bipyramidal (or tetra-pyramidal) to octahedral, which shows that the coordination configurations of the tripodal complexes can be influenced by the molecular structures of the pyridine compounds; finally, the crystal structures of **3** and **4** are quite similar, where one metal center has a six-coordinated octahedral geometry, and the another metal atom is in a five-coordinated trigonal bipyramidal environment. The $N_{pyridine}$ and one $O_{carboxyl}$ of pyridine-2,6-bicarboxylate coordinate with a metal center, and two $O_{carboxyl}$ atoms of the other carboxyl group bridge link two metal centers to form a novel asymmetric binuclear structure, which is different from the symmetric dimers reported in the literature [22,23]. The coordinated model of the bridging ligand is shown in Scheme 2.

5. Supplementary data

CCDC 288920, 288921, 292233, 285074 and 294162 contains the supplementary crystallographic data for **1**, **2**, **3**, **4** and **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

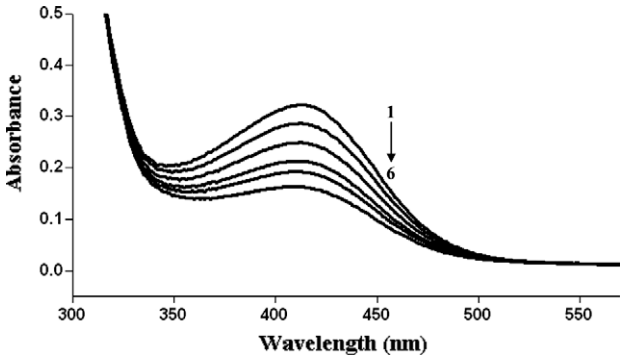

Fig. 1. Spectroscopic changes occurring in the oxidation of ATN by DPC at 27 °C. [DPC] = 5.0×10^{-5}; [ATN] = 5.0×10^{-4}; [OH^-] = 0.04 and I = 0.10 mol dm^{-3} with scanning time interval of 1 min.

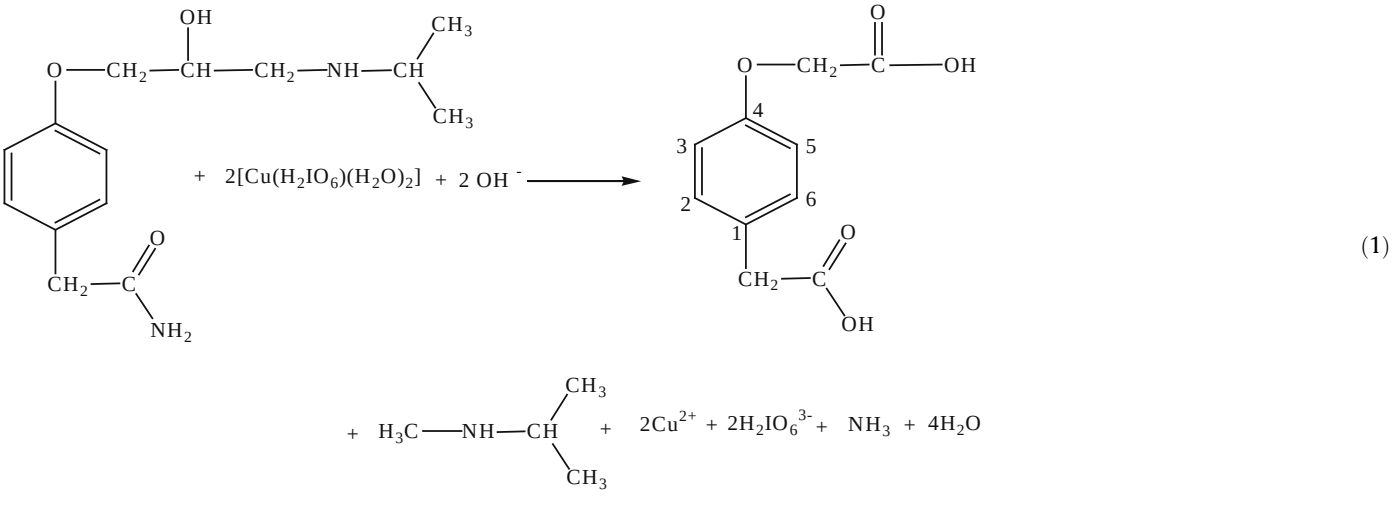
2. Experimental

2.1. Materials and reagents

All chemicals used were of reagent grade, and doubly distilled water was used throughout the work. A solution of ATN (M/s. S.S.Antibiotics Pvt. Ltd., Aurangabad, India) was prepared by dissolving an appropriate amount of ATN in doubly distilled water. The required concentration of ATN was prepared from its stock solution. The copper(III) periodate complex was prepared by standard procedure [20,21]. Existence of copper(III) complex was verified by its UV–Vis spectrum, which showed an absorption band with maximum absorption at 415 nm. The aqueous solution of copper(III) was standardized by iodometric titration and gravimetrically by the thiocyanate [22] method. The copper(II) solution was prepared by dissolving the known amount of copper sulfate (BDH) in distilled water. Periodate solution was prepared by weighing the required amount of sample in hot water and used after keeping it for 24 h. Its concentration was ascertained iodometrically [23] at neutral pH by phosphate buffer. KOH and KNO_3 (BDH, AR) were employed to maintain the required alkalinity and ionic strength, respectively, in reaction solutions.

2.2. Kinetic measurements

Since the initial rate was fast, the kinetic measurements were performed on a Hitachi 150-20 UV–Visible spectrophotometer attached to a rapid kinetic accessory (HI-TECH SFA-12). The kinetics was followed under pseudo first order condition, where [ATN] > [DPC] at 27 ± 0.1 °C, unless specified. The reaction was initiated by mixing the DPC with ATN solution, which also contained the required concentration of KNO_3, KOH, and KIO_4, and the progress of the reaction was followed spectrophotometrically at 415 nm by monitoring the decrease in absorbance due to DPC with the molar absorbancy index, ε to be 6230 ± 100 dm^3 mol^{-1} cm^{-1}. It was verified that there is a negligible interference from other species present in the reaction mixture at this wavelength.



The pseudo first order rate constants, k_{obs}, were determined from the log (absorbance) versus time plots. The plots were linear up to 80% completion of reaction under the range of [OH^-] used. The orders for various species were determined from the slopes of plots of log k_{obs} versus respective concentration of species except for [DPC] in which no variation of k_{obs} was observed as expected to the reaction condition. During the kinetics, a constant concentration viz. 1.0×10^{-4} mol dm^{-3} of KIO_4 was used throughout the study unless otherwise stated. Since periodate is present in the excess in DPC, the possibility of oxidation of ATN by periodate in alkaline medium at 27 °C was tested. The progress of the reaction was followed iodometrically. However, it was found that there was no significant reaction under the experimental conditions employed compared to the DPC oxidation of ATN. The total concentrations of periodate and OH^- was calculated by considering the amount present in the DPC solution and that additionally added. Kinetics runs were also carried out in N_2 atmosphere in order to understand the effect of dissolved oxygen on the rate of reaction. No significant difference in the results was obtained under a N_2 atmosphere and in the presence of air. In view of the ubiquitous contamination of carbonate in the basic medium, the effect of carbonate was also studied. Added carbonate had no effect on the reaction rates. The spectral changes during the reaction are shown in Fig. 1. It is evident from the figure that the concentration of DPC decreases by observing the absorbance at 415 nm.

Regression analysis of experimental data to obtain the regression coefficient r and standard deviation S of points from the regression line was performed using Microsoft 2003 Excel program.

3. Results and discussion

3.1. Stoichiometry and product analysis

Different sets of reaction mixtures containing various ratios of DPC to ATN in the presence of constant amounts of OH^- and KNO_3 were kept for 2 h in a closed vessel under nitrogen atmosphere. The remaining concentration of DPC was estimated by spectrophotometrically. The results indicated 1:2 stoichiometry as given in Eq. (1).

(1)

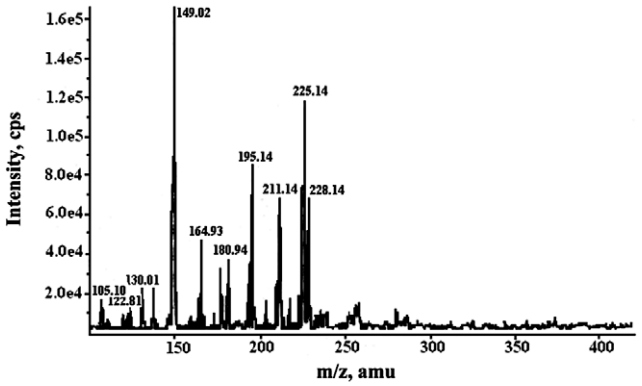


Fig. 2. LC–ESI-MS spectra of ammoniated 4-carboxy methoxy phenyl acetic acid.

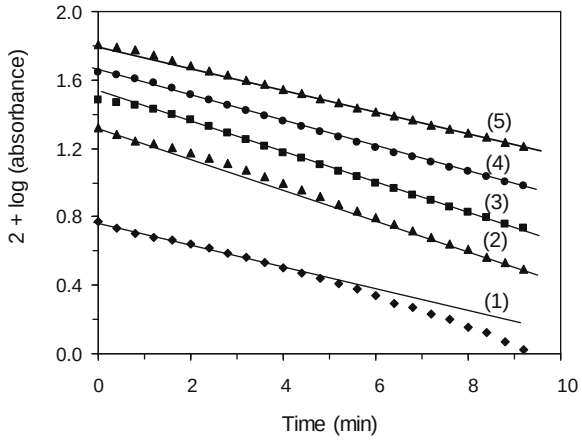

Fig. 3. First order plots on the oxidation of ATN by DPC in aqueous alkaline medium. [DPC]: (1) 1.0, (2) 3.0, (3) 5.0, (4) 7.0 and (5) 10.0×10^{-5} mol dm^{-3}.

The reaction product was extracted with ether and recrystallised form aqueous alcohol and the purity was checked by HPLC. This was identified as 4-carboxy methoxy phenyl acetic acid by its IR spectrum, which showed a band at 1690 cm^{-1} due to >C=O stretching of acid and a broad band at 2845 cm^{-1} due to O–H stretching. 4-Carboxy methoxy phenyl acetic acid was further characterized by ^{1}H NMR spectrum (DMSO), showed a singlet at 9.6 δ due to two carboxylic OH, a doublet at 6.94 δ due to C_3 and C_5-protons, another doublet at at 7.20 δ due to C_2 and C_6-protons, a singlet at 3.53 δ due to methylene protons of ph-CH_2- and another singlet at 4.58 δ due to methylene protons of ph-O-CH_2-, respectively. Further, the product was subjected to LC–Mass spectral analysis with ESI technique (solvents: acetonitrile + water + ammonium acetate). Ammoniated peak at 228 amu (M^+ +17) was obtained, which conforms M^+ at 211 amu, which corresponds to 4-carboxy methoxy phenyl acetic acid (Fig. 2). Ammonia was qualitatively identified using Nessler's reagent. N-isopropylmethylamine, which is highly soluble in water, was identified by spot test [24]. Another product Cu(II), was identified by UV–Vis spectra. The reaction products do not undergo further oxidation under the present kinetic conditions.

3.2. Reaction orders

The reaction orders were determined from the slope of log k_{obs} versus log (concentration) plots by varying the concentrations of ATN, alkali, and periodate in turn, while keeping all other concentrations and conditions constant, except for DPC concentration.

3.3. Effect of [DPC]

The oxidant DPC concentration was varied in the range 1.0×10^{-5}–1.0×10^{-4} mol dm^{-3}, and the fairly constant k_{obs} values indicate that order with respect to [DPC] was unity (Table 1). This was also confirmed by linearity of the plots of log [absorbance] versus time ($r \geqslant 0.986$, $S \leqslant 0.013$) up to 80% completion of the reaction (Fig. 3).

3.4. Effect of [ATN]

The effect of ATN on the rate of reaction was studied at constant concentrations of alkali, DPC, and periodate at a constant ionic strength of 0.10 mol dm^{-3}. The substrate, ATN, was varied in the range 1.0×10^{-4}–1.0×10^{-3} mol dm^{-3}. The k_{obs} values increased with increase in concentration of ATN. The order with respect to [ATN] was found to be less than unity (Table 1) ($r \geqslant 0.991$, $S \leqslant 0.007$) under the experimental concentrations. However, at lower concentrations of ATN, the reaction was first order in [ATN] and at high concentration of ATN, the reaction was independent

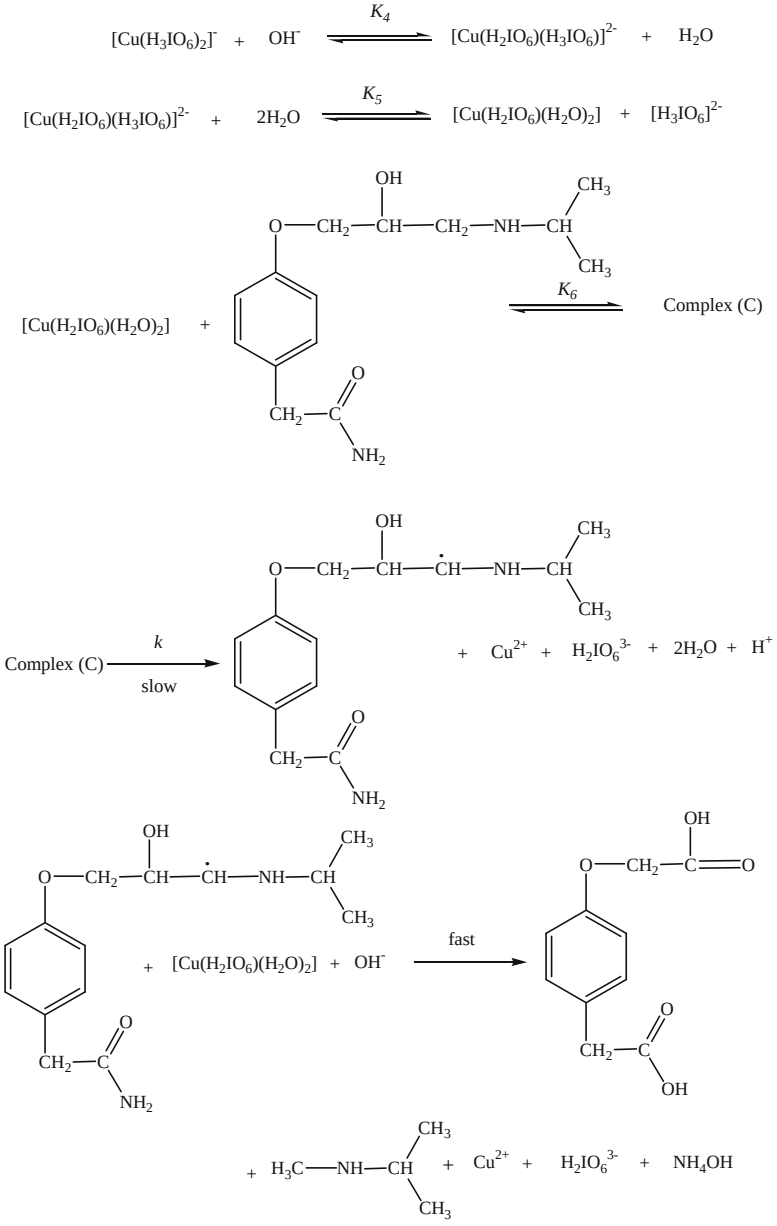
of [ATN]. The order in [ATN] changes from first order to zero order as [ATN] varies.

3.5. Effect of [alkali]



The effect of increase in concentration of alkali on the reaction was studied at constant concentrations of ATN, DPC, and periodate at a constant ionic strength of 0.10 mol dm^{-3} at 27 °C. The rate constants increased with increase in alkali concentration (Table 1), indicating fractional order dependence of rate on alkali concentration ($r \geqslant 0.989$, $S \leqslant 0.006$). Similar to as in the case of ATN, the order in alkali changes from first order to zero order as [OH$^-$] increases.

3.6. Effect of [periodate]

The effect of increasing concentration of periodate was studied by varying the periodate concentration from 5.0×10^{-5} to 5.0×10^{-4} mol dm^{-3} keeping all other reactants concentrations constant. It was found that the added periodate had a retarding effect on the rate of reaction, the order with respect to periodate concentration being negative less than unity (Table 1).

3.7. Effect of ionic strength (I) and dielectric constant of the medium (D)

The addition of KNO_3 at constant [DPC], [ATN], [OH$^-$], and [IO^{-4}] was found that with increasing ionic strength of the medium, rate of the reaction increased. The plot of log k_{obs} versus $I^{1/2}$ was found to be linear with negative slope. Dielectric constant of the medium, D, was varied by varying t-butyl alcohol and water percentage. The D values were calculated from the equation $D = D_wV_w + D_BV_B$, where D_w and D_B are dielectric constants of pure water and t-butyl alcohol, respectively, and V_w and V_B are the volume fractions of components water and t-butyl alcohol, respectively, in the total mixture. With the decrease in dielectric

Scheme 1. Detailed mechanistic scheme for the oxidation of ATN by alkaline diperiodatocuprate(III).

constant of the reaction medium, rate of the reaction increased. The plot of log k_{obs} versus $1/D$ was linear with a negative slope.

3.8. Effect of added products

The externally added product, copper(II) ($CuSO_4$) in the range 1.0×10^{-4}–1.0×10^{-3} mol dm^{-3} did not have any significant effect on the rate of the reaction.

3.9. Polymerization study

The intervention of free radicals in the reaction was examined as follows. The reaction mixture, to which a known quantity of acrylonitrile monomer was initially added, was kept for 2 h in an inert atmosphere. On diluting the reaction mixture with methanol, a white precipitate was formed, indicating the intervention of free radicals in the reaction. The blank experiments of either DPC or ATN alone with acrylonitrile did not induce any polymerization under the same condition as those induced for reaction mixture. Initially, the added acrylonitrile decreased the rate of reaction indicating free radical intervention, which is the case in earlier work [25,26].

3.10. Effect of temperature

The kinetics was studied at four different temperatures under varying concentrations of ATN, alkali, and periodate, keeping other conditions constant. The rate constants were found to increase with increase in temperature. The rate constants (k) of the slow step of Scheme 1 were obtained from the slopes and intercepts of $1/k_{obs}$ versus 1/[ATN], $1/k_{obs}$ versus [$H_3IO_6^{2-}$], and $1/k_{obs}$ versus 1/[OH^-] plots at four different temperatures and were used to calculate the activation parameters. The energy of activation corresponding to these constants was evaluated from the Arrhenius plot of log k versus $1/T$ ($r \geqslant 0.996$, $S \leqslant 0.011$), and other activation parameters obtained are tabulated in Table 2.

Table 2
Thermodynamic activation parameters for the oxidation of ATN by DPC in aqueous alkaline medium with respect to the slow step of Scheme 1.

Temperature (K)			$k \times 10^2$ (s^{-1})
(A) Effect of temperature			
300			0.99
305			1.39
310			1.89
320			3.06
(B) Activation parameters (Scheme 1)			
Parameters			Values
Ea(kJ mol^{-1})			44.7 ± 1.5
$\Delta H^{\#}$ (kJ mol^{-1})			42.2 ± 0.6
$\Delta S^{\#}$ (JK^{-1} mol^{-1})			−142 ± 5
$\Delta G^{\#}$ (kJ mol^{-1})			86 ± 2
Log A			5.8 ± 0.3
Temperature (K)	K_4 (dm^3 mol^{-1})	$K_5 \times 10^3$ (mol dm^{-3})	$K_6 \times 10^{-3}$ (dm^3 mol^{-1})
(C) Effect of temperature on equilibrium constants of Scheme 1 for the oxidation of ATN by diperiodatocuprate(III) in alkaline medium.			
300	1.03 ± 0.02	0.99 ± 0.05	4.1 ± 0.2
305	1.32 ± 0.03	0.71 ± 0.06	5.4 ± 0.2

Thermodynamic quantities	Values from K_4	Values from K_5	Values from K_6
(D) Thermodynamic quantities using K_4, K_5 and K_6			
ΔH (k J mol^{-1})	32.7 ± 1.4	−62.8 ± 2.0	43.3 ± 1.0
ΔS (J K^{-1} mol^{-1})	110 ± 3	−268 ± 4	215 ± 4
ΔG_{320} (k J mol^{-1})	−2.1 ± 0.1	21.1 ± 1.2	−23.4 ± 1.0

The water-soluble copper(III) periodate complex is reported [27] to be $[Cu(HIO_6)_2]^{5-}$. However, in an aqueous alkaline medium and at a high pH range as employed in the study, periodate is unlikely to exist as HIO_6^{4-} (as present in the complex) as is evident from its involvement in the multiple equilibria [28] ((2)–(4)) depending on the pH of the solution.

$$H_5IO_6 \overset{K_1}{\rightleftharpoons} H_4IO_6^- + H^+ \quad K_1 = 5.1 \times 10^{-4} \tag{2}$$

$$H_4IO_6^- \overset{K_2}{\rightleftharpoons} H_3IO_6^{2-} + H^+ \quad K_2 = 4.9 \times 10^{-9} \tag{3}$$

$$H_3IO_6^{2-} \overset{K_3}{\rightleftharpoons} H_2IO_6^{3-} + H^+ \quad K_3 = 2.5 \times 10^{-12} \tag{4}$$

Periodic acid exists in acid medium as H_5IO_6 and as $H_4IO_6^-$ around pH 7. Thus, under the conditions employed in alkaline medium, the main species are expected to be $H_3IO_6^{2-}$ and $H_2IO_6^{3-}$. At higher concentrations, periodate also tends to dimerize [29]. However, formation of this species is negligible under conditions employed for kinetic study. Hence, at the pH employed in this study, the soluble copper(III) periodate complex exists as diperiodatocuprate(III), $[Cu(H_3IO_6)(H_2IO_6)]^{2-}$, a conclusion also supported by earlier work [30,31].

The reaction between the diperiodatocuprate(III) complex and atenolol in alkaline medium has the stoichiometry 1:2 (ATN:DPC) with a first order dependence on [DPC] and an apparent order of less than unity in [substrate], [alkali] and negative fractional order dependence on the periodate. No effect of added products was observed. Based on the experimental results, a mechanism is proposed for which all the observed orders in each constituent such as [oxidant], [reductant], [OH^-], and [IO^{-4}] may be well accommodated. Lister [32] proposed three forms of copper(III) periodate in alkaline medium as diperiodatocuprate(III)(DPC), monoperiodatocuprate(III) (MPC), and tetrahydroxocuprate(III). The latter is ruled out, as its equilibrium constant is 8.0×10^{-11} at 40 °C. Hence, in the present study, DPC and MPC are to be considered as active forms of copper(III) periodate complex. It may be expected that a lower periodate complex such as MPC is more important in the reaction than the DPC. The results of increase in the rate with increase in alkali concentration and decrease in the rate with increase in periodate concentration suggest that equilibria of different copper(III) periodate complexes are possible as in Eqs. (5) and (6).

$$[Cu(H_3IO_6)_2]^- + OH^- \overset{K_4}{\rightleftharpoons} [Cu(H_2IO_6)(H_3IO_6)]^{2-} + H_2O \tag{5}$$

$$[Cu(H_2IO_6)(H_3IO_6)]^{2-} + 2H_2O \overset{K_5}{\rightleftharpoons} [Cu(H_2IO_6)(H_2O)_2] + [H_3IO_6]^{2-} \tag{6}$$

The less than unit order in [ATN] presumably results from formation of a complex (C) between the oxidant and atenolol prior to the formation of the products. K_6 is the composite equilibrium constant comprising the equilibrium to bind active species of ATN to MPC species to form a complex (C). Then, this complex (C) decomposes in a slow step to form a free radical derived from ATN. This free radical species further reacts with another molecule of MPC species in a fast step to yield the products such as 4-carboxy methoxy phenyl acetic acid, N-isopropylmethylamine, ammonia, Cu(II), and periodate. So, the detailed mechanistic scheme for the oxidation of ATN by diperiodatocuprate(III) is presented in Scheme 1.

Since Scheme 1 is in accordance with the generally well-accepted principle of non-complementary oxidations taking place in sequence of one-electron steps, the reaction between the substrate and oxidant would afford a radical intermediate. A free radical scavenging experiment revealed such a possibility. This type of radical intermediate has also been observed in earlier work [33,34]. Spectroscopic evidence for the complex formation between oxidant and substrate was obtained from UV–Vis spectra

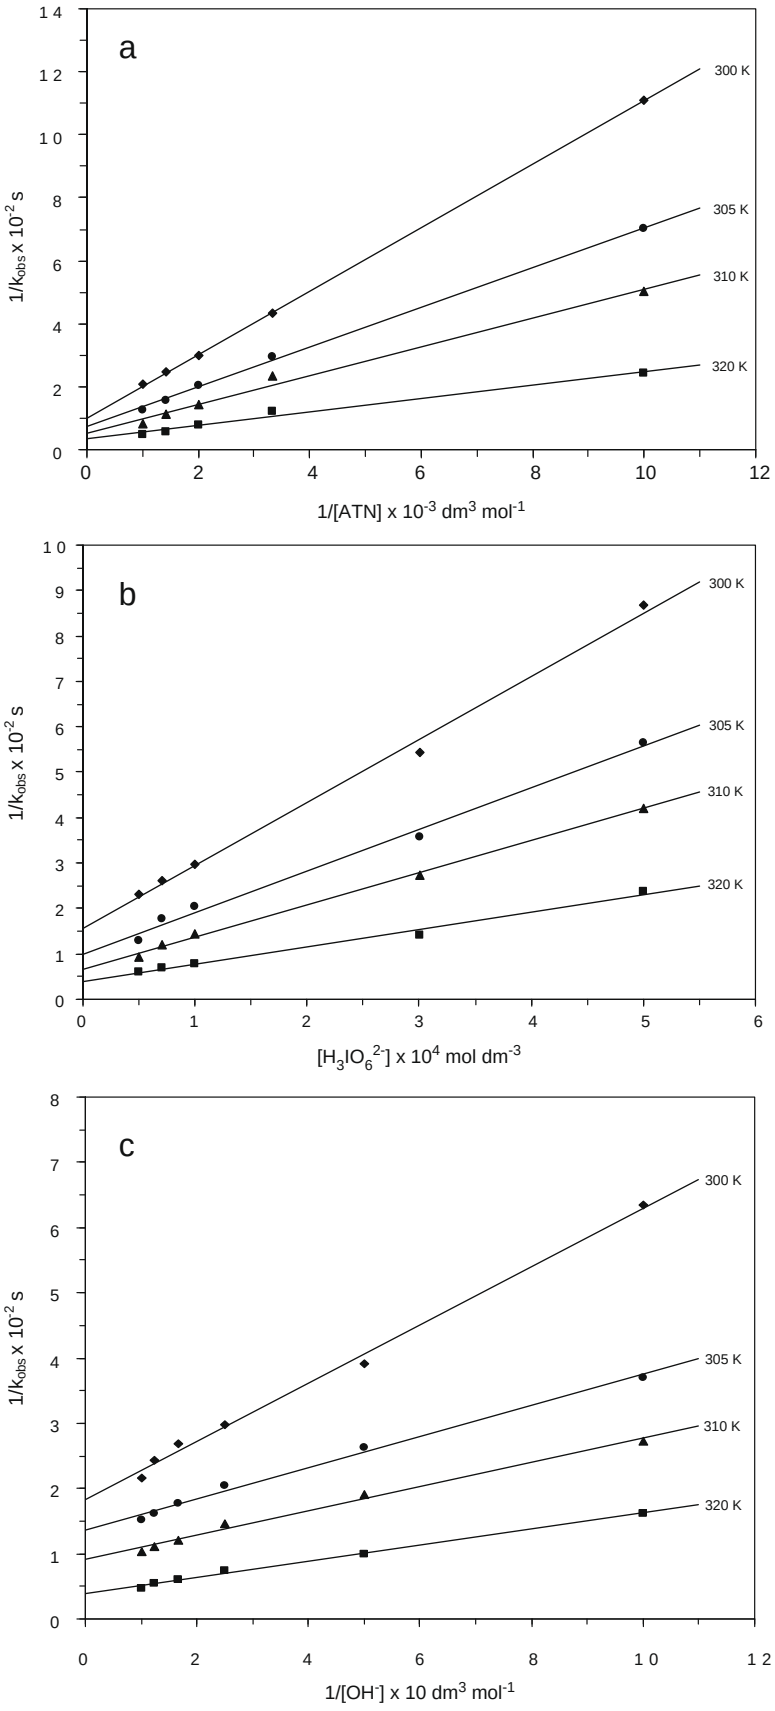

Fig. 4. (a) Plots of $1/k_{obs}$ versus 1/[ATN] at four different temperatures (conditions as in Table 1). (b) Plots of $1/k_{obs}$ versus $[H_3IO_6^{2-}]$ at four different temperatures (conditions as in Table 1). (c) Plots of $1/k_{obs}$ versus $1/[OH^-]$ at four different temperatures (conditions as in Table 1).

of ATN (5.0×10^{-4}), DPC (5.0×10^{-5}), $[OH^-] = 0.04$ mol dm^{-3} and mixture of both. A hypsochromic shift of about 5 nm from 306 to 301 nm in the spectra of ATN was observed. The Michaelis–Menten plot also proved the complex formation between DPC and ATN, which explains the less than unit order dependence on [ATN]. Such a complex between a substrate and an oxidant has been observed in other studies [35,36].

Scheme 1 leads to the rate law as

$$\text{Rate} = \frac{-\text{d}[\text{DPC}]}{\text{dt}} = \frac{kK_4K_5K_6[\text{DPC}][\text{ATN}][\text{OH}^-]}{[\text{H}_3\text{IO}_6^{2-}] + K_4[\text{OH}^-][\text{H}_3\text{IO}_6^{2-}] + K_4K_5[\text{OH}^-] + K_4K_5K_6[\text{ATN}][\text{OH}^-]} \quad (7)$$

which explains all the observed kinetic orders of different species.

$$k_{obs} = \frac{\text{Rate}}{[\text{DPC}]} = \frac{kK_4K_5K_6[\text{ATN}][\text{OH}^-]}{[\text{H}_3\text{IO}_6^{2-}] + K_4[\text{OH}^-][\text{H}_3\text{IO}_6^{2-}] + K_4K_5[\text{OH}^-] + K_4K_5K_6[\text{ATN}][\text{OH}^-]} \quad (8)$$

The rate law (8) can be rearranged into the following form, which is suitable for verification.

$$\frac{1}{k_{obs}} = \frac{[\text{H}_3\text{IO}_6^{2-}]}{kK_4K_5K_6[\text{OH}^-][\text{ATN}]} + \frac{[\text{H}_3\text{IO}_6^{2-}]}{kK_4K_5K_6[\text{ATN}]} + \frac{1}{kK_6[\text{ATN}]} + \frac{1}{k} \quad (9)$$

According to Eq. (9), other conditions being constant, plots of $1/k_{obs}$ versus $1/[OH^-]$ ($r \geqslant 0.995$, $S \leqslant 0.029$), $1/k_{obs}$ versus 1/[ATN] ($r \geqslant 0.997$, $S \leqslant 0.016$), and $1/k_{obs}$ versus $[H_3IO_6^{2-}]$ ($r \geqslant 0.998$, $S \leqslant 0.011$) should be linear and are found to be so (Fig. 4). The slopes and intercepts of such plots lead to the values of K_4, K_5, K_6, and k as (1.03 ± 0.03) dm^3 mol^{-1}, $(9.94 \pm 0.30) \times 10^{-4}$ mol dm^{-3}, $(4.10 \pm 0.10) \times 10^3$ dm^3 mol^{-1}, and $(9.91 \pm 0.40) \times 10^{-3}$ s^{-1}, respectively. The values of K_4 and K_5 are in agreement with earlier data [37]. Using these K_4, K_5, K_6, and k values, the rate constants under different experimental conditions were calculated by Eq. (8) and compared with experimental data. There is a good agreement between them (Table 1), which fortifies the Scheme 1. The equilibrium constant K_4 is far greater than K_5. This may be attributed to the greater tendency of DPC to undergo hydrolysis compared to the dissociation of hydrolyzed species in alkaline medium.

The effect of ionic strength on the rate of reaction is not in accordance with proposed mechanism, which might be due to the presence of high ionic strength used in the reaction. Increase in the content of t-butanol in the reaction medium leads to an increase in the rate of reaction, which seems to be contrary to the expected interaction between neutral species in media of lower relative permittivity. However, an increase in the rate of reaction with decrease in dielectric constant may be due to stabilization of the complex C at low relative permittivity, which is less solvated than MPC at higher dielectric constant because of its larger size.

The thermodynamic quantities for the first, second, and third equilibrium steps of Scheme 1 can be evaluated as follows. The $[H_3IO_6^{2-}]$, [ATN], and $[OH^-]$ (as in Table 1) were varied at four different temperatures. The plots of $1/k_{obs}$ versus $1/[OH^-]$, $1/k_{obs}$ versus 1/[ATN], and $1/k_{obs}$ versus $[H_3IO_6^{2-}]$ should be linear (Fig. 4). From the slopes and intercepts, the values of K_4 were calculated at different temperatures and these values are given in Table 2. A vant Hoff's plot was made for variation of K_4 with temperature (log K_4 vs. $1/T$ ($r \geqslant 0.997$, $S \leqslant 0.006$) and the values of enthalpy of reaction ΔH, entropy of reaction ΔS, and free energy of reaction ΔG were calculated for the first equilibrium step. These values are given in Table 2. A comparison of ΔH value (32.7 ± 1.4) from K_4 with that of $\Delta H^{\#}$ (42.2 ± 0.6) of rate limiting step supports that the first step of Scheme 1 is fairly fast since it involves low activation energy with those obtained for the slow step of the reaction [38,39]. In the same manner, K_5 and K_6 values were calculated at different temperatures and their corresponding values of the thermodynamic quantities are given in the Table 2.

The values of $\Delta H^{\#}$ and $\Delta S^{\#}$ were both favorable for electron transfer processes. The negative value of $\Delta S^{\#}$ indicates that the complex (C) is more ordered than the reactants [40]. The value of $\Delta S^{\#}$ within the range for radical reaction has been ascribed [41] to the nature of electron pairing and unpairing processes and to the loss of degrees of freedom formerly available to the reactants upon the formation of rigid transition state. The observed modest enthalpy of activation and a relatively low value of the entropy of activation as well as a higher rate constant of the slow step indicate that the oxidation presumably occurs via inner-sphere mechanism. This conclusion is supported by earlier observation [42,43].

4. Conclusion

Among the various species of DPC in aqueous alkaline medium, $[Cu(H_2IO_6)(H_2O)_2]$ is considered as active species for the title reaction. The results indicated that in carrying out this reaction, the role of pH in the reaction medium is crucial. Rate constant of slow step and other equilibrium constants involved in the mechanism are evaluated. The activation parameters with respect to slow step of mechanism were computed. The overall mechanistic sequence described here is consistent with product and kinetic studies.

Absorption spectral data for **1** in MeOH in terms of λ_{max}/nm (ε/lit mol^{-1} cm^{-1}): 247 (49 690), 263 (44 040), 294 (30 510), 377 (17 800). Single crystals of **1** were obtained from slow evaporation of DMF solution at room temperature.

2.4. Dinuclear Ti(IV) complex **2**

H_4L, 4,4′-methylene-bis(3-hydroxy-2-naphthalene carboxylic acid) (0.388 g, 1.0 mmol) was dissolved in 10 mL DMF. To this clear solution *cis*-bis(acetylacetonato)dichloro-titanium(IV), *cis*-[Ti(acac)$_2$Cl$_2$], (0.316 g, 1 mmol) dissolved in 10 mL DMF was slowly added and the color of the solution changed from yellow to orange. After 1 h of stirring, 4,4′-bipyridine (0.156 g, 1.0 mmol) was added to the reaction mixture and the resulting solution was stirred for 6 h. The solution was then filtered and kept at room temperature. After 10–15 days the orange colored crystals start were obtained from the solution. Yield, 52%. M.p: >300 °C. *Anal.* Calc. for $C_{69}H_{73}N_7O_{20}Ti_2$: C, 58.52; H, 5.20; N, 6.92. Found: C, 58.31; H, 5.19; N, 6.19%. Selected IR (KBr, cm^{-1}): 3435(s), 3043 (s), 1621 (s), 1593(s), 1572(w), 1552(w), 1451(w), 1421(s). ^{1}H NMR (DMSO-d$_6$, δ ppm): 8.79 (d, 4H, 4,4′-BiPy-H), 8.52 (d, 2H, naph-H), 8.40 (d, 2H, naph-H), 8.14 (d, 2H, naph-H), 7.89 (d, 4H, 4,4′-BiPy-H), 7.77 (d, 2H, naph-H), 7.62 (t, 2H, naph-H), 7.52 (d, 2H, naph-H), 7.46 (d, 2H, naph-H) 7.34 (t, 2H, naph-H), 7.01 (t, 2H, naph-H), 6.99 (t, 2H, naph-H), 5.02, 4.79 (s, 4H, Ar–CH$_2$–Ar). ^{13}C NMR (CDCl$_3$, δ ppm): 22.92 (Ar–CH$_2$–Ar), 119.63, 120.55, 121.07, 122.91, 123.28, 124.08, 126.61, 127.40, 128.86, 129.76, 130.78, 131.27, 134.93, 135.52, 158.83, 159.53, 170.00, 170.93 (Nap-C and 4,4′-bipyridine-C), 34.47, 35.87, 160.43, 162.77 (DMF-C). Absorption spectral data for **2** in MeOH in terms of λ_{max}/nm (ε/lit mol^{-1} cm^{-1}): 251(49 540), 264 (46 480), 278 (44 900), 375 (21 690). Single crystals of **2** were obtained by slow evaporation of DMF solution at room temperature.

2.5. Crystallography

Single crystal X-ray diffraction data were collected for H_4L, **1** and **2** on an OXFORD DIFFRACTION XCALIBUR-S CCD system by ω-2θ scan mode and the absorption corrections were applied by using multi-scan method. Preliminary data corresponding to the data collection and refinement are given in Table 1. The structure was solved by direct methods SHELXS97 and refined by full-matrix least squares against F^2 using SHELXL97 software [15]. Non-hydrogen atoms were refined with anisotropic thermal parameters. All hydrogen atoms were geometrically fixed and allowed to refine using a riding model.

3. Results and discussions

3.1. Structure of H_4L

The ligand, H_4L has been synthesized starting from 3-hydroxy-2-naphthoic acid in a single step as reported in the literature [14]

and the product has been characterized by analytical and spectral methods as given in the experimental. The structure of H_4L has been established by single crystal XRD. It has been crystallized in monoclinic system with *C*2/*c* space group and there is only one half of the molecule in the asymmetric unit. The structure shown in Fig. 1 indicates *anti-like* (*staggered-like*) conformation present in H_4L where in the functional groups are disposed to two different directions, so as the molecule cannot use all its functional groups simultaneously to bind to the same metal ion center. The distances observed between the corresponding atoms of the two pendants, *viz*., O1···O1′ (4.28 Å), C5···C5′ (7.27 Å), O2···O2′ (7.52 Å) and O3···O3′ (9.09 Å) are all indicative of *staggered-like* conformation of the two pendants with respect to the naphthyl moieties (Fig. 1). On the other hand, if the two pendants were to be on the same side, the O1···O1′ distance is expected to be around 3 Å. The inclination angle (C2–C1–C2′) between the two naphthyl moieties was found to be 114.82(0)° and angle between two naphthyl planes was 89.13 (24)°. Crystal structure of H_4L was already known in the literature as DMF adduct [7] where the volume of the unit cell was found to be at least three fold greater when compared to the present one. Though the crystal system was found to be the same in both the cases, the space group was found to be different. Intramolecular dihedral angles (Table 3) between the naphthalene groups were found to be in the same as that observed in the literature [7]. In another report in the literature, the structure of H_4L has been generated from powder X-ray data [12].

In the crystal lattice of H_4L (Fig. 2), each naphthylic-OH is involved in an intramolecular hydrogen bond with the adjacent carboxylic group (O1–H101···O2: 0.968(21), 1.725(19) and 2.623(2) Å, 153.72(6)°) and thus stabilized by two such interactions. Further, such H_4L are connected through intermolecular H-bonds between the neighbor –COOH moieties (O3–H102···O2′: 1.027(23), 1.624(23) and 2.647(2) Å, 175.14(1)°) to result in the formation of supramolecular helical chains as shown in Fig. 2. These hydrogen bonds are reminiscent of the well known benzoic acid dimer in the solid state [16,17]. Thus each H_4L present in the chain is connected through four intermolecular H-bonds, where two were extended from each –COOH moiety. In the lattice, these helices form corrugated sheet structure. These helical chains are further stabilized through weak inter-chain π···π interactions through naphthyl moieties that cuts across the chains where the distance between the two adjacent naphthyl moieties is 4.76 Å.

C34–C33–C35–C36		−115.84	48.90

Due to the presence of lattice solvent molecules, such supramolecular chain could not be formed in case of structure reported in the literature [7], though the powder diffraction data revealed the formation of such chain structure [12].

3.2. Complexation with Ti(IV)

As reported earlier by us, the reaction of *cis*-$[TiCl_2(acac)_2]$ with a variety of hydroxy-containing ligands in 1:1 mole ratio, resulted only in the formation of mononuclear complexes [18]. On the contrary, in the present case, when one equivalent of H_4L was reacted with one equivalent of *cis*-$[TiCl_2(acac)_2]$ in DMF, it resulted in the formation of oxo-bridged dinuclear titanium(IV) complex wherein the crystals isolated from this reaction exhibited a composition, *viz.*, $[(HL)_2Ti_2(\mu\text{-}O)(DMF)_2]\cdot(DMF)_6$ for **1**. When the same reaction was carried out in the presence of one equivalent of co-ligand, *viz.*, 4,4′-bipyridine, the product **2** obtained from this reaction resulted in crystals having a composition, $[(L)_2Ti_2(\mu\text{-}O)(DMF)_2]\cdot(DMF)_4(4,4'\text{-Bipy-}2H)(H_2O)$. The structural details of **1** and **2**, and their similarities and differences are discussed later in this paper. On the other hand, both **1** and **2** were characterized by spectral and analytical techniques.

3.3. Characterization of *1* and *2*

On going from H_4L to **1** and **2**, the ν_{OH} vibration that appears around 3300 cm^{-1} in H_4L disappears completely, suggesting the binding of naphthylic-OH group to Ti(IV) via deprotonation. A sharp peak arising from $\nu_{C=O}$ at 1659 cm^{-1} shows 10–40 cm^{-1} shift to lower frequency, *viz.*, 1621–1650 cm^{-1}, upon co-ordination to Ti(IV) suggesting the binding of carboxylate moiety. The IR spectrum of **1** and **2** shows asymmetric (1621–1654 cm^{-1}) and symmetric (~1450 and ~1420 cm^{-1}) stretching bands indicating the mono-dentate co-ordination nature of the carboxylate moiety in these complexes. The absorption spectrum of the complexes shows characteristic differences from that of the ligand (H_4L) by exhibiting ligand to metal charge transfer transition bands (Fig. 3, experimental) in solution. The main band observed at 374 nm for H_4L in solution was shifted to 424 nm, while the width of the band was doubled in the solid state. There is no considerable shift observed in this band in solution on going from H_4L to **1** to **2**, however, a substantial shift was observed in this band position in the solid state which moves from 424 to 469 to 495 nm, respectively and the peak widths increase dramatically.

H_4L shows strong fluorescence emission ~500 nm upon exciting the sample at 385 nm whereas the fluorescence intensity was quenched almost completely in **1** and **2** (Fig. 4a and b). In order to find whether this quenching is because of the formation of anion or otherwise, the fluorescence of pamoic acid (H_4L) was measured in NaOH and found enhancement of the fluorescence intensity. Thus the fluorescence quenching in **1** and **2** may be attributed to the binding to Ti(IV) followed by relative orientation of the naphthyl moieties which are inturn responsible for the fluorescence

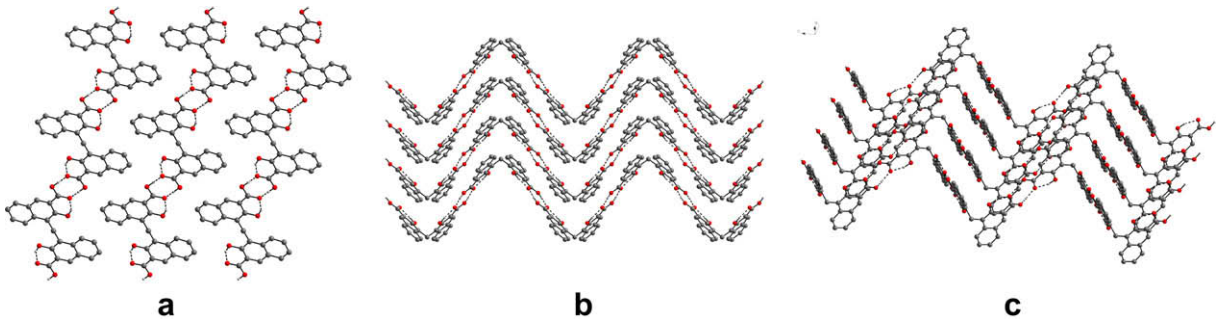

Fig. 2. Lattice structure of H_4L: (a) viewed along *b*-axis, (b) viewed along *a*-axis and (c) viewed along slightly rotated *a*-axis.

(a) Fluorescence spectral traces obtained during the titration of **1** with HCl with varying mole ratios of HCl to a maximum of 100 mole equiv., (b) Plot of relative fluorescence intensity (I/I_o) vs. [HCl]/[**1**] mole ratio in the titration of **1** with HCl, at varying concentrations of HCl.

emission. This has been found to be true both in the solution as well as in their solid states.

The complexation in **1** has been further supported by titrating this with HCl and measuring their fluorescence spectra. The titration resulted in an increase of fluorescence as a function of addition of HCl to **1** suggesting the release of the ligand from the complex upon reacting with HCl (Fig. 5). Similar results were observed when **2** was titrated with HCl.

The TGA curves for H_4L, **1** and **2** in the temperature range of 30–1000 °C as measured in N_2 atmosphere are shown in Fig. 6. The weight loss behavior of H_4L can be broken into three parts, one in 255–375 °C (~68%), the second in 375–450 °C (~5%) and the third in 450–1000 °C (~10%) and about 15–17% accounts for residual mass even at 1000 °C, thus indicating the major weight loss being below 400 °C. On the other hand, both **1** and **2** exhibit at least five weight losses under the same conditions. In the entire temperature range, the weight loss observed with **1** is higher than **2**. Within 300 °C the weight loss in case of **1** is ~38% and in **2** it is about ~32%, both accounting the solvent present in their crystals either as bound to metal ion or as loosely present in the lattice. Both **1** and **2** exhibited high residual mass when compared to the ligand as expected owing to the formation of titanium oxides. The residual mass follows a trend, *viz.*, **2** (34%) > **1** (28%) > H_4L (18%) indicating that **2** possessing the protonated 4,4′-bipyridyl needs higher temperature for decomposition.

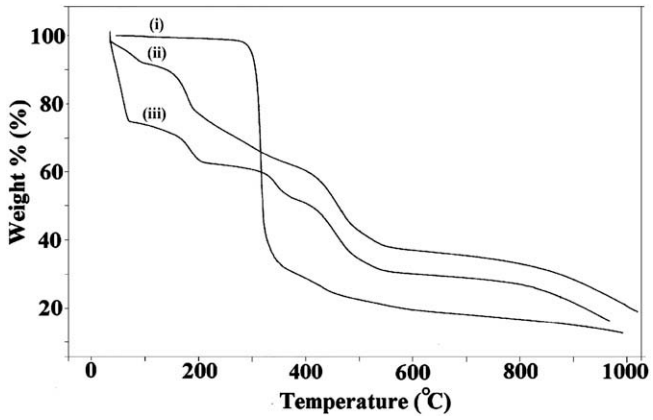

Fig. 6. TGA curves for H_4L and complexes: (i) H_4L, (ii) **2** and (iii) **1**.

3.4. Molecular structures

Both **1** and **2** were crystallized in triclinic crystal system with $P\bar{1}$ space group. The bond lengths and bond angles covering the primary co-ordination sphere are given in Table 2. In **1**, the asymmetric unit contains a dinuclear $[(HL)_2Ti_2(\mu\text{-}O)(DMF)_2]$ moiety besides six unbound DMF molecules whereas in **2**, the asymmetric unit contains a dinuclear $[(L)_2Ti_2(\mu\text{-}O)(DMF)_2]$ moiety besides four unbound DMF molecules, one water molecule and one half of the molecule of protonated 4,4′-bipyridine. In both the cases the metal ion to the ligand ratio is 1:1 with the presence of a 2:2 μ-oxo dinuclear Ti(IV), wherein the molecular structures differ between **1** and **2**.

In **1**, the ligand acts as trinegative through deprotonation of both the naphthylic-OH groups and one of the carboxylic moiety ($H_4L–3H^+ = HL$) but as tetradentate wherein the each half-portions of the pamoic acid binds to one Ti(IV) center as bidentate, thus bridging between the two titanium centers connected by a

μ-oxo moiety to result in a neutral complex species (Fig. 7). In order that each pamoic acid is able to bind to the dinculear Ti(IV) center, the molecule must undergo conformational changes since the functional moieties present on two-halves of the pamoic acids are oriented *trans-like* fashion in the free ligand. The dihedral angles that determines the orientation of the two naphthylic-OH groups of the pamoic acid change from −60.4° and −60.4° in free ligand to 49.11° to 59.90° and −112.58° to −115.85° and brings the naphthylic-OH groups from 4.280 Å to 3.037 Å (Table 3). As a result of these changes, the two-half portions of the pamoic acid orient in such a way that these can simultaneously bind to a dinuclear moiety as seen in case of **1**. However, the structures reported in the literature were polymeric through metal ion complexation and in such cases dihedral changes are not required [5–10].

Another major difference that one finds between **1** and those published in literature is that the involvement of both the naphthylic-OH as well as the carboxylic moieties in the present case, where as it is mainly through carboxylic in case of the reported ones [5–10], owing to their polymeric nature. Among the two carboxylic groups present on the pamoic acid, one of it binds as C–O$^-$ and the other binds through the C=O (Table 4). In **1**, both the titanium centers are co-ordinatively equivalent by exhibiting octahedral geometry wherein each of the pamoic acid moiety extends two of its oxygen centers for binding. The remaining two co-ordinations are filled by a μ-oxo and a DMF. The naphthylic-O$^-$ binds always trans to the carboxylate binding at both the Ti(IV) centers. The charge state of each of these groups, *viz*., naphthylic-OH versus naphthylic-O$^-$ and the –COOH versus –COO$^-$, can also be supported by comparing the metric parameters. In the primary co-ordination sphere (Table 2), while the Ti···O distances vary between 1.801 and 2.146 Å, the trans-angles vary between 164.3° and 176.2°, indicating highly distorted octahedral Ti(IV) centers in **1**. The bond length of Ti···O of the carboxylate moieties is shorter by 0.016 Å when it is bonded through the C–O$^-$ rather than the C=O of the carboxylate moiety and thereby indicate the charge state of this moiety in the complex. Thus the Ti···O distances

Table 4
The C–O bond lengths (Å) in H_4L, **1** and **2**.

	H_4L	**1**	**2**		H_4L	**1**	**2**
C–O_{naph}	1.364(1)	1.348(6)	1.338(4)	C–O_{carb}	1.316(3)	1.223(6)	1.256(4)
		1.334(6)	1.341(4)			1.236(6)	1.300(4)
		1.334(6)	1.337(4)			1.221(6)	1.312(4)
		1.342(6)	1.341(4)			1.239(6)	1.299(4)
C=O_{carb}	1.242(2)	1.223(6)	1.278(4)	C=O_{dmf}		1.232(7)	1.256(5)
		1.236(6)	1.232(4)			1.243(7)	1.261(4)
		1.221(6)	1.236(4)				
		1.239(6)	1.235(4)				

naph = naphthyl; carb = carboxylic; dmf = N,N –dimethylformamide.

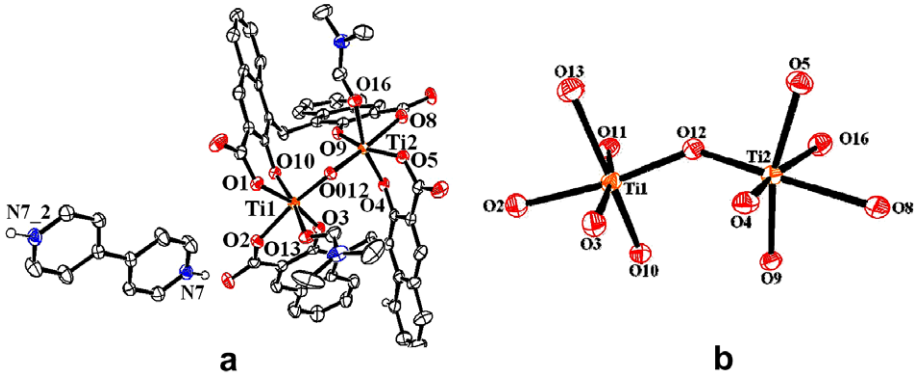

Fig. 8. (a) ORTEP diagram of the dimeric unit present in case of **2** and (b) ORTEP diagram of the metal ion core of **2** showing 50% ellipsoids.

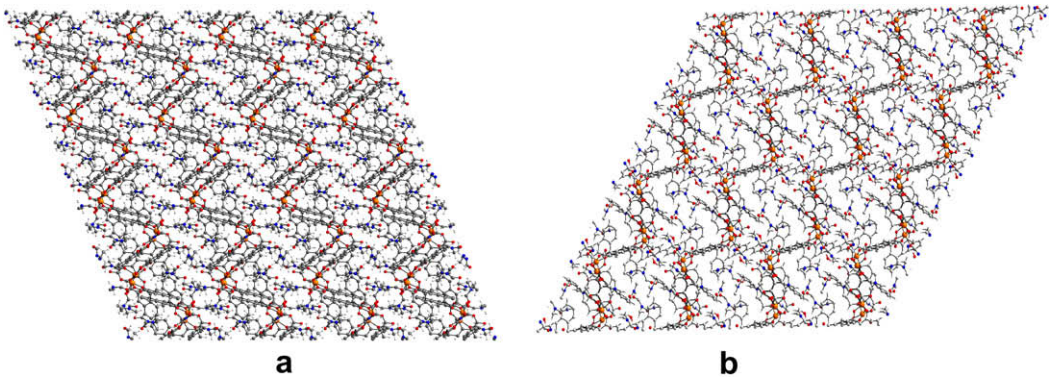

Fig. 9. Lattice structures: (a) **1** and (b) **2**.

follow an order, *viz.*, Ti···O=C > Ti···O–C > Ti···O_{naph}. Even the shorter Ti···O bond observed with DMF (2.07 Å) when compared to the O=C moiety of pamoic acid (2.15 Å) can be attributed to the involvement of nitrogen lone pair present in DMF. Average distance observed for C=O (1.23 Å) is short enough when compared to C–O (1.34 Å) to differentiate the two portions of the carboxylic moiety present in pamoic acid in **1**. The intra-naphthyl inclination angles in any pamoic acid moiety changes between 0° and 10° upon complexation as observed in **1**.

In **2**, the ligand acts as tetranegative through deprotonation of all the naphthylic-OH as well as carboxylic groups ($H_4L–4H^+ = L$), while it is trinegative in **1**, bound across the dinuclear Ti(IV)–O–Ti(IV) unit resulting in an overall di-anionic complex species (Fig. 8). The ionic nature of **2** has been cross checked by measuring the conductance that favors a 1:1 electrolyte. The charge on this anionic species has been neutralized by the di-protonated 4,4′-bipy found in the structure of **2**. Otherwise, the binding features of both the pamoic acid moieties in **2** are same as that noticed in the structure **1**. The orientation of both the naphthyl moieties of the pamoic acid present in **2** has almost same dihedral angles as that observed in case of **1** and hence resulted in $O_{naph}···O_{naph}$ distance of 2.98 Å exhibiting a syn-like orientation. The binding nature of the carboxylate moieties in **2** remains same as that observed in **1**. Binding as well as the metric parameters of the dinuclear Ti(IV) core in **2** is similar to that observed in **1**. In the dinuclear cores, the two titanium centers were separated by 3.408(15) and 3.416(6) Å in **1** and **2**, respectively, indicating no possibility of interaction between the metal centers as no interaction is expected between the two Ti(IV) centers of d^0 nature.

3.5. Lattice structures

The lattice structures of **1** and **2** are rather similar in spite of varying solvation in both the cases (Fig. 9). While there are six DMF molecules present per dimer unit in the lattice of **1**, there are four DMF, one water and one di-protonated-4,4′-bipy present per dimer in case of **2**. The dimeric Ti(IV) units stack in the lattice to form columns that exhibit corrugated sheet structures wherein the columns can be described as formed by ABABAB... type repetitivity, where as the immediate adjacent chain runs as BABABA... type. The space between the adjacent columns is being filled by the solvent molecules in **1** and solvent plus the protonated 4,4′-bipy in the lattice of **2**. Thus the neighbor columns interact through weak hydrogen bonds extended by the solvent molecules present between the columns. These hydrogen bonds are extended through the free oxygens of the bound ligand moiety, DMF oxygen and the protonated N–H of 4,4′-bipy as in **2**. This resulted in O–H···O, N–H···O and C–H···O type of hydrogen bonds. List of such hydrogen bond interactions including those of weak type are given in Table 5 for **1** as well as **2**. Within each corrugated chain, the dinuclear Ti(IV) centers are separated by ~13 Å in both the cases. The two nearest dinuclear neighbors present in the adjacent columns are separated by ~9.0 and ~15.0 Å.

4. Conclusions

The ligand, H_4L and complexes **1** and **2** have been synthesized and characterized by analytical and spectral methods and the structures have been established by single crystal XRD. Unlike the reported polymeric structures observed in case of pamoic acid, in the present paper we demonstrate that the anti-conformation of H_4L changes to syn-orientation to avoid poly-metallic complex formation, as noticed in **1** and **2**. Thus, to our knowledge, only **1** and **2** are the first non-polymeric structures to be reported for pamoic acid. The dimeric Ti(IV) units stack in the lattice to form helical col-

umns and the space between the adjacent columns is being filled by the solvent molecules in **1** and solvent plus the protonated 4,4′-bipy in the lattice of **2** and thus the neighbor columns are connected through weak interactions. The presence of protonated 4,4′-bipy in the lattice of **2** was further confirmed by the conductivity experiments. However, the presence of 4, 4′-bipy could not prevent the formation of dinuclear species, but it could bring some changes in the co-ordination characteristics of the pamoic acid moiety, yet maintaining the helical structure.

Supplementary data

CCDC 711046, 710613 and 710614 contains the supplementary crystallographic data for H4L, **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Acknowledgements

CPR acknowledges the financial support by DST, CSIR and DAE. GSB acknowledge CSIR, New Delhi for fellowship. We thank Mr. Shaikh M. Mobin for helping with the diffraction data.

Scheme 1. Preparation of **4**–**6**.

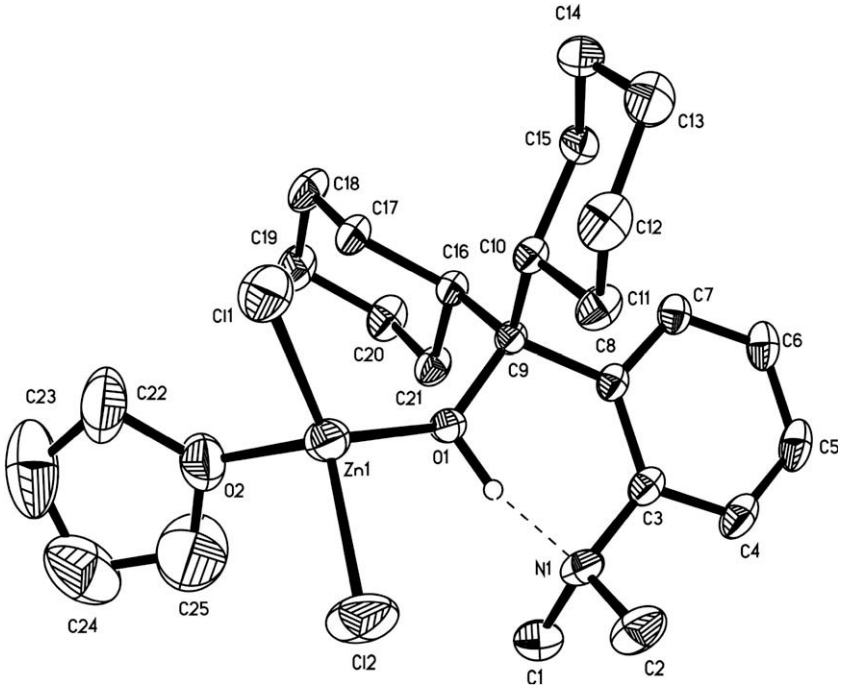

Fig. 1. Molecular structure of **5** showing the atom numbering scheme employed (ORTEP, 50% probability, SHELXTL-PLUS; XP) [18]. Hydrogen atoms (other than O–H) are omitted for clarity.

Table 1
Selected bond lengths (Å) and bond angles (°) for **5**.

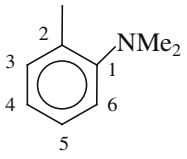
Zn(1)–O(1)	1.973(1)	O(1)–Zn(1)–Cl(1)	123.44(4)
Zn(1)–O(THF)$_{av.}$	2.058(2)	O(THF)–Zn(1)–Cl(1)$_{av.}$	102.3(3)
Zn(1)–Cl(1)	2.1949(6)	O(1)–Zn(1)–Cl(2)	98.91(4)
Zn(1)–Cl(2)	2.2092(7)	O(THF)–Zn(1)–Cl(2)$_{av.}$	104.1(4)
Cl(1)–Zn(1)–Cl(2)	122.62(4)	O(1)–Zn(1)–O(THF)$_{av.}$	102.6(6)

$(CH_2OH)C_5H_4N)]$ [2.123(3) Å], and similar to those found in {*N*,*N*′-bis[1-(2-hydroxy-4-methoxyphenyl)ethylidene]ethylenediamine-κ^2O,O'}dichlorozinc(II) [1.975(5) Å] [7]. The Zn–Cl bond lengths (Table 1) are in the same range and comparable to those found in $[ZnCl_2(C_{10}H_{12}NO_2)_2]$ [2.219(2)–2.233(2) Å] [7] and $[ZnCl_2$(8-(diphenylphosphino)quinoline] [2.218(2) and 2.201(2) Å] [17].

The non-involvement of the NMe_2 nitrogen atom in zinc coordination seems to be due to two combined factors: the better donor quality of the THF molecule, and the strong intramolecular O(1)–H(9)···N(1) hydrogen bond [O–H 0.94(3) Å, H···N 1.55(3) Å, O···N 2.464(2) Å, O–H–N 160(3)°]. The intramolecular O(1)–H(9)···N(1) hydrogen bond of **5** is stronger than that in the free ligand **2** [O–H 0.92(2) Å, N···H 1.73(2) Å, N···O 2.591(1) Å, N–H···O 155(2)°] [12]. The bond lengths and angles of the organic fragment of **5** are similar to those observed for the corresponding free ligand **2** [12].

3. Experimental

All experiments were carried out under purified dry nitrogen. Solvents were dried and freshly distilled under nitrogen [19]. The NMR spectra were recorded with an AVANCE DRX 400 spectrometer (Bruker). Chemical shifts for ^1H and ^{13}C NMR spectra are reported in parts per million (ppm) at 400.13 MHz and 100.63 MHz with tetramethylsilane as external standard. Elemental analyses were determined with a VARIO EL (Heraeus). Melting points (Gallenkamp) are uncorrected. Mass spectra were recorded with an MAT-8230 (EI-MS, 70 eV). 1-$HOCPh_2$-2-$NMe_2C_6H_4$ (**1**) [11,12], 1-$HOC(C_6H_{11})_2$-2-$NMe_2C_6H_4$ (**2**) [12], and 1-$HOCPh_2CH_2$-2-$NMe_2C_6H_4$ (**3**) [12,13] were prepared by literature procedures.



3.1. Preparation of $[ZnCl_2(THF)\{1\text{-}HOCPh_2\text{-}2\text{-}NMe_2C_6H_4\}]$ (**4**)

A 150 ml Schlenk flask was charged with 1-$HOCPh_2$-2-$NMe_2C_6H_4$ (**1**) (0.48 g, 1.6 mmol) and tetrahydrofuran (50 ml). Then $ZnCl_2$ (0.22 g, 1.6 mmol) was added at room temperature. The solution was stirred for about 3 h. The remaining solid was then removed by filtration and the solution was concentrated to give the product in 94% yield. Mp. 177–178 °C. ^1H NMR (DMSO, δ/ppm): 1.76 (m, 4H, CH_2 (THF)), 3.44 (s, 6H, $N(CH_3)_2$), 3.60 (m, 4H, CH_2O (THF)), 6.56–7.54 (m, vbr, 14H, C_6H_4 and C_6H_5), 9.75 (s, 1H, OH). $^{13}C\{^1H\}$ NMR (DMSO, δ/ppm): 21.0 (THF), 45.1 ($N(CH_3)_2$), 67.0 (THF), 82.3 (C–O), 124.3 (s, C6 in C_6H_4), 125.2 (s, C4 in C_6H_4), 126.9 (s, C3 in C_6H_4), 127.8 (s, C5 in C_6H_4), 128.6 (s, *p*-C in C_6H_5), 129.5 (s, *o*-C in C_6H_5), 139.0 (s, *m*-C in C_6H_5), 142.3 (s, C2 in C_6H_4), 147.5 (s, C1 in C_6H_4), 152.0 (s, *ipso*-C in C_6H_5). MS: *m/z* 303.4 (M^+-$ZnCl_2$-THF). Found: C, 58.64; H, 5.69; N, 2.72%. Calcd. for $C_{25}H_{29}Cl_2NO_2Zn$ (511.80): C, 58.67; H, 5.71; N, 2.74%.

3.2. Preparation of [$ZnCl_2$(THF){1-HOCCy$_2$-2-NMe$_2$C$_6$H$_4$}] (**5**)

A similar procedure to that described for **4** was used here, except 1-HOC(C_6H_{11})$_2$-2-NMe$_2$C$_6$H$_4$ (**2**) (0.51, 1.6 mmol) was employed instead of **1** and colorless crystals were obtained from tetrahydrofuran at 20 °C in 80% yield. Mp. 170–172 °C. ^{1}H NMR (DMSO, δ/ppm): 0.69–1.73 (vbr, 22H, C_6H_{11}), 1.77 (m, 4H, CH_2 (THF)), 3.38 (s, 6H, N(CH_3)$_2$), 3.61 (m, 4H, CH_2O (THF)), 10.31 (s, 1H, OH), 7.04–7.39 (m, 4H, C_6H_4). ^{13}C {^{1}H} NMR (DMSO, δ/ppm): 21.0 (THF), 26.4 (s, C4 in C_6H_{11}), 29.2 (s, C3/C5 in C_6H_{11}), 30.4 (s, C2/C6 in C_6H_{11}), 45.8 (s, C1 in C_6H_{11}), 46.4 (N(CH_3)$_2$), 67.0 (THF), 83.2 (C–O), 124.5 (s, C6 in C_6H_4), 125.4 (s, C4 in C_6H_4), 126.1 (s, C3 in C_6H_4), 127.3 (s, C5 in C_6H_4), 137.8 (s, C2 in C_6H_4), 153.3 (s, C1 in C_6H_4). MS: m/z 315.6 (M^+-$ZnCl_2$-THF). Found: C, 57.10; H, 7.87; N, 2.66%. Calcd. for $C_{25}H_{41}Cl_2NO_2Zn$ (523.89): C, 57.32; H, 7.89; N, 2.67%.

3.3. Preparation of [$ZnCl_2$(THF){1-HOCPh$_2$CH$_2$-2-NMe$_2$C$_6$H$_4$}] (**6**)

A similar procedure to that described for **4** was used here, except 1-HOCPh$_2$CH$_2$-2-NMe$_2$C$_6$H$_4$ (**3**) (0.51, 1.6 mmol) was employed instead of **1** and the product was obtained from tetrahydrofuran at 20 °C in 80% yield. Mp. 190–192 °C. ^{1}H NMR (DMSO, δ/ppm): 1.77 (m, 4H, CH_2 (THF)), 2.49 (s, 6H, N(CH_3)$_2$), 3.61 (m, 4H, CH_2O (THF)), 3.73 (s, 2H, CH_2), 7.14 (s, 1H, OH), 7.16–7.45 (m, vbr, 14H, C_6H_4 and C_6H_5). ^{13}C {^{1}H} NMR (DMSO, δ/ppm): 21.0 (THF), 44.7 (CH_2), 45.0 (N(CH_3)$_2$), 67.0 (THF), 77.0 (C–O), 124.5 (s, C6 in C_6H_4), 125.4 (s, C4 in C_6H_4), 126.1 (s, C3 in C_6H_4), 127.6 (s, C5 in C_6H_4), 128.4 (s, p-C in C_6H_5), 130.0 (s, m-C in C_6H_5), 130.9 (s, o-C in C_6H_5), 142.0 (s, C2 in C_6H_4), 148.0 (s, C1 in C_6H_4), 152.3 (s, $ipso$-C in C_6H_5). MS: m/z 317.3 (M^+-$ZnCl_2$-THF). Found: C, 59.37; H, 5.94; N, 2.65%. Calcd. for $C_{26}H_{31}Cl_2NO_2Zn$ (525.83): C, 59.39; H, 5.94; N, 2.66%.

3.4. Data collection and structure refinement of **5**

Crystallographic data are given in Table 2. Data [λ(Mo Kα) = 0.71073 Å] were collected with a Siemens CCD (SMART) diffractometer. All observed reflections were used for determination of the unit cell parameters. Empirical absorption correction was performed with SADABS [20]. The structure was solved by direct methods (SHELXTL-PLUS [15]). H atoms were located by difference maps and refined isotropically, except for the hydrogen atoms of the disordered THF ligand (O2, C22–C25 and O3, C26–C29; these atoms were refined with 63% and 37% occupancy, respectively).

Appendix A. Supplementary data

CCDC 194393 contains the supplementary crystallographic data for **5**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

performed with a Siemens SMART CCD diffractometer using fine focus sealed graphite-monochromatized Mo Kα radiation (λ = 0.71073 Å) for $[Co(SEtaaiNEt)_2](ClO_4)_2$ (**2d**) and $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**). Reflections were recorded using the ω scan technique. Data were corrected for Lorentz polarization effects and for linear decay. Semi-empirical absorption corrections based on ψ-scans were applied with the help of SADABS (Multi-scan). The structures were solved by direct methods using SHELXS-97 [22] and successive difference Fourier syntheses. Both of the perchlorate anions are disordered. Three oxygen atoms around Cl1 are disordered over two crystallographically independent orientations (O2A/O2B, O3A/O3B, O4A/O4B) with occupancy ratios 0.88/0.12, 0.67/0.37, 0.53/0.47, respectively. In total this affords disordering of the oxygen atoms over 6 positions. One oxygen atom around Cl2 is disordered over two orientations (O6A/O6B) with an occupancy ratio 0.78/0.22. The thermal ellipsoids of the O atoms show that the disordered ClO_4^- ions deviate from the original orientations, which is also supported by the C–H···O(ClO_3) hydrogen bonding interaction. All non-hydrogen atoms were refined anisotropically. The H atoms were not refined but they were treated as riding on their parent atoms. In the final difference Fourier map the residual minima and maxima were [−0.145 and 0.153 (e/$Å^3$) for **2d**; −0.448 and 0.697 (e/$Å^3$) for **3b**], carried out using SHELXL-97 [23]. The structures were drawn using the ORTEP-32 [24], and PLATON-99 [25] programs.

2.4. Synthesis of the complexes

2.4.1. $[Co(SMeaaiNMe)_2](ClO_4)_2$

1-Methyl-2-[*o*-(thiomethyl)phenylazo]imidazole (SMeaaiNMe) (0.4 g, 1.72 mmol) in methanol (15 ml) was added dropwise to $Co(ClO_4)_2{\cdot}6H_2O$ (0.3 g, 0.82 mmol) in the same solvent (10 ml) at 298 K under a N_2 environment. The solution was stirred and refluxed for 3 h. The orange–brown solution was then filtered and N_2 gas was bubbled through to reduce its volume to 10 ml. To this solution a N_2 flushed $NaClO_4$ solution (1 g in 5 ml aqueous solution) was added and the reaction flask was corked. The solution was then kept in a freezer for 12 h. A dark brown mass precipitated at the bottom of the container, which was filtered. The residue was then washed with cold water followed by methanol-water (1:1, v/v) and dried in a vacuum over $CaCl_2$. The yield was 0.37 g (60%).

All the other complexes were prepared by the same procedure. The yields varied from 50–65%.

2.4.2. $[Co(SMeaaiNMe)_2(SCN)_2]$ (3a)

1-Methyl-2-[*o*-(thiomethyl)phenylazo]imidazole (SMeaaiNMe) (0.4 g, 1.72 mmol)) in methanol 20 ml) was added dropwise to a solution (10 ml) of $Co(OAc)_2{\cdot}4H_2O$ (0.22 g, 0.88 mmol) in the same solvent at 298 K in an inert (N_2) environment. The resulting orange–brown solution was stirred for 30 min. To this solution NH_4SCN (0.15 g, 1.97 mmol) was added in a small volume of water. The resulting brown red solution was then stirred for an additional 1 h, then filtered and left undisturbed for a week. A dark crystalline compound separated out. The crystals were filtered, washed with water, cold methanol and dried over $CaCl_2$ in *vacuo*. The yield was 0.30 g, (54%). All the other complexes were prepared by the same procedure. The yields varied from 50–70%.

Microanalytical data: Anal. Calc. for $[Co(SMeaaiNMe)_2(SCN)_2]$ (**3a**): C, 45.08; H, 3.76; N, 21.91. Found: C, 45.00; H, 3.73; N, 21.85%. *Anal.* Calc. for $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**): C, 46.78; H, 4.20; N, 20.99. 3. Results and discussion

3.1. Synthesis and formulation

1-Alkyl-2-[*o*-(thiomethyl)phenylazo]imidazole ($SRaaiNR^l$) reacts with $Co(ClO_4)_2.6H_2O$ in a 1:2 molar ratio under a N_2

environment in MeOH to isolate shining dark crystals on slow cooling (Scheme 1). The composition of the complexes, $[Co(SRaaiNR^{/})_2](ClO_4)_2$ (**2**) is supported by microanalytical data. Addition of an aqueous solution of NH_4SCN (2 equivalents) to a mixture of $Co(OAc)_2{\cdot}4H_2O$ and $SRaaiNR^{/}$ (1:2 mole ratio) in MeOH in an inert (N_2) atmosphere has isolated crystalline compounds of the formulation $[Co(SRaaiNR^{/})_2(SCN)_2]$ (**3**). The complexes are soluble in methanol, ethanol, chloroform, dichloromethane and acetonitrile, but are insoluble in hexane, benzene and toluene. Complexes **2** show 1:2 molar conductivity (Λ_M = 160–170 Ω^{-1} cm^2 mol^{-1} in MeOH) while complexes **3** are non-conducting in methanol/acetonitrile solution. The effective magnetic moments (μ) of $[Co(SRaaiNR^{/})_2](ClO_4)_2$, **2**, lie in the range 2.0–2.1 BM, and those of **3** show μ values in the range 4.0–4.2 BM. These data undoubtedly suggest low spin $t_{2g}^6eg^1$ for **2** and high spin, $t_{2g}^5eg^2$ for **3**. The magnetic moment data are slightly higher than the spin only value [26].

3.2. Molecular structures

3.2.1. $[Co(SEtaaiNEt)_2](ClO_4)_2$ (2d)

The X-ray structure of $[Co(SEtaaiNEt)_2](ClO_4)_2$ (**2d**) is shown in Fig. 1. Selected bond lengths and angles are given in Table 2. The coordination environment of cobalt includes imidazole-N(N), azo-N($N^{/}$) and thioether-S in a CoN_4S_2 system. The ligands bind in two meridional segments, each of the N, $N^{/}$, S type. Each Co-$NN^{/}S$ fragment is planar (mean deviation <0.03 Å). The donor centres are arranged in a *cis–trans–cis* configuration in the sequence N(imidazole), N(azo) and S donor centres. The bond lengths and angles (Table 2) suggest a distorted octahedral geometry around the Co centre. The Co–N distances vary in the range 1.88–2.05 Å. The distances are comparable with previously reported structures of cobalt(II) complexes of 1-alkyl-2-(arylazo)imidazole [27–29]. The Co–S distances are Co–S(1), 2.3934(12) Å and Co–S(2), 2.3703(13) Å. The N=N distances differ slightly in the two Co(N,$N^{/}$,S) motifs (N(1)–N(2), 1.281(4) Å; N(3)–N(4), 1.293(4) Å) (Table 2), though they are both longer than the free ligand values (1.250(1) Å) [30], 1.261(2) Å [31]). The two chelate planes [Co,S(1),C(1),C(6),N(1), deviation ⩽ 0.1 Å; Co,N(4),C(9),N(1),N(2), mean deviation ⩽ 0.07 Å] are no longer planar and makes a dihedral angle of 4.80(20)°. The chelate angles in Co(N,$N^{/}$) (∠N(1)–Co–N(4), 80.8 (2)°; ∠N(5)–Co–N(8), 79.82(16)°) are smaller than the Co($N^{/}$,S) chelate (∠S(1)–Co–N(1), 86.43(14)° and ∠S(2)–Co–N(8), 85.00(12)°). The two ClO_4^- units are not equivalent. The three oxygen atoms around Cl1 are disordered over two crystallographically independent orientations, with variable occupancy ratios, and one oxygen atom around Cl2 is disordered over two orientations (*vide* Section 2).

Table 2c
Hydrogen bonded metric parameters of **2d**.

	H···A, Å	D···A, Å	∠D–H···A, °
C(7)–H(7)···O(7)	2.39	3.3061	169
C(8)–H(8)···O(6)	2.25	3.1300	158
C(14)···H(14)···O(7)[a]	2.45	3.3268	157
C(16)–H(16)···O(3)	2.40	3.3019	162
C(17)–H(17)···O(4)[b]	2.50	3.1515	127
C(21)–H(21B)···N(4)(Intra)	2.51	3.2787	136

[a] Symmetry: $1/2 - x, -1/2 + y, z$.
[b] Symmetry: $3/2 - x, 1/2 + y, z$.

The hydrogen bonding interaction, C–H···O(ClO_3) forms a 1-D chain. The supramolecular parameters are listed in Table 2c. Intramolecular hydrogen bonding is also observed with the azo-N and imidazole-N(1)–CH_2 group to stabilize the molecular union.

3.2.2. $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**)

The X-ray structure of $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**) is shown in Fig. 2. Selected bond distances and angles are given in Table 2b. The structure is a distorted octahedron with a CoN_6 configuration. SMeaaiNEt acts as a bidentate N(imidazole), N(azo) chelator, unlike the structure of **2d**, and two –N(CS) groups fulfill the charge and coordination number. The Co–N(azo) distances, Co(1)–N(7), 2.488(7) Å and Co(1)–N(27), 2.441(2) Å, are elongated by 0.4–0.5 Å compared to **2d** (Fig. 1a, Table 2a). The Co–N(azo) distances (Co(1)–N(7/27)) are longer than those of Co–N(imidazole) (Co(1)–N(1/21)) by ~0.4 Å, but the former are sufficiently below the sum of the van der Waals radii of Co(II) (2.00 Å) and azo-N (1.50 Å) [32]. This signifies a covalent interaction between Co(II) and N(azo). The chelate angles are ∠N(1)–Co(1)–N(7), 70.49(4)° and ∠N(21)–Co(1)–N(27), 71.60(7)°. The structural distortion in **3b** may arise from the long Co–N(azo) distance and small Co(N,N′) chelate angles, which may be due to the demand of the larger stereochemical space of azo-N; thus the distortion arises *via* elongation of the Co–N(azo) distance. The N=N bond lengths [N(6)–N(7), 1.280(3) Å; N(26)–N(27), 1.280(3) Å] are longer than the free ligand values (1.250(1) Å) [30], 1.261(2) Å [31]. The elongation of this bond in the complex with reference to the free ligand value (by 0.03 Å) may be due to a dπ(Co)–π*(azo) backbonding charge transfer.

A DFT calculation has been performed for the two different molecules $[Co(SEtaaiNEt)_2](ClO_4)_2$ (**2d**) and $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**). The optimized structure of these molecules are developed using the GAUSSIAN 03 analyses package. Structural agreement has been observed from a comparison of bond distances and angles between the calculated and X-ray determined structures. The bond lengths in the theoretically generated molecules are elongated by 0.005–0.01 Å compared to those of the experimental structures.

3.3. Spectral studies

The infrared spectra of the complexes are assigned by comparing with spectra of the free ligands and some cobalt(II) complexes of arylazoimidazoles [20,27–29]. The spectra of the complexes **2** show a strong band at 1085–1093 cm^{-1} with a weak stretch at 624–627 cm^{-1}, which are assigned to $\nu(ClO_4)$. The characteristic strong transmission of **3** at 2060–2075 cm^{-1} is referred to $\nu_{asym}(SCN)$. Moderately intense stretchings at 1583–1600 and 1438–1452 cm^{-1} are due to ν(C=N) and ν(N=N), respectively, for the coordinated SRaaiNR′ ligands.

Solution electronic spectra of the complexes were recorded in acetonitrile solution in the UV–Vis region (250–900 nm). The data are listed in Table 3. The visible region of the spectra show three transitions: for **2** the transitions are 600–635, 450–470 and 410–420 nm, along with two transitions in the UV region; 355–375, 240–255 nm. The complexes **3** exhibit transitions at 530–610, 410–430 and 365–370 nm. The longer wavelength bands are weaker than the bands <430 nm. Based on the low intensity and low energy nature, the bands are considered to be d–d transitions in an octahedral geometry. The high intense transition <430 nm may be assigned to MLCT transitions.

The theoretically generated structures of $[Co(SEtaaiNEt)_2](ClO_4)_2$ (**2d**) and $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**) are used to calculate the composition and energy of the functions. These are used to explain the electronic properties of the complexes. The orbital energies along with contributions from the ligands and metal are given in the Supplementary Materials Tables S1 and S2. Fig. 4 depicts the selected occupied and unoccupied frontier orbitals. In the complexes the highest occupied MO is singly occupied and is abbreviated SOMO. The MOs are destabilized on going from $[Co(SEtaaiNEt)_2](ClO_4)_2$ (**2d**) to $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**): E_{SOMO} (**2d**), −11.17 eV and E_{SOMO} (**3b**), −4.40 eV; E_{LUMO} (**2d**), −9.14 eV and E_{LUMO} (**3b**), −3.13 eV. This may be attributed to structural distortion, coordination of different donor centres, number of chelate rings etc.

The SOMO of **2d** is constituted of Co (35%) and the chelating ligand, SEtaaiNEt (65%), while the main contribution to HOMO-1, HOMO-2 etc is from SEtaaiNEt (>90%). In $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**) the SOMO and other occupied MOs (HOMO-1, HOMO-2 etc) are mainly composed of the –NCS group (>90%) and the unoccupied MOs (except LUMO+2) of SMeaaiNEt (>95%). The LUMO+2 is composed of Co (75%), –NCS (10%) and SMeaaiNEt (15%). The calculated transitions are grouped in the Supplementary Materials Table S2. The intensity of these transitions has been assessed from the oscillator strength (*f*). In **2d**, the visible region (400–570 nm) transitions are assigned to SOMO → LUMO+1, HOMO-1 → LUMO/LUMO+1, HOMO-3 → LUMO/LUMO+1/LUMO+2, HOMO-4 → LUMO/LUMO+1/LUMO+2 etc. The calculated transitions at 470–570 nm are weak (*f*, 0.005–0.007) and are assigned to an admixture of MLCT (metal-to-ligand charge transfer) and ILCT (intraligand charge transfer) transitions. An intense band is calculated at 430 nm (*f*, 0.1095) which is an ILCT band. $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**) shows longer wavelength transitions (>600 nm), but they are weaker than those of **2d**. One of these transitions at 833 nm is assigned to XMCT (X = NCS) and is weak (*f*, 0.002). It originates from the SOMO → L+2 transition. The transitions 710–730 and 650–670 nm are also weak (*f*, 0.001–0.002) and have been assigned to an admixture of XMCT, MLCT, ILCT and XLCT. They are characterized as SOMO-1 → LUMO+1/L+2; SOMO-1 → LUMO+1; S−2/S−3 → L+2, etc.

3.4. Redox behavior

Cyclic voltammetry was used to examine the redox nature of the complexes in acetonitrile solution in the potential range −1.6 to 1.2 V versus a SCE electrode. A representative voltammogram

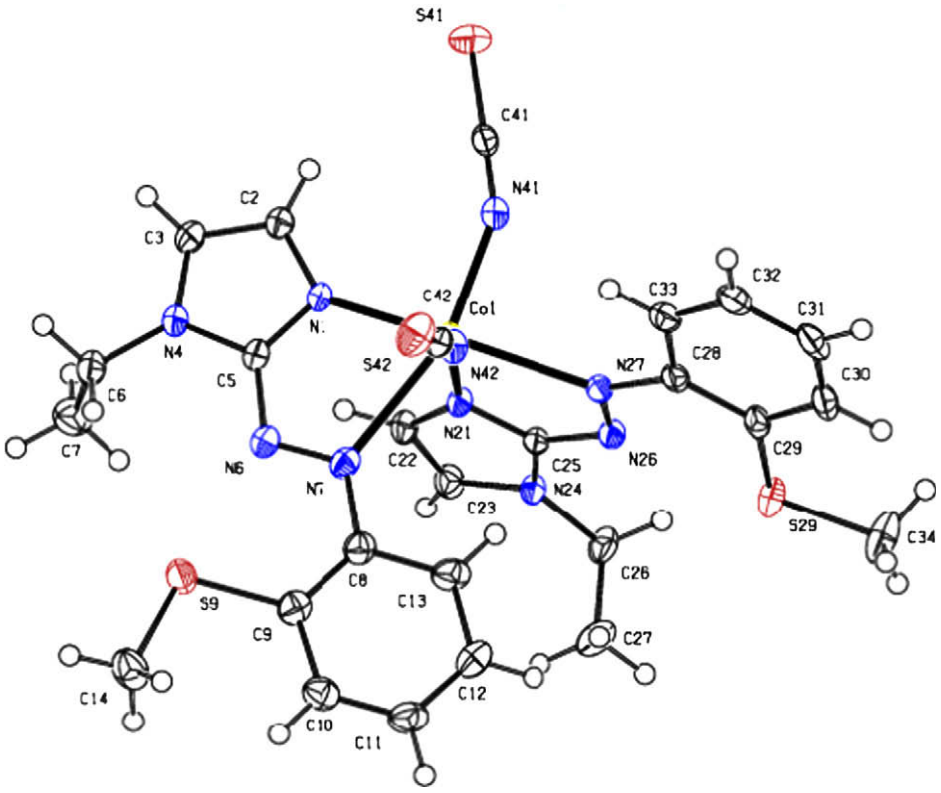

Fig. 2. Molecular structures of $[Co(SMeaaiNEt)_2(NCS)_2]$ (**3b**).

Table 3
UV–Vis spectral and bulk magnetic data.

Compounds	UV–Vis spectra in MeOH Λ_{ms} (nm) (ε in $dm^3\ mol^{-1}\ cm^{-1}$)	Magnetic moment, μ (BM)

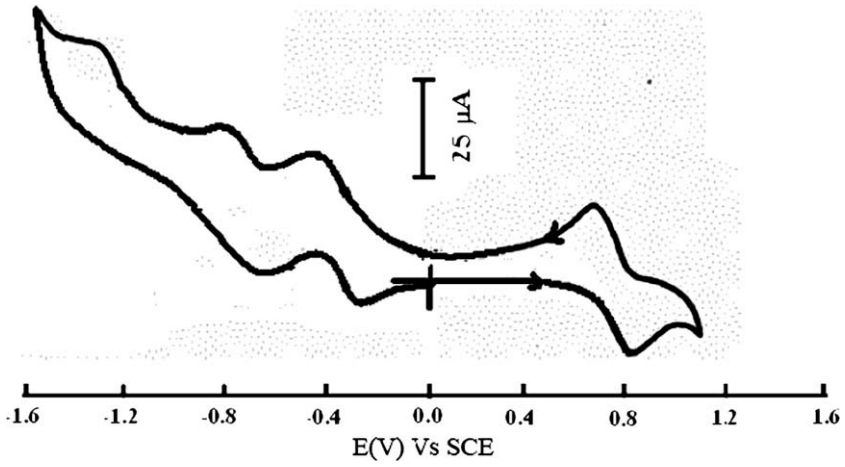

Fig. 3. Cyclic voltammograms $[Co(SMeaaiNEt)_2](ClO_4)_2$ (**2b**) in MeCN solution.

is shown in Fig. 3 and data are given in Table 4. The complexes display a quasireversible (peak-to-peak separation 100–130 mV) one-electron response at 0.6–0.8 V, which may be assigned to a Co(III)/Co(II) redox response. On scanning to the negative direction

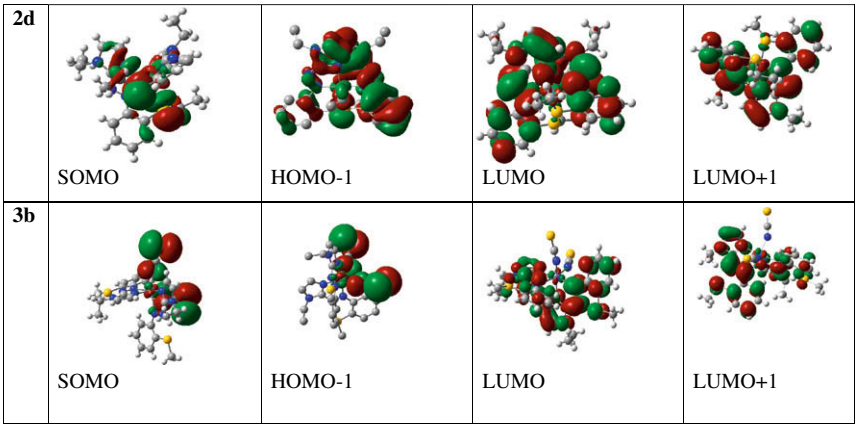

Fig. 4. Some orbital pictures of **2d** and **3b**.

(0.0 to −1.6 V), three redox responses were observed at ∼−0.4, −0.8 and −1.4 V. Two of the reductive couples (∼−0.4, −0.8 V) are quasireversible (ΔEp ⩾ 100 mV), while the third one at −1.4 V is irreversible. The couples negative to SCE are reductive in nature, and the first two reductions are referred to azo/azo^{-} and azo^{-}/azo$^{=}$ respectively [19]. The irreversible reduction at the very high negative potential (−1.4 V) may be considered electron accommodation to a thiocyanato dominated redox level. The coulometric data of $[Co(SRaaiNR^{/})_2]^{2+}$ (**2**) confirms the one-electron stoichiometry, however, we could not run a coulometric oxidation of $[Co(SRaaiNR^{/})(SCN)_2]$ (**3**). The anodic current began to increase progressively above ∼0 .7 V and there were signs of a very ill defined anodic response near 1 V, not associated with a cathodic counterpart on scan reversal. The multicyclic voltammetric response is supportive of this change and it is observed that both the current height and peak-potential position are shifted in a more negative direction. This may support the decomposition of the depolarizer structure under the influence of the electrode field. Ligand reductions appear at more negative values for $[Co(SRaaiNR^{/})_2(SCN)_2]$ compared to $[Co(SRaaiNR^{/})_2](ClO_4)_2$, which may be due to the better stability of the tridentate chelation in latter complex. The higher Co(III)/Co(II) redox potential for $[Co(SRaaiNR^{/})_2]^{2+}$ compared to $[Co(SRaaiNR^{/})_2(SCN)_2]$ suggests a fairly stable Co(II) in **2** compared to that of **3**.

$$[Co(N,N^{/},S)_2]^{3+} + e \rightleftharpoons [Co(N,N^{/},S)_2]^{2+} \quad (1)$$

The cyclic voltammetric behavior of **2** and **3** are readily accountable from the DFT calculation. Because of the significant metal (Co) function in the SOMO of **2d** the complexes show metal oxidation, which is indeed observed. The unoccupied MOs are significantly dominated by the azoimine function, thus reduction may refer to electron accommodation at the azo dominated orbital of the ligand. So the assignments of azo reductions are justified. A DFT calculation on $[Co(SMeaaiNEt)_2(SCN)_2]$ (**3b**) shows a weak Co contribution (<4%) in the SOMO, and HOMO-4 has a significant (46%) Co contribution. The SOMO is dominated by a NCS contribution. The oxidation, which refers to electron extraction from the complex, may be attributed to the NCS group followed by the Co centre. So the terminal oxidation may be assigned to Co(II) → Co(III). The LUMO and other unoccupied MOs are SMeaaiNEt dominated (>95%), so reduction is, as usual, the following:

$$—N{=}N— + e \rightarrow —N^{\cdot\cdot}—N—^{-}. \quad (2)$$

Table 4
UV–Vis spectra[a] cyclic voltametric[b] data.

Compound	CV data E^0 (V) (ΔE_P, mV)			
	E_M[c]	Ligand reductions

4. Conclusion

Co(II)-1-alkyl-2-[(*o*-thioalkyl)phenylazo]imidazole (SRaaiNR$^{/}$) complexes are described in this work. The complexes have been structurally established. In $[Co(SRaaiNR^{/})_2]^{2+}$ the ligand serves as a tridentate N(imidazole), N(azo), S(thioether) chelator and forms a meridionally bonded octahedral geometry. The complex, $[Co(SRaaiNR^{/})_2(SCN)_2]$ is also distorted octahedral and SRaaiNR$^{/}$ shows a bidentate imidazole-N, azo-N chelation. The X-ray structure parameters confirm a higher degree of distortion in the latter case. The $[Co(SRaaiNR^{/})_2](ClO_4)_2$ complexes are low spin $t_{2g}^6e_g^1$ while the $[Co(SRaaiNR^{/})_2(SCN)_2]$ complexes are high spin $t_{2g}^5e_g^2$. DFT calculations of the optimized geometries of the complexes are used to explain the electronic properties of the complexes.

2. Experimental

2.1. Materials and physical measurements

All chemicals and reagents were of analytical grade, and were used as received from commercial sources (Sigma–Aldrich and Alfa Aesar). Elemental analyses for C, H and N were performed on an Elementar Vario III EL. The FT-IR spectrum was recorded in the 4000–400 cm^{-1} region with a Bruker Optics, Vertex 70 FT-IR spectrometer using ATR techniques. Thermal analysis was performed on a SII Exstar 6000 TG/DTA 6300 model using a platinum crucible with a 10 mg sample. TG/DTA measurement was taken in static air, within the 20–700 °C temperature range. The UV–Vis spectrum was obtained for the solid state, aqueous solution and DMSO solution of the complex (10^{-3} M) and the free ligands, ap and H_2dipic (10^{-3} M), with a SHIMADZU UV-2550 spectrometer in the range 900–200 nm. Magnetic susceptibility measurement at room temperature was performed using a Sherwood Scientific Magway MSB MK1 model magnetic balance by the Gouy method using $Hg[Co(SCN)_4]$ as the calibrant. Molar conductance of the compound was determined in DMSO (10^{-3} M) at room temperature using a WTW Cond 315i/SET Model conductivity meter.

2.2. Synthesis of $[Cu(\mu\text{-ap})(dipic)(H_2O)]_2{\cdot}4H_2O$ (**1**)

A solution of $Cu(CH_3COO)_2{\cdot}H_2O$ (0.199 g, 1 mmol) in water (10 mL) was added dropwise to a mixed-ligand solution of 2,6-pyridinedicarboxylic acid (0.167 g, 1 mmol) and 2-aminopyridine (0.094 g, 1 mmol) in water (20 mL) with stirring at room temperature for 1 h. The reaction mixture was kept at room temperature for 2 weeks to give a green crystalline solid (0.5 g, 66% yield). On recrystallisation, green crystals of **1** suitable for X-ray diffraction were separated and washed with water. *Anal.* Calcd. for $C_{24}H_{30}N_6O_{14}Cu_2$: C, 38.25; H, 4.01; N, 11.15. Found: C, 38.30; H, 4.04; N, 11.21%.

2.3. X-ray data collection and structure refinement

The crystal and instrumental parameters used in the unit-cell determination and data collection are summarized in Table 1 for complex **1**. Diffraction measurements were made at room temperature on a Stoe IPDS II CCD X-ray diffractometer employing plane graphite monochromatized Mo Kα radiation (λ = 0.71073 Å), using the $\omega - 2\theta$ scan mode. Unit-cell dimensions were determined and refined by using the angular settings of 25 automatically centered reflections in the $1.61 \leqslant \theta \leqslant 26.50$ range. The structure was solved by direct methods using SHELXS-97 and refined by full-matrix least-squares techniques on F^2 with SHELXL-97 [32]. Empirical absorption corrections were applied by the integration method via X-RED software [33]. H atoms of NH_2 group and water molecules were located in difference syntheses and refined as riding atoms, with distances of N–H = 0.82(3)–0.84(3) Å and O–H = 0.801(17)–0.818(17) Å and with $U_{iso}(H) = 1.2U_{eq}(N,O)$. The remaining H atoms were placed geometrically at distances of 0.93 Å from their parent atoms for N–H and C–H bonds. ORTEP drawings [34] of complex **1** with 40% probability displacement thermal ellipsoids and the atom-labelling scheme are shown in Figs. 1–3.

$wR(F^2)$	0.0701
Goodness-of-fit on F^2	1.030
Largest difference in peak and hole (Å^{-3})	−0.352 and 0.287

2.4. Bioassays

2.4.1. Antimicrobial assay

2.4.1.1. Microorganisms and inoculum preparation for biological activity. Microorganisms were obtained from various sources (see Table 2) and stored at −85 °C in 50% glycerol until used in the antimicrobial assays. The bacteria and yeasts were first refreshed in Mueller Hinton Broth (Merck) at 35–37 °C, and were then inoculated on Mueller Hinton Agar (Mast Diagnostics) plates for a purity check. After sufficient growth the microbial cultures were transferred to liquid medium and were overnight grown suspensions were calibrated to McFarland No: 0.5 using a densitometer (Biosan).

2.4.1.2. Antimicrobial assay. Micro-dilution broth susceptibility assay was used [35–37]. Stock solutions of the test samples and the standard antibacterial agent Chloramphenicol and the antifungal agent Ketoconazole were prepared in 25% DMSO (Carlo-Erba). Dilution series were prepared from 4 mg/mL to 0.003 mg/mL in 96-well microtiter plates. One hundred microliters of the previously prepared microbial suspensions were then transferred to each well. The last row, containing only the serial dilutions of the antifungal agent without the microorganism, was used as a negative control. After incubation at 37 °C for 24–48 h, the first well without turbidity was determined as the minimal inhibitory concentration (MIC). Ten microliters of tetrazolium salt (TTC) was also added to each well to confirm the MIC values. The assays were repeated twice and the results are given as the average.

2.4.2. Qualitative radical scavenging assay using DPPH·

The test substances were screened for their radical scavenging activity preliminary at 0.5 mg/mL concentration in MeOH qualitatively using a thin layer assay [38,39] to detect possible active substances in comparison with the standard antioxidant substance vitamin C.

3. Results and discussion

3.1. IR spectrum

The significant frequencies in the IR spectrum of **1** are given in Table 3. There is a broad absorption band at 3340 cm^{-1} attributed to the ν(OH) vibrations of water molecules in the crystal. The absorption bands at 3202 and 3280 cm^{-1} are due to the ν(NH)

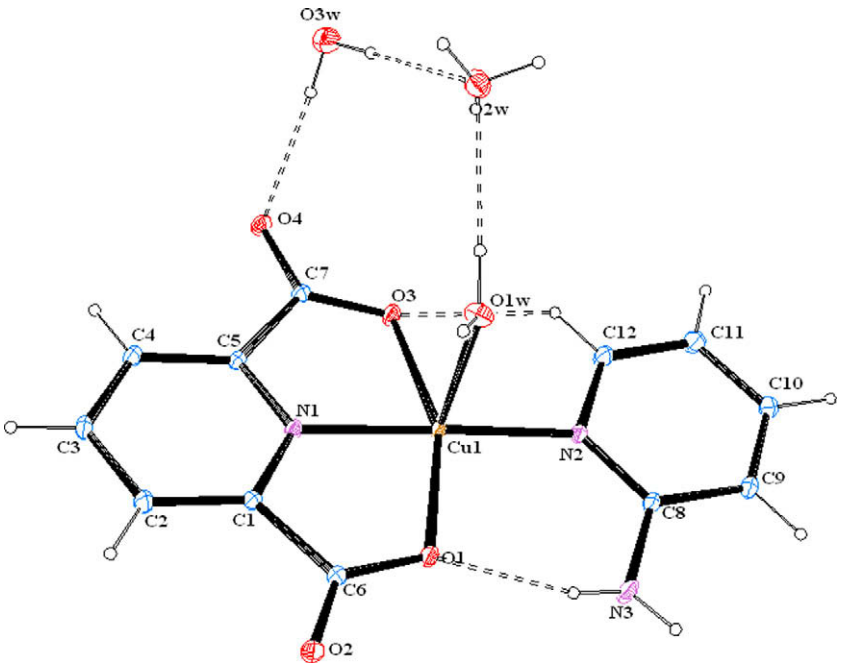

Fig. 1. An ORTEP drawing of **1** with the atom-numbering scheme. Displacement ellipsoids are drawn at the 40% probability level.

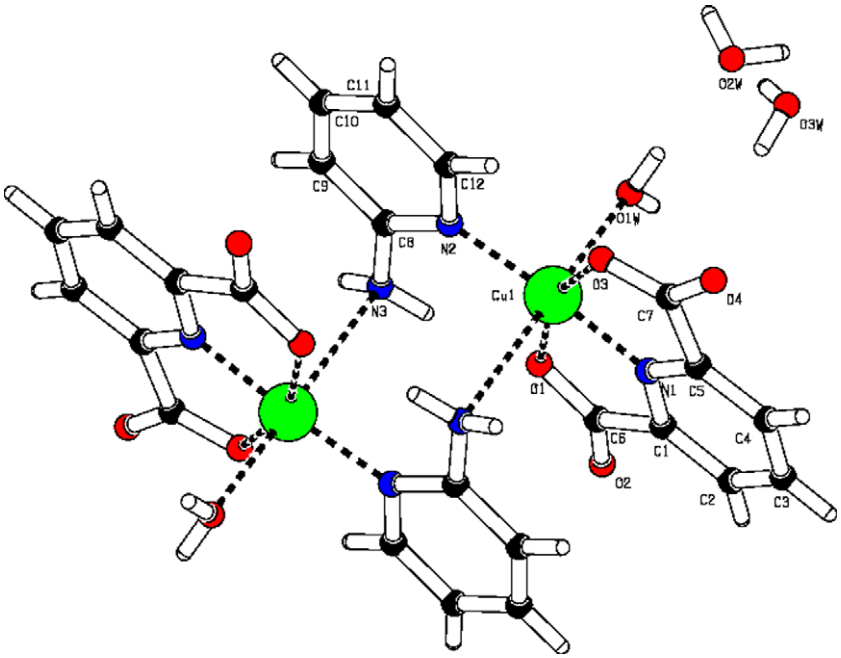

Fig. 2. An ORTEP drawing of **1** with intra- and intermolecular interactions.

vibrations of the coordinated 2-aminopyridine ligand. The relatively weak band at 3098 cm^{-1} is due to ν(CH) vibrations of aromatic rings. The carboxylate groups exhibit strong bands in the region 1690–1570 cm^{-1}. In the Cu(II) complex **1**, these strong bands were shifted and broadened with respect to the corresponding ones in the free dipicolinic acid. The present bands of the carboxylate COO^- group are reflected by IR spectrum of the asymmetric (ν_{as}) and symmetric (ν_s) stretching vibrations at 1660 and 1494 cm^{-1}, respectively. In addition, the differences between the asymmetric and symmetric stretches of the carboxylate groups of **1**, Δ = 166 cm^{-1}, suggest a monodentate binding of the carboxylate group to the metal ion [40]. The strong absorption bands at 1617 and 1566–1592 cm^{-1} are attributed to the ν(C=N) and ν(C=C) vibrations in the ligands, respectively [41]. The ν(C–O) vibrations were observed at 1079, 1275 and 1358 cm^{-1}, as indicated in [42–44]. The ring wagging vibrations of the pyridine groups are also observed at 677 and 760 cm^{-1}. The weak bands at 593 and 432 cm^{-1} are from the Cu–N and Cu–O vibrations, respectively, of complex **1**.

3.2. Crystal structure of $[Cu(\mu\text{-ap})(dipic)(H_2O)]_2{\cdot}4H_2O$ (**1**)

The molecular structure of **1**, with the atom labeling, and the intra- and intermolecular interactions, are shown in Figs. 1 and 2. The crystal packing diagram of **1** is shown in Fig. 3. The details of

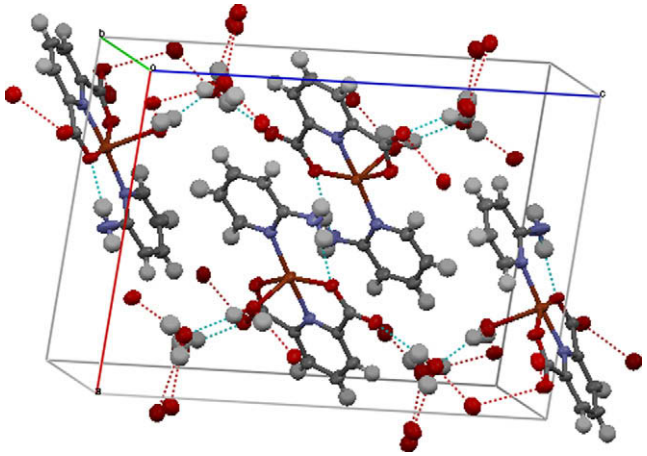

Fig. 3. Crystal packing diagram of **1**.

the crystal structure solution are given in Table 1, whereas the selected bond lengths and angles, and hydrogen bonding geometries are listed in Tables 4 and 5, respectively. The compound crystallizes in the monoclinic $P2_1/c$ space group. The asymmetric unit contains one dipic ion, one ap molecule, one Cu(II) ion, one coordinated water molecule and two uncoordinated water molecules (Fig. 1). The value of the structural index τ is 0.26 and the coordination environment of the Cu(II) atom is best described as a distorted square-pyramid [45]. The penta-coordinated central Cu(II) ion resides on a centre of symmetry comprising two N atoms, one from dipic (N1) and one from the ap ring (N2), two carboxylate O atoms from dipic (O1 and O3) and one O atom from water (O1w). Two N atoms from two different ligands, dipic and ap, fulfill the apical positions with Cu–N distances of 1.9228(17) and 1.9797(17) Å for Cu–N1 and Cu–N2, respectively, and the bond distances are similar to the those found in other related Cu(II) complexes [5,46,47]. The Cu–O bond distances are 2.0533(16) and 2.0543(17) Å, observed from the carboxylate coordination to the center metal ion, and are well consistent with those observed in the literature data [5,44,45,48]. The Cu–O1w bond distance, arising from coordination of the water molecule to the central metal ion, is 2.2776(19) Å, which is much longer than the Cu–O (carboxylate) bond distances.

In the symmetric unit, the distances between the two bilateral pyridine rings are in the range 3.326(3)–3.584(3) Å and these distances are categorized as π–π stacking (Fig. 2). These values are close to the distance between the layers in the structure of graphite. 2-Aminopyridine coordinates the Cu(II) ion through the nitrogen of the ring (N2) (1.9797(17) Å) and the amino group (N3) also participates in coordination with a long distance to combine the asymmetric units (2.918(3) Å). This is categorized as a van der Waals interaction which reduces the molecular volume and thus facilitates the packing in the crystal.

Hydrogen bonds between the carboxylate group and water molecules play important roles in stabilizing the crystal structure. The ranges of the D–H···A angles and those of the H···A and D···A distances indicate the presence of strong and weak hydrogen bonding

Table 3
IR spectral data of **1** (cm^{-1})[a].

[a] Chloramphenicol for bacteria as antibacterial standard.
[b] Ketoconazole for yeast as antifungal standard.

(Table 5). Two uncoordinated water molecules in the asymmetric unit have no symmetry center; hence they could not be located in the second half of the symmetric unit (Figs. 2 and 3).

3.3. UV–Vis spectrum, magnetic susceptibility and conductivity

The electronic spectra of **1** and the free ligands, ap and H_2dipic, were recorded in the solid state with KBr and in solution at a 1×10^{-3} M concentration at room temperature (Fig. 4). In the solid state absorption spectra of the free ligands there are similar absorption peaks (234 and 298 nm for ap, 230 and 265 nm for H_2dipic) due to the π–π^* transitions. Characteristic π–π^* transitions are in the spectrum of **1** (208, 218, 263 and 272 nm) with the same profiles as the free ligands. These π–π^* transition bands for all compounds are located in two regions, 220 and 270 nm, and are red-shifted in the solution spectra. (Fig. 4a–c and Table 6). The absorption bands profiles of the solution UV–Vis studies are similar to those absorption maxima of the corresponding ligands and complex **1** in the solid state. All the π–π^* transition bands for the ligands and the copper(II) complex in water and DMSO are observed in the range 290–315 nm (Fig. 4b and c and Table 6).

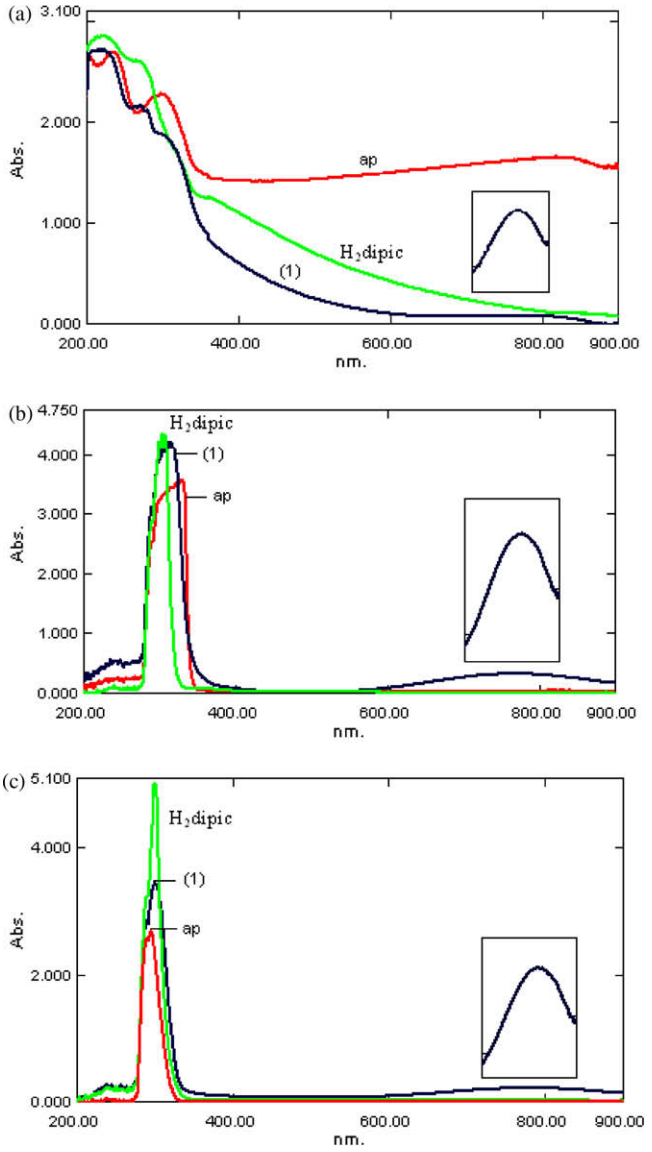

Fig. 4. UV–Vis spectra of complex **1** and the free ligands, ap and H_2dipic, (a) in the solid state phase (KBr), (b) in water, and (c) in DMSO.

Table 6
Optical properties of complex **1** and the free ligands, ap and H_2dipic, in the solid state phase (KBr), water and DMSO.

	λ_{max} (nm) (ε (M^{-1} cm^{-1}))		
	ap	H_2dipic	**1**
Solid		265	777
	298	230	272
	234		263
			218
			208
Water	295 (2678)	299 (10 000)	783 (212)
	290 (2561)		300 (3456)
DMSO	330 (3587)	303 (4340)	768 (325)
	315 (3556)		313 (4229)
			304 (4119)

The bands for the d–d transitions show a similar pattern at the maxima 777 nm in the solid state, 783 nm in water and 768 nm in DMSO for the copper(II) complex and suggest that the Cu(II) ion has the characteristics of a penta-coordinated copper complex with distortion (Fig. 4a–c) [49]. All the data which we obtained from the electronic spectra of the solutions do not show any marked differences from that of the solid, so it may be assumed that the bonding modes of the ligands as well as the geometry of the complex do not change in solution [50].

The room temperature magnetic moment of the Cu(II) complex is 1.63 BM per Cu(II) ion in the crystal structure, indicating the presence of one unpaired electron. The conductivity in DMSO is 1.8 Ω^{-1} cm^2 mol^{-1}, which indicates that complex **1** is non-ionic [51]. This result shows that 2,6-pyridinedicarboxylic acid coordinates to the Cu(II) ion as 2,6-pyridinedicarboxylate to form a neutral coordination compound.

3.4. Thermal analysis of [Cu(μ-ap)(dipic)(H_2O)]$_2$·4H_2O (**1**)

Fig. 5 shows the TG-DTG and DTA curves of complex **1**. The first stage, an endothermic peak (DTG_{max} = 97.4 °C) between 30 and 110 °C, corresponds to the loss of the 6 moles of crystal water molecules (found 14.40, calcd. 14.33%). The second stage, an endothermic peak (DTG_{max} = 269.6 °C) between 110 and 280 °C, corresponds to the loss of the 2 moles of 2-aminopyridine molecules (found 24.90, calcd. 24.95%). Two 2,6-pyridinedicarboxylate ions are decomposed in the third stage between 280 and 369 °C with DTG_{max} at 293.5 and 302.3 °C (found 44.09, calcd. 44.28%). The final decomposition product was CuO, identified by IR spectroscopy (found 20.8%, calcd. 21.1%).

3.5. Biological activity

A panel of selected human microbial pathogens were used to evaluate the effects of the starting materials and the resulting crystal complex. A microdilution assay was used with Ketoconazole and Chloramphenicol as standard antimicrobial agents. The Gram positive and negative bacteria were found to be more resistant when compared with the tested yeasts, where better inhibitory concentrations were observed, as listed in Table 2. The MIC values were determined as 0.0625–0.25 mg/mL, relatively good inhibitions when compared with a standard antifungal agent. The variation in the effectiveness of different compounds against different organisms depend either on the impermeability of the cells of the microbes or the difference in the ribosomes of the microbial cells [52,53].

The preliminary radical scavenging assay resulted in a low activity range, suggesting that these compounds are not of an antioxidative nature in the DPPH assay. However it is also worthwhile to evaluate other antioxidant assays. Compounds such

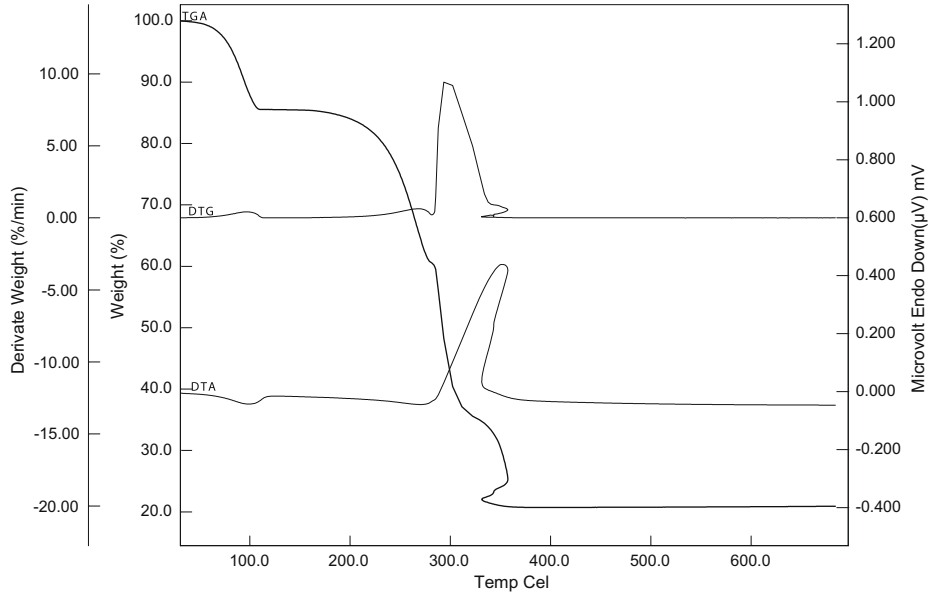

Fig. 5. The TG-DTG and DTA curves of **1**.

as [Cu(L1)(L′)Cl2]·3H2O L1 = 2,6-pyridinedicarboxaldehydebis(*p*-hydroxyphenylimine), L′ = 2-aminopyridine and [Cu(L2)(L′)Cl2]·H2O L1 = 2,6-pyridinedicarboxaldehydebis(*o*-hydroxyphenylimine), L′ = 2-aminopyridine were inactive or less active against some Gram positive and Gram negative bacteria [54]. M(L)Cl2 L = *N*,*N*-diethylpiperazinyl,2,6-pyridinedicarboxylate) and the ligand were also screened against various pathogens in order to study their antibacterial action [55]. The results revealed that the Cu(II) complex has activity comparable with the reference drugs gentamycin and flucanzole. The antibacterial results evidently show that the activity of the ligand becomes more pronounced and significant when coordinated to the metal ion. This enhancement in the activity was suggested to be possibly due to an efficient diffusion of the metal complexes into the bacterial cell or interaction with the bacterial cell walls [55].

4. Conclusions

In this present work, a Cu(II) complex with mixed ligands was prepared for the first time. The Cu(II) ion resides on a centre of symmetry in a distorted square-pyramidal coordination environment comprising two N atoms, one from dipic (N1) and one from the ap ring (N2), two carboxylate O atoms from dipic (O1 and O3) and one O atom from water (O1w). Intermolecular N–H···O and O–H···O hydrogen bonds and π–π stacking interactions seem to be effective in the stabilization of the crystal structure. Elemental analyses and all measurements show good agreement with the structure. The free ligands and the Cu(II) complex possess antifungal activity against *Candida* sp. The preliminary biological evaluation suggests that derivatives of such complexes are worthwhile for further antifungal *in vitro* and *in vivo* tests.

Fig. 1. Ligands under discussion in this paper.

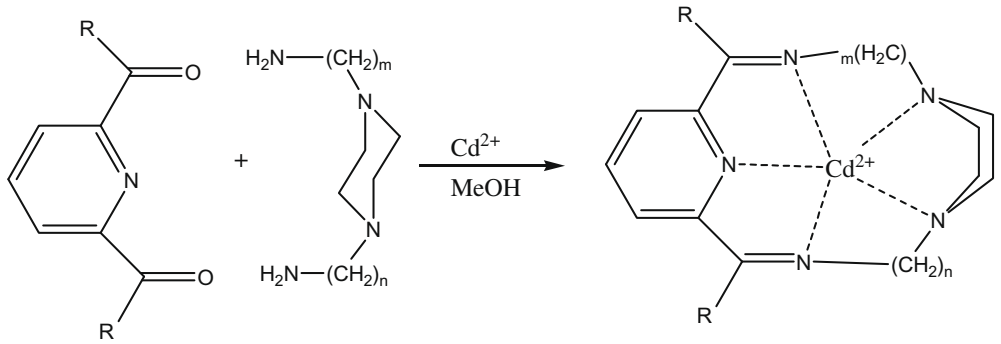
2. Experimental

2.1. Starting materials

2,6-Pyridinedicarbaldehyde was prepared according to the literature method [19]. N,N′(2-aminoethyl)(3-aminopropyl)piperazine was synthesized according to the literature method [18]. 2,6-Diacetylpyridine, N,N′-bis(3-aminopropyl)piperazine, 2-aminoethyl piperazine and the metal salts were commercial products (from Merck, Aldrich and Fluka) and were used without further purification. Solvents were of reagent grade purified by the usual methods.

Caution! Perchlorate salts are potentially explosive. Only small amount of material should be prepared and handled with great care.

2.2. Instrumentation



Elemental analyses were performed in a Carlo-Erba EA microanalyser. FT-IR spectra in the 4000–400 cm^{-1} region were recorded from KBr pellets on Bruker VECTOR 22 and Perkin–Elmer GX spectrophotometers. FAB mass spectra were recorded using a Kratos-MS-50T spectrometer connected to a DS90 data system using 3-nitrobenzyl alcohol as the matrix. Conductivimetry measurements were carried out in 10^{-3} mol dm^{-3} dimethylformamide solutions at 20 °C using a CARISON GLP32 conductivimeter. ^1H and ^{13}C NMR spectra were recorded on a Bruker 300 and 400 MHz using DMSO as solvent.

2.3. X-ray crystal structure determination

X-ray data for $[CdL^4|(NO_3)(H_2O)]^+$ was performed on STOE IPDS-II two circle diffractometer, using graphite monochromated Mo Kα X-ray radiation (λ = 0.7107 nm). The data collection was performed at room temperature using the ω-scan technique and using the STOE X-AREA software package [20]. The crystal structures were solved by direct methods [21] and refined by using X-STEP32 crystallographic software package [22]. All of the non-hydrogen atoms were refined anisotropically. All of hydrogen atoms were located in ideal positions. X-ray data for $[CdL^2Cl]^+$ were measured on a Bruker Smart 1000 CCD diffractometer at CACTI (Universidade de Vigo) at 20 °C using graphite monochromated Mo Kα radiation (λ = 0.71073 Å). All data were corrected for Lorentz and polarization effects. Empirical absorption corrections were also applied for all the crystal structures obtained [23]. Complex scattering factors were taken from the program package SHELXTL [24]. The structures were solved by direct methods which revealed the position of all non-hydrogen atoms. All the structures were refined on F^2 by a full-matrix least-squares procedure using anisotropic displacement parameters for all non-hydrogen atoms. Crystal data and structure refinement for both complexes are shown in Table 1.

2.4. Computational method

The geometries of the ligands, L^2 and L^4 and their Cd(II) complexes in the gas phase were fully optimized at DFT (B3LYP) [25] level of theory using the GAUSSIAN 98 set of programs [26]. The ligands were studied using by two different 6-31G* and lanl2dz basis sets [27]. The latter basis set was also used for calculation of the complexes. The standard 6-311+G* basis set was also used for single-point calculations on the structure of ligands derived from above calculations. Vibrational frequency analyses, calculated at the same level of theory, indicate that all optimized structures

are at the stationary points corresponding to local minima without any imaginary frequency. The initial atomic coordinates for DFT calculations were derived from X-ray data.

2.5. Synthesis of complexes

2.5.1. General procedure

2.5.1.1. Method A. A solution of NaOH (2 mmol) in absolute ethanol (10 mL) was added to a suspension of the N,N′(2-aminoethyl)(3-aminopropyl)piperazine tetrahydrochloride (0.5 mmol) in absolute ethanol (10 mL). The mixture was stirred at room temperature for a few minutes then filtered, and the precipitate was washed well with absolute ethanol (10 mL).The washings and the filtrate were

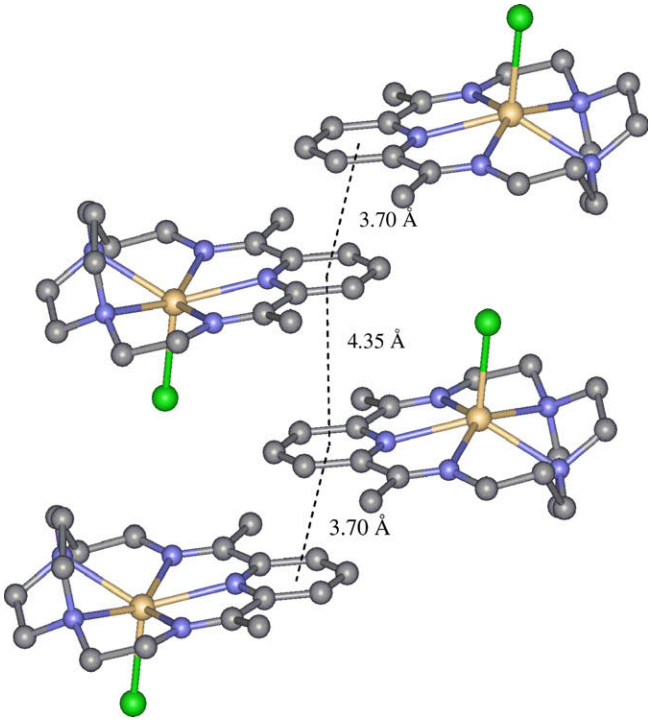

Fig. 3. The π,π-interactions in the cation $[CdL^2Cl]^+$.

combined and this solution was added dropwise to a hot solution of $Cd(ClO_4)_2{\cdot}6H_2O$ (0.5 mmol) and 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde (0.5 mmol) in absolute methanol (20 mL), over a period of 2 h. After refluxing the solution for 24 h it was filtered. Crystalline compound was obtained by slow diffusion of diethyl ether vapor into the MeOH/MeCN solution of the above solid.

2.5.2. $[CdL^1Cl]ClO_4{\cdot}H_2O$ (**1**)

Yield: 0.198 g (36%), *Anal.* Calc. for $C_{16}H_{25}CdCl_2N_5O_5$: C, 34.9; H, 4.6; N, 12.7. Found: C, 35.3; H, 4.4; N, 12.9%. IR (KBr, cm^{-1}): 3442, 1659, 1643 $\upsilon_{(C=N)}$, 1589, 1450 [$\upsilon_{(C=C)}$ and $\upsilon_{(C=N)py}$], 1089, 623 cm^{-1} $\upsilon(ClO_4^-)$, FAB-MS, (positive FAB in 3-nitrobenzyl alcohol): m/z (%), $[Cd\ L^1Cl]^+$, 434(100%). Λ_M/Ω^{-1} cm^2 mol^{-1} (in DMF): 120 (2:1).

2.5.3. $[CdL^2Cl](CH_3OH)ClO_4{\cdot}H_2O$ (**2**)

Yield: 0.230g (40%), *Anal.* Calc. for $C_{19}H_{31}CdCl_2N_5O_6$; C: 37.5; H: 5.1; N: 11.5. Found: C, 37.1; H, 4.9; N, 11.7%. IR (KBr, cm^{-1}): 3445, 1652, 1630($_{C=N}$), 1586, 1456 [$\upsilon_{(C=C)}$ and $\upsilon_{(C=N)py}$], 1096, 623 cm^{-1} $\upsilon(ClO_4^-)$, FAB-MS, (positive FAB in 3-nitrobenzyl alcohol): m/z (%): $[Cd\ L^2Cl]^+$, 462(100%). Λ_M/Ω^{-1} cm^2 mol^{-1} (in DMF): 146 (2:1).

2.5.3.1. Method B. A solution of N,N′-bis(3-aminopropyl)piperazine(0.5 mmol) in MeOH(10 mL) was added dropwise to a hot solution of $Cd(NO_3)_2{\cdot}6H_2O$ or $Cd(ClO_4)_2{\cdot}6H_2O$ (0.5 mmol) and 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde (0.5 mmol) in absolute methanol (20 mL) over a period of 2 h. After refluxing the solution for 24 h it was filtered whilst hot and $NaClO_4$ (1 mmol) was added to the filtrate. Crystalline compound (**4**) was obtained by slow diffusion of Et_2O vapor into the methanol solution of the above solid.

2.5.4. $[CdL^3](ClO_4)_2$ (**3**)

Yield: 0.230g (38%), *Anal.* Calc. for $C_{17}H_{25}CdCl_2N_5O_8$; C, 33.4; H, 4.1; N, 11.5. Found: C, 33.4; H, 4.4; N, 11.7%. IR (KBr, cm^{-1}): 3441, 1650 $\upsilon_{(C=N)}$, 1590, 1465, [$\upsilon_{(C=C)}$ and $\upsilon_{(C=N)py}$], 1097, 623 cm^{-1}

3. Results and discussion

3.1. Synthesis and characterization

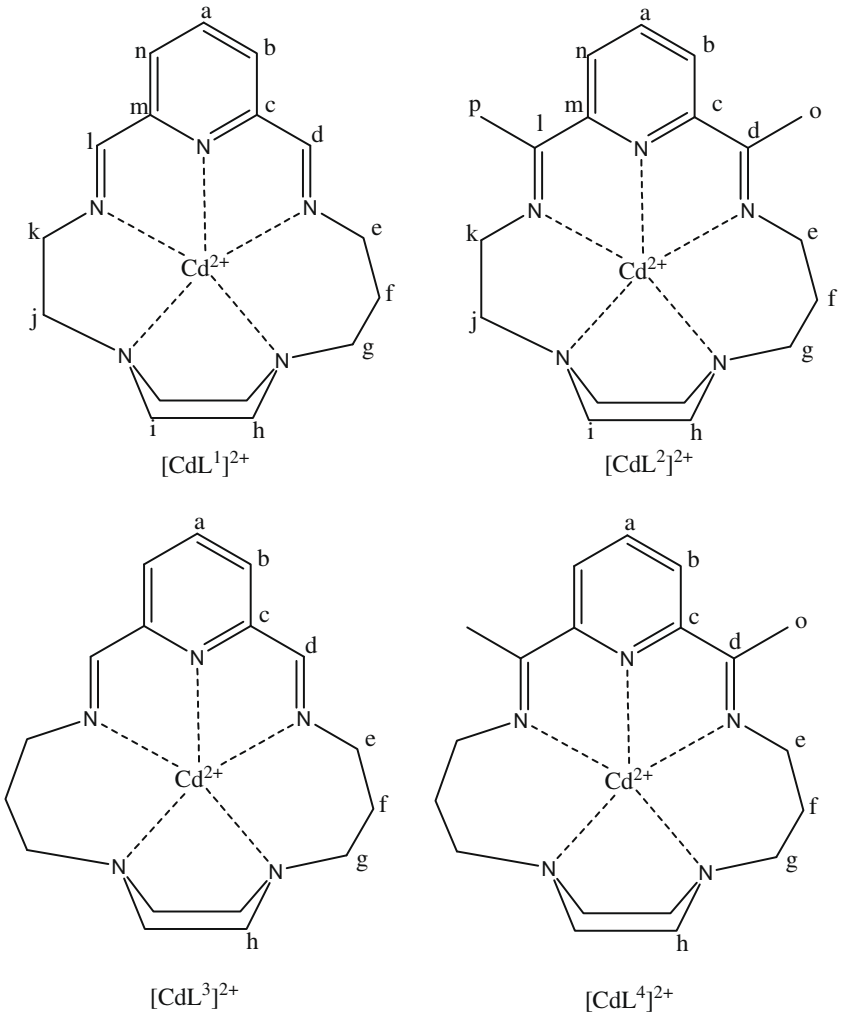
The diimine macrocyclic complexes were synthesized by the metal templated cyclocondensation of 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde and the amines N,N′-bis(3-aminopropyl)piperazine and HCl salt of N,N′(2-aminoethyl)(3-aminopropyl) piperazine in refluxing methanol in the presence of appropriate cadmium(II) salts. The complexes were characterized by elemental analysis, IR, NMR (^{1}H, ^{13}C, DEPt, COSY and HMQC) and FAB-MS. The X-ray structure analysis of $[CdL^2Cl](CH_3OH)ClO_4$ and $[CdL^4(NO_3)(H_2O)]ClO_4$ were carried out.

All complexes exhibit a υ(C=N) vibration in the range 1633–1659 cm^{-1} correspond to the imine C=N, and also bands at *ca.* 1600 and 1450 cm^{-1} associated with $\upsilon_{(C=N)py}$ and $\upsilon_{(C=C)}$ vibrations from the pyridine and phenyl rings [28] are present in the spectra, but no bands for the free carbonyls or primary diamines are observed indicating that complete condensation has occurred. Individual spectra are consistent with the presence of water, or other solvent molecules when indicated to be present from the microanalytical data. For the perchlorate complexes, absorptions attributable to ionic perchlorate were found at approximately 1100 and 625 cm^{-1} [29]. The lack of splitting of these bands suggests that the perchlorate anions are not coordinated [30]. The molar conductance values of the complexes measured in dimethylformamide lie in the range reported for 2:1 electrolytes in this solvent [31]. FAB mass spectrometry provided further evidence for cyclocondensation and the formation of the macrocyclic complexes of L^1, L^2, L^3 or L^4. The most intense peak in the spectrum of each complex is observed at *m*/*z* 434, *m*/*z* 462, *m*/*z* 512 and *m*/*z* 540 corresponding to $[CdL^1(Cl)]^+$,$[CdL^2(Cl)]^+$,$[CdL^3](ClO_4)^+$and $[CdL^4](ClO_4)^+$, respectively.

3.2. X-ray crystal structure

The crystal structure of the two Cd(II) complexes with formula $[CdL^2Cl](CH_3OH)ClO_4$ and $[CdL^4(NO_3)((H_2O)]ClO_4$ have been determined by single-crystal X-ray diffraction. The projection view of the molecular structures of the cationic unit present in the complexes with non-hydrogen atoms represented by 50% thermal ellipsoids are shown in Figs. 2 and 4, respectively. Selected bond lengths and bond angles relating the coordination environment of the metals in $[CdL^2Cl](CH_3OH)ClO_4$ and $[CdL^4(NO_3)(H_2O)]ClO_4$ are shown in Table 2.

The $[CdL^2Cl](CH_3OH)ClO_4$ complex crystallizes in the monoclinic $P_{2(1)/c}$ space group and shows that the metal atom is six coordinated in a slightly distorted pentagonal pyramidal geometry, with the metal ion into the macrocyclic cavity, five nitrogen atoms from the ligand lying in a approximately pentagonal plane (rms 0.184) and one Cl ion occupying the axial position. A similar six coordinate geometry has been found for other Cd(II) complexes with N_5 macrocyclic ligands [16].Then, the ligand shows a nearly plane conformation, with the Cd(II) ion 0.553 Å out of the plane formed by the five N atoms. The sum of the five N–Cd–N chelate angles (350.8°) is near 360° for an ideal planar structure. The five Cd–N bond lengths are in the range 2.345–2.434 Å, affording an average Cd–N bond distance of 2.392 Å. The perchlorate ion is non-coordinating reflecting the low coordination ability of this anion.



Analysis of short intermolecular interactions reveals the presence of π,π-interactions between the pyridine rings of adjacent ligands (see Fig. 3) giving rise to columnar pyridyl stacks. The pyridine rings involved in the columns are parallel, showing distances between centroids alternatively of 3.70 and 4.32 Å. The planes containing these aromatic groups are 3.44 and 3.45 Å, respectively. No interactions between the chains are observed.

The $[CdL^4(NO_3)(H_2O)]ClO_4$ complex crystallizes in the orthorhombic, $P2_12_12_1$ space group and shows that the metal atom is seven coordinated in a pentagonal bipyramidal geometry, arising from coordination by the five N atoms of the macrocycle with the axial positions being occupied by two oxygen atoms from a water molecule (O(1)) and a monodentate nitrate anion (O(2)). A similar six coordinate geometry has been found for other Cd(II) complexes with N_5 macrocyclic ligands [16].

As in the previous complex, the ligand shows a nearly plane conformation. The rms of the plane formed by the five N atoms is 0.122, showing that these atoms are almost coplanar, with the Cd(II) ion 0.031 Å out of this plane. The sum of the five N–Cd–N

Scheme 2. Schematic structures of the $[CdL^n]^{2+}$ cations showing the lettering scheme for NMR assignments.

chelate angles (360.64°) is almost 360° for an ideal planar structure. The five Cd–N bond lengths are in the range 2.33–2.50 Å, affording an average Cd–N bond distance of 2.45 Å. The O(1) and O(2) donor atoms are sited *trans* to the macrocyclic plane, with an angle O(1)–Cd–O(2) of 167.4(2), near to 180°. The pyridine nitrogen atom provides the shortest bond to the Cd atom in both cases. An uncoordinated perchlorate anion balances the ionic charge of the complex cation.

The hydrogen atoms belonging to the bounded water molecule have been encountered and they establish hydrogen bonds interactions with adjacent perchlorate and nitrate anions: [O1–H1C···O4 = 2.180 Å, 166.07°, O1-H1D···O7 = 1.768 Å, 167.96°] (Fig. 5).

No intermolecular π,π-interactions have been observed in the net.

3.3. NMR studies

The ^1H and ^{13}C NMR data for all Cd^{2+} complexes dissolved in DMSO-d_6 are shown in Table 3, which uses the lettering scheme shown in Scheme 2. The ^1H and ^{13}C signals were assigned using one- and two-dimensional ^1H–^1H COSY, ^1H–^{13}C HMQC and DEPT spectra.

The NMR spectra of the complexes confirm the formation of fully condensed macrocyclic Schiff-base complexes. The ^1H NMR spectra of the Cd^{2+} complexes from the asymmetric ligands L^1 and L^2 are more complicated than those from the symmetric L^3 and L^4 ligands.

In $[CdL^1Cl]ClO_4{\cdot}H_2O$ the presence of two signals at *ca.* 8.75 and 8.91 ppm demonstrate the non-equivalence of the two imine protons in the molecule. The ^1H–^{13}C HMQC spectrum shows their correlation with two signals at 158.5 and 160.8 ppm in the ^{13}C NMR spectrum. Also, three signals corresponding to the three aromatic protons of the pyridine rings are observed in the aromatic region of the spectrum. In the aliphatic region of the ^1H NMR spectrum seven signals are observed due to the CH_2 protons belonging to the ethylenic and propylenic protons of the links and also to the piperazine ring. Most of them appear as broad signals reflecting probably intramolecular conformational exchange processes in solution at this temperature. The ^1H NMR spectrum of $[CdL^2Cl](CH_3OH)$-$ClO_4{\cdot}H_2O$ shows that the three pyridine protons collapse in an overlapped broad signal at δ 8.48 ppm as has been previously reported for Nelson and co-workers [32]. The ^1H–^{13}C HMQC spectrum confirm the connectivity between that signal and the three corresponding ones in the ^{13}C NMR spectrum. Two signals due to the imine resonance at δ 163.13, 164.16 ppm in the ^{13}C NMR spectrum, shows again the non-equivalence of the two imine environments. Again, the presence of asymmetric ethylenic and propylenic linkages in L^2 gives rise to a complicated aliphatic region in the spectrum. As in the previous complex, independent signals are

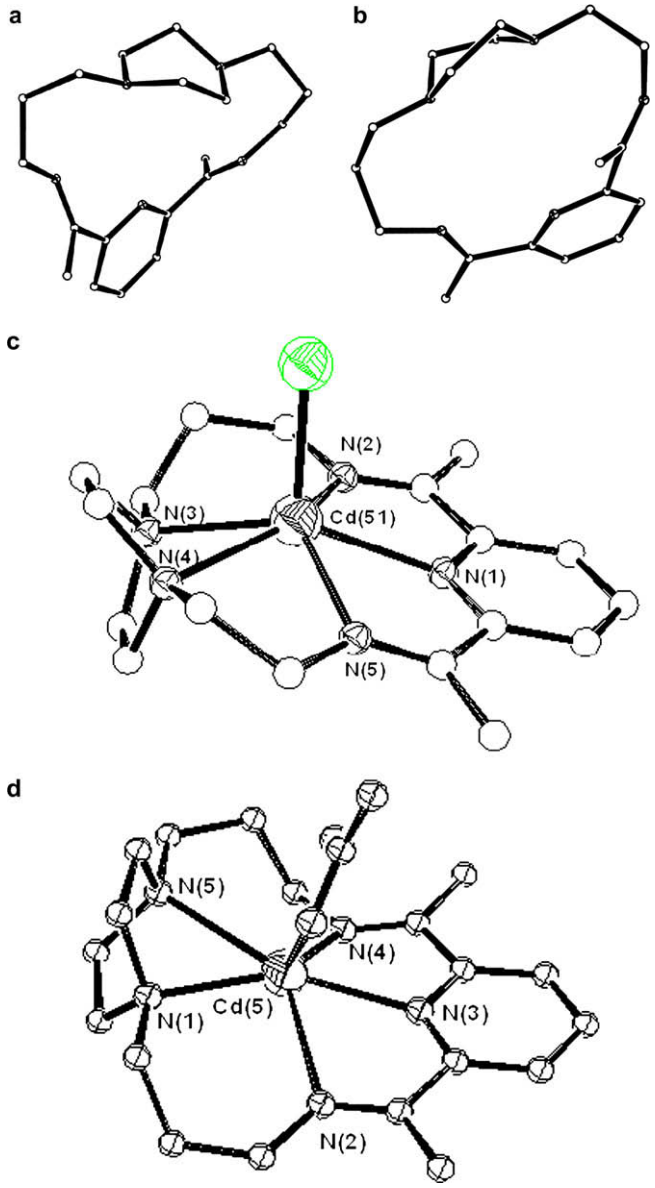

Fig. 6. The DFT optimized structures of the ligands, L^2 and L^4 and their Cd(II) complexes, (a) L^2 at B3lyp/6-31G*; (b) L^4 at B3lyp/6-31G*; (c) $[CdL^2Cl]^+$ at B3lyp/Lanl2dz; (d) $[CdL^4(NO_3)]^+$ at B3lyp/Lanl2dz.

observed for each of the protons of the molecule. The methylene protons of the piperazine ring are all appeared as triplet of doublets. Both the geminal coupling as well as coupling with the adjacent methylene groups (H_h–H_i) was confirmed by the ^1H–^1H COSY spectrum. The ^1H–^{13}C HMQC spectrum clearly shows that the four set of signals observed for latter methylene groups in the ^1H NMR spectrum are connected to two signals at v 47.67 and 50.83 ppm in the ^{13}C NMR spectrum. In this case, the methyl groups belonging to the 2,6-diacetylpyridine precursor appear at δ 2.52 and 2.54 ppm as two singlets, the ^1H–^{13}C HMQC spectrum showing connection with the signals at δ 15.39 and 15.91 ppm.

The ^1H NMR spectrum of $[CdL^3](ClO_4)_2$ shows the imine resonance at δ 8.79 ppm, demonstrating the equivalence of the two imine environments. That signal have two satellite peaks ($^3J \approx 28$ Hz for C_d–H_e) with intensities 1:6:1 due to coupling with neighboring $^{111/113}Cd$ at natural abundance (^{111}Cd, 12.81; ^{113}Cd, 12.22%). This coupling constant is smaller than those reported for other cadmium(II) macrocyclic or macroacyclic Schiff-base complexes [33,34]. The aliphatic region show the presence of the protons from the propylenic chains as broad signals showing again the presence of intermolecular conformational exchange processes, whilst the ethylenic chains protons of the piperazine rings are equivalents and they appear as two doublets due to the geminal coupling. For $[CdL^4(NO_3)(H_2O)]ClO_4$ the ^1H NMR spectrum is very clear. Only one signal appear in the aromatic region at δ 8.51 ppm, as has been observed in $[CdL^2Cl]\,ClO_4{\cdot}H_2O$, which is connected with the two corresponding ones in the ^{13}C NMR spectrum at δ 143.21 and 127.15 ppm. As in the previous complex the protons from the propylenic chains appear as broad signals, whilst two doublets due to the geminal coupling in ethylenic chains protons of the piperazine rings appear at δ 2.12 and 3.37 ppm overlapped with the water signal. The ^{13}C NMR spectrum shows also the imine resonance at δ 167.46 ppm demonstrating the equivalence of the two imine environments, and the signal at δ 16.90 ppm belonging to the methyl groups.

3.4. Ab initio and DFT studies

We have seen that Cd(II) metal ion is an effective template to promote the formation of ligands L^1–L^4 starting from 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde with two different amine precursors having piperazine molecules. We were interested to know whether the structures of ligands L^2 and L^4 in the metal complexes are different from their structures in the free state. For that, we have carried out theoretical calculations in order to determine the difference in energy between them. The DFT optimized structures of the ligands, L^2 and L^4 and the related Cd(II) complexes are shown in Fig. 6. Table 4 shows the comparison between some selected calculated bond lengths and angles for the metal complexes with the corresponding X-ray. The results show that in the case of $[CdL^2Cl]^+$ the gas-phase structure is very close to the solid state structure. Although some calculated bond lengths are somewhat different from the solid state values, there is a good agreement between the calculated bond angles and those from the solid state crystal structure. However, the optimized structure for $[CdL^4(H_2O)(NO_3)]^+$ complex was dissimilar with its solid state structure, due to an intramolecular hydrogen bond interaction between the coordinated H_2O molecule and one of the imine nitrogen atoms from the ligand. Thus, we removed the H_2O molecule from its solid state structure and used the resulting structure for present calculations. With it, we found a good agreement between theoretical and experimental data and the results are shown in Table 4.

It has been experimentally/theoretically confirmed that the chair conformation is usually more stable than boat conformation for saturated six-membered rings [35]. On the other hand, obviously, only a boat conformation is suitable for coordination of piperazine nitrogen atoms in ligands L^2 and L^4 to the metal ion (see Figs. 2, 4 and 6). As it can be seen in Fig. 6, due to the ring constraint, a distorted chair conformation is adopted by piperazine rings even in the optimized structures of uncoordinated free ligands. Furthermore, the constraint in macrocyclic rings affect the diacetylpyridine moiety, which shows the methyl groups significantly departed from the plane of pyridine unit in contrast to the structure found in metal complexes, which show the imine-pyridine-imine fragment planar as expected. Thus it seems that the cyclocondensation of the dialdehyde and diamine precursors to give rise the macrocylic ligands L^2 and L^4 in the absence of metal ion is hardly possible and the use of a metal template (Cd(II) in the present study) is necessary to achieve the formation of the ligands. The results of single-point calculations on optimized structure of ligands and on the structure of ligand in their optimized Cd complexes are given in Table 5. The data show that the rearrangement in the structure of ligands L^2 and L^4 from their free state to the corresponding structure in Cd complexes needs energy about 8 and 15.4 kcal/mol, respectively, for Lanl2DZ optimized

Table 5
Single point energies of ligands L^2 and L^4 at B3LYP/6-311+G* level of theory. Optimization were performed at various methods and assigned in column 1.

Level of optimization	L^2		L^4	
	E_{el} (Hartree)[a]	ΔE (kcal/mol)	E_{el} (Hartree)	ΔE (kcal/mol)
B3LYP/6-31G*	−976.06717	0	−1015.39721	0
B3LYP/LanL2DZ	−976.07701	+6.2	−1015.40113	+2.5
B3LYP/LanL2DZ[b]	−976.05433	+14.2	−1015.37253	+17.9

[a] The energy different with most stable structure.
[b] The structure of ligand in its optimized Cd complex is used for single-point calculations.

structures. We also performed the 6-31G* calculations to confirm the result of the Lanl2DZ optimized structure of the ligands in their free state (see Fig. 6). Obviously the optimized structures at LanL2DZ level of theory are less stable than those derived form 6-31G* calculations.

4. Conclusion

The Cd(II) metal templated cyclocondensation of four pentaaza macrocyclic ligands L^1–L^4 starting from 2,6-diacetylpyridine or 2,6-pyridinedicarbaldehyde with two different tetra-amines containing piperazine moiety have been successfully achieved. The crystal structure of $[CdL^2Cl](CH_3OH)ClO_4$ and $[CdL^4(NO_3)(H_2O)]ClO_4$ show the Cd(II) ion endo-macrocyclicly coordinated to the five N atoms from the molecule in slightly distorted pentagonal pyramidal and pentagonal bipyramidal geometries, respectively. It is interesting that in the presence of steric hindrance due to structural restriction of piperazine, which is confirmed by theoretical calculations, cyclocondensation has occurred in the presence of Cd metal ion and pentaaza macrocyclic complexes were produced.

5. Supplementary data

CCDC 672131 and 610457 contain the supplementary crystallographic data for $[CdL^2(Cl)](CH_3OH)ClO_4$ and $[CdL^3(NO_3)(H_2O)]ClO_4$. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. Procedure of synthesis and the coordination mode of the N_2O_2 donor Schiff base ligand [$\mathbf{H_2L}$].

complex were spectroscopically characterised. A single crystal X-ray diffraction study revealed the unusual structural aspects of **1**. Unlike the previously reported antiferromagnetically coupled copper(II) trinuclear complexes, there is a more abrupt decrease in $\chi_m T$ product observed for **1** at very low temperatures and this is attributed to weak antiferromagnetic inter-trimer interactions. Thus the cryomagnetic investigation supported the presence of inter-trimer as well as intra-trimer antiferromagnetic interactions in **1**.

2. Experimental

2.1. Materials

All solvents were of reagent grade and used without further purification. 1,3-diaminopentane and salicylaldehyde were purchased from Aldrich Chemical Company and were used as received. Copper perchlorate hexahydrate was prepared by treatment of copper carbonate (E. Merck, India) with 60% perchloric acid (E. Merck, India) followed by the slow evaporation on the steam bath. It was then filtered through a fine glass-frit and preserved in a $CaCl_2$ desiccator for further use.

2.2. Syntheses

Caution! Perchlorate salts are potentially explosive and should be used in small quantity and with much care.

2.2.1. Synthesis of the Schiff base Ligand [$\mathbf{H_2L}$]

The Schiff base ligand [$\mathbf{H_2L}$] was prepared by the reflux condensation of a methanolic solution of 1,3-diaminopentane (0.59 ml, 5 mmol) with 10 mmol salicylaldehyde (1.04 ml) shown in Scheme 1. The ligand was refluxed for 2 h when yellow coloured solution developed. The colour indicated the formation of the Schiff base. Slow evaporation of the resulting solution yielded shiny yellow crystalline Schiff base [$\mathbf{H_2L}$]. They were dried and stored in vacuo over $CaCl_2$ for subsequent use. *Anal.* Calc. for [$C_{19}H_{22}N_2O_2$]: C, 73.55; H, 7.09; N, 9.03. Found: C, 73.58; H, 7.11; N, 9.04%.

2.2.2. Synthesis of [$Cu_3(\mu$-$\mathbf{L})_2(ClO_4)_2$] [$Cu_3(\mu$-$\mathbf{L})_2(H_2O)(ClO_4)_2$] (**1**)

$Cu(ClO_4)_2{\cdot}6H_2O$ (0.56 g, 1.5 mmol) was dissolved in 20 ml methanol and warmed. About 10 mL of yellow methanolic solution of the Schiff base [$\mathbf{H_2L}$] (0.354 g, 1 mmol), was added to it dropwise. The mixture was allowed to stir for 2 h at 50 °C. The dark green solution was filtered and maintained at 22 °C for crystallisation by slow evaporation. After one week, green block shaped crystals suitable for X-ray crystallography were obtained. Crystals were isolated by filtration and were air-dried. *Anal.* Calc. for [$C_{37}H_{40}Cl_2Cu_3N_4O_{14}$]: C, 43.26; H, 3.90; N, 19.10. Found: C, 43.30; H, 3.92; N, 19.13%.

2.3. Physical measurements

The Fourier transform infrared spectra were recorded in the range 4000–400 cm^{-1} on a Perkin–Elmer RX I FT-IR spectrophotometer with solid KBr disc. The electronic spectra were recorded at 300 K on a Perkin–Elmer Lambda 40 (UV–Vis) spectrometer using HPLC grade acetonitrile as solvent with a 1 cm quartz cuvette in the range 200–800 nm. ^1H NMR spectra were recorded on a BRUKER 300 MHz FT-NMR spectrometer using trimethyl silane as an internal standard in $CDCl_3$. C, H, N microanalysis was carried out with a Perkin–Elmer 2400 II elemental analyser. Electrochemical measurement was performed on a VersaStat-PotentioStat II cyclic voltammeter using HPLC grade acetonitrile as solvent where tetrabutylammonium perchlorate was used as supporting electrolyte at a scan rate 50 mV/s. Platinum and saturated calomel electrode (SCE) were the working and the reference electrodes in the process, respectively. The magnetic susceptibility measurements were carried out in the temperature range 2–300 K with an applied magnetic field of 0.1 T on a polycrystalline sample of **1** (mass = 31.71 mg) with a Quantum Design MPMS-XL-5 SQUID magnetometer. The isothermal magnetization was performed on

the same sample at 2 K with magnetic fields up to 5 T. The susceptibility data were corrected for the sample holders previously measured using the same conditions and for the diamagnetic contributions of the salt as deduced by using Pascal's constant tables ($\chi_{dia} = -534 \times 10^{-6}$ emu mol^{-1}).

2.4. X-ray crystallography

The X-ray diffraction experiment was carried out at 100(2) K on a green block shaped single crystal (0.38 × 0.20 × 0.08 mm) of **1**. The crystal was mounted on a Bruker X8 Apex 2 CCD area diffractometer equipped with Mo Kα radiation (λ = 0.71073 Å). The lattice constants were refined by least-square refinement using 7542 reflections ($2.35° < \theta < 21.31°$), 9171 unique reflection (R_{int} = 0.0863). Structure solution and refinement based on 4644 observed reflections with $I > 2\sigma(I)$ and 579 parameters gave final R = 0.0716, wR = 0.1865 and S = 1.022. Data collection and data reduction were performed with the APEX 2 suite of programs [23]. All non hydrogen atoms were refined anisotropically by full-matrix least-squares based on F^2. The H atoms were generated geometrically (apart from H atoms bound to O2W which were located in the difference map with O–H distances restrained to 0.90(2) Å and all were included in the refinement in the riding model approximation. The components of the disordered ethyl groups (C45 and C45A, C46 and C46A) had relative occupancies refined to 69%:31%, respectively. Restraints were applied to the displacement parameters. 50% Occupancy was assigned as an estimate for ethyl C atoms C22 and C23 because full occupancy resulted in unreasonable displacement ellipsoids. However location of the second disordered ethyl group fragment which would be expected to be bound to C12 was not discernable (highest residual peak 1.156 e Å^{-3}). C–C bond distances in the ethyl groups were restrained to 1.50(2) Å. In the disordered perchlorate ion four of the five O atoms were assigned occupancies of 75%. The fifth retained full occupancy.

Selected crystallographic data, experimental conditions and some important features of the structural refinements of both the complexes are summarized in the Table 1.

3. Results and discussion

3.1. Fourier transform IR spectroscopy

The IR spectrum of **1** was analysed and compared with that of its free ligand **H_2L** in the region 4000–400 cm^{-1}. A strong sharp absorption band around 1631 cm^{-1} in the spectrum of the Schiff base ligand can be assigned to the C=N stretching. In the complex, this band is shifted to 1618 cm^{-1} upon complexation with the metal, which can be attributed to the coordination of the imine nitrogen to the metal centre [24–26]. The ligand shows a well-defined band at 3537 cm^{-1} due to O–H stretching which disappears in the complex, indicating the deprotonation of the Schiff base ligand upon complexation. The strong phenolic C–O absorption band at 1214 cm^{-1} observed in the spectrum of **H_2L** shifts to lower frequency at 1192 cm^{-1}, supporting the coordination of the deprotonated phenolic oxygen atoms to the metal centres in the complex [26]. A broad band at 3300–3450 cm^{-1} indicates that water is present in **1**. The characteristic bifurcated absorption band at 1098–1121 cm^{-1} in the spectrum of the complex indicates the presence of perchlorate anions. The ligand coordination to the metal centre is substantiated by a band appearing at 427 cm^{-1} which is mainly attributed to ν_{Cu-N} in the complex.

3.2. UV–Vis spectroscopy

UV–Vis spectra of the free ligand and **1** were recorded at 300 K in HPLC grade acetonitrile solution. The UV–Vis spectrum of the Schiff base ligand [**H_2L**] exhibits two charge transfer (CT) bands at 255 and 308 nm attributed to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions within the Schiff base ligand. In the spectrum of the complex the CT band at 255 nm remains intact, in agreement with the $\pi \rightarrow \pi^*$ transition of the Schiff base ligand. Another band at 340 nm is detected in the spectrum of **1**. The band at 308 nm observed in the spectrum of the free ligand [**H_2L**] is red shifted to 340 nm (in **1**) in form of ligand to metal charge transfer (LMCT) transition. Unlike the spectrum of the free ligand, much weaker and less well-defined broad bands are found in the spectrum of the complex at 650 and 600 nm which are assigned to the d–d transitions. The two different d–d bands are in good agreement with the presence of two different coordination environments in **1**. The band at 650 nm is associated with a copper(II) centre having square–pyramidal geometry and the d–d transition at 600 nm may be attributed to structurally well characterised square–planar copper(II) complexes [27].

3.3. ^{1}H NMR spectroscopy

^{1}H NMR spectroscopy has been used to extract information regarding the coordination mode of the ligand **H_2L** with the metal ion for **1**. It is generally seen that ^{1}H NMR spectra of the coordination complexes containing paramagnetic metal ions are broadened to some extent but for **1** fairly sharp and well-resolved spectrum was obtained which is probably due to sufficiently short electronic relaxation time [28–30]. Unlike the spectrum of **H_2L**, the chemical shifts of the hyperfine-shifted signals of **1** appeared within a short range 0 to +15 ppm. For **1** the signal due to the protons closer to the respective metal centres experience stronger paramagnetic effects and consequently they are most downfield shifted. The NMR proton numbering scheme of **H_2L** along with the ^{1}H NMR spectra of the ligand and the complex are represented in Fig. 1a and b. The ^{1}H NMR data are summarized in Table 2. In the NMR spectrum of the free ligand **H_2L** no broad peak was observed due to free amine protons in the region 5.0–8.0 ppm indicating that, both $-NH_2$ functions of the 1,3-diamine have undergone condensation with the

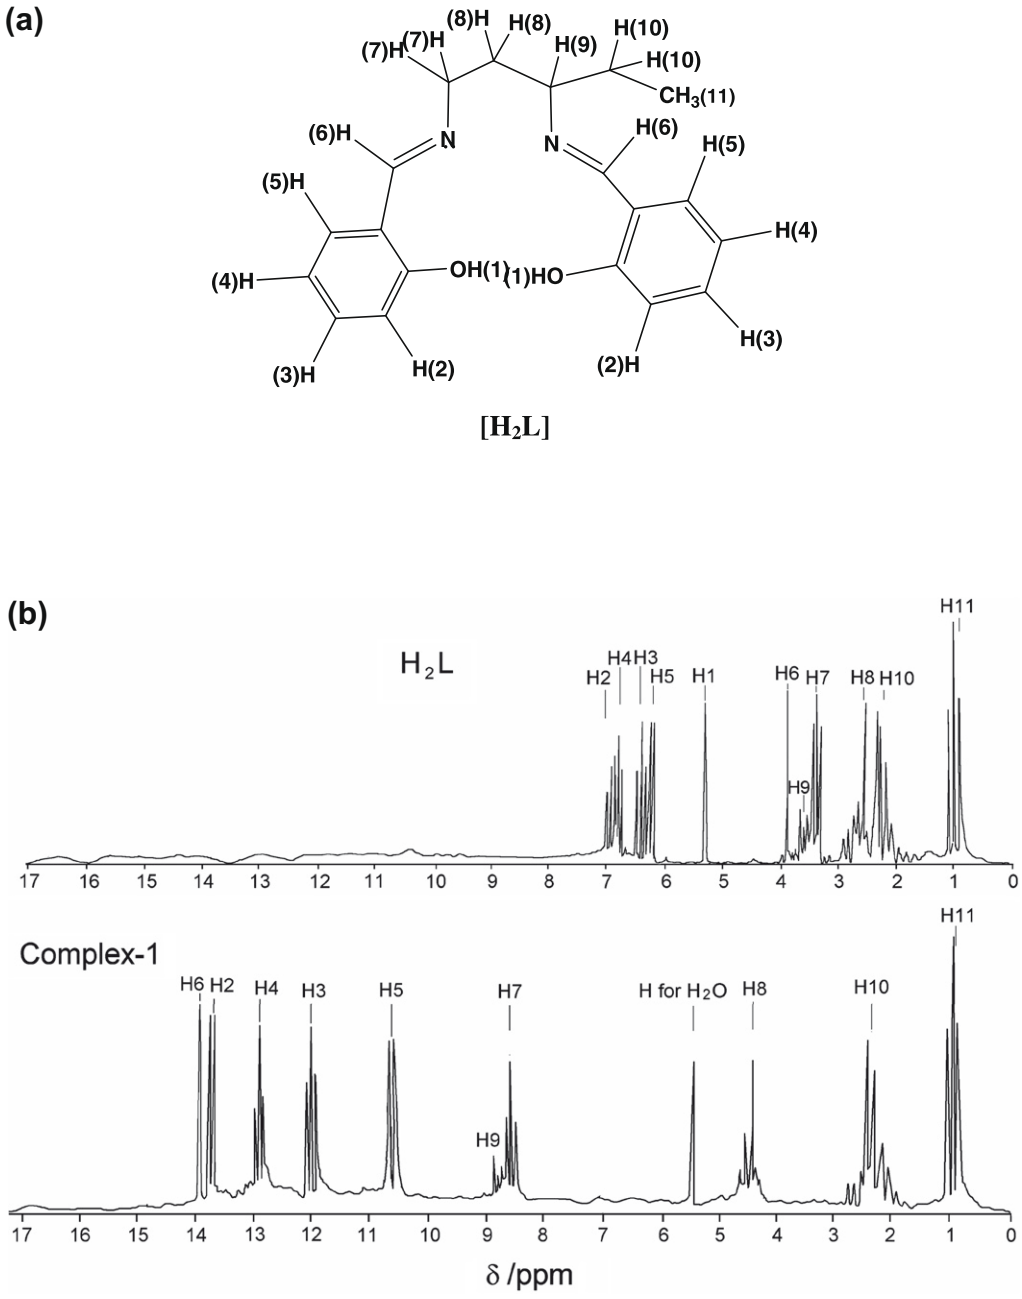

Fig. 1. (a) NMR proton numbering scheme of **H_2L**. (**b**) ^{1}H NMR spectra of **H_2L** and **1**.

Table 2
^{1}H NMR data for the **H_2L** and **1**.

Schiff base/complex	δ (in ppm)
H_2L	0.89 (3H, t, H11); 2.24 (2H, m, H10); 2.5 (2H, m, H8); 3.42 (2H, t, H7); 3.50 (1H, m, H9); 3.8 (2H, s, H6); 5.26 (2H, s, H1); 6.35(2H, d, H5); 6.41 (2H, t, H3); 6.80 (2H, t, H4); 6.85 (2H, d, H2)
1	0.89 (3H, t, H11); 2.24 (2H, m, H10); 4.5 (2H, m, H8); 5.5 (2H, s, H_2O); 8.52 (2H, t, H7); 8.8 (1H, m, H9); 10.55 (2H, d, H5); 11.91 (2H, t,H3); 12.90 (2H, t, H4); 13.75 (2H, d, H2); 13.9 (2H, s, H6)

carbonyl functional group of salicylaldehyde to result the Schiff base ligand **H_2L** [31]. The ^{1}H NMR spectra (Fig. 1) show that the signal due to the phenolic hydrogen (H1) of the free ligand **H_2L** (5.26 ppm) is absent in the spectrum of **1**. The imino proton (H6) is assumed to be significantly downfield shifted (10.1 ppm) due to the coordination of the Schiff base ligand in **1** through imine nitrogen atoms. The largest paramagnetic deshielding effect on H6 indicates that it is in the closest vicinity to the metal centre. The phenyl hydrogens also show significant chemical shifts [4.2 ppm (H5), 5.5 ppm (H3), 6.1 ppm (H4), 6.90 ppm (H2)] indicating the participation of the deprotonated phenolato oxygen in the coordination with the metal centres [31]. The ortho (H2) and para (H4) hydrogens are significantly downfield shifted due to large spin delocalization effect through π-bonding of the aromatic

ring. H2 being ortho to the coordinated phenolato oxygen, is closer to the metal centre and undergoes larger paramagnetic deshielding effect than H4. In **1** the methylene protons (H7) and methine proton (H9) both being very close to imine nitrogens show downfield shifts of 5.1 and 5.3 ppm, respectively from the free ligand values which are attributed to the coordination of the imine nitrogens to the metal centres. Unlike the spectrum of the free ligand the ^{1}H NMR spectrum of **1** contains a singlet at 5.5 ppm which can be assigned to the protons of the coordinated water molecules. The results obtained from the NMR spectra are in agreement with the structure obtained by the X-ray analysis.

3.4. Cyclic voltammetry

The electrochemical behaviour of **1** was studied in HPLC grade acetonitrile medium with tetrabutylammonium perchlorate as supporting electrolyte at a scan rate of 50 mV/s. Complex **1** shows a reductive response at −0.608 V versus SCE, which is assigned to $Cu^{II} \rightarrow Cu^{I}$ reduction and an oxidative response at −0.526 V versus SCE was assigned for $Cu^{I} \rightarrow Cu^{II}$ oxidation (Fig. S1: provided as Supplementary data). This reduction and oxidation are quasi reversible, characterised by a peak to peak separation (ΔE_p) of 82 mV which remain unchanged upon changing the scan rate. The anodic peak current (i_{pa}) is almost equal to the cathodic peak current (i_{pc}) as expected for a quasi reversible electron transfer process. The $E_{1/2}$ value for **1** is −0.57 V. The $E_{1/2}$ value and the quasi reversible nature of the cyclic voltammogram of **1** is in good agreement with that of the earlier reported doubly phenoxo bridged dicopper(II) complex $[Cu_2L^1(ClO_4)_2]\cdot 2CH_3OH\cdot 2H_2O$ (−0.52 V) [32].

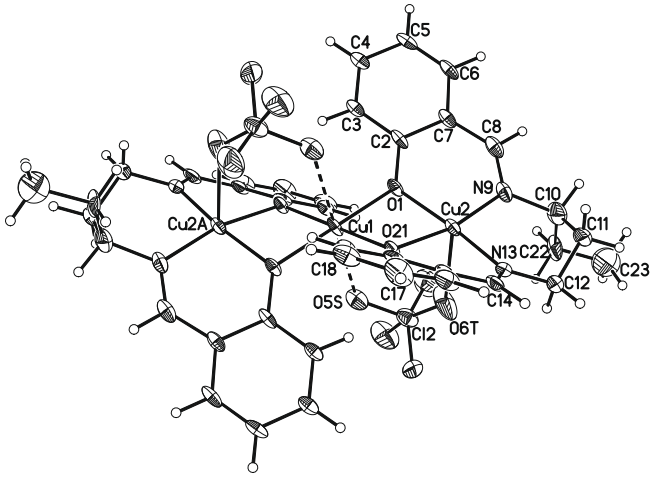

Fig. 2. ORTEP diagram of **I**. The label suffix A denotes the symmetry operation $x + 1/2, -y + 3/2$ used to generate this symmetry equivalent atom.

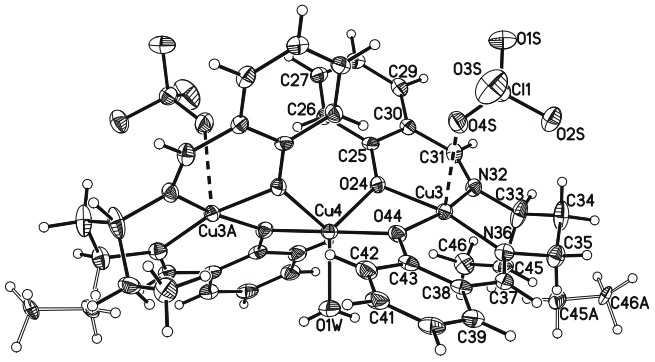

Fig. 3. ORTEP diagram of **II**. The label suffix A denotes the symmetry operation $x + 1, y, -z + 1/2$ used to generate this symmetry equivalent atom.

3.5. Description of the crystal structure of *1*

The asymmetric unit of **1** comprises two structurally independent trinuclear units $[Cu_3(\mu\text{-}\mathbf{L})_2(ClO_4)_2]$ (**I**) and $[Cu_3(\mu\text{-}\mathbf{L})_2(H_2O)(ClO_4)_2]$ (**II**) shown in Figs. 2 and 3, respectively. The main bond lengths and angles are summarised in Tables 3 and 4 and the H-bonding data are listed in Table 5. In the trinuclear units (**I** and **II**) there are two geometrically distinct copper(II) centres [Cu(1) and Cu(2) for **I** and Cu(3) and Cu(4) for **II**]. Cu(1) sits on a centre of inversion, while Cu(4) is positioned on a twofold axis. Thus **I** is constrained by crystallographic symmetry to be linear but **II** can be bent and is found in this case.

The trinuclear unit **I** is very similar to the previously reported trinuclear copper(II) complex $[Cu_3(\mu\text{-}\mathbf{L}')_2(ClO_4)_2]$ (**A**) [**L**′ = $OHC_6H_4CH{=}NCH_2{-}CH_2{-}CH_2N{=}CHC_6H_4OH$] [17], where the three copper(II) centres are held together by two doubly phenoxo bridged oxygen atoms of the deprotonated tetradentate Schiff base ligands $[\mathbf{L}]^{2-}$ and $[\mathbf{L}']^{2-}$, respectively (Fig. 2). In both trinuclear complexes (**I** and **A**) the respective Schiff bases behave as N_2O_2 donor ligands with two perchlorate ions coordinating with the two terminal copper atoms

[Cu(2), Cu(2A)] in a monodentate fashion in **A**, but in **I** the perchlorate ions appear bidentate, coordinating to the terminal Cu(2) and central Cu(1) centres. However, this perchlorate is disordered and it is one of the disordered atoms which bonds to Cu(2). The geometry of the terminal copper centres in both these complexes is best described as a distorted (4 + 1) (ONNO + O) square based pyramid with Addison parameters $\tau = 0.057$ for **A** and $\tau = 0.007$ for **I** ($\tau = 0$ corresponds to a perfect square pyramidal geometry and $\tau = 1$ to a perfect trigonal bipyramidal geometry). The four bonds constituting the basal plane of the external Cu(2) ions of **I** show very similar Cu–N and Cu–O bond distances [in the range 1.939(7)–1.956(5) Å]. The axial site is occupied by an oxygen atom of a coordinated perchlorate ion [Cu–O 2.395(9) Å]. The central copper atom in **I** is bound by four phenolato oxygens of the Schiff base ligands [Cu–O 1.952(5) and 1.960(4) Å] and can be described as having square planar coordination if the long Cu(1)–O(5s) [2.495(7) Å] contacts are not included.

The asymmetric unit of **1** contains a second independent bent trinuclear unit $[Cu_3(\mu\text{-}\mathbf{L})_2(H_2O)(ClO_4)_2]$ (**II**) where the three copper centres are also linked by doubly bridging μ-phenolato oxygen atoms of two units of the tetradentate N_2O_2 donor Schiff base ligands (Fig. 3). Unlike **I**, which is constrained to be linear by crystallographic symmetry, **II** is slightly distorted from linearity with a Cu(3)–Cu(4)–Cu(3) angle of 161.39(6)°. Additionally, the coordination environment of the two terminal Cu(3) centres and central Cu(4) centre in **II** are quite different to that in **I**. Although the terminal copper centres are very similar in **I** and **II** being square pyramidal and bound by the N_2O_2 donor atoms of the deprotonated Schiff bases and a terminally coordinating perchlorate anion, the central copper centres have different coordination environments. In **II** perchlorates do not bridge the terminal and central copper atoms, instead one water molecule coordinates to Cu(4) in addition to the four Schiff base oxygen atoms. The central Cu(4) atom has five coordinate trigonal bipyramidal geometry with an Addison parameter, $\tau = 0.917$. The equatorial sites of Cu(4) are occupied by two symmetry equivalent phenolato oxygen atoms [O(24)] and the coordinated water molecule [O(1W)]. The axial sites are occupied by the two remaining deprotonated phenolato oxygen atoms [O(44)] which also have the shortest Cu–O distances in that coordination sphere [Cu(4)–O(44), 1.935(6) Å; O(44)–Cu(4)–O(44)#2, 179.7(3)°, where #2 is the symmetry operation $-x+1, y, -z+1/2$].

A hydrogen bonded chain linking the trinuclear species **II** is formed between the bound water molecule and an uncoordinated solvent water molecule which in turn forms a OH···O hydrogen bond to the perchlorate anion bound to Cu(3) resulting in a double stranded chain running parallel to the *b* axis. Alongside, the trinuclear unit **I** forms parallel stacks and the coordinated perchlorate forms C–H···O hydrogen bonds with the Schiff base (Fig. 4). The benzene rings C(1)–C(6) overlap slightly with their symmetry equivalents in the neighbouring complex in the same stack but their centroids are too far apart for effective π–π-stacking.

3.6. Magnetic properties

The thermal variation of the molar magnetic susceptibility per two copper(II) trimers times the temperature ($\chi_m T$) for compound **1** shows a room temperature value of ca. 1.24 emu K mol^{-1} (Fig. 5), much lower than the spin only expected one for six non interacting copper(II), $S = 1/2$ ions (2.25 emu K mol^{-1}). On lowering the temperature, the $\chi_m T$ product shows a fast decrease that softens at low temperatures to reach a value of ca. 0.80 emu K mol^{-1} at ca. 50 K. At lower temperatures (below ca. 10 K) the $\chi_m T$ product shows a more pronounced decrease to reach a value of ca. 0.70 emu K mol^{-1} at 2 K (inset in Fig. 5). This behaviour clearly indicates that compound **1** presents a strong antiferromagnetic coupling, as deduced form the decrease in the $\chi_m T$ product already observed at room temperatures. The softening observed at low

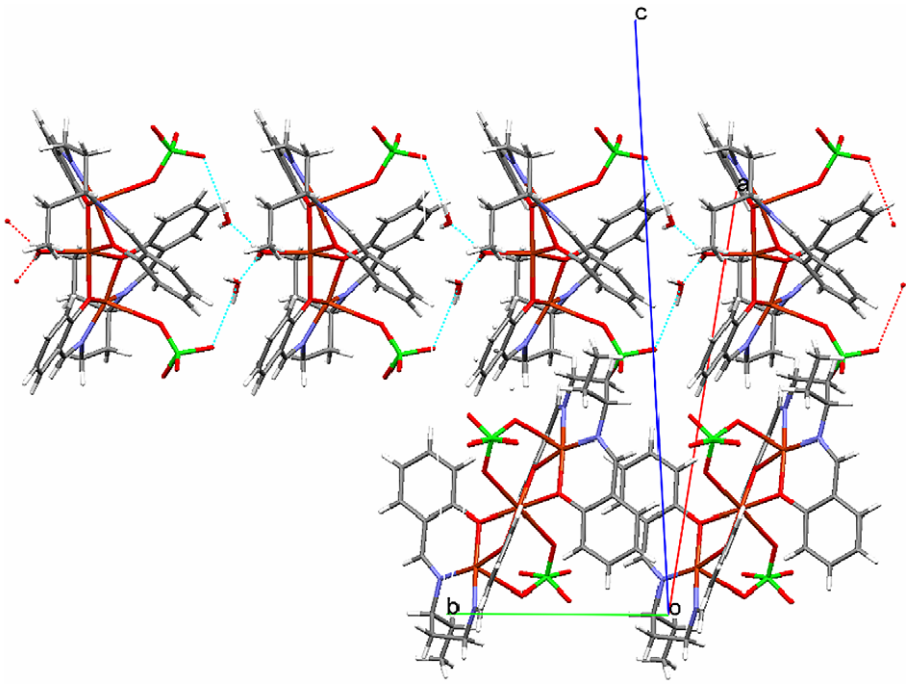

Fig. 4. Hydrogen bonded chains involving **I** alongside stacked molecules of **II** (hydrogen bonds drawn as dotted lines).

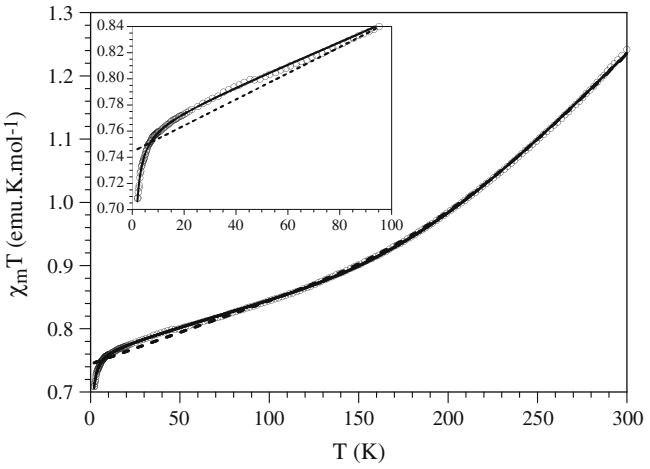

Fig. 5. Thermal variation of the $\chi_m T$ product per two copper(II) trimers for **1**. Inset shows the low temperature region. Solid and dashed lines represent the best fit to the $S = 1/2$ trimer model with and without inter-trimer interactions, respectively (see text).

temperatures suggests that this strong antiferromagnetic exchange does not lead to a diamagnetic spin ground state, in agreement with the expected behaviour for two independent antiferromagnetically coupled copper(II) trimers. Since each copper(II) trimer is expected to present an $S = 1/2$ spin ground state as a result of the intra-trimer antiferromagnetic coupling, the expected $\chi_m T$ value should be ca. 0.40 emu K mol^{-1} per copper(II) trimer (i.e., 0.80 emu K mol^{-1} for the two independent copper(II) trimers), in agreement with the experimental value. The more abrupt decrease observed at very low temperatures should therefore be attributed to weak antiferromagnetic inter-trimer interactions, as confirmed by the fitting results (see below). Since, as already mentioned, the structure of **1** shows the presence of two different copper(II) trimers, we have tried to fit the magnetic properties using a simple model containing the sum of two different $S = 1/2$ copper(II) linear trimers (the Hamiltonian is written as $H = -J_n[S_1S_2 + S_2S_3]$, where J_n is the intra-trimer exchange coupling constant of the trimer n, S_2 is the spin of the central copper(II) ion and S_1 and S_3 correspond to the terminal ones): [33]

$$\chi_{trim} = \frac{Ng^2\beta^2}{4kT}\frac{1 + e^{2x} + 10e^{3x}}{1 + e^{2x} + 2e^{3x}} \quad \text{with } x = J_n/kT \tag{1}$$

This model satisfactorily reproduces the magnetic data of **1** with $g = 1.992(1)$, $J_1 = J_2 = -327(2)$ K $= -227(1)$ cm^{-1} (dashed line in Fig. 5). Note that despite no restriction in the model used, the best values are obtained for $J_1 = J_2$. Although at high temperatures this simple model reproduces satisfactorily the magnetic properties of **1**, the low temperature behaviour is not so well reproduced, especially the sharp decrease observed below ca. 10 K (inset in Fig. 5). In order to better reproduce the magnetic behaviour of **1** at low temperatures, we have included a weak inter-trimer exchange interaction by using the molecular field approximation [34].

$$\chi'_{trim} = \frac{\chi_{trim}}{1 - (2zJ'/Ng^2\beta^2)\chi_{trim}},$$

where χ_{trim} is the susceptibility of the two independent $S = 1/2$ trimers (Eq. (1) with J_1 and J_2 for the two contributing trimers) and J' is the inter-trimer exchange coupling of the z interacting trimers. This more complete model reproduces very satisfactorily the magnetic data of **1** over the whole temperature range with the following parameters: $g = 2.0166(5)$, $J_1 = -291(4)$ K $= -202(3)$ cm^{-1}, $J_2 = -336(5)$ K $= -233(3)$ cm^{-1} and $zJ' = -0.16(1)$ K $= -0.11(1)$ cm^{-1} (solid line in Fig. 5). This model reproduces very satisfactorily the decrease observed at very low temperatures and provides a more realistic g value than the isolated trimers model. However, it could be argued that this improvement may only be due to the increase in the number of adjustable parameters (from two/three to four), so we have run a fit using the second model with J_1 and J_2 fixed to the values obtained in the first one ($J_1 = J_2 = -327$ K). This more restricted model (with only two free parameters) also gives a very good agreement with the experimental data over the whole temperature range, including the decrease at low temperatures with $g = 2.0082(8)$ and $zJ' = -0.13(1)$ K. In all cases the g value is lower than the values usually found for copper(II) complexes, suggesting the presence of a small diamagnetic impurity that reduces the magnetic signal of the sample.

A confirmation of the $S = 1/2$ ground spin state arising from the antiferromagnetically coupled trimers in **1** is provided by the isothermal magnetization data at 2 K (Fig. 6) that shows a saturation value close to 2 μ_B, the expected value for two non interacting $S = 1/2$ ions and that can be very well reproduced with the sum of two identical Brillouin functions for $S = 1/2$ with a reduced g value of 1.967(1) as a consequence of the inter-trimer antiferromagnetic coupling (solid line in Fig. 6).

The strong antiferromagnetic couplings observed in both copper(II) trimers in **1** can be easily rationalized from the similar structural features found in both trimers (Fig. 7). Thus, both trimers present a symmetrical distribution of the copper(II) ions with a perfect linear arrangement in trimer **I** (Fig. 7a) and an almost linear arrangement in trimer **II** (with a Cu3–Cu4–Cu3 angle of 161.4°, Fig. 7b). This arrangement implies that the two possible coupling constants inside each trimer are identical (given the symmetry of both trimers) and that the possible interaction between the terminal copper(II) atoms (Cu2 and Cu3) must be negligible, justifying the symmetrical linear trimer model used to fit the magnetic properties (see above). In both trimers the copper(II) ions are connected through double phenoxo bridges with very similar Cu–O bond distances and Cu–O–Cu bond angles (Fig. 7). Note that the possible perchlorate bridges imply a much longer Cu–O–Cl–O–Cu pathway with Cu–O bond distances ca. 0.5 Å longer than those of the bridging oxygen atoms and, therefore, they are negligible when compared with the much shorter double phenoxo bridges. From the several magneto-structural correlations established for double oxo bridged copper(II) complexes with the oxo bridges laying in the equatorial plane [35–38], the magnetic coupling in both trimers are expected to be strong and antiferromagnetic, in agreement with the observed behaviour. Thus, the correlation

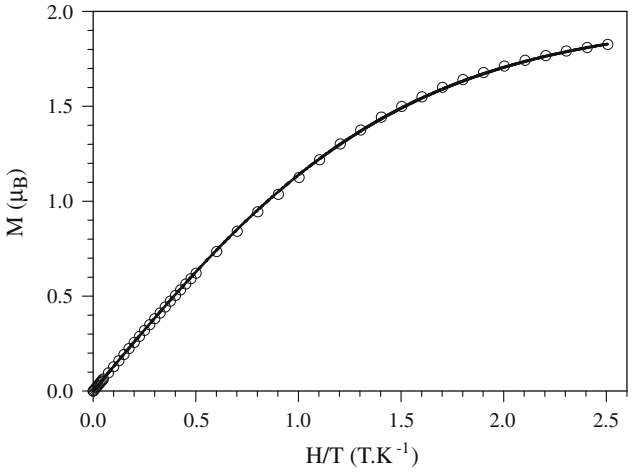

Fig. 6. Isothermal magnetization at 2 K of **1**. Solid line is the best fit to the sum of two identical $S = 1/2$ Brillouin functions (see text).

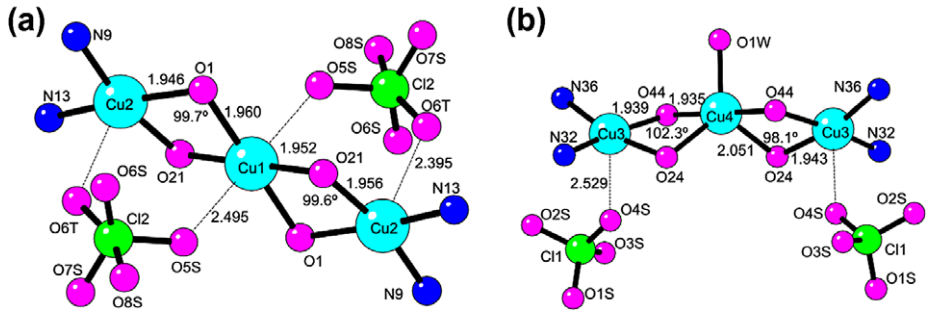

Fig. 7. Coordination environments of the two copper(II) trimers in **1** showing the bridging bond distances (Å) and angles (°) (colour code: Cu = light blue, N = dark blue, O = pink, Cl = green). (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

established between the Cu–Cu distance (R) and the J parameter, predicts strong antiferromagnetic couplings of ca. −220 and −290 cm^{-1} for trimers **I** and **II** (where the Cu–Cu distances are 2.985 and 3.018 Å, respectively). Furthermore, the Cu–O–Cu bond angle, which is the other structural parameter also used to estimate the J value, gives an estimation for the J values of ca. −160 cm^{-1} for trimer **I** (where the Cu–O–Cu bond angles are 99.6 and 99.7°, Fig. 7 and Table 4) and ca. −210 cm^{-1} for trimer **II** (where the Cu–O–Cu bond angles are ca. 98.1 and 102.3°, Fig. 7 and Table 4). Note that both magneto-structural correlations give J values in good agreement with the experimental ones even if these estimated values are approximate since these correlations do not include the torsion angle inside the Cu_2O_2 moieties and, even more important, in trimer **II** the central copper(II) ion presents a trigonal bipyramid geometry (τ = 0.92). Nevertheless, these correlations allow us to suggest that in **1** the strongest antiferromagnetic coupling (J_2 = −233(3) cm^{-1}) should be assigned to trimer **II** whereas the weakest coupling (J_1 = −202(3) cm^{-1}) should be attributed to trimer **I**. The weak antiferromagnetic intermolecular coupling can be attributed to the presence of the H-bond network, as also observed in other similar copper(II) trimers [39].

4. Conclusion

In this paper, we have described the structural and magnetic properties of a novel and very original copper(II) complex presenting two structurally different copper(II) trinuclear units. It is really interesting to note that in **1** although the coordination environment of the central copper(II) centres in the two independent linear trinuclear units are quite different from one another, they exist in the same crystallographic asymmetric unit. From the structural point of view, the title compound represents, the first example of two chemically distinct, doubly phenoxo bridged copper(II) trinuclear units. The magnetic properties of the title compound clearly show that both the trinuclear units present similar strong antiferromagnetic coupling between the copper(II) ions through the doubly phenoxo bridges and is in good agreement with the expected value obtained from previous magneto-structural correlations for doubly phenoxo bridged copper(II) complexes.

2. Experimental

2.1. General

All the reactions were carried out under aerobic conditions. $[Fe_3EuO_2(O_2CCCl_3)_8(H_2O)(THF)_3]$ [9a], $[Fe_2CaO(O_2CCCl_3)_6(THF)_4]$ [9b] and $[Fe_3O(O_2CCMe_3)_6(H_2O)_3]NO_3$ [10] were obtained as reported. 1,1′-Ferrocenedicarboxylic acid ($fcdcH_2$) was obtained from commercial sources and was used without further purification. Elemental analyses for C and H were carried out at the Institute for Inorganic Chemistry at the University of Karlsruhe.

2.2. Preparations

2.2.1. $[Fe_4O_2(O_2CCCl_3)_6(fcdc)(THF)_2(H_2O)_2]\cdot 1.5C_7H_8$, (**1**)$\cdot 1.5C_7H_8$

(Method **A**) A mixture of $[Fe_3EuO_2(O_2CCCl_3)_8(H_2O)(THF)_3]$ (0.18 g, 0.10 mmol) and $HOOCC_5H_4FeC_5H_4COOH$ (0.055 g, 0.20 mmol) in toluene (10 ml) was heated to ~50 °C for 30 min, resulting in the immediate formation of a dark red solution. The solution was filtered and the filtrate was allowed to stand undisturbed at room temperature. Dark red crystals of **1** formed over four days. Yield 14%. Elemental *Anal.* Calc. (%) for **1**: $C_{32}H_{28}O_{22}Cl_{18}Fe_5$ (dried): C, 22.85; H, 1.67. Found: C, 22.72; H, 1.78%.

(Method **B**) $[Fe_2CaO(O_2CCCl_3)_6(THF)_4]$ (0.272 g, 0.20 mmol) and $HOOCC_5H_4FeC_5H_4COOH$ (0.055 g, 0.20 mmol) were mixed in toluene (20 ml) and heated to ~50 °C for 30 min, resulting in the formation of a dark red solution. The solution was filtered and the filtrate was allowed to stand undisturbed at room temperature. Dark red crystals of **1** formed over two days, were washed 3 times with water and air dried. Yield ~67%. Elemental *Anal.* Calc. (%) for **1**: $C_{32}H_{28}O_{22}Cl_{18}Fe_5$ (dried): C, 22.85; H, 1.67. Found: C, 22.94; H, 1.81%.

2.2.2. $[Fe_6O_2(OH)_2(O_2CCMe_3)_{10}(fcdc)(H_2O)_2]$ (**2**)

A mixture of $[Fe_3O(O_2CCMe_3)_6(H_2O)_3]NO_3$ (0.19 g, 0.20 mmol) and $HOOCC_5H_4FeC_5H_4COOH$ ($fcdcH_2$) (0.055 g, 0.20 mmol) in toluene (10 ml) was heated under reflux for 3 h, resulting in the immediate formation of a dark green solution. The solution was filtered and the filtrate was allowed to stand undisturbed at room temperature. Dark red crystals of **2** formed over two days and were isolated in an overall yield of 65%. Elemental *Anal.* Calc. (%) for $C_{62}H_{104}O_{30}Fe_7$ (dried): C, 43.28; H, 6.09. Found: C, 43.12; H, 5.94%.

2.3. Physical measurements

2.3.1. Mössbauer measurements

The Mössbauer spectra were acquired using a conventional spectrometer in the constant-acceleration mode equipped with a ^{57}Co source (3.7 GBq) in a rhodium matrix. Isomer shifts are given relative to α-Fe at room temperature. The sample was inserted inside an Oxford Instruments Mössbauer-Spectromag 4000 Cryostat. The sample temperature can be varied between 3.0 and 300 K. The spectra were fitted using the NORMOS Mössbauer Fitting Program.

2.3.2. Magnetic measurements

The magnetic measurements were carried out with the use of a Quantum Design SQUID magnetometer MPMS-XL. This magnetometer works between 1.8 and 400 K for dc applied fields ranging from −7 to 7 T. Measurements were performed on polycrystalline samples. The magnetic data were corrected for the sample holder and the diamagnetic contribution estimated from Pascal constants.

2.4. Powder diffraction/crystal structure determination

2.4.1. X-ray crystal and molecular structural analyses

X-ray single-crystal diffraction data for complexes **1** and **2** were collected on a Nonius Kappa CCD diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71069 Å). Intensities were integrated using DENZO and scaled with SCALEPACK. The structures were solved and refined using the SHELXTL software [11]. The high *R* values of both compounds were caused by a systematic twining and poor diffraction of the small crystals. Further details of the data collection and refinement are given in Table 1.

3. Results and discussion

3.1. Synthesis

Various strategies have been utilized in the synthesis of coordination compounds with ferrocenedicarboxylic acid [4]. All our attempts to synthesize iron(III) complexes using only ferrocenedicarboxylic acid as a ligand failed because of the low solubility of the final products. Therefore, to produce Fe(III) cage complexes featuring ferrocenedicarboxylates we have developed a route in which ferrocenedicarboxylic acid is introduced with a coligand. Small changes to this method in terms of the ratio of starting materials were made and in all cases the reactions gave compounds discussed in this work. Although in the synthetic approach both of the possible starting materials we used, $[Fe_3EuO_2(O_2CCCl_3)_8(H_2O)$- $(THF)_3]$ and $[Fe_2CaO(O_2CCCl_3)_6(THF)_4]$, are heterometallic compounds, the reason why the calcium containing compound leads to a much higher yield of the target compound is unclear.

3.2. Structural analysis

The crystal structure of **1** represents a butterfly structure, but the structure of **2** consists of six Fe^{3+} centres arranged in two triangular subunits bridged at two vertices.

Complex **2** crystallizes in the orthorhombic space group *Pccn* with half a molecule in the asymmetric unit located on a twofold rotation axis (Fig. 2). The core contains the well-known $[Fe_6(\mu_3\text{-}O)_2]^{14+}$ core [12,13], comprising two linked Fe_3O units; a $fcdc^{2-}$ dianion,

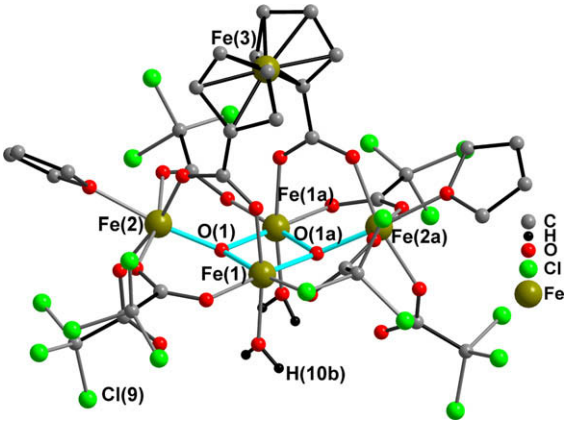

Fig. 1. Molecular structure of **1**. Hydrogen atoms of THF and $fcdc^{2-}$ rings are omitted for clarity.

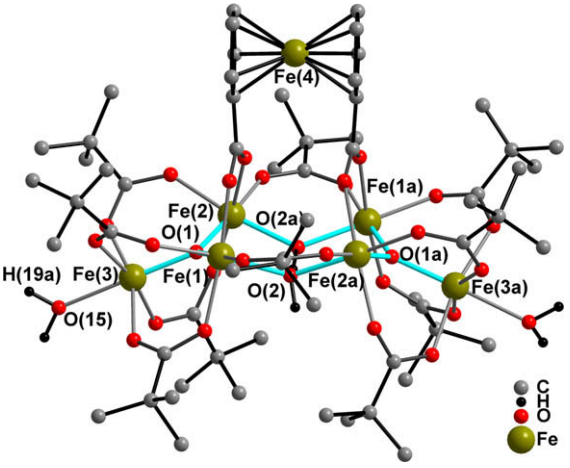

Fig. 2. Molecular structure of **2**. Hydrogen atoms of pivalates and $fcdc^{2-}$ rings are omitted for clarity.

two pivalate and two hydroxide ligands bridge the two Fe_3 halves of the complex, and a trigonal planar oxide and four pivalate ligands bridge within the Fe_3 units at each end. Each Fe^{III} ion is six-coordinate in a distorted octahedral geometry with Fe(3) and Fe(3a) each coordinated to a water molecule.

Complex **1** crystallizes in the orthorhombic space group *Pbcn* with two half molecules again located on twofold rotation axes in the asymmetric unit. One of the essentially identical molecules is shown in Fig. 1. The central $\{Fe_4O_2\}$ core of **1** can be structurally described as two condensed iron Fe_2O units forming a butterfly motif of the iron atoms with a dihedral angle between the planes Fe(1)–Fe(1a)–Fe(2) and Fe(1)–Fe(1a)–Fe(2a) of 29°. In contrast to **2** the terminal iron atom Fe(2) is only bridged by two trichloroacetates and one carboxylate group of fcdc, whereas one THF and one trichloroacetate act as monodentate ligands. The bridging by fcdc leads to a twist of the $\{Fe_3O\}$ unit with a strongly distorted trigonal oxide, which lies 0.336(4) Å out of the iron plane. In comparison with **2**, where the environment of the O(1) atom is trigonal planar with a sum of the angles around O(1) of 359.5°, this twisting in **1** leads to a sum of 350.1° (Table 2).

The $fcdc^{2-}$ ligand acts as a flexible connector between the metal ions because the two cp rings of the $fcdc^{2-}$ can rotate. Different steric configurations are possible, depending on the torsion angle φ of the two carboxylate groups of $fcdc^{2-}$. For **1**, the φ value is about 25°. That is, both carboxylate groups of $fcdc^{2-}$ show a synclinal staggered conformation. For **2**, the φ value is 2°, showing the conformation of carboxylate groups is synperiplanar.

3.3. Mössbauer spectroscopy of *1* and *2*

We used Mössbauer spectroscopy as a means to investigate the electronic structures of both compounds since they are not soluble in any solvents useful for cyclic voltammetry. The Mössbauer spectra of **1** were recorded at 300 and 150 K and are shown in Fig. 3. At both temperatures the spectra consist of an inner- and outer-doublet with a ratio of 4:1. The inner doublet observed at each temperature can be fit by two doublets of equal area originating respectively from the wing- and body-iron atoms of the $Fe_4(\mu_3\text{-}O)_2$ core, whose isomer shifts (δ) and quadrupole splitting (ΔE_Q) values

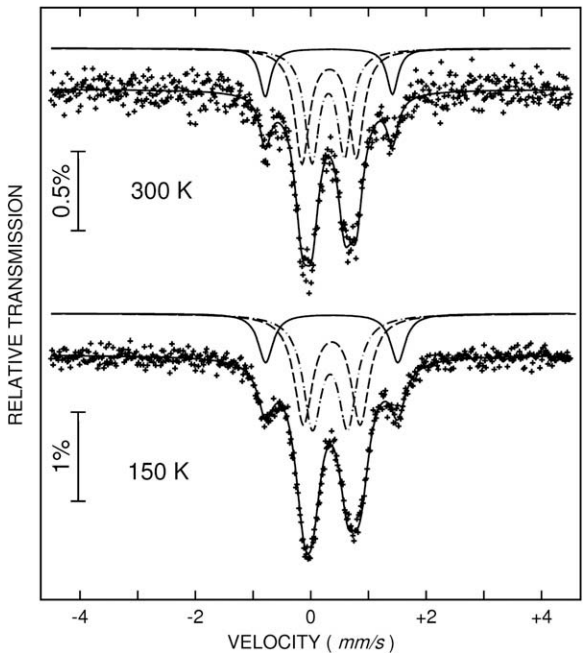

Fig. 3. Zero-field Mössbauer spectra of solid compound **1** at different temperatures.

Table 3
Mössbauer data for compound **1**.

T, K	Type of Fe	δ[a], mm/s	ΔE_Q, mm/s	Γ, mm/s
300	$2 \times Fe_w$	0.42(3)	0.93(1)	0.30(2)
	$2 \times Fe_b$	0.41(2)	0.563(7)	0.29(3)
	$1 \times Fe_{fc}$	0.52(1)	2.204(8)	0.23(2)
150	$2 \times Fe_w$	0.472(7)	0.982(6)	0.383(4)
	$2 \times Fe_b$	0.441(4)	0.610(8)	0.38(2)
	$1 \times Fe_{fc}$	0.54(2)	2.290(3)	0.317(3)

[a] Relative to α-Fe at room temperature. The statistical errors are given in parentheses. The relative area for the spectra for compound **1** has been constrained to 2:2:1 ratios, respectively.

are listed in Table 3. While the δ values for both doublets are very similar, the ΔE_Q values are quite different. The values for δ are within the range expected for iron(III) high-spin complexes and show little temperature dependence. They are comparable to those of other complexes with Fe_4O_2 butterfly cores [14]. The Fe_{body} exhibits an O_6 coordination sphere with distances corresponding to a more symmetric coordination environment than for Fe_{wing} with the bond length distortion values 2.85 and 2.42 for Fe_{wing} and Fe_{body}, respectively. The Mössbauer signal for Fe_{body} is therefore assigned to the smaller ΔE_Q value of 0.563–0.609 mm/s, whereas the doublet showing a ΔE_Q value of 0.937–0.982 mm/s is assigned to the Fe_{wing} ion. The outer-doublet with the δ and ΔE_Q values of ~0.45 mm/s and ~2.25 mm/s, respectively, is characteristic for Fe^{II} low-spin of the ferrocene unit.

The Mössbauer spectra of compound **2** are displayed in Fig. 4. The isomer shifts and quadrupole splitting values at three temperatures in zero applied magnetic field are listed in Table 4. As for **1**, the spectra were fit by three doublets originating respectively from the central and lateral high-spin Fe(III) ions of the $Fe_6(\mu_3\text{-}O)_2(\mu\text{-}OH)_2$ core and Fe^{II} of the $fcdc^{2-}$ anions. The predicted proportions of Fe(II) and Fe(III) from the structural study of compound **2** are 14.3% and 85.7%, respectively. If the fitting of the Mössbauer spectra is done through a free iteration method, then the obtained values for absorption areas for the Fe(II) and Fe(III) centres are close to the predicted percentages; the small discrepancies probably result from different recoilless fractions for the ferrous and ferric subsites in the cluster.

The most important observation from the Mössbauer measurements for both compounds is that the ratio between the areas of the inner- and outer-doublets does not change with temperature. This effect proves that there is no interaction or electron-transfer from the Fe(II) of ferrocene to the Fe(III) ions of the main cores of both compounds. According to the classification scheme proposed by Robin and Day [15], these results support assignment of the complexes **1** and **2** as a class I mixed-valence complexes.

3.4. Magnetic properties of 1–2

The magnetic susceptibility of compounds **1** and **2** was measured at 0.1 T in the range from 1.8 to 300 K. For compound **1**, a plot of $\chi_M T$ per $Fe^{III}{}_4$ (Fe^{II} is diamagnetic) versus temperature is given in Fig. 5 (left). The data clearly indicate that this complex possesses an $S = 0$ ground state, in accord with what has been observed before for molecules of a similar structure [14]. In a qualitative sense, the $S = 0$ state can be thought of in terms of an antiferromagnetic coupling of the four high-spin Fe(III) ions to produce a ground state of zero net spin.

For compound **2**, the room temperature value of $\chi_M T$ per $Fe^{III}{}_6$ (Fe^{II} is diamagnetic) (Fig. 5 (right)) is 5.07 $cm^3\,K\,mol^{-1}$ and it decreases further, reaching a value close to zero already at 8.00 K. The 300 K value is considerably less than the 26.34 $cm^3\,K\,mol^{-1}$ expected for a hexa-nuclear species containing non-interacting Fe^{III} ($S = 5/2$) ions, suggesting the presence of relatively strong

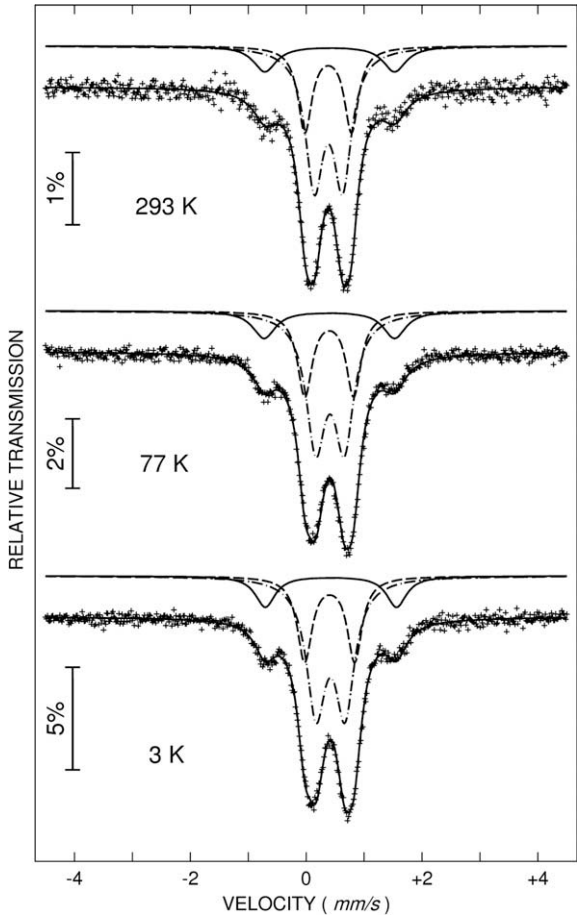

Fig. 4. Zero-field Mössbauer spectra of solid compound **2** at different temperatures.

Table 4
Mössbauer data for compound **2**.

T, K	Type of Fe	δ[a], mm/s	ΔE_Q, mm/s	Γ, mm/s
293	$2 \times Fe_{lat}$	0.486(4)	0.80(2)	0.29(1)
	$4 \times Fe_{centr}$	0.490(2)	0.486(7)	0.37(2)
	$1 \times Fe_{fc}$	0.51(1)	2.23(7)	0.38(1)
77	$2 \times Fe_{lat}$	0.505(7)	0.84(2)	0.31(2)
	$4 \times Fe_{centr}$	0.517(8)	0.492(7)	0.404(2)
	$1 \times Fe_{fc}$	0.527(3)	2.25(1)	0.33(2)
3	$2 \times Fe_{lat}$	0.512(5)	0.862(6)	0.30(1)
	$4 \times Fe_{centr}$	0.526(1)	0.498(3)	0.401(5)
	$1 \times Fe_{fc}$	0.53(1)	2.26(2)	0.41(2)

[a] Relative to α-Fe at room temperature. The statistical errors are given in parentheses. The relative area for the spectra for compound **2** has been constrained to 2:4:1 ratios, respectively.

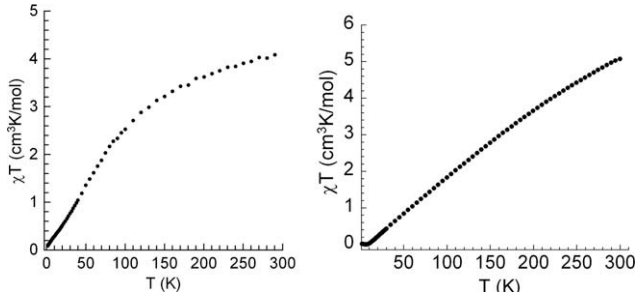

Fig. 5. $\chi_M T$ versus T plot for complexes **1** (left) and **2** (right) in a 1 kG field.

antiferromagnetic exchange interactions in **2**. The continuous decrease at the lowest temperatures is strongly suggestive of an $S = 0$ ground state. The $S = 0$ ground state for such type of compounds with six iron(III) ions, with few exceptions [12], is expected [13b,12c] and the observed overall magnetic behaviour thus indicates that essentially antiferromagnetic coupling interactions are operative between the six Fe^{III} centres and that this topology does not introduce large amounts of spin frustration.

4. Conclusions

In conclusion, the use of ferrocenedicarboxylic acid in reactions with preformed iron clusters has allowed us to obtain two new penta- and hepta-nuclear iron(III) complexes, **1** and **2**. The structures of these compounds are similar to many tetra- and hexa-nuclear iron(III) complexes described in literature [12–14], the main difference here being the presence of one redox centre in the structure. Although the compounds are not soluble in any solvents suitable for cyclic voltammetry, we were able to investigate the electronic structures in the solid-state using Mössbauer spectroscopy. This allowed us to establish that in both cases no electronic communication occurs. Nevertheless, the combination of high-spin Fe(III) with the redox-active ferrocenyl moiety in complexes **1** and **2** could provide a fascinating playground for the study of single electron-transfer. In addition, it should be possible to replace the solvent molecules in **1** (THF) and **2** (H_2O) with other functional (e.g. bridging) ligands. **1** and **2** are therefore possible prototypes for a wide range of crystal engineered one-dimensional redox-active polymers. Studies along these lines are in progress.

Supplementary data

CCDC 661893 and 661896 contains the supplementary crystallographic data for **1** and **2**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

molecular and electronic structure and biological activity of new preparations.

Not only is the geometric structure interesting for us, but also the determination of electronic charge distribution and the degree of bond polarity. It is well known that biological activity depends on a compound's reactivity and its stability, which finally depend on the electronic charge distribution. To determine the electronic charge distribution, the following experimental and theoretical methods were used: FT-IR, NMR, FT-Raman, UV/Vis and quantum calculations. Application of the different complementary methods lets us to draw adequate conclusions. To search for the effect of alkali metal series on the electronic structure of ligands, it was necessary to obtain anhydrous complexes, the structures of which are the same. Changes in the number of water molecules or crystallographic structure bring about extra perturbations in the series of the studied salts and complexes.

2. Experimental

Lithium, sodium, potassium, rubidium and cesium 2-aminonicotinates were prepared by dissolving the powder of 2-aminonicotinic acid in a water solution of the appropriate alkali metal hydroxide in a stoichiometric ratio. All reagents were Aldrich analytical chemicals, with the exception of LiOH (Sigma). The mixed solution was slowly condensed at 70 °C. The products precipitated by slow evaporation. Then the salts were dissolved and crystallized from demineralised water. After drying, the IR spectra were recorded. The composition of the obtained salts and degree of dehydration was determined by spectroscopic methods (by analysis of ranges characteristic for H_2O bands in the IR and Raman spectra). Preparing anhydrous salts is important for the comparison of the electronic structures of the studied compounds and to evaluate the alkali metal effect.

The IR spectra were recorded with the EQUINOX 55, BRUKER FT-IR spectrometer within the range 4000–400 cm^{-1}. Samples in the solid state were measured in a KBr matrix and with ATR attachments. Pellets were obtained with a hydraulic press under 739 MPa pressure. Raman spectra of solid samples in capillary tubes were recorded in the range 4000–400 cm^{-1} with a FT-Raman accessory of the Perkin Elmer System 2000. The resolution of the spectrometer was 1 cm^{-1}. The NMR spectra of DMSO saturated solutions were recorded with the NMR AC 200 F, Bruker unit at room temperature. TMS was used as an internal reference.

To calculate the optimized geometrical structures, the DFT hybrid method B3LYP with non-local correlation provided by the Lee–Yang–Parr expression was used. The 6-311++G** basis set was used as the standard basis set available for all atoms in the studied molecules. All theoretical calculations were performed using the GAUSSIAN 98W (version 5.4) package of programs [12] running on a PC computer.

3. Results and discussion

3.1. Calculated geometrical structure

Optimized geometrical structures of 2-aminonicotinic acid were obtained using the B3LYP/6-311++G** quantum chemical method. The obtained data are gathered in Table 1. Structure number 1, whose energy is the least, is the most stable structure. Having calculated the optimal structure for the acid molecule, we performed calculations for alkali metal salts for the same structure. The results of the calculations of 2-aminonicotinates in comparison with the 2-aminonicotinic acid molecule are gathered in Table 2. Our results calculated for the acid molecule were compared with literature experimental data [13]. Quite a good correlation between experimental and calculated values for bond lengths was noted ($R = 0.979$). Magnetic and geometric aromaticity indices [14–17] as well as the values of the largest differences of bond lengths and bond angles in the heterocyclic ring of the lithium, sodium and potassium 2-aminonicotinates in comparison with the acid are also presented (Table 2).

The geometric criterion of aromaticity is based on the π-electron delocalization manifested in planar geometry, symmetry, equalization of the bond lengths and angles. The values of the HOMA geometric aromaticity index (abbreviation from Harmonic Oscillator Model of Aromaticity) significantly increase, which indicates the increase of aromaticity in the series 2-aminonicotinic acid < Li < Na < K 2-aminonicotinate. On the other hand, values of I_6 (Bird's index, which describes the geometric contribution to the aromaticity) decrease, which shows the de-

crease of aromaticity of the salt molecules. The values of the magnetic aromaticity indices NICS (Nucleus-Independent Chemical Shifts) were also calculated. The obtained negative values of NICS (Table 2) denote about the aromaticity of the studied molecules [15,16]. These values show a decrease of aromaticity for lithium 2-aminonicotinate in comparison with the acid molecule, but in the series Li → Na → K-salt an increase of aromaticity was observed.

Atomic charges calculated by NPA (Natural Population Analysis) are gathered in Table 3. The total atomic charges of the carboxylate and amino groups, as well as the heterocyclic ring, are also presented. A significant increase of electron charge density was noted in the case of the carboxylate group for 2-aminonicotinates. A less significant increase of electron charge density for ring atoms and a decrease for the amino group were observed in the series acid → Li → Na → K-salt.

On comparing values of dipole moments (Table 4) for molecules of 2-aminonicotinic acid and alkali metal salts, an increasing tendency along the series: acid → lithium → sodium → potassium 2-aminonicotinate was observed. In the case of nicotinates, the dipole moment increases in the same order (4.394, 4.679, 7.130, 8.713). The values of the energy of aminonicotinates (Table 4) as well as nicotinates (0.00, −31.51, 53.82, 36.76) show a significantly increasing tendency along the series Li < acid < K < Na salts. This indicates that the stability of the studied molecules decreases in this order.

3.2. Vibrational spectra

The vibrational spectra of the synthesized 2-aminonicotinates were recorded and assigned. The observed Raman and IR (KBr, ATR) bands, together with their relative intensities and band assignments, of the studied metal salts are presented in Tables 5 and 6, respectively. The bands are numbered along with the notation used by Varsányi and ourselves [18]. Theoretical calculations by the B3LYP method at the 6-311++G** level were used to obtain values of wavenumbers and intensities of IR and Raman spectra (Table 7). Calculated normal vibrations were characterized by computer animation. A good correlation between experimental and theoretical IR and Raman spectra was noted. The correlation coefficients for the IR spectra are in the range 0.9954–0.9964; for Raman 0.9943–0.9963. Raman and IR (ATR) spectra of 2-aminonicotinic acid and its lithium and cesium salts, as examples, are presented in Figs. 1 and 2.

The changes of intensities and wavenumbers of the bands of the aromatic system and amino group in the case of salts were discussed, in comparison with the free ligand. Characteristic bands occurring in the IR spectra of 2-aminobenzoates (symmetric or asymmetric vibrations of the carboxylic group, for example), which do not exist in the spectra of free acid, as well as the lack of some other bands, which are characteristic for it (the C=O band, 1703 cm^{-1} (KBr) and1696 cm^{-1} (ATR); ν(C–OH) band, 1321 cm^{-1}

(KBr) and 1318 cm^{-1} (ATR), for example) were observed. The appearance of bands connected with the carboxylate group $\nu_{as}(COO^-)$, in the range 1612–1608 cm^{-1} IR (KBr), (1613–1607 cm^{-1} – ATR; 1614–1600 cm^{-1} – Raman), $\nu_s(COO^-)$: 1398–1380 cm^{-1} IR (KBr) (1393–1972 cm^{-1} – ATR; 1404–1375 cm^{-1} – Raman), $\beta_{as}(COO^-)$: 551–539 cm^{-1} IR (KBr) (541–530 cm^{-1} – Raman), $\beta_s(COO^-)$: 895–891 cm^{-1} IR (KBr) (894–889 cm^{-1} – ATR; 899–891 cm^{-1} – Raman) and $\gamma_s(COO^-)$: 772–770 cm^{-1} IR (KBr) (777–768 cm^{-1} – ATR; 777–772 cm^{-1} – Raman) was observed.

The wavenumbers of bands connected with symmetric and asymmetric vibrations of amino group in the experimentally obtained IR (KBr and ATR) and Raman spectra increase in the salts in comparison with the acid. In theoretical spectra these values decrease. The bands of $\beta_s(NH_2)$ change to lower values in both experimental and theoretical IR and Raman spectra. Two bands were observed for asymmetrical in plane deformations $\beta_{as}(NH_2)$. In IR (ATR) spectra the wavenumbers of both of them decrease in salts in comparison with the acid. In the IR (KBr) spectra one of the bands changes to a lower wavenumber, but the other changes to a higher value. In IR theoretical obtained spectra, the wavenumbers of these bands increase. The same tendency was observed in Raman spectra (one band changes to lower wavenumbers, but another to higher) except for the sodium salt. Bands of $\gamma_s(NH_2)$ shifted to lower values of wavenumbers in the Raman spectra of salts, but to higher values in the theoretical IR spectra. In the experimentally obtained IR spectra regular changes were not noted.

The influence of the alkali metal in the series Li → Cs on the vibrational structure of 2-aminonicotinic acid was also observed. The wavenumbers of symmetric stretching vibration bands of the carboxylate group in the IR spectra were changed to lower values in the series Li → Na → K → Rb salt, but the asymmetric band does not change. The magnitudes of separation between the wavenumbers due to asymmetrical and symmetrical stretching vibrations of the COO^- group ($\Delta\nu = \nu_{asym} - \nu_{sym}$) increase in the series Li → Na → K → Rb 2-aminonicotinates. These values were used by Nakamoto [19] as a criteria of the way of the carboxylate was bound with metal ions. The structure changes in the order: bidentate (chelating) → bridging → ionic → unidentate with an increase of the $\Delta\nu$(COO) value. The values of $\Delta\nu$(COO) in IR (KBr) spectra of lithium, sodium, potassium, rubidium and cesium 2-aminonicotinates amount to 213, 216, 229, 231and 226 cm^{-1}, respectively. These values are insignificantly higher in comparison with alkali metal nicotinates (193, 211, 192, 209, 210 cm^{-1}, these values are from our previous paper [3]). It suggests that the bonds between the alkali metal cation and the carboxylate anion in 2-aminonicotinate molecules have more ionic nature than those in nicotinates. These values in the Raman spectra are in the range 198–228 cm^{-1} for 2-aminonicotinates and 171–209 cm^{-1} for nicotinates [3]. The values of $\Delta\beta(COO) = \beta_s - \beta_{as}$ amount to 355, 352, 340, 340,

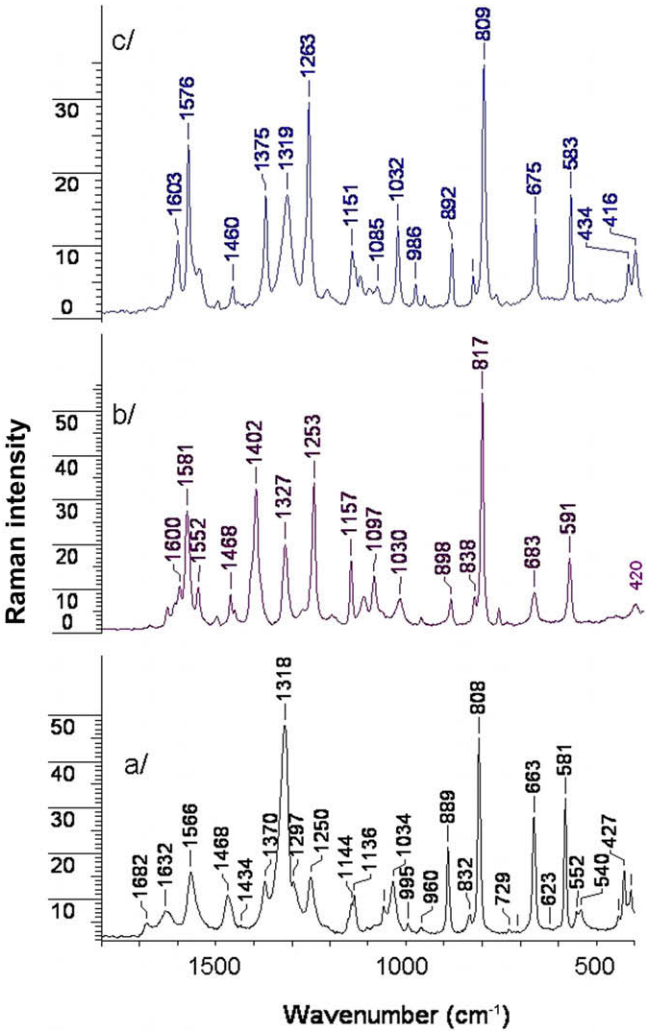

Fig. 1. Raman spectra of 2-aminonicotinic acid (a) and its lithium (b) and cesium (c) salts.

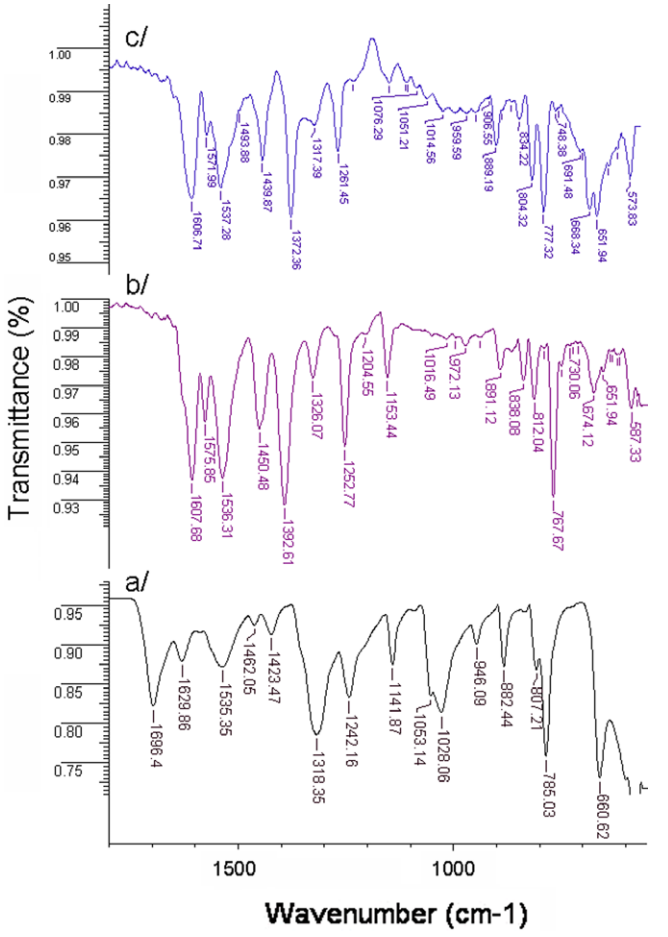

Fig. 2. IR–ATR spectra of 2-aminonicotinic acid (a) and lithium (b) and cesium (c) 2-aminonicotinates.

340 cm^{-1} for 2-AN in the IR(KBr) spectra and for nicotinates they are in the range of 315–323 cm^{-1} [3]. In the theoretical spectra of 2-aminonicotinates, the values of $\Delta\nu$(COO) and $\Delta\beta$(COO) are in the range 127–140 and 268–304 cm^{-1}, respectively.

The wavenumbers of ν(C–NH_2) and $\gamma_s(NH_2)$ in the IR (KBr) spectra decrease in the order Li → Na → K → Rb. A decrease of wavenumbers of ϕ(C–C), β(CH) and $\nu_s(NH_2)$ bands in the IR (ATR) spectra in the series Li → Na → K → Rb → Cs was noted, but an increase of wavenumbers of the $\beta_{as}(NH_2)$ band was noted in the order Li → Na → K = Rb → Cs. In the Raman spectra, the wavenumbers of ϕ(C–C), ν(C–N), $\nu_s(NH_2)$ and $\gamma_s(NH_2)$ bands decrease in following order: Li → Na → K → Rb → Cs.

The decrease of wavenumbers and intensities of the aromatic ring bands indicate an increase in the perturbation of the aromatic system. In the case of the studied molecules, the wavenumbers only of the 8b, 8a and 4 bands change to lesser values in comparison with the acid. The intensity of these bands increases or does not change. Based on this criterion, it is difficult to draw a clear conclusion.

The correlation between selected bands and some metal parameters such as electronegativity, atom and ionic radius, ionization energy and ionic potential (defined as the ratio of the charge of the cation and the ionic radius) was studied. The wavenumbers of those bands correlate in a linear fashion with all the tested factors at a statistically important level. The best correlation coefficients were obtained for electronegativity [$\beta_{as}(COO^-)$: 0.9808] and ionic potential [$\beta_{as}(COO^-)$: 0.9883] in the IR (KBr) spectra; ionic radius [$\nu_s(NH_2)$: 0.9909], atomic radius [$\nu_s(COO^-)$: 0.9998] and ionic potential [β(CH): 0.9888] in IR (ATR) and ionic radius [$\nu_s(NH_2)$: 0.9990] in Raman spectra. According to our previous study on benzoates, salicylates and nicotinates [3,4], the best statistical results were obtained for the ionic potential of the alkali metals.

It was interesting to note the linear correlation between wavenumbers of the $\nu_s(COO^-)$ band in the IR (KBr) spectra and the calculated Me–O bond length. The correlation coefficient amounts to 0.9325.

3.3. NMR spectra

Experimental and theoretical chemical shifts of 2-aminonicotinates in ^1H NMR and ^{13}C NMR spectra were recorded. The geometrical structures of the studied compounds were optimized by the GIAO DFT method [20]. The obtained data, in comparison with 2-aminonicotinic acid, are gathered in Table 8. In order to calculate optimized geometrical structures of the studied compounds, density functional theory at the B3LYP/6-311++G** level was used. Theoretical calculations for optimized structures were performed using the GIAO method in the GAUSSIAN 98W package.

A linear correlation between calculated and experimental data of ^1H and ^{13}C NMR is noted. Correlation coefficients for ^{13}C NMR for 2-aminonicotinic acid, lithium, sodium and potassium salts

amount to 0.9938, 0.9917, 0.9945 and 0.9913, respectively. The corresponding values of correlation coefficients for ^{1}H NMR amount to 0.9994, 0.9999, 0.9993 and 0.9996.

The chemical shifts of protons (^{1}H NMR) and carbons (^{13}C NMR) in the series of alkali metals express the influence of the studied metal on the electronic charge around those atoms. In the ^{1}H NMR spectra of 2-aminonicotinates, all the protons are shifted diamagnetically in comparison to 2-aminonicotinic acid. This suggests that all metals cause a decrease of current intensity, along with the literature data decrease of aromaticity [2]. The differences of chemical shifts of protons along the metal series are small, however they are higher than those of nicotinates [2]. This is an evidence that alkali metals perturb the aromatic system of the 2-aminonicotinic acid molecule to a higher degree than that of nicotinic acid. The chemical shifts of protons numbered 4 and 6 are higher then that of the H5 atom. It means that the electronic charge density around positions 4 and 6 is lower compared to position 5 [21]. The same conclusion was made in the case of nicotinates.

The chemical shifts of the carbon atoms in positions 1, 2, 5 and 7 change to higher values in the salts compared to 2-aminonicotinic acid. The chemical shifts of the carbon atoms in positions 4 and 6 change to smaller values. In the case of nicotinates, all carbon atoms except the C1 and C7 atoms change to lower value chemical shifts. The highest changes of chemical shifts are observed for C1 > C4 > C5 atoms, for the other atoms the chemical shifts change to a lesser degree. The changes of chemical shifts of carbon atoms along metal series are not so clear as in the ^{1}H NMR spectra. Only the chemical shifts of the C5 atom increase regularly in the series Li → Cs. The values of the chemical shifts of the C6, C1 and C4 carbon atoms decrease from lithium to potassium 2-aminobenzoates and from the potassium to the cesium salts they increase. The values of the chemical shifts of the C2 carbon atom decrease from the lithium to the potassium 2-aminobenzoate and increase from the potassium to the rubidium salt, and then decrease again from the rubidium to the cesium salt. For the C7 carbon atom these values change inversely.

The values of chemical shifts for the carbon atoms in positions 1 and 5 are smaller than for the other carbon atoms. The smallest value is observed for carbon 1. It means that the electronic charge density around the C1 atom is bigger than around the other atoms. Comparing the NMR spectra of alkali metal 2-aminonicotinates with those of nicotinates [2], higher values of chemical shifts of all protons and carbons (with the exception of the C1 and C5 atoms) were observed in the case of the nicotinates.

4. Conclusions

Substitution of hydrogen with alkali metals in the carboxylic group brought some characteristic changes in molecular spectra as well as in geometrical structures of the studied molecules.

A decrease of chemical shifts of almost all protons of 2-aminonicotinates in the ^{1}H NMR spectra was observed in comparison with the spectra of the acid, which indicates that the alkali metal ions perturb the electronic system of the molecule and the perturbation significantly increases in the series: H → Li → Na → K → Rb → Cs 2-aminonicotinates. The differences of chemical shifts of protons along this metal series are small, however they are higher than those of nicotinates [2]. This is an evidence that the perturbation effect of alkali metals on the aromatic system of the 2-aminonicotinic acid molecule is higher than that of nicotinic acid. The changes of chemical shifts of carbon atoms along the metal series are not so clear as in the ^{1}H NMR spectra. Comparing the NMR spectra of alkali metal 2-aminonicotinates with those of nicotinates, higher values of chemical shifts of all protons and carbons (with the exception of the C1 and C5 atoms) were observed in the case of nicotinates.

The decrease of wavenumbers and intensities of aromatic ring bands indicates an increase of perturbation of the aromatic system. In the case of the studied molecules, only the wavenumbers of the 8b, 8a and 4 bands change to lesser values in comparison with the acid. The intensities of these bands increase or do not change. Based on this criterion it is difficult to draw a clear conclusion. The values of $\Delta\nu$(COO) suggest that the bonds between the alkali metal cation and carboxylate anion in 2-aminonicotinate molecules have more ionic nature than those in nicotinates. This conclusion is confirmed by the values of dipole moments and the total atomic charge of the carboxylate group.

The conclusions obtained by aromatic indices are not congruent, because the differences between their values are small in the studied series of alkali metal salts. HOMA indices show a slight increase of aromaticity in the series 2-ANA < Li 2-AN < Na 2-AN < K 2-AN. According to the NICS values, an increase of aromaticity is observed in the series Li < Na < K-salts, but for lithium and sodium 2-aminonicotinate a decrease of aromaticity is noted in comparison with 2-aminonicotinic acid molecule.

The conclusions, which are drawn from different applications of work methods are not quite identical. The differences may be explained by the fact that our researches were provided for different states (IR and Raman spectra for solid state, NMR for solution, and calculations for isolated molecules).

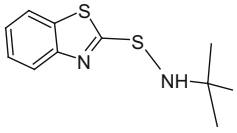
complexes were obtained (Table 1). IR spectra (4000–450 cm^{-1}) were recorded on a Perkin–Elmer Spectrum One FT-IR spectrometer using KBr pellets. Absorption electron spectra (45 000–9090 cm^{-1}) were carried out on a Perkin–Elmer Lambda 35 UV/VIS spectrophotometer using N,N-dimethylformamide as solvent. Conductivities were measured with an LF 330/SET conductivity meter (WTW GmbH) at 25 °C. Room temperature magnetic susceptibilities were measured by the Faraday method using $Co[Hg(NCS)_4]$ as a calibrant on a laboratory designed instrument with a Sartorius 4434 MP-8 microbalance. Thermal analysis was performed on Exstar 6000 device (Seiko Instruments Inc.).



Anticholinesterase activity measurement: Electrochemical strips with platinum working (diameter 1 mm), Ag/AgCl reference and platinum auxiliary electrodes were obtained from BVT (Brno, Czech Republic). Acetylcholinesterase (AChE) from electric eel (obtained from Sigma–Aldrich) was immobilized onto the working electrode as a precipitate with glutaraldehyde and bovine serum albumin (BSA). Two microliter of mixture consisting of total 0.01 nkat of AChE, 1 mg BSA and 0.1% glutaraldehyde was injected onto the working electrode and let to form a layer in a closed chamber.

In order to realize the assay, biosensor was fixed horizontally and connected with an electrochemical device EmStat (Palmsens, Houten, The Netherlands). Twenty microliter of 1 mmol acetylthiocholine chloride (ATChCl) in 50 mmol phosphate buffer pH 7.4 was spread over the electrodes commonly with another 20 μl of tested sample in DMSO. The output current was measured after one minute. The percentage of AChE activity inhibition (***I***) was calculated using the following equation:

$$I = \left(1 - \frac{i_i}{i_t}\right) \times 100$$

where i_i means the current provided by the biosensor inhibited by the sample and i_t by the intact biosensor (20 μl of DMSO solution only) [30].

Vulcanization activity measurement: As standards, the following materials were used: Vuchtalink FMI/G-80 (1.96 dsk, antireversible and adhesion agent); Santocure TBBS GRS 2 MM (0.92 dsk, accelerator of vulcanization: *N*-tert-butyl-2-benzothiazolesulfenamide); Sulphur N (5.03 dsk, vulcanizing agent); Duslin G-80 (0.12 dsk, inhibitor of overvulcanization); Rubber mixture I.° (190.18 dsk).

Vulcanization standard Santocure TBBS GRS 2 MM

The efficiency of the samples as vulcanization accelerators for the side-wall mixtures for car radial tyres was studied. The rubber mixtures were prepared by the double-stirring procedure. In the first step, rubber mixture was recovered directly from the industrial process. In the second step, the accelerator of TBBS type (*N*-tert-butyl-2-benzothiazolesulfenamide) was replaced by the selected samples (other vulcanizing system dopes were unchanged). Preparation of the rubber mixture was performed by Plastograf – Brabender device (Plastograf Duisburg, DE) at 110 °C, during 7 min with a stirring speed 50 min^{-1} according [31]. After the preparation, the rubber mixture was left to stand for 24 h and the appropriate vulcanizing curves were recorded (Table 7). For this purpose, the Monsanto 100 device at 150 °C was used (recording time 60 min) by the normalized procedure mentioned above. The vulcanization of the rubber compound was implemented in a laboratory press BUZULUK (Buzuluk Komárov, CZ) at 150 °C under the pressure of 20 MPa. After vulcanization, the rubber mixtures were left to stand at laboratory temperature for 24 h and the double-sided paddle testing elements for stress–strain measurements were isolated. Stress–strain properties were measured with the shredder machine INSTRON and the hardness of rubber mixture was measured manually by the IRHD device by the normalized procedure [31].

2.2. Syntheses

For syntheses of complexes with the bdt, tdt-ligands, the modified procedure of Darkwa [21] was used: Complexes with the bdt, tdt-ligands were obtained by mixing the appropriate ligand: tdt (0.16 g, 1 mmol) or bdt (0.14 g, 1 mmol) in toluene (10 ml) with triethylamine (0.3 ml). Finally, $NiCl_2{\cdot}6H_2O$ (0.24 g, 1 mmol) in methanol (10 ml) and the appropriate P,P-ligand – dppe (0.40 g), dppp (0.41 g), dppb (0.42 g) or dpppn (0.44 g) in toluene (40 ml). The resulting mixture was stirred under reflux at 50 °C for 1 h. The resulted powder substance was separated by filtration, washed with methanol and diethylether and dried at room temperature (yield 85%).

For syntheses of complexes with mnt, the modified procedure of Bowmaker [28] was performed: $Na_2(CN)_2C_2S_2$ (0.19 g, 1 mmol), $NiCl_2{\cdot}6H_2O$ (0.24 g, 1 mmol) and P,P-ligand – dppe (0.40 g), dppp (0.41 g), dppb (0.42 g) or dpppn (0.44 g) were mixed as solids, and acetone (40 ml) was added. The resulting solution was stirred for 1 h. The complexes were precipitated by the slow addition of water and vigorous stirring. The solid substance was filtered from the solution, washed with water, ethanol and diethylether and dried at room temperature (yield 98%).

Crystals of [Ni(dpppn)(mnt)] for X-ray analysis were obtained in a similar way, using methanol (30 ml). During 24 h, the brown prismatic crystals precipitated and a single crystal suitable for X-ray analysis was selected.

2.3. X-ray crystallography

X-ray data collection for [Ni(dpppn)(mnt)] was performed on an Oxford Diffraction Xcalibur™2 four circle κ-axis diffractometer

equipped with a Sapphire2 CCD detector, a monochromator Enhance and a Cryojet cooler system, using Mo Kα radiation at 105(2) K. CRYSALIS program package (1.171.7, Oxford Diffraction) was used for data reduction. The structure was solved by direct methods using SHELX programs [32,33] and refined anisotropically for all non-hydrogen atoms by full-matrix least-squares procedures. All hydrogen atoms were found from the Fourier map and were refined isotropically. Additional calculations were performed using the PARST program [34]. Basic X-ray data are summarized in Tables 3–5.

3. Results and discussion

3.1. Physical techniques

Selected physical data for all complexes are summarized in Table 2. Results of IR-spectroscopy show that all complexes exhibit vibrations typical for dithiolates υ(C–S) at 866–920 cm^{-1} [35,36]. For P,P-ligands typical υ(P–C_{Ph}) vibrations [37] were found at 1433–1435 cm^{-1} for all complexes (these vibrations for single P,P-ligand are at 1432 cm^{-1}). A small shift can be assigned to the coordination of both P-atoms to the central atom. Moreover, the υ(C≡N) vibrations at 2197–2204 cm^{-1}, typical of complexes **I–IV** with the mnt-ligand are recorded [38,39]. The planar coordination of the nickel is also supported by electron UV/Vis absorbance spectroscopy; the bands of bdt and tdt complexes **V–XII** observed in the 17 180–21 120 cm^{-1} region can be assigned to the $^1A_{1g}$–$^1A_{2g}$ transitions typical of planar nickel(II) complexes [40]. The appropriate bands for complexes **I–III** with mnt-ligand were not observed, probably due to the CT overlap appeared bands in interval 25 700–27 700 cm^{-1}. In good accordance with the assumption of a planar arrangement of the coordination sphere are also the results of conductivity measurements (all complexes are non-electrolytes) [41].

The complexes **I, II, IV, V, VI, VII, VIII, IX**,**X**, and **XI** are diamagnetic, which is also in accord with the supposed square-planar arrangement of NiS_2N_2 chromophore [42]; but for complexes **III** and **XII**, a slight paramagnetism was found (see Table 2) and cannot be eliminated by repeated purification. This fact was recently for similar complexes described [6] and cannot be simply explained; maybe it is due to the exchange intermolecular interactions of the samples [43].

The results of thermal analysis of the selected sample **I** (used also for vulcanization measurements) show that the sample is stable in the range 20–340 °C (Fig. 3). Further thermal decomposition without thermally stable intermediates is accompanied by two sharp *exo*-effects at 339 and 371 °C probably due to the burning of the sample. The final product of thermal decomposition is a mixture of $Ni(PO_3)_2$ and $Ni_2P_2O_7$ (evidence by powder X-ray diffraction). These results are not sufficient for explanation of vulcanization activity, which proceeded under non comparable conditions (high pressure).

The X-ray structure of [Ni(dpppn)(mnt)] (Fig. 1, Tables 3–5) confirmed a distorted square-planar geometry of NiS_2P_2 chromophore. The deviations of all atoms from an ideal NiS_2P_2 plane are less than 0.2 Å and appropriate bond angles around central atom are in the interval 86.46(3)–93.95(3)°. The dihedral angle between Ni1P1P2S1S2 and Ni1S1S2C1C3 planes is 6.45(6)°. Three possible hydrogen bond interactions between hydrogen atoms of phenyl rings and nitrogen atoms of cyano groups were identified in the structure.

Anticholinesterase activity of the selected compounds [Ni(dppp)(tdt)], [Ni(dppp)(mnt)] and of dppp, mnt as free ligands is shown in Table 6 and Fig. 2. The data were achieved using biosensor technology and it was processed in Origin 6.1. The

experiments confirmed a slow inhibition effect of dppp and mnt-ligands. The ligand dppp was a milder inhibitor. The ligand mnt reached stronger anticholinesterase activity. The dissociable nickel salt ($NiSO_4$) alone was not found to inhibit. However, the complex [Ni(dppp)(tdt)] acts as a strong inhibitor. The strongest inhibition activity was displayed by the [Ni(dppp)(mnt)] complex [44].

As for the influence of selected complexes on the vulcanization process, the basic results are summarized in Tables 7 and 8. All vulcanizing curves are characterized by the slight reversibility. The values of maximal torsion moments (M_L) of samples are lower compared to the standard (the viscosity values of these mixtures

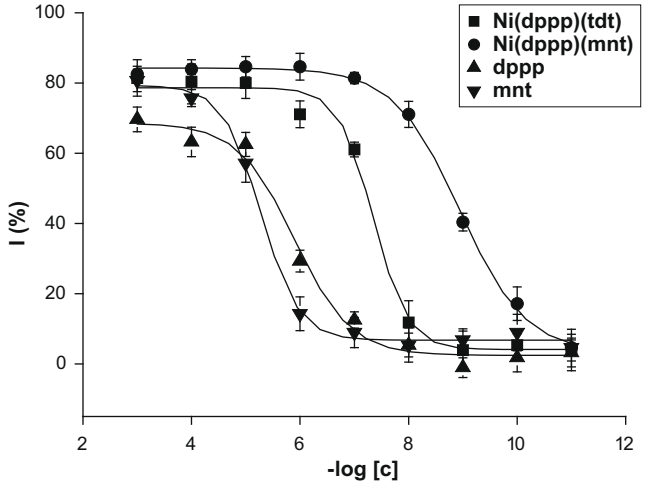

Fig. 2. Expression of ligands and Ni complexes anticholinesterase activity using electrochemical biosensor. Error bars indicate standard deviation ($n = 4$). Data were processed in Origin 6.1 and overlaid with sigmoidal fit.

X. [Ni(dppp)(tdt)]	4.50×10^{-8}

after vulcanization are lower). The minimal torsion moments (M_H) are almost identical with the standard (the viscosity of rubber mixture at the beginning of vulcanization process is almost identical). The start of vulcanization (t_{02} parameter) is also similar. On the other hand, the optimal values of vulcanization (t_{90}) of rubber mixtures with our samples as vulcanizing agents are significantly less than the standard value. The better activity of the vulcanization system with our samples as dopes is confirmed by higher values of vulcanizing speed coefficients (R_V). The obtained values of solidity characteristics are almost identical with the reference sample; the best values were reached by sample **IX** (Table 8), which corresponds to the lowest values of t_{02} and t_{90} (vulcanization process is more effective). The hardness IRHD values are slightly lower than the hardness of reference samples, but the dif-

Table 7

Compound	M_H [dN/m]	M_L [dN/m]	t_{02} [dN/m]	t_{90} [dN/m]	R_v [min^{-1}]
Santocure TBBS	13.5	104.0	3.0	15.5	8.00
I. [Ni(dppe)(mnt)]	13.0	92.5	2.5	12.5	10.00
V. [Ni(dppe)(bdt)]	14.0	95.0	3.0	12.5	10.53
IX. [Ni(dppe)(tdt)]	15.5	92.0	2.0	12.0	10.00

Table 8
Physical and mechanical properties of selected compounds.

Compound	Tensile strength [MPa]	Elongation [%]	Hardness [IRHD]	Crosslink density [mol/cm^3]
Santocure TBBS	15.93	256	92.6	2.702×10^{-4}
I. [Ni(dppe)(mnt)]	16.52	266	90.8	3.490×10^{-4}
V. [Ni(dppe)(bdt)]	15.91	248	89.9	2.904×10^{-4}
IX. [Ni(dppe)(tdt)]	17.56	281	89.8	2.651×10^{-4}

ferences are not significant. This fact is confirmed by the lower values of viscosity rubber mixture (lower M_L values, Table 7). The grid density is a parameter that gives information about the vulcanization network formation quality. It is connected with the number of cross-bonds in the rubber (tire). Determination of the crosslink density was performed by the [45] methodology; crosslink density values are higher for samples **I** and **V**; in the case of sample **IX** it is only slightly lower than the standard value.

In conclusion, all the measured samples proved to be better sulfur vulcanization accelerators than the commercially used sulfenamide type accelerator TBBS. They increase the vulcanization speed in comparison with the standard by 20%, while the most important physical and mechanical properties and crosslink density values are well-kept. Moreover, the crosslink density of samples **I** and **V**, as well as the vulcanization speed coefficients values, are better than the standard procedure values.

Supplementary data

CCDC 731400 contains the supplementary crystallographic data for JK05. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

$[Zn(L)Cl_2]$ and $[Pd(L)Cl]Cl$, respectively, where L stands for 2-formylpyridine *S*-methylisothiosemicarbazone [35,36].

With 2-acetylpyridine *S*-methylisothiosemicarbazone (HL), a limited number of complexes of Fe(II), Co(II), Ni(II) and Cu(II) have been reported to date, presuming different coordination modes of the ligand [37]. With the aim of checking the coordination mode of the ligand, in this work we performed an X-ray analysis of the ligand itself and its three complexes with copper(II) of the formulae: $[Cu(HL)SO_4(H_2O)]\cdot H_2O$, $[Cu_2(HL)_2(\mu\text{-}SO_4)_2]\cdot 2H_2O$ and [Cu(HL)(NCS)-(SCN)], involving the NNN tridentate coordination mode.

2. Experimental

2.1. Materials and physical measurements

All chemicals for the syntheses were analytical reagent grade. Elemental analysis (C, H, N) was carried out by standard micromethods. Magnetic susceptibility measurements were conducted at room temperature on a MSB-MKI magnetic susceptibility balance, Sherwood Scientific Ltd., Cambridge. Molar conductivities of freshly prepared 1 mM solutions were measured on a Jenway 4010 conductivity meter. IR spectra were recorded at room temperature using KBr pellets, in the range 4000–400 cm^{-1} on a Thermo Nicolet (NEXUS 670 FT-IR) spectrophotometer. Electronic spectra of 0.5–1 mM methanolic solutions of the ligand and complexes were recorded on a T80+ UV/VIS spectrophotometer, PG Instruments Ltd. in the spectral range 190–1100 nm.

TA measurements were carried out using simultaneous TGA-DSC thermal analyzer SDT Q600, TA instruments in open sample holders made of aluminum, with sample masses of about 2 mg. The decomposition was recorded in air and nitrogen atmospheres at a heating rate of 20 °C/min. The carrier gas flow rate was 100 cm^3/min. Before the run, the samples were equilibrated for 5 min at room temperature.

2.2. Preparation of the ligand

Single crystals of 2-acetylpyridine *S*-methylisothiosemicarbazone hydrogen iodide ($H_2L^+I^-$) were obtained by recrystallization from warm EtOH of the product synthesized according to our previous procedure [37]. Conductivity (λ_o, Ω^{-1} cm^2 mol^{-1}) in H_2O and MeOH: 114 and 93, respectively. IR (KBr, cm^{-1}): $\nu(NH_2)$ 3354, 3244, 3143; ν(C=N) 1604; δ(py) 605. UV–Vis [λ_{max}/nm ($\log \varepsilon/M^{-1}cm^{-1}$)]: 219(4.36), 295(4.28), 386(3.23).

2.3. Preparation of the copper(II) complexes

$[Cu(HL)SO_4(H_2O)]\cdot H_2O$ (**1**)/$[Cu_2(HL)_2(\mu\text{-}SO_4)_2]\cdot 2H_2O$ (**2**). To a warm solution of the ligand, $H_2L^+I^-$ (0.34 g, 1 mmol) in 15 cm^3 EtOH/MeOH, respectively, 0.40 g (1.5 mmol) of $CuSO_4\cdot 5H_2O$ dissolved in 5 cm^3 H_2O/MeOH, was added. The mixture was mildly heated to start the formation of CuI, which was filtered off after cooling the solution. After 24 h at room temperature, green single crystals were separated and washed with EtOH and Et_2O. Yield: 0.26 g/0.24 g (65%/32%), respectively.

(**1**) *Anal.* Calc. for $C_9H_{16}CuN_4O_6S_2$: C, 26.76; H, 3.99; N, 13.87. Found: C, 26.55; H, 4.01; N, 13.62%. Magnetic moment (μ, BM): 1.78. Conductivity (λ_o, Ω^{-1} cm^2 mol^{-1}) in MeOH and DMF: 20 and 37, respectively. IR (KBr, cm^{-1}): ν(OH) 3467; ν(NH) 3325; ν(C=N) 1648; $\nu(SO_4)$ 1180, 1115, 619; δ(py) 644. UV–Vis [λ_{max}/nm ($\log \varepsilon/M^{-1}cm^{-1}$)]: 225(4.16), 253sh(4.00), 296(3.93), 317(3.91), 410(3.74), 665(2.03).

(**2**) *Anal.* Calc. for $C_{18}H_{28}Cu_2N_8O_{10}S_4$: C, 28.01; H, 3.66; N, 14.52. Found: C, 27.88; H, 3.59; N, 14.38%. Magnetic moment (μ, BM): 1.57 per Cu atom. Conductivity (λ_o, Ω^{-1} cm^2 mol^{-1}) in MeOH and DMF: 117 and 92, respectively. IR (KBr, cm^{-1}): ν(OH) 3511; ν(NH) 3325, 3367; ν(C=N) 1638; $\nu(SO_4)$ 1180, 1117, 619; δ(py) 650. UV–Vis [λ_{max}/nm ($\log \varepsilon/M^{-1}cm^{-1}$)]: 225(4.43), 259(4.27), 326(4.24), 410(3.49), 681(2.26).

[Cu(HL)(NCS)(SCN)] (**3**). To a warm solution of $H_2L^+I^-$ (0.17 g, 0.5 mmol) in 10 cm^3 MeOH, 0.28 g (0.75 mmol) of $Cu(ClO_4)\cdot 6H_2O$ dissolved in 5 cm^3 MeOH was added and heated mildly. The readily formed CuI was filtered off after 2 h, and 3 cm^3 of triethyl orthoformate was added. After 20 h, 0.09 g (1.2 mmol) of NH_4SCN dissolved in 4 cm^3 MeOH was added and the mixture was heated mildly. After 4 h, green monocrystals were separated and washed with MeOH and Et_2O. Yield: 0.12 g (63%).

Anal. Calc. for $C_{11}H_{12}CuN_6S_3$: C, 34.05; H, 3.12; N, 21.66. Found: C, 34.17; H, 3.18; N, 21.88; Cu. Magnetic moment (μ, BM): 1.80. Conductivity (λ_o, Ω^{-1} cm^2 mol^{-1}) in MeOH and DMF: 69 and 63, respectively. IR (KBr, cm^{-1}): ν(NH) 3330; ν(C=N) 1640; ν(NCS) 2102, 2072; δ(py) 646. UV–Vis [λ_{max}/nm ($\log \varepsilon/M^{-1}cm^{-1}$)]: 223(4.30), 254(4.04), 328(3.97), 404(3.23), 672(2.19).

2.4. X-ray crystal structure determination

Single green crystals of copper(II) complexes **1**–**3** and yellow crystals of $H_2L^+I^-$ were selected and glued onto glass fibers. Diffraction data were collected on an Oxford Diffraction KM4 four-circle goniometer equipped with a Sapphire CCD detector. The crystals to detector distance was 45.0 mm and graphite monochromated Mo Kα (λ = 0.71073 Å) radiation was employed in all measurements. A frame width of 1° in ω, within 1.5–17.4 s was used to acquire each frame for measurements of all crystals in the present work. More than one hemisphere of the three-dimensional data was collected in all measurements. The data were reduced using the Oxford Diffraction program CrysAlis^{Pro}. A semi-empirical absorption-correction based upon the intensities of equivalent reflections was applied, and the data were corrected for Lorentz, polarization, and background effects. Scattering curves for neutral atoms, together with anomalous-dispersion corrections, were taken from the International Tables for X-ray Crystallography [38]. The structures were solved by direct methods [39] and the figures were drawn using Mercury [40]. Refinements were based on F^2 values and done by full-matrix least-squares [41] with all non-H atoms anisotropic. The positions of all non-H atoms were located by direct methods. The positions of hydrogen atoms were found from the inspection of the difference Fourier maps. The final refinement included atomic positional and displacement parameters for all non-H atoms. The non-H atoms were refined anisotropically, while H sites of the water molecules were refined with isotropic displacement parameters. However, at the final stage of the refinement, H atoms belonging to HL were positioned geometrically (N–H = 0.86 and C–H = 0.93 and 0.97 Å for CH and CH_3, respectively) and refined using a riding model with fixed isotropic displacement parameters. Crystal data and refinement parameters are listed in Table 1.

3. Result and discussion

3.1. Synthesis and characterization

The complexes were prepared using the protonated form of the ligand, $H_2L^+I^-$, obtained by the previously described reaction [37]. The ligand is well soluble in H_2O, less soluble in EtOH and MeOH, and insoluble in Et_2O. Molar conductivities in H_2O and MeOH solutions correspond to the electrolyte type 1:1 [42]. The substance is stable in air, not only at room temperature, but also at somewhat elevated temperatures (*vide infra*).

The sulfato complexes of copper(II), $[Cu(HL)SO_4(H_2O)]\cdot H_2O$ (**1**) and $[Cu_2(HL)_2(\mu\text{-}SO_4)_2]\cdot 2H_2O$ (**2**), were prepared by the reaction of warm EtOH/MeOH solutions of the ligand with a H_2O/MeOH solution of $CuSO_4\cdot 5H_2O$, respectively. The complexes are well soluble in H_2O, MeOH and DMF, and less in EtOH. The molar conductivity of a solution of complex **1** is significantly smaller than λ_o for a complex that is a 1:1 electrolyte, in contrast to λ_o of complex **2**, which corresponds to a 1:1 type of electrolyte, suggesting a lower stability of complex **2** [42]. The μ_{eff} value of complex **1** is characteristic of a mononuclear magnetically isolated Cu(II) complex, in contrast to complex **2** which has a lower μ_{eff} value (1.57 BM), in agreement with its dinuclear structure [43].

Complex [Cu(HL)(NCS)(SCN)] (**3**) was obtained by mixing MeOH solutions of the ligand and $Cu(ClO_4)_2\cdot 6H_2O$, adding triethyl orthoformate and NH_4NCS. The compound is well soluble in MeOH and DMF, less soluble in EtOH and poorly soluble in H_2O. The molar conductivity of its solution corresponds to a 1:1 type of electrolyte, which suggests replacement of one coordinated NCS group with solvent molecules [42]. The effective magnetic moment of complex **3** (μ_{eff} = 1.80 BM), like that of complex **1**, is in agreement with its mononuclear structure [43].

The thermal stability of the compounds was found to be independent of the atmosphere. The onset temperature of the ligand decomposition is 206 °C. The desolvation temperature of **1** is in accordance with its crystal structure. The evaporation of crystal water from **2**, near to the boiling point of water, is probably due to hindered diffusion. The desolvated complexes **1** and **2**, as well as **3**, are thermally stable up to 160 °C. Detailed analysis of the thermal data is given in the Supplementary data.

The IR and electronic spectra of the ligand and complexes are discussed in the Supplementary data.

3.2. Structure of the ligand

The triclinic ($P\bar{1}$) elementary cell of the $H_2L^+I^-$ monocrystal consists of well developed separated structural units of H_2L^+ cations, containing a protonated pyridine nitrogen atom and an I^- anion. Fig. 1 shows the composition of the asymmetric elementary cell unit and enumeration of the ligand atoms, while Table 2 lists the interatomic distances and angles. The magnitude of the angle C(5)–N(4)–C(9) (124.1(2)°) confirms that the nitrogen atom of the pyridine ring is protonated [44]. The H_2L^+ cation has an E-configuration (*cis*-position of N atoms) with respect to the C(1)–N(2) bond. The structure of the ligand is characterized by high polarity, and the deviation from the best mean plane is within the range 0.001–0.145 Å. The iodide anions are located close to the ligand plane. The isothiosemicarbazide fragment is in its amido form, which is characterized by a mild delocalization of the electronic density [30]. The delocalization is also suggested by the N(1)–C(1), C(1)–N(2) and N(2)–N(3) distances of 1.331(4), 1.301(4) and 1.385(2) Å, respectively. The C(3)–N(3) distance (1.285(3) Å) corresponds to a localized double bond.

Apart from the ionic character of the bond, the packing of the structural units is also strongly influenced by hydrogen bonds, as both potential H donors (N atoms from the pyridine and thioamide fragments) participate in the formation of the N–H···I interactions as the only hydrogen bonds. In addition to the hydrogen bonds, the structural units also involve van der Waals contacts, which yield to

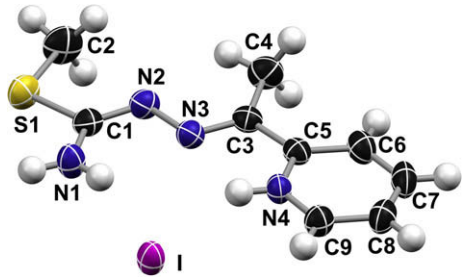

Fig. 1. View of the asymmetric part of the elementary cell and atom labeling in the ligand $H_2L^+I^-$.

the formation of specific supramolecular forms in the shape of double-layer regions along the [1 1 0] direction, about 10.5 Å wide and 3.3 Å thick (see Fig. S1 in the supplementary data). Along their surfaces, the layers are approximately perpendicular to the direction [−1 1 1]. Along each of the double-layer regions, there appear alternate domains populated with I^- and H_2L^+ ions (see Fig. S2 in the supplementary data). The developed network of hydrogen bonds is realized solely within the double-layer areas via the I atom and the N atom of the pyridine ring (N4), and that of the thioamide group (N1). These bonds are characterized by the following parameters: I···H(4)N(4) = 3.513(2) Å, ∠(N(4)–H(4)–I) = 143.2(1)°; I···H(1A)N(1) = 3.729(3) Å, ∠(N(1)–H(1A)···I) = 156.6(2)°, I···H(1B)N(1) = 3.697(3) Å, ∠(I–H(1B)–N(1) = 144.9(2)°. In addition to the hydrogen bonds, the double-layers also involve van der Waals contacts of the type (CH···I): I···C(7) = 4.050(3) Å; I···C(4) = 4.040(5) Å.

3.3. Structure of the complexes

Complexes **1**, **2** and **3** have a slightly distorted square-pyramidal environment around the Cu(II) centers (τ = 0.18, 0.08 and 0.18, respectively). Three coordination sites in the square base are occupied by the neutral 2-acetylpyridine *S*-methylisothiosemicarbazone ligand, which behaves as a tridentate NNN ligand. Namely, HL is coordinated through the pyridine, azomethine and isothioamide nitrogen atoms, forming thus two five-membered metallocycles of high planarity.

The isothioamide and azomethine nitrogens, N(1) and N(3), form bonds with the copper atom, whose lengths are in the range from 1.949 to 1.974 Å, whereas the pyridine nitrogen N(4) forms somewhat longer bonds (2.011–2.017 Å) (Table 2). In contrast to the free ligand, which is in the amido form, the coordinated ligand in all three complexes is in its imido form, resulting from prototropic tautomerization, that is the migration of the hydrogen atom of the NH_2 group of the isothioamide fragment to the adjacent hydrazine N(2) atom. Coordination in the imido form is also characteristic of other isothiosemicarbazones [30]. The existence of the imido form is also unequivocally confirmed by the presence of hydrogen bonds in the crystal structures of all three complexes, in which N(2) appears as an electron donor. In the structure of the coordinated ligand, the bond lengths C(1)–N(2) (1.370–1.379 Å) and N(2)–N(3) (1.354–1.366 Å) are between the values corresponding to the lengths of localized single and double C–N and N–N bonds, which indicates the delocalization of the electronic density in the isothiosemicarbazide fragment [30]. In contrast to these bonds, the bonds C(1)–N(1) (1.271–1.285 Å) and C(3)–N(3) (1.271–1.289 Å) in all three structures correspond to localized double bonds.

The bonds between the atoms of the ligator of the square base and Cu(II) are significantly shorter (1.908–2.016 Å) compared to the bonds of Cu(II) and the apical atoms of the ligator, whose lengths in complexes **1** and **2** are 2.289(2) and 2.250(2) Å, respectively, which has also been observed in a number of copper(II) complexes of a square-pyramidal (4+1) geometry [45]. As expected, the apical Cu–S bond in complex **3** is the longest (2.684(2) Å), and its length is practically identical to the same bond (2.682(1) Å) in the square-pyramidal tridentate triaza complex Cu(NNN)(NCS)(SCN) [46].

3.3.1. Structure of complex *1*

The asymmetric part of the elementary cell (Fig. 2) of **1**, apart from the neutral complex molecule [Cu(HL)SO_4(H_2O)], also contains a molecule of crystal water. The interatomic distances and angles for complex **1** are shown in Table 2.

As is known, in metal-sulfato complexes the SO_4^{2-} ligand can be bonded in many ways, i.e. via two terminal (monodentate, bidentate chelating) and 16 different bridging coordination modes [47]. It has been previously observed that mononuclear square-pyramidal Cu(II) complexes involve a monodentate sulfato group, i.e. the 1.1000 coordinated sulfate mode [47], which can occupy either an equatorial position, with the shortest Cu–O bond length of 1.949(3) Å [48], or an axial position, with the longest Cu–O bond length of 2.414(9) Å [49].

The square base around the Cu(II) in complex **1** is formed of three nitrogen atoms of the chelate ligand and an oxygen atom of the coordinated water (Cu–O(5) = 1.943(2) Å), whereas the apical position is occupied by the O(1) atom of the sulfate group coordinated in the 1.1000 mode (Cu–O(1) = 2.289(2) Å). The Cu(II)

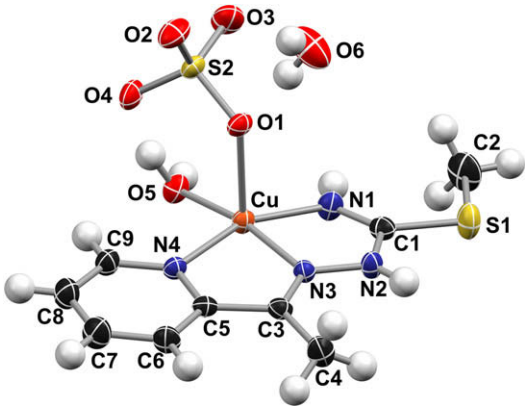

Fig. 2. Contents of the asymmetric part of the elementary cell and atom labeling in the structure of complex **1**.

atom sticks out by 0.177(2) Å from the mean plane of the square base towards the axial position.

The stable bonding of the structural units in the crystal space of complex **1** is realized by the existence of the developed 3-D network of hydrogen bonds, formed thanks to a number of potential donor and acceptor atoms in the structure. Thus, in addition to the O atoms of the coordinated and crystal water, the thioamide nitrogen and the nitrogen of the N(2) hydrazine residue from the chelate ligand play the role of donors. Each oxygen atom of the SO_4 group also plays the role of a single or double hydrogen acceptor. All the existing hydrogen bonds (six in total) are in the range 2.592–3.037 Å and, together with the corresponding angles, are listed in Table 3. The shortest hydrogen bond (O(5)–O(4)) is intramolecular, and it appears between the coordinated water and sulfate group. Packing of the structural units in the crystalline space of complex **1** is presented in Fig. S3 in the supplementary data.

3.3.2. Structure of complex *2*

In the dinuclear complex $[Cu_2(HL)_2(\mu\text{-}SO_4)_2]\cdot 2H_2O$ (**2**), two sulfato *exo*-bidentate ligands are 2.1100 bridged [47] between two metal centers at a distance of 4.744(2) Å, forming a centrosymmetric dinuclear complex with an eight-membered metallo-ring in a chair arrangment, which is a most unusual bridging mode of this ligand. The same coordination mode of two sulfate groups is also found in the structure of the dinuclear Cu(II) complexes $[Cu_2L_2(SO_4)_2]$ (L = dipyridophenazine, diacetyl monoxime-2-pyridyl hydrazone) [50,51], as well as in the tetranuclear $[Cu_4(L)_2(SO_4)_2(H_2O)_{10}](SO_4)_2\cdot 4H_2O$ (L = 3-2(pyridyl)-triazino[5,6-*f*]1,10-phenanthroline) [52].

The square bases of both coordination polyhedra of complex **2** are formed by the nitrogen atoms N(1), N(3) and N(4) from the corresponding HL and the oxygen atoms O(1) from the symmetrically identical (−1) bridging sulfate groups, whereas the apical positions are occupied by the oxygen atoms O(2), also from the bridging sulfate groups (Fig. 3). The Cu(II) atoms deviate by 0.247(2) Å from the mean square base towards the apical position. The Cu–O distance in the apical position is longer (Cu–O(2) = 2.250(2) Å) compared to the equatorial Cu–O(1) distance (1.916(2) Å) (Table 2), which is in good agreement with the corresponding literature data [50,51]. The bridging coordination of the sulfate group distorts its tetrahedral symmetry. The angle O(1)–S(2)–O(2) is the smallest (106.4(1)°), whereas the angle O(4)–S(2)–O(3) is the largest (112.9(1)°). As a consequence of the coordination, the bonds S(2)–O(1) and S(2)–O(2) become longer, amounting to 1.481(2) and 1.494(2) Å, respectively.

Table 3
Hydrogen bonding in complex **1**.

Donor	Acceptor	Distance (Å)	Dist.–vdW (Å)
N2	O1^{i}	2.691	−0.379
N1	O3^{ii}	3.037	−0.033
O5	O2^{ii}	2.691	−0.349
O5	O4^{iii}	2.592	−0.448
O6	O2^{ii}	2.860	−0.180
O6	O3^{iii}	2.858	−0.182
Donor–H–acceptor	Angle (°)	Donor–H–Acceptor	Angle (°)
N1–H1–O3	138.6	O5–H51–O4	159.4
N2–H2–O1	149.2	O6–H61–O3	175.0
O5–H52–O2	174.0	O6–H62–O2	170.0

Symmetry transformations to generate equivalent atoms: (i) (1 − *x*, −*y*, 2 − *z*), (ii) (1/2 + *x*, 1/2 − *y*, 1/2 + *z*), (iii) (*x*, *y*, *z*).

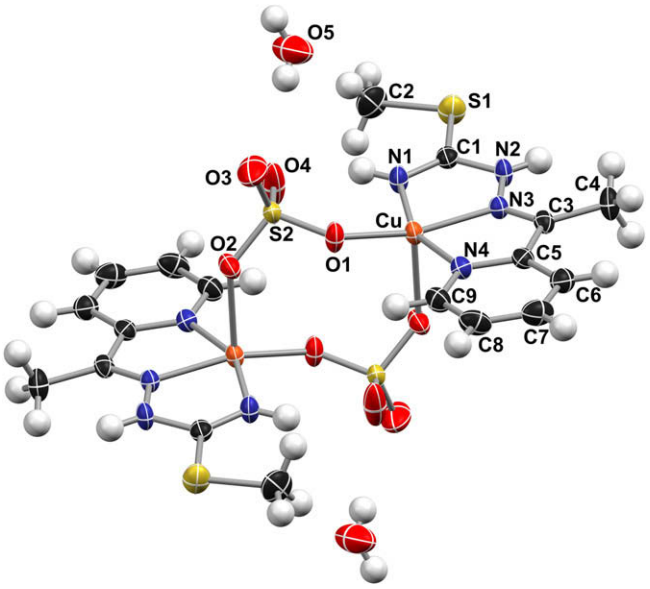

Fig. 3. Contents of the elementary cell and atom labeling in the structure of complex **2**.

The triclinic ($P\bar{1}$) elementary cell of complex **2**, along with the dimeric complex unit, contains also a molecule of crystal water. The bonds between the adjacent units are realized via the branched system of hydrogen bonds. In all, there are four different hydrogen bonds, established between water molecules and N-atoms of the isothioamide group and hydrazine residue of the chelate ligand as hydrogen donors and only O atoms of the sulfate group that do not belong to the basal plane of the coordination polyhedron as hydrogen acceptors. Out of all of them, only N(1)–H(1)···O(4) = 2.799(3) Å, ∠N(1)–H(1)–O(4) = 129.4(2)° is intramolecular, whereas the intermolecular hydrogen bonds in the structure of the complex are: N(2)H···O(1) = 2.668(4) Å, ∠(N(2)–H(2)–O(1)) = 150.0(2)°; O(5)H(51)···O(3) = 2.768(4) Å, ∠(O(5)–H(51)–O(3)) = 164(4)° and O(5)H(52)···O(4) = 2.948(2) Å, ∠(O(5)–H(52)–O(4)) = 156(5)°. The spatial network of hydrogen bonds connects adjacent dimers via water molecules into chains that are parallel in the direction [1 0 1], as is shown in Fig. 4.

3.3.3. Structure of complex *3*

The asymmetric part of the monoclinic ($P2_1/c$) elementary cell contains only one structural unit, and the neutral complex is shown in Fig. 5. The distances and angles in the coordination polyhedron as well as in the chelate ligand are given in Table 2.

The square base around Cu(II) is formed by the tetraaza donor set of atoms, consisting of the tridentate NNN HL ligand and the NCS group, which is coordinated via the nitrogen atom. The apical

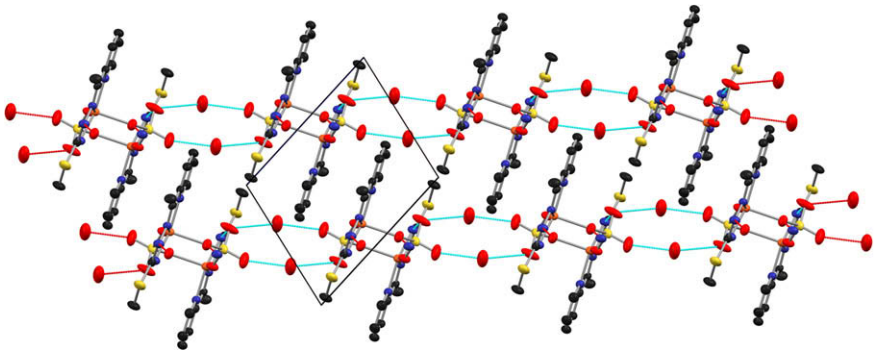

Fig. 4. View along the *b* axis of packing in the structure of complex **2**. H atoms are omitted for better clarity. Crystal water molecules (O5) form hydrogen bonds with free sulfate O atoms, bonding the adjacent dimers along the direction [1 0 1].

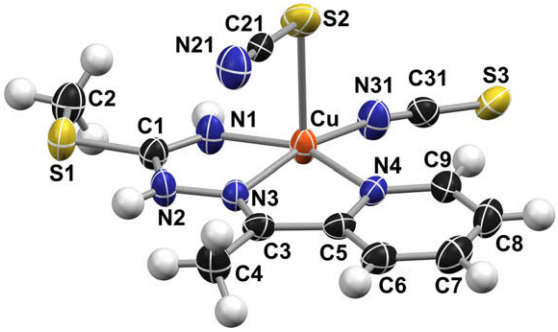

Fig. 5. View of the asymmetric part of the elementary cell and atom labeling in the structure of complex **3**.

position of the square pyramid is occupied by the other NCS group, whose coordination is realized via the sulfur atom. The NCS group of the square base, as well as the apical NCS group, are practically linear, with N–C–S angles of 178.6(4)° and 177.4(4)°, respectively. The NCS group from the square base forms a Cu–N(31)–C(31) angle of 168.8(3)°, whereas the apical NCS group forms almost a right angle (the angle Cu–S(2)–C(21) is 99.8(2)°).

It is known that the ambidenticity of the NCS^- ion allows two modes of its terminal coordination. Copper(II), as a metal of the first transition series, forms most frequently the Cu–N bond with the NCS^- ion, although there are also some examples of S-bonded coordination, which is explained by the formation of NH···N(NCS) hydrogen bonds that stabilize the crystal structure [46,53]. Coordination via the sulfur atom is energetically unfavorable, as it is in contradiction to the Pearson's hard-soft interactions, which assumes that the hardnesses of the base and acid should match each other. The factors influencing bonding properties of this ion are diverse [54], and in the case of the same ligands the condition of the synthesis itself may play a decisive role in the coordination mode of the NCS group [53]. It has been reported [55] that a polynuclear Cu(II) complex, apart from bridging, contains also terminal N- and S-bonded NCS groups. Relatively rare, and difficult to prepare, are metal complexes containing simultaneously one S- and one N-bonded non-bridging thiocyanate to the same metal ion, as was found in the complex [Pd(L)(NCS)(SCN)] (L = 1-phenylphosphino-3-dimethylaminopropane) [56], [Cu(L)(NCS)(SCN) (L = condensation product of 2-(2-aminoethyl)pyridine with 4-methylimidazole-5-carboxaldehyde) [46] and $[Cu^{II}(L)_2][Cu^{I}(L)(NCS)_2(SCN)]$ (L = 2,2′-biimidazole) [57], which the authors [46,57] explain by the formation of the corresponding intermolecular hydrogen bond between the N atom of the thiocyanate and the N–H proton of the ligand L of an adjacent molecule.

In the case of our complex, the S-coordination of the apical NCS group might also be explained by the formation of an intermolecular hydrogen bond between the nitrogen atom of the hydrazine residue N(2) and the rhodanide N(21): N(2)H–N(21) = 2.806(5) Å, ∠(N(2)–H(2)–N(21)) = 167.9(2)°. These hydrogen bridges, formed between adjacent molecules of the complex, give rise to a centrosymmetric pseudo-dimeric structure, which stabilizes an energetically unfavorable mode of coordination of the apical NCS group. Analogous coordination modes of the NCS group, as well as the formation of a pseudo-dimeric structure was also found in the structure of the already mentioned [CuL(NCS)(SCN)] complex [46].

Apart from the above mentioned hydrogen bond, the complex structure also involves a bond between the coordinated sulfur atom of the apical NCS group and the nitrogen atom of the isothioamide group of an adjacent molecule (N(1)H–S(2) = 3.368(3) Å, ∠(N(1)–H(1)···S(2)) = 147.6(2)°), allowing more extensive binding of dimeric units into a 3-D network (see Fig. S4 in the supplementary data). All other intermolecular contacts may be ascribed to van der Waals type bonds, and they exceed 3.50 Å.

4. Conclusion

It has been shown that the coordination mode of the sulfato ligand, and hence the composition and structure of copper(II) complexes with the tridentate NNN 2-acetylpyridine *S*-methylisothiosemicarbazone ligand (HL), is essentially influenced by the conditions of the synthesis. Namely, the reaction of an aqueous solution of $CuSO_4{\cdot}5H_2O$ and an EtOH solution of $H_2L^+I^-$ yielded the mononuclear square-pyramidal complex $[Cu(HL)SO_4(H_2O)]{\cdot}H_2O$, with a monodentate SO_4 group in the apical position. However, the reaction of MeOH solutions of the same reactants resulted in a dinuclear centrosymmetric, also square pyramidal complex $[Cu_2(HL)_2(\mu\text{-}SO_4)_2]{\cdot}2H_2O$, with the *exo*-bidentate coordination of both SO_4 groups, whose oxygen atoms occupy the apical position of both coordination polyhedra, as well as an equatorial position. Beside these two complexes, we also present the complex [Cu(HL)(NCS)(SCN)] which is formed in the reaction of MeOH solutions of $Cu(ClO_4)_2$, $H_2L^+I^-$ and NH_4SCN in the presence of triethyl orthoformate. This, also square pyramidal complex contains differently coordinated NCS groups. For Cu(II), as a moderately hard acid, the usual way of coordination through the sulfur atom of the apical SCN as a soft base, is a consequence of the formation of an intermolecular hydrogen bond.

Fig. 1. Diagram showing structural formula of the ligands H_2B^1, H_2B^2, H_2B^3 and H_2B^4.

shown that one of these ligands has the potential to demonstrate a metal selective binding mode owing to the presence of multiple binding sites of varying types. Thus our aim is to observe the changes in luminescent behavior of the ligands with different guest (metal ions) inputs. We have also found that fluorescent emissions of the ligands are dependant on the substituents present on the extended conjugated backbone of the ligands. Dioxomolybdenum complexes **1–4** of all the ligands H_2B^1, H_2B^2, H_2B^3 and H_2B^4 have been prepared and characterized. The complexes exhibit quenched emission compared to the respective ligands. One of these complexes, $[MoO_2(B^1)H_2O]$ (**1**), when treated with equimolar amounts of Cu^{2+}, Co^{2+} or Ni^{2+} ions in solution shows further quenching. However with Zn^{2+} ion input to complex **1**, enhancement of fluorescence up to the level of the free ligand was observed. The Cu^{2+} complex (**5**) was isolated and characterized. Again on reduction via oxo abstraction by PPh_3, complex **3** is converted to complex **6**, a monooxo Mo(IV) complex. Fluorescence emission of **6** was found to be less intense than **3**.

2. Experimental

$MoO_2(acac)_2$ was prepared as described in the literature [23]. Reagent grade solvents were used as received. 1-(2-Pyridyl)-5-methyl pyrazole-3-carbohydrazide was prepared from ethyl 1-(2-pyridyl)-5-methyl pyrazole-3-carboxylate [24] by following the literature method. Salicylaldehyde, 5-bromo salicylaldehyde, 5-nitro salicylaldehyde and o-hydroxy acetophenone were purchased from Aldrich Chemical Company, USA and were used as received. Tetraethyl ammonium perchlorate (TEAP) used for electrochemical work was prepared as reported in the literature [25].

2.1. Preparation of the ligands

All the four ligands H_2B^1, H_2B^2, H_2B^3 and H_2B^4 were synthesized in a similar way by refluxing an ethanolic solution (20 ml) of 1-(2-pyridyl)-5-methyl pyrazole-3-carbohydrazide (10 mmol, 2.17 g) with salicylaldehyde (10 mmol, 1.22 g for H_2B^1), *o*-hydroxy acetophenone (10 mmol, 1.36 g for H_2B^2), 5-bromo salicylaldehyde (10 mmol, 2.01 g for H_2B^3) and 5-nitrosalicylaldehyde (10 mmol, 1.67 g for H_2B^4), respectively, also taken in ethanol (20 ml). The reflux was continued for ca. 2 h at water bath temperature, during which a solid compound separated. It was filtered, washed with ethanol and dried over fused $CaCl_2$ .The crude product was recrystallized from an ethanol–water mixture (4:1 V/V). Single crystals of H_2B^2 and H_2B^3 were isolated and their structures were determined.

H_2B^1: M.P.: 193 °C. Yield: 2.57 g (80%). IR (KBr pellet) cm^{-1}: ν(N–H) 3223, ν(O–H) 3066, ν(C=O) 1663, ν(C=C) 1611, ν(C=N) 1546.9. ^1H NMR (D_6-DMSO) δ, ppm: (C_3–H, C_6–H of C_6H_4–) 6.9d(2), (C_4–H, C_5–H of C_6H_4–) 7.45t(2), (–CH=N–) 8.69s(1), (aromatic-OH) 12.08(1), (C_2–H of pyridine) (8.5)d(1), (C_5–H of pyridine) 8.1d(1), (C_3–H and C_4–H of pyridine) 7.25t(2) (pyrazole C–H) 6.79 m(1), (Pyz–CH_3) 2.60s(1).

H_2B^2: M.P.: 138 °C. Yield: 2.68 g. (80%). IR (KBr pellet) cm^{-1}: ν(N–H) 3264, ν(O–H) 3056 ν(C=O) 1698, ν(C=C) 1590, ν(C=N) 1526. ^1H NMR (D_6-DMSO) δ, ppm: (C_3–H, C_6–H of C_6H_4–) 6.85d(2), (C_4–H, C_5–H of C_6H_4–) 7.45t(2), (aromatic-OH) 12.08(1), (C_2–H of pyridine) (8.5)d(1), (C_5–H of pyridine) 8.15d(1), (C_3–H and C_4–H of pyridine) 7.25t(2), (pyrazole C–H) 6.70 m(1), (Pyz–CH_3) 2.60s(1), (–N=C–CH_3) 2.65s(3).

H_2B^3: M.P.: 218 °C. Yield: 3.20 g (80%). IR (KBr pellet) cm^{-1}: ν(N–H) 3308, ν(O–H) 3085, ν(C=O) 1655, ν(C=C) 1591, ν(C=N) 1535. ^1H NMR (D_6-DMSO) δ, ppm: (C_3–H, C_4–H of C_6H_4–) 6.9d(2), (C_6–H of C_6H_4–) 7.9s(1), (–CH=N–) 8.81s(1), (aromatic-OH) 12.20(1), (C_6–H of pyridine) (8.5)d(1), (C_3–H of pyridine) 7.6d(1), (C_4–H of pyridine) 7.4t(1), (C_5–H of pyridine) 8.1t(1), (pyrazole C–H) 6.70 m(1), (Pyz–CH_3) 2.60s(1).

H_2B^4: M.P.: 196 °C. Yield: 2.20 g (60%). IR (KBr pellet) cm^{-1}: ν(N–H) 3304, ν(O–H) 3134 ν(C=O) 1662, ν(C=C) 1620, ν(C=N) 1545. ^1H NMR (D_6-DMSO) δ, ppm: (C_3–H, C_4–H of C_6H_4–) 6.9d(2), (C_6–H of C_6H_4–) 7.9s(1), (–CH=N–) 8.87s(1), (aromatic-OH) 12.08(1), (C_6–H of pyridine) (8.8)d(1), (C_3–H of pyridine) 8.5d(1), (C_4–H of pyridine) 8.0t(1), (C–H of pyridine) 8.3t(1), (pyrazole C–H) 6.70 m(1), (Pyz–CH_3) 2.60s(1).

2.2. Preparation of complexes *1–4*

The complexes $[MoO_2(B^1)H_2O]$ (**1**), $[MoO_2(B^2)EtOH]$ (**2**), $[MoO_2(B^3)EtOH]$ (**3**) and $[MoO_2(B^4)EtOH]$ (**4**) were prepared in a similar way by refluxing an ethanolic solution (10 ml) of $MoO_2(acac)_2$ (0.5 mmol, 0.163 g) with ethanolic solutions of H_2B^1 (0.5 mmol, 0.161 g), H_2B^2 (0.5 mmol, 0.168 g), H_2B^3 (0.5 mmol, 0.200 g) and H_2B^4 (0.5 mmol, 0.183 g), respectively. On mixing the two components, immediately an orange yellow colour was observed. The mixture was then refluxed for 1 h. The respective complexes separated as orange microcrystalline compounds during the reflux or afterwards on slow evaporation of the reaction mixture. These were filtered, washed with ethanol and dried over fused $CaCl_2$.

$[MoO_2(B^1)H_2O]$ (**1**): Yield 0.140 g (60%). Elemental analysis: *Anal.* Calc. for $C_{17}N_5O_5H_{17}Mo$: C, 43.77; H, 3.66; N, 15.02. Found: C, 43.61; H, 3.59; N, 15.23%. IR ($\nu_{(Mo=O)}/cm^{-1}$): 902, 941, UV–Vis (λ_{max}/nm) ($\varepsilon/dm^3\ mol^{-1}\ cm^{-1}$): 392, 327. NMR ($^1H/\delta$ TMS): (–N=CH–) 8.85s, (H_2O) 3.2d. CV (E_{pc}/V): −1.12 [Mo(VI)/Mo(V)], −1.64 [Mo(V)/Mo(IV)].

X-ray quality crystals of (**1**) were obtained from the reaction mixture on slow evaporation.

$[MoO_2(B^2)EtOH]$ (**2**): Yield 0.127 g (50%) Elemental analysis: *Anal.* Calc. for $C_{20}N_5O_5H_{25}Mo$: C, 47.21; H, 4.52; N, 13.77. Found: C, 47.13,; H, 4.50; N, 13.85%. IR ($\nu_{(Mo=O)}/cm^{-1}$): 891, 935. UV–Vis (λ_{max}/nm) ($\varepsilon/dm^3\ mol^{-1}\ cm^{-1}$): 385, 313. NMR ($^1H/\delta$ TMS): (–N=C–CH_3) 2.75s(3), (CH_3CH_2OH) 1.01t, (CH_3CH_2OH) 2.46 m, (CH_3CH_2OH) 3.52s. CV (E_{pc}/V): −1.21 [Mo(VI)/Mo(V)], −1.52 [Mo(V)/Mo(IV)].

$[MoO_2(B^3)EtOH]$ (**3**): Yield 0.143 g (50%) Elemental analysis: *Anal.* Calc. for $C_{19}N_5O_5H_{20}BrMo$: C, 39.72; H, 3.48; N, 12.19. Found: C, 38.80; H, 3.56; N, 11.87%. IR ($\nu_{(Mo=O)}/cm^{-1}$): 917, 936. UV–Vis (λ_{max}/nm) ($\varepsilon/dm^3\ mol^{-1}\ cm^{-1}$): 411, 321, 303. NMR ($^1H/\delta$ TMS):

(–N=CH–) 8.89s, (CH_3CH_2OH) 1.01t, (CH_3CH_2OH) 2.46m, (CH_3CH_2OH) 3.50s. CV (E_{pc}/V): −1.02 [Mo(VI)/Mo(V)], −1.54 [Mo(V)/Mo(IV)].

[$MoO_2(B^4)EtOH$] (**4**): Yield 0.139 g (50%). Elemental analysis: *Anal.* Calc. for $C_{19}N_6O_7H_{20}Mo$: C, 42.30; H, 3.71; N, 15.58. Found: C, 42.25; H, 3.67; N, 15.61%. IR ($\nu_{(Mo=O)}$/cm^{-1}): 917, 945. UV–Vis (λ_{max}/nm) (ε/$dm^3\ mol^{-1}\ cm^{-1}$): 412, 285. NMR ($^1H/\delta$ TMS): (–N=CH) 9.10s, (CH_3CH_2OH) 1.01t, (CH_3CH_2OH) 2.46m, (CH_3CH_2OH) 3.50s. CV (E_{pc}/V): −0.85[Mo(VI)/Mo(V)].

2.3. Preparation of complex **5**

When an ethanolic solution of $Cu(NO_3)_2{\cdot}6H_2O$ (0.295 g, 1 mmol) was added to an ethanolic solution of complex **1** (0.466 g, 1 mmol), immediately a green colloidal precipitate started to appear. To that, acetonitrile was added in a 1:1 proportion (v/v) and the resulting mixture was allowed to reflux for an hour. A clear green solution resulted. It was filtered and kept for slow evaporation. [$Cu(HB^1)NO_3$] (**5**), which may also be treated as the symmetry related binuclear complex [$Cu_2(HB^1)_2(NO_3)_2$], appeared as dark green crystals within a week.

[$Cu(HB^1)NO_3$] (**5**): Yield 0.258 g (50%). Elemental analysis: *Anal.* Calc. for $C_{17}N_6O_5H_{13}Cu$: C, 45.79; H, 3.14; N, 15.71. Found: C, 45.75; H, 3.11; N, 15.64%. UV–Vis (λ_{max}/nm) (ε/$dm^3\ mol^{-1}\ cm^{-1}$): 393, 669. CV (E/V), E_{pa}: 0.480 [Cu(II)/Cu(III)], 0.367 [Cu(III)/Cu(II)], E_{pc}: −0.467[Cu(II)/Cu(I)].

2.4. Preparation of complex **6**

[$MoO(L^3)CH_3CN$] (**6**): Complex **3** (0.25 mmol, 0.143 g) was taken in a suspension of 40 ml degassed acetonitrile, PPh_3 (2.25 mmol, 5.50 g) was added and the mixture was refluxed at water bath temperature under a dinitrogen atmosphere for 1 h. The green compound obtained as a residue was filtered on a sintered gooch crucible and washed with acetonitrile. It was dried in a vacuum desiccator over concentrated H_2SO_4. Yield: 0.055 g (52%). Elemental analysis: *Anal.* Calc. for $C_{19}N_6O_3H_{18}BrMo$: C, 41.30; H, 3.26; N, 15.21. Found: C, 40.8; H, 3.12; N, 15.01%. IR (ν_{max}/cm^{-1}): 926 (Mo=O) UV–Vis (λ_{max}(DMF)/nm) (ε/$dm^3\ mol^{-1}\ cm^{-1}$): 438 (5467), 686 (1765). CV (E/V) E_{pa}: 1.48 [Mo(VI)/Mo(IV)], E_{pc}: −1.21, E_{pa}: −0.71[Mo(IV)/Mo(III)], ΔE_p:0.51, $E_{1/2}$: 0.925.

2.5. Physical measurements

Elemental analyses were performed at IACS, Kolkata on a Perkin–Elmer 2400 CHN analyzer. The ^1H NMR spectra of the complexes and the ligands were recorded on a Bruker AM300L (300 MHz) superconducting FT-NMR spectrometer. IR spectra were recorded in KBr pellets on a Perkin–Elmer FTIR spectrophotometer. UV–Vis spectra and DRS were measured on a Hitachi U-3501 spectrophotometer. Cyclic Voltammetry was carried out using a Sycopel model AEW21820F/L instrument. The measurements were carried out at 293 K in DMF solutions containing 0.2 M TEAP as a supporting electrolyte and 10^{-3} to 10^{-4} M solutions of the complexes deoxygenated by bubbling with nitrogen. The working, counter and reference electrodes used were a Pt wire, platinum coil and an SCE, respectively. The fluorescence spectra were recorded on a Perkin–Elmer LS 50B fluorimeter.

2.6. Crystallographic measurements

The crystals were measured on a Bruker SMART 1K CCD diffractometer using Mo Ka radiation (λ = 0.71073 Å). Positions of the hydrogen atoms were calculated from the geometry of the molecular skeleton and their thermal displacement parameters were refined isotropically on a group-wise basis. Essential crystal parameters for H_2B^2, H_2B^3, complex **1** and complex **5** are provided in Table 1. Selected bond lengths and angles are reported in Table 2. Unit cell and reflection data were obtained by standard methods [26,27]. The structures were solved, refined and prepared for publication using the SHEXTL package [28] (structure solution refinements and molecular graphics). Two of the structures, i.e. ligand H_2B^2 and complex **5**, contained a few disorders. In H_2B^2 the atoms of the pyrimidine ring C14, C15, C16, C17, C18 and N5 are disordered over two positions denoted by A and B suffixes. The occupancies are divided in each case in a ratio A:B of 52.9:47.0. In complex **5** the disorder is limited

to only one atom of the coordinated nitrate ion, i.e. O2N. Here also the disordered positions are assigned using A and B suffixes (O2NA and O2NB). The occupancies are in a ratio O2NA:O2NB of 17.6(5):82.4(6). The three restrains imposed on the structure of complex **1** are all based on interatomic distances of the coordinated water molecule. They are O4–H41, O4–H42 fixed at 0.82 Å and H41–H42 fixed at 1.29 Å.

2.7. Quantum yield calculation

The fluorescence quantum yields of the ligands H_2B^1, H_2B^2, H_2B^3, their Mo(VI) complexes **1–4** and the solutions resulting by adding equimolar proportions of Cu(II) and Zn(II) salts to solutions of **1** in DMF and methanol solvents are measured relative to recrystallized β-naphthol as the secondary standard, and are calculated on the basis of the following equation [29,30].

$$\Phi_f = \Phi_f^{\circ} \frac{n_{\circ}^2 A^{\circ} \int I_f(\lambda_f) d\lambda_f}{n^2 A \int I_f^{\circ}(\lambda_f) d\lambda_f}$$

where n_0 and n are the refractive indices of the solvents, A^0 and A are absorbances, ϕ°_f and φ_f are quantum yields, and the integrals denote the area of the fluorescence bands for the standard and sample, respectively. The fluorescence quantum yields of the different solutions are given in Table 3.

3. Results and discussion

3.1. Synthesis

The ligand H_2B^1 was prepared by a simple condensation reaction following the same procedure as described in our previous publication [22]. H_2B^2, H_2B^3 and H_2B^4 were also prepared by the same procedure using the same molar ratio. All the Mo(VI) complexes were obtained from a refluxing mixture of the respective ligand and the bis(acetylacetonato) dioxomolybdenum(VI) precursor, taken in a 1:1 molar proportion in purified ethanol. Complex **1** separated with a composition of $[MoO_2(B^1)H_2O]$, while the others separated as $[MoO_2(B^n)EtOH]$ (n = 2–4, complexes **2–4**). These complexes were found to be fairly soluble in most common organic solvents. Magnetic susceptibility and molar conductance data show that the complexes are diamagnetic and electrically non-conducting in nature. Following our observations regarding the change of emission behavior of complex **1** on adding Cu(II) salts, we tried to isolate the resulting species in a solution containing one molar equivalent each of $Cu(NO_3)_2{\cdot}6H_2O$ and complex **1**. The green colloidal precipitate which was obtained first on adding Cu(II) salt to an ethanolic solution of **1** was dissolved in an ethanol–acetonitrile mixture (50:50 v/v), and from that mother liquor, crystals of complex **5** were obtained. The green colloidal precipitate was found to be of same composition as **5**, using common analytical techniques such as UV–Vis spectroscopy, IR and CV studies.

Oxo transfer reactions from dioxomolybdenum(VI) complexes to substrates such as PPh_3 are well known. As complex **3** has the most prominent fluorescence emission among the dioxomolybdenum(VI) complexes, we have chosen it to study the change in emission behavior with oxo abstraction. Thus complex **3** was reacted with PPh_3 under refluxing conditions, and the resulting Mo(IV) complex was also isolated.

3.2. Spectral characterization and electrochemistry

All the dioxomolybdenum(VI) complexes are characterized by the presence of strong IR bands for the symmetric and asymmetric stretching of Mo=O bonds between 891 and 945 cm^{-1} [31]. For the Mo(IV) species, complex **6**, a single peak at 926 cm^{-1} signifies the presence of a single Mo=O bond [32]. The sixth coordination position of complex **1** is occupied by a water molecule. The peaks obtained in the NMR spectra of **1** at δ 3.2 [33] supplements the results obtained from the X-ray crystal analysis. The presence of EtOH as the sixth ligand in complexes **2–4** was indicated by the NMR spectra of these complexes, as shown in the experimental section. In all the complexes, the complexation by the azomethine nitrogen is shown by a more deshielded signal of the azomethine N–H/N–CH_3 compared to those of the ligands [34]. The UV–Vis spectra of complexes **1–4** show CT bands at 385–412 nm, corresponding to ligand to metal charge transfers [35]. The Cu(II) complex **5** also shows a similar CT band at 403 nm [36]. Each of the complexes **1–4** shows two other CT bands at 313–327 nm. The d–d band of complex **5** appears at 669 nm [37]. The DRS spectrum of complex **6** shows a broad CT band, accompanied by a shoulder, at 654 nm which is characteristic of Mo(IV) species [38].

The dioxomolybdenum(VI) complexes **1–4** show two irreversible reductive responses for the Mo(VI)/Mo(V) and Mo(V)/M0(IV) reductions, the latter one taking place at a more negative potential than the former. The electron donating ability of the ligands have a clear effect on the reduction potential values. The Mo(IV) complex **6**, resulting from an oxo-transfer reaction of complex **3**, shows an irreversible oxidation on an anodic scan at 1.48 V. The cathodic scan revealed a redox cycle assigned as a Mo(III)/Mo(IV) response. Complex **5** shows the usual one electron reduction for Cu(II)/Cu(I)

Table 3
Emission behavior of the ligands and their complexes.

Samples	Solvent	$\lambda_{max(abs)}$ (nm)	$\lambda_{max(Emi)}$ (nm)	λ_{Ex} (nm)	ϕ_f
H_2B^1	DMF	325, 390	467, 467	392, 323	2.4×10^{-3}
H_2B^1	MeOH	325, 390	466, 466	310, 380

$MoO_2(B^1)H_2O/H_2B^1 + MoO_2(acac)_2$ (1:1)	DMF	327, 390	473, 473	392	7.83×10^{-4}
$MoO_2(B^1)H_2O/H_2B^1 + MoO_2(acac)_2$ (1:1)	MeOH	327, 390	460, 460	310, 380	
$MoO_2(B^2)EtOH/H_2B^2 + MoO_2(acac)_2$ (1:1)	DMF	314, 387	450, 450	368	7.80×10^{-4}
$MoO_2(B^3)EtOH/H_2B^3 + MoO_2(acac)_2$ (1:1)	DMF	321, 411	474, 474	402	3.70×10^{-4}
$MoO_2(B^4)EtOH/H_2B^4 + MoO_2(acac)_2$ (1:1)	DMF	412			
$MoO_2(B^1)H_2O + Cu(NO_3)_2{\cdot}6H_2O$ (1:1)	DMF	317, 390	450, 450 (low intensity)		7.72×10^{-5}
$MoO_2(B^1)H_2O + Co(NO_3)_2{\cdot}6H_2O$ (1:1)	DMF	400	445 (very low intensity)		
$MoO_2(B^1)H_2O + Ni(NO_3)_2{\cdot}6H_2O$ (1:1)	DMF	410	453 (very low intensity)		
$MoO_2(B^1)H_2O + Zn(NO_3)_2{\cdot}6H_2O$ (1:1)	DMF	400, 317	471, 482, 472	395, 393	2.39×10^{-3}
$Cu(HB^1)NO_3$	DMF	317, 390	450, 450	360, 284	7.69×10^{-5}
$MoO_2(B^1)H_2O + MoO_2(acac)_2$ (1:1)	DMF	327, 390	478, 478	388	4.67×10^{-4}

at −0.467 V. The anodic scan of **5** shows a redox cycle with an oxidation peak for Cu(II)/Cu(III) at 0.480 V and the corresponding reduction peak at 0.367 V.

3.3. Description of the crystal structures

The structure of the ligand H_2B^1 has been discussed in an earlier publication [22] on this ligand. Here we present the structures of H_2B^2 and H_2B^3 (Figs. 2 and 3). A notable feature of the structures is that in H_2B^2 the atoms responsible for chelation of the MoO_2^{2+} core, i.e. the phenoxide oxygen, the azomethine nitrogen and the enolate oxygen atoms, are arranged in the same direction as the extended conjugated backbone of the ligands while in H_2B^3 the presence of bulky bromine atoms results in a conformation where the phenoxide and enolate oxygen atoms are trans to each other. The two rings of the fluorophoric 1-(2-pyridyl) 5-methyl pyrazole are essentially planar in H_2B^3 (the same as H_2B^1), but in H_2B^2 the pyridine ring acquires a conformation disordered over two positions. In both of the disordered positions the pyridine ring is not in the same plane as the pyrazole ring (the dihedral angle between the mean planes of the pyrazole and pyridine rings are 12.13° and 17.76°, respectively). However in both ligands the pyrazole ring is fairly planar with the carbohydrazone portion.

The ligand H_2B^1, as expected, acts as a tridentate binegative donor for the MoO_2^{2+} core, donating through the phenolate oxygen (O1), the azomethine nitrogen (N1) and the enolate oxygen (O2). Despite the presence of a highly potential NN donor site at the 1-(2-pyridyl) 5-methyl pyrazole part of the ligand, the highly charged Mo center has chosen the oxygen rich ONO donor center at the other end. The environment of the Mo(VI) center can be described as a distorted octahedral one with a NO_5 chromophore. The ligand donors occupy the three equatorial positions with one oxo group, and the axial positions are shared by the other oxo group and a weakly bonded H_2O molecule. The Mo is found to be raised 0.320 Å above the plane containing the equatorial donors O1, N1, O2 and O5. The ligand maintains a fairly planar conformation as all the atoms, except the phenolate oxygen atom, are at less than 0.2 Å deviation from the ligand mean plane. The phenolate oxygen is raised by 0.38 Å from the mean plane. This ensures sufficient electron delocalization within the ligand and endows stability to the complex. The bond angles in the coordination sphere are unexceptional. Among the Mo-oxo bonds, the axial one is marginally longer. The Mo–enolate O bond is shorter than the Mo–phenolate bond. The Mo–O4 bond is the weakest and has the largest bond distance (2.334 Å). There are two intermolecular H-bonding interactions of considerable strength in the complex between the azomethine nitrogen (N2) and the oxygen (O4) of the H_2O ligand as well as between one oxo atom (O5) and the O4 of H_2O (Fig. 4). This H-bonding pattern mainly governs the packing in this complex. The coordination sphere of complex **5** (Fig. 5) is very similar to another published structure from one of our previous publications [22]. The only difference is in the fifth coordination position. Here it is occupied by a NO_3^- ion instead of ClO_4^- in the earlier structure. The binding mode of the ligand is completely different from that in complex **1** as the ligand adjusts to the change of metal ion to be accommodated. In complex **1**, as we have already

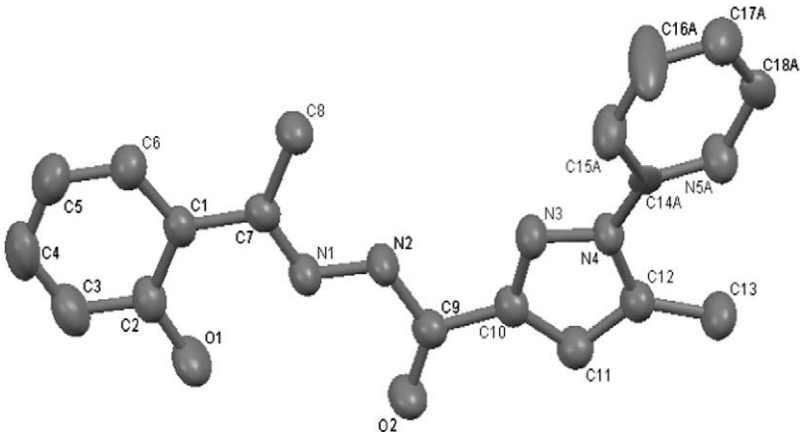

Fig. 2. Representative diagram of the crystal of H_2B^2 (the disorder of the pyridine ring is omitted for clarity).

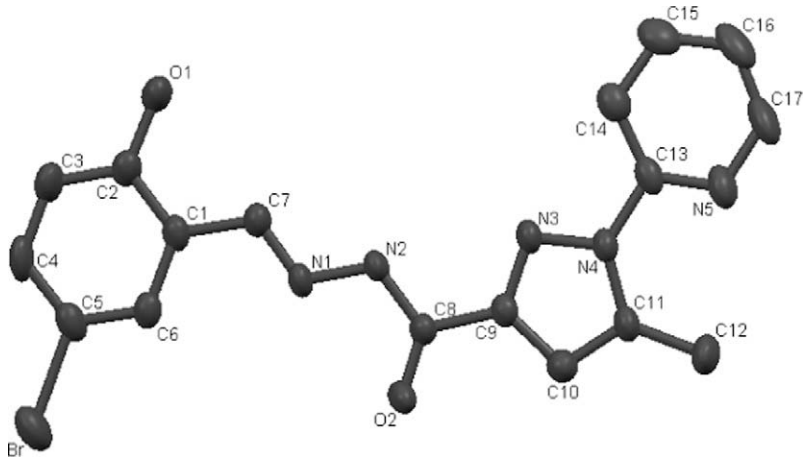

Fig. 3. Representative diagram of the crystal of H_2B^3.

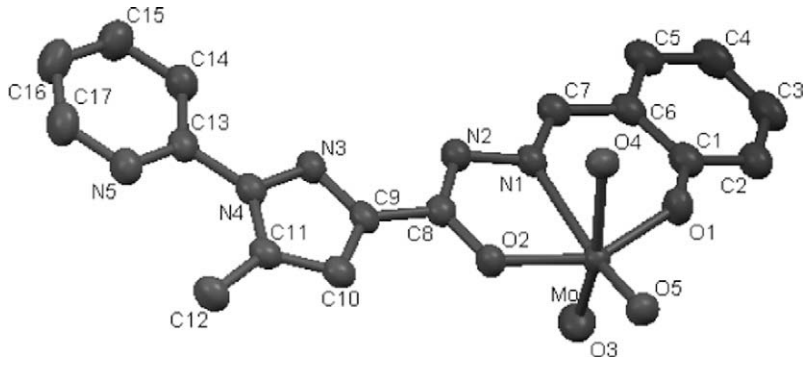

Fig. 4. Representative diagram of the crystal of complex **1**.

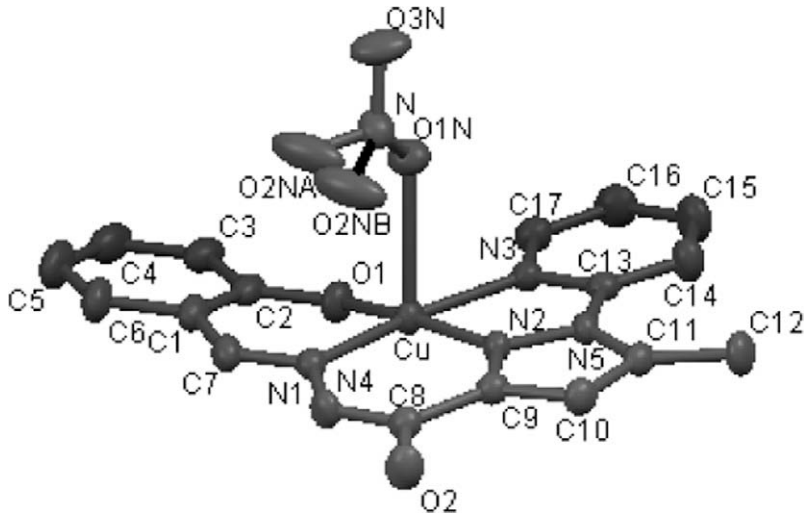

Fig. 5. Representative diagram of the crystal of complex **5** showing the coordination sphere around a single Cu atom.

discussed, the ligand acts as a tridentate binegative one. Here it acts as tetradentate mononegative donor. This change in binding mode probably contributes to the change in emission behavior. The isolation and characterization of **5** is justified as it helps to comprehend the chemistry leading to its formation and also helps to rationalize the change in emission behavior that takes place with its formation in solution.

3.4. Emission behavior

3-(2-Pyridyl) pyrazole and some of its derivatives are known to show considerably high fluorescence [39–41]. Photophysical studies on it and many of its complexes have been explored well. In our ligand system the presence of the 1-(2-pyridyl) 5-methyl pyrazole unit is responsible for the emission behavior. The salicyl

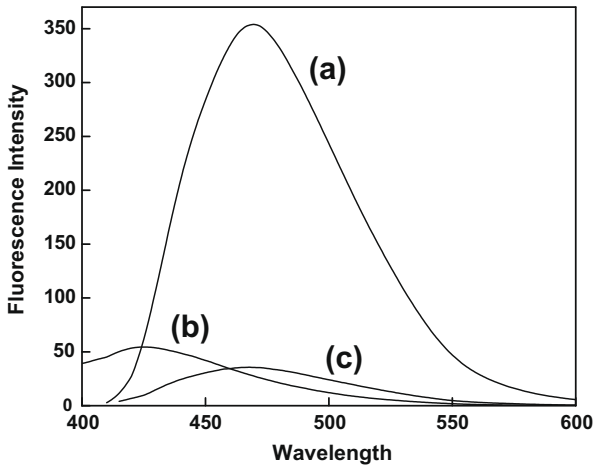

Fig. 6. Fluorescence emissions of the ligands H_2B^3 (a), H_2B^2 (b), H_2B^1 (c). All the spectra were taken in 2×10^{-5} molar solution in DMF. λ_{ex} (H_2B^1) = 390 nm, λ_{ex} (H_2B^2) = 387 nm, λ_{ex} (H_2B^3) = 397 nm.

carbohydrazone substitution at the 3-position of the pyrazole ring, which is in conjugation with the fluorophore, has the capability to regulate its florescence characteristics. Among the ligands H_2B^1, H_2B^2, H_2B^3 and H_2B^4, the former three show emission to a varying degree (Fig. 6). H_2B^4, being the nitro substituted salicyl hydrazone ligand, does not show any fluorescence. In nitro compounds the lowest energy absorption is for a n-π^* transition. Hence no emission could be recorded [42]. Both the ligands H_2B^1 and H_2B^2 shows fluorescence emission which is much diminished in intensity compared to that of H_2B^3. This may be explained by the presence of a fluorescence quenching intra-ligand PET process which takes place from the conjugated salicyl hydrazone portions of the ligands towards the fluorophore [43]. The presence of the electron withdrawing bromo substituent may hinder this process in H_2B^3 to ensure its high quantum yield [44]. Thus H_2B^3 is the ligand which has the highest exploitable fluorescence [45] among these three ligands. As the studies are made in DMF, a polar solvent which facilitates PET, the effects of the presence of an electron withdrawing group is expressed better [46]. The emission from H_2B^2 is blue shifted compared to the other two, in tune with its high energy absorption maxima. It has been observed that the fluorescence excitation spectra exactly follow the absorption spectra in DMF solution, indicating that the fluorescence is taking place from the excited ligand molecules and not from any other species in the solution.

The potential of the ligand molecules to act as a 'FSR' (fluorophore-spacer-receptor) unit has been observed while studying the emission behavior of the metal complexes. The 1:1 dioxomolybdenum(VI) complexes of the ligands exhibit fluorescence quenching compared to the free ligands. However, the position of the fluorescent maxima in each case remains almost unchanged from those of the free ligands. The MoO_2^{2+} unit binds to the salicyl carbohydrazone portion of the ligand leaving the 1-(2-pyridyl) 5-methyl pyrazole free. This should cause a fluorescent enhancement by creating hindrance to the intra-ligand PET process. The observation is, however, quite the opposite. The partial oxidative PET from the fluorophore to the metal center through the conjugated backbone of the ligand combined with the higher probability of radiationless decay (through ISC) in the complexes [47] (heavy metal effect) becomes the overwhelming factors leading to more than a 2/3rds reduction in the fluorescence intensities as compared to free ligands in each case (Fig. 7).

As we have discussed earlier, addition of one molar equivalent of first row transition metal ions, such as Cu(II), to the solution of the dioxomolybdenum(VI) complex **1** lures the ligand to shift its loyalty from the MoO_2^{2+} species to the guest ions with a concomitant change of its binding mode. Thus the formation of complex **5** is achieved with enhanced thermodynamic stability. This action leaves ample evidence with the emission behavior of the newly formed complexes (Fig. 8). The emission intensity is found

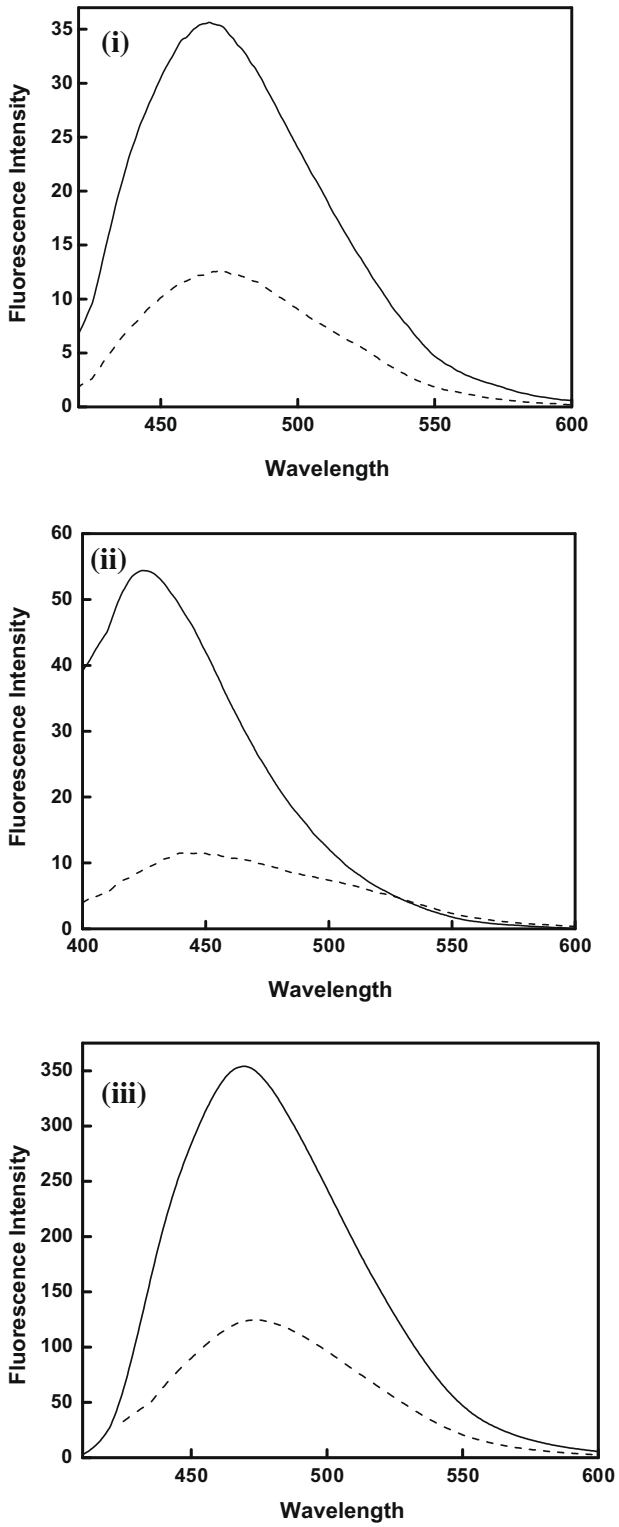

Fig. 7. Comparative emissions of the ligands and their dioxomolybdenum(VI) complexes. All the spectra were taken in 2×10^{-5} molar solution in DMF. (i) H_2B^1 (λ_{ex} = 390 nm, solid line) and complex **1** (λ_{ex} = 390 nm, dotted line). (ii) H_2B^2 (λ_{ex} = 387 nm, solid line) and complex **2** (λ_{ex} = 387 nm, dotted line). (iii) H_2B^3 (λ_{ex} = 397 nm, solid line) and complex **3** (λ_{ex} = 411 nm, dotted line).

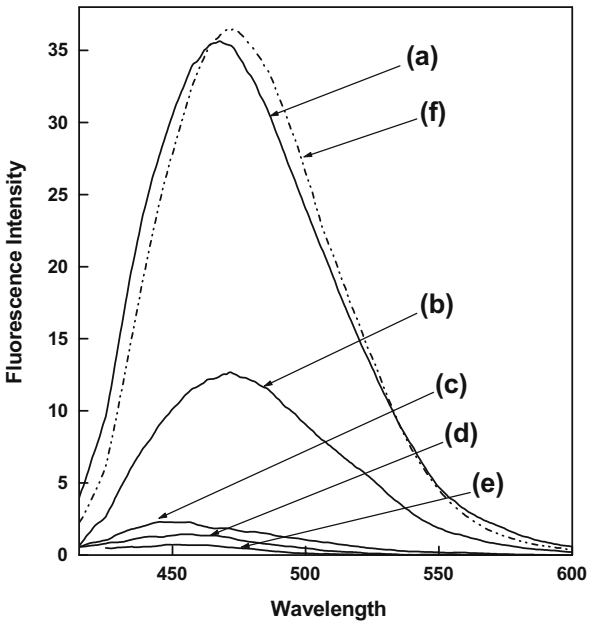

Fig. 8. Fluorescence emissions of (a) a solution of H_2B^1 (λ_{ex} = 390 nm), (b) an equimolar solution of H_2B^1 and $MoO_2(acac)_2$ (λ_{ex} = 390 nm), (c) an equimolar solution containing complex **1** and $Cu(NO_3)_2{\cdot}6H_2O$ (λ_{ex} = 390 nm), (d) an equimolar solution containing complex **1** and $Ni(NO_3)_2{\cdot}6H_2O$ (λ_{ex} = 400 nm), (e) an equimolar solution containing complex **1** and $Co(NO_3)_2{\cdot}6H_2O$ (λ_{ex} = 410 nm) and (f) an equimolar solution containing complex **1** and $Zn(NO_3)_2{\cdot}6H_2O$ (λ_{ex} = 400 nm, 317 nm). All the solutions were 2×10^{-5} molar with respect to each constituent in DMF.

to reduce further from the Mo(VI) complex **1** almost to a 'zero emission' state. We have obtained similar observations with other first row transition metals, such as Co(II) and Ni(II) (Fig. 8). The ligands ability to adjust its binding mode with the change of metal ion seems to be responsible for the secondary quenching. The structure of complex **5** shows that here the ligand actually encompasses the metal ion, occupying all the equatorial positions in its coordination sphere. The nitrogens of the 1-(2-pyridyl) 5-methyl pyrazole unit bind the metal ion with two other N donors from the hydrazone unit. This direct fluorophore–metal interaction enhances the oxidative PET and causes further quenching [48]. A similar change in the metal binding mode can be predicted when Co(II) and Ni(II) are added. However when the zinc(II) ion is added to a solution of complex **1**, a complete restoration of the fluorescence is observed. The closed shell Zn(II) ion is known to be non-quenching in nature as it does not allow a fluorophore–metal oxidative PET [49] (Fig. 8). Although we have not been able to isolate the resulting complex, the complete restoration of fluorescence up to the level of the free ligand indicates that the zinc(II) ion added to complex **1** also causes a stripping of the Mo(VI) species from complex **1**, and a new Zn(II) complex of the ligand H_2B^1 is formed. Most likely, the binding mode of the ligand is different from both **1** and **5**. From the emission properties it may be predicted that the Zn^{2+} ion binds to the heterocyclic chelator end but does not involve the N and O donors of the conjugated backbone as it prefers a tetrahedral arrangement to a square planar one.

When 1 mol equivalent of $MoO_2(acac)_2$ is added to a solution of complex **1** in DMF, fluorescence quenching is observed, but not comparable to the extent that was observed with Cu(II), Co(II) or Ni(II). This indicates that the interaction of complex **1** with the Mo precursor in solution is merely collisional in nature. The free 1-(2-pyridyl) pyrazole portion of complex **1** does not bind the guest Mo(VI) species (Fig. 9).

Emission of the Mo(IV) complex **6** was studied in solid state. Florescence quenching of **6** is much more pronounced than **3**,

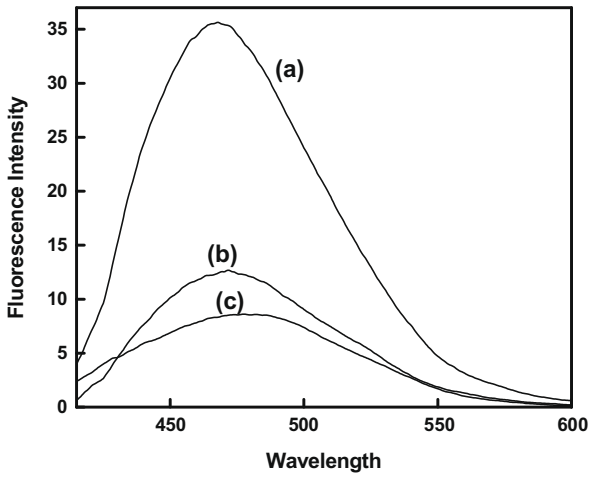

Fig. 9. Fluorescence spectra of the ligand (a) H_2B^1 (λ_{ex} = 390 nm), $H_2B^1 + MoO_2(acac)_2$ (1:1) (λ_{ex} = 390 nm), $H_2B^1 + MoO_2(acac)_2$ (1:2) (λ_{ex} = 390 nm). All the spectra were taken in 2×10^{-5} molar solution in DMF.

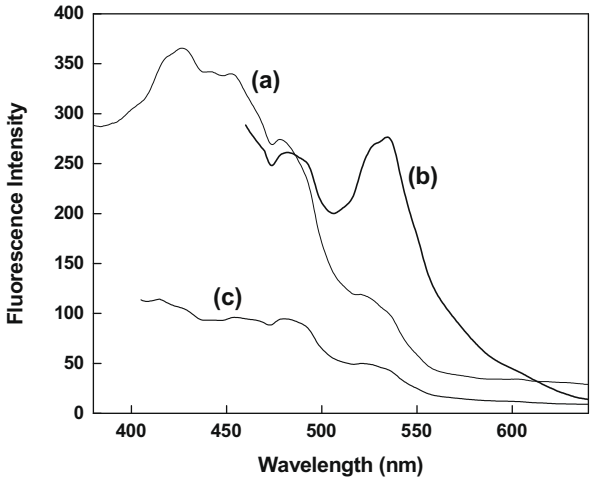

Fig. 10. Solid state fluorescence of (a) H_2B^3 (λ_{ex} = 369 nm), (b) complex **3** (λ_{ex} = 441 nm) and (c) complex **6** (λ_{ex} = 385 nm).

when both are compared to the free ligand H_2B^3. Probably with the reduction of the Mo center to Mo(IV), a metal to ligand reductive PET is initiated which was absent with the d^0 Mo(VI) state (Fig. 10).

Based on these observations, the ligands used here may be used to create a fluorescent 'On–Off' signaling system. The free ligands represent the 'On' state and the Cu(II), Co(II) or Ni(II) complexes represent the 'Off' state. The ligand H_2B^3 is expected to be the most suitable ligand as it exhibits the maximum difference between the 'exploitable fluorescence' in the 'On' state and the 'residual fluorescence' in the 'Off' state. Further using Mo complexes (e.g. complex **1**) inbetween the two states a 'Regulator' effect may be brought in, i.e. by adding 1 equivalent of Mo(VI) salt followed by 1 equivalent of Cu(II) salt to the ligand solution a stepwise quenching of the fluorescence may be achieved. Again an 'On–Off–On' switch may be achieved by the addition of Mo(VI) and Zn(II) salts sequentially in the same molar proportion to the ligand solution. Here the Mo(VI) complex represents the 'Off' state, which is not really a zero emission state but is rather a highly quenched 'On' state. The difference between the 'On' and 'Off' states, i.e. the sensitivity of the system, may be tuned by choosing the most suitable ligand among the three ligands.

4. Conclusion

The stepwise reduction of fluorescence intensity observed here with two different metal ion inputs added to a solution of H_2B^1 is quite unusual, if not unique, in the field of fluorescence signaling. The recovery of fluorescence intensity by altering the second input as Zn^{2+} in place of partially filled shell transition metal ions (Cu^{2+}, Co^{2+} or Ni^{2+}) is also potentially useful in developing a both way switch. The solid state fluorescence of H_2B^3, **3** and **6** shows that reduction of the Mo(IV) center causes further quenching of the fluorescence emission of complex. This observation may be potentially useful in studying enzymatic catalysis reactions of oxo-transferase type molybdoenzymes in living systems with fluorescent tags.

5. Supplementary data

CCDC numbers 716097, 716098, 716099 and 716100 contain the supplementary crystallographic data for the H_2B^2, H_2B^3, complex **5** and complex **1** respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Center, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336 033; or email: deposit@ccdc.cam.ac.uk.

2.3. a. Preparation of 1,3-dimethyl-2-(phenylazo)imidazolium iodide

To a solution (20 ml) of 2-(phenylazo)imidazole (HaaiH) (0.2 g, 1.16 mmol) in dry THF, NaH (50% paraffin) was added pinch wise and stirred for 30 min. Methyl iodide (0.39 g, 2.75 mmol) was added drop by drop for 10 min. and the resulting solution was refluxed for another 2 h. It was then cooled, filtered and the filtrate was evaporated in vacuum. The dry orange residue after extracting with $CHCl_3$ was recrystallised from warm water. Yield. 0.3 g (80%).

All other imidazolium iodides were prepared following identical procedure. The microanalitical data of ligands are as follows.

[HaaiMe$_2^+$] I$^-$ (**1a**) (m. p. 215 ± 1 °C): *Anal.* Calc. for $C_{11}H_{13}N_4I$: C, 34.55; H, 3.96; N, 17.07. Found: C, 34.43; H, 3.87; N, 17.02%. [MeaaiMe$_2^+$] I$^-$ (**1b**) (m. p. 218 ± 1 °C): *Anal.* Calc. for $C_{12}H_{15}N_4I$: C, 42.11; H, 4.39; N, 16.37. Found: C, 42.03; H, 4.28; N, 16.26%. [HaaiEt$_2^+$] I$^-$ (**2a**) (m. p. 225 ± 1°C): *Anal.* Calc. For $C_{13}H_{17}N_4I$: C, 43.82; H, 4.78; 15.73. Found: C, 43.77; H,4.71; N, 15.65%. [MeaaiEt$_2^+$] I$^-$ (**2b**) (m. p. 220 ± 2°C): *Anal.* Calc. For $C_{14}H_{19}N_4I$: C, 45.41; H, 5.14; N, 15.14. Found: C, 45.36; H, 5.06; N, 15.07%. [Meaai(CH$_2$Ph)$_2^+$] I$^-$ (**3b**) (m. p. 320 ± 1 °C): *Anal.* Calc. For $C_{24}H_{23}N_4I$: C, 58.29; H, 4.66; N, 11.34. Found: C, 58.21; H, 4.58; N, 11.26%. [HaaiMe(CH$_2$Ph)$^+$] I$^-$ (**4a**) (m. p. 289 ± 1° C): *Anal.* Calc. For $C_{17}H_{17}N_4I$: C, 50.50; H, 4.21; N,13.86. Found: C, 50.42; H, 4.26; N, 13.80%. [MeaaiMe(CH$_2$Ph)$^+$] I$^-$ (**4b**) (m. p. 276 ± 1 °C): *Anal.* Calc. For $C_{18}H_{19}N_4I$: C, 51.69; H, 4.55; N, 13.40%. Found: C, 51.77; H, 4.48; N, 13.46.

2.3. b. Synthesis of [(MeaaiMe(Bz))$^+$]$_2$ [Cu$_2$I$_4$] (**8b**)

To a solution (25 ml) of [MeaaiMe(CH$_2$Ph)]$^+$ I$^-$ (1-methyl-3-benzyl-2-(*p*-tolylazo)imidazolium iodide) (147 mg, 0.35 mmol) in methanol, CuI (70 mg, 0.37 mmol) in acetonitrile, was added, stirred and refluxed for 3 h . The solution was filtered at hot through G4 crucible and was left to evaporate slowly in air. Block shaped black micro crystals, deposited on the wall of beaker, were collected by filtration. X-ray quality black coloured block shaped crystals were obtained by recrystallising from DMF–MeOH (1:2 v/v) solution. The yield was 0.15 g (71%).

All other complexes were prepared by the same procedure. In all cases, crystalline products were obtained. The yield varied from 70% to 80% and microanalytical data of the complexes are as follows. The microanalytical data of the complexes are as follows: [HaaiMe$_2$]$_2$[Cu$_2$I$_4$] (**5a**) *Anal.* Calc. for $C_{11}H_{13}N_4I_2Cu$: C, 25.48; H, 2.53; N, 10.80. Found: C, 25.51; H, 2.54; N, 10.78%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1420; ν(C=N), 1588 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 245 (46.70), 360 (35.30), 420 (4.35). [MeaaiMe$_2$]$_2$[Cu$_2$I$_4$] (**5b**) *Anal.* Calc. for $C_{12}H_{15}N_4I_2Cu$: C, 27.06; H, 2.84; N, 10.52. Found: C, 27.00; H, 2.82; N, 10.54%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1428; ν(C=N), 1594 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 244 (39.98), 367 (32.8). [HaaiEt$_2$]$_2$[Cu$_2$I$_4$] (**6a**) *Anal.* Calc. for $C_{13}H_{17}N_4I_2Cu$: C, 28.55; H, 3.11; N, 10.25. Found: C, 28.44; H, 3.04; N, 10.38%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1416; ν(C=N), 1593 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 248 (44.90), 360 (38.20), 424 (7.80). [MeaaiEt$_2$]$_2$[Cu$_2$I$_4$] (**6b**) *Anal.* Calc for $C_{14}H_{19}N_4I_2Cu$: C, 29.97; H, 3.39; N, 9.99. Found: C, 27.00; H, 2.82; N, 10.54%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1418; ν(C=N), 1598 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 244 (39.25), 365 (30.73). [HaaiBz$_2$]$_2$[Cu$_2$I$_4$] (**7a**) *Anal.* Calc. for $C_{23}H_{21}N_4I_2Cu$: C, 41.16; H, 3.13; N, 8.35. Found: C, 41.23; H, 3.10; N, 8.42%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1425; ν(C=N), 1588 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 245 (41.2), 373 (34.5). FT-IR (KBr disc, cm^{-1}), ν(N=N), 1430; ν(C=N), 1596 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 248 (42.7), 373(35.6). [HaaiMe(Bz)]$_2$[Cu$_2$I$_4$] (**8a**) *Anal.* Calc. for $C_{17}H_{17}N_4I_2Cu$: C, 34.31; H, 2.86; N, 9.42. Found: C, 34.39; H, 2.83; N, 9.39%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1425; ν(C=N), 1590 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 243(41.5), 376(40.7). [MeaaiMe(Bz)]$_2$[Cu$_2$I$_4$] (**8b**) *Anal.* Calc. for $C_{18}H_{19}N_4I_2Cu$: C, 35.51; H, 3.12; N, 9.20. Found: C, 35.49; H, 3.17; N, 9.18%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1428; ν(C=N), 1596 cm^{-1}. UV–VIS spectral data in CH_3CN (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 242.75(38.5), 374.21(32.1).

2.3. c. Synthesis of [MeaaiMe$_2$]2[Ag$_3$I$_5$] (**9b**)

To a solution (25 ml) of [MeaaiMe$_2$]$^+$ I$^-$ (1,3-dimethyl-2-(*p*-tolylazo)imidazolium iodide) (120 mg, 0.35 mmol) in methanol, AgI (75 mg, 0.32 mmol) was added pinch wise, stirred and refluxed for 4 h. The solution was filtered at hot and allowed to evaporate slowly in air. Orange color micro-crystals, deposited at the bottom of the beaker, were collected by filtration. X-ray quality orange cubic crystals were obtained by recrystallising from DMF-MeOH (1:2 v/v) solution. The yield was 0.17 g (71%).

All other complexes were prepared by the same procedure. In all cases, crystalline products were obtained. The yield varied from 70% to 80%. The microanalytical data of the complexes are as follows: [HaaiMe$_2$]$_2$[Ag$_3$I$_5$] (**9a**) *Anal.* Calc. for $C_{22}H_{26}N_8I_5Ag_3$: C, 19.40; H, 1.91; N, 8.23. Found: C, 19.44; H, 1.95; N, 8.21%. FT-IR (KBr disc, cm^{-1}), ν(N=N), 1437; ν(C=N), 1606 cm^{-1}. UV–VIS spectral data in DMF (λ_{max}(nm)(10^{-3} (dm^3 mol^{-1} cm^{-1}): 365(63.4), 462(45.3). precipitant at ambient condition. Diffraction data were collected with the Bruker SMART 1 K CCD area-detector diffractometer using fine focused sealed tube graphite-monochromatized Mo Kα radiation ($\lambda = 0.71073$ Å). Unit cell parameters were determined from least-squares method in the range of $-10 \leqslant h \leqslant 10$, $-12 \leqslant k \leqslant 12$, $-13 \leqslant l \leqslant 13$ and angle varies 3.64 2 50.1° for (**8b**); $-24 \leqslant h \leqslant 29$, $-19 \leqslant k \leqslant 20$, $-20 \leqslant l \leqslant 20$ and angle varies 2.1 2 68.1° for (**9b**). A summary of the crystallographic data and structure refinement parameters are given in Table 1. Data were corrected for Lorentz and polarization effects. Data reduction was carried out by using SAINT programme. The structure was solved by direct method using SHELXS-97 [30] and successive difference Fourier syntheses. All non-hydrogen atoms were refined anisotropically. Full matrix least squares refinements on F_0^2 were carried out using SHELXL-97 [31] with anisotropic displacement parameters for all non-hydrogen atoms. Hydrogen atoms were constrained to ride on the respective carbon or nitrogen atoms with anisotropic displacement parameters equal to 1.2 times the equivalent isotropic displacement of their parent atom in all cases. All calculations were carried out using SHELXS-97 [30], PLATON 99 [32], ORTEP-3 [33] programs.

3. Results and discussion

3.1. Azoimidazolium halide

Alkylation of 2-(arylazo)imidazoles (RaaiH) with excess alkyl iodide (MeI, EtI, $PhCH_2I$) in dry THF has afforded 1,3-dialkyl-2-(arylazo)imidazolium iodides ($RaaiR'_2{}^+I^-$, **1**–**3**) and 1-methyl-3-benzyl-2-(arylazo)imidazolium iodides ($RaaiR'R''^+I^-$, **4**). 1-Alkyl-2-(arylazo)imidazoles (RaaiR′) are low melting solids or gummy mass [28] while $[RaaiR'_2{}^+](I^-)$ are orange crystalline compounds. Molar conductance data shows that di-alkyl-imidazolium iodides are 1:1 electrolytes.

The IR spectra of $[[RaaiR'_2{}^+](I^-)]$ (**1**–**3**) and ($RaaiR'R''^+I^-$, **4**) show broad, medium intense band centred at 3420 cm^{-1} which is referred to $\nu(H_2O)$ and a medium intense band at 1620–1640 cm^{-1} corresponding to bending mode of water cluster [34]. Upon heating in the temperature range 90–110 °C the crystallized water is removed and IR spectra do not further show the vibrations corresponding to H_2O even on exposure to air for long time. The –N=N– and –CN– appear at 1400–1420 and 1600–1630 cm^{-1}, respectively. Thermogravimetric analysis (TGA) shows that these compounds do not have any associated solvent molecule, and alkyl iodide is removed from the molecule upon heating.

The absorption spectra of $[RaaiR/] + I- /(RaaiR/R//) + I-)$ in methanol solution show absorption band at 330–400 nm with a molar absorption coefficient in the order of $10^4\ dm^3\ mol^{-1}\ cm^{-1}$ and a tail extending into 500 nm. From the analogy with the

R = H (**a**), Me (**b**); R′, R′ = -$^{12}CH_3$ (**1**); -$^{12}CH_2$-$^{13}CH_3$ (**2**); -$^{12}CH_2$-Ph (13-17) (**3**); R′ = $^{12}CH_3$, R″ = -$^{12}CH_2$-Ph (**4**)

Scheme 1.

absorption spectrum of azobenzene [35], it is likely that the intense absorption band corresponds to $\pi-\pi^*$ transitions, while the tail corresponds to $n-\pi^*$ transition. However, the $\pi-\pi^*$ band exhibits bathochromic shifts by ~30 nm compared with azobenzene, while the $n-\pi^*$ band shows little shift. As a consequence, the energy separation between the $\pi-\pi^*$ and $n-\pi^*$ transitions in arylazoimidazoles is narrower than that of azobenzene.

The ^{1}H NMR spectra of 1,3-dialkyl-2-(arylazo)imidazolium iodide, [RaaiR$'_2^+$](I$^-$) (**1–3**) and 1-methyl-3-benzyl-2-(arylazo)imidazolium iodide [RaaiR$'$R$''^+$](I$^-$) (**4**) are taken in CD_3CN. The atom numbering pattern of the ligands is shown in Scheme 1. The proton signals of [RaaiR$'_2^+$](I$^-$) are assigned on comparing with the spectra of RaaiR$'$ [29,32–35], spin-spin interaction and effect of substitution. 1,3-Dialkyl-2-(arylazo)imidazolium iodide show a single resonance for two R$'$: 1,3-Me$_2$ of (**1**) show a sharp singlet at 4.25 ppm; 1,3-Et$_2$ of [RaaiEt$_2^+$](I$^-$) (**2**) exhibit 1-(CH$_2$)– as quartet at *av.* 4.85 ppm and methyl (-Me) as triplet splitting pattern at *av.* 1.5 ppm; [Raai(CH$_2$Ph)$_2^+$](I$^-$) (**3**) and [Raai(Me)(CH$_2$Ph)$^+$](I$^-$) (**4**) show singlet proton signal at 5.3–5.5 ppm which has been assigned to –CH$_2$– of N(1)–CH$_2$–Ph . Imidazole protons (4-, 5-H) appear as broad single resonance at 7.0–7.2 ppm. The broadening may be due to rapid proton exchange between two positions. The aryl protons (7-H to 11-H) are upfield shifted on going from phenylazo (**a**) to *p*-tolylazo (**b**) which may be due to +I effect of Ar–Me group.

3.2. Iodometallates

1,3-Di-alkyl-2-(arylazo)imidazolium iodides (symmetrical: [RaaiR$'_2^+$]I$^-$, R$'$ = Me, Me (**1**); Et, Et (**2**); CH$_2$Ph, CH$_2$Ph (**3**) and R = H (**a**), Me (**b**); unsymmetrical: [RaaiMe(CH$_2$Ph)$^+$]I$^-$ (**4**)) are used as cation source and I$^-$ are utilized in the formation of iodometallates. The reaction between [RaaiR$'_2^+$]I$^-$ and MI (M = Cu (**5-8**), Ag (**9–12**)) in 1:1 mole ratio in methanol and acetonitrile mixture has afforded polymeric ionic solid (Eqs. (1) and (2)). The molar conductance measurements show that iodocuprates(I) are 1:1 electrolyte while iodoargentates (I) are 2:1 conductor.

$$Cu_2I_2 + 2RaaiR'R'' + I^- \rightarrow \underset{\mathbf{5-8}}{[RaaiR'/R'']_2}[Cu_2I_4] \quad (1)$$

$$3AgI + 2RaaiR'/R'' + I^- \rightarrow \underset{\mathbf{9-12}}{[RaaiR'/R'']_2}[Ag_3I_5] \quad (2)$$

Thermal studies of the complexes show two steps elimination of alkyl iodide within temperature range 200–250 °C and 290–380 °C (Supplementary data). Mass loss perfectly matches with the calculated data.

3.2. Spectral studies

Moderately intense stretching at 1595–1600 and 1435–1445 cm^{-1} are due to ν(C=N) and ν(N=N), respectively, for the complexes. Other bands are shifted to lower frequency in the iodometallates (**5–12**) compared to the free ligand values.

The solution spectra of azoimidazolium iodocuprate (I) (**5–8**) were recorded in acetonitrile. Because of sparing solubility of azoimidazolium iodoargentate(I) (**9–12**) in acetonitrile we have taken solution spectra in DMF in wavelength range 230–600 nm. Intense ($\in \sim 10^4$ mol^{-1} dm^3 cm^{-1}) bands 240–260, 340–360 nm for **5–8** and 240–260, 340–360 and 430–460 nm for **9–12** were observed. On comparing with free ligand spectra [29,32–35], we may conclude that the bands <400 nm are due to intramolecular charge transfer transitions and the bands 430–460 nm may be due to MLCT, d^{10}(Cu(I)/Ag(I)) → π^*(azoimine) transition [26–31].

The ^{1}H NMR spectra of [RaaiR$'$R$''$]$_2$[Cu$_2$I$_4$] (**5–8**) are recorded in $CDCl_3$. The NMR spectra of [RaaiR$'$R$''$]$_2$[Ag$_3$I$_5$] (**9–12**) are recorded in DMSO-d$_6$ due to solubility problem of them in $CDCl_3$. Data (Table 2) reveal that the signals in the spectra of the complexes are shifted to downfield side relative to free ligand values [24,28,29]. This supports some interaction of iodometallates with azoimidazolium unit. Besides, the signals in these compounds are shifted to higher chemical shift data (δ) than that of [azoimidazolium$^+$][Pb(μ-I)$_3^-$] [24]. Imidazole protons suffer downfield shifting by 0.4–0.6 ppm compared to the azoimidazolium ions. Aryl signals shift to the lower field side on Me-substitution to the aryl ring. This is due to electron donating effect of the Me- group.

3.3. Molecular structures

3.3.1. [MeaaiMe(Bz)$^+$]$_2$[Cu$_2$I$_4$]$^{2-}$ (*8b*)

The molecular unit of **8b** is shown in Fig. 1a and bond parameters are listed in Table 3. The iodo-bridged [Cu$_2$(μ-I)$_2$I$_2$]$^{2-}$ (copper(I)-I dimmer) and [MeaaiMe(CH$_2$Ph)]$^+$ are integral parts of the

structure. There are bridge-I and terminal-I bonded to Cu(I) in $[Cu_2(\mu\text{-}I)_2I_2]^{2-}$ motif. The terminal Cu–I bond distances (Cu–I(1), 2.5004(16) Å) are shorter than bridged Cu–I(2) distances (Cu–I(2), 2.5716(19) Å and $Cu^{\#}$–I(2), 2.5888(17) Å). The $[Cu_2(\mu\text{-}I)_2I_2]^{2-}$ is hydrogen bonded to imidazole-H *via* C(9)–H(9)...I1(#1) forming neutral chain (Supplementary material Fig. S1). The hydrogen bonding in C–H–I pattern are scarce [36,37]. In $[MeaaiMe(CH_2Ph)]^+$ the azophenyl and imidazole rings are virtually coplanar as indicated by the torsion angle, C(1)–N(1)–N(2)–C(7), 179.2(9)° and the dihedral angle of two planes, 6.20(12)°. Nonplanarity of benzylic phenyl group (C(11)–C(16)) with imidazole ring is due to $-CH_2-$ group and makes an angle of 112° with imidazole unit. The N(1)–N(2) bond length is 1.234(11) Å which is lower than reported free ligand data (1.252(2) Å for 1-methyl-2-(phenylazo)imidazolium perchlorate) [38–40]. The N(azo)–C(imidazole) distance, N(2)–C(8), 1.359(13) Å, is shorter than N(azo)–C(phenyl), N(1)–C(5), 1.418(13) Å which indicates a stronger intramolecular interaction between azo and imidazole group.

Table 3

		Ag(1)–I(3)–Ag(3B)	53.72(5)

[a] $1-x, -y, 1-z$.
[b] $x, 3/2-y, -1/2+z$.

Azoimidazolium unit contains three different aromatic rings: *p*-tolyl (*p*-Tol), phenyl (Ph) and imidazole (Imz). The face-to-face (Cg(2)–Cg(3)(#1)), 3.7867 Å (symmetry, $-x$, $1-y$, $-z$) ; and Cg(3)–Cg(3)(#3) (3.8424 Å) (symmetry, $1-x$, $1-y$, $-z$) where Cg(20) refers to Imz, N(3)–C(8)–N(4)–C(10)–C(9) and Cg(3), refers to *p*-Tol, C(2)–C(3)–C(4)–C(5)–C(6)–C(7)) π–π stacking interactions are observed between aromatic rings belonging to adjacent chains in the network (Supplementary material Fig. S1b). The π-chains so formed exhibit C–H–π interactions (H or C–Centroid (Cg) of Ph): C(4)-H(4)–Cg(4) (#1), 2.712(7) Å (symmetry, $-x$, $1-y$, $-z$); C(11)–H(11A)–Cg(4) (#2), 3.197(4) Å (symmetry, $-x$, $1-y$, $1-z$); C(18)-H(18C)–Cg(3) (#1), 3.162(8) Å (symmetry, $-x$, $1-y$, $-z$) Cg(2), Cg(3) are defined earlier. Cg(4) is –(N(1)–CH_2–)–Ph (C(12)–C(13)–C(14)–C(15)–C(16)–C(17)) (Fig. 2). Inter-chain face-to-face π–π interaction enable to form a π-sheet (Supplementary material Fig. S2).

3.3.2. Structure of [MeaaiMe$_2^+$]$_2$

The crystal structure unit of $[MeaaiMe_2^+]_2$ $[Ag_3I_5^{2-}]$ (**9b**) is shown in (Fig. 3a) and bond parameters are given in Table 3 (full data are

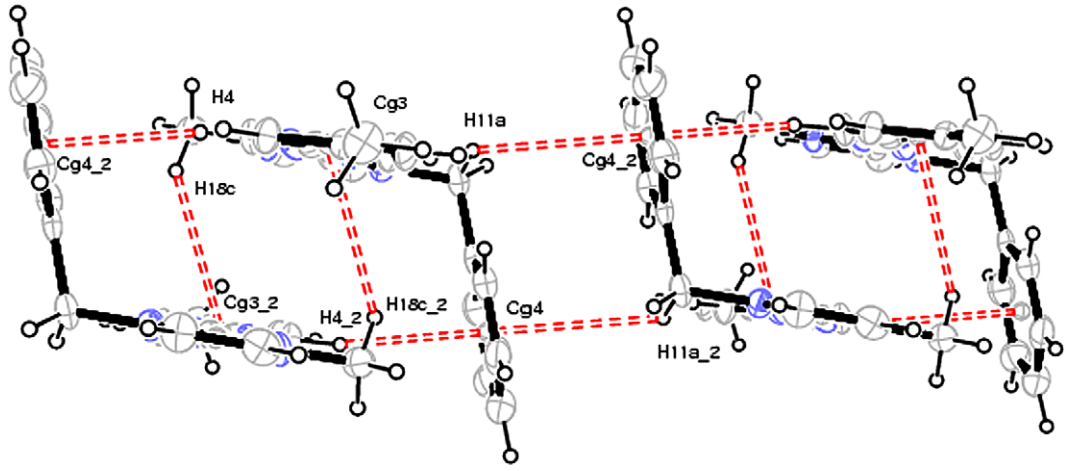

Fig. 2. C–H–π interaction leading to 1-D chain of $[MeaaiMe(CH_2Ph)^+]_2[Cu_2I_4]^{2-}$ (**8b**).

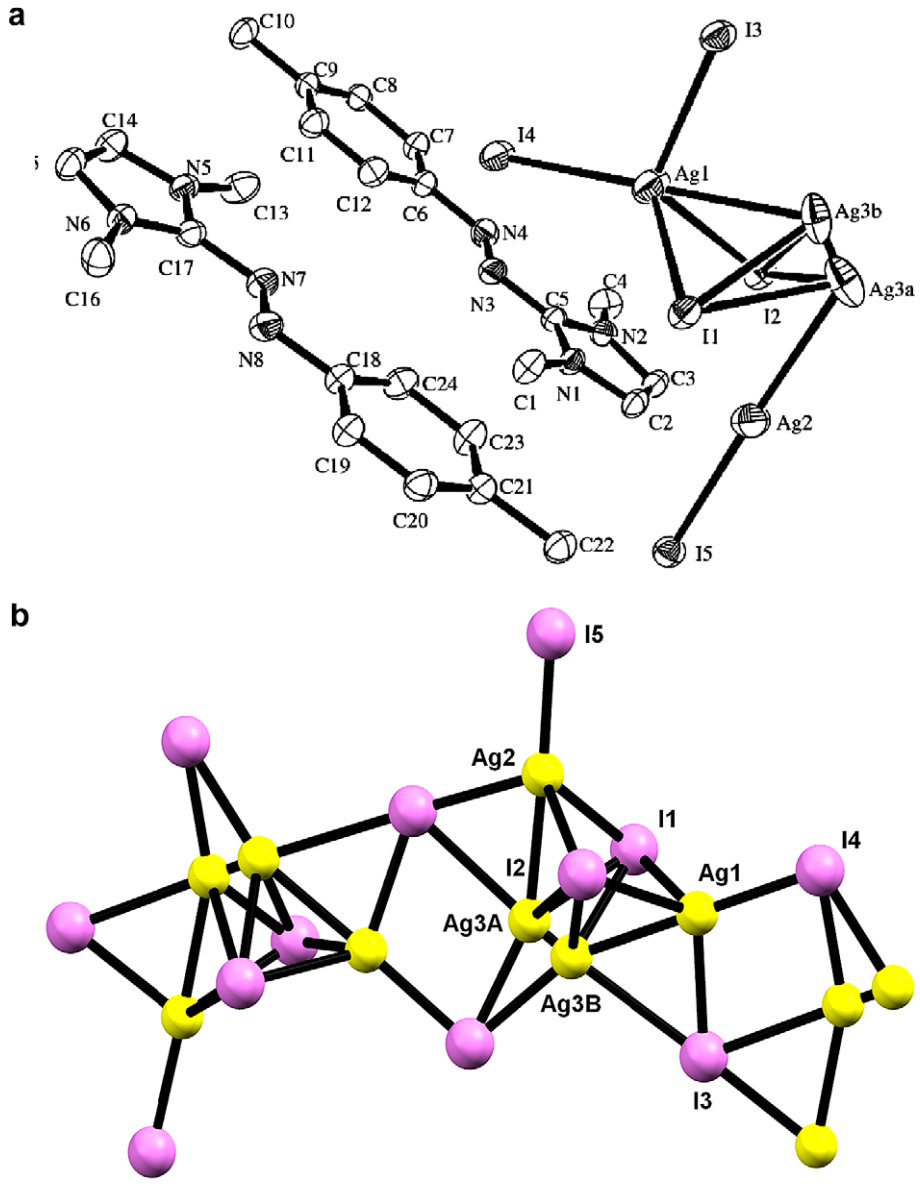

Fig. 3. (a) Structural unit of $[MeaaiMe_2^+]_2\,[Ag_3I_5^{2-}]$ (**9b**) and (b) polymeric chain of $[Ag_3(I_5^{2-}]$.

given in Supplementary Material, Table S1). The structure shows a one-dimensional chain constructed from $[MeaaiMe_2^+]$ and $[Ag_3I_5^{2-}]$. Anion, $[Ag_3I_5^{2-}]$ exists as iodo bridged chain (Fig. 3b). In monomeric unit two Ag atoms (Ag1 and Ag2) are bridged by I(1) and I(2) and Ag(3) is doubly bridged with two μ-I. Ag(3) significantly perturbed and is assigned Ag(3A) and Ag(3B). Three terminal Is (I(3), I(4), I(5)) of $[Ag_3I_5^{2-}]$ are responsible to form chain structure *via* vertices sharing and Ag–I–Ag bridge. Because of the bridging nature of iodine atoms, the coordination environment of the silver atom is distorted from that of a perfect tetrahedron. The AgI_4 tetrahedron is highly distorted, with Ag–I bond distances ranging from 2.7163(9) to 2.9781(8) Å. There are two types of bridging-I: μ_2-I ((I(3), I(4), I(5)) bridge two Ag centers) and μ_3-I (I(1), I(2) bridges three Ag centers Ag(1), Ag(2) and Ag(3A, 3B)). The I–Ag–I bond angles range from 88.28(2) to 122.69(3)° (Table 3), and the Ag–I–Ag bond angles range from 57.42(8) to 172.10(5)°, deviating significantly from 109.5° for an ideal tetrahedron.

The distance between two Ag atoms are Ag(1)–Ag(3B), 2.799(5) and Ag(2)–Ag(3A), 2.8229(17) Å., shorter than sum of van der Waals radii silver (3.44 Å) [41]. The argentophilicity may be the reason for metal–metal interaction between d^{10} and d^{10} closed-shell metals which promotes the aggregation of silver(I) centers. Compounds possessing argentophilicity can be potentially used in silver-containing antibacterial reagents [42]. The *p*-tolylazo and imidazole rings of $MeaaiMe_2^+$, are virtually coplanar and the dihedral angle of two planes is 2.08(19) Å. The N(3)–N(4) and N(7)–N(8) bond lengths are 1.236(7) and 1.242(7) Å which are comparable with $[MeaaiMe(CH_2Ph)^+]_2[Cu_2(\mu\text{-}I)_2I_2]^{2-}$ (**8b**). Pendant phenyl ring and imidazole unit of neighboring cations undergo C–H–π and π–π interaction resulting layers of organic cations. Polyanion chains of $[Ag_3I_5^{2-}]_n$ may act as channels whereas organic cations lie sandwiched between two adjacent chains. Organic groups do not participate in coordination but connect with inorganic moieties by noncovalent interactions: electrostatic force. The organic and inorganic moieties alternate to form a so-called organic-inorganic hybrid structure (Supplementary material, Fig. S3).

4. Conclusion

In summary, we have prepared and structurally characterized hybrid azoimidazolium iodocuprate(I) and iodoargentate(I) compounds. The single crystal X-ray structural characterization shows

di-iodo bridged dimmer $[Cu_2(\mu\text{-}I)_2I_2]^{2-}$ is associated with organic cation $[MeaaiMe(CH_2Ph)^+]$ through electrostatic attraction. In iodoargentate(I) the monomeric unit is $[Ag_3I_5]^{2-}$ that has two μ_3-I and monomer forms 1D chain by Ag–I–Ag bridge. The chains of $[Ag_3I_5^{2-}]_n$ serve as channels wherein organic cations, $[MeaaiMe_2]^+$ is sandwiched. Organic groups do not participate in coordination but connect with inorganic moieties by noncovalent interactions. On the basis of this work, further investigations of new inorganic–organic hybrid metal halides with azoimidazolium derivatives are under way in our laboratory.

5. Supplementary materials

CCDC 614001 and 602165 contain the supplementary crystallographic data for $[MeaaiMe(Bz)^+]_2[Cu_2(\mu\text{-}I)_2I_2]^{2-}$ (**8b**) and for $[MeaaiMe_2^+]_2$ $[Ag_3I_5^{2-}]$ (**9b**). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

(Merck) was distilled over a sodium–potassium alloy under an atmosphere of dry argon. Silica gel (Merck 60, 0.063–0.200 mm) was used for column chromatography. All reactions were performed under a dry argon atmosphere.

2.2. Methods

Thin layer chromatography (TLC) was performed on Merck Silica gel plates (Merck 60, 0.25 mm thickness) with F_{254} indicator. Column chromatography was performed on silica gel (Merck 60, 0.063–0.200 mm; for 3 g crude mixture, 120 g silica gel was used in a column of 3 cm in diameter and 110 cm in length). Mass spectra were recorded on a Bruker MicroTOF LC–MS spectrometer using the electrospray ionisation (ESI) method; ^{35}Cl values were used for calculated masses. Analytical ^{1}H, ^{19}F and ^{31}P NMR spectra were recorded for $CDCl_3$ solutions on a Bruker DRX 500 MHz spectrometer using TMS as an internal reference for ^{1}H, $CFCl_3$ as an internal reference for ^{19}F and 85% H_3PO_4 as an external reference for ^{31}P. In order to assign the signals of some compounds both proton-coupled and proton-decoupled ^{19}F and ^{31}P NMR spectra were recorded.

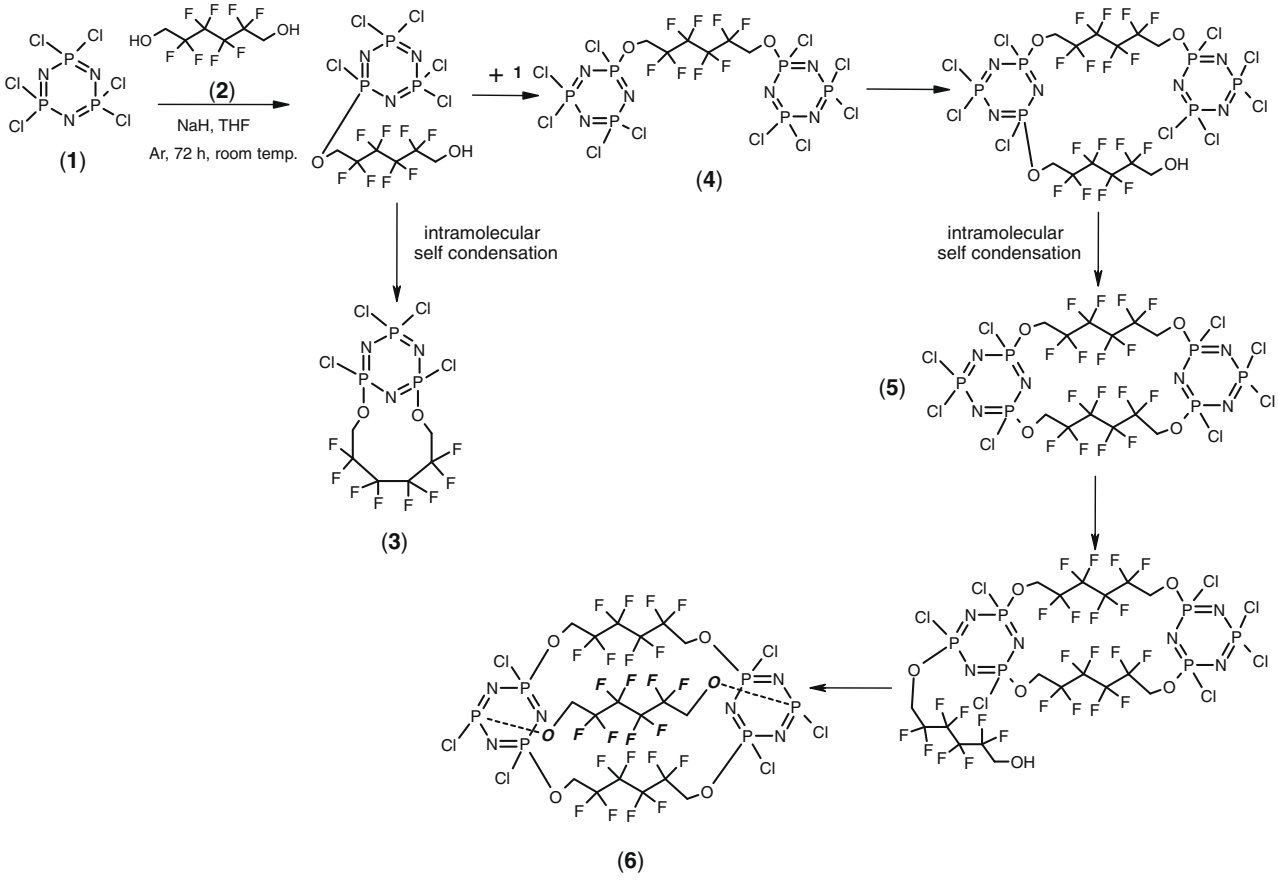
2.3. Reaction of cyclotriphosphazene (*1*) with 2,2,3,3,4,4,5,5-octafluoro-1,6-hexanediol (*2*)

Cyclophosphazene (3.48 g, 10 mmol) and 2,2,3,3,4,4,5,5-octafluoro-1,6-hexanediol (3,14 g, 12 mmol) were dissolved in 150 mL of dry THF in a 250 mL three-necked round-bottomed flask. The reaction mixture was cooled in an ice-bath and NaH (60% oil suspension, 1 g, 24 mmol) in 20 mL of dry THF was quickly added to the stirred solution under an argon atmosphere. The reaction mixture was stirred for 72 h at room temperature and the reaction was followed on TLC silica gel plates using hexane–DCM (3:1), giving four new products. The reaction mixture was filtered to remove the sodium chloride and any other insoluble material. The solvent was removed at reduced pressure and the resulting colourless oil was subjected to column chromatography, using hexane–DCM (3:1) as the eluant. Unreacted trimer (**1**) (0.81 g, 23%) was eluted first from the column. The first product eluted is the mono-ansa derivative $N_3P_3Cl_4[OCH_2(CF_2)_4CH_2O]$ (**3**), (1.13 g, 21%, mp 124 °C). *Anal.* Calc. for $C_6H_4Cl_4F_8N_3O_2P_3$ (M, 536.8): C, 13.42; H, 0.75; N, 7.83. Found (M^+, 537.9): C, 13.40; H, 0.72; N, 7.80%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.50 ppm, 4H, (OCH_2). The second product is the single-bridged derivative $N_3P_3Cl_5[OCH_2(CF_2)_4CH_2O]N_3P_3Cl_5$ (**4**), (1.20 g, 27%, viscous oil). *Anal.* Calc. for $C_6H_4Cl_{10}F_8N_6O_2P_6$ (M, 884.5): C, 8.15; H, 0.83; N, 9.50. Found (M^+, 876.7): C, 8.12; H, 0.81; N, 8.49%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.49 ppm, 4H, (OCH_2). The third separated product is the double-bridged derivative(s) $N_3P_3Cl_4[OCH_2(CF_2)_4CH_2O]_2N_3P_3Cl_4$ (**5**) shown to exist as a mixture of two isomers by ^{31}P NMR spectroscopy. A compound crystallised from the column fraction solvent was shown by X-ray crystallography to be the double-bridged compound (**5**-*anti* isomer). The ^{31}P NMR spectrum of the solvent residue showed it to be other isomer (**5**-*syn*), as also observed in the ^{31}P NMR spectrum of the reaction mixture. *Anal.* Calc. for isomers $C_{12}H_8Cl_8F_{16}N_6O_4P_6$ (M, 1073.7): C, 13.42; H, 0.75; N, 7.83. (**5**-*anti*) (0.50 g, 9%, mp 141 °C) Found (M^-, 1072.7): C, 13.40; H, 0.74; N, 7.78%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.54 ppm, 8H, (OCH_2). (**5**-*syn*) (0.22 g, 4%, oil) Found (M^+, 1074.8): C, 13.44; H, 0.77; N, 7.75%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.46 ppm, 8H, (OCH_2). The last product eluted is the triple-bridged derivative $N_3P_3Cl_3[OCH_2(CF_2)_4CH_2O]_3N_3P_3Cl_3$ (**6**), (0.12 g, 2%, mp 250.87 °C). *Anal.* Calc. for $C_{18}H_{12}Cl_6F_{24}N_6O_6P_6$ (M, 1262.9): C, 17.12; H, 0.96; N, 6.65. Found (M^+, 1262.7): C, 17.10; H, 0.92; N, 6.63%. ^{1}H NMR, $CDCl_3$, 298 K; complex multiplet, 4.50 ppm, 12H, (OCH_2). Compounds **3**, **5**-*anti* and **6** crystallized from hexane–DCM (3:1) and were obtained as white crystals suitable for X-ray crystallography.

2.4. X-ray crystallography

Intensity data were recorded on a Nonius KappaCCD diffractometer driven by COLLECT [14] and DENZO [15] software. Details of data collection and structure refinement for all compounds are given in Table 2. Structures were determined using the direct methods procedure in SHELXS-97 and refined by full-matrix least squares on F^2 using SHELXL-97 [16].

3. Results and discussion



3.1. Characterisation of reaction products by ^{1}H, ^{19}F and ^{31}P NMR spectroscopy

Cyclotriphosphazene (**1**) was reacted with the sodium salt 2,2,3,3,4,4,5,5-octafluorohexane-1,6-diol (**2**) in THF solution under the same solution conditions as those used previously for the reaction of (**1**) with 2,2,3,3-tetrafluorobutane-1,4-diol [10] and 2,2,3,3,4,4-hexafluoropentane-1,5-diol [11]. The ^{31}P NMR spectrum of the reaction mixture indicated five products, which were separated by column chromatography and characterised by ^{1}H, ^{19}F and ^{31}P NMR spectroscopy; the mono-ansa compound $N_3P_3Cl_4(OCH_2(CF_2)_4CH_2O)$ (**3**), the single-bridged compound $N_3P_3Cl_5[OCH_2(CF_2)_4CH_2O]N_3P_3Cl_5$, (**4**), the double-bridged compound $N_3P_3Cl_4(OCH_2(CF_2)_4CH_2O)_2N_3P_3Cl_4$, (**5**) [later characterised as two compounds (**5**-*anti*, **5**-*syn*)], and the triple-bridged compound $N_3P_3Cl_3(OCH_2(CF_2)_4CH_2O)_3N_3P_3Cl_3$ (**6**) (Scheme 1).

Except for the triple-bridged compound (**6**), all the cyclotriphosphazene derivatives contain both PCl(OR) and PCl_2 groups and the ^{31}P NMR spectra are observed as A_2X (or A_2B) spin systems, which can be readily assigned by consideration of signal intensities, chemical shifts and coupling patterns. The triple-bridged cyclophosphazene derivative (**6**) only contains PCl(OR) groups and the ^{31}P NMR spectrum is a single line. The ^{31}P NMR chemical shifts and ^{2}J(PP) values of the compounds are summarised in Table 1. The ^{1}H NMR results for each new compound are provided as part of the analytical data in the synthesis section.

The proton-decoupled ^{19}F NMR spectrum of the bridged forms of the octafluoro-1,6-dioxy moiety shows two single-line signals in a 1:1 ratio (A_2B_2 spin system) for compounds **4**, **5**-*anti*, **5**-*syn* and **6**, whereas the ansa form for compound **3** gives rise to two AB spin systems with ^{2}J(FF) *ca.* 302.6 and 301.7 Hz. Each F atom of the CF_2 groups in the ansa moiety are non-equivalent because they have different spatial relationships with respect to the cyclophosphazene ring and so each peak is split due to geminal coupling ^{2}J(FCF). The ^{19}F chemical shifts and coupling constants of the products are given in Table 1. The magnitudes of ^{2}J(FCF) are in line with previous results on geminal coupling [10,11,17]. It should be noted that the line widths of the ^{19}F NMR signals of the bridged moiety are narrower than those for the ansa moiety, which might reflect the fact that the bridge moiety is more flexible than the ansa moiety.

It is known that there are two configurational isomers for diamino double-bridged cyclotriphosphazene compounds, *i.e.* there are two different meso forms, one has a centre of symmetry and the other has plane of symmetry [9b]. By analogy, the double-bridged diol compound (**5**) has the potential to exist as two configurational isomers (Scheme 2) and so particular attention was taken in analysing by ^{31}P NMR spectroscopy appropriate fractions in the chromatographic separation of the reaction mixture. An example is given (Fig. 1a) for compound (**5**), where the ^{31}P NMR spectrum is observed as two sets of closely spaced signals

Scheme 1. The reaction of cyclotriphosphazene (**1**) with 2,2,3,3,4,4,5,5-octafluorohexane-1,6-diol (**2**) and structures of the products, compounds (**3**)–(**6**).

[e] Magnitude of $^{2}J_{FCF}$ corresponds to signals at *ca.* −119 to −121 ppm.

in an approximate 2:1 ratio showing partial separation by column chromatography. The column fraction was then crystallized and the ^{31}P NMR spectrum of the re-dissolved crystal (Fig. 1b) showed one of the diastereoisomers and the ^{31}P NMR spectrum of the solvent residue (Fig. 1c) show the other diastereoisomer. X-ray crystallography is needed to characterise which form of compound (**5**) crystallised.

*3.2. Characterisation of compounds (**3**), (**5**-anti) and (**6**) by X-ray crystallography and, hence, (**5**-syn) by ^{31}P NMR spectroscopy*

The X-ray crystal structures are reported for compounds (**3**), (**5**-*anti*) and (**6**) (Figs. 2–4), with data collection and refinement parameters reported in Table 2.

The cyclophosphazene ring in each structure exhibits no unusual deviations in bond lengths and angles from either that of the parent $N_3P_3Cl_6$ structure (CSD code KAGKUY) [18] or from that observed in similar structures in the Cambridge Structural Database [19]. The cyclotriphosphazene rings are quite planar, with a deviation of individual atoms from the N_3P_3 plane in all structures ranging from 0.024 to 0.137 Å with an average of 0.090 Å, *viz.* **3** (0.024), **5**-*anti* (0.137, 0.137) and **6** (molecule 1, 0.076, 0.122; molecule 2, 0.122, 0.072; molecule 3, 0.080, 0.062; molecule 4 0.058, 0.098 Å).

The molecular structure of **3** (Fig. 2) confirms the *cis*-ansa structure with one diol moiety linked between phosphorus moieties on the same cyclophosphazene ring. The molecular structure of **5** (Fig. 3) show the double-bridged derivative, in which the diol chains are in a *cis*-configuration and the two cyclotriphosphazene rings are in an antiparallel arrangement with respect to the plane of ring formed from the two diol bridges; hence, it has been designated **5**-*anti* to distinguish it from the configurational analogue **5**-

syn (Scheme 2). The two phosphorus atoms attached to the diol bridges in a single cyclotriphosphazene moiety of **5**-*anti* exhibit *R* and *S* configurations and an inversion centre in the middle of the molecule generates the opposite handed chirality at the symmetry generated phosphorus centres.

The structure of compound **6** (Fig. 4) shows that it is the triply-bridged derivative, in which the three diol chains connect the two cyclophosphazene rings in a *cis*-configuration and the resulting molecular morphology of the compound is cylindrical, or 'barrel-shaped'. There are four chemically identical, yet crystallographically unique molecules, in the asymmetric unit of **6**, which arise from the number of different torsional degrees of freedom that three bridging 8-membered chains can adopt. The number of degrees of freedom can be demonstrated by the considerable differences in separation between equivalent phosphorus centres connected by a bridge [molecule 1 = 10.03, 9.98, 10.22 Å; molecule 2 = 10.09, 9.91, 10.03 Å; molecule 3 = 10.43, 9.35, 9.99 Å; molecule 4 = 10.14, 9.69, 9.90 Å].

The crystal structure of the double-bridged compound (**5**) shows it to be the *anti*-isomer (Scheme 2) indicating that under these solution conditions, the diastereoisomer with a centre of symmetry crystallises more readily than the *syn*-isomer, which has a plane of symmetry. Characterisation of (**5**-*anti*) by X-ray crystallography enables the ^{31}P NMR spectra of both diastereoisomers of (**5**-*anti*) and (**5**-*syn*) to assign unequivocally (Table 1).

Scheme 2. The (*R*/*S*) configurational isomers of double-bridged cyclotriphosphazene derivatives.

3.3. Effect of size of the ansa ring for fluorinated diol derivatives of cyclophosphazene

The characteristics of the mono-ansa compound (**3**) formed from the octafluorohexane-1,6-diol in this work may be compared with those for analogous compounds (**7**) and (**8**) formed from the hexafluoropentane-1,5-diol [11] and tetrafluorobutane-1,4-diol [10], respectively (Scheme 3). A summary of the structural parameters (Table 3) shows that the size of the ansa ring has little effect on various bond lengths and angles defined in Scheme 3 but that the major difference for the compounds is observed in the maximum deviation from the mean plane of the N_3P_3 ring for ansa compounds (**3**) (0.024), (**7**) (0.099) and (**8**) (0.125 Å), respectively. These values indicate that the greatest strain on the phosphazene ring is caused by the 9-membered ansa ring of compound (**8**), with progressively less strain for the 10-membered ansa ring of (**7**) and the least strain caused by the 11-membered ansa ring (**3**). Previous work has shown that the effect of the strain for cyclotriphosphazenes with smaller ansa rings is also reflected in the minimum value of the P···P distances of the cyclophosphazene ring, which is about 2.6 Å for 8-membered ansa compounds [20,21] but greater than 2.7 Å for unstrained cyclotriphosphazene rings [19]. It is seen in Table 3 that for each of the compounds (**3**), (**7**) and (**8**) the minimum P···P distance is greater than 2.7 Å showing that this parameter is not a sensitive indicator of strain in phosphazene rings caused by derivatives with at least 9-membered ansa rings.

3.4. Influence of chain length of fluorinated diols on the formation of reaction products

There is now available detailed information on the products of the reaction of cyclotriphosphazene (**1**) with three fluorinated diols of different chain length. Reaction of the fluorinated butane- and pentane-diols with (**1**) leads exclusively to the formation of spiro and ansa derivatives [10,11] by intramolecular cyclisation

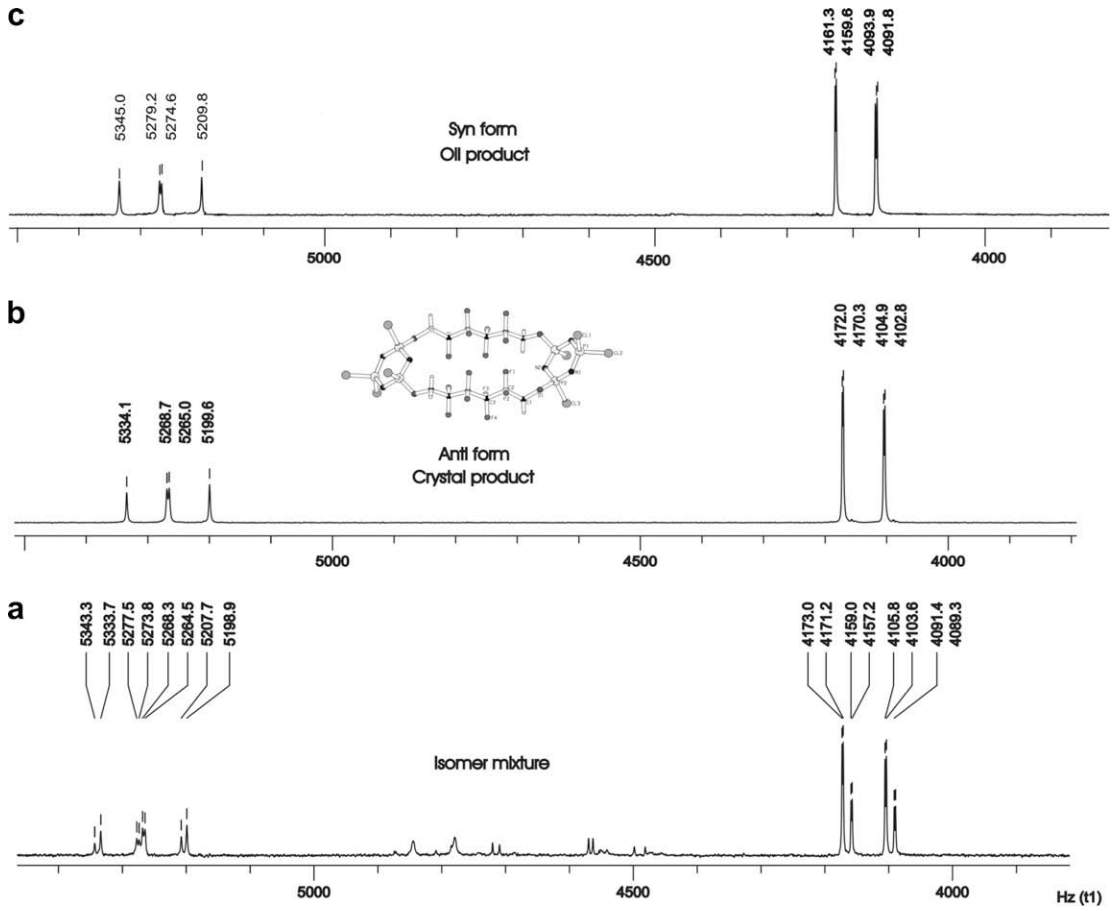

Fig. 1. ^{31}P NMR spectra of (a) mixture of double-bridged diastereoisomers of (**5**), (b) *anti* form of isomer and (c) *syn* form of isomer.

reactions (Scheme 4), whereas for the fluorinated hexanediol intermolecular reactions are predominant to form bridged compounds and the small proportion of intramolecular cyclisation gives the ansa derivative and only a trace of the spiro derivative. Hence, it is important to consider the factors that may be involved in the competition between the intra- and intermolecular mechanisms for reactions of these fluorinated diols with compound (**1**).

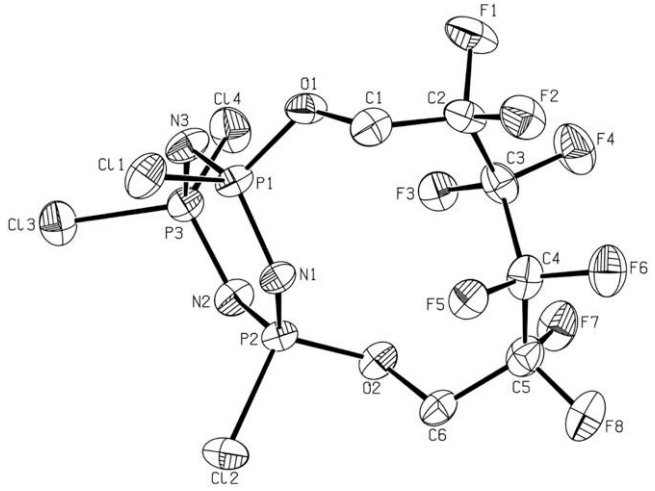

Fig. 2. X-ray crystal structure of (**3**) with ellipsoids plotted at 50% probability.

Using ^{31}P NMR spectra of the reaction mixtures to quantify the formation of products, it is found that the proportion of the monospiro derivative decreases with increasing chain length of the fluorinated diol; 45% of total products for the butane-diol [10], 29% for the pentane-diol [11] and <1% for the hexanediol in this work. Concomitantly, there is an increase in the relative proportion of monoansa derivatives. It is known that reaction of cyclophosphazenes with alkoxides promotes the stereoselective formation of disubstituted derivatives with a *cis*-configuration, which has been rationalised in terms of the co-coordination (cooperative binding) with the attacking oxy-nucleophile of the sodium counterion already present in an oxy-substituent [2,22]. A similar explanation has been given for the stereoselective formation of the *cis*-ansa macrocyclic derivative of cyclotriphosphazene with disodium oxy[tetraethylenoxy] glycolate [23]. Although the cation-assisted mechanism should apply to the formation *cis*-ansa compounds with the fluorinated diols, it is likely that formation of the *cis*-ansa derivatives (**3**, **7** and **8**) will also be influenced by steric effects for these shorter chain diols forming 11-, 10- and 9-membered rings, respectively. Hence, it is not surprising that there is a greater relative proportion of ansa derivatives with increasing chain length, because X-ray crystallographic results have shown (Table 3) that there is less strain in the cyclotriphosphazene ring with increasing size of the ansa ring.

The most interesting finding in the present work on the reaction of cyclotriphosphazene (**1**) with the octafluorohexanediol (**2**) is the formation of single-, double- and triple-bridged derivatives. Although some double-bridged diamino derivatives of (**1**) have been reported previously [9b,12], there is only one mention of a double-bridged diol derivative [13] and its crystal structure was

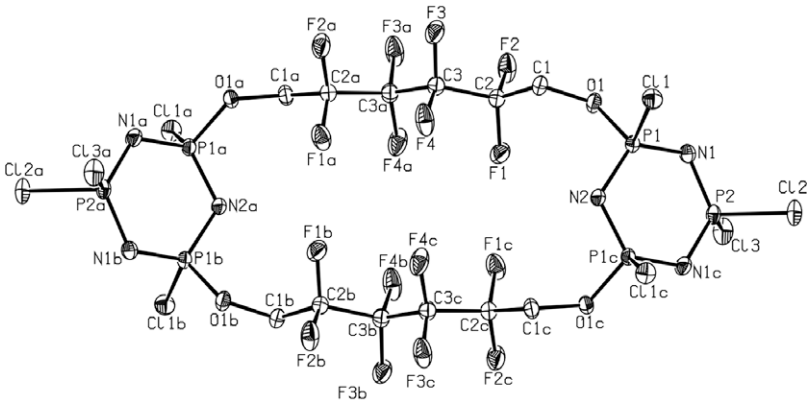

Fig. 3. X-ray crystal structure of (**5**-*anti*) with ellipsoids plotted at 50% probability.

not reported, whereas in this work both a double-bridged (Fig. 3) and a triple-bridged (Fig. 4) have been characterised. It is found that there is a preference for formation of the single-bridged derivative (27% yield) compared to the double-bridged (13% total) and the triple-bridged (2%) derivatives, which is not surprising given the standardised molar ratio of 1:1.2 for reaction of (**1**) with (**2**) for comparison with the other fluorinated diols [10,11]. It is likely that formation of bridged derivatives with the hexanediol results from the flexibility of the longer-chain of the mono-substituted intermediate such that the terminal alkoxy group preferentially reacts with the P–Cl group of a neighbouring cyclotriphosphazene molecule (intermolecular reaction) rather than an intramolecular reaction to form either a spiro or ansa derivative (Scheme 3). It is also of interest to observe that there are two double-bridged diol derivatives that are analogous to the two double-bridged amino derivatives observed previously [9b]. Although the bridging P(OR)Cl group is a centre of chirality, both double-bridged derivatives are meso, one with a centre of symmetry (in which the cyclotriphosphazene are in an *anti* configuration) and the other with a plane of symmetry (*syn*) as summarised in Scheme 2. In principle, one might expect these two stereoisomers to be formed with equal probability but it appears from the ^{31}P NMR of the isomer mixture (Fig. 1) and from the amounts of each compound isolated (**5**-*anti*, 9% yield; **5**-*syn*, 4%) that there is a preference for the stereoisomer having the centre of symmetry. However, ^{31}P NMR of the reaction mixture showed similar proportions for **5**-*anti* and **5**-*syn*, as expected, indicating that the separation procedure favoured the *anti*-

hydrophilic tris(hydroxymethyl)phosphine (thp) allowed the preparation of more hydrophilic species stable in aqueous media with improved cytotoxic properties [12]. In particular, mononuclear copper(I) complexes of the type {[L]Cu(thp)$_2$} (L = [HC(CO$_2$)(tz)$_2$]$^-$ or [HC(CO$_2$)[(pz^{Me_2})$_2$]$^-$) were found to possess antiproliferative activity against different human tumor cell lines markedly higher than that shown by cisplatin [12]. Chemosensitivity tests performed on cisplatin sensitive and resistant human cancer cell lines (ovarian cancer 2008 versus C13* and cervix cancer A431 versus A431/Pt) established that (scorpionate)Cu(thp)$_2$ type compounds were able to overcome cisplatin resistance, supporting the hypothesis of a different mechanism of action compared to that exhibited by the reference drug. Marzano et al. hypothesized that the cytotoxic activity of these copper(I) complexes might be correlated to their ability to trigger paraptosis, a non-apoptotic mechanism of cell death [11]. The ^{64}Cu-labeled complexes of two scorpionate ligands, with the thp co-ligands, [HC(CO$_2$)(pz^{Me_2})$_2$Cu(thp)$_2$] and [HC(CO$_2$)(tz)$_2$Cu(thp)$_2$], have been prepared to evaluate their usefulness as PET radiopharmaceuticals [13].

Since the intrinsic difficulty of growing an appropriate crystal of these [(scorpionate)Cu(PR$_3$)$_2$]-type complexes, the local structure of the metal site (Cu) is unknown. However, structural informations are likely to be obtained using the X-ray absorption spectroscopy technique (XAS). In the past decades, XAS has been proved to be a strong structural tool [14–16], for the characterization of amorphous [17] and disordered materials [18], inorganic materials [19–21], biological materials [22,23] solutions [24], has been also applied to in situ techniques [25,26].

This paper describes the identification of the metal sites occupied by copper in the {[H$_2$B(tz$_2^{NO}$)$_2$]Cu(dppe)} [11], {[H$_2$B(tz^{NO_2})$_2$]-Cu[P(p-tolyl)$_3$]$_2$} [11] and {[HC(CO$_2$)(pz^{Me_2})$_2$]Cu(thp)$_2$} [12] complexes.

2. Experimental

2.1. Synthesis

All reagents were purchased from Aldrich and used without further purification. The complexes {[H$_2$B(tz^{NO_2})$_2$]Cu(dppe)} (**1**) [11], {[H$_2$B(tz^{NO_2})$_2$]Cu[P(p-tolyl)$_3$]$_2$} (**2**) [11] and {[HC(CO$_2$)(pz^{Me_2})$_2$]Cu(thp))$_2$} (**3**) [12] were prepared in accordance with the literature methods.

2.2. XAS data collection

Samples for the XAS experiments were mixed with boron nitride and then pressed as pellets (3 tons). X-ray absorption experiments were performed at the synchrotron radiation source (SRS) at Daresbury Laboratory, Warrington, England, using the beam line 7.1. The storage ring operates at 1.6 GeV and a typical current of 240 mA. Internal references for energy calibration were used for copper at each scan. This allows for a continuous monitoring of the energy during consecutive scans. No energy drifts of the monochromator were observed during the experiments. Data were acquired in transmission mode. The ionization chamber was filled with an Ar/He gas mixture. Harmonics were rejected by detuning (80%). X-ray absorption spectroscopy (XAS) spectra were collected from 200 eV before the edge up to k = 13 every 0.03 k with a three second integration time. A Cu foil internal energy calibration was measured simultaneously with each spectrum.

2.3. XAS data analysis

X-ray absorption spectroscopy (XAS) spectra were calibrated using the EXCALIB program. The pre-edge background was removed by subtraction of a linear function extrapolated from the pre-edge region, and the XANES spectra were normalized at the unity (9000 eV) by extrapolation of the atomic background as it comes out from the EXAFS analysis (evaluated using a polynomial function).

The EXAFS analysis has been performed by using the GNXAS package [27,28] that takes into account multiple scattering (MS) theory. The method is based on the decomposition of the EXAFS signals into a sum of several contributions, that are the n-body terms. It allows the direct comparison of the raw experimental data with a model theoretical signal. The procedure avoids any filtering of the data and allows a statistical analysis of the results. The theoretical signal is calculated *ab initio* and contains the relevant two-body $\gamma^{(2)}$ and the three-body $\gamma^{(3)}$ multiple scattering (MS) terms. The contribution from four-body $\gamma^{(4)}$ terms [29] has been checked out, but it was found to be negligible. The two-body terms are associated with pairs of atoms and probe their distances and variances. The three-body terms are associated with triplets of atoms and probe angles, bond–bond and bond–angle correlations. If useful, a single effective MS signal $\eta^{(3)}$ that includes both $\gamma^{(2)}$ and the $\gamma^{(3)}$ contributions can be used for the shells beyond the second one by using the same three-atom coordinates both for the two-atom and the three-atom contributions. The full definition of the parameters associated with the triplet of atoms is found in Ref. [28]. Data analysis is performed by minimizing a χ^2-like function that compares the theoretical model to the experimental signal. The phase shifts for the photoabsorber and backscatterer atoms were calculated *ab initio* starting from the structural model [30]. They were calculated according to the muffin-tin approximation. The Hedin–Lundqvist complex potential [31] was used for the exchange–correlation potential of the excited state. The core hole lifetime, Γ_c, was fixed to the tabulated value [32] and included in the phase shift calculation. The experimental resolution used in the fitting analysis was about 2 eV, in agreement with the stated value for the beamline used. The relevant E_0 values were found to be displaced by several eV with respect to the edge inflection point. They are summarized in Table 1 together with the structural parameters. The values of S_0^2 have been found to be in the 0.81–0.89 range and are also displayed in Table 1. The fitting procedure at the Cu K-edge was also performed including the relevant set of multiple scatter-

[a] Data obtained from the three-body configuration (using Cu–P–C angle and P–C distances).

ing paths that may originate from the structure of this class of compounds. Hence, referring to Fig. 1, the theoretical signals included in the fitting procedures are: the two-atom contributions $\gamma_1^{(2)}$ Cu–N with degeneracy of two, the two-atom contributions $\gamma_2^{(2)}$ Cu–P with degeneracy of two, the three-body contribution $\eta^{(3)}$ Cu–N–N with degeneracy of two, the three-body contribution $\eta^{(3)}$ Cu–N–N with degeneracy of two, the three-body contribution $\eta_2^{(3)}$ Cu–P–C with degeneracy of four. Actually the first 2 three-body signals have been grouped considering both the equivalence of the sites where the atoms are placed and the similarity of the C and N atoms in terms of phase shift. Hence, the sum signal is defined in term of $\eta_1^{(3)}$ Cu–N–N(C) with degeneracy of four. This approximation has been checked and produces similar results using less structural parameters. It is noteworthy that the inclusion of the three-body term $\eta^{(3)}$ allows monitoring the shells beyond the first one by using the same three-atom coordinates both for the two-atom and the three-atom contributions. In fact, the three-body signal $\eta_2^{(3)}$ Cu–P–C includes both $\gamma^{(2)}$ Cu–C and $\gamma^{(3)}$ Cu–P–C contributions. Also, the fitting procedure of complex **3** includes the two-atom contributions $\gamma_2^{(2)}$ Cu–O with degeneracy of one. Based on this model, the total number of parameters taken into account in the fitting procedure (including the structural and non-structural terms E_0, S_0^2 and the experimental resolution) is found to be 19 for complexes **1** and **2** and 21 for complex **3**. Besides, it is worth mentioning that in all cases the number of fitting parameters does not exceed the estimated 'number of independent data points' $N_{ind} = (2\delta k \delta R/\pi) + 2$, ensuring that the fit is well determined and does not lead to parameters with very large errors, thus confirming the reliability of the minimization. In order to evaluate the effect of the structural disorder, the simulation was done by considering a non-Gaussian type of pair distribution functions for the $\gamma^{(2)}$ Cu–N and $\gamma^{(2)}$ Cu–P signals. In fact, because of the non-crystalline nature of the compound, a more flexible model replacing the simple Gaussian function might be required. The gamma like (Γ) distribution has been used here [33,34] and proved to be very useful in previous studied systems [35–37]. This function depends on three parameters: the average bond distance, the bond variance, and the asymmetry coefficient (skewness) β, defined as K_3/σ^3 where K_3 is the third cumulant of the distribution. The full definition of the function is described in Refs. [28,34].

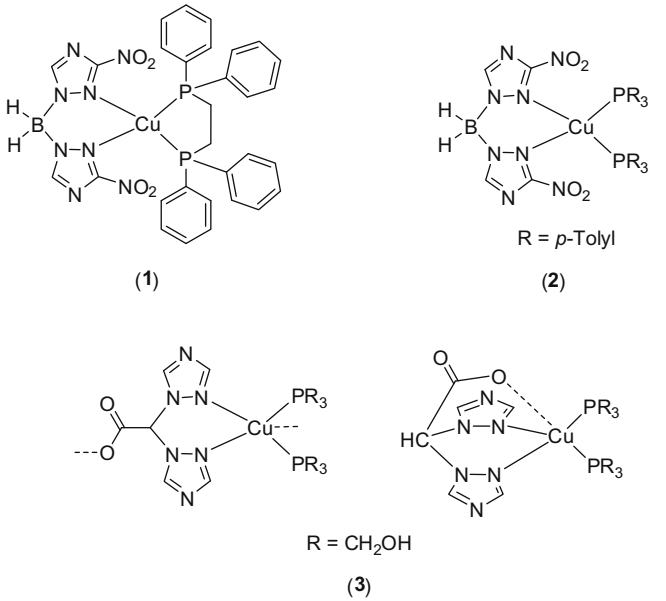

Fig. 1. Structures of the Cu(I) complexes **1**–**3**.

3. Results and discussion

The k^2-extracted EXAFS signals of the investigated samples are shown in Fig. 2 (dot lines). The sinusoidal curves are generated by the atomic environment around the photo-absorber atom, i.e. copper, and are similar for all the investigated compounds. Hence, the structural information provided out by the signals, which is typically extracted by a fitting procedure which compares a model compound with the experimental one, should be not so different. The observed sinusoidal signals for each complex suggest a main contribution of the first shell, which should be the main structural parameter to be studied in the present analysis. As reported in Fig. 1, the first shell of the studied complexes is comparable: the scorpionate ligand coordinates the metal center by two nitrogen atoms, and two additional mono-phosphine co-ligands or a diphosphine complete the 4-fold coordination of Cu(I). In addition, complex **3** is characterized by a carboxylate fragment which makes available an oxygen atom for a possible 5-fold coordination of copper(I). This is not observed insofar and would be a major task of the present analysis, as the EXAFS probe is a unique one for non-crystalline compounds.

As a customary, the EXAFS fitting analysis is conducted by means of a model compound since it permits to compute the various singular EXAFS signals. Because the atomic coordinates of this class of compounds are not available in the literature, we have used those of similar complexes with a different coordinated metal [30]. Of course, the starting theoretical signals have been later recalculated to account for any important structural variation from the model. In fact, when a deviation of more that 10% of a selected structural parameter (e.g. atomic distance or angle) occurred, the corresponding theoretical signal has been recalculated before being used in the fitting procedure. As a consequence, the theoretical model has been adapted to be used in this paper.

The best-fit results concerning the fitting procedures for the investigated complexes (all details specified in Section 2) are illustrated in Figs. 2–4. Fig. 2 shows the comparison of the experimental and theoretical curves of the k^2-extracted EXAFS, and Fig. 3 displays the comparison of the corresponding Fourier Transforms (FTs). We can observe that the theoretical curves match well with the experimental ones, indicating the reliability of the adapted-structural model and the accuracy of the data analysis. The FT curves of Fig. 3 confirm the existence, in all of the three complexes, of a main first shell contribution, and of some multiple scattering (MS) contributions at higher frequencies, i.e. distances. Fig. 4 reports the details of the EXAFS analysis. Each panel reports the various contributions to the theoretical signals and the comparison of

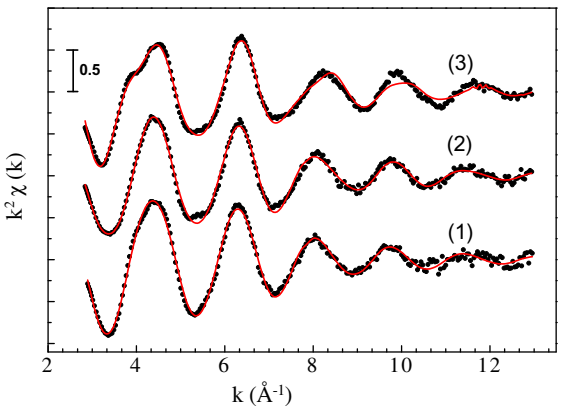

Fig. 2. Best fit of the copper K-edge EXAFS signals of complexes **1**–**3**. The figure shows the comparison of the experimental (···) and theoretical (–) k-extracted EXAFS signals.

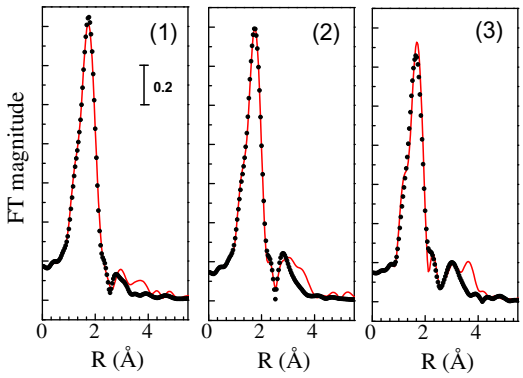

Fig. 3. Best fit of the copper K-edge EXAFS signals of complexes **1**–**3**. The figure shows the comparison of the experimental (···) and theoretical (–) Fourier transform signals, obtained in the 2.5–13 $Å^{-1}$ *k* space, of the EXAFS signals.

the total theoretical signal with the experimental one. Besides the fact that the Cu–P and Cu–N first shell largely contribute in all panels, hence confirming the at-a-glance explanation of Fig. 2 as above, all signals are rather important in the determination of the total theoretical one. It is also interesting to notice the two-body Cu–O signal of the complex **3**, whose intensity is comparable to the three-body ones.

The inter-atomic distances and the corresponding EXAFS Debye–Waller factor (best-fit) of the samples investigated are shown in Table 1. The statistical errors associated with the parameters obtained with the EXAFS analysis are also indicated. They were determined by correlation maps (contour plots) for each pair of parameters. Fig. 5 shows the contour plots for complex **3**, as an example. These plots were selected among the parameters having strong correlation to reflect the highest error. The estimated statistical error [38] is associated with the 95% confidence interval. It is important to emphasize that this evaluation provides only statistical errors on EXAFS refined parameters and it does not accounts for systematic errors in the theory or peculiar to the experimental technique. This values of statistical errors are slightly longer than those normally quoted for non-crystalline and amorphous compounds [36,39].

From Table 1 we can observe that the Cu–N first shell distances, as well as the Cu–P ones for complexes **1** and **2**, are similar and that this holds true also for their bond length variances. Some differences arise in the case of compound **3** where the metallacycle is rather different; the Cu–N distance shortens by about 5 hundredth of an angstrom and the Cu–P interaction becomes longer. Complex **3** also displays a Cu–O interaction at about 2.29 Å, due to the carboxylic tail of the scorpionate ligand. Anyway, these bond lengths reflect the ones normally quoted for copper derivatives of scorpionate ligands [40–43].

A close inspection of Table 1 reveals also other differences of the structural parameters in compounds **1** and **2** in comparison to compound **3**: the Cu–N–N and the Cu–P–C angles are slightly different, and consequently the P–C interaction changes too. This is due to the nature of the metallacycle system, and in particular to the presence, in complex **3**, of a close oxygen for a Cu–O coordination which leads to a slightly different site where the copper is located (the 4-fold coordinated Cu site becomes 5-fold coordinated).

3.1. On the Cu–O interaction in complex *3*

The coordination of copper in compound **3** deserves a special attention. Of course, the structure proposed in Fig. 1 suggests a close interaction between copper and the oxygen fragment. The complex may form the 6-atom cycle Cu–N–N–C–C–O, which seems plausible if a chair configuration of the Cu–N–N–C–N–N cycle takes place (right side of Fig. 1 for complex **3**). The EXAFS probe used in our experiment suggests not only a Cu–O interaction at about 2.29 ± 0.02 Å but also a non-negligible contribution of the Cu–O signal to the total theoretical one. In fact, as underlined by the plot 3 of Fig. 4, the intensity of the $\gamma^{(2)}$ Cu–O is relevant. The importance of this signal has been explored more fully by considering what the fit result would be without the Cu–O interaction (Fig. 6). The upper panel shows the comparison between the total theoretical signal

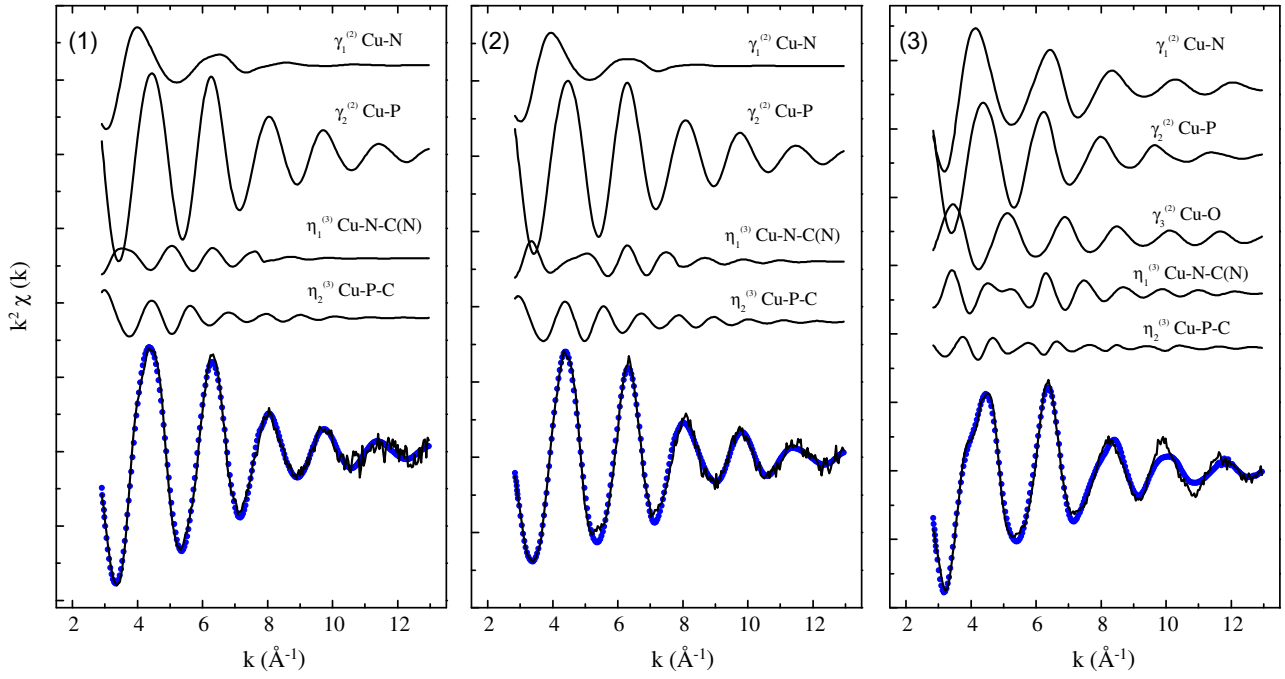

Fig. 4. Details of the EXAFS analysis of the Cu K-edge of complexes **1**–**3**. Each panel of the figure shows the individual EXAFS contributions, in terms of two-body and three-body signals, to the total theoretical signal. The comparison of the total theoretical signal (–) with the experimental one (···) is also reported at the bottom of each panel.

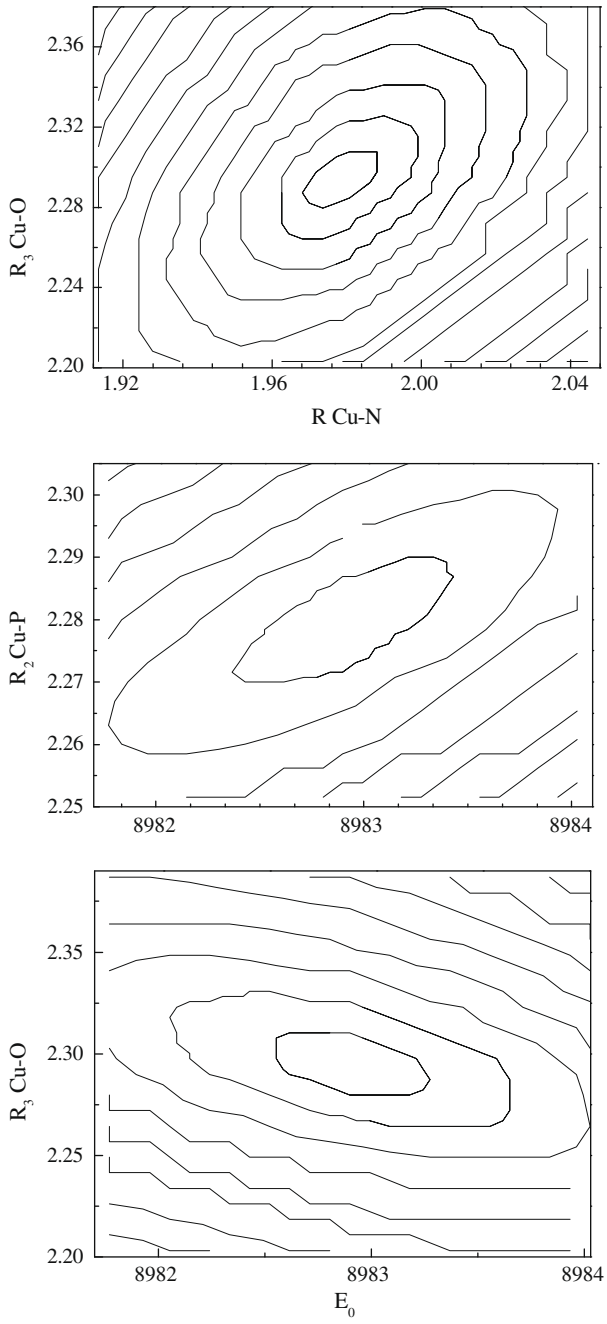

Fig. 5. Examples of the two dimensional section of the parameter space (contour plots) for complex **3**. These plots were selected among the parameters having strong correlation to reflect the highest error. The inner elliptical contour corresponds to the 95% confidence level.

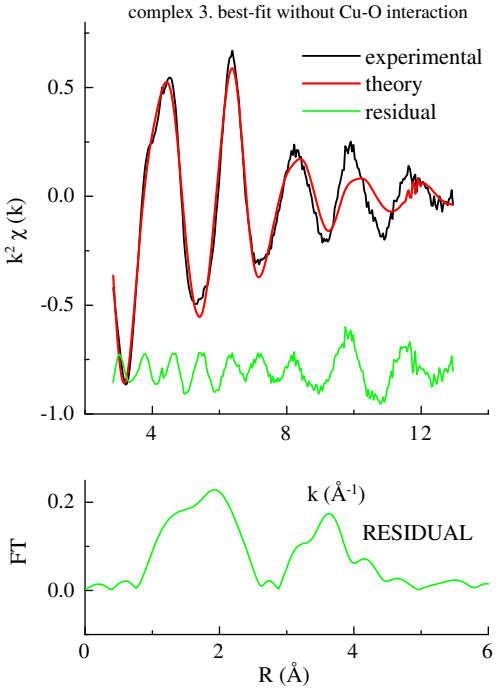

Fig. 6. Former EXAFS analysis of the Cu K-edge of complex **3**. The upper panel displays the comparison of the experimental (···) and theoretical (–) k-extracted EXAFS signals. Fit has been obtained considering a 4-fold coordinated Cu(I) structural model (no Cu–O interaction included). The residual curve is also reported. The lower panel displays the corresponding Fourier transform of the residual curve.

and the experimental one, and the residual curve as well. It is clear that the theoretical curve does not match well with the experimental, especially at high *k*-values. The mismatch appears evident considering the residual curve: a low frequency sinusoidal signal is mainly missed from the calculation, accompanied by a high frequency signal. This is confirmed by the signal at the bottom which displays the corresponding FT curve of the residual curve only. The observed broad peak at about 2 Å confirms a main low-frequency missed and may correspond to the Cu–O contributions, considering the phase shifts issue. The other contributions at higher frequency, from 3 to 4 Å, may origin from the calculation, due to the fact that the missing Cu–O frequency may force other signals, especially those related to the three-body terms, the Multiple Scattering $\eta^{(3)}$s, to compensate the mismatch between the experimental and the theoretical signal, leading to an odd result. Overall, this finding demonstrated the 5-fold coordination geometry of the copper in complex **3**, by means of an additional Cu–O interaction.

In addition, the EXAFS results of complex **3** appear unable to effectively discriminate between the two proposed structures reported in Fig. 1. In any case, the Cu–O bond length quotation at 2.29 Å is short enough to be typical of a strong interaction among Cu and O, and so does the corresponding EXAFS bond variance of 0.004 $Å^2$, which is characteristic of a chemical bond. Hence, both monomeric or polymeric structures depicted for compound **3** in Fig. 1 are probable.

3.2. XANES spectra of Cu(I) complexes

More information about the copper coordination in a complex as well as information about the electronic transitions and the effective charge associated to the absorbing atom, can be obtained from the X-ray absorption near edge structure (XANES) region. XANES spectra of Cu complexes display a pre-edge features which is assigned to the 1s → 4p electronic transition [44,45]. For Cu(I) the pre-edge transition occurs at about 8982–8984 eV, while for Cu(II) it shifts to higher energies, at about 8987 eV. In the case of Cu(I) the transition shows the highest intensity and resolution for linear two-coordinated complexes and becomes less intense and broadened as the coordination number increases and/or the symmetry is lowered [44,45]. This sensitivity of Cu XANES to geometry has proved particularly useful in studies where conversion from two-coordinate to three-coordinate site appeared [46].

Fig. 7 displays the Cu K-edge XANES spectra of complexes **1**–**3**. The general shape of the curves is different, demonstrating the

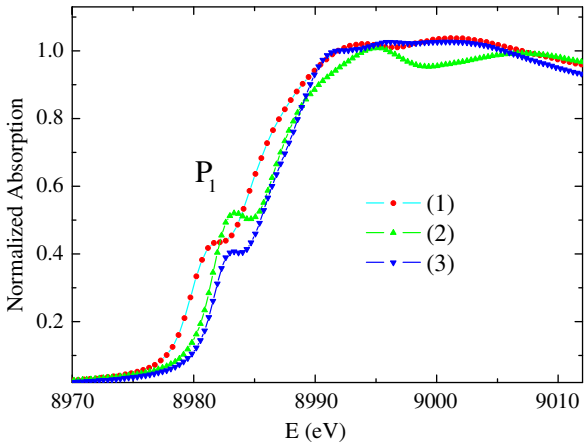

Fig. 7. Normalized XANES spectra at the Cu K-edge of complexes **1**–**3**. The pre-edge features (P_1) is assigned to the 1s → 4p transitions.

sensitivity of the local geometry of the photo-absorber atom (Cu) to the XANES profile. This is not surprisingly by considering the different structures of Fig. 1. As expected for a Cu(I) complex, a pre-edge feature at about 8983 eV appears in each spectrum, and small differences in the normalized intensities are revealed. It can be seen that the intensities of the 8983 eV peak are not indicative of diagonal or trigonal geometry [47,48], but they all resemble those of 4-coordinated Cu(I) complexes [44]. The lower intensity is found for complex **3** whose the present EXAFS analysis indicated to be a *distorted* 5-fold coordinated. This behavior agrees to that observed from Kau et al. about the coordination number increases and symmetry lowering [44]. A close inspection of the figure reveals a 1 eV chemical shift toward lower energy of the 1s → 4p peak for compound **1** respect to **2** and **3**. This may be due to the local coordination geometry as well as to the combined inductive and steric effects of co-ligands in complex **1**, which makes the charge of the coordination metal less positive.

4. Conclusions

The coordination metal core of copper(I) complexes containing the dihydridobis(3-nitro-1,2,4-triazol-1-yl)borate and the bis(1,2,4-triazol-1-yl)acetate ligands have been identified by EXAFS spectroscopy, due to the intrinsic difficulty of growing appropriate crystals of these [(scorpionate)Cu(PR_3)$_2$]-type complexes. The EXAFS analysis has been performed taking into account the Multiple Scattering formalism, allowing the determination of the first shell distances as well as the contribution of the outer shells. Copper is found to be 4-fold coordinated in the dihydridobis(3-nitro-1,2,4-triazol-1-yl)borate complexes, with a CuN_2P_2 core due to the chelation of the scorpionate ligand by two nitrogen atoms and due to two additional mono-phosphine co-ligand or a diphosphine. A $CuON_2P_2$ coordination core is revealed for the copper(I) complex of the bis(1,2,4-triazol-1-yl)acetate due to the carboxylate fragment of the ligand which makes available an oxygen atom for a possible 5-fold coordination of copper(I). The additional interaction of the metal with the oxygen of the acetate sting of the scorpionate ligand is not observed insofar and it is the major task of the present analysis, as the EXAFS probe is a unique one for non-crystalline compounds. The 1s → 4p transition which is a typical feature of the XANES spectrum on Cu(I) samples couples well with the EXAFS results, since the smaller 1s → 4p peak intensity is found for complex **3** and the EXAFS analysis indicates the existence of a 5-fold coordination, with the copper interacting with the acetate of the scorpionate ligand to form a monomeric or polymeric structure.

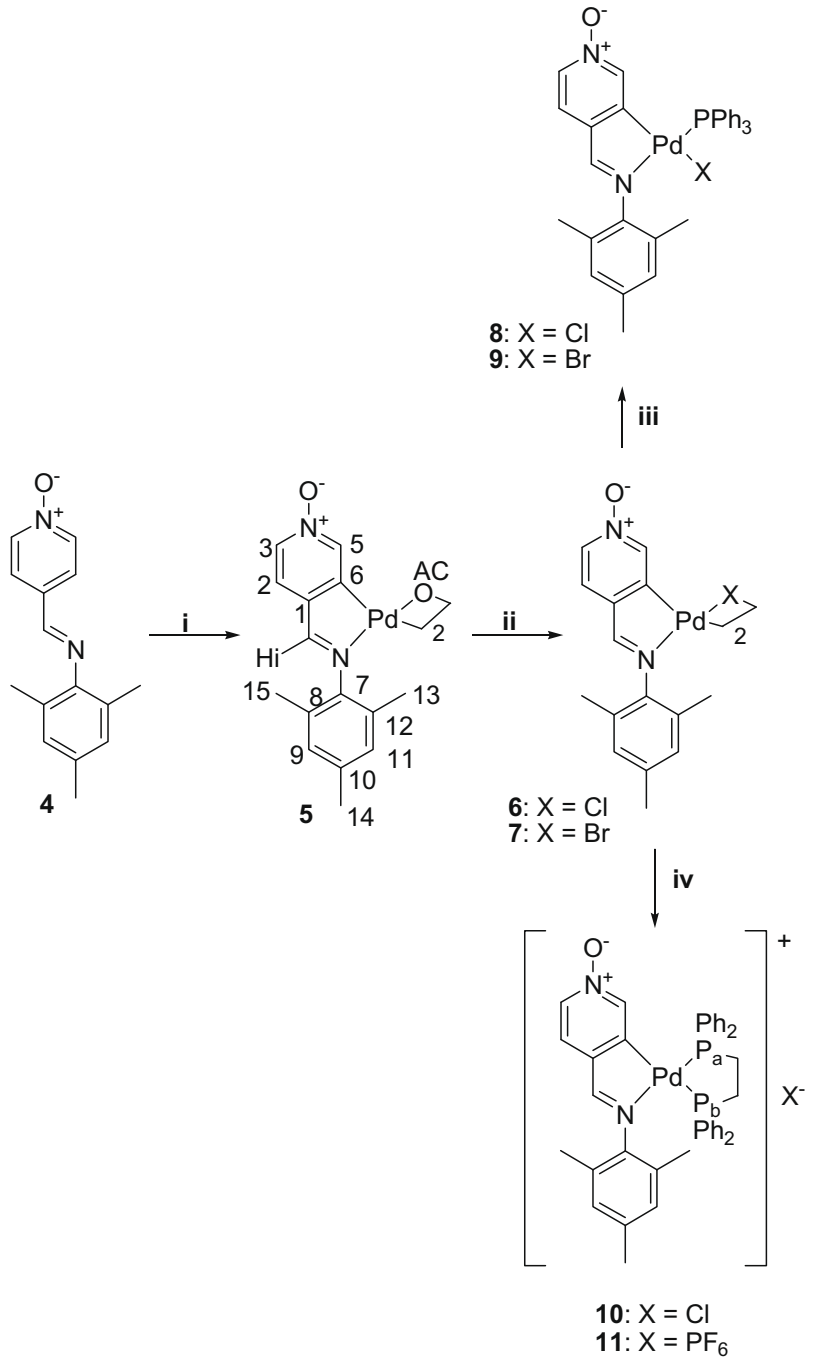
Scheme 1. (i) $Pd(OAc)_2$, toluene, 60 °C; (ii) MeI, toluene, 90 °C.

analysis. Reaction of the Schiff base ligand **1** with palladium(II) acetate in toluene at 60 °C for 24 h gave the non-cyclometallated complex **2** with two ligands coordinated to the palladium atom through the pyridine nitrogen. The doublet signals assignable to the H2/H6 protons, in the ^{1}H NMR spectrum, was in agreement with absence of Pd–C bond formation in **1**. The values shown by the ν(C=N) stretch, 1610 cm^{-1}, in the IR spectrum and by the the *HC*=N resonance in the ^{1}H NMR spectrum, 8.22 ppm, were similar to those for the free ligand, in accordance with the absence of bonding between the palladium and the non-aromatic iminic nitrogen [22,23]. Two strong bands at 1300 and 1555 cm^{-1} were assigned to the symmetric and asymmetric ν(COO) vibrations, respectively, in agreement with those expected for mono-coordinate acetato ligands [24,25]. The ^{1}H NMR spectrum showed a singlet signal for the acetate CH_3COO^- protons at 2.29 ppm and the ^{13}C{1H} NMR two signals assigned to the CH_3COO and the CH_3COO acetate carbons at 178.36 and 23.23 ppm, respectively. Regardless of the reaction conditions used (dichloromethane, room temperature; acetic acid, reflux) the reaction between ligand **1** and palladium(II) acetate gave in all cases the coordination complex **2** and not the expected cyclometallated compound.

The pyridine nitrogen of ligand **1** could be *N*-methylated with MeI in toluene at 90 °C in order to hinder its coordination through the pyridine nitrogen and, consequently, favour the cyclometallation reaction. However, reaction of the methylated Schiff base **3** with palladium(II) acetate under analogous reaction conditions as used in the synthesis of **2** (toluene, 60 °C) did not yield the desired product; instead of this a large amount of black palladium appeared in the reaction tube and an untreatable reaction mixture was isolated from the solution. Other reaction conditions ($Pd(OAc)_2$, CH_2Cl_2, r.t.; K_2PdCl_4, H_2O, r.t.; Li_2PdCl_4, MeOH, r.t.) failed to produce the expected complexes.

However, treatment of the *N*-oxide of the Schiff base, **4**, with $Pd(OAC)_2$ in toluene at 75 °C for 48 h gave the dimer **5**, metallated at the aromatic C6 carbon atom. The IR spectrum of **5** showed the ν(C=N) stretching band (see Section 3) shifted to lower frequency (compared to the free imine) in agreement with nitrogen coordination to metal center [22]. This was supported by the characteristic upfield shift (0.43 ppm) of the NMR signal for the imine proton, observed in the cyclometallated complexes as a consequence of *N*-coordination [23,26–28]. The IR spectrum showed to strong bands ν_{as}(COO) and ν_s(COO) at 1577 and 1420 cm^{-1}, respectively, in accordance with bridging acetate groups [24,26,28]. The *trans* geometry of the cyclometallated moieties was determined by the presence at 2.44 ppm of a singlet signal in the ^{1}H NMR spectrum, assigned to the two equivalent methyl acetate protons [29]. Complex **5** was also characterized by ^{13}C{1H} NMR spectroscopy, being the most noticeable feature the shift to higher frequency of the C6, C=N, and C1 resonances (as compared to the uncoordinated ligand or the non cyclometallated complex **2**), confirming the formation of the cyclometallated ring [25,30,31]. The FAB-mass spectrum showed at 809 amu the cluster of peaks assigned to $[\{(L\text{-}H)(OAc)Pd\}_2]^+$ (L-H = cyclometallated ligand), thereby confirming the dinuclear nature of the complex [32].



Complex **5** readily experimented metathesis reactions with sodium chloride or lithium bromide in acetone/water or methanol/water, respectively, to give the corresponding complexes with bridging halide ligands **6** and **7**. The mass spectra showed peaks assigned to $[\{(L\text{-}H)XPd\}_2H]^+$ (X = Cl, 763 amu; X = Br, 853 amu), consequent with the dinuclear formulation of the complexes. The IR and ^{1}H NMR spectra were similar to those for complex **5**, being the most noticeable differences the absence of the characteristic acetate bridging ligand signals.

Reaction of the halide-bridged complexes **6** and **7** with triphenylphosphine in chloroform gave the mononuclear complexes **8** and **9**, respectively, which were fully characterized (see Section 3). The IR spectra of these complexes showed the typical low-frequency shift of the ν(C=N) band (*vide supra*). In the ^{1}H NMR spectra the *HC*=N and H5 protons were coupled to the ^{31}P nucleus [δ *ca.* 8.08 ppm (J(PH) = 7.8 Hz) and δ *ca.* 7.0 ppm (J(PH) = 3.9 Hz), respectively], and the ^{31}P{1H} NMR spectra showed singlet resonances at *ca.* 39.5 ppm. In the ^{13}C{1H} spectra the low-field shift observed for the C6, C=N, and C1 resonances was similar to those found in the spectrum of **5** (*vide supra*) and the C5, resonance showed the coupling to the ^{31}P nucleus [J(C5P) *ca.* 11]. The mass spectra of **8** and **9** showed peaks centred at 607 amu corresponding to the loss of the halide ligand and, for complex **8** at 643 amu assigned to the molecular ion.

2.1. Molecular structure of complex **9**

Suitable crystals were grown by slowly evaporating a chloroform solution of **9**. The molecular structure is illustrated in Fig. 1.

The asymmetric unit comprises two solvent molecules of chloroform and a molecule of complex **9**; molecules of **9** are aligned along the *a*-axis and packed in layers parallel to *a* and *c*, between which the chloroform solvent molecules are located. The palladium atom is bonded in a slightly distorted square-planar geometry to the C(1) carbon atom of the pyridine ring, the imine N(1) atom, the Br(1) atom and to the P(1) phosphorus atom of the triphenylphosphine ligand. The angles between adjacent atoms in the coordination sphere of palladium are close to the expected value of 90° with the most noticeable distortions corresponding to the bite angle C(1)–Pd(1)–N(1) of 81.06(9)°. The sum of the angles about palladium is approximately 360°.

Scheme 2. (i) $Pd(OAc)_2$, toluene, 75 °C; (ii) complex **6**: $NaCl_{aq}$, acetone; complex **7**: $LiBr_{aq}$, methanol; (iii) PPh_3, chloroform; (iv) complex **10**: dppe, chloroform; complex **11**: dppe, NH_4PF_6, acetone.

The geometry around palladium is planar [mean deviation from the least square plane Pd(1), C(1), N(1), P(1), Cl(1), (plane 1), of 0.097 Å] and approximately co-planar with the metallated ring [Pd(1), C(1), C(5), C(6), N(1); mean deviation 0.0035 Å (plane 2)] and with the pyridine ring [plane 3, mean deviation of 0.0050 Å] (angles between planes are: plane 1:2, 0.7°; plane 1:3, 0.9°; 2:3, 1.0°). The Pd–N(1), 2.099(2) Å, Pd–C(1), 2.016(2), Pd(1)–P(1), 2.246(1) and Pd(1)–Br(1), 2.459(1), bond distances are within the range found earlier [33–36].

Reaction of complexes **6** and **7** with the diphosphine $Ph_2P(CH_2)_2PPh_2$, (dppe), in a 1:2 molar ratio (followed by treatment with ammonium hexafluorophosphate in the case of **7**) gave the mononuclear complexes, **10** and **11**, respectively, as air-stable solids which were fully characterized (see Section 3). The main difference between them was the counter ion [Cl^- in **10** and PF_6^- in **11**] in spite of which, the NMR spectra showed significant differences indicating that the interaction between the anion and the cation remains in solution. In the ^1H NMR spectrum of **10** the *HC*=N resonance at δ 8.44 ppm was a singlet; however, in the spectrum of **11** it appeared as a doublet at 8.10 ppm, by coupling to the ^{31}P nucleus *trans* to nitrogen (J(HP) = 7.5 Hz); less significant shifts were observed for the signals assigned to the H3 and H9/H11 protons. The $^{31}P\{1H\}$ NMR spectra showed two doublets for the two non-equivalent phosphorus nuclei, but in the spectrum of **10** the

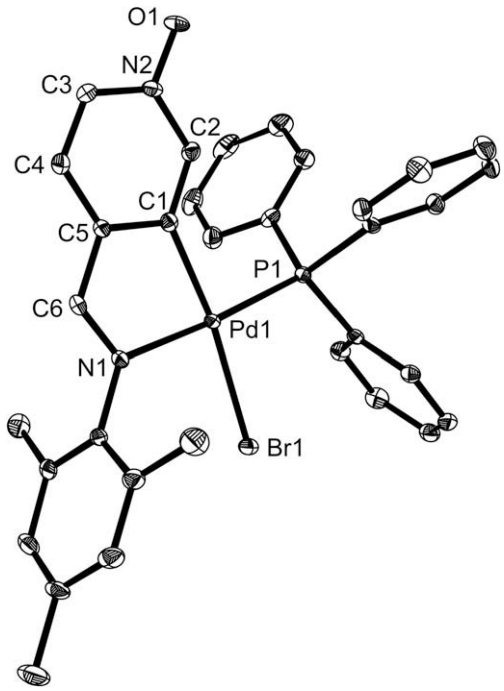


Fig. 1. Molecular structure of Pd{4-(O)$NC_5H_3C(H)$=N[2′,4′,6′-$(CH_3)C_6H_2$]}(Br)(PPh_3)], **9**. Ellipsoids drawn at the 40%. Selected bond distances (Å) and angles (°): Pd(1)–N(1) 2.099(2), Pd(1)–C(1) 2.016(2), Pd(1)–Br(1) 2.459(1), Pd(1)–P(1) 2.246(1), C(1)–C(5) 1.418(3), C(5)–C(6) 1.443(3), N(1)–C(6) 1.284(3), N(2)–O(1) 1.304(3); N(1)–Pd(1)–C(1) 81.06(9), N(1)–Pd(1)–Br(1) 90.85(6), C(1)–Pd(1)–Br(1) 171.87(7), N(1)–Pd(1)–P(1) 175.56(6), C(1)–Pd(1)–P(1) 94.54(7), Br(1)–Pd(1)–P(1) 93.57(2).

signals appeared high-field shifted (δ 55.18, 39.98 ppm; J(PP) = 22.7 Hz, for **10** *vs.* δ 61.12, 46.47 ppm; J(PP) = 24.5 Hz for **11**). The resonance at lower frequency was assigned to the phosphorus nucleus *trans* to the phenyl carbon atom, in accordance with the higher *trans* influence of the latter with respect to the C=N nitrogen atom [37]. The $^{13}C\{1H\}$ spectra showed the HC=N resonance coupled to the *trans*-nitrogen phosphorus nuclei and considerably high-field shifted in the case of **10** [δ 164.66 ppm, J(CP) = 2.0 Hz; 180.11 ppm, J(CP) = 3.1 Hz for **10** and **11**, respectively]. The C5 and C6 resonances also showed coupling to the phosphorus nucleus.

Accordingly, the most significant differing shifts in the ^1H and ^{13}C MNR spectra of complexes **10** and **11** corresponded to the HC=N group. This is indicative that in solution the interaction between the cation and its counteraction takes place through the imine proton. This feature may be used to determine the anions present in the solution and, therefore, complexes **10** and **11** may be used as anion sensors.

In the mass spectra of **10** and **11** the cluster of peaks centred at 743 amu were assigned to the $[\{(L\text{-}H)Pd(dppe)\}]^+$ fragment due to the loss of the counterion. Conductivity measurements were in accordance with a 1:1 electrolyte formulation.

3. Experimental

3.1. General remarks

Solvents were purified by standard methods [38]. Chemicals were reagent grade. Microanalyses were carried out using a Carlo Erba Elemental Analyser, Model 1108. IR spectra were recorded as KBr discs on a Satellite FTIR. NMR spectra were obtained as $CDCl_3$ solutions and referenced to $SiMe_4$ (^1H, $^{13}C\{1H\}$) or 85% H_3PO_4 ($^{31}P\{1H\}$) and were recorded on a Bruker AV-300F spectrometer. All chemical shifts were reported downfield from standards. The FAB mass spectra were recorded using a FISONS Quatro mass spectrometer with a Cs ion gun; 3-nitrobenzyl alcohol was used as the matrix. The ESI mass spectra were recorded using a QSTAR Elite mass spectrometer, using dichloromethane/acetonitrile or dichloromethane/ethanol as solvents.

3.2. Syntheses

3.2.1. Preparation of $NC_5H_4C(H)$=N[2′,4′,6′-$(CH_3)C_6H_2$] (**1**)

4-(COH)NC_5H_4 (0.173 g, 1.61 mmol) and 2,4,6-$Me_3C_6H_2NH_2$ (0.211 g, 1.56 mmol) were added to 50 cm^3 of dry chloroform. The mixture was heated under reflux in a Dean-Stark apparatus for 48 h. After cooling to room temperature, the solvent was evaporated to give a yellow oil. Yield: 93%. *Anal.* Calc. for: $C_{15}H_{16}N_2$: C, 80.2; H, 7.2; N, 12.5. Found. C, 80.0; H, 6.9; N, 12.7%. IR: ν(C=N) = 1605m cm^{-1}. NMR ^1H (300.13 MHz, $CDCl_3$, δ ppm, J Hz): δ = 8.79 [m, 2H, H3/H5]; 8.23 (s, 1H, Hi); 7.78 [m, 2H, H2/H6]; 6.91 (s, 2H, H9/H11); 2.30 (s, 3H, –CH_3); 2.12 (s, 6H, 2CH_3).

3.2.2. Preparation of [Pd{$NC_5H_4C(H)$=N[2′,4′,6′-$(CH_3)C_6H_2$]}$_2$($OCOCH_3$)$_2$] (**2**)

A pressure tube containing Schiff base 1 (0.150 g, 0.666 mmol), palladium(II) acetate (0.150 g, 0.668 mmol) and 20 cm^3 of dry toluene was sealed under argon. The resulting yellow solution was stirred for 24 h at 60 °C. The green solid obtained was filtered off and dried *in vacuo*. Yield: 46%. *Anal.* Calc. for $C_{34}H_{38}N_4O_4Pd$ requires: C, 60.7; H, 5.7; N, 8.3. Found: C, 60.5; H, 5.4; N, 8.6%. IR: ν(C=N) = 1610s; [ν_{as}(COO) = 1558s, ν_s(COO) = 1300s]cm^{-1}. NMR ^1H (300.13 M, $CDCl_3$, δ ppm, J Hz): δ = 8.84 [d, 2H, H3,H5 ^3J(H2H3) = 6.6]; 8.22 (s, 1H, Hi); 7.82 [d, 2H, H2, H6, ^3J(H6H5) = 6.6]; 6.95 (s, 2H, H9/H11); 2.29 (s, 3H, –OAc); 1.89 (s, 3H, –CH_3); 2.10 (s, 6H, 2CH_3). NMR $^{13}C\{1H\}$ (75.47 MHz, $CDCl_3$, δ ppm, J Hz): δ = 178.36 (s, –CO_2CH_3); 158.76 (s, Ci); 122.13 (s, C3/C5); 147.33, 144.83, 134.25, 126.75 (s, C1, C7, C10); 129.01 (s, C2/C6); 128.22 (s, C8/C12); 123.03 (s, C9/C11); 23.23 (s, –CO_2CH_3); 20.76 (s, C13/C15); 18.22 (s, C14).

3.2.3. Preparation of [4-(Me)$NC_5H_4C(H)$=N{2′,4′,6′-$(CH_3)C_6H_2$}][I] (**3**)

A pressure tube containing Schiff base 1 (0.180 g, 0.803 mmol), IMe (0.114 g, 0.803 mmol) and 20 cm^3 of dry toluene was sealed under argon. The resulting yellow solution was stirred for 24 h at 90 °C. The orange solid obtained was filtered off and dried *in vacuo*. Yield: 22%. *Anal.* Calc. $C_{16}H_{19}N_2I$ requires: C, 52.5; H, 5.2; N, 7.6. Found: C, 52.6; H, 5.4; N, 7.6%. IR: ν(C=N) = 1610s cm^{-1}. NMR ^1H (300.13 MHz, $CDCl_3$, δ ppm, J Hz): δ = 8.31 [d, 2H, H3/H5, ^3J(H2H3) = 6.6]; 8.47 (s, 1H, Hi); 8.52 [d, 2H, H2/H6, ^3J(H2H3) = 6.6]; 6.93 (s, 2H, H9/H11); 4.77 (s, 3H, N–CH_3); 2.36 (s, 3H, –CH_3); 2.16 (s, 6H, 2CH_3). Specific molar conductivity Λ_m = 97.5 cm^2 mol^{-1}(in dry acetonitrile).

Compound **4** was obtained as yellow solid, following a similar procedure to that used in the preparation of **1**.

3.2.4. Preparation of 4-(O)$NC_5H_4C(H)$=N[2′,4′,6′-$(CH_3)C_6H_2$] (**4**)

Yield: 93%. *Anal.* Calc. $C_{15}H_{16}N_2O$ requires: C, 75.0.2; H, 6.7; N, 11.7. Found: C, 75.5; H, 6.6; N, 12.0%. IR: ν(C=N) = 1603m cm^{-1}. NMR ^1H (300.13 MHz, $CDCl_3$, δ ppm, J Hz): δ = 8.27 [d, 2H, H3/H5, ^3J(H2H3) = 7.2]; 8.15 (s, 1H, Hi); 7.78 [d, 2H, H2/H6, ^3J(H2H3) = 7.2]; 6.90 (s, 2H, H9/H11); 2.29 (s, 3H, –CH_3); 2.11 (s, 6H, 2CH_3). NMR $^{13}C\{1H\}$ (75.47 MHz, $CDCl_3$, δ ppm, J Hz): δ = 157.76 (s, Ci); 147.57 (s, C7); 139.60 (s, C3/C5); 133.92, 132.91 (s, C1, C10); 128.89 (s, C9/C11); 126.79 (s, C8/C12); 124.70 (s, C2/C6); 20.70 (s, C14); 18.19 (s, C13/C15).

*3.2.5. Preparation of [Pd{4-(O)NC$_5$H$_3$C(H)=N[2′,4′,6′-(CH$_3$)C$_6$H$_2$]}(OCOCH$_3$)]$_2$ (**5**)*

A pressure tube containing Schiff base **4** (0.196 g, 0.816 mmol), palladium(II) acetate (0.186 g, 0.816 mmol) and 20 cm^3 of dry toluene was sealed under argon. The resulting yellow solution was stirred for 48 h at 75 °C, filtered trough celite to remove the black palladium formed and the solvent removed under vacuum. The brown oil obtained was tritured with ether to give a brown solid which was filtered off and dried *in vacuo*. Yield: 93%. *Anal.* Calc. $C_{34}H_{36}N_4O_6Pd_2$ requires: C, 50.4; H, 4.5; N, 6.9. NMR $^{31}P\{^1H\}$ (121.50 MHz, $CDCl_3$, δ ppm, J Hz): 61.12 [d, P_a, $^2J(P_a,P_b)$ = 24.5]; 46.47 [d, P_b, $^2J(P_a,P_b)$ = 24.5] ppm. ESI-mass: $[\{(L\text{-}H)Pd(dppe)\}]^+$ = 743.16 amu. Specific molar conductivity Λ_m = 82.1 $cm^2\ mol^{-1}$ (in dry acetonitrile).

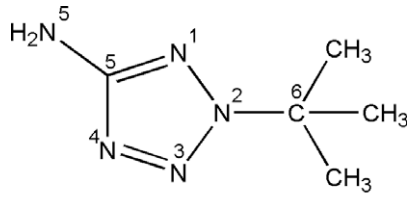
3.3. Single-crystal X-ray diffraction analysis

3.3.1. Crystal data

$C_{33}H_{30}BrN_2OPPd{\cdot}2CHCl_3$; M = 926.61. Orthorhombic, a = 13.192(3), b = 19.889(5), c = 29.047(3) Å, U = 7621(4) $Å^3$, Z = 8, D_c = 1.615 g cm^{-3}, Space Group Pbca, μ(Mo Kα) = 2.029 mm^{-1}, T = 100 K. Three-dimensional, room temperature X-ray data were collected on a Bruker X8 Apex diffractometer using graphite-monochromated Mo Kα radiation. Of the 43653 reflections measured, all of which were corrected for Lorentz and polarisation effects and for absorption using a semi-empirical correction based on symmetry-equivalent and repeated reflections (max, min transmissions 0.83, 0.45), 7263 independent reflections exceeded the significance level $|F|/\sigma(|F|) > 4.0$ The structure was solved by direct methods and refined by full matrix least squares on F^2. Hydrogen atoms were included in calculated positions and refined in riding mode. Refinement converged at a final R = 0.0328 (wR_2 = 0.0722 for all 9490 unique data), with allowance for the thermal anisotropy of all non hydrogen atoms. Minimum and maximum final electron density −0.912 and 1.151 $eÅ^{-3}$. The structure solution and refinement were carried out using the program package SHELX-97 [39].

Supplementary data

CCDC 730623 contains the supplementary crystallographic data for compound **8**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.



Acknowledgments

We thank the Ministerio de Educación y Ciencia (Projects CTQ2006-15621-C02-01/BQU and CTQ2006-15621-C02-02/BQU), the Xunta de Galicia (Projects INCITE07PXI103083ES and INCITE08ENA209044ES), and the Universidad de la Coruña for financial support.

Scheme 1. Classical representation and numbering of 5-amino-2-*tert*-butyltetrazole.

(1.3 g, 77%) as white crystals. Mp 115–116 °C (from water). ^{1}H NMR δ (ppm): 5.90 (s, 2H, NH_2), 1.51 (s, 9H, *t*-Bu); ^{13}C NMR δ (ppm): 167.2 (CN_4), 62.6 (CMe_3), 29.2 (Me). FT-IR (cm^{-1}): 3431 (s), 3324 (s), 3232 (s), 3175 (s), 3080 (m), 2988 (s), 2939 (s), 2912 (m), 2876 (m), 1636 (s), 1565 (s), 1539 (s), 1462 (s), 1403 (m), 1373 (s), 1310 (m), 1219 (s), 1196 (s), 1118 (w), 1081 (w), 1037 (w), 1015 (m), 939 (w), 823 (w), 778 (w), 762 (w), 654 (w br), 578 (w), 429 (vw), 315 (m), 262 (w), 192 (m), 142 (s), 111 (w), 92 (m). *Anal.* Calc. for $C_5H_{11}N_5$: C, 42.5; H, 7.8; N, 49.6. Found: C, 42.7; H, 7.6; N, 49.8%.

2.3. Synthesis of CuL_3Cl_2 (**2**)

Copper(II) chloride dihydrate (1 mmol, 0.17 g) was added to a solution of **1** (2 mmol, 0.282 g) in 20 mL of 1,2-dichloroethane. The resulting mixture was stirred at room temperature for 1 h and filtered. Slow evaporation of obtained solution at ambient conditions gave green crystals of complex **2** with quantitative yield (0.37 g). Calc. for $Cu(C_{15}H_{33}N_{15})Cl_2$: Cu 11.39. Found: Cu 11.20%. FT-IR (cm^{-1}): 3436 (s), 3332 (s), 3188 (s), 3071 (w), 2986 (s), 2938 (s), 2911 (w), 2876 (w), 1624 (vs), 1560 (vs), 1458 (s), 1438 (sh), 1404 (m), 1373 (s), 1331 (s), 1305 (m), 1236 (m), 1190 (vs), 1120 (m), 1083 (vw), 1036 (w), 1015 (s), 937 (w), 828 (m), 785 (m), 752 (m), 699 (w), 655 (w br), 576 (m), 429 (m), 354 (s), 322 (m), 312 (m), 274 (w), 241 (m), 194 (m), 173 (s), 143 (s), 134 (w), 128 (m), 123 (m), 96 (s), 68 (w).

2.4. Synthesis of PtL_2Cl_2 (**3**)

Platinum(II) chloride (1 mmol, 0.266 g) was added to the solution of **1** (2 mmol, 0.282 g) in mixture of toluene–THF (2:1). The resulting mixture was stirred at room temperature for 1 h and filtered. Slow evaporation of obtained solution at ambient conditions gave yellow crystals of **3**. Yield (0.47 g, 86%). Calc. for $Pt(C_{10}H_{22}N_{10})Cl_2$: Pt 35.58. Found: Pt 35.23%. FT-IR (cm^{-1}): 3446 (s), 3350 (s), 3165 (w), 3087 (vw), 2987 (s), 2939 (m), 2874 (w), 1618 (vs), 1550 (s), 1455 (s), 1429 (sh), 1403 (m), 1371 (s), 1331 (s), 1299 (s), 1239 (m), 1189 (vs), 1078 (vw), 1034 (w), 1022 (m), 937 (w), 827 (m), 789 (w), 744 (w), 573 (m), 475 (w), 437 (m), 342 (m), 307 (w), 236 (s), 217 (s), 160 (m), 129 (s), 73 (w).

2.5. Synthesis of PdL_2Cl_2 (**4**)

A solution of **1** (2 mmol, 0.282 g) in 20 ml of ethanol was dropped with stirring to a solution of palladium(II) chloride dihydrate (1 mmol, 0.214 g) in 20 ml of 1% hydrochloric acid. The resulting mixture was stirred at room temperature for 20 min. The resulting yellow solid residue was filtered, washed with water, dried and recrystallized from water/ethanol mixture (1/1) to give yellow crystals of **4**. Yield (0.432 g, 94%). Calc. for $Pd(C_{10}H_{22}N_{10})Cl_2$: Pd 23.15. Found: Pd 22.78%. FT-IR (cm^{-1}): 3440 (s), 3414 (s), 3390 (s), 3347 (s), 3158 (w), 3062 (vw), 2987 (s), 2939 (m), 2874 (w), 1612 (vs), 1551 (s), 1453 (s), 1430 (sh), 1403 (m), 1371 (s), 1327 (s), 1299 (s), 1237 (m), 1192 (vs), 1147 (w), 1078 (vw), 1027 (m), 1022 (m), 937 (w), 827 (m), 786 (w), 745 (w), 572 (m), 439 (w), 353 (m), 332 (w), 319 (w), 307 (w), 253 (w), 226 (s), 160 (m), 132 (s).

2.6. X-ray structure determinations

Suitable single crystals for X-ray analysis were picked directly from the reaction products. In the case of palladium complex **4**, single crystals of two polymorphs, marked as **4a** and **4b**, were found. They are triclinic and monoclinic, respectively. Crystal data, data collection and refinement details for the structures reported are summarized in Table 1. X-Ray data were collected on a Nicolet *R*3*m* diffractometer using graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature. The structures were solved by direct methods (SIR2004 [18]) and refined by full matrix least square technique (SHELXL 97 [19]). In **1**, **2** and **4b**, rotational disorder of the *tert*-butyl groups over two positions was observed. For the disordered groups, bond lengths C–C(*tert*-butyl) and distances C(methyl)···N (where N is the tetrazole ring atom bonded to the *tert*-butyl group) were restrained to be equal, respectively. The amino group H atoms were localized from difference Fourier maps. For **1**, coordinates of amino H atoms were refined freely, whereas for all complexes, bond lengths N–H were restrained to 0.88 Å. U_{iso}(H) values were set to 1.2U_{eq}(N) for all compounds. Molecular graphics was performed with the program PLATON [20].

2.7. Cytotoxicity

In vitro cytotoxicity tests were performed at N.N. Alexandrov National Cancer Centre of Belarus, Minsk, Belarus.

2.7.1. Cell culture

HeLa cells (human cervical carcinoma) were obtained from the cell culture collection of Research Institute for Epidemiology and Microbiology (RIEM, Minsk, Belarus). The cells were cultured as a monolayer in culture flasks covered with 199 medium (RIEM) supplemented with 10% fetal calf serum (RIEM) and 100 μg/mL kanamycin.

2.7.2. Cytotoxicity assay

All the experiments were carried out on exponentially growing cells. Cell monolayer was detached from the culture flasks with 0.02% versen (DIALEK, Belarus), plated at a concentration of 2×10^5 cells/flask and incubated for 24 h at 37 °C. Stock 10^{-2} M solutions of test compounds were freshly prepared in dimethylsulfoxide (DMSO), then dilutions from 10^{-4} to 10^{-6} M in distilled water were made. On the day of the experiment, 50, 100 or 200 μL of drug dilutions were added into the flasks with cell monolayer at final concentrations of 0–50 μM. The cells were incubated in water bath at 37.0 °C for 48 h. Then treated and control cell monolayers were versenized and viable cells were counted using trypan-blue exclusion on a haemocytometer [21]. The mean ± standard deviation was calculated from three experiments. IC_{50} values (drug concentration at which 50% of the cells are viable relative to the control) were determined for each experiment using regression analysis of the data received.

3. Results and discussion

3.1. Preparation of complexes

Tetrazole **1** was found to react smoothly with transition metal(II) chlorides in solutions without heating giving highly crystalline colored complexes CuL_3Cl_2 (**2**), PtL_2Cl_2 (**3**) and PdL_2Cl_2 (**4**) in

yields >80%. It should be noted that observed composition of copper chloride complex is rather unexpected since till now only complexes with lower content of ligand (CuL_2Cl_2, $CuLCl_2$ or $Cu_3L_4Cl_6$, where L = *N*-alkyltetrazoles) have been synthesized [8].

3.2. Thermal analysis

According to the data of complex thermal analysis (Figs. 1–4), metal complexes show the higher thermal stability in comparison with free ligand. Free ligand undergoes decomposition immediately after melting (117 °C), whereas its complexes decompose at temperature higher ~140 °C. Decomposition of copper, palladium and platinum complexes is characterized with first endothermal peak at 154 °C, 223 °C and 254 °C, correspondingly.

It should be noted that decomposition of tetrazole **1** proceeds endothermally. This behavior is characteristic for N-substituted 5-aminotetrazoles. In spite of high positive enthalpies of formation, they decompose endothermally under flow of nitrogen. Such behavior is explained by the evolution of highly energetic and

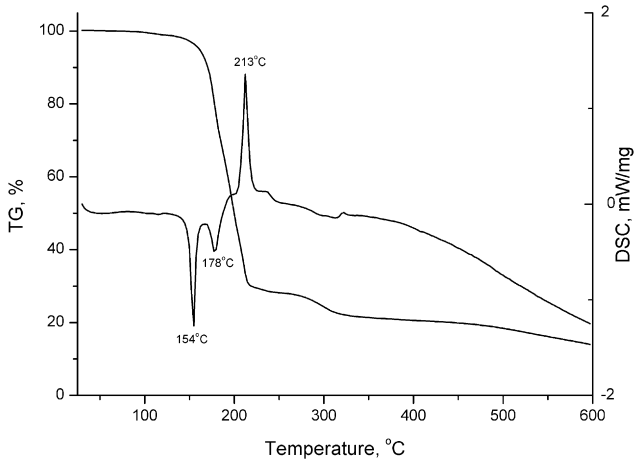

Fig. 2. Curves of thermal analysis of **2**.

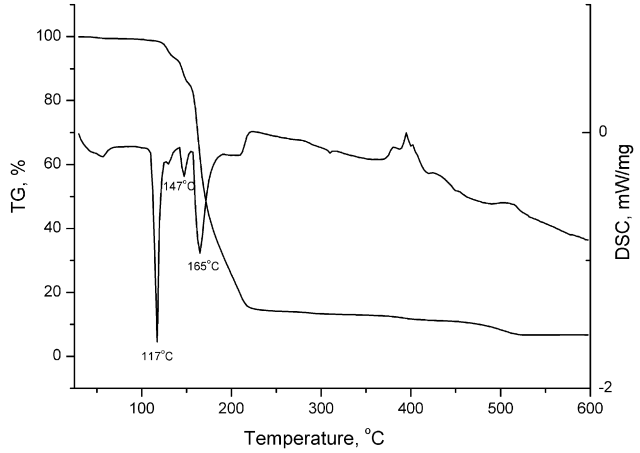

Fig. 1. Curves of thermal analysis of **1**.

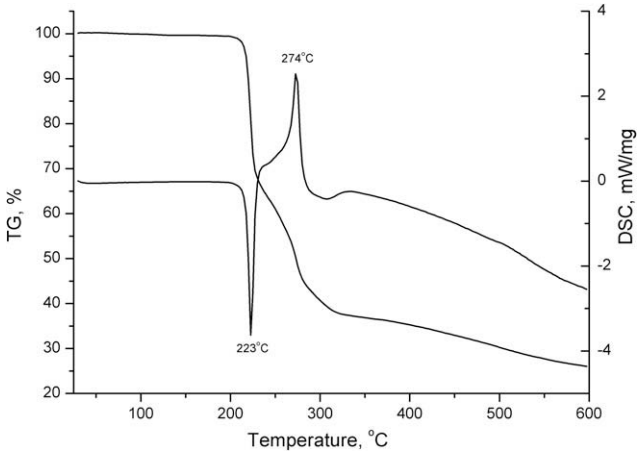

Fig. 3. Curves of thermal analysis of **4**.

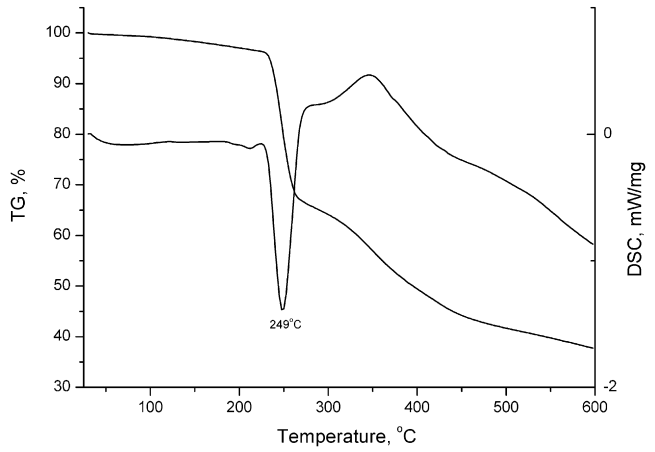

Fig. 4. Curves of thermal analysis of **3**.

readily volatile products which are removed from the reaction zone in the nitrogen steam [2]. Based on data on thermolysis of 2,5-disubstituted tetrazoles we can predict formation of *tert*-butyl azide and cyanamide when tetrazole **1** decomposes [22].

3.3. IR spectra

Free ligand **1** and complexes **2–4** were characterized by vibrational spectroscopy. The assignments were performed based on literature data on IR spectroscopy of related compounds, in particular 1- and 2-methyl-5-aminotetrazoles [12,23], N-alkyltetrazoles and their metal complexes [24]. Coordination with metal ion leads to the significant changes in frequencies of the ν(C=N) (1440–1460 cm^{-1}) and ν(N=N) (1300–1330 cm^{-1}) bands of the tetrazole ring as well as in the region of the stretching ν(N–H) (3450–3330 cm^{-1}) and deformation δ(N–H) (1640–1540 cm^{-1}) bands. The spectrum of the platinum complex has shown the presence of two bands in the stretching ν(N–H) region (3446 and 3350 cm^{-1}), while a number of bands (3347, 3391, 3414, 3342 cm^{-1}) have been observed in the spectrum of the palladium complex, which could be explained by overlapping of the corresponding bands of the two polymorphic modifications of palladium complex **4a** and **4b**, which were revealed during X-ray study.

In general, the spectra of both platinum and palladium complexes in the region 1700–500 cm^{-1} are almost identical. In the spectra of both complexes the bands of combined stretching ν(C–NH_2) and deformation δ(N–H) vibrations were observed at lower frequencies (1550 and 1618 cm^{-1} for **3**; 1551 and 1612 cm^{-1} for **4**) as compared with non-coordinated ligand (1565 and 1635 cm^{-1}), which is in agreement with changes in the spectrum of silver complexes of 5-amino-2-methyltetrazole [12]. No significant change is observed in the $\delta(C–H)_{oop}$ bands (1371–1373 cm^{-1}). The stretching ν(C=N) band of tetrazole ring decreases in frequency by about 10 cm^{-1} from 1462 cm^{-1} in the spectrum of **1** to 1458, 1455, and 1453 cm^{-1} in the spectra of **2**, **3**, and **4**, respectively. The stretching ν(N=N) band (1310 cm^{-1} for **1**) splits in two after the complexation, those are observed at 1299–1305 and 1327–1331 cm^{-1} [24]. The mid-IR spectrum of **2** not significantly differs from both described above. The most noticeable features concern the region of stretching and stretching-deformation vibrations of the tetrazole ring where several bands (1120 and 655 cm^{-1}) almost identical with the spectrum of the ligand are observed.

The far-IR spectra of complexes show ligand vibrations as well as new bands originating from metal–Cl and metal–N stretchings. In particular, the platinum complex gave only one stretching ν(Pt–Cl) band at 342 cm^{-1} which is consistent with a *trans* Cl–Pt–Cl configuration, whereas the palladium complex gave two well separated bands at 332 and at 353 cm^{-1} associated probably with Pd–Cl stretching in the two polymorphic modifications **4a** and **4b**. In the spectrum of copper complex stretching ν(Cu–Cl) band is observed at 354 cm^{-1}. The bands at 241 cm^{-1} for copper, at 253 cm^{-1} for palladium and at 236 cm^{-1} for platinum complexes, respectively, might be described as ν(M–N) stretching bands, although in case of the platinum complex it seems to be rather combinational band with the tetrazole ring vibrations, similarly to assignments in other Pt-heterocyclic amines spectra [25].

3.4. Description of crystal structures

Selected bond lengths for the investigated compounds are given in Table 2. Some structural features are shown in Figs. 5–10.

Compounds **2–4** are molecular complexes in which the ligand molecules are monodentate and coordinate to the metal ion *via* endocyclic N4 atom. In only one structurally characterized complex of 2-substituted 5-aminotetrazoles, namely $AgL(ClO_4)$, where L = 5-amino-2-methyltetrazole, ligand coordinates by N1 and N4 atoms [12].

In the crystal structure of **1**, the tetrazole ring is planar to within 0.0028(17) Å. As seen from Table 2, N2–N3 bond is the shortest in the ring, while the remaining bond lengths are rather similar. This is indicative of essentially aromatic character of this ring. The *tert*-butyl group is disordered over two positions, A and B, with occupancies of 0.564(9) and 0.436(9), respectively (Fig. 5). The amino group is close to planar, with the sum of the angles at amino N atom *ca.* 352°, and lies almost in the tetrazole ring plane. The flattened geometry of the amino group is probably caused by conjugation of the N atom lone pair with the tetrazole ring π-system. Both H atoms of the amino group form hydrogen bonds (HB) with the

[a] For atom-numbering see Scheme 1. M – metal atom.

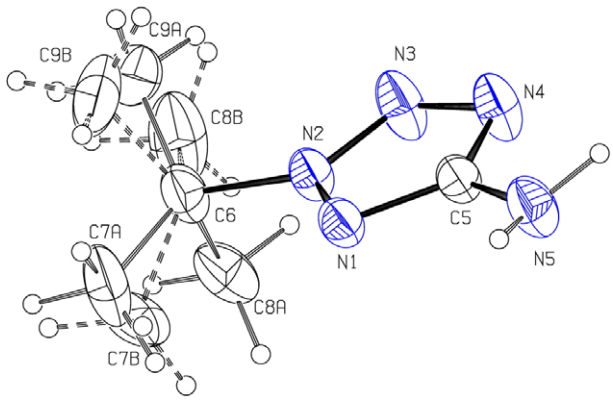

Fig. 5. The molecule of **1** with the atom-numbering scheme (A and B label disorder positions of the *tert*-butyl group). Displacement ellipsoids are drawn at the 30% probability level.

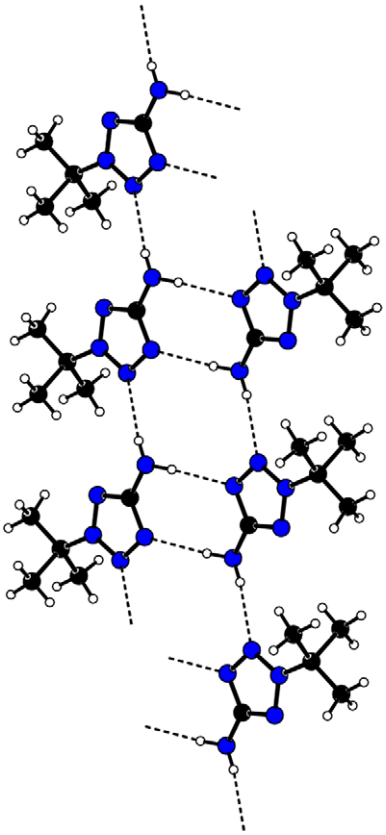

Fig. 6. Hydrogen bonded polymeric chain in the structure of **1**. Dashed lines show hydrogen bonding. Disorder of the *tert*-butyl groups is not shown.

tetrazole ring N atoms, namely N5–H5A···N4^{a} and N5–H5B···N3^{b} (symmetry transformations: *a*: $-x, -y, -z$; *b*: $x-1, y, z$). HB geometry characteristics, distance D···A and angle D–H···A, take of the values 3.090(3) Å, 176(3)° and 3.278(4) Å, 166(3)°, respectively. These HB are responsible for formation of polymeric chains running along the *a* axis, with van der Waals interactions between the chains (Fig. 6).

Asymmetric unit of **2** contains one Cu, two Cl atoms and three ligand molecules. Compound **2** presents molecular complex shown in Fig. 7. Coordination polyhedron of Cu atom is distorted square pyramid with τ descriptor value of 0.28 ($\tau = 0$ for square pyramid and $\tau = 1$ for trigonal bipyramid) [26]. The basal positions are occu-

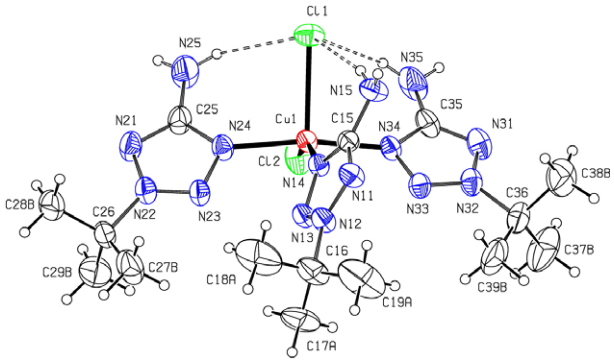

Fig. 7. The complex molecule of **2** with the atom-numbering scheme. Displacement ellipsoids are drawn at the 30% probability level. Disorder of the *tert*-butyl groups is not shown. Dashed lines show intramolecular hydrogen bonds of the amino groups.

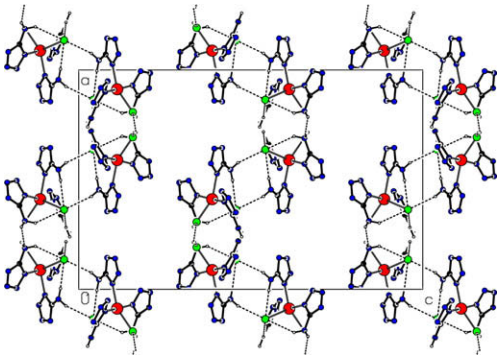

Fig. 8. The crystal packing of **2** viewed along the *b* axis. Dashed lines show hydrogen bonds. *tert*-Butyl groups are omitted for clarity.

pied by one chlorine atom and three N4 atoms of the ligand molecules. Another Cl atom lies in an apical position of the pyramid. In each ligand molecule, the *tert*-butyl group is disordered over two positions with rather different occupancies. Geometries of the tetrazole rings in three ligand molecules are similar being close to that in **1** (Table 2). There are three intramolecular hydrogen bonds N–H···Cl shown in Fig. 7, with distances N···Cl ranged from 3.295(4) to 3.505(6) Å and angles N–H···Cl being in the range of 147(5)–166(4)°, providing additional stabilization of the complex molecule. Three hydrogen atoms, which do not participate in intramolecular hydrogen bonds, form three intermolecular hydrogen bonds N–H···Cl, with distances N···Cl and angles N–H···Cl lying in the ranges 3.234(4)–3.684(5) Å and 146(5)–163(4)°, respectively. These HB link complex molecules into polymeric layers parallel with the *ab* plane (Fig. 8).

Complexes **3** and **4a** are isostructural. They reveal rather distorted square-planar coordination of Pt and Pd atoms, formed by atoms N4 of two ligand molecules and two chlorine atoms. Similar to **2**, these compounds are molecular complexes. As seen from Fig. 9 **3** and **4a** are *trans*-isomers. In both compounds, hydrogen bonds of the amino groups, N–H···Cl and N–H···N, are responsible for formation of polymeric chains along the *c* axis (Fig. 10).

Molecular arrangement in polymorph **4b** is very close to that in **4a**, however some structural differences take place. Pd atom lies on an inversion center and adopts more symmetrical square-planar coordination (*trans*-isomer). In contrast to **4a**, the *tert*-butyl groups are disordered over two positions. In polymorph **4b,** hydrogen bonded polymeric chains (along the *c* axis) are formed due to bonds N–H···Cl and N–H···N of the unique amino group. In **4a**, however, one of two amino group is hydrogen bonded to two Cl

3	5.6
4	>100
Cisplatin	0.7
Carboplatin	12.5

atoms but another amino group forms only one hydrogen bond N–H···N (Fig. 10).

Comparison of the tetrazole ring geometry of **1** with that in complexes **2**–**4** revealed their similarity. All corresponding bond lengths are the same within 3σ (Table 2). However, they contradict to classical representation of the tetrazole ring (Scheme 1). So, formal single bond N2–N3 is shorter than formal double bonds N3=N4 and N1=C5. These features are observed for some examples of 2-mono- and 2,5-disubstituted tetrazoles [27]. Hence, this question may be a topic of detailed theoretical considerations.

In all compounds **1**–**4,** the amino group atoms lie practically in the tetrazole ring plane, allowing the amino group to be considered as conjugated with the ring π-system similar to other 5-aminotetrazoles [27a,28].

3.5. Cytotoxic activity

The cytotoxic activity of the copper, platinum, and palladium complexes was investigated on human cervical carcinoma cell line (HeLa). Cisplatin and carboplatin were included in the assay as a positive control. The determined IC_{50} values, the concentration of complex needed to inhibit 50% of cell growth, are summarized in Table 3. The palladium complex **4** turned out to be inactive, the copper complex **2** showing only moderate activity. The platinum complex **3** demonstrates promising activity, with IC_{50} value average between those of cisplatin and carboplatin. So its activity is close to those of other *trans*-platinum complexes with N-containing heterocycles [29].

Trans-platinum compounds are of great interest because of their ability to overcome cisplatin resistance. The cytotoxic effect of platinum antitumor drugs is based upon the formation of platinum-DNA adducts and modification of DNA structure. Relatively high activity of *trans*-platinum complexes with planar N-heterocycles is considered to be due to different reactivity of these complexes with DNA and such cellular components as glutathione and ability to form structurally different DNA adducts in different proportions in comparison with *cis*-platinum compounds [30]. Recent studies revealed that cytotoxic properties of platinum complexes strongly depend not only on their geometry, but also on structure of heterocyclic ligands [29b,29c]. Further investigations are required for clarifying influence of the tetrazole containing ligand on mechanistic aspects of compound **3** interactions with DNA and capacity of tetrazole based complexes to overcome tumor resistance to common platinum therapeutics.

4. Conclusion

5-Amino-2-*tert*-butyltetrazole reacts with metal(II) chlorides giving molecular complexes, CuL_3Cl_2, PdL_2Cl_2 and PtL_2Cl_2 in which the ligand molecules are monodentate and coordinate to the metal *via* endocyclic N4 atom. Platinum complex demonstrates promising cytotoxicity against human cervical carcinoma cells, with IC_{50} value being average between those of cisplatin and carboplatin.

4. Supplementary data

CCDC 737579, 737580, 737581, 737582 and 737583 contains the supplementary crystallographic data for **1**, **2**, **3**, **4a** and **4b**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

been recently reported [30]. All solutions (315 μM) were prepared in millipore water from a Milli-Q Water system (Millipore Corp., Bedford, MA USA).

2.2. Methods

The fabrication of the nanostructures was performed according to the method of Wang et al. [23] as follows: 3 ml of the freshly prepared negatively charged MTSPc solutions (315 μM) were each mixed with 3 ml of a freshly prepared solution of QInPyPc (315 μM) and kept in the dark for 5 days to aggregate. Afterwards the aggregates were adsorbed on glass surface by putting a few drops of the solution enough to cover the surface and dried in an oven at 70 °C for 30 min. The aggregates in solution or on glass substrate were investigated using UV–Vis spectrophotometer, transmission electron microscopy (TEM) and FT-Raman spectrometer and Ramanscope microscope. The UV–Vis spectra of freshly prepared solutions of the precursors were obtained in water and in DMSO.

2.3. Equipment

UV–Vis spectra were performed using Shimadzu UV-2550 spectrophotometer. Transmission electron microscopy (TEM) images were recorded with a JEOL 1210 (80 KV) and the surface onto which samples were deposited before imaging was carbon coated grids. Raman spectra and images were obtained using Bruker Ram II FT-Raman spectrometer and Ramanscope microscope,

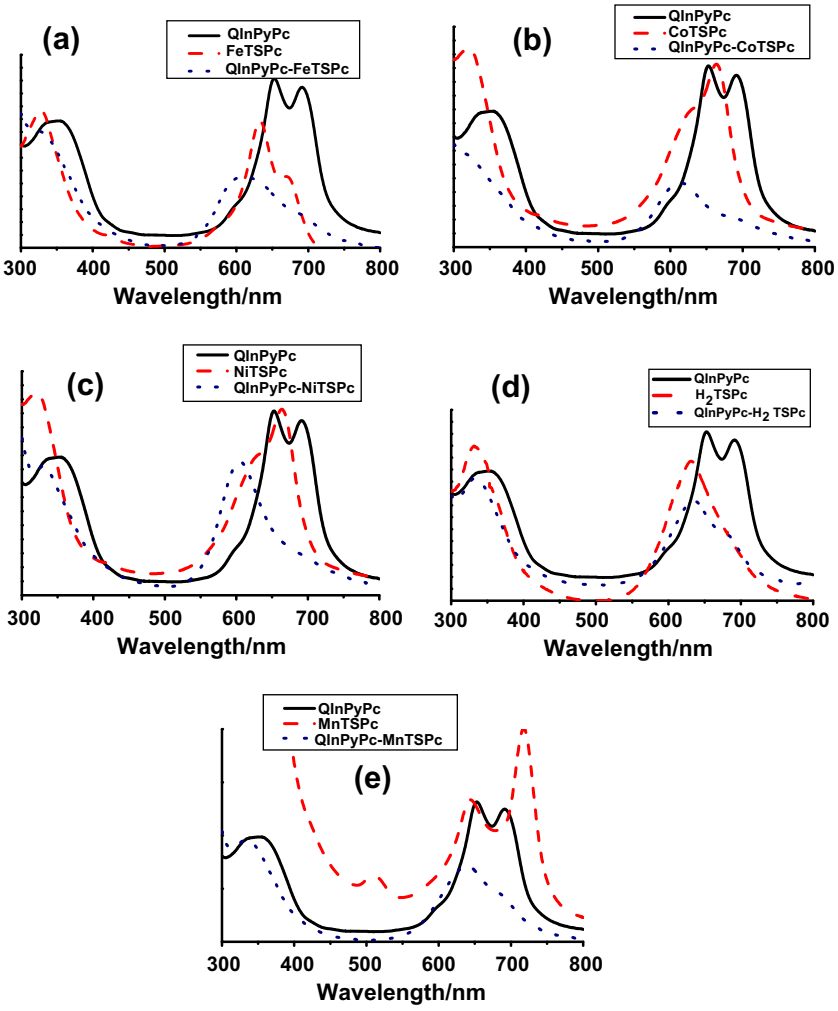

Fig. 4. UV–Vis spectra of precursors and heteroaggregates of the various mixtures (a) FeTSPc–QInPyPc, (b) CoTSPc–QInPyPc, (c) NiTSPc–QInPyPc, (d) H_2TSPc–QInPyPc and (e) MnTSPc–QInPyPc. Concentration of precursors $\sim 2 \times 10^{-5}$ M.

respectively. The excitation source was Nd:YAG of wavelength 1064 nm. Raman spectra were obtained for samples in solution and on glass substrate. The Raman instrument is coupled with a microscope (with a lens of magnification 40×) which was used to study the aggregates on the glass substrate.

3. Results and discussion

3.1. Spectroscopic characterization

Pcs (especially water soluble derivatives) readily form aggregates in solution. Aggregation is usually depicted as a coplanar association of rings progressing from monomer to dimers and higher order aggregates. It is dependent on concentration, nature of the solvent, nature of the substituents, complexed metal ions and temperature. Aggregation generally results in broadening (or splitting) of spectra, with spectra of the aggregate being blue or red shifted, relative to the main absorption peak (the Q band) in MPc complexes. The common aggregation in Pc complexes is characterized by a blue shift in the Q band due to the formation of H aggregates. According to exciton coupling theory [31], the H aggregates are formed when the angle (θ) between the line of the molecular center and the polarization axis is $\geqslant 57.4°$. Its counterpart, the J-aggregate has $\theta \leqslant 57.4°$ resulting in red shifting.

In Fig. 2, the Q bands, observed at the longer wavelengths (~670 nm) are due to the monomeric species and shorter wavelength absorptions (~630 nm) are due to the aggregates (H aggregates) [32]. Thus in water, FeTSPc (Fig. 2a) and NiTSPc (Fig. 2b) are mainly in the aggregated form, while for CoTSPc (Fig. 2c), the monomer peak is more dominant. In DMSO, FeTSPc, NiTSPc and CoTSPc are not aggregated, Fig 2a–c. The H_2TSPc species (Fig. 2d) in DMSO shows splitting of the Q band with maxima at 666 nm and 692 nm. In water H_2TSPc is highly aggregated and does not show the normal splitting of the Q band that is typical of free base phthalocyanines, the lack of split in the Q band in aggregated H_2Pc derivates has been reported before [33]. It has also been documented that in strongly basic solvents, the inner pyrrole hydrogens are acidic enough to dissociate resulting in increased symmetry and an unsplit Q band [34]. However, this is not observed in DMSO (Fig. 2d).

The UV–Vis spectrum of MnTSPc in DMSO has four peaks between 490 nm and 720 nm as seen in Fig. 2e. The peaks have been attributed to the existence of three species [34], Mn^{III}Pc at 721 nm accompanied by a charge transfer band at 500 nm, Mn^{II}Pc at 686 and μ-oxoMnPc at 645 nm. In water the Mn^{II}Pc peak is not observed and three main peaks are observed at 716 nm, 639 nm and 510 nm.

It has been suggested that an equilibrium exists between MnPc species in the presence of oxygen as shown by Eqs. (1)–(5) [35,36].

$$PcMn^{II} + O_2 \rightleftarrows PcMn^{III}(O_2) \quad (1)$$

$$PcMn^{III}(O_2) + PcMn^{II} \rightleftarrows PcMn^{III} - O_2 - Mn^{III}Pc \quad (2)$$

$$PcMn^{III} - O_2 - Mn^{III}Pc \rightleftarrows 2PcMn^{IV}O \quad (3)$$

$$2PcMn^{IV}O + 2PcMn^{II} \rightleftarrows 2PcMn^{III} - O - Mn^{III}Pc \quad (4)$$

$$4PcMn^{II} + O_2 \rightarrow 2PcMn^{III} - O - Mn^{III}Pc \text{ (Net equation)} \quad (5)$$

Eq. (6) is the reversible hydrolysis of μ-oxo-dimer into the oxides species in aqueous media:

$$PcMn^{III} - O - Mn^{III}Pc \overset{H_2O}{\rightleftarrows} 2PcMn^{III} + 2OH^- \quad (6)$$

hence in aqueous media, the $PcMn^{II}$ is not observed.

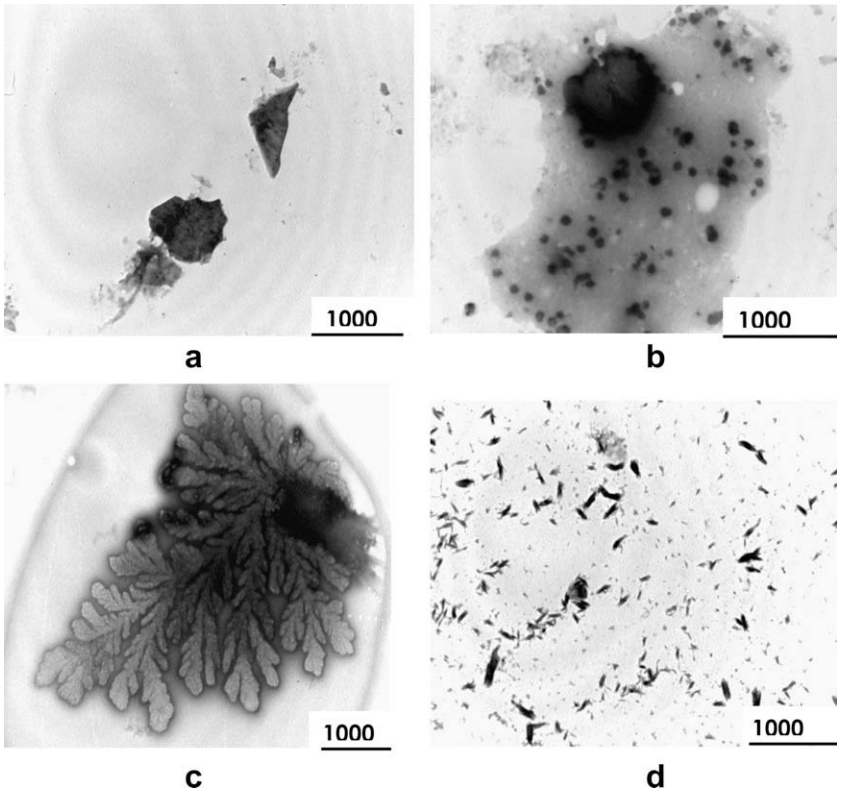

Fig. 5. TEM images of heteroaggregates: (a) H_2TSPc–QInPyPc, (b) MnTSPc–QInPyPc, (c) CoTSPc–QInPyPc and (d) NiTSPc–QInPyPc.

The spectra of QInPyPc showed aggregation in water with two peaks observed at 652 nm (aggregates) and 690 nm (monomer). In DMSO, the aggregate band is completely absent and the band of the monomeric species occurs at 700 nm. The band near 600 nm is vibronic in nature. The broad B-band (350–370 nm) is due to the superimposition of the B_1 and B_2 band [30] (Fig. 2f).

The aggregates in Fig. 2 may be referred to as homoaggregates since they arise from the same Pc molecules. The mixture of oppositely charged Pcs results in aggregated species of a different type, referred to here as heteroaggregates since they are a result of mixing of different Pc molecules. According to Wang et al. [23], the mixtures of oppositely charged porphyrin/phthalocyanine precursors were left to form well-defined heteroaggregates over a period of 3 days but for this work an additional 2 days were required. In this work, a 1:1 mixture of negatively charged MTSPc with positively charged QInPyPc was employed. The ratio of 1:1 of the precursor was chosen based on the data obtained from the UV–Vis spectra (Fig. 3). In Fig. 3 various ratios (1:1–1:5) of QInPyPc:NiTSPc show a shift in the position of the Q band to shorter wavelength as the amount of NiTSPc is decreased and the ratio approaches 1:1. The most blue shifted was the ratio of 1:1 occurring at 605 nm, while ratios 1:2, 1:3, 1:4, 1:5 are at 612 nm, 617 nm, 618 nm and 620 nm, respectively. When the amount of QInPyPc exceeded that of NiTSPC (e.g., QInPyPc:NiTSPc 2:1) no further shifting in spectra (from 605 nm) was observed.

Fig. 4 compares the spectra of the freshly prepared precursors (MTSPc and QInPyPc) in water (which will be aggregated as shown in Fig. 2 forming homoaggregates) with those of the 5-days old aggregate formed by mixing the positively and negatively charged species (heteroaggregates), represented as H_2TSPc–QInPyPc, CoTSPc–QInPyPc, MnTSPc–QInPyPc, NiTSPc–QInPyPc, and FeTSPc–QInPyPc. For FeTSPc (Fig. 4a), CoTSPc (Fig. 4b) and NiTSPc (Fig. 4c), a further blue shift of the Q band is observed for MTSPc–QInPyPc compared to MTSPc or QInPyPc alone. Heteroggregates show extensive broadening in each case. For H_2TSPc (Fig. 4d), the spectrum of the mixture is not shifted, suggesting that the interaction between H_2TSPc and QInPyPc (Fig. 4d) does not result in a heteroaggregation or the heteroaggregates formed do not result in shifted

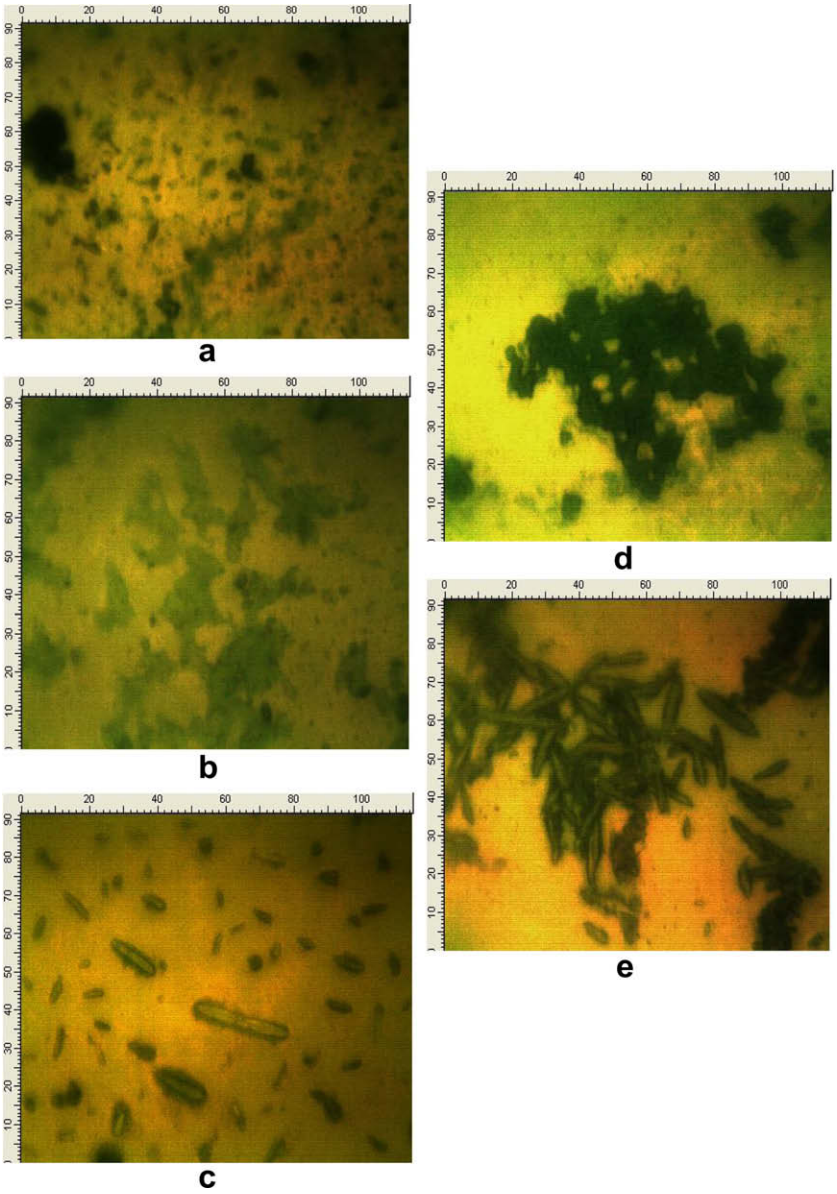

Fig. 6. Ramanscope images of heteroaggregates on glass substrate (a) H_2TSPc–QInPyPc, (b) MnTSPc–QInPyPc, (c) FeTSPc–QInPyPc, (d) CoTSPc–QInPyPc and (e) NiTSPc–QInPyPc.

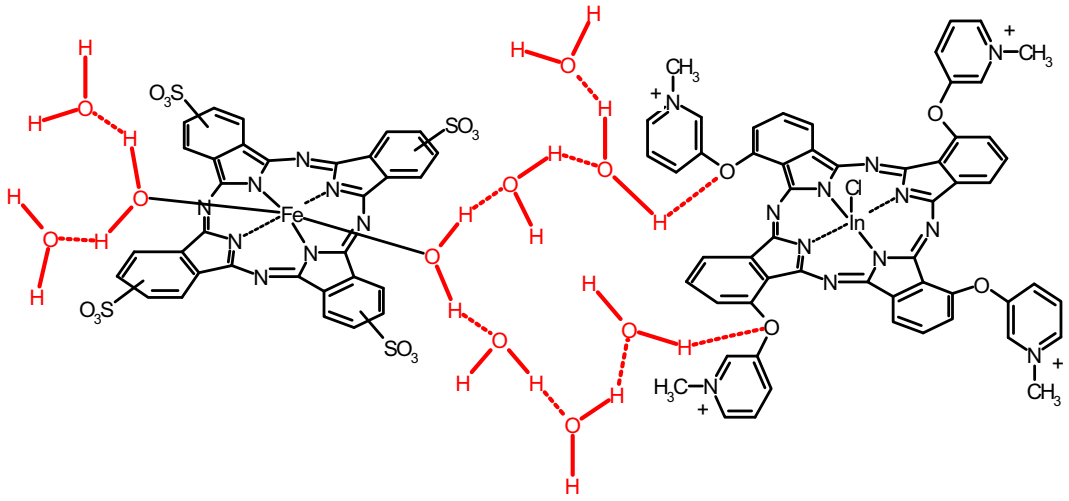

Fig. 7. A representation of the electrostatic and H-bonding interaction responsible for aggregation.

spectra. The mixture between the QInPyPc and MnTSPc (Fig. 4e), gives a peak that has a blue shift of 8 nm from the μ-oxoMnPc at 645 nm and 13 nm from the homoaggregate band peak of QInPyPc, suggesting the formation of the heteroaggregates.

3.2. Imaging studies

Robust nanostructures are structures with well-defined shapes. From the TEM studies, Fig. 5, it was observed that quaternized tetra-(3-pyridyloxyphthalocyaninato)indium phthalocyanines formed robust structures with all the metallated tetrasulfonated Pcs (Fig. 5b–d) and not with the free base tetrasulfonated phthalocyanines (Fig. 5a). The aggregates of MnTSPc–QInPyPc (Fig. 5b) and CoTSPc–QInPyPc (Fig. 5c) appear as leaf-like nanostructures. For MnTSPc, the structure shows a dark ring base and then the aggregates spread out like a leaf. CoTSPc–QInPyPc (Fig. 5c) nanoleaves have veins like a real leaf; those of MnTSPc–QInPyPc (Fig. 5b) have spherical dark specks. FeTSPc–QInPyPc and NiTSPc–QInPyPc (Fig. 5d) formed rod-like nanostructures. H_2TSPc–QInPyPc (Fig. 5a) aggregation did not result in any well-defined structures. The Ramanscope images (Fig. 6) on glass substrate shows the rod-like structures of FeTSPc–QInPyPc (Fig. 6c) and NiTSPc–QInPyPc (Fig. 6e). MnTSPc–QInPyPc (Fig. 6b) and CoTSPc–QInPyPc (Fig. 6d) did not retain the structures seen in the TEM (Fig. 5). H_2TSPc gave less defined structures in the Ramanscope, suggesting the presence of weak heteroaggregates.

It is apparent that to form a robust structure the presence of a metal in the central cavity is required. Previous studies have [28] shown that MTSPc in aqueous solution under aerobic conditions are all spin paired, hence they are less likely to be involved in metal–metal bonding in the aggregates. The central metals in MTSPc complexes are more likely to co-ordinate water and to form H-bond. Fig. 7 is a representation of the proposed arrangement of molecules and interaction with water molecules. The contribution of axial ligation in stacking arrangement in phthalocyanines has been reported in [37].

3.3. FT-Raman spectral studies

Fig. 8 is an example of the Raman spectra obtained for the precursor (QInPyPc and FeTSPc), and the aggregate on glass substrate and in solution. Generally prominent peaks are observed in region between 2700–3300 cm^{-1} and around 1000 cm^{-1} (Tables 1 and 2). Most diagnostic work done on phthalocyanines using this technique has focused on the region 200–2000 cm^{-1} as it highlights the internal vibration of the macrocycle [38–42]. The peaks around 3000 cm^{-1} are assigned to the stretching mode of water (used as a solvent before evaporation and used as a solvent for solution Raman spectra) C–O bonds [41]. These peaks are more intense (×10) than those with wavenumbers less than 2000 cm^{-1}.

Another significant peak is the metal sensitive band which has been calculated to be 1517 cm^{-1} for ZnPc [40]. The shift of this peak has been attributed to the displacement of the C–N–C bridge bond of the internal cavity of the Pc ring depending on the size of the central metal [40]. While this peak is present in the spectra of the precursors (ranging from 1448.9 to 1630.0 cm^{-1} when Pcs are adsorbed on a glass substrate), they appear very weak in solution occurring between 1395 and 1673 cm^{-1} and absent in the spectra of the aggregates deposited on the glass substrate. The Raman spectra also show the peak at 605.3 cm^{-1} for QInPyPc is shifted to higher wave numbers in MnTSPc–QInPyPc (615.1 cm^{-1}) but shift to lower energy in CoTSPc–QInPyPc, NiTSPc–QInPyPc, FeTSPc–QInPyPc (602.9 cm^{-1}) and remained the same for H_2TSPc–QInPyPc (605.3 cm^{-1}). This band according to Bovill et al. [38] might be due to the twisting motion of the pyrrole ring which, being strong in parent molecules become very in weak the spectra of aggregates in solution and is absent in spectra of aggregates on glass substrate

[a] w = weak, s = strong, vs = very strong, vw = very weak.

4. Conclusion

Self-assembly of water soluble phthalocyanine was based on electrostatic interaction between the oppositely charged molecules. The presence of central metal has a major role in the formation of robust nanostructures as it seems to be a contributing force towards the heteroaggregation. Based on the results obtained it is inferred that the arrangement of these molecules in the hetetoaggregates is face-to-face consisting of alternating charged molecules. The formation of rod (for NiTSPc–QInPyPc and FeTSPc–QInPyPc) and leaf-like (for CoTSPc–QInPyPc and MnTSPc–QInPyPc) shapes were revealed by TEM, depending on the nature of the central metal. Further work would be done to investigate the effect on the magnetic properties of the central metal on the shape of the aggregate.

recent years [12]. Analogous approaches were employed to decompose complex heterometallic compounds with the composition $[Li(H_2O)M(N_2H_3CO_2)_3]\cdot 0.5H_2O$ (M = Co or Ni), which were considered as the only precursors for the preparation of layered $LiMO_2$ materials [13]. In this case, a very low yield of the starting molecular precursors presents a serious problem. Apparently, this precludes the extensive use of these precursors in thermal synthesis.

The aim of the present study was to search for new molecular systems capable of generating lithium cobaltate through mild thermolysis. The requirement for the organic components involved in the heterometallic complexes is that they can be easily eliminated with the retention of the ratio of metals in the final product.

2. Experimental

2.1. Synthesis

The new coordination polymer **1** was synthesised with the use of freshly distilled THF and MeCN. The starting cobalt pivalate $[Co(Piv)_2]_n$ was prepared according to a known procedure [14]. In the synthesis of complex **1**, commercial 2-amino-5-methylpyridine (Fluka) was used.

2.1.1. $[Li_2Co_2(Piv)_6(2\text{-amino-5-methylpyridine})_2]_n$ (**1**)

Tetrahydrofuran (40 ml) was added to a mixture of $[Co(Piv)_2]_n$ (0.5 g, 1.9 mmol), LiPiv (0.207 g, 1.9 mmol) and 2-amino-5-methylpyridine (0.205 g, 0.9 mmol). The reaction mixture was stirred at 60 °C for 20 min. The resulting brown solution was concentrated to 10 ml, MeCN (40 ml) was added, and the mixture was concentrated to 10 ml at 80 °C. The solution was kept at +5 °C for 24 h. Brown crystals suitable for X-ray diffraction were separated from the solution by decantation, washed with cold MeCN, and dried in air. The yield of crystals of **1** is 81% based on $[Co(Piv)_2]_n$. Found (%): C, 52.95; H, 7.35; N, 5.66. $C_{21}H_{35}CoLiN_2O_6$: C, 52.84; H, 7.39; N, 5.87. IR, ν/cm^{-1}: 3384 m, 3130 m, 2960 s, 2928 m, 2868 m, 1612 v.s, 1572 v.s, 1564 v.s, 1520 m, 1504 s, 1484 v.s, 1424 v.s, 1400 v.s, 1376 m, 1364 v.s, 1300 w, 1260 w, 1228 c, 1144 w, 1120 w, 1044 w, 1032 m, 972 m, 952 m, 936 m, 904 s, 848 m, 824 m, 800 s, 792 s, 764 s, 744 w, 664 m, 608 v.s, 568 s, 528 m, 452 v.s, 436 v.s, 416 v.s, 400 v.s.

2.2. Methods

The elemental analysis of complex **1** was carried out on a Carlo Erba analyzer in the Center of Collaborative Research of the N.S. Kurnakov Institute of General and Inorganic Chemistry of the Russian Academy of Sciences. The spectra were measured on a Specord M-80 IR spectrometer in KBr pellets. The magnetochemical measurements were performed on a MPMS-5S SQUID magnetometer (Quantum Design) in the 2–300 K temperature range at a magnetic field strength $H = 5$ kOe. The molar magnetic susceptibility χ was calculated taking into account the atomic diamagnetism according to the Pascal additive scheme. In the paramagnetic region, the effective magnetic moment was calculated by the equation $\mu_{eff} = [(3k/N_A\beta 2)\chi T]^{1/2} \approx (8\chi T)^{1/2}$, where k is the Boltzmann constant, N_A is Avogadro's number and β is the Bohr magneton.

2.3. X-ray data collection

The X-ray diffraction study of complex **1** was carried out on an Enraf Nonius CAD-4 diffractometer (λMo, graphite monochromator, ω-scanning technique, the scan step was 0.3°, the exposure time per frame was 10 s) according to a standard technique [15]. The structure of complex **1** was solved by direct methods and refined by the full-matrix least-squares method with anisotropic displacement parameters for all non-hydrogen atoms. The hydrogen atoms of the carbon-containing ligands were positioned geometrically and refined using a riding model. All calculations were carried out with the use of the SHELX97 program package [16]. The *tert*-butyl substituents at the carboxylate groups are partially disordered. The positions of all methyl carbon atoms in the disordered CMe_3 fragments were located in difference Fourier maps and refined with occupancies of 0.506(12) and 0.494(12) for the *tert*-butyl group at the atom C(1), 0.674(10) and 0.326(10) at the atom C(6), and 0.531(17) and 0.469(17) at the atom C(11). The crystallographic parameters for complex **1** at $T = 293$ K are as follows: $C_{21}H_{35}CoLiN_2O_6$, $fw = 477.38$, blue, prismatic, crystal size $0.45 \times 0.23 \times 0.25$ mm, monoclinic system, space group $P2_1/c$, $a = 12.4255(10)$ Å, $b = 22.1287(10)$ Å, $c = 9.4545(10)$ Å, $\beta = 103.253(10)°$, $V = 2530.4(4)$ Å^3, $\lambda = 0.71073$, $Z = 4$, $\rho_{calc} = 1.253$ g cm^{-3}, $\mu = 7.13$ cm^{-1}, 5775 measured reflections, 3113 reflections with $I > 4.0\sigma(I)$, $R_{int} = 0.0843$, $\theta_{max} = 26.97$, $GOF = 1.047$, R_1 ($I > 2\sigma(I)$) = 0.0502, wR_2 ($I > 2\sigma(I)$) = 0.1365, R_1 (all data) = 0.1173, wR_2 (all data) = 0.1663, $T_{min/max} = 0.9006/0.7397$ [17], full-matrix least-squares on F^2.

The X-ray powder diffraction analysis of the solid decomposition products in air was carried out on a G670 (HUBER) Guinier camera using CuKα1 radiation. The X-ray powder diffraction analysis of the solid decomposition products in an inert atmosphere was performed on a FR-552 monochromator chamber (CuKα1 radiation) using germanium as the internal standard (X-ray diffraction patterns were processed on an IZA-2 comparator with an accuracy of ±0.01 mm).

2.4. Thermal decomposition

The thermal decomposition of compound **1** was studied by differential scanning calorimetry (DSC) and thermogravimetry (TGA). The thermogravimetric measurements were performed in an artificial air flow (20 ml/min) and in an argon flow (20 ml/min) on a *NETZSCH TG 209 F1* instrument in alundum crucibles at a heating rate of 10 °C/min. The composition of the gas phase below 250 °C was studied on a QMS 403C Aëolos mass-spectrometric unit under TGA conditions. The ionizing electron energy was 70 eV; the largest determined mass number (the mass-to-charge ratio) was 300 amu. The weight of the samples for thermogravimetric experiments was 0.5–3 mg. The differential scanning calorimetry study, in a dry artificial air flow (O_2, 20.8%; CH_4, <0.0001%) and in an argon flow (Ar, >99.998%; O_2, 0.0002%; N_2, <0.001%; aqueous vapor, <0.0003%; CH_4, <0.0001%), was carried out on a *NETZSCH DSC 204 F1* calorimeter in aluminum cells at a heating rate of 10 °C/min. The weight of the samples was 4–10 mg. Each experiment was repeated at least three times. The temperature scales and the calorimeter were calibrated based on the phase transition temperatures of standard compounds (C_6H_{12}, Hg, KNO_3, In, Sn, Bi and CsCl; 99.99% purity; ISO/CD 11357-1). For the TGA and DSC experiments, the samples were weighed on a *SARTORIUS RESEARCH R 160P* analytical balance with an accuracy of 1×10^{-2} mg.

2.5. Heat capacity

The heat capacities were measured by DSC on a *NETZSCH 204 F1* instrument in a dry argon flow (10 ml/min) in the 123–373 K temperature range at a heating rate of 10 °C/min in aluminum specimen containers ($V = 56$ mm^3, $d = 6$ mm) equipped with lids with a hole (the ratio of the surface area of the bottom of the container to the surface area of the hole was about 36).

The average weight of the samples for heat capacity measurements was about 10 mg. The heat capacity was calculated in accordance with the *ASTM E 1269* standard by the equation:

$$C_{p,S} = \frac{m_{St}}{m_S}\frac{DSC_S - DSC_{BL}}{DSC_{St} - DSC_{BL}}C_{p,St} \quad (1)$$

where the indices S, St and BL refer to the cell containing the sample, the cell containing the standard compound, and the empty cell, respectively. Sapphire (m = 12.69 mg) was used as the standard. Four series of measurements were carried out. The results were processed statistically. The controlled cooling of the measuring cells was performed manually using a liquid-nitrogen cooling system.

The differential scanning calorimeter was calibrated against the heat flux with the use of sapphire as the standard (ISO/CD 11357-1) according to the equation:

$$E(T) = \frac{DSC_{St}(T) - DSC_{BL}(T)}{m_{St}C_{p,St}(T)\beta} \quad (2)$$

where the indices St and BL refer to the cell containing the standard and the empty cell, respectively, $E(T)$ is the temperature-dependent calibration coefficient, DSC is the experimental DSC signal, m is the mass, C_p is the isobaric heat capacity, and β is the heating rate of the furnace. The calibration against the heat flux was carried out before each measurement throughout the temperature range of interest. The experimental data were processed using the *NETZSCH Proteus Thermal Analysis* program package.

3. Results and discussion

3.1. Synthesis, structure and magnetic properties of the coordination polymer $[Li_2Co_2(Piv)_6(\mu\text{-}L)_2]_n$

We chose the product prepared by the reaction of polymeric cobalt(II) pivalate $[Co(Piv)_2]_n$, lithium pivalate LiPiv and 2-amino-5-methylpyridine (L) in the Co:Li:L ratio of 2:2:1 in THF as the possible molecular precursor for the synthesis of $LiCoO_2$. This reaction afforded a coordination polymer with the composition $[Li_2Co_2(Piv)_6(\mu\text{-}L)_2]_n$ (**1**) in high yield (81%).

According to X-ray diffraction data, compound **1** is a 1D polymer containing the heteronuclear fragment $\{Li_2Co_2(Piv)_6(\mu\text{-}L)_2\}$ as the elementary unit (Fig. 1). This fragment consists of two symmetrically arranged dinuclear units $\{LiCo(Piv)_3\}$, in which the cobalt and lithium atoms are linked by three non-equivalent bridging pivalate anions. The centrosymmetric repeating unit $\{Li_2Co_2(Piv)_6(\mu\text{-}L)_2\}$ contains the square O_2Li_2 fragment (Table 1). The polymer chain is formed by linking adjacent cobalt atoms from different repeating heteronuclear fragments $\{Li_2Co_2(Piv)_6(\mu\text{-}L)_2\}$ by two bridging 2-amino-5-methylpyridine molecules (Fig. 1, Table 1). In the elementary unit, each cobalt atom is coordinated by the pyridine nitrogen atom of one bridging N-donor ligand and the amino nitrogen atom of the bridging ligand from the adjacent fragment. The proton of the coordinated amino group is involved in hydrogen bonding with the oxygen atom of the bridging carboxylate group (Fig. 1, Table 1).

Table 1
Selected bond lengths [Å] and bond angles [°] for compound **1**.

Parameter	Value
Li(1A)–Li(1)–Co(1)	125.7(3)
Li(1)–Co(1)–N(1)	156.76(15)
Li(1)–Co(1)–N(2)	113.79(13)

Co(1)–O(1)	2.141(3)
Co(1)–O(2)	2.225(3)
Co(1)–O(3)	2.004(2)
Co(1)–O(5)	2.026(2)
Li(1)–O(2)	1.947(6)
Li(1)–O(4)	1.876(6)
Li(1)–O(6)	1.901(6)
Li(1)–O(6A)	1.973(6)
C–O (range)	1.234(4)–1.265(4)
N(2)···O(3)*	2.828(4)

* N(2)–H(2B)–O(3) 155.3°, H(2B)···O(3) 1.98 Å.

It should be noted that the distance between the cobalt atom and the nitrogen atom of the amino group (Co(1)–N(2)) is substantially elongated (2.372(3) Å), which is indicative of weak interactions between these atoms. This situation is typical of amino derivatives of pyridine serving as a bridging ligand in polynuclear cobalt-containing pivalates, and has been observed earlier [18,19].

The magnetic behavior of compound **1** is unusual. At room temperature, the effective magnetic moment of compound **1** is 4.77 μ_B (per cobalt atom) (Fig. 2), which is close to the known experimental values for high-spin Co^{II} atoms (S = 3/2) taking into account spin-orbital interactions (4.4–5.2 μ_B) [20]. The magnetic moment

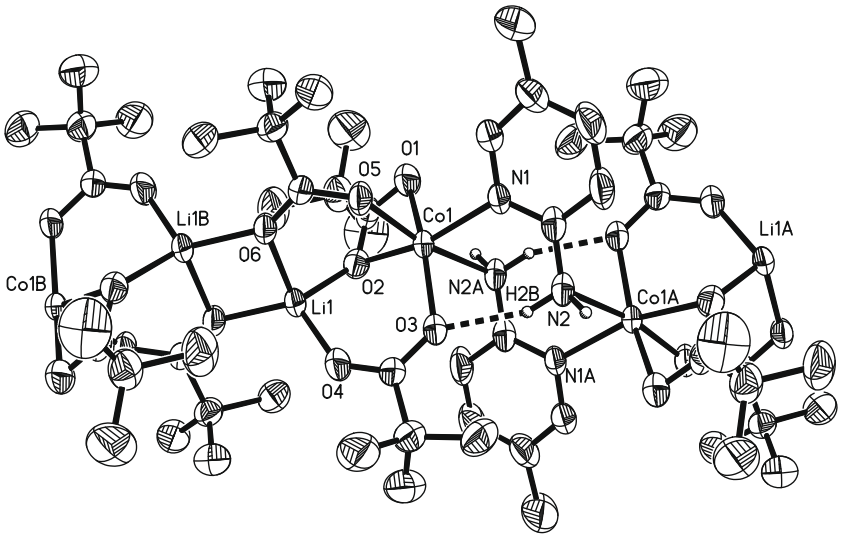

Fig. 1. Fragment of the polymer chain of compound **1** (only one component of each of the distorted *tert*-butyl groups is drawn, hydrogen atoms of the carboxylate and 2-amino-5-methylpyridine ligands (except for amino groups) are omitted for clarity, 50% thermal probability ellipsoids).

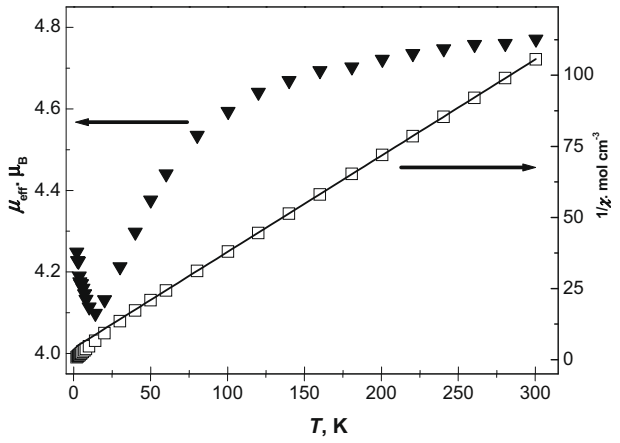

Fig. 2. Magnetic properties of complex **1**: the temperature dependence of the magnetic moment (▼), the curve $1/\chi$ (□); the calculated data are represented by the line.

μ_{eff} decreases with decreasing temperature (to 4.10 μ_B at 14 K). This fact can be attributed to both antiferromagnetic spin-spin exchange interactions between the cobalt atoms and the spin-orbital effect. However, μ_{eff} increases at temperatures below 14 K and reaches 4.25 μ_B at 2 K. Apparently, this effect is indicative of a ferromagnetic contribution to the exchange interactions between the Co^{II} atoms in the polymer chain.

In the 50–300 K temperature range, the temperature dependence of the inverse susceptibility follows the Curie–Weiss law with the parameters $C = 2.96$ mol cm^{-3} and $\theta = -11.96$ K (Fig. 2). The value $C = 2.96$ is larger than the theoretical pure spin value ($C = 1.875$ for $S = 3/2$ and $g = 2$), which is consistent with the orbital contribution to the magnetic susceptibility, typical of Co^{II} ions and g factors larger than 2.

3.2. Thermal decomposition

According to the TGA data, the decomposition of complex **1** in an artificial air flow and in a dry argon flow does not afford stable intermediates (Fig. 3).

The decomposition onset temperature for complex **1** is virtually the same (180 ± 3 °C) both in air and under an inert atmosphere (argon). The mass spectra of the gas phase in the 150–250 °C temperature range correspond to the spectrum of 2-amino-5-methylpyridine [21]. The initial step of decomposition of complex **1** (180–280 °C) is endothermic (the second endothermic peak in the DSC curves; see Fig. 3); the absorbed energy in air is 73.5 ± 5.3 kJ/mol per elementary unit of $Li_2Co_2(Piv)_6(L)_2$. The end of the second endothermic peak (260 ± 3 °C) corresponds to a 22.4 ± 1.5% weight loss. The number of 5-methyl-2-pyridineamine molecules calculated from the empirical formula is 22.67% per $Li_2Co_2(Piv)_6(L)_2$ formula unit. Presumably, heating in air in the above-mentioned temperature range leads to elimination of the N-donor ligand. Under an inert atmosphere, the endothermic effect in this temperature range has a complex character, and it is impossible to separate the thermal effect associated with elimination of the N-donor ligand. The inflection point in the weight loss curve at 280 ± 3 °C corresponds to a 21.7 ± 1.5% weight loss. At higher temperatures, further destructive decomposition of complex **1** is observed. It should be noted that the processes under an inert atmosphere differ from those in air. In an air flow, a highly exothermic oxidative destruction occurs in the 260–410 °C temperature range. The temperature of the end of the exothermic peak in air is virtually equal to the temperature of the end of the weight loss (Fig. 3b).

Under an inert atmosphere, the further weight loss occurs in the 280–470 °C temperature range. This process is accompanied by complex energy changes. According to the X-ray powder diffraction data, a heterogeneous mixture of cobalt oxide CoO and lithium oxide Li_2O is formed as the solid decomposition product of complex **1** under an inert atmosphere at temperatures below 500 °C (Table 2). The weight of the solid residue was 19.5 ± 1.5% of the weight of the starting sample, which agrees within experimental error to the value of 18.91% calculated from the empirical formula on the assumption that the decomposition affords a mixture of the Li_2O and CoO phases.

Unlike the inert conditions, the decomposition of polymer **1** in air (below 500 °C) affords a solid heterogeneous mixture of mixed-valence cobalt oxide Co_3O_4, lithium oxide Li_2O and lithium cobaltate $LiCoO_2$ (X-ray powder diffraction data; Table 2). However, the further storage of the thermolysis product under temperature-controlled conditions at 500 °C for 30–90 min led to the complete disappearance of the simple oxides, which is confirmed by the disappearance of reflections of the simple oxides in the X-ray diffraction patterns (Table 3). The weight of the solid residue upon thermolysis in air is 22.3 ± 1.5% of the weight of the starting sample, which agrees within experimental error to the value of 20.69% calculated from the empirical formula on the assumption that the decomposition affords $LiCoO_2$.

3.3. Heat capacity measurements

Differential scanning calorimetry studies showed that the endothermic effect in the 77–130 °C (350–405 K) temperature range

observed both under an inert atmosphere and in air is not associated with decomposition of the samples (Fig. 3) and is reproduced upon successive cooling and heating of the samples (Fig. 4).

To elucidate the nature of this thermal transformation, we measured the temperature dependence of the heat capacity. In addition, we intended to obtain thermodynamic characteristics for complex **1**, which are necessary for the construction of the thermodynamic model of the thermolysis. This model and the temperature program maintaining the constant level of gas evolution throughout the temperature range of thermolysis, which was calculated from the results of the thermal analysis, allow the optimization of the conditions for the preparation of lithium cobaltate films from the molecular precursor under consideration.

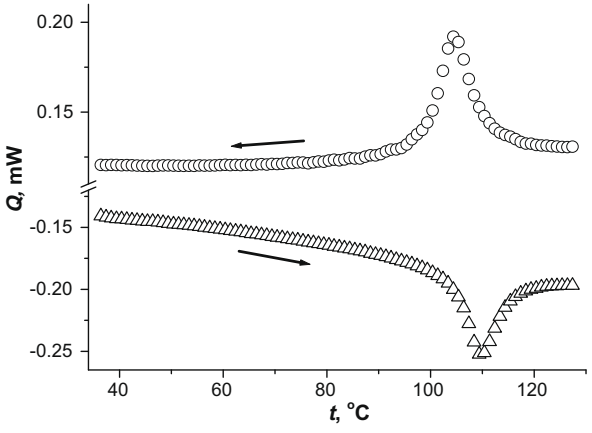

Fig. 4. Changes in the heat flux during heating (△) and cooling (○) of complex **1**.

The results of heat capacity measurements for complex **1** obtained by the statistical processing of experimental data are presented in Fig. 5. The experimental points deviate from the average smoothed curve by no more than 1.4%. The temperature dependence of C_p for complex **1** shows some anomalies. These anomalies are well reproduced, the characteristics of the anomalies being independent of the thermal history of the sample (anomaly 1: T_{onset} = 232.5 ± 0.5 K, Q = 79.1 ± 8.8 J/mol; anomaly 2: T_{onset} = 378.32 ± 0.26 K, Q = 6531 ± 715 J/mol).

According to the X-ray diffraction data, the crystal system and the space group of complex **1** remain unchanged in the 300–190 K temperature range (Table 4), but the unit cell parameters and the unit cell volume change non-monotonically. Hence, the low-temperature anomaly is presumably attributed to the phase transition associated with freezing of vibrations of the *tert*-butyl substituents at the carboxylate groups. Earlier, we have observed an analogous situation for the heteronuclear pivalate complex $Co_2Sm(Piv)_7(2,4\text{-Lut})_2$ [22].

The endothermic effect in the 350–405 K temperature range is apparently attributed to the cleavage of a large number of hydrogen bonds formed between the protons of the coordinated amino group and the oxygen atoms of the bridging and chelate bridging carboxylate groups, accompanied by energy release. The thermal effect of this transformation is comparable with the hydrogen bond energy [23].

190	−83	12.414(5)	22.122(8)	9.332(4)	103.931(17)	2487.4(1.5)

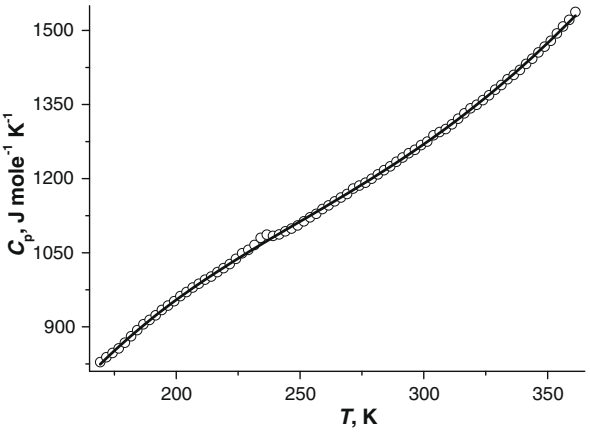

Fig. 6. Dependence of the heat capacity of complex **1**: experimental data (○); the calculated data are represented by the line (a_1 = 1396, θ_1 = 437, a_2 = 7779, θ_2 = 2617).

The absolute entropies of complex **1** were calculated from the limited region of the heat capacity curve (120–350 K) by extrapolating the results of DSC heat capacity measurements from the boiling point of liquid-nitrogen to the absolute zero temperature (0 K). This method gives the physically correct behavior of the temperature dependence of the heat capacity and the mathematically correct standard entropies [22]. To calculate the thermodynamic functions of the complexes, we separated the regular heat capacity contribution and approximated it to 0 by the function:

$$c_p(T) = \sum_i a_i C_{En}\left(\frac{\theta_i}{T}\right) \quad (3)$$

$$\text{where} \quad C_{En}(x) = 3Rx^2\frac{\exp(x)}{[\exp(x)-1]^2}, \quad x = \frac{\theta}{T}$$

The best results were obtained by approximating with function (3), consisting of two summands (Fig. 6).

The standard entropies S^o_{298} of the complexes were estimated by the equation:

$$S(T) = \sum_i a_i S_{En}\left(\frac{\theta_i}{T}\right) \quad (4)$$

$$\text{where} \quad S_{En}(x) = 3R\left[\frac{x}{(\exp(x)-1)} - \ln(1-\exp(-x))\right], \quad x = \frac{\theta}{T}.$$

We took into account the change in the entropy as a result of the transition associated with the anomaly in the curve for C_p according to the equation $\Delta S^{\circ}_{T_{onset}} = \frac{AREA}{T_{onset}}$, where AREA is the measured surface area of the peak in the experimental temperature dependence of the heat capacity. Table 5 gives the experimental (average and smoothed) heat capacities, the temperature contributions to the enthalpy calculated from the heat capacities, and the standard entropies (the latter parameters were determined with the use of the calculated value of S^o_{298}).

Table 5
Thermodynamic functions of compound **1**.

T (K)	C_p (±11.1) (J/mol K)	$H^o_T - H^o_{170}$ (kJ/mol)	S^o_T (J/mol K)
170	828.5	0	403
180	867.8	8.4	451
190	914.2	17.3	500
200	952.0	26.7	547
210	987.2	36.3	595
220	1018.7	46.3	642
250	1105.2	78.3	778
260	1138.5	89.5	822
270	1168.8	101.0	866
280	1199.8	112.8	909
290	1234.0	124.9	952
298	1267.7	137.4	994
310	1300.4	150.2	1036
320	1342.3	163.4	1078
330	1380.1	177.0	1120
340	1420.0	190.9	1162
350	1467.2	205.3	1204

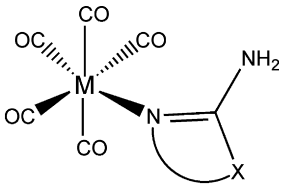
Hence, the study of the heat capacity of coordination polymer **1** in the 123–373 K temperature range revealed two anomalies associated with phase transitions. The parameters of these transitions were determined. The thermodynamic functions ($C^o_p(T)$, $S^0(T)$ and $H^0(T)$–$H^0(170)$) in the 170−350 K temperature range were calculated based on the results of the calorimetric measurements.

4. Conclusions

The above-considered data show that the new heterometallic coordination polymer **1** can apparently be used as an efficient molecular precursor for the synthesis of lithium cobaltate. Under the conditions of the experiments (heating at a rate of 10 °C/min), $LiCoO_2$ can be prepared as the only solid thermolysis product, only after additional storage under temperature-controlled conditions at 500 °C. Preliminary investigations into the preparation of films from saturated solutions of complex **1** on different supports (an alundum support, a stabilized zirconium dioxide support and a sapphire support) showed that homogeneous uniform $LiCoO_2$ films can be formed with the use of a temperature program, which was calculated from the kinetic model of the thermolysis of complex **1**, designed based on the results of thermal analysis and which maintains a constant (3%/min) gas evolution rate during decomposition of coordination polymer **1**.

Supplementary data

CCDC 730046 contains the supplementary crystallographic data for compound **1**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cam-



bridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

in vacuo, the residue extracted with diethyl ether, the extract filtered through SiO_2 and the filtrate stripped of solvent to obtain the microcrystalline products. The products are soluble in organic solvents but not very stable in solution as the presence of metal hexacarbonyl peaks in the IR spectra indicate (*vide infra*). Crystals suitable for single crystal X-ray diffraction were obtained by slow diffusion of pentane into a solution of the product in diethyl ether (**2a** and **4b**) or acetone (**2b**, **3b**, **4a** and **5a**) at −22 °C.

2.2. Characterisation

The molecular ions of all the new products as well as fragments representing the sequential loss of CO-ligands were observed in their mass spectra, confirming that the 2-aminoazoles were coordinated to the pentacarbonyl group 6 metal fragments. No MS data for **5a** could be collected as the compound is too unstable in solution. This kinetic instability might be the result of greater electron delocalisation in the pseudo-aromatic ring of the 2-amino-azole ligand. The synthesis of the analogous complex with W was not attempted.

$(CO)_5ML$ complexes have C_{4v} local symmetry and thus four vibration bands, ν(CO), are expected in their IR spectra. The characteristic $A_1^{(1)}$ vibration (located at high frequency) was recorded at *ca.* 2065 cm^{-1}(m) for all of the Cr and *ca.* 2070 cm^{-1}(m) for all of the W complexes, followed by the intense E_1 band at *ca.* 1935 cm^{-1} (vs) for the Cr and *ca.* 1930 cm^{-1} (vs) for the W complexes, with one or two weaker bands, which are located to the left (B_1) (~1980 cm^{-1}, obscured by $Cr(CO)_6$ or $W(CO)_6$) and to the right of this band, $A_1^{(2)}$, at *ca.* 1918 cm^{-1}(s) for the complexes recorded in hexane. The normally Raman active but IR inactive band, B_1, if present is obscured by the $M(CO)_6$ peak. These data are very similar to the reported IR data of (4,5-dihydrido-2-methylthiazole)$W(CO)_5$ (2070 w, 1932 vs 1921 m cm^{-1} in pentane) [14]. For complexes **4b** and **5a**, recorded in $CHCl_3$, a vibration representing the E_1 band is observed at *ca.* 1929 cm^{-1} and a shoulder at *ca.* 1890 cm^{-1} can be assigned to the $A_1^{(2)}$ band. The observed decrease in frequency and broadening of the E_1 and $A_1^{(2)}$ bands can be ascribed to the polar solvent, $CHCl_3$ used in the collection of the spectra [15,16]. The E_1 band is less sensitive to the polar solvent than the $A_1^{(2)}$ band as its dipole is perpendicular to the molecular dipole whereas the dipole of the $A_1^{(2)}$ band is parallel to the molecular dipole and thus the $A_1^{(2)}$ band is more affected by interaction with the polar solvent and appears at a lower frequency [17]. An examination of the CO stretching frequency data for the E_1 vibration of 2-aminopyrimidine and 4-aminopyrimidine complexes of $W(CO)_5$ have shown that the infrared technique is not diagnostic of the coordination mode of endocyclic imine versus excocyclic amine donors [12].

The signals in the ^{1}H NMR spectra of the new complexes appear downfield by up to $\Delta\delta$ 0.5 ppm when compared to the corresponding signals for the free ligand, an indication of coordination of the ligand to the metal. The resonances for the NH_2 groups when observed (2-amino-4-methylthiazole, 2-aminothiazoline, and their complexes and 2-aminobenzothiazole) appear between δ 4.71 and 7.81. These signals are known to be solvent and concentration dependent [18]. No NMR data for **5a** could be collected as the compound is too unstable in solution.

In the ^{13}C NMR spectra the resonances for the *cis* and *trans* CO-groups appear with the customary intensities and at the familiar chemical shifts (220 for *trans* and 215 for *cis* CO in Cr complexes and 205 for *trans* and 199 for *cis* CO in W complexes). The $J_{W\text{-}C}$ couplings are not observed as a result of the low signal intensities, a consequence of the long relaxation times of CO carbons. As in the ^{1}H NMR spectra, signals in the ^{13}C NMR spectra generally appear at a lower field strength (>6 ppm) when compared to the corresponding signals in the free ligand. The exceptions are some of the signals for the C atoms located further away from the heterocyclic ring in the benzene rings, in the 2-aminobenzothiazole and 2-aminobenzimidazole derived complexes. The signals for these C atoms can experience a small upfield change (>5 ppm) in chemical shift. This observation is not unusual as the total chemical shift σ ($\sigma = \sigma_p + \sigma_d$) in the ^{13}C NMR does not only reflect shielding and deshielding [19]. The total chemical shift consists of two parts, namely the paramagnetic contribution (σ_p) and diamagnetic contribution (σ_d), in the equation $\sigma = \sigma_p + \sigma_d$. The diamagnetic component can be ignored in ^{1}H NMR spectra where chemical shifts only reflect shielding and deshielding but the diamagnetic contribution plays a more significant role in ^{13}C NMR and cannot be ignored. Thus the ^{13}C NMR chemical shifts do not simply reflect shielding and deshielding as in ^{1}H NMR spectra.

The signal for the NH_2 nitrogen in the ^{15}N NMR spectra of the ligands of complexes **1**–**4** could all be detected by ^{1}H–^{15}N gHMQC or directly (**4**). The resonance for the N=C nitrogens in the thiazole compounds were all located by using ^{1}H–^{15}N gHSQC. In the instance of **4** the signal for NH could not be detected but a signal, possibly, for the N=C nitrogen appears at δ −200, well upfield from the other N=C signals. Delocalisation could render the endocyclic NH and N=C nitrogens in **4** isochronous. Bond distances in the molecular structure determination of 3-methyl-3*H*-imidazo [4,5-f]quinolin-2-ylamine [20], **4a**, **4b** and **5b** also suggest delocalization.

Upon coordination of the ligands, the signal for the N=C nitrogen in the ^{15}N NMR spectra of **1b** and **3b** is detected *upfield* by 70–76 ppm. This is consistent with the results observed for imine coordinated gold(I) complexes of thiazoles [7] and imidazoles [21]. The signal for the NH_2 group appears downfield by 20–24 ppm. Although one would expect a downfield change in chemical shift for the imine N upon metal coordination as a result of the electronic redistribution of charge, this upfield change in chemical shift correlates to results observed for the protonation of imine nitrogens, especially if the isolobal relationship between H^+ and the $W(CO)_5$ unit [22] is taken into consideration. Similar changes in chemical shift were observed during the protonation of prototypical ATP derivatives [23]. An upfield change in chemical shift of about 70 ppm was observed for the imine nitrogen where protonation occurred, in the pyrimidine ring of the adenine unit of these compounds. A downfield change in chemical shift of 9–10 ppm was observed for the exocyclic amine in this instance. These changes were ascribed to the increase in sp^3 character of the imine N and increase in sp^2 character for the excocyclic amine N.

The ^{15}N NMR data suggests endocyclic imine coordination thus providing the only clue from physical measurements as to the site of metal coordination. The endocyclic thioether S is unlikely to be the site of coordination as ^{14}N NMR data suggests that the lone pair of the sulfur is delocalized into the conjugated ring [24].

2.3. Molecular structures of **2a**, **2b**, **3b**, **4a**, **4b** and **5a**

No literature examples of X-ray crystal structure determinations of aminoazole group 6 pentacarbonyl complexes were found. The single crystal X-ray diffraction structure determinations confirmed that the ligands in all complexes are imine coordinated (Figs. 1–6). The unit cells of **2a** and **5a** contain two asymmetric molecules but bond lengths and angles do not differ significantly. The two molecules in the asymmetric unit of **5a** are related by a pseudo-inversion centre. All the complexes essentially display the octahedral coordination geometry adopted by their $M(CO)_6$ synthetic ancestors (C–M–C and C–M–N angles are ~175°). The largest deviation from the ideal 180° angles involving *trans* oriented donor atoms and the central metal, occurs in the *cis* CO-ligands which are slightly bent away from the non-carbonyl ligand in order to accommodate its steric requirements. The ligands are

Table 1

virtually planar and are staggered with respect to the *cis* carbonyl ligands (C5–M1–N1–C10 torsion angles −38 to −55°, Table 1) to avoid steric congestion.

The Cr1–N1 and W1–N1 distances are within the norm set by other M–N bonds in $(CO)_5ML$ complexes with an N(sp^2)-bonded N-heterocyclic ligand (L = 3-ethoxy-1*H*-isoindole [2.134(3) Å] [25], 3,3-diethyl-5-methoxycarbonyl-3*H*-pyrazole [2.138(2) Å] [26], 4-ethoxy-1,2,6,6a-tetrahydro-1-methyl-6-phenylcyclopenta(d)imidazole [2.126(3) Å] [27] and 4-(diethylamino)-2-ethoxy-3-methyl-2,5-diphenyl-2*H*-pyrrole [2.160(2) Å] [28] for M = Cr and L = 4,5-dihydrido-2-methylthiazole [2.287(6) Å] [14], benzoxazole [2.257(6), 2.270(7) Å] [29], 2-methyl-1-(pyridine-2-yl)-1,2,4-triazole [2.273(7) Å] [30] and 5-*t*-butylpyrazol-2-yl [2.236(4) Å] [31] for M = W). The M–CO bonds in each complex *trans* to the M–N bonds are significantly shorter than the other M–CO bonds reflecting the significant *trans* influence of the imine donor. The M–CO bond distances range from 1.832(6) to 1.922(4) Å for M = Cr and from 1.960(5) to 2.055(4) Å for M = W and are in good agreement with the same bond distances in the above mentioned examples.

Bond distances and angles in the ligands (2-aminobenzothiazole [32], 2-aminothiazoline [33], 2-aminobenzimidazole [34] and 2-amino-1-methyl-imidazole compared to 2-amino-3-methylimidazo(4,5-f)quinoline [20]) do not change significantly upon coordination to the metal. The C=N bonds in **2a**, **2b**, **3b**, **4a**, **4b**, and **5a** are somewhat longer than the standard value for a C(sp^2)=N(sp^2) bond (1.30 Å) [35] and the C–N bonds in **4a**, **4b** and **5a** are shorter than the standard value for C(sp^2)–N(sp^3) bonds (1.41 Å) [35]. The two C–S bonds in **2a** and **2b** do not differ significantly from each other whereas they do in **3b**. These facts indicate a degree of delocalization and thus pseudo-aromatic characteristics especially for the 2-aminobenzothiazole and -imidazole ligands.

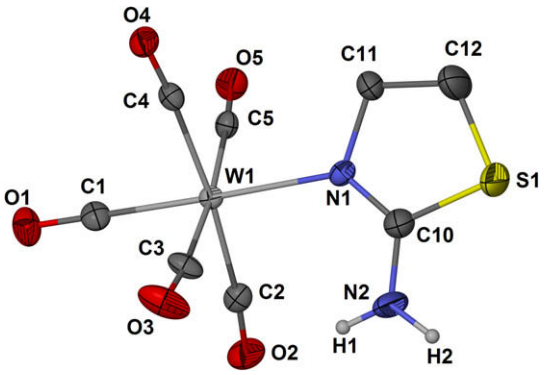

Fig. 3. The molecular structure of **3b**.

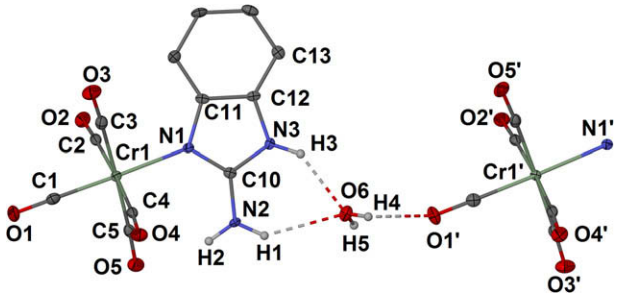

Fig. 4. The molecular structure of **4a**. One symmetry generated ($x-1$, $3/2-y$, $z-1/2$) $Cr(CO)_5$ fragment is shown to indicate the hydrogen bonding motif.

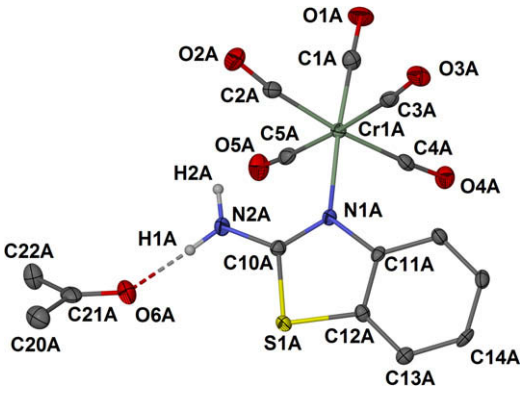

Fig. 1. The molecular structure of **2a**, showing one of the asymmetric molecules per unit cell.

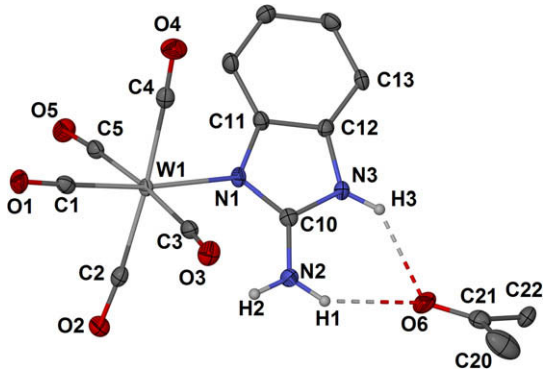

Fig. 5. The molecular structure of **4b**.

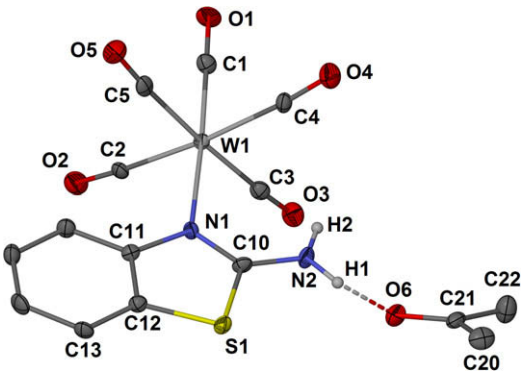

Fig. 2. The molecular structure of **2b**.

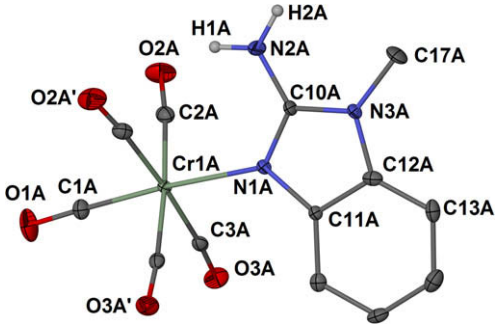

Fig. 6. The molecular structure of **5a**, showing one of the asymmetric molecules per unit cell.

In the crystal structures of **2a**, **2b**, **4a** and **4b** both hydrogen bonding between the amino group on the ligand and included solvent molecules and π-stacking between the 5- and 6-membered rings of neighbouring molecules govern the solid-state arrangement (3.93, 3.78, 3.97 and 3.73 Å in **2a**, 3.99 and 3.76 Å in **2b**, 3.50 Å in **4a**, 3.98 and 3.84 Å in **4b**). The molecular assembly of **5a** is determined by π-stacking between the 5- and 6-membered rings of neighbouring molecules (3.77 and 3.67 Å). No hydrogen bonding is observed in the crystal structure of **3b**.

3. Conclusions

Contrary to expectation when electronic charge redistribution is considered, the signal for the N=C nitrogen in 2-aminothiazoles upon coordination to pentacarbonyl chromium or tungsten, is detected upfield by 70–76 ppm in ^{15}N NMR spectra. This is the only clue presented by IR, NMR and MS analysis of the product complexes as to the preferred coordination site of the metal on the 2-aminoazole ligand. The first molecular structures of pentacarbonyl chromium and tungsten complexes coordinated to 2-aminoazoles were determined and confirmed metal coordination to the softer endocyclic imine rather than the hard excocyclic amine.

4. Experimental

4.1. Synthesis

All reactions were carried out under nitrogen or argon using standard vacuum-line and Schlenk techniques. Tetrahydrofuran (THF), hexane, pentane and diethyl ether were dried and deoxygenated by distillation from sodium benzophenone ketyl, and dichloromethane and *N,N*-dimethylformamide from CaH_2. $Cr(CO)_6$, $W(CO)_6$, 2-amino-4-methylthiazole, 2-aminobenzothiazole, 2-aminothiazoline, 2-aminobenzimidazole and 2-amino-1-methylbenzimidazole were purchased from commercial suppliers and used without further purification. Flash column chromatography was performed with "flash grade" SiO_2 (SDS 230–400 mesh). The starting materials, pentacarbonyl(tetrahydrofuran)chromium(0) and its tungsten analogue [36] and 2-amino-1-methylbenzimidazole [37] were prepared according to literature procedures.

Melting points were determined on a Stuart SMP3 apparatus and are uncorrected. Mass spectra were recorded on a VG 70 SEQ (FAB, 70 eV, *m*-nitrobenzylalcohol matrix) or VG Quattro (ESI, 70 eV, solvent acetonitrile) instrument, the infrared spectra on a Thermo Nicolet Avatar 330 FT-IR instrument equipped with a SMART OMNI ATR (attenuated total reflectance, Zn Se) sampler and NMR spectra on a Varian 300 FT or INOVA 600 MHz spectrometer (^{1}H NMR at 300/600 MHz, ^{13}C{^{1}H} NMR at 75/150 MHz and ^{15}N NMR at 60.8 MHz; δ reported relative to the solvent resonance or external reference, neat CH_3NO_2). Elemental analyses were carried out at the Soil Science Department, University of the Stellenbosch. Prior to elemental analysis, the products were evacuated under high vacuum for 10 h.

4.2. Preparation of (2-amino-4-methylthiazole)pentacarbonylchromium(0), **1a**

The irradiation of hexacarbonylchromium(0) (0.44 g, 2.0 mmol) in 150 ml of THF for 2 h yielded an orange solution. The solution was transferred to a Schlenk tube *via* a cannula whereupon the ligand, 2-amino-4-methylthiazole (0.23 g, 2.0 mmol), was added. The mixture was stirred at room temperature for 2 h. The resulting yellow solution was stripped of solvent *in vacuo*. The yellow residue was then extracted with diethyl ether (60 ml) and filtered through SiO_2 to remove solid impurities. After the removal of solvent from the yellow solution, a yellow microcrystalline product was obtained (0.10 g, 52%). TLC analysis with a 1:1 ratio of hexane/diethyl ether was used to confirm that only one product was present. Mp 86–88 °C (decomp.). IR (hexane, cm^{-1}) ν(CO): 2067 m, 1936 vs 1918 s. ESMS, *m/z* (relative intensity) for $C_9H_6CrN_2O_5S$: 305 (M^+–H, 2), 277 (M−CO–H, 5), 249 (M−2CO−H, 88), 221 (M−3CO−H, 57), 193 (M−4CO−H, 15), 165 (M−5CO−H, 15). ^{1}H NMR (CD_2Cl_2, δ): 6.28 (bs, 1H, SCH), 5.58 (bs, 2H, NH_2), 2.42 (bs, 3H, CH_3). ^{13}C NMR (CD_2Cl_2, δ): 221.7 (s, CO_{trans}), 215.1 (s, CO_{cis}), 170.5 (s, NCS), 150.9 (s, CH_3C), 104.0 (s, SC), 20.2 (s, CH_3). *Anal.* Calc. for $C_9H_6CrN_2O_5S$ (306.22): C, 35.30; H, 1.98; N, 9.15. Found: C, 35.53; H, 1.74; N, 9.09%.

4.3. Preparation of (2-amino-4-methylthiazole)pentacarbonyltungsten, **1b**

The same experimental procedure as described for **1a** was used to prepare **1b** from hexacarbonyltungsten(0) (0.45 g, 1.3 mmol) and 2-amino-4-methylthiazole (0.29 g, 2.0 mmol). Yellow, microcrystalline **1b** was obtained (0.44 g, 50%). Mp 106–108 °C (decomp.). IR (hexane, cm^{-1}) ν(CO): 2071 m, 1931 vs 1919 s. EIMS, *m/z* (relative intensity) for $C_9H_6N_2O_5SW$: 437 (M^+, 27), 407 (M−CO, 35), 381 (M−2CO, 20), 353 (M−3CO, 11), 325 (M−4CO, 4), 114 ($C_4H_6N_2S$, 45), 81 ($C_4H_6N_2S$–NH_2–CH_3, 20). ^{1}H NMR ($(CD_3)_2CO$, δ): 7.17 (bs, 2H, NH_2), 6.56 (s, 1H, CSH), 2.43 (s, 3H, CH_3). ^{13}C NMR ($(CD_3)_2CO$, δ): 203.2 (s, CO_{trans}), 199.9 (s, CO_{cis}), 174.0 (s, NCS), 150.7 (s, CH_3C), 104.5 (s, SC), 22.6 (s, CH_3). ^{15}N NMR ($(CD_3)_2CO$, δ): −198.5 (WN), −293.6 (NH_2). *Anal.* Calc. for $C_9H_6N_2O_5SW$ (438.07): C, 24.68; H, 1.38; N, 6.39. Found: C, 24.41; H, 1.43; N, 6.12%.

4.4. Preparation of (2-aminobenzothiazole)pentacarbonylchromium, **2a**

Complex **2a** was prepared as described above employing hexacarbonylchromium(0) (0.44 g, 2.0 mmol) and 2-aminobenzothiazole (0.19 g, 1.3 mmol), yielding a yellow microcrystalline solid (0.32 g, 47%). Crystals of **2a** were obtained by the slow diffusion of *n*-pentane into a concentrated diethyl ether solution. Mp 149–150 °C (decomp.). IR (hexane, cm^{-1}) ν(CO): 2068 m, 1936 vs 1917 s. ESMS, *m/z* (relative intensity) for $C_{12}H_6CrN_2O_5S$: 341 (M^+−H, 9), 313 (M–CO–H, 15), 285 (M–2CO–H, 2), 229 (M–4CO–H, 19), 201 (M–5CO–H, 17). ^{1}H NMR ($(CD_3)_2CO$, δ): 7.40 (m, 6H, NH_2, CH). ^{13}C NMR ($(CD_3)_2CO$, δ): 222.9 (s, CO_{trans}), 216.3 (s, CO_{cis}), 171.6 (s, NCS), 153.5 (s, NCCHCH), 130.4 (s, SCCHCH), 128.2 (s, SCCHCH), 125.0 (s, NCCHCH), 123.5 (s, SCCHCH), 121.9 (s, NCCHCH). *Anal.* Calc. for $C_{12}H_6CrN_2O_5S$ (342.25): C, 42.11; H, 1.77; N, 8.19. Found: C, 42.25; H, 1.47; N, 8.20%.

4.5. Preparation of (2-aminobenziothiazole)pentacarbonyltungsten, **2b**

Complex **2b** was prepared from hexacarbonyltungsten(0) (0.45 g, 1.28 mmol) and 2-aminobenziothiazole (0.3 g, 2 mmol) as described above. The mixture was stirred for 1 h and after work up a microcrystalline yellow product in a moderate yield (0.476 g, 51%) was isolated. Yellow crystals of complex **2b** were obtained *via* slow diffusion of *n*-pentane into an acetone solution at −22 °C. Mp 146–147 °C (decomp.). IR (hexane, cm^{-1}) ν(CO): 2071 m, 1932 vs 1919 s. EIMS, *m/z* (relative intensity) for $C_{12}H_6N_2O_5SW$: 474 (M^+, 22), 446 (M–CO, 5), 418 (M–2CO, 8), 390 (M–3CO, 12), 362 (M–4CO, 3). ^{1}H NMR ($(CD_3)_2CO$, δ): 7.95 (dm, 1H, ^3J 7.8 Hz, NCCH), 7.81 (bs, 2H, NH_2), 7.75 (dm, 1H, ^3J 7.8 Hz, SCCH), 7.52 (tm, 1H, ^3J 7.8 Hz, NCCHCH), 7.28 (tm, 1H, ^3J 7.8 Hz, SCCHCH). ^{13}C NMR ($(CD_3)_2CO$, δ): 203.4 (s, CO_{trans}), 199.6 (s, CO_{cis}), 172.6 (s, NCS), 153.4 (s, NCCHCH), 129.8 (s, SCCHCH), 128.5 (s, SCCHCH), 125.3 (s, NCCHCH), 123.6 (s, SCCHCH), 123.0 (s,

NCCHCH). *Anal.* Calc. for $C_{12}H_6N_2O_5SW$ (474.11): C, 30.40; H, 1.28; N, 5.91. Found: C, 30.58; H, 1.43; N, 5.85%.

4.6. Preparation of (2-aminothiazoline)pentacarbonylchromium, **3a**

Complex **3a** was prepared using the same method as for the preparation of **2a** employing hexacarbonylchromium(0) (0.46 g, 2.0 mmol) and 2-aminothiazoline (0.21 g, 2.0 mmol), yielding a yellow microcrystalline solid (0.26 g, 45%). TLC analysis in 1:1 hexane/diethyl ether indicated the presence of a single pure product. Mp 81–87 °C (114 °C decomp.). IR (hexane, cm^{-1}) ν(CO): 2066 m, 1934 vs 1917 s. ESMS, *m/z* (relative intensity) for $C_8H_6CrN_2O_5S$: 293 (M^+–H, 1), 237 (M–2CO–H, 88), 209 (M–3CO–H, 10), 181 (M–4CO–H, 29), 153 (M–5CO–H, 19). ^{1}H NMR ($(CD_3)_2CO$, δ): 6.54 (bs, 2H, NH_2), 3.96 (t, 2H, ^3J 7.5 Hz, NCH_2), 3.38 (t, 2H, ^3J 7.5 Hz, SCH_2). ^{13}C NMR ($(CD_3)_2CO$, δ): 222.6 (s, CO_{trans}), 216.5 (s, CO_{cis}), 168.6 (s, NCS), 69.7 (s, NCH_2), 33.9 (s, SCH_2). *Anal.* Calc for $C_8H_6CrN_2O_5S$ (294.21): C, 32.66; H, 2.06; N, 9.52. Found: C, 32.44; H, 2.23; N, 9.27%.

4.7. Preparation of (2-aminothiazoline)pentacarbonyltungsten, **3b**

The same method as above was used to prepare **3b**, utilising hexacarbonyltungsten(0) (1.40 g, 4.0 mmol) and 2-aminothiazoline (0.4 g, 4.0 mmol) producing a yellow microcrystalline product **3b** in low yield (0.60 g, 35%). Yellow needles were obtained by the slow diffusion of *n*-pentane into a concentrated acetone solution of the product. Mp 109–110 °C (153 °C decomp.). IR (hexane, cm^{-1}) ν(CO): 2069 m, 1929 vs 1919 s. EIMS, *m/z* (relative intensity) for $C_8H_6N_2O_5SW$: 424 (M^+, 18), 397 (M–CO, 12), 371 (M–2CO, 10), 342 (M–3CO, 2), 306 ($3 \times C_3H_6N_2S$, 21). ^{1}H NMR ($(CD_3)_2CO$, δ): 6.80 (bs, 2H, NH_2), 4.12 (t, 2H, ^3J 7.5 Hz, NCH_2), 3.42 (t, 2H, ^3J 7.5 Hz, SCH_2). ^{13}C NMR ($(CD_3)_2CO$, δ): 203.7 (s, CO_{trans}), 199.7 (s, CO_{cis}), 170.3 (s, NCS), 71.4 (s, NCH_2), 34.7 (s, SCH_2). ^{15}N NMR ($(CD_3)_2CO$, δ): −233.0 (N≡C), −282.7 (NH_2). *Anal.* Calc. for $C_8H_6N_2O_5SW$ (426.06): C, 22.55; H, 1.42; N, 6.57. Found: C, 22.71; H, 1.67; N, 6.49%.

4.8. Preparation of (2-aminobenzimidazole)pentacarbonylchromium, **4a**

Complex **4a** was prepared implementing the procedures mentioned above using equimolar amounts of hexacarbonylchromium(0) (0.44 g, 2.0 mmol) and 2-aminobenzimidazole (0.27 g, 2.0 mmol). TLC analysis in 1:1 hexane/diethyl ether indicated the presence of a single pure product (0.64 g, 97%). Yellow single crystals were obtained by slow diffusion of *n*-pentane into a concentrated solution of **4a** in acetone maintained at −22 °C. Mp 148–150 °C (decomp.). IR (hexane, cm^{-1}) ν(CO): 2065 m, 1932 vs 1924 sh. ESMS, *m/z* (relative intensity) for $C_{12}H_7CrN_3O_5$: 324 (M^+–H, 7), 296 (M–CO–H, 14), 268 (M–2CO–H, 100). ^{1}H NMR (CD_3OD, δ): 7.53 (dm, 1H, ^3J 7.6 Hz, CrNCC*H*), 7.10 (m, 3H,

Found: C, 44.56; H, 2.08; N, 12.76%.

4.9. Preparation of (2-aminobenzimidazole)pentacarbonyltungsten, **4b**

Compound **4b** was prepared employing the method described above using hexacarbonyltungsten(0) (0.45 g, 1.3 mmol) and an excess of 2-aminobenzimidazole (0.27 g, 2 mmol) and produced a yellow microcrystalline solid after work up (0.16 g, 27%). Slow diffusion of *n*-pentane into a solution containing **4b** in diethyl ether at −22 °C produced yellow needle-like crystals. Mp 165–167 °C (decomp.). IR ($CHCl_3$, cm^{-1}) ν(CO): 2069 m, 1925 vs 1888 sh. EIMS, *m/z* (relative intensity) for $C_{12}H_7N_3O_5W$: 456 (M^+, 13), 429 (M−CO, 3), 399 (M–2CO, 13), 306 (M–2CO–NH_2–Ph, 22). ^{1}H NMR (CD_3OD, δ): 7.52 (dm, 1H, ^3J 7.6 Hz, CrNCC*H*), 7.10 (m, 3H, NCC*H*(*CH*)$_2$). ^{13}C NMR (CD_3OD, δ): 202.7 (s, CO_{trans}), 199.2 (s, CO_{cis}), 157.7 (s, NCN), 144.6 (s, CrNCCHCH), 133.9 (s, NCCHCH), 122.6 (s, CrNCC*H*CH), 122.4 (s, NCCH*C*H), 118.1 (s, CrCCCH*C*H), 110.8 (s, NCCH*C*H). *Anal.* Calc. for $C_{12}H_7N_3O_5W$ (457.04): C, 31.54; H, 1.54; N, 9.19. Found: C, 31.45; H, 1.73; N, 9.23%.

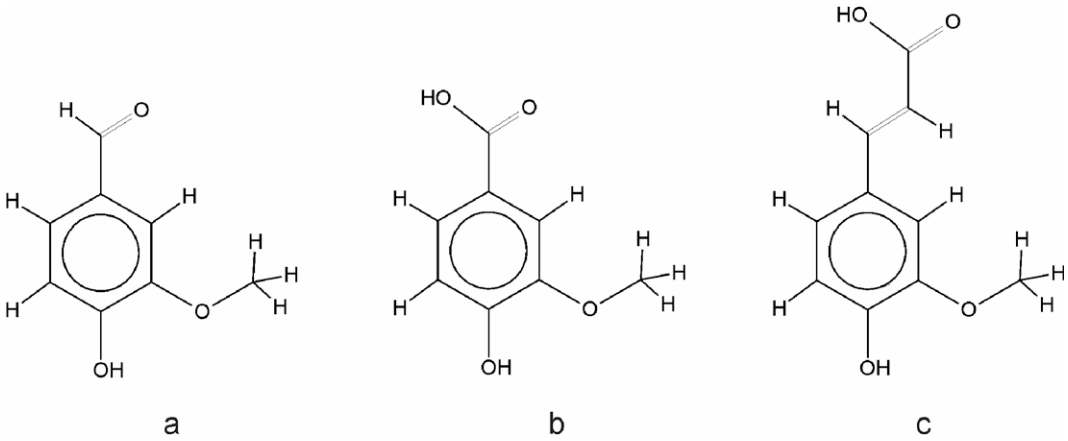
4.10. Preparation of (2-amino-1-methylbenzimidazole) pentacarbonylchromium, **5a**

Complex **5a** was prepared as described above using hexacarbonylchromium(0) (0.28 g, 1.3 mmol) and 2-amino-1-methylbenzimidazole (0.19 g, 1.3 mmol), yielding a yellow solid (0.18 g, 42%). TLC analysis in 1:1 hexane/diethyl ether indicated the presence of a single pure product. Colourless prisms were obtained by slow diffusion of *n*-pentane into an acetone solution. Mp 148–149 °C (decomp.). IR ($CHCl_3$, cm^{-1}) ν(CO): 2066 m, 1931 vs 1894 sh. *Anal.* Calc. for $C_{12}H_9CrN_3O_5$ (327.22): C, 44.32; H, 2.17; N, 12.92. Found: C, 44.62; H, 2.13; N, 12.83%.

4.11. X-ray data collection

Crystal data collection and refinement details of compounds, **2a**, **2b**, **3b**, **4a**, **4b** and **5a** are summarised in Table 2. Data sets were collected on a Bruker SMART Apex CCD diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) [38]. Intensities were measured using the ω-scan mode and were corrected for Lorentz and polarisation effects. Data reduction was carried out with standard methods using the software package Bruker SAINT absorption correction was applied using SADABS [39–41]. All the structures were solved using direct methods, which yielded the position of the metal atoms, and conventional difference Fourier methods. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares calculations on F^2 using SHELX-97 [42] within the X-seed environment [43,44]. The hydrogen atoms were fixed in calculated positions unless otherwise stated. Figures were generated with POV Ray for Windows, with the displacement ellipsoids at 50% probability level.

Supplementary data



CCDC 729257, 729258, 729259, 729260, 729261 and 729262 contains the supplementary crystallographic data for **2a**, **2b**, **3b**, **4a**, **4b** and **5a**. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

Scheme 1. The guaiacyl model molecules, vanillin (a), vanillic acid (b) and ferulic acid (c).

off and dried in a desiccator over solid KOH for 24 h, giving final air stable **1a**. Yield: 50% (300 mg, 0.34 mmol); UV–Vis λ_{max}/nm: 250, 340, 450 (sh), 650; IR $\bar{\nu}_{max}$/cm^{-1}: 3350 υ(OH), 2900, 1683, 1635, 1591, 1575 $\upsilon_{as}(O_2C)$, 1511, 1447, 1427, 1401 $\upsilon_s(O_2C)$, 1273; *Anal.* Calc. for $C_{40}H_{36}Cu_2O_{16}$ **1a** (M_r = 899.8): C, 53.4; H, 4.03. Found: C, 53.6; H, 4.22%. Magnetic susceptibility μ_{eff}/B.M.: 1.40; EPR: B_{z1} 15.3 mT, $B_{\perp 2}$ 459 mT, B_{z2} 583 mT, $g_{||}$ 2.35, $g_{\perp}$ 2.08, D 0.329 cm^{-1}, $-J$ 280 cm^{-1}.

*2.1.2. $[Cu_2(C_{10}H_9O_4)_4(C_6H_6N_2O)_2]\cdot 4CH_3CN$ (**2**), $[Cu_2(C_{10}H_9O_4)_4(C_6H_6N_2O)_2]$ (**2a**)*

Eighty milliliter of acetonitrile was added to a solid mixture of 130 mg (0.91 mmol) Cu_2O, 11 mg (0.11 mmol) CuCl and 405 mg (2.1 mmol) of ferulic acid (a diluted version as for **1**, with less CuCl and more Cu_2O to prevent further oxidation). The resulting mixture was allowed to stand in a closed flask at room temperature. The unreacted solid Cu_2O was removed next day by filtration, while the green filtrate was introduced dropwise into the flask with 81 mg (0.66 mmol) of solid nicotinamide ($C_6H_6N_2O$). Small light-green crystals of **2** were noticed and immediately filtered off to prevent side reactions to brown solid. The product **2** was dried in a desiccator over solid KOH for 24 h, resulting in the air stable light-green **2a**. Yield: 41% (309 mg, 0.27 mmol); UV–Vis λ_{max}/nm: 250, 340, 450 (sh), 660; IR $\bar{\nu}_{max}$/cm^{-1}: 3326 υ(OH), 2900, 1679, 1638, 1605, 1579 $\upsilon_{as}(O_2C)$, 1511, 1447, 1426, 1401 $\upsilon_s(O_2C)$, 1273; *Anal.* Calc. for $C_{52}H_{48}Cu_2N_4O_{18}$ **2a** (M_r = 1144.1): C, 54.6; H, 4.23; N, 4.90. Found: C, 54.9; H, 4.19; N, 4.38%. Magnetic susceptibility μ_{eff}/B.M.: 1.48; EPR: B_{z1} 18.3 mT, $B_{\perp 2}$ 461 mT, B_{z2} 582 mT, $g_{||}$ 2.37, $g_{\perp}$ 2.08, D 0.332 cm^{-1}, $-2J$ 245 cm^{-1}.

Some of the crystals obtained by the described procedures for **1** and **2** were suitable also for the XRD single-crystal analysis.

2.2. Measurements

Elemental (C, H, N) analysis was obtained using a Perkin–Elmer Elemental Analyzer 2400 CHN. Infrared spectra of the solid samples were recorded using a Perkin–Elmer Spectrum 100, equipped with a Specac Golden Gate Diamond ATR as a solid sample support. Electronic spectra with nujol suspensions were measured by a Perkin–Elmer UV/VIS/NIR Spectrophotometer Lambda 19. X-ray powder diffraction data were obtained using PANalytical X'Pert PRO MPD with Cu Kα radiation (λ = 1.5406 Å). The magnetic susceptibility data of powdered samples were measured with a Johnson Matthey Alfa Products Sherwood Scientific Magnetic Balance, using Evans's method. Diamagnetic corrections were estimated from Pascal's constants [24]. X-band powder EPR spectra were obtained at various temperatures with a Bruker ELEXSYS E500 spectrometer. The spectra of **1** and **2** were measured by the solid samples on the bottom of the closed tube in the presence of the mother liquid, while the final products **1a** and **2a** as a dry powder.

Single-crystal X-ray diffraction data were collected with a Nonius Kappa CCD diffractometer with the graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at room temperature for **1** and at 150 K for **2**, respectively. A multiscan absorption correction was performed [25]. The structures were solved by direct methods (SHELXS-97 [26] for **1** and SIR-97 [27] for **2**) and refined by a full-matrix least-squares procedure based on F^2 (SHELXL-97) [26]. Hydrogen atoms attached to N2 atoms in **2** were visible in the last stages of refinement and were refined freely. All the remaining H atoms in both structures were placed at calculated positions and treated using appropriate riding models. The atoms of CH_3CN molecules in **2** were refined isotropically and the H atoms of those molecules were not located. The residual density peak in structure of **2** (in the vicinity of CH_3CN molecule) was undefinable and therefore was not included in the model. The crystal data and details of the data collection and refinement are collected in Table 1.

3. Results and discussion

3.1. Crystal structures

X-ray structure determination of $[Cu_2(C_{10}H_9O_4)_4(CH_3CN)_2]$ **1** and $[Cu_2(C_{10}H_9O_4)_4(C_6H_6N_2O)_2]\cdot 4CH_3CN$ **2** reveals tetragonal-pyramidal (4 + 1) arrangement of copper(II) acetate hydrate type, with the inversion center located between copper(II) ions. The coordinated nitrogen atom of the acetonitrile (**1**)/nicotinamide (**2**) group is located on the top of the pyramid and four carboxylato oxygen atoms of four ferulic acid anions in the basal square-plane (Fig. 1). Cu–O (1.964(3)-1.970(3) Å for **1**, 1.965(3)–1.970(3) Å for **2**), Cu–N (2.182(4) Å for **1**, 2.176(3) Å for **2**) and Cu···Cu (2.6277(8) Å for **1**, 2.6371(12) Å for **2**) distances (Table 2) are in agreement with the values reported in the literature [28].

The binuclear moieties are mutually assembled in a canal-like 3D structure, held together by H-bonds (Fig. 2, Table 3). The corners of the canals in **1** are occupied by the dicopper moieties, while these corners are mutually connected by the ferulic acid anions on one side to the carboxylate group on the other. Each of two corners are H-bonded by two such bridges via head to tail orientation (O7–H7···O2 2.828(6) Å, 152°; O8–H8···O3 2.819(7) Å, 150°). The axial acetonitrile molecules in **1** are not H-bonded. A similar canal-like structure is found also in the crystal structure of **2** (Fig. 2), though some differences are noticed due to involvement of the axial nicotinamide ligands in the H-bonding network

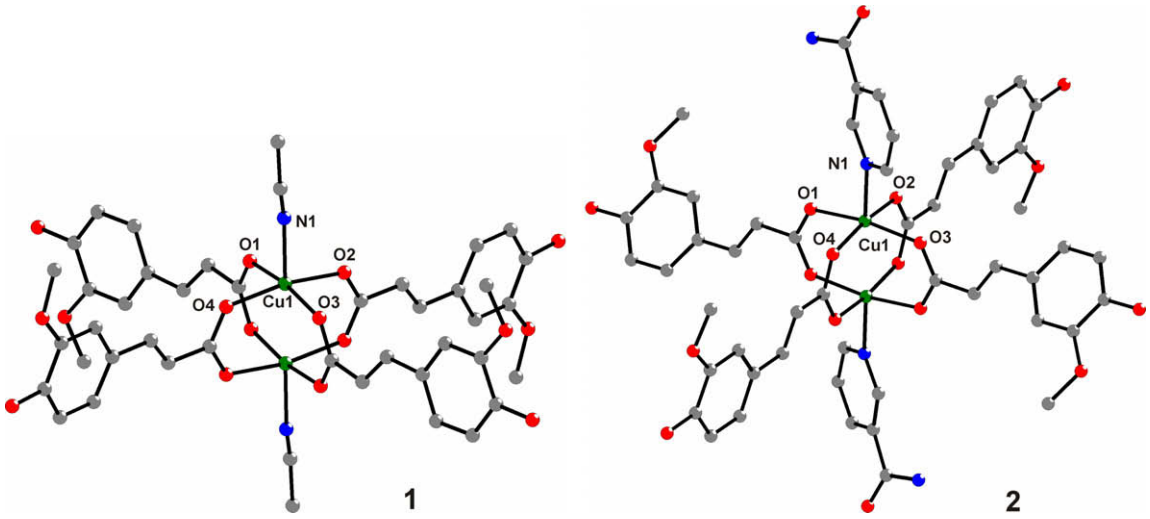

Fig. 1. Molecular structures of coordination compounds **1** and **2**. The hydrogen atoms of both compounds and the lattice CH_3CN molecules of **2** have been omitted for clarity.

(O8–H8···O1 2.738(3) Å, 154°; O7–H7···O8 2.771(3) Å, 151°; N2–H1N···O7 3.011(6) Å, 157(4)°). The solvent acetonitrile molecules in **2** do not participate in any distinguished H-bond, but are found in the voids of the canals. Therefore, the bridging nature of a ferulic acid anion via the carboxylato and phenolato groups is thus seen in both molecular structures of **1** and **2**. This may indeed be possible due to such a H-bonding network as well as coordination bonding. Nevertheless, a stability of **1** and **2** is strongly dependant on the acetonitrile molecules found in both compounds. Namely, the crystal structures of **1** and **2** are not stable outside mother liquid and they both decompose by removal of the acetonitrile molecules (CHN analysis, powder diffraction patterns – see the Supplementary data), giving the final solid products **1a** and **2a**, respectively. It seems that this decomposition is not destruct-

ing a whole structure (see the magnetic susceptibility and EPR analysis) and the dicopper tetracarboxylate moieties may be still present in **1a** and **2a**. Nevertheless, a preservation of the canal-like structure is not certain, though the removed acetonitrile molecules (**1** → **1a**, **2** → **2a**) seem not to support the molecular structures of **1** and **2** significantly. Contrary to **1** and **2**, a similar canal-like binuclear crystal structure with related vanillic acid anions in $[Cu_2(C_8H_7O_4)_4(C_6H_6N_2O)_2]$ [21] retains its 3D structure also outside mother liquid.

3.2. Magnetic susceptibility and EPR

The green color of the air stable **1a** and **2a** is suggesting a presence of copper(II), not differing much to the original solid **1** and **2** from the reaction mixture. Additionally, the room temperature effective magnetic moment μ_{eff}/B.M. 1.40 (**1a**) and 1.48 (**2a**) is as expected for the dicopper(II) tetracarboxylates with a strong antiferromagnetic (AFM) interaction between the dipoles taking place via four carboxylate bridges. A similar conclusion may be drawn from the EPR spectra that show three typical triplet signals ($E \sim 0$) for **1a** and **2a** showing B_{Z1} (15.3, 18.3 mT), $B_{\perp 2}$ (459, 461 mT), B_{Z2} (583, 582 mT) and $-2J = (280, 245\ cm^{-1})$ [29] (Fig. 3). The magnitude of the AFM coupling was determined using the EPR data and equations described by Wasserman (Supplementary) derived from the Hamiltonian (Eq. (1)) [30,31]. The room temperature EPR spectra of **1a** and **2a** additionally show the 300 mT $S = ½$ signals of mononuclear impurities. A weaker intensity of the $S = ½$ signals as compared to those of the triplet $S = 1$ (binuclear) shows that a majority of the copper(II) species remain

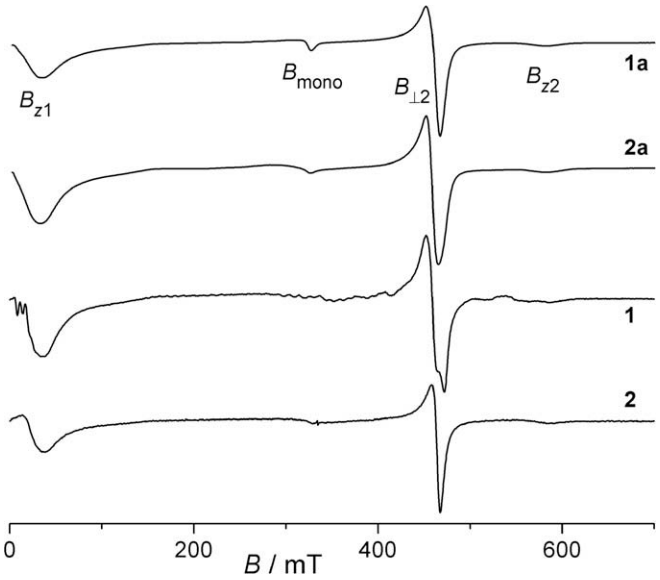

Fig. 3. The room temperature EPR spectra of the solid **1** and **2** (in a presence of the mother liquid) and of the final powdered solid products **1a** and **2a**, all showing the typical triplet signals of $S = 1$ system (**1a**: $g_{||} = 2.35$, $g_{\perp} = 2.08$, $D = 0.329\ cm^{-1}$, $-2J = 280\ cm^{-1}$; **2a**: $g_{||} = 2.37$, $g_{\perp} = 2.08$, $D = 0.332\ cm^{-1}$, $-2J = 245\ cm^{-1}$).

in the binuclear *paddle-wheel* units despite a decomposition (**1** → **1a**, **2** → **2a**). Additionally, the EPR spectra of **2** and **2a** are almost identical, while only some smaller deviations are noticed between the spectra of **1** and **1a** (E is not negligible for **1**). Due to a clear resemblance of the EPR spectra of both pairs, namely **1**/**1a** and **2**/**2a**, respectively, almost complete preservation of the dicopper tetracarboxylato core structure in **1a** and **2a** as found in **1** and **2** is firmly shown. This is proving also a coexistence of the 'oxidative' copper(II) cation and 'antioxidative' ferulic acid anion at a distance of a coordination bond.

$$\hat{H} = \beta B \cdot g \cdot \hat{S} + D\left(\hat{S}_{z^2} - \frac{2}{3}\right) + E(\hat{S}_{x^2} - \hat{S}_{y^2}) \quad (1)$$

4. Conclusions

The first two molecular structures of the coordination compounds with the ferulic acid anion, namely $[Cu_2(C_{10}H_9O_4)_4(CH_3CN)_2]$ **1** and $[Cu_2(C_{10}H_9O_4)_4(C_6H_6N_2O)_2]\cdot 4CH_3CN$ **2** are presented. Due to the reported antioxidative properties of the ferulic acid, and unsuccessful application of copper(II) starting compounds, copper(I) species were used as the starting materials in the acetonitrile solution. Outside the mother liquid, both compounds **1** and **2** decompose by the acetonitrile evaporation, thus giving the final $[Cu_2(C_{10}H_9O_4)_4]$ **1a** and $[Cu_2(C_{10}H_9O_4)_4(C_6H_6N_2O)_2]$ **2a**. The central core structure of the final products most probably remains as in **1** and **2**, as suggested by the magnetic susceptibility data and the EPR spectra. It is thus shown that the 'antioxidative' ferulic acid may be stable in the presence of the 'oxidative' copper(II) ions in the acetonitrile solution and in the solid state. The bridging nature of the ferulic acid is seen herein by the coordination as well as by the H-bonding, both playing the key role in the structure stabilization.

There are antecedents that the complexation of several drugs with copper ions caused changes in the pharmacological and physiological effects. For instance, copper complex of pindolol has shown higher efficiency than the free ligand regarding its effect on the heart rate of rats [10]. Besides, in the literature reports of several copper complexes with beta-blocker antihypertensive drugs can be found [11,12] but only a few X-ray crystallographic structures have been reported [10,13,14] and none of them with propranolol.

Due to these antecedents and in order to continue our studies on medicinal chemistry [15–17], our aim was to obtain copper beta-blocker complexes in the search of new species with better pharmacological properties and/or that will provide biological information.

In this work, the synthesis and spectroscopic characterization of a new copper complex with propranolol (1-(isopropylamino)-3-(1-naphthyloxy)-2-propanol) are presented.

Fig. 1 shows the structure of propranolol, showing the amino and hydroxyl groups suitable for coordination of metal ions.

First of all we studied the structure in solid state. The X-ray crystal structure of $[Cu(propranolol)_2]\cdot 2H_2O$ was determined and the IR and EPR spectra were analyzed. Besides, this work is the first that reports the chirality of the beta-blocker ligands coordinated to copper. This is an important datum for understanding the pharmacological properties due to the fact that the enantioselectivity influences the pharmacokinetics of these drugs and also it is associated with changes in the pharmacodynamic profile [18].

The structural information in solid state was used as a base for the characterization of the species in DMSO solution that will be administered in the biological assays. Besides, the stability of this solution was studied. Moreover, an analysis of the effect on the contraction force and heart rate, and the block of response to adrenaline were performed.

2. Experimental

2.1. Synthesis of the complex and analytical characterization

Aqueous solutions of *dl*-propranolol hydrochloride (1 mmol, 0.295 g), SIGMA and of $CuSO_4\cdot 5H_2O$ (0.5 mmol, 0.085 g), FLUKA were mixed. After stirring 1 mL of 1 M NaOH was added. Upon mixture a violet precipitate was formed. It was washed with water and recrystallized from methanol. The violet crystals obtained were separated by filtration and dried at room-temperature.

The elemental analysis was performed with a Carlo Erba EA1108 elemental analyzer and copper content was determined by iodimetry.

Anal. Calc. for $[Cu(propranolol)_2]\cdot 2H_2O$ ($C_{32}H_{44}N_2O_6Cu$): C, 62.37; N, 4.55; H, 7.20; Cu, 10.31. Found: C, 62.00; N, 4.44; H, 7.11; Cu, 10.31. Yield 38%.

2.2. Crystal structure determination of $[Cu(propranolol)_2]\cdot 2H_2O$

Room temperature X-ray diffraction data collection for $[Cu(propranolol)_2]\cdot 2H_2O$ was performed on an Enraf-Nonius Kappa-CCD diffractometer, using graphite-monochromated Mo Kα radiation (0.71073 Å). Data were collected up to 50.0° in 2. The final unit cell parameters were based on all reflections. Data collections were made using the COLLECT program [19]. Integration and scaling of the reflections were performed with the HKL Denzo–Scalepack system of programs [20]. Multi-scan absorption corrections were applied [21].

The structure was solved by direct methods with SHELXS-97 [22]. The model was refined by full-matrix least-squares on F^2 with SHELXL-97 [23]. All the hydrogen atoms were stereochemically positioned and refined with the riding model [23]. Data collections and experimental details for the complexes are summarized in Table 1. The programs SHELXL-97, and ORTEP-3 [24] were used within WINGX [25].

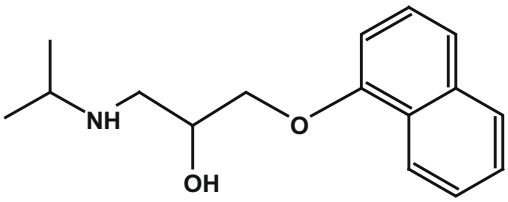

Fig. 1. Scheme of propranolol.

2.3. Spectroscopic measurements

Electronic spectrum of a DMSO solution was registered on a Milton Roy Spectronic 3000 spectrophotometer.

Low-temperature (77 K) EPR experiments were performed using a Varian E109 spectrometer equipped with a rectangular cavity. To perform the experiments on solution-state samples, powder samples of the titled complexes were dissolved in DMSO. The solution-state samples were then centrifuged, and the supernatants were drawn in a quartz sample tube for low-temperature EPR experiments. General experimental conditions were: microwave power, 20 mW; modulation amplitude, 2.0 G; modulation frequency, 100 kHz. The g- and A-values were obtained by means of spectral simulation using the software package EASYSPIN [26].

IR spectra, in the range between 4000 and 200 cm^{-1}, were recorded on a BOMEM M 102 FTIR spectrophotometer using the KBr pellet technique.

2.4. Thermogravimetric measurements

Thermogravimetric measurements were obtained with a Shimadzu TGA 50 thermobalance, with a platinum cell, working under flowing air (50 mL min^{-1}) and at a heating rate of 6 °C min^{-1}.

2.5. Stability tests

Conductimetric measurements using a Conductivity Meter 4310 Jenway were performed at 37 °C in a DMSO solution (0.5×10^{-3} M). Besides, the DMSO solution was mixed (1:10) with Tyrode solution and the absence of turbidity was observed. Both tests were performed with the aim of studying the stability of the complex in the solution that was administered in the biological studies.

2.6. Biological evaluation by Langendorff technique

The biological evaluation of the complex and the free ligand was performed using an isolated heart technique according to Langendorff [27].

Guinea pigs weighing 400–600 g were heparinized (1000 UI/kg) 10 min before the procedure. Then they were anaesthetized with a sodium pentothal intraperitoneal injection (50 mg/kg).

The hearts were rapidly removed and placed into a dish containing oxygenated Tyrode solution (see composition below) at room-temperature. The aorta was cannulated and the heart was perfused retrogradely via the aortic cannula, at a constant flow rate of 6 mL min^{-1} with Tyrode solution containing: NaCl 137, KCl 2.68, $MgCl_2$ 1.05, $NaHCO_3$ 12, $CaCl_2$ 1.8, NaH_2PO_4 0.38, glucosa 5.5 nM.

By means of Langendorff equipment the perfusate was kept at 36 ± 1 °C. Solution was aerated with a gas mixture of 95% of O_2 and 5% of CO_2 in order to obtain a pH of 7.4. Myocardial contractile force was evaluated measuring the left ventricular pressure. The left atrial appendage was removed to access to the mitral valve orifice, a small hand-made latex balloon was inserted through it, and placed into the left ventricular cavity. The balloon previously filled with saline solution was connected to a pressure transducer (Statham) by means of a catheter. The manometer was connected to a suitable amplifier, and the signals were fed into a digital to analog converter device (Lab Master). Finally signals were displayed and stored into a computer. The basal conditions were controlled and the experiments were started after the parameters reached a steady state.

The protocol followed for the determination of the effect on contraction force and heart rate was the following:

A *bolus* of 0.1 mL of propranolol solution in DMSO (10^{-3} M, $n = 5$) or 0.1 mL of [Cu(propranolol)$_2$]·$2H_2O$ solution in DMSO (0.5×10^{-3} M, $n = 5$) was administered, both equimolar solutions in propranolol. The contraction force and heart rate were measured before and after administration.

The protocol followed for the determination of the inhibition of response to adrenaline was the following:

The heart was stimulated with a *bolus* of 0.1 mL of adrenaline 30 M injected through the side branch of the perfusion cannula. The response in terms of contraction force and heart rate was measured. After this stimulation, the heart was washed and stabilized with the perfusion solution for 15 min. Then a *bolus* of 0.1 mL of propranolol solution

(10^{-3} M, $n = 5$) or 0.1 mL of [Cu(propranolol)$_2$]· $2H_2O$ solution (0.5×10^{-3} M, $n = 4$), was administered and the heart was stabilized during 4 min. Finally, a similar dose of adrenaline was injected and the response was measured and compared with the first stimulation.

Controls with *bolus* of Tyrode, DMSO and with copper salt dissolved in DMSO were performed in both protocols.

3. Results and discussion

3.1. Crystal structure of [Cu(propranolol)$_2$].$2H_2O$

The copper complex crystallized in a triclinic system with a $P\bar{1}$ spatial group as shown Table 1.

The structure consists of two units, each containing a copper center coordinated to two deprotonated propranolol molecules acting as a bidentate ligand, in a distorted square-based environment. Fig. 2 presents an ORTEP view of a unit, showing the atom labels and 50% probability ellipsoids. As Fig. 2 shows each copper ion coordinates through the N atom from the amine group and the O atom from the alkoxide, in a *trans* geometry.

The crystal structure is completed with the presence of two hydration water molecules per complex. Selected bond distances and angles around the copper center are summarized in Table 2.

In comparison with related copper compounds, Cu–$O_{alcohol}$ distances found in this work (1.874 and 1.894 Å) are shorter than those of the Cu(II) complex with nadolol (1.910 Å) [28], with etilefrin (Effortil) (1.905 Å) [29], with propafenone (1900 Å) [30] and clenbuterol (1898 Å) [31] and for one of the Cu–O bonds from the Cu(II) complex with oxprenolol (1.909 Å) [13]. In the case of Cu–N_{amine} distances (2.020 and 2.033 Å) the results are similar to those reported for the compounds mentioned above. The dihedral angle between the planes determined by O11–N1–Cu and O21–N2–Cu is 20.5(3)°, showing the distortion of the arrangement.

The centrosymmetry of the space group found in this work requires that both the R,R and S,S complexes be present. This new complex presents different propranolol isomers coordinated to each copper ion. As it is known propranolol has one chiral carbon

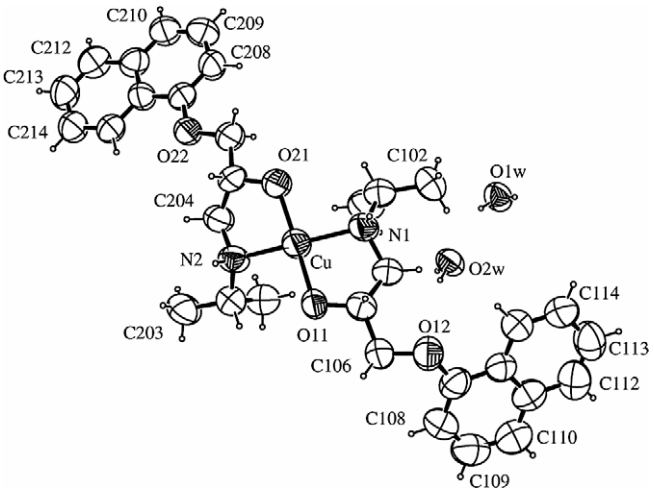

Fig. 2. ORTEP view of one unit of the complex, showing the atom labeling and the 50% probability ellipsoids.

atom and it can form two enantiomers. The usual pharmaceutical formulations are prepared with the racemic mixture. In the synthesis of $[Cu(propranolol)_2]\cdot 2H_2O$ a racemic mixture of propranolol was used but as Fig. 3 shows, each copper unit in the obtained structure coordinates with the same isomer, and the compound could be better described as $[Cu(R\text{-propranololate})_2][Cu(S\text{-propranololate})_2]\cdot 4H_2O$.

No report of the coordinated isomers was found in the previously referred articles related to copper complexes with beta-blockers.

The study of the crystal packing shows that the three-dimensional structure is stabilized by six intermolecular hydrogen bonds as shown in Table 3.

All these intermolecular interactions give rise to the formation of double infinite chains and layers of complex molecules alternate with layers of water molecules (see Fig. 4).

This particular crystal packing, with its water channels could be important for pharmacotechnic processes.

3.2. Thermogravimetric measurements

Thermogravimetric results showed that the weight loss at 50–85 °C range was 6%, in accordance with the release of two hydration water molecules. Beyond 230 °C the degradation of the ligand was observed.

3.3. Stability tests

The conductivity of a DMSO solution of $[Cu(propranolol)_2]\cdot 2H_2O$ was very similar to that of the pure solvent. This behavior is in agreement with the neutral charge of the complex, according to the stoichiometry. In addition, the conductivity was measured during 24 h and no major changes were observed. This result showed that the complex maintained the neutral charge and therefore the Cu–propranolol bonds remained in the structure in solution. Besides, when the DMSO solution of the complex was mixed with the Tyrode solution no turbidity was observed. Taking into account that the propranolol is insoluble in this solution, this result shows that the propranolol is not free.

3.4. Spectroscopic measurements

The electronic spectrum of $[Cu(propranolol)_2]\cdot 2H_2O$ in DMSO presented one broad band at 685 nm, due to the d–d band transition. This result is in agreement with the reported data for the square planar CuN_2O_2 chromophore [32]. The substitution of the propranolol molecules by DMSO is not observed since the spectrum of copper sulfate in DMSO shows a $\lambda_{max} = 813$ nm.

Low-temperature X-band EPR spectra of the titled compound in the polycrystalline form displayed a single resonance around ~330 mT (Fig. 6A) with no detectable hyperfine interaction between the magnetic moments of the $S = 1/2$ d^9 copper unpaired electron and of the $I = 3/2$ copper nuclear spin. The powder-like spectra is characteristic of monomeric species interacting via weak superexchange interactions, which smear out the hyperfine lines, and are probably mediated by non-covalent bridges as is usually observed in copper complexes in the solid state [33,34]. Simulation of that spectrum yielded g-values: $g_x = g_y = 2.0407$ (perpendicular direction) and $g_z = 2.1312$ (parallel direction), thus indicating an axially symmetric environment experienced by the copper ion, which is in good agreement with the structural data presented above.

Upon dilution in DMSO solvent, EPR spectra of the compound at liquid nitrogen temperature readily showed the four hyperfine

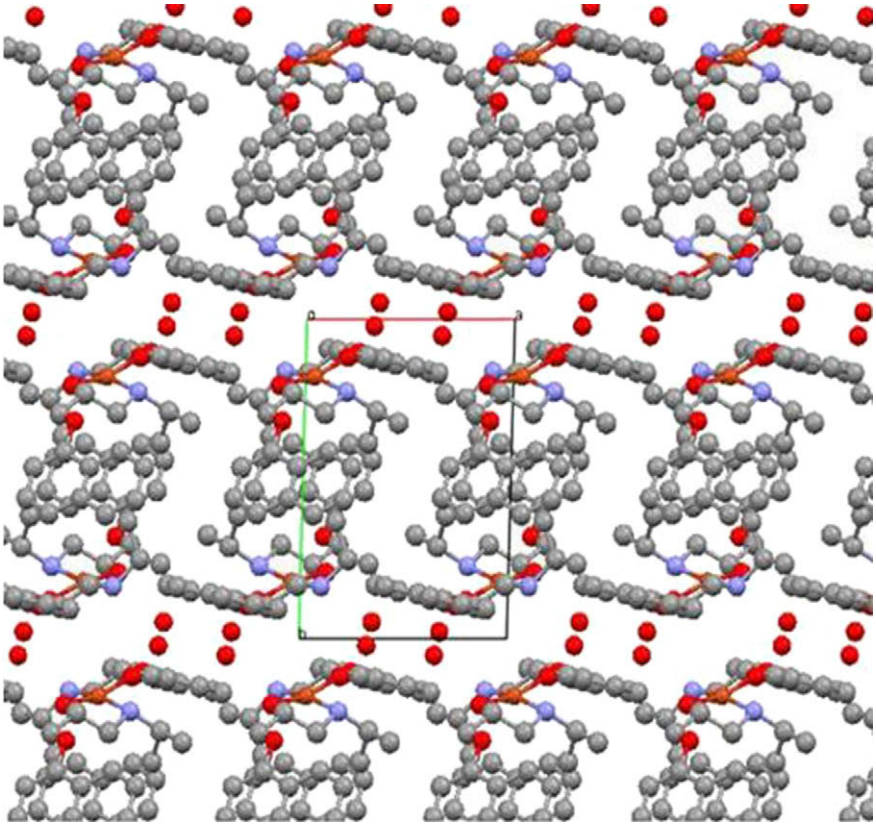

Fig. 4. Crystal packing of $[Cu(propranolol)_2]\cdot 2H_2O$ along *c*-axis.

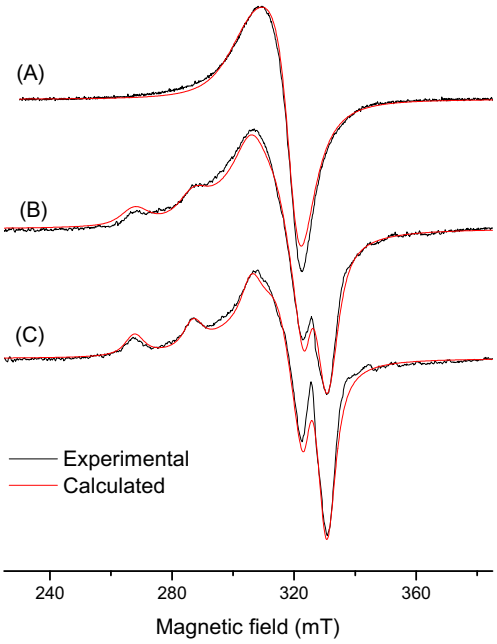

Fig. 5. Low-temperature X-band EPR spectra of $[Cu(propranolol)_2]\cdot 2H_2O$ in: (A) solid state, (B) fresh DMSO solution and (C) DMSO solution after 24 h of the dilution experimental and calculated spectra are shown as black and red lines, respectively. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

lines (Fig. 6B) characteristic of a $S = 1/2$ spin system interacting with $I = 3/2$ nuclear spin. The appearance of hyperfine structure suggests that the connections supporting exchange interactions in the solid state are disrupted upon dilution in DMSO, indicating that those connections are not provided by covalent bonds between monomers. To further characterize this spectrum, theoretical simulation was performed using the software EASYSPIN. The simulation involved the use of a spin Hamiltonian constituted by Zeeman and hyperfine interactions along with two linewidth parameters that take care of extra broadening mechanisms. The final calculated spectrum showed a very good agreement with the experimental data and the best-fit magnetic parameters (g and hyperfine) thus determined were: $g_x = 2.059$, $g_y = 2.025$, $g_z = 2.200$, $A_z = 19.2$ mT. The values of the A_x and A_y components could not be determined since the spectrum does not show any splitting due to those components. The g_z and A_z values can be used to determine the atoms coordinated to the copper ion following the method of Peisach that correlate those values with the coordination sphere of copper in several complexes [35]. In our case, the values of g_z and A_z indicate a N_2O_2 equatorial coordination that agrees with the X-ray single-crystal data presented above. Thus, in solution the copper environment is distorted from its solid state axial symmetry, without changes in atoms coordinated (it is maintained with two nitrogen and two oxygen atoms).

To investigate the structural stability of the compound after dilution in DMSO, we also performed a low-temperature EPR experiment on a sample after 24 h of dilution in DMSO. The spectrum is shown in Fig. 5C and shows no major difference when compared with the spectrum measured right after mixture with DMSO (Fig. 5B). The simulation of this last spectrum resulted in the same set of magnetic parameters except for the line widths parameters, which had to be readjusted to achieve optimal fitting of the experimental data. This strongly suggests that the structure of the compound is stable without major difference 24 h after dilution in DMSO.

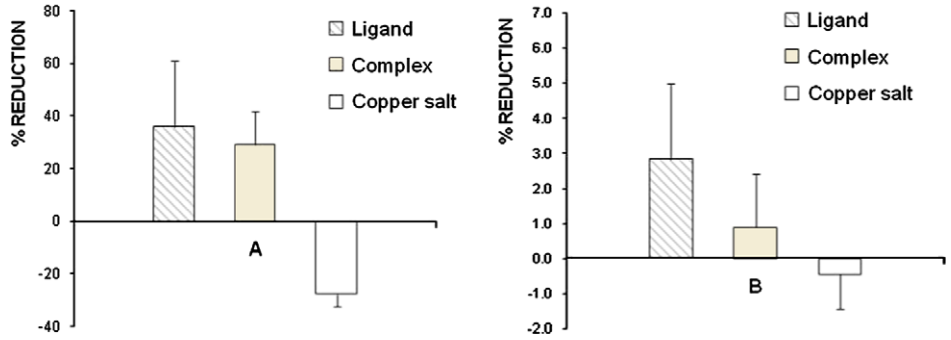

Fig. 6. Effect of *bolus* of $[Cu(propranolol)_2]\cdot 2H_2O$ (0.5×10^{-3} M), propranolol (10^{-3} M) and copper salt (0.5×10^{-3} M) on myocardial contractile force (A) and heart rate (B).

The IR spectrum of the complex was compared with that of the free propranolol and the similar reported complexes [14,36–39].

The free ligand spectrum exhibits three strong bands at 3323, 3281 and 3227 cm^{-1} corresponding to the ν(OH), νa(–NH_2^+–) and νs(–NH_2^+–) engaged in H-bonds. In addition, combination bands, enhanced by Fermi resonance, are found in the range 2710–2395 cm^{-1} [14,36,38]. The $NH2^+$ deformation band is overlapped by the aromatic bands.

After coordination the –NH_2^+– is deprotonated and a band at 3377 cm^{-1} is observed in the complex spectrum in agreement with bibliographic data [36]. Furthermore the disappearance of the bands due to the combination modes, which is characteristic of the protonated amines, is also in agreement with the coordination through this group.

Regarding OH group, in the complex spectrum there is one less band in the range assigned to ν(OH) and ν(–NH_2^+–) engaged in H-bonds, due to the deprotonation of this group upon coordination, and the band at 1324 cm^{-1} in the free ligand, corresponding to σ(HC–OH) shifts to 1312 cm^{-1} upon complexation. This behavior supports the coordination through this group. Further evidence of this is found in the fact that the ν(C–O) band of the ligand at 1107 cm^{-1} shifts to 1098 cm^{-1} [36].

Another observation in the complex spectrum is the appearance of new bands at 604 cm^{-1} and 497 cm^{-1}, assigned to Cu–N and Cu–O bonds respectively, in accordance with bibliographic data [14].

3.5. Biological evaluation

3.5.1. Determination of the effect on contraction force and heart rate

Fig. 6 shows the effect of the administration of propranolol (10^{-3} M), $[Cu(propranolol)_2]\cdot 2H_2O$ (0.5×10^{-3} M) and copper salt (0.5×10^{-3} M) on myocardial contractile force and heart rate.

As can be seen in Fig. 7A the effect of propranolol and $[Cu(propranolol)_2]\cdot 2H_2O$ on myocardial contractile force is to reduce it to a rather similar extent. On the other hand, both complex and free ligand reduced heart rate but the reduction obtained with the complex is lower than that obtained with the free ligand, as shown in Fig. 7B. The reduction on the heart rate performed by the complex is approximately 30% of that produced by the free ligand.

The controls performed with DMSO and Tyrode did not significantly change the signals. On the contrary, the *bolus* of Cu(II) salt produced a slight increase both in myocardial contractile force and heart rate, which differs from the copper complex's effect.

3.5.2. Determination of inhibition of response to adrenaline

Fig. 7 shows that both species block the response to adrenaline to a similar extent when contractility is measured. Adrenaline's effect on heart rate was blocked by either complex or ligand at the dose used.

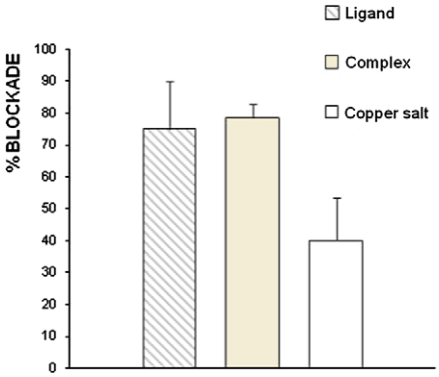

Fig. 7. Percentage of blockade of the complex (0.5×10^{-3} M), free propranolol (10^{-3} M) and copper salt (0.5×10^{-3} M) measuring the response as variation in myocardial contractile force.

The control performed with Cu(II) salt (0.5×10^{-3} M), produced a much lesser blockade when contractility was measured.

4. Conclusions

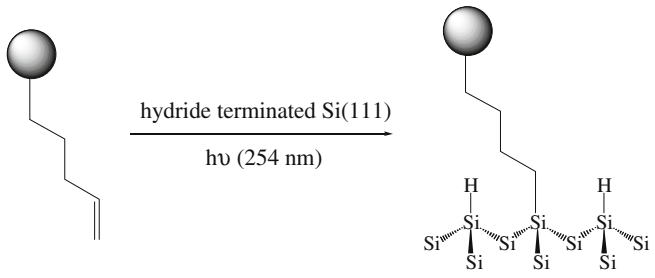
A new Cu–propranolol complex was synthesized and characterized by spectroscopic measurements including X-ray diffraction. Specially the chirality of this new complex was observed showing that the compound could be better described as $[Cu(R\text{-propranololate})_2][Cu(S\text{-propranololate})_2]\cdot 4H_2O$. Besides, in accordance with the conductivity assay, the electronic spectrum, the propranolol is still coordinates with copper ion in a 10^{-3} M DMSO solution. The magnitude of A_z and g_z obtained from the EPR spectra indicated that Cu is equatorially coordinated through two nitrogen and two oxygen atoms. These structural data in solution agree with the X-ray single-crystal data. In addition, the conductivity measurements and the EPR spectra showed that this solution is stable at least during 24 h.

About the biological assay, the effect of $[Cu(propranolol)_2]\cdot 2H_2O$ on contractility was very similar to that of the free propranolol while the reduction on the heart rate is approximately 30% of that of the free ligand. The block of the response to adrenaline is at least similar for both ligand and complex. Therefore we obtained a new complex that affects specially the contractility and to a minor extent the heart rate.

The results are certainly encouraging due to the fact that the search for new beta-blocker drugs that have lesser effect on heart rate is one of the important topics in cardiac pharmacology.

Supplementary data

CCDC 682936 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge via



<http://www.ccdc.cam.ac.uk/conts/retrieving.html>, or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223-336-033; or e-mail: deposit@ccdc.cam.ac.uk.

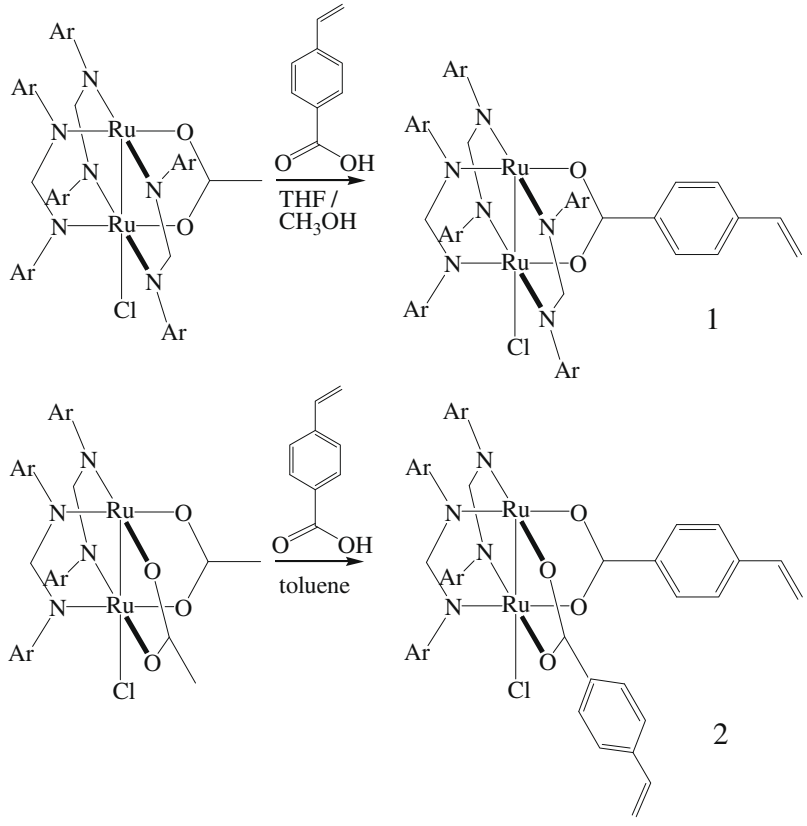
Scheme 1. Functionalization of Si surface with olefin-capped molecule (solid ball represent the head group).

satisfactory combustion analysis results. All four compounds are paramagnetic with the room temperature effective magnetic moments in a narrow range of 3.81–3.93 Bohr magneton, which is consistent with the presence of three unpaired electrons [12,16].



2.2. Molecular structures

Both compounds **1** and **2** crystallize in the space group $P\bar{1}$, and the asymmetric unit contains a complete diruthenium molecule in each case. The structural plot of **1**, Fig. 1, reveals the presence of three D(3,5-Cl_2Ph)F ligands and one 4-vinylbenzoate around the diruthenium core. The coordination sphere of the Ru_2 unit is completed with a chloro and a water ligand in the axial positions, which were disordered over both axial sites and refined with 50% occupancy each for Cl and O (labeled as Cl′ in Fig. 1). Hence, the Ru–Cl′ distance is shorter than the Ru1–Cl1 bond in **2** but longer than the Ru–O(OH_2) distance in Ru_2(D(3,5-Cl_2Ph)F)$_2$(μ-O_2CMe)$_2$Cl(H_2O) (2.362 Å) [9]. It is clear from the structural plot of **2** (Fig. 2) that the coordination sphere of the Ru_2 unit consists of two D(3,5-Cl_2Ph)F and two 4-vinylbenzoate bridging bidentate ligands in a *cis*-arrangement, and a chloro and an ethanol axial ligands.

Listed in Table 1 are the selected bond lengths and angles data for compounds **1** and **2**. The Ru–Ru bond length in **1** (2.3381(4) Å) is slightly longer than that in the precursor Ru_2(D(3,5-Cl_2Ph)F)$_3$(μ-O_2CMe)Cl (2.3220(7) Å), and the shortness of Ru–Ru bond in the latter is attributed to the absence of axial water ligand [9]. The Ru–Ru bond length in **2** (2.319(2) Å) is slightly shorter than that of and Ru_2(D(3,5-Cl_2Ph)F)$_2$(μ-O_2CMe)$_2$Cl(H_2O) (2.327 Å) [9], reflecting the weak ligating ability of ethanol in comparison with water. The equatorial Ru–O and Ru–N bond lengths are all in good agreement with those of related compounds reported earlier [9,11].

2.3. Voltammetry

Similar to other Ru_2(DArF)$_{4-x}$(carboxylate)$_x$ type compounds, compounds **1**–**4** display cyclic voltammograms (CV, Fig. 3) with rich features. Common to all compounds are three Ru_2-centered one-electron events: the quasi-reversible oxidation (**A**), quasi-reversible reduction (**B**), and subsequent irreversible reduction (**D**) as illustrated in Scheme 3. It is clear from Table 2 that the mono-carboxylate species **1**, **3** and **4** have nearly identical electrode potentials. Interestingly, the voltammetric characteristic of the dicarboxylate species **2** is comparable to those of the other three compounds, except that the couple **D** of **2** is anodically shifted. Additional features such as peaks **C** and **E** are related to the dissociation/association of the chloro ligand (Scheme 3), as discussed in our prior study of related species [11]. Peaks **F** and **G** are also prevalent and could be related to the dissociation/association of axially bound solvent molecule, although there is no concrete evidence supporting this speculation.

Scheme 2. Preparation of diruthenium-4-vinylbenzoate compounds.

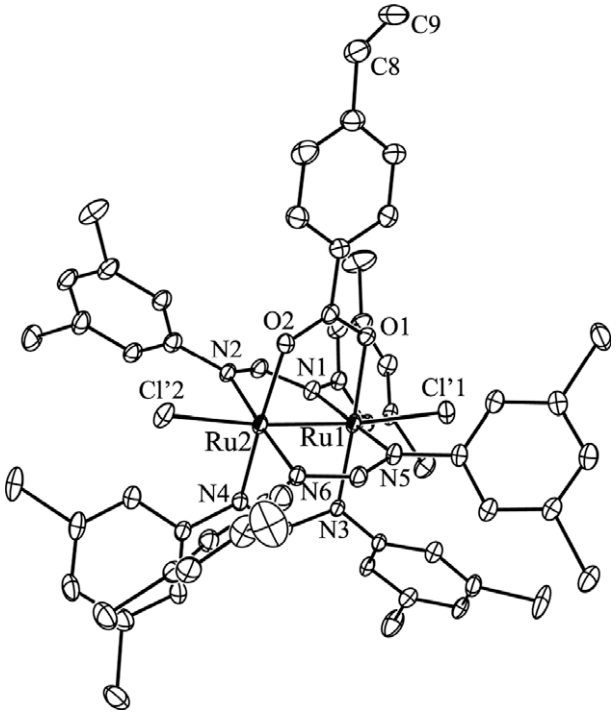


Fig. 1. Structural plot of molecule **1**. Hydrogen atoms were omitted for clarity.

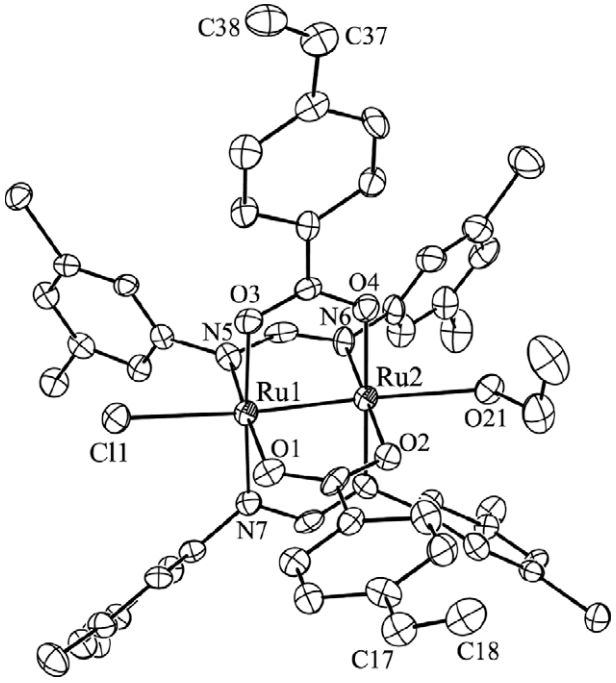

Fig. 2. Structural plot of molecule **2**·(HOEt). Hydrogen atoms were omitted for clarity.

3. Conclusion

We have successfully prepared several diruthenium species with terminal olefin that may be suitable for photolytic immobilization on Si surfaces, and are currently exploring and optimizing conditions for the immobilization of these novel Ru_2 compounds on various Si surfaces.

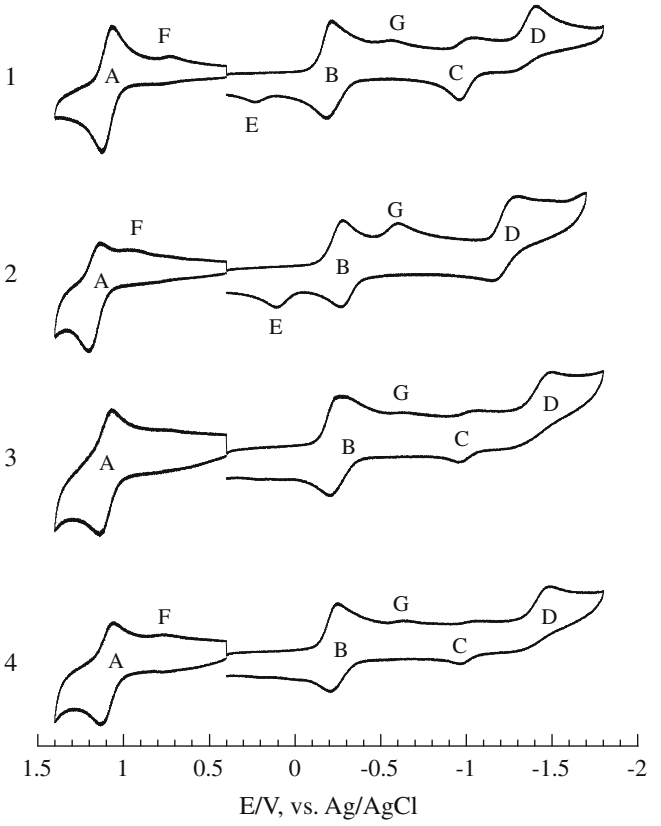

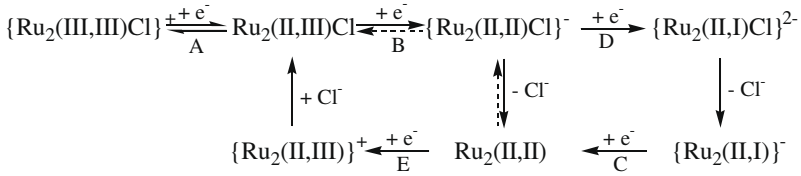

Fig. 3. Cyclic voltammograms of compounds **1–4** recorded in 0.20 M THF solution of Bu_4NPF_6 at a scan rate of 0.10 V/s.

4. Experimental

4.1. General

4-Vinylbenzoic acid, 5-hexenoic acid, and 6-heptenoic acid were purchased from Aldrich. $Ru_2(D(3,5\text{-}Cl_2Ph)F)_3(OAc)Cl$ and *cis*-$Ru_2(D(3,5\text{-}Cl_2Ph)F)_2(OAc)_2Cl$ were prepared using a literature procedure [9]. Vis–NIR spectra in THF were obtained with a JASCO V-670 UV–Vis–NIR spectrophotometer. Magnetic susceptibility was measured at 294 K with a Johnson Matthey Mark-I magnetic susceptibility balance. Cyclic voltammograms were recorded in 0.2 M *n*-Bu_4NPF_6 solution (THF, N_2-degassed) on a CHI620A voltammetric analyzer with a glassy carbon working electrode (diam-

Table 2
Electrode potentials of compounds **1–4**.

Compounds	$E_{1/2}$(**A**) (V)	$E_{1/2}$(**B**) (V)	E_{pc}(**D**) (V)
1	1.09	−0.20	−1.41
2	1.17	−0.27	−1.29
3	1.11	−0.22	−1.50
4	1.10	−0.23	−1.48

eter = 2 mm), a Pt-wire auxiliary electrode, and a Ag/AgCl reference electrode. The concentration of diruthenium species is always 1.0 mM. The ferrocenium/ferrocene couple was observed at 0.606 V (versus Ag/AgCl) under the experimental conditions.

4.2. Preparation of $Ru_2(D(3,5\text{-}Cl_2Ph)F)_3(\mu\text{-}O_2CC_6H_4\text{-}4\text{-}CH{=}CH_2)Cl$ (**1**)

A mixture of $Ru_2(D(3,5\text{-}Cl_2Ph)F)_3(OAc)Cl$ (200 mg, 0.15 mmol), 4-vinylbenzoic acid (222 mg, 1.5 mmol), THF (20 mL), and methanol (20 mL) was refluxed in air overnight. After the solvent removal, the residue was washed with H_2O, ethanol and hexanes to yield a purple solid. Further purification was carried out by recrystallization from a mixed solvent of THF/ethanol (1:5, v:v) to yield a purple solid (172 mg, 83% based on Ru). Vis, λ_{max} (nm, $\varepsilon(M^{-1}\,cm^{-1})$): 520(5000). *Anal. Calc.* for $C_{48}H_{31}N_6O_2Cl_{13}Ru_2{\cdot}H_2O$: C, 41.04; H, 2.37; N, 5.98. Found: C, 40.85; H, 2.36; N, 5.78%. $\mu_{eff} = 3.93\mu_B$.

4.3. Preparation of cis-$Ru_2(D(3,5\text{-}Cl_2Ph)F)_2(\mu\text{-}O_2CC_6H_4\text{-}4\text{-}CH{=}CH_2)_2Cl$ (**2**)

A 100 mL round-bottom flask was charged with *cis*-$Ru_2(D(3,5\text{-}Cl_2Ph)F)_2(OAc)_2Cl$ (200 mg, 0.20 mmol), 4-vinylbenzoic acid (65 mg, 0.44 mmol) and 40 mL toluene. The flask was mounted with a MicroSoxhlet extractor containing a thimble filled with K_2CO_3. The reaction mixture was refluxed in air for 6 h. Solvent was removed, and the residue was washed with H_2O, ethanol and hexanes to yield a dark red solid. Further purification was carried out by recrystallization from a mixed solvent of THF/ethanol (1:5, v:v) to yield a purple solid (182 mg, 76% based on Ru). Vis, λ_{max} (nm, $\varepsilon(M^{-1}\,cm^{-1})$): 535(3550). *Anal. Calc.* for $C_{44}H_{30}N_4O_4Cl_9Ru_2{\cdot}THF$: C, 45.32; H, 3.01; N, 4.40. Found: C, 45.18; H, 3.02; N, 4.38%. $\mu_{eff} = 3.81\mu_B$.

4.4. Preparation of $Ru_2(D(3,5\text{-}Cl_2Ph)F)_3(\mu\text{-}O_2CCH_2CH_2CH_2CH{=}CH_2)Cl$ (**3**)

A mixture of $Ru_2(D(3,5\text{-}Cl_2Ph)F)_3(OAc)Cl$ (200 mg, 0.15 mmol), 5-hexenoic acid (0.18 mL, 1.5 mmol), THF (20 mL), and methanol (20 mL) was refluxed in air overnight. After the solvent removal, the resultant oily residue was dissolved in dichloromethane, and then washed with water, brine and dried with anhydrous Na_2SO_4. After the solvent removal, the residue was mixed with small amount of *n*-pentane, and kept at −20 °C overnight. The precipitate was collected by filtration and washed with a mixed solvent of THF/*n*-pentane (1:10, v:v) to yield a purple solid (145 mg, 71% based on Ru). Vis, (nm, $\varepsilon(M^{-1}\,cm^{-1})$): 520 (5100). *Anal. Calc.* for $C_{45}H_{33}N_6O_2Cl_{13}Ru_2{\cdot}THF$: C, 41.30; H, 2.90; N, 5.90. Found: C, 41.35; H, 2.58; N, 5.87%. $\mu_{eff} = 3.91\mu_B$.

4.5. Preparation of $Ru_2(D(3,5\text{-}Cl_2Ph)F)_3(\mu\text{-}O_2CCH_2CH_2CH_2CH_2CH{=}CH_2)Cl$ (**4**)

This compound was prepared using the same synthetic procedure as that of the above compound except that 6-heptenoic acid (0.20 mL, 1.5 mmol) was used in place of 5-hexenoic acid. Yield: 150 mg (73% based on Ru). Vis, (nm, $\varepsilon(M^{-1}\,cm^{-1})$): 520(5520). *Anal.* Calc. for $C_{46}H_{35}N_6O_2Cl_{13}Ru_2{\cdot}0.5THF$: C, 41.10; H, 2.80; N, 5.99. Found: C, 41.08; H, 2.55; N, 6.01%. $\mu_{eff} = 3.90\mu_B$.

4.6. X-ray diffraction study of compounds **1** and **2**

Single crystals of compound **1** and **2** were obtained by slow diffusion of hexanes into a THF solution and slow cooling of a THF/ethanol (1:5, v:v) solution in refrigerator, respectively. The X-ray intensity data were collected at 150 K on a Nonius Kappa CCD X-ray diffractometer system using Mo Kα (λ = 0.71073 Å). The structures were solved by direct methods using SIR2004 [17] and refined using the SHELX-97 in the space group $P\bar{1}$ for both **1** and **2** [18]. The asymmetric unit of **1** contains one diruthenium molecule and three THF solvent molecules, while that of **2** contains one diruthenium molecule, a coordinating ethanol and four interstitial ethanol molecules. Relevant information on the data collection and the figures of merit of final refinement are listed in Table 3.

Supplementary data

CCDC 735349 and 735350 contain the supplementary crystallographic data for **1** and **2**, respectively. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/conts/retrieving.html, or from the Cambridge Crystallographic Data Centre, 12

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2009, volume 28 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2009, volume 28 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2009, volume 28 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

M. Yamashita *(Sendai, Japan)*

Aims and Scope

Polyhedron will publish original, fundamental, experimental and theoretical work of the highest quality in all the major areas of inorganic chemistry. These include synthetic chemistry, coordination chemistry, organometallic chemistry, bioinorganic chemistry, and solid-state and materials chemistry. Papers should be complete pieces of work, and the inclusion of results from spectroscopic and/or physical techniques is encouraged. Papers merely reporting the preparation and X-ray structural characterization of only a single compound will not be considered appropriate unless the compound and its structure are particularly interesting.

Similarly, papers concerned solely with stability constants determined by potentiometric titration data unsupported by other e.g. spectroscopic techniques will not be acceptable nor will solvent extraction data unless supported by other data of interest to inorganic chemists. Unnecessary fragmentation of work is not acceptable.

In addition Polyhedron publishes specially commissioned review articles (Polyhedron Reports) and collections of original research papers (Polyhedron Symposia-in-Print) of appropriate timeliness.

Publication Information: Polyhedron (ISSN 0277-5387). For 2009, volume 28 is scheduled for publication. Subscription prices are available upon request from the Publisher or from the Regional Sales Office nearest you or from this journal's website (http://www.elsevier.com/locate/poly). Further information is available on this journal and other Elsevier products through Elsevier's website (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

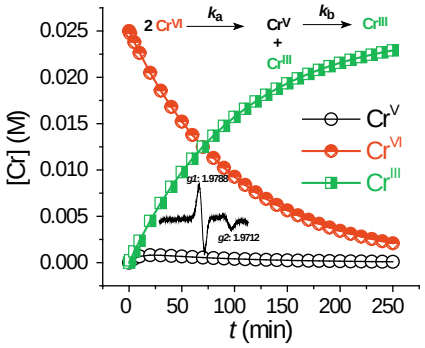
journal homepage: www.elsevier.com/locate/poly

Contents



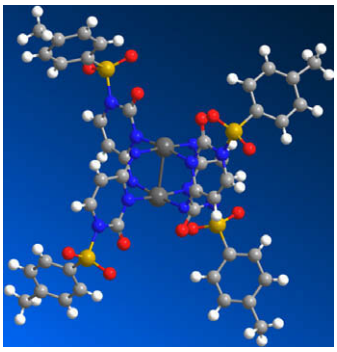
Papers

María Inés Frascaroli, Juan Manuel Salas-Peregrin, Luis F. Sala and Sandra Signorella

Polyhedron 28 (2009) 1049

Kinetics and mechanism of the chromic oxidation of 3-*O*-methyl-D-glucopyranose

The reaction of Cr^{VI} with 3-*O*-methyl-D-glucose yields 2-*O*-methyl-D-arabinose, formic acid and Cr^{III} through a combination of $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{II}$ and $Cr^{VI} \rightarrow Cr^{IV} \rightarrow Cr^{III}$ pathways.

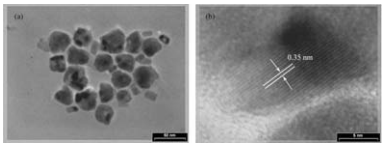


Aleksandar Višnjevac, Marija Luić, Renata Kobetić, Dubravka Gembarovski and Biserka Žinić

Polyhedron 28 (2009) 1057

Stabilization of the *N*-1-substituted cytosinate iminooxo form in dinuclear palladium complexes

The synthesis and characterization of 1-(*p*-toluenesulfonyl)cytosine (**1**), and its dinuclear cytosinato complexes $Pd_2(1\text{-}TosC^{-}\text{–}N3,N4)_4$ (**3**) and $Pd_2(1\text{-}TosC^{-}\text{–}N3,N4)_2DMSO_2Cl_2$ (**4**) are described. Complex **3** has an intriguing paddle-wheel structure with two parallel square-planar coordination spheres, consisting of four N atoms each.

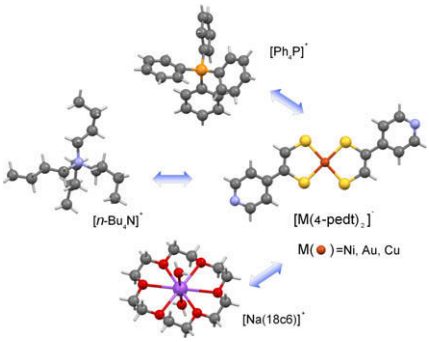


Masoud Salavati-Niasari, Zeinab Fereshteh and Fatemeh Davar

Polyhedron 28 (2009) 1065

Synthesis of cobalt nanoparticles from [bis(2-hydroxyacetophenato)cobalt(II)] by thermal decomposition

[Bis(2-hydroxyacetophenato)cobalt(II)] was used as a new precursor to prepare cobalt (Co) and tricobalt tetraoxide (Co_3O_4) nanoparticles of 15–25 nm in average diameter by thermal decomposition. The products were characterized by X-ray diffraction (XRD), transmission electron microscopy (TEM), high-resolution transmission electron microscopy (HRTEM) and Fourier transform infrared (FT-IR) spectroscopy. The magnetic property was studied with vibrating sample magnetometer (VSM).



Sandra Rabaça, Ana C. Cerdeira, Ana I.S. Neves, Sandra I.G. Dias, Cécile Mézière, Isabel C. Santos, Laura C.J. Pereira, Marc Fourmigué, Rui T. Henriques and Manuel Almeida

Polyhedron 28 (2009) 1069

Complexes based on asymmetrically substituted pyridine–dithiolene ligands [M(4-pedt)$_2$] (M = Au, Cu, Ni; 4-pedt = 1-(pyridin-4-yl)-ethylene-1,2-dithiolate): Synthesis, structure and physical properties

The synthesis of M(4-pedt)$_2$ complexes of nickel, copper and gold obtained as tetrabutylammonium, tetraphenylphosphonium or sodium 18-crown-6 ether salts are described and these compounds are characterised by single-crystal X-ray diffraction, cyclic voltammetry, EPR and magnetic susceptibility measurements.

Polyhedron 28 (2009) 1079

A new π-acidity scale for several N-donor heterocycles as ligands in neutral gold(III) complexes

A computational DFT approach for the comparison of the π-acceptor character of some N-donor heterocycles L {L = pyridines, pyrimidines, imidazoles, pyrazoles and isoxazoles} in neutral AuCl$_3$L complexes is reported. The π-acceptor ability scale pyridines ≈ pyrimidines < imidazoles < pyrazoles ≈ isoxazoles has been derived. Moreover, the minimum proton affinity value for a meaningful interaction between the ligands and the AuCl$_3$ fragment has been estimated.

Synthesis and characterization of NiO nanoclusters via thermal decomposition

Thermal decomposition process has been developed to synthesize nickel oxide (NiO) nanoclusters via the reaction between a new precursor, nickel oxalate $[Ni(O_4C_2)(H_2O)_4]$ and oleylamine ($C_{18}H_{37}N$). The combinations of triphenylphosphine ($C_{18}H_{15}P$) and $C_{18}H_{37}N$ were added as surfactants to control the particle size. The products were characterized different methods. The synthesized NiO nanoclusters have a cubic structure with average size 2–10 nm.

Exploring weak interactions to assemble a nitrosyl–ruthenium compound able to release NO under visible light irradiation

Compound *cis*-$[Ru(bpy)_2(qui)NO](PF_6)_3 \cdot (qui)$ (qui = quinazoline) was synthesized and characterized. The association with an additional *qui* leads to an absorption band in the visible region which is able to photoinduce the NO release. The transition energy presents reversible dependence on pH and solvent effects, suggesting that the association is driven by π-stacking.

The pH-specific synthesis, spectroscopic, structural, and magnetic properties of a new Ni(II) species containing the plant physiological binder D-(−)-quinic acid: Association with the aqueous speciation of the binary Ni(II) quinate system

Reaction of Ni(II) with D-(−)-quinic acid (pH ~5.5) leads to a new species $Na[Ni(C_7H_{11}O_6)_3] \cdot 2.75H_2O$(**1**), characterized analytically, spectroscopically, magnetically, and structurally. The physicochemical profile of **1** is reflected into its partner $[NiL_2]^0$ species in the aqueous speciation of the Ni(II)–quinate binary system, thus aiding in understanding of Ni(II)–hydroxycarboxylate interactions in cellular physiology/toxicity.

Polyhedron 28 (2009) 903

Synthesis and characterization of a new series of unsymmetrical macrocyclic binuclear vanadyl(IV) complexes: Electrochemical, antimicrobial, DNA binding and cleavage studies

A series of unsymmetrical macrocyclic binuclear bis-phenoxo bridged oxidovanadium(IV) complexes have been synthesized and characterized by elemental and spectral techniques. A cyclic voltammetric investigation of these complexes evidenced that two successive quasi-reversible one electron transfer reduction waves in the negative and positive potential regions, E^1_{pc} = –0.54 to –0.67 V, E^2_{pc} = –0.80 to –0.85 V and E^1_{pc} = +0.63 to +0.78 V, E^2_{pc} = +0.82 to +0.97 V, respectively, are obtained. The aromatic diimine containing macrocyclic $V^{IV}O$ complexes display better DNA interactions than the aliphatic diimine containing $V^{IV}O$ analogues. These complexes significantly promote the oxidative cleavage of supercoiled plasmid DNA in the presence of H_2O_2. All the complexes display noticeable antifungal and antibacterial activities.

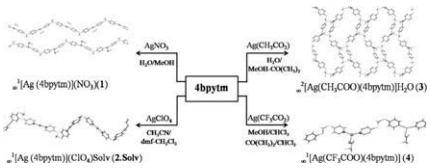
Polyhedron 28 (2009) 917

pH and molar ratio dependent formation of monomeric, dimeric and tetrameric cobalt malate complexes

The formation of monomeric, dimeric and tetrameric cobalt malate complexes is dependent on the pH value and molar ratio of the reactants, while less relevant to the temperature and counterions. The dimeric species further connects into a two-dimensional coordination polymer, and the tetramer is a mixed-valence cobalt(II/III) complex.



Rosa Carballo, Berta Covelo, Emilia García-Martínez, Ana Belén Lago and Ezequiel M. Vázquez-López

Polyhedron 28 (2009) 923

Role of inorganic and organic anions in the formation of metallosupramolecular assemblies of silver(I) coordination polymers with the twisted ligand bis(4-pyridylthio)methane

The reaction of the twisted ligand 4bpytm with $AgNO_3$ and $AgClO_4$ afforded 1D cationic coordination polymers but with the carboxylate anions, $CH_3CO_2^-$ and $CF_3CO_2^-$ 2D and 1D neutral coordination polymers were obtained. Different anion coordination abilities and different conformation arrangements with different symmetries and axial chirality in the ligand 4bpytm were observed in these compounds. Secondary interactions such as Ag···S, Ag···O or Ag···Ag play a crucial role in the self-organization of supramolecular polymers.

Polyhedron 28 (2009) 947

The architectures of 1D coordination polymers with the versatile 7-chloroquinoline-4-alanine ligand mediated by anions: Syntheses, structures and luminescent properties

Three new coordination polymers based on the 7-chloroquinolin-4-alanine ligand have been synthesized and characterized. The cooperative effect of the anion and the ligand produce a one-dimensional ladder-like polymer and a 3D supramolecular framework formed by π π stacking interactions. The non-cooperative effect of the anion and ligand give a 3D supramolecular framework with 1D channels. The results suggest that the cooperative effect of the anion and the ligand plays a role in mediating the structure in crystal engineering.

Diphenyllead(IV) thiosemicarbazonates and pyrazolonates: Synthesis and characterization

Cyclization of thiosemicarbazones derived from β-keto esters and β-keto amides (HTSC) in the presence of diphenyllead(IV) acetate have been studied. The complexes were isolated and characterized by X-ray crystallography and IR and NMR spectroscopy. Only β-keto ester TSCs underwent cyclization to give the corresponding pyrazolone (HL).

Polyhedron 28 (2009) 1040

Different crystal structures and luminescent properties of zinc and cadmium coordination polymers constructed from two flexible thioether ligands with different alkyl chains

Two series of complexes were prepared from reactions of two dithioether ligands (1,3-bis (4-(pyridin-3-yl) pyrimidin-2-ylthio) propane and 1,2-bis (4-(pyridin-3-yl) pyrimidin-2-ylthio) ethane) with zinc or cadmium salts, respectively. A small difference of the alkyl length between two ligands led to conspicuous changes of the fluorescent properties of both ligands and their complexes with different structural networks.

Cadmium thiosemicarbazide complexes as precursors for the synthesis of nanodimensional crystals of CdS

Anisotropic cadmium sulfide nanocrystals have been prepared from two thiosemicarbazide complexes. Thermal decomposition of the precursors in hexadecylamine (HDA) results in the formation of nanorods of different dimensions. The powder X-ray diffraction patterns of the nanodimensional materials reveal differences in the phases of the CdS synthesized from the two complexes. Transmission Electron Microscopy (TEM) was used to study the morphology of the final materials.

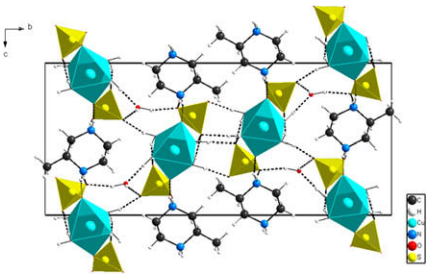
Polyhedron 28 (2009) 2103

Synthesis and structures of nickel(II) and copper(II) compounds of 5,5,7,13-tetramethyl-13-nitro-1,4,8,11-tetraazacyclotetradecane and the 13-ethyl-5,5,7-trimethyl-homologue

The imine functions of the nitro-substituted imine–triamine azamacrocycle cations are reduced by $NaBH_4$ to form the nitro-substituted cyclic tetraamine cations. The structures of five compounds with cations with M = Ni^{II}, R = Me and one with M = Cu^{II}, R = Et are reported.



M = Ni^{II}, Cu^{II}, R = Me, Et

Polyhedron 28 (2009) 2113

Synthesis, structural characterisation and thermal decomposition of a new organic–inorganic hybrid material $(C_5H_{14}N_2)[Cu(SO_4)_2(H_2O)_4] \cdot H_2O$

The centric crystal structure of the title compound was expected from the racemic character of the 2-methypiperazine amine used in the synthesis. The structure consists of $[Cu(SO_4)_2(H_2O)_4]$ units, built from copper (II) octahedron and two sulfate tetrahedra linked by corner sharing, water molecules, and diprotonated 2-methylpiperazine cations connected together by hydrogen bonds only.

Polyhedron 28 (2009) 2119

Ovalbumin mediated synthesis of Mn_3O_4

By using Mn^{2+} and Mn^{3+} salts, and freshly extracted ovalbumin, Mn_3O_4 nanocrystals have been synthesized successfully. The X-ray diffraction results indicated that the synthesized nanoparticles have only the spinel structure without the presence of any other phase impurities. As the ovalbumin-water mixture was highly basic, the process did not require any use of base to increase the pH where hydrolysis took place. A gel formed where water soluble ovalbumin proteins served as a perfect matrix for entrapment of metal ions (Mn^{2+} and Mn^{3+}). Upon heat treatment, the dried gel precursor decomposed into nanocrystalline Mn_3O_4. The discrepancy between the crystallite size from XRD and particle size SEM analysis reveals polycrystalline nature of the synthesized particles with this route. EPR analysis of Mn_3O_4 show a narrow and symmetric line indicating the absence of hyperfine splitting.

Polyhedron 28 (2009) 2149

X-ray structure and spectroscopic characterization of doubly-bridged binuclear copper(II) complexes in symmetric and asymmetric coordination environments

μ-1,3-Acetamide or acetate bridged, symmetric and asymmetric dicopper(II) complexes *viz* $[Cu_2(P1\text{-}O^-)(NHAc^-)](ClO_4)_2$ (**1**), $[Cu_2(P2\text{-}O^-)(OAc^-)](ClO_4)_2$ (**2**) and $[Cu_2(P2'\text{-}O^-)(OAc^-)(H_2O)](ClO_4)_2$ (**3**) were synthesized by employing classic dinucleating ligands; P1-OH, P2-OH (symmetric), and P2′-OH (asymmetric) and their structures were determined by X-ray crystallography. In solution, they were characterized by various spectroscopic techniques, which include ESI-MS, FT-IR, optical, solution magnetic moment, paramagnetic ^1H NMR and EPR. The solution magnetic moment of these complexes at room temperature suggests a weak magnetic interaction between the two Cu(II) centers.

Polyhedron 28 (2009) 2171

Synthesis, electrochemical, *in situ* spectroelectrochemical and *in situ* electrocolorimetric characterization of new phthalocyanines peripherally fused to four flexible crown ether moieties

Novel Ni(II), Zn(II), Co(II) and Cu(II) phthalocyanines with four peripheral 4-[methyleneoxy(18-crown-6)] groups have been synthesized via the cyclic tetramerization of 4-[{(18-crown-6)-yl}methyleneoxy]phthalonitrile and the corresponding metal salts ($NiCl_2$, $Zn(CH_3COO)_2$, $CoCl_2$ and $CuCl_2$). The thermal stabilities of the metal-free and metallophthalocyanine compounds were determined by thermogravimetric analysis. The structures of the target compounds were confirmed using elemental analysis, IR, ^1H NMR, ^{13}C NMR, UV–Vis and MS spectral data. Voltammetric and *in situ* spectroelectrochemical measurements show that while the cobalt phthalocyanine complex gives both metal-based and ring-based redox processes, the metal-free, nickel, zinc and copper phthalocyanines show only ring-based reduction and oxidation processes. An *in situ* electrocolorimetric method has been applied to investigate the color of the electro-generated anionic and cationic forms of the complexes.

The time differential perturbed angular correlation study of binding of hafnium to humic acid and its model compound

Time differential perturbed angular correlation (TDPAC) spectroscopy has been used to study the binding of hafnium to mandelic acid, which is a model compound of humic acid. The Fourier transform of TDPAC spectrum of Hf–mandelate complex showed two ω values, namely, ω_{Q1} = 77 (±0.4) Mrad/s and ω_{Q2} = 111 (±3.1) Mrad/s. The asymmetry parameters for the two sites were found to be 0.7 and 0.3, respectively. The electric field gradient (EFG) around the metal ion was theoretically calculated using the computer code GAMESS. The calculated EFG value was found to be in reasonable agreement with that deduced from experiment. Contrary to Hf–mandelate, the TDPAC spectrum of Hf–humate system did not show characteristic features of discrete binding sites.

Copper(I) complexes with fluorinated hydrotris(pyrazolyl)borate: Influence of electronic effects on their structure, physicochemical properties, and reactivity

Copper(I) coordination complexes of the anionic fluorinated ligand, hydrotris(3-trifluoromethyl-5-methyl-1-pyrazolyl)borate were synthesized and structurally characterized. While X-ray crystallography did not show definitive trends in terms of copper(I) atom geometry, the clear influence of the electronic structure of the pyrazolyl rings is observed by spectroscopic techniques, namely, IR and multinuclear NMR spectroscopy. Finally, the relative stability of the copper(I) complexes is discussed.

A simple route to synthesize nanocrystalline nickel ferrite ($NiFe_2O_4$) in the presence of octanoic acid as a surfactant

Nanocrystalline nickel ferrite ($NiFe_2O_4$) powder was prepared by a co-precipitation method from Ni and Fe chlorides. The as-prepared nickel ferrite nanocrystals were characterized by XRD, SEM, TEM, and FTIR. SEM and TEM indicated that the particles were spherical with particle sizes in the range 25 ± 5 nm. The magnetic properties of the sample were measured by using a vibration sample magnetometer, which showed that the sample exhibited typical ferromagnetic behavior at room temperature, while a finite coercivity of 245.5 Oe was present at 300 K.

Co(III) complexes of the type $[(L)Co(O_2CO)]^+$ (L = tripodal tetraamine ligand): Synthesis, structure, DFT calculations and ^{59}Co NMR

New $[(L)Co(O_2CO)]ClO_4$ complexes, where L = an "asymmetric" tripodal tetraamine ligand, have been prepared and characterised. The single geometric isomer isolated from these syntheses is generally that predicted by DFT calculations. An excellent correlation between Δ and $\delta(^{59}Co)$ for these, and other similar complexes is detailed.

Polyhedron 28 (2009) 1469

Structural organization of a $\{ruthenium[tris(bipyridyl)]\}^{2+}$ complex by strong π–π stacking of a tethered 1,8-naphthalimide synthon: Impact on electrochemical and spectral properties

The $\{Ru(bipyridyl)_2\}^{2+}$ complex of the new ligand *N*-(5-methyl-2,2′-bipyridyl)-1,8-naphthalimide, containing both a bipyridyl and 1,8-naphthalimide group, has been prepared and shown to be organized into dimers in both the solid and solution phase by strong, directionally oriented π–π stacking. UV–VIS, fluorescence spectroscopy and electrochemical studies indicate that the 1,8-naphthalimide groups does not have a significant influence on the properties of the $[Ru(bipy)_3]^{2+}$ core.

Polyhedron 28 (2009) 1490

Synthesis and liquid crystal properties of phthalocyanine bearing a star polytetrahydrofuran moiety

In this study, a new polymeric ligand, 6-(3,4-dicyanophenylthio)-hexyl-2-polytetrahydrofuran-acetate and its liquid crystalline polymeric phthalocyanine, 2,9,16,23-tetrakis-{6-(polytetrahydrofuran-2-carboxylate)-hexylthio-phthalocyaninatocobalt(II) (CoPcLC) have been prepared. CoPcLC promotes a greater interaction between the mesogens resulting in solution aggregations together with a red-shift in the Q-band in the presence of the soft Ag^+ ion. The dielectric anisotropy and phase transition temperature values of CoPcLC doped with 4-cyano-4′-n-pentylbiphenyl (5CB) were found to be 7.17 and 40.5 °C, respectively. The liquid crystal structure changes from the positive to negative type. The current–voltage characteristics of the 5CBCoPcLC liquid crystal show non-linear behaviour.

Metal-directed supramolecular assembly of metal(II) benzoates (M = Co, Ni, Cu, Zn, Mn, and Cd) with 4,4′-bipyridine: Effects of metal coordination modes and novel catalytic activities

We have presented a systematic investigation on the coordination polymers assembled from metal benzoates and 4,4′-bpy. Since different structures provide different coordination geometry of each metal ion, it is clear that selection of appropriate metal ions can control the coordination geometry of each metal ion to form different crystal structures. Reactivity study of seven compounds for the transesterification of a variety of esters has shown that **4**-Zn and **5**-Zn are very efficient and the best among them. It can be possible to tune the catalytic activities by changing from Zn to those metals such as Cd, a kinetically inert metal, or Cu, Mn, and Co, the redox-active metals.

High-dimensional mixed-valence copper cyanide complexes: Syntheses, structural characterizations and magnetism

The syntheses, structural characterization and magnetic properties of two mixed-valence copper cyanide compounds $[Cu^{II}(bpy)Cu^{I}(CN)_3]_n$, (**1**) and $\{[Cu^{II}(tn)_2][Cu^{I}_4(CN)_6]\}_n$ (**2**) are presented. The 3-D structure of **1**, is generated by μ_2- and μ_3-cyanide bridges (–Cu^{II}–NC–Cu^{I}– and –Cu^{II}–NC–$(Cu^{I})_2$–), while the 2-D hexagonal networks of **2** are generated by only –Cu^{I}–NC–Cu^{I}– bridges. Compound **1** presents an unexpected weak ferromagnetic coupling through the "a priori diamagnetic" –NC–Cu^{I}–CN– bridges.

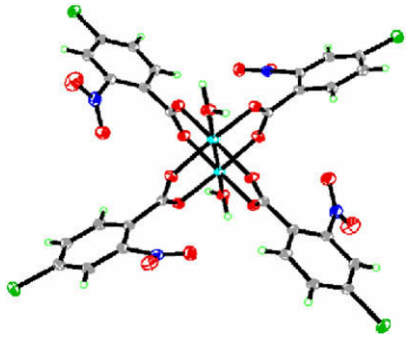
Polyhedron 28 (2009) 1315

Kinetics of ligand exchange between 2-thenoyltrifluoroacetone and zirconium-lactate solution in weakly acidic lactate buffers

Under the conditions, $T_{HT} \ll T_{Zr} \ll T_L$, "zirconium-lactate" ($Zr_2L_6$) reacts with 2-thenoyltrifluoroacetone (HT) to produce Zr_2L_5E and L; the equilibrium constant $K = 3.2$: $k_{-1} = 4.9 \times 10^{-3}$ s^{-1}, $k_1K_AK_B = 2.62 \times 10^{-6}$ dm^6 mol^{-2} s^{-1} at $T = 25.0$ °C.

$Zr_2L_6 + 2H_2O$ — $Zr_2L_5(OH_2)_2^+ + L^-$ K_A (rapid equilibrium)

$Zr_2L_5(OH_2)_2^+$ — $Zr_2L_5(OH_2)(OH) + H^+$ K_B (rapid equilibrium)



$Zr_2L_5(OH_2)(OH) + HT$ — $Zr_2L_5E + 2H_2O$ k_1 , k_{-1} (slow r.d.s)

Polyhedron 28 (2009) 1320

Characterization, nucleolytic, cytotoxic and antibacterial property of tetrakis(μ-4-chloro-2-nitrobenzoato-κ^2O,O')bis[aquacopper(II)], tetrakis(μ-2-chloro-6-fluorobenzoato-κ^2O,O')bis[aquacopper(II)] and tetrakis(μ-2-chlorobenzoato-κ^2O,O')bis[aquacopper(II)]

The dimeric Cu(II) complexes are redox active and display two quasi-reversible redox behaviour corresponding to the $Cu^{II}Cu^{II}$ to $Cu^{II}Cu^{I}$ and $Cu^{II}Cu^{I}$ to $Cu^{I}Cu^{I}$ redox process, respectively. Oxidative cleavage of pBr322 DNA occurs in the presence of hydrogen peroxide for which the hydroxyl radical is the reactive oxygen species that is responsible for the cleavage reaction.

Synthesis, spectroscopic characterization, X-ray structure and DFT calculations of copper(II) complex with 2-(2-pyridyl)benzimidazole

The $[Cu(pybzim)_2(NO_3)](NO_3)$ complex has been isolated from the reaction of copper(II) nitrate trihydrate and 2-(2-pyridyl)benzimidazole (pybzim) in methanol. The compound has been studied by IR, UV–Vis spectroscopy and X-ray crystallography. The electronic structure of the $[Cu(pybzim)_2(NO_3)]^+$ cation has been calculated with the density functional theory (DFT) method. The spin-allowed doublet–doublet electronic transitions of $[Cu(pybzim)_2(NO_3)]^+$ have been calculated with the time-dependent DFT method, and the UV–Vis spectrum of the title compound has been discussed on this basis.

Nickel complexes bearing [N,N] 2-pyridylbenzamidine ligands: Syntheses, characterizations, and catalytic properties for ethylene oligomerization

Four 2-pyridylbenzamidine nickel complexes were synthesized and characterized. These nickel complexes showed moderate activities for ethylene oligomerization after activated with MAO. The solvent played an important role on catalytic products. In toluene, ethylene oligomers, alkylated toluene and ditolylmethanes were detected, while only ethylene oligomers were found in dichloromethane.

The Publisher encourages the submission of articles in electronic form thus saving time and avoiding rekeying errors. For detailed instructions on the preparation of manuscripts and of electronic artwork, consult the Author Gateway for Elsevier at http://authors.elsevier.com

New type dithiolene complex based on 4,5-(1,4-dioxane-2,3-diyldithio)-1,3-dithiol ligand: Synthesis, experimental and theoretical investigation

A new Nickel complex with an extended multisulfur dithiolene ligand $Ni(edodddt)_2$ (edodddt = 2,3,4α,8α-tetrahydro-dithiine [2,3-b] [1,4] dioxo-6,7-dithiolene) has been synthesized and characterized by electrochemical measurements, IR, UV–Vis and NMR spectroscopy. Its crystal structure was resolved by X-ray diffraction on a single crystal. DFT calculations were made in order to compare the results with the experimental findings and gain an insight of the properties of this new dithiolene complex.

The supramolecular chemistry of metal complexes with heavily substituted imidazoles as ligands: Cobalt(II) and zinc(II) complexes of 1-methyl-4,5-diphenylimidazole

Two isomorphous, octahedral cobalt(II) and zinc(II) nitrato complexes and one tetrahedral, cobalt(II) isothiocyanato complex, all with two 1-methyl-4,5-diphenylimidazole ligands, possess a characteristic mode of packing between neighbouring ligands of the complexes, expressed through intramolecular π–π interactions between the 4,5-diphenylimidazole moieties.

Spin dynamics in the molecule-based ferromagnet decamethylferrocenium tetracyanoethanide $[FeCp_2^*][TCNE]$, as probed by ^1H NMR relaxation

The electron spin dynamics of the molecule-based ferromagnet decamethylferrocenium tetracyanoethenide, $[FeCp_2^*][TCNE]$, has been investigated at a local level using ^1H NMR experiments. The NMR relaxation measurements verify that $[FeCp_2^*][TCNE]$ is an 1D ferromagnetic Ising-like chain with significant short range order at temperatures above the magnetic ordering transition.

Synthesis, properties and crystal structures of volatile β-ketoiminate Pd complexes, precursors for palladium chemical vapor deposition

Two aminovinylketones and two bis-ketoiminates Pd have been synthesized. All the compounds were identified by elemental analysis, ^{1}H and ^{13} NMR, IR-spectroscopy and were characterized by TGA and a single-crystal X-ray diffraction study. In the chelates, the Pd atom has a square coordination environment, Pd O_2N_2.

Polyhedron 28 (2009) 2371

Ni(II) complexes of stereo-isomeric hexaza-macrocyclic ligands derived from 2,6-diacetylpyridine

A new series of nitrate and perchlorate Ni(II) complexes of the stereo-isomeric hexaazamacrocyclic ligands L^1 and L^2 derived from 2,6-diacetylpyridine were synthesized by reaction of the ligand and the appropriate salt in refluxing acetonitrile. The reactions gave analytically pure products that were characterized by elemental analysis, LSI-MS, conductivity measurements, IR, UV–Vis spectroscopy and magnetic studies.
Crystal structures of $L^1{\cdot}2H_2O$ as well as of the complexes $[NiL^1](ClO_4)_2$ and $[NiL^2](NO_3)_2$ have also been determined. The X-ray studies show the presence of mononuclear endomacrocyclic complexes with the metal ion coordinated to all the nitrogen donor atoms from the macrocyclic framework in a N6 core. The geometry around the metal ions can be described as distorted octahedral. The nitrate and perchlorate anions do not coordinate to the metal ions, but they are involved in intermolecular interactions through hydrogen bonds to the amine groups of the macrocyclic ligands.

Novel rhenium(III) complexes with the picolinate ligand: Synthesis, spectroscopic investigations, X-ray structures and DFT calculations for $[ReX_2(pic)(PPh_3)_2]$ complexes

The paper presents a combined experimental and computational study of novel rhenium(III) complexes with picolinate ligand – $[ReCl_2(pic)(PPh_3)_2]$ (**1**) and $[ReBr_2(pic)(PPh_3)_2]$ (**2**). The both complexes **1** and **2** have been characterised spectroscopically and structurally (by single-crystal X-ray diffraction). The complex **1** has been additionally studied by magnetic measurement. The magnetic behavior is characteristic of mononuclear complexes with d^4 low-spin octahedral Re(III) complexes ($^3T_{1g}$ ground state) and arise because of the large spin-orbit coupling (ζ = 2500 cm^{-1}), which gives diamagnetic ground state. DFT and time-dependent (TD)DFT calculations have been carried out for complex **1**, and UV–Vis spectra of the $[ReX_2(pic)(PPh_3)_2]$ compounds have been discussed on this basis.

Polyhedron 28 (2009) 2494

Various coordination architectures constructed from *N*-[(carboxyphenyl)-sulfonyl]glycine: Structural variation *via* ligand isomerism effects and metal-directed assembly

Using Cu(II), Mn(II) or Co(II) salt and the flexible ligands, *N*-[(4-carboxyphenyl)-sulfonyl]glycine and *N*-[(3-carboxyphenyl)-sulfonyl]glycine, a series of new coordination polymers have been synthesized and structurally characterized. Their structures range from a 0D cation–anion species to a 3D network with different structural motifs. This work indicates that the positional isomer of the anionic *N*-[(carboxyphenyl)-sulfonyl]glycine is significant in the construction of these network structures, which are also well regulated by the metal centers.

Polyhedron 28 (2009) 2522

Synthesis and surface chemistry of nano silver particles

Silver nano particles of the size 40–80 nm are formed in the process of oxidation of glucose to gluconic acid by amine in the presence of silver nitrate, and the gluconic acid caps the nano silver particle. The presence of gluconic acid on the surface of nano silver particles was confirmed by XPS and FTIR studies. As the nano silver particle is encapsulated by gluconic acid, there was no surface oxidation, as confirmed by XPS studies. The nano silver particles have also been studied for their formation, structure, morphology and size using UV–Visible spectroscopy, XRD and SEM. Further, the antibacterial properties of these nano particles show promising results for *E. coli*. The influence of the alkaline medium towards the particle size and yield was also studied by measuring the pH during the course of the reaction for various bases including DEA, NaOH and Na_2CO_3.

Polyhedron 28 (2009) 647

Syntheses, characterization and luminescent properties of two lead(II) fumarate metal-organic frameworks

Two photoluminescent lead(II) MOFs, $\{[Pb_2(fum)_2(H_2O)_4]\cdot 2H_2O\}_n$ (**1**) and $[Pb(fum)]_n$ (**2**), were synthesized by the reaction of the fum dianion with the lead(II) ion in the presence of pyrazole and pyrazine, respectively. The arrangement of the ligands exhibits a coordination gap around the Pb atom, occupied possibly by a stereoactive lone pair of electrons on lead(II), with the coordination around both the eight-coordinated lead atom in **1** and six-coordinated lead atom in **2** exhibiting a hemidirected geometry. The fum ligand shows different ligation behavior toward the lead(II) ions in these complexes.

Polyhedron 28 (2009) 653

Segregated self-assembly and pillaring action of aliphatic dicarboxylic acids in the super structure of Cu–picolinate complexes

Co-crystals of [Cu(2-picolinate)$_2$] and malonic or succinic acid reveal that supramolecular association of the monomeric complex units leads to the formation of layers through hydrogen bonding. The co-crystallized dicarboxylic acid connects these 2-D layers, acting as pillars to form the final 3-D supramolecular structure.

Polyhedron 28 (2009) 661

Synthesis and physical properties of ruthenium bipyridine complexes with TCNQ and TCNE ligands

The physical properties such as charge uptake, absorption, emission, and oxidation state of the TCNX ligands in the [Ru(bpy)(dcbH$_2$)(TCNQ)Cl] and [Ru(bpy)(dcbH$_2$)(TCNE)Cl] complexes, where bpy = 2,2′-bipyridine and dcbH$_2$ = 4,4′-dicarboxy-2,2′-bipyridine, were investigated. The obtained results suggest not only the anion radical form, $TCNX^{\bullet -}$, for the TCNX ligands upon coordination, but also that the TCNE species presents a higher charge uptake capability than TCNQ ligand.

Polyhedron 28 (2009) 665

Concomitant polymorphism of an antiferromagnetically coupled dicopper(II,II) complex with single strand helical assembly: Synthesis, structure, DSC, magnetic and heterogeneous catalytic studies

Two concomitant polymorphic coordination complexes (**I** and **II**) have been characterized crystallographically. Complex **I** shows the presence of a strong antiferromagnetic interaction and good catalytic efficiency in the liquid phase partial oxidation of olefins when immobilized on 2D-hexagonal mesoporous silica.

Polyhedron 28 (2009) 673

Neutral nickel complexes chelating monoamidinate ligands: Syntheses, characterizations and catalytic properties toward ethylene oligomerization and norbornene polymerization

Three monoamidinate nickel complexes were synthesized, characterized and used as precatalyst for ethylene oligomerization and norbronene polymerization. The nickel complexes oligomerized ethylene producing a mixture of dimers and trimers with a moderate turnover frequency, while exhibited very high activity for the vinyl-addition polymerization of norbornene in the presence of MAO.

Polyhedron 28 (2009) 679

Construction of metal–organic frameworks with transitional metals based on the 3,5-bis(4-pyridyl)-1*H*-1,2,4-triazole ligand

The versatile ligand 3,5-bis(4-pyridyl)-1*H*-1,2,4-triazole was synthesized using an in situ metal/ligand reaction. Based on which, six coordination complexes have been prepared, in which the bpt ligand manages the metal ions to form 0-D point, (4,4) layers and a variety of 3-D ($4^{12} \cdot 6^3$), ($6^4 \cdot 8^2$) topological networks.

Polyhedron 28 (2009) 689

Synthesis and spectroscopic characterization of tris(*O*,*O*′-ditolyl dithiophosphato) arsenic/antimony/bismuth(III) compounds: Crystal structures of $[As\{S_2P(OC_6H_4Me\text{-}m)_2\}_3] \cdot 0.5C_6H_{14}$, $[Sb\{S_2P(OC_6H_4Me\text{-}m)_2\}_3]$ and $[Bi\{S_2P(OC_6H_4Me\text{-}m)_2\}_3]$

Arsenic(III), antimony(III) and bismuth(III) compounds of the type, $[M\{S_2P(OR)_2\}_3]$ (where M = As, Sb and Bi; R = *o*-, *m*-, *p*-C_6H_4Me) were obtained. These compounds were characterized by elemental analysis, IR, ^1H NMR and ^{31}P NMR spectroscopy. The single crystal X-ray structures of three representative compounds, $[As\{S_2P(OC_6H_4Me\text{-}m)_2\}_3] \cdot 0.5C_6H_{14}$, $[Sb\{S_2P(OC_6H_4Me\text{-}m)_2\}_3]$ and $[Bi\{S_2P(OC_6H_4Me\text{-}m)_2\}_3]$ were determined.

Polyhedron 28 (2009) 695

Ferromagnetic exchange coupling in a new bis(μ-chloro)-bridged copper(II) Schiff base complex: Synthesis, structure, magnetic properties and catalytic oxidation of cycloalkanes

A new doubly chloro-bridged complex $[Cu(HL)Cl]_2 \cdot H_2O$ (**1**) has been prepared using a ONO donor Schiff base ligand $\mathbf{H_2L}$, 2-((*E*)-(2-hydroxyethylimino)methyl)-4-bromophenol. Each copper(II) atom in the dimer is square-pyramidal having an axial–equatorial configuration of the bridging chlorine atoms. Temperature dependence of magnetic susceptibility measurements show a high ferromagnetic coupling between two copper(II) ions in **1** with $J = +43.2(5)\ cm^{-1}$. The complex also exhibits efficient catalytic properties leading to the facile oxidation of cyclohexane and cycloheptane in presence of hydrogen peroxide as terminal oxidant.

Polyhedron 28 (2009) 711

Molybdenum(VI) complexes of a few pyrimidine derived ligands and the study of metal mediated C═N bond cleavage resulting in ligand transformation during complex formation

The syntheses of three mononuclear dioxomolybdenum (VI) complexes and a binuclear oxo μ-oxo molybdenum(VI) complex have been described. Three of these four complexes are the result of an in situ transformation of the used pyrimidine derived Schiff base ligands. The ligand transformation may have been initiated by Mo mediated C═N bond cleavage.

Polyhedron 28 (2009) 733

A novel tridentate Schiff base dioxo-molybdenum(VI) complex: Synthesis, crystal structure and catalytic performance in green oxidation of sulfides by urea hydrogen peroxide

A new dioxo-molybdenum(VI) complex $[MoO_2(L)(CH_3OH)]$ has been synthesized using a tridentate ONO Schiff base ligand (H_2L). The X-ray crystallography showed a monoclinic space group $P2_1/c$ for this complex. The high catalytic activity of this Schiff base complex has been observed in the oxidation of sulfides by urea hydrogen peroxide in ethanol with high/excellent yields and selectivity.

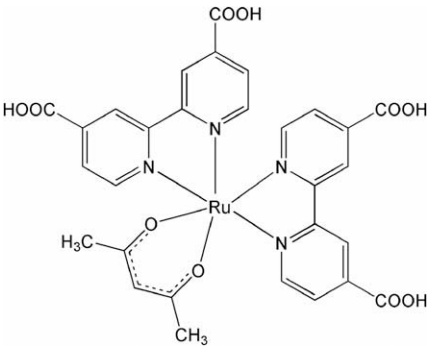
Polyhedron 28 (2009) 749

Fe(II) hydroxycarbonate $Fe_2(OH)_2CO_3$ (chukanovite) as iron corrosion product: Synthesis and study by Fourier Transform Infrared Spectroscopy

$Fe(OH)_2$ was prepared by mixing $FeCl_2 \cdot 4H_2O$ and NaOH solutions. A $NaHCO_3$ solution was then added to the suspension, so that $[NaHCO_3]/[NaOH] = 0.9$. The system was aged at RT. ATR/FT-IR spectra after 24 h and 2 months show that the precipitate transformed progressively into chukanovite.



Heléne Gamstedt, Anders Hagfeldt and Lars Kloo

Polyhedron 28 (2009) 757

Photoelectrochemical studies of ionic liquid-containing solar cells sensitized with different polypyridyl–ruthenium complexes

The efficiency of a selection of ionic liquid electrolytes combined with standard, hydrophobic and cationic organometallic sensitizing dyes have been investigated as components in dye-sensitized solar cells. Also effects of co-adsorbent and nanoparticle additives to the electrolytes have been investigated.

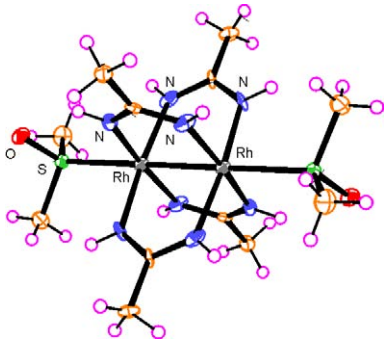
Polyhedron 28 (2009) 763

Interaction between aspergillic acid and iron(III): A potentiometric, UV–Vis, ^{1}H NMR and quantum chemical study

The complex formation equilibria of aspergillic acid with iron(III) were studied potentiometrically and spectrophotometrically. Some structural features of ligand, prepared biosynthetically, are discussed on the basis of NMR results. Iron(III) coordination model is examined on the grounds of quantum chemical calculations and compared with those of two other cyclic hydroxamates.



Florian P. Pruchnik, Hanna Pruchnik and Andrzej Kochel

Polyhedron 28 (2009) 769

Structure and properties of tetra-μ-ethanimidamidato-κ*N*:κ*N*′-dirhodium(1+) complexes

Reaction of $Na_4[Rh_2(\mu\text{-}CO_3)_4]$ with ethanimidamide hydrochloride leads to the $[Rh_2\{\mu\text{-}HN(HN{=})CCH_3\}_4L_2]Cl$ complexes. DFT calculations and EPR spectra indicate that δ^*_{RhRh} is SOMO orbital. The rhodium atoms are equivalent in the $[Rh_2\{\mu\text{-}HN(HN{=})CCH_3\}_4L_2]^+$ compounds, and nonequivalent in $[Rh_2\{\mu\text{-}HN(HN{=})CCH_3\}_4LL']^+$ complexes. The intense bands in the electronic spectra in the range 13 000–19 000 cm^{-1} are caused by transitions with prevailing d–d character.

Polyhedron 28 (2009) 782

Hypervalence in germanium compounds containing the tetracylic moiety $\{S(C_6H_3S)_2O\}Ge$ via O···Ge transannular interactions: A structural study

The synthesis of $[\{S(C_6H_3S)_2O\}GeR_nHal_{2-n}]$ compounds (R = Et, Ph; Hal = Cl, Br; n = 2–0) is described. The acidity of the $GeRHal^{2+}$ fragment enhances a transannular O···Ge interaction, prompting a trigonal bipyramidal germanium local geometry; the GeR_2^{2+} less acid fragment present has an opposite effect.

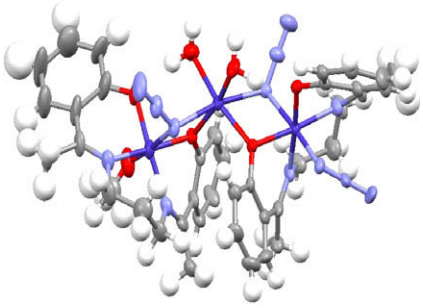
Polyhedron 28 (2009) 789

New synthetic and structural studies on nitroso-*ortho*-carboranes $RCB_{10}H_{10}CNO$ and bis-(*ortho*-carboranyl)amines $(RCB_{10}H_{10}C)_2NH$ (R = Ph or Me)

Improved syntheses of nitroso-carboranes and dicarboranylamines are described and crystal structures of $PhCB_{10}H_{10}CNO$ and $[(PhCB_{10}H_{10}C)_2N]^-$ reveal cage C…C distances of 1.68 and 1.99 Å, respectively.



Aurkie Ray, Georgina M. Rosair, Ramakant Kadam and Samiran Mitra

Polyhedron 28 (2009) 796

Three new mono–di–trinuclear cobalt complexes of selectively and non-selectively condensed Schiff bases with N_2O and N_2O_2 donor sets: Syntheses, structural variations, EPR and DNA binding studies

Three new mono–di–trinuclear cobalt complexes of three different Schiff bases have been synthesised. Of the three Schiff bases, $\mathbf{HL^1}$ and $\mathbf{HL^2}$ were obtained by selective condensation of two different 1,3-diamines with 2-hydroxyacetophenone and $\mathbf{H_2L^3}$ resulted from the non-selective condensation of 1,3-diamine with 2-hydroxyacetophenone. The three complexes have been characterised using IR, UV–Vis spectroscopy and cyclic voltammetry. Structural aspects of the cobalt complexes have been described by performing single crystal X-ray analysis. EPR analysis and DNA binding abilities of the complexes have also been studied in detail.

Polyhedron 28 (2009) 819

A novel tetra(μ_3-phenoxo) bridged copper(II) Schiff base complex containing a Cu_4O_4 cubane core: Synthesis, structural aspects and magneto-structural correlations

A novel tetranuclear copper(II) complex $[Cu_4L_4] \cdot Na \cdot ClO_4$ has been synthesized exploiting the tetradentate donor set of a hydrazone ligand $\mathbf{H_2L}$, *N′*-(2-hydroxy-3-methoxybenzylidene)-benzohydrazide. The Cu_4O_4 core consists of a rare μ_3-phenoxo-bridged copper(II) atoms giving an approximately cubic array of alternating copper and oxygen atoms. Cryomagnetic susceptibility measurements over a wide range of temperature (2–300 K) demonstrate both ferro- [J_{11} = +13.6(4) cm^{-1}] and antiferromagnetic [J_{12} = −34.9(4) cm^{-1}] interactions in a 2*J* model resulting in an overall antiferromagnetic behaviour of the magnetically coupled system.

Divalent metal succinate/perchlorate coordination polymers incorporating a kinked hydrogen-bonding capable diimine: Chains, layers and a (5,6)-connected binodal network featuring alternating rectangular and hexagonal grids

Hydrothermal synthesis has afforded succinate (suc) or 2,2-dimethylsuccinate (dmsuc) perchlorate coordination polymers incorporating the hydrogen-bonding capable tethering ligand 4,4′-dipyridylamine (dpa). $\{[Co(suc)(Hdpa)_2(H_2O)_2](ClO_4)_2 \cdot 7.5H_2O\}_n$ (**1**) manifests simple cationic 1D polymeric chains, while $\{[Cd_3(suc)_{2.5}(dpa)_2](ClO_4)\}_n$ (**2**) possesses a 3D binodal (5,6)-connected network. The network of **2** can be viewed as alternating (4,4) rectangular and (6,3) hexagonal grids being joined by pillaring ligands. The *gem*-dimethyl substituents within the dmsuc ligands promote a 2D (6,3) herringbone net in $\{[Cd_2(dmsuc)_2(dpa)(Hdpa)](ClO_4) \cdot 6H_2O\}_n$ (**3**).

Polyhedron 28 (2009) 865

Synthesis, structure and properties of a series of scorpionate oxovanadium(IV)–carboxylate complexes

The one-step reaction of $VOSO_4 \cdot nH_2O$, pyrazole or 3,5-dimethylpyrazole, potassium poly(pyrazolyl)borate and carboxylic acids in methanol resulted in six new complexes, **1–6**. The synthetic process described here is different from those in literature reports. Structural analyses show that in all of these complexes, the vanadium atoms are six-coordinated with a N_4O_2 donor set in a distorted-octahedral geometry, the carboxylate groups are coordinated as monodentate and the uncoordinated oxygen atom of the carboxylate groups form intra- or inter-molecular hydrogen bonds with the NH group of the corresponding coordinated neutral pyrazole (pzH/pzH*).

Effects of chloride ions on electrochemical reactions of manganese(III) complexes

Electrochemical reactions of manganese(III) complexes such as Mn^{III}(R1-salen)Cl were investigated by voltammetry in the absence/presence of Cl^-. By the addition of Cl^-, oxidation processes of Mn^{III}(salen)Cl have been found to be improved from quasi-reversible to reversible, and their oxidation products, $[Mn^{IV}(salen)Cl]^+$ was stabilized by the combination with Cl^- resulting in $[Mn^{IV}(salen)Cl_2]$. The present study may clarify the role of Cl^- being involved in OEC in photosystem II.

Polyhedron 28 (2009) 437

Novel dinuclear and polynuclear copper(II)-pyrazine-2,3-dicarboxylate supramolecular complexes with 1,3-propanediamine, *N*,*N*,*N*′,*N*′-tetramethylethylenediamine and 2,2′-bipyridine

We have successfully synthesized and characterized the novel dinuclear and polynuclear Cu(II)-pyrazine-2,3-dicarboxylate complexes. The molecular structures of dinuclear **(1)** and polynuclear **(2, 3)** complexes have also been determined by the single crystal X-ray diffraction technique. The pyrazine-2,3-dicarboxylate ligand acts as a tridentate bridge between the metal ions forming one-dimensional polymeric chains, its coordination sites being the O atom of carboxylate and N atom of ring and one O atom of neighboring carboxylate group.

Polyhedron 28 (2009) 445

Synthesis and structural characterization of copper(II), cadmium(II) and zinc(II) complexes with 4,5-diazaspirobifluorene and bis-9-biphenyl-4,5-diazafluorenyl peroxide

The synthesis and structural chemistry of four new divalent transition metal complexes (M^{II} = Cu, Cd or Zn) of the fluorene ligands 4,5-diazaspirobifluorene (L1) and bis-9-biphenyl-4,5-diazafluorenyl peroxide (L2) are reported. Single-crystal X-ray diffraction analysis reveal that the four complexes exhibit various frameworks due to diverse coordination modes and different conformations of ligands L1 or L2, as well as nitrate, acetate or chloro counterions. L1 in complexes **1**, **2** and **3** present an asymmetric rigid bidentate ligand with two nitrogen atoms as the donor sites. Novel complex **4** was formed through complexation between conformationally bent shaped peroxide ligands and zinc(II) dichlorides that adopt a linear coordination geometry, which can also give rise to extended polymeric chains with a zigzag secondary structure.

Syntheses and X-ray crystallographic studies of $\{[Ni(en)_2(pot)_2]0.5CHCl_3\}$ and $[Ni(en)_2](3\text{-pytol})_2$

Two new Ni(II) complexes, $\{[Ni(en)_2(pot)_2]0.5CHCl_3\}$(**3**) and $[Ni(en)_2](3\text{-pytol})_2$ (**4**), have been synthesized and characterized by spectroscopic and spectrometric methods, and their X-ray crystallography structures are reported. In complex **3**, the 2D lattices resulting from a parallel stacking of $\{[Ni(en)_2(pot)_2]0.5CHCl_3\}$ form regular open channels in which the $CHCl_3$ solvent molecules are enclosed along the a axis.

Polyhedron 28 (2009) 467

Synthesis, characterization and crystal structures of organolead dithiolate compounds displaying transannular interactions D···Pb (D = O, S)

The syntheses of the stable organolead dithiolate compounds $[\{O(C_6H_4S)_2\}PbPh_2]$, $[\{S(C_6H_4S)_2\}PbPh_2]$ and $[\{S(C_6H_3S)_2O\}PbPh_2]$ are described. The lead atom acts as an acceptor atom exhibiting weak intramolecular transannular interactions with the donor D atom. The crystals are stabilized by several intermolecular non-bonded interactions.

Polyhedron 28 (2009) 473

The modifications of copper work function by layer-by-layer deposition of $[W(CN)_8]^{4-}$ – Co^{2+} bimetallic nanolayers

The layer-by-layer deposition of a $[W(CN)_8]^{4-}$/Co^{2+}_{aq} on a monocrystalline [3 1 1] and polycrystalline copper resulted in the work function change by 0.4 eV at *ca.* 3 nm layer thickness. The work function change was then independent of layer thickness up to 40 nm. At the low amount of $[W(CN)_8]^{4-}$ ion in solution, deposited layers did not cover totally the copper surface and oscillations in the work function change were observed. The oscillation depended on anion used (Cl^- or NO_3^-) and number of layers deposited. After total surface coverage work function change reached plateau.

Synthesis, spectroscopic characterization, crystal and molecular structure of [ReOBr(hmquin-7-COOH)$_2$] and [ReOCl(hmquin-7-COOH)$_2$] · MeCN complexes. DFT and TD-DFT calculations for [ReOBr(hmquin-7-COOH)$_2$]

Novel [ReOBr(hmquin-7-COOH)$_2$] (**1**) and [ReOCl(hmquin-7-COOH)$_2$]·MeCN (**2**·MeCN) complexes have been prepared by treatment of [ReOX$_3$(AsPh$_3$)$_2$] with an excess of 8-hydroxy-2-methylquinoline-7-carboxylic acid in acetonitrile. The compounds were characterised structurally and spectroscopically. The electronic structure of **1** has been calculated with the density functional theory (DFT) method, and additional information about binding has been obtained by NBO analysis. The UV-Vis spectrum of **1** has been discussed on the basis of TDDFT calculations.

Designing dicyanamide bridged 1D molecular architecture from a mononuclear copper(II) Schiff base precursor: Syntheses, structural variations and magnetic study

A new tridentate N$_2$O donor Schiff base ligand was obtained by 1:1 condensation of benzoylacetone with 2-picolylamine and has been used to synthesise a mononuclear [CuLCl] (**1**) and an *end-to-end* dicyanamide bridged polynuclear {[Cu$_2$(μ-L)$_2$(μ_2-1,5-(CN)$_2$N)]ClO$_4$}$_n$ (**2**) copper(II) complexes. The Schiff base ligand [**LH**] shows a significant variation in its coordination behaviour with copper(II) ion in absence and in presence of dicyanamide ion in **1** and **2** respectively. Variable temperature magnetic susceptibility measurements for **2** in the temperature range 2–300 K reveal the presence of weak antiferromagnetic exchange interactions in the polymeric chain.

Polyhedron 28 (2009) 525

Tungsten(0)–carbonyl complexes of naphthylazoimidazoles

$[W(CO)_5(\alpha\text{-NaiR-N})]$ are reported in this work. The complexes have been transformed to $[W(CO)_4(\alpha\text{-NaiR-N,N}')]$ at higher temperatures (where α-NaiR-N is a monodentate imidazole-N donor ligand and α-NaiR-N,N′ denotes a bidentate imidazole-N, azo-N donor ligand). The emission of $[W(CO)_4(\alpha\text{-NaiR-N,N}')]$ shows a higher quantum yield (ϕ = 0.05–0.07) than $[W(CO)_5(\alpha\text{-NaiR-N})]$ (ϕ = 0.01–0.02). Cyclic voltammetry exhibits metal oxidation and ligand reductions. The DFT calculations of $[W(CO)_5(\alpha\text{-NaiMe-N})]$ show contributions from the metal d-orbitals and π-orbitals of the CO ligands to the HOMO while the LUMOs are α-NaiMe dominated. The back bonding interaction thus originates from the $W(CO)_n$ moiety to the LUMO of α-NaiR.

Controlling self-assembly of zinc(II)-benzoate coordination complexes with 1,4-bis(4-pyridyl)-ethane by varying solvent and ligand-to-metal ratio: Their catalytic activities

Zinc-benzoates can be rationally tuned to form four different structures with a bridging bpe ligand by controlling ligand-to-zinc-benzoate molar ratios and by using different solvent systems, and reveal three coordination polymers having similar one-dimensional characteristics but having different mono-, di-, trinuclear nodes (**1**–**3**), and a dinuclear ring type molecule (**4**). This work reveals that the ligand-to-metal ratio and solvent play very important roles in the formation of different coordination structures. We have also shown that the compounds **1**–**4** catalyzed efficiently the transesterification of a variety of esters.

Mechanism of complex formation between [AuCl$_4$]$^-$ and L-methionine

The kinetics of the reaction between the tetrachloroaurate(III) and L-methionine have been studied spectrophotometrically using a stopped-flow technique at different temperatures. The substitution reaction was ascribed to the formation of the short-lived square-planar Au(III)–(L-Met) that was followed by the replacement of a Cl$^-$ ligand and reduction to Au(I)–(L-Met). The activation parameters for substitution and reduction were determined. IR spectroscopy indicates that L-methionine acts as a bidentate ligand, most likely coordinating *via* the S and N atoms, while ^{1}H and ^{13}C NMR data indicate methionine sulfoxide as the final product. The components of the reaction were treated thermally in order to investigate the solid phase synthesis of the resulting complex.

Polyhedron 28 (2009) 269

Investigation of the kinetics of aquation of the 1:2 complex between Cr^{III} and nitrilotriacetic acid

Kinetics of aquation of the 1:2 complex between Cr^{III} and nitrilotriacetic acid (NTA) was measured using a combination of capillary electrophoresis (CE), UV–Vis spectrophotometry, and ATR-FTIR spectroscopy. The aquation products were identified as the 1:1 Cr^{III} complex with NTA and "free" NTA. Observed first-order rate constants, k_{obs}, exhibited a complicated pH dependence which was successfully modeled by considering five distinct reaction pathways. The 1:1 complex dimerized to form a 2:2 complex in a slower subsequent reaction step.

Synthesis, structure characterization and thermal properties of $[Zr_6(\mu_3\text{-}O)_4(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$

$[Zr_6(\mu_3\text{-}O_4)(\mu_3\text{-}OH)_4(OOCCH_2{}^tBu)_9(\mu_2\text{-}OH)_3]_2$ has been isolated, when $Zr(O^iPr)_4$ reacted with an 2-fold excess of 3,3-dimethylbutyric acid. Analysis of single crystal X-ray diffraction data showed that this complex crystallizes in hexagonal system ($P6_3/m$ (no. 176)). Results of variable temperature IR spectroscopy and DSC studies revealed phase transitions at 143–183 and 203–293 K. Thermal analysis showed that its decomposition proceeds with complete conversion to ZrO_2 between 603 and 803 K.

Synthesis and characterization of mono and polymeric cyclopalladated compounds: Crystal and molecular structure of $[\{Pd(dmba)(ONO_2)\}_2(\mu\text{-}pz)] \cdot H_2O$ (pz = pyrazine)

The compound $[Pd(dmba)(NCMe)_2](NO_3)$ (NCMe = acetonitrile) (**1**) reacts with *m*-nitroaniline (*m*-NAN) and pirazine (pz), affording $[Pd(dmba)(ONO_2)(m\text{-}NAN)]$ (**2**), $[\{Pd(dmba)(ONO_2)\}_2(\mu\text{-}pz)] \cdot H_2O$ (**3**), respectively. The IR spectra of (**2**–**3**) display typical bands of monodentade O-bonded nitrate groups. The crystal structure of compound **3** consists of a supramolecular chain formed by hydrogen bonding between the water molecule and the nitrato ligands of two consecutive $[Pd_2(dmba)_2(ONO_2)_2(\mu\text{-}pz)]$ units.

Silver nitrate molecular species and coordination polymers with divergent supramolecular morphology constructed from hydrogen-bonding capable dipyridyl ligands

Solution phase reaction of silver nitrate with various hydrogen-bonding capable dipyridyl ligands has resulted in three 1-D coordination polymers and one discrete cationic species with diverse silver coordination spheres. Long-range Ag···O interactions and/or hydrogen-bonding promote the formation of different supramolecular aggregations such as a 2-D double layer slab and a threefold interpenetrated 3-D diamondoid network. Two of the complexes undergo weak blue–violet luminescence upon irradiation with ultraviolet light.

Nano-sized Co(II)-8-hydroxyquinolate complex thin film via surface layer-by-layer chemical deposition method: Optimized factors and optical properties

Thin film formation of nano-sized Co(II)-8-hydroxyquinolate complex by surface layer-by-layer chemical deposition method was studied and evaluated on the basis of metal analysis, SEM, EI-MS, FT-IR and TGA. Several controlling factors were optimized for thin film formation including the stoichiometric ratio of metal to ligand, number of dipping cycles and immersion times, pH value of interacting species and the solvent effect. The optical properties of Co(II)-8-hydroxyquinolate thin film were also explored and proved its potential applications as a hybrid organic/inorganic semi-conductor type.

Experimental (FT-IR, FT-Raman, ^{1}H, ^{13}C NMR) and theoretical study of alkali metal 2-aminonicotinates

The influence of lithium, sodium, potassium, rubidium and cesium on the electronic system of the 2-aminonicotinic acid was studied by the molecular spectroscopy methods. Optimized geometrical structures of studied compounds were calculated by B3LYP method using 6-311++G** basis set. The theoretical NMR, IR and Raman spectra were determined.

Planar Ni(II) 1,2-dithiolenes involving bidentate *P*-donor ligands

Molecular electronic properties of Ni(II) dithiolene complexes with P,P-ligands and their practical applications (anticholinesterase activity, vulcanization accelerators) were studied. The figure in the graphical abstract shows a molecular structure of [Ni(dppn))(mnt)] complex, dppn = l,5-bis(diphenylphodphino)-pentane, mnt = maleonitriledithiol. The geometry of NiS_2P_2 chromophore is approximately planar.

Transition metal complexes with thiosemicarbazide-based ligands. Part 56. Square-pyramidal complexes of copper(II) with 2-acetylpyridine *S*-methylisothiosemicarbazone

The subject of this work is the synthesis and single-crystal X-ray analysis of two sulfato and one thiocyanato copper(II) complex with 2-acetylpyridine *S*-methylisothiosemicarbazone (HL) of the formulae: $[Cu(HL)SO_4(H_2O)]\cdot H_2O$ (**1**), $[Cu_2(HL)_2(\mu\text{-}SO_4)_2]\cdot 2H_2O$ (**2**) and $[Cu(HL)(NCS)(SCN)]$ (**3**), as well as the structure of the protonated ligand $H_2L^+I^-$. In contrast to complex **2**, which is an authentic dimer, formed on account of the *exo*-bidentate coordination of both sulfato ligands, the structure of complex **3**, thanks to hydrogen bonding, may be thought of as being a pseudo-dimer. All three complexes have slightly deformed square-pyramidal structures with the tridentate NNN neutral ligand in the basal plane. For complex **3**, different modes of bonding of the ambidentate NCS group were discussed.

Azoimidazolium iodocuprate(I) and iodoargentate(I)

1,3-Di-alkyl-2-(arylazo)imidazolium iodocuprate(I) and iodoargentate(I) are described in this work. Iodocuprate forms iodo bridged dimmer ($Cu_2I_4^{2-}$) that is electrostatically attracted and has hydrogen bonded to imidazole-H of imidazolium ion. Iodoargentate forms trimeric unit $[Ag_3I_5]^{2-}$ who constitutes iodo bridged 1D chain and anion is placed in the network formed by imidazolium motif.

Polyhedron 28 (2009) 3642

Copper(II) coordination compounds with ferulic acid

The first two molecular structures of the ferulic acid coordination compounds in $[Cu_2(C_{10}H_9O_4)_4(CH_3CN)_2]$ **1** and $[Cu_2(C_{10}H_9O_4)_4(C_6H_6N_2O)_2]\cdot 4CH_3CN$ ($C_6H_6N_2O$ = nicotinamide) **2** are presented. Both compounds were synthesised from the starting copper(I) upon copper oxidation in the acetonitrile solution. They are unstable outside mother liquid giving final $[Cu_2(C_{10}H_9O_4)_4]$ **1a** and $[Cu_2(C_{10}H_9O_4)_4(C_6H_6N_2O)_2]$ **2a**. The triplet $S = 1$ EPR spectra and $\mu_{eff} \sim 1.45$ B.M. confirm the antiferromagnetic interaction in the final products, and consequently a preservation and stability of the *paddle–wheel* structures in **1a** and **2a** by 'oxidative' copper(II) cations and 'antioxidative' ferulic acid anions.

Polyhedron 28 (2009) 2591

Synthesis, structure and DNA binding studies of mononuclear copper(II) complexes with mixed donor macroacyclic ligands, 2,6-bis({*N*-[2&3-(phenylselenato)alkyl]}benzimidoyl)-4-methylphenol

Two new phenol based macroacyclic Schiff base ligands, 2,6-bis({*N*-[2-(phenylselenato)ethyl]}benzimidoyl)-4-methylphenol (bpebmpH, **1**) and 2,6-bis({*N*-[3-(phenylselenato)propyl]}benzimidoyl)-4-methylphenol (bppbmpH, **2**) of the Se_2N_2O type have been prepared by the condensation of 4-methyl-2,6-dibenzoylphenol (mdbpH) with the appropriate (for specific reactions) phenylselenato(alkyl)amine. These ligands with Cu(II) acetate monohydrate in a 2:1 molar ratio in methanol form complexes of the composition $[(C_6H_2(O)(CH_3)\{(C_6H_5)C{=}N(CH_2)_n\text{-}Se(C_6H_5)\}\{(C_6H_5)C{=}O\}_2Cu]$ (**3** (n = 2), **4** (n = 3)) with the loss of phenylselenato(alkyl)amine and acetic acid. In both these complexes, one arm of the ligand molecule undergoes hydrolysis, and links with Cu(II) in a bidentate (NO) fashion, as confirmed by single crystal X-ray crystallography of complex **3**. The selenium atoms do not form part of the copper(II) distorted square planar coordination sphere which has a *trans*-CuN_2O_2 core. The average Cu–N and Cu–O distances are, respectively, 1.973(3) and 1.898(2) Å. The N–Cu–N and O–Cu–O angles are, respectively, 167.4(11)° and 164.5(12)°. The compounds **1**–**4** have been characterized by elemental analysis, conductivity measurements, mass spectrometry, IR, electronic, ^1H and $^{77}Se\{^1H\}$ NMR spectroscopy and cyclic voltammetry. The interaction of complex **3** with calf thymus DNA has been investigated by a spectrophotometric method and cyclic voltammetry.

Polyhedron 28 (2009) 2619

New rhenium(I) compounds containing the donor–acceptor diphosphine ligands 2-(ferrocenylidene)-4,5-bis(diphenylphosphino)4-cyclopenten-1,3-dione (fbpcd) and 2-(3-ferrocenylprop-2-ynylidene)-4,5-bis(diphenylphosphino)4-cyclopenten- 1,3-dione (fpbpcd): Electrochemical behavior, MO properties, and X-ray diffraction structure of *fac*-Br$Re(CO)_3$(fpbpcd)

The diphosphine ligands fbpcd and fpbpcd react with $BrRe(CO)_3(THF)_2$ to furnish the diphosphine-substituted compounds *fac*-$BrRe(CO)_3$(fbpcd) (**2**) and *fac*-$BrRe(CO)_3$(fpbpcd) (**3**), respectively. The more highly conjugated fpbpcd ligand was prepared from 3-ferrocenylpropynal and 4,5-bis(diphenylphosphino)-4-cyclopenten-1,3-dione (bpcd) via a Knoevenagel condensation. **2** and **3** have been isolated and fully characterized by a combination of IR and NMR spectroscopies, mass spectrometry, and X-ray diffraction analysis in the case of **3**. Cyclic voltammetric studies reveal well-defined 0/1^+ and 0/1^- redox couples for both new rhenium compounds, and the nature of the HOMO and LUMO levels is discussed relative to MO calculations at the extended Hückel level.

Synthesis of *N*-(thio)phosphorylated thiosemicarbazides RC(S)NHP(X)(O*i*Pr)$_2$ (X = S, R = NH_2N(Me)–; X = O, R = NH_2N(Me)–, PhNHNH–): Reaction of NH_2N(Me)C(S)NHP(S)(O*i*Pr)$_2$ with acetone

Three new *N*-(thio)phosphorylated thiosemicarbazides of the common formula R–C(S)–NH–P(X)(O*i*Pr)$_2$ [X = S, R = NH_2N(Me)– (**1**); X = O, R = NH_2N(Me)– (**2**), PhNHNH– (**3**)] have been synthesized and characterized by NMR spectroscopy. The structures of the thiosemicarbazides **1–3** in $CDCl_3$ and acetone-d_6 solutions have been discussed in comparison with the *N*-(thio)phosphorylated thioureas Me–NH–C(S)–NH–P(X)(O*i*Pr)$_2$ [X = S (**4**), O (**5**)]. Reaction of **1** with acetone leads to the five-membered substituted 1,3,4-thiadiazolidine S—C(Me)$_2$—NH—N(Me)—C=N—P(S)(O*i*Pr)$_2$ (**6**).

Synthesis and structure of anhydrous complexes of magnesium(II) with β-ketoesters of higher alcohols

Methods for the synthesis of anhydrous complexes of magnesium(II) with β-ketoesters of higher alcohols have been developed. A number of novel magnesium complexes of the general formula MgL_2 have been synthesized. It has been found by X-ray crystallography that bis(1-adamantyl acetoacetato)magnesium(II) has a trimeric structure. The structure of the complexes in solutions is discussed.

Sterically hindered cyclopentadienyl and phospholyl ligands in dysprosium chemistry

A general method for the synthesis of unsolvated organometallic complexes of dysprosium(III) with very sterically hindered π-ligands is presented. It consists in the reaction of potassium cyclopentadienides or phospholides with a dysprosium(III) iodide in refluxing toluene. A dysprosium(II) ate-complex, obtained by reduction of a bis(cyclopentadienyl)dysprosium(III) bromide, was re-oxidised with fluorenone into a charge-separated dysprosium(III) ionic complex featuring a fluorenone radical-anion liganded to dysprosium through the oxygen atom.

Polyhedron 28 (2009) 2759

A small methanoato ligand in the structural differentiation of copper(II) complexes

Monomeric $[Cu(O_2CH)_2(2\text{-mpy})_2]$, dimeric $[Cu_2(\mu\text{-}O_2CH)_4(2\text{-mpy})_2]$ and two polymeric complexes of alternate monomeric and dimeric building blocks, $\{[Cu(\mu\text{-}O_2CH)_2(2\text{-mpy})_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$ (2-mpy = 2-methylpyridine) and $\{Na_2[Cu(\mu\text{-}O_2CH)_2(O_2CH)_2][Cu_2(\mu\text{-}O_2CH)_4]\}_n$, have been characterized. A very strong antiferromagnetic (AFM) interaction is found for all the complexes with *paddle-wheel* building blocks $[Cu_2(\mu\text{-}O_2CH)_4]$ ($2J$ = 444–482 cm^{-1}), attributed to the methanoate intra-binuclear bridges. This strong AFM coupling also plays an important role in the EPR signals of the two polymeric complexes, and differs structurally, especially with the monomer-dimer intra-chain bridges.

Rhodium(III) and cadmium(II) complexes based on the polypyridyl ligand 2,3,5,6-tetrakis-(2-pyridyl)pyrazine (tppz)

Tppz (2,3,5,6-tetrakis(2-pyridyl)pyrazine) complexes [Rh(tppz)(bpy)Cl][PF_6]$_2$.acetylacetone (bpy = 2,2′-bipyridine) and [{$CdCl_2$}$_2$(μ-tppz)]. ethylene glycol have been synthesized and characterized. Solid state structures of both complexes have been determined by single-crystal X-ray crystallography. The structural determination shows that the dinuclear Cd(II) complex, [{$CdCl_2$}$_2$(μ-tppz)], is a 1D coordination polymer. An ORTEP drawing of [Rh(tppz)-(bpy)Cl][PF_6]$_2$.acetylacetone shows that the coordination geometry around the Rh(III) is a distorted octahedron.

Coordination chemistry of di-2-pyridylketone. Synthesis, spectroscopic investigations, X-ray studies and DFT calculations of Re(III) and Re(V) complexes

The paper presents a combined experimental and computational study of Re(III) and Re(V) complexes containing di-2-pyridylketone and its gem-diol form – $[ReCl_3(dpk\text{-}N,O)(PPh_3)]$ (**1**), $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ (**2**) and $[ReOBr_3(dpk\text{-}OH)]\cdot 2(dpkH^+Br^-)$ (**3**). All the complexes have been characterized spectroscopically and structurally (by single-crystal X-ray diffraction). The complex **2** has been additionally studied by magnetic measurement. The magnetic behavior is characteristic of mononuclear octahedral Re(III) complex with d^4 low-spin ($^3T_{1g}$ ground state) and arise because of the large spin–orbit coupling (ζ = 2500 cm^{-1}), which gives diamagnetic ground state. DFT and time-dependent (TD)DFT calculations have been carried out for $[ReCl_3(dpk\text{-}N,N')(OPPh_3)]$ and $[ReOBr_3(dpk\text{-}OH)$, and their UV–vis spectra have been discussed on this basis.

Structural and magnetic properties of $Co_xZn_{1-x}Fe_2O_4$ nanocrystals synthesized by microwave method

Microwave assisted combustion method was used to produce nanocrystalline cobalt doped zinc ferrite, $Co_xZn_{1-x}Fe_2O_4$, from stoichiometric mixture of $(Co(NO_3)_2{\cdot}6H_2O)$, $(Fe(NO_3)_3{\cdot}9H_2O)$, $(Zn(NO_3)_2{\cdot}6H_2O)$, and urea $(CO(NH_2)_2)$ as a fuel. The structural, morphological and magnetic properties of the products were determined by X-ray powder diffractometry (XRD), Fourier transmission infrared spectroscopy (FTIR), scanning electron microscopy (SEM), vibrating sample magnetometer (VSM) respectively. The average crystallite sizes obtained from XRD were between 35 and 39 nm. Magnetization measurements indicate that samples with less Co content have superparamagnetic behavior at room temperature. When the Co substitution increases the saturation magnetization and coercivity also increase due to anisotropic nature of cobalt. The $Co_xZn_{1-x}Fe_2O_4$ nanoparticles exhibit typical features of an assembly of magnetic particles with a distribution of blocking temperatures and indicate the spin-glass behavior.

Uncompensated magnetization in the layered molecular antiferromagnet $\{N(n\text{-}C_5H_{11})_4[Mn^{II}\text{-}Fe^{III}(ox)_3]\}_\infty$

The honeycomb layered $\{N(n\text{-}C_5H_{11})_4[Mn^{II}\text{-}Fe^{III}(ox)_3]\}_\infty$ antiferromagnet, where both Mn^{II} and Fe^{III} ions have spin $S = 5/2$, shows anisotropy and an uncompensated moment below T_N of 27 K. The Mössbauer spectrum in the applied magnetic field reveals the presence of two $Fe^{III}{}_A$ and $Fe^{III}{}_B$ spin sites with different responses towards the external magnetic field that is most probably responsible for the uncompensated magnetization. Breaking the local symmetry of the Fe^{III} sites by the bulky $N(n\text{-}C_5H_{11})_4$ cations together with a small difference in g-factors for Mn^{II} and Fe^{III} ions and a relatively large zero-field splitting for Mn^{II} may be a reason for the two non-equivalent sites within the iron sublattice.

Synthesis, *in situ* spectroelectrochemical, *in situ* electrocolorimetric and electrocatalytic investigation of brown-manganese phthalocyanines

α- and β-substituted tetrakis{6-hydroxyhexylthiol)phthalocyaninato manganese (III) chloride complexes have been prepared via cyclotetramerization and characterized by elemental analysis, FTIR, MS and UV–Vis spectral data. The voltammetric and *in situ* spectroelectrochemical studies of the complexes reveal that both complexes exhibit an oxidation and three reduction processes having reversible, one-electron, and diffusion controlled mass transfer characters, which are assigned to $Mn^{III}Pc^{2-}/Mn^{II}Pc^{2-}$, $Mn^{II}Pc^{2-}/Mn^{I}Pc^{2-}$, $Mn^{I}Pc^{2-}/Mn^{I}Pc^{3-}$ and $Mn^{III}Pc^{2-}/Mn^{IV}Pc^{2-}$ couples respectively. Existence of oxygen in solution significantly affects the *in situ* spectroelectrochemical behaviors of the complexes due to the formation of μ-oxo MnPc species. An *in situ* electrocolorimetric method has been applied to investigate the colors of the electro-generated anionic and cationic forms of the complexes for the first time in this study. The complexes coated on a glassy carbon electrode potentiostatically show considerably high electrocatalytic activity to the hydrogen evolution reaction in aqueous solution.

Reactivity of $[ReOX_3(PPh_3)_2]$ and $[ReOX_3(AsPh_3)_2]$ towards 2-(2-hydroxyphenyl)-1H-benzimidazole: Synthesis, X-ray studies, spectroscopic characterization and DFT calculations for $[ReOX_2(hpb)(EPh_3)]$ and $[ReO(OMe)(hpb)_2]\cdot$MeCN

The paper presents a combined experimental and computational study of mono- and disubstituted Re(V) oxocomplexes obtained in the reactions of $[ReOX_3(EPh_3)_2]$ (X=Cl, Br; E=P, As) with 2-(2-hydroxyphenyl)-1H-benzimidazole (Hhpb). From the reactions of $[ReOX_3(PPh_3)_2]$ with Hhpb in molar ratio 1:1 *cis* and *trans* stereoisomers of $[ReOX_2(hpb)(PPh_3)]$ were isolated, whereas the $[ReOX_3(AsPh_3)_2]$ oxocompounds react with Hhpb to give only *cis*-halide isomers. The $[ReOX_2(hpb)(EPh_3)]$ and $[ReO(OMe)(hpb)_2]$ MeCN complexes have been characterised spectroscopically and structurally (by single-crystal X-ray diffraction). The DFT and TDDFT calculations have been carried out for the *trans*-$[ReOBr_2(hpb)(PPh_3)]$, *cis*-$[ReOBr_2(hpb)(AsPh_3)]$ and $[ReO(OMe)(hpb)_2]$, and their UV-Vis spectra have been discussed on this basis.

Self-assembly of water cluster in iron(III) oxalate-bridged complexes

The synthesis and crystal structural characterization of the compound of formula $\{[Fe^{II}(phen)_3]_2[Fe_2^{III}ox_5]\}\cdot 11H_2O$ (**1**) has been reported. The most interesting feature of the solid state structure of **1** is the formation of decanuclear water clusters self-assembled by means of hydrogen bonding interactions between water molecules. The $(H_2O)_{10}$ clusters display extensive multiple interactions with the dimeric units, leading to the formation of an extended 3D supramolecular assembly, wherein hexameric water clusters interconnected with dodecameric hybrid water–$O_{oxalate}$ clusters can be recognized. The comparison of this supramolecular architecture with that found in the already known compound of formula $[Fe(bpm)_3]_2[Fe_2(ox)_5]\cdot 8H_2O$ (**2**) allows some preliminary observations on the design and control of hydrate formation depending on the size and shape of templating cations.

Three copper(II) complexes of thiophene-2,5-dicarboxylic acid with dissimilar ligands: Synthesis, IR and UV–Vis spectra, thermal properties and structural characterizations

We have synthesized and structurally characterized three 3D Cu(II) complexes which are derived from 2,5-thiophenedicarboxylate with dissimilar ligands. One of the complexes has a 1-D zigzag polymeric structure and tdc behaves as a bidentate ligand. In the other complexes, the tdc dianion acts as a counter ion. In all these complexes the Cu(II) atom has a distorted octahedral coordination geometry. Three-dimensional frameworks are constructed though hydrogen bonding and/or C–H···π interactions in all the synthesized complexes.

Oliver Kahn Lecture: Composition and structure of the $V[TCNE]_x$ (TCNE = tetracyanoethylene) room-temperature, organic-based magnet – A personal perspective

The formulation and structure of the $V[TCNE]_x$ (TCNE = tetracyanoethylene) room temperature, inhomogeneous, nonstoichiometric, organic-based magnet is reviewed. It is best described as $V^{II}[TCNE]^{\cdot-}_{z}[TCNE]^{2-}_{1-z/2}$ ($1 < z < 2$).

A possible approach towards spin-polarized transport through single molecule magnets: Mn_{12} on Au(1 0 0)/Fe(1 0 0)/MgO(1 0 0)

Mn_{12} single molecule magnets have been deposited on a Au/Fe/MgO layer system. The results represent the first deposition of Mn_{12} molecules on Au(1 0 0) and provide evidence that the iron layer is not oxidized during the wet chemical preparation.

One laser shot induced complete phase transition in the spin crossover complex Fe(pyrazine)$[Pt(CN)_4]$

A complete photo-induced phase transition from the low-spin to the high-spin state is triggered by exciting the spin crossover complex Fe(pyrazine)$[Pt(CN)_4]$ with a single laser shot at 532 nm. A non-linear behaviour of the photo-conversion efficiency characterised by the occurrence of an energy density threshold is notably observed.

Frustration effects in antiferromagnetic molecules: The cuboctahedron

Frustration of magnetic systems which is caused by competing interactions is the driving force of several unusual phenomena such as plateaus and jumps of the magnetization curve as well as of unusual energy spectra with for instance many singlet levels below the first triplet state. The antiferromagnetic cuboctahedron can serve as a paradigmatic example of certain frustrated antiferromagnets. The graphics displays the heat capacity for the regular cuboctahedron with $s = 1/2$, $s = 1$, and $s = 3/2$. The low-lying singlets lead to a prominent sharp peak at low temperatures especially in the case of $s = 1/2$.

A resonating broken-symmetry CI study of cationic states of phenalenyl dimeric compounds

We investigated phenalenyl cation dimers by several ab initio methods. As in the case of simple diatomic cation dimers, the resonating configuration interaction (Res-CI) method correctly yields both the potential surface and the charge distribution of the through-space phenalenyl cation dimer, while the B3LYP and UHF methods fail to describe the potential surface and the charge distribution, respectively. On the other hands, the UHF solution reduces to the ROHF solution for the acethylene-bridged phenalynyl dimer, implying that this bridge plays a role to enhance the conductivity between phenalenyl units. In contrast, the ethylene-bridge leads to a slightly complicated Res-CI solutions based on spin-density wave types of UHF solutions.

Synthesis and physical properties of a new single-component molecular conductor [Au(dhdt)$_2$]

New Au(III) complexes coordinated by π-reduced TTF-type ligands were prepared and crystal structure of the tetraphenylphosphonium salt was clarified. A neutral complex [Au(dhdt)$_2$] was obtained by the electrochemical oxidation of (n-Bu$_4$N)[Au(dhdt)$_2$]. Conducting behavior of [Au(dhdt)$_2$] was semiconductive with conductivity at room temperature of 8.3 Scm^{-1}, indicating the neutral complex [Au(dhdt)$_2$] is a single-component conductor. Magnetic susceptibility of [Au(dhdt)$_2$] was well explained by the sum of the Curie and temperature independent components.

A comparative EPR study of high- and low-spin Mn_6 single-molecule magnets

The results of high-frequency (50–350 GHz) electron paramagnetic resonance (EPR) studies of two complexes from a family of recently discovered Mn^{III}_6 single-molecule magnets (SMMs), are presented. The experimental findings were compared with numerical calculations, where the total anisotropy for a complex is determined in terms of single-ion anisotropies using both projection operator techniques and exact matrix diagonalization methods. It is shown clearly that the product of the molecular anisotropy, D, and spin, S, does not change significantly upon switching from $S = 4$ to 12, i.e. D goes down as S goes up but the barrier height to the magnetization reversal, U, does increase, and it goes roughly as S^1 rather that S^2 or S^0.

Magnetic properties and DMRG modeling of the 1D bimetallic thiocyanate bridged compound $\{(CuL_1)[Co(NCS)_4]\}$ (L_1 = *N*-rac-5,12-Me_2-[14]-4,11-dieneN_4)

The magnetic properties of the bimetallic compound $\{(CuL_1)[Co(NCS)_4]\}$, where L_1 = *N*-rac-5,12-dimethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene have been numerically analysed on the basis of the anisotropic Heisenberg spin-chain model. In the model the single-ion anisotropy of the Co(II) ions is taken into account and the interchain interactions are neglected. The thermodynamic properties are calculated using the DMRG technique adapted to the molecular-based chains for the first time which is reliable in the entire temperature region. The high accuracy results of our simulations have been successfully fitted to the corresponding experimental susceptibility and magnetization data measured for the powder sample and the model parameters (the exchange coupling *J*, the absolute value of the anisotropy constant *D*, the anisotropic *g* factors) have been estimated. The quantum model parameters are consistent with the previous findings, although the ferromagnetic interactions between Cu(II) and Co(II) ions through the thiocyanate bridge are somewhat weaker (J/k_B = 1.0 ± 0.1) than found before.

Quantum dynamic simulations for single molecular magnets using anisotropic spin models

We performed quantum spin dynamics in anisotropic electron-spin systems to clarify the mechanism in single molecular magnets (SMM) theoretically. In order to examine the effects of such anisotropic magnetic terms (D and E), model systems with large spin multiplicity of the ground state were treated. In DC-external magnetic field, magnetic quantum tunneling (MQT) behavior was found. Moreover, in AC-external magnetic field, frequency dependence of real (χ') and imaginary (χ'') parts of χ can be shown and Cole-Cole plot can be drawn.

Polyhedron 28 (2009) 1

Copper(II) complexes of tetradentate N2S2 donor sets: Synthesis, crystal structure characterization and reactivity

Three copper(II) complexes of NSSN type ligands, two mononuclear $[Cu^{II}(L^1)Cl]ClO_4$ (**1**), $[Cu^{II}(L_2)Cl]ClO_4$(**2**) and one binuclear $[Cu^{II}_2(L^3)_2Cl_2](ClO_4)_2$ (**3**) were isolated in pure form. The dinuclear copper(II) complex **3** changed to a colorless dinuclear copper(I) species of formula $[Cu^{I}_2(L^3)_2](ClO_4)_2$ (**4**) in dimethylformamide even in the presence of air at ambient temperature, while complexes **1** and **2** showed no change under similar conditions.

Polyhedron 28 (2009) 7

Photophysical properties of copper(I) and zinc(II) complexes containing phosphinoquinoline ligands

Copper(I) and zinc(II) complexes of 8-phosphinoquinoline derivatives containing both imine and phosphine moieties have successfully been synthesized and characterized. Emissive properties of these complexes both in solution and in the solids state are described.

Polyhedron 28 (2009) 13

Investigations of bis(methyltetrazolyl)triazenes as nitrogen-rich ingredients in solid rocket propellants – Synthesis, characterization and properties

The synthesis and characterization of several bis(methyltetrazolyl)-triazenes and triazenates is reported. The compounds are, due to their high thermal stability and positive heat of formation, promising candidates as additives in new solid propellants. Therefore a comprehensive description of the crystal structures and energetic properties (thermal behavior, sensitivities, calculation of detonation and propulsion parameter) is given.

Multinuclear NIR luminescent 1,4-BDC bridged Schiff-base complexes of Nd(III)

Solvent and reaction stoichiometry dictate the products from reactions $[ZnNdL(H_2O)(NO_3)_3]$ (H_2L = *N*,*N*′-bis(3-methoxy-salicylidene)ethylene-1,2-diamine) with 1,4-benzenedicarboxylate (1,4-BDC). A 2:1 molar ratio of ZnNd:1,4-BDC in CH_3CN–EtOH gave $[Zn_2Nd_2L_2(1,4\text{-}BDC)(NO_3)_4(EtOH)_2] \cdot 2MeCN$ (**1**) while hexanuclear $[Zn_4Nd_2L_4(1,4\text{-}BDC)_2] \cdot (NO_3)_2 \cdot 2Et_2O \cdot 4H_2O$ (**2**) is formed in a DMF–EtOH mixture. A 4:1 mole ratio in DMF–EtOH gave $[Zn_4Nd_2L_4(1,4\text{-}BDC)_2] \cdot [ZnNdL(NO_3)_3(OAc)]_2$ (**3**).

Polyhedron 28 (2009) 33

Synthesis and electrochemistry of tetrakis(7-coumarinthio-4-methyl)-phthalocyanines, and preparation of their cinnamic acid and sodium cinnamate derivatives

Novel water soluble free-base, Zn(II) and Co(II) metallo phthalocyanines with four cinnamic acid moieties were prepared from the corresponding tetrakis(7-coumarinthio-4-methyl)-phthalocyanine by the lactone ring opening reaction. The new compounds were purified and characterized by elemental analysis, ^1H NMR, Maldi-TOF, FT-IR and UV–Vis spectral data. Cyclic and differential pulse voltammetry and *in situ* spectroelectrochemistry of the 2,9,16,23-tetrakis(7-coumarinthio-4-methyl) substituted free-base **1a**, Zn(II) **1b** and Co(II) **1c** phthalocyanines, employed as the starting compounds have been studied. This allowed us not only to identify metal- and phthalocyanine ring-based redox processes of the complexes, but also the effect of aggregation on these processes.

Polyhedron 28 (2009) 43

The effect of water-miscible organic solvents on the substitution reaction of Keggin-type heteropolysilicates and -germanates with vanadium(V) ion

The substitution reaction of Keggin-type polyoxometalates, $[XM_{12}O_{40}]^{n-}$ (X = Si, Ge, P, or As; M = Mo or W), with vanadium(V) ion was investigated with cyclic voltammetry, Raman spectroscopy, and ^{31}P NMR. The effect of organic solvents, such as acetonitrile, tetrahydrofuran, formamide, N-methylformamide, and N-methylacetoamide, on their substitution reactions was examined.

Polyhedron 28 (2009) 49

New polyaza macrobicyclic binucleating ligands and their binuclear copper(II) complexes: Electrochemical, catalytic and DNA cleavage studies

A new symmetrical polyaza macrocyclic binucleating ligand $\mathbf{L}^1$ and its permethylated derivative ligand $\mathbf{L}^2$ have been synthesized by using the precursor compound 2-[2-(2,6-diformyl-4-methylphenoxy)propoxy]-5-methylisophthalaldehyde and bis(aminoethyl) amine. The molecular structure of the precursor compound and the ligand $\mathbf{L}^2$ were determined by the single crystal XRD method. The ligands $\mathbf{L}^1$ and $\mathbf{L}^2$ were treated with two equivalents of $Cu(ClO_4)_2 \cdot 6H_2O$ to afford the new binuclear complexes $[Cu_2L^1(\mu\text{-}OH)(ClO_4)_2](ClO_4)$ (**1**) and $[Cu_2L^2(\mu\text{-}OH)(ClO_4)_2](ClO_4)$ (**2**), respectively. Both the complexes were characterized by elemental and spectral methods. A cyclic voltammetric investigation of these Cu(II) complexes show a quasireversible followed by an irreversible one electron reduction process around E^1_{pc} = −0.59 V and −0.55 V, and E^2_{pc} = −1.07 V and −1.02 V. ESR spectra of the copper(II) complexes **1** and **2** show a broad signal at g = 2.08 and 2.10, and μ_{eff} values of 1.43 and 1.46 BM, respectively, which convey a spin–spin interaction between the two copper(II) ions. The initial rate (V_{in}) for the oxidation of 3,5-di-*tert*-butylcatechol to *o*-quinone by the binuclear Cu(II) complexes **1** and **2** are 1.15×10^{-4} and 1.66×10^{-4} Ms^{-1}, respectively. Both the complexes remarkably promote the hydrolytic cleavage of supercoiled plasmid DNA under physiological conditions in the presence of H_2O_2 at pH 7.2 and 37 °C. The reaction profile for the complex **1** mediated reaction displayed approximately pseudo-first-order kinetic behavior, with $k_{obs} \sim 0.07$ min^{-1} and R^2 = 0.984.

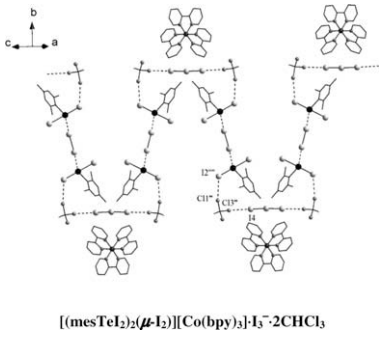
Polyhedron 28 (2009) 57

Novel η^1-allyl– and acyliridium(III)/pybox complexes

The synthesis of enantiopure η^1-allyliridium(III) complexes [IrCl(η^1-$CH_2CH{=}CHR$)(L)(κ^3-*N*,*N*,*N*-^{i}Pr-pybox)][PF_6] (R = H, L = $MeO_2CC{\equiv}CCO_2Me$, MeCN; R = Ph, L = C_2H_4, MeCN), [IrCl(η^1-$CH_2CH{=}CHPh$)(η^2-C_2H_4)(κ^3-*N*,*N*,*N*-Ph-pybox)][PF_6] is reported. The results suggest that a η^1-coordination of allyl group is favoured in the case of DMAD and MeCN ligands. The complexes [IrCl(COR)(MeCN)(κ^3-*N*,*N*,*N*-^{i}Pr-pybox)][PF_6] (R = Me, Ph) are obtained by the stereoselective oxidative addition of acyl chloride to the iridium(I) precursors. The structure of the complex **7** · CH_2Cl_2 has been determined by an X-ray monocrystal study.

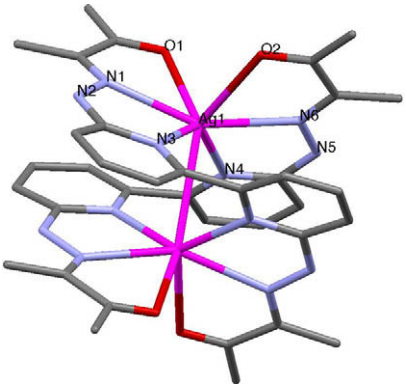


Eliandro Faoro, Gelson Manzoni de Oliveira and Ernesto Schulz Lang

Polyhedron 28 (2009) 63

Attainment of new Te^{II} and Te^{IV} iodides by unexpected removal of the mesityl group of [mesTeI_2]$^-$: Synthesis and structural features of [TeI_4][Co(*en*)$_3$] · I, [TeI_6][Co(*en*)$_3$] · I, [{TeI_6}-{Te_2I_{10}}][Co(NH_3)$_6$]$_2$ · 2I · 6H_2O and [(mesTeI_2)$_2$(μ-I_2)][Co(bpy)$_3$] · I_3 · 2$CHCl_3$ (mes = 2,4,6-trimetylphenyl; *en* = ethylenediamine; bpy = bipyridine)

(MesTe)$_2$ reacts with I_2 and [CoL_n]I_3 {L = (NH_3)$_6$, (*en*)$_3$} in a chloroform/water mixture to give [TeI_4][Co(*en*)$_3$] · I^-, [TeI_6][Co(*en*)$_3$] · I^- and [{TeI_6}-{Te_2I_{10}}] [Co(NH_3)$_6$]$_2$ · 2I^- · 6H_2O in the interface of the two phases. If the crystallization occurs with [Co(bpy)$_3$]I_3 under addition of THF, the final product is [(mesTeI_2)$_2$(μ-I_2)][Co(bpy)$_3$] · I_3^- · 2$CHCl_3$, obtained in the organic phase. The known species {mesTeI···I(mes)Te–Te(mes)$_2$} appears as subproduct in the three first syntheses.



Abdurrahman Şengül, Wen-Jwu Wang and Simon J Coles

Polyhedron 28 (2009) 69

A novel dinuclear double-stranded helical complexes of bis(terdentate) N_4O_2 donor ligand with silver(I) and zinc(II) d^{10} metal ions

A novel hexadentate N_4O_2 ligand 6,6′-bis(3-hydrazonobutan-2-one)-2,2′-bipyridine was shown to self-assembly into double-stranded helical complexes with d^{10} silver and zinc cations in solution; the corresponding $[Ag_2L_2]^{2+}$ helicate (**1a**) shows a pseudo octahedral geometry about each silver(I) centre sharing a short Ag···Ag interaction to accomplish a seven-coordinate mono-capped trigonal prismatic arrangement.

Polyhedron 28 (2009) 85

Synthesis and characterization of adducts of bis(*O,O′*-ditolyl/dibenzyl dithiophosphato)cobalt(II) with pyridine: Crystal structures of $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(C_5H_5N)_2]$ and $[Co\{S_2P(OC_6H_4Me\text{-}p)_2\}_2(NH_3)]$

Bis(*O,O′*-ditolyl/dibenzyl dithiophosphato)-cobalt(II) complexes with pyridine ligands of the type $[Co\{S_2P(OR)_2\}_2(C_5H_5N)_2]$ (R = *o*-, *m*-, *p*-C_6H_4Me, CH_2Ph) have been synthesized by the reaction of $CoCl_2(C_5H_5N)_2$ and the corresponding ammonium salt of *O,O′*-ditolyl/dibenzyl dithiophosphate in methanol. These newly synthesized adducts were characterized by elemental analysis, IR, UV–Vis spectroscopy, magnetic susceptibility measurements and single crystal X-ray diffraction. These structures confirm that in the pyridine complex the geometry around the cobalt metal centre is distorted octahedral, and in the amine complex it is distorted trigonal bipyramidal.

Polyhedron 28 (2009) 107

Synthesis, characterization and spectroscopic studies of a new ligand [N′-(2-methoxybenzoyl)hydrazinecarbodithioate] ethyl ester and its Mn(II) and Cd(II) complexes: X-ray structural study of Mn(II) complex

Complexes of the types $[M(Hmbhce)_2]_n$ {M = Mn(II), Cd(II)} with a new ligand, H_2mbhce = [N′-(2-methoxy-benzoylhydrazine]-scarbodithioic acid ethyl ester have been synthesized and characterized. X-ray study of $[Mn(Hmbhce)_2]_n$ indicates, the ligand acts as an uninegative, tridentate forming five membered chelate ring. The intermediate bond distances in the chelate ring suggest delocalization of charge and support the development of aromaticity in the chelate ring.

Polyhedron 28 (2009) 113

Photocatalytic self-assembled solid porphyrin microcrystals from water-soluble porphyrins: Synthesis, characterization and application

The formation of highly stable multi-porphyrin micro-crystals using water-soluble porphyrins at room temperature is described. The structure is characterized by means of powder X-ray diffraction, UV-vis spectroscopy, fluorescence spectroscopy, and optical microscopy. The micro-crystals are shown to be a photocatalytic agent for the degradation of 2,4,6-trinitrotoluene.

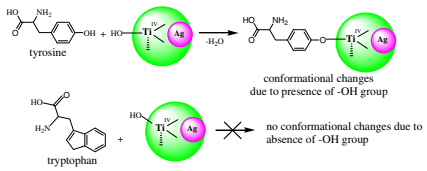
Polyhedron 28 (2009) 150

Coordination polymers of Mn(II) and Cu(II) orotate with 2-methylimidazole and *N,N,N′,N′*-tetramethylethylenediamine ligands: Syntheses, spectroscopic and thermal analyses and crystal structures of *mer*-$[Mn(\mu\text{-}HOr)(H_2O)(2\text{-}meim)_2]_n$ and thermochromic $\{[Cu(\mu\text{-}HOr)(tmen)] \cdot 1.5H_2O\}_n$ complexes

Two novel coordination polymers of Mn(II) and Cu(II) orotate with 2-methylimidazole and *N,N,N′,N′*-tetramethylethylenediamine ligands have been synthesized and described. The orotate ligand acts as a bridging ligand with two different coordination modes, forming a one-dimensional (1D) chain. These polymer chains are linked by hydrogen-bond interactions, forming a three-dimensional network. The complex $\{[Cu(\mu\text{-}HOr)(tmen)] \cdot 1.5H_2O\}_n$ (**2**) exhibits irreversible thermochromism and on dehydration the color of the complex changes from blue to green.



Thermochromic behaviour of complex **2**.

Polyhedron 28 (2009) 157

Interaction of colloidal $AgTiO_2$ nanoparticles with bovine serum albumin

The interaction between colloidal $AgTiO_2$ nanoparticles and bovine serum albumin (BSA) has been studied by absorption, steady state, time resolved and synchronous fluorescence spectroscopic techniques. The quenching rate constant, binding constant and number of binding sites were calculated according to the relevant fluorescence quenching data. From the synchronous fluorescence spectra, it can be shown that the conformational change of BSA is induced by the interaction of colloidal $AgTiO_2$ nanoparticles with the tyrosine micro-region of BSA molecules. This study is expected to provide important insight in the interactions of physiologically important protein BSA with metal nanoparticles.
